Fix $\sigma \in \left(-\frac{1}{3}, \frac{1}{3}\right)$. Let $e_i = T_i \cap T_{i+1}$, and let ν_i denote the outer unit normal to triangle T_i along the edge e_i for $i = 1, 2$. Note that

$$\xi_1 := \xi(1, \sigma; \nu_1) = 1. \tag{6.26}$$

Indeed, the entropy solution of the Riemann problem for the Burgers' equation with initial data $u(0, x) = 1$, $x < 0$, and $u(0, x) = \sigma$, $x > 0$, is a shock propagating with speed $s = \frac{1}{2}(1 + \sigma)$ and having values 1 and σ on the left and on the right, respectively. With the choice of σ we have $s > \frac{1}{3} = -\frac{\nu_{1,t}}{\nu_{1,x}}$, which implies (6.26). Similarly, $\xi_2 := \xi(\sigma, -1; \nu_2) = -1$. One can then check by an easy calculation that the equation is satisfied; indeed, this is almost obvious by symmetry. Hence, (6.25) is a solution for all $\sigma \in (-1/3, 1/3)$, as asserted.

7. Convergence and entropy inequalities. In this section we give the remainder of the arguments needed for the proof of Theorem 3.3. We also show at the end of the section, in Example 7.1, why the assumption (3.23) is needed.

Proof of Theorem 3.3. Recall that for this theorem we assume that $\mathcal{T}_h$ is a causal or a patchwise causal partition for $f, \mathcal{D}$, where f is the flux function for a genuinely nonlinear Temple class system and $\mathcal{D}$ satisfies (2.7). We also assume that $\mathcal{T}_h$ satisfies (3.23), (3.24), and (3.27), with constants independent of h. Since a causal triangulation is also patchwise causal (in which each causal patch consists of a single triangle), we consider only the case when $\mathcal{T}_h$ is patchwise causal.

Step 1. First, results in Lemma 6.2 about existence and uniqueness of solutions on a single causal patch (once the inflow data is known), together with remarks in section 3.4 about the patch-by-patch solution strategy, imply that there exists a unique solution $u_h \in \mathcal{P}_h$ of (3.3) satisfying the elementwise Riemann invariant bounds (3.25) on each triangle. (Recall that $\mathcal{P}_h$ denotes the space of piecewise constants on the triangulation $\mathcal{T}_h$.)

Step 2. Next, let u_{0h} be the discretization of the data u_0 implicit in the discrete initial condition (3.4), so that u_{0h} is constant on intervals $I \subset \mathbb{R}$ such that $\{t = 0\} \times I = (\partial T \cap \{t = 0\})$ for some $T \in \mathcal{T}_h^0$, and on each such interval

$$u_{0h} = \frac{1}{\mathcal{H}^1(I)} \int_I u_0 \, dx.$$

It is easy to check that for x in an interval I as above, $\|u_{0h}(x) - u_0(x)\| \le TV(u_0; I)$, where the right-hand side denotes the total variation of u_0 in the interval I. From this one can check that

$$\|u_{0h} - u_0\|_{L^1(\mathbb{R})} \to 0 \quad \text{as } h \to 0 \qquad \text{and} \tag{7.1}$$

$$TV(u_{0h}) \le 3\, TV(u_0) \quad \text{for all } h. \tag{7.2}$$

Step 3. Fix a patchwise causal partition $\mathcal{T}_h$, and let $u_h \in \mathcal{P}_h$ be the corresponding approximate solution satisfying local Riemann invariant bounds. Let $w_h = b(u_h)$ denote the approximate solution expressed in terms of the Riemann invariant coordinates, and similarly $w_{0h} = b(u_{0h})$. We next establish the claim (3.26) that $TV(w_h^i(t, \cdot))$ is nonincreasing in t for every i. The conclusion will follow only from

assumptions about the triangulation and from the local Riemann invariant bounds (6.10). We view this as *nearly* geometrically obvious, but we give a detailed proof for the sake of completeness.

Fix $i \in \{1, \dots, n\}$. To simplify the notation we drop the sub- and superscripts for this part of our argument and simply write w.

Our assumptions about the mesh (in particular, (3.24) and (3.27)) imply that there exists $\delta > 0$ such that for every T in $\mathcal{T}_h$ and every nontrivial edge $e \subset \partial T$,

$$\sup\{t : (t,x) \in e\} - \inf\{t : (t,x) \in e\} \geq \delta h. \tag{7.3}$$

We will show that

$$TV(w(\sigma,\cdot)) \geq TV(w(\tau,\cdot)) \quad \text{whenever } 0 \leq \sigma < \tau \leq \sigma + \delta h. \tag{7.4}$$

This clearly suffices to prove (3.26).

Fix $0 \leq \sigma < \tau < \sigma + \delta h$ and choose a sequence of points $\cdots < y_j < y_{j+1} < \cdots$ with the property that, for each triangle T such that $T^o \cap \{t = \tau\} \neq \emptyset$, there exists exactly one point $(\tau, y_j) \in T^o$. (Here T^o denotes the interior of T.) Then

$$TV(w(\tau,\cdot)) = \sum_j |w(\tau, y_j) - w(\tau, y_{j-1})|.$$

We will write T_j to denote the triangle containing the point (τ, y_j).

Next, for triangles $S, T \in \mathcal{T}_h$, we write $S \sim T$ if S and T are separated by a trivial edge, as defined immediately before (3.24). In particular, if $S \sim T$, then $w_S = w_T$. We define

$$I := \left\{ j \in \mathbb{Z} : \text{either } T_j^o \cap \{t = \sigma\} \neq \emptyset \text{ or } \exists S \text{ with } S \sim T_j \text{ and } S^o \cap \{t = \sigma\} \neq \emptyset \right\}.$$

We can index the elements of I by the integers, with $\cdots < j_{-1} < j_0 < j_1 < \cdots$. For $j_\ell \in I$, let

$$S_\ell := \begin{cases} T_{j_\ell} & \text{if } T_{j_\ell}^o \cap \{t = \sigma\} \neq \emptyset, \\ \text{the triangle } S \text{ such that } S \sim T_{j_\ell},\ S^o \cap \{t = \sigma\} \neq \emptyset & \text{if not,} \end{cases}$$

and for each ℓ let x_ℓ be a point such that $(\sigma, x_\ell) \in S_\ell^o$. The definitions imply that $x_\ell < x_{\ell+1}$ and that $w(\sigma, x_\ell) = w(\tau, y_{j_\ell})$ for all ℓ. Thus

$$TV(w(\sigma,\cdot)) \geq \sum_\ell |w(\sigma, x_\ell) - w(\sigma, x_{\ell-1})| = \sum_\ell |w(\tau, y_{j_\ell}) - w(\tau, y_{j_{\ell-1}})|.$$

Thus to prove (7.4) it suffices to show that

$$|w(\tau, y_{j_\ell}) - w(\tau, y_{j_{\ell-1}})| = \sum_{m=j_{\ell-1}+1}^{j_\ell} |w(\tau, y_m) - w(\tau, y_{m-1})| \tag{7.5}$$

when $j_{\ell-1}, j_\ell$ are adjacent points in I. To simplify the notation, let us assume that $j_\ell = 0$, and let us also write $k+1 := j_{\ell+1}$. We may assume that $k \geq 1$, as otherwise (7.5) is trivial.

We claim that if $j \notin I$, then T_j must have *exactly* one vertex, say Q_j, in $[\sigma, \tau) \times \mathbb{R}$. It is easy to see from the definition of I that T_j must have at least one such vertex.

And if T_j has two vertices in this slab, then (7.3) and the assumption that $\tau < \sigma + \delta h$ imply that the edge e joining these two vertices must be trivial, and so $T_j \sim T_{j,e}$. Again from (7.3) and the choice of σ, τ, it follows that $T^o_{j,e} \cap \{t = \sigma\} \neq \emptyset$, which would imply that $j \in I$.

Next note that for $j = 1, \dots, k-1$, T_j and T_{j+1} intersect along an edge that terminates at a shared vertex of T_j, T_{j+1} in the set $(0, \tau) \times \mathbb{R}$, and hence in the slab $[\sigma, \tau) \times \mathbb{R}$. It follows that $Q_1 = Q_2 = \cdots = Q_k =: Q$. Thus triangles $T_1, \dots, T_k$ appear exactly as pictured in Figure 3. For the duration of this discussion, we adopt the notation for edges and normals displayed in Figure 3. Assumption (3.23) implies that e^o_j is outflow for $j = 1, \dots, k$, as in Figure 3.

Now consider triangle T_1. We claim that e_0 is an inflow edge for T_1, or equivalently an outflow edge for T_0. To prove this, recall that either $T^o_0 \cap \{t = \sigma\} \neq \emptyset$ or $T_0 \sim S_\ell$ for some S_ℓ such that $S^o_\ell \cap \{t = \sigma\} \neq \emptyset$. In the former case, the claim then follows from assumption (3.23). In the latter case, it follows from the fact that (by definition of $\sim$) the edge $T_0 \cap S_\ell$ is a trivial edge, which (by the definition of a trivial edge) means that the other edges of T_0 are outflow.

The same considerations show that e_k is an inflow edge for T_k. Now let $k_* = \max\{j : e_j \text{ is inflow for } T_{j+1}\}$ and $k^* = \min\{j : e_{j+1} \text{ is inflow for } T_{j+1}\}$, and note that $k_* < k^*$. It is now straightforward to check the following.

First, if $k_* > 1$, then edges $e_0, \dots, e_{k_*-1}$ are all trivial, and as a result $w(\tau, y_0) = \cdots = w(\tau, y_{k_*-1})$. Similarly, if $k^* < k$, then $w(\tau, y_{k^*+1}) = \cdots = w(\tau, y_{k+1})$.

Second, $T_{k_*} \cup \cdots \cup T_{k^*}$ form a causal patch (consisting possibly of a single triangle), and so (6.10) implies that

$$|w_{k^*+1} - w_{k_*-1}| = \sum_{j=k_*}^{k^*+1} |w_j - w_{j-1}|.$$

Combining the last observations, we obtain (7.5), so this completes the proof of (3.26).

Step 4. We next show that there exists a constant C, depending only on $TV(u_0)$ and the constants K_0 from (2.8) and α from (3.24), such that for any $\tau > 0$,

$$\int_0^\tau \int_{\mathbb{R}} (|u_{h,x}| + |u_{h,t}|) \;\le\; C\,\tau. \tag{7.6}$$

Here $|u_{h,x}|$ and $|u_{h,t}|$ are understood as measures on $(0, \infty) \times \mathbb{R}$. To prove (7.6), first note that, for any $t > 0$,

$$\begin{aligned} TV(u_h(t, \cdot)) \le K_0\, TV(w_h(t, \cdot)) \le K_0 \sum_{i=1}^n TV(w^i_h(t, \cdot)) &\le K_0 \sum_{i=1}^n TV(w^i_{0h}) \\ &\le n\, K_0^2\, TV(u_{0h}), \end{aligned}$$

using (2.8) and (3.26). Thus $\int_0^\tau \int_{\mathbb{R}} |u_{h,x}| = \int_0^\tau TV(u_h(t, \cdot))\, dt \le C\,\tau$, by (7.2) and the assumption that $TV(u_0)$ is finite. Also, (3.24) together with standard facts about functions of bounded variation show that

$$\int_A |u_{h,t}| \;\le\; \frac{1}{\alpha} \int_A |u_{h,x}|$$

for every $A \subset [0, \infty) \times \mathbb{R}$. By combining these last two inequalities, we arrive at (7.6).

From (7.6), a version of Rellich's compactness theorem implies that the sequence $\{u_h\}$ is precompact in $L^1_{loc}([0, \infty) \times \mathbb{R})$.

Completion of the proof. The proof that any limit of a convergent subsequence is an entropy solution of (1.1) follows by standard arguments, along the lines of the proof of the Lax–Wendroff theorem. A detailed exposition is presented in [9]. □

Example 7.1. In this example we show why assumption (3.23) is needed in order to deduce from elementwise Riemann invariant bounds (3.25) that property (3.26) holds.

Consider Burgers' equation with $\mathcal{D} = [a, b]$, for $0 < a < b < 1$. Then a triangulation is causal if and only if no triangle has an edge that is a subset of a line with slope in the interval $[\frac{1}{b}, \frac{1}{a}]$. In particular the mesh shown in Figure 5 is causal (assuming that the vertical and horizontal scales are related in a suitable way.) Let the initial data be given by $u_0 = b$ to the left of point Q and $u_0 = a$ to the right of Q. Note that the total variation of the initial data is $b - a$. Let u_i denote the approximate solution in triangle T_i. Clearly, $u_1 = b$, $u_3 = a$, and by Lemma 5.1 we have $u_2 \in (a, b)$. Since the edge separating triangles T_2 and T_4 is trivial, we conclude $u_4 = u_2$. Finally, again by Lemma 5.1, we obtain that $a < u_5 < u_2 < b$. Thus the total variation of the approximate solution at time $t = t_1$ is at least

$$|u_1 - u_2| + |u_2 - u_3| + |u_3 - u_5| = b - a + (u_5 - a),$$

which is strictly greater than the total variation at $t = 0$.

B-SPLINE LINEAR MULTISTEP METHODS AND THEIR CONTINUOUS EXTENSIONS*

FRANCESCA MAZZIA†, ALESSANDRA SESTINI‡, AND DONATO TRIGIANTE§

Abstract. In this paper, starting from a sequence of results which can be traced back to I. J. Schoenberg, we analyze a class of spline collocation methods for the numerical solution of ordinary differential equations (ODEs) with collocation points coinciding with the knots. Such collocation methods are naturally associated to a special class of linear multistep methods, here called B-spline (BS) methods, which are able to generate the spline values at the knots. We prove that, provided the additional conditions are appropriately chosen, such methods are all convergent and A-stable. The convergence property of the BS methods is naturally inherited by the related spline extensions, which, by the way, are easily and safely computable using their B-spline representation.

Key words. ordinary differential equations, linear multistep methods, boundary value methods, spline collocation, continuous extensions

DOI. 10.1137/040614748

1. Introduction.

We analyze a class of spline collocation methods for the numerical solution of the general ordinary differential equation

$$\mathbf{y}'(x) = f(x, \mathbf{y}(x)),\ x \in [a, b], \tag{1.1}$$

that could be subject to either boundary ($\mathbf{g}(\mathbf{y}(a), \mathbf{y}(b)) = 0$) or initial ($\mathbf{y}(a) = \mathbf{y_a}$) conditions; $f : [a\,,\, b] \times \mathbb{R}^d \to \mathbb{R}^d$ is a sufficiently smooth function.

We started our research by reconsidering the classical papers [16] and [17], where a spline collocation approach at uniform knots is presented. In those papers, using $x_i = a + ih, i = 0, \ldots, N, h = (b-a)/N$ as knots, a spline of degree $k+1$, collocating the differential equation at the knots, is constructed with a forward approach, which is possible thanks to the use of $k-1$ additional initial conditions. The authors also prove that the knot restriction of the defined spline is the numerical solution of a suitable linear k-step method. It turned out that the approach was effective only for $k \leq 2$, that is, for the trapezoidal and the Simpson rules, because in this case it allowed the authors to define a convergent spline with uniform convergence order equal to 2 and 4, respectively. Unfortunately the convergence was lost for $k > 2$. This is clear considering that the resulting methods are not 0-stable, as proved in [16], for such values of k, and then not even convergence at knots can be obtained.

We first revisit this class of methods, showing how they can be implemented effectively as boundary value methods (BVMs) (see [5, 6] for a more detailed description of BVMs; also see section 4 below) and discussing in detail their stability properties.

Then we explain how we have changed the approach introduced in [17] for defining the related spline extension, showing that convergence is recovered for all values of k. In our version, the spline is constructed in two successive steps: first, we compute a numerical solution of (1.1) by using the underlying multistep methods as BVMs, and then we construct a related spline extension by solving a linear system. The main features of this approach are that

1. it is a collocation method related to a class of linear multistep methods;
2. the continuous extension has the derivatives globally continuous up to order k;
3. we do not use extra collocation points which are different from the knots.

Other approaches devoted to obtaining spline collocation methods are well known in the literature; see, for example, those presented in [3, 4, 10, 25] that are related to Runge–Kutta methods, or the ones presented in [22, 23]. In this paper we rather prefer proving some mathematical properties of this approach than comparing it numerically with existing ones. Such an analysis allows us to gain insight into its deep relations with the BVM approach. As a matter of fact, it may be seen as an alternative way of constructing a BVM.

The importance of having a continuous extension of the solution provided by multistep methods is particularly relevant when we deal with a mesh refinement strategy, such as, for example, in the solution of boundary value problems, where it is necessary to work on the entire interval of integration $[a\,,\,b]$. In our case, we have implemented some BVMs in the code TOM [18, 20] (available at http://www.dm.uniba.it/~mazzia/bvp/index.html) and we have realized that, for many difficult problems, the interpolation needed by the mesh selection strategy may be a critical component. In the current version available on the Web, the solver uses cubic spline interpolation of the discrete computed solution as a tool to evaluate the approximation of the solution at off-mesh points.

The paper is organized as follows. In section 2 we introduce the special class of symmetric schemes we shall deal with, which will be called BS methods, since they are derived from B-splines. A detailed analysis of both their order of accuracy and their stability properties then follows. In sections 3 and 4 the problems of the computation of the related spline extensions and of choosing correctly the additional boundary conditions are considered, respectively. In section 5 we give the related global convergence analysis. As usual, all the properties are studied on a uniform mesh. Naturally, to have a class of methods that could be effectively implemented, it is necessary to extend them in order to use them on a nonuniform mesh. An extended treatment of the computation of the variable coefficients on a nonuniform mesh is presented in [19]. A preliminary implementation of the BS methods using a mesh selection strategy similar to the one described in [7, 8, 20], an error control strategy, and a technique for the solution of the nonlinear systems similar to the ones described in [18] has been done. As a tool to evaluate the approximation of the solution at off-mesh points, such an implementation uses the previously mentioned spline extension of the numerical solution. Some numerical results, using both uniform and nonuniform meshes, are reported in section 6 to confirm the features of the presented approach.

2. The BS linear multistep methods. Let $x_i = a + ih, i = 0, \ldots, N$, $h = (b-a)/N$, be a uniform partition of the integration interval $[a\,,\,b]$, and let us denote by $\mathbf{y}_i$ an approximation of $\mathbf{y}(x_i)$. For any $k \geq 1$, let us consider the classical B-spline $B_{k+2}(\cdot)$ of degree $(k+1)$ with uniform integer active knots $0, 1, \ldots, k+1, k+2$, which

is given, using the notation of truncated power [9], by

$$B_{k+2}(x) := \frac{1}{(k+1)!}\sum_{i=0}^{k+2}(-1)^i \binom{k+2}{i} (x-i)_+^{k+1}. \tag{2.1}$$

As proved in [16, Thm. 3], if a spline function $\mathbf{s}(x)$ of degree $k+1$ collocates the differential equation at the knots (that is, $\mathbf{s}'(x_i) = f(x_i, \mathbf{s}(x_i))$), then $\mathbf{s}(x)$ satisfies the following relation:

$$\sum_{i=0}^{k} \alpha_i^{(k)}\, \mathbf{s}(x_{n+i}) \;=\; h \sum_{i=0}^{k} \beta_i^{(k)}\, \mathbf{s}'(x_{n+i}), \quad n =, 0, \ldots, N-k, \tag{2.2}$$

with

$$\begin{cases} \alpha_i^{(k)} & := B'_{k+2}(k-i+1), \\ & \qquad\qquad i = 0, \ldots, k. \\ \beta_i^{(k)} & := B_{k+2}(k-i+1), \end{cases} \tag{2.3}$$

This result is a consequence of the previous theorem in the same paper, [16, Thm. 2], attributed to I. J. Schoenberg. In our notation it can be stated as follows,

THEOREM 1 (Schoenberg). *For any spline function* $\mathbf{s}$ *of degree* $k+1$ *and uniform knots* $0, h, \ldots, (n-1)h$, $n \geq k+1$, *the following relation holds:*

$$\sum_{i=0}^{k} \alpha_i^{(k)}\, \mathbf{s}(ih) \;=\; h \sum_{i=0}^{k} \beta_i^{(k)}\, \mathbf{s}'(ih), \tag{2.4}$$

where $\alpha_i^{(k)}$ *and* $\beta_i^{(k)}$ *are defined as in* (2.3).

The BS method with k steps is defined as follows:

$$\sum_{i=0}^{k} \alpha_i^{(k)}\, \mathbf{y}_{n+i} \;=\; h\sum_{i=0}^{k} \beta_i^{(k)}\, f(x_{n+i}, \mathbf{y}_{n+i}), \quad n = 0, \ldots, N-k. \tag{2.5}$$

Considering the symmetry properties of uniform B-splines, it can be shown that we are dealing with symmetric schemes, i.e.,

$$\alpha_i^{(k)} = -\alpha_{k-i}^{(k)}; \qquad \beta_i^{(k)} = \beta_{k-i}^{(k)}.$$

In addition, the following relations among the β coefficients come from the well-known recurrence relation for B-splines,

$$\beta_i^{(k)} \;=\; \frac{1}{k+1}[(k-i+1)\beta_{i-1}^{(k-1)} \;+\; (i+1)\beta_i^{(k-1)}], \;\; i = 0, \ldots, k, \tag{2.6}$$

where $\beta_{-1}^{(k-1)} = \beta_k^{(k-1)} = 0$. In Table 2.1 the $\alpha^{(k)}$ and $\beta^{(k)}$ coefficients of the BS methods with $k = 1, \ldots, 5$ are reported.

The related $\rho^{(k)}$ and $\sigma^{(k)}$ polynomials (that arise in the standard stability analysis of these formulas) are defined as

$$\rho^{(k)}(z) := \sum_{i=0}^{k} \alpha_i^{(k)}\, z^i, \qquad \sigma^{(k)}(z) := \sum_{i=0}^{k} \beta_i^{(k)}\, z^i.$$

TABLE 2.1
The $\alpha^{(k)}$ and $\beta^{(k)}$ coefficients of the BS methods with $k = 1, \ldots, 5$.

k	$\alpha^{(k)}$						$\beta^{(k)}$					
1	-1	1					$\frac{1}{2}$	$\frac{1}{2}$				
2	$-\frac{1}{2}$	0	$\frac{1}{2}$				$\frac{1}{6}$	$\frac{4}{6}$	$\frac{1}{6}$			
3	$-\frac{1}{6}$	$-\frac{1}{2}$	$\frac{1}{2}$	$\frac{1}{6}$			$\frac{1}{24}$	$\frac{11}{24}$	$\frac{11}{24}$	$\frac{1}{24}$		
4	$-\frac{1}{24}$	$-\frac{5}{12}$	0	$\frac{5}{12}$	$\frac{1}{24}$		$\frac{1}{120}$	$\frac{13}{60}$	$\frac{11}{20}$	$\frac{13}{60}$	$\frac{1}{120}$	
5	$-\frac{1}{120}$	$-\frac{5}{24}$	$-\frac{1}{3}$	$\frac{1}{3}$	$\frac{5}{24}$	$\frac{1}{120}$	$\frac{1}{720}$	$\frac{19}{240}$	$\frac{151}{360}$	$\frac{151}{360}$	$\frac{19}{240}$	$\frac{1}{720}$

An investigation of some properties of this class of methods is carried out in the following subsections.

Remark 1. We have used here an approach slightly different from that presented in [17]. In that paper the collocation spline of degree $k+1$ and smoothness C^k is first defined by using a forward approach based on the use of $k-1$ additional initial conditions. Then it is shown that its restriction to the knots verifies (2.5) with coefficients defined as in (2.3). Here we first compute the values generated by the linear multistep method at the knots, and then we compute the spline continuous extension. On the other hand, we observe that, if we had used the same approach, then the C^k continuity conditions at the knots would have generated exactly the conditions expressed in (2.5) (this assertion can be proved by considering the result of Theorem 6). The converse is also true; that is, the choice (2.3) of the coefficients will permit the definition of a spline extension of smoothness C^k collocating the differential equation at the knots (see section 3).

2.1. Order of the BS methods. The order of the k-step BS method can be proved by the following theorem.

THEOREM 2. *A k-step BS method is of order $p = k+1$ if k is odd and of order $p = k+2$ if k is even.*

Proof. The proof that p is at least $k+1$ can be obtained easily by using Theorem 1, by considering that any polynomial of degree less than or equal to $k+1$ is a spline of degree $k+1$, and that the relations defined in (2.4) are, if $\mathbf{s}$ is a polynomial, nothing but the order conditions. A direct proof that $p \geq k+1$, along the lines of the usual methodology used in the ordinary differential equation (ODE) setting, is reported in the appendix.

The fact that $p = k+2$ when k is even can be proved by using the symmetry of the BS methods. If $\mathbf{s}(x)$ is an even function with respect to the midpoint $x = kh/2$ of the interval $[0\,,\, kh]$, we have that $\sum_{i=0}^{k} \alpha_i^{(k)}\, \mathbf{s}(ih) = h \sum_{i=0}^{k} \beta_i^{(k)}\, \mathbf{s}'(ih) = 0$. Now, since for $k = 2\nu$ the polynomial $(x-\nu)^{k+2}$ is an even function with respect to ν, we can conclude that (2.4) still holds for $\mathbf{s}(x) = (x-\nu)^{k+2}$. ∎

2.2. Behavior of the polynomials $\boldsymbol{\rho^{(k)}(z)}$ and $\boldsymbol{\sigma^{(k)}(z)}$. Concerning the polynomial $\rho^{(k)}(z)$, by using the derivative formula for B-splines (see for instance [24,

p. 141], it can be observed that

$$\rho^{(k)}(z) = (z-1)\,\sigma^{(k-1)}(z). \tag{2.7}$$

Then its behavior depends on that of the σ polynomials.

Considering the symmetry of the B-splines, it is also easy to verify that $\sigma^{(k)}(z)$ has the root $z_1 = -1$ if k is odd and that in all the cases, if z is one of its roots, then $w = 1/z$ is also one of them. In addition, it will be proved that all the roots of $\sigma^{(k)}(z)$, except $z_1 = -1$ for k odd, do not belong to the boundary of the unit circle of the complex plane. This statement is important in proving the stability properties of the methods [5, 11], and its proof needs some preliminary considerations.

To begin with, it is almost trivial to recognize that, for any symmetric k-step linear multistep method, $\sigma^{(k)}(z)$ has the following form when evaluated at $z = e^{\mathbf{i}\theta}$:

$$\sigma^{(k)}(e^{\mathbf{i}\theta}) = \begin{cases} 2\,f_k(\theta)\cos(\frac{\theta}{2})\,e^{\mathbf{i}\,k\frac{\theta}{2}} & \text{if } k = 2\nu-1, \\ 2\,f_k(\theta)\,e^{\mathbf{i}\,k\frac{\theta}{2}} & \text{if } k = 2\nu, \end{cases} \tag{2.8}$$

where ν is any positive integer and $f_k(\theta)$ is a trigonometric polynomial defined as

$$\begin{cases} f_k(\theta) := \beta^{(k)}_{\nu-1} + \dfrac{1}{\cos(\frac{\theta}{2})}\displaystyle\sum_{j=2}^{\nu}\beta^{(k)}_{\nu-j}\cos\left((2j-1)\,\dfrac{\theta}{2}\right) & \text{if } k = 2\nu-1, \\ f_k(\theta) := \dfrac{\beta^{(k)}_{\nu}}{2} + \displaystyle\sum_{j=1}^{\nu}\beta^{(k)}_{\nu-j}\cos(j\,\theta) & \text{if } k = 2\nu \end{cases} \tag{2.9}$$

(in fact, for all $j \in \mathbb{N}^+$, $\cos\frac{\theta}{2}$ divides $\cos\,(2j-1)\frac{\theta}{2}$ exactly; see also below).

From (2.8), it follows that the proof that the polynomials $\sigma^{(k)}(z)$ have no roots of unit modulus, except for $z = -1$ for odd values of k, is equivalent to the statement that the trigonometric polynomials $f_k(\theta)$ are of constant sign in $[0\,,\,2\pi]$. Now, the problem of establishing whether a trigonometric polynomial of the form (2.9) does not change sign is well known in the literature. Results may be found in [12, 21]; more recent results can be found in [2]. Unfortunately, it seems that our coefficients $\beta^{(k)}_i, i = 0,\ldots,k$, do not satisfy the conditions established in the above mentioned references, and we need to look for new conditions valid for our case. In order to consider simultaneously both the odd and even cases, we introduce the following vector $\mathbf{b}^{(k)} \in \mathbb{R}^{k+1}$:

$$\mathbf{b}^{(k)} := \begin{cases} (0, \beta^{(k)}_{\nu-1}, 0, \beta^{(k)}_{\nu-2}, 0, \ldots, \beta^{(k)}_0)^T & \text{if } k = 2\nu-1, \\ (\beta^{(k)}_{\nu}/2, 0, \beta^{(k)}_{\nu-1}, \ldots, \beta^{(k)}_0)^T & \text{if } k = 2\nu, \end{cases} \tag{2.10}$$

and the vector function $\mathbf{v}^{(k)}(\theta) : [0\,,\,2\pi] \to \mathbb{R}^{k+1}$,

$$\mathbf{v}^{(k)}(\theta) := \left(1, \cos\left(\frac{\theta}{2}\right), \cos\left(2\frac{\theta}{2}\right), \cos\left(3\frac{\theta}{2}\right), \ldots, \cos\left(k\frac{\theta}{2}\right)\right)^T. \tag{2.11}$$

Using this notation, we can write

$$\begin{cases} \cos\left(\dfrac{\theta}{2}\right) f_k(\theta) = [\mathbf{b}^{(k)}]^T\,\mathbf{v}^{(k)}(\theta) & \text{if } k = 2\nu-1, \\ f_k(\theta) = [\mathbf{b}^{(k)}]^T\,\mathbf{v}^{(k)}(\theta) & \text{if } k = 2\nu. \end{cases}$$

Now, considering that $\cos(j\theta/2) = T_j(\cos(\theta/2))$, where T_j are the Chebyshev polynomials of first kind, an infinite matrix C can be found such that, for all $k \in \mathbb{N}^+$, the following formula holds:

$$\mathbf{v}^{(k)}(\theta) = C_{k+1}\, \mathbf{w}^{(k)}(\theta), \tag{2.12}$$

where C_{k+1} is the principal submatrix of order $k+1$ of C and the vector function $\mathbf{w}^{(k)}(\theta)$ is defined as

$$\mathbf{w}^{(k)}(\theta) := (1, \cos(\theta/2), \cos^2(\theta/2), \ldots, \cos^k(\theta/2))^T.$$

The infinite matrix C is lower triangular and its principal submatrix C_2 is coincident with the identity matrix I_2. The entries of the other rows are defined by the following recurrence relations (derived from the recurrence relation for Chebyshev polynomials):

$$\begin{cases} C_{i,j} & := -\,C_{i-2,j} & \text{if } j = 1,\ i \geq 3, \\ C_{i,j} & := 2\,C_{i-1,j-1} - C_{i-2,j} & \text{if } j \geq 2,\ i \geq 3. \end{cases}$$

For example, its principal submatrix C_8 is

$$C_8 = \begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -1 & 0 & 2 & 0 & 0 & 0 & 0 & 0 \\ 0 & -3 & 0 & 4 & 0 & 0 & 0 & 0 \\ 1 & 0 & -8 & 0 & 8 & 0 & 0 & 0 \\ 0 & 5 & 0 & -20 & 0 & 16 & 0 & 0 \\ -1 & 0 & 18 & 0 & -48 & 0 & 32 & 0 \\ 0 & -7 & 0 & 56 & 0 & -112 & 0 & 64 \end{pmatrix}.$$

We remark that through (2.12) the cosine of the jth multiple of $\theta/2$ is expressed as a linear combination of powers of $\cos(\theta/2)$ of degree $\leq j$. In particular, because of the checkerboard structure of C, cosines of even multiples of $\theta/2$ become linear combinations of even powers, while cosines of odd multiples are transformed into linear combinations of odd powers. We are now in the position to prove the following theorem.

THEOREM 3. *For all $k \in \mathbb{N}^+$, if*

$$\hat{\mathbf{b}}^{(k)} := C_{k+1}^T\, \mathbf{b}^{(k)}$$

is nonnegative with at least one positive entry, then the trigonometric polynomials f_k defined in (2.9) *are positive.*

Proof. The proof is almost trivial considering that the entries of $\hat{\mathbf{b}}^{(k)}$ are the coefficients of the trigonometric polynomials in the new basis of powers of $\cos(\theta/2)$. In fact, as already observed, if k is even only even powers are involved in the expression of $f_k(\theta)$. If k is odd, only odd powers are involved in the expression of $\cos(\theta/2)\, f_k(\theta)$. Then, again, only even powers are involved in the expression of $f_k(\theta)$. ∎

We remark that the theorem holds true for any class of symmetric linear multistep methods and it allows us to assert that the polynomial $\sigma^{(k)}(z)$ has no roots of unit modulus, except $z_1 = -1$ when k is odd, provided that the vector $\hat{\mathbf{b}}^{(k)}$ is nonnegative with at least one positive entry. In the case of BS methods, such a question is settled by the following theorem.

THEOREM 4. *If BS methods are considered, then for all $k \in \mathbb{N}^+$ the vector $\hat{\mathbf{b}}^{(k)}$ is nonnegative with at least one positive entry.*

Proof. This can be proved by taking into account (2.6). In fact, by using the same notation as before, such a relation can be posed in matrix form as

$$\mathbf{b}_k = \frac{1}{k+1} A^{(k)} \mathbf{b}_{k-1}, \tag{2.13}$$

where $A^{(k)}$ is a bidiagonal rectangular matrix ($A_{i,j} \neq 0$ only if $j = i-1$ or $j = i+1$) of size $(k+1) \times k$ whose nonzero entries are as follows, assuming that $\nu = \lceil k/2 \rceil$:

$$\begin{cases} A^{(k)}_{2,1} & = 2\nu, \\ A^{(k)}_{3,2} & = \nu, \\ A^{(k)}_{2i,2i-1} & = \nu + 1 - i, \quad i = 2, \ldots, \nu - 1, \\ A^{(k)}_{2i+1,2i} & = \nu + 1 - i, \quad i = 2, \ldots, \nu - 1, \\ A^{(k)}_{2\nu,2\nu-1} & = 1, \\ A^{(k)}_{2i-1,2i} & = \nu + i, \qquad i = 1, \ldots, \nu - 1, \\ A^{(k)}_{2i,2i+1} & = \nu + i, \qquad i = 1, \ldots, \nu - 1. \end{cases}$$

These relations need to be completed by the following two nonzero entries when k is even ($k = 2\nu$):

$$\begin{cases} A^{(2\nu)}_{2\nu+1,2\nu} & = 1, \\ A^{(2\nu)}_{2\nu-1,2\nu} & = 2\nu. \end{cases}$$

Consequently, the vectors $\hat{\mathbf{b}}_k$ satisfy the recurrence relation

$$\hat{\mathbf{b}}_k = \frac{1}{k+1} R^{(k)} \hat{\mathbf{b}}_{k-1},$$

where $R^{(k)} = C^T_{k+1} A^{(k)} (C^{-T}_k)$. Such a matrix can be constructed in explicit form considering the checkerboard and bidiagonal structures, respectively, of C_k and $A^{(k)}$. It is not difficult to see that $R^{(k)}$ has the same structure of $A^{(k)}$. Moreover, its nonzero entries are, still assuming that $\nu = \lceil k/2 \rceil$,

$$\begin{cases} R^{(k)}_{2i,2i-1} & = 2\,(\nu + 1 - i), \quad i = 1, \ldots, \nu - 1, \\ R^{(k)}_{2i+1,2i} & = 2\,(\nu + 1 - i), \quad i = 1, \ldots, \nu - 1, \\ R^{(k)}_{2\nu,2\nu-1} & = 2, \\ R^{(k)}_{j,j+1} & = j, \qquad\qquad j = 1, \ldots, k - 1, \end{cases} \tag{2.14}$$

which must be completed, if $k = 2\nu$, by

$$R^{(2\nu)}_{2\nu+1,2\nu} = 2.$$

These relations can be proved by checking that $C^T_{k+1} A^{(k)} = R^{(k)} C^T_k$. Thus, noting that $R^{(k)}$ is a nonnegative matrix and that $\hat{\mathbf{b}}_1 = (0, 1/2)^T$, the theorem is proved by induction. ∎

Before stating Corollary 1, we need the following definition.

DEFINITION 2.1. *A k-degree polynomial is of type* $(r, k-r-s, s)$*, with* $r+s \le k$*,* $r, s \ge 0$ *if it has* r *roots inside the open unit disk,* $k-r-s$ *roots on the unit circle, and* s *roots outside the closed unit disk.*

We can now state the following corollary.

COROLLARY 1. *For all* $k \in \mathbb{N}^+$*, the trigonometric polynomial* $f_k(\theta)$ *defined in* (2.9) *and associated with the kth step BS method is positive in* $[0\,,\,2\pi]$*. Consequently, if* $k_1 = \lceil \frac{k}{2} \rceil$ *and* $k_2 = \lfloor \frac{k}{2} \rfloor$*, the corresponding* $\sigma^{(k)}(z)$ *polynomial is of type* $(k_1, 0, k_2)$ *if* k *is even and of type* $(k_1 - 1, 1, k_2)$ *if* k *is odd.*

Proof. The proof trivially follows from Theorems 3 and 4. ∎

2.3. Stability of the BS methods. Taking into account (2.7), Corollary 1 implies that the BS methods with $k \ge 3$ are not 0-stable and, as a consequence, they cannot be used as initial value methods because convergence is lost, as already pointed out by Loscalzo [17]. However, convergence can be recovered if they are used as BVMs with $k_1 = \lceil \frac{k}{2} \rceil$ initial and $k_2 = \lfloor \frac{k}{2} \rfloor$ final conditions. This can be proved by noting that such methods are $0_{k1,k2}$-stable, which is a concept generalizing the classical 0-stability. A deeper discussion about the generalization of the concept of 0-stability and A-stability (see A_{k_1,k_2}-stability below) can be found in [5, 6]. In fact (2.7) implies that $\rho^{(k)}(z)$ has k_1 and k_2 roots whose modulus is less than or equal to 1 and greater than 1, respectively, and that the roots on the unit circle (1 and, for k even, -1) are simple. Together with the fact that these methods have order $p \ge k+1$, this leads to convergence, provided that the additional conditions are appropriately chosen.

On the other hand, we are not only interested in convergence, but also in a good behavior of the methods for fixed h. More explicitly, we would like these methods, for fixed h, to generate well-conditioned discrete problems when applied to well-conditioned continuous ones. In this regard, a BVM using k_1 initial and k_2 final conditions is said to be A_{k_1,k_2}-stable if it generates a well-conditioned discrete problem for each well-conditioned continuous linear problem, thus generalizing the well-known concept of A-stability. We say that a method is *precisely* A_{k_1,k_2}*-stable* if the associated Dahlquist polynomial $\pi^{(k)}(z,q) := \rho^{(k)}(z) - q\sigma^{(k)}(z)$ has constant type $(k_1, 0, k_2)$ only for all $q \in \mathbf{C}^-$. This implies that the boundary of the stability region is the imaginary axis. Precisely A_{k_1,k_2}-stable methods are the safest in the case of nondissipative problems. In fact it can be proved that A_{k_1,k_2}-stable methods which are not precisely stable can give wrong results for such problems [5].

The connection between the type of the Dahlquist polynomial and the position of q in the complex plane can be investigated by looking at the *boundary locus* (see (2.15) below) associated to the method considered. Essentially, such a set is the locus in the complex plane, where $\pi^{(k)}(z,q)$ changes its type, that is, one root reaches the unit circle. For the BS method, we have the following result.

THEOREM 5. *The boundary locus related to the k-step BS method is the imaginary axis of the complex plane if* k *is odd and is just a segment of the imaginary axis of the complex plane if* k *is even.*

Proof. The boundary locus Γ_k of a k-step linear multistep method is defined as

$$\Gamma_k := \left\{ q_k(\theta) \in \mathbf{C} \mid q_k(\theta) = \frac{\rho^{(k)}(e^{\mathbf{i}\theta})}{\sigma^{(k)}(e^{\mathbf{i}\theta})},\ \theta \in [0\,,\,2\pi] \right\}. \tag{2.15}$$

Considering (2.7), we have now that for the k-step BS method the boundary locus is

$$q_k(\theta) = k\,(e^{\mathbf{i}\theta} - 1)\,\frac{\sigma^{(k-1)}(e^{\mathbf{i}\theta})}{\sigma^{(k)}(e^{\mathbf{i}\theta})}. \tag{2.16}$$

On the other hand, (2.8) implies that we can also write

$$q_k(\theta) = \begin{cases} k\,\mathbf{i}\,\sin(\theta)\,\frac{f_{k-1}(\theta)}{f_k(\theta)} & \text{if } k = 2\nu, \\ 2k\,\mathbf{i}\,\tan(\frac{\theta}{2})\,\frac{f_{k-1}(\theta)}{f_k(\theta)} & \text{if } k = 2\nu+1, \end{cases} \tag{2.17}$$

where $\mathbf{i}$ denotes the imaginary unit. The statement of the theorem is proved by using the result proved in Corollary 1. □

Noting that Γ_k is the locus where the Dahlquist polynomial changes its type it then follows that such a type is constantly equal to $(k_1, 0, k_2)$ in $\mathbf{C}^-$ for all k. Since Γ_k coincides with the imaginary axis for k odd, in this case $\pi^{(k)}(z, q)$ changes its type, moving from $\mathbf{C}^-$ to $\mathbf{C}^+$. Consequently, we can conclude that the BS methods are always A_{k_1,k_2}-stable and that they are precisely A_{k_1,k_2}-stable if k is odd (see [5]).

We postpone until section 4, after the definition of the spline extension, the discussion about possible strategies for choosing the necessary additional conditions. At the moment, we assume that each method, together with the given initial or boundary condition and with the $k-1$ additional conditions, generates a unique discrete solution.

3. The spline extension. Let us now assume that a numerical solution $\{\mathbf{y}_i, i = 0, \ldots, N\}$ has been computed by the k-step BS method used as a BVM. Thus, if we put $\mathbf{y}'_i := f(x_i, \mathbf{y}_i), i = 0, \ldots, N$, we are interested in determining a vector spline function $\mathbf{s}_k(x) = (s_k^1(x), \ldots, s_k^d(x))^T$ with $s_k^j \in S_{k,N}, j = 1, \ldots, d$, such that

$$\begin{cases} \mathbf{s}_k(x_i) &= \mathbf{y}_i, \quad i = 0, \ldots, N, \\ \mathbf{s}'_k(x_i) &= \mathbf{y}'_i, \quad i = 0, \ldots, N \end{cases} \tag{3.1}$$

(i.e., a spline solution of the Hermite interpolation problem at the mesh points), where $S_{k,N}$ denotes the classical linear functional space of piecewise polynomials of degree $k+1$ and knots x_i, $i = 0, \ldots, N$, with global smoothness $C^k([a\,,\,b])$. Now, after defining $k+1$ auxiliary left knots $x_i = a + ih, i = -(1+k), \ldots, -1$, and $k+1$ auxiliary right knots $x_i = a + ih, i = N+1, \ldots, N+k+1$, we can write

$$S_{k,N} := \langle\, B_{-(1+k),k+2}, \ldots, B_{N-1,k+2} \,\rangle,$$

where

$$B_{j,k+2}(x) := B_{k+2}\left(\frac{x - x_j}{h}\right),\ j = -(1+k), \ldots, N-1. \tag{3.2}$$

Thus, using the B-spline representation of any $s_k^j \in S_{k,N}$, we can write

$$\mathbf{s}_k(x) = \sum_{i=-(1+k)}^{N-1} \mathbf{c}_i B_{i,k+2}(x),\ x \in [a, b], \tag{3.3}$$

where $\mathbf{c}_i \in \mathbb{R}^d, i = -(1+k), \ldots, N-1$, are the vector spline coefficients we are looking for. Consequently, (3.1) can be rewritten in the compact form

$$(A \otimes I_d)\,\mathbf{c} \;=\; (\mathbf{y}_0^T, \ldots, \mathbf{y}_N^T, h(\mathbf{y}'_0)^T, \ldots, h(\mathbf{y}'_N)^T)^T, \tag{3.4}$$

where $\mathbf{c} = (\mathbf{c}_{-(1+k)}^T, \ldots, \mathbf{c}_{N-1}^T)^T \in \mathbb{R}^{d\,(N+k+1)}$, I_d is the identity matrix of size $d \times d$, and A is the block matrix

$$A := \begin{pmatrix} A_1 \\ A_2 \end{pmatrix}. \tag{3.5}$$

Considering (3.2) and (2.3), it is easy to show that both the block matrices A_1, A_2 in (3.5) are Toeplitz matrices of size $(N+1) \times (N+k+1)$,

$$A_1 := \begin{pmatrix} \beta_0^{(k)} & \cdots & \beta_k^{(k)} & 0 & \dots & \dots & 0 \\ 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & 0 & \beta_0^{(k)} & \cdots & \beta_k^{(k)} \end{pmatrix}, \tag{3.6}$$

$$A_2 := \begin{pmatrix} \alpha_0^{(k)} & \cdots & \alpha_k^{(k)} & 0 & \dots & \dots & 0 \\ 0 & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & 0 \\ 0 & \cdots & \cdots & 0 & \alpha_0^{(k)} & \cdots & \alpha_k^{(k)} \end{pmatrix}. \tag{3.7}$$

The spline solution of (3.1), $\mathbf{s}_k(x)$, is uniquely determined, as proved in the following theorem.

THEOREM 6. *The rectangular linear system* (3.4) *has only one solution if the entries of the vector on the right-hand side satisfy* (2.5) *with* α *and* β *coefficients as defined in* (2.3).

Proof. From the classical theory of spline interpolation, we know that the coefficient matrix defined in (3.5) is a full rank matrix. In fact, this is a consequence of the general results about osculatory spline interpolation first presented in the classic paper [15] and reported also in [9, Thm. XIII.4, p. 228]. On the other hand, we know that the right-hand side of (3.4), $(\mathbf{y}_0^T, \dots, \mathbf{y}_N^T, h(\mathbf{y}_0')^T, \dots, h(\mathbf{y}_N')^T)^T$, satisfies the $N-k+1$ linear conditions given in (2.5), because the numerical solution is computed using just these relations. Now it is also easy to verify that, if $\mathbf{a}_1^{(j)}, \dots, \mathbf{a}_{N+1}^{(j)}$ denote the rows of $A_j, j = 1, 2$, then

$$\sum_{i=0}^{k} \alpha_i^{(k)} \, \mathbf{a}_{n+i}^{(1)} = \sum_{i=0}^{k} \beta_i^{(k)} \, \mathbf{a}_{n+i}^{(2)}, \ n = 0, \dots, N-k.$$

Consequently, in (3.4) there are $N-k+1$ redundancies, and this implies that there exists a unique solution of it since A is a full rank matrix. ∎

3.1. Procedure for constructing the spline extension. Once we have proved that there exists a unique solution, $\mathbf{s}_k(x)$, of (3.1), we need to choose an algorithm for the computation of its coefficient vectors $\mathbf{c}_i, i = -(1+k), \dots, N-1$. Clearly, we could solve (3.4) in the least squares sense, but this is too expensive, considering we know that there exists an exact solution of it. From spline theory (see again [9, Thm.

XIII.4, p. 228]), we know that the square submatrix M_1 of A, given by

$$M_1 := \begin{pmatrix} \begin{pmatrix} \mathbf{a}_1^{(2)} \\ \vdots \\ \mathbf{a}_{k_1}^{(2)} \end{pmatrix} \\ A_1 \\ \begin{pmatrix} \mathbf{a}_{N-k_2+1}^{(2)} \\ \vdots \\ \mathbf{a}_N^{(2)} \end{pmatrix} \end{pmatrix}, \tag{3.8}$$

is nonsingular, where we recall that $k_1 = \lceil \frac{k}{2} \rceil$ and $k_2 = \lfloor \frac{k}{2} \rfloor$. So we could solve the equivalent square linear system

$$\begin{aligned} &(M_1 \otimes I_d)\,\mathbf{c} \\ &\quad = (h(\mathbf{y}'_0)^T, \ldots, h(\mathbf{y}'_{k_1})^T, \mathbf{y}_0^T, \ldots, \mathbf{y}_N^T, h(\mathbf{y}'_{N-k_2+1})^T, \ldots, h(\mathbf{y}'_N)^T)^T. \end{aligned} \tag{3.9}$$

In the case of odd degree splines, interpolants at the knots are often determined by solving such a system. Nevertheless, this is a good idea only if k is even. Looking at Table 3.1, it is possible to realize that the condition number of M_1 does not depend on N (i.e., M_1 is *well conditioned*) only if k is even. If k is odd, it grows with N in a linear fashion (i.e., M_1 is *weakly well conditioned*). This behavior is explained by Theorem 7 and Corollary 2.

Unfortunately it is the case of k odd that we are more interested in because of the precise stability feature of the corresponding BS methods (see Theorem 5). Since we have the freedom of choosing from among the equations in (3.4), we have replaced (3.9) with the equivalent linear system

$$\begin{aligned} &(M_2 \times I_d)\,\mathbf{c} \\ &\quad = (\mathbf{y}_0^T, \ldots, \mathbf{y}_{k_1}^T, (\mathbf{y}_0 + h\mathbf{y}'_0)^T, \ldots, (\mathbf{y}_N + h\mathbf{y}'_N)^T, \mathbf{y}_{N-k_2+1}^T, \ldots, \mathbf{y}_N^T)^T, \end{aligned} \tag{3.10}$$

where

$$M_2 := \begin{pmatrix} \begin{pmatrix} \mathbf{a}_1^{(1)} \\ \vdots \\ \mathbf{a}_{k_1}^{(1)} \end{pmatrix} \\ A_1 + A_2 \\ \begin{pmatrix} \mathbf{a}_{N-k_2+1}^{(1)} \\ \vdots \\ \mathbf{a}_N^{(1)} \end{pmatrix} \end{pmatrix}. \tag{3.11}$$

TABLE 3.2
The condition numbers of M_2 in the Euclidean norm.

N	$k=1$	$k=2$	$k=3$	$k=4$	$k=5$
5	4.6	10.5	46.6	493.4	6179.7
10	4.6	10.3	46.3	432.6	4861.2
20	4.6	10.3	46.3	416.5	4850.7
40	4.6	10.3	46.3	416.1	4850.2
80	4.6	10.3	46.3	416.1	4850.2

Now the condition number of the new matrix M_2 does not depend on N for any value of k, as confirmed by Table 3.2 and explicitly proved in Theorem 7 and Corollary 3. Before introducing Theorem 7, we recall that the *polynomial* and the *symbol* associated to a $(k+1)$-banded Toeplitz matrix $T = (t_{i,j}), t_{i,j} = \tau_{j-i}$, with k_1 nonzero lower diagonals are $p(z) = \sum_{i=0}^{k} \tau_{-k_1+i}\, z^i$ and $z^{-k_1}p(z)$, respectively (see, e.g., [13, 14]).

THEOREM 7. *Assume that*

1. *k, k_1, and k_2 are three positive integers, with $1 \le k_1 < k$ and $k_2 = k - k_1$;*
2. *$M = T + R$, where T is an $n \times n, n > 2k$, $(k+1)$-banded Toeplitz matrix with k_1 nonzero lower diagonals;*
3. *R is a matrix having nonzero entries $R_{i,j}$ only if $i = 1, \ldots, k_1$ and $j = 1, \ldots, k + k_1$ or if $i = n - k_2 + 1, \ldots, n$ and $j = n - k - k_2 + 1, \ldots, n$;*
4. *the polynomial $p(z)$ associated to T is of type $(k_1 - s, s, k_2)$, $s = 0, 1$.*

Then, constants $\eta > 0$ and $0 < \zeta < 1$ independent of n exist such that the following two statements hold:

(a) *The matrix $|M^{-1}|$ whose entries are the absolute values of the corresponding ones in M^{-1} satisfies the componentwise bound*

$$\begin{array}{ll} |M^{-1}| \le \eta(I_n + \Delta_n + \Delta_n^T) & \text{for } s = 0, \\ |M^{-1}| \le \eta(I_n + \Omega_n + \Delta_n^T) & \text{for } s = 1, \end{array} \tag{3.12}$$

where

$$\Delta_n := \begin{pmatrix} 0 & 0 & \ldots & 0 \\ \zeta & 0 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ \zeta^{n-1} & \ddots & \zeta & 0 \end{pmatrix}_{n\times n} \quad \text{and} \quad \Omega_n = \begin{pmatrix} 0 & 0 & \ldots & 0 \\ 1 & 0 & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 1 & \ddots & 1 & 0 \end{pmatrix}_{n\times n};$$

(b) $||M^{-1}||_\infty,\ ||M^{-1}||_1,\ ||M^{-1}||_2 \le \frac{\eta}{1-\zeta}$ *for $s = 0$,*
$||M^{-1}||_\infty,\ ||M^{-1}||_1,\ ||M^{-1}||_2 \le \eta n$ *for $s = 1$.*

Proof. If the perturbation matrix R is not taken into account, the proof follows immediately from a more general result about conditioning of banded Toeplitz matrices given in [1] and in [5, p. 74]. Then, since the matrix M^{-1} can be recast as

$$M^{-1} = (I_n + T^{-1}R)^{-1}T^{-1}, \tag{3.13}$$

the proof is reduced to showing that the matrix $(I_n + T^{-1}R)^{-1}$ exists and has entries bounded with respect to n. This has been done in [14], and we omit the long manipulation for brevity. ∎

COROLLARY 2. *The matrix M_1 defined in* (3.8) *is well conditioned in the case of k even and weakly well conditioned in the case of k odd.*

Proof. M_1 can be split as $M_1 = T_1 + R_1$, where T_1 is a $(k+1)$-banded Toeplitz matrix whose associated symbol is $z^{-k_1}\sigma^{(k)}(z)$ and R_1 satisfies the related hypothesis assumed in Theorem 7. Having proved in section 2.2 that $\sigma^{(k)}(z)$ is of type $(k_1, 0, k_2)$ if k is even and of type $(k_1 - 1, 1, k_2)$ if k is odd, the proof follows from the previous theorem. ∎

COROLLARY 3. *The matrix M_2 defined in* (3.11) *is well conditioned for all values of k.*

Proof. M_2 can be split as $M_2 = T_2 + R_2$, where T_2 is a k-banded Toeplitz matrix whose associated symbol is $z^{-k_1}(\rho^{(k)}(z) + \sigma^{(k)}(z))$. In section 2.3 it has been proved that the k-step BS method is A_{k_1,k_2}-stable. This implies that the polynomial $\rho^{(k)}(z) - q\sigma^{(k)}(z)$ always has the same type $(k_1, 0, k_2)$ for all $q \in \mathbf{C}^-$. By taking $q = -1$, the corollary follows from the previous theorem. ∎

4. The additional conditions. The BVM usage of a k-step linear multistep formula does not impose all the $k-1$ additional conditions at the beginning of the interval, but it carefully splits such conditions at the beginning and at the end of the interval. It is interesting to note that the construction of interpolating splines has exactly the same degrees of freedom, and usually the required additional conditions are split similarly. In order to show the deep similarity between the spline interpolation process and the BVM approach, we consider the classical cubic spline interpolation; see [9, p. 53]. If the free slopes denoted there by $s_i, i = 2, n-1$ are taken to be equal to $f(x_i, y_i)$ defined in (1.1), then the continuity conditions give rise to the 2-step BS method, i.e., Simpson's method. On the other hand, it is known that the boundary conditions suggested in [9] are imposed one at the beginning and the other at the end of the interval, as suggested, using different reasoning, in [5]. The use of Simpson's method with both conditions at the beginning gives rise to a very unstable method.

Therefore, in order to use the k-step BS method correctly as a BVM we need to define the $k_1 = \lceil \frac{k}{2} \rceil$ initial and the $k_2 = \lfloor \frac{k}{2} \rfloor$ final conditions. One condition is naturally given by problem (1.1); the others need to be defined. There are many possible choices for the additional boundary conditions, precisely as in the classical definition of spline interpolating functions. Usually, they are obtained by using different linear multistep methods of order $\geq p - 1$. Here, alternatively, we can take advantage of the methodology used in the spline setting. One possibility is to use the so called "not-a-knot" condition which implies that some knots of the spline near the extremes of the integration interval are removed. The not-a-knot condition at the generic point x_j is $\mathbf{s}_k^{(k+1)}(x_j^-) = \mathbf{s}_k^{(k+1)}(x_j^+)$. Such a condition can be translated into a linear condition on the functional and derivative values assumed by the spline at the knots. Each translated condition will become an additional condition. For example, it is known (see [9]) that for the Simpson method the not-a-knot condition at x_{N-1} corresponds to the equation

$$-\mathbf{y}_{N-2} - 4\mathbf{y}_{N-1} + 5\,\mathbf{y}_N = h\,(4\mathbf{y}'_{N-1} + 2\mathbf{y}'_N). \tag{4.1}$$

For brevity, we avoid presenting the manipulation needed to obtain such conditions for $k > 2$ (it is fully introduced in the general case of a nonuniform mesh in [19]).

Different techniques are also possible. For example, one can compute an estimate of some derivatives of $\mathbf{y}(x)$ at the boundary points using finite differences. In the above example, a good choice (which does not affect the fourth order convergence) could be to compute the derivative using the backward differentiation formula of the

same order, that is,

$$\mathbf{y}'_N = \frac{-2\mathbf{y}_{N-3} + 9\mathbf{y}_{N-2} - 18\mathbf{y}_{N-1} + 11\mathbf{y}_N}{6h}.$$

This means that $\mathbf{y}'_N$ is taken to be equal to the derivative value at x_N of the cubic polynomial passing through $(x_i, \mathbf{y}_i), i = N-3, \ldots, N$.

5. Convergence of the spline extension. An important feature of the class of BS methods is the convergence in the uniform norm of the related continuous extension $\mathbf{s}_k(x)$ to the solution $\mathbf{y}(x)$ of (1.1). We now prove the following theorem, where for the sake of brevity we restrict ourselves to $d = 1$.

THEOREM 8. *Let us assume that $y \in C^{k+2}[a, b]$. Then*

$$\|s_k - y\|_\infty \leq C_{k,y}\, h^p,$$

where $C_{k,y}$ is a suitable constant depending on k and y and

$$p = \begin{cases} k+2 & \text{if } k \text{ is even,} \\ k+1 & \text{if } k \text{ is odd.} \end{cases} \tag{5.1}$$

Proof. Clearly, we can write

$$\|s_k - y\|_\infty \leq \|s_k - \hat{s}_k\|_\infty + \|\hat{s}_k - y\|_\infty, \tag{5.2}$$

where $\hat{s}_k(x) \in S_{k,N}$ is the best approximation of $y(x)$ in $S_{k,N}$. The second term on the right-hand side of (5.2) can be bounded using the general result proved in the Jackson-type theorem reported in [9, Thm. XII.1, p. 170],

$$\|\hat{s}_k - y\|_\infty \leq C_k^{(1)}\, h^{k+2}\, \|y^{(k+2)}\|_\infty, \tag{5.3}$$

where $C_k^{(1)}$ is a constant depending only on k and $y^{(k+2)}$ denotes the $(k+2)$-derivative of y.

So let us consider the first term on the right-hand side of (5.2). If $s_k(x) = \sum_{i=-(1+k)}^{N-1} c_i\, B_{i,k+2}(x)$, and $\hat{s}_k(x) = \sum_{i=-(1+k)}^{N-1} \hat{c}_i\, B_{i,k+2}(x)$, since the B-splines $B_{i,k+2}(\cdot), i = (-1+k), \ldots, N-1$, are nonnegative and satisfy the unit partition property in $[a\,, b]$, we can write

$$\|s_k - \hat{s}_k\|_\infty = \left\| \sum_{i=-(1+k)}^{n-1} (c_i - \hat{c}_i)\, B_{i,k+2}(x) \right\|_\infty \leq \|\mathbf{c} - \hat{\mathbf{c}}\|_\infty.$$

Now, as mentioned in section 4.1, the coefficient vector $\mathbf{c}$ can be safely computed for all k by solving linear system (3.10). Thus, considering that p defined in (5.1) is the order of the k-step BS method, we can write

$$M_2\, \mathbf{c} = \mathbf{b}_y + O\,(h^p), \tag{5.4}$$

where M_2 is the square matrix defined in (3.11) and $\mathbf{b}_y = (y(x_0), \ldots, y(x_{k_1}), y(x_0) + hy'(x_0), \ldots, y(x_N) + hy'(x_N), y(x_{n-k_2+1}), \ldots, y(x_N))^T$. On the other hand, since M_2 is nonsingular, we can also write

$$M_2\, \hat{\mathbf{c}} = \mathbf{b}_{\hat{s}_k},$$

where $\mathbf{b}_{\hat{s}_k}$ is defined similarly to $\mathbf{b}_y$. Now, (5.3) implies that $\mathbf{b}_{\hat{s}_k} = \mathbf{b}_y + O(h^{k+2})$. Thus,

$$M_2(\mathbf{c} - \hat{\mathbf{c}}) = O(h^p).$$

Recalling from section 4.1 that the condition number of M_2 does not depend on N, we can conclude that $\|\mathbf{c} - \hat{\mathbf{c}}\|_\infty = O(h^p)$, and this implies that there exists a suitable constant $\bar{C}_{k,y}$ depending on k and y such that

$$\|s_k - \hat{s}_k\|_\infty \leq \bar{C}_{k,y}\, h^p. \tag{5.5}$$

Now, using (5.2), the statement of the theorem is proved. ∎

6. Numerical results. In order to test the features of the BS methods and of the related spline extensions, we have applied the methods for the numerical solution of classical test problems for which we know the exact solutions. We presents numerical results using both uniform (Problem 1 and 2) and nonuniform (Problem 3) meshes.

The additional $(k_1 - 1) = \lceil \frac{k}{2} \rceil - 1$ left and $k_2 = \lfloor \frac{k}{2} \rfloor$ right conditions have been chosen by requiring that the associated spline extension $\mathbf{s}_k$ verifies the not-a-knot condition at the knots $x_1, \ldots, x_{k_1-1}$ and $x_{N-k_2}, \ldots, x_{N-1}$. As pointed out in section 4, alternative choices are possible, but this one guarantees a quite natural additional request to the spline extension.

In the case of a nonuniform mesh we use a preliminary implementation of the BS methods written in MATLAB that is very similar to the one presented in [18, 20] for the code TOM; they are especially similar concerning the stepsize variation strategy and the solution of the nonlinear equations. The continuous extension is used to compute the new approximation of the solution if the mesh is changed. This approximation is also used in the stopping criteria for the quasi-linearization procedure. We do not give details of this implementation because here we are interested only in showing that these methods can be effectively used for the numerical solution of boundary value problems. The extension of the BS methods to the general case of a nonuniform mesh requires the computation of the variable coefficients of the numerical scheme. Details on this topic are presented in [19].

Problem 1. The first problem is the second order boundary value problem

$$\begin{cases} \epsilon y''(x) = y'(x), \ x \in [0\,,\,1], \\ y(0) = 1, \qquad y(1) = 0. \end{cases} \tag{6.1}$$

with $\epsilon = 0.05$, which corresponds to a moderately and poorly conditioned continuous problem. The results related to this test problem are presented in Table 6.1. For each value of N and k two relative errors are reported, one related to the numerical solution and the other to the spline extension, defined by $Em_N^{(k)} := \max_{i=0,\ldots,N} |s_k(x_i) - y(x_i)| / \max(1, |y(x_i)|)$ and $Es_N^{(k)} := \|(s_k - y)/\max(1, |y|)\|_\infty$, respectively. The latter has always been evaluated sampling both s_k and y on 3000 uniformly spaced points of the integration interval.

Table 6.1 shows both $Em_N^{(k)}$ and $Es_N^{(k)}$ for different values of k. More precisely, each row contains the results for two successive BS methods of the same order (i.e., $Em_N^{(k)}, Es_N^{(k)}$ and $Em_N^{(k+1)}, Es_N^{(k+1)}$ for a fixed even value of k). The columns labeled L_N contain the values of the numerically computed order of convergence for the spline extension. It is evident that for k even the error in the solution is greater with respect to the method of the same order with odd k.

TABLE 6.1
Test problem 1.

k	N	$Em_N^{(k+1)}$	$Es_N^{(k+1)}$	$L_N^{(k+1)}$	$Em_N^{(k)}$	$Es_N^{(k)}$	$L_N^{(k)}$
2	40	$2.36\,10^{-4}$	$2.42\,10^{-4}$	3.96	$1.54\,10^{0}$	$1.55\,10^{0}$	
2	80	$1.11\,10^{-5}$	$1.13\,10^{-5}$	4.42	$8.87\,10^{-2}$	$8.88\,10^{-2}$	4.12
2	160	$4.32\,10^{-7}$	$4.33\,10^{-7}$	4.71	$6.59\,10^{-3}$	$6.60\,10^{-3}$	3.75
2	320	$1.50\,10^{-8}$	$1.50\,10^{-8}$	4.85	$4.54\,10^{-4}$	$4.51\,10^{-4}$	3.87
2	640	$4.96\,10^{-10}$	$4.92\,10^{-10}$	4.93	$2.98\,10^{-5}$	$2.95\,10^{-5}$	3.93
4	40	$1.75\,10^{-5}$	$1.83\,10^{-5}$	5.39	$2.60\,10^{-3}$	$2.60\,10^{-3}$	4.11
4	80	$2.59\,10^{-7}$	$2.63\,10^{-7}$	6.12	$7.87\,10^{-5}$	$7.87\,10^{-5}$	5.04
4	160	$2.80\,10^{-9}$	$2.81\,10^{-9}$	6.54	$1.70\,10^{-6}$	$1.70\,10^{-6}$	5.53
4	320	$2.58\,10^{-11}$	$2.58\,10^{-11}$	6.76	$3.13\,10^{-8}$	$3.13\,10^{-8}$	5.76
4	640	$2.19\,10^{-13}$	$2.17\,10^{-13}$	6.89	$5.30\,10^{-10}$	$5.26\,10^{-10}$	5.90

We can thus conclude that, in general, BS methods with odd k are preferable.

Problem 2. The second test considered is the harmonic oscillator equation with boundary conditions described by

$$\begin{cases} \mathbf{y}'(x) &= A\,\mathbf{y}(x),\ x \in [0\,,\,2\pi], \\ y_1(0) &= 3, \\ y_2(2\pi) &= 3, \end{cases} \tag{6.2}$$

where $A = \begin{pmatrix} 0 & 5 \\ -5 & 0 \end{pmatrix}$. As is known, the solution in the phase plane is a circle (with radius $3\sqrt{2}$). Figures 6.1 and 6.2 show the obtained results. The values used for k are 3 and 5. In both cases the spline extension does not introduce undesirable additional perturbations, but for relatively small mesh sizes it nicely reproduces the shape of the continuous solution.

Problem 3. The third test problem is

$$\begin{cases} \epsilon y''(x) = y(x) + y^2(x) - \exp(-2x/\sqrt{\epsilon}),\ x \in [0\,,\,1], \\ y(0) = 1, \qquad y(1) = \exp(-1/\sqrt{\epsilon}), \end{cases} \tag{6.3}$$

whose exact solution is $y(x) = \exp(-x/\sqrt{\epsilon})$. This is a nonlinear problem that has been solved using a variable stepsize implementation of the numerical schemes with k odd. This problem has been chosen because we know the exact solution, so we can compute the error. Moreover, the numerical solution presents a boundary layer at $x = 0$, and the use on a nonuniform mesh is preferable.

Table 6.2 reports the numerical results obtained for different values of ϵ and different values of the relative and absolute tolerances used to compute the solution. In the example we use $tol = rtol = atol$ and we accept the solution if

$$\max_{i=1,N} |y_i - \hat{y}_i| / \max(atol, rtol|\hat{y}_i|) < 1,$$

where y_i is the computed solution at the mesh points, and $\hat{y}_i$ is an approximation of the exact solution computed using a higher order method in the same class by a deferred correction like procedure. We compare the order 4, 6, and 8 ($k = 3, 5, 7$) schemes. Their behavior seems to be consistent with the order of the methods. For lower values of the tolerances the order 8 scheme reaches the solution using the minimum number of mesh points ($N_{\max}$ in the table). The error at the mesh points and the error in the spline are very similar, so we report only the error at the mesh points (Em in the table).

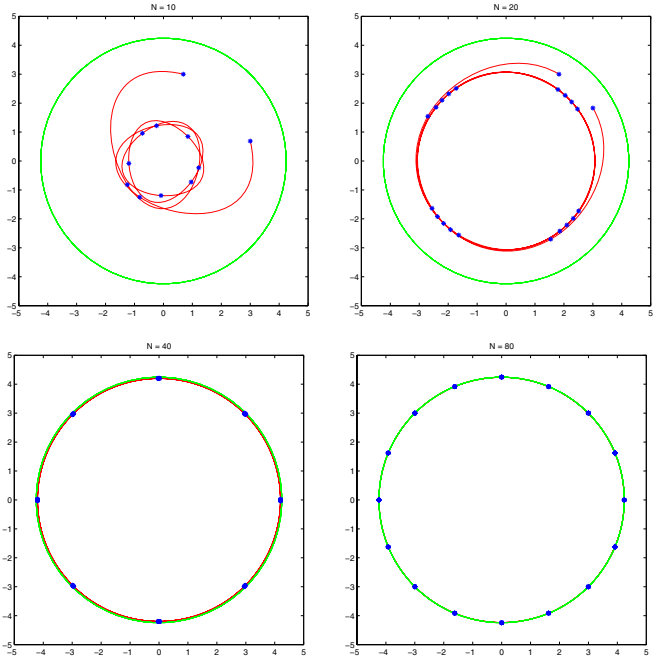

FIG. 6.1. *Test problem* (6.2). *Results for the case when* $k = 3$ *('-' exact solution; '-*' computed solution and mesh points).*

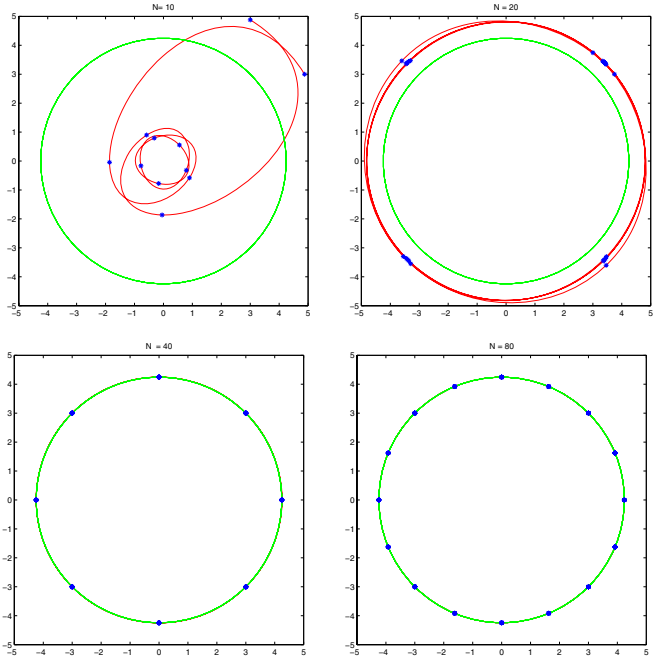

FIG. 6.2. *Test problem* (6.2). *Results for the case when* $k = 5$ *('-' exact solution; '-*' computed solution and mesh points).*

TABLE 6.2
Test problem 3.

	$k=3$			$k=5$			$k=7$		
ϵ	N_{max}	$\frac{h_{\max}}{h_{min}}$	E_m	$N_{\max}$	$\frac{h_{\max}}{h_{\min}}$	E_m	$N_{\max}$	$\frac{h_{\max}}{h_{\min}}$	E_m
	tol = 1e-4								
10^{-2}	21	1.0e0	2.0e-4	21	1.0e0	1.1e-4	21	1.0e0	1.1e-04
10^{-4}	97	2.7e1	3.8e-6	105	2.8e1	3.7e-6	99	2.0e1	3.7e-06
10^{-6}	131	1.3e3	5.7e-7	133	1.3e3	2.9e-7	156	5.1e2	7.1e-08
	tol = 1e-6								
10^{-2}	87	2.5e0	6.4e-8	21	1.0e0	1.5e-5	21	1.0e0	1.9e-06
10^{-4}	169	1.3e1	1.8e-7	105	2.8e1	9.3e-8	99	2.0e1	9.1e-08
10^{-6}	331	6.4e2	2.3e-7	233	3e+2	3.6e-9	192	2.5e2	1.2e-09
	tol = 1e-8								
10^{-2}	173	4.5e0	4.8e-09	41	1.0e0	2.3e-07	41	1.0e0	6e-09
10^{-4}	631	2.7e1	3.5e-09	185	1.4e1	6.8e-10	99	2.0e1	2.7e-09
10^{-6}	1085	2.6e3	1.2e-08	249	3e2	6.0e-10	284	2.1e2	3.4e-11

The behavior of E_m is consistent with the order of the methods. For lower values of the tolerances higher order methods reach the solution using a smaller number of mesh points. As expected, the ratio $h_{\max}/h_{\min}$ increases as ϵ decreases, showing that the BS methods could also be used with the nonuniform mesh. More details and examples about the BS methods on nonuniform grids are presented in [19].

Appendix (alternative proof of the convergence order). We give here an alternative proof that $p \geq k+1$, starting from the following identity, which holds for arbitrary $t, x \in \mathbb{R}$, (see for instance [24, Thm. 4.21, p. 125]):

$$(t - x)^{k+1} = \sum_{i=-\infty}^{+\infty} \phi_{i,k+1}(t)\, B_{k+2}(x-i), \tag{A.1}$$

where $\phi_{i,k+1} \in \Pi_{k+1}$ is the factorial power

$$\phi_{i,k+1}(t) := (t-i-1)^{(k+1)}.$$

Deriving (A.1) successively with respect to t, we get

$$(k+1)^{(j)}\,(t-x)^{k+1-j} = \sum_{i=-\infty}^{+\infty} \frac{d^j\,\phi_{i,k+1}}{d^j\,t}(t)\; B_{k+2}(x-i),\; j=0,\ldots,k+1. \tag{A.2}$$

Assuming that $t = x$, these identities allow us to rederive the well-known partition of unity property of B-splines (obtained for $j = k+1$),

$$\sum_{i=-\infty}^{+\infty} B_{k+2}(x-i) = 1, \tag{A.3}$$

and the identities

$$\sum_{i=-\infty}^{+\infty} \frac{d^j\,\phi_{i,k+1}}{d^j\,x}(x)\; B_{k+2}(x-i) = 0,\; j=0,\ldots,k. \tag{A.4}$$

If we consider $x \in [k+1\,,\,k+2]$, the range for the index i in both (A.3) and (A.4) can be restricted to $i = 0, \ldots, k+1$ and so these identities can be rewritten in matrix form using finite matrices as

$$Z(x)\,\mathbf{B}(x) \;=\; (1, 0, \ldots, 0)^T, \tag{A.5}$$

where $\mathbf{B}(x) := (B_{k+2}(x), \ldots, B_{k+2}(x-k-1))^T$ and where $Z(x)$ is a square matrix of order $k+2$ defined as

$$Z(x) \;:=\; \begin{pmatrix} 1 & \cdots & 1 \\ \frac{d^k\,\phi_{0,k+1}}{d^k\,x}(x) & \cdots & \frac{d^k\,\phi_{k+1,k+1}}{d^k\,x}(x) \\ \vdots & \vdots & \vdots \\ \phi_{0,k+1}(x) & \cdots & \phi_{k+1,k+1}(x) \end{pmatrix}.$$

Now each $\phi_{i,k+1}(x)$ is a polynomial of degree $k+1$ and can be expressed in terms of the classical power basis as

$$\phi_{i,k+1}(x) = \sum_{r=0}^{k+1} S_r^{(k+1)}\,(x-i-1)^r,$$

where the coefficients $S_r^{(k+1)}, r = 0, \ldots, k+1$, are the Stirling numbers of first kind. Thus, there exists a nonsingular constant lower triangular matrix L such that

$$Z(x) \;=\; L\,W(x), \tag{A.6}$$

where $W(x)$ is the Vandermonde matrix

$$W(x) \;:=\; \begin{pmatrix} 1 & \cdots & 1 \\ x-1 & \cdots & x-k-2 \\ \vdots & \vdots & \vdots \\ (x-1)^{k+1} & \cdots & (x-k-2)^{k+1} \end{pmatrix},$$

and where the nonzero elements of L are $L_{1,1} \;=\; 1$ and $L_{i,j} \;=\; S_{j+k-i+1}^{(k+1)}\,(j+k-i+1)^{(k+2-i)}, j \le i\,,\; i = 2, \ldots, k+2$.

Replacing (A.6) in (A.5), we get $W(x)\,\mathbf{B}(x) \;=\; L^{-1}(1, 0, \ldots, 0)^T$ and, deriving with respect to x, we obtain the formula

$$W'(x)\,\mathbf{B}(x) \;+\; W(x)\,\mathbf{B}'(x) = 0, \tag{A.7}$$

where the meanings of $W'(x)$ and $\mathbf{B}'(x)$ are obvious. Considering that

$$W'(x) \;=\; \begin{pmatrix} 0 & \cdots & \cdots & \cdots & 0 \\ 1 & \ddots & & \cdots & \vdots \\ 0 & 2 & \ddots & \cdots & \vdots \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \cdots & k+1 & 0 \end{pmatrix} W(x)\,,$$

and that

$$\begin{cases} \mathbf{B}(k+2) & = (0, \beta_0^{(k)}, \ldots, \beta_k^{(k)})^T \;=\; \quad (0, \beta_k^{(k)}, \ldots, \beta_0^{(k)})^T, \\ \mathbf{B}'(k+2) & = (0, \alpha_0^{(k)}, \ldots, \alpha_k^{(k)})^T \;=\; -\quad (0, \alpha_k^{(k)}, \ldots, \alpha_0^{(k)})^T, \end{cases}$$

evaluating (A.7) in $x = k + 2$, we get the usual $k + 1$ order conditions (expressed in matrix form, see, e.g., [5]).

WEIGHTED-NORM FIRST-ORDER SYSTEM LEAST SQUARES (FOSLS) FOR PROBLEMS WITH CORNER SINGULARITIES*

E. LEE†, T. A. MANTEUFFEL†, AND C. R. WESTPHAL‡

Abstract. A weighted-norm least-squares method is considered for the numerical approximation of solutions that have singularities at the boundary. While many methods suffer from a global loss of accuracy due to boundary singularities, the least-squares method can be particularly sensitive to a loss of regularity. The method we describe here requires only a rough lower bound on the power of the singularity and can be applied to a wide range of elliptic equations. Optimal order discretization accuracy is achieved in weighted H^1, and functional norms and L^2 accuracy are retained for boundary value problems with a dominant div/curl operator. Our analysis, including interpolation bounds and several Poincaré-type inequalities, are carried out in appropriately weighted Sobolev spaces. Numerical results confirm the error bounds predicted in the analysis.

Key words. least squares, finite element method, singularities, weighted norm, weighted Sobolev space

1. Introduction.

In this paper, we develop a method for treating div/curl systems with reduced regularity. While motivated by first-order systems that arise from second-order elliptic boundary value problems, div/curl systems appear in many contexts, such as for example, Maxwell's equations and the vorticity form of Stokes equations. These problems have the fortunate property of a guaranteed smooth solution as long as the data and domain are smooth. However, many problems of interest are posed in nonsmooth domains and, as a consequence, lose this property at a finite number of points on the boundary in two dimensions or along curves on the boundary in three dimensions. In the present paper, we study two-dimensional problems that have nonsmooth solutions at *irregular boundary points*, that is, points that are corners of polygonal domains, locations of changing boundary condition type, or both. Similar behavior occurs in problems with discontinuous material coefficients, and the methods presented here can easily be extended to that situation.

Standard solution techniques that attempt to approximately solve a div/curl system with reduced regularity using H^1-conforming finite elements will, in general, fail to converge. This phenomenon can be explained by noting that the Sobolev space $(H^1)^2$ is a closed subspace of $H(\mathrm{div})\cap H(\mathrm{curl})$ (see section 2), which implies either that $(H^1)^2 = H(\mathrm{div}) \cap H(\mathrm{curl})$, the case of full regularity, or $(H^1)^2$ is a proper subspace. In this case, the codimension is finite and is spanned by so-called singular functions. In the presence of reduced regularity, the solution will, in general, not be in $(H^1)^2$. A standard finite element method using H^1-conforming elements will converge to the

element of $(H^1)^2$ closest to the true solution in the $H(\mathrm{div}) \cap H(\mathrm{curl})$ norm. Local mesh refinement will not alter this outcome.

If a basis for the singular functions is known, it can be incorporated directly into the finite element space (cf. [10, 16, 24]). In [3, 4], this approach is applied to div/curl systems and shown to restore optimal convergence throughout the domain at a minimal additional cost. For some two-dimensional problems, the singular basis functions are known and can be included in the finite element space. For the other problems, or in three dimensions, the exact character of the singular functions is less understood, which makes this approach more difficult to implement.

As a different type of remedy for this so-called pollution effect, least-squares methods based on inverse norms can be effective for problems with irregular boundary points, discontinuous coefficients, and data in H^{-1}. For example, in [5, 8, 11, 12, 13, 19], the functional is posed in terms of H^{-1}-norms rather than L^2-norms, resulting in optimal L^2-approximations to the solution. A more recent approach, called FOSLL*, uses an inverse norm induced by the equations and is shown in [14, 22] to be more efficient than the H^{-1}-norm methods.

Graded mesh refinement in weighted Sobolev spaces has been shown to be effective in restoring optimal convergence, in L^2- and H^1-norms, in the context of a Galerkin formulation of second-order elliptic problems with reduced regularity (cf. [2, 1]). However, in that context, the solution is in H^1. Convergence would occur, although more slowly, without weighting and mesh refinement.

In [15], a weighted norm and a sequence of graded meshes is used in an $H(\mathrm{div})$ least-squares functional, arising from a second-order elliptic problem, to restore optimal convergence for the primal variable, in both L^2- and H^1-norms, if the flux variable is approximated in a finite element space satisfying the grid decomposition property, for example, Raviart–Thomas elements (cf. [6]). The flux variable converges in a weighted $H(\mathrm{div})$-norm.

In this paper we examine div/curl systems that lack regularity within the first-order system least-squares (FOSLS) framework. The basic FOSLS approach is to recast the original system as an appropriate first-order system and apply an L^2 minimization principle over the residual of the equations. If possible, this reformulation is done by minimizing a functional whose quadratic part is equivalent to the product H^1-norm, indicating that the process is similar to solving a weakly coupled system of Poisson-like equations. This equivalence also guarantees optimal H^1-accuracy for standard discretizations. For div/curl systems with reduced regularity, as briefly mentioned above, the L^2-based functional fails to be H^1-equivalent and, as a consequence, standard discretizations suffer from the pollution effect. Here, a weighted-norm least-squares method is developed that restores optimal convergence using H^1-conforming finite elements without graded mesh refinement. It replaces the L^2-norms in the FOSLS functional with weighted L^2-norms, making the functional norm equivalent to a weighted H^1-norm. With an appropriate weighting function, this method recovers optimal order accuracy in the weighted L^2- and H^1-norms and retains optimal L^2 convergence even near the singularity. Our method requires only the power of the singularity (not the actual singular solution) to be known a priori and, in practice, can be used with only a rough estimate of the power of the singularity, which can be adaptively determined if unknown (cf. [4]).

The method developed here has some similarity to [15] but considers an $H(\mathrm{div}) \cap H(\mathrm{curl})$ functional and considers more general boundary conditions. Most important, our analysis admits a more aggressive weighting, resulting in optimal order accuracy in the weighted norms without mesh refinement. In addition, we prove several Poincaré-

type inequalities in weighted Sobolev spaces under a variety of boundary conditions that, in addition to being necessary for our main result, may be of independent interest.

We use Poisson's equation on a domain with a reentrant corner as a model problem and as the formal setting for analysis. The resulting div/curl system is the focus. The analysis in this paper is restricted to two dimensions. However, the approach suggests a natural generalization to problems with reduced regularity due to discontinuous coefficients and to problems in three dimensions.

This paper is organized as follows. Section 2 contains notation and a preliminary discussion. In section 3, the weighted FOSLS functionals are described. Section 4 contains Poincaré inequalities and regularity results in weighted Sobolev spaces. Error bounds for the weighted FOSLS functional are presented in section 5, and section 6 contains computational results.

2. Singular solutions and preliminaries. For vector function $\mathbf{u} = (u_1, u_2)^t$, let the divergence and curl of $\mathbf{u}$ be defined in the standard way: $\nabla \cdot \mathbf{u} = \partial_x u_1 + \partial_y u_2$ and $\nabla \times \mathbf{u} = \partial_x u_2 - \partial_y u_1$. Further, define the formal adjoint of the curl operator by

$$\nabla^{\perp} q = \begin{pmatrix} \partial_y q \\ -\partial_x q \end{pmatrix}.$$

We use standard notation for Sobolev spaces $H^k(\Omega)^d$, corresponding inner product $(\cdot,\cdot)_{k,\Omega}$, and norm $\|\cdot\|_{k,\Omega}$, for $k \geq 0$. We drop subscript Ω and superscript d when the domain and dimension are clear by context. Since $H^0(\Omega)$ coincides with $L^2(\Omega)$ we often denote $\|\cdot\|_0$ by $\|\cdot\|$. Define the subspaces of $L^2(\Omega)$ induced by the divergence and curl of $\mathbf{u}$ by

$$H(\mathrm{div}) = \{\mathbf{u} \in L^2(\Omega) : \|\nabla \cdot \mathbf{u}\| < \infty\},$$
$$H(\mathrm{curl}) = \{\mathbf{u} \in L^2(\Omega) : \|\nabla \times \mathbf{u}\| < \infty\}.$$

We also make use of the following general inequalities for nonnegative a and b:

$$|a|^2 + |b|^2 \leq |a+b|^2 \leq 2(|a|^2 + |b|^2). \tag{2.1}$$

Consider the function $f(r,\theta) = r^a$ in two-dimensional polar coordinates. Assume that the origin lies on the boundary of domain

$$\Omega_w = \{(r,\theta) : 0 < r < R,\ 0 < \theta < \omega < 2\pi\},$$

as pictured in Figure 2.1. By a direct computation it is clear that $f \in H^k(\Omega)$ only for $k < a + 1$.

Now, consider Poisson's equation on a domain in $\mathbb{R}^2$ with a corner of interior angle ω. It is well known that, for the case of Dirichlet or Neumann boundary conditions, the solutions of this boundary value problem may include those with radial part of the form $p \sim r^{\frac{\pi}{\omega}}$ in a local polar coordinate system centered at the corner. Thus, for the case of reentrant corners, $\omega > \pi$, the solution fails to be in $H^2(\Omega)$ and we say that the problem has a singularity (or singular solution). For problems with Dirichlet and Neumann boundary conditions meeting at the corner, solutions may have components of the form $p \sim r^{\frac{\pi}{(2\omega)}}$. Thus, for mixed boundary conditions, singularities may occur at corners with $\omega > \pi/2$. We now explore this issue in more detail.

Define the power of the singularity to be $\alpha = \pi/\omega$ for Dirichlet or Neumann boundary conditions and $\alpha = \pi/(2\omega)$ for mixed boundary conditions. The solution

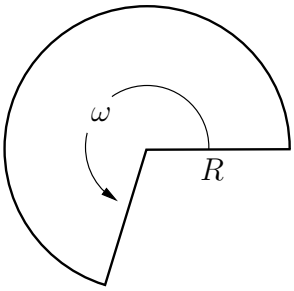

FIG. 2.1. *Simple wedge-shaped domain, Ω_w.*

to Poisson's equation may be written as

$$p(r,\theta) = p_0(r,\theta) + s(r,\theta),$$

where $p_0(r,\theta) \in H^2(\Omega)$ and $s(r,\theta) \in H^{1+m}(\Omega)$ for $m < \alpha$. The singular part of the solution has the form

$$s(r,\theta) = r^\alpha(\kappa_1 \sin(\alpha\theta) + \kappa_2 \cos(\alpha\theta)),$$

where the values of κ_1 and κ_2 depend on boundary conditions (see [17, 18]).

For the FOSLS formulation of this problem, we may similarly decompose unknown $\mathbf{u} = \nabla p$ as

$$\mathbf{u}(r,\theta) = \mathbf{u}_0(r,\theta) + \nabla s(r,\theta),$$

where $\nabla s(r,\theta)$ has the form

$$\nabla s(r,\theta) = \alpha r^{\alpha-1} \begin{pmatrix} \kappa_1 \sin(\alpha-1)\theta + \kappa_2 \cos(\alpha-1)\theta \\ \kappa_1 \cos(\alpha-1)\theta - \kappa_2 \sin(\alpha-1)\theta \end{pmatrix}.$$

Thus, the unknown $\mathbf{u}(r,\theta)$ is in $H^k(\Omega)$ only for $k < \alpha$.

For example, consider Poisson's equation posed on the simple domain in Figure 2.1. Let the solution to this boundary value problem in polar coordinates be $p = \chi(r) r^{\frac{2}{3}} \sin(2\theta/3)$, where $\chi(r)$ is a smooth transition function that is 1 on a platform near the origin and vanishes at the boundaries not adjacent to the origin. Then, $p = 0$ on $\partial\Omega$ and

$$\begin{aligned} \Delta p &= \frac{1}{r}\partial_r(r\partial_r p) + \frac{1}{r^2}\partial^2_{\theta\theta} p \\ &= \left(r^{\frac{2}{3}}\chi''(r) + \frac{7}{3} r^{\frac{-1}{3}} \chi'(r) \right) \sin(2\theta/3), \end{aligned}$$

and, thus, it is clear that $\Delta p \in L^2(\Omega)$, but $p \notin H^2(\Omega)$. We say this problem fails to provide *full lifting* of the data (from $L^2(\Omega)$ to $H^2(\Omega)$, for example). The solution, $\mathbf{u} = \nabla p$, is thus not in $H^1(\Omega)$.

3. Weighted-norm least squares. As before, let Ω be a domain with a corner of interior angle ω at the origin, and we may, without loss of generality, further assume $diam(\Omega) \leq 1$. For $f \in L^2(\Omega)$, let p satisfy

$$\begin{cases} -\Delta p = f & \text{in} \quad \Omega, \\ p = 0 & \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot \nabla p = 0 & \text{on} \quad \Gamma_N, \end{cases} \tag{3.1}$$

where $\mathbf{n}$ is the outward unit normal to Ω and $\partial\Omega = \bar{\Gamma}_D \cup \bar{\Gamma}_N$. When this problem is H^2 regular, the normal FOSLS methodology is to introduce the new unknown, $\mathbf{u} = \nabla p$, and rewrite system (3.1) as

$$\begin{cases} \mathbf{u} - \nabla p = 0 & \text{in} \quad \Omega, \\ -\nabla \cdot \mathbf{u} = f & \text{in} \quad \Omega, \\ \nabla \times \mathbf{u} = 0 & \text{in} \quad \Omega, \\ \boldsymbol{\tau} \cdot \mathbf{u} = 0 & \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot \mathbf{u} = 0 & \text{on} \quad \Gamma_N, \\ p = 0 & \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot \nabla p = 0 & \text{on} \quad \Gamma_N. \end{cases} \tag{3.2}$$

Here, $\boldsymbol{\tau}$ is the counterclockwise unit tangential vector to Ω. Since this system can be posed completely in terms of $\mathbf{u}$, we may decouple the equations in (3.2), solve for $\mathbf{u}$ first, and then recover p from $\mathbf{u}$. To this end, define the two L^2-norm functionals,

$$\begin{aligned} G(\mathbf{u}; f) &= \|\nabla \cdot \mathbf{u} + f\|^2 + \|\nabla \times \mathbf{u}\|^2, \\ G_2(p; \mathbf{u}) &= \|\mathbf{u} - \nabla p\|^2, \end{aligned}$$

and the spaces,

$$\begin{aligned} \mathcal{V} &= \{\mathbf{v} \in H^1(\Omega) : \ \boldsymbol{\tau} \cdot \mathbf{v} = 0 \ \text{ on } \ \Gamma_D, \ \ \mathbf{n} \cdot \mathbf{v} = 0 \ \text{ on } \ \Gamma_N\}, \\ \mathcal{W} &= \{q \in H^1(\Omega) : \ q = 0 \ \text{ on } \ \Gamma_D\}. \end{aligned}$$

Thus, the two-stage solution process is to minimize $G(\mathbf{v}; f)$ over $\mathcal{V}$ and then, given the minimizer $\mathbf{u}$, minimize G_2 over $\mathcal{W}$:

$$G(\mathbf{u}; f) = \inf_{\mathbf{v} \in \mathcal{V}} G(\mathbf{v}; f), \tag{3.3a}$$

$$G_2(p; \mathbf{u}) = \inf_{q \in \mathcal{W}} G_2(q; \mathbf{u}). \tag{3.3b}$$

The goal of the FOSLS methodology is, generally, to formulate functionals whose quadratic part is equivalent to the H^1-norm whenever possible. The second stage functional is H^1-equivalent and the solution we seek is always in H^1. The first stage functional, however, is not always H^1-equivalent. For domains with reentrant corners, there is no H^1 sequence of functions that converges to the solution in the $H(\text{div}) \cap H(\text{curl})$ norm. To see an illustration, consider the example above, where $p = \chi(r) r^{\frac{2}{3}} \sin(2\theta/3)$ and $\mathbf{u} = \nabla p$. A simple computation reveals that $\nabla \cdot \mathbf{u}, \nabla \times \mathbf{u} \in L^2(\Omega)$, but $\mathbf{u} \notin H^1(\Omega)$.

Define the weighted functional by

$$G_w(\mathbf{u}; f) = \|w(\nabla \cdot \mathbf{u} + f)\|^2 + \|w \nabla \times \mathbf{u}\|^2, \tag{3.4}$$

where the weight function has the form $w = r^\beta$ for some $\beta > 0$.

Define the weighted Sobolev norm, $\|\cdot\|_{k,\beta}$, on Ω in terms of the standard L^2 norm, $\|\cdot\|_0$, by

$$\|q\|_{k,\beta} = \left(\sum_{|j| \le k} \|r^{\beta - k + |j|} D^j q\|_0^2 \right)^{\frac{1}{2}}, \tag{3.5}$$

where D^j is the standard distributional derivative of order j. Similarly, define the weighted seminorm by

$$|q|_{k,\beta} = \left(\sum_{|j|=k} \|r^{\beta-k+|j|} D^j q\|_0^2 \right)^{\frac{1}{2}} \tag{3.6}$$

and the associated weighted Sobolev space by

$$H^k_\beta(\Omega) = \{q : \|q\|_{k,\beta} < \infty\}. \tag{3.7}$$

Define the div/curl operator, L, and vector $\mathbf{f}$ by $L = \begin{pmatrix} \nabla \cdot \\ \nabla \times \end{pmatrix}$ and $\mathbf{f} = \begin{pmatrix} f \\ 0 \end{pmatrix}$. We may now write the weighted functional from (3.4) as

$$G_w(\mathbf{u}; f) = \|L\mathbf{u} - \mathbf{f}\|^2_{0,\beta}.$$

The weighted-norm least-squares minimization problem for the first-stage solution is then the following: Find $\mathbf{u} \in \mathcal{V}$ such that

$$G_w(\mathbf{u}; f) = \inf_{\mathbf{v} \in \mathcal{V}} G_w(\mathbf{v}; f).$$

The second-stage solution for p remains as described above. We seek values of β that make $H^1(\Omega)$ dense in $H(\text{div}) \cap H(\text{curl})$ in the weighted functional norm and result in the most accurate discretizations possible.

For the discrete problem, we may choose any finite-dimensional subset of H^1 over which to minimize the weighted functional. Let $\mathcal{P}^h$ denote the space of C^0 piecewise polynomial (or tensor product) elements on triangles (or quadrilaterals) of meshsize h, and let $\mathcal{V}^h$ denote the subspace of $\mathcal{P}^h$ that satisfies the appropriate boundary conditions on Ω:

$$\mathcal{V}^h = \{\mathbf{v}^h \in \mathcal{P}^h : \ \boldsymbol{\tau} \cdot \mathbf{v}^h = 0 \ \text{ on } \ \Gamma_D, \ \ \mathbf{n} \cdot \mathbf{v}^h = 0 \ \text{ on } \ \Gamma_N\}.$$

The discrete weighted-norm least-squares minimization problem is, then, to minimize the discrete functional as follows: Find $\mathbf{u}^h \in \mathcal{V}^h$ such that

$$G_w(\mathbf{u}^h; f) = \min_{\mathbf{v}^h \in \mathcal{V}^h} G_w(\mathbf{v}^h; f). \tag{3.8}$$

By unweighting the equations near the singularity, the functional is freed from trying to approximate the solution (which is not in $H^1(\Omega)$) in the H^1 sense near the singularity. But, away from the singularity, the weighted functional retains the same character as the normal nonweighted functional. We now consider the choice of weight parameter β and its relation to weighted and nonweighted a priori error bounds on the approximated solution.

4. Poincaré bounds and regularity estimates. In this section, we establish several theoretical results in weighted Sobolev spaces and error bounds for the weighted-norm method.

Here, we establish several Poincaré bounds in the domain Ω_w. We prove first a result for the scalar pure Neumann and pure Dirichlet problems and then for the scalar mixed boundary condition problem. These results lead to a Poincaré inequality for the vector case.

LEMMA 4.1. *Take $\Omega = \Omega_w$ and let $\beta > 0$, $\epsilon > 0$, and $\gamma = \beta - 3/2 - \epsilon$. Further, assume that $\gamma \neq -2$. For functions $q \in H^1_\beta(\Omega)$, with $r^{\beta-\epsilon}\nabla q, r^{\gamma+1}\nabla q \in L^2(\Omega)$, that can be chosen to satisfy*

$$\iint_\Omega r^\gamma \, q(r,\theta)\, r \, dr \, d\theta = 0, \tag{4.1}$$

we have the bound

$$\|q\|_{0,\beta-1} \leq C(\epsilon)\|\nabla q\|_{0,\beta-\epsilon}, \tag{4.2}$$

where $C(\epsilon)$ depends on ϵ, β, and Ω and $C(\epsilon) \to \infty$ as $\epsilon \to 0$.

Proof. For any two points (r,θ) and (r_0,θ_0) in Ω, write $q(r,\theta)$ as

$$q(r,\theta) = q(r_0,\theta_0) + \int_{r_0}^{r} \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, d\hat{r} + \int_{\theta_0}^{\theta} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\hat{\theta}.$$

Multiplying both sides of the equation by $r_0^{\gamma+1}$, integrating with respect to r_0 and θ_0 over Ω, and using Fubini's theorem yield

$$\begin{aligned}
&\frac{R^{\gamma+2}\omega}{\gamma+2} q(r,\theta) \\
&= \int_0^\omega \int_0^R \int_{r_0}^r r_0^{\gamma+1} \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, d\hat{r}\, dr_0\, d\theta_0 + \int_0^\omega \int_0^R \int_{\theta_0}^\theta r_0^{\gamma+1} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\hat{\theta}\, dr_0\, d\theta_0 \\
&= \omega \int_0^r \int_0^{\hat{r}} r_0^{\gamma+1} \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, dr_0\, d\hat{r} - \omega \int_r^R \int_{\hat{r}}^R r_0^{\gamma+1} \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, dr_0\, d\hat{r} \\
&\quad + \int_0^R \int_0^\theta \int_0^{\hat{\theta}} r_0^{\gamma+1} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\theta_0\, d\hat{\theta}\, dr_0 - \int_0^R \int_\theta^\omega \int_{\hat{\theta}}^\omega r_0^{\gamma+1} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\theta_0\, d\hat{\theta}\, dr_0 \\
&= \frac{\omega}{\gamma+2} \int_0^R \hat{r}^{\gamma+2} \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, d\hat{r} - \frac{\omega R^{\gamma+2}}{\gamma+2} \int_r^R \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\, d\hat{r} \\
&\quad + \int_0^R \int_0^\omega \hat{\theta}\, r_0^{\gamma+1} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\hat{\theta}\, dr_0 - \omega \int_0^R \int_0^\omega r_0^{\gamma+1} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}}\, d\hat{\theta}\, dr_0.
\end{aligned}$$

Note from above that q is, by assumption, sufficiently smooth to apply Fubini's theorem. By the triangle inequality, we have that

$$\begin{aligned}
&\left| \frac{R^{\gamma+2}\omega}{\gamma+2} q(r,\theta) \right| \\
&\leq \frac{\omega}{\gamma+2} \int_0^R \hat{r}^{\gamma+2} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| d\hat{r} + \frac{\omega R^{\gamma+2}}{\gamma+2} \int_r^R \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| d\hat{r} \\
&\quad + 2\omega \int_0^R \int_0^\omega r_0^{\gamma+1} \left| \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}} \right| d\hat{\theta}\, dr_0.
\end{aligned}$$

Now, squaring each side and using $(a+b+c)^2 \le 3(a^2+b^2+c^2)$, we get

$$
\begin{aligned}
|q(r,\theta)|^2 \le{}& \frac{3}{R^{2(\gamma+2)}} \left(\int_0^R \hat{r}^{\gamma+2} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 + 3 \left(\int_r^R \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 \\
&+ \frac{12(\gamma+2)^2}{R^{2(\gamma+2)}} \left(\int_0^R \int_0^\omega r_0^{\gamma+1} \left| \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}} \right| \, d\hat{\theta} \, dr_0 \right)^2 .
\end{aligned} \tag{4.3}
$$

Multiply each side of (4.3) by $r^{2\beta-1}$ and integrate with respect to r and θ over Ω. We consider each of the terms on the resulting right-hand side separately. First,

$$
\begin{aligned}
&\int_0^\omega \int_0^R r^{2\beta-1} \left(\int_0^R \hat{r}^{\gamma+2} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 dr \, d\theta \\
&\quad \le R \int_0^\omega \int_0^R \int_0^R r^{2\beta-1} \, \hat{r}^{2\gamma+4} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r} \, dr \, d\theta \\
&\quad = \frac{R^{2\beta+1}}{2\beta} \int_0^\omega \int_0^R \hat{r}^{2\gamma+3} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 \hat{r} \, d\hat{r} \, d\theta \\
&\quad \le \frac{R^{2\beta+1}}{2\beta} \|\nabla q\|^2_{0,\gamma+\frac{3}{2}}.
\end{aligned}
$$

We now consider the second term in (4.3). Since by the Schwarz inequality,

$$
\begin{aligned}
&\left(\int_r^R \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 \\
&\quad = \left(\int_r^R \hat{r}^{(\epsilon-1)/2} \hat{r}^{(1-\epsilon)/2} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 \\
&\quad \le \int_r^R \hat{r}^{\epsilon-1} \, d\hat{r} \int_r^R \hat{r}^{1-\epsilon} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r} \\
&\quad = \frac{R^\epsilon}{\epsilon} \int_r^R \hat{r}^{1-\epsilon} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r},
\end{aligned}
$$

we can apply Fubini's theorem to bound the second term:

$$
\begin{aligned}
&\int_0^\omega \int_0^R r^{2\beta-1} \left(\int_r^R \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right| \, d\hat{r} \right)^2 dr \, d\theta \\
&\quad \le \frac{R^\epsilon}{\epsilon} \int_0^\omega \int_0^R \int_r^R r^{2\beta-1} \, \hat{r}^{1-\epsilon} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r} \, dr \, d\theta \\
&\quad = \frac{R^\epsilon}{\epsilon} \int_0^\omega \int_0^R \int_0^{\hat{r}} r^{2\beta-1} \, \hat{r}^{1-\epsilon} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 dr \, d\hat{r} \, d\theta \\
&\quad = \frac{R^\epsilon}{2\epsilon\beta} \int_0^\omega \int_0^R \hat{r}^{2\beta-\epsilon} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 \hat{r} \, d\hat{r} \, d\theta \\
&\quad = \frac{R^\epsilon}{2\epsilon\beta} \|\nabla q\|^2_{0,\beta-\frac{\epsilon}{2}} \\
&\quad \le \frac{R^\epsilon}{2\epsilon\beta} \|\nabla q\|^2_{0,\beta-\epsilon},
\end{aligned}
$$

The third term can be bounded similarly:

$$\begin{aligned}
&\int_0^\omega \int_0^R r^{2\beta-1} \left(\int_0^R \int_0^\omega r_0^{\gamma+1} \left| \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}} \right| \, d\hat{\theta}\, dr_0 \right)^2 dr\, d\theta \\
&\quad \leq \left(\int_0^R \int_0^\omega r^{2\beta-1} \, dr\, d\theta \right) R\omega \int_0^\omega \int_0^R r_0^{2\gamma+2} \left| \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}} \right|^2 \, dr_0\, d\hat{\theta} \\
&\quad = \frac{R^{2\beta+1}\omega^2}{2\beta} \int_0^\omega \int_0^R r_0^{2\gamma+3} \left| \frac{1}{r_0} \frac{\partial q(r_0,\hat{\theta})}{\partial \hat{\theta}} \right|^2 r_0 \, dr_0\, d\hat{\theta} \\
&\quad = \frac{R^{2\beta+1}\omega^2}{2\beta} \|\nabla q\|^2_{0,\gamma+\frac{3}{2}}.
\end{aligned}$$

Putting the three terms together and substituting $\gamma = \beta - 3/2 - \epsilon$, we may now write the bound

$$\begin{aligned}
&\int_0^\omega \int_0^R r^{2\beta-2} \left| q(r,\theta) \right|^2 r \, dr\, d\theta \\
&\quad \leq \left(\frac{3R^{-2\epsilon}}{2\beta} + \frac{3R^{\epsilon}}{2\epsilon\beta} + \frac{6(\beta+\frac{1}{2}-\epsilon)^2 R^{-2\epsilon}\omega^2}{\beta} \right) \|\nabla q\|^2_{0,\beta-\epsilon},
\end{aligned}$$

and the lemma follows by taking the square root of both sides. ∎

In what follows, let χ be a smooth function of r, where $\chi = 1$ for $r < \eta$ and $\chi = 0$ for $r > 2\eta$. We take η to be sufficiently small to ensure that $\mathrm{supp}(\chi) \subset \Omega$.

LEMMA 4.2. *Take $\Omega = \Omega_w$ and let q be a scalar function in $H^1_\beta(\Omega)$, where $\beta > 0$. The following bound holds for χ as defined above:*

$$\|\chi q\|_{0,\beta-1} \leq \frac{1}{\beta} \|\nabla(\chi q)\|_{0,\beta}. \tag{4.4}$$

Proof. Hardy's inequality for $f(t)$ defined for $t > 0$ with $\lim_{t\to 0} f(t) = 0$ gives (see [20])

$$\int_0^\infty \frac{f^2}{t^2} \, dt \leq 4 \int_0^\infty |f'|^2 \, dt. \tag{4.5}$$

The lemma follows after a change of variables, $t = r^{-2\beta}$, a substitution $f(r) = \chi q(r,\theta)$ for fixed θ, and an integration on both sides with respect to θ. ∎

LEMMA 4.3. *Take $\Omega = \Omega_w$ and let either $q \in H^1_\beta(\Omega)$ with $q = 0$ on $\partial\Omega$ or $q \in H^1_\beta(\Omega)/\mathbb{R}$ with $n \cdot \nabla q = 0$ on $\partial\Omega$. Then*

$$\|q\|_{0,\beta-1} \leq C \|\nabla q\|_{0,\beta} \tag{4.6}$$

for $\beta > 0$, where C depends only on Ω and β.

Proof. First, if $q = 0$ on $\partial\Omega$, write $q = q(r,\theta)$ as

$$q(r,\theta) = \int_0^\theta \frac{\partial q(r,\hat{\theta})}{\partial \hat{\theta}} \, d\hat{\theta}.$$

Square both sides and multiply by $r^{2\beta-1}$:

$$r^{2\beta-1}\,|q(r,\theta)|^2 = r^{2\beta-1}\left|\int_0^\theta \frac{\partial q(r,\hat{\theta})}{\partial\hat{\theta}}\,d\hat{\theta}\right|^2 \le r^{2\beta+1}\omega\int_0^\omega\left|\frac{1}{r}\frac{\partial q(r,\hat{\theta})}{\partial\hat{\theta}}\right|^2 d\hat{\theta}.$$

Integrate both sides with respect to r and θ over Ω:

$$\int_0^\omega\int_0^R r^{2\beta-2}\,|q(r,\theta)|^2\;r\,dr\,d\theta \le \omega\int_0^\omega\int_0^{R_0} r^{2\beta+1}\int_0^\omega\left|\frac{1}{r}\frac{\partial q(r,\hat{\theta})}{\partial\hat{\theta}}\right|^2 d\hat{\theta}\;dr\,d\theta \le \omega^2\int_0^\omega\int_0^{R_0} r^{2\beta}\left|\frac{1}{r}\frac{\partial q(r,\hat{\theta})}{\partial\hat{\theta}}\right|^2 r\,dr\,d\hat{\theta}.$$

The lemma follows since the right-hand side is bounded by $C\|\nabla q\|^2_{0,\beta}$.

Now, if $q \in H^1_\beta(\Omega)/\mathbb{R}$, then it may be chosen to satisfy

$$\iint_\Omega r^\gamma\, q\, r\,dr\,d\theta = 0 \tag{4.7}$$

for γ chosen as in Lemma 4.1. By the triangle inequality and Lemma 4.2, we get

$$\begin{aligned}\|q\|_{0,\beta-1} &\le \|\chi\, q\|_{0,\beta-1} + \|(1-\chi)q\|_{0,\beta-1}\\ &\le C\|\nabla(\chi q)\|_{0,\beta} + \left(\int_0^\omega\int_\eta^R\left(\frac{r}{\eta}\right)^2 r^{2\beta-2}(1-\chi)^2\,q^2\,r\,dr\,d\theta\right)^{\frac{1}{2}}\\ &\le C\left(\|\nabla(q)\|_{0,\beta} + \|q\|_{0,\beta}\right).\end{aligned}$$

Apply Lemma 4.1 with $\epsilon = 1$ to the $\|q\|_{0,\beta}$ term on the right-hand side, and the Lemma follows. ∎

For the problem with mixed boundary conditions, consider Ω_w partitioned into subdomains $\Omega_0 = \{(r,\theta) : r \le \frac{1}{2}R_0, 0 \le \theta \le \omega\}$ and $\Omega_1 = \Omega\backslash\Omega_0$, as shown in Figure 4.1.

LEMMA 4.4. *Consider domain $\Omega = \Omega_w$, as pictured in Figure* 4.1*, and let $q \in H^1_\beta(\Omega)$ vanish on the line segment of $\partial\Omega$ corresponding to $\theta = 0$ and $r < R_0$. Then there is a constant, C, dependent only on Ω, β, and R_0, such that*

$$\|q\|_{0,\beta-1} \le C\|\nabla q\|_{0,\beta} \tag{4.8}$$

for $\beta > 0$.

Proof. For points (r,θ) in Ω_0 we may derive the bound,

$$\|q\|_{0,\beta-1,\Omega_0} \le C\|\nabla q\|_{0,\beta,\Omega_0}, \tag{4.9}$$

completely analogous to the proof of Lemma 4.3. Now, consider points (r,θ) in Ω_1. We may write $q = q(r,\theta)$ as

$$q(r,\theta) = \int_{\tilde{r}}^r \frac{\partial q(\hat{r},\theta)}{\partial\hat{r}}\,d\hat{r} + \int_0^\theta \frac{\partial q(\tilde{r},\hat{\theta})}{\partial\hat{\theta}}\,d\hat{\theta},$$

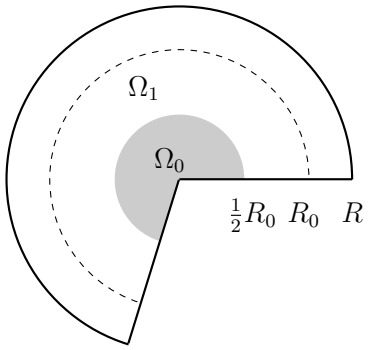

FIG. 4.1. *Wedge-shaped domain, Ω_w, partitioned into subdomains Ω_0 and Ω_1.*

where the point $(\tilde{r}, 0)$ is on the part of $\partial\Omega_1$ where q vanishes. By the Schwarz inequality, the triangle inequality, and inequality (2.1), we have the bound

$$|q(r,\theta)|^2 \leq 2(R - \frac{1}{2}R_0) \int_{\tilde{r}}^{r} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r} + 2\omega \int_0^{\theta} \left| \frac{\partial q(\tilde{r},\hat{\theta})}{\partial \hat{\theta}} \right|^2 d\hat{\theta}. \tag{4.10}$$

We now expand the limits in the integrals, multiply each side by $r^{2\beta-1}$, integrate with respect to r over $(\frac{1}{2}R_0, R)$, integrate with respect to θ over $(0, \omega)$, and integrate with respect to $\tilde{r}$ over $(\frac{1}{2}R_0, R_0)$, and apply Fubini's theorem to get

$$\begin{aligned} &\left(\frac{1}{2}R_0\right) \int_0^{\omega} \int_{\frac{1}{2}R_0}^{R} r^{2\beta-1} |q(r,\theta)|^2 \, dr \, d\theta \\ &\quad \leq 2\left(R - \frac{1}{2}R_0\right) \int_{\frac{1}{2}R_0}^{R_0} \int_0^{\omega} \int_{\frac{1}{2}R_0}^{R} \int_{\frac{1}{2}R_0}^{R} r^{2\beta-1} \left| \frac{\partial q(\hat{r},\theta)}{\partial \hat{r}} \right|^2 d\hat{r} \, dr \, d\theta \, d\tilde{r} \\ &\quad + 2\omega \int_{\frac{1}{2}R_0}^{R_0} \int_0^{\omega} \int_{\frac{1}{2}R_0}^{R} \int_0^{\theta} \left| \frac{\partial q(\tilde{r},\hat{\theta})}{\partial \hat{\theta}} \right|^2 d\hat{\theta} \, dr \, d\theta \, d\tilde{r}. \end{aligned} \tag{4.11}$$

We use the inequalities

$$\frac{1}{2}R_0 \leq \tilde{r} \leq R_0, \quad \tilde{r} \leq \hat{r} \leq r \leq R$$

to derive the following simple bounds:

$$1 \leq \left(\frac{2\hat{r}}{R_0}\right), \quad r \leq \left(\frac{2R}{R_0}\right)\hat{r}, \quad r \leq \left(\frac{2R}{R_0}\right)\tilde{r}. \tag{4.12}$$

By applying the bounds in (4.12) and by Fubini's theorem, we may now write (4.11) as

$$\begin{aligned}
&\left(\frac{1}{2}R_0\right)\int_0^{\omega}\int_{\frac{1}{2}R_0}^{R} r^{2\beta-2}|q(r,\theta)|^2 r\; dr\, d\theta \\
&\quad\le \left(R-\frac{1}{2}R_0\right)^2 R_0 \int_0^{\omega}\int_{\frac{1}{2}R_0}^{R}\left(\frac{2\hat{r}}{R_0}\right)^2\left(\frac{2R}{R_0}\right)^{2\beta-1}\hat{r}^{2\beta-1}\left|\frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\right|^2 d\hat{r}\, d\theta \\
&\qquad + 2\omega^2\left(R-\frac{1}{2}R_0\right)\int_{\frac{1}{2}R_0}^{R_0}\int_0^{\omega}\left(\frac{2R}{R_0}\right)^{2\beta-1}\tilde{r}^{2\beta-1}\left|\frac{\partial q(\tilde{r},\hat{\theta})}{\partial \hat{\theta}}\right|^2 d\hat{\theta}\, d\tilde{r} \\
&\quad\le 2^{2\beta+1}\left(R-\frac{1}{2}R_0\right)^2 R_0^{-2\beta}R^{2\beta-1}\int_0^{\omega}\int_{\frac{1}{2}R_0}^{R}\hat{r}^{2\beta}\left|\frac{\partial q(\hat{r},\theta)}{\partial \hat{r}}\right|^2 \hat{r}\; d\hat{r}\, d\theta \\
&\qquad + 2^{2\beta}\omega^2\left(R-\frac{1}{2}R_0\right)\left(\frac{R}{R_0}\right)^{2\beta-1}\int_{\frac{1}{2}R_0}^{R}\int_0^{\omega}\tilde{r}^{2\beta}\left|\frac{1}{\tilde{r}}\frac{\partial q(\tilde{r},\hat{\theta})}{\partial \hat{\theta}}\right|^2 \tilde{r}\; d\hat{\theta}\, d\tilde{r},
\end{aligned}$$

which directly implies

$$\|q\|_{0,\beta-1,\Omega_1} \le C\|\nabla q\|_{0,\beta,\Omega_1}, \tag{4.13}$$

where

$$C = 2^{2\beta+1}\left(R-\frac{1}{2}R_0\right)R^{2\beta-1}R_0^{-2\beta-1}\left(2(R-\frac{1}{2}R_0)+\frac{\omega^2}{R_0}\right).$$

Combining inequalities (4.9) and (4.13) completes the lemma. ∎

We now consider a similar Poincaré inequality for the vector case. Again, consider $\Omega = \Omega_w$, where $\partial\Omega$ is partitioned into Dirichlet and Neumann boundaries Γ_D and Γ_N, respectively. The following lemma is valid for the pure Dirichlet and Neumann cases and for the mixed boundary condition cases when Γ_D includes a part of the boundary adjacent to the origin and $\omega \neq \frac{3\pi}{2}$.

LEMMA 4.5. *Take $\Omega = \Omega_w$ and let $\mathbf{u} \in H^1_\beta(\Omega)^2$ satisfy $\boldsymbol{\tau}\cdot\mathbf{u} = 0$ on Γ_D and $\mathbf{n}\cdot\mathbf{u} = 0$ on Γ_N. Assume for the mixed boundary condition case that $\omega \neq 3\pi/2$. Then there is a constant, C, dependent only on Ω, β, and the length of the segments of Γ_D and Γ_N adjacent to the origin, such that*

$$\|\mathbf{u}\|_{0,\beta-1} \le C\|\nabla\mathbf{u}\|_{0,\beta} \tag{4.14}$$

for $\beta > 0$.

Proof. First, consider the case when $\boldsymbol{\tau}\cdot\mathbf{u} = 0$ on $\partial\Omega$. Denote the part of $\partial\Omega$ aligned with $\theta = 0$ as Γ_1 and the part of $\partial\Omega$ aligned with $\theta = \omega$ as Γ_2. Thus, $u_1 = 0$ on Γ_1 and $\tau_x u_1 + \tau_y u_2 = 0$ on Γ_2. Since u_1 and $\tau_x u_1 + \tau_y u_2$ satisfy the conditions in Lemma 4.4, we may use

$$\|u_1\|_{0,\beta-1} \le C\|\nabla u_1\|_{0,\beta}$$

and

$$\|\tau_x u_1 + \tau_y u_2\|_{0,\beta-1} \le C\|\nabla(\tau_x u_1 + \tau_y u_2)\|_{0,\beta}.$$

Further, take $\tau_y \neq 0$, since $\tau_y = 0$ corresponds to either $\omega = \pi$, for which the result holds trivially since the boundary is smooth, or $\omega = 2\pi$, which we do not consider. Now,

$$\begin{aligned}
\|\mathbf{u}\|^2_{0,\beta-1} &= \|u_1\|^2_{0,\beta-1} + \|u_2\|^2_{0,\beta-1} \\
&= \|u_1\|^2_{0,\beta-1} + \frac{1}{\tau_y^2}\|\tau_x u_1 - \tau_x u_1 + \tau_y u_2\|^2_{0,\beta-1} \\
&\leq \left(1 + 2\frac{\tau_x^2}{\tau_y^2}\right)\|u_1\|^2_{0,\beta-1} + \frac{2}{\tau_y^2}\|\tau_x u_1 + \tau_y u_2\|^2_{0,\beta-1} \\
&\leq C(\|\nabla u_1\|^2_{0,\beta} + \|\nabla(\tau_x u_1 + \tau_y u_2)\|^2_{0,\beta}) \\
&\leq C\|\nabla \mathbf{u}\|^2_{0,\beta}.
\end{aligned}$$

The case when $\mathbf{n}\cdot\mathbf{u} = 0$ on $\partial\Omega$ is analogous since $u_2 = 0$ on Γ_1 and $n_x u_1 + n_y u_2 = 0$ on Γ_2. Also, when $\omega \neq \frac{\pi}{2}, \frac{3\pi}{2}$, the case for mixed boundary conditions follows similarly using the result of Lemma 4.4. The case for mixed boundary conditions when $\omega = \pi/2$ follows from appealing to symmetry in pure Dirichlet problem for $\omega = \pi$. ∎

Remark 4.6. Lemma 4.5 can be directly extended to more generally shaped domains. The proof of the scalar Poincaré bounds in Lemmas 4.1, 4.2, 4.3, and 4.4 is simplified when the domain has the shape of Ω_w with only one irregular boundary point. Since we are primarily interested in a local result, proving Lemma 4.5 in the simple domain is sufficient for our purposes.

Consider the following scalar Poisson problem in Ω_w:

$$\begin{cases} \Delta p = f & \text{in} \quad \Omega, \\ p = 0 & \text{on} \quad \Gamma_D, \\ \mathbf{n}\cdot\nabla p = 0 & \text{on} \quad \Gamma_N. \end{cases} \tag{4.15}$$

We refer to system (4.15) as the pure Dirichlet problem when $\partial\Omega = \Gamma_D$; the pure Neumann problem when $\partial\Omega = \Gamma_N$; and the mixed boundary condition problem when Γ_D includes the part of $\partial\Omega$ coinciding with one of either $\theta = 0$ or $\theta = \omega$, and $\Gamma_N = \partial\Omega\backslash\Gamma_D$ with $\Gamma_N \neq \emptyset$.

The following regularity results can be found in [23] and [21].

LEMMA 4.7. *Assume $|1-\beta| < \pi/\omega$ for the pure Dirichlet problem, $0 < |1-\beta| < \pi/\omega$ for the pure Neumann problem, and $|1-\beta| < \pi/2\omega$ for the mixed boundary condition problem. Then, for every $f \in H^0_\beta(\Omega)$, there exists a unique solution to* (4.15)*, $p \in H^2_\beta(\Omega)$ for the pure Dirichlet and mixed boundary condition cases, and $p \in H^2_\beta(\Omega)/\mathbb{R}$ for the pure Neumann problem. Moreover, there exists a constant, C, independent of p, such that*

$$\|p\|_{2,\beta} \leq C\|f\|_{0,\beta}. \tag{4.16}$$

Proof. See Chapter 1 of [23] for the Dirichlet and Neumann problems and Chapter 2 of [21] for the mixed boundary problem. ∎

Define the subspace of functions in $H^1_\beta(\Omega)$ satisfying the appropriate boundary conditions by

$$\mathcal{V}_\beta = \{\mathbf{v} \in H^1_\beta(\Omega) : \boldsymbol{\tau}\cdot\mathbf{v} = 0 \text{ on } \Gamma_D, \ \mathbf{n}\cdot\mathbf{v} = 0 \text{ on } \Gamma_N\}.$$

We now prove a regularity result for functions in $\mathcal{V}_\beta$. Recall that the power of the singularity is defined as $\alpha = \pi/\omega$ for Dirichlet or Neumann boundary conditions and $\alpha = \pi/(2\omega)$ for mixed boundary conditions.

LEMMA 4.8. *Consider domain $\Omega = \Omega_w$. Then there is a positive constant, C, independent of $\mathbf{u}$, such that, for $|1-\beta| < \alpha$, the following bound holds for all $\mathbf{u} \in \mathcal{V}_\beta$:*

$$\|\mathbf{u}\|_{1,\beta} \leq C\|L\mathbf{u}\|_{0,\beta}. \tag{4.17}$$

Proof. From Lemma 4.7 we know that any $\mathbf{u} \in \mathcal{V}_\beta$ has the decomposition

$$\mathbf{u} = \nabla\phi + \nabla^\perp\psi, \tag{4.18}$$

where $\phi, \psi \in H^2_\beta(\Omega)$ satisfy

$$\begin{cases} \Delta\phi = \nabla \cdot \mathbf{u} & \text{in} \quad \Omega, \\ \phi = 0 & \text{on} \quad \partial\Omega, \end{cases} \tag{4.19}$$

and

$$\begin{cases} \Delta\psi = \nabla \times \mathbf{u} & \text{in} \quad \Omega, \\ \mathbf{n} \cdot \nabla\psi = 0 & \text{on} \quad \partial\Omega. \end{cases} \tag{4.20}$$

Then, by applying Lemma 4.7 to problems (4.19) and (4.20) we have

$$\begin{aligned} \|\mathbf{u}\|_{1,\beta} &= \|\nabla\phi + \nabla^\perp\psi\|_{1,\beta} \leq \|\nabla\phi\|_{1,\beta} + \|\nabla^\perp\psi\|_{1,\beta} \\ &\leq \|\phi\|_{2,\beta} + \|\psi\|_{2,\beta} \leq C(\|\nabla \cdot \mathbf{u}\|_{0,\beta} + \|\nabla \times \mathbf{u}\|_{0,\beta}) \leq C\|L\mathbf{u}\|_{0,\beta}, \end{aligned}$$

which completes the proof. ∎

5. Error bounds. Let $\mathcal{T}^h = \cup_{i=1}^N \tau_i$ be a quasi-uniform triangulation of polygonal domain Ω. Let $\mathcal{I}^h$ represent standard interpolation onto a piecewise polynomial finite element space of degree k. From finite element theory, we have the following interpolation bounds.

LEMMA 5.1. *Let Ω be a polygonal domain. There exists a constant, C, independent of v, such that, for all $v \in H^m(\Omega)$,*

$$\left(\sum_{\tau \in \mathcal{T}^h} \|v - \mathcal{I}^h v\|^2_{s,\tau} \right)^{1/2} \leq Ch^{m-s}|v|_m \tag{5.1}$$

for $0 \leq s \leq m$ and $1 < m$. Here, $\mathcal{I}^h$ denotes interpolation by a piecewise polynomial of degree $k = m-1$. (Note that here the norm $\|\cdot\|_{s,\tau}$ is the standard $H^s(\tau)$ norm.)

Proof. See [9] or [7]. ∎

We now consider a weighted interpolation bound for functions on domains with a polygonal corner at the origin. Define the modified interpolation operator, $\mathcal{I}^h_0$, by

$$\mathcal{I}^h_0 u|_\tau \;=\; \begin{cases} \mathcal{I}^h u = \sum_{i=0}^n u(a_i)\phi_i & \text{if } \overline{\tau} \text{ does not intersect the origin,} \\ \sum_{i=1}^n u(a_i)\phi_i & \text{if } \overline{\tau} \text{ intersects the origin,} \end{cases}$$

where $\mathcal{I}^h$ is a standard polynomial interpolation operator, ϕ_i are basis functions corresponding to the $n+1$ nodal points, a_i, and a_0 is the origin, $(0,0)$. Thus, the

modified interpolation has a value of zero at the origin and resembles $\mathcal{I}^h$ away from the origin.

LEMMA 5.2. *Let Ω be a polygonal domain. There exists a constant, C, independent of u, such that, for all $u \in H^m_\beta(\Omega)$ satisfying* (4.8),

$$\left(\sum_{\tau \in \mathcal{T}^h} \|u - \mathcal{I}_0^h u\|^2_{1,\beta,\tau} \right)^{1/2} \leq Ch^{m-1} \|u\|_{m,\beta}, \tag{5.2}$$

for $1 < m$ and $\beta > 0$, where $\mathcal{I}_0^h$ is the modified interpolation operator onto piecewise polynomials of degree $k = m - 1$ defined above.

Proof. Define $K_0 = \{\tau \mid \bar{\tau} \cap (0,0) \neq \emptyset\}$ as the set of elements adjacent to the origin. On $\mathcal{T}^h \backslash K_0$, we have $h \leq r_{min} \leq r = \sqrt{x^2 + y^2} \leq r_{max} \leq r_{min} + \sqrt{2}h$ with $r_{min} = \inf\{r | (x,y) \in \tau\}$ and $r_{max} = \sup\{r | (x,y) \in \tau\}$ in τ, and

$$\begin{aligned}
\|u - \mathcal{I}_0^h u\|^2_{1,\beta,\tau} &= \|u - \mathcal{I}^h u\|^2_{1,\beta,\tau} \\
&= \int_\tau r^{2\beta} |\nabla(u - \mathcal{I}^h u)|^2 + r^{2(\beta-1)} |u - \mathcal{I}^h u|^2 d\tau \\
&\leq r_{max}^{2\beta} \int_\tau |\nabla(u - \mathcal{I}^h u)|^2 d\tau + r_{max}^{2\beta} r_{min}^{-2} \int_\tau |u - \mathcal{I}^h u|^2 d\tau \\
&\leq C r_{max}^{2\beta} h^{2(m-1)} |u|^2_{m,0,\tau} + C r_{max}^{2\beta} r_{min}^{-2} h^{2m} |u|^2_{m,0,\tau} \\
&= C r_{max}^{2\beta} h^{2(m-1)} (1 + r_{min}^{-2} h^2) |u|^2_{m,0,\tau} \leq C r_{max}^{2\beta} h^{2(m-1)} |u|^2_{m,0,\tau} \\
&\leq C h^{2(m-1)} r_{max}^{2\beta} r_{min}^{-2\beta} \int_\tau r^{2\beta} |D^m u|^2 d\tau \\
&\leq C h^{2(m-1)} \left(\frac{r_{min} + \sqrt{2}h}{r_{min}} \right)^{2\beta} \int_\tau r^{2\beta} |D^m u|^2 d\tau \\
&\leq C h^{2(m-1)} \int_\tau r^{2\beta} |D^m u|^2 d\tau.
\end{aligned}$$

We now consider the case for which $\tau \in K_0$. Let $\delta \in \mathcal{C}^\infty$ be a cut-off function defined by

$$\delta(r) = \begin{cases} 1 & \text{if} \quad r \leq h/3, \\ 0 & \text{if} \quad r > 2h/3, \end{cases}$$

with $|\delta^{(m)}| \leq ch^{-m}$, where $\delta^{(m)}$ is the mth derivative of δ. By the triangle inequality,

$$\|u - \mathcal{I}_0^h u\|_{1,\beta,\tau} \leq \|\delta u - \mathcal{I}_0^h(\delta u)\|_{1,\beta,\tau} + \|(1-\delta)u - \mathcal{I}_0^h((1-\delta)u)\|_{1,\beta,\tau}. \tag{5.3}$$

By the definition of δ we have $\mathcal{I}_0^h((1-\delta)u) = \mathcal{I}^h((1-\delta)u)$ and $\mathcal{I}_0^h(\delta u) = 0$. For the second term in (5.3), we apply Lemmas 4.4 and 5.1, the properties in δ, and Fubini's

theorem to obtain

$$\begin{aligned}
&\|(1-\delta)u-\mathcal{I}_0^h((1-\delta)u)\|_{1,\beta,\tau}^2=\|(1-\delta)u-\mathcal{I}^h((1-\delta)u)\|_{1,\beta,\tau}^2\\
&\le C\|\nabla((1-\delta)u-\mathcal{I}^h((1-\delta)u))\|_{0,\beta,\tau}^2\le Ch^{2\beta}\int_\tau|\nabla((1-\delta)u-\mathcal{I}^h((1-\delta)u))|^2d\tau\\
&\le Ch^{2(\beta+m-1)}\int_\tau|D^m((1-\delta)u)|^2d\tau\le Ch^{2(\beta+m-1)}\int_\tau\sum_{|j|\le m}|D^{m-j}(1-\delta)D^ju|^2d\tau\\
&\le Ch^{2(\beta+m-1)}\left(\iint_{\frac{h}{3}}^{\frac{2h}{3}}\sum_{|j|\le m-1}|h^{|j|-m}D^ju|^2d\tau+\iint_{\frac{h}{3}}^{r(\theta)}|(1-\delta)D^mu|^2d\tau\right)\\
&\le Ch^{2(\beta+m-1)}\left(\sum_{|j|\le m-1}\iint_{\frac{h}{3}}^{\frac{2h}{3}}h^{-2\beta}r^{2(\beta+|j|-m)}|D^ju|^2d\tau+\iint_{\frac{h}{3}}^{r(\theta)}\Big(\frac{r}{h}\Big)^{2\beta}|D^mu|^2d\tau\right)\\
&=Ch^{2(m-1)}\sum_{|j|\le m}\int_\tau r^{2(\beta+|j|-m)}|D^ju|^2d\tau=Ch^{2(m-1)}\|u\|_{m,\beta,\tau}^2.
\end{aligned}$$

Using the properties of δ and Fubini's theorem results in a similar bound for the first term in (5.3):

$$\begin{aligned}
&\|\delta u-\mathcal{I}_0^h(\delta u)\|_{1,\beta,\tau}^2=\|\delta u\|_{1,\beta,\tau}^2=\int_\tau r^{2\beta}|\nabla(\delta u)|^2+r^{2(\beta-1)}|\delta u|^2d\tau\\
&\le C\int_\tau r^{2\beta}(|\nabla\delta\cdot u|^2+|\delta\nabla u|^2)+r^{2(\beta-1)}|\delta u|^2d\tau\\
&\le C\iint_{\frac{h}{3}}^{\frac{2h}{3}}r^{2\beta}h^{-2}|u|^2d\tau+C\iint_0^{\frac{2h}{3}}r^{2\beta}|\nabla u|^2+r^{2(\beta-1)}|u|^2d\tau\\
&\le C\iint_{\frac{h}{3}}^{\frac{2h}{3}}r^{2(\beta-1)}|u|^2d\tau+C\iint_0^{\frac{2h}{3}}r^{2\beta}|\nabla u|^2+r^{2(\beta-1)}|u|^2d\tau\\
&\le C\int_\tau r^{2(m-1)}(r^{2(\beta-m+1)}|\nabla u|^2+r^{2(\beta-m)}|u|^2)d\tau\le Ch^{2(m-1)}\|u\|_{m,\beta,\tau}^2.
\end{aligned}$$

Thus we have

$$\sum_{\tau\in\mathcal{T}_h}\|u-\mathcal{I}_0^hu\|_{1,\beta,\tau}^2\le Ch^{2(m-1)}\sum_{\tau\in\mathcal{T}_h}\|u\|_{m,\beta,\tau}^2\le Ch^{2(m-1)}\|u\|_{m,\beta}^2,$$

and the lemma follows. ∎

LEMMA 5.3. *Assume* (4.14) *holds in* Ω. *Then, for all* $\mathbf{u}^h\in\mathcal{V}^h$,

$$\|\mathbf{u}^h\|_{0,\beta}\le Ch^{-\eta}\|\mathbf{u}^h\|_{0,\beta+\eta} \tag{5.4}$$

for $\beta>-1$ *and* $\eta>0$.

Proof. Using Lemma 4.5 and an inverse inequality, we may write

$$\|\mathbf{u}^h\|_{0,\beta}\le C\|\nabla\mathbf{u}^h\|_{0,\beta+1}\le Ch^{-1}\|\mathbf{u}^h\|_{0,\beta+1},$$

which establishes (5.4) for $\eta=1$. Repeated application of this inequality thus validates (5.4) for any positive integer. Now consider

$$\begin{aligned}
\|\mathbf{u}^h\|_{0,\beta}^2&=\langle r^\beta\mathbf{u}^h,r^\beta\mathbf{u}^h\rangle=\langle r^{\beta-1/2}\mathbf{u}^h,r^{\beta+1/2}\mathbf{u}^h\rangle\\
&\le\|\mathbf{u}^h\|_{0,\beta-1/2}\|\mathbf{u}^h\|_{0,\beta+1/2}\le Ch^{-1}\|\mathbf{u}^h\|_{0,\beta+1/2}^2.
\end{aligned}$$

Taking the square root establishes (5.4) for $\eta = 1/2$. Repeating these steps leads to (5.4) for all $\eta = \eta_n = k_n/2^{\ell_n}$ for any nonnegative integers k_n and ℓ_n. For any $\eta > 0$, choose a monotonically decreasing sequence, $\{\eta_n\}$, such that $\eta_n > \eta$ and $\lim_{n\to\infty} |\eta_n - \eta| = 0$. Now, $g_n = (r^{\beta+\eta_n}\mathbf{u}^h)^2$ is a monotonically increasing function that converges to $g = (r^{\beta+\eta}\mathbf{u}^h)^2$ pointwise everywhere. Thus, by the Lebesgue monotone convergence theorem, we have

$$\|\mathbf{u}^h\|^2_{0,\beta+\eta} = \int g dx = \lim_n \int g_n dx = \lim_n \|\mathbf{u}^h\|^2_{0,\beta+\eta_n}$$

and, therefore,

$$\begin{aligned}\|\mathbf{u}^h\|_{0,\beta} &= \lim_n \|\mathbf{u}^h\|_{0,\beta} \\ &\le \lim_n Ch^{-\eta_n}\|\mathbf{u}^h\|_{0,\beta+\eta_n} \\ &= (\lim_n Ch^{-\eta_n})(\lim_n \|\mathbf{u}^h\|_{0,\beta+\eta_n}) \\ &= Ch^{-\eta}\|\mathbf{u}^h\|_{0,\beta+\eta},\end{aligned}$$

which completes the proof. ∎

Define an *irregular boundary point* of polygonal domain Ω to be a point on $\partial\Omega$, where interior angle ω satisfies $\omega > \pi$ when Dirichlet or Neumann boundary conditions are applied on both sides of the point or $\omega > \pi/2$ when one Dirichlet boundary condition and one Neumann boundary meet at the corner. We now present error bounds for the numerical solution in weighted and unweighted norms.

THEOREM 5.4. *Let Ω be a polygonal domain with one irregular boundary point of interior angle ω and let $\mathbf{f} \in L^2(\Omega)$. Suppose $\mathbf{u} \in \mathcal{V}$ satisfy $L\mathbf{u} = \mathbf{f}$. If $\mathbf{u}^h \in \mathcal{V}^h$ is chosen to minimize the weighted functional,*

$$G_w(\mathbf{u}^h;\mathbf{f}) = \|L\mathbf{u}^h - \mathbf{f}\|^2_{0,\beta} = \inf_{\mathbf{v}^h\in\mathcal{V}^h} \|L\mathbf{v}^h - \mathbf{f}\|^2_{0,\beta},$$

for $|1-\beta| < \alpha$, then the approximation error, $\mathbf{u} - \mathbf{u}^h$, satisfies the following bounds:

$$\|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} \le Ch^{\alpha+\beta-1}\|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{5.5}$$

$$G_w(\mathbf{u} - \mathbf{u}^h;\mathbf{0})^{\frac{1}{2}} \le Ch^{\alpha+\beta-1}\|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{5.6}$$

$$\|\mathbf{u} - \mathbf{u}^h\|_{0,\beta} \le Ch^{s+\beta}\|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{5.7}$$

$$\|\mathbf{u} - \mathbf{u}^h\|_0 \le Ch^s\|\mathbf{u}\|_{\alpha+\beta,\beta}, \tag{5.8}$$

where $s < \alpha$, for $\alpha + \beta \le k+1$ with k the degree of the piecewise polynomial elements in $\mathcal{V}^h$.

Proof. By Lemmas 4.8 and 5.2, we have

$$\begin{aligned}\|\mathbf{u} - \mathbf{u}^h\|_{1,\beta} &\le C\|L(\mathbf{u} - \mathbf{u}^h)\|_{0,\beta} \le C\|L(\mathbf{u} - \mathcal{I}^h_0\mathbf{u})\|_{0,\beta} \\ &\le C\|\mathbf{u} - \mathcal{I}^h_0\mathbf{u}\|_{1,\beta} \le Ch^{\alpha+\beta-1}\|\mathbf{u}\|_{\alpha+\beta,\beta},\end{aligned}$$

which establishes both (5.5) and (5.6) since we may write

$$\|L(\mathbf{u} - \mathbf{u}^h)\|_{0,\beta} = G_w(\mathbf{u} - \mathbf{u}^h;\mathbf{0})^{\frac{1}{2}}.$$

Note that Lemmas 4.8 and 5.2 are satisfied for $|1-\beta| < \alpha$ and $\alpha + \beta \le 2$.

For the weighted L^2-norm, we write

$$\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta}^2 = \sum_{\tau\in\mathcal{T}^h} \|\mathbf{u}-\mathbf{u}^h\|_{0,\beta,\tau}^2.$$

The Cauchy inequality yields, for any $\epsilon \in (0,1)$,

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta,\tau}^2 &= \int_\tau r^{2\beta}|\mathbf{u}-\mathbf{u}^h|^2 d\tau \le \left(\int_\tau 1 d\tau\right)^{1-\epsilon}\left(\int_\tau \left(r^{2\beta}|\mathbf{u}-\mathbf{u}^h|^2\right)^{\frac{1}{\epsilon}} d\tau\right)^{\epsilon}\\ &\le Ch^{2-2\epsilon}\left(\int_\tau \left(r^\beta|\mathbf{u}-\mathbf{u}^h|\right)^{\frac{2}{\epsilon}} d\tau\right)^{\frac{\epsilon}{2}\cdot 2} = Ch^{2-2\epsilon}\|r^\beta(\mathbf{u}-\mathbf{u}^h)\|_{L^{\frac{2}{\epsilon}}(\tau)}^2.\end{aligned}$$

Since $H^1(\Omega)$ is continuously imbedded into $L^q(\Omega)$ for all $q\in[1,\infty)$,

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta}^2 &= \sum_{\tau\in\mathcal{T}^h}\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta,\tau}^2 \le Ch^{2-2\epsilon}\sum_{\tau\in\mathcal{T}^h}\|r^\beta(\mathbf{u}-\mathbf{u}^h)\|_{L^{\frac{2}{\epsilon}}(\tau)}^2\\ &\le Ch^{2-2\epsilon}\|r^\beta(\mathbf{u}-\mathbf{u}^h)\|_{L^{\frac{2}{\epsilon}}(\Omega)}^2 \le Ch^{2-2\epsilon}\|r^\beta(\mathbf{u}-\mathbf{u}^h)\|_{H^1(\Omega)}^2\\ &\le Ch^{2-2\epsilon}\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta}^2.\end{aligned}$$

Thus, by (5.5), we have

$$\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta} \le Ch^{1-\epsilon}\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta} \le Ch^{s+\beta}\|\mathbf{u}\|_{\alpha+\beta,\beta},$$

where any $s<\alpha$.

We now consider the bound on $\|\mathbf{u}-\mathbf{u}^h\|_0$. Let $K_0=\{\tau \mid \bar\tau\cap(0,0)\neq\emptyset\}$ and $K_1=\mathcal{T}^h\backslash K_0$. First, we consider the case $\beta<1$. If $\tau\in K_0$, then $r\le Ch$ and $r^{1-\beta}\le Ch^{1-\beta}$. Thus, we have

$$\|\mathbf{u}-\mathbf{u}^h\|_{0,\tau}^2 \le Ch^{2(1-\beta)}\|\mathbf{u}-\mathbf{u}^h\|_{0,\beta-1,\tau}^2 \le Ch^{2(1-\beta)}\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta,\tau}^2. \tag{5.9}$$

If $\tau\in K_1$, we use the technique above to get

$$\|\mathbf{u}-\mathbf{u}^h\|_{0,\tau}^2 \le Ch^{2(1-\epsilon)}\|\mathbf{u}-\mathbf{u}^h\|_{L^{\frac{2}{\epsilon}}(\tau)}^2.$$

Again, since H^1 is continuously imbedded into L^q for all $q\in[1,\infty)$, we have

$$\begin{aligned}&\sum_{\tau\in K_1}\|\mathbf{u}-\mathbf{u}^h\|_{0,\tau}^2 \le Ch^{2-2\epsilon}\sum_{\tau\in K_1}\|\mathbf{u}-\mathbf{u}^h\|_{L^{\frac{2}{\epsilon}}(\tau)}^2\\ &\le Ch^{2-2\epsilon}\|\mathbf{u}-\mathbf{u}^h\|_{L^{\frac{2}{\epsilon}}(K_1)}^2 \le Ch^{2-2\epsilon}\|\mathbf{u}-\mathbf{u}^h\|_{H^1(K_1)}^2\\ &= Ch^{2-2\epsilon}\int_{K_1} r^{-2\beta}r^{2\beta}\left(|\mathbf{u}-\mathbf{u}^h|^2+|\nabla(\mathbf{u}-\mathbf{u}^h)|^2\right)d\Omega\\ &\le Ch^{2(1-\beta-\epsilon)}\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta,K_1}^2. \qquad (5.10)\end{aligned}$$

Hence by (5.9), (5.10), and (5.5) we have

$$\begin{aligned}\|\mathbf{u}-\mathbf{u}^h\|_0^2 &= \sum_{\tau\in K_0}\|\mathbf{u}-\mathbf{u}^h\|_{0,\tau}^2 + \sum_{\tau\in K_1}\|\mathbf{u}-\mathbf{u}^h\|_{0,\tau}^2 \le h^{2(1-\beta-\epsilon)}\|\mathbf{u}-\mathbf{u}^h\|_{1,\beta}^2\\ &\le Ch^{2s}\,\|\mathbf{u}\|_{\alpha+\beta,\beta}^2,\end{aligned}$$

where $s<\alpha$. The proof for $\beta\ge 1$ follows analogously. ∎

Remark 5.5. For the optimal finite element convergence of $O(h)$ with respect to the weighted functional and H^1-norms, we select $\beta = 2 - \alpha$. But Theorem 5.4 also requires that $\beta < 1 + \alpha$. Thus, when $\alpha \in [1/2, 1)$, we may use a weighting with $\beta = 2 - \alpha$ and expect optimal rates, but when $\alpha \in (0, 1/2)$, our theory guarantees only at best $O(2\alpha)$ convergence using $\beta = 1 + \alpha$. Numerical results, however, indicate that values of β larger than the theory allows can be used to recover optimal rates. We explore this in the next section.

6. Computational results. In this section, we present some numerical examples of the weighted-norm procedure to validate the error bounds in the previous section.

As a test problem, we minimize the weighted functional on the following L-shaped domain: $\Omega = (-0.5, 0.5)^2 \setminus [0, 0.5) \times (-0.5, 0]$, which yields $\alpha = \pi/\omega = 2/3$. Function $\mathbf{f}$ is chosen so that the solution of this test problem is $\mathbf{u} = \nabla(\chi(r) r^{\frac{2}{3}} \sin(2\theta/3))$, where $\chi(r) = 1$ for $r < 1/8$, $\chi(r) = 0$ for $r > 3/8$, and $\chi(r)$ is C^2 smooth. Again, note that $\mathbf{f} \in L^2(\Omega)$ but $\mathbf{u} \notin H^1(\Omega)$.

Define the following measures of the accuracy of the computed solution, $\mathbf{u}^h$:

nonweighted functional norm	$G^{1/2} = (\|\nabla \cdot \mathbf{u}^h - f\|_0^2 + \|\nabla \times \mathbf{u}^h\|_0^2)^{1/2}$,
nonweighted L^2-norm of the error	$\epsilon^0 = \|\mathbf{u} - \mathbf{u}^h\|_0$,
nonweighted H^1 seminorm of the error	$\epsilon^1 = \|\mathbf{u} - \mathbf{u}^h\|_1$,
weighted functional norm	$G_w^{1/2} = G_w(\mathbf{u}^h; f)^{1/2}$,
weighted L^2-norm of the error	$\epsilon_w^0 = \|\mathbf{u} - \mathbf{u}^h\|_{0,\beta}$,
weighted H^1 seminorm of the error	$\epsilon_w^1 = \|\mathbf{u} - \mathbf{u}^h\|_{1,\beta}$.

Since $\alpha = 2/3$, we choose the optimal weight parameter, $\beta = 2 - \alpha = 4/3$, for our computations. Table 6.1 summarizes discretization error and convergence rates for $\beta = 4/3$.

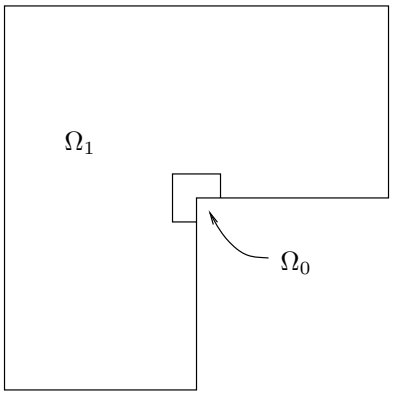

FIG. 6.1. *L-shaped domain Ω and subdomains Ω_0 and Ω_1.*

TABLE 6.2
Accuracy in Ω_0, Ω_1, and Ω with $\beta = 2 - \alpha$.

	$G_w^{1/2}$	$G^{1/2}$	ϵ_w^1	ϵ^1	ϵ_w^0	ϵ^0
Ω_1	$O(h)$	$O(h)$	$O(h)$	$O(h)$	$O(h^2)$	$O(h^2)$
Ω_0	$O(h)$	$O(1)$	$O(h)$	$O(1)$	$O(h^2)$	$O(h^{\frac{2}{3}})$
Ω	$O(h)$	$O(1)$	$O(h)$	$O(1)$	$O(h^2)$	$O(h^{\frac{2}{3}})$

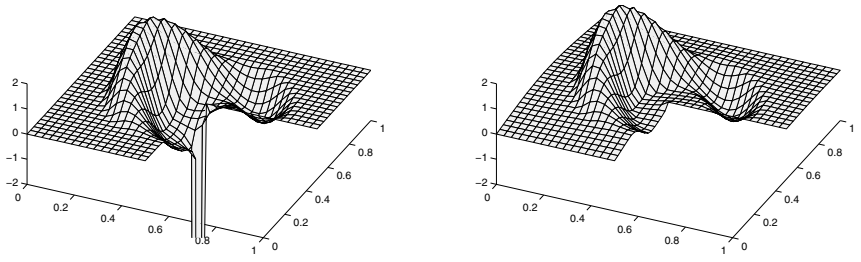
Asymptotic convergence rates in Ω are found to be approximately $O(h)$ for $G_w^{\frac{1}{2}}$ and ϵ_w^1, $O(h^2)$ for ϵ_w^0, and $O(h^{\frac{2}{3}})$ for ϵ_0. The approximation does not converge in either the ϵ_1 or $G^{\frac{1}{2}}$ measures since $\mathbf{u} \notin H^1(\Omega)$.

To distinguish between behavior near to and away from the singularity, we consider the error of the solution above on a partitioning of Ω. Define $\Omega_0 = \Omega \cap (\frac{3}{8}, \frac{5}{8})^2$ and $\Omega_1 = \Omega \backslash \Omega_0$; see Figure 6.1.

Table 6.2 summarizes the asymptotic discretization accuracy obtained at the finest mesh size in subdomains Ω_0 and Ω_1. Away from the singularity we observe optimal accuracy in all measures. As expected, near the singularity, the solution fails to converge in the nonweighted functional and H^1-norms. The nonweighted L^2 error achieves accuracy of approximately $O(h^{\frac{2}{3}})$ near the singularity.

Figure 6.2 shows the first component of the exact solution, u_1, and the standard FOSLS approximation u_1^h. Figure 6.3 shows the error of the first component of the approximated solution for the standard FOSLS and the weighted-norm FOSLS methods. We see that the error in the approximation in standard FOSLS is highest near the singularity but remains large even away from the corner point. In the weighted-norm FOSLS implementation, the error remains large near the singularity, as we expect, but is now concentrated only near the corner point. The pollution effect is removed by the weighting procedure.

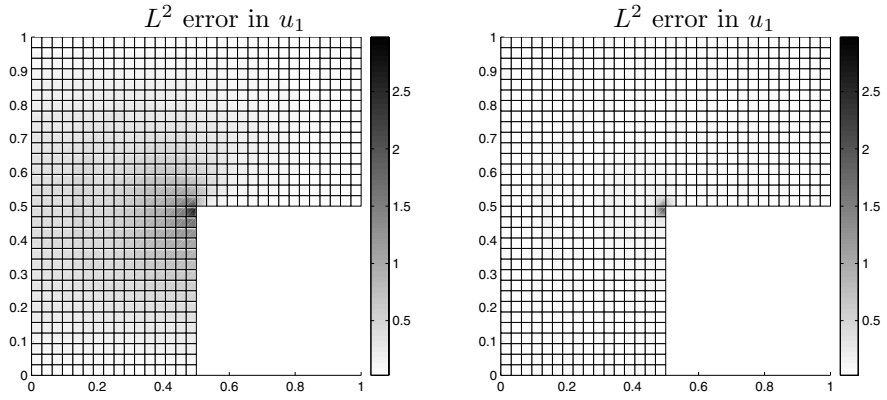
There are many boundary value problems not directly covered by the theory presented here that are of interest. For example, Poisson's equation with mixed boundary conditions on the domain used above has a value of $\alpha = 1/3$. To recover optimal convergence for this problem, the weighted-norm method requires a value of



(a) Exact component u_1.

(b) Component u_1^h computed by standard FOSLS.

FIG. 6.2. *Exact solution component u_1 and solution component u_1^h approximated by standard FOSLS on the $h = 32^{-1}$ mesh.*



(a) Standard FOSLS.

(b) Weighted-norm FOSLS, $\beta = 2 - \alpha$.

FIG. 6.3. *Reduction of the pollution effect by the weighted-norm procedure. Each plot is the error of solution component u_1^h on the $h = 32^{-1}$ mesh.*

β larger than Theorem 5.4 allows. In other elliptic equations (e.g., Stokes or the linear elasticity equations), the value of α is generally smaller than for Poisson's equation for the same domain and boundary condition type. In each of these cases, a larger β value is necessary for optimal convergence. This leads us to consider using larger β than the theory allows.

Consider the same example problem as above on uniform mesh sizes of $h = 1/8, 1/16, \ldots, 1/512$, and values of β ranging from $1/3$ to $23/6$.

Figure 6.4 plots the convergence rate at the finest level for the weighted functional norm, $G_w^{1/2}$; the weighted L^2-norm, ϵ_w^0; and the L^2-norm, ϵ^0. While the functional norm retains optimal accuracy for large values of β, the solution fails to converge in the weighted and nonweighted L^2 measures for $\beta \gtrsim 3$. This indicates that, although the weighted-norm approach seems to be more robust than the theory allows, large values of β should still be used with caution.

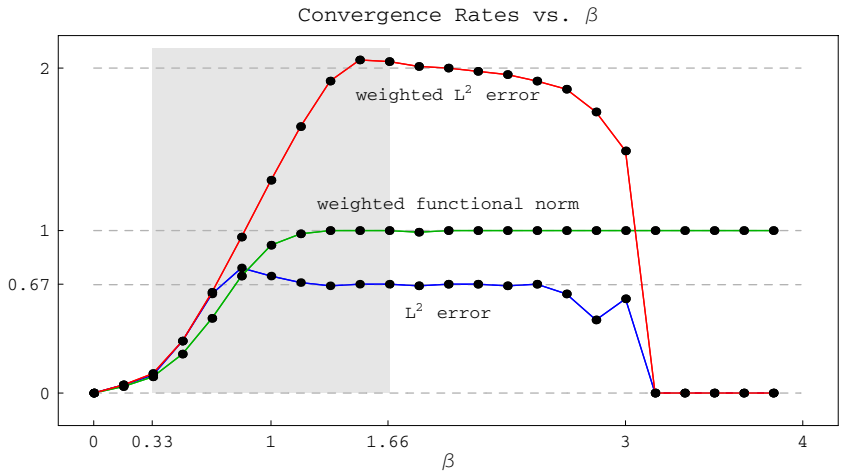


FIG. 6.4. *Convergence rates versus β. The shaded region indicates values of β for which the assumptions of Theorem* 5.4 *are satisfied.*

The method presented here is applicable to a wide range of problems and provides an efficient alternative to more specialized techniques for treating singularities in boundary value problems.

CONVERGENCE OF A COMPACT SCHEME FOR THE PURE STREAMFUNCTION FORMULATION OF THE UNSTEADY NAVIER–STOKES SYSTEM*

MATANIA BEN-ARTZI†, JEAN-PIERRE CROISILLE‡, AND DALIA FISHELOV§

Abstract. This paper is devoted to the analysis of a new compact scheme for the Navier–Stokes equations in pure streamfunction formulation. Numerical results using that scheme have been reported in [M. Ben-Artzi et al., *J. Comput. Phys.*, 205 (2005), pp. 640–664]. The scheme discussed here combines the Stephenson scheme for the biharmonic operator and ideas from box-scheme methodology. Consistency and convergence are proved for the full nonlinear system. Instead of customary periodic conditions, the case of boundary conditions is addressed. It is shown that in one dimension the truncation error for the biharmonic operator is $O(h^4)$ at interior points and $O(h)$ at near-boundary points. In two dimensions the truncation error is $O(h^2)$ at interior points (due to the cross-terms) and $O(h)$ at near-boundary points. Hence the scheme is globally of order four in the one-dimensional periodic case and of order two in the two-dimensional periodic case, but of order 3/2 for one- and two-dimensional nonperiodic boundary conditions. We emphasize in particular that there is no special treatment of the boundary, thus allowing robust use of the scheme. The finite element analogy of the finite difference schemes is invoked at several stages of the proofs in order to simplify their verifications.

Key words. finite difference compact schemes, Stephenson scheme, box schemes, finite elements, Navier–Stokes equations, streamfunction formulation, biharmonic problem, fourth order problem

1. Introduction.

In a recent paper [3] we presented a fourth-order compact scheme for the pure streamfunction formulation of the two-dimensional (incompressible) Navier–Stokes equations. We have given there a convergence analysis for the linearized model. In this paper we prove the convergence of the nonlinear scheme, without any further assumptions. Recall that the pure streamfunction formulation of the (two-dimensional) Navier–Stokes equations is classical [15]. It has the advantage of reducing the system to a single evolution equation for the scalar streamfunction having the form

$$\frac{\partial \Delta\psi}{\partial t} + \nabla^{\perp}\psi \cdot \nabla\Delta\psi - \nu\Delta^2\psi = 0. \tag{1}$$

The velocity field is $(u, v) = \nabla^{\perp}\psi = (-\frac{\partial\psi}{\partial y}, \frac{\partial\psi}{\partial x})$, and the vorticity is $\omega = \Delta\psi$. The price paid for reducing the system to a single equation is that one must now deal with the biharmonic Δ^2 operator. There are therefore two boundary conditions imposed

on ψ. For the typical "no-leak no-slip" conditions (vanishing velocity on the fixed boundary) we have

$$\nabla\psi = 0 \qquad \text{on the boundary.} \tag{2}$$

Since the function ψ is only determined up to a constant, condition (2) is equivalent to

$$\psi = \frac{\partial\psi}{\partial n} = 0, \tag{3}$$

which, for simplicity, will be the case treated in this paper. Clearly (2) is equivalent to the assumption $\psi \in H_0^2$, the closure of smooth compactly supported test functions in the Sobolev space of functions having square-summable derivatives up to second order.

Our scheme can be described as follows (see [3] for details). At each time step the scheme solves a time implicit version of (1). This leads to a fourth-order biharmonic problem of the form

$$\Delta\psi - \nu\Delta^2\psi = f, \tag{4}$$

subject to the boundary conditions (2).

The spatial discretization of (4) makes use of the Stephenson scheme for the the biharmonic operator introduced in [19], [12]. See also [2]. This scheme can be interpreted as a mixed scheme in $(\psi, \nabla\psi)$, similar in form to a version of a box scheme [14], [7]. More specifically, its design is obtained by a spline collocation procedure on a nine-point stencil, which we recall in section 3 below.

The streamline-vorticity formulation has been extensively used for the simulation of the two-dimensional Navier–Stokes system. As representative references we mention [17], [8], [5], [9], [13], and the references therein. One difficult point is that "... the $\psi - \omega$ system is inextricably coupled; BC's and solution methods must contend with this fact..." [10, p. 431]. Indeed, one must cope with the vorticity boundary values, resulting from the fact that the relation $\Delta\psi = \omega$ is overdetermined under condition (2). An attempt to avoid this difficulty has been made in [4], where the need to determine these values was circumvented by switching to the biharmonic equation (at each time step), exploiting the natural condition (2). The scheme presented in [3], whose convergence is proved here, has avoided all explicit mention of the vorticity by using a pure streamfunction formulation. We mention that recently in [11] a very similar algorithm has been proposed, but it deals only with the steady-state Navier–Stokes system.

The paper is organized as follows. First, we introduce in section 2 our notation and the setup for our discrete spaces. Then we establish in sections 3 and 4 the necessary analytic properties of the scheme in one and two dimensions. In particular, in analogy with the coercivity of Δ^2 in H_0^2, we prove the coercivity of the discretized biharmonic operator in a suitable discrete analogue of H_0^2. We prove that the truncation error of the biharmonic scheme is of order four in one dimension and of order two in two dimensions, at all interior points and of first order at near-boundary points, giving a 3/2 order of convergence rate in the natural discrete L^2 norm. Note that in the periodic case all points are interior. Then in section 5, we prove that the same order of convergence extends to the spatial semidiscrete version of the full nonlinear scheme. We emphasize the fact that we do not need any special treatment of boundary points, and the boundary condition (2) is naturally incorporated here. As mentioned above,

this causes a reduced (from four to one) order of local truncation error at the boundary, and is reflected in the fact that our result yields a 3/2 convergence rate in the discrete L^2 norm. The present convergence result can be compared to the convergence results obtained in [9], [13]. In both papers, the time evolution is performed on the vorticity, and hence a very careful treatment of the vorticity boundary conditions is required, either by "ghost-points" [9] or by replacing condition (2) on the normal derivative of the streamfunction by boundary conditions on the vorticity [13] (which, as these authors observe, amounts to an algorithm for vorticity generation on the boundary).

2. Discrete spaces and basic inequalities. Let $0 \le i, j \le N$. We denote by (ih, jh) a finite difference mesh on the square $[0,1]^2$, with equal mesh size $h = 1/N$ in the x and y directions. We denote by $u_{i,j}$ a grid function on $[0,1]^2$, with $0 \le i, j \le N$. The centered and upwind derivative operators δ_x, $\delta_x^{\pm}$ are defined as usual in each direction by

$$\delta_x u_{i,j} = \frac{u_{i+1,j} - u_{i-1,j}}{2h}, \quad \delta_x^+ u_{i,j} = \frac{u_{i+1,j} - u_{i,j}}{h}, \quad \delta_x^- u_{i,j} = \frac{u_{i,j} - u_{i-1,j}}{h}, \tag{5}$$

and similarly in the y direction:

$$\delta_y u_{i,j} = \frac{u_{i,j+1} - u_{i,j-1}}{2h}, \quad \delta_y^+ u_{i,j} = \frac{u_{i,j+1} - u_{i,j}}{h}, \quad \delta_y^- u_{i,j} = \frac{u_{i,j} - u_{i,j-1}}{h}. \tag{6}$$

The centered second-order derivatives are

$$\delta_x^2 u_{i,j} = \frac{u_{i+1,j} + u_{i-1,j} - 2u_{i,j}}{h^2}, \quad \delta_y^2 u_{i,j} = \frac{u_{i,j+1} + u_{i,j-1} - 2u_{i,j}}{h^2}. \tag{7}$$

The five-point Laplacian is

$$\Delta_h u_{i,j} = \delta_x^2 u_{i,j} + \delta_y^2 u_{i,j} = \frac{u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1} - 4u_{i,j}}{h^2}. \tag{8}$$

The crossed derivative operators δ_{xy}^+, δ_{xy}^-, δ_{xy} are

$$\delta_{xy}^+ u_{i,j} = \delta_x^+ \delta_y^+ u_{i,j} = \frac{u_{i+1,j+1} - u_{i+1,j} - u_{i,j+1} + u_{i,j}}{h^2}, \tag{9}$$

$$\delta_{xy}^- u_{i,j} = \delta_x^- \delta_y^- u_{i,j} = \frac{u_{i,j} - u_{i,j-1} - u_{i-1,j} + u_{i-1,j-1}}{h^2}, \tag{10}$$

$$\delta_{xy} u_{i,j} = \delta_x \delta_y u_{i,j} = \frac{u_{i+1,j+1} - u_{i-1,j+1} - u_{i+1,j-1} + u_{i-1,j-1}}{4h^2}. \tag{11}$$

It is easy to check that

$$\delta_x^2 \delta_y^2 u_{i,j} = \delta_{xy}^+ \delta_{xy}^- u_{i,j}. \tag{12}$$

The L_h^2 space is the space of sequences $u_{i,j}$, $0 \le i, j \le N$. $L_{h,0}^2$ is the subspace of $u_{i,j}$ with zero boundary conditions $u_{i,j} = 0$ for $i \in \{0, N\}$ or $j \in \{0, N\}$. The scalar product on $L_{h,0}^2$ is

$$(u, v)_h = h^2 \sum_{i,j=1}^{N-1} u_{i,j} v_{i,j}, \tag{13}$$

with the corresponding norm

$$|u|_h = \left\{ h^2 \sum_{i,j=1}^{N-1} (u_{i,j})^2 \right\}^{1/2}. \tag{14}$$

Furthermore, we denote by l_h^2 the space of sequences u_i, $0 \le i \le N$, and by $l_{h,0}^2$ the subspace of sequences with zero boundary conditions. The scalar product and the norm on $l_{h,0}^2$ are

$$(u,v)_h = h \sum_{i=1}^{N-1} u_i v_i, \quad |u|_h^2 = \left\{ h \sum_{i=1}^{N-1} u_i^2 \right\}^{1/2}. \tag{15}$$

We also define the discrete infinity norm

$$|u|_{\infty,h} = \max_i |u_i|. \tag{16}$$

We skip the proof of the following lemma, which states the discrete integration by parts in $L_{h,0}^2$ for the operators $\delta_x^{\pm}$, δ_x^2. For each grid function $u \in L_{h,0}^2$, we denote the one-dimensional column vector $u^j = [u_{1,j}, u_{2,j}, \ldots, u_{N-1,j}]^T$, $1 \le j \le N-1$.

LEMMA 2.1 (discrete integration by parts). *For any $u, v \in L_{h,0}^2$, we have*

$$\text{(i)} \quad (\delta_x^+ u, v)_h = -(u, \delta_x^- v)_h; \tag{17}$$

$$\text{(ii)} \quad (\delta_x^2 u, v)_h = -(\delta_x^+ u, \delta_x^+ v)_h = -(\delta_x^- u, \delta_x^- v)_h. \tag{18}$$

Note that in (17), (18), the finite difference operators are extended to the points $i = 0$, $i = N$ by

$$\delta_x^{\pm} u_0 = \delta_x^{\pm} u_N = 0, \quad \delta_x^2 u_0 = \delta_x^2 u_N = 0. \tag{19}$$

Observe that this assumption is only for notational convenience, in order to have formally $\delta_x^{\pm} u, \delta_x^2 u \in L_{h,0}^2$. Results similar to (17), (18) in the y direction are obtained by substituting the subscript y to the subscript x. The following lemma is the counterpart of the Poincaré inequality at the discrete level.

LEMMA 2.2 (discrete Poincaré inequality). *For all $u \in L_{h,0}^2$ and any $1 \le j \le N-1$,*

$$|u^j|_h \le 2 |\delta_x^+ u^j|_h. \tag{20}$$

COROLLARY 2.1. *For all $u \in L_{h,0}^2$,*

$$|u|_h \le \sqrt{2} \left[|\delta_x^+ u|_h^2 + |\delta_y^+ u|_h^2 \right]^{1/2}. \tag{21}$$

Proof. For all $u \in l_{h,0}^2$, we have

$$|u|_h^2 = h \sum_{i_0=1}^{N-1} u_{i_0}^2. \tag{22}$$

For all $1 \le i_0 \le N-1$,

$$\begin{aligned} u_{i_0}^2 &= \sum_{i=0}^{i_0-1} (u_{i+1} - u_i)(u_{i+1} + u_i) = \sum_{i=0}^{i_0-1} h \delta_x^+ u_i (u_i + (Su)_i) \\ &\le 2 |\delta_x^+ u|_h |u|_h, \end{aligned}$$

where $(Su)_j = u_{j+1}$, $j = 0, \dots, N-1$. Therefore,

$$|u|_h^2 = h \sum_{i_0=1}^{N-1} u_{i_0}^2 \le 2|\delta_x^+ u|_h |u|_h, \tag{23}$$

which gives (20).

Now for all $u \in L_{h,0}^2$, we have

$$\begin{aligned} |u|_h^2 = h \sum_{j_0=1}^{N-1} |u^{j_0}|_h^2 &\le 2h \sum_{j_0=1}^{N-1} |\delta_x^+ u^{j_0}|_h |u^{j_0}|_h \\ &\le 2\Big(\sum_{j_0=1}^{N-1} h|\delta_x^+ u^{j_0}|^2 \Big)^{1/2} \Big(\sum_{j_0=1}^{N-1} h|u^{j_0}|^2 \Big)^{1/2} \\ &\le 2|\delta_x^+ u|_h |u|_h. \end{aligned} \tag{24}$$

In a similar way, we obtain in the y direction

$$|u|_h^2 \le 2|\delta_y^+ u|_h |u|_h. \tag{25}$$

Summing (24) and (25), we obtain (21). ∎

3. The Stephenson scheme in one dimension.

3.1. Design by collocation. Consider the one-dimensional biharmonic equation

$$\begin{cases} u^{(4)}(x) = f(x), \quad 0 < x < 1, \\ u(0) = u(1) = u_x(0) = u_x(1) = 0. \end{cases} \tag{26}$$

Suppose that at each node $x_j = jh$, $0 \le j \le N$, of a finite difference grid, there are two unknowns u_j and $u_{x,j}$ approximating, respectively, $u(x_j)$ and $u_x(x_j)$, which is referred to as a "mixed scheme." The values u_j, $u_{x,j}$ are solutions of the linear system, designed by the following Galerkin collocation method. At each interior node j, $1 \le j \le N-1$, we consider a fourth-order polynomial, with domain $[x_{j-1}, x_{j+1}]$

$$Q(x) = a_0 + a_1(x - x_j) + a_2(x - x_j)^2 + a_3(x - x_j)^3 + a_4(x - x_j)^4. \tag{27}$$

The five coefficients a_k, $k \in \{0, 1, 2, 3, 4\}$, are defined by the five collocation conditions on the compact stencil $\{x_{j-1}, x_j, x_{j+1}\}$ (see Figure 1):

$$\begin{cases} Q(x_{j-1}) = u_{j-1}, \quad Q(x_j) = u_j, \quad Q(x_{j+1}) = u_{j+1}, \\ Q'(x_{j-1}) = u_{x,j-1}, \quad Q'(x_{j+1}) = u_{x,j+1}. \end{cases} \tag{28}$$

The five coefficients of the unique polynomial (27), solution of (28), are given by

$$\begin{cases} a_0 = u_j, \\ a_1 = \dfrac{3}{2}\delta_x u_j - \dfrac{1}{4}(u_{x,j+1} + u_{x,j-1}), \\ a_2 = \delta_x^2 u_j - \dfrac{1}{2}(\delta_x u_x)_j, \\ a_3 = \dfrac{1}{h^2}(\delta_x u_j - u_{x,j}) = \dfrac{1}{6}(\delta_x^2 u_x)_j, \\ a_4 = \dfrac{1}{2h^2}\big[(\delta_x u_x)_j - \delta_x^2 u_j\big]. \end{cases} \tag{29}$$

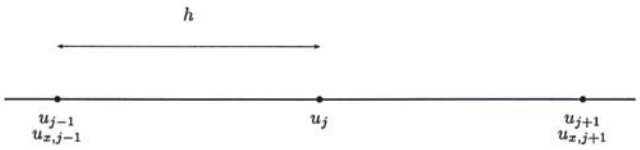

FIG. 1. *Stephenson's scheme for $u^{(4)} = f$: The finite difference operator $\delta_x^4 u_j$ at point j is $Q^{(4)}(x_j)$, where $Q(x) \in P^4[x_{j-1}, x_{j+1}]$ is defined by the five collocated values for u_{j-1}, u_j, u_{j+1}, $u_{x,j-1}$, $u_{x,j+1}$.*

Now, since $Q'(x_j) = a_1$ and $Q''''(x_j) = 24a_4$, it is natural to define the following compact scheme: find $[u_0, u_1, \ldots, u_{N-1}, u_N]$, $[u_{x,0}, u_{x,1}, \ldots, u_{x,N-1}, u_{x,N}] \in l^2_{h,0}$, which solve

$$\begin{cases} \text{(a)} \ \ (P_x u_x)_j = \delta_x u_j, \quad 1 \le j \le N-1, \\ \text{(b)} \ \ \delta_x^4 u_j = f(x_j), \quad 1 \le j \le N-1, \\ \text{(c)} \ \ u_0 = u_1 = u_{x,0} = u_{x,N} = 0, \end{cases} \tag{30}$$

where the operators P_x, δ_x^4 are, respectively, defined in (31), (34).

For $u \in l^2_{h,0}$, the operator P_x is defined by

$$(P_x u)_j = \frac{1}{6} u_{j-1} + \frac{2}{3} u_j + \frac{1}{6} u_{j+1}, \quad 1 \le j \le N-1. \tag{31}$$

P_x will be referred to as the *Simpson operator* in the x direction, because the coefficients in (30) are those of the Simpson quadrature formula over $[x_{j-1}, x_{j+1}]$. Note also that

$$P_x = I + \frac{h^2}{6} \delta_x^2. \tag{32}$$

We also note that the connection (30)(a) is already given in the classical book by Collatz [6, Chap. III, Eq. 2.9]. We call $\mathcal{S}$ the discrete space of grid functions $(u, u_x) \in l^2_{h,0} \times l^2_{h,0}$,

$$\mathcal{S} = \big\{ (u, u_x) \in l^2_{h,0} \text{ such that } P_x u_x = \delta_x u \big\}. \tag{33}$$

In (30), we define the *Stephenson discrete biharmonic* to be the compact difference operator given on $\mathcal{S}$ by

$$\delta_x^4 u_j = \frac{12}{h^2} \big\{ (\delta_x u_x)_j - \delta_x^2 u_j \big\}, \quad 1 \le j \le N-1. \tag{34}$$

This is a one-dimensional version of the original scheme proposed by Stephenson in [19]. Note that for simplicity, we will refer in what follows to a grid function in $\mathcal{S}$ by $u \in \mathcal{S}$, meaning that it is the first component of a pair $(u, u_x) \in \mathcal{S}$.

Remark. We note that the implicit scheme (30)(a) defining the grid function u_x as a function of u is exactly the one obtained in the piecewise cubic spline interpolation; see, e.g., [18]. The classical question that occurs in spline interpolation about fixing the two degrees of freedom $u_{x,0}$, $u_{x,N}$ at end points is here pointless, since they are precisely given in (30)(c).

3.2. Consistency. On a periodic grid, the order of consistency can be obtained by a simple Taylor expansion at point x_j. Equivalently, one can compute the symbol of the operators. Recall that in the context of finite difference operators, we have to use the semidiscrete Fourier transform; see, e.g., [20]. In practice, if the values of the periodic grid function (u_j) are represented by $e^{ij\xi h}$, then the symbol of the linear operator L_h is $l_h(\xi)$ defined by

$$L_h u_j = l_h(\xi) u_j. \tag{35}$$

Furthermore, if $l(\xi)$ is the symbol of L, then the order of consistency is given by the greatest value $p > 0$ such that (see [20])

$$l_h(\xi) - l(\xi) = O(h^p). \tag{36}$$

Doing so, it is quite easy to verify that the Stephenson gradient is fourth-order accurate and that the biharmonic operator (34) is as well. Indeed, we verify the following:

- The symbol of the discrete operator u_x in (30)(a) is

$$g_h(\xi) = i\xi - \frac{1}{180} i\xi^5 h^4 + O(h^6), \tag{37}$$

so that the order of accuracy with respect to the operator ∂_x, whose symbol is $i\xi$, is

$$g_h(\xi) - i\xi = O(h^4). \tag{38}$$

- The symbol of the discrete operator $\delta_x^4 u$ in (34) is

$$d_h(\xi) = \xi^4 - \frac{1}{720} \xi^8 h^4 + O(h^6), \tag{39}$$

so that the order of accuracy with respect to ∂_x^4 is

$$d_h(\xi) - (i\xi)^4 = O(h^4). \tag{40}$$

On a finite grid with homogeneous boundary conditions at the two ends, we have to perform a more careful analysis, because the symbolic computation no longer holds in this case.

LEMMA 3.1. *Suppose that $u(x)$ is a regular function on $[0,1]$. Then the finite difference gradient u_x defined from the values $u(x_j)$, $0 \le j \le N$, by $(P_x u_x)_j = \delta_x u(x_j)$ has a truncation error $(u_x)_j - u'(x_j)$ of order four at each point x_j. More precisely,*

$$|(u_x)_j - u'(x_j)| \le C h^4 |u^{(5)}|_{\infty,[0,1]}. \tag{41}$$

Proof. The Stephenson gradient u_x is defined in the space $l^2_{h,0}$ by

$$(P_x u_x)_j = (\delta_x u)_j, \quad 1 \le j \le N-1, \tag{42}$$

where P_x is the $N-1 \times N-1$ matrix-operator acting on $l^2_{h,0}$ as defined in (31), that is,

$$P_x = \begin{pmatrix} \frac{2}{3} & \frac{1}{6} & 0 & \dots & 0 \\ \frac{1}{6} & \frac{2}{3} & \frac{1}{6} & \ddots & \\ \vdots & & \ddots & \ddots & \\ 0 & \dots & \frac{1}{6} & \frac{2}{3} & \frac{1}{6} \\ 0 & \dots & \dots & \frac{1}{6} & \frac{2}{3} \end{pmatrix}. \tag{43}$$

Consider a regular function $u(x)$, differentiable as much as needed, and denote by u', $u'', \ldots, u^{(p)}$, its derivatives. At each point x_j, $1 \le j \le N-1$, the Taylor formula gives (we note $u_j^{(m)} = u^{(m)}(x_j)$)

$$(\delta_x u)(x_j) = u'_j + \frac{h^2}{6} u_j^{(3)} + \frac{h^4}{2\,5!}\big[u^{(5)}(\xi_{1,j}^-) + u^{(5)}(\xi_{1,j}^+)\big], \tag{44}$$

where $\xi_{1,j}^- \in]x_{j-1}, x_j[$ and $\xi_{1,j}^+ \in]x_j, x_{j+1}[$. Similarly, there exist $\xi_{2,j}^- \in]x_{j-1}, x_j[$, $\xi_{2,j}^+ \in]x_j, x_{j+1}[$ such that

$$(\delta_x^2 u)(x_j) = u''_j + \frac{h^2}{4!}\big[u^{(4)}(\xi_{2,j}^-) + u^{(4)}(\xi_{2,j}^+)\big]. \tag{45}$$

We deduce that, applying (45) to u',

$$\begin{aligned}
\delta_x u(x_j) - P_x u'(x_j) &= \delta_x u(x_j) - \left[u'(x_j) + \frac{h^2}{6}\delta_x^2 u'(x_j)\right] \\
&= u'_j + \frac{h^2}{6} u_j^{(3)} + \frac{h^4}{2.5!}\left(u^{(5)}(\xi_{1,j}^-) + u^{(5)}(\xi_{1,j}^+)\right) \\
&\quad - \left[u'_j + \frac{h^2}{6}\left(u_j^{(3)} + \frac{h^2}{4!}\big[u^{(5)}(\xi_{2,j}^-) + u^{(5)}(\xi_{2,j}^+)\big]\right)\right] \\
&= h^4 v_j,
\end{aligned}$$

where the grid function v_j is defined by

$$v_j = \frac{1}{2.5!}\big(u^{(5)}(\xi_{1,j}^+) + u^{(5)}(\xi_{1,j}^-)\big) - \frac{1}{6.4!}\big(u^{(5)}(\xi_{2,j}^-) + u^{(5)}(\xi_{2,j}^+)\big). \tag{46}$$

Therefore, the grid function $u \in l^2_{h,0}$ verifies the identity

$$\delta_x u(x_j) - P_x u'(x_j) = h^4 v_j. \tag{47}$$

On the other hand, $u_x \in l^2_{h,0}$ is defined by

$$\delta_x u - P_x u_x = 0. \tag{48}$$

Subtracting (48) from (47), we obtain the identity in $l^2_{h,0}$,

$$u' - u_x = h^4 P_x^{-1} v, \tag{49}$$

where $u' = [u'(x_1), \ldots, u'(x_{N-1})]$. Writing $P_x = I + \frac{h^2}{6}\delta_x^2$, the inverse of P_x is obtained by the Neumann series

$$P_x^{-1} = \sum_{k=0}^{\infty} \left(-\frac{h^2}{6}\delta_x^2\right)^k, \tag{50}$$

which gives the estimate of $|P_x^{-1}|_{\infty,h}$,

$$|P_x^{-1}|_{\infty,h} \le \sum_{k=0}^{\infty} \frac{h^{2k}}{6^k} |\delta_x^2|_{\infty,h}^k \le \sum_{k=0}^{\infty} \left(\frac{2}{3}\right)^k = 3. \tag{51}$$

Observe that the matrix-operator δ_x^2 above is defined at the near-boundary points $j = 1$, $j = N - 1$ by

$$\delta_x^2 u_1 = \frac{u_2 - 2u_1}{h^2}, \quad \delta_x^2 u_{N-1} = \frac{u_{N-2} - 2u_{N-1}}{h^2}. \tag{52}$$

We deduce now from (49) and (51) that

$$|u' - u_x|_{\infty,h} \le h^4 |P_x^{-1}|_{\infty,h} |v|_{\infty,h} \le C h^4 |u^{(5)}|_{\infty,[0,1]}. \qquad \square \tag{53}$$

LEMMA 3.2. *Suppose that $u(x)$ is a regular function on $[0,1]$. Then the Stephenson biharmonic operator δ_x^4 defined by* (34) *has a truncation error $\delta_x^4 u - u^{(4)}$ of order $3/2$ in the $l_{h,0}^2$ norm,*

$$|\delta_x^4 u - u^{(4)}|_h \le C h^{3/2} \big(|u^{(6)}|_{\infty,[0,1]} + |u^{(5)}|_{\infty,[0,1]} \big), \tag{54}$$

where the notation $u^{(4)}$ stands for

$$u^{(4)} = [u^{(4)}(x_1), \dots, u^{(4)}(x_{N-1})] \in l_{h,0}^2. \tag{55}$$

Remark. The difference in accuracy between the periodic case and the nonperiodic case is only due to the near-boundary points 1 and $N - 1$.

Proof. Recall that the finite difference biharmonic operator δ_x^4 is the three-points compact operator, expressed in terms of u and u_x by

$$\delta_x^4 u_j = \frac{12}{h^2} \big[\delta_x u_x - \delta_x^2 u \big]. \tag{56}$$

Here, we handle the finite difference operators acting on one-dimensional grid functions $u = [u_1, \dots, u_{N-1}]$, as $N - 1 \times N - 1$ matrices; see [3]. We can rewrite (30)(a) as

$$P_x u_x = \frac{1}{2h} K u = \delta_x u \in l_{h,0}^2, \tag{57}$$

where the antisymmetric matrix $K = \{K_{i,m}\}_{1 \le i,m \le N-1}$ is given by

$$K_{i,m} = \begin{cases} \operatorname{sgn}(m - i), & |m - i| = 1, \\ 0, & |m - i| \ne 1, \end{cases} \tag{58}$$

and the operator δ_x is expressed as

$$\delta_x = \frac{1}{2h} K. \tag{59}$$

In matrix form, (57) is simply written as

$$P_x u_x = \delta_x u \quad \text{or} \quad u_x = P_x^{-1} \delta_x u. \tag{60}$$

Using (34), the operator δ_x^4 can be rewritten in matrix form

$$\begin{aligned} \delta_x^4 &= \frac{12}{h^2} \big[\delta_x P_x^{-1} \delta_x - \delta_x^2 \big] \\ &= \frac{12}{h^2} \big[P_x^{-1} (\delta_x)^2 + \big[\delta_x P_x^{-1} - P_x^{-1} \delta_x \big] \delta_x - \delta_x^2 u \big]. \end{aligned}$$

Applying the operator P_x, we obtain, for all $u \in l^2_{h,0}$,

$$P_x\left[\delta_x^4 u - u^{(4)}\right] = \frac{12}{h^2}\left[(\delta_x)^2 u + [P_x\delta_x - \delta_x P_x]P_x^{-1}\delta_x u - P_x\delta_x^2 u\right] - P_x u^{(4)} := v. \tag{61}$$

Note that in (60)–(61), we refer to P_x as the symmetric positive definite matrix (see (32)–(43)),

$$(P_x)_{i,m} = \begin{cases} \frac{2}{3}, & m = i, \\ \frac{1}{6}, & |m-i| = 1, \\ 0, & |m-i| \geq 2. \end{cases} \tag{62}$$

Clearly the commutator $[P_x, K] = P_x K - K P_x$ is

$$(P_x K - K P_x)_{i,j} = \begin{cases} -\frac{1}{3}, & i = j = 1, \\ \frac{1}{3}, & i = j = N-1, \\ 0 & \text{otherwise}, \end{cases} \tag{63}$$

so that the commutator $[P_x, \delta_x] = \frac{1}{2h}[P_x, K]$ is

$$P_x\delta_x - \delta_x P_x = \begin{cases} -\frac{1}{6h}, & i = j = 1, \\ \frac{1}{6h}, & i = j = N-1, \\ 0 & \text{otherwise}. \end{cases} \tag{64}$$

This means that the operators P_x and δ_x do not commute and that the nonzero commutator values are restricted to points $j = 1$ and $j = N-1$.

Let us first evaluate (61) at points $j = 2, 3, \ldots, N-2$.

$$\begin{aligned} \frac{12}{h^2}\left[(\delta_x)^2 u_j - P_x\delta_x^2 u_j\right] - P_x u_j^{(4)} = \frac{12}{h^2}\Bigg\{ & (\delta_x)^2 u_j \\ & - \left[\frac{2}{3}\delta_x^2 u_j + \frac{1}{6}\delta_x^2 u_{j+1} + \frac{1}{6}\delta_x^2 u_{j-1}\right]\Bigg\} \\ & - \left[\frac{2}{3}u_j^{(4)} + \frac{1}{6}u_{j-1}^{(4)} + \frac{1}{6}u_{j+1}^{(4)}\right]. \end{aligned} \tag{65}$$

The first term on the right-hand side of (65) is

$$(\delta_x)^2 u_j = u_j'' + \frac{h^2}{3}u_j^{(4)} + \frac{32}{6!}h^4 u_j^{(6)} + \frac{128}{8!}h^6 u_j^{(8)} + Ch^8 u^{(10)}(\xi_j). \tag{66}$$

Using (45) for evaluating $\delta_x^2 u_m$ at $m = j-1, j, j+1$, we find that $P_x\delta_x^2 u_j$ in (65) is

$$\frac{2}{3}\delta_x^2 u_j + \frac{1}{6}\delta_x^2 u_{j+1} + \frac{1}{6}\delta_x^2 u_{j-1} = u_j'' + \frac{1}{4}h^2 u_j^{(4)} + \frac{22}{6!}h^4 u_j^{(6)} + \frac{86}{8!}h^6 u_j^{(8)} + h^8 w_j, \tag{67}$$

where $|w_j| \leq C|u^{(10)}|_{\infty,[0,1]}$. In addition, we have that the third line of the right-hand side in (65) is

$$\left[\frac{2}{3}u_j^{(4)} + \frac{1}{6}u_{j-1}^{(4)} + \frac{1}{6}u_{j+1}^{(4)}\right] = u_j^{(4)} + \frac{1}{6}h^2 u_j^{(6)} + Ch^4 z_j, \tag{68}$$

where $|z_j| \le C|u^{(8)}|_{\infty,[0,1]}$. Therefore, we have, for $2 \le j \le N-2$,

$$\left| \frac{12}{h^2}\big[(\delta_x)^2 u - P_x \delta_x^2 u_j\big] - P_x u_j^{(4)} \right| \le Ch^4 |u^{(8)}|_{\infty,[0,1]}, \tag{69}$$

and this order is optimal. Consider now the truncation term for $j = 1$ (the computation is the same for $j = N-1$). We have

$$(\delta_x^4 u)_1 = \frac{12}{h^2}\big[(\delta_x u_x)_1 - \delta_x^2 u_1\big]. \tag{70}$$

Since $|u_{x,j} - u'_j| \le Ch^4 |u^{(5)}|_{\infty,[0,1]}$, we have

$$\begin{aligned} (\delta_x u_x)_1 &= \frac{u_{x,2}}{2h} = \frac{u_{x,2} - u_{x,0}}{2h} \\ &= \frac{u'(x_2) - u'(x_0)}{2h} + \tilde{v} \\ &= u''(x_1) + \frac{h^2}{6} u^{(4)}(x_1) + \tilde{v}, \end{aligned} \tag{71}$$

where $\tilde{v}$ stands for a generic term such that $|\tilde{v}| \le Ch^3 |u^{(5)}|_{\infty,[0,1]}$. In addition, we have

$$(\delta_x^2 u)_1 = u''(x_1) + \frac{h^2}{12} u^{(4)}(x_1) + w, \tag{72}$$

where

$$|w| \le Ch^4 |u^{(6)}|_{\infty,[0,1]}. \tag{73}$$

Therefore (71), (73) show that the truncation error at the near-boundary point x_1 is

$$\frac{12}{h^2}\big[(\delta_x u_x)_1 - (\delta_x^2 u)_1\big] - u^{(4)}(x_1) = t_1, \text{ with } |t_1| \le Ch |u^{(5)}|_{\infty,[0,1]}. \tag{74}$$

We deduce from (61), (69), (74) that the truncation error $e = \delta_x^4 u - u^{(4)}$ is the solution of the linear system

$$\overline{P}_x e = v, \quad v \in l^2_{h,0}, e \in l^2_{h,0}, \tag{75}$$

where $\overline{P}_x$ is the matrix

$$\overline{P}_x = \begin{bmatrix} 1 & 0 & 0 & \dots & 0 \\ \frac{1}{6} & \frac{2}{3} & \frac{1}{6} & \dots & 0 \\ \vdots & \vdots & \vdots & \dots & \vdots \\ 0 & \dots & \frac{1}{6} & \frac{2}{3} & \frac{1}{6} \\ 0 & \dots & 0 & 0 & 1 \end{bmatrix}, \tag{76}$$

and v is such that

$$|v_1|, |v_{N-1}| \le Ch |u^{(5)}|_{\infty,[0,1]}; \quad |v_j| \le Ch^4 |u^{(8)}|_{\infty,[0,1]}, \ \ j = 2, \dots, N-2. \tag{77}$$

By Gerschgorin's theorem, $\overline{P}_x^{-1}$ is a bounded matrix independent of h; therefore $e = \overline{P}_x^{-1} v$ is such that

$$|e|_h \le C|v|_h, \tag{78}$$

where

$$|v|_h^2 \le Ch\left(2h^2 + \sum_{j=2}^{N-2} h^8\right) \le Ch^3. \tag{79}$$

Taking the square root in (79), we obtain (54) (using the weaker estimate $|v_j| \le Ch^2|u^{(6)}|_{\infty,[0,1]}$ at interior points). ∎

Remark. Note that the error at the interior points is fourth order and that the $h^{3/2}$ error is fully due to the loss of accuracy at the two boundary points $j = 1$, $j = N - 1$.

3.3. Interpretation with finite elements. In this section, we establish the finite element counterpart of scheme (30). This allows us to obtain in a simple way the stability of the Stephenson finite difference operator δ_x^4. To each grid function $v \in l_{h,0}^2$, we match the function $v_h(x)$ defined by $v_h(x_j) = v_j$, in the finite element space $P_{c,0}^1$, the space of continuous functions, piecewise linear in each interval $[x_j, x_{j+1}]$, $j = 0, \ldots, N-1$, and such that $v_h(x_0) = v_h(x_N) = 0$. Clearly, it is an isomorphism between $l_{h,0}^2$ and $P_{c,0}^1$. In addition, starting with $v \in l_{h,0}^2$, we introduce the two piecewise constant functions $\bar{v}_h$ and $v_{h,x}$, defined in each interval $K_{j+1/2} =]x_j, x_{j+1}[$ by

$$\bar{v}_{h,j+1/2} = \frac{v_j + v_{j+1}}{2}, \quad v_{h,x,j+1/2} = \frac{v_{j+1} - v_j}{h}. \tag{80}$$

An important aspect of using $P_{c,0}^1$ in the study of finite difference schemes is that it allows one to streamline analytic operations like integration by parts or averaged quantities over intervals $K_{j+1/2} = [x_j, x_{j+1}]$. The $L^2[0,1]$ scalar product is denoted by

$$(\varphi, \psi) = \int_0^1 \varphi(x)\psi(x)dx. \tag{81}$$

Writing the representation of $u_h(x)$ in $K_{j+1/2}$ as ($x_{j+1/2} = \frac{1}{2}(x_{j+1} + x_j)$),

$$u_h(x)_{|K_{j+1/2}} = \bar{u}_{h,j+1/2} + u_{h,x,j+1/2}(x - x_{j+1/2}), \tag{82}$$

we can compare different scalar products for $(.,.)_h$ and in $L^2(0,1)$ as follows.

LEMMA 3.3. *For any $u, v \in l_{h,0}^2$, let $u_h(x), v_h(x) \in P_{c,0}^1$ be the corresponding finite element functions. Then we have*

$$\text{(i)} \quad (u,v)_h = (u_h, v_h) + \frac{h^2}{6}(u_{h,x}, v_{h,x}) = (\bar{u}_h, \bar{v}_h) + \frac{h^2}{4}(u_{h,x}, v_{h,x}); \tag{83}$$

$$\text{(ii)} \quad (\delta_x u, v)_h = (u_{h,x}, v_h); \tag{84}$$

$$\text{(iii)} \quad (\delta_x^2 u, v)_h = -(\delta_x^+ u, \delta_x^+ v)_h = -(\delta_x^- u, \delta_x^- v)_h = -(u_{h,x}, v_{h,x}) \text{ (see (18))}. \tag{85}$$

Proof. The proof is an elementary computation resulting from the piecewise linearity of $u_h(x)$ in each $K_{j+1/2} = [x_j, x_{j+1}]$ given by (82). In fact, it clearly suffices to check that (83), (84), (85) hold for $u_h = \varphi_k$, $v_h = \varphi_m$, where (φ_k) is a basis of $P_{c,0}^1$. ∎

Let $(u, u_x) \in \mathcal{S}$. Since $u_x \in l_{h,0}^2$, it has a matching function $p_h \in P_{c,0}^1$. On the other hand, we have the piecewise constant function $u_{h,x}$. The connection between these two functions is given by the following lemma.

LEMMA 3.4. (i) *Let $u \in \mathcal{S}$ with grid gradient $u_x \in l^2_{h,0}$. Then the finite element function $p_h(x) \in P^1_{c,0}$ corresponding to u_x is the orthogonal projection of the piecewise constant function $u_{h,x}$ onto $P^1_{c,0}$. In other words, it is the unique solution $p_h \in P^1_{c,0}$ of*

$$(p_h, q_h) = (u_{h,x}, q_h) \qquad \forall q_h \in P^1_{c,0}. \tag{86}$$

In addition, we have, with $q_h \in P^1_{c,0}$ corresponding to $q \in l^2_{h,0}$,

$$(P_x u_x, q)_h = (p_h, q_h) = (u_x, P_x q)_h. \tag{87}$$

(ii) *Let $u, v \in \mathcal{S}$ and let $(u_h, p_h), (v_h, q_h) \in P^1_{c,0} \times P^1_{c,0}$ be the matching finite element functions. Then the bilinear form $\langle .;. \rangle_h$ defined on $\mathcal{S} \times \mathcal{S}$ by*

$$\langle u, v \rangle_h = (\delta_x^4 u, v)_h = \frac{12}{h^2}\big(u_{h,x} - p_h, v_{h,x} - q_h\big) = (u, \delta_x^4 v)_h \tag{88}$$

is a scalar product on $\mathcal{S} \times \mathcal{S}$.

(iii) *Translated in terms of finite difference operators,* (88) *is*

$$\begin{aligned}\langle u, v \rangle_h = &\sum_{j=0}^{N-1} h \frac{u_{x,j+1} - u_{x,j}}{h} \frac{v_{x,j+1} - v_{x,j}}{h} \\ &+ \frac{12}{h^2} \sum_{j=0}^{N-1} h \left[\frac{u_{j+1} - u_j}{h} - \frac{1}{2}(u_{x,j} + u_{x,j+1})\right]\left[\frac{v_{j+1} - v_j}{h} - \frac{1}{2}(v_{x,j} + v_{x,j+1})\right].\end{aligned} \tag{89}$$

Proof. (i) The discrete gradient $u_x \in l^2_{h,0}$ is defined by

$$\big[P_x u_x\big]_j = \delta_x u_j, \quad 1 \le j \le N-1, \tag{90}$$

where P_x is the Simpson operator given in (31). Equation (90) is equivalent to

$$(u_x, q)_h + \frac{1}{6} h^2 (\delta_x^2 u_x, q)_h = (\delta_x u, q)_h \qquad \forall q \in l^2_{h,0}. \tag{91}$$

Taking any $q \in l^2_{h,0}$ and the p_h corresponding to $u_x \in l^2_{h,0}$, and using (83), (84), and (85), we can rewrite (91) as

$$\begin{aligned}(u_{h,x}, q_h) = (\delta_x u, q)_h &= (u_x, q)_h + \frac{h^2}{6}(\delta_x^2 u_x, q)_h \\ &= (p_h, q_h) + \frac{h^2}{6}(p_{h,x}, q_{h,x}) - \frac{h^2}{6}(p_{h,x}, q_{h,x}) \\ &= (p_h, q_h),\end{aligned}$$

which gives (86). The symmetry of P_x is clear from the definition; see (31), (62). In addition, we have

$$(P_x u_x, q)_h = (\delta_x u, q)_h = (u_{h,x}, q_h) = (p_h, q_h), \tag{92}$$

which proves (87).

(ii) The Stephenson biharmonic operator is (see (34))

$$\delta_x^4 u_j = \frac{12}{h^2}\Big\{(\delta_x u_x)_j - \delta_x^2 u_j\Big\}. \tag{93}$$

We have

$$(\delta_x^4 u, v)_h = \frac{12}{h^2}\big[(p_{h,x}, v_h) + (u_{h,x}, v_{h,x})\big] = \frac{12}{h^2}\big(v_{h,x}, u_{h,x} - p_h\big). \tag{94}$$

Subtracting $(q_h, u_{h,x} - p_h) = 0$ from (94), we deduce

$$\langle u, v\rangle_h = (\delta_x^4 u, v)_h = \frac{12}{h^2}\big(u_{h,x} - p_h, v_{h,x} - q_h\big). \tag{95}$$

We verify now that $\langle u, u\rangle_h^{1/2}$ is a norm on $\mathcal{S}$. $\langle u, u\rangle_h = 0$ is equivalent to $|u_{h,x} - p_h| = 0$. Therefore the piecewise affine function $p_h \in P_{c,0}^1$ is actually piecewise constant. Since it vanishes at $x = 0$ and is continuous at any x_j, we have $p_h \equiv 0$, which is $u_{h,x} \equiv 0$. Therefore u_h is piecewise constant as well. Since $u_h(0) = 0$ we have also $u_h \equiv 0$.

Finally, we prove (89). Recall that for any $q_h \in P_{c,0}^1$, the difference $q_h - \overline{q}_h$ is orthogonal to piecewise constant functions. Thus, replacing in (95) p_h, q_h by $\overline{p}_h$, $\overline{q}_h$, respectively, and noting (see (83)) that

$$(p_h, q_h) = (\overline{p}_h, \overline{q}_h) + \frac{h^2}{12}(p_{h,x}, q_{h,x}), \tag{96}$$

we get

$$\langle u, v\rangle_h = (p_{h,x}, q_{h,x}) + \frac{12}{h^2}(u_{h,x} - \bar{p}_h, v_{h,x} - \bar{q}_h), \tag{97}$$

which gives (89) using (80). ∎

Remarks. The result of Lemma 3.4(ii) gives the uniqueness of the discrete solution of scheme (30).

The following lemma states the discrete counterpart of the equivalence of

(i) $|u_x|$ and $\|u\|_{H_1}$ for $u \in H_0^1$;

(ii) $|u_{xx}|$ and $\|u\|_{H_2}$ for $u \in H_0^2$.

LEMMA 3.5. *There exist constants C, C', C'' independent of h such that for any grid function $u \in \mathcal{S}$,*

$$\text{(i) } |u_h| \le |u|_h \le C|\delta_x^+ u|_h = C|u_{h,x}| \quad (\textit{Poincaré inequality}); \tag{98}$$

$$\text{(ii) } |\delta_x^+ u|_h \le C'\langle u, u\rangle_h^{1/2}; \tag{99}$$

$$\text{(iii) } |\delta_x^+ u_x|_h \le C''\langle u, u\rangle_h^{1/2}. \tag{100}$$

Proof. Inequality (i) is simply the Poincaré inequality (21) in the one-dimensional setting, reformulated with the finite element notation. Inequality (iii) follows directly from (97) since $\delta_x^+ u_x = p_{h,x}$ as piecewise constant functions.

For (ii), we use the notation p for the grid function u_x and, as before, denote by u_h, p_h the $P_{c,0}^1$ functions associated with u, p, respectively. In view of (86), we have

$$\begin{aligned} |\delta_x^+ u|_h^2 = |u_{h,x}|^2 &= (u_{h,x} - p_h, u_{h,x} - p_h) + (p_h, p_h) \\ &= \frac{h^2}{12}\langle u, u\rangle_h + |p_h|^2, \end{aligned} \tag{101}$$

where in the second equality we have used (95). Now, applying the Poincaré inequality (98) to p instead of u, we get

$$|p_h|^2 \le C^2 |\delta_x^+ p|_h^2 \le C^2 (C'')^2 \langle u, u\rangle_h, \tag{102}$$

where in the last inequality we have used (100). Inserting this inequality in (101), we obtain (99) with $C' = CC''$. ∎

Remarks. 1. We know that $|u_{xx}|_{0,[0,1]}$ is a norm on the Sobolev space H_0^2. We may wonder if, at the discrete level, $|\delta_x^+ u_x|_h = |p_{h,x}|_{0,[0,1]}$ is a norm on $\mathcal{S}$. Actually it is a norm only if the number of points N is an even integer. We have that $p_{h,x} = 0$ implies $p_h = 0$. But the relation $P_x u_x = \delta_x u$ implies only $\delta_x u = 0$, which gives $u = 0$ only if N is an even integer.

2. For other finite difference schemes for the biharmonic problem and their link with the finite element method, we refer to the book by Li, Chen, and Wu [16].

3.4. Convergence of the Stephenson scheme. We derive now the following convergence result

PROPOSITION 3.1. *Let U be the $P_{c,0}^1$ Lagrange interpolate of the exact solution $u(x)$ of (26) and $\tilde{u}$ the discrete solution of (30). Then the following error estimate holds in the mesh dependent norm $\langle \tilde{v}, \tilde{v}\rangle_h^{1/2}$,*

$$\langle U - \tilde{u}, U - \tilde{u}\rangle_h^{1/2} \le Ch^{3/2}\big(|f''|_{\infty,[0,1]} + |f'|_{\infty,[0,1]}\big), \tag{103}$$

where the constant C is independent of h.

Proof. We estimate as usual the error by the sum of the approximation error and of the consistency error. Here, we work with the discrete norm $\langle ., .\rangle_h^{1/2}$, so that there is no approximation error. We have

$$\langle U - \tilde{u}, U - \tilde{u}\rangle_h^{1/2} = \sup_{\tilde{v}\in\mathcal{S}, \tilde{v}\neq 0} \frac{\langle U - \tilde{u}, \tilde{v}\rangle_h}{\langle \tilde{v}, \tilde{v}\rangle_h^{1/2}}. \tag{104}$$

For the numerator on the right-hand side of (104),

$$\langle U - \tilde{u}, \tilde{v}\rangle_h = (\delta_x^4 (U - \tilde{u}), \tilde{v})_h = h \sum_{j=1}^{N-1} (\delta_x^4 U_j - f_j)\tilde{v}_j. \tag{105}$$

Therefore, in view of Lemma 3.2,

$$\begin{aligned} |\langle U - \tilde{u}, \tilde{v}\rangle_h| &\le |\delta_x^4 U - f|_h |\tilde{v}|_h \\ &\le Ch^{3/2} |\tilde{v}|_h \big(|f''|_{\infty,[0,1]} + |f'|_{\infty,[0,1]}\big). \end{aligned} \tag{106}$$

Using the fact that $|\tilde{v}|_h \le C\langle \tilde{v}, \tilde{v}\rangle_h^{1/2}$ (see (99), (100)), we find that

$$|\langle U - \tilde{u}, \tilde{v}\rangle_h| \le Ch^{3/2} \langle \tilde{v}, \tilde{v}\rangle_h^{1/2} \big(|f''|_{\infty,[0,1]} + |f'|_{\infty,[0,1]}\big), \tag{107}$$

which gives the result. ∎

4. The Stephenson scheme in two dimensions.

4.1. The compact biharmonic scheme of Stephenson. We consider in this section the biharmonic problem in a square $\Omega =]0,1[^2$:

$$\begin{cases} \Delta^2 u(x,y) = \partial_x^4 u(x,y) + \partial_y^4 u(x,y) + 2\partial_{xy}^2 u(x,y) = f(x,y), \quad (x,y) \in \Omega, \\ u = \frac{\partial u}{\partial n} = 0 \quad \text{on } \partial\Omega. \end{cases} \tag{108}$$

For any $f \in L^2(\Omega)$, problem (108) has a unique solution $u \in H_0^2(\Omega)$. Its discrete version, using the Stephenson scheme, is to find a solution $u_{i,j} \in L_{h,0}^2$ to the equation

$$\begin{cases} \Delta_h^2 u_{i,j} = f(x_i, y_j), \quad 1 \le i,j \le N-1, \\ u_{i,j} = u_{x,i,j} = u_{y,i,j} = 0 \quad \text{for } \{i,j\} \in \{0,N\}. \end{cases} \tag{109}$$

The Stephenson biharmonic operator Δ_h^2 is defined by

$$\Delta_h^2 u_{i,j} = \delta_x^4 u_{i,j} + \delta_y^4 u_{i,j} + 2\delta_x^2 \delta_y^2 u_{i,j}. \tag{110}$$

For any $u \in L_{h,0}^2$, the grid gradient $(u_x, u_y) \in (L_{h,0}^2)^2$ is defined by

$$\begin{cases} P_x u_{x,i,j} = \delta_x u_{i,j}, \quad 1 \le i,j \le N-1, \\ P_y u_{y,i,j} = \delta_y u_{i,j}, \quad 1 \le i,j \le N-1, \end{cases} \tag{111}$$

where P_x, P_y are the Simpson operators (see (31)),

$$\begin{cases} P_x = Id + \dfrac{1}{6} h^2 \delta_x^2, \\ P_y = Id + \dfrac{1}{6} h^2 \delta_y^2. \end{cases} \tag{112}$$

The one-dimensional operators $\delta_x^4 u_{i,j}$, $\delta_y^4 u_{i,j}$ are given as functions of u, u_x, u_y by

$$\delta_x^4 u_{i,j} = \frac{12}{h^2}\big[(\delta_x u_x)_{i,j} - (\delta_x^2 u)_{i,j}\big], \;\; \delta_y^4 u_{i,j} = \frac{12}{h^2}\big[(\delta_y u_y)_{i,j} - (\delta_y^2 u)_{i,j}\big]. \tag{113}$$

For the convenience of the reader, we recall briefly how the operator Δ_h^2 has been originally derived by Stephenson [19]. At each point (x_i, y_j) of the grid, $0 \le i,j \le N$, are attached the three unknowns $u_{i,j}$, $u_{x,i,j}$, $u_{y,i,j}$ as well as a fourth-order polynomial $P_{i,j}$, simply denoted $P(x,y)$,

$$P(x,y) = \sum_{x^l y^m \in \mathcal{V}} a_{l,m} x^l y^m, \tag{114}$$

where the monomial set $\mathcal{V}$ is

$$\mathcal{V} = \{1, x, y, x^2, y^2, xy, x^3, x^2 y, xy^2, y^3, x^4, x^2 y^2, y^4\}, \quad \#\mathcal{V} = 13. \tag{115}$$

The 13 coefficients $a_{l,m}$ are uniquely determined by the following collocation conditions (see Figure 2):

$$\begin{cases} \bullet \text{ 9 collocations for } u_{l,m} \text{ at points } (x_l, y_m) \text{ for } l \in \{i-1, i, i+1\}, \\ \quad m \in \{j-1, j, j+1\}. \\ \bullet \text{ 2 collocations for } u_{x,l,m} \text{ at points } (x_{i-1,j}, y_{i,j}),\ (x_{i+1,j}, y_{i,j}). \\ \bullet \text{ 2 collocations for } u_{y,l,m} \text{ at points } (x_{i,j}, y_{i,j+1}),\ (x_{i,j}, y_{i,j-1}). \end{cases} \tag{116}$$

The collocation system gives a 13×13 linear system which can be solved explicitly. The result is given by [19].

LEMMA 4.1. *Denoting by* $\diamond$, $\square$, *and* $\diamond'$ *the finite difference operators*

$$\begin{cases} \diamond u_{i,j} = u_{i-1,j} + u_{i+1,j} + u_{i,j+1} + u_{i,j-1}, \\ \square u_{i,j} = u_{i+1,j+1} + u_{i+1,j-1} + u_{i-1,j-1} + u_{i-1,j+1}, \\ \diamond' u_{i,j} = u_{x,i+1,j} - u_{x,i-1,j} + u_{y,i,j+1} - u_{y,i,j-1}, \end{cases} \tag{117}$$

the 13 *coefficients* $a_{l,m}$ *of* $P(x,y)$ *at point* (x_i, y_j) *uniquely determined by the* 13 *conditions* (116) *are*

(118)

$$\begin{cases} a_{0,0} = u_{i,j}, \\ a_{1,0} = \dfrac{3}{2}\delta_x u_{i,j} - \dfrac{1}{4}(u_{x,i+1,j} + u_{x,i-1,j}), \quad a_{0,1} = \dfrac{3}{2}\delta_y u_{i,j} - \dfrac{1}{4}(u_{y,i,j+1} + u_{y,i,j-1}), \\ a_{2,0} = \delta_x^2 u_{i,j} - \dfrac{1}{2}(\delta_x u_x)_{i,j}, \quad a_{0,2} = \delta_y^2 u_{i,j} - \dfrac{1}{2}(\delta_y u_y)_{i,j}, \quad a_{1,1} = \delta_{xy} u_{i,j}, \\ a_{3,0} = \dfrac{1}{6}(\delta_x^2 u_x)_{i,j}, \quad a_{0,3} = \dfrac{1}{6}(\delta_y^2 u_y)_{i,j}, \\ a_{2,1} = \dfrac{1}{2}(\delta_x^2 \delta_y u)_{i,j}, \quad a_{1,2} = \dfrac{1}{2}(\delta_y^2 \delta_x u)_{i,j}, \\ a_{4,0} = \dfrac{1}{2h^2}\big[(\delta_x u_x)_{i,j} - \delta_x^2 u_{i,j}\big], \quad a_{0,4} = \dfrac{1}{2h^2}\big[(\delta_y u_y)_{i,j} - \delta_y^2 u_{i,j}\big], \\ a_{2,2} = \dfrac{1}{4}(\delta_x^2 \delta_y^2 u)_{i,j}. \end{cases}$$

The gradient of $P(x,y)$ at (x_i, y_j) is $(\partial_x P(x_i,y_j), \partial_y P(x_i,y_j)) = (a_{1,0}, a_{0,1})$. Defining $u_{x,i,j} = P_x(x_i,y_j)$, $u_{y,i,j} = P_y(x_i,y_j)$, we obtain (111). Furthermore the operators δ_x^4, δ_y^4 are defined by

$$\begin{cases} \delta_x^4 u_{i,j} = \partial_x^4 P(x_i,y_j) = 24 a_{4,0}, \\ \delta_y^4 u_{i,j} = \partial_y^4 P(x_i,y_j) = 24 a_{0,4}, \end{cases} \tag{119}$$

which is (113). Finally the operator $\Delta_h^2 u_{i,j}$ is defined by $\Delta_h^2 u_{i,j} = \Delta^2 P(x_i,y_j) = 24a_{4,0} + 8a_{2,2} + 24a_{0,4}$, which is (110). Furthermore, by expanding the finite difference operators, we find the following expression for the biharmonic operator Δ_h^2:

$$\begin{aligned} \Delta_h^2 u_{i,j} = \frac{1}{h^4}\Big\{ & 56 u_{i,j} - 16\big[u_{i+1,j} + u_{i,j+1} + u_{i-1,j} + u_{i,j-1}\big] \\ & + 2\big[u_{i+1,j+1} + u_{i-1,j+1} + u_{i-1,j-1} + u_{i+1,j-1}\big] \\ & + 6h\big[(u_x)_{i+1,j} - (u_x)_{i-1,j} + (u_y)_{i,j+1} - (u_y)_{i,j-1}\big] \Big\}. \end{aligned}$$

For alternative schemes for (108), see [19, 1].

4.2. Consistency and convergence for the elliptic operator. The order of consistency is deduced from the consistency in the one-dimensional case.

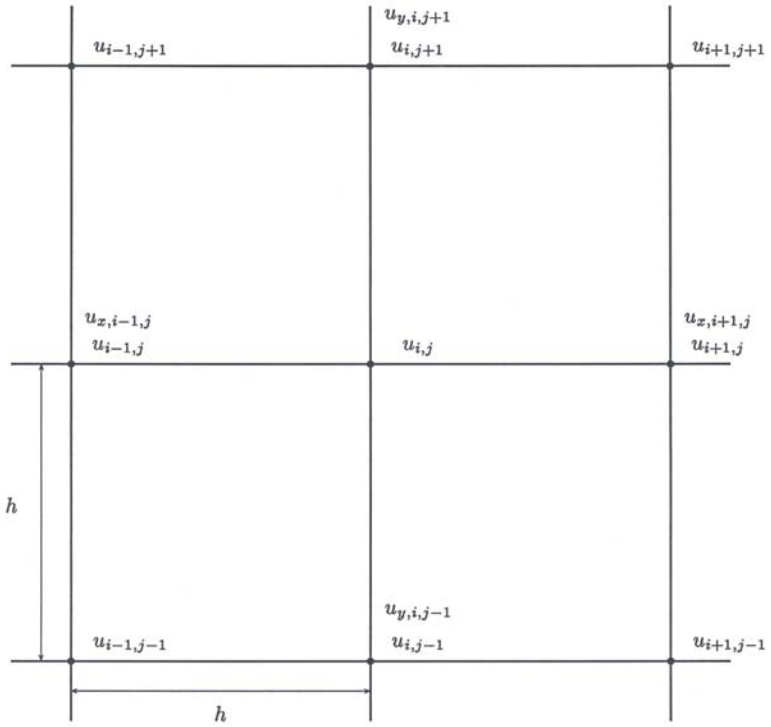

FIG. 2. *Stephenson's scheme for $\Delta^2 u = f$: The finite difference operator $\Delta_h^2 u_{i,j}$ at point (i,j) is $\Delta_h^2 u_{i,j} = \Delta^2 Q(x_i, y_j)$, where $Q(x,y) \in P^{3.5}([x_{i-1}, x_{i+1}] \times [y_{j-1}, y_{j+1}])$ is defined by the 13 collocated values on the picture.*

LEMMA 4.2. *Let u be continuously differentiable up to sixth order in Ω and suppose that it vanishes, along with its gradient on $\partial\Omega$. Then the truncation grid function $e = \Delta_h^2 u(x_i, y_j) - \Delta^2 u(x_i, y_j) \in L_{h,0}^2$ satisfies*

$$|e|_h \le Ch^{3/2} \|u\|_{6,\infty}, \tag{120}$$

where $\|u\|_{6,\infty}$ is

$$|u|_{6,\infty} = \sum_{0 \le \alpha_1 + \alpha_2 \le 6} |\partial_x^{\alpha_1} \partial_y^{\alpha_2} u|_{\infty,[0,1]^2}.$$

Proof. We have

$$|\Delta_h^2 u - \Delta^2 u|_h \le |\delta_x^4 u - \partial_x^4 u|_h + |\delta_y^4 u - \partial_y^4 u|_h + 2|\delta_x^2 \delta_y^2 u - \partial_x^2 \partial_y^2 u|_h. \tag{121}$$

Using the consistency result (54) row by row and column by column we obtain

$$|\delta_x^4 u - \partial_x^4 u|_h \le Ch^{3/2} \big(|\partial_x^6 u|_{\infty,[0,1]^2} + |\partial_x^5 u|_{\infty,[0,1]^2} \big), \tag{122}$$

$$|\delta_y^4 u - \partial_y^4 u|_h \le Ch^{3/2} \big(|\partial_y^6 u|_{\infty,[0,1]^2} + |\partial_y^5 u|_{\infty,[0,1]^2} \big). \tag{123}$$

The consistency for the mixed term is deduced from (45):

$$|\delta_x^2\delta_y^2 u - \partial_x^2\partial_y^2 u|_h \le Ch^2\Big(\sum_{\alpha_1+\alpha_2=6} |\partial_x^{\alpha_1}\partial_y^{\alpha_2} u|_{\infty,[0,1]^2}\Big). \qquad \square \tag{124}$$

In order to carry out convergence analysis, we need to develop discrete analogues of the basic differential estimates, as in the one-dimensional case of section 3. We do this in the framework of a suitable "finite element" space, namely, the Q_c^1 space of continuous functions in Ω satisfying the following condition: In every cell $K_{i+1/2,j+1/2} = [x_i, x_{i+1}] \times [y_j, y_{j+1}]$, they are linear (separately) in x, y. Otherwise stated, it is (in every cell) in $\mathrm{Span}(1, x, y, xy)$. The subspace of interest to us is $Q_{c,0}^1$, consisting of functions (in Q_c^1) vanishing on $\partial\Omega$. It is clear how to match an element $u_h \in Q_{c,0}^1$ to a given $u \in L_{h,0}^2$: we simply take the function $a_0 + a_1 x + a_2 y + a_3 xy$, which interpolates the four values $u_{i,j}$, $u_{i+1,j}$, $u_{i,j+1}$, $u_{i+1,j+1}$. Since $u_h(x, y)$ is linear in x (resp., in y) for every fixed value of y (resp., of x), we can in particular treat the function $u(x_i, y_j)$, for every fixed j, as a function of x_i in $l_{h,0}^2$ and then associate with it the functions u_x in $l_{h,0}^2$ (see (30)) and u_h, p_h, their associated $P_{c,0}^1$ functions.

Note that these functions are determined for each fixed value of y_j. In the same way, we define the piecewise constant in $[x_j, x_{j+1}]$ function $u_{h,x}(., y_j)$. We define also the analogous functions in the y direction. Finally, $u_{h,xy}$ is the piecewise (in cells) constant function given by the coefficient a_3 above. We now equip $Q_{c,0}^1$ with two scalar products. Each of them corresponds to an $L^2(0,1)$ product in one direction (i.e., the function is regarded as an element of $P_{c,0}^1$ in that direction), followed by an $l_{h,0}^2$ product in the other direction. They are given by

$$\begin{cases} (u_h, v_h)^x = h\sum_{j=1}^{N-1} (u_h(., y_j), v_h(., y_j))_{L^2(0,1)}, \\ (u_h, v_h)^y = h\sum_{i=1}^{N-1} (u_h(x_i, .), v_h(x_i, .))_{L^2(0,1)}. \end{cases} \tag{125}$$

The link between the grid scalar product $(u, v)_h$ on $L_{h,0}^2$ and the two scalar products $(u_h, v_h)^x$, $(u_h, v_h)^y$ is given by (see (83))

$$(u, v)_h = (u_h, v_h)^x + \frac{h^2}{6}(u_{h,x}, v_{h,x})^x, \tag{126}$$

$$(u, v)_h = (u_h, v_h)^y + \frac{h^2}{6}(u_{h,y}, v_{h,y})^y. \tag{127}$$

As in the one-dimensional case (see (33)), we introduce here a space $\mathcal{S}$ consisting of triples $(u, u_x, u_y) \in L_{h,0}^2$, where u_x, u_y are related to u by (111). For brevity, we shall sometimes refer to the triple simply by $u \in \mathcal{S}$. As in the one-dimensional case (see Lemma 3.4), we have the following result.

LEMMA 4.3. *Let $u \in \mathcal{S}$. Let $p_h, q_h \in Q_{c,0}^1$ correspond to u_x, u_y, respectively. Then they are the projections of $u_{h,x}$, $u_{h,y}$ in the following sense:*

$$(p_h, v_h)^x = (u_{h,x}, v_h)^x,\ (q_h, v_h)^y = (u_{h,y}, v_h)^y \qquad \forall v_h \in Q_{c,0}^1. \tag{128}$$

Proof. For each $1 \le j_0 \le N-1$, it results from (86) that

$$\begin{aligned}(p_h, v_h)^x &= h \sum_{j=1}^{N-1} (p_h(.,y_j), v_h(.,y_j))_{L^2(0,1)} \\ &= h \sum_{j=1}^{N-1} (u_{h,x}(.,y_j), v_h(.,y_j))_{L^2(0,1)} \\ &= (u_{h,x}, v_h)^x.\end{aligned}$$

Therefore, the function $p_h \in Q^1_{c,0}$ matching $u_x \in L^2_{h,0}$ is the unique solution of

$$(p_h, v_h)^x = (u_{h,x}, v_h)^x \qquad \forall v_h \in Q^1_{c,0}. \tag{129}$$

The proof is the same for $u_{h,y}$. ∎

We summarize in the following proposition the basic properties of the discrete operator Δ_h^2. As in the one-dimensional case, that operator gives rise to a *positive definite* bilinear form.

PROPOSITION 4.1. (i) *Let* $(u, u_x, u_y), (v, v_x, v_y) \in \mathcal{S}$, *and let* (u_h, p_h, q_h), (v_h, r_h, z_h) *be their matches, respectively, in* $Q^1_{c,0}$. *Then the discrete biharmonic operator* Δ_h^2 *defined by*

$$\Delta_h^2 u_{i,j} = \delta_x^4 u_{i,j} + \delta_y^4 u_{i,j} + 2\delta_x^2 \delta_y^2 u_{i,j}, \quad 1 \le i,j \le N-1, \tag{130}$$

induces a scalar product $\langle u, v\rangle_h = (\Delta_h^2 u, v)_h$ *on* $\mathcal{S} \times \mathcal{S}$ *defined by*

$$\begin{aligned}\langle u, v\rangle_h = (\Delta_h^2 u, v)_h = {} & \frac{12}{h^2}(u_{h,x} - p_h, v_{h,x} - r_h)^x + \frac{12}{h^2}(u_{h,y} - q_h, v_{h,y} - z_h)^y \\ & + 2(u_{h,xy}, v_{h,xy}).\end{aligned} \tag{131}$$

In particular, the discrete operator Δ_h^2 *is symmetric positive definite on* $\mathcal{S}$.

(ii) *In terms of the basic finite difference operators, the product* $\langle u, v\rangle_h$ *is given by*

$$\begin{aligned}(\Delta_h^2 u, v)_h = {} & (\delta_x^+ u_x, \delta_x^+ v_x)_h + (\delta_y^+ u_y, \delta_y^+ v_y)_h + 2(\delta_x^+ \delta_y^+ u, \delta_x^+ \delta_y^+ v)_h \\ & + \frac{12}{h^2}\left(\delta_x^+ u - \frac{1}{2}(u_x + u_{x,i+1,j}), \delta_x^+ v - \frac{1}{2}(v_x + v_{x,i+1,j})\right)_h \\ & + \frac{12}{h^2}\left(\delta_y^+ v - \frac{1}{2}(u_y + u_{y,i,j+1}), \delta_y^+ v - \frac{1}{2}(v_y + v_{y,i,j+1})\right)_h.\end{aligned} \tag{132}$$

(iii) *We have the two following coercivity properties of the norm* $\langle u, u\rangle_h = (\Delta_h^2 u, u)_h$*:*

$$\langle u, u\rangle_h \ge C\left[|\delta_x^+ u_x|_h^2 + |\delta_y^+ u_y|_h^2 + |\delta_x^+ u_y|_h^2 + |\delta_y^+ u_x|_h^2\right] \tag{133}$$

and

$$\langle u, u\rangle_h^{1/2} \ge C' |u|_h, \tag{134}$$

where C, C' *are constants independent of* h.

Proof. (i) By (130), we have

$$(\Delta_h^2 u, v)_h = \underbrace{(\delta_x^4 u, v)_h}_{\text{(I)}} + \underbrace{(\delta_y^4 u, v)_h}_{\text{(II)}} + 2\underbrace{(\delta_x^2\delta_y^2 u, v)_h}_{\text{(III)}}. \tag{135}$$

We consider separately each term (I), (II), (III). For the term (I), we have

$$\begin{aligned}(\delta_x^4 u, v)_h &= h\sum_{j=1}^{N}\Big(\delta_x^4 u(\cdot, y_j), v(\cdot, y_j)\Big)_h \\ &= h\sum_{j=1}^{N}\left\{\frac{12}{h^2}(u_{h,x}(\cdot, y_j) - p_h, v_{h,x}(\cdot, y_j) - r_h(\cdot, y_j)\right\} \\ &= \frac{12}{h^2}(u_{h,x} - p_h, v_{h,x} - r_h)^x.\end{aligned}$$

In the same way

$$(\delta_y^4 u, v)_h = \frac{12}{h^2}(u_{h,y} - q_h, v_{h,y} - z_h)^y. \tag{136}$$

For (III), we just note that

$$(\delta_x^2\delta_y^2 u, v)_h = (\delta_x^+\delta_y^+ u, \delta_x^+\delta_y^+ u)_h = (u_{h,xy}, v_{h,xy}). \tag{137}$$

Consider now the positive-definiteness of (131). Suppose that $(\Delta_h^2 u, u) = 0$. Then $p_h(., y_j)$ is constant and continuous and is zero at the end points; therefore $p_h = 0$. The same result holds for q_h and u_h. We conclude that $\langle u, u\rangle_h^{1/2} = (\Delta_h^2 u, u)_h^{1/2}$ is a norm in $\mathcal{S}$.

(ii) Translating (131) in term of finite difference operators, we obtain (132), as in (89).

(iii) It results from (132) that

$$(\Delta_h^2 u, u)_h \geq |\delta_x^+ u_x|_h^2 + |\delta_y^+ u_y|_h^2 + 2|\delta_x^+\delta_y^+ u|_h^2. \tag{138}$$

For the mixed term $\delta_x^+\delta_y^+ u$, we will show next that

$$|\delta_x^+\delta_y^+ u|_h \geq \frac{1}{6}|\delta_x^+ u_y|_h. \tag{139}$$

Indeed

$$\delta_x^+\delta_y^+ u_{i,j} = \frac{\delta_y^+ u_{i+1,j} - \delta_y^+ u_{i,j}}{h}. \tag{140}$$

Using $\delta_y^+ u_{i,j} = \delta_y u_{i,j} + \frac{h}{2}\delta_y^2 u_{i,j}$ and the definition of P_y (see (112)), we deduce

$$\begin{aligned}\delta_x^+\delta_y^+ u_{i,j} &= \frac{\delta_y u_{i+1,j} - \delta_y u_{i,j}}{h} + \frac{1}{2}\big[\delta_y^2 u_{i+1,j} - \delta_y^2 u_{i,j}\big] \\ &= \frac{1}{h}\big[u_{y,i+1,j} - u_{y,i,j}\big] + \frac{h}{6}\big[\delta_y^2 u_{y,i+1,j} - \delta_y^2 u_{y,i,j}\big] + \frac{1}{2}\big[\delta_y^2 u_{i+1,j} - \delta_y^2 u_{i,j}\big] \\ &= \delta_x^+ u_{y,i,j} + \frac{h^2}{6}\delta_y^2\delta_x^+ u_{y,i,j} + \frac{1}{2}h\delta_y^2\delta_x^+ u_{i,j}.\end{aligned}$$

In addition, using the definition of δ_y^2 we have

$$|\delta_y^2 \delta_x^+ u_y| \le \frac{4}{h^2} |\delta_x^+ u_y|_h \tag{141}$$

and

$$|\delta_y^2 \delta_x^+ u|_h \le \frac{2}{h} |\delta_y^+ \delta_x^+ u|_h. \tag{142}$$

Therefore, we have

$$\begin{aligned} |\delta_x^+ \delta_y^+ u|_h &\ge |\delta_x^+ u_y|_h - \frac{h^2}{6} |\delta_y^2 \delta_x^+ u_y|_h - \frac{h}{2} |\delta_y^2 \delta_x^+ u|_h \\ &\ge |\delta_x^+ u_y|_h - \frac{2}{3} |\delta_x^+ u_y|_h - |\delta_x^+ \delta_y^+ u|_h, \end{aligned}$$

which gives finally $2|\delta_x^+ \delta_y^+ u|_h \ge \frac{1}{3} |\delta_x^+ u_y|_h$, or equivalently (139). We proceed in the same way in proving the symmetric estimate

$$|\delta_x^+ \delta_y^+ u|_h \ge \frac{1}{6} |\delta_y^+ u_x|_h. \tag{143}$$

Finally, the last coercivity inequality (134) is obtained starting from

$$|\delta_x^+ u|_h^2 = (|u_{h,x}|^x)^2 \tag{144}$$

and following along the same lines as in the proof of (99) in Lemma 3.5. ∎

We conclude this section with the following error estimate.

PROPOSITION 4.2. *Let U be the $Q_{c,0}^1$ Lagrange interpolation of the exact solution $u(x)$ of* (108) *and $\tilde{u}$ the discrete solution of* (109). *Then there exists a constant C independent of h such that*

$$\langle U - \tilde{u}, U - \tilde{u} \rangle_h^{1/2} \le C h^{3/2} \sum_{\alpha_1 + \alpha_2 \le 6} |\partial_x^{\alpha_1} \partial_y^{\alpha_1} u|_{\infty, [0,1]^2}. \tag{145}$$

Proof. The proof follows along the same lines as the one of Proposition 3.1. We use in particular (134). ∎

5. A Stephenson-based compact scheme for the streamfunction formulation of the Navier–Stokes equations. The pure streamfunction form of the Navier–Stokes equation is

$$\partial_t \Delta \psi = -\nabla^\perp \psi \cdot \nabla(\Delta \psi) + \nu \Delta^2 \psi. \tag{146}$$

The streamfunction was introduced already by Lagrange; see [15, Chap. IV]. For simplicity, we deal only with the "no-slip" boundary condition, namely, the velocity vanishes on the boundary. This implies that we seek the streamfunction $\psi \in H_{h,0}^2$ (see [3] for a full discussion of the functional space for ψ). The notation is as follows. We denote by $\psi_{i,j} \in L_{h,0}^2$ a grid function and by $\psi_{x,i,j}, \psi_{y,i,j} \in L_{h,0}^2$ the Stephenson gradient defined by

$$P_x \psi_x = \delta_x \psi, \qquad P_y \psi_y = \delta_y \psi, \tag{147}$$

where the interpolation operators P_x, P_y are (see (112))

$$P_x\psi_{|i,j} = \frac{1}{6}\psi_{i-1,j} + \frac{2}{3}\psi_{i,j} + \frac{1}{6}\psi_{i+1,j}, \quad P_y\psi_{|i,j} = \frac{1}{6}\psi_{i,j-1} + \frac{2}{3}\psi_{i,j} + \frac{1}{6}\psi_{i,j+1}. \tag{148}$$

The discrete gradient $\nabla_h\psi$ is defined as the pair of the discrete functions (ψ_x, ψ_y) and the discrete velocity is defined as the discrete curl of the streamfunction in the sense

$$\nabla_h^\perp\psi_{i,j} = U_{i,j} = \big[u_{i,j}, v_{i,j}\big] = \big[-\psi_{y,i,j}, \psi_{x,i,j}\big]. \tag{149}$$

The discrete Laplacian is defined by the standard five-points formula

$$\Delta_h\psi_{i,j} = \delta_x^2\psi_{i,j} + \delta_y^2\psi_{i,j}. \tag{150}$$

The discrete Stephenson biharmonic Δ_h^2 introduced in (109) is

$$\Delta_h^2 u_{i,j} = \delta_x^4 u_{i,j} + \delta_y^4 u_{i,j} + 2\delta_x^2\delta_y^2 u_{i,j}, \quad 1 \le i, j \le N-1. \tag{151}$$

Δ_h^2 is a nine point operator acting at every point (i, j) interior to the domain. The semidiscrete scheme associated with (146) consists in finding $\widetilde{\psi}(t) \in L^2_{h,0}$, which satisfies the evolution equation

$$\partial_t\Delta_h\widetilde{\psi} = -\nabla_h^\perp\widetilde{\psi}\cdot(\Delta_h\nabla_h\widetilde{\psi}) + \nu\Delta_h^2\widetilde{\psi}, \tag{152}$$

with initial condition

$$\widetilde{\psi}_{i,j}(0) = (\psi_0)(x_i, y_j). \tag{153}$$

Note that in (152) and in what follows we use pointwise multiplication of functions in $L^2_{h,0}$, i.e., $(u\cdot v)_{i,j} = u_{i,j}v_{i,j}$. We denote by $e(t) = \widetilde{\psi}(t) - \psi(t)$ the difference between the computed and exact solutions. The exact solution verifies

$$\partial_t\Delta_h\psi = -\nabla_h^\perp\psi\cdot\big[\Delta_h\nabla_h(\psi)\big] + \nu\Delta_h^2\psi + F, \tag{154}$$

where F is the truncation error of the scheme depending on the regularity of the exact solution. We call U and $\widetilde{U}$ the discrete velocities associated to ψ, $\widetilde{\psi}$ by

$$U = (-\psi_y, \psi_x), \quad \widetilde{U} = (-\widetilde{\psi}_y, \widetilde{\psi}_x). \tag{155}$$

Recall that in (155), the x and y subscripts stand for the discrete derivatives defined in (147). In particular, ψ_x, ψ_y are not the values of the exact derivatives of ψ. The error $e(t)$ evolves according to

$$\partial_t\Delta_h e - \nu\Delta_h^2 e = -\big[\widetilde{U}\cdot\Delta_h(\widetilde{\psi}_x, \widetilde{\psi}_y) - U\cdot\Delta_h(\psi_x, \psi_y)\big] - F. \tag{156}$$

The right-hand side of (156) is decomposed into four terms:

$$\begin{aligned}\big[(\widetilde{U}\cdot\Delta_h(\widetilde{\psi}_x, \widetilde{\psi}_y) - U\cdot\Delta_h(\psi_x, \psi_y)\big] + F = {}& (\widetilde{U} - U)\cdot\Delta_h\big[(\widetilde{\psi} - \psi)_x, (\widetilde{\psi} - \psi)_y\big] \\ & + (\widetilde{U} - U)\cdot\Delta_h\big[(\psi_x, \psi_y\big] \\ & + U\cdot\Delta_h\big[(\widetilde{\psi} - \psi)_x, (\widetilde{\psi} - \psi)_y\big] + F.\end{aligned}$$

Taking the h scalar product with $e(t)$, we obtain

$$
\begin{aligned}
(\partial_t \Delta_h e_h - \nu \Delta_h^2 e, e)_h = &-\Big((\widetilde{U} - U) \cdot \Delta_h \big[(\widetilde{\psi} - \psi)_x, (\widetilde{\psi} - \psi)_y \big], e \Big)_h \\
&- \big((\widetilde{U} - U) \cdot \Delta_h (\psi_x, \psi_y), e \big)_h \\
&- \Big(U \cdot \Delta_h \big[(\widetilde{\psi} - \psi)_x, \widetilde{\psi} - \psi)_y \big], e \Big)_h \\
&- \big(F, e \big)_h .
\end{aligned} \tag{157}
$$

We denote the four terms of the right-hand side by J_1, J_2, J_3, J_4:

$$
\begin{aligned}
J_1 &= \big((\widetilde{U} - U) \cdot \Delta_h (\widetilde{\psi} - \psi)_x, (\widetilde{\psi} - \psi)_y, e \big)_h , \\
J_2 &= \big((\widetilde{U} - U) \cdot \Delta_h (\psi_x, \psi_y), e \big)_h , \\
J_3 &= \big(U \cdot \Delta_h (\widetilde{\psi} - \psi)_x, (\widetilde{\psi} - \psi)_y, e \big)_h , \\
J_4 &= (F, e)_h .
\end{aligned}
$$

We estimate separately the four terms J_1, J_2, J_3, J_4.

Term J_1. The term J_1 is

$$
J_1 = \big((\widetilde{U} - U) \cdot \Delta_h (e_x, e_y), e \big)_h . \tag{158}
$$

We have

$$
\widetilde{U} - U = \big[- (\widetilde{\psi} - \psi)_y, (\widetilde{\psi} - \psi)_x \big] = (-e_y, e_x), \tag{159}
$$

where the subscripts x and y are the Stephenson derivation operators. Therefore

$$
\begin{aligned}
J_1 &= \big((\widetilde{U} - U) \cdot \Delta_h (e_x, e_y), e \big)_h = \big(- e_y (\delta_x^2 e_x + \delta_y^2 e_x) + e_x (\delta_x^2 e_y + \delta_y^2 e_y), e \big)_h \\
&= \big(- e_y (\delta_x^2 e_x + \delta_y^2 e_x), e \big)_h + \big(e_x (\delta_x^2 e_y + \delta_y^2 e_y), e \big)_h \\
&= - \big(\delta_x^2 e_x, e e_y \big)_h - \big(\delta_y^2 e_x, e e_y \big)_h + \big(\delta_x^2 e_y, e e_x \big)_h + \big(\delta_y^2 e_y, e e_x \big)_h \\
&= \big(\delta_x^+ e_x, \delta_x^+ (e e_y) \big)_h + \big(\delta_y^+ e_x, \delta_y^+ (e e_y) \big)_h \\
&\quad - \big(\delta_x^+ e_y, \delta_x^+ (e e_x) \big)_h - \big(\delta_y^+ e_y, \delta_y^+ (e e_x) \big)_h .
\end{aligned}
$$

In order to formulate a discrete Leibniz rule for $w, z \in L^2_{h,0}$ we use the "shift operators" $(S_x w)_{i,j} = w_{i+1,j}, (S_y z)_{i,j} = z_{i,j+1}$. In terms of these operators we have

$$
\delta_x^+ (wz) = (S_x w)_{i,j} \delta_x^+ z + z \delta_x^+ w, \tag{160}
$$

which is quite easy to verify. Using (160), we expand J_1 in the sum of eight terms:

$$
\begin{aligned}
J_1 = &\big(\delta_x^+ e_x, (S_x e_y)_{i,j} \delta_x^+ e \big)_h + \big(\delta_x^+ e_x, e \delta_x^+ e_y \big)_h \\
&+ \big(\delta_y^+ e_x, (S_y e_y)_{i,j} \delta_y^+ e \big)_h + \big(\delta_y^+ e_x, e \delta_y^+ e_y \big)_h \\
&- \big(\delta_x^+ e_y, (S_x e_x)_{i,j} \delta_x^+ e \big)_h - \big(\delta_x^+ e_y, e \delta_x^+ e_x \big)_h \\
&- \big(\delta_y^+ e_y, (S_y e_x)_{i,j} \delta_y^+ e \big)_h - \big(\delta_y^+ e_y, e \delta_y^+ e_x \big)_h .
\end{aligned}
$$

There is a cancellation of terms 2 and 6 on one hand, and 4 and 8 on the other hand, so that

$$J_1 = \big(\delta_x^+ e_x, (S_x e_y)\delta_x^+ e\big)_h + \big(\delta_y^+ e_x, (S_y e_y)\delta_y^+ e\big)_h \\ + \big(\delta_x^+ e_y, (S_x e_x)\delta_x^+ e\big)_h + \big(\delta_y^+ e_y, (S_y e_x)\delta_y^+ e\big)_h.$$

We now observe that if $\theta \in L^2_{h,0}$, then $|\theta|_{\infty,h} \le \frac{1}{h}|\theta|_h$. We can therefore estimate J_1 as follows:

$$\begin{aligned} |J_1| &= \big|\big((\widetilde{U} - U)\cdot \Delta_h(e_x, e_y), e\big)_h\big| \\ &\le \varepsilon\big[|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_x|_h^2 + |\delta_x^+ e_y|_h^2 + |\delta_y^+ e_y|_h^2\big] + \frac{1}{4\varepsilon}\big[|(e_x, e_y)|_{\infty,h}^2\big(|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big)\big] \\ &\le \varepsilon\big[|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_x|_h^2 + |\delta_x^+ e_y|_h^2 + |\delta_y^+ e_y|_h^2\big] + \frac{C}{\varepsilon h^2}\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big]^2, \end{aligned}$$

where in the last step we have used (51) to estimate $|e_x|_{\infty,h} \le C|\delta_x^+ e|_{\infty,h}$ and $|e_y|_{\infty,h} \le C|\delta_y^+ e|_{\infty,h}$ with a constant independent of h. The factor $\varepsilon > 0$ will be specified later.

Term J_2. The term J_2 is estimated by (C is a generic constant)

$$|J_2| = |\big((\widetilde{U} - U)\cdot \Delta_h(\psi_x, \psi_y), e\big)_h| \le C\big[|\widetilde{U} - U|_h^2 + |e|_h^2\big]. \tag{161}$$

We have used that $\Delta_h(\psi_x, \psi_y)$ is the discrete operator Δ_h composed by the Stephenson gradient applied to the exact solution, and is bounded if the exact solution is sufficiently regular. In addition, using the fact that $\widetilde{U} - U = \big[-(\widetilde{\psi}_y - \psi_y), \widetilde{\psi}_x - \psi_x\big]$, we have

$$|\widetilde{U} - U|_h^2 = |e_x|_h^2 + |e_y|_h^2. \tag{162}$$

Furthermore, we have, in view of (60), (78),

$$|e_x|_h \le C|\delta_x^+ e|_h, \quad |e_y|_h \le C|\delta_y^+ e|_h, \tag{163}$$

and, due to the Poincaré inequality (21), we deduce

$$|J_2| \le C\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big]. \tag{164}$$

Term J_3. We have

$$J_3 = \big[U\cdot \Delta_h(e_x, e_y), e\big]_h = \underbrace{(u\delta_x^2 e_x, e)_h}_{J_{3,1}} + \underbrace{(u\delta_y^2 e_x, e)_h}_{J_{3,2}} \\ + \underbrace{(v\delta_x^2 e_y, e)_h}_{J_{3,3}} + \underbrace{(v\delta_y^2 e_y, e)_h}_{J_{3,4}}.$$

We have

$$J_{3,1} = (u\delta_x^2 e_x, e)_h = (\delta_x^2 e_x, ue)_h = -\big[\delta_x^+ e_x, \delta_x^+(ue)\big]_h. \tag{165}$$

Using (160), the term $J_{3,1}$ is estimated by

$$\begin{aligned} |J_{3,1}| = |\big[\delta_x^+ e_x, \delta_x^+(ue)\big]_h &\le |\delta_x^+ e_x|_h |\delta_x^+(ue)|_h \\ &\le |\delta_x^+ e_x|_h\big[|(S_x u)_{i,j}\delta_x^+ e|_h + |e\delta_x^+ u|_h\big] \\ &\le |\delta_x^+ e_x|_h\big[|u|_{\infty,h}|\delta_x^+ e|_h + |\delta_x^+ u|_{\infty,h}|e|_h\big]. \end{aligned}$$

Therefore, using the Poincaré inequality (21), the term $J_{3,1}$ is estimated by

$$|J_{3,1}| \le \max\big[|u|_{\infty,h}, |\delta_x^+ u|_{\infty,h}\big]\left[\varepsilon|\delta_x^+ e_x|_h^2 + \frac{1}{4\varepsilon}(|\delta_x^+ e|_h + |e|_h)^2\right]$$
$$\le \max(|u|_{\infty,h}, |\delta_x^+ u|_{\infty,h})\left[\varepsilon|\delta_x^+ e_x|_h^2 + \frac{C}{\varepsilon}(|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2)\right].$$

Using the same principle in the y direction, we obtain for the term $J_{3,2}$

(166)
$$|J_{3,2}| = |(u\delta_y^2 e_x, e)_h| \le \max(|u|_{\infty,h}, |\delta_y^+ u|_{\infty,h})\left[\varepsilon|\delta_y^+ e_x|_h^2 + \frac{C}{\varepsilon}(|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2)\right].$$

Therefore, with $m(u) = \max\big[|u|_{\infty,h}, |\delta_x^+ u|_{\infty,h}, |\delta_y^+ u|_{\infty,h}\big]$, the estimate for the term $J_{3,1} + J_{3,2}$ is

(167)
$$|J_{3,1} + J_{3,2}| \le |J_{3,1}| + |J_{3,2}| \le m(u)\left[\varepsilon\big\{|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_x|_h^2\big\} + \frac{C}{\varepsilon}\big\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big\}\right].$$

Treating the term $J_{3,3} + J_{3,4}$ in the same way, we obtain

(168)
$$|J_{3,3} + J_{3,4}| \le |J_{3,3}| + |J_{3,4}| \le m(v)\left[\varepsilon\{|\delta_x^+ e_y|_h^2 + |\delta_y^+ e_y|_h^2\} + \frac{C}{\varepsilon}\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\}\right].$$

The estimate for the term J_3 is finally, with $M(u,v) = \max(m(u), m(v))$,

(169)
$$|J_3| \le M(u,v)\left[\varepsilon\big\{|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_x|_h^2 + |\delta_x^+ e_y|_h^2 + |\delta_y^+ e_y|_h^2\big\} + \frac{2C}{\varepsilon}\big\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big\}\right].$$

Term J_4. The term J_4 is the truncation error and is of order 3/2 (in the $|\cdot|_h$ norm) in view of Lemmas 3.1 and 4.2. For any time $T > 0$, the term J_4 is estimated by

$$|J_4| \le C(T)|e|_h h^{3/2} \le C(T)\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2 + h^3\big], \tag{170}$$

where $C(T)$ is a constant depending only on $T > 0$ and on the regularity of the exact solution $\psi(t)$ on $[0,T]$.

Turning back to (157), we have, on $[0, T_0]$,

$$\left(\frac{\partial}{\partial t}\Delta_h e, e\right)_h - \nu(\Delta_h^2 e, e)_h = -\frac{1}{2}\frac{d}{dt}\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\} - \nu(\Delta_h^2 e, e)_h$$
$$= -J_1 - J_2 - J_3 - J_4,$$

or

$$\frac{1}{2}\frac{d}{dt}\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\} = J_1 + J_2 + J_3 + J_4 - \nu(\Delta_h^2 e, e)_h$$
$$\le |J_1| + |J_2| + |J_3| + |J_4| - \nu(\Delta_h^2 e, e)_h$$
$$\le |J_1| + |J_2| + |J_3| + |J_4|$$
$$- C\nu\big[|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_y|_h^2 + |\delta_x^+ e_y|_h^2 + |\delta_y^+ e_x|_h^2\big],$$

where in the last inequality we have used the coercivity property (133). Collecting the terms of the form $|\delta_x^+ e_x|_h^2 + |\delta_y^+ e_y|_h^2 + |\delta_x^+ e_y|_h^2 + |\delta_y^+ e_x|_h^2$, which appear in the estimates for J_1, J_2, J_3, J_4, and selecting $\varepsilon > 0$ sufficiently small, we find that these terms are absorbed in the right-hand side of the last inequality. We are therefore left with the estimate

$$\frac{d}{dt}\big\{|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big\} \le C\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big]\left[1 + \frac{1}{h^2}(|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2)\right] + C'h^3, \tag{171}$$

where C, C' depend on the exact solution ψ and on the viscosity coefficient ν but not on h.

In order to prove convergence of the approximate solution $\widetilde{\psi}$ to the exact solution ψ using (171), we proceed as follows. We use the fact that at $t = 0$ the error $e = 0$ to prove an estimate for $|\delta_x^+ e|_h + |\delta_y^+ e|_h$ up to any given time $T > 0$.

THEOREM 5.1. *Let $T > 0$. Then there exist constants $C, h_0 > 0$, depending possibly on T, ν, and the exact solution ψ, such that, for all $0 \le t \le T$,*

$$|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2 \le Ch^3, \quad 0 < h \le h_0. \tag{172}$$

Using Corollary 2.1, we obtain a 3/2 convergence rate in the discrete L^2 norm.

Proof. Fix some $K > 0$. Observe that at $t = 0$ we have $e = 0$; hence also $\delta_x^+ e = \delta_y^+ e = 0$ (at $t = 0$). Thus, taking $h > 0$, there exists a time $\tau > 0$ (in general depending on h) such that

$$\sup_{0 \le t \le \tau} \big\{|\delta_x^+ e|_h + |\delta_y^+ e|_h\big\} \le Kh. \tag{173}$$

Inserting (173) in (171) we have for $t \le \tau$

$$\frac{d}{dt}\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big] \le C(1 + K^2)\big[|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2\big] + C'h^3, \quad 0 < h \le h_0; \tag{174}$$

hence by Gronwall's inequality (174) gives

$$|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2 \le C_1 e^{C(1+K^2)t} h^3, \quad t \le \tau, \tag{175}$$

with a suitable constant $C_1 > 0$. Observe that in (175) τ depends on h, and define $\tau_0 = \tau_0(h)$ by

$$\tau_0 = \sup\{t > 0 \text{ such that } |\delta_x^+ e|_h + |\delta_y^+ e|_h \le Kh\}. \tag{176}$$

We have $\tau_0 \ge \tau$ and, as in (175), we obtain

$$|\delta_x^+ e|_h^2 + |\delta_y^+ e|_h^2 \le C_1 e^{C(1+K^2)t} h^3, \quad t \le \tau_0. \tag{177}$$

We can now select h_0 so small that

$$C_1 e^{C(1+K^2)T} h_0 < K^2. \tag{178}$$

Now the definition of τ_0 and (177)–(178) imply that, for any $0 < h \le h_0$, we have $\tau_0(h) \ge T$ and, in particular, for such h, the estimate (175) holds true for all $t \le T$. This concludes the proof of the theorem. ∎

NUMERICAL ANALYSIS OF VANKA-TYPE SOLVERS FOR STEADY STOKES AND NAVIER–STOKES FLOWS*

S. MANSERVISI†

Abstract. We consider Vanka-type smoothers for solving Stokes and Navier–Stokes problems. In each iteration step, this smoother requires the solution of several small local subproblems over finite element blocks. It is shown that for particular choices for the blocks, the algorithm always converges to the solution of the Stokes problem and, under suitable conditions, to the solution of the Navier–Stokes problem. The convergence properties are analyzed and numerical examples are presented.

Key words. Navier–Stokes equations, Vanka solvers, finite elements

1. Introduction.

In recent years, a new multigrid method has been proposed for solving the Navier–Stokes equations based on the iterative solution of several problems over small overlapping domains; for examples, see [12, 13, 14, 24, 25]. This smoothing procedure can be considered a block Gauss–Seidel algorithm whose iteration step consists of solving local problems for each block of unknowns involving pressure and velocity over small subdomains. In this multigrid smoothing step the solution must be computed and updated subdomain by subdomain as in a multiplicative Schwarz-type iterative algorithm. This multigrid technique shows excellent convergence and is naturally suitable for domain decomposition problems and parallel computing [2, 4, 5, 12, 13, 14, 24]. It is not restricted to the Navier–Stokes equations since it can be easily extended to elliptic operators and mixed variational problems if the appropriate local problems for the smoothing procedure are identified. The finite element method introduces a natural decomposition of the problem in subdomains which turns out to be ideal for block subdivisions. For particular blocks of elements some Vanka-type smoothers are well known to be computationally among the best laminar solvers of the stationary Stokes problem [12, 24].

Despite these excellent properties very little is known so far about convergence and smoothing properties of this Gauss–Seidel block iterative method. There is substantial literature on Schwarz alternating methods for the incompressible Navier–Stokes equations for domain decomposition (see, for example, [6, 9, 10, 15, 16, 17, 22, 26] and the references therein), but nothing at all on Vanka-type smoothers. An attempt to investigate this method can be found in [19, 21]. In the first paper a Fourier analysis for a simple model for the Poisson equation in one dimension is presented. In [21] an additive Schwarz-type version of the iterative algorithm for the Stokes problem is presented and transformed into an inexact Uzawa methods under suitable condi-

tions. These conditions cannot in general be satisfied and the additive version of the algorithm does not match the real multiplicative Schwarz-type nature of the iterative method.

The aim of this paper is to prove that, for a particular choice of the block, this method leads to a monotonic convergent algorithm for the steady Stokes problem and that the same algorithm applied to the nonlinear Navier–Stokes equations converges for relative small Reynolds numbers. In this paper we consider conforming finite elements and construct the unknown block directly from the finite element discretization. We investigate the convergence for two Vanka-type smoothers which we call type A and type B blocks. In type A we consider finite element blocks of unknowns whose solution leads to divergence-free approximate solutions, i.e., all the approximates satisfy the global divergence-free constraint. In type B we consider finite element blocks of unknowns whose solution does not satisfy the global divergence-free constraint but only a local one. In type B the global constraint is satisfied only when convergence is reached. We will prove that this local problem for the Stokes system can be obtained as a minimization problem of a suitable functional of the residuals. This leads to a monotonic convergence of the residual norm and the smoothing property for the multigrid algorithm. The same algorithm for the steady Navier–Stokes system cannot converge unconditionally but will be proved to be convergent for small Reynolds numbers. This iterative algorithm has been applied successfully to domain decomposition and optimal flow control problems [2, 3, 18, 4, 5]. We leave the numerical analysis of these problems to future papers.

The paper is organized as follows. In section 2 we introduce the variational problem and the continuous domain decomposition problem. In section 3, we give a precise definition of the discrete finite element problem with Vanka-type smoothers. We prove convergence and some properties. Issues related to the numerical implementation of the fully discrete algorithms and some computational experiments are discussed in section 4.

2. Formulation of the variational problem.

2.1. Notation. We introduce the following standard notation over a bounded, connected, open set Ω with polygonal boundary Γ. We shall use the standard notation for the vector-valued Sobolev spaces $H^s(\Omega)$ with its norm $\|\cdot\|_s$ ($H^0(\Omega) = L^2(\Omega)$ and $\|\cdot\|_0 = \|\cdot\|$). Let $H_0^1(\Omega)$ denote the closure of $C_0^\infty(\Omega)$ under the norm $\|\cdot\|_1$ and let $H^{-1}(\Omega)$ be the dual space of $H_0^1(\Omega)$. Also, we define

$$L_0^2(\Omega) = \left\{ p \in L^2(\Omega) : \int_\Omega p \, d\vec{x} = 0 \right\}.$$

In the remainder of the paper $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $H_0^1(\Omega)$ and $H^{-1}(\Omega)$ and $(\cdot, \cdot)_0$ the usual scalar product in $L^2(\Omega)$. The scalar product in $H_0^1(\Omega)$ is denoted by $(\cdot, \cdot)_1$, which defines the seminorm $|\cdot|_1$ in the same space. Let $\mathbf{V}_0(\Omega)$ be the space of divergence-free vectors that vanish on the boundary. We define $\mathbf{V}_0^\perp(\Omega)$, the orthogonal complement of $\mathbf{V}_0(\Omega)$ in $\mathbf{H}_0(\Omega)$ with respect to the scalar product $(\cdot, \cdot)_1$, by

$$\mathbf{V}_0^\perp(\Omega) = \{ \vec{u} \in \mathbf{H}_0^1(\Omega) : (\vec{u}, \vec{v})_1 = 0 \ \forall \, \vec{v} \in \mathbf{V}_0(\Omega) \},$$

which can also be identified with the following set [11]:

$$\{ \vec{v} \in \mathbf{H}_0^1(\Omega) : \vec{v} = -A^{-1} B^* p; p \in L_0^2(\Omega) \}, \tag{2.1}$$

where A^{-1} is the Green's function which solves the Laplacian problem with homogeneous boundary conditions; see (2.5) for the definition of B. For details concerning these spaces, see [1, 11, 23]. In order to define the weak form of the Stokes and Navier–Stokes equations, we introduce two continuous bilinear forms,

$$a(\vec{u},\vec{v}) = 2\nu \sum_{i,j=1}^{n} \int_\Omega D_{ij}(\vec{u}) D_{ij}(\vec{v})\, d\vec{x} \qquad \forall\, \vec{u},\vec{v} \in H^1(\Omega),$$

$$b(\vec{v},q) = -\int_\Omega q \vec{\nabla}\cdot\vec{v}\, d\vec{x} \qquad \forall q \in L^2_0, \quad \forall\, \vec{v} \in H^1(\Omega),$$

and the trilinear form,

$$c(\vec{w};\vec{u},\vec{v}) = \sum_{i,j=1}^{n} \int_\Omega w_j \left(\frac{\partial u_i}{\partial x_j}\right) v_i\, d\vec{x} \qquad \forall\, \vec{w},\vec{u},\vec{v} \in H^1(\Omega),$$

where $D(\vec{u}) = \frac{1}{2}(\nabla\vec{u} + \nabla\vec{u}^T)$. It is well known that (see, e.g., [11, 18, 23])

$$\begin{aligned} &c(\vec{u};\vec{v},\vec{w}) = -c(\vec{u};\vec{w},\vec{v}) \qquad \forall\, \vec{u} \in V(\Omega), \quad \forall\, \vec{v},\vec{w} \in H^1(\Omega),\\ &c(\vec{u};\vec{v},\vec{v}) = 0 \quad \forall\, \vec{u} \in V(\Omega), \qquad \forall\, \vec{v} \in H^1(\Omega),\\ &|c(\vec{u};\vec{v},\vec{w})| \le C|\vec{u}|_1\,|\vec{v}|_1\,|\vec{w}|_1 \qquad \forall\, \vec{u},\vec{v},\vec{w} \in H^1_0(\Omega), \end{aligned} \tag{2.2}$$

where C is independent of the functions $\vec{u}, \vec{w}$, and $\vec{v}$. For details concerning notation employed and properties of the forms, one may consult, e.g., [11, 23].

We will also make use the following operators:

$$A : H^1(\Omega) \to H^{-1}(\Omega)$$
$$\langle A\vec{u},\vec{v}\rangle = a(\vec{u},\vec{v}) \qquad \forall\, \vec{u} \in H^1(\Omega), \quad \forall\, \vec{v} \in H^1_0(\Omega), \tag{2.3}$$

$$C : H^1(\Omega) \times H^1(\Omega) \to H^{-1}(\Omega)$$
$$\langle C(\vec{w})\vec{u},\vec{v}\rangle = c(\vec{w};\vec{u},\vec{v}) \qquad \forall\, \vec{w},\vec{u} \in H^1(\Omega), \quad \forall\, \vec{v} \in H^1_0(\Omega), \tag{2.4}$$

$$B : H^1(\Omega) \to L^2_0(\Omega)$$
$$\langle B\vec{u}, p\rangle = b(\vec{u},p) \qquad \forall\, p \in L^2_0(\Omega), \quad \forall\, \vec{u} \in H^1(\Omega), \tag{2.5}$$

$$B^* : L^2_0(\Omega) \to H^{-1}(\Omega)$$
$$\langle \vec{u}, B^*p\rangle = b(\vec{u},p) \qquad \forall\, p \in L^2_0(\Omega), \quad \forall\, \vec{u} \in H^1_0(\Omega). \tag{2.6}$$

With this notation we can introduce the Stokes problem from different points of view. In the rest of the paper we assume homogeneous Dirichlet boundary conditions, but a generalization to nonhomogeneous Dirichlet and Neumann boundary conditions can be extended in a straightforward manner.

THEOREM 2.1. *Let Ω be a Lipschitz open bounded domain and $\vec{f} \in \mathbf{H}^{-1}(\Omega)$. These formulations of the Stokes problems are equivalent:*

(a) *Find $(\vec{u},p) \in \mathbf{H}^1_0(\Omega) \times L^2_0(\Omega)$, solution of the system*

$$\begin{cases} \nu a(\vec{u},\vec{v}) + b(\vec{v},p) = \langle \vec{f},\vec{v}\rangle \qquad \forall\, \vec{v} \in \mathbf{H}^1_0(\Omega),\\ b(\vec{u},q) = 0 \qquad \forall\, q \in L^2_0(\Omega). \end{cases} \tag{2.7}$$

(b) *Find $(\vec{u},p) \in \mathbf{H}^1_0(\Omega) \times L^2_0(\Omega)$, which solves the saddle point problem*

$$\min_{\widetilde{u} \in \mathbf{H}^1_0(\Omega)} \Big(\sup_{\widetilde{p} \in L^2_0(\Omega)} L(\widetilde{u},\widetilde{p}) \Big), \tag{2.8}$$

where

$$L(\widetilde{u},\widetilde{p}) = \frac{1}{2}\nu a(\widetilde{u},\widetilde{u}) + b(\widetilde{u},\widetilde{p}) - \langle \vec{f},\widetilde{u}\rangle. \tag{2.9}$$

(c) *Find* $\vec{u} \in \mathbf{V}_0(\Omega)$*, which solves*

$$\nu a(\vec{u},\vec{v}) = \langle \vec{f},\vec{v}\rangle \qquad \forall\, \vec{v} \in \mathbf{V}_0(\Omega). \tag{2.10}$$

(d) *Find* $\vec{u} \in \mathbf{V}_0(\Omega)$*, which minimizes the functional*

$$L(\widetilde{u}) = \frac{1}{2}\nu a(\widetilde{u},\widetilde{u}) - \langle \vec{f},\widetilde{u}\rangle \tag{2.11}$$

for all $\widetilde{u} \in \mathbf{V}_0^1(\Omega)$.

(e) *Find* $\vec{u}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega)$*, which solves*

$$\nu a(\vec{u}^{\perp},\vec{v}^{\perp}) + \langle \vec{f},\vec{v}^{\perp}\rangle = 0 \qquad \forall\, \vec{v}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega). \tag{2.12}$$

(f) *Find* $\vec{u}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega)$*, which minimizes the functional*

$$L(\widetilde{u}^{\perp}) = \frac{1}{2}\nu a(\widetilde{u}^{\perp},\widetilde{u}^{\perp}) + \langle \vec{f},\widetilde{u}^{\perp}\rangle \tag{2.13}$$

for all $\widetilde{u}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega)$.

Proof. The proof can be found in [11]. □

The formulations in (2.12) and (2.13) take into account the decomposition $\mathbf{V}_0(\Omega)+\mathbf{V}^{\perp}(\Omega)$ of the space $\mathbf{H}_0^1(\Omega)$. We also remark that the formulation in (2.12) is the Schur complement formulation when the equation is written in pressure terms. The equations in (2.12) and (2.10) can be solved separately and yield the uncoupled form of the Stokes problem. However, this uncoupled form is not very useful from the numerical point of view since the construction of test functions in $\mathbf{V}_0^{\perp}(\Omega)$ involves the construction of a scalar function as in the original formulation.

Now we can introduce the Navier–Stokes problem. Let $\vec{f} \in H^{-1}(\Omega)$ denote the steady distributed force and $\vec{u} \in H_0^1(\Omega)$ and $p \in L_0^2(\Omega)$ the state variables, i.e., the velocity and pressure fields, respectively. The state variables are constrained to satisfy the weak form of the following Navier–Stokes equations:

$$\begin{cases} a(\vec{u},\vec{v}) + c(\vec{u};\vec{u},\vec{v}) + b(\vec{u},p) = \langle \vec{f},\vec{v}\rangle \qquad \forall\, \vec{v} \in H_0^1(\Omega), \\ b(\vec{u},p) = 0 \qquad \forall\, q \in L_0^2(\Omega), \end{cases} \tag{2.14}$$

with Dirichlet boundary conditions $\vec{u} = 0$ over Γ.

Existence and uniqueness results for solutions of the system (2.14) are contained in the following theorem; see, e.g., [23].

THEOREM 2.2. *Let* Ω *be an open, bounded set with polygonal boundary* Γ*. Let* $\vec{f} \in \mathbf{H}^{-1}(\Omega)$*. Then*

(i) *there exists at least one solution* $(\vec{u},p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ *of* (2.14)*;*

(ii) *the set of velocity fields that are solutions of* (2.14) *is closed in* $\mathbf{H}_0^1(\Omega)$ *and is compact in* $\mathbf{L}_0^2(\Omega)$*;*

(iii) *if* $\nu > \nu_0(\Omega,\vec{f})$ *for some positive* ν_0 *whose value is determined by the given data, then the set of solutions of* (2.14) *consists of a single element.*

Note that solutions of (2.14) exist for any value of the Reynolds number. However, (iii) implies that uniqueness can be guaranteed only for "large enough" values of ν or for "small enough" data $\vec{f}$.

2.2. Vanka-type smoothers and domain decomposition. Let Ω be an open, bounded, and simply connected domain with polygonal boundary such that $\Omega = \cup_i^m \Omega^i$, where the subdomains Ω^i have smooth boundary Γ^i and are overlapping in the sense that $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2) + \cdots + \mathbf{H}_0^1(\Omega^m)$. The idea behind the Vanka-type smoother is that it is possible to solve the problem over the domain Ω simply by updating and solving a sequence of local problems over all the overlapping subdomains. In the discrete case the subdomain is taken as a small block of finite elements, but at the continuous level this method can be seen as a domain decomposition method over a countable number of overlapping smooth subdomains. We will show that in both the discrete and the continuous cases convergence can be proved. In the rest of the paper we use "hat" notation to denote functions defined over the whole domain Ω and standard notation for local variables defined over the subregions Ω^i.

For example, we can define the local problem i over the domain Ω^i in the following way. Given the velocity field $\widehat{u}^{\,i-1} \in \mathbf{V}_0(\Omega)$ at step $i-1$, we define the local problems for the state $(\vec{u}^{\,i}, p^{\,i}) \in \mathbf{H}_0^1(\Omega^i) \times L_0^2(\Omega^i)$ over the subregion Ω^i by

$$\begin{cases} \nu a(\vec{u}^{\,i}, \vec{v}^{\,i}) + c(\vec{u}^{\,i}, \vec{u}^{\,i}, \vec{v}^{\,i}) + b(p^{\,i}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in H_0^1(\Omega^i), \\ b(r^i, \vec{v}^{\,i}) = 0 \qquad \forall r^i \in L_0^2(\Omega^i), \end{cases} \tag{2.15}$$

with boundary condition $\vec{u}^{\,i} = \widehat{u}^{\,i-1}$ over Γ^i. At each iteration the global solution $(\widehat{u}^{\,i}, \widehat{p}^{\,i})$ is determined by the local solution as $\widehat{u}^{\,i} = \vec{u}^{\,i}$, $\widehat{p}^{\,i} = p^{\,i}$ over Ω^i and $\widehat{u}^{\,i} = \widehat{u}^{\,i-1}$, $\widehat{p}^{\,i} = \widehat{p}^{\,i-1}$ over $\Omega - \Omega^i$. We remark that the local pressure $p^{\,i}$ is the solution of the system (2.15) and a constant must be determined such that the global solution $\widehat{p}^{\,i}$ is in $L_0^2(\Omega)$.

The problem over this subdomain Ω^i can be rewritten in a more appropriate way. As in the standard Schwarz alternating method we can define $\vec{w}^{\,i}$ by $\vec{u}^{\,i} - \widehat{u}^{\,i-1}$ over Ω^i and zero over $\Omega - \Omega^i$ and solve the residual equation instead of the original problem (2.15). The function $\vec{w}^{\,i}$ is in $\mathbf{V}_0(\Omega^i)$ and the residual equation takes the form

$$\begin{cases} \nu a(\vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{v}^{\,i}) + c(\vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i), \\ b(r^i, \vec{w}^{\,i}) = 0 \qquad \forall r^i \in L_0^2(\Omega^i), \end{cases}$$

with boundary condition $\vec{w}^{\,i} = 0$ over Γ^i. Now the solution of the Navier–Stokes equations over different domains is in the standard space $\mathbf{H}_0^1(\Omega^i)$ and the old velocity field $\widehat{u}^{\,i-1}$ over Ω^i can be seen as the projection from the space $\mathbf{V}_0(\Omega)$ to the space $\mathbf{V}_0(\Omega^i)$ with respect to the scalar product $(\cdot,\cdot)_1$. It is clear that the convergence of the Vanka-type smoother is related to the properties of these projection operators, and the starting point is to investigate the decomposition of the global solution into the sum of many local solutions. We start to state a space decomposition theorem which was partially shown in [15, 16, 17].

THEOREM 2.3. *Let* $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2) + \mathbf{H}_0^1(\Omega^3) \cdots \mathbf{H}_0^1(\Omega^m)$ *and* $\mathbf{H}_0^1(\Omega^i) = \mathbf{V}_0^{\perp}(\Omega^i) + \mathbf{V}_0(\Omega^i)$ *for all* $i = 1, \ldots, m$, *where* $\mathbf{V}_0(\Omega^i)$ *and* $\mathbf{V}_0^{\perp}(\Omega^i)$ *are the divergence-free function space and its orthogonal complement in* $\mathbf{H}_0^1(\Omega^i)$ *with respect to the inner product* $(\cdot,\cdot)_1$ *over* Ω^i. *Then we have*

(a) $\mathbf{V}_0(\Omega) = \mathbf{V}_0(\Omega^1) + \mathbf{V}_0(\Omega^2) + \mathbf{V}_0(\Omega^3) \cdots \mathbf{V}_0(\Omega^m)$;

(b) $\mathbf{V}_0^{\perp}(\Omega) = \mathbf{V}_0^{\perp}(\Omega^1) + \mathbf{V}_0^{\perp}(\Omega^2) + \mathbf{V}_0^{\perp}(\Omega^3) \cdots \mathbf{V}_0^{\perp}(\Omega^m)$.

Proof. (a) In [15] it is proved that if $\Omega = \Omega^1 \cup \Omega^2$ and $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2)$, then $\mathbf{V}_0(\Omega) = \mathbf{V}_0(\Omega^1) + \mathbf{V}_0(\Omega^2)$. In the case of m domains we can write

$\Omega^* = \Omega^1 \cup \Omega^2 \cup \Omega^3 \cup \cdots \cup \Omega^{m-1}$ and prove the assertion by induction. By induction hypothesis $\mathbf{H}_0^1(\Omega^*) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2) + \mathbf{H}_0^1(\Omega^3) \cdots \mathbf{H}_0^1(\Omega^{m-1})$ and $\mathbf{V}_0(\Omega^*) = \mathbf{V}_0(\Omega^1) + \mathbf{V}_0(\Omega^2) + \mathbf{V}_0(\Omega^3) \cdots \mathbf{V}_0(\Omega^{m-1})$. Combining this and the result in [15] we have $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^*) + \mathbf{H}_0^1(\Omega^m)$ and $\mathbf{V}_0(\Omega) = \mathbf{V}_0(\Omega^*) + \mathbf{V}_0(\Omega^m)$.

(b) First consider the case for $m = 2$. Let $\vec{u}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega_h)$. Since the domains are overlapping in the space $\mathbf{H}_0^1(\Omega)$ we can write $\vec{u}^{\perp} = \vec{u}_1 + \vec{u}_2$ with $\vec{u}_i \in \mathbf{H}_0^1(\Omega^i)$, $i = 1, 2$. The vector $\vec{u}_1$ can be decomposed in $\mathbf{H}_0^1(\Omega^1)$ as $\vec{u}_1 = \vec{u}_1^{\perp} + \vec{u}_1^{o}$ with $\vec{u}_1^{\perp} \in \mathbf{V}_0^{\perp}(\Omega^1)$ and $\vec{u}_1^{o} \in \mathbf{V}_0(\Omega^1)$.

Consider the zero extension $\vec{w}_1^{\perp}$ and $\vec{w}_1^{o}$ to Ω of $\vec{u}_1^{\perp}$ and $\vec{u}_1^{o}$. The vectors $\vec{w}_1^{\perp}$ and $\vec{w}_1^{o}$ are in $\mathbf{V}_0^{\perp}(\Omega)$ and $\mathbf{V}_0(\Omega)$, respectively. The extension $\vec{w}_1$ of $\vec{u}_1$ to Ω can be written as $\vec{w}_1 = \vec{w}_1^{\perp} + \vec{w}_1^{o}$.

In a similar way we can decompose $\vec{u}_2 = \vec{u}_2^{\perp} + \vec{u}_2^{o}$ with $\vec{u}_2^{\perp} \in \mathbf{V}_0^{\perp}(\Omega^2)$ and $\vec{u}_1^{o} \in \mathbf{V}_0(\Omega^1)$. The extension $\vec{w}_2$ of $\vec{u}_2$ to Ω can be written as $\vec{w}_2 = \vec{w}_2^{\perp} + \vec{w}_2^{o}$, where $\vec{w}_2^{\perp}$ and $\vec{w}_2^{o}$ are the corresponding extensions. From the hypothesis we have that $\vec{u}^{\perp} = \vec{u}_1 + \vec{u}_2$ and therefore $\vec{u}_2 = \vec{u}^{\perp} - \vec{u}_1$ and $\vec{w}_2 = \vec{u}^{\perp} - \vec{w}_1$. The unique decomposition of $\vec{w}_2$ over the subspaces $\mathbf{V}_0^{\perp}(\Omega)$ and $\mathbf{V}_0(\Omega)$ implies that $\vec{u}_2^{o} = -\vec{u}_1^{o}$ and that $\vec{u}_1^{o} = \vec{w}_1^{o}$ is zero over $\Omega - (\Omega^1 \cap \Omega^2)$. Therefore $\vec{u}_1^{\perp} = \vec{u}_1 - \vec{u}_1^{o} \in \mathbf{V}_0^{h\perp}(\Omega^1)$ and $\vec{u}_2^{\perp} = \vec{u}^{\perp} - \vec{u}_1 + \vec{u}_1^{o} \in \mathbf{V}_0^{\perp}(\Omega^2)$ give the desired decomposition $\vec{u}^{\perp} = \vec{u}_1^{\perp} + \vec{u}_2^{\perp}$. For any m the theorem can be proved by induction using the case $m = 2$ and standard techniques [15, 16, 11]. In the case of m domains we can write $\Omega^* = \Omega^1 \cup \Omega^2 \cup \Omega^3 \cup \cdots \cup \Omega^{m-1}$ and prove the assertion by induction. By induction hypothesis $\mathbf{H}_0^1(\Omega^*) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2) + \mathbf{H}_0^1(\Omega^3) \cdots \mathbf{H}_0^1(\Omega^{m-1})$ and $\mathbf{V}_0^{\perp}(\Omega^*) = \mathbf{V}_0^{\perp}(\Omega^1) + \mathbf{V}_0^{\perp}(\Omega^2) + \mathbf{V}_0^{\perp}(\Omega^3) \cdots \mathbf{V}_0^{\perp}(\Omega^{m-1})$. Combining this and the above results for $m = 2$ we have $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^*) + \mathbf{H}_0^1(\Omega^m)$ and $\mathbf{V}_0^{\perp}(\Omega) = \mathbf{V}_0^{\perp}(\Omega^*) + \mathbf{V}_0^{\perp}(\Omega^m)$. □

Let T_i, P_i, and Π_i denote the orthogonal projections from $\mathbf{H}_0^1(\Omega), \mathbf{V}_0(\Omega), \mathbf{V}_0^{\perp}(\Omega)$ onto $\mathbf{H}_0^1(\Omega^i), \mathbf{V}_0^i(\Omega^i)$, and $\mathbf{V}_0^{\perp i}(\Omega^i)$ with respect to the inner product $(\cdot, \cdot)_1$ defined by the operator $a(\vec{u}, \vec{v})$ for all $\vec{u}$ and $\vec{v}$ in $\mathbf{H}_0^1(\Omega)$. The projections $T_i\,\widehat{u}, P_i\,\widehat{u}, \Pi_i\,\widehat{u}$ of $\widehat{u}$ from $\mathbf{H}_0^1(\Omega), \mathbf{V}_0(\Omega), \mathbf{V}_0^{\perp}(\Omega)$ onto $\mathbf{H}_0^1(\Omega^i), \mathbf{V}_0(\Omega^i), \mathbf{V}_0^{\perp}(\Omega^i)$ are defined by the solutions of the equations

$$
\begin{aligned}
&a(T_i\widehat{u}, \vec{v}^{\,i}) = a(\widehat{u}, \vec{v}^{\,i}) \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i),\\
&a(P_i\widehat{u}, \vec{v}^{\,i}) = a(\widehat{u}, \vec{v}^{\,i}) \qquad \forall \vec{v}^{\,i} \in \mathbf{V}_0(\Omega^i),\\
&a(\Pi_i\widehat{u}, \vec{v}^{\,\perp i}) = a(\widehat{u}, \vec{v}^{\,\perp i}) \qquad \forall \vec{v}^{\,\perp i} \in \mathbf{V}_0^{\perp i}(\Omega^i),
\end{aligned}
$$

respectively. We note that $\Pi_i\widehat{u}$ is in general different from $\widehat{u}$ due to the homogeneous boundary conditions on the boundary Γ^i. The orthogonal projections T_i, P_i, and Π_i have the following properties [15, 6].

THEOREM 2.4. *Let Ω be a bounded simply connected domain with smooth boundary and let Ω^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains with smooth boundary such that $\Omega = \Omega^1 \cup \Omega^2 \cdots \Omega^m$. Let T_i (P_i or Π_i) be the orthogonal projection from $\mathbf{H}_0^1(\Omega)$ ($\mathbf{V}_0(\Omega)$ or $\mathbf{V}_0^{\perp}(\Omega)$) onto $\mathbf{H}_0^1(\Omega^i)$ ($\mathbf{V}_0(\Omega^i)$ or $\mathbf{V}_0^{\perp}(\Omega^i)$) for $i = 1, 2, \ldots, m$. Then*

(a) $|I - T_i|_1 \le 1$ ($|I - P_i|_1 \le 1$ *or* $|I - \Pi_i|_1 \le 1$) *for* $i = 1, 2, \ldots, m$;

(b) $|\Pi_{i=1}^m (I - T_i)|_1 < 1$ ($|\Pi_{i=1}^m (I - P_i)|_1 < 1$ *or* $|\Pi_{i=1}^m (I - \Pi_i)|_1 < 1$).

Proof. We use a standard minimization approach. Let $\mathbf{V}(\Omega)$ be a subspace of $\mathbf{H}_0^1(\Omega)$ such that $\mathbf{V}(\Omega) = \mathbf{V}(\Omega^1) + \mathbf{V}(\Omega^2) + \cdots + \mathbf{V}(\Omega^m)$ with $\mathbf{V}(\Omega^i) \subseteq \mathbf{H}_0^1(\Omega^i)$ for $i = 1, 2, \ldots, m$. Here $\mathbf{V}(\mathbf{\Omega})$ could be $\mathbf{H}_0^1(\Omega)$, $\mathbf{V}_0(\Omega)$, or $\mathbf{V}_0^{\perp}(\Omega)$. Consider the Laplace operator $A : H_0^1(\Omega) \to H^{-1}(\Omega)$ defined by

$$
\langle A\vec{u}, \vec{v} \rangle = (\vec{u}, \vec{v})_1 \qquad \forall\, \vec{u} \in H_0^1(\Omega), \quad \forall\, \vec{v} \in H_0^1(\Omega)
$$

and the following equation for $\vec{u} \in \mathbf{V}(\Omega)$ with homogeneous Dirichlet boundary condition:

$$\langle A\vec{u}, \vec{v}\rangle = \langle \vec{f}, \vec{v}\rangle \qquad \forall \vec{v} \in \mathbf{V}(\Omega). \tag{2.16}$$

We note that the operator A is elliptic, and therefore the natural approach is the minimization of the associated functional

$$L = \left(\frac{1}{2}(A\widetilde{u}, \widetilde{u}) - \langle \vec{f}, \widetilde{u}\rangle + \frac{1}{2}\langle A^{-1}\vec{f}, \vec{f}\rangle\right) \tag{2.17}$$

over the sequence of spaces $\mathbf{V}(\Omega^i)$ for $i = 1, 2, \ldots, m$. The constant $\frac{1}{2}\langle A^{-1}\vec{f}, \vec{f}\rangle$ is used to vanish the functional at the critical point, and the operator A^{-1} from $\mathbf{H}^{-1}(\Omega)$ to $\mathbf{H}_0^1(\Omega)$ denotes the Green's operator of the homogeneous problem with the operator A. We remark that (2.17) can also be written as

$$L = \left(\frac{1}{2}(A\,\widetilde{u}, \widetilde{u}) - \langle A\,\vec{u}, \widetilde{u}\rangle + \frac{1}{2}\langle A\vec{u}, \vec{u}\rangle\right) = \frac{1}{2}(A\,\widetilde{u} - \vec{u}, \widetilde{u} - \vec{u}),$$

where $\vec{u}$ is the unique critical point which solves (2.16). Let $\widehat{u}^{\,i-1}$ be the solution at step $i-1$ over Ω and let R_i be the projector from $\mathbf{V}(\Omega)$ to $\mathbf{V}(\Omega^i)$. The operator $\Pi_{i=1}^m(I - R_i)$ is defined from the solution sequence of the minimization problem over $\mathbf{V}(\Omega^i)$ for $i = 1, 2, \ldots, m$. In fact the minimization over Ω^i gives

$$(A\vec{u}^{\,i}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i}\rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{V}(\Omega^i). \tag{2.18}$$

If we set $\vec{w}^{\,i} = \vec{u}^{\,i} - \widehat{u}^{\,i-1} \in \mathbf{V}(\Omega^i)$, then (2.18) gives

$$(A\vec{w}^{\,i}, \vec{v}^{\,i}) + (A\widehat{u}^{\,i-1}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i}\rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{V}(\Omega^i). \tag{2.19}$$

Let $\vec{u}$ be the solution of (2.16) and let $\vec{e}^{\,i} = \vec{u}^{\,i} - \vec{u}$ over Ω^i and $\widehat{e}^{\,i-1} = \widehat{u}^{\,i-1} - \vec{u}$ over Ω. We have $\vec{w}^{\,i} = \vec{e}^{\,i} - \widehat{e}^{\,i-1}$ and $\vec{w}^{\,i}$ and $\vec{e}^{\,i}$ can be seen as a local error over Ω^i or as a global error over Ω if the corresponding extensions are considered. We use "hat" notation for functions defined over the domain Ω or the corresponding extensions. We remark that $\widehat{w}^{\,i}$ is the zero extension to Ω of $\vec{w}^{\,i}$. With this notation the above equation becomes

$$(A\vec{w}^{\,i}, \vec{v}^{\,i}) + (A\widehat{e}^{\,i-1}, \vec{v}^{\,i}) = 0 \qquad \forall \vec{v}^{\,i} \in \mathbf{V}(\Omega^i),$$

which is solved by

$$\vec{u}^{\,i} = (I - R_i)\,\widehat{u}^{\,i-1} + A^{-1}\vec{f} \quad \text{or} \quad \widehat{e}^{\,i} = (I - R_i)\,\widehat{e}^{\,i-1}. \tag{2.20}$$

Since this estimate is true for all $i = 1, 2, \ldots, m$ we can combine them in the following solution:

$$\widehat{e}^{\,m} = \Pi_{i=1}^m(I - R_i)\,\widehat{e}^{\,0}, \tag{2.21}$$

which gives the global error over Ω needed to estimate the functional L^i and the operator norm over the domain Ω.

Now we show that the functional L^i, which is the norm of the error $\widehat{e}^{\,i}$, is monotonically decreasing for increasing i for all initial guesses $\widehat{e}^{\,0} \in \mathbf{V}(\Omega^i)$. In fact

$$\begin{aligned} L^i &= \frac{1}{2}(A\widehat{u}^{\,i}, \widehat{u}^{\,i}) - \langle \vec{f}, \widehat{u}^{\,i}\rangle + \frac{1}{2}\langle A^{-1}\vec{f}, \vec{f}\rangle \\ &= \frac{1}{2}(A(\vec{w}^{\,i} + \widehat{u}^{\,i-1}), \vec{w}^{\,i} + \widehat{u}^{\,i-1}) - \langle \vec{f}, \vec{w}^{\,i} + \widehat{u}^{\,i-1}\rangle + \frac{1}{2}\langle A^{-1}\vec{f}, \vec{f}\rangle \\ &= L^{i-1} + \frac{1}{2}(A\vec{w}^{\,i}, \vec{w}^{\,i}) + (A\widehat{u}^{\,i-1}, \vec{w}^{\,i}) - \langle \vec{f}, \vec{w}^{\,i}\rangle, \end{aligned}$$

and by using the optimality condition (2.19) we have

$$L^i = L^{i-1} - \frac{1}{2}(A\vec{w}^{\,i}, \vec{w}^{\,i}), \tag{2.22}$$

which implies $L^i \le L^{i-1}$ or $L^i < L^{i-1}$ if we assume $\vec{w} \neq 0$. Now

$$L^i = \frac{1}{2}(\widehat{u}^{\,i} - A^{-1}\vec{f}, \widehat{u}^{\,i} - A^{-1}\vec{f}) = \frac{1}{2}(\widehat{e}^{\,i}, \widehat{e}^{\,i})_1 < L^{i-1} = \frac{1}{2}(\widehat{e}^{\,i-1}, \widehat{e}^{\,i-1})_1,$$

and therefore

$$|\widehat{e}^{\,i}|_1^2 = (\widehat{e}^{\,i}, \widehat{e}^{\,i})_1 \le (\widehat{e}^{\,i-1}, \widehat{e}^{\,i-1})_1 = |\widehat{e}^{\,i-1}|_1^2. \tag{2.23}$$

Since $|\widehat{e}^{\,i}|_1^2 \le |\widehat{e}^{\,i-1}|_1^2$ for all initial vectors $\widehat{e}^{\,i-1} \in \mathbf{V}(\Omega)$ this implies that $|(I - R_i)|_1 \le 1$ for all $i = 1, \ldots, m$, which proves (a).

(b) We use the same notation as in (a). By starting with an initial guess $\widehat{u}^{\,0} \in \mathbf{V}(\Omega)$ after a smoothing step over m domains, from (2.22), we have

$$L^m = L^0 - \frac{1}{2}\sum_{i=1}^{m} |\widehat{w}^{\,i}|_1^2,$$

with $\widehat{w}^{\,i} = -R_i\widehat{e}^{\,i-1}$, $L^m = |\widehat{e}^{\,m}|_1^2/2$, and $L^0 = |\widehat{e}^{\,0}|_1^2/2$. Also we have $\widehat{e}^{\,m} = \Pi_{i=1}^m (I - R_i)\,\widehat{e}^{\,0}$ for all $\widehat{e}^{\,0} \in \mathbf{V}(\Omega)$. From the definition of norm we have

$$|\Pi_{i=1}^m (I - R_i)|_1 = \sup |\widehat{e}^{\,m}|_1 = \sqrt{1 - \inf \sum_{i=1}^{m} |\widehat{w}^{\,i}|_1^2}, \tag{2.24}$$

where the sup and inf are taken over the set of functions $\widehat{e}^{\,0} \in \mathbf{V}(\Omega)$ with $|\widehat{e}^{\,0}|_1 = 1$. The infimum is the minimizer of the minimization problem

$$\min \sum_{i=1}^{m} |\widehat{w}^{\,i}|_1^2,$$

where the minimum is taken over all the functions $\widehat{e}^{\,0}$ in $\mathbf{V}(\Omega)$ with $|\widehat{e}^{\,0}|_1 = 1$. We remark that $\sum_{i=1}^m |\widehat{w}^{\,i}|_1^2 = |\widehat{e}^{\,m} - \widehat{e}^{\,0}|_1^2$. Standard theory can be applied to prove existence, well-posedness, and uniqueness of the solution of the problem over the set $\mathbf{V}(\Omega)$. Now by contradiction we prove that the minimum cannot be zero and the corresponding norm $|\Pi_{i=1}^m (I - R_i)|_1 < 1$. Suppose that the minimum is zero; then this implies, from the definition of the norm itself, that there exists an $\widehat{e}^{\,0}$ in $\mathbf{V}(\Omega)$ such that $\widehat{e}^{\,m} = \widehat{e}^{\,0}$, and therefore $\widehat{w}^{\,i} = -R_i\widehat{e}^{\,0} = 0$ for all $i = 1, 2, \ldots, m$. Such a function $\widehat{e}^{\,0}$ has norm 1 but zero projections over all $\mathbf{V}(\Omega^i)$, $i = 1, 2, \ldots, m$, and this contradicts the fact that $\mathbf{V}(\Omega) = \mathbf{V}(\Omega^1) + \mathbf{V}(\Omega^2) + \cdots + \mathbf{V}(\Omega^m)$; i.e., the domains are overlapping in the space $\mathbf{V}(\Omega)$. Therefore the functional must be different from zero and must assume a well-defined positive value at the critical point. Combining this result with (3.15), we obtain the inequality $|\Pi_{i=1}^m (I - R_i)|_1 < 1$. ∎

2.3. Domain decomposition of type A. The projections introduced above can be used to solve the Stokes and the Navier–Stokes equations with different types of domain decompositions. There are several different possible domain decompositions, but we are interested only in the discussion of domain decompositions whose discretization leads to the Vanka-type smoothers with elements of our interest.

Consider the following domain decomposition algorithm, which we can call type A domain decomposition since all the approximates satisfy globally the divergence-free constraint. Let Ω be an open, bounded, and simply connected domain with polygonal boundary. Let $\Omega = \cup_i^m \Omega^i$, where the subdomains Ω^i have smooth boundary Γ^i and are overlapping in the sense that $\mathbf{H}_0^1(\Omega) = \mathbf{H}_0^1(\Omega^1) + \mathbf{H}_0^1(\Omega^2) + \cdots + \mathbf{H}_0^1(\Omega^m)$. Given the velocity field $\widehat{u}^{\,i-1} \in \mathbf{V}_0(\Omega)$ at step $i-1$ we define the local problem over the domain Ω^i for the unknown $\vec{w}^{\,i} = \vec{u}^{\,i} - \widehat{u}^{\,i-1} \in \mathbf{V}_0(\Omega^i)$ by

$$a(\vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{v}^{\,i}) + c(\vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{w}^{\,i} + \widehat{u}^{\,i-1}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{V}_0(\Omega^i),$$

with boundary condition $\vec{w}^{\,i} = 0$. We remark that $\vec{w}^{\,i}$ is solved over Ω^i and can be extended to Ω such that $\widehat{u}^{\,i} = \widehat{w}^{\,i} + \widehat{u}^{\,i-1}$ is defined over the whole domain Ω. Also we note that the vector solution $\vec{w}^{\,i}$ is in the standard space $\mathbf{V}_0(\Omega^i)$, but the old velocity field $\widehat{u}^{\,i-1}$ is in $\mathbf{V}_0(\Omega^i)$, and therefore it can be seen as a projection from the space $\mathbf{V}_0(\Omega)$ to the space $\mathbf{V}_0(\Omega^i)$ with respect to the scalar product $(\cdot,\cdot)_1$. At the ith iteration the global solution $\widehat{u}^{\,i}$ is determined by the local solution as $\widehat{u}^{\,i} = \vec{u}^{\,i}$ over the subdomain Ω^i and $\widehat{u}^{\,i} = \widehat{u}^{\,i-1}$ over $\Omega - \Omega^i$. We remark that if $\widehat{u}^{\,0}$ is in $\mathbf{V}_0(\Omega)$, then the sequence $\widehat{u}^{\,i}$ is in $\mathbf{V}_0(\Omega)$ for all $i = 1, 2, \ldots, m$.

This domain decomposition algorithm can be proved to be convergent for the Stokes problem.

Details on the Stokes problem for finite element discretizations are reported in the next sections. The Navier–Stokes case requires more restrictions since the uniqueness of the solution can be guaranteed only for small Reynolds numbers, as stated in Theorem 2.2. Therefore we state a convergence theorem only for small Reynolds numbers [16, 17].

THEOREM 2.5. *Let Ω be a bounded simply connected domain with smooth boundary and let Ω^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains with smooth boundary such that $\Omega = \Omega^1 \cup \Omega^2 \cup \cdots \cup \Omega^m$. Let the jth smoothing step $\widehat{u}^{\,j,m} \in \mathbf{V}_0(\Omega)$ be defined by solving iteratively the local system over the domain Ω^i for $i = 1, \ldots, m$ with $\widehat{u}^{\,j,0} = \widehat{u}^{\,j-1,m} \in \mathbf{V}_0(\Omega)$. The global sequence is defined by $\widehat{u}^{\,j,i} = \vec{w}^{\,i} + \widehat{u}^{\,j,i-1}$ over the subdomain Ω^i and $\widehat{u}^{\,j,i} = \widehat{u}^{\,j,i-1}$ over $\Omega - \Omega^i$ $(i = 1, \ldots, m)$, where $\vec{w}^{\,i} \in \mathbf{V}_0(\Omega^i)$ solves the local problem*

(2.25)
$$\nu a(\vec{w}^{\,i} + \widehat{u}^{\,j,i-1}, \vec{v}^{\,i}) + c(\vec{w}^{\,i} + \widehat{u}^{\,j,i-1}, \vec{w}^{\,i} + \widehat{u}^{\,j,i-1}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{V}_0(\Omega^i),$$

with boundary condition $\vec{w}^{\,i} = 0$.

Let $\widehat{u}^{\,0,0} \in \mathbf{V}_0(\Omega)$. Then the global sequence $\widehat{u}^{\,j,m} \in \mathbf{V}_0(\Omega)$ converges $(j \to \infty)$ for sufficiently small Reynolds number to the solution of the Navier–Stokes problem in (2.14).

Proof. At the smoothing step j over the subdomain Ω^i in (2.25) we have

$$\nu a(\vec{w}^{\,i}, \vec{v}^{\,i}) + c(\vec{u}^{\,i}, \vec{u}^{\,i}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle - \nu a(\widehat{u}^{\,j,i-1}, \vec{v}^{\,i}), \tag{2.26}$$

where $\vec{u}^{\,i} = \vec{w}^{\,i} + \widehat{u}^{\,j,i-1}$ is the local unknown velocity field defined over Ω^i. Let $\vec{u} \in \mathbf{V}_0(\Omega)$ be the solution of the Navier–Stokes problem in (2.14), i.e., $\vec{u}$ is the solution of the equation

$$\nu a(\vec{u}^{\,j}, \vec{v}^{\,i}) + \Delta t\, c(\vec{u}^{\,j}, \vec{u}^{\,j}, \vec{v}^{\,i}) = (\vec{u}^{\,j-1}, \vec{v}^{\,i}) + \Delta t\, \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{V}_0(\Omega^i),$$

with the appropriate boundary conditions over Γ^i. The appropriate boundary conditions are Dirichlet boundary conditions that match the global solution $\vec{u}$ itself over Γ_i.

We note that $\vec{w}^{\,i}$ is in $\mathbf{V}_0(\Omega^i)$ but that $\widehat{u}^{\,j,i-1}$ and $\vec{u}^{\,i}$ do not vanish on the boundary Γ^i, and therefore they are not in $\mathbf{V}_0(\Omega^i)$. Equation (2.26) becomes

$$\begin{aligned} &\nu a(\vec{w}^{\,i} + P_i\,(\widehat{u}^{\,j,i-1} - \vec{u}), \vec{v}^{\,i}) + c(\vec{u}^{\,i} - \vec{u}, \vec{u}^{\,i} - \vec{u}, \vec{v}^{\,i}) \\ &+ c(\vec{u}, \vec{u}^{\,i} - \vec{u}, \vec{v}^{\,i}) + c(\vec{u}^{\,i} - \vec{u}, \vec{u}, \vec{v}^{\,i}) = 0, \end{aligned} \tag{2.27}$$

where P_i is the projector operator from $\mathbf{V}_0(\Omega)$ to $\mathbf{V}_0(\Omega^i)$. Let $\vec{e}^{\,j,i} = \vec{u}^{\,i} - \vec{u}$ and $\vec{e}^{\,j,i-1} = \widehat{u}^{\,j,i-1} - \vec{u}$ be the errors at smoothing steps i and $i-1$, respectively. The error functions $\vec{e}^{\,j,i}$ and $\vec{e}^{\,j,i-1}$ defined over Ω^i can be extended over Ω naturally and will be denoted by $\widehat{e}^{\,j,i}$ and $\widehat{e}^{\,j,i-1}$, respectively. Then (2.27) can be written in operator form as

$$A(\vec{w}^{\,i} + P_i\,\widehat{e}^{\,j,i-1}) + \frac{1}{\nu}\Big(C(\vec{e}^{\,j,i})\vec{e}^{\,j,i} + C(\vec{u})\,\vec{e}^{\,j,i} + C(\vec{e}^{\,j,i})\vec{u}\Big) = 0 \quad \text{on } \Omega^i \tag{2.28}$$

or

$$\vec{w}^{\,i} + P_i\,\widehat{e}^{\,j,i-1} = -\frac{1}{\nu}\,A_i^{-1}\Big(C(\vec{e}^{\,j,i})\vec{e}^{\,j,i} + C(\vec{u})\,\vec{e}^{\,j,i} + C(\vec{e}^{\,j,i})\vec{u}\Big) \text{ over } \Omega^i, \tag{2.29}$$

where A_i^{-1} is the inverse operator of A over the domain Ω^i with homogeneous boundary condition on Γ^i. If we define $\widehat{w}^{\,j,i}$ as the zero extension over Ω of $\vec{w}^{\,i}$, then (2.29) gives a global estimate in $\widehat{e}^{\,j,i}$ which satisfies

$$\widehat{e}^{\,j,i} = (I - P_i)\,\widehat{e}^{\,j,i-1} - \frac{1}{\nu}\,A_i^{-1}\Big(C(\vec{e}^{\,j,i})\vec{e}^{\,j,i} - C(\vec{u})\,\vec{e}^{\,j,i} - C(\vec{e}^{\,j,i})\vec{u}\Big). \tag{2.30}$$

Now we can prove that the error $\widehat{e}^{\,j,i}$ is bounded for large values of ν. By using the Schwarz inequality and (2.2) in (2.30) we have

$$|\widehat{e}^{\,j,i}|_1 \le |(I - P_i)\,\widehat{e}^{\,j,i-1}|_1 + \frac{1}{\nu}\,K\,(|\widehat{e}^{\,j,i}|_1^2 + |\vec{u}|_1\,|\widehat{e}^{\,j,i}|_1) \tag{2.31}$$

for some K constant. Let the initial error $|\widehat{e}^{\,j,0}|_1$ be bounded by M and let λ be a positive number such that $\lambda < 1 - |\Pi_{i=1}^m (I - P_i)|_1^{1/m}$. Theorem 2.4 assures us that $\lambda > 0$ since $|\Pi_{i=1}^m (I - P_i)|_1 < 1$. Since $|\vec{u}|_1$ is bounded, then from a simple geometric consideration there exists a ν^* such that if $\nu > \nu^*$, then

$$\lambda x > \frac{K}{\nu}\,(x^2 + x|\vec{u}^{\,j}|_1) \tag{2.32}$$

for $0 \le x \le M/(1-\lambda)^m = M'$. It is easy to see that if $|\widehat{e}^{\,j,0}|_1 \le M$, then $|\widehat{e}^{\,j,i}|_1 \le M'$ for all $i = 1, 2, \ldots, m$. In fact for $i = m$ in (3.27) and $\nu > \nu^*$ we have

$$(1 - \lambda)|\widehat{e}^{\,j,m}|_1 \le |\widehat{e}^{\,j,m-1}|_1,$$

and for $i = m - 1$ and $\nu > \nu^*$ we can write

$$(1 - \lambda)^2|\widehat{e}^{\,j,m}|_1 \le |\,\widehat{e}^{\,j,m-2}|_1$$

since $|(I - P_m)|_1 \le 1$. We can obtain similar estimates for $i = m-2, m-3, \ldots, 1$ and combine them to obtain

$$|\widehat{e}^{\,j,i}|_1 \le \frac{|\,\widehat{e}^{\,j,0}|_1}{(1-\lambda)^i} \le M' \tag{2.33}$$

for all $i = 1, \ldots, m$ and $\nu > \nu^*$. However, this estimate is not sharp enough since M' can be much larger than M and the global sequence in j may diverge. In order to improve the bound we need to take larger values of ν and prove that the sequence $|\widehat{e}^{\,j,m}|$ is monotone decreasing. Consider (3.27) and the fact that $|\widehat{e}^{\,j,m}|_1 \leq |\widehat{e}^{\,j,0}|_1/(1-\lambda)^m$ and $|\widehat{e}^{\,j,0}|_1 \leq M$ for some large $\nu > \nu^*$. We can write, for $i = m$,

$$|\widehat{e}^{\,j,m}|_1 \leq |(I - P_m)\,\widehat{e}^{\,j,m-1}|_1 + \frac{1}{\nu}\,C\,|\widehat{e}^{\,j,0}|_1 \tag{2.34}$$

for some constant C and $\nu > \nu^*$. By substituting (2.30) for $i = m-1$ in (2.34) and using the same estimates, we have

$$|\widehat{e}^{\,j,m}|_1 \leq |(I - P_m)(I - P_{m-1})\,\widehat{e}^{\,j,m-2}|_1 + 2\frac{1}{\nu}\,C\,|\widehat{e}^{\,j,0}|_1\,.$$

Again by using (2.30) for $i = m-2, \ldots, 1$ we finally obtain

$$|\widehat{e}^{\,j,m}|_1 \leq |\Pi_{i=1}^{m}(I - P_i)\,\widehat{e}^{\,j,0}|_1 + m\frac{1}{\nu}\,C\,|\widehat{e}^{\,j,0}|_1\,.$$

We remark that this is not a very sharp bound and can be improved, i.e., for example, the integer number m in the bound can be substituted by the maximum number of overlapping domains. If ν is taken greater than $\nu_1 = (1 - |\Pi_{i=1}^{m}(I - P_i)|_1)\frac{1}{m\,C}$, then

$$|\widehat{e}^{\,j,m}|_1 < |\widehat{e}^{\,j,0}|_1.$$

We can apply this technique to each smoothing step for $j = 1, 2, \ldots$ and claim that, for $\nu > \nu_1 > \nu^*$, the sequence $|\vec{e}^{\,j,m}|_1$ is bounded by the initial error M. Also the sequence $|\widehat{e}^{\,j,m}|_1$ converges to zero and therefore $\widehat{u}^{\,j,m}$ to solution of (2.14). ∎

2.4. Domain decomposition of type B. The domain decomposition algorithm of type A keeps the global solution divergence-free at each step. This could be computationally very expensive since the divergence-free constraint must be satisfied everywhere and at each iteration. This global constraint could be relaxed and imposed only locally if we use a different form of the Navier–Stokes system. Since any vector $\vec{u}^{\,'} \in \mathbf{H}_0^1(\Omega)$ can be written in a unique way as $\vec{u} + \vec{u}^{\,\perp}$ where $\vec{u} \in \mathbf{V}_0(\Omega)$ and $\vec{u}^{\,\perp} \in \mathbf{V}_0^{\perp}(\Omega)$ we can set $\vec{u} = \vec{u}^{\,'} - \vec{u}^{\,\perp}$ in the Navier–Stokes system (2.14) and write

$$\begin{cases} \nu a(\vec{u}^{\,'}, \vec{v}) - a(\vec{u}^{\,\perp}, \vec{v}) + c(\vec{u}, \vec{u}, \vec{v}) + b(p, \vec{v}) = \langle \vec{f}, \vec{v} \rangle \quad \forall \vec{v} \in \mathbf{H}_0^1(\Omega), \\ b(r, \vec{u}^{\,\perp}) = b(r, \vec{u}^{\,'}) \qquad \forall r \in L_0^2(\Omega), \\ \vec{u} = \vec{u}^{\,'} - \vec{u}^{\,\perp}. \end{cases} \tag{2.35}$$

Since the Stokes operator in the continuous form satisfies the LBB condition from the definition of $\mathbf{V}_0^{\perp}(\Omega)$ in (2.1) for each $p \in L_0^2(\Omega)$ there is a unique $\vec{u}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega)$ such that [11]

$$a(\vec{u}^{\,\perp}, \vec{v}) = b(p, \vec{v}) \qquad \forall \vec{v} \in \mathbf{H}_0^1(\Omega).$$

We identify $\vec{u}^{\,\perp}$ with p, and this implies that the system (2.35) can be written as

$$\begin{cases} \nu a(\vec{u}^{\,'}, \vec{v}) + c(\vec{u}, \vec{u}, \vec{v}) = \langle \vec{f}, \vec{v} \rangle \qquad \forall \vec{v} \in \mathbf{H}_0^1(\Omega), \\ a(\vec{v}^{\perp}, \vec{u}^{\,\perp}) = a(\vec{v}^{\perp}, \vec{u}^{\,'}) \qquad \forall \vec{v}^{\perp} \in \mathbf{V}_0^{\perp}(\Omega), \\ \vec{u}^{\,'} = \vec{u} + \vec{u}^{\,\perp}. \end{cases} \tag{2.36}$$

The second equation in (2.36) can be seen as a simple projection of $\vec{u}'$ from the space $\mathbf{H}_0^1(\Omega)$ to $\mathbf{V}_0^\perp(\Omega)$ or as an equation formulated in terms of the Schur complement operator. The Navier–Stokes system is reduced to solving its Schur complement equation, and this form of the Navier–Stokes system allows us to relax the divergence-free constraint. A new domain decomposition theorem can be proved for this different class of problems.

THEOREM 2.6. *Let Ω be a bounded simply connected domain with smooth boundary and let Ω^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains with smooth boundary such that $\Omega = \Omega^1 \cup \Omega^2 \cup \cdots \cup \Omega^m$. Let the jth smoothing step $(\widehat{u}'^{j,m}, \widehat{u}^{j,m\perp}) \in \mathbf{H}_0^1(\Omega) \times \mathbf{V}_0^\perp(\Omega)$ be defined by solving iteratively the local system over the domain Ω^i for $i = 1, \ldots, m$ with $\widehat{u}'^{j,0} = \widehat{u}'^{j-1,m}$ and $\widehat{u}^{\perp j,0} = \widehat{u}^{\perp j-1,m}$. The global sequence is defined by $\widehat{u}'^{j,i} = \vec{w}'^{\,i} + \widehat{u}'^{j,i-1}$, $\widehat{u}^{\perp j,i} = \vec{z}^{\perp i} + \widehat{u}^{\perp j,i-1}$ over Ω^i and $\widehat{u}'^{j,i} = \widehat{u}'^{j,i-1}$, $\widehat{u}^{\perp j,i} = \widehat{u}^{\perp j,i-1}$ over $\Omega - \Omega^i$ $(i = 1, \ldots, m)$, where $(\vec{w}'^{\,i}, \vec{z}^{\perp i})$ solves the local problem*

$$
\begin{cases}
\nu a(\vec{w}'^{\,i} + \widehat{u}'^{j,i-1}, \vec{v}^{\,i}) + c(\vec{u}^{\,i}, \vec{u}^{\,i}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i), \\
a(\vec{z}^{\perp i} + \widehat{u}^{\perp j,i-1}, \vec{v}^{\perp i}) = a(\vec{w}'^{\,i} + \widehat{u}'^{j,i-1}, \vec{v}^{\perp i}) \qquad \forall \vec{v}^{\perp i} \in \mathbf{V}_0^\perp(\Omega^i), \\
\widehat{u}'^{j,i} = \vec{u}^{\,i} + \widehat{u}^{\perp j,i} \qquad \text{on} \quad \Omega^i.
\end{cases} \tag{2.37}
$$

Let $(\widehat{u}'^{0,0}, \widehat{u}^{\perp 0,0})$ be in $\mathbf{H}_0^1(\Omega) \times \mathbf{V}_0^\perp(\Omega)$. Then the global sequence $(\widehat{u}'^{j,m}, \widehat{u}^{\perp j,m})$ converges $(j \to \infty)$ for sufficiently small Reynolds numbers to the solution of the Navier–Stokes problem in (2.36).

Proof. Let $(\vec{u}', \vec{u}^\perp) \in \mathbf{H}_0^1(\Omega) \times \mathbf{V}_0^\perp(\Omega)$ be the solution of the Navier–Stokes problem in (2.36). Then $(\vec{u}', \vec{u}^\perp)$ satisfies

$$
\nu a(\vec{u}', \vec{v}^{\,i}) + c(\vec{u}, \vec{u}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i), \tag{2.38}
$$

$$
a(\vec{u}^{\,\perp}, \vec{v}^{\perp i}) = a(\vec{u}', \vec{v}^{\perp i}) \qquad \forall \vec{v}^{\perp i} \in \mathbf{V}_0^\perp(\Omega^i), \tag{2.39}
$$

with $\vec{u} = \vec{u}' - \vec{u}^\perp$ and appropriate Dirichlet boundary conditions, i.e., the solution $(\vec{u}', \vec{u}^\perp)$ matches the boundary condition over Γ^i. With this notation at the smoothing step j and over Ω^i, the function $\vec{w}'^{\,i}$ satisfies

$$
\begin{aligned}
&\nu a(\vec{w}'^{\,i}, \vec{v}^{\,i}) + c(\vec{u}^{\,i} - \vec{u}, \vec{u}^{\,i} - \vec{u}, \vec{v}^{\,i}) + c(\vec{u}, \vec{u}^{\,i} - \vec{u}, \vec{v}^{\,i}) \\
&+ c(\vec{u}^{\,i} - \vec{u}, \vec{u}, \vec{v}^{\,i}) + \nu a(\widehat{u}'^{j,i-1} - \vec{u}', \vec{v}^{\,i}) = 0 \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i).
\end{aligned} \tag{2.40}
$$

We define $\vec{e}^{\,j,i} = \vec{u}^{\,j,i} - \vec{u}$, $\vec{e}^{\,j,i-1} = \widehat{u}^{\,j,i-1} - \vec{u}$, $\vec{e}^{\,\prime j,i} = \vec{u}'^{j,i} - \vec{u}'$, $\vec{e}'^{j,i-1} = \widehat{u}'^{j,i-1} - \vec{u}'$ over Ω^i and the corresponding extensions as $\widehat{e}^{\,j,i}$, $\widehat{e}^{\,j,i-1}$, $\widehat{e}^{\,\prime j,i}$, $\widehat{e}^{\,\prime j,i-1}$ over Ω in the usual way. Then (2.40) gives

$$
\begin{aligned}
&\nu a(\vec{w}'^{\,i}, \vec{v}^{\,i}) + c(\vec{e}^{\,j,i}, \vec{e}^{\,j,i}, \vec{v}^{\,i}) \\
&+ c(\vec{u}, \vec{e}^{\,j,i}, \vec{v}^{\,i}) + c(\vec{e}^{\,j,i}, \vec{u}, \vec{v}^{\,i}) + \nu a(\vec{e}'^{\,j,i-1}, \vec{v}^{\,i}) = 0.
\end{aligned} \tag{2.41}
$$

Again we note that $\vec{w}'^{\,i}$ is in $\mathbf{H}_0^1(\Omega^i)$ and that $\widehat{u}'^{j,i-1}$, $\vec{u}'^{\,i}$ do not vanish on the boundary Γ^i. For this reason we need to introduce T_i, the projector operator from $\mathbf{H}_0^1(\Omega)$ to $\mathbf{H}_0^1(\Omega^i)$, and write (2.41) in the form

$$
A(\vec{w}'^{\,i} + T_i \widehat{e}'^{j,i-1}) + \frac{1}{\nu}\left(C(\vec{e}^{\,j,i})\,\vec{e}^{\,j,i} + C(\vec{u})\,\vec{e}^{\,j,i} + C(\vec{e}^{\,j,i})\vec{u}^{\,j} \right) = 0 \quad \text{over } \Omega^i \tag{2.42}
$$

or

$$\widehat{e}^{\,\prime j,i} = (I - T_i)\,\widehat{e}^{\,\prime j,i-1} + \frac{1}{\nu}\,A_{*i}^{-1}\left(C(\vec{e}^{\,j,i})\vec{e}^{\,j,i} + C(\vec{u})\,\vec{e}^{\,j,i} + C(\vec{e}^{\,j,i})\vec{u}\right) \tag{2.43}$$

by introducing A_{*i}^{-1}, the inverse operator of A_* over the domain Ω^i with homogeneous boundary condition on Γ^i and the global estimate $\widehat{e}^{\,j,i}$ over Ω.

Now it is possible to prove that $|\widehat{e}^{\,j,i}|_1$ is bounded for $i = 1, 2, \ldots, m$ and $|\widehat{e}^{\,j,m}|_1$ monotonically decreases as j increases for large values of ν. In fact from (2.43) by using the Schwarz inequality and the inequalities in (2.2), since $|\widehat{e}^{\,j,i}|_1 \le |\widehat{e}^{\,\prime j,i}|_1$, we have

$$|\widehat{e}^{\,\prime j,i}|_1 \le |(I - T_i)\,\widehat{e}^{\,\prime j,i-1}|_1 + \frac{K}{\nu}\,(|\widehat{e}^{\,\prime j,i}|_1^2 + |\vec{u}|_1\,|\widehat{e}^{\,\prime j,i}|_1) \tag{2.44}$$

for some K constant. Let the initial error $|\vec{e}^{\,\prime j,0}|_1$ be bounded by M and therefore by $M' = M/(1-\lambda)^m$, where $\lambda = 1 - |\Pi(I - T_i)|_1^{1/m} > 0$. By following the same steps as in the previous theorem we can claim that for ν sufficiently large, the error $|\vec{e}^{\,\prime j,i}|_1$ is bounded by M' for $i = 1, 2, \ldots, m$ and $|\vec{e}^{\,\prime j,m}|_1 < |\vec{e}^{\,\prime j,0}|_1$ for $j = 1, 2, \ldots$.

Now consider (2.37) in the form

$$a(\vec{z}^{\,\perp j,i} - \vec{w}^{\,\prime i}, \vec{v}^{\,\perp i}) + a(\widehat{u}^{\,\perp j,i-1} - \widehat{u}^{\,\prime j,i-1}, \vec{v}^{\,\perp i}) = 0$$

or

$$a(\vec{z}^{\,\perp j,i} - S\,\vec{w}^{\,\prime j,i} + \Pi_i(\widehat{u}^{\,\perp\prime j,i-1} - S\,\widehat{u}^{\,\prime j,i-1}), \vec{v}^{\,\perp i}) = 0, \tag{2.45}$$

where Π_i is the projector from $\mathbf{V}_0^{\perp}(\Omega)$ to $\mathbf{V}_0^{\perp}(\Omega^i)$ and S is the projection operator from $\mathbf{H}_0^1(\Omega)$ to $\mathbf{V}_0^{\perp}(\Omega)$. Let $\vec{r}^{\,j,i} = \widehat{u}^{\,\perp j,i} - S\,\vec{u}^{\,\prime j,i}$ and $\vec{r}^{\,j,i-1} = \widehat{u}^{\,\perp j,i-1} - S\,\vec{u}^{\,\prime j,i-1}$ over Ω^i and let the corresponding extension over Ω be denoted by $\widehat{r}^{\,j,i}$ and $\widehat{r}^{\,j,i-1}$, respectively. With this notation (2.45) becomes

$$a(\vec{z}^{\,\perp j,i} - S\,\vec{w}^{\,\prime j,i} + \Pi_i\widehat{r}^{\,j,i-1}, \vec{v}^{\,\perp i}) = 0 \tag{2.46}$$

and its solution $\vec{z}^{\,\perp j,i} - S\,\vec{w}^{\,\prime j,i} = -\Pi_i\,\widehat{r}^{\,j,i-1}$. If we consider the zero extension of $\vec{z}^{\,\perp j,i}$ and $\vec{w}^{\,\prime j,i}$ and the corresponding extension $\widehat{r}^{\,j,i}$ over Ω, then the global solution $\widehat{r}^{\,j,i}$ satisfies

$$\widehat{r}^{\,j,i} = (I - \Pi_i)\,\widehat{r}^{\,j,i-1}$$

for $i = 1, 2, \ldots, m$, which implies

$$\widehat{r}^{\,j,m} = \Pi_{i=1}^{m}(I - \Pi_i)\,\widehat{r}^{\,j,0}.$$

Since $|\Pi_{i=1}^{m}(I - \Pi_i)|_1 < 1$ we have $|\widehat{r}^{\,j,m}|_1 < |\widehat{r}^{\,j,0}|_1$. Applying the same procedure for each smoothing step j we have that the sequence $|\widehat{r}^{\,j,m}|_1$ monotonically decreases for increasing j. However, from the previous estimate, the sequence $|\widehat{e}^{\,\prime j,m}|_1$ is monotonically decreasing and therefore $\widehat{u}^{\,\prime j,m}$ tends to $\widehat{u}^{\,\prime}$. The sequence $\widehat{u}^{\,\perp j,m}$ tends to $S\,\vec{u}^{\,\prime j,m}$ and therefore to $S\vec{u}^{\,\prime} = \vec{u}^{\perp}$, which is the solution of (2.36) as j tends to infinity. ∎

We can reformulate the above algorithm with standard notation in velocity and pressure. Given $(\widehat{u}^{\,i-1}, \widehat{p}^{\,i-1}) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ at the local step $i-1$ we define the local problem for $\vec{w}^{\,i} = \vec{u}^{\,i} - \widehat{u}^{\,i-1} \in \mathbf{H}_0^1(\Omega^i)$ and $z^{\,i} = p^{\,i} - p^{\,i-1} \in L_0^2(\Omega^i)$ by

$$\begin{cases} \nu a(\vec{w}^{\,i}, \vec{v}^{\,i}) + b(z^{\,i}, \vec{v}^{\,i}) + c(\vec{w}^{\,i}, \vec{w}^{\,i}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i}\rangle - \nu a(\widehat{u}^{\,i-1}, \vec{v}^{\,i}) - b(\widehat{p}^{\,i}, \vec{v}^{\,i}) \\ \qquad - c(\widehat{u}^{\,i-1}, \vec{w}^{\,i}, \vec{v}^{\,i}) - c(\vec{w}^{\,i}, \widehat{u}^{\,i-1}, \vec{v}^{\,i}) \qquad \forall \vec{v}^{\,i} \in \mathbf{H}_0^1(\Omega^i), \\ b(r^i, \vec{w}^{\,i}) + b(r^i, \widehat{u}^{\,i-1}) = 0 \qquad \forall r^i \in L_0^2(\Omega^i), \end{cases}$$

with boundary condition $\vec{w}^{\,i} = 0$. The global solution $(\widehat{u}^{\,i}, \widehat{p}^{\,i})$ is determined by the local solution as $\widehat{u}^{\,i} = \vec{w}^{\,i} + \widehat{u}^{\,i-1}$, $\widehat{p}^{\,i} = z^{\,i} + \widehat{p}^{\,i-1}$ over the subdomain Ω^i and $\widehat{u}^{\,i} = \widehat{u}^{\,i-1}$, $\widehat{p}^{\,i} = \widehat{p}^{\,i-1}$ over $\Omega - \Omega^i$. We remark that the restriction of $\widehat{u}^{\,i}$ over Ω^i is in $\mathbf{V}_0(\Omega^i)$, but the global function $\widehat{u}^{\,i}$ is not in $\mathbf{V}_0(\Omega)$. The divergence-free constraint is relaxed and is matched only in the limit of the algorithm when convergence is reached.

3. Formulation of the discrete problem.

3.1. Introduction. In this section we investigate the numerical behavior of the Vanka-type smoothers by using the finite element method. The finite element method is particularly suitable for multigrid and Vanka-type smoothers since the domain geometry is well defined by the finite element structure and the local problems can be solved at the element level, where the topology is already available. In this paper we deal only with the convergence issue and leave the multigrid discussion to successive papers. In particular we would like to discuss the convergence of the Vanka smoothers when the local solution is obtained over overlapping subdomains that consist of a cluster of a few finite elements. It is possible to show that smoothers based on these blocks lead to the solution of the Stokes system for any value of viscosity. The same smoothers can be used to solve the Navier–Stokes system but only at low Reynolds numbers. The issue of the high Reynolds is not treated here but can be studied in the analysis of the time-dependent Navier–Stokes formulation.

In order to avoid technicalities in this approach we use rectangular conforming finite elements (standard Taylor–Hood). It is possible to generalize to triangular elements in a very straightforward manner. It is also possible to use different elements and generalize the analysis to nonstandard Taylor–Hood elements. Under these assumptions we consider two cases. In case A the local subdomain Ω^i consists of one quadrilateral finite element and all its neighboring elements. In order to solve the local problem we have to solve for all the velocity and pressure unknowns. The boundary conditions are imposed along the boundary Γ_h^i of the subdomain Ω^i. For the two-dimensional case we can see such an element in Figure 3.1 on the left. In the case of Taylor–Hood finite elements we have sixteen unknowns for each velocity component and pressure.

Case B consists of one quadrilateral finite element and all its neighboring elements, but we do not solve for the pressure on the boundary Γ_h^i. The two-dimensional case can be seen in Figure 3.1 on the right. The two-dimensional case for the Taylor–Hood rectangular finite element has four pressure unknowns and sixteen nodes for each velocity component.

Other elements have been used with Vanka-type smoothers and many, especially nonconforming elements, can be found in the literature; see, for example, [13, 14, 24] and the references therein.

Let Ω_h be a polygonal domain with boundary Γ_h. Then we subdivide the domain Ω_h into the rectangle elements by using unstructured families of meshes, T_h^{i,l_0}. In this analysis we consider only conforming finite element approximations. Let $X^h \subset H^1(\Omega)$ and $P^h \subset L^2(\Omega)$ be two families of finite-dimensional subspaces parameterized by h, which tends to zero. We also denote $X_0^h = X^h \cap H_0^1(\Omega)$ and $P_0^h = P^h \cap L_0^2(\Omega)$. We make the following assumptions on X^h and P^h:

(a) *The approximation hypotheses:* there exists an integer l and a constant C, independent of h, $\vec{u}$, and p, such that for $1 \le k \le l$ we have

$$\inf_{\vec{u}_h \in X^h} \|\vec{u}_h - \vec{u}\|_1 \le C h^k \|\vec{u}\|_{k+1} \qquad \forall\, \vec{u} \in H^{k+1}(\Omega) \cap H_0^1(\Omega), \tag{3.1}$$

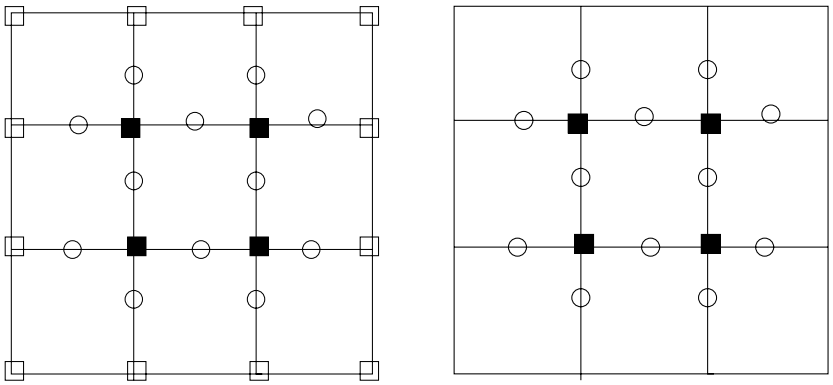

FIG. 3.1. *A block of type A (on the left) and a block of type B (on the right) with velocity (circle), pressure (square), and velocity-pressure (black square) nodes for rectangular Taylor–Hood elements in the two-dimensional geometry.*

$$\inf_{p_h \in P^h} \|p - p_h\| \le C h^k \|p\|_k \qquad \forall\, p \in H^k(\Omega) \cap L_0^2(\Omega). \tag{3.2}$$

(b) *The inf-sup condition or LBB condition:* there exists a constant C', independent of h, such that

$$\inf_{0 \neq q_h \in P^h} \sup_{0 \neq \vec{u}_h \in X^h} \frac{\int_\Omega q_h div \vec{u}_h}{\|\vec{u}_h\|_1 \|q_h\|} \ge C' > 0. \tag{3.3}$$

This condition assures the stability of the discrete Navier–Stokes solutions and plays a key role in the case of blocks of type B.

3.2. Stokes problem with element blocks of type A. Let Ω_h be a bounded simply connected domain with polygonal boundary Γ_h and rectangular triangulations. Let $\Omega_h = \cup_i^m \Omega_h^i$, where the subdomains Ω_h^i are blocks of finite elements of type A with boundary Γ_h^i. This family of subdomains is overlapping in the sense that $\mathbf{X}_0^h(\Omega_h) = \mathbf{X}_0^h(\Omega_h^1) + \mathbf{X}_0^h(\Omega_h^2) + \cdots + \mathbf{X}_0^h(\Omega_h^m)$.

We introduce the divergence-free function space as

$$\mathbf{V}_0^h(\Omega_h) = \{\vec{u}_h \in \mathbf{X}_0^h(\Omega_h) :\, b(\vec{u}_h, r_h) = 0 \quad \forall r_h \in P_0^h(\Omega_h)\},$$

which is also $\mathbf{V}_0^h(\Omega_h) = \mathrm{Ker}\,(B_h) \cap \mathbf{X}_0^h(\Omega_h)$, and note that this is not a subspace of $\mathbf{V}_0(\Omega_h)$. We equip $\mathbf{X}_0^h(\Omega_h)$ and $\mathbf{V}_0^h(\Omega_h)$ with the scalar product $(\cdot,\cdot)_1$ and the norm $|\cdot|_1$ defined by $(\vec{v}_h, \vec{u}_h)_1 = a(\vec{v}_h, \vec{u}_h)$ and $|\vec{u}_h|_1 = a_h(\vec{u}_h, \vec{u}_h)$ for all $\vec{v}_h$, $\vec{u}_h$ in $\mathbf{X}_0^h(\Omega_h)$, respectively.

With this notation we can introduce the Stokes problem over the domain Ω_h.

Given $\vec{f} \in \mathbf{H}^{-1}(\Omega_h)$, find the pair $(\vec{u}_h, p_h) \in \mathbf{X}_0^h(\Omega_h) \times P_0^h(\Omega_h)$ solution of

$$\begin{cases} a(\vec{u}_h, \vec{v}_h) + b(p_h, \vec{v}_h) = \langle \vec{f}, \vec{v}_h \rangle \qquad \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h), \\ b(r_h, \vec{v}_h) = 0 \qquad \forall r_h \in P_0^h(\Omega_h), \end{cases} \tag{3.4}$$

with boundary condition $\vec{v}_h^i = 0$ over Γ_h.

The Vanka-type smoother of type A is an iterative method which computes the solution of the Stokes problem in (3.4) by solving local Stokes problems over the unknowns which are located in a finite element block of type A. The main characteristic

of this block is that the velocity solution $\vec{v}_h$ is in $\mathbf{V}_0^h(\Omega_h)$ at each step and is determined by the solution of a Stokes local problem. More precisely, given the state solution $(\vec{v}_h^{\,i-1}, p_h^{\,i-1}) \in \mathbf{V}_0^h(\Omega_h) \times \mathbf{P}_0^h(\Omega_h)$ at step $i-1$, we define the ith local problem for the pair $(\vec{v}_h^{\,i}, p_h^{\,i}) \in \mathbf{X}^h(\Omega_h^i) \cap \mathbf{V}^h(\Omega_h^i) \times \mathbf{P}_0^h(\Omega_h^i)$ by

$$\begin{cases} a(\vec{u}_h^{\,i}, \vec{v}_h^{\,i}) + b(p_h^i, \vec{v}_h^{\,i}) = \langle \vec{f}, \vec{v}_h^{\,i} \rangle \qquad \forall \vec{v}_h^{\,i} \in \mathbf{X}_0^h(\Omega_h^i), \\ b(r_h^i, \vec{v}_h^{\,i}) = 0 \qquad \forall r_h^i \in P_0^h(\Omega_h^i), \end{cases} \tag{3.5}$$

with boundary conditions $\vec{v}_h^{\,i} = \vec{v}_h^{\,i-1}$ over Γ_h^i and $\vec{v}_h^{\,i} = 0$ over $\Gamma_h^i \cap \Gamma_h$. At the ith iteration the global solution $(\widehat{u}^{\,i}, \widehat{p}^{\,i})$ is determined by the local solution as $\widehat{u}^{\,i} = \vec{u}^{\,i}$, $\widehat{p}^{\,i} = p^{\,i}$ over Ω_h^i and by the old solution as $\widehat{u}^{\,i} = \widehat{u}^{\,i-1}$, $\widehat{p}^{\,i} = \widehat{p}^{\,i-1}$ over $\Omega_h - \Omega_h^i$.

The local problem in (3.5) can be written in the natural way as a projection of the initial Stokes problem over the domain Ω_h^i if we use the variable $\vec{w}^{\,i} = \vec{u}^{\,i} - \widehat{u}^{\,i-1} \in \mathbf{X}_0^h(\Omega_h^i) \cap \mathbf{V}_0^h(\Omega_h^i)$ and rewrite the system as

$$\begin{cases} a(\vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + b(p_h^i, \vec{v}_h^{\,i}) + a(\widehat{u}_h^{\,i-1}, \vec{v}_h^{\,i}) = \langle \vec{f}, \vec{v}_h^{\,i} \rangle \qquad \forall \vec{v}_h^{\,i} \in \mathbf{X}_0^h(\Omega_h^i), \\ b(r_h^i, \vec{w}_h^{\,i}) = 0 \qquad \forall r_h^i \in P_0^h(\Omega_h^i), \end{cases}$$

with boundary condition $\vec{w}_h^{\,i} = 0$ over Γ_h^i.

If the projection P_h^i from $\mathbf{V}_0^h(\Omega_h^i)$ onto $\mathbf{V}_0^h(\Omega_h^i)$ with respect to the inner product $(\cdot,\cdot)_1$ is introduced, then we can write the local problem for $\vec{w}_h^{\,i} \in \mathbf{X}_0^h$ as

$$a(\vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + a(P_h^i \widehat{u}_h^{\,i-1}, \vec{v}_h^{\,i}) = \langle \vec{f}, \vec{v}_h^{\,i} \rangle \qquad \forall \vec{v}_h^{\,i} \in \mathbf{V}_0^h(\Omega_h^i), \tag{3.6}$$

which matches exactly the projection of the Stokes problem over $\mathbf{V}_0^h(\Omega_h^i)$. The global solution $\widehat{u}_h^i$ can be computed by $\vec{w}_h^{\,i} + \widehat{u}_h^{\,i-1}$. The solution of (3.6) is clearly $\vec{w}_h^{\,i} = -P_i^h \widehat{u}_h^{\,i-1} + A_{ih}^{-1} \vec{f}$ and the global solution simply $\widehat{u}_h^i = (I - P_i^h)\widehat{u}_h^{\,i-1} + A_i^{-1} \vec{f}$, where A_{ih}^{-1} is the green operator of the Laplacian operator over Ω_h^i with homogeneous boundary conditions on Γ_h^i. Therefore we start to discuss convergence for these Vanka smoothers by investigating the properties of the operators $(I - P_h^i)$.

In order to study the behavior of the projection operator P_i^h we state a space decomposition theorem which allows us to search the solution of the original Stokes problem in the projection spaces.

THEOREM 3.1. *Let Ω_h be a bounded simply connected domain with polygonal boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains obtained by clustering blocks of elements of type A such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cdots \Omega_h^m$ and $\mathbf{X}_0^1(\Omega_h) = \mathbf{X}_0^h(\Omega_h^1) + \mathbf{X}_0^h(\Omega_h^2) + \mathbf{X}_0^h(\Omega_h^3) \cdots \mathbf{X}_0^h(\Omega_h^m)$. Let $\mathbf{V}_0^h(\Omega_h^i)$ be the divergence-free function space in $\mathbf{X}_0^h(\Omega_h^i)$ with respect to the inner product $(\cdot,\cdot)_1$ for $i = 1, 2, \ldots, m$. Then we have that $\mathbf{V}_0^h(\Omega_h) = \mathbf{V}_0^h(\Omega_h^1) + \mathbf{V}_0^h(\Omega_h^2) + \mathbf{V}_0^h(\Omega_h^3) \cdots \mathbf{V}_0^h(\Omega^m)$.*

Proof. First consider the case for $m = 2$. Let $\vec{v}_h \in \mathbf{V}_0^h(\Omega_h)$. Since the domains are overlapping in the space $\mathbf{X}_0^h(\Omega_h)$ we can write $\vec{v}_h = \vec{v}_{1h} + \vec{v}_{2h}$ with $\vec{v}_{ih} \in \mathbf{X}_0^h(\Omega_h^i)$, $i = 1, 2$. Let $\Omega_{12}^h = \Omega_h^1 \cap \Omega_2^h$. Then there exists an $\vec{s}_h$ over Ω_{12}^h with zero extension such that $B_h(\vec{s}_h - \vec{v}_{1h}) = 0$. Then $\vec{v}_{1h}^{\,'} = \vec{v}_{1h} - \vec{s}_h$ and $\vec{v}_{2h}^{\,'} = \vec{v}_{2h} - \vec{s}_h$ gives the desired decomposition. For any m the theorem can be proved by induction by clustering the subdomains into two groups and using the result for $m = 2$ [15, 16, 11]. ∎

In order to prove convergence of the algorithm we need to use the following properties of the projection P_h^i.

THEOREM 3.2. *Let Ω_h be a bounded simply connected domain with polygonal boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains obtained*

by clustering blocks of elements of type A such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cdots \Omega_h^m$. *Let* P_i^h *be the orthogonal projections from* $\mathbf{V}_0^h(\Omega_h)$ *onto* $\mathbf{V}_0^h(\Omega_h^i)$ *for* $i = 1, 2, \ldots, m$. *Then* $|\Pi_{i=1}^m (I - P_i^h)|_1 < 1$.

Proof. As in the continuous case we use a standard minimization approach. Given $\vec{f} \in L^2(\Omega_h)$ consider the solution $\widehat{u}_h \in \mathbf{V}_0^h(\Omega_h)$ of the following Laplace problem:

$$a(\widehat{u}_h, \widehat{v}_h) = \langle \vec{f}, \widehat{v}_h \rangle \qquad \forall \widehat{v}_h \in \mathbf{V}_0^h(\Omega_h), \tag{3.7}$$

with homogeneous Dirichlet boundary condition or the equivalent minimization problem

$$\widehat{u}_h = \min_{\widetilde{u} \in \mathbf{V}_0^h(\Omega_h)} \left(\frac{1}{2}(A_h \widetilde{u}_h, \widetilde{u}_h) - \langle \vec{f}, \widetilde{u}_h \rangle + \frac{1}{2} \langle A_h^{-1} \vec{f}, \vec{f} \rangle \right). \tag{3.8}$$

The constant $\frac{1}{2}\langle A_h^{-1}\vec{f}, \vec{f}\rangle$ is added to the functional in order to make the functional vanish at the critical point $\widetilde{u}_h = \widehat{u}_h$, and the operator A_h^{-1} from $\mathbf{H}^{-1}(\Omega_h)$ to $\mathbf{X}_0^h(\Omega_h)$ denotes the Green's operator of the homogeneous problem with the operator A_h.

Given $\widehat{u}_h \in \mathbf{V}_0^h(\Omega_h)$, then the projection $\vec{u}_h^i = P_h^i \widehat{u}_h$ from $\mathbf{V}_0^h(\Omega_h)$ to $\mathbf{V}_0^h(\Omega_h^i)$ can be seen as a solution of the following problem:

$$(A_h \vec{u}_h^i, \vec{v}_h^i) = (A_h \widehat{u}_h, \vec{v}_h^i) \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i), \tag{3.9}$$

with homogeneous boundary conditions over Ω_h^i. The residual vector can be written as $\vec{w}_h^i = \widehat{u}_h - \vec{u}_h^i$ over Ω_h^i or $\widehat{w}_h^i = \widehat{u}_h - P_h^i \widehat{u}_h^i = (I - P_h^i)\widehat{u}_h^i$ over Ω_h. The natural approach of studying the operator $\Pi_{i=1}^m (I - P_h^i)$ is to minimize (3.8) over the sequence of domains Ω_h^i in the space $\mathbf{V}_0^h(\Omega_h^i)$ for $i = 1, 2, \ldots, m$ and solve for the residual vector. Let $\widehat{u}_h^{i-1}$ be the iterative solution over the whole domain Ω_h at step $i-1$ and let P_i^h be the projector from $\mathbf{V}_0^h(\Omega_h)$ to $\mathbf{V}_h^i(\Omega_h^i)$. Minimization with respect to the unknowns $\widetilde{u}_h^i$ related to the domain Ω_h^i gives

$$(A_h \vec{u}_h^i, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i), \tag{3.10}$$

where $\vec{v}_h^i$ is set to be equal to the variation $\delta \widetilde{u}_h^i$ and $\vec{u}_h^i$ is the minimizer over $\mathbf{V}_0^h(\Omega_h^i)$. If we set $\vec{w}_h^i = \vec{u}_h^i - \widehat{u}_h^{i-1}$ over the domain Ω_h^i, then (3.10) gives

$$(A_h \vec{w}_h^i, \vec{v}_h^i) + (A_h \widehat{u}_h^{i-1}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i).$$

It is clear that in the above equation the information on the boundary is taken from the old solution $\widehat{u}_h^{i-1}$. If we use the exact solution $\vec{u}_h$ which satisfies

$$(A_h \vec{u}_h, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \quad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i),$$

then we have

$$(A_h \vec{w}_h^i, \vec{v}_h^i) + (A_h(\widehat{u}_h^{i-1} - \vec{u}_h), \vec{v}_h^i) = 0 \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i),$$

which is solved by

$$\vec{w}_h^i = -P_i^h(\widehat{u}_h^{i-1} - \vec{u}_h) \tag{3.11}$$

over Ω_h^i or

$$\widehat{u}_h^i = (I - P_i^h)\, \widehat{u}_h^{i-1} + P_i^h \vec{u}_h \tag{3.12}$$

over Ω_h, where the extension $\widehat{u}_h^i$ of $\vec{u}_h^i$ over $\Omega_h - \Omega_h^i$ is taken to be equal to $\widehat{u}_h^{i-1}$. If we define the error as the difference between the iterative and the finite element solution,

$$\widehat{e}_h^{\,i-1} = \widehat{u}_h^{i-1} - \vec{u}_h \quad \text{and} \quad \widehat{e}_h^{\,i} = \widehat{u}_h^{i} - \vec{u}_h,$$

then the solution error of the Laplace problem satisfies

$$\widehat{e}_h^{\,i} = (I - P_i^h)\,\widehat{e}_h^{\,i-1}. \tag{3.13}$$

Since these estimates are true for all $i = 1, 2, \ldots, m$, we can combine them in the following solution:

$$\widehat{e}_h^{\,m} = \Pi_{i=1}^m (I - P_i^h)\,\widehat{e}_h^{\,0}, \tag{3.14}$$

which gives the global error over Ω_h needed to estimate the functional L_h^i and the operator norm over the domain Ω_h.

Now we show that the functional L_h^i, which is the norm of the error $\widehat{e}_h^{\,i}$, is monotonically decreasing for increasing i for all initial guesses $\widehat{e}_h^{\,0} \in \mathbf{V}_0^h(\Omega_h^i)$. In fact

$$\begin{aligned} L_h^i &= \frac{1}{2}(A_h \widehat{u}_h^i, \widehat{u}_h^i) - \langle \vec{f}, \widehat{u}_h^i \rangle + \frac{1}{2}\langle A_h^{-1}\vec{f}, \vec{f}\rangle \\ &= \frac{1}{2}(A_h(\vec{w}_h^i + \widehat{u}_h^{i-1}), \vec{w}_h^i + \widehat{u}_h^{i-1}) - \langle \vec{f}, \vec{w}_h^i + \widehat{u}_h^{i-1}\rangle + \frac{1}{2}\langle A_h^{-1}\vec{f}, \vec{f}\rangle \\ &= L_h^{i-1} + \frac{1}{2}(A_h \vec{w}_h^i, \vec{w}_h^i) + (A_h \widehat{u}_h^{i-1}, \vec{w}_h^i) - \langle \vec{f}, \vec{w}_h^i\rangle, \end{aligned}$$

and by using the optimality condition (3.10),

$$L_h^i = L_h^{i-1} - \frac{1}{2}(A_h \vec{w}_h^i, \vec{w}_h^i).$$

Therefore, by starting with an initial guess $\widehat{u}_h^0 \in \mathbf{V}_0^h(\Omega_h)$ after a smoothing step over m domains, we have

$$L^m = L^0 - \frac{1}{2}\sum_{i=1}^m |\widehat{w}_h^i|_1^2,$$

with $\widehat{w}_h^i = -P_i^h \widehat{e}_h^{\,i-1}$, $L_h^m = |\widehat{e}_h^{\,m}|_1^2/2$, and $L_h^0 = |\widehat{e}_h^{\,0}|_1^2/2$. Also we have $\widehat{e}_h^{\,m} = \Pi_{i=1}^m (I - P_i^h)\,\widehat{e}_h^{\,0}$ for all $\widehat{e}_h^{\,0} \in \mathbf{V}_0^h(\Omega_h)$. From the definition of norm we have

$$|\Pi_{i=1}^m (I - P_i^h)|_1 = \sup \ |\widehat{e}_h^{\,m}|_1 = \sqrt{1 - \inf \sum_{i=1}^m |\widehat{w}_h^i|_1^2}, \tag{3.15}$$

where the sup and inf are taken over the set of functions $\widehat{e}_h^{\,0} \in \mathbf{V}_0^h(\Omega_h)$ with $|\widehat{e}_h^{\,0}|_1 = 1$. The infimum is the minimizer of the minimization problem

$$\min \ \sum_{i=1}^m |\widehat{w}_h^i|_1^2,$$

where the minimum is taken over all the functions $\widehat{e}_h^{\,0}$ in $\mathbf{V}_0^h(\Omega_h)$ with $|\widehat{e}_h^{\,0}|_1 = 1$. Standard theory can be applied to prove existence, well-posedness, and uniqueness of

the solution of the problem over the set $\mathbf{V}_0^h(\Omega_h)$. Now we prove that the minimum cannot be zero and the corresponding norm $|\Pi_{i=1}^m (I - P_i^h)|_1 < 1$. Suppose that the minimum is zero. Then this implies, from the definition of the norm itself, that there exists an $\widehat{e}_h^0$ in $\mathbf{V}_0^h(\Omega_h)$ such that $\widehat{e}_h^n = \widehat{e}_h^0$, and therefore $P_i^h \widehat{e}_h^0 = 0$ for all $i = 1, 2, \ldots, m$. Such a function $\widehat{e}_h^0$ has norm 1 but zero projections over all $\mathbf{V}_0^h(\Omega_h^i)$ $i = 1, 2, \ldots, m$, and this contradicts the fact that $\mathbf{V}_0^h(\Omega_h) = \mathbf{V}_0^h(\Omega_h^1) + \mathbf{V}_0^h(\Omega_h^2) + \cdots + \mathbf{V}_0^h(\Omega_h^m)$, i.e., the domains are overlapping in the space $\mathbf{V}_0^h(\Omega_h)$. Therefore the functional must be different from zero and must assume a well-defined positive value at the critical point. Combining this result with (3.15), the inequality $|\Pi_{i=1}^m (I - P_i^h)|_1 < 1$ is obtained. ∎

The projections introduced above can be used to solve the Stokes and the Navier–Stokes equations with different types of domain decompositions.

Now we are ready to state a convergence theorem for the Stokes problem.

THEOREM 3.3. *Let Ω_h be a bounded simply connected domain with polygonal boundary Γ_h and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type A such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$. Let the jth smoothing step $\widehat{u}_h^{j,m} \in \mathbf{V}_0^h(\Omega_h)$ be defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$ with $\widehat{u}^{j,0} = \widehat{u}^{j-1,m} \in \mathbf{V}_0^h(\Omega_h)$. The global sequence is defined by $\widehat{u}_h^{j,i} = \vec{w}_h^i + \widehat{u}_h^{i-1}$ over Ω_h^i and $\widehat{u}_h^{j,i} = \widehat{u}_h^{i-1}$ over $\Omega_h - \Omega_h^i$ $(i = 1, \ldots, m)$, where $\vec{w}_h^i \in \mathbf{V}_0^h(\Omega_h^i)$ solves the local problem*

$$\nu a(\vec{w}_h^i, \vec{v}_h^i) + \nu a(\widehat{u}_h^{i-1}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i), \tag{3.16}$$

with boundary condition $\vec{w}_h^i = 0$ over Γ^i.

Let $\widehat{u}^{0,0}$ be in $\mathbf{V}_0^h(\Omega_h)$. Then global sequence $\widehat{u}^{j,m}$ converges $(j \to \infty)$ to the solution of the Stokes problem in (3.4).

Proof. Let $\widehat{u}_h^{j,i-1}$ be in $\mathbf{V}_0^h(\Omega_h)$. In (3.16) we have

$$\nu a(\vec{w}_h^{j,i}, \vec{v}_h^i) + \nu a(\widehat{u}_h^{j,i-1}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i).$$

Let $\vec{u}_h$ be the solution of the Stokes problem. Then

$$\nu a(P_i \vec{u}_h, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{V}_0^h(\Omega_h^i),$$

and therefore

$$\nu a(\vec{w}_h^{j,i}, \vec{v}_h^i) + \nu a(P_i^h(\widehat{u}_h^{j,i-1} - \vec{u}_h), \vec{v}_h^i) = 0. \tag{3.17}$$

If we set $\vec{e}_h^{j,i} = \widehat{u}_h^{j,i} - \vec{u}_h$ over Ω_h^i and $\widehat{e}_h^{j,i-1} = \widehat{u}_h^{j,i-1} - \vec{u}_h$ over Ω_h, the solution of (3.17) gives

$$\vec{e}_h^{j,i} = (I - P_i^h)\, \widehat{e}_h^{j,i-1}.$$

We can define $\widehat{e}_h^{j,i}$ as the extension of $\widehat{e}_h^{j,i}$ over Ω_h and write the solution as

$$\widehat{e}_h^{j,i} = (I - P_i^h)\, \widehat{e}_h^{j,i-1}. \tag{3.18}$$

Since (3.18) is true for all i and j, then

$$\widehat{e}_h^{j,m} = (I - P_m^h)(I - P_{m-1}^h)(I - P_{m-2}^h) \cdots (I - P_2^h)(I - P_1^h)\, \widehat{e}_h^{j,0}, \tag{3.19}$$

and from Theorem 3.2 we have that

$$|\widehat{e}_h^{j,m}|_1 = \lambda_j\, |\widehat{e}_h^{j,0}|_1,$$

with $\lambda_j < 1$. Since $\lambda_j < 1$ for all j the sequence $\widehat{e}_h^{\,j,m}$ converges to zero as $j \to \infty$, and therefore $\widehat{u}_h^{j,m}$ to $\vec{u}_h$. ∎

Now we analyze the algorithm with blocks of type A for the Navier–Stokes system.

Given $\vec{f} \in H^{-1}(\Omega)$, then $(\vec{u}_h, p_h)$ is called a *generalized solution* of the fully discrete approximate Navier–Stokes equations if $\vec{u}_h \in \mathbf{X}_0^h(\Omega_h)$, $p_h \in S_0^h(\Omega_h)$ and satisfies the following system of equations:

$$\begin{cases} \nu a(\vec{u}_h, \vec{v}_h) + c(\vec{u}_h; \vec{u}_h, \vec{v}_h) + b(\vec{v}_h, p_h) = 0 \qquad \forall\, \vec{v}_h \in \mathbf{X}_0^h(\Omega_h), \\ b(\vec{v}_h, q_h) = 0 \qquad \forall\, q_h \in S_0^h(\Omega_h). \end{cases} \tag{3.20}$$

The Vanka smoother of type A for the steady Navier–Stokes problem can be proved to be convergent only for small Reynolds numbers.

THEOREM 3.4. *Let Ω_h be a bounded simply connected domain with smooth boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type A such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$. Let the jth smoothing step $\widehat{u}_h^{j,m} \in \mathbf{V}_0^h(\Omega_h)$ be defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$ with $\widehat{u}_h^{j,0} = \widehat{u}_h^{j-1,m} \in \mathbf{V}_0^h(\Omega_h)$. The global sequence is defined by $\widehat{u}_h^{j,i} = \vec{w}_h^{\,i} + \widehat{u}_h^{j,i}$ over Ω_h^i and $\widehat{u}_h^{j,i} = \widehat{u}_h^{i-1}$ over $\Omega_h - \Omega_h^i$ $(i = 1, \ldots, m)$, where $\vec{w}_h^{\,i} \in \mathbf{V}_0^h(\Omega_h^i)$ solves the local problem*

$$\nu a(\vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + c(\vec{w}_h^{\,i} + \widehat{u}^{\,i-1}, \vec{w}_h^{\,i} + \widehat{u}^{\,i-1}, \vec{v}_h^{\,i}) = \langle \vec{f}, \vec{v}_h^{\,i} \rangle - \nu a(\widehat{u}_h^{\,i-1}, \vec{v}_h^{\,i}) \tag{3.21}$$

for all $\vec{v}_h^{\,i} \in \mathbf{V}_0^1(\Omega_h^i)$ with boundary condition $\vec{w}_h^{\,i} = 0$ over Γ_h^i.

Let $\widehat{u}^{\,0,0}$ be in $\mathbf{V}_0(\Omega_h)$. Then the global sequence $\widehat{u}_h^{j,m}$ converges $(j \to \infty)$ for sufficiently small Reynolds numbers to the solution of the Navier–Stokes problem in (3.20).

Proof. The proof follows the Stokes approach. From (3.21) we have

$$\nu a(\vec{w}^{\,i}, \vec{v}_h^{\,i}) + c(\widehat{w}^{\,i} + \widehat{u}^{\,j,i-1}, \widehat{w}^{\,i} + \widehat{u}^{\,j,i-1}, \vec{v}_h^{\,i}) + \nu a(\widehat{u}^{\,j,i-1}, \vec{v}^{\,i}) = \langle \vec{f}, \vec{v}^{\,i} \rangle \tag{3.22}$$

for all $\vec{v}_h^{\,i} \in \mathbf{V}_0^1(\Omega_h^i)$. Let $\vec{u}_h$ be the solution of the Navier–Stokes problem in (3.20) with the appropriate boundary condition. Then we have

$$\nu a(\vec{u}_h, \vec{v}_h^{\,i}) + c(\vec{u}_h, \vec{u}_h, \vec{v}_h^{\,i}) = \langle \vec{f}, \vec{v}_h^{\,i} \rangle \qquad \forall \vec{v}_h^{\,i} \in \mathbf{V}_0^h(\Omega^h),$$

and we can rewrite (3.22) in the following form:

$$\nu a(\vec{w}_h^{\,j,i} + \widehat{u}_h^{\,j,i-1}, \vec{v}^{\,i}) + c(\vec{w}_h^{\,j,i} + \widehat{u}_h^{\,j,i-1}, \vec{w}_h^{\,j,i} + \widehat{u}_h^{\,j,i-1}, \vec{v}^{\,i}) = c(\vec{u}_h, \vec{u}_h, \vec{v}_h^{\,i}). \tag{3.23}$$

If we set $\vec{e}_h^{\,j,i} = \vec{w}_h^{\,j,i} + \widehat{u}_h^{\,j,i-1} - \vec{u}_h$ over Ω_h^i and $\widehat{e}_h^{\,j,i-1} = \widehat{u}_h^{\,j,i-1} - \vec{u}_h$ over Ω_h, then (3.23) gives

$$\nu a(\vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + c(\vec{u}_h, \widehat{e}_h^{\,j,i}, \vec{v}_h^{\,i}) + c(\widehat{e}^{\,j,i}, \vec{u}_h, \vec{v}_h^{\,i}) + \nu a(\widehat{e}_h^{\,j,i-1}, \vec{v}_h^{\,i}) = 0. \tag{3.24}$$

We note that $\vec{w}_h^{\,i} = \vec{e}_h^{\,j,i} - \widehat{e}_h^{\,j,i-1}$ is in $\mathbf{V}_0^1(\Omega_h^i)$. By using the zero extension of $\vec{w}_h^{\,i}$ we can define the extension $\widehat{e}_h^{\,j,i} = \widehat{e}_h^{\,j,i-1} + \vec{w}_h^{\,i}$ of $\vec{e}_h^{\,j,i}$ to Ω_h. Then (3.24) can be written in operator form as

$$A(\vec{w}_h^{\,i} + P_i^h\, \widehat{e}_h^{\,j,i-1}) + \frac{1}{\nu} \Big(C(\vec{e}_h^{\,j,i}) \vec{e}_h^{\,j,i} + C(\vec{u}_h)\, \vec{e}_h^{\,j,i} + C(\vec{e}_h^{\,j,i}) \vec{u} \Big) = 0 \quad \text{on } \Omega_h^i \tag{3.25}$$

or

$$\widehat{e}_h^{\,j,i} = (I - P_i^h)\,\widehat{e}_h^{\,j,i-1} + \frac{1}{\nu}\,A_i^{-1}\Big(\,C(\vec{e}_h^{\,j,i})\vec{e}_h^{\,j,i} + C(\vec{u}_h)\,\vec{e}_h^{\,j,i} + C(\vec{e}_h^{\,j,i})\vec{u}_h\Big) \tag{3.26}$$

over Ω_h^i, where A_i^{-1} is the inverse operator of A over the domain Ω_h^i with homogeneous boundary condition on Γ_h^i. By using the discrete analogous inequalities (2.2) we estimate

$$|\widehat{e}_h^{\,j,i}|_1 \le |(I - P_i^h)\,\widehat{e}_h^{\,j,i-1}|_1 + \frac{1}{\nu}\,K\,(|\widehat{e}_h^{\,j,i}|_1^2 + |\vec{u}_h|_1\,|\widehat{e}_h^{\,j,i}|_1) \tag{3.27}$$

for some K constant.

By using the same approach as in the continuous case we can prove that the error $\widehat{e}_h^{\,j,i}$ is bounded for large values of ν; i.e., if the initial error $|\widehat{e}_h^{\,0,0}|_1$ is bounded by M, then for some large $\nu > \nu^*$, the error in the smoothing step $|\widehat{e}_h^{\,j,i}|_1$ can be bounded for $i = 1, 2, \ldots, m$. Also we can prove, with the same approach used in the continuous case, that $|\widehat{e}_h^{\,j,m}| < |\widehat{e}_h^{\,j,0}|_1$ for large $\nu > \nu_1 > \nu^*$. Since ν_1 and ν^* are independent of j, then we can claim that the sequence $|\vec{e}_h^{\,j,m}|_1$ is bounded by the initial error M and converges to zero. Therefore $\widehat{u}_h^{\,j,m}$ tends to the solution of (3.20) for small Reynolds numbers $1/\nu$. ∎

In primitive variables $\widehat{u}_h^{\,j,i} = \vec{w}_h^{\,i} + \widehat{u}_h^{\,j,i-1}$ and p_h^i, the local problem, corresponds to solve

$$\begin{cases} \nu a(\vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + c(\vec{w}_h^{\,i}, \vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + c(\vec{w}_h^{\,i}, \widehat{u}_h^{\,i-1}, \vec{v}_h^{\,i}) + c(\widehat{u}_h^{\,i-1}, \vec{w}_h^{\,i}, \vec{v}_h^{\,i}) + b(p_h^i, \vec{v}_h^{\,i}) \\ \quad = \langle \vec{f}, \vec{v}_h^{\,i}\rangle - a(\vec{u}_h^{\,i-1}, \vec{v}_h^{\,i}) - c(\widehat{u}_h^{\,i-1}, \widehat{u}_h^{\,i-1}, \vec{v}_h^{\,i}) \qquad \forall \vec{v}_h^{\,i} \in \mathbf{V}_0^h(\Omega_h^i), \\ b(r_h^i, \vec{w}_h^{\,i}) = -b(r_h^i, \vec{u}_h^{\,i-1}) \qquad \forall r_h^i \in P_0^h(\Omega_h^i), \end{cases} \tag{3.28}$$

with homogeneous boundary condition over Γ_h^i. In order to solve the system (3.28) we must solve the pressure at all points of the block and keep the global solution divergence-free. If parabolic or linear finite elements are used in order to satisfy the divergence-free constraint, all the equations that contain the block variables must be solved. Sometimes this is too expensive and the block of type B seems more attractive.

3.3. Stokes problem with block of type B. The Vanka solver with blocks of type A keeps the solution divergence-free at each iteration but has a high number of equations to be solved. The divergence-free constraint on the boundary of the block can be relaxed and the pressure on the border taken from the previous iteration, which leads to a block of type B. In order to prove convergence for this type of block we need to write the Stokes problem without using the divergence-free functions or the divergence-free constraints.

Given $P_0^h(\Omega_h)$ and $\mathbf{X}_0^h(\Omega_h)$ we can define the set $\mathbf{V}_0^{\,h}(\Omega_h)$ of free-divergence vectors and its orthogonal complement with respect to the scalar product $(\cdot,\cdot)_1$ by

$$\mathbf{V}_0^{h\perp}(\Omega_h) = \{\vec{u}_h \in \mathbf{X}_0^h(\Omega_h) : (\vec{u}_h, \vec{v}_h)_1 = 0 \quad \forall \vec{v}_h \in \mathbf{V}_0^h(\Omega_h)\}.$$

Suppose that the functions in the space $\mathbf{X}_0^h(\Omega_h)$ and $\mathbf{V}_0^h(\Omega_h)$ satisfy the approximation properties and in particular the LLB condition. Then the orthogonal $\mathbf{V}_0^{h\perp}(\Omega_h)$ of $\mathbf{V}_0^h(\Omega_h)$ in $\mathbf{X}_0^h(\Omega_h)$ is a well-defined space (see, for example, [11] for a more abstract setting).

For each $\vec{u}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$ there is an associated pressure p_h which is the solution of the following Stokes problem:

$$\begin{cases} a(\vec{u}_h, \vec{v}_h) + b(p_h, \vec{v}_h) = a(\vec{u}_h^{\perp}, \vec{v}_h) & \forall \vec{v}_h \in \mathbf{X}_0^h, \\ b(\vec{u}_h, r_h) = 0 \qquad \forall r_h \in P_0^h(\Omega_h). \end{cases} \tag{3.29}$$

The solution p_h is unique in $P_0^h(\Omega_h)$ and $\vec{u}_h$ is zero. If $\vec{u}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$, the set of all solutions p_h is a subspace of $P_0^h(\Omega_h)$. We introduce the natural space for the discrete pressure by

$$S_0^h(\Omega_h) = \{p_h \in P_0^h : p_h \text{ is a solution of (3.29)} \quad \forall \vec{u}_h \in \mathbf{V}_0^h(\Omega_h)\}.$$

The set $S_0^h(\Omega_h) \subseteq P_0^h(\Omega_h) \subseteq L_0^2(\Omega_h)$ is a space equipped with the norm $\|\cdot\|_{S_h}$ generated by the Schur complement operator $S_h = B_h A_h^{-1} B_h^T$. The Schur complement norm is the natural norm for the set $S_0^h(\Omega_h)$ which is defined by (3.29). The LBB condition assures that $\|\cdot\|_{S_h}$ is a norm (see, for example, [20, 7]). The solution of (3.29) is unique and therefore for each $\vec{u}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$ there is a unique $p_h \in S_0^h(\Omega_h)$. Also for each $p_h \in S_0^h(\Omega_h)$ there is an element $\vec{u}_h^{\perp} \in \mathbf{V}_0^{\perp h}(\Omega_h)$ such that $\vec{u}_h^{\perp}$ is the unique solution of

$$a(\vec{u}_h^{\perp}, \vec{v}_h) = b(p_h, \vec{v}_h) \qquad \forall \vec{v}_h \in \mathbf{X}_0^h. \tag{3.30}$$

Clearly for all $\vec{v}_h \in \mathbf{V}_0^h(\Omega_h)$ we have $(\vec{u}_h^{\perp}, \vec{v}_h)_1 = a(\vec{u}_h^{\perp}, \vec{v}_h) = b(\vec{v}_h, p_h) = 0$, which implies that the $\vec{u}_h^{\perp} \in \mathbf{X}_0^h(\Omega_h)$ is indeed in $\mathbf{V}_0^{h\perp}(\Omega_h)$. Therefore for all $p_h \in S^h(\Omega_h)$, (3.30) associates a vector $\vec{u}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$.

With these spaces we can write the Stokes problem in a different equivalent way; i.e., given $\vec{f} \in H^{-1}(\Omega_h)$, find $(\vec{u}_h^{'}, \vec{u}_h, \vec{u}_h^{\perp}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$, which solves the following system:

$$\begin{cases} \nu a(\vec{u}_h^{'}, \vec{v}_h) = (\vec{f}, \vec{v}_h) \qquad \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h), \\ a(\vec{u}_h^{\perp}, \vec{v}_h^{\perp}) = (\vec{u}_h^{'}, \vec{v}_h^{\perp})_1 \qquad \forall \vec{v}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h), \\ \vec{u}_h^{'} = \vec{u}_h + \vec{u}_h^{\perp}. \end{cases} \tag{3.31}$$

The second equation in (3.31) can be seen as a projection of $\vec{u}_h^{'}$ over the space $\mathbf{V}_0^{h\perp}$ or the Schur complement equation for the pressure. The system in (3.31) is an uncoupled system of equations in the sense that we can solve first for the variable $\vec{u}_h^{'}$, then for the variable $\vec{u}_h^{\perp}$, and finally for $\vec{u}_h$. It is clear that $\vec{u}_h$ is in $\mathbf{V}_0^h(\Omega_h)$ since the second equation in (3.31) implies that

$$(\vec{u}_h, \vec{v}_h^{\perp})_1 = (\vec{u}_h^{'} - \vec{u}_h^{\perp}, \vec{v}_h^{\perp})_1 = (\vec{u}_h^{'} \vec{v}_h^{\perp})_1 - (\vec{u}_h^{\perp}, \vec{v}_h^{\perp})_1 = 0$$

for all $\vec{v}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$. It is also clear that the solution of the second equation cannot be done easily since this involves the construction of basis functions in the space $\mathbf{V}_0^{h\perp}(\Omega_h)$. However, the formulation in (3.31) is very useful from the theoretical point of view, especially in the analysis of algorithms that relax the incompressibility constraints. The equivalence between these two forms of the Stokes system is a consequence of the LBB inf-sup hypothesis [11] and is stated in the following theorem.

THEOREM 3.5. *The solution* $(\vec{u}_h, \vec{u}_h^{\perp}) \in \times \mathbf{V}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$ *in* (3.31) *solves*

$$\begin{cases} \nu a(\vec{u}_h, \vec{v}_h) + b(p_h, \vec{v}_h) = (\vec{f}_h, \vec{v}_h) & \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h), \\ b(r_h, \vec{u}_h) = 0 & \forall r_h \in P_0^h(\Omega_h), \end{cases} \tag{3.32}$$

with p_h *defined by* (3.29)*, and conversely, if* $(\vec{u}_h, p_h) \in \mathbf{V}_0^h(\Omega_h) \times S_0^h(\Omega_h)$ *is a solution of* (3.32)*, then it solves* (3.31) *with* $\vec{u}_h^{\perp}$ *defined by* (3.30).

Proof. If $(\vec{u}_h, \vec{u}_h^{\perp}) \in \mathbf{V}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$ solves (3.31) with p_h defined by (3.29), we have $\vec{u}_h \in \mathbf{V}_0^h$, $b(r_h, \vec{u}_h) = 0$ for all $r_h \in P_0^h(\Omega_h)$, and $\vec{u}_h^{'} = \vec{u}_h + \vec{u}_h^{\perp}$, namely,

$$\nu a(\vec{u}_h^{'}, \vec{v}_h) = \nu a(\vec{u}_h + \vec{u}_h^{\perp}, \vec{v}_h) = \nu a(\vec{u}_h, \vec{v}_h) + \nu a(\vec{u}_h^{\perp}, \vec{v}_h) = \nu a(\vec{u}_h, \vec{v}_h) + b(p_h, \vec{u}_h)$$

which implies that $(\vec{u}_h, p_h)$ solves (3.32).

Conversely, if $(\vec{u}_h, p_h)$ solves (3.32) with (3.30) and $\vec{u}_h^{'} = \vec{u}_h + \vec{u}_h^{\perp}$, then from the first equation we obtain

$$a(\vec{u}_h^{'}, \vec{v}_h) = (\vec{f}, \vec{v}_h) \qquad \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h). \tag{3.33}$$

If we set $\vec{v}_h = \vec{v}_h^{\perp} \in \mathbf{V}_0^{\perp}(\Omega_h)$, the first equation in (3.32) and the above equation give

$$a(\vec{u}_h^{\perp}, \vec{v}_h^{\perp}) = (\vec{u}_h, \vec{v}_h^{\perp})_1 \qquad \forall \vec{v}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h), \tag{3.34}$$

which proves the theorem. ∎

The formulation in (3.31) can be seen as a simple change of the variable p_h in the Stokes formulation. There is no advantage in this formalism from the numerical point of view, but in the formulation (3.31) the system can now be solved in sequence and the divergence-free constraint can be relaxed during the iteration.

In order to prove convergence for our algorithm we should be able to decompose the global problem into a sequence of local subproblems over the projection subspaces. First we state a space decomposition theorem which allows us to search the solution of the original Stokes problem in the projection spaces.

THEOREM 3.6. *Let* Ω_h *be a bounded simply connected domain with polygonal boundary and let* Ω_h^i, $i = 1, 2, \ldots, m$, *be a sequence of overlapping subdomains obtained by clustering blocks of elements of type A or B such that* $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cdots \Omega_h^m$ *and* $\mathbf{X}_0^1(\Omega_h) = \mathbf{X}_0^h(\Omega_h^1) + \mathbf{X}_0^h(\Omega_h^2) + \mathbf{X}_0^h(\Omega_h^3) \cdots \mathbf{X}_0^h(\Omega_h^m)$. *Let* $\mathbf{V}_0^{h\perp}(\Omega_h^i)$ *be the orthogonal space to the divergence-free function space* $\mathbf{V}_0^h(\Omega_h^i)$ *in* $\mathbf{X}_0^h(\Omega_h^i)$ *with respect to the inner product* $(\cdot, \cdot)_1$ *over* Ω_h^i. *Then we have that* $\mathbf{V}_0^{h\perp}(\Omega_h) = \mathbf{V}_0^{h\perp}(\Omega_h^1) + \mathbf{V}_0^{h\perp}(\Omega_h^2) + \mathbf{V}_0^{h\perp}(\Omega_h^3) + \cdots + \mathbf{V}_0^{h\perp}(\Omega^m)$.

Proof. First consider the case for $m = 2$. Let $\vec{u}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h)$. Since the domains are overlapping in the space $\mathbf{X}_0^h(\Omega_h)$ we can write $\vec{u}_h^{\perp} = \vec{u}_1 + \vec{u}_2$ with $\vec{u}_i \in \mathbf{X}_0^h(\Omega_h^i)$, $i = 1, 2$. The vector $\vec{u}_1$ can be decomposed in $\mathbf{X}_0^h(\Omega_h^1)$ as $\vec{u}_1 = \vec{u}_1^{\perp} + \vec{u}_1^o$, with $\vec{u}_1^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h^1)$ and $\vec{u}_1^o \in \mathbf{V}_0^h(\Omega_h^1)$.

Consider the zero extension $\vec{w}_1^{\perp}$ and $\vec{w}_1^o$ to Ω^h of $\vec{u}_1^{\perp}$ and $\vec{u}_1^o$. The vectors $\vec{w}_1^{\perp}$ and $\vec{w}_1^o$ are in $\mathbf{V}_0^{h\perp}(\Omega_h)$ and $\mathbf{V}_0^h(\Omega_h)$, respectively. The extension of $\vec{w}_1$ of $\vec{u}_1$ to Ω_h can be written as $\vec{w}_1 = \vec{w}_1^{\perp} + \vec{w}_1^o$.

In a similar way we can decompose $\vec{u}_2 = \vec{u}_2^{\perp} + \vec{u}_2^o$ with $\vec{u}_2^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h^2)$ and $\vec{u}_1^o \in \mathbf{V}_0^h(\Omega_h^1)$. The extension of $\vec{w}_2$ of $\vec{u}_2$ to Ω_h can be written as $\vec{w}_2 = \vec{w}_2^{\perp} + \vec{w}_2^o$, where $\vec{w}_2^{\perp}$ and $\vec{w}_2^o$ are the corresponding extensions. From the hypothesis we have that $\vec{u}_h^{\perp} = \vec{u}_1 + \vec{u}_2$, and therefore $\vec{u}_2 = \vec{u}_h^{\perp} - \vec{u}_1$ and $\vec{w}_2 = \vec{u}_h^{\perp} - \vec{w}_1$. The unique decomposition of $\vec{w}_2$ over the subspaces $\mathbf{V}_0^{h\perp}(\Omega_h)$ and $\mathbf{V}_0^h(\Omega_h)$ implies that $\vec{u}_2^o = -\vec{u}_1^o$ and that $\vec{u}_1^o = \vec{w}_1^o$ is zero over $\Omega_h - (\Omega_h^1 \cap \Omega_h^2)$. Therefore $\vec{u}_1^{\perp} = \vec{u}_1 - \vec{u}_1^o \in \mathbf{V}_0^{h\perp}(\Omega_h^1)$

and $\vec{u}_2^{\perp} = \vec{u}_h^{\perp} - \vec{u}_1 + \vec{u}_1^{\,o} \in \mathbf{V}_0^{h\perp}(\Omega_h^2)$ gives the desired decomposition $\vec{u}_h^{\perp} = \vec{u}_1^{\perp} + \vec{u}_2^{\perp}$. For any m the theorem can be proved by induction using the case $m = 2$ and standard techniques [15, 16, 11]. ∎

Let T_i^h, P_i^h, and Π_i^h denote the orthogonal projections from $\mathbf{X}_0^h(\Omega_h)$, $\mathbf{V}_0^h(\Omega_h)$, and $\mathbf{V}_0^{h\perp}(\Omega_h)$ onto $\mathbf{X}_0^h(\Omega_h^i)$, $\mathbf{V}_0^h(\Omega_h^i)$, and $\mathbf{V}_0^{h\perp}(\Omega_h^i)$ with respect to the inner product $(\cdot,\cdot)_1$ defined by the operator $a(\cdot,\cdot)$. The projection $T_i^h\vec{u}_h$, $P_i^h\vec{u}_h$, and $\Pi_i^h\vec{u}_h$ of $\vec{u}_h$ onto $\mathbf{X}_0^h(\Omega_h^i)$, $\mathbf{V}_0^h(\Omega_h^i)$, and $\mathbf{V}_0^{h\perp}(\Omega_h^i)$ is defined by

$$\begin{aligned} &a(T_i^h\vec{u}_h, \vec{v}_h) = a(\vec{u}_h, \vec{v}_h) \qquad \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h^i),\\ &a(P_i^h\vec{u}_h, \vec{v}_h^{\perp}) = a(\vec{u}, \vec{v}_h^{\perp}) \qquad \forall \vec{v}_h^{\perp} \in \mathbf{V}_0^h(\Omega_h^i),\\ &a(\Pi_i^h\vec{u}_h, \vec{v}_h^{\perp}) = a(\vec{u}, \vec{v}_h^{\perp}) \qquad \forall \vec{v}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h^i), \end{aligned}$$

respectively.

It is possible to prove that the iterative application of these operators leads to a contraction in norm $|\cdot|_1$.

THEOREM 3.7. *Let Ω_h be a bounded simply connected domain with polygonal boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type B with boundary such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$. Let T_i^h, P_i^h, and Π_i^h be the orthogonal projections from $\mathbf{X}_0^h(\Omega_h), \mathbf{V}_0^h(\Omega_h)$, and $\mathbf{V}_0^{h\perp}(\Omega_h)$ onto $\mathbf{X}_0^h(\Omega_h^i), \mathbf{V}_0^h(\Omega_h^i)$, and $\mathbf{V}_0^{h\perp}(\Omega_h^i)$, respectively, for $i = 1, 2, \ldots, m$. Then $|\Pi_{i=1}^m(I - T_i)|_1 < 1$, $|\Pi_{i=1}^m(I - P_i)|_1 < 1$ and $|\Pi_{i=1}^m(I - \Pi_i)|_1 < 1$.*

Proof. The proof can follow the approach used in Theorem 2.4 or 3.2. Let $\mathbf{V}^h(\Omega_h)$ be a closed subspace of $\mathbf{X}_0^h(\Omega_h)$ such that $\mathbf{V}^h(\Omega_h) = \mathbf{V}^h(\Omega_h^1) + \mathbf{V}^h(\Omega_h^2) + \cdots + \mathbf{V}^h(\Omega_h^m)$ with $\mathbf{V}^h(\Omega_h^i) \subseteq \mathbf{X}_0^h(\Omega_h^i)$ for $i = 1, 2, \ldots, m$. Here $\mathbf{V}^h$ could be $\mathbf{X}_0^h$, $\mathbf{V}_0^h$, or $\mathbf{V}_0^{h\perp}$. Given $\vec{f} \in H^{-1}(\Omega_h)$, consider the solution $\widehat{u}_h \in \mathbf{V}^h(\Omega_h)$ of the discrete Laplace equation

$$a(\widehat{u}_h, \widehat{v}_h) = \langle \vec{f}, \widehat{v}_h \rangle \qquad \forall \widehat{v}_h \in \mathbf{V}(\Omega_h), \tag{3.35}$$

with homogeneous Dirichlet boundary condition or the equivalent minimization problem

$$\widehat{u}_h = \min_{\widetilde{u} \in \mathbf{V}^h(\Omega_h)} \left(\frac{1}{2}(A\widetilde{u}_h, \widetilde{u}_h) - \langle \vec{f}, \widetilde{u}_h \rangle + \frac{1}{2}\langle A^{-1}\vec{f}, \vec{f} \rangle \right), \tag{3.36}$$

where the constant $\frac{1}{2}\langle A^{-1}\vec{f}, \vec{f}\rangle$ is introduced in order to vanish the functional at the critical point $\widetilde{u}_h = \widehat{u}_h$. The natural approach is to minimize (3.36) over the sequence of domains Ω_h^i in the space $\mathbf{V}^h(\Omega_h^i)$ for $i = 1, 2, \ldots, m$. Let $\widehat{u}_h^{i-1}$ be the solution of the minimization problem over the whole domain Ω_h at step $i - 1$ and let R_i^h be the projector from $\mathbf{V}^h(\Omega_h)$ onto $\mathbf{V}^h(\Omega_h^i)$. By proceeding as in Theorem 2.4 we have $|\Pi_{i=1}^m (I - R_i^h)|_1 < 1$. ∎

Now we are ready to state a convergence theorem for the Stokes problem. If a subdomain of type B is used, the classical Stokes formulation must be modified since the divergence-free constraint is not satisfied at each iteration. The formulation in (3.32) can be used where the solution is written in the variables $\vec{u}_h^{\,'}$ and $\vec{u}_h^{\perp}$ (which represents the pressure distribution).

THEOREM 3.8. *Let Ω_h be a bounded simply connected domain with polygon boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type B such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$. Let the jth smoothing step $(\widehat{u}_h^{\,'j,m}, \widehat{u}_h^{\perp j,m}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$ be defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$ with $\widehat{u}_h^{\,'j,0} = \widehat{u}_h^{\,'j-1,m} \in \mathbf{X}_0^h(\Omega_h)$ and $\widehat{u}_h^{\perp j,0} = \widehat{u}_h^{\perp j-1,m} \in \mathbf{V}_0^{h\perp}(\Omega_h)$.*

Let the global sequence be defined by $\widehat{u}_h^{'j,i} = \vec{w}_h^{'i} + \widehat{u}_h^{'j,i-1}$, $\widehat{u}_h^{\perp j,i} = \vec{z}_h^{\perp i} + \widehat{u}_h^{\perp j,i-1}$ *over* Ω_h^i *and* $\widehat{u}_h^{'j,i} = \widehat{u}_h^{'j,i-1}$, $\widehat{u}_h^{\perp j,i} = \widehat{u}_h^{\perp j,i-1}$ *over* $\Omega_h - \Omega_h^i$ $(i = 1, \ldots, m)$, *where* $(\vec{w}_h^{'i}, \vec{z}_h^{\perp i}) \in \mathbf{X}_0^h(\Omega_h^i) \times \mathbf{V}_0^{h\perp}(\Omega_h^i)$ *solves the local problem*

$$(3.37)\quad \begin{cases} \nu a(\vec{w}_h^{'i}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}^i \rangle - \nu a(\vec{u}_h^{'j,i-1}, \vec{v}_h^i) \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i), \\ a(\vec{z}_h^{\perp i}, \vec{v}_h^{\perp i}) = a(\vec{w}_h^{'i}, \vec{v}_h^{\perp i}) + a(\widehat{u}_h^{'j,i-1}, \vec{v}_h^{\perp i}) - a(\widehat{u}_h^{\perp j,i-1}, \vec{v}_h^{\perp i}) \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall \vec{v}_h^{\perp i} \in \mathbf{V}_0^{h\perp}(\Omega_h^i), \end{cases}$$

with boundary condition $\vec{w}_0^{'i} = 0$ *over* Γ_h^i.

Given $(\widehat{u}_h^{'0,0}, \widehat{u}_h^{\perp 0,0}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$, *then the global sequence* $(\widehat{u}_h^{'j,m}, \widehat{u}^{\perp j,m})$ *converges* $(j \to \infty)$ *to the solution of the Stokes problem in* (3.32).

Proof. At the smoothing step j and iteration over Ω^i in (3.37) we have

$$\nu a(\vec{w}_h^{'i}, \vec{v}_h^i) + \nu a(\widehat{u}_h^{'j,i-1}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i).$$

Let $\vec{u}_h^{'}$ be the solution of the Stokes problem in (3.31). Then

$$\nu a(\vec{u}_h^{'}, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i),$$

and therefore

$$(3.38)\qquad \nu a(\vec{w}_h^{'i}, \vec{v}_h^i) + \nu a(\widehat{u}_h^{'j,i-1} - \vec{u}_h^{'}, \vec{v}_h^i) = 0.$$

If we set $\vec{e}_h^{'j,i} = \vec{w}_h^{'i} + \widehat{u}_h^{'j,i-1} - \vec{u}_h^{'}$ over Ω_h^i and $\widehat{e}_h^{'j,i-1} = \widehat{u}_h^{'j,i-1} - \vec{u}_h^{'}$ over Ω_h, the solution of (3.38) is

$$\vec{e}^{\,'j,i} = (I - T_i^h)\, \widehat{e}_h^{'j,i-1}.$$

The global error $\widehat{e}_h^{'j,i}$ over Ω_h satisfies

$$(3.39)\qquad \widehat{e}^{\,'j,i} = (I - T_i^h)\, \widehat{e}_h^{'j,i-1}.$$

Now consider the second equation in (3.37). We have

$$a(\vec{z}^{\perp i} - \vec{w}^{\,'i}, \vec{v}_h^{\perp i}) + a(\widehat{u}^{\perp j,i-1} - \widehat{u}^{\,'j,i-1}, \vec{v}_h^{\perp i}) = 0.$$

Let $\vec{r}_h^{j,i} = \vec{z}^{\perp i} - \vec{w}^{\,'i} \in \mathbf{X}_0^h(\Omega_h^i)$ and $\widehat{r}_h^{j,i-1} = \widehat{u}^{\perp j,i-1} - \widehat{u}^{\,'j,i-1}$ over Ω_h. Then the solution error for $\vec{r}_h^{j,i}$ is given by

$$\vec{r}_h^{j,i} = (I - \Pi_i^h)\, \widehat{r}_h^{j,i-1}.$$

If we extend the function $\vec{r}_h^{j,i}$ to Ω_h^i, then the extension $\widehat{r}_h^{j,i}$ satisfies

$$(3.40)\qquad \widehat{r}_h^{j,i} = (I - \Pi_i^h)\, \widehat{r}_h^{j,i-1}.$$

Since (3.39)–(3.40) are true for all i and j, then

$$(3.41)\qquad \widehat{e}_h^{'j,m} = (I - T_m^h)(I - T_{m-1}^h)(I - T_{m-2}^h) \cdots (I - T_2^h)(I - T_1^h)\, \widehat{e}_h^{'j,0},$$

$$(3.42)\qquad \widehat{r}_h^{j,m} = (I - \Pi_m^h)(I - \Pi_{m-1}^h)(I - \Pi_{m-2}^h) \cdots (I - \Pi_2^h)(I - \Pi_1^h)\, \widehat{r}_h^{j,0}.$$

By using Theorem 3.7 we have $|\widehat{e}_h^{\,'j,m}|_1 < |\widehat{e}_h^{\,'j,0}|_1$ and $|\widehat{r}_h^{j,m}|_1 < |\widehat{r}_h^{j,0}|_1$. Since this is true for all j, then the sequences $|\widehat{e}_h^{\,'j,m}|_1$ and $|\widehat{r}_h^{j,m}|_1$ converge to zero as $j \to \infty$. The sequence $(\widehat{u}_h^{\,'j,m}, \widehat{u}_h^{\perp j,m})$ tends to $(\vec{u}_h^{\,'}, \vec{u}_h^{\perp})$, which is the solution of (3.31). ∎

For elements of type B the Navier–Stokes system must be written in a different form. If we proceed as in the Stokes case, then the problem is reduced to finding $(\vec{u}_h^{\,'}, \vec{u}_h, \vec{u}_h^{\perp}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$, which solves the following system:

$$\begin{cases} \nu a(\vec{u}_h^{\,'}, \vec{v}_h) + c(\vec{u}_h, \vec{u}_h, \vec{v}_h) = (\vec{f}_h, \vec{v}_h) \qquad \forall \vec{v}_h \in \mathbf{X}_0^h(\Omega_h), \\ a(\vec{u}_h^{\perp}, \vec{v}_h^{\perp}) = (\vec{u}_h^{\,'}, \vec{v}_h^{\perp})_1 \qquad \forall \vec{v}_h^{\perp} \in \mathbf{V}_0^{h\perp}(\Omega_h), \\ \vec{u}_h = \vec{u}_h^{\,'} - \vec{u}_h^{\perp}. \end{cases} \tag{3.43}$$

We can solve the Navier–Stokes system above as a sequence of local problems over subdomains of type B. The following theorem states the convergence for small Reynolds numbers.

THEOREM 3.9. *Let Ω_h be a bounded simply connected domain with polygon boundary and let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type B such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$. Let the jth smoothing step $(\widehat{u}_h^{\,'j,m}, \widehat{u}_h^{\perp j,m}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$ be defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$ with $\widehat{u}_h^{\,'j,0} = \widehat{u}_h^{\,'j-1,m} \in \mathbf{X}_0^h(\Omega_h)$ and $\widehat{u}_h^{\perp j,0} = \widehat{u}_h^{\perp j-1,m} \in \mathbf{V}_0^{h\perp}(\Omega_h)$. Let the global sequence be defined by $\widehat{u}_h^{\,'j,i} = \vec{w}_h^{\,'i} + \widehat{u}_h^{\,'j,i-1}$, $\widehat{u}_h^{\perp j,i} = \vec{z}_h^{\perp i} + \widehat{u}_h^{\perp j,i-1}$ over Ω_h^i and $\widehat{u}_h^{\,'j,i} = \widehat{u}_h^{\,'j,i-1}$, $\widehat{u}_h^{\perp j,i} = \widehat{u}_h^{\perp j,i-1}$ over $\Omega_h - \Omega_h^i$ $(i = 1, \ldots, m)$, where $(\vec{w}_h^{\,'i}, \vec{z}_h^{\perp i}) \in \mathbf{X}_0^h(\Omega_h^i) \times \mathbf{V}_0^{h\perp}(\Omega_h^i)$ solves the local problem*

$$\begin{cases} \nu a(\vec{w}_h^{\,'i}, \vec{v}_h^i) + c(\vec{u}_h^i, \vec{u}_h^i, \vec{v}_h^i) = \langle \vec{f}, \vec{v}^{\,i} \rangle - \nu a(\widehat{u}_h^{\,'j,i-1}, \vec{v}_h^i) \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i), \\ a(\vec{z}_h^{\perp i}, \vec{v}_h^{\perp i}) + a(\widehat{u}_h^{\perp j,i-1}, \vec{v}_h^{\perp i}) = (\vec{w}_h^{\,'i}, \vec{v}_h^{\perp i})_1 + (\widehat{u}_h^{\,'j,i-1}, \vec{v}_h^{\perp i})_1 \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \forall \vec{v}_h^{\perp i} \in \mathbf{V}_0^{h\perp}(\Omega_h^i), \\ \vec{u}_h^i = \vec{u}_h^{\,'i} - \vec{u}_h^{\perp i}, \end{cases} \tag{3.44}$$

with boundary condition $\vec{w}_0^{\,'i} = 0$ over Γ_h^i.

Given $(\widehat{u}_h^{\,'0,0}, \widehat{u}^{\perp 0,0})_h \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{V}_0^{h\perp}(\Omega_h)$, then the global sequence $(\widehat{u}_h^{\,'j,m}, \widehat{u}^{\perp j,m})$ converges $(j \to \infty)$ to the solution of the Navier–Stokes problem in (3.43).

Proof. For the first equation the estimate can be obtained by using the same techniques as in the continuous case.

Let $\vec{e}_h^{\,'j,i} = \vec{w}_h^{\,'i} + \widehat{u}_h^{\,'j,i-1} - \vec{u}_h^{\,'}$ in Ω_h^i and $\widehat{e}_h^{\,'j,i-1} = \widehat{u}_h^{\,'j,i-1} - \vec{u}_h^{\,'}$ over Ω_h, where $\vec{u}_h^{\,'}$ is the solution of the problem in (3.43). Also let $\widehat{e}_h^{\,'j,i}$ be the extension of $\vec{e}_h^{\,'j,i}$ to Ω_h when the corresponding zero extension of $\vec{w}_h^{\,'i}$ is considered. Following the same steps as in the continuous case we obtain

$$|\widehat{e}_h^{\,'j,m}|_1 < |\widehat{e}_h^{\,'j,0}|_1 \tag{3.45}$$

for all $j = 1, 2, \ldots$ and for small Reynolds numbers. Consider the second equation in the following form:

$$a(\vec{z}_h^{\perp i} - \vec{w}_h^{\,'i}, \vec{v}_h^{\perp i}) + a(\widehat{u}_h^{\perp j,i-1} - \widehat{u}_h^{\,'j,i-1}, \vec{v}_h^{\perp i}) = 0 \qquad \forall \vec{v}_h^{\perp i} \in \mathbf{V}_0^{h\perp}(\Omega_h^i).$$

Let $\vec{r}_h^{\,j,i} = \vec{z}_h^{\perp i} - \vec{w}_h^{\,'i} + \widehat{u}_h^{\perp j,i-1} - \widehat{u}_h^{\,'j,i-1}$ over Ω_h^i and $\widehat{r}_h^{\,j,i-1} = \widehat{u}_h^{\perp j,i-1} - \widehat{u}_h^{\,'j,i-1}$ over Ω_h. If $\widehat{r}_h^{\,j,i}$ is the extension of $\vec{r}_h^{\,j,i}$ obtained with the zero extension of $\vec{z}_h^{\perp i} - \vec{w}_h^{\,'i}$ over

Ω_h, then, following the same steps as in the continuous case, we obtain

$$|\widehat{r}_h^{\,j,m}|_1 < |\widehat{r}_h^{\,j,0}|_1$$

for small Reynolds numbers. By using standard arguments we can conclude that the errors vanish as j tends to infinity. ∎

The Vanka-type smoother of type B in the standard velocity and pressure variable solves the following local problem over the subregion Ω_h^i of type B.

Given the global solution $(\widehat{u}_h^{i-1}, \widehat{p}_h^{i-1}) \in \mathbf{X}_0^h(\Omega_h) \times P_0^h(\Omega_h)$ obtained after solving and updating the solution over the block Ω_h^{i-1}, we solve for the variable $(\vec{w}_h^i, z_h^i) \in \mathbf{X}_0^h(\Omega_h^i) \times P_0^h(\Omega_h^i)$ the following local problem:

$$\left\{\begin{array}{l} \nu a(\vec{w}_h^i, \vec{v}_h^i) + b(\vec{z}_h^i, \vec{v}_h^i) + c(\vec{w}_h^i + \widehat{u}_h^{i-1}, \vec{w}_h^i + \widehat{u}_h^{i-1}, \vec{v}_h^i) \\ \qquad\qquad = \langle \vec{f}, \vec{v}_h^i \rangle - \nu a(\widehat{u}_h^{i-1}, \vec{v}_h^i) - b(\widehat{p}_h^{i-1}, \vec{v}_h^i) \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i), \\ b(\vec{w}_h^i, r_h) = -b(\widehat{u}_h^{i-1}, r_h) \qquad \forall r_h \in P_0^h(\Omega_h^i), \end{array}\right. \tag{3.46}$$

with boundary condition $\vec{w}_h^i = 0$ over Γ_h^i. The update for the solution $(\widehat{u}_h^{j,i}, \widehat{p}_h^{j,i})$ is defined by $(\vec{w}_h^i + \widehat{u}_h^{i-1}, z_h^i + \widehat{p}_h^{i-1})$ over Ω_h^i and by $(\widehat{u}_h^{i-1}, \widehat{p}_h^{i-1})$ over $\Omega_h - \Omega_h^i$.

We remark that only the node inside the block of element of type B must be solved, and therefore the divergence-free constraint is enforced only inside the domain.

The area close to the boundary Γ_h^i is not divergence-free and there the pressure can take the value of the previous iteration. Only when convergence is reached does the value of the pressure match the global solution and the divergence-free constraint is completely enforced.

4. Computational examples. In order to compute the solution of the Navier–Stokes equation we combine standard finite element techniques in conjunction with multigrid methods. It is well known that Vanka smoothers converge slowly, but the combination of these smoothers with multigrid methods shows that they are extremely competitive in both CPU time and accuracy (see [13, 24]). We would like to use rectangular conforming finite elements (standard Taylor–Hood) over the domain Ω_h and a Vanka-type smoother with blocks of type B. By starting at the multigrid coarse level l_0, we subdivide Ω_h into unstructured families of rectangular meshes, T_h^{i,l_0}. Based on the simple element midpoint refinement, different multigrid levels can be constructed to reach the finest multigrid level l. The unique representations of $\vec{u}_{h_l}$ and p_{h_l} as a function of the nodal point values $\vec{u}_l(k_1, n)$ and $p_l(k_2, n)$ ($k_1 = 1, 2, \ldots, nvt$, with nvt = number of velocity nodal points, and $k_2 = 1, 2, \ldots, npt$, with npt = number of pressure nodal points) define the finite element isomorphisms $\Phi_l : U_l \to X^{h_l}$, $\Psi_l : \Pi_l \to S^{h_l}$ between the vector spaces U_l, Π_l of nvt-dimension and npt-dimension vectors and the finite element spaces X^{h_l}, S^{h_l} at the multigrid level l.

Essential elements of a multigrid algorithm are the velocity and pressure prolongation maps

$$P_{l,l-1}(u) : U_{l-1} \to U_l, \qquad P_{l,l-1}(p) : \Pi_{l-1} \to \Pi_l \tag{4.1}$$

and the velocity and pressure restriction operators

$$R_{l-1,l}(u) = P_{l,l-1}^*(u) : U_l \to U_{l-1}, \qquad R_{l-1,l}(u) = P_{l,l-1}^*(u) : \Pi_l \to \Pi_{l-1}. \tag{4.2}$$

Since we would like to use conforming Taylor–Hood finite element approximation spaces we have the nested finite element hierarchies $X^{h_0} \subseteq X^{h_1} \subseteq \cdots \subseteq X^{h_l}$ and

$S^{h_0} \subseteq S^{h_1} \subseteq \cdots \subseteq S^{h_l}$, and the canonical prolongation maps $P_{l,l-1}(u)$, $P_{l,l-1}(p)$ can be obtained simply by

$$P_{l,l-1}(u) = \Phi_{l-1}(\Phi_l^{-1}(u)), \tag{4.3}$$

$$P_{l,l-1}(p) = \Psi_{l-1}(\Psi_l^{-1}(p)). \tag{4.4}$$

Let Ω_h^i, $i = 1, 2, \ldots, m$, be a sequence of overlapping subdomains of type B such that $\Omega_h = \Omega_h^1 \cup \Omega_h^2 \cup \cdots \cup \Omega_h^m$ and the jth smoothing step be defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$. Given the global solution $(\widehat{u}_h^{i-1}, \widehat{p}_h^{i-1}) \in \mathbf{X}_0^h(\Omega_h) \times P_0^h(\Omega_h)$, obtained after solving and updating the solution over the block Ω_h^{i-1}, we solve for $(\vec{w}_h^i, z_h^i) \in \mathbf{X}_0^h(\Omega_h^i) \times P_0^h(\Omega_h^i)$ the following local problem:

$$\begin{cases} \nu a(\vec{w}_h^i, \vec{v}_h^i) + b(\vec{z}_h^i, \vec{v}_h^i) + c(\vec{w}_h^i, \vec{w}_h^i, \vec{v}_h^i) + c(\vec{w}_h^i, \widehat{u}_h^{i-1}, \vec{v}_h^i) \\ \qquad + c(\widehat{u}_h^{i-1}, \vec{w}_h^i, \vec{v}_h^i) = \langle \vec{f}, \vec{v}_h^i \rangle - \nu a(\widehat{u}_h^{i-1}, \vec{v}_h^i) \\ \qquad - b(\widehat{p}_h^{i-1}, \vec{v}_h^i) - c(\widehat{u}_h^{i-1}, \widehat{u}_h^{i-1}, \vec{v}_h^i) \qquad \forall \vec{v}_h^i \in \mathbf{X}_0^h(\Omega_h^i), \\ b(\vec{w}_h^i, r_h) + b(\widehat{u}_h^{i-1}, r_h) = 0 \qquad \forall r_h \in P_0^h(\Omega_h^i), \end{cases} \tag{4.5}$$

with boundary condition $\vec{w}_h^i = 0$ over Γ_h^i. Then the global sequence is defined by $\widehat{u}_h^{j,i} = \vec{w}_h^i + \widehat{u}_h^{i-1}$, $\widehat{p}_h^{j,i} = z_h^i + \widehat{p}_h^{i-1}$ over Ω_h^i and $\widehat{u}_h^{j,i} = \widehat{u}_h^{i-1}$, $\widehat{p}_h^{j,i} = p_h^{i-1}$ over $\Omega_h - \Omega_h^i$ $(i = 1, \ldots, m)$. The jth smoothing step $(\widehat{u}_h^{j,m}, \widehat{p}_h^{j,m}) \in \mathbf{X}_0^h(\Omega_h) \times \mathbf{S}_0^h(\Omega_h)$ is defined by solving iteratively the local system over the domain Ω_h^i for $i = 1, \ldots, m$, with $\widehat{u}_h^{j,0} = \widehat{u}_h^{j-1,m} \in \mathbf{X}_0^h(\Omega_h)$ and $\widehat{p}_h^{j,0} = \widehat{p}_h^{j-1,m} \in \mathbf{S}_0^h(\Omega_h)$.

We solve the coupled system (4.5) exactly, but preconditioner or other iterative methods can be used. However, we remark that the exact solution or the coupled in velocity-pressure solution of (4.5) allows us to solve unconditionally the Stokes problem. In the remainder of the paper we perform two tests to show the stability of the convergence and the capability for parallel computations.

4.1. Convergence test. In this test we compute the solution of the Navier–Stokes system with different Reynolds numbers and by using the iterative method proposed in the previous section when we impose a velocity and pressure test field defined by

$$\begin{cases} \vec{u} = \sin(\pi x)^2 \, \sin(2\pi y), \\ \vec{v} = -\sin(\pi y)^2 \, \sin(2\pi x), \\ p = xy. \end{cases} \tag{4.6}$$

The results are shown in Tables 4.1 and 4.2. As expected this Vanka-type smoother cannot converge around 1000 Reynolds $(1/\nu)$ and therefore the results are given in the range 0–500 Reynolds. However, with this resolution it is possible to compute a solution beyond 10000 Reynolds if the time-dependent Navier–Stokes equation is solved with reasonable small time steps. Also the range of Reynolds numbers can be substantially increased if a regularization term is included in the formulation. In Tables 4.1 and 4.2 the norms of the error between the computed solution and the true solution in (4.6) are shown. The error for the velocity is given in the L^2 and H^1 norms as a function of different Reynolds numbers and different resolutions. The error in pressure is shown only in the L^2 norm. All the results are obtained by using a Vanka-type smoother with block of type B and a V multigrid cycle. The convergence is considered achieved when the multigrid residual norm reaches 10^{-13}.

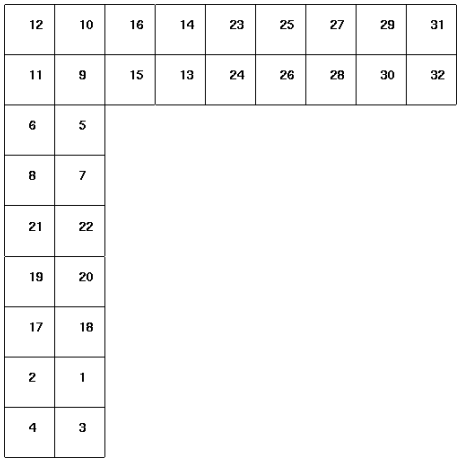

FIG. 4.1. *L-shaped domain configuration at the multigrid low level* l_0.

4.2. L-shaped channel. In this second numerical experiment parallel computations of a flow through an L-shaped channel is presented. The first multigrid level l_0 is the coarse mesh designed to contains all relevant information such as boundary conditions and geometric details and is shown in Figure 4.1. The mesh is an unstructured coarse mesh of rectangular finite elements for P_2/P_1 velocity/pressure representation. The other levels l_i $(i = 1, 2, 3)$ are generated by an unstructured grid generator by

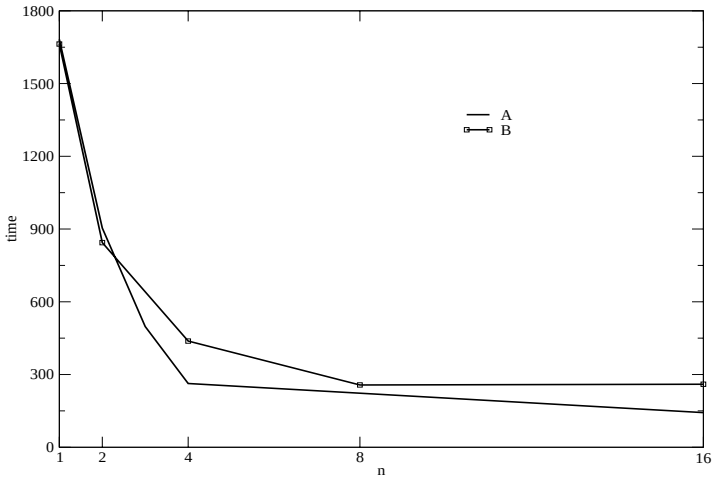

FIG. 4.2. *CPU time (on the left) with exchange at the end of the block relaxation (case A) and at the end of the grid relaxation (case B) as a function of the number n of the CPUs used.*

midpoint refinements. With Vanka-like solvers we can partition the domain and the processor load at the element block over the level l_0 and therefore in a very efficient and flexible way. The processors are distributed in a different way for different cases in order to balance the load and speed up the computations. In this case all the processors are distributed uniformly over the 32 elements of level l_0. Since we have 32 elements in the coarse grid, no more than 32 processors can be used. However, since the communication time should be optimized it is reasonable to use only 16 processors and assign the pair elements along the L-shape to only one processor. We compute and compare the solutions of the problem obtained by using 1, 2, 4, 8, and 16 processors, respectively.

The boundary conditions for this problem are inflow boundary conditions on the bottom with parabolic profile and outflow boundary conditions on the right side. Dirichlet boundary conditions are applied at the rest of the boundary. In the configuration proposed the solution is obtained at the level l_3 by a standard V-cycle multigrid and is stopped when the residual of the linear system is 10^{-13} for the velocity. The reference velocity is 1 m/s, which is the maximum velocity of the parabolic inflow profile at the inlet.

In the Vanka relaxation approach the solution of the multigrid algebraic system requires the solution, block by block, of several small algebraic systems and the iterative update of the solution. We call the solution of this small algebraic system a block relaxation since this operation gives the solutions and the new update for the block unknowns. Since our solving block is based on an element the update between different processor regions can be performed in many ways. In order to minimize the communication among processors the necessary data exchange for the update during the global relaxation can be performed after a fixed number of block relaxations. In this paper we explore the different possibilities by computing the two limiting cases: the data exchange is performed after every element block relaxation (case A) or the data exchange is performed at the end of a global relaxation (grid relaxation) (case B). In Figure 4.2 we show the CPU time and in Figure 4.3 the relative speedup for the parallel computations for these two different communication configurations (cases A

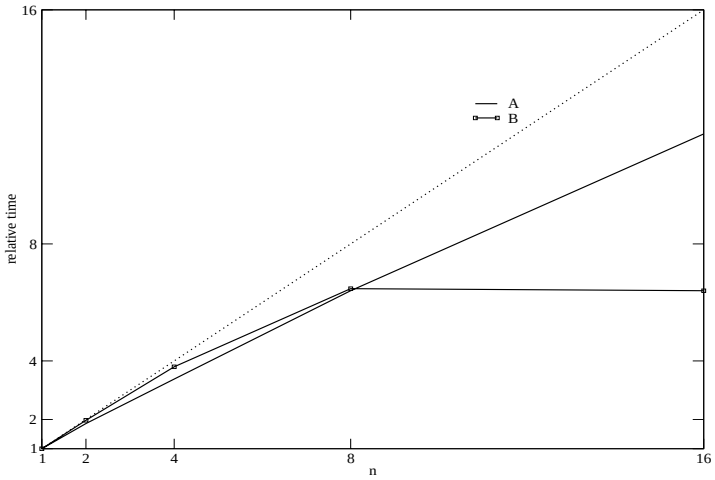

FIG. 4.3. *CPU relative time with exchange at the end of the block relaxation (case A) and at the end of the grid relaxation (case B) as a function of the number n of the CPUs used.*

and B). We note that the use of parallel computing can reduce the time of computation enormously. This test is not intended to show the performance, which can be improved with a real full parallel Vanka smoother, but rather the natural way in which the Vanka-type smoothers can be implemented in the finite element framework. In Figure 4.3 we have the relative speedup as a function of the number of CPUs for cases A and B. All the results are relative to the computation with one single CPU. We note that the relative speedup scales with the number of processors in case A but not in case B. In this case it converges very slowly with this data exchange and the speedup reaches a saturation value. The updating of the solution after a single block relaxation appears to be important for a very fast and regular convergence of the multigrid. However, this could be an effect of the geometry since the domain is divided into very narrow regions. Also we remark that the absolute CPU time is not significantly reduced if the communication is performed at the end of the grid relaxation instead of the end of a single block relaxation. This suggests that the communication time is negligible.

All the computations are performed at 150 Reynolds number in the steady laminar regime. We have performed computation at different Reynolds numbers with similar results.

5. Conclusions. In this paper we have investigated the numerical convergence of a Vanka-type multigrid solver for the Navier–Stokes equations based on the iterative solution of several problems over small overlapping domains. In each iteration step, this smoother requires the solution of several small local subproblems over finite element blocks. We prove that for a particular choice of the block, this method leads to a monotonic convergent algorithm for the steady Stokes problem and that the same algorithm applied to the nonlinear Navier–Stokes equations converges for relative small Reynolds numbers. It is shown that for particular choices for the blocks, the algorithm always converges to the solution of the Stokes problem and, under suitable conditions, to the solution of the Navier–Stokes problem.

FIRST-ORDER SYSTEM LEAST SQUARES FOR GEOMETRICALLY NONLINEAR ELASTICITY*

T. A. MANTEUFFEL†, S. F. MCCORMICK†, J. G. SCHMIDT‡, AND C. R. WESTPHAL§

Abstract. We present a first-order system least-squares (FOSLS) method to approximate the solution to the equations of geometrically nonlinear elasticity in two dimensions. With assumptions of regularity on the problem, we show H^1 equivalence of the norm induced by the FOSLS functional in the case of pure displacement boundary conditions as well as local convergence of Newton's method in a nested iteration setting. Theoretical results hold for deformations satisfying a small strain assumption, a set we show to be largely coincident with the set of deformations allowed by the model. Numerical results confirm optimal multigrid performance and finite element approximation rates of the discrete functional with a total work bounded by about 25 fine-grid relaxation sweeps.

1. Introduction.

The primary goal in the study of elasticity is to model the deformation of an elastic body under applied forces, including both internal body forces, such as gravity, and applied surface tractions. For simplicity, we consider forces whose associated density per unit volume is independent of the deformation. Under these applied forces, the elastic body is said to occupy the deformed configuration and, in the absence of forces, the reference configuration. With this in mind, we may think of the central problem as one of finding the mapping from the reference configuration to the deformed configuration. We refer to this mapping function as the deformation and to the Jacobian of the map as the deformation gradient. Two tensor-valued physical quantities are also of interest: strain and stress. The strain tensor, a completely geometrical quantity, is purely a measure of deviation from the reference configuration, while the stress tensor is directly related to the internal force density across the deformed configuration. While the deformation itself is usually the primary unknown in the study of elasticity, the resulting stress and strain are often of interest as well. In this case, the solution methodology we describe in this paper has a distinct advantage over more traditional approaches.

The partial differential equations that are commonly used to govern the deformation are composed of two main components: the equilibrium equation and a constitutive equation. The equilibrium equation and associated boundary conditions relate a balance of forces in the deformed configuration. But, since the deformed configuration is unknown, the equation is mapped back to the reference configuration. The necessity of this mapping introduces a source of nonlinearity into the equations of elasticity.

The constitutive equation, or material law, as it is sometimes called, relates the stress to the strain, taking the material properties into account. In general, a material law may be designed for a specific material in a specific range of deformations, as is often the case in applications. There can be as many material laws as materials, but we focus here on a general two-parameter linear relationship between the stress and strain. When this approximation is valid for homogeneous, isotropic materials, we call them St. Venant–Kirchhoff materials. To understand the general behavior of the elasticity system, such materials are considered exclusively.

The model we have described here is both three-dimensional and nonlinear. In this paper, we consider the plane strain model of two-dimensional elasticity, which retains the same character as the full three-dimensional problem both physically and mathematically. It is common to linearize this problem about the reference configuration. However, inherent in the linearization of this naturally nonlinear model is the additional assumption that the displacement is small. There are many applications in which this is a valid assumption and the resulting solution remains sufficiently accurate. For example, a structure whose displacement is magnitudes of order smaller than the structure itself may be accurately modeled by this linear approximation. However, when the small displacement assumption is unreasonable, the partial differential equations of linear elasticity should be used with caution. For this reason, we choose to study a more realistic problem.

In [5, 6, 8, 16], the first-order system least-squares (FOSLS) method is applied to the equations of linear elasticity using the displacement gradient as a new variable. A suitable least-squares functional is minimized over finite element subspaces of H^1. This method allows for the displacement gradient and displacement to be approximated in a two-stage algorithm, with full H^1 control on all variables when the solution is sufficiently smooth. More recent methods, developed in [4, 9, 10], use the stress and displacement as primary unknowns for linear elasticity. The stress, which for linear elasticity is naturally in $H(\mathrm{div})$, is approximated in an $H(\mathrm{div})$ conforming space, thereby avoiding the need to consider effects of boundary singularities. Results from these studies show that a least-squares formulation can be effective for elasticity problems.

This leads us to consider a least-squares method for the geometrically nonlinear model of elasticity that relaxes the small displacement assumption while retaining a linear material law, thus widening the scope of problems that can be effectively treated by least-squares methods. In this model, a linear stress-strain relationship is assumed, but the full nonlinear strain-displacement relationship is preserved. Such a formulation is accurate for the "large displacement, small strain" cases. While not necessarily the best model to use for a given material or for configurations with large strain, this is a common model for elastic materials, and certainly more accurate than linear elasticity. See [11] for further background on elasticity theory.

Our general approach is to linearize the equations of elasticity about a current approximation by Newton's method, to reformulate the resulting linear problem as a well-posed least-squares minimization problem, and to let its minimizer become the new approximation. The reference configuration (i.e., zero displacement) is always taken to be the initial approximation. Thus, the first Newton step reduces to the equations of linear elasticity and subsequent steps are corrections thereof. Since the constitutive equation involves products of the unknowns, we focus on using the displacement gradient as the new dependent variable. The stress and strain tensors are then just simple combinations of this new dependent variable and can be computed

in a postprocessing stage with no loss of accuracy. Each Newton step is cast as an appropriate first-order system, and the associated least-squares functional is minimized over an appropriate finite element subspace of $H^1(\Omega)$.

Our approach also employs a two-stage solution process. The first stage solves for the displacement gradients, while the second stage recovers the actual displacement vector. This decoupling of the unknowns in stages is desirable for several reasons. First, when the primary interest is in the stress or strain, the second stage does not need to be performed. Second, if the problem requires several Newton steps, the deformations can be retrieved after the first stage converges. Third, this approach obviates the need to determine relative weights for the stages if they are incorporated into a single functional. Finally, decoupling the variables is somewhat more efficient than solving for them simultaneously.

We define the term H^1 ellipticity to mean H^1 equivalence with the norm induced by the homogeneous FOSLS functional. The focus of much of this paper is on the formulation and efficiency of the first-stage algorithm by establishing H^1 ellipticity of the FOSLS functional for a general linearization step. The second stage is essentially a coupled Poisson problem that is ideally suited for FOSLS and already discussed in some detail in [6, 8].

2. Notation. Throughout this paper, we refer to our Newton-FOSLS algorithm as *linearized elasticity* (linearized about a current approximation) and to the first Newton step as *linear elasticity* (linearized about the reference configuration). This is not strictly standard convention, but one we find convenient in what follows.

Vector $\mathbf{u}$ and matrix $\mathbf{U}$ are represented componentwise by

$$\mathbf{u} = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \quad \text{and} \quad \mathbf{U} = \begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix}.$$

The gradient of scalar p and vector $\mathbf{u}$ are given by

$$\nabla p = \begin{pmatrix} \partial_x p \\ \partial_y p \end{pmatrix} \quad \text{and} \quad \nabla \mathbf{u} = \begin{pmatrix} \partial_x u_1 & \partial_y u_1 \\ \partial_x u_2 & \partial_y u_2 \end{pmatrix}.$$

Define the respective divergence, curl, and trace operators by

$$\nabla \cdot \mathbf{u} = \partial_x u_1 + \partial_y u_2, \quad \nabla \cdot \mathbf{U} = \begin{pmatrix} \partial_x U_{11} + \partial_y U_{12} \\ \partial_x U_{21} + \partial_y U_{22} \end{pmatrix},$$
$$\nabla \times \mathbf{U} = \begin{pmatrix} \partial_x U_{12} - \partial_y U_{11} \\ \partial_x U_{22} - \partial_y U_{21} \end{pmatrix}, \quad \text{and} \quad \operatorname{tr}(\mathbf{U}) = U_{11} + U_{22}.$$

Also, denoting the formal adjoint of the curl operator by $\nabla^\perp$, we define

$$\nabla^\perp p = \begin{pmatrix} \partial_y p \\ -\partial_x p \end{pmatrix} \quad \text{and} \quad \nabla^\perp \mathbf{u} = \begin{pmatrix} \partial_y u_1 & -\partial_x u_1 \\ \partial_y u_2 & -\partial_x u_2 \end{pmatrix}.$$

We extend the respective outward unit normal and counterclockwise unit tangential operators, $\mathbf{n}\cdot$ and $\boldsymbol{\tau}\cdot$, componentwise to block column vectors and matrices in the natural way:

$$\mathbf{n} \cdot \mathbf{U} = \begin{pmatrix} n_x U_{11} + n_y U_{12} \\ n_x U_{21} + n_y U_{22} \end{pmatrix} \quad \text{and} \quad \boldsymbol{\tau} \cdot \mathbf{U} = \begin{pmatrix} \tau_x U_{11} + \tau_y U_{12} \\ \tau_x U_{21} + \tau_y U_{22} \end{pmatrix}.$$

We also note that $n_x = \tau_y$ and $n_y = -\tau_x$, and that $\mathbf{n} \cdot \nabla = -\boldsymbol{\tau} \cdot \nabla^\perp$.

We use standard notation for Sobolev spaces $H^k(\Omega)^d$, corresponding inner product $(\cdot,\cdot)_{k,\Omega}$, and norm $\|\cdot\|_{k,\Omega}$ for $k \geq 0$. We drop subscript Ω and superscript d when the domain and dimension are clear by context. For noninteger k, $H^k(\Omega)$ is the interpolation space between $H^{\lfloor k \rfloor}(\Omega)$ and $H^{\lceil k \rceil}(\Omega)$ as in [17]. The case of $k = 0$ corresponds to the Lebesgue measurable space, $L^2(\Omega)$, in which case we generally denote the norm and inner product by $\|\cdot\|$ and $\langle \cdot, \cdot \rangle$, respectively. Define the subspaces of $L^2(\Omega)$ induced by the divergence and the curl of vector $\mathbf{u}$ by

$$H(\mathrm{div}) = \{\mathbf{u} \in L^2(\Omega) : \|\nabla \cdot \mathbf{u}\| < \infty\},$$
$$H(\mathrm{curl}) = \{\mathbf{u} \in L^2(\Omega) : \|\nabla \times \mathbf{u}\| < \infty\},$$

with norms

$$\|\mathbf{u}\|^2_{H(\mathrm{div})} = \|\mathbf{u}\|^2 + \|\nabla \cdot \mathbf{u}\|^2,$$
$$\|\mathbf{u}\|^2_{H(\mathrm{curl})} = \|\mathbf{u}\|^2 + \|\nabla \times \mathbf{u}\|^2.$$

Denote by $C^k(\Omega)$ the space of k times continuously differentiable functions on Ω, an open set in $\mathbb{R}^2$. The boundary of Ω, denoted by $\partial\Omega$, is of class C^k if it satisfies the conditions of a Lipschitz boundary (see [20]) and is the union of the graphs of a finite number of C^k functions. We say that $\partial\Omega$ is a $C^{k,l}$ boundary when it is Lipschitz and is the graph of the union of a finite number of Hölder continuous $C^{k,l}$ functions.

We also make use of the following general inequalities:

$$|a|^2 + |b|^2 \leq |a+b|^2 \leq 2(|a|^2 + |b|^2). \tag{2.1}$$

3. The nonlinear problem. Let Ω be a bounded open connected subset of $\mathbb{R}^2$ with boundary $\partial\Omega$, which is partitioned into displacement, Γ_D, and traction, Γ_T, segments ($\bar{\Gamma}_D \cup \bar{\Gamma}_T = \partial\Omega$ and $\Gamma_D \cap \Gamma_T = \emptyset$). For simplicity, we assume that the displacements vanish on Γ_D, as is often the case in practice. The geometrically nonlinear elasticity equations may be written as

$$\begin{cases} \nabla \cdot [(\mathbf{I} + \nabla \mathbf{u})\Sigma] = \mathbf{f} & \text{in} \quad \Omega, \\ \mathbf{n} \cdot [(\mathbf{I} + \nabla \mathbf{u})\Sigma] = \mathbf{g} & \text{on} \quad \Gamma_T, \\ \mathbf{u} = \mathbf{0} & \text{on} \quad \Gamma_D, \end{cases} \tag{3.1}$$

where the material law,

$$\Sigma = \Sigma(\mathbf{E}) = \lambda \mathrm{tr}(\mathbf{E})\mathbf{I} + 2\mu\mathbf{E}, \tag{3.2}$$

is the second Piola–Kirchhoff stress tensor and

$$\mathbf{E} = \mathbf{E}(\nabla \mathbf{u}) = \frac{\mathbf{1}}{\mathbf{2}}(\nabla \mathbf{u} + \nabla \mathbf{u}^{\mathbf{t}} + \nabla \mathbf{u}^{\mathbf{t}} \nabla \mathbf{u}) \tag{3.3}$$

is the Green–St. Venant strain tensor. This problem is often referred to as one for a St. Venant–Kirchhoff material. Again, this describes materials in configurations in which the "large displacement, small strain" assumption is valid.

We may also separate the linear and nonlinear parts of the first equation in (3.1) and write it as

$$\mu \Delta \mathbf{u} + (\lambda + \mu) \nabla \nabla \cdot \mathbf{u} + \nabla \cdot \mathbf{P_3}(\nabla \mathbf{u}) = \mathbf{f}, \tag{3.4}$$

where $\Delta\mathbf{u} = \nabla \cdot \nabla\mathbf{u}$ is the vector Laplacian of $\mathbf{u}$ and $\mathbf{P_3}(\nabla\mathbf{u})$ is the following matrix of degree 3 polynomials of the components of $\nabla\mathbf{u}$:

$$\mathbf{P_3}(\mathbf{X}) = \frac{1}{2}\lambda\left(\mathrm{tr}(\mathbf{X}^t\mathbf{X})\mathbf{I} + \mathrm{tr}(\mathbf{X} + \mathbf{X}^t + \mathbf{X}^t\mathbf{X})\mathbf{X}\right) + \mu\left(\mathbf{X}^2 + \mathbf{X}^t\mathbf{X} + \mathbf{X}\mathbf{X}^t + \mathbf{X}\mathbf{X}^t\mathbf{X}\right).$$

The linear part of the left-side operator in (3.4) is simply the linear elasticity equations, and the nonlinear part can be thought of as a perturbation that begins to dominate as $\nabla\mathbf{u}$ becomes large compared to $\mathbf{u}$.

The unknown, $\mathbf{u}$, is the usual displacement vector. We assume that the Lamé constants, λ and μ, are bounded by satisfying $0 < \mu_0 < \mu < \mu_1$ and $0 < \lambda_0 < \lambda < \lambda_1$, for appropriate positive bounds. Physically, this corresponds to an assumption of compressibility of the material. The more difficult problem of incompressible materials is considered for linear elasticity in [5, 6, 8, 16]. A complete study of the geometrically nonlinear elasticity problem in a least-squares context in the incompressible limit remains an open problem. Without loss of generality, we scale the problem so that $\mu = 1$ and let λ determine the level of compressibility. See section 11 for examples of Lamé constants for different materials.

The case where $\Gamma_T = \emptyset$ corresponds to a pure displacement problem, $\Gamma_D = \emptyset$ a pure traction problem, and otherwise a mixed boundary condition problem.

4. Existence and uniqueness of solutions. In this section, we establish existence and uniqueness results that confirm well-posedness of system (3.1). We restrict ourselves here to the pure displacement problem on domains with sufficiently smooth data and boundaries (see Remark 4.3 at the end of this section).

Let ∂ represent either first partial derivative, ∂_x or ∂_y, and suppose $\delta > 0$ and $k \geq 0$. The following lemma addresses smoothness of products of functions in $H^{1+\delta}(\Omega)$ and $H^{1+k}(\Omega)$.

LEMMA 4.1. *Let Ω be a bounded Lipschitz domain in $\mathbb{R}^2$. Then there exists a constant, C, depending only on Ω, such that, for $u \in H^{1+\delta}(\Omega)$ and $v \in H^{1+k}(\Omega)$, the product uv satisfies*

$$\|uv\|_{1+k} \leq C\|u\|_{1+\delta}\|v\|_{1+k},$$
$$\|\partial(uv)\|_k \leq C\|u\|_{1+\delta}\|v\|_{1+k}.$$

Proof. This is a consequence of the Sobolev imbedding theorem, and a proof can be seen in Chapter 1 of [14]. ∎

The following theorem establishes criteria for existence and uniqueness of solutions to problem (3.1).

THEOREM 4.2. *Let Ω be a domain in $\mathbb{R}^2$ with boundary of class C^{2+m} for some $m > 0$. Then there exists a neighborhood, $\mathcal{Q}_0^m$, of the origin in $H^m(\Omega)$ and a neighborhood, $\mathcal{U}_0^{1+m}$, of the origin in $\mathcal{U}^{1+m} = \{\nabla\mathbf{v} : \mathbf{v} \in H^{2+m}(\Omega), \mathbf{v} = \mathbf{0} \text{ on } \partial\Omega\} \subset H^{1+m}(\Omega)$ such that for each $\mathbf{f} \in \mathcal{Q}_0^m$, the boundary value problem*

$$\mathcal{L}(\nabla\mathbf{u}) := \nabla \cdot [(\mathbf{I} + \nabla\mathbf{u})\Sigma(\mathbf{E}(\nabla\mathbf{u}))] = \mathbf{f} \tag{4.1}$$

has exactly one solution, $\nabla\mathbf{u}^*$, in $\mathcal{U}_0^{1+m}$.

Proof. We observe that nonlinear operator $\mathcal{L}$ maps $\nabla\mathbf{u} \in H^{1+m}(\Omega)$ into $H^m(\Omega)$ by applying Lemma 4.1, and that $\mathcal{L}$ is differentiable between these spaces (in fact, all derivatives of order ≥ 4 are zero).

Since $\mathcal{L}(\mathbf{0}) = \mathbf{0}$, we can then apply the implicit function theorem in a neighborhood of the origin in $\mathcal{U}^{1+m} \times H^m(\Omega)$. Thus, we now only need to check that the

derivative of $\mathcal{L}$ at the origin, $\mathcal{L}'(\mathbf{0})$, is bijective between $\mathcal{U}^{1+m}$ and $H^m(\Omega)$ and has continuous inverse.

But $\mathcal{L}'(\mathbf{0})$ is exactly the operator of linear elasticity. It is known that if $\partial\Omega$ is a C^{2+m} boundary and $\mathbf{f} \in H^m(\Omega)$, then there is a unique weak solution to the linear pure displacement problem, $\mathbf{u} \in H^{2+m}(\Omega)$ (see [11]). This immediately implies $\nabla\mathbf{u} \in H^{1+m}(\Omega)$. Thus, we have shown that continuous operator $\mathcal{L}'(\mathbf{0})$ is bijective. Now since $\mathcal{L}'(\mathbf{0})$ is a continuous, bijective, linear map between two Banach spaces, by the closed graph theorem, it must have a continuous inverse.

By the implicit function theorem there is, therefore, a neighborhood, $\mathcal{Q}_0^m$, of the origin in $H^m(\Omega)$ and a neighborhood, $\mathcal{U}_0^{1+m}$, of the origin in $\mathcal{U}^{1+m}$ such that there is a unique solution, $\nabla\mathbf{u}^* \in \mathcal{U}_0^{1+m}$, for any function $\mathbf{f} \in \mathcal{Q}_0^m$. □

Thus, the pure displacement problem with sufficiently smooth data and domain is well-posed, and the solution, $\nabla\mathbf{u}$, remains small in the H^{1+m} norm, with no direct restriction on $\mathbf{u}$ itself. This is consistent with the small strains assumption in the geometrically nonlinear elastic model.

Remark 4.3. We are ultimately interested in nonhomogeneous problems on polygonal domains, which are known to have solutions less smooth than described above. At corner points and/or points of changing boundary condition type on the boundary, a locally weighted norm can be used to remove the effect of the nonsmooth solution. In [19] a weighted-norm least-squares method is developed for problems with boundary singularities. For simplicity, we choose here to focus on the formulation and analysis of the linearized problem since, even for problems lacking full global regularity, we may expect the regularity predicted in Theorem 4.2 away from abruptly changing material interfaces in the interior of Ω for sufficiently smooth data $\mathbf{f}$.

5. Least-squares formulation. We want to replace the nonlinear elasticity problem with a series of linear problems, which we then reformulate as a first-order system. Introducing the deformation, $\boldsymbol{\phi} = \mathbf{x} + \mathbf{u}$, the deformation gradient, $\boldsymbol{\Phi} = \nabla\boldsymbol{\phi}$, and the displacement gradient, $\mathbf{U} = \nabla\mathbf{u}$, we see that problem (3.1) becomes one of finding the zero of

$$\mathcal{F}(\mathbf{U}) = \nabla \cdot \left[\frac{1}{2}\lambda \mathrm{tr}(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})(\mathbf{I} + \mathbf{U}) + (\mathbf{I} + \mathbf{U})(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})\right] - \mathbf{f} \tag{5.1}$$

subject to the constraint

$$\nabla \times \mathbf{U} = \mathbf{0} \tag{5.2}$$

for $\mathbf{U}$ satisfying appropriate boundary conditions (recall also that we assume $\mu = 1$).

The Fréchet derivative of $\mathcal{F}(\mathbf{U})$ in the direction of $\mathbf{V}$ is

$$\begin{aligned}\mathcal{F}'(\mathbf{U})[\mathbf{V}] = \nabla \cdot \Bigg[&\lambda \mathrm{tr}\left(\mathbf{U} + \frac{1}{2}\mathbf{U}^t\mathbf{U}\right)\mathbf{V} + \lambda \mathrm{tr}(\mathbf{V} + \mathbf{V}^t\mathbf{U})(\mathbf{I} + \mathbf{U}) \\ &+ (\mathbf{I} + \mathbf{U})(\mathbf{V} + \mathbf{V}^t + \mathbf{U}^t\mathbf{V} + \mathbf{V}^t\mathbf{U}) + \mathbf{V}(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})\Bigg].\end{aligned} \tag{5.3}$$

Thus, Newton's method for approximating the solution of (5.1) is given by iteratively solving the linear problem

$$\begin{cases} \mathcal{F}'(\mathbf{U}_n)[\mathbf{U}_{n+1}] = \mathcal{F}'(\mathbf{U}_n)[\mathbf{U}_n] - \mathcal{F}(\mathbf{U}_n), \\ \quad \nabla \times \mathbf{U}_{n+1} = \mathbf{0} \end{cases} \tag{5.4}$$

for $\mathbf{U}_{n+1}$, with initial approximation $\mathbf{U}_0 = \mathbf{0}$.

It is convenient to view 2×2 matrices as 4×1 vectors so that general linear operators on such quantities can be written as 4×4 matrices. Thus, define operator $\mathcal{K} : \mathbb{R}^{2\times 2} \to \mathbb{R}^{4\times 1}$ by

$$\mathcal{K}\begin{pmatrix} U_{11} & U_{12} \\ U_{21} & U_{22} \end{pmatrix} = (U_{11}, U_{12}, U_{21}, U_{22})^t$$

for any 2×2 matrix, $(\mathbf{U})_{ij} = U_{ij}$. If A is a 4×4 matrix, then the quantity $A\mathbf{U}$ should be interpreted as $A\mathbf{U} = \mathcal{K}^{-1}(A\mathcal{K}\mathbf{U})$.

With the relation $\mathbf{\Phi} = \mathbf{I} + \mathbf{U}$, we define the following linear operators:

$$M_1(\mathbf{\Phi}) = \begin{pmatrix} \Phi_{11}^2 & \Phi_{11}\Phi_{12} & \Phi_{11}\Phi_{21} & \Phi_{11}\Phi_{22} \\ \Phi_{12}\Phi_{11} & \Phi_{12}^2 & \Phi_{12}\Phi_{21} & \Phi_{12}\Phi_{22} \\ \Phi_{21}\Phi_{11} & \Phi_{21}\Phi_{12} & \Phi_{21}^2 & \Phi_{21}\Phi_{22} \\ \Phi_{22}\Phi_{11} & \Phi_{22}\Phi_{12} & \Phi_{22}\Phi_{21} & \Phi_{22}^2 \end{pmatrix},$$

$$M_2(\mathbf{\Phi}) = (\Phi_{11}^2 + \Phi_{12}^2 + \Phi_{21}^2 + \Phi_{22}^2 - 2)I,$$

$$M_3(\mathbf{\Phi}) = \begin{pmatrix} 3\Phi_{11}^2 + \Phi_{12}^2 + \Phi_{21}^2 & 2\Phi_{11}\Phi_{12} + \Phi_{21}\Phi_{22} & 2\Phi_{11}\Phi_{21} + \Phi_{12}\Phi_{22} & \Phi_{12}\Phi_{21} \\ 2\Phi_{11}\Phi_{12} + \Phi_{21}\Phi_{22} & \Phi_{11}^2 + 3\Phi_{12}^2 + \Phi_{22}^2 & \Phi_{11}\Phi_{22} & \Phi_{11}\Phi_{21} + 2\Phi_{12}\Phi_{22} \\ 2\Phi_{11}\Phi_{21} + \Phi_{12}\Phi_{22} & \Phi_{11}\Phi_{22} & \Phi_{11}^2 + 3\Phi_{21}^2 + \Phi_{22}^2 & \Phi_{11}\Phi_{12} + 2\Phi_{21}\Phi_{22} \\ \Phi_{12}\Phi_{21} & \Phi_{11}\Phi_{21} + 2\Phi_{12}\Phi_{22} & \Phi_{11}\Phi_{12} + 2\Phi_{21}\Phi_{22} & \Phi_{12}^2 + \Phi_{21}^2 + 3\Phi_{22}^2 \end{pmatrix}.$$

Using the relation $\mathbf{\Phi} = \mathbf{I} + \mathbf{U}$ as a change of variables, define the system matrix, A, as a function of $\mathbf{U}$ by

$$A(\mathbf{U}) = \lambda M_1(\mathbf{I} + \mathbf{U}) + \frac{1}{2}\lambda M_2(\mathbf{I} + \mathbf{U}) + M_3(\mathbf{I} + \mathbf{U}) - \mathbf{I}.$$

In this way, we may denote the linear operator in (5.4) as

$$\mathcal{F}'(\mathbf{U})[\mathbf{V}] = \nabla \cdot A(\mathbf{U})\mathbf{V}.$$

Denoting $A_n = A(\mathbf{U}_n)$ and $\mathcal{F}_n = \mathcal{F}(\mathbf{U}_n)$, the Newton step for the $(n+1)$st iterate $\mathbf{U}$ (dropping the subscript) may now be written as

$$\begin{cases} \nabla \cdot A_n\mathbf{U} = \nabla \cdot A_n\mathbf{U}_n - \mathcal{F}_n, \\ \quad \nabla \times \mathbf{U} = \mathbf{0}. \end{cases} \tag{5.5}$$

We may apply an analogous linearization technique to the traction boundary conditions by defining

$$\mathcal{T}(\mathbf{U}) = \mathbf{n} \cdot \left[\frac{1}{2}\lambda \mathrm{tr}(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})(\mathbf{I} + \mathbf{U}) + (\mathbf{I} + \mathbf{U})(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})\right] - \mathbf{g}$$

and letting $\mathcal{T}_n = \mathcal{T}(\mathbf{U}_n)$. The corresponding Newton step for the traction boundaries then becomes

$$\mathbf{n} \cdot A_n\mathbf{U} = \mathbf{n} \cdot A_n\mathbf{U}_n - \mathcal{T}_n \quad \text{on} \quad \Gamma_T. \tag{5.6}$$

Since $\mathbf{u} = \mathbf{0}$ on the displacement boundaries, we may enforce the derivative of $\mathbf{u}$ along those boundaries to be zero:

$$\boldsymbol{\tau} \cdot \mathbf{U} = \mathbf{0} \quad \text{on} \quad \Gamma_D. \tag{5.7}$$

Thus, we may completely decouple the unknowns in $\mathbf{u}$ from the unknowns in $\mathbf{U}$. We concentrate here on the first-stage solution of $\mathbf{U}$, that is, solving the problem for $\mathbf{U}$ and later recovering $\mathbf{u}$, if necessary.

We take the initial approximation for Newton's method to be the reference configuration, $\mathbf{U}_0 = \mathbf{0}$; the system matrix for the first Newton step is

$$A_0 = \begin{pmatrix} \lambda+2 & 0 & 0 & \lambda \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 1 & 0 \\ \lambda & 0 & 0 & \lambda+2 \end{pmatrix};$$

and we can write $\nabla \cdot (A_0 \mathbf{U}_0) - \mathcal{F}_0 = \mathbf{f}$ and $\mathbf{n} \cdot (A_0 \mathbf{U}_0) - \mathcal{T}_0 = \mathbf{g}$. Thus, we may write the first step of Newton's method as

$$\begin{cases} \nabla \cdot (A_0 \mathbf{U}) = \mathbf{f} & \text{in} \quad \Omega, \\ \nabla \times \mathbf{U} = \mathbf{0} & \text{in} \quad \Omega, \\ \boldsymbol{\tau} \cdot \mathbf{U} = \mathbf{0} & \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot (A_0 \mathbf{U}) = \mathbf{g} & \text{on} \quad \Gamma_T. \end{cases} \tag{5.8}$$

This is the form of the linear elasticity equations studied in [5, 8].

System (5.5) depends explicitly on the current approximation to the solution. Specifically, matrix A_n deviates from A_0 as $\mathbf{\Phi}$ deviates from the identity (or, as $\mathbf{U}$ deviates from $\mathbf{0}$). Much is known about the first Newton step because it is exactly the linear elasticity case. For example, assuming sufficient smoothness of the solution, a least-squares functional associated with system (5.8) can be shown to be H^1 elliptic with the aid of Korn's inequality. In fact, this ellipticity property is even retained for a modification of system (5.8) in the incompressible limit in [8]. Existence, uniqueness, and optimal finite element approximation bounds immediately follow (see [5, 8]). For the linearized problem, however, the literature reflects relatively little theory in $W^{k,2}$ Sobolev spaces, and a thorough study of these equations in a least-squares context has, to our knowledge, not been explored. Thus, we are led to develop new theory that establishes well-posedness of, and a fast solution technique for, the linearized equations consisting of (5.5), (5.6), and (5.7).

6. Problem modification. One goal of the least-squares methodology is to develop a functional that is H^1 elliptic whenever possible. It is well known that such systems admit uniform and optimal H^1 approximations when using standard finite elements for the discretization and standard multigrid solvers for the resulting linear system (see [7]). For system (5.5), this poses a challenge because the system matrix, A_n, is generally pointwise indefinite. In this section, we introduce a modification to (5.5) that overcomes this difficulty, and we make a reasonable physical assumption that guarantees positive-definiteness of the modified system matrix. To this end, consider modifying A_n by adding to it a matrix of the form

$$B(c) = \begin{pmatrix} 0 & 0 & 0 & c \\ 0 & 0 & -c & 0 \\ 0 & -c & 0 & 0 \\ c & 0 & 0 & 0 \end{pmatrix},$$

where c is any fixed constant. It is easy to see that $\nabla \cdot B(c) \nabla \mathbf{p} = \mathbf{0}$ for any function $\mathbf{p}$, so the solution to (5.5) is unaffected by replacing A_n with $A_n + B(c)$. (We note,

however, that this modification cannot be applied to the traction boundary conditions given in (5.6).) In [5, 8], this idea is applied with $c = \mu = 1$ in conjunction with a rotation of the unknowns so that the equations of linear elasticity in the incompressible limit mirror the Stokes equations. We apply the same idea here, not to transform the equations to a more well known form, but rather to shift the spectrum to be positive. Indeed, in the linear case, the spectrum of A_0, which is $\{0, 2, 2, 2\lambda+2\}$, can be shifted by $B(1)$ so that the spectrum of $A_0 + B(1)$ becomes $\{1, 1, 1, 2\lambda + 3\}$. Numerical experiments on the spectrum of A_n indicate that a choice of $c = 1$ is also most effective for shifting the spectrum to be positive for general deformations. We now study this question analytically.

Matrix $\tilde{A}_n = A_n + B(1)$ seems to depend on the four linearly independent components of $\mathbf{\Phi}_n$. However, under an appropriate change of variables, the eigenvalues can be exactly expressed in terms of just two scalar functions over Ω:

$$\begin{aligned} \sigma &= \Phi_{11}^2 + \Phi_{12}^2 + \Phi_{21}^2 + \Phi_{22}^2, \\ \delta &= \Phi_{11}\Phi_{22} - \Phi_{12}\Phi_{21}. \end{aligned} \tag{6.1}$$

In fact, the eigenvalues of $\tilde{A}_n$ are as follows:

$$\begin{aligned} \mathbf{\Lambda}_1 &= \frac{1}{2}(\lambda+2)\sigma - \delta - \lambda, \\ \mathbf{\Lambda}_2 &= \frac{1}{2}(\lambda+2)\sigma + \delta - \lambda - 2, \\ \mathbf{\Lambda}_3 &= \left(\lambda + \frac{3}{2}\right)\sigma - (\lambda+1) - \sqrt{\frac{1}{4}(\lambda+3)^2\sigma^2 - (6\lambda+9)\delta^2 + 2\lambda\delta + 1}, \\ \mathbf{\Lambda}_4 &= \left(\lambda + \frac{3}{2}\right)\sigma - (\lambda+1) + \sqrt{\frac{1}{4}(\lambda+3)^2\sigma^2 - (6\lambda+9)\delta^2 + 2\lambda\delta + 1}. \end{aligned} \tag{6.2}$$

That the spectrum can be represented by only two independent quantities is surprising, but that the two quantities have such an obvious physical meaning is remarkable. For example, δ, the determinant of the Jacobian of the mapping of the current approximation, is a local measure of change in volume: $\delta > 1$ indicates areas under tension and $\delta < 1$ indicates areas under compression. Similarly, $\sigma < 2$ when there is significant local compression. In general, we know that in the small strains regime $\sigma \approx 2$ and $0 < \delta \approx 1$.

Since the model for the geometrically nonlinear elasticity equations assumes a deformed configuration with small strains, we may assume small strains of the solution. We show in section 8 that for an initial guess sufficiently close to the solution, each iterate remains bounded near the solution and Newton's method converges. Under these constraints, we take each iterate to satisfy some small strain condition of the form $\|\mathbf{E}\| \ll 1$. We now choose the norm to enforce this condition.

Define the following *Frobenius* norm for tensor-valued quantities:

$$\|\mathbf{X}\|_{Fr}^2 = \sup_{\Omega} \sum_{ij} \left(\mathbf{X}_{ij}\right)^2.$$

Thus, we may write $\|\mathbf{\Phi}\|_{Fr} = \|\sigma\|_\infty$. We can also express the Frobenius norm of the strain tensor exactly in terms of variables σ and δ. We now establish bounds on the strain that guarantee that the modified system matrix is uniformly symmetric positive definite.

Recall that the strain tensor is given by $\mathbf{E}(\mathbf{U}) = \frac{1}{2}(\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U})$. Define

$$\mathcal{S}_\lambda = \left\{ \mathbf{U} : \|\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U}\|_{Fr} < \frac{\sqrt{2}}{\lambda + 3} \right\}$$

as the set of all displacement gradients corresponding to deformations with "small strains." We may choose $\mathcal{Q}_0^m$ small enough to ensure that $\mathbf{f} \in \mathcal{Q}_0^m$ guarantees $\mathbf{U} \in \mathcal{S}_\lambda$. Thus, the condition of small strains follows from the assumptions in Theorem 4.2. We explore the regime of small strains in more detail in section 11.

THEOREM 6.1. *For all* $\mathbf{U} \in \mathcal{S}_\lambda$, *matrix* $\tilde{A} = A(\mathbf{U}) + B(1)$ *is uniformly positive definite over* Ω.

Proof. We directly compute positive lower bounds on each eigenvalue of $\tilde{A}$. For convenience, we work with $\mathbf{\Phi} = \mathbf{I} + \mathbf{U}$, where $\mathbf{U} + \mathbf{U}^t + \mathbf{U}^t\mathbf{U} = \mathbf{\Phi}^t\mathbf{\Phi} - \mathbf{I}$. Let $\varepsilon = \|\mathbf{\Phi}^t\mathbf{\Phi} - \mathbf{I}\|_{Fr}$. By direct computation, we write

$$\varepsilon^2 = (\sigma - 1)^2 - 2\delta^2 + 1. \tag{6.3}$$

We also have

$$\sigma \geq 2\delta \tag{6.4}$$

because $\sigma - 2\delta = (\Phi_1 - \Phi_{22})^2 + (\Phi_{12} + \Phi_{21})^2 \geq 0$. Using (6.4), we can also establish upper and lower bounds on σ in terms of ε. Specifically, $\varepsilon^2 = (\sigma - 1)^2 - 2\delta^2 + 1 \geq (\sigma - 1)^2 - \frac{1}{2}\sigma^2 - 1 = \frac{1}{2}(\sigma - 2)^2$, so

$$2 - \sqrt{2}\varepsilon \leq \sigma \leq 2 + \sqrt{2}\varepsilon. \tag{6.5}$$

Expressions for the eigenvalues of $\tilde{A}$ are given in (6.2). Starting with $\mathbf{\Lambda}_1$ and using (6.4) and (6.5), we obtain

$$\begin{aligned}
\mathbf{\Lambda}_1 &= \frac{1}{2}(\lambda + 2)(\sigma - 2) - \delta + 2 \\
&\geq \frac{1}{2}(\lambda + 2)(\sigma - 2) - \tfrac{1}{2}\sigma + 2 \\
&= \frac{1}{2}(\lambda + 1)\sigma - \lambda \\
&\geq \frac{1}{2}(\lambda + 1)(2 - \sqrt{2}\varepsilon) - \lambda \\
&= 1 - \frac{\sqrt{2}}{2}(\lambda + 1)\varepsilon,
\end{aligned}$$

which is strictly positive when $\varepsilon < \frac{\sqrt{2}}{\lambda+1}$.

Again, using (6.4) and (6.5) along with (6.3), the second eigenvalue satisfies

$$\begin{aligned}
\mathbf{\Lambda}_2 &= \frac{1}{2}(\lambda + 2)(\sigma - 2) + \delta \\
&\geq \frac{1}{2}(\lambda + 2)(2\delta - 2) + \delta \\
&= \delta(\lambda + 3) - (\lambda + 2) \\
&= \frac{\sqrt{2}}{2}((\sigma - 1)^2 + 1 - \varepsilon^2)^{\frac{1}{2}}(\lambda + 3) - (\lambda + 2)
\end{aligned}$$

$$\begin{aligned}
&\geq \frac{\sqrt{2}}{2}((1-\sqrt{2}\varepsilon)^2+1-\varepsilon^2)^{\frac{1}{2}}(\lambda+3)-(\lambda+2)\\
&= \left(1-\sqrt{2}\varepsilon+\frac{1}{2}\varepsilon^2\right)^{\frac{1}{2}}(\lambda+3)-(\lambda+2),
\end{aligned}$$

which is strictly positive when $f(\varepsilon)=\frac{1}{2}\varepsilon^2-\sqrt{2}\varepsilon+1-(\frac{\lambda+2}{\lambda+3})^2>0$. Solving for the roots of $f(\varepsilon)$, we see that $f(\varepsilon)$ is positive for $\varepsilon<\frac{\sqrt{2}}{\lambda+3}$.

The third eigenvalue is more cumbersome to treat and requires a bit more care than the first two. Write $\mathbf{\Lambda}_3 = R-\sqrt{Z}$, where $R=(\lambda+\frac{3}{2})\sigma-(\lambda+1)$ and $Z=\frac{1}{4}(\lambda+3)^2\sigma^2-(6\lambda+9)\delta^2+2\lambda\delta+1$. It can be seen that Z must be nonnegative for $\lambda>0$ by writing

$$\begin{aligned}
Z &= \frac{1}{4}(\lambda+3)^2\sigma^2-(6\lambda+9)\delta^2+2\lambda\delta+1\\
&= \frac{1}{4}\lambda^2\sigma^2+\tfrac{1}{4}(6\lambda+9)(\sigma+2\delta)(\sigma-2\delta)+2\lambda\delta+1\\
&> 0,
\end{aligned}$$

since $\sigma\geq 2\delta$. From the bound on $\mathbf{\Lambda}_2$ and (6.5), we know, for $\lambda>0$, that

$$\sigma \;\geq\; 2-\sqrt{2}\varepsilon \;>\; 2-\sqrt{2}\left(\frac{\sqrt{2}}{\lambda+3}\right) \;>\; \frac{4}{3}$$

and, thus, $R>0$. Therefore, $\mathbf{\Lambda}_3$ is positive when R^2-Z is positive. But we may write

$$\begin{aligned}
R^2-Z &= \left(\lambda+\frac{3}{2}\right)^2\sigma^2-2(\lambda+1)\left(\lambda+\frac{3}{2}\right)\sigma+(\lambda+1)^2\\
&\quad -\frac{1}{4}(\lambda+3)^2\sigma^2+(6\lambda+9)\delta^2-2\lambda\delta-1\\
&\geq \left(\lambda+\frac{3}{2}\right)^2\sigma^2-2(\lambda+1)\left(\lambda+\frac{3}{2}\right)\sigma+(\lambda+1)^2\\
&\quad -\frac{1}{4}(\lambda+3)^2\sigma^2+(6\lambda+9)\delta^2-\lambda\sigma-1\\
&= \left(\lambda+\frac{3}{2}\right)^2\sigma^2-2(\lambda+1)\left(\lambda+\frac{3}{2}\right)\sigma+(\lambda+1)^2\\
&\quad -\frac{1}{4}(\lambda+3)^2\sigma^2+\frac{1}{2}(6\lambda+9)((\sigma-1)^2-\varepsilon^2+1)-\lambda\sigma-1\\
&= \frac{1}{4}(\lambda^2+6\lambda+6)(3\sigma-2)(\sigma-2)+(2\lambda+3)\left(1-\frac{3}{2}\varepsilon\right).
\end{aligned}$$

Since $\sigma>\frac{4}{3}$ implies that the quadratic term in σ, $(3\sigma-2)(\sigma-2)$, is monotonically increasing, we can apply the lower bound in (6.5) to get

$$\begin{aligned}
R^2-Z &\geq \frac{1}{4}(\lambda^2+6\lambda+6)(3\sigma-2)(\sigma-2)+(2\lambda+3)\left(1-\frac{3}{2}\varepsilon\right)\\
&\geq \frac{1}{4}(\lambda^2+6\lambda+6)\left(-\sqrt{2}\varepsilon+\frac{3}{2}\varepsilon^2\right)+(2\lambda+3)\left(1-\frac{3}{2}\varepsilon\right)\\
&= \frac{3}{2}(\lambda^2+4\lambda+3)\varepsilon^2-\sqrt{2}(\lambda^2+6\lambda+6)\varepsilon+2\lambda+3.
\end{aligned}$$

Again, solving for the roots of this quadratic equation in ε, we see that $R^2 - Z$ is positive when $\varepsilon < \frac{\sqrt{2}}{\lambda+3}$.

Finally, the fourth eigenvalue, $\mathbf{\Lambda}_4$, is bounded below by $\mathbf{\Lambda}_3$ and the proof is complete. ∎

It is interesting to note that the bounds for the first three eigenvalues are of the same order (the second and third are even the exact same bound). This suggests that the modification to matrix A_n is optimally balanced with $B(c)$ for $c = 1$.

The full, modified, linearized system may now be written as

$$\begin{cases} \nabla \cdot (\tilde{A}_n \mathbf{U}) = \mathbf{f}_n & \text{in} \quad \Omega, \\ \nabla \times \mathbf{U} = \mathbf{0} & \text{in} \quad \Omega, \\ \boldsymbol{\tau} \cdot \mathbf{U} = \mathbf{0} & \text{on} \quad \Gamma_D, \\ \mathbf{n} \cdot (A_n \mathbf{U}) = \mathbf{g}_n & \text{on} \quad \Gamma_T, \end{cases}$$

where $\mathbf{f}_n = \nabla \cdot (\tilde{A}_n \mathbf{U}_n) - \mathcal{F}_n$ and $\mathbf{g}_n = \mathbf{n} \cdot (A_n \mathbf{U}) - \mathcal{T}_n$.

Define the L^2 functional

$$G(\mathbf{U}; \mathbf{U}_n, \mathbf{f}_n) = \|\nabla \cdot (\tilde{A}_n \mathbf{U}) - \mathbf{f}_n\|^2 + \|\nabla \times \mathbf{U}\|^2, \tag{6.6}$$

and define, for any $m > 0$, the space

$$\mathcal{V}^m = \{\mathbf{V} \in H^m(\Omega)^4 : \ \mathbf{n} \cdot (A_n \mathbf{V}) = \mathbf{g}_n \text{ on } \Gamma_T, \ \boldsymbol{\tau} \cdot \mathbf{V} = \mathbf{0} \text{ on } \Gamma_D\}.$$

In the case of pure displacement boundary conditions ($\Gamma_N = \emptyset$), we denote the space by $\mathcal{V}_D^m$.

The least-squares minimization problem for each Newton step is as follows: given $\mathbf{U}_n$, $\mathbf{f}_n$, and $\mathbf{g}_n$, find $\mathbf{U} \in \mathcal{V}^1$ such that

$$G(\mathbf{U}; \mathbf{U}_n, \mathbf{f}_n) = \inf_{\mathbf{V} \in \mathcal{V}^1} G(\mathbf{V}; \mathbf{U}_n, \mathbf{f}_n).$$

7. Ellipticity. To use the L^2-based functional in (6.6) on each Newton step, we must assume that the previous iterate is in $H^{1+\delta}(\Omega)$ for some $\delta > 0$ because (6.6) is composed of derivatives of products of the unknown and the previous solution and, in $\mathbb{R}^2$, the space $H^{1+\delta}(\Omega)$ is closed under multiplication only for $\delta > 0$ (see Lemma 4.1). Thus, showing only H^1 ellipticity of (6.6) is not sufficient to establish a well-defined Newton iteration; we must show that each iterate remains in $H^{1+\delta}(\Omega)$. In this section, we establish H^{1+k} ellipticity of an H^k-based functional for $k \geq 0$ and show that minimizing the L^2-based functional is sufficient to guarantee the required smoothness of each iterate. Our theoretical results hold for the pure displacement problem.

For clarity, we use the following conventions: $\delta > 0$ and $k \geq 0$ (our final results require the cases $k = 0$ and $k = \delta$).

In Theorem 6.1, matrix $\tilde{A} = A(\mathbf{U}) + B(1)$ is uniformly symmetric positive definite over Ω when the strain of $\mathbf{U}$ is sufficiently small, that is, for $\mathbf{U} \in \mathcal{S}_\lambda$. In this section, we assume this property holds and consider the solution of a general Newton step of the pure displacement problem by minimizing the more general H^k-based functional

$$G_k(\mathbf{U}; \mathbf{U}_n, \mathbf{f}_n) = \|\nabla \cdot (\tilde{A}_n \mathbf{U}) - \mathbf{f}_n\|_k^2 + \|\nabla \times \mathbf{U}\|_k^2. \tag{7.1}$$

Its associated minimization problem is as follows: given $\mathbf{U}_n \in H^{1+\delta}(\Omega)$ and $\mathbf{f}_n \in H^k(\Omega)$, find $\mathbf{U} \in \mathcal{V}_D^{1+k}$ such that

$$G_k(\mathbf{U}; \mathbf{U}_n, \mathbf{f}_n) = \inf_{\mathbf{V} \in \mathcal{V}_D^{1+k}} G_k(\mathbf{V}; \mathbf{U}_n, \mathbf{f}_n). \tag{7.2}$$

By Lemma 4.1, it is clear that $\mathbf{U} \in H^{1+k}(\Omega)$ and $\mathbf{U}_n \in H^{1+\delta}(\Omega)$ are sufficient to ensure that $\nabla \cdot (\tilde{A}_n \mathbf{U}) \in H^k(\Omega)$.

The following series of lemmas leads to establishing equivalence of $G_k(\mathbf{U}; \mathbf{U}_n, \mathbf{0})^{\frac{1}{2}}$ to the H^{1+k} norm.

LEMMA 7.1. *Let Ω be a simply connected domain in $\mathbb{R}^2$ and suppose $\mathbf{V} \in L^2(\Omega)^4$. Then $\nabla \cdot \mathbf{V} = \mathbf{0}$ and $\int_{\partial\Omega} \mathbf{n} \cdot \mathbf{V} = \mathbf{0}$ if and only if there exists a function $\mathbf{r} \in H^1(\Omega)^2$ such that $\mathbf{V} = \nabla^\perp \mathbf{r}$. Furthermore, $\mathbf{r} \in H^1(\Omega)^2$ is unique up to an additive constant vector in $\mathbb{R}^2$.*

Proof. The result follows by applying Theorem 3.1 in Chapter I of [14] to each block component of $\mathbf{V}$. ∎

LEMMA 7.2. *Let Ω be a simply connected domain in $\mathbb{R}^2$. Every $\mathbf{V} \in L^2(\Omega)^4$ has the orthogonal decomposition $\mathbf{V} = \nabla \mathbf{p} + \nabla^\perp \mathbf{q}$ for $\mathbf{p} \in H^1(\Omega)^2, \mathbf{q} \in H_0^1(\Omega)^2$. Furthermore, $\mathbf{q}$ is unique in $H_0^1(\Omega)^2$ and $\mathbf{p}$ is unique in $H^1(\Omega)^2$ up to an additive constant vector in $\mathbb{R}^2$.*

Proof. The result follows by applying Theorem 3.2 in Chapter I of [14] to each block component of $\mathbf{V}$. ∎

LEMMA 7.3. *Assume that $\mathbf{U} \in \mathcal{S}_\lambda$ and denote $\tilde{A} = A + B$, with $A = A(\mathbf{U})$ and $B = B(1)$ as defined in section 6. Also assume that $A\mathbf{Z}$ and $B\mathbf{Z}$ are in $L^2(\Omega)^4$. If $\mathbf{Z} \in \mathcal{V}_D^1$ satisfies the system*

$$\begin{cases} \nabla \cdot \tilde{A}\mathbf{Z} = \mathbf{0} & \text{in} \quad \Omega, \\ \nabla \times \mathbf{Z} = \mathbf{0} & \text{in} \quad \Omega, \end{cases} \tag{7.3}$$

then it must be the trivial solution, $\mathbf{Z} = \mathbf{0}$.

Proof. By Lemma 7.2, $\mathbf{Z} = \nabla \mathbf{p} + \nabla^\perp \mathbf{q}$ for $\mathbf{p} \in H^1(\Omega)^2, \mathbf{q} \in H_0^1(\Omega)^2$. The second equation in (7.3) implies

$$\mathbf{0} = \nabla \times \mathbf{Z} = \nabla \times \nabla \mathbf{p} + \nabla \times \nabla^\perp \mathbf{q} = -\Delta \mathbf{q},$$

and, since $\mathbf{q} \in H^1(\Omega)_0^2$, we must have $\mathbf{q} = \mathbf{0}$. Thus, $\mathbf{Z} = \nabla \mathbf{p}$.

Now, using Green's formula with $\mathbf{1} = (1, 1)^t$, we get

$$\mathbf{0} = \langle \nabla \cdot A\mathbf{Z}, \mathbf{1} \rangle + \langle A\mathbf{Z}, \nabla \mathbf{1} \rangle = \int_{\partial\Omega} \mathbf{n} \cdot A\mathbf{Z}.$$

Applying Lemma 7.1 to $A\mathbf{Z}$ yields $A\mathbf{Z} = \nabla^\perp \mathbf{r}$ for $\mathbf{r} \in H^1(\Omega)^2$. Since $\mathbf{0} = \boldsymbol{\tau} \cdot \mathbf{Z} = \boldsymbol{\tau} \cdot \nabla \mathbf{p}$ on $\partial\Omega$, we know that $\mathbf{p} = \mathbf{p}_0$ is constant on $\partial\Omega$. We thus have

$$\begin{aligned} \langle A\mathbf{Z}, \mathbf{Z} \rangle &= \langle \nabla^\perp \mathbf{r}, \nabla \mathbf{p} \rangle \\ &= \langle -\nabla \cdot \nabla^\perp \mathbf{r}, \mathbf{p} \rangle + \int_{\partial\Omega} (\mathbf{n} \cdot \nabla^\perp \mathbf{r}) \mathbf{p} \\ &= \int_{\partial\Omega} (\mathbf{n} \cdot \nabla^\perp \mathbf{r}) \mathbf{p} \\ &= \mathbf{p}_0 \int_{\partial\Omega} \mathbf{n} \cdot A\mathbf{Z} \\ &= \mathbf{0}. \end{aligned}$$

Since $\mathbf{Z} = \nabla \mathbf{p}$, we may then write $B\mathbf{Z} = \nabla^{\perp}\mathbf{s}$, where $\mathbf{s} = \left(\begin{smallmatrix} p_2 \\ -p_1 \end{smallmatrix}\right)$. Thus,

$$\begin{aligned}\langle B\mathbf{Z}, \mathbf{Z}\rangle &= \langle \nabla^{\perp}\mathbf{s}, \nabla \mathbf{p}\rangle \\ &= \langle \mathbf{s}, \nabla \times \nabla \mathbf{p}\rangle - \int_{\partial\Omega} (\boldsymbol{\tau} \cdot \nabla \mathbf{p})\mathbf{s} \\ &= -\int_{\partial\Omega} (\boldsymbol{\tau} \cdot \nabla \mathbf{p}_0)\mathbf{s} \\ &= \mathbf{0},\end{aligned}$$

which implies $\langle \tilde{A}\mathbf{Z}, \mathbf{Z}\rangle = \mathbf{0}$. Since $\mathbf{U} \in \mathcal{S}_{\lambda}$, matrix $\tilde{A}$ is positive definite, and we must have $\mathbf{Z} = \mathbf{0}$. ∎

Now consider the following elliptic boundary value problem:

$$\nabla \cdot M \nabla \mathbf{p} = \mathbf{f} \quad \text{in} \quad \Omega, \tag{7.4}$$

satisfying either $\mathbf{p} = \mathbf{0}$ or $\mathbf{n} \cdot M\nabla \mathbf{p} = \mathbf{0}$ on $\partial\Omega$. When Ω has $C^{1+k,1}$ boundary and M is uniformly positive definite over Ω with coefficients in $C^{k,1}(\bar{\Omega})$, problem (7.4) admits the regularity bound,

$$\|\mathbf{p}\|_{2+k} \leq C\|\mathbf{f}\|_k, \tag{7.5}$$

for $\mathbf{p} \in H^{2+k}(\Omega)$. Chapter 2 of [15] establishes this for integer values of k. For noninteger k, we may appeal to interpolation in Sobolev norms as in [17]. Similar regularity results, with different assumptions than here, are given in [1, 2, 12].

LEMMA 7.4. *Assume a solution to nonlinear problem* (5.1)*:* $\mathbf{U}^* \in \mathcal{V}_D^{2+k} \cap \mathcal{S}_{\lambda}$. *Assume also that* Ω *is smooth enough to admit* (7.5) *for* $k \geq 0$. *Let* $\tilde{A}_* = A(\mathbf{U}^*) + B(1)$. *Then there exists a positive constant,* c_**, independent of* $\mathbf{U}$*, such that*

$$\|\mathbf{U}\|_{1+k} \leq c_*(\|\nabla \cdot \tilde{A}_*\mathbf{U}\|_k + \|\nabla \times \mathbf{U}\|_k)$$

for all $\mathbf{U} \in \mathcal{V}_D^{1+k}$.

Proof. Consider the skew-symmetric orthogonal matrix

$$Q = \begin{pmatrix} 0 & 1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & -1 & 0 \end{pmatrix}. \tag{7.6}$$

The following relations are easily derived:

$$\begin{aligned} \nabla\times &= \nabla \cdot Q, \\ \nabla\cdot &= \nabla \times Q^t, \\ \nabla^{\perp} &= Q\nabla, \\ \nabla &= Q^t\nabla^{\perp}, \\ \mathbf{n}\cdot &= -\boldsymbol{\tau} \cdot Q, \\ \boldsymbol{\tau}\cdot &= \mathbf{n} \cdot Q^t. \end{aligned} \tag{7.7}$$

Since $\tilde{A}_*$ is uniformly positive definite over Ω, there are constants, λ_1, $\lambda_2 > 0$, such that

$$\lambda_1 \boldsymbol{\xi}^t\boldsymbol{\xi} \leq \boldsymbol{\xi}^t\tilde{A}_*\boldsymbol{\xi} \leq \lambda_2\boldsymbol{\xi}^t\boldsymbol{\xi} \tag{7.8}$$

and

$$\frac{1}{\lambda_2}\boldsymbol{\xi}^t\boldsymbol{\xi} \le \boldsymbol{\xi}^t\tilde{A}_*^{-1}\boldsymbol{\xi} \le \frac{1}{\lambda_1}\boldsymbol{\xi}^t\boldsymbol{\xi} \tag{7.9}$$

for any $\boldsymbol{\xi} \in \mathbb{R}^4$. Define

$$\mathcal{C} = Q^t\tilde{A}_*^{-1}Q,$$

and note that

$$\boldsymbol{\xi}^t\boldsymbol{\xi} = \boldsymbol{\xi}^tQ^tQ\boldsymbol{\xi} = (Q\boldsymbol{\xi})^t(Q\boldsymbol{\xi})$$

and

$$\boldsymbol{\xi}^t\mathcal{C}\boldsymbol{\xi} = \boldsymbol{\xi}^tQ^t\tilde{A}_*^{-1}Q\boldsymbol{\xi} = (Q\boldsymbol{\xi})^t\tilde{A}_*^{-1}(Q\boldsymbol{\xi}).$$

Now, it can easily be seen that $\mathcal{C}$ is symmetric and uniformly positive definite over Ω:

$$\frac{1}{\lambda_2}\boldsymbol{\xi}^t\boldsymbol{\xi} \le \boldsymbol{\xi}^t\mathcal{C}\boldsymbol{\xi} \le \frac{1}{\lambda_1}\boldsymbol{\xi}^t\boldsymbol{\xi}. \tag{7.10}$$

We also note that

$$\nabla \times \tilde{A}_*^{-1}\nabla^\perp = \nabla \cdot Q\tilde{A}_*^{-1}Q\nabla = -\nabla \cdot \mathcal{C}\nabla.$$

With $\mathbf{U}^* \in \mathcal{V}_D^{2+k}$ and $\mathbf{U} \in \mathcal{V}_D^{1+k}$, we have that $\nabla \cdot \tilde{A}_*\mathbf{U} \in H^k(\Omega)$, and thus, for any $\mathbf{U} \in \mathcal{V}_D^{1+k}$, there is a unique $\mathbf{p} \in H^{2+k}(\Omega)$ that satisfies

$$\begin{cases} \nabla \cdot \tilde{A}_*\nabla\mathbf{p} = \nabla \cdot \tilde{A}_*\mathbf{U} & \text{in} \quad \Omega, \\ \qquad\quad \mathbf{p} = \mathbf{0} & \text{on} \quad \partial\Omega \end{cases} \tag{7.11}$$

and a $\mathbf{q} \in H^{2+k}(\Omega)$ that satisfies

$$\begin{cases} -\nabla \cdot \mathcal{C}\nabla\mathbf{q} = \nabla \times \mathbf{U} & \text{in} \quad \Omega, \\ \mathbf{n} \cdot \mathcal{C}\nabla\mathbf{q} = \mathbf{0} & \text{on} \quad \partial\Omega, \end{cases} \tag{7.12}$$

and $\int_\Omega \mathbf{q}\, dx = \mathbf{0}$. Now define $\mathbf{Z} = \mathbf{U} - \nabla\mathbf{p} - \tilde{A}_*^{-1}\nabla^\perp\mathbf{q}$. Note that $\mathbf{Z} \in H^{1+k}(\Omega)$ and, on $\partial\Omega$, that

$$\begin{aligned} \boldsymbol{\tau} \cdot \mathbf{Z} &= \boldsymbol{\tau} \cdot \mathbf{U} - \boldsymbol{\tau} \cdot \nabla\mathbf{p} - \boldsymbol{\tau} \cdot \tilde{A}_*^{-1}\nabla^\perp\mathbf{q} \\ &= -\boldsymbol{\tau} \cdot Q\mathcal{C}Q^t\nabla^\perp\mathbf{q} \\ &= \mathbf{n} \cdot \mathcal{C}\nabla\mathbf{q} \\ &= \mathbf{0}. \end{aligned}$$

Thus, $\mathbf{Z} \in \mathcal{V}_D^{1+k}$. We further see that

$$\begin{aligned} \nabla \cdot \tilde{A}_*\mathbf{Z} &= \nabla \cdot \tilde{A}_*\mathbf{U} - \nabla \cdot \tilde{A}_*\nabla\mathbf{p} - \nabla \cdot \tilde{A}_*\tilde{A}_*^{-1}\nabla^\perp\mathbf{q} \\ &= \mathbf{0} \end{aligned}$$

and

$$\begin{aligned} \nabla \times \mathbf{Z} &= \nabla \times \mathbf{U} - \nabla \times \nabla\mathbf{p} - \nabla \times \tilde{A}_*^{-1}\nabla^\perp\mathbf{q} \\ &= \nabla \times \mathbf{U} + \nabla \cdot \mathcal{C}\nabla\mathbf{q} \\ &= \mathbf{0}. \end{aligned}$$

By Lemma 7.3, we therefore conclude that $\mathbf{Z} = \mathbf{0}$. Since $\mathbf{U}^* \in H^{2+k}(\Omega) \subseteq C^{k,1}(\bar{\Omega})$, we may apply (7.5) to problems (7.11) and (7.12). Combining these bounds with the triangle inequality and (7.9), we may write

$$\begin{aligned}\|\mathbf{U}\|_{1+k} &\leq \|\nabla \mathbf{p}\|_{1+k} + \|\tilde{A}_*^{-1}\nabla^{\perp}\mathbf{q}\|_{1+k} \\ &\leq \|\mathbf{p}\|_{2+k} + 1/\lambda_1\|\mathbf{q}\|_{2+k} \\ &\leq C(\|\nabla \cdot \tilde{A}_*\mathbf{U}\|_k + \|\nabla \times \mathbf{U}\|_k).\end{aligned}$$

Application of (2.1) completes the proof. ∎

Recall that we cast the solution of nonlinear problem (3.1) as the zero of $\mathcal{F}(\mathbf{U})$, where $\mathcal{F}'(\mathbf{U})[\mathbf{V}]$ is given in (5.3). We consider the boundedness of the second Fréchet derivative of $\mathcal{F}(\mathbf{U})$ in directions $\mathbf{V}$ and $\mathbf{W}$ in the following lemma.

LEMMA 7.5. *For all $\mathbf{U}, \mathbf{V} \in H^{1+\delta}(\Omega)$ and $\mathbf{W} \in H^{1+k}(\Omega)$, there exists a positive constant, c_2, such that*

$$\|\mathcal{F}''(\mathbf{U})[\mathbf{V}, \mathbf{W}]\|_k \leq c_2\|\mathbf{U}\|_{1+\delta}\|\mathbf{V}\|_{1+\delta}\|\mathbf{W}\|_{1+k}. \tag{7.13}$$

Proof. Writing the second Fréchet derivative of $\mathcal{F}$ in the directions $\mathbf{V}$ and $\mathbf{W}$ as

$$\begin{aligned}\mathcal{F}''(\mathbf{U})[\mathbf{V}, \mathbf{W}] = \nabla \cdot \big[&\lambda \mathrm{tr}(\mathbf{W}^t\mathbf{V})(\mathbf{I}+\mathbf{U}) + \lambda \mathrm{tr}(\mathbf{V}^t(\mathbf{I}+\mathbf{U}))\mathbf{W} + \lambda|\mathrm{tr}(\mathbf{W}^t(\mathbf{I}+\mathbf{U}))\mathbf{V} \\ &+ (\mathbf{I}+\mathbf{U})(\mathbf{W}^t\mathbf{V} + \mathbf{V}^t\mathbf{W}) + \mathbf{V}(\mathbf{W} + \mathbf{W}^t + W^t\mathbf{U} + \mathbf{U}^t\mathbf{W}) \\ &+ \mathbf{W}(\mathbf{V} + \mathbf{V}^t + V^t\mathbf{U} + \mathbf{U}^t\mathbf{V})\big],\end{aligned}$$

we see that each component may be written as a linear combination of terms of the form $\partial(W_iV_jU_k)$ or $\partial(W_iV_j)$, $i, j, k = 1, 2, 3, 4$, where ∂ again represents either ∂_x or ∂_y. The lemma then follows by the triangle inequality and by applying Lemma 4.1 to each term once or twice. ∎

Define the $H^{1+\delta}$ neighborhood of the solution by

$$\mathcal{B}_r = \{\mathbf{U} \in H^{1+\delta}(\Omega) : \|\mathbf{U} - \mathbf{U}^*\|_{1+\delta} < r\}.$$

We now are able to state the main result of this section.

THEOREM 7.6. *Assume Ω has C^{3+k} boundary and that $\mathbf{f} \in H^{1+k}(\Omega)$ is small enough to guarantee that problem (5.1) has solution $\mathbf{U}^* \in H^{2+k}(\Omega) \cap \mathcal{S}_\lambda$ by Theorem 4.2. Then there exist some $r > 0$ and constants $c_0, c_1 > 0$, depending only on f and Ω, such that, for all $\mathbf{U}_n \in \mathcal{V}_D^{1+\delta} \cap \mathcal{B}_r$,*

$$c_0\|\mathbf{U}\|_{1+k}^2 \;\leq\; G_k(\mathbf{U}; \mathbf{U}_n, \mathbf{0}) \;\leq\; c_1\|\mathbf{U}\|_{1+k}^2 \tag{7.14}$$

for every $\mathbf{U} \in \mathcal{V}_D^{1+k}$ for $k \geq 0$.

Proof. The upper bound follows from the triangle inequality and Lemma 4.1. With $\mathbf{U}_n \in H^{1+\delta}(\Omega)$, Lemma 4.1 guarantees that $A\mathbf{U}, B\mathbf{U} \in H^{1+k}(\Omega)$ when $\mathbf{U} \in H^{1+k}(\Omega)$. By Theorem 4.2 with $m = 1 + k$, there is a solution to problem (5.1), $\mathbf{U}^* \in H^{2+k}(\Omega) \cap \mathcal{S}_\lambda$. Thus, by Lemma 7.4, we know there exists a positive constant, c_*, independent of $\mathbf{U}$, such that

$$\|\mathbf{U}\|_{1+k} \leq c_*(\|\nabla \cdot \tilde{A}(\mathbf{U}^*)\mathbf{U}\|_k + \|\nabla \times \mathbf{U}\|_k) \tag{7.15}$$

for all $\mathbf{U} \in \mathcal{V}_D^{1+k}$. We now need only to extend this result to the operator linearized about $\mathbf{U}_n$ rather than $\mathbf{U}^*$. Recall that we may denote $\mathcal{F}'(\mathbf{U}_n)[\mathbf{U}] = \nabla \cdot A(\mathbf{U}_n)\mathbf{U}$ and $\mathcal{F}'(\mathbf{U}^*)[\mathbf{U}] = \nabla \cdot A(\mathbf{U}^*)\mathbf{U}$. By the mean value theorem, we may write

$$\mathcal{F}'(\mathbf{U}_n)[\mathbf{U}] - \mathcal{F}'(\mathbf{U}^*)[\mathbf{U}] = \mathcal{F}''(\hat{\mathbf{U}})[\mathbf{U}, \mathbf{U}_n - \mathbf{U}^*] \tag{7.16}$$

for some $\hat{\mathbf{U}} = \theta\mathbf{U}_n + (1-\theta)\mathbf{U}^*$ with $\theta \in [0,1]$. Since $\mathbf{U}_n \in \mathcal{B}_r$, $\hat{\mathbf{U}}$ can be bounded in the $H^{1+\delta}$ norm in the following way:

$$\begin{aligned}\|\hat{\mathbf{U}}\|_{1+\delta} &= \|\theta\mathbf{U}_n + (1-\theta)\mathbf{U}^*\|_{1+\delta} \\ &\le \|\theta(\mathbf{U}_n - \mathbf{U}^*)\|_{1+\delta} + \|\mathbf{U}^*\|_{1+\delta} \\ &\le r + \|\mathbf{U}^*\|_{1+\delta}.\end{aligned} \tag{7.17}$$

So, by (7.16), the triangle inequality, (7.13), and (7.15), we have

$$\begin{aligned}&\|\nabla\cdot\tilde{A}(\mathbf{U}_n)\mathbf{U}\|_k + \|\nabla\times\mathbf{U}\|_k \\ &\quad= \|\mathcal{F}'(\mathbf{U}_n)[\mathbf{U}]\|_k + \|\nabla\times\mathbf{U}\|_k \\ &\quad= \|\mathcal{F}'(\mathbf{U}^*)[\mathbf{U}] + \mathcal{F}''(\hat{\mathbf{U}})[\mathbf{U},\mathbf{U}_n-\mathbf{U}^*]\|_k + \|\nabla\times\mathbf{U}\|_k \\ &\quad\ge \|\mathcal{F}'(\mathbf{U}^*)[\mathbf{U}]\|_k - \|\mathcal{F}''(\hat{\mathbf{U}})[\mathbf{U},\mathbf{U}_n-\mathbf{U}^*]\|_k + \|\nabla\times\mathbf{U}\|_k \\ &\quad\ge \|\nabla\cdot A(\mathbf{U}^*)\mathbf{U}\|_k + \|\nabla\times\mathbf{U}\|_k - c_2\|\hat{\mathbf{U}}\|_{1+\delta}\|\mathbf{U}\|_{1+k}\|\mathbf{U}_n-\mathbf{U}^*\|_{1+\delta} \\ &\quad\ge c_*^{-1}\|\mathbf{U}\|_{1+k} - c_2 r(r+\|\mathbf{U}^*\|_{1+\delta})\|\mathbf{U}\|_{1+k} \\ &\quad= (c_*^{-1} - c_2 r(r+\|\mathbf{U}^*\|_{1+\delta}))\|\mathbf{U}\|_{1+k} \\ &\quad\ge C\|\mathbf{U}\|_{1+k},\end{aligned} \tag{7.18}$$

where C is guaranteed to be positive for r sufficiently small. Application of (2.1) completes the proof. ∎

COROLLARY 7.7. *Assume that Ω, $\mathbf{f}$, $\mathbf{U}^*$, and $\mathbf{U}_n \in \mathcal{V}_D^{1+\delta} \cap \mathcal{B}_r$ satisfy the assumptions of Theorem* 7.6. *Then, for some r sufficiently small, the unique $\mathbf{U}$ that satisfies*

$$G_0(\mathbf{U};\mathbf{U}_n,\mathbf{f}_n) = \inf_{\mathbf{V}\in\mathcal{V}_D^1} G_0(\mathbf{V};\mathbf{U}_n,\mathbf{f}_n) \tag{7.19}$$

also satisfies

$$G_\delta(\mathbf{U};\mathbf{U}_n,\mathbf{f}_n) = \inf_{\mathbf{V}\in\mathcal{V}_D^{1+\delta}} G_\delta(\mathbf{V};\mathbf{U}_n,\mathbf{f}_n). \tag{7.20}$$

Proof. From the Riesz representation theorem and Theorem 7.6 with $k=0$, we have a unique minimizer, $\mathbf{U}$, of the L^2-based functional in (7.19) in $H^1(\Omega)$. Similarly, for $k=\delta>0$, we also have a unique minimizer, $\mathbf{U}'$, of the H^δ-based functional in (7.20) in $H^{1+\delta}(\Omega)$. Since these functionals both have zero minimum, $\mathbf{U}'$ must also minimize the functional in (7.19). Thus, $\mathbf{U} = \mathbf{U}' \in H^{1+\delta}(\Omega)$. ∎

Therefore, we are able to conclude that under sufficient smoothness requirements, minimizing the L^2-based functional is sufficient to guarantee that each Newton iterate, $\mathbf{U} = \mathbf{U}_{n+1}$, remains in $H^{1+\delta}(\Omega)$.

8. Convergence of Newton's method. We now consider the sequence of iterates arising from the minimization of each linearized functional under the assumptions of Theorem 7.6. This section details the theory and assumptions for the convergence of Newton's method. As in Theorem 7.6, we assume the solution to the previous Newton step to be in $\mathcal{B}_r$. Here, we show convergence of the iterates in the $H^{1+\delta}$ norm and that each iterate remains in $\mathcal{B}_r$.

Consider the Taylor expansion of $\mathcal{F}(\mathbf{U}^*)$ about the current approximation $\mathbf{U}_n$:

$$\mathbf{0} = \mathcal{F}(\mathbf{U}^*) = \mathcal{F}(\mathbf{U}_n) + \mathcal{F}'(\mathbf{U}_n)[\mathbf{U}^*-\mathbf{U}_n] + \frac{1}{2}\mathcal{F}''(\tilde{\mathbf{U}})[\mathbf{U}^*-\mathbf{U}_n,\mathbf{U}^*-\mathbf{U}_n] \tag{8.1}$$

for $\tilde{\mathbf{U}} = \omega \mathbf{U}_n + (1-\omega)\mathbf{U}^*$ with $\omega \in [0,1]$. As in (7.17), if $\mathbf{U}_n \in \mathcal{B}_r$, then $\tilde{\mathbf{U}}$ satisfies

$$\|\tilde{\mathbf{U}}\|_{1+\delta} \leq r + \|\mathbf{U}^*\|_{1+\delta}. \tag{8.2}$$

Recall that we may write the Newton iterate, $\mathbf{U}$, as the solution to problem (7.2) and, thus,

$$\mathcal{F}'(\mathbf{U}_n)[\mathbf{U} - \mathbf{U}_n] = -\mathcal{F}(\mathbf{U}_n), \tag{8.3}$$

with $\nabla \times \mathbf{U} = \nabla \times \mathbf{U}_n = \nabla \times \mathbf{U}^* = 0$.

Applying (8.1), (8.3), (7.13), and (8.2) to the bound in (7.18), and recalling that $\mathbf{U}_n \in \mathcal{B}_r$, we get

$$\begin{aligned}
\|\mathbf{U}^* - \mathbf{U}\|_{1+\delta} &\leq \frac{1}{\sqrt{c_0}} \|\mathcal{F}'(\mathbf{U}_n)[\mathbf{U}^* - \mathbf{U}]\|_\delta + \|\nabla \times (\mathbf{U}^* - \mathbf{U})\|_\delta \\
&= \frac{1}{\sqrt{c_0}} \|\mathcal{F}'(\mathbf{U}_n)[\mathbf{U}^* - \mathbf{U}_n] - \mathcal{F}'(\mathbf{U}_n)[\mathbf{U} - \mathbf{U}_n]\|_\delta \\
&= \frac{1}{2\sqrt{c_0}} \|\mathcal{F}''(\tilde{\mathbf{U}})[\mathbf{U}^* - \mathbf{U}_n, \mathbf{U}^* - \mathbf{U}_n]\|_\delta \\
&\leq \frac{c_2}{2\sqrt{c_0}} \|\tilde{\mathbf{U}}\|_{1+\delta} \|\mathbf{U}^* - \mathbf{U}_n\|_{1+\delta} \|\mathbf{U}^* - \mathbf{U}_n\|_{1+\delta} \\
&\leq \frac{c_2}{2\sqrt{c_0}} (r + \|\mathbf{U}^*\|_{1+\delta}) r \|\mathbf{U}^* - \mathbf{U}_n\|_{1+\delta} \\
&:= c_3 \; r \; \|\mathbf{U}^* - \mathbf{U}_n\|_{1+\delta},
\end{aligned} \tag{8.4}$$

which proves that Newton's method converges for r sufficiently small. Again noting that $\mathbf{U}_n \in \mathcal{B}_r$, we further note that

$$\begin{aligned}
\|\mathbf{U}^* - \mathbf{U}\|_{1+\delta} &\leq c_3 r \|\mathbf{U}^* - \mathbf{U}_n\|_{1+\delta} \\
&\leq c_3 r^2.
\end{aligned}$$

To verify that $\mathbf{U} \in \mathcal{B}_r$, we only need to show that $c_3 r^2 < r$. Substituting the definition of c_3, we see that this is satisfied for

$$r \; < \; \frac{1}{2} \left(\sqrt{\|\mathbf{U}^*\|_{1+\delta}^2 + \eta} - \|\mathbf{U}^*\|_{1+\delta} \right) \; < \; \frac{\eta}{4\|\mathbf{U}^*\|_{1+\delta}},$$

where $\eta = \frac{8\sqrt{c_0}}{c_2}$. This shows that for guaranteed convergence, larger solutions require better initial guesses than smaller solutions (as measured in the $H^{1+\delta}$ norm). We now consider the issue of finding an appropriate "good" initial guess.

9. Multilevel solution. As described above, the solution to nonlinear system (3.1) is generally comprised of several Newton iterations. The first few iterations are crude approximations to the true solution of the nonlinear problem. It is therefore appropriate to represent the early approximations on a mesh with fewer degrees of freedom. As the Newton iterates remove more of the error due to the nonlinearity, the approximations can be represented on increasingly finer meshes. In other words, we wish to eliminate as much of the nonlinear error as possible on coarse grids where it is less expensive.

The approach in [13] uses this multilevel nested iteration Newton idea with a FOSLS finite element discretization and a multigrid solver to achieve a robust solution strategy for a certain class of nonlinear problems. Under particular assumptions

on the form of the nonlinearity, the finite element spaces used, the smoothness of the solution, and the ellipticity of the linearized equations, convergence to the solution is established with accuracy comparable to discretization error on the finest level at a cost proportional to the degrees of freedom on the finest level. We briefly summarize this nested iteration-Newton-FOSLS-multigrid (NI-Newton-FOSLS-MG) algorithm and detail the additional assumptions we must make for application to the geometrically nonlinear elasticity system.

Define the hierarchy of discrete nested subspaces,

$$\mathcal{V}^{h_0} \subset \mathcal{V}^{h_1} \cdots \subset \mathcal{V}^{h_J} \subset \mathcal{V}_D^{1+\delta}. \tag{9.1}$$

The following algorithm describes the NI-Newton-FOSLS-MG method:

1. Begin with a zero approximation, $\mathbf{U}_0$, on coarsest level $\mathcal{V}^{h_0}$.
2. Linearize the equations about the current approximation and form the discrete least-squares minimization problem.
3. Apply m multigrid cycles to the resulting matrix equations.
4. Repeat steps 2 and 3 n times on the current level.
5. Interpolate the current approximation to the next finer level, $\mathcal{V}^{h_i}$.
6. Repeat steps 2–5 until desired accuracy is achieved.

To apply the results of [13] to the nonlinear elasticity system, we must make the following series of assumptions.

A1. Assume the existence of a solution, $\mathbf{U}^* \in H^{2+\delta}(\Omega)$, to problem (3.1). For our problem, this is justified in section 4. Theorem 4.2 with $m = 1 + \delta$ requires that the boundary of Ω be $C^{3+\delta}$ smooth and $\mathbf{f} \in H^{1+\delta}(\Omega)$ in order to guarantee $\mathbf{U}^* \in H^{2+\delta}(\Omega)$. In the context of elasticity, the internal forcing function, $\mathbf{f}$, is generally at least this smooth for a wide range of practical problems. Assuming a very smooth domain, however, is a stronger restriction than we generally wish to adhere to in practice. We do find that in practice this can be relaxed in some cases, but in many cases we must consider complimentary methods for dealing with nonsmooth domains.

A2. Assume the operator of linearized elasticity maps $\mathcal{V}_D^{1+k}$ into $H^k(\Omega)$. This is established in section 7.

A3. Assume H^{1+k} ellipticity of the functional as in (7.1). Theorem 7.6 establishes this for the pure displacement problem under the small strains assumption of Theorem 6.1.

A4. Assume boundedness of the second Fréchet derivative of $\mathcal{F}$ as in (7.13). Justification of this is established in Lemma 7.5.

A5. Assume the finite element spaces in (9.1) guarantee the following approximation properties and inverse estimate. Let I_ν^h be a bounded H^ν projection onto finite element space $\mathcal{V}^h$. We assume interpolation bounds of the form

$$\|\mathbf{U} - I_{1+\delta}^h \mathbf{U}\|_\gamma \leq C h^{2+\delta-\gamma} \|\mathbf{U}\|_{2+\delta} \quad \forall \gamma \in [0, 1+\delta]$$

and the inverse estimate

$$\|\mathbf{U}\|_\beta \leq \frac{C}{h^{\beta-\gamma}} \|\mathbf{U}\|_\gamma \quad \forall \mathbf{U} \in \mathcal{V}^h,\ \beta \in [0, 1+\delta],\ \gamma \in [0, \beta].$$

We concentrate on standard finite element subspaces of H^1 (for example, bilinears on rectangles) which exhibit these properties; see [3] for details.

A6. Assume a sufficiently fine coarsest level by insisting that $\mathcal{B}_r \cap \mathcal{V}^{h_0} \neq \emptyset$ and that the initial guess is sufficiently close to the solution by choosing $\mathbf{U}_0 \in \mathcal{B}_r \cap \mathcal{V}^{h_0}$. Bounds on r can be found in the full theory in [13].

Under these assumptions, we may directly apply the theory developed in [13]. By this theory, there are values of m and n, independent of h, in the multilevel algorithm described above that result in an approximation on the finest level that is accurate to the level of discretization error at a cost proportional to the degrees of freedom on the finest level.

There are many contributions to the error in each approximation in the NI-Newton-FOSLS-MG solution process. In the innermost iteration, the multigrid solver reduces the algebraic error by performing a number of multigrid cycles before relinearizing. On each grid level, there is discretization error associated with the finite element space used. A sufficient number of Newton steps must be performed on each level to eliminate the error associated with the nonlinearity. For a truly optimal algorithm, we must consider the sources of error that contribute to the total error in the current approximation, and make decisions on how to proceed in the algorithm in order to efficiently reduce the total error to an acceptable level.

10. Computational results. To validate the theory presented above, consider the numerical approximation to the solution of a pure displacement problem on domain $\Omega = [0,1]^2$, with Lamé constants $\lambda = 2.15$, $\mu = 1$. As a test problem, we choose the solution to nonlinear problem (3.1) to be

$$\mathbf{u}^* = \begin{pmatrix} x(1-x)y^2(1-y)^2\sin(\pi x) \\ x^2(1-x)^2y^2(1-y)^2\cos(\pi y) \end{pmatrix},$$

and let $\mathbf{U}^* = \nabla\mathbf{u}^*$ be the exact solution for the first-stage problem. The right-side function, $\mathbf{f}$, is computed accordingly.

Denote by $\mathcal{V}^h$ the space of continuous piecewise bilinear finite elements on a uniform grid of mesh size h. For convenience, we use this space for all test problems. Each step of the pure displacement problem is found by minimizing the discrete functional,

$$G(\mathbf{U}^h; \mathbf{U}_n^h, \mathbf{f}_n) = \|\nabla\cdot(\tilde{A}_n\mathbf{U}^h) - \mathbf{f}_n\|^2 + \|\nabla\times\mathbf{U}^h\|^2, \tag{10.1}$$

over the space

$$\mathcal{V}_D^h = \{\mathbf{V}^h \in \mathcal{V}^h : \boldsymbol{\tau}\cdot\mathbf{V}^h = \mathbf{0} \text{ on } \partial\Omega\}.$$

We begin with an initial guess of $\mathbf{U}_0 = \mathbf{0}$ so that the first Newton step corresponds to the linear elasticity case. Recall that we seek the solution to the original nonlinear problem as well as each linearized step. Define the following nonlinear functional to measure the convergence to nonlinear problem (3.1):

$$\mathcal{G}(\mathbf{U};\mathbf{f}) = \|\mathcal{F}(\mathbf{U})\|^2 + \|\nabla\times\mathbf{U}\|^2. \tag{10.2}$$

In an $H^{1+\delta}$ neighborhood near the solution, a simple computation on a Taylor series of $\mathcal{F}$ about $\mathbf{U}^*$ (invoking Lemma (7.5)) shows that $\mathcal{G}(\mathbf{U};\mathbf{f})$ is equivalent to $G(\mathbf{U};\mathbf{U}^*,\mathbf{0})$, indicating that the H^1 norm of the error to the nonlinear problem can be effectively monitored by $\mathcal{G}(\mathbf{U};\mathbf{f})$. Near convergence of Newton's method, the nonlinear and linearized functionals tend to take on the same values. Thus, a practical measure of how much of the error in the approximation is due to the nonlinearity can be obtained by the difference in the linearized and nonlinear functional values.

For the test problem summarized in Table 10.1, we ensure that essentially all algebraic error is removed from each system by reducing the residual by a factor of

10^6 using $V(1,1)$ cycles. Numerical results are reported for the following: grid level, N ($h = (N+1)^{-1}$); Newton step, m; linearized functional norm, $G(\mathbf{U}^h; \mathbf{U}_n^h, \mathbf{f})^{\frac{1}{2}}$; nonlinear functional norm, $\mathcal{G}(\mathbf{U}^h; \mathbf{f})^{\frac{1}{2}}$; L^2 error of the solution, $\|\mathbf{U}^* - \mathbf{U}^h\|$; and asymptotic multigrid convergence factor, ρ. On each mesh size, the Newton iterations were started with initial guess $\mathbf{U}_0^h = \mathbf{0}$.

By comparing the functional norm and L^2 error values after three Newton steps on a sequence of levels in Table 10.1, we see that the method achieves the optimal discretization accuracy of $O(h^2)$ with respect to the L^2 error norm, and $O(h)$ with respect to the linearized and nonlinear functional norms. Newton's method essentially converges by the second iteration independent of the mesh size. But, even with such fast convergence, we see that the nonlinear functional values of the first Newton step on each level essentially stall, indicating that, even for this relatively simple problem, the linear elasticity approximation is a poor approximation to the geometrically nonlinear approximation.

We see that, for this problem, the multigrid convergence factors based on $V(1,1)$ cycles are bounded above by about 0.8. While these are acceptable convergence factors, in the remainder of the numerical test problems, we use an AMG $V(1,1)$ preconditioned conjugate gradient cycle to improve performance. We denote these accelerated cycles by $V(1,1)$-*pcg*, and because these cycles generally do not reduce the error by a consistent amount, we report the average convergence factor, $\bar{\rho}$, rather than the asymptotic convergence factor. Refer to [18] for complete details on such cycles.

The convergence factor does not take into account the amount of work done per cycle. For an appropriate measure of the work expended by a multigrid cycle, we define the cycle complexity as the total work per cycle relative to one fine grid relaxation sweep. To obtain a numerical estimate of the cycle complexity, we compute the total number of nonzero matrix entries on each level, multiplied by the number of relaxation sweeps on that level, divided by the number of nonzero matrix entries of the finest level operator. Define the work per Newton step as the work per cycle multiplied by the number of cycles per step, and the total work, W_T, as the cumulative amount of work expended relative to the current level. One such work unit is equivalent to one relaxation sweep on the finest level.

We now wish to solve the same problem as above, but in the most efficient way possible. To this end, we implement the nested iteration strategy described in section 9. Instead of reducing the residual of each linear system by a given amount, we take only three $V(1,1)$-*pcg* cycles per Newton step and one Newton step per level. Table 10.2 summarizes these results.

TABLE 10.2
Numerical results for the pure displacement problem with known smooth solution, using nested iteration and three $V(1,1)$-pcg cycles per step.

N	m	$\mathcal{G}(\mathbf{U}^h;\mathbf{f})^{\frac{1}{2}}$	$\bar{\rho}$	W_T	time (s)
8	2	2.64e-02	0.29	12.3	1
16	3	1.31e-02	0.25	16.0	4
32	4	6.61e-03	0.24	19.0	15
64	5	3.32e-03	0.24	20.8	60
128	6	1.66e-03	0.23	21.6	242

As Tables 10.1 and 10.2 show, the nested iteration method achieves optimal discretization accuracy, and the nonlinear functional on the finest grid is within 5% of discretization error. The average convergence factors for the $V(1,1)$-*pcg* cycles remain bounded and of very reasonable size for this problem. The total amount of work required for the solution at each level is essentially bounded at less than 25 work units, and the time to solution for each level scales almost exactly with the number of degrees of freedom of the problem.

The numerical results presented here are for the pure displacement problem with small strains. In practice, we find that the method performs similarly to the results shown here for mixed boundary conditions and for somewhat larger strains than the theory allows. In the next section, we show that the small strains assumption admits a large class of interesting problems.

11. Validating the small strains assumption. According to Ciarlet in [11], for any homogeneous, isotropic, elastic material, the stress and strain tensors satisfy the relation given by

$$\Sigma(\mathbf{E}) = \lambda \mathrm{tr}(\mathbf{E})\mathbf{I} + 2\mu\mathbf{E} + o(\mathbf{E}). \tag{11.1}$$

But the model of geometrically nonlinear elasticity uses the linear stress-strain relation given in (3.2), that is, we drop the higher-order terms, $o(\mathbf{E})$, under an assumption of small strains. Thus, in analysis of the geometrically nonlinear elasticity system, we are free to impose reasonable restrictions on the size of $\|\mathbf{E}\|$ without limiting the scope of the model.

In Theorem 6.1, we assume that the strain associated with the solution of each Newton iterate satisfies

$$\|\mathbf{\Phi}^t\mathbf{\Phi} - \mathbf{I}\|_{Fr} < \frac{\sqrt{2}}{\lambda + 3}, \tag{11.2}$$

where we have scaled the problem such that $\mu = 1$. In this section, we investigate this restriction and provide examples of different configurations and their relation to (11.2) and material constant λ.

Since physically we must have $\lambda > 0$, we first see that an upper bound on the allowed strain is at $\|\mathbf{\Phi}^t\mathbf{\Phi} - \mathbf{I}\|_{Fr} = \sqrt{2}/3 \approx 0.471$. We further notice that bound (11.2) is always violated by any nonzero strain in the limit as $\lambda \to \infty$. Thus, our

TABLE 11.1

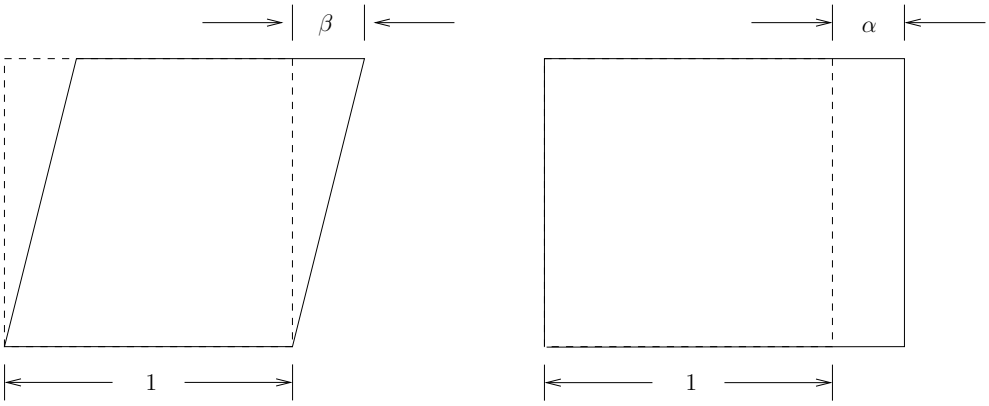

FIG. 11.1. *Pure shear and pure tensile strains.*

notion of "small strains" is coupled to the assumption of compressibility. The Poisson ratio of an elastic material is given by

$$\nu = \frac{\lambda}{2(\lambda + \mu)},$$

and we may think of the incompressible limit as $\lambda \to \infty$ (for bounded μ) or $\nu \to 0.5$. In Table 11.1, we provide a few examples of common materials and their material properties. Because we are chiefly concerned with the value of λ relative to μ, we report the unitless $\lambda \leftarrow \lambda/\mu$. For unscaled constants with meaningful physical units, consult [11].

For the numerical test problems in this paper, we uniformly choose to use $\lambda = 2.15$, that of aluminum, as the level of compressibility.

Consider the two basic modes of strain: shear and tensile strain. A unit square domain under either uniform shear or uniform tensile strain has corresponding displacements of the form

$$\mathbf{u}_{shear} = \begin{pmatrix} \beta y \\ 0 \end{pmatrix} \text{ or } \mathbf{u}_{tensile} = \begin{pmatrix} \alpha x \\ 0 \end{pmatrix}.$$

Parameters β and α determine the extent of deformation as pictured in Figure 11.1.

Under these deformations, we may apply (6.1) and (6.3) to satisfy (11.2) for these two cases. For pure shear strain, we require β and λ to satisfy

$$(\lambda + 3)^2 \beta^2 (\beta^2 + 2) - 2 < 0,$$

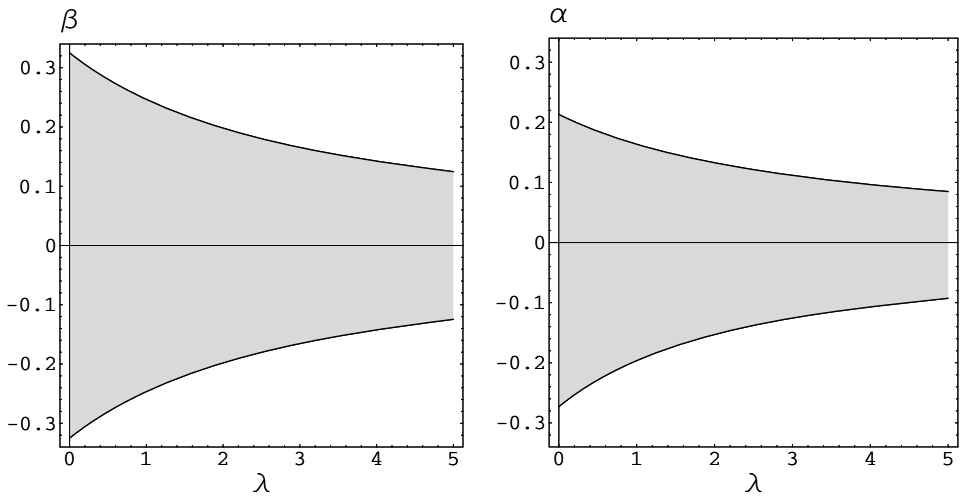

FIG. 11.2. *Shear and tensile strain limits for small strains.*

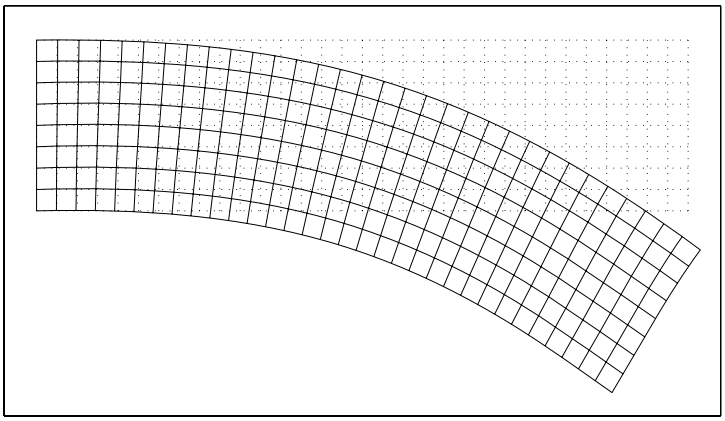

FIG. 11.3. *Displacement plot for cantilever beam displaying "large displacement and small strains."*

and, for pure tensile strain, we require α and λ to satisfy

$$(\lambda + 3)^2\alpha^2(\alpha + 2)^2 - 2 < 0.$$

These relations are satisfied for the parameters in the shaded regions shown in Figure 11.2.

Now consider the following example of a deformed configuration with large displacements but small strains. The strain of the discrete approximation is computed pointwise from (6.3) for mesh size $h = 1/16$. The deformation is from a simple cantilever beam under a constant gravitational force. The max pointwise strain is 0.241 and, for this configuration to satisfy (11.2), the largest allowable λ is approximately 2.88, which corresponds to a Poisson ratio of $\nu = 0.37$. Figure 11.3 shows a plot of the deformed configuration.

A MULTIPOINT FLUX MIXED FINITE ELEMENT METHOD*

MARY F. WHEELER† AND IVAN YOTOV‡

Abstract. We develop a mixed finite element method for single phase flow in porous media that reduces to cell-centered finite differences on quadrilateral and simplicial grids and performs well for discontinuous full tensor coefficients. Motivated by the multipoint flux approximation method where subedge fluxes are introduced, we consider the lowest order Brezzi–Douglas–Marini (BDM) mixed finite element method. A special quadrature rule is employed that allows for local velocity elimination and leads to a symmetric and positive definite cell-centered system for the pressures. Theoretical and numerical results indicate second-order convergence for pressures at the cell centers and first-order convergence for subedge fluxes. Second-order convergence for edge fluxes is also observed computationally if the grids are sufficiently regular.

Key words. mixed finite element, multipoint flux approximation, cell-centered finite difference, tensor coefficient, error estimates

1. Introduction.

Mixed finite element (MFE) methods have been widely used for modeling flow in porous media due to their local mass conservation, accurate approximation of the velocity, and proper treatment of discontinuous coefficients. A computational drawback of these methods is the need to solve an algebraic system of saddle point type. One possible approach to address this issue is to use the hybrid form of the MFE method [9, 15]. In this case the method can be reduced to a symmetric positive definite system for the pressure Lagrange multipliers on the element faces. Alternatively, it was established in [29] that, in the case of diagonal tensor coefficients and rectangular grids, MFE methods can be reduced to cell-centered finite differences (CCFD) for the pressure through the use of a quadrature rule for the velocity mass matrix. This relationship was explored in [33] to obtain convergence of CCFD on rectangular grids. This result was extended to full tensor coefficients and logically rectangular grids in [7, 6], where the expanded mixed finite element (EMFE) method was introduced. The EMFE method is very accurate for smooth grids and coefficients, but loses accuracy near discontinuities. This is due to the arithmetic averaging of discontinuous coefficients. Higher order accuracy can be recovered if pressure Lagrange multipliers are introduced along discontinuous interfaces [6], but then the cell-centered structure is lost.

Several other methods have been introduced that handle well rough grids and coefficients. The control volume mixed finite element (CVMFE) method [16] is based on discretizing Darcy's law on specially constructed control volumes. Mimetic finite difference (MFD) methods [23] are designed to mimic on the discrete level critical

properties of the differential operators. The approximating spaces in both methods are closely related to RT_0, the lowest order Raviart–Thomas MFE spaces [27]. These relationships have been explored in [17, 30] and [10, 12] to establish convergence of the CVMFE methods and the MFD methods, respectively. However, as in the case of MFE methods, both methods lead to an algebraic saddle point problem. The multipoint flux approximation (MPFA) method [1, 2, 19, 20] has been developed as a finite volume method and combines the advantages of the above mentioned methods; i.e., it is accurate for rough grids and coefficients and reduces to a cell-centered stencil for the pressures. However, due to the nonvariational formulation of the MPFA, there exist only limited theoretical results in the literature for the well posedness and convergence of this method [24].

In this paper we design a MFE method that reduces to accurate CCFD for full tensors and irregular grids and performs well for discontinuous coefficients. Motivated by the MPFA [2, 20], where subedge fluxes are introduced, we consider the lowest order Brezzi–Douglas–Marini (BDM) MFE method [14, 15]. In two dimensions, for example, there are two velocity degrees of freedom per edge. A special quadrature rule is employed that allows for local velocity elimination and leads to a cell-centered stencil for the pressures. The resulting algebraic system is symmetric and positive definite. We call our method a multipoint flux mixed finite element (MFMFE) method, due to its close relationship with the MPFA method.

We emphasize that the formulation of the MFMFE method involves K^{-1}; see (2.41)–(2.42). For diagonal discontinuous K, the resulting coefficient is a harmonic average. This explains the superior performance of the MFMFE method for problems with rough grids and coefficients, compared to the EMFE method.

The MFMFE method results in a smaller algebraic system than the hybrid MFE method does, since finite element partitions have fewer elements than edges or faces. Moreover, many existing petroleum simulators are based on cell-centered discretizations and their data structures are more compatible with the MFMFE method than with the hybrid MFE method.

The variational framework allows for MFE analysis tools to be combined with quadrature error analysis to establish well posedness and accuracy of the MFMFE method. We formulate and analyze the method on simplicial grids in two and three dimensions as well as on quadrilateral grids. We obtain first order convergence for the pressure in the L^2-norm and for the velocity in the $H(\mathrm{div})$-norm. A duality argument is employed to establish second order convergence for the pressure in a discrete L^2-norm involving the centers of mass of the elements.

The analysis in the quadrilateral case is more involved, since it requires mapping to a reference element. As a result a restriction needs to be imposed on the geometry of each quadrilateral, namely, that it is an $O(h^2)$-perturbation of a parallelogram; see (3.1). We have verified numerically that this restriction is not just an artifact of the analysis, but is needed in practice as well. We also note that second order convergence is observed numerically for the velocities at the midpoints of the edges on h^2-parallelogram grids.

The techniques used in this paper can be employed to formulate and analyze extensions of the MFMFE method to nonmatching multiblock grids via mortar finite elements in the spirit of [5], multiscale MFMFE methods in the spirit of [4], and adaptive mortar MFMFE methods in the spirit of [34].

The rest of the paper is organized as follows. The method is developed in section 2. Sections 3 and 4 are devoted to the error analysis of the velocity and the pressure, respectively. Numerical experiments are presented in section 5. We end with some

conclusions in section 6.

2. Definition of the method.

2.1. Preliminaries. We consider the second order elliptic problem written as a system of two first order equations,

$$\mathbf{u} = -K\nabla p \quad \text{in } \Omega, \tag{2.1}$$

$$\nabla \cdot \mathbf{u} = f \quad \text{in } \Omega, \tag{2.2}$$

$$p = g \quad \text{on } \Gamma_D, \tag{2.3}$$

$$\mathbf{u} \cdot \mathbf{n} = 0 \quad \text{on } \Gamma_N, \tag{2.4}$$

where the domain $\Omega \subset \mathbf{R}^d$, $d = 2$ or 3, has a boundary $\partial\Omega = \overline{\Gamma}_D \cup \overline{\Gamma}_N$, $\Gamma_D \cap \Gamma_N = \emptyset$, measure$(\Gamma_D) > 0$, $\mathbf{n}$ is the outward unit normal on $\partial\Omega$, and K is a symmetric, uniformly positive definite tensor satisfying, for some $0 < k_0 \le k_1 < \infty$,

$$k_0\xi^T\xi \le \xi^T K(\mathbf{x})\xi \le k_1\xi^T\xi \quad \forall \mathbf{x} \in \Omega \ \forall \xi \in \mathbf{R}^d. \tag{2.5}$$

In flow in porous media modeling, p is the pressure, $\mathbf{u}$ is the Darcy velocity, and K represents the permeability divided by the viscosity. The choice of boundary conditions is made for the sake of simplicity. More general boundary conditions, including nonhomogeneous full Neumann problems, can also be treated.

Throughout this paper, C denotes a generic positive constant that is independent of the discretization parameter h. We will also use the following standard notation. For a domain $G \subset \mathbf{R}^d$, the $L^2(G)$ inner product and norm for scalar and vector valued functions are denoted $(\cdot,\cdot)_G$ and $\|\cdot\|_G$, respectively. The norms and seminorms of the Sobolev spaces $W^{k,p}(G)$, $k \in \mathbf{R}$, $p > 0$ are denoted by $\|\cdot\|_{k,p,G}$ and $|\cdot|_{k,p,G}$, respectively. The norms and seminorms of the Hilbert spaces $H^k(G)$ are denoted by $\|\cdot\|_{k,G}$ and $|\cdot|_{k,G}$, respectively. We omit G in the subscript if $G = \Omega$. For a section of the domain or element boundary $S \subset \mathbf{R}^{d-1}$ we write $\langle\cdot,\cdot\rangle_S$ and $\|\cdot\|_S$ for the $L^2(S)$ inner product (or duality pairing) and norm, respectively. For a tensor-valued function M, let $\|M\|_\alpha = \max_{i,j}\|M_{ij}\|_\alpha$ for any norm $\|\cdot\|_\alpha$. We will also use the space

$$H(\mathrm{div};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^d : \nabla \cdot \mathbf{v} \in L^2(\Omega)\}$$

equipped with the norm

$$\|\mathbf{v}\|_{\mathrm{div}} = (\|\mathbf{v}\|^2 + \|\nabla \cdot \mathbf{v}\|^2)^{1/2}.$$

The weak formulation of (2.1)–(2.4) is the following: find $\mathbf{u} \in \mathbf{V}$ and $p \in W$ such that

$$(K^{-1}\mathbf{u}, \mathbf{v}) = (p, \nabla \cdot \mathbf{v}) - \langle g, \mathbf{v} \cdot \mathbf{n}\rangle_{\Gamma_D}, \quad \mathbf{v} \in \mathbf{V}, \tag{2.6}$$

$$(\nabla \cdot \mathbf{u}, w) = (f, w), \quad w \in W, \tag{2.7}$$

where

$$\mathbf{V} = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v} \cdot \mathbf{n} = 0 \text{ on } \Gamma_N\}, \quad W = L^2(\Omega).$$

It is well known [15, 28] that (2.6)–(2.7) has a unique solution.

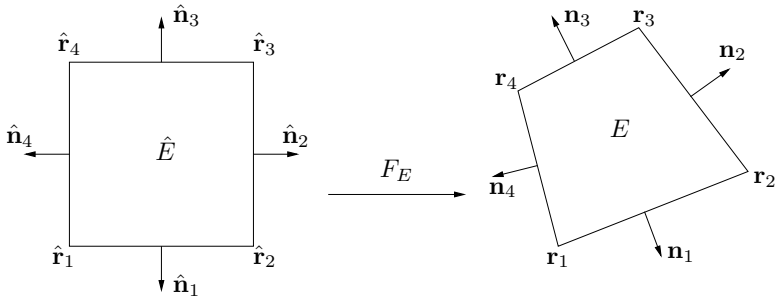

FIG. 2.1. *Mapping in the case of a quadrilateral.*

2.2. Finite element mappings. Consider a polygonal domain $\Omega \in \mathbf{R}^d$ and let $\mathcal{T}_h$ be a finite element partition of Ω consisting of triangles and/or convex quadrilaterals in two dimensions and tetrahedra in three dimensions, where $h = \max_{E\in\mathcal{T}_h} \operatorname{diam}(E)$. We assume that $\mathcal{T}_h$ is shape regular and quasi-uniform [18]. For any element $E \in \mathcal{T}_h$ there exists a bijection mapping $F_E : \hat{E} \to E$ where $\hat{E}$ is the reference element. Denote the Jacobian matrix by DF_E and let $J_E = |\det(DF_E)|$. Denote the inverse mapping by F_E^{-1}, its Jacobian matrix by DF_E^{-1}, and let $J_{F_E^{-1}} = |\det(DF_E^{-1})|$. We have that

$$DF_E^{-1}(x) = (DF_E)^{-1}(\hat{x}), \qquad J_{F_E^{-1}}(x) = \frac{1}{J_E(\hat{x})}.$$

In the case of convex quadrilaterals, $\hat{E}$ is the unit square with vertices $\hat{\mathbf{r}}_1 = (0,\,0)^T$, $\hat{\mathbf{r}}_2 = (1,\,0)^T$, $\hat{\mathbf{r}}_3 = (1,\,1)^T$, and $\hat{\mathbf{r}}_4 = (0,\,1)^T$. Denote by $\mathbf{r}_i = (x_i,\,y_i)^T$, $i = 1,\ldots,4$, the four corresponding vertices of element E as shown in Figure 2.1. The outward unit normal vectors to the edges of E and $\hat{E}$ are denoted by $\mathbf{n}_i$ and $\hat{\mathbf{n}}_i$, $i = 1,\ldots,4$, respectively. In this case F_E is the bilinear mapping given by

$$\begin{aligned} F_E(\hat{\mathbf{r}}) &= \mathbf{r}_1\,(1-\hat{x})(1-\hat{y}) + \mathbf{r}_2\,\hat{x}(1-\hat{y}) + \mathbf{r}_3\,\hat{x}\hat{y} + \mathbf{r}_4\,(1-\hat{x})\hat{y} \\ &= \mathbf{r}_1 + \mathbf{r}_{21}\hat{x} + \mathbf{r}_{41}\hat{y} + (\mathbf{r}_{34} - \mathbf{r}_{21})\hat{x}\hat{y}, \end{aligned} \tag{2.8}$$

where $\mathbf{r}_{ij} = \mathbf{r}_i - \mathbf{r}_j$. It is easy to see that DF_E and J_E are linear functions of $\hat{x}$ and $\hat{y}$:

$$\begin{aligned} DF_E &= [(1-\hat{y})\,\mathbf{r}_{21} + \hat{y}\,\mathbf{r}_{34},\ (1-\hat{x})\,\mathbf{r}_{41} + \hat{x}\,\mathbf{r}_{32}] \\ &= [\mathbf{r}_{21}, \mathbf{r}_{41}] + [(\mathbf{r}_{34} - \mathbf{r}_{21})\hat{y}, (\mathbf{r}_{34} - \mathbf{r}_{21})\hat{x}], \end{aligned} \tag{2.9}$$

$$J_E = 2|T_1| + 2(|T_2| - |T_1|)\hat{x} + 2(|T_4| - |T_1|)\hat{y}, \tag{2.10}$$

where $|T_i|$ is the area of the triangle formed by the two edges sharing $\mathbf{r}_i$. Since E is convex, the Jacobian determinant J_E is uniformly positive, i.e., $J_E(\hat{x},\hat{y}) > 0$.

In the case of triangles, $\hat{E}$ is the reference right triangle with vertices $\hat{\mathbf{r}}_1 = (0,\,0)^T$, $\hat{\mathbf{r}}_2 = (1,\,0)^T$, and $\hat{\mathbf{r}}_3 = (0,\,1)^T$. Let $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_3$ be the corresponding vertices of E, oriented in a counterclockwise direction. The linear mapping for triangles has the form

$$F_E(\hat{\mathbf{r}}) = \mathbf{r}_1(1-\hat{x}-\hat{y}) + \mathbf{r}_2\hat{x} + \mathbf{r}_3\hat{y}, \tag{2.11}$$

with respective Jacobian matrix and Jacobian determinant

$$DF_E = [\mathbf{r}_{21}, \mathbf{r}_{31}]^T \quad \text{and} \quad J_E = 2|E|. \tag{2.12}$$

The mapping in the case of tetrahedra is described similarly to the triangular case. Note that in the case of simplicial elements the mapping is affine and the Jacobian matrix and its determinant are constants.

Using the mapping definitions (2.8)–(2.12), it is easy to check that for any edge (face) $e_i \subset \partial E$

$$\mathbf{n}_i = \frac{1}{|e_i|} J_E (DF_E^{-1})^T \hat{\mathbf{n}}_i. \tag{2.13}$$

It is also easy to see that, for all element types, the mapping definitions and the shape-regularity and quasiuniformity of the grids imply that

$$\|DF_E\|_{0,\infty,\hat{E}} \sim h, \quad \|J_E\|_{0,\infty,\hat{E}} \sim h^d, \quad \text{and} \quad \|J_{F_E^{-1}}\|_{0,\infty,\hat{E}} \sim h^{-d} \quad \forall\, E \in \mathcal{T}_h, \tag{2.14}$$

where the notation $a \sim b$ means that there exist positive constants c_0 and c_1 independent of h such that $c_0 b \le a \le c_1 b$.

2.3. Mixed finite element spaces. Let $\mathbf{V}_h \times W_h$ be the lowest order BDM_1 MFE spaces [14, 15]. On the reference unit square these spaces are defined as

$$\begin{aligned} \hat{\mathbf{V}}(\hat{E}) &= P_1(\hat{E})^2 + r\ \mathrm{curl}(\hat{x}^2\hat{y}) + s\ \mathrm{curl}(\hat{x}\hat{y}^2) \\ &= \begin{pmatrix} \alpha_1\hat{x} + \beta_1\hat{y} + \gamma_1 + r\hat{x}^2 + 2s\hat{x}\hat{y} \\ \alpha_2\hat{x} + \beta_2\hat{y} + \gamma_2 - 2r\hat{x}\hat{y} - s\hat{y}^2 \end{pmatrix}, \quad \hat{W}(\hat{E}) = P_0(\hat{E}), \end{aligned} \tag{2.15}$$

where $\alpha_1, \alpha_2, \beta_1, \beta_2, \gamma_1, \gamma_2, s, r$ are real constants and P_k denotes the space of polynomials of degree $\le k$. In the case where the reference element $\hat{E}$ is the unit triangle or tetrahedron, the BDM_1 spaces are defined as

$$\hat{\mathbf{V}}(\hat{E}) = P_1(\hat{E})^d, \quad \hat{W}(\hat{E}) = P_0(\hat{E}). \tag{2.16}$$

Note that in all three cases $\hat{\nabla} \cdot \hat{\mathbf{V}}(\hat{E}) = \hat{W}(\hat{E})$ and that for all $\hat{\mathbf{v}} \in \hat{\mathbf{V}}(\hat{E})$ and for any edge (or face) $\hat{e}$ of $\hat{E}$,

$$\hat{\mathbf{v}} \cdot \hat{\mathbf{n}}_{\hat{e}} \in P_1(\hat{e}).$$

It is well known [14, 15] that the degrees of freedom for $\hat{\mathbf{V}}(\hat{E})$ can be chosen to be the values of $\hat{\mathbf{v}} \cdot \hat{\mathbf{n}}_{\hat{e}}$ at any two points on each edge $\hat{e}$ if $\hat{E}$ is the unit triangle or the unit square, or any three points on each face $\hat{e}$ if $\hat{E}$ is the unit tetrahedron. *We choose these points to be the vertices of* $\hat{e}$; see Figure 2.2 for the quadrilateral case. This choice is motivated by the requirement of accuracy and certain orthogonalities for the quadrature rule introduced in the next section.

The BDM_1 spaces on any element $E \in \mathcal{T}_h$ are defined via the transformations

$$\mathbf{v} \leftrightarrow \hat{\mathbf{v}} : \mathbf{v} = \frac{1}{J_E} DF_E \hat{\mathbf{v}} \circ F_E^{-1}, \quad w \leftrightarrow \hat{w} : w = \hat{w} \circ F_E^{-1}.$$

The vector transformation is known as the Piola transformation. It is designed to preserve the normal components of the velocity vectors on the edges (faces) and satisfies the important properties [15]

$$(\nabla \cdot \mathbf{v}, w)_E = (\hat{\nabla} \cdot \hat{\mathbf{v}}, \hat{w})_{\hat{E}} \qquad \text{and} \qquad \langle \mathbf{v} \cdot \mathbf{n}_e, w \rangle_e = \langle \hat{\mathbf{v}} \cdot \hat{\mathbf{n}}_{\hat{e}}, \hat{w} \rangle_{\hat{e}}. \tag{2.17}$$

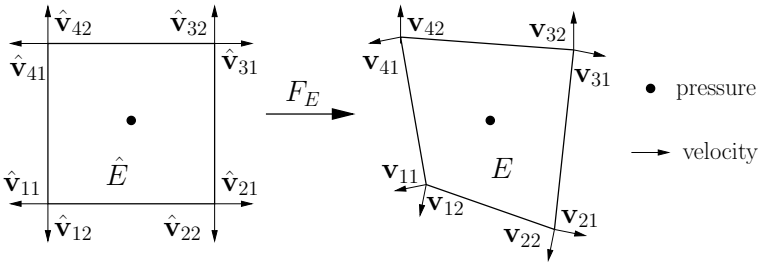

FIG. 2.2. *Degrees of freedom and basis functions for the BDM_1 spaces on quadrilaterals.*

Moreover, (2.13) implies

$$\mathbf{v}\cdot\mathbf{n}_e = \frac{1}{J_E} DF_E\hat{\mathbf{v}}\cdot\frac{1}{|e|}J_E(DF_E^{-1})^T\hat{\mathbf{n}}_{\hat{e}} = \frac{1}{|e|}\hat{\mathbf{v}}\cdot\hat{\mathbf{n}}_{\hat{e}}. \tag{2.18}$$

Also note that the first equation in (2.17) and $(\nabla\cdot\mathbf{v}, w)_E = (\widehat{\nabla\cdot\mathbf{v}}, \hat{w}J_E)_{\hat{E}}$ imply

$$\nabla\cdot\mathbf{v} = \left(\frac{1}{J_E}\hat{\nabla}\cdot\hat{\mathbf{v}}\right)\circ F_E^{-1}(\mathbf{x}). \tag{2.19}$$

Therefore on quadrilaterals $\nabla\cdot\mathbf{v}|_E \neq$ constant.

The BDM_1 spaces on $\mathcal{T}_h$ are given by

$$\begin{aligned} \mathbf{V}_h &= \{\mathbf{v}\in\mathbf{V}\colon \quad \mathbf{v}|_E \leftrightarrow \hat{\mathbf{v}},\ \hat{\mathbf{v}}\in\hat{\mathbf{V}}(\hat{E}) \quad \forall E\in\mathcal{T}_h\},\\ W_h &= \{w\in W\colon \quad w|_E \leftrightarrow \hat{w},\ \hat{w}\in\hat{W}(\hat{E}) \quad \forall E\in\mathcal{T}_h\}. \end{aligned} \tag{2.20}$$

It is known [14, 15, 32] that there exists a projection operator Π from $\mathbf{V}\cap(H^1(\Omega))^d$ onto $\mathbf{V}_h$ satisfying

$$(\nabla\cdot(\Pi\mathbf{q}-\mathbf{q}), w) = 0 \qquad \forall\, w\in W_h. \tag{2.21}$$

The operator Π is defined locally on each element E by

$$\Pi\mathbf{q}\leftrightarrow\widehat{\Pi\mathbf{q}}, \quad \widehat{\Pi\mathbf{q}} = \hat{\Pi}\hat{\mathbf{q}}, \tag{2.22}$$

where $\hat{\Pi}: (H^1(\hat{E}))^d \to \hat{\mathbf{V}}(\hat{E})$ is the reference element projection operator satisfying

$$\forall\,\hat{e}\subset\partial\hat{E}, \qquad \langle(\hat{\Pi}\hat{\mathbf{q}}-\hat{\mathbf{q}})\cdot\hat{\mathbf{n}}, \hat{p}_1\rangle_{\hat{e}} = 0 \qquad \forall\,\hat{p}_1\in P_1(\hat{e}). \tag{2.23}$$

To see that $\Pi\mathbf{q}\cdot\mathbf{n} = 0$ on Γ_N if $\mathbf{q}\cdot\mathbf{n} = 0$ on Γ_N, note that for any $e\in\Gamma_N$ and for all $p_1\leftrightarrow\hat{p}_1\in P_1(\hat{e})$,

$$\langle\Pi\mathbf{q}\cdot\mathbf{n}, p_1\rangle_e = \langle\widehat{\Pi\mathbf{q}}\cdot\hat{\mathbf{n}}, \hat{p}_1\rangle_{\hat{e}} = \langle\hat{\Pi}\hat{\mathbf{q}}\cdot\hat{\mathbf{n}}, \hat{p}_1\rangle_{\hat{e}} = \langle\hat{\mathbf{q}}\cdot\hat{\mathbf{n}}, \hat{p}_1\rangle_{\hat{e}} = 0,$$

implying $\Pi\mathbf{q}\cdot\mathbf{n} = 0$, where we have used (2.17), (2.22), and (2.23).

In addition to the mixed projection operator Π onto $\mathbf{V}_h$, we will use a similar projection operator onto the lowest order Raviart–Thomas spaces [27, 15]. The RT_0 spaces are defined on the unit square as

$$\hat{\mathbf{V}}^0(\hat{E}) = \begin{pmatrix}\alpha_1+\beta_1\hat{x}\\ \alpha_2+\beta_2\hat{y}\end{pmatrix}, \quad \hat{W}^0(\hat{E}) = P_0(\hat{E}), \tag{2.24}$$

and on the unit triangle as

$$\hat{\mathbf{V}}^0(\hat{E}) = \begin{pmatrix} \alpha_1 + \beta\hat{x} \\ \alpha_2 + \beta\hat{y} \end{pmatrix}, \quad \hat{W}^0(\hat{E}) = P_0(\hat{E}). \tag{2.25}$$

On the unit tetrahedron $\hat{\mathbf{V}}^0(\hat{E})$ has an additional component $\alpha_3 + \beta\hat{z}$. In all cases $\hat{\nabla}\cdot\hat{\mathbf{V}}^0(\hat{E}) = \hat{W}^0(\hat{E})$ and $\hat{\mathbf{v}}\cdot\hat{\mathbf{n}}_{\hat{e}} \in P_0(\hat{e})$. The degrees of freedom of $\hat{\mathbf{V}}^0(\hat{E})$ are the values of $\hat{\mathbf{v}}\cdot\hat{\mathbf{n}}_{\hat{e}}$ at the midpoints of all edges (faces) $\hat{e}$. The projection operator $\hat{\Pi}_0 : (H^1(\hat{E}))^d \to \hat{\mathbf{V}}^0(\hat{E})$ satisfies

$$\forall\, \hat{e} \subset \partial\hat{E}, \qquad \langle(\hat{\Pi}_0\hat{\mathbf{q}} - \hat{\mathbf{q}})\cdot\hat{\mathbf{n}}, \hat{p}_0\rangle_{\hat{e}} = 0 \qquad \forall\, \hat{p}_0 \in P_0(\hat{e}). \tag{2.26}$$

The spaces $\mathbf{V}_h^0$ and W_h^0 on $\mathcal{T}_h$ and the projection operator $\Pi_0 : (H^1(\Omega))^d \to \mathbf{V}_h^0$ are defined similarly to the case of BDM_1 spaces. Note that $\mathbf{V}_h^0 \subset \mathbf{V}_h$ and $W_h^0 = W_h$. It follows immediately from the definition of Π_0 that

$$\nabla\cdot\mathbf{v} = \nabla\cdot\Pi_0\mathbf{v} \quad \forall\, \mathbf{v} \in \mathbf{V}_h \tag{2.27}$$

and

$$\|\Pi_0\mathbf{v}\| \le C\|\mathbf{v}\| \quad \forall\, \mathbf{v} \in \mathbf{V}_h. \tag{2.28}$$

2.4. The BDM_1 method. The BDM_1 mixed finite element method is based on approximating the variational formulation (2.6)–(2.7) in the discrete spaces $\mathbf{V}_h \times W_h$: find $\mathbf{u}_h^{bdm} \in \mathbf{V}_h$ and $p_h^{bdm} \in W_h$ such that

$$(K^{-1}\mathbf{u}_h^{bdm}, \mathbf{v}) = (p_h^{bdm}, \nabla\cdot\mathbf{v}) - \langle g, \mathbf{v}\cdot\mathbf{n}\rangle_{\Gamma_D}, \quad \mathbf{v} \in \mathbf{V}_h, \tag{2.29}$$

$$(\nabla\cdot\mathbf{u}_h^{bdm}, w) = (f, w), \quad w \in W_h. \tag{2.30}$$

The method has a unique solution and is second order accurate for the velocity and first order accurate for the pressure in L^2-norms on affine grids [14, 32]. It handles well discontinuous coefficients due to the presence of K^{-1} in the mass matrix. A drawback is that the resulting algebraic system is a large coupled velocity-pressure system of a saddle point problem type. In the next section we develop a quadrature rule that allows for local elimination of the velocities and results in a positive definite cell-centered pressure matrix.

2.5. A quadrature rule. For $\mathbf{q}, \mathbf{v} \in \mathbf{V}_h$, define the global quadrature rule

$$(K^{-1}\mathbf{q}, \mathbf{v})_Q \equiv \sum_{E\in\mathcal{T}_h} (K^{-1}\mathbf{q}, \mathbf{v})_{Q,E}.$$

The integration on any element E is performed by mapping to the reference element $\hat{E}$. The quadrature rule is defined on $\hat{E}$. Using the definition (2.20) of the finite element spaces and omitting the subscript E, we have

$$\begin{aligned}\int_E K^{-1}\mathbf{q}\cdot\mathbf{v}\,\mathrm{d}\mathbf{x} &= \int_{\hat{E}} \hat{K}^{-1}\frac{1}{J}DF\hat{\mathbf{q}}\cdot\frac{1}{J}DF\hat{\mathbf{v}}\,J\,\mathrm{d}\hat{\mathbf{x}} \\ &= \int_{\hat{E}} \frac{1}{J}DF^T\hat{K}^{-1}DF\hat{\mathbf{q}}\cdot\hat{\mathbf{v}}\,\mathrm{d}\hat{\mathbf{x}} \equiv \int_{\hat{E}} \mathcal{K}^{-1}\hat{\mathbf{q}}\cdot\hat{\mathbf{v}}\,\mathrm{d}\hat{\mathbf{x}},\end{aligned}$$

where

$$\mathcal{K} = JDF^{-1}\hat{K}(DF^{-1})^T. \tag{2.31}$$

Clearly, due to (2.14),

$$\|\mathcal{K}\|_{0,\infty,\hat{E}} \sim h^{d-2}\|K\|_{0,\infty,E} \quad \text{and} \quad \|\mathcal{K}^{-1}\|_{0,\infty,\hat{E}} \sim h^{2-d}\|K^{-1}\|_{0,\infty,E}. \tag{2.32}$$

The quadrature rule on an element E is defined as

$$(K^{-1}\mathbf{q},\mathbf{v})_{Q,E} \equiv (\mathcal{K}^{-1}\hat{\mathbf{q}},\hat{\mathbf{v}})_{\hat{Q},\hat{E}} \equiv \frac{|\hat{E}|}{s}\sum_{i=1}^{s}\mathcal{K}^{-1}(\hat{\mathbf{r}}_i)\hat{\mathbf{q}}(\hat{\mathbf{r}}_i)\cdot\hat{\mathbf{v}}(\hat{\mathbf{r}}_i), \tag{2.33}$$

where $s = 3$ for the unit triangle and $s = 4$ for the unit square or the unit tetrahedron. Note that on the unit square this is the trapezoidal quadrature rule.

The corner vector $\hat{\mathbf{q}}(\hat{\mathbf{r}}_i)$ is uniquely determined by its normal components to the two edges (or three faces) that share that vertex. Recall that we chose the velocity degrees of freedom on any edge (face) $\hat{e}$ to be the normal components at the vertices of $\hat{e}$. Therefore, there are two (three) degrees of freedom associated with each corner $\hat{\mathbf{r}}_i$ and they uniquely determine the corner vector $\hat{\mathbf{q}}(\hat{\mathbf{r}}_i)$. More precisely,

$$\hat{\mathbf{q}}(\hat{\mathbf{r}}_i) = \sum_{j=1}^{d}\hat{\mathbf{q}}\cdot\hat{\mathbf{n}}_{ij}(\hat{\mathbf{r}}_i)\hat{\mathbf{n}}_{ij},$$

where $\hat{\mathbf{n}}_{ij}$, $j = 1,\dots,d$, are the outward unit normal vectors to the two edges (three faces) intersecting at $\hat{\mathbf{r}}_i$, and $\hat{\mathbf{q}}\cdot\hat{\mathbf{n}}_{ij}(\hat{\mathbf{r}}_i)$ are the velocity degrees of freedom associated with this corner. Let us denote the basis functions associated with $\hat{\mathbf{r}}_i$ by $\hat{\mathbf{v}}_{ij}$, $j = 1,\dots,d$; see Figure 2.2, i.e.,

$$\hat{\mathbf{v}}_{ij}\cdot\hat{\mathbf{n}}_{ij}(\hat{\mathbf{r}}_i) = 1,\ \ \hat{\mathbf{v}}_{ij}\cdot\hat{\mathbf{n}}_{ik}(\hat{\mathbf{r}}_i) = 0,\ k \neq j,\ \text{and}\ \hat{\mathbf{v}}_{ij}\cdot\hat{\mathbf{n}}_{lk}(\hat{\mathbf{r}}_l) = 0,\ l \neq i,\ k = 1,\dots,d.$$

Clearly the quadrature rule (2.33) couples only the two (or three) basis functions associated with a corner. On the unit square, for example,

$$(\mathcal{K}^{-1}\hat{\mathbf{v}}_{11},\hat{\mathbf{v}}_{11})_{\hat{Q},\hat{E}} = \frac{\mathcal{K}_{11}^{-1}(\hat{\mathbf{r}}_1)}{4}, \quad (\mathcal{K}^{-1}\hat{\mathbf{v}}_{11},\hat{\mathbf{v}}_{12})_{\hat{Q},\hat{E}} = \frac{\mathcal{K}_{12}^{-1}(\hat{\mathbf{r}}_1)}{4}, \tag{2.34}$$

and

$$(\mathcal{K}^{-1}\hat{\mathbf{v}}_{11},\hat{\mathbf{v}}_{ij})_{\hat{Q},\hat{E}} = 0 \quad \forall\, ij \neq 11, 12. \tag{2.35}$$

Remark 2.1. The quadrature rule can be defined directly on an element E. It is easy to see from (2.10) and (2.12) that on simplicial elements

$$(K^{-1}\mathbf{q},\mathbf{v})_{Q,E} = \frac{|E|}{s}\sum_{i=1}^{s}K^{-1}(\mathbf{r}_i)\mathbf{q}(\mathbf{r}_i)\cdot\mathbf{v}(\mathbf{r}_i), \tag{2.36}$$

and on quadrilaterals

$$(K^{-1}\mathbf{q},\mathbf{v})_{Q,E} = \frac{1}{2}\sum_{i=1}^{4}|T_i|K^{-1}(\mathbf{r}_i)\mathbf{q}(\mathbf{r}_i)\cdot\mathbf{v}(\mathbf{r}_i). \tag{2.37}$$

The above quadrature rules are closely related to some inner products used in the mimetic finite difference methods [23]. We note that in the case of quadrilaterals, it is simpler to evaluate the quadrature rule on the reference element $\hat{E}$.

Denote the element quadrature error by

$$\sigma_E(K^{-1}\mathbf{q},\mathbf{v}) \equiv (K^{-1}\mathbf{q},\mathbf{v})_E - (K^{-1}\mathbf{q},\mathbf{v})_{Q,E} \tag{2.38}$$

and define the global quadrature error by $\sigma(K^{-1}\mathbf{q},\mathbf{v})|_E = \sigma_E(K^{-1}\mathbf{q},\mathbf{v})$. Similarly, denote the quadrature error on the reference element by

$$\hat{\sigma}_{\hat{E}}(\mathcal{K}^{-1}\hat{\mathbf{q}},\hat{\mathbf{v}}) \equiv (\mathcal{K}^{-1}\hat{\mathbf{q}},\hat{\mathbf{v}})_{\hat{E}} - (\mathcal{K}^{-1}\hat{\mathbf{q}},\hat{\mathbf{v}})_{\hat{Q},\hat{E}}. \tag{2.39}$$

The next two lemmas will be used in the analysis.

LEMMA 2.1. *On simplicial elements, if* $\mathbf{q} \in \mathbf{V}_h(E)$, *then*

$$\sigma_E(\mathbf{q},\mathbf{v}_0) = 0 \quad \textit{for all constant vectors } \mathbf{v}_0.$$

Proof. It is enough to consider $\mathbf{v}_0 = (1,0)^T$ or $\mathbf{v}_0 = (1,0,0)^T$; the arguments for the other cases are similar. We have

$$(\mathbf{q},\mathbf{v}_0)_{Q,E} = \frac{|E|}{s}\sum_{i=1}^{s} q_1(\mathbf{r}_i) = \int_E \mathbf{q}\cdot\mathbf{v}_0\,d\mathbf{x},$$

using that the quadrature rule $(\varphi)_E = \frac{|E|}{s}\sum_{i=1}^{s}\varphi(\mathbf{r}_i)$ is exact for linear functions. ∎

LEMMA 2.2. *On the reference square, for any* $\hat{\mathbf{q}} \in \hat{\mathbf{V}}(\hat{E})$,

$$(\hat{\mathbf{q}} - \hat{\Pi}_0\hat{\mathbf{q}},\hat{\mathbf{v}}_0)_{\hat{Q},\hat{E}} = 0 \quad \textit{for all constant vectors } \hat{\mathbf{v}}_0. \tag{2.40}$$

Proof. On any edge $\hat{e}$, if the degrees of freedom of $\hat{\mathbf{q}}$ are $\hat{q}_{\hat{e},1}$ and $\hat{q}_{\hat{e},2}$, then (2.26) and an application of the trapezoidal quadrature rule imply that $\hat{\Pi}_0\hat{\mathbf{q}}|_{\hat{e}} = (\hat{q}_{\hat{e},1} + \hat{q}_{\hat{e},2})/2$. The assertion of the lemma follows from a simple calculation, using (2.33). ∎

2.6. The multipoint flux mixed finite element method. We are now ready to define our method. We seek $\mathbf{u}_h \in \mathbf{V}_h$ and $p_h \in W_h$ such that

$$(K^{-1}\mathbf{u}_h,\mathbf{v})_Q = (p_h,\nabla\cdot\mathbf{v}) - \langle g,\mathbf{v}\cdot\mathbf{n}\rangle_{\Gamma_D}, \quad \mathbf{v}\in\mathbf{V}_h, \tag{2.41}$$

$$(\nabla\cdot\mathbf{u}_h,w) = (f,w), \quad w\in W_h. \tag{2.42}$$

Remark 2.2. We call the method (2.41)–(2.42) a MFMFE method, since it is related to the MPFA method.

To prove that (2.41)–(2.42) is well posed, we first show that the quadrature rule (2.33) produces a coercive bilinear form. We will need the following auxiliary result.

LEMMA 2.3. *If* $E \in \mathcal{T}_h$ *and* $\mathbf{q} \in (L^2(E))^d$, *then*

$$\|\mathbf{q}\|_E \sim h^{\frac{2-d}{2}}\|\hat{\mathbf{q}}\|_{\hat{E}}. \tag{2.43}$$

Proof. The assertion of the lemma follows from the relations

$$\int_E \mathbf{q}\cdot\mathbf{q}\,d\mathbf{x} = \int_{\hat{E}} \frac{1}{J}DF\hat{\mathbf{q}}\cdot\frac{1}{J}DF\hat{\mathbf{q}}\,J\,d\hat{\mathbf{x}},$$

$$\int_{\hat{E}} \hat{\mathbf{q}}\cdot\hat{\mathbf{q}}\,d\hat{\mathbf{x}} = \int_E \frac{1}{J_{F^{-1}}}DF^{-1}\mathbf{q}\cdot\frac{1}{J_{F^{-1}}}DF^{-1}\mathbf{q}J_{F^{-1}}\,d\mathbf{x},$$

and bounds (2.14). ∎

LEMMA 2.4. *There exists a positive constant C independent of h such that*

$$(K^{-1}\mathbf{q},\mathbf{q})_Q \geq C\|\mathbf{q}\|^2 \quad \forall \mathbf{q}\in \mathbf{V}_h. \tag{2.44}$$

Proof. Let $\mathbf{q}=\sum_{i=1}^{s}\sum_{j=1}^{d} q_{ij}\mathbf{v}_{ij}$ on an element E. Using (2.36)–(2.37) and (2.5) we obtain

$$(K^{-1}\mathbf{q},\mathbf{q})_{Q,E} \geq C\frac{|E|}{k_1}\sum_{i=1}^{s}\mathbf{q}(\mathbf{r}_i)\cdot\mathbf{q}(\mathbf{r}_i) \geq C\frac{|E|}{k_1}\sum_{i=1}^{s}\sum_{j=1}^{d} q_{ij}^2.$$

On the other hand,

$$\|\mathbf{q}\|_E^2 = \left(\sum_{i=1}^{s}\sum_{j=1}^{d} q_{ij}\mathbf{v}_{ij}, \sum_{k=1}^{s}\sum_{l=1}^{d} q_{kl}\mathbf{v}_{kl}\right) \leq C|E|\sum_{i=1}^{s}\sum_{j=1}^{d} q_{ij}^2.$$

A combination of the above two estimates implies the assertion of the lemma. ∎

COROLLARY 2.5. *The bilinear form $(K^{-1}\mathbf{q},\mathbf{v})_Q$ is an inner product in $\mathbf{V}_h$ and $(K^{-1}\mathbf{q},\mathbf{q})_Q^{1/2}$ is a norm in $\mathbf{V}_h$ equivalent to $\|\cdot\|$.*

Proof. Since $(K^{-1}\mathbf{q},\mathbf{v})_Q$ is linear and symmetric, Lemma 2.4 implies that it is an inner product and that $(K^{-1}\mathbf{q},\mathbf{q})_Q^{1/2}$ is a norm in $\mathbf{V}_h$. Let us denote this norm by $\|\cdot\|_{Q,K^{-1}}$. It remains to show that it is bounded above by $\|\cdot\|$. Using (2.32), (2.5), the equivalence of norms on reference element $\hat{E}$, and (2.43), we have that for all $\mathbf{q}\in\mathbf{V}_h$

$$(K^{-1}\mathbf{q},\mathbf{q})_{Q,E} = (\mathcal{K}^{-1}\hat{\mathbf{q}},\hat{\mathbf{q}})_{\hat{Q},\hat{E}} \leq C\frac{h^{2-d}}{k_0}\|\hat{\mathbf{q}}\|_{\hat{E}}^2 \leq C\|\mathbf{q}\|_E^2,$$

which, combined with (2.44), implies that

$$c_0\|\mathbf{q}\| \leq \|\mathbf{q}\|_{Q,K^{-1}} \leq c_1\|\mathbf{q}\| \tag{2.45}$$

for some positive constants c_0 and c_1. ∎

Remark 2.3. The results of Lemma 2.4 and Corollary 2.5 hold if K^{-1} is replaced by any symmetric and positive definite matrix M.

We are now ready to establish the solvability of (2.41)–(2.42).

LEMMA 2.6. *The MFMFE method* (2.41)–(2.42) *has a unique solution.*

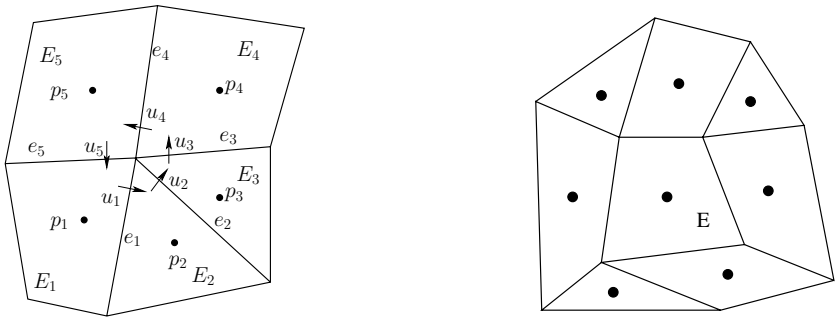
Proof. Since (2.41)–(2.42) is a square system, it is enough to show uniqueness. Let $f=0$, $g=0$, and take $\mathbf{v}=\mathbf{u}_h$ and $w=p_h$. This implies that $(K^{-1}\mathbf{u}_h,\mathbf{u}_h)_Q=0$, and therefore $\mathbf{u}_h=0$, due to (2.44). We now consider the auxiliary problem

$$\begin{aligned} -\nabla\cdot K\nabla\phi &= -p_h \quad \text{in} \quad \Omega,\\ \phi &= 0 \quad \text{on} \quad \Gamma_D,\\ -K\nabla\phi\cdot\mathbf{n} &= 0 \quad \text{on} \quad \Gamma_N. \end{aligned}$$

The choice $\mathbf{v}=\Pi K\nabla\phi\in\mathbf{V}_h$ in (2.41) gives

$$0=(p_h,\nabla\cdot\Pi K\nabla\phi)=(p_h,\nabla\cdot K\nabla\phi)=\|p_h\|^2,$$

therefore $p_h=0$. ∎



A. Five elements sharing a vertex. B. Pressure stencil.

FIG. 2.3. *Interactions of the degrees of freedom in MFMFE.*

2.7. Reduction to a cell-centered stencil. We next describe how the MFMFE method reduces to a system for the pressures at the cell centers. Let us consider any interior vertex $\mathbf{r}$ and suppose that it is shared by k elements $E_1, \ldots, E_k$; see Figure 2.3(A) for a specific example with 5 elements. We denote the edges (faces) that share the vertex by $e_1, \ldots, e_k$, the velocity basis functions on these edges (faces) that are associated with the vertex by $\mathbf{v}_1, \ldots, \mathbf{v}_k$, and the corresponding values of the normal components of $\mathbf{u}_h$ by $u_1, \ldots, u_k$. Note that for clarity the normal velocities on Figure 2.3(A) are drawn at a distance from the vertex.

Since the quadrature rule $(K^{-1}\cdot,\cdot)_Q$ localizes the basis functions interaction (see (2.34)–(2.35)), taking $\mathbf{v} = \mathbf{v}_1$ in (2.41), for example, will only lead to coupling u_1 with u_5 and u_2. Similarly, u_2 will only be coupled with u_1 and u_3, etc. Therefore, the k equations obtained from taking $\mathbf{v} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ form a linear system for $u_1, \ldots, u_k$.

PROPOSITION 2.7. *The $k \times k$ local linear system described above is symmetric and positive definite.*

Proof. The system is obtained by taking $\mathbf{v} = \mathbf{v}_1, \ldots, \mathbf{v}_k$ in (2.41). On the left-hand side we have

$$(K^{-1}\mathbf{u}_h, \mathbf{v}_i)_Q = \sum_{j=1}^{k} u_j (K^{-1}\mathbf{v}_j, \mathbf{v}_i)_Q \equiv \sum_{j=1}^{k} a_{ij} u_j, \quad i = 1, \ldots, k.$$

Using Corollary 2.5 we conclude that the matrix $\bar{A} = \{a_{ij}\}$ is symmetric and positive definite. ∎

Solving the small $k \times k$ linear system allows us to express the velocities u_i in terms of the cell-centered pressures p_i, $i = 1, \ldots, k$. Substituting these expressions into the mass conservation equation (2.42) leads to a cell-centered stencil. The pressure in each element E is coupled with the pressures in the elements that share a vertex with E; see Figure 2.3(B).

For any vertex on the boundary $\partial\Omega$, the size of the local linear system equals the number of non-Neumann (interior or Dirichlet) edges/faces that share that vertex. Inverting the local system allows one to express the velocities in terms of the element pressures and the boundary data.

We use the example in Figure 2.3(A) to describe the CCFD equations obtained from the above procedure. Taking $\mathbf{v} = \mathbf{v}_1$ in (2.41), on the left-hand side we have

$$(K^{-1}\mathbf{u}_h, \mathbf{v}_1)_Q = (K^{-1}\mathbf{u}_h, \mathbf{v}_1)_{Q,E_1} + (K^{-1}\mathbf{u}_h, \mathbf{v}_1)_{Q,E_2}. \tag{2.46}$$

The first term on the right in (2.46) gives

$$\begin{aligned}(K^{-1}\mathbf{u}_h,\mathbf{v}_1)_{Q,E_1} &= (\mathcal{K}^{-1}\hat{\mathbf{u}}_h,\hat{\mathbf{v}}_1)_{\hat{Q},\hat{E}}\\ &= \frac{1}{4}(\mathcal{K}^{-1}_{11,E_1}\hat{u}_1\hat{v}_{1,1}+\mathcal{K}^{-1}_{12,E_1}\hat{u}_5\hat{v}_{1,1})\\ &= \frac{1}{4}(\mathcal{K}^{-1}_{11,E_1}|e_1|u_1+\mathcal{K}^{-1}_{12,E_1}|e_5|u_5)|e_1|,\end{aligned} \tag{2.47}$$

where we have used (2.18) for the last equality. Here $\mathcal{K}^{-1}_{ij,E_1}$ denotes a component of $\mathcal{K}^{-1}$ in E_1 and all functions are evaluated at the vertex of $\hat{E}$ corresponding to vertex $\mathbf{r}$ in the mapping F_{E_1}. Similarly,

$$(K^{-1}\mathbf{u}_h,\mathbf{v}_1)_{Q,E_2} = \frac{1}{6}(\mathcal{K}^{-1}_{11,E_2}|e_1|u_1+\mathcal{K}^{-1}_{12,E_2}|e_2|u_2)|e_1|. \tag{2.48}$$

For the right-hand side of (2.41) we write

$$\begin{aligned}(p_h,\nabla\cdot\mathbf{v}_1) &= (p_h,\nabla\cdot\mathbf{v}_1)_{E_1}+(p_h,\nabla\cdot\mathbf{v}_1)_{E_2}\\ &= \langle p_h,\mathbf{v}_1\cdot\mathbf{n}_{E_1}\rangle_{e_1}+\langle p_h,\mathbf{v}_1\cdot\mathbf{n}_{E_2}\rangle_{e_1}\\ &= \langle\hat{p}_h,\hat{\mathbf{v}}_1\cdot\hat{\mathbf{n}}_{E_1}\rangle_{\hat{e}_1}+\langle\hat{p}_h,\hat{\mathbf{v}}_1\cdot\hat{\mathbf{n}}_{E_2}\rangle_{\hat{e}_1}\\ &= \frac{1}{2}(p_1-p_2)|e_1|,\end{aligned} \tag{2.49}$$

where we have used the trapezoidal rule for the integrals on $\hat{e}_1$, which is exact since $\hat{p}_h$ is constant and $\hat{\mathbf{v}}_1\cdot\hat{\mathbf{n}}$ is linear. A combination of (2.46)–(2.49) gives the equation

$$\left(\frac{1}{2}\mathcal{K}^{-1}_{11,E_1}+\frac{1}{3}\mathcal{K}^{-1}_{11,E_2}\right)|e_1|u_1+\frac{1}{2}\mathcal{K}^{-1}_{12,E_1}|e_5|u_5+\frac{1}{3}\mathcal{K}^{-1}_{12,E_2}|e_2|u_2 = p_1-p_2.$$

The other four equations of the local system for $u_1,\dots,u_5$ are obtained similarly.

We end the section with a statement about an important property of the CCFD algebraic system.

PROPOSITION 2.8. *The CCFD system for the pressure obtained from* (2.41)–(2.42) *using the procedure described above is symmetric and positive definite.*

Proof. Let $\{\mathbf{v}_i\}$ and $\{w_j\}$ be the bases of $\mathbf{V}_h$ and W_h, respectively. The algebraic system that arises from (2.41)–(2.42) is of the form

$$\begin{pmatrix}A & B^T\\ B & 0\end{pmatrix}\begin{pmatrix}U\\ P\end{pmatrix}=\begin{pmatrix}G\\ F\end{pmatrix}, \tag{2.50}$$

where $A_{ij}=(K^{-1}\mathbf{v}_i,\mathbf{v}_j)_Q$ and $B_{ij}=-(\nabla\cdot\mathbf{v}_i,w_j)$. The matrix A is block-diagonal with symmetric and positive definite blocks, as noted in Proposition 2.7. The elimination of U leads to a system for P with a matrix

$$BA^{-1}B^T,$$

which is symmetric and positive semidefinite. In the proof of Lemma 2.6 we showed that $B^TP=0$ implies $P=0$. Therefore $BA^{-1}B^T$ is positive definite. ∎

3. Velocity error analysis. Although our method can be defined and is well posed on general quadrilaterals (see section 2), for the convergence analysis we need to impose a restriction on the element geometry. This is due to the reduced approximation properties of the MFE spaces on general quadrilaterals [8]. The restriction

is not needed for theoretical purpose only; deterioration of convergence is observed computationally as well [3].

For the remainder of the paper we will assume that the quadrilateral elements are $O(h^2)$-perturbations of parallelograms:

$$\|\mathbf{r}_{34} - \mathbf{r}_{21}\| \le Ch^2. \tag{3.1}$$

We call such elements h^2-parallelograms, following the terminology from [21]. Elements of this type are obtained by uniform refinements of a general quadrilateral grid. It is not difficult to check that in this case $||T_2| - |T_1|| \le Ch^3$, $||T_4| - |T_1|| \le Ch^3$, and

$$|DF_E|_{1,\infty,\hat{E}} \le Ch^2 \quad \text{and} \quad \left|\frac{1}{J_E} DF_E\right|_{j,\infty,\hat{E}} \le Ch^{j-1}, \quad j = 1, 2. \tag{3.2}$$

In this section we establish first-order convergence for the velocity. We start with several auxiliary results that will be used in the analysis.

In addition to the mixed projection operators defined earlier, we will also make use of the L^2-orthogonal projection onto W_h: for any $\phi \in L^2(\Omega)$, let $\mathcal{Q}_h\phi \in W_h$ satisfy

$$(\phi - \mathcal{Q}_h\phi, w) = 0 \qquad \forall w \in W_h.$$

We state several well-known approximation properties of the projection operators. On simplices and h^2-parallelograms,

$$\|\phi - \mathcal{Q}_h\phi\| \le C\|\phi\|_r h^r, \quad 0 \le r \le 1, \tag{3.3}$$

$$\|\mathbf{q} - \Pi\mathbf{q}\| \le C\|\mathbf{q}\|_r h^r, \quad 1 \le r \le 2, \tag{3.4}$$

$$\|\mathbf{q} - \Pi_0\mathbf{q}\| \le C\|\mathbf{q}\|_1 h, \tag{3.5}$$

$$\|\nabla \cdot (\mathbf{q} - \Pi\mathbf{q})\| + \|\nabla \cdot (\mathbf{q} - \Pi_0\mathbf{q})\| \le C\|\nabla \cdot \mathbf{q}\|_r h^r, \quad 0 \le r \le 1. \tag{3.6}$$

Bound (3.3) is a standard L^2-projection approximation results [18]; bounds (3.4), (3.5), and (3.6) can be found in [15, 28] for affine elements and [32, 8] for h^2-parallelograms. We note that on general quadrilaterals bounds (3.3) and (3.5) are also true, while bounds (3.4) and (3.6) are only valid for $r = 1$ and $r = 0$, respectively [8].

It was shown in [21, Lemma 5.5] that on h^2-parallelograms, for $\mathbf{u} \in H^j(E)$,

$$|\hat{\mathbf{u}}|_{j,\hat{E}} \le Ch^j \|\mathbf{u}\|_{j,E}, \quad j \ge 0. \tag{3.7}$$

We will make use of the following continuity bounds for Π and Π_0.

LEMMA 3.1. *For all elements E there exists a constant C independent of h such that*

$$\|\Pi\mathbf{q}\|_{j,E} \le C\|\mathbf{q}\|_{j,E} \quad \forall \mathbf{q} \in (H^j(E))^d, \quad j = 1, 2, \tag{3.8}$$

$$\|\Pi_0\mathbf{q}\|_{1,E} \le C\|\mathbf{q}\|_{1,E} \quad \forall \mathbf{q} \in (H^1(E))^d. \tag{3.9}$$

Proof. The proof uses the inverse inequality

$$\|\mathbf{v}\|_{j,E} \le Ch^{-1}\|\mathbf{v}\|_{j-1,E}, \quad j = 1, 2 \quad \forall\, E \in \mathcal{T}_h,\ \mathbf{v} \in \mathbf{V}_h(E), \tag{3.10}$$

which is well known for affine elements [18] and can be shown for quadrilaterals via mapping to the reference element $\hat{E}$ and using the standard inverse inequality on $\hat{E}$; see [11] for details.

Let $\bar{\mathbf{q}}$ be the $L^2(E)$-projection of $\mathbf{q}$ onto the space of constant vectors on E. Using (3.10), we have

$$\begin{aligned}|\Pi\mathbf{q}|_{1,E} &= |\Pi\mathbf{q} - \bar{\mathbf{q}}|_{1,E} \le Ch^{-1}\|\Pi\mathbf{q} - \bar{\mathbf{q}}\|_E \\ &\le Ch^{-1}(\|\Pi\mathbf{q} - \mathbf{q}\|_E + \|\mathbf{q} - \bar{\mathbf{q}}\|_E) \le C\|\mathbf{q}\|_{1,E},\end{aligned}$$

where we have used the approximation properties (3.3) and (3.4) for the last inequality.

Similarly, taking $\mathbf{q}_1$ to be the $L^2(E)$-projection of $\mathbf{q}$ onto the space of linear vectors on E, we obtain

$$\begin{aligned}|\Pi\mathbf{q}|_{2,E} &= |\Pi\mathbf{q} - \mathbf{q}_1|_{2,E} \le Ch^{-2}\|\Pi\mathbf{q} - \mathbf{q}_1\|_E \\ &\le Ch^{-2}(\|\Pi\mathbf{q} - \mathbf{q}\|_E + \|\mathbf{q} - \mathbf{q}_1\|_E) \le C\|\mathbf{q}\|_{2,E}.\end{aligned}$$

The bound $\|\Pi\mathbf{q}\|_E \le C\|\mathbf{q}\|_{1,E}$ follows from the approximation property (3.4). This completes the proof of (3.8). The proof of (3.9) is similar. ∎

The following two lemmas will also be used in the analysis.

LEMMA 3.2. *If E is an h^2-parallelogram, then there exists a constant C independent of h such that*

$$|\mathcal{K}^{-1}|_{j,\infty,\hat{E}} \le Ch^j\|K^{-1}\|_{j,\infty,E}, \quad j = 1, 2. \tag{3.11}$$

Proof. Using (3.2), we have

$$|\mathcal{K}^{-1}|_{1,\infty,\hat{E}} \le C(|\hat{K}^{-1}|_{1,\infty,\hat{E}} + h\|\hat{K}^{-1}\|_{0,\infty,\hat{E}}) \le Ch\|K^{-1}\|_{1,\infty,E},$$

where the last inequality follows from the use of the chain rule and (2.14). Similarly,

$$|\mathcal{K}^{-1}|_{2,\infty,\hat{E}} \le C(|\hat{K}^{-1}|_{2,\infty,\hat{E}} + h|\hat{K}^{-1}|_{1,\infty,\hat{E}} + h^2\|\hat{K}^{-1}\|_{0,\infty,\hat{E}}) \le Ch^2\|K^{-1}\|_{2,\infty,E},$$

where we have also used $|DF_E|_{2,\infty,\hat{E}} = 0$. ∎

Let $W^{\alpha}_{\mathcal{T}_h}$ consist of functions φ such that $\varphi|_E \in W^{\alpha}(E)$ for all $E \in \mathcal{T}_h$ and $\|\varphi\|_{\alpha,E}$ is uniformly bounded, independently of h. Let $\|\varphi\|_{\alpha} = \max_{E\in\mathcal{T}_h}\|\varphi\|_{\alpha,E}$.

LEMMA 3.3. *On h^2-parallelograms, if $K^{-1} \in W^{1,\infty}_{\mathcal{T}_h}$, then there exists a constant C independent of h such that for all $\mathbf{v} \in \mathbf{V}_h$*

$$|(K^{-1}\Pi\mathbf{u}, \mathbf{v} - \Pi_0\mathbf{v})_Q| \le Ch\|\mathbf{u}\|_1\|\mathbf{v}\|. \tag{3.12}$$

Proof. On any element E we have

$$\begin{aligned}(K^{-1}\Pi\mathbf{u}, \mathbf{v} - \Pi_0\mathbf{v})_{Q,E} &= (\mathcal{K}^{-1}\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}} \\ &= ((\mathcal{K}^{-1} - \overline{\mathcal{K}^{-1}})\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}} + (\overline{\mathcal{K}^{-1}}\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}},\end{aligned} \tag{3.13}$$

where $\overline{\mathcal{K}^{-1}}$ is the mean value of $\mathcal{K}^{-1}$ on $\hat{E}$. Using Taylor expansion and (2.45), we have for the first term on the right above

$$\begin{aligned}|((\mathcal{K}^{-1} - \overline{\mathcal{K}^{-1}})\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}}| &\le C|\mathcal{K}^{-1}|_{1,\infty,\hat{E}}\|\hat{\Pi}\hat{\mathbf{u}}\|_{\hat{E}}\|\hat{\mathbf{v}}\|_{\hat{E}} \\ &\le Ch\|K^{-1}\|_{1,\infty,E}\|\mathbf{u}\|_{1,E}\|\mathbf{v}\|_E,\end{aligned} \tag{3.14}$$

where we have used (3.11), (2.43), and (3.8) for the last inequality. Using (2.40) and letting $\overline{\hat{\Pi}\hat{\mathbf{u}}}$ be the L^2-projection of $\hat{\Pi}\hat{\mathbf{u}}$ onto the space of constant vectors on $\hat{E}$, we bound the last term in (3.13) as follows:

(3.15)
$$|(\overline{\mathcal{K}^{-1}}\hat{\Pi}\hat{\mathbf{u}}, \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}}| = |(\overline{\mathcal{K}^{-1}}(\hat{\Pi}\hat{\mathbf{u}} - \overline{\hat{\Pi}\hat{\mathbf{u}}}), \hat{\mathbf{v}} - \hat{\Pi}_0\hat{\mathbf{v}})_{\hat{Q},\hat{E}}|$$
$$\leq C\|\mathcal{K}^{-1}\|_{0,\infty,\hat{E}}|\hat{\Pi}\hat{\mathbf{u}}|_{1,\hat{E}}\|\hat{\mathbf{v}}\|_{\hat{E}} \leq Ch\|K^{-1}\|_{0,\infty,E}\|\mathbf{u}\|_{1,E}\|\mathbf{v}\|_E,$$

where we have also used (2.32), (3.7), and (3.8). The proof is completed by combining (3.13)–(3.15). ∎

3.1. First-order convergence for the velocity. Subtracting the numerical method (2.41)–(2.42) from the variational formulation (2.6)–(2.7), we obtain the error equations

$$(K^{-1}(\Pi\mathbf{u} - \mathbf{u}_h), \mathbf{v})_Q = (Q_h p - p_h, \nabla\cdot\mathbf{v})$$
$$- (K^{-1}\mathbf{u}, \mathbf{v}) + (K^{-1}\Pi\mathbf{u}, \mathbf{v})_Q, \quad \mathbf{v} \in \mathbf{V}_h, \tag{3.16}$$
$$(\nabla\cdot(\Pi\mathbf{u} - \mathbf{u}_h), w) = 0, \quad w \in W_h. \tag{3.17}$$

The last two terms in (3.16) can be manipulated as follows:

$$\begin{aligned} -(K^{-1}\mathbf{u}, \mathbf{v}) + (K^{-1}\Pi\mathbf{u}, \mathbf{v})_Q &= -(K^{-1}\mathbf{u}, \mathbf{v} - \Pi_0\mathbf{v}) - (K^{-1}(\mathbf{u} - \Pi\mathbf{u}), \Pi_0\mathbf{v}) \\ &\quad - (K^{-1}\Pi\mathbf{u}, \Pi_0\mathbf{v}) + (K^{-1}\Pi\mathbf{u}, \Pi_0\mathbf{v})_Q + (K^{-1}\Pi\mathbf{u}, \mathbf{v} - \Pi_0\mathbf{v})_Q. \end{aligned} \tag{3.18}$$

For the first term on the right above we have

$$(K^{-1}\mathbf{u}, \mathbf{v} - \Pi_0\mathbf{v}) = 0, \tag{3.19}$$

which follows by taking $\mathbf{v} - \Pi_0\mathbf{v}$ as a test function in the variational formulation (2.6) and using (2.27). Using (3.4) and (2.28), the second term on the right in (3.18) can be bounded as

$$|(K^{-1}(\mathbf{u} - \Pi\mathbf{u}), \Pi_0\mathbf{v})| \leq Ch\|K^{-1}\|_{0,\infty}\|\mathbf{u}\|_1\|\mathbf{v}\|. \tag{3.20}$$

The third and fourth term on the right in (3.18) represent the quadrature error, which can be bounded by Lemma 3.5 as

$$|\sigma(K^{-1}\Pi\mathbf{u}, \Pi_0\mathbf{v})| \leq Ch|||K^{-1}|||_{1,\infty}\|\mathbf{u}\|_1\|\mathbf{v}\|, \tag{3.21}$$

using also (3.8) and (2.28). The last term on the right in (3.18) is bounded in Lemma 3.3.

We take $\mathbf{v} = \Pi\mathbf{u} - \mathbf{u}_h$ in the error equation (3.16) above. Note that

$$\nabla\cdot(\Pi\mathbf{u} - \mathbf{u}_h) = 0, \tag{3.22}$$

since, due to (2.19), we can choose $w = J_E\nabla\cdot(\Pi\mathbf{u} - \mathbf{u}_h) \in W_h$ on any element E in (3.17) and J_E is uniformly positive. Combining (3.18)–(3.21) with (2.44) and (3.12), we obtain

$$\|\Pi\mathbf{u} - \mathbf{u}_h\| \leq Ch|||K^{-1}|||_{1,\infty}\|\mathbf{u}\|_1. \tag{3.23}$$

The theorem below now follows from (3.23), (3.22), (3.4), and (3.6).

THEOREM 3.4. *If $K^{-1} \in W^{1,\infty}_{\mathcal{T}_h}$, then, for the velocity $\mathbf{u}_h$ of the MFMFE method (2.41)–(2.42), there exists a constant C independent of h such that*

$$\|\mathbf{u} - \mathbf{u}_h\| \le Ch\|\mathbf{u}\|_1, \tag{3.24}$$

$$\|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\| \le Ch\|\nabla \cdot \mathbf{u}\|_1. \tag{3.25}$$

We now proceed with the analysis of the quadrature error.

LEMMA 3.5. *If $K^{-1} \in W^{1,\infty}_{\mathcal{T}_h}$, then there exists a constant C independent of h such that for all $\mathbf{q} \in \mathbf{V}_h$ and for all $\mathbf{v} \in \mathbf{V}_h^0$,*

$$|\sigma(K^{-1}\mathbf{q}, \mathbf{v})| \le C \sum_{E \in \mathcal{T}_h} h\|K^{-1}\|_{1,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_E. \tag{3.26}$$

Proof. We first consider the case of simplicial elements. We have on any element E

$$|\sigma_E(K^{-1}\mathbf{q}, \mathbf{v})| \le |\sigma_E((K^{-1} - \overline{K^{-1}})\mathbf{q}, \mathbf{v})| + |\sigma_E(\overline{K^{-1}}\mathbf{q}, \mathbf{v})|, \tag{3.27}$$

where $\overline{K^{-1}}$ is the mean value of K^{-1} on E. For the first term on the right we have

$$|\sigma_E((K^{-1} - \overline{K^{-1}})\mathbf{q}, \mathbf{v})| \le Ch|K^{-1}|_{1,\infty,E}\|\mathbf{q}\|_E\|\mathbf{v}\|_E, \tag{3.28}$$

where we have used Taylor expansion and (2.45). Let $\overline{\mathbf{q}}$ be the L^2-projection of $\mathbf{q}$ onto the space of constant vectors on E. For the second term on the right in (3.27), using Lemma 2.1, we have that

$$|\sigma_E(\overline{K^{-1}}\mathbf{q}, \mathbf{v})| = |\sigma_E(\overline{K^{-1}}(\mathbf{q} - \overline{\mathbf{q}}), \mathbf{v})| \le Ch\|K^{-1}\|_{0,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_E, \tag{3.29}$$

using (3.3). Combining (3.27)–(3.29), we obtain

$$|\sigma_E(K^{-1}\mathbf{q}, \mathbf{v})| \le Ch\|K^{-1}\|_{1,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_E, \tag{3.30}$$

completing the proof of (3.26) for simplicial elements.

Next, consider the quadrature error on h^2-parallelograms. We have

$$\sigma_E(K^{-1}\mathbf{q}, \mathbf{v}) = \hat{\sigma}_{\hat{E}}(\mathcal{K}^{-1}\hat{\mathbf{q}}, \hat{\mathbf{v}}) = \hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1} - \overline{\mathcal{K}^{-1}})\hat{\mathbf{q}}, \hat{\mathbf{v}}) + \hat{\sigma}_{\hat{E}}(\overline{\mathcal{K}^{-1}}\hat{\mathbf{q}}, \hat{\mathbf{v}}), \tag{3.31}$$

where $\overline{\mathcal{K}^{-1}}$ is the mean value of $\mathcal{K}^{-1}$ on $\hat{E}$. Using Taylor expansion, the first term on the right above can be bounded as

$$|\hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1} - \overline{\mathcal{K}^{-1}})\hat{\mathbf{q}}, \hat{\mathbf{v}})| \le C|\mathcal{K}^{-1}|_{1,\infty,\hat{E}}\|\hat{\mathbf{q}}\|_{\hat{E}}\|\hat{\mathbf{v}}\|_{\hat{E}} \le Ch\|K^{-1}\|_{1,\infty,E}\|\mathbf{q}\|_E\|\mathbf{v}\|_E, \tag{3.32}$$

where we used (3.11) and (2.43) for the last inequality. For the last term in (3.31) we have that $\hat{\sigma}_{\hat{E}}(\overline{\mathcal{K}^{-1}}\hat{\mathbf{q}}_0, \hat{\mathbf{v}}) = 0$ for any constant vector $\hat{\mathbf{q}}_0$, since the trapezoidal quadrature rule $(\cdot,\cdot)_{\hat{Q},\hat{E}}$ is exact for linear functions. Hence, the Bramble–Hilbert lemma [13] implies

$$|\hat{\sigma}_{\hat{E}}(\overline{\mathcal{K}^{-1}}\hat{\mathbf{q}}, \hat{\mathbf{v}})| \le C\|\mathcal{K}^{-1}\|_{0,\infty,\hat{E}}|\hat{\mathbf{q}}|_{1,\hat{E}}\|\hat{\mathbf{v}}\|_{\hat{E}}.$$

Using (3.7) and (2.32), we obtain

$$|\hat{\sigma}_{\hat{E}}(\overline{K^{-1}}\hat{\mathbf{q}},\hat{\mathbf{v}})| \le Ch\|K^{-1}\|_{0,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_E. \tag{3.33}$$

The above bound, together with (3.31)–(3.32), implies that

$$|\sigma_E(K^{-1}\mathbf{q},\mathbf{v})| \le Ch\|K^{-1}\|_{1,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_E.$$

The proof is completed by summing over all elements E. ∎

4. Error estimates for the pressure. In this section we use a standard inf-sup argument to prove optimal convergence for the pressure. We also employ a duality argument to establish superconvergence for the pressure at the element centers of mass.

4.1. First-order convergence for the pressure. We start with an optimal error bound for the pressure.

THEOREM 4.1. *If $K^{-1} \in W^{1,\infty}_{\mathcal{T}_h}$, then, for the pressure p_h of the MFMFE method* (2.41)–(2.42)*, there exists a constant C independent of h such that*

$$\|p - p_h\| \le Ch(\|\mathbf{u}\|_1 + \|p\|_1).$$

Proof. It is well known [27, 15, 32] that the RT_0 spaces $\mathbf{V}_h^0 \times W_h^0$ satisfy the inf-sup condition

$$\inf_{0\neq w\in W_h^0}\sup_{0\neq \mathbf{v}\in\mathbf{V}_h^0}\frac{(\nabla\cdot\mathbf{v},w)}{\|\mathbf{v}\|_{\mathrm{div}}\|w\|} \ge \beta, \tag{4.1}$$

where β is a positive constant independent of h. Using (4.1) and (3.16), we obtain

$$\begin{aligned}
&\|\mathcal{Q}_h p - p_h\| \\
&\quad\le \frac{1}{\beta}\sup_{0\neq\mathbf{v}\in\mathbf{V}_h^0}\frac{(\nabla\cdot\mathbf{v},\mathcal{Q}_h p - p_h)}{\|\mathbf{v}\|_{\mathrm{div}}} \\
&\quad= \frac{1}{\beta}\sup_{0\neq\mathbf{v}\in\mathbf{V}_h^0}\frac{(K^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\mathbf{v})_Q - (K^{-1}(\Pi\mathbf{u}-\mathbf{u}),\mathbf{v}) + \sigma(K^{-1}\Pi\mathbf{u},\mathbf{v})}{\|\mathbf{v}\|_{\mathrm{div}}} \\
&\quad\le \frac{C}{\beta}h|||K^{-1}|||_{1,\infty}\|\mathbf{u}\|_1,
\end{aligned}$$

where we have used the Cauchy–Schwarz inequality, (3.23), and (3.26) in the last inequality. The proof is completed by an application of the triangle inequality and (3.3). ∎

4.2. Second-order convergence for the pressure. We continue with the superconvergence estimate. We first present a bound on the quadrature error that will be used in the analysis.

LEMMA 4.2. *Let $K^{-1} \in W^{2,\infty}_{\mathcal{T}_h}$. On simplicial elements, for all $\mathbf{v},\mathbf{q} \in \mathbf{V}_h$, there exists a positive constant C independent of h such that*

$$|\sigma(K^{-1}\mathbf{q},\mathbf{v})| \le C\sum_{E\in\mathcal{T}_h} h^2\|K^{-1}\|_{2,\infty,E}\|\mathbf{q}\|_{1,E}\|\mathbf{v}\|_{1,E}. \tag{4.2}$$

On h^2-parallelograms, for all $\mathbf{q} \in \mathbf{V}_h$, $\mathbf{v} \in \mathbf{V}_h^0$, there exists a positive constant C independent of h such that

$$|\sigma(K^{-1}\mathbf{q}, \mathbf{v})| \leq C \sum_{E \in \mathcal{T}_h} h^2 \|K^{-1}\|_{2,\infty,E} \|\mathbf{q}\|_{2,E} \|\mathbf{v}\|_{1,E}. \tag{4.3}$$

Proof. We present first the proof for simplicial elements. For any element E, using Lemma 2.1, we have

$$\begin{aligned} \sigma_E(K^{-1}\mathbf{q}, \mathbf{v}) = {} & \sigma_E((K^{-1} - \overline{K^{-1}})(\mathbf{q} - \bar{\mathbf{q}}), \mathbf{v}) + \sigma_E((K^{-1} - \overline{K^{-1}})\bar{\mathbf{q}}, \mathbf{v} - \bar{\mathbf{v}}) \\ & + \sigma_E(K^{-1}\bar{\mathbf{q}}, \bar{\mathbf{v}}) + \sigma_E(\overline{K^{-1}}(\mathbf{q} - \bar{\mathbf{q}}), \mathbf{v} - \bar{\mathbf{v}}), \end{aligned} \tag{4.4}$$

where $\bar{\mathbf{q}}$ and $\bar{\mathbf{v}}$ are the $L^2(E)$-orthogonal projections of $\mathbf{q}$ and $\mathbf{v}$, respectively, onto the space of constant vectors, and $\overline{K^{-1}}$ is the mean value of K^{-1} on E. Using (2.45), the first, second, and fourth term on the right above are bounded by

$$Ch^2 \|K^{-1}\|_{1,\infty,E} \|\mathbf{q}\|_{1,E} \|\mathbf{v}\|_{1,E}. \tag{4.5}$$

For the third term on the right in (4.4) it is easy to check that the quadrature rule is exact for linear tensors. An application of the Bramble–Hilbert lemma [13] gives

$$|\sigma_E(K^{-1}\bar{\mathbf{q}}, \bar{\mathbf{v}})| \leq Ch^2 |K^{-1}\bar{\mathbf{q}}|_{2,E} \|\bar{\mathbf{v}}\|_E \leq Ch^2 |K^{-1}|_{2,\infty,E} \|\mathbf{q}\|_E \|\mathbf{v}\|_E. \tag{4.6}$$

A combination of (4.4)–(4.6) completes the proof for simplicial elements.

We proceed with the bound on the quadrature error in the case of h^2-parallelograms. We have

$$\sigma_E(K^{-1}\mathbf{q}, \mathbf{v}) = \hat{\sigma}_{\hat{E}}(\mathcal{K}^{-1}\hat{\mathbf{q}}, \hat{\mathbf{v}}) = \hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1}\hat{\mathbf{q}})_1, \hat{v}_1) + \hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1}\hat{\mathbf{q}})_2, \hat{v}_2). \tag{4.7}$$

Let us consider the first term on the right. Since the quadrature rule is exact for linear functions, the Peano kernel theorem [31, Theorem 5.2–3] implies

$$\begin{aligned} \hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1}\hat{\mathbf{q}})_1, \hat{v}_1) = {} & \int_0^1 \int_0^1 \varphi(\hat{x}) \frac{\partial^2}{\partial \hat{x}^2} ((\mathcal{K}^{-1}\hat{\mathbf{q}})_1 \hat{v}_1)(\hat{x}, 0) d\hat{x}\, d\hat{y} \\ & + \int_0^1 \int_0^1 \varphi(\hat{y}) \frac{\partial^2}{\partial \hat{y}^2} ((\mathcal{K}^{-1}\hat{\mathbf{q}})_1 \hat{v}_1)(0, \hat{y})\, d\hat{x} d\hat{y} \\ & + \int_0^1 \int_0^1 \psi(\hat{x}, \hat{y}) \frac{\partial^2}{\partial \hat{x} \partial \hat{y}} ((\mathcal{K}^{-1}\hat{\mathbf{q}})_1 \hat{v}_1)(\hat{x}, \hat{y}) d\hat{x}\, d\hat{y}, \end{aligned} \tag{4.8}$$

where $\varphi(s) = s(s-1)/2$ and $\psi(s,t) = (1-s)(1-t) - 1/4$. Therefore, using that $\hat{\mathbf{v}}$ is linear,

$$\begin{aligned} |\hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1}\hat{\mathbf{q}})_1, \hat{v}_1)| \leq {} & C((|\mathcal{K}^{-1}|_{1,\infty,\hat{E}} \|\hat{\mathbf{q}}\|_{\hat{E}} + \|\mathcal{K}^{-1}\|_{0,\infty,\hat{E}} |\hat{\mathbf{q}}|_{1,\hat{E}}) |\hat{\mathbf{v}}|_{1,\hat{E}} \\ & + (|\mathcal{K}^{-1}|_{2,\infty,\hat{E}} \|\hat{\mathbf{q}}\|_{\hat{E}} + |\mathcal{K}^{-1}|_{1,\infty,\hat{E}} |\hat{\mathbf{q}}|_{1,\hat{E}} + \|\mathcal{K}^{-1}\|_{0,\infty,\hat{E}} |\hat{\mathbf{q}}|_{2,\hat{E}}) \|\hat{\mathbf{v}}\|_{\hat{E}}). \end{aligned}$$

The term $\hat{\sigma}_{\hat{E}}((\mathcal{K}^{-1}\hat{\mathbf{q}})_2, \hat{v}_2)$ in (4.7) can be bounded similarly. Using (4.7), (2.32), (3.11), and (3.7), we obtain

$$|\sigma_E(K^{-1}\mathbf{q}, \mathbf{v})| \leq Ch^2 \|K^{-1}\|_{2,\infty,E} \|\mathbf{q}\|_{2,E} \|\mathbf{v}\|_{1,E}.$$

Summing over all elements completes the proof. ∎

We are now ready to establish superconvergence of the pressure at the cell centers.

THEOREM 4.3. *Assume that* $K \in W^{1,\infty}_{\mathcal{T}_h}$ *and* $K^{-1} \in W^{2,\infty}_{\mathcal{T}_h}$ *and the elliptic regularity* (4.11) *below holds. Then, for the pressure* p_h *of the MFMFE method* (2.41)–(2.42)*, there exists a constant* C *independent of* h *such that*

$$\|\mathcal{Q}_h p - p_h\| \le Ch^2(\|\mathbf{u}\|_1 + \|\nabla\cdot\mathbf{u}\|_1) \quad \text{on simplices} \tag{4.9}$$

and

$$\|\mathcal{Q}_h p - p_h\| \le Ch^2\|\mathbf{u}\|_2 \quad \text{on } h^2\text{-parallelograms.} \tag{4.10}$$

Proof. The proof is based on a duality argument. Let ϕ be the solution of

$$\begin{aligned} -\nabla\cdot K\nabla\phi &= -(\mathcal{Q}_h p - p_h) && \text{in } \Omega,\\ \phi &= 0 && \text{on } \Gamma_D,\\ -K\nabla\phi\cdot\mathbf{n} &= 0 && \text{on } \Gamma_N. \end{aligned}$$

We assume that this problem has H^2-elliptic regularity:

$$\|\phi\|_2 \le C\|\mathcal{Q}_h p - p_h\|_0. \tag{4.11}$$

Sufficient conditions for (4.11) can be found in [22, 26]. For example, (4.11) holds if the components of $K \in C^{0,1}(\overline{\Omega})$, $\partial\Omega$ is smooth enough, and either Γ_D or Γ_N is empty.

Let us consider first the case of simplicial elements. Here it is more convenient to rewrite the error equation (3.16) as

$$(K^{-1}(\mathbf{u}-\mathbf{u}_h),\mathbf{v}) = (Q_h p - p_h, \nabla\cdot\mathbf{v}) - \sigma(K^{-1}\mathbf{u}_h,\mathbf{v}). \tag{4.12}$$

Take $\mathbf{v} = \Pi K\nabla\phi \in \mathbf{V}_h$ in (4.12) to get

$$\begin{aligned} \|\mathcal{Q}_h p - p_h\|_0^2 &= (\mathcal{Q}_h p - p_h, \nabla\cdot\Pi K\nabla\phi)\\ &= (K^{-1}(\mathbf{u}-\mathbf{u}_h),\Pi K\nabla\phi) + \sigma(K^{-1}\mathbf{u}_h,\Pi K\nabla\phi). \end{aligned} \tag{4.13}$$

For the first term on the right above we have

$$\begin{aligned} &(K^{-1}(\mathbf{u}-\mathbf{u}_h),\Pi K\nabla\phi)\\ &\quad= (K^{-1}(\mathbf{u}-\mathbf{u}_h),\Pi K\nabla\phi - K\nabla\phi) + (\mathbf{u}-\mathbf{u}_h,\nabla\phi)\\ &\quad= (K^{-1}(\mathbf{u}-\mathbf{u}_h),\Pi K\nabla\phi - K\nabla\phi) - (\nabla\cdot(\mathbf{u}-\mathbf{u}_h),\phi-\mathcal{Q}_h\phi)\\ &\quad\le C(h\|\mathbf{u}-\mathbf{u}_h\|\|K\|_{1,\infty}\|\phi\|_2 + h\|\nabla\cdot(\mathbf{u}-\mathbf{u}_h)\|\|\phi\|_1)\\ &\quad\le Ch^2\|K\|_{1,\infty}(\|\mathbf{u}\|_1 + \|\nabla\cdot\mathbf{u}\|_1)\|\phi\|_2, \end{aligned} \tag{4.14}$$

where we have used (3.4) and (3.3) for the first inequality, and (3.24) and (3.25) for the second inequality.

Using (4.2), we bound the second term on the right in (4.13) as

$$\begin{aligned} &|\sigma(K^{-1}\mathbf{u}_h,\Pi K\nabla\phi)|\\ &\quad\le C\|K^{-1}\|_{2,\infty}\sum_{E\in\mathcal{T}_h} h^2\|\mathbf{u}_h\|_{1,E}\|\Pi K\nabla\phi\|_{1,E}\\ &\quad\le C\|K^{-1}\|_{2,\infty}\sum_{E\in\mathcal{T}_h} h^2(\|\mathbf{u}_h-\Pi\mathbf{u}\|_{1,E} + \|\Pi\mathbf{u}\|_{1,E})\|K\nabla\phi\|_{1,E}\\ &\quad\le C\|K^{-1}\|_{2,\infty}\sum_{E\in\mathcal{T}_h} h^2(h^{-1}\|\mathbf{u}_h-\Pi\mathbf{u}\|_E + \|\mathbf{u}\|_{1,E})\|K\|_{1,\infty,E}\|\phi\|_{2,E}\\ &\quad\le Ch^2\|K^{-1}\|_{2,\infty}\|K\|_{1,\infty}\|\mathbf{u}\|_1\|\phi\|_2, \end{aligned} \tag{4.15}$$

where we have used (3.8), the inverse inequality (3.10), and (3.23). Now (4.9) follows from (4.13)–(4.15) and (4.11).

For the analysis on h^2-parallelograms we rewrite the error equation (3.16) in the form

$$(K^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\mathbf{v})_Q=(Q_hp-p_h,\nabla\cdot\mathbf{v})+(K^{-1}(\Pi\mathbf{u}-\mathbf{u}),\mathbf{v})-\sigma(K^{-1}\Pi\mathbf{u},\mathbf{v}). \tag{4.16}$$

Take $\mathbf{v}=\Pi_0K\nabla\phi\in\mathbf{V}_h$ in (4.16) to get

$$\begin{aligned}\|\mathcal{Q}_hp-p_h\|_0^2&=(\mathcal{Q}_hp-p_h,\nabla\cdot\Pi_0K\nabla\phi)\\&=(K^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K\nabla\phi)_Q-(K^{-1}(\Pi\mathbf{u}-\mathbf{u}),\Pi_0K\nabla\phi)\\&\quad+\sigma(K^{-1}\Pi\mathbf{u},\Pi_0K\nabla\phi).\end{aligned} \tag{4.17}$$

Using (3.4) and (3.9), the second term on the right above can be bounded as

$$|(K^{-1}(\Pi\mathbf{u}-\mathbf{u}),\Pi_0K\nabla\phi)|\le Ch^2\|K^{-1}\|_{0,\infty}|\!|\!|K|\!|\!|_{1,\infty}\|\mathbf{u}\|_2\|\phi\|_2. \tag{4.18}$$

For the last term on the right in (4.17), bounds (4.3), (3.8), and (3.9) imply that

$$\sigma(K^{-1}\Pi\mathbf{u},\Pi_0K\nabla\phi)\le Ch^2|\!|\!|K^{-1}|\!|\!|_{2,\infty}|\!|\!|K|\!|\!|_{1,\infty}\|\mathbf{u}\|_2\|\phi\|_2. \tag{4.19}$$

The first term on the right in (4.17) can be manipulated as follows:

$$\begin{aligned}&(K^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K\nabla\phi)_{Q,E}\\&\quad=((K^{-1}-K_0^{-1})(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K\nabla\phi)_{Q,E}+(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0(K-K_0)\nabla\phi)_{Q,E}\\&\qquad+(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K_0(\nabla\phi-\nabla\phi_1))_{Q,E}+(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K_0\nabla\phi_1)_{Q,E},\end{aligned} \tag{4.20}$$

where K_0 is the value of K at the center of E and ϕ_1 is a linear approximation to ϕ such that (see [13])

$$\|\phi-\phi_1\|_E\le Ch^2\|\phi\|_{2,E},\quad \|\phi-\phi_1\|_{1,E}\le Ch\|\phi\|_{2,E}. \tag{4.21}$$

Using (3.9), the first term on the right in (4.20) can be bounded as

$$|((K^{-1}-K_0^{-1})(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K\nabla\phi)_{Q,E}|\le Ch\|K^{-1}\|_{1,\infty,E}\|K\|_{1,\infty,E}\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi\|_{2,E}. \tag{4.22}$$

For the second and third terms on the right in (4.20) we use that for any $\psi\in(H^1(E))^2$

$$\|\Pi_0\psi\|_E\le\|\Pi_0\psi-\psi\|_E+\|\psi\|_E\le C(h\|\psi\|_{1,E}+\|\psi\|_E)$$

to obtain

$$|(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0(K-K_0)\nabla\phi)_{Q,E}|\le Ch\|K^{-1}\|_{0,\infty,E}\|K\|_{1,\infty,E}\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi\|_{2,E} \tag{4.23}$$

and

$$\begin{aligned}&|(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K_0(\nabla\phi-\nabla\phi_1))_{Q,E}|\\&\quad\le Ch\|K^{-1}\|_{0,\infty,E}\|K\|_{0,\infty,E}\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi\|_{2,E},\end{aligned} \tag{4.24}$$

having also used (4.21) in the last inequality. For the last term in (4.20) we have

(4.25)
$$(K_0^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K_0\nabla\phi_1)_{Q,E}=(\Pi\mathbf{u}-\mathbf{u}_h,\nabla\phi_1)_{Q,E}=(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}\hat{\phi}_1)_{\hat{Q},\hat{E}},$$

using $\nabla\phi_1=(DF^{-1})^T\hat{\nabla}\hat{\phi}_1$ in the second equality. Note that $\hat{\phi}(\hat{x},\hat{y})$ is a bilinear function. Let $\tilde{\phi}_1$ be the linear part of $\hat{\phi}_1$. We have

$$(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}\hat{\phi}_1)_{\hat{Q},\hat{E}}=(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}(\hat{\phi}_1-\tilde{\phi}_1))_{\hat{Q},\hat{E}}+(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}\tilde{\phi}_1)_{\hat{Q},\hat{E}}. \tag{4.26}$$

Since (see (2.8))

$$\hat{\nabla}(\hat{\phi}_1-\tilde{\phi}_1)=[(\mathbf{r}_{34}-\mathbf{r}_{21})\cdot\nabla\phi_1]\begin{pmatrix}\hat{y}\\ \hat{x}\end{pmatrix},$$

(3.1) implies

(4.27)
$$\begin{aligned}|(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}(\hat{\phi}_1-\tilde{\phi}_1))_{\hat{Q},\hat{E}}|&\le Ch^2\|\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h\|_{\hat{E}}\|\nabla\phi_1\|_{\hat{E}}\\ &\le Ch\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\nabla\phi_1\|_E\le Ch\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi\|_{2,E}.\end{aligned}$$

It remains to bound the last term in (4.26). Using (2.40) and the fact that the trapezoidal rule is exact for linear functions, we have

$$\begin{aligned}(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h,\hat{\nabla}\tilde{\phi}_1)_{\hat{Q},\hat{E}}&=(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}\tilde{\phi}_1)_{\hat{Q},\hat{E}}=(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}\tilde{\phi}_1)_{\hat{E}}\\ &=(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}(\tilde{\phi}_1-\hat{\phi}_1))_{\hat{E}}+(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}\hat{\phi}_1)_{\hat{E}}.\end{aligned} \tag{4.28}$$

The first term on the right in (4.28) is bounded similarly to (4.27):

$$|(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}(\tilde{\phi}_1-\hat{\phi}_1))_{\hat{E}}|\le Ch\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi\|_{2,E}. \tag{4.29}$$

For the last term in (4.28) we have

$$(\hat{\Pi}_0(\hat{\Pi}\hat{\mathbf{u}}-\hat{\mathbf{u}}_h),\hat{\nabla}\hat{\phi}_1)_{\hat{E}}=(\Pi_0(\Pi\mathbf{u}-\mathbf{u}_h),\nabla\phi_1)_E. \tag{4.30}$$

Combining (4.20)–(4.30) and summing over all elements, we obtain

$$(K^{-1}(\Pi\mathbf{u}-\mathbf{u}_h),\Pi_0K\nabla\phi)_Q=R+\sum_{E\in\mathcal{T}_h}(\Pi_0(\Pi\mathbf{u}-\mathbf{u}_h),\nabla\phi_1)_E, \tag{4.31}$$

where

$$|R|\le Ch^2|||K^{-1}|||_{1,\infty}|||K|||_{1,\infty}\|\mathbf{u}\|_1\|\phi\|_2, \tag{4.32}$$

having also used (3.23). For the last term in (4.31), using the regularity of ϕ, (3.22), (2.27), and that $(\Pi\mathbf{u}-\mathbf{u}_h)\cdot\mathbf{n}=0$ on Γ_N and $\phi=0$ on Γ_D, we obtain

$$\begin{aligned}\left|\sum_{E\in\mathcal{T}_h}(\Pi_0(\Pi\mathbf{u}-\mathbf{u}_h),\nabla\phi_1)_E\right|&=\left|\sum_{E\in\mathcal{T}_h}(\Pi_0(\Pi\mathbf{u}-\mathbf{u}_h),\nabla(\phi_1-\phi))_E\right|\\ &\le C\sum_{E\in\mathcal{T}_h}\|\Pi\mathbf{u}-\mathbf{u}_h\|_E\|\phi_1-\phi\|_{1,E}\\ &\le Ch^2|||K^{-1}|||_{1,\infty}\|\mathbf{u}\|_1\|\phi\|_2,\end{aligned} \tag{4.33}$$

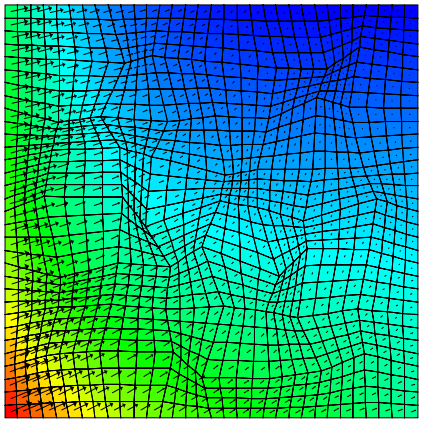


FIG. 5.1. *Computed solution on the second level of refinement in Example* 1.

where we have used (3.23) and (4.21). The proof of (4.10) is completed by combining (4.17)–(4.19) and (4.31)–(4.33), and using (4.11). ∎

Remark 4.1. Since $\mathcal{Q}_h p$ is $O(h^2)$-close to p at the center of mass of each element, the above theorem implies that

$$|||p - p_h||| \le Ch^2,$$

where $|||\cdot||| = \left(\sum_E |E|(p(m_E) - p_h)^2\right)^{1/2}$ and m_E is the center of mass of E.

5. Numerical experiments. In this section we present several numerical results on quadrilateral grids that confirm the theoretical results from the previous sections.

In the first example we test the method on a sequence of meshes obtained by a uniform refinement of an initial rough quadrilateral mesh. The boundary conditions are of Dirichlet type. The tensor coefficient and the true solution are

$$K = \begin{pmatrix} 5 & 1 \\ 1 & 2 \end{pmatrix}, \quad p(x,y) = (1-x)^4 + (1-y)^3(1-x) + \sin(1-y)\cos(1-x).$$

The initial 8×8 mesh is generated from a square mesh by randomly perturbing the location of each vertex within a disk centered at the vertex with a radius $h\sqrt{2}/3$. Due to (2.31), the nonsmoothness of the grid translates into a discontinuous computational permeability $\mathcal{K}$. The computed solution on the second level of refinement is shown in Figure 5.1. The colors represent the pressure values and the arrows represent the velocity vectors. The numerical errors and asymptotic convergence rates are obtained on a sequence of six mesh refinements and are reported in Table 5.1. Here, for scalar functions $|||w|||$ is the discrete L^2-norm defined in Remark 4.1 and for vectors $|||\mathbf{v}|||$ denotes a discrete vector L^2-norm that involves only the normal vector components at the midpoints of the edges. We note that the obtained convergence rates of $O(h^2)$ for $|||p-p_h|||$ and $O(h)$ for $\|\mathbf{u}-\mathbf{u}_h\|$ confirm the theoretical results. The $O(h^2)$ accuracy for $|||\mathbf{u} - \mathbf{u}_h|||$ and $|||\nabla \cdot (\mathbf{u} - \mathbf{u}_h)|||$ indicates superconvergence for the normal velocities at the midpoints of the edges and for the divergence at the cell-centers.

In the second example we consider an irregularly shaped domain consisting of two subdomains; see Figure 5.2. The grid is nonsmooth across the interface leading

to a discontinuous computational permeability $\mathcal{K}$. The permeability tensor and true solution are

$$K = \begin{pmatrix} 4+(x+2)^2+y^2 & 1+\sin(xy) \\ 1+\sin(xy) & 2 \end{pmatrix}, \quad p(x,y) = (\sin(3\pi x))^2(\sin(3\pi y))^2.$$

The boundary conditions are of Neumann type. The computed solution on the second refinement level is shown in Figure 5.2. The numerical errors and asymptotic convergence rates are presented in Table 5.2. As in the previous example, the numerical convergence rates confirm the theory.

6. Conclusions. We have presented a BDM_1-based MFE method with quadrature that reduces to CCFD for the pressure on simplicial and quadrilateral grids. The resulting algebraic system is symmetric and positive definite. The method is closely related to the MPFA method and it performs well on irregular grids and rough coefficients. The analysis is based on combining MFE techniques with quadrature error estimates. First order convergence is obtained for the pressure and the velocity in their natural norms. Second order convergence is obtained for the pressure and the element centers of mass. Computational results also indicate superconvergence for the velocity at the midpoints of the edges on h^2-parallelogram grids. We have also developed and analyzed the method on hexahedral elements that are $O(h^2)$-perturbations of parallelepipeds. These results will be presented in a forthcoming paper.

Remark 6.1. We recently learned of the concurrent and related work of Klausen and Winther [25]. They formulate the MPFA method from [1] as a MFE method

STABILIZED FEM-BEM COUPLING FOR HELMHOLTZ TRANSMISSION PROBLEMS*

R. HIPTMAIR† AND P. MEURY†

Abstract. We consider time-harmonic acoustic scattering at a nonsmooth penetrable object and coupled boundary element finite element schemes for its numerical simulation. Straightforward coupling approaches are haunted by instabilities at wave numbers related to interior resonances, the so-called spurious resonances. A remedy is offered by adopting the idea underlying the widely used combined field integral equations. We apply it in the form of modified trace operators. These will also feature regularizing operators to offset the lack of compactness of the double-layer potential integral operators on nonsmooth surfaces. Calderón projectors can be defined based on the modified trace operators. Thus, Costabel's approach to the symmetric coupling of domain variational formulations and boundary integral equations carries over. The modified traces guarantee uniqueness of solutions of the coupled problem, whereas regularization ensures coercivity. From this we immediately concludeasymptotic quasi-optimality of a combined finite element and boundary element Galerkin discretization for all frequencies.

Key words. acoustic scattering, boundary integral equations, combined field integral equations, Galerkin discretization, finite elements, boundary elements

1. Introduction.

Let $\Omega^- \subset \mathbb{R}^3$ denote volume occupied by an inhomogeneous bounded object.[1] Plane time harmonic sound waves described by a pressure amplitude U^{i} propagate in the exterior homogeneous air region $\Omega^+ := \mathbb{R}^3 \setminus \bar{\Omega}^-$, hit the object, and get scattered.

As explained in [14, sect. 2.1], a suitably scaled pressure amplitude U of the resulting sound field will satisfy the homogeneous Helmholtz equation

$$-\Delta U - \kappa^2 n(\mathbf{x}) U = 0 \quad \text{in } \Omega^- \cup \Omega^+, \tag{1}$$

plus suitable radiation boundary conditions at ∞. The refractive index n belongs to $L^\infty\left(\mathbb{R}^3\right)$. It is allowed to vary spatially inside Ω^-, but is equal to 1 in Ω^+. Furthermore, we assume the *wave number* κ to be positive and real.

The numerical simulation of this acoustic scattering problem is faced with the unbounded domain Ω^+. Many different strategies have been devised to cope with this challenge: one could truncate Ω^+ and use standard finite elements in conjunction with absorbing boundary conditions [22]. An alternative is provided by infinite elements in Ω^+ [5, 3] or the method of fundamental solutions [20].

However, in this article we will restrict ourselves to another possibility, namely boundary integral equation methods, which reduce the problem in Ω^+ to equations on the bounded surface $\Gamma := \partial\Omega^-$. Boundary integral equations come in different varieties, among them direct and indirect methods [21, Ch. 8].

Useful integral equations remain elusive for boundary value problems with nonconstant coefficients. This is the case inside Ω^- and, therefore, we are forced to use a

[1]We assume that Ω^- is a curvilinear Lipschitz-polyhedron in the sense of [17, sect. 1].

classical spatial discretization like the finite element method to discretize (1) in Ω^-. This entails linking the weak variational formulation of (1) with boundary integral equations on Γ.

In short, coupled problems are derived by expressing the Dirichlet-to-Neumann map of the exterior problem by means of boundary integral operators. This can be done in many ways. Yet, in many cases, in particular with so-called indirect formulations, the resulting operator lacks structural properties of the Dirichlet-to-Neumann map. This is blatantly obvious in the case of second order elliptic problems [25]. If structure is not preserved, theoretical analysis becomes much more difficult, and the linear systems of equations obtained through Galerkin boundary element discretization are adversely affected.

For second order elliptic problems, Costabel [15] discovered that the so-called direct boundary integral equations provide a remedy. The key concept is that of the Calderón projector acting on the Cauchy data of the problem. For details and theoretical examinations we refer to [12, sect. 4.5] and [18]. In short, the Calderón projector supplies two sets of boundary integral equations. Judiciously combining them yields a version of the Dirichlet-to-Neumann map that perfectly lends itself to a Galerkin discretization. The realization of Costabel's idea is called the "symmetric coupling approach" to marrying finite elements and boundary elements. It has been applied to a wide range of transmission problems; see, among many others, [11, 23, 27, 24].

Unfortunately, for the acoustic scattering problem the direct symmetric coupling approach invariably leads to equations vulnerable to spurious resonances [19, 31]: if κ^2 agrees with a Dirichlet or Neumann eigenvalue (resonant frequency) of the Laplacian in Ω^-, then the integral equations may fail to possess a unique solution, though the overall scattering problem remains well posed.

One way to deal with spurious resonances is the use of integral operators with modified kernels [35, 26]. Here we will restrict our attention to another remedy, namely the widely used combined field integral equations (CFIE). They owe their name to the typical complex linear combination of different boundary integral operators on the left-hand side of the final boundary integral equation. In the case of indirect schemes this trick has been discovered independently by Brakhage and Werner [6], Leis [28], and Panich [30] in 1965. In 1971 Burton and Miller used the same idea to obtain direct boundary integral equations without spurious resonances [10]. Meanwhile, CFIEs have become the foundation for numerous numerical methods in direct and inverse acoustic and electromagnetic scattering [14, Ch. 3 & 6].

We aim to pursue symmetric coupling based on CFIE. To do so we first have to identify related Calderón projectors. Second, we have to overcome a potential lack of coercivity of the coupled system due to the fact that the double-layer integral operators fail to be compact on nonsmooth surfaces. Both problems are tackled by introducing modified trace operators. These are motivated by the regularization approach to CFIE developed in [7, 8, 9] based on ideas by Panich [30]. We remark that introducing additional operators into boundary integral equations in order to improve their properties has also been successful in the case of high frequency scattering [1, 2].

Throughout this paper, we adopt a theoretical focus stressing complete and rigorous mathematical analysis of the resulting variational formulations. Assessing the practical relevance of the new approach is difficult, because gains from unconditional stability have to be weighed against increased computational effort.

2. The transmission problem. We depart from a formulation of the scattering problem as a transmission problem. To do so we have to rely on the following continuous and surjective trace mappings [16, Lemma 3.2]:

$$\begin{aligned} \text{Dirichlet trace} \quad & \gamma_0^{\pm} : H^1_{\mathrm{loc}}\left(\Omega^{\pm}\right) \to H^{\frac{1}{2}}\left(\Gamma\right), \\ \text{Neumann trace} \quad & \gamma_1^{\pm} : H_{\mathrm{loc}}\left(\Delta, \Omega^{\pm}\right) \to H^{-\frac{1}{2}}\left(\Gamma\right). \end{aligned}$$

We refer to [29, Ch. 3] for the definitions of function spaces $H^1_{\mathrm{loc}}\left(\Omega^{\pm}\right)$, $H_{\mathrm{loc}}\left(\Delta, \Omega^{\pm}\right)$, $H^{\frac{1}{2}}\left(\Gamma\right)$, and $H^{-\frac{1}{2}}\left(\Gamma\right)$. The trace operators generalize the following pointwise restrictions of smooth functions $V \in C^{\infty}\left(\overline{\Omega^{\pm}}\right)$:

$$(\gamma_0^{\pm} V)(\mathbf{x}) := V(\mathbf{x}) \quad \text{and} \quad (\gamma_1^{\pm} V)(\mathbf{x}) := \mathbf{grad}\, V(\mathbf{x}) \cdot \mathbf{n}(\mathbf{x}), \quad \mathbf{x} \in \Gamma.$$

Then the mathematical model for the acoustic scattering problem boils down to the following transmission problem for the Helmholtz equation; see [32, sect. 2.9]:

$$\begin{aligned} -\Delta U - \kappa^2 n(\mathbf{x}) U = f(\mathbf{x}) \quad \text{in } \Omega^-, \qquad & -\Delta U^{\mathrm{s}} - \kappa^2 U^{\mathrm{s}} = 0 \quad \text{in } \Omega^+, \\ \gamma_0^+ U^{\mathrm{s}} - \gamma_0^- U = g_0 \quad \text{on } \Gamma, \qquad & \gamma_1^+ U^{\mathrm{s}} - \gamma_1^- U = g_1 \quad \text{on } \Gamma, \\ \frac{\partial U^{\mathrm{s}}}{\partial r} - i\kappa U^{\mathrm{s}} = o(r^{-1}) \quad & \text{uniformly for } r := |\mathbf{x}| \to \infty, \end{aligned} \tag{2}$$

with the refractive index $n \in L^{\infty}\left(\Omega^-\right)$, the source term $f \in H^{-1}\left(\Omega^-\right)$, and the wave number $\kappa > 0$. In the case of excitation by an incident field U^{i} the generic jump data $g_0 \in H^{\frac{1}{2}}\left(\Gamma\right)$ and $g_1 \in H^{-\frac{1}{2}}\left(\Gamma\right)$ evaluate to the Dirichlet and Neumann data of U^{i} on the boundary Γ:

$$g_0 := -\gamma_0^+ U^{\mathrm{i}}, \quad g_1 := -\gamma_1^+ U^{\mathrm{i}}.$$

It is known that the transmission problem (2) has a unique solution $u \in H_{\mathrm{loc}}\left(\Delta, \mathbb{R}^3\right)$ [32, sect. 2.10].

Remark 2.1. Please note that inside Ω^- the field U in (2) refers to the total field, whereas in Ω^+ we write U^{s} for the scattered field. There the total field can be recovered through $U = U^{\mathrm{s}} + U^{\mathrm{i}}$.

3. Potentials and boundary integral operators. In this section we define relevant boundary integral operators and review some of their properties. Only sketches of proofs will be given and the reader is referred to [32, 29, 16] for details. To begin with, let us fix some notations and notions: jumps of traces across Γ will be designated by

$$[\gamma_0 V]_{\Gamma} := \gamma_0^+ V - \gamma_0^- V, \quad [\gamma_1 V]_{\Gamma} := \gamma_1^+ V - \gamma_1^- V,$$

and averages across Γ will be denoted by

$$\{\gamma_0 V\}_{\Gamma} := \tfrac{1}{2}\left(\gamma_0^+ V + \gamma_0^- V\right), \quad \{\gamma_1 V\}_{\Gamma} := \tfrac{1}{2}\left(\gamma_1^+ V + \gamma_1^- V\right).$$

For a fixed wave number $\kappa > 0$ a distribution U on $\mathbb{R}^3$ is called a *radiating Helmholtz solution* if

$$\Delta U + \kappa^2 U = 0 \quad \text{in } \Omega^- \cup \Omega^+, \qquad \lim_{r \to \infty} r \left(\frac{\partial U}{\partial r} - i\kappa U \right) = 0,$$

where the limit is assumed to hold uniformly in all directions. Based on the Helmholtz kernel

$$G_\kappa(z) := \frac{1}{4\pi}\frac{\exp(i\kappa z)}{z} \tag{3}$$

we can state the transmission formula for radiating Helmholtz solutions U [32, Thm. 3.1.6] as

$$U = -\Psi^\kappa_{\mathrm{SL}}([\gamma_1 U]_\Gamma) + \Psi^\kappa_{\mathrm{DL}}([\gamma_0 U]_\Gamma), \tag{4}$$

with the potentials

$$\text{single-layer potential}\quad \Psi^\kappa_{\mathrm{SL}}(\vartheta)(\mathbf{x}) := \int_\Gamma G_\kappa(|\mathbf{x}-\mathbf{y}|)\,\vartheta(\mathbf{y})\,\mathrm{d}S(\mathbf{y}),$$

$$\text{double-layer potential}\quad \Psi^\kappa_{\mathrm{DL}}(v)(\mathbf{x}) := \int_\Gamma \frac{\partial G_\kappa(|\mathbf{x}-\mathbf{y}|)}{\partial \mathbf{n}(\mathbf{y})} v(\mathbf{y})\,\mathrm{d}S(\mathbf{y}).$$

The potentials provide radiating Helmholtz solutions and continuous mappings [32, Thm. 3.1.16]

$$\Psi^\kappa_{\mathrm{SL}} : H^{-\frac{1}{2}}(\Gamma) \to H^1_{\mathrm{loc}}(\mathbb{R}^3) \cap H_{\mathrm{loc}}(\Delta, \Omega^- \cup \Omega^+),$$
$$\Psi^\kappa_{\mathrm{DL}} : H^{\frac{1}{2}}(\Gamma) \to H_{\mathrm{loc}}(\Delta, \Omega^- \cup \Omega^+).$$

Applying the trace mappings yields the following four continuous boundary integral operators:

$$\begin{aligned}
\mathsf{V}_\kappa &: H^{s-\frac{1}{2}}(\Gamma) \to H^{s+\frac{1}{2}}(\Gamma), & \mathsf{V}_\kappa &:= \{\gamma_0 \Psi^\kappa_{\mathrm{SL}}\}_\Gamma,\\
\mathsf{K}_\kappa &: H^{s+\frac{1}{2}}(\Gamma) \to H^{s+\frac{1}{2}}(\Gamma), & \mathsf{K}_\kappa &:= \{\gamma_0 \Psi^\kappa_{\mathrm{DL}}\}_\Gamma,\\
\mathsf{K}'_\kappa &: H^{s-\frac{1}{2}}(\Gamma) \to H^{s-\frac{1}{2}}(\Gamma), & \mathsf{K}'_\kappa &:= \{\gamma_1 \Psi^\kappa_{\mathrm{SL}}\}_\Gamma,\\
\mathsf{W}_\kappa &: H^{s+\frac{1}{2}}(\Gamma) \to H^{s-\frac{1}{2}}(\Gamma), & \mathsf{W}_\kappa &:= -\{\gamma_1 \Psi^\kappa_{\mathrm{DL}}\}_\Gamma,
\end{aligned}$$

for a scale of Sobolev spaces with $|s| < \frac{1}{2}$; see [16, Thm. 1]. From the *jump relations* [32, Thm. 3.3.1]

$$\begin{aligned}
[\gamma_0 \Psi^\kappa_{\mathrm{SL}}(\vartheta)]_\Gamma &= 0, & [\gamma_1 \Psi^\kappa_{\mathrm{SL}}(\vartheta)]_\Gamma &= -\vartheta & &\forall \vartheta \in H^{-\frac{1}{2}}(\Gamma),\\
[\gamma_0 \Psi^\kappa_{\mathrm{DL}}(\varphi)]_\Gamma &= \varphi, & [\gamma_1 \Psi^\kappa_{\mathrm{DL}}(\varphi)]_\Gamma &= 0 & &\forall \varphi \in H^{\frac{1}{2}}(\Gamma),
\end{aligned} \tag{5}$$

we can directly deduce the following four identities:

$$\begin{aligned}
\gamma_0^\pm \Psi^\kappa_{\mathrm{SL}} &= \mathsf{V}_\kappa, & \gamma_1^\pm \Psi^\kappa_{\mathrm{SL}} &= \mathsf{K}_\kappa \pm \tfrac{1}{2}\mathsf{Id},\\
\gamma_0^\pm \Psi^\kappa_{\mathrm{DL}} &= \mathsf{K}'_\kappa \mp \tfrac{1}{2}\mathsf{Id}, & \gamma_1^\pm \Psi^\kappa_{\mathrm{DL}} &= -\mathsf{W}_\kappa.
\end{aligned} \tag{6}$$

In what follows $(\cdot,\cdot)_\Gamma$ will stand for the $L^2(\Gamma)$-inner product

$$(\vartheta, \varphi)_\Gamma := \int_\Gamma \overline{\vartheta}\varphi\,\mathrm{d}S, \qquad \vartheta, \varphi \in L^2(\Gamma),$$

which can be extended to a duality pairing on $H^{-\frac{1}{2}}(\Gamma) \times H^{\frac{1}{2}}(\Gamma)$. Adjoints of operators with respect to $(\cdot,\cdot)_\Gamma$ will be tagged by $*$.

Crucial for any variational formulation based on boundary integral operators will be the following three lemmata; see [32, Lemma 3.9.8], [16, Thm. 2].

LEMMA 3.1. *The following operators are compact:*

$$\begin{aligned}
\mathsf{V}_\kappa - \mathsf{V}_0 &: H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma),\\
\mathsf{K}_\kappa - \mathsf{K}_0 &: H^{\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma),\\
\mathsf{K}'_\kappa - \mathsf{K}'_0 &: H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma),\\
\mathsf{W}_\kappa - \mathsf{W}_0 &: H^{\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma).
\end{aligned}$$

The proof relies on the fact that both $\mathsf{V}_\kappa - \mathsf{V}_0$ and $\mathsf{K}_\kappa - \mathsf{K}_0$ turn out to be integral operators with continuous and bounded kernels, which ensures that they map into $H^1(\Gamma)$, which is compactly embedded in $H^{\frac{1}{2}}(\Gamma)$. Details can be found in [8, sect. 2]. This result combined with the ellipticity of both V_0 and W_0 in $H^{-\frac{1}{2}}(\Gamma)$ and $H^{\frac{1}{2}}(\Gamma)$, respectively, yields the next lemma.

LEMMA 3.2. *The operators V_κ and W_κ satisfy a generalized Gårding inequality in the sense that there exist a constant $\gamma > 0$ and compact operators*

$$\mathsf{T}_\mathsf{V} : H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma), \qquad \mathsf{T}_\mathsf{W} : H^{\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$$

such that

$$\begin{aligned}
\operatorname{Re}\left\{\left(\vartheta, \left(\mathsf{V}_\kappa + \mathsf{T}_\mathsf{V}\right)(\vartheta)\right)_\Gamma\right\} &\geq \gamma \left\|\vartheta\right\|^2_{H^{-\frac{1}{2}}(\Gamma)},\\
\operatorname{Re}\left\{\left(\left(\mathsf{W}_\kappa + \mathsf{T}_\mathsf{W}\right)(\varphi), \varphi\right)_\Gamma\right\} &\geq \gamma \left\|\varphi\right\|^2_{H^{\frac{1}{2}}(\Gamma)}
\end{aligned}$$

holds true for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ and $\varphi \in H^{\frac{1}{2}}(\Gamma)$.

Finally, K'_κ is the $(\cdot,\cdot)_\Gamma$-adjoint of K_κ up to a compact perturbation.

LEMMA 3.3. *There exists a compact operator $\mathsf{T}_\mathsf{K} : H^{-\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$ such that*

$$\left(\mathsf{K}^*_\kappa(\vartheta), \varphi\right)_\Gamma = \left(\left(\mathsf{K}'_\kappa + \mathsf{T}_\mathsf{K}\right)(\vartheta), \varphi\right)_\Gamma$$

holds true for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ and $\varphi \in H^{\frac{1}{2}}(\Gamma)$, where K^*_κ denotes the $L^2(\Gamma)$-adjoint of K_κ.

Proof. Following [32, sect. 3.1] and [16], we recall the representations

$$\mathsf{K}_\kappa = \{\gamma_0\}_\Gamma \circ \mathcal{N}_\kappa \circ {\gamma_1}^*, \qquad \mathsf{K}'_\kappa = \{\gamma_1\}_\Gamma \circ \mathcal{N}_\kappa \circ {\gamma_0}^*,$$

where $\mathcal{N}_\kappa : H^{-1}_{\text{comp}}\left(\mathbb{R}^3\right) \to H^1_{\text{loc}}\left(\mathbb{R}^3\right)$ is the Newton potential for the Helmholtz kernel.

$${\mathsf{K}_\kappa}^* - \mathsf{K}'_\kappa = \{\gamma_1\}_\Gamma \circ \left(\mathcal{N}_\kappa - {\mathcal{N}_\kappa}^*\right) \circ {\gamma_0}^*.$$

Observe that

$$\left(\mathcal{N}_\kappa - {\mathcal{N}_\kappa}^*\right)(V)(\mathbf{x}) = \frac{i}{2\pi} \int_{\mathbb{R}^3} \frac{\sin(\kappa|\mathbf{x}-\mathbf{y}|)}{|\mathbf{x}-\mathbf{y}|} V(\mathbf{y})\, \mathrm{d}\mathbf{y}$$

is an integral operator with analytic kernel, which maps continuously $H^{-1}_{\text{comp}}\left(\mathbb{R}^3\right) \mapsto H^s_{\text{loc}}(\mathbb{R}^3)$ for any $s \in \mathbb{R}$. Thus, $\mathsf{K}^*_\kappa - \mathsf{K}'_\kappa : H^{-\frac{1}{2}}(\Gamma) \mapsto H^1(\Gamma)$ is continuous and the compact embedding $H^1(\Gamma) \hookrightarrow H^{-\frac{1}{2}}(\Gamma)$ finishes the proof. ∎

4. Calderón projectors. A crucial tool for the coupling of the variational equations on Ω^- and boundary integral equations on Γ are the two *Calderón projectors* [32, sect. 3.6]

$$\mathsf{P}_\pm := \begin{bmatrix} \frac{1}{2}\mathsf{Id} \pm \mathsf{K}_\kappa & \mp\mathsf{V}_\kappa \\ \mp\mathsf{W}_\kappa & \frac{1}{2}\mathsf{Id} \mp \mathsf{K}'_\kappa \end{bmatrix} : H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma) \mapsto H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma).$$

They arise from applying the trace operators $\gamma_0^\pm$ and $\gamma_1^\pm$ to (4) and using (6). The operators P_+ and P_- obviously satisfy the identity

$$\mathsf{P}_+ + \mathsf{P}_- = \mathsf{Id}. \tag{7}$$

The Calderón projectors can be used to characterize pairs of functions in $H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma)$ that are eligible as traces of Helmholtz solutions; see [36].

THEOREM 4.1. *If and only if* $(\varphi, \vartheta) \in H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma)$ *belongs to the range of* $\mathsf{P}_\pm$*, there is a Helmholtz solution* U *such that* $\varphi = \gamma_0^\pm U$ *and* $\vartheta = \gamma_1^\pm U$*.*

The theorem paves the way for establishing expressions for the exterior *Dirichlet-to-Neumann* map for the Helmholtz problem in Ω^+. This is the operator $\mathrm{DtN}_\kappa^+ : H^{\frac{1}{2}}(\Gamma) \mapsto H^{-\frac{1}{2}}(\Gamma)$ returning the Neumann traces of an exterior Helmholtz solution matching prescribed Dirichlet boundary conditions on Γ. Three different formulas can instantly be obtained from (4.1), at least formally, because the inverses of operators might not exist:

$$\mathrm{DtN}_\kappa^+ := {\mathsf{V}_\kappa}^{-1} \circ \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right), \tag{8}$$

$$\mathrm{DtN}_\kappa^+ := -\left(\tfrac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right)^{-1} \circ \mathsf{W}_\kappa, \tag{9}$$

$$\mathrm{DtN}_\kappa^+ := -\mathsf{W}_\kappa + \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right) \circ {\mathsf{V}_\kappa}^{-1} \circ \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right). \tag{10}$$

Only the third formula reflects the essential symmetry of the boundary value problem in the case $\kappa = 0$. It will be the starting point for symmetric coupling.

Remark 4.2. If the incident wave U^{i} can be extended to an interior Helmholtz solution, which is evidently the case, when U^{i} is a plane wave or generated by a sound source compactly supported in Ω^+, then, by (4) and (5), its traces on Γ will fulfill

$$\begin{bmatrix} \gamma_0 U^{\mathrm{i}} \\ \gamma_1 U^{\mathrm{i}} \end{bmatrix} = \mathsf{P}_- \begin{bmatrix} \gamma_0 U^{\mathrm{i}} \\ \gamma_0 U^{\mathrm{i}} \end{bmatrix} \quad \Leftrightarrow \quad \mathsf{P}_+ \begin{bmatrix} \gamma_0 U^{\mathrm{i}} \\ \gamma_1 U^{\mathrm{i}} \end{bmatrix} = 0. \tag{11}$$

For the same reasons, the scattered field U^{s} satisfies

$$\begin{bmatrix} \gamma_0^+ U^{\mathrm{s}} \\ \gamma_1^+ U^{\mathrm{s}} \end{bmatrix} = \mathsf{P}_+ \begin{bmatrix} \gamma_0^+ U^{\mathrm{s}} \\ \gamma_1^+ U^{\mathrm{s}} \end{bmatrix}. \tag{12}$$

Since the total field in Ω^+ is given by $U = U^{\mathrm{s}} + U^{\mathrm{i}}$, we can eliminate U^{s} from (11) and (12) and end up with

$$\begin{bmatrix} \gamma_0^+ U \\ \gamma_1^+ U \end{bmatrix} = \mathsf{P}_+ \begin{bmatrix} \gamma_0^+ U \\ \gamma_1^+ U \end{bmatrix} - \begin{bmatrix} g_0 \\ g_1 \end{bmatrix}. \tag{13}$$

As above, Dirichlet-to-Neumann maps for the total field can be constructed from this relationship.

5. Classical symmetric coupling. For the sake of completeness we will review the classical approach to the coupling of boundary integral equations and variational formulation in Ω^- due to Costabel [15]. First, integration by parts shows that a solution U of problem (2) will fulfill

$$\mathsf{a}(U,V) - \left(\gamma_1^- U, \gamma_0^- V\right)_\Gamma = \mathsf{f}(v) \quad \forall v \in H^1\left(\Omega^-\right), \tag{14}$$

where we have used the abbreviations

$$\begin{aligned} \mathsf{a}(U,V) &:= \int_{\Omega^-} \mathbf{grad}\overline{U} \cdot \mathbf{grad} V - \kappa^2 n(\mathbf{x})\, \overline{U}\, V \,\mathrm{d}\mathbf{x}, && U, V \in H^1\left(\Omega^-\right), \\ \mathsf{f}(V) &:= \int_{\Omega^-} \overline{f}\, V \,\mathrm{d}\mathbf{x}, && V \in H^1\left(\Omega^-\right). \end{aligned}$$

LEMMA 5.1. *The sesquilinear form* a *satisfies a generalized Gårding inequality in the sense that there exists a constant* $\gamma > 0$ *and a compact sesquilinear form*

$$\mathsf{k} : H^1\left(\Omega^-\right) \times H^1\left(\Omega^-\right) \to \mathbb{C}$$

such that

$$\mathrm{Re}\left\{\mathsf{a}(U,U) + \mathsf{k}(U,U)\right\} \geq \gamma \left\|U\right\|^2_{H^1(\Omega^-)}$$

holds true for all $u \in H^1(\Omega^-)$.

Proof. The lemma is a straightforward consequence of the compact embedding $H^1(\Omega^-) \hookrightarrow L^2(\Omega^-)$. ∎

The variational problem associated with the classical symmetric coupling approach emerges by employing the transmission conditions of (2) and using the Dirichlet-to-Neumann map (10) to express $\gamma_1^- U$ in (14). In order to avoid the operator products occurring in (10) we also introduce $\gamma_1^+ U^{\mathrm{s}}$ as the new variable,

$$\vartheta := \left({\mathsf{V}_\kappa}^{-1} \circ \left(\mathsf{K}_\kappa - \tfrac{1}{2} Id\right)\right)\left(\gamma_0^- U + g_0\right) \in H^{-\frac{1}{2}}(\Gamma).$$

Thus, we end up with: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$ there holds

$$\begin{aligned} \mathsf{a}(U,V) + \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma - \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right)(\vartheta), \gamma_0^- V\right)_\Gamma &= \widetilde{f}(V), \\ \left(\varphi, \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}_\kappa\right)\left(\gamma_0^- U\right)\right)_\Gamma + \left(\varphi, \mathsf{V}_\kappa(\vartheta)\right)_\Gamma &= \widetilde{g}(\varphi), \end{aligned} \tag{15}$$

where

$$\begin{aligned} \widetilde{f}(V) &:= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma - \left(\mathsf{W}_\kappa(g_0), \gamma_0^- V\right)_\Gamma, \\ \widetilde{g}(\varphi) &:= \left(\varphi, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)(g_0)\right)_\Gamma. \end{aligned}$$

Using the lemmata of the previous section it is not difficult to verify that the bilinear form associated with (15) satisfies a Gårding inequality. Unfortunately, this is no safeguard against spurious resonances.

Assume the resonance case, that is, κ^2, is a Dirichlet eigenvalue of $-\Delta$ in Ω^-. Then we can find $U \in H^1(\Omega^-) \setminus \{0\}$ such that

$$\Delta U + \kappa^2 U = 0 \quad \text{in } \Omega^- \quad \text{and} \quad U = 0 \quad \text{on } \Gamma.$$

Since $\gamma_0^- U = 0$, by Theorem 4.1 we have that

$$\begin{bmatrix} 0 \\ \gamma_1^- U \end{bmatrix} = \mathsf{P}_- \begin{bmatrix} 0 \\ \gamma_1^- U \end{bmatrix} = \begin{bmatrix} \mathsf{V}_\kappa \left(\gamma_1^- U\right) \\ \left(\frac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right)\left(\gamma_1^- U\right) \end{bmatrix},$$

which means that $(0, \gamma_1^- U)$ provides a solution of (15) in the case $\widetilde{f} = \widetilde{g} = 0$.

Even in the resonance case, the right-hand side of (15) will be consistent and the variational problem still has solutions (U, ϑ), whose first component will still be unique. Alas, this is little comfort as far as numerical solution procedures are concerned: first, inevitable perturbations introduced by discretization will destroy the consistency of the right-hand side. Second, whenever κ^2 is merely close to an interior resonant frequency, the resulting linear systems of equations may not be useless, but will be extremely ill-conditioned; see the profound analysis of the impact of spurious resonances in the case of electromagnetic scattering given in [13].

So, from a numerical point of view suppressing spurious resonances is essential for the efficacy of methods based on boundary integral equations.

Remark 5.2. Under the assumptions made in Remark 4.2 we may use a symmetric Dirichlet-to-Neumann map derived from (13). This will lead to a coupled variational problem of the form (15) with much simpler right-hand sides $\widetilde{f}(V) = \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma$ and $\widetilde{g}(\varphi) = -\left(\varphi, g_0\right)_\Gamma$.

6. Transformed traces. As pointed out at the end of the previous section, the existence of spurious resonances is directly linked to the fact that for certain κ there are nontrivial interior Helmholtz solutions U that satisfy $\gamma_0^- U = 0$. We know that there are Robin-type (mixed) boundary conditions that ensure the unique solvability of the corresponding boundary value problem for $-\Delta U - \kappa^2 U = 0$ in Ω^-. Note that we can rely on two Robin-type boundary operators to state the transmission conditions of (2) as long as we can recover from them the conventional Dirichlet and Neumann trace. In fact, this idea can serve as the starting point for the derivation of all CFIEs. Here, it motivates the introduction of the following generic trace transformation operator:

$$\mathcal{T} := \begin{bmatrix} \mathsf{A} & \mathsf{B} \\ \mathsf{C} & \mathsf{D} \end{bmatrix} : H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma) \times H^{-\frac{1}{2}}(\Gamma). \tag{16}$$

We demand that the interior homogeneous "Dirichlet problem" for $-\Delta U - \kappa^2 U = 0$ and the modified traces have a unique solution for every κ. In light of Theorem 4.1 this amounts to the following assumption.

ASSUMPTION 6.1. *The trace transformation operator $\mathcal{T}$ satisfies*

$$\operatorname{Range}\left(\mathcal{T} \circ \mathsf{P}_-\right) \cap \left(\{0\} \times H^{-\frac{1}{2}}(\Gamma)\right) = \{0\}.$$

Then one can use $\mathcal{T}$, build associated Calderón projectors for the modified traces, derive symmetrically coupled variational problems, and check their properties. Here, we would like to skip this tedious process of creative discovery and present the final finding on what is required for $\mathcal{T}$.

ASSUMPTION 6.2. *The blocks of the transformation operator $\mathcal{T}$ from* (16) *are assumed to possess the following properties:*

1. $\mathcal{T} : H^{-\frac{1}{2}}(\Gamma) \times H^{\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma) \times H^{\frac{1}{2}}(\Gamma)$ *is bijective,*
2. $\mathsf{A} : H^{\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma)$ *is bounded and bijective,*
3. $\mathsf{B} : H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma)$ *is compact,*

4. $\mathsf{C} : H^{\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$ *is compact,*
5. $\mathsf{D} : H^{-\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$ *is bounded and bijective.*

The first requirement enables us to retrieve the conventional Dirichlet and Neumann trace from their transformed counterparts. This is essential because it is these traces that will invariably occur in (14) so that we have to resort to them in one way or another when pursuing the coupling of (14) with boundary integral equations. Switching back and forth between conventional and transformed traces employs the following splitting of the trace transformation operator:

$$\mathcal{T} = \mathcal{R} + \mathcal{S}, \qquad \mathcal{R} := \begin{bmatrix} \mathsf{A} & 0 \\ 0 & \mathsf{D} \end{bmatrix}, \qquad \mathcal{S} := \begin{bmatrix} 0 & \mathsf{B} \\ \mathsf{C} & 0 \end{bmatrix}. \tag{17}$$

Based on the splitting above, we define the following generalized Calderón projectors:

$$\mathcal{P}_\pm := \mathcal{R}^{-1} \circ (\mathcal{T} \circ \mathsf{P}_\pm - \mathcal{S}). \tag{18}$$

Note that they are meant to act on conventional traces. Let us make the transformed exterior Calderón projector more explicit: an elementary computation yields

$$\mathcal{P}_+ = \begin{bmatrix} \mathbb{A} & \mathbb{B} \\ \mathbb{C} & \mathbb{D} \end{bmatrix}, \tag{19}$$

where the entries of the operator matrix are given by

$$\mathbb{A} := \tfrac{1}{2}\mathsf{Id} + \mathsf{K}_\kappa - \mathsf{A}^{-1} \circ \mathsf{B} \circ \mathsf{W}_\kappa, \tag{20}$$

$$\mathbb{B} := -\mathsf{A}^{-1} \circ \mathsf{B} \circ \left(\tfrac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right) - \mathsf{V}_\kappa, \tag{21}$$

$$\mathbb{C} := \mathsf{D}^{-1} \circ \mathsf{C} \circ \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right) - \mathsf{W}_\kappa, \tag{22}$$

$$\mathbb{D} := \tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa - \mathsf{D}^{-1} \circ \mathsf{C} \circ \mathsf{V}_\kappa. \tag{23}$$

An analogue of Theorem 4.1 still holds for the transformed Calderón projectors.

LEMMA 6.3. *If and only if U is an exterior/interior radiating Helmholtz solution we have*

$$\mathcal{P}_\pm \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} = \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix}.$$

Proof. As $\mathcal{T}$ is one-to-one, we immediately conclude from Theorem 4.1 that U is an exterior/interior radiating Helmholtz solution if and only if

$$\begin{array}{c} \mathsf{P}_\pm \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} = \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} \\ \Updownarrow \\ (\mathcal{T} \circ \mathsf{P}_\pm) \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} = \mathcal{T} \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} = (\mathcal{R} + \mathcal{S}) \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} \\ \Updownarrow \\ \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix} = \mathcal{R}^{-1} \circ (\mathcal{T} \circ \mathsf{P}_\pm - \mathcal{S}) \begin{bmatrix} \gamma_0^\pm U \\ \gamma_1^\pm U \end{bmatrix}. \end{array} \tag{24}$$

□

Now, the same formal manipulations as in section 4 yield the following operator expression for the Dirichlet-to-Neumann map:

$$\mathrm{DtN}_\kappa^+ := \mathbb{C} + \mathbb{D} \circ \mathbb{B}^{-1} \circ (\mathsf{Id} - \mathbb{A}), \tag{25}$$

which maps exterior Dirichlet traces of radiating Helmholtz solutions U to exterior Neumann traces.

Remark 6.4. Again, if the incident wave U^{i} can be extended to an interior Helholtz solution, then we can apply the trace transformation operator to (13) and end up with

$$\mathcal{T}\begin{bmatrix}\gamma_0^+U\\ \gamma_1^+U\end{bmatrix} = (\mathcal{T}\circ\mathsf{P}_+)\begin{bmatrix}\gamma_0^+U\\ \gamma_1^+U\end{bmatrix} - \mathcal{T}\begin{bmatrix}g_0\\ g_1\end{bmatrix}. \tag{26}$$

Using the operator splitting (17) and definition (18) of the generalized Calderón projector we can eliminate the trace transformation operator $\mathcal{T}$ from the left-hand side of (26) and obtain

$$\begin{bmatrix}\gamma_0^+U\\ \gamma_1^+U\end{bmatrix} = \mathcal{P}_+\begin{bmatrix}\gamma_0^+U\\ \gamma_1^+U\end{bmatrix} - \left(\mathcal{R}^{-1}\circ\mathcal{T}\right)\begin{bmatrix}g_0\\ g_1\end{bmatrix}. \tag{27}$$

As above this relationship can be used to construct new Dirchlet-to-Neumann maps for the total field.

We end this section with an easily verifiable criterion telling us when Assumption 6.1 is satisfied.

LEMMA 6.5. *If the following equivalence holds:*

$$\mathrm{Im}\left\{\left(\vartheta, \left(\mathsf{A}^{-1}\circ\mathsf{B}\right)(\vartheta)\right)_\Gamma\right\} = 0 \Leftrightarrow \vartheta = 0,$$

then

$$\mathrm{Range}\left(\mathcal{T}\circ\mathsf{P}_-\right)\cap\left(\{0\}\times H^{-\frac{1}{2}}(\Gamma)\right) = \{0\}.$$

Proof. If $\xi\in H^{-\frac{1}{2}}(\Gamma)$ satisfies

$$\begin{bmatrix}0\\ \xi\end{bmatrix}\in\mathrm{Range}\left(\mathcal{T}\circ\mathsf{P}_-\right),$$

then there exists $\vartheta\in H^{\frac{1}{2}}(\Gamma)$ and $\varphi\in H^{-\frac{1}{2}}(\Gamma)$ such that

$$\begin{bmatrix}0\\ \xi\end{bmatrix} = (\mathcal{T}\circ\mathsf{P}_-)\begin{bmatrix}\vartheta\\ \varphi\end{bmatrix}.$$

Taking the transformed interior traces of the function

$$U(\mathbf{x}) := -\Psi_{\mathrm{DL}}^\kappa(\vartheta)(\mathbf{x}) + \Psi_{\mathrm{SL}}^\kappa(\varphi)(\mathbf{x}), \qquad \mathbf{x}\in\Omega^-$$

gives us the following set of equations:

$$\mathcal{T}\begin{bmatrix}\gamma_0^-U\\ \gamma_1^-U\end{bmatrix} = (\mathcal{T}\circ\mathsf{P}_-)\begin{bmatrix}\vartheta\\ \varphi\end{bmatrix} = \begin{bmatrix}0\\ \xi\end{bmatrix}. \tag{28}$$

Thus U is a solution to the boundary value problem

$$\Delta U + \kappa^2 U = 0 \quad \text{in } \Omega^-, \tag{29}$$

$$\mathsf{A}\left(\gamma_0^-U\right) + \mathsf{B}\left(\gamma_1^-U\right) = 0 \quad \text{on } \Gamma. \tag{30}$$

Recalling (14) and using that A is bijective, we obtain

$$\mathsf{a}(U,U) - \left(\gamma_1^- U, \gamma_0^- U\right)_\Gamma = \mathsf{a}(U,U) + \left(\gamma_1^- U, (\mathsf{A}^{-1}\circ\mathsf{B})\left(\gamma_1^- U\right)\right)_\Gamma = 0.$$

Since, $\mathsf{a}(U,U) \in \mathbb{R}$, by taking the imaginary part we get

$$\operatorname{Im}\left\{\left(\gamma_1^- U, \left(\mathsf{A}^{-1}\circ\mathsf{B}\right)\left(\gamma_1^- U\right)\right)_\Gamma\right\} = 0.$$

Thus, the assumption of the lemma implies $\gamma_1^- U = 0$, and via (30) we conclude $\gamma_0^- U = 0$. Eventually, (28) shows that $\xi = 0$. ∎

7. Stabilized coupling. Parallel to the approach in section 5, we use (14) in combination with the transformed Dirichlet-to-Neumann map (25) and introduce the new variable

$$\vartheta := -\left(\mathbb{B}^{-1}\circ(\mathsf{Id}-\mathbb{A})\right)\left(\gamma_0^- U + g_0\right) \in H^{-\frac{1}{2}}(\Gamma). \tag{31}$$

If U solves the Helmholtz transmission problem (2), then $\gamma_0^- U + g_0 = \gamma_0^+ U^{\mathrm{s}}$, and we learn from Lemma 6.3 and (19) that actually $\vartheta = -\gamma_1^+ U^{\mathrm{s}}$. As in the case of classical coupling, ϑ will supply the exterior Neumann trace of the scattered field.

Thus we arrive at the following *regularized variational formulation*: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$ there holds

$$\begin{aligned} \mathsf{a}(U,V) - \left(\mathbb{C}\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma + \left(\mathbb{D}(\vartheta), \gamma_0^- V\right)_\Gamma &= \widehat{f}(V), \\ \left(\varphi, (\mathbb{A}-\mathsf{Id})\left(\gamma_0^- U\right)\right)_\Gamma - \left(\varphi, \mathbb{B}(\vartheta)\right)_\Gamma &= \widehat{g}(\varphi), \end{aligned} \tag{32}$$

where

$$\widehat{f}(V) := \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma + \left(\mathbb{C}(g_0), \gamma_0^- V\right)_\Gamma, \tag{33}$$

$$\widehat{g}(V) := \left(\varphi, (\mathsf{Id}-\mathbb{A})(g_0)\right)_\Gamma. \tag{34}$$

We first investigate the $H^1(\Omega^-)\times H^{-\frac{1}{2}}(\Gamma)$-coercivity of the sesquilinear form underlying (32). From Assumption 6.2 it is immediate that the operators $\mathsf{A}^{-1}\circ\mathsf{B}$, $\mathsf{D}^{-1}\circ\mathsf{C}$ are compact. This plays a key role in the proofs of the following two lemmata.

LEMMA 7.1. *There exists a constant $\gamma > 0$ and compact operators*

$$\mathsf{T}_{\mathbb{B}} : H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma), \qquad \mathsf{T}_{\mathbb{C}} : H^{\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$$

such that

$$\begin{aligned} -\operatorname{Re}\left\{\left(\vartheta, (\mathbb{B}+\mathsf{T}_{\mathbb{B}})(\vartheta)\right)_\Gamma\right\} &\geq \gamma \left\|\vartheta\right\|^2_{H^{-\frac{1}{2}}(\Gamma)}, \\ -\operatorname{Re}\left\{\left(\varphi, (\mathbb{C}+\mathsf{T}_{\mathbb{C}})(\varphi)\right)_\Gamma\right\} &\geq \gamma \left\|\varphi\right\|^2_{H^{\frac{1}{2}}(\Gamma)} \end{aligned}$$

for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ and $\varphi \in H^{\frac{1}{2}}(\Gamma)$.

Proof. Using (21) and (22) a straightforward application of Lemma 3.2 yields

$$\begin{aligned} &\operatorname{Re}\left\{-\left(\vartheta, \mathbb{B}(\vartheta)\right)_\Gamma - \left(\vartheta, \left(\mathsf{A}^{-1}\circ\mathsf{B}\circ\left(\tfrac{1}{2}\mathsf{Id}+\mathsf{K}'_\kappa\right)\right)(\vartheta)\right)_\Gamma + \left(\vartheta, \mathsf{T}_{\mathsf{V}}(\vartheta)\right)_\Gamma\right\} \\ &\quad = \operatorname{Re}\left\{\left(\vartheta, (\mathsf{V}_\kappa + \mathsf{T}_{\mathsf{V}})(\vartheta)\right)_\Gamma\right\} \geq \gamma \left\|\vartheta\right\|^2_{H^{-\frac{1}{2}}(\Gamma)}, \\ &\operatorname{Re}\left\{-\left(\mathbb{C}(\varphi), \varphi\right)_\Gamma + \left(\left(\mathsf{D}^{-1}\circ\mathsf{C}\circ\left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)\right)(\varphi), \varphi\right)_\Gamma + \left(\mathsf{T}_{\mathsf{W}}(\varphi), \varphi\right)_\Gamma\right\} \\ &\quad = \operatorname{Re}\left\{\left((\mathsf{W}_\kappa + \mathsf{T}_{\mathsf{W}})(\varphi), \varphi\right)_\Gamma\right\} \geq \gamma \left\|\varphi\right\|^2_{H^{\frac{1}{2}}(\Gamma)} \end{aligned}$$

for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, $\varphi \in H^{\frac{1}{2}}(\Gamma)$. ∎

LEMMA 7.2. *There exist compact operators*

$$\mathsf{T}_{\mathbb{A}} : H^{\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma), \qquad \mathsf{T}_{\mathbb{D}} : H^{-\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$$

such that

$$(\vartheta, (\mathbb{A} - \mathsf{Id} + \mathsf{T}_{\mathbb{A}})(\varphi))_\Gamma + ((\mathbb{D} + \mathsf{T}_{\mathbb{D}})(\vartheta), \varphi)_\Gamma = 0$$

for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, $\varphi \in H^{\frac{1}{2}}(\Gamma)$.

Proof. We begin with an application of Lemma 3.3 and obtain

$$\begin{aligned}&\left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right)(\vartheta), \varphi\right)_\Gamma + \left(\vartheta, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)(\varphi)\right)_\Gamma \\ &\quad = \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}^*_\kappa + \mathsf{T}_{\mathsf{K}}\right)(\vartheta), \varphi\right)_\Gamma - \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}^*_\kappa\right)(\vartheta), \varphi\right)_\Gamma\end{aligned}$$

for all $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, $\varphi \in H^{\frac{1}{2}}(\Gamma)$. Using this result we finally arrive at the following equation:

$$\begin{aligned}&(\vartheta, (\mathbb{A} - \mathsf{Id})(\varphi))_\Gamma + (\mathbb{D}(\vartheta), \varphi)_\Gamma \\ &\quad = \left(\left(\mathsf{T}_{\mathsf{K}} - \mathsf{D}^{-1} \circ \mathsf{C} \circ \mathsf{K}_\kappa\right)(\vartheta), \varphi\right)_\Gamma - \left(\vartheta, \left(\mathsf{A}^{-1} \circ \mathsf{B} \circ \mathsf{W}_\kappa\right)(\varphi)\right)_\Gamma,\end{aligned}$$

which holds for arbitrary $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, $\varphi \in H^{\frac{1}{2}}(\Gamma)$. ∎

Summing up, from the previous lemmata and Lemma 5.1 we conclude that the sesquilinear form of the regularized variational problem (32) satisfies a Gårding inequality in $H^1(\Omega^-) \times H^{-\frac{1}{2}}(\Gamma)$. It remains to establish uniqueness of solutions, which amounts to confirming that (32) is really immune to spurious resonances.

THEOREM 7.3. *Solutions to the regularized variational problem* (32) *are unique.*

Proof. In order to establish uniqueness of solutions of (32) we consider the case $\widehat{f} = \widehat{g} = 0$: seek $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$ there holds

$$\mathsf{a}(U, V) - \left(\mathbb{C}\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma + \left(\mathbb{D}(\vartheta), \gamma_0^- V\right)_\Gamma = 0, \tag{35}$$

$$\left(\varphi, (\mathbb{A} - \mathsf{Id})\left(\gamma_0^- U\right)\right)_\Gamma - (\varphi, \mathbb{B}(\vartheta))_\Gamma = 0. \tag{36}$$

Using integration by parts, we obtain

$$\Delta U + \kappa^2 n(\mathbf{x}) U = 0 \qquad \text{in } \Omega^-.$$

As a consequence, $\mathsf{a}(U, V) = \left(\gamma_1^- U, \gamma_0^- V\right)_\Gamma$. Plugging this identity into (35) and using the definition of $\mathcal{P}_+$ from (18), the identity

$$\begin{bmatrix} \gamma_0^- U \\ \gamma_1^- U \end{bmatrix} = \mathcal{P}_+ \begin{bmatrix} \gamma_0^- U \\ -\vartheta \end{bmatrix} \tag{37}$$

is immediate. By the definition of $\mathcal{P}_+$ and (7)

$$\begin{aligned}\mathcal{P}_+ &= \mathcal{R}^{-1} \circ (\mathcal{T} \circ \mathsf{P}_+ - \mathcal{S}) \\ &= \mathcal{R}^{-1} \circ (\mathcal{T} \circ (\mathsf{Id} - \mathsf{P}_-) - \mathcal{S}) \\ &= \mathcal{R}^{-1} \circ (\mathcal{R} + \mathcal{S} - \mathcal{T} \circ \mathsf{P}_- - \mathcal{S}) \\ &= \mathsf{Id} - \mathcal{R}^{-1} \circ \mathcal{T} \circ \mathsf{P}_-,\end{aligned}$$

and we infer

$$\mathcal{T} \circ \mathsf{P}_- = \mathcal{R} \circ (\mathsf{Id} - \mathcal{P}_+).$$

Together with (37) this identity confirms

$$(\mathcal{T} \circ \mathsf{P}_-) \begin{bmatrix} \gamma_0^- U \\ -\vartheta \end{bmatrix} = -\mathcal{R} \begin{bmatrix} 0 \\ \gamma_1^- U + \vartheta \end{bmatrix} \in \left(\{0\} \times H^{\frac{1}{2}}(\Gamma) \right),$$

and, by Assumption 6.1,

$$\mathcal{R} \begin{bmatrix} 0 \\ \gamma_1^- U + \vartheta \end{bmatrix} = 0 \quad \Rightarrow \quad \mathsf{D}(\gamma_1^- U + \vartheta) = 0.$$

Next, from Assumption 6.2, 5., we conclude that

$$\gamma_1^- U = -\vartheta. \tag{38}$$

From this and (37) we directly obtain, as in (24) in the proof of Lemma 6.3,

$$\begin{bmatrix} \gamma_0^- U \\ \gamma_1^- U \end{bmatrix} = \mathsf{P}_+ \begin{bmatrix} \gamma_0^- U \\ -\vartheta \end{bmatrix}.$$

Hence, by virtue of Theorem 4.1, setting

$$W(\mathbf{x}) := \begin{cases} U(\mathbf{x}), & \mathbf{x} \in \Omega^-, \\ \Psi_{\mathrm{DL}}^\kappa \left(\gamma_0^- U \right)(\mathbf{x}) - \Psi_{\mathrm{SL}}^\kappa (-\vartheta)(\mathbf{x}), & \mathbf{x} \in \Omega^+ \end{cases}$$

provides us with a solution to the Helmholtz transmission problem with zero right-hand side, and uniqueness of solutions to the Helmholtz transmission problem ensures $U = 0$ and, by (38), $\vartheta = 0$. We have demonstrated that (35) and (36) only possess the trivial solution and this finishes the proof. ∎

Eventually, the existence of solutions to the variational problem (32) follows from Theorem 7.3 and a Fredholm argument; see, for instance, [29, Thm. 2.33].

Finally, the arguments in the proof of Theorem 7.3 have also confirmed that we really get information about the solution of the Helmholtz transmission problem from (32).

COROLLARY 7.4. *If* $(W, \vartheta) \in H^1(\Omega^-) \times H^{-\frac{1}{2}}(\Gamma)$ *solves* (32)*, then* $W = U$ *and* $\vartheta = -\gamma_1^+ U^s$ *with* (U, U^s) *solving* (2)*.*

8. Regularization operators. In this section we present a rather simple specimen of a trace transformation operator $\mathcal{T}$, which satisfies both Assumptions 6.2 and 6.1. Its main ingredient is a *regularizing operator*

$$\mathsf{M} : H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma),$$

which satisfies the following assumption.

ASSUMPTION 8.1. *We suppose that*

1. $\mathsf{M} : H^{-\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma)$ *is compact, and*
2. $(\vartheta, \mathsf{M}(\vartheta))_\Gamma > 0$ *for all* $\vartheta \in H^{-\frac{1}{2}}(\Gamma) \setminus \{0\}$.

Various examples of such operators are discussed in [9]. Below we will present a concrete representative. Then, for $\eta \in \mathbb{R} \setminus \{0\}$ we choose the following trace transformation operators:

$$\mathcal{T}_1 := \begin{bmatrix} \mathsf{Id} & i\eta\mathsf{M} \\ i\eta & \mathsf{Id} \end{bmatrix}, \qquad \mathcal{T}_2 := \begin{bmatrix} \mathsf{Id} & i\eta\mathsf{M} \\ 0 & \mathsf{Id} \end{bmatrix}. \tag{39}$$

Now, we have to verify Assumptions 6.1 and 6.2. We note that Assumption 6.1 can instantly be concluded from Assumption 8.1, 2., and Lemma 6.5. Items 2. through 5. of Assumption 6.2 are evidently appealing to 1. in Assumption 8.1. It is also obvious that $\mathcal{T}_2$ is bijective with

$$\mathcal{T}_2{}^{-1} = \begin{bmatrix} \mathsf{Id} & -i\eta\mathsf{M} \\ 0 & \mathsf{Id} \end{bmatrix}.$$

It remains to be established whether $\mathcal{T}_1$ is bijective, too. The key will be the following lemma.

LEMMA 8.2. *For $\zeta \in \mathbb{R}_+$ or $\zeta \in i\mathbb{R}$ the following operators are bijective:*

$$\mathsf{Id} + \zeta\mathsf{M} : H^{-\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma), \qquad \mathsf{Id} + \zeta\mathsf{M} : H^{\frac{1}{2}}(\Gamma) \to H^{\frac{1}{2}}(\Gamma).$$

Proof. We verify that the operators have trivial kernel. In the first case we find that $(\mathsf{Id} + \zeta\mathsf{M})(\vartheta) = 0$ implies

$$(\vartheta, \varphi)_\Gamma + \overline{\zeta}\,(\mathsf{M}(\vartheta), \varphi)_\Gamma = 0,$$

which holds true for all $\varphi \in H^{\frac{1}{2}}(\Gamma)$. We choose $\varphi := \mathsf{M}(\vartheta)$ and we obtain

$$(\vartheta, \mathsf{M}(\vartheta))_\Gamma + \overline{\zeta}\,\|\mathsf{M}(\vartheta)\|^2_{L^2(\Gamma)} = 0.$$

For either $\zeta > 0$ or $\zeta \in i\mathbb{R}$ Assumption 8.1, 2., implies

$$(\vartheta, \mathsf{M}(\vartheta))_\Gamma = 0 \Leftrightarrow \vartheta = 0.$$

Thanks to Assumption 8.1, 1., we have a Fredholm alternative argument [29, Thm. 2.27] at our disposal and conclude that the operator $\mathsf{Id} + \zeta\mathsf{M} : H^{-\frac{1}{2}}(\Gamma) \to H^{-\frac{1}{2}}(\Gamma)$ is surjective from the fact that it is injective.

In the $H^{\frac{1}{2}}(\Gamma)$-setting $(\mathsf{Id} + \zeta\mathsf{M})(\varphi) = 0$ is equivalent to

$$(\vartheta, \varphi)_\Gamma + \zeta\,(\vartheta, \mathsf{M}(\varphi))_\Gamma = 0 \quad \forall \vartheta \in H^{-\frac{1}{2}}(\Gamma).$$

The same reasoning as above also settles this case. ∎

The lemma tells us that the formal inverse

$$\mathcal{T}_1{}^{-1} = \left(\mathsf{Id} + \eta^2\mathsf{M}\right)^{-1} \circ \begin{bmatrix} \mathsf{Id} & -i\eta\mathsf{M} \\ -i\eta & \mathsf{Id} \end{bmatrix}$$

is well defined, which implies Assumption 6.2, 1., for $\mathcal{T}_1$.

A particularly convenient regularizing operator has been presented in [8]: there, $\mathsf{M} : H^{-1}(\Gamma) \to H^1(\Gamma)$ is implicitly defined by

$$(\mathbf{grad}_\Gamma \mathsf{M}(p), \mathbf{grad}_\Gamma q)_\Gamma + (\mathsf{M}(p), q)_\Gamma = (p, q)_\Gamma \tag{40}$$

for all $q \in H^1(\Gamma)$. It is an easy exercise to verify Assumption 8.1 for this M; see [8, sect. 4.2]. For later use we define the following sesquilinear form:

$$\mathsf{b}(p, q) := (\mathbf{grad}_\Gamma p, \mathbf{grad}_\Gamma q)_\Gamma + (p, q)_\Gamma, \qquad p, q \in H^1(\Gamma), \tag{41}$$

which allows us to restate definition (40) as

$$\mathsf{b}(\mathsf{M}(p), q) = (p, q)_\Gamma \quad \forall q \in H^1(\Gamma). \tag{42}$$

9. Mixed regularized variational formulations. Using the two trace transformation operators we obtain two variational formulations which are free from spurious resonances. However, from the point of view of boundary element discretization, they are not yet useful, because they still contain products of (nonlocal) operators that elude a straightforward Galerkin discretization. To get rid of the operator products, we rely on the usual trick and introduce extra unknown functions. We discuss the resulting variational problems for the trace transformation operators $\mathcal{T}_1$ and $\mathcal{T}_2$ from (39) and M given by (40).

Case $\mathcal{T} = \mathcal{T}_1$: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$

(43)
$$\begin{aligned} \mathsf{a}(U,V) - \left(\left(i\eta\left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right) - \mathsf{W}_\kappa\right)\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma \\ + \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa - i\eta\mathsf{V}_\kappa\right)(\vartheta), \gamma_0^- V\right)_\Gamma = f_1(V), \\ \left(\varphi, \left(i\eta\mathsf{M}\circ\left(\tfrac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right) + \mathsf{V}_\kappa\right)(\vartheta)\right)_\Gamma + \left(\varphi, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id} - i\eta\mathsf{M}\circ\mathsf{W}_\kappa\right)\left(\gamma_0^- U\right)\right)_\Gamma = g_1(\varphi), \end{aligned}$$

where the right-hand sides are given by

$$\begin{aligned} f_1(V) &:= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma + \left(\left(i\eta\left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right) - \mathsf{W}_\kappa\right)(g_0), \gamma_0^- V\right)_\Gamma, \\ g_1(\varphi) &:= \left(\varphi, \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}_\kappa + i\eta\mathsf{M}\circ\mathsf{W}_\kappa\right)(g_0)\right)_\Gamma. \end{aligned}$$

Case $\mathcal{T} = \mathcal{T}_2$: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$

(44)
$$\begin{aligned} \mathsf{a}(U,V) + \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma + \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right)\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma = f_2(V), \\ \left(\varphi, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id} - i\eta\mathsf{M}\circ\mathsf{W}_\kappa\right)\left(\gamma_0^- U\right)\right)_\Gamma + \left(\varphi, \left(i\eta\mathsf{M}\circ\left(\tfrac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right) + \mathsf{V}_\kappa\right)(\vartheta)\right)_\Gamma = g_2(\varphi), \end{aligned}$$

where the right-hand sides are given by

$$\begin{aligned} f_2(V) &:= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma - \left(\mathsf{W}_\kappa(g_0), \gamma_0^- V\right)_\Gamma, \\ g_2(\varphi) &:= \left(\varphi, \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}_\kappa + i\eta\mathsf{M}\circ\mathsf{W}_\kappa\right)(g_0)\right)_\Gamma. \end{aligned}$$

Both regularized variational formulations contain the same operator products, namely

$$\begin{aligned} -\mathbb{B} &= \mathsf{V}_\kappa + i\eta\mathsf{M}\circ\left(\tfrac{1}{2}\mathsf{Id} + \mathsf{K}'_\kappa\right), \\ \mathbb{A} - \mathsf{Id} &= \mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id} - i\eta\mathsf{M}\circ\mathsf{W}_\kappa. \end{aligned}$$

This suggests that we introduce the new variable

$$p := \left(\mathsf{M}\circ\left(\tfrac{1}{2} + \mathsf{K}'_\kappa\right)\right)(\vartheta) - (\mathsf{M}\circ\mathsf{W}_\kappa)\left(\gamma_0^- U + g_0\right) \in H^1(\Gamma), \tag{45}$$

which converts (32) into the following two variational problems. The first arises from using $\mathcal{T}_1$: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, and $p \in H^1(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$, and $q \in H^1(\Gamma)$ there holds

(46)
$$\begin{aligned} \mathsf{a}(U,V) + i\eta\left(\left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma + \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma \\ + \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right)(\vartheta), \gamma_0^- V\right)_\Gamma + i\eta\left(\mathsf{V}_\kappa(\vartheta), \gamma_0^- V\right)_\Gamma = f_1(V), \\ \left(\varphi, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)\left(\gamma_0^- U\right)\right)_\Gamma + (\varphi, \mathsf{V}_\kappa(\vartheta))_\Gamma + i\eta(\varphi, p)_\Gamma = g_1(\varphi), \\ \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), q\right)_\Gamma - \left(\left(\mathsf{K}'_\kappa + \tfrac{1}{2}\mathsf{Id}\right)(\vartheta), q\right)_\Gamma + \mathsf{b}(p,q) = h_1(q), \end{aligned}$$

with right-hand sides

$$\begin{aligned} f_1(V) &:= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma - i\eta \left(\left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)(g_0), \gamma_0^- V\right)_\Gamma - \left(\mathsf{W}_\kappa(g_0), \gamma_0^- V\right)_\Gamma, \\ g_1(\varphi) &:= \left(\varphi, \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}_\kappa\right)(g_0)\right)_\Gamma, \\ h_1(q) &:= -\left(\mathsf{W}_\kappa(g_0), q\right)_\Gamma. \end{aligned}$$

The second arises from using $\mathcal{T}_2$: find $U \in H^1(\Omega^-)$, $\vartheta \in H^{-\frac{1}{2}}(\Gamma)$, and $p \in H^1(\Gamma)$ such that for all $V \in H^1(\Omega^-)$, $\varphi \in H^{-\frac{1}{2}}(\Gamma)$, and $q \in H^1(\Gamma)$ there holds

$$\begin{aligned} \mathsf{a}(U,V) + \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), \gamma_0^- V\right)_\Gamma + \left(\left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}'_\kappa\right)(\vartheta), \gamma_0^- V\right)_\Gamma &= f_2(V), \\ \left(\varphi, \left(\mathsf{K}_\kappa - \tfrac{1}{2}\mathsf{Id}\right)\left(\gamma_0^- U\right)\right)_\Gamma + (\varphi, \mathsf{V}_\kappa(\vartheta))_\Gamma + i\eta(\varphi, p)_\Gamma &= g_2(V), \\ \left(\mathsf{W}_\kappa\left(\gamma_0^- U\right), q\right)_\Gamma - \left(\left(\mathsf{K}'_\kappa + \tfrac{1}{2}\mathsf{Id}\right)(\vartheta), q\right)_\Gamma + \mathsf{b}(p,q) &= h_2(q), \end{aligned} \tag{47}$$

with right-hand sides

$$\begin{aligned} f_2(V) &:= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma - \left(\mathsf{W}_\kappa(g_0), \gamma_0^- V\right)_\Gamma, \\ g_2(\varphi) &:= \left(\varphi, \left(\tfrac{1}{2}\mathsf{Id} - \mathsf{K}_\kappa\right)(g_0)\right)_\Gamma, \\ h_2(q) &:= -\left(\mathsf{W}_\kappa(g_0), q\right)_\Gamma. \end{aligned}$$

In order to settle the issue of existence and uniqueness of solutions of (46) and (47) we first observe that by the very definition of M in (40) and (45) the first two components of any solution (U, ϑ, p) of (46) and (47) will also solve (43) and (44), respectively. Since these are special cases of (32) and both $\mathcal{T}_1$ and $\mathcal{T}_2$ are valid trace transformation operators, Theorem 7.3 yields uniqueness.

Next, it follows directly from the compact embeddings $H^1(\Gamma) \hookrightarrow H^{\frac{1}{2}}(\Gamma)$ and $H^{-\frac{1}{2}}(\Gamma) \hookrightarrow H^{-1}(\Gamma)$ that all new off-diagonal terms are compact sesquilinear forms. Since b is $H^1(\Gamma)$-elliptic, we obtain that the sesquilinear forms for both variational formulations satisfy a generalized Gårding inequality.

Again, a Fredholm argument ensures the existence of solutions from the uniqueness result. The statement of Corollary 7.4 directly carries over to the (U, ϑ)-components of (43) and (44). Thus we have obtained two well-posed variational formulations which yield weak solutions to the Helmholtz transmission problem 2 and which are also amenable to standard Galerkin discretizations.

We finish this section by making an important observation: (45) can be recast into

$$p = \left(\mathsf{M} \circ \left(\tfrac{1}{2} + \mathsf{K}'_\kappa\right)\right)(\vartheta) - (\mathsf{M} \circ \mathsf{W}_\kappa)\left(\gamma_0^- U + g_0\right).$$

At second glance, we realize that $p = 0$, if (U, ϑ) solves (43) and (44), respectively. This directly follows from Corollary 7.4, Theorem 4.1, and the definition of the exterior Calderón projector P_+. In short, p is a "dummy variable."

Remark 9.1. Under the assumptions made in Remark 4.2 we can derive a Dirichlet-to-Neumann map from (27) to obtain coupled variational problems of the form (46) and (47) with much simpler right-hand sides:

$$\begin{aligned} f_1(V) &= \mathsf{f}(V) + i\eta\left(g_0, \gamma_0^- V\right)_\Gamma - \left(g_1, \gamma_0^- V\right)_\Gamma, & f_2(V) &= \mathsf{f}(V) - \left(g_1, \gamma_0^- V\right)_\Gamma, \\ g_1(\varphi) &= (\varphi, g_0)_\Gamma, & g_2(\varphi) &= +(\varphi, g_0)_\Gamma, \\ h_1(q) &= -(g_1, q)_\Gamma, & h_2(q) &= -(g_1, q)_\Gamma. \end{aligned} \tag{48}$$

The solution U in Ω^- will remain the same.

10. Galerkin discretization. With operator products removed, the Galerkin discretization of the variational problems (43) and (44) is easily achieved by restricting them to finite element subspaces $\mathcal{V}_h$ of $H^1(\Omega^-)$ and boundary element subspaces Θ_h and $\mathcal{Q}_h$ of $H^{-\frac{1}{2}}(\Gamma)$ and $H^1(\Gamma)$, respectively. A powerful theorem about the Galerkin approximation of coercive variational problems, see [33] and [37], will then yield the *asymptotic quasi-optimality* of the Galerkin solutions: assuming a minimal resolution of $\mathcal{V}_h$, Θ_h, and $\mathcal{Q}_h$, existence and uniqueness of discrete solutions $(U_h, \vartheta_h, p_h) \in \mathcal{V}_h \times \Theta_h \times \mathcal{Q}_h$ of (43) and (44) is guaranteed and we have the a priori error estimate

$$\begin{aligned}(49)\quad &\|U-U_h\|_{H^1(\Omega^-)} + \|\vartheta-\vartheta_h\|_{H^{-\frac{1}{2}}(\Gamma)} \\ &\qquad \leq \gamma\left(\inf_{V_h\in\mathcal{V}}\|U-V_h\|_{H^1(\Omega^-)} + \inf_{\varphi_h\in\Theta_h}\|\vartheta-\varphi_h\|_{H^{-\frac{1}{2}}(\Gamma)}\right),\end{aligned}$$

where the constant $\gamma > 0$ does not depend on the discrete trial spaces.

The standard choices for $\mathcal{V}_h$, Θ_h, and $\mathcal{Q}_h$ are based on a tetrahedral or quadrilateral mesh $\mathcal{M}$ of Ω^-, which yields a mesh $\mathcal{M}_\Gamma$ of Γ by plain restriction to Γ. Then we may pick

$$\begin{aligned}(50)\quad V_h &:= \{V \in C^0(\Omega^-) :\ V_{|K} \in \mathcal{P}_k(K)\ \forall K \in \mathcal{M}\},\\ \Theta_h &:= \{\varphi \in L^2(\Gamma) :\ \varphi_{|K} \in \mathcal{P}_{k-1}(K)\ \forall K \in \mathcal{M}_\Gamma\},\\ \mathcal{Q}_h &:= \{q \in C^0(\Gamma) :\ q_{|K} \in \mathcal{P}_k(K)\ \forall K \in \mathcal{M}_\Gamma\}.\end{aligned}$$

Here, $\mathcal{P}_k(K)$ stands for the space of polynomials of degree $\leq k$ on the cell K. This refers to the total degree in the case of tetrahedra and the degree in each variable in the case of hexahedra.

Then, the usual best approximation estimates [32] for the h-version of finite elements and boundary elements give us

$$\begin{aligned}\inf_{V_h\in\mathcal{V}_h}\|U-V_h\|_{H^1(\Omega^-)} &\leq \gamma h^{\min\{s-1,k\}}\|U\|_{H^s(\Omega^-)},\\ \inf_{\varphi_h\in\Theta_h}\|\vartheta-\varphi_h\|_{H^{-\frac{1}{2}}(\Gamma)} &\leq \gamma h^{\min\{s+1/2,k\}}\|\vartheta\|_{H^s(\Gamma)},\end{aligned}$$

with constants depending on the shape regularity of $\mathcal{M}$ and $h > 0$ denoting the meshwidth of $\mathcal{M}$.

Remark 10.1. Why do we have to approximate the dummy variable p at all, since it vanishes and apparently the choice of $\mathcal{Q}_h$ does not affect the convergence of Galerkin solutions? The reason is that (49) is an asymptotic statement, whose proof also hinges on sufficiently good approximation properties of $\mathcal{Q}_h$. In the context of the h-version of finite elements and boundary elements, this means that the mesh has to be sufficiently fine to make (49) hold.

11. Numerical experiments. Limited computational resources allow the numerical exploration of asymptotic convergence rates only in two dimensions. Fortunately, the above theoretical developments carry over to two dimensions verbatim, when replacing the kernel G_κ by

$$(51)\qquad G_\kappa(z) := \frac{i}{4}H_0^{(1)}(kz),$$

where $H_0^{(1)}$ is the Hankel function of the first kind of order zero.

For the numerical experiments we considered the following:

- The unit circle $\Omega_\circ^- := \{\mathbf{x} \in \mathbb{R}^2 : |\mathbf{x}| < 1\}$ as a specimen of a domain with smooth boundary. The two smallest interior resonant frequencies are $\kappa_1 = 5.5201$ and $\kappa_2 = 11.7915$, which correspond to the second and fourth zero of the Bessel function $J_0(x)$.
- The unit square $\Omega_\square^- := \{\mathbf{x} \in \mathbb{R}^2 : -1/2 < x_1, x_2 < 1/2\}$, as representative of polygonal domains. The associated two lowest resonant frequencies are $\kappa_3 = 2\pi/\sqrt{2}$ and $\kappa_4 = 5\pi/\sqrt{2}$.

On each domain finite element meshes $\mathcal{M}_l$, $l \in \mathbb{N}$, consisting of quadrilaterals with straight edges were used. In the case of $\Omega_\circ^-$ the triangulation $\mathcal{M}_l$ is created by inscribing $\Omega_\circ^-$ a regular 2^{l+3}-gon and a centered unit square. The portions of the line segments from the center to the corners of the polygon are split into 2^l equal parts, whose endpoints are connected to form a quadrilateral mesh outside the unit square. This is extended by an orthogonal tensor product mesh inside the unit square. The mesh $\mathcal{M}_1$ is drawn in Figure 1. The family of meshes arising from this construction will be quasi-uniform and shape-regular with meshwidth h of $\mathcal{M}_l$ being proportional to $2^{-(l+1)}$.

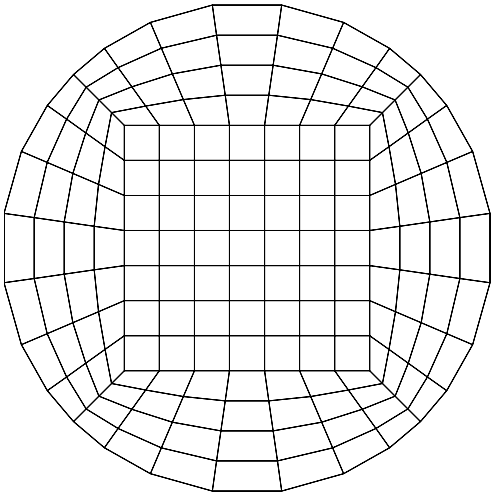

FIG. 1. *Quadrilateral mesh of the unit circle.*

On $\Omega_\square^-$ the mesh $\mathcal{M}_l$ is a plain uniform orthogonal tensor product grid with meshwidth $h = 2^{-(l+1)}$.

We used mapped bilinear Lagrangian finite elements to build $\mathcal{V}_h$, piecewise constants on $\mathcal{M}_\Gamma$ for Θ_h, and linear surface elements for $\mathcal{Q}_h$, that is, the case $k = 1$ of (50). The finite element stiffness matrix was assembled using a four-point Gaussian quadrature rule on the reference element. The dense matrices of the discrete boundary integral operators were computed using Duffy's trick and highly accurate adaptive composite Gauss–Legendre quadrature as proposed in [32, Example 5.1.9] and [34]. All computations were done in MATLAB and a direct solver was used whenever we aimed to study discretization errors.

In all the experiments we used $n(\mathbf{x}) = 1$ in Ω^- and excitation by incident plane waves. These will also provide the exact solutions. Please note that in this setting $\vartheta = -\gamma_1^+ U$, because there is no scattered field. As far as the stable regularized

coupled schemes are concerned we consistently used the second regularized variational formulation (47) together with the simple right-hand sides (48).

When analytic solutions are known, we measure the discretization error in the interior total field in either the $H^1(\Omega^-)$ or the $L^2(\Omega^-)$-norm and the error in ϑ in either the $H^{-\frac{1}{2}}(\Gamma)$ or the $L^2(\Gamma)$-norm. Integer Sobolev norms are calculated by means of four-point Gaussian quadrature. The $H^{-\frac{1}{2}}$-norm is evaluated by means of the discrete single layer potential operator on the current mesh after the exact solution for ϑ has been projected onto Θ_h.

Experiment 1. A plane incident wave $U^{\mathrm{i}}(\mathbf{x}) = \exp(-i\kappa\mathbf{d}\cdot\mathbf{x})$, $|\mathbf{d}| = 1$, is used, where the incident angle between the propagation direction $\mathbf{d}$ and the x-axis is $\pi/4$. We measure the discretization errors in different norms on the domain $\Omega^-_{\square}$ for the two frequencies κ_3 and κ_4 on the series of shape-regular meshes and for a regularization parameter $\eta = 1$; see Figures 2 and 3 for results. Table 1 lists the observed convergence rates, which are very low because of the corner discontinuity of ϑ.

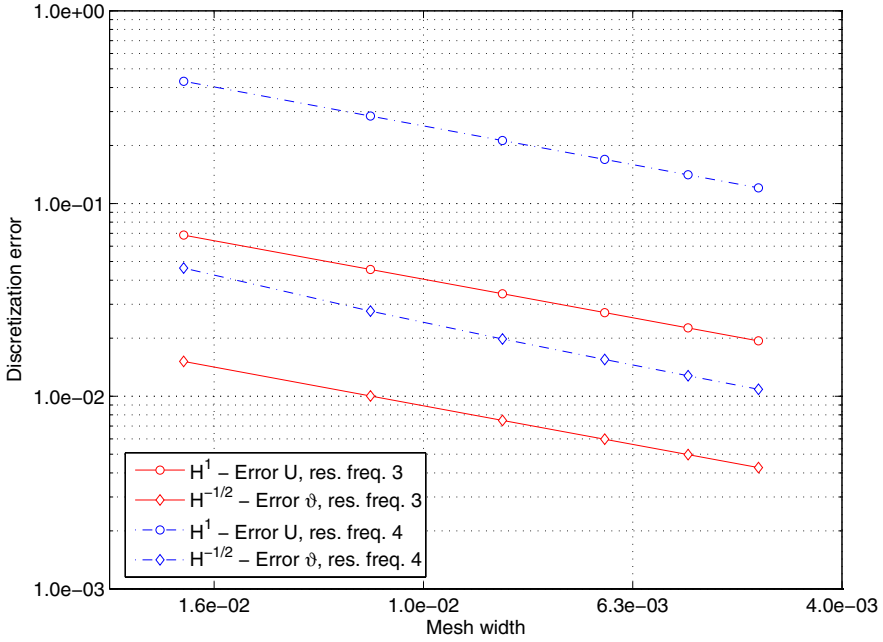

FIG. 2. *Discretization errors for* κ_3 $(-)$ *and* κ_4 $(-\cdot)$ *on the unit square* $\Omega^-_{\square}$.

TABLE 1
Observed convergence rates for different error norms.

	$\|U-U_h\|_{H^1(\Omega^-)}$	$\|U-U_h\|_{L^2(\Omega^-)}$	$\|\vartheta-\vartheta_h\|_{H^{-\frac{1}{2}}(\Gamma)}$	$\|\vartheta-\vartheta_h\|_{L^2(\Gamma)}$
Exp. 1	$O(h)$	$O(h)$	$O(h)$	$O(h^{\frac{1}{2}})$
Exp. 2	$O(h)$	$O(h^2)$	$O(h^2)$	$O(h)$

Experiment 2. Using the same excitation as before, we measure the discretization errors on the series of shape-regular meshes of the unit circle $\Omega^-_{\circ}$ for the two frequencies κ_1 and κ_2; see Figures 4 and 5. Now both ϑ and U are smooth, which translates into optimal convergence rates; see Table 1.

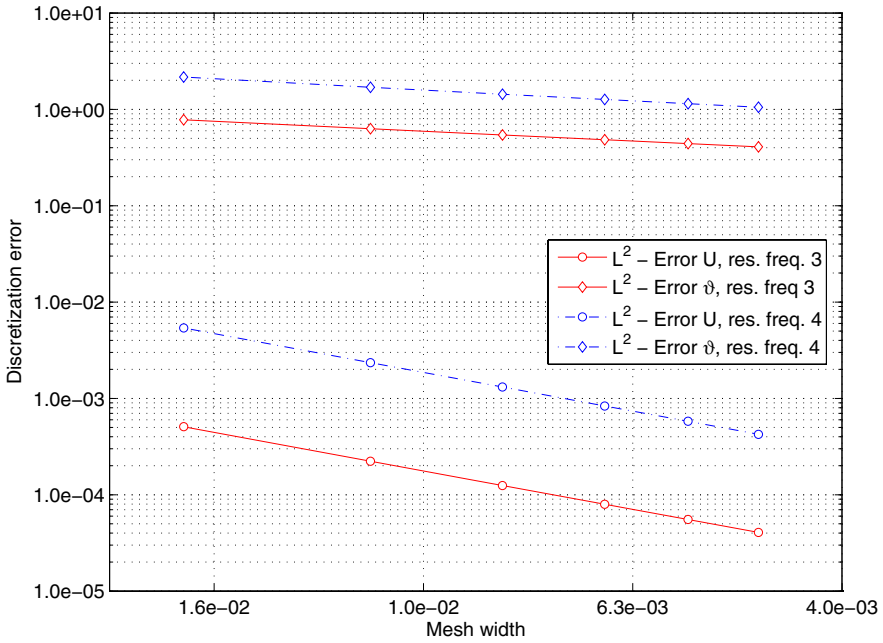

FIG. 3. *Discretization errors for* κ_3 $(-)$ *and* κ_4 $(-\cdot)$ *on the unit square* $\Omega_{\square}^{-}$.

Experiment 3. We examine the dependence of the discretization error, measured in the $H^1(\Omega^-)$, and $H^{-\frac{1}{2}}(\Gamma)$-norms, respectively, on the wave number for a mesh of the domain $\Omega_{\square}^{-}$ with 14161 elements. The results for conventional symmetric FEM-BEM coupling (15) are recorded in Figure 6. In Figure 7 the discretization errors are plotted for the second version of regularized FEM-BEM coupling (47). We note that the discretization errors for both methods are of exactly the same size. Moreover, they grow as κ increases. This is hardly surprising, because this is already observed for low order finite element discretizations of the Helmholtz equation [4].

The pronounced spikes in the discretization error graph for the ϑ-component in Figure 7 are due to the resonant frequencies which affect the conventional symmetric FEM-BEM coupling. In contrast, they are completely suppressed when using the second version of regularized FEM-BEM coupling (47) as we can see in Figure 6.

Experiment 4. We recorded the dependence of the spectral condition number of the entire system matrix on the wave number for

1. the symmetric FEM-BEM coupling (15) and
2. the second version of regularized FEM-BEM coupling (47)

in the neighborhood of the resonant frequency κ_3 for a mesh of the domain $\Omega_{\square}^{-}$ with 14161 elements; see Figure 8. In each case the extremal eigenvalues were computed by means of direct and inverse power iterations. Obviously, regularization manages to suppress the pronounced peak in the condition number in the case of the symmtrically coupled problem.

OPTIMAL DISCONTINUOUS GALERKIN METHODS FOR WAVE PROPAGATION*

ERIC T. CHUNG† AND BJÖRN ENGQUIST‡

Abstract. We have developed and analyzed a new class of discontinuous Galerkin methods (DG) which can be seen as a compromise between standard DG and the finite element (FE) method in the way that it is explicit like standard DG and energy conserving like FE. In the literature there are many methods that achieve some of the goals of explicit time marching, unstructured grid, energy conservation, and optimal higher order accuracy, but as far as we know only our new algorithms satisfy all the conditions. We propose a new stability requirement for our DG. The stability analysis is based on the careful selection of the two FE spaces which verify the new stability condition. The convergence rate is optimal with respect to the order of the polynomials in the FE spaces. Moreover, the convergence is described by a series of numerical experiments.

Key words. discontinuous Galerkin, wave propagation, optimal rate of convergence

1. Introduction.

Many applications involve the solution of wave equations. Examples are electromagnetic waves for radar and communication as well as acoustic and seismic wave propagation. Let $\Omega \subset \mathbb{R}^2$ be a two dimensional polygonal domain with outward normal vector n and let $T > 0$ be a fixed time. Given two positive constants $a_1 > 0$, $a_2 > 0$ and two given functions $F_1(x,t)$, $F_2(x,t)$, we will consider, for $(x,t) \in \Omega \times (0,T)$, the following wave propagation problem: find a function $u(x,t)$ and a vector field $v(x,t) \in \mathbb{R}^2$ such that

$$a_1 \frac{\partial u}{\partial t} + Bv = F_1, \tag{1.1}$$

$$a_2 \frac{\partial v}{\partial t} - B^* u = F_2, \tag{1.2}$$

where the two operators B and B^* satisfy

$$\int_{\Omega_0} (B^*\phi)\psi \, dx - \int_{\Omega_0} (B\psi)\phi \, dx = \int_{\partial\Omega_0} (L\psi)\phi \, d\sigma \tag{1.3}$$

for all subset $\Omega_0 \subset \Omega$. Here L is some operator depending on the two operators B, B^* and the subdomain Ω_0. We also denote by $L^\perp$ the operator such that $|\psi|^2 = |L\psi|^2 + |L^\perp\psi|^2$. Assume that there is an operator $B^\perp$ such that $BB^\perp p = 0$ for all p. Acting $(B^\perp)^*$ to (1.2) and using $(B^\perp)^* B^* = 0$, we have the following:

$$\frac{\partial}{\partial t}(a_2 (B^\perp)^* v) = (B^\perp)^* F_2. \tag{1.4}$$

The condition (1.4) usually has important physical significance. For example, in the case of electromagnetic wave propagation (see (E) in the following), v represents the electric field, $(B^\perp)^*$ is the divergence operator, and (1.4) is just the continuity equation expressing the conservation of charges. We supplement the system (1.1)–(1.2) with boundary condition

$$Lv = 0 \quad \forall x \in \partial\Omega \tag{1.5}$$

and initial conditions

$$u(x,0) = u_0(x) \quad \text{and} \quad v(x,0) = v_0(x) \quad \forall x \in \Omega, \tag{1.6}$$

where $u_0(x)$ and $v_0(x)$ are given. In particular, we are interested in the acoustic and the electromagnetic wave equations, which correspond to the following choice of B and B^*:

(A) Acoustic: $Bv = -\nabla \cdot v$, $B^*u = \nabla u$, and $Lv = v \cdot n$.

(E) Electromagnetic: $Bv = \nabla \times v$, $B^*u = \nabla \times u$, and $Lv = v \times n$.

Notice that, in (1.1)–(1.2), $u(x,t)$ is a function while $v(x,t) = (v^1(x,t), v^2(x,t))$ is a vector having two components. So the operator $\nabla\times$ is defined as $\nabla \times v = \partial_1 v^2 - \partial_2 v^1$ for any vector field v and $\nabla \times u = (\partial_2 u, -\partial_1 u)$ for any function u. Here $v \times n = v^1 n_2 - v^2 n_1$ with $n = (n_1, n_2)$. In (A) and (E), we use n to denote generically the unit normal vector of the corresponding subdomain which defines L and $L^\perp$. Moreover, we have $L^\perp\psi = \psi \times n$ for (A) while $L^\perp\psi = \psi \cdot n$ for (E). Furthermore, we have $B^\perp p = \nabla \times p$ and $(B^\perp)^* p = \nabla \times p$ for (A) while $B^\perp p = \nabla p$ and $(B^\perp)^* p = -\nabla \cdot p$ for (E). Wave propagation problems can be solved by partial differential equation (PDE) techniques, integral equation techniques, and asymptotic techniques. Among PDE techniques, finite difference (FD) method, finite volume (FV) method, finite element (FE) method, and discontinuous Galerkin (DG) method are the most popular choices. The FD method provides a simple way to solve wave propagation problems, but it is typically low order and applies only to structured grids. The FV method can be seen as a generalization of the FD method to unstructured grids, but it is still low order. The FE and DG methods provide high order solvers for the time dependent wave equations on unstructured grids.

Nédélec [15] introduces a curl-conforming FE method for solving Maxwell's equations. Geveci [8] proposed a mixed FE method for the scalar wave equation. The inversion of the mass matrix at each time step causes some possible drawback in the efficiency of those methods. Mass lumping techniques can be used to avoid solving linear systems. In Cohen and Monk [6], a mass lumping method for rectangular grids is developed. In Bécache, Joly, and Tsogka [1], a new class of mixed FE method, which is suitable for mass lumping, is developed for the scalar wave equation. Cohen, Joly, Torjman, and Roberts [5] design a mass lumping technique for triangular grids for polynomial order up to five. Discontinuous Galerkin methods provide explicit schemes in the sense that only block diagonal mass matrices have to be inverted. Hesthaven and Warburton [10] proposed a DG method based on upwind flux and Cockburn, Li, and Shu [4] proposed a DG method based on locally divergence free basis and upwind flux. While the schemes are successful, energy is not conserved due to the upwinding. Fezoui, Lanteri, Lohrengel, and Piperno [7] proposed a DG method based on central flux. This method preserves energy, but the convergence rate of the scheme is suboptimal. Recently, a new DG method has been developed for the wave equation in second order form; see Grote, Schneebeli, and Schötzau [9]. The method is also energy conserving

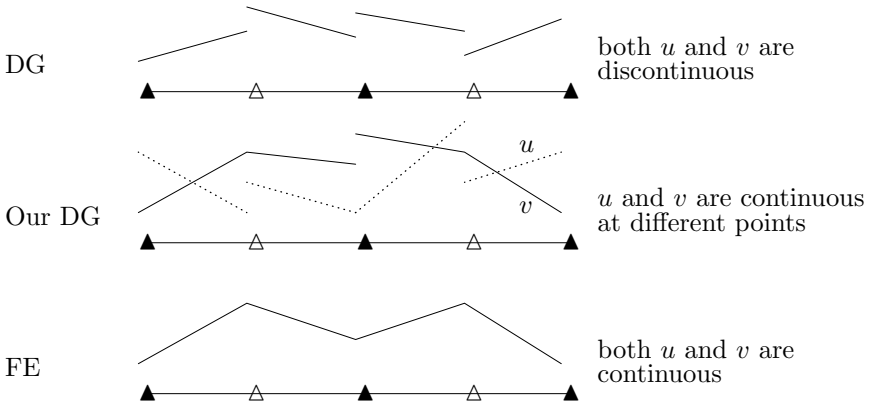

FIG. 1.1. *Comparison among standard DG, our new DG, and FE methods.*

in the sense of a newly defined energy. A space-time DG method has also been developed in Monk and Richter [14].

In this paper, we will develop and analyze a new class of DG methods which can be seen as a compromize between FE and DG methods. Our new DG method combines the advantages of FE and DG methods in the sense that it is both energy conserving and explicit. The idea is to use discontinuous functions with extra continuity. In the velocity-potential formulation of the scalar wave equation (A), we will add extra continuity to the velocity where the potential is discontinuous and add extra continuity to the potential where the velocity is discontinuous. For Maxwell's equations (E), a similar idea can be applied to the electric and magnetic fields. As a result, the flux integrals are evaluated exactly, which is the basis of energy conservation. However, the addition of the extra continuity cannot be done arbitrarily due to stability concerns. It has to be done in such a way that some inf-sup conditions are satisfied. In Figure 1.1, we illustrate this idea in one space dimension. For standard DG, both unknown functions u and v, which are velocity and potential for scalar wave equation and are electric and magnetic fields for Maxwell's equations, are discontinuous at cell boundaries. For FE methods, both u and v are continuous. For our new DG, the two functions are continuous at different points.

Yee's scheme [16] has been a very popular numerical method for computational electromagnetics. It is a second order central FD method on structured grids. The success of the scheme is due to the use of a staggered grid. Our new DG method is a FE method on staggered grids and can be seen as a higher generalization of Yee's scheme on unstructured grids. In particular, in one space dimension, our new DG method with piecewise constant approximation is the same as Yee's scheme. In two space dimensions, our new DG method in the lowest order is some averaged version of Yee's scheme.

The rest of the paper is organized as follows. In section 2, we will introduce the new FE spaces and prove the corresponding unisolvence and interpolation error estimates. The new DG is then derived in section 3. In section 4, under the assumption of some inf-sup conditions, the stability and convergence of the method are proved. The inf-sup conditions are then verified in section 5. Furthermore, some numerical experiments are presented in section 6. The paper ends with a conclusion.

Remark. We consider only two space dimensions in this paper. For three space dimensions, a careful choice of the two FE spaces U_h and V_h that verify (3.1) and

(3.2) as well as the two inf-sup conditions (4.1)–(4.2) are required. This work will be developed in a forthcoming paper.

2. FE spaces. Assume the domain Ω is triangulated by a family of triangles $\mathcal{T}$ so that $\Omega = \cup\{\tau \mid \tau \in \mathcal{T}\}$. Let $\tau \in \mathcal{T}$. We define h_τ as the diameter of τ and ρ_τ as the supremum of the diameters of the circles inscribed in τ. The mesh size h is defined as $h = \max_{\tau\in\mathcal{T}} h_\tau$. We will assume the set of triangles $\mathcal{T}$ forms a regular family of triangulation of Ω so that there exist a uniform constant K independent of the mesh size such that [3]

$$h_\tau \leq K\rho_\tau \quad \forall \tau \in \mathcal{T}.$$

In addition, we will assume the triangulation satisfies the inverse assumption [3].

Let $\mathcal{E}$ be the set of all edges and let $\mathcal{E}^0 \subset \mathcal{E}$ be the set of all interior edges of the triangles in $\mathcal{T}$. The length of $\sigma \in \mathcal{E}$ will be denoted by h_σ. We also denote by $\mathcal{N}$ the set of all interior nodes of the triangles in $\mathcal{T}$. Here, by interior edge and interior node, we mean any edge and node that does not lie on the boundary $\partial\Omega$. Let $\nu \in \mathcal{N}$. We define

$$\mathcal{S}(\nu) = \cup\{\tau \in \mathcal{T} \mid \nu \in \tau\}. \tag{2.1}$$

That is, $\mathcal{S}(\nu)$ is the union of all triangles having vertex ν. We will assume the triangulation of Ω satisfies the following condition.

Assumption on triangulation: There exists a subset $\mathcal{N}_1 \subset \mathcal{N}$ such that

(A1) $\Omega = \cup\{\mathcal{S}(\nu) \mid \nu \in \mathcal{N}_1\}$.

(A2) $\mathcal{S}(\nu_i) \cap \mathcal{S}(\nu_j) \in \mathcal{E}^0$ for all distinct $\nu_i, \nu_j \in \mathcal{N}_1$.

Let $\nu \in \mathcal{N}_1$. We define

$$\mathcal{E}_u(\nu) = \{\sigma \in \mathcal{E} \mid \nu \in \sigma\}. \tag{2.2}$$

That is, $\mathcal{E}_u(\nu)$ is the set of all edges that have ν as one of their endpoints. We further define

$$\mathcal{E}_u = \cup\{\mathcal{E}_u(\nu) \mid \nu \in \mathcal{N}_1\} \quad \text{and} \quad \mathcal{E}_v = \mathcal{E}\backslash\mathcal{E}_u. \tag{2.3}$$

Notice that $\mathcal{E}_u$ contains only interior edges since one of the endpoints of edges in $\mathcal{E}_u$ has a vertex from $\mathcal{N}_1$. On the other hand, $\mathcal{E}_v$ has both interior and boundary edges. So, we also define $\mathcal{E}_v^0 = \mathcal{E}_v \cap \mathcal{E}^0$ which contains elements from $\mathcal{E}_v$ that are interior edges. Notice that we have $\mathcal{E}_v\backslash\mathcal{E}_v^0 = \mathcal{E} \cap \partial\Omega$. Furthermore, for $\sigma \in \mathcal{E}_v^0$, we will let $\mathcal{R}(\sigma)$ be the union of the two triangles sharing the same edge σ. For $\sigma \in \mathcal{E}_v\backslash\mathcal{E}_v^0$, we will let $\mathcal{R}(\sigma)$ be the only triangle having the edge σ.

In practice, triangulations that satisfy assumptions (A1)–(A2) are not difficult to construct. In Figure 2.1, we illustrate how this kind of triangulation is generated. First, the domain Ω is triangulated by a family of triangles, called $\tilde{\mathcal{T}}$. Each triangle in this family is then subdivided into three subtriangles by connecting a point inside the triangle with its three vertices. Then we define the union of all these subtriangles to be our triangulation $\mathcal{T}$. Each triangle in $\tilde{\mathcal{T}}$ corresponds to an $\mathcal{S}(\nu)$ for some ν inside the triangle. In Figure 2.1, we show two of the triangles, enclosed by solid lines, in this family $\tilde{\mathcal{T}}$. This corresponds to 6 triangles in the triangulation $\mathcal{T}$. The dotted lines represent edges in the set $\mathcal{E}_u$ while solid lines represent edges in the set $\mathcal{E}_v$.

LEMMA 2.1. *Each $\tau \in \mathcal{T}$ has exactly two edges that belong to $\mathcal{E}_u$.*

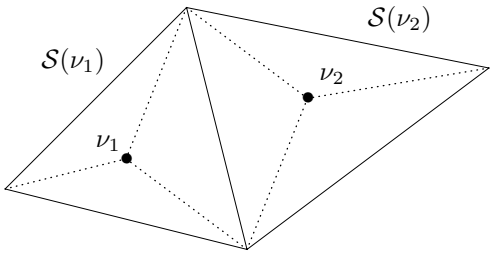

FIG. 2.1. *Triangulation.*

Proof. First of all, τ has at least one interior vertex. We will show that there is exactly one vertex of τ that belongs to $\mathcal{N}_1$. If none of the three vertices of τ belong to $\mathcal{N}_1$, then $\tau^0 \cap \mathcal{S}(\nu)$ is an empty set for all $\nu \in \mathcal{N}_1$, where τ^0 is the interior of τ. Then, $\cup\{\mathcal{S}(\nu) \mid \nu \in \mathcal{N}_1\} \cap \tau^0$ is an empty set. So, $\cup\{\mathcal{S}(\nu) \mid \nu \in \mathcal{N}_1\} \neq \Omega$, which violates assumption (A1). If τ has two vertices, ν_i and ν_j, that belong to $\mathcal{N}_1$, then $\mathcal{S}(\nu_i) \cap \mathcal{S}(\nu_j)$ contains τ. So, it violates assumption (A2). The case that τ has all vertices belonging to $\mathcal{N}_1$ can be discussed in the same way. In conclusion, τ has exactly one vertex which belongs to $\mathcal{N}_1$. So, by the definition of $\mathcal{E}_u$, the two edges having the vertex in $\mathcal{N}_1$ belong to $\mathcal{E}_u$. ∎

Given $\tau \in \mathcal{T}$, we will denote by $\nu(\tau)_1$, $\nu(\tau)_2$, and $\nu(\tau)_3$ the three vertices of τ. Moreover, $\nu(\tau)_1$ is the vertex that is one of the endpoints of the two edges of τ that belong to $\mathcal{E}_u$. Then $\nu(\tau)_2$ and $\nu(\tau)_3$ are named in a counterclockwise direction. In addition, $\lambda_{\tau,1}(x)$, $\lambda_{\tau,2}(x)$, and $\lambda_{\tau,3}(x)$ are the barycentric coordinates on τ with respect to the three vertices $\nu(\tau)_1$, $\nu(\tau)_2$, and $\nu(\tau)_3$.

Now, we will discuss the FE spaces. Let $k \geq 0$ be a nonnegative integer. Let $\tau \in \mathcal{T}$. We define $P^k(\tau)$ as the space of polynomials of degree less than or equal to k on τ. We also define

$$R^k(\tau) = P^k(\tau) \oplus \tilde{P}^{k+1}(\tau), \tag{2.4}$$

where $\tilde{P}^{k+1}(\tau)$ is the space of homogeneous polynomials of degree $k+1$ on τ in the two variables $\lambda_{\tau,2}$ and $\lambda_{\tau,3}$ such that the sum of the coefficients of $\lambda_{\tau,2}^{k+1}$ and $\lambda_{\tau,3}^{k+1}$ is equal to zero. That is, any function in $\tilde{P}^{k+1}(\tau)$ can be written as $\sum_{i+j=k+1, i\geq 0, j\geq 0} a_{i,j}\lambda_{\tau,2}^i\lambda_{\tau,3}^j$ such that $a_{k+1,0} + a_{0,k+1} = 0$. Now, we define

$$U_h = \{\phi \mid \phi|_\tau \in R^k(\tau); \phi \text{ is continuous at the } k+1 \text{ Gaussian points of } \sigma \ \forall \sigma \in \mathcal{E}_u\}.$$

For any edge σ, we use $P^k(\sigma)$ to represent the space of one dimensional polynomials of degree less than or equal to k on σ. We define the following degrees of freedom:

(UD1) For each edge $\sigma \in \mathcal{E}_u$, we have

$$\int_\sigma \phi p_k \, d\sigma$$

for all $p_k \in P^k(\sigma)$.

(UD2) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau \phi p_{k-1} \, dx$$

for all $p_{k-1} \in P^{k-1}(\tau)$ (for $k \geq 1$).

Notice that (UD1) is equivalent to $\phi(\alpha_i)$ where α_i, for $i = 1, 2, \dots, k+1$, are the $k+1$ Gaussian points of σ. For a smooth function ϕ, we will define $\mathcal{I}_u\phi \in U_h$ by the following degrees of freedom:

(U1) For each edge $\sigma \in \mathcal{E}_u$, we have

$$\int_\sigma (\mathcal{I}_u\phi - \phi)p_k = 0$$

for all $p_k \in P^k(\sigma)$.

(U2) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau (\mathcal{I}_u\phi - \phi)p_{k-1}\, dx = 0$$

for all $p_{k-1} \in P^{k-1}(\tau)$ (for $k \geq 1$).

THEOREM 2.2. *Let $\mathcal{I}_u : \Pi_{\nu\in\mathcal{N}_1} W^{k+1,p}(\mathcal{S}(\nu)) \to U_h$. Then $\mathcal{I}_u$ is uniquely determined by* (U1)–(U2)*. Moreover,*

$$|\phi - \mathcal{I}_u\phi|_{W^{m,p}(\mathcal{S}(\nu))} \leq Kh^{k+1-m}|\phi|_{W^{k+1,p}(\mathcal{S}(\nu))}. \tag{2.5}$$

Proof. Notice that $\dim(P^k) = \frac{1}{2}(k+1)(k+2)$. Then (UD1) gives $(k+1)|\mathcal{E}_u|$ conditions while (UD2) gives $\frac{1}{2}k(k+1)|\mathcal{T}|$ conditions where $|\mathcal{S}|$ is the number of elements in the set $\mathcal{S}$. Notice that $|\mathcal{S}(\nu)| = |\mathcal{E}_u(\nu)|$ for all $\nu \in \mathcal{N}_1$. So, by the assumption (A1)–(A2) and the definition of $\mathcal{E}_u$, we have $|\mathcal{T}| = \sum_{\nu\in\mathcal{N}_1} |\mathcal{S}(\nu)| = \sum_{\nu\in\mathcal{N}_1} |\mathcal{E}_u(\nu)| = |\mathcal{E}_u|$. So, the total number of degrees of freedom defined by (UD1)–(UD2) is $\frac{1}{2}(k+1)(k+2)|\mathcal{T}|$. Next, we will find the $\dim(U_h)$. Notice that $\dim(\tilde{P}^{k+1}(\tau)) = k+1$. So, we have $\dim(U_h) = \frac{1}{2}(k+1)(k+2)|\mathcal{T}| + (k+1)|\mathcal{T}| - (k+1)|\mathcal{E}_u|$, where the subtraction of the third term is due to the continuity condition imposed on the $k+1$ Gaussian points of each edge in $\mathcal{E}_u$. Since $|\mathcal{T}| = |\mathcal{E}_u|$, we have $\dim(U_h) = \frac{1}{2}(k+1)(k+2)|\mathcal{T}|$, which is equal to the number of degrees of freedom defined by (UD1)–(UD2).

Next, we will show $\mathcal{I}_u\phi = 0$ if $\phi = 0$. Let $\tau \in \mathcal{T}$. Then the degree of freedom (UD1) implies that $\mathcal{I}_u\phi$ is zero at the $k+1$ Gaussian points of the two edges of τ that belong to $\mathcal{E}_u$. More precisely, we denote by α_j $(j = 1, 2, \dots, k+1)$ the $k+1$ Gaussian points of the edge of τ having endpoints $\nu(\tau)_1$ and $\nu(\tau)_2$. Then we define real numbers w_j $(j = 1, 2, \dots, k+1)$ such that $0 < w_1 < w_2 < \cdots < w_{k+1} < 1$ and $\alpha_j = (1-w_j)\nu(\tau)_1 + w_j\nu(\tau)_2$. Moreover, we denote by β_j $(j = 1, 2, \dots, k+1)$ the $k+1$ Gaussian points of the edge of τ having endpoints $\nu(\tau)_1$ and $\nu(\tau)_3$. Then the real numbers w_j also satisfy $\beta_j = (1-w_j)\nu(\tau)_1 + w_j\nu(\tau)_3$. So, we have

$$\mathcal{I}_u\phi = c\Pi_{j=1}^{k+1}(\lambda_{\tau,2} - w_j) + c\Pi_{j=1}^{k+1}(\lambda_{\tau,3} - w_j) - c(-1)^{k+1}\Pi_{j=1}^{k+1}w_j + \lambda_{\tau,2}\lambda_{\tau,3}q_{k-1}$$

for some $q_{k-1} \in P^{k-1}(\tau)$. By the definition of $R^k(\tau)$, the sum of the coefficients of $\lambda_{\tau,2}^{k+1}$ and $\lambda_{\tau,3}^{k+1}$ is zero. So, we have $c = 0$. Using (UD2), we have $\int_\tau \lambda_{\tau,2}\lambda_{\tau,3}q_{k-1}^2\, dx = 0$. Since $\lambda_{\tau,2}\lambda_{\tau,3} > 0$ in the interior of τ, we have $q_{k-1} = 0$. Hence, $\mathcal{I}_u\phi = 0$.

Now, we will prove (2.5). Let $\tau \in \mathcal{T}$ and let $p_k \in P^k(\tau)$. It suffices to show that $\mathcal{I}_u$ preserves polynomials. By (U1), $\mathcal{I}_u p_k - p_k$ is zero at the $k+1$ Gaussian points of the two edges that belong to $\mathcal{E}_u$. So,

$$\begin{aligned}\mathcal{I}_u p_k - p_k = {} & b\Pi_{j=1}^{k+1}(\lambda_{\tau,2} - w_j) + b\Pi_{j=1}^{k+1}(\lambda_{\tau,3} - w_j) \\ & -b(-1)^{k+1}\Pi_{j=1}^{k+1}w_j + \lambda_{\tau,2}\lambda_{\tau,3}r_{k-1}\end{aligned}$$

for some constant d and $r_{k-1} \in P^{k-1}(\tau)$. Since $\mathcal{I}_u p_k \in R^k(\tau)$, we have $b = 0$. Using (U2), we have $r_{k-1} = 0$. Hence, $\mathcal{I}_u p_k = p_k$. ∎

We define

$$V_h = \{\psi \mid \psi|_\tau \in P^k(\tau)^2; L\psi \text{ is continuous along } \sigma \forall \sigma \in \mathcal{E}_v; L\psi = 0 \text{ on } \partial\Omega\}.$$

We also define the following degrees of freedom:

(VD1) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau (L^\perp \psi) p_k \, dx \quad \forall p_k \in P^k(\tau).$$

(VD2) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau (L\psi) \lambda_{\tau,1} p_{k-1} \, dx \quad \forall p_{k-1} \in P^{k-1}(\tau).$$

(VD3) For each edge $\sigma \in \mathcal{E}_v^0$, we have

$$\int_\sigma (L\psi) q_k \, d\sigma \quad \forall q_k \in P^k(\sigma).$$

Furthermore, for a smooth vector field ψ, we define $\mathcal{I}_v \psi$ as the corresponding interpolation operator by the following degrees of freedom:

(V1) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau L^\perp (\mathcal{I}_v \psi - \psi) p_k \, dx = 0 \quad \forall p_k \in P^k(\tau).$$

(V2) For each triangle $\tau \in \mathcal{T}$, we have

$$\int_\tau L(\mathcal{I}_v \psi - \psi) \lambda_{\tau,1} p_{k-1} \, dx = 0 \quad \forall p_{k-1} \in P^{k-1}(\tau).$$

(V3) For each edge $\sigma \in \mathcal{E}_v^0$, we have

$$\int_\sigma L(\mathcal{I}_v \psi - \psi) q_k \, d\sigma = 0 \quad \forall q_k \in P^k(\sigma).$$

THEOREM 2.3. *Let $\mathcal{I}_v : \Pi_{\sigma \in \mathcal{E}_v^0} W^{k+1,p}(\mathcal{R}(\sigma))^2 \to V_h$. Then $\mathcal{I}_v$ is uniquely determined by* (V1), (V2), *and* (V3). *Moreover,*

$$|\psi - \mathcal{I}_v \psi|_{W^{m,p}(\mathcal{R}(\sigma))^2} \le K h^{k+1-m} |\psi|_{W^{k+1,p}(\mathcal{R}(\sigma))^2}. \tag{2.6}$$

Proof. First of all, the number of degrees of freedom defined by (VD1), (VD2), and (VD3) are $\frac{1}{2}(k+1)(k+2)|\mathcal{T}|$, $\frac{1}{2}k(k+1)|\mathcal{T}|$, and $(k+1)|\mathcal{E}_v^0|$, respectively. Also, the dimension of V_h is given by

$$\dim(V_h) = 2\frac{1}{2}(k+1)(k+2)|\mathcal{T}| - (k+1)|\mathcal{E}_v^0| - (k+1)|\mathcal{E}_v \backslash \mathcal{E}_v^0|,$$

where the second term on the right-hand side is due to the continuity condition that $L\psi$ is continuous on σ for all $\sigma \in \mathcal{E}_v^0$, and the third term on the right-hand side is due to the boundary condition $L\psi = 0$ on $\partial\Omega$. Notice that $|\mathcal{T}| = 2|\mathcal{E}_v^0| + |\mathcal{E}_v \backslash \mathcal{E}_v^0|$.

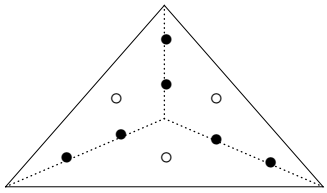

FIG. 2.2. $\mathcal{S}(\nu)$ *for* $k = 1$.

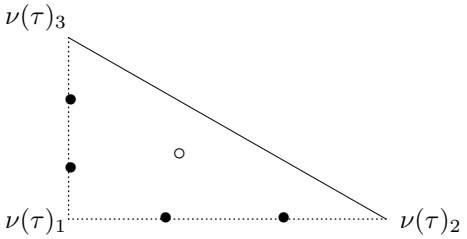

FIG. 2.3. *A single triangle for* $k = 1$.

Now, a direct calculation shows that $\dim(V_h)$ is equal to the total number of degrees of freedom defined by (VD1), (VD2), and (VD3).

Now, we will show $\mathcal{I}_v\psi = 0$ if $\psi = 0$. First, (VD1) implies that $L^\perp(\mathcal{I}_v\psi) = 0$ on each $\tau \in \mathcal{T}$. Using (VD3), we have $L(\mathcal{I}_v\psi) = 0$ on each $\sigma \in \mathcal{E}_v^0$. So, on each $\tau \in \mathcal{T}$, we have $L(\mathcal{I}_v\psi) = \lambda_{\tau,1}q_{k-1}$ for some $q_{k-1} \in P^{k-1}(\tau)$. Indeed, we can write

$$L(\mathcal{I}_v\psi) = a + \sum_{j=1}^{k}(b_j\lambda_{\tau,1}^j + c_j\lambda_{\tau,2}^j).$$

Since $L(\mathcal{I}_v\psi)|_\sigma = 0$, we have $a = 0$, $c_j = 0$, and $L(\mathcal{I}_v\psi) = \sum_{j=1}^{k} b_j\lambda_{\tau,1}^j$. Applying (VD2), we have $L(\mathcal{I}_v\psi) = 0$ on each $\tau \in \mathcal{T}$. Since $|\mathcal{I}_v\psi|^2 = |L^\perp(\mathcal{I}_v\psi)|^2 + |L(\mathcal{I}_v\psi)|^2$, we have $\mathcal{I}_v\psi = 0$.

The estimate (2.6) follows from the fact that the operator $\mathcal{I}_v$ preserves polynomials of degree k. ∎

Let us consider an example for $k = 1$. For U_h, the degrees of freedom are the two Gaussian points on each edge belonging to $\mathcal{E}_u$ and the cell center. In Figure 2.2, we illustrate three triangles in the triangulation which corresponds to an $\mathcal{S}(\nu)$ for some $\nu \in \mathcal{N}_1$. The dotted lines denote edges from the set $\mathcal{E}_u$ while solid lines denote edges from the set $\mathcal{E}_v$. The solid dots denote the continuity points defined by (UD1), which are the two Gaussian points of the edges in $\mathcal{E}_u$. The circle in each triangle represents the degree of freedom defined by (UD2). In Figure 2.3, we show the degrees of freedom on a single triangle. Any function $\phi \in R^k(\tau)$ can be expressed as

$$\phi = a + b\lambda_{\tau,2} + c\lambda_{\tau,3} + d(\lambda_{\tau,2}^2 - \lambda_{\tau,3}^2) + e\lambda_{\tau,2}\lambda_{\tau,3}.$$

For V_h, $L\psi$ is defined as a linear function which is continuous on the edge σ while $L^\perp$ is defined as a linear function on each triangle with no continuity requirement. In Figure 2.4, we illustrate an $\mathcal{R}(\sigma)$ for some $\sigma \in \mathcal{E}_v^0$, where σ is represented by the solid line. We represent the degrees of freedom of $L\psi$ by solid dots and the degrees of freedom of $L^\perp\psi$ by circles.

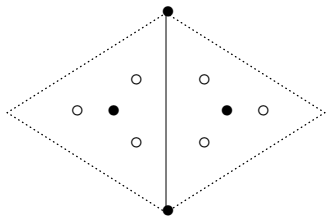

FIG. 2.4. $\mathcal{R}(\sigma)$ *for* $k = 1$.

3. The new scheme. In this section, we will derive the new discontinuous Galerkin method for the wave propagation problem (1.1)–(1.2). Multiplying both sides of (1.1) by ϕ, integrating the resulting equation on $\mathcal{S}(\nu)$, and using (1.3) yields

$$a_1 \int_{\mathcal{S}(\nu)} \frac{\partial u}{\partial t}\phi \, dx + \int_{\mathcal{S}(\nu)} (B^*\phi)v \, dx - \int_{\partial\mathcal{S}(\nu)} (Lv)\phi \, d\sigma = \int_{\mathcal{S}(\nu)} F_1\phi \, dx.$$

Summing over all $\nu \in \mathcal{N}_1$,

$$a_1 \int_{\Omega} \frac{\partial u}{\partial t}\phi \, dx + \int_{\Omega} (B^*\phi)v \, dx - \sum_{\nu\in\mathcal{N}_1} \int_{\partial\mathcal{S}(\nu)} (Lv)\phi \, d\sigma = \int_{\Omega} F_1\phi \, dx.$$

If Lv is continuous along each $\sigma \in \mathcal{E}_v^0$ and Lv is zero along each edge in $\mathcal{E}_v \backslash \mathcal{E}_v^0$, then

$$\sum_{\nu\in\mathcal{N}_1} \int_{\partial\mathcal{S}(\nu)} (Lv)\phi \, d\sigma = \sum_{\sigma\in\mathcal{E}_v^0} \int_{\sigma} (Lv)[\phi] \, d\sigma, \tag{3.1}$$

where $[\phi] = \phi^+ - \phi^-$ is the jump of ϕ along σ. Similarly, multiplying both sides of (1.2) by ψ, integrating the resulting equation on $\mathcal{R}(\sigma)$, and using (1.3) yields

$$a_2 \int_{\mathcal{R}(\sigma)} \frac{\partial v}{\partial t}\psi \, dx - \int_{\mathcal{R}(\sigma)} (B\psi)u \, dx - \int_{\partial\mathcal{R}(\sigma)} (L\psi)u \, d\sigma = \int_{\mathcal{R}(\sigma)} F_2\psi \, dx.$$

Summing for all $\sigma \in \mathcal{E}_v$,

$$a_2 \int_{\Omega} \frac{\partial v}{\partial t}\psi \, dx - \int_{\Omega} (B\psi)u \, dx - \sum_{\sigma\in\mathcal{E}_v} \int_{\partial\mathcal{R}(\sigma)} (L\psi)u \, d\sigma = \int_{\Omega} F_2\psi \, dx.$$

Now if $L\psi$ is a polynomial of degree k and u is a $(k+1)$th degree polynomial which is continuous at the $k+1$ Gaussian points of $\sigma \in \mathcal{E}_u$, then

$$\sum_{\sigma\in\mathcal{E}_v} \int_{\partial\mathcal{R}(\sigma)} (L\psi)u \, d\sigma = \sum_{\sigma\in\mathcal{E}_u} \int_{\sigma} [L\psi]u \, d\sigma, \tag{3.2}$$

where $[L\psi]$ denotes the jump of $L\psi$ along σ. Then, the new discontinuous Galerkin method is defined as follows.

The new discontinuous Galerkin method: Find $u_h \in U_h$ and $v_h \in V_h$ such that

$$a_1 \int_{\Omega} \frac{\partial u_h}{\partial t}\phi \, dx + B_h(v_h, \phi) = \int_{\Omega} F_1\phi \, dx, \tag{3.3}$$

$$a_2 \int_{\Omega} \frac{\partial v_h}{\partial t}\psi \, dx - B_h^*(u_h, \psi) = \int_{\Omega} F_2\psi \, dx \tag{3.4}$$

for all $\phi \in U_h$ and $\psi \in V_h$, where

$$B_h(v_h, \phi) = \int_\Omega (B^*\phi)v_h \, dx - \sum_{\sigma \in \mathcal{E}_v^0} \int_\sigma (Lv_h)[\phi] \, d\sigma, \tag{3.5}$$

$$B_h^*(u_h, \psi) = \int_\Omega (B\psi)u_h \, dx + \sum_{\sigma \in \mathcal{E}_u} \int_\sigma [L\psi]u_h \, d\sigma. \tag{3.6}$$

The initial conditions $u_h(0)$ and $v_h(0)$ will be defined as $u_h(0) = \mathcal{I}_u u_0$ and $v_h(0) = \mathcal{I}_v v_0$. We remark here that we define the spaces U_h and V_h so that (3.1) and (3.2) are valid. Furthermore, we define the discrete derivative operators B_h and B_h^* by

$$\langle B_h\psi, \phi\rangle = B_h(\psi, \phi) \quad \forall \phi \in U_h,$$
$$\langle B_h^*\phi, \psi\rangle = B_h^*(\phi, \psi) \quad \forall \psi \in V_h.$$

The two operators B_h and B_h^* are the discrete analogue of the two derivative operators B and B^*.

LEMMA 3.1. *For all $\phi \in U_h$ and $\psi \in V_h$, we have*

$$B_h(\psi, \phi) = B_h^*(\phi, \psi). \tag{3.7}$$

Proof. Let $\phi \in U_h$ and $\psi \in V_h$. Then, by the definition of B_h and (3.1),

$$\begin{aligned} B_h(\psi, \phi) &= \int_\Omega (B^*\phi)v_h \, dx - \sum_{\sigma \in \mathcal{E}_v^0} \int_\sigma (Lv_h)[\phi] \, d\sigma \\ &= \int_\Omega (B^*\phi)\psi \, dx - \sum_{\nu \in \mathcal{N}_1} \int_{\partial \mathcal{S}(\nu)} (L\psi)\phi \, d\sigma \\ &= \sum_{\nu \in \mathcal{N}_1} \left\{ \int_{\mathcal{S}(\nu)} (B^*\phi)\psi \, dx - \int_{\partial \mathcal{S}(\nu)} (L\psi)\phi \, d\sigma \right\}. \end{aligned}$$

Using integration by parts on each triangle,

$$B_h(\psi, \phi) = \sum_{\nu \in \mathcal{N}_1} \left\{ \int_{\mathcal{S}(\nu)} \phi(B\psi) \, dx + \sum_{\sigma \in \mathcal{E}_u(\nu)} \int_\sigma [L\psi]u \, d\sigma \right\} = B_h^*(\phi, \psi).$$

This completes the proof. ∎

We define the discrete L^2 norms and H^1 norms in the following ways. For all $\phi \in U_h$, we define

$$\|\phi\|_W^2 = \int_\Omega \phi^2 \, dx + \sum_{\sigma \in \mathcal{E}_u} (h_\sigma)^2 \sum_{j=1}^{k+1} \phi(\alpha_j)^2, \tag{3.8}$$

$$\|\phi\|_Z^2 = \int_\Omega (B^*\phi)^2 \, dx + \sum_{\sigma \in \mathcal{E}_v} h_\sigma^{-1} \int_\sigma [\phi]^2 \, d\sigma. \tag{3.9}$$

For all $\psi \in V_h$, we define

$$\|\psi\|_{W'}^2 = \int_\Omega \psi^2 \, dx + \sum_{\sigma \in \mathcal{E}_v} h_\sigma \int_\sigma (L\psi)^2 \, d\sigma, \tag{3.10}$$

$$\|\psi\|_{Z'}^2 = \int_\Omega (B\psi)^2 \, dx + \sum_{\sigma \in \mathcal{E}_u} (h_\sigma)^{-1} \int_\sigma [L\psi]^2 \, d\sigma. \tag{3.11}$$

With these definitions, we have the following continuity conditions for all $\phi \in U_h$ and $\psi \in V_h$:

$$|B_h(\psi,\phi)| \le K\|\psi\|_{W'}\|\phi\|_Z, \tag{3.12}$$

$$|B_h(\psi,\phi)| \le K\|\psi\|_{Z'}\|\phi\|_W. \tag{3.13}$$

Moreover, we have, in U_h, the norm $\|\phi\|_W$ is equivalent to the standard L^2 norm $\|\phi\|$, while in V_h, the norm $\|\psi\|_{W'}$ is equivalent to the standard L^2 norm $\|\psi\|$. That is, there are two uniform constants K_1 and K_2 such that

$$K_1\|\phi\| \le \|\phi\|_W \le K_2\|\phi\| \quad \forall \phi \in U_h, \tag{3.14}$$

$$K_1\|\psi\| \le \|\psi\|_{W'} \le K_2\|\psi\| \quad \forall \psi \in V_h. \tag{3.15}$$

Now, we will prove the following interpolation error estimates. The first one is the interpolation error in the discrete L^2 norms.

LEMMA 3.2. *Assume $(u,v) \in W^{k+1,\infty}(\Omega)^3$. Then for any integer m with $1 \le m \le k+1$,*

$$\|u - \mathcal{I}_u u\|_W \le Kh^m |u|_{W^{m,\infty}(\Omega)}, \quad \|v - \mathcal{I}_v v\|_{W'} \le Kh^m |v|_{W^{m,\infty}(\Omega)^2}. \tag{3.16}$$

Proof. By the definition of W-norm and W'-norm,

$$\|u - \mathcal{I}_u u\|_W \le K\|u - \mathcal{I}_u u\|_{L^\infty(\Omega)}, \quad \|v - \mathcal{I}_v v\|_{W'} \le K\|v - \mathcal{I}_v v\|_{L^\infty(\Omega)^2}.$$

The proof is complete by using (2.5) and (2.6). ∎

The second one is the interpolation error in the discrete H^1 norms.

LEMMA 3.3. *Assume $(u,v) \in H^{k+1}(\Omega)^3$. Then for any integer m with $1 \le m \le k$,*

$$\|u - \mathcal{I}_u u\|_Z \le Kh^m |u|_{H^{m+1}(\Omega)}, \quad \|v - \mathcal{I}_v v\|_{Z'} \le Kh^m |v|_{H^{m+1}(\Omega)^2}. \tag{3.17}$$

Proof. Let $\mathcal{I}_u u \in U_h$ be the interpolant of u. By the definition of Z-norm,

$$\|\mathcal{I}_u u - u\|_Z^2 = \int_\Omega (B^*(\mathcal{I}_u u - u))^2 \, dx + \sum_{\sigma \in \mathcal{E}_v^0} (h_\sigma)^{-1} \int_\sigma [\mathcal{I}_u u - u]^2 \, d\sigma.$$

The first term will be estimated by using the inverse inequality and the interpolation estimate (2.5)

$$\int_\Omega (B^*(\mathcal{I}_u u - u))^2 \, dx \le Kh^{2k} |u|^2_{H^{k+1}(\Omega)}.$$

For the second term, we will use the trace inequality

$$\int_\sigma (\mathcal{I}_u u - u)^2 \, d\sigma \le K(\|\mathcal{I}_u u - u\|_{L^2(\mathcal{R}(\tau))} \|\nabla(\mathcal{I}_u u - u)\|_{L^2(\mathcal{R}(\tau))} + h^{-1}\|\mathcal{I}_u u - u\|^2_{L^2(\mathcal{R}(\tau))}).$$

So,

$$\int_\sigma [\mathcal{I}_u u - u]^2 \, d\sigma \le Kh^{2k+1} |u|^2_{H^{k+1}(\Omega)},$$

and this implies

$$\|\mathcal{I}_u u - u\|_Z \le Kh^k |u|_{H^{k+1}(\Omega)}.$$

The estimate for $\|v - \mathcal{I}_v v\|_{Z'}$ can be proved by a similar argument. ∎

4. Stability and convergence analysis. In this section, we will prove the stability and convergence of the scheme (3.3)–(3.4). We write $\langle u, v\rangle = \int_\Omega uv\, dx$ and $\|u\| = \langle u, u\rangle^{\frac{1}{2}}$. In order to obtain an optimal error estimate, we will assume the following.

The inf-sup conditions:

$$\inf_{\psi\in V_h}\sup_{\phi\in U_h}\frac{B_h(\psi,\phi)}{\|\psi\|_{Z'}\|\phi\|_W}\geq K, \tag{4.1}$$

$$\inf_{\phi\in U_h}\sup_{\psi\in V_h}\frac{B_h^*(\phi,\psi)}{\|\phi\|_Z\|\psi\|_{W'}}\geq K. \tag{4.2}$$

For a general introduction to this topic; see Brezzi and Fortin [2].

Consequently, we have

$$\|B_h\psi\|_W \geq K\|\psi\|_{Z'}, \tag{4.3}$$

$$\|B_h^*\phi\|_{W'} \geq K\|\phi\|_Z. \tag{4.4}$$

By the continuity conditions (3.12) and (3.13), we have

$$K_1\|\psi\|_{Z'} \leq \|B_h\psi\|_W \leq K_2\|\psi\|_{Z'}, \tag{4.5}$$

$$K_1\|\phi\|_Z \leq \|B_h^*\phi\|_{W'} \leq K_2\|\phi\|_Z. \tag{4.6}$$

So, the discrete H^1 norm is equivalent to the discrete L^2 norm of the discrete derivative operator. Notice that, the above two inf-sup conditions (4.3)–(4.4) imply the existence of projection operators $\mathcal{P}_v$ and $\mathcal{P}_u$ such that

$$B_h(\mathcal{P}_v v - v, \phi) = 0 \quad \forall\phi\in U_h, \tag{4.7}$$

$$B_h^*(\mathcal{P}_u u - u, \psi) = 0 \quad \forall\psi\in V_h. \tag{4.8}$$

Regarding the initial condition $u_h(0)$ and $v_h(0)$, we can obtain them by solving the following:

$$B_h(\mathcal{P}_v v_0 - v_0, \phi) = 0 \quad \forall\phi\in U_h, \tag{4.9}$$

$$B_h^*(\mathcal{P}_u u_0 - u_0, \psi) = 0 \quad \forall\psi\in V_h; \tag{4.10}$$

then set $u_h(0) = \mathcal{P}_u u_0$ and $v_h(0) = \mathcal{P}_v v_0$. However, in order to retain the accuracy of the approximation, the initial conditions can also be defined as $u_h(0) = \mathcal{I}_u u_0$ and $v_h(0) = \mathcal{I}_v v_0$, where $\mathcal{I}_u$ and $\mathcal{I}_v$ are some interpolation operators with the same order of accuracy and stability estimates $\|u_h(0)\| \leq K\|u_0\|$ and $\|v_h(0)\| \leq K\|v_0\|$.

One important property of the numerical approximation (3.3)–(3.4) is that energy is conserved, as is the case for the continuous problem (1.1)–(1.2). In particular, the method (3.3)–(3.4) is stable in the discrete L^2 norm. Moreover, the convergence in the L^2 norm is optimal. We state these results in the following theorem.

THEOREM 4.1. *Let $u \in U$ and $v \in V$ be the solution to* (1.1)–(1.2) *and let $u_h \in U_h$ and $v_h \in V_h$ be the solution to the numerical scheme* (3.3)–(3.4). *Then, energy is conserved, namely*

$$\frac{d}{dt}(\|u_h\|^2 + \|v_h\|^2) = 0. \tag{4.11}$$

Moreover, for $0 \le t \le T$, *we have*

$$\begin{aligned}
&\|(u-u_h)(t)\| + \|(v-v_h)(t)\| \\
&\quad \le K\Big\{ \inf_{\phi\in U_h} \|u-\phi\|_W + \inf_{\psi\in V_h} \|v-\psi\|_{W'} \\
&\qquad + \int_0^t \Big(\inf_{\phi\in U_h} \|u_t-\phi\|_W + \inf_{\psi\in V_h} \|v_t-\psi\|_{W'} \Big)\, ds \Big\}.
\end{aligned} \tag{4.12}$$

Proof. Taking $\phi = u_h$ and $\psi = v_h$ in (3.3)–(3.4) yields

$$a_1\left\langle \frac{du_h}{dt}, u_h \right\rangle + B_h(v_h, u_h) = 0,$$
$$a_2\left\langle \frac{dv_h}{dt}, v_h \right\rangle - B_h^*(u_h, v_h) = 0.$$

Adding the two equations and using (3.7), we obtain (4.11).

In the following, we will prove (4.12). Let $\mathcal{I}_u u$ and $\mathcal{I}_v v$ be arbitrary elements in U_h and V_h, respectively. First, we have

$$a_1\left\langle \frac{d(u-u_h)}{dt}, \phi \right\rangle + B_h(v-v_h, \phi) = 0 \quad \forall \phi \in U_h, \tag{4.13}$$

$$a_2\left\langle \frac{d(v-v_h)}{dt}, \psi \right\rangle - B_h^*(u-u_h, \psi) = 0 \quad \forall \psi \in V_h. \tag{4.14}$$

By the definitions of the projection operators $\mathcal{P}_u$ and $\mathcal{P}_v$, we obtain

$$a_1\left\langle \frac{d(u-u_h)}{dt}, \phi \right\rangle + B_h(\mathcal{P}_v v - v_h, \phi) = 0 \quad \forall \phi \in U_h, \tag{4.15}$$

$$a_2\left\langle \frac{d(v-v_h)}{dt}, \psi \right\rangle - B_h^*(\mathcal{P}_u u - u_h, \psi) = 0 \quad \forall \psi \in V_h. \tag{4.16}$$

Let $Q_u^2 : U_h \to \ker(B_h^*)^\perp$ and $Q_v^2 : V_h \to \ker(B_h)^\perp$ be the projection operators. Taking $\phi = Q_u^2(\mathcal{P}_u u - u_h)$ and $\psi = Q_v^2(\mathcal{P}_v v - v_h)$, we have, by adding the two equations,

$$a_1\left\langle \frac{d(u-u_h)}{dt}, Q_u^2(\mathcal{P}_u u - u_h) \right\rangle + a_2\left\langle \frac{d(v-v_h)}{dt}, Q_v^2(\mathcal{P}_v v - v_h) \right\rangle = 0, \tag{4.17}$$

which implies

$$\begin{aligned}
&\frac{d}{dt}(a_1\|Q_u^2(\mathcal{P}_u u - u_h)\|^2 + a_2\|Q_v^2(\mathcal{P}_v v - v_h)\|^2) \\
&\quad = a_1\left\langle \frac{d(\mathcal{P}_u u - u)}{dt}, Q_u^2(\mathcal{P}_u u - u_h) \right\rangle + a_2\left\langle \frac{d(\mathcal{P}_v v - v)}{dt}, Q_v^2(\mathcal{P}_v v - v_h) \right\rangle.
\end{aligned}$$

This can be rewritten as

$$\begin{aligned}
&\frac{d}{dt}(a_1\|Q_u^2(\mathcal{P}_u u - u_h)\|^2 + a_2\|Q_v^2(\mathcal{P}_v v - v_h)\|^2) \\
&\quad = a_1\left\langle \frac{d(\mathcal{P}_u u - \mathcal{I}_u u)}{dt}, Q_u^2(\mathcal{P}_u u - u_h) \right\rangle + a_2\left\langle \frac{d(\mathcal{P}_v v - \mathcal{I}_v v)}{dt}, Q_v^2(\mathcal{P}_v v - v_h) \right\rangle \\
&\qquad + a_1\left\langle \frac{d(\mathcal{I}_u u - u)}{dt}, Q_u^2(\mathcal{P}_u u - u_h) \right\rangle + a_2\left\langle \frac{d(\mathcal{I}_v v - v)}{dt}, Q_v^2(\mathcal{P}_v v - v_h) \right\rangle.
\end{aligned}$$

Consequently,

$$\begin{aligned}
&\|a_1 Q_u^2(\mathcal{P}_u u - u_h)\| + \|a_2 Q_v^2(\mathcal{P}_v v - v_h)\| \\
&\quad \leq K \int_0^t \left\{ \|Q_u^2(\mathcal{P}_u u_t - \mathcal{I}_u u_t)\| + \|Q_v^2(\mathcal{P}_v v_t - \mathcal{P}_v v_t)\| \right\} ds \\
&\qquad + K \int_0^t \left\{ \|\mathcal{I}_u u_t - u_t\| + \|\mathcal{I}_v v_t - v_t\| \right\} ds.
\end{aligned}$$

Using the triangle inequality, we finally have

$$\begin{aligned}
&\|a_1 Q_u^2(\mathcal{I}_u u - u_h)\| + \|a_2 Q_v^2(\mathcal{I}_v v - v_h)\| \\
&\quad \leq K(\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\| + \|Q_v^2(\mathcal{P}_v v - \mathcal{I}_v v)\|) \\
&\qquad + K \int_0^t \left\{ \|Q_u^2(\mathcal{P}_u u_t - \mathcal{I}_u u_t)\| + \|Q_v^2(\mathcal{P}_v v_t - \mathcal{P}_v v_t)\| \right\} ds \\
&\qquad + K \int_0^t \left\{ \|\mathcal{I}_u u_t - u_t\| + \|\mathcal{I}_v v_t - v_t\| \right\} ds.
\end{aligned}$$

It suffices to estimate the norms $\|Q_v^2(\mathcal{P}_v v - \mathcal{I}_v v)\|$ and $\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\|$. In particular, we will prove $\|Q_v^2(\mathcal{P}_v v - \mathcal{I}_v v)\| \leq K\|v - \mathcal{I}_v v\|_{W'}$ and $\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\| \leq K\|u - \mathcal{I}_u u\|_W$.

We consider the following variational problem: Given $u_2 \in \ker(B_h^*)^\perp$, find $\tilde{\psi} \in V_h$ such that

$$B_h(\tilde{\psi}, \phi) = \langle u_2, \phi \rangle \quad \forall \phi \in U_h. \tag{4.18}$$

The existence of $\tilde{\psi}$ is ensured by the fact that $B_h : V_h \to \ker(B_h^*)^\perp$ is surjective. Taking the supremum in ϕ and using (4.3), we derive the following estimate:

$$\|\tilde{\psi}\|_{Z'} \leq K\|u_2\|. \tag{4.19}$$

Now, we have

$$\begin{aligned}
\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\|^2 &= B_h(\tilde{\psi}, Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)) \\
&= B_h^*(Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u), \tilde{\psi}) \\
&= B_h^*(\mathcal{P}_u u - \mathcal{I}_u u, \tilde{\psi}) \\
&= B_h^*(u - \mathcal{I}_u u, \tilde{\psi}) \\
&\leq \|\psi\|_{Z'} \|u - \mathcal{I}_u u\|_W \\
&\leq K\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\| \|u - \mathcal{I}_u u\|_W.
\end{aligned}$$

Hence, we have

$$\|Q_u^2(\mathcal{P}_u u - \mathcal{I}_u u)\| \leq \|u - \mathcal{I}_u u\|_W. \tag{4.20}$$

Replacing u by u_t, we have

$$\|Q_u^2(\mathcal{P}_u u_t - \mathcal{I}_u u_t)\| \leq \|u_t - \mathcal{I}_u u_t\|_W. \tag{4.21}$$

Similarly, we consider the problem: Given $v_2 \in \ker(B_h)^\perp$, find $\tilde{\phi} \in U_h$ such that

$$B_h^*(\tilde{\phi}, \psi) = \langle v_2, \psi \rangle \quad \forall \psi \in V_h \tag{4.22}$$

with the estimate

$$\|\tilde{\phi}\|_Z \le K\|v_2\|. \tag{4.23}$$

Hence, we have

$$\|Q_v^2(\mathcal{P}_v v - \mathcal{I}_v v)\| \le \|v - \mathcal{I}_v v\|_{W'}. \tag{4.24}$$

Replacing v by v_t, we have

$$\|Q_v^2(\mathcal{P}_v v_t - \mathcal{I}_v v_t)\| \le \|v_t - \mathcal{I}_v v_t\|_{W'}. \tag{4.25}$$

This finishes the proof of estimates of the components of the errors in $\ker(B_h^*)^\perp$ and $\ker(B_h)^\perp$. In the following, we will estimate the components of errors in $\ker(B_h^*)$ and $\ker(B_h)$.

Define $Q_u^1 : U_h \to \ker(B_h^*)$ and $Q_v^1 : V_h \to \ker(B_h)$ as the orthogonal projection operators. Taking $\phi = Q_u^1(\mathcal{I}_u u - u_h)$ and $\psi = Q_v^1(\mathcal{I}_v v - v_h)$, we have

$$a_1\left\langle \frac{d(u-u_h)}{dt}, Q_u^1(\mathcal{I}_u u - u_h)\right\rangle + a_2\left\langle \frac{d(v-v_h)}{dt}, Q_v^1(\mathcal{I}_v v - v_h)\right\rangle = 0.$$

Hence, we obtain

$$\|a_1 Q_u^1(\mathcal{I}_u u - u_h)\| + \|a_2 Q_v^1(\mathcal{I}_v v - v_h)\| \le \int_0^t \Big\{\|\mathcal{I}_u u_t - u_t\| + \|\mathcal{I}_v v_t - v_t\|\Big\}\, ds.$$

Combining all results,

$$\begin{aligned}\|\mathcal{I}_u u - u_h\|_u + \|\mathcal{I}_v v - v_h\|_v \le K\Big\{&\|Q_u^1(\mathcal{I}_u u - u_h)\|_u + \|Q_u^2(\mathcal{I}_u u - u_h)\|_u \\ &+ \|Q_v^1(\mathcal{I}_v v - v_h)\|_v + \|Q_v^2(\mathcal{I}_v v - v_h)\|_v\Big\}.\end{aligned}$$

The proof is complete by noticing that

$$\begin{aligned}\|u - u_h\| &\le \|u - \mathcal{I}_u u\| + \|\mathcal{I}_u u - u_h\|,\\ \|v - v_h\| &\le \|v - \mathcal{I}_v v\| + \|\mathcal{I}_v v - v_h\|. \qquad \square\end{aligned}$$

Now, we will state the convergence theorems. The following is the convergence in L^2 norm. We see that the numerical scheme is $O(h^{k+1})$ when the FE spaces U_h and V_h contain polynomials of degree k.

COROLLARY 4.2. *Let $(u, v) \in W^{1,1}(0, T; W^{k+1,\infty}(\Omega))^3$ be the exact solution to the wave propagation problem* (1.1)–(1.2) *and let (u_h, v_h) be the solution to* (3.3)–(3.4). *Then*

$$\|u - u_h\| + \|v - v_h\| \le Kh^{k+1}(\|u\|_{W^{1,1}(0,T;W^{k+1,\infty}(\Omega))} + \|v\|_{W^{1,1}(0,T;W^{k+1,\infty}(\Omega))^2}). \tag{4.26}$$

Theorem 4.1 and Corollary 4.2 state that the numerical scheme (3.3)–(3.4) is stable and convergent, with optimal rate, with respect to the discrete L^2-norms. The L^2 stability can be satisfied by a very large class of spaces U_h and V_h. However, with L^2 stability only, it is not sufficient to deduce the weak convergence to the true solution;

see Joly [11]. As a result, the numerical solution may behave badly and the optimal rate of convergence is not achieved. This fact can be seen by some numerical examples in the following sections. The extra conditions needed are the inf-sup conditions (4.1)–(4.2), as many mixed FE methods require some compatibility conditions between the two spaces U_h and V_h. These conditions yield a stability in the discrete H^1 norm and we state this result in the following theorem.

THEOREM 4.3. *Let $u_h \in U_h$ and $v_h \in V_h$ be the solution to the numerical scheme* (3.3)–(3.4). *Then*

$$\|u_h\|_Z + \|v_h\|_{Z'} \leq K\left\{\left\|\frac{du_0}{dt}\right\| + \left\|\frac{dv_0}{dt}\right\| + \int_0^t \left(\left\|\frac{dF_1}{dt}\right\| + \left\|\frac{dF_2}{dt}\right\|\right) ds\right\}. \tag{4.27}$$

Proof. Taking t-derivative in (3.3)–(3.4), we have

$$\begin{aligned} a_1\left\langle \frac{d^2u_h}{dt^2}, \phi\right\rangle + B_h\left(\frac{dv_h}{dt}, \phi\right) &= \left\langle \frac{dF_1}{dt}, \phi\right\rangle \quad \forall \phi \in U_h, \\ a_2\left\langle \frac{d^2v_h}{dt^2}, \psi\right\rangle - B_h^*\left(\frac{du_h}{dt}, \psi\right) &= \left\langle \frac{dF_2}{dt}, \psi\right\rangle \quad \forall \psi \in V_h. \end{aligned}$$

Taking $\phi = \frac{du_h}{dt}$ and $\psi = \frac{dv_h}{dt}$ and adding the two equations, we obtain

$$\frac{1}{2}\frac{d}{dt}\left(a_1\left\|\frac{du_h}{dt}\right\|^2 + a_2\left\|\frac{dv_h}{dt}\right\|^2\right) = \left\langle \frac{dF_1}{dt}, \frac{du_h}{dt}\right\rangle + \left\langle \frac{dF_2}{dt}, \frac{dv_h}{dt}\right\rangle,$$

and consequently

$$\left\|a_1\frac{du_h}{dt}\right\| + \left\|a_2\frac{dv_h}{dt}\right\| \leq K\left\{\left\|\frac{du_0}{dt}\right\| + \left\|\frac{dv_0}{dt}\right\| + \int_0^t \left(\left\|\frac{dF_1}{dt}\right\| + \left\|\frac{dF_2}{dt}\right\|\right) ds\right\}.$$

By using (4.3),

$$\|v_h\|_{Z'} \leq K\|B_h v_h\|_W = K \sup_{\phi \in U_h} \frac{|B_h(v_h, \phi)|}{\|\phi\|_W} \leq K \sup_{\phi \in U_h} \frac{|\langle \frac{du_h}{dt}, \phi\rangle|}{\|\phi\|_W} = K\left\|\frac{du_h}{dt}\right\|.$$

Similarly, we have

$$\|u_h\|_Z \leq K\left\|\frac{dv_h}{dt}\right\|.$$

This completes the proof. ∎

Before we state the convergence theorem, we will state a L^2 convergence result which is very similar to Theorem 4.1—that all functions are replaced by their time derivative. It can be proved in exactly the same way as the proof of Theorem 4.1.

LEMMA 4.4. *Let $u \in U$ and $v \in V$ be the solution to* (1.1)–(1.2) *and let $u_h \in U_h$ and $v_h \in V_h$ be the solution to the numerical scheme* (3.3)–(3.4). *Then for $0 \leq t \leq T$, we have*

$$\begin{aligned} \left\|\frac{d}{dt}(u - u_h)(t)\right\| + \left\|\frac{d}{dt}(v - v_h)(t)\right\| \leq K\Big\{ &\inf_{\phi \in U_h} \|u_t - \phi\|_W + \inf_{\psi \in V_h} \|v_t - \psi\|_{W'} \\ &+ \int_0^t \Big(\inf_{\phi \in U_h} \|u_{tt} - \phi\|_W + \inf_{\psi \in V_h} \|v_{tt} - \psi\|_{W'}\Big) ds\Big\}. \end{aligned} \tag{4.28}$$

The following theorem states the convergence of the method (3.3)–(3.4) in the discrete H^1 norm. It can be seen that the H^1 error is optimal with respect to the norms and the FE spaces.

THEOREM 4.5. *Let $u \in U$ and $v \in V$ be the solution to* (1.1)–(1.2) *and let $u_h \in U_h$ and $v_h \in V_h$ be the solution to the numerical scheme* (3.3)–(3.4). *Then for $0 \le t \le T$, we have*

$$\|v - v_h\|_{Z'} \le K\left(\left\|\frac{d}{dt}(u - u_h)\right\| + \inf_{\psi \in V_h} \|\psi - v\|_{Z'}\right), \tag{4.29}$$

$$\|u - u_h\|_{Z} \le K\left(\left\|\frac{d}{dt}(v - v_h)\right\| + \inf_{\phi \in U_h} \|\phi - u\|_{Z}\right). \tag{4.30}$$

Proof. By the inf-sup condition (4.3), we obtain

$$\|\mathcal{P}_v v - v_h\|_{Z'} \le K\|B_h(\mathcal{P}_v v - v_h)\|_W = K \sup_{\phi \in U_h} \frac{B_h(\mathcal{P}_v v - v_h, \phi)}{\|\phi\|_W}.$$

Recalling (4.15), we have

$$\left\langle \frac{d(u - u_h)}{dt}, \phi \right\rangle + B_h(\mathcal{P}_v v - v_h, \phi) = 0 \quad \forall \phi \in U_h,$$

and consequently,

$$\|\mathcal{P}_v v - v_h\|_{Z'} \le K\left\|\frac{d}{dt}(u - u_h)\right\|.$$

Let $\mathcal{I}_v v \in V_h$ be an arbitrary element of the FE space V_h, using the triangle inequality

$$\|v - v_h\|_{Z'} \le \|v - \mathcal{I}_v v\|_{Z'} + \|\mathcal{I}_v v - \mathcal{P}_v v\|_{Z'} + \|\mathcal{P}_v v - v_h\|_{Z'}.$$

Following the proof of Theorem 4.1, we have

$$\|\mathcal{I}_v v - \mathcal{P}_v v\|_{Z'} \le K\|\mathcal{I}_v v - v\|_{Z'}.$$

Hence, we obtain

$$\|v - v_h\|_{Z'} \le K\left(\left\|\frac{d}{dt}(u - u_h)\right\| + \|\mathcal{I}_v v - v\|_{Z'}\right).$$

Since $\mathcal{I}_v v$ is arbitrary,

$$\|v - v_h\|_{Z'} \le K\left(\left\|\frac{d}{dt}(u - u_h)\right\| + \inf_{\psi \in V_h} \|\psi - v\|_{Z'}\right).$$

So, (4.29) is proved. The estimte (4.30) can be proved in a similar fashion. ∎

Now, we state and prove the convergence in the discrete H^1 norm. We see that the numerical scheme is $O(h^k)$ in the discrete H^1 norm when the FE spaces U_h and V_h contain polynomials of degree k.

COROLLARY 4.6. *Assume $k \ge 0$ is the largest integer such that U_h and V_h contain polynomials of degree k. Let $(u, v) \in W^{1,p}(0, T; H^{k+1}(\Omega))^3 \cap W^{2,p}(0, T; W^{k,\infty}(\Omega))^3$,*

for $p > 1$, be the exact solution to the wave propagation problem (1.1)–(1.2)*, and let (u_h, v_h) be the solution to the numerical scheme* (3.3)–(3.4)*. Then*

$$\|u - u_h\|_Z + \|v - v_h\|_{Z'} \leq Kh^k(\|(u,v)\|_{W^{1,p}(0,T;H^{k+1}(\Omega))^3} + \|(u,v)\|_{W^{2,p}(0,T;W^{k,\infty}(\Omega))^3}). \tag{4.31}$$

Next, we prove a superconvergence result for some component of the derivative of u_h. We state this result as the following theorem.

THEOREM 4.7. *Let u be the exact solution to the wave propagation problem* (1.1)–(1.2) *and let u_h be the solution to the numerical method* (3.3)–(3.4)*. Then*

$$\begin{aligned}&\|L^\perp B^*(u - u_h)\|_{L^2(\Omega)} \\ &\quad \leq Kh^{k+1}\big\{\|(u,v)\|_{W^{2,1}(0,T;W^{k+1,\infty}(\Omega))^3} + \|u\|_{W^{1,1}(0,T;H^{k+2}(\Omega))}\big\}.\end{aligned} \tag{4.32}$$

Proof. To prove this, we observe that for all $\psi \in V_h$

$$a_2 \int_\Omega \frac{\partial}{\partial t}(v - v_h) \cdot \psi \, dx - B_h^*(u - u_h, \psi) = 0.$$

Let $\pi_h u$ be a function such that $\pi_h u|_\tau$ is a $(k+1)$th degree polynomial interpolant of $u|_\tau$. Then we have

$$B_h^*(u_h - \pi_h u, \psi) = B_h^*(u - \pi_h u, \psi) - a_2 \int_\Omega \frac{\partial}{\partial t}(v - v_h) \cdot \psi \, dx.$$

Recalling the definition of B_h^*, we have

$$B_h^*(u_h - \pi_h u, \psi) = \int_\Omega B^*(u_h - \pi_h u)\psi \, dx + \sum_{\sigma \in \mathcal{E}_u} \int_\sigma [u_h - \pi_h u] L\psi \, d\sigma.$$

Now, we choose $\psi \in V_h$ such that $L\psi = 0$ and $L^\perp \psi = L^\perp B^*(u_h - \pi_h u)$. This is equivalent to sets (VD2) and (VD3) to being zero. Therefore,

$$\begin{aligned}B_h^*(u_h - \pi_h u, \psi) &= \int_\Omega (L^\perp B^*(u_h - \pi_h u))^2 \, dx, \\ \|\psi\|_{L^2(\Omega)} &= \|L^\perp B^*(u_h - \pi_h u)\|_{L^2(\Omega)}.\end{aligned}$$

Consequently, we have

$$\|L^\perp B^*(u_h - \pi_h u)\|_{L^2(\Omega)}^2 = B_h^*(u - \pi_h u, \psi) - a_2 \int_\Omega \frac{\partial}{\partial t}(v - v_h) \cdot \psi \, dx. \tag{4.33}$$

Now we will estimate the right-hand side of (4.33). By Lemma 4.4 and interpolation error estimates (3.16), the second term on the right-hand side of (4.33) can be estimated by

$$\left\| \frac{\partial}{\partial t}(v - v_h) \right\|_{L^2(\Omega)} \leq Kh^{k+1}(\|u\|_{W^{2,1}(0,T;W^{k+1,\infty}(\Omega))} + \|v\|_{W^{2,1}(0,T;W^{k+1,\infty}(\Omega))^2}).$$

Using inverse type inequalities, we have

$$\|B^*(u - \pi_h u)\|_{L^2(\Omega)} \leq Kh^{k+1}|u|_{H^{k+2}(\Omega)}, \quad \|\psi \cdot l\|_{L^2(\sigma)} \leq Kh^{-\frac{1}{2}}\|\psi\|_{L^2(\tau')},$$

and by the trace inequality, we obtain

$$\|u - \pi_h u\|_{L^2(\sigma)} \le K h^{k+\frac{3}{2}} |u|_{H^{k+2}(\Omega)}.$$

Then the first term on the right-hand side of (4.33) can be estimated by

$$\begin{aligned} B_h^*(u - \pi_h u, \psi) &\le \|B^*(u - \pi_h u)\|_{L^2(\Omega)} \|\psi\|_{L^2(\Omega)} \\ &\quad + \sum_{\sigma \in \mathcal{E}_u} \|u - \pi_h u\|_{L^2(\sigma)} \|L\psi\|_{L^2(\sigma)} \\ &\le K h^{k+1} |u|_{H^{k+2}(\Omega)} \|\psi\|_{L^2(\Omega)}. \end{aligned}$$

Combining the result, we prove the theorem. ∎

Now, we will discuss the condition (1.4). In the following theorem, we show that the numerical solution v_h satisfies (1.4) in a weak sense. Let S_h be the space of standard H^1-conforming FE space of degree $k+1$, namely $p \in S_h$ if $p|_\tau \in P^{k+1}(\tau)$ and p is continuous across each $\sigma \in \mathcal{E}$.

THEOREM 4.8. *Let v be the exact solution of the wave propagation problem* (1.1)–(1.2) *and let v_h be the numerical solution to the numerical scheme* (3.3)–(3.4). *Then*

$$\int_\Omega \frac{\partial (v - v_h)}{\partial t} \psi \, dx = 0 \tag{4.34}$$

if and only if $\psi = B^\perp p$ for $p \in S_h$.

Proof. If $\psi = \nabla p$ for $p \in S_h$, then $\psi \in V_h$. Using (4.16), we have proved (4.34). Assume (4.34) holds. Then, using (4.16), we have $B_h^*(\mathcal{P}_u u - u_h, \psi) = 0$. By (4.3), we have $\|\psi\|_{Z'} = 0$. By the definition of Z'-norm, we have $B\psi = 0$ and $[L\psi]|_\sigma = 0$ for all $\sigma \in \mathcal{E}_u$. Using $B\psi = 0$, we have $\psi = B^\perp p$ for some p. Since $\psi|_\tau \in P^k(\tau)^2$, we have $p|_\tau \in P^{k+1}(\tau)$. Notice that $L\psi$ is continuous on each edge in $\mathcal{E}_v^0$. Using this and $[L\psi]|_\sigma = 0$ for all $\sigma \in \mathcal{E}_u$, we have that p is continuous across each edge in $\mathcal{E}_u \cup \mathcal{E}_v^0$. So, the proof is complete. ∎

5. Verification of inf-sup conditions. Now, we are in a position to prove that the choice of U_h and V_h above satisfies the inf-sup condition (4.1)–(4.2).

THEOREM 5.1. *There is a uniform constant $K > 0$ such that*

$$\inf_{\psi \in V_h} \sup_{u \in U_h} \frac{B_h^*(u, \psi)}{\|u\|_W \|\psi\|_{Z'}} \ge K. \tag{5.1}$$

Proof. Let $\psi \in V_h$. It suffices to find $u \in U_h$ such that

$$B_h^*(u, \psi) \ge K \|\psi\|_{Z'}^2 \quad \text{and} \quad \|u\| \le K \|\psi\|_{Z'}. \tag{5.2}$$

Recalling the definition of B_h^*, we have

$$B_h^*(u, \psi) = \int_\Omega u (B\psi) \, dx + \sum_{\sigma \in \mathcal{E}_u} \int_\sigma [L\psi] u \, d\sigma.$$

First, we will define $u_1 \in U_h$ such that

$$\int_\Omega u_1 (B\psi) \, dx \ge K \int_\Omega (B\psi)^2 \, dx \quad \text{and} \quad \int_\Omega (u_1)^2 \, dx \le \int_\Omega (B\psi)^2 \, dx. \tag{5.3}$$

Let $\tau \in \mathcal{T}$. We define the function u_1 such that $u_1|_\tau = \lambda_{\tau,2}\lambda_{\tau,3}B\psi$. Notice that $B\psi|_\tau \in P^{k-1}(\tau)$ and $u_1|_\tau$ is zero on the two edges of τ that belong to $\mathcal{E}_u$, so $u_1|_\tau \in R^k(\tau)$. Since $\lambda_{\tau,2}\lambda_{\tau,3} \leq 1$, the second equation in (5.3) holds. Notice that the quantity $\int_\tau q_{k-1}^2 \lambda_{\tau,2}\lambda_{\tau,3}\, dx$ defines a norm for q_{k-1} in the space $P^{k-1}(\tau)$. Since norms in finite dimensional spaces are equivalent, we have

$$\int_\tau \lambda_{\tau,2}\lambda_{\tau,3}(B\psi)^2\, dx \geq K \int_\tau (B\psi)^2\, dx.$$

Summing up this equation for all $\tau \in \mathcal{T}$ proves the first equation in (5.3).

Next, we will define $u_2 \in U_h$ such that

$$\sum_{\sigma\in\mathcal{E}_u} \int_\sigma [L\psi]u_2\, d\sigma = \sum_{\sigma\in\mathcal{E}_u} (h_\sigma)^{-1} \int_\sigma [L\psi]^2\, d\sigma, \tag{5.4}$$

$$\int_\Omega (u_2)^2\, dx \leq K \sum_{\sigma\in\mathcal{E}_u} (h_\sigma)^{-1} \int_\sigma [L\psi]^2\, d\sigma. \tag{5.5}$$

To do so, we define u_2 so that

1. $u_2 = (h_\sigma)^{-1}[L\psi]$ at the $k+1$ Gaussian points of σ for all $\sigma \in \mathcal{E}_u$, and
2. $\int_\tau u_2 q_{k-1}\, dx = 0$ for all $q_{k-1} \in P^{k-1}(\tau)$ and $\tau \in \mathcal{T}$.

Then, clearly, (5.4) is satisfied. We will define a subspace U_h^0 of U_h by

$$U_h^0 = \left\{ \phi \in U_h \mid \int_\tau \phi q_{k-1}\, dx = 0, \forall q_{k-1} \in P^{k-1}(\tau), \forall \tau \in \mathcal{T} \right\}.$$

Then the following quantity

$$\sum_{\sigma\in\mathcal{E}_u} h_\sigma^2 \sum_{j=1}^{k+1} \phi(\alpha_j)^2$$

defines a norm for U_h^0. Since norms in finite dimensional spaces are equivalent, we have

$$\int_\tau u_2^2\, dx \leq K \sum_{\sigma\in\mathcal{E}_u} h_\sigma^2 \sum_{j=1}^{k+1} u_2(\alpha_j)^2.$$

By the definition of u_2,

$$\int_\tau u_2^2\, dx \leq K \sum_{\sigma\in\mathcal{E}_u} \sum_{j=1}^{k+1} [L\psi(\alpha_j)]^2.$$

Since $[L\psi]$ is a polynomial of degree k, we have

$$\sum_{j=1}^{k+1} [L\psi(\alpha_j)]^2 \leq K(h_\sigma)^{-1} \int_\sigma [L\psi]^2\, dx,$$

which follows from norm equivalence in finite dimensional spaces. So, (5.5) is proved.

To prove (5.2), we take $u = u_1 + u_2$. Notice that by the definitions of u_1 and u_2, we have

$$\int_\tau u_2(B\psi)\, dx = 0 \quad \text{and} \quad \int_\sigma [L\psi]u_1\, d\sigma = 0.$$

Using this together with (5.3), (5.4), and (5.5), we have proved (5.2). ∎

THEOREM 5.2. *There is a uniform constant $K > 0$ such that*

$$\inf_{\phi \in U_h} \sup_{v \in V_h} \frac{B_h(v,\phi)}{\|v\|_{W'} \|\phi\|_Z} \geq K. \tag{5.6}$$

Proof. Let $\phi \in U_h$. As in the proof of the previous theorem, we find $v \in V_h$ such that

$$B_h(v,\phi) \geq K\|\phi\|_Z^2 \quad \text{and} \quad \|v\| \leq K\|\phi\|_Z. \tag{5.7}$$

Recalling the definition of B_h, we have

$$B_h(v,\phi) = \int_\Omega (B^*\phi)v \, dx - \sum_{\sigma \in \mathcal{E}_v^0} \int_\sigma (Lv)[\phi] \, d\sigma.$$

We define $v_1 \in V_h$ such that

$$\int_\Omega (B^*\phi)v_1 \, dx \geq K_1 \int_\Omega |B^*\phi|^2 \, dx \quad \text{and} \quad \int_\Omega |v_1|^2 \, dx \leq K \int_\Omega |B^*\phi|^2 \, dx. \tag{5.8}$$

We define the set

$$V_h^1(\tau) = \{v|_\tau \mid v \in V_h; Lv|_\sigma = 0 \ \forall \sigma \in \mathcal{E}_v\}$$

and the linear functional

$$f_\tau(\eta) = \int_\tau (B^*\phi)\eta \, dx$$

for $\eta \in V_h^1(\tau)$. With the standard L^2 norm, $V_h^1(\tau)$ is a Hilbert space. By the Riesz representation theorem, there exist $v_{1,\tau} \in V_h^1(\tau)$ such that

$$f_\tau(\eta) = \int_\tau v_{1,\tau}\eta \, dx \quad \text{and} \quad \|v_{1,\tau}\|_{L^2(\tau)} = \|f_\tau\|_{L^2(\tau)^*},$$

where $*$ denotes a norm in the dual space. That is,

$$\|f_\tau\|_{L^2(\tau)^*} = \sup_{\eta \in V_h^1(\tau)} \frac{f_\tau(\eta)}{\|\eta\|_{L^2(\tau)}}.$$

We define v_1 such that $v_1|_\tau = v_{1,\tau}$. Then

$$\int_\Omega |v_1|^2 \, dx = \sum_{\tau \in \mathcal{T}} \int_\tau |v_{1,\tau}|^2 \, dx \leq \sum_{\tau \in \mathcal{T}} \int_\tau |B^*\phi|^2 \, dx = \int_\Omega |B^*\phi|^2 \, dx,$$

which proves the second inequality in (5.8). To prove the first inequality in (5.8), we will first show $\|f_\tau\|_{L^2(\tau)^*}$ defines a norm for B^*U_h on τ. So, it suffices to show $B^*\phi = 0$ if $\|f_\tau\|_{L^2(\tau)^*} = 0$. Assume $\|f_\tau\|_{L^2(\tau)^*} = 0$. Then we have $\int_\tau (B^*\phi)\eta \, dx = 0$ for all $\eta \in V_h^1(\tau)$. Notice that $B^*\phi \in P^k(\tau)^2$. Taking $L\eta = 0$ and $L^\perp\eta = L^\perp(B^*\phi)$ yields $\int_\tau (L^\perp(B^*\phi))^2 \, dx = 0$. So, we have $L^\perp(B^*\phi) = 0$ on τ. By the definitions of $L^\perp$ and B^*, we have $(\partial_{\lambda_{\tau,2}} - \partial_{\lambda_{\tau,3}})\phi = 0$. So, we have

$$\phi = \sum_{j=0}^{k+1} c_j(\lambda_{\tau,2} + \lambda_{\tau,3})^j.$$

Since $\phi \in U_h$, we have $c_{k+1} = 0$ and therefore $L(B^*\phi) \in P^{k-1}(\tau)$. Taking $L^\perp \eta = 0$ and $L\eta = \lambda_{\tau,1} L(B^*\phi)$, we have $\int_\tau \lambda_{\tau,1}(L(B^*\phi))^2\, dx = 0$, which implies $L(B^*\phi) = 0$. Hence $B^*\phi = 0$. Since norms in finite dimensional spaces are equivalent, we have $\|f_\tau\|_{L^2(\tau)^*} \geq K\|B^*\phi\|_{L^2(\tau)}$. Consequently, we obtain

$$\int_\Omega (B^*\phi)v_1\, dx = \sum_{\tau\in\mathcal{T}} \int_\tau (B^*\phi)v_{1,\tau}\, dx = \sum_{\tau\in\mathcal{T}} f_\tau(v_{1,\tau}) = \sum_{\tau\in\mathcal{T}} \int_\tau v_{1,\tau}^2\, dx,$$

which proves the first inequality in (5.8).

We will find $v_2 \in V_h$ and a function v^+ such that

$$-\sum_{\sigma\in\mathcal{E}_v} \int_\sigma (L(v_2 + v^+))[\phi]\, d\sigma \geq K_2 \sum_{\sigma\in\mathcal{E}_v^0} (h_\sigma)^{-1} \int_\sigma [\phi]^2\, d\sigma, \tag{5.9}$$

$$\int_\Omega |v_2 + v^+|^2\, dx \leq K_3 \sum_{\sigma\in\mathcal{E}_v^0} (h_\sigma)^{-1} \int_\sigma [\phi]^2\, d\sigma. \tag{5.10}$$

Let $\sigma \in \mathcal{E}_v^0$ and let $\tau, \tilde{\tau}$ be the two triangles sharing the same edge σ. We define $V_h^2(\tau \cup \tilde{\tau})$ as follows:

$$V_h^2(\tau\cup\tilde{\tau}) = \{v|_{\tau\cup\tilde{\tau}} + \nabla(\lambda_{\tau,2}\lambda_{\tau,3}q_k) \mid v \in V_h, (VD1) = (VD2) = 0; q_k \in P^k(\tau\cup\tilde{\tau})\}.$$

Here, by (VD1) = (VD2) = 0, we mean both the degrees of freedom defined by (VD1) and (VD2) are equal to zero. Also, the polynomial q_k is fixed and will be chosen in the following. With the standard $L^2(\tau\cup\tilde{\tau})^2$ norm, $V_h^2(\tau\cup\tilde{\tau})$ is a Hilbert space. We also define the following linear functional:

$$g_\tau(\eta) = \int_\sigma (L\eta)[\phi]\, d\sigma$$

for all $\eta \in V_h^2(\tau\cup\tilde{\tau})$. By the Riesz representation theorem, there is an element $v_{2,\tau} + v_\tau^+ \in V_h^2(\tau\cup\tilde{\tau})$ such that

$$g_\tau(\eta) = \int_{\tau\cup\tilde{\tau}} (v_{2,\tau} + v_\tau^+)\eta\, dx \quad \text{and} \quad \|v_{2,\tau} + v_\tau^+\|_{L^2(\tau\cup\tilde{\tau})^2} = \|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*},$$

where the norm $\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*}$ is defined as

$$\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*} = \sup_{\eta\in V_h^2(\tau\cup\tilde{\tau})} \frac{g_\tau(\eta)}{\|\eta\|_{L^2(\tau\cup\tilde{\tau})^2}}.$$

We then define v_2 by $v_2|_\tau = v_{2,\tau}$ and v^+ by $v^+|_\tau = v_\tau^+$. Since $\int_\sigma (L\eta)^2\, d\sigma \leq K(h_\sigma^{-1}) \int_{\tau\cup\tilde{\tau}} |\eta|^2\, dx$, we have

$$\|g_\tau\|^2_{(L^2(\tau\cup\tilde{\tau})^2)^*} \leq \frac{1}{\|\eta\|^2_{L^2(\tau\cup\tilde{\tau})^2}} \int_\sigma (L\eta)^2\, d\sigma \int_\sigma [\phi]^2\, d\sigma \leq K h_\sigma^{-1} \int_\sigma [\phi]^2\, d\sigma.$$

Summing up all $\tau \in \mathcal{T}$ proves (5.10). To prove (5.9), we will first show that $[\phi]|_\sigma = 0$ if $\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*} = 0$. Now, we assume $\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*} = 0$. Then we have

$\int_\sigma (L\eta)[\phi]\ d\sigma = 0$ for all $\eta \in V_h^2(\tau \cup \tilde{\tau})$. We take $\eta|_\tau \in P^k(\tau)^2$ and $\eta|_{\tilde{\tau}} \in P^k(\tilde{\tau})^2$ such that $L\eta = [\phi]$ at the $k+1$ Gaussian points of σ. Then, $\eta \in V_h^2(\tau \cup \tilde{\tau})$ and

$$h_\sigma \sum_{j=1}^{k+1} w_j [\phi(\alpha_j)]^2\ dx = \int_\sigma (L\eta)[\phi]\ dx = 0,$$

where the first equality follows from the Gaussian quadrature rule; here w_j denotes the weight and α_j denotes the quadrature point. Since the weights $w_j > 0$, we have $[\phi] = 0$ at the $k+1$ Gaussian points of σ. Notice that $[\phi]|_\sigma$ is a polynomial of degree $k+1$. So, we have that $[\phi]|_\sigma$ is a scalar multiple of the $(k+1)$th degree Legendre polynomial, namely $[\phi]|_\sigma = b\mathbb{P}_{k+1}$ for some constant b, where $\mathbb{P}_{k+1}$ is the Legendre polynomial of degree $k+1$. We take $\eta = \nabla(\lambda_{\tau,2}\lambda_{\tau,3}q_k)$ with q_k to be determined below. Notice that $L\eta$ is the tangential derivative of $\lambda_{\tau,2}\lambda_{\tau,3}q_k$ along σ. By a change of variable, we have

$$\begin{aligned}\int_\sigma (L\eta)[\phi]\ d\sigma &= d\int_{-1}^1 \frac{d}{dz}((1-z^2)q_k(z))[\phi(z)]\ dz \\ &= d\int_{-1}^1 \frac{d}{dz}((1-z^2)q_k(z))b\mathbb{P}_{k+1}(z)\ dz\end{aligned}$$

for some constant $d > 0$. Notice that $\mathbb{P}_{k+1}$ satisfies the Legendre differential equation

$$\frac{d}{dz}\left((1-z^2)\frac{d\mathbb{P}_{k+1}}{dz}\right) = -(k+1)(k+2)\mathbb{P}_{k+1}.$$

So, we take $q_k|_\sigma = \frac{d\mathbb{P}_{k+1}}{dz}$ and extend the definition of q_k over all of $\tau \cup \tilde{\tau}$. Then we obtain

$$\int_\sigma (L\eta)[\phi]\ dx = -bd(k+1)(k+2)\int_{-1}^1 \mathbb{P}_{k+1}^2(z)\ dz.$$

This implies that $b = 0$. Hence $[\phi] = 0$. So, $\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*}$ defines a norm on $L^2(\sigma)$. Since norms in finite dimensional spaces are equivalent, we obtain

$$\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*} \geq K(\tau \cup \tilde{\tau})\|[\phi]\|_{L^2(\sigma)}.$$

A standard scale change argument yields

$$\|g_\tau\|_{(L^2(\tau\cup\tilde{\tau})^2)^*} \geq K(h_\sigma)^{-\frac{1}{2}}\|[\phi]\|_{L^2(\sigma)},$$

which proves (5.9).

Combining (5.8), (5.9), and (5.10), we have

$$\begin{aligned}B_h(\delta v_1 + v_2 + v^+, \phi) \geq \delta K_1 \int_\Omega |B^*\phi|^2\ dx + K_2 \sum_{\sigma\in\mathcal{E}_v} (h_\sigma)^{-1}\int_\sigma [\phi]^2\ d\sigma \\ + \int_\Omega (B^*\phi)(v_2 + v^+)\ dx.\end{aligned}$$

By the Cauchy–Schwarz inequality,

$$\int_\Omega (B^*\phi)(v_2 + v^+)\ dx \geq -\frac{K_2}{2K_3}\int_\Omega |v_2 + v^+|^2\ dx - \frac{K_3}{2K_2}\int_\Omega |B^*\phi|^2\ dx.$$

So, we have

$$B_h(\delta v_1 + v_2 + v^+, \phi) \geq \left(\delta K_1 - \frac{K_3}{2K_2}\right) \int_\Omega |B^*\phi|^2 \, dx + \frac{K_2}{2} \sum_{\sigma \in \mathcal{E}_v} (h_\sigma)^{-1} \int_\sigma [\phi]^2 \, d\sigma.$$

Now, we choose δ such that $\delta K_1 - \frac{K_3}{2K_2} = 1$. Then we have

$$B_h(\delta v_1 + v_2 + v^+, \phi) \geq \min\left(1, \frac{K_2}{2}\right) \|\phi\|_Z^2.$$

Since $B_h(v^+, \phi) = 0$, we have

$$B_h(\delta v_1 + v_2, \phi) \geq \min\left(1, \frac{K_2}{2}\right) \|\phi\|_Z^2.$$

We take $v = \delta v_1 + v_2 \in V_h$ so that the first inequality in (5.7) is proved. To prove the second inequality in (5.7), we first notice that $\|v_{2,\tau}\|_{L^2(\sigma)}$ defines a norm for $V_h^2(\tau \cup \tilde{\tau})$ since $\|v_{2,\tau}\|_{L^2(\sigma)} = 0$ implies (VD3) $= 0$ which in turn implies $v_{2,\tau} = 0$ by unisolvence of the FE space V_h. By norm equivalence in finite dimensional spaces, we have $\|v_{2,\tau}\|_{L^2(\tau)} \leq Kh^{\frac{1}{2}} \|v_{2,\tau}\|_{L^2(\sigma)} \leq \|v_{2,\tau}\|_{L^2(\tau)}$. Then we obtain

$$\|\delta v_1 + v_2\|_{L^2(\tau)} \leq \delta \|v_1\|_{L^2(\tau)} + \|v_2\|_{L^2(\tau)} \leq K\|v_1\|_{L^2(\tau)} + h^{\frac{1}{2}} \|v_2\|_{L^2(\sigma)}.$$

Furthermore, we have the following orthogonality condition:

$$\begin{aligned} \int_\sigma v_{2,\tau} v_\tau^+ \, d\sigma &= \int_{-1}^1 v_{2,\tau} \frac{d}{dz}\left((1-z^2)\frac{d\mathbb{P}_{k+1}}{dz}\right) dz \\ &= -(k+1)(k+2) \int_{-1}^1 v_{2,\tau} \mathbb{P}_{k+1} \, dz = 0 \end{aligned}$$

since the function $\mathbb{P}_{k+1}$ is equal to zero at the $k+1$ Gaussian points of σ. By the orthogonality condition,

$$\|v_2\|_{L^2(\sigma)}^2 \leq \|v_2\|_{L^2(\sigma)}^2 + \|v^+\|_{L^2(\sigma)}^2 = \|v_2 + v^+\|_{L^2(\sigma)}^2 \leq Kh^{-1} \|v_2 + v^+\|_{L^2(\tau \cup \tilde{\tau})}^2,$$

where the last inequality follows from trace inequality. So, we have

$$\|\delta v_1 + v_2\|_{L^2(\tau \cup \tilde{\tau})^2} \leq K\|v_1\|_{L^2(\tau \cup \tilde{\tau})^2} + K\|v_2 + v^+\|_{L^2(\tau \cup \tilde{\tau})^2}.$$

Summing up all $\tau \in \mathcal{T}$ and using estimates (5.8) and (5.10) completes the proof. ∎

6. Numerical examples. In this section we present a series of numerical experiments which give quantitative results and confirm the rate of convergence of the method (3.3)–(3.4). We will, in particular, consider the TE mode of Maxwell's equations (E) and set $\Omega = [0, 2\pi]^2$, $a_1 = a_2 = 1$, and $F_1 = F_2 = 0$. In addition, the function u is the magnetic field H while the vector v is the electric field E. The exact solution to Maxwell's equations is

$$\begin{aligned} H(x,t) &= \cos(t)\cos(x_1) + \cos(t)\cos(x_2), \\ E_1(x,t) &= -\sin(t)\sin(x_2), \\ E_2(x,t) &= \sin(t)\sin(x_1). \end{aligned}$$

The domain Ω is triangulated in the following manner. First, we divide Ω into $N \times N$ uniform squares. Then, we subdivide each square by connecting the lower left corner and the upper right corner to obtain two triangles. We further subdivide each triangle into three triangles by connecting the center of the triangle to its three vertices. For the resulting ODE system in time, we use the standard leap-frog scheme. Below we use NT to represent the number of time steps.

We first consider an example for the first order method, that is, $k = 0$. We then test the rate of convergence by comparing the solution to the scheme (3.3)–(3.4) and the exact solution at $T = \frac{\pi}{4}$. Table 6.1 shows the discrete L^2 errors for various mesh sizes, from $N = 10$ to $N = 320$. Here, we choose the time step small enough so that a suitable CFL condition for the leap-frog scheme is satisfied. We will use the results from Table 6.1 and the least squares method to estimate the rates of convergence of the scheme in the discrete L^2 norm. More precisely, we assume the error is proportional to h^β for some $\beta \in \mathbb{R}$, and then perform a least square data fitting using the data from Table 6.1. Doing this, the numerical rate of convergence is 1.0298. This confirms that the scheme is first order convergence in the discrete L^2 norm.

Next, we consider an example with $k = 1$, that is, the FE spaces U_h and V_h, which contain all linear polynomials and a subset of quadratic polynomials. We will test the rates of convergence in various norms at $T = \pi/4$. Table 6.2 shows the results of error in various norms with various mesh sizes. In the third column of Table 6.2, we give the sum of the error for both H and E in the discrete L^2 norm. In the fourth column, we have the error for the magnetic field in the Z-norm. In the fifth column, we have the error for the electric field in the Z'-norm. Table 6.3 shows the estimated rates of convergence. From the table, we see that the estimated rate of convergence in the discrete L^2 norm is approximately 2. Moreover, the estimated rates of convergence in H^1 semi-norms are approximately equal to 1. Our theoretical statements are thus confirmed by this experiment.

In Table 6.4, we also show the error for the divergence of E as well as the normal jump of E. We have not proved convergence results in these two norms, but they are implied by the estimates that we proved in previous sections. The error in the

TABLE 6.3

$\|E - E_h\|_{Z'}$	0.9489

TABLE 6.4
Normal jump and divergence errors at $T = \pi/4$ for $k = 1$.

N	NT	$\sum_{\sigma\in\mathcal{E}}(h_\sigma^{-\frac{1}{2}})\|L^\perp(E - E_h)\|_{L^2(\sigma)}$	$\|\mathrm{div}(E - E_h)\|_{L^2(\Omega)}$
10	100	1.212	0.2519
20	200	0.5692	0.1180
40	400	0.2610	0.05039
80	800	0.1387	0.03494
160	1600	0.06686	0.01632

divergence of E is measured by $\|\mathrm{div}(E - E_h)\|_{L^2(\Omega)}$ while the error in the normal jump of E is measured by $\sum_{\sigma\in\mathcal{E}}(h_\sigma^{-\frac{1}{2}})\|L^\perp(E - E_h)\|_{L^2(\sigma)}$. The estimated rates in both norms are 0.9652 and 1.040, respectively. So, the rates of convergence are indeed first order for these two norms.

In what follows, we will consider the one dimensional scalar wave equation on $\Omega = [0, 2\pi]$,

$$\frac{\partial u}{\partial t} = \frac{\partial v}{\partial x}, \quad \frac{\partial v}{\partial t} = \frac{\partial u}{\partial x},$$

with periodic boundary condition. The purpose is to compare our new optimal DG with the central DG method. The central DG method is typically based on piecewise polynomial approximation without continuity requirement across cell interfaces. Flux integrals along cell boundaries are evaluated by using the average of two values of the numerical solutions from the two neighboring cells, or the so called central numerical flux; see, for example, [7]. We choose $u(x, t) = e^{\sin(x-t)}$ and $v(x, t) = -e^{\sin(x-t)}$ to be the exact solution. We will compare the numerical solutions by the two methods at $T = 20$ using 20 spatial cells and the leap-frog scheme for the time discretization. Figure 6.1 shows the numerical solutions. First, we see that both methods preserve energy. Second, we see that there are spurious modes in the numerical solutions obtained by the central DG. It can be shown that the central DG does not satisfy the inf-sup conditions that we introduce in this paper. With our new optimal DG, which verifies the inf-sup conditions, we see that there is no spurious mode appearing in the numerical solution.

Now we will compare our new DG with an upwind DG method. The upwind DG method is typically based on piecewise polynomial approximation without continuity requirement. Flux integrals along cell boundaries are evaluated by taking the upwind value of the numerical solution from the two neighboring cells, or the so called upwind numerical flux; see, for example, [10]. We will compare the numerical solutions by both methods using the same setting except that $T = 100$ and the 4th order Runge–Kutta method is used for time stepping for the upwind DG. Figure 6.2 shows the numerical results. We see that both methods contain no spurious mode. For the

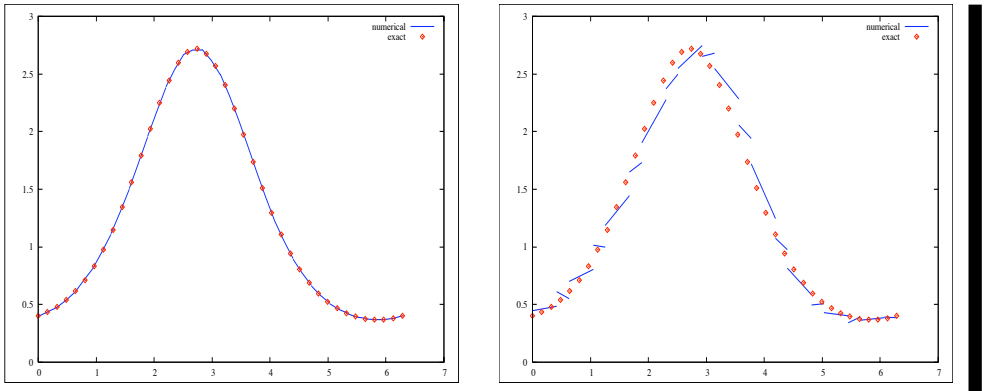

FIG. 6.1. *Comparison of the optimal DGM and central DGM.*

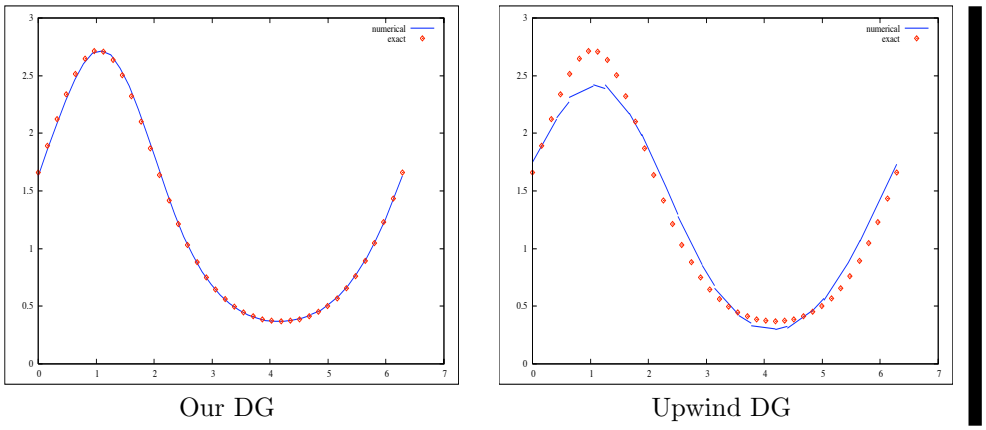

FIG. 6.2. *Comparison of the optimal DGM and upwind DGM.*

upwind DG, it is well known that it is dissipative as seen from the numerical result. On the contrary, our optimal DG preserves energy well.

Before ending this section, we will compare the upwind DG, central DG, and our new optimal DG with piecewise linear approximation. Due to the nature of the three schemes, they are all explicit and suitable for unstructured grids. Because of upwinding, the upwind DG is not energy preserving. In terms of the total number of degrees of freedom (DOF), both the upwind DG and the central DG need $4N$ unknowns. This is because there are 4 unknowns on each cell. On the contrary, owing to the extra continuity conditions, our new DG needs only $3N$ unknowns, which is more efficient in terms of memory storage. In addition, the central DG is only first order accurate, which is suboptimal since we are considering piecewise linear approximation. Both the upwind DG and our new DG have optimal order of convergence, namely, second order in the L^2 norm. We summarize all these properties in Table 6.5.

7. Conclusion. In this paper, we have developed and analyzed a new class of discontinuous Galerkin methods. This new DG can be seen as a compromise between

TABLE 6.5
Comparison among upwind, central, and our new DG with piecewise linear polynomials.

	Upwind	Central	Our
Explicit scheme	Y	Y	Y
Unstructured grid	Y	Y	Y
Energy conservation	N	Y	Y

Order	$O(h^2)$	$O(h)$	$O(h^2)$

the standard DG and the FE in the sense that our new DG is explicit as standard DG and is energy conserving as FE. Energy conservation is an important property for a large class of applications that involves the numerical solutions of wave equations while explicitness provides a more efficient scheme where no matrix inversion is needed at each time step. We have shown that the new DG is stable in both the discrete L^2 norm and discrete H^1 norm. Moreover, the convergence rate is optimal with respect to the order of the polynomial space. To the best of our knowledge, our new DG is the first method that satisfies all of the following properties: explicit, energy conserving, suitable for unstructured grids, and optimal rate of convergence.

ANALYSIS OF A STABILIZED FINITE ELEMENT APPROXIMATION OF THE TRANSIENT CONVECTION-DIFFUSION EQUATION USING AN ALE FRAMEWORK*

SANTIAGO BADIA† AND RAMON CODINA†

Abstract. In this paper we analyze a stabilized finite element method to approximate the convection-diffusion equation on moving domains using an arbitrary Lagrangian Eulerian (ALE) framework. As basic numerical strategy, we discretize the equation in time using first and second order backward differencing (BDF) schemes, whereas space is discretized using a stabilized finite element method (the *orthogonal subgrid scale* formulation) to deal with convection dominated flows. The semidiscrete problem (continuous in space) is first analyzed. In this situation it is easy to identify the error introduced by the ALE approach. After that, the fully discrete method is considered. We obtain optimal error estimates in both space and time in a mesh dependent norm. The analysis reveals that the ALE approach introduces an upper bound for the time step size for the results to hold. The results obtained for the fully discretized second order scheme (in time) are associated to a *weaker* norm than the one used for the first order method. Nevertheless, optimal convergence results have been proved. For fixed domains, we recover stability and convergence results with the strong norm for the second order scheme, stressing the aspects that make the analysis of this method much more involved.

Key words. stabilized finite elements, second order backward differencing, arbitrary Lagrangian Eulerian

1. Introduction.

In this paper we propose and analyze two time integration schemes, of first and of second order, for the numerical approximation of the transient convection-diffusion equation in moving domains. This equation is written in an arbitrary Lagrangian Eulerian (ALE) framework, in which the temporal derivatives are expressed with respect to the reference of a moving domain Ω_t obtained from a mapping of the domain at the initial time. The space discretization is carried out using a stabilized finite element method (FEM) that allows us to deal with convection dominated flows.

The ALE framework, initially used with a finite element approximation in [14], has become widely popular when simulating fluid-structure interaction problems. Even though one can find a lot of numerical experimentation using the ALE approach, some aspects have remained in the dark for a long time. For instance, the meaning and effect of the *geometric conservation law* (GCL) and how the accuracy of a numerical method in fixed domains is spoiled when introducing moving domains with an ALE formulation were not clear. Farhat, Geuzaine, and Grandmont have shown in [15] that the GCL makes the numerical scheme preserve a maximum principle. In [18], the authors have shown that this condition is not necessary to obtain second order ALE

schemes in a finite volume framework. More recently, in a finite element setting where the transient convection-diffusion equation is taken as the *model* equation, works such as [16] and [25] have also clarified the effect of the GCL on the stability properties, identified the different behavior of conservative and nonconservative formulations, and proved some convergence results. Further analyses, for second order schemes, have been developed in later works, such as [17] and [3]. Herein we use the mathematical setting used, e.g., in [25] for the description of this method.

The ALE framework itself does not introduce any error at the continuous level. However, when the problem is discretized in time, some errors due to the ALE description arise. At this step, for fixed domains, the only source error is the time derivative of the unknown. In addition, for moving domains, the error from the evaluation of the mesh velocity also has to be accounted for. This velocity is calculated as the time derivative of the space position of a particle. Thus, an error is induced when this time derivative is calculated numerically.

On the other hand, in practical applications the mesh velocity belongs to the finite element space and does not introduce any interpolation error. Thus, we consider that the ALE formulation is better understood by analyzing the problem semidiscretized in time. However, most numerical analyses (see [16], [17], and [3]) first study the semidiscrete problem in space and then the fully discretized problem.

The convection-diffusion equation (as the Navier–Stokes equations) when discretized in space with the standard Galerkin formulation shows numerical oscillations if the convective term is dominant. With the aim of developing an FEM free of spurious oscillations many methods have been proposed during the last twenty years, such as streamline upwind/Petrov–Galerkin (SUPG) (see [6]), Galerkin/least-squares (see [24]), or the subgrid scale stabilization (see [22]). A comparison of different stabilization methods can be found in [7]. The *orthogonal subgrid scale* (OSS) method used in this paper belongs to this last family and was introduced by Codina in [8]. The method is designed by taking as starting point the subgrid scale variational setting proposed by Hughes et al. in [23] and modeling the subgrid problem in a certain way, in particular by taking the subgrid scales orthogonal to the finite element space. The common aspect of all of these methods is found in the convergence analysis of the discrete problem in space. For the Galerkin approximation, the error estimate bound depends on the physical properties (the Péclet number for the convection-diffusion equation) and increases as the convective term is more dominant. In fact, the stability bound blows up as diffusion goes to zero, reflecting the fact that the continuous problem is a singularly perturbed one. But when using stabilized methods this negative feature does not appear anymore. This is because the new terms introduced by the stabilization control the convective term norm. In the present analysis we have been able to obtain appropriate error estimates by controlling only a part of the convective term, which is an innovative result.

As far as we know, most of the existing stabilization techniques are extended to transient problems using the framework of the discontinuous Galerkin space-time formulation, increasing notably the computer cost for schemes in time of order two or higher. This situation has been improved by Guermond in [20], where he analyzes the introduction of a certain numerical subgrid viscosity. Optimal convergence results are obtained for an evolutionary equation. The key point is the uncoupling of the stabilization terms with the temporal derivative of the unknown. Another stabilization method with this feature is presented in [4].

Codina and Blasco analyze in [12] the transient convection-diffusion-reaction equation discretized in space using the OSS method and in time with the backward

Euler time integration. Further, they consider the *tracking* of the subscales in time. Optimal convergence and stability results are obtained.

The present paper can be viewed as an extension of [12]. We generalize the situation to moving domains (using an ALE approach). In addition, first and second order backward differencing (BDF) time integration schemes are considered, which will be denoted by BDF1 and BDF2, respectively. The blend of a stabilized FEM with the use of an ALE framework is one of the innovative aspects of this paper.

In order to analyze the stabilized method for transient problems, the following strategy is adopted in [12]: First the semidiscrete problem is studied (where no stabilization terms appear) and later the fully discrete method is analyzed. As shown in [12], this provides a natural way to deal with the subscales whose approximation enhances the stability and accuracy of the formulation. The main drawback of this strategy is that space regularity for the convergence analysis needs to be assumed for the semidiscrete solution, not for the continuous one.

The first time integration scheme considered uses the classical backward Euler formula for the approximation of both the time derivative of the unknown and the calculation of the mesh velocity. We label this method as follows:

- BDF1-BDF1$_{\delta t}$ for the problem semidiscretized in time,
- BDF1-BDF1$_{\delta t,h}$ for the fully discretized problem using the classical Galerkin approximation in space,
- BDF1-BDF1-OSS$_{\delta t,h}$ for the fully discretized problem using the OSS method in space,
- BDF1-OSS$_{\delta t,h}$ for the fully discretized problem using the OSS method in space on fixed domains (not in an ALE framework).

In the second method the time integration makes use of the second order BDF formula. Again, we use the following notation:

- BDF2-BDF2$_{\delta t}$ for the problem semidiscretized in time,
- BDF2-BDF2$_{\delta t,h}$ for the fully discretized problem using the classical Galerkin approximation in space,
- BDF2-BDF2-OSS$_{\delta t,h}$ for the fully discretized problem using the OSS method in space,
- BDF2-OSS$_{\delta t,h}$ for the fully discretized problem using the OSS method in space on fixed domains (not in an ALE framework).

Let us underline what is new in each case. The BDF1-BDF1$_{\delta t,h}$ method has been analyzed in [16]. As explained above, we change the order of the discretization: First we analyze BDF1-BDF1$_{\delta t}$ and then BDF1-BDF1-OSS$_{\delta t,h}$, introducing the appropriate stabilization terms. For fixed domains, BDF1-OSS$_{\delta t,h}$ has been analyzed in [12]. However, the analysis herein is slightly different. The analysis of convergence and stability of the semidiscrete method BDF2-BDF2$_{\delta t}$ is new, as it is for the method's fully discrete stabilized version BDF2-BDF2-OSS$_{\delta t,h}$. We specially note the fact that convergence results independent of the physical properties can be obtained without the full norm of the convective term. Even for fixed domains, the stability and convergence results for BDF2-OSS$_{\delta t,h}$ are new. In all cases the long-term behavior has been considered.

Numerical experimentation with the ALE methods (for diffusion dominated problems using the Galerkin method) BDF1-BDF1$_{\delta t,h}$ and BDF2-BDF2$_{\delta t,h}$ can be found in [17], [3], and [25], showing the expected behavior. The application of BDF1-OSS$_{\delta t,h}$ and BDF2-OSS$_{\delta t,h}$ can be found in [9] and [11] for the solution of fluid problems. Finally, the blend of these methods, BDF1-BDF1-OSS$_{\delta t,h}$ and BDF2-BDF2-OSS$_{\delta t,h}$, has been used for simulating engineering problems in [1], with excellent results.

The paper is organized as follows. In section 2 we state the governing equations for moving domains in an ALE framework. Some important ingredients needed to define the ALE approach are introduced. The semidiscrete problem is formulated for both BDF1 and BDF2. The section ends with the presentation of the OSS stabilization method and the fully discrete problem. Section 3 is devoted to the semidiscrete problem. First and second order methods are considered, for which stability and optimal convergence estimates are obtained. Section 4 presents an analogous analysis to that of section 3 but for the fully discrete problem. Finally, some conclusions are drawn in section 5.

In Table 1.1 we have summarized the main results proved in this paper in order to provide the reader with a *road map* for the subsequent discussion. The concepts used in this table (*weak*, *strong*, and Λ-coercivity) will be introduced later.

2. Problem statement.

2.1. The continuous problem. In order to study the ALE framework together with a stabilized FEM, we take as a model test problem the transient convection-diffusion equation. The problem written in an Eulerian framework consists in finding a function u such that

$$\frac{\partial u}{\partial t} - \nu\Delta u + \boldsymbol{a}\cdot\nabla u = f \quad \text{in } \Omega_t \times (0,T), \tag{2.1a}$$

$$u = 0 \quad \text{on } \partial\Omega_t \times (0,T), \tag{2.1b}$$

$$u(\boldsymbol{x}_0, 0) = u_0 \quad \text{in } \Omega_0 \times \{0\}, \tag{2.1c}$$

where $\Omega_t \subset \mathbb{R}^d$ (d=2,3) is a bounded and polyhedral domain (moving in time), $[0,T]$ is the time interval of analysis, $\boldsymbol{a}$ is a divergence-free velocity field, and $\nu > 0$ is the diffusion coefficient. Homogeneous boundary conditions are assumed to clarify the analysis. We also assume the following regularity of the data:

$$f \in L^2(0,T;H^{-1}(\Omega_t)), \quad u_0 \in L^2(\Omega_0), \quad \boldsymbol{a} \in \boldsymbol{L}^\infty(\Omega_t),$$

assuring the existence of a unique solution $u(t) \in L^2(0,T;H^1(\Omega_t)) \cap \mathcal{C}^0(0,T;L^2(\Omega_t))$.

We introduce some key ingredients of an ALE framework. Let $\mathcal{A}_t$ be a family of mappings, which for all $t \in [0,T]$ map a point $\boldsymbol{x}_0 \in \Omega_0$ into a point $\boldsymbol{x} \in \Omega_t$:

$$\mathcal{A}_t : \Omega_0 \longrightarrow \Omega_t, \quad \boldsymbol{x}(\boldsymbol{x}_0, t) = \mathcal{A}_t(\boldsymbol{x}_0).$$

We assume that $\mathcal{A}_t$ is invertible with inverse $\mathcal{A}_t^{-1}$. For $t_1, t_2 \in [0,T]$ we define

$$\mathcal{A}_{t_1,t_2} : \Omega_{t_1} \longrightarrow \Omega_{t_2}, \quad \mathcal{A}_{t_1,t_2} = \mathcal{A}_{t_2} \circ \mathcal{A}_{t_1}^{-1}.$$

We note that the family of mappings is arbitrary. Several techniques have been suggested in order to construct this ALE mapping. If $\mathcal{A}_t$ is the mapping arising from the motion of the particles, the resulting formulation would be of pure Lagrangian type.

Let us consider a function $f : \Omega_t \times [0,T] \longrightarrow \mathbb{R}$. We indicate with $\hat{f} = f \circ \mathcal{A}_t$ the corresponding function in the ALE frame:

$$\hat{f} : \Omega_0 \times [0,T] \longrightarrow \mathbb{R}, \quad \hat{f}(\boldsymbol{x}_0, t) = f(\mathcal{A}_t(\boldsymbol{x}_0), t).$$

Furthermore, the time derivatives in the ALE frame are defined as follows:

$$\left.\frac{\partial f}{\partial t}\right|_{\boldsymbol{x}_0} : \Omega_t \times [0,T] \longrightarrow \mathbb{R}, \quad \left.\frac{\partial f}{\partial t}\right|_{\boldsymbol{x}_0}(\boldsymbol{x}, t) = \frac{\partial \hat{f}}{\partial t}(\boldsymbol{x}_0, t).$$

The domain velocity $\boldsymbol{w}$ is calculated using the expression

$$\boldsymbol{w}(\boldsymbol{x}, t) = \left.\frac{\partial \boldsymbol{x}}{\partial t}\right|_{\boldsymbol{x}_0} = \frac{\partial \mathcal{A}_t(\boldsymbol{x}_0)}{\partial t},$$

and the Jacobian of the ALE mapping is given by

$$J_t = \det(\boldsymbol{J}_t), \quad \boldsymbol{J}_t = \frac{\partial \boldsymbol{x}}{\partial \boldsymbol{x}_0}.$$

We recall the *Reynolds transport formula*. Let $\psi(\boldsymbol{x}, t)$ be a function defined in Ω_t. Then, for any subdomain $V_t \subseteq \Omega_t$ such that $V_t = \mathcal{A}_t(V_0)$ with $V_0 \subseteq \Omega_0$, it holds that

$$\frac{d}{dt}\int_{V_t} \psi(\boldsymbol{x}, t)\, \mathrm{d}V = \int_{V_t} \left(\left.\frac{\partial \psi}{\partial t}\right|_{\boldsymbol{x}_0} + \psi \nabla \cdot \boldsymbol{w} \right) \mathrm{d}V.$$

In particular, if $v : \Omega_t \longrightarrow \mathbb{R}$, that is, if v does not depend explicitly on time, we have that

$$\frac{d}{dt}\int_{\Omega_t} v\, \mathrm{d}\Omega = \int_{\Omega_t} v \nabla \cdot \boldsymbol{w}\, \mathrm{d}\Omega. \tag{2.2}$$

With all this notation introduced, we are ready to write (2.1) in the ALE framework. It now reads

$$\left.\frac{\partial u}{\partial t}\right|_{\boldsymbol{x}_0} - \nu \Delta u + (\boldsymbol{a} - \boldsymbol{w}) \cdot \nabla u = \boldsymbol{f} \quad \text{in } \Omega_t \times (0,T), \tag{2.3a}$$

$$u = 0 \quad \text{on } \partial\Omega_t \times (0,T), \tag{2.3b}$$

$$\boldsymbol{u}(\boldsymbol{x}_0, 0) = \boldsymbol{u}_0 \quad \text{in } \Omega_0 \times \{0\}. \tag{2.3c}$$

The functional space

$$\mathcal{V}(\Omega_t) := \left\{ v : \Omega_t \to \mathbb{R}, v = \hat{v} \circ \mathcal{A}_t^{-1}, \hat{v} \in H_0^1(\Omega_0) \right\}, \quad t \in (0,T),$$

allows us to write (2.3) in its variational form. The variational problem reads as follows: find $u(t) \in \mathcal{V}(\Omega_t)$ for all $t \in (0,T)$ such that

$$\left(\frac{\partial u(t)}{\partial t}, v \right)_{\Omega_t} + \nu \left(\nabla u(t), \nabla v \right)_{\Omega_t} + \left((\boldsymbol{a} - \boldsymbol{w}(t)) \cdot \nabla u(t), v \right)_{\Omega_t} = \langle f(t), v \rangle_{\Omega_t}, \tag{2.4}$$

for all $v \in \mathcal{V}(\Omega_t)$, where $(\cdot,\cdot)_{\Omega_t}$ stands for the $L^2(\Omega_t)$ inner product and $\langle \cdot, \cdot \rangle_{\Omega_t}$ for the duality pairing in $H^{-1}(\Omega_t) \times H_0^1(\Omega_t)$.

Let us rescale the time variable as $t \leftarrow t/T$ so that the new time interval is $[0,1]$ and the coefficient $1/T$ has to be inserted in front of the time derivatives. The reason for this change is to display which terms in the stability and convergence results disappear as $T \to \infty$, that is, the long-term behavior. After rescaling, problem (2.4) is transformed into

$$\frac{1}{T} \left(\frac{\partial u(t)}{\partial t}, v \right)_{\Omega_t} + \nu \left(\nabla u(t), \nabla v \right)_{\Omega_t} + \left((\boldsymbol{a} - \boldsymbol{w}(t)) \cdot \nabla u(t), v \right)_{\Omega_t} = \langle f(t), v \rangle_{\Omega_t}, \tag{2.5}$$

and now the domain velocity is

$$\boldsymbol{w}(\boldsymbol{x}, t) = \frac{1}{T} \left. \frac{\partial \boldsymbol{x}}{\partial t} \right|_{\boldsymbol{x}_0}. \tag{2.6}$$

We take into account this rescaling in property (2.2), which now reads

$$\frac{1}{T} \frac{d}{dt} \int_{\Omega_t} v \, \mathrm{d}\Omega = \int_{\Omega_t} v \nabla \cdot \boldsymbol{w} \, \mathrm{d}\Omega. \tag{2.7}$$

2.2. The semidiscrete problem in time. Let us introduce some notation that we will use throughout the work. Consider a uniform partition of $[0,1]$ into N time intervals of length δt. Let us denote by f^n the approximation of a time dependent function f at time level $t^n = n\delta t$. We will also denote

$$\begin{aligned} \delta f^{n+1} &\equiv \delta^{(1)} f^{n+1} = f^{n+1} - f^n, \\ \delta^{(i+1)} f^{n+1} &= \delta^{(i)} f^{n+1} - \delta^{(i)} f^n, \ i = 1, 2, 3, \ldots . \end{aligned}$$

The discrete operators $\delta^{(i+1)}$ are centered. We will also use the backward difference operators

$$\begin{aligned} D_1 f^{n+1} &= \frac{\delta f^{n+1}}{\delta t} = \frac{f^{n+1} - f^n}{\delta t}, \\ D_2 f^{n+1} &= \frac{3}{2\delta t} \left(f^{n+1} - \frac{4}{3} f^n + \frac{1}{3} f^{n-1} \right). \end{aligned}$$

Let us discretize problem (2.5) in time, once t has been normalized. We assume the force term is continuous in time and denote the time level by a superscript. We start using the BDF1 time integration scheme. It leads to the following problem: for $n = 0, 1, \ldots, N-1$, given u^n, find $u^{n+1} \in \mathcal{V}(\Omega_{t^{n+1}})$ such that

$$\begin{aligned} &\frac{1}{T} \left(u^{n+1} - u^n, v^{n+1} \right)_{\Omega_{t^{n+1}}} + \delta t \nu \left(\nabla u^{n+1}, \nabla v^{n+1} \right)_{\Omega_{t^{n+1}}} \\ &\quad + \delta t \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla u^{n+1}, v^{n+1} \right)_{\Omega_{t^{n+1}}} = \delta t \langle f^{n+1}, v^{n+1} \rangle_{\Omega_{t^{n+1}}}, \end{aligned} \tag{2.8}$$

with $u^0 = u_0$ in $L^2(\Omega_0)$.

Furthermore, we discretize in time the ALE mapping using a linear interpolation. The discretized ALE mapping $\mathcal{A}_t^{n+1}$ is defined for a given time slab $[t^n, t^{n+1}]$ as

$$\mathcal{A}_t^{n+1}(\boldsymbol{x}_0, t) = \frac{t - t^n}{\delta t}\mathcal{A}_{t^{n+1}}(\boldsymbol{x}_0) + \frac{t^{n+1} - t}{\delta t}\mathcal{A}_{t^n}(\boldsymbol{x}_0).$$

Thus, the mesh velocity is constant on each time step and is given by

$$\hat{\boldsymbol{w}}^{n+1}(\boldsymbol{x}_0) = \frac{\mathcal{A}_{t^{n+1}}(\boldsymbol{x}_0) - \mathcal{A}_{t^n}(\boldsymbol{x}_0)}{T\delta t}$$

and $\boldsymbol{w}^{n+1}(\boldsymbol{x}, t) = \hat{\boldsymbol{w}}^{n+1}((\mathcal{A}_t^{n+1})^{-1}(\boldsymbol{x}))$ for $t \in (t^n, t^{n+1}]$. Equation (2.8) with this mesh velocity defines the BDF1-BDF1$_{\delta t}$ method. Note that the superscript $n+1$ in $\boldsymbol{w}$ denotes that it varies with time within the time interval $(t^n, t^{n+1}]$ where it is defined. However, in section 3 we will simply denote $\boldsymbol{w}^{n+1} \equiv \boldsymbol{w}^{n+1}(\boldsymbol{x}, t^{n+1})$. Since $\mathcal{A}_{t^{n+1}}^{n+1} = \mathcal{A}_{t^{n+1}}$, we will write $\boldsymbol{w}^{n+1}(\boldsymbol{x}, t^{n+1}) = \hat{\boldsymbol{w}}^{n+1}(\mathcal{A}_{t^{n+1}}^{-1}(\boldsymbol{x}))$ or, for $\boldsymbol{x}$ arbitrary, $\boldsymbol{w}^{n+1} = \hat{\boldsymbol{w}}^{n+1} \circ \mathcal{A}_{t^{n+1}}^{-1}$.

For the numerical analysis we rewrite the transient problem using a different setting. The sequence of problems (2.8) can be written in a unified manner as follows: find a sequence $U = \{u^0, u^1, u^2, \ldots, u^N\}$ such that

$$B(U, V) = L(V) \tag{2.9}$$

for all sequences V, where

$$\begin{aligned} B(U,V) := \frac{1}{2T}\left(u^0, v^0\right)_{\Omega_0} + \sum_{n=0}^{N-1}\Bigg[\frac{1}{T}\left(\delta u^{n+1}, v^{n+1}\right)_{\Omega_{t^{n+1}}} + \delta t\nu\left(\nabla u^{n+1}, \nabla v^{n+1}\right)_{\Omega_{t^{n+1}}} \\ + \delta t\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}, v^{n+1}\right)_{\Omega_{t^{n+1}}}\Bigg], \end{aligned} \tag{2.10}$$

$$L(V) := \frac{1}{2T}\left(u^0, v^0\right)_{\Omega_0} + \sum_{n=0}^{N-1}\delta t\langle f^{n+1}, v^{n+1}\rangle_{\Omega_{t^{n+1}}}. \tag{2.11}$$

Observe that the initial condition has been embedded in the variational problem.

In order to reach second order accuracy in time, the BDF2 integration scheme is used. It leads to the following time discretization of (2.5):

$$\begin{aligned} &\frac{1}{2T}\left(3u^{n+1} - 4u^n + u^{n-1}, v^{n+1}\right)_{\Omega_{t^{n+1}}} + \delta t\nu\left(\nabla u^{n+1}, \nabla v^{n+1}\right)_{\Omega_{t^{n+1}}} \\ &\quad + \delta t\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}, v^{n+1}\right)_{\Omega_{t^{n+1}}} = \delta t\langle f^{n+1}, v^{n+1}\rangle_{\Omega_{t^{n+1}}}. \end{aligned} \tag{2.12}$$

This problem has to be initialized. For instance, we can obtain u^1 with (2.8) and $u^0 = u_0$ in $L^2(\Omega_0)$ keeping the order of convergence of the method. In order to keep this accuracy, a quadratic interpolation is used to approximate the ALE mapping. For a given time slab $[t^n, t^{n+1}]$, this interpolation is given by

$$\begin{aligned} \mathcal{A}_t^{n+1}(\boldsymbol{x}_0, t) = &\frac{(t - t^n)(t - t^{n-1})}{2\delta t^2}\mathcal{A}_{t^{n+1}}(\boldsymbol{x}_0) \\ &- \frac{(t - t^{n+1})(t - t^{n-1})}{2\delta t^2}\mathcal{A}_{t^n}(\boldsymbol{x}_0) + \frac{(t - t^{n+1})(t - t^n)}{2\delta t^2}\mathcal{A}_{t^{n-1}}(\boldsymbol{x}_0). \end{aligned}$$

Thus, the mesh velocity on each time step is linear in time and is given by

$$\hat{\boldsymbol{w}}^{n+1}(\boldsymbol{x}_0,t) = \frac{2t-t^n-t^{n-1}}{2T\delta t^2}\mathcal{A}_{t^{n+1}}(\boldsymbol{x}_0) - \frac{2t-t^{n+1}-t^{n-1}}{2T\delta t^2}\mathcal{A}_{t^n}(\boldsymbol{x}_0) + \frac{2t-t^{n+1}-t^n}{2T\delta t^2}\mathcal{A}_{t^{n-1}}(\boldsymbol{x}_0)$$

and $\boldsymbol{w}^{n+1}(\boldsymbol{x},t) = \hat{\boldsymbol{w}}^{n+1}((\mathcal{A}_t^{n+1})^{-1}(\boldsymbol{x}),t)$ for $t \in (t^n, t^{n+1}]$. It is easily checked that at t^{n+1} we recover the BDF2 formula for the mesh velocity.

Again, we can rewrite the transient problem as an abstract "variational" problem (2.9), now with the bilinear form

$$\begin{aligned} B(U,V) = {} & \frac{1}{T}\left(u^1-u^0,v^1\right)_{\Omega_{t^1}} + \delta t\nu\left(\nabla u^1,\nabla v^1\right)_{\Omega_{t^1}} + \delta t\left((\boldsymbol{a}-\boldsymbol{w}^1)\cdot\nabla u^1,v^1\right)_{\Omega_{t^1}} \\ & + \frac{1}{2T}\left(u^0,v^0\right)_{\Omega_0} + \sum_{n=1}^{N-1}\left[\frac{1}{2T}\left(3u^{n+1}-4u^n+u^{n-1},v^{n+1}\right)_{\Omega_{t^{n+1}}}\right. \\ & \left. + \delta t\nu\left(\nabla u^{n+1},\nabla v^{n+1}\right)_{\Omega_{t^{n+1}}} + \delta t\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1},v^{n+1}\right)_{\Omega_{t^{n+1}}}\right] \end{aligned} \tag{2.13}$$

and the linear form

$$L(V) := \frac{1}{2T}\left(u^0,v^0\right)_{\Omega_0} + \sum_{n=0}^{N-1}\delta t\langle f^{n+1},v^{n+1}\rangle_{\Omega_{t^{n+1}}}. \tag{2.14}$$

We end this subsection by giving the norm for which stability and convergence results are obtained in section 3 for the previous semidiscrete problems:

$$|||V|||^2 = \frac{1}{T}\sup_{n\in[0,N]}\|v^n\|^2_{L^2(\Omega_{t^n})} + \sum_{n=0}^{N-1}\delta t\nu\left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}. \tag{2.15}$$

Given a normed space X, for $1 \le q < \infty$ we define the space $\ell^q(X)$ as that of sequences $V = \{v^n\}_{n=0}^N$ such that $\sum_{n=0}^N \delta t\|v^n\|_X^q < \infty$, and $\ell^\infty(X)$ the space of sequences such that $\sup_{n=0,\dots,N}\|v^n\|_X < \infty$. With this notation, the norm defined in (2.15) can be considered that of $\ell^\infty(L^2(\Omega_t)) \cap \ell^2(H_0^1(\Omega_t))$. Here, the subscript t has to be understood as t^n for the nth component of the sequence.

2.3. The fully discrete problem. At this point we treat the space discretization of systems (2.8) and (2.12). The BDF1-BDF1-OSS$_{\delta t,h}$ reads as follows: for $n = 0, 1, \dots, N-1$, given u_h^n, find $u_h^{n+1} \in \mathcal{V}_h(\Omega_t)$ such that

$$\begin{aligned} & \frac{1}{T}\left(u_h^{n+1}-u_h^n,v_h^{n+1}\right)_{\Omega_{t^{n+1}}} + \delta t\nu\left(\nabla u_h^{n+1},\nabla v_h^{n+1}\right)_{\Omega_{t^{n+1}}} \\ & \quad + \delta t\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u_h^{n+1},v_h^{n+1}\right)_{\Omega_{t^{n+1}}} \\ & \quad + \delta t\left(\Pi_h^\perp\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u_h^{n+1}\right),\tau^{n+1}(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla v_h^{n+1}\right)_{\Omega_{t^{n+1}}} \\ & \quad = \delta t\langle f^{n+1},v_h^{n+1}\rangle_{\Omega_{t^{n+1}}}, \end{aligned} \tag{2.16}$$

where $\mathcal{V}_h(\Omega_t)$ is a finite element approximation space of $\mathcal{V}(\Omega_t)$, τ^{n+1} is a mesh dependent parameter, which we will call the *stabilization parameter*, whose expression is detailed later, and $\Pi_h^\perp(\cdot) =: Id(\cdot) - \Pi_h(\cdot)$, with Id the identity in $L^2(\Omega_t)$ and $\Pi_h(\cdot)$ the L^2-projection onto this finite element space (and therefore $\Pi_h^\perp(\cdot)$ is the

projection orthogonal to the finite element space). The description and motivation of this formulation, which we call OSS stabilization, can be found in [10].

Let Θ_h^t be a finite element partition of the domain Ω_t in a family of elements $\{K_e\}_{e=1}^{n_{el}}$, n_{el} being the number of elements. We denote the diameter of the sphere that circumscribes element K by h_K and the diameter of the sphere inscribed in K by ϱ_K. We also call $h = \max_{K\in\Theta_h^t}(h_K)$ and $\varrho = \min_{K\in\Theta_h^t}(\varrho_K)$. We assume that all the element domains $K \in \Theta_h^t$ are the image of a reference element $\tilde{K}$ through polynomial mappings F_K, affine for simplicial elements, bilinear for quadrilaterals, and trilinear for hexahedra. On $\tilde{K}$ we define the polynomial spaces $R_p(\tilde{K})$, where R_p is, for simplicial elements, the set of polynomials in $x_1, \ldots, x_d$ of degree less than or equal to p, called P_p. For quadrilaterals and hexahedra, R_p consists of polynomials in $x_1, \ldots, x_d$ of degree less than or equal to p in each variable, a set called Q_p. The finite element spaces introduced before and that we will use in the following are

$$\begin{aligned}
\mathcal{V}_h^f(\Omega_0) &= \{\widehat{v}_h \in \mathcal{C}^0(\Omega_0) \mid \widehat{v}_h|_K = \tilde{v} \circ F_K^{-1},\ \tilde{v} \in R_p(\tilde{K}),\ K \in \Theta_h^t\},\\
\mathcal{V}_h(\Omega_0) &= \{v_h \in \mathcal{V}_h(\Omega_0) \mid v_h|_{\partial\Omega_0} = 0\},\\
\mathcal{V}_h^f(\Omega_t) &= \{v_h \in \mathcal{C}^0(\Omega_t) \mid v_h = \widehat{v}_h \circ \mathcal{A}_t^{-1},\ \widehat{v}_h \in \mathcal{V}_h(\Omega_0)\},\\
\mathcal{V}_h(\Omega_t) &= \{v_h \in \mathcal{C}^0(\Omega_t) \mid v_h = \widehat{v}_h \circ \mathcal{A}_t^{-1},\ \widehat{v}_h \in \mathcal{V}_{h,0}(\Omega_0)\}.
\end{aligned}$$

Moreover, Θ_h^t is assumed to be quasi-uniform; that is to say, there exists a constant $\varrho_2 > 0$, independent of h, such that $\frac{\varrho}{h} \geq \varrho_2 > 0$ as h tends to zero. This will simplify the analysis and, in particular, will allow us to use stabilization parameters constant in space.

Let us note that in practical applications $\mathcal{A}_{t^{n+1}}$ maps Θ_h^0 onto Θ_h^{n+1}. Therefore, it is easily checked that $\boldsymbol{w}^{n+1} \in (\mathcal{V}_h(\Omega_{t^{n+1}}))^d$. In the following we will not distinguish between $\boldsymbol{w}^{n+1}$ and $\boldsymbol{w}_h^{n+1}$.

Also in this case we can write the problem using a "variational" formalism. The fully discrete sequence of problems given by (2.16) can be written as follows: find a sequence $U_h = \{u_h^0, u_h^1, \ldots, u_h^N\}$ such that

$$B_h(U_h, V_h) = L(V_h) \tag{2.17}$$

for all sequences V_h, with the bilinear form B_h given by

$$\begin{aligned}
B_h(U_h, V_h) &= \frac{1}{2T}\left(u_h^0, v_h^0\right)_{\Omega_0}\\
&\quad + \sum_{n=0}^{N-1}\left[\frac{1}{T}\left(u_h^{n+1} - u_h^n, v_h^{n+1}\right)_{\Omega_{t^{n+1}}} + b_h\left(\boldsymbol{w}^{n+1}; u_h^{n+1}, v_h^{n+1}\right)_{\Omega_{t^{n+1}}}\right],
\end{aligned} \tag{2.18}$$

where b_h is defined as

$$\begin{aligned}
b_h\left(\boldsymbol{w}^{n+1}; u_h^{n+1}, v_h^{n+1}\right)_{\Omega_{t^{n+1}}} &= \delta t\nu\left(\nabla u_h^{n+1}, \nabla v_h^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&\quad + \delta t\left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla u_h^{n+1}, v_h^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&\quad + \delta t\left(\Pi_h^{\perp}\left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla u_h^{n+1}\right), \tau^{n+1}(\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v_h^{n+1}\right)_{\Omega_{t^{n+1}}}.
\end{aligned} \tag{2.19}$$

The OSS method modifies the discretized equation of the classical Galerkin method by introducing the last term, which enhances the stability of the original method. The value of the stabilization parameter τ^{n+1} has been justified in [10]. In an ALE

framework it depends on the difference between the advection velocity $\boldsymbol{a}$ and the mesh velocity $\boldsymbol{w}$. The expression we use is

$$\tau^{n+1} = \left(c_1 \frac{\nu}{h^2} + c_2 \frac{\|\boldsymbol{a} - \boldsymbol{w}\|_{L^\infty(\Omega_{t^{n+1}})}}{h} \right)^{-1}, \tag{2.20}$$

which is constant in space. Here, c_1 and c_2 are algorithmic constants that depend on the order of the finite element interpolation. As will be shown later (see (4.7)), they are related to the constant C_{inv} in the inverse estimate introduced in (4.1).

As in [12], we will make further assumptions. We assume that for each n the parameter τ^n satisfies

$$\tau^n \leq CT\delta t, \tag{2.21}$$

which in particular implies that we cannot let $\delta t \to 0$ without refining the finite element mesh. This condition is not only theoretical, but probably has practical consequences. It is shown in [2] in a particular numerical example that instabilities occur in the case of the transient Stokes problem if a condition similar to (2.21) is violated. Moreover, from the theoretical point of view there is a way to circumvent this, which consists in considering the subscales time dependent. This is the approach followed in [13], where stability of a stabilized FEM for the linearized Navier–Stokes equations is proved with and without condition (2.21).

For the space discretization of the second order method (2.12), the bilinear form is given by

(2.22)

$$\begin{aligned} &B_h\left(U_h, V_h\right) \\ &\quad = \sum_{n=1}^{N-1} \left[\frac{1}{2T} \left(3u_h^{n+1} - 4u_h^n + u_h^{n-1}, v_h^{n+1}\right)_{\Omega_{t^{n+1}}} + b_h\left(\boldsymbol{w}^{n+1}; u_h^{n+1}, v_h^{n+1}\right)_{\Omega_{t^{n+1}}} \right] \\ &\qquad + \frac{1}{T}\left(u_h^1 - u_h^0, v_h^1\right)_{\Omega_{t^1}} + b_h\left(\boldsymbol{w}^1; u_h^1, v_h^1\right)_{\Omega_{t^1}} + \frac{1}{T}\left(u_h^0, v_h^0\right)_{\Omega_0}. \end{aligned}$$

We end this section with two norms that are useful in the following numerical analysis. The first is a norm that we will call *weak*, which is given by

$$\begin{aligned} |||V|||_w^2 = \frac{1}{T} \sup_{n\in[0,N]} \|v^n\|^2_{L^2(\Omega_{t^n})} &+ \sum_{n=0}^{N-1} \delta t\nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \\ &+ \sum_{n=0}^{N-1} \delta t\tau^{n+1} \left\|\Pi_h^\perp\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}. \end{aligned}$$

Observe that only the orthogonal projection of the convective term appears. The full convective term appears in the norm that we will call *strong*, given by

$$\begin{aligned} |||V|||_s^2 &= \frac{1}{T} \sup_{n\in[0,N]} \|v^n\|^2_{L^2(\Omega_{t^n})} + \sum_{n=0}^{N-1} \delta t\nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \\ &\quad + \sum_{n=0}^{N-1} \delta t\tau^{n+1} \left\|(\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \\ &= |||V|||_w^2 + \sum_{n=0}^{N-1} \delta t\tau^{n+1} \left\|\Pi_h\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}. \end{aligned}$$

3. Analysis of the semidiscrete problem. In this section we analyze problems BDF1-BDF1$_{\delta t}$ and BDF2-BDF2$_{\delta t}$. In both cases, stability and error estimates will be given. We denote by C a positive constant, possibly with different values at different appearances.

3.1. Analysis of BDF1-BDF1$_{\delta t}$. Let us define by $U_{\text{ex}} = \{u_0, u(t^1), u(t^2), \ldots, u(t^N)\}$ the sequence of solutions of the continuous problem (2.4) and by $U = \{u^0, u^1, u^2, \ldots, u^N\}$ the sequence of solutions of the semidiscrete problem (in time) (2.9)–(2.11). We start by obtaining a stability result for this method. With this aim, first we prove that the bilinear form (2.10) that governs the semidiscrete problem is coercive.

THEOREM 3.1 (coercivity). *There exists δt^1_{cr} such that for $0 < \delta t < \delta t^1_{\text{cr}}$ the bilinear form $B(\cdot,\cdot)$ defined in* (2.10) *is coercive; that is, for every sequence $V = \{v^n\}_{n=0}^N$, with $v^n \in \mathcal{V}(\Omega_{t^n})$,*

$$B(V,V) \geq \beta_1 |||V|||^2$$

for a certain constant $\beta_1 > 0$.

Proof. We know, from the definition of the bilinear form, that

$$\begin{aligned} B(V,V) = \sum_{n=0}^{N-1} \Bigg[& \frac{1}{T} \left(v^{n+1} - v^n, v^{n+1}\right)_{\Omega_{t^{n+1}}} + \delta t \nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \\ & + \delta t \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1}, v^{n+1}\right)_{\Omega_{t^{n+1}}} \Bigg] \\ & + \frac{1}{2T} \left\|v^0\right\|^2_{L^2(\Omega_0)}. \end{aligned}$$

We can rewrite the term coming from the time derivative as follows:

$$\begin{aligned} & \frac{1}{T} \left(v^{n+1} - v^n, v^{n+1}\right)_{\Omega_{t^{n+1}}} \\ & \quad = \frac{1}{2T} \left[\left\|v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} - \left\|v^n\right\|^2_{L^2(\Omega_{t^{n+1}})} + \left\|v^{n+1} - v^n\right\|^2_{L^2(\Omega_{t^{n+1}})} \right]. \end{aligned}$$

Integrating (2.7) from t^n to t^{n+1} for the function $(v^n)^2$, we get

$$\frac{1}{T} \left\|v^n\right\|^2_{L^2(\Omega_{t^{n+1}})} = \frac{1}{T} \left\|v^n\right\|^2_{L^2(\Omega_{t^n})} + \int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1})(v^n)^2 \, \mathrm{d}\Omega \, \mathrm{d}s,$$

where we have profited from the fact that the discrete mesh velocity is constant at every time step. On the other hand, due to the fact that the convective velocity $\boldsymbol{a}$ is divergence-free, we get

$$\begin{aligned} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1}, v^{n+1}\right)_{\Omega_{t^{n+1}}} &= -\frac{1}{2} \int_{\Omega_{t^{n+1}}} \boldsymbol{w}^{n+1} \cdot \nabla (v^{n+1})^2 \, \mathrm{d}\Omega \\ &= \frac{1}{2} \int_{\Omega_{t^{n+1}}} (\nabla \cdot \boldsymbol{w}^{n+1})(v^{n+1})^2 \, \mathrm{d}\Omega. \end{aligned}$$

We bound the terms associated to the mesh velocity as follows:

$$\int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla\cdot\boldsymbol{w}^{n+1})(v^n)^2 \,\mathrm{d}\Omega\,\mathrm{d}s \leq \delta t \sup_{s\in(t^n,t^{n+1})} \left\| J_{\mathcal{A}_{t^{n+1},s}} \nabla\cdot\boldsymbol{w}^{n+1} \right\|_{L^\infty(\Omega_{t^{n+1}})} \|v^n\|^2_{L^2(\Omega_{t^{n+1}})},$$

$$-\delta t \int_{\Omega_{t^{n+1}}} \boldsymbol{w}^{n+1}\cdot\nabla(v^{n+1})^2 \,\mathrm{d}\Omega = \delta t \int_{\Omega_{t^{n+1}}} (\nabla\cdot\boldsymbol{w}^{n+1})(v^{n+1})^2 \,\mathrm{d}\Omega \leq \delta t \left\|\nabla\cdot\boldsymbol{w}^{n+1}\right\|_{L^\infty(\Omega_{t^{n+1}})} \left\|v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}.$$

Let us define the parameters

$$\gamma_1^{n+1} = T \sup_{s\in(t^n,t^{n+1})} \left\| J_{\mathcal{A}_{t^{n+1},s}} \nabla\cdot\boldsymbol{w}^{n+1} \right\|_{L^\infty(\Omega_{t^{n+1}})} \tag{3.1}$$

for $n=-1,\dots,N-2$ and $\gamma_1^N=0$, together with

$$\gamma_2^{n+1} = T \left\|\nabla\cdot\boldsymbol{w}^n\right\|_{L^\infty(\Omega_{t^{n+1}})} \tag{3.2}$$

for $n=0,\dots,N-1$ and $\gamma_2^0=0$.

With the inequalities just proved we can easily obtain that

$$B(V,V) + \frac{1}{2T}\sum_{n=-1}^{N-1} \delta t(\gamma_1^{n+1}+\gamma_2^{n+1}) \left\|v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \geq \sup_{n\in[-1,N-1]} \frac{1}{2T}\left\|v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} + \sum_{n=0}^{N-1} 2\delta t\nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}.$$

If the maximum of $\|v^n\|_{L^2(\Omega_{t^n})}$ is achieved at $n=N_m$, the sequence

$$\{v^0, v^1, \dots, v^{N_m}, 0, \dots, 0\}$$

has to be added to the test sequence. Sometimes in the paper we obtain the maximum using this technique. Invoking the Gronwall lemma (see [21]), we can absorb the second term of the left-hand side with the first term of the right-hand side for a δt small enough. More precisely, the time step must be such that

$$\delta t < \frac{1}{\sup_{n\in[0,N]}(\gamma_1^n+\gamma_2^n)} =: \delta t^1_{\mathrm{cr}}.$$

We note that this is the time step size of the *normalized* problem in time. The original δt^1_{cr} does not depend on T any longer. ∎

This result, together with the continuity of $L(\cdot)$ proved in the next lemma, will lead us to a classical stability bound.

LEMMA 3.2 (continuity). *The following inequality holds:*

$$L(V) \leq \sum_{n=0}^{N-1} \frac{\delta t}{2\beta\nu}\left\|f^{n+1}\right\|^2_{H^{-1}(\Omega_{t^{n+1}})} + \sum_{n=0}^{N-1}\frac{\delta t\beta\nu}{2}\left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} + \frac{1}{4T}\left\|u^0\right\|^2_{L^2(\Omega_0)} + \frac{1}{4T}\left\|v^0\right\|^2_{L^2(\Omega_0)}$$

for all $\beta>0$.

Proof. The right-hand side has the following expression:

$$L(V) = \frac{1}{2T}\left(u^0, v^0\right)_{\Omega_0} + \sum_{n=0}^{N-1} \delta t \langle f^{n+1}, v^{n+1}\rangle_{\Omega_{t^{n+1}}}.$$

The Cauchy–Schwarz inequality leads to

$$L(V) \leq \left(\sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\|f^{n+1}\right\|^2_{H^{-1}(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}} \left(\sum_{n=0}^{N-1} \delta t \nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}} + \frac{1}{2T}\left\|u^0\right\|_{L^2(\Omega_0)} \left\|v^0\right\|_{L^2(\Omega_0)}.$$

The proof is finished by invoking Young's inequality. ∎

From Theorem 3.1 and Lemma 3.2 the following stability result is straightforward.

COROLLARY 3.3 (stability). *There exists $\delta t^1_{\rm cr}$ such that, for $0 < \delta t < \delta t^1_{\rm cr}$, the sequence U, solution of problem* (2.9)–(2.11)*, is bounded as follows:*

$$|||U|||^2 \leq C\left\{\frac{1}{T}\left\|u^0\right\|^2_{L^2(\Omega_0)} + \sum_{n=0}^{N-1} \frac{\delta t}{\nu}\left\|f^{n+1}\right\|^2_{H^{-1}(\Omega_{t^{n+1}})}\right\}.$$

Remark 3.1. The BDF1 method is unconditionally stable for fixed domains. However, for moving domains this property is not maintained anymore. In this case only conditional stability can be proved, with the critical time step value obtained above.

The next task is to obtain an optimal convergence result. In the following theorem, relying on the stability properties proved in Corollary 3.3, *optimal* error estimates are obtained. We denote by $e^{n+1} := u(t^{n+1}) - u^{n+1}$ the error introduced by the time integration at time t^{n+1}, and by $E := U_{\rm ex} - U$ the sequence of these errors.

THEOREM 3.4 (convergence). *There exists $\delta t^1_{\rm cr}$ such that, for $0 < \delta t < \delta t^1_{\rm cr}$, the sequence of errors $E = U_{\rm ex} - U$ satisfies the following error estimate:*

$$|||E|||^2 \leq C\frac{\delta t^2}{T}\sum_{n=0}^{N-1}\delta t\left(\left\|\left.\frac{\partial^2 u}{\partial t^2}\right|_{\boldsymbol{x}_0}\right\|^2_{L^2(\Omega_{t^{n+1}})} + \sup_{s\in(t^n,t^{n+1})}\left\|\left|\frac{\partial^2 \mathcal{A}_s}{\partial t^2}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}\right). \tag{3.3}$$

Proof. We start by taking the exact solution sequence $U_{\rm ex}$ in the bilinear form. We get

$$B(U_{\rm ex}, V) = L(V) + \sum_{n=0}^{N-1}\frac{1}{T}\left(u(t^{n+1}) - u(t^n) - \delta t\left.\frac{\partial u}{\partial t}\right|_{t^{n+1}}, v^{n+1}\right)_{\Omega_{t^{n+1}}} - \sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1} - \boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}), v^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

We subtract the equation for the semidiscrete sequence of solutions to the previous

equations and arrive at

$$B(U-U_{\rm ex},V) = -\sum_{n=0}^{N-1}\frac{1}{T}\left(u(t^{n+1})-u(t^n)-\delta t\,\frac{\partial u}{\partial t}\Big|_{t^{n+1}},v^{n+1}\right)_{\Omega_{t^{n+1}}} + \sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}),v^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

We test the previous equation with $V = U - U_{\rm ex} = E$, obtaining

$$B(E,E) = -\sum_{n=0}^{N-1}\frac{1}{T}\left(u(t^{n+1})-u(t^n)-\delta t\,\frac{\partial u}{\partial t}\Big|_{t^{n+1}},e^{n+1}\right)_{\Omega_{t^{n+1}}} + \sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}),e^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

Exploiting the fact that the bilinear form is coercive, the remaining ingredient is an appropriate bound for the error terms associated to the time discretization. Let us start with the terms related to the time derivative. We use the following Taylor formula for u:

(3.4)
$$\frac{u(\boldsymbol{x}_0,t^{n+1})-u(\boldsymbol{x}_0,t^n)}{T\delta t}-\frac{1}{T}\,\frac{\partial u}{\partial t}\Big|_{\boldsymbol{x}_0}(t^{n+1}) = -\frac{1}{T\delta t}\int_{t^n}^{t^{n+1}}(s-t^n)\,\frac{\partial^2 u}{\partial t^2}\Big|_{\boldsymbol{x}_0}(s)\,\mathrm{d}s.$$

For the mesh velocity, we use

$$\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}) = -\frac{1}{T\delta t}\left(\int_{t^n}^{t^{n+1}}(s-t^n)\frac{\partial^2\mathcal{A}_s}{\partial t^2}\,\mathrm{d}s\right)\circ\mathcal{A}^{-1}_{t^{n+1}}. \tag{3.5}$$

As explained in section 2, it is understood with this notation that this equality holds for arbitrary $\boldsymbol{x}\in\Omega_t$.

With (3.4) we get a bound for the term associated to the time derivative of u as follows:

$$\begin{aligned}
&\int_{\Omega_{t^{n+1}}} e^{n+1}\cdot\left(\int_{t^n}^{t^{n+1}}(s-t^n)\,\frac{\partial^2 u}{\partial t^2}\Big|_{\boldsymbol{x}_0}(\boldsymbol{x}_0,s)\,\mathrm{d}s\right)\circ\mathcal{A}^{-1}_{t^{n+1}}\,\mathrm{d}\Omega\\
&\quad\le\int_{t^n}^{t^{n+1}}\int_{\Omega_0}J_{\mathcal{A}_{t^{n+1}}}(s-t^n)\widehat{e^{n+1}}\,\widehat{\frac{\partial^2 u}{\partial t^2}}\,\mathrm{d}\Omega\,\mathrm{d}s\\
&\quad\le\left(\int_{t^n}^{t^{n+1}}(s-t^n)^2\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac12}\\
&\qquad\times\left(\int_{t^n}^{t^{n+1}}\int_{\Omega_0}J_{\mathcal{A}_{t^{n+1}}}\left(\widehat{\frac{\partial^2 u}{\partial t^2}}\right)^2\mathrm{d}\Omega\,\mathrm{d}s\right)^{\frac12}\\
&\quad\le\frac{\beta_1\delta t}{2}\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}+C\delta t^3\left\|\frac{\partial^2 u}{\partial t^2}\Big|_{\boldsymbol{x}_0}\right\|^2_{L^2(\Omega_{t^{n+1}})},
\end{aligned}$$

where β_1 is the coercivity constant introduced in Theorem 3.1. Similarly, using (3.5) for the term related to the time derivative of the mapping, we get

$$
\begin{aligned}
&-\int_{\Omega_{t^{n+1}}} e^{n+1}\left(\int_{t^n}^{t^{n+1}} (s-t^n)\frac{\partial^2 \mathcal{A}_s}{\partial t^2}\,\mathrm{d}s\right)\circ\mathcal{A}_{t^{n+1}}^{-1}\cdot\nabla u^{n+1}\,\mathrm{d}\Omega\\
&\quad\le \int_{t^n}^{t^{n+1}}\int_{\Omega_0} J_{\mathcal{A}_{t^{n+1}}}(s-t^n)\widehat{e^{n+1}}\frac{\partial^2\mathcal{A}_s}{\partial t^2}\cdot\nabla\widehat{u^{n+1}}\,\mathrm{d}\Omega\,\mathrm{d}s\\
&\quad\le \left(\int_{t^n}^{t^{n+1}}(s-t^n)^2\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\,\mathrm{d}s\right)^{\frac{1}{2}}\\
&\qquad\times\left(\int_{t^n}^{t^{n+1}}\left\|\left|\frac{\partial^2\mathcal{A}_s}{\partial t^2}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}\,\mathrm{d}s\right)^{\frac{1}{2}}\\
&\quad\le \frac{\beta_1\delta t}{2}\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}+C\delta t^3\sup_{s\in(t^n,t^{n+1})}\left\|\left|\frac{\partial^2\mathcal{A}_s}{\partial t^2}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}.
\end{aligned}
$$

With these results we can write

$$
\begin{aligned}
B(E,E)\le\frac{1}{T}\sum_{n=0}^{N-1}\Bigg(&\delta t\beta_1\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}+C\delta t^3\left\|\left.\frac{\partial^2 u}{\partial t^2}\right|_{\boldsymbol{x}_0}\right\|^2_{L^2(\Omega_{t^{n+1}})}\\
&+C\delta t^3\sup_{s\in(t^n,t^{n+1})}\left\|\left|\frac{\partial^2\mathcal{A}_s}{\partial t^2}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}\Bigg).
\end{aligned}
\tag{3.6}
$$

At this point we invoke the coercivity property of the bilinear form proved in Theorem 3.1. Thus, the first term of the right-hand side in (3.6) can be absorbed using the Gronwall lemma. We note that in this case we can apply the Gronwall lemma without any extra condition over the time step size (see [21]). ∎

Clearly, the second term in the right-hand side of (3.3) is bounded if the second time derivatives of the ALE mapping are uniformly bounded in $[0,T]$. In this case, its norm in the space $L^\infty(0,T;L^\infty(\Omega_0))$ can be taken out of the sum, and the stability estimate of Corollary 3.3 allows us to bound the remaining term. However, we have kept expression (3.3) to display the structure of the error bound.

We conclude this subsection with the following improved stability estimate.

COROLLARY 3.5 (stability in $\ell^\infty(H^2(\Omega_t))$). *Under the conditions of Theorem* 3.4, *suppose additionally that the right-hand side of* (3.3) *is bounded, that* $u\in L^\infty(0,T;H^2(\Omega_t))$, *and that the domain* Ω_t *is such that* $\Delta u\in L^2(\Omega_t)$ *implies* $u\in H^2(\Omega_t)$. *Then,* $U\in\ell^\infty(H^2(\Omega_t))$.

Proof. At each time step we can write the error equation

$$
\begin{aligned}
\nu\Delta(u^{n+1}-u(t^{n+1}))=&(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla(u^{n+1}-u(t^{n+1}))\\
&+(\boldsymbol{w}(t^{n+1})-\boldsymbol{w}^{n+1})\cdot\nabla u(t^{n+1})+\frac{1}{\delta t}(u^{n+1}-u^n)-\left.\frac{\partial u}{\partial t}\right|_{t^{n+1}}.
\end{aligned}
$$

By virtue of Theorem 3.4, all the terms in the right-hand side are bounded in $L^2(\Omega_{t^{n+1}})$

for $n = 0, \dots, N-1$. Since

$$\|\Delta u^{n+1}\|_{L^2(\Omega_{t^{n+1}})} \leq \|\Delta u^{n+1} - \Delta u(t^{n+1})\|_{L^2(\Omega_{t^{n+1}})} + \|\Delta u(t^{n+1})\|_{L^2(\Omega_{t^{n+1}})},$$

it follows that $\{\Delta u^{n+1}\}_{n=0}^{N-1} \in \ell^\infty(L^2(\Omega_t))$. The assumption on the domain Ω_t implies that $\{u^{n+1}\}_{n=0}^{N-1} \in \ell^\infty(H^2(\Omega_t))$. ∎

This justifies our strategy of first analyzing the problem semidiscretized in time and then the fully discrete problem. When we will require $U \in \ell^2(H^{p+1}(\Omega_t))$ to obtain optimal order of convergence in space, we know that at least for $p = 1$ this holds under the same condition on the domain Ω_t as for the sequence of solutions of the continuous problem, U_{ex}. It is well known that this condition on Ω_t holds, for example, if it is convex and polyhedral (see, for example, [19]).

3.2. Analysis of BDF2-BDF2$_{\delta t}$. For the second order method we follow the same procedure used above. In this case the problem that we analyze can be written using (2.9) together with the bilinear form (2.13) and the right-hand side linear form (2.14), and we denote by $U = \{u^0, u^1, u^2, \dots, u^N\}$ the sequence of solutions of this problem.

We start by again proving that the corresponding bilinear form is coercive.

THEOREM 3.6 (coercivity). *There exists δt_{cr}^2 such that for $0 < \delta t < \delta t_{\text{cr}}^2$ the bilinear form $B(\cdot,\cdot)$ defined in (2.12) is coercive; that is, for every sequence $V = \{v^n\}_{n=0}^N$, with $v^n \in \mathcal{V}(\Omega_{t^n})$,*

$$B(V,V) \geq \beta_2 |||V|||^2$$

for a certain constant $\beta_2 > 0$.

Proof. We know, from the definition of the bilinear form, that

$$\begin{aligned} B(V,V) = &\sum_{n=0}^{N-1} \left[\delta t \left\| \nabla v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} + \delta t \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1}, v^{n+1} \right)_{\Omega_{t^{n+1}}} \right] \\ &+ \sum_{n=1}^{N-1} \frac{1}{2T} \left(3v^{n+1} - 4v^n + v^{n-1}, v^{n+1} \right)_{\Omega_{t^{n+1}}} + \frac{1}{T} \left(v^1 - v^0, v^1 \right)_{\Omega_{t^1}} \\ &+ \frac{1}{2T} \left\| v^0 \right\|^2_{L^2(\Omega_0)}. \end{aligned} \tag{3.7}$$

Integrating (2.7) from t^n to t^{n+1} for the functions v^n and $2v^n - v^{n-1}$, we can express the term corresponding to the discrete time derivative as follows:

$$\begin{aligned} &\frac{1}{2T}(3v^{n+1} - 4v^n + v^{n-1}, 4v^{n+1})_{\Omega_{t^{n+1}}} \\ &\quad = \frac{1}{T} \left(\left\| v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} - \|v^n\|^2_{L^2(\Omega_{t^n})} + \left\| 2v^{n+1} - v^n \right\|^2_{L^2(\Omega_{t^{n+1}})} \right. \\ &\qquad \left. - \left\| 2v^n - v^{n-1} \right\|^2_{L^2(\Omega_{t^n})} + \left\| \delta^2 v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} \right) \\ &\qquad + \int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1}(s))(v^n)^2 \, \mathrm{d}\Omega \, \mathrm{d}s \\ &\qquad + \int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1}(s))(2v^n - v^{n-1})^2 \, \mathrm{d}\Omega \, \mathrm{d}s. \end{aligned} \tag{3.8}$$

The mesh velocity terms are bounded as follows:

(3.9)
$$\int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1}(s))(v^n)^2 \,\mathrm{d}\Omega \,\mathrm{d}s + \int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1}(s))(2v^n - v^{n-1})^2 \,\mathrm{d}\Omega \,\mathrm{d}s$$
$$\leq \delta t \sup_{s\in(t^n,t^{n+1})} \left\| J_{\mathcal{A}_{t^{n+1},s}} \nabla \cdot \boldsymbol{w}^{n+1}(s) \right\|_{L^\infty(\Omega_{t^{n+1}})} \times \left(\|v^n\|^2_{L^2(\Omega_{t^{n+1}})} + \left\|2v^n - v^{n-1}\right\|^2_{L^2(\Omega_{t^{n+1}})} \right).$$

On the other hand, we can exploit the fact that the convective velocity $\boldsymbol{a}$ is divergence-free, obtaining for the convective term that

$$\begin{aligned} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1}, 4v^{n+1}\right)_{\Omega_{t^{n+1}}} &= -2\delta t \int_{\Omega_{t^{n+1}}} \boldsymbol{w}^{n+1} \cdot \nabla (v^{n+1})^2 \,\mathrm{d}\Omega \\ &= 2\delta t \int_{\Omega_{t^{n+1}}} (\nabla \cdot \boldsymbol{w}^{n+1})(v^{n+1})^2 \,\mathrm{d}\Omega \\ &\leq 2 \left\|\nabla \cdot \boldsymbol{w}^{n+1}\right\|_{L^\infty(\Omega_{t^{n+1}})} \left\|u_h^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}. \end{aligned} \tag{3.10}$$

We use inequalities (3.9) and (3.10) in (3.7) and invoke again the Gronwall lemma. This leads to the desired bound for a time step size:

$$\delta t < \frac{1}{\sup\limits_{n\in[0,N]} (\gamma_1^n + 2\gamma_2^n)} =: \delta t^2_{\mathrm{cr}},$$

slightly different from the one obtained for the first order method. ∎

The previous theorem and Lemma 3.2 allow us to obtain the same stability result as for the previous case, stated in the next corollary.

COROLLARY 3.7 (stability). *There exists δt^2_{cr} such that for $0 < \delta t < \delta t^2_{\mathrm{cr}}$ the sequence U solution of problem* (2.9), (2.13), (2.14) *is bounded as follows:*

$$|||U|||^2 \leq C \sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\|f^{n+1}\right\|^2_{H^{-1}(\Omega_{t^{n+1}})}.$$

Furthermore, we can obtain optimal error estimates under some regularity assumptions. For the sake of clearness we assume that the initialization is calculated exactly. It can be easily checked from Theorem 3.4 that the error introduced by the initialization is optimal.

THEOREM 3.8 (convergence). *There exist δt^2_{cr} such that for $0 < \delta t < \delta t^2_{\mathrm{cr}}$ the sequence of errors $E = U_{ex} - U$ satisfies the following error estimate:*

$$|||E|||^2 \leq C \frac{\delta t^4}{T} \sum_{n=0}^{N-1} \delta t \left(\left\| \left. \frac{\partial^3 u}{\partial t^3} \right|_{\boldsymbol{x}_0} \right\|^2_{L^2(\Omega_{t^{n+1}})} + \sup_{s\in(t^n,t^{n+1})} \left\| \left| \frac{\partial^3 \mathcal{A}_s}{\partial t^3} \right|^2 \right\|_{L^\infty(\Omega_0)} \left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})} \right).$$

Proof. We start by taking the exact solution sequence U_{ex} in the bilinear form. We get

$$B(U_{ex},V)=L(V)+\sum_{n=0}^{N-1}\frac{1}{2T}\left(3u(t^{n+1})-4u(t^n)+u(t^{n-1})-\delta t\,\frac{\partial u}{\partial t}\bigg|_{t^{n+1}},v^{n+1}\right)_{\Omega_{t^{n+1}}}$$
$$-\sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}),v^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

Now we subtract the equation for the semidiscrete sequence of solutions to the previous equations and arrive at

$$B(U-U_{ex},V)=-\sum_{n=0}^{N-1}\frac{1}{T}\left(3u(t^{n+1})-4u(t^n)+u(t^{n-1})-\delta t\,\frac{\partial u}{\partial t}\bigg|_{t^{n+1}},v^{n+1}\right)_{\Omega_{t^{n+1}}}$$
$$+\sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}),v^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

We test the previous equation with $V=U-U_{ex}=E$, obtaining

$$B(E,E)=-\sum_{n=0}^{N-1}\frac{1}{T}\left(3u(t^{n+1})-4u(t^n)+u(t^{n-1})-\delta t\,\frac{\partial u}{\partial t}\bigg|_{t^{n+1}},e^{n+1}\right)_{\Omega_{t^{n+1}}}$$
$$+\sum_{n=0}^{N-1}\delta t\left((\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1}))\cdot\nabla u(t^{n+1}),e^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

The truncation error introduced by the time integration scheme BDF2 is evaluated using the following Taylor formula:

(3.11)
$$\frac{3u(\boldsymbol{x}_0,t^{n+1})-4u(\boldsymbol{x}_0,t^n)+u(\boldsymbol{x}_0,t^{n-1})}{T\delta t}-\frac{1}{T}\,\frac{\partial u}{\partial t}\bigg|_{\boldsymbol{x}_0}(t^{n+1})$$
$$=-\frac{1}{T\delta t}\int_{t^{n-1}}^{t^{n+1}}(s-t^n)^2\,\frac{\partial^3 u}{\partial t^3}\bigg|_{\boldsymbol{x}_0}(s)\,\mathrm{d}s-\frac{1}{T\delta t}\int_{t^n}^{t^{n+1}}(s-t^n)^2\,\frac{\partial^3 u}{\partial t^3}\bigg|_{\boldsymbol{x}_0}(s)\,\mathrm{d}s.$$

The evaluation of the mesh velocity (2.6) requires a time derivative. Its numerical approximation using the second order BDF2 scheme can be written again as a truncation error:

$$\boldsymbol{w}^{n+1}-\boldsymbol{w}(t^{n+1})$$
$$=-\frac{1}{T\delta t}\left(\int_{t^n-1}^{t^{n+1}}(s-t^n)^2\frac{\partial^3\mathcal{A}_s}{\partial t^3}\,\mathrm{d}s+\int_{t^n}^{t^{n+1}}(s-t^n)^2\frac{\partial^3\mathcal{A}_s}{\partial t^3}\,\mathrm{d}s\right)\circ\mathcal{A}^{-1}_{t^{n+1}},\tag{3.12}$$

which holds for all $\boldsymbol{x}\in\Omega_t$. Recall that $\boldsymbol{w}^{n+1}$ stands for the mesh velocity evaluated at t^{n+1}.

The error related to the time derivative of u can be bounded using the following inequality:

$$\begin{aligned}\int_{\Omega_{t^{n+1}}} e^{n+1}\cdot\Bigg(&\int_{t^{n-1}}^{t^{n+1}}(s-t^n)^2\left.\frac{\partial^3 u}{\partial t^3}\right|_{\boldsymbol{x}_0}(s)\,\mathrm{d}s\\ &-\frac{1}{T\delta t}\int_{t^n}^{t^{n+1}}(s-t^n)^2\left.\frac{\partial^3 u}{\partial t^3}\right|_{\boldsymbol{x}_0}(s)\,\mathrm{d}s\Bigg)\circ\mathcal{A}^{-1}_{t^{n+1}}\,\mathrm{d}\Omega\\ &\le\frac{\beta_2\delta t}{2}\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}+C\delta t^5\left\|\left.\frac{\partial^2 u}{\partial t^2}\right|_{\boldsymbol{x}_0}\right\|^2_{L^2(\Omega_{t^{n+1}})},\end{aligned}\tag{3.13}$$

where β_2 is the coercivity constant introduced in Theorem 3.6.

We obtain the following inequality in order to bound the error introduced by the evaluation of the mesh velocity,

$$\begin{aligned}-\int_{\Omega_{t^{n+1}}} e^{n+1}\Bigg(&\int_{t^n-1}^{t^{n+1}}(s-t^n)^2\frac{\partial^3\mathcal{A}_s}{\partial t^3}\,\mathrm{d}s\\ &+\int_{t^n}^{t^{n+1}}(s-t^n)^2\frac{\partial^3\mathcal{A}_s}{\partial t^3}\,\mathrm{d}s\Bigg)\circ\mathcal{A}^{-1}_{t^{n+1}}\cdot\nabla u^{n+1}\,\mathrm{d}\Omega\\ &\le\frac{\beta_2\delta t}{2}\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}+\delta t^5\sup_{s\in(t^{n-1},t^{n+1})}\left\|\left|\frac{\partial^3\mathcal{A}_s}{\partial t^3}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}.\end{aligned}\tag{3.14}$$

Using the error expressions (3.11) and (3.12) and bounds (3.13) and (3.14), we get

$$\begin{aligned}B(E,E)\le\frac{1}{T}\sum_{n=0}^{N-1}\delta t\beta_2\left\|e^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}&+C\frac{\delta t^4}{T}\sum_{n=0}^{N-1}\delta t\left\|\left.\frac{\partial^3 u}{\partial t^3}\right|_{\boldsymbol{x}_0}\right\|^2_{L^2(\Omega_{t^{n+1}})}\\ &+C\frac{\delta t^4}{T}\sum_{n=0}^{N-1}\delta t\sup_{s\in(t^n,t^{n+1})}\left\|\left|\frac{\partial^3\mathcal{A}_s}{\partial t^3}\right|^2\right\|_{L^\infty(\Omega_0)}\left\|u^{n+1}\right\|^2_{H^1(\Omega_{t^{n+1}})}.\end{aligned}$$

Again, we can apply the Gronwall lemma without any extra condition over the time step size. ∎

4. The fully discrete problem. In this section we analyze the fully discrete problems BDF1-BDF1-OSS$_{\delta t,h}$ and BDF2-BDF2-OSS$_{\delta t,h}$. In both cases, stability and error estimates are obtained.

Observe from (2.20) that τ^n has been taken constant in space. Further, we assume Θ_h^t quasi-uniform. In this case, the following inverse estimate holds (see [5]):

$$\|\nabla v_h\|_{L^2(\Omega_t)}\le\frac{C_{\mathrm{inv}}}{h}\|v_h\|_{L^2(\Omega_t)}.\tag{4.1}$$

In order to obtain optimal convergence results, we assume that $u^{n+1}\in H^{p+1}(\Omega_t)$ for $n=0,\dots,N-1$, where p is the degree of the polynomial defining the finite element

space $\mathcal{V}_h$. We also assume that for any function $v \in H^{p+1}(\Omega_t)$ there exists a finite element interpolation $\pi_h(v)$ such that

$$\|v - \pi_h(v)\|_{H^m(\Omega_t)} \leq C_h h^{p+1-m} \|v\|_{H^{p+1}(\Omega_t)}.$$

We need to prove that the L^2-projection onto the finite element space is an optimal interpolation in the $L^2(\Omega_t)$-norm and the seminorm $\|\nabla(\cdot)\|_{L^2(\Omega_t)}$. We show this in the following lemma.

LEMMA 4.1. *Given a function $v \in H^{p+1}(\Omega_t)$ with $p \geq 1$, its L^2-projection onto the finite element space $\Pi_h(v)$ satisfies*

$$\|v - \Pi_h(v)\|_{L^2(\Omega_t)} \leq C_h h^{p+1} \|v\|_{H^{p+1}(\Omega_t)} \tag{4.2}$$

and also

$$h^2 \|\Delta v - \Pi_h(\Delta v)\|_{L^2(\Omega_t)} \leq C h^{p+1} \|v\|_{H^{p+1}(\Omega_t)}. \tag{4.3}$$

If the inverse estimate (4.1) *holds true,*

$$\|\nabla(v - \Pi_h(v))\|_{L^2(\Omega_t)} \leq C h^p \|v\|_{H^{p+1}(\Omega_t)} \tag{4.4}$$

is satisfied.

The proof of this lemma is straightforward and relies on classical interpolation inequalities.

As in the previous section, C is a positive constant, possibly with different values at different appearances.

4.1. Analysis of BDF1-BDF1-OSS$_{\delta t,h}$. In this subsection we analyze the fully discrete problem (2.17) with the bilinear form $B_h(\cdot,\cdot)$ defined in (2.18) and right-hand side (2.14). We denote by $U = \{u^0, u^1, u^2, \ldots, u^N\}$ the sequence of solutions of the semidiscrete problem (in time) (2.9)–(2.11) and by $U_h = \{u_h^0, u_h^1, u_h^2, \ldots, u_h^N\}$ its fully discrete counterpart, solution of (2.17), (2.18), (2.14).

We start by proving the coercivity of the bilinear form for the *weak* norm $|||\cdot|||_w$. This result will be used in the convergence analysis.

THEOREM 4.2 (coercivity). *There exists δt_{cr}^1 such that for $0 < \delta t < \delta t_{\mathrm{cr}}^1$ the bilinear form $B_h(\cdot,\cdot)$ defined in* (2.18) *is coercive. That is, for every sequence $V = \{v^n\}_{n=0}^N$, with $v^n \in \mathcal{V}(\Omega_{t^n})$,*

$$B_h(V,V) \geq \beta_1 |||V|||_w^2$$

for a certain constant $\beta_1 > 0$ independent of h.

Proof. The bilinear form analyzed in this theorem is equal to the one for which coercivity is proved in Theorem 3.1 plus the stabilization term. We can easily get

$$\begin{aligned} B_h(V,V) = {} & \frac{1}{2T} \left\|v^N\right\|_{L^2(\Omega^N)}^2 + \frac{1}{2T} \sum_{n=0}^{N-1} \left\|\delta v^{n+1}\right\|_{L^2(\Omega_{t^{n+1}})}^2 \\ & + \sum_{n=0}^{N-1} \left[\delta t \nu \left\|\nabla v^{n+1}\right\|_{L^2(\Omega_{t^{n+1}})}^2 + \delta t \tau^{n+1} \left\|\Pi_h^{\perp}\left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1}\right)\right\|_{L^2(\Omega_{t^{n+1}})}^2\right] \\ & + \frac{1}{2} \sum_{n=0}^{N-1} \delta t \left(\nabla \cdot \boldsymbol{w}^{n+1}, (v^{n+1})^2\right)_{\Omega_{t^{n+1}}} + \frac{1}{2} \sum_{n=0}^{N-1} \int_{t^n}^{t^{n+1}} \int_{\Omega_t} (\nabla \cdot \boldsymbol{w}^{n+1})(v^{n+1})^2 \, \mathrm{d}\Omega. \end{aligned} \tag{4.5}$$

Due to the fact that the stabilization term does not affect the treatment of the mesh velocity terms in Theorem 3.1, we refer to this theorem for the remainder of the proof. ∎

Let us define the Λ-coercivity property associated to a bilinear form that will be used in the following analysis.

DEFINITION 4.3 (Λ-coercivity). *Let $\mathcal{V}$ be a functional space and $\zeta : \mathcal{V} \times \mathcal{V} \longrightarrow \mathbb{R}$ a bilinear form. We say that ζ is Λ-coercive with respect to the norm $|||\cdot|||$ and the linear operator $\Lambda : \mathcal{V} \longrightarrow \mathcal{V}$ if there exists a constant $\beta > 0$ such that*

$$\zeta(v, \Lambda(v)) \geq \beta |||v|||^2 \quad \forall v \in \mathcal{V}. \tag{4.6}$$

The bilinear form $\zeta(\cdot,\cdot)$ also satisfies an *inf-sup* condition under the conditions of the following lemma.

LEMMA 4.4. *If Λ is continuous with respect to the norm $|||\cdot|||$ and $\zeta(\cdot,\cdot)$ is Λ-coercive, then there exists $\gamma > 0$ such that*

$$\inf_{u\in\mathcal{V}} \sup_{v\in\mathcal{V}} \frac{\zeta(u,v)}{|||u||| \, |||v|||} \geq \gamma.$$

The proof of the previous lemma is straightforward from Definition 4.3 and the continuity of the operator $\Lambda(\cdot)$.

We now show that the bilinear form $B_h(\cdot,\cdot)$ of our problem is Λ-coercive for the *strong* norm $|||\cdot|||_s$.

THEOREM 4.5 (Λ-coercivity). *Let $V = \{v^n\}_{n=0}^N$ be a sequence of functions such that $v^n \in \mathcal{V}(\Omega_{t^n})$ and consider the operator*

$$\Lambda(V) = V + \left\{0, \frac{1}{2}\left\{\tau^{n+1}\Pi_h\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\}_0^{N-1}\right\}.$$

Then, there exists δt^1_{cr} such that, for $0 < \delta t < \delta t^1_{\mathrm{cr}}$, the bilinear form $B_h(\cdot,\cdot)$ is Λ-coercive:

$$B_h\left(V, \Lambda(V)\right) \geq \beta_1 |||V|||_s^2$$

for a certain constant $\beta_1 > 0$ independent of h.

Proof. Testing (2.18) with the sequence of functions that belong to the finite element space

$$\Pi_0(\tau, V) := \{0, \{\tau^{n+1}\Pi_0(v^{n+1})\}\}_{n=0}^{N-1} := \{0, \{\tau^{n+1}\Pi_h\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\}_{n=0}^{N-1}\},$$

we have

$$\begin{aligned} B_h(V, \Pi_0(\tau, V)) \geq & \sum_{n=0}^{N-1} \phi^{n+1}\delta t\tau^{n+1} \left\|\Pi_h\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})} \\ & - \sum_{n=0}^{N-1}\left[\frac{1}{T}\left\|\delta v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} + \delta t\nu \left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\right. \\ & \left. + \delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left((\boldsymbol{a} - \boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right], \end{aligned} \tag{4.7}$$

where

$$\phi^{n+1} := 1 - \frac{1}{4}\frac{\tau^{n+1}}{T\delta t} - \frac{1}{4}\tau^{n+1}\frac{\nu C^2_{\mathrm{inv}}}{h^2} - \frac{1}{4}(\tau^{n+1})^2\frac{\left\|\boldsymbol{a} - \boldsymbol{w}^{n+1}\right\|^2_{L^\infty(\Omega_{t^{n+1}})} C^2_{\mathrm{inv}}}{h^2}. \tag{4.8}$$

To obtain (4.7) we have made use of Young's inequality and the inverse estimate (4.1). Assuming now that the constants c_1 and c_2 in (2.20) are such that $c_1 \leq C_{\text{inv}}^2$ and $c_2 \leq C_{\text{inv}}$ and the constant C in (2.21) is $C \leq 1$, it follows that $\phi^{n+1} \geq 1/4$.

The combination of (4.7) and (4.5) leads to

$$
\begin{aligned}
B_h(V, 2V + \Pi_0(\tau, V)) &\geq \frac{1}{T} \left\| v^N \right\|^2_{L^2(\Omega^N)} + \sum_{n=0}^{N-1} \delta t \nu \left\| \nabla v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + C \sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\| (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + \sum_{n=0}^{N-1} \delta t \left(\nabla \cdot \boldsymbol{w}^{n+1}, (v^{n+1})^2 \right)_{\Omega_{t^{n+1}}} + \sum_{n=0}^{N-1} \int_{t^n}^{t^{n+1}} \int_{\Omega_s} (\nabla \cdot \boldsymbol{w}^{n+1})(v^{n+1})^2 \, \mathrm{d}\Omega \, \mathrm{d}s \\
&\geq \frac{1}{T} \left\| v^N \right\|^2_{L^2(\Omega^N)} + \sum_{n=0}^{N-1} \delta t \nu \left\| \nabla v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + C \sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\| \Pi_h \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1} \right) \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad - \sum_{n=0}^{N-1} \delta t \gamma_{n+1} \left\| v^{n+1} \right\|^2_{L^2(\Omega_{t^{n+1}})},
\end{aligned}
$$

with $\gamma_{n+1} := \gamma_1^{n+1} + \gamma_2^{n+1}$ and γ_1^{n+1}, γ_2^{n+1} defined in (3.1) and (3.2). Using the Gronwall lemma, we finally get the coercivity stated in the theorem. We point out that the critical time step δt_{cr}^1 in this case is identical to the one obtained for the semidiscrete problem. ∎

In order to satisfy the continuity of $\Lambda(\cdot)$ needed to obtain the *inf-sup* condition in Lemma 4.4, we have to restrict the situation to the discrete finite element space $\mathcal{V}_h$.

LEMMA 4.6 (continuity). *Let $V_h = \{v_h^n\}_{n=0}^N$ be a finite element sequence such that $v_h^n \in \mathcal{V}_h(\Omega_{t^n})$, and consider the operator Λ introduced in Theorem 4.5. Then, $\Lambda(\cdot)$ is continuous with respect to the norm $|||\cdot|||_s$ for every finite element sequence V_h:*

$$
|||\Lambda(V_h)|||_s \leq \rho |||V_h|||_s \tag{4.9}
$$

for a certain constant $\rho > 0$ independent of h.

Proof. Defining $\Pi_0(\tau, V_h)$ as in the proof of the previous theorem, we have from the definition of the norm that

$$
\begin{aligned}
|||\Pi_0(\tau, V_h)|||_s^2 &= \frac{1}{T} \sup_{n \in [0, N-1]} \left\| \tau^{n+1} \Pi_0(v_h^{n+1}) \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + \sum_{n=0}^{N-1} \delta t \nu \left\| \tau^{n+1} \nabla \Pi_0(v_h^{n+1}) \right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + \sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\| \tau^{n+1} (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla \Pi_0(v_h^{n+1}) \right\|^2_{L^2(\Omega_{t^{n+1}})}.
\end{aligned} \tag{4.10}
$$

Invoking the expression for τ^{n+1} and the inverse estimate (4.1), we can easily bound every term by $|||V|||_s^2$. ∎

Remark 4.1. The fact that we need to use the inverse estimate (4.1) in order to bound *the first term in* (4.10) restricts the continuity of $\Lambda(\cdot)$ to finite element sequences (for the rest of the terms the inverse estimate is applied to derivatives of $\Pi_h((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v^{n+1})$, a finite element function even if v^{n+1} is not in the finite element space). However, this restriction does not complicate the convergence analysis, where only the Λ-coercivity is invoked.

From Lemmas 4.4 and 4.6 we obtain the *discrete inf-sup* condition.

COROLLARY 4.7 (discrete inf-sup condition). *Let* $U_h = \{u_h^n\}_{n=0}^N$ *and* $V_h = \{v_h^n\}_{n=0}^N$ *be sequences of finite element functions such that* $u^n, v^n \in \mathcal{V}(\Omega_{t^n})$. *There exists* δt_{cr}^1 *such that, for* $0 < \delta t < \delta t_{\text{cr}}^1$, *the bilinear form* $B_h(\cdot,\cdot)$ *satisfies the following condition:*

$$\inf_{U_h \in \mathcal{V}_h} \sup_{V_h \in \mathcal{V}_h} \frac{B_h\left(U_h, V_h\right)}{|||U_h|||_s \, |||V_h|||_s} \geq \widetilde{\beta}_1$$

for a certain constant $\widetilde{\beta}_1 > 0$ *independent of* h.

At this point, the only other ingredient needed for a stability result is the continuity of the *force term*, provided by Lemma 3.2. The stability result is stated in the next corollary.

COROLLARY 4.8 (stability). *There exists* δt_{cr}^1 *such that, for* $0 < \delta t < \delta t_{\text{cr}}^1$, *the sequence* U_h, *solution of problem* (2.17), (2.18), (2.11), *is bounded as follows:*

$$|||U_h|||_s^2 \leq C \sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|_{H^{-1}(\Omega_{t^{n+1}})}^2 .$$

For the convergence analysis, let us define the difference between the solution of (2.8) and (2.16) as $e_d^{n+1} := u_h^{n+1} - u^{n+1}$, and the sequence of these errors by E_d. From Theorem 4.5, which proves the Λ-coercivity of the bilinear form B_h for Λ defined in this theorem, we know that

$$B_h\left(E_d, \Lambda(E_d)\right) \geq \beta_1 |||E_d|||_s^2. \tag{4.11}$$

We subtract the discrete bilinear form (2.18) from its semidiscrete counterpart (2.10) tested with finite element sequences in order to get

$$\begin{aligned} B_h\left(E_d, V_h\right) &= \epsilon_c(V_h) \\ &:= -\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left(\Pi_h^{\perp} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla u^{n+1} \right), (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla v_h^{n+1} \right)_{\Omega_{t^{n+1}}}, \end{aligned}$$

where $\epsilon_c(V_h)$ accounts for the consistency error. After some manipulations, we can write

$$\begin{aligned} B_h\left(E_d, \Lambda(E_d)\right) &= B_h\left(E_d, E_d\right) + \frac{1}{2} B_h\left(E_d, \Pi_0(\tau, E_d)\right) \\ &= B_h\left(E_d, \Pi_h(U) - U\right) + \epsilon_c(U_h - \Pi_h(U)) + \frac{1}{2}\epsilon_c(\Pi_0(\tau, E_d)), \end{aligned}$$

where $\Pi_h(U) := \{\Pi_h(u^n)\}_{n=0}^N$.

We distinguish between *interpolation* error, the first term of the right-hand side, and the *consistency* error associated to the second and third terms. In the following

two lemmas we bound these error terms. We start with the interpolation error, obtaining the result stated in the following lemma.

LEMMA 4.9 (interpolation error). *The error sequence $E_d = U_h - U$ satisfies the following inequality:*

(4.12)
$$B_h\left(E_d, \Pi_h(U) - U\right) \leq C|||E_d|||_w \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.$$

Proof. Let us expand the expression of the interpolation error, making use of the definition of the bilinear form associated to the problem we are analyzing:

$$\begin{aligned}
&B_h\left(E_d, \Pi_h(U) - U\right) \\
&= \sum_{n=0}^{N-1} \Bigg[\frac{1}{T}\left(e_d^{n+1} - e_d^n, \Pi_h\left(u^{n+1}\right) - u^{n+1}\right)_{\Omega_{t^{n+1}}} \\
&\quad + \delta t \nu \left(\nabla e_d^{n+1}, \nabla(\Pi_h\left(u^{n+1}\right) - u^{n+1})\right)_{\Omega_{t^{n+1}}} \\
&\quad + \delta t \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1}, \Pi_h\left(u^{n+1}\right) - u^{n+1}\right)_{\Omega_{t^{n+1}}} \\
&\quad + \delta t \tau^{n+1} \left(\Pi_h^{\perp}\left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1}\right), (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla \left(\Pi_h\left(u^{n+1}\right) - u^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \Bigg].
\end{aligned}$$

We must control each term separately. Let us start with the discrete time derivative term. Using assumption (2.21) we have that

$$\begin{aligned}
&\sum_{n=0}^{N-1} \frac{1}{T}\left(e_d^{n+1} - e_d^n, \Pi_h\left(u^{n+1}\right) - u^{n+1}\right)_{\Omega_{t^{n+1}}} \\
&\qquad \leq C \left(\sum_{n=0}^{N-1} \frac{1}{T} \left\|e_d^{n+1} - e_d^n\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}} \\
&\qquad\quad \times \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.
\end{aligned}$$

For the viscosity term, using the definition of τ^{n+1} and the inverse estimate (4.5), we have that

$$\begin{aligned}
&\sum_{n=0}^{N-1} \delta t \nu \left(\nabla e_d^{n+1}, \nabla(\Pi_h\left(u^{n+1}\right) - u^{n+1})\right)_{\Omega_{t^{n+1}}} \\
&\qquad \leq C \left(\sum_{n=0}^{N-1} \delta t \nu \left\|\nabla e_d^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}} \\
&\qquad\quad \times \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.
\end{aligned}$$

Similar arguments allow us to obtain a bound for the convective term,

$$\sum_{n=0}^{N-1} \delta t \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1}, \Pi_h \left(u^{n+1} \right) - u^{n+1} \right)_{\Omega_{t^{n+1}}}$$

$$\leq C \left(\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\| \Pi_h^{\perp} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1} \right) \right\|^2_{L^2(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}$$

$$\times \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}, \tag{4.13}$$

and for the stabilization term we obtain

$$\sum_{n=0}^{N-1} \delta t \tau^{n+1}$$

$$\times \left(\Pi_h^{\perp} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1} \right), (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla \left(\Pi_h \left(u^{n+1} \right) - u^{n+1} \right) \right)_{\Omega_{t^{n+1}}}$$

$$\leq C \left(\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\| \Pi_h^{\perp} \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla e_d^{n+1} \right) \right\|^2_{L^2(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}$$

$$\times \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}.$$

All the terms have been bounded by the right-hand side of (4.12), and therefore the proof is finished. ∎

Remark 4.2. Invoking the interpolation error (4.2) in (4.13) has allowed us to obtain an optimal bound for the interpolation error without the control of the full convective term in the norm $|||\cdot|||_w$. This fact will be used for the analysis of the second order method.

The following lemma is devoted to the control of the consistency error. Since we are interested in smooth solutions, say $u \in L^2(0,T;H^{p+1}(\Omega_t))$ (with the obvious modifications for u less regular), we assume that f is also smooth, in particular $f \in L^2(0,T;H^{p-1}(\Omega_t))$. Thus, for $p \geq 1$, $\langle f, v_h \rangle_{\Omega_t} = (\Pi_h(f), v_h)_{\Omega_t}$. Therefore, the finite element solution is not altered if we assume $\Pi_h^{\perp}(f) = 0$.

LEMMA 4.10 (consistency error). *The following inequality holds:*

$$\epsilon_c \left(U_h - \Pi_h(U) + \frac{1}{2} \Pi_0(\tau, E_d) \right)$$

$$\leq C \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}$$

$$\times \left(|||E_d|||_s^2 + h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}. \tag{4.14}$$

Proof. From the expression of the consistency error we arrive at

$$
\begin{aligned}
&-\epsilon_c(U_h-\Pi_h(U))\\
&=\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}\right),(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla(u_h^{n+1}-\Pi_h\left(u^{n+1}\right))\right)_{\Omega_{t^{n+1}}}\\
&=\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}\right),(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla e_d^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&+\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}\right),(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla(u^{n+1}-\Pi_h\left(u^{n+1}\right))\right)_{\Omega_{t^{n+1}}}.
\end{aligned}
\tag{4.15}
$$

On the other hand, from the equation for the semidiscrete unknown (2.8), we can easily check that

$$
\begin{aligned}
&\left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}\right),v^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&\qquad=\left(\Pi_h^{\perp}\left(\nu\Delta u^{n+1}-\frac{1}{T\delta t}(u^{n+1}-u^n)\right),v^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&\qquad=:\left(\Pi_h^{\perp}\left(\lambda(u^{n+1})\right),v^{n+1}\right)_{\Omega_{t^{n+1}}},
\end{aligned}
\tag{4.16}
$$

where $\lambda(\cdot):=\nu\Delta(\cdot)-\frac{\delta(\cdot)}{T\delta t}$. Note that we have not included $\Pi_h^{\perp}(f)$ in the previous equation.

Now, using (4.16) in (4.15) we can split the error into two different terms bounded as follows:

$$
\begin{aligned}
&\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left(\Pi_h^{\perp}\left(\lambda(u^{n+1})\right),(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla e_d^{n+1}\right)_{\Omega_{t^{n+1}}}\\
&\qquad\le\ C\left(\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\lambda(u^{n+1})\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}\\
&\qquad\quad\times\left(\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla e_d^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}},
\end{aligned}
$$

$$
\begin{aligned}
&\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left(\Pi_h^{\perp}\left(\lambda(u^{n+1})\right),(\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla\left(u^{n+1}-\Pi_h\left(u^{n+1}\right)\right)\right)_{\Omega_{t^{n+1}}}\\
&\qquad\le\ C\left(\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\lambda(u^{n+1})\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}\\
&\qquad\quad\times\left(h^{2(p+1)}\sum_{n=0}^{N-1}\delta t(\tau^{n+1})^{-1}\left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.
\end{aligned}
$$

On the other hand, the term related to the perturbation of the test function $\Pi_0(\tau,E_d)$

appearing in (4.14) can be bounded using similar arguments, leading to

$$
\begin{aligned}
&\epsilon_c(\Pi_0(\tau, E_d)) \\
&= \sum_{n=0}^{N-1} \delta t \tau^{n+1} \left(\Pi_h^{\perp}\left(\lambda(u^{n+1})\right), (\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla\left(\tau^{n+1}\Pi_h\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla e_d^{n+1}\right)\right)\right)_{\Omega_{t^{n+1}}} \\
&\le C\left(\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\lambda(u^{n+1})\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}} \\
&\quad\times\left(\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla e_d^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.
\end{aligned}
$$

It remains only to prove that

$$
\sum_{n=0}^{N-1}\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\lambda(u^{n+1})\right)\right\|^2_{L^2(\Omega_{t^{n+1}})} \le Ch^{2(p+1)}\sum_{n=0}^{N-1}\delta t(\tau^{n+1})^{-1}\left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}.
$$

This inequality can be easily obtained from the expression of τ^{n+1}, assumption (2.21), and the interpolation error estimate (4.3). ∎

We end this section with the following main convergence result, which is a direct consequence of inequality (4.11) and Lemmas 4.9 and 4.10.

THEOREM 4.11 (convergence). *There exist δt^1_{cr} such that, for $0<\delta t<\delta t^1_{\mathrm{cr}}$, the sequence of errors $E_d = U_h - U$ satisfies the following error estimate:*

$$
|||E_d|||_s^2 \le Ch^{2(p+1)}\sum_{n=0}^{N-1}\delta t(\tau^{n+1})^{-1}\left\|u^{n+1}\right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}.
$$

4.2. Analysis of BDF2-BDF2-OSS$_{\delta t,h}$. In this subsection we analyze the fully discrete problem (2.17) with the bilinear form $B_h(\cdot,\cdot)$ defined in (2.22) and right-hand side (2.14). We denote by $U=\{u^0,u^1,u^2,\dots,u^N\}$ the sequence of solutions of the second order semidiscrete problem (in time) (2.9), (2.13), (2.14) and by $U_h = \{u_h^0,u_h^1,u_h^2,\dots,u_h^N\}$ its fully discrete counterpart, solution of (2.17), (2.22), (2.14).

We have obtained the results of this section using the *weak* norm $|||\cdot|||_w$. Let us start with a theorem proving coercivity under the *weaker* norm.

THEOREM 4.12 (coercivity). *There exists δt^2_{cr} such that, for $0<\delta t<\delta t^2_{\mathrm{cr}}$, the bilinear form $B_h(\cdot,\cdot)$ defined in (2.22) is coercive. That is, for every sequence $V=\{v^n\}_{n=0}^N$ with $v^n\in V(\Omega_{t^n})$*

$$
B_h(V,V) \ge \beta_2|||V|||_w^2
$$

for a certain constant $\beta_2>0$ independent of h.

Proof. It can be easily shown that

$$
\begin{aligned}
B_h(V,4V) &\ge \frac{1}{T}\left(\left\|v^N\right\|^2_{L^2(\Omega^N)} + \sum_{n=0}^{N-1}\left\|\delta^2 v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})}\right) \\
&\quad + \sum_{n=0}^{N-1} 4\delta t\nu\left\|\nabla v^{n+1}\right\|^2_{L^2(\Omega_{t^{n+1}})} + \sum_{n=0}^{N-1}4\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})} \\
&\quad + \int_{t^n}^{t^{n+1}}\int_{\Omega_s}(\nabla\cdot\boldsymbol{w}(s))(v^n)^2\,\mathrm{d}\Omega\,\mathrm{d}s + \int_{t^n}^{t^{n+1}}\int_{\Omega_s}(\nabla\cdot\boldsymbol{w}(s))(2v^n-v^{n-1})^2\,\mathrm{d}\Omega\,\mathrm{d}s.
\end{aligned}
$$

Manipulating the mesh velocity as for the BDF2-BDF2$_{\delta t}$ formulation (see Theorem 3.6) and applying the Gronwall lemma we obtain the desired result. ∎

Stability is now straightforward from Theorem 4.12 and Lemma 3.2.

COROLLARY 4.13 (stability). *There exists $\delta t_{\rm cr}^2$ such that, for $0 < \delta t < \delta t_{\rm cr}^2$, the sequence U_h, solution of problem* (2.17), (2.22), (2.14), *is bounded as follows:*

$$|||U_h|||_w^2 \leq C \sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|_{H^{-1}(\Omega_{t^{n+1}})}^2 .$$

This stability result can be considered *weak*. However, we will see that this result is enough to obtain error estimates that do not blow up for large Péclet numbers, the original motivation of stabilization methods for convection-diffusion problems.

Let us now obtain error estimates for the BDF2-BDF2-OSS$_{\delta t,h}$ formulation. We start with an auxiliary lemma that will be useful in what follows.

LEMMA 4.14. *Let $X = \{x^n\}_{n=0}^N$ and $V = \{v^n\}_{n=0}^N$ be two sequences of functions such that $x^n, v^n \in H^{p+1}(\Omega_{t^n})$. Then, the bilinear form* (2.22) *satisfies the following bound:*

$$B_h\left(X, \Pi_h^\perp(V)\right) \leq C \left(|||X|||_w^2 + \sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1} \|\Pi_h^\perp(x^{n+1})\|_{L^2(\Omega_{t^{n+1}})}^2 \right)^{\frac{1}{2}} \times \left(h^{2(p+1)} \sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| v^{n+1} \right\|_{H^{p+1}(\Omega_{t^{n+1}})}^2 \right)^{\frac{1}{2}} .$$

Proof. From (2.22) we have that

$$\begin{aligned} B_h\left(X, \Pi_h^\perp(V)\right) = & \sum_{n=0}^{N-1} b_h\left(\boldsymbol{w}^{n+1}; x^{n+1}, \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \\ & + \sum_{n=1}^{N-1} \frac{1}{2T}\left(3x^{n+1} - 4x^n + x^{n-1}, \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \\ & + \frac{1}{T}\left(x^1 - x^0, \Pi_h^\perp\left(v^1\right)\right)_{\Omega_{t^1}} + \frac{1}{T}\left(x^0, \Pi_h^\perp\left(v^0\right)\right)_{\Omega_0} , \end{aligned}$$

where

$$\begin{aligned} & \sum_{n=0}^{N-1} b_h\left(\boldsymbol{w}^{n+1}; x^{n+1}, \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \\ & = \sum_{n=0}^{N-1} \delta t \Big[\nu \left(\nabla x^{n+1}, \nabla \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} + \left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla x^{n+1}, \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \\ & \qquad + \tau^{n+1}\left(\Pi_h^\perp\left((\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla x^{n+1}\right), (\boldsymbol{a} - \boldsymbol{w}^{n+1}) \cdot \nabla \Pi_h^\perp\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} \Big] . \end{aligned}$$

Now we have to bound every term of the right-hand side in order to complete the proof. We start with the first term:

$$\begin{aligned} & \sum_{n=0}^{N-1} \delta t \nu \left(\nabla x^{n+1}, \nabla\left(\Pi_h^\perp\left(v^{n+1}\right)\right)\right)_{\Omega_{t^{n+1}}} \\ & \qquad \leq \left(\sum_{n=0}^{N-1} \delta t \nu \left\| \nabla x^{n+1} \right\|_{L^2(\Omega_{t^{n+1}})}^2 \right)^{\frac{1}{2}} \left(\sum_{n=0}^{N-1} \delta t \nu \left\| \nabla \Pi_h^\perp\left(v^{n+1}\right) \right\|_{L^2(\Omega_{t^{n+1}})}^2 \right)^{\frac{1}{2}} . \end{aligned}$$

The second term in the right-hand side can be bounded as

$$\sum_{n=0}^{N-1} \delta t \left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla x^{n+1}, \Pi_h^{\perp}\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}}$$
$$\leq \left(\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\|\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla x^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}$$
$$\times \left(\sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\|\Pi_h^{\perp}\left(v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}},$$

and the third term as

$$\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla x^{n+1}\right), (\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla\Pi_h^{\perp}\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}}$$
$$\leq \left(\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\|\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla x^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}$$
$$\times \left(\sum_{n=0}^{N-1} \delta t \tau^{n+1} \left\|\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla\Pi_h^{\perp}\left(v^{n+1}\right)\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.$$

The term related to the time derivative is bounded after recalling assumption (2.21) for the stabilization parameter τ^{n+1}:

$$\sum_{n=1}^{N-1} \frac{1}{2T}\left(3x^{n+1}-4x^n+x^{n-1}, \Pi_h^{\perp}\left(v^{n+1}\right)\right)_{\Omega_{t^{n+1}}} + \frac{1}{T}\left(x^1-x^0, \Pi_h^{\perp}\left(v^1\right)\right)_{\Omega_{t^1}}$$
$$+ \frac{1}{T}\left(x^0, \Pi_h^{\perp}\left(v^0\right)\right)_{\Omega_0} \leq C\left(\sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1}\left\|\Pi_h^{\perp}\left(x^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}$$
$$\times \left(\sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1}\left\|\Pi_h^{\perp}\left(v^{n+1}\right)\right\|^2_{L^2(\Omega_{t^{n+1}})}\right)^{\frac{1}{2}}.$$

We now have to use (4.4) of Lemma 4.1 and the expression (2.20) of the stabilization parameter τ^{n+1} to conclude the proof. ∎

To obtain the error estimate, we also need to invoke the coercivity of $B_h(\cdot,\cdot)$, which leads to

$$B_h\left(E_d, E_d\right) \geq \beta_2 |||E_d|||_w^2.$$

Subtracting the equation for the semidiscrete velocity and the discrete velocity, we get

$$B_h\left(E_d, V_h\right) =: \epsilon_c(V_h)$$
$$= -\sum_{n=0}^{N-1} \delta t \tau^{n+1}\left(\Pi_h^{\perp}\left((\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla u^{n+1}\right), (\boldsymbol{a}-\boldsymbol{w}^{n+1})\cdot\nabla v_h^{n+1}\right)_{\Omega_{t^{n+1}}}.$$

Using the previous equation, we can obtain

$$B_h\left(E_d, E_d\right) = B_h\left(E_d, \Pi_h(U) - U\right) + \epsilon_c(U_h - \Pi_h(U)).$$

The first term is due to the interpolation error, whereas the second is the consistency error. In the following lemma we obtain a bound for the interpolation error.

LEMMA 4.15 (interpolation error). *The following inequality holds:*

$$B_h\left(E_d, \Pi_h^{\perp}\left(U\right)\right) \leq C \left(|||E_d|||_w^2 + h^{2(p+1)} \sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}} \times \left(h^{2(p+1)} \sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}.$$

Proof. Invoking Lemma 4.14 and using the fact that $\Pi_h\left(U\right) - U = -\Pi_h^{\perp}\left(U\right)$ and $\Pi_h^{\perp}\left(E_d\right) = -\Pi_h^{\perp}\left(U\right)$, we immediately get the result. ∎

In order to bound the consistency error we again follow the technique developed in Lemma 4.10. The only difference between these two cases is the term associated to the time derivative, which does not essentially affect the proof.

LEMMA 4.16 (consistency error). *The following inequality holds:*

$$\epsilon_c(U_h - \Pi_h(U)) \leq C \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}} \times \left(|||E_d|||_w^2 + h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})} \right)^{\frac{1}{2}}.$$

Again, we end with the following desired convergence result, which is straight from Lemma 4.16 for the bound of the consistency error, Lemma 4.15 for the bound of the interpolation error, and Theorem 4.12, which gives coercivity of the bilinear form.

THEOREM 4.17 (convergence). *There exists δt_{cr}^2 such that, for $0 < \delta t < \delta t_{\text{cr}}^2$, the sequence of errors $E_d = U_h - U$ satisfies the following error estimate:*

$$|||E_d|||_w^2 \leq C h^{2(p+1)} \sum_{n=-1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| u^{n+1} \right\|^2_{H^{p+1}(\Omega_{t^{n+1}})}.$$

This error estimate is optimal.

From this analysis, we can easily obtain stability and convergence results when the domain is fixed, that is, when the mesh velocity vanishes.

4.3. Analysis of BDF2-OSS$_{\delta t,h}$. The previous results are new even for fixed domains. The OSS stabilization method was analyzed in [12] using the backward Euler time integration. It can be easily seen that for fixed domains, i.e., when $\boldsymbol{w}^{n+1} = \mathbf{0}$, there is no critical time step size, the method becoming unconditionally stable. In this case, the problem to be solved reads as follows: find a sequence of finite element functions U_h such that

$$B_h(U_h, V_h) = L(V_h) \tag{4.17}$$

with the bilinear form

$$B_h\left(U_h, V_h\right) = \sum_{n=1}^{N-1}\left[\frac{1}{2T}\left(3u_h^{n+1} - 4u_h^n + u_h^{n-1}, v_h^{n+1}\right) + b_h\left(u_h^{n+1}, v_h^{n+1}\right)\right]$$
$$+ \frac{1}{T}\left(u_h^1 - u_h^0, v_h^1\right) + b_h\left(u_h^1, v_h^1\right) + \frac{1}{T}\left(u_h^0, v_h^0\right), \tag{4.18}$$

where now $b_h(u_h^{n+1}, v_h^{n+1})$ denotes $b_h(\mathbf{0}; u_h^{n+1}, v_h^{n+1})$, with $b_h(\boldsymbol{w}^{n+1}; u_h^{n+1}, v_h^{n+1})$ defined in (2.19). The right-hand side linear form is given again by (2.14).

In this case two different sets of results are obtained. The first one with the *weak* norm $|||\cdot|||_w$, and the second one with the *strong* norm $|||\cdot|||_s$. The main difference is that in the second norm, $B_h(\cdot,\cdot)$ loses coercivity. This complicates the analysis.

We state the results with the norm $|||\cdot|||_w$ in the following corollaries. Their proofs are straightforward from the previous analysis.

COROLLARY 4.18 (stability). *The sequence U_h solution of problem* (4.17) *is bounded as follows:*

$$|||U_h|||_w^2 \leq C\sum_{n=0}^{N-1}\frac{\delta t}{\nu}\left\|f^{n+1}\right\|_{H^{-1}(\Omega)}^2$$

for all $\delta t > 0$.

Again, we denote by $U = \{u^0, u^1, u^2, \ldots, u^N\}$ the sequence of solutions of the second order semidiscrete problem (in time) (2.9), (2.13), (2.14), now with $\Omega_t \equiv \Omega$.

COROLLARY 4.19 (convergence). *The error sequence $E_d = U_h - U$ satisfies the following error estimate:*

$$|||E_d|||_w^2 \leq Ch^{2(p+1)}\sum_{n=-1}^{N-1}\delta t(\tau^{n+1})^{-1}\|u^{n+1}\|_{H^{p+1}(\Omega)}^2$$

for all $\delta t > 0$.

The remainder of this section is devoted to improving these stability and convergence estimates. The improvement consists in obtaining estimates in the *stronger* norm $|||\cdot|||_s$. This is possible for *fixed* domains, but we have not been able to obtain estimates similar to those presented next for *moving* domains. Nevertheless, some additional assumptions will be required. We will also note the aspects that make the analysis of the BDF2-OSS$_{\delta t,h}$ method much more involved than that of the BDF1-OSS$_{\delta t,h}$ formulation.

Let us introduce some new notation. We modify the bilinear form as

$$B_h^*\left(U_h, V_h\right) = \sum_{n=0}^{N-1} b_h\left(u_h^{n+1}, v_h^{n+1}\right) + \sum_{n=1}^{N-1}\frac{1}{2T}(3u_h^{n+1} - 4u_h^n + u_h^{n-1}, v_h^{n+1})$$
$$+ \frac{1}{T}(u_h^1 - u_h^0, v_h^1) + \frac{1}{T}(u_h^0, v_h^0) + \frac{1}{T\delta t}(u_h^{-1}, v_h^{-1}), \tag{4.19}$$

and the right-hand-side linear form as

$$L^*(V_h) = \sum_{n=0}^{N-1}\delta t\langle f^{n+1}, v_h^{n+1}\rangle + \frac{1}{T}(u_0, v_h^0) + \frac{1}{T\delta t}(u_{1,h} - \Pi_h(u_0), v_h^{-1}), \tag{4.20}$$

where u_0 is obviously the initial condition and $u_{1,h}$ is the solution at the first time step obtained with the scheme used to initialize the BDF2 scheme. For example, the BDF1 scheme can be used, and this is precisely what is assumed in the expression of $B_h^*(\cdot,\cdot)$. Note that now the sequences of finite element functions start at $n=-1$.

It is easily checked that the solution of (2.9) with the bilinear form (2.12) is equivalent to

$$B_h^*(U_h, V_h) = L^*(V_h).$$

Observe that this problem yields $u_h^{-1} = u_{1,h} - \Pi_h(u_0)$, $u_h^0 = \Pi_h(u_0)$, and $u_h^1 = u_{1,h}$. The rest of the terms of the sequence of unknowns $U = \{u_h^{-1}, u_h^0, u_h^2, \dots, u_h^N\}$ are the same as those in the solution of problem (4.17).

Let us introduce some additional ingredients. Given a sequence

$$V = \{v^{-1}, v^0, v^1, v^2, \dots, v^N\},$$

we define

$$d^{1,*}(V) = \{0, 0, 0, \delta v^2, \delta v^3, \dots, \delta v^{N-1}, \delta v^N\},$$
$$d^{2,*}(V) = \{0, 0, -\delta v^2, -\delta^2 v^2, -\delta^2 v^3, \dots, -\delta^2 v^N, \delta v^N\}.$$

These operators on sequences have the following property: for all sequences $X = \{x^n\}_{n=-1}^N$ it holds that

$$\begin{aligned} B_h^*\left(X, d^{2,*}(V)\right) &= \sum_{n=1}^{N-1} b_h\left(\delta x^{n+1}, \delta v^{n+1}\right) + \sum_{n=2}^{N-1} \frac{1}{2T}(3\delta x^{n+1} - 4\delta x^n + \delta x^{n-1}, \delta v^{n+1}) \\ &\quad + \frac{3}{2T}(\delta x^2 - \delta x^1, \delta v^2) \\ &= B_h^*\left(d^{1,*}(X), d^{1,*}(V)\right) + \frac{1}{2T}(\delta x^1, \delta v^3 - 3\delta v^2). \end{aligned} \tag{4.21}$$

Remark 4.3. The previous property is not satisfied for moving domains due to the fact that the convective velocity changes at every time step. It introduces an extra term $b_h\left(\delta \boldsymbol{w}^{n+1}; u^n, \delta v^{n+1}\right)_{\Omega_{t^{n+1}}}$ that cannot be bounded as required in the following analysis.

In the next theorem we obtain Λ-coercivity for the norm $|||\cdot|||_s$.

THEOREM 4.20 (Λ-coercivity). *Let $V = \{v^n\}_{n=-1}^N$ be a sequence of functions such that $v^n \in \mathcal{V}(\Omega)$, $n = 0, 1, \dots, N$, and $v^{-1} = v^1 - v^0$, and consider the operator*

$$\Lambda(V) = V + \left\{0, 0, \frac{1}{4}\{\tau^{n+1}\Pi_h\left(\boldsymbol{a}\cdot\nabla v^{n+1}\right)\}_0^{N-1}\right\} + \delta t^{-1} d^{2,*}(V).$$

Then, the bilinear form $B_h^*(\cdot,\cdot)$ is Λ-coercive. In particular, the following inequality holds:

$$B_h^*(V, \Lambda(V)) \geq \beta_2\left(|||V|||_s^2 + \delta t^{-1}|||d^{1,*}(V)|||_w^2 + \frac{1}{T\delta t}\|v^{-1}\|_{L^2(\Omega)}^2\right)$$

for a certain constant $\beta_2 > 0$ independent of h.

Proof. It can be easily shown that

$$
\begin{aligned}
&B_h^*(V,4V)\\
&\quad=\sum_{n=0}^{N-1}4b_h\left(v^{n+1},v^{n+1}\right)+\sum_{n=2}^{N-1}\frac{4}{2T}\left(3v^{n+1}-4v^n+v^{n-1},v^{n+1}\right)\\
&\qquad+\frac{4}{T}\left(v^1-v^0,v^1\right)+\frac{4}{T}\left(v^0,v^0\right)+\frac{4}{T\delta t}\left(v^{-1},v^{-1}\right)\\
&\quad\geq\sum_{n=0}^{N-1}4\left[\delta t\nu\left\|\nabla v^{n+1}\right\|_{L^2(\Omega)}^2+\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\boldsymbol{a}\cdot\nabla v^{n+1}\right)\right\|_{L^2(\Omega)}^2\right]\\
&\qquad+\frac{1}{T}\left[\left\|v^{N+1}\right\|_{L^2(\Omega)}^2+\sum_{n=1}^{N-1}\left\|\delta^2v^{n+1}\right\|_{L^2(\Omega)}^2+2\left\|v^0\right\|_{L^2(\Omega)}^2+\frac{4}{\delta t}\|v^{-1}\|_{L^2(\Omega)}^2\right].
\end{aligned}
$$

In order to obtain stability for the component of the convective term in the finite element space, we use as test function the sequence $\{0,0,\{\tau^{n+1}\Pi_h(\boldsymbol{a}\cdot\nabla v^{n+1})\}_0^{N-1}\}=:\Pi_0(\tau,V)$ which starts with 0 in the components -1 and 0. Exactly as in the proof of Theorem 4.5, we now obtain

$$
\begin{aligned}
B_h^*\left(V,\Pi_0(\tau,V)\right)&\geq\sum_{n=0}^{N-1}\phi^{n+1}\delta t\tau^{n+1}\left\|\Pi_h\left(\boldsymbol{a}\cdot\nabla v^{n+1}\right)\right\|_{L^2(\Omega)}^2\\
&\quad-\sum_{n=0}^{N-1}\left[\delta t\nu\left\|\nabla v^{n+1}\right\|_{L^2(\Omega)}^2+\delta t\tau^{n+1}\left\|\Pi_h^{\perp}\left(\boldsymbol{a}\cdot\nabla v^{n+1}\right)\right\|_{L^2(\Omega)}^2\right]\\
&\quad-\sum_{n=1}^{N-1}\frac{1}{4T}\left\|3v^{n+1}-4v^n+v^{n-1}\right\|_{L^2(\Omega)}^2-\frac{1}{T}\left\|v^1-v^0\right\|_{L^2(\Omega)}^2,
\end{aligned}
\tag{4.22}
$$

with the expression of ϕ^{n+1} given in (4.8). We do not have control over the term related to the time derivative needing a further step. We now use as test function $d^{2,*}(V)$. From the first step in (4.21) it follows that

$$
\begin{aligned}
\delta t^{-1}B_h^*\left(V,4d^{2,*}(V)\right)&\geq\delta t^{-1}|||d^{1,*}(V)|||_w^2-\frac{3}{T\delta t}\left\|\delta v^1\right\|_{L^2(\Omega)}^2\\
&=\delta t^{-1}|||d^{1,*}(V)|||_w^2-\frac{3}{T\delta t}\left\|v^{-1}\right\|_{L^2(\Omega)}^2.
\end{aligned}
\tag{4.23}
$$

Combining the previous inequalities and invoking the Gronwall lemma (without any assumption over the time step size) we can conclude the proof of the theorem. ∎

Remark 4.4. In (4.22) we do not have control over the term associated to the time derivative. It makes the analysis for the second order method more intricate than for the first order method, for which the time derivative term is easily controlled (see (4.7)). The control of this term has motivated the introduction of $d^{2,*}(V)$ in the test sequence used.

In order to obtain stability it remains to prove some kind of continuity with respect to the operator Λ. This is what the next theorem states.

THEOREM 4.21 (Λ-continuity). *The following inequality holds:*

$$L^*(\Lambda(V)) \leq \left(\sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N-1} \frac{\delta t^2}{\nu} \left\| D_1 f^{n+1} \right\|^2_{H^{-1}(\Omega)} \right.$$
$$\left. + \frac{1}{T} \left\| u_0 \right\|^2_{L^2(\Omega)} + \frac{\delta t}{T} \left\| \frac{u_{1,h} - \Pi_h\left(u_0\right)}{\delta t} \right\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}}$$
$$\times \left(|||V|||_s^2 + \delta t^{-1} |||d^{1,*}(V)|||_w^2 + \frac{1}{T} \left\| v^0 \right\|^2_{L^2(\Omega)} + \frac{1}{T\delta t} \| v^{-1} \|^2_{L^2(\Omega)} \right)^{\frac{1}{2}}.$$

Proof. The following inequalities can be easily obtained:

$$L^*(V) \leq \left(\sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|^2_{H^{-1}(\Omega)} + \frac{1}{T} \left\| u_0 \right\|^2_{L^2(\Omega)} + \frac{\delta t}{T} \left\| \frac{u_{1,h} - \Pi_h\left(u_0\right)}{\delta t} \right\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}}$$
$$\times \left(\sum_{n=0}^{N-1} \delta t \nu \left\| \nabla v^{n+1} \right\|^2_{L^2(\Omega)} + \frac{1}{T} \left\| v^0 \right\|^2_{L^2(\Omega)} + \frac{1}{T\delta t} \left\| v^{-1} \right\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}},$$

$$L^*(\delta t^{-1} d^{2,*}(V)) \leq \left(\sum_{n=1}^{N-1} \frac{\delta t^2}{\nu} \left\| D_1 f^{n+1} \right\|^2_{H^{-1}(\Omega)} \right)^{\frac{1}{2}} \left(\sum_{n=1}^{N-1} \delta t^2 \nu \left\| D_1 v^{n+1} \right\|^2_{H^1(\Omega)} \right)^{\frac{1}{2}},$$

$$L^*(\Pi_0(\tau, V)) \leq \left(\sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|^2_{H^{-1}(\Omega)} \right)^{\frac{1}{2}}$$
$$\times \left(\sum_{n=0}^{N-1} \delta t \nu \left\| \tau^{n+1} \nabla (\Pi_h \left(\boldsymbol{a} \cdot \nabla v^{n+1} \right)) \right\|^2_{L^2(\Omega)} \right)^{\frac{1}{2}},$$

and

$$\nu \left\| \tau^{n+1} \nabla \left(\Pi_h \left(\boldsymbol{a} \cdot \nabla v^{n+1} \right) \right) \right\|^2_{L^2(\Omega)} \leq \frac{C_{\text{inv}}^2 \nu}{h^2} (\tau^{n+1})^2 \left\| \Pi_h \left(\boldsymbol{a} \cdot \nabla v^{n+1} \right) \right\|^2_{L^2(\Omega)}$$
$$\leq C \tau^{n+1} \left\| \boldsymbol{a} \cdot \nabla v^{n+1} \right\|^2_{L^2(\Omega)}.$$

From all these inequalities the theorem follows easily. ∎

The two previous theorems lead to the following stability result.

COROLLARY 4.22 (stability II). *The sequence U_h, solution of problem* (4.17), *is bounded as follows:*

$$|||U_h|||_s^2 + \delta t^{-1} |||d^{1,*} U_h|||_w^2$$
$$\leq C \left(\sum_{n=0}^{N-1} \frac{\delta t}{\nu} \left\| f^{n+1} \right\|^2_{H^{-1}(\Omega)} + \sum_{n=1}^{N-1} \frac{\delta t^2}{\nu} \left\| D_1 f^{n+1} \right\|^2_{H^{-1}(\Omega)} \right.$$
$$\left. + \frac{1}{T} \left\| u^0 \right\|^2_{L^2(\Omega)} + \frac{\delta t}{T} \left\| \frac{u_{1,h} - \Pi_h\left(u_0\right)}{\delta t} \right\|^2_{L^2(\Omega)} \right)$$

for all $\delta t > 0$.

Obviously, this stability bound makes sense if the initialization is such that the last term on the right-hand side is bounded. Using, for example, the backward Euler scheme, it is easy to show that this last term is bounded if $h^{p+1} \leq CT\delta t$, and this condition is automatically satisfied thanks to assumption (2.21).

The final result we obtain is an error estimate in the *strong* norm $|||\cdot|||_s$. At this point we introduce the sequence $U = \{u_h^{-1}, u^0, u^1, u^2, \dots, u^N\}$, which consists of the sequence of solutions of the semidiscrete problem (2.9)–(2.11) supplemented with u_h^{-1} at $n = -1$. It can be easily checked that this sequence satisfies

$$B_h^*(U, V) = L^*(V) - \epsilon_c(V).$$

Thus, $E_d := U_h - U = \{0, u_h^0 - u^0, u_h^1 - u^1, \dots, u_h^N - u^N\}$ satisfies

$$B_h^*(E_d, V_h) = \epsilon_c(V_h).$$

We point out that for fixed domains the critical time step size does not appear anymore due to the fact that $\boldsymbol{w} = \mathbf{0}$. The method is unconditionally stable, as expected.

We stress the fact that $e_d^{-1} \neq e_d^1 - e_d^0$, and therefore E_d does not verify the statement of Theorem 4.20. The only place where the fact that $v^{-1} = v^1 - v^0$ is used is in (4.23). When the test sequence does not satisfy the assumption $v^{-1} = v^1 - v^0$ of Theorem 4.20, we have to modify the Λ-coercivity proved in this theorem as follows:

$$\frac{4}{T\delta t}\left\|\delta e_d^1\right\|_{L^2(\Omega)}^2 + B_h^*(E_d, \Lambda(E_d)) \geq \beta_2\left(|||E_d|||_s^2 + \delta t^{-1}|||d^{1,*}(E_d)|||_w^2\right). \tag{4.24}$$

With the expression of $\Lambda(\cdot)$ given in Theorem 4.20, we arrive at

$$\begin{aligned} B_h^*(E_d, \Lambda(E_d)) &= B_h^*(E_d, E_d) + \frac{1}{4}\epsilon_c(\Pi_0(\tau, E_d)) + \delta t^{-1} B_h^*\left(E_d, d^{2,*}E_d\right) \\ &= B_h^*(E_d, \Pi_h(U) - U) + \epsilon_c(U_h - \Pi_h(U)) + \frac{1}{4}\epsilon_c(\Pi_0(\tau, E_d)) \\ &\quad + \delta t^{-1} B_h^*\left(E_d, d^{2,*}(\Pi_h(U) - U)\right) + \delta t^{-1}\epsilon_c(d^{2,*}(U_h - \Pi_h(U))). \end{aligned} \tag{4.25}$$

Again, we group the different terms as interpolation and consistency errors and bound them separately in the next lemmas.

LEMMA 4.23 (interpolation error). *The following inequality holds:*

$$\begin{aligned} &B_h^*\left(E_d, \Pi_h^\perp(U)\right) + \delta t^{-1} B_h^*\left(E_d, d^{2,*}(\Pi_h^\perp(U)\right) \\ &\quad \leq \Bigg(|||E_d|||_w^2 + \delta t^{-1}|||d^{1,*}(E_d)|||_w^2 \\ &\qquad + h^{2(p+1)} \sum_{n=0}^{N-1} \delta t(\tau^{n+1})^{-1}\left(\left\|u^{n+1}\right\|_{H^{p+1}(\Omega)}^2 + \left\|\sqrt{\delta t} D_1 u^{n+1}\right\|_{H^{p+1}(\Omega)}^2\right)\Bigg)^{\frac{1}{2}} \\ &\qquad \times \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t(\tau^{n+1})^{-1}\left(\left\|u^{n+1}\right\|_{H^{p+1}(\Omega)}^2 + \left\|\sqrt{\delta t} D_1 u^{n+1}\right\|_{H^{p+1}(\Omega)}^2\right)\right)^{\frac{1}{2}}. \end{aligned}$$

Proof. The bound for the first term of the left-hand side of the inequality is easily obtained from the proof of Lemma 4.15, since $e_d^{-1} = 0$. For the second term we use property (4.21) and again the fact that $e_d^{-1} = 0$, getting

$$\begin{aligned} &B_h^*\left(E_d, d^{2,*}(\Pi_h^\perp(U))\right) \\ &\quad = B_h(d^{1,*}(E_d), d^{1,*}(\Pi_h^\perp(U))) - \frac{1}{2T}\left(\delta e_d^1, \delta\left(\Pi_h\left(u^3\right) - 3\Pi_h\left(u^2\right)\right)\right). \end{aligned}$$

Note that when we write $B_h(d^{1,*}(E_d), d^{1,*}(\Pi_h^\perp(U)))$ we eliminate the element -1 of the sequences to apply the bilinear form $B_h(\cdot,\cdot)$.

Using Lemma 4.14 we get

$$\begin{aligned}
&\delta t^{-1} B_h(d^{1,*}(E_d), d^{1,*}(\Pi_h^\perp(U))) \\
&\quad \leq C \left(\delta t^{-1} |||d^{1,*} E_d|||_w^2 + h^{2(p+1)} \sum_{n=1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right)^{\frac{1}{2}} \\
&\qquad \times \left(h^{2(p+1)} \sum_{n=1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right)^{\frac{1}{2}}.
\end{aligned}$$

Exploiting the fact that $\Pi_h^\perp\left(e_d^1\right) = \Pi_h\left(u^1\right) - u^1$, we can easily get that

$$\begin{aligned}
&\frac{1}{2T\delta t} \left(\delta e_d^1, \delta \left(\Pi_h\left(u^3\right) - 3\Pi_h\left(u^2\right) \right) \right) \\
&\qquad \leq C h^{2(p+1)} \sum_{n=0}^{2} \delta t (\tau^{n+1})^{-1} \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2.
\end{aligned}$$

The proof is concluded. ∎

LEMMA 4.24 (consistency error). *The following inequality holds:*

$$\begin{aligned}
&\epsilon_c \left(U_h - \Pi_h(U) + \frac{1}{4} \Pi_0(\tau, E_d) + \delta t^{-1} d^{2,*}(U_h - \Pi_h(U)) \right) \\
&\leq C \left(h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left(\left\| u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 + \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right) \right)^{\frac{1}{2}} \\
&\times \left(|||E_d|||_w^2 + h^{2(p+1)} \sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left(\left\| u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 + \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right) \right)^{\frac{1}{2}}.
\end{aligned}$$

Proof. Due to the fact that $e_d^{-1} = 0$, we can profit from the bounds obtained in Lemmas 4.10 and 4.16. The remaining term associated to $d^{2,*}(\cdot)$ can be bounded as follows:

$$\begin{aligned}
\epsilon_c(\delta t^{-1} d^{2,*}(U_h - \Pi_h(U))) &= \sum_{n=1}^{N-1} \tau^{n+1} \left(\Pi_h^\perp \left(\boldsymbol{a} \cdot \nabla \delta u^{n+1} \right), \boldsymbol{a} \cdot \nabla \Pi_h^\perp \left(\delta u^{n+1} \right) \right) \\
&= \sum_{n=1}^{N-1} \tau^{n+1} \left(\Pi_h^\perp \left(\lambda(\delta u^{n+1}) \right), \boldsymbol{a} \cdot \nabla \Pi_h^\perp \left(\delta u^{n+1} \right) \right) \\
&\leq C \left(\sum_{n=1}^{N-1} \delta t \tau^{n+1} \left\| \Pi_h^\perp \left(\sqrt{\delta t} \lambda(D_1 u^{n+1}) \right) \right\|_{L^2(\Omega)}^2 \right)^{\frac{1}{2}} \\
&\quad \times \left(h^{2(p+1)} \sum_{n=1}^{N-1} \delta t (\tau^{n+1})^{-1} \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right)^{\frac{1}{2}},
\end{aligned}$$

with $\lambda(\cdot)$ introduced in Lemma 4.10. The term related to $\lambda(D_1 u^{n+1})$ can be easily bounded from the expression of τ^{n+1}, assumption (2.19), and the interpolation error estimate (4.3), as pointed out in Lemma 4.10. ∎

We end with the convergence result of the method in the norm $|||\cdot|||_s$.

THEOREM 4.25 (convergence II). *The sequence of errors $E_d = U_h - U$ satisfies the following error estimate:*

$$|||E_d|||_s^2 \leq Ch^{2(p+1)} \left[\sum_{n=0}^{N-1} \delta t (\tau^{n+1})^{-1} \left(\left\| u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 + \left\| \sqrt{\delta t} D_1 u^{n+1} \right\|_{H^{p+1}(\Omega)}^2 \right) \right.$$

$$\left. + (\tau^1)^{-1} \left\| u^1 \right\|_{H^{p+1}(\Omega)} + (\tau^1)^{-1} \left\| u^0 \right\|_{H^{p+1}(\Omega)} \right] \tag{4.26}$$

for all $\delta t > 0$.

Proof. Using Lemmas 4.23 and 4.24 in expressions (4.24) and (4.25), we can easily get the desired bound for $|||E_d|||_s^2$ in terms of $\frac{4}{T\delta t} \left\| \delta e_d^1 \right\|_{L^2(\Omega)}^2$. Using as initialization the backward Euler scheme and the convergence result of Theorem 4.11 for the semidiscrete problem, it follows that

$$\begin{aligned} \frac{1}{T\delta t} \left\| \delta e_d^1 \right\|_{L^2(\Omega)}^2 &\leq \frac{C}{T\delta t} \left(\left\| e_d^1 \right\|_{L^2(\Omega)}^2 + \left\| u^0 - \Pi_h(u^0) \right\|_{L^2(\Omega)}^2 \right) \\ &\leq C(\tau^1)^{-1} h^{2(p+1)} \left(\left\| u^1 \right\|_{H^{p+1}(\Omega)} + \left\| u^0 \right\|_{H^{p+1}(\Omega)} \right), \end{aligned}$$

from which we obtain the desired result. ∎

Remark 4.5. From (4.26) it is seen that we need $\{\sqrt{\delta t} D_1 u^{n+1}\}$ bounded in the norm of $\ell^2(H^{p+1}(\Omega))$. This can be understood as additional regularity on the data or as an additional assumption on the asymptotic behavior of the time step size in terms of h. From the semidiscrete equation, it is immediate to bound $\|D_1 u^{n+1}\|_{H^q(\Omega)}$ in terms of the $H^q(\Omega)$-norm of the rest of the terms of the equation. In particular, the viscous term implies that the $H^q(\Omega)$-norm of $D_1 u^{n+1}$ can be bounded in terms of the $H^{q+2}(\Omega)$-norm of u^{n+1}. If only the $H^{p+1}(\Omega)$-norm of u^{n+1} is bounded, we have to take $q = p-1$, and thus $h^{2(p+1)} \|\sqrt{\delta t} D_1 u^{n+1}\|_{H^{p+1}(\Omega)}^2$ has to be replaced by $h^{2(p-1)} \|\sqrt{\delta t} D_1 u^{n+1}\|_{H^{p-1}(\Omega)}^2$, and therefore we need $\delta t \leq Ch^4$ in order to maintain the optimal order of accuracy.

5. Conclusions. In this paper we have analyzed a stabilized FEM to approximate the convection-diffusion equation on moving domains. The OSS formulation has been used as a stabilization technique, and an ALE framework has been used in order to deal with moving domains.

In the first part of the paper we have analyzed the semidiscrete problem (in time). Two methods have been considered: a first order accurate method, where the time derivatives are computed using the BDF1 scheme, and a second order accurate method, where the BDF2 scheme has been used. In this analysis it is easy to identify the error introduced by the ALE formulation. The mesh velocity is computed as the time derivative of the mesh displacement. The numerical approximation of this time derivative is the only source of error introduced by the ALE formulation. As a conclusion, *in order to keep the accuracy of a kth order (in time) method on fixed domains, we must compute the mesh velocity using a time integration scheme of at least order k of accuracy.* The only negative aspect is that *unconditional stable methods for fixed domains become conditionally stable.*

In the second part of the paper we have analyzed a stabilized transient convection-diffusion equation in an ALE framework. We have introduced the concept of Λ-coercivity that has been used for obtaining stability results and error estimates. It has

been shown that the OSS method can be easily extended to transient problems. For the BDF1 time integration scheme we have stability of the convective term norm, as is usual when using stabilization techniques. The analysis of BDF2 is more complicated. We have control over only the *orthogonal projection* of the convective term. However, optimal convergence results with constants that do not depend on the Péclet number can be proved. Finally, for fixed domains, we have been able to recover *stronger* stability and convergence involving the full norm of the convective term, but the analysis is much more involved and requires more regularity assumptions.

DISCONTINUOUS GALERKIN APPROXIMATION OF THE MAXWELL EIGENPROBLEM*

ANNALISA BUFFA† AND ILARIA PERUGIA‡

Abstract. A theoretical framework for the analysis of discontinuous Galerkin approximations of the Maxwell eigenproblem with discontinuous coefficients is presented. Necessary and sufficient conditions for a spurious-free approximation are established, and it is shown that, at least on conformal meshes, basically all the discontinuous Galerkin methods in the literature actually fit into this framework. Relations with the classical theory for conforming approximations are also discussed.

Key words. discontinuous Galerkin methods, Maxwell's equations, eigenvalue problems

1. Introduction.

One of the most relevant problems in computational electromagnetics is the one of computing eigenfrequencies of the Maxwell equations in a cavity: find $\mathbf{u} \neq 0$ and ω such that

$$\nabla \times (\mu^{-1} \nabla \times \mathbf{u}) - \omega^2 \varepsilon \mathbf{u} = 0, \tag{1.1}$$

with suitable boundary conditions, where μ and ε are the magnetic permeability and the electric permittivity, respectively.

Finite element techniques are widely used to approximate problem (1.1), and, in recent years, a complete mathematical theory has been developed for *conforming* approximations, identifying the properties that the underlying finite element spaces need to fulfill in order to guarantee spurious-free approximations. We refer the reader to the pioneering work [12] and to [33] or [38] and the references therein (we point, in particular, to the fundamental papers [10], [18], [24], and [16]).

On the other hand, the use of discontinuous Galerkin (DG) methods in electromagnetism is attractive thanks to their flexibility in the mesh design and in the choice of shape functions. A unified presentation and analysis of all the DG methods available in the literature, in the elliptic context, are contained in [5], whereas the extension of these methods to the time-domain and frequency-domain Maxwell equations is the object of ongoing research (see, among others, [43], [34], [30], and [31]).

The main difficulties encountered in the analysis of DG approximations of the Maxwell equations are related to the lack of ellipticity and underlying compactness property of the Maxwell operator, which is "amplified" by the use of *nonconforming* approximation spaces.

The first studies on DG approximations of the Maxwell eigenproblem are contained in the recent papers [32] and [45]. There, the main goal was to investigate the role of the penalty parameter appearing in the local discontinuous Galerkin method in avoiding the pollution of the lowest part of the spectrum by eigenvalues related to the

nonconformity of the approximation spaces for a fixed mesh size. That analysis approach and thorough numerical tests have highlighted the links between the spectral properties of DG and curl-conforming methods. In this paper, we aim at developing an *asymptotic* analysis (i.e., for mesh sizes which tend to zero) of DG approximations of the eigenproblem (1.1) in the spirit of [10], [18], [24], and [16].

The spectral theory for DG methods developed in [3] for elliptic problems (with associated compact inverse operators) needs to be extended to treat problems with noncompact inverse operators of the type (1.1). In this case, the lack of compactness results in the presence of an essential spectrum $\sigma^{ess} = \{0\}$, the eigenspace associated with the eigenvalue 0 being infinite dimensional. More precisely, we provide a general framework with a set of sufficient (and necessary) conditions for a DG method to provide a *spurious-free* approximation of problem (1.1), i.e., an approximation with the following properties (see [18]):

(i) *isolation of discrete kernel*; i.e., all discrete eigenvalues approaching the essential spectrum $\sigma^{ess} = \{0\}$ are separated from the other ones (see section 4.1 for a precise definition);
(ii) *nonpollution of the spectrum*; i.e., there are no discrete spurious eigenvalues;
(iii) *completeness of the spectrum*; i.e., all continuous eigenvalues smaller than an arbitrarily large fixed number are approximated for sufficiently fine meshes;
(iv) *nonpollution and completeness of the eigenspaces*; i.e., there are no spurious eigenfunctions, and the eigenspace approximations associated with eigenvalues which are not approaching $\sigma^{ess} = \{0\}$ have the right dimension.

The analysis presented in this paper is carried out along the lines of [18] and [16], and it is based on the theory developed in [25] and [26]. It is worth noting that our general framework applies to both hermitian and non-hermitian DG methods. The two key assumptions which ensure spurious-free DG approximations are (i) a discrete Friedrichs inequality (see Assumption 5) and (ii) a gap property (see Assumption 6). They are the DG analogue of the discrete Friedrichs inequality for discrete, weakly divergence-free curl-conforming vector fields and of the discrete compactness property (see, e.g., [37]), respectively, which have been proved to be necessary and sufficient conditions to have conforming spurious-free approximations to the Maxwell eigenproblem (1.1) (see [10] and [18]). Like for conforming approximations, we show the necessity of these assumptions restricting ourselves, for simplicity, to hermitian DG methods only.

We point out that our theory is able to treat general piecewise smooth material coefficients. In this respect, the appendix is devoted to the analysis of the approximation properties of the DG solutions under minimal regularity assumptions on the solutions of the corresponding continuous problem. This analysis is technical, extends the results of [42], and is, to our knowledge, new.

As a direct consequence of the spectral theory developed in this paper, we obtain well-posedness and quasi-optimal error estimates for DG discretizations, for sufficiently fine meshes, of the Maxwell source problem

$$\nabla \times (\mu^{-1} \nabla \times \mathbf{u}) - \omega^2 \varepsilon \mathbf{u} = \mathbf{f}, \tag{1.2}$$

with suitable boundary conditions, where ω is a fixed frequency, away from the eigen-

frequencies of the continuous problem. Indeed, the fact that a spurious-free finite element method is also a stable and convergent method for (1.2) is based on a general reasoning which is, to our knowledge, new.

Finally, applying our theory, we analyze the spectral approximation properties of several DG methods, such as the methods of the interior penalty family (interior penalty (IP), nonsymmetric interior penalty (NIP), and incomplete interior penalty (IIP); see [4], [44], and [23], respectively) and the local discontinuous Galerkin method (LDG; see [21]). Our theoretical results can be summarized as follows:

1. on conformal tetrahedral/triangular meshes, these methods are spurious-free when the approximation spaces are made of elementwise polynomials of degree ℓ in each variable as well as of elementwise Nédélec elements of the first family [39];
2. on conformal hexahedral/quadrilateral meshes, these methods are spurious-free when the approximation spaces are made of elementwise Nédélec elements of the first family, whereas they produce spurious modes when the approximation spaces are made of elementwise polynomials of degree ℓ in each variable;
3. the convergence rates of the eigenfunction approximations are optimal, i.e., for smooth solutions, $\mathcal{O}(h^{\ell})$ for elements of degree ℓ, whereas the convergence rates of the eigenvalue approximations are optimal, i.e., for smooth solutions, $\mathcal{O}(h^{2\ell})$ for hermitian DG methods, and suboptimal $\mathcal{O}(h^{\ell})$ for non-hermitian DG methods.

We point out that all the results obtained here for the DG spectral approximations of the *curl-curl* operator carry over to the DG spectral approximations of the *grad-div* operator encountered, for instance, in fluid-structure problems (see, e.g., [9] and [8]).

Some questions still remain open and are the object of ongoing research: (i) Can one use a mesh with hanging nodes? (ii) Can one use approximation spaces made of elementwise divergence-free polynomial spaces (see [6] and [20])? A partial answer to the first question has been provided by numerical tests performed while this paper was undergoing the review process (see [17]).

The paper is organized as follows: in sections 2 and 3 we set the notation and the definitions for the continuous and the discrete problems, respectively. Section 4 is the core of the paper and contains the analysis of the DG spectral approximation, under a minimal set of assumptions, which are indeed proved to also be necessary for spurious-free approximations in section 5. In section 6 we analyze the consequences of our theory on the Maxwell source problem (1.2), and finally in section 7 we apply our framework to the most used DG methods applied to the Maxwell equations. Here, the link between our assumptions and their conforming analogue is made clear for the interested reader. Finally, in section 8, we summarize our results.

2. Continuous problem. For a bounded domain D in $\mathbb{R}^d$, $d = 2, 3$, we denote by $H^s(D)$ the standard Sobolev space of order $s \geq 0$ of real or complex functions and by $\|\cdot\|_{s,D}$ the usual Sobolev norm. For $s = 0$, we write $L^2(D)$ in lieu of $H^0(D)$. We also use $\|\cdot\|_{s,D}$ to denote the norm for the space $H^s(D)^d$.

We denote by Ω the problem domain, which we assume to be a bounded Lipschitz polygonal or polyhedral domain in $\mathbb{R}^d$, $d = 2, 3$, and by $\mathbf{n}$ the normal unit vector to its boundary $\partial\Omega$, pointing outside Ω. Whenever $\partial\Omega$ is not connected, we denote by Γ_i, $i = 1, \ldots, n_\Gamma$, its connected components.

If $d = 3$, we assume Ω to be occupied by inhomogeneous, anisotropic materials, i.e., for which the electric permittivity $\varepsilon = \varepsilon(\mathbf{x})$ and magnetic permeability $\mu = \mu(\mathbf{x})$

are second order, real, symmetric, tensor-valued functions, satisfying

$$0 < \varepsilon_\star(\mathbf{x}) \le \sum_{i,j=1}^{3} \varepsilon_{i,j}\xi_i\xi_j \le \varepsilon^\star(\mathbf{x}) \qquad \text{a.e. in } \Omega \quad \forall \xi \in \mathbb{R}^3,\ \|\xi\| = 1, \tag{2.1}$$

$$0 < \mu_\star(\mathbf{x}) \le \sum_{i,j=1}^{3} \mu_{i,j}\xi_i\xi_j \le \mu^\star(\mathbf{x}) \qquad \text{a.e. in } \Omega \quad \forall \xi \in \mathbb{R}^3,\ \|\xi\| = 1, \tag{2.2}$$

where $\varepsilon^\star,\ \varepsilon_\star,\ \mu^\star,\ \mu_\star \in L^\infty(\Omega)$. If $d = 2$, $\varepsilon = \varepsilon(\mathbf{x})$ is again a second order tensor, whereas $\mu = \mu(\mathbf{x})$ is a scalar; therefore, the conditions on ε are analogous to (2.1), whereas (2.2) becomes $0 < \mu_\star(\mathbf{x}) = \mu(\mathbf{x}) = \mu^\star(\mathbf{x})$. Finally, we assume that there exists a partition of Ω into Lipschitz subdomains such that in each of them ε, μ, and μ^{-1} are smooth.

We define, as usual, the following spaces of complex functions:

$$\begin{aligned}
H(\mathrm{curl};\Omega) &= \{\mathbf{v} \in L^2(\Omega)^d :\ \nabla \times \mathbf{v} \in L^2(\Omega)^{2d-3}\},\\
H_0(\mathrm{curl};\Omega) &= \{\mathbf{v} \in H(\mathrm{curl};\Omega) :\ \mathbf{n} \times \mathbf{v} = \mathbf{0} \text{ on } \partial\Omega\},\\
H_0(\mathrm{curl}^0;\Omega) &= \{\mathbf{v} \in H_0(\mathrm{curl};\Omega) :\ \nabla \times \mathbf{v} = \mathbf{0}\},\\
H(\mathrm{div}^0_\varepsilon;\Omega) &= \left\{\mathbf{v} \in L^2(\Omega)^d :\ \nabla \cdot (\varepsilon\mathbf{v}) = 0,\ \int_{\Gamma_i} (\varepsilon\mathbf{v}) \cdot \mathbf{n}\, ds = 0,\ i = 1,\dots,n_\Gamma\right\};
\end{aligned}$$

if $\partial\Omega$ is connected, then $H(\mathrm{div}^0_\varepsilon;\Omega) = \{\mathbf{v} \in L^2(\Omega)^d :\ \nabla \cdot (\varepsilon\mathbf{v}) = 0\}$. Moreover, we set

$$\mathbf{V} = H_0(\mathrm{curl};\Omega), \qquad \mathbf{V}^0 = H_0(\mathrm{curl}^0;\Omega), \qquad \mathbf{W} = \mathbf{V} \cap H(\mathrm{div}^0_\varepsilon;\Omega).$$

Finally, we denote by $(\cdot,\cdot)$ the standard inner product in $L^2(\Omega)^d$ given by $(\mathbf{u},\mathbf{v}) = \int_\Omega \mathbf{u} \cdot \overline{\mathbf{v}}\, d\mathbf{x}$ and write $L^2_\varepsilon(\Omega)^d$ for the space $L^2(\Omega)^d$ endowed with the ε-weighted inner product $(\mathbf{u},\mathbf{v})_\varepsilon = \int_\Omega \varepsilon\mathbf{u} \cdot \overline{\mathbf{v}}\, d\mathbf{x}$. The L^2-norm and the L^2_ε-norm are clearly equivalent, due to the assumptions on ε.

We endow $\mathbf{V}$ with the seminorm $|\mathbf{v}|_{\mathbf{V}} = \|\mu^{-1/2}\nabla \times \mathbf{v}\|_{0,\Omega}$, the inner product $(\mathbf{u},\mathbf{v})_{\mathbf{V}} = (\mu^{-1}\nabla \times \mathbf{u}, \nabla \times \mathbf{v}) + (\mathbf{u},\mathbf{v})_\varepsilon$, and the norm $\|\mathbf{v}\|^2_{\mathbf{V}} = \|\mu^{-1/2}\nabla \times \mathbf{v}\|^2_{0,\Omega} + \|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega}$.

The following decompositions are L^2_ε-orthogonal (see [28]):

$$L^2(\Omega)^d = H(\mathrm{div}^0_\varepsilon;\Omega) \oplus \mathbf{V}^0, \qquad \mathbf{V} = \mathbf{W} \oplus \mathbf{V}^0. \tag{2.3}$$

Define the (hermitian) bilinear forms $a : \mathbf{V} \times \mathbf{V} \to \mathbb{C}$ and $b : \mathbf{V} \times \mathbf{V} \to \mathbb{C}$ as

$$\begin{aligned}
a(\mathbf{u},\mathbf{v}) &= (\mu^{-1}\nabla \times \mathbf{u}, \nabla \times \mathbf{v}),\\
b(\mathbf{u},\mathbf{v}) &= a(\mathbf{u},\mathbf{v}) + (\mathbf{u},\mathbf{v})_\varepsilon = (\mathbf{u},\mathbf{v})_{\mathbf{V}}.
\end{aligned}$$

The variational formulation of the eigenproblem we are interested in is the following: find $(\mathbf{0} \neq \mathbf{u}, \omega) \in \mathbf{W} \times \mathbb{C}$ such that

$$a(\mathbf{u},\mathbf{v}) = \omega^2(\mathbf{u},\mathbf{v})_\varepsilon \qquad \forall \mathbf{v} \in \mathbf{W}.$$

A standard way to discretize this problem consists in neglecting the constraint $\mathbf{u} \in \mathbf{W}$ and adding a zero frequency eigenspace corresponding to the *infinite-dimensional* space $\mathbf{V}^0$, leading to the following variational problem.

PROBLEM 1. *Find* $(\mathbf{0} \neq \mathbf{u}, \omega) \in \mathbf{V} \times \mathbb{C}$*:*

$$a(\mathbf{u}, \mathbf{v}) = \omega^2 (\mathbf{u}, \mathbf{v})_\varepsilon \qquad \forall \mathbf{v} \in \mathbf{V}.$$

Clearly, $\omega^2 = 0$ is an eigenvalue of Problem 1 with associated eigenspace $\mathbf{V}^0$. Moreover, the eigenvalue $\omega^2 = 0$ is isolated, all the other eigenvalues are real, positive, and isolated and form a sequence accumulating only at $+\infty$, and their associated eigenspaces are finite dimensional. Finally, eigenspaces associated with different eigenvalues are L^2_ε-orthogonal and $\mathbf{V}$-orthogonal (see, e.g., [38, Section 4.7]).

For the purpose of the analysis, following [18], we introduce the following auxiliary eigenproblem with a positive definite operator.

PROBLEM 2. *Find* $(\mathbf{0} \neq \mathbf{u}, \widetilde{\omega}) \in \mathbf{V} \times \mathbb{C}$*:*

$$b(\mathbf{u}, \mathbf{v}) = \widetilde{\omega}^2 (\mathbf{u}, \mathbf{v})_\varepsilon \qquad \forall \mathbf{v} \in \mathbf{V}.$$

The eigenvalues of Problem 1 and those of Problem 2 are such that $\widetilde{\omega}^2 = \omega^2 + 1$; thus, $\widetilde{\omega}^2 = 1$ is an eigenvalue of Problem 2 with infinite multiplicity and associated eigenspace $\mathbf{V}^0$.

Define the solution operator $A : L^2(\Omega)^d \to \mathbf{V}$ as follows: given $\mathbf{f} \in L^2(\Omega)^d$, $A\mathbf{f}$ is the (unique) element of $\mathbf{V}$ which satisfies

$$b(A\mathbf{f}, \mathbf{v}) = (\mathbf{f}, \mathbf{v})_\varepsilon \qquad \forall \mathbf{v} \in \mathbf{V}.$$

We have that $A \in \mathcal{L}(L^2(\Omega)^d, \mathbf{V})$. Notice that $(\mathbf{u}, \omega)$ is an eigenpair of Problem 1 if and only if $(\mathbf{u}, \lambda = \frac{1}{\omega^2+1})$ is an eigenpair of A.

Denote by $\sigma(A)$ and $\rho(A)$ the spectrum and the resolvent set (in the complex plane), respectively, of the solution operator A. Finally, for any $z \in \rho(A)$, we define the resolvent operator $R_z(A) = (z - A)^{-1}$ from $\mathbf{V}$ to $\mathbf{V}$.

3. Discontinuous Galerkin approximation: Assumptions. Let $\mathcal{T}_h$ be a shape-regular, not necessarily conformal, triangular ($d = 2$) or tetrahedral ($d = 3$) mesh aligned with the possible discontinuities of ε and μ. We suppose that there exists a $\overline{\mu} > 0$, independent of the mesh size, such that

$$\max_{\mathbf{x} \in K} \frac{\mu^\star(\mathbf{x})}{\mu_\star(\mathbf{x})} \leq \overline{\mu} \qquad \forall\, K \in \mathcal{T}_h. \tag{3.1}$$

We consider a complex vector-valued DG finite element space $\mathbf{V}_h$ (i.e., a discontinuous piecewise polynomial space on $\mathcal{T}_h$) and define the sum space $\mathbf{V}(h) = \mathbf{V} + \mathbf{V}_h$.

Given a seminorm $|\cdot|_{\mathbf{V}(h)}$ on $\mathbf{V}(h)$, we endow both $\mathbf{V}_h$ and $\mathbf{V}(h)$ with the norm

$$\|\mathbf{v}\|^2_{\mathbf{V}(h)} = |\mathbf{v}|^2_{\mathbf{V}(h)} + \|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega} \qquad \forall \mathbf{v} \in \mathbf{V}(h),$$

which we assume to be Hilbertian; we denote by $(\cdot,\cdot)_{\mathbf{V}(h)}$ the associated inner product.

Let $a_h : \mathbf{V}_h \times \mathbf{V}_h \to \mathbb{C}$ be the DG bilinear form obtained by discretizing $a : \mathbf{V} \times \mathbf{V} \to \mathbb{C}$ by a DG method, and define

$$b_h(\mathbf{u}, \mathbf{v}) = a_h(\mathbf{u}, \mathbf{v}) + (\mathbf{u}, \mathbf{v})_\varepsilon \qquad \forall \mathbf{u}, \mathbf{v} \in \mathbf{V}_h.$$

In this section we formulate general assumptions on the space $\mathbf{V}_h$ and on the bilinear form $a_h(\cdot,\cdot)$ under which our theory is developed.

Assumption 1 (norm compatibility). If $\mathbf{v} \in \mathbf{V}(h)$ and $|\mathbf{v}|_{\mathbf{V}(h)} = 0$, then $\mathbf{v} \in \mathbf{V}^0$; moreover, if $\mathbf{v} \in \mathbf{V}$, then $|\mathbf{v}|_{\mathbf{V}(h)} = |\mathbf{v}|_{\mathbf{V}}$.

Notice that Assumption 1 implies that $|\mathbf{v}|_{\mathbf{V}(h)} = 0$ if and only if $\mathbf{v} \in \mathbf{V}^0$. The space $\mathbf{V}(h)$ is a Hilbert space and the $\mathbf{V}(h)$-norm coincides with the $\mathbf{V}$-norm on $\mathbf{V}$.

For the DG space $\mathbf{V}_h$, we make the following approximation assumption.

Assumption 2 (approximation property of $\mathbf{V}_h$). There holds

$$\lim_{h\to 0} \inf_{\mathbf{v}_h \in \mathbf{V}_h} \|\mathbf{v} - \mathbf{v}_h\|_{\mathbf{V}(h)} = 0 \qquad \forall \mathbf{v} \in \mathbf{W}.$$

We assume the following properties to be satisfied.

Assumption 3 (coercivity in seminorm and continuity). There exist positive constants α, γ independent of the mesh size such that

$$\begin{aligned} \text{Re}\,[a_h(\mathbf{v},\mathbf{v})] &\geq \alpha\,|\mathbf{v}|^2_{\mathbf{V}(h)} && \forall \mathbf{v} \in \mathbf{V}_h, \\ |a_h(\mathbf{u},\mathbf{v})| &\leq \gamma \|\mathbf{u}\|_{\mathbf{V}(h)} \|\mathbf{v}\|_{\mathbf{V}(h)} && \forall \mathbf{u},\mathbf{v} \in \mathbf{V}_h. \end{aligned}$$

Define the kernel of $a_h(\cdot,\cdot)$ and its $\mathbf{V}(h)$-orthogonal complement as follows:

$$\begin{aligned} K_h &= \{\mathbf{v} \in \mathbf{V}_h : a_h(\mathbf{v},\mathbf{w}) = 0 \quad \forall \mathbf{w} \in \mathbf{V}_h\}, \\ K_h^\perp &= \{\mathbf{v} \in \mathbf{V}_h : (\mathbf{v},\mathbf{w})_{\mathbf{V}(h)} = 0 \quad \forall \mathbf{w} \in K_h\}. \end{aligned}$$

If $a_h(\cdot,\cdot)$ is non-hermitian, we also assume that left and right kernels coincide, i.e.,

$$a_h(\mathbf{v},\mathbf{w}) = 0 \qquad \forall \mathbf{v} \in \mathbf{V}_h, \mathbf{w} \in K_h. \tag{3.2}$$

Remark 3.1. From Assumption 3 it follows that

$$\text{Re}\,[b_h(\mathbf{v},\mathbf{v})] \geq \min\{\alpha, 1\} \|\mathbf{v}\|^2_{\mathbf{V}(h)} \qquad \forall \mathbf{v} \in \mathbf{V}_h \tag{3.3}$$

and that

$$|\mathbf{v}|_{\mathbf{V}(h)} = 0 \qquad \forall \mathbf{v} \in K_h. \tag{3.4}$$

The coercivity property (3.3) guarantees that, for any given $\mathbf{f} \in L^2(\Omega)^d$, there exists a unique $\mathbf{u}_h \in \mathbf{V}_h$ such that $b_h(\mathbf{u}_h,\mathbf{v}) = (\mathbf{f},\mathbf{v})_\varepsilon$ for all $\mathbf{v} \in \mathbf{V}_h$, and $\|\mathbf{u}_h\|_{\mathbf{V}(h)} \leq C\|\mathbf{f}\|_{0,\Omega}$, with $C > 0$ independent of the mesh size and of the right-hand side $\mathbf{f}$. The identity (3.4), together with Assumption 1, implies that $K_h \subset \mathbf{V}^0$; consequently,

$$K_h^\perp = \{\mathbf{v} \in \mathbf{V}_h : (\mathbf{v},\mathbf{w})_{\mathbf{V}(h)} = (\mathbf{v},\mathbf{w})_\varepsilon = 0 \quad \forall \mathbf{w} \in K_h\}.$$

For the following assumption on the DG method, we introduce the broken spaces

$$\begin{aligned} H^s(\mathcal{T}_h)^d &= \{\mathbf{v} \in L^2(\Omega)^d : \mathbf{v}|_K \in H^s(K)^d \quad \forall K \in \mathcal{T}_h\} \quad \text{for } s \geq 0, \\ H^r(\text{curl};\mathcal{T}_h) &= \{\mathbf{v} \in L^2(\Omega)^d : \varepsilon\mathbf{v}|_K \in H^r(K)^d, \\ &\qquad \mu^{-1}\nabla\times\mathbf{v}|_K \in H^r(K)^{2d-3} \quad \forall K \in \mathcal{T}_h\} \quad \text{for } r > 0 \end{aligned}$$

and the norms

$$\begin{aligned} \|\mathbf{v}\|^2_{H^s(\mathcal{T}_h)^d} &= \sum_{K\in\mathcal{T}_h} \|\mathbf{v}\|^2_{s,K}, \\ \|\mathbf{v}\|^2_{H^r(\text{curl};\mathcal{T}_h)} &= \sum_{K\in\mathcal{T}_h} \left(\|\varepsilon^{1/2}\mathbf{v}\|^2_{r,K} + \|\mu^{-1/2}\nabla\times\mathbf{v}\|^2_{r,K} \right). \end{aligned}$$

Assumption 4 (convergence). Let $\mathbf{f}$ be in $H(\mathrm{div}^0_\varepsilon;\Omega)$; denote by $\mathbf{u}_s \in \mathbf{V}$ the solution to the coercive source problem $b(\mathbf{u}_s,\mathbf{v}) = (\mathbf{f},\mathbf{v})_\varepsilon$ for all $\mathbf{v} \in \mathbf{V}$ and by $\mathbf{u}_h \in \mathbf{V}_h$ its Galerkin projection which satisfies $b_h(\mathbf{u}_h,\mathbf{v}) = (\mathbf{f},\mathbf{v})_\varepsilon$ for all $\mathbf{v} \in \mathbf{V}_h$. Whenever $\mathbf{u}_s \in H^r(\mathrm{curl};\mathcal{T}_h)$, with $r > 0$, and $\mathbf{f} \in H^s(\mathcal{T}_h)^d$, with $s \geq 0$, then

$$\exists\, t > 0 : \qquad \|\mathbf{u}_s - \mathbf{u}_h\|_{\mathbf{V}(h)} \leq C h^t \left(\|\mathbf{u}_s\|_{H^r(\mathrm{curl};\mathcal{T}_h)} + \|\mathbf{f}\|_{H^s(\mathcal{T}_h)^d} \right), \tag{3.5}$$

where $C > 0$ is independent of the mesh size. The bound (3.5), together with the regularity results in [22], implies that

$$\exists\, \sigma > 0 : \qquad \|\mathbf{u}_s - \mathbf{u}_h\|_{\mathbf{V}(h)} \leq C h^\sigma \|\mathbf{f}\|_{0,\Omega} \qquad \forall \mathbf{f} \in H(\mathrm{div}^0_\varepsilon;\Omega),$$

where $C > 0$ is independent of the mesh size.

For the most common DG methods, the proof that Assumption 4 holds true makes use of results proved in the appendix (see Proposition 7.3).

We define the DG solution operator $A_h : L^2(\Omega)^d \to \mathbf{V}_h$ as follows: given $\mathbf{f} \in L^2(\Omega)^d$, $A_h\mathbf{f}$ is the (unique) element of $\mathbf{V}_h$ which satisfies

$$b_h(A_h\mathbf{f},\mathbf{v}) = (\mathbf{f},\mathbf{v})_\varepsilon \qquad \forall \mathbf{v} \in \mathbf{V}_h.$$

The operator A_h is well defined and $A_h \in \mathcal{L}(L^2(\Omega)^d, \mathbf{V}_h)$ (see Remark 3.1).

As in the continuous case, we denote by $\sigma(A_h)$ and $\rho(A_h)$ the spectrum and the resolvent set, respectively, of the DG solution operator A_h. Finally, for any $z \in \mathbb{C}$, we formally define the resolvent operator $R_z(A_h) = (z - A_h)^{-1}$ from $\mathbf{V}_h$ to $\mathbf{V}_h$.

The previous assumptions imply the following properties of the discrete eigenvalues and eigenfunctions.

PROPOSITION 3.2. *If $\lambda_h \in \sigma(A_h)$, then $0 < \mathrm{Re}\,[\lambda_h] \leq 1$. Moreover, $1 \in \sigma(A_h)$ and its associated eigenspace is K_h.*

Proof. Let $\mathbf{v} \neq \mathbf{0}$ be an eigenfunction associated with $\lambda_h \in \sigma(A_h)$. We have

$$\begin{aligned} \overline{\lambda}_h \|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega} &= (\mathbf{v},\lambda_h\mathbf{v})_\varepsilon = b_h(A_h\mathbf{v},\lambda_h\mathbf{v}) = b_h(\lambda_h\mathbf{v},\lambda_h\mathbf{v}) \\ &= a_h(\lambda_h\mathbf{v},\lambda_h\mathbf{v}) + |\lambda_h|^2 \|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega}, \end{aligned}$$

and thus $\mathrm{Re}\,[\lambda_h]\|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega} = \mathrm{Re}\,[a_h(\lambda_h\mathbf{v},\lambda_h\mathbf{v})] + |\lambda_h|^2\|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega}$. Since, owing to Assumption 3, $\mathrm{Re}\,[a_h(\lambda_h\mathbf{v},\lambda_h\mathbf{v})] \geq 0$, we readily have $\mathrm{Re}\,[\lambda_h] > 0$ and $\mathrm{Re}\,[\lambda_h] \geq |\lambda_h|^2$, from which $\mathrm{Re}\,[\lambda_h] \leq 1$. The second part of the statement is obvious. ∎

Clearly, whenever $a_h(\cdot,\cdot)$ is hermitian, then all the discrete eigenvalues are real.

PROPOSITION 3.3. (i) *Let $\mathbf{v} \neq 0$ be an eigenfunction of A_h associated with an eigenvalue $\lambda_h \neq 1$. Then $(\mathbf{v},\mathbf{w})_\varepsilon = (\mathbf{v},\mathbf{w})_{\mathbf{V}(h)} = b_h(\mathbf{v},\mathbf{w}) = 0$ for all $\mathbf{w} \in K_h$.*

(ii) *If $a_h(\cdot,\cdot)$ is hermitian, for all eigenfunctions $\mathbf{v}_1$, $\mathbf{v}_2$ associated with different eigenvalues, it holds that $(\mathbf{v}_1,\mathbf{v}_2)_\varepsilon = b_h(\mathbf{v}_1,\mathbf{v}_2) = 0$.*

Proof. For the proof of (i), let $\mathbf{w} \in K_h$. Since $a_h(\mathbf{v},\mathbf{w}) = 0$, we can write

$$(\mathbf{v},\mathbf{w})_\varepsilon = \lambda_h b_h(\mathbf{v},\mathbf{w}) = \lambda_h(\mathbf{v},\mathbf{w})_\varepsilon;$$

then, $\lambda_h \neq 1$ implies $(\mathbf{v},\mathbf{w})_\varepsilon = 0$ and $b_h(\mathbf{v},\mathbf{w}) = 0$. Moreover, since $|\mathbf{w}|_{\mathbf{V}(h)} = 0$, we also have $(\mathbf{v},\mathbf{w})_{\mathbf{V}(h)} = (\mathbf{v},\mathbf{w})_\varepsilon$. The proof of (ii) is trivial. ∎

4. Spurious-free discontinuous Galerkin approximations. In order to guarantee a *spurious-free* DG approximation to Problem 1 (see the introduction), in addition to Assumptions 1–4, we need to make sure that the two additional properties are verified.

PROPERTY 1 (isolation of discrete kernel). *There exists* $0 < \beta < 1$ *independent of the mesh size such that if* $1 \neq \lambda_h \in \sigma(A_h)$*, then*

$$\text{Re } [\lambda_h] \leq \beta.$$

For a linear, continuous operator $L : V_1 \to V_2$, with V_1 and V_2 Hilbert spaces, we define

$$\|L\|_{\mathcal{L}(V_1,V_2)} = \sup_{\substack{v \in V_1 \\ \|v\|_{V_1}=1}} \|Lv\|_{V_2}.$$

PROPERTY 2 (convergence in mesh-dependent norm).

$$\lim_{h \to 0} \|A - A_h\|_{\mathcal{L}(\mathbf{V}_h, \mathbf{V}(h))} = 0.$$

We remark that Property 2 is the DG analogue of [15, P1, p. 100] and that the norm $\|\cdot\|_{\mathcal{L}(\mathbf{V}_h,\mathbf{V}(h))}$ coincides with the mesh-dependent norm $\|\cdot\|_h$ of [25].

In the following two sections we formulate key assumptions on the DG spaces and bilinear forms which guarantee the validity of Properties 1 and 2, respectively.

4.1. Isolation of discrete kernel. We prove that the following assumption implies Property 1.

Assumption 5 (discrete Friedrichs inequality). There exists $C > 0$ independent of the mesh size such that

$$\|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega}^2 \leq C \,\text{Re } [a_h(\mathbf{v}, \mathbf{v})] \qquad \forall \mathbf{v} \in K_h^{\perp}.$$

PROPOSITION 4.1. *Assumption* 5 *implies Property* 1.

Proof. If $\mathbf{v}$ is an eigenfunction of A_h associated with an eigenvalue $\lambda_h \neq 1$, then $\mathbf{v}$ belongs to $K_h^{\perp}$ (see Proposition 3.3). From Assumption 5 we have

$$\begin{aligned}\frac{|\lambda_h|^2}{C} \|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega}^2 &\leq \text{Re } [a_h(\lambda_h\mathbf{v}, \lambda_h\mathbf{v})] = \text{Re } [a_h(A_h\mathbf{v}, \lambda_h\mathbf{v})] \\ &= \text{Re } [b_h(A_h\mathbf{v}, \lambda_h\mathbf{v}) - (A_h\mathbf{v}, \lambda_h\mathbf{v})_\varepsilon] \\ &= \text{Re } [(\mathbf{v}, \lambda_h\mathbf{v})_\varepsilon - (\lambda_h\mathbf{v}, \lambda_h\mathbf{v})_\varepsilon] = (\text{Re } [\lambda_h] - |\lambda_h|^2)\|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega}^2.\end{aligned}$$

Property 1 readily follows with $\beta = C/(1 + C)$. ∎

Remark 4.2. The $\mathbf{V}(h)$-ellipticity of $a_h(\cdot, \cdot)$ on $K_h^{\perp}$ follows from Assumptions 3 and 5. In fact, if $\mathbf{v} \in K_h^{\perp}$, the definition of $\|\cdot\|_{\mathbf{V}(h)}$, Assumptions 3 and 5 give

$$\|\mathbf{v}\|_{\mathbf{V}(h)}^2 = |\mathbf{v}|_{\mathbf{V}(h)}^2 + \|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega}^2 \leq \left(\frac{1}{\alpha} + C\right) \text{Re } [a_h(\mathbf{v}, \mathbf{v})].$$

4.2. Convergence of solution operators in mesh-dependent norm. First, we note that Property 2 can be rephrased as follows: for all h small enough,

$$\|(A - A_h)\mathbf{f}_h\|_{\mathbf{V}(h)} \leq \xi_h \|\mathbf{f}_h\|_{\mathbf{V}(h)} \qquad \forall \mathbf{f}_h \in \mathbf{V}_h, \tag{4.1}$$

with $\xi_h \to 0$ as $h \to 0$.

The aim of this section is to prove that the following key assumption implies Property 2.

Assumption 6 (gap property). For all h small enough, for any $\mathbf{w}_h \in K_h^\perp$ there exists $\mathbf{w} = \mathbf{w}(h) \in H(\mathrm{div}_\varepsilon^0;\Omega)$ such that

$$\|\mathbf{w} - \mathbf{w}_h\|_{0,\Omega} \le \eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)},$$

with $\eta_h \to 0$ as $h \to 0$.

Assumption 6 is related to the approximation properties of $K_h^\perp$ and K_h in $\mathbf{W}$ and in $\mathbf{V}^0$, respectively (see section 5).

In order to prove Property 2, we state the following lemma.

LEMMA 4.3. *For all* $\mathbf{f}_h^0 \in K_h$, *we have* $(A - A_h)\mathbf{f}_h^0 = 0$.

Proof. The condition $\mathbf{f}_h^0 \in K_h$ implies that $\mathbf{f}_h^0 \in \mathbf{V}_h \cap \mathbf{V}^0$ (see Remark 3.1). Therefore, $b(A\mathbf{f}_h^0, \mathbf{v}) = (\mathbf{f}_h^0, \mathbf{v})_\varepsilon$ for all $\mathbf{v} \in \mathbf{V}$ implies that $A\mathbf{f}_h^0$ is solution to $b(\mathbf{u}, \mathbf{v}) = (\mathbf{f}_h^0, \mathbf{v})_\varepsilon$ for all $\mathbf{v} \in \mathbf{V}$. Since $\mathbf{f}_h^0 \in \mathbf{V}^0$, then $\mathbf{u} = \mathbf{f}_h^0$ is a solution; uniqueness implies that $A\mathbf{f}_h^0 = \mathbf{f}_h^0$. Therefore, we need only prove that $A_h\mathbf{f}_h^0 = \mathbf{f}_h^0$. But $a_h(\mathbf{f}_h^0, \mathbf{v}) = 0$ for all $\mathbf{v} \in \mathbf{V}_h$ implies that

$$b_h(A_h\mathbf{f}_h^0, \mathbf{v}) = (\mathbf{f}_h^0, \mathbf{v})_\varepsilon = b_h(\mathbf{f}_h^0, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathbf{V}_h,$$

from which $A_h\mathbf{f}_h^0 = \mathbf{f}_h^0$, owing to the well-posedness in Remark 3.1, and the proof is complete. ∎

PROPOSITION 4.4. *Property* 2 *holds true.*

Proof. Decompose $\mathbf{f}_h \in \mathbf{V}_h$ as $\mathbf{f}_h = \mathbf{f}_h^0 + \mathbf{f}_h^\perp$, with $\mathbf{f}_h^0 \in K_h$ and $\mathbf{f}_h^\perp \in K_h^\perp$ and $\|\mathbf{f}_h\|_{\mathbf{V}(h)}^2 = \|\mathbf{f}_h^0\|_{\mathbf{V}(h)}^2 + \|\mathbf{f}_h^\perp\|_{\mathbf{V}(h)}^2$. Owing to Lemma 4.3, it is enough to prove that, for all h small enough,

$$\|(A - A_h)\mathbf{f}_h^\perp\|_{\mathbf{V}(h)} \le \xi_h \|\mathbf{f}_h^\perp\|_{\mathbf{V}(h)} \qquad \forall \mathbf{f}_h^\perp \in K_h^\perp, \tag{4.2}$$

with $\xi_h \to 0$ as $h \to 0$. For h small enough, we can write

$$\|(A - A_h)\mathbf{f}_h^\perp\|_{\mathbf{V}(h)} \le \|(A - A_h)(\mathbf{f} - \mathbf{f}_h^\perp)\|_{\mathbf{V}(h)} + \|(A - A_h)\mathbf{f}\|_{\mathbf{V}(h)}, \tag{4.3}$$

with $\mathbf{f} \in H(\mathrm{div}_\varepsilon^0;\Omega)$ as in Assumption 6.

For the first term on the right-hand side in (4.3), we have

$$\begin{aligned}\|(A - A_h)(\mathbf{f} - \mathbf{f}_h^\perp)\|_{\mathbf{V}(h)} &\le \left(\|A\|_{\mathcal{L}(L^2(\Omega)^d,\mathbf{V})} + \|A_h\|_{\mathcal{L}(L^2(\Omega)^d,\mathbf{V}_h)}\right) \|\mathbf{f} - \mathbf{f}_h^\perp\|_{0,\Omega} \\ &\le C\,\eta_h\,\|\mathbf{f}_h^\perp\|_{\mathbf{V}(h)},\end{aligned}$$

owing to the continuity of A_h (see Remark 3.1) and Assumption 6.

For the second term on the right-hand side in (4.3), since $\mathbf{f} \in H(\mathrm{div}_\varepsilon^0;\Omega)$, from Assumption 4 we have that there exists a $\sigma > 0$ such that

$$\begin{aligned}\|(A - A_h)\mathbf{f}\|_{\mathbf{V}(h)} &\le Ch^\sigma \|\mathbf{f}\|_{0,\Omega} \le Ch^\sigma(\|\mathbf{f} - \mathbf{f}_h^\perp\|_{0,\Omega} + \|\mathbf{f}_h^\perp\|_{0,\Omega}) \\ &\le Ch^\sigma(\eta_h + 1)\|\mathbf{f}_h^\perp\|_{\mathbf{V}(h)},\end{aligned}$$

where we have again used Assumption 6 and the definition of the $\mathbf{V}(h)$-norm.

Therefore, (4.2) holds true with $\xi_h = h^\sigma(\eta_h + 1)$. ∎

4.3. Nonpollution of the spectrum. This section is devoted to the proof of the following theorem.

THEOREM 4.5 (nonpollution of the spectrum). *Let* $G \subset \mathbb{C}$ *be an open set containing* $\sigma(A)$. *Then, for* h *small enough,* $\sigma(A_h) \subset G$.

We proceed by establishing few intermediate results.

LEMMA 4.6. *Fix $0 \neq z \in \rho(A)$. There exists a positive constant C depending only upon Ω and $|z|$ such that, for all $\mathbf{f} \in \mathbf{V}(h)$,*

$$\|(z - A)\mathbf{f}\|_{\mathbf{V}(h)} \geq C\|\mathbf{f}\|_{\mathbf{V}(h)}.$$

Proof. The proof is similar to the one of [3, Lemma 4.2]. Let $\mathbf{f} \in \mathbf{V}(h)$ and $\mathbf{g} := (z - A)\mathbf{f}$. By construction, $\mathbf{g} \in \mathbf{V}(h)$ and $z\mathbf{f} - \mathbf{g} \in \mathbf{V}$. Moreover, $(z\mathbf{f} - \mathbf{g})$ solves

$$B^{-1}(z\mathbf{f} - \mathbf{g}) - \frac{1}{z}(z\varepsilon\mathbf{f} - \varepsilon\mathbf{g}) = \frac{1}{z}\varepsilon\mathbf{g},$$

where B^{-1} is the operator $\nabla \times (\mu^{-1}\nabla \times (\cdot)) + \varepsilon(\cdot)$. Since $z \in \rho(A)$, and $z\mathbf{f} - \mathbf{g}$ verifies homogeneous Dirichlet boundary condition, well-posedness implies that

$$\|z\mathbf{f} - \mathbf{g}\|_{\mathbf{V}} \leq \frac{C}{|z|}\|\varepsilon^{1/2}\mathbf{g}\|_{0,\Omega} \leq \frac{C}{|z|}\|\mathbf{g}\|_{\mathbf{V}(h)}.$$

Owing to Assumption 1, it holds that $\|z\mathbf{f} - \mathbf{g}\|_{\mathbf{V}} = \|z\mathbf{f} - \mathbf{g}\|_{\mathbf{V}(h)}$. Therefore

$$\|\mathbf{f}\|_{\mathbf{V}(h)} \leq \frac{1}{|z|}\left(\|z\mathbf{f} - \mathbf{g}\|_{\mathbf{V}} + \|\mathbf{g}\|_{\mathbf{V}(h)}\right) \leq C(|z|)\|\mathbf{g}\|_{\mathbf{V}(h)}. \qquad \square$$

THEOREM 4.7. *Fix $0 \neq z \in \rho(A)$. For h small enough, there exists a positive constant C depending only upon Ω and $|z|$ such that, for all $\mathbf{f} \in \mathbf{V}_h$,*

$$\|(z - A_h)\mathbf{f}\|_{\mathbf{V}(h)} \geq C\|\mathbf{f}\|_{\mathbf{V}(h)}.$$

Proof. By triangle inequality, we have

$$\|(z - A_h)\mathbf{f}\|_{\mathbf{V}(h)} \geq \|(z - A)\mathbf{f}\|_{\mathbf{V}(h)} - \|(A - A_h)\mathbf{f}\|_{\mathbf{V}(h)}.$$

Lemma 4.6 and the continuity of the operator $A - A_h$ yield

$$\|(z - A_h)\mathbf{f}\|_{\mathbf{V}(h)} \geq (C - \|A - A_h\|_{\mathcal{L}(\mathbf{V}_h, \mathbf{V}(h))})\|\mathbf{f}\|_{\mathbf{V}(h)},$$

and Property 2 allows us to conclude. $\square$

Theorem 4.7 implies that, for any $0 \neq z \in \rho(A)$ and h small enough, $(z - A_h)$ is an invertible operator and the following result holds true.

COROLLARY 4.8. *Let $F \subset \rho(A)$ be closed. Then, there exists a positive constant C independent of the mesh size such that, for h small enough, we have*

$$\|R_z(A_h)\|_{\mathcal{L}(\mathbf{V}_h, \mathbf{V}_h)} \leq C$$

for all $z \in F$, with $C > 0$ independent of the mesh size.

Proof. We observe that if $\mathbf{f} \in \mathbf{V}_h$, then $(z - A_h)^{-1}\mathbf{f} \in \mathbf{V}_h$. In fact, $\mathbf{g} := (z - A_h)^{-1}\mathbf{f}$ $\Rightarrow (z - A_h)\mathbf{g} = \mathbf{f} \Rightarrow z\mathbf{g} = \mathbf{f} + A_h\mathbf{g} \in \mathbf{V}_h$. Theorem 4.7 then says that, for all $z \in F$ and h sufficiently small, the continuous operator $(z - A_h) : \mathbf{V}_h \to \mathbf{V}_h$ is invertible with continuous inverse and continuity constant independent of the mesh size. The statement readily follows. $\square$

Theorem 4.5 is a direct consequence of Corollary 4.8.

Remark 4.9. For fixed $z \in \rho(A)$ and $\mathbf{f} \in \mathbf{V}(h)$, we can write

$$\|(z - A)\mathbf{f}\|_{\mathbf{V}(h)} \leq |z|\|\mathbf{f}\|_{\mathbf{V}(h)} + \|A\mathbf{f}\|_{\mathbf{V}} \leq |z|\|\mathbf{f}\|_{\mathbf{V}(h)} + C\|\mathbf{f}\|_{0,\Omega} \leq C(|z|)\|\mathbf{f}\|_{\mathbf{V}(h)},$$

owing to the stability estimate of the continuous problem and the definition of the $\mathbf{V}(h)$-norm. This, together with the result of Lemma 4.6, implies that, for all fixed $0 \neq z \in \rho(A)$, $(z - A) : \mathbf{V}(h) \to \mathbf{V}(h)$ is a continuous invertible operator with continuous inverse. An immediate consequence of this fact is the analogue of Corollary 4.8: Let $F \subset \rho(A)$ be closed. Then, there exists a positive constant C independent of the mesh size such that, for all $z \in F$,

$$\|R_z(A)\|_{\mathcal{L}(\mathbf{V}(h),\mathbf{V}(h))} \leq C.$$

4.4. Nonpollution and completeness of the eigenspaces, and completeness of the spectrum. Let λ be an eigenvalue of A with algebraic multiplicity m, and let Γ be a circle in the complex plane centered at λ which lies in $\rho(A)$ and does not enclose any other point of $\sigma(A)$. According to [36, p. 178], we define the *spectral projections* E and, for h small enough, E_h from $\mathbf{V}_h$ into $\mathbf{V}(h)$ by

$$E = E_\lambda = \frac{1}{2\pi i}\int_\Gamma R_z(A)\,dz, \qquad E_h = E_{h,\lambda} = \frac{1}{2\pi i}\int_\Gamma R_z(A_h)\,dz, \tag{4.4}$$

respectively. Theorem 4.5 guarantees that, for h small enough, E_h is well defined.

We have the following uniform convergence result, analogous to [25, Lemma 2].

THEOREM 4.10. *We have*

$$\lim_{h\to 0} \|E - E_h\|_{\mathcal{L}(\mathbf{V}_h,\mathbf{V}(h))} = 0.$$

Proof. Since $(z - A)^{-1} - (z - A_h)^{-1} = (z - A)^{-1}(A - A_h)(z - A_h)^{-1}$, we have

$$R_z(A) - R_z(A_h) = R_z(A)(A - A_h)R_z(A_h).$$

Therefore, for $\mathbf{f} \in \mathbf{V}_h$,

$$\begin{aligned}&\|R_z(A)(A - A_h)R_z(A_h)\mathbf{f}\|_{\mathbf{V}(h)}\\ &\quad\leq \|R_z(A)\|_{\mathcal{L}(\mathbf{V}(h),\mathbf{V}(h))}\|A - A_h\|_{\mathcal{L}(\mathbf{V}_h,\mathbf{V}(h))}\|R_z(A_h)\|_{\mathcal{L}(\mathbf{V}_h,\mathbf{V}_h)}\|\mathbf{f}\|_{\mathbf{V}(h)}.\end{aligned}$$

Owing to Remark 4.9, Property 2, and Corollary 4.8, we get the result. ∎

If Y and Z are closed subspaces of $\mathbf{V}(h)$, we define

$$\delta_h(\mathbf{x}, Y) := \inf_{\mathbf{y}\in Y} \|\mathbf{x} - \mathbf{y}\|_{\mathbf{V}(h)}, \qquad \delta_h(Y, Z) := \sup_{\substack{\mathbf{y}\in Y\\ \|\mathbf{y}\|_{\mathbf{V}(h)}=1}} \delta_h(\mathbf{y}, Z),$$

$$\widehat{\delta}_h(Y, Z) := \max\{\delta_h(Y, Z), \delta_h(Z, Y)\}.$$

The following result holds true (compare with [25, Theorem 2]).

THEOREM 4.11 (nonpollution of the eigenspaces). *We have*

$$\lim_{h\to 0} \delta_h(E_h(\mathbf{V}_h), E(\mathbf{V})) = 0.$$

Proof. We start by observing that $E(\mathbf{V}) = E(L^2(\Omega)^d)$. Indeed, $E(\mathbf{V})$ is the projection onto the eigenspace associated with the eigenvalue λ of the operator $A : \mathbf{V} \to \mathbf{V}$, and $E(L^2(\Omega)^d)$ is the projection onto the eigenspace associated with the eigenvalue λ of the operator $A : L^2(\Omega)^d \to L^2(\Omega)^d$ (see, e.g., [27, Theorem 5, p. 579]).

Since all eigenfunctions of $A : L^2(\Omega)^d \to L^2(\Omega)^d$ are in $\mathbf{V}$, the two eigenspaces coincide, i.e., $E(\mathbf{V}) = E(L^2(\Omega)^d)$. Therefore,

$$\begin{aligned}\sup_{\substack{\mathbf{y}_h \in E_h(\mathbf{V}_h)\\ \|\mathbf{y}_h\|_{\mathbf{V}(h)}=1}} \inf_{\mathbf{x}\in E(\mathbf{V})} \|\mathbf{y}_h - \mathbf{x}\|_{\mathbf{V}(h)} &= \sup_{\substack{\mathbf{y}_h \in E_h(\mathbf{V}_h)\\ \|\mathbf{y}_h\|_{\mathbf{V}(h)}=1}} \inf_{\mathbf{x}\in E(L^2(\Omega)^d)} \|\mathbf{y}_h - \mathbf{x}\|_{\mathbf{V}(h)}\\ &= \sup_{\substack{\mathbf{y}_h \in E_h(\mathbf{V}_h)\\ \|y_h\|_{\mathbf{V}(h)}=1}} \inf_{\mathbf{x}\in L^2(\Omega)^d} \|E_h\mathbf{y}_h - E\mathbf{x}\|_{\mathbf{V}(h)},\end{aligned}$$

where in the last step we have used that $E_h\mathbf{y}_h = \mathbf{y}_h$ for all $\mathbf{y}_h \in E_h(\mathbf{V}_h)$. Taking $\mathbf{x} = \mathbf{y}_h$, Theorem 4.10 allows us to conclude. ∎

For eigenspaces associated with eigenvalues $\lambda \neq 1$, we have the following result (compare with [25, Theorem 3]).

THEOREM 4.12 (completeness of the eigenspaces). *If $E = E_\lambda$ is associated with an eigenvalue $\lambda \neq 1$, then*

$$\lim_{h\to 0} \delta_h(E(\mathbf{V}), E_h(\mathbf{V}_h)) = 0.$$

Proof. Since $EE\mathbf{y} = E\mathbf{y}$ for all $\mathbf{y} \in \mathbf{V}$, we can write

$$\delta_h(E(\mathbf{V}), E_h(\mathbf{V}_h)) = \sup_{\substack{\mathbf{x}\in E(\mathbf{V})\\ \|\mathbf{x}\|_{\mathbf{V}(h)}=1}} \inf_{\mathbf{x}_h\in\mathbf{V}_h} \|E\mathbf{x} - E_h\mathbf{x}_h\|_{\mathbf{V}(h)}.$$

Fix $\mathbf{x} \in E(\mathbf{V})$. Then, $E\mathbf{x} = \mathbf{x}$ and $\mathbf{x} \in \mathbf{W}$. By Assumption 2, there exists $\widetilde{\mathbf{x}}_h \in \mathbf{V}_h$ such that

$$\lim_{h\to 0} \|\mathbf{x} - \widetilde{\mathbf{x}}_h\|_{\mathbf{V}(h)} = 0. \tag{4.5}$$

Therefore,

$$\begin{aligned}\inf_{\mathbf{x}_h\in\mathbf{V}_h} \|E\mathbf{x} - E_h\mathbf{x}_h\|_{\mathbf{V}(h)} &\le \|E\mathbf{x} - E_h\widetilde{\mathbf{x}}_h\|_{\mathbf{V}(h)}\\ &\le \|E(\mathbf{x} - \widetilde{\mathbf{x}}_h)\|_{\mathbf{V}(h)} + \|(E - E_h)\widetilde{\mathbf{x}}_h\|_{\mathbf{V}(h)}\\ &\le \|E\|_{\mathcal{L}(\mathbf{V}(h),\mathbf{V}(h))}\|\mathbf{x} - \widetilde{\mathbf{x}}_h\|_{\mathbf{V}(h)} + \|E - E_h\|_{\mathcal{L}(\mathbf{V}_h,\mathbf{V}(h))}\|\widetilde{\mathbf{x}}_h\|_{\mathbf{V}(h)}.\end{aligned}$$

The first term on the right-hand side tends to zero, as $h \to 0$, due to (4.5), whereas the second term tends to zero, as $h \to 0$, owing to Theorem 4.10. Since $E(\mathbf{V})$ is the eigenspace associated with $\lambda \neq 1$, it is finite dimensional; therefore, pointwise convergence implies uniform convergence in $E(\mathbf{V})$, and the result readily follows. ∎

Finally, we have the following result.

THEOREM 4.13 (completeness of the spectrum). *For all $\lambda \in \sigma(A)$,*

$$\lim_{h\to 0} \delta_h(\lambda, \sigma(A_h)) = 0.$$

Proof. For $\lambda = 1$, since $\lambda_h = 1 \in \sigma(A_h)$, the result is obvious. For $\lambda \neq 1$, Theorems 4.11 and 4.12 imply that, for $E = E_\lambda$,

$$\lim_{h\to 0} \widehat{\delta}_h(E(\mathbf{V}), E_h(\mathbf{V}_h)) = 0. \tag{4.6}$$

Now, let m and m_h be the (finite) dimensions of $E(\mathbf{V})$ and $E_h(\mathbf{V}_h)$, respectively. Then, (4.6) implies that, for h small enough, $m_h = m$ (see [36, p. 200]). In particular, denoting by D_Γ the domain of $\mathbb{C}$ bounded by Γ, if $D_\Gamma \cap (\sigma(A) \setminus \{1\}) \neq \emptyset$, then, for h small enough, $D_\Gamma \cap (\sigma(A_h) \setminus \{1\}) \neq \emptyset$. The fact that all the eigenvalues are isolated allows us to conclude. ∎

4.5. Approximation of eigenvalues and eigenfunctions. In this section we report the consequences of the results obtained in the previous section on the approximation of the eigenvalues and the eigenfunctions. The results in this section are stated without proof, since their proofs are standard and the paper [26] can be used as a reference; the proof of the eigenvalue estimates is also reported in [3].

Let $\lambda \neq 1$ be an eigenvalue of A, and let m be its (finite) multiplicity. We denote by E and E_h the associated continuous and discrete spectral projections, respectively. At the end of the previous section, we have proved that there exist exactly m eigenvalues $\{\lambda_{1,h}, \dots, \lambda_{m,h}\}$ of A_h (repeated with their multiplicities) which converge to λ, i.e.,

$$\lim_{h\to 0} \sup_{1\le i\le m} |\lambda - \lambda_{i,h}| = 0.$$

In the following theorem, we analyze the convergence rate of this limit (convergence of eigenvalues) and the one of the limits in Theorem 4.12 (convergence of eigenfunctions).

THEOREM 4.14. *Let $\lambda \neq 1$ be an eigenvalue of A, and let E and E_h be the associated continuous and discrete spectral projections, respectively. Then, for h small enough, it holds that*

$$\delta_h(E(\mathbf{V}), E_h(\mathbf{V}_h)) \le Ch^t,$$
$$\sup_{1\le i\le m} |\lambda - \lambda_{i,h}| \le Ch^t,$$

where t is the maximal exponent which can be used in the bound (3.5) *of Assumption* 4 *for all $\mathbf{f} \in E(\mathbf{V})$, and the constant C depends only on λ (and deteriorates for small values of λ). Moreover, for hermitian DG methods, we have*

$$\sup_{1\le i\le m} |\lambda - \lambda_{i,h}| \le Ch^{2t}.$$

5. Remarks on Assumptions 5 and 6. In this section we make some remarks on our key assumptions, Assumptions 5 and 6. More precisely, in sections 5.1 and 5.2, respectively, we show that

(i) Assumptions 5 and 6 are not only sufficient but also necessary for a spurious-free DG approximation of Problem 1; therefore, provided that Assumptions 1–4 are satisfied, Assumptions 5 and 6 are *necessary and sufficient* for a DG method to provide a spurious-free approximation of Problem 1;

(ii) Assumption 6 implies that $K_h^\perp$ and K_h are approximating in $\mathbf{W}$ and in $\mathbf{V}^0$, respectively (see (2.3)), provided that $\mathbf{V}_h$ is approximating in $\mathbf{V}$.

5.1. Necessity of Assumptions 5 and 6. For simplicity, we restrict ourselves to hermitian formulations and prove the necessity of Assumptions 5 and 6 for a spurious-free DG approximation of Problem 1.

PROPOSITION 5.1. *Any spurious-free hermitian DG method satisfies Assumption* 5.

Proof. We proceed as in the proof of [18, Lemma 6.5]. Let $\mathbf{v}$ be in $K_h^\perp$, and consider its spectral decomposition

$$\mathbf{v} = \sum_{1\neq\lambda_h\in\sigma(A_h)} \mathbf{v}_{\lambda_h},$$

with $\mathbf{v}_{\lambda_h}$ being an eigenfunction associated with $\lambda_h \in \sigma(A_h)$. Since $a_h(\cdot,\cdot)$ is hermitian, $a_h(\mathbf{v},\mathbf{v})$ is real; thus we can write

$$\begin{aligned} a_h(\mathbf{v},\mathbf{v}) &= \sum_{1\neq\lambda_h\in\sigma(A_h)} \sum_{1\neq\nu_h\in\sigma(A_h)} a_h(\mathbf{v}_{\lambda_h},\mathbf{v}_{\nu_h}) \\ &= \sum_{1\neq\lambda_h\in\sigma(A_h)} \sum_{1\neq\nu_h\in\sigma(A_h)} \left(\frac{1}{\lambda_h}-1\right)(\mathbf{v}_{\lambda_h},\mathbf{v}_{\nu_h})_\varepsilon \geq \frac{1-\beta}{\beta}\|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega}^2, \end{aligned}$$

due to Property 1; therefore Assumption 5 is satisfied with $C = \beta/(1-\beta)$. ∎

PROPOSITION 5.2. *Any spurious-free hermitian DG method satisfies Assumption* 6.

Proof. The proof is similar to the one of [18, Lemma 6.3]. Assumption 6 can be rewritten as follows: for all $\eta > 0$, there is $\overline{h} > 0$ such that, for all $h \in (0,\overline{h})$, for any $\mathbf{w}_h \in K_h^\perp$ with $\|\mathbf{w}_h\|_{\mathbf{V}(h)} = 1$, there exists $\mathbf{w} \in H(\mathrm{div}_\varepsilon^0;\Omega)$ such that

$$\|\varepsilon^{1/2}(\mathbf{w}-\mathbf{w}_h)\|_{0,\Omega} \leq \eta$$

(we have used the equivalence between the L^2-norm and the L^2_ε-norm).

Let $\{\lambda_j\}_{j=1}^\infty$ be the decreasing sequence of all the continuous eigenvalues $1 \neq \lambda_j \in \sigma(A)$, where each distinct λ_j appears only once in the sequence, independently of its multiplicity m_j. Denoting by n_h the dimension of $K_h^\perp$, let $\{\lambda_{i,h}\}_{i=1}^{n_h}$ be the nonincreasing sequence of all the discrete eigenvalues $1 \neq \lambda_{i,h} \in \sigma(A_h)$, repeated according to their multiplicity.

Fix $\eta > 0$. Since $\lambda_1 \leq \frac{1}{1+\alpha_c} < 1$, with α_c being the $\mathbf{V}$-ellipticity constant of $a(\cdot,\cdot)$ in $\mathbf{W}$, there exists $k > 0$ such that $\lambda_k < \frac{\eta^2}{8\gamma} - \frac{1}{4}\frac{\eta^2}{8\gamma}$, where γ is the continuity constant of the form $a_h(\cdot,\cdot)$ (see Assumption 3); moreover, we can choose mutually disjoint neighborhoods $N(\lambda_j)$ of λ_j, $1 \leq j \leq k$, such that $N(\lambda_j) \subset (\lambda_j - \frac{1}{4}\frac{\eta^2}{8\gamma}, \lambda_j + \frac{1}{4}\frac{\eta^2}{8\gamma})$. From Theorem 4.5 and Property 1, there is $h_1 > 0$ such that, for all $h < h_1$, $N(\lambda_j)$ contains exactly m_j discrete eigenvalues, $1 \leq j \leq k$; moreover, $N(1)$ can be chosen in such a way that $N(1) \cap \{\lambda_{i,h}\}_{i=1}^{n_h} = \emptyset$. Set $m = \sum_{j=1}^k m_j$; obviously, $m \leq n_h$.

Now, take $h < h_1$, fix $\mathbf{w}_h \in K_h^\perp$, with $\|\mathbf{w}_h\|_{\mathbf{V}(h)} = 1$, and consider its spectral decomposition

$$\mathbf{w}_h = \sum_{i=1}^{n_h} \mathbf{w}_{i,h} = \sum_{i=1}^{m} \mathbf{w}_{i,h} + \sum_{i=m+1}^{n_h} \mathbf{w}_{i,h} =: \mathbf{w}_h^1 + \mathbf{w}_h^2.$$

For the term $\mathbf{w}_h^2$, we use Proposition 3.3(ii). Denoting by $\lambda_{\ell,h}$ the eigenvalue corresponding to $\mathbf{w}_{\ell,h}$, we can write

$$\begin{aligned} \|\varepsilon^{1/2}\mathbf{w}_h^2\|_{0,\Omega}^2 &= \sum_{i=m+1}^{n_h} \|\varepsilon^{1/2}\mathbf{w}_{i,h}\|_{0,\Omega}^2 = \sum_{i=m+1}^{n_h} b_h(A_h\mathbf{w}_{i,h},\mathbf{w}_{i,h}) \\ &= \sum_{i=m+1}^{n_h} \lambda_{i,h} b_h(\mathbf{w}_{i,h},\mathbf{w}_{i,h}) \leq \lambda_{m,h} \sum_{i=m+1}^{n_h} b_h(\mathbf{w}_{i,h},\mathbf{w}_{i,h}) \\ &= \lambda_{m,h} b_h(\mathbf{w}_h^2,\mathbf{w}_h^2) \leq 2\gamma\lambda_{m,h}\|\mathbf{w}_h^2\|_{\mathbf{V}(h)}^2. \end{aligned}$$

Since $\|\mathbf{w}_h^2\|_{\mathbf{V}(h)} \leq \|\mathbf{w}_h\|_{\mathbf{V}(h)} = 1$ and $\lambda_{m,h} < \frac{\eta^2}{8\gamma}$, due to $\lambda_{m,h} \in N(\lambda_k)$, we obtain

$$\|\varepsilon^{1/2}\mathbf{w}_h^2\|_{0,\Omega} \leq \frac{\eta}{2}. \tag{5.1}$$

Let us turn now to the term $\mathbf{w}_h^1$, and consider its spectral decomposition

$$\mathbf{w}_h^1 = \sum_{i=1}^{m} \mathbf{w}_{i,h} = \sum_{j=1}^{k} \sum_{i=a_j}^{b_j} \mathbf{w}_{i,h} =: \sum_{j=1}^{k} \widetilde{\mathbf{w}}_{j,h},$$

where $a_j = \sum_{i=1}^{j-1} m_i$ and $b_j = \sum_{i=1}^{j} m_i$. Owing to Theorem 4.11, in correspondence with η, there is $h_2 > 0$ such that, for all $h < h_2$, for each $1 \le j \le k$, there exists a continuous eigenfunction $\mathbf{w}_j$ associated with λ_j such that $\|\mathbf{w}_j - \widetilde{\mathbf{w}}_{j,h}\|_{\mathbf{V}(h)} \le \frac{\eta}{2k}$. Set $\mathbf{w} = \sum_{j=1}^{k} \mathbf{w}_j$; clearly, $\mathbf{w} \in \mathbf{W}$. Then,

$$\|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h^1)\|_{0,\Omega} \le \sum_{j=1}^{k} \|\varepsilon^{1/2}(\mathbf{w}_j - \widetilde{\mathbf{w}}_{j,h})\|_{0,\Omega} \le \frac{\eta}{2}. \tag{5.2}$$

Therefore, for all $h < \overline{h} = \min\{h_1, h_2\}$, in correspondence to any $\mathbf{w}_h \in K_h^\perp$ with $\|\mathbf{w}_h\|_{\mathbf{V}(h)=1}$, we have found $\mathbf{w} \in \mathbf{W} \subset H(\mathrm{div}_\varepsilon^0; \Omega)$ such that

$$\|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega} \le \|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h^1)\|_{0,\Omega} + \|\varepsilon^{1/2}\mathbf{w}_h^2\|_{0,\Omega} \le \eta,$$

owing to (5.1) and (5.2), which concludes the proof. ∎

Remark 5.3. From the proof of Proposition 5.2 it is clear that a spurious-free hermitian DG method satisfies Assumption 6 with $\mathbf{w} \in \mathbf{W}$.

5.2. Gap properties. Let $P : L^2(\Omega)^d \to H(\mathrm{div}_\varepsilon^0; \Omega)$ and $Q = I - P$ be the projection operators associated with the first decomposition in (2.3). Notice that, for all $\mathbf{v} \in \mathbf{V}(h)$, $P\mathbf{v}$ and $Q\mathbf{v}$ belong to $\mathbf{V}(h)$, and $Q \in \mathcal{L}(L^2(\Omega)^d, \mathbf{V}(h))$. The restrictions of P and Q to $\mathbf{V}$ are onto $\mathbf{W}$ and $\mathbf{V}^0$, respectively, and coincide with the projection operators associated with the second decomposition in (2.3). We will make use of the following lemma.

LEMMA 5.4. *Assumption* 6 *implies that, for all* h *small enough,*

$$\|\mathbf{w}_h - P\mathbf{w}_h\|_{\mathbf{V}(h)} = \|Q\mathbf{w}_h\|_{\mathbf{V}(h)} \le \eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)} \qquad \forall \mathbf{w}_h \in K_h^\perp,$$

with $\eta_h \to 0$ *as* $h \to 0$.

Proof. Let us rewrite Assumption 6 as follows: for all h small enough, there exists an operator $\Pi_h : K_h^\perp \to H(\mathrm{div}_\varepsilon^0; \Omega)$ such that $\Pi_h \in \mathcal{L}(\mathbf{V}(h), L^2(\Omega)^d)$ and

$$\|\mathbf{w}_h - \Pi_h \mathbf{w}_h\|_{0,\Omega} \le \eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)}, \tag{5.3}$$

with $\eta_h \to 0$ as $h \to 0$.

Then, for all h small enough, due to $\Pi_h \mathbf{w}_h \in H(\mathrm{div}_\varepsilon^0; \Omega)$ and to (5.3), we have

$$\begin{aligned} \|\mathbf{w}_h - P\mathbf{w}_h\|_{\mathbf{V}(h)} &= \|Q\mathbf{w}_h\|_{\mathbf{V}(h)} = \|Q(\mathbf{w}_h - \Pi_h \mathbf{w}_h)\|_{\mathbf{V}(h)} \\ &\le \|Q\|_{\mathcal{L}(L^2(\Omega)^d, \mathbf{V}(h))} \|\mathbf{w}_h - \Pi_h \mathbf{w}_h\|_{0,\Omega} \le C\eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)}, \end{aligned}$$

with $\eta_h \to 0$, as $h \to 0$. ∎

We have the following result.

PROPOSITION 5.5. *Assumptions* 1, 2, 3, *and* 6 *imply that* $K_h^\perp$ *is approximating in* $\mathbf{W}$, *i.e.,*

$$\lim_{h \to 0} \inf_{\mathbf{w}_h \in K_h^\perp} \|\mathbf{w} - \mathbf{w}_h\|_{\mathbf{V}(h)} = 0 \qquad \forall \mathbf{w} \in \mathbf{W}.$$

Moreover, provided that, in addition, Assumption 2 *holds true for all* $\mathbf{v} \in \mathbf{V}$*, we also have that* $K_h \subset \mathbf{V}^0$ *is approximating in* $\mathbf{V}^0$*, i.e.,*

$$\lim_{h\to 0} \inf_{\mathbf{k}_h \in K_h} \|\mathbf{k} - \mathbf{k}_h\|_{0,\Omega} = 0 \qquad \forall \mathbf{k} \in \mathbf{V}^0.$$

Proof. We use similar arguments as in [16, Theorem 3.3]. Let $P_h : \mathbf{V}_h \to K_h^\perp$ and $Q_h = I - P_h$ be the projection operators associated with the $\mathbf{V}(h)$-orthogonal decomposition $\mathbf{V}_h = K_h \oplus K_h^\perp$, and let $I_h : \mathbf{V} \to \mathbf{V}_h$ be the $\mathbf{V}(h)$-orthogonal projection. We proceed in two steps.

(i) $K_h^\perp$ *is approximating in* $\mathbf{W}$. We start by observing that if $\mathbf{w} \in \mathbf{W}$, then $I_h\mathbf{w} \in K_h^\perp$; in fact, for all $\mathbf{k}_h \in K_h$, since $K_h \subset \mathbf{V}^0$, we have $(I_h\mathbf{w}, \mathbf{k}_h)_{\mathbf{V}(h)} = (\mathbf{w}, \mathbf{k}_h)_{\mathbf{V}(h)} = (\mathbf{w}, \mathbf{k}_h)_\varepsilon$, which is equal to zero, due to the L^2_ε-orthogonality between $\mathbf{V}^0$ and $\mathbf{W}$. Now, given $\mathbf{w} \in \mathbf{W}$, we let $\mathbf{w}_h \in K_h^\perp$ be defined by $\mathbf{w}_h = I_h\mathbf{w}$. Assumption 2 ensures that $\|\mathbf{w} - I_h\mathbf{w}\|_{\mathbf{V}(h)}$ converges to zero, as $h \to 0$, and the proof of (i) is complete.

(ii) K_h *is approximating in* $\mathbf{V}^0$. Given $\mathbf{k} \in \mathbf{V}^0$, we let $\mathbf{k}_h \in K_h$ be defined by $\mathbf{k}_h = Q_h I_h \mathbf{k}$. Since $\mathbf{k} - \mathbf{k}_h = Q(\mathbf{k} - I_h\mathbf{k}) + (Q - Q_h)I_h\mathbf{k}$, we have

$$\|\mathbf{k} - \mathbf{k}_h\|_{0,\Omega} \le \|Q(\mathbf{k} - I_h\mathbf{k})\|_{0,\Omega} + \|(Q - Q_h)I_h\mathbf{k}\|_{0,\Omega}.$$

For the first term, we have

$$\|Q(\mathbf{k} - I_h\mathbf{k})\|_{0,\Omega} \le \|Q\|_{\mathcal{L}(L^2(\Omega)^d, L^2(\Omega)^d)} \|\mathbf{k} - I_h\mathbf{k}\|_{0,\Omega},$$

which converges to zero, as $h \to 0$, since we have supposed Assumption 2 to be satisfied for all functions in $\mathbf{V}$. For the second term, we have

$$(Q - Q_h)I_h\mathbf{k} = (Q - Q_h)(P_h I_h\mathbf{k} + Q_h I_h\mathbf{k}) = QP_h I_h\mathbf{k},$$

since, due to $K_h \subset \mathbf{V}^0$, Q is identity on K_h. Therefore,

$$\|(Q - Q_h)I_h\mathbf{k}\|_{0,\Omega} = \|QP_h I_h\mathbf{k}\|_{0,\Omega} \le \eta_h \|P_h I_h\mathbf{k}\|_{0,\Omega} \le C\eta_h \|\mathbf{k}\|_{0,\Omega},$$

owing to Lemma 5.4 and the fact that P_h and I_h are $\mathbf{V}(h)$-orthogonal projections and $\mathbf{k} \in \mathbf{V}^0$. This completes the proof. ∎

6. The indefinite Maxwell source problem. Consider the following indefinite Maxwell source problem: given $\mathbf{f} \in L^2(\Omega)^d$ and $\omega \in \mathbb{R}$ such that ω^2 is not an eigenvalue of Problem 1, find $\mathbf{u} \in \mathbf{V}$ such that

$$\nabla \times (\mu^{-1}\nabla \times \mathbf{u}) - \omega^2 \varepsilon \mathbf{u} = \mathbf{f}. \tag{6.1}$$

The theory developed so far guarantees that, for the DG method for (6.1), i.e., find $\mathbf{u}_h \in \mathbf{V}_h$ such that

$$a_h(\mathbf{u}_h, \mathbf{v}) - \omega^2 (\mathbf{u}_h, \mathbf{v})_\varepsilon = (\mathbf{f}, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathbf{V}_h, \tag{6.2}$$

the following result holds true.

THEOREM 6.1. *Provided that Assumptions* 1–6 *are satisfied, for* h *small enough, the DG method* (6.2) *is well-posed.*

Proof. Let $\mathbf{g}_h$ be the (unique) element of $\mathbf{V}_h$ such that

$$(\mathbf{g}_h, \mathbf{v})_\varepsilon = (\mathbf{f}, \mathbf{v}) \qquad \forall \mathbf{v} \in \mathbf{V}_h. \tag{6.3}$$

Then, since $a_h(\mathbf{u}_h,\mathbf{v})-\omega^2(\mathbf{u}_h,\mathbf{v})_\varepsilon = b_h(\mathbf{u}_h,\mathbf{v})-(1+\omega^2)(\mathbf{u}_h,\mathbf{v})_\varepsilon$, setting $z=1/(1+\omega^2)$, we can write (6.2) as

$$b_h(z\mathbf{u}_h,\mathbf{v}) = z(\mathbf{g}_h,\mathbf{v})_\varepsilon + (\mathbf{u}_h,\mathbf{v})_\varepsilon \qquad \forall \mathbf{v}\in\mathbf{V}_h$$

or, equivalently, using the definition of the solution operator A_h,

$$b_h(A_h\mathbf{u}_h + zA_h\mathbf{g}_h - z\mathbf{u}_h,\mathbf{v}) = 0 \qquad \forall \mathbf{v}\in\mathbf{V}_h.$$

From this, due to the coercivity of $b_h(\cdot,\cdot)$ (see Assumption 3 and Remark 3.1), it holds that

$$(z-A_h)\mathbf{u}_h = zA_h\mathbf{g}_h. \tag{6.4}$$

Since ω^2 is not an eigenvalue of Problem 1, then $0\neq z\in\rho(A)$; thus Theorem 4.7 applies, and we have that (6.4) admits the unique solution $\mathbf{u}_h = z(z-A_h)^{-1}A_h\mathbf{g}_h$ for h small enough. Moreover, due to Corollary 4.8 and $A_h\in\mathcal{L}(L^2(\Omega)^d,\mathbf{V}_h)$, there exists $C>0$ independent of the mesh size such that

$$\|\mathbf{u}_h\|_{\mathbf{V}(h)} \le C\|\mathbf{g}_h\|_{0,\Omega} \le C\|\mathbf{f}\|_{0,\Omega}, \tag{6.5}$$

where the second inequality follows from (6.3) and the equivalence between the L^2-norm and the L^2_ε-norm. ∎

We end this section by proving the following inf-sup condition.

PROPOSITION 6.2. *With the assumptions of Theorem* 6.1*, for h small enough, there exists a constant $\kappa>0$ independent of h such that*

$$\inf_{\mathbf{0}\neq\mathbf{u}_h\in\mathbf{V}_h}\sup_{\mathbf{0}\neq\mathbf{v}_h\in\mathbf{V}_h}\frac{\mathrm{Re}\,[a_h(\mathbf{u}_h,\mathbf{v}_h)-\omega^2(\mathbf{u}_h,\mathbf{v}_h)_\varepsilon]}{\|\mathbf{u}_h\|_{\mathbf{V}(h)}\|\mathbf{v}_h\|_{\mathbf{V}(h)}} \ge \kappa. \tag{6.6}$$

Proof. Theorem 6.1 implies that, for h small enough, there exists a constant $\kappa'>0$ independent of h such that

$$\inf_{\mathbf{0}\neq\mathbf{v}_h\in\mathbf{V}_h}\sup_{\mathbf{0}\neq\mathbf{u}_h\in\mathbf{V}_h}\frac{\mathrm{Re}\,[a_h(\mathbf{u}_h,\mathbf{v}_h)-\omega^2(\mathbf{u}_h,\mathbf{v}_h)_\varepsilon]}{\|\mathbf{u}_h\|_{\mathbf{V}(h)}\|\mathbf{v}_h\|_{\mathbf{V}(h)}} \ge \kappa'. \tag{6.7}$$

In fact, fix $\mathbf{v}_h\in\mathbf{V}_h$ and set $\mathbf{u}_h=\mathbf{u}_h^1+(1+\omega^2)\mathbf{u}_h^2$, with $\mathbf{u}_h^1=\mathbf{v}_h$ and $\mathbf{u}_h^2$ solution to (6.2) with $\mathbf{f}=\varepsilon\mathbf{v}_h$; the stability estimate (6.5) and the coercivity in Assumption 3 lead to (6.7).

If $a_h(\cdot,\cdot)$ is hermitian, (6.6) coincides with (6.7), and the proof is complete. Otherwise, we prove the well-posedness of the adjoint problem as follows: given $\mathbf{f}\in L^2(\Omega)^d$ and $\omega\in\mathbb{R}$ such that ω^2 is not an eigenvalue of Problem 1, find $\mathbf{v}_h\in\mathbf{V}_h$ such that

$$a_h(\mathbf{w}_h,\mathbf{v}_h)-\omega^2(\mathbf{w}_h,\mathbf{v}_h)_\varepsilon = (\mathbf{f},\mathbf{w}_h) \qquad \forall \mathbf{w}_h\in\mathbf{V}_h. \tag{6.8}$$

Existence and uniqueness of the solution of (6.8), for h small enough, immediately follow from Theorem 6.1, due to finite dimensionality. For the stability, due to (6.7), in correspondence to $\mathbf{v}_h$, we can find $\mathbf{0}\neq\mathbf{w}_h\in\mathbf{V}_h$ such that

$$\begin{aligned}\kappa'\|\mathbf{w}_h\|_{\mathbf{V}(h)}\|\mathbf{v}_h\|_{\mathbf{V}(h)} &\le \mathrm{Re}\,[a_h(\mathbf{w}_h,\mathbf{v}_h)-\omega^2(\mathbf{w}_h,\mathbf{v}_h)_\varepsilon] = \mathrm{Re}\,[(\mathbf{f},\mathbf{w}_h)]\\ &\le \|\mathbf{f}\|_{L^2(\Omega)^d}\|\mathbf{w}_h\|_{\mathbf{V}(h)},\end{aligned}$$

which immediately gives $\|\mathbf{v}_h\|_{\mathbf{V}(h)}\le C\|\mathbf{f}\|_{L^2(\Omega)^d}$, with $C>0$ independent of h.

Therefore, the inf-sup condition (6.6) follows from the well-posedness of the adjoint problem (6.8), the same way as the inf-sup condition (6.7) follows from the well-posedness of problem (6.2), and the proof is complete. ∎

Remark 6.3. It is well known that the inf-sup condition (6.6) is a key ingredient in the proof of error estimates; see Remark 7.11.

7. Application to some discontinuous Galerkin methods. In this section we apply the theory developed in the previous sections to some of the DG methods present in the literature, more precisely, to the methods of the interior penalty family (interior penalty (IP), nonsymmetric interior penalty (NIP), and incomplete interior penalty (IIP); see [4], [44], and [23], respectively) and to the local discontinuous Galerkin method (LDG; see [21]). We point out that everything stated below holds true also for the variants of the IP and LDG methods introduced in [7] and [14], respectively. We restrict ourselves to the case of *conformal meshes*, i.e., with no *hanging nodes*.

This section is organized as follows: in sections 7.1 and 7.2 the DG spaces and bilinear forms are defined and proved to fulfill the assumptions in section 3; in section 7.3 we prove that Assumption 5 is satisfied. In section 7.4, Assumption 6 is proved, and a few remarks aiming at specializing the results of our theory to the examples presented here are provided. Finally, in section 7.5 we investigate the relation of Assumption 6 with the discrete compactness property (see Property 3).

7.1. Meshes, trace operators, finite element spaces, and norms. Consider conformal, shape-regular partitions $\mathcal{T}_h$ of Ω into simplices $\{K\}$, where $h = \max_{K\in\mathcal{T}_h} h_K$, with $h_K = \operatorname{diam}(K)$ for all $K \in \mathcal{T}_h$. We denote by $\mathcal{F}_h^{\mathcal{I}}$ the set of all interior faces (edges if $d = 2$) of $\mathcal{T}_h$ and by $\mathcal{F}_h^{\mathcal{B}}$ the set of all boundary faces of $\mathcal{T}_h$, and we set $\mathcal{F}_h = \mathcal{F}_h^{\mathcal{I}} \cup \mathcal{F}_h^{\mathcal{B}}$. For a piecewise smooth vector-valued function $\mathbf{v}$, we introduce the following trace operators. Let $f \in \mathcal{F}_h^{\mathcal{I}}$ be an interior face shared by two neighboring elements K^+ and K^-; we write $\mathbf{n}^\pm$ to denote the outward normal unit vectors to the boundaries $\partial K^\pm$, respectively. Denoting by $\mathbf{v}^\pm$ the traces of $\mathbf{v}$ taken from within $K^\pm$, respectively, we define the tangential jumps and averages across f by

$$[\![\mathbf{v}]\!]_T := \mathbf{n}^+ \times \mathbf{v}^+ + \mathbf{n}^- \times \mathbf{v}^-, \qquad \{\!\{\mathbf{v}\}\!\} := (\mathbf{v}^+ + \mathbf{v}^-)/2,$$

respectively; if $d = 2$, defining the tangential vectors $\mathbf{t}^\pm = (-n_2^\pm, n_1^\pm)$, we understand $[\![\mathbf{v}]\!]_T$ as $\mathbf{v}^+ \cdot \mathbf{t}^+ + \mathbf{v}^- \cdot \mathbf{t}^-$.

On a boundary face $f \in \mathcal{F}_h^{\mathcal{B}}$, we set $[\![\mathbf{v}]\!]_T := \mathbf{n} \times \mathbf{v}$ and $\{\!\{\mathbf{v}\}\!\} := \mathbf{v}$.

For a given partition $\mathcal{T}_h$ of Ω and an approximation order $\ell \geq 1$, we define the complex vector-valued discontinuous finite element space

$$\mathbf{V}_h := \{\mathbf{v} \in L^2(\Omega)^d : \mathbf{v}|_K \in \mathcal{P}^\ell(K)^d \quad \forall K \in \mathcal{T}_h\}, \tag{7.1}$$

where $\mathcal{P}^\ell(K)$ is the space of complex polynomials of total degree at most ℓ on K. We also need to define the complex scalar-valued discontinuous finite element space

$$Q_h = \{q \in L^2(\Omega) : \mathbf{v}|_K \in \mathcal{P}^{\ell+1}(K) \quad \forall K \in \mathcal{T}_h\}.$$

We point out that all the results of this section hold true also with the choice of the local Nédélec elements of the first type [40], instead of the full polynomials of degree ℓ, in (7.1). For the case of parallelograms or parallelepipeds, see Remark 7.14.

We endow both $\mathbf{V}_h$ and $\mathbf{V}(h) = \mathbf{V} + \mathbf{V}_h$ with the seminorm and norm

$$|\mathbf{v}|^2_{\mathbf{V}(h)} = \|\mu^{-1/2}\nabla_h \times \mathbf{v}\|^2_{0,\Omega} + \|\mathtt{h}^{-1/2}[\![\mathbf{v}]\!]_T\|^2_{0,\mathcal{F}_h},$$
$$\|\mathbf{v}\|^2_{\mathbf{V}(h)} = |\mathbf{v}|^2_{\mathbf{V}(h)} + \|\varepsilon^{1/2}\mathbf{v}\|^2_{0,\Omega},$$

where we have denoted by ∇_h the elementwise application of the ∇ operator and used the notation $\|\varphi\|^2_{0,\mathcal{F}_h} := \sum_{f\in\mathcal{F}_h} \|\varphi\|^2_{0,f}$. In the following, we will also use the notation $\int_{\mathcal{F}_h} \varphi\, ds := \sum_{f\in\mathcal{F}_h} \int_f \varphi\, ds$.

The mesh function $\mathtt{h} \in L^\infty(\mathcal{F}_h)$ is defined by

$$\mathtt{h}(\mathbf{x}) := h_f\, \mathtt{m}(\mathbf{x}), \qquad \mathbf{x} \in f,\ f \in \mathcal{F}_h,$$

with h_f denoting the diameter of the face f and the function $\mathtt{m} \in L^\infty(\mathcal{F}_h)$ being defined as follows: if μ_K denotes the extension of $\mu_{|_K}$ up to ∂K, and $|\mu_K(\mathbf{x})|$ denotes the spectral norm of the tensor $\mu_K(\mathbf{x})$, then $\mathtt{m}(\mathbf{x}) = \min\{|\mu_{K^+}(\mathbf{x})|, |\mu_{K^-}(\mathbf{x})|\}$ if $\mathbf{x}$ is in the interior of $\partial K^+ \cap \partial K^-$ and $\mathtt{m}(\mathbf{x}) = |\mu_K(\mathbf{x})|$ if $\mathbf{x}$ is in the interior of $\partial K \cap \partial\Omega$.

The following result is then evident.

PROPOSITION 7.1. *Assumptions* 1 *and* 2 *are satisfied.*

7.2. Discontinuous Galerkin bilinear forms. We recall the expressions of the DG bilinear forms associated with the IP methods and with the LDG method applied to the Maxwell equations, pointing for further details to [43], [35] for the IP method and to [42], [31], [32] for the LDG method.

Define the IP, NIP, and IIP forms $a_h^{IP(k)} : \mathbf{V}_h \times \mathbf{V}_h \to \mathbb{C}$

$$\begin{aligned} a_h^{IP(k)}(\mathbf{u},\mathbf{v}) :=& (\mu^{-1}\nabla_h \times \mathbf{u}, \nabla_h \times \mathbf{v}) - \int_{\mathcal{F}_h} [\![\overline{\mathbf{v}}]\!]_T \cdot \{\!\{\mu^{-1}\nabla_h \times \mathbf{u}\}\!\}\, ds \\ & - k \int_{\mathcal{F}_h} [\![\mathbf{u}]\!]_T \cdot \{\!\{\mu^{-1}\nabla_h \times \overline{\mathbf{v}}\}\!\}\, ds + \int_{\mathcal{F}_h} \mathtt{a}\, [\![\mathbf{u}]\!]_T \cdot [\![\overline{\mathbf{v}}]\!]_T\, ds, \end{aligned}$$

where $k = 1$ for the IP method, $k = -1$ for the NIP method, and $k = 0$ for the IIP method, and the stabilization function $\mathtt{a} \in L^\infty(\mathcal{F}_h)$ is defined by

$$\mathtt{a} := a_{\mathrm{stab}}\, \mathtt{h}^{-1}, \tag{7.2}$$

with $a_{\mathrm{stab}} > 0$ independent of the mesh size and the material coefficients.

The LDG form is defined as follows:

$$a_h^{LDG}(\mathbf{u},\mathbf{v}) := (\mu^{-1}(\nabla_h \times \mathbf{u} - \mathcal{L}(\mathbf{u})), \nabla_h \times \mathbf{v} - \mathcal{L}(\mathbf{v})) + \int_{\mathcal{F}_h} \mathtt{a}\, [\![\mathbf{u}]\!]_T \cdot [\![\overline{\mathbf{v}}]\!]_T\, ds, \tag{7.3}$$

with $\mathtt{a}$ again as in (7.2), and $\mathcal{L}$ is the *lifting operator* from $\mathbf{V}(h)$ into $\mathbf{V}_h$ defined by

$$(\mathcal{L}(\mathbf{v}), \mathbf{w}) = \int_{\mathcal{F}_h^{\mathcal{I}}} \mathtt{b} [\![\mathbf{v}]\!]_T \cdot [\![\overline{\mathbf{w}}]\!]_T\, ds + \int_{\mathcal{F}_h} [\![\mathbf{v}]\!]_T \cdot \{\!\{\overline{\mathbf{w}}\}\!\}\, ds \qquad \forall \mathbf{w} \in \mathbf{V}_h;$$

here, $\mathtt{b} \in L^\infty(\mathcal{F}_h)$ is a bounded function independent of the mesh size.

Remark 7.2. The LDG method is usually defined by introducing the auxiliary variable $\mathbf{s} := \mu^{-1}\nabla \times \mathbf{u}$ and rewriting the second order problem in mixed form as a first order system; then an element-by-element integration by parts is performed, and the traces along the elemental boundaries are replaced by the so-called *numerical fluxes*, obtaining an $(\mathbf{s},\mathbf{u})$-formulation of the method, which is equivalent to the $\mathbf{u}$-formulation $a_h^{LDG}(\mathbf{u},\mathbf{v}) = \omega(\mathbf{u},\mathbf{v})_\varepsilon$, with $a_h^{LDG}(\mathbf{u},\mathbf{v})$ as in (7.3), after elimination of the auxiliary variable $\mathbf{s}$ in terms of $\mathbf{u}$ (see [42] for details). Here, we concentrate on the $\mathbf{u}$-formulation because we are concerned only with the analysis of the method in the framework presented in this paper.

We prove that the DG bilinear forms in this section fulfill Assumptions 3 and 4.

PROPOSITION 7.3. *Provided that* a_{stab} *in* (7.2) *is large enough, in the case of the IP and IIP methods, for all the considered DG bilinear forms Assumptions* 3 *and* 4 *are*

satisfied. Moreover, the exponent t *in* (3.5) *can be chosen as* $t = \min\{\ell, r\}$. *Finally, the condition* (3.2) *is satisfied.*

Proof. The validity of Assumption 3 is standard and the one of (3.2) is straightforward. The proof of Assumption 4 is technical, and we postpone it to the appendix. Note that existent results (see [42], [35], or [34]) apply only when $r > 1/2$. ∎

7.3. Discrete Friedrichs inequality (Assumption 5). Denote by $H^1_\Gamma(\Omega)$ the subspace of $H^1(\Omega)$ whose functions have zero trace on Γ_1, the outer boundary of Ω, and constant traces on the other connected components Γ_i of $\partial\Omega$, $i = 2, \dots, n_\Gamma$; notice that if $\partial\Omega$ is connected, then $H^1_\Gamma(\Omega) = H^1_0(\Omega)$. We set $\mathbf{V}_h^c = \mathbf{V}_h \cap \mathbf{V}$ and $Q_h^c = Q_h \cap H^1_\Gamma(\Omega)$; notice that $\mathbf{V}_h^c$ coincides with the $H_0(\mathrm{curl};\Omega)$-conforming Nédélec elements of the second family of degree ℓ (see [41]), and Q_h^c coincides with the space of continuous nodal elements of degree $\ell+1$ with zero trace on Γ_1 and constant traces on Γ_i, $i = 2, \dots, n_\Gamma$. Notice that, due to Assumption 1, we have

$$K_h = \mathbf{V}_h^c \cap \mathbf{V}^0 = \nabla Q_h^c,$$

and we denote by $\mathbf{W}_h^c$ its L^2_ε-orthogonal complement in $\mathbf{V}_h^c$, i.e.,

$$\mathbf{W}_h^c = \{\mathbf{v} \in \mathbf{V}_h^c : (\mathbf{v}, \nabla q)_\varepsilon = 0 \quad \forall q \in Q_h^c\}.$$

By definition, the splitting

$$\mathbf{V}_h^c = \mathbf{W}_h^c \oplus \nabla Q_h^c \tag{7.4}$$

is orthogonal in both the L^2_ε-norm and the $\mathbf{V}$-norm. Moreover, the discrete Friedrichs inequality holds in $\mathbf{W}_h^c$ (see [38, Corollary 7.22]):

$$\|\varepsilon^{1/2}\mathbf{w}\|_{0,\Omega} \le C|\mathbf{w}|_{\mathbf{V}} \qquad \forall\, \mathbf{w} \in \mathbf{W}_h^c. \tag{7.5}$$

We first establish a decomposition of $\mathbf{V}_h$ which will be used in order to prove both Assumptions 5 and 6; the proof is based on the following result (see [34, Proposition 4.5 and the appendix]).

THEOREM 7.4. *There exists an operator* $\Pi_h^c : \mathbf{V}_h \to \mathbf{V}_h^c$ *such that*

$$\|\mathbf{v} - \Pi_h^c \mathbf{v}\|^2_{0,\Omega} \le C \int_{\mathcal{F}_h} \mathtt{h} |[\![\mathbf{v}]\!]_T|^2 \, ds, \tag{7.6}$$

$$\|\mathbf{v} - \Pi_h^c \mathbf{v}\|^2_{\mathbf{V}(h)} \le C \int_{\mathcal{F}_h} \mathtt{h}^{-1} |[\![\mathbf{v}]\!]_T|^2 \, ds \tag{7.7}$$

for all $\mathbf{v} \in \mathbf{V}_h$, *with a constant* $C > 0$ *independent of the mesh size.*

The following proposition is a consequence of Theorem 7.4.

PROPOSITION 7.5. *There exists a complement* $\mathbf{V}_h^\perp$ *of* $\mathbf{V}_h^c := \mathbf{V}_h \cap \mathbf{V}$ *in* $\mathbf{V}_h$ *such that the decomposition* $\mathbf{V}_h = \mathbf{V}_h^c \oplus \mathbf{V}_h^\perp$ *is stable in* $\mathbf{V}_h$, *i.e.,*

$$\mathbf{v}_h = \mathbf{v}_h^c + \mathbf{v}_h^\perp, \qquad \|\mathbf{v}_h^c\|_{\mathbf{V}(h)} + \|\mathbf{v}_h^\perp\|_{\mathbf{V}(h)} \le C\|\mathbf{v}_h\|_{\mathbf{V}(h)}. \tag{7.8}$$

Moreover, it holds that

$$\|\mathbf{v}_h^\perp\|_{0,\Omega} \le Ch|\mathbf{v}_h^\perp|_{\mathbf{V}(h)} \qquad \forall \mathbf{v}_h^\perp \in \mathbf{V}_h^\perp. \tag{7.9}$$

The constant $C > 0$ *is independent of the mesh size.*

Proof. The operator Π_h^c defined in Theorem 7.4 is continuous thanks to (7.7). Moreover, let $\mathbf{v}_h^c \in \mathbf{V}_h^c$, and using again (7.7), we have $\Pi_h^c \mathbf{v}_h^c = \mathbf{v}_h^c$, since $[\![\mathbf{v}_h^c]\!]_T = 0$. This proves that Π_h^c is a projection and that it is surjective. Thus, it defines a stable decomposition of $\mathbf{V}_h$ as $\mathbf{V}_h = \mathbf{V}_h^c \oplus \mathbf{V}_h^\perp$, with $\mathbf{V}_h^\perp = \ker\{\Pi_h^c\}$. In other words, any $\mathbf{v}_h \in \mathbf{V}_h$ is decomposed as $\mathbf{v}_h = \mathbf{v}_h^c + \mathbf{v}_h^\perp$, $\mathbf{v}_h^c = \Pi_h^c \mathbf{v}_h$ and $\mathbf{v}_h^\perp = (I - \Pi_h^c)\mathbf{v}_h$. The estimate (7.7) provides (7.8), and (7.6) provides (7.9), since

$$\|\mathbf{v}_h^\perp\|_{0,\Omega}^2 \le C \int_{\mathcal{F}_h} \mathtt{h} |[\![\mathbf{v}_h]\!]_T|^2 \, ds \le C h^2 \int_{\mathcal{F}_h} \mathtt{h}^{-1} |[\![\mathbf{v}_h^\perp]\!]_T|^2 \, ds \le C h^2 |\mathbf{v}_h^\perp|_{\mathbf{V}(h)}^2. \qquad \square$$

We proceed now by proving Assumption 5. For this, we need the following lemma.

LEMMA 7.6. *We have*

$$\|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega} \le C |\mathbf{v}|_{\mathbf{V}(h)} \qquad \forall \mathbf{v} \in K_h^\perp,$$

with a positive constant C independent of the mesh size.

Proof. Fix $\mathbf{v} \in K_h^\perp$ and decompose it, according to the decompositions (7.8) and (7.4), as $\mathbf{v} = \mathbf{v}^c + \mathbf{v}^\perp = \mathbf{w} + \nabla p + \mathbf{v}^\perp$, with $\mathbf{w} \in \mathbf{W}_h^c$, $p \in Q_h^c$, and $\mathbf{v}^\perp = \mathbf{v} - \Pi_h^c \mathbf{v}$, where Π_h^c is the operator defined in Theorem 7.4. Since $(\mathbf{w}, \nabla q)_\varepsilon = 0$ for all $q \in Q_h^c$, the condition $(\mathbf{v}, \nabla q)_\varepsilon = 0$ for all $q \in Q_h^c$ becomes

$$(\nabla p, \nabla q)_\varepsilon = -(\mathbf{v}^\perp, \nabla q)_\varepsilon \qquad \forall q \in Q_h^c.$$

By taking $q = p$, we obtain that $\|\varepsilon^{1/2}\nabla p\|_{0,\Omega} \le \|\varepsilon^{1/2}\mathbf{v}^\perp\|_{0,\Omega}$, and thus

$$\|\varepsilon^{1/2}\mathbf{v}\|_{0,\Omega} \le \|\varepsilon^{1/2}\mathbf{w}\|_{0,\Omega} + 2\,\|\varepsilon^{1/2}\mathbf{v}^\perp\|_{0,\Omega}. \tag{7.10}$$

For the first term on the right-hand side of (7.10), from the discrete Friedrichs inequality for the conforming Nédélec elements (7.5), the triangle inequality, and (7.7), we get

$$\begin{aligned} \|\varepsilon^{1/2}\mathbf{w}\|_{0,\Omega} &\le C\,\|\mu^{-1/2}\nabla \times \mathbf{w}\|_{0,\Omega} \\ &\le C\left(\|\mu^{-1/2}\nabla_h \times (\mathbf{w} + \mathbf{v}^\perp)\|_{0,\Omega} + \|\mu^{-1/2}\nabla_h \times \mathbf{v}^\perp\|_{0,\Omega}\right) \\ &\le C\left(\|\mu^{-1/2}\nabla_h \times \mathbf{v}\|_{0,\Omega} + \|\mathtt{h}^{-1/2}[\![\mathbf{v}^\perp]\!]_T\|_{0,\mathcal{F}_h}\right) \le C\,|\mathbf{v}|_{\mathbf{V}(h)}. \end{aligned} \tag{7.11}$$

Using again (7.7), we bound the second term on the right-hand side of (7.10) as

$$\|\varepsilon^{1/2}\mathbf{v}^\perp\|_{0,\Omega} \le C\,|\mathbf{v}|_{\mathbf{V}(h)}. \tag{7.12}$$

Inserting (7.11) and (7.12) into (7.10) proves the lemma. $\square$

The following proposition is an immediate consequence of the coercivity in Assumption 3 and Lemma 7.6.

PROPOSITION 7.7. *Assumption* 5 *holds true.*

7.4. Gap property (Assumption 6). The following proposition concludes the analysis of the IP methods and the LDG method.

PROPOSITION 7.8. *Assumption* 6 *holds true.*

Proof. Due to the discrete compactness property for the conforming Nédélec elements (we refer the reader to [18] and [19] for the case of varying coefficients; see also [38, Theorem 7.18]), it can be seen as in [16] that Assumption 6 for the conforming

Nédélec elements holds true (see also the proof of (i) in Proposition 7.13): for all h small enough, for any $\mathbf{w}_h \in \mathbf{W}_h^c$ there exists $\mathbf{w} = \mathbf{w}(h) \in H(\mathrm{div}_\varepsilon^0; \Omega)$ such that

$$\|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega} \leq \eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)}, \tag{7.13}$$

with $\eta_h \to 0$ as $h \to 0$ (we have used the equivalence between the L^2-norm and the L^2_ε-norm).

Now, fix $\mathbf{w}_h \in K_h^\perp$ and decompose it, according to (7.8) and (7.4), as $\mathbf{w}_h = \mathbf{w}_h^c + \mathbf{w}_h^\perp = \mathbf{w}_h^0 + \nabla p_h + \mathbf{w}_h^\perp$, with $\mathbf{w}_h^0 \in \mathbf{W}_h^c$, $p_h \in Q_h^c$, and $\mathbf{w}_h^\perp = \mathbf{w}_h - \Pi_h^c \mathbf{w}_h$, where Π_h^c is the operator defined in Theorem 7.4. For all h small enough, in correspondence to $\mathbf{w}_h^0$, let $\mathbf{w}$ be an element of $H(\mathrm{div}_\varepsilon^0; \Omega)$ which satisfies (7.13). The Cauchy–Schwarz inequality and the L^2_ε-orthogonality of ∇Q_h^c to both $K_h^\perp$ and $H(\mathrm{div}_\varepsilon^0; \Omega)$ give

$$\begin{aligned}
\|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega}^2 &= (\mathbf{w} - \mathbf{w}_h, \mathbf{w} - \mathbf{w}_h)_\varepsilon \\
&= (\mathbf{w} - \mathbf{w}_h, \mathbf{w} - \mathbf{w}_h^0)_\varepsilon - (\mathbf{w} - \mathbf{w}_h, \nabla p_h)_\varepsilon - (\mathbf{w} - \mathbf{w}_h, \mathbf{w}_h^\perp)_\varepsilon \\
&\leq \|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h)\|_{0,\Omega} (\|\varepsilon^{1/2}(\mathbf{w} - \mathbf{w}_h^0)\|_{0,\Omega} + \|\varepsilon^{1/2}\mathbf{w}_h^\perp\|_{0,\Omega}).
\end{aligned}$$

The bounds (7.13) and (7.9), together with the $\mathbf{V}(h)$-stability of the decompositions (7.4) and (7.8), give Assumption 6. ∎

Remark 7.9. With our choice of $\mathbf{V}(h)$, if σ_λ is the regularity exponent of the eigenspace $E(\mathbf{V})$ associated with an eigenvalue $\lambda \neq 1$ of the operator A, i.e., $\mathbf{u} \in H^{\sigma_\lambda}(\mathrm{curl}; \mathcal{T}_h)$ for all $\mathbf{u} \in E(\mathbf{V})$, the exponent t in the eigenvalue and eigenfunction estimates of Theorem 4.14 is given by

$$t = \min\{\ell, \sigma_\lambda\}.$$

Remark 7.10. Numerical results reported in [3] for DG spectral approximations of the Laplace operator have shown that the suboptimal eigenvalue convergence rate of Theorem 4.14 in the case of non-hermitian DG methods (t instead of $2t$) is actually sharp, at least for even approximation polynomial degrees; for odd degrees, one order of convergence better than expected has been observed for smooth solutions. The same behavior has been reported in [29] in the context of error estimation of linear target functionals of the solutions to advection-diffusion-reaction problems.

Remark 7.11. Well-posedness of the DG discretization, for h small enough, of the indefinite source problem (6.1), with ω away from the eigenfrequencies of the continuous problem, has been established in our abstract framework in section 6, together with an inf-sup condition. The result provided in the appendix, together with consistency, guarantees the validity of a quasi-optimal error estimate.

7.5. Relations between Assumption 6 and the discrete compactness property. We conclude this section by establishing directly the relations between Assumption 6 and the so-called *discrete compactness property*.

The discrete compactness property plays a crucial role in the theory of *conforming* finite element methods for the Maxwell eigenproblem (1) (see, e.g., [37], [10], [24]). Here we rephrase this property in the context of nonconforming approximations.

PROPERTY 3 (discrete compactness property). *Let $\{h_n\}_{n=1}^\infty$ be a sequence of decreasing mesh sizes, with $h_n \to 0$ as $n \to \infty$, and let $\{\mathbf{w}_{h_n}\}_{n=1}^\infty$ be a sequence such that $\mathbf{w}_{h_n} \in K_{h_h}^\perp$ and $\|\mathbf{w}_{h_n}\|_{\mathbf{V}(h)} \leq 1$ for all h_n. Then, there exists a subsequence, still denoted $\{\mathbf{w}_{h_n}\}_{n=1}^\infty$, and an element $\mathbf{v} \in L^2(\Omega)^3$ such that*

$$\lim_{h_n \to 0} \|\mathbf{w}_{h_n} - \mathbf{v}\|_{0,\Omega} = 0.$$

Note that if $\mathbf{V}_h \subset \mathbf{V}$ and $\|\cdot\|_{\mathbf{V}(h)} = \|\cdot\|_{\mathbf{V}}$, Property 3 is the standard discrete compactness property for conforming spaces.

It is known that Property 3, the completeness of the approximation spaces (cf. Assumption 2), and the discrete Friedrichs inequality (cf. Assumption 5) are *necessary* and *sufficient* conditions for spurious-free *conforming* approximations (see [18, Theorem 6.8]).

Remark 7.12. If the completeness of the approximation spaces and the discrete Friedrichs inequality hold true, Propositions 2.18 and 2.21 of [18] apply and guarantee that, for conforming approximations, the limit in Property 3 actually belongs to $\mathbf{W}$.

In the following proposition we establish directly the relations between Assumption 6 and Property 3.

PROPOSITION 7.13. *Let Assumption* 1 *hold true. Then, Assumption* 6 *is equivalent to Property* 3 *with strong limit in* $\mathbf{W}$.

Proof. (i) *Property* 3 $\Rightarrow$ *Assumption* 6. We proceed by contradiction. Let Assumption 6 be false; then there exists $\eta > 0$ such that, for all $\bar{h} > 0$, there is $h \in (0, \bar{h})$ and $\mathbf{w}_h \in K_h^\perp$ with $\|\mathbf{w}_h\|_{\mathbf{V}(h)} \le 1$ such that

$$\|\mathbf{w}_h - \mathbf{w}\|_{0,\Omega} > \eta \qquad \forall \mathbf{w} \in H(\mathrm{div}_\varepsilon^0; \Omega). \tag{7.14}$$

Now, select a sequence $\{h_n\}_{n=1}^\infty$ with $h_n \to 0$ as $n \to \infty$. The previous assertion allows us to construct, in correspondence with $\{h_n\}_{n=1}^\infty$, a sequence $\{\mathbf{w}_{h_n}\}_{n=1}^\infty$ with $\mathbf{w}_{h_n} \in K_{h_n}^\perp$ and $\|\mathbf{w}_{h_n}\|_{\mathbf{V}(h_n)} \le 1$ for all h_n, which does not contain any subsequence converging to an element $\mathbf{w} \in H(\mathrm{div}_\varepsilon^0; \Omega)$, owing to (7.14). This contradicts Property 3 with strong limit in $\mathbf{W}$.

(ii) *Assumption* 6 $\Rightarrow$ *Property* 3. Let $\mathbf{w}_h$ be in $K_h^\perp$, and select $\mathbf{w} \in H(\mathrm{div}_\varepsilon^0; \Omega)$ as $\mathbf{w} = P\mathbf{w}_h$, with P being the operator defined at the beginning of section 5.2. Owing to Lemma 5.4, we know that

$$\|\mathbf{w}_h - \mathbf{w}\|_{\mathbf{V}(h)} \le \eta_h \|\mathbf{w}_h\|_{\mathbf{V}(h)}, \tag{7.15}$$

with $\eta_h \to 0$, as $h \to 0$.

Now, let $\{\mathbf{w}_{h_n}\}_{n=1}^\infty$ be a sequence in $K_{h_n}^\perp$, bounded in the $\mathbf{V}(h)$-norm. Decompose $\mathbf{w}_{h_n}$ as $\mathbf{w}_{h_n} = \mathbf{w}_{h_n}^c + \mathbf{w}_{h_n}^\perp$, according to (7.8). The sequence $\{\mathbf{w}_n\}_{n=1}^\infty := \{P\mathbf{w}_{h_n}^c\}_{n=1}^\infty \subset \mathbf{W}$ also is bounded in the $\mathbf{V}(h)$-norm, owing to (7.15). From the compactness of $\mathbf{W}$, endowed with the $\mathbf{V}(h)$-norm, in $L^2(\Omega)^d$, there exists a subsequence still denoted $\{\mathbf{w}_n\}_{n=1}^\infty$ and an element $\mathbf{v} \in \mathbf{W}$ such that

$$\lim_{n\to\infty} \|\mathbf{w}_n - \mathbf{v}\|_{0,\Omega} = 0. \tag{7.16}$$

If $\{\mathbf{w}_{h_n}\}_{n=1}^\infty$ is such that $\mathbf{w}_{h_n} = \mathbf{w}_{h_n}^c + \mathbf{w}_{h_n}^\perp$, according to (7.8), and $P\mathbf{w}_{h_n}^c = \mathbf{w}_n$ for all n, by the triangle inequality we have

$$\|\mathbf{w}_{h_n} - \mathbf{v}\|_{0,\Omega} \le \|\mathbf{w}_{h_n} - P\mathbf{w}_{h_n}\|_{0,\Omega} + \|\mathbf{w}_n - \mathbf{v}\|_{0,\Omega} + \|P\mathbf{w}_{h_n}^\perp\|_{0,\Omega}.$$

The first two terms on the right-hand side converge to zero, owing to (7.15) and (7.16), respectively; since the projector P is L^2-stable, also the third term converges to zero, due to (7.9) and the $\mathbf{V}(h)$-stability of the decomposition (7.8). Thus, Property 3 holds true with strong limit in $\mathbf{W}$. ∎

Remark 7.14. On parallelograms or parallelepipeds, all the results in this section apply to the choice of $\mathbf{V}_h$ in (7.1) with the local Nédélec elements of the first type of degree ℓ, instead of the full polynomials of degree ℓ, allowing us to conclude that

the obtained approximation of Problem 1 is spurious-free. This is not true for the full polynomials of degree ℓ in each variable, namely the local Nédélec elements of the second type of degree ℓ. In fact, let K_h^c be the discrete kernel of the corresponding conforming approximation, and consider the $\mathbf{V}$-orthogonal decomposition $\mathbf{V}_h^c = K_h^c \oplus K_h^{\perp,c}$. Since $\mathbf{V}_h^c \subseteq \mathbf{V}_h$ and $K_h = K_h^c$, then $K_h^{\perp,c} \subseteq K_h^\perp$. Recalling that the conforming Nédélec elements of the second type do not satisfy the discrete compactness property (see [11]), Proposition 7.13 says that they do not satisfy Assumption 6; the inclusion $K_h^{\perp,c} \subseteq K_h^\perp$ implies that also for their discontinuous counterpart Assumption 6 is not satisfied, and then the obtained method cannot be spurious-free.

8. Conclusions. We have presented a theoretical framework for the analysis of DG approximations of the Maxwell eigenproblem with possibly discontinuous coefficients. In particular, we have restricted our attention to DG methods satisfying the usual assumptions for a correct approximation to the coercive Maxwell source problem $\nabla \times (\mu^{-1}\nabla \times \mathbf{u}) + \varepsilon \mathbf{u} = \mathbf{f}$ in the domain Ω with suitable boundary conditions. For these methods, necessary and sufficient conditions for a spurious-free approximation are (i) a discrete Friedrichs inequality and (ii) a gap property between the orthogonal complement of the discrete kernel and the space of divergence-free functions. We have also proved that basically all the DG methods present in the literature actually fit into this framework, at least on meshes with no hanging nodes (the extension to meshes with hanging nodes is currently under investigation). It is worth pointing out that all these methods provide optimal convergence of the eigenfunctions, while the convergence of the eigenvalues is optimal for hermitian DG methods and suboptimal for non-hermitian DG methods. Another consequence of the theory developed in this paper is that all these methods provide a correct approximation to the indefinite Maxwell source problem $\nabla \times (\mu^{-1}\nabla \times \mathbf{u}) - \omega^2 \varepsilon \mathbf{u} = \mathbf{f}$ in Ω, with suitable boundary conditions, also in the case of discontinuous coefficients ε and μ, extending in this way the results obtained in [34] for smooth coefficients.

Appendix. The aim of this appendix is to prove a continuity estimate for all the DG bilinear forms $a_h(\cdot,\cdot)$ introduced in section 7.2. More precisely, we prove that, given $r > 0$ and σ such that $0 < \sigma < \min\{1/2, r\}$, there exists a mesh-dependent seminorm $|\cdot|_{+,\sigma}$ such that the norm

$$\|\boldsymbol{\xi}\|_{+,\sigma}^2 = \|\boldsymbol{\xi}\|_{\mathbf{V}(h)}^2 + |\boldsymbol{\xi}|_{+,\sigma}^2, \tag{8.1}$$

defined for functions $\boldsymbol{\xi} \in H^r(\mathrm{curl}; \mathcal{T}_h)$ with $\nabla_h \times (\mu^{-1}\nabla_h \times \boldsymbol{\xi}) \in L^2(\Omega)^d$, satisfies

$$|a_h(\boldsymbol{\xi}, \mathbf{v}_h)| \le C \|\boldsymbol{\xi}\|_{+,\sigma} \|\mathbf{v}_h\|_{\mathbf{V}(h)} \tag{8.2}$$

for all $\boldsymbol{\xi} \in H^r(\mathrm{curl}; \mathcal{T}_h)$ with $\nabla_h \times (\mu^{-1}\nabla_h \times \boldsymbol{\xi}) \in L^2(\Omega)^d$, and $\mathbf{v}_h \in \mathbf{V}_h$, with a constant $C > 0$ independent of the mesh size. Moreover, for any $s \ge 0$, there holds that

$$\begin{aligned} &\inf_{\mathbf{v}_h \in \mathbf{V}_h} \|\boldsymbol{\xi} - \mathbf{v}_h\|_{+,\sigma} \\ &\qquad \le C h^{\min\{r,\ell,s+1\}} \left(\|\boldsymbol{\xi}\|_{H^r(\mathrm{curl};\mathcal{T}_h)} + \left(\sum_{K \in \mathcal{T}_h} M_K \|\nabla \times (\mu^{-1}\nabla \times \boldsymbol{\xi})\|_{s,K}^2 \right)^{1/2} \right), \end{aligned} \tag{8.3}$$

for all $\boldsymbol{\xi} \in H^r(\mathrm{curl}; \mathcal{T}_h)$ with $\nabla_h \times (\mu^{-1}\nabla_h \times \boldsymbol{\xi}) \in H^s(\mathcal{T}_h)^d$, where M_K is defined as $M_K = \max_{\mathbf{x} \in \overline{K}} |\mu_K(\mathbf{x})|$, and the constant C is independent of the mesh size.

Note that the continuity property (8.2) and the best approximation estimate (8.3) provide a proof for Proposition 7.3 (indeed, they also prove that DG methods provide quasi-optimal approximations for the coercive source problem introduced in Assumption 4) and jointly with consistency and the inf-sup condition (6.6) provide quasi-optimal error estimates for DG solutions to the indefinite problem (6.1).

PROPOSITION 8.1. *With the notation introduced here above,* (8.2) *and* (8.3) *hold true with the seminorm in* (8.1) *defined by*

$$|\boldsymbol{\xi}|^2_{+,\sigma} = \sum_{K\in\mathcal{T}_h} \left(h_K^{2\sigma} M_K \|\mu^{-1}\nabla\times\boldsymbol{\xi}\|^2_{\sigma,K} + h_K^2 M_K \|\nabla\times(\mu^{-1}\nabla\times\boldsymbol{\xi})\|^2_{0,K}\right),$$

where we have set $M_K = \max_{\mathbf{x}\in\overline{K}}|\mu_K(\mathbf{x})|$.

We remark that, whenever μ is an elementwise constant tensor, then

$$|\boldsymbol{\xi}|^2_{+,\sigma} = \sum_{K\in\mathcal{T}_h} \left(h_K^{2\sigma} \|\mu^{-1/2}\nabla\times\boldsymbol{\xi}\|^2_{\sigma,K} + h_K^2 M_K \|\nabla\times(\mu^{-1}\nabla\times\boldsymbol{\xi})\|^2_{0,K}\right).$$

In order to prove Proposition 8.1, we need the following technical lemma.

LEMMA 8.2. *With the notation introduced above, for any* $f\in\mathcal{F}_h$, *we have*

(8.4)
$$\int_f [\![\overline{\mathbf{v}}]\!]_T\cdot(\mu^{-1}\nabla_h\times\boldsymbol{\xi})^{\pm}\,ds \le C|\mathbf{v}|_{\mathbf{V}(h)}(h^{\sigma}_{K^\pm}M^{1/2}_{K^\pm}\|\mu^{-1}\nabla\times\boldsymbol{\xi}\|_{\sigma,K} + h_{K^\pm}M^{1/2}_{K^\pm}\|\nabla\times(\mu^{-1}\nabla\times\boldsymbol{\xi})\|_{0,K^\pm}),$$

where $K^\pm$ *are the two tetrahedra sharing the face* f, *and* $C>0$ *is independent of the mesh size.*

Proof. We assume, to fix the ideas, that $d=3$. We start by introducing some notation. Let K be a tetrahedron, f one of its faces, and $\mathbf{n}$ the normal at f pointing outside K. Let $\boldsymbol{\eta}\in H^{1/2}(f)^3$ be such that $\boldsymbol{\eta}\cdot\mathbf{n}=0$ and $\boldsymbol{\eta}\times\mathbf{n} = [\![\overline{\mathbf{v}}]\!]_T$, and set $\boldsymbol{\phi}=\mu^{-1}\nabla\times\boldsymbol{\xi}$ on K; we know that $\boldsymbol{\phi}\in H^\sigma(K)^3$ and $\nabla\times\boldsymbol{\phi}\in L^2(K)^3$.

We decompose $\boldsymbol{\eta}$ as $\boldsymbol{\eta}=\boldsymbol{\eta}_0+\boldsymbol{\eta}_M$, with $\boldsymbol{\eta}_M = \frac{1}{|f|}\int_f\boldsymbol{\eta}\,ds$, and $\boldsymbol{\eta}_0=\boldsymbol{\eta}-\boldsymbol{\eta}_M$. Note that $\boldsymbol{\eta}_0$ has zero mean value on f, and it holds that

$$\|\boldsymbol{\eta}\|^2_{0,f} = \|\boldsymbol{\eta}_0\|^2_{0,f} + \|\boldsymbol{\eta}_M\|^2_{0,f}. \tag{8.5}$$

We can write

$$\int_f(\boldsymbol{\eta}\times\mathbf{n})\cdot\boldsymbol{\phi}\,ds = \int_f(\boldsymbol{\eta}_0\times\mathbf{n})\cdot\boldsymbol{\phi}\,ds + \int_f(\boldsymbol{\eta}_M\times\mathbf{n})\cdot\boldsymbol{\phi}\,ds = \text{(I)}+\text{(II)}. \tag{8.6}$$

Estimate of (I). If we map vector fields onto the reference tetrahedron $\widehat{K}$ by means of the standard curl-conforming transformation (see [38, p. 77]), we have (with self-evident notation)

$$\int_f(\boldsymbol{\eta}_0\times\mathbf{n})\cdot\boldsymbol{\phi}\,ds = \pm\int_{\widehat{f}}(\widehat{\boldsymbol{\eta}}_0\times\widehat{\mathbf{n}})\cdot\widehat{\boldsymbol{\phi}}\,d\widehat{s}$$

(see [38, p. 80]). Notice that $\int_f\boldsymbol{\eta}_0\,ds=0$ implies $\int_{\widehat{f}}\widehat{\boldsymbol{\eta}}_0\,ds=0$, and

$$|\widehat{\boldsymbol{\eta}}_0|_{1/2,f}\le\|\widehat{\boldsymbol{\eta}}_0\|_{1/2,f}\le C|\widehat{\boldsymbol{\eta}}_0|_{1/2,f}. \tag{8.7}$$

Let $\mathrm{R} : H^{1/2-\sigma}(\widehat{f})^2 \to H^{1-\sigma}(\widehat{K})^3$ be a continuous lifting operator from $\widehat{f}$ to $\widehat{K}$ such that $\mathrm{R}\widehat{\boldsymbol{\eta}}_0$ has zero tangential trace on $\partial\widehat{K} \setminus \widehat{f}$ (note that this lifting is the standard one, component by component). By continuity of R, we have

$$\|\mathrm{R}\widehat{\boldsymbol{\eta}}_0\|_{0,\widehat{K}} + \|\widehat{\nabla} \times \mathrm{R}\widehat{\boldsymbol{\eta}}_0\|_{-\sigma,\widehat{K}} \le C(\sigma)|\widehat{\boldsymbol{\eta}}_0|_{1/2-\sigma,\widehat{f}} \le C(\sigma)|\widehat{\boldsymbol{\eta}}_0|_{1/2,\widehat{f}},$$

where $\widehat{\nabla} \times \cdot$ denotes the curl operator with respect to the reference coordinates. By integration by parts, since $\mathrm{R}\widehat{\boldsymbol{\eta}}_0$ has zero trace on $\partial\widehat{K} \setminus \widehat{f}$, we get

$$\int_{\widehat{K}} \widehat{\nabla} \times \mathrm{R}\widehat{\boldsymbol{\eta}}_0 \cdot \mathbf{e}_i = \int_{\partial\widehat{K}} (\mathbf{e}_i \times \widehat{\mathbf{n}}) \cdot \mathrm{R}\widehat{\boldsymbol{\eta}}_0 = \int_{\widehat{f}} (\mathbf{e}_i \times \widehat{\mathbf{n}}) \cdot \widehat{\boldsymbol{\eta}}_0 = 0\,, \qquad i = 1,2,3, \tag{8.8}$$

where $\mathbf{e}_i$, $i = 1,2,3$, are the canonical basis vectors in $\mathbb{R}^3$. This means each component of $\widehat{\nabla} \times \mathrm{R}\widehat{\boldsymbol{\eta}}_0$ has zero mean value. Thus, it holds that

$$\begin{aligned}
\int_{\widehat{f}} (\widehat{\boldsymbol{\eta}}_0 \times \widehat{\mathbf{n}}) \cdot \widehat{\boldsymbol{\phi}}\, d\widehat{s} &= \int_{\widehat{K}} (\widehat{\nabla} \times \widehat{\boldsymbol{\phi}} \cdot \mathrm{R}\widehat{\boldsymbol{\eta}}_0 - \widehat{\boldsymbol{\phi}} \cdot \widehat{\nabla} \times \mathrm{R}\widehat{\boldsymbol{\eta}}_0)\, d\widehat{\mathbf{x}} \\
&\le C\|\widehat{\nabla} \times \widehat{\boldsymbol{\phi}}\|_{0,\widehat{K}} \|\mathrm{R}\widehat{\boldsymbol{\eta}}_0\|_{0,\widehat{K}} + |\widehat{\boldsymbol{\phi}}|_{\sigma,K} \|\nabla \times \mathrm{R}\widehat{\boldsymbol{\eta}}_0\|_{-\sigma,\widehat{K}} \\
&\le C(\|\widehat{\nabla} \times \widehat{\boldsymbol{\phi}}\|_{0,\widehat{K}} + |\widehat{\boldsymbol{\phi}}|_{\sigma,\widehat{K}}) |\widehat{\boldsymbol{\eta}}_0|_{1/2,\widehat{f}},
\end{aligned}$$

where we have used the continuity estimate for R, (8.7), and (8.8). Scaling arguments can be applied (see [2, Lemma 5.5]), using the shape regularity of the meshes

$$\begin{aligned}
|\widehat{\boldsymbol{\eta}}_0|_{1/2,\widehat{f}} &\le C h_K^{1/2} |\boldsymbol{\eta}_0|_{1/2,f}, \\
\|\widehat{\nabla} \times \widehat{\boldsymbol{\phi}}\|_{0,\widehat{K}} &\le C h_K^{1/2} \|\nabla \times \boldsymbol{\phi}\|_{0,K}, \\
|\widehat{\boldsymbol{\phi}}|_{\sigma,\widehat{K}} &\le C h_K^{-1/2+\sigma} |\boldsymbol{\phi}|_{\sigma,K},
\end{aligned}$$

and we obtain

$$\int_f (\boldsymbol{\eta}_0 \times \mathbf{n}) \cdot \boldsymbol{\phi}\, ds \le C(h_K \|\nabla \times \boldsymbol{\phi}\|_{0,K} + h_K^{\sigma} |\boldsymbol{\phi}|_{\sigma,K}) |\boldsymbol{\eta}_0|_{1/2,f}.$$

Since, by inverse inequality and (8.5), it holds that

$$|\boldsymbol{\eta}_0|_{1/2,f} \le C\|h_f^{-1/2}\boldsymbol{\eta}_0\|_{0,f} \le C\|h_f^{-1/2}\boldsymbol{\eta}\|_{0,f},$$

and the definition of $\mathtt{h}$ implies that

$$\|h_f^{-1/2}\boldsymbol{\eta}\|_{0,f} = \|\mathtt{m}^{1/2} h_f^{-1/2} \mathtt{m}^{-1/2} \boldsymbol{\eta}\|_{0,f} \le M_K^{1/2} \|\mathtt{h}^{-1/2}\boldsymbol{\eta}\|_{0,f}, \tag{8.9}$$

we have

$$\text{(I)} \le C(h_K M_K^{1/2} \|\nabla \times \boldsymbol{\phi}\|_{0,K} + h_K^{\sigma} M_K^{1/2} |\boldsymbol{\phi}|_{\sigma,K}) \|\mathtt{h}^{-1/2}\boldsymbol{\eta}\|_{0,f}. \tag{8.10}$$

Estimate of (II). From the "lifting property" proved in [13], we know that, for any fixed $t < 2$, there exists a function $\varphi_f \in H^1(K)$ such that

$$\begin{aligned}
\varphi_f &= 1 \text{ on } f\,, \qquad \varphi_f = 0 \text{ on } \partial K \setminus f, \\
\|\varphi_f\|_{0,K} &\le C h_K^{3/2}, \qquad \|\nabla\varphi_f\|_{L^t(K)^3} \le C h_K^{3/t-1}.
\end{aligned}$$

By taking t' such that $1/t' + 1/t = 1$, it holds that

$$\begin{aligned}\int_f (\boldsymbol{\eta}_M \times \mathbf{n}) \cdot \boldsymbol{\phi}\, ds &= \int_f (\varphi_f \boldsymbol{\eta}_M \times \mathbf{n}) \cdot \boldsymbol{\phi}\, ds \\ &= \int_K \nabla \times \boldsymbol{\phi} \cdot (\varphi_f \boldsymbol{\eta}_M)\, d\mathbf{x} - \int_K \boldsymbol{\phi} \cdot \nabla \times (\varphi_f \boldsymbol{\eta}_M)\, d\mathbf{x} \\ &\le C(h_K^{3/2} \|\nabla \times \boldsymbol{\phi}\|_{0,K} |\boldsymbol{\eta}_M| + h_K^{3/t-1} \|\boldsymbol{\phi}\|_{L^{t'}(K)^3} |\boldsymbol{\eta}_M|) \\ &\le C(h_K \|\nabla \times \boldsymbol{\phi}\|_{0,K} + h_K^{3/t-3/2} \|\boldsymbol{\phi}\|_{L^{t'}(K)^3})(h_K^{-1/2} \|\boldsymbol{\eta}_M\|_{0,f}),\end{aligned}$$

where $|\boldsymbol{\eta}_M|$ denotes the modulus of the constant vector $\boldsymbol{\eta}_M$ and where we have used $|\boldsymbol{\eta}_M| \le C h_K^{-1} \|\boldsymbol{\eta}_M\|_{0,f}$. Now, let $t' = \frac{6}{3-2\sigma}$; by Sobolev embedding theorem (see, e.g., [1, p. 217]), we have that

$$\|\boldsymbol{\phi}\|_{L^{t'}(K)^3} \le C \|\boldsymbol{\phi}\|_{\sigma,K}.$$

The shape regularity of the meshes and (8.5) imply $h_K^{-1/2} \|\boldsymbol{\eta}_M\|_{0,f} \le C \|h_f^{-1/2} \boldsymbol{\eta}\|_{0,f}$; thus, by using (8.9) and simple algebra, we obtain

$$\text{(II)} \le C(h_K M_K^{1/2} \|\nabla \times \boldsymbol{\phi}\|_{0,K} + h_K^{\sigma} M_K^{1/2} \|\boldsymbol{\phi}\|_{\sigma,K}) \|\mathfrak{h}^{-1/2} \boldsymbol{\eta}\|_{0,f}. \tag{8.11}$$

Taking into account the definitions of $\boldsymbol{\phi}$, $\boldsymbol{\eta}$ and of $|\cdot|_{\mathbf{V}(h)}$, the expression (8.6) and the estimates (8.10) and (8.11) give (8.4), and the proof is complete. ∎

We are now in a position to prove Proposition 8.1.

Proof of Proposition 8.1. For all the DG methods of section 7.2, it is easy to see that, for all $\boldsymbol{\xi} \in H^r(\mathrm{curl}; \mathcal{T}_h)$ with $\nabla_h \times (\mu^{-1} \nabla_h \times \boldsymbol{\xi}) \in L^2(\Omega)^3$ and $\mathbf{v} \in \mathbf{V}_h$, it holds that

$$a_h(\boldsymbol{\xi}, \mathbf{v}_h) \le C \|\boldsymbol{\xi}\|_{\mathbf{V}(h)} \|\mathbf{v}_h\|_{\mathbf{V}(h)} + C' \int_{\mathcal{F}_h} [\![\overline{\mathbf{v}_h}]\!]_T \cdot \{\!\{\mu^{-1} \nabla_h \times \boldsymbol{\xi}\}\!\}\, ds. \tag{8.12}$$

Summing (8.4) of Lemma 8.2 over all $f \in \mathcal{F}_h$ gives

$$\int_{\mathcal{F}_h} [\![\overline{\mathbf{v}_h}]\!]_T \cdot \{\!\{\mu^{-1} \nabla_h \times \boldsymbol{\xi}\}\!\}\, ds \le C |\boldsymbol{\xi}|_{+,\sigma} \|\mathbf{v}_h\|_{\mathbf{V}(h)}.$$

Inserting this into (8.12) completes the proof of (8.2). The best approximation estimate (8.3) is a direct consequence of standard polynomial approximation properties. ∎

AN ALGEBRAIC PROCEDURE FOR THE SPECTRAL CORRECTIONS USING THE MISS-DISTANCE FUNCTIONS IN REGULAR AND SINGULAR STURM–LIOUVILLE PROBLEMS*

LIDIA ACETO†, PAOLO GHELARDONI†, AND GIOVANNI GHERI†

Abstract. A general method based on the evaluation of the zeros of a suitable polynomial is suggested in order to have an estimation of the spectral error in the numerical treatment of Sturm–Liouville problems. The method is strictly concerned with the miss-distance function arising in the shooting algorithm for eigenvalues. The error correcting procedure derived from the method is particularly helpful when difficulties arise in the numerical integration. Two kinds of Sturm–Liouville problems are considered: the standard regular problems on a closed interval and the problems where an eigenvalue is nonlinearly involved and embedded in an essential spectrum giving origin to an inner singularity. Numerical experiments clearly highlight the efficaciousness of the proposed method both in the regular and singular case.

Key words. Sturm–Liouville problem, algebraic spectral correction, miss-distance

1. Introduction.

The subject matter of this paper is the numerical computation of the eigenvalues in a Sturm–Liouville problem (SLP) by the shooting technique and a corresponding spectral error correcting procedure based on the evaluation of the zeros of a suitable polynomial. Two classes of problems are considered here. The first is concerned with the classical SLP in its regular form given by the differential equation

$$-(p(x)y'(x))' + q(x)y(x) = \lambda w(x)y(x) \tag{1.1}$$

on a finite interval $a < x < b$ with the boundary conditions (BCs)

$$\begin{aligned} a_1 y(a) - a_2 p(a) y'(a) &= 0, \\ b_1 y(b) - b_2 p(b) y'(b) &= 0. \end{aligned} \tag{1.2}$$

In the differential equation the real functions $q(x)$ and $w(x)$ are continuous on the interval $[a, b]$ with $w(x) > 0$, while the real function $p(x)$ is strictly positive and almost once differentiable. In the BCs the constants a_1 and a_2 are real and not both equal to zero; similarly for b_1 and b_2.

In section 4 these conditions will be sharpened and the problem (1.1)–(1.2) mainly considered in the following equivalent matrix form:

$$z' = H(x, \lambda)z, \quad a < x < b, \tag{1.3}$$

where

$$z(x) = \begin{bmatrix} y(x) \\ y'(x) \end{bmatrix}, \quad H(x, \lambda) = \begin{bmatrix} 0 & 1 \\ \frac{q - \lambda w}{p} & -\frac{p'}{p} \end{bmatrix}. \tag{1.4}$$

*Received by the editors July 4, 2005; accepted for publication (in revised form) May 3, 2006; published electronically November 14, 2006.

The BCs (1.2) will be written as

$$\alpha^T Jz(a) = 0, \quad \beta^T Jz(b) = 0, \tag{1.5}$$

with

$$J = \begin{bmatrix} 0 & -1 \\ 1 & 0 \end{bmatrix}, \quad \alpha = \begin{bmatrix} a_2 p(a) \\ a_1 \end{bmatrix}, \quad \beta = \begin{bmatrix} b_2 p(b) \\ b_1 \end{bmatrix}. \tag{1.6}$$

The second kind of SLP which we consider here is given by the differential equation

$$-y''(x) = g(x,\lambda)y(x), \quad a < x < b, \tag{1.7}$$

with the BCs

$$\begin{aligned} a_1 y(a) - a_2 y'(a) &= 0, \\ b_1 y(b) - b_2 y'(b) &= 0, \end{aligned} \tag{1.8}$$

and a_1, a_2, b_1, b_2 satisfying the same conditions as in the regular case; however in sections 3, 4, and 5 we will require more strong conditions.

In this section we assume that

$$g(x,\lambda) = \lambda + \frac{q(x)}{u(x) - \lambda}$$

with $\lambda \in \mathbb{R}$, $q(x), u(x) \in C^1([a,b])$ and $u(x)$ strictly monotone increasing. Thus if $\lambda \in [u(a), u(b)]$, then there is a unique point $x_\lambda \in [a,b]$ such that $u(x_\lambda) = \lambda$.

In what follows we also require $q(x) > 0$ for all $x \in [a,b]$. Then it is well known that the problem (1.7)–(1.8) can be set in the so-called λ-linear block operator problem

$$\begin{bmatrix} -\frac{d^2}{dx^2} & \sqrt{q(x)} \\ \sqrt{q(x)} & u(x) \end{bmatrix} \tilde{y} = \lambda \tilde{y}, \tag{1.9}$$

where $\tilde{y} = \left[y, -\frac{y\sqrt{q}}{u-\lambda} \right]^T$.

Problems of this type, both (1.7) and (1.9), have been investigated recently (see, for instance, [1, 13, 14]) and play an important role in magnetohydrodynamics such as Hain–Lüst equations (see, for example, [15]) and also go by the name of λ-rational SLPs.

For a given $\lambda \in [u(a), u(b)]$ a solution of (1.7) is a function $y(x)$ satisfying (1.7) for $x \neq x_\lambda$ and such that

$$\lim_{x \to x_\lambda} g(x,\lambda)y(x) \quad \text{exists.} \tag{1.10}$$

If $y(x)$ satisfies the BCs (1.8), then we say that $y(x)$ is an eigenfunction associated with the eigenvalue λ embedded in the essential spectrum.

As for the regular case, beside the scalar form (1.7)–(1.8) we consider the matrix representation

$$z' = K(x,\lambda)z, \quad a < x < b\,, \tag{1.11}$$

with

$$z(x) = \begin{bmatrix} y(x) \\ y'(x) \end{bmatrix}, \quad K(x,\lambda) = \begin{bmatrix} 0 & 1 \\ -g(x,\lambda) & 0 \end{bmatrix} \tag{1.12}$$

and the boundary conditions

$$\tilde{\alpha}^T Jz(a) = 0, \quad \tilde{\beta}^T Jz(b) = 0, \tag{1.13}$$

where

$$\tilde{\alpha} = \begin{bmatrix} a_2 \\ a_1 \end{bmatrix}, \quad \tilde{\beta} = \begin{bmatrix} b_2 \\ b_1 \end{bmatrix}, \tag{1.14}$$

and J as in (1.6).

The key for the shooting is given by the Theorem 4.1 in [1] which we quote here for completeness in the following simplified form.

THEOREM 1.1. *For $\lambda \in [u(a), u(b)]$ there is a unique solution $y(x)$ of (1.7) fulfilling the conditions $y(x_\lambda) = 0$, $y'(x_\lambda) = 1$.*

Thus, with regard to the matrix formulation (1.11) of the problem, the condition for $z(x)$ when $x = x_\lambda$ is given by

$$z(x_\lambda) = \begin{bmatrix} 0 \\ 1 \end{bmatrix}. \tag{1.15}$$

From this we see that an eigenvalue embedded in the essential spectrum represents a pathological case because its eigenfunction must satisfy not only the BCs (1.13) but also the inner condition (1.15).

As far as the problem approximating the eigenvalues in a general SLP is concerned, several papers have been produced (see, for instance, [2, 3, 12, 18, 19]).

In [7, 8] a technique is proposed to obtain a spectral correction based on a particular discretization parameter. Nevertheless the present paper differs from the other ones because it is a generalization of a spectral correcting procedure obtained in [9] starting from a straight computation of the discretization error and an extension to the parallel shooting.

In the next section we look onto the parallel shooting both for the regular and singular case and we build up the corresponding miss-distance functions, namely the functions describing the extent to which some matching conditions fail to be satisfied at the shooting nodes or at the boundary points.

In section 3 we describe the discretization procedure based on the boundary value method (BVM) [4]. We state the reason for this choice observing that BVM is a high order procedure without barriers to the numerical stability. Furthermore the use of a BVM having symmetric scheme [4, p. 159] leads to an approximate solution analytic in a discretization parameter (see, for instance, Gragg's theorem in [10]) allowing particular facilities in theorem proving.

In that section we also highlight that the BVM experiences a decay of its performances in the presence of the inner singularity rendering the correcting procedure particularly useful.

In sections 4 and 5 the correcting procedures in the regular and singular cases are given.

Section 6 is devoted to some numerical experiments underlining the effectiveness of the methods proposed.

2. Building up the miss-distances. We begin with the regular case splitting the problem (1.3)–(1.5) into two initial value problems (IVPs)

$$z' = H(x, \lambda)z, \quad z(a) = \alpha, \tag{2.1}$$

$$z' = H(x, \lambda)z, \quad z(b) = \beta. \tag{2.2}$$

Let c be a point of $[a,b]$. In order to integrate (2.1) left to right we consider m_a+1 shooting nodes ξ_i, $i=0,1,\dots,m_a$, such that $a=\xi_0<\xi_1<\cdots<\xi_{m_a}=c$ and the IVPs

$$\begin{aligned} U_j'(x) &= H(x,\lambda)U_j(x), \quad \xi_{j-1}<x\le\xi_j,\\ U_j(\xi_{j-1}) &= I, \qquad\qquad\qquad j=1,2,\dots,m_a, \end{aligned} \tag{2.3}$$

I being the identity matrix of order two. Thus the solution of (2.1) is

$$z_L(x)\equiv z_j(x)=U_j(x)s_j, \quad j=1,2,\dots,m_a, \tag{2.4}$$

where the vectors $s_1,s_2,\dots,s_{m_a}$ are chosen to ensure the continuity of $z_L(x)$ across the interior nodes. Namely the conditions $z_j(\xi_j)=z_{j+1}(\xi_j)$, $j=1,2,\dots,m_a-1$ are equivalent to the conditions $U_j(\xi_j)s_j=s_{j+1}$, $j=1,2,\dots,m_a-1$. By recurrence, we have $s_{m_a}=U_{m_a-1}(\xi_{m_a-1}),\dots,U_1(\xi_1)s_1$, and from (2.4) $z_L(\xi_{m_a})=U_{m_a}(\xi_{m_a})s_{m_a}=U_{m_a}(\xi_{m_a}),\dots,U_1(\xi_1)s_1$. Because $z_L(a)=U_1(a)s_1=s_1=\alpha$, setting

$$U=U_{m_a}(\xi_{m_a}),\dots,U_1(\xi_1), \tag{2.5}$$

we can write $z_L(\xi_{m_a})=U\alpha$.

We integrate the IVP (2.2) right to left considering the m_b+1 shooting nodes θ_i, $i=0,1,\dots,m_b$, such that $c=\theta_{m_b}<\theta_{m_b-1}<\cdots<\theta_0=b$ and the IVPs

$$\begin{aligned} V_j'(x) &= H(x,\lambda)V_j(x), \quad \theta_j\le x<\theta_{j-1},\\ V_j(\theta_{j-1}) &= I, \qquad\qquad\qquad j=1,2,\dots,m_b. \end{aligned} \tag{2.6}$$

Then the solution of (2.2) is

$$z_R(x)\equiv z_j(x)=V_j(x)\sigma_j, \quad j=1,2,\dots,m_b,$$

where the vectors $\sigma_1,\sigma_2,\dots,\sigma_{m_b}$ play the same role in the right side of the vectors as $s_1,s_2,\dots,s_{m_a}$ in the left one. Repeating almost verbatim the foregoing considerations, we find that $z_R(\theta_{m_b})=V\beta$, where

$$V=V_{m_b}(\theta_{m_b}),\dots,V_1(\theta_1). \tag{2.7}$$

Consider now the Wronskian determinant

$$\det(z_R(\theta_{m_b}),z_L(\xi_{m_a}))=z_L^T(\xi_{m_a})Jz_R(\theta_{m_b})=\alpha^TU^TJV\beta. \tag{2.8}$$

The matching condition at $\xi_{m_a}=\theta_{m_b}=c$ is satisfied if the values of λ are eigenvalues of the SLP (1.3)–(1.5), namely solutions of the equation

$$\alpha^TU^TJV\beta=0.$$

In what follows we no longer mark the left solution as $z_L(x)$ and the right one as $z_R(x)$ because it will be clear from the context which is the $z(x)$ to consider.

In practice we integrate the IVPs (2.3) and (2.6) using a numerical method with a constant stepsize h and starting up with an initial guess μ of λ.

In the left side we consider $x_n=a+nh$, $n=0,1,\dots,n_a=\frac{c-a}{h}$, assuming, for the sake of simplicity, c and h such that $\frac{c-a}{h}$ is an integer number. Thus the shooting nodes can be defined as $\xi_j=x_{jl_a}$, $j=0,1,\dots,m_a$ for some integer l_a with $m_al_a=n_a$.

Let $U_{j,n}$ be the approximation to $U_j(x_n)$ and z_n the one to $z(x_n)$ obtained using a numerical method. We assume $U_{j,n}$ and z_n depend on μ and on some discretization parameter t, that is $U_{j,n} = U_{j,n}(\mu, t)$ and $z_n = z_n(\mu, t)$, with $(j-1)l_a \le n \le jl_a$, $j = 1, 2, \ldots, m_a$.

Furthermore we assume t to be a function on h, i.e., $t = t(h)$ with the property

$$t(h) \neq 0 \quad \text{if} \quad h \neq 0, \quad \lim_{h\to 0} t(h) = 0. \tag{2.9}$$

For a classical method of order p we have $t(h) = h^p$.

Analogously in the right side we consider $x_n = b - nh$, $n = 0, 1, \ldots, n_b = \frac{b-c}{h}$, with $\frac{b-c}{h}$ an integer number, and choosing the shooting nodes as $\theta_j = x_{jl_b}$, $j = 0, 1, \ldots, m_b$ for some integer l_b such that $m_b l_b = n_b$.

Using the same numerical method we integrate the IVPs in (2.6) with μ instead of λ obtaining $V_{j,n}(\mu, t) \simeq V_j(x_n)$ and $z_n(\mu, t) \simeq z(x_n)$, $(j-1)l_b \le n \le jl_b$, $j = 1, 2, \ldots, m_b$.

Denoting $U_{j,jl_a}(\mu, t)$ by $U_j(\mu, t)$, $j = 1, 2, \ldots, m_a$, and $V_{j,jl_b}(\mu, t)$ by $V_j(\mu, t)$, $j = 1, 2, \ldots, m_b$, (2.5) and (2.7) become, respectively,

$$U(\mu, t) = U_{m_a}(\mu, t), \ldots, U_1(\mu, t) \quad \text{and} \quad V(\mu, t) = V_{m_b}(\mu, t), \ldots, V_1(\mu, t).$$

With these notations the Wronskian determinant (2.8) takes the form

$$F(\mu, t) = \alpha^T U(\mu, t)^T J V(\mu, t)\beta, \tag{2.10}$$

and goes by the name of *miss-distance*.

Assuming that

$$\lim_{t\to 0} U_{j,n}(\mu, t) = U_j(x_n), \quad \lim_{t\to 0} V_{j,n}(\mu, t) = V_j(x_n), \quad \lim_{t\to 0} z_n(\mu, t) = z(x_n),$$

then, for a fixed t, μ is an approximation to λ if μ is a zero of the miss-distance $F(\mu, t)$. Thus we admit that μ is dependent on t as well, i.e., $\mu = \mu(t)$ and $\lim_{t\to 0} \mu(t) = \lambda$. By consequence we are allowed to state by definition

$$U(\lambda, 0) = U, \quad V(\lambda, 0) = V, \quad F(\lambda, 0) = 0.$$

We remark that if $c = b$ we have the forward parallel shooting, while if $c = a$ we have the backward parallel shooting. If $l_a = n_a$ or $l_b = n_b$ the corresponding shooting is simple.

We consider now the λ-rational SLP (1.11)–(1.14).

Owing to (1.10) and Theorem 1.1, the parallel shooting is carried out starting from the singular point. Let c_a, c_b be points of $[a, x_\lambda)$ and $(x_\lambda, b]$, respectively. We split the SLP into two couples of IVPs:

$$z'(x) = K(x, \lambda)z(x), \quad a < x \le c_a, \quad z(a) = \tilde{\alpha}, \tag{2.11}$$

$$z'(x) = K(x, \lambda)z(x), \quad c_a \le x < x_\lambda, \quad z(x_\lambda) = \gamma, \tag{2.12}$$

where, according to (1.15), we have indicated that $\gamma = [0, 1]^T$ and

$$z'(x) = K(x, \lambda)z(x), \quad x_\lambda < x \le c_b, \quad z(x_\lambda) = \gamma, \tag{2.13}$$

$$z'(x) = K(x, \lambda)z(x), \quad c_b \le x < b, \quad z(b) = \tilde{\beta}. \tag{2.14}$$

Let μ be an initial guess of λ somehow estimated and x_μ the solution of the equation $u(x)-\mu=0$. Following a procedure quite similar to that previously seen, we consider the leftward problem (2.11) with μ in place of λ setting $x_n = a+nh$, $n=0,1,\dots,n_a = \frac{c_a-a}{h}$, and assuming as shooting nodes $\xi_j = x_{jk_a}$, $j=0,1,\dots,r_a$, with $r_a k_a = n_a$. Then we integrate with a numerical method the IVPs

$$\begin{aligned} X_j'(x) &= K(x,\mu)X_j(x), \quad && \xi_{j-1} < x \le \xi_j, \\ X_j(\xi_{j-1}) &= I, && j=1,2,\dots,r_a, \end{aligned} \tag{2.15}$$

obtaining $X_{j,n}(\mu,t) \simeq X_j(x_n)$, $(j-1)k_a \le n \le jk_a$, $j=1,2,\dots,r_a$. Then denoting $X_{j,jk_a}(\mu,t)$ by $X_j(\mu,t)$ we are able to define $X(\mu,t) = X_{r_a}(\mu,t),\dots,X_1(\mu,t)$.

In the same way we consider the problem (2.12) with μ in place of λ and x_μ in place of x_λ setting $x_n = x_\mu - nh$, $n=0,1,\dots,n_{\mu_a} = \frac{x_\mu - c_a}{h}$ and assuming as shooting nodes $\theta_j = x_{jk_{\mu_a}}$, $j=0,1,\dots,r_\mu$ with $r_\mu k_{\mu_a} = n_{\mu_a}$. With the same numerical method we integrate the IVPs

$$\begin{aligned} Y_j'(x) &= K(x,\mu)Y_j(x), \quad && \theta_j \le x < \theta_{j-1}, \\ Y_j(\theta_{j-1}) &= I, && j=1,2,\dots,r_\mu. \end{aligned} \tag{2.16}$$

With obvious notations we define $Y(\mu,t) = Y_{r_\mu}(\mu,t),\dots,Y_1(\mu,t)$.

Thus the miss-distance function for the interval $[a,x_\mu]$ is

$$F_a(\mu,t) = \tilde{\alpha}^T X^T(\mu,t) J Y(\mu,t)\gamma. \tag{2.17}$$

Referring to the problem (2.13) with μ and x_μ instead of λ and x_λ, we consider $x_n = x_\mu + nh$, $n=0,1,\dots,n_{\mu_b} = \frac{c_b - x_\mu}{h}$ and the shooting nodes $\xi_j = x_{jk_{\mu_b}}$, $j=0,1,\dots,s_\mu$, with $s_\mu k_{\mu_b} = n_{\mu_b}$. Then, upon numerical integration of the IVPs

$$\begin{aligned} R_j'(x) &= K(x,\mu)R_j(x), \quad && \xi_{j-1} < x \le \xi_j, \\ R_j(\xi_{j-1}) &= I, && j=1,2,\dots,s_\mu, \end{aligned} \tag{2.18}$$

it is possible to define $R(\mu,t) = R_{s_\mu}(\mu,t),\dots,R_1(\mu,t)$.

Finally, denoting by $S_j(x)$, $j=1,2,\dots,s_b$, the fundamental solutions associated to the problem (2.14), where λ is replaced with μ, and following the same procedure as before, we integrate

$$\begin{aligned} S_j'(x) &= K(x,\mu)S_j(x), \quad && \theta_j \le x < \theta_{j-1}, \\ S_j(\theta_{j-1}) &= I, && j=1,2,\dots,s_b, \end{aligned} \tag{2.19}$$

where $\theta_0 = b$, so that we can define $S(\mu,t) = S_{s_b}(\mu,t),\dots,S_1(\mu,t)$.

By consequence the miss-distance in the interval $[x_\mu,b]$ is

$$F_b(\mu,t) = \gamma^T R^T(\mu,t) J S(\mu,t)\tilde{\beta}. \tag{2.20}$$

Thus μ is an approximation to λ if μ is a zero both for $F_a(\mu,t)$ and $F_b(\mu,t)$.

3. The discretization method and its behavior in the singular case. We use a BVM endowed with a symmetric scheme in order to integrate the IVPs (2.3), (2.6) in the regular case and the IVPs (2.15), (2.16), (2.18), (2.19) in the singular case. In any event, the general form of these problems in each shooting interval is

$$\begin{aligned} Z'(x) &= \Gamma(Z(x),\lambda), \\ Z(x_0) &= I, \end{aligned}$$

where $\Gamma(Z(x),\lambda) = H(x,\lambda)Z(x)$ or $\Gamma(Z(x),\lambda) = K(x,\lambda)Z(x)$ depending on whether we consider the regular or singular SLP.

Thus the general form of BVM [4] with (k_1,k_2)-boundary conditions is

$$\begin{aligned}
&\sum_{i=0}^{r^*}\alpha_{i\nu}Z_i = h\sum_{i=0}^{r^*}\beta_{i\nu}\Gamma_i, \quad \nu = 1,\dots,k_1-1,\\
&\sum_{i=0}^{k^*}\alpha_i Z_{\nu+i-k_1} = h\sum_{i=0}^{k^*}\beta_i\Gamma_{\nu+i-k_1}, \quad \nu = k_1,\dots,N-k_2,\\
&\sum_{i=0}^{s^*}\alpha_{i\nu}Z_{\nu+i-s^*} = h\sum_{i=0}^{s^*}\beta_{i\nu}\Gamma_{\nu+i-s^*}, \quad \nu = N-k_2+1,\dots,N,
\end{aligned} \tag{3.1}$$

where N is the number of subintervals in the shooting interval considered, $r^*, s^* \le k^* = k_1 + k_2$, $Z_i \simeq Z(x_i)$, $\Gamma_i = \Gamma(Z_i,\lambda)$, $i = 0,1,\dots,N$.

In the case of a λ-rational SLP, if the BVM (3.1) numbers among its nodes the point x_λ, we then need to compute $K(x,\lambda)$ in the singular point. Thus, in order to avoid numerical overflow, we introduce an artificial layer δ in width with

$$0 < \delta < h \le h^* < 1 \tag{3.2}$$

and we choose as the starting point for the shooting $x_0 = x_\lambda - \delta$ or $x_0 = x_\lambda + \delta$ according to whether we integrate right to left or left to right.

The layer option partly inhibits the classical order of convergence of a BVM when applied to the SLP (1.11)–(1.13).

Actually the general solution of the differential equation $-v'' = g(x,\lambda)v$ in $[a,x_0]$ or in $[x_0,b]$ with the initial conditions $v(x_0) = 0$ and $v'(x_0) = 1$ takes the form $v(x) = Ay(x) + Cw(x)$, where

$$w(x) = -1 + \frac{q(x_\lambda)}{u'(x_\lambda)}(x - x_\lambda)\log|x - x_\lambda| + O(x - x_\lambda)$$

for $x \to x_\lambda$ and A and C depend on λ [1, Theorem 4.2].

Thus the explanation for this behavior of the BVMs is that the "nice" solution of (1.7) satisfying the conditions of Theorem 1.1 lies, in fact, in $C^\infty([a,b])$ whereas the solution $v(x)$ has singularities in the higher order derivatives inherited from the function $w(x)$.

A general discussion on this topic is in [9, section 3]. More detailed considerations show that for a class of BVMs, when applied to the SLP (1.11)–(1.13) using the simple shooting, the best accuracy is $t(h) = h^2\log h$ for a method whose classical order is 2 and $t(h) = h^2$ for a method whose classical order is greater than 2 [8, Theorem 5.2]. In the parallel shooting the starting shooting subinterval bordering on a singular point is precisely in the aforementioned conditions.

4. The errors polynomial: the regular case. In what follows we consider the miss-distance $F(\mu,t)$ as in (2.10) differentiable with respect to t as we need and the same for $U(\mu,t)$ and $V(\mu,t)$ with respect to μ.

LEMMA 4.1. *Let $q_0 = 0$, $q_j = i_1 + i_2 + \cdots + i_j$ be for some nonnegative integers $i_1, i_2, \dots, i_j$. Denote by $W_j(\mu,t)$, $j = 1,2,\dots,m$, second order matrices depending on μ and t. Let $W_j^{(s)}(\mu,t) = (\partial^s/\partial\mu^s)\,W_j(\mu,t)$ and $W(\mu,t) = W_m(\mu,t),\dots,W_1(\mu,t)$.*

Define the formal product operators

$$p_j(m) = \prod_{r=0}^{m-2} \sum_{i_{r+1}=0}^{j-q_r} \binom{j-q_r}{i_{r+1}}, \quad j \geq q_r,$$

acting on the matrices

$$P_j(W,m) = W_m^{(j-q_{m-1})}(\mu,t) \prod_{r=0}^{m-2} W_{m-1-r}^{(i_{m-1-r})}(\mu,t), \quad j \geq q_{m-1}.$$

Then

$$\begin{aligned} F^{(k)}(\mu,t) &= \left(\partial^k/\partial\mu^k\right) F(\mu,t) \\ &= \alpha^T \left\{ \sum_{i=0}^{k} \binom{k}{i} \left[p_{k-i}(m_a) P_{k-i}(U,m_a)\right]^T J p_i(m_b) P_i(V,m_b) \right\} \beta. \end{aligned} \tag{4.1}$$

Proof. Using the Newton–Leibnitz binomial expansion we get

$$F^{(k)}(\mu,t) = \alpha^T \left\{ \sum_{i=0}^{k} \binom{k}{i} \left[U^{(k-i)}(\mu,t)\right]^T J V^{(i)}(\mu,t) \right\} \beta. \tag{4.2}$$

The term $U^{(k-i)}(\mu,t)$ in this equation can be expressed by again using the Newton–Leibnitz binomial expansion and taking advantage of the associative property for matrices. That is to say, with $s = k - i$,

$$U^{(s)}(\mu,t) = \left(\partial^s/\partial\mu^s\right)\left[A_2(\mu,t)U_1(\mu,t)\right] = \sum_{i_1=0}^{s} \binom{s}{i_1} A_2^{(s-i_1)}(\mu,t) U_1^{(i_1)}(\mu,t),$$

where $A_2(\mu,t) = U_m(\mu,t), \ldots, U_2(\mu,t)$, then considering

$$A_2^{(s-i_1)}(\mu,t) = \left(\partial^{s-i_1}/\partial\mu^{s-i_1}\right)\left[A_3(\mu,t)U_2(\mu,t)\right],$$

where $A_3(\mu,t) = U_m(\mu,t), \ldots, U_3(\mu,t)$, and so on as far as the term $U^{(s)}(\mu,t) = p_s(m_a)$ $P_s(U,m_a)$ is obtained. By the same way we get $V^{(i)}(\mu,t) = p_i(m_b)P_i(V,m_b)$. ∎

LEMMA 4.2. *Denote by $U_j(x,\mu)$, $j = 1,2,\ldots,m_a$ the solutions of the IVPs* (2.3) *with μ in place of λ, namely the IVPs*

$$\begin{aligned} &U_j'(x,\mu) = H(x,\mu)U_j(x,\mu), \quad \xi_{j-1} < x \leq \xi_j, \\ &U_j(\xi_{j-1},\mu) = I, \quad j = 1,2,\ldots,m_a. \end{aligned} \tag{4.3}$$

Then the terms $U_j^{(s)}(x,\mu)$, $s = k-i$, $j = 1,2,\ldots,m_a$, in (4.2) *are the numerical solutions of the IVPs*

$$\begin{aligned} &\left(U_j^{(s)}(x,\mu)\right)' = H(x,\mu)U_j^{(s)}(x,\mu) + sH^{(1)}(x,\mu)U_j^{(s-1)}(x,\mu), \xi_{j-1} < x \leq \xi_j, \\ &U_j^{(s)}(\xi_{j-1},\mu) = 0, \quad j = 1,2,\ldots,m_a, \end{aligned} \tag{4.4}$$

where $H^{(1)}(x,\mu) = (\partial/\partial\mu)\, H(x,\mu)$.

Proof. Consider $s \geq 1$, the case $s = 0$ being trivial. Equation (4.4) is obtained by taking the s-derivative with respect to μ of the left and right-hand sides of (4.3), owing to the linearity of $H(x, \mu)$ with respect to μ, and using the Schwartz theorem. Then a numerical integration of (4.4) with a method having t as the discretization parameter gives rise to $U_j^{(s)}(x, \mu)$. □

With obvious changes this lemma can be restated in order to compute the terms $V_j^{(s)}(\mu, t)$, $s = i$, $j = 1, 2, \ldots, m_b$.

The following theorem gives an explicit form of the polynomial whose zeros are reliable evaluations of the error $\lambda - \mu$.

THEOREM 4.3. *Let μ be an estimation of λ and $t(h)$ as in* (2.9). *Let h_i, $i = 1, 2, \ldots, r$, be distinct values of the stepsize h with*

$$0 < h_1, h_2, \ldots, h_r \leq h^*$$

and suppose that

$$t(h_i) \neq t(h_j), \quad 1 \leq i \neq j \leq r.$$

Define the vectors $\gamma^{(k)} = [\gamma_1^{(k)}, \gamma_2^{(k)}, \ldots, \gamma_r^{(k)}]^T$, $k = 0, 1, \ldots, m$, whose components are

$$\gamma_i^{(k)} = F^{(k)}(\mu, t(h_i)), \quad i = 1, 2, \ldots, r,$$

$F^{(k)}(\mu, t)$ being as in (4.1). *Let T be the square matrix whose elements are given by*

$$(T)_{ij} = [t(h_i)]^{j-1}, \quad 1 \leq i, j \leq r.$$

Then

$$\lambda = \mu + \epsilon, \tag{4.5}$$

ϵ being a solution of

$$\hat{\phi}(\epsilon) + O(\epsilon^{m+1}) = 0, \tag{4.6}$$

where

$$\hat{\phi}(\epsilon) = \sum_{k=0}^{m} \hat{\phi}_k \epsilon^k. \tag{4.7}$$

The coefficients of the polynomial (4.7) *are*

$$\hat{\phi}_k = \frac{1}{k!} e^{(1)^T} T^{-1} \left(\gamma^{(k)} + O(t_\rho^r)\right), \tag{4.8}$$

$e^{(1)}$ being the first column of the identity matrix of order r and t_ρ such that

$$t_\rho = \max \left\{ |t(h_1)|, |t(h_2)|, \ldots, |t(h_r)| \right\}. \tag{4.9}$$

Proof. With $\epsilon = \lambda - \mu$ and $F^{(k)}(\mu, 0) = (\partial^k / \partial \mu^k) F(\mu, 0)$ we have

$$F(\lambda, 0) = \sum_{k=0}^{m} \frac{1}{k!} F^{(k)}(\mu, 0) \epsilon^k + O(\epsilon^{m+1}). \tag{4.10}$$

Furthermore

$$F^{(k)}(\mu, t(h)) = \sum_{i=0}^{r-1} w_i^{(k)} \left[t(h)\right]^i + O\left(\left[t(h)\right]^r\right), \tag{4.11}$$

where

$$w_i^{(k)} = \frac{1}{i!}\left[(\partial^i/\partial t^i) F^{(k)}(\mu, t)\right]_{t=0}, \quad i = 0, 1, \ldots, r-1.$$

Then writing (4.11) for $t(h) = t(h_j)$, $j = 1, 2, \ldots, r$, and defining the vector $w^{(k)} = (w_0^{(k)}, w_1^{(k)}, \ldots, w_{r-1}^{(k)})^T$ we have

$$\gamma^{(k)} = T w^{(k)} + O(t_\rho^r). \tag{4.12}$$

Noticing that $w_0^{(k)} = F^{(k)}(\mu, 0)$ and because T is a nonsingular Vandermonde matrix, from (4.12) and (4.10) (4.8) is obtained. ∎

We remark that in (4.7) a root of $\hat{\phi}(\epsilon)$ going to zero when $\mu \to \lambda$ at least exists. As a matter of fact $\hat{\phi}_0 = F(\mu, 0)$ from (4.8) and $F(\mu, 0) \to F(\lambda, 0) = 0$ by definition when $\mu \to \lambda$.

In practice, for h^* sufficiently small we are allowed to leave out the term $O(\epsilon^{m+1})$ in (4.6) and $O(t_\rho^r)$ in (4.8).

Thus (4.5) can be written as

$$\lambda \simeq \lambda^{(c)} = \mu + \epsilon, \tag{4.13}$$

where now ϵ is a zero of the polynomial

$$\phi(\epsilon) = \sum_{k=0}^{m} \phi_k \epsilon^k \tag{4.14}$$

with

$$\phi_k = \frac{1}{k!} e^{(1)^T} T^{-1} \gamma^{(k)}.$$

A very simple and useful case is $m = 2$, so that it is possible to pick out as correcting term in (4.13) the root

$$\epsilon = \frac{-\phi_1 + \frac{\phi_1}{|\phi_1|}\sqrt{\phi_1^2 - 4\phi_0\phi_2}}{2\phi_2}$$

which is, for h^* small, real and goes to zero when $\mu \to \lambda$.

A further correction procedure that is easy to use is obtained with $m = 3$ because at least one real zero of (4.14) exists. Going into details, if we set

$$\begin{aligned}
\omega_0 &= \frac{1}{27\phi_3^3}(2\phi_2^3 - 9\phi_1\phi_2\phi_3 + 27\phi_0\phi_3^2), \\
\omega_1 &= \frac{1}{\phi_3^2}\left(\phi_1\phi_3 - \frac{1}{3}\phi_2^2\right), \\
\varrho &= \sqrt{\left(\frac{\omega_0}{2}\right)^2 + \left(\frac{\omega_1}{3}\right)^3} - \frac{\omega_0}{2},
\end{aligned}$$

then the roots of (4.14) are (see, for instance, [5, 6])

$$\epsilon_{1,2,3} = \varrho^{1/3} - \frac{\omega_1}{3}\varrho^{-1/3} - \frac{1}{3}\frac{\phi_2}{\phi_3} \tag{4.15}$$

with the same determination for the cubic root. If $\left(\frac{\omega_0}{2}\right)^2 + \left(\frac{\omega_1}{3}\right)^3 \geq 0$ (the reducible case), a suitable choice in (4.13) for ϵ is the one in (4.15) with real value for $\varrho^{1/3}$.

5. The errors polynomial: the singular case. We consider the IVPs (2.11), (2.12), (2.13), (2.14), and the IVPs giving the corresponding fundamental solutions in the intervals $[a, c_a]$, $[c_a, x_\mu]$, $[x_\mu, c_b]$, $[c_b, b]$. Let $F(\mu, t)$ be the left miss-distance (2.17) or the right one (2.20) as the case may be. At present the matrix $K(x, \mu)$ depends nonlinearly on μ so that the derivatives with respect to μ look very knotty to be computed. Moreover, the singular point x_μ is μ-depending so that the initial condition in (4.4) represents a doubtful issue. By consequence Lemmas 4.1 and 4.2 are all but useless and Theorem 4.3 can be restated using a different way to compute $\gamma^{(k)}$, $k = 0, 1, \ldots, m$. To this end the following procedure based on the numerical differentiation using the method of undetermined coefficients (see, for instance, [11, chap. 6, sec. 5]) provides a simple and helpful alternative to overcome the obstacle.

Consider $\nu + 1$ distinct values of μ obtained during the same iterative rootfinding process and, without loss of generality, take them ordered by $\mu_0 < \mu_1 < \cdots < \mu_\nu$. Define the functions

$$g_j(\mu) = F(\mu, t(h_j)), \quad j = 1, 2, \ldots, r,$$

where $t(h_1), t(h_2), \ldots, t(h_r)$ are as in Theorem 4.3. Denote by $p_j(\mu)$, $j = 1, 2, \ldots, r$, the νth degree interpolation polynomials for $g_j(\mu)$ with respect to the $\nu + 1$ points $\mu_0, \mu_1, \ldots, \mu_\nu$, namely $p_j(\mu_l) = g_j(\mu_l)$, $l = 0, 1, \ldots, \nu$. We seek a formula of the form

$$p_j^{(k)}(\mu_\eta) = \sum_{l=0}^{\nu} c_l g_j(\mu_l), \quad j = 1, 2, \ldots, r, \tag{5.1}$$

where $p_j^{(k)}(\mu) = (\partial^k/\partial\mu^k)p_j(\mu)$ and $0 \leq \eta \leq \nu$.

For this purpose we choose the c_l coefficients in order that (5.1) will be the most accurate approximations to $p_j^{(k)}(\mu_\eta)$ when

$$g_j(\mu) = (\mu - \mu_\eta)^l, \quad l = 0, 1, \ldots, \nu.$$

Because

$$\left[(\partial^k/\partial\mu^k)g_j(\mu)\right]_{\mu=\mu_\eta} = k!\delta_{lk},$$

we obtain the linear system

$$M(\mu_\eta)c = b^{(k)}, \tag{5.2}$$

where $c = (c_0, c_1, \ldots, c_\nu)^T$, $b^{(k)} = k!(\delta_{0k}, \delta_{1k}, \ldots, \delta_{\nu k})^T$ and

$$(M(\mu))_{lr} = (\mu_r - \mu)^l, \quad 0 \leq l, r \leq \nu. \tag{5.3}$$

It is clear that the system (5.2) has a unique solution since (5.3) is a nonsingular Vandermonde matrix. Besides, it is possible to prove [11, chap. 6, sec. 5, Theorem 1] that

$$F^{(k)}(\mu, t(h_j)) = p_j^{(k)}(\mu) + \chi_j^{(k)}(\mu), \quad j = 1, 2, \ldots, r, \tag{5.4}$$

having set

$$\chi_j^{(k)}(\mu) = \prod_{i=0}^{\nu-k} (\mu - \tau_i) \frac{F^{(\nu+1)}(\xi, t(h_j))}{(\nu+1-k)!}, \tag{5.5}$$

when the $\nu + 1 - k$ distinct points τ_i are independent of μ and lie in the intervals (μ_i, μ_{i+k}), $i = 0, 1, \ldots, \nu - k$, and $\xi = \xi(\mu)$ is some point in the interval containing μ and τ_i.

We are now able to restate Theorem 4.3 in the following form suitably modified for the present case.

THEOREM 5.1. *Let μ be an estimation of λ and $t(h_i)$, $i = 1, 2, \ldots, r$, as in Theorem* 4.3. *Let μ_l, $l = 0, 1, \ldots, \nu$, be values of μ obtained during the same rootfinding process and ordered by $\mu_0 < \mu_1 < \cdots < \mu_\nu$. Define the matrix G whose elements are*

$$(G)_{jl} = g_{jl} = F(\mu_l, t(h_j)), \quad 0 \le l \le \nu, \quad 1 \le j \le r,$$

and let $M(\mu)$ be as in (5.3). *Denote again by $\gamma^{(k)}$ the vector whose components are $\gamma_j^{(k)} = F^{(k)}(\mu, t(h_j))$, $j = 1, 2, \ldots, r$, and let T be the Vandermonde matrix as in Theorem* 4.3.

Then

$$\lambda = \mu + \epsilon, \tag{5.6}$$

ϵ being a solution of

$$\hat{\psi}(\epsilon) + O(\epsilon^{m+1}) = 0, \tag{5.7}$$

where

$$\hat{\psi}(\epsilon) = \sum_{k=0}^{m} \hat{\psi}_k \epsilon^k. \tag{5.8}$$

The coefficients in (5.8) *are given by*

$$\hat{\psi}_k = \frac{1}{k!} e^{(1)^T} T^{-1} \big(G M^{-1}(\mu) b^{(k)} + \chi^{(k)} + O(t_\rho^r) \big), \tag{5.9}$$

where, from (5.5),

$$\chi^{(k)} = \big(\chi_1^{(k)}(\mu), \chi_2^{(k)}(\mu), \ldots, \chi_r^{(k)}(\mu) \big)^T$$

and t_ρ being as in (4.9).

Proof. The proof runs as the proof of Theorem 4.3. We have to use only for components of $\gamma^{(k)}$ (5.4) instead of (4.2) and observe that from (5.1) and (5.2) we obtain

$$p_j^{(k)}(\mu) = \big(G M^{-1}(\mu) b^{(k)} \big)_j, \quad j = 1, 2, \ldots, r. \qquad \square$$

Leaving out the terms $O(\epsilon^{m+1})$ in (5.7), $\chi^{(k)}$, and $O(t_\rho^r)$ in (5.9), (5.6) can be written as

$$\lambda \simeq \lambda^{(c)} = \mu + \epsilon,$$

where now ϵ is a zero of the polynomial

$$\psi(\epsilon) = \sum_{k=0}^{m} \psi_k \epsilon^k \tag{5.10}$$

with

$$\psi_k = \frac{1}{k!} e^{(1)^T} T^{-1}\big(GM^{-1}(\mu) b^{(k)}\big).$$

As in the regular case a simple but powerful correcting procedure is obtained with $m = 2$. If $r = 3$ and μ_0, μ_2 are such that $|\mu_0 - \mu_2|$ is sufficiently small, define $\mu_1 = \frac{1}{2}(\mu_0 + \mu_2)$ and $\sigma = \mu_0 - \mu_1 = \mu_1 - \mu_2$. Therefore it is not difficult to verify that

$$\gamma_j^{(1)} = \frac{g_{j0} - g_{j2}}{2\sigma} + O(\sigma^2), \quad j = 1, 2, 3,$$
$$\gamma_j^{(2)} = \frac{g_{j0} - 2g_{j1} + g_{j2}}{\sigma^2} + O(\sigma^2), \quad j = 1, 2, 3,$$

where $\gamma_j^{(0)}$, $\gamma_j^{(1)}$, and $\gamma_j^{(2)}$ are computed for $\mu = \mu_1$. Then the correction is given by

$$\lambda \simeq \lambda^{(c)} = \mu_1 + \epsilon,$$

where

$$\epsilon = \frac{-\psi_1 + \frac{\psi_1}{|\psi_1|}\sqrt{\psi_1^2 - 4\psi_0\psi_2}}{2\psi_2}.$$

With $m = 3$, since ψ_k have been computed in (5.10), the correction can be performed as at the end of section 4.

We remark that the procedure described in this section to compute the vectors $\gamma^{(k)}$ can be used in the regular case too. Still it is worth mentioning that the use of Lemmas 4.1 and 4.2 for the regular case seems to be theoretically more correct. As a matter of fact the vectors $\gamma^{(k)}$ depend on the solutions of the differential equations describing the analytical behavior of the derivatives $F^{(k)}(\mu, t)$ of the miss-distance itself. Consequently, if these solutions are carried out by means of the same discretization method employed for the "principal" problems (2.1) and (2.2), no additional truncation error substantially different from the "principal" one is introduced.

Nevertheless, when k is increasing, the bigger computational cost could be disguising for this distinctive feature.

6. Numerical experiments. We apply the techniques exposed in sections 4 and 5 both to a regular and λ-rational SLP.

In the following examples the used BVM is the fourth order extended trapezoidal rule of second kind (ETR_2) coupled with its boundary conditions [4, p. 164]:

$$\frac{1}{24}(-17Z_0 + 9Z_1 + 9Z_2 - Z_3) = \frac{h}{4}(\Gamma_0 + 3\Gamma_1),$$
$$\frac{1}{12}(-Z_{\nu-2} - 9Z_{\nu-1} + 9Z_\nu + Z_{\nu+1}) = \frac{h}{2}(\Gamma_{\nu-1} + \Gamma_\nu), \quad \nu = 2, \ldots, N-1,$$
$$\frac{1}{24}(Z_{N-3} - 9Z_{N-2} - 9Z_{N-1} + 17Z_N) = \frac{h}{4}(3\Gamma_{N-1} + \Gamma_N).$$

Moreover, the approximations to the eigenvalues are obtained by choosing the secant method as rootfinding process.

Example 1 (see [16, p. 134]). Consider the regular SLP

$$-y''(x) + \exp(x)y(x) = \lambda y(x), \quad 0 \le x \le \pi,$$

$$y(0) = 0, \quad y(\pi) = 0.$$

We shall denote by

- λ_k the kth eigenvalue computed with the SLEIGN code (see [17, Appendix C]) and considered as "exact";
- $\mu_k \equiv \mu_k^{(j+1)}$ the approximation to λ_k obtained by using the rootfinding process with a constant stepsize h and the stopping criterion given by
$$| \mu_k^{(j+1)} - \mu_k^{(j)} | \le 10^{-4};$$
- $\lambda_k^{(c)}$ the corrected eigenvalue derived by fixing $h_i = h/i$, $i = 1, 2, \ldots, r$ (see Theorem 4.3).

In Table 6.1 we get the results choosing $h = \pi/1000$, $r = 2, 3$, the polynomials (4.14) having degree $m = 1, 2, 3$. Moreover, we fix 10 shooting intervals and the matching point $c = \pi/2$. It is worth noting that the correction does not depend on the selected value of c. Although the used stopping criterion leads to a rough enough approximation μ_k, the correction technique is able to give a value $\lambda_k^{(c)}$ which emphasizes a remarkable improvement of accuracy. However, as the index k increases, we observe a loss of precision as a consequence of the rounding off errors in the computation of the coefficients defining the polynomials (4.14).

Example 2 (see [9, p. 375]). We consider the λ-rational SLP

$$-y''(x) = \left(\lambda + \frac{\exp(-x)}{\exp(-x_*) - \exp(-x) - \lambda}\right) y(x), \quad -5 \le x \le 5,$$

$$\exp(5)y(-5) - (\exp(-x_*) - \exp(5))y'(-5) = 0,$$

$$\exp(-5)y(5) - (\exp(-x_*) - \exp(-5))y'(5) = 0.$$

	$6.77\ 10^{-13}$	1.0000	$3.01\ 10^{-13}$	1.0000	3

This problem has an embedded eigenvalue $\lambda = 0$ corresponding to the solution $y(x) = \exp(-x_*) - \exp(-x)$ in the interval $[-5, 5]$.

In Table 6.2 we report the results obtained by approximating the eigenvalue λ on the interval $[-5, x_\lambda]$ with $x_\lambda \equiv x_* = 0$ and introducing the artificial layer δ (see (3.2)) equal to 10^{-15}. The involved differential problems are solved fixing 10 shooting intervals and matching point $c = -5$. In Table 6.3 the interval $[x_\lambda, 5]$ has been considered choosing the same parameters as before, except for the matching point here taken as $c = 5$. In both tables we have denoted with μ and $\lambda^{(c)}$ the approximation and correction to λ, respectively. In accordance with what we have pointed out on the order of convergence in section 3, we have used $t(h) = h^2$. The approximation μ is obtained by the same stopping criterion used in the regular case.

Remark 6.1. Despite that this correction technique may be easily used for polynomials (5.10) having any degree, from the shown results we see that the approximation of the eigenvalue does not noticeably improve as the degree m of (5.10) becomes greater than two. This behavior can appear fairly surprising. Nevertheless, it is worth taking into account that the correction is rather strong even if $m = 1$ or $m = 2$. Thus we are allowed to interpret these results as a kind of numerical saturation of the algorithm as regards the attainable accuracy. Consequently, in the present case, it seems insignificant to consider $m > 2$.

		$3.60\ 10^{-3}$	0.9469	$1.47\ 10^{-4}$	0.9978	3

Finally, in order to stress that the multiple shooting works better than the simple one, we have quoted in Table 6.4 the results obtained with Example 1 when the simple shooting is used, and in Table 6.5 the same example in the case of multiple shooting. In both cases we have selected $h = \frac{\pi}{500}$ and λ_{50} the eigenvalue to be approximated. In the multiple shooting we have chosen 50 shooting intervals (and 10 steps in each interval) and $c = \pi$ as matching point. We see that in the simple shooting the second degree polynomial has complex zeroes. Thus, we are compelled to gain the advantage from the use of first or third degree polynomials where a real zero always exists. Tables 6.6 and 6.7 are the same as the previous ones but with $h = \frac{\pi}{600}$ and 60 shooting intervals in the multiple shooting.

Acknowledgment. The authors would like to thank the anonymous referee very much for his valuable comments and suggestions enabling an improvement of the technical correctness of the paper.

CFL CONDITION AND BOUNDARY CONDITIONS FOR DGM APPROXIMATION OF CONVECTION-DIFFUSION*

JEAN-BAPTISTE APOUNG KAMGA† AND BRUNO DESPRÉS‡

Abstract. We propose a general method for the design of discontinuous Galerkin methods (DGMs) for nonstationary linear equations. The method is based on a particular splitting of the bilinear forms that appear in the weak DGM. We prove that an appropriate time splitting gives a stable linear explicit scheme whatever the order of the polynomial approximation. Numerical results are presented.

Key words. discontinuous Galerkin method, advection diffusion, stability, CFL condition

1. Introduction.

The convection-diffusion equation is widely used in real-life problems such as contaminant transport in porous media [1, 8, 26]. Due to the geological structure of the problem, the equation is convection-dominant in random distributed parts of the media. This makes its numerical resolution difficult. While difference schemes suffer from the complex geometry of the domain, ordinary finite element methods suffer from their lack of local conservativity [28], and finite volume methods suffer from their low order of accuracy (due to low order polynomial approximation). The discontinuous Galerkin method (DGM or DG), introduced in 1973 by Reed and Hill [32], in its development [24] found here a good field of application. In a computational aspect, the DGM can be used efficiently to handle the advection part in an operator splitting technique scheme [27]. But this strategy may break apart at boundary conditions of mixed type, where it is difficult to determine whether the boundary condition is more in the advection step or in the diffusion step. For real-life problems [8], the Dirichlet part of the boundary can also be split into inflow and outflow parts. This boundary condition can astutely be distributed in between the advection terms and diffusion terms [5, 6]. In a mathematical aspect, it is more convenient to have a unique bilinear form even if the splitting technique is used [20, 37, 33]. This leads to an ordinary differential equation, a different approach is [39]. Assuming for example that the DGM is used only in space to exploit the block diagonal mass matrix obtained, most time discretizations are explicit and therefore require a CFL condition.

In the one-dimensional case, using Von Neumann analysis, Chavent & Cockburn [11] proved that explicit linear Euler time integration of the DGM is unconditionally unstable if the ratio $\frac{\Delta t}{\Delta x}$ is held constant. To overcome this striking difficulty and still keep high order accuracy, Cockburn and Shu [19, 20, 21, 22] introduced the RKDG (Runge–Kutta discontinuous Galerkin method). It uses at each time step an

explicit Euler scheme, stabilized by a particular slope limiter, which makes the scheme nonlinear. Due to this nonlinearity, proof of convergence of the fully discrete explicit DGM is not possible except perhaps in very rare and special cases. We refer the reader to Cockburn [18] for a presentation of the convergence theory for the DGM. Despite this lack of theory, numerical experiments show the convergence. For example, in the one-dimensional case for advection, the convergence is observed if the CFL condition is of the form $\frac{1}{2k+1}$ for polynomials of order k [18]. To the best of our knowledge, the analysis of the fully discrete explicit DGM scheme remains an open problem.

In this work we propose a way to solve this problem. We propose an abstract functional formalism. Within this formalism, it is easy to design explicit (only local-in-the-cell) computations, which are linear and stable under CFL DGMs. Then we apply this method to our model problem, which is advection diffusion in two dimensions,

$$\partial_t c + \mathbf{u}.\nabla c - \nabla.(K\nabla c) = 0, \quad x \in \mathbf{R}^2,\ t > 0. \tag{1.1}$$

The diffusion coefficient is nonnegative $K \geq 0$, and the velocity is divergence-free $\nabla.\mathbf{u} = 0$. Boundary conditions are general and are specified in the core of the paper. Due to the stability (under the CFL condition) and linearity of our explicit DGM scheme, we are able to prove the convergence by a standard method. For example, we obtain the estimate of convergence in two dimensions for the advection case ($K = 0$),

$$\|c(n\Delta t) - c_h^n\|_{L^2} \leq C_1 \Delta t^2 + C_2 h^p + E.$$

E is an error term due the discretization of the initial condition and can be taken as small as desired. This estimate is true for the second order in time discretization. The order in space is p, which is the degree of the polynomial basis. Since the optimal order in space is $p + 1/2$, we think this loss of $1/2$ is an artifact of the analysis, which could be corrected with a more sophisticated technique [13, 14, 15]. To our knowledge, such an estimate is new and was not possible to get for previous fully discrete explicit DGM schemes.

At the theoretical level the key idea is to reformulate (1.1) as a weak problem

$$\left(\frac{\partial}{\partial t}U, V\right) + \mathcal{A}_0(U,V) + \mathcal{A}_1(U,V) - \mathcal{A}_2(U,V) = 0 \ \ \forall V \in \mathcal{V}, \tag{1.2}$$

where U is the solution, V is a test function, $(.,.)$ is the standard L^2 scalar product, and $\mathcal{A}_{0,1,2}$ are some bilinear forms defined later in this paper. The space is $\mathcal{V} \subset \sum_k L^2(\Omega_k)$, where (Ω_k) is a partition of the plane, i.e., is the mesh. Among other properties, the local bilinear forms $\mathcal{A}_0(U,V)$, $\mathcal{A}_1(U,V)$, and $\mathcal{A}_2(U,V)$ satisfy

$$\mathcal{A}_0(U,U) + \mathcal{A}_1(U,U) - \mathcal{A}_2(U,U) \geq 0. \tag{1.3}$$

The first order time discretization of (1.3) is as follows: Find $U_h^n, U_h^{n+1} \in \mathcal{V}_h$ such that for all test functions $V_h \in \mathcal{V}_h$,

$$\left(\frac{U_h^{n+1} - U_h^n}{\Delta t}, V_h\right) + \mathcal{A}_0(U_h^{n+1}, V_h) + \mathcal{A}_1(U_h^n, V_h) - \mathcal{A}_2(U_h^n, V_h) = 0. \tag{1.4}$$

When applied to (1.1), the bilinear form $\mathcal{A}_0$ is local-in-the-cell, and this is why the scheme is explicit. The main stability property that we prove is the inequality

$$||U_h^{n+1}||_{L^2(\mathbf{R}^2)} \leq ||U_h^n||_{L^2(\mathbf{R}^2)} \quad \forall n \ \in \mathbb{N}, \tag{1.5}$$

which is true under a CFL condition that is studied in detail. It guarantees stability whatever the order of the polynomial approximation. Since $\mathcal{A}_0$ is in practice a local-in-the-cell bilinear form, the scheme is explicit at the price of the resolution of a local-in-the-cell linear system. At the implementation level, it does not cost more than inverting the local mass matrix. We also study the second order discretization in time,

$$\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},V_h\right)+\frac{2}{3}\mathcal{A}_0(U_h^{n+1},V_h) + \frac{2}{3}\mathcal{A}_1(2U_h^n-U_h^{n-1},V_h)-\frac{2}{3}\mathcal{A}_2(2U_h^n-U_h^{n-1},V_h)=0. \tag{1.6}$$

The CFL condition is twice as stringent for (1.6) than for (1.4). It is possible to define all the parameters of the method in order to optimize the CFL condition. We will apply this method for our convection-diffusion problem.

The paper is organized as follows. In section 2 we consider a general setting. We present the properties which the bilinear forms should satisfy in this framework. Assuming these properties, we discuss some time schemes and derive the abstract CFL condition that guarantees their stability. In section 3 we address the convection-diffusion equation within the discontinuous Galerkin approximation and show how to cast the bilinear form to fit within the abstract formalism. We show how to introduce commonly used boundary conditions. In section 4 we analyze the abstract CFL condition in the case of a uniform grid and give values to all constants. We give the bilinear forms in particular cases of pure advection and pure diffusion. We conclude that the totally discrete schemes introduced for the convection-diffusion equation make up a continuous interpolation between the scheme for pure advection and the scheme for pure diffusion. In section 5 we analyze the convergence of the second order schemes in the case of the pure advection equation. Finally, in section 6 we present numerical results for advection and diffusion and compare them with other DGMs.

2. The abstract discontinuous Galerkin formalism. We first consider an abstract formalism in a more general setting and derive some time discretization, which will be stable under an abstract CFL condition.

2.1. Abstract formalism. Let us define the spaces

$$\mathcal{V}\subset\mathcal{H}. \tag{2.1}$$

$\mathcal{H}$ is endowed with a scalar product, namely $(.,.)$. In practice $\mathcal{H}=L^2(\Omega)$.

DEFINITION 2.1. *A sequence $(U^p)_p\in\mathcal{V}$ will be said to be L^2 stable if there exists a constant $C\in\mathbb{R}$ such that $(U^p,U^p)\le C$ for all $p\in\mathbb{N}$.*

Let $\mathcal{A}_i, i=0,1,2$, be three bilinear forms on $\mathcal{V}$ satisfying the following properties:

(2.2)
$$\begin{cases}\mathcal{A}_1 \text{ is symmetric nonnegative.}\\ \text{There exist a bilinear form } \mathcal{A}_3 \text{ also defined on } \mathcal{V} \text{ such that}\\ \mathcal{A}_0(U,U)\ge\frac{1}{2}\left(-\mathcal{A}_1(U,U)+\mathcal{A}_3(U,U)\right) \text{ and } \mathcal{A}_2(U,V)\le\dfrac{1}{2}\left(\mathcal{A}_1(U,U)+\mathcal{A}_3(V,V)\right).\end{cases}$$

A consequence of (2.2) is

$$\mathcal{A}_0(U,U)+\mathcal{A}_1(U,U)-\mathcal{A}_2(U,U)\ge 0\quad\forall U\in\mathcal{V}.$$

We now consider the problem (2.3):

$$\text{(2.3)}\qquad \begin{cases} \text{Given} \quad U_0 \in \mathcal{V}, \\ \text{find} \quad U \in C^1(0,T;\mathcal{V}) \quad \text{such that} \quad \forall V \in \mathcal{V}, \\ \left(\dfrac{\partial}{\partial t}U, V\right) + \mathcal{A}_0(U,V) + \mathcal{A}_1(U,V) - \mathcal{A}_2(U,V) = 0, \\ U = U_0 \quad \text{at} \quad t = 0. \end{cases}$$

In what follows we will assume that it has a unique solution.

LEMMA 2.2. *Assume that the bilinear forms $\mathcal{A}_i, i = 0,1,2$, satisfy* (2.2). *Then the solution to* (2.3) *is L^2 stable.*

Proof. Choosing $V = U$ and using the property of (2.2) one gets directly that $d_t\left[\frac{1}{2}(U,U)(t)\right] \leq 0$. Therefore the energy $t \mapsto (U,U)(t)$ decreases. ∎

2.2. Time and space discretizations and abstract CFL conditions. Let $\mathcal{V}_h \subset \mathcal{V}$ be a finite-dimensional vectorial subspace of $\mathcal{V}$. The unknown at time step n is $U_h^n \in \mathcal{V}_h$. The test function is denoted by $V_h^n \in \mathcal{V}_h$. Under assumptions (2.2) on bilinear forms $\mathcal{A}_i, i = 0,1,2$, we can now derive some fully discrete schemes, which are stable under abstract CFL conditions.

2.2.1. First order scheme. The first order scheme reads

$$\text{(2.4)}\qquad \left(\frac{U_h^{n+1} - U_h^n}{\Delta t}, V_h\right) + \mathcal{A}_0(U_h^{n+1}, V_h) + \mathcal{A}_1(U_h^n, V_h) - \mathcal{A}_2(U_h^n, V_h) = 0 \quad \forall V_h.$$

We have the following result.

THEOREM 2.3. *Assuming that the bilinear forms $\mathcal{A}_i, i = 0,1,2$, satisfy the properties* (2.2), *we assume that the time step satisfies the abstract CFL requirement*

$$\text{(2.5)}\qquad \Delta t \mathcal{A}_1(U_h, U_h) \leq (U_h, U_h) \quad \forall U_h \in \mathcal{V}_h.$$

Then scheme (2.4) *is L^2 stable and*

$$\text{(2.6)}\qquad \left(U_h^{n+1}, U_h^{n+1}\right) \leq \left(U_h^n, U_h^n\right).$$

$\Delta t > 0$ exists because the dimension of $\mathcal{V}_h$ is finite.

Proof. The proof explicitly uses the inequalities of (2.2). The scalar product of (2.4) with U_h^{n+1} gives

$$\begin{aligned} &\left(U_h^{n+1}, U_h^{n+1}\right) \\ &= \left(U_h^n, U_h^{n+1}\right) - \Delta t \mathcal{A}_0(U_h^{n+1}, U_h^{n+1}) - \Delta t \mathcal{A}_1(U_h^n, U_h^{n+1}) + \Delta t \mathcal{A}_2(U_h^n, U_h^{n+1}) \\ &\leq \left(U_h^n, U_h^{n+1}\right) - \Delta t \mathcal{A}_0(U_h^{n+1}, U_h^{n+1}) - \Delta t \mathcal{A}_1(U_h^n, U_h^{n+1}) \\ &\quad + \frac{\Delta t}{2}\left(\mathcal{A}_1(U_h^n, U_h^n) + \mathcal{A}_3(U_h^{n+1}, U_h^{n+1})\right) \\ &\leq \left(U_h^n, U_h^{n+1}\right) + \frac{\Delta t}{2}\left(\mathcal{A}_1(U_h^n, U_h^n) - 2\mathcal{A}_1(U_h^n, U_h^{n+1}) + \mathcal{A}_1(U_h^{n+1}, U_h^{n+1})\right). \end{aligned}$$

Using the symmetry of bilinear form $\mathcal{A}_1$ and the scalar product, we rewrite the previous inequality as

$$\begin{aligned} &\left(U_h^{n+1}, U_h^{n+1}\right) \leq \left(U_h^{n+1}, U_h^{n+1}\right) \\ &- \left(\left(U_h^{n+1} - U_h^n, U_h^{n+1} - U_h^n\right) - \Delta t \mathcal{A}_1\left(U_h^{n+1} - U_h^n, U_h^{n+1} - U_h^n\right)\right). \end{aligned}$$

Assuming the abstract CFL-like condition (2.5), the result is proved. ∎

2.2.2. Second order scheme. Extending to second order time discretization the abstract DGM already mentioned is not easy. After numerous attempts, we focused on the following approach, which is based on the theory of A-stable time integration for stiff equations; see [25]. First, we begin with the retrograde second order time integration,

$$\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},V_h\right)+\frac{2}{3}\left(\mathcal{A}_0+\mathcal{A}_1-\mathcal{A}_2\right)(U_h^{n+1},V_h)=0\quad\forall V_h. \tag{2.7}$$

Its stability can be proved, by taking $V_h=U_h^{n+1}$ in (2.7). The scheme is fully implicit in the sense that it requires the inversion of a global linear system to get the new value. Let us now define a semi-implicit second order time scheme. The idea is to get rid of the cell-to-cell coupling that appears in (2.7). For this we use the relation $U((n+1)\Delta t)=2U(n\Delta t)-U((n-1)\Delta t)+O(\Delta t^2)$, which is true provided that U is smooth. Then we eliminate some occurrences of U_h^{n+1} in (2.7) using transformation $U_h^{n+1}\leftarrow 2U_h^n-U_h^{n-1}$. It gives the scheme

$$\begin{aligned}\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},V_h\right)+\frac{2}{3}\mathcal{A}_0(U_h^{n+1},V_h)\\ +\frac{2}{3}\mathcal{A}_1(2U_h^n-U_h^{n-1},V_h)-\frac{2}{3}\mathcal{A}_2(2U_h^n-U_h^{n-1},V_h)=0\quad\forall V_h.\end{aligned} \tag{2.8}$$

We will see that in practice, $\mathcal{A}_0$ is of local-in-the-cell bilinear form. In this case, scheme (2.8) is only locally implicit, and we need only inverse local linear systems to get the new solution. Hence scheme (2.8) is in practice an explicit one.

THEOREM 2.4. *Assume the bilinear forms $\mathcal{A}_i, i=0,1,2$, satisfy the properties* (2.2)*, and assume the time step satisfies the abstract CFL requirement*

$$2\Delta t\mathcal{A}_1(U_h,U_h)\le(U_h,U_h)\quad\forall U_h\in\mathcal{V}_h. \tag{2.9}$$

Then scheme (2.8) *is L^2 stable and*

$$\begin{aligned}\left(U_h^{n+1},U_h^{n+1}\right)+\left(2U_h^{n+1}-U_h^n,2U_h^{n+1}-U_h^n\right)\\ \le(U_h^n,U_h^n)+\left(2U_h^n-U_h^{n-1},2U_h^n-U_h^{n-1}\right).\end{aligned} \tag{2.10}$$

Proof. Let us take $V_h=U_h^{n+1}$ in (2.8). We get

$$\begin{aligned}\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},U_h^{n+1}\right)+\frac{2}{3}\mathcal{A}_0(U_h^{n+1},U_h^{n+1})\\ +\frac{2}{3}\mathcal{A}_1(2U_h^n-U_h^{n-1},U_h^{n+1})-\frac{2}{3}\mathcal{A}_2(2U_h^n-U_h^{n-1},U_h^{n+1})=0.\end{aligned}$$

We can give a lower bound to $\mathcal{A}_0(U_h^{n+1},U_h^{n+1})$ and $-\mathcal{A}_2(2U_h^n-U_h^{n-1},U_h^{n+1})$ using (2.2). Therefore

$$\begin{aligned}\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},U_h^{n+1}\right)+\frac{1}{3}(\mathcal{A}_3-\mathcal{A}_1)(U_h^{n+1},U_h^{n+1})\\ +\frac{2}{3}\mathcal{A}_1(2U_h^n-U_h^{n-1},U_h^{n+1})-\frac{1}{3}\mathcal{A}_1(2U_h^n-U_h^{n-1},2U_h^n-U_h^{n-1})-\frac{1}{3}\mathcal{A}_3(U_h^{n+1},U_h^{n+1})\le 0,\end{aligned}$$

that is,

$$\frac{1}{3}\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},U_h^{n+1}\right) - \frac{1}{3}\mathcal{A}_1(U_h^{n+1}-2U_h^n+U_h^{n-1},U_h^{n+1}-2U_h^n+U_h^{n-1})\le 0.$$

Let us define the energy

$$E(n+1)=\left(U_h^{n+1},U_h^{n+1}\right)+\left(2U_h^{n+1}-U_h^n,2U_h^{n+1}-U_h^n\right).$$

One has the equality

$$E(n+1)-E(n)=6\left(\frac{3U_h^{n+1}-4U_h^n+U_h^{n-1}}{\Delta t},U_h^{n+1}\right) - \left(U_h^{n+1}-2U_h^n+U_h^{n-1},U_h^{n+1}-2U_h^n+U_h^{n-1}\right).$$

Plugging in the previous inequality, we obtain

$$E(n+1)\le E(n)-\left(U_h^{n+1}-2U_h^n+U_h^{n-1},U_h^{n+1}-2U_h^n+U_h^{n-1}\right) + 2\Delta t\mathcal{A}_1(U_h^{n+1}-2U_h^n+U_h^{n-1},U_h^{n+1}-2U_h^n+U_h^{n-1}).$$

Under the abstract CFL condition (2.9), the result is proved. ∎

2.2.3. Implicit scheme. The implicit scheme is

$$\left(\frac{U_h^{n+1}-U_h^n}{\Delta t},V_h\right)+\mathcal{A}_0(U_h^{n+1},V_h)+\mathcal{A}_1(U_h^{n+1},V_h)-\mathcal{A}_2(U_h^{n+1},V_h)=0. \tag{2.11}$$

LEMMA 2.5. *The implicit scheme* (2.11) *is L^2 stable unconditionally.*

Proof. The proof is left to the reader. ∎

2.3. Optimization of numerical parameters. It is well known that the DGM applied to convection-diffusion needs the definition of some arbitrary numerical parameters in order to completely define the bilinear forms at interfaces. We refer to [30, 12], where the dependence between the convergence of the DGM for stationary problems and the numerical parameters is analyzed. In what follows, we analyze the influence of the numerical parameters on the CFL condition (for nonstationary problems, of course). An open problem is to show that the parameter which is optimal with respect to the CFL condition is also optimal for convergence.

By inspection of the bilinear forms defined in the following section for convection-diffusion, it is enough to consider the abstract problem

$$\left(\frac{\partial}{\partial t}U,V\right)+\mathcal{A}_0(U,V)+\mathcal{A}_1^\alpha(U,V)-\mathcal{A}_2^\alpha(U,V)=0\ \ \forall V\in\mathcal{V}. \tag{2.12}$$

The bilinear forms $\mathcal{A}_0,\mathcal{A}_1^\alpha,\mathcal{A}_2^\alpha$ satisfy (2.2). The dependence to the arbitrary parameters is represented by α. The CFL condition takes the form

$$\left(\max_{U_h\in\mathcal{V}_h,\,U_h\neq 0}\frac{\mathcal{A}_1^\alpha(U_h,U_h)}{(U_h,U_h)}\right)\Delta t\le C, \tag{2.13}$$

where $C = 1$ for the first order scheme (2.5) and $C = \frac{1}{2}$ for the second order scheme (2.9). So the best α, denoted as $\alpha_{\rm opt}$, is the one that minimizes the constant in this inequality. We obtain the min-max problem for $\alpha_{\rm opt}$,

$$\left(\max_{U_h \in \mathcal{V}_h,\, U_h \neq 0} \frac{\mathcal{A}_1^{\alpha_{\rm opt}}(U_h, U_h)}{(U_h, U_h)} \right) \leq \left(\max_{U_h \in \mathcal{V}_h,\, U_h \neq 0} \frac{\mathcal{A}_1^{\alpha}(U_h, U_h)}{(U_h, U_h)} \right) \quad \forall \alpha.$$

We will apply this method in order to define optimized coefficients for DGM discretization for convection-diffusion in section 3.

3. Advection-diffusion with discontinuous coefficients and boundary conditions. In what follows, we describe the introduction of mixed-type boundary conditions in an advection-diffusion problem. We show that physically correct boundary conditions fit into the framework. So the stability of the scheme is guaranteed for all boundary conditions described below. Let us recall the model equation

$$\partial_t c + \mathbf{u}.\nabla c - \nabla.(K \nabla c) = 0, \quad x \in \Omega \subset \mathbf{R}^2,\ t > 0. \tag{3.1}$$

Ω is a bounded smooth open set of $\mathbf{R}^2$.

3.1. Abstract discontinuous Galerkin formalism of problem (3.1). We are now going to show how to cast the discontinuous Galerkin formulation of problem (3.1) so that the bilinear forms fit with properties (2.2).

3.1.1. Notation. We begin with some notation. Let (Ω_k) be a mesh of the plane. The cells Ω_k do not overlap. They cover the plane. The boundary of cell Ω_k is $\partial\Omega_k$. The intersection of the boundary of cell Ω_j and cell Ω_k is referred to as $\Sigma_{jk} = \Sigma_{kj}$. The outgoing normal from Ω_k is $\mathbf{n}_k$.

The velocity field $\mathbf{u}$ is not necessarily constant but is divergence-free. Therefore the degrees of freedom of $\mathbf{u}$ are naturally described in terms of its fluxes $(\mathbf{u}_{kj}, \mathbf{n}_k)$ across Σ_{jk}. The diffusion coefficient is assumed to be positive and lower bounded, but not necessarily constant. Let K_k denote the value of the diffusion coefficient in cell Ω_k. For simplicity, K_k is considered constant in the cell, but there is no real issue if it is not, except at the implementation level. We will describe the boundary conditions later on. If necessary we will assumed that the outgoing unit normal is split into two parts

$$\begin{cases} \text{if } (\mathbf{u}, \mathbf{n}_k) \geq 0, & \text{then } \mathbf{n}_k^+ = \mathbf{n}_k & \text{and } \mathbf{n}_k^- = 0, \\ \text{if } (\mathbf{u}, \mathbf{n}_k) < 0, & \text{then } \mathbf{n}_k^+ = 0 & \text{and } \mathbf{n}_k^- = \mathbf{n}_k. \end{cases} \tag{3.2}$$

Let us define the spaces

$$\mathcal{V} = \oplus_k H^2(\Omega_k) \subset \mathcal{H} = \oplus_k L^2(\Omega_k). \tag{3.3}$$

$\mathcal{H}$ is endowed with a scalar product $(U, V) = \sum_k \int_{\Omega_k} u_k(x) v_k(x) dx$.

3.1.2. Construction of the bilinear forms. Next we assume that c is smooth. Let us define $U = (u_k)$ with $u_k = c_{|\Omega_k}$. The test function is $V = (v_k)$. Let us define the local bilinear form

$$\mathcal{A}_0(U, V) = \sum_k \int_{\Omega_k} \left(-u_k(t,x) \mathbf{u}.\nabla v_k(x) + u_k \nabla.(K_k \nabla v_k) + 2 K_k \nabla u_k.\nabla v_k \right) dx. \tag{3.4}$$

We also need to define $\mathcal{A}_1$ and $\mathcal{A}_2$. So let us compute

$$(\partial_t U, V) + \mathcal{A}_0(U,V) = \sum_k \int_{\Omega_k} \left(-\mathbf{u}.\nabla u_k + \nabla.(K_k \nabla u_k)\right) v_k$$
$$+ \sum_k \int_{\Omega_k} \left(-u_k(t,x)\mathbf{u}.\nabla v_k(x) + u_k \nabla.(K_k \nabla v_k) + 2K_k \nabla u_k.\nabla v_k\right) dx$$
$$= \sum_k \int_{\partial\Omega_k} \left(-u_k v_k(\mathbf{u}_{kj},\mathbf{n}_k) + u_k K_k \frac{\partial}{\partial n_k} v_k + v_k K_k \frac{\partial}{\partial n_k} u_k.\right) d\sigma = \text{R.H.S.}$$

Next we need to transform the right-hand side (R.H.S.) in order to be able to define $\mathcal{A}_1$ and $\mathcal{A}_2$. For this task we define

$$\begin{cases} w_k^+ = K_k \frac{\partial}{\partial n_k} u_k - \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) u_k + \alpha_{jk} u_k, \\ w_k^- = -K_k \frac{\partial}{\partial n_k} u_k + \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) u_k + \alpha_{jk} u_k \end{cases}$$

and

$$\begin{cases} z_k^+ = K_k \frac{\partial}{\partial n_k} v_k - \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) v_k + \alpha_{jk} v_k, \\ z_k^- = -K_k \frac{\partial}{\partial n_k} v_k + \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) v_k + \alpha_{jk} v_k. \end{cases}$$

The value of the positive parameter $\alpha_{jk} = \alpha_{kj}$ will be specified later on. Then the R.H.S. is also

$$\text{R.H.S.} = \sum_k \int_{\partial\Omega_k} \left[u_k \left(K_k \frac{\partial}{\partial n_k} v_k - \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) v_k \right) + v_k \left(K_k \frac{\partial}{\partial n_k} u_k - \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) u_k \right) \right] d\sigma,$$
$$\text{R.H.S.} = \sum_k \int_{\partial\Omega_k} \frac{1}{2\alpha_{jk}} (w_k^+ z_k^+ - w_k^- z_k^-) d\sigma.$$

The nonnegative symmetric bilinear form is given by the $w^- z^-$ part of the integral. Therefore we define

$$\mathcal{A}_1(U,V) = \sum_k \int_{\partial\Omega_k} \frac{1}{2\alpha_{jk}} \left(-K_k \frac{\partial}{\partial n_k} u_k + \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) u_k + \alpha_{jk} u_k \right)$$
$$\times \left(-K_k \frac{\partial}{\partial n_k} v_k + \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) v_k + \alpha_{jk} v_k \right) d\sigma \tag{3.5}$$

so that we now have the relation

$$(\partial_t U, V) + \mathcal{A}_0(U,V) + \mathcal{A}_1(U,V) - \sum_k \int_{\partial\Omega_k} \frac{1}{2\alpha_{jk}} w_k^+ z_k^+ d\sigma = 0. \tag{3.6}$$

It is the place into which boundary conditions must be plugged. Let us start with some notation. The boundary between two cells Ω_k and Ω_j is still referred to as Σ_{jk}. The exterior boundary of cell Ω_k is Γ_k,

$$\Gamma_k = \partial\Omega_k \cap \partial\Omega, \quad \partial\Omega_k = (\cup_j \Sigma_{jk}) \cup \Gamma_k. \tag{3.7}$$

To transform the residual in (3.6) we use the continuity equation

$$w_k^+ = w_j^- \text{ on } \Sigma_{jk} \tag{3.8}$$
$$\iff K_k \frac{\partial}{\partial n_k} u_k - \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_k) u_k + \alpha_{jk} u_k = -K_k \frac{\partial}{\partial n_j} u_j + \frac{1}{2}(\mathbf{u}_{kj},\mathbf{n}_j) u_j + \alpha_{jk} u_j.$$

For mathematical convenience we consider that all boundary conditions may be rewritten as

$$w_k^+ = R_k^\alpha w_k^- \text{ on } \Gamma_k, \tag{3.9}$$

where $R_k^\alpha \in \mathbf{R}$ characterizes the boundary condition. This coefficient R_k^α is very similar to a reflexion coefficient in time-harmonic wave equations. It will be more obvious later on that physically correct boundary conditions are such that $|R_k^\alpha| \le 1$. α_{kk} stands for the value of the artificial parameter on Γ_k, and $(\mathbf{u}_{kj}, \mathbf{n}_k)$ stands for the value of the velocity flux on the boundary. We now define

$$\begin{aligned}\mathcal{A}_2(U,V) = \sum_{kj} \int_{\Sigma_{kj}} \frac{1}{2\alpha_{jk}} \left(-K_j \frac{\partial}{\partial n_j} u_j + \frac{1}{2}(\mathbf{u}_{kj}, \mathbf{n}_j) u_j + \alpha_{jk} u_j\right) \\ \times \left(K_k \frac{\partial}{\partial n_k} v_k - \frac{1}{2}(\mathbf{u}_{kj}, \mathbf{n}_k) v_k + \alpha_{jk} v_k\right) d\sigma \\ + \sum_k \int_{\Gamma_k} \frac{R_k^\alpha}{2\alpha_{kk}} \left(-K_k \frac{\partial}{\partial n_k} u_k + \frac{1}{2}(\mathbf{u}_{kk}, \mathbf{n}_k) u_k + \alpha_{kk} u_k\right) \\ \times \left(K_k \frac{\partial}{\partial n_k} v_k - \frac{1}{2}(\mathbf{u}_{kk}, \mathbf{n}_k) v_k + \alpha_{kk} v_k\right) d\sigma.\end{aligned} \tag{3.10}$$

The bilinear form $\mathcal{A}_3$ is

$$\begin{aligned}\mathcal{A}_3(U,V) = \sum_k \int_{\partial\Omega_k} \frac{1}{2\alpha_{jk}} \left(K_k \frac{\partial}{\partial n_k} u_k - \frac{1}{2}(\mathbf{u}_{kj}, \mathbf{n}_k) u_k + \alpha_{jk} u_k\right) \\ \times \left(K_k \frac{\partial}{\partial n_k} v_k - \frac{1}{2}(\mathbf{u}_{kj}, \mathbf{n}_k) v_k + \alpha_{jk} v_k\right) d\sigma.\end{aligned} \tag{3.11}$$

Now that we have defined all the bilinear forms, let us show that they satisfy the required properties.

LEMMA 3.1. *Consider the bilinear forms* (3.4), (3.5), (3.10), (3.11). *Assume that* $|R_k^\alpha| \le 1$. *Then properties* (2.2) *are satisfied.*

Proof. One has

$$\begin{aligned}\mathcal{A}_0(U,U) &= \sum_k \int_{\Omega_k} (-u_k(t,x)\mathbf{u}.\nabla u_k(x) + u_k \nabla.(K_k \nabla u_k) + 2K_k \nabla u_k.\nabla u_k)\, dx \\ &\ge \sum_k \int_{\partial\Omega_k} \left(-\frac{1}{2}(\mathbf{u}, \mathbf{n}_k) u_k^2 + u_k K \frac{\partial}{\partial n_k} u_k\right) d\sigma = \frac{1}{2}\left(-\mathcal{A}_1(U,U) + \mathcal{A}_3(U,U)\right),\end{aligned}$$

which proves the first part of (2.2). Then using the Cauchy–Schwarz inequality and property $|R_k^\alpha| \le 1$, one gets $\mathcal{A}_2(U,V) \le \frac{1}{2}(\mathcal{A}_1(U,U) + \mathcal{A}_3(V,V))$, which is the second part of (2.2). $\mathcal{A}_1$ is obviously symmetric nonnegative. ∎

3.1.3. Boundary conditions. One major particularity of this formalism is the way boundary conditions are introduced. They are all defined by giving different values to parameter R_k^α. Equation (3.9) shows how to introduce homogeneous boundary conditions. The expressions of R_k^α for commonly used boundary conditions are given in Table 3.1. For the Robin-type boundary condition, we need to restrict the admissible boundary conditions to $\frac{1}{2}(\mathbf{u}, \mathbf{n}) + \sigma \ge 0$ so that $|R_k^\alpha| \le 1$.

LEMMA 3.2. *All* R_k^α *given in Table* 3.1 *satisfy the inequality* $|R_k^\alpha| \le 1$.

Proof. The proof is obtained by straightforward computation. ∎

TABLE 3.1
Values of R_k^α for commonly used boundary conditions in the convection-diffusion equation.

Outgoing	$K_k = 0$, $(\mathbf{u}, \mathbf{n}) > 0$	$R_k^\alpha = \frac{-(\mathbf{u},\mathbf{n})+\alpha}{(\mathbf{u},\mathbf{n})+\alpha}$
Ingoing Dirichlet	$K_k = 0$, $(\mathbf{u}, \mathbf{n}) < 0$	$R_k^\alpha = 0$
Dirichlet	$K_k > 0$, $(\mathbf{u}, \mathbf{n}) = 0$	$R_k^\alpha = -1$
Neumann	$K_k > 0$, $(\mathbf{u}, \mathbf{n}) = 0$	$R_k^\alpha = 1$
Mixed or Robin	$K_k \frac{\partial}{\partial n} c + \sigma c = 0$	$R_k^\alpha = \frac{\alpha - \frac{1}{2}(\mathbf{u},\mathbf{n}) - \sigma}{\alpha + \frac{1}{2}(\mathbf{u},\mathbf{n}) + \sigma}$

3.2. Fully discrete DGM. Now we need to choose the space $\mathcal{V}_h$. The standard choice for DGMs is $\mathcal{V}_h = \mathcal{V}_p \subset \mathcal{V}$ with

$$\mathcal{V}_p = \oplus_k P_p(\Omega_k), \tag{3.12}$$

where $P_p(\Omega_k)$ is the space of all polynomial functions of degree $p \in \mathbf{N}$ or less on cell Ω_k. Applying the time discretization defined in section 2.2, we obtain the fully discrete DGM. By construction, this DGM is L^2 stable for all p and without the need of any limiter. Therefore this method is different from the standard RKDG approach. The bilinear form $\mathcal{A}_0$ is local-to-one-cell so that both the first (2.4) and the second (2.7) order schemes are semi-implicit. In fact, one needs only inverse local linear systems to get the new solutions. Let us now analyze the abstract CFL condition in the case of uniform meshes.

4. CFL analysis. In this section we show that the abstract CFL condition (2.5) is equivalent to standard CFL requirements for the convection-diffusion equation, which is a kind of interpolation between pure convection and pure diffusion.

LEMMA 4.1. *Consider (for simplicity) a sequence of triangular and conformal meshes. Assume the sequence of meshes is uniformly regular. Denote by h a characteristic length of the mesh. Consider the first order scheme* (2.4) *with bilinear forms* (3.4), (3.5), (3.10).

For all $p \in \mathbf{N}$, there exists two constants $C_p^1 > 0, C_p^2 > 0$ such that if

$$\frac{3}{2}\Delta t \max_k \left(\frac{\alpha_{kj}}{C_p^1 h} + \frac{|\mathbf{u}|^2}{4\alpha_{kj} C_p^1 h} + \frac{K_k^2}{\alpha_{kj} C_p^2 h^3} \right) \leq 1, \tag{4.1}$$

then the abstract CFL condition (2.5) *holds, and* (2.4) *is L^2 stable. Assuming that K is constant for simplicity, the optimal value of α corresponding to the least stringent CFL constraint is*

$$\alpha_{opt} = \sqrt{\frac{|\mathbf{u}|^2}{4} + \frac{K^2 C_p^1}{C_p^2 h^2}}. \tag{4.2}$$

Proof. First, the abstract CFL condition (2.5) is

$$\Delta t \max_k \left(\max_{\text{degree}(u_k) \leq p} \frac{1}{2\alpha_{kj}} \frac{\int_{\partial\Omega_k} (\alpha_{kj} u_k + \frac{1}{2}(\mathbf{u}, \mathbf{n}_k) u_k - K \frac{\partial}{\partial n_k} u_k)^2}{\int_{\Omega_k} u_k^2} \right) \leq 1.$$

This is true once the following inequality is satisfied:

$$\Delta t \max_k (T_1^k + T_2^k + T_3^k) \leq 1,$$

where T_1^k, T_2^k, T_3^k are given by

$$T_1^k = 3 \max_{\text{degree}(u_k)\le p} \frac{1}{2\alpha_{kj}} \frac{\int_{\partial\Omega_k} (\alpha_{kj} u_k)^2}{\int_{\Omega_k} u_k^2},$$
$$T_2^k = 3 \max_{\text{degree}(u_k)\le p} \frac{1}{2\alpha_{kj}} \frac{\int_{\partial\Omega_k} (\frac{1}{2}(\mathbf{u}, \mathbf{n}_k) u_k)^2}{\int_{\Omega_k} u_k^2},$$
$$T_3^k = 3 \max_{\text{degree}(u_k)\le p} \frac{1}{2\alpha_{kj}} \frac{\int_{\partial\Omega_k} (K \frac{\partial}{\partial n_k} u_k)^2}{\int_{\Omega_k} u_k^2}.$$

Let us introduce the linear transformation F_k that maps the triangular cell Ω_k onto the reference cell $\hat{T}$. Using the regularity of the mesh,

$$T_1^k \le 3 \frac{\alpha_{kj}}{2hc_k} \left(\max_{\text{degree}(\hat{u}_k)\le p} \frac{\int_{\partial\hat{T}} \hat{u}_k^2}{\int_{\hat{T}} \hat{u}_k^2} \right),$$

where c_k depends on transformation F_k. Since the mesh is assumed to be uniformly regular, c_k is uniformly bounded from below. Let us define

$$c^p = \max_{\text{degree}(\hat{u}_k)\le p} \frac{\int_{\partial\hat{T}} \hat{u}_k^2}{\int_{\hat{T}} \hat{u}_k^2} \quad \text{and} \quad C_p^1 = \frac{\min_k c^k}{c^p}. \quad \text{Then} \quad T_1^k \le \frac{3}{2} \frac{\alpha_{kj}}{h} \frac{1}{C_p^1}.$$

Also, one has

$$T_2^k \le \frac{3}{2} \frac{|\mathbf{u}|^2}{4h} \frac{1}{\alpha_{kj} C_p^1}.$$

Using again the regularity of the mesh, we have

$$T_3^k \le \frac{3}{2} \frac{K_k^2}{\alpha_{kj}} \frac{d_k}{h^3} \left(\max_{\text{degree}(u_k)\le p} \frac{\int_{\partial\hat{T}} (\frac{\partial}{\partial\hat{n}_k} u_k)^2}{\int_{\hat{T}} \hat{u}_k^2} \right),$$

where d_k depends on F_k. Since the mesh is assumed to be uniformly regular, d_k is uniformly upper bounded. Let us define

$$e_p = \max_{\text{degree}(\hat{u}_k)\le p} \frac{\int_{\partial\hat{T}} \frac{\partial}{\partial\hat{n}} u_k^2}{\int_{\hat{T}} \hat{u}_k^2} \quad \text{and} \quad C_p^2 = \frac{1}{e_p \max_k d_k}. \quad \text{Then} \quad T_3^k \le \frac{3}{2} \frac{K_k^2}{\alpha_{kj}} \frac{d_k}{h^3} \frac{1}{C_p^2}.$$

Putting this all together, we have

$$\Delta t \max_k (T_1^k + T_2^k + T_3^k) \le \frac{3}{2} \Delta t \max_k \left(\frac{\alpha_{kj}}{C_p^1 h} + \frac{|\mathbf{u}|^2}{4\alpha_{kj} C_p^1 h} + \frac{K_k^2}{\alpha_{kj} C_p^3 h^3} \right).$$

The abstract CFL condition is thus satisfied once we have

$$\frac{3}{2} \Delta t \max_k \left(\frac{\alpha_{kj}}{C_p^1 h} + \frac{|\mathbf{u}|^2}{4\alpha_{kj} C_p^1 h} + \frac{K_k^2}{\alpha_{kj} C_p^3 h^3} \right) \le 1.$$

Assuming K is constant, the optimal value of parameter α is the one that minimizes the multiplicative constant in front of Δt. Since the constant is $a\alpha + \frac{1}{\alpha b}$, where $a > 0$ and $b > 0$ are constants, then the optimal value is the solution of the equation $\frac{d}{d\alpha} \left(a\alpha + \frac{b}{\alpha} \right) = 0$, that is, $\alpha = \sqrt{\frac{b}{a}}$. Expanding with the definition of a and b, it gives (4.2). ∎

4.1. Particular cases. This section discusses the particular cases of the pure advection equation (i.e., $K \equiv 0, \mathbf{u}$ constant) and pure diffusion equation (i.e., $\mathbf{u} \equiv 0$ but $K > 0$).

4.1.1. Pure advection. In this particular case we have ($K \equiv 0, \mathbf{u}$ constant). Notation is still the same as in section 3.1.1. A consequence of Lemma 4.1 is the following.

LEMMA 4.2. *Consider a sequence of triangular and conformal meshes. Assume the sequence of meshes is uniformly regular. Denote by h a characteristic length of the mesh. For all $p \in \mathbf{N}$, there exists a $C_p^1 > 0$ such that if*

$$|\mathbf{u}|\Delta t \leq C_p^1 h, \tag{4.3}$$

then the abstract CFL condition is true.

4.1.2. Pure diffusion. In this particular case we have ($K > 0$ but $\mathbf{u} \equiv 0$). The equation is

$$\partial_t c - \nabla.(K \nabla c) = 0. \tag{4.4}$$

We consider $\alpha_{kj} \equiv \alpha > 0$ for simplicity of notation. Asfwe s in Lemma 4.1 we have the following.

LEMMA 4.3. *Consider a sequence of triangular and conformal meshes. Assume the sequence of meshes is uniformly regular. Denote by h a characteristic length of the mesh. For all $p \in \mathbf{N}$, there exists a $C_p^2 > 0$ such that if*

$$\Delta t \leq \frac{1}{\frac{\alpha}{C_p^1 h} + \frac{K^2}{\alpha C_p^2 h^3}}, \tag{4.5}$$

then the abstract CFL condition is true. Both constants C_p^1, C_p^2 depend only on the mesh and the degree of the polynomials, and not on the parameters of the equations or on α.

For an optimal value for parameter α, we also have the following.

LEMMA 4.4. *Consider the CFL inequality* (4.5)*, with parameter α set to*

$$\alpha = \frac{K}{h}. \tag{4.6}$$

Then inequality (4.5) *is equivalent to the more standard CFL inequality*

$$K\Delta t \leq C_p^3 h^2, \quad \frac{1}{C_p^3} = \frac{1}{C_p^1} + \frac{1}{C_p^2}. \tag{4.7}$$

The proof is left to the reader.

The value (4.6) is optimal, since we recover the classical time step CFL constraint for explicit discretization of diffusion.

Remark. Formula (4.2) is a kind of continuous interpolation between (4.3) and (4.7). More importantly, if $K \equiv 0$, then $\alpha = \frac{|\mathbf{u}|}{2}$ and the scheme defined by (3.4), (3.5), (3.10) is *equal* to the standard DGM for the pure advection case. On the other hand, if $\mathbf{u} \equiv 0$, then the method is *equal* to the DGM defined above for the pure diffusion case. Therefore (4.2) ensures that the scheme for advection-diffusion is a continuous interpolation between the scheme for pure advection and the scheme for pure diffusion.

5. Convergence analysis for the advection case. Let us now state the convergence result. We restrict the analysis to the DGM for advection and leave convergence analysis of diffusion for future studies. Let us define an L^2 projection $\pi_h : \mathcal{H} \to \mathcal{V}_p$,

$$\pi_h(u) = (u_k) \Longleftrightarrow \int_{\Omega_k} u_k(x)v_k(x)dx = \int_{\Omega_k} u(x)v_k(x)dx \quad \forall v_k,\ \forall k. \tag{5.1}$$

The scheme that we analyze in this section is defined by

$$\begin{cases} U_h^0 = \pi_h(u_0), \text{ where } u_0 \text{ is the initial condition,} \\ U_h^1 \text{ is the solution of the first order time scheme (2.4),} \\ U_h^{n+1} \text{ is the solution of the second order time scheme (2.8),} \\ \text{the bilinear forms are } \mathcal{A}_0,\ \mathcal{A}_1,\ \mathcal{A}_2,\ \mathcal{A}_3, \\ \qquad\qquad \text{as defined in section 3.1.2 in the case } K \equiv 0. \end{cases} \tag{5.2}$$

We will use the following approximation property of the projection π_h.

LEMMA 5.1. *Let E be an element (a triangle or a tetrahedron) in $\mathbb{R}^n (n = 2, 3)$ of diameter h_E. Then for any $u \in H^{k+1}(E)$,*

$$\|u - \pi_h u\|_{H^r(E)} \le C h_E^{k+1-r} \|u\|_{H^{k+1}(E)} \qquad r = 0,\ 1,$$

where C is independent of h_E. See [2].

LEMMA 5.2 (trace inequality). *Let E be an element in $\mathbb{R}^n (n = 2, 3)$ of diameter h_E. Let e_k be an edge or a face of E. Then for any f in $H^s(E)$ and for $s \ge 2$,*

$$\|f\|_{L^2(e_k)} \le \hat{C} |e_k|^{\frac{1}{2}} |E|^{-\frac{1}{2}} (\|f\|_{L^2(E)} + h_E \|\nabla f\|_{L^2(E)}).$$

If f is a polynomial of degree $p > 0$ on E,

$$\|f\|_{L^2(e_k)} \le \hat{C} p^2 |e_k|^{\frac{1}{2}} |E|^{-\frac{1}{2}} (\|f\|_{L^2(E)}).$$

Here $\hat{C}$ is a constant independent of h_E and p. See [33].

LEMMA 5.3. *Let $c \in \mathcal{V}$ be the solution of the advection equation and $U_h^n \in \mathcal{V}_p$ be the solution of* (5.2). *Then*

$$\theta_{l+1}^2 - \theta_l^2 \le 6 \Delta t r^{l+1}, \tag{5.3}$$

where

$$\begin{aligned} \theta_l^2 &= (\xi^l, \xi^l) + (2\xi^l - \xi^{l-1}, 2\xi^l - \xi^{l-1}) \quad \forall\ l \ge 1, \\ \xi^l &= \pi_h u(l\Delta t) - U_h^l, \\ 6\chi^l &= \pi_h u(l\Delta t) - u(l\Delta t) \text{ and} \\ r^{l+1} &= \frac{1}{3}\left(\frac{3\chi^{l+1} - 4\chi^l + \chi^{l-1}}{\Delta t}, \xi^{l+1}\right) + \frac{2}{3}\mathcal{A}_0(\chi^{l+1}, \xi^{l+1}) \\ &\quad + \frac{2}{3}\mathcal{A}_1(2\chi^l - \chi^{l-1}, \xi^{l+1}) - \frac{2}{3}\mathcal{A}_2(2\chi^l - \chi^{l-1}, \xi^{l+1}) \\ &\quad + \frac{1}{3}\left(\frac{3u^{l+1} - 4u^l + u^{l-1}}{\Delta t} - 2\partial_t u((l+1)\Delta t), \xi^{l+1}\right) \\ &\qquad + \frac{2}{3}\mathcal{A}_1(2u^l - u^{l-1} - u^{l+1}, \xi^{l+1}) r \\ &\qquad - \frac{2}{3}\mathcal{A}_2(2u^l - u^{l-1} - u^{l+1}, \xi^{l+1}). \end{aligned}$$

Proof. Taking $V_h = \xi^{l+1}$ in (2.8) with U_h^l replaced by $\pi_h u(l\Delta t)$, and subtracting the resulting equation in which $V_h = \xi^{l+1}$, from (2.8), gives

$$\frac{1}{3}\left(\frac{3\xi^{l+1}-4\xi^l+\xi^{l-1}}{\Delta t},\xi^{l+1}\right)+\frac{2}{3}\mathcal{A}_0(\xi^{l+1},\xi^{l+1}) + \frac{2}{3}\mathcal{A}_1(2\xi^l-\xi^{l-1},\xi^{l+1})-\frac{2}{3}\mathcal{A}_2(2\xi^l-\xi^{l-1},\xi^{l+1})=r^{l+1}.$$

Using the lower bounds of $\mathcal{A}_0$ and $\mathcal{A}_2$ given by (2.2) and the symmetry of the bilinear form $\mathcal{A}_1$, we have

$$\frac{1}{3}\left(\frac{3\xi^{l+1}-4\xi^l+\xi^{l-1}}{\Delta t},\xi^{l+1}\right)+\frac{1}{3}\mathcal{A}_1(\xi^{l+1}-2\xi^l+\xi^{l-1},\xi^{l+1}-2\xi^l+\xi^{l-1})\le r^{l+1}.$$

Now applying the abstract CFL condition (2.9), we further obtain

$$\frac{1}{3}\left(\frac{3\xi^{l+1}-4\xi^l+\xi^{l-1}}{\Delta t},\xi^{l+1}\right)-\frac{1}{6\Delta t}(\xi^{l+1}-2\xi^l+\xi^{l-1},\xi^{l+1}-2\xi^l+\xi^{l-1})\le r^{l+1}$$

which, from the equality

$$(\theta_{l+1}^2-\theta_l^2)/(6\Delta t)=\frac{1}{3}\left(\frac{3\xi^{l+1}-4\xi^l+\xi^{l-1}}{\Delta t},\xi^{l+1}\right)-\frac{1}{6\Delta t}(\xi^{l+1}-2\xi^l+\xi^{l-1},\xi^{l+1}-2\xi^l+\xi^{l-1}),$$

reduces to $\theta_{l+1}^2-\theta_l^2 \le 6\Delta t\, r^{l+1}$. This ends the proof. ∎

LEMMA 5.4. *Notation is the same as in Lemma* 5.3. *Let us assume that the solution c is sufficiently smooth. Then there exist two constants, C_1 and C_2 not depending on l, Δt, and h such that*

$$|r^{l+1}| \le (C_1(\Delta t)^2 + C_2 h^{\mu-1})\theta_{l+1}. \tag{5.4}$$

Here $\mu = \min(p+1, s)$ and s is the order of regularity of the solution in Sobolev's spaces.[1]

Proof. The velocity $\mathbf{u}$ is constant. In this proof we denote its module by $c_{vel} = |\mathbf{u}|$. The method consists of estimating all the terms in the right hand side in the definition of r^{l+1} in lemma 5.3. By the definition of the projection π_h, we have

$$\frac{1}{3}\left(\frac{3\chi^{l+1}-4\chi^l+\chi^{l-1}}{\Delta t},\xi^{l+1}\right)=0.$$

Since $\mathbf{u}.\nabla\xi_k^{l+1} \in \mathcal{V}_p$, we have $\int_{\Omega_k}\chi_k^{l+1}\mathbf{u}.\nabla\xi_k^{l+1}dx = 0$. Therefore $\mathcal{A}_0(\chi^{l+1},\xi^{l+1})=0$. Let us estimate $|\mathcal{A}_1(2\chi^l-\chi^{l-1},\xi^{l+1})|$.

$$\begin{aligned}
|\mathcal{A}_1(2\chi^l-\chi^{l-1},\xi^{l+1})| &\le \sum_k \int_{e\in\partial\Omega_k} c_{vel}|(2\chi_k^l-\chi_k^{l-1})||\xi_k^{l+1}| \\
&\le \sum_k c_{vel}h^{-1}\left(\|(2\chi_k^l-\chi_k^{l-1})\|_{L^2(\Omega_k)}\right. \\
&\qquad \left. + h\|\nabla(2\chi_k^l-\chi_k^{l-1})\|_{L^2(\Omega_k)}\right)\|\xi_k^{l+1}\|_{L^2(\Omega_k)} \\
&\le \sum_k c_{vel}c_1 h^{\mu-1}\|\xi_k^{l+1}\|_{L^2(\Omega_k)} \\
&\le Ch^{\mu-1}(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}}.
\end{aligned} \tag{5.5}$$

[1] A requirement of which is that $u \in C^1([0,T];H^s(\Omega))$, $u_{tt} \in L^\infty([0,T];L^\infty(\Omega))$, and $u_{ttt} \in L^\infty([0,T];L^2(\Omega))$.

Similarly,

$$
\begin{aligned}
|\mathcal{A}_2(2\chi^l-\chi^{l-1},\xi^{l+1})| &\le \sum_{k,j}\int_{e\in\partial\Omega_k\cap\partial\Omega_j} c_{vel}|(2\chi_j^l-\chi_j^{l-1})||\xi_k^{l+1}| \\
&\le \sum_{k,j} c_{vel}h^{-1}\left(\|(2\chi_j^l-\chi_j^{l-1})\|_{L^2(\Omega_j)}\right. \\
&\qquad \left. + h\|\nabla(2\chi_j^l-\chi_j^{l-1})\|_{L^2(\Omega_j)}\right)\|\xi_k^{l+1}\|_{L^2(\Omega_k)} \\
&\le Ch^{\mu-1}(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}}.
\end{aligned} \tag{5.6}
$$

The two other terms are

$$
\begin{aligned}
\left|\left(\frac{3u^{l+1}-4u^l+u^{l-1}}{\Delta t}-2(\partial_t u)^{l+1},\xi_k^{l+1}\right)\right| &\le (\Delta t)^2\sum_k\int_{\Omega_k} c_{vel}|\partial_{ttt}u(t^*,x)||\xi_k^{l+1}(x)| \\
&\le C(\Delta t)^2\|\partial_{ttt}u\|_{L^\infty(0,T;L^2(\Omega))}(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}} \\
&\le C(\Delta t)^2(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}}.
\end{aligned}
$$

Also,

$$
\begin{aligned}
|\mathcal{A}_1(2u^l-u^{l-1}-u^{l+1},\xi^{l+1})| &\le (\Delta t)^2\sum_k\int_{e\in\partial\Omega_k} c_{vel}|\partial_{tt}u(t^*,x)||\xi_k^{l+1}(x)| \\
&\le (\Delta t)^2\sum_k c_{vel}\|\partial_{tt}u(t^*)\|_{L^\infty(\Omega_k)}\int_{e\in\partial\Omega_k}|\xi_k^{l+1}(x)| \\
&\le (\Delta t)^2\sum_k c_{vel}\|\partial_{tt}u(t^*)\|_{L^\infty(\Omega_k)}h^{\frac{1}{2}}h^{-\frac{1}{2}}\|\xi_k^{l+1}\|_{L^2(\Omega_k)} \\
&\le C(\Delta t)^2\|\partial_{tt}u\|_{L^\infty(0,T;L^\infty(\Omega))}(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}} \\
&\le C(\Delta t)^2(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}}.
\end{aligned}
$$

Proceeding as above, we have

$$
|\mathcal{A}_2(2u^l-u^{l-1}-u^{l+1},\xi^{l+1})| \le C(\Delta t)^2(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}}.
$$

Now observing that $(\xi^{l+1},\xi^{l+1})^{\frac{1}{2}} \le \theta_{l+1}$, we obtain the result by summing all the above inequalities. ∎

THEOREM 5.5 (L^2 error estimate for pure advection). *Let $c\in\mathcal{V}$ be the solution of* (1.1) *in the advection case ($K\equiv 0$) with initial condition $c_0\in H^s(s\ge 2)$ and $U_h\in\mathcal{V}_p$ the solution of* (2.8)*, with the initial condition given by* (5.2)*. Assume the CFL condition* (2.9)*. Then there exist two constants C_1 and C_2 depending only on T and u such that*

$$
\|(u-U_h)(T)\|_{L^2} \le 3\|\pi_h u(\Delta t)-U_h^1\|_{L^2} + C_1(\Delta t)^2 + C_2h^{\mu-1},
$$

where $\mu=\min(p+1,s)$.

Proof. Using the triangular inequality, we have

$$
\|(u-U_h)(T)\|_{L^2} \le \|(u-\pi_h u)(T)\|_{L^2} + \|(\pi_h u-U_h)(T)\|_{L^2}.
$$

The first term on the R.H.S. is bounded using the classical approximation theory [16] $\|(u-\pi_h u)(T)\|_{L^2}\le c(u)h^\mu$. Observe that by

$$
\|(\pi_h u-U_h)(T)\|_{L^2}^2 = (\xi^N,\xi^N),
$$

it is possible to give an upper bound where N is defined by $T = N\Delta t$. Therefore according to Lemma 5.3, we have

$$\left(\theta_{n+1}^2 - \theta_n^2\right)/6\Delta t \leq r^{n+1}.$$

From Lemma 5.4 there exist two constants C_1 and C_2 such that

$$\theta_{n+1}^2 - \theta_n^2 \leq 6\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1})\theta_{n+1}.$$

We then have $\theta_{n+1}^2 - 6\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1})\theta_{n+1} \leq \theta_n^2$, which can be rewritten as

$$\left(\theta_{n+1} - 3\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1})\right)^2 \leq \theta_n^2 + \left(3\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1})\right)^2.$$

Therefore $\theta_{n+1} - \theta_n \leq 6\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1})$. Summing this inequality over all n from 1 to $N-1$ produces

$$\theta_N \leq \theta_0 + \sum_{n=1}^{n=N-1} 6\Delta t(C_1(\Delta t)^2 + C_2 h^{\mu-1}).$$

Since

$$\begin{aligned}\theta_0^2 &= (\xi^1, \xi^1) + (2\xi^1 - \xi^0, 2\xi^1 - \xi^0)\\ &\leq ((\xi^1, \xi^1)^{\frac{1}{2}} + (2\xi^1 - \xi^0, 2\xi^1 - \xi^0)^{\frac{1}{2}})^2\\ &\leq (3(\xi^1, \xi^1)^{\frac{1}{2}} + (\xi^0, \xi^0)^{\frac{1}{2}})^2,\end{aligned}$$

we have $\theta_0 \leq 3(\xi^1, \xi^1)^{\frac{1}{2}} + (\xi^0, \xi^0)^{\frac{1}{2}}$. By definition of the scheme, initials values are such that

$$\xi^1 = \pi_h u(\Delta t) - U_h^1 \text{ and } \xi^0 = 0.$$

Also one has $N\Delta t = T$ so that $\sum_1^{N-1}(6\Delta t) \leq 6T$. Therefore taking $C_i = C_i 6T, i = 1, 2$, ends the proof. □

Remark.

- The above theorem shows the convergence of the second order time discretization. Note that since it is second order in time, two initial conditions are needed: U_h^0, U_h^1. We have taken U_h^1 as the solution of a particular iteration of the first order scheme. So $\pi_h u(\Delta t) - U_h^1$ can be kept as small as we need.
- One can observe that in the demonstration above, except in Lemma 5.4, we have used only the property of the bilinear forms $\mathcal{A}_0, \mathcal{A}_1, \mathcal{A}_2$. So by just giving an analogous lemma for pure diffusion and for mixed convection-diffusion equations, one obtains the convergence result for those equations. It is possible to guess that, in general, one has

  $$|r^{l+1}| \leq (C_1(\Delta t)^\nu + C_2 h^\mu)(\xi^{l+1}, \xi^{l+1})^{\frac{1}{2}},$$

  where $\nu = 1, 2$ is the order of time discretization and μ is the order of the approximation error seen by the bilinear forms $\mathcal{A}_0, \mathcal{A}_1, \mathcal{A}_2$. Note that μ can be kept optimal by replacing the L^2-projection with a well-chosen projection $\mathbf{R}_h$ related to the Gauss quadrature formula; see [17].

6. Numerical results. This section is devoted to the study of the order of convergence of our method by means of numerical tests and comparison with other methods. The algorithm presented in this work is denoted by the words "new formalism."

6.1. Pure advection. In this example, we consider (1.1) in the case when $K \equiv 0$. The computational domain is $(\Omega = (-0.5, 0.5)^2)$. The initial condition and the inflow boundary condition are taken from the exact solution, which is chosen here to be

$$c(t,x,y) = \exp\left(-\frac{(\hat{x}-x_c)^2 + (\hat{y}-y_c)^2}{2\sigma^2}\right).$$

The velocity field is $u = (-1,1)^T$ and $\hat{x} = x + t, \hat{y} = y - t$. The parameters are $x_c = 0.25, y_c = -0.25, 2\sigma^2 = 0.004$. The time interval for the simulation is $(0, 0.5)$, which is the required time to shift the cone from its initial position to the symmetric position with respect to the center $(0,0)$. The domain is subdivided into an initial mesh consisting of $8\times8\times2 = 138$ uniform regular triangles. We then successively refine the mesh and compute L^2 and L^∞ errors e_h on the mesh of size h and the numerical convergence rates by the ratio $\ln(e_h/e_{h/2})/\ln(2)$. The use of uniform meshes leads to the following values for the parameters in the CFL analysis. In formula (4.3) the value of C_p^1 is

$$C_p^1 = \begin{cases} \frac{1}{4+4\sqrt{2}} & \text{for } \ p = 1, \\ \frac{1}{6+6\sqrt{2}} & \text{for } \ p = 2. \end{cases}$$

For a second order in time discretization the value of C_p^1 is divided by 2. In our computations we divide it by 10, just to stay away from the optimal value. Table 6.1 shows the behavior of our formalism with respect to the order of the polynomial basis and time discretization. In Table 6.2 we compare the new formalism with RKDG (without flux limiting), RKDG (with the Cockburn–Shu flux limiting) that we call TVBMRKDG (total variation bounded modified slope limiter; see [23]), and with a Crank–Nicholson scheme applied to the stabilized DGM formulation of convection-equation introduced by Brezzi, Marini, and Süli [10]. The last one is introduced to compare our results to schemes in which the global matrix is inverted at every time step. We have done an element renumbering in that Crank–Nicholson scheme in order to have a thin band global matrix. We factor the global matrix before entering into loops, which leads to a gain in time compared to a sparse direct resolution of the global algebraic equation at every time step. The time required to do this operation is denoted by R in Table 6.2.

Observations. From Table 6.1, the error at the time T is of the form $C_1(\Delta t)^\alpha + C_2 h^\beta$, where α is the order of the time discretization and β is a real whose optimal value is $\beta = p + 1$ (where p is the degree of the polynomials). Even if constants C_1, C_2 influence the computed convergence rate, one can still observe that when using polynomials of order p with second order time discretization, the L^2 error is at least of order p in space. By comparison with other theoretical results [10] it is possible to conjecture a behavior of the form $O(\Delta t^2) + O(h^{p+\frac{1}{2}})$. But for this test problem the error in time is clearly dominant over the error in space. Therefore it is difficult to clearly identify the asymptotic order of convergence when using the second order in time discretization. At a more general level, it shows the interest of the second order in time discretization. This is seen in Table 6.2, where we observe the same convergence rate with RKDG without flux limiting, which is of order 2 for polynomials of order 1. The same convergence rate is observed for the Crank–Nicholson scheme applied to the formulation of [10]. These three second order formulations produce the same convergence rate for first order polynomials.

TABLE 6.1

Numerical L^2 errors, L^∞ errors, and convergence rate at time $t = 0.5s$, for first and second order in time with first and second order basis polynomials, in the new formalism ((2.4), (2.8)) scheme applied to the pure advection equation.

6.2. Pure diffusion. In this example we consider the Dirichlet equation (1.1) with $(K \equiv 1, u \equiv 0)$. The computational domain is $\Omega = (0,1)^2$. The boundary condition is homogeneous so that the exact solution is

$$c(t,x,y) = \sin(\pi x)\sin(\pi y)\exp(-2\pi^2 t).$$

The initial condition is taken from this exact solution. The time interval is $(0, 1.510^{-2})$. This is the required time to reduce the maximum of the exact solution by about 25%. The domain is meshed into 16 uniform regular triangles. We successively refine this mesh uniformly. For each mesh of size h we compute the L^2 and L^∞ errors e_h and the numerical convergence rates given by the ratio $\ln(e_h/e_{h/2})/\ln(2)$. The use of uniform meshes leads to the following values of C_p^2 in formula (4.5): $C_p^2 = \frac{1}{12+6\sqrt{2}}$ for $p = 1$ and $C_p^2 = \frac{1}{120+66\sqrt{2}}$ for $p = 2$.

In order to enforce a better interelement continuity for small p, one can choose the parameter α to be of the form $\alpha = \beta\frac{K}{h}$, where $\beta \geq 1$ is a user-defined constant.

The optimal value of β is $\beta = \sqrt{\frac{C_p^1}{C_p^2}}$. Therefore our optimal value for C_p^3 in formula (4.7) is in this case $C_p^3 = \sqrt{C_p^1 C_p^2}$. In Table 6.4 we compare the new formalism for first order in time and second order polynomials with computed solutions obtained by Nonsymmetric Interior Penalty Galerkin (NIPG) and Symmetric Interior Penalty Galerkin (SIPG) GDMs [7, 35, 36]. For this first order in time, we have used an implicit scheme to discretize the SIPG and NIPG methods. We intended to do the same comparison for the second order in time. We tried a θ-scheme (see [34]) to discretize time in both SIPG and NIPG (note that implicit scheme corresponds to a θ-scheme with $\theta = 1$, as in [29], while the Crank–Nicholson scheme corresponds to $\theta = 0$ as described in [34]). But we noticed that using the same time step for the new formalism and for SIPG and NIPG Galerkin methods with the Crank–Nicholson scheme leads to instabilities in SIPG and NIPG. So for that time step, θ must stay in the interval $]0, 1]$, and therefore the θ-scheme is no longer of second order. This is a significant advantage of our formalism over the two others. We have taken the stabilization parameter $\sigma = 1$ for NIPG and $\sigma = 10$ for SIPG; see [35, 36]. The time step has also been multiplied by 10 in SIPG and NIPG, which are implicit methods ($\theta = 1$).

Observations. Here, as in the pure advection case, the error is of the form $C_1(\Delta t)^\alpha + C_2 h^\beta$. Since we have used the optimal CFL condition while refining the mesh, $\Delta t \approx Ch^2$, the convergence rate obtained numerically should be close to

$$\gamma = \min(2\alpha, \beta).$$

Let us discuss the values of α, β, and γ observed in Tables 6.3 and 6.5. For first order time discretization, $\alpha = 1$. Therefore $\gamma = \min(2, \beta)$. It shows that for first order or second order polynomials in conjunction with first order time discretization, we obtain a convergence rate of order 2. This is what we get in Table 6.3. Second order time discretization with first order polynomials gives also a convergence rate of $\gamma = 2$. Hence $\beta = 2$ for first order polynomials, and the convergence in space is optimal in this case. It is also seen in Table 6.3 that when we use second order polynomials with second order time discretization, the convergence rate starts from almost 3 and tends asymptotically to $\gamma = 2$. This shows that $\alpha = 2$ and $\beta = 2$ for second order time discretization with second order polynomials. Hence the convergence in space is suboptimal in this case. However, this is only a matter of worst behavior for even order polynomials. To view that, let us try third order polynomials with a sufficiently small CFL condition so that the error in time is absolutely negligible and we get an accurate value for β. Table 6.5 shows a convergence rate of order $\gamma = \min(2\times 2, 4) = 4$. By inspection of all these results we deduce that the new formalism presented in this paper keeps (on pure diffusion) the optimal space convergence rate for polynomials of odd order. This behavior is similar to other nonsymmetric discretizations like NIPG.

In order to analyze the advantage of our method over NIPG and SIPG for this kind of test problem, let us analyze the ratio accuracy/CPU time of the computation (see the last line of Table 6.4). We see that the error is slightly smaller for our method. But more important is the CPU time required to perform the computation. Due to well-known stability issues, NIPG and SIPG are implicit, which means a certain CPU time is needed to factorize and invert the matrix. This CPU time is denoted as R in the table. It is well known that R can be quite large. In our computations, R is about the same order as the CPU time needed to perform the whole computation. But here the matrix is factorized only once because the coefficients of the problem are constant

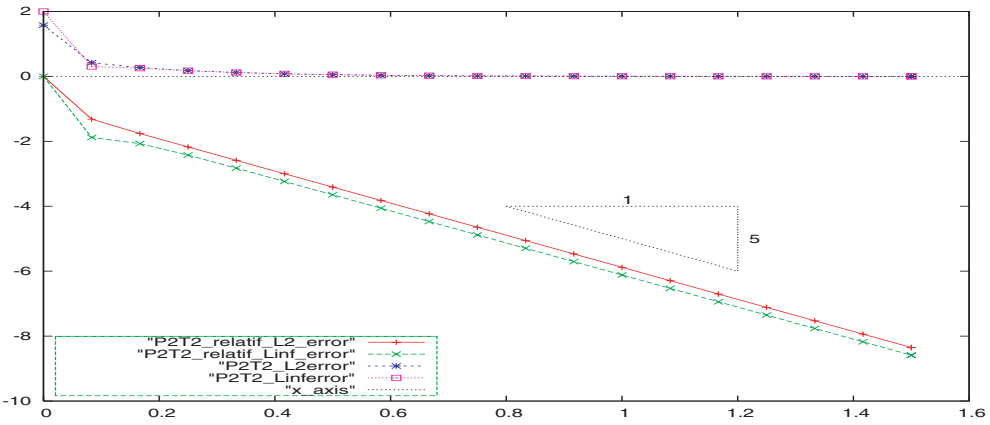

FIG. 6.1. *L^2 and L^∞ convergence errors at different times steps for the pure diffusion equation with nonhomogeneous boundary conditions. The computation is done using the new formalism with polynomials of order 2 in space and second order time discretization. The notation $P2T2$ stands for polynomials of order 2 in space ($P2$) with second order ($T2$) time discretization.*

in time. So if ever one desires to apply NIPG and SIPG to problems with variable coefficients, then R is to be multiplied by the number of iterations. Note that in our calculations, we have adapted the time step for NIPG and SIPG so that the number of time steps is already 10 times smaller for NIPG and SIPG. An even much greater time step is possible for NIPG and SIPG but at the price of a loss of accuracy of the discretization in time. In this case the new method, which is explicit, is much better than NIPG and SIPG.

6.3. An example with a nonhomogeneous Dirichlet boundary condition. Here is an example with a nonhomogeneous boundary Dirichlet condition. Instead of simply writing $\omega_k^+ = R_k^\alpha \omega_k^-$ (see Table 3.1), one uses

$$\omega_k^+ = R_k^\alpha \omega_k^- + \alpha_k (1 - R_k^\alpha) c_d \quad \text{for Dirichlet boundary condition } c = c_d,$$
$$\omega_k^+ = R_k^\alpha \omega_k^- + (1 + R_k^\alpha) g_N \quad \text{for Neumann boundary condition } K \frac{\partial}{\partial n} c = g_N.$$

We now take the same test case as above ($K \equiv 1, u \equiv 0$), with R.H.S. $f(t,x,y) = -4$, and a nonhomogeneous Dirichlet boundary condition $g_D(x,y) = x^2 + y^2$. We know that the limit of the exact solution as time tends to infinity is the solution of the stationary problem. That limit solution is in fact the function we have chosen as the Dirichlet boundary condition. In order to show that the new formalism handles nonhomogeneous boundary conditions, we have computed the solution with the initial condition taken to be $c(t = 0, x, y) = 0$ which is not related to the exact solution. The computational domain is $\Omega = (-1,1)^2$, meshed with nonuniform triangles (with 21 vertices per side) to show that the behavior of the formalism is well suited to the nonuniform mesh. Different steps of the solution are shown in Figure 6.2. Figure 6.1 shows the convergence to the exact solution as L^2 and L^∞ errors (measured by $||u(\infty) - u(t_n)||$) and relative L^2 and L^∞ errors (measured by $\log(||u(\infty) - u(t_n)||/||u(\infty)||)$) at every time step. Here $u(\infty)$ denotes the limit solution.

Observations. In Figure 6.2 the initial solution is zero, and as the time passes the convergence to the exact solution is achieved. It shows that boundary conditions of Dirichlet type are correctly discretized by this method.

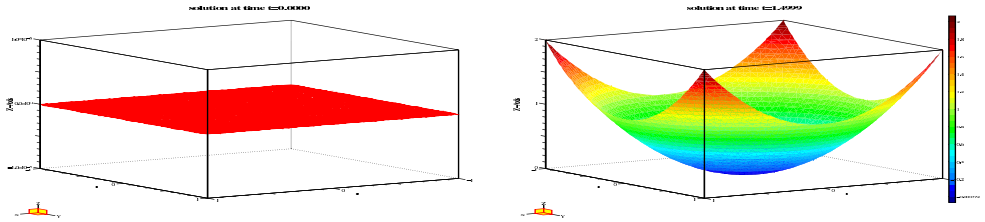

FIG. 6.2. *Asymptotic solution of the pure diffusion equation with nonhomogeneous boundary conditions, on a nonuniform mesh. On the left is the initial solution; on the right is the solution at* $t = 1.5s$. *The computations are done using the new formalism with second order polynomials in space and second order time discretization.*

6.4. A convection-diffusion example. In this section we consider the rotating pulse problem. The spatial domain is $\Omega = (-0.5, 0.5) \times (-0.5, 0.5)$, and the rotating field is imposed as $\mathbf{u} = (-4y, 4x)$. The initial condition and Dirichlet boundary condition are taken from the exact solution

$$c(t, x, y) = \frac{2\sigma^2}{2\sigma^2 + 4Kt} \exp(-\frac{(\bar{x} - x_c)^2 + (\bar{y} - y_c)^2}{2\sigma^2 + 4Kt},$$

where $\bar{x} = x\cos(4t) + y\sin(4t)$ and $\bar{y} = -x\sin(4t) + y\cos(4t)$. Here K is the constant diffusion coefficient. The R.H.S. is $f = 0$. This example was considered in [38], where only maxima and minima of many methods were listed. It is also used as a model equation in [4] to compare the L^2 error of a higher order DGM with various other methods on uniform rectangular meshes. Here we consider the same model problem on uniform triangular meshes, and we evaluate the L^2 and L^∞ errors and the convergence rate for the first and second order schemes presented in this paper. We take the same parameters as in [38, 4]: $K = 10^{-4}, x_c = 0.25, y_c = 0$, and $2\sigma^2 = 0.004$. The time interval for the simulation is $[0, T] = [0, \pi/4]$, which is the time for a half rotation. We begin with a uniform mesh of the domain made up of $8 \times 8 \times 2 = 138$ uniform triangles. We then successively refine the mesh and compute the L^2 and L^∞ errors e_h on the mesh of size h and the numerical convergence rates by the ratio $\ln(e_h/e_{h/2})/\ln(2)$. The time step is chosen so that the ratio $\Delta t/h$ is kept constant. The constant value is $1/82$ for first order time discretization and $1/164$ for the second order time scheme. The results obtained are recorded in Table 6.6.

Observations. This numerical test [38] is advection dominant in most parts of the domain and is diffusion dominant in the center of the domain. We solve it with the formalism presented in this paper with a constant ratio $\Delta t/h$. This constant ratio is obtained when we use the optimal parameter α (4.2) to determine the CFL condition (4.1). The second order in time scheme gives good results with higher order polynomials. Table 6.6 shows that using the constant ratio $\Delta t/h$, the convergence rate is greater than 2. Hence in second order time discretization, the time discretization error is small compared to the space discretization error for this test problem. This is a good feature when dealing with a coarse mesh. The second order time discretization is well suited for this kind of problem, where fine meshes are prohibitive due to memory management.

6.5. Conclusion driven from numerical experiments. The theoretical analysis is confirmed by numerical experiments. In particular we have L^2 stability and correct treatment of boundary conditions whatever the order of the polynomials is.

TABLE 6.6

Numerical L^2 errors, L^∞ errors, and convergence rates for first and second order time discretization schemes (2.4), (2.8) *applied to constant diffusion but variable velocity convection-diffusion equation. The convergence rates are obtained by computing the ratio* $\ln(e_h/e_{h/2})/\ln(2)$ *as the mesh is been refined. The polynomial space is of order* $0, 1, 2,$ *and* 3*, and the ratio* $\Delta t/h$ *is kept constant during the mesh refinement. The experimental order is* 1 *for first order in time integration and greater than* 2 *for second order in time integration.*

ERROR ANALYSIS OF COARSE-GRAINING FOR STOCHASTIC LATTICE DYNAMICS*

MARKOS A. KATSOULAKIS†, PETR PLECHÁČ‡, AND ALEXANDROS SOPASAKIS†

Abstract. The coarse-grained Monte Carlo (CGMC) algorithm was originally proposed in the series of works [M. A. Katsoulakis, A. J. Majda, and D. G. Vlachos, *J. Comput. Phys.*, 186 (2003), pp. 250–278; M. A. Katsoulakis, A. J. Majda, and D. G. Vlachos, *Proc. Natl. Acad. Sci. USA*, 100 (2003), pp. 782–787; M. A. Katsoulakis and D. G. Vlachos, *J. Chem. Phys.,* 119 (2003), pp. 9412–9427]. In this paper we further investigate the approximation properties of the coarse-graining procedure and provide both analytical and numerical evidence that the hierarchy of the coarse models is built in a systematic way that allows for error control in both transient and long-time simulations. We demonstrate that the numerical accuracy of the CGMC algorithm as an approximation of stochastic lattice spin flip dynamics is of order two in terms of the coarse-graining ratio and that the natural small parameter is the coarse-graining ratio over the range of particle/particle interactions. The error estimate is shown to hold in the weak convergence sense. We employ the derived analytical results to guide CGMC algorithms and demonstrate a CPU speed-up in demanding computational regimes that involve nucleation, phase transitions, and metastability.

Key words. coarse-grained stochastic processes, Monte Carlo simulations, birth-death process, detailed balance, Arrhenius dynamics, Gibbs measures, weak error estimates, microscopic reconstruction

1. Introduction.

Microscopic computational models for complex systems such as molecular dynamics (MD) and Monte Carlo (MC) algorithms are typically formulated in terms of simple rules describing interactions between individual particles or spin variables. The large number of variables and even larger number of interactions between them present the principal limitation for efficient simulations. Another restricting factor is illustrated by the essentially sequential nature of approximating the time evolution in particle systems that yields a substantial slowdown in the resolution of dynamics, especially in metastable regimes.

In [19, 20, 23] the authors started developing systematic mathematical strategies for the coarse-graining of microscopic models, focusing on the paradigm of stochastic lattice dynamics and the corresponding MC simulators. In principle, coarse-grained models are expected to have fewer observables than the original microscopic system, making them computationally more efficient than the direct numerical simulations. In these papers a hierarchy of coarse-grained stochastic models—referred to as coarse-grained MC (CGMC)—was derived from the microscopic rules through a stochastic closure argument. The CGMC hierarchy is reminiscent of multiresolution analysis approaches to the discretization of operators [3], spanning length/time scales from the microscopic to the mesoscopic. The resulting *stochastic coarse-grained processes*

involve Markovian birth-death and generalized exclusion processes and their combinations, and as demonstrated in [19, 20, 23], they share the same ergodic properties with their microscopic counterparts. The full hierarchy of the coarse-grained stochastic dynamics satisfies detailed balance relations and, as a result, not only yields self-consistent random fluctuation mechanism, but are consistent with the underlying microscopic fluctuations and the unresolved degrees of freedom. From the computational complexity perspective, a comparison of CGMC with conventional MC methods for the same real time shows [19] that the CPU time can decrease approximately as $O(1/q^2)$ or faster, where q is the number of aggregated lattice sites (referred to as the level of coarse-graining), as demonstrated for spin-flip lattice dynamics. Thus, while for macroscopic size systems in the millimeter length scale or larger, microscopic MC simulations are impractical on a single processor, the computational savings of CGMC make it a suitable tool capable of capturing large scale features, while retaining microscopic information on intermolecular forces and particle fluctuations.

In the recent paper [22] the authors rigorously analyzed CGMC models as approximations of conventional MC in *nonequilibrium*, by estimating the *information loss* between microscopic and coarse-grained adsorption/desorption lattice dynamics. In analogy to the numerical analysis for PDEs, an error analysis was carried out between the *exact microscopic process* $\{\sigma_t\}_{t\geq 0}$ and the *approximating coarse-grained process* $\{\eta_t\}_{t\geq 0}$. The key step in this direction was to use, as a quantitative measure for the loss of information in the coarse-graining from finer to coarser scales, the information-theoretic concept of the *relative entropy* between probability measures, [9]. Such relative entropy estimates give a first mathematical reasoning for the parameter regimes, i.e., the degree of coarse-graining versus the interaction range, for which CGMC is expected to give errors within a given tolerance. In this paper using the rigorous results in [22] as a starting point, we focus on carrying out a detailed numerical analysis of the error propagation for spin-flip lattice dynamics. Due to the numerical intractability of the relative entropy for a large particle system, we employ in the numerical error calculations *targeted* coarse observables. The latter point of view necessitates in the use of a weak convergence framework for the study of the error between CGMC and direct numerical simulations of the stochastic lattice dynamics. We demonstrate that the numerical accuracy of the CGMC algorithm is of order two in terms of the ratio of the coarse-graining over the range of particle/particle interactions. We also refer to recent work in [21] on weak error estimates between microscopic MC algorithms and therein derived SDE approximations. Further details about a priori estimates for weak convergence of approximations to SDEs can be found in [2, 34, 26]. Related a posteriori estimates are discussed in [33]. We further employ the derived analytical results to guide CGMC algorithms and we demonstrate a CPU speed-up in demanding computational regimes that involve nucleation, phase transitions, and metastability. We demonstrate computationally that CGMC probes efficiently the energy landscape, yielding *spatial pathwise* agreement with the underlying microscopic lattice dynamics, at least for fairly long but still finite interactions.

The mathematical difficulty in carrying out our error estimates primarily rests with the fact that the projection of the exact microscopic process $\{\sigma_t\}_{t\geq 0}$ on the coarse grid denoted by $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ needs to be compared with the derived approximating process $\{\eta_t\}_{t\geq 0}$. However, $\mathbf{T}\sigma_t$ does not necessarily define a Markov process, while the approximating process $\{\eta_t\}_{t\geq 0}$ is constructed as a Markov process defined by (3.5). To circumvent this technical difficulty the authors in [22] suggested constructing an auxiliary Markov process $\{\gamma_t\}_{t\geq 0}$ as an intermediate step in the estimation of the relative entropy between $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ and $\{\eta_t\}_{t\geq 0}$. We adopt the same

strategy here in order to make a comparison between observables which depend on Markovian processes $\{\sigma_t\}_{t\geq 0}$ and $\{\gamma_t\}_{t\geq 0}$. The *reconstructed microscopic Markov process* $\{\gamma_t\}_{t\geq 0}$ can be directly synthesized from the coarse-grained process $\{\eta_t\}_{t\geq 0}$, and these two processes induce the same probability measure on the coarse-grained path space. Such reconstruction is an inverse procedure to the projection from fine to coarse configuration space and a simple choice of a reconstruction is to distribute particles uniformly on the coarse cells. This action enforces a local equilibrium in each coarse cell, parametrized by the coarse variables. From the technical point of view the reconstruction allows for explicit calculations of averaged quantities in each coarse cell and is crucial in obtaining the second order accuracy of our methods. It is conceivable that the synthetic process $\{\gamma_t\}_{t\geq 0}$ can be used not only as a technical tool but also as a systematic procedure for reconstructing the microscopic process $\{\sigma_t\}_{t\geq 0}$ for the purpose of model refinement or adaptivity since, as shown in Theorem 4.7, the reconstruction is done under rigorous error estimates.

The CGMC algorithms discussed here are related to a number of methods involving coarse-graining at various levels; for instance, fast summation techniques, computational renormalization and simulation, and multiscale computational methods for stochastic systems. One of the sources of the computational complexity of molecular simulations arises in the calculation of particle/particle interactions, especially in the case where long range forces are relevant. The evaluation cost of such pairwise interactions can be significantly reduced by applying well-controlled approximation schemes and/or a hierarchical decomposition of the computation. Typically, once the interaction terms are computed with one of these fast summation methods, they are entered in the microscopic algorithm where a simulation with a large number of individually tracked particles still has to be carried out. The point of view adopted by CGMC is related to these methods in the sense that the interaction potential or operator is approximated in terms of a truncated multiresolution decomposition within a given tolerance. The CGMC is subsequently defined at the coarse level specified by the truncation of the decomposition. However, a notable difference is that CGMC models track much fewer coarse observables instead of simulating every individual particle. The equilibrium setup of CGMC is essentially given by the renormalized Hamiltonian after a single iteration in the renormalization group flow. It is not surprising that such an approach, when applied to near critical temperature simulations, has many limitations. For example, in the nearest-neighbor Ising-type models this fact is manifested in the aforementioned error estimates and the comparative simulations in [19]. On the other hand the focus of CGMC is dynamic simulations usually coupled to a macroscopic system (see, for instance, the hybrid systems in [35, 18]), where criticality may not be as important due to the presence of a time-varying external field. Nevertheless, further corrections to the CGMC dynamics from the renormalization group flow given by RGMC and multigrid MC methods [4, 6, 12] can improve the order of convergence of the CGMC. We refer to [17] for higher order accurate CGMC methods based on cluster expansions, where the coarse-graining procedure described here is the model around which a cluster expansion is carried out with controlled errors. As explained in section 4, in the sense that the CGMC method is of order two accurate in terms of the small parameter q/L, where L is the radius of interaction.

As is the case with most asymptotic results, from a practical point of view a small parameter q/L does not need to be "very small" in order for the asymptotics to work. The case here is no exception even in the phase transitions regime. This observation is further amplified by the higher order estimate $(q/L)^2$ in Theorem 4.7. A typical example of long range interactions is the electrostatic potential; however, the methods

proposed here cannot (yet) handle the singular part of the potential which is close to the origin. However, they can easily handle, with error estimates, the slowly decaying part of the potential (away from the origin), which is a primary computational hurdle for direct numerical simulations with standard MC methods. On the other hand the proposed methods are expected to work well when local averaging gives a good error control in the potentials, as in Lemma 3.2. Such examples include Morse-type potentials as well as oscillating indirect exchange potentials of RKKY type [30] arising in magnetic materials. Furthermore some intermediate-range potentials can be obtained from detailed experiments. Such an example arising in surface processes is described in [31], where a potential with 36 neighbors is obtained. In such a setup the CGMC method would be expected to apply.

In recent years there has been a growing interest in developing and analyzing coarse-graining methods for the purpose of modelling and simulation across scales. Such systems arise in a broad spectrum of scientific disciplines ranging from materials science to macromolecular dynamics, to epidemiology, and to atmosphere/ocean science. Various coarse-graining approaches may yield explicitly derived stochastic coarse models using different coarse approximations, e.g., [13, 15, 28, 32, 8, 36], or can be statistics-based [29] or may rely on on-fly simulations, e.g., the equation-free method [24], the heterogeneous multiscale method [11], or multiscale finite-element methods [14]. A systematic approach to the upscaling of stochastic systems has also been proposed from the multilevel perspective in [7, 1, 5], where the authors proposed algorithms for efficient multiscale simulations using MC methods. Other coarse-graining techniques in the polymer science literature include the bond fluctuation model and its variants [27]. Such coarse-graining methodologies often rely on parametrization, hence at different conditions (e.g., temperature, density, composition) coarse potentials need to be re-parametrized [29].

2. Microscopic lattice models. The presented analysis applies to the class of Ising-type lattice systems. For the sake of simplicity we assume that the computational domain is defined as the discrete periodic lattice $\Lambda_N = \frac{1}{n}\mathbb{Z}^d \cap \mathbb{T}$ which represents discretion of the d-dimensional torus $\mathbb{T} = [0,1)^d$ and d denotes the spatial dimension. We restrict presentation of the results to $d = 1$; nevertheless higher dimensional cases are obtained without significant changes. However, the algorithms can also be implemented on bounded domains with usual boundary conditions. The number of lattice sites $N = n^d$ is fixed. The microscopic degrees of freedom or the microscopic order parameter is given by the spin-like variable $\sigma(x)$ defined at each site $x \in \Lambda_N$. In this paper we discuss only the case of discrete spin variables, i.e., $\sigma(x) \in \Sigma$ with $\Sigma = \{-1, 1\}$, $\Sigma = \{0, 1\}$ (Ising model), or $\Sigma = \{0, 1, \dots s\}$ (Potts models). The case of the spin variable belonging to a compact Riemannien manifold, e.g., $\Sigma = \mathbb{S}^2$ (Heisenberg model), $\Sigma = \mathrm{SU}(2)$ (matrix model), will be studied elsewhere. We denote by $\sigma = \{\sigma(x) \,|\, x \in \Lambda_N\}$ a configuration of spins on the lattice, i.e., an element of the configuration space $\mathcal{S}_N = \Sigma^{\Lambda_N}$. The interactions between spins at a given configuration σ are defined by the microscopic Hamiltonian

$$H(\sigma) = -\frac{1}{2}\sum_{x\in\Lambda_N}\sum_{y\neq x} J(x-y)\sigma(x)\sigma(y) + \sum_{x\in\Lambda_N} h(x)\sigma(x)\,, \tag{2.1}$$

where $h(x)$ denotes the external field at the site x. The two-body interparticle potential J accounts for interactions between individual spins. We consider the class of

potentials with a finite range interaction length L

$$J(x-y) = \frac{1}{L^d} V\left(\frac{n}{L}|x-y|\right), \quad x, y \in \Lambda_N, \tag{2.2}$$

$$V : \mathbb{R} \to \mathbb{R}, \quad V(r) = V(-r), \quad V(r) = 0, \quad \text{if } |r| \geq 1. \tag{2.3}$$

We impose additional assumptions on V which allow us to derive explicit error estimates:

$$V \text{ is smooth on } \mathbb{R} \setminus \{0\}, \tag{2.4}$$

$$\int_{\mathbb{R}} |V(r)|\, dr < \infty, \text{ and } \int_{\mathbb{R}} |\partial_r V(r)|\, dr < \infty. \tag{2.5}$$

Note that the summability condition for V guarantees that the potential J is also summable due to the scaling factor. Hence the Hamiltonian is well defined even for $N, L \to \infty$. The canonical equilibrium state is given in terms of the Gibbs measure

$$\mu_{N,\beta}(d\sigma) = \frac{1}{Z_{N,\beta}} e^{-\beta H(\sigma)} \mathrm{P}_N(d\sigma), \qquad Z_{N,\beta} = \int_{\mathcal{S}_N} e^{-\beta H(\sigma)} \mathrm{P}_N(d\sigma), \tag{2.6}$$

where $\mathrm{P}_N(d\sigma) = \prod_{x \in \Lambda_N} \rho(d\sigma(x))$ is the product measure on $\mathcal{S}_N$ and the spins $\sigma(x)$ are independent identically distributed (i.i.d.) random variables with the common distribution ρ. For example, in the Ising model the prior distribution on $\Sigma = \{0, 1\}$ would typically be $\rho(0) = \rho(1) = 1/2$.

The microscopic dynamics are defined as a continuous-time jump Markov process that defines a change of the spin $\sigma(x)$ with the probability $c(x, \sigma; \xi)\Delta t$ over the time interval $[t, t + \Delta t]$. The function $c : \Lambda_N \times \mathcal{S}_N \times \Sigma \to \mathbb{R}$ is called a rate of the process. The jump process $\{\sigma_t\}_{t \geq 0}$ is constructed in the following way: suppose that at the time t the configuration is σ_t, then the probability of changing the spin at the site $x \in \Lambda_N$ spontaneously from $\sigma_t(x)$ to a new value $\xi \in \Sigma$ over the time interval $[t, t+\Delta t]$ is $c(x, \sigma; \xi)\Delta t + O(\Delta t^2)$. We denote the resulting configuration by $\sigma^{x,\xi}$. In the case of the Ising-type state space and spin-flip dynamics we omit ξ in this notation. The generator $\mathcal{L} : L^\infty(\mathcal{S}_N) \to L^\infty(\mathcal{S}_N)$ of the Markov process acting on a bounded test function $\phi \in L^\infty(\mathcal{S}_N)$ defined on the space of configurations is given by

$$(\mathcal{L}\phi)(\sigma) = \sum_{x \in \Lambda_N} \int_\Sigma c(x, \sigma; \xi) \left(\phi(\sigma^{x,\xi}) - \phi(\sigma)\right) d\xi. \tag{2.7}$$

The evolution of an observable (a test function) ϕ is given by

$$\frac{d}{dt} \mathbb{E}\left[\phi(\sigma_t)\right] = \mathbb{E}\left[\mathcal{L}\phi(\sigma_t)\right], \tag{2.8}$$

where the expectation operator $\mathbb{E}[.]$ is, with respect to a measure, conditioned to the initial configuration $\sigma_{t=0} = \sigma_0$. We require that the dynamics are of a relaxation type such that the invariant measure of this Markov process is the Gibbs measure (2.6). The sufficient condition is known as *detailed balance* (DB) and it imposes a condition on the form of the rate

$$c(x, \sigma; \xi) e^{-\beta H(\sigma)} = c(x, \sigma^{x,\xi}; \sigma(x)) e^{-\beta H(\sigma^{x,\xi})}. \tag{2.9}$$

This condition has a simple interpretation: $c(x, \sigma; \xi)$ is the rate of converting $\sigma(x)$ to the value ξ while $c(x, \sigma^{x,\xi}; \sigma(x))$ is the rate of changing the spin with the value ξ at

the site x back to $\sigma(x)$. The widely used class of Metropolis-type dynamics satisfies (2.9) and has the rate given by

$$c(x,\sigma;\xi) = G(\beta\Delta_{x,\xi}H(\sigma))\,, \text{ where } \Delta_{x,\xi}H(\sigma) = H(\sigma^{x,\xi}) - H(\sigma), \tag{2.10}$$

where G is a continuous function satisfying: $G(r) = G(-r)e^{-r}$ for all $r \in \mathbb{R}$. The most common choices in physics simulations are $G(r) = \frac{1}{1+e^r}$ (Glauber dynamics), $G(r) = e^{-[r]_+}$ (Metropolis dynamics), with $[r]_+ = r$ if $r \geq 0$ and $= 0$ otherwise, or $G(r) = e^{-r/2}$. Such dynamics are often used as samplers from the canonical equilibrium Gibbs measure. However, the kinetic MC method is also used for simulations of nonequilibrium processes. The dynamics in such a case are known as *Arrhenius dynamics*, whose rates are usually derived from transition state theory or obtained from molecular dynamics simulations.

To avoid unnecessary generality we restrict the description to the Ising-type model with $\Sigma = \{0,1\}$ used for modeling adsorption/desorption processes. We also omit ξ in the notation. The Arrhenius rate is defined as follows:

$$c(x,\sigma) = \begin{cases} d_0 & \text{if } \sigma(x) = 0, \\ d_0 e^{-\beta U(x,\sigma)} & \text{if } \sigma(x) = 1, \end{cases} \tag{2.11}$$

where

$$U(x,\sigma) = \sum_{y\in\Lambda_N\,, y\neq x} J(x-y)\sigma(y) - h(x)\,. \tag{2.12}$$

Furthermore, the spin-flip rule is given by

$$\sigma^x(y) = \begin{cases} 1-\sigma(x) & \text{if } y = x, \\ \sigma(y) & \text{if } y \neq x. \end{cases}$$

With the introduced notation the coarse-graining algorithm can be described as an *approximation* of the microscopic dynamics, i.e., of the process $\{\sigma_t\}_{t\geq 0}$ by a coarse-grained process $\{\eta_t\}_{t\geq 0}$, where the approximation is done in a controlled way. We are interested not only in the approximation of the invariant measure $\mu_{N,\beta}(d\sigma)$ (see (2.6)), but also in the approximation of the measure on the path space.

3. Approximation of the coarse-grained process. The coarse-graining is defined in a geometric way by introducing the coarse-grained observables as block-spin variables. This approach follows the standard procedure of real-space renormalization; see, for example, [16]. We remark that although we introduce block-spins our aim is not to approximate the renormalization group flow (either on the space of Gibbs measures or on the path space), but rather to find an approximation that is constructed with low computational cost and with controlled and computable error estimates.

In general terms we define the coarse-graining operator $\mathbf{T} : \mathcal{S}_N \to \mathcal{S}^c_{M,q}$, where the coarse configuration space $\mathcal{S}^c_{M,q}$ is defined on the coarse lattice Λ^c_M, and with the new state space Σ^c, i.e., $\mathcal{S}^c_{M,q} = (\Sigma^c)^{\Lambda^c_M}$. The coarse configuration $\eta = \mathbf{T}\sigma \in \mathcal{S}^c_{M,q}$ is defined on a smaller lattice with M lattice sites and with the coarse state space Σ^c for the new lattice spins $\eta(k)$. The parameter q defines the coarse-graining ratio. The operator $\mathbf{T}$ induces an operator $\mathbf{T}_*$ on the space of probability measures

$$\mathbf{T}_* : \mathcal{P}(\mathcal{S}_N) \to \mathcal{P}(\mathcal{S}^c_{M,q})\,, \quad \mu(\sigma) \mapsto \mu^c(\eta) := \mu\{\sigma \in \mathcal{S}_N \,|\, \mathbf{T}\sigma = \eta\}\,.$$

Ising-type spins. To be more specific we analyze the following case of Ising spin-flip dynamics $\mathcal{S}_N = \{0,1\}^{\Lambda_N}$. Each coarse lattice site $k \in \Lambda_M^c$ represents a cube C_k that contains q sites of the microscopic lattice Λ_N. The projection operator defines the block-spin at the coarse site k to be

$$(\mathbf{T}\sigma)(k) := \sum_{x \in C_k} \sigma(x)\,. \tag{3.1}$$

If the dimension d of the lattice is greater than one, we understand k and x as multi-indices $k = (k_1, \ldots, k_d)$, and we index the corresponding lattice sites in the natural order. Choosing the projection operator in this way defines the coarse state space as $\Sigma^c = \{0, 1, \ldots, q\}$. Given the Markov process $(\{\sigma_t\}_{t\geq 0}, \mathcal{L})$ with the generator $\mathcal{L}$ we obtain a coarse-grained process $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ which is *not*, in general, a Markov process. From the computational point of view this may cause significant difficulties should sampling of such a process be implemented on the computer. Therefore we derive an *approximating* Markov process $(\{\eta_t\}_{t\geq 0}, \bar{\mathcal{L}}^c)$ which can be easily implemented once its generator is given explicitly.

For the model Ising system the projected generator of the coarse-grained process $\{\eta_t\}_{t\geq 0}$ can be evaluated explicitly by rearranging the summations on the lattice Λ_N; given the microscopic state σ and corresponding coarse state $\eta = \mathbf{T}\sigma$,

$$\begin{aligned} \mathcal{L}\psi(\mathbf{T}\sigma) = &\sum_{k\in\Lambda_M^c} \left[\sum_{x\in C_k} c(x,\sigma)(1-\sigma(x))\right] [\psi(\eta+\delta_k) - \psi(\eta)] \\ &+ \sum_{k\in\Lambda_M^c} \left[\sum_{x\in C_k} c(x,\sigma)\sigma(x)\right] [\psi(\eta-\delta_k) - \psi(\eta)]\,. \end{aligned} \tag{3.2}$$

The configuration δ_k defined on the coarse state space is equal to zero at all sites except the site $k \in \Lambda_M^c$ where it is equal 1, i.e., $\delta_k(j) = 1$ for $j = k$ and $= 0$ otherwise. We see from the formula (3.2) that the exact generator for the coarse process can be written in the form

$$\mathcal{L}^c\psi(\eta) = \sum_{k\in\Lambda_M^c} c_a(k)\,[\psi(\eta+\delta_k) - \psi(\eta)] + \sum_{k\in\Lambda_M^c} c_d(k)\,[\psi(\eta-\delta_k) - \psi(\eta)]\,, \tag{3.3}$$

where the new rates

$$c_a(k) = \sum_{x\in C_k} c(x,\sigma)(1-\sigma(x))\,, \qquad c_d(k) = \sum_{x\in C_k} c(x,\sigma)\sigma(x) \tag{3.4}$$

correspond to the adsorption and desorption processes. In this form the rates depend on the microscopic configuration σ and not on the coarse random variable $\mathbf{T}\sigma$. Therefore, it is reasonable to propose an approximating Markov process, which for the case of desorption/adsorption is a *birth-death* process $\{\eta_t\}_{t\geq 0}$ defined on the state space $\Sigma^c = \{0, 1, \ldots q\}$. This process is defined by the generator $\bar{\mathcal{L}}^c$ of the form (3.3) where the rates c_a and c_d are replaced by approximate rates

$$\bar{c}_a(k,\eta) = d_0(q - \eta(k))\,, \qquad \bar{c}_d(k,\eta) = d_0\eta(k)e^{-\beta\bar{U}(k,\eta)}\,. \tag{3.5}$$

For details we refer to [19]. The new rates have a simple interpretation in terms of fluctuations on each cell: $\bar{c}_a(k,\eta)$ describes the rate with which the coarse variable

$\eta(k)$ is increased by one (i.e., adsorption of a single particle in the coarse cell C_k) and $\bar{c}_d(k,\eta)$ defines the rate with which it is decreased by one (desorption in C_k). The new interaction potential $\bar{U}(\eta)$ represents the approximation of the original interaction $U(\sigma)$.

DEFINITION 3.1. *We define the approximation $\bar{U}(k,\eta)$ of the potential $U(x,\sigma)$, (2.12), at the coarse level*

$$\bar{U}(k,\eta) = \sum_{\substack{l\in\Lambda_M^c \\ l\neq k}} \bar{J}(k,l)\eta(l) + \bar{J}(0,0)(\eta(k)-1) - \bar{h}(k)\,. \tag{3.6}$$

The coarse-grained interaction potential $\bar{J}$ is computed as the average of the pairwise interactions between microscopic spins between the coarse cells C_k and C_l,

$$\bar{J}(k,l) = \frac{1}{q^2}\sum_{x\in C_k}\sum_{y\in C_l} J(x-y) \quad \textit{for all } k,l\in\Lambda_M^c, \textit{ such that } k\neq l, \textit{ and} \tag{3.7}$$

$$\bar{J}(k,k) \equiv J(0,0) = \frac{1}{q(q-1)}\sum_{x\in C_k}\sum_{\substack{y\in C_k \\ y\neq x}} J(x-y)\,. \tag{3.8}$$

The error estimate for the projection follows directly from the assumptions on the regularity of J (or V) (2.4)–(2.5). We state it as a separate lemma without the proof, which is obtained by applying the Taylor expansion of the potential J.

LEMMA 3.2. *Assume that J satisfies (2.4)–(2.5); then the coarse-grained interaction potential $\bar{J}$ at the coarse-graining level q approximates the potential J with the error*

$$|J(x-y) - \bar{J}(k,l)| \le \frac{1}{L}c_d \sup_{\substack{x'\in C_k \\ y'\in C_l}} ||\nabla V(x'-y')|| \le \mathrm{O}\left(\frac{q}{L^2}\right), \tag{3.9}$$

$$|J(x-y) - \bar{J}(0,0)| \le \frac{1}{L}c_d \sup_{\substack{x',y'\in C_k \\ y'\neq x'}} ||\nabla V(x'-y')|| \le \mathrm{O}\left(\frac{q}{L^2}\right), \tag{3.10}$$

where $c_d = \max_{k\in\Lambda_M^c}\{\mathrm{diam}\,(C_k)\}$.

From Lemma 3.2 we derive the error bound for the approximation of the coarse-grained potential $\bar{U}$. Note that in the definition of U the principle contribution to the summation involves interactions within the interaction range L and thus we have the following estimate.

COROLLARY 3.3. *The microscopic potential $U(x,\sigma)$ is approximated by $\bar{U}(k,\eta)$, with the error*

$$\Delta_{q,N}(\bar{U},U) \equiv |\bar{U}(k,\mathbf{T}\sigma) - U(x,\sigma)| = \mathrm{O}\left(\frac{q}{L}\right) \quad \textit{for all } x\in C_k. \tag{3.11}$$

Note that this approximation represents the direct projection of the interaction kernel J on the coarse space and the contribution from fine scales are neglected. This procedure differs from the renormalization group approach where fluctuations from the fine scales contribute to the transformed Hamiltonian. However, in the case of finite-range interaction kernels J treated here, the above projection yields approximation of the order $O(q/L)^2$ as we discuss in the next section. The coarse

interaction Hamiltonian is then given explicitly in terms of $\bar{J}$ and $\bar{h}$ as

$$\bar{H}(\eta) = -\frac{1}{2}\sum_{l\in\Lambda_M^c}\sum_{k\neq l}\bar{J}(k,l)\eta(k)\eta(l) - \frac{1}{2}\bar{J}(0,0)\sum_{l\in\Lambda_M^c}\eta(l)(\eta(l)-1) + \sum_{l\in\Lambda_M^c}\bar{h}(l)\eta(l)\,. \tag{3.12}$$

A direct calculation by verifying the condition of detailed balance [19],

$$\begin{aligned}\bar{c}_a(k,\eta)\mu_{M,q,\beta}(\eta) &= \bar{c}_d(k,\eta+\delta_k)\mu_{M,q,\beta}(\eta+\delta_k)\,,\\ \bar{c}_d(k,\eta)\mu_{M,q,\beta}(\eta) &= \bar{c}_a(k,\eta-\delta_k)\mu_{M,q,\beta}(\eta-\delta_k)\,,\end{aligned}$$

shows that the invariant measure of the Markov process $\{\eta_t\}_{t\geq 0}$ generated by $\bar{\mathcal{L}}^c$ is again a canonical Gibbs measure,

$$\mu^c_{M,q,\beta}(d\eta) = \frac{1}{Z_{M,q,\beta}}e^{-\beta\bar{H}(\eta)}\mathrm{P}_{M,q}(d\eta)\,, \tag{3.13}$$

where the product measure $\mathrm{P}_{M,q}(d\eta)$ is the coarse-grained prior distribution. Note that the prior distribution is altered by the coarse-graining procedure and different projection operators $\mathbf{T}$ may yield prior distributions that are computationally intractable. For example, the coarse-grained prior arising from the uniform microscopic prior ($\rho(0)=\rho(1)=1/2$) is the binomial distribution corresponding to q independent sites:

$$\mathrm{P}_{M,q}(d\eta) = \prod_{k\in\Lambda_M^c}\rho_q^c(d\eta(k))\,,\qquad \rho_q^c(\eta(k)=p) = \frac{q!}{p!(q-p)!}\left(\frac{1}{2}\right)^q\,.$$

The coarse-graining procedure described here satisfies basic criteria imposed on an approximating process:

(i) Error control on a finite-time interval $[0,T]$. In particular, the derived coarse-grained stochastic process $\{\eta_t\}_{t\geq 0}$ approximates a prespecified observable on a finite-time interval $[0,T]$, e.g., (3.1). In particular, time-dependent error estimates such as (4.2) can rigorously demonstrate that the process $\{\eta_t\}_{t\geq 0}$ keeps track of fluctuations from the microscopic level. Consequently expected values of certain path-dependent (global) quantities can be properly estimated. We characterize approximation properties of $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ by $\{\eta_t\}_{t\geq 0}$ using a suitable probability metric on the path space.

(ii) Approximation of the invariant (equilibrium) measure. The invariant measure $\mu^c_{M,q,\beta}(d\eta)$ for the process $\{\eta_t\}_{t\geq 0}$ defined on $\mathcal{S}^c_{M,q}$ is close, in a suitable probability metric, to the projection of the microscopic measure $\mathbf{T}_*(\mu_{N,\beta}(d\sigma))$. In particular the error estimates in (4.1) demonstrate that the coarse-grained process can preserve the ergodicity properties of the microscopic process within a prescribed tolerance. We also note that the coarse-graining modifies the microscopic prior $\mathrm{P}_N(d\sigma)$ in (2.6), yielding the coarse prior $\mathrm{P}_{M,q}(d\eta)$.

If the approximating process follows the basic principles (i) and (ii), then we observe as a result of the error estimates presented here and in [22] that both the transient, as well as the long time dynamics, are expected to be captured accurately by the coarse-graining. Although this is not a complete proof of a controlled error for infinite time, it constitutes a first rigorous step in this direction. The approximation properties are also supported by the numerics presented here and in the references.

4. Error analysis and a priori estimates for coarse-grained processes. As described in the previous section we construct a new process which only approximates the projected process $\{\mathbf{T}\sigma_t\}_{t\geq 0}$. We do not attempt to capture the effect of fine scales exactly and incorporate them into the coarse model through the renormalization group transformation. Instead we construct an approximate process $\{\eta_t\}_{t\geq 0}$, with the invariant measure $\mu^c_{M,q,\beta}$. The approximation properties of such construction are quantified in this section.

4.1. Information theory estimates. The first question which needs to be addressed is comparison and an error estimate for the exactly coarse-grained equilibrium measure, i.e., $\mathbf{T}_*\mu_{N,\beta}$, and its approximation $\mu^c_{M,q,\beta}$. We recall that $\mathbf{T}_*$ is the projection operator induced by the fine-to-coarse projection of spin variables. For the comparison of the nonequilibrium processes $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ and $\{\eta_t\}_{t\geq 0}$, we need to carry out a similar a priori analysis on the coarse path space $\mathcal{D}(\mathcal{S}^c_{M,q})$, i.e., on the space of all right-continuous paths $\eta_t : [0,\infty) \to \mathcal{S}^c_{M,q}$. We denote by $Q_{\sigma_0,[0,T]}$ the measure on $\mathcal{D}(\mathcal{S}_N)$ for the process $\{\sigma_t\}_{t\in[0,T]}$ on the interval $[0,T]$ with the initial distribution σ_0. Similarly $Q^c_{\eta_0,[0,T]}$ denotes the measure on the coarse path space $\mathcal{D}(\mathcal{S}^c_{M,q})$. With a slight abuse of notation we also use $\mathbf{T}_*Q$ to denote the projection of the measure Q on the coarse path space, i.e., the exact coarsening of the measure Q.

The principal idea proposed in [22, 23] is to control *the specific loss of information* quantified by the relative entropy.

PROPOSITION 4.1. (i) see [23]: *Let $\mu^c_{M,q,\beta}$ be the approximating measure defined by* (3.13) *and $\mathbf{T}_*\mu_{N,\beta}$ be the exact projection of the microscopic equilibrium measure, then the specific relative entropy is estimated by*

$$\begin{aligned}(4.1)\qquad &\frac{1}{N}\mathcal{R}\left(\mu^c_{M,q,\beta} \,|\, \mathbf{T}_*\mu_{N,\beta}\right)\\ &:= \frac{1}{N}\sum_{\eta\in\mathcal{S}^c_{M,q}} \log\left(\frac{\mu^c_{M,q,\beta}(\eta)}{\mu_{N,\beta}(\{\sigma\in {\mathcal{S}_N}^{\Lambda_N} \,|\, \mathbf{T}\sigma=\eta\})}\right)\mu^c_{M,q,\beta}(\eta) = O\left(\frac{q}{L}\right).\end{aligned}$$

(ii) see [22]: *Suppose the process $\{\eta_t\}_{t\in[0,T]}$, given by the coarse generator $\bar{\mathcal{L}}^c$, defines the coarse approximation of the microscopic process $\{\sigma_t\}_{t\in[0,T]}$ then for any $q<L$ and N, $Mq=N$, the information loss as $q/L\to 0$ is*

$$(4.2)\qquad \frac{1}{N}\mathcal{R}\left(Q^c_{\eta_0,[0,T]} \,|\, \mathbf{T}_*Q_{\mathbf{T}_*\sigma_0,[0,T]}\right) = T\,O\left(\frac{q}{L}\right).$$

We recall that the relative entropy for two probability measures $\pi_1(\sigma)$ and $\pi_2(\sigma)$ on the countable state space $\mathcal{S}$ is defined as

$$(4.3)\qquad \mathcal{R}\left(\pi_1 \,|\, \pi_2\right) = \sum_{\sigma\in\mathcal{S}} \pi_1(\sigma)\log\frac{\pi_1(\sigma)}{\pi_2(\sigma)}.$$

We refer to [9] for a detailed discussion of relative entropy, its properties, and connections to information theory.

Remark. Although the previous estimate is for finite times $[0,T]$ only, and grows with T, in many cases the system nucleates a new phase at the initial stage of its evolution and thus the estimate ensures good approximation of the nucleation phase. It is worth noticing that the relative entropy estimate clearly demonstrates limitations of the coarse-graining method since it gives the error of order one for short-range interactions (the nearest neighbor interaction corresponds to $L=1$). On the other

hand the analysis using the relative entropy (information) distance identifies the small parameter in the asymptotic expansion of the blocking error, the ratio q/L.

In the next estimate we derive a lower bound for the loss of information in terms of coarser observables.

PROPOSITION 4.2 (lower bound). *Suppose the process* $(\{\eta_t\}_{t\in[0,T]}, \bar{\mathcal{L}}^c)$*, defined by the coarse-graining operator* $\mathbf{T}$ *with coarse-graining parameters* $Mq = N$*, is the coarse approximation of the microscopic process* $\{\sigma_t\}_{t\in[0,T]}$*. Let* $\mathbf{T}^{M',q'}$ *be another coarse-graining operator, such that* $M' \le M$*,* $M'q' = Mq = N$*. Then the following estimate for the invariant microscopic measure* $\mu_{N,\beta}$ *and the coarse approximation* $\mu^c_{M,q,\beta}$ *holds:*

$$\mathcal{R}\left(\mu^c_{M,q,\beta} \,|\, \mathbf{T}_*\mu_{N,\beta}\right) \ge \mathcal{R}\left(\mathbf{T}_*^{M',q'}\mu^c_{M,q,\beta} \,|\, \mathbf{T}_*^{M',q'}\mu_{N,\beta}\right). \tag{4.4}$$

Moreover, on any finite-time interval $[0,T]$*,*

$$\mathcal{R}\left(\mathbf{T}_*Q_{\mathbf{T}\sigma_0,[0,T]} \,|\, Q^c_{\eta_0,[0,T]}\right) \ge \mathcal{R}\left(\mathbf{T}_*^{M',q'}Q_{\mathbf{T}\sigma_0,[0,T]} \,|\, \mathbf{T}_*^{M',q'}Q^c_{\eta_0,[0,T]}\right). \tag{4.5}$$

Proof. We first recall the variational formulation for the relative entropy

$$\mathcal{R}\left(\mu \,|\, \nu\right) = \sup_f \left\{ \int f\, d\mu - \log \int e^f\, d\nu \right\}, \tag{4.6}$$

where the supremum is over all bounded functions in the space where the measures are defined. This inequality now readily implies the result since

$$\mathcal{R}\left(\mu \,|\, \nu\right) \ge \sup_{f\circ\mathbf{T}} \left\{ \int f\circ\mathbf{T}\, d\mu - \log \int e^{f\circ\mathbf{T}}\, d\nu \right\} = \mathcal{R}\left(\mathbf{T}_*\mu \,|\, \mathbf{T}_*\nu\right), \tag{4.7}$$

where $\mathbf{T}$ is the projection operator (superscripts omitted) in the statement of the proposition.

Remark. This estimate provides a lower bound for the loss of information in terms of coarser observables, hence the condition $M' \le M$ where $M'q' = Mq = N$. For instance if $M' = 1, q' = N$, then the measures $\mathbf{T}_*^{M',q'}\mu^c_{M,q,\beta}$ and $\mathbf{T}_*^{M',q'}\mu_{N,\beta}$ are the PDFs of the total coverage with respect to the coarse-grained (essentially mean field with a noise) and the microscopic Gibbs states, respectively. At first glance it may appear that such an estimate is hard to implement since it depends on the exact microscopic MC; however, when M' is small, i.e., $M' = 1, 2, 3\ldots$, the PDFs can be calculated as a histogram by MC and subsequently the relative entropy in the lower bound is straightforward to compute.

4.2. Microscopic reconstruction and weak convergence estimates. In many practical MC simulations the main goal is to estimate averages (expected values) of specific observables. Therefore it is natural to analyze the weak approximation properties of the coarse-graining procedure. The weak error is defined as the quantity $e_w \equiv |\mathbb{E}_S\left[\psi(\mathbf{T}\sigma_t)\right] - \mathbb{E}_S\left[\psi(\eta_t)\right]|$, where the expectation $\mathbb{E}_S\left[\cdot\right]$ is defined for the path conditioned on the initial configuration $\eta_0 = \mathbf{T}\sigma_0 = S$. Alternatively we can compare the microscopic process $\{\sigma_t\}_{t\ge0}$ with its synthetic process $\{\gamma_t\}_{t\ge0}$, which is reconstructed from the coarse process $\{\eta_t\}_{t\ge0}$. The weak error is then defined as $e_w \equiv |\mathbb{E}_S\left[\phi(\sigma_t)\right] - \mathbb{E}_S\left[\phi(\gamma_t)\right]|$, where the expectation $\mathbb{E}_S\left[\cdot\right]$ is now defined for the path conditioned on the initial configuration $\sigma_0 = S$. Here and in what follows ϕ denotes a test function (observable) on the fine level while ψ is used for a test function on the

coarse level. Theorem 4.7 and Corollary 4.8 quantify the rate of convergence for the weak error on both levels as $q/L \to 0$. We refer to [21] for error estimates in the weak topology between microscopic MC algorithms and therein derived approximations by stochastic differential equations.

Before we formulate the proposition and proceed with the proof it is worth clarifying the difficulty of comparing the projected process $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ with the approximating process $\{\eta_t\}_{t\geq 0}$. The projection $\mathbf{T}\sigma_t$ of the microscopic process on the coarse grid does not necessarily define a Markov process. On the other hand the approximating process $\{\eta_t\}_{t\geq 0}$ is constructed as a Markov process $(\{\eta_t\}_{t\geq 0}, \bar{\mathcal{L}}^c)$ with the generator $\bar{\mathcal{L}}^c$ defined by (3.5). To circumvent the technical difficulty the authors in [22] suggested constructing an auxiliary process $\{\gamma_t\}_{t\geq 0}$ as an intermediate step in the estimation of the relative entropy between the processes $\{\sigma_t\}_{t\geq 0}$ and $\{\eta_t\}_{t\geq 0}$. We adopt the same strategy in order to make a comparison between observables which depend on Markovian processes $\{\sigma_t\}_{t\geq 0}$ and $\{\gamma_t\}_{t\geq 0}$. The process $\{\gamma_t\}_{t\geq 0}$ can be directly reconstructed from the coarse-grained process $\{\eta_t\}_{t\geq 0}$. Thus we are led to the definition of the *synthetic microscopic (Markov) process* $\{\gamma_t\}_{t\geq 0}$ associated with the process $\{\sigma_t\}_{t\geq 0}$.

DEFINITION 4.3 (synthetic microscopic process). *The auxiliary process $\{\gamma_t\}_{t\geq 0}$ is defined on the microscopic configuration space $\mathcal{S}_N$ by the generator $\mathcal{L}^\gamma : L^\infty(\mathcal{S}_N) \to \mathbb{R}$*

$$(\mathcal{L}^\gamma \phi)(\sigma) = \sum_{x\in\Lambda_N} c_\gamma(x,\sigma)(\phi(\sigma^x) - \phi(\sigma))\,, \tag{4.8}$$

where the rate function $c_\gamma(x,\sigma)$ is defined in terms of the coarse-grained interaction potential

$$c_\gamma(x,\sigma) = d_0(1-\sigma(x)) + d_0\sigma(x)e^{-\beta\bar{U}(k(x),\mathbf{T}\sigma)}\,.$$

The coarse-grained interaction potential $\bar{U}(k,\eta)$ has been defined in (3.6). *The piecewise constant interpolation is used to extend the function $\bar{U}(.,.)$ from the coarse lattice to the fine lattice. We denote $k(x)$ to be the cell index of the cell to which the site x belongs, i.e., $x \in C_{k(x)}$.*

The properties of $\{\gamma_t\}_{t\geq 0}$ were studied in [22] and the following was proved:

(i) The coarse-grained projection $\{\mathbf{T}\gamma_t\}_{t\geq 0}$ of the Markov process $(\{\gamma_t\}_{t\geq 0}, \mathcal{L}^\gamma)$ is still a Markov process.

(ii) The processes $\{\mathbf{T}\gamma_t\}_{t\geq 0}$ and $\{\eta_t\}_{t\geq 0}$ have the same transition rates. Hence, whenever the processes have the same initial distribution they induce the same probability measure on the coarse-grained path space $\mathcal{D}(\mathcal{S}^c_{M,q})$. If we define $Q^c_{\eta_0}(\eta,t)$ and $Q_{\gamma_0}(\gamma,t)$ to be the probability measures of the Markov processes $\{\eta_t\}_{t\geq 0}$ and $\{\gamma_t\}_{t\geq 0}$, respectively (conditioned on the initial condition $\eta_0 = \mathbf{T}\gamma_0$), then for all $t > 0$ we have the projection

$$Q^c_{\eta_0}(\eta,t) = \mathbf{T}_* Q_{\gamma_0}(\gamma,t) \equiv \sum_{\{\gamma\,|\,\mathbf{T}\gamma=\eta_t\}} Q_{\gamma_0}(\gamma,t)\,,$$

provided this relation is satisfied at $t = 0$. Hence this property allows us to compare the processes in a pathwise way.

(iii) The microscopic process $\{\gamma_t\}_{t\geq 0}$ can be reconstructed from the approximating coarse process $\{\eta_t\}_{t\geq 0}$. Such reconstruction is an inverse procedure to the projection from fine to coarse configuration space. In such a way we can compare the original microscopic process with the approximation on the

coarse configuration space. A simple choice of a reconstruction operator is to distribute spins $\gamma_t(x)$ for $x \in C_k$ uniformly so that $\mathbf{T}\gamma_t|_{C_k} = \eta_t(k)$.

Remark. It is conceivable that the synthetic process $\{\gamma_t\}_{t\geq 0}$ can be used not only as a technical tool but also as a systematic procedure for reconstructing the microscopic process $\{\sigma_t\}_{t\geq 0}$ for the purpose of model refinement or adaptivity since, as shown in Theorem 4.7, the reconstruction is done under rigorous error estimates. In the estimates derived below we deal with a specific class of test functions $\phi \in L^\infty(\mathcal{S}_N)$ which depend only on the coarse variable $\eta = \mathbf{T}\sigma$. In other words we impose the assumption

(A1) $\phi(\sigma) = \psi(\mathbf{T}\sigma)\,,$ where $\psi \in L^\infty(\mathcal{S}^c_{M,q})$, and
$$\sum_{x\in\Lambda_N} |\partial_x \phi(\sigma)| \leq C\,, \quad \text{where } C \text{ is a constant independent of } N.$$

Remark. Observables, such as the total coverage used in the numerical simulations, satisfy this assumption.

The principal tool for analyzing the weak error is its representation in terms of solutions to the final value problem on $\mathcal{S}_N$,

$$\partial_t v(t,\sigma) + \mathcal{L}v(t,\sigma) = 0 \qquad v(T,.) = \phi(.) \quad \text{for } t < T\,,$$

where $\mathcal{L}$ is a generator of the Markov semigroup that defines the lattice dynamics. Before we state the main estimate of the weak error and its proof we need several preliminary lemmata that characterize properties of the semigroup generated by the operator $\mathcal{L}$ defined by (2.7). The specific calculations are better presented by introducing an alternative notation for the generator $\mathcal{L}$. We define an operator of discrete differentiation for functions $f \in L^\infty(\mathcal{S}_N)$

$$\partial_x f(\sigma) \equiv f(\sigma^x) - f(\sigma) \quad \text{for all } x \in \Lambda_N, \tag{4.9}$$

and we introduce two vectors indexed by the lattice sites $x \in \Lambda_N$

$$\nabla_\sigma f(\sigma) \equiv (\partial_x f(\sigma))_{x\in\Lambda_N}\,, \quad \mathbf{c}(\sigma) \equiv (c(x,\sigma))_{x\in\Lambda_N}\,.$$

The scalar product is defined in the natural way as $\mathbf{c}(\sigma)\cdot\nabla_\sigma f(\sigma) \equiv \sum_{x\in\Lambda_N} c(x,\sigma)\partial_x f(\sigma)$. Using this notation we write

$$\mathcal{L}f(\sigma) = \mathbf{c}(\sigma)\cdot\nabla_\sigma f(\sigma) \quad \text{for all } \sigma \in \mathcal{S}_N. \tag{4.10}$$

The space of functions defined on the configuration space $\mathcal{S}_N$ is equipped with the strong L^∞ topology given by the norm $||f||_\infty \equiv \sup_\sigma\{f(\sigma)\}$.

To prove the estimate in Theorem 4.7 we need an estimate for the difference operator ∇_σ stated here as a separate lemma.

LEMMA 4.4. *Let $v(t,\sigma)$ be the solution of*

$$\partial_t v + \mathcal{L}v = 0\,, \quad v(T,\sigma) = \phi(\sigma) \ \textit{for } t < T, \tag{4.11}$$

on a given interval $t \leq T$; then

$$\sum_{x\in\Lambda_N} ||\partial_x v(t,.)||_\infty \leq C_T \sum_{x\in\Lambda_N} ||\partial_x \phi||_\infty\,. \tag{4.12}$$

Moreover, the constant C_T depends exponentially on the final time T.

Proof. Using the notation introduced above and the definition of $\mathcal{L}$ we recast the evolution equation (4.11) into a familiar form of a transport equation on the configuration space

$$\partial_t v + \mathbf{c}(\sigma) \cdot \nabla_\sigma v = 0\,, \quad \sigma \in \mathcal{S}_N\,,\ t > 0\,. \tag{4.13}$$

Subtracting (4.13) for $v(t,\sigma^x)$ and $v(t,\sigma)$ we have

$$\partial_t(v(t,\sigma^x) - v(t,\sigma)) + \mathbf{c}(\sigma)\cdot(\nabla_\sigma v(t,\sigma^x) - \nabla_\sigma v(t,\sigma)) + (\mathbf{c}(\sigma^x) - \mathbf{c}(\sigma))\cdot\nabla_\sigma v(t,\sigma^x) = 0\,,$$

which we write as

$$\partial_t\left(\partial_x v(t,\sigma)\right) + \mathbf{c}(\sigma)\cdot\nabla_\sigma\left(\partial_x v(t,\sigma)\right) + \partial_x\mathbf{c}(\sigma)\cdot\nabla_\sigma v(t,\sigma^x) = 0\,. \tag{4.14}$$

Next we derive L^∞-bounds for the discrete derivatives $\partial_x\mathbf{c}(\sigma)$ using the explicit definition of the rates $c(x,\sigma)$ in (2.11). For each component, indexed by $z \in \Lambda_N$, of the vector $\mathbf{c}(\sigma)$ we have

$$\partial_x c(z,\sigma) = c(z,\sigma^x) - c(z,\sigma) = (1-\sigma^x(z)) + \sigma^x(z)e^{-U(z,\sigma^x)} - (1-\sigma(z)) + \sigma(z)e^{-U(z,\sigma)}\,.$$

For the spin-flip dynamics, i.e., $\sigma^x(y) = 1-\sigma(y)$ if $x = y$ and $\sigma^x(y) = \sigma(y)$ otherwise, a straightforward calculation gives $\partial_x U(z,\sigma) \equiv U(z,\sigma^x) - U(z,\sigma) = J(z-x)(1-2\sigma(x))$ if $z \neq x$ and it is equal to zero otherwise. Thus the discrete derivate $\partial_x\mathbf{c}(\sigma)$ is

$$\partial_x c(z,\sigma) = \begin{cases} (2\sigma(x)-1)(1-e^{-U(x,\sigma)}) & \text{for } z = x,\\ \sigma(z)e^{-U(z,\sigma)}\left(1-e^{J(x-z)(1-2\sigma(x))}\right) & \text{if } z \neq x. \end{cases}$$

Recalling the definition (2.3) of the interaction potential J we have that $J(z-x) \sim 1/L$ for $|z-x| \leq L$ and $J = 0$ otherwise. Hence we derived L^∞-bounds for the discrete derivative of the rates

$$\partial_x c(z,\sigma) \sim \begin{cases} \mathrm{O}(1) & \text{for } z = x,\\ \mathrm{O}(1/L) & \text{for } |z-x| < L,\\ 0 & \text{otherwise.} \end{cases} \tag{4.15}$$

Going back to (4.14), we have for all $x \in \Lambda_N$

$$\partial_t\left(\partial_x v(t,\sigma)\right) + \mathcal{L}\partial_x v(t,\sigma) + \sum_{z\in\Lambda_N}\partial_x c(z,\sigma)\partial_z v(t,\sigma^x) = 0\,. \tag{4.16}$$

The estimates in (4.15) imply that

$$\partial_t\partial_x v(t,\sigma) + \mathcal{L}\partial_x v(t,\sigma) + \mathrm{O}(1)\partial_x v(t,\sigma^x) + \mathrm{O}\left(\frac{1}{L}\right)\sum_{\substack{z\in\Lambda_N\\ |z-x|\leq L}}\partial_z v(t,\sigma^x) = 0\,, \tag{4.17}$$

and we have for all $\sigma \in \mathcal{S}_N$ the solution formula

$$\partial_x v(t,\sigma) = e^{t\mathcal{L}}[\partial_x v(0,\sigma)] + \int_t^T e^{(s-t)\mathcal{L}}\left[\mathrm{O}(1)\partial_x v(s,\sigma^x) + \mathrm{O}(1/L)\sum_{|z-x|\leq L}\partial_z v(s,\sigma^x)\right]ds\,.$$

By the contractive property of the semigroup $e^{t\mathcal{L}}$ we have the estimate

$$||\partial_x v(t,\cdot)||_\infty \le ||\partial_x v(0,\cdot)||_\infty + \int_t^T \mathrm{O}(1)||\partial_x v(s,\cdot)||_\infty \, ds + \int_t^T \mathrm{O}(1/L) \sum_{|z-x|\le L} ||\partial_z v(s,\cdot)||_\infty \, ds$$

for all $x \in \Lambda_N$. Thus summing over all $x \in \Lambda_N$, we obtain

$$\sum_{x\in\Lambda_N} ||\partial_x v(t,\cdot)||_\infty \le \sum_{x\in\Lambda_N} ||\partial_x v(0,\cdot)||_\infty + \int_t^T \left(\mathrm{O}(1) \sum_{x\in\Lambda_N} ||\partial_x v(s,\cdot)||_\infty + \mathrm{O}(1/L) \sum_{x\in\Lambda_N} \sum_{|z-x|\le L} ||\partial_z v(s,\cdot)||_\infty \right) ds \,,$$

where the last double sum in the integrand is bounded by $2L \sum_x ||\partial_x v(s,\cdot)||_\infty$. Hence by setting $\theta(t) = \sum_x ||\partial_x v(t,\cdot)||_\infty$ we have

$$\theta(t) \le \theta(0) + \int_t^T \mathrm{O}(1)\theta(s) \, ds \,,$$

from which, by using Gronwall's inequality, we obtain the bound

$$\theta(t) \le e^{c(T-t)}\theta(T) \,,$$

which concludes the proof of (4.4).

Next we establish an L^∞-bound for discrete derivatives of solutions generated by semigroups $e^{t\mathcal{L}}$ and $e^{t\mathcal{L}^\gamma}$.

LEMMA 4.5. *Let $u(t,\sigma)$ be the solution of*

$$\partial_t u + \mathcal{L}u = 0, \quad u(T,.) = \phi \ \text{ for } t < T,$$

and let $v(t,\sigma)$ solve

$$\partial_t v + \mathcal{L}^\gamma v = 0, \quad v(T,.) = \psi \ \text{ for } t < T,;$$

then for any $t \le T$ the following estimate holds:

$$\sum_{x\in\Lambda_N} ||\partial_x u(t,\cdot) - \partial_x v(t,\cdot)||_\infty \le C_1(T) \sum_{x\in\Lambda_N} ||\partial_x\phi - \partial_x\psi||_\infty + C_2(T)\left(\frac{q}{L}\right). \tag{4.18}$$

The constants C_1 and C_2 are independent of q and L but depend exponentially on the final time T.

Proof. We use the same approach and notation as in the proof of Lemma 4.4. Subtracting the evolution equations and defining $w_x(t,\sigma) \equiv \partial_x u(t,\sigma) - \partial_x v(t,\sigma)$, $\mathbf{w}(t,\sigma) \equiv (w_x(t,\sigma))_{x\in\Lambda_N}$, we have

$$\partial_t w_x(t,\sigma) + \mathcal{L}w_x(t,\sigma) \tag{4.19}$$

$$+ (\mathbf{c}_\gamma(\sigma) - \mathbf{c}(\sigma)) \cdot \nabla_\sigma v(t,\sigma^x) \tag{4.20}$$

$$+ \partial_x \mathbf{c}(\sigma) \cdot \mathbf{w}(t,\sigma^x) \tag{4.21}$$

$$+ (\partial_x \mathbf{c}(\sigma) - \partial_x \mathbf{c}_\gamma(\sigma)) \cdot \nabla_\sigma v(t,\sigma^x) = 0 \,. \tag{4.22}$$

From Lemma 4.4 we have estimates for the terms involving $\nabla_\sigma v(t,.)$ (notice that the lemma essentially gives the estimate of $||\nabla_\sigma v(t,.)||_\infty$). Furthermore, from the definition of rates $c(x,\sigma)$ and $c_\gamma(x,\sigma)$ direct calculation (similar to that used in the proof of Lemma 4.4) yields the estimate

$$||\mathbf{c}-\mathbf{c}_\gamma||_\infty = \mathrm{O}\left(\frac{q}{L}\right), \tag{4.23}$$

which allows us to control (4.20) and (4.22). Term (4.21) is treated in the same way as a similar term in the proof of Lemma 4.4. Hence for all $x \in \Lambda_N$ we obtain

$$\partial_t w_x(t,\sigma) + \mathcal{L} w_x(t,\sigma) + \mathrm{O}(1/L) \sum_{|z-x|\le L} w_x(z,\sigma^x) \le \mathrm{O}(q/L)||\partial_x v(t,.)||_\infty .$$

Similarly, as in the proof of Lemma 4.4, we complete the proof by summing over $x \in \Lambda_N$ and applying Gronwall's inequality.

Since we are comparing the process $\{\sigma_t\}_{t\ge 0}$ with the process $\{\gamma_t\}_{t\ge 0}$, which is defined only up to the equivalence given by the projection operator $\mathbf{T}$, we have to establish the uniqueness of solutions for initial data satisfying the assumption (A1).

LEMMA 4.6. *Let $\phi \in L^\infty(\mathcal{S}_N)$, $\psi \in L^\infty(\mathcal{S}^c_{M,q})$ be test functions satisfying* (A1). *Assume that $v(t,\gamma)$ is the solution of the final value problem*

$$\partial_t v + \mathcal{L}^\gamma v = 0, \quad v(T,\gamma) = \phi(\gamma) = \psi(\mathbf{T}\gamma); \tag{4.24}$$

then for all $\gamma, \gamma' \in \mathcal{S}_N$ such that $\mathbf{T}\gamma = \mathbf{T}\gamma'$

$$v(t,\gamma) = v(t,\gamma') \quad \textit{for all } t \le T. \tag{4.25}$$

Proof. For convenience we write $v(t,\gamma) = v(t,\mathbf{T}\gamma)$. Given a configuration $\gamma \in \mathcal{S}_N$ we can reconstruct an arbitrary configuration $\gamma' \in \mathcal{S}_N$ such that $\mathbf{T}\gamma' = \mathbf{T}\gamma$ by considering a permutation $\pi : \Lambda_N \to \Lambda_N$, $\pi = (\pi_1, \dots, \pi_M)$ such that

$$\pi_k : C_k \to C_k, \quad k = 1, \dots, M .$$

The action of π on the configuration space is defined in a natural way $\gamma' = \gamma \circ \pi$, or equivalently $\gamma'(x) = \gamma(\pi x)$. Since the permutation does not change the total spin in the cell we have $\mathbf{T}\gamma \circ \pi = \mathbf{T}\gamma$. Hence we write $v(t,\gamma') = v(t,\gamma\circ\pi)$ and $v(T,\gamma\circ\pi) = v(T,\gamma) = \psi(\mathbf{T}\gamma)$. It is sufficient to show that the function $u(t,\gamma) \equiv v(t,\gamma\circ\pi)$ is a solution of (4.24). From the uniqueness of solutions to (4.24) we conclude immediately that $u(t,\gamma) = v(t,\gamma)$. From the definition of the generator $\mathcal{L}^\gamma$ we have

$$\partial_t v(t,\gamma\circ\pi) + \sum_{k\in\Lambda^c_M} \sum_{x\in C_k} c_\gamma(x,\gamma\circ\pi)(v(t,(\gamma\circ\pi)^x) - v(t,\gamma\circ\pi)) = 0 . \tag{4.26}$$

Recall the definition of the rate c_γ

$$c_\gamma(x,\gamma) = d_0(1-\gamma(x)) + d_0\gamma(x)e^{-\beta\bar{U}(k(x),\mathbf{T}\gamma)},$$

and denote $c_\gamma(x,\gamma)$ by $C_\gamma(\gamma(x),k,\mathbf{T}\gamma)$ to emphasise the dependence on $\gamma(x)$, k, and $\eta = \mathbf{T}\gamma$ only. Thus the inner summation in (4.26) becomes

$$\sum_{x\in C_k} C_\gamma(\gamma\circ\pi,k,\mathbf{T}\gamma)(v(t,(\gamma\circ\pi)^x) - v(t,\gamma\circ\pi)) . \tag{4.27}$$

On the other hand the definition of spin-flip dynamics leads to

(4.28)
$$(\gamma\circ\pi)^x(z)=\begin{cases}\gamma(\pi z), & z\neq x,\\ 1-\gamma(\pi x), & z=x,\end{cases}\quad\text{while }\gamma^{(\pi x)}(\pi z)=\begin{cases}\gamma(\pi z), & z\neq x\,,\\ 1-\gamma(\pi x), & z=x\,.\end{cases}$$

Hence we obtain

$$(\gamma\circ\pi)^x(z)=\gamma^{(\pi x)}(\pi z)=\left(\gamma^{\pi x}\circ\pi\right)(z)\,, \tag{4.29}$$

and substituting to the expression (4.27) leads to

$$\begin{aligned}&\sum_{x\in C_k}C_\gamma(\gamma(\pi x),k,\mathbf{T}\gamma)(v(t,(\gamma\circ\pi)^x)-v(t,\gamma\circ\pi))\\ &=\sum_{x\in C_k}C_\gamma(\gamma(\pi x),k,\mathbf{T}\gamma)(v(t,\gamma^{\pi x}\circ\pi)-v(t,\gamma\circ\pi))\\ &=\sum_{y\in C_k}C_\gamma(\gamma(y),k,\mathbf{T}\gamma)(v(t,\gamma^{y}\circ\pi)-v(t,\gamma\circ\pi))\\ &=\sum_{y\in C_k}C_\gamma(\gamma(y),k,\mathbf{T}\gamma)(u(t,\gamma^{y})-u(t,\gamma))\,.\end{aligned}$$

Thus we have shown that

$$\partial_t u(t,\gamma)+\sum_{k\in\Lambda_M^c}\sum_{x\in C_k}c_\gamma(x,\gamma)(u(t,\gamma^x)-u(t,\gamma))=0\,.$$

Recalling the definition of $u(t,\gamma)$ we obtain that $v(t,\gamma\circ\pi)$ also solves (4.24). The uniqueness of solutions to (4.24) implies that $v(t,\gamma\circ\pi)=v(t,\gamma)$ for all γ or $v(t,\gamma')=v(t,\gamma)$ for all γ' such that $\mathbf{T}\gamma'=\mathbf{T}\gamma$. □

Now we can formulate and prove the weak error estimate that allows us to compare the microscopic process and its coarse-level approximation. We estimate the weak error on the microscopic level by comparing the microscopic process and its synthetic process.

THEOREM 4.7 (weak error). *Let $\phi\in L^\infty(\mathcal{S}_N)$ be a test function (observable) on the microscopic space satisfying* (A1) *and let $(\{\gamma_t\}_{t\geq0},\mathcal{L}^\gamma)$ be the synthetic Markov process (in the sense of Definition* 4.3*) of the microscopic process $(\{\sigma_t\}_{t\geq0},\mathcal{L})$ with the initial condition $\sigma_0=S$; then the weak error satisfies, for $0<T<\infty$,*

$$\left|\mathbb{E}_S\left[\phi(\sigma_T)\right]-\mathbb{E}_S\left[\phi(\gamma_T)\right]\right|\leq C_T\left(\frac{q}{L}\right)^2\,, \tag{4.30}$$

where the constant C_T is independent of q and L but depends on T.

Proof. The two ingredients of the proof, the Feynman–Kac formula and the martingale property, follow from the standard properties of Markov processes (see, for example, [25]). If we define, for the microscopic process $\{\sigma_t\}_{t\geq0}$ defined by the generator $\mathcal{L}$, the function

$$u(t,S)=\mathbb{E}\left[\phi(\sigma_T)\,|\,\sigma_t=S\right],$$

then from the Feynman–Kac formula with the zero potential it follows that the function $u(t,S)$ solves the final value problem

$$\partial_t u+\mathcal{L}u=0\,,\qquad u(T,.)=\phi\,,\quad t<T\,. \tag{4.31}$$

On the other hand the martingale property implies that for any smooth function $v(t,S)$ and the process $\{\gamma_t\}_{t\geq 0}$ with the generator $\mathcal{L}^\gamma$ we have

$$\mathbb{E}_S\left[v(T,\gamma_T)\right] = \mathbb{E}_S\left[v(0,\gamma_0)\right] + \int_0^T \mathbb{E}_S\left[(\partial_s + \mathcal{L}^\gamma)v(s,\gamma_s)\right] ds\,.$$

The definition of $u(t,S)$ leads to the representation of the error $|\mathbb{E}_S\left[\phi(\sigma_T)\right] - \mathbb{E}_S\left[\phi(\gamma_T)\right]|$ by $e_w = |\mathbb{E}_S\left[u(0,S)\right] - \mathbb{E}_S\left[u(T,\gamma_T)\right]|$ and hence

$$e_w = \left| \int_0^T \mathbb{E}_S\left[(\partial_s + \mathcal{L}^\gamma)\, u(s,\gamma_s)\right] ds \right|\,.$$

The function $u(t,S)$ solves the equation $\partial_t u = -\mathcal{L}u$. Thus we obtain

$$\mathbb{E}_S\left[\phi(\sigma_T) - \phi(\gamma_T)\right] = \int_0^T \mathbb{E}_S\left[\mathcal{L}^\gamma u(t,\gamma_t) - \mathcal{L}u(t,\gamma_t)\right]dt$$
$$= \int_0^T \mathbb{E}_S\left[\sum_{x\in\Lambda_N} \left(c(x,\gamma_t) - c_\gamma(x,\gamma_t)\right)\partial_x u(t,\gamma_t)\right] dt\,.$$

We split the summation $\sum_{x\in\Lambda_N}$ which gives us

$$\mathbb{E}_S\left[\phi(\sigma_T) - \phi(\gamma_T)\right] = \int_0^T \mathbb{E}_S\left[\sum_{k\in\Lambda_M^c}\sum_{x\in C_k} \left(c(x,\gamma_t) - c_\gamma(x,\gamma_t)\right)\partial_x u(t,\gamma_t)\right] dt$$
$$= \int_0^T \mathbb{E}_S\left[\sum_{k\in\Lambda_M^c}\sum_{x\in C_k} \gamma_t(x)(e^{-\beta U(x,\gamma_t)} - e^{-\beta\bar{U}(k(x),\mathbf{T}\gamma_t)})(\partial_k v(t,\mathbf{T}\gamma_t) + R_T^{q,L}(x))\right] dt\,.$$

Here we need to replace $\partial_x u$ by $\partial_x v$, where v solves the final value problem (4.31) with $\mathcal{L}$ replaced by $\mathcal{L}^\gamma$. From Lemma 4.5 we know that the error term $R_T^{q,L}(x) = \partial_x u(t,\gamma) - \partial_x v(t,\gamma)$ is controlled by $\mathrm{O}(q/L)$ in $||\cdot||_\infty$. Furthermore, Lemma 4.6 guarantees that with the final condition ϕ which satisfies assumption (A1) the solution depends only on $\mathbf{T}\gamma$ and hence we can replace the discrete difference $\partial_x v$ by the difference $\partial_k v(t,\eta) \equiv v(t,\eta+\delta_k) - v(t,\eta)$, where $\eta = \mathbf{T}\gamma$. Next we expand the exponentials to obtain

$$\Gamma(k,\gamma) \equiv \sum_{x\in C_k} \beta\gamma(x) e^{-\beta\bar{U}(k(x),\mathbf{T}\gamma)} \left(\Delta(\bar{U},U) + \frac{1}{2}\beta^2\Delta^2(\bar{U},U) + \mathrm{O}\left(\beta^3\Delta^3(\bar{U},U)\right)\right)\,,$$

and we recast the error representation into

$$\mathbb{E}_S\left[\phi(\sigma_T) - \phi(\gamma_T)\right]$$
$$= \int_0^T \mathbb{E}_S\left[\sum_{k\in\Lambda_M^c} \Gamma(k,\gamma_t)\partial_k v(t,\mathbf{T}\gamma_t) + \sum_{x\in\Lambda_N} \left(c(x,\gamma_t) - c_\gamma(x,\gamma_t)\right)R_T^{q,L}(x)\right] dt$$
$$= \int_0^T \mathbb{E}_S\left[q\sum_{k\in\Lambda_M^c} \partial_k v(t,\eta_t)\,\mathbb{E}\left[\Gamma(k,\gamma)\big|\mathbf{T}\gamma = \eta_t\right]\right] dt \tag{4.32}$$
$$+ \int_0^T \mathbb{E}_S\left[\sum_{x\in\Lambda_N} \left(c(x,\gamma_t) - c_\gamma(x,\gamma_t)\right)R_T^{q,L}(x)\right] dt\,. \tag{4.33}$$

Assumption (A1) and Lemma 4.4 imply that the term $q\sum_{k\in\Lambda_M^c}\partial_k v(t,\eta_t)$ is bounded. To estimate the conditional expectation we use the property of the reconstruction operator for the process $\{\gamma_t\}_{t\geq 0}$, in particular on each cell $\gamma_t(x)$ is reconstructed from $\eta_t(k)$ by assuming a "local" equilibrium and distributing $\gamma_t(x)$ uniformly in the cell $C_{k(x)}$. Using this property we can compute the conditional expectation explicitly and obtain for $l\neq k$

$$\mathbb{E}\left[\sum_{x\in C_k}\gamma(x)\Delta(\bar{U},U)\big|\mathbf{T}\gamma=\eta\right]=\eta_k\eta_l\sum_{\substack{x\in C_k\\ y\in C_l}}\left(J(x-y)-\bar{J}_{kl}\right)=0\,.$$

Similarly we handle the case $l=k$ and conclude that, after averaging, the first-order term $\Delta(\bar{U},U)$ in $\Gamma(k,\gamma)$ vanishes. We recall (see (3.3)) that

$$\Delta(\bar{U},U)\equiv\bar{U}(k(x),\mathbf{T}\gamma)-U(x,\gamma)=\mathrm{O}\left(\frac{q}{L}\right)\,,$$

and hence we can estimate (4.32) by $O(q^2/L^2)$. For the term (4.33) we use the estimate $\sum_{x\in\Lambda_N}|R_T^{q,L}(x)|\sim\mathrm{O}(q/L)$ from Lemma 4.5 and the Hölder inequality

$$\mathbb{E}_S\left[\sum_{x\in\Lambda_N}(c(x,\gamma_t)-c_\gamma(x,\gamma_t))R_T^{q,L}(x)\right]\leq||\mathbf{c}-\mathbf{c}_\gamma||_\infty\mathbb{E}_S\left[\sum_{x\in\Lambda_N}|R_T^{q,L}(x)|\right].$$

The first term on the right-hand side is estimated from (4.23) by $C(q/L)$ and hence the left-hand side behaves as $\mathrm{O}(q^2/L^2)$. Combining the estimates of (4.32) and (4.33) we conclude the proof.

Using the estimate for the synthetic process and its reconstruction from the coarse-grained process $\{\eta_t\}_{t\geq 0}$ we can compare the projected process $\{\mathbf{T}\sigma_t\}_{t\geq 0}$ and the coarse-grained process $\{\eta_t\}_{t\geq 0}$ also on the coarse level. The weak error for observables on the coarse space is also natural in simulations where we usually project finer simulations on the coarse level and use estimators for the coarse processes.

COROLLARY 4.8. *Let $\psi\in L^\infty(\mathcal{S}_{M,q}^c)$ be a test function on the coarse level such that there exists a test function $\phi\in L^\infty(\mathcal{S}_N)$ satisfying* (A1) *with the property $\psi(\mathbf{T}\sigma)=\phi(\sigma)$. Given the initial configuration σ_0 we define the coarse configuration $\eta_0=\mathbf{T}\sigma_0$. Assume the microscopic process $(\{\sigma_t\}_{t\geq 0},\mathcal{L})$ with the initial condition σ_0 and the approximating coarse process $(\{\eta_t\}_{t\geq 0},\bar{\mathcal{L}}^c)$ with the initial condition $\eta_0=\mathbf{T}\sigma_0$; then the weak error satisfies, for $0<T<\infty$,*

$$\left|\mathbb{E}_S\left[\psi(\mathbf{T}\sigma_T)\right]-\mathbb{E}_S\left[\psi(\eta_T)\right]\right|\leq C_T\left(\frac{q}{L}\right)^2\,, \tag{4.34}$$

where the constant C_T is independent of q and L but depends on T.

We conclude this section with a brief remark on regimes of applicability and limitations of the derived coarse-grained approximation. In the introduction we mentioned a few examples of physically relevant problems where the CGMC method is applicable. However, a closer inspection of the estimate in Theorem 4.7 reveals further regimes of validity for the approximation beyond the smallness of the ratio q/L. More specifically, we note that at high temperatures, i.e., $\beta\ll 1$, the error terms are small. Thus CGMC provides a good approximation even if the involved potentials are of a short range. Furthermore, in the presence of a strong external field, $|h|\gg 1$, the CGMC dynamics also provide a good approximation even for short-range interactions. In such a case we have (almost uniform) clusters of 0's or 1's, hence with large probability $\sigma(\cdot)\approx\eta(\cdot)/q\approx 0$, or 1; therefore, $\mathbb{E}\Delta(\bar{U},U)\ll 1$, and hence the error in Theorem 4.7 is small.

5. Numerical simulations. We use the CGMC described and analyzed in the previous sections for efficient simulations in the spin systems that undergo phase transitions; for the implementation details we refer to [19]. Within the context of spin-flip dynamics a typical example is nucleation of spatial regions of a new phase or a transition from one phase (all spins equal to zero) to another (all spins equal to one). In such simulations the emphasis is on the pathwise properties of the coarse-grained process so that the switching mechanism is simulated efficiently while approximation errors are controlled. We compare simulations on the microscopic level $q = 1$ with those performed on different levels of coarse-graining hierarchy parametrized by q.

The qualitative behavior of the Ising model with a long-range potential can be understood from the mean-field approximation of the equilibrium total coverage $c(\sigma)$. Below the critical temperature the Gibbs measure is not unique (in the thermodynamic limit $N \to \infty$) and two phases can coexist. When the energy landscape is probed by changing the external field h we observe nonuniqueness of the equilibrium coverage. The fluctuations allow for transitions between the equilibrium which leads to nucleation of regions with a different phase. Changing the external field h makes the original phase unstable and a switching occurs—the system transforms into the other equilibrium configuration.

The parameters in the simulations have been chosen as follows: We use a uniform finite range potential for all examples presented. We simulate a finite lattice with a total of $N = 1000$ microscopic nodes and allow a potential interaction range of $2L+1$ for $L = 100$. We choose the constant $d_0 = 1$ so that $c_a = 1$ and $c_d = 1$. Hence in this case the critical value β_c is given by $\beta_c J_0 = 4$. If $\beta J_0 > \beta_c J_0 = 4$, then the system is in the phase transition regime and the two phases can coexist. In this region we typically observe a transition from one phase (e.g., zero (low) coverage) to the other phase (e.g., full coverage). For the phase transition examples we fix $\beta J_0 = 6 > \beta_c J_0$. The simulations become difficult when $\beta \simeq \beta_c$ and there is no external field h applied. We note that the coarse-graining algorithm will not perform well close to the critical point β_c when $h = 0$. In the numerical studies we first investigate approximation properties of the CGMC algorithms for certain global quantities.

Coverage: We define the coverage c_t to be the process computed as the spatial mean

$$c_t(\sigma_t) = \frac{1}{N} \sum_{x \in \Lambda_N} \sigma_t(x)\,, \qquad c_t^q(\eta_t) = \frac{1}{qM} \sum_{l \in \Lambda_M^c} \eta_t(k)\,.$$

First we present, in Figure 5.1, a simulation for the coverage in the absence of phase transitions where we see a remarkable pathwise agreement. Time evolution of the coverage at the phase transition regime, $\beta J_0 = 6$, is depicted in Figure 5.2 for different values of q. Note that the case $q = 1000$, $m = 1$ which corresponds to the mean-field approximation ("over coarse-grained" interactions) does not follow the phase transition path of the other simulations. On the other hand the agreement in the results is extremely good for the remaining values of q. Furthermore, these numerical results indicate pathwise (strong) approximation of the microscopic process by the coarse-grained process. This observation suggests a stronger error control than the relative entropy estimate provided by Proposition 4.1.

To quantify the error behavior we calculate two errors between the exact stochastic process c_t and its coarse approximation c_t^q at the level of coarse-graining q. We define

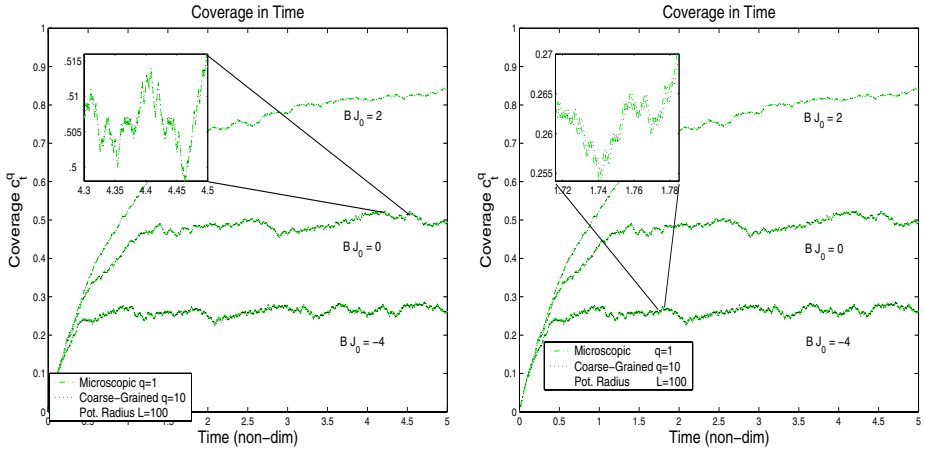

FIG. 5.1. *Relaxation dynamics. Comparison of microscopic* ($q = 1$) *and coarse-grained* ($q = 10$) *simulations. The plot depicts a short time simulation in order to calibrate the code and compare to Figure* 4 *from* [19].

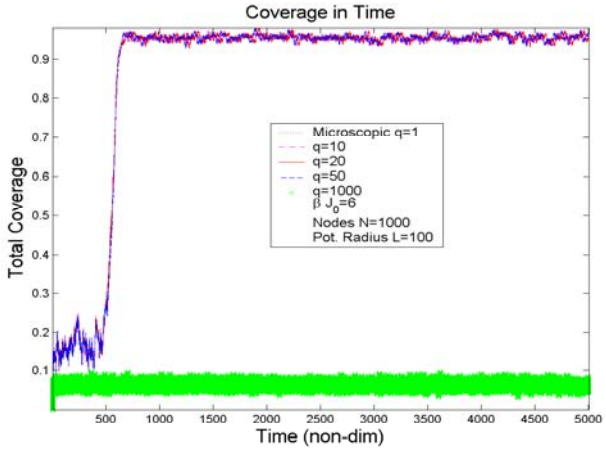

FIG. 5.2. *Time series of the coverage* c_t^q. *Simulations for different coarse-graining ratios are shown in the phase transition regime. The case* $q = 1000$, $m = 1$ *(mean-field approximation) shows significant discrepancy. Parameters used: potential radius length* $L = 100$, $\beta J_0 = 6$, $d_0 = 1$, $c_0 = .072$.

the weak error $e_w[c]$ and the strong error $e_s[c]$, respectively:

$$e_w[c] = \int_0^T |\mathbb{E}[c_t] - \mathbb{E}[c_t^q]|\, dt\,, \quad e_s[c] = \int_0^T \mathbb{E}[|\mathbf{T}c_t - c_t^q|]dt\,.$$

The expected values are estimated by empirical means and the integral in time by the piecewise constant quadrature.

The simulations allow us to estimate the convergence rate for both errors. The rates in the case of fixed parameters $L = 100$, $d_0 = 1.0$, $c_0 = 0.07$, and $\beta J_0 = 6$ on the lattice of the size $N = 1000$ are depicted in Figure 5.3. Note that we need to eliminate the statistical error, arising from approximation of expected values by empirical means. However, as seen in Figure 5.3 the estimator of the rate converges

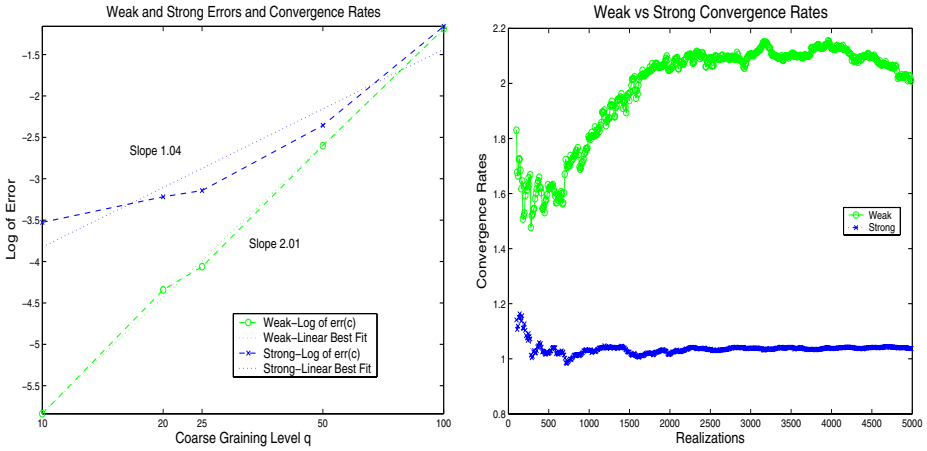

FIG. 5.3. *Estimated weak $e_w[c]$ and strong $e_s[c]$ errors. We compare the exact process c_t, $q = 1$ with coarse approximations c_t^q, $q = 10$, 25, 50, and 100. The simulation parameters were fixed at $L = 100$, $d_0 = 1$, $c_0 = .07$, $\beta J_0 = 6 > \beta_c J_0$, and the lattice size $N = 1000$. The convergence rates depicted are estimated by the linear best fit on the logarithmic scale. The statistical error or dependence of the estimates on the number of realizations is depicted in the right figure.*

	20	.1760	.1767	.1812
1	100	.0010	.0010	.0025
	40	.0036	.0040	.0054
	20	.0016	.0043	.0065

as the number of realizations tends to infinity.

Since the coarse-grained Hamiltonian neglects higher order corrections arising from the fluctuations on fine scales, one may expect that the approximation is poor if q/L is not very small. This is certainly true at the critical point (i.e., $\beta = \beta_c$ and $h = 0$) but further from the critical point the approximation properties are improved. This is demonstrated in Table 5.1, where the simulations were performed in the presence of different (large) external fields. The relative error becomes small even for fairly crude coarse-graining $q = 20$ in the case of shorter interaction radii L.

Mean time to reach phase transition: One quantity of interest that is calculated from the simulations is the mean time $\bar{\tau}_T = \mathbb{E}[\tau_T]$ until the coverage reaches C^+ in its phase transition regime (see Figure 5.2). The random exit time is defined as $\tau_T = \inf\{t > 0 \,|\, c_t \geq C^+\}$. We estimate the probability distributions ρ_τ and ρ_τ^q from the simulations. We record a phase transition at the time $\bar{\tau}_T$ when the coverage exceeds the threshold value $C^+ = 0.9$. The relative error for the estimated mean time $\bar{\tau}_T$ at different levels q is tabulated in Table 5.2 together with estimated relative entropy for the random variable τ_T. In Figure 5.4 we plot approximations of the

TABLE 5.2

probability density functions (PDFs) of τ_T and compare them for different values of q.

Nucleation: The nucleation of a new phase is a typical phenomenon in the regime where $\beta > \beta_c$. Essentially, there exist two equilibria (phases). Random fluctuations will induce transitions from one state to another by overcoming energy barriers that separate the equilibria. We investigate approximation of the pathwise behavior on the configuration space for nucleation of a new phase. Two different initial configurations are used.

Test case I: The initial state is at the metastable equilibrium where the coverage is zero. The fluctuations will cause the transition to the full coverage equilibrium which is stable due to the external applied field. We present only qualitative comparison in the series of snapshots (Figure 5.5) of the phase transition from the uniform (zero) initial coverage to the full coverage. We observe a striking pathwise agreement on the

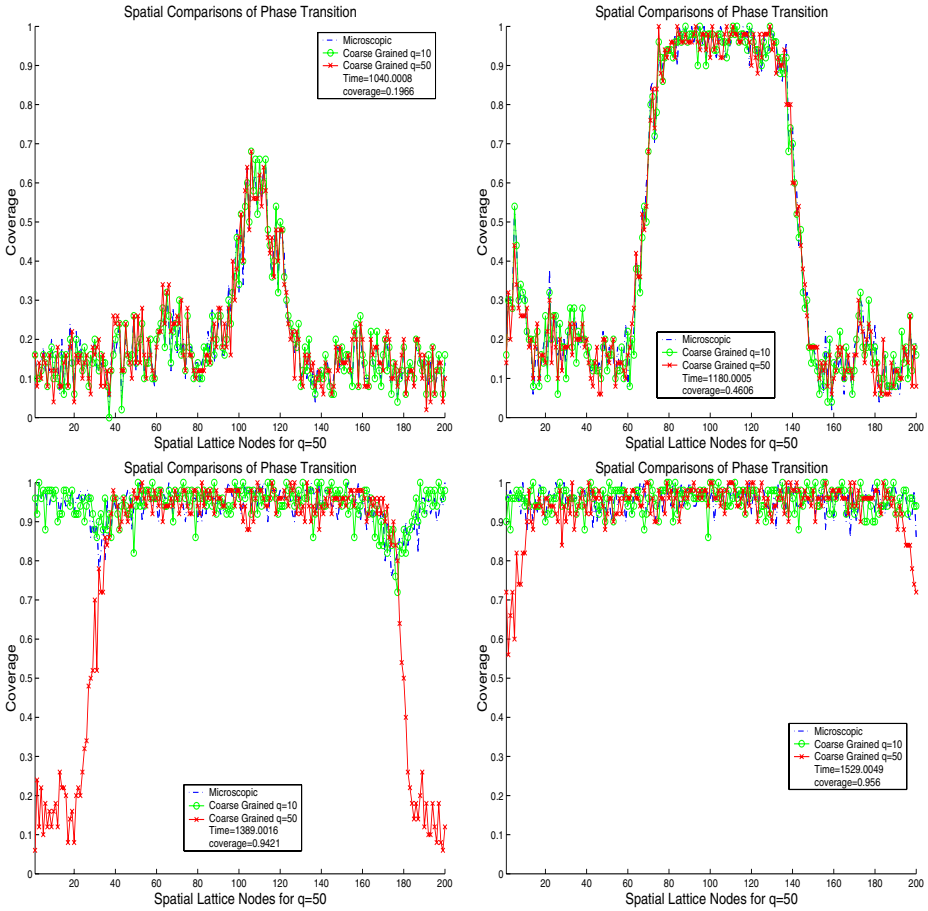

FIG. 5.5. *Snapshots of the transition from zero initial spatial distribution. Comparisons between the microscopic* $q = 1$ *and two coarse-grained simulations* $q = 10$ *and* $q = 50$. *The interaction radius is set to* $L = 200$ *while total nodes are* $N = 10000$.

configuration space for relatively large values of q compared to the interaction radius L. However, as the ratio q/L increases the corresponding coarse-grained process lags behind, which is also demonstrated in the expected values of transition times. Such behavior suggests that fluctuations at regions with uniform states are well-approximated by a highly coarse-grained process while finer resolution is necessary for resolving nucleation of new phases through islands.

Test case II: We have already documented the pathwise agreement of the approximating dynamics under both transition and relaxation cases. In this example we examine the spinodal decomposition phenomenon at the phase transition regime, $\beta J_0 = 6$. We chose the initial state to be at a saddle point of the energy surface, i.e., the mean coverage is set to 0.5. Snapshots of the spatial distribution of spins are presented in Figure 5.6. Under all four dynamics examined, $q = 1, 5, 10$, and 20, we observe complete spatial pathwise agreement. Over time the total coverage may fall towards zero or rise towards one in which case it will remain there since we are at the phase transition regime where these represent stable equilibria. The application of Theorem 4.7 for this case is not immediately obvious as the constant in the error

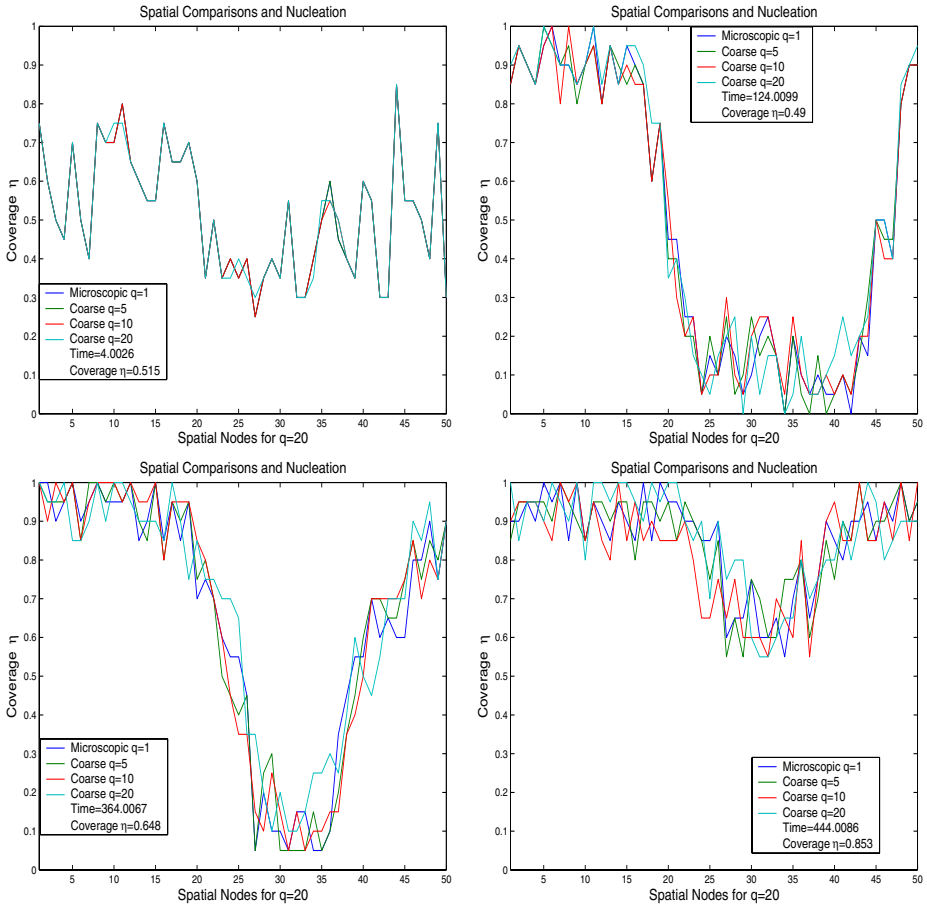

FIG. 5.6. *Snapshots of the transition from the initial state with the mean coverage at* 0.5. *Comparisons between the microscopic* $q = 1$ *and coarse-grained simulations* $q = 5, 10$ *and* $q = 20$. *The interaction radius is set to* $L = 100$, *the external field* $c_0 = 0.0492$, $d_0 = 1$, *and the total number of lattice sites* $N = 1000$.

estimate depends exponentially on the final time. On the other hand it was shown in [10] that in the case of Kac potentials the phases appear at length scales of the order $\log L$ as $L \to \infty$. Thus the error at spinodal decomposition times is controlled by a term of the order $\mathrm{O}(q^2/L)$.

LOCKING-FREE OPTIMAL DISCONTINUOUS GALERKIN METHODS FOR TIMOSHENKO BEAMS*

FATIH CELIKER†, BERNARDO COCKBURN†, AND HENRYK K. STOLARSKI‡

Abstract. In this paper, we consider the so-called *hp*-version of discontinuous Galerkin methods for Timoshenko beams. We prove that, when the numerical traces are properly chosen, the methods display optimal convergence uniformly with respect to the thickness of the beam. These methods are thus free from shear locking. We also prove that, when polynomials of degree p are used, *all* the numerical traces superconverge with a rate of order h^{2p+1}/p^{2p+1}. Numerical experiments verifying the above-mentioned theoretical results are shown.

Key words. discontinuous Galerkin methods, Timoshenko beams, locking, superconvergence

1. Introduction.

In this paper, we present the first rigorous analysis of discontinuous Galerkin (DG) methods for the Timoshenko beam model [24]

$$\begin{aligned}
\frac{d\bar{w}(\bar{x})}{d\bar{x}} &= \bar{\theta}(\bar{x}) - \frac{\bar{T}(\bar{x})}{(\bar{G}\bar{A})(\bar{x})},\\
\frac{d\bar{\theta}(\bar{x})}{d\bar{x}} &= \frac{\bar{M}(\bar{x})}{(\bar{E}\bar{I})(\bar{x})},\\
\frac{d\bar{M}(\bar{x})}{d\bar{x}} &= \bar{T}(\bar{x}),\\
\frac{d\bar{T}(\bar{x})}{d\bar{x}} &= \bar{q}(\bar{x})
\end{aligned}$$

for all $\bar{x} \in \bar{\Omega} := (0, L)$. Here, the unknowns are the transverse displacement $\bar{w}$, the rotation of the transverse cross-section of the beam $\bar{\theta}$, the bending moment $\bar{M}$, and the shear force $\bar{T}$. The material and geometrical properties of the beam are characterized by the shear modulus $\bar{G}$, the cross-section area $\bar{A}$, the Young modulus $\bar{E}$, and the moment of inertia $\bar{I}$. The remaining data of the problem are the transverse load, $\bar{q}$, and the boundary conditions which we take to be

$$\bar{w}(0) = \bar{w}_0, \qquad \bar{\theta}(0) = \bar{\theta}_0, \qquad \bar{w}(L) = \bar{w}_L, \quad \text{and} \quad \bar{\theta}(L) = \bar{\theta}_L.$$

The main motivation for considering this simple, one-dimensional model is that it constitutes a stepping stone towards the more challenging goal of devising DG methods for shells. The construction of numerical methods for shells is delicate because, as the thickness of the shell decreases to zero, the numerical method can exhibit what is

known in the engineering literature as *shear* and *membrane locking*. Mathematically, this is reflected in the deterioration of the convergence properties of the method as the thickness becomes small. Since some numerical methods for the Timoshenko beam model exhibit (shear) locking (as the thickness of the beam goes to zero), it is instructive to devise locking-free DG methods for this model before considering shells.

A considerable amount of effort has been devoted to the understanding and resolution of shear and membrane locking in structures. Considering the nature of the problem, it is understandable that such effort originated in engineering applications and was first documented in the engineering literature. The seminal publication in the area, by Zienkiewicz, Taylor, and Too [28], documents the difficulty related to shear effects and uses the so-called "reduced integration" technique to mitigate the problem. The physical understanding of the problem was critical to devise a remedy, and the resulting technique (reduced integration) is to this day widely used in various commercial software. The term "shear locking" appears to have been coined by Hughes, Taylor, and Kanoknukulchai [13] in the context of plate analysis.

In parallel with developments related to shear locking, researchers struggled with similar difficulties caused by membrane effects, manifesting themselves in curved structures, such as arches and shells; see, for example, Ashwell and Sabir [4], Lee and Pian [14], and Parisch [17]. A more thorough explanation of those effects was provided by Stolarski and Belytschko [21], who also introduced the term "membrane locking." They subsequently showed that in some models of curved structures there is a delicate interaction between shear and membrane effects [22].

Over the last two decades or so, there has been a flurry of research activities dealing with shear and membrane locking, and a large number of publications have appeared. Several variations of the known approaches and a number of new ones were developed and described in literature within that time. While related to this work, those approaches address the problem of locking somewhat differently from what we describe here; the interested reader is therefore referred to [23] for a review of many of them. For a locking-free finite element method for shells we refer to Arnold and Brezzi [2], and to Arnold, Brezzi, and Marini [3] for a recently uncovered family of locking-free DG methods for the Reissner–Mindlin plates.

While deeply rooted in physical attributes of the analyzed phenomena, locking is essentially a mathematical problem and its challenge was undertaken by mathematicians early on. Arnold [1] proved that shear locking continuous finite element methods can become locking-free if they are modified by the reduced integration technique. His method of proving error estimates independent of the thickness follows from an equivalence between certain mixed methods and the reduced integration technique; for a discussion of this equivalence in a more general setting we refer to [16]. In [15], Li analyzed the p- and hp-versions of the continuous finite element method and proved error estimates independent of the thickness of the beam. These versions of the method take advantage of the extra degrees of freedom gained by increasing the polynomial degree of the approximation. In [25], [26], and [27], Zhang considered circular arch problems. Here shear locking (and also membrane locking) is again an issue when the arch is thin. Indeed, if the primal form of the method is used where the only unknowns are the displacement and the rotation, both p- and hp-versions exhibit locking. On the other hand, if the shear force is introduced as an additional unknown, along with the membrane forces, and a mixed formulation is employed, then both versions can be made free from locking. Following an approach similar to that of Arnold's, Zhang [25], [26], [27] was able to prove error estimates independent of the thickness of the arch.

In [10], the DG methods for the Timoshenko beams were introduced and sufficient conditions that ensure the existence and uniqueness of their approximate solutions were proved. Moreover, preliminary numerical experiments were obtained which indicated that, when polynomials of degree p are used, the optimal order of convergence of $p+1$ is achieved for the h-version; exponential convergence for the p-version of a DG method was also obtained numerically. Later, in [8], the fact that *all* the numerical traces of the h-version of the DG method superconverge with order $2p+1$ was uncovered, and a local postprocessing resulting in a uniformly accurate solution of order $2p+1$ was devised and numerically tested. These results hold uniformly with respect to the thickness of the beam. In this paper, we put all the above-mentioned numerical results on firm mathematical ground.

The rest of the paper is organized as follows. In section 2, we describe a large class of DG methods and briefly discuss the existence and uniqueness of their approximate solution. Then, we pick a particular DG method for which we state and discuss the main results of our a priori error analysis. This DG method is particularly difficult to analyze due to that fact that it has practically no jump-stabilization terms associated to the interelement boundaries. Section 3 is devoted to the proof of those results and section 4 to some extensions of the main results. Numerical results verifying the theoretical results are presented in section 5. We end in section 6 with some concluding remarks.

2. Main results.

2.1. The dimensionless form of the model. To carry out our analysis, we nondimensionalize the equations of the model. We set $x = \bar{x}/L$, $\Omega = (0,1)$, $w(x) = \bar{w}(\bar{x})/L$, $w_0 = \bar{w}_0/L$, $w_1 = \bar{w}_L/L$, $\theta_0 = \bar{\theta}_0$, $\theta_1 = \bar{\theta}_L$. Suppose that there exist four constants a^*, b^*, E^*, and G^* such that

$$C_1 \le \frac{a^*}{\bar{a}(\bar{x})}, \frac{b^*}{\bar{b}(\bar{x})}, \frac{E^*}{\bar{E}(\bar{x})}, \frac{G^*}{\bar{G}(\bar{x})} \le C_2 \quad \forall\ \bar{x} \in \bar{\Omega}, \tag{2.1}$$

where $\bar{a}(\bar{x})$ and $\bar{b}(\bar{x})$ are the depth and thickness of the beam at the point $\bar{x}$, respectively. We further introduce $A^* := a^* b^*$ and $I^* := a^*(b^*)^3/12$ and then set $M(x) = \bar{M}(\bar{x})L/(E^*I^*)$, $T(x) = \bar{T}(\bar{x})\,L^2/(E^*I^*)$, $(EI)(x) = (\bar{E}\bar{I})(\bar{x})/(E^*I^*)$, $(GA)(x) = (\bar{G}\bar{A})(\bar{x})/(G^*A^*)$, and $q(x) = \bar{q}(\bar{x})\,L^3/(E^*I^*)$. We then rewrite the equations as

$$\frac{dw}{dx} = \theta - d^2\frac{T}{GA}, \qquad \frac{d\theta}{dx} = \frac{M}{EI}, \qquad \frac{dM}{dx} = T, \qquad \frac{dT}{dx} = q \qquad \text{in } \Omega, \tag{2.2}$$

where

$$w(0) = w_0, \qquad w(1) = w_1, \qquad \theta(0) = \theta_0, \quad \text{and} \quad \theta(1) = \theta_1. \tag{2.3}$$

Here,

$$d^2 := \frac{E^*I^*}{G^*A^*L^2} = \frac{E^*}{12\,G^*}\left(\frac{b^*}{L}\right)^2. \tag{2.4}$$

Thus the parameter d is proportional to the thickness of the beam to its length, and for small d the equations (2.2) model a thin beam; if the numerical method is not properly devised, shear locking might occur when the parameter d goes to zero. For further discussion of the locking effects in the finite element method, we refer the reader to Babuška and Suri [5].

2.2. General DG methods. To define the DG methods, we follow [10]. We begin by partitioning the computational domain into intervals. Given the set of *nodes* $\mathscr{E}_h := \{x_i\}_{i=0}^N$, where $0 = x_0 < x_1 < \cdots < x_{N-1} < x_N = 1$, we set $I_i := (x_{i-1}, x_i)$, $h_i := x_i - x_{i-1}$ and $h := \max_{1\le i\le N} h_i$.

The approximate solution $(T_h, M_h, \theta_h, w_h)$ given by the DG method is sought in the finite dimensional space $V_h^{p_1} \times V_h^{p_2} \times V_h^{p_3} \times V_h^{p_4}$, where

$$V_h^p := \{v : \Omega_h \mapsto \mathbb{R} : \quad v|_{I_j} \in P^p(I_j), \quad j = 1, \dots, N\}$$

and $P^p(K)$ is the set of all polynomials on K of degree not exceeding p. It is determined by requiring that

$$-(w_h, v_1')_{\Omega_h} + \langle \widehat{w}_h, [\![v_1\, n]\!]\rangle_{\mathscr{E}_h} = (\theta_h, v_1)_{\Omega_h} - d^2\,(T_h/GA, v_1)_{\Omega_h}\,, \tag{2.5a}$$

$$-(\theta_h, v_2')_{\Omega_h} + \langle \widehat{\theta}_h, [\![v_2\, n]\!]\rangle_{\mathscr{E}_h} = (M_h/EI, v_2)_{\Omega_h}\,, \tag{2.5b}$$

$$-(M_h, v_3')_{\Omega_h} + \langle \widehat{M}_h, [\![v_3\, n]\!]\rangle_{\mathscr{E}_h} = (T_h, v_3)_{\Omega_h}\,, \tag{2.5c}$$

$$-(T_h, v_4')_{\Omega_h} + \langle \widehat{T}_h, [\![v_4\, n]\!]\rangle_{\mathscr{E}_h} = (q, v_4)_{\Omega_h} \tag{2.5d}$$

hold for all $v_i \in V_h^{p_i}$ for $i = 1, 2, 3, 4$. Here, $\Omega_h = \cup_{j=1,\dots,N} I_j$ and

$$(u, v)_{\Omega_h} := \sum_{j=1}^N (u, v)_{I_j}, \quad \text{where} \quad (u, v)_{I_j} := \int_{I_j} u(x)v(x)\,dx.$$

Moreover, we introduce

$$\langle R, [\![u\, n]\!]\rangle_{\mathscr{E}_h} := \sum_{j=0}^N R(x_j)\,[\![u\, n]\!](x_j),$$

where R is any function defined on the set of nodes $\mathscr{E}_h$ and $[\![u\, n]\!]$ is the *jump* of function u across nodes which is defined as follows:

$$[\![u\, n]\!](x_j) = \begin{cases} -u(0^+) & \text{for } j = 0, \\ -u(x_j^+) + u(x_j^-) & \text{for } 0 < j < N, \\ +u(1^-) & \text{for } j = N. \end{cases}$$

Here, $u(x_j^\pm) := \lim_{\epsilon\downarrow 0} u(x_j \pm \epsilon)$.

To complete the definition of the method, we have to define the numerical traces $(\widehat{T}_h, \widehat{M}_h, \widehat{\theta}_h, \widehat{w}_h)$ at the nodes. We assume that the general form of these traces is as follows. For $x_i \in \mathscr{E}_h^\circ := \{x_1, x_2, \dots, x_{N-1}\}$, we take

$$\begin{aligned}
\widehat{w}_h &= \{\!\{\, w_h \,\}\!\} + C_{11}[\![w_h\, n]\!] + C_{12}[\![\theta_h\, n]\!] + C_{13}[\![M_h\, n]\!] + C_{14}[\![T_h\, n]\!], \\
\widehat{\theta}_h &= \{\!\{\, \theta_h \,\}\!\} + C_{21}[\![w_h\, n]\!] + C_{22}[\![\theta_h\, n]\!] + C_{23}[\![M_h\, n]\!] + C_{24}[\![T_h\, n]\!], \\
\widehat{M}_h &= \{\!\{M_h\}\!\} + C_{31}[\![w_h\, n]\!] + C_{32}[\![\theta_h\, n]\!] + C_{33}[\![M_h\, n]\!] + C_{34}[\![T_h\, n]\!], \\
\widehat{T}_h &= \{\!\{\, T_h \,\}\!\} + C_{41}[\![w_h\, n]\!] + C_{42}[\![\theta_h\, n]\!] + C_{43}[\![M_h\, n]\!] + C_{44}[\![T_h\, n]\!],
\end{aligned} \tag{2.6}$$

where $\{\!\{\varphi\}\!\}(x_i) := \frac{1}{2}(\varphi(x_i^+) + \varphi(x_i^-))$. At $x = 0$, we take

$$\begin{aligned}
\widehat{w}_h(0) &= w_0, \\
\widehat{\theta}_h(0) &= \theta_0, \\
\widehat{M}_h(0) &= M_h(0^+) + C_{31}(0)(w_0 - w_h(0^+)) + C_{32}(0)(\theta_0 - \theta_h(0^+)), \\
\widehat{T}_h(0) &= T_h(0^+) + C_{41}(0)(w_0 - w_h(0^+)) + C_{42}(0)(\theta_0 - \theta_h(0^+)).
\end{aligned} \tag{2.7}$$

And at $x = 1$,

$$
\begin{aligned}
&\widehat{w}_h(1) = w_1,\\
&\widehat{\theta}_h(1) = \theta_1,\\
&\widehat{M_h}(1) = M_h(1^-) + C_{31}(1)(w_h(1^-) - w_1) + C_{32}(1)(\theta_h(1^-) - \theta_1),\\
&\widehat{T_h}(1) = T_h(1^-) \ + C_{41}(1)(w_h(1^-) - w_1) + C_{42}(1)(\theta_h(1^-) - \theta_1).
\end{aligned} \tag{2.8}
$$

The definition of the DG method is now complete.

This method has a unique solution provided the parameters C_{ij}, $i, j = 1, 2, 3, 4$, and the polynomial degrees p_i, $i = 1, 2, 3, 4$, are suitably chosen. The following theorem proven in [10] gives sufficient conditions for this to happen.

THEOREM 2.1 (existence and uniqueness of the DG approximation). *Consider the DG method defined by the weak formulation* (2.5) *and the numerical traces* (2.6), (2.7), *and* (2.8). *Assume that*

$$
C_{21} = C_{43},\ -C_{22} = C_{33},\ C_{24} = C_{13},\ C_{31} = C_{42},\ C_{34} = C_{12},\ -C_{11} = C_{44}, \tag{2.9}
$$

and that

$$
C_{14},\ -C_{23},\ -C_{32},\ C_{41} \geq 0. \tag{2.10}
$$

Then the method has a unique solution in the following cases:

Case 1: $C_{41}, -C_{32} > 0$ *on* $\mathscr{E}_h$, $p_2 \geq p_3 - 1$, *and* $p_1 \geq p_4 - 1$.

Case 2: $C_{ij} = 0$ *on* $\mathscr{E}_h^\circ$, *except* $C_{11} = C_{22} = -C_{33} = -C_{44} = 1/2$, $C_{41}(1) > 0$, $-C_{32}(1) > 0$, $p_2 \geq p_3$, *and* $p_1 \geq p_4$.

Case 3: $p_2 \geq p_3 + 1$ *and* $p_1 \geq p_4 + 1$.

Note that thanks to equations (2.9), only 10 of the 16 coefficients C_{ij} are independent. Moreover, the condition (2.10) states that four of those must have a specific sign. This last condition can be better understood thanks to the so-called discrete energy equality.

PROPOSITION 2.2 (discrete energy identity [10]). *Assume that the hypotheses of Theorem* 2.1 *hold. Then*

$$
(M_h/EI, M_h)_{\Omega_h} + d^2\,(T_h/GA, T_h)_{\Omega_h} + \Theta_{jumps} = (q, w_h)_{\Omega_h} + bc + \Theta_{bc,h}, \tag{2.11}
$$

where

$$
\begin{aligned}
bc &= w_0\,T_h(0^+) - w_1\,T_h(1^-) - \theta_0\,M_h(0^+) + \theta_1\,M_h(1^-),\\
\Theta_{bc,h} &= w_0\left[C_{41}(0)w_h(0^+) - C_{31}(0)\theta_h(0^+)\right] + \theta_0[C_{42}(0)w_h(0^+) - C_{32}(0)\theta_h(0^+)]\\
&\quad + w_1\left[C_{41}(1)w_h(1^-) - C_{31}(1)\theta_h(1^-)\right] + \theta_1[C_{42}(1)w_h(1^-) - C_{32}(1)\theta_h(1^-)]\,,\\
\Theta_{jumps} &= \sum_{x_i \in \mathscr{E}_h} \left(C_{14}[\![T_h\,n]\!]^2 - C_{23}[\![M_h\,n]\!]^2 - C_{32}[\![\theta_h\,n]\!]^2 + C_{41}[\![w_h\,n]\!]^2\right)(x_i),
\end{aligned}
$$

where we set $C_{14} = C_{23} = 0$ *at the boundary nodes.*

We can thus see that the four coefficients that appear in the condition (2.10) are precisely those associated with the energy produced by the jumps of the approximations; they can also be thought of as penalizing the corresponding jumps. As a consequence, if we penalize the jumps "too much," the DG method might behave like a typical continuous method and might lock: It would produce very bad approximations for small values of d. On the contrary, if these penalization parameters are chosen appropriately, the DG method will produce a very good approximation.

We illustrate this phenomenon in Figure 1. Therein, we display the exact solution corresponding to $q(x) = e^x, (EI)(x) = e^x, (GA)(x) = e^{-x}$, together with homogeneous boundary conditions $w_0 = w_1 = \theta_0 = \theta_1 = 0$. We also show approximations by two of the DG methods just described. Both methods take

$$C_{11}(x) = C_{22}(x) = -C_{33}(x) = -C_{44}(x) = 1/2,$$

at all interior nodes $x \in \mathscr{E}_h^\circ$, and all the remaining coefficients equal to zero, except for C_{32} and C_{41}. The first DG method *strongly* penalizes the jumps of the vertical displacement w and the rotation θ, since it takes

$$-C_{32}(x) = C_{41}(x) = 10^6$$

for all nodes. We can see in Figure 1, left column, that, as expected, it locks. The second method, however, does *not* penalize those jumps *at all* since it takes

$$C_{32}(x) = C_{41}(x) = 0$$

at all the nodes except at $x = 1$. At $x = 1$, it takes

$$-C_{32}(1) = C_{41}(1) = 16/h$$

to enforce the Dirichlet boundary condition there. In Figure 1, right column, we can see that the method produces an excellent approximation of the exact solution. In this paper, we study this method in detail; other shear-locking-free DG methods are briefly discussed in section 4.

2.3. A priori error estimates. In this section, we present and briefly discuss a priori error estimates for the DG method obtained by setting

$$C_{11} = C_{22} = -C_{33} = -C_{44} \,=\, 1/2$$

at all interior nodes,

$$-C_{32}(1) = C_{41}(1) \;=\; \mathsf{c}\,\frac{\mathsf{p}}{h_N},$$

and all of the remaining coefficients to zero. Here c is a positive real number and $\mathsf{p} := \max\{1, p\}$. We also assume that $(T_h, M_h, \theta_h, w_h) \in [V_h^p]^4$, where $p \geq 0$. A simple computation gives that, for an interior node $x_j \in \mathscr{E}_h^\circ$,

$$\begin{aligned} &\widehat{w}_h(x_j) = w_h(x_j^-), \quad \widehat{M}_h(x_j) = M_h(x_j^+), \\ &\widehat{\theta}_h(x_j) = \theta_h(x_j^-), \quad \widehat{T}_h(x_j) = T_h(x_j^+), \end{aligned} \tag{2.12}$$

that, at $x = 0$,

$$\begin{aligned} &\widehat{w}_h(0) = w_0, \quad \widehat{M}_h(0) = M_h(0^+), \\ &\widehat{\theta}_h(0) = \theta_0, \quad \widehat{T}_h(0) = T_h(0^+), \end{aligned} \tag{2.13}$$

and that, at $x = 1$,

$$\begin{aligned} &\widehat{w}_h(1) = w_1, \quad \widehat{M}_h(1) = M_h(1^-) - \mathsf{c}\frac{\mathsf{p}}{h_N}(\theta_h(1^-) - \theta_1), \\ &\widehat{\theta}_h(1) = \theta_1, \quad \widehat{T}_h(1) = T_h(1^-) + \mathsf{c}\frac{\mathsf{p}}{h_N}(w_h(1^-) - w_1). \end{aligned} \tag{2.14}$$

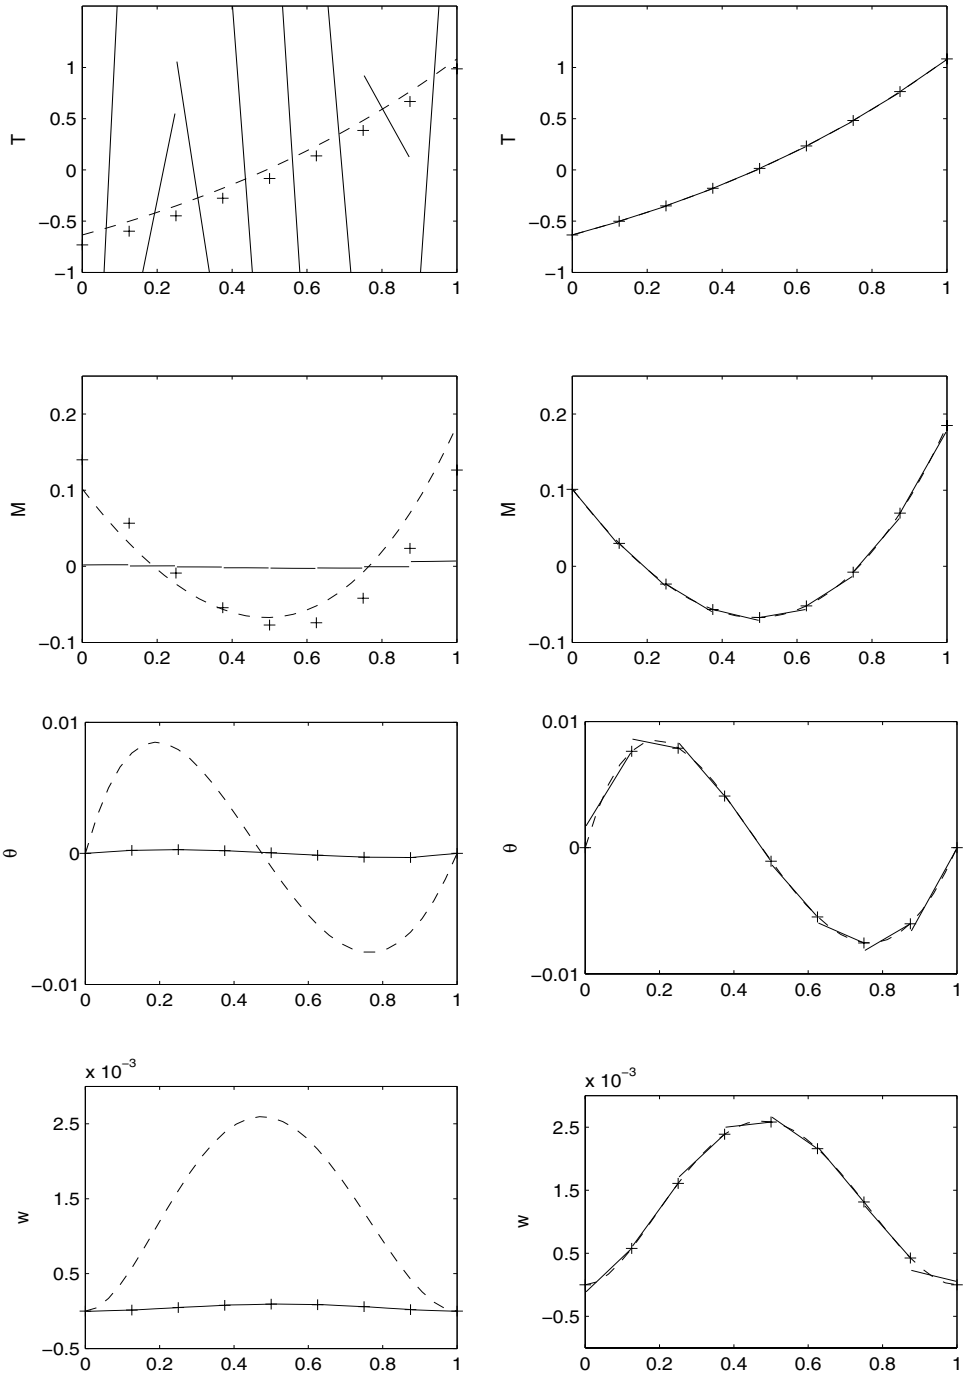

FIG. 1. *The case $d = 10^{-3}$ and $h = 1/8$: Exact (dashed line) and DG approximation (solid line and, for the numerical traces, +). Left column: $-C_{32} = C_{41} = 10^6$ on all the nodes. Right column: $C_{32} = C_{41} = 0$ on all the nodes except at $x = 1$, and $-C_{32}(1) = C_{41}(1) = 16/h = 128$.*

A similar DG method for convection-diffusion problems was introduced in [11]; its *hp*-version was analyzed first in [6] and its superconvergence properties proved later in [9].

We have chosen to analyze this method for two main reasons. The first is that it gives better error estimates in the energy seminorm (see section 4.3), the second is that it is more difficult to analyze. To give a brief idea why it is so, we note that for this DG method the discrete energy associated with the jumps is

$$\Theta_{jumps} = \mathsf{c}\frac{\mathsf{p}}{h_N}\left([\![\theta_h\, n]\!]^2(1) + [\![w_h\, n]\!]^2(1)\right).$$

We thus see that the DG method *penalizes* the jumps of w_h and θ_h only at $x = 1$. This penalization weakly enforces the boundary conditions at $x = 1$ and ensures existence and uniqueness of the approximate solution; see Case 2 of Theorem 2.1. Note, however, that no such penalization is enforced at any other node of the mesh, and in particular at the border $x = 0$. This lack of extra *stabilization* is what renders the analysis of this method more challenging and interesting than that of the other DG methods. Technical details of how the analysis differs and becomes simpler when stabilization is present at all nodes of the mesh are given in Celiker [7].

To state our main results we need to introduce some notation. We begin by setting

$$\begin{aligned}|(u_1,u_2,u_3,u_4)|^2_{\mathscr{A}_h} :=\ & (u_2/EI,u_2)_{\Omega_h} + d^2\,(u_1/GA,u_1)_{\Omega_h}\\ & + \mathsf{c}\frac{\mathsf{p}}{h_N}\left([\![u_3\, n]\!]^2(1) + [\![u_4\, n]\!]^2(1)\right)\end{aligned} \tag{2.15}$$

for all $(u_1,u_2,u_3,u_4) \in [H^1(\Omega_h)]^4$. Since we can rewrite the discrete energy identity of Proposition 2.2 as

$$|(T_h,M_h,\theta_h,w_h)|^2_{\mathscr{A}_h} = (q,w_h)_{\Omega_h} + bc + \Theta_{bc,h},$$

we call this seminorm, the *energy* seminorm. The estimate of the approximation error in this seminorm plays a fundamental role in our error analysis.

Next, we define Green's functions for the problem under consideration. For any superindex $\star = T, M, \theta$ or w, and any point $y \in (0,1)$, we define $(\varphi^\star_{T,y}, \varphi^\star_{M,y}, \varphi^\star_{\theta,y}, \varphi^\star_{w,y})$ as the solution of

$$-\frac{d\varphi^\star_{w,y}}{dx} = \varphi^\star_{\theta,y} - d^2\frac{\varphi^\star_{T,y}}{GA}, \quad -\frac{d\varphi^\star_{\theta,y}}{dx} = \frac{\varphi^\star_{M,y}}{EI}, \quad -\frac{d\varphi^\star_{M,y}}{dx} = \varphi^\star_{T,y}, \quad -\frac{d\varphi^\star_{T,y}}{dx} = 0 \tag{2.16}$$

in $(0,y)\cup(y,1)$ that satisfies the boundary conditions

$$\varphi^\star_{w,y}(0) = \varphi^\star_{w,y}(1) = \varphi^\star_{\theta,y}(0) = \varphi^\star_{\theta,y}(1) = 0 \tag{2.17}$$

and the jump conditions

$$[\![\varphi^\star_{w,y}\, n]\!](y) = \delta_{\star\, T}, \quad [\![\varphi^\star_{\theta,y}\, n]\!](y) = \delta_{\star\, M}, \quad [\![\varphi^\star_{M,y}\, n]\!](y) = \delta_{\star\,\theta}, \quad [\![\varphi^\star_{T,y}\, n]\!](y) = \delta_{\star\, w}. \tag{2.18}$$

Here, $\delta_{ab} = 1$ if $a = b$ and $\delta_{ab} = 0$ otherwise. We also define, for $z \in \{0,1\}$,

$$(\varphi^\star_{T,z}, \varphi^\star_{M,z}, \varphi^\star_{\theta,z}, \varphi^\star_{w,z}) := \lim_{y\to z}(\varphi^\star_{T,y}, \varphi^\star_{M,y}, \varphi^\star_{\theta,y}, \varphi^\star_{w,y}).$$

Note that this implies that the function $(\varphi^\star_{T,z}, \varphi^\star_{M,z}, \varphi^\star_{\theta,z}, \varphi^\star_{w,z})$ is identically equal to zero for $z \in \{0,1\}$ and $\star = \theta, w$.

We denote by $\|\cdot\|_{s,\Omega_h}$ and $|\cdot|_{s,\Omega_h}$ the usual norm and seminorm in $H^s(\Omega_h)$, respectively. We set

$$\begin{aligned}|\,(T,M,\theta,w)\,|_{s,p,\Omega_h} := {} & |\,T\,|_{\min(p,s)+1,\Omega_h} + |\,M\,|_{\min(p,s+1)+1,\Omega_h} \\ & + |\,\theta\,|_{\min(p,s+2)+1,\Omega_h} + |\,w\,|_{\min(p,s+1)+1,\Omega_h}.\end{aligned}$$

The use of this seminorm is motivated by the fact that if the load q is assumed to belong to $H^s(\Omega_h)$ and the functions EI and GA are very smooth in Ω_h, then (2.2), (2.3), and (2.4) indicate that the solution (T,M,θ,w) belongs to the Sobolev space $H^{s+1}(\Omega_h) \times H^{s+2}(\Omega_h) \times H^{s+3}(\Omega_h) \times H^{s+2}(\Omega_h)$.

Finally, for any real number $k \geq 0$, we define

$$|\varphi^\star_{x_i}|_{k,\Omega_h} := \max\{|\varphi^\star_{T,x_i}|_{k,\Omega_h}, |\varphi^\star_{M,x_i}|_{k,\Omega_h}, |\varphi^\star_{\theta,x_i}|_{k,\Omega_h}, |\varphi^\star_{w,x_i}|_{k,\Omega_h}\},$$

where $\star = T$, M, θ or w.

We are ready to state and discuss our main results.

THEOREM 2.3. *Assume that, for some $s \geq 0$, (T,M,θ,w) belong to $H^{s+1}(\Omega_h) \times H^{s+2}(\Omega_h) \times H^{s+3}(\Omega_h) \times H^{s+2}(\Omega_h)$. Set*

$$\boldsymbol{e} := (e_T, e_M, e_\theta, e_w) = (T - T_h, M - M_h, \theta - \theta_h, w - w_h),$$

where $(T_h, M_h, \theta_h, w_h)$ is the approximation given by the DG method (2.5), (2.12), (2.13), *and* (2.14) *with $p \geq 1$. Then, for small enough h or big enough p, we have that*

$$|\boldsymbol{e}|_{\mathscr{A}_h} \leq C_s \, \frac{h^{\min(p,s)+1}}{p^{\min(p,s)+1}} \, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h},$$

and that

$$\begin{aligned}\|e_T\|_{0,\Omega_h} &\leq C_s \, \frac{h^{\min(p,s)+1}}{p^{\min(p,s)+1}} (1 + |\varphi^T_{x_N}|_{p+1,\Omega_h}) \, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h}, \\ \|e_M\|_{0,\Omega_h} + \|e_\theta\|_{0,\Omega_h} + \|e_w\|_{0,\Omega_h} &\leq C_s \, \frac{h^{\min(p,s)+1}}{p^{\min(p,s)+1}} \, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h},\end{aligned}$$

for some constant C_s independent of p, h, and d.

Our second result estimates the errors at each of the nodes.

THEOREM 2.4. *With the same hypotheses as those of Theorem* 2.3, *we have that*

$$|\,\widehat{e_u}(x_i)\,| \leq C_s \, \frac{h^{\min(p,s)+p+1}}{p^{\min(p,s)+p+1}} |\varphi^u_{x_i}|_{p+1,\Omega_h} \, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h}$$

for $u = T, M, \theta$ or w and all the nodes x_i.

Let us emphasize that (not reported) numerical experiments indicate that the condition "small enough h or big enough p" in the results above seems to be unnecessary. It stems from a technicality in our proof and, most probably, could be removed.

Note that all of the estimates appearing in the above theorems show that, for $p \geq 1$, the DG method under consideration is *locking-free* because the constants appearing on the right-hand side of all the estimates do not depend on the parameter

d and because the seminorms appearing on the right-hand side of the estimates can be bounded uniformly with respect to d. Similar results holds for $p = 0$; see section 4.

To see that the seminorms of the exact solution can be uniformly bounded with respect to d, we note that the exact solution is given by

$$
\begin{aligned}
T(x) &= \int_0^x q(r)\,dr + c_1,\\
M(x) &= \int_0^x \int_0^r q(s)\,ds\,dr + c_1 x + c_2,\\
\theta(x) &= \int_0^x \frac{1}{EI(r)} \left[\int_0^r \int_0^s q(t)\,dt\,ds + c_1 r + c_2 \right] dr + c_3,\\
w(x) &= \int_0^x \left[\int_0^r \frac{1}{EI(s)} \left(\int_0^s \int_0^t q(u)\,du\,dt + c_1 s + c_2 \right) ds + c_3 \right] dr\\
&\quad - d^2 \left[\int_0^x \frac{1}{GA(r)} \left(\int_0^r q(s)\,ds + c_1 \right) dr \right] + c_4,
\end{aligned}
$$

where c_1, c_2, c_3, and c_4 are integration constants to be determined by the boundary conditions (2.3). Since EI and GA are piecewise very smooth functions of order one, and d^2 appears only as a factor in $w(x)$, it is easy to see that the seminorms $|T|_{\min(p,s)+1,\Omega_h}$, $|M|_{\min(p,s+1)+1,\Omega_h}$, $|\theta|_{\min(p,s+2)+1,\Omega_h}$, and $|w|_{\min(p,s+1)+1,\Omega_h}$ remain bounded as $d \to 0$. A similar remark is valid for the seminorm $|\varphi^u_{x_i}|_{p+1,\Omega_h}$.

Note also that the above results imply that the h-version of the DG method converges with the optimal order of $p+1$ in the energy norm and in the L^2-norm for *all* variables. They also imply that *all* the numerical traces superconverge with order $2p+1$ at each node. This puts on firm mathematical ground the assumption of superconvergence taken in [8].

In the p-version of the DG method, we have spectral convergence with a rate of order p^{-s-1} for *all* the unknowns. In the case of a piecewise analytic function, by using the approach used in, for example, [20], [18], [19], it is possible to prove that the p-version of the DG method actually achieves exponential rates of convergence,

$$|(e_T, e_M, e_\theta, e_w)|_{\mathscr{A}_h} \le Ce^{-bp},$$

and

$$\|e_u\|_{0,\Omega_h} + \|\widehat{e_u}\|_{L^\infty(\mathscr{E}_h)} \le Ce^{-bp}$$

for $u = T, M, \theta$ or w, for some constants C and b independent of p and d.

Finally, let us point out that if the data E, G, A, and I are constants, then, for $p \ge 3$, Theorem 2.4 implies that, for any node x_i,

$$\widehat{e_u}(x_i) = 0,$$

for $u = T, M, \theta$ or w. Indeed, in this case the Green's functions are piecewise polynomials of degree at most 3 and hence $|\varphi^u_{x_i}|_{p+1,\Omega_h} = 0$.

2.4. Sketch of the proofs. Next, we give a brief outline of the main steps of our proofs. We proceed in three steps.

We begin by estimating the errors in the L^2-norm in terms of the error in the energy seminorm and the error in the numerical traces.

LEMMA 2.5. *We have*

$$\begin{aligned}
\|e_w\|_{0,\Omega_h} &\le C_s \left(|\boldsymbol{e}|_{\mathscr{A}_h} + \|e_\theta\|_{0,\Omega_h} + \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\, (T,M,\theta,w) \,|_{s,p,\Omega_h} \right), \\
\|e_\theta\|_{0,\Omega_h} &\le C_s \left(|\boldsymbol{e}|_{\mathscr{A}_h} + \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\, (T,M,\theta,w) \,|_{s,p,\Omega_h} \right), \\
\|e_M\|_{0,\Omega_h} &\le C_s \quad |\boldsymbol{e}|_{\mathscr{A}_h}, \\
\|e_T\|_{0,\Omega_h} &\le |\widehat{e_T}(1)| + C_s \, \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\, (T,M,\theta,w) \,|_{s,p,\Omega_h}.
\end{aligned}$$

Here C_s is a constant independent of p, h, and d.

Next, we show that the error in the numerical traces can be estimated in terms of the error in the energy seminorm.

LEMMA 2.6. *For sufficiently small mesh-size h or sufficiently big polynomial degree p, we have*

$$|\, \widehat{e_u}(x_i) \,| \le C_s \left(|\boldsymbol{e}|_{\mathscr{A}_h} + \frac{h^{\min(s,p)}}{\mathsf{p}^{\min(s,p)}} \,|\, (T,M,\theta,w) \,|_{s,p,\Omega_h} \right) \frac{h^{p+1}}{\mathsf{p}^{p+1}} \,|\varphi^u_{x_i}|_{p+1,\Omega_h}$$

for $u = T, M, \theta$ or w and for all nodes x_i. Here C_s is a constant independent of p, h, and d.

Finally, we obtain an estimate of the error estimate in the energy seminorm.

LEMMA 2.7. *With the same notation as in Theorem* 2.3, *we have that*

$$|\boldsymbol{e}|_{\mathscr{A}_h} \le C_s \, \frac{h^{\min(s,p)+1}}{\mathsf{p}^{\min(s,p)+1}} \,|\, (T,M,\theta,w) \,|_{s,p,\Omega_h}.$$

Here C_s is a constant independent of p, h, and d.

It is now easy to see that Theorems 2.3 and 2.4 follow from the three above lemmas.

3. Proofs. To prove the lemmas in the previous subsection, we rely, as expected, on the error equations, namely,

$$\begin{aligned}
&-(e_w, v_1')_{\Omega_h} + \langle \widehat{e_w}, [\![v_1\, n]\!] \rangle_{\mathscr{E}_h} = (e_\theta, v_1)_{\Omega_h} - d^2 (e_T/GA, v_1)_{\Omega_h}, && \text{(3.1a)} \\
&-(e_\theta, v_2')_{\Omega_h} + \langle \widehat{e_\theta}, [\![v_2\, n]\!] \rangle_{\mathscr{E}_h} = (e_M/EI, v_2)_{\Omega_h}, && \text{(3.1b)} \\
&-(e_M, v_3')_{\Omega_h} + \langle \widehat{e_M}, [\![v_3\, n]\!] \rangle_{\mathscr{E}_h} = (e_T, v_3)_{\Omega_h}, && \text{(3.1c)} \\
&-(e_T, v_4')_{\Omega_h} + \langle \widehat{e_T}, [\![v_4\, n]\!] \rangle_{\mathscr{E}_h} = 0 && \text{(3.1d)}
\end{aligned}$$

for any $v_i \in V_h^p, i = 1,2,3,4$. They are easily obtained by noting that the exact solution (T, M, θ, w) also satisfies the DG formulation (2.5).

We also rely on interpolation operators naturally associated with the numerical traces of the method. For any $u \in H^1(\Omega_h)$, the function $\pi^\pm u \in V_h^p$ is defined on the element I_j by

$$\begin{aligned}
&(u - \pi^\pm u, v)_{I_j} = 0 \qquad \forall v \in P^{p-1}(I_j) \quad \text{if } p > 0, && \text{(3.2a)} \\
&(\pi^- u)(x_j^-) = u(x_j^-), \qquad (\pi^+ u)(x_{j-1}^+) = u(x_{j-1}^+). && \text{(3.2b)}
\end{aligned}$$

Finally, we use the following notation:

$$\begin{aligned}
\boldsymbol{\pi e} &:= (\pi^+ e_T, \pi^+ e_M, \pi^- e_\theta, \pi^- e_w), && \text{(3.3a)} \\
\boldsymbol{\xi} &:= \boldsymbol{e} - \boldsymbol{\pi e} = (\xi_T^+, \xi_M^+, \xi_\theta^-, \xi_w^-). && \text{(3.3b)}
\end{aligned}$$

3.1. Proof of Lemma 2.5. To prove Lemma 2.5, we begin by obtaining the following representation formulas.

LEMMA 3.1. *Let $\psi \in L^2(\Omega_h)$ and define $\Psi(x) := \int_0^x \psi(s)ds$. Then the following expressions hold:*

$$(e_w,\psi)_{\Omega_h} = -\left((\xi_w^+)',\xi_\Psi^+\right)_{\Omega_h} + e_w(1^-)\xi_\Psi^+(1^-) - \left(e_\theta - d^2\frac{e_T}{GA},\pi^+\Psi\right)_{\Omega_h}, \tag{3.4a}$$

$$(e_\theta,\psi)_{\Omega_h} = -\left((\xi_\theta^+)',\xi_\Psi^+\right)_{\Omega_h} + e_\theta(1^-)\xi_\Psi^+(1^-) - \left(\frac{e_M}{EI},\pi^+\Psi\right)_{\Omega_h}, \tag{3.4b}$$

$$(e_T,\psi)_{\Omega_h} = -\left((\xi_T^-)',\xi_\Psi^-\right)_{\Omega_h} + \widehat{e_T}(1)\Psi(1). \tag{3.4c}$$

Proof. We only prove (3.4a) since the proofs of the other identities are similar. We begin by using the trivial identity

$$(e_w,\psi)_{\Omega_h} = (e_w,\Psi')_{\Omega_h} = (e_w,(\xi_\Psi^+)')_{\Omega_h} + (e_w,(\pi^+\Psi)')_{\Omega_h}.$$

Next, we obtain an expression for $(e_w,(\pi^+\Psi)')_{\Omega_h}$. Taking $v_1 = \pi^+\Psi$ in the first error equation (3.1), we get

$$\begin{aligned}(e_w,\psi)_{\Omega_h} =&(e_w,(\xi_\Psi^+)')_{\Omega_h} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h} - \left(e_\theta - d^2\,\frac{e_T}{GA},\pi^+\Psi\right)_{\Omega_h}\\ =&-\left((\xi_w^+)',\xi_\Psi^+\right)_{\Omega_h} + e_w(1^-)\xi_\Psi^+(1^-) - \left(e_\theta - d^2\frac{e_T}{GA},\pi^+\Psi\right)_{\Omega_h} + \Theta_h,\end{aligned}$$

where

$$\Theta_h := (e_w,(\xi_\Psi^+)')_{\Omega_h} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h} + \left((\xi_w^+)',\xi_\Psi^+\right)_{\Omega_h} - e_w(1^-)\xi_\Psi^+(1^-).$$

It remains to be proven that $\Theta_h = 0$. Integrating by parts the first term of the right-hand side, we get

$$\begin{aligned}\Theta_h =&-((e_w)',\xi_\Psi^+)_{\Omega_h} + \langle 1,[\![e_w\,(\xi_\Psi^+)\,n]\!]\rangle_{\mathscr{E}_h} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h}\\ &+((\xi_w^+)',\xi_\Psi^+)_{\Omega_h} - e_w(1^-)\xi_\Psi^+(1^-)\\ =&-((e_w-\xi_w^+)',\xi_\Psi^+)_{\Omega_h} - e_w(0^+)\xi_\Psi^+(0^+) + \langle 1,[\![e_w\,(\xi_\Psi^+)\,n]\!]\rangle_{\mathscr{E}_h^\circ} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ},\end{aligned}$$

where

$$\langle\eta,\zeta\rangle_{\mathscr{E}_h^\circ} := \sum_{j=1}^{N-1}\eta(x_j)\zeta(x_j).$$

Hence, by the definition of $\pi^\pm$, (3.2),

$$\begin{aligned}\Theta_h &= \langle 1,[\![e_w\,(\xi_\Psi^+)\,n]\!]\rangle_{\mathscr{E}_h^\circ} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ}\\ &= \langle 1,[\![e_w\,(\Psi-\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ} + \langle\widehat{e_w},[\![(\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ} && \text{by definition of } \xi_\Psi^+,\\ &= \langle 1,[\![e_w\,(\Psi-\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ} + \langle\widehat{e_w},[\![(\pi^+\Psi-\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ} && \text{by the continuity of } \Psi,\\ &= \langle 1,[\![(e_w-\widehat{e_w})\,(\Psi-\pi^+\Psi)\,n]\!]\rangle_{\mathscr{E}_h^\circ}\\ &= 0.\end{aligned}$$

Indeed, for any interior node x_j,

$$\begin{aligned}[\![(e_w-\widehat{e_w})\,(\Psi-\pi^+\Psi)\,n]\!](x_j) = &\,(e_w(x_j^-)-\widehat{e_w}(x_j))\,(\Psi(x_j)-\pi^+\Psi(x_j^-))\\ &-(e_w(x_j^+)-\widehat{e_w}(x_j))\,(\Psi(x_j)-\pi^+\Psi(x_j^+)) = 0,\end{aligned}$$

since $\widehat{e_w}(x_j) = e_w(x_j^-)$ and $\pi^+\Psi(x_j^+) = \Psi(x_j)$. This completes the proof. ∎

The proof of Lemma 2.5 now follows from Lemma 3.1 and the following proposition which contains the approximation results of the projection operators $\pi^{\pm}$; see [20] and, for example, [6] or [12].

LEMMA 3.2. *Let $I_j \subset \Omega_h$ be an arbitrary element, and suppose that $u \in H^{t+1}(I_j)$ for some nonnegative real number t. Then*

$$\begin{aligned}\left\|u-\pi^{\pm}u\right\|_{0,I_j}+\frac{h_j}{\mathsf{p}}\left\|(u-\pi^{\pm}u)'\right\|_{0,I_j} &\le C_t\frac{h_j^{\sigma+1}}{\mathsf{p}^{\sigma+1}}|u|_{\sigma+1,I_j},\\ |(u-\pi^{-}u)(x_{j-1}^{+})|+|(u-\pi^{+}u)(x_j^{-})| &\le C_t\frac{h_j^{\sigma+1/2}}{\mathsf{p}^{\sigma+1/2}}|u|_{\sigma+1,I_j},\end{aligned}$$

where $0 \le \sigma \le \min(p,t)$ for some constant C_t depending solely on t.

Proof of Lemma 2.5. Since all the estimates are obtained in a similar way, we prove only the second. To do this, we take $\psi = e_\theta$ in (3.4b) to obtain

$$\|e_\theta\|_{0,\Omega_h}^2 = -\left((\theta-\pi^{+}\theta)',\Psi-\pi^{+}\Psi\right)_{\Omega_h}+e_\theta(1^{-})(\Psi-\pi^{+}\Psi)(1^{-})-(e_M/EI,\pi^{+}\Psi)_{\Omega_h},$$

where $\Psi(x)=\int_0^x e_\theta(s)ds$. Then

$$\begin{aligned}\|e_\theta\|_{0,\Omega_h}^2 \le{}& \left\|(\theta-\pi^{+}\theta)'\right\|_{0,\Omega_h}\left\|\Psi-\pi^{+}\Psi\right\|_{0,\Omega_h}+|\,e_\theta(1^{-})\,|\,|\,(\Psi-\pi^{+}\Psi)(1^{-})\,|\\ &+\|e_M/EI\|_{0,\Omega_h}\left(\|\Psi\|_{0,\Omega_h}+\left\|\Psi-\pi^{+}\Psi\right\|_{0,\Omega_h}\right).\end{aligned}$$

By the approximation results in Lemma 3.2,

$$\begin{aligned}&\left\|(\theta-\pi^{+}\theta)'\right\|_{0,\Omega_h}\le C_t\frac{h^{\sigma}}{\mathsf{p}^{\sigma}}|\theta|_{\sigma+1,\Omega_h},\quad \left\|\Psi-\pi^{+}\Psi\right\|_{0,\Omega_h}\le C_t\frac{h}{\mathsf{p}}|\Psi|_{1,\Omega_h},\\ &|(\Psi-\pi^{+}\Psi)(1^{-})|\le C_t\frac{h^{1/2}}{\mathsf{p}^{1/2}}|\Psi|_{1,\Omega_h},\quad \|\Psi\|_{0,\Omega_h}\le C|\Psi|_{1,\Omega_h},\end{aligned}$$

where $0 \le \sigma \le \min(p,t)$, and by the definition of the seminorm $|\cdot|_{\mathscr{A}_h}$, (2.15),

$$|e_\theta(1^{-})|\le C_t\,\frac{h^{1/2}}{\mathsf{p}^{1/2}}\,|\boldsymbol{e}|_{\mathscr{A}_h},\qquad \|e_M/EI\|_{0,\Omega_h}\le C\,|\boldsymbol{e}|_{\mathscr{A}_h}.$$

Hence, we get

$$\|e_\theta\|_{0,\Omega_h}^2 \le C_t\left(|\boldsymbol{e}|_{\mathscr{A}_h}+\frac{h^{\sigma+1}}{\mathsf{p}^{\sigma+1}}|\theta|_{\sigma+1,\Omega_h}\right)|\Psi|_{1,\Omega_h},$$

and since $|\Psi|_{1,\Omega_h}=\|e_\theta\|_{0,\Omega_h}$,

$$\begin{aligned}\|e_\theta\|_{0,\Omega_h} &\le C_t\left(|\boldsymbol{e}|_{\mathscr{A}_h}+\frac{h^{\sigma+1}}{\mathsf{p}^{\sigma+1}}|\theta|_{\sigma+1,\Omega_h}\right)\\ &\le C_s\left(|\boldsymbol{e}|_{\mathscr{A}_h}+\frac{h^{\min(p,s+2)+1}}{\mathsf{p}^{\min(p,s+2)+1}}|\theta|_{\min(p,s+2)+1,\Omega_h}\right)\qquad \text{for } \sigma=\min(p,s+2),\\ &\le C_s\left(|\boldsymbol{e}|_{\mathscr{A}_h}+\frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}}\,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\right),\end{aligned}$$

and the estimate follows. This completes the proof of Lemma 2.5.

3.2. Proof of Lemma 2.6. To prove this lemma we proceed in two steps. In the first, we establish representation formulas for the errors in the numerical traces. In the second, we use approximation results to estimate them.

Step 1. *The error representation formulas.* We begin by expressing the numerical traces in terms of certain integrals involving the Green's functions.

LEMMA 3.3 (error representation formulas). *Let x_i be an arbitrary node and let φ^u_{w,x_i}, φ^u_{θ,x_i}, φ^u_{M,x_i}, φ^u_{T,x_i}, for $u = T, M, \theta$ or w, be the functions defined by* (2.16), (2.17), *and* (2.18). *Then*

$$\begin{aligned}\widehat{e_u}(x_i) = {} & ((\theta - \pi^-\theta)', \pi^+\varphi^u_{M,x_i} - \varphi^u_{M,x_i})_{\Omega_h} + e_\theta(1^-)\,(\pi^+\varphi^u_{M,x_i} - \varphi^u_{M,x_i})(1^-) \\ & + ((M - \pi^- M)', \pi^+\varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i})_{\Omega_h} + ((T - \pi^- T)', \pi^+\varphi^u_{w,x_i} - \varphi^u_{w,x_i})_{\Omega_h} \\ & + (e_M/EI, \pi^+\varphi^u_{M,x_i} - \varphi^u_{M,x_i})_{\Omega_h} + (e_T, \pi^-\varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i})_{\Omega_h}.\end{aligned}$$

To prove this lemma we need a couple of auxiliary results. The first establishes a relation between the errors in the numerical traces and the Green's functions.

LEMMA 3.4. *Set*

$$\Theta^u_i := \langle \widehat{e_w}, [\![\varphi^u_{T,x_i}\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_\theta}, [\![\varphi^u_{M,x_i}\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_M}, [\![\varphi^u_{\theta,x_i}\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_T}, [\![\varphi^u_{w,x_i}\, n]\!]\rangle_{\mathscr{E}_h}.$$

Then, we have

$$\begin{aligned}\Theta^u_i = {} & (e_w, (v_1 - \varphi^u_{T,x_i})')_{\Omega_h} + \langle \widehat{e_w}, [\![(\varphi^u_{T,x_i} - v_1)\, n]\!]\rangle_{\mathscr{E}_h} \\ & + (e_\theta, (v_2 - \varphi^u_{M,x_i})')_{\Omega_h} + \langle \widehat{e_\theta}, [\![(\varphi^u_{M,x_i} - v_2)\, n]\!]\rangle_{\mathscr{E}_h} \\ & + (e_M, (v_3 - \varphi^u_{\theta,x_i})')_{\Omega_h} + \langle \widehat{e_M}, [\![(\varphi^u_{\theta,x_i} - v_3)\, n]\!]\rangle_{\mathscr{E}_h} \\ & + (e_T, (v_4 - \varphi^u_{w,x_i})')_{\Omega_h}, + \langle \widehat{e_T}, [\![(\varphi^u_{w,x_i} - v_4)\, n]\!]\rangle_{\mathscr{E}_h} \\ & + (e_\theta, v_1 - \varphi^u_{T,x_i})_{\Omega_h} + (e_M/EI, v_2 - \varphi^u_{M,x_i})_{\Omega_h} \\ & + (e_T, v_3 - \varphi^u_{\theta,x_i})_{\Omega_h} - d^2(e_T/GA, v_1 - \varphi^u_{T,x_i})_{\Omega_h}\end{aligned}$$

for any $v_i \in V_h^p$, $i = 1, 2, 3, 4$.

Proof. Since we can write $\Theta^u_i = \Upsilon^u_i + \Delta^u_i$, where

$$\begin{aligned}\Upsilon^u_i := {} & \langle \widehat{e_w}, [\![v_1\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_\theta}, [\![v_2\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_M}, [\![v_3\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_T}, [\![v_4\, n]\!]\rangle_{\mathscr{E}_h}, \\ \Delta^u_i := {} & \langle \widehat{e_w}, [\![(\varphi^u_{T,x_i} - v_1)\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_\theta}, [\![(\varphi^u_{M,x_i} - v_2)\, n]\!]\rangle_{\mathscr{E}_h} \\ & + \langle \widehat{e_M}, [\![(\varphi^u_{\theta,x_i} - v_3)\, n]\!]\rangle_{\mathscr{E}_h} + \langle \widehat{e_T}, [\![(\varphi^u_{w,x_i} - v_4)\, n]\!]\rangle_{\mathscr{E}_h},\end{aligned}$$

we only have to find an expression for Υ^u_i.

To do that, we proceed as follows. First, note that by the definition of Green's functions, we have

$$\begin{aligned} -(e_w, (\varphi^u_{T,x_i})')_{\Omega_h} &= 0, \\ -(e_\theta, (\varphi^u_{M,x_i})')_{\Omega_h} &= (e_\theta, \varphi^u_{T,x_i})_{\Omega_h}, \\ -(e_M, (\varphi^u_{\theta,x_i})')_{\Omega_h} &= (e_M/IE, \varphi^u_{M,x_i})_{\Omega_h}, \\ -(e_T, (\varphi^u_{w,x_i})')_{\Omega_h} &= (e_T, \varphi^u_{\theta,x_i} - d^2\,\varphi^u_{T,x_i}/GA)_{\Omega_h}. \end{aligned}$$

We add these equations and then subtract the result from the addition of all the error equations (3.1). After rearranging terms, we obtain the expression for Υ^u_i we were

seeking, namely,

$$\begin{aligned}\Upsilon_i^u &= \langle \widehat{e_w}, [\![v_1\, n]\!] \rangle_{\mathscr{E}_h} + \langle \widehat{e_\theta}, [\![v_2\, n]\!] \rangle_{\mathscr{E}_h} + \langle \widehat{e_M}, [\![v_3\, n]\!] \rangle_{\mathscr{E}_h} + \langle \widehat{e_T}, [\![v_4\, n]\!] \rangle_{\mathscr{E}_h} \\ &= (e_w, (v_1 - \varphi^u_{T,x_i})')_{\Omega_h} + (e_\theta, (v_2 - \varphi^u_{M,x_i})')_{\Omega_h} \\ &\quad + (e_M, (v_3 - \varphi^u_{\theta,x_i})')_{\Omega_h} + (e_T, (v_4 - \varphi^u_{w,x_i})')_{\Omega_h} \\ &\quad + (e_\theta, v_1 - \varphi^u_{T,x_i})_{\Omega_h} + (e_M/EI, v_2 - \varphi^u_{M,x_i})_{\Omega_h} \\ &\quad + (e_T, v_3 - \varphi^u_{\theta,x_i})_{\Omega_h} - d^2 (e_{T,x_i}/GA, v_1 - \varphi^u_{T,x_i})_{\Omega_h}.\end{aligned}$$

The expression for Θ_i^u immediately follows. This completes the proof. ∎

The second result is needed to evaluate the expression for Θ_i^u.

LEMMA 3.5. *For any functions e, φ in $H^1(\Omega_h)$, set*

$$R = (e, (\pi^\pm \varphi - \varphi)')_{\Omega_h} + \langle \widehat{e}^{\,\mp}, [\![(\varphi - \pi^\pm \varphi)\, n]\!] \rangle_{\mathscr{E}_h},$$

where $\widehat{e}^{\,\mp}(x_j) = e(x_j^\mp)$ for $j = 1, \dots, N-1$. Then

$$R = ((e - \pi^\mp e)', \pi^\pm \varphi - \varphi)_{\Omega_h} - \langle (e - \widehat{e}^{\,\mp}), (\pi^\pm \varphi - \varphi)\, n \rangle_{\partial\Omega^\pm},$$

where

$$\begin{aligned}\langle (e - \widehat{e}^{\,-}), (\pi^+ \varphi - \varphi)\, n \rangle_{\partial\Omega^+} &= (e(1^-) - \widehat{e}^{\,-}(1))\, (\pi^+ \varphi - \varphi)(1^-), \\ \langle (e - \widehat{e}^{\,+}), (\pi^- \varphi - \varphi)\, n \rangle_{\partial\Omega^-} &= -(e(0^+) - \widehat{e}^{\,\mp}(0))\, (\pi^- \varphi - \varphi)(0^+).\end{aligned}$$

Proof. After a simple integration by parts, we get

$$\begin{aligned}R =& - (e', \pi^\pm \varphi - \varphi)_{\Omega_h} + \langle 1, [\![(e - \widehat{e}^{\,\mp})(\pi^\pm \varphi - \varphi)\, n]\!] \rangle_{\mathscr{E}_h} \\ =& ((e - \pi^\mp e)', \pi^\pm \varphi - \varphi)_{\Omega_h} - \langle 1, [\![(e - \widehat{e}^{\,\mp})(\pi^\pm \varphi - \varphi)\, n]\!] \rangle_{\mathscr{E}_h},\end{aligned}$$

by the orthogonality properties of the operators $\pi^\pm$, (3.2a).

Now, by the definition of the operators $\pi^\pm$ at the borders of the intervals, (3.2b), and by the definition of the numerical trace $\widehat{e}^{\,\mp}$, we have

$$-\langle 1, [\![(e - \widehat{e}^{\,\mp})(\pi^\pm \varphi - \varphi)\, n]\!] \rangle_{\mathscr{E}_h} = -\langle (e - \widehat{e}^{\,\mp}), (\pi^\pm \varphi - \varphi)\, n \rangle_{\partial\Omega^\pm},$$

and the result follows. This completes the proof. ∎

We are now ready to prove our representation result.

Proof of Lemma 3.3. We begin by noting that, by the definition of the Green's functions, (2.17) and (2.18), we have

$$\Theta_i^u = \widehat{e_u}(x_i).$$

On the other hand, setting $(v_1, v_2, v_3, v_4) = (\pi^+ \varphi^u_{T,x_i}, \pi^+ \varphi^u_{M,x_i}, \pi^- \varphi^u_{\theta,x_i}, \pi^- \varphi^u_{w,x_i})$ in Lemma 3.4 ,we get

$$\begin{aligned}\widehat{e_u}(x_i) =& (e_w, (\pi^+ \varphi^u_{T,x_i} - \varphi^u_{T,x_i})')_{\Omega_h} + \langle \widehat{e_w}, [\![(\varphi^u_{T,x_i} - \pi^+ \varphi^u_{T,x_i})\, n]\!] \rangle_{\mathscr{E}_h} \\ &+ (e_\theta, (\pi^+ \varphi^u_{M,x_i} - \varphi^u_{M,x_i})')_{\Omega_h} + \langle \widehat{e_\theta}, [\![(\varphi^u_{M,x_i} - \pi^+ \varphi^u_{M,x_i})\, n]\!] \rangle_{\mathscr{E}_h} \\ &+ (e_M, (\pi^- \varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i})')_{\Omega_h} + \langle \widehat{e_M}, [\![(\varphi^u_{\theta,x_i} - \pi^- \varphi^u_{\theta,x_i})\, n]\!] \rangle_{\mathscr{E}_h} \\ &+ (e_T, (\pi^- \varphi^u_{w,x_i} - \varphi^u_{w,x_i})')_{\Omega_h}, + \langle \widehat{e_T}, [\![(\varphi^u_{w,x_i} - \pi^- \varphi^u_{w,x_i})\, n]\!] \rangle_{\mathscr{E}_h} \\ &+ (e_\theta, \pi^+ \varphi^u_{T,x_i} - \varphi^u_{T,x_i})_{\Omega_h} + (e_M/EI, \pi^+ \varphi^u_{M,x_i} - \varphi^u_{M,x_i})_{\Omega_h} \\ &+ (e_T, \pi^- \varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i})_{\Omega_h} - d^2 (e_T/GA, \pi^+ \varphi^u_{T,x_i} - \varphi^u_{T,x_i})_{\Omega_h}.\end{aligned}$$

Now, by Lemma 3.5,

$$\begin{aligned}\widehat{e_u}(x_i) = &((e_w-\pi^- e_w)', \pi^+\varphi^u_{T,x_i}-\varphi^u_{T,x_i})_{\Omega_h} - \langle (e_w-\widehat{e_w}), (\pi^+\varphi^u_{T,x_i}-\varphi^u_{T,x_i})\, n\rangle_{\partial\Omega^+}\\ &((e_\theta-\pi^- e_\theta)', \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} - \langle (e_\theta-\widehat{e_\theta}), (\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})\, n\rangle_{\partial\Omega^+}\\ &((e_M-\pi^+ e_M)', \pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h} - \langle (e_M-\widehat{e_M}), (\pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})\, n\rangle_{\partial\Omega^-}\\ &((e_T-\pi^+ e_T)', \pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})_{\Omega_h} - \langle (e_T-\widehat{e_T}), (\pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})\, n\rangle_{\partial\Omega^-}\\ &+ (e_\theta, \pi^+\varphi^u_{T,x_i}-\varphi^u_{T,x_i})_{\Omega_h} + (e_M/EI, \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h}\\ &+ (e_T, \pi^-\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h} - d^2(e_T/GA, \pi^+\varphi^u_{T,x_i}-\varphi^u_{T,x_i})_{\Omega_h}.\end{aligned}$$

Since the operators $\pi^\pm$ reproduce polynomials of degree p (see (3.2)) and since $\pi^+\varphi^u_{T,x_i}=\varphi^u_{T,x_i}$ (notice that φ^u_{T,x_i} is a constant function), we obtain

$$\begin{aligned}\widehat{e_u}(x_i) = &((\theta-\pi^-\theta)', \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} - \langle (e_\theta-\widehat{e_\theta}), (\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})\, n\rangle_{\partial\Omega^+}\\ &((M-\pi^+ M)', \pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h} - \langle (e_M-\widehat{e_M}), (\pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})\, n\rangle_{\partial\Omega^-}\\ &((T-\pi^+ T)', \pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})_{\Omega_h} - \langle (e_T-\widehat{e_T}), (\pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})\, n\rangle_{\partial\Omega^-}\\ &+ (e_M/EI, \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} + (e_T, \pi^-\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h}.\end{aligned}$$

Finally, by the definition of the numerical traces at $\partial\Omega$, (2.13) and (2.14), we have that

$$\begin{aligned}\langle (e_\theta-\widehat{e_\theta}), (\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})\, n\rangle_{\partial\Omega^+} &= e_\theta(1^-)\,(\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})(1^-),\\ \langle (e_M-\widehat{e_M}), (\pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})\, n\rangle_{\partial\Omega^-} &= 0,\\ \langle (e_T-\widehat{e_T}), (\pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})\, n\rangle_{\partial\Omega^-} &= 0,\end{aligned}$$

and hence,

$$\begin{aligned}\widehat{e_u}(x_i) = &((\theta-\pi^-\theta)', \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} + e_\theta(1^-)\,(\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})(1^-)\\ &+ ((M-\pi^- M)', \pi^+\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h} + ((T-\pi^- T)', \pi^+\varphi^u_{w,x_i}-\varphi^u_{w,x_i})_{\Omega_h}\\ &+ (e_M/EI, \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} + (e_T, \pi^-\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h}.\end{aligned}$$

This completes the proof. □

Step 2. *Estimating the errors in the numerical traces.* Here, we apply the approximation results of Lemma 3.2 to the representation formulas of Lemma 3.3 to prove Lemma 2.6.

Proof of Lemma 2.6. From the representation formulas in Lemma 3.3, we get

$$|\widehat{e_u}(x_i)| \le H_1 + H_2 + H_3,$$

where

$$\begin{aligned}H_1 &= |((\pi^-\theta-\theta)',\ \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h}| + |((\pi^+ M-M)',\ \pi^-\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h}|\\ &\quad + |((\pi^+ T-T)',\ \pi^-\varphi^u_{w,x_i}-\varphi^u_{w,x_i})_{\Omega_h}|,\\ H_2 &= |(e_M/EI,\ \pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})_{\Omega_h} + |e_\theta(1^-)(\pi^+\varphi^u_{M,x_i}-\varphi^u_{M,x_i})(1^-)|,\\ H_3 &= |(e_T,\ \pi^-\varphi^u_{\theta,x_i}-\varphi^u_{\theta,x_i})_{\Omega_h}|.\end{aligned}$$

Let us estimate H_1. By using the approximation inequalities of Lemma 3.2, we immediately obtain that

$$H_1 \le C_s\,\frac{h^{\min(s,p)}}{\mathsf{p}^{\min(s,p)}}\,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\,\frac{h^{p+1}}{\mathsf{p}^{p+1}}\,|\varphi^u_{x_i}|_{p+1,\Omega_h}.$$

To estimate H_2, we use the fact that, from the definition of the seminorm $|\cdot|_{\mathscr{A}_h}$, (2.15),

$$\|e_M/EI\|_{0,\Omega_h} \le C\,|\boldsymbol{e}|_{\mathscr{A}_h}\,, \qquad |e_\theta(1^-)| \le C(h/\mathsf{p})^{1/2}\,|\boldsymbol{e}|_{\mathscr{A}_h}$$

to get

$$H_2 \le C_s\ |\boldsymbol{e}|_{\mathscr{A}_h}\ \frac{h^{p+1}}{\mathsf{p}^{p+1}}\,|\varphi^u_{x_i}|_{p+1,\Omega_h}.$$

Here, we have used once again the approximation results of Lemma 3.2.

The estimate of H_3 term is more delicate. To estimate it, we proceed as follows. We begin by noting that, by (3.4c) of Lemma 3.1, we have that

$$(e_T,\psi)_{\Omega_h} = -\left((\xi_T^-)',\xi_\Psi^-\right)_{\Omega_h} + \widehat{e_T}(1)\Psi(1)$$

for any $\psi \in L^2(\Omega_h)$. Taking $\psi = \pi^-\varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i}$ and using the approximation results in Lemma 3.2 we obtain

$$H_3 \le\ C_s\ \frac{h^\sigma}{\mathsf{p}^\sigma}|T|_{\sigma+1,\Omega_h}\frac{h}{\mathsf{p}}|\Psi|_{1,\Omega_h} + |\widehat{e_T}(1)|\left\|\pi^-\varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i}\right\|_{0,\Omega_h},$$

and since

$$|\Psi|_{1,\Omega_h} = |\Psi'|_{0,\Omega_h} = \left\|\pi^-\varphi^u_{\theta,x_i} - \varphi^u_{\theta,x_i}\right\|_{0,\Omega_h} \le C\frac{h^{p+1}}{\mathsf{p}^{p+1}}|\varphi^u_{\theta,x_i}|_{p+1,\Omega_h}$$

for some constant C independent of p, h, and d, we get

$$H_3 \le C_s\left(\frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}}|T|_{\min(p,s)+1,\Omega_h} + |\widehat{e_T}(1)|\right)\ \frac{h^{p+1}}{\mathsf{p}^{p+1}}\,|\varphi^u_{\theta,x_i}|_{p+1,\Omega_h}$$

with $\sigma = \min(p,s)$ in Lemma 3.2.

Thus, we get

$$|\,\widehat{e_u}(x_i)\,| \le C_s\left(|\boldsymbol{e}|_{\mathscr{A}_h} + |\widehat{e_T}(1)| + \frac{h^{\min(s,p)}}{\mathsf{p}^{\min(s,p)}}\,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\right)\ \frac{h^{p+1}}{\mathsf{p}^{p+1}}\,|\varphi^u_{x_i}|_{p+1,\Omega_h}.$$

We clearly see that the estimates for $u = M,\theta,w$ follow from that of $u = T$. Such an estimate immediately follows if we assume that

$$C_s\frac{h^{p+1}}{\mathsf{p}^{p+1}}\ \sup_{y\in(0,1)}\ |\varphi^T_y|_{p+1,\Omega_h} \le \kappa < 1,$$

that is, if h is sufficiently small or p sufficiently big. This completes the proof. ∎

3.3. Proof of Lemma 2.7. Lemma 2.7 follows immediately from the following auxiliary results.

LEMMA 3.6. *We have* $\boldsymbol{e} = \boldsymbol{\xi} + \boldsymbol{\pi e}$ *and* $|\boldsymbol{\pi e}|^2_{\mathscr{A}_h} = J_1 + J_2 + J_3$, *where*

$$\begin{aligned}
J_1 &= -\left(\xi^+_M/EI,\,\pi^+e_M\right)_{\Omega_h} - d^2\left(\xi^+_T/GA,\,\pi^+e_T\right)_{\Omega_h},\\
J_2 &= \xi^+_M(1^-)(\pi^-e_\theta)(1^-) - \xi^+_T(1^-)(\pi^-e_w)(1^-),\\
J_3 &= \left(\xi^-_\theta,\,\pi^+e_T\right)_{\Omega_h} - \left(\xi^+_T,\,\pi^-e_\theta\right)_{\Omega_h}.
\end{aligned}$$

LEMMA 3.7. *We have*

$$
\begin{aligned}
|\boldsymbol{\xi}|_{\mathscr{A}_h} &\le C_s \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h},\\
|\,J_1\,| &\le C_s \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\ |\boldsymbol{\pi e}|_{\mathscr{A}_h},\\
|\,J_2\,| &\le C_s \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\ |\boldsymbol{\pi e}|_{\mathscr{A}_h},\\
|\,J_3\,| &\le C_s \frac{h^{2\min(p,s)+3}}{\mathsf{p}^{2\min(p,s)+3}} \,|\,(T,M,\theta,w)\,|^2_{s,p,\Omega_h}\\
&\quad + C_s\ |\boldsymbol{\pi e}|_{\mathscr{A}_h}\ \frac{h^{\min(p,s)+2}}{\mathsf{p}^{\min(p,s)+3/2}} \,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}.
\end{aligned}
$$

We prove these results in several steps.

Step 1. *Preliminaries.* We begin by rewriting the method in its classical mixed formulation. Thus, if we add (2.5a) to (2.5d) and subtract (2.5b) and (2.5c) from the resulting expression, we obtain, after rearranging terms,

$$
\begin{aligned}
&(M_h/EI, v_2)_{\Omega_h} + d^2\,(T_h/GA, v_1)_{\Omega_h}\\
&\quad - (w_h, v_1')_{\Omega_h} + \langle \widehat{w}_h, [\![v_1\, n]\!]\rangle_{\mathscr{E}_h} - (T_h, v_4')_{\Omega_h} + \langle \widehat{T}_h, [\![v_4\, n]\!]\rangle_{\mathscr{E}_h}\\
&\quad + (\theta_h, v_2')_{\Omega_h} - \langle \widehat{\theta}_h, [\![v_2\, n]\!]\rangle_{\mathscr{E}_h} + (M_h, v_3')_{\Omega_h} - \langle \widehat{M}_h, [\![v_3\, n]\!]\rangle_{\mathscr{E}_h}\\
&\quad - (\theta_h, v_1)_{\Omega_h} + (T_h, v_3)_{\Omega_h}\\
&= (q, v_4)_{\Omega_h}.
\end{aligned}
$$

Inserting the definition of the numerical traces, (2.12), (2.13), and (2.14), and moving to the right-hand side all the terms containing boundary data, we obtain

$$
\mathscr{A}_h(T_h, M_h, \theta_h, w_h;\, v_1, v_2, v_3, v_4) = b_h(v_1, v_2, v_3, v_4) \quad \forall v_i \in V_h^p, \quad i = 1, 2, 3, 4,
$$

where, writing $\mathscr{A}_h$ for $\mathscr{A}_h(u_1, u_2, u_3, u_4;\, v_1, v_2, v_3, v_4)$,

$$
\begin{aligned}
\mathscr{A}_h &:= (u_2/EI, v_2)_{\Omega_h} + d^2 (u_1/GA, v_1)_{\Omega_h}\\
&\quad + \mathsf{c}\frac{\mathsf{p}}{h_N}\,\big[u_4(1^-)\,v_4(1^-) + u_3(1^-)\,v_3(1^-)\big]\\
&\quad + \mathscr{S}_h(u_1, u_2, u_3, u_4;\, v_1, v_2, v_3, v_4),
\end{aligned}
\tag{3.5}
$$

and, writing $\mathscr{S}_h$ for $\mathscr{S}_h(u_1, u_2, u_3, u_4;\, v_1, v_2, v_3, v_4)$,

$$
\begin{aligned}
\mathscr{S}_h &:= -(u_4, v_1')_{\Omega_h} - (u_1, v_4')_{\Omega_h} + \sum_{j=1}^{N-1} \Big(u_4^-\,[\![v_1\, n]\!] + u_1^+\,[\![v_4\, n]\!]\Big)(x_j)\\
&\quad - u_1(0^+)\,v_4(0^+) + u_1(1^-)\,v_4(1^-)\\
&\quad + (u_3, v_2')_{\Omega_h} + (u_2, v_3')_{\Omega_h} - \sum_{j=1}^{N-1} \Big(u_3^-\,[\![v_2\, n]\!] + u_2^+\,[\![v_3\, n]\!]\Big)(x_j)\\
&\quad - u_2(0^+)\,v_3(0^+) + u_2(1^-)\,v_3(1^-)\\
&\quad - (u_3, v_1)_{\Omega_h} + (u_1, v_3)_{\Omega_h}.
\end{aligned}
$$

Finally,

$$b_h(v_1,v_2,v_3,v_4) := (q,v_4)_{\Omega_h} + \mathsf{c}\frac{\mathsf{p}}{h_N}\left[\, w_1\, v_4(1^-) - \theta_1\, v_3(1^-)\right] + w_0\, v_1(0^+) - w_1\, v_1(1^-) - \theta_0\, v_2(0^+) + \theta_1\, v_2(1^-).$$

The first property we are going to use is the so-called Galerkin orthogonality, namely,

$$\mathscr{A}_h(e_T, e_M, e_\theta, e_w;\, v_1, v_2, v_3, v_4) = 0 \quad \forall v_i \in V_h^p, \tag{3.6}$$

and it follows directly from the error equations (3.1). The second property is that

$$|\boldsymbol{v}|_{\mathscr{A}_h} = \mathscr{A}_h(\boldsymbol{v},\boldsymbol{v})^{1/2} \qquad \text{for any } \boldsymbol{v} \in [V_h^p]^4. \tag{3.7}$$

Indeed, a simple calculation shows that $\mathscr{S}_h(v_1,v_2,v_3,v_4;\, v_1,v_2,v_3,v_4) \equiv 0$.

Step 2. *Proof of the auxiliary Lemma* 3.6. We have

$$\begin{aligned}
|\boldsymbol{\pi e}|^2_{\mathscr{A}_h} &= \mathscr{A}_h(\boldsymbol{\pi e};\, \boldsymbol{\pi e}) && \text{by (3.7)},\\
&= \mathscr{A}_h(\boldsymbol{e}-\boldsymbol{\xi};\, \boldsymbol{\pi e}) && \text{by (3.3b)},\\
&= -\mathscr{A}_h(\boldsymbol{\xi};\, \boldsymbol{\pi e}) && \text{by (3.6)},\\
&= -\left(\xi_M^+/EI,\, \pi^+ e_M\right)_{\Omega_h} - d^2\left(\xi_T^+/GA,\, \pi^+ e_T\right)_{\Omega_h}\\
&\quad + \xi_M^+(1^-)(\pi^- e_\theta)(1^-) - \xi_T^+(1^-)(\pi^- e_w)(1^-)\\
&\quad + \left(\xi_\theta^-,\, \pi^+ e_T\right)_{\Omega_h} - \left(\xi_T^+,\, \pi^- e_\theta\right)_{\Omega_h} && \text{by (3.2)},\\
&= J_1 + J_2 + J_3,
\end{aligned}$$

as claimed. This completes the proof of Lemma 3.6.

Step 3. *Estimate of* $|\boldsymbol{\xi}|_{\mathscr{A}_h}$. We have

$$\begin{aligned}
|\boldsymbol{\xi}|^2_{\mathscr{A}_h} &= \left(\xi_M^+/EI, \xi_M^+\right)_{\Omega_h} + d^2\left(\xi_T^+/GA, \xi_T^+\right)_{\Omega_h} + \mathsf{c}\frac{\mathsf{p}}{h_N}\left(\llbracket \xi_\theta^-\, n\rrbracket^2(1) + \llbracket \xi_w^-\, n\rrbracket^2(1)\right)\\
&= \left(\xi_M^+/EI, \xi_M^+\right)_{\Omega_h} + d^2\left(\xi_T^+/GA, \xi_T^+\right)_{\Omega_h},
\end{aligned}$$

by definition of π^-, (3.2). Hence,

$$\begin{aligned}
|\boldsymbol{\xi}|_{\mathscr{A}_h} &\le C_s\left(\left\|\xi_M^+\right\|_{0,\Omega_h} + \left\|\xi_T^+\right\|_{0,\Omega_h}\right)\\
&\le C_s \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}}\, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h}
\end{aligned}$$

for some constant C_s depending solely on s, by the approximation results of Lemma 3.2 with $\sigma = \min(p,s)$ for T and $\sigma = \min(p,s+1)$ for M. This completes the proof of the estimate.

Step 4. *Estimate of* J_1. To estimate J_1, we proceed as follows:

$$\begin{aligned}
|\,J_1\,| &\le |\left(\xi_M^+/EI,\, \pi^+ e_M\right)_{\Omega_h}| + d^2|\left(\xi_T^+/GA,\, \pi^+ e_T\right)_{\Omega_h}|\\
&\le C\left\|\xi_M^+\right\|_{0,\Omega_h} |\boldsymbol{\pi e}|_{\mathscr{A}_h} + Cd\left\|\xi_T^+\right\|_{0,\Omega_h} |\boldsymbol{\pi e}|_{\mathscr{A}_h}\\
&\le C_s\, \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}}\, |\,(T,M,\theta,w)\,|_{s,p,\Omega_h}\, |\boldsymbol{\pi e}|_{\mathscr{A}_h},
\end{aligned}$$

by the approximation results of Lemma 3.2 with $\sigma = \min(p,s)$ for T and $\sigma = \min(p,s+1)$ for M.

Step 5. *Estimate of* J_2. The estimate of J_2 is obtained in a similar way. We have

$$\begin{aligned}
|\, J_2 \,| &\le |\, \xi_M^+(1^-)(\pi^- e_\theta)(1^-) \,| + |\, \xi_T^+(1^-)(\pi^- e_w)(1^-) \,| \\
&\le \left(|\, \xi_M^+(1^-) \,|^2 + |\, \xi_T^+(1^-) \,|^2\right)^{1/2} \left(|\, (\pi^- e_\theta)(1^-) \,|^2 + |\, (\pi^- e_w)(1^-) \,|^2\right)^{1/2} \\
&= \frac{h_N^{1/2}}{\mathsf{p}^{1/2}} \left(|\, \xi_M^+(1^-) \,|^2 + |\, \xi_T^+(1^-) \,|^2\right)^{1/2} |\boldsymbol{\pi e}|_{\mathscr{A}_h} \quad \text{by definition of } |\cdot|_{\mathscr{A}_h},\ (2.15), \\
&\le C_s \frac{h^{\min(p,s)+1}}{\mathsf{p}^{\min(p,s)+1}} \,|\, (T, M, \theta, w) \,|_{s,p,\Omega_h} \,|\boldsymbol{\pi e}|_{\mathscr{A}_h} \,,
\end{aligned}$$

by the approximation results of Lemma 3.2 with $\sigma = \min(p, s)$ for T and $\sigma = \min(p, s+1)$ for M.

Step 6. *Estimate of* J_3. The estimate of this term requires a very delicate analysis captured in the following auxiliary result.

LEMMA 3.8. *Assume that in the interval* $I = (a, b)$, *we have, for all* $v \in P^p(I)$,

$$\begin{aligned}
&\text{(i)} && -(e, v')_I + \widehat{e}(b)\, v(b) - \widehat{e}(a)\, v(a) = (f, v)_I, \\
&\text{(ii)} && (\xi, v')_I = 0, \\
&\text{(iii)} && \pi e \in P^p(I).
\end{aligned}$$

Then,

$$|\, (\xi, \pi e)_I \,| \le C\, \frac{h^{1/2}}{p^{1/2}} \left(\frac{h}{p} \,\|\, f \,\|_{L^\infty(I)} + \min_{c \in \{a,b\}} |\, \widehat{e}(c) - \pi e(c) \,| \right) \,\|\, \xi \,\|_{0,I},$$

where $h = b - a$ *and* C *is independent of* h, p, *and* e.

Proof. By (iii), we can write $\pi e = \mathbb{P}_{p-1} e + \alpha \ell_p$, where $\mathbb{P}_{p-1}$ is the L^2-projection into $P^{p-1}(I)$, and $\ell_n(x) = P_n\left(\frac{x-(a+b)/2}{h/2}\right)$, where P_n is the Legendre polynomial of degree n. By (ii), this implies that

$$(\xi, \pi e)_I = (\xi, \mathbb{P}_{p-1} e + \alpha \ell_p)_I = \alpha\, (\xi, \ell_p)_I,$$

and, since $\|\, \ell_p \,\|_{0,I}^2 = h/(2\,p+1)$, we get

$$|\, (\xi, \pi e)_I \,| \le |\, \alpha \,| \left(\frac{h}{2\,p+1} \right)^{1/2} \|\, \xi \,\|_{0,I} \le |\, \alpha \,| \, \frac{h^{1/2}}{p^{1/2}} \,\|\, \xi \,\|_{0,I}.$$

It remains to estimate $|\, \alpha \,|$.

Since $|\, \ell_p(c) \,| = 1$, we immediately get that

$$\alpha = \ell_p(c)(-\mathbb{P}_{p-1} e(c) + \pi e(c)).$$

This implies that to estimate α, we need to obtain an expression for $\mathbb{P}_{p-1} e(c)$. We claim that, for $c \in \{a, b\}$,

$$\mathbb{P}_{p-1} e(x) = \widehat{e}(c) - \mathbb{P}_{p-1} g_c(x) \qquad \text{for } x \in I,$$

where $g_c(x) = \int_x^c f(s)\, ds$. Assuming that this is true, we obtain

$$\begin{aligned}
|\, \alpha \,| &\le |\, \mathbb{P}_{p-1} g_c(c) \,| + |\, \pi e(c) - \widehat{e}(c) \,| \\
&\le |\, \mathbb{P}_{p-1} g_c(c) - g_c(c) \,| + |\, \pi e(c) - \widehat{e}(c) \,| \\
&\le C\, \frac{h}{p} \,\|\, f \,\|_{L^\infty(I)} + |\, \pi e(c) - \widehat{e}(c) \,|,
\end{aligned}$$

and the result follows.

It remains to prove the claim. Let us begin with the case $c = a$. Since, by (i),

$$-(e, v')_I + (\widehat{e}(b) - \widehat{e}(a))\, v(b) + \widehat{e}(a)\,(v(b) - v(a)) = (f, v)_I,$$

we get

$$(-e + \widehat{e}(a), v')_I = (f, v)_I - (\widehat{e}(b) - \widehat{e}(a))\, v(b).$$

Setting $v = 1$ in (i), we obtain that

$$\widehat{e}(b) - \widehat{e}(a) = (f, 1)_I,$$

and so

$$(-e + \widehat{e}(a), v')_I = (f, v - v(b))_I = (g_a, v')_I,$$

and the claim follows. The case $c = b$ is proven in a similar way.

This completes the proof. □

We are now ready to estimate $J_3 = (\xi_\theta^-,\, \pi^+ e_T)_{\Omega_h} - (\xi_T^+,\, \pi^- e_\theta)_{\Omega_h}$. Let us begin by noting that

$$(\xi_\theta^-,\, \pi^+ e_T)_{\Omega_h} = 0.$$

To see this, notice that the previous lemma is satisfied with $e = e_T$, $\xi = \xi_\theta^-$, $\pi = \pi^+$, and $f = 0$, thanks to the error equation (3.1d), and that, by the definition of the numerical trace $\widehat{e_T}$ we have that $\widehat{e_T}(x_j) = e_T(x_j^+) = \pi^+ e_T(x_j)$ for $j = 0, \ldots, N-1$.

This implies that

$$|\, J_3 \,| \le \sum_{j=1}^{N} |\, (\xi_T^+,\, \pi^- e_\theta)_{I_j} \,|.$$

To estimate each of the terms of the right-hand side, we use Lemma 3.8 once more. By the error equation (3.1b), the result holds with $e = e_\theta$, $\xi = \xi_T^+$, $\pi = \pi^-$ and $f = e_M/EI$. Hence,

$$|\, (\xi_T^+,\, \pi^- e_\theta)_{I_j} \,| \le C\, \frac{h_j^{1/2}}{p^{1/2}} \left(\frac{h_j}{p} \| \, e_M/EI \, \|_{L^\infty(I_j)} + \Xi_j \right) \| \, \xi_T^+ \, \|_{0,I_j},$$

where $\Xi_j := \min_{c \in \{x_{j-1}, x_j\}} |\, \widehat{e}_\theta(c) - \pi^- e_\theta(c) \,|$. Since $\Xi_j = 0$ for $j = 1, \ldots, N-1$, and $\Xi_N = e_\theta(1^-) = \pi^- e_\theta(1^-)$, and since

$$\begin{aligned} \| \, e_M/EI \, \|_{L^\infty(I_j)} &\le \| \, (M - \pi^+ M)/EI \, \|_{L^\infty(I_j)} + \| \, \pi^+ e_M/EI \, \|_{L^\infty(I_j)} \\ &\le C_s\, \frac{h_j^{\min(p,s)+1/2}}{p^{\min(p,s)+1/2}}\, |\, M \,|_{\min(p,s+1)+1, I_j} \\ &\quad + C_s\, \frac{p}{h_j^{1/2}} \| \, \pi^+ e_M \, \|_{0,I_j}, \end{aligned}$$

by the approximation result of Lemma 3.2 with $\sigma = \min(p, s+1)$, we get

$$\begin{aligned} |\, J_3 \,| &\le C_s\, \frac{h^{\min(p,s)+2}}{p^{\min(p,s)+2}}\, |\, M \,|_{\min(p,s+1)+1, \Omega_h} \| \, \xi_T^+ \, \|_{0,\Omega_h} \\ &\quad + C_s \left(\frac{h}{p^{1/2}} \| \, \pi^+ e_M/EI \, \|_{0,\Omega_h} + \frac{h^{1/2}}{p^{1/2}}\, |\, \pi^- e_\theta(1^-) \,| \right) \| \, \xi_T^+ \, \|_{0,\Omega_h} \\ &\le C_s \left(\frac{h^{\min(p,s)+2}}{p^{\min(p,s)+2}}\, |\, M \,|_{\min(p,s+1)+1, \Omega_h} + \frac{h}{p^{1/2}}\, |\boldsymbol{\pi e}|_{\mathscr{A}_h} \right) \| \, \xi_T^+ \, \|_{0,\Omega_h} \end{aligned}$$

by the definition of the energy seminorm $|\cdot|_{\mathscr{A}_h}$, (2.15). Finally, using the approximation results of Lemma 3.2, we get

$$\begin{aligned}|\,J_3\,| \le & C_s\,\frac{h^{2\min(p,s)+3}}{p^{2\min(p,s)+3}}\,|\,(T,M,\theta,w)\,|^2_{s,p,\Omega_h}\\ &+ C_s\;|\boldsymbol{\pi e}|_{\mathscr{A}_h}\,\frac{h^{\min(p,s)+2}}{p^{\min(p,s)+3/2}}\,|\,(T,M,\theta,w)\,|_{s,p,\Omega_h}.\end{aligned}$$

This completes the proof of Lemma 3.6 and hence that of our main results.

4. Extensions.

4.1. Uniform convergence for piecewise-constant approximations. In the case of piecewise-constant approximation, $p = 0$, we obtain the following result.

THEOREM 4.1. *Assume that, for some $s \ge 0$, (T, M, θ, w) belongs to $H^{s+1}(\Omega_h) \times H^{s+2}(\Omega_h) \times H^{s+3}(\Omega_h) \times H^{s+2}(\Omega_h)$. Assume also that $q \in L^\infty(\Omega_h)$. Set*

$$\boldsymbol{e} := (e_T, e_M, e_\theta, e_w) = (T - T_h, M - M_h, \theta - \theta_h, w - w_h),$$

where $(T_h, M_h, \theta_h, w_h)$ is the approximation given by the DG method (2.5), (2.12), (2.13), *and* (2.14) *with $p = 0$. Then, for small enough h, we have that, for $u = T, M, \theta$, or w,*

$$\|\,e_u\,\|_{L^\infty(\Omega_h)} + \frac{\mathsf{c}}{h}\left(|\,e_\theta(1^-)\,| + |\,e_w(1^-)\,|\right) \le C_s\,h\,\left(\|\,q\,\|_{L^\infty(\Omega_h)} + |\,(T,M,\theta,w)\,|_{s,0,\Omega_h}\right)$$

for some constant C_s independent of h and d.

This result implies that the DG method in its specific form, which we discussed here, does not suffer from shear locking, even if it uses piecewise-constant approximation for all the unknowns. It also implies the unexpected superconvergence of the approximations to w and θ superconverge at the border $x = 1$.

Proof. To prove this result, we only have to slightly modify the proof of our main results. Indeed, we only have to modify the estimate of the terms J_3 in Lemma 3.7. We proceed in several steps.

Step 1. *Estimate of J_3.* We estimate such a term as follows:

$$\begin{aligned}J_3 &= (\xi_\theta^-,\,\pi^+ e_T)_{\Omega_h} - (\xi_T^+,\,\pi^- e_\theta)_{\Omega_h}\\ &= \sum_{j=1}^{N}\left((\xi_\theta^-,\,e_T(x_{j-1}^+))_{I_j} - (\xi_T^+,\,e_\theta(x_j^-))_{I_j}\right) \qquad \text{by definition of } \pi^\pm,\ (3.2),\\ &= \sum_{j=1}^{N}(\xi_\theta^-,1)_{I_j}\,\widehat{e_T}(x_j) - \sum_{j=1}^{N-1}(\xi_T^+,1)_{I_j}\,\widehat{e_\theta}(x_j) - (\xi_T^+,1)_{I_N}\,e_\theta(1^-),\end{aligned}$$

by the definition of the numerical traces $\widehat{T}_h$ and $\widehat{\theta}_h$, (2.12)–(2.14). Hence

$$\begin{aligned}|\,J_3\,| &\le C_s\left(\|\widehat{e_T}\|_{L^\infty(\mathscr{E}_h)} + \|\widehat{e_\theta}\|_{L^\infty(\mathscr{E}_h)} + |\pi\boldsymbol{e}|_{\mathscr{A}_h}\right)\,h\,(|\,\theta\,|_{1,\Omega_h} + |\,T\,|_{1,\Omega_h})\\ &\le C_s\left(\|\widehat{e_T}\|_{L^\infty(\mathscr{E}_h)} + \|\widehat{e_\theta}\|_{L^\infty(\mathscr{E}_h)} + |\pi\boldsymbol{e}|_{\mathscr{A}_h}\right)\,h\,|\,(T,M,\theta,w)\,|_{s,0,\Omega_h},\end{aligned}$$

by the definition of $|\cdot|_{\mathscr{A}_h}$, (2.15), and the approximation results of Lemma 3.2.

Step 2. *Estimate of* $|\,\widehat{e_u}(x_i)\,|$. Combining the above estimate with the results of Lemmas 3.6 and 3.7, we easily get

$$|\boldsymbol{e}|_{\mathscr{A}_h} \leq C_s\, h \left(\|\widehat{e_T}\|_{L^\infty(\mathscr{E}_h)} + \|\widehat{e_\theta}\|_{L^\infty(\mathscr{E}_h)} + |\,(T,M,\theta,w)\,|_{s,0,\Omega_h} \right).$$

Inserting this estimate into the estimate of Lemma 2.6, we get

$$|\,\widehat{e_u}(x_i)\,| \leq C_s\, h \left(\|\widehat{e_T}\|_{L^\infty(\mathscr{E}_h)} + \|\widehat{e_\theta}\|_{L^\infty(\mathscr{E}_h)} + |\,(T,M,\theta,w)\,|_{s,0,\Omega_h} \right),$$

which implies that, for small enough h,

$$|\,\widehat{e_u}(x_i)\,| \leq C_s\, h |\,(T,M,\theta,w)\,|_{s,0,\Omega_h}.$$

Step 3. *Estimate of* $\|\,e_T\,\|_{L^\infty(\Omega_h)}$ *and* $\|\,e_w\,\|_{L^\infty(\Omega_h)}$. Let us begin by estimating the error in T. For $x \in I_j$, we have

$$\begin{aligned} |\,e_T(x)\,| &= |\,T(x) - T(x_{j-1}) + e_T(x_{j-1}^+)\,| \\ &= |\,T(x) - T(x_{j-1}) + \widehat{e_T}(x_{j-1})\,| \\ &\leq C\, h\, \|\,T'\,\|_{L^\infty(I_j)} + |\,\widehat{e_T}(x_{j-1})\,|, \end{aligned}$$

and, since $T' = q$,

$$\|\,e_T\,\|_{L^\infty(\Omega_h)} \leq C\, h\, \left(\|\,q\,\|_{L^\infty(\Omega_h)} + |\,(T,M,\theta,w)\,|_{s,0,\Omega_h} \right).$$

Now, let us estimate the error in w. For $x \in I_j$, $j = 1, \ldots, N-1$,

$$\begin{aligned} |\,e_w(x)\,| &= |\,w(x) - w(x_j) + e_w(x_j^-)\,| \\ &= |\,w(x) - w(x_j) + \widehat{e_w}(x_j)\,| \\ &\leq C\, h\, \|\,w'\,\|_{L^\infty(I_j)} + |\,\widehat{e_T}(x_{j-1})\,|, \end{aligned}$$

and, since $w' = \theta - d^2\, T/GA$,

$$\|\,e_w\,\|_{L^\infty(I_j)} \leq C\, h\, |\,(T,M,\theta,w)\,|_{s,0,\Omega_h}.$$

It remains to consider the interval I_N. It enough to show that $e_w(1^-)$ is of order h^2. To do that, we note that, by the definition of $\widehat{T}_h(1)$,

$$e_w(1^-) = \frac{h}{\mathsf{c}}(\widehat{e_T}(1) - e_T(1^-)),$$

and hence,

$$|\,e_w(1^-)\,| \leq C\, \frac{h^2}{\mathsf{c}} \left(\|\,q\,\|_{L^\infty(\Omega_h)} + |\,(T,M,\theta,w)\,|_{s,0,\Omega_h} \right).$$

This implies that

$$\|\,e_w\,\|_{L^\infty(I_N)} \leq C\, h\, \|\,w'\,\|_{L^\infty(I_j)} + |\,e_w(1^-)\,|,$$

and since $w' = \theta - d^2\, T/GA$,

$$\|\,e_w\,\|_{L^\infty(I_N)} \leq C\, h\, |\,(T,M,\theta,w)\,|_{s,0,\Omega_h}.$$

Step 4. *Conclusion.* The estimates of $\|\,e_M\,\|_{L^\infty(\Omega_h)}$, $\|\,e_\theta\,\|_{L^\infty(\Omega_h)}$, and $|\,e_\theta(1^-)\,|$ can be obtained in a similar way. This completes the proof. ∎

4.2. The *hp*-version of the method. It is straightforward to extend the error analysis we have presented to the DG method that takes the approximation $(T_h, M_h, \theta_h, w_h)$ on the interval I_j in the space $P^{p_j}(I_j) \times P^{p_j}(I_j) \times P^{p_j}(I_j) \times P^{p_j}(I_j)$. It is also possible to choose different polynomial degrees for different variables in each interval according to Theorem 2.1; see [10].

4.3. Two other families of locking-free DG methods. In this paper we have analyzed a specific DG method, namely, the method which corresponds to Case 2 of Theorem 2.1. Reasons for concentrating on this particular case were given in section 2.3. In this subsection we briefly mention theoretical results for DG methods corresponding to Cases 1 and 3 of Theorem 2.1.

Given a polynomial degree $p \geq 0$, let

$$C_{14}(x) = -C_{23}(x) = -C_{32}(x) = C_{41}(x) = \mathsf{c} \quad \forall x \in \mathscr{E}_h$$

for some arbitrary positive number c independent of the mesh-size h or the polynomial degree p. Suppose further that

$$(C_{ii}(x) - 1/2)^2 \leq \mathsf{c} \qquad \text{for } i = 1, 2, 3, 4,$$
$$C_{12}^2(x),\, C_{13}^2(x),\, C_{21}^2(x),\, C_{24}^2(x),\, C_{31}^2(x),\, C_{34}^2(x),\, C_{42}^2(x),\, C_{43}^2 \leq \mathsf{c}$$

for all $x \in \mathscr{E}_h$.

Suppose that the polynomial degrees defining the DG method are such that $p_i = p$ for $i = 1, 2, 3, 4$. Then, the method defines a unique approximate solution by Case 1 of Theorem 2.1. Moreover, the method is free from shear locking. For these DG methods, the order of convergence of the error in the energy seminorm is now smaller by $1/2$, both in h and in p; this is, however, a sharp estimate. The orders of convergence of the errors in the L^2-norm and those of the errors in the numerical traces remain the same.

If we take $p_1 = p_2 = p + 1$ and $p_3 = p_4 = p$, then the existence and uniqueness of the DG approximation is guaranteed by Case 3 of Theorem 2.1. These methods as well are free from shear locking. On the other hand, although they have more degrees of freedom, the orders of convergence remain the same as ones for the methods with $p_i = p$ for $i = 1, 2, 3, 4$. This is simply due to the fact that θ_h and w_h are still being approximated by polynomials of degree p, even though T_h and M_h are being approximated by those of degree $p+1$. Once again, however, these estimates are sharp; see [7].

5. Numerical results. In this section, we display numerical results verifying our theoretical findings. For a set of numerical experiments verifying the superconvergence predicted by Theorem 2.4 we refer to [8]. Therein, it was also shown how to post-process the original DG solution in an element-by-element fashion to obtain a better approximation which converges to the exact solution with order $2\,p + 1$ *uniformly* throughout the domain, rather than just at the nodes of the mesh.

We solve the equations (2.2) with $q(x) = e^x$, $(EI)(x) = e^x$, $(GA)(x) = e^{-x}$ together with the boundary conditions $w_0 = w_1 = \theta_0 = \theta_1 = 0$. To verify that the DG method is locking-free, the thickness of the beam, d, is taken to be 10^{-2} and then decreased to 10^{-16}.

We consider two DG methods. The first is the one analyzed in full detail in this paper; it is defined by the numerical traces (2.12)–(2.14). The second is a particular

example of a class of DG methods analyzed in [7]. Its numerical fluxes are obtained by setting

$$C_{14}(x) = -C_{23}(x) = -C_{32}(x) = C_{41}(x) = 1 \quad \forall x \in \mathscr{E}_h$$

and $C_{ij} = 0$ at all nodes for all the remaining coefficients.

We display our results in Tables 1 through 4. Therein, p indicates the polynomial degree we used to define the DG method, and "mesh = i" means we employed a uniform mesh with 2^i elements. We also display numerical rates of convergence which are computed as follows. Let $e_u(i)$ denote the error where a mesh with 2^i elements has been employed to obtain the DG solution. Then the order of convergence, r_i, at level i is defined as

$$r_i := \frac{\log\left(\frac{e_u(i-1)}{e_u(i)}\right)}{\log 2}.$$

In Tables 1 and 2, we display the numerical results for the first DG method, for $d = 10^{-2}$ and $d = 10^{-16}$, respectively. We see that the optimal rates of convergence predicted by the error estimates given in section 2 are indeed achieved. As predicted by our error estimates the DG method is completely robust with respect to this parameter. In Tables 3 and 4, we display the numerical results for the second DG method. We also see that the predicted orders of convergence are actually achieved. Notice, in particular, that the energy seminorm converges with an order which is smaller by 1/2, as expected.

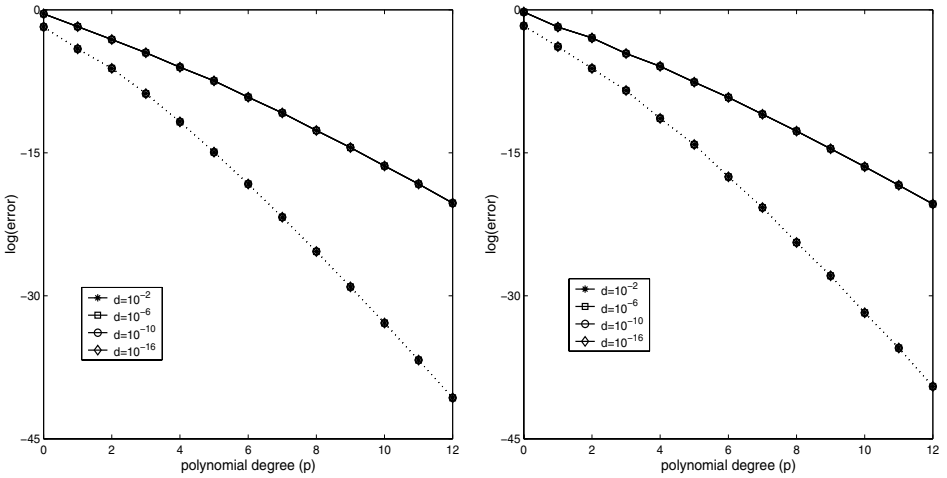

FIG. 2. *Robust exponential convergence for $\lVert e_w\rVert_{0,\Omega_h}$ (solid line) and $\left\lVert \widehat{e_w}\right\rVert_{L^\infty(\mathscr{E}_h)}$ (dotted line). First DG method (left) and second DG method (right).*

In Figure 2, we display the performance of the p-version of both DG methods. On the left we display the semilogarithmic plot of $\|e_w\|_{0,\Omega_h}$ and that of $\|\widehat{e_w}\|_{L^\infty(\mathscr{E}_h)}$ versus the polynomial degree. The DG solution is computed on a uniform mesh with 2 elements, and the polynomial degree is increased from 0 to 12, while the mesh is kept fixed. We display four different plots on the same figure, namely $d = 10^{-2}, d = 10^{-6}, d = 10^{-10}$, and $d = 10^{-16}$. Notice that the curves are practically on top of each other and that the order of convergence of the maximum error in the numerical trace of the displacement is twice as fast as that of the $L^2(\Omega_h)$-norm of its error. Similar results are obtained for the other three variables.

6. Concluding remarks. We have shown that DG methods can be devised which are free from shear locking. We achieved this by a careful study of the relation between the definition of the numerical traces and the corresponding convergence properties of the methods. This provides a powerful approach for devising locking-free DG methods for the much more challenging problems of thin plates and shells which constitutes the subject of ongoing work.

We have not addressed the issue of the actual implementation of the DG methods. In particular, we have not identified DG methods that could be considered extensions of the LDG methods [11] for second-order elliptic problems. This constitutes the subject of ongoing work.

Finally, we note that even though we have carried out our error analysis for the *hp*-version of the methods, we only displayed numerical results for either their h- or p-versions. The study of *hp*-adaptive algorithms for these methods constitutes the subject of ongoing work.

EXISTENCE OF SOLUTIONS TO SYSTEMS OF UNDERDETERMINED EQUATIONS AND SPHERICAL DESIGNS*

XIAOJUN CHEN† AND ROBERT S. WOMERSLEY‡

Abstract. This paper is concerned with proving the existence of solutions to an underdetermined system of equations and with the application to existence of spherical t-designs with $(t+1)^2$ points on the unit sphere S^2 in R^3. We show that the construction of spherical designs is equivalent to solution of underdetermined equations. A new verification method for underdetermined equations is derived using Brouwer's fixed point theorem. Application of the method provides spherical t-designs which are close to extremal (maximum determinant) points and have the optimal order $O(t^2)$ for the number of points. An error bound for the computed spherical designs is provided.

Key words. verification, underdetermined system, spherical designs, extremal points, interpolation, numerical integration

1. Introduction.

Let $c : R^n \to R^m$ be a continuously differentiable function with $m < n$. Suppose that $\hat{x}$ is an approximate solution of the underdetermined system of nonlinear equations

$$c(x) = 0 \tag{1.1}$$

and the Jacobian $c'(x)$ of c at $\hat{x}$ has full row rank. We are interested in the existence of a solution of (1.1) in a neighborhood of $\hat{x}$.

Underdetermined systems of equations arise in constrained optimization problems, continuation methods for underdetermined equations, etc. [3, 12, 14, 21]. This paper gives a verification method for solutions of the underdetermined equations (1.1). The main difficulty in proving the existence of solutions of an underdetermined system of equations is that the Jacobian $c'(x)$ is an $m \times n$ matrix with $m < n$. Let $c'(\hat{x})^+$ be the Moore–Penrose pseudoinverse of $c'(\hat{x})$. A popular method for verifying the existence of solutions of nonlinear equations is to use a Krawczyk-type interval operator [1]. Replacing the inverse by a Moore–Penrose pseudoinverse, we can get a Krawczyk-type interval operator

$$\mathcal{K}(X) = \hat{x} - c'(\hat{x})^+ c(\hat{x}) + (I - c'(\hat{x})^+ C'(X))(X - \hat{x}), \tag{1.2}$$

where X is an interval in R^n defined by

$$X = [\hat{x} - h, \hat{x} + h], \qquad h \in R^n, \quad h \geq 0,$$

and $C'(X)$ is an interval arithmetic evaluation satisfying

$$c'(x) \in C'(X) \qquad \text{for } x \in X.$$

It can be shown [1] that there is a solution of (1.1) in X if

$$\mathcal{K}(X) \subseteq X \tag{1.3}$$

and $c'(\hat{x})$ has full row rank. However, the enclosure (1.3) rarely holds due to the equality [8]

$$\|I - c'(\hat{x})^+ c'(\hat{x})\|_2 = \min\{1, n-m\}$$

and the fact that

$$\mathcal{K}(X) \subseteq X \quad \Rightarrow \quad \|I - c'(\hat{x})^+ c'(x)\|_\infty \leq 1 \quad \forall\, x \in X.$$

In section 2 we present a new verification method for underdetermined systems of (1.1) which does not need the generalized inverse $c'(\hat{x})^+$.

A cubature (numerical integration) rule for the unit sphere $S^2 = \{y \in R^3 \ : \ \|y\|_2 = 1\}$ is a set of N points $y_\ell \in S^2$ and weights w_ℓ for $\ell = 1, \ldots, N$ such that

$$\int_{S^2} f(y)dy \approx \sum_{\ell=1}^{N} w_\ell f(y_\ell).$$

Let $\mathbb{P}_t \equiv \mathbb{P}_t(S^2)$ be the linear space of restrictions of polynomials of degree $\leq t$ in 3 variables to S^2. The dimension of the space $\mathbb{P}_t$ is $d_t := (t+1)^2$. Spherical t-designs, introduced in [5], are sets of N points $\{y_1, y_2, \ldots, y_N\} \subset S^2$ such that the equally weighted ($w_\ell = |S^2|/N = 4\pi/N$, $\ell = 1, \ldots, N$) cubature rule is exact for all spherical polynomials of degree at most t, that is,

$$\int_{S^2} p(y)dy = \frac{4\pi}{N} \sum_{\ell=1}^{N} p(y_\ell) \qquad \forall p \in \mathbb{P}_t.$$

For $t \geq 1$, the existence of a spherical t-design was proved in [19]. Commonly, the interest is in the smallest number N_t^* of points required to give a spherical t-design. Lower bounds on N_t^* given in [5] are

$$N_t^* \geq \frac{(t+1)(t+3)}{4} \quad \text{if } t \text{ is odd},$$
$$N_t^* \geq \frac{(t+2)^2}{4} \quad \text{if } t \text{ is even}.$$

A spherical t-design which achieves the lower bounds is called a tight spherical t-design. However, for $t \geq 2$, it is known that tight spherical t-designs do not exist [5]. Hardin and Sloane [7] have extensively investigated spherical designs on S^2 and suggested a sequence of putative spherical t-designs with $\frac{1}{2}t^2 + o(t^2)$ points. A 7-design with 24 points was first found by McLaren in 1963 [13]. Korevaar and Meyers [10] considered the construction for spherical t-designs with $O(t^3)$ points on S^2. An approach for the numerical calculation of spherical designs using multiobjective optimization was studied by Maier [11], and computational proof of the existence of spherical designs using interval methods [9] was investigated by Hardin and Sloane [7].

Extremal (or maximum determinant) points [20] are sets of $(t+1)^2$ points on S^2 which maximize the determinant of a basis matrix for an arbitrary basis of $\mathbb{P}_t$. Sloan and Womersley [20, 22] showed that extremal systems have very nice geometrical

properties as the points are well separated and the computed interpolatory cubature weights are positive ($w_\ell > |S^2|/(2N)$ for $\ell = 1, \ldots, N$ for degrees up to $t = 150$). Also the condition number of the basis matrix grows slowly, giving confidence in the calculated cubature weights. Proving the positivity of the cubature weights for all degrees t for the extremal points is still an open question. Other systems of points, such as minimum energy points, often have basis matrices with such high condition numbers that no confidence can be placed in the calculated cubature weights.

Equal weight cubature rules, or spherical designs, are simpler to implement and there is no question about the positivity of the weights. There are many different characterizations of spherical t-designs [6]. However, these can be very ill conditioned. Extremal points provide excellent starting points for numerically finding solutions to an underdetermined, but highly nonlinear, system of equations which characterize spherical t-designs with $(t+1)^2$ points. Application of the verification method to the system of equations then proves the existence of spherical t-designs which are close to the calculated points and have the optimal order $O(t^2)$ for the number of points. Moreover, spherical designs with $(t+1)^2$ points which also have a basis matrix with a determinant close to the maximum are simultaneously good for cubature and interpolation. Computed spherical t-designs with $(t+1)^2$ points for degrees up to $t = 50$ are available from http://www.maths.unsw.edu.au/∼rsw/Sphere.

The focus here is not on finding a spherical t-design with the minimal number of points, but rather proving the existence of spherical t-designs with $(t+1)^2$ points close to an extremal system. Once existence of a spherical design with $(t+1)^2$ points is established one can then look for *extremal spherical designs*, that is, systems of $(t+1)^2$ points which maximize the determinant of a basis matrix subject to the constraints that they are spherical t-designs.

In section 3 we reformulate the calculation of a spherical t-design with $(t+1)^2$ points as an underdetermined system of nonlinear equations (1.1) with $m = (t+1)^2-1$ equations and $n = 2(t+1)^2 - 3$ variables. We show that a sufficient and necessary condition for the existence of solutions to the system of equations is existence of a spherical t-design with $(t+1)^2$ points. In section 4, we apply the verification method to find new spherical t-designs. The computed spherical designs $\hat{Y} = \{\hat{y}_1, \ldots, \hat{y}_{d_t}\}$ are compared with the extremal (maximum determinant) points, and error bounds of $\hat{Y}$ to exact spherical designs are given.

For a given $m \times n$ matrix A, let $A_{\mathcal{I}}$ be the submatrix of A whose entries lie in the columns of A indexed by $\mathcal{I}$. For a given vector $x \in R^n$, let $x_{\mathcal{I}}$ be the subvector of x whose entries of x are indexed by $\mathcal{I}$.

2. A verification method. Let $\hat{x}$ be a computed solution of (1.1). Let $\mathcal{B}$ be an index set $\{k_1, k_2, \ldots, k_m\}$ such that $c'_{\mathcal{B}}(\hat{x}) \in R^{m\times m}$ is nonsingular. Define the function $H : R^n \to R^n$ by

$$H_{\mathcal{B}}(x) = x_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1} c(x), \tag{2.1}$$

$$H_{\mathcal{N}}(x) = x_{\mathcal{N}} - \alpha(x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}), \tag{2.2}$$

where $\mathcal{N} = \{1, 2, \ldots, n\}/\mathcal{B}$ and $\alpha \in (0, 1)$ is a constant. Obviously, if $x^* \in R^n$ is a fixed point of H, that is, $H(x^*) = x^*$, then we have $c(x^*) = 0$ with $x^*_{\mathcal{N}} = \hat{x}_{\mathcal{N}}$. Choose two nonnegative numbers r_1 and r_2 and define the convex set

$$X = \{\, x \in R^n : \|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \le r_1, \|x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}\| \le r_2 \,\}.$$

THEOREM 2.1. *Suppose that $c : R^n \to R^m$ is continuously differentiable, c' has full row rank at $\hat{x}$, and*

$$\|c'_{\mathcal{B}}(x) - c'_{\mathcal{B}}(\hat{x})\| \le K\|x - \hat{x}\| \text{ for } x \in X. \tag{2.3}$$

(1) *There is a solution of* (1.1) *in X if*

$$\|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| + \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\left(\frac{1}{2}K(r_1+r_2)r_1 + \max_{x\in X}\|c'_{\mathcal{N}}(x)\|r_2\right) \le r_1. \tag{2.4}$$

(2) *There is no solution of* (1.1) *in X if*

$$\|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| - \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\left(\frac{1}{2}K(r_1+r_2)r_1 + \max_{x\in X}\|c'_{\mathcal{N}}(x)\|r_2\right) > r_1. \tag{2.5}$$

Proof. (1) By the continuity of $c'(x)$ and the mean value theorem, we find

$$\begin{aligned}
H_{\mathcal{B}}(x) &= \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x}) + x_{\mathcal{B}} - \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}(c(x) - c(\hat{x}))\\
&= \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x}) + x_{\mathcal{B}} - \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}\int_0^1 c'(x + t(\hat{x}-x))(x-\hat{x})dt\\
&= \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x}) + x_{\mathcal{B}} - \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}\int_0^1 c'_{\mathcal{B}}(x + t(\hat{x}-x))(x_{\mathcal{B}}-\hat{x}_{\mathcal{B}})dt\\
&\quad - c'_{\mathcal{B}}(\hat{x})^{-1}\int_0^1 c'_{\mathcal{N}}(x + t(\hat{x}-x))(x_{\mathcal{N}}-\hat{x}_{\mathcal{N}})dt\\
&= \hat{x}_{\mathcal{B}} - c'_{\mathcal{B}}(\hat{x})^{-1}\left[c(\hat{x}) + \int_0^1 (c'_{\mathcal{B}}(\hat{x}) - c'_{\mathcal{B}}(x + t(\hat{x}-x)))(x_{\mathcal{B}}-\hat{x}_{\mathcal{B}})dt\right.\\
&\qquad \left. + \int_0^1 c'_{\mathcal{N}}(x + t(\hat{x}-x))(x_{\mathcal{N}}-\hat{x}_{\mathcal{N}})dt\right].
\end{aligned}$$

Therefore, for any $x \in X$, we have

$$\begin{aligned}
&\|H_{\mathcal{B}}(x) - \hat{x}_{\mathcal{B}}\|\\
&\le \|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| + \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\int_0^1 \|c'_{\mathcal{B}}(\hat{x}) - c'_{\mathcal{B}}(x + t(\hat{x}-x))\|\|x_{\mathcal{B}}-\hat{x}_{\mathcal{B}}\|dt\\
&\quad + \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\int_0^1 \|c'_{\mathcal{N}}(x + t(\hat{x}-x))\|\|x_{\mathcal{N}}-\hat{x}_{\mathcal{N}}\|dt\\
&\le \|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| + \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\left(\int_0^1 (1-t)K\|\hat{x}-x\|r_1 dt + \int_0^1 \max_{x\in X}\|c'_{\mathcal{N}}(x)\|r_2 dt\right)\\
&\le \|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| + \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\left(\frac{1}{2}K(r_1+r_2)r_1 + \max_{x\in X}\|c'_{\mathcal{N}}(x)\|r_2\right).
\end{aligned}$$

Here we use the facts that $x + t(\hat{x}-x) \in X$, $\|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \le r_1$, and $\|x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}\| \le r_2$ for all $x \in X$ and $t \in [0,1]$.

This implies that if (2.4) holds, then for any $x \in X$ we have

$$\|H_{\mathcal{B}}(x) - \hat{x}_{\mathcal{B}}\| \le r_1.$$

Moreover, by the definition of H, we always have

$$\|H_{\mathcal{N}}(x) - \hat{x}_{\mathcal{N}}\| = (1-\alpha)\|x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}\| \le r_2.$$

Therefore, (2.4) implies that H maps X into itself; that is,

$$H(x) \in X \quad \text{for any } x \in X. \tag{2.6}$$

Using Brouwer's fixed point theorem, (2.6) implies that there is a fixed point x^* of H in X. From the definition of H, x^* is a solution of (1.1).

(2) Assume that (2.5) holds and there is a solution x^* in X. Following the proof for part (1), we have

$$\begin{aligned}
r_1 &\geq \|x^*_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \\
&= \|H_{\mathcal{B}}(x^*) - \hat{x}_{\mathcal{B}}\| \\
&\geq \|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| - \|c'_{\mathcal{B}}(\hat{x})^{-1}\| \int_0^1 \|c'_{\mathcal{B}}(\hat{x}) - c'_{\mathcal{B}}(x^* + t(\hat{x} - x^*))\|\|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\|dt \\
&\quad -\|c'_{\mathcal{B}}(\hat{x})^{-1}\| \int_0^1 \|c'_{\mathcal{N}}(x^* + t(\hat{x} - x^*))\|\|x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}\|dt \\
&\geq \|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\| - \|c'_{\mathcal{B}}(\hat{x})^{-1}\| \left(\frac{1}{2}K(r_1 + r_2)r_1 + \max_{x\in X}\|c'_{\mathcal{N}}(x)\|r_2\right) > r_1.
\end{aligned}$$

This is a contradiction, which completes the proof. □

Without loss of generality, we assume that $r_1 \neq 0$. Let $\tau \in (0, \frac{1}{2})$. Define a subset of X:

$$X_\tau = \{\, x \mid \|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \leq \tau r_1, \|x_{\mathcal{N}} - \hat{x}_{\mathcal{N}}\| \leq \tau r_2\}.$$

Then we have the following corollary.

COROLLARY 2.2. *Under the assumptions of Theorem* 2.1*, inequality* (2.4) *implies that* $c'_{\mathcal{B}}(x)$ *is nonsingular for all* $x \in X_\tau$ *and the solution* x^* *of* (1.1) *with* $x^*_{\mathcal{N}} = \hat{x}_{\mathcal{N}}$ *is unique in* X_τ.

Proof. For any $x \in X_\tau$ $(x \neq \hat{x})$, inequality (2.4) implies that

$$\begin{aligned}
r_1 &\geq \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\frac{1}{2}K(r_1 + r_2)r_1 \\
&\geq \|c'_{\mathcal{B}}(\hat{x})^{-1}\|\frac{1}{2\tau}K\|x - \hat{x}\|r_1 \\
&> \|c'_{\mathcal{B}}(\hat{x})^{-1}\|K\|x - \hat{x}\|r_1 \\
&\geq r_1\|c'_{\mathcal{B}}(\hat{x})^{-1}\|\|c'_{\mathcal{B}}(\hat{x}) - c'_{\mathcal{B}}(x)\| \\
&\geq r_1\|I - c'_{\mathcal{B}}(\hat{x})^{-1}c'_{\mathcal{B}}(x)\|.
\end{aligned}$$

Dividing r_1 in both sides, we find

$$\|I - c'_{\mathcal{B}}(\hat{x})^{-1}c'_{\mathcal{B}}(x)\| < 1.$$

Hence $c'_{\mathcal{B}}(x)$ is nonsingular. By the implicit function theorem [16], the solution x^* of (1.1) with $x^*_{\mathcal{N}} = \hat{x}_{\mathcal{N}}$ is unique in X_τ. □

Remark 2.1. For the case $m = n$, we have $x = x_{\mathcal{B}}$, $c'_{\mathcal{B}}(x) = c'(x)$, and (2.4) reduces to

$$\|c'(\hat{x})^{-1}c(\hat{x})\| + \frac{1}{2}K\|c'(\hat{x})^{-1}\|r^2 \leq r. \tag{2.7}$$

This is a quadratic inequality in r. If

$$\rho := K\|c'(\hat{x})^{-1}c(\hat{x})\|\|c'(\hat{x})^{-1}\| \le \frac{1}{2}, \tag{2.8}$$

then (2.7) holds for all r satisfying

$$\frac{1-\sqrt{1-2\rho}}{K\|c'(\hat{x})^{-1}\|} \le r \le \frac{1+\sqrt{1-2\rho}}{K\|c'(\hat{x})^{-1}\|}.$$

By Theorem 2.1, there is a solution in $X = \{x \in R^n : \|x - \hat{x}\| \le r\}$. Therefore, Theorem 2.1 is a generalization of the Kantorovich theorem [16] for the existence of the solution.

3. Spherical designs. In this section we describe a method of reformulating construction of spherical t-designs as an underdetermined system of nonlinear equations.

For a given positive integer t, a set of points $Y = \{y_1, \dots, y_{d_t}\} \subset S^2$ is called a fundamental system if the zero polynomial is the only member of $\mathbb{P}_t$ that vanishes at each point y_j, $j = 1, 2, \dots, d_t$. The requirement

$$d_t = (t+1)^2 = \dim \mathbb{P}_t$$

ensures that the basis matrix is square.

Y is called an extremal system if these points maximize the determinant of the interpolation matrix with respect to an arbitrary basis of $\mathbb{P}_t$. An extremal system is obviously a fundamental system. Sloan and Womersley [20] showed that the extremal fundamental systems have excellent geometrical properties and surprisingly good performance for numerical integration. However, it is unknown whether there is always a spherical t-design in a neighborhood of an extremal fundamental system. Our aim is to verify its existence.

Let $L_\ell : [-1, 1] \to R$ be the usual Legendre polynomial [2]. The Rodrigues representation yields

$$L_\ell(z) = \frac{1}{2^\ell} \sum_{k=0}^{[\ell/2]} \frac{(-1)^k (2\ell - 2k)!}{k!(\ell-k)!(\ell-2k)!} z^{\ell-2k}, \tag{3.1}$$

where $[\ell/2]$ is the floor function. Let

$$J_t(z) = \frac{1}{4\pi} \sum_{\ell=0}^{t} (2\ell+1) L_\ell(z), \qquad z \in [-1, 1],$$

which is a normalized Jacobi polynomial. The Gram matrix $G \equiv G(Y)$ is a symmetric positive semidefinite $d_t \times d_t$ matrix with elements

$$G_{i,j} = J_t(y_i^T y_j).$$

The functions

$$g_i(y) = J_t(y_i^T y), \ i = 1, \dots, d_t, \ y \in S^2,$$

belong to $\mathbb{P}_t$. If G is nonsingular, $\{g_1, \ldots, g_{d_t}\}$ is a basis for $\mathbb{P}_t$. For a given arbitrary function $f \in C(S^2)$, the unique polynomial interpolant Λf for the set Y is

$$(\Lambda f)(y) = \sum_{i=1}^{d_t} v_i g_i(y).$$

Here the vector of weights $v = (v_1, \ldots, v_{d_t})$ is the solution of the linear system of equations

$$Gv = b, \tag{3.2}$$

where $b_i = f(y_i), i = 1, 2 \ldots, d_t$.

The cubature rule

$$Q_{d_t}(f) = \sum_{i=1}^{d_t} w_i f(y_i) \approx \int_{S^2} f(y) dy$$

is exact for all polynomials p of degree $\leq t$ if w satisfies the system of linear equations

$$Gw = e, \tag{3.3}$$

where $e = (1, 1, \ldots, 1)^T \in R^{d_t}$. In particular, the cubature rule is exact for the constant polynomial $1 \in \mathbb{P}_t$. Thus

$$\int_{S^2} 1 \, dy = |S^2| = 4\pi = \sum_{i=1}^{d_t} w_i.$$

Hence the average cubature weight is

$$w_{\text{avg}} = \frac{4\pi}{d_t}.$$

Numerical results given in [22] show that the weights defined by (3.3) with the coefficient matrix $G(\bar{Y})$, where

$$\log \det G(\bar{Y}) = \max_{Y \subset S^2} \log \det G(Y), \tag{3.4}$$

are all positive and the scaled weights w_i / w_{avg} lie in $[1/2, 3/2]$.

The set of points $\bar{Y} = \{\bar{y}_1, \ldots, \bar{y}_{d_t}\}$ defined by (3.4) is an extremal fundamental system. It is conjectured that there is a spherical t-design which is very close to an extremal fundamental system; that is, there is a set of points $Y^* = \{y_1^*, y_2^*, \ldots, y_{d_t}^*\}$ in a neighborhood of $\bar{Y} = \{\bar{y}_1, \ldots, \bar{y}_{d_t}\}$ such that

$$\int_{S^2} p(y) dy = \sum_{i=1}^{d_t} w_i p(y_i^*) \qquad \forall p \in \mathbb{P}_t$$

and equal weights

$$w_i = \frac{4\pi}{d_t}, \;\; i = 1, 2, \ldots, d_t. \tag{3.5}$$

To explore this conjecture, we reformulate the problem as an underdetermined system of nonlinear equations. The matrix G is rotationally invariant, so the set of points can be normalized so that the first point is at the north pole and the second is on the prime meridian. Hence a spherical parametrization $\theta_j \in [0, \pi]$ and $\phi_j \in [0, 2\pi)$ of the points y_j, $j = 1, 2, \ldots, d_t$, has $\phi_1 = 0$, $\theta_1 = 0$, and $\phi_2 = 0$, giving a total of $2d_t - 3$ variables.

Let

$$n = 2d_t - 3, \qquad m = d_t - 1,$$

and let

$$\begin{aligned} x_{i-1} &= \theta_i, & i &= 2, 3, \ldots, d_t, \\ x_{d_t+i-3} &= \phi_i, & i &= 3, 4, \ldots, d_t. \end{aligned}$$

The set of points $Y = \{y_1, \ldots, y_{d_t}\}$ and the vector of variables $x \in R^n$ are uniquely related by

$$y_1 = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}, \quad y_2 = \begin{bmatrix} \sin x_1 \\ 0 \\ \cos x_1 \end{bmatrix}, \quad y_i = \begin{bmatrix} \sin\theta_i \cos\phi_i \\ \sin\theta_i \sin\phi_i \\ \cos\theta_i \end{bmatrix} = \begin{bmatrix} \sin x_{i-1} \cos x_{d_t+i-3} \\ \sin x_{i-1} \sin x_{d_t+i-3} \\ \cos x_{i-1} \end{bmatrix}.$$

The simple bounds on θ_i and ϕ_i can be ignored due to the periodicity of the sin and cos functions. Hence the matrix G can be regarded as a function of x whose elements are defined by

$$G_{i,j}(x) = J_t(y_i^T y_j).$$

Define the function $c : R^n \to R^m$ by

$$c(x) = EG(x)e, \tag{3.6}$$

where E is the $m \times d_t$ matrix

$$E = \begin{pmatrix} 1 & -1 & 0 & \ldots & 0 \\ 1 & 0 & -1 & \ddots & \vdots \\ \vdots & \vdots & \ddots & \ddots & 0 \\ 1 & 0 & \ldots & 0 & -1 \end{pmatrix}.$$

This is motivated by the simple, but critical, observation that any cubature rule which is exact for constants has $\sum_{i=1}^{d_t} w_i = 4\pi$, so one only requires that $w_1 = w_i$ for $i = 2, \ldots, d_t$ to get (3.5). In fact the system of d_t equations $G(x)e - w_{avg}e = 0$ has a Jacobian with only rank $d_t - 1$.

The following theorem states the relation between a spherical t-design and a zero of the function c defined by (3.6).

THEOREM 3.1. *Suppose that $G(x^*)$ is nonsingular. Then x^* corresponds to a spherical t-design with $(t+1)^2$ points if and only if $c(x^*) = 0$.*

Proof. Let x^* be a solution of $c(x) = 0$, and let $\{y_1^*, y_2^*, \ldots, y_{d_t}^*\}$ be the set of points defined by x^*. First it is shown that $\{y_1^*, y_2^*, \ldots, y_{d_t}^*\}$ is a spherical t-design.

Since $G(x^*)$ is nonsingular, $\{y_1^*, y_2^*, \ldots, y_{d_t}^*\}$ is a fundamental system and the functions

$$g_j(y) = G({y_j^*}^T y), \quad j = 1, 2, \ldots, d_t,$$

form a basis of $\mathbb{P}_t$. Hence for any $p \in \mathbb{P}_t$ there are scalars $\alpha_j, j = 1, \ldots, d_t$, such that

$$p(y) = \sum_{j=1}^{d_t} \alpha_j g_j(y).$$

Note that (see [17] for an example)

$$\int_{S^2} g_j(y)dy = 1 \quad \forall\, j = 1, \ldots, d_t. \tag{3.7}$$

Moreover, $c(x^*) = 0$ implies that all components of $G(x^*)e$ are equal. Hence we can write

$$G(x^*)e = \mu e,$$

where μ is a scalar. Because of the nonsingularity of $G(x^*)$, $\mu \neq 0$. This yields

$$\int_{S^2} g_j(y)dy = 1 = \frac{1}{\mu} \sum_{k=1}^{d_t} G_{j,k}(x^*), \qquad j = 1, 2, \ldots, d_t.$$

We calculate the integral

$$\begin{aligned}
\int_{S^2} p(y)dy &= \sum_{j=1}^{d_t} \alpha_j \int_{S^2} g_j(y)dy \\
&= \frac{1}{\mu} \sum_{j=1}^{d_t} \alpha_j \sum_{k=1}^{d_t} G_{j,k}(x^*) \\
&= \frac{1}{\mu} \sum_{k=1}^{d_t} \sum_{j=1}^{d_t} \alpha_j G_{j,k}(x^*) \\
&= \frac{1}{\mu} \sum_{k=1}^{d_t} \sum_{j=1}^{d_t} \alpha_j g_j(y_k^*) \\
&= \frac{1}{\mu} \sum_{k=1}^{d_t} p(y_k^*).
\end{aligned}$$

In particular, for $p(y) \equiv 1$, the area of the sphere is

$$|S^2| = 4\pi = \int_{S^2} p(y)dy = \frac{1}{\mu} \sum_{k=1}^{d_t} p(y_k^*) = \frac{d_t}{\mu}.$$

Thus $\mu = d_t/4\pi$, and therefore $\{y_1^*, y_2^*, \ldots, y_{d_t}^*\}$ is a spherical t-design.

Now we prove that $c(x^*) = 0$ if x^* corresponds to a spherical t-design with $(t+1)^2$ points. By the definition of a spherical t-design, for any $p \in \mathbb{P}_t$,

$$\int_{S^2} p(y)dy = \frac{4\pi}{d_t} \sum_{k=1}^{d_t} p(y_k^*).$$

In particular, as $g_j \in \mathbb{P}_t$,

$$\int_{S^2} g_j(y)dy = \frac{4\pi}{d_t}\sum_{k=1}^{d_t} g_j(y_k^*), \qquad j = 1, 2, \ldots, d_t.$$

Hence, from the definition of g_j and (3.7), we find

$$\frac{4\pi}{d_t}\sum_{k=1}^{d_t} G_{j,k}(x^*) = \frac{4\pi}{d_t}\sum_{k=1}^{d_t} g_j(y_k^*) = 1.$$

This implies

$$G(x^*)e = \frac{d_t}{4\pi}e,$$

and thus

$$c(x^*) = EG(x^*)e = \frac{d_t}{4\pi}Ee = 0. \qquad \square$$

Let $\hat{x} \in R^n$ correspond to the set of points $\hat{Y} = \{\hat{y}_1, \ldots, \hat{y}_{d_t}\}$ on the sphere. The condition for the cubature rule

$$Q_{d_t}(f) = \sum_{i=1}^{d_t} w_i f(\hat{y}_i)$$

to be exact for all polynomials in $\mathbb{P}_t$ is that $w = (w_1, \ldots, w_{d_t})^T$ is the solution of

$$G(\hat{x})w = e.$$

From Theorem 3.1, we know that $w = G(\hat{x})^{-1}e = (4\pi/d_t)e$ if and only if $c(\hat{x}) = 0$. The following theorem gives a result of the weights for the case $c(\hat{x}) \neq 0$.

THEOREM 3.2. *Suppose that $G(\hat{x})$ is nonsingular. Let $w = G(\hat{x})^{-1}e$. Then*

$$\max_{1\le i\le d_t} |w_1 - w_i| \le \frac{4}{\|G(\hat{x})e\|_\infty}\|G(\hat{x})^{-1}\|_\infty \|c(\hat{x})\|_\infty. \tag{3.8}$$

Proof. Let $\|\cdot\| = \|\cdot\|_\infty$ and let $|(G(\hat{x})e)_{i_0}| = \|G(\hat{x})e\|$. Then $\mu := (G(\hat{x})e)_{i_0} \neq 0$ and

$$\begin{aligned}\|\mu e - G(\hat{x})e\| &\le \|\mu e - (G(\hat{x})e)_1 e\| + \|(G(\hat{x})e)_1 e - G(\hat{x})e\| \\ &\le 2\|c(\hat{x})\|.\end{aligned}$$

Now, by the definition of the matrix E, we have

$$\begin{aligned}\max_{1\le i\le d_t} |w_1 - w_i| &= \|EG(\hat{x})^{-1}e\| \\ &= \|EG(\hat{x})^{-1}e - \frac{1}{\mu}Ee\| \\ &= \frac{1}{|\mu|}\|\mu EG(\hat{x})^{-1}e - EG(\hat{x})^{-1}G(\hat{x})e\| \\ &= \frac{1}{|\mu|}\|EG(\hat{x})^{-1}(\mu e - G(\hat{x})e)\| \\ &\le \frac{2}{|\mu|}\|E\|\|G(\hat{x})^{-1}\|\|c(\hat{x})\| \\ &= \frac{4}{|\mu|}\|G(\hat{x})^{-1}\|\|c(\hat{x})\|. \qquad \square\end{aligned}$$

4. Numerical verification of spherical *t*-designs. In this section, we use Theorems 2.1 and 3.1 to verify the existence of spherical t-designs. In particular, we use (2.4) to verify the existence of solutions to the system

$$c(x) := EG(x)e = 0. \tag{4.1}$$

Note that the highly nonlinear function $c(\cdot)$ is in $C^\infty(R^n)$ as long as the points are not at the south pole, which can easily be checked. (The first point is always the north pole and is not allowed to vary.) To save computational cost, let $x_{\mathcal{B}} = (x_1, \ldots, x_{d_t-1})^T$ and set $r_2 = 0$. Hence $c'_{\mathcal{B}}(x)$ is the first $(d_t - 1)$ columns of $c'(x)$ for $x \in X$, where

$$X = \{x \mid \|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \le r_1,\ x_{\mathcal{N}} = \hat{x}_{\mathcal{N}}\}.$$

The expansion (3.1) is used to calculate the derivatives of $c_i(x)$. Moreover, we can give an upper bound for the second derivatives. Since for $i, j = 1, \ldots, d_t$, $G_{ij}(x)$ are polynomials of degree t, the function

$$c_i(x) = (G(x)e)_1 - (G(x)e)_{i+1} = \frac{1}{4\pi}\sum_{j=1}^{d_t}\sum_{\ell=0}^{t}(2\ell+1)\left(L_\ell(y_1^T y_j) - L_\ell(y_{i+1}^T y_j)\right)$$

is polynomial of degree $\le t$. The first derivative of c_i is

$$\frac{\partial c_i(x)}{\partial x_k} = \frac{1}{4\pi}\sum_{j=1}^{d_t}\sum_{\ell=0}^{t}(2\ell+1)\left(L'_\ell(y_1^T y_j)\frac{\partial(y_1^T y_j)}{\partial x_k} - L'_\ell(y_{i+1}^T y_j)\frac{\partial(y_{i+1}^T y_j)}{\partial x_k}\right),$$

and the second derivative of c_i is

$$\frac{\partial^2 c_i(x)}{\partial x_k \partial x_\nu} = \frac{1}{4\pi}\sum_{j=1}^{d_t}\sum_{\ell=0}^{t}(2\ell+1)\Bigg(L''_\ell(y_1^T y_j)\frac{\partial(y_1^T y_j)}{\partial x_k}\frac{\partial(y_1^T y_j)}{\partial x_\nu} + L'_\ell(y_1^T y_j)\frac{\partial^2(y_1^T y_j)}{\partial x_k \partial x_\nu}$$

$$-L''_\ell(y_{i+1}^T y_j)\frac{\partial(y_{i+1}^T y_j)}{\partial x_k}\frac{\partial(y_{i+1}^T y_j)}{\partial x_\nu} - L'_\ell(y_{i+1}^T y_j)\frac{\partial^2(y_{i+1}^T y_j)}{\partial x_k \partial x_\nu}\Bigg).$$

Note that we consider only the first $(d_t - 1)$ columns of $c'(x)$ with respect to $x_{\mathcal{B}}$. Let

$$\nabla y_2 = \begin{bmatrix} \cos x_1 \\ 0 \\ -\sin x_1 \end{bmatrix}, \qquad \nabla y_i = \begin{bmatrix} \cos x_{i-1}\cos x_{d_t+i-3} \\ \cos x_{i-1}\sin x_{d_t+i-3} \\ -\sin x_{i-1} \end{bmatrix}.$$

For $k, \nu \le d_t - 1$, we have

$$\frac{\partial(y_1^T y_j)}{\partial x_k} = \begin{cases} y_1^T \nabla y_j & \text{if } k = j-1, \\ 0 & \text{otherwise;} \end{cases} \qquad \frac{\partial^2(y_1^T y_j)}{\partial x_k \partial x_\nu} = \begin{cases} -y_1^T y_j & \text{if } k = \nu = j-1, \\ 0 & \text{otherwise;} \end{cases}$$

$$\frac{\partial(y_{i+1}^T y_j)}{\partial x_k} = \begin{cases} y_{i+1}^T \nabla y_j & \text{if } k = j-1, \\ y_j^T \nabla y_{i+1} & \text{if } k = i, \\ 0 & \text{otherwise;} \end{cases} \qquad \frac{\partial^2(y_{i+1}^T y_j)}{\partial x_k \partial x_\nu} = \begin{cases} -y_{i+1}^T y_j & \text{if } k = \nu = j-1 \\ & \text{or } k = \nu = i, \\ \nabla y_i^T \nabla y_j & \text{if } k = j-1, \nu = i \\ & \text{or } k = i, \nu = j-1, \\ 0 & \text{otherwise.} \end{cases}$$

We use the relations $|y_i^T y_j| \le 1$ and $|\nabla y_i^T y_j| \le 1$ to give an upper bound K for the second derivatives of $c(\cdot)$ with respect to the first $d_t - 1$ variables. This, together with $x_{\mathcal{N}} = \hat{x}_{\mathcal{N}}$, implies

$$\|c'_{\mathcal{B}}(x) - c'_{\mathcal{B}}(\hat{x})\| \le K\|x - \hat{x}\|.$$

The infinity norm was used in the numerical implementation, so in the rest of this section $\|\cdot\|$ denotes $\|\cdot\|_\infty$.

The procedure for verifying the existence of a spherical t-designs is as follows:

1. Find an approximate solution $\hat{x}$ of $c(x) = 0$ starting from $\bar{x}$ corresponding to an extremal fundamental system $\bar{Y}$.
2. Calculate $c'_{\mathcal{B}}(\hat{x})$ and K.
3. Calculate

$$\rho = K\|c'_{\mathcal{B}}(\hat{x})^{-1}c(\hat{x})\|\ \|c'_{\mathcal{B}}(\hat{x})^{-1}\|. \tag{4.2}$$

If $\rho \le \frac{1}{2}$, then there is a solution of (4.1) in the set

$$X = \{x \in R^n : \|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \le r_1, x_{\mathcal{N}} = \hat{x}_{\mathcal{N}}\},$$

where

$$r_1 = \frac{1 - \sqrt{1 - 2\rho}}{K\|c'_{\mathcal{B}}(\hat{x})^{-1}\|}.$$

If $\rho > \frac{1}{2}$, then (4.1) has no solution in

$$X = \{x \in R^n : \|x_{\mathcal{B}} - \hat{x}_{\mathcal{B}}\| \le \gamma_1, x_{\mathcal{N}} = \hat{x}_{\mathcal{N}}\},$$

where

$$\gamma_1 = \frac{\sqrt{1 + 2\rho} - 1}{K\|c'_{\mathcal{B}}(\hat{x})^{-1}\|}.$$

Note that the natural residual $\|c(x)\|_2$ has many local minimizers. To find a good approximate solution of $c(x) = 0$, we choose several starting points around the extremal system and use the Gauss–Newton method with line search. The interest in starting from an extremal system stems from Figure 2 in [20] and Theorem 3.1. The cubature weights for the computed extremal system of [20] are very close to $4\pi/d_t$ and they maximize the determinant $G(x)$. Extremal systems can be downloaded from http://www.maths.unsw.edu.au/∼rsw/Sphere.

Numerical results are given in Table 1, where $\bar{x}$ is the vector corresponding to an extremal fundamental system $\bar{Y}$, $\hat{x}$ is an approximate solution of $c(x) = 0$,

$$\hat{w} = G(\hat{x})^{-1}e$$

is the weight for the cubature rule, and $\hat{Y} = \{\hat{y}_1, \ldots, \hat{y}_{d_t}\}$ is the set of points corresponding to $\hat{x}$.

As the cubature rule is exact for the constant polynomial $1 \in \mathbb{P}_t$, the average weight is $\hat{w}_{avg} = 4\pi/d_t$. From the last column of Table 1, we see that all weights are positive and

$$\left|\hat{w}_i - \frac{4\pi}{d_t}\right| \le w_{\max} - w_{\min} \approx 0.$$

TABLE 1

Hence the set $\hat{Y}$ can be considered as computed spherical t-designs. These designs are new. Moreover, from Theorem 2.1 and $\|\hat{x} - x^*\| \le r_1$, an error bound for the computed spherical t-designs to an exact spherical design $\{y_1^*, \ldots, y_{d_t}^*\}$ corresponding to the exact solution x^* of $c(x) = 0$ is

$$\max_{1 \le i \le d_t} \|y_i^* - \hat{y}_i\| \le 2\|\hat{x} - x^*\| \le 2r_1,$$

where the first inequality uses the relation between x and y.

The numerical results also give an error bound for the extremal system

$$\begin{aligned} \max_{1 \le i \le d_t} \|y_i^* - \bar{y}_i\| &\le 2\|x^* - \bar{x}\| \\ &\le 2(\|x^* - \hat{x}\| + \|\hat{x} - \bar{x}\|) \\ &\le 2(r_1 + \|\bar{x} - \hat{x}\|). \end{aligned}$$

The interpolatory cubature rule

$$E_t(f) = \frac{4\pi}{d_t} \sum_{j=1}^{d_t} f(\hat{y}_j)$$

associated with $\hat{Y}$ provides high-order numerical integration on the sphere. In particular, by Theorem 4.1 in [20], the worst-case error in a particular Sobolev space is

$$\left| \int_{S^2} f(y) d(y) - E_t(f) \right| = 4\pi D(\hat{Y}) =: e(E_t),$$

where $D(\hat{Y})$ is the Cui–Freeden generalized discrepancy [4]

$$D(\hat{Y}) = \frac{1}{2\sqrt{\pi} d_t} \left[\sum_{j=1}^{d_t} \sum_{i=1}^{d_t} \left(1 - 2\log\left(1 + \sqrt{(1 - \hat{y}_i^T \hat{y}_j)/2} \right) \right) \right]^{1/2}.$$

Table 2 gives the values $D(\hat{Y})$ and $e(E_t)$. These values are better than the values reported by Sloan and Womersley [20]. The values given in [20] use extremal points and are better than the values reported by Cui and Freeden [4].

The computed spherical t-designs with $(t+1)^2$ points are available from http://www.st.hirosaki-u.ac.jp/∼chen/index.html. Computations for these low degrees were

performed by using MATLAB 6.1 on an IBM PC with 128MB memory and 500 MHz [15, 18].

Remark 4.1. This paper presents a new verification method for underdetermined systems of equations and uses this method to verify computed spherical t-designs. In comparison the Krawczyk-type interval operator method (1.3) failed for these underdetermined equations. This can be explained as follows.

Consider $\mathcal{K}(X)$ on an interval X which has an interior point $\hat{x}$. For any $x \in X$, $c'(x)$ is singular, and there is an x_b on the boundary of X such that $c'(x)(x_b - \hat{x}) = 0$. This implies that

$$x_b - c'(\hat{x})^+ c(\hat{x}) = \hat{x} - c'(\hat{x})^+ c(\hat{x}) + (I - c'(\hat{x})^+ c'(x))(x_b - \hat{x}) \in \mathcal{K}(X).$$

It is almost impossible to have $x_b - c'(\hat{x})^+ c(\hat{x}) \in X$ for all such boundary points x_b of X with $c'(\hat{x})^+ c(\hat{x}) \neq 0$. Hence $\mathcal{K}(X) \subseteq X$ always fails. On the other hand, the new verification method has no problems with the null space of $c'(x)$. The following example shows the advantage of the new method. Let

$$c(x) = 1 + x_1 + x_2 + x_1 x_2, \quad X = \frac{1}{4}\begin{pmatrix} [-5,-1] \\ [1+h, 3-h] \end{pmatrix}, \quad \hat{x} = \frac{1}{4}\begin{pmatrix} -3 \\ 2 \end{pmatrix},$$

where $h \in [0,1]$. Let $\mathcal{B} = \{1\}$ and $\mathcal{N} = \{2\}$. Straightforward calculation gives

$$c(\hat{x}) = \frac{3}{8}, \quad c'(x) = (1 + x_2, 1 + x_1), \quad c'(\hat{x}) = \frac{1}{4}(6,1), \quad c'_{\mathcal{B}}(\hat{x})^{-1} c(\hat{x}) = \frac{1}{4}.$$

It is easy to show that a Lipschitz constant for $c'_{\mathcal{B}}(x)$ is $K = 1$, and that

$$\max_{x \in N} \|c'_{\mathcal{N}}(x)\| = \frac{3}{4}.$$

Hence statement (1) of Theorem 2.1 holds with

$$\|c'_{\mathcal{B}}(\hat{x})^{-1} c(\hat{x})\| + \|c'_{\mathcal{B}}(\hat{x})^{-1}\| \left(\frac{1}{2} K(r_1 + r_2) r_1 + \max_{x \in N} \|c'_{\mathcal{N}}(x)\| r_2 \right) = \frac{1}{2} - \frac{h}{6} \leq r_1 = \frac{1}{2}$$

for all $h \in [0,1]$. Now we show that $\mathcal{K}(X) \subseteq X$ fails for all $h \in [0,1]$. Interval calculation gives

$$c'(\hat{x})^+ C'(X) = \frac{4}{37}\begin{pmatrix} 6 \\ 1 \end{pmatrix} \left(1 + \frac{1}{4}[1+h, 3-h],\ 1 + \frac{1}{4}[-5,-1] \right),$$

$$(I - c'(\hat{x})^+ C'(X))(X - \hat{x}) = \frac{1}{37 \times 4} \begin{pmatrix} [-80 + 30h,\ 80 - 30h] \\ [-52 + 40h,\ 52 - 40h] \end{pmatrix},$$

and the radii of X and $\mathcal{K}(X)$ satisfy

$$R(X) - R(\mathcal{K}(X)) = \frac{1}{4} \begin{pmatrix} 2 \\ 1 - h \end{pmatrix} - \frac{1}{148} \begin{pmatrix} 80 - 30h \\ 52 - 40h \end{pmatrix} = \frac{1}{148} \begin{pmatrix} -6 + 30h \\ -15 + 3h \end{pmatrix}.$$

Since the second component of the radii $R_2(X) - R_2(\mathcal{K}(X)) < 0$ for all $h \in [0, 1]$, we find that $\mathcal{K}(X) \not\subseteq X$ for all $h \in [0, 1]$.

Acknowledgment. We thank Prof. Andreas Frommer for his encouraging comments on Remark 4.1.

OPTIMIZING TALBOT'S CONTOURS FOR THE INVERSION OF THE LAPLACE TRANSFORM*

J. A. C. WEIDEMAN†

Abstract. Talbot's method for the numerical inversion of the Laplace transform consists of numerically integrating the Bromwich integral on a special contour by means of the trapezoidal or midpoint rules. In this paper we address the issue of parameter selection in the method, for the particular situation when parabolic PDEs are solved. In the process the well-known subgeometric convergence rate $O(\exp(-c\sqrt{N}))$ of this method is improved to the geometric rate $O(\exp(-cN))$, with N the number of nodes in the integration rule. The value of the maximum decay rate c is explicitly determined. Numerical results for two versions of the heat equation are presented. With the choice of parameters derived here, the rule of thumb is that to achieve an accuracy of $10^{-\ell}$ at any given time, the associated elliptic problem has to be solved no more than ℓ times.

1. Introduction.

The Laplace transform is a classical technique for solving linear differential equations. For computational work, however, this approach never really became popular, as for many years numerical analysts tended to focus on discretization methods such as finite differences and finite elements, possibly combined with linear multistep or Runge–Kutta formulas for integration in time. We conjecture that this lack of interest shown by numerical analysts in the Laplace transform is partly due to the following two factors.

First, the Laplace transform restricts one to linear differential equations and in many applications one ultimately aims to solve nonlinear problems. Second, the Laplace transform, particularly its numerical inversion, has a reputation for being a computational challenge. This has to do with the fact that the inverse problem is by nature ill-conditioned when the transform is known only as a real-valued function. When the transform can be sampled in the complex plane the conditioning seems better, but then complex arithmetic is required.

Despite these apparent drawbacks of the Laplace transform, there has been a recent resurgence of the technique, as evidenced by the number of papers on this topic that have appeared since the year 2000; see, for example, [4, 8, 12, 14, 17, 18]. This renewed activity is in part due to recent interest in linear parabolic PDEs of fractional type, which are naturally posed in a transform setting. (These fractional PDEs model phenomena such as anomalous diffusion in several financial and biological applications.) In addition, MATLAB and other modern computational environments make complex arithmetic as easy to work with as real arithmetic and therefore complex inversion formulas become feasible.

†Department of Applied Mathematics, University of Stellenbosch, Private Bag X1, Matieland 7602, South Africa (weideman@dip.sun.ac.za). This work was done at the Oxford University Computing Laboratory, as Visiting Fellow of Exeter College, Oxford, while the author was on sabbatical leave from the University of Stellenbosch, South Africa.

To introduce the problem, consider the linear system of ODEs

$$\frac{d\boldsymbol{f}}{dt} = A\boldsymbol{f}, \qquad \boldsymbol{f}(0) = \boldsymbol{f}_0, \tag{1.1}$$

where A is an $M \times M$ real matrix, $\boldsymbol{f}(t)$ an $M \times 1$ real vector, and $\boldsymbol{f}_0$ the initial condition. We are primarily interested in the case where A is the result of semi-discretization of a parabolic PDE (examples are given in section 5). We assume, therefore, that the eigenvalues of A are real and negative.

The formal solution to (1.1) is

$$\boldsymbol{f}(t) = \exp(At)\,\boldsymbol{f}_0,$$

and this reduces the problem to that of computing the matrix exponential of a (typically) large matrix. To be more precise, we need to compute the product of the matrix exponential and a vector, which can be done without actually computing the matrix exponential itself [15].

The authors of [4, 8, 12, 14, 17, 18] all compute this product by numerically approximating the inverse Laplace transform

$$\boldsymbol{f}(t) = \frac{1}{2\pi i}\int_\Gamma e^{zt}\boldsymbol{F}(z)\,dz, \qquad \boldsymbol{F}(z) \equiv (zI - A)^{-1}\boldsymbol{f}_0. \tag{1.2}$$

In this formula, known as the Bromwich integral, I is the $M \times M$ identity matrix and Γ is the contour of integration. At least initially, Γ is the Bromwich line $\operatorname{Re} z = \sigma$, where the parameter σ should be large enough that all eigenvalues of A lie in the half-plane $\operatorname{Re} z < \sigma$.

The typical approach is to deform the Bromwich line into a curve that begins and ends in the left half-plane, such that $\operatorname{Re} z \to -\infty$ on the contour; see Figure 1.1. Owing to the exponential factor e^{zt}, the integrand decays rapidly on such a contour, and if the contour is smooth this turns the problem into one of the classic situations where the trapezoidal rule converges extraordinarily rapidly [5, 10, 22, 23].

The articles [4, 8, 12, 14, 17, 18] differ with respect to the choice of the integration contour Γ, and how this contour is parameterized. A short summary of contours and convergence rates is given in section 6.

Suprisingly, none of the above references seriously considers Talbot's contour [19], rated in some circles as one of the best methods for inverting the Laplace transform; see [6]. (The method is mentioned in [12, 18], but is neither implemented nor analyzed there.) This contour may not be suitable when part of the spectrum of A is located off the negative real axis, but for pure parabolic problems the method is very accurate, as the numerical results of this paper will testify.

Talbot's contour is parameterized by

$$\Gamma: \quad z(\theta) = \sigma + \mu\,(\theta\cot\theta + \nu\,i\,\theta), \qquad -\pi \le \theta \le \pi, \tag{1.3}$$

where σ, μ, and ν are real parameters that determine the geometry of the curve. Both μ and ν are positive. For the eigenvalues of A to be enclosed by the contour one needs $z(0) > \lambda$, where λ is the largest eigenvalue of A, i.e.,

$$\sigma + \mu > \lambda. \tag{1.4}$$

A typical Talbot contour is shown in Figure 1.1.

A related contour is obtained by replacing the function $\theta\cot\theta$ in (1.3) with the first two terms in its partial fraction expansion,

$$\Gamma: \quad z(\theta) = \sigma + \mu\left(1 + \frac{2\theta^2}{\theta^2-\pi^2} + \nu\, i\,\theta\right), \qquad -\pi \le \theta \le \pi. \tag{1.5}$$

This contour is equivalent to one mentioned in Talbot's original paper [19], from which we quote: "... and indeed such functions can give good results, though their potentialities have not yet been explored."

It will turn out that the contour (1.5) is easier to analyze than (1.3), so for much of the paper we shall focus on the second contour. We shall also show, however, that the first Talbot contour yields superior accuracy.

Using either (1.3) or (1.5), the Bromwich integral (1.2) can be expressed as

$$\boldsymbol{f}(t) = \frac{1}{2\pi i}\int_{-\pi}^{\pi} e^{z(\theta)t}\boldsymbol{F}\big(z(\theta)\big)z'(\theta)\,d\theta, \tag{1.6}$$

where, respectively,

$$z'(\theta) = \mu\,(\cot\theta - \theta\csc^2\theta + \nu\, i) \quad \text{or} \quad z'(\theta) = \mu\Big(-\frac{4\pi^2\theta}{(\theta^2-\pi^2)^2} + \nu\, i\Big).$$

The integral (1.6) is typically approximated by the trapezoidal rule on a uniform partition of $[-\pi,\pi]$. Instead, we prefer to use the equally accurate midpoint rule with an even number of intervals, say $2N$. This is a practical choice that avoids sampling the integrand at the removable singularity at $\theta = 0$, as well as at the essential singularities at $\theta = \pm\pi$.

We hence define the grid

$$\theta_k = (2k+1)\frac{\pi}{2N}, \qquad k = -N, \ldots, N-1, \tag{1.7}$$

and denote the approximation to (1.6) by

$$\boldsymbol{f}_N(t) = \frac{1}{2Ni}\sum_{k=-N}^{N-1} e^{z(\theta_k)t}\, z'(\theta_k)\,\boldsymbol{F}_k,$$

or

$$\boldsymbol{f}_N(t) = \frac{1}{N}\,\mathrm{Im}\left\{\sum_{k=0}^{N-1} e^{z(\theta_k)t}\, z'(\theta_k)\,\boldsymbol{F}_k\right\}, \tag{1.8}$$

if symmetry is used. Here the vectors $\boldsymbol{F}_k \equiv \boldsymbol{F}(z(\theta_k))$ are solved from

$$\Big(z(\theta_k)\,I - A\Big)\boldsymbol{F}_k = \boldsymbol{f}_0, \qquad k = 0, \ldots, N-1. \tag{1.9}$$

Unless A is sparse, the solution of the N linear systems (1.9) represents the bulk of the computational cost of the algorithm. It should, however, be noted that the systems (1.9) can be solved independently and in parallel [10, 17]. In addition, it is possible to solve all N systems (1.9) efficiently using a single Hessenberg or Schur decomposition of A; see Problem P7.4.2 in [9, p. 350].

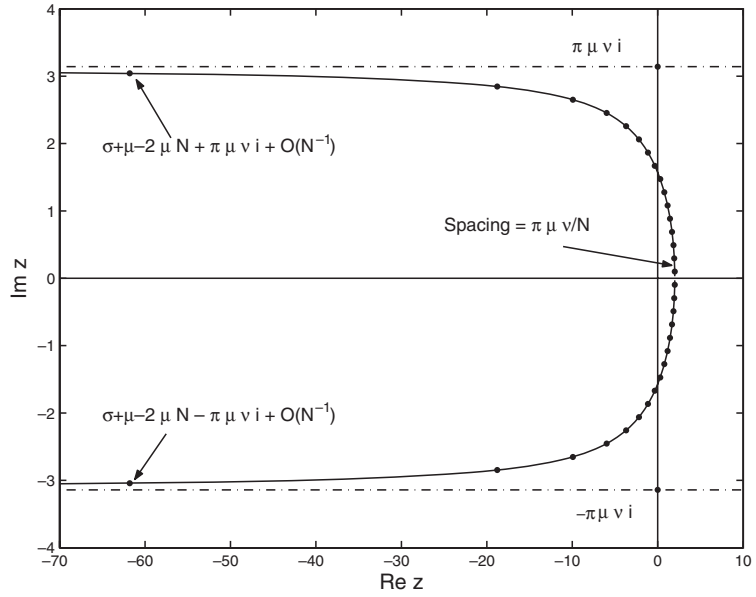

FIG. 1.1. *Talbot's contour* (1.3) *with parameter values* $\sigma = 0$, $\mu = 2$, $\nu = 0.5$. *The dots are the images in the z-plane of the midpoint abscissas* (1.7).

In this paper, we shall aim to optimize the convergence rate $\boldsymbol{f}_N(t) \to \boldsymbol{f}(t)$ as $N \to \infty$, keeping t fixed, by selecting the parameters (σ, μ, ν) in (1.3) and (1.5) to be asymptotically optimal. This is achieved by making σ and μ both proportional to the ratio N/t. By doing so, a geometric convergence rate, $O(e^{-cN})$ as $N \to \infty$, can be obtained. It is well known that Talbot's method with fixed (and therefore suboptimal) parameters converges at a subgeometric rate of $O(e^{-c\sqrt{N}})$; see [19].

To conclude this introduction, we offer Figure 1.1 as a summary of the role of the parameters (σ, μ, ν) in the contour (1.3). The parameter σ represents a shift to the left or right. The parameter μ controls the distance that the two extreme nodes extend into the left half-plane. The parameter ν determines the width of the contour in the sense that the contour approaches two horizontal asymptotes at distance proportional to $\mu\nu$ from the real axis as $\mathrm{Re}\, z \to -\infty$. The factor $\mu\nu$ also determines the spacing of the nodes near the real axis.

The outline of the paper is as follows. In section 2, we indicate how the well-known $O(e^{-c\sqrt{N}})$ convergence rate can be rederived by analyzing the scalar model problem

$$f(t) = e^{\lambda t}, \qquad F(z) = (z - \lambda)^{-1}. \tag{1.10}$$

This analysis suggests the reparameterization that we alluded to above, namely to make σ and μ both proportional to N/t. A saddle point method is used in section 3 to demonstrate that this rescaling of parameters leads to an improved convergence rate $O(e^{-cN})$. In section 4, we determine the value of ν and the proportionality constants in $\sigma \propto N/t$, $\mu \propto N/t$ that will maximize the decay rate, c. We hence obtain the attractive convergence rates $O(e^{-1.90N})$ and $O(e^{-1.73N})$, respectively, for the two versions of the Talbot contour (1.3) and (1.5). A further improvement, which involves omitting those outlying nodes on the Talbot contour that make a negligible

contribution to the midpoint sum, improves these two convergence rates to effectively $O(e^{-2.41N})$ and $O(e^{-2.56N})$. The theory of sections 3 and 4 is tested on two parabolic PDEs in section 5. In section 6, we discuss a few alternate contours, and we also contrast the parameter suggestions of this paper with those made by Talbot in [19].

2. Analysis of the scalar problem. We suppose the matrix A, which may or may not be symmetric, has real and negative eigenvalues, λ_j, corresponding to a complete set of eigenvectors, $\boldsymbol{v}_j$, $j = 1, \ldots, M$. If one expands the initial condition as a linear combination of eigenvectors,

$$\boldsymbol{f}_0 = c_1\boldsymbol{v}_1 + \cdots + c_M\boldsymbol{v}_M,$$

then (1.2) can be expressed as

$$\boldsymbol{f}(t) = \frac{c_1}{2\pi i}\Big(\int_\Gamma \frac{e^{zt}}{z-\lambda_1}\,dz\Big)\boldsymbol{v}_1 + \cdots + \frac{c_M}{2\pi i}\Big(\int_\Gamma \frac{e^{zt}}{z-\lambda_M}\,dz\Big)\boldsymbol{v}_M.$$

Applying Talbot's method to the right-hand side is therefore equivalent to applying it to the scalar problem (1.10), where λ represents a real and negative eigenvalue of A. For any fixed t, we shall restrict attention to λ in the range $|\lambda t| = O(1)$ as $M \to \infty$. We consider this sufficient because in the actual solution,

$$\boldsymbol{f}(t) = c_1 e^{\lambda_1 t}\boldsymbol{v}_1 + \cdots + c_M e^{\lambda_M t}\boldsymbol{v}_M,$$

modes that satisfy $|\lambda t| \gg 1$ are negligible.

Our task is therefore to estimate the error when approximating the integral

$$f(t) = \frac{1}{2\pi i}\int_{-\pi}^{\pi} \frac{e^{z(\theta)t}}{z(\theta)-\lambda} z'(\theta)\,d\theta \tag{2.1}$$

with the midpoint rule, with $z(\theta)$ defined by (1.3) or (1.5), and $\lambda < 0$. To start, we recall an error formula for the midpoint rule.

Consider an integral on $[-\pi, \pi]$ and its midpoint rule approximation

$$I(g) = \int_{-\pi}^{\pi} g(\theta)\,d\theta, \qquad M_N(g) = \frac{\pi}{N}\sum_{k=-N}^{N-1} g(\theta_k), \tag{2.2}$$

where the nodes θ_k are defined by (1.7). Suppose that the function $g(\theta)$ has an absolutely convergent Fourier series expansion

$$g(\theta) = \sum_{k=-\infty}^{\infty} c_k e^{ik\theta}, \qquad \text{with} \qquad c_k = \frac{1}{2\pi}\int_{-\pi}^{\pi} g(\theta)e^{-ik\theta}\,d\theta.$$

Then it is possible to insert these formulas into (2.2), followed by termwise integration and summation, to obtain

$$I(g) = 2\pi c_0, \qquad M_N(g) = 2\pi c_0 + 2\pi \sum_{\substack{\ell=-\infty \\ \ell\neq 0}}^{\infty} (-1)^\ell c_{2\ell N}.$$

The error is therefore given by

$$I(g) - M_N(g) = -2\pi \sum_{\substack{\ell=-\infty \\ \ell\neq 0}}^{\infty} (-1)^\ell c_{2\ell N}. \tag{2.3}$$

(The trapezoidal rule error would be similar, except for the absence of the $(-1)^\ell$ factor; see [23].)

When the periodic extension of $g(\theta)$ is infinitely differentiable on $[-\pi, \pi]$, the Fourier coefficients c_k decay rapidly. In fact, repeated integration by parts can then be used to establish $c_k = O(|k|^{-m})$ for each positive integer m. In such cases a good error estimate can be obtained by retaining only the leading two terms in (2.3), as follows:

$$\begin{aligned} I(g) - M_N(g) &\sim 2\pi\Big(c_{-2N} + c_{2N}\Big) \\ &= \int_{-\pi}^{\pi} g(\theta) e^{-2Ni\theta}\, d\theta + \int_{-\pi}^{\pi} g(\theta) e^{+2Ni\theta}\, d\theta. \end{aligned}$$

One may apply this estimate to the special integral (2.1). The factor $e^{z(\theta)t}$ decays sufficiently rapidly as $\theta \to \pm\pi$ to ensure infinite differentiability of the periodic extension of the integrand. We therefore propose to analyze the error estimate,

$$f(t) - f_N(t) \sim E_N^-(t) + E_N^+(t), \qquad N \to \infty,$$

where, using symmetry,

$$E_N^\pm(t) = \frac{1}{\pi} \mathrm{Im} \left\{ \int_{-\pi}^{0} \frac{e^{z(\theta)t \pm 2iN\theta}}{z(\theta) - \lambda} z'(\theta)\, d\theta \right\}. \tag{2.4}$$

We shall keep both $t > 0$ and $\lambda < 0$ fixed, as well as the parameters σ, μ, and ν in the contours (1.3) or (1.5); our interest is the behavior of (2.4) as $N \to \infty$.

We digress for a moment to point out that error estimates such as (2.4) were used to good effect by Lin, to numerically predict optimal parameters for Talbot's contour [11]. A wide range of transforms was considered there, not just the $F(z) = 1/(z - \lambda)$ considered here.

Rather than using numerical optimization, we shall instead use the saddle point method to estimate analytically the two integrals (2.4). Since this analysis is primarily used to justify the form of the rescaling of parameters in section 3, and not in the determination of the actual optimal numbers itself, we omit the details. (A sketch of the derivation can be found in [24].) The result is that, with $E_N(t) \equiv E_N^-(t) + E_N^+(t)$,

$$E_N(t) = O\Big(e^{(\sigma+\mu)t - 2\sqrt{\pi\mu t N}}\Big), \qquad N \to \infty, \tag{2.5}$$

in the case of contour (1.3), and

$$E_N(t) = O\Big(e^{(\sigma+\frac{5}{2}\mu)t - 2\sqrt{\pi\mu t N}}\Big), \qquad N \to \infty, \tag{2.6}$$

in the case of (1.5). Results similar to these were obtained by Talbot [19, eq. (15)], who used a different method to prove that

$$E_N(t) = O\Big(N^2 e^{(\sigma+a\mu)t - b\sqrt{tN}}\Big).$$

The constants a and b depend on the transform and the contour.

The factor 5/2 that appears in (2.6) indicates that the error constant associated with the modified contour (1.5) is larger than that of the original contour (1.3). This was confirmed by the numerical experiments in [24].

The estimates (2.5)–(2.6) suggest the strategy of choosing $\sigma, \mu \propto N/t$. This should improve the subgeometric convergence rate, $O(e^{-c\sqrt{N}})$, to pure geometric convergence, $O(e^{-cN})$. We consider this next.

3. New parameters for the contour. Consider the rescaling

$$\sigma = -s\frac{N}{t}, \qquad \mu = m\frac{N}{t}, \qquad \nu = n, \tag{3.1}$$

where s, m, and n are real parameters to be determined. Both m and n are positive, and in accordance with (1.4) we require that

$$s < m - \frac{\lambda t}{N}. \tag{3.2}$$

The constant λ is defined in (1.10), which we continue to use as the model problem.

Because the parameters become dependent on t, so does the contour and hence also the integration nodes. This means that the N linear systems (1.9) have to be solved for each value of t, which may be inefficient. We therefore intend this rescaling to be used when the solution is required at only a few values of t.

Using the new parameters (3.1) we define $\zeta(\theta) = (t/N)\, z(\theta)$; i.e.,

$$\zeta(\theta) = -s + m\left(\theta\cot\theta + i\,n\,\theta\right) \tag{3.3}$$

in the case of the contour (1.3), and

$$\zeta(\theta) = -s + m\left(1 + \frac{2\theta^2}{\theta^2 - \pi^2} + i\,n\,\theta\right) \tag{3.4}$$

in the case of (1.5). The two error integrals (2.4) therefore become

$$E_N^{\pm}(t) = \frac{1}{\pi}\mathrm{Im}\left\{\int_{-\pi}^{0} \frac{e^{Ng_{\pm}(\theta)}}{\zeta(\theta) - \lambda t/N}\zeta'(\theta)\, d\theta\right\}, \tag{3.5}$$

where

$$g_{\pm}(\theta) = \zeta(\theta) \pm 2\,i\,\theta.$$

We apply the saddle point method to (3.5). (For details of this method, we refer the reader to [1, sect. 6.4; 3, sect. 6.6].) The idea is to deform the interval of integration, $[-\pi, 0]$, to a special contour in the complex θ-plane on which the integral can be estimated accurately. By Cauchy's theorem such a deformed contour will be permissible as long as it starts at $\theta = -\pi$, terminates at $\theta = 0$, and does not cross any singularities of the integrand in between. Suitable contours are steepest descent curves, defined by $\mathrm{Im}\{g_{\pm}(\theta)\} = \text{constant}$, for these remove the oscillations from the integrands in (3.5). The constants are chosen such that the contours pass through the saddle points, $\theta = \theta_+$ and $\theta = \theta_-$, respectively, defined by

$$g'_+(\theta) = 0, \qquad g'_-(\theta) = 0. \tag{3.6}$$

To ensure analyticity of the integrand, one needs to take into consideration the singularities associated with the vanishing of the denominator in (3.5), i.e., the zeros of $\zeta(\theta) = \lambda t/N$. In view of the discussion in the first paragraph of section 2, we shall assume $|\lambda t| \ll N$ and ignore the right-hand side of this equation. We therefore define the critical points, $\theta = \theta_*$, as the zeros of

$$\zeta(\theta) = 0. \tag{3.7}$$

This is the same as setting $\lambda = 0$, and in accordance with (3.2) we shall therefore consider only $m > s$.

To apply the saddle point method, we have to know where the critical points and saddle points are. We restrict ourselves to the modified contour (1.5); i.e., we assume $\zeta(\theta)$ is defined by (3.4). For this contour (3.6) and (3.7) reduce to polynomial equations of degrees 4 and 3, respectively, which can in principle be solved explicitly. The results are unwieldy, however, and we follow a more elementary approach.

In order to work with equations with real coefficients, we introduce the variable ϕ by $\theta = i\phi$. After denominators have been cleared, (3.6) can be factored into

$$\big(mn \pm 2\big)\big(\phi^2 + \pi^2\big)^2 = 4m\pi^2\phi, \tag{3.8}$$

and (3.7) into

$$\big(mn\phi + s - m\big)\big(\phi^2 + \pi^2\big) = 2m\phi^2. \tag{3.9}$$

Assuming $m > s \geq 0$ and working with these two representations, we were able to establish the following properties of the roots of (3.6)–(3.7).

Starting with the cubic equation (3.9), it is readily established that it always has a positive real root. The remaining two roots may either be real as well or occur as a conjugate pair. In the latter case the real part of these roots is positive, and the imaginary part is bounded in absolute value by π. Transplanting this information from the ϕ variable to θ, we deduce that the three critical points θ_* defined by (3.7) are all in the upper half-plane, with real parts in the interval $(-\pi, \pi)$. At least one root lies on the positive imaginary axis. The other two roots may be pure imaginary as well, or they may be located symmetrically with respect to the imaginary axis. (In the next section, we shall conjecture that the optimal configuration occurs when this pair of roots coalesces into a double root on the imaginary axis.)

Turning to (3.8), one notices that it is a quartic equation with real coefficients that is missing its cubic term. The typical configuration of roots is therefore one in each quadrant of the complex θ-plane, at equal distances from the real axis. The exception is when (3.8) admits four real roots, which would mean saddle points on the imaginary θ-axis. Considering the minus sign in (3.8) we see this cannot happen when $mn < 2$, and because of (3.10) below, we disregard this possibility.

Figure 3.1 shows a typical configuration of critical and saddle points. The roots of (3.6) are represented by $+$'s and $\times$'s (corresponding to the $+$ and $-$ signs, respectively), and the roots of (3.7) are plotted as the $*$'s.

We propose a saddle point analysis based on the contours shown in the figure. The $\Gamma_\pm$ are the curves of steepest descent $\mathrm{Im}\big\{g_\pm(\theta)\big\} = \text{constant}$. Writing $\theta = x + yi$, they can be expressed as

$$\Gamma_\pm : \quad \frac{4m\pi^2 xy}{(x^2 - y^2 - \pi^2)^2 + 4x^2y^2} - (mn \pm 2)x = c_\pm.$$

The constants $c_\pm$ are determined by the requirement that each $\Gamma_\pm$ passes through its corresponding saddle point, θ_+ or θ_-, as defined by (3.6).

In the lower half-plane, Γ_- starts at $\theta = -\pi$, passes through θ_-, and continues to $\theta = -i\infty$. This is valid since the integrand in (3.5), with minus sign, approaches zero as $\theta \to -i\infty$, provided that

$$mn < 2. \tag{3.10}$$

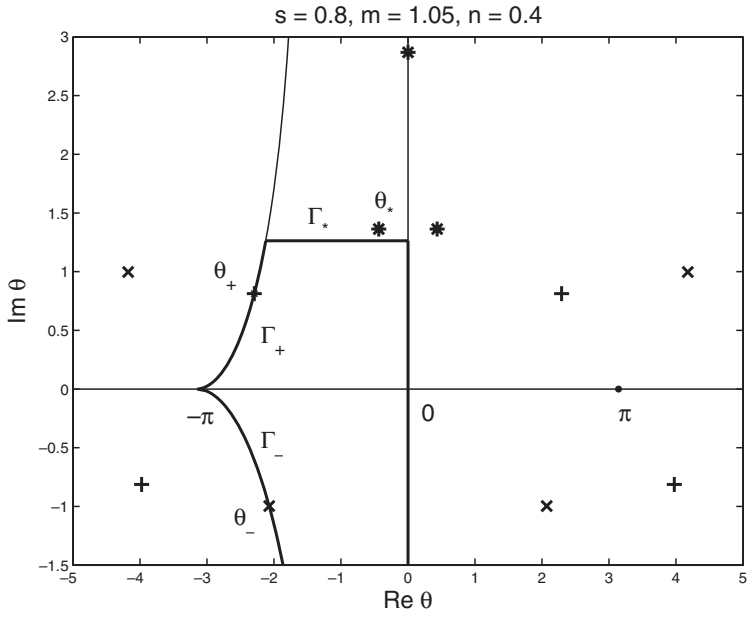

FIG. 3.1. *Saddle points, θ_- and θ_+, critical points θ_*, and steepest descent contours used in deriving the error estimates* (3.11)–(3.13).

(The corresponding restriction for the contour (1.3) is $m(1+n) < 2$.) The contour is then closed at $-i\infty$ and returns to the origin via the negative imaginary θ-axis. On this axis the contribution can be ignored, since the integrand is real. The error $E_N^-(t)$ is therefore solely determined by the saddle point contribution, which can be computed in the usual manner as [1, sect. 6.4; 3, sect. 6.6]

$$E_N^-(t) = O\big(e^{d_- N}\big), \qquad d_- = \mathrm{Re}\big\{g_-(\theta_-)\big\}. \tag{3.11}$$

In the upper half-plane a similar approach is used, except for the fact that the critical points θ_* have to be taken into account. The contour Γ_+ is not continued to $\theta = +i\infty$, as it will not be possible to return to the origin without crossing the singular points $\theta = \theta_*$. To maintain analyticity of the integrand, we introduce a third contour, Γ_*, that branches off from Γ_+ and has a constant imaginary part, say $\mathrm{Im}\{\Gamma_*\} = b$. Typically, the value of b would be determined by the critical point θ_* nearest to the real axis. By letting Γ_* approach such a limiting θ_* from below, it is possible to establish

$$E_N^+(t) = O\big(e^{d_* N}\big), \qquad d_* = \mathrm{Re}\big\{g_+(\theta_*)\big\}. \tag{3.12}$$

If θ_+ lies below Γ_*, a saddle point contribution similar to (3.11),

$$E_N^+(t) = O\big(e^{d_+ N}\big), \qquad d_+ = \mathrm{Re}\big\{g_+(\theta_+)\big\}, \tag{3.13}$$

is to be added to (3.12).

In our numerical experiments, the total error was dominated either by (3.11) or by (3.12). We have not found a set of parameters (s, m, n) for which (3.13) dominates, but neither have we tried to prove that this is impossible.

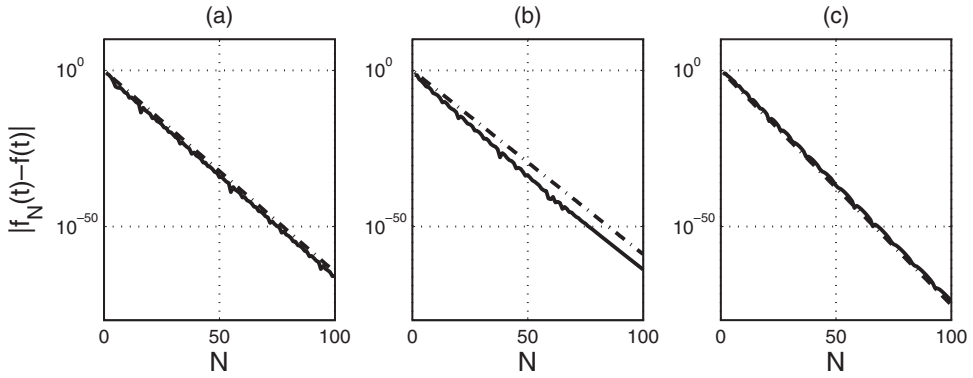

FIG. 3.2. *Convergence curves for Talbot's method applied to the model problem* (1.10), *with* $\lambda = -1$, $t = 1$, *and using contour* (1.5). *The solid curves represent the actual errors, and the dash-dot lines* (*virtually indistinguishable in* (a) *and* (c)) *their theoretical estimates. The plots* (a)–(c) *correspond to three different choices of* (s, m, n), *as summarized in the appendix.*

In Figure 3.2, we offer numerical verification of these error estimates. In the appendix, the corresponding values of saddle points, critical points, and expected convergence rates are summarized. We have picked sets of parameter values (s, m, n) for which (a) the saddle point contribution (3.11) dominates, (b) the critical point contribution (3.12) dominates, and (c) these two contributions are equal (the conjectured optimal situation). Also shown, as the dash-dot curves, are the predicted convergence rates, i.e., the maximum of (3.11) and (3.12). Here we should point out that these estimates are asymptotic, and much information is suppressed by the order notation of (3.11)–(3.13). Therefore, in some cases N has to be large for the estimate to become valid. This can be seen in part (b) of Figure 3.2, for example, where N has to be greater than 70, roughly, before (3.12) becomes evident.

In Figure 3.2, and elsewhere in the paper where multiprecision arithmetic was required, we computed in Maple and exported the numbers to MATLAB for plotting.

4. Computing the optimal parameters. A first attempt at finding optimal parameters (s, m, n) was based on a numerical optimization strategy, involving the objective function

$$F(s, m, n) \equiv \max\left\{d_+, d_-, d_*\right\} = \text{minimum}. \tag{4.1}$$

Here d_+, d_-, d_* are the decay constants in the error estimates (3.13), (3.11), and (3.12). For each set of parameters (s, m, n), the value of F can be computed by first solving (3.6) and (3.7) to obtain θ_+, θ_-, and θ_*. These values are then substituted into $g_\pm(\theta)$, to compute d_+, d_-, d_* as defined by (3.11)–(3.13).

In the case of contour (1.5), (3.6) and (3.7) can be solved with polynomial rootfinding routines, and in this case MATLAB's function `roots` was used. In the case of contour (1.3) a complex Newton process was used. When solving (3.7), one should take care to select the correct root θ_*.

The problem (4.1) was solved using MATLAB's function `fminsearch`, a routine suitable for nonsmooth, unconstrained optimization. Aside from some mild ill-conditioning that will be explained below, this approach worked well.

In the case of contour (1.5), this yielded the parameters presented as case (c) in Figure 3.2, namely

$$s = 0.7556, \quad m = 0.8597, \quad n = 0.3029. \tag{4.2}$$

The corresponding saddle and critical points are summarized in the appendix. The predicted optimal convergence rate is

$$E_N(t) = O\big(e^{-1.7303N}\big), \qquad N \to \infty. \tag{4.3}$$

Applying the same algorithm to the original Talbot contour (1.3), we obtained a better convergence rate, namely

$$E_N(t) = O\big(e^{-1.8975N}\big), \qquad N \to \infty. \tag{4.4}$$

This corresponds to parameter values

$$s = 0.4814, \quad m = 0.6443, \quad n = 0.5653, \tag{4.5}$$

with saddle points and critical point given by

$$\theta_+ = -2.5293 + 0.7435\,i, \quad \theta_- = -2.4158 - 0.9487\,i, \quad \theta_* = 0.9487\,i, \tag{4.6}$$

and decay rates

$$d_+ = -2.5048, \quad d_- = -1.8975, \quad d_* = -1.8975.$$

In Figure 4.1, we show the θ_+, θ_-, and θ_* defined by (4.6) in the top figure, and their images in the z-plane in the bottom figure. Also shown are the nodes of the midpoint approximation, with $N = 16$.

Examining the numerical results (4.5)–(4.6), we conjecture that in the optimal configuration,

(a) θ_* is on the positive imaginary axis,
(b) $\zeta'(\theta_*) = 0$,
(c) $\mathrm{Im}(\theta_*) = -\mathrm{Im}(\theta_-)$, and
(d) $d_+ < d_- = d_*$

for both contours (1.3) and (1.5). All of these properties seem plausible, but we have not pursued rigorous proofs.

Property (b) indicates that θ_* is a double root of (3.7), which is the source of the ill-conditioning mentioned at the beginning of the section. Fortunately, assuming properties (a)–(d) to be true, the problem can be reformulated such that it becomes explicitly solvable. The details are as follows.

Using properties (a) and (c) above, we write

$$\theta_* = y\,i, \qquad \theta_- = x - y\,i,$$

where $x < 0$ and $y > 0$. Because of property (d), we shall ignore θ_+ and try to solve for x, y, s, m, and n from the following five (real) equations: the right-hand equality in (3.6) (two real equations), (3.7), property (b), and the equality in (d).

Using a straightforward but tedious hand calculation this 5×5 system was reduced to a 2×2 system involving x and y. In the case of contour (1.5) this system is

$$\begin{aligned} x(P^2 - Q^2) + 2yPQ &= 0, \\ (5y^2 + \pi^2)(P^2 + Q^2) + P(y^2 + \pi^2)^2 &= 0, \end{aligned} \tag{4.7}$$

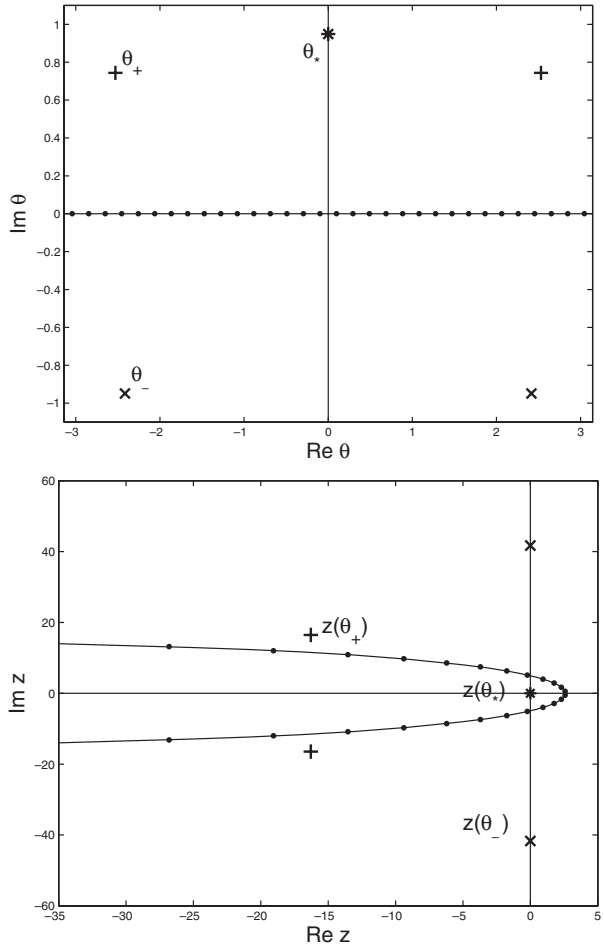

FIG. 4.1. *The optimal configuration of saddle points and critical points in the θ-plane (top) as well as their images in the z-plane (bottom). The dots are the nodes used in the midpoint rule, with* $N = 16$. *Note that in the bottom figure, four sets of nodes lie offscale (towards* $\mathrm{Re}\, z = -\infty$*). The contour is given by* (1.3), *but the figure is qualitatively similar for* (1.5).

where

$$P = x^2 - y^2 - \pi^2, \qquad Q = 2xy.$$

For further simplification we turned to Maple, which produced an explicit solution

$$y = \pi\sqrt{v},$$

where $v \approx 0.07584$ is the smallest positive root of

$$41v^4 - 308v^3 - 98v^2 - 4v + 1 = 0.$$

With this value of v, x is given by

$$x = -\frac{\pi}{4\sqrt{2}}\sqrt{41 - 209v - 1581v^2 + 205v^3}.$$

These formulas yield the values $y \approx 0.8652$ and $x \approx -2.2315$, as obtained above. The values of s, m, and n given in (4.2) follow from

$$n = \frac{4\pi^2 y}{(y^2+\pi^2)^2}, \quad m = \frac{2(R^2+S^2)}{4\pi^2(yR-xS)+n(R^2+S^2)}, \quad s = m\left(\frac{3y^4+\pi^4}{(y^2+\pi^2)^2}\right),$$

where

$$R = P^2 - Q^2, \qquad S = 2PQ.$$

In the case of contour (1.3) the analogue of the system (4.7) is

$$A - x\left(A^2 - B^2 + 1\right) - 2yAB = 0,$$
$$xA + yB + y\left(\coth y - 2\,y\,\mathrm{csch}^2 y\right) = 0,$$

where we have defined $A = \mathrm{Re}\{\cot\theta_-\}$, $B = \mathrm{Im}\{\cot\theta_-\}$, i.e.,

$$A = \frac{\sin x \cos x}{\sin^2 x + \sinh^2 y}, \qquad B = \frac{\sinh y \cosh y}{\sin^2 x + \sinh^2 y}.$$

A numerical solution of this system yields the value of $\theta_- = x - iy$ reported in (4.6). The values of the other parameters can be computed via

$$n = \coth y - y\,\mathrm{csch}^2 y, \quad m = \frac{2}{B + y(A^2 - B^2 + 1) - 2xAB + n}, \quad s = my^2\,\mathrm{csch}^2 y.$$

As verification that the parameters derived here are indeed close to optimal, we offer Figure 4.2. There we show, as the thicker curve, the numerically computed error $E_N(t)$ as a function of N, corresponding to parameters (4.5). Virtually on top of this curve and shown as a dash-dot line is the theoretical error estimate (4.4). To show the near-optimality of these curves, we have computed errors using a uniform sampling of parameter space $(s,m,n) \in (0,1)\times(0,1)\times(0,1)$, with step-size 0.05 in each direction. (That is, $19^3 = 6859$ different parameter sets were used for each value of N.) The vertical line segments in the figure represent the range of these computed errors, with the minima and maxima indicated by the tiny horizontal bars.

We should not neglect to point out that if our sampling of parameter space were finer, some of the lower error bars in this figure could extend further down to 0. This will happen when the two error components, $E_N^+(t)$ and $E_N^-(t)$ in (2.4), are approximately of equal magnitude but of opposite sign. Such instances of fortuitous cancellation will, however, be rare when the matrix as opposed to the scalar problem is solved. We believe that Figure 4.2 represents solid evidence that the suggested parameter values in (4.5) and (4.2) are indeed asymptotically optimal.

To conclude this section, we point out a redundancy in the Talbot contour as noted by Trefethen [21]. Recall Figure 4.1, where the optimal Talbot contour was shown for the case $N = 16$, and recall also that four pairs of nodes were located outside the frame of the figure, towards $\mathrm{Re}\,z = -\infty$. In fact, the contribution of each of these outlying nodes is negligible, as $|e^{z(\theta_k)t}| \le e^{-1.90N}$ when $|k| \ge 3N/4$. It appears that practically no accuracy is lost by including only the middle 75% of nodes and discarding the outlying 25%. A more careful calculation shows that the actual fraction of nodes retained should be about 0.7409. Since $1.8975/0.7409 \approx 2.5611$, the effective convergence rate improves from about $O(e^{-1.90N})$ to $O(e^{-2.56N})$. In the case of the modified Talbot contour (1.5) about 28% of the nodes can be discarded, which increases the effective rate from $O(e^{-1.73N})$ to roughly $O(e^{-2.41N})$.

In the next section we solve two parabolic problems to test some of these convergence estimates.

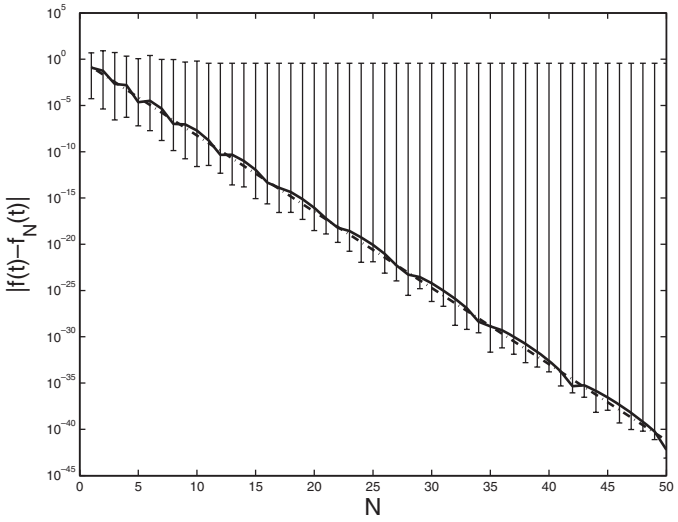

FIG. 4.2. *Absolute errors when Talbot's method is applied to the model function* (1.10), *with* $t = 1, \lambda = -1$, *using the original contour* (1.3). *(The figure is qualitatively similar for the modified contour* (1.5).*) The thicker curve represents the errors computed with the optimal parameters* (4.5). *The dash-dot line (hardly visible) represents the theoretical error estimate* (4.4). *The vertical line segments represent the range of errors computed in a uniform sampling of parameter space.*

5. Application to PDEs. The prototype parabolic PDE is the heat equation

$$u_t = u_{xx}, \qquad 0 \le x \le \pi, \tag{5.1}$$

and here we consider boundary conditions

$$u(0,t) = 0, \qquad u(\pi,t) = 1, \qquad t > 0, \tag{5.2}$$

and an initial condition

$$u(x,0) = 0, \qquad 0 \le x \le \pi. \tag{5.3}$$

The exact solution can be represented either as a Fourier series [2, p. 91], or an infinite series involving the complementary error function [2, p. 93] (efficient for large and small t, respectively).

For numerical work, we let $v(x,t) = u(x,t) - x/\pi$ and rewrite the PDE as

$$v_t = v_{xx}, \tag{5.4}$$

now with homogeneous boundary conditions

$$v(0,t) = 0, \qquad v(\pi,t) = 0, \qquad t > 0, \tag{5.5}$$

but inhomogeneous initial condition

$$v(x,0) = -x/\pi, \qquad 0 \le x \le \pi.$$

To semidiscretize (5.4), a suitable partition $\{x_j\}_{j=1}^{M}$ of $[0,\pi]$ is introduced, along with an $M \times M$ matrix D that represents the approximation to d^2/dx^2 and which

incorporates the boundary conditions (5.5). The approximation to (5.1) is then given by the linear system of ODEs

$$\boldsymbol{v}_t = D\boldsymbol{v}, \qquad \boldsymbol{v}(0) = \boldsymbol{v}_0. \tag{5.6}$$

Here $\boldsymbol{v} = \boldsymbol{v}(t)$ is the $M \times 1$ column vector $[v_1(t), v_2(t), \ldots, v_M(t)]^T$, with $v_j(t)$ representing the approximation to $v(x_j, t)$. Likewise $\boldsymbol{v}_0$ is the vector consisting of samples of $v(x, 0)$ at the grid-points x_j.

Traditionally, the system (5.6) is integrated by a Runge–Kutta or multistep formula (the method of lines). Here we use the transform approach instead. That is, we compute the midpoint sum

$$\boldsymbol{v}_N(t) = \frac{1}{N} \operatorname{Im} \left\{ \sum_{k=0}^{N-1} e^{z(\theta_k)t}\, z'(\theta_k)\, \boldsymbol{F}_k \right\}, \tag{5.7}$$

where $z(\theta)$ is given by (1.3) and θ_k by (1.7). The vectors $\boldsymbol{F}_k$ are solved from

$$\Big(z(\theta_k)\, I - D\Big)\boldsymbol{F}_k = \boldsymbol{v}_0, \qquad k = 0, \ldots, N-1. \tag{5.8}$$

The details of our particular implementation are as follows. Since we have established that the Talbot contour (1.3) is superior to the contour (1.5), we consider only the former. As for the choice of $\{x_j\}_{j=1}^M$ and D, we use the Chebyshev spectral collocation method; i.e., the nodes are the Chebyshev points of the second kind, and D is the corresponding spectral second derivative matrix incorporating the boundary conditions (5.2). The canonical interval for the Chebyshev points is $[-1, 1]$, which we transform to $[0, \pi]$ with $x \mapsto (\pi/2)(x + 1)$. (Codes for computing $\{x_j\}_{j=1}^M$ and D and further details of the spectral method can be found in [7, 20, 25].)

We shall report errors in the L_2-norm, as approximated by the Clenshaw–Curtis rule (the natural quadrature rule for the Chebyshev method). That is, we define as error norm

$$E_N(t) = \sqrt{\frac{\pi}{2} \sum_{j=1}^{M} w_j \Big(v(x_j, t) - v_j(t)\Big)^2}, \tag{5.9}$$

where the w_j are the weights defined in [20, p. 128], and the factor $\pi/2$ comes from the transformation of $[-1, 1]$ to $[0, \pi]$. The exact solution, $v(x, t)$, was computed by the series expansions mentioned below (5.3).

Our first aim is to demonstrate that the convergence estimate (4.4), derived for the model problem (2.1), is also valid for the solution of a PDE. In the latter case, there is of course a spectrum of λ's present, not only the single λ that was assumed in sections 2 and 3. For this reason we chose the side conditions (5.2)–(5.3) to represent a discontinuous solution at $t = 0$. Our interest will therefore be in the regime $t \to 0$, when high frequency modes are relevant.

In Figure 5.1 we show solutions of (5.1)–(5.3) at various values of t. We also show the error, $E_N(t)$, as a function of N, for the corresponding values of t. We have chosen the $M \times M$ Chebyshev matrices D sufficiently large to fully resolve the solution; i.e., the errors reported in the figure are solely due to the Laplace transform quadrature error and not due to inadequate spatial resolution. Owing to the smoothing property of the heat equation the order of D can of course be reduced as t increases, and suitably large values of M were determined by trial and error.

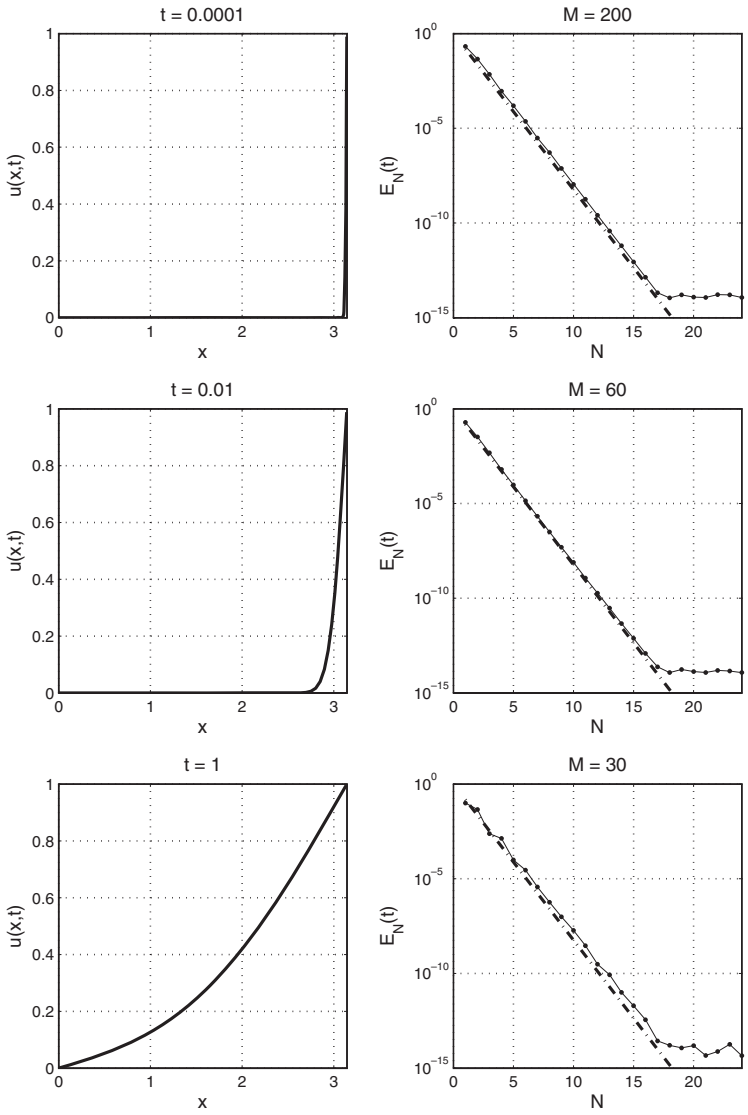

FIG. 5.1. *The left column shows the actual solution of* (5.1)–(5.3) *at various times. The right column shows convergence curves when the solution on the left is approximated with a Chebyshev spectral differentiation matrix of order* $M \times M$ *and Talbot's quadrature rule* (5.7) *using the contour* (1.3) *with optimal parameters* (4.5). *The thinner, dotted curves show the computed errors, and the thicker, dash-dot lines the error model* $\exp(-1.90N)$*; cf.* (4.4). *The error* $E_N(t)$ *is defined by* (5.9).

Assessing these figures, it is clear that the error estimate (4.4) is valid for this problem, even for small t. In addition, one should keep in mind that these results can be achieved by solving effectively only $0.74N$ linear systems (recall the discussion at the end of section 4). This allows us to formulate the rule of thumb stated in the abstract. Suppose an accuracy of $10^{-\ell}$ is required at a particular value of t. By considering

$$e^{-2.56N} = 10^{-\ell} \qquad \Longrightarrow \qquad N \approx 0.9\ell$$

one concludes that this should require no more than ℓ solutions of the system (5.8).

We remark that discretization in space is, strictly speaking, not necessary for (5.1)–(5.3), as the Laplace transform can be obtained explicitly, as follows [2, p. 89]:

$$F(z) = \frac{\sinh(x\sqrt{z})}{z\sinh(\pi\sqrt{z})}.$$

Talbot's method (or any other inversion algorithm) may be applied to this transform for any x in $[0, \pi]$. For problems with nonconstant coefficients or with complicated boundary conditions, however, such explicit representations may not exist.

As a second example, we consider the fractional heat equation

$$D_t^\alpha u = u_{xx}, \tag{5.10}$$

subject to boundary conditions (5.5) and initial condition

$$u(x,0) = \sin\, x, \qquad 0 \le x \le \pi. \tag{5.11}$$

Here D_t^α is the Caputo fractional derivative, defined by [16, p. 79]

$$D_t^\alpha f(t) = \frac{1}{\Gamma(1-\alpha)} \int_0^t \frac{f'(s)}{(t-s)^\alpha}\, ds \qquad (0 < \alpha < 1).$$

It can be shown [16, p. 79] that if $f(t)$ is twice continuously differentiable, then in the limit $\alpha \to 1$ this formula reproduces the ordinary derivative, in which case (5.10) reduces to the standard heat equation (5.1).

The analytical solution to (5.10)–(5.11) can be written as

$$u(x,t) = M(t)\sin x,$$

where $M(t)$ can be expressed in terms of the Mittag–Leffler function. In the case $\alpha \to 1$, it reduces to $M(t) = e^{-t}$. In the case $\alpha = 1/2$, the function can be expressed in terms of the complementary error function, namely

$$M(t) = e^t \mathrm{erfc}(\sqrt{t}).$$

The qualitative properties of this $\alpha = 1/2$ solution are similar to those of the ordinary heat equation, but steady-state is approached on a longer time scale (subdiffusion).

For the numerical solution of (5.10)–(5.11), one takes a Laplace transform of (5.10), which yields

$$\boldsymbol{F}(z) = \left(zI - z^{1/2}D\right)^{-1}\boldsymbol{u}_0.$$

We shall continue to let D be the Chebyshev second derivative matrix that incorporates the boundary conditions (5.5). The modification to the Talbot method (5.7)–(5.8) is obvious: the scalar $z(\theta_k)^{1/2}$ should be inserted to multiply D in (5.8).

Finding optimal parameters for Talbot's method for the problem (5.10)–(5.11) would mean analyzing $F(z) = 1/(z - z^{1/2}\lambda)$ as a test function. Note that the singularities are no longer isolated, but a branch cut on the negative real axis. Instead of performing such an analysis, we merely demonstrate numerically that Talbot's method with the parameter choices of section 3 is very accurate for this problem as well. The error curves shown in Figure 5.2 confirm that the convergence rate is, to a good approximation, again given by $O(e^{-1.90N})$.

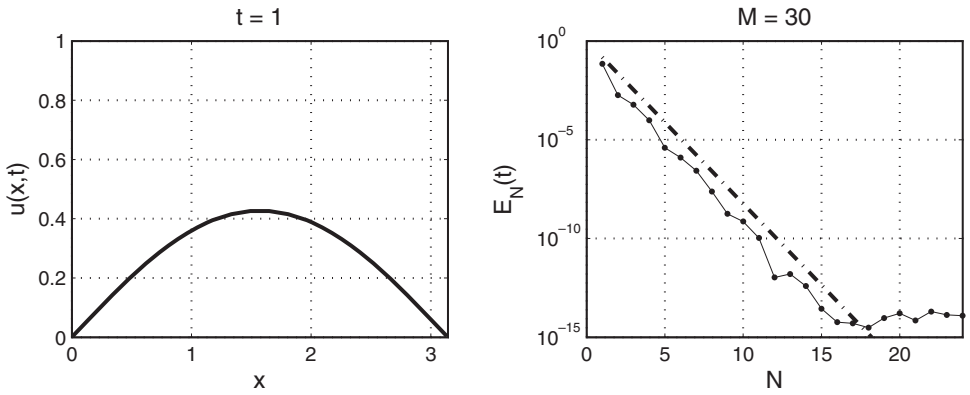

FIG. 5.2. *Same as Figure* 5.1, *but the problem is the fractional PDE* (5.10)–(5.11), *with* $\alpha = 1/2$.

6. Comparisons. Using a combination of asymptotics and heuristics, Talbot made some suggestions for parameter selection in the original paper [19]. In the case of singularities on the real negative axis, the suggested values are

$$\sigma = 0, \qquad \mu = \frac{\omega}{t}, \qquad \nu = 1.$$

The recommended value of ω is 6 (resp., 11) for single (resp., double) precision. In our notation $\omega = mN$, and using $m = 0.6443$ we find that $\omega = 6$ (resp., 11) corresponds to $N \approx 9$ (resp., 17). This is commensurate with our results, as $\exp(-1.90\times 9) \approx 3.7\,10^{-8}$ (approx. single precision) and $\exp(-1.90\times 17) \approx 9.4\,10^{-15}$ (approx. double precision). The recommended values $\sigma = 0$ and $\nu = 1$, however, are suboptimal. Indeed, in the abstract of [19] it is stated that "The required number of points depends on t... and for moderate t is typically 11 for orders of 10^{-6}, 18 for order 10^{-10}, 35 for order 10^{-20}." Fitting a model $E_N = \text{const.} \times e^{-cN}$ to these data yields $c \approx 1.35$, which is not as good as the $c \approx 1.90$ and $c \approx 2.56$ obtained here.

To be fair to Talbot, the aims of the paper [19] were more ambitious than those of the present paper. To begin with, all singularity distributions were taken into account, not just poles on the negative imaginary axis. In addition, Talbot considered finite precision tolerances, and therefore had to deal with the locations of the singularities. By contrast, we let $N \to \infty$, thereby making the errors independent of the singularities, and trusted in the power of asymptotics to make the parameters thus found relevant for finite (indeed, relatively small) values of N as well.

More recently, hyperbolic and parabolic contours have been considered as alternatives to Talbot's contours. Published convergence rates are all subgeometric, namely $O(e^{-cN^{1/2}})$ for the hyperbola of [14], $O(e^{-cN^{2/3}})$ for the parabola of [8], and $O(e^{-cN/\log N})$ for the hyperbola of [12]. The hyperbola has the advantage that it can handle singularities that lie in a sectorial region about the negative real axis; see [12].

Using a rescaling similar to (3.1), the above convergence rates were subsequently improved to the geometric $O(e^{-cN})$; see [13, 26]. In fact, the optimal decay constant c is marginally better for parabolas and hyperbolas than for Talbot contours. With the modification introduced at the end of section 4, however, the Talbot contours regain their superiority.

Appendix. Table A.1 lists saddle points, critical points, and estimated convergence rates corresponding to cases (a)–(c) in Figure 3.2.

TABLE A.1

Case	Parameters	Roots of (3.6)(+)	Roots of (3.6)(−)	Roots of (3.7)	θ_+, θ_-, θ_*	d_+, d_-, d_*	Conv. rate
(a)	$s = 0.8$	$\pm 3.9751 - 0.8123i$	$\pm 4.1761 + 0.9975i$	$2.8686i$	$-2.2930 + 0.8123i$	-2.2380	
	$m = 1.05$	$\pm 2.2930 + 0.8123i$	$\pm 2.0710 - 0.9975i$	$\pm 0.4351 + 1.3633i$	$-2.0710 - 0.9975i$	-1.4859	$\exp(-1.4859N)$
	$n = 0.4$				$-0.4351 + 1.3633i$	-2.7267

DISCONTINUOUS GALERKIN METHODS FOR FRIEDRICHS' SYSTEMS. PART II. SECOND-ORDER ELLIPTIC PDES*

ALEXANDRE ERN† AND JEAN-LUC GUERMOND‡

Abstract. This paper is the second part of a work attempting to give a unified analysis of discontinuous Galerkin methods. The setting under scrutiny is that of Friedrichs' systems endowed with a particular 2×2 structure in which one unknown can be eliminated to yield a system of second-order elliptic-like PDEs for the remaining unknown. A general discontinuous Galerkin method for approximating such systems is proposed and analyzed. The key feature is that the unknown that can be eliminated at the continuous level can also be eliminated at the discrete level by solving local problems. All the design constraints on the boundary operators that weakly enforce boundary conditions and on the interface operators that penalize interface jumps are fully stated. Examples are given for advection-diffusion-reaction, linear continuum mechanics, and a simplified version of the magneto-hydrodynamics equations. Comparisons with well-known discontinuous Galerkin approximations for the Poisson equation are presented.

Key words. Friedrichs' systems, finite elements, partial differential equations, discontinuous Galerkin method

1. Introduction.

Friedrichs' systems [10] are systems of first-order PDEs endowed with a symmetry and a positivity property. Such systems embrace both elliptic and hyperbolic PDEs; i.e., they include advection-reaction, advection-diffusion-reaction, linear continuum mechanics, and Maxwell's equations in the elliptic regime, to cite a few examples. The analysis of this class of problems and its approximation by means of discontinuous Galerkin (DG) methods has been initiated by Lesaint [13], Lesaint and Raviart [12], and Johnson, Nävert, and Pitkäranta [11]. A thorough systematic analysis generalizing [13, 12, 11] has been undertaken in the first part of this work [9].

In this second part, we specialize the setting to two-field Friedrichs' systems such that (i) the dependent variable z can be partitioned into the form $z = (z^\sigma, z^u)$, and (ii) the σ-component, z^σ, can be eliminated to yield a system of second-order PDEs for the u-component, z^u, which is of elliptic type. To efficiently approximate the above Friedrichs' systems using DG methods, it is desirable to reproduce at the discrete level the possibility of eliminating the σ-component of the discrete unknown *locally* on each mesh element. This feature induces a nontrivial modification of the analysis presented in [9] that constitutes the scope of the present work. In particular, the design of boundary and interface operators has to be revised. The analysis presented herein shows that to recover stability while allowing for the local elimination in question requires an enhanced penalty on the boundary conditions and on the interface jumps of the discrete u-component.

This paper is organized as follows. Section 2 briefly restates the main theoretical results of [9] on the well-posedness of Friedrichs' systems and introduces the above-mentioned two-field structure. Section 3 presents three important examples of two-field Friedrichs' systems, namely advection-diffusion-reaction equations written in mixed form, linear continuum mechanics equations written in the stress-pressure-displacement form, and a simplified form of the magnetohydrodynamics (MHD) equations. Section 4 formulates a general DG method for two-field Friedrichs' systems and describes the technique to locally eliminate the σ-component of the discrete solution. The convergence analysis constitutes the scope of section 5. All the design assumptions on the boundary operators which weakly enforce boundary conditions and on the interface operators which penalize interface jumps are stated. The key results are Theorem 5.8, which contains the main estimate for the σ- and u-component of the approximation error, and Theorem 5.14, which contains an improved estimate for the u-component of the error in the L^2-norm obtained using a duality argument. Finally, section 6 applies the DG method to the PDE systems presented in section 3; in particular, the link with the unified analysis of Arnold et al. [1] for the Poisson equation is explicated to illustrate the fact that various DG methods presented in the literature, e.g., the local discontinuous Galerkin (LDG) method of Cockburn and Shu [7], the interior penalty (IP) method of Baker [3] and Arnold [2], the method of Brezzi et al. [6], and the methods of Bassi and Rebay [5] and Bassi et al. [4], fit into the present framework.

2. Two-field Friedrichs' systems.

Section 2.1 is meant to recall well-posedness results proved in part I, [9]. The reader familiar with this material can jump to section 2.2, where the notion of two-field Friedrichs' systems is introduced.

2.1. Main results on one-field Friedrichs' systems.

Let Ω be a bounded, open, connected, Lipschitz domain in $\mathbb{R}^d$. Let m be a positive integer and set $L = [L^2(\Omega)]^m$ equipped with the canonical L^2-induced inner product $(\cdot,\cdot)_L$. Let $\mathcal{K}$ and $\{\mathcal{A}^k\}_{1\le k\le d}$ be $(d+1)$ functions on Ω with values in $\mathbb{R}^{m,m}$ such that

$$\mathcal{K} \in [L^\infty(\Omega)]^{m,m}, \tag{A1}$$

$$\forall k \in \{1,\dots,d\}, \quad \mathcal{A}^k \in [L^\infty(\Omega)]^{m,m} \quad \text{and} \quad \sum_{k=1}^d \partial_k \mathcal{A}^k \in [L^\infty(\Omega)]^{m,m}, \tag{A2}$$

$$\forall k \in \{1,\dots,d\}, \quad \mathcal{A}^k = (\mathcal{A}^k)^t \ \text{ a.e. in } \Omega, \tag{A3}$$

$$\exists \mu_0 > 0, \quad \mathcal{K} + \mathcal{K}^t - \sum_{k=1}^d \partial_k \mathcal{A}^k \ge 2\mu_0 \mathcal{I}_m \ \text{ a.e. on } \Omega, \tag{A4}$$

where $\mathcal{I}_m$ is the identity matrix in $\mathbb{R}^{m,m}$. To alleviate notation we define the operator $K \in \mathcal{L}(L;L)$ by $K : L \ni z \longmapsto \mathcal{K}z \in L$ and it adjoint $K^* \in \mathcal{L}(L;L)$ by $K^* : L \ni z \longmapsto \mathcal{K}^t z \in L$.

Let $\mathfrak{D}(\Omega)$ be the space of $\mathfrak{C}^\infty$ functions that are compactly supported in Ω. A function z in L is said to have an A-weak derivative in L if the linear form

$$[\mathfrak{D}(\Omega)]^m \ni \phi \longmapsto -\int_\Omega \sum_{k=1}^d z^t \partial_k(\mathcal{A}^k\phi) \in \mathbb{R} \tag{2.1}$$

is bounded on L. In this case, the function in L that can be associated with the above linear form by means of the Riesz representation theorem is denoted by Az. Define the so-called graph space $W = \{z \in L;\, Az \in L\}$ equipped with the graph

norm $\|z\|_W = \|Az\|_L + \|z\|_L$. The space W is endowed with a Hilbert structure when equipped with the scalar product $(z,y)_L + (Az,Ay)_L$. For $z \in W$, the function in L that can be associated with the linear form $[\mathfrak{D}(\Omega)]^m \ni \phi \longmapsto \int_\Omega \sum_{k=1}^d z^t \mathcal{A}^k \partial_k \phi \in \mathbb{R}$ is denoted by $\tilde{A}z$. Clearly, $A \in \mathcal{L}(W;L)$ and $\tilde{A} \in \mathcal{L}(W;L)$ and if z is smooth, e.g., $z \in [\mathfrak{C}^1(\overline{\Omega})]^m$,

$$Az = \sum_{k=1}^d \mathcal{A}^k \partial_k z, \qquad \tilde{A}z = -\sum_{k=1}^d \partial_k(\mathcal{A}^k z). \tag{2.2}$$

Furthermore, we set $T = K + A$, $\tilde{T} = K^* + \tilde{A}$. Note that $\tilde{A}$ and $\tilde{T}$ are the formal adjoints of A and T, respectively, owing to (A3). Assumption (A4) implies

$$\forall z \in W, \quad (Tz,z)_L + (z,\tilde{T}z)_L \geq 2\mu_0 \|z\|_L^2. \tag{2.3}$$

Let $D \in \mathcal{L}(W;W')$ be the operator defined by

$$\forall (z,y) \in W \times W, \quad \langle Dz, y\rangle_{W',W} = (Az,y)_L - (z,\tilde{A}y)_L. \tag{2.4}$$

Observe that D is self-adjoint by construction; moreover, it is a boundary operator in the sense that $\mathrm{Ker}(D)$ is the closure of $[\mathfrak{D}(\Omega)]^m$ in W; see [8] for further results.

Consider the following problem: For $f \in L$, seek $z \in W$ such that $Tz = f$. In general, boundary conditions must be enforced for this problem to be well-posed. In other words, one must find a closed subspace V of W such that the restricted operator $T : V \to L$ is an isomorphism. To achieve this goal, a simple approach inspired from Friedrichs' work [9, 10] consists of introducing an operator $M \in \mathcal{L}(W;W')$ such that

(M1) M is positive, i.e., $\langle Mz, z\rangle_{W',W} \geq 0 \quad \forall z$ in W,

(M2) $W = \mathrm{Ker}(D-M) + \mathrm{Ker}(D+M)$.

Then by setting

$$V = \mathrm{Ker}(D-M) \qquad \text{and} \qquad V^* = \mathrm{Ker}(D+M^*), \tag{2.5}$$

where $M^* \in \mathcal{L}(W;W')$ is the adjoint of M and V and V^* are equipped with the graph norm, the following theorem can be proved (see [8, 9] for a proof).

THEOREM 2.1. *Assume* (A1)–(A4) *and* (M1)–(M2). *Then, the restricted operators* $T : V \to L$ *and* $\tilde{T} : V^* \to L$ *are isomorphisms.*

As a result, for f in L, the following two problems are well-posed:

$$\text{Seek } z \in V \text{ such that } Tz = f, \tag{2.6}$$

$$\text{Seek } z^* \in V^* \text{ such that } \tilde{T}z^* = f. \tag{2.7}$$

A key observation at this point is that the boundary conditions enforced in (2.6) and (2.7) are essential; i.e., they are enforced strongly by seeking the solutions in V and V^*, respectively. The key reason that led us to focus on the theory of Friedrichs' systems is that it yields a way to enforce boundary conditions naturally, thus leading to a suitable framework for developing a DG theory. To see this, we introduce the following bilinear forms on $W \times W$:

$$a(z,y) = (Tz,y)_L + \tfrac{1}{2}\langle (M-D)z, y\rangle_{W',W}, \tag{2.8}$$

$$a^*(z,y) = (\tilde{T}z,y)_L + \tfrac{1}{2}\langle (M^*+D)z, y\rangle_{W',W}. \tag{2.9}$$

It is clear that a and a^* are in $\mathcal{L}(W\times W;\mathbb{R})$. Equipped with these two new bilinear forms, we now consider the following problems: For $f\in L$,

$$\text{Seek } z\in W \text{ such that } a(z,y)=(f,y)_L \quad \forall y\in W, \tag{2.10}$$

$$\text{Seek } z^*\in W \text{ such that } a^*(z^*,y)=(f,y)_L \quad \forall y\in W. \tag{2.11}$$

The key result of this section is the following

THEOREM 2.2. *Assume* (A1)–(A4) *and* (M1)–(M2). *Then,*

(i) *there is a unique solution to* (2.10) *and this solution solves* (2.6)*;*

(ii) *there is a unique solution to* (2.11) *and this solution solves* (2.7).

Theorem 2.2 is proven in [9]. Contrary to (2.6) and (2.7), the boundary conditions in (2.10) and (2.11) are natural; i.e., they are weakly enforced. For this reason, problem (2.10) will constitute our working basis for designing DG methods; see section 4.

2.2. The two-field structure. We now particularize the above setting by assuming that the $(d+1)$ $\mathbb{R}^{m,m}$-valued fields $\mathcal{K}$ and $\{\mathcal{A}^k\}_{1\le k\le d}$ have a 2×2 block structure; i.e., there are two positive integers m_σ and m_u such that $m=m_\sigma+m_u$ and

$$\mathcal{K}=\left[\begin{array}{c:c}\mathcal{K}^{\sigma\sigma}&\mathcal{K}^{\sigma u}\\ \hdashline \mathcal{K}^{u\sigma}&\mathcal{K}^{uu}\end{array}\right],\qquad \mathcal{A}^k=\left[\begin{array}{c:c}0&\mathcal{B}^k\\ \hdashline [\mathcal{B}^k]^t&\mathcal{C}^k\end{array}\right], \tag{2.12}$$

with obvious notation for the blocks of $\mathcal{K}$ and where for all $k\in\{1,\dots,d\}$, $\mathcal{B}^k$ is an $m_\sigma\times m_u$ matrix field and $\mathcal{C}^k$ is a symmetric $m_u\times m_u$ matrix field. To simplify the notation, define the operators $B=\sum_{k=1}^d\mathcal{B}^k\partial_k$, $B^\dagger=\sum_{k=1}^d[\mathcal{B}^k]^t\partial_k$, $\nabla\cdot B=\sum_{k=1}^d\partial_k\mathcal{B}^k$, $C=\sum_{k=1}^d\mathcal{C}^k\partial_k$, $C^\dagger=\sum_{k=1}^d[\mathcal{C}^k]^t\partial_k$, and $\nabla\cdot C=\sum_{k=1}^d\partial_k\mathcal{C}^k$. Set $L_\sigma=[L^2(\Omega)]^{m_\sigma}$ and $L_u=[L^2(\Omega)]^{m_u}$.

The two key hypotheses on which the present work is based are the following:

$$\exists k_0>0\quad \forall\xi\in\mathbb{R}^{m_\sigma},\quad \xi^t\mathcal{K}^{\sigma\sigma}\xi\ge k_0\|\xi\|^2_{\mathbb{R}^{m_\sigma}}\quad \text{a.e. on } \Omega, \tag{A5}$$

$$\forall k\in\{1,\dots,d\},\quad \text{the } m_\sigma\times m_\sigma \text{ upper-left block of } \mathcal{A}^k \text{ is zero.} \tag{A6}$$

Assumption (A5), which means that $\mathcal{K}^{\sigma\sigma}$ is uniformly positive definite, implies that the matrix $\mathcal{K}^{\sigma\sigma}$ is invertible.

Assumptions (A5) and (A6) allow for the elimination of z^σ from the PDE system $Tz=f$. With obvious notation, partition z and f into (z^σ,z^u) and (f^σ,f^u), respectively. Then, z^σ is given by

$$z^\sigma=[\mathcal{K}^{\sigma\sigma}]^{-1}\Big(f^\sigma-\mathcal{K}^{\sigma u}z^u-Bz^u\Big), \tag{2.13}$$

and z^u solves the following second-order PDE:

$$\begin{aligned}-B^\dagger[\mathcal{K}^{\sigma\sigma}]^{-1}Bz^u+(C-B^\dagger[\mathcal{K}^{\sigma\sigma}]^{-1}\mathcal{K}^{\sigma u}-\mathcal{K}^{u\sigma}[\mathcal{K}^{\sigma\sigma}]^{-1}B)z^u\\ +(\mathcal{K}^{uu}-\mathcal{K}^{u\sigma}[\mathcal{K}^{\sigma\sigma}]^{-1}\mathcal{K}^{\sigma u})z^u=f^u-(\mathcal{K}^{u\sigma}+B^\dagger)[\mathcal{K}^{\sigma\sigma}]^{-1}f^\sigma.\end{aligned} \tag{2.14}$$

The objective of the present work is to design DG methods for approximating (2.14). The strategy we are going to follow consists of constructing a DG approximation to (2.10), but at variance with what has been done in [9], the construction is now specialized to the above 2×2 block structure so that the approximate unknown corresponding to z^σ can be eliminated locally on each mesh element by solving local problems.

Remark 2.1. The present study does not cover the DG approximation of the whole realm of second-order PDEs. Indeed, it is clear from (2.14) that the leading-order term in the PDE, namely $B^\dagger[\mathcal{K}^{\sigma\sigma}]^{-1}Bz^u$ (up to first-order terms), has a very particular structure since the matrices $(\mathcal{B}^k)^t[\mathcal{K}^{\sigma\sigma}]^{-1}\mathcal{B}^k$ are positive semidefinite. Hence, the PDEs covered by this work are elliptic-like; see section 3 for various examples.

Remark 2.2. In some applications, K has no local representation; i.e., there is no local field $\mathcal{K}$ to represent K. This is indeed the case for the neutron transport equation, where K is a scattering operator. Everything that is said hereafter is also valid in this case, provided the matrix block representation of $\mathcal{K}$ is replaced by the operator block representation of K and provided $K^{\sigma\sigma}$ has a local representation, i.e., $(K^{\sigma\sigma}z^\sigma, y^\sigma)_{L_\sigma} = \int_\Omega (y^\sigma)^t \mathcal{K}^{\sigma\sigma} z^\sigma$.

2.3. Integral representation of boundary operators. Let $n = (n_1, \dots, n_d)^t$ be the unit outward normal to $\partial\Omega$. Henceforth, we assume that the fields $\{\mathcal{A}^k\}_{1\le k\le d}$ are sufficiently smooth for the matrix $\mathcal{D} = \sum_{k=1}^d n_k \mathcal{A}^k$ to be meaningful at the boundary. Hence, the following representation holds:

$$\langle Dz, y\rangle_{W',W} = \int_{\partial\Omega} y^t \mathcal{D} z \tag{2.15}$$

whenever z and y are smooth functions. Owing to (2.12), $\mathcal{D}$ has a 2×2 block structure with $\mathcal{D}^{\sigma u} = \sum_{k=1}^d n_k \mathcal{B}^k$, $\mathcal{D}^{u\sigma} = [\mathcal{D}^{\sigma u}]^t$, $\mathcal{D}^{uu} = \sum_{k=1}^d n_k \mathcal{C}^k$, and

$$\mathcal{D}^{\sigma\sigma} = 0. \tag{2.16}$$

Likewise, we assume that the boundary operator M has an integral representation; i.e., there exists a matrix-valued field $\mathcal{M} : \partial\Omega \longrightarrow \mathbb{R}^{m,m}$ such that

$$\langle Mz, y\rangle_{W',W} = \int_{\partial\Omega} y^t \mathcal{M} z \tag{2.17}$$

whenever z and y and smooth functions. We denote by $\mathcal{M}^{\sigma u}$, $\mathcal{M}^{u\sigma}$, and $\mathcal{M}^{uu}$ the top-right, bottom-left, and bottom-right blocks of $\mathcal{M}$, respectively. Henceforth, we assume that

$$\mathcal{M}^{\sigma\sigma} = 0. \tag{2.18}$$

This assumption holds for all the two-field Friedrichs' systems presented in section 3. For instance, the Dirichlet-like boundary condition $\mathcal{D}^{\sigma u} z^u = 0$ can be enforced by taking

$$\mathcal{M} = \left[\begin{array}{c|c} 0 & -\mathcal{D}^{\sigma u} \\ \hline \mathcal{D}^{u\sigma} & \mathcal{M}^{uu} \end{array}\right], \tag{2.19}$$

where $\mathcal{M}^{uu}$ is a positive matrix in $\mathbb{R}^{m_u,m_u}$ (this means that for all $\zeta \in \mathbb{R}^{m_u}$, $\zeta^t \mathcal{M}^{uu}\zeta \ge 0$) and is constructed so that $\mathrm{Ker}(\mathcal{D}^{\sigma u}) \subset \mathrm{Ker}(\mathcal{M}^{uu} - \mathcal{D}^{uu})$ (for instance take $\mathcal{M}^{uu} = \mathcal{D}^{uu} + c\,(\mathcal{D}^{u\sigma}\mathcal{D}^{\sigma u})^{\frac{1}{2}}$ with c large enough for $\mathcal{M}^{uu}$ to be positive). Similarly, taking

$$\mathcal{M} = \left[\begin{array}{c|c} 0 & \mathcal{D}^{\sigma u} \\ \hline -\mathcal{D}^{u\sigma} & \mathcal{M}^{uu} \end{array}\right], \tag{2.20}$$

where $\mathcal{M}^{uu}$ is a positive matrix in $\mathbb{R}^{m_u,m_u}$, yields the Robin boundary condition $2\mathcal{D}^{u\sigma}z^\sigma + (\mathcal{D}^{uu} - \mathcal{M}^{uu})z^u = 0$. The homogeneous Neumann boundary condition is obtained by setting $\mathcal{M}^{uu} = \mathcal{D}^{uu}$ whenever $\mathcal{D}^{uu}$ is positive. See (3.7) and (6.3) for examples.

3. Examples. This section presents three examples of Friedrichs' systems endowed with the 2×2 block structure introduced in section 2.2.

3.1. Advection-diffusion-reaction. Consider the PDE

$$-\nabla\cdot(\kappa\nabla u) + \beta\cdot\nabla u + \mu u = f, \tag{3.1}$$

with $\beta \in [L^\infty(\Omega)]^d$, $\nabla\cdot\beta \in L^\infty(\Omega)$, $\mu \in L^\infty(\Omega)$, $f \in L^2(\Omega)$, and where $\kappa = (\kappa_{kl})_{1\le k,l\le d}$ is a symmetric positive definite tensor-valued field defined on Ω whose lowest eigenvalue is uniformly bounded away from zero. Assume also that

$$\mu - \tfrac{1}{2}\nabla\cdot\beta \ge \mu_0 > 0 \quad \text{a.e. in } \Omega. \tag{3.2}$$

The PDE (3.1) can be written as a system of first-order PDEs in the form

$$\begin{cases} \kappa^{-1}\sigma + \nabla u = 0, \\ \mu u + \nabla\cdot\sigma + \beta\cdot\nabla u = f. \end{cases} \tag{3.3}$$

Set $m = d+1$, $m_\sigma = d$, and $m_u = 1$. Then, the mixed formulation (3.3) can be cast into the form of a two-field Friedrichs' system by introducing $(d+1)$ functions with values in $\mathbb{R}^{m,m}$, namely $\mathcal{K}$ and $\{\mathcal{A}^k\}_{1\le k\le d}$ such that

$$\mathcal{K} = \left[\begin{array}{c:c} \kappa^{-1} & 0 \\ \hdashline 0 & \mu \end{array}\right], \qquad \mathcal{A}^k = \left[\begin{array}{c:c} 0 & e^k \\ \hdashline (e^k)^t & \beta^k \end{array}\right], \tag{3.4}$$

where e^k is the kth vector in the canonical basis of $\mathbb{R}^d$ and β^k is the kth component of β in this basis. It is clear that hypotheses (A1)–(A6) hold. The graph space is $W = H(\mathrm{div};\Omega) \times H^1(\Omega)$ and for all $(\sigma,u),(\tau,v) \in W$,

$$\langle D(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \sigma\cdot n, v\rangle_{-\frac{1}{2},\frac{1}{2}} + \langle \tau\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}} + \int_{\partial\Omega} (\beta\cdot n)uv, \tag{3.5}$$

where $\langle,\rangle_{-\frac{1}{2},\frac{1}{2}}$ denotes the duality pairing between $H^{-\frac{1}{2}}(\partial\Omega)$ and $H^{\frac{1}{2}}(\partial\Omega)$. Note that (3.5) makes sense since functions in $H^1(\Omega)$ have traces in $H^{\frac{1}{2}}(\partial\Omega)$ and vector fields in $H(\mathrm{div};\Omega)$ have normal traces in $H^{-\frac{1}{2}}(\partial\Omega)$.

Homogeneous Dirichlet boundary conditions can be enforced by setting

$$\langle M(\sigma,u),(\tau,v)\rangle_{W',W} = \langle \sigma\cdot n, v\rangle_{-\frac{1}{2},\frac{1}{2}} - \langle \tau\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}}. \tag{3.6}$$

With this choice $V = V^* = H(\mathrm{div};\Omega)\times H^1_0(\Omega)$. Let $\varrho \in L^\infty(\partial\Omega)$ be such that $2\varrho + \beta\cdot n \ge 0$ a.e. in $\partial\Omega$. Then, setting

$$\langle M(\sigma,u),(\tau,v)\rangle_{W',W} = -\langle \sigma\cdot n, v\rangle_{-\frac{1}{2},\frac{1}{2}} + \langle \tau\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}} + \int_{\partial\Omega} (2\varrho + \beta\cdot n)uv, \tag{3.7}$$

the spaces V and V^* are defined by $V = \{(\sigma,u) \in W;\, (-\sigma\cdot n + \varrho u)|_{\partial\Omega} = 0\}$ and $V^* = \{(\sigma,u) \in W;\, (\sigma\cdot n + (\varrho + \beta\cdot n)u)|_{\partial\Omega} = 0\}$; i.e., a Robin boundary condition is enforced. A Neumann condition corresponds to $\varrho = 0$. We refer the reader to [9] for more details.

Remark 3.1. When κ is not invertible, Friedrichs' formalism can be extended as detailed in [8].

3.2. Linear continuum mechanics. Let α and γ be two positive functions in $L^\infty(\Omega)$ uniformly bounded away from zero by α_0 and γ_0, respectively. Consider the following set of PDEs:

$$\begin{cases} \sigma + p\mathcal{I}_d - \frac{1}{2}(\nabla u + (\nabla u)^t) = 0, \\ \mathrm{tr}(\sigma) + (d+\gamma)p = 0, \\ -\frac{1}{2}\nabla\cdot(\sigma+\sigma^t) + \alpha u = f, \end{cases} \tag{3.8}$$

where σ is $\mathbb{R}^{d,d}$-valued, p is scalar-valued, u is $\mathbb{R}^d$-valued, and $f \in [L^2(\Omega)]^d$. The first and second equations in (3.8) imply $p = -\gamma^{-1}\nabla\cdot u$ and $\sigma = \frac{1}{2}(\nabla u + (\nabla u)^t) + \gamma^{-1}(\nabla\cdot u)\mathcal{I}_d$; γ is a compressibility coefficient, σ is the stress tensor, $\frac{1}{2}(\nabla u + (\nabla u)^t)$ is the strain tensor, and u represents the displacement field in solid mechanics and the velocity field in fluid mechanics. In the usual solid mechanics equations, the function α vanishes identically. The function α has been introduced in (3.8) to ensure that the positivity property (A4) holds; see (3.10). In a forthcoming work, it will be shown that provided mild additional assumptions are made, the positivity property (A4) can be replaced by the weaker assumption (7.1), thus allowing α to vanish identically.

Set $m = d^2 + 1 + d$. The tensor σ in $\mathbb{R}^{d,d}$ is identified with the vector $\overline{\sigma} \in \mathbb{R}^{d^2}$ by setting $\overline{\sigma}_{[ij]} = \sigma_{ij}$ with $1 \le i,j \le d$ and $[ij] = d(j-1)+i$. Then, the mixed formulation (3.8) can be cast into the form of a Friedrichs' system by introducing the $(d+1)$ $\mathbb{R}^{m,m}$-valued fields with the following 3×3 block structure

$$\mathcal{K} = \left[\begin{array}{c|c|c} \mathcal{I}_{d^2} & \mathcal{Z} & 0 \\ \hline (\mathcal{Z})^t & (d+\gamma) & 0 \\ \hline 0 & 0 & \alpha\mathcal{I}_d \end{array}\right], \qquad \mathcal{A}^k = \left[\begin{array}{c|c|c} 0 & 0 & \mathcal{E}^k \\ \hline 0 & 0 & 0 \\ \hline (\mathcal{E}^k)^t & 0 & 0 \end{array}\right], \tag{3.9}$$

where $\mathcal{Z} \in \mathbb{R}^{d^2}$ has components given by $\mathcal{Z}_{[ij]} = \delta_{ij}$ with $1 \le i,j \le d$, and for all $k \in \{1,\dots,d\}$, $\mathcal{E}^k \in \mathbb{R}^{d^2,d}$ has components given by $\mathcal{E}^k_{[ij],l} = -\frac{1}{2}(\delta_{ik}\delta_{jl} + \delta_{il}\delta_{jk})$ with $1 \le i,j,l \le d$; here, the δ's denote Kronecker symbols.

To recover the 2×2 structure introduced in section 2.2, set $m_\sigma = d^2+1$ and $m_u = d$; i.e., the σ-component corresponds to the pair $(\overline{\sigma}, p)$. Then, hypotheses (A1)–(A6) hold. In particular, (A4)–(A5) result from the fact that for all $z = (\overline{\sigma}, p, u) \in \mathbb{R}^m$,

$$z^t\mathcal{K}z \ge \left(1 - \frac{d}{d+\frac{\gamma_0}{2}}\right)\overline{\sigma}^2 + \frac{\gamma_0}{2}p^2 + \frac{d}{d+\frac{\gamma_0}{2}}\left(\overline{\sigma} + \frac{d+\frac{\gamma_0}{2}}{d}p\mathcal{Z}\right)^2 + \alpha_0 u^2 \ge c(\overline{\sigma}^2 + p^2 + u^2), \tag{3.10}$$

where c depends only on d, α_0, and γ_0. Using the second Korn inequality for the variable u, it is readily seen that the graph space is $W = H_{\overline{\sigma}}\times L^2(\Omega)\times[H^1(\Omega)]^d$ with $H_{\overline{\sigma}} = \{\overline{\sigma} \in [L^2(\Omega)]^{d^2};\ \nabla\cdot(\sigma+\sigma^t) \in [L^2(\Omega)]^d\}$. The boundary operator D takes the following form: For all $(\overline{\sigma},p,u), (\overline{\tau},q,v) \in W$,

$$\langle D(\overline{\sigma},p,u), (\overline{\tau},q,v)\rangle_{W',W} = -\langle\tfrac{1}{2}(\tau+\tau^t)\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}} - \langle\tfrac{1}{2}(\sigma+\sigma^t)\cdot n, v\rangle_{-\frac{1}{2},\frac{1}{2}}, \tag{3.11}$$

where $\langle,\rangle_{-\frac{1}{2},\frac{1}{2}}$ denotes the duality pairing between $[H^{-\frac{1}{2}}(\partial\Omega)]^d$ and $[H^{\frac{1}{2}}(\partial\Omega)]^d$.

To enforce boundary conditions for (3.8), one possibility consists of setting for all $(\overline{\sigma},p,u), (\overline{\tau},q,v) \in W$,

$$\langle M(\overline{\sigma},p,u), (\overline{\tau},q,v)\rangle_{W',W} = \langle\tfrac{1}{2}(\tau+\tau^t)\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}} - \langle\tfrac{1}{2}(\sigma+\sigma^t)\cdot n, v\rangle_{-\frac{1}{2},\frac{1}{2}}. \tag{3.12}$$

With this choice, the u-component is set to zero at $\partial\Omega$ (i.e., a homogeneous Dirichlet boundary condition on the displacement (in solid mechanics) or on the velocity (in fluid mechanics) is enforced) as shown in the following

LEMMA 3.1. *Let M be given by* (3.12). *Then, $V = V^* = H_{\overline{\sigma}}\times L^2(\Omega)\times[H_0^1(\Omega)]^d$.*

Proof. It is clear that $V = V^*$ since $M + M^* = 0$. Observe that

$$\langle (D-M)(\overline{\sigma},p,u),(\overline{\tau},q,v)\rangle_{W',W} = -\langle (\tau+\tau^t)\cdot n, u\rangle_{-\frac{1}{2},\frac{1}{2}}. \tag{3.13}$$

Hence, it is clear that $H_{\overline{\sigma}}\times L^2(\Omega)\times[H_0^1(\Omega)]^d \subset \mathrm{Ker}(D-M) = V$. Conversely, let $(\overline{\sigma},p,u)\in\mathrm{Ker}(D-M)$. Let $\theta\in[H^{-\frac{1}{2}}(\partial\Omega)]^d$. Consider the following problem: Seek $v_\theta\in[H^1(\Omega)]^d$ such that for all $w\in[H^1(\Omega)]^d$,

$$(v_\theta,w)_{[L^2(\Omega)]^d} + (\nabla v_\theta + (\nabla v_\theta)^t, \nabla w + (\nabla w)^t)_{[L^2(\Omega)]^{d,d}} = \langle\theta,w\rangle_{-\frac{1}{2},\frac{1}{2}}.$$

This problem is well-posed owing to the second Korn inequality and the Lax–Milgram lemma. Set $\tau_\theta = \nabla v_\theta + (\nabla v_\theta)^t$. Since $\overline{\tau}_\theta\in H_{\overline{\sigma}}$, one can take $(\overline{\tau},q,v) = (\overline{\tau}_\theta,0,0)$ in (3.13) yielding $\langle\theta,u\rangle_{-\frac{1}{2},\frac{1}{2}} = 0$. Since θ is arbitrary in $[H^{-\frac{1}{2}}(\partial\Omega)]^d$, it is inferred that $u\in[H_0^1(\Omega)]^d$. ∎

3.3. Simplified MHD. For the sake of simplicity we assume that the space dimension is three, i.e., $d=3$. Let ν, μ, and σ be three functions in $L^\infty(\Omega)$, and let $\beta\in[L^\infty(\Omega)]^3$ be a vector field. A simplified (time-discretized) version of the MHD equations consists of seeking the electric field E and the magnetic field H such that

$$\begin{cases} \nu H + \nabla\times E = 0, \\ \sigma(E+\beta\times(\mu H)) - \nabla\times H = j, \end{cases} \tag{3.14}$$

where $j\in[L^2(\Omega)]^3$ is a given source term. The separation of the electromagnetic field (H,E) into magnetic and electric fields induces a natural partitioning of $[L^2(\Omega)]^6$ into $[L^2(\Omega)]^3\times[L^2(\Omega)]^3$. The PDEs (3.14) are recast into the form of a Friedrichs' system by introducing the following block structured matrices in $\mathbb{R}^{6,6}$:

$$\mathcal{K} = \left[\begin{array}{c:c} \nu\mathcal{I}_3 & 0 \\ \hdashline \sigma\mu\mathcal{V} & \sigma\mathcal{I}_3 \end{array}\right], \qquad \mathcal{A}^k = \left[\begin{array}{c:c} 0 & \mathcal{R}^k \\ \hdashline (\mathcal{R}^k)^t & 0 \end{array}\right], \tag{3.15}$$

where $\mathcal{R}^k_{ij} = \epsilon_{ikj}$ is the Levi-Civita permutation tensor, $1\le i,j,k\le 3$, and $\mathcal{V}_{ij} = \sum_{k=1}^d \epsilon_{ikj}\beta^k$. Assume that ν and σ are positive functions on Ω uniformly bounded away from zero and that there is $\alpha_0>0$ such that a.e. in Ω, $2\left(\frac{\nu}{\sigma}\right)^{\frac{1}{2}} - \mu\|\beta\|_{[L^\infty(\Omega)]^d} \ge \alpha_0$. In the above framework, one readily verifies that (A1)–(A6) hold with $m=6$, $m_\sigma=3$, and $m_u=3$. In the full MHD equations, the off-diagonal term induced by β is compensated by a term originating from the conservation of momentum in the Navier–Stokes equations so that the condition for (A4) to hold is simply that ν and σ be uniformly bounded away from zero.

The graph space is $W = H(\mathrm{curl};\Omega)\times H(\mathrm{curl};\Omega)$ and for all $(H,E),(h,e)\in W$,

$$\begin{aligned}\langle D(H,E),(h,e)\rangle_{W',W} = {}& (\nabla\times E,h)_{[L^2(\Omega)]^3} - (E,\nabla\times h)_{[L^2(\Omega)]^3} \\ & + (H,\nabla\times e)_{[L^2(\Omega)]^3} - (\nabla\times H,e)_{[L^2(\Omega)]^3}.\end{aligned} \tag{3.16}$$

When (H,E) and (h,e) are smooth, the above duality product can be interpreted as the boundary integral $\int_{\partial\Omega}[(n\times E)\cdot h + (n\times e)\cdot H]$.

An admissible boundary condition for (3.14) consists of setting

$$\begin{aligned}\langle M(H,E),(h,e)\rangle_{W',W} = &-(\nabla\times E,h)_{[L^2(\Omega)]^3}+(E,\nabla\times h)_{[L^2(\Omega)]^3}\\ &+(H,\nabla\times e)_{[L^2(\Omega)]^3}-(\nabla\times H,e)_{[L^2(\Omega)]^3}\end{aligned}\tag{3.17}$$

for all $(H,E),(h,e)\in W$. Assuming $[H^1(\Omega)]^3$ is dense in $H(\mathrm{curl};\Omega)$, this choice yields $V=V^*=H(\mathrm{curl};\Omega)\times H_0(\mathrm{curl};\Omega)$; i.e., the tangential component of the electric field is set to zero; see [8] for the analysis.

4. Two-field DG approximation. In this section we design a DG method to approximate the two-field Friedrichs' systems introduced in section 2.2. The key feature is that the discrete σ-component can be eliminated locally.

4.1. The discrete setting. Let $\{\mathcal{T}_h\}_{h>0}$ be a family of meshes of Ω. The meshes are assumed to be affine to avoid unnecessary technicalities; i.e., Ω is assumed to be a polyhedron. For $K\in\mathcal{T}_h$, h_K denotes its diameter and we set $h=\max_{K\in\mathcal{T}_h}h_K$. Henceforth, the notation $\xi\lesssim\zeta$ means that there is a positive c, *independent of* h, such that $\xi\le c\zeta$. For any measurable subset E of Ω, we denote by $(\cdot,\cdot)_{L,E}$ the usual scalar product in $[L^2(E)]^m$. We define similarly $(\cdot,\cdot)_{L_u,E}$ and $(\cdot,\cdot)_{L_\sigma,E}$.

We denote by $\mathcal{F}_h^{\mathrm{i}}$ the set of interfaces; i.e., $F\in\mathcal{F}_h^{\mathrm{i}}$ if F is a (d-1)-dimensional manifold and there are $K_1(F)$ and $K_2(F)\in\mathcal{T}_h$ such that $F=K_1(F)\cap K_2(F)$. For $F\in\mathcal{F}_h^{\mathrm{i}}$, we set $\mathcal{T}(F)=K_1(F)\cup K_2(F)$. We denote by $\mathcal{F}_h^{\partial}$ the set of the faces that separate the mesh from the exterior of Ω; i.e., $F\in\mathcal{F}_h^{\partial}$ if F is a (d-1)-dimensional manifold and there is $K(F)\in\mathcal{T}_h$ such that $F=K(F)\cap\partial\Omega$. For $F\in\mathcal{F}_h^{\partial}$, we set $\mathcal{T}(F)=K(F)$. For all $F\in\mathcal{F}_h^{\mathrm{i}}$, we denote by n_F the unit normal vector on F pointing from $K_1(F)$ to $K_2(F)$. For all $F\in\mathcal{F}_h^{\partial}$, we denote by n_F the unit normal vector on F pointing outside Ω. Finally, we set $\mathcal{F}_h=\mathcal{F}_h^{\mathrm{i}}\cup\mathcal{F}_h^{\partial}$. For all $F\in\mathcal{F}_h$, it is assumed that

$$h_{\mathcal{T}(F)}\lesssim h_F,\tag{4.1}$$

where $h_{\mathcal{T}(F)}$ denotes the diameter of $\mathcal{T}(F)$ and h_F that of F. No other assumption than (4.1) is made on the matching of element faces.

For a nonnegative integer p, consider the finite element space of scalar-valued functions

$$P_{h,p}=\{v_h\in L^2(\Omega);\,\forall K\in\mathcal{T}_h,\,v_h|_K\in\mathbb{P}_p\},\tag{4.2}$$

where $\mathbb{P}_p$ denotes the vector space of polynomials with real coefficients and with total degree less than or equal to p. The mesh family $\{\mathcal{T}_h\}_{h>0}$ is assumed to be regular enough for the following inverse and trace inverse inequalities to hold: For all $v_h\in P_{h,p}$,

$$\forall K\in\mathcal{T}_h,\quad \|\nabla v_h\|_{[L^2(K)]^d}\lesssim h_K^{-1}\|v_h\|_{L^2(K)},\tag{4.3}$$

$$\forall F\in\mathcal{F}_h,\quad \|v_h\|_{L^2(F)}\lesssim h_F^{-\frac12}\|v_h\|_{L^2(\mathcal{T}(F))}.\tag{4.4}$$

Let p_u and p_σ be two integers such that

$$1\le p_u\qquad\text{and}\qquad p_u-1\le p_\sigma.\tag{4.5}$$

Define the following vector spaces:

$$U_h=[P_{h,p_u}]^{m_u},\qquad \Sigma_h=[P_{h,p_\sigma}]^{m_\sigma},\qquad W_h=U_h\times\Sigma_h,\tag{4.6}$$

and set $U(h) = [H^1(\Omega)]^{m_u} + U_h$, $\Sigma(h) = [H^1(\Omega)]^{m_\sigma} + \Sigma_h$, and $W(h) = [H^1(\Omega)]^m + W_h$. Obviously, inequalities (4.3) and (4.4) can be applied componentwise to all functions in U_h and in Σ_h. Moreover, since every function v in $U(h)$ has a (possibly two-valued) trace a.e. on $F \in \mathcal{F}_h^{\mathrm{i}}$, we set

$$[\![v]\!] = v^1 - v^2, \qquad \{v\} = \tfrac{1}{2}(v^1 + v^2), \tag{4.7}$$

where for a.e. $x \in F$, $v^\nu(x) = \lim_{y \to x} v(y)|_{K_\nu(F)}$, $\nu \in \{1,2\}$. We define τ^1, τ^2, and $[\![\tau]\!]$ similarly for all τ in $\Sigma(h)$. The arbitrariness in the choice of $K_1(F)$ and $K_2(F)$ could be avoided by choosing intrinsic notations that would, however, unnecessarily complicate the presentation; nothing that is said hereafter depends on this choice. The above mean and jump operators are extended to boundary faces $F \in \mathcal{F}_h^\partial$ by taking the value of the function on that face.

4.2. Boundary and interface operators. For all $F \in \mathcal{F}_h$, we define the matrix-valued field $\mathcal{D}_F : F \to \mathbb{R}^{m,m}$ by

$$\mathcal{D}_F(x) = \sum_{k=1}^d n_{F,k} \mathcal{A}^k(x) \quad \text{a.e. on } F, \tag{4.8}$$

where $n_F = (n_{F,1}, \dots, n_{F,d})^t$. Owing to (2.12), $\mathcal{D}_F$ has a 2×2 block structure with $\mathcal{D}_F^{\sigma u} = \sum_{k=1}^d n_{F,k} \mathcal{B}^k$, $\mathcal{D}_F^{u\sigma} = [\mathcal{D}_F^{\sigma u}]^t$, $\mathcal{D}_F^{uu} = (\mathcal{D}_F^{uu})^t = \sum_{k=1}^d n_{F,k} \mathcal{C}^k$, and

$$\mathcal{D}_F^{\sigma\sigma} = 0. \tag{4.9}$$

The definition (4.8) is clearly compatible with that of $\mathcal{D}$; i.e., if $F \in \mathcal{F}_h^\partial$, $\mathcal{D}_F = \mathcal{D}$. Moreover, observe that for all z, y in $W(h)$ and for all $K \in \mathcal{T}_h$,

$$\sum_{F \subset \partial K} n_F \cdot n_K (\mathcal{D}_F z, y)_{L,F} = (Az, y)_{L,K} - (z, \tilde{A} y)_{L,K}. \tag{4.10}$$

We now extend the matrix-valued field $\mathcal{D}$ to interfaces as follows. For all $F \in \mathcal{F}_h^{\mathrm{i}}$, $\mathcal{D}|_F$ is two-valued, the two values being $n_F \cdot n_{K_1(F)} \mathcal{D}_F$ and $n_F \cdot n_{K_2(F)} \mathcal{D}_F$. Note that $\{\mathcal{D}\} = 0$ a.e. on $\mathcal{F}_h^{\mathrm{i}}$ since $\sum_{k=1}^d \partial_k \mathcal{A}^k$ is bounded owing to (A2).

To weakly enforce boundary conditions, we introduce for all $F \in \mathcal{F}_h^\partial$ a linear operator

$$M_F = \left[\begin{array}{c:c} M_F^{\sigma\sigma} & M_F^{\sigma u} \\ \hdashline M_F^{u\sigma} & M_F^{uu} \end{array}\right] \in \mathcal{L}([L^2(F)]^m; [L^2(F)]^m). \tag{4.11}$$

Note that M_F is not necessarily the restriction of M to functions defined on F; see Remark 5.2 below. Similarly, to penalize interface jumps, we introduce for all $F \in \mathcal{F}_h^{\mathrm{i}}$ a linear operator

$$S_F = \left[\begin{array}{c:c} S_F^{\sigma\sigma} & S_F^{\sigma u} \\ \hdashline S_F^{u\sigma} & S_F^{uu} \end{array}\right] \in \mathcal{L}([L^2(F)]^m; [L^2(F)]^m). \tag{4.12}$$

Star superscripts denote the L^2-adjoint of M_F, S_F, or any block thereof. For instance, $(M_F^{u\sigma})^* \in \mathcal{L}([L^2(F)]^{m_u}; [L^2(F)]^{m_\sigma})$ is defined such that $((M_F^{u\sigma})^*(v), \tau)_{L_\sigma,F} = (M_F^{u\sigma}(\tau), v)_{L_u,F}$ for all $v \in [L^2(F)]^{m_u}$ and for all $\tau \in [L^2(F)]^{m_\sigma}$. Finally, we introduce for all $F \in \mathcal{F}_h$ a linear operator

$$R_F \in \mathcal{L}([L^2(\mathcal{F}_h)]^{m_u}; [L^2(F)]^{m_u}). \tag{4.13}$$

The purpose of this operator is to reduce computational costs when solving the discrete problem for the u-component once the discrete σ-component has been eliminated locally; see section 4.4 and, in particular, (4.31). A simple choice consists of setting $R_F \equiv 0$ for all $F \in \mathcal{F}_h$; an example with nonzero R_F's is the IP method discussed in section 6.1.2.

The operators M_F, S_F, and R_F satisfy various design criteria which are collected in section 5.1. For the time being, we solely mention the important assumption

$$M_F^{\sigma\sigma} = 0 \qquad \text{and} \qquad S_F^{\sigma\sigma} = 0. \tag{4.14}$$

Hence, the jumps across interfaces of the σ-component of the unknown are not controlled. This is the key property that allows for the local elimination of the σ-component of the discrete solution z_h; see section 4.4. This is the most important difference with respect to the DG method analyzed in [9].

4.3. The discrete problem and the notion of fluxes. Drawing inspiration from (2.10), we introduce the bilinear form a_h such that for all z, y in $W(h)$,

$$\begin{aligned} a_h(z,y) = &\sum_{K\in\mathcal{T}_h} (Tz,y)_{L,K} + \sum_{F\in\mathcal{F}_h^\partial} \tfrac{1}{2}(M_F(z) - \mathcal{D}z, y)_{L,F} - \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} 2(\{\mathcal{D}z\}, \{y\})_{L,F} \\ &+ \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (S_F([\![z]\!]), [\![y]\!])_{L,F} + \sum_{F\in\mathcal{F}_h} (R_F([\![z^u]\!]), [\![y^u]\!])_{L_u,F}. \end{aligned} \tag{4.15}$$

The first and second term in the right-hand side come directly from (2.8). The third term is meant to ensure that a_h satisfies a coercivity property on W_h (see Lemma 5.4) in a manner consistent with the continuous setting (this term is zero whenever z is smooth). The fourth term is used to control the jump of the discrete solution across interfaces. The last term is a perturbation (possibly $R_F \equiv 0$) which allows for some modifications of the second and third terms to alleviate computational costs; see the end of section 4.4 and the IP method discussed in section 6.1.2.

The discrete counterpart of (2.10) is the following: For $f = (f^\sigma, f^u) \in L$,

$$\begin{cases} \text{Seek } z_h = (z_h^\sigma, z_h^u) \in W_h \text{ such that} \\ a_h(z_h, y_h) = (f, y_h)_L \quad \forall y_h = (y_h^\sigma, y_h^u) \in W_h. \end{cases} \tag{4.16}$$

As in [9], the discrete problem (4.16) can be localized by using the notion of flux. Let K be a mesh element in $\mathcal{T}_h$ and let $z \in W(h)$. The element flux of z on ∂K, say $\phi_{\partial K}(z) \in [L^2(\partial K)]^m$, is defined by its restriction to the faces F of ∂K as follows:

$$\phi_{\partial K}(z)|_F = \begin{cases} \tfrac{1}{2}(\mathcal{D}z + M_F(z) + 2R'_F(z^u)) & \text{if } F \in \mathcal{F}_h^\partial, \\ n_F{\cdot}n_K(\mathcal{D}_F\{z\} + S_F([\![z]\!]) + R'_F([\![z^u]\!])) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}, \end{cases} \tag{4.17}$$

where $R'_F(z^u) = (0, R_F(z^u)) \in [L^2(F)]^m$.

The discrete problem (4.16) is equivalently reformulated in terms of the following local problems posed for all $K \in \mathcal{T}_h$:

$$\begin{cases} \text{Seek } z_h \in W_h \text{ such that } \forall q = (q^\sigma, q^u) \in [\mathbb{P}_{p_\sigma}(K)]^{m_\sigma} \times [\mathbb{P}_{p_u}(K)]^{m_u}, \\ (Kz_h, q)_{L,K} + (Az_h, q)_{L,K} + (\phi_{\partial K}(z_h) - n_F{\cdot}n_K\mathcal{D}_F z_h|_K, q)_{L,\partial K} = (f,q)_{L,K}, \end{cases} \tag{4.18}$$

or equivalently using the local integration by parts formula (4.10),

$$\begin{cases} \text{Seek } z_h \in W_h \text{ such that } \forall q = (q^\sigma, q^u) \in [\mathbb{P}_{p_\sigma}(K)]^{m_\sigma} \times [\mathbb{P}_{p_u}(K)]^{m_u}, \\ (Kz_h, q)_{L,K} + (z_h, \tilde{A}q)_{L,K} + (\phi_{\partial K}(z_h), q)_{L,\partial K} = (f, q)_{L,K}. \end{cases} \tag{4.19}$$

4.4. Eliminating the σ-component. We now rewrite (4.18) using the 2×2 block structure, and we show how the unknown z_h^σ can be locally eliminated. To simplify, we assume that $f^\sigma \equiv 0$ (this is a natural assumption to define z^σ in physical models). Recall that the σ-component of the element flux is

$$\phi_{\partial K}^\sigma(z^u)|_F = \begin{cases} \frac{1}{2}(\mathcal{D}^{\sigma u} + M_F^{\sigma u})z^u & \text{if } F \in \mathcal{F}_h^\partial, \\ n_F{\cdot}n_K(\mathcal{D}_F^{\sigma u}\{z^u\} + S_F^{\sigma u}([\![z^u]\!])) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}, \end{cases} \tag{4.20}$$

where we stress that $\phi_{\partial K}^\sigma$ solely depends on z^u owing to (4.14). Then, (4.18) implies that z_h^σ solves the following local problems: For all $q^\sigma \in \mathbb{P}_\sigma(K) := [\mathbb{P}_{p_\sigma}(K)]^{m_\sigma}$,

$$(\mathcal{K}^{\sigma\sigma} z_h^\sigma + \mathcal{K}^{\sigma u} z_h^u + B z_h^u, q^\sigma)_{L_\sigma,K} + (\phi_{\partial K}^\sigma(z_h^u) - \mathcal{D}_{\partial K}^{\sigma u} z_h^u|_K, q^\sigma)_{L_\sigma,\partial K} = 0. \tag{4.21}$$

For all $K \in \mathcal{T}_h$, let θ_K^1 be the L^2-orthogonal projection from $[L^2(K)]^{m_\sigma}$ onto $\mathbb{P}_\sigma(K)$ and let $\theta_K^2 : \mathbb{P}_\sigma(K) \to \mathbb{P}_\sigma(K)$ be the mapping such that for all $q^\sigma \in \mathbb{P}_\sigma(K)$, $(\theta_K^2(q^\sigma), r^\sigma)_{L_\sigma,K} = (\mathcal{K}^{\sigma\sigma} q^\sigma, r^\sigma)_{L_\sigma,K}$ for all $r^\sigma \in \mathbb{P}_\sigma(K)$ (note that θ_K^2 is the identity whenever $\mathcal{K}^{\sigma\sigma}$ is the identity matrix in $\mathbb{R}^{m_\sigma,m_\sigma}$). Let $F \in \mathcal{F}_h$. Define the mapping $r_F : [L^2(F)]^{m_\sigma} \longrightarrow \Sigma_h$ so that for all $z^\sigma \in [L^2(F)]^{m_\sigma}$, $r_F(z^\sigma)$ solves

$$(r_F(z^\sigma), y_h^\sigma)_{L_\sigma} = (z^\sigma, \{y_h^\sigma\})_{L_\sigma,F} \quad \forall y_h^\sigma \in \Sigma_h. \tag{4.22}$$

Observe that the support of $r_F(z^\sigma)$ is contained in $\mathcal{T}(F)$. Then, (4.21) yields the local reconstruction formula for the discrete σ-component in the form

$$\forall K \in \mathcal{T}_h, \quad z_h^\sigma|_K = \mathfrak{R}_K(z_h^u) + \mathfrak{R}_{\Delta_K}([\![z_h^u]\!]), \tag{4.23}$$

where

$$\mathfrak{R}_K(z_h^u) = -(\theta_K^2)^{-1}\theta_K^1(\mathcal{K}^{\sigma u} z_h^u + B z_h^u|_K) \tag{4.24}$$

is supported on K, and where

$$\mathfrak{R}_{\Delta_K}([\![z_h^u]\!]) = -(\theta_K^2)^{-1} \sum_{F \subset \partial K} r_F(\psi_{F,K}([\![z_h^u]\!])) \tag{4.25}$$

is supported on $\Delta_K = \{K' \in \mathcal{T}_h;\ \exists F \in \mathcal{F}_h^{\mathrm{i}};\ F = K \cap K'\}$. Here,

$$\psi_{F,K}(v) = \begin{cases} \frac{1}{2}(M_F^{\sigma u} - \mathcal{D}^{\sigma u})v & \text{if } F \in \mathcal{F}_h^\partial, \\ (2n_F{\cdot}n_K S_F^{\sigma u} - \mathcal{D}_F^{\sigma u})v & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}. \end{cases} \tag{4.26}$$

Then, using (4.23) in (4.19) shows that z_h^u solves the following problems: For all $K \in \mathcal{T}_h$ and for all $q^u \in \mathbb{P}_u(K) := [\mathbb{P}_{p_u}(K)]^{m_u}$,

(4.27)

$$\begin{aligned} &((\mathcal{K}^{u\sigma} - (\nabla{\cdot}B)^*)(\mathfrak{R}_K(z_h^u) + \mathfrak{R}_{\Delta_K}([\![z_h^u]\!])) + (\mathcal{K}^{uu} - \nabla{\cdot}C) z_h^u - f^u, q^u)_{L_u,K} \\ &- (z_h^u, C^\dagger q^u)_{L_u,K} - (\mathfrak{R}_K(z_h^u) + \mathfrak{R}_{\Delta_K}([\![z_h^u]\!]), B^\dagger q^u)_{L_u,K} + (\phi_{\partial K}^u(z_h^u), q^u)_{L_u,\partial K} = 0, \end{aligned}$$

where for $F \in \mathcal{F}_h^\partial$,

$$\phi^u_{\partial K}(z^u_h)|_F = \tfrac{1}{2}(M^{u\sigma}_F + \mathcal{D}^{u\sigma})(\mathfrak{R}_K(z^u_h) + \mathfrak{R}_{\Delta_K}([\![z^u_h]\!])) + \tfrac{1}{2}(M^{uu}_F + \mathcal{D}^{uu})z^u_h + R_F([\![z^u_h]\!]), \tag{4.28}$$

and for $F \in \mathcal{F}^{\mathrm{i}}_h$,

$$\phi^u_{\partial K}(z^u_h)|_F = n_F{\cdot}n_K(\mathcal{D}^{u\sigma}_F\{\mathfrak{R}_K(z^u_h) + \mathfrak{R}_{\Delta_K}([\![z^u_h]\!])\} + \mathcal{D}^{uu}_F\{z^u_h\} + S^{u\sigma}_F([\![\mathfrak{R}_K(z^u_h) + \mathfrak{R}_{\Delta_K}([\![z^u_h]\!])]\!]) + S^{uu}_F([\![z^u_h]\!]) + R_F([\![z^u_h]\!])). \tag{4.29}$$

This readily yields the following.

PROPOSITION 4.1. *If the pair* (z^σ_h, z^u_h) *solves* (4.16)*, then* (4.23) *holds and* z^u_h *solves* (4.27)*. Conversely, if* z^u_h *solves* (4.27) *and if* z^σ_h *is defined by* (4.23)*, then the pair* (z^σ_h, z^u_h) *solves* (4.16)*.*

At this point, it is important to observe that owing to the presence of the nonlocal term $\mathfrak{R}_{\Delta_K}$ in the flux $\phi^u_{\partial K}$, the problem (4.27) couples the degrees of freedom for z^u_h in a given element to those in the neighboring elements and also to those in the neighbors of the neighbors. Let us assume that $S^{u\sigma}_F \equiv 0$ and, for simplicity, that Dirichlet boundary conditions are enforced so that $M^{\sigma u}_F = -\mathcal{D}^{\sigma u}$ and $M^{u\sigma}_F = \mathcal{D}^{u\sigma}$ (Neumann/Robin boundary conditions can be treated as well). Then, if R_F is defined so that for all $F \subset \partial K$,

$$R_F([\![z^u_h]\!]) + \mathcal{D}^{u\sigma}_F\{\mathfrak{R}_{\Delta_K}([\![z^u_h]\!])\} = 0, \tag{4.30}$$

the terms involving $\mathfrak{R}_{\Delta_K}([\![z^u_h]\!])$ are eliminated from (4.28)–(4.29). Owing to this elimination, problem (4.27) couples the degrees of freedom for z^u_h in a given element only to those in the neighboring elements. Using (4.25), it is readily verified that (4.30) holds if R_F is designed such that

$$R_F([\![z^u_h]\!]) = \tfrac{1}{2}\mathcal{D}^{u\sigma}_F \sum_{i=1}^{2} (\theta^2_{K_i(F)})^{-1} \sum_{F' \in \partial K_i(F)} r_{F'}(\psi_{F',K_i(F)}([\![z^u_h]\!]))|_F. \tag{4.31}$$

Finally, a further simplification occurs whenever $\mathcal{K}^{u\sigma} - (\nabla{\cdot}B)^* \equiv 0$ since, in this case, the term $\mathfrak{R}_{\Delta_K}([\![z^u_h]\!])$ needs not be evaluated to solve (4.27) for z^u_h; i.e., the reconstruction of z^σ_h from (4.23) can be performed as a postprocessing step.

5. Convergence analysis. In this section, we present the design criteria for the above DG method and perform the error analysis. The main results are Theorem 5.8, which estimates the error in the norm (5.10), and Theorem 5.14, which improves the L_u-estimate of the u-component of the error by means of a duality argument. Throughout this section, we assume the following:

- For all $k \in \{1, \dots, d\}$ and for all $K \in \mathcal{T}_h$, $\mathcal{B}^k \in [\mathcal{C}^{0,1}(K)]^{m_\sigma, m_u}$.
- The mesh family $\{\mathcal{T}_h\}_{h>0}$ is such that (4.1), (4.3), and (4.4) hold.
- The approximation spaces are defined according to (4.2), (4.5), and (4.6).

5.1. The design criteria for the boundary and interface operators. For all $F \in \mathcal{F}_h^\partial$, for all $v, w \in [L^2(F)]^{m_u}$, and for all $\tau \in [L^2(F)]^{m_\sigma}$, we assume that

(DG1) $M_F^{\sigma\sigma} = 0,$

(DG2) $M_F^{\sigma u} + (M_F^{u\sigma})^* = 0,$

(DG3) $(M_F^{uu}(v), v)_{L_u,F} \geq 0,$

(DG4) $|(M_F^{\sigma u}(v) - \mathcal{D}^{\sigma u} v, \tau)_{L_\sigma,F}| \lesssim h_F^{\frac{1}{2}} |v|_{M,F} \|\tau\|_{L_\sigma,F},$

(DG5) $|(M_F^{uu}(v) + \mathcal{D}^{uu} v, w)_{L_u,F}| \lesssim h_F^{-\frac{1}{2}} \|v\|_{L_u,F} |w|_{M,F},$

(DG6) $|(M_F^{uu}(v) - \mathcal{D}^{uu} v, w)_{L_u,F}| \lesssim h_F^{-\frac{1}{2}} |v|_{M,F} \|w\|_{L_u,F},$

(DG7) $\mathrm{Ker}(\mathcal{M} - \mathcal{D}) \subset \mathrm{Ker}(M_F - \mathcal{D}),$

(DG8) $\mathrm{Ker}(\mathcal{M}^t + \mathcal{D}) \subset \mathrm{Ker}(M_F^* + \mathcal{D}),$

where we have introduced the following seminorms:

$$\forall v \in U(h), \qquad |v|_M^2 = \sum_{F \in \mathcal{F}_h^\partial} |v|_{M,F}^2 \qquad \text{with} \qquad |v|_{M,F}^2 = (M_F^{uu}(v), v)_{L_u,F}. \tag{5.1}$$

For all $F \in \mathcal{F}_h^{\mathrm{i}}$, for all $v, w \in [L^2(F)]^{m_u}$, and for all $\tau \in [L^2(F)]^{m_\sigma}$, we assume that

(DG9) $S_F^{\sigma\sigma} = 0,$

(DG10) $S_F^{\sigma u} + (S_F^{u\sigma})^* = 0,$

(DG11) $(S_F^{uu}(v), v)_{L_u,F} \geq 0,$

(DG12) $|(S_F^{uu}(v), w)_{L_u,F}| \lesssim h_F^{-\frac{1}{2}} \|v\|_{L_u,F} |w|_{S,F},$

(DG13) $|(S_F^{uu}(v), w)_{L_u,F}| \lesssim h_F^{-\frac{1}{2}} |v|_{S,F} \|w\|_{L_u,F},$

(DG14) $|(S_F^{\sigma u}(v), \tau)_{L_\sigma,F}| \lesssim h_F^{\frac{1}{2}} |v|_{S,F} \|\tau\|_{L_\sigma,F},$

(DG15) $|(\mathcal{D}^{\sigma u} v, \tau)_{L_\sigma,F}| \lesssim h_F^{\frac{1}{2}} |v|_{S,F} \|\tau\|_{L_\sigma,F},$

(DG16) $|(\mathcal{D}^{uu} v, w)_{L_u,F}| \lesssim h_F^{-\frac{1}{2}} |v|_{S,F} \|w\|_{L_u,F},$

where we have introduced the following seminorms:

$$\forall v \in U(h), \qquad |v|_S^2 = \sum_{F \in \mathcal{F}_h^{\mathrm{i}}} |v|_{S,F}^2 \qquad \text{with} \qquad |v|_{S,F}^2 = (S_F^{uu}(v), v)_{L_u,F}. \tag{5.2}$$

Finally, the design of the operators R_F is based on the following assumptions:

(DG17) $\forall z_h \in W_h, \quad \rho_h([\![z_h^u]\!], [\![z_h^u]\!]) \geq -\frac{1}{4}(|z_h^u|_J^2 + |z_h^u|_M^2),$

(DG18) $\forall (z, y_h) \in W(h) \times W_h, \quad \rho_h([\![z^u]\!], [\![y_h^u]\!]) \lesssim (|z^u|_J + |z^u|_M)(|y_h^u|_J + |y_h^u|_M),$

where $\rho_h([\![z^u]\!], [\![y^u]\!]) := \sum_{F \in \mathcal{F}_h} (R_F([\![z^u]\!]), [\![y^u]\!])_{L_u,F}$ and where for all $z^u \in U(h)$,

$$|z^u|_J^2 = \sum_{F \in \mathcal{F}_h^{\mathrm{i}}} |z^u|_{J,F}^2 \qquad \text{with} \qquad |z^u|_{J,F} = |[\![z^u]\!]|_{S,F}. \tag{5.3}$$

Theorem 5.8 relies only on assumptions (DG1)–(DG5), (DG7), (DG9)–(DG12), (DG14)–(DG15), and (DG17)–(DG18), collectively referred to as (DG$^\flat$). The additional assumptions (DG6), (DG8), (DG13), and (DG16) are needed to prove Theorem 5.14. Assumptions (DG1)–(DG18) are collectively referred to as (DG$^\sharp$).

Remark 5.1. Assumptions (DG1)–(DG6) imply that for all $(\tau, v) \in [L^2(F)]^m$,

$$|v|_{M,F} \lesssim h_F^{-\frac{1}{2}} \|v\|_{L_u,F}, \tag{5.4}$$

$$|(M_F^{\sigma u}(v), \tau)_{L_\sigma,F}| \lesssim \|v\|_{L_u,F} \|\tau\|_{L_\sigma,F}, \tag{5.5}$$

$$|(M_F^{u\sigma}(\tau) + \mathcal{D}^{u\sigma}\tau, v)_{L_u,F}| \lesssim h_F^{\frac{1}{2}} |v|_{M,F} \|\tau\|_{L_\sigma,F}. \tag{5.6}$$

For instance, taking $v = w$ in (DG6) and using the fact that $\mathcal{D}^{uu}$ is bounded yields $|v|_{M,F}^2 \lesssim \|v\|_{L_u,F}^2 + h_F^{-\frac{1}{2}} |v|_{M,F} \|v\|_{L_u,F}$, whence (5.4) readily follows. Properties (5.4)–(5.6) will be used in what follows.

Remark 5.2. Assumptions (DG7) and (DG8) are consistency hypotheses which trivially hold if $M_F(z) = \mathcal{M} z|_F$. However, it is not always possible to make this simple choice because it is sometimes necessary to penalize the boundary values of the u-component of the unknown. For instance, when Dirichlet-like boundary conditions are enforced, i.e., $\mathcal{M}^{\sigma u} = -\mathcal{D}^{\sigma u}$, it may happen that $\mathcal{M}^{uu} = 0$ (see the examples discussed in section 3). In this circumstance, assumptions (DG4)–(DG6) cannot be satisfied if we set $M_F^{uu}(v) = \mathcal{M}^{uu} v|_F = 0$, since $|v|_{M,F} = 0$ for all $v \in [L^2(F)]^{m_u}$. Instead, it is necessary that M_F^{uu} scale like h_F^{-1}. The consistency hypotheses (DG7) and (DG8) then mean that the extra control required by (DG4)–(DG6) is compatible with the way boundary conditions are enforced (see also Remark 6.2 and section 6.1.1, section 6.2, and section 6.3 for examples).

While assumptions (DG$^\sharp$) are just what it takes to prove Theorems 5.8 and 5.14, it is simpler in practice to work with a simplified set of assumptions. These are summarized in the following lemmas. Lemma 5.1 is tailored for the case when Dirichlet-like boundary conditions are enforced, while Lemma 5.2 is tailored for the case when Neumann or Robin boundary conditions are enforced. For brevity, only the proof of Lemma 5.1 is detailed, the other two proofs being similar.

LEMMA 5.1 (Dirichlet-like BCs). *Assume $M_F^{\sigma\sigma} = 0$, $M_F^{\sigma u}(v) = -\mathcal{D}^{\sigma u} v$ for all $v \in [L^2(F)]^{m_u}$, $M_F^{u\sigma} = -(M_F^{\sigma u})^*$, M_F^{uu} is self-adjoint, and*

$$h_F |\mathcal{D}^{uu}| + h_F^{-1} (\mathcal{D}^{u\sigma} \mathcal{D}^{\sigma u})^{\frac{1}{2}} \lesssim M_F^{uu} \lesssim h_F^{-1} \mathcal{I}_{m_u}, \tag{5.7}$$

where $\mathcal{I}_{m_u}$ is the identity matrix in $\mathbb{R}^{m_u, m_u}$. Then, (DG1)–(DG6) *hold.*

Proof. Assumptions (DG1)–(DG3) are evident. To prove (DG4), observe that for every positive semidefinite matrix $\mathcal{Z} \in \mathbb{R}^{m_u, m_u}$ and for all $x \in \mathbb{R}^{m_u}$, $(\mathcal{Z}x, x) \le \|\mathcal{Z}^{1/2}\| (\mathcal{Z}^{1/2} x, x)$. Let $v \in [L^2(F)]^{m_u}$; upon observing that $\mathcal{D}^{u\sigma}\mathcal{D}^{\sigma u}$ is positive semidefinite, we apply the above result to derive

$$\begin{aligned} \|\mathcal{D}^{\sigma u} v\|_{L_\sigma,F} &= (\mathcal{D}^{\sigma u} v, \mathcal{D}^{\sigma u} v)_{L_\sigma,F}^{\frac{1}{2}} = (\mathcal{D}^{u\sigma}\mathcal{D}^{\sigma u} v, v)_{L_u,F}^{\frac{1}{2}} \\ &\lesssim ((\mathcal{D}^{u\sigma}\mathcal{D}^{\sigma u})^{\frac{1}{2}} v, v)_{L_u,F}^{\frac{1}{2}} \lesssim h_F^{\frac{1}{2}} |v|_{M,F}, \end{aligned}$$

whence (DG4) is readily inferred. To prove (DG5)–(DG6), let $v, w \in [L^2(F)]^{m_u}$. Then, $|(M_F^{uu}(v), w)_{L_u,F}| \lesssim |v|_{M,F} |w|_{M,F}$ and since $(\mathcal{D}^{uu})^2$ is positive semidefinite,

$$\|\mathcal{D}^{uu} v\|_{L_u,F} \lesssim (|\mathcal{D}^{uu}| v, v)_{L_u,F}^{\frac{1}{2}} \lesssim h_F^{-\frac{1}{2}} |v|_{M,F},$$

whence (DG5)–(DG6) are readily deduced. ∎

LEMMA 5.2 (Neumann–Robin BCs). *Assume $M_F^{\sigma\sigma} = 0$, $M_F^{\sigma u}(v) = \mathcal{D}^{\sigma u} v$ for all $v \in [L^2(F)]^{m_u}$, $M_F^{u\sigma} = -(M_F^{\sigma u})^*$, M_F^{uu} is self-adjoint, and*

$$h_F |\mathcal{D}^{uu}| \lesssim M_F^{uu} \lesssim h_F^{-1} \mathcal{I}_{m_u}. \tag{5.8}$$

Then, (DG1)–(DG6) *hold.*

LEMMA 5.3 (interface operator). *Assume* $S_F^{\sigma\sigma}=0$, $S_F^{u\sigma}=0$, $S_F^{\sigma u}=0$, S_F^{uu} *is self-adjoint, and*

$$h_F|\mathcal{D}^{uu}|+h_F^{-1}(\mathcal{D}^{u\sigma}\mathcal{D}^{\sigma u})^{\frac12}\lesssim S_F^{uu}\lesssim h_F^{-1}\mathcal{I}_{m_u}. \tag{5.9}$$

Then, (DG9)–(DG16) *hold.*

Remark 5.3. Conditions (5.7) and (5.9) generally imply that S_F^{uu} and M_F^{uu} are of order h_F^{-1}; this differs from the condition derived in [9], where S_F and M_F are of order 1. Roughly speaking, to be able to eliminate the discrete σ-component, it is necessary to have a stronger control of the interface jumps and of the boundary values of the discrete u-component.

5.2. The direct argument. To perform the error analysis we introduce the following two discrete norms on $W(h)$:

$$\|z\|_{h,A}^2=\|z^\sigma\|_{L_\sigma}^2+\|z^u\|_{L_u}^2+|z^u|_J^2+|z^u|_M^2+\sum_{K\in\mathcal{T}_h}\|Bz^u\|_{L_\sigma,K}^2, \tag{5.10}$$

$$\|z\|_{h,1}^2=\|z\|_{h,A}^2+\sum_{K\in\mathcal{T}_h}[h_K^{-2}\|z^u\|_{L_u,K}^2+h_K^{-1}\|z^u\|_{L_u,\partial K}^2+h_K\|z^\sigma\|_{L_\sigma,\partial K}^2]. \tag{5.11}$$

The norm $\|\cdot\|_{h,A}$ is used to measure the approximation error, and the norm $\|\cdot\|_{h,1}$ serves to measure the interpolation properties of the discrete space W_h. In this section, it is implicitly assumed that (DG$^\flat$) holds.

LEMMA 5.4 (L-coercivity). *For all h and for all $z_h=(z_h^\sigma,z_h^u)$ in W_h,*

$$\|z_h^\sigma\|_{L_\sigma}^2+\|z_h^u\|_{L_u}^2+|z_h^u|_J^2+|z_h^u|_M^2\lesssim a_h(z_h,z_h). \tag{5.12}$$

Proof. Proceeding as in the proof of Lemma 4.1 in [9] and using the skew-symmetry assumptions (DG2) and (DG10) yields for all $z_h\in W_h$,

$$\|z_h^\sigma\|_{L_\sigma}^2+\|z_h^u\|_{L_u}^2+|z_h^u|_J^2+\tfrac12|z_h^u|_M^2+\rho_h([\![z_h^u]\!],[\![z_h^u]\!])\lesssim a_h(z_h,z_h).$$

Then, the desired result follows from (DG17). ∎

LEMMA 5.5 (stability). *The following holds:*

$$\forall z_h\in W_h,\quad \|z_h\|_{h,A}\lesssim\sup_{y_h\in W_h\backslash\{0\}}\frac{a_h(z_h,y_h)}{\|y_h\|_{h,A}}. \tag{5.13}$$

Proof. Let $z_h=(z_h^\sigma,z_h^u)\in W_h\backslash\{0\}$ and set $\mathbb{S}=\sup_{y_h\in W_h\backslash\{0\}}\frac{a_h(z_h,y_h)}{\|y_h\|_{h,A}}$.

(1) Owing to Lemma 5.4, it is inferred that

$$\|z^\sigma\|_{L_\sigma}^2+\|z^u\|_{L_u}^2+|z^u|_J^2+|z^u|_M^2\lesssim a_h(z_h,z_h)\le\mathbb{S}\,\|z_h\|_{h,A}.$$

(2) Control of Bz_h^u. Let $K\in\mathcal{T}_h$. Denote by $\overline{\mathcal{B}_K^k}$ the mean-value of $\mathcal{B}^k$ over K; then,

$$\|\mathcal{B}^k-\overline{\mathcal{B}_K^k}\|_{[L^\infty(K)]^{m_\sigma,m_u}}\le h_K\|\mathcal{B}^k\|_{[\mathcal{C}^{0,1}(K)]^{m_\sigma,m_u}}. \tag{5.14}$$

Define the field π_h such that $\pi_h|_K=\sum_{k=1}^d\overline{\mathcal{B}_K^k}\partial_k z_h^u$. Set $\varpi_h=(\pi_h,0)$. It is clear that $\pi_h\in\Sigma_h$ since $p_u-1\le p_\sigma$; hence, $\varpi_h\in W_h$. Using (5.14), together with the inverse inequalities (4.3) and (4.4), leads, for all $F\subset\partial K$, to

$$\begin{cases}\|\pi_h\|_{L_\sigma,F}\lesssim h_F^{-\frac12}\|\pi_h\|_{L_\sigma,\mathcal{T}(F)}, & \text{if } F\in\mathcal{F}_h^\partial,\\ \|\{\pi_h\}\|_{L_\sigma,F}+\|[\![\pi_h]\!]\|_{L_\sigma,F}\lesssim h_F^{-\frac12}\|\pi_h\|_{L_\sigma,\mathcal{T}(F)} & \text{if } F\in\mathcal{F}_h^{\mathrm{i}},\end{cases} \tag{5.15}$$

$$\|\pi_h\|_{L_\sigma,K}\lesssim\|Bz_h^u\|_{L_\sigma,K}+\|z_h^u\|_{L_u,K}, \tag{5.16}$$

whence it is readily inferred that

$$\|\varpi_h\|_{h,A} = \|\pi_h\|_{L_\sigma} \lesssim \|z_h\|_{h,A}.$$

Furthermore, from the definition of a_h it follows that

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} \|Bz_h^u\|_{L_\sigma,K}^2 &= a_h(z_h,\varpi_h) + \sum_{K\in\mathcal{T}_h} (Bz_h^u, Bz_h^u - \pi_h)_{L_\sigma,K} \\ &\quad - (\mathcal{K}^{\sigma\sigma} z_h^\sigma + \mathcal{K}^{\sigma u} z_h^u, \pi_h)_{L_\sigma} - \sum_{F\in\mathcal{F}_h^\partial} \tfrac{1}{2}(M_F^{\sigma u}(z_h^u) - \mathcal{D}^{\sigma u} z_h^u, \pi_h)_{L_\sigma,F} \\ &\quad + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} 2(\{\mathcal{D}^{\sigma u} z_h^u\}, \{\pi_h\})_{L_\sigma,F} - \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (S_F^{\sigma u}([\![z_h^u]\!]), [\![\pi_h]\!])_{L_\sigma,F} \\ &= a_h(z_h,\varpi_h) + R_1 + R_2 + R_3 + R_4 + R_5,\end{aligned}$$

where R_1 to R_5 denote the second to sixth terms in the right-hand side. Proceeding as in the proof of Lemma 4.3 in [9] and using (DG4), (DG14), (DG15), the terms R_1–R_5 are bounded from above as follows:

$$\sum_{i=1}^5 |R_i| \lesssim (\|z_h^\sigma\|_{L_\sigma}^2 + \|z_h^u\|_{L_u}^2 + |z_h^u|_M^2 + |z_h^u|_J^2) + \gamma \sum_{K\in\mathcal{T}_h} \|Bz_h^u\|_{L_\sigma,K}^2,$$

where $\gamma > 0$ can be chosen as small as needed. Hence,

$$\sum_{K\in\mathcal{T}_h} \|Bz_h^u\|_{L_\sigma,K}^2 \lesssim a_h(z_h,\varpi_h) + a_h(z_h,z_h) \lesssim \mathbb{S}\,\|z_h\|_{h,A}.$$

(3) Collecting the above bounds yields $\|z_h\|_{h,A}^2 \lesssim \mathbb{S}\,\|z_h\|_{h,A}$, thereby completing the proof. ∎

LEMMA 5.6 (continuity). *The following holds:*

$$\forall (z,y_h) \in W(h)\times W_h, \quad a_h(z,y_h) \lesssim \|z\|_{h,1}\|y_h\|_{h,A}. \tag{5.17}$$

Proof. The main idea is to integrate by parts $a_h(z,y_h)$ by using the formal adjoint $\tilde{A}$. Proceeding as in the proof of Lemma 4.4 in [9] leads to

$$\begin{aligned}a_h(z,y_h) = &\sum_{K\in\mathcal{T}_h} [(Kz,z)_{L,K} + (z,\tilde{A}y_h)_{L,K}] + \sum_{F\in\mathcal{F}_h^\partial} \tfrac{1}{2}(M_F(z) + \mathcal{D}z, y_h)_{L,F} \\ &+ \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} \tfrac{1}{2}([\![\mathcal{D}z]\!], [\![y_h]\!])_{L,F} + \rho_h([\![z^u]\!], [\![y_h^u]\!]) + \sum_{F\in\mathcal{F}_h^{\mathrm{i}}} (S_F([\![z]\!]), [\![y_h]\!])_{L,F}.\end{aligned} \tag{5.18}$$

Let R_1 to R_5 be the five terms in the right-hand side.

(1) Using the Cauchy–Schwarz inequality and inverse inequalities, we obtain

$$|R_1| \lesssim \sum_{K\in\mathcal{T}_h} \|z\|_{L,K}\|y_h\|_{L,K} + \|z^\sigma\|_{L_\sigma,K}\|By_h^u\|_{L_\sigma,K} + h_K^{-1}\|z^u\|_{L_u,K}\|y_h\|_{L,K}.$$

Hence, $|R_1| \lesssim \|z\|_{h,1}\|y_h\|_{h,A}$.

(2) For the second term, we have

$$\begin{aligned}|R_2| \le \tfrac{1}{2} \sum_{F\in\mathcal{F}_h^\partial} |&(M_F^{\sigma u}(z^u) + \mathcal{D}^{\sigma u} z^u, y_h^\sigma)_{L_\sigma,F} + (M_F^{uu}(z^u) + \mathcal{D}^{uu} z^u, y_h^u)_{L_u,F} \\ &+ (M_F^{u\sigma}(z^\sigma) + \mathcal{D}^{u\sigma} z^\sigma, y_h^u)_{L_u,F}|.\end{aligned}$$

Using (5.5), (DG5), the boundedness of $\mathcal{D}$, (5.6), and the inverse inequality (4.4), each term in the above equality is bounded as follows:

$$|(M_F^{\sigma u}(z^u)+\mathcal{D}^{\sigma u}z^u,y_h^\sigma)_{L_\sigma,F}|\lesssim\|z^u\|_{L_u,F}\|y_h^\sigma\|_{L_\sigma,F}\lesssim h_F^{-\frac12}\|z^u\|_{L_u,F}\|y_h^\sigma\|_{L_\sigma,\mathcal{T}(F)},$$
$$|(M_F^{uu}(z^u)+\mathcal{D}^{uu}z^u,y_h^u)_{L_u,F}|\lesssim h_F^{-\frac12}\|z^u\|_{L_u,F}|y_h^u|_{M,F},$$
$$|(M_F^{u\sigma}(z^\sigma)+\mathcal{D}^{u\sigma}z^\sigma,y_h^u)_{L_u,F}|\lesssim h_F^{\frac12}\|z^\sigma\|_{L_\sigma,F}|y_h^u|_{M,F}.$$

As a result, $|R_2|\lesssim\|z\|_{h,1}\|y_h\|_{h,A}$.

(3) For the third term, we have

$$|R_3|\le\tfrac12\sum_{F\in\mathcal{F}_h^{\mathrm{i}}}|(\llbracket\mathcal{D}^{\sigma u}z^u\rrbracket,\llbracket y_h^\sigma\rrbracket)_{L_\sigma,F}+(\llbracket\mathcal{D}^{uu}z^u\rrbracket,\llbracket y_h^u\rrbracket)_{L_u,F}+(\llbracket\mathcal{D}^{u\sigma}z^\sigma\rrbracket,\llbracket y_h^u\rrbracket)_{L_u,F}|.$$

Using the boundedness of $\mathcal{D}$, the inverse inequality (4.4), and (DG15), each term in the above equality is bounded as follows:

$$|(\llbracket\mathcal{D}^{\sigma u}z^u\rrbracket,\llbracket y_h^\sigma\rrbracket)_{L_\sigma,F}|\lesssim\|\{z^u\}\|_{L_u,F}\|\llbracket y_h^\sigma\rrbracket\|_{L_\sigma,F}\lesssim h_F^{-\frac12}\|\{z^u\}\|_{L_u,F}\|y_h^\sigma\|_{L_\sigma,\mathcal{T}(F)},$$
$$|(\llbracket\mathcal{D}^{uu}z^u\rrbracket,\llbracket y_h^u\rrbracket)_{L_u,F}|\lesssim\|\{z^u\}\|_{L_u,F}\|\llbracket y_h^u\rrbracket\|_{L_u,F}\lesssim h_F^{-\frac12}\|\{z^u\}\|_{L_u,F}\|y_h^u\|_{L_u,\mathcal{T}(F)},$$
$$|(\llbracket\mathcal{D}^{u\sigma}z^\sigma\rrbracket,\llbracket y_h^u\rrbracket)_{L_u,F}|=|(\{z^\sigma\},\mathcal{D}_F^{\sigma u}\llbracket y_h^u\rrbracket)_{L_\sigma,F}|\lesssim h_F^{\frac12}\|\{z^\sigma\}\|_{L_\sigma,F}|y_h^u|_{J,F}.$$

As a result, $|R_3|\lesssim\|z\|_{h,1}\|y_h\|_{h,A}$.

(4) The fourth term is controlled using (DG18).

(5) For the fifth term, we have

$$|R_5|\le\sum_{F\in\mathcal{F}_h^{\mathrm{i}}}|(S_F^{\sigma u}(\llbracket z^u\rrbracket),\llbracket y_h^\sigma\rrbracket)_{L_\sigma,F}+(S_F^{uu}(\llbracket z^u\rrbracket),\llbracket y_h^u\rrbracket)_{L_u,F}+(S_F^{u\sigma}(\llbracket z^\sigma\rrbracket),\llbracket y_h^u\rrbracket)_{L_u,F}|.$$

Using (DG12) and (DG14), together with the inverse inequality (4.4), each term in the above equality is bounded as follows:

$$|(S_F^{\sigma u}(\llbracket z^u\rrbracket),\llbracket y_h^\sigma\rrbracket)_{L_\sigma,F}|\lesssim h_F^{\frac12}|z^u|_{J,F}\|\llbracket y_h^\sigma\rrbracket\|_{L_\sigma,F}\lesssim|z^u|_{J,F}\|y_h^\sigma\|_{L_\sigma,\mathcal{T}(F)},$$
$$|(S_F^{uu}(\llbracket z^u\rrbracket),\llbracket y_h^u\rrbracket)_{L_u,F}|\lesssim h_F^{-\frac12}\|\llbracket z^u\rrbracket\|_{L_u,F}|y_h^u|_{J,F},$$
$$|(S_F^{u\sigma}(\llbracket z^\sigma\rrbracket),\llbracket y_h^u\rrbracket)_{L_u,F}|\lesssim h_F^{\frac12}\|\llbracket z^\sigma\rrbracket\|_{L_\sigma,F}|y_h^u|_{J,F}.$$

As a result, $|R_5|\lesssim\|z\|_{h,1}\|y_h\|_{h,A}$. The proof is complete. ∎

LEMMA 5.7 (consistency). *Let $z\in V\cap[H^1(\Omega)]^m$ solve (2.6) and let z_h solve (4.16). Then,*

$$\forall y_h\in W_h,\quad a_h(z-z_h,y_h)=0. \tag{5.19}$$

Proof. Let $y_h\in W_h$ and use (4.15) to evaluate $a_h(z,y_h)$. Since z solves (2.6), the first term in the right-hand side of (4.15) is equal to $(f,y_h)_L$. Owing to the consistency assumption (DG7), the second term in the right-hand side of (4.15) vanishes. Furthermore, since for all $F\in\mathcal{F}_h^{\mathrm{i}}$, $\{\mathcal{D}z\}=\mathcal{D}_F\llbracket z\rrbracket=0$ and $\llbracket z\rrbracket=0$ because $z\in[H^1(\Omega)]^m$, the third, fourth, and fifth terms in (4.15) are also zero. As a result, $a_h(z,y_h)=(f,y_h)_L=a_h(z_h,y_h)$, completing the proof. ∎

THEOREM 5.8 (convergence). *Let $z \in V \cap [H^1(\Omega)]^m$ solve (2.6) and let z_h solve (4.16). Then,*

$$\|z - z_h\|_{h,A} \lesssim \inf_{y_h \in W_h} \|z - y_h\|_{h,1}. \tag{5.20}$$

Proof. The proof follows from the second Strang lemma. ∎

Owing to the regularity of the mesh family $\{\mathcal{T}_h\}_{h>0}$, the following interpolation property holds: For all $z \in [H^{p_\sigma+1}(\Omega)]^{m_\sigma} \times [H^{p_u+1}(\Omega)]^{m_u}$, there is $y_h \in W_h$ satisfying

$$\|z - y_h\|_{h,1} \lesssim (h^{p_\sigma+1} + h^{p_u})\big(\|z^\sigma\|_{[H^{p_\sigma+1}(\Omega)]^{m_\sigma}} + \|z^u\|_{[H^{p_u+1}(\Omega)]^{m_u}}\big). \tag{5.21}$$

Since $p_u - 1 \le p_\sigma$, the above interpolation error is of order h^{p_u}.

COROLLARY 5.9. *Let $z \in [H^{p_\sigma+1}(\Omega)]^{m_\sigma} \times [H^{p_u+1}(\Omega)]^{m_u}$ solve (2.6) and let z_h solve (4.16). Then,*

$$\|z - z_h\|_{h,A} \lesssim h^{p_u}\big(\|z^\sigma\|_{[H^{p_\sigma+1}(\Omega)]^{m_\sigma}} + \|z^u\|_{[H^{p_u+1}(\Omega)]^{m_u}}\big). \tag{5.22}$$

Remark 5.4. For both the σ- and the u-component of the solution, the error estimate in the L^2-norm is $\mathcal{O}(h^{p_u})$. If $p_\sigma = p_u := p$, this result is suboptimal when compared with that obtained using the DG method analyzed in [9], which yields $\mathcal{O}(h^{p+\frac{1}{2}})$ error estimates. The reason for this slight optimality loss is that in the present method the interface jumps of the σ-component are not controlled to allow for this component to be locally eliminated, the consequence being that the jumps on the u-component must be penalized with an $\mathcal{O}(h^{-1})$ weight. If $p_\sigma = p_u - 1$, (5.22) is still suboptimal for the u-component but is optimal in the L^2-norm for the σ-component.

Finally, when the exact solution z is only in the graph space W, i.e., when z is not in $[H^1(\Omega)]^m$ so that $a_h(z,\cdot)$ may not be meaningful, we use a density argument to infer the convergence of the DG approximation. For $z \in W + W_h$, define the norm

$$\|z\|_{W^-} = \|z\|_L + \left(\sum_{K \in \mathcal{T}_h} \|Bz^u\|^2_{L_\sigma,K}\right)^{\frac{1}{2}}. \tag{5.23}$$

Observe that $\|z\|_{W^-} \le \|z\|_{h,A}$.

COROLLARY 5.10. *Assume that there is $\gamma > 0$ such that $[H^{\gamma+1}(\Omega)]^m \cap V$ is dense in V. Let z solve (2.6) and let z_h solve (4.16). Then,*

$$\lim_{h\to 0} \|z - z_h\|_{W^-} = 0. \tag{5.24}$$

Proof. Let $\epsilon > 0$. There is $z_\epsilon \in [H^{\gamma+1}(\Omega)]^m \cap V$ such that $\|z - z_\epsilon\|_W \le \frac{\epsilon}{2}$. Let $z_{\epsilon h}$ be the unique solution in W_h such that $a_h(z_{\epsilon h}, y_h) = (Tz_\epsilon, y_h)_L$ for all $y_h \in W_h$. From the regularity of z_ϵ together with Theorem 5.8 and Corollary 5.9, it is inferred that $\lim_{h\to 0} \|z_{\epsilon h} - z_\epsilon\|_{h,A} = 0$. Furthermore, using the discrete inf-sup condition (5.13) yields

$$\begin{aligned}\|z_{\epsilon h} - z_h\|_{W^-} &\lesssim \sup_{y_h \in W_h \setminus \{0\}} \frac{a_h(z_{\epsilon h}, y_h) - a_h(z_h, y_h)}{\|y_h\|_{h,A}} = \sup_{y_h \in W_h \setminus \{0\}} \frac{(T(z_\epsilon - z), y_h)_L}{\|y_h\|_{h,A}} \\ &\le \|T(z_\epsilon - z)\|_L \sup_{y_h \in W_h \setminus \{0\}} \frac{\|y_h\|_L}{\|y_h\|_{h,A}} \le \|z - z_\epsilon\|_W \le \frac{\epsilon}{2},\end{aligned}$$

where we have used the fact that for all $y_h \in W_h$, $a_h(z_h, y_h) = (Tz, y_h)_L$. Finally, using the triangle inequality $\|z - z_h\|_{W^-} \le \|z - z_\epsilon\|_{W^-} + \|z_\epsilon - z_{\epsilon h}\|_{W^-} + \|z_{\epsilon h} - z_h\|_{W^-}$, we deduce that $\limsup_{h\to 0} \|z - z_h\|_{W^-} \le \epsilon$. ∎

5.3. The duality argument. We now improve the error estimate on the L^2-norm of the u-component of the solution by using a duality argument. In this section, it is implicitly assumed that (DG$^\sharp$) holds.

Let z solve (2.6) and let z_h solve (4.16). Let $\psi := (\psi^\sigma, \psi^u) \in V^*$ solve

$$\tilde{T}\psi = (0, z^u - z_h^u). \tag{5.25}$$

We assume that the above problem yields (elliptic) regularity; i.e., ψ^u is in $[H^2(\Omega)]^{m_u}$, ψ^σ is in $[H^1(\Omega)]^{m_\sigma}$, and the following uniform bound holds:

$$\|\psi^u\|_{[H^2(\Omega)]^{m_u}} + \|\psi^\sigma\|_{[H^1(\Omega)]^{m_\sigma}} \lesssim \|z^u - z_h^u\|_{L_u}. \tag{5.26}$$

LEMMA 5.11. *Under the above hypotheses, the following holds:*

$$a_h(y, \psi) = (y^u, z^u - z_h^u)_{L_u} \quad \forall y \in W(h). \tag{5.27}$$

Proof. Let $y \in W(h)$. By integrating by parts (i.e., using (5.18)) and using the fact that ψ is continuous across interfaces, we obtain

$$a_h(y, \psi) = \sum_{K \in \mathcal{T}_h} (y, \tilde{T}\psi)_{L,K} + \sum_{F \in \mathcal{F}_h^\partial} \tfrac{1}{2}(M_F(y) + \mathcal{D}y, \psi)_{L,F}.$$

Since $\psi \in V^* \cap [H^1(\Omega)]^m$, (DG8) implies $(M_F(y) + \mathcal{D}y, \psi)_{L,F} = 0$ for all $F \in \mathcal{F}_h^\partial$. The conclusion is straightforward since ψ solves (5.25). ∎

To avoid lengthy technicalities, we introduce the following norms:

$$\|y^\sigma\|_{h,\widetilde{1}} = \left(\sum_{K \in \mathcal{T}_h} [h_K^2 \|y^\sigma\|^2_{[H^1(K)]^{m_\sigma}} + h_K \|y^\sigma\|^2_{L_\sigma, \partial K}] \right)^{\frac{1}{2}}, \tag{5.28}$$

$$\|y\|_{h,A^+} = \|y\|_{h,A} + \|y^\sigma\|_{h,\widetilde{1}}, \tag{5.29}$$

$$\|y\|_{h,1^+} = \|y\|_{h,1} + \|y^\sigma\|_{h,\widetilde{1}}. \tag{5.30}$$

The DG method converges optimally in the $\|\cdot\|_{h,A^+}$-norm as stated in the following.

COROLLARY 5.12. *Let $z \in V \cap [H^1(\Omega)]^m$ solve* (2.6) *and let z_h solve* (4.16). *Then,*

$$\|z - z_h\|_{h,A^+} \lesssim \inf_{y_h \in W_h} \|z - y_h\|_{h,1^+}. \tag{5.31}$$

Proof. Let y_h be an arbitrary element in W_h. Using inverse inequalities yields

$$\begin{aligned}
\|z^\sigma - z_h^\sigma\|_{h,\widetilde{1}} &\le \|z^\sigma - y_h^\sigma\|_{h,\widetilde{1}} + \|y_h^\sigma - z_h^\sigma\|_{h,\widetilde{1}} \lesssim \|z^\sigma - y_h^\sigma\|_{h,\widetilde{1}} + \|y_h^\sigma - z_h^\sigma\|_{L_\sigma} \\
&\le \|z^\sigma - y_h^\sigma\|_{h,\widetilde{1}} + \|y_h^\sigma - z^\sigma\|_{L_\sigma} + \|z^\sigma - z_h^\sigma\|_{L_\sigma} \\
&\le \|z^\sigma - y_h^\sigma\|_{h,\widetilde{1}} + \|z - y_h\|_{h,A} + \|z - z_h\|_{h,A} \\
&\lesssim \|z - y_h\|_{h,A^+} + \|z - z_h\|_{h,A}.
\end{aligned}$$

Hence, using the above inequality along with (5.20) leads to

$$\|z - z_h\|_{h,A^+} \lesssim \|z - y_h\|_{h,A^+} + \|z - y_h\|_{h,1} \lesssim \|z - y_h\|_{h,1^+}.$$

That concludes the proof since y_h is arbitrary in W_h. ∎

LEMMA 5.13 (continuity). *Assume that for all $K \in \mathcal{T}_h$ and for all $y \in W(h)$,*

$$\|Cy^u\|_{L_u,K} \lesssim \|By^u\|_{L_\sigma,K} + \|y^u\|_{L_u,K}. \tag{5.32}$$

Then, the following holds:

$$\forall (r,y)\in W(h)\times W(h),\quad a_h(r,y)\lesssim \|r\|_{h,A^+}\|y\|_{h,1}. \tag{5.33}$$

Proof. Let us bound all the terms in the right-hand side of (4.15).

(1) For the first term, say R_1, we proceed as follows:

$$\begin{aligned}|(Tr,y)_{L,K}| &\le |(Kr,y)_{L,K}| + |(Br^u,y^\sigma)_{L_\sigma,K}| + |(B^\dagger r^\sigma + Cr^u,y^u)_{L_u,K}|\\ &\lesssim \|r\|_{L,K}\|y\|_{L,K} + \|Br^u\|_{L_\sigma,K}\|y\|_{L,K} + \|r^\sigma\|_{[H^1(K)]^{m_\sigma}}\|y^u\|_{L_u,K}\\ &\lesssim (\|r\|_{L,K}^2 + \|Br^u\|_{L_\sigma,K}^2 + h_K^2\|r^\sigma\|_{[H^1(K)]^{m_\sigma}}^2)^{\frac12}(\|y\|_{L,K}^2 + h_K^{-2}\|y^u\|_{L_u,K}^2)^{\frac12},\end{aligned}$$

where (5.32) has been used to bound $\|Cr^u\|$. Hence, $|R_1|\lesssim \|r\|_{h,A^+}\|y\|_{h,1}$.

(2) To bound the second term, say R_2, use (DG4), (DG6), (5.5), and the boundedness of $\mathcal{D}$ to infer

$$\begin{aligned}&|(M_F^{\sigma u}(r^u) - \mathcal{D}^{\sigma u}r^u, y^\sigma)_{L_\sigma,F}| \lesssim |r^u|_{M,F}\, h_F^{\frac12}\|y^\sigma\|_{L_\sigma,F},\\ &|(M_F^{uu}(r^u) - \mathcal{D}^{uu}r^u, y^u)_{L_u,F}| \lesssim |r^u|_{M,F}\, h_F^{-\frac12}\|y^u\|_{L_u,F},\\ &|(M_F^{u\sigma}(r^\sigma) - \mathcal{D}^{u\sigma}r^\sigma, y^u)_{L_u,F}| \lesssim \|r^\sigma\|_{L_\sigma,F}\|y^u\|_{L_u,F} \lesssim h_F^{\frac12}\|r^\sigma\|_{L_\sigma,F}\, h_F^{-\frac12}\|y^u\|_{L_u,F}.\end{aligned}$$

As a result, $|R_2|\lesssim \|r\|_{h,A^+}\|y\|_{h,1}$.

(3) To bound the third term, say R_3, use (DG15), (DG16), and the boundedness of $\mathcal{D}$ to infer

$$\begin{aligned}&|(\{\mathcal{D}^{\sigma u}r^u\},\{y^\sigma\})_{L_\sigma,F}| = |2(\mathcal{D}^{\sigma u}_{\partial K_1(F)}[\![r^u]\!],\{y^\sigma\})_{L_\sigma,F}| \lesssim |r^u|_{J,F}\, h_F^{\frac12}\|\{y^\sigma\}\|_{L_\sigma,F},\\ &|(\{\mathcal{D}^{uu}r^u\},\{y^u\})_{L_u,F}| = |2(\mathcal{D}^{uu}_{\partial K_1(F)}[\![r^u]\!],\{y^u\})_{L_u,F}| \lesssim |r^u|_{J,F}\, h_F^{-\frac12}\|\{y^u\}\|_{L_u,F},\\ &|(\{\mathcal{D}^{u\sigma}r^\sigma\},\{y^u\})_{L_u,F}| \lesssim \|[\![r^\sigma]\!]\|_{L_\sigma,F}\|\{y^u\}\|_{L_u,F} \lesssim h_F^{\frac12}\|[\![r^\sigma]\!]\|_{L_\sigma,F}\, h_F^{-\frac12}\|\{y^u\}\|_{L_u,F}.\end{aligned}$$

These bounds yield $|R_3|\lesssim \|r\|_{h,A^+}\|y\|_{h,1}$.

(4) To bound the fourth term, use (DG18).

(5) To bound the fifth term, say R_5, use (DG10), (DG13), and (DG14) to infer

$$\begin{aligned}&|(S_F^{\sigma u}([\![r^u]\!]),[\![y^\sigma]\!])_{L_\sigma,F}| \lesssim |r^u|_{J,F}\, h_F^{\frac12}\|[\![y^\sigma]\!]\|_{L_\sigma,F},\\ &|(S_F^{uu}([\![r^u]\!]),[\![y^u]\!])_{L_u,F}| \lesssim |r^u|_{J,F}\, h_F^{-\frac12}\|[\![y^u]\!]\|_{L_u,F},\\ &|(S_F^{u\sigma}([\![r^\sigma]\!]),[\![y^u]\!])_{L_u,F}| \lesssim h_F^{\frac12}\|[\![r^\sigma]\!]\|_{L_\sigma,F}\,|y^u|_{J,F}.\end{aligned}$$

Hence, $|R_5|\lesssim \|r\|_{h,A^+}\|y\|_{h,1}$. The proof is complete. ∎

THEOREM 5.14 (convergence). *Let $z\in V\cap[H^1(\Omega)]^m$ solve* (2.6) *and let z_h solve* (4.16). *Assume elliptic regularity, i.e.,* (5.26)*, and that* (5.32) *holds. Then,*

$$\|z^u - z_h^u\|_{L_u} \lesssim h \inf_{y_h\in W_h}\|z-y_h\|_{h,1^+}. \tag{5.34}$$

Proof. Using $z-z_h$ as test function in (5.27) we infer $a_h(z-z_h,\psi) = \|z^u - z_h^u\|_{L_u}^2$. Then, using the consistency property stated in Lemma 5.7, this yields for all $\psi_h\in W_h$, $a_h(z-z_h,\psi-\psi_h) = \|z^u - z_h^u\|_{L_u}^2$. Lemma 5.13 in turn implies

$$\|z^u - z_h^u\|_{L_u}^2 \lesssim \|z-z_h\|_{h,A^+}\|\psi-\psi_h\|_{h,1}\quad \forall \psi_h\in W_h.$$

Then, using the elliptic regularity (5.26) and the fact that $p_u \geq 1$ leads to

$$\begin{aligned}\|z^u - z_h^u\|_{L_u}^2 &\lesssim \|z - z_h\|_{h,A^+} \inf_{\psi_h \in W_h} \|\psi - \psi_h\|_{h,1} \\ &\lesssim h\|z - z_h\|_{h,A^+}(\|\psi^u\|_{[H^2(\Omega)]^{m_u}} + \|\psi^\sigma\|_{[H^1(\Omega)]^{m_\sigma}}) \\ &\lesssim h\|z - z_h\|_{h,A^+}\|z^u - z_h^u\|_{L_u}.\end{aligned}$$

The conclusion follows readily using Corollary 5.12. ∎

Remark 5.5. Stability and convergence in the $\|\cdot\|_{h,A^+}$-norm could have been proved directly by adding the quantity $(\sum_{K\in\mathcal{T}_h} h_K^2\|B^\dagger y^\sigma + Cy^u\|_{L_u,K}^2)^{\frac{1}{2}}$ in the definition of the $\|\cdot\|_{h,A}$-norm, but this significantly lengthens the proof of Lemma 5.5. With this modification of the $\|\cdot\|_{h,A}$-norm, hypothesis (5.32) can be removed. However, this appears to be a minor issue since (5.32) holds for all the two-field Friedrichs' systems presented in section 3.

6. Applications. In this section we apply the DG method designed in section 4 and analyzed in section 5 to the Friedrichs' systems presented in section 3.

6.1. Advection-diffusion-reaction. We describe various DG methods that can be used to approximate the advection-diffusion-reaction equation introduced in section 3.1 and in which the σ-component of the unknown can be eliminated locally. Comparisons with the unified approached developed by Arnold et al. [1] are presented to illustrate the fact that the present DG method generalizes some of the DG methods that have been previously developed in the literature for the Poisson equation.

6.1.1. A first example: The LDG method. Consider first Dirichlet boundary conditions. Owing to (3.5) and (3.6), the integral representations (2.15) and (2.17) hold with the $\mathbb{R}^{d+1,d+1}$-valued boundary fields

$$\mathcal{D} = \left[\begin{array}{c:c} 0 & n \\ \hdashline n^t & \beta\cdot n \end{array}\right] \qquad \text{and} \qquad \mathcal{M} = \left[\begin{array}{c:c} 0 & -n \\ \hdashline n^t & 0 \end{array}\right], \tag{6.1}$$

where n is the unit outward normal to $\partial\Omega$. Let $\varsigma > 0$ and $\eta > 0$ (these design parameters can vary from face to face). For all $F \in \mathcal{F}_h$, set $R_F \equiv 0$ and

$$\mathcal{M}_F = \left[\begin{array}{c:c} 0 & -n_F \\ \hdashline n_F^t & \varsigma h_F^{-1} \end{array}\right], \qquad \mathcal{S}_F = \left[\begin{array}{c:c} 0 & 0 \\ \hdashline 0 & \eta h_F^{-1} \end{array}\right], \tag{6.2}$$

and define for all $y \in [L^2(F)]^{d+1}$, $M_F(y) = \mathcal{M}_F y$ and $S_F(y) = \mathcal{S}_F y$.

LEMMA 6.1. *Let M_F, S_F, and R_F be defined as above. Then, properties* (DG$^\sharp$) *hold.*

Proof. The consistency properties (DG7) and (DG8) are readily verified. Properties (DG17)–(DG18) are evident. The remaining properties are direct consequences of Lemmata 5.1 and 5.3. ∎

Remark 6.1. Let $\delta \in \mathbb{R}^d$. A slightly more general choice for the interface operator consists of setting for all $F \in \mathcal{F}_h^{\mathrm{i}}$, $\mathcal{S}_F^{\sigma u} = (\delta\cdot n_F)n_F$, where n_F is any of the two unit normal vectors to F. This choice leads to the so-called LDG method of Cockburn and Shu [7] as considered in the unified approach of [1] for the Poisson equation.

When Neumann and Robin boundary conditions are enforced, the integral representation (2.17) holds for the $\mathbb{R}^{d+1,d+1}$-valued boundary field

$$\mathcal{M} = \left[\begin{array}{c:c} 0 & n \\ \hdashline -n^t & 2\varrho + \beta\cdot n \end{array}\right]. \tag{6.3}$$

Assume that $\varrho \geq (\beta{\cdot}n)^-$, the negative part of $\beta{\cdot}n$ (this is not restrictive in practice since the usual Robin condition at an inflow boundary uses $\varrho = -\beta{\cdot}n \geq 0$). For all $F \in \mathcal{F}_h$, set $R_F \equiv 0$ and

$$\mathcal{M}_F = \left[\begin{array}{c|c} 0 & n_F \\ \hline -n_F^t & 2\varrho + \beta{\cdot}n_F \end{array}\right], \qquad \mathcal{S}_F = \left[\begin{array}{c|c} 0 & 0 \\ \hline 0 & \eta h_F^{-1} \end{array}\right], \tag{6.4}$$

and for all $y \in [L^2(F)]^{d+1}$, define $M_F(y) = \mathcal{M}_F y$ and $S_F(y) = \mathcal{S}_F y$. Then, it is easily verified that (5.8) holds. Hence, Lemma 5.2 implies that assumptions (DG1)–(DG6) hold. Moreover, the consistency assumptions (DG7) and (DG8) trivially hold. Of course, (DG9)–(DG16) hold since the definition of $\mathcal{S}_F$ is independent of the type of boundary condition. Finally, (DG17)–(DG18) are evident since $R_F \equiv 0$.

Remark 6.2. Observe that the scalings of the block $\mathcal{M}_F^{uu}$ are radically different whether Dirichlet or Robin/Neumann boundary conditions are enforced.

6.1.2. Comparison with other methods. In this section we restrict the setting to the equation $u - \Delta u = f$ and to homogeneous Dirichlet boundary conditions so as to make comparisons with the unified approach developed in [1], where it is shown that most of the DG methods amount to solving the following problem:

$$\begin{cases} \text{Seek } z_h = (\sigma_h, u_h) \in W_h \text{ such that } \forall y_h \in [\mathbb{P}_{p_\sigma}(K)]^d \times \mathbb{P}_{p_u}(K), \\ (z_h, \tilde{T} y_h)_{L,K} + (\widehat{\phi}_{\partial K}(z_h), y_h)_{L,\partial K} = (f, y_h)_{L,K}, \end{cases} \tag{6.5}$$

where the so-called numerical fluxes $\widehat{\phi}_{\partial K}(z_h)$ depend on the method under consideration. In view of (4.17) and (4.19), the link between the present formalism and that of [1] is based on the identification $\widehat{\phi}_{\partial K}(z_h)|_F = \phi_{\partial K}(z_h)|_F$. For the purpose of comparison, we restrict ourselves to boundary and interface operators such that for all $F \in \mathcal{F}_h$, for all $v \in L^2(F)$, and for all $\tau \in [L^2(F)]^d$,

$$M_F^{\sigma u}(v) = -n_F v, \qquad M_F^{u\sigma}(\tau) = \tau{\cdot}n_F, \tag{6.6}$$

$$S_F^{\sigma u}(v) = 0, \qquad S_F^{u\sigma}(\tau) = 0. \tag{6.7}$$

Therefore, the methods that can be constructed from this set of assumptions differ only in the design of M_F^{uu}, S_F^{uu}, and R_F. We set $\widehat{\phi}_{\partial K}(z_h) = (\widehat{u}_K n_K, \widehat{\sigma}_K{\cdot}n_K)$ (note that $\widehat{u}_K$ is $\mathbb{R}$-valued, $\widehat{\sigma}_K$ is $\mathbb{R}^d$-valued, and the sign convention we use herein for σ_h and $\widehat{\sigma}_K$ is opposite to that in [1]). Then, the above identification of the fluxes is possible if the DG method under consideration is such that

$$\widehat{\phi}_{\partial K}(z_h) = \begin{cases} (0, \sigma_h{\cdot}n_F + \frac{1}{2} M_F^{uu}(u_h) + R_F(u_h)) & \text{if } F \in \mathcal{F}_h^\partial, \\ (\{u_h\}\, n_K, \{\sigma_h\}\cdot n_K + n_F{\cdot}n_K (S_F^{uu}([\![u_h]\!]) + R_F([\![u_h]\!]))) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}. \end{cases} \tag{6.8}$$

The DG methods that belong to this class are those from [3, 5, 4, 6] together with that of [7] already discussed above. Observe that in this setting, the local flux reconstruction formula (4.23) takes the form

$$\forall K \in \mathcal{T}_h, \quad z_h^\sigma|_K = -\nabla z_h^u|_K + \sum_{F \subset \partial K} r_F([\![z_h^u]\!] n_F). \tag{6.9}$$

Comparison with the method of Brezzi et al. The method described by Brezzi et al. [6] (see also [1]) is such that

$$\widehat{\phi}_{\partial K}(z_h) = \begin{cases} (0, \sigma_h{\cdot}n_F + \frac{1}{2}\varsigma r_F(u_h n_F){\cdot}n_F) & \text{if } F \in \mathcal{F}_h^\partial, \\ (\{u_h\}\, n_K, \{\sigma_h\}\cdot n_K + \eta\, \{r_F([\![u_h]\!] n_F)\}\cdot n_K) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}, \end{cases} \tag{6.10}$$

where ς and η are positive constants. This amounts to specifying M_F^{uu}, S_F^{uu}, and R_F such that for all $v \in L^2(F)$,

$$M_F^{uu}(v) = \varsigma r_F(vn_F)\cdot n_F, \qquad S_F^{uu}(v) = \eta \{r_F(vn_F)\}\cdot n_F, \qquad R_F(v) \equiv 0. \tag{6.11}$$

The operator r_F is endowed with the following property.

LEMMA 6.2. *For all $F \in \mathcal{F}_h$ and for all $\tau_h \in [\mathbb{P}_{p_\sigma}(F)]^d$,*

$$h_F^{-\frac{1}{2}} \|\tau_h\|_{L_\sigma,F} \lesssim \|r_F(\tau_h)\|_{L_\sigma,\mathcal{T}(F)} \lesssim h_F^{-\frac{1}{2}} \|\tau_h\|_{L_\sigma,F}. \tag{6.12}$$

This lemma and the definition of r_F imply that for all $F \in \mathcal{F}_h$ and for all $v_h \in \mathbb{P}_{p_u}(F)$,

$$h_F^{-1}\|v_h\|_{L_u,F}^2 \lesssim (\{r_F(v_h n_F)\}\cdot n_F, v_h)_{L_u,F} \lesssim h_F^{-1}\|v_h\|_{L_u,F}^2. \tag{6.13}$$

These inequalities are just what is takes to prove that if the boundary and interface operators are defined using (6.6), (6.7), and (6.11), properties (DG$^\sharp$) hold. Therefore, the conclusions of Theorems 5.8 and 5.14 hold.

Comparison with the IP method. Let ς and η be two positive constants. The IP method of Baker [3] (see also Arnold [2]) is such that the flux is defined by

$$\widehat{\phi}_{\partial K}(z_h) = \begin{cases} (0, \sigma_h\cdot n_F + \frac{1}{2}\frac{\varsigma}{h_F} u_h + \rho_F(\llbracket u_h \rrbracket)\cdot n_F) & \text{if } F \in \mathcal{F}_h^\partial, \\ (\{u_h\} n_K, \{\sigma_h\}\cdot n_K + \frac{\eta}{h_F}\llbracket u_h \rrbracket n_F\cdot n_K + \rho_F(\llbracket u_h \rrbracket)\cdot n_K) & \text{if } F \in \mathcal{F}_h^{\mathrm{i}}, \end{cases} \tag{6.14}$$

where the operator $\rho_F : L^2(\Delta_F) \longrightarrow L^2(F)$ is defined by

$$\rho_F(v) = -\sum_{F' \in \Delta_F} \{r_{F'}(vn_{F'})\}, \tag{6.15}$$

and $\Delta_F = \{F' \in \mathcal{F}_h;\ \exists K' \in \mathcal{T}_h,\ F \cup F' \subset \partial K'\}$. This method fits the present framework if we set

$$M_F^{uu}(v) = \varsigma h_F^{-1} v, \qquad S_F^{uu}(v) = \eta h_F^{-1} v, \qquad R_F(v) = \rho_F(v)\cdot n_F. \tag{6.16}$$

Using Lemma 6.2, it is readily seen that (DG18) holds and that (DG17) holds if the design parameters ς and η are large enough. Therefore, the conclusions of Theorems 5.8 and 5.14 hold for the IP method. Note that the expression (4.31) derived for R_F in the general setting of two-field Friedrichs' systems reduces to (6.16) for the Poisson problem with Dirichlet boundary conditions.

Comparison with the methods of Bassi et al. The method proposed by Bassi and Rebay [5] corresponds to the choice of $M_F^{uu} \equiv 0$, $S_F^{uu} \equiv 0$, and $R_F \equiv 0$. Our analysis needs to be revised to account for this situation. Obviously, the L^2-coercivity still holds in the form $\|y\|_L^2 \lesssim a_h(y,y)$ for all $y \in W(h)$. Moreover, one easily derives the following continuity estimate: For all $(y, y_h) \in W(h) \times W_h$,

$$|a_h(y, y_h)| \lesssim \left(\sum_{K \in \mathcal{T}_h} [\|Ty\|_{L,K}^2 + h_K^{-1}\|y\|_{L,\partial K}^2] \right)^{\frac{1}{2}} \|y_h\|_L. \tag{6.17}$$

Then, provided $p_\sigma = p_u := p$, the second Strang lemma implies $\|z - z_h\|_L \lesssim h^p \|z\|_{[H^{p+1}(\Omega)]^m}$. Although this estimate is not optimal, it shows that the method of Bassi and Rebay is (possibly nonoptimally) convergent. Finally, the method proposed by Bassi et al. [4] fits the present framework by defining the operators

$$M_F^{uu}(v) = \varsigma r_F(vn_F)\cdot n_F, \qquad S_F^{uu}(v) = \eta \{r_F(vn_F)\}\cdot n_F, \tag{6.18}$$

and the operator R_F as in the IP method, i.e., (6.16). By using what has been shown above for the method of Brezzi et al. and the IP method, it is clear that the conclusions of Theorems 5.8 and 5.14 hold in this case also, provided ς and η are large enough.

6.2. Linear continuum mechanics. Consider the linear continuum mechanics equations introduced in section 3.2 and let us describe a DG method where the $(\overline{\sigma}, p)$-component of the unknown can be eliminated locally. Owing to (3.11) and (3.12), the integral representations (2.15) and (2.17) hold with the $\mathbb{R}^{m,m}$-valued boundary fields (recall that $m = d^2 + 1 + d$)

$$\mathcal{D} = \left[\begin{array}{c:c} 0 & \mathcal{H} \\ \hdashline \mathcal{H}^t & 0 \end{array}\right] \qquad \text{and} \qquad \mathcal{M} = \left[\begin{array}{c:c} 0 & -\mathcal{H} \\ \hdashline \mathcal{H}^t & 0 \end{array}\right], \tag{6.19}$$

where $\mathcal{H} = \sum_{k=1}^{d} n_k(\mathcal{E}^k, 0)^t \in \mathbb{R}^{d^2+1,d}$. Observe that for all $\xi \in \mathbb{R}^d$, $\mathcal{H}\xi = (-\frac{1}{2}(n\otimes\xi + \xi\otimes n), 0)$. Let $\varsigma > 0$ and $\eta > 0$ (these design parameters can vary from face to face). For all $F \in \mathcal{F}_h$, set $R_F \equiv 0$ and

$$\mathcal{M}_F = \left[\begin{array}{c:c} 0 & -\mathcal{H}_F \\ \hdashline \mathcal{H}_F^t & \varsigma h_F^{-1}\mathcal{I}_d \end{array}\right], \qquad \mathcal{S}_F = \left[\begin{array}{c:c} 0 & 0 \\ \hdashline 0 & \eta h_F^{-1}\mathcal{I}_d \end{array}\right], \tag{6.20}$$

where $\mathcal{H}_F$ is defined as $\mathcal{H}$ with n_F substituting for n. Define, for all $y \in [L^2(F)]^m$, $M_F(y) = \mathcal{M}_F y$ and $S_F(y) = \mathcal{S}_F y$. Then, using Lemmata 5.1 and 5.3, one readily verifies that properties (DG$^\sharp$) hold. An IP-like method can be derived as well.

6.3. Simplified MHD. Consider the simplified MHD equations introduced in section 3.3 and let us describe a DG method where the H-component of the unknown can be eliminated locally (the derivation of a DG method where the E-component of the unknown can be eliminated locally is similar). To recover the notation of section 5, set $\sigma \equiv H$ and $u \equiv E$. Owing to (3.16) and (3.17), the integral representations (2.15) and (2.17) hold with the $\mathbb{R}^{6,6}$-valued boundary fields

$$\mathcal{D} = \left[\begin{array}{c:c} 0 & \mathcal{N} \\ \hdashline \mathcal{N}^t & 0 \end{array}\right] \qquad \text{and} \qquad \mathcal{M} = \left[\begin{array}{c:c} 0 & -\mathcal{N} \\ \hdashline \mathcal{N}^t & 0 \end{array}\right], \tag{6.21}$$

where $\mathcal{N} = \sum_{k=1}^{3} n_k\mathcal{R}^k$, and the $\mathbb{R}^{3,3}$-valued fields $\mathcal{R}^1$, $\mathcal{R}^2$, and $\mathcal{R}^3$ are defined in section 3.3. Observe that for all $\xi \in \mathbb{R}^3$, $\mathcal{N}\xi = n\times\xi$. Let $\varsigma > 0$ and $\eta > 0$ (these design parameters can vary from face to face). For all $F \in \mathcal{F}_h$, set $R_F \equiv 0$ and

$$\mathcal{M}_F = \left[\begin{array}{c:c} 0 & -\mathcal{N}_F \\ \hdashline \mathcal{N}_F^t & \varsigma h_F^{-1}\mathcal{N}_F^t\mathcal{N}_F \end{array}\right], \qquad \mathcal{S}_F = \left[\begin{array}{c:c} 0 & 0 \\ \hdashline 0 & \eta h_F^{-1}\mathcal{N}_F^t\mathcal{N}_F \end{array}\right], \tag{6.22}$$

where $\mathcal{N}_F$ is defined as $\mathcal{N}$ by using n_F instead of n. For all $y \in [L^2(F)]^6$, let $M_F(y) = \mathcal{M}_F y$ and $S_F(y) = \mathcal{S}_F y$. Then, using Lemmata 5.1 and 5.3, one readily verifies that properties (DG$^\sharp$) hold. An IP-like method can be derived as well.

Remark 6.3. As opposed to advection-diffusion-reaction equations, the upper bounds in (5.7) and (5.9) are not sharp for the simplified MHD equations since the operators M_F and S_F do not need to control the whole L^2-norm of the electric field.

7. Conclusions. It happens sometimes that (A4) does not hold; instead, the following weaker inequality holds:

$$\exists \mu_0 > 0 \quad \forall z \in W, \qquad (Tz, z)_L + (z, \tilde{T}z)_L \geq 2\mu_0 \|\pi z^\sigma\|_{L_\sigma}^2, \tag{7.1}$$

where $\pi \in \mathcal{L}(L_\sigma; L_\sigma)$ may not be injective. In other words, coercivity no longer holds on the u-component of the unknown but holds only on a piece of the σ-component,

namely πz^σ. The equation $-\Delta u = f$ corresponds to this situation with π equal to the identity. The linear continuum mechanics equations in the incompressible limit, e.g., the Stokes equations, also fall in this framework with a nontrivial noninjective operator π. It will be shown in a forthcoming third part that, provided additional mild assumptions are made on the differential operators and on the DG setting, all that has been said herein in the fully L-coercive case remains valid in the situation with partial coercivity.

ON THE LOCAL LINEAR INDEPENDENCE OF GENERALIZED SUBDIVISION FUNCTIONS*

JÖRG PETERS† AND XIAOBIN WU†

Abstract. Characterizing the linear and local linear independence of the functions that span a linear space is a key task if the space is to be used computationally. Given a control net, the spanning functions of one spatial coordinate of a generalized subdivision surface are called nodal functions. They are the limit, under subdivision, of associating the value one with one control net node and zero with all others. No characterization of independence of nodal functions has been published to date, even for the two most popular generalized subdivision algorithms, Catmull–Clark subdivision and Loop's subdivision. This paper provides a road map for the verification of linear and local linear independence of generalized subdivision functions. It proves the conjectured global independence of the nodal functions of both algorithms, disproves local linear independence (for higher valences), and establishes linear independence on every surface region corresponding to a facet of the control net. Subtle exceptions, even to global independence, underscore the need for a detailed analysis to provide a sound basis for a number of recently developed computational approaches.

Key words. linear independence, nodal functions, subdivision surfaces, basis, Loop's scheme, Catmull–Clark scheme, local linear independence, condition number

1. Introduction.

Subdivision algorithms create an ever-tighter approximation of a smooth free-form surface by recursively refining and smoothing a polyhedral input mesh, known as control net, or mesh (see Figure 1.1). The two most popular subdivision algorithms, Catmull–Clark and Loop, replace at each step one facet with four. Catmull–Clark subdivision meshes consist of four-sided facets [3] and Loop meshes consist of triangles [11]. The two refinement methods are very popular in graphics, and, although the resulting surfaces are not "fair" enough for high-end industrial styling purposes [14], they are increasingly considered for computational purposes [9, 4]. It is therefore important to know whether the functions, associated with each control node of the mesh, are linearly independent, or what dependence exists. Locally, on a fixed domain Ω, the pieces of the subdivision surfaces have the form $\sum_i \mathbf{a}_i \nu_i$, $\mathbf{a}_i \in \mathbb{R}^3$, i.e., they are a linear combination of *nodal functions* ν_i.

A number of publications have tacitly assumed that the nodal functions ν_i are linearly independent. Without proof, [9, 8, 4] call the nodal functions subdivision basis functions, [12] uses the nodal functions as scaling functions to form a "basis" of the coarsest level of a multiresolution hierarchy, [13] fits subdivision surfaces by allowing one interpolation condition for each mesh node, and [17, 16, 19] call certain eigenfunctions (a set closely related to the set of nodal functions) an "eigenbasis"; and the analysis via universal surfaces, e.g., [19], is error prone unless the eigenfunctions form a basis. In fact, while generically true, for Catmull–Clark subdivision the assumption of linear independence of the nodal functions is false in some cases. The eight nodal functions of the simplest quadrilateral control mesh, a cube, are globally

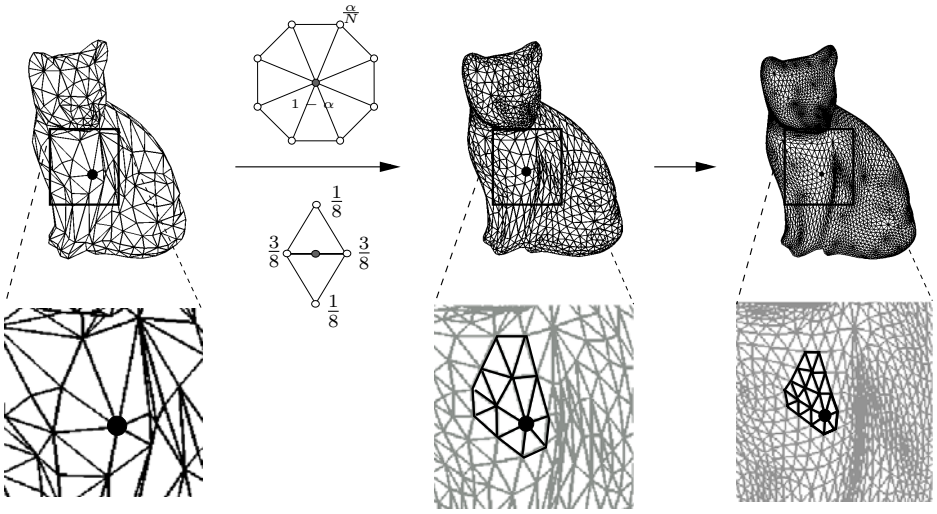

FIG. 1.1. *Modeling with Loop's subdivision. Top: A triangulated cat sculpture refined by Loop subdivision. Two stencils give the weights for averaging new nodes from old ones. The "vertex rule" (above the arrow) is centrally symmetric with* $64\alpha := 40 - (3 + 2\cos(2\pi/N))^2$ *and preserves the number N of neighbors, i.e., the node's valence. The "edge rule" creates nodes of valence six for each edge. Bottom, solid lines: Sequence of submeshes defining one of* $N = 7$ *triangular surface pieces that surround the limit point of the sequence of extraordinary nodes* $\bullet$.

linearly dependent (see Lemma 4.1); in general, we cannot fit eight arbitrary data points by adjusting the coefficients $\mathbf{a}_i$ of the corresponding surface $\sum_{i=1}^{8} \mathbf{a}_i \nu_i$.

For the well-known tensor-product spline functions, (global) linear independence may be interpreted as linear independence over the checkerboard grid of the union of domain rectangles delineated by the knot lines and joined by identifying edges of the rectangles in the natural fashion. generalizes to subdivision surfaces This definition as follows. Let Ω be a unit square if the kth facet of the control mesh has four vertices; let Ω be a unit triangle if it has three vertices. Let Γ be the union of all domains (Ω, k), indexed by their control mesh facet index, with edges topologically identified if the facets share edges. This gives Γ the structure of a 2-manifold homeomorphic to the control mesh. Global linear independence is linear independence with respect to Γ.

DEFINITION 1.1 (global linear independence). *A set of nodal functions are* globally linearly independent *if they are independent over the domain manifold* Γ. *That is, if* $\forall \mathbf{u} \in \Gamma : \sum_i \mathbf{a}_i \nu_i(\mathbf{u}) = \mathbf{0}$, *then* $\mathbf{a}_i = 0$.

While some numerical methods require only standard (global) linear independence, others, such as local Hermite interpolation and localized multiresolution, rely on stronger notions of independence. We need to analyze independence on certain ring-shaped annuli $\mathcal{A}$ and on subsets Ω_i of Ω. A stronger, subtle notion of independence is local linear independence.

DEFINITION 1.2 (local linear independence). *A set of nodal functions are* locally linearly independent *if for any bounded open* $G \subseteq \Gamma$, *all the nodal functions having some support in G are linearly independent on G.*

Remarkably, for box-splines and B–splines, the standard notion of (global) linear independence is equivalent to local linear independence [6, (II.57) Theorem, p. 51]. That is, if all coefficients $\mathbf{a}_i$ have to vanish in order that $\sum_i \mathbf{a}_i \nu_i \equiv \mathbf{0}$ (global linear

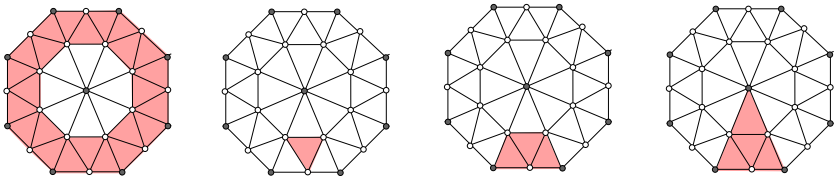

FIG. 1.2. *Summary of findings for Loop subdivision. Domains G (shaded) and valence N for which the nodal functions with support on G are linearly independent.*

independence) then the coefficients of all nodal functions that are nonzero on any open set G have to vanish if $\sum_i \mathbf{a}_i \nu_i$ vanishes on G (local linear independence). Since G can be arbitrarily small, local linear independence is a stricter requirement on the nodal functions than global linear independence. By contrast, local and global independence are not equivalent for subdivision nodal functions. This observation provides rare insight into the structural difference between subdivision and spline surfaces. Specifically, we show that for Catmull–Clark and Loop subdivision,

(i) the nodal functions are globally linearly independent[1];

(ii) the nodal functions are linearly independent over an annulus[1] such as in Figure 1.2, see Lemma 2.2;

(iii) for valence N higher than the "regular" valence, the nodal functions are not locally linearly independent;

(iv) the nodal functions are linearly independent on each domain Ω naturally associated with one facet of the control net[1].

Points (i)–(iv) have direct implications on interpolation (to be compared with the Schoenberg–Whitney theorem of spline interpolation). Consider interpolation with Loop subdivision surfaces. If all three vertices of a facet have valence six, interpolating 12 data points on a domain Ω, by adjusting 12 control points, is a well-posed problem with a unique solution. However, if one of the vertices has valence $N < 6$, then matching 12 data points represents too many constraints; if $N > 6$, then the fitting problem is underconstrained. If we choose the number of interpolation conditions to equal the number of nodal functions that are nonzero on Ω, i.e., if we specify $N + 6$ interpolation points, we find that, if the points belong to a subregion Ω_1 the problem is overconstrained for $N > 6$. (Ω_1 is the shaded area in Figure 1.2, labeled Conjecture 1.) Interpolation with Catmull–Clark subdivision follows a similar pattern with an additional complication for $N = 3$.

The analysis is made easier by the fact that the component functions of most popular subdivision schemes, and in particular of both Catmull–Clark and Loop subdivision, are variations of the well-understood box-spline subdivision [6]; much of the subdivision limit surfaces, corresponding to quads with 4-valent vertices, respectively, triangles with 6-valent vertices are "regular," i.e., are spline surfaces generated by box-splines. This box-spline connection should make us cautious since the shifts of box-splines are, in general, not linearly independent. For example, the four-direction

[1]There is one exception: Catmull–Clark subdivision applied to nodes with valence $N = 3$; see Lemma 4.1.

(quincunx) subdivision, which gives rise to 4–8 subdivision [18], has dependent nodal functions. Catmull–Clark subdivision rules generalize the two-direction box-spline rules, i.e., the rules of the bicubic tensor-product spline; and Loop subdivision generalizes a three-direction box-spline, the convolution of the linear "hat" function with itself. For both splines we know [6] that the nodal functions form a basis and therefore are independent. This means we can focus on submeshes that define the neighborhood of extraordinary nodes, where the connectivity of the control mesh differs from the regular connectivity of the box-spline, namely submeshes surrounding nodes of valence $N \neq 4$ for Catmull–Clark meshes and of valence $N \neq 6$ for Loop meshes. We do not assume that all direct neighbors of these extraordinary nodes are of regular valence.

We first discuss Loop's subdivision, proposed for computational purposes in [9, 8, 4], then Catmull–Clark subdivision, and then generalize the key results.

2. Loop subdivision. A subdivision algorithm states how a new node is computed from a (small local) submesh of old nodes, and how this new node is to be connected to other new nodes. In particular, for Loop subdivision, there are only two rules: to compute new nodes, corresponding to edges of the old mesh, and to compute new nodes, corresponding to old nodes. These rules are expressed by the two stencils (weighted neighborhood graphs) in Figure 1.1, above and below the arrow. A node of a Loop mesh is *extraordinary* if it does not have six neighbors.

Due to the small footprint of the rules, a submesh consisting of one triangle and all triangles attached to it defines, by going to the limit, a triangular piece of the surface adjacent to the limit of the extraordinary node. If all nodes of the central triangle are of valence six, the surface is a polynomial piece of a three-direction box-spline and its properties are well understood. Since new edge nodes have valence six, extraordinary nodes are more isolated under refinement, and we can focus on triangles with one extraordinary node of valence $N \neq 6$. In the following, the subscript 0 refers to a mesh where any two extraordinary nodes are separated by at least one node of valence six. This may be the result of one subdivision applied to the original mesh.

While the typical application of Loop subdivision creates a parametrized surface in $\mathbb{R}^3$, *for the analysis it is sufficient to look at one spatial coordinate since the coordinates do not interact.* The nodal function ν_i may then be defined by choosing an association of the control points a_j with the domain, setting one scalar control point a_i to 1 and all others to 0 and applying subdivision. The relevant submesh defining the triangular surface piece consists of $K := N + 6$ nodes that can be labeled as in Figure 2.1 (top left). We store the submesh as a vector

$$\mathbf{c}_0 := (\mathbf{c}_{0,1}, \dots \mathbf{c}_{0,K}) \in \mathbb{R}^K.$$

Subdivision generates a new set of $M := K+6$ control vertices as shown in Figure 2.1 (top right). We store those control vertices in a new vector

$$\mathbf{c}_1 := (\mathbf{c}_{1,1}, \dots, \mathbf{c}_{1,K}, \mathbf{c}_{1,K+1}, \dots \mathbf{c}_{1,M}).$$

If we represent the averaging rules as rows of a $M \times K$ matrix $\mathbf{A}$ (with row sum one), then the subdivision rules to compute the vector $\mathbf{c}_1$ from $\mathbf{c}_0$ are

$$\mathbf{c}_1 = \mathbf{A}\mathbf{c}_0, \quad \text{where } \mathbf{A} := \begin{pmatrix} \mathbf{A}_{11} & 0 \\ \mathbf{A}_{21} & \mathbf{A}_{22} \\ \mathbf{A}_{31} & \mathbf{A}_{32} \end{pmatrix}.$$

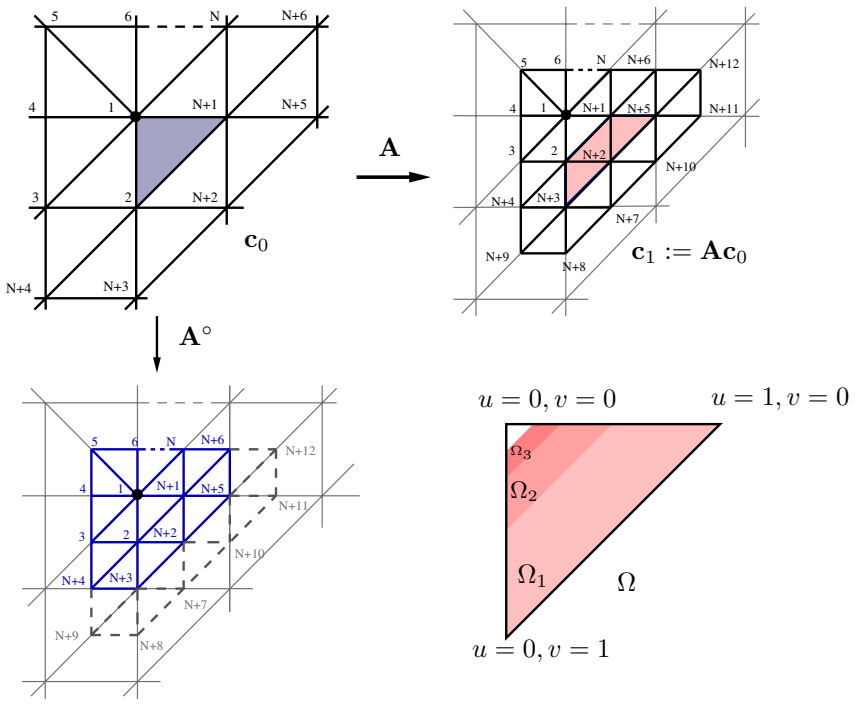

FIG. 2.1. *Top left: Labeling of the submesh that defines a triangular surface piece (schematically represented by the shaded area) near an extraordinary node (label 1). Top right: Refined submesh,* $\mathbf{A}\mathbf{c}_0$. *Bottom left: Refined submesh,* $\mathbf{A}^\circ\mathbf{c}_0$, *used to evaluate the next spline ring. Bottom right: The domain* Ω *of the composite triangular surface piece consists of an infinite sequence of quadrilateral (chopped triangle) subdomains. The first three such subdomains,* Ω_1, Ω_2, Ω_3, *are shaded.*

Here $\mathbf{A}_{11}$ is an $(N+1)\times(N+1)$-matrix that computes the new extraordinary node and the vertices adjacent to it (note that this also holds for an optional initial refinement to generate $\mathbf{c}_0$ from a mesh that has neighboring extraordinary nodes); $\mathbf{A}_{21}$ and $\mathbf{A}_{22}$ determine the five vertices with indices $N+4, N+3, N+2, N+5, N+6$ of the next layer; and $\mathbf{A}_{31}$ and $\mathbf{A}_{32}$ define the six outermost nodes. The sizes of $\mathbf{A}_{22}$ and $\mathbf{A}_{32}$ are 5×5 and 6×5, respectively. Leaving out the direct neighbors of the extraordinary node, $\mathbf{c}_{1,4}, \mathbf{c}_{1,5}, \ldots, \mathbf{c}_{1,N-1}$, the remaining control points

$$\mathbf{c}_1^{\text{box}} := (\mathbf{c}_{1,1}, \mathbf{c}_{1,2}, \mathbf{c}_{1,3}, \mathbf{c}_{1,N}, \ldots \mathbf{c}_{1,M})$$

define three triangular polynomial pieces shown as shaded in Figure 2.1 (top right).

To compute the nodes of the next subdivision step, we need only the first K control points of $\mathbf{c}_1$ (see Figure 2.1 bottom left),

$$(\mathbf{c}_{1,1}, \mathbf{c}_{1,2}, \ldots, \mathbf{c}_{1,K}) = \mathbf{A}^\circ\mathbf{c}_0 := \begin{pmatrix} \mathbf{A}_{11} & 0 \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{pmatrix} \mathbf{c}_0.$$

By repeating the process, an infinite sequence of piecewise polynomial rings is generated. We can choose their domains Ω_ℓ so that their union fills out the triangular domain Ω:

$$\Omega := \{(u,v) | u+v+w = 1, u, v, w \geq 0\} = \cup_{\ell=1}^{\infty}\Omega_\ell \qquad \Omega_1 := \Omega \backslash \frac{1}{2}\Omega, \quad \Omega_{\ell+1} := \frac{1}{2}\Omega_\ell.$$

The control vertices $\mathbf{c}_n$ after n subdivision steps that determine the function on Ω_n are

$$\mathbf{c}_n = \mathbf{A}(\mathbf{A}^\circ)^{n-1}\mathbf{c}_0, \qquad n \geq 1. \tag{2.1}$$

From the recursion in 2.1, it is evident that the eigenstructure of $\mathbf{A}^\circ$ plays a crucial rule in determining the properties of the subdivision surfaces such as the computation of the limit position, tangent plane, and shape analysis [7, 1, 15, 14, 10].

Using Fourier transform, it is easy to derive the vector of eigenvalues Λ_{11} of $\mathbf{A}_{11}$,

$$\Lambda_{11} := \left[1, \frac{5}{8} - \alpha(N), f(1), \ldots, f(N-1)\right],$$

where

$$f(k) := \frac{3 + 2\cos(2\pi k/N)}{8}, \qquad \alpha(N) := \frac{5}{8} - f(1)f(1),$$

and Λ_{22} of $\mathbf{A}_{22}$,

$$\Lambda_{22} := \left[\frac{1}{8}, \frac{1}{8}, \frac{1}{8}, \frac{1}{16}, \frac{1}{16}\right].$$

Except for the case $N = 3$, $\mathbf{A}^\circ$ can be diagonalized by the matrix $\mathbf{V}$ of its eigenvectors (details of the eigenanalysis of $\mathbf{A}^\circ$ can be found, e.g., in [16]):

$$\mathbf{A}^\circ = \mathbf{V}\Lambda\mathbf{V}^{-1}, \quad \Lambda = \operatorname{diag}(\Lambda_{11}, \Lambda_{22}), \mathbf{V} = \begin{pmatrix} \mathbf{U}_0 & 0 \\ \mathbf{U}_1 & \mathbf{W}_1 \end{pmatrix}, \tag{2.2}$$

where the submatrices $\mathbf{U}_0$ and $\mathbf{W}_1$ are the eigenvectors of $\mathbf{A}_{11}$ and $\mathbf{A}_{22}$, respectively. For $N > 3$, the columns of $\mathbf{V}$ are linearly independent vectors in $\mathbb{R}^K$.

Now let the initial submesh $\mathbf{c}_0 := \mathbf{v}_i$ be an eigenvector associated with eigenvalue λ_i and φ_i the corresponding linear combination of nodal functions. Then, after n steps of subdivision,

$$\mathbf{c}_n|_{\mathbf{c}_0=\mathbf{v}_i} = \mathbf{A}(\mathbf{A}^\circ)^{n-1}\mathbf{v}_i = \mathbf{A}\lambda_i^{n-1}\mathbf{v}_i = \lambda_i^{n-1}\mathbf{A}\mathbf{v}_i = \lambda_i^{n-1}\mathbf{c}_1|_{\mathbf{c}_0=\mathbf{v}_i}.$$

Therefore $\varphi_i(\Omega_{n+1})$ is a scaled multiple of $\varphi_i(\Omega_1)$. Precisely,

$$\forall (u,v) \in \Omega \text{ and } \forall n \geq 1, \varphi_i\left(\frac{u}{2^n}, \frac{v}{2^n}\right) = \lambda_i^n \varphi_i(u,v). \tag{2.3}$$

In [16] these K functions φ_i are called eigenbasis. However, adjacent to an extraordinary node, each φ_i consists of an infinite union of polynomial pieces. The subtle but important point to be settled here is that, even if the columns of $\mathbf{V}$ are independent, the corresponding functions can be dependent. We therefore call the functions φ_i *eigenfunctions*. We note that, to be scalable, the control net of an eigenfunction are only well defined if the extraordinary node is surrounded by regular nodes. For the proofs of independence of *nodal functions*, we will be allowed to assume that the extraordinary node is isolated. An *extraordinary node is isolated* if it is surrounded by regular nodes. For, if $\mathbf{c}_0$ is isolated as the result of one refinement, and we show that $\mathbf{c}_0$ is zero, then the values associated with the unrefined nodes must also be zero since the matrix $\mathbf{A}_{11}$ that maps the original nodes to the refined nodes is of full rank for all valences. To see that $\mathbf{A}_{11}$ is of full rank also for $N = 3$, we need only

observe that $\Lambda_{11} = [1, f(1)f(1), f(1), f(1)]$, $f(1) = 1/4$ and the eigenvectors of $f(1)$ are independent.

LEMMA 2.1. $\mathbf{A}_{11}$ *is of full rank for all valences.*

To show that subdivision near extraordinary nodes is similar to but different from spline representations, we will show that the eigenfunctions are linearly independent over Ω, but linearly dependent on certain subsets of Ω.

To show that the nodal functions of Loop subdivision are (globally) linearly independent, we focus on subdomains that form an annulus surrounding the preimage of a sequence of extraordinary nodes. With the natural topological identification of edges to induce the structure of a 2-manifold with two boundaries, we define an annulus as N copies of Ω_1,

$$\mathcal{A} := \{1, \ldots, N\} \times \Omega_1.$$

Note that this requires that the extraordinary node is isolated.

LEMMA 2.2. *The nodal functions of Loop subdivision with support on* $\mathcal{A}$ *are linearly independent over* $\mathcal{A}$.

Proof. For $\mathcal{A}$ to be well defined, the extraordinary node must be isolated. Let $f := \sum_i \mathbf{c}_{0,i}\nu_i$ be zero on all of $\mathcal{A}$. Then the subset of nodes $\mathbf{c}_1^{\text{box}}$ can be interpreted as a regular three-direction box-spline control net defining three polynomial pieces near the extraordinary node. Since the box-splines are locally linearly independent [6], all box-spline control points defining f on $\mathcal{A}$ are zero. Since all eigenvalues of $\mathbf{A}^\circ$ are positive for $N > 3$, $\mathbf{A}^\circ$ is of full rank and for $N = 3$, Lemma 3.5 shows that the matrix M is of full rank. Therefore all $\mathbf{c}_{0,i}$ must be zero. ∎

Now consider *all* nodal functions of a once-refined control net. Lemma 2.2 proves linear independence of these nodal functions on the union of all annuli $\mathcal{A}$. By Lemma 2.1, the original control nodes must also be zero if the function vanishes on all annuli.

COROLLARY 2.3. *The nodal functions of Loop subdivision are globally linearly independent.*

3. Local linear independence of Loop subdivision. In this section, we characterize the local linear independence of Loop subdivision nodal functions.

LEMMA 3.1. *For general* N*, the nodal functions of Loop subdivision are* not locally linearly independent. *Specifically, for any* k *there exists a valence* N *so that the nodal functions of Loop subdivision with support on* Ω_k*,* $\nu_i, i = 1 \ldots N + 6$*, are* locally linearly dependent *on* Ω_k *and even on* $\cup_{\ell=1}^{k}\Omega_\ell$.

Proof. All nodal functions corresponding to $\mathbf{c}_0$ have support (are nonzero) on each subdomain Ω_k. Each vector $\mathbf{c}_k^{\text{box}}$ corresponding to Ω_k has 16 entries. For sufficiently large valence, the nodal functions on Ω_k must therefore be dependent. By the same reasoning, for sufficiently large valence, the nodal functions on $\cup_{\ell=1}^{k}\Omega_\ell$, for finite k, must be dependent. ∎

As could be hoped by the failure of the above counting argument, nodal functions are locally linearly independent for sufficiently low valence N.

LEMMA 3.2. *For* $N \leq 6$ *the nodal functions* $\nu_i, i = 1 \ldots N+6$*, are locally linearly independent.*

Proof. Denote by $\mathbf{P}_i, i = 1, 2, 3$ the three $12 \times (N + 12)$ picking matrices that select the box-spline coefficients of each of the three triangular domain parts. Since $\mathbf{P}_i\mathbf{A}, i = 1, 2, 3$ is of full rank $\mathbf{c}_0$ must be zero if the 12 box-spline control points are zero. Then local linear independence of the three-direction box-spline implies the claim on Ω_1. Since the control points on Ω_ℓ are computed from $\mathbf{c}_0$ by applying

$$\mathbf{P}_i\mathbf{A}(\mathbf{A}^\circ)^{\ell-1}$$

local linear independence on Ω_1 implies local linear independence on Ω_ℓ for $N > 3$. For $N = 3$, the claim follows from Lemma 3.5. ∎

For $N = 7$, the nodal functions are independent on Ω_1 and hence on $\cup_{\ell=1}^{k}\Omega_\ell$, but, due to the dimension of the three polynomial pieces corresponding to Ω_1, they are not linearly independent on subsets of Ω_1 that do not straddle all three piecewise polynomial domains. As the valence N increases, a subtle pattern emerges.

CONJECTURE 1. *For $k := \lfloor (N-6)/2 \rfloor + 1 > 1$, the nodal functions of Loop subdivision $\nu_i, i = 1 \dots N+6$ are linearly independent on $\cup_{i=1}^{k}\Omega_i$ and linearly dependent on $\cup_{i=1}^{k-1}\Omega_i$.*

We verified the conjecture for isolated extraordinary nodes by symbolic calculation up to $N = 30$, which should cover most cases of practical interest.

To investigate linear independence on the natural domains corresponding to control facets, namely on $\Omega = \cup_{\ell=1}^{\infty}\Omega_\ell$, we need a better strategy. We use the eigenproperty of the eigenfunctions, that additional layers are scaled copies of the earlier layers.

LEMMA 3.3. *For valence $N > 3$, the* eigenfunctions φ_i, $i = 1, \dots N+6$, *of Loop subdivision are linearly independent on Ω.*

Proof. The proof is by contradiction. All eigenvalues λ_i of $\mathbf{A}^\circ$ are positive. We sort the eigenfunctions φ_i $(i = 1, \dots N+6)$ so that their associated eigenvalues λ_i descend from the largest to the smallest. Suppose there exist scalars $a_1, a_2, \dots a_{N+6}$, not all zero, such that

$$\sum_{i=1}^{N+6} a_i \varphi_i = 0.$$

Let λ_j be the largest eigenvalue such that $a_j \neq 0$. Then with $w_i := -a_i/a_j$, we write

$$\varphi_j = \sum_{i=j+1}^{N+6} w_i \varphi_i.$$

For $\forall (u,v) \in \Omega$ and $\forall n \geq 1$, $(\frac{u}{2^n}, \frac{v}{2^n}) \in \Omega$, with the above equation and (2.3), we have

$$\begin{aligned}
\varphi_j\left(\frac{u}{2^n}, \frac{v}{2^n}\right) &= \sum_{i=j+1}^{N+6} w_i \varphi_i\left(\frac{u}{2^n}, \frac{v}{2^n}\right), \\
\Rightarrow \lambda_j^n \varphi_j(u,v) &= \sum_{i=j+1}^{N+6} w_i \lambda_i^n \varphi_i(u,v), \\
\Rightarrow \varphi_j(u,v) &= \sum_{i=j+1}^{N+6} w_i \left(\frac{\lambda_i}{\lambda_j}\right)^n \varphi_i(u,v).
\end{aligned}$$

Since $(\frac{\lambda_i}{\lambda_j})^n \to 0$ as $n \to \infty$ unless $\lambda_i = \lambda_j$,

$$\varphi_j(u,v) = \sum_{i \in \{i | \lambda_i = \lambda_j\}} w_i \varphi_i(u,v)$$

must hold. Therefore the eigenfunctions associated with λ_j must be linearly dependent. In the remainder of the proof, we show this to be false. In other words, the

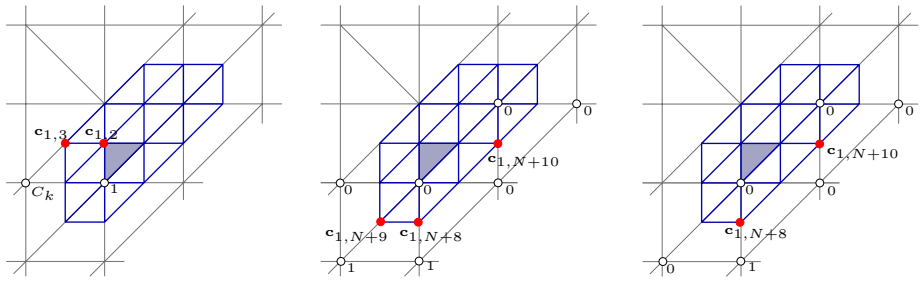

FIG. 3.1. *The box-spline control points* $\mathbf{c}_{1,i}$ *(solid dots) used to certify that pairs and triples of eigenfunctions are independent.*

problem of proving the linear independence of all eigenfunctions has been reduced to the independence of the eigenfunctions with the same eigenvalue.

Because of the eigenstructure of $\mathbf{A}^\circ$, the multiplicities of its eigenvalues are small (at most four) and do not increase with N. Recall that the eigenvalues of $\mathbf{A}^\circ$ are

$$\left[1, \frac{5}{8} - \alpha(N), f(1), \ldots, f(N-1), \frac{1}{8}, \frac{1}{8}, \frac{1}{8}, \frac{1}{16}, \frac{1}{16}\right],$$

where

$$\alpha(N) := \frac{5}{8} - \frac{(3 + 2\cos(2\pi/N))^2}{64}, f(k) := \frac{3 + 2\cos(2\pi k/N)}{8}.$$

To find the repeated eigenvalues, we observe that for $k \in \{1 \ldots N-1\}$,

1. $f(k) = f(N-k)$,
2. if N is even and $k = N/2$, $f(k) = \frac{1}{8}$; otherwise $f(k) \notin \{\frac{1}{8}, \frac{1}{16}\}$,
3. $f(k) \neq 1$ and $f(k) \neq \frac{5}{8} - \alpha(N)$.

That is, if λ is an eigenvalue of $\mathbf{A}$ with multiplicity greater than one, then $\lambda = f(k) \neq \frac{1}{8}$, or $\lambda = \frac{1}{8}$, or $\lambda = \frac{1}{16}$. In particular, all relevant eigenvalues are nonzero. We look at each case individually.

- *Case* 1. $\lambda = f(k) \neq \frac{1}{8}$
  In this case λ has multiplicity 2 and the associated eigenvectors $\mathbf{u}_k$ and $\mathbf{w}_k$ are given in [16]:

$$\mathbf{u}_k^T = (0, 1, C_k, C_{2k}, \ldots C_{(N-1)k}, \ldots) \qquad \text{and}$$
$$\mathbf{w}_k^T = (0, 0, S_k, S_{2k}, \ldots S_{(N-1)k}, \ldots),$$

  where $C_k := \cos(2\pi k/N)$ and $S_k := \sin(2\pi k/N)$. To show the two eigenfunctions defined by $\mathbf{u}_k$ and $\mathbf{w}_k$ are linearly independent, we consider the two box-spline entries of $\mathbf{c}_{1,2}$ and $\mathbf{c}_{1,3}$ (solid dots in Figure 3.1, left) after one step of subdivision applied to the mesh $\mathbf{c}_0 := \mathbf{u}_k$ and one step applied with $\mathbf{c}_0 := \mathbf{w}_k$. The two corresponding eigenfunctions are independent because

$$\det \begin{pmatrix} \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{u}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{u}_k} \\ \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{w}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{w}_k} \end{pmatrix} = \lambda^2 \det \begin{pmatrix} 1 & C_k \\ 0 & S_k \end{pmatrix} \neq 0,$$

  since $S(k) \neq 0$ because $f(k) \neq \frac{1}{8}$ and hence $k \neq \frac{N}{2}$.

- *Case* 2. $\lambda = \frac{1}{8}$
  In this case λ can have multiplicity of 3 or 4. We first show that the eigenfunctions corresponding to the first three columns $\mathbf{y}_1, \mathbf{y}_2, \mathbf{y}_3$ of $\binom{0}{\mathbf{W}_1}$ are independent. The eigendecomposition (2.2) of $\mathbf{A}_{22}$ is (see [16])

$$\mathbf{W}_1 = \begin{pmatrix} 0 & 0 & 1 & 0 & 0 \\ 1 & 0 & 1 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 1 & 0 \\ 0 & 1 & 0 & 0 & 0 \end{pmatrix}.$$

  The independence of the eigenfunctions follows from the independence of the three box-spline control points $\mathbf{c}_{1,N+8}, \mathbf{c}_{1,N+9}, \mathbf{c}_{1,N+10}$ (solid dots in Figure 3.1, middle) after one subdivision:

$$\det \begin{pmatrix} \mathbf{c}_{1,N+8}|_{\mathbf{c}_0=\mathbf{y}_1} & \mathbf{c}_{1,N+9}|_{\mathbf{c}_0=\mathbf{y}_1} & \mathbf{c}_{1,N+10}|_{\mathbf{c}_0=\mathbf{y}_1} \\ \mathbf{c}_{1,N+8}|_{\mathbf{c}_0=\mathbf{y}_2} & \mathbf{c}_{1,N+9}|_{\mathbf{c}_0=\mathbf{y}_2} & \mathbf{c}_{1,N+10}|_{\mathbf{c}_0=\mathbf{y}_2} \\ \mathbf{c}_{1,N+8}|_{\mathbf{c}_0=\mathbf{y}_3} & \mathbf{c}_{1,N+9}|_{\mathbf{c}_0=\mathbf{y}_3} & \mathbf{c}_{1,N+10}|_{\mathbf{c}_0=\mathbf{y}_3} \end{pmatrix} = \frac{1}{8^3} \det \begin{pmatrix} 4 & 4 & 0 \\ 0 & 0 & 1 \\ 1 & 4 & 4 \end{pmatrix} \neq 0.$$

  If the multiplicity of $\frac{1}{8}$ is three, then we are done. Otherwise, $\lambda = f(N/2)$ for N is even and we have one additional eigenvector $\mathbf{u}_k$ from $\binom{\mathbf{U}_0}{\mathbf{U}_1}$. After one subdivision, the box-spline control point $\mathbf{c}_{1,3}$ is zero for $\mathbf{y}_1, \mathbf{y}_2, \mathbf{y}_3$ and nonzero for $\mathbf{u}_k$. This proves independence of all four eigenfunctions.
- *Case* 3. $\lambda = \frac{1}{16}$
  The eigenvectors of the two eigenfunctions associated with $\frac{1}{16}$ correspond to the last two columns $\mathbf{z}_1$ and $\mathbf{z}_2$ of $\binom{0}{\mathbf{W}_1}$. Pairwise independence follows from the independence of the two box-spline control points $\mathbf{c}_{1,N+8}, \mathbf{c}_{1,N+10}$ (solid dots in Figure 3.1, right)

$$\det \begin{pmatrix} \mathbf{c}_{1,N+8}|_{\mathbf{c}_0=\mathbf{z}_1} & \mathbf{c}_{1,N+10}|_{\mathbf{c}_0=\mathbf{z}_1} \\ \mathbf{c}_{1,N+8}|_{\mathbf{c}_0=\mathbf{z}_2} & \mathbf{c}_{1,N+10}|_{\mathbf{c}_0=\mathbf{z}_2} \end{pmatrix} = \frac{1}{8^2} \det \begin{pmatrix} 0 & 3 \\ 3 & 0 \end{pmatrix} \neq 0.$$

This completes the proof of Lemma 3.3. ∎

We can now address our original goal of showing that the nodal functions ν_i are linearly independent.

COROLLARY 3.4. *For $N > 3$, the nodal functions of Loop subdivision, $\nu_i, i = 1 \ldots N+6$, are linearly independent on Ω.*

Proof. Each nodal function ν_i is generated by subdivision when setting control point i to 1 and all others to 0. If the extraordinary node is surrounded by regular nodes,

$$[\varphi_1, \ldots, \varphi_K] = \mathbf{V}[\nu_1, \ldots, \nu_K], \qquad K = N + 6,$$

and independence follows since, for $N > 3$, the matrix $\mathbf{V}$ of eigenvectors is an invertible matrix. The general case follows by one step of subdivision and the full rank of $\mathbf{A}_{11}$. ∎

For the special case $N = 3$, the matrix $\mathbf{A}^\circ$ has a nontrivial Jordan block and cannot be diagonalized. However, since the number of nodal functions is small, namely nine, we need not decompose into the eigenspace.

LEMMA 3.5. *For $N = 3$, the nodal functions of Loop subdivision, $\nu_i, i = 1 \ldots N+6$, are linearly independent on Ω.*

Proof. If the extraordinary node is isolated, we explicitly determine the $(N + 12) \times 9$ matrix $\mathbf{M}$ that maps $\mathbf{c}_0$ to the box-spline control points $\mathbf{c}_1^{\text{box}}$.

$$\frac{1}{16}\begin{bmatrix}
7 & 3 & 3 & 3 & 0 & 0 & 0 & 0 & 0\\
6 & 6 & 2 & 2 & 0 & 0 & 0 & 0 & 0\\
6 & 2 & 6 & 2 & 0 & 0 & 0 & 0 & 0\\
6 & 2 & 2 & 6 & 0 & 0 & 0 & 0 & 0\\
2 & 6 & 0 & 6 & 2 & 0 & 0 & 0 & 0\\
1 & 10 & 1 & 1 & 1 & 1 & 1 & 0 & 0\\
2 & 6 & 6 & 0 & 0 & 0 & 2 & 0 & 0\\
1 & 1 & 1 & 10 & 1 & 0 & 0 & 1 & 1\\
2 & 0 & 6 & 6 & 0 & 0 & 0 & 0 & 2\\
0 & 6 & 0 & 2 & 6 & 2 & 0 & 0 & 0\\
0 & 6 & 0 & 0 & 2 & 6 & 2 & 0 & 0\\
0 & 6 & 2 & 0 & 0 & 2 & 6 & 0 & 0\\
0 & 2 & 0 & 6 & 6 & 0 & 0 & 2 & 0\\
0 & 0 & 0 & 6 & 2 & 0 & 0 & 6 & 2\\
0 & 0 & 2 & 6 & 0 & 0 & 0 & 2 & 6
\end{bmatrix}.$$

Since $\mathbf{M}$ has full rank and since the box-splines associated with each of $\mathbf{c}_{1,1}, \mathbf{c}_{1,2} \ldots \mathbf{c}_{1,N+12}$ are linearly independent, the $\nu_i, i = 1 \ldots 9$ are also linearly independent. The general case follows by one step of subdivision and the full rank of $\mathbf{A}_{11}$. ∎

Together, Corollary 3.4 and Lemma 3.5 prove the main Theorem 3.6.

THEOREM 3.6. *The nodal functions of Loop subdivision, $\nu_i, i = 1 \ldots N + 6$, are linearly independent over Ω.*

The theorem sharply characterizes the locality of linear independence. On any finite union of Ω_ℓ the nodal functions are linearly dependent for sufficiently high valence. Only once we take the union to the limit Ω, do we obtain linear independence of the nodal functions for all possible valences.

Lemmas 3.3 and 3.5 imply the analogous result for eigenfunctions.

COROLLARY 3.7. *For all N, the* eigenfunctions *φ_i, $i = 1, \ldots N + 6$, of Loop subdivision are linearly independent and form a basis for the Loop subdivision functions over Ω.*

In particular, we can now call the Loop eigenfunctions an *eigenbasis*.

4. Catmull–Clark subdivision. In this section, we investigate another widely used subdivision scheme, Catmull–Clark subdivision. The Catmull–Clark algorithm [3] accepts input meshes that have m-sided facets and vertices with N neighbors. However, all m-sided facets are split into m quadrilaterals in the first step as follows. A new face node is computed as the average of the facet vertices, a new edge node as the average of the edge endpoints and the two new face nodes of the faces joined by the edge, and a new vertex node of valence N is computed as

$$(Q + 2R + (N - 3)S)/N,$$

where Q is the average of the new face nodes of all faces adjacent to the old vertex, R is the average of the midpoints of all old edges incident on the old vertex point, and S is the old vertex point. A new quadrilateral facet then consists of consecutive edge node, vertex node, edge node, and the face node. The rules are consistent with the Catmull–Clark stencils for quadrilateral meshes listed in Figure 4.1. The standard Catmull–Clark choices for α, β, and γ are

$$\alpha := 1 - \frac{7}{4N}, \quad \beta := \frac{3}{2N^2}, \quad \gamma := \frac{1}{4N^2}.$$

If each node of a quadrilateral mesh facet has valence $N = 4$, Catmull–Clark subdivision amounts to tensor product bicubic spline subdivision. In this case, the nodal functions are the standard tensor product uniform B-spline basis functions whose independence is well documented. Since the extraordinary nodes (with valence $N \neq 4$) are always isolated after two subdivision steps, i.e., any two extraordinary

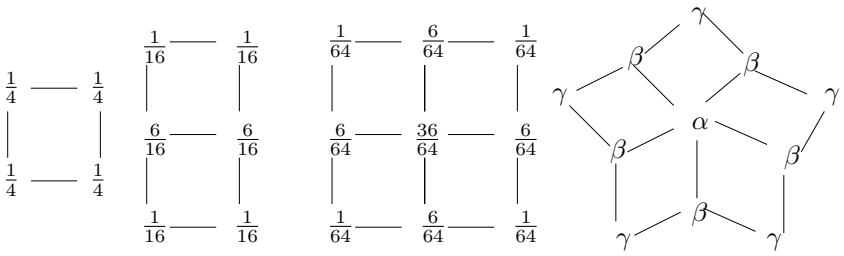

FIG. 4.1. *Refinement stencils of generalized Catmull–Clark subdivision.*

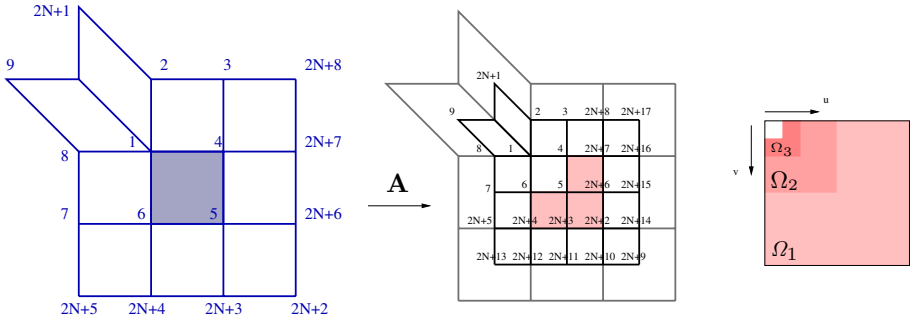

FIG. 4.2. *Left. Indices of Catmull–Clark nodes near a facet with one extraordinary node ($N = 5$). Middle. The indices of the new control points after one subdivision. Three quarters of the domain now have well-defined tensor product B-spline structure. Right. The complete rectangular domain is composed of an infinite number of L shaped regions Ω_ℓ.*

nodes are separated by at least one node of valence four, we can focus our local analysis on surface parts adjacent to a single extraordinary node. That is, the subscript 0 refers to a mesh with isolated extraordinary nodes.

The indices of the $K := 2N + 8$ adjacent control points are stored in $\mathbf{c}_0$ as in Figure 4.2, left:

$$\mathbf{c}_0 := (\mathbf{c}_{0,1}, \dots \mathbf{c}_{0,K}).$$

After subdivision, the new set of $M := K + 9$ control vertices is ordered as shown in Figure 4.2, middle and stored in the vector

$$\mathbf{c}_1 := (\mathbf{c}_{1,1}, \dots, \mathbf{c}_{1,K}, \mathbf{c}_{1,K+1}, \dots \mathbf{c}_{1,M}).$$

The subdivision rules are again denoted by

$$\mathbf{c}_1 = \mathbf{A}\mathbf{c}_0, \quad \text{where } \mathbf{A} := \begin{pmatrix} \mathbf{A}_{11} & 0 \\ \mathbf{A}_{21} & \mathbf{A}_{22} \\ \mathbf{A}_{31} & \mathbf{A}_{32} \end{pmatrix}.$$

Here $\mathbf{A}_{11}$ is an $(2N + 1) \times (2N + 1)$-matrix that computes the new extraordinary node and the vertices adjacent to it; $\mathbf{A}_{21}$ and $\mathbf{A}_{22}$ determine the seven vertices with indices $2N + 2, \dots, 2N + 8$, in the middle vertex ring; and $\mathbf{A}_{31}$ and $\mathbf{A}_{32}$ compute the last nine vertices with indices $2N + 9, \dots, 2N + 17$. We have enough control points in $\mathbf{c}_1$ to evaluate three regular patches (see shaded area in Figure 4.2, middle). The first K control points of $\mathbf{c}_1$,

$$(\mathbf{c}_{1,1}, \mathbf{c}_{1,2}, \dots, \mathbf{c}_{1,K}) = \mathbf{A}^\circ \mathbf{c}_0 := \begin{pmatrix} \mathbf{A}_{11} & 0 \\ \mathbf{A}_{21} & \mathbf{A}_{22} \end{pmatrix} \mathbf{c}_0,$$

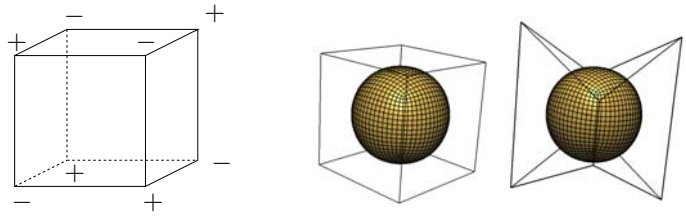

FIG. 4.3. *Global linear dependence of Catmull–Clark subdivision. Left: An alternative representation of the zero function with + indication any nonzero number and - its negative value. Right: Two control nets with the connectivity of a cube but different node positions. They generate the same Catmull–Clark surface!*

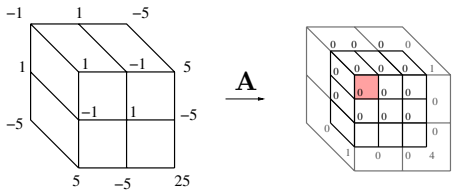

FIG. 4.4. *Nonzero input coefficients of the eigenfunction corresponding to the eigenvalue zero generating the zero function on* $\cup_{i=2}^{\infty}\Omega_i$ *(shaded area).*

are used as the control points for the next subdivision step. $\mathbf{A}^\circ$ can always be diagonalized by its eigenvectors $\mathbf{V}$,

$$\mathbf{A}^\circ = \mathbf{V}\Lambda\mathbf{V}^{-1}.$$

All eigenvalues are nonzero, except for $N = 3$ when one eigenvalue is zero. (The second eigenvalue of the zero Fourier block.) For $N > 3$, the linear independence of the nodal functions on $\mathcal{A}$ follows, just as in the case of Loop subdivision, from the local linear independence of tensor-product splines and the full rank of $\mathbf{A}^\circ$. The full rank of $\mathbf{A}_{11}$ implies *global linear independence* for $N > 3$.

The case $N = 3$ merits closer scrutiny.

LEMMA 4.1. *The nodal functions of Catmull–Clark subdivision corresponding to the graph in Figure* 4.3 *are (globally) linearly dependent.*

Proof. Given the displayed choice of nonzero values at the vertices, all new face nodes have value 0 and all averages of two old nodes connected by an edge have value 0. Therefore all new edge nodes have value zero and so do the new vertex nodes: $(Q + 2R + (N - 3)S)/N = (0 + 0 + 0S)/3 = 0$. □

Figure 4.3, right, illustrates dependence as the nonuniqueness of the control net for a given surface. Interestingly, an early version of the Catmull–Clark subdivision algorithm, quoted by Doo and Sabin [7], can be shown to be locally linearly independent for $N = 3$. Here a new vertex node of valence N is computed as $(Q+R+2S)/4$.

In general, on $\cup_{i=2}^{\infty}\Omega_i$, the nodal functions associated with the mesh for $N = 3$ are locally linearly dependent as illustrated in Figure 4.4. On Ω_1, if at least one node involved has valence $N \neq 3$, then $\mathbf{A}$ has full rank and the nodal functions are linearly independent. This implies global linear independence.

Therefore we have:

LEMMA 4.2. *The nodal functions of Catmull–Clark subdivision with support on* $\mathcal{A}$ *are linearly independent over* $\mathcal{A}$ *unless their nodes all have valence* $N = 3$.

5. Local linear independence of Catmull–Clark subdivision. Since the valence N can be arbitrary but each layer of the subdivision function corresponding to a region Ω_ℓ is defined by a finite number of B-spline control points, the nodal functions of Catmull–Clark subdivision cannot in general be locally linearly independent over any subset of Ω.

LEMMA 5.1. *The nodal functions of Catmull–Clark subdivision are locally linearly independent if and only if* $N = 4$.

Proof. For $N = 3$, the nodal functions are not linearly independent over $\cup_{i=2}^{\infty}\Omega_i$ due to the example given in Figure 4.4.

If $N = 4$, the local linearly independence follows from the local linearly independence of tensor product B-splines.

For $N = 5$, the nodal functions are independent on Ω_1, (which implies linear independence on $\cup_{\ell=1}^{k}\Omega_\ell$ since all eigenvalues are positive) and on any subset of Ω_1 that straddles at least two of the three quad subdomains of Ω_1 on which the subdivision surface is a single polynomial. However, due to the dimension of a polynomial piece (16), on any single one of the subdomains, the $2N+8$ nodal functions must be linearly dependent.

For $N > 5$, the nodal functions are linearly dependent on Ω_1. ∎

Just as for Loop subdivision, for any k there exists a valence N so that the nodal functions ν_i of Catmull–Clark subdivision with support on Ω_k are locally linearly dependent on Ω_k and even on $\cup_{\ell=1}^{k}\Omega_\ell$. The pattern, verified by symbolic calculation for isolated extraordinary nodes up to $N = 20$, is as follows.

CONJECTURE 2. *For* $k := N - 4 > 0$, *the nodal functions of Catmull–Clark subdivision* $\nu_i, i = 1 \dots 2N + 8$ *are linearly independent on* $\cup_{i=1}^{k}\Omega_i$ *but linearly dependent on* $\cup_{i=1}^{k-1}\Omega_i$.

Next, we show that this characterization of the localness of linear independence is sharp: once we take the union of regions to the limit Ω, the nodal functions are linearly independent regardless of valence. As before, we first prove independence over Ω of the eigenfunctions defined by the column vectors in $\mathbf{V}$. Then we conclude independence of the nodal functions for Catmull–Clark subdivision over Ω. As always, to be scalable, the control net of an eigenfunction is only well defined if the extraordinary node is isolated.

LEMMA 5.2. *The eigenfunctions of Catmull–Clark subdivision are linearly independent over* Ω.

Proof. For $N > 3$, analogous to the proof of Lemma 3.3, we can reduce the problem to the independence of the eigenfunctions associated with the same eigenvalue.

According to [1, 2, 10], the eigenvalues of $\mathbf{A}_{11}$,

$$\lambda_k := \frac{1}{16}(C_k + 5 \pm \sqrt{(C_k + 9)(C_k + 1)}), \quad k = 1, \dots N - 1,$$

each have a multiplicity of two. We have $\lambda_k \neq 0$ since $(C_k + 5)^2 \neq (C_k + 9)(C_k + 1)$.

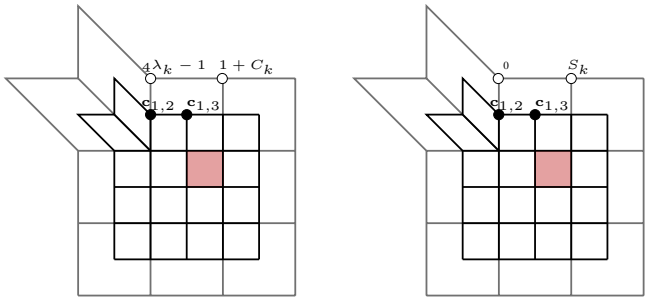

FIG. 5.1. *The B-spline control points* $\mathbf{c}_{1,2}, \mathbf{c}_{1,3}$ *(red points) used to certify that the eigenfunctions associated with* $\mathbf{u}_k$ *and* $\mathbf{w}_k$ *are independent.*

When $k \neq N/2$, the associated eigenvectors $\mathbf{u}_k$ and $\mathbf{w}_k$ are (see [17])

$$\mathbf{u}_k = \begin{pmatrix} 0 \\ 4\lambda_k - 1 \\ 1 + C_k \\ (4\lambda_k - 1)C_k \\ C_k + C_{2k} \\ \vdots \\ (4\lambda_k - 1)C_{(N-1)k} \\ C_{(N-1)k} + 1 \end{pmatrix} \quad \text{and} \quad \mathbf{w}_k = \begin{pmatrix} 0 \\ 0 \\ S_k \\ (4\lambda_k - 1)S_k \\ S_k + S_{2k} \\ \vdots \\ (4\lambda_k - 1)S_{(N-1)k} \\ S_{(N-1)k} \end{pmatrix},$$

where $C_k := \cos(2\pi k/N)$ and $S_k := \sin(2\pi k/N)$. To show that the two eigenfunctions defined by $\mathbf{u}_k$ and $\mathbf{w}_k$ are linearly independent, we consider the tensor-product B-spline entries $\mathbf{c}_{1,2}$ and $\mathbf{c}_{1,3}$ of $\mathbf{c}_1|_{\mathbf{c}_0=\mathbf{u}_k}$ and $\mathbf{c}_1|_{\mathbf{c}_0=\mathbf{w}_k}$ (solid dots in Figure 5.1). The two eigenfunctions are linearly independent over the shaded region if they generate independent B-spline control points $\mathbf{c}_{1,2}$ and $\mathbf{c}_{1,3}$, i.e., if

$$\det \begin{pmatrix} \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{u}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{u}_k} \\ \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{w}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{w}_k} \end{pmatrix} = \lambda_k^2 \det \begin{pmatrix} 4\lambda_k - 1 & 1 + C_k \\ 0 & S_k \end{pmatrix} \neq 0.$$

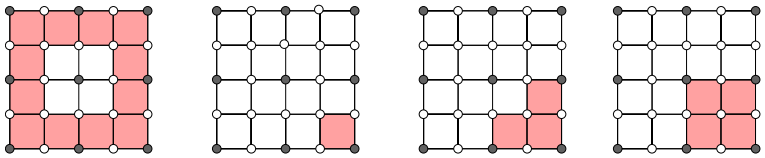
In fact,

$$\begin{aligned} & 4\lambda_k - 1 \neq 0 \\ \iff & \frac{1}{4}(C_k + 5 \pm \sqrt{(C_k + 9)(C_k + 1)}) \neq 1, \\ \iff & (C_k + 5) \pm \sqrt{(C_k + 9)(C_k + 1)}) \neq 4, \\ \iff & (\pm\sqrt{(C_k + 9)(C_k + 1)}) \neq -1 - C_k, \\ \iff & (C_k + 9)(C_k + 1) \neq (-1 - C_k)^2, \\ \iff & 8C_k + 8 \neq 0, \\ \iff & C_k \neq -1. \end{aligned}$$

$C_k \neq -1$ and $S_k \neq 0$ follows from $k \neq N/2$.

When $k = N/2$, the eigenvectors of $\lambda_k = \frac{1}{4}$ are

$$\begin{aligned} \mathbf{u}_k^T &= (0, 1, 0, -1, 0, 1, 0, \ldots, -1, 0, \ldots) \quad \text{and} \\ \mathbf{w}_k^T &= (0, 0, 1, 0, -1, 0, 1, \ldots, 0, -1, \ldots), \end{aligned}$$



$\forall N$ (Lemma 4.2) | $N \le 4$ (Lemma 5.1) | $N \le 5$ (Conjecture 2) | $\forall N$ (Theorem 5.3)

FIG. 5.2. *Summary of findings for Catmull–Clark subdivision. Domains G (shaded) and valence N for which the nodal functions with support on G are linearly independent.*

then

$$\det \begin{pmatrix} \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{u}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{u}_k} \\ \mathbf{c}_{1,2}|_{\mathbf{c}_0=\mathbf{w}_k} & \mathbf{c}_{1,3}|_{\mathbf{c}_0=\mathbf{w}_k} \end{pmatrix} = \lambda_k^2 \det \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \neq 0.$$

For the eigenvalues of $\mathbf{A}_{22}$, $\{\frac{1}{8}, \frac{1}{8}, \frac{1}{16}, \frac{1}{16}, \frac{1}{32}, \frac{1}{32}, \frac{1}{64}\}$, the eigenfunctions are the tensor-product power basis functions [17]

$$\{u^3, v^3, u^3v, uv^3, u^3v^2, u^2v^3, u^3v^3\}$$

whose pairwise independence is well known.

For the special case $N = 3$, there is a zero eigenvalue and, as illustrated in Figure 4.4, the associated eigenfunction has zero values on $\cup_{i=2}^{\infty}\Omega_i$. But the remaining eigenfunctions are linearly independent on $\cup_{i=2}^{\infty}\Omega_i$ and, if at least one neighbor of the central node has valence $N \neq 3$, the zero eigenfunction has nonzero values on Ω_1. ∎

Since the transformation between the eigenfunctions and nodal functions are invertible, provided the extraordinary node is surrounded by regular nodes, all such nodal functions are linearly independent and form a basis when the eigenfunctions do. If the nodal functions were the result of one refinement, then full rank of $\mathbf{A}_{11}$ (unless all relevant nodes have valence $N = 3$) establishes the main result.

THEOREM 5.3. *The nodal functions of Catmull–Clark subdivision that have support on Ω are linearly independent over Ω unless their nodes all have valence $N = 3$. The findings are summarized in Figure* 5.2.

6. Primal schemes. We now collect the key ideas of the preceding analyses. An extraordinary node is a control net node of valence different from the "regular" majority. A subdivision scheme is called primal if there exists a sequence of extraordinary nodes converging towards each extraordinary point. While the typical application of subdivision creates a parametrized surface in $\mathbb{R}^3$, for the analysis, it is sufficient to look at one spatial coordinate since the coordinates do not interact.

Near extraordinary points, subdivision surfaces can be understood as an infinite union of nested surface rings [15]. An extraordinary node is *isolated* if at least one surface ring separates it from any other extraordinary node. If the extraordinary node is isolated, then $\mathcal{A} := \{1, \ldots, N\} \times \Omega_1$, the domain of the first surface ring, is well defined. We denote by $\{g_i\}$ the nodal functions corresponding to regular nodes that generate the first subdivision surface ring. For Loop's subdivision, the g_i are three-direction box-splines. For Catmull–Clark subdivision, they are tensor-product bicubic B-splines. Denote by A_* the refinement matrix from the input control net to a control net with isolated extraordinary node. This may be the identity if all extraordinary nodes are already isolated. To show that the nodal functions of a subdivision scheme are (globally) linearly independent, we focus on $\mathcal{A}$.

LEMMA 6.1 (global linear independence). *If the functions g_i are linearly independent and the matrix A_* is of full rank, then the nodal functions ν_j of the subdivision are globally linearly independent.*

Proof. By assumption, the nodal functions g_i of the once-refined control net are linearly independent on the union of all local domain rings $\mathcal{A}$. Since A_* is of full rank and, as a refinement matrix, its rank is less than the number of g_i, the coefficients of the input control net are zero. ∎

For example, if the functions g_i are four-direction box-splines, then the nodal functions are not globally independent since this space of splines has dependent generating g_i [6]. The example of Figure 4.3 underscores the need for the assumption on A_*—a counting argument shows that typical schemes are not locally linearly independent.

LEMMA 6.2 (local dependence for high valence). *Let ν_0 be the nodal function associated with an extraordinary node of valence N and ν_ℓ, $\ell = 1, \dots, N$ the nodal functions of its direct neighbor nodes. Denote by x_i^m the ith segment of the mth surface ring and assume that x_i^m belongs to a space of fixed finite dimension that is independent of N. If each ν_j has support on $\Omega_k \, \forall \, k \geq k_0$, then there exists $m \in \mathbb{Z}$ so that ν_ℓ, $\ell = 0, \dots, n$ are* locally linearly dependent *on Ω_m.*

Proof. For sufficiently large valence N, the number of ν_j with support on the domain of x_i^m exceeds the fixed dimension of the space from which x_i^m is drawn. ∎

The assumptions of the lemma hold in particular for symmetric C^1 subdivision schemes derived from box-splines since each x_i^m is finitely generated and the ν_j must all interact at the extraordinary point to guarantee smoothness and partition of unity. For such schemes, nodal functions contribute to the whole spline ring x^m of high valence only after a number of subdivision steps k_0.

As the example in Figure 4.4 shows, failure of the counting argument for low valences does not imply that the nodal functions are locally linearly independent. To establish local linear independence and also to find the m in Lemma 6.2 beyond which the nodal functions are locally linearly dependent, requires an analysis specific to each scheme.

To investigate linear independence on the domains Ω, corresponding to control facets surrounding an extraordinary node, we use eigenfunctions.

LEMMA 6.3 (linear independence of eigenfunctions). *The eigenfunctions φ_i, $i = 1, \dots, k$ are linearly independent on Ω if the eigenfunctions corresponding to each eigenvalue, separately, are independent.*

Proof. Let λ_i be sorted by absolute value and $\lambda_0 = 1$. Suppose there exist scalars $a_1, a_2, \dots a_k$, not all zero, such that $\sum_{i=1}^k a_i \varphi_i = 0$. Let λ_j be an absolute largest eigenvalue such that $a_j \neq 0$. If $\lambda_j = 0$, then the eigenfunctions to the eigenvalue 0 are dependent contradicting the assumptions. If $\lambda_j \neq 0$, then, with $w_i := -a_i/a_j$, we can write $\varphi_j = \sum_{i=j+1}^k w_i \varphi_i$. and, by the defining property of eigenfunctions, for any $(u, v) \in \mathcal{A}$,

$$\varphi_j\left(\frac{u}{2^m}, \frac{v}{2^m}\right) = \sum_{i=j+1}^{k} w_i \varphi_i\left(\frac{u}{2^m}, \frac{v}{2^m}\right) \quad \Rightarrow \quad \varphi_j(u, v) = \sum_{i=j+1}^{k} w_i \left(\frac{\lambda_i}{\lambda_j}\right)^m \varphi_i(u, v).$$

Since the equality has to hold for all m and $(\frac{\lambda_i}{\lambda_j})^m$ goes to zero or repeatedly changes sign, this implies $\varphi_j = \sum_{i:\lambda_i = \lambda_j} w_i \varphi_i$. That is, the eigenfunctions associated with the same eigenvalue λ_j must be linearly dependent in contradiction to the assumption. ∎

While the, possibly generalized, eigenvectors of an eigenvalue are independent, checking that the corresponding eigenfunctions are independent requires an analysis

specific to each scheme.

We can now characterize when the nodal functions ν_i are linearly independent.

COROLLARY 6.4. *If the refinement matrix A_* from the input mesh to a mesh with isolated extraordinary nodes is of full rank and the scheme has only effective and nonzero eigenvalues and the eigenfunctions corresponding to each eigenvalue, separately, are independent, then the nodal functions $\nu_i, i = 1 \dots K$ are linearly independent on Ω.*

Proof. If the extraordinary node is isolated, then nodal functions and eigenfunctions are related by the invertible matrix V of the generalized eigenvectors of the Jordan decomposition of the subdivision matrix:

$$[\varphi_1, \dots, \varphi_k] = V[\nu_1, \dots, \nu_k].$$

The general case follows by subdivision and the full rank of A_*. ∎

Corollary 6.4 and Lemma 6.2 characterize the locality of linear independence of subdivision schemes. On any finite union of Ω_ℓ, the nodal functions are linearly dependent for sufficiently high valence. On the infinite union Ω, the nodal functions are typically linearly independent provided the underlying regular spline functions g_i are. Subtle exceptions, illustrated by the examples in Figures 4.3 and 4.4, underscore the need for the assumption on A_*.

7. Summary and related open issues. The characterization of linear independence is a vital part of the foundations of generalized subdivision and illuminates the numerical properties of the nodal functions. It implies a cautionary note for computational use: near vertices of high valence, the nodal functions may not be linearly independent.

If the nodal functions are linearly independent, hence form a basis, we can additionally analyze the *condition* of the basis. The condition number of a nodal basis can be defined analogous to the condition of the B-spline basis (see, e.g., [5]). This concept is not to be confused with the condition number of the subdivision matrix but *quantifies* linear independence of the basis. At present, the notion of condition has not been explored in the context of subdivision surfaces although some implications are familiar: the poor condition of the Loop nodal basis for low valences explains, for example, why designers need to strongly exaggerate some features in the Loop control net.

Acknowledgments. The presentation benefited from the kind suggestions of the reviewers and the editor.

DISCONTINUOUS GALERKIN FINITE ELEMENT METHOD FOR THE WAVE EQUATION*

MARCUS J. GROTE†, ANNA SCHNEEBELI†, AND DOMINIK SCHÖTZAU‡

Abstract. The symmetric interior penalty discontinuous Galerkin finite element method is presented for the numerical discretization of the second-order wave equation. The resulting stiffness matrix is symmetric positive definite, and the mass matrix is essentially diagonal; hence, the method is inherently parallel and leads to fully explicit time integration when coupled with an explicit time-stepping scheme. Optimal a priori error bounds are derived in the energy norm and the L^2-norm for the semidiscrete formulation. In particular, the error in the energy norm is shown to converge with the optimal order $\mathcal{O}(h^{\min\{s,\ell\}})$ with respect to the mesh size h, the polynomial degree ℓ, and the regularity exponent s of the continuous solution. Under additional regularity assumptions, the L^2-error is shown to converge with the optimal order $\mathcal{O}(h^{\ell+1})$. Numerical results confirm the expected convergence rates and illustrate the versatility of the method.

Key words. discontinuous Galerkin finite element methods, wave equation, acoustic waves, second-order hyperbolic problems, a priori error analysis, explicit time integration

DOI. 10.1137/05063194X

1. Introduction.

The numerical solution of the wave equation is of fundamental importance to the simulation of time dependent acoustic, electromagnetic, or elastic waves. For such wave phenomena the scalar second-order wave equation often serves as a model problem. Finite element methods (FEMs) can easily handle inhomogeneous media or complex geometry. However, if explicit time-stepping is subsequently employed, the mass matrix arising from the spatial discretization by standard continuous finite elements must be inverted at each time step: a major drawback in terms of efficiency. For low-order Lagrange ($\mathcal{P}^1$) elements, so-called mass lumping overcomes this problem [6, 15], but for higher-order elements this procedure can lead to unstable schemes unless particular finite elements and quadrature rules are used [11]. In addition, continuous Galerkin methods impose significant restrictions on the underlying mesh and discretization; in particular, they do not easily accommodate hanging nodes.

To avoid these difficulties, we consider instead discontinuous Galerkin (DG) methods. Based on discontinuous finite element spaces, these methods easily handle elements of various types and shapes, irregular nonmatching grids, and even locally varying polynomial order; thus, they are ideally suited for *hp*-adaptivity. Here continuity is weakly enforced across mesh interfaces by adding suitable bilinear forms, so-called numerical fluxes, to standard variational formulations. These fluxes are easily included within an existing conforming finite element code.

Because individual elements decouple, DGFEMs are also inherently parallel; see [8, 9, 10, 7] for further details and recent reviews. Moreover, the mass matrix arising from the spatial DG discretization is block-diagonal, with block size equal to the number of degrees of freedom per element; it can therefore be inverted at very low computational cost. In fact, for a judicious choice of (locally orthogonal) shape functions, the mass matrix is diagonal. When combined with explicit time integration, the resulting time marching scheme will be fully explicit.

The origins of DG methods can be traced back to the 1970s, when they were proposed for the numerical solution of hyperbolic neutron transport equations, as well as for the weak enforcement of continuity in Galerkin methods for elliptic and parabolic problems; see Cockburn, Karniadakis, and Shu [8] for a review of the development of DG methods. When applied to second-order hyperbolic problems, most DG methods first require the problem to be reformulated as a first-order hyperbolic system, for which various DG methods are available. In [9], for instance, Cockburn and Shu used a DGFEM in space combined with a Runge–Kutta scheme in time to discretize hyperbolic conservation laws. Hesthaven and Warburton [13] used the same approach to implement high-order methods for Maxwell's equations in first-order hyperbolic form. Space-time DG methods for linear symmetric first-order hyperbolic systems were presented by Falk and Richter in [12] and later generalized by Monk and Richter in [17] and by Houston, Jensen, and Süli in [14]. A first DG method for the acoustic wave equation in its original second-order formulation was recently proposed by Rivière and Wheeler [21]; it is based on a *nonsymmetric* interior penalty formulation and requires additional stabilization terms for optimal convergence in the L^2-norm [20].

Here we propose and analyze the *symmetric* interior penalty DG method for the spatial discretization of the second-order scalar wave equation. In particular, we shall derive optimal a priori error bounds in the energy norm and the L^2-norm for the semidiscrete formulation. Besides the well-known advantages of DG methods mentioned above, a symmetric discretization of the wave equation in its second-order form offers an additional advantage, which also pertains to the classical continuous Galerkin formulation: since the stiffness matrix is positive definite, the semidiscrete formulation conserves (a discrete version of) the energy for all time; thus, it is free of any (unnecessary) damping. The dispersive properties of the symmetric interior penalty DG method were recently analyzed by Ainsworth, Monk, and Muniz [1].

The outline of our paper is as follows. In section 2 we describe the setting of our model problem. Next, we present in section 3 the symmetric interior penalty DG method for the wave equation. Our two main results, optimal error bounds in the energy norm and the L^2-norm for the semidiscrete scheme, are stated at the beginning of section 4 and proved subsequently. The analysis relies on an idea suggested by Arnold et al. [2] together with the approach presented by Perugia and Schötzau in [18] to extend the DG bilinear forms by suitable lifting operators. In section 5, we demonstrate the sharpness of our theoretical error estimates by a series of numerical experiments. By combining our DG method with the second-order Newmark scheme, we obtain a fully discrete method. To illustrate the versatility of our method, we also propagate a wave across an inhomogenous medium with discontinuity, where the underlying finite element mesh contains hanging nodes. Finally, we conclude with some remarks on possible extensions of our DG method to electromagnetic and elastic waves.

2. Model problem. We consider the (second-order) scalar wave equation

$$u_{tt} - \nabla \cdot (\, c\, \nabla u) = f \qquad \text{in } J \times \Omega, \tag{2.1}$$

$$u = 0 \qquad \text{on } J \times \partial\Omega, \tag{2.2}$$

$$u|_{t=0} = u_0 \qquad \text{in } \Omega, \tag{2.3}$$

$$u_t|_{t=0} = v_0 \qquad \text{in } \Omega, \tag{2.4}$$

where $J = (0, T)$ is a finite time interval and Ω is a bounded domain in $\mathbb{R}^d$, $d = 2, 3$. For simplicity, we assume that Ω is a polygon ($d = 2$) or a polyhedron ($d = 3$). The (known) source term f lies in $L^2(J; L^2(\Omega))$, while $u_0 \in H_0^1(\Omega)$ and $v_0 \in L^2(\Omega)$ are prescribed initial conditions. We assume that the speed of propagation, $\sqrt{c(x)}$, is piecewise smooth and satisfies the bounds

$$0 < c_\star \le c(x) \le c^\star < \infty, \qquad x \in \overline{\Omega}. \tag{2.5}$$

The standard variational form of (2.1)–(2.4) is to find $u \in L^2(J; H_0^1(\Omega))$, with $u_t \in L^2(J; L^2(\Omega))$ and $u_{tt} \in L^2(J; H^{-1}(\Omega))$, such that $u|_{t=0} = u_0$, $u_t|_{t=0} = v_0$, and

$$\langle u_{tt}, v\rangle + a(u, v) = (f, v) \qquad \forall v \in H_0^1(\Omega) \quad \text{a.e. in } J. \tag{2.6}$$

Here, the time derivatives are understood in a distributional sense, $\langle \cdot, \cdot \rangle$ denotes the duality pairing between $H^{-1}(\Omega)$ and $H_0^1(\Omega)$, $(\cdot, \cdot)$ is the inner product in $L^2(\Omega)$, and $a(\cdot, \cdot)$ is the elliptic bilinear form given by

$$a(u, v) = (c\, \nabla u, \nabla v). \tag{2.7}$$

It is well known that problem (2.6) is well posed [16]. Moreover, the weak solution u can be shown to be continuous in time; that is,

$$u \in C^0(\overline{J}; H_0^1(\Omega)), \qquad u_t \in C^0(\overline{J}; L^2(\Omega)); \tag{2.8}$$

see [16, Chapter III, Theorems 8.1 and 8.2] for details. In particular, this result implies that the initial conditions in (2.3) and (2.4) are well defined.

3. Discontinuous Galerkin discretization. We shall now discretize the wave equation (2.1)–(2.4) by using the interior penalty discontinuous Galerkin finite element method in space, while leaving the time dependence continuous.

3.1. Preliminaries. We consider shape-regular meshes $\mathcal{T}_h$ that partition the domain Ω into disjoint elements $\{K\}$ such that $\overline{\Omega} = \cup_{K \in \mathcal{T}_h} \overline{K}$. For simplicity, we assume that the elements are triangles or parallelograms in two space dimensions, and tetrahedra or parallelepipeds in three dimensions, respectively. The diameter of element K is denoted by h_K, and the mesh size h is given by $h = \max_{K \in \mathcal{T}_h} h_K$. We assume that the partition is aligned with the discontinuities of the wave speed $\sqrt{c}$. Generally, we allow for irregular meshes with hanging nodes. However, we assume that the local mesh sizes are of bounded variation; that is, there is a positive constant κ, depending only on the shape-regularity of the mesh, such that

$$\kappa h_K \le h_{K'} \le \kappa^{-1} h_K \tag{3.1}$$

for all neighboring elements K and K'.

An interior face of $\mathcal{T}_h$ is the (nonempty) interior of $\partial K^+ \cap \partial K^-$, where K^+ and K^- are two adjacent elements of $\mathcal{T}_h$. Similarly, a boundary face of $\mathcal{T}_h$ is the (nonempty)

interior of $\partial K \cap \partial\Omega$, which consists of entire faces of ∂K. We denote by $\mathcal{F}_h^{\mathcal{I}}$ the set of all interior faces of $\mathcal{T}_h$ and by $\mathcal{F}_h^{\mathcal{B}}$ the set of all boundary faces and set $\mathcal{F}_h = \mathcal{F}_h^{\mathcal{I}} \cup \mathcal{F}_h^{\mathcal{B}}$. Here we generically refer to any element of $\mathcal{F}_h$ as a "face," in both two and three dimensions.

For any piecewise smooth function v we now introduce the following trace operators. Let $F \in \mathcal{F}_h^{\mathcal{I}}$ be an interior face shared by two neighboring elements K^+ and K^- and let $x \in F$; we write $\mathbf{n}^{\pm}$ to denote the unit outward normal vectors on the boundaries $\partial K^{\pm}$. Denoting by $v^{\pm}$ the trace of v taken from within $K^{\pm}$, we define the jump and average of v at $x \in F$ by

$$[\![v]\!] := v^+\mathbf{n}^+ + v^-\mathbf{n}^-, \qquad \{\!\{v\}\!\} := (v^+ + v^-)/2,$$

respectively. On every boundary face $F \in \mathcal{F}_h^{\mathcal{B}}$, we set $[\![v]\!] := v\mathbf{n}$ and $\{\!\{v\}\!\} := v$. Here, $\mathbf{n}$ is the unit outward normal vector on $\partial\Omega$.

For a piecewise smooth vector-valued function $\mathbf{q}$, we analogously define the average across interior faces by $\{\!\{\mathbf{q}\}\!\} := (\mathbf{q}^+ + \mathbf{q}^-)/2$, and on boundary faces we set $\{\!\{\mathbf{q}\}\!\} := \mathbf{q}$. The jump of a vector-valued function will not be used. For a vector-valued function $\mathbf{q}$ with *continuous* normal components across a face f, the trace identity

$$v^+(\mathbf{n}^+ \cdot \mathbf{q}^+) + v^-(\mathbf{n}^- \cdot \mathbf{q}^-) = [\![v]\!] \cdot \{\!\{\mathbf{q}\}\!\} \quad \text{on } f$$

immediately follows from the definitions.

3.2. Discretization in space. For a given partition $\mathcal{T}_h$ of Ω and an approximation order $\ell \geq 1$, we wish to approximate the solution $u(t,\cdot)$ of (2.1)–(2.4) in the finite element space

$$V^h := \{v \in L^2(\Omega) : \, v|_K \in \mathcal{S}^\ell(K) \ \ \forall K \in \mathcal{T}_h\}, \tag{3.2}$$

where $\mathcal{S}^\ell(K)$ is the space $\mathcal{P}^\ell(K)$ of polynomials of total degree at most ℓ on K if K is a triangle or a tetrahedra, or the space $\mathcal{Q}^\ell(K)$ of polynomials of degree at most ℓ in each variable on K if K is a parallelogram or a parallelepiped.

Then, we consider the following (semidiscrete) DG approximation of (2.1)–(2.4): find $u^h : \overline{J} \times V^h \to \mathbb{R}$ such that

$$(u^h_{tt}, v) + a_h(u^h, v) = (f, v) \qquad \forall v \in V^h, \quad t \in J, \tag{3.3}$$

$$u^h|_{t=0} = \Pi_h u_0, \tag{3.4}$$

$$u^h_t|_{t=0} = \Pi_h v_0. \tag{3.5}$$

Here, Π_h denotes the L^2-projection onto V^h, and the discrete bilinear form a_h on $V^h \times V^h$ is given by

$$\begin{aligned} a_h(u,v) := & \sum_{K\in\mathcal{T}_h} \int_K c\,\nabla u \cdot \nabla v \, dx - \sum_{F\in\mathcal{F}_h} \int_F [\![u]\!] \cdot \{\!\{c\,\nabla v\}\!\}\, dA \\ & - \sum_{F\in\mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{c\,\nabla u\}\!\}\, dA + \sum_{F\in\mathcal{F}_h} \int_F \mathtt{a}\,[\![u]\!] \cdot [\![v]\!]\, dA. \end{aligned} \tag{3.6}$$

The last three terms in (3.6) correspond to jump and flux terms at element boundaries; they vanish when $u, v \in H_0^1(\Omega) \cap H^{1+\sigma}(\Omega)$ for $\sigma > \frac{1}{2}$. Hence the above semidiscrete DG formulation (3.3) is consistent with the original continuous problem (2.6).

In (3.6) the function $\mathtt{a}$ penalizes the jumps of u and v over the faces of $\mathcal{T}_h$. It is referred to as the interior penalty stabilization function and is defined as follows. We first introduce the function $\mathtt{h}$ by

$$\mathtt{h}|_F = \begin{cases} \min\{h_K, h_{K'}\}, & F \in \mathcal{F}_h^{\mathcal{I}},\ F = \partial K \cap \partial K', \\ h_K, & F \in \mathcal{F}_h^{\mathcal{B}},\ F = \partial K \cap \partial\Omega. \end{cases}$$

For $x \in F$, we further define $\mathtt{c}$ by

$$\mathtt{c}|_F(x) = \begin{cases} \max\{c|_K(x), c|_{K'}(x)\}, & F \in \mathcal{F}_h^{\mathcal{I}},\ F = \partial K \cap \partial K', \\ c|_K(x), & F \in \mathcal{F}_h^{\mathcal{B}},\ F = \partial K \cap \partial\Omega. \end{cases}$$

Then, on each $F \in \mathcal{F}_h$, we set

$$\mathtt{a}|_F := \alpha\, \mathtt{ch}^{-1}, \tag{3.7}$$

where α is a positive parameter independent of the local mesh sizes and the coefficient c.

To conclude this section we recall the following stability result for the DG form a_h.

LEMMA 3.1. *There exists a threshold value $\alpha_{\min} > 0$ which depends only on the shape-regularity of the mesh, the approximation order ℓ, the dimension d, and the bounds in* (2.5)*, such that for $\alpha \geq \alpha_{\min}$*

$$a_h(v,v) \geq C_{\mathrm{coer}} \left(\sum_{K \in \mathcal{T}_h} \|c^{\frac{1}{2}} \nabla v\|_{0,K}^2 + \sum_{F \in \mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}} [\![v]\!]\|_{0,F}^2 \right), \qquad v \in V^h,$$

where the constant C_{coer} is independent of c and h.

The proof of this lemma follows readily from the arguments in [2]. However, to make explicit the dependence of $\alpha_{\min}$ on the bounds in (2.5), we present the proof of a slightly more general stability result in Lemma 4.4 below. Throughout the rest of the paper we shall assume that $\alpha \geq \alpha_{\min}$, so that by Lemma 3.1 the semidiscrete problem (3.3)–(3.5) has a unique solution.

We remark that the condition $\alpha \geq \alpha_{\min}$ can be omitted by using other symmetric DG discretizations of the div-grad operator, such as the local discontinuous Galerkin (LDG) method; see, e.g., [2] for details. It can also be avoided by using the nonsymmetric interior penalty method proposed in [20]. However, since the symmetry of a_h is crucial in the analysis below, our error estimates (section 4) do not hold for the nonsymmetric DG method in [20].

Remark 3.2. Because the bilinear form a_h is symmetric and coercive, for $\alpha \geq \alpha_{\min}$, the semidiscrete DG formulation (3.3)–(3.5) with $f = 0$ conserves the (discrete) energy

$$E_h(t) := \frac{1}{2}\|u_t^h(t)\|_0^2 + \frac{1}{2} a_h(u^h(t), u^h(t)).$$

4. A priori error estimates. We shall now derive optimal a priori error bounds for the DG method (3.3)–(3.5), first with respect to the DG energy norm and then with respect to the L^2-norm. These two key results are stated immediately below, while their proofs are postponed to subsequent sections.

4.1. Main results. To state our a priori error bounds, we define the space

$$V(h) = H_0^1(\Omega) + V^h.$$

On $V(h)$, we define the DG energy norm

$$\|v\|_h^2 := \sum_{K\in\mathcal{T}_h} \|c^{\frac{1}{2}}\nabla v\|_{0,K}^2 + \sum_{F\in\mathcal{F}_h} \|\mathsf{a}^{\frac{1}{2}}[\![v]\!]\|_{0,F}^2.$$

Furthermore, for $1 \le p \le \infty$ we will make use of the Bochner space $L^p(J;V(h))$, endowed with the norm

$$\|v\|_{L^p(J;V(h))} = \begin{cases} \big(\int_J \|v\|_h^p\,dt\big)^{1/p}, & 1\le p<\infty,\\ \operatorname{ess\,sup}_{t\in J}\|v\|_h, & p=\infty. \end{cases}$$

Our first main result establishes an optimal error estimate of the energy norm $\|\cdot\|_h$ of the error. It also gives a bound in the $L^2(\Omega)$-norm on the error in the first time derivative.

THEOREM 4.1. *Let the analytical solution u of* (2.1)–(2.4) *satisfy*

$$u \in L^\infty(J;H^{1+\sigma}(\Omega)),\qquad u_t \in L^\infty(J;H^{1+\sigma}(\Omega)),\qquad u_{tt}\in L^1(J;H^\sigma(\Omega))$$

for a regularity exponent $\sigma > \frac{1}{2}$, and let u^h be the semidiscrete discontinuous Galerkin approximation obtained by (3.3)–(3.5), *with $\alpha \ge \alpha_{\min}$. Then, the error $e = u - u^h$ satisfies the estimate*

$$\begin{aligned}\|e_t\|_{L^\infty(J;L^2(\Omega))} + \|e\|_{L^\infty(J;V(h))} &\le C\Big[\|e_t(0)\|_0 + \|e(0)\|_h\Big]\\ &\quad + Ch^{\min\{\sigma,\ell\}}\Big[\|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + T\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + \|u_{tt}\|_{L^1(J;H^\sigma(\Omega))}\Big],\end{aligned}$$

with a constant C that is independent of T and h.

We remark that the fact that $u_t \in L^\infty(J;H^{1+\sigma}(\Omega))$ implies that u is continuous in time on $\overline{J}$ with values in $H^{1+\sigma}(\Omega)$. Similarly, $u_{tt} \in L^1(J;H^\sigma(\Omega))$ implies the continuity of u_t on $\overline{J}$ with values in $H^\sigma(\Omega)$. In Theorem 4.1 we thus implicitly assume that the initial conditions satisfy $u_0 \in H^{1+\sigma}(\Omega)$ and $v_0 \in H^\sigma(\Omega)$. Hence, standard approximation properties imply that

$$\|e_t(0)\|_0 = \|v_0 - \Pi_h v_0\|_0 \le C\,h^{\min\{\sigma,\ell+1\}}\|v_0\|_\sigma,$$

$$\|e(0)\|_h = \|u_0 - \Pi_h u_0\|_h \le C\,h^{\min\{\sigma,\ell\}}\|u_0\|_{1+\sigma};$$

see also Lemma 4.6 below. As a consequence, Theorem 4.1 yields optimal convergence in the (DG) energy norm

$$\|e_t\|_{L^\infty(J;L^2(\Omega))} + \|e\|_{L^\infty(J;V(h))} \le Ch^{\min\{\sigma,\ell\}},$$

with a constant $C = C(T)$ that is independent of h.

Next, we state an optimal error estimate with respect to the L^2-norm (in space). To do so, we need to assume elliptic regularity; that is, we assume that there is a stability constant C_S such that for any $\lambda \in L^2(\Omega)$ the solution of the problem

$$-\nabla\cdot(c\nabla z) = \lambda \quad \text{in } \Omega,\qquad z = 0 \quad \text{on } \Gamma, \tag{4.1}$$

belongs to $H^2(\Omega)$ and satisfies the stability bound

$$\|z\|_2 \le C_S \|\lambda\|_0. \tag{4.2}$$

This condition is certainly satisfied for convex domains and smooth coefficients. Then, the following L^2-error bound holds.

THEOREM 4.2. *Assume elliptic regularity as in* (4.1)–(4.2)*, and let the analytical solution* u *of* (2.1)–(2.4) *satisfy*

$$u \in L^\infty(J; H^{1+\sigma}(\Omega)), \qquad u_t \in L^\infty(J; H^{1+\sigma}(\Omega)), \qquad u_{tt} \in L^1(J; H^\sigma(\Omega))$$

for a regularity exponent $\sigma > \frac{1}{2}$*. Let* u^h *be the semidiscrete DG approximation obtained by* (3.3)–(3.5) *with* $\alpha \ge \alpha_{\min}$*. Then, the error* $e = u - u^h$ *satisfies the estimate*

$$\|e\|_{L^\infty(J;L^2(\Omega))} \le C h^{\min\{\sigma,\ell\}+1} \big[\|u_0\|_{1+\sigma} + \|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + T\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))} \big],$$

with a constant C *that is independent of* T *and the mesh size.*

For smooth solutions, Theorem 4.2 thus yields optimal convergence rates in the L^2-norm:

$$\|e\|_{L^\infty(J;L^2(\Omega))} \le C h^{\ell+1},$$

with a constant C that is independent of h.

The rest of this section is devoted to the proofs of Theorems 4.1 and 4.2. We shall first collect preliminary results in section 4.2. In section 4.3, we present the proof of Theorem 4.1. Following an argument by Baker [3] for conforming finite element approximations, we shall then derive the estimate of Theorem 4.2 in section 4.4.

4.2. Preliminaries.

Extension of the DG form a_h. The DG form a_h in (3.6) does not extend in a standard way to a continuous form on the (larger) space $V(h) \times V(h)$. Indeed the average $\{\!\{c\nabla v\}\!\}$ on a face $F \in \mathcal{F}_h$ is not well defined in general for $v \in H^1(\Omega)$. To circumvent this difficulty, we shall extend the form a_h in a nonstandard and nonconsistent way to the space $V(h) \times V(h)$ by using the lifting operators from [2] and the approach in [18]. Thus, for $v \in V(h)$ we define the lifted function, $\mathcal{L}_c(v) \in \big(V^h\big)^d$, $d = 2, 3$, by requiring that

$$\int_\Omega \mathcal{L}_c(v) \cdot \mathbf{w}\, dx = \sum_{F \in \mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{c\mathbf{w}\}\!\}\, dA, \qquad \mathbf{w} \in \big(V^h\big)^d,$$

where c is the material coefficient from (2.1). We shall now show that the lifting operator $\mathcal{L}_c$ is stable in the DG norm; see [18] for a similar result for the LDG method.

LEMMA 4.3. *There exists a constant* C_{inv} *which depends only on the shape-regularity of the mesh, the approximation order* ℓ*, and the dimension* d *such that*

$$\|\mathcal{L}_c(v)\|_0^2 \le \alpha^{-1} c^\star\, C_{\mathrm{inv}}^2 \sum_{F \in \mathcal{F}_h} \|\mathsf{a}^{\frac{1}{2}} [\![v]\!]\|_{0,F}^2$$

for any $v \in V(h)$.

Moreover, if the speed of propagation $c^{\frac{1}{2}}$ is piecewise constant, with discontinuities aligned with the finite element mesh $\mathcal{T}_h$, then

$$\|c^{-\frac{1}{2}}\mathcal{L}_c(v)\|_0^2 \le \alpha^{-1}C_{\mathrm{inv}}^2 \sum_{F\in\mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}}[\![v]\!]\|_{0,F}^2.$$

Proof. We have

$$\begin{aligned}
\|\mathcal{L}_c(v)\|_0 &= \max_{\mathbf{w}\in(V^h)^d} \frac{\sum_{F\in\mathcal{F}_h}\int_F [\![v]\!]\cdot\{\!\{c\mathbf{w}\}\!\}\,dA}{\|\mathbf{w}\|_0}\\
&\le \max_{\mathbf{w}\in(V^h)^d} \frac{\left(\sum_{F\in\mathcal{F}_h}\int_F \mathtt{a}[\![v]\!]^2\,dA\right)^{\frac{1}{2}}\left(\sum_{F\in\mathcal{F}_h}\int_F \mathtt{a}^{-1}|\{\!\{c\mathbf{w}\}\!\}|^2\,dA\right)^{\frac{1}{2}}}{\|\mathbf{w}\|_0}\\
&\le \alpha^{-\frac{1}{2}} \max_{\mathbf{w}\in(V^h)^d} \frac{\left(\sum_{F\in\mathcal{F}_h}\int_F \mathtt{a}[\![v]\!]^2\,dA\right)^{\frac{1}{2}}\left(\sum_{F\in\mathcal{F}_h}\int_F \mathtt{hc}^{-1}|\{\!\{c\mathbf{w}\}\!\}|^2\,dA\right)^{\frac{1}{2}}}{\|\mathbf{w}\|_0}\\
&\le \alpha^{-\frac{1}{2}}\,(c^\star)^{\frac{1}{2}} \max_{\mathbf{w}\in(V^h)^d} \frac{\left(\sum_{F\in\mathcal{F}_h}\int_F \mathtt{a}[\![v]\!]^2\,dA\right)^{\frac{1}{2}}\left(\sum_{K\in\mathcal{T}_h} h_K\int_{\partial K}|\mathbf{w}|^2\,dA\right)^{\frac{1}{2}}}{\|\mathbf{w}\|_0}.
\end{aligned}$$

Here, we have used the Cauchy–Schwarz inequality, the definition of $\mathtt{a}$ in (3.7), and the upper bound for c in (2.5). We recall the inverse inequality

$$\|\mathbf{w}\|_{0,\partial K}^2 \le C_{\mathrm{inv}}^2 h_K^{-1}\|\mathbf{w}\|_{0,K}^2, \qquad \mathbf{w}\in\left(\mathcal{S}^\ell(K)\right)^d, \tag{4.3}$$

with a constant C_{inv} that depends only on the shape-regularity of the mesh, the approximation order ℓ, and the dimension d. Using this bound, we obtain

$$\left(\sum_{K\in\mathcal{T}_h} h_K\int_{\partial K}|\mathbf{w}|^2\,dA\right)^{\frac{1}{2}} \le C_{\mathrm{inv}}\|\mathbf{w}\|_0,$$

which shows the first statement.

With $c^{\frac{1}{2}}$ piecewise constant, we have $c^{-\frac{1}{2}}z\in\left(V^h\right)^d$ for all $z\in\left(V^h\right)^d$. Hence, we obtain as before

$$\begin{aligned}
\|c^{-\frac{1}{2}}\mathcal{L}_c(v)\|_0 &= \max_{\mathbf{w}\in(V^h)^d} \frac{\sum_{F\in\mathcal{F}_h}\int_F [\![v]\!]\cdot\{\!\{c^{\frac{1}{2}}\mathbf{w}\}\!\}\,dA}{\|\mathbf{w}\|_0}\\
&\le \alpha^{-1}C_{\mathrm{inv}}^2 \sum_{F\in\mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}}[\![v]\!]\|_{0,F}^2,
\end{aligned}$$

which completes the proof. ∎

Next, we introduce the auxiliary bilinear form

$$\begin{aligned}
\widetilde{a}_h(u,v) := &\sum_{K\in\mathcal{T}_h}\int_K c\,\nabla u\cdot\nabla v\,dx - \sum_{K\in\mathcal{T}_h}\int_K \mathcal{L}_c(u)\cdot\nabla v\,dx\\
&- \sum_{K\in\mathcal{T}_h}\int_K \mathcal{L}_c(v)\cdot\nabla u\,dx + \sum_{F\in\mathcal{F}_h}\int_F \mathtt{a}\,[\![u]\!]\cdot[\![v]\!]\,dA.
\end{aligned} \tag{4.4}$$

The following result establishes that $\widetilde{a}_h$ is continuous and coercive on the entire space $V(h)\times V(h)$; hence it is well defined. Furthermore, since

$$\widetilde{a}_h = a_h \quad \text{on } V^h\times V^h, \qquad \widetilde{a}_h = a \quad \text{on } H_0^1(\Omega)\times H_0^1(\Omega), \tag{4.5}$$

the form $\widetilde{a}_h$ can be viewed as an extension of the two forms a_h and a to the space $V(h) \times V(h)$.

LEMMA 4.4. *Let the interior penalty parameter* $\mathtt{a}$ *be defined as in* (3.7)*, and set*

$$\alpha_{\min} = 4\, c_\star^{-1} c^\star\, C_{\mathrm{inv}}^2$$

for a general piecewise smooth c*, and*

$$\alpha_{\min} = 4\, C_{\mathrm{inv}}^2$$

for a piecewise constant c*, with discontinuities aligned with the finite element mesh* $\mathcal{T}_h$*.* C_{inv} *is the constant from Lemma* 4.3*.*

Setting $C_{\mathrm{cont}} = 2$ *and* $C_{\mathrm{coer}} = 1/2$*, we have for* $\alpha \geq \alpha_{\min}$

$$\begin{aligned} |\widetilde{a}_h(u,v)| &\leq C_{\mathrm{cont}} \|u\|_h \|v\|_h, \qquad && u, v \in V(h), \\ \widetilde{a}_h(u,u) &\geq C_{\mathrm{coer}} \|u\|_h^2, && u \in V(h). \end{aligned}$$

In particular, the coercivity bound implies the result in Lemma 3.1*.*

Proof. By taking into account the bounds in (2.5) and Lemma 4.3, application of the Cauchy–Schwarz inequality readily gives in the general case

$$|\widetilde{a}_h(u,v)| \leq \max\{2, \alpha^{-1} c_\star^{-1} c^\star\, C_{\mathrm{inv}}^2 + 1\} \|u\|_h \|v\|_h.$$

For $\alpha \geq \alpha_{\min}$, the continuity of $\widetilde{a}_h$ immediately follows. The case of piecewise constant c follows analogously.

To show the coercivity of the form $\widetilde{a}_h$, we note that

$$\widetilde{a}_h(u,u) = \sum_{K \in \mathcal{T}_h} \|c^{\frac{1}{2}} \nabla u\|_{0,K}^2 - 2 \sum_{K \in \mathcal{T}_h} \int_K \mathcal{L}_c(u) \cdot \nabla u \, dx + \sum_{F \in \mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}} [\![u]\!]\|_{0,F}^2.$$

By using the weighted Cauchy–Schwarz inequality, the geometric-arithmetic inequality $ab \leq \frac{\varepsilon a^2}{2} + \frac{b^2}{2\varepsilon}$, valid for any $\varepsilon > 0$, the bounds in (2.5), and the stability bound for the lifting operator in Lemma 4.3, we obtain for general c

$$\begin{aligned} 2 \sum_{K \in \mathcal{T}_h} \int_K \mathcal{L}_c(u) \cdot \nabla u \, dx &= 2 \sum_{K \in \mathcal{T}_h} \int_K c^{-\frac{1}{2}} \mathcal{L}_c(u) \cdot c^{\frac{1}{2}} \nabla u \, dx \\ &\leq 2 \sum_{K \in \mathcal{T}_h} \|c^{-\frac{1}{2}} \mathcal{L}_c(u)\|_{0,K} \|c^{\frac{1}{2}} \nabla u\|_{0,K} \\ &\leq \varepsilon \sum_{K \in \mathcal{T}_h} \|c^{\frac{1}{2}} \nabla u\|_{0,K}^2 + \varepsilon^{-1} c_\star^{-1} \sum_{K \in \mathcal{T}_h} \|\mathcal{L}_c(u)\|_{0,K}^2 \\ &\leq \varepsilon \sum_{K \in \mathcal{T}_h} \|c^{\frac{1}{2}} \nabla u\|_{0,K}^2 + \varepsilon^{-1} \alpha^{-1} c_\star^{-1} c^\star\, C_{\mathrm{inv}}^2 \sum_{F \in \mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}} [\![u]\!]\|_{0,F}^2 \end{aligned}$$

for a parameter $\varepsilon > 0$ still at our disposal. We conclude that

$$\widetilde{a}_h(u,u) \geq (1-\varepsilon) \sum_{K \in \mathcal{T}_h} \|c^{\frac{1}{2}} \nabla u\|_{0,K}^2 + \big(1 - \varepsilon^{-1} \alpha^{-1} c_\star^{-1} c^\star\, C_{\mathrm{inv}}^2\big) \sum_{F \in \mathcal{F}_h} \|\mathtt{a}^{\frac{1}{2}} [\![u]\!]\|_{0,F}^2.$$

For $\varepsilon = \frac{1}{2}$ and $\alpha \geq \alpha_{\min}$, we obtain the desired coercivity bound.

For a piecewise constant c we use the bound for $\|c^{-\frac{1}{2}} \mathcal{L}_c(u)\|_0^2$ from Lemma 4.4 and proceed analogously. ∎

Error equation. Because $\widetilde{a}_h$ coincides with a_h on $V^h \times V^h$, the semidiscrete scheme in (3.3)–(3.5) is equivalent to the following:

Find $u^h : \overline{J} \times V^h \to \mathbb{R}$ such that $u^h|_{t=0} = \Pi_h u_0$, $u_t^h|_{t=0} = \Pi_h v_0$, and

$$(u_{tt}^h, v) + \widetilde{a}_h(u^h, v) = (f, v) \qquad \forall v \in V^h. \tag{4.6}$$

We shall use the formulation in (4.6) as the basis of our error analysis.

To derive an error equation, we first define for $u \in H^{1+\sigma}(\Omega)$ with $\sigma > 1/2$

$$r_h(u; v) = \sum_{F \in \mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{ c \nabla u - c \Pi_h(\nabla u) \}\!\} \, dA, \qquad v \in V(h). \tag{4.7}$$

Here Π_h denotes the L^2-projection onto $(V^h)^d$. The assumption $u \in H^{1+\sigma}(\Omega)$ ensures that $r_h(u; v)$ is well defined. From the definition in (4.7) it is immediate that $r_h(u; v) = 0$ when $v \in H_0^1(\Omega)$.

LEMMA 4.5. *Let the analytical solution u of* (2.1)–(2.4) *satisfy*

$$u \in L^\infty(J; H^{1+\sigma}(\Omega)), \qquad u_{tt} \in L^1(J; L^2(\Omega)).$$

Let u^h be the semidiscrete DG approximation obtained by (4.6). *Then, the error $e = u - u^h$ satisfies*

$$(e_{tt}, v) + \widetilde{a}_h(e, v) = r_h(u; v) \qquad \forall v \in V^h \text{ a.e. in } J,$$

with $r_h(u; v)$ given in (4.7).

Proof. Let $v \in V^h$. Since $u_{tt} \in L^1(J; L^2(\Omega))$, we have $\langle u_{tt}, v \rangle = (u_{tt}, v)$ almost everywhere in J. Hence, using the discrete formulation in (3.3)–(3.5), we obtain that

$$(e_{tt}, v) + \widetilde{a}_h(e, v) = (u_{tt}, v) + \widetilde{a}_h(u, v) - (f, v) \qquad \text{a.e. in } J.$$

Now, by definition of $\widetilde{a}_h$, the fact that $\mathcal{L}_c(u) = 0$ and that $[\![u]\!] = 0$ on all faces, the defining properties of the L^2-projection Π_h, and the definition of the lifted element $\mathcal{L}_c(v)$, we obtain

$$\widetilde{a}_h(u, v) = \sum_{K \in \mathcal{T}_h} \int_K c \nabla u \cdot \nabla v \, dx - \sum_{F \in \mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{ c \Pi_h(\nabla u) \}\!\} \, dA.$$

Since $u_{tt} \in L^1(J; L^2(\Omega))$ and $f \in L^2(J; L^2(\Omega))$, we have that $\nabla \cdot (c \nabla u) \in L^2(\Omega)$ almost everywhere in J, which implies that $c \nabla u$ has continuous normal components across all interior faces. Therefore, elementwise integration by parts combined with the trace operators defined in section 3.1 yields

$$\begin{aligned} \widetilde{a}_h(u, v) = &- \sum_{K \in \mathcal{T}_h} \int_K \nabla \cdot (c \nabla u) \, v \, dx + \sum_{F \in \mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{ c \nabla u \}\!\} \, dA \\ &- \sum_{F \in \mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{ c \Pi_h(\nabla u) \}\!\} \, dA. \end{aligned}$$

From the definition of $r_h(u, v)$ in (4.7), we therefore conclude that

$$(u_{tt}, v) + \widetilde{a}_h(u, v) = (u_{tt} - \nabla \cdot (c \nabla u), v) + r_h(u; v)$$

and obtain

$$(e_{tt}, v) + \widetilde{a}_h(e, v) = (u_{tt} - \nabla \cdot (c \nabla u) - f, v) + r_h(u; v) = r_h(u; v),$$

where we have used the differential equation (2.1). ∎

Approximation properties. Let Π_h and Π_h denote the L^2-projections onto V^h and $(V^h)^d$, respectively. We recall the following approximation properties; see [6].

LEMMA 4.6. *Let $K \in \mathcal{T}_h$. Then the following hold:*

(i) *For $v \in H^t(K)$, $t \geq 0$, we have*

$$\|v - \Pi_h v\|_{0,K} \leq C h_K^{\min\{t,\ell+1\}} \|v\|_{t,K},$$

with a constant C that is independent of the local mesh size h_K and depends only on the shape-regularity of the mesh, the approximation order ℓ, the dimension d, and the regularity exponent t.

(ii) *For $v \in H^{1+\sigma}(K)$, $\sigma > \frac{1}{2}$, we have*

$$\begin{aligned} \|\nabla v - \nabla(\Pi_h v)\|_{0,K} &\leq C h_K^{\min\{\sigma,\ell\}} \|v\|_{1+\sigma,K}, \\ \|v - \Pi_h v\|_{0,\partial K} &\leq C h_K^{\min\{\sigma,\ell\}+\frac{1}{2}} \|v\|_{1+\sigma,K}, \\ \|\nabla v - \Pi_h(\nabla v)\|_{0,\partial K} &\leq C h_K^{\min\{\sigma,\ell+1\}-\frac{1}{2}} \|v\|_{1+\sigma,K}, \end{aligned}$$

with a constant C that is independent of the local mesh size h_K and depends only on the shape-regularity of the mesh, the approximation order ℓ, the dimension d, and the regularity exponent σ.

As a consequence of the approximation properties in Lemma 4.6, we obtain the following results.

LEMMA 4.7. *Let $u \in H^{1+\sigma}(\Omega)$, $\sigma > \frac{1}{2}$. Then the following hold:*

(i) *We have*

$$\|u - \Pi_h u\|_h \leq C_A h^{\min\{\sigma,\ell\}} \|u\|_{1+\sigma},$$

with a constant C_A that is independent of the mesh size and depends only on α, the constant κ in (3.1), *the bounds in* (2.5), *and the constants in Lemma* 4.6.

(ii) *For $v \in V(h)$, the form $r_h(u;v)$ in* (4.7) *can be bounded by*

$$|r_h(u;v)| \leq C_R h^{\min\{\sigma,\ell\}} \left(\sum_{F \in \mathcal{F}_h} \|\mathsf{a}^{\frac{1}{2}} [\![v]\!]\|_{0,F}^2 \right)^{\frac{1}{2}} \|u\|_{1+\sigma},$$

with a constant C_R independent of h, which depends only on α, the bounds in (2.5), *and the constants in Lemma* 4.6.

Proof. The estimate in (i) is an immediate consequence of Lemma 4.6, the definition of a, and the bounded variation property (3.1). To show the bound in (ii), we apply the Cauchy–Schwarz inequality and obtain

$$\begin{aligned} |r_h(u;v)| &\leq \left(\sum_{F \in \mathcal{F}_h} \int_F \mathsf{a} [\![v]\!]^2 \, ds \right)^{\frac{1}{2}} \left(\sum_{F \in \mathcal{F}_h} \int_F \mathsf{a}^{-1} |\{\!\{ c \nabla u - c \Pi_h(\nabla u) \}\!\}|^2 \, ds \right)^{\frac{1}{2}} \\ &\leq \alpha^{-\frac{1}{2}} c_\star^{-\frac{1}{2}} c^\star \left(\sum_{F \in \mathcal{F}_h} \|\mathsf{a}^{\frac{1}{2}} [\![v]\!]\|_{0,F}^2 \right)^{\frac{1}{2}} \left(\sum_{K \in \mathcal{T}_h} h_K \|\nabla u - \Pi_h(\nabla u)\|_{0,\partial K}^2 \right)^{\frac{1}{2}}. \end{aligned}$$

Applying the approximation properties in Lemma 4.6 completes the proof. ∎

4.3. Proof of Theorem 4.1. We are now ready to complete the proof of Theorem 4.1. We begin by proving the following auxiliary result.

LEMMA 4.8. *Let the analytical solution u of (2.1)–(2.4) satisfy*

$$u \in L^\infty(J; H^{1+\sigma}(\Omega)), \qquad u_t \in L^\infty(J; H^{1+\sigma}(\Omega))$$

for $\sigma > \frac{1}{2}$. Let $v \in C^0(\overline{J}; V(h))$ and $v_t \in L^1(J; V(h))$. Then we have

$$\int_J |r_h(u; v_t)|\, dt \le C_R\, h^{\min\{\sigma,\ell\}}\, \|v\|_{L^\infty(J;V(h))} \cdot \Big[2\,\|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + T\,\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}\Big],$$

where C_R is the constant from the bound (ii) *in Lemma* 4.7.

Proof. From the definition of r_h in (4.7) and integration by parts, we obtain

$$\begin{aligned}
\int_J r_h(u; v_t)\, dt &= \int_J \sum_{F\in\mathcal{F}_h} \int_F [\![v_t]\!] \cdot \{\!\{c\,\nabla u - c\,\Pi_h(\nabla u)\}\!\}\, dA\, dt \\
&= -\int_J \sum_{F\in\mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{c\,\nabla u_t - c\,\Pi_h(\nabla u_t)\}\!\}\, dA\, dt \\
&\quad + \Big[\sum_{F\in\mathcal{F}_h} \int_F [\![v]\!] \cdot \{\!\{c\,\nabla u - c\,\Pi_h(\nabla u)\}\!\}\, dA\Big]_{t=0}^{t=T} \\
&= -\int_J r_h(u_t; v)\, dt + \Big[r_h(u; v)\Big]_{t=0}^{t=T}.
\end{aligned}$$

Lemma 4.7 then implies the two estimates

$$\left|\int_J r_h(u_t; v)\, dt\right| \le C_R h^{\min\{\sigma,\ell\}}\, T\, \|v\|_{L^\infty(J;V(h))} \|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}$$

and

$$\left|\Big[r_h(u; v)\Big]_{t=0}^{t=T}\right| \le 2C_R h^{\min\{\sigma,\ell\}} \|v\|_{L^\infty(J;V(h))} \|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))},$$

which concludes the proof of the lemma. ∎

To complete the proof of Theorem 4.1, we now set $e = u - u^h$ and recall that Π_h is the L^2-projection onto V^h. Because of (2.8), we have

$$e \in C^0(\overline{J}; V(h)) \cap C^1(\overline{J}; L^2(\Omega)).$$

Next, we use the symmetry of $\widetilde{a}_h$ and the error equation in Lemma 4.5 to obtain

$$\begin{aligned}
\frac{1}{2}\frac{d}{dt}\big[\|e_t\|_0^2 + \widetilde{a}_h(e,e)\big] &= (e_{tt}, e_t) + \widetilde{a}_h(e, e_t) \\
&= (e_{tt}, (u - \Pi_h u)_t) + \widetilde{a}_h(e, (u - \Pi_h u)_t) \\
&\quad + r_h(u; (\Pi_h u - u^h)_t).
\end{aligned} \tag{4.8}$$

We fix $s \in J$ and integrate (4.8) over the time interval $(0, s)$. This yields

$$\begin{aligned}
\frac{1}{2}\|e_t(s)\|_0^2 + \frac{1}{2}\widetilde{a}_h(e(s), e(s)) &= \frac{1}{2}\|e_t(0)\|_0^2 + \frac{1}{2}\widetilde{a}_h(e(0), e(0)) \\
&\quad + \int_0^s (e_{tt}, (u - \Pi_h u)_t)\, dt + \int_0^s \widetilde{a}_h(e, (u - \Pi_h u)_t)\, dt \\
&\quad + \int_0^s r_h(u; (\Pi_h u - u^h)_t)\, dt.
\end{aligned}$$

Integration by parts of the third term on the right-hand side yields

$$\int_0^s (e_{tt}, (u - \Pi_h u)_t)\, dt = -\int_0^s (e_t, (u - \Pi_h u)_{tt})\, dt + \Big[(e_t, (u - \Pi_h u)_t)\Big]_{t=0}^{t=s}.$$

From the stability properties of $\widetilde{a}_h$ in Lemma 4.4 and standard Hölder's inequalities, we conclude that

$$\begin{aligned}
\frac{1}{2}\|e_t(s)\|_0^2 + \frac{1}{2}C_{\rm coer}\|e(s)\|_h^2 \le\ & \frac{1}{2}\|e_t(0)\|_0^2 + \frac{1}{2}C_{\rm cont}\|e(0)\|_h^2 \\
&+ \|e_t\|_{L^\infty(J;L^2(\Omega))}\Big(\|(u - \Pi_h u)_{tt}\|_{L^1(J;L^2(\Omega))} + 2\|(u - \Pi_h u)_t\|_{L^\infty(J;L^2(\Omega))}\Big) \\
&+ C_{\rm cont}T\|e\|_{L^\infty(J;V(h))}\, \|(u - \Pi_h u)_t\|_{L^\infty(J;V(h))} \\
&+ \left| \int_J r_h(u; (\Pi_h u - u^h)_t)\, dt \right|.
\end{aligned}$$

Since this inequality holds for any $s \in J$, it also holds for the maximum over J, that is

$$\|e_t\|_{L^\infty(J;L^2(\Omega))}^2 + C_{\rm coer}\|e\|_{L^\infty(J;V(h))}^2 \le \|e_t(0)\|_0^2 + C_{\rm cont}\|e(0)\|_h^2 + T_1 + T_2 + T_3,$$

with

$$\begin{aligned}
T_1 &= 2\|e_t\|_{L^\infty(J;L^2(\Omega))}\Big(\|(u - \Pi_h u)_{tt}\|_{L^1(J;L^2(\Omega))} + 2\|(u - \Pi_h u)_t\|_{L^\infty(J;L^2(\Omega))}\Big), \\
T_2 &= 2C_{\rm cont}T\|e\|_{L^\infty(J;V(h))}\, \|(u - \Pi_h u)_t\|_{L^\infty(J;V(h))}, \\
T_3 &= 2\left| \int_J r_h(u; (\Pi_h u - u^h)_t)\, dt \right|.
\end{aligned}$$

Using the geometric-arithmetic mean inequality $|ab| \le \frac{1}{2\varepsilon}a^2 + \frac{\varepsilon}{2}b^2$, valid for any $\varepsilon > 0$, and the approximation results in Lemma 4.6, we conclude that

$$\begin{aligned}
T_1 &\le \frac{1}{2}\|e_t\|_{L^\infty(J;L^2(\Omega))}^2 + 2\Big(\|(u - \Pi_h u)_{tt}\|_{L^1(J;L^2(\Omega))} + 2\|(u - \Pi_h u)_t\|_{L^\infty(J;L^2(\Omega))}\Big)^2 \\
&\le \frac{1}{2}\|e_t\|_{L^\infty(J;L^2(\Omega))}^2 + 4\|(u - \Pi_h u)_{tt}\|_{L^1(J;L^2(\Omega))}^2 + 16\|(u - \Pi_h u)_t\|_{L^\infty(J;L^2(\Omega))}^2, \\
&\le \frac{1}{2}\|e_t\|_{L^\infty(J;L^2(\Omega))}^2 + Ch^{2\min\{\sigma,\ell\}}\left(\|u_{tt}\|_{L^1(J;H^\sigma(\Omega))}^2 + h^2\, \|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}^2 \right),
\end{aligned}$$

with a constant C that depends only on the constants in Lemma 4.6. Similarly,

$$\begin{aligned}
T_2 &\le \frac{1}{4}C_{\rm coer}\|e\|_{L^\infty(J;V(h))}^2 + 4\frac{C_{\rm cont}^2}{C_{\rm coer}}T^2\|(u - \Pi_h u)_t\|_{L^\infty(J;V(h))}^2 \\
&\le \frac{1}{4}C_{\rm coer}\|e\|_{L^\infty(J;V(h))}^2 + T^2Ch^{2\min\{\sigma,\ell\}}\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}^2,
\end{aligned}$$

where the constant C depends on $C_{\rm coer}$, $C_{\rm cont}$, and the constant C_A in Lemma 4.7.

It remains to bound the term T_3. To do so, we use Lemma 4.8 to obtain

$$T_3 \le 2C_R\mathcal{R}\, h^{\min\{\sigma,\ell\}}\|\Pi_h u - u^h\|_{L^\infty(J;V(h))},$$

with

$$\mathcal{R} := \Big[2\|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + T\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}\Big].$$

The triangle inequality, the geometric-arithmetic mean, and the approximation properties of Π_h in Lemma 4.7 then yield

$$\begin{aligned} T_3 &\le 2C_R\mathcal{R}\, h^{\min\{\sigma,\ell\}} \left[\|e\|_{L^\infty(J;V(h))} + \|u-\Pi_h u\|_{L^\infty(J;V(h))}\right] \\ &\le \frac{1}{4}C_{\mathrm{coer}}\|e\|^2_{L^\infty(J;V(h))} + Ch^{2\min\{\sigma,\ell\}}\left[\|u\|^2_{L^\infty(J;H^{1+\sigma}(\Omega))} + \mathcal{R}^2\right], \end{aligned}$$

with a constant C that depends only on C_{coer}, C_R, and C_A. Combining the above estimates for T_1, T_2, and T_3 then shows that

$$\begin{aligned} &\frac{1}{2}\|e_t\|^2_{L^\infty(J;L^2(\Omega))} + \frac{1}{2}C_{\mathrm{coer}}\|e\|^2_{L^\infty(J;V(h))} \le \|e_t(0)\|_0^2 + C_{\mathrm{cont}}\|e(0)\|_h^2 \\ &\qquad + Ch^{2\min\{\sigma,\ell\}}\left[\|u_{tt}\|^2_{L^1(J;H^\sigma(\Omega))} + T^2\|u_t\|^2_{L^\infty(J;H^{1+\sigma}(\Omega))} + \|u\|^2_{L^\infty(J;H^{1+\sigma}(\Omega))}\right], \end{aligned}$$

with a constant that is independent of T and the mesh size. This concludes the proof of Theorem 4.1.

4.4. Proof of Theorem 4.2. To prove the error estimate in Theorem 4.2, we first establish the following variant of [3, Lemma 2.1].

LEMMA 4.9. *For $u \in H^{1+\sigma}(\Omega)$ with $\sigma > \frac{1}{2}$, let $w^h \in V^h$ be the solution of*

$$\widetilde{a}_h(w^h, v) = \widetilde{a}_h(u, v) - r_h(u; v) \qquad \forall v \in V^h.$$

Then, we have

$$\|u - w^h\|_h \le C_E\, h^{\min\{\sigma,\ell\}}\|u\|_{1+\sigma},$$

with a constant C_E that is independent of h and depends only on C_{coer}, C_{cont} in Lemma 4.4 and C_A, C_R in Lemma 4.7.

Moreover, if the elliptic regularity defined in (4.1) and (4.2) holds, we have the L^2-bound

$$\|u - w^h\|_0 \le C_L\, h^{\min\{\sigma,\ell\}+1}\|u\|_{1+\sigma},$$

with a constant C_L that is independent of h and depends only on the stability constant C_S in (4.2); C_{coer}, C_{cont} in Lemma 4.4; and C_A, C_R in Lemma 4.7.

Proof. We first remark that the approximation w^h is well defined because of the stability properties in Lemma 4.4 and the estimates in Lemma 4.7. To prove the estimate for $\|u - w^h\|_h$, we first use the triangle inequality,

$$\|u - w^h\|_h \le \|u - \Pi_h u\|_h + \|\Pi_h u - w^h\|_h. \tag{4.9}$$

From the approximation properties of Π_h in Lemma 4.7, we immediately infer that

$$\|u - \Pi_h u\|_h \le C_A h^{\min\{\sigma,\ell\}}\|u\|_{1+\sigma}.$$

It remains to bound $\|\Pi_h u - w^h\|_h$. From the coercivity and continuity of $\widetilde{a}_h$ in Lemma 4.4, the definition of w^h, and the bound in Lemma 4.7, we conclude that

$$\begin{aligned} C_{\mathrm{coer}}\|\Pi_h u - w^h\|_h^2 &\le \widetilde{a}_h(\Pi_h u - w^h, \Pi_h u - w^h) \\ &= \widetilde{a}_h(\Pi_h u - u, \Pi_h u - w^h) + \widetilde{a}_h(u - w^h, \Pi_h u - w^h) \\ &= \widetilde{a}_h(\Pi_h u - u, \Pi_h u - w^h) + r_h(u; \Pi_h u - w^h) \\ &\le C_{\mathrm{cont}}\|\Pi_h u - u\|_h\|\Pi_h u - w^h\|_h + C_R h^{\min\{\sigma,\ell\}}\|u\|_{1+\sigma}\|\Pi_h u - w^h\|_h. \end{aligned}$$

Thus,

$$\|\Pi_h u - w^h\|_h \le \left(\frac{C_{\rm cont} C_A + C_R}{C_{\rm coer}}\right) h^{\min\{\sigma,\ell\}} \|u\|_{1+\sigma},$$

which proves the bound for $\|u - w^h\|_h$.

We shall now prove the L^2-bound. To do so, let $z \in H_0^1(\Omega)$ be the solution of

$$-\nabla \cdot (c\,\nabla z) = u - w^h \quad \text{in } \Omega, \qquad z = 0 \quad \text{on } \Gamma. \tag{4.10}$$

Then, the elliptic regularity assumption in (4.1) and (4.2) implies that

$$z \in H^2(\Omega), \qquad \|z\|_2 \le C_S \|u - w^h\|_0. \tag{4.11}$$

Next, we multiply (4.10) by $u - w^h$ and integrate the resulting expression by parts. Since $c\,\nabla z$ has continuous normal components across all interior faces, we have

$$\begin{aligned}\|u - w^h\|_0^2 &= \sum_{K\in\mathcal{T}_h} \left[\int_K c\nabla z \cdot \nabla(u - w^h)\,dx - \int_{\partial K} c\nabla z \cdot \mathbf{n}_K (u - w^h)\,dA\right] \\ &= \sum_{K\in\mathcal{T}_h} \int_K c\nabla z \cdot \nabla(u - w^h)\,dx - \sum_{F\in\mathcal{F}_h} \int_F \{\!\{c\nabla z\}\!\} \cdot [\![u - w^h]\!]\,dA,\end{aligned}$$

with $\mathbf{n}_K$ denoting the unit outward normal on ∂K. By definition of $\widetilde{a}_h$ and r_h, we immediately find that

$$\|u - w^h\|_0^2 = \widetilde{a}_h(z, u - w^h) - r_h(z; u - w^h).$$

From the symmetry of $\widetilde{a}_h$, the definition of w^h, and the fact that $[\![z]\!] = 0$ on all faces, we conclude that

$$\begin{aligned}\|u - w^h\|_0^2 &= \widetilde{a}_h(u - w^h, z - \Pi_h z) - r_h(u; z - \Pi_h z) - r_h(z; u - w^h) \\ &=: T_1 + T_2 + T_3.\end{aligned} \tag{4.12}$$

We shall now derive upper bounds for each individual term T_1, T_2, and T_3 in (4.12).

To estimate the term T_1, we use the continuity of $\widetilde{a}_h$, the approximation result in Lemma 4.7 with $\sigma = 1$, and the bound in (4.11). Thus,

$$\begin{aligned}T_1 &\le C_{\rm cont} \|u - w^h\|_h \|z - \Pi_h z\|_h \\ &\le C_{\rm cont} C_A h \|u - w^h\|_h \|z\|_2 \\ &\le C_{\rm cont} C_A C_S h \|u - w^h\|_h \|u - w^h\|_0.\end{aligned}$$

By using Lemma 4.7 and the stability bound in (4.11), we can estimate T_2 by

$$\begin{aligned}T_2 &\le C_R h^{\min\{\sigma,\ell\}} \|z - \Pi_h z\|_h \|u\|_{1+\sigma} \\ &\le C_R C_A h^{\min\{\sigma,\ell\}+1} \|z\|_2 \|u\|_{1+\sigma} \\ &\le C_R C_A C_S h^{\min\{\sigma,\ell\}+1} \|u - w^h\|_0 \|u\|_{1+\sigma}.\end{aligned}$$

Similarly,

$$T_3 \le C_R h \|z\|_2 \|u - w^h\|_h \le C_R C_S h \|u - w^h\|_0 \|u - w^h\|_h.$$

The use of these bounds for T_1, T_2, and T_3 in (4.12) then leads to

$$\|u - w^h\|_0 \le Ch\|u - w^h\|_h + Ch^{\min\{\sigma,\ell\}+1}\|u\|_{1+\sigma},$$

which completes the proof of the lemma, since $\|u - w^h\|_h \le Ch^{\min\{\sigma,\ell\}}\|u\|_{1+\sigma}$. ∎

Now, let u be defined by the exact solution of (2.1)–(2.4). We may define $w^h(t,\cdot) \in V^h$ almost everywhere in J by

$$\widetilde{a}_h(w^h(t,\cdot), v) = \widetilde{a}_h(u(t,\cdot), v) - r_h(u(t,\cdot); v) \qquad \forall v \in V^h. \tag{4.13}$$

If $u \in L^\infty(J; H^{1+\sigma}(\Omega))$, it can be readily seen that $w^h \in L^\infty(J; V(h))$. Moreover, if we also have $u_t \in L^\infty(J; H^{1+\sigma}(\Omega))$, then $w^h_t \in L^\infty(J; V(h))$ and

$$\widetilde{a}_h(w^h_t, v) = \widetilde{a}_h(u_t, v) - r_h(u_t; v), \qquad v \in V^h \text{ a.e. in } J,$$

as well as

$$\widetilde{a}_h(w^h(0), v) = \widetilde{a}_h(u_0, v) - r_h(u_0; v), \qquad v \in V^h.$$

Therefore Lemma 4.9 immediately implies the following estimates.

LEMMA 4.10. *Let w^h be defined by* (4.13). *Under the regularity assumptions of Theorem* 4.2, *we have*

$$\begin{aligned} \|(u - w^h)_t\|_{L^\infty(J;V(h))} &\le C_E\, h^{\min\{\sigma,\ell\}}\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}, \\ \|(u - w^h)(0)\|_h &\le C_E\, h^{\min\{\sigma,\ell\}}\|u_0\|_{1+\sigma}. \end{aligned}$$

Moreover, if elliptic regularity as defined in (4.1) *and* (4.2) *holds, we have the L^2-bounds*

$$\begin{aligned} \|(u - w^h)_t\|_{L^\infty(J;L^2(\Omega))} &\le C_L\, h^{\min\{\sigma,\ell\}+1}\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}, \\ \|(u - w^h)(0)\|_0 &\le C_L\, h^{\min\{\sigma,\ell\}+1}\|u_0\|_{1+\sigma}. \end{aligned}$$

The constants C_E and C_L are as in Lemma 4.9.

To complete the proof of Theorem 4.2, let $w^h \in L^\infty(J; V(h))$ be defined by (4.13) and consider

$$\|e\|^2_{L^\infty(J;L^2(\Omega))} \le 2\|u - w^h\|^2_{L^\infty(J;L^2(\Omega))} + 2\|w^h - u^h\|^2_{L^\infty(J;L^2(\Omega))}. \tag{4.14}$$

The first term can be estimated from the L^2-bounds in Lemma 4.9. We shall now derive an estimate for the second term. First, we fix $v \in L^\infty(J; V^h)$ and assume that $v_t \in L^\infty(J; V^h)$. From the definition of w^h in (4.13) and the error equation in Lemma 4.5, we have

$$\begin{aligned} ((u^h - w^h)_{tt}, v) + \widetilde{a}_h(u^h - w^h, v) &= (u^h_{tt}, v) + \widetilde{a}_h(u^h, v) - \widetilde{a}_h(w^h, v) - (w^h_{tt}, v) \\ &= (u^h_{tt}, v) + \widetilde{a}_h(u^h - u, v) + r_h(u; v) - (w^h_{tt}, v) \\ &= (u_{tt}, v) - (w^h_{tt}, v). \end{aligned}$$

We rewrite this identity as

$$\frac{d}{dt}((u^h - w^h)_t, v) - ((u^h - w^h)_t, v_t) + \widetilde{a}_h(u^h - w^h, v) = \frac{d}{dt}((u - w^h)_t, v) - ((u - w^h)_t, v_t),$$

which yields

$$-((u^h - w^h)_t, v_t) + \widetilde{a}_h(u^h - w^h, v) = \frac{d}{dt}((u - u^h)_t, v) - ((u - w^h)_t, v_t). \tag{4.15}$$

Let $\tau \in (0, T]$ be fixed, and consider the function

$$\widehat{v}(t, \cdot) = \int_t^\tau (u^h - w^h)(s, \cdot)\, ds, \qquad t \in \overline{J}.$$

Note that

$$\widehat{v}(\tau, \cdot) = 0, \qquad \widehat{v}_t(t, \cdot) = -(u^h - w^h)(t, \cdot) \qquad \text{a.e. } t \in \overline{J}.$$

Next, choose $v = \widehat{v}$ in (4.15) which yields

$$((u^h - w^h)_t, u^h - w^h) - \widetilde{a}_h(\widehat{v}_t, \widehat{v}) = \frac{d}{dt}((u - u^h)_t, \widehat{v}) + ((u - w^h)_t, u^h - w^h).$$

Since the DG form $\widetilde{a}_h(\cdot, \cdot)$ is symmetric, we obtain

$$\frac{1}{2}\frac{d}{dt}\|u^h - w^h\|_0^2 - \frac{1}{2}\frac{d}{dt}\widetilde{a}_h(\widehat{v}, \widehat{v}) = \frac{d}{dt}((u - u^h)_t, \widehat{v}) + ((u - w^h)_t, u^h - w^h).$$

Integration over $(0, \tau)$ and using that $\widehat{v}(\tau, \cdot) = 0$ then yield

$$\begin{aligned} &\|(u^h - w^h)(\tau)\|_0^2 - \|(u^h - w^h)(0)\|_0^2 + \widetilde{a}_h(\widehat{v}(0), \widehat{v}(0)) \\ &\qquad = -2((u - u^h)_t(0), \widehat{v}(0)) + 2\int_0^\tau ((u - w^h)_t, u^h - w^h)\, dt. \end{aligned} \tag{4.16}$$

Since $u_t(0) = v_0$, $u_t^h(0) = \Pi_h v_0$, and $\widehat{v}(0)$ belongs to V^h, we conclude that

$$((u - u^h)_t(0), \widehat{v}(0)) = (v_0 - \Pi_h v_0, \widehat{v}(0)) = 0.$$

Hence, the first term on the right-hand side of (4.16) vanishes. Moreover, the coercivity of the form $\widetilde{a}_h$ in Lemma 4.4 ensures that $\widetilde{a}_h(\widehat{v}(0), \widehat{v}(0)) \geq 0$. This leads to the inequality

$$\|(u^h - w^h)(\tau)\|_0^2 \leq \|(u^h - w^h)(0)\|_0^2 + 2\int_0^\tau \|(u - w^h)_t\|_0 \|u^h - w^h\|_0\, dt. \tag{4.17}$$

By using the Cauchy–Schwarz inequality and the geometric-arithmetic mean inequality, we obtain

$$\begin{aligned} 2\int_0^\tau \|(u - w^h)_t\|_0 \|u^h - w^h\|_0\, dt &\leq 2T\, \|(u - w^h)_t\|_{L^\infty(J;L^2(\Omega))} \|u^h - w^h\|_{L^\infty(J;L^2(\Omega))} \\ &\leq \frac{1}{2}\|u^h - w^h\|_{L^\infty(J;L^2(\Omega))}^2 + 2T^2\, \|(u - w^h)_t\|_{L^\infty(J;L^2(\Omega))}^2. \end{aligned}$$

Because this upper bound is independent of τ, it also holds for the supremum over $\tau \in J$, which yields the estimate

$$\begin{aligned} \frac{1}{2}\|u^h - w^h\|_{L^\infty(J;L^2(\Omega))}^2 &\leq \|(u^h - w^h)(0)\|_0^2 + 2T^2 \|(u - w^h)_t\|_{L^\infty(J;L^2(\Omega))}^2 \\ &\leq 2\,\|(u^h - u)(0)\|_0^2 + 2\|(u - w^h)(0)\|_0^2 + 2T^2 \|(u - w^h)_t\|_{L^\infty(J;L^2(\Omega))}^2. \end{aligned}$$

Next, we use this estimate in (4.14) to obtain

$$\|e\|^2_{L^\infty(J;L^2(\Omega))} \le 2\|u - w^h\|^2_{L^\infty(J;L^2(\Omega))} + 8\,\|u_0 - \Pi_h u_0\|_0^2 + 8\|u_0 - w^h(0)\|_0^2 + 8T^2\|(u-w^h)_t\|^2_{L^\infty(J;L^2(\Omega))}.$$

From the L^2-approximation properties in Lemma 4.6, Lemma 4.9, and Lemma 4.10, we finally conclude that

$$\|e\|^2_{L^\infty(J;L^2(\Omega))} \le h^{2\min\{\sigma,\ell\}+2}\Big[\max\{8C, 8C_L^2\}\|u_0\|^2_{1+\sigma} + 2C_L^2\|u\|^2_{L^\infty(J;H^{1+\sigma}(\Omega))} + 8C_L T^2\|u_t\|^2_{L^\infty(J;H^{1+\sigma}(\Omega))}\Big].$$

Here, C is the constant from Lemma 4.6. This completes the proof of Theorem 4.2.

5. Numerical results. We shall now present a series of numerical experiments which verify the sharpness of the theoretical error bounds stated in Theorems 4.1 and 4.2. Furthermore, we shall demonstrate the robustness and flexibility of our DG method by propagating a pulse through an inhomogeneous medium with discontinuity on a finite element mesh with hanging nodes.

To obtain a fully discrete discretization of the wave equation, we choose to augment our DG spatial discretization with the second-order Newmark scheme in time; see, e.g., [19, sections 8.5–8.7]. The resulting scheme has been implemented using the general purpose finite element library `deal.II`,[1] which provides powerful C^{++} classes to handle the finite element mesh and the degrees of freedom, and to solve the linear system of equations; see [5, 4]. In all our examples, the DG stabilization parameter is set to $\alpha = 20$.

5.1. Time discretization. The discretization of (2.1)–(2.4) in space by the DG method (3.3)–(3.5) leads to the linear second-order system of ordinary differential equations

$$\mathbf{M}\ddot{\mathbf{u}}^h(t) + \mathbf{A}\mathbf{u}^h(t) = \mathbf{f}^h(t), \qquad t \in J, \tag{5.1}$$

with initial conditions

$$\mathbf{M}\mathbf{u}^h(0) = \mathbf{u}_0^h, \quad \mathbf{M}\dot{\mathbf{u}}^h(0) = \mathbf{v}_0^h. \tag{5.2}$$

Here, $\mathbf{M}$ denotes the mass matrix and $\mathbf{A}$ the stiffness matrix. To discretize (5.1) in time, we employ the Newmark time-stepping scheme; see, e.g., [19]. We let k denote the time step and set $t_n = n \cdot k$. Then the Newmark method consists in finding approximations $\{\mathbf{u}_n^h\}_n$ to $\mathbf{u}^h(t_n)$ such that

$$(\mathbf{M} + k^2\beta\mathbf{A})\mathbf{u}_1^h = \left[\mathbf{M} - k^2\left(\frac{1}{2} - \beta\right)\mathbf{A}\right]\mathbf{u}_0^h + k\mathbf{M}\mathbf{v}_0^h + k^2\left[\beta\mathbf{f}_1^h + \left(\frac{1}{2} - \beta\right)\mathbf{f}_0^h\right] \tag{5.3}$$

and

$$\begin{aligned}(\mathbf{M} + k^2\beta\mathbf{A})\mathbf{u}_{n+1}^h = {} & \left[2\mathbf{M} - k^2\left(\frac{1}{2} - 2\beta + \gamma\right)\mathbf{A}\right]\mathbf{u}_n^h - \left[\mathbf{M} + k^2\left(\frac{1}{2} + \beta - \gamma\right)\mathbf{A}\right]\mathbf{u}_{n-1}^h \\ & + k^2\left[\beta\mathbf{f}_{n+1}^h + \left(\frac{1}{2} - 2\beta + \gamma\right)\mathbf{f}_n + \left(\frac{1}{2} + \beta - \gamma\right)\mathbf{f}_{n-1}\right]\end{aligned} \tag{5.4}$$

[1] See www.dealii.org.

for $n = 1, \ldots, N-1$. Here, $\mathbf{f}_n := \mathbf{f}(t_n)$, while $\beta \geq 0$ and $\gamma \geq 1/2$ are free parameters that still can be chosen. We recall that for $\gamma = 1/2$ the Newmark scheme is second-order accurate in time, whereas it is only first-order accurate for $\gamma > 1/2$. For $\beta = 0$, the Newmark scheme (5.3)–(5.4) requires at each time step the solution of a linear system with the mass matrix $\mathbf{M}$. However, because individual elements decouple, $\mathbf{M}$ is block-diagonal with a block size equal to the number of degrees of freedom per element. It can be inverted at very low computational cost, and the scheme is essentially fully explicit. In fact, if the basis functions are chosen mutually orthogonal, $\mathbf{M}$ reduces to the identity; see [8] and the references therein. Then, with $\gamma = 1/2$, the explicit Newmark method corresponds to the standard leap-frog scheme.

For $\beta > 0$, the resulting scheme is implicit and involves the solution of a linear system with the symmetric positive definite stiffness matrix $\mathbf{A}$ at each time step. We finally note that the second-order Newmark scheme with $\gamma = 1/2$ is unconditionally stable for $\beta \geq 1/4$, whereas for $1/4 > \beta \geq 0$ the time step k has to be restricted by a CFL condition. In the case $\beta = 0$, that condition is $k^2 \lambda_{\max}(\mathbf{A}) \leq 4(1-\varepsilon)$, $\varepsilon \in (0,1)$, where $\lambda_{\max}(\mathbf{A})$ is the maximal eigenvalue of the DG stiffness matrix $\mathbf{A}$ (which is of the order $\mathcal{O}(h^{-2})$ and also depends on α).

In all our tests, we will employ the explicit second-order Newmark scheme, setting $\gamma = 1/2$ and $\beta = 0$ in (5.3)–(5.4).

5.2. Example 1: Smooth solution. First, we consider the two-dimensional wave equation (2.1)–(2.4) in $J \times \Omega = (0,1) \times (0,1)^2$, with $c \equiv 1$ and data f, u_0, and v_0 chosen such that the analytical solution is given by

$$u(x_1, x_2, t) = t^2 \sin(\pi x_1) \sin(\pi x_2). \tag{5.5}$$

This solution is arbitrarily smooth so that all our theoretical regularity assumptions are satisfied. We discretize this problem using the polynomial spaces $\mathcal{Q}^\ell(K)$, $\ell = 1, 2, 3$, on a sequence $\{\mathcal{T}_h\}_{i \geq 1}$ of square meshes of size $h_i = 2^{-i}$. With increasing polynomial degree ℓ and decreasing mesh size h_i, smaller time steps k_i are necessary to ensure stability. We found that the choice $k_i = h_i/20$ provides a stable time discretization on every mesh. Because our numerical scheme is second-order accurate in time, the time integration of (5.5) is exact so that the spatial error is the only error component in the discrete solution.

In Figure 5.1 we show the relative errors at time $T = 1$ in the energy norm and in the L^2-norm, as we decrease the mesh size h_i. The numerical results corroborate with the expected theoretical rates of $\mathcal{O}(h^\ell)$ for the energy norm and of $\mathcal{O}(h^{\ell+1})$ for the L^2-norm; see Theorems 4.1 and 4.2.

Next, we modify the data so that the analytical solution u is given by

$$u(x_1, x_2, t) = \sin(t^2) \sin(\pi x_1) \sin(\pi x_2). \tag{5.6}$$

Although u remains arbitrarily smooth, it is no longer integrated exactly in time by (5.3)–(5.4). Since the Newmark scheme is only second-order accurate, we repeat the above experiment only for the lowest order spatial discretization, $\ell = 1$. Again, we set $k_i = h_i/20$. In Figure 5.2, the relative errors for the fully discrete approximation of (5.6) show convergence rates of order h in the energy norm and order h^2 in the L^2-norm, thereby confirming the theoretical estimates of Theorems 4.1 and 4.2.

5.3. Example 2: Singular solution. Here, we consider the two-dimensional wave equation (2.1)–(2.4) on the L-shaped domain $\Omega = (-1,1)^2 \backslash [0,1)^2$. We set $c = 1$

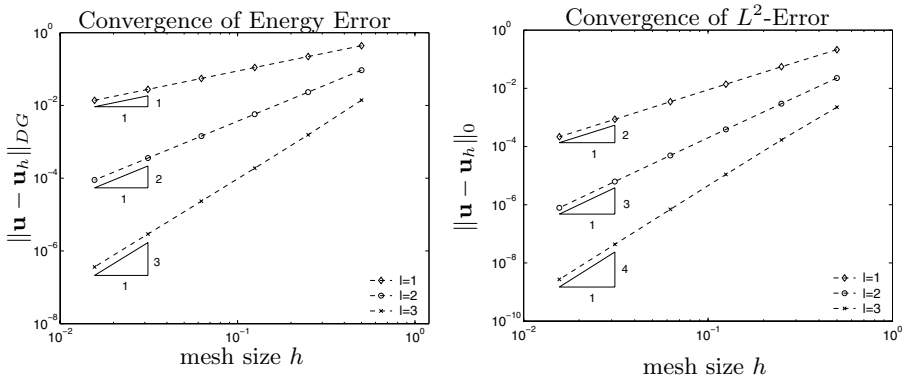

FIG. 5.1. *Example* 1: *Convergence of the error at time* $T = 1$ *in the energy norm and the* L^2*-norm for* $\ell = 1, 2, 3$.

everywhere and choose the data f, u_0, and v_0 such that the analytical solution u is given by

$$u(r, \phi, t) = t^2\, r^{2/3} \sin(2/3\, \phi) \tag{5.7}$$

in polar coordinates (r, ϕ). Although u is smooth in time (and can even be integrated exactly in time), it has a spatial singularity at the origin, such that $u \in C^\infty(\overline{J}; H^{5/3}(\Omega))$. Hence, this example is well suited to establishing the sharpness of the regularity assumptions in our theoretical results. Since u is inhomogeneous at the boundary of Ω, we need to impose inhomogeneous Dirichlet conditions within our DG discretization. We do so in straightforward fashion by modifying the semidiscrete formulation as follows: find $u^h(t, \cdot) : J \to V^h$ such that

$$(u^h_{tt}, v) + a_h(u^h, v) = (f, v) + \sum_{F \in \mathcal{F}_h^{\mathcal{B}}} \int_F g\, (\mathbf{a} v - c \nabla v \cdot \mathbf{n})\, dA. \tag{5.8}$$

Here, g is the boundary data and $\mathbf{n}$ is the outward unit normal vector on $\partial\Omega$.

We discretize (5.8) by using bilinear polynomials ($\ell = 1$) on the same sequence of meshes as before. Again, we set $k_i = h_i/20$ and integrate the problem up to $T = 1$. For the analytical solution u in (5.7), the regularity assumptions in Theorem 4.1 hold

TABLE 5.1
Example 2: *Relative errors at time* $T = 1$ *in the energy norm and* L^2*-norm, and corresponding numerical convergence rates.*

i	Cells	Energy-error		L^2-error	
1	12	1.11e-01	-	1.61e-02	-
2	48	7.18e-02	0.62	5.96e-03	1.43
3	192	4.61e-02	0.64	2.27e-03	1.40
4	768	2.94e-02	0.65	8.72e-04	1.38
5	3072	1.87e-02	0.66	3.38e-04	1.37
6	12288	1.18e-02	0.66	1.32e-04	1.36

with $\sigma = 2/3$. Thus, Theorem 4.1 predicts numerical convergence rates of $2/3$ in the energy norm, as confirmed by our numerical results in Table 5.1.

As the elliptic regularity assumptions (4.1)–(4.2) from Theorem 4.2 are violated, we do not expect L^2-error rates of the order $1+\sigma$ for this problem. Indeed, in Table 5.1 we observe convergence rates close to $4/3$. To explain this behavior, let us consider the following weaker elliptic regularity assumption: for any $\lambda \in L^2(\Omega)$ we assume that the solution of the problem

$$-\nabla \cdot (c\nabla z) = \lambda \quad \text{in } \Omega, \qquad z = 0 \quad \text{on } \partial\Omega, \tag{5.9}$$

belongs to $H^{1+s}(\Omega)$ for a parameter $s \in (1/2, 1]$ and satisfies the stability bound

$$\|z\|_{1+s} \le C_S \|\lambda\|_0 \tag{5.10}$$

for a stability constant C_S. The results from Lemmas 4.9 and 4.10 can be easily adapted to this case. As a consequence, the L^2-bound for $e = u - u^h$ from Theorem 4.2 can then be generalized to this weaker setting as

$$\|e\|_{L^\infty(J;L^2(\Omega))} \le Ch^{\min\{\sigma,\ell\}+s}\big[\|u_0\|_{1+\sigma} + \|u\|_{L^\infty(J;H^{1+\sigma}(\Omega))} + T\|u_t\|_{L^\infty(J;H^{1+\sigma}(\Omega))}\big].$$

For the L-shaped domain Ω and $c \equiv 1$, the (weaker) regularity assumption in (5.9)–(5.10) holds with $s = 2/3$, which underpins the rate $\sigma + s = 4/3$ observed in Table 5.1.

5.4. Example 3: Inhomogeneous medium. Finally, we consider (2.1)–(2.4) on the rectangular domain $\Omega = (-1, 2)\times(-1, 1)$, with homogeneous initial and boundary conditions and the piecewise constant material coefficient

$$c(x_1, x_2) = \begin{cases} 0.1, & x_1 \le 0, \\ 1, & \text{else.} \end{cases}$$

The wave is locally excited until $t = 0.2$ by the source term

$$f(x_1, x_2, t) = \begin{cases} 1, & 0.2 < x_1 < 0.4 \text{ and } t < 0.2, \\ 0, & \text{else.} \end{cases}$$

We discretize the problem by the DG method (3.3)–(3.5) on a fixed mesh $\mathcal{T}_h$ that consists of *nonmatching components*, which are adapted to the discontinuity c; see Figure 5.3. The mesh $\mathcal{T}_h$ is composed of 9312 nonuniform squares, where the smallest local mesh size is given by $h_{min} \approx 0.016$. The hanging nodes are naturally incorporated in the DG method without any difficulty. Here, the time step $k = 0.002$,

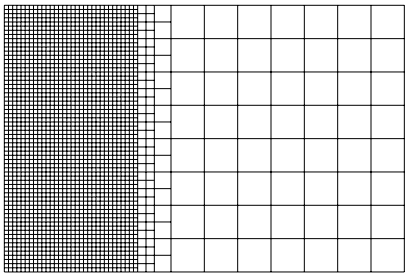

FIG. 5.3. *Example* 3: *Domain* Ω *with a finite element mesh* $\mathcal{T}_h$ *adapted to the values of the piecewise constant wave speed* $\sqrt{c} = 0.1$ *(left),* $\sqrt{c} = 1$ *(right).*

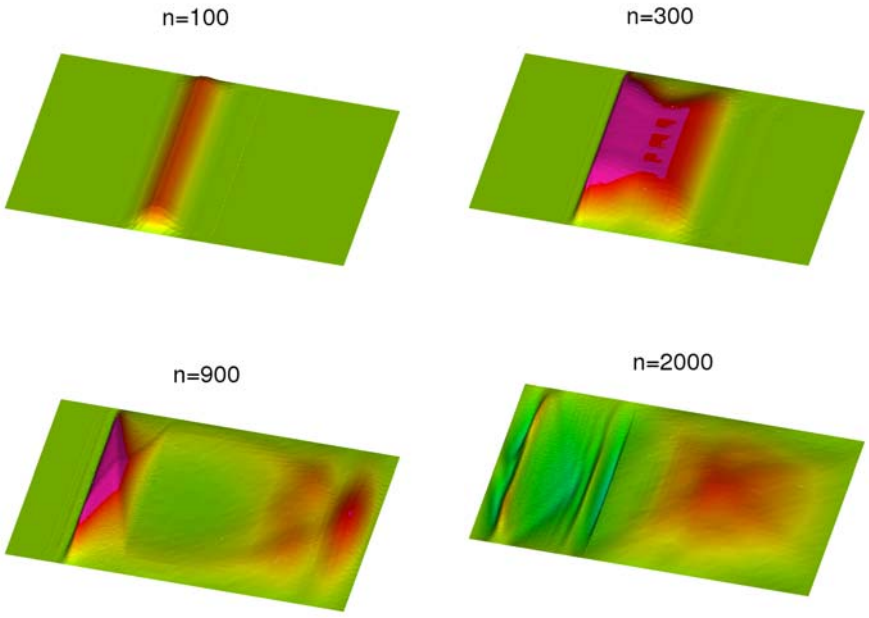

FIG. 5.4. *Example* 3: *The approximate DG solutions* u_n^h *shown at times* $t_n = 0.2, 0.6, 1.8, 4$ *display the behavior of a wave propagating through an inhomogeneous medium with homogeneous Dirichlet boundary.*

that is, $k \approx h_{\min}/8$, proved to be sufficiently small to ensure the stability of the explicit Newmark method ($\beta = 0$).

In Figure 5.4, the numerical solution is shown after $n = 100, 300, 900$, and 2000 time steps. The initial pulse splits into two planar wave fronts propagating in opposite directions to either side of the domain. After $n = 300$ time steps, the left-moving wave hits the much slower medium in the region $x_1 \leq 0$, resulting in a much steeper and narrower wave front. Meanwhile, the right-moving wave rapidly reaches the boundary at $x_1 = 2$, where it is reflected and eventually enters the slow medium, too. The discontinuous interface at $x_1 = 0$ generates multiple reflections, which interact with each other at later times.

6. Conclusion. We have presented and analyzed the symmetric interior penalty discontinuous Galerkin finite element method (DGFEM) for the numerical solution of the (second-order) scalar wave equation. Taking advantage of the symmetry of the method, we have carried out an a priori error analysis of the semidiscrete method and derived optimal error bounds in the energy norm and, under additional regularity assumptions, optimal error bounds in the L^2-norm. Our numerical results confirm the expected convergence rates and demonstrate the versatility of the method. The error analysis of the fully discrete scheme is the subject of ongoing work.

Based on discontinuous finite element spaces, the proposed DG method easily handles elements of various types and shapes, irregular nonmatching grids, and even locally varying polynomial order. As continuity is only weakly enforced across mesh interfaces, domain decomposition techniques immediately apply. Since the resulting mass matrix is essentially diagonal, the method is inherently parallel and leads to fully explicit time integration schemes. Moreover, as the stiffness matrix is symmetric positive definite, the DG method shares the following two important properties with the classical continuous Galerkin approach. First, the semidiscrete formulation conserves (a discrete version of) the energy for all time and therefore is nondissipative. Second, if implicit time integration is used to overcome CFL constraints, the resulting linear system to be solved at each time step will also be symmetric positive definite.

The symmetric interior penalty DGFEM, applied here to the scalar wave equation, can also be utilized for other second-order hyperbolic equations, such as in electromagnetics or elasticity. In fact, our error analysis for the semidiscrete (scalar) case readily extends to the second-order (vector) wave equation for time dependent elastic waves. The same DG approach also extends to Maxwell's equations in second-order form:

$$\varepsilon\,\mathbf{u}_{tt} + \sigma\mathbf{u}_t + \nabla \times (\mu^{-1}\,\nabla \times \mathbf{u}) = \mathbf{f}, \qquad \sigma \geq 0.$$

Here, DG discretizations with standard discontinuous piecewise polynomials indeed offer an alternative to edge elements, as typically used in conforming discretizations of Maxwell's equations. The corresponding error analysis, however, is more involved and will be reported elsewhere in the near future.

BDDC ALGORITHMS FOR INCOMPRESSIBLE STOKES EQUATIONS*

JING LI† AND OLOF WIDLUND‡

Abstract. The purpose of this paper is to extend the balancing domain decomposition by constraints (BDDC) algorithm to saddle-point problems that arise when mixed finite element methods are used to approximate the system of incompressible Stokes equations. The BDDC algorithms are iterative substructuring methods which form a class of domain decomposition methods based on the decomposition of the domain of the differential equations into nonoverlapping subdomains. They are defined in terms of a set of primal continuity constraints which are enforced across the interface between the subdomains and which provide a coarse space component of the preconditioner. Sets of such constraints are identified for which bounds on the rate of convergence can be established that are just as strong as previously known bounds for the elliptic case. In fact, the preconditioned operator is effectively positive definite, which makes the use of a conjugate gradient method possible. A close connection is also established between the BDDC and dual-primal finite element tearing and interconnecting (FETI-DP) algorithms for the Stokes case.

Key words. domain decomposition, incompressible Stokes, preconditioners, mixed finite elements

1. Introduction.

The balancing domain decomposition by constraints (BDDC) algorithms are domain decomposition methods based on nonoverlapping subdomains into which the domain of a given partial differential equation has been divided. Introduced by Dohrmann [4] and analyzed in the elliptic case by Dohrmann, Mandel, and Tezaur [30, 31], these methods represent an important advance over the balancing Neumann–Neumann methods that have been used extensively in the past to solve large finite element problems; cf. [37, section 6.2] where references to earlier work can also be found. Just as the classical balancing methods have much in common with the original one-level finite element tearing and interconnecting (FETI) methods, BDDC is closely related to the more recent dual-primal FETI (FETI-DP) methods. Each BDDC and FETI-DP method is defined in terms of a set of *primal* continuity constraints across the interface Γ formed by the parts of the subdomain boundaries which are common to at least two subdomains. In addition to, or instead of, point constraints, it is important to make certain averages over edges or faces of the interface the same. In some applications, we also should have certain first order moments, over edges, with common values; see [23, 18] for a discussion of such fully primal edges for three-dimensional elasticity.

In an important contribution to the theory, Mandel, Dohrmann, and Tezaur [31] established that the preconditioned operators of a pair of BDDC and FETI-DP algo-

rithms, with the same primal constraints, have the same nonzero eigenvalues, except possibly for an eigenvalue equal to 1. We note that this fact was first observed experimentally by Fragakis and Papadrakakis [11] for pairs of balancing Neumann–Neumann and one-level FETI methods; these authors also discussed primal iterative substructuring methods which are close counterparts to various FETI algorithms. An important consequence of the results in [11, 31] is that these algorithms, which can be built from the same set of subprograms, have very similar performance. The choice of algorithm can therefore be based on other considerations. We believe that it is easier to introduce inexact subdomain and coarse level problem solvers in the BDDC algorithms than in FETI-DP algorithms; cf. [7, 16, 28, 38, 41].

In a recent paper [29], the authors rederived the BDDC and FETI-DP algorithms for elliptic problems and also gave a short proof of the main result in [31]. A key to these simplifications is a change of variables so that, e.g., a primal constraint on the average over an interface edge or face is represented by a single primal variable in the new coordinate system. Simultaneously, a complementary set of dual displacement variables is introduced, for each of which the edge or face averages vanish; an illustrative example of how the change of variables can be carried out is given in [29]. This leads to a clear separation of the different sets of variables, and the description and analysis of the algorithm are simplified considerably. This approach has also been the basis for a successful and highly accurate implementation of FETI-DP algorithms; cf. [23, 17, 18, 16].

Brenner and Sung [3] have also recently established that any such common eigenvalue of the FETI-DP and BDDC algorithms, not equal to 0 or 1, has the same multiplicity. In addition, they give an example for which the eigenvalues of the FETI-DP operator all exceed 1 while the BDDC operator has an eigenvalue equal to 1.

In this paper, a BDDC algorithm is developed for mixed finite element approximations of the incompressible Stokes equations in a way very similar to [29]. If the set of primal constraints on the velocity across the interface satisfies a certain assumption, we are then able to show that the preconditioned saddle-point problem is positive definite when restricted to the subspace that satisfies the primal constraints and that the iterates stay in this subspace. We are then able to use a preconditioned conjugate gradient method and we can, if an additional assumption is satisfied, also prove as strong a bound on the convergence rate as for the standard elliptic case.

We note that the new algorithm has much in common with relatively recent extensions of the classical balancing Neumann–Neumann method to the Stokes equations and almost incompressible elasticity by Pavarino, Goldfeld, and the second author (see [33, 13, 12]), and extensions of the FETI-DP methods developed by the first author in [25, 26, 27]. We note that, in our experience, all these methods converge quite rapidly. Just as in our earlier work, we will work with *benign subspaces*, i.e., subspaces of the mixed finite element spaces on which the saddle-point problem is positive definite. (We note that the same space of functions is called *balanced* in [37, section 9.4.2].) We are also able to prove that any two BDDC and FETI-DP methods, with the same set of primal constraints and which satisfy our first assumption, have the same set of nonzero eigenvalues with the possible exception of 1; this is the same result as given in [31, 29, 3] for the elliptic case.

We note that Dohrmann [5, 6] has recently developed and tested a BDDC method for the related problem of almost incompressible elasticity. We will comment further on his work in section 7. Results for FETI-DP are given by Klawonn, Rheinbach, and Wohlmuth [20]. Recent results on BDDC algorithms for flow in porous media, discretized by mixed finite element methods, are given by Tu [42, 39, 40]. The BDDC

algorithms have also been extended to mortar finite element methods by Kim, Dryja, and the second author [15]. For older references to domain decomposition algorithms for mixed finite element approximations, see [37, Chapter 9].

In addition to deriving and analyzing the algorithms, we also report on some numerical experiments in the final section.

2. Discretization of a saddle-point problem. Let us consider the incompressible Stokes problem on a bounded, polyhedral domain Ω, in two or three dimensions. We denote the boundary of the domain by $\partial\Omega$; for simplicity a homogeneous Dirichlet boundary condition is enforced. (Generally, in order for a divergence free extension of the boundary values to exist, the integral of the normal component of the velocity over the boundary of the region must vanish.) The weak solution satisfies the following saddle-point problem: find $\mathbf{u} \in (H_0^1(\Omega))^d = \{\mathbf{v} \in (H^1(\Omega))^d \mid \mathbf{v} = \mathbf{0} \text{ on } \partial\Omega\}$, $d = 2$ or 3, and $p \in L_0^2(\Omega) = \{q \in L^2(\Omega) \mid \int_\Omega q = 0\}$ such that

$$\begin{cases} a(\mathbf{u},\mathbf{v}) + b(\mathbf{v},p) = (\mathbf{f},\mathbf{v}) & \forall \mathbf{v} \in \left(H_0^1(\Omega)\right)^d, \\ b(\mathbf{u},q) \qquad\qquad = 0 & \forall q \in L_0^2(\Omega)\ , \end{cases} \tag{1}$$

where $b(\mathbf{u},q) = -\int_\Omega (\nabla\cdot\mathbf{u})q$, and $a(\mathbf{u},\mathbf{v}) = \int_\Omega \nabla\mathbf{u} : \nabla\mathbf{v}$, or $a(\mathbf{u},\mathbf{v}) = 2\int_\Omega \epsilon(\mathbf{u}) : \epsilon(\mathbf{v})$. Here the strain tensor $\epsilon(\mathbf{u})$ is defined by $\epsilon_{ij}(\mathbf{u}) = \frac{1}{2}\left(\frac{\partial u_i}{\partial x_j} + \frac{\partial u_j}{\partial x_i}\right)$, and

$$\nabla\mathbf{u} : \nabla\mathbf{v} = \sum_{i,j=1}^{d} \frac{\partial u_i}{\partial x_j}\frac{\partial v_i}{\partial x_j} \quad \text{and} \quad \epsilon(\mathbf{u}) : \epsilon(\mathbf{v}) = \sum_{i,j=1}^{d} \epsilon_{ij}(\mathbf{u})\epsilon_{ij}(\mathbf{v}).$$

The operator form of the Stokes problem with Dirichlet boundary conditions is the same for either choice of the bilinear form $a(\cdot,\cdot)$, but we will adopt the second, which gives rise to a natural boundary condition of the form

$$2\sum_{j=1}^{d} \epsilon_{ij} n_j - p n_i = g_i \ \text{ on } \partial\Omega, \quad i = 1,\dots,d. \tag{2}$$

This is the normal component of the stress field. We note that this approach is consistent with the derivation of a physically relevant interface condition in Batchelor's book [1] and also with the discussion in Quarteroni and Valli [35, section 5.3]. There is the further advantage that we will develop a theory which is equally valid for almost incompressible elasticity and that we can draw very directly on some recent results on compressible elasticity by Klawonn and the second author [23]. The following lemma (see [21, Lemma 4], [12, Lemma 1.3], and [23, Lemma 6.4]) shows the equivalence between the chosen bilinear form and that of H^1. Essentially, it is a variant of Korn's second inequality; here $\|\epsilon(\mathbf{u})\|^2_{L^2(\Omega)} = \int_\Omega \epsilon(\mathbf{u}) : \epsilon(\mathbf{u})$.

LEMMA 2.1. *There exists a constant $c > 0$ such that*

$$c\|\nabla\mathbf{u}\|_{L^2(\Omega)} \le \|\epsilon(\mathbf{u})\|_{L^2(\Omega)} \le \|\nabla\mathbf{u}\|_{L^2(\Omega)} \quad \forall \mathbf{u} \in (H^1(\Omega))^d,\ \mathbf{u} \perp \ker(\epsilon),$$

where $\ker(\epsilon)$ *is the space of rigid body motions of the elasticity problem.*

In our mixed finite element methods for solving the saddle-point problem (1), the velocity space (or the space of displacements for the elasticity problems) will be denoted by $\widehat{\mathbf{W}}$. It consists of vector-valued, low order piecewise polynomial functions which are continuous across element boundaries. The pressure space $Q \subset L_0^2(\Omega)$

will consist of scalar, discontinuous, piecewise polynomial functions. A characteristic diameter of the elements of the underlying triangulation is denoted by h. The finite element approximation $(\mathbf{u}, p)$ of the variational problem (1) satisfies

$$\begin{bmatrix} A & B^T \\ B & 0 \end{bmatrix} \begin{bmatrix} \mathbf{u} \\ p \end{bmatrix} = \begin{bmatrix} \mathbf{f} \\ 0 \end{bmatrix}, \tag{3}$$

where the matrices A and B represent the restrictions of the bilinear forms $a(\cdot,\cdot)$ and $b(\cdot,\cdot)$ to the finite-dimensional space $\widehat{\mathbf{W}} \times Q$. (We will use the same notation for vectors of nodal values and the corresponding finite element functions.)

We will always assume that the chosen mixed finite element space $\widehat{\mathbf{W}} \times Q$ is inf-sup stable, i.e., that there exists a positive constant β, independent of h, such that

$$\sup_{\mathbf{w} \in \widehat{\mathbf{W}}} \frac{b(\mathbf{w}, q)}{\|\mathbf{w}\|_{H^1}} \geq \beta \|q\|_{L^2} \qquad \forall q \in Q. \tag{4}$$

We note that we will only need this estimate for the subdomains, which we will introduce in the next section. This assumption will guarantee that the local subdomain problems, as well as the global one, are well posed.

3. Reduced subdomain interface problem. The domain Ω is decomposed into N nonoverlapping polyhedral subdomains Ω_i, $i = 1, 2, \ldots, N$, of characteristic diameter H. We assume that each of them is a union of a number of shape-regular tetrahedra (or triangles), that there is a uniform bound on these numbers, and that the faces of the subdomains are all convex. The nodes on the boundaries of neighboring subdomains match across the interface $\Gamma = (\cup \partial\Omega_i) \backslash \partial\Omega$. The interface of an individual subdomain Ω_i is defined by $\Gamma_i = \partial\Omega_i \cap \Gamma$. We will denote the set of nodes on Γ_i by $\Gamma_{i,h}$, etc. We assume, as is customary in domain decomposition theory, that the triangulation of each subdomain is quasi-uniform. Our algorithms are also well defined for more irregular subdomains such as those that result from a mesh partitioner, but our theory does not fully cover such cases. The requirements on the subdomains in our full theory are discussed systematically in [37, section 4.2].

We decompose the discrete velocity and pressure spaces $\widehat{\mathbf{W}}$ and Q into

$$\widehat{\mathbf{W}} = \mathbf{W}_I \bigoplus \widehat{\mathbf{W}}_\Gamma, \quad Q = Q_I \bigoplus Q_0. \tag{5}$$

$\mathbf{W}_I$ and Q_I are products of subdomain interior velocity spaces $\mathbf{W}_I^{(i)}$ and subdomain interior pressure spaces $Q_I^{(i)}$, respectively; i.e.,

$$\mathbf{W}_I = \prod_{i=1}^{N} \mathbf{W}_I^{(i)}, \qquad Q_I = \prod_{i=1}^{N} Q_I^{(i)}.$$

The elements of $\mathbf{W}_I^{(i)}$ are supported in the subdomain Ω_i and vanish on its interface Γ_i, while the elements of $Q_I^{(i)}$ are restrictions of elements in Q to Ω_i which satisfy $\int_{\Omega_i} q_I^{(i)} = 0$. $\widehat{\mathbf{W}}_\Gamma$ is the space of traces on Γ of functions in $\widehat{\mathbf{W}}$ and Q_0 is the subspace of Q with constant values $q_0^{(i)}$ in the subdomain Ω_i that satisfy $\int_\Omega q_0 dx = \sum_{i=1}^{N} q_0^{(i)} m(\Omega_i) = 0$, where $m(\Omega_i)$ is the measure of the subdomain Ω_i.

We denote the space of interface velocity variables of the subdomain Ω_i by $\mathbf{W}_\Gamma^{(i)}$, and the associated product space by $\mathbf{W}_\Gamma = \prod_{i=1}^{N} \mathbf{W}_\Gamma^{(i)}$; generally functions in $\mathbf{W}_\Gamma$ are

discontinuous across the interface. $R_\Gamma^{(i)}$ is the restriction operator which maps functions in the continuous interface velocity space $\widehat{\mathbf{W}}_\Gamma$ to their subdomain components in the space $\mathbf{W}_\Gamma^{(i)}$. The direct sum of the $R_\Gamma^{(i)}$ is denoted by R_Γ.

With this decomposition of the solution space as in (5), the global saddle-point problem (3) can be written as follows: find $(\mathbf{u}_I, p_I, \mathbf{u}_\Gamma, p_0) \in (\mathbf{W}_I, Q_I, \widehat{\mathbf{W}}_\Gamma, Q_0)$ such that

$$\begin{bmatrix} A_{II} & B_{II}^T & \widehat{A}_{\Gamma I}^T & 0 \\ B_{II} & 0 & \widehat{B}_{I\Gamma} & 0 \\ \widehat{A}_{\Gamma I} & \widehat{B}_{I\Gamma}^T & \widehat{A}_{\Gamma\Gamma} & \widehat{B}_{0\Gamma}^T \\ 0 & 0 & \widehat{B}_{0\Gamma} & 0 \end{bmatrix} \begin{bmatrix} \mathbf{u}_I \\ p_I \\ \mathbf{u}_\Gamma \\ p_0 \end{bmatrix} = \begin{bmatrix} \mathbf{f}_I \\ 0 \\ \mathbf{f}_\Gamma \\ 0 \end{bmatrix}. \tag{6}$$

The leading two-by-two block of this matrix can, by a symmetric permutation, be made into a block diagonal matrix with blocks corresponding to independent subdomain problems. The lower left block in (6) is zero since the bilinear form $b(\mathbf{v}_I, q_0)$ always vanishes for any $\mathbf{v}_I \in \mathbf{W}_I$ and $q_0 \in Q_0$. The blocks related to the continuous interface velocity are assembled from the corresponding subdomain submatrices, e.g., $\widehat{A}_{\Gamma\Gamma} = \sum_{i=1}^N {R_\Gamma^{(i)}}^T A_{\Gamma\Gamma}^{(i)} R_\Gamma^{(i)}$, $\widehat{B}_{0\Gamma} = \sum_{i=1}^N B_{0\Gamma}^{(i)} R_\Gamma^{(i)}$. Correspondingly, the right-hand-side vector $\mathbf{f}_I$ consists of subdomain vectors $\mathbf{f}_I^{(i)}$, and $\mathbf{f}_\Gamma$ is assembled from the subdomain components $\mathbf{f}_\Gamma^{(i)}$. We denote the spaces of right-hand-side vectors $\mathbf{f}_I$ and $\mathbf{f}_\Gamma$ by $\mathbf{F}_I$ and $\mathbf{F}_\Gamma$, respectively; we will also use $\widetilde{\mathbf{F}}_\Gamma$, $\widehat{\mathbf{F}}_\Gamma$, $\widehat{\mathbf{F}}_\Pi$, $\mathbf{F}_\Delta^{(i)}$, and F_0 to represent different spaces of right-hand-side vectors in this paper without providing much detail.

Eliminating the independent subdomain interior variables $(\mathbf{u}_I, p_I)$ from the global problem (6), we have the global interface problem

$$\begin{bmatrix} \widehat{S}_\Gamma & \widehat{B}_{0\Gamma}^T \\ \widehat{B}_{0\Gamma} & 0 \end{bmatrix} \begin{bmatrix} \mathbf{u}_\Gamma \\ p_0 \end{bmatrix} = \begin{bmatrix} \mathbf{g}_\Gamma \\ 0 \end{bmatrix}, \tag{7}$$

where the right-hand-side vector $\mathbf{g}_\Gamma$ is given by

$$\mathbf{g}_\Gamma = \sum_{i=1}^N {R_\Gamma^{(i)}}^T \left\{ \mathbf{f}_\Gamma^{(i)} - \begin{bmatrix} A_{\Gamma I}^{(i)} & B_{I\Gamma}^{(i)^T} \end{bmatrix} \begin{bmatrix} A_{II}^{(i)} & B_{II}^{(i)^T} \\ B_{II}^{(i)} & 0 \end{bmatrix}^{-1} \begin{bmatrix} \mathbf{f}_I^{(i)} \\ 0 \end{bmatrix} \right\}.$$

$\widehat{S}_\Gamma$ is assembled from subdomain Stokes–Schur complements $S_\Gamma^{(i)}$, which are defined by the following: given $\mathbf{w}_\Gamma^{(i)} \in \mathbf{W}_\Gamma^{(i)}$, determine $S_\Gamma^{(i)} \mathbf{w}_\Gamma^{(i)} \in \mathbf{F}_\Gamma^{(i)}$ such that

$$\begin{bmatrix} A_{II}^{(i)} & B_{II}^{(i)^T} & A_{\Gamma I}^{(i)^T} \\ B_{II}^{(i)} & 0 & B_{I\Gamma}^{(i)} \\ A_{\Gamma I}^{(i)} & B_{I\Gamma}^{(i)^T} & A_{\Gamma\Gamma}^{(i)} \end{bmatrix} \begin{bmatrix} \mathbf{w}_I^{(i)} \\ p_I^{(i)} \\ \mathbf{w}_\Gamma^{(i)} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ 0 \\ S_\Gamma^{(i)} \mathbf{w}_\Gamma^{(i)} \end{bmatrix}. \tag{8}$$

The leading two-by-two block of (8) corresponds to a Dirichlet problem on the subdomain Ω_i and it is always nonsingular; this is a direct consequence of the assumption of inf-sup stability. We see from (8) that the action of $S_\Gamma^{(i)}$ on a vector can be evaluated at a cost of solving a Dirichlet problem on Ω_i and a few matrix-vector multiplies. We denote the direct sum of the $S_\Gamma^{(i)}$ by S_Γ. Then $\widehat{S}_\Gamma$ is given by

$$\widehat{S}_\Gamma = R_\Gamma^T S_\Gamma R_\Gamma = \sum_{i=1}^N {R_\Gamma^{(i)}}^T S_\Gamma^{(i)} R_\Gamma^{(i)}. \tag{9}$$

We denote the operator of the interface problem (7) by $\widehat{S}$. Since $\widehat{S}$ is symmetric and indefinite, we could use the minimal residual method, possibly with a positive definite block preconditioner, as in [37, section 9.2], to solve problem (7). We will instead propose a different type of preconditioner and show that the preconditioned operator is positive definite, provided that a suitable set of primal constraints are chosen; cf. Assumption 1. A preconditioned conjugate gradient method can then be used.

4. A BDDC preconditioner for Stokes equations. When using a BDDC or FETI-DP method, we relax most, but not all, of the continuity constraints on the velocity across the interface; we will always retain sufficiently many *primal* continuity constraints to assure that we will never encounter a need for solving any singular linear systems of algebraic equations. In a BDDC algorithm, full continuity is restored, at the end of each iteration step, by using an averaging operator, while in a FETI-DP algorithm, continuity will not be fully satisfied until the algorithm has converged. The primal constraints should also be chosen so that the rate of convergence of the iterative method is enhanced.

For our purposes, we introduce a partially assembled interface velocity space $\widetilde{\mathbf{W}}_\Gamma$:

$$\widetilde{\mathbf{W}}_\Gamma = \widehat{\mathbf{W}}_\Pi \bigoplus \mathbf{W}_\Delta = \widehat{\mathbf{W}}_\Pi \bigoplus \left(\prod_{i=1}^{N} \mathbf{W}_\Delta^{(i)} \right).$$

Here, $\widehat{\mathbf{W}}_\Pi$ is the continuous, coarse level, primal interface velocity space which is typically spanned by subdomain vertex nodal basis functions, and/or by interface edge and/or face basis functions with constant values, or with values of positive weight functions, on these edges or faces. These basis functions correspond to the primal interface velocity continuity constraints, which will be discussed in section 7. We will always assume that the basis has been changed so that each primal basis function corresponds to an explicit degree of freedom. In other words, we will have explicit primal unknowns corresponding to the primal continuity constraints on edges or faces as indicated in section 1, and further described in [29], [23, section 4], and [17]. The primal, coarse level degrees of freedom are shared by neighboring subdomains. The complementary space $\mathbf{W}_\Delta$ is the product of the subdomain dual interface velocity spaces $\mathbf{W}_\Delta^{(i)}$, which correspond to the remaining interface velocity degrees of freedom and are spanned by basis functions which vanish at the primal degrees of freedom. Thus, an element in the space $\widetilde{\mathbf{W}}_\Gamma$ has a continuous primal velocity component and typically a discontinuous dual velocity component.

We need to introduce several restriction, extension, and scaling operators between a variety of spaces. As in section 3, $R_\Gamma^{(i)}$ is the restriction operator which maps a function in the space $\widehat{\mathbf{W}}_\Gamma$ to its component in $\mathbf{W}_\Gamma^{(i)}$. We define $R_\Delta^{(i)}$ as the operator which maps functions in the space $\widehat{\mathbf{W}}_\Gamma$ to its dual component in the space $\mathbf{W}_\Delta^{(i)}$. $R_{\Gamma\Pi}$ is the restriction operator from the space $\widehat{\mathbf{W}}_\Gamma$ to its subspace $\widehat{\mathbf{W}}_\Pi$; $R_\Pi^{(i)}$ is the operator which maps $\widehat{\mathbf{W}}_\Pi$ into its Γ_i-component. $\widetilde{R}_\Gamma$ is the direct sum of $R_{\Gamma\Pi}$ and the $R_\Delta^{(i)}$, and it is a map from $\widehat{\mathbf{W}}_\Gamma$ into $\widetilde{\mathbf{W}}_\Gamma$.

In order to define certain scaling operators, which will be used in the definition of the BDDC preconditioner, we introduce a positive scaling factor $\delta_i^\dagger(x)$ for the nodes x on the interface Γ_i of each subdomain Ω_i. For the incompressible Stokes problems, with $\mathcal{I}_x$ the set of indices of the subdomains which have x on their boundaries, we will only need to use inverse counting functions defined by $\delta_i^\dagger(x) = 1/card(\mathcal{I}_x), x \in \Gamma_{i,h}$,

where $card(\mathcal{I}_x)$ is the number of the subdomain boundaries to which x belongs. It is then easy to see that $\sum_{j\in\mathcal{I}_x}\delta_j^\dagger(x)=1$ for any $x\in\Gamma_{i,h}$. Given the scaling factors at the subdomain interface nodes, we can define scaled restriction operators $R_{D,\Delta}^{(i)}$. We first note that each row of $R_\Delta^{(i)}$ has only one nonzero entry, which corresponds to a node $x\in\Gamma_{i,h}$. Multiplying each such element with the scaling factor $\delta_i^\dagger(x)$ gives us $R_{D,\Delta}^{(i)}$. The scaled operator $\widetilde{R}_{D,\Gamma}$ is the direct sum of $R_{\Gamma\Pi}$ and the $R_{D,\Delta}^{(i)}$. (For elasticity problems, these scaling factors should depend on the first Lamé constant μ, which can be allowed to change across the interface between neighboring subdomains; see [37, section 8.5.1] and [23].)

The interface velocity Schur complement $\widetilde{S}_\Gamma$ is defined on the partially assembled interface velocity space $\widetilde{\mathbf{W}}_\Gamma$ by the following: given $\mathbf{w}_\Gamma\in\widetilde{\mathbf{W}}_\Gamma$, $\widetilde{S}_\Gamma\mathbf{w}_\Gamma\in\widetilde{\mathbf{F}}_\Gamma$ satisfies

$$\begin{bmatrix} A_{II}^{(1)} & B_{II}^{(1)^T} & A_{\Delta I}^{(1)^T} & & \widetilde{A}_{\Pi I}^{(1)^T} \\ B_{II}^{(1)} & 0 & B_{I\Delta}^{(1)} & & \widetilde{B}_{I\Pi}^{(1)} \\ A_{\Delta I}^{(1)} & B_{I\Delta}^{(1)^T} & A_{\Delta\Delta}^{(1)} & & \widetilde{A}_{\Pi\Delta}^{(1)^T} \\ & & & \ddots & \vdots \\ \widetilde{A}_{\Pi I}^{(1)} & \widetilde{B}_{I\Pi}^{(1)^T} & \widetilde{A}_{\Pi\Delta}^{(1)} & \dots & \widetilde{A}_{\Pi\Pi} \end{bmatrix} \begin{bmatrix} \mathbf{w}_I^{(1)} \\ p_I^{(1)} \\ \mathbf{w}_\Delta^{(1)} \\ \vdots \\ \mathbf{w}_\Pi \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ 0 \\ (\widetilde{S}_\Gamma\mathbf{w}_\Gamma)_\Delta^{(1)} \\ \vdots \\ (\widetilde{S}_\Gamma\mathbf{w}_\Gamma)_\Pi \end{bmatrix}. \tag{10}$$

Here $\widetilde{A}_{\Pi\Pi}=\sum_{i=1}^N R_\Pi^{(i)^T}A_{\Pi\Pi}^{(i)}R_\Pi^{(i)}$, $\widetilde{A}_{\Pi I}^{(i)}=R_\Pi^{(i)^T}A_{\Pi I}^{(i)}$, $\widetilde{A}_{\Pi\Delta}^{(i)}=R_\Pi^{(i)^T}A_{\Pi\Delta}^{(i)}$, and $\widetilde{B}_{I\Pi}^{(i)}=B_{I\Pi}^{(i)}R_\Pi^{(i)}$.

From the definition of $\widetilde{S}_\Gamma$, we see that it can be obtained from the subdomain Schur complements $S_\Gamma^{(i)}$ by assembling only with respect to the primal interface velocity part, i.e., as

$$\widetilde{S}_\Gamma=\overline{R}_\Gamma^T S_\Gamma\overline{R}_\Gamma. \tag{11}$$

Here $\overline{R}_\Gamma$ is the restriction from the space $\widetilde{\mathbf{W}}_\Gamma$ into the product space $\mathbf{W}_\Gamma$ associated with the set of subdomains. We recall that the global interface Schur operator $\widehat{S}_\Gamma$ is obtained by fully assembling the $S_\Gamma^{(i)}$ across the subdomain interface; cf. (9). $\widehat{S}_\Gamma$ can therefore also be obtained from $\widetilde{S}_\Gamma$ by further assembling with respect to the dual interface velocity part; i.e., we have $\widehat{S}_\Gamma=\widetilde{R}_\Gamma^T\widetilde{S}_\Gamma\widetilde{R}_\Gamma$. Correspondingly, we define an operator $\widetilde{B}_{0\Gamma}$, which maps the partially assembled interface velocity space $\widetilde{\mathbf{W}}_\Gamma$ into F_0, the space of right-hand sides corresponding to Q_0. $\widetilde{B}_{0\Gamma}$ is obtained from the subdomain operators $B_{0\Gamma}^{(i)}$ by assembling with respect to the primal interface velocity part. The operator $\widehat{B}_{0\Gamma}$ can then be obtained from $\widetilde{B}_{0\Gamma}$ by assembling with respect to the dual interface velocity part on the subdomain interfaces, i.e., $\widehat{B}_{0\Gamma}=\widetilde{B}_{0\Gamma}\widetilde{R}_\Gamma$. We can then write $\widehat{S}$, the operator of the global interface problem (7), as

$$\widehat{S}=\begin{bmatrix} \widehat{S}_\Gamma & \widehat{B}_{0\Gamma}^T \\ \widehat{B}_{0\Gamma} & 0 \end{bmatrix}=\begin{bmatrix} \widetilde{R}_\Gamma^T\widetilde{S}_\Gamma\widetilde{R}_\Gamma & \widetilde{R}_\Gamma^T\widetilde{B}_{0\Gamma}^T \\ \widetilde{B}_{0\Gamma}\widetilde{R}_\Gamma & 0 \end{bmatrix}=\widetilde{R}^T\widetilde{S}\widetilde{R}, \tag{12}$$

where we use the notation

$$\widetilde{R}=\begin{bmatrix} \widetilde{R}_\Gamma & \\ & I \end{bmatrix},\quad \widetilde{S}=\begin{bmatrix} \widetilde{S}_\Gamma & \widetilde{B}_{0\Gamma}^T \\ \widetilde{B}_{0\Gamma} & 0 \end{bmatrix}. \tag{13}$$

The preconditioner for solving the global interface saddle-point problem (7) is

$$M^{-1} = \widetilde{R}_D^T \widetilde{S}^{-1} \widetilde{R}_D. \tag{14}$$

Here $\widetilde{R}_D$ is of the same form as $\widetilde{R}$ in (13), except that $\widetilde{R}_\Gamma$ is replaced by the scaled operator $\widetilde{R}_{D,\Gamma}$. It is easy to see that $\widetilde{R}_{D,\Gamma}$ is of full rank and that the preconditioner is nonsingular. To determine $\widetilde{S}^{-1}\mathbf{g}$ for any given $\mathbf{g} = (\mathbf{g}_\Gamma, g_0) \in \widetilde{\mathbf{F}}_\Gamma \times F_0$, we need to solve the linear system

$$\begin{bmatrix} \widetilde{S}_\Gamma & \widetilde{B}_{0\Gamma}^T \\ \widetilde{B}_{0\Gamma} & 0 \end{bmatrix} \begin{bmatrix} \mathbf{u}_\Gamma \\ p_0 \end{bmatrix} = \begin{bmatrix} \mathbf{g}_\Gamma \\ g_0 \end{bmatrix}. \tag{15}$$

Given the definition of $\widetilde{S}_\Gamma$ in (10), we know that solving (15) is equivalent to solving

$$\begin{bmatrix} A_{II}^{(1)} & B_{II}^{(1)^T} & A_{\Delta I}^{(1)^T} & & \widetilde{A}_{\Pi I}^{(1)^T} & \\ B_{II}^{(1)} & 0 & B_{I\Delta}^{(1)} & & \widetilde{B}_{I\Pi}^{(1)} & \\ A_{\Delta I}^{(1)} & B_{I\Delta}^{(1)^T} & A_{\Delta\Delta}^{(1)} & & \widetilde{A}_{\Pi\Delta}^{(1)^T} & B_{0\Delta}^{(1)^T} \\ & & & \ddots & \vdots & \\ \widetilde{A}_{\Pi I}^{(1)} & \widetilde{B}_{I\Pi}^{(1)^T} & \widetilde{A}_{\Pi\Delta}^{(1)} & \dots & \widetilde{A}_{\Pi\Pi} & \widetilde{B}_{0\Pi}^T \\ & & B_{0\Delta}^{(1)} & & \widetilde{B}_{0\Pi} & \end{bmatrix} \begin{bmatrix} \mathbf{u}_I^{(1)} \\ p_I^{(1)} \\ \mathbf{u}_\Delta^{(1)} \\ \vdots \\ \mathbf{u}_\Pi \\ p_0 \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ 0 \\ \mathbf{g}_\Delta^{(1)} \\ \vdots \\ \mathbf{g}_\Pi \\ g_0 \end{bmatrix}, \tag{16}$$

where $\widetilde{B}_{0\Pi} = \sum_{i=1}^N B_{0\Pi}^{(i)} R_\Pi^{(i)}$. As in [29], a block factorization can be used to solve (16). The leading diagonal subdomain matrix blocks are eliminated to form a coarse level Schur complement problem for $(\mathbf{u}_\Pi, p_0)$. After solving the coarse level problem, the subdomain variables $(\mathbf{u}_I^{(i)}, p_I^{(i)}, \mathbf{u}_\Delta^{(i)})$ are computed by solving independent subdomain problems.

5. Benign subspaces and quotient spaces. The subdomain Schur complements $S_\Gamma^{(i)}$ are symmetric, positive semidefinite. This is a consequence of a well-known result on the inertia of Schur complements. We know, e.g., that the number of negative eigenvalues of a symmetric, two-by-two block matrix equals the sum of the number of negative eigenvalues of the leading block and those of the Schur complement formed by eliminating the variables of the leading block. Thus, we have the following lemma.

LEMMA 5.1. *The subdomain Schur complements $S_\Gamma^{(i)}$, defined in* (8)*, are symmetric, positive semidefinite, and singular for any subdomain with a boundary that does not intersect $\partial\Omega$.*

The $S_\Gamma^{(i)}$- and S_Γ-seminorms are defined by $|\mathbf{w}_\Gamma^{(i)}|^2_{S_\Gamma^{(i)}} = \mathbf{w}_\Gamma^{(i)^T} S_\Gamma^{(i)} \mathbf{w}_\Gamma^{(i)}$ and $|\mathbf{w}_\Gamma|^2_{S_\Gamma} = \mathbf{w}_\Gamma^T S_\Gamma \mathbf{w}_\Gamma = \sum_{i=1}^N |\mathbf{w}_\Gamma^{(i)}|^2_{S_\Gamma^{(i)}}$. The $|\cdot|_{\mathbf{E}(\Gamma_i)}$-seminorm is defined on the space $\mathbf{W}_\Gamma^{(i)}$ by

$$|\mathbf{w}_\Gamma^{(i)}|_{\mathbf{E}(\Gamma_i)} = \inf_{\substack{\mathbf{v}^{(i)} \in (H^1(\Omega_i))^d \\ \mathbf{v}^{(i)}|_{\Gamma_i} = \mathbf{w}_\Gamma^{(i)}}} \|\epsilon(\mathbf{v}^{(i)})\|_{L^2(\Omega_i)},$$

and a seminorm on $\mathbf{W}_\Gamma$ by $|\mathbf{w}_\Gamma|^2_{\mathbf{E}(\Gamma)} = \sum_{i=1}^N |\mathbf{w}_\Gamma^{(i)}|^2_{\mathbf{E}(\Gamma_i)}$.

The following lemma shows the equivalence of the $|\cdot|_{S_\Gamma}$- and $|\cdot|_{\mathbf{E}(\Gamma)}$-seminorms. It can be found essentially in Bramble and Pasciak [2, Theorem 4.1], or Pavarino and

Widlund [33, Lemma 3.1], for incompressible Stokes problems. This same result is also valid for the incompressible elasticity problem and with the underlying bilinear form $a(\cdot,\cdot)$ given in terms of the strain tensor; cf. Lemma 2.1 and [23].

LEMMA 5.2. *There exists a positive constant c, which is independent of H and h, such that*

$$c\beta^2|\mathbf{w}_\Gamma^{(i)}|^2_{S_\Gamma^{(i)}} \leq |\mathbf{w}_\Gamma^{(i)}|^2_{\mathbf{E}(\Gamma_i)} \leq |\mathbf{w}_\Gamma^{(i)}|^2_{S_\Gamma^{(i)}} \quad \forall \mathbf{w}_\Gamma^{(i)} \in \mathbf{W}_\Gamma^{(i)},$$

where β is the inf-sup stability constant defined in (4).

The operators $\widehat{S}_\Gamma$ and $\widetilde{S}_\Gamma$, given in (9) and (11), are both symmetric, positive definite because of the Dirichlet boundary conditions on $\partial\Omega$ and the fact that sufficiently many primal continuity constraints are always chosen. We can then define the $\widehat{S}_\Gamma$- and $\widetilde{S}_\Gamma$-norms on the spaces $\widehat{\mathbf{W}}_\Gamma$ and $\widetilde{\mathbf{W}}_\Gamma$, respectively, by

$$\|\mathbf{w}_\Gamma\|^2_{\widehat{S}_\Gamma} = \mathbf{w}_\Gamma^T R_\Gamma^T S_\Gamma R_\Gamma \mathbf{w}_\Gamma = |R_\Gamma \mathbf{w}_\Gamma|^2_{S_\Gamma} \quad \forall \mathbf{w}_\Gamma \in \widehat{\mathbf{W}}_\Gamma, \tag{17}$$

$$\|\mathbf{w}_\Gamma\|^2_{\widetilde{S}_\Gamma} = \mathbf{w}_\Gamma^T \overline{R}_\Gamma^T S_\Gamma \overline{R}_\Gamma \mathbf{w}_\Gamma = |\overline{R}_\Gamma \mathbf{w}_\Gamma|^2_{S_\Gamma} \quad \forall \mathbf{w}_\Gamma \in \widetilde{\mathbf{W}}_\Gamma. \tag{18}$$

Two subspaces of $\widehat{\mathbf{W}}_\Gamma$ and $\widetilde{\mathbf{W}}_\Gamma$ are defined as follows.

DEFINITION 1.

$$\widehat{\mathbf{W}}_{\Gamma,B} = \{\mathbf{w}_\Gamma \in \widehat{\mathbf{W}}_\Gamma \mid \widehat{B}_{0\Gamma}\mathbf{w}_\Gamma = 0\} \text{ and } \widetilde{\mathbf{W}}_{\Gamma,B} = \{\mathbf{w}_\Gamma \in \widetilde{\mathbf{W}}_\Gamma \mid \widetilde{B}_{0\Gamma}\mathbf{w}_\Gamma = 0\}.$$

We will call $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$ and $\widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$ the *benign subspaces* of $\widehat{\mathbf{W}}_\Gamma \times Q_0$ and $\widetilde{\mathbf{W}}_\Gamma \times Q_0$, respectively. The interface problem operator $\widehat{S}$ of (7) is indefinite on the space $\widehat{\mathbf{W}}_\Gamma \times Q_0$. But restricted to the subspace $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, it is positive semidefinite, which follows from the fact that, for any $\mathbf{w} = (\mathbf{w}_\Gamma, q_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$,

$$\mathbf{w}^T \widehat{S}\mathbf{w} = \begin{bmatrix} \mathbf{w}_\Gamma^T & q_0^T \end{bmatrix} \begin{bmatrix} \widehat{S}_\Gamma & \widehat{B}_{0\Gamma}^T \\ \widehat{B}_{0\Gamma} & 0 \end{bmatrix} \begin{bmatrix} \mathbf{w}_\Gamma \\ q_0 \end{bmatrix} = \mathbf{w}_\Gamma^T \widehat{S}_\Gamma \mathbf{w}_\Gamma = \|\mathbf{w}_\Gamma\|^2_{\widehat{S}_\Gamma} \geq 0. \tag{19}$$

The same is also true for the operator $\widetilde{S}$ on the space $\widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$. Thus, $\widehat{S}$- and $\widetilde{S}$-seminorms can be defined on the benign subspaces by

$$|\mathbf{w}|^2_{\widehat{S}} = \mathbf{w}^T \widehat{S}\mathbf{w} = \|\mathbf{w}_\Gamma\|^2_{\widehat{S}_\Gamma} \qquad \forall \mathbf{w} = (\mathbf{w}_\Gamma,\ q_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0, \tag{20}$$

$$|\mathbf{w}|^2_{\widetilde{S}} = \mathbf{w}^T \widetilde{S}\mathbf{w} = \|\mathbf{w}_\Gamma\|^2_{\widetilde{S}_\Gamma} \qquad \forall \mathbf{w} = (\mathbf{w}_\Gamma,\ q_0) \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0. \tag{21}$$

For elements $\mathbf{w} = (\mathbf{0}, q_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, $\mathbf{w}^T \widehat{S}\mathbf{w} = 0$; we denote the space of such elements by $\widehat{Y}$ and introduce the quotient space $(\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0)/\widehat{Y}$. An element of this space, $\{\mathbf{w}_\Gamma,\ q_0\}$, is the congruence class containing the vector $(\mathbf{w}_\Gamma,\ q_0)$. Two elements of $(\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0)/\widehat{Y}$, $\{\mathbf{v}_\Gamma, p_0\}$ and $\{\mathbf{w}_\Gamma, q_0\}$, are the same if $\mathbf{v}_\Gamma = \mathbf{w}_\Gamma$ and the zero element of the space can be represented by any $(\mathbf{0}, q_0)$.

We see that even though $\widehat{S}$ is only positive semidefinite on the space $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, it becomes positive definite when considered on the quotient space $(\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0)/\widehat{Y}$. In the next section, we will show that, under an assumption on the choice of the primal velocity continuity constraints of the BDDC algorithm, the preconditioned BDDC operator $M^{-1}\widehat{S}$ is positive definite on the quotient space and that, correspondingly, a preconditioned conjugate gradient iteration restricted to the quotient space will be successful.

6. Condition number bounds. We first define an averaging operator $E_D = \widetilde{R}\widetilde{R}_D^T$, which maps $\widetilde{\mathbf{W}}_\Gamma \times Q_0$, with generally discontinuous interface velocities, to elements with continuous interface velocities in the same space: for any $\mathbf{w} = (\mathbf{w}_\Gamma, q_0) \in \widetilde{\mathbf{W}}_\Gamma \times Q_0$,

(22)
$$E_D \begin{bmatrix} \mathbf{w}_\Gamma \\ q_0 \end{bmatrix} = \begin{bmatrix} \widetilde{R}_\Gamma & \\ & I \end{bmatrix} \begin{bmatrix} \widetilde{R}_{D,\Gamma}^T & \\ & I \end{bmatrix} \begin{bmatrix} \mathbf{w}_\Gamma \\ q_0 \end{bmatrix} = \begin{bmatrix} E_{D,\Gamma}\mathbf{w}_\Gamma \\ q_0 \end{bmatrix} \in \widetilde{\mathbf{W}}_\Gamma \times Q_0,$$

where $E_{D,\Gamma} = \widetilde{R}_\Gamma \widetilde{R}_{D,\Gamma}^T$ provides the average of the interface velocities across the interface Γ.

Two assumptions will be needed for the condition number bound of the preconditioned operator; recipes for which these assumptions hold will be provided in section 7. The first assumption is a requirement on the primal velocity continuity constraints of the BDDC algorithm.

Assumption 1. The primal interface velocity continuity constraints in the BDDC algorithm are chosen such that $\int_{\partial\Omega_i} (R_\Delta^{(i)}\mathbf{w}_\Gamma) \cdot \mathbf{n}_i = 0 \ \forall \mathbf{w}_\Gamma \in \widehat{\mathbf{W}}_\Gamma$, with $\mathbf{n}_i$ the unit outward normal of $\partial\Omega_i$. Equivalently, $B_{0\Delta}^{(i)}(R_\Delta^{(i)}\mathbf{w}_\Gamma) = 0$.

The following results follow from Assumption 1.

LEMMA 6.1. *Let Assumption* 1 *hold. Then all matrices* $B_{0\Delta}^{(i)}$, $i = 1, \ldots, N$, *vanish.*

Proof. Since $R_\Delta^{(i)}$ is a mapping onto the space $\mathbf{W}_\Delta^{(i)}$, on which $B_{0\Delta}^{(i)}$ is defined, it follows from Assumption 1 that $B_{0\Delta}^{(i)}$ must vanish. ∎

LEMMA 6.2. *Let Assumption* 1 *hold. Then* $\widetilde{R}_D^T\mathbf{w} \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$ *for any* $\mathbf{w} \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$.

Proof. We need to show that given $\mathbf{w}_\Gamma = \mathbf{w}_\Pi + \mathbf{w}_\Delta \in \widetilde{\mathbf{W}}_{\Gamma,B}$, $\widehat{B}_{0\Gamma}\widetilde{R}_{D,\Gamma}^T\mathbf{w}_\Gamma = 0$. Since $\widetilde{B}_{0\Gamma}\mathbf{w}_\Gamma = 0$, we have from Lemma 6.1 that $\widetilde{B}_{0\Gamma}\mathbf{w}_\Gamma = \widetilde{B}_{0\Pi}R_{\Gamma\Pi}\widetilde{R}_\Gamma^T\mathbf{w}_\Gamma = \widetilde{B}_{0\Pi}\mathbf{w}_\Pi = 0$. From Lemma 6.1, we also know that $\widehat{B}_{0\Gamma}\widetilde{R}_{D,\Gamma}^T\mathbf{w}_\Gamma = \widetilde{B}_{0\Pi}R_{\Gamma\Pi}\widetilde{R}_{D,\Gamma}^T\mathbf{w}_\Gamma = \widetilde{B}_{0\Pi}\mathbf{w}_\Pi$. Therefore, $\widehat{B}_{0\Gamma}\widetilde{R}_{D,\Gamma}^T\mathbf{w}_\Gamma = 0$. ∎

LEMMA 6.3. *Let Assumption* 1 *hold. Then* $\widehat{S}$ *is an isomorphism from the space* $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$ *to* $\widehat{\mathbf{F}} \times \{0\}$ *and* M^{-1} *an isomorphism from the space* $\widehat{\mathbf{F}} \times \{0\}$ *to* $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$. *For any* $q_0 \in Q_0$,

$$M^{-1} \begin{bmatrix} \widehat{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ q_0 \end{bmatrix}.$$

Proof. We know from (7) that $\widehat{S}$ maps the space $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$ into $\widehat{\mathbf{F}} \times \{0\}$, and from (14), (15), and Lemma 6.2 that M^{-1} maps $\widehat{\mathbf{F}} \times \{0\}$ into $\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$. The first part of the lemma then follows since we have established that $\widehat{S}$ and M^{-1} are invertible.

To prove the second part, we observe, using Lemma 6.1, that for any $q_0 \in Q_0$, $\widehat{B}_{0\Gamma}^T q_0 = R_{\Gamma\Pi}^T \widetilde{B}_{0\Pi}^T q_0$, and $\widetilde{B}_{0\Gamma}^T q_0 = \widetilde{R}_\Gamma R_{\Gamma\Pi}^T \widetilde{B}_{0\Pi}^T q_0$, which equals $\widetilde{R}_{D,\Gamma} R_{\Gamma\Pi}^T \widetilde{B}_{0\Pi}^T q_0$ since $\widetilde{R}_{D,\Gamma}$ does not change the primal part of any element. We then have, from the definition of M^{-1}, that

$$M^{-1} \begin{bmatrix} \widehat{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix} = \widetilde{R}_D^T \widetilde{S}^{-1} \widetilde{R}_D \begin{bmatrix} R_{\Gamma\Pi}^T \widetilde{B}_{0\Pi}^T q_0 \\ 0 \end{bmatrix} = \widetilde{R}_D^T \widetilde{S}^{-1} \begin{bmatrix} \widetilde{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix}.$$

From the definition of $\widetilde{S}$ in (15), we know that the right-hand side equals $(\mathbf{0}, q_0)$. ∎

LEMMA 6.4. *Let Assumption* 1 *hold. Then any vector of the form* $\mathbf{u} = (\mathbf{0}, q_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$ *is an eigenvector of the preconditioned operator* $M^{-1}\widehat{S}$ *with an eigenvalue equal to* 1.

Proof. Given any vector $\mathbf{u} = \left[\begin{smallmatrix} \mathbf{0} \\ q_0 \end{smallmatrix}\right] \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$,

$$\widehat{S}\mathbf{u} = \begin{bmatrix} \widehat{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix}.$$

The lemma then follows from Lemma 6.3. ∎

The eigenvalues of the preconditioned operator $M^{-1}\widehat{S}$, when restricted to the quotient space $(\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0)/\widehat{Y}$, are determined by the eigenvalues of $M^{-1}\widehat{S}$ with eigenvectors with nonzero velocity components. We first prove a lower bound on the eigenvalues of $M^{-1}\widehat{S}$, when restricted to the quotient space.

LEMMA 6.5. *For any* $\mathbf{u} = (\mathbf{u}_\Gamma, p_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$,

$$\langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}} \leq \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}.$$

Proof. Given $\mathbf{u} \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, let $\mathbf{w} = \widetilde{S}^{-1}\widetilde{R}_D\widehat{S}\mathbf{u} \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$. We have, from the fact that $\widetilde{R}^T\widetilde{R}_D = \widetilde{R}_D^T\widetilde{R} = I$,

$$\langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}} = \mathbf{u}^T\widehat{S}\widetilde{R}_D^T\widetilde{R}\mathbf{u} = \mathbf{u}^T\widehat{S}\widetilde{R}_D^T\widetilde{S}^{-1}\widetilde{S}\widetilde{R}\mathbf{u} = \left\langle \mathbf{w}, \widetilde{R}\mathbf{u} \right\rangle_{\widetilde{\mathrm{S}}}. \tag{23}$$

Using the Cauchy–Schwarz inequality and the fact that $\widehat{S} = \widetilde{R}^T\widetilde{S}\widetilde{R}$, we find that

$$\left\langle \mathbf{w}, \widetilde{R}\mathbf{u} \right\rangle_{\widetilde{\mathrm{S}}} \leq \langle \mathbf{w}, \mathbf{w} \rangle_{\widetilde{\mathrm{S}}}^{1/2} \left\langle \widetilde{R}\mathbf{u}, \widetilde{R}\mathbf{u} \right\rangle_{\widetilde{\mathrm{S}}}^{1/2} = \langle \mathbf{w}, \mathbf{w} \rangle_{\widetilde{\mathrm{S}}}^{1/2} \langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}}^{1/2}. \tag{24}$$

Therefore, from (23) and (24), we have $\langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}} \leq \langle \mathbf{w}, \mathbf{w} \rangle_{\widetilde{\mathrm{S}}}$. Since

$$\langle \mathbf{w}, \mathbf{w} \rangle_{\widetilde{\mathrm{S}}} = \mathbf{u}^T\widehat{S}\widetilde{R}_D^T\widetilde{S}^{-1}\widetilde{S}\widetilde{S}^{-1}\widetilde{R}_D\widehat{S}\mathbf{u} = \left\langle \mathbf{u}, \widetilde{R}_D^T\widetilde{S}^{-1}\widetilde{R}_D\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}} = \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}, \tag{25}$$

we have $\langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}} \leq \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}$. ∎

In order to obtain a scalable upper eigenvalue bound, we need a second assumption which concerns the stability of the averaging operator $E_{D,\Gamma}$ on the space $\widetilde{\mathbf{W}}_\Gamma$; it is quite similar to those introduced in [32, 24, 23], for standard elliptic problems.

Assumption 2. There exists a positive constant C, which is independent of H, h, and the number of subdomains, such that

$$|\overline{R}_\Gamma \left(E_{D,\Gamma}\mathbf{w}_\Gamma\right)|_{\mathbf{E}(\Gamma)} \leq C\left(1 + \log\frac{H}{h}\right)|\overline{R}_\Gamma\mathbf{w}_\Gamma|_{\mathbf{E}(\Gamma)} \quad \forall \mathbf{w}_\Gamma \in \widetilde{\mathbf{W}}_\Gamma.$$

The following lemma can be proved by using Assumptions 1 and 2.

LEMMA 6.6. *Let Assumptions* 1 *and* 2 *hold. There then exists a positive constant* C*, which is independent of* H*,* h*, and the number of subdomains, such that*

$$|E_D\mathbf{w}|_{\widetilde{\mathrm{S}}} \leq C\frac{1}{\beta}\left(1 + \log\frac{H}{h}\right)|\mathbf{w}|_{\widetilde{\mathrm{S}}} \quad \forall \mathbf{w} = (\mathbf{w}_\Gamma, q_0) \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0,$$

where β is the inf-sup stability constant of (4).

Proof. Given any vector $\mathbf{w} = (\mathbf{w}_\Gamma, q_0) \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$, we know, from Lemma 6.2, that $\widetilde{R}_D^T \mathbf{w} \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$. Therefore, $E_D \mathbf{w} = \widetilde{R}\widetilde{R}_D^T \mathbf{w} \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$. From the definition of the $\widetilde{S}$-seminorm in (21), we have

$$|E_D \mathbf{w}|_{\widetilde{\mathrm{S}}}^2 = \|E_{D,\Gamma} \mathbf{w}_\Gamma\|_{\widetilde{\mathrm{S}}_\Gamma}^2 = |\overline{R}_\Gamma \left(E_{D,\Gamma} \mathbf{w}_\Gamma\right)|_{S_\Gamma}^2 \leq C \frac{1}{\beta^2} |\overline{R}_\Gamma \left(E_{D,\Gamma} \mathbf{w}_\Gamma\right)|_{\mathbf{E}(\Gamma)}^2, \tag{26}$$

where the last inequality follows from Lemma 5.2.

We have, from Assumption 2, Lemma 5.2, and (18),

$$\begin{aligned} |\overline{R}_\Gamma \left(E_{D,\Gamma} \mathbf{w}_\Gamma\right)|_{\mathbf{E}(\Gamma)}^2 &\leq C \left(1 + \log \frac{H}{h}\right)^2 |\overline{R}_\Gamma \mathbf{w}_\Gamma|_{\mathbf{E}(\Gamma)}^2 \\ &\leq C \left(1 + \log \frac{H}{h}\right)^2 |\overline{R}_\Gamma \mathbf{w}_\Gamma|_{S_\Gamma}^2 = C \left(1 + \log \frac{H}{h}\right)^2 \|\mathbf{w}_\Gamma\|_{\widetilde{\mathrm{S}}_\Gamma}^2. \end{aligned} \tag{27}$$

Then from (26), (27), and (21), we have

$$|E_D \mathbf{w}|_{\widetilde{\mathrm{S}}}^2 \leq C \frac{1}{\beta^2} \left(1 + \log \frac{H}{h}\right)^2 \|\mathbf{w}_\Gamma\|_{\widetilde{\mathrm{S}}_\Gamma}^2 = C \frac{1}{\beta^2} \left(1 + \log \frac{H}{h}\right)^2 |\mathbf{w}|_{\widetilde{\mathrm{S}}}^2. \qquad \square$$

THEOREM 6.7. *Let Assumptions* 1 *and* 2 *hold. The preconditioned operator $M^{-1}\widehat{S}$ is then symmetric, positive definite with respect to the bilinear form $\langle \cdot, \cdot \rangle_{\widehat{\mathrm{S}}}$ on the space $(\widehat{\mathbf{W}}_{\Gamma,B} \times Q_0)/\widehat{Y}$. Its eigenvalues are bounded from below by* 1 *and from above by $C \frac{1}{\beta^2} \left(1 + \log(H/h)\right)^2$, where C is a constant which is independent of H, h, and the number of subdomains and β is the inf-sup stability constant defined in* (4).

Proof. It is sufficient to prove that, for any $\mathbf{u} = (\mathbf{u}_\Gamma, p_0) \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, with $\mathbf{u}_\Gamma \neq \mathbf{0}$,

$$\langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}} \leq \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}} \leq C \frac{1}{\beta^2} \left(1 + \log \frac{H}{h}\right)^2 \langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}}.$$

The lower bound has already been established in Lemma 6.5. For the upper bound, given $\mathbf{u} \in \widehat{\mathbf{W}}_{\Gamma,B} \times Q_0$, let $\mathbf{w} = \widetilde{S}^{-1}\widetilde{R}_D \widehat{S}\mathbf{u} \in \widetilde{\mathbf{W}}_{\Gamma,B} \times Q_0$, the same element as in the proof of the lower bound in Lemma 6.5. We have $\widetilde{R}_D^T \mathbf{w} = M^{-1}\widehat{S}\mathbf{u}$. Since $\widehat{S} = \widetilde{R}^T \widetilde{S} \widetilde{R}$, we have, by using Lemma 6.6,

$$\begin{aligned} \left\langle M^{-1}\widehat{S}\mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}} = \left\langle \widetilde{R}_D^T \mathbf{w}, \widetilde{R}_D^T \mathbf{w} \right\rangle_{\widehat{\mathrm{S}}} &= \left\langle \widetilde{R}\widetilde{R}_D^T \mathbf{w}, \widetilde{R}\widetilde{R}_D^T \mathbf{w} \right\rangle_{\widetilde{\mathrm{S}}} \\ = |E_D \mathbf{w}|_{\widetilde{\mathrm{S}}}^2 &\leq C \frac{1}{\beta^2} \left(1 + \log \frac{H}{h}\right)^2 |\mathbf{w}|_{\widetilde{\mathrm{S}}}^2. \end{aligned}$$

Therefore, from (25), we have

$$\left\langle M^{-1}\widehat{S}\mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}} \leq C \frac{1}{\beta^2} \left(1 + \log \frac{H}{h}\right)^2 \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}. \tag{28}$$

Using the Cauchy–Schwarz inequality and (28), we have

$$\begin{aligned} \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}} &\leq \langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}}^{1/2} \left\langle M^{-1}\widehat{S}\mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}^{1/2} \\ &\leq C \frac{1}{\beta} \left(1 + \log \frac{H}{h}\right) \langle \mathbf{u}, \mathbf{u} \rangle_{\widehat{\mathrm{S}}}^{1/2} \left\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u} \right\rangle_{\widehat{\mathrm{S}}}^{1/2}. \end{aligned}$$

This gives $\langle \mathbf{u}, M^{-1}\widehat{S}\mathbf{u}\rangle_{\widehat{\mathbb{S}}} \leq C\frac{1}{\beta^2}\left(1+\log(H/h)\right)^2 \langle \mathbf{u},\mathbf{u}\rangle_{\widehat{\mathbb{S}}}$ and the upper bound of the eigenvalues. ∎

The preconditioned conjugate gradient iteration for $M^{-1}\widehat{S}$ is given in Algorithm 1. It is a preconditioned conjugate gradient iteration restricted to the quotient space $(\widehat{\mathbf{W}}_{\Gamma,B}\times Q_0)/\widehat{Y}$. Its convergence will be established in Theorem 6.10, and its convergence rate is determined by the eigenvalue bounds of $M^{-1}\widehat{S}$ given in Theorem 6.7.

Algorithm 1. (Preconditioned Conjugate Gradient Algorithm For Solving (7))

1. *Initialization:* $u^0=0$, $r^0=b=\begin{bmatrix}\mathbf{g}_\Gamma\\ 0\end{bmatrix}\left(=\begin{bmatrix}\widehat{S}_\Gamma\mathbf{u}_\Gamma+\widehat{B}_{0\Gamma}^T p_0\\ 0\end{bmatrix}\right)$, $k=1$.
2. *while* $\langle r^{k-1}, r^{k-1}\rangle_{M^{-1}} \geq$ *tolerance*

$$\begin{aligned} z^{k-1} &= M^{-1}r^{k-1}\\ \beta^k &= \langle z^{k-1}, r^{k-1}\rangle \,/\, \langle z^{k-2}, r^{k-2}\rangle \;; \quad [\ \beta^1=0\ ]\\ d^k &= z^{k-1}+\beta^k d^{k-1}\;; \quad [\ d^1=z^0\ ]\\ \alpha^k &= \langle z^{k-1}, r^{k-1}\rangle \,/\, \langle d^k, d^k\rangle_{\widehat{S}}\\ u^k &= u^{k-1}+\alpha^k d^k\\ r^k &= r^{k-1}-\alpha^k \widehat{S}d^k\\ k &= k+1 \end{aligned}$$

3. $u = u^{k-1}+M^{-1}r^{k-1}$

The following lemma will be used in the proof of Theorem 6.10 to show that the denominators in Algorithm 1 cannot vanish in the iteration.

Lemma 6.8. *Let Assumption* 1 *hold. Then any vector of the form*

$$\mathbf{f}=\widehat{S}\mathbf{w}=\begin{bmatrix}\widehat{S}_\Gamma\mathbf{w}_\Gamma+\widehat{B}_{0\Gamma}^T q_0\\ 0\end{bmatrix}, \quad \textit{where} \quad \mathbf{w}=\begin{bmatrix}\mathbf{w}_\Gamma\\ q_0\end{bmatrix}\in\widehat{\mathbf{W}}_{\Gamma,B}\times Q_0, \tag{29}$$

satisfies $\langle \mathbf{f},\mathbf{f}\rangle_{M^{-1}}=0$ *if and only if* $\mathbf{w}_\Gamma=\mathbf{0}$. *If* $\mathbf{w}_\Gamma\neq\mathbf{0}$ *in* (29), *then the velocity component of* $M^{-1}\mathbf{f}$ *is also nonzero.*

Proof. We know from Lemma 6.3 that if $\mathbf{w}_\Gamma=\mathbf{0}$ in (29), then

$$\mathbf{f}^T M^{-1}\mathbf{f}=\begin{bmatrix}\widehat{B}_{0\Gamma}^T q_0\\ 0\end{bmatrix}^T M^{-1}\begin{bmatrix}\widehat{B}_{0\Gamma}^T q_0\\ 0\end{bmatrix}=\begin{bmatrix}\widehat{B}_{0\Gamma}^T q_0\\ 0\end{bmatrix}^T\begin{bmatrix}\mathbf{0}\\ q_0\end{bmatrix}=0.$$

On the other hand, if $\langle \mathbf{f},\mathbf{f}\rangle_{M^{-1}}=0$, then $\langle \mathbf{w}, M^{-1}\widehat{S}\mathbf{w}\rangle_{\widehat{\mathbb{S}}}=0$. By Lemma 6.5 $\langle \mathbf{w},\mathbf{w}\rangle_{\widehat{\mathbb{S}}}=0$, and by (19) $\mathbf{w}_\Gamma$ must vanish.

To prove the second part of this lemma, we know, from Lemma 6.3, that M^{-1} is a one-to-one map from the space of vectors $\mathbf{f}$ with $\mathbf{w}_\Gamma=\mathbf{0}$ in (29) to the space $\{\mathbf{0}\}\times Q_0$. Since for any nonzero $\mathbf{w}_\Gamma\in\widehat{\mathbf{W}}_{\Gamma,B}$, $\widehat{S}_\Gamma\mathbf{w}_\Gamma\notin\mathbf{range}\,(\widehat{B}_{0\Gamma}^T)$ (otherwise the system matrix of (7) would be singular), we know that for any vector $\mathbf{f}$ with $\mathbf{w}_\Gamma\neq\mathbf{0}$ in (29) the image $M^{-1}\mathbf{f}$ cannot be in the space $\{\mathbf{0}\}\times Q_0$; therefore, the velocity component of $M^{-1}\mathbf{f}$ must be nonzero. ∎

The following lemma can be found in [14, equation (10.3.4)].

Lemma 6.9. *The residuals* r^k *in Algorithm* 1 *are* M^{-1}*-orthogonal; i.e., for any* $i\neq j$, $\langle r^i, r^j\rangle_{M^{-1}}=0$.

THEOREM 6.10. *Let Assumption* 1 *hold. The preconditioned conjugate gradient algorithm then converges and at convergence* u *is the solution of* (7).

Proof. We will show that, for any $k = 1, 2, \ldots$, if $\left\langle r^{k-1}, r^{k-1}\right\rangle_{M^{-1}} \neq 0$, then the denominator $\left\langle d^k, d^k\right\rangle_{\widehat{\mathrm{S}}}$ cannot vanish in the iteration. (It is easy to see that the other denominator $\left\langle z^{k-2}, r^{k-2}\right\rangle = \left\langle r^{k-2}, r^{k-2}\right\rangle_{M^{-1}} > 0$.) We see from Algorithm 1 that

$$\begin{aligned} span\{r^0, r^1, \ldots, r^{k-1}\} &= span\{r^0,\ \widehat{S}M^{-1}r^0, \ldots,\ (\widehat{S}M^{-1})^{k-1}r^0\}, \\ span\{d^1, d^2, \ldots, d^k\} &= span\{M^{-1}r^0,\ M^{-1}r^1, \ldots,\ M^{-1}r^{k-1}\}. \end{aligned}$$

The vectors r^i, for $i = 0, 1, \ldots, k-1$, and d^k can be written as

$$r^i = \begin{bmatrix} \widehat{S}_\Gamma \mathbf{w}_\Gamma^i + \widehat{B}_{0\Gamma}^T q_0^i \\ 0 \end{bmatrix},\ i = 0, 1, \ldots, k-1, \tag{30}$$

$$d^k = M^{-1} \begin{bmatrix} \widehat{S}_\Gamma(\mathbf{w}_\Gamma^{k-1} + \sum_{i=0}^{k-2} s_i \mathbf{w}_\Gamma^i) + \widehat{B}_{0\Gamma}^T(q_0^{k-1} + \sum_{i=0}^{k-2} t_i q_0^i) \\ 0 \end{bmatrix}, \tag{31}$$

where $\mathbf{w}_\Gamma^i \in \widehat{W}_{\Gamma,B}$, $q_0^i \in Q_0$, for $i = 0, 1, \ldots, k-1$, and s_i and t_i are scalar factors.

For $k = 1$, and if $\left\langle r^0, r^0\right\rangle_{M^{-1}} > 0$, then by Lemma 6.8, $\mathbf{w}_\Gamma^0 \neq \mathbf{0}$ in the formula for r^0 in (30). We then see from Lemma 6.8 that the velocity component of $d^1 = M^{-1}r^0$ must be nonzero; therefore, by (19), $\left\langle d^1, d^1\right\rangle_{\widehat{\mathrm{S}}} > 0$.

For any $k > 1$, if $\left\langle r^{k-1}, r^{k-1}\right\rangle_{M^{-1}} > 0$, then, by Lemma 6.8, $\mathbf{w}_\Gamma^{k-1} \neq \mathbf{0}$ in the formula for r^{k-1} in (30). We will show that $\mathbf{w}_\Gamma^{k-1}$ cannot be written as a linear combination of $\mathbf{w}_\Gamma^i$, $i = 0, \ldots, k-2$. Assuming $\mathbf{w}_\Gamma^{k-1} = \sum_{i=0}^{k-2} c_i \mathbf{w}_\Gamma^i$, we would have

$$r^{k-1} = \begin{bmatrix} \widehat{S}_\Gamma \mathbf{w}_\Gamma^{k-1} + \widehat{B}_{0\Gamma}^T q_0^{k-1} \\ 0 \end{bmatrix} = \sum_{i=0}^{k-2} c_i r^i + \begin{bmatrix} \widehat{B}_{0\Gamma}^T(q_0^{k-1} - \sum_{i=0}^{k-2} c_i q_0^i) \\ 0 \end{bmatrix}.$$

Then, from Lemmas 6.9 and 6.3, we would have

$$\begin{aligned} 0 = \left\langle \sum_{i=0}^{k-2} c_i r^i, r^{k-1} \right\rangle_{M^{-1}} &= \left(\sum_{i=0}^{k-2} c_i r^{i^T} \right) M^{-1} \left\{ \sum_{i=0}^{k-2} c_i r^i + \begin{bmatrix} \widehat{B}_{0\Gamma}^T(q_0^{k-1} - \sum_{i=0}^{k-2} c_i q_0^i) \\ 0 \end{bmatrix} \right\} \\ &= \left\langle \sum_{i=0}^{k-2} c_i r^i, \sum_{i=0}^{k-2} c_i r^i \right\rangle_{M^{-1}} + \left(\sum_{i=0}^{k-2} c_i r^{i^T} \right) \begin{bmatrix} 0 \\ q_0^{k-1} - \sum_{i=0}^{k-2} c_i q_0^i \end{bmatrix} \\ &= \left\langle \sum_{i=0}^{k-2} c_i r^i, \sum_{i=0}^{k-2} c_i r^i \right\rangle_{M^{-1}} = \sum_{i=0}^{k-2} |c_i|^2 \left\langle r^i, r^i \right\rangle_{M^{-1}} > 0, \end{aligned}$$

which is a contradiction. Therefore, $\mathbf{w}_\Gamma^{k-1} + \sum_{i=0}^{k-2} s_i \mathbf{w}_\Gamma^i$ cannot vanish and by Lemma 6.8, $\left\langle d^k, d^k\right\rangle_{\widehat{\mathrm{S}}} > 0$.

At full convergence (*tolerance* $= 0$) of Algorithm 1, we have $\left\langle r^{k-1}, r^{k-1}\right\rangle_{M^{-1}} = 0$, and

$$b - \widehat{S}u = b - \widehat{S}\left(u^{k-1} + M^{-1}r^{k-1}\right) = r^{k-1} - \widehat{S}M^{-1}r^{k-1}.$$

Since $\left\langle r^{k-1}, r^{k-1}\right\rangle_{M^{-1}} = 0$, we know from Lemma 6.8 that r^{k-1} is of the form

$$r^{k-1} = \begin{bmatrix} \widehat{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix}.$$

Therefore, from Lemma 6.3,

$$\widehat{S}M^{-1}r^{k-1} = \widehat{S}\begin{bmatrix} 0 \\ q_0 \end{bmatrix} = \begin{bmatrix} \widehat{B}_{0\Gamma}^T q_0 \\ 0 \end{bmatrix} = r^{k-1},$$

and hence $b - \widehat{S}u = 0$; i.e., u is the solution of (7). ∎

7. Satisfying the assumptions: Choosing primal constraints. Assumptions 1 and 2 can be satisfied with appropriate choices of the primal continuity constraints on the interface velocity variables. We first describe a recipe for two-dimensional problems, and then one for the more complicated three-dimensional case.

For two-dimensional problems, it is natural to make all subdomain vertices primal, i.e., make both components of the velocity continuous at those nodes. The vertex constraints by themselves are able to control the subdomain rigid body modes. It is straightforward to modify the concept of *fully primal* faces, introduced for three-dimensional elasticity in [23] and outlined later in this section, and to prove that any edge, with two primal variables at each of its end points, is fully primal. It is then easy to prove that Assumption 2 holds.

In order to satisfy Assumption 1, additional constraints are necessary. For each interface edge Γ^{ij}, which is shared by a pair of subdomains Ω_i and Ω_j, we enforce

$$\int_{\Gamma^{ij}} \mathbf{w}_\Gamma^{(i)} \cdot \mathbf{n}_{ij} = \int_{\Gamma^{ij}} \mathbf{w}_\Gamma^{(j)} \cdot \mathbf{n}_{ij}, \tag{32}$$

with a fixed selection of the normal $\mathbf{n}_{ij}$ to Γ^{ij}. We implement a change of basis choosing an edge basis element vector with components $\int_{\Gamma^{ij}} \varphi_k^{\Gamma^{ij}} \cdot \mathbf{n}_{ij}$ at the interior nodes k of Γ^{ij} which vanishes at the end points of the edge. Here $\varphi_k^{\Gamma^{ij}}$ is the nodal finite element velocity basis function of the node k. All the other, complementary velocity element vectors of this edge are chosen to be orthogonal to the special primal edge basis function just introduced and the integrals of their normal components will therefore vanish; i.e., $\int_{\Gamma^{ij}} \mathbf{w}_\Delta^{(i)} \cdot \mathbf{n}_{ij} = 0$ for any $\mathbf{w}_\Delta^{(i)} \in \mathbf{W}_\Delta^{(i)}$. Since $\partial\Omega_i$ is a union of edges, Assumption 1 is satisfied. For details on the implementation of the change of basis, see [29], [23, section 4], and [17].

For three-dimensional problems, the interface Γ is composed of subdomain faces, denoted by $\mathcal{F}^l$, shared by two subdomains, edges $\mathcal{E}^k$, which make up parts of the boundaries of faces, and are often shared by more than two subdomains, and vertices which are the end points of the edges. We will use a partition of unity to separate contributions from the faces, edges, and vertices; cf. [37, section 4.6]. For each face $\mathcal{F}^l$, we denote by $\theta_{\mathcal{F}^l}$ the finite element cut-off function which equals 1 at the interior nodes of the face $\mathcal{F}^l$ and vanishes at all other nodes on the interface. For each edge $\mathcal{E}^k$, we denote by $\theta_{\mathcal{E}^k}$ the finite element cut-off function which equals 1 at all the interior nodes of $\mathcal{E}^k$ and vanishes at all other nodes. We denote the set of faces which share the edge $\mathcal{E}^k$ by $\mathcal{M}_{\mathcal{E}^k}$. We also select a normal $\mathbf{n}_l$ for each face $\mathcal{F}^l$.

Our recipe for satisfying Assumption 1 in three dimensions is similar to that of the two-dimensional case. We will consider each face of the interface separately and also make all velocity components at all subdomain vertices primal. We can then use a partition of unity based only on face and edge functions and find that for any dual velocity element $\mathbf{w}_\Delta^{(i)} \in \mathbf{W}_\Delta^{(i)}$,

$$\int_{\mathcal{F}^l} \mathbf{w}_\Delta^{(i)} \cdot \mathbf{n}_l = \int_{\mathcal{F}^l} I^h\left(\theta_{\mathcal{F}^l}\mathbf{w}_\Delta^{(i)}\right) \cdot \mathbf{n}_l + \sum_{\mathcal{E}^k \subset \partial\mathcal{F}^l} \int_{\mathcal{F}^l} I^h\left(\theta_{\mathcal{E}^k}\mathbf{w}_\Delta^{(i)}\right) \cdot \mathbf{n}_l. \tag{33}$$

Here I^h is the interpolation operator into the velocity finite element space.

On the face $\mathcal{F}^l$, shared by a pair of subdomains Ω_i and Ω_j, we enforce

$$\int_{\mathcal{F}^l} I^h\left(\theta_{\mathcal{F}^l}\mathbf{w}_\Gamma^{(i)}\right)\cdot\mathbf{n}_l = \int_{\mathcal{F}^l} I^h\left(\theta_{\mathcal{F}^l}\mathbf{w}_\Gamma^{(j)}\right)\cdot\mathbf{n}_l, \tag{34}$$

in the same way as for the edge constraints in two dimensions. This face average corresponds to a face average basis element, which is made primal, and the dual interface velocities $\mathbf{w}_\Delta^{(i)}$ always satisfy $\int_{\mathcal{F}^l} I^h(\theta_{\mathcal{F}^l}\mathbf{w}_\Delta^{(i)})\cdot\mathbf{n}_l = 0$.

The discussion of the edge terms is complicated by the fact that the nodal basis functions associated with an edge node will differ from zero in narrow strips on the boundaries of all subdomains that share that edge. For an edge $\mathcal{E}^k$ and on each face $\mathcal{F}^m \in \mathcal{M}_{\mathcal{E}^k}$ which shares this edge, and for all pairs of subdomains Ω_i and Ω_j which share this edge, we will enforce

$$\int_{\mathcal{F}^m} I^h\left(\theta_{\mathcal{E}^k}\mathbf{w}_\Gamma^{(i)}\right)\cdot\mathbf{n}_m = \int_{\mathcal{F}^m} I^h\left(\theta_{\mathcal{E}^k}\mathbf{w}_\Gamma^{(j)}\right)\cdot\mathbf{n}_m. \tag{35}$$

The number of faces in the set $\mathcal{M}_{\mathcal{E}^k}$ is denoted by m_k; this many primal degrees of freedom are required to satisfy the constraints (35). The corresponding primal basis element vectors are determined by the integrals of the normal components of the edge nodal finite element basis functions over the relevant faces. As in two dimensions, the dual velocity basis element vectors are made orthogonal to all the primal basis vectors. Therefore, the dual interface velocities $\mathbf{w}_\Delta^{(i)}$ will always satisfy $\int_{\mathcal{F}^m} I^h\big(\theta_{\mathcal{E}^k}\mathbf{w}_\Delta^{(i)}\big)\cdot\mathbf{n}_m = 0$. By enforcing the constraints (34) and (35), the integral (33) is always zero and Assumption 1 is satisfied.

It can easily happen that the m_k primal basis vectors, for the edge $\mathcal{E}^k$, are linearly dependent. This happens, e.g., in the case when the subdomains are cubes and a uniform mesh is used. In general, we must make sure that the primal basis functions maintain linear independence for each edge separately. We can use a singular value decomposition, in a preprocessing step of the algorithm, to single out only those that are numerically linearly independent and should be retained. This device for eliminating linearly dependent coarse level primal constraints has previously been applied for both FETI-DPH (a variant for Helmholtz's equation) and BDDC algorithms; see [10, 5, 6].

Remark 1. A different BDDC algorithm was introduced in [5, 6] by Dohrmann for solving nearly incompressible elasticity problems. Zero divergence constraints were used for the substructure corrections to keep the volume change of each substructure small for nearly incompressible materials. For two-dimensional problems, our constraints (32) are the same as those in [5, 6]; the same type of constraints have also been used previously in FETI-DP algorithms for Stokes problems; cf. [27]. For three-dimensional problems, our vertex and face constraints are the same as Dohrmann's. But for each edge $\mathcal{E}^k$, Dohrmann requires, on each subdomain Ω_i which shares this edge, that the integrals

$$\sum_{\mathcal{F}^l\subset\partial\Omega_i}\int_{\mathcal{F}^l} I^h\left(\theta_{\mathcal{E}^k}\mathbf{w}_\Gamma^{(m)}\right)\cdot\mathbf{n}_l \tag{36}$$

be the same for all $m \in \mathcal{N}_{\mathcal{E}^k}$; here $\mathcal{N}_{\mathcal{E}^k}$ is the set of indices of the subdomains which have the edge $\mathcal{E}^k$ in common. While either set of edge constraints, (35) or

(36), together with the face and vertex constraints will satisfy Assumption 1, we have adopted the form (35) to facilitate the analysis.

We also have to make sure that we have a set of constraints which guarantees a stable $E_{D,\Gamma}$ operator, as in Assumption 2, for three-dimensional problems. The continuity constraints (34) and (35), together with the vertex constraints, developed for Assumption 1, are not always sufficient for Assumption 2 to hold. We will show that some additional edge tangential continuity constraints are sometimes needed. Such a constraint is introduced on an edge $\mathcal{E}^k$, by requiring that $\int_{\mathcal{E}^k} I^h(\theta_{\mathcal{E}^k}\mathbf{w}_\Gamma^{(i)})\cdot\mathbf{t}_{\mathcal{E}^k}$ takes on a common value. Here $\mathbf{t}_{\mathcal{E}^k}$ is the unit vector tangent to $\mathcal{E}^k$. By selecting a primal degree of freedom corresponding to this tangential edge integral, we can make the resulting dual interface variables satisfy $\int_{\mathcal{E}^k} I^h(\theta_{\mathcal{E}^k}\mathbf{w}_\Delta^{(i)})\cdot\mathbf{t}_{\mathcal{E}^k}=0$. We note that only one extra primal variable will be introduced for each such edge.

We recall that the space of rigid body modes on each subdomain Ω_i is spanned by the three translations

$$\mathbf{r}_1 := \begin{bmatrix} 1\\0\\0\end{bmatrix},\quad \mathbf{r}_2 := \begin{bmatrix} 0\\1\\0\end{bmatrix},\quad \mathbf{r}_3 := \begin{bmatrix} 0\\0\\1\end{bmatrix}, \tag{37}$$

and the three rotations

$$\mathbf{r}_4 := \frac{1}{H_i}\begin{bmatrix} x_2-\hat{x}_2\\ -x_1+\hat{x}_1\\ 0\end{bmatrix},\quad \mathbf{r}_5 := \frac{1}{H_i}\begin{bmatrix} -x_3+\hat{x}_3\\ 0\\ x_1-\hat{x}_1\end{bmatrix},\quad \mathbf{r}_6 := \frac{1}{H_i}\begin{bmatrix} 0\\ x_3-\hat{x}_3\\ -x_2+\hat{x}_2\end{bmatrix}. \tag{38}$$

Here $\hat{\mathbf{x}}\in\Omega_i$ and H_i denotes the diameter of Ω_i. (The shift of the origin makes the basis for the space of rigid body modes well conditioned, and the scaling and shift make the $L^2(\Omega_i)$-norms of these six functions scale similarly with H_i.) For each subdomain face $\mathcal{F}^l$, we represent the primal continuity constraints enforced on its edges (excluding the vertex constraints) in terms of a set of linear functionals $f_m^l(\cdot)$, $m=1,2,\ldots,M_l$. All the $f_m^l(\cdot)$ vanish when applied to the dual velocity component. We will use the idea of *fully primal* faces, which has been developed in [23] for compressible elasticity; see Definition 2 below. We will use our functionals, which define our edge constraints, to create a basis, $\{g_k\}_1^6$, which, when restricted to the six-dimensional space of rigid body modes, is a dual basis. Each g_k will be a linear combination of the constraint functionals for the face in question. We will also require certain bounds for the linear functionals; these bounds enter into the bound for the condition number of our algorithm. We note that the quality of these bounds is better than what can be accomplished with vertex constraints. It is in fact known that the exclusive use of point constraints leads to less satisfactory performance; see, e.g., [9, 34, 19].

DEFINITION 2. *A face $\mathcal{F}^l$ of subdomain Ω_i is fully primal if a set of six continuity constraints $g_k(\cdot), k=1,2,\ldots,6$, are enforced on the edges of $\mathcal{F}^l$ and satisfy*

$$|g_k(\mathbf{w}^{(i)})|^2 \le CH^{-1}\left(1+\log\left(\frac{H}{h}\right)\right)\left\{|\mathbf{w}^{(i)}|^2_{H^{1/2}(\mathcal{F}^{ij})}+\frac{1}{H}\|\mathbf{w}^{(i)}\|^2_{L^2(\mathcal{F}^{ij})}\right\}, \tag{39}$$

$$g_k(\mathbf{r}_j)=\delta_{kj}\quad \forall k,j=1,\ldots,6. \tag{40}$$

Essentially the same proof as for [23, Lemma 8.4] can be used to prove the following lemma; establishing the inequalities (39) is a key part in any such proof.

LEMMA 7.1. *Assumption* 2 *is satisfied for the three-dimensional problems if all the faces* $\mathcal{F}^l$ *of the interface* Γ *are fully primal and all the subdomain vertices are primal.*

We will now consider a set of sufficient conditions for the conditions of Definition 2 to hold. Many details can again be found in [23], e.g., the bounds for the functionals associated with the tangential components of the velocity. We only indicate how to bound the functionals associated with the constraints on the normal components and the edges; the constraint given by (34) will play no role in establishing that faces are fully primal. We have the following result.

LEMMA 7.2. *Let the* $f_m^l(\cdot)$, $m = 1, 2, \ldots, M_l$, *be given by the continuity constraints* (35) *and a tangential edge constraint for each of the edges of a face* $\mathcal{F}^l$. *Then* $\mathcal{F}^l$ *is fully primal.*

Proof. Using a normalization as in [23], the constraint (35) associated with an edge $\mathcal{E}^k$ and a normal component is represented by a functional

$$f_m^l(\mathbf{w}^{(i)}) = \frac{\int_{\mathcal{E}^{k+}} I^h(\theta_{\mathcal{E}^k}\mathbf{w}^{(i)}) \cdot \mathbf{n}_l \; ds}{\int_{\mathcal{E}^{k+}} 1 ds},$$

where $\mathbf{w}^{(i)} \in \mathbf{W}^{(i)}$, $\mathbf{n}_l$ is a unit normal to the face $\mathcal{F}^l$, and $\mathcal{E}^{k+}$ represents the strip of elements next to the edge $\mathcal{E}^k$ on $\mathcal{F}^l$. By using the Cauchy–Schwarz inequality, we have $|f_m^l(\mathbf{w}^{(i)})|^2 \leq CH^{-1}\|\theta_{\mathcal{E}^k}\mathbf{w}^{(i)}\|^2_{L^2(\mathcal{E}^{ij})} \leq CH^{-1}\|\mathbf{w}^{(i)}\|^2_{L^2(\mathcal{E}^{ij})}$. Using [23, Lemma 7.4] or [8, Lemma 3.3], we have

$$|f_m^l(\mathbf{w}^{(i)})|^2 \leq CH^{-1}\left(1 + \log\left(\frac{H}{h}\right)\right)\left\{|\mathbf{w}^{(i)}|^2_{H^{1/2}(\mathcal{F}^{ij})} + \frac{1}{H}\|\mathbf{w}^{(i)}\|^2_{L^2(\mathcal{F}^{ij})}\right\}. \tag{41}$$

What is now left is to show that among the given edge normal constraints (35) and tangential edge constraints for the edges of a face $\mathcal{F}^l$, we can choose six functionals, denoted by $f_m^l(\cdot)$, $m = 1, 2, \ldots, 6$, such that if $f_m^l(\mathbf{r}) = 0, m = 1, 2, \ldots, 6$, for a rigid body mode $\mathbf{r}$, then $\mathbf{r}$ must vanish. Once this has been established, the g_k of Definition 2 can be chosen as linear combinations of these f_m^l.

Let us, without loss of generality, consider a face $\mathcal{F}^l$ which is part of the $x_1 - x_2$ plane and let $\hat{\mathbf{x}} = 0$. Since we have weighted edge average constraints in (35) for the third component over all, i.e., at least three edges of the face, we can conclude that the third component of the rigid body mode $\mathbf{r}$ must vanish at three or more points which are not colinear; we recall that we have assumed that all faces are convex. We denote the three corresponding edge normal continuity functionals by $f_m^l(\cdot)$, $m = 3, 5, 6$. Since this third component of $\mathbf{r}$ is a linear combination of the third component of the three basis elements $\mathbf{r}_3$, $\mathbf{r}_5$, and $\mathbf{r}_6$, the rigid body mode $\mathbf{r}$ cannot have any component involving these three basis elements. The remaining part is a linear combination of $\mathbf{r}_1$, $\mathbf{r}_2$, and $\mathbf{r}_4$, i.e., effectively a rigid body mode in two dimensions. It has the form of a first order Nédélec element on the face,

$$\mathbf{r} = \begin{bmatrix} a_1 + bx_2 \\ a_2 - bx_1 \\ 0 \end{bmatrix}, \tag{42}$$

where a_1, a_2, and b are the three remaining degrees of freedom of the rigid body mode for this two-dimensional surface.

We will now show that the tangential edge constraints will make it possible to conclude that $a_1 = a_2 = b = 0$. It is known, and easy to show, that the first order

Nédélec elements have a constant tangential component on each edge. It is then easy to see that any three edge tangential constraints will make it possible to conclude that the remaining rigid body components must vanish; these three selected edge tangential continuity functionals, $f_m^l(\cdot)$, $m = 1, 2, 4$, complete the set of functionals. ∎

We note that one can also check numerically if the normal face and edge constraints (34) and (35) will, in themselves, make a face fully primal. What matters is if a full dual basis can be constructed when these functionals are restricted to the space of rigid body motions.

We end this section by discussing the need for edge tangential constraints; this discussion concerns only the final three constraints. By a relatively simple computation, we can show that only two tangential edge constraints on two adjacent edges are needed for each face $\mathcal{F}^l$ to make it fully primal; the third one can be replaced by an already existing edge normal continuity constraint. One can also show that these two edge tangential continuity constraints are not always necessary and that one will suffice at times. To understand why tangential constraints appear to be required in some cases, we consider a face with three edges only and with constant weights. Then, by the divergence theorem and the fact that the rigid body modes are divergence free, we have linear dependence since the integral of the normal component over one edge equals the negative of the sum over the integrals over the other two. A simple computation reveals that the rank is also two for a rectangular face. In such a case, at least one tangential continuity constraint will be needed to make such a face fully primal.

8. Connections with the FETI-DP algorithms. In the FETI-DP algorithms developed in [27] for incompressible Stokes equations, the subdomain problems are also assembled only at the coarse level, primal velocity degrees of freedom, which are shared by neighboring subdomains. Lagrange multipliers are then introduced on the interface to enforce the continuity of the dual velocity variables, by requiring that $B_\Delta \mathbf{u}_\Delta = \sum_{i=1}^N B_\Delta^{(i)} \mathbf{u}_\Delta^{(i)} = 0$. Here, the subdomain matrices $B_\Delta^{(i)}$ have elements chosen from the set $\{0, 1, -1\}$. The original problem is then reduced to a linear system for the Lagrange multipliers by eliminating the other variables; cf. [27]. The FETI-DP operator for the Lagrange multipliers is $B_\Delta \widetilde{S}_\Delta^{-1} B_\Delta^T$, where the operator $\widetilde{S}_\Delta$ is defined by $\widetilde{S}_\Delta^{-1} = R_\Delta \widetilde{S}^{-1} R_\Delta^T$ and R_Δ is the restriction map from $\widetilde{\mathbf{W}}_\Gamma \times Q_0$ to $\mathbf{W}_\Delta$.

The preconditioner used in [27] for the FETI-DP algorithm is $B_{D,\Delta} S_\Delta B_{D,\Delta}^T$, where $B_{D,\Delta}$ is constructed from the subdomain operators $B_{D,\Delta}^{(i)}$ in the same way as B_Δ from the $B_\Delta^{(i)}$; a constant scaling factor was used for $B_{D,\Delta}^{(i)}$ for two-dimensional problems. In general, $B_{D,\Delta}^{(i)}$ is defined as follows: each nonzero element of $B_\Delta^{(i)}$ corresponds to a Lagrange multiplier connecting the subdomain Ω_i to a neighboring subdomain Ω_j at a point $x \in \partial\Omega_{i,h} \cap \partial\Omega_{j,h}$. Multiplying each such element with the positive scaling factor $\delta_j^\dagger(x)$ gives us $B_{D,\Delta}^{(i)}$. S_Δ is the direct sum of subdomain Schur operators $S_\Delta^{(i)}$, which are defined on the dual subdomain velocity space $\mathbf{W}_\Delta^{(i)}$ as the $S_\Gamma^{(i)}$ in (8), except that the operator is restricted to the dual interface velocity variables; S_Δ can be written as the restriction of the operator $\widetilde{S}$ to the space $\mathbf{W}_\Delta$, i.e., $S_\Delta = R_\Delta \widetilde{S} R_\Delta^T$.

Therefore, the preconditioned FETI-DP operator can be written as

$$B_{D,\Delta} R_\Delta \widetilde{S} R_\Delta^T B_{D,\Delta}^T B_\Delta R_\Delta \widetilde{S}^{-1} R_\Delta^T B_\Delta^T. \tag{43}$$

Since the diagonal blocks corresponding to the dual interface velocity part in $\mathbf{W}_\Delta$ of the matrices $\widetilde{S}$ and $\widetilde{S}^{-1}$ are positive definite, both $R_\Delta \widetilde{S} R_\Delta^T$ and $R_\Delta \widetilde{S}^{-1} R_\Delta^T$ are positive definite. When nonredundant Lagrange multipliers are used, the matrices B_Δ^T

and $B_{D,\Delta}^T$ are of full rank and the FETI-DP operator (43) is therefore a product of two positive definite matrices; cf. [37, section 6.4]. If redundant Lagrange multipliers are used, as in [22, 37], then B_Δ^T will not be of full rank. But this does not matter; the Lagrange multiplier is always restricted to $\mathbf{range}\,(B_\Delta)$, which is orthogonal to the null space of B_Δ^T (cf. [22]).

We now introduce the operator $P_D = R_\Delta^T B_{D,\Delta}^T B_\Delta R_\Delta$, which maps the space $\widetilde{\mathbf{W}}_\Gamma \times Q_0$ into itself. It computes the jump across the subdomain interface of the dual interface velocity component, and maps any element in the primal space $\widehat{\mathbf{W}}_\Pi \times Q_0$ to zero; cf. [29]. It can then be verified that E_D and P_D are complementary projectors with $E_D + P_D = I$ and $E_D P_D = P_D E_D = 0$; cf. [29, Lemma 1].

Since, for any two matrices Z and T, the nonzero eigenvalues of the two products ZT and TZ—assuming that they both exist—are the same, we know that the preconditioned FETI-DP operator (43) has the same nonzero eigenvalues as the operator $P_D^T \widetilde{S} P_D \widetilde{S}^{-1}$, where we have moved the last factor $R_\Delta^T B_\Delta^T$ of (43) to the front. The preconditioned BDDC operator $M^{-1}\widehat{S}$, which is $\widetilde{R}_D^T \widetilde{S}^{-1} \widetilde{R}_D \widetilde{R}^T \widetilde{S} \widetilde{R}$, has the same nonzero eigenvalues as $E_D \widetilde{S}^{-1} E_D^T \widetilde{S}$, where we have moved the last factor $\widetilde{R}$ to the front. We can then prove, just as in the elliptic case (see [29]) that $P_D^T \widetilde{S} P_D \widetilde{S}^{-1}$ and $E_D \widetilde{S}^{-1} E_D^T \widetilde{S}$ have the same nonzero eigenvalues with the possible exception of 1. We obtain the following theorem.

THEOREM 8.1. *Let Assumption* 1 *hold. The preconditioned FETI-DP and BDDC operators, given by* (43) *and* $M^{-1}\widehat{S}$*, respectively, have the same nonzero eigenvalues with the possible exception of* 1*.*

This is the same result as for the positive definite elliptic problems; cf. [31, 11, 29, 3].

9. Numerical experiments. We solve a lid-driven-cavity problem on the domain $\Omega = [0,1] \times [0,1]$ with the Dirichlet boundary condition, where the velocity is $(1,0)$ on the upper side and vanishes on the other three sides. We use a uniform mesh, as in Figure 1. The mixed finite elements are also indicated in Figure 1; the velocity is continuous and linear in each element, and the pressure is constant on macroelements which are unions of four triangles. The inf-sup stability of these mixed finite elements can easily be proved by using the macroelement technique developed in [36].

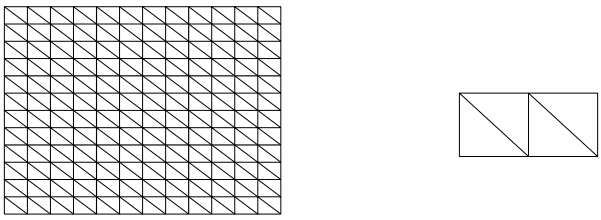

FIG. 1. *The mesh and the mixed finite elements.*

Both the BDDC and FETI-DP algorithms have been tested. The preconditioned conjugate gradient method is used and the iteration is halted when the L^2-norm of the residual has been reduced by a factor 10^{-6}. In our experiments, we have used three different sets of primal constraints. The first two satisfy both Assumptions 1 and 2 and we see that both the BDDC and FETI-DP operators are positive definite and that the results are fully consistent with our theory. Our third choice violates Assumption 1 and the BDDC operator is then no longer positive definite.

TABLE 1

Spectral bounds and iteration counts for a pair of BDDC and FETI-DP algorithms, with different numbers of subdomains, for $H/h = 8$ and a primal space spanned by both corner and normal edge basis functions.

20×20	1.00	2.65	9	1.00	2.65	10

In the first case, the primal velocity space is spanned by the subdomain vertex nodal basis functions for both components and by a constant vector in the direction normal to the edge for each interface edge as in (32). From Tables 1 and 2, we see that the preconditioned BDDC and FETI-DP operators are both positive definite and quite well conditioned as established in Theorems 6.7 and 8.1. We observe that the extreme eigenvalues and the iteration counts of the BDDC and FETI-DP algorithms match very well, and that the condition numbers of both algorithms are independent of the number of subdomains and increase only slowly with the number of elements across each subdomain, all as predicted by the theory. In our experiments, the extreme eigenvalues are estimated by using the tridiagonal Lanczos matrix generated by the preconditioned conjugate gradient method.

In the experiments of Tables 3 and 4, the integrals of both velocity components are required to have common values across each interface edge. The subdomain corner degrees of freedom are also chosen as primal variables as in the first case. Both Assumptions 1 and 2 are again satisfied and we observe similar, slightly faster convergence compared with the first experiments since the primal, coarse level problem has been enlarged.

In Tables 5 and 6, the primal velocity space is spanned only by the corner basis

TABLE 4

Spectral bounds and iteration counts for a pair of BDDC and FETI-DP algorithms, with different H/h, for 4×4 subdomains and a primal space spanned by both corner and two edge basis functions for each edge.

16			19	0.48	5.13	19
32			21	0.48	6.99	21

functions; Assumption 1, then, does not hold. In this case, the preconditioned BDDC operator is no longer positive definite and the iterates will no longer stay in the benign space of the saddle-point problem. However, the FETI-DP operator (43) is still positive definite. The interface problems of both the BDDC and the FETI-DP algorithms are solved by a preconditioned conjugate gradient method, but the residual norm of the BDDC methods is no longer strictly decreasing. We see that the iteration counts of the BDDC and FETI-DP algorithms still match very well, but that for both algorithms this count will now depend on the number of subdomains as well as on the number of elements across each subdomain. These results are less satisfactory than those of the previous two choices of primal constraints.

CONVERGENCE ANALYSIS OF THE ENERGY AND HELICITY PRESERVING SCHEME FOR AXISYMMETRIC FLOWS*

JIAN-GUO LIU† AND WEI-CHENG WANG‡

Abstract. We give an error estimate for the energy and helicity preserving scheme (EHPS) in second order finite difference setting on axisymmetric incompressible flows with swirling velocity. This is accomplished by a weighted energy estimate, along with careful and nonstandard local truncation error analysis near the geometric singularity and a far field decay estimate for the stream function. A key ingredient in our a priori estimate is the permutation identities associated with the Jacobians, which are also a unique feature that distinguishes EHPS from standard finite difference schemes.

Key words. incompressible viscous flow, Navier–Stokes equation, pole singularity, conservative scheme, Jacobian, permutation identity, geometric singularity

1. Introduction.

Axisymmetric flow is an important subject in fluid dynamics and has become standard textbook material (e.g., [2]) as a starting point of theoretical study for complicated flow patterns. Although the number of independent spatial variables is reduced by symmetry, some of the essential features and complexities of generic three-dimensional (3D) flows remain. For example, when the swirling velocity is nonzero, there is a vorticity stretching term present. This is widely believed to account for possible singularity formation for Navier–Stokes and Euler flows. For general smooth initial data, it is well known that the solution remains smooth for a short time in Euler [8] and Navier–Stokes flows [9]. A fundamental regularity result concerning the solution of the Navier–Stokes equation (NSE) is given in the pioneering work of Caffarelli, Kohn, and Nirenberg [3]: The 1D Hausdorff measure of the singular set is zero. As a consequence, the only possible singularity for axisymmetric Navier–Stokes flows would be on the axis of rotation. This result has motivated subsequent research activities concerning the regularity of axisymmetric solutions of the NSE. Some regularity and partial regularity results for axisymmetric Euler and Navier–Stokes flows can be found, for example, in [4] and the references therein. To date, the regularity of the Navier–Stokes and Euler flows, whether axisymmetric or not, remains a challenging open problem. For a comprehensive review of the regularity of the NSE, see [10] and the references therein.

Due to the subtle regularity issue, the numerical simulation of axisymmetric flows is also a challenging subject for computational fluid dynamicists. The earliest attempt at a numerical search for potential singularities of axisymmetric flows dates back to the 90s [5, 6]. In a recent work [11], the authors have developed a class of energy and helicity preserving schemes (EHPS) for incompressible Navier–Stokes and MHD

equations. There the authors extended the vorticity-stream formulation of axisymmetric flows given in [5] and proposed a generalized vorticity-stream formulation for 3D Navier–Stokes and MHD flows with coordinate symmetry. In the case of axisymmetric flows, the major difference between EHPS and the formulation in [5] is the expression and numerical discretization of the nonlinear terms. It is shown in [11] that all the nonlinear terms in the Navier–Stokes and MHD equation, including convection, vorticity stretching, geometric source, Lorentz force, and electro-motive force, can be written as Jacobians. Associated with the Jacobians is a set of permutation identities which leads naturally to the conservation laws for first and second moments. The primary feature of the EHPS is the numerical realization of these conservation laws. In addition to preserving physically relevant quantities, the discrete form of conservation laws provides numerical advantages as well. In particular, the conservation of energy automatically enforces nonlinear stability of EHPS. For 2D flows, EHPS is equivalent to the energy and enstrophy preserving scheme of Arakawa [1], who first pointed out the importance of discrete conservation laws in long time numerical simulations.

Other than the Jacobian approach, most of the energy conserving finite difference schemes for standard flows (without geometric singularity) are based on discretization of the fluid equation in primitive variables. A well-known trick that dates back to the 70s is to take the average of conservative and nonconservative discretizations of convection term (Piacsek and Williams [16]). In [14], Morinishi et al. further explored and compared various combinations among conservative, nonconservative, and rotation forms of the convection term. More recently in [18], Verstappen and Veldman proposed a discretization for the convection term that resulted in a skew-symmetric difference operator and therefore the conservation of energy could be achieved.

A potential difficulty associated with axisymmetric flows is the appearance of a $\frac{1}{r}$ factor which becomes infinite at the axis of rotation, and therefore sensitive to inconsistent or low order numerical treatment near this "pole singularity." In [11], the authors proposed a second order finite difference scheme and handled the pole singularity by shifting the grids a half-grid length away from the origin. Remarkably, the permutation identities and therefore the energy and helicity identities remain valid in this case. There are alternative numerical treatments proposed in literatures (e.g., [6]) to handle this coordinate singularity. However, rigorous justifications for various pole conditions are yet to be established.

The purpose of this paper is to give a rigorous error estimate of EHPS for axisymmetric flows. To focus on the pole singularity and avoid complication caused by physical boundary conditions, we consider here only the whole space problem with the swirling components of velocity and vorticity decaying fast enough at infinity. The error analysis of numerical methods for NSE with nonslip physical boundary condition has been well studied. We refer the works of Hou and Wetton [7] and Wang and Liu [19] to interested readers. Our proof is based on a weighted energy estimate along with a careful and detailed pointwise local truncation error analysis. A major ingredient in our energy estimate is the permutation identities associated with the Jacobians (4.17). These identities are key to the energy and helicity preserving property of EHPS for general symmetric flows. Here the same identities enable us to obtain a priori estimate even in the presence of the pole singularity; see section 5 for details. To our knowledge, this is the first rigorous convergence proof for finite difference schemes devised for axisymmetric flows.

In our pointwise local truncation error estimate, a fundamental issue is the identification of smooth flows in the vicinity of the pole. Using a symmetry argument,

it can be shown [12] that if the swirling component is even in r (or more precisely, is the restriction of an even function on $r > 0$), the vector field is in fact singular. See Example 1 in section 2 for details. This is an easily overlooked mistake that even appeared in some research papers targeted at numerical search for potential formation of finite time singularities. In addition to the regularity issue at the axis of symmetry, a refined decay estimate for the stream function also plays an important role in our analysis. In general, the stream function only decays as $O((x^2 + r^2)^{-1})$ at infinity. Accordingly, we have selected an appropriate combination of weight functions that constitute an r-homogeneous norm. As a result, the slow decay of the stream function is compensated by the fast decay of velocity and vorticity. Overall, we obtained a second order error estimate on axisymmetric flows.

The rest of this paper is organized as follows: In section 2, we give a brief review of the regularity results developed in [12], including the characterization of pole regularity for general axisymmetric solenoidal vector fields and solutions of the axisymmetric NSE (2.2). In section 3, we formulate a regularity assumption on the solution of NSE at infinity. We basically assume that the swirling components of velocity and vorticity decay fast enough at infinity, and use this to analyze the decay rate of the stream function. In section 4, we briefly review the energy and helicity preserving property for EHPS and use it to prove our main theorem by energy estimate in section 5. The proof of some technical lemmas is given in the Appendix.

2. Generalized vorticity-stream formulation for axisymmetric flows. In this section, we review the generalized vorticity-stream formulation of axisymmetric NSE

$$\begin{aligned} &\partial_t \boldsymbol{u} + (\nabla \times \boldsymbol{u}) \times \boldsymbol{u} + \nabla p = -\nu \nabla \times \nabla \times \boldsymbol{u} \\ &\nabla \cdot \boldsymbol{u} = 0 \end{aligned} \tag{2.1}$$

and related regularity issues.

Denoting by the x-axis the axis of symmetry, the axisymmetric NSE in the cylindrical coordinate system $x = x$, $y = r\cos\theta$, $z = r\sin\theta$ can be written as [11]

$$\begin{aligned} &u_t + \tfrac{1}{r^2} J\left(ru, r\psi\right) = \nu(\nabla^2 - \tfrac{1}{r^2})u\,, \\ &\omega_t + J\left(\tfrac{\omega}{r}, r\psi\right) = \nu(\nabla^2 - \tfrac{1}{r^2})\omega + J\left(\tfrac{u}{r}, ru\right)\,, \\ &\omega = -(\nabla^2 - \tfrac{1}{r^2})\psi\,, \end{aligned} \tag{2.2}$$

where $J(a,b) = (\partial_x a)(\partial_r b) - (\partial_r a)(\partial_x b)$.

In (2.2), $u(t;x,r)$, $\omega(t;x,r)$, and $\psi(t;x,r)$ represent the swirling components of velocity, vorticity, and stream function, respectively. The quantity $r\psi$ is also known as Stokes' stream function and the formal correspondence between the solutions of (2.1) and (2.2) is given by

$$\boldsymbol{u} = u\boldsymbol{e}_\theta + \nabla \times (\psi \boldsymbol{e}_\theta) = \frac{\partial_r(r\psi)}{r}\boldsymbol{e}_x - \partial_x \psi \boldsymbol{e}_r + u\boldsymbol{e}_\theta, \tag{2.3}$$

where $\boldsymbol{e}_x$, $\boldsymbol{e}_r$, and $\boldsymbol{e}_\theta$ are the unit vectors in the x, r, and θ directions, respectively. The vorticity-stream formulation (2.2) has appeared in [5] with an alternative expression for the nonlinear terms. In [11], the authors have generalized the vorticity formulation to general symmetric flows with the nonlinear terms recast in Jacobians as in (2.2) and proposed a class of EHPS based on discretizing (2.2). In sections 4 and 5, we will review EHPS for (2.2) and give a rigorous error estimate in second order finite

difference setting. The error bound certainly depends on the regularity of the solution to (2.2). Although (2.2) can be derived formally from (2.1), the equivalence between the two expressions in terms of regularity of solutions is not quite obvious. An essential prerequisite to our analysis is to characterize the proper meaning of "smoothness" of solutions to (2.2). This turns out to be a subtle issue.

Example 1. Take

$$u(x,r) = r^2 e^{-r}, \qquad \omega = \psi \equiv 0. \tag{2.4}$$

It is easy to verify that (2.4) is an *exact* stationary solution of the Euler equation ($\nu = 0$ in (2.2)). Note that $u = O(r^2)$ near the axis and $\partial_r^2 u(x, 0^+) \neq 0$. Similar functions can be found in literatures as initial data in numerical search for finite time singularities. Although $u \in C^\infty(R \times \overline{R^+})$, the following regularity lemma for general axisymmetric solenoidal vector fields shows that $\boldsymbol{u} = u\boldsymbol{e}_\theta$ is not even in $C^2(R^3, R^3)$.

LEMMA 1 (see [12]). *Denote the axisymmetric divergence free subspace of C^k vector fields by*

$$\mathcal{C}_s^k \overset{def}{=} \{\boldsymbol{u} \in C^k(R^3, R^3), \quad \partial_\theta u_x = \partial_\theta u_r = \partial_\theta u_\theta = 0, \quad \nabla \cdot \boldsymbol{u} = 0\}. \tag{2.5}$$

Then

(a) *for any $\boldsymbol{u} \in \mathcal{C}_s^k$, there exists a unique (u, ψ) such that*

$$\boldsymbol{u} = u\boldsymbol{e}_\theta + \nabla \times (\psi \boldsymbol{e}_\theta) = \frac{\partial_r(r\psi)}{r}\boldsymbol{e}_x - \partial_x \psi \boldsymbol{e}_r + u\boldsymbol{e}_\theta, \qquad r > 0, \tag{2.6}$$

with

$$u(x,r) \in C^k(R \times \overline{R^+}), \quad \partial_r^{2\ell} u(x, 0^+) = 0 \text{ for } 0 \leq 2\ell \leq k, \tag{2.7}$$

and

$$\psi(x,r) \in C^{k+1}(R \times \overline{R^+}), \quad \partial_r^{2\ell} \psi(x, 0^+) = 0 \text{ for } 0 \leq 2\ell \leq k+1. \tag{2.8}$$

(b) *If (u, ψ) satisfies* (2.7), (2.8) *and $\boldsymbol{u}$ is given by* (2.6) *for $r > 0$, then $\boldsymbol{u} \in \mathcal{C}_s^k$ with a removable singularity at $r = 0$.*

Here in (2.5) and throughout this paper, the subscripts of u are used to denote components rather than partial derivatives. The proof of Lemma 1 is based on the observation that $\boldsymbol{e}_\theta$ changes direction across the axis of symmetry; therefore $u = u_\theta$ must admit an odd extension in order to compensate for this discontinuity. The details can be found in [12].

For simplicity of presentation, we recast Lemma 1 as follows.

LEMMA 1′.

$$\mathcal{C}_s^k = \{u\boldsymbol{e}_\theta + \nabla \times (\psi \boldsymbol{e}_\theta) \,|\, u \in C_s^k(R \times \overline{R^+}),\ \psi \in C_s^{k+1}(R \times \overline{R^+})\}, \tag{2.9}$$

where

$$C_s^k\left(R \times \overline{R^+}\right) \overset{def}{=} \left\{ f(x,r) \in C^k\left(R \times \overline{R^+}\right), \quad \partial_r^{2j} f(x, 0^+) = 0,\ 0 \leq 2j \leq k \right\}. \tag{2.10}$$

From Lemma 1 and Example 1, it is clear that the proper meaning of the smooth solution to (2.2) should be supplemented by the pole conditions (2.7), (2.8). In the case of NSE ($\nu > 0$), our main concern in this paper, (2.2) is an elliptic-parabolic

system on a semibounded region ($r > 0$). From standard PDE theory, we need to assign one and only one boundary condition for each of the variables ψ, u, and ω. An obvious choice is the zeroth order part of the pole conditions (2.7), (2.8):

$$\psi(x,0) = u(x,0) = \omega(x,0) = 0. \tag{2.11}$$

It is therefore a natural question to ask whether a smooth solution of (2.2), (2.11) in the class

$$\begin{aligned} &\psi(t;x,r) \in C^1\left(0,T;C^{k+1}(R\times\overline{R^+})\right),\\ &u(t;x,r) \in C^1\left(0,T;C^{k}(R\times\overline{R^+})\right),\\ &\omega(t;x,r) \in C^1\left(0,T;C^{k-1}(R\times\overline{R^+})\right) \end{aligned} \tag{2.12}$$

will give rise to a smooth solution of (2.2). In other words, is the pole condition (2.7), (2.8) automatically satisfied if only the zeroth order part (2.11) is imposed?

The answer to this question is affirmative.

THEOREM 1 (see [12]).

(a) *If $(\boldsymbol{u},p)$ is an axisymmetric solution to (2.1) with $\boldsymbol{u} \in C^1(0,T;\mathcal{C}_s^k)$, $p \in C^0(0,T;C^{k-1}(R^3))$, and $k \geq 3$, then there is a solution (ψ,u,ω) to (2.2) in the class*

$$\begin{aligned} &\psi(t;x,r) \in C^1\left(0,T;C_s^{k+1}(R\times\overline{R^+})\right),\\ &u(t;x,r) \in C^1\left(0,T;C_s^{k}(R\times\overline{R^+})\right),\\ &\omega(t;x,r) \in C^1\left(0,T;C_s^{k-1}(R\times\overline{R^+})\right), \end{aligned} \tag{2.13}$$

and $\boldsymbol{u} = u\boldsymbol{e}_\theta + \nabla\times(\psi\boldsymbol{e}_\theta)$.

(b) *If (ψ,u,ω) is a solution to (2.2), (2.11) in the class (2.12) with $k \geq 3$, then (ψ,u,ω) is in the class (2.13), $\boldsymbol{u} \overset{def}{=} u\boldsymbol{e}_\theta + \nabla\times(\psi\boldsymbol{e}_\theta) \in C^1(0,T;\mathcal{C}_s^k)$, and there is an axisymmetric scalar function $p \in C^0(0,T;C^{k-1}(R^3))$ such that $(\boldsymbol{u},p)$ is a solution to (2.1).*

The proof of Theorem 1 can be found in [12]. We remark here that Theorem 1 not only establishes the equivalence between (2.1) and (2.2) for classical solutions; the fact that smooth solutions to (2.2) automatically satisfy the pole condition (2.13) is also crucial to our local truncation error analysis. See the appendix for details.

3. Regularity assumption on solutions of NSE at infinity. The focus of this paper is the convergence rate of EHPS in the presence of the pole singularity. To separate difficulties and avoid complications introduced by physical boundaries, we only consider the whole space problems with solutions decaying rapidly at infinity.

To be more specific, we restrict our attention to the case where the supports of the initial data $u(x,0)$ and $\omega(x,0)$ are essentially compact. Since (2.2) is a transport diffusion equation for u and ω with initially finite speed of propagation, we expect u and ω to be essentially compactly supported, at least for short time. In the case of *linear* transport diffusion equations, the solution together with its derivatives will then decay faster than polynomials at infinity for $t > 0$. Some rigorous results concerning the spatial decay rate for the solutions of axisymmetric flows can be found in [4] and the references therein. In particular, it is shown in [4] that both u and ω decay algebraically at infinity as long as this is the case initially. Here we make a stronger

yet plausible assumption along this direction. The precise form of our assumption is formulated in terms of weighted norms and is less stringent than the analogy we draw from linear transport diffusion equations; see Assumption 1 below.

To quantify our assumption, we first introduce a family of r-homogeneous composite norms and corresponding function spaces which turn out to be natural for our pointwise energy estimate.

DEFINITION 1.

$$\|a\|_{\ell,\alpha,\beta} = \sum_{\ell_1+\ell_2=\ell} \| (1+r)^{\alpha}(1+|x|)^{\beta}|\partial_x^{\ell_1}\partial_r^{\ell_2}\left(\frac{a}{r}\right)| \|_{L^{\infty}(R\times\overline{R^+})}, \tag{3.1}$$

$$|\!|\!| a |\!|\!|_{k,\alpha,\beta} = \sum_{0\le\ell\le k} \|a\|_{k-\ell,\alpha-\ell,\beta}. \tag{3.2}$$

Note that the norms (3.1), (3.2) are well defined for functions in $C_s^k(R\times\overline{R^+})$ that decay properly at infinity. We denote them by

$$C_s^{k,\alpha,\beta} = \left\{ a(x,r) \in C_s^k\left(R\times\overline{R^+}\right), |\!|\!| a |\!|\!|_{k,\alpha,\beta} < \infty \right\}. \tag{3.3}$$

In section 5, we will show that EHPS is second order accurate provided the solution satisfies

$$\begin{cases} (\psi,\omega) \in C^1\left(0,T; C_s^{4,\alpha+\frac{7}{2},\beta} \cap C_s^{4,2\alpha+2,2\beta}\right), \\ u \in C^1\left(0,T; C_s^{4,2\alpha+2,2\beta} \cap C_s^{1,2,0}\right), \end{cases} \qquad \alpha > \frac{1}{2},\ \beta > \frac{1}{4}. \tag{3.4}$$

In view of (3.4), we formulate our regularity assumption as follows.

Assumption 1.

$$(\psi,\omega) \in C^1\left(0,T; C_s^{4,\gamma,\delta}\right), \quad u \in C^1\left(0,T; C_s^{4,5,\delta}\right), \quad \gamma > 4,\ \delta > \frac{1}{2}. \tag{3.5}$$

Although we expect u, ω and their derivatives to decay faster than any polynomial at infinity, the same expectation is not realizable for ψ. As we will see, generically ψ only decays like $O((x^2+r^2)^{-1})$ at infinity. Nevertheless, we will show that Assumption 1 is still realizable if ω decays fast enough.

To analyze the decay rate of ψ, we start with the integral expression for ψ. From the vorticity-stream relation

$$\nabla\times\nabla\times\boldsymbol{\psi} = \boldsymbol{\omega}$$

and the identification

$$\psi(x,r) = \psi_z(x,y,z)|_{y=r,z=0}, \qquad \omega(x,r) = \omega_z(x,y,z)|_{y=r,z=0},$$

one can derive the following integral formula for ψ [17]:

$$\psi(x,r) = \int_0^{\infty}\int_{-\infty}^{\infty} \omega(x',r')K(x-x',r,r')dx'dr', \tag{3.6}$$

where

$$\begin{aligned} K(x-x',r,r') &= r'\tfrac{1}{4\pi}\int_0^{2\pi} \frac{\cos\theta}{\sqrt{(x-x')^2+(r-r'\cos\theta)^2+(r'\sin\theta)^2}}d\theta \\ &= r'^2\tfrac{2}{\pi}\int_0^{\frac{\pi}{2}} \frac{r\cos^2\theta}{\rho_+\rho_-(\rho_++\rho_-)}d\theta \end{aligned} \tag{3.7}$$

and

$$\rho_\pm^2 = (x - x')^2 + (r \pm r' \cos\theta)^2 + (r' \sin\theta)^2.$$

As a consequence, we have the following far field estimate for K.

LEMMA 2.

$$|\partial_x^\ell \partial_r^m K(x - x', r, r')| \le C_{\ell,m}(x', r') \left(\sqrt{x^2 + r^2}\right)^{-2-\ell-m} \quad as \quad x^2 + r^2 \to \infty.$$

Proof. We will derive a far field estimate for the integrand in (3.7). We first consider a typical term

$$\lim_{x^2+r^2\to\infty} |\partial_x^\ell \partial_r^m \rho|$$

with

$$\rho^2 = (x - x_0)^2 + (r - r_0)^2 + c_0^2,$$

where x_0, r_0, and c_0 are some constants.

With the change of variables

$$\begin{aligned} r - r_0 &= \sigma \cos\lambda, \\ x - x_0 &= \sigma \sin\lambda, \end{aligned}$$

we can rewrite the x and r derivatives by

$$\begin{aligned} \partial_r \rho = \partial_r \sqrt{\sigma^2 + c_0^2} &= (\partial_r \sigma)\partial_\sigma \sqrt{\sigma^2 + c_0^2} + (\partial_r \lambda)\partial_\lambda \sqrt{\sigma^2 + c_0^2} = \tfrac{\sigma}{\rho} \cos\lambda, \\ \partial_x \rho = \partial_x \sqrt{\sigma^2 + c_0^2} &= (\partial_x \sigma)\partial_\sigma \sqrt{\sigma^2 + c_0^2} + (\partial_x \lambda)\partial_\lambda \sqrt{\sigma^2 + c_0^2} = \tfrac{\sigma}{\rho} \sin\lambda. \end{aligned}$$

Therefore by induction

$$\partial_x^\ell \partial_r^m \rho = P^{\ell,m}(\cos\lambda, \sin\lambda) Q^{\ell,m}(\sigma, \rho),$$

where $P^{\ell,m}(\cos\lambda, \sin\lambda)$ is a polynomial of degree $\ell+m$ in its arguments and $Q^{\ell,m}(\sigma, \rho)$ a rational function of σ and ρ of degree $1 - \ell - m$. By degree of a rational function we mean the degree of the numerator subtracting the degree of the denominator.

Since $\sigma = O(\sqrt{x^2 + r^2})$ and $\rho = O(\sqrt{x^2 + r^2})$, we conclude that

$$|\partial_x^\ell \partial_r^m \rho| = O\left(\sqrt{x^2 + r^2}^{1-\ell-m}\right).$$

We can now apply the argument above and Leibniz's rule to get

$$\partial_x^\ell \partial_r^m \frac{r}{\rho_+ \rho_- (\rho_+ + \rho_-)} = \sum_j^{J_{\ell,m}} \tilde{P}_j^{\ell,m}(\cos\lambda_+, \sin\lambda_+, \cos\lambda_-, \sin\lambda_-) \tilde{Q}_j^{\ell,m}(\sigma_+, \rho_+, \sigma_-, \rho_-, r),$$

where $J_{\ell,m}$ is a finite integer, $\sigma_\pm$ and $\rho_\pm$ are defined by

$$\begin{aligned} r \pm r' \cos\theta &= \sigma_\pm \cos\lambda_\pm, \\ x - x_0 &= \sigma_\pm \sin\lambda_\pm, \end{aligned}$$

and $\tilde{P}_j^{\ell,m}$, $\tilde{Q}_j^{\ell,m}$ are polynomials and rational functions of degrees $\ell + m$, $-2 - \ell - m$ in their arguments, respectively. The lemma follows by integrating θ over $(0, \frac{\pi}{2})$ in (3.7). ∎

We close this section by noting that ψ exhibits slow decay rate at infinity as a consequence of (3.6) and Lemma 2. More precisely, $\psi(x,r) \sim O((x^2+r^2)^{-1})$ in general. This may seem to raise the question whether Assumption 1 is realizable at all.

Indeed, using a similar calculation as in the proof of Lemma 2, one can derive the following.

PROPOSITION 1. *If $\gamma+\delta < k+2$ and $\omega \in C_s^{k,\gamma',\delta'}$ for sufficiently large γ' and δ', then $\psi \in C_s^{k,\gamma,\delta}$.*

As a consequence, we see that the range of γ and δ in (3.5) is not void provided ω decays fast enough at infinity. This justifies Assumption 1.

4. Energy and helicity preserving scheme. In this section, we outline the derivation of the discrete energy and helicity identities for EHPS. A key ingredient in the derivation is the reformulation of nonlinear terms into Jacobians. The details can be found in [11].

We introduce the standard notations:

$$D_x\phi(x,r) = \frac{\phi(x+\frac{\Delta x}{2},r)-\phi(x-\frac{\Delta x}{2},r)}{\Delta x}, \quad D_r\phi(x,r) = \frac{\phi(x,r+\frac{\Delta r}{2})-\phi(x,r-\frac{\Delta r}{2})}{\Delta r},$$

$$\tilde{D}_x\phi(x,r) = \frac{\phi(x+\Delta x,r)-\phi(x-\Delta x,r)}{2\Delta x}, \quad \tilde{D}_r\phi(x,r) = \frac{\phi(x,r+\Delta r)-\phi(x,r-\Delta r)}{2\Delta r},$$

and

$$\tilde{\nabla}_h = (\tilde{D}_x, \tilde{D}_r), \quad \tilde{\nabla}_h^\perp = (-\tilde{D}_r, \tilde{D}_x).$$

The finite difference approximation of ∇^2 and the Jacobians are given by

$$\nabla_h^2\psi = D_x\left(D_x\psi\right) + \frac{1}{r}\left(D_r(rD_r\psi)\right)$$

and

$$J_h(f,g) = \frac{1}{3}\left\{\tilde{\nabla}_h^\perp f\cdot\tilde{\nabla}_h g + \tilde{\nabla}_h^\perp\cdot(f\tilde{\nabla}_h g) + \tilde{\nabla}_h\cdot(g\tilde{\nabla}_h^\perp f)\right\}. \tag{4.1}$$

Altogether, the second order finite difference version of EHPS is

$$\begin{aligned} &\partial_t u_h + \tfrac{1}{r^2}J_h\left(ru_h, r\psi_h\right) = \nu(\nabla_h^2 - \tfrac{1}{r^2})u_h,\\ &\partial_t\omega_h + J_h\left(\tfrac{\omega_h}{r}, r\psi_h\right) = \nu(\nabla_h^2-\tfrac{1}{r^2})\omega_h + J_h\left(\tfrac{u_h}{r}, ru_h\right),\\ &\omega_h = (-\nabla_h^2+\tfrac{1}{r^2})\psi_h. \end{aligned} \tag{4.2}$$

To derive the discrete energy and helicity identity, we first introduce the discrete analogue of weighted inner products

$$\langle a,b\rangle_h = \sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}(rab)_{i,j}\,\Delta x\Delta r, \tag{4.3}$$

$$\begin{aligned}[a,b]_h = \Bigg(&\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\left(r(D_xa)(D_xb)\right)_{i-\frac{1}{2},j}\\ &+\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}{}'\left(r(D_ra)(D_rb)\right)_{i,j-\frac{1}{2}}\Bigg)\Delta x\Delta r + \langle\tfrac{a}{r},\tfrac{b}{r}\rangle_h, \end{aligned} \tag{4.4}$$

and the corresponding norms

$$\|a\|_{0,h}^2 = \langle a, a\rangle_h, \qquad \|a\|_{1,h}^2 = [a, a]_h, \tag{4.5}$$

where the grids have been shifted [13] to avoid placing the grid points on the axis of rotation:

$$x_i = i\Delta x, \quad i = 0, \pm 1, \pm 2, \ldots, \quad r_j = \left(j - \frac{1}{2}\right)\Delta r, \quad j = 1, 2, \ldots, \tag{4.6}$$

and

$$\sum_{j=1}^{\infty}{}' f_{j-\frac{1}{2}} = \frac{1}{2} f_{\frac{1}{2}} + \sum_{j=2}^{\infty} f_{j-\frac{1}{2}}. \tag{4.7}$$

The evaluation of the $\tilde{D}_r$ and ∇_h^2 terms in (4.2) at $j = 1$ involves the dependent variables u_h, ψ_h, ω_h and the stretching factor $h_3 = |\nabla\theta|^{-1} = r$ at the ghost points $j = 0$. In view of Lemma 1, we impose the following reflection boundary condition across the axis of rotation:

$$u_h(i, 0) = -u_h(i, 1), \quad \psi_h(i, 0) = -\psi_h(i, 1), \quad \omega_h(i, 0) = -\omega_h(i, 1). \tag{4.8}$$

Furthermore, we take even extension for the coordinate stretching factor $h_3 = |\nabla\theta|^{-1} = r$ which appears in the evaluation of the Jacobians at $j = 1$:

$$h_3(i, 0) = h_3(i, 1). \tag{4.9}$$

We will show in the remaining sections that the extensions (4.8) and (4.9) indeed give rise to a discrete version of energy and helicity identity and optimal local truncation error. As a consequence, second order accuracy of EHPS is justified for axisymmetric flows.

Remark 1. At first glance, the extension (4.9) may seem to contradict (4.6) on the ghost points $j = 0$. A less ambiguous restatement of (4.9) is to incorporate it into (4.2) as

(4.10)

$$\partial_t u_h + \tfrac{1}{r^2} J_h\left(|r|u_h, |r|\psi_h\right) = \nu(\nabla_h^2 - \tfrac{1}{r^2})u_h,$$

$$\partial_t \omega_h + J_h\left(\tfrac{\omega_h}{|r|}, |r|\psi_h\right) = \nu(\nabla_h^2 - \tfrac{1}{r^2})\omega_h + J_h\left(\tfrac{u_h}{|r|}, |r|u_h\right) \quad \text{on } (x_i, r_j), \quad j \geq 1,$$

$$\omega_h = (-\nabla_h^2 + \tfrac{1}{r^2})\psi_h.$$

The following identities are essential to the discrete energy and helicity identity and the error estimate.

LEMMA 3. *Suppose* (a, b, c) *satisfies the reflection boundary condition*

$$a(i, 0) = -a(i, 1), \quad b(i, 0) = -b(i, 1), \quad c(i, 0) = -c(i, 1)$$

and define

$$T_h(a, b, c) := \frac{1}{3}\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\left(c\tilde{\nabla}_h^{\perp} a \cdot \tilde{\nabla}_h b + a\tilde{\nabla}_h^{\perp} b \cdot \tilde{\nabla}_h c + b\tilde{\nabla}_h^{\perp} c \cdot \tilde{\nabla}_h a\right)_{i,j} \Delta x \Delta r. \tag{4.11}$$

Then

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty} c_{i,j}J_h(a,b)_{i,j}\Delta x\Delta r = T_h(a,b,c), \tag{4.12}$$

and

$$\left\langle a, \left(-\nabla_h^2 + \frac{1}{r^2}\right) b\right\rangle_h = [a,b]_h. \tag{4.13}$$

Proof. We first derive (4.12). In view of (4.1) and (4.11), it suffices to show that

$$\sum_j\sum_i c\tilde{\nabla}_h^{\perp}\cdot(a\tilde{\nabla}_h b) = -\sum_{i,j} a\tilde{\nabla}_h^{\perp}c\cdot\tilde{\nabla}_h b, \tag{4.14}$$

$$\sum_i\sum_j c\tilde{\nabla}_h\cdot(b\tilde{\nabla}_h^{\perp}a) = -\sum_{i,j} b\tilde{\nabla}_h c\cdot\tilde{\nabla}_h^{\perp}a \tag{4.15}$$

or, since there is no boundary terms in the x direction, simply

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}(f\tilde{D}_r g)_{i,j} = -\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}(g\tilde{D}_r f)_{i,j} \tag{4.16}$$

with $f = c$ and $g = b\tilde{D}_x a - a\tilde{D}_x b$.

Using the summation-by-parts identity (see, for example, [15] or [11]), it is straightforward to verify that

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}(f\tilde{D}_r g)_{i,j} = -\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}(g\tilde{D}_r f)_{i,j} - \sum_{i=-\infty}^{\infty}(f_{i,0}g_{i,1} + g_{i,0}f_{i,1}).$$

In the derivation of the discrete energy and helicity identities (see (4.18)–(4.20) below), a typical triplet (a,b,c) is given by, say, $a = r\psi_h$, $b = ru_h$, and $c = \frac{u_h}{r}$. From the reflection boundary condition (4.8) and (4.9), we see that

$$f_{i,0} = -f_{i,1}, \quad g_{i,0} = g_{i,1}.$$

This gives (4.16), and therefore (4.14), (4.15), and (4.12).

Next we derive (4.13). From the identity

$$\sum_{j=1}^{\infty} f_j(g_{j+\frac{1}{2}} - g_{j-\frac{1}{2}}) = -\sum_{j=1}^{\infty}{}'(f_j - f_{j-1})g_{j-\frac{1}{2}} - \frac{1}{2}(f_1 + f_0)g_{\frac{1}{2}}$$

and $r_{\frac{1}{2}} = 0$, it is easy to show that

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty} a_{i,j}D_r(rD_r b)_{i,j} = -\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}{}'(D_r a)_{i,j-\frac{1}{2}}r_{j-\frac{1}{2}}(D_r b)_{i,j-\frac{1}{2}}\,.$$

Therefore (4.13) follows. ∎

From (4.11), we can easily derive the permutation identities

$$T_h(a,b,c) = T_h(b,c,a) = T_h(c,a,b), \qquad T_h(a,b,c) = -T_h(b,a,c)\,. \tag{4.17}$$

Moreover, from (4.12), (4.13), it follows that

$$\langle \upsilon, \partial_t u_h\rangle_h + T_h(ru_h, r\psi_h, \tfrac{\upsilon}{r}) = \nu\langle \upsilon, (\nabla_h^2 - \tfrac{1}{r^2})u_h\rangle_h,$$

$$[\varphi, \partial_t \psi_h]_h + T_h(\tfrac{\omega_h}{r}, r\psi_h, r\varphi) = \nu\langle \varphi, (\nabla_h^2 - \tfrac{1}{r^2})\omega_h\rangle_h + T_h(\tfrac{u_h}{r}, ru_h, r\varphi), \tag{4.18}$$

$$\langle \xi, \omega_h\rangle_h = [\xi, \psi_h]_h$$

for all υ, φ, and ξ satisfying

$$\upsilon(i,0) = -\upsilon(i,1), \quad \varphi(i,0) = -\varphi(i,1), \quad \xi(i,0) = -\xi(i,1).$$

As a direct consequence of the permutation identity (4.17), we take $(\upsilon, \varphi) = (u_h, \psi_h)$ in (4.18) and recover the discrete energy identity

$$\frac{d}{dt}\frac{1}{2}(\langle u_h, u_h\rangle_h + [\psi_h, \psi_h]_h) + \nu([u_h, u_h]_h + \langle \omega_h, \omega_h\rangle_h) = 0. \tag{4.19}$$

Similarly, the discrete helicity identity

$$\frac{d}{dt}\langle u_h, \omega_h\rangle_h + \nu\left([u_h, \omega_h]_h - \left\langle \omega_h, \left(\nabla_h^2 - \frac{1}{r^2}\right)u_h\right\rangle_h\right) = 0 \tag{4.20}$$

follows by taking $(\upsilon, \varphi) = (\omega_h, u_h)$ in (4.18).

Remark 2. In the presence of physical boundaries, the no-slip boundary condition gives

$$\boldsymbol{u}\cdot\boldsymbol{n} = \partial_\tau(r\psi) = 0, \quad \boldsymbol{u}\cdot\boldsymbol{\tau} = \partial_n(r\psi) = 0, \quad \boldsymbol{u}\cdot\boldsymbol{e}_\theta = u = 0, \tag{4.21}$$

where $\boldsymbol{\tau} = \boldsymbol{n}\times\boldsymbol{e}_\theta$ and $\boldsymbol{e}_\theta$ is the unit vector in θ direction. When the cross section Ω is simply connected, (4.21) reads as follows:

$$u = 0, \quad \psi = 0, \quad \partial_n(r\psi) = 0 \quad \text{on} \quad \partial\Omega\,. \tag{4.22}$$

It can be shown that the energy and helicity identities (4.19), (4.20) remain valid in the presence of physical boundary conditions [11]. The numerical realization of the no-slip condition (4.22) introduced in [11] is second order accurate and seems to be new even for usual 2D flows. The convergence proof for this new boundary condition will be reported elsewhere.

5. Energy estimate and the main theorem. In this section, we proceed with the main theorem of the error estimate. We denote by $(\psi_h,\ u_h,\ \omega_h)$ the numerical solution satisfying

$$\begin{aligned}
&\partial_t u_h + \tfrac{1}{r^2}J_h(ru_h, r\psi_h) = \nu(\nabla_h^2 - \tfrac{1}{r^2})u_h,\\
&\partial_t \omega_h + J_h\left(\tfrac{\omega_h}{r}, r\psi_h\right) = \nu(\nabla_h^2 - \tfrac{1}{r^2})\omega_h + J_h\left(\tfrac{u_h}{r}, ru_h\right),\\
&\omega_h = (-\nabla_h^2 + \tfrac{1}{r^2})\psi_h,
\end{aligned} \tag{5.1}$$

and $(\psi,\ u,\ \omega)$ the exact solution to (2.2),

$$\begin{aligned}
&\partial_t u + \tfrac{1}{r^2}J_h(ru, r\psi) = \nu(\nabla_h^2 - \tfrac{1}{r^2})u + \mathcal{E}_1,\\
&\partial_t \omega + J_h\left(\tfrac{\omega}{r}, r\psi\right) = \nu(\nabla_h^2 - \tfrac{1}{r^2})\omega + J_h\left(\tfrac{u}{r}, ru\right) + \mathcal{E}_2,\\
&\omega = (-\nabla_h^2 + \tfrac{1}{r^2})\psi + \mathcal{E}_3,
\end{aligned} \tag{5.2}$$

where the local truncation errors $\mathcal{E}_j$ can be derived by subtracting (2.2) from (5.2):

$$\begin{aligned}
&\mathcal{E}_1 = \tfrac{1}{r^2}(J_h - J)(ru, r\psi) - \nu(\nabla_h^2 - \nabla^2)u,\\
&\mathcal{E}_2 = (J_h - J)\left(\tfrac{\omega}{r}, r\psi\right) - \nu(\nabla_h^2 - \nabla^2)\omega - (J_h - J)\left(\tfrac{u}{r}, ru\right),\\
&\mathcal{E}_3 = (\nabla_h^2 - \nabla^2)\psi.
\end{aligned} \tag{5.3}$$

From (5.1) and (5.2), we see that

$$\partial_t(u - u_h) + \frac{1}{r^2}\left(J_h(ru, r\psi) - J_h(ru_h, r\psi_h)\right) = \nu\left(\nabla_h^2 - \frac{1}{r^2}\right)(u - u_h) + \mathcal{E}_1, \tag{5.4}$$

$$\begin{aligned}
&\partial_t(\omega - \omega_h) + \left(J_h\left(\tfrac{\omega}{r}, r\psi\right) - J_h\left(\tfrac{\omega_h}{r}, r\psi_h\right)\right)\\
=\;& \nu(\nabla_h^2 - \tfrac{1}{r^2})(\omega - \omega_h) + \left(J_h\left(\tfrac{u}{r}, ru\right) - J_h\left(\tfrac{u_h}{r}, ru_h\right)\right) + \mathcal{E}_2,
\end{aligned} \tag{5.5}$$

$$(\omega - \omega_h) = \left(-\nabla_h^2 + \frac{1}{r^2}\right)(\psi - \psi_h) + \mathcal{E}_3. \tag{5.6}$$

Lemmas 4 and 5 below are key to our error estimate. The permutation identities (4.17) associated with EHPS result in exact cancellation among the nonlinear terms and lead to an exact identity (5.7). The estimates for the trilinear form in (5.13), (5.14) then furnish necessary inequalities for our a priori error estimate. The proof for Lemma 5 and the local truncation error analysis, Lemma 6, is given in the appendix.

LEMMA 4.

$$\begin{aligned}
&\tfrac{1}{2}\partial_t(\|u - u_h\|_{0,h}^2 + \|\psi - \psi_h\|_{1,h}^2) + \nu(\|u - u_h\|_{1,h}^2 + \|\omega - \omega_h\|_{0,h}^2)\\
&= \langle u - u_h, \mathcal{E}_1\rangle_h + \langle \psi - \psi_h, \mathcal{E}_2 - \partial_t\mathcal{E}_3\rangle_h + \nu\langle \omega - \omega_h, \mathcal{E}_3\rangle_h - T_h\left(\tfrac{u - u_h}{r}, r(u - u_h), r\psi\right)\\
&\quad - T_h\left(r(\psi - \psi_h), \tfrac{(\omega - \omega_h)}{r}, r\psi\right) + T_h\left(r(\psi - \psi_h), \tfrac{u}{r}, r(u - u_h)\right).
\end{aligned} \tag{5.7}$$

Proof. We take the weighted inner product of $u - u_h$ with (5.4) to get

$$\begin{aligned}
&\tfrac{1}{2}\partial_t\|u - u_h\|_{0,h}^2 + \langle u - u_h, \tfrac{1}{r^2}\left(J_h(ru, r\psi) - J_h(ru_h, r\psi_h)\right)\rangle_h\\
&= \nu\langle u - u_h, (\nabla_h^2 - \tfrac{1}{r^2})(u - u_h)\rangle_h + \langle u - u_h, \mathcal{E}_1\rangle_h.
\end{aligned} \tag{5.8}$$

The second term on the left-hand side of (5.8) can be rewritten as

$$\begin{aligned}
&\langle u - u_h, \tfrac{1}{r^2}\left(J_h(ru, r\psi) - J_h(ru_h, r\psi_h)\right)\rangle_h\\
&= T_h\left(\tfrac{u - u_h}{r}, ru, r\psi\right) - T_h\left(\tfrac{u - u_h}{r}, ru_h, r\psi_h\right)\\
&= -T_h\left(\tfrac{u - u_h}{r}, r(u - u_h), r(\psi - \psi_h)\right) + T_h\left(\tfrac{u - u_h}{r}, r(u - u_h), r\psi\right)\\
&\qquad + T_h\left(\tfrac{u - u_h}{r}, ru, r(\psi - \psi_h)\right).
\end{aligned} \tag{5.9}$$

In addition, from (4.13) we have

$$\nu\left\langle u - u_h, \left(\nabla_h^2 - \frac{1}{r^2}\right)(u - u_h)\right\rangle_h = -\nu[u - u_h, u - u_h]_h = -\nu\|u - u_h\|_{1,h}^2.$$

Thus

$$
\begin{aligned}
&\tfrac{1}{2}\partial_t\|u-u_h\|_{0,h}^2 - T_h\left(\tfrac{u-u_h}{r}, r(u-u_h), r(\psi-\psi_h)\right) + \nu\|u-u_h\|_{1,h}^2 \\
&= \langle u-u_h, \mathcal{E}_1\rangle_h - T_h\left(\tfrac{u-u_h}{r}, r(u-u_h), r\psi\right) - T_h\left(\tfrac{u-u_h}{r}, ru, r(\psi-\psi_h)\right).
\end{aligned} \tag{5.10}
$$

Similarly, we take the weighted inner product of $\psi-\psi_h$ with (5.5) and proceed as (5.9)–(5.10) to get

$$
\begin{aligned}
&\tfrac{1}{2}\partial_t\|\psi-\psi_h\|_{1,h}^2 + T_h\left(r(\psi-\psi_h), \tfrac{(\omega-\omega_h)}{r}, r\psi\right) \\
&= -T_h\left(r(\psi-\psi_h), \tfrac{(u-u_h)}{r}, r(u-u_h)\right) + T_h\left(r(\psi-\psi_h), \tfrac{u}{r}, r(u-u_h)\right) \\
&\quad + T_h\left(r(\psi-\psi_h), \tfrac{(u-u_h)}{r}, ru\right) + \langle \psi-\psi_h, \mathcal{E}_2 - \partial_t\mathcal{E}_3\rangle_h \\
&\quad + \nu\langle(\psi-\psi_h), (\nabla_h^2 - \tfrac{1}{r^2})(\omega-\omega_h)\rangle_h .
\end{aligned} \tag{5.11}
$$

Next, we apply (4.13) twice to get

$$
\begin{aligned}
\nu\left\langle(\psi-\psi_h), \left(\nabla_h^2 - \frac{1}{r^2}\right)(\omega-\omega_h)\right\rangle_h &= \nu\left\langle\left(\nabla_h^2 - \frac{1}{r^2}\right)(\psi-\psi_h), \omega-\omega_h\right\rangle_h \\
&= -\nu\|\omega-\omega_h\|_{0,h}^2 + \nu\langle\omega-\omega_h, \mathcal{E}_3\rangle_h,
\end{aligned} \tag{5.12}
$$

and (5.7) follows. This completes the proof of this lemma. ∎

We now proceed with the estimate for the trilinear form T_h.

LEMMA 5. *For a, b, and $c \in C_s^2(R\times\overline{R^+})$, we have*

$$
|T_h\left(ra, rb, \frac{c}{r}\right)| \le C\|a\|_{1,h}\|b\|_{1,h}|\!|\!|c|\!|\!|_{1,2,0} \tag{5.13}
$$

and

$$
|T_h\left(\frac{a}{r}, rb, rc\right)| \le C\|a\|_{0,h}\|b\|_{1,h}|\!|\!|c|\!|\!|_{2,2,0}. \tag{5.14}
$$

Proof. See section A.1. ∎

From Lemmas 4 and 5, we can therefore derive

$$
\begin{aligned}
&\tfrac{1}{2}\partial_t(\|u-u_h\|_{0,h}^2 + \|\psi-\psi_h\|_{1,h}^2) + \nu(\|u-u_h\|_{1,h}^2 + \|\omega-\omega_h\|_{0,h}^2) \\
\le\ & |\langle u-u_h, \mathcal{E}_1\rangle_h| + |\langle\psi-\psi_h, \mathcal{E}_2-\partial_t\mathcal{E}_3\rangle_h| + \nu|\langle\omega-\omega_h, \mathcal{E}_3\rangle_h| \\
&+ C\|u-u_h\|_{0,h}\|u-u_h\|_{1,h}|\!|\!|\psi|\!|\!|_{2,2,0} + C\|\omega-\omega_h\|_{0,h}\|\psi-\psi_h\|_{1,h}|\!|\!|\psi|\!|\!|_{2,2,0} \\
&+ C\|\psi-\psi_h\|_{1,h}\|u-u_h\|_{1,h}|\!|\!|u|\!|\!|_{1,2,0}.
\end{aligned} \tag{5.15}
$$

Since

$$
\|\frac{a}{r}\|_{0,h} \le \|a\|_{1,h},
$$

we can further estimate the first few terms on the right-hand side of (5.15) by

$$
|\langle u-u_h, \mathcal{E}_1\rangle_h| = |\left\langle\frac{u-u_h}{r}, r\mathcal{E}_1\right\rangle_h| \le \frac{\nu}{4}\|u-u_h\|_{1,h}^2 + \frac{1}{\nu}\|r\mathcal{E}_1\|_{0,h}^2,
$$

$$
|\langle\psi-\psi_h, \mathcal{E}_2-\partial_t\mathcal{E}_3\rangle_h| \le \|\psi-\psi_h\|_{1,h}^2 + \|r(\mathcal{E}_2-\partial_t\mathcal{E}_3)\|_{0,h}^2,
$$

and

$$|\langle \omega - \omega_h, \mathcal{E}_3 \rangle_h| \le \frac{1}{2}\|\omega - \omega_h\|_{0,h}^2 + \frac{1}{2}\|\mathcal{E}_3\|_{0,h}^2.$$

Applying Hölder's inequality to the remaining terms of (5.15), we have derived the following proposition.

PROPOSITION 2.

$$\begin{aligned}
&\tfrac{1}{2}\partial_t(\|u-u_h\|_{0,h}^2 + \|\psi-\psi_h\|_{1,h}^2) + \tfrac{\nu}{4}(\|u-u_h\|_{1,h}^2 + \|\omega-\omega_h\|_{0,h}^2) \\
&\le \|\psi-\psi_h\|_{1,h}^2 + \tfrac{C}{\nu}\|r\mathcal{E}_1\|_{0,h}^2 + \|r\mathcal{E}_2\|_{0,h}^2 + \|r\partial_t\mathcal{E}_3\|_{0,h}^2 \\
&\quad + \nu\|\mathcal{E}_3\|_{0,h}^2 + \tfrac{C}{\nu}\|u-u_h\|_{0,h}^2 |\!|\!| \psi |\!|\!|_{2,2,0}^2 \\
&\quad + \tfrac{C}{\nu}\|\psi-\psi_h\|_{1,h}^2 |\!|\!| \psi |\!|\!|_{2,2,0}^2 + \tfrac{C}{\nu}\|\psi-\psi_h\|_{1,h}^2 |\!|\!| u |\!|\!|_{1,2,0}^2.
\end{aligned} \tag{5.16}$$

With Proposition 2, it remains to estimate $\|r\mathcal{E}_1\|_{0,h}$, $\|r\mathcal{E}_2\|_{0,h}$, $\|r\partial_t\mathcal{E}_3\|_{0,h}$, and $\|\mathcal{E}_3\|_{0,h}$. We summarize the results in the following lemma.

LEMMA 6. *Let $(\psi, u, \omega) \in C^1(0,T;C_s^4)$ be a solution of the axisymmetric NSE* (2.2) *and $\mathcal{E}_1$, $\mathcal{E}_2$, $\mathcal{E}_3$ be defined by* (5.2). *Then we have the following pointwise local truncation error estimate for $\alpha, \beta \in R$:*

$$r|\mathcal{E}_1| \le C\frac{\Delta x^2 + \Delta r^2}{(1+r)^{2\alpha}(1+|x|)^{2\beta}} \left(|\!|\!| \psi |\!|\!|_{4,\alpha+\frac{7}{2},\beta} |\!|\!| u |\!|\!|_{4,\alpha+\frac{7}{2},\beta} + |\!|\!| u |\!|\!|_{4,2\alpha+2,2\beta} \right), \tag{5.17}$$

$$r|\mathcal{E}_2| \le C\frac{\Delta x^2 + \Delta r^2}{(1+r)^{2\alpha}(1+|x|)^{2\beta}} \left(|\!|\!| \psi |\!|\!|_{4,\alpha+\frac{7}{2},\beta} |\!|\!| \omega |\!|\!|_{4,\alpha+\frac{7}{2},\beta} + |\!|\!| u |\!|\!|_{4,\alpha+\frac{7}{2},\beta}^2 + |\!|\!| \omega |\!|\!|_{4,2\alpha+2,2\beta} \right), \tag{5.18}$$

$$r|\partial_t\mathcal{E}_3| \le C\frac{\Delta x^2 + \Delta r^2}{(1+r)^{2\alpha}(1+|x|)^{2\beta}} |\!|\!| \partial_t\psi |\!|\!|_{4,2\alpha+2,2\beta}, \tag{5.19}$$

and

$$|\mathcal{E}_3| \le C\frac{\Delta x^2 + \Delta r^2}{r(1+r)^{2\alpha}(1+|x|)^{2\beta}} |\!|\!| \psi |\!|\!|_{4,2\alpha+2,2\beta}. \tag{5.20}$$

Proof. See section A.2. ∎

From Lemma 4 to 6, our main result follows.

THEOREM 2. *Let (ψ, u, ω) be a solution of the axisymmetric NSE* (2.2) *satisfying*

$$(\psi, \omega) \in C^1\left(0,T;C_s^{4,\gamma,\delta}\right), \quad u \in C^1\left(0,T;C_s^{4,5,\delta}\right), \qquad \gamma > 4,\ \delta > \frac{1}{2}. \tag{5.21}$$

Then

$$\begin{aligned}
&\sup_{[0,T]} \left(\|u-u_h\|_{0,h}^2 + \|\psi-\psi_h\|_{1,h}^2\right) \\
&\qquad + \int_0^T (\|u-u_h\|_{1,h}^2 + \|\omega-\omega_h\|_{0,h}^2)dt \le C(\Delta x^4 + \Delta r^4)|\log \Delta r|,
\end{aligned} \tag{5.22}$$

where $C = C(\psi, u, \nu, T)$.

Proof. From Lemma 6, we have

$$\begin{aligned}&\|r\mathcal{E}_1\|_{0,h}^2+\|r\mathcal{E}_2\|_{0,h}^2+\|r\partial_t\mathcal{E}_3\|_{0,h}^2\\ &\le C(\Delta x^4+\Delta r^4)\left(\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\frac{r_j\Delta r\Delta x}{(1+r_j)^{4\alpha}(1+|x_i|)^{4\beta}}\right)\\ &\quad\times\left(|\!|\!|(\psi,u,\omega)|\!|\!|_{4,\alpha+\frac{7}{2},\beta}^4+|\!|\!|(u,\omega,\partial_t\psi)|\!|\!|_{4,2\alpha+2,2\beta}^2\right).\end{aligned}$$

Similarly,

$$\|\mathcal{E}_3\|_{0,h}^2\le C(\Delta x^4+\Delta r^4)\left(\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\frac{\Delta r\Delta x}{r_j(1+r_j)^{4\alpha}(1+|x_i|)^{4\beta}}\right)|\!|\!|\psi|\!|\!|_{4,2\alpha+2,2\beta}^2.$$

Since

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\frac{r_j\Delta r\Delta x}{(1+r_j)^{4\alpha}(1+|x_i|)^{4\beta}}\le C\qquad\text{for }\alpha>\frac{1}{2},\ \beta>\frac{1}{4}$$

and

$$\sum_{i=-\infty}^{\infty}\sum_{j=1}^{\infty}\frac{\Delta r\Delta x}{r_j(1+r_j)^{4\alpha}(1+|x_i|)^{4\beta}}\le C|\log\Delta r|\qquad\text{for }\alpha>0,\ \beta>\frac{1}{4},$$

it follows that

(5.23)
$$\|r\mathcal{E}_1\|_{0,h}^2+\|r\mathcal{E}_2\|_{0,h}^2+\|r\partial_t\mathcal{E}_3\|_{0,h}^2\le C(\Delta x^4+\Delta r^4)\left(|\!|\!|(\psi,u,\omega)|\!|\!|_{4,\gamma,\delta}^4+|\!|\!|(u,\omega,\partial_t\psi)|\!|\!|_{4,\gamma,\delta}^2\right)$$

and

$$\|\mathcal{E}_3\|_{0,h}^2\le C(\Delta x^4+\Delta r^4)|\log\Delta r||\!|\!|\psi|\!|\!|_{4,\gamma,\delta}^2 \tag{5.24}$$

provided $\gamma>4$, $\delta>\frac{1}{2}$.

Under assumption (5.21), we have, in particular, $\psi\in C_s^{2,2,0}$, $u\in C_s^{1,2,0}$. It follows from Proposition 2 and (5.23), (5.24) that

$$\begin{aligned}&\tfrac{1}{2}\partial_t(\|u-u_h\|_{0,h}^2+\|\psi-\psi_h\|_{1,h}^2)+\tfrac{\nu}{4}(\|u-u_h\|_{1,h}^2+\|\omega-\omega_h\|_{0,h}^2)\\ \le\ & C\|u-u_h\|_{0,h}^2+C\|\psi-\psi_h\|_{1,h}^2+C(\Delta x^4+\Delta r^4)|\log\Delta r|.\end{aligned}$$

The error estimate (5.22) then follows from Gronwall's inequality. ∎

6. Conclusion. The importance and subtlety of the pole singularity has been a major difficulty in theoretical analysis and algorithm design for axisymmetric flows. The numerical analysis near the pole singularity is much more complicated than that of standard smooth flows. The principal ingredients of our error analysis are as follows:

(a) The fact that smooth solutions to (2.2) automatically satisfy the pole condition and thus belong to the class (2.13). This symmetry property plays an essential role in the local truncation error analysis.

(b) Proper formulation and discretization of the nonlinear terms. Here the Jacobian formulation along with the distinctive discretization (4.1) result in exact cancellation among the nonlinear terms in the energy estimate and therefore lead to conservation identities in discrete setting.

These ingredients may also serve as a guideline of algorithm design for axisymmetric flows.

In addition, the slow decay of the stream function at infinity poses extra technical difficulties in analyzing the whole space problem. This difficulty is carefully resolved by choosing a properly weighted r-homogeneous norm (3.2). On the one hand, (3.2) takes into account the local behavior of the swirling components near the pole singularity. On the other hand, it incorporates free parameters so that the slow decay of the stream function can be properly compensated by tuning the parameters through careful analysis.

Appendix A. Proof of technical lemmas.

A.1. Estimate for the trilinear form T_h—proof of Lemma 5. We start with the following basic identities.

PROPOSITION 3. *Define*

$$(\widetilde{A}_x f)_{i,j} = \frac{1}{2}(f_{i+1,j} + f_{i-1,j}), \qquad (\widetilde{A}_r f)_{i,j} = \frac{1}{2}(f_{i,j+1} + f_{i,j-1}).$$

Then the following estimates hold for $j \geq 1$:

$$|\widetilde{D}_r(ra)| \leq C|\widetilde{A}_r a| + Cr|\widetilde{D}_r a|, \tag{A.1}$$

$$|\widetilde{D}_r(\frac{a}{r})| \leq C\frac{|\widetilde{A}_r a|}{r^2} + C\frac{|\widetilde{D}_r a|}{r}, \tag{A.2}$$

$$|\widetilde{A}_r(ra)| \leq Cr\widetilde{A}_r|a|, \tag{A.3}$$

$$|\Delta r\widetilde{D}_r a| \leq \widetilde{A}_r|a|, \quad |\Delta x\widetilde{D}_x a| \leq \widetilde{A}_x|a|. \tag{A.4}$$

Remark 3. As in Remark 1, the stretching factor r in the arguments of the left-hand side of (A.1)–(A.3) satisfy the even extension (4.9). A more precise statement for, say, (A.1) is given by

$$|\widetilde{D}_r(|r|a)|_{i,j} \leq C|\widetilde{A}_r a|_{i,j} + Cr_j|\widetilde{D}_r a|_{i,j}, \qquad j \geq 1.$$

For simplicity of presentation, we will adopt the expression as in (A.1)–(A.3) through the rest of the paper.

Proof of Proposition 3. It is easy to verify that

$$\widetilde{D}_r(fg) = (\widetilde{A}_r f)(\widetilde{D}_r g) + (\widetilde{A}_r g)(\widetilde{D}_r f), \quad \widetilde{D}_x(fg) = (\widetilde{A}_x f)(\widetilde{D}_x g) + (\widetilde{A}_x g)(\widetilde{D}_x f).$$

A straightforward calculation shows that

$$(\tilde{A}_r|r|)_j \leq Cr_j, \quad |\,\tilde{D}_r|r|\,|_j \leq C$$

and

$$\tilde{A}_r\left(\frac{1}{|r|}\right)_j \leq C\frac{1}{r_j}, \quad |\tilde{D}_r\left(\frac{1}{|r|}\right)|_j \leq C\frac{1}{r_j^2}$$

for $j \geq 1$. The estimates (A.1)–(A.3) then follow. The proof for (A.4) is also straightforward. ∎

Proof of Lemma 5. We begin with the proof of (5.13). We expand the left-hand side as

$$\begin{aligned} T_h\left(ra, rb, \tfrac{c}{r}\right) &= \tfrac{1}{3}\Big(\langle \tfrac{c}{r^2}, \tilde{\nabla}_h^{\perp}(ra)\cdot\tilde{\nabla}_h(rb)\rangle_h + \langle a, \tilde{\nabla}_h^{\perp}(rb)\cdot\tilde{\nabla}_h(\tfrac{c}{r})\rangle_h \\ &\qquad + \langle b, \tilde{\nabla}_h^{\perp}(\tfrac{c}{r})\cdot\tilde{\nabla}_h(ra)\rangle_h\Big) \\ &= \tfrac{1}{3}(I_1 + I_2 + I_3) \end{aligned}$$

and estimate the I_j's term by term. First, we have

$$|I_1| = |\left\langle \frac{c}{r^2}, \tilde{\nabla}_h^{\perp}(ra)\cdot\tilde{\nabla}_h(rb)\right\rangle_h| = |\left\langle c, -\frac{1}{r}\tilde{D}_r(ra)\tilde{D}_x(b) + \tilde{D}_x(a)\frac{1}{r}\tilde{D}_r(rb)\right\rangle_h|;$$

therefore the estimate

$$\begin{aligned} |I_1| &\leq C\left\langle |c|, \left(|\frac{\tilde{A}_r(a)}{r}| + |\tilde{D}_r(a)|\right)|\tilde{D}_x(b)| + \left(|\frac{\tilde{A}_r(b)}{r}| + |\tilde{D}_r(b)|\right)|\tilde{D}_x(a)|\right\rangle_h \\ &\leq C\|a\|_{1,h}\|b\|_{1,h}\|c\|_{0,1,0} \end{aligned}$$

follows from (A.1), Hölder's inequality, and the inequality $|c| = |r\frac{c}{r}| \leq \|c\|_{0,1,0}$.

Second, we have

$$\begin{aligned} |I_2| &\leq C\langle |a|, |\tfrac{\tilde{A}_r(b)}{r}| + |\tilde{D}_r(b)||\tilde{D}_x(c)|\rangle_h + C\langle |a|, |\tilde{D}_r(c)||\tilde{D}_x(b)|\rangle_h \\ &\qquad + C\langle \tfrac{|a|}{r}, |A_r(c)||\tilde{D}_x(b)|\rangle_h \\ &= C\langle \tfrac{|a|}{r}, |\tfrac{\tilde{A}_r(b)}{r}| + |\tilde{D}_r(b)||r\tilde{D}_x(c)|\rangle_h + C\langle \tfrac{|a|}{r}, |r\tilde{D}_r(c)||\tilde{D}_x(b)|\rangle_h \\ &\qquad + C\langle \tfrac{|a|}{r}, |A_r(c)||\tilde{D}_x(b)|\rangle_h \\ &\leq C\|a\|_{1,h}\|b\|_{1,h}(\|c\|_{0,1,0} + \|c\|_{1,2,0}) \leq C\|a\|_{1,h}\|b\|_{1,h}\|c\|_{1,2,0}. \end{aligned}$$

The estimate for I_3 is similar and (5.13) follows.

Next we proceed with (5.14). Since

$$|T_h\left(\frac{a}{r}, rb, rc\right)| = |\left\langle a, \frac{1}{r^2}J_h(rb, rc)\right\rangle_h| \leq \|a\|_{0,h}\|\frac{1}{r^2}J_h(rb, rc)\|_{0,h},$$

it suffices to give a pointwise estimate for the integrand $J_h(rb, rc)$ as follows:

(A.5)

$$\begin{aligned} -3J_h(rb, rc) &= \widetilde{D}_r(rb)\widetilde{D}_x(rc) - \widetilde{D}_x(rb)\widetilde{D}_r(rc) + \widetilde{D}_r\big(rb\widetilde{D}_x(rc)\big) - \widetilde{D}_x\big(rb\widetilde{D}_r(rc)\big) \\ &\quad + \widetilde{D}_x\big(rc\widetilde{D}_r(rb)\big) - \widetilde{D}_r\big(rc\widetilde{D}_x(rb)\big) \\ &= \widetilde{D}_r(rb)(I + \widetilde{A}_r)\widetilde{D}_x(rc) - \widetilde{D}_x(rb)(I + \widetilde{A}_x)\widetilde{D}_r(rc) \\ &\quad + (\widetilde{A}_r - \widetilde{A}_x)(rb)\widetilde{D}_r\widetilde{D}_x(rc) + (\tilde{A}_x - \tilde{A}_r)(rc)\tilde{D}_x\tilde{D}_r(rb) \\ &\quad + \widetilde{D}_x(rc)\widetilde{A}_x\widetilde{D}_r(rb) - \widetilde{D}_r(rc)\widetilde{A}_r\widetilde{D}_x(rb) \\ &= \widetilde{D}_r(rb)(I + \widetilde{A}_r)\widetilde{D}_x(rc) - \widetilde{D}_x(rb)(I + \widetilde{A}_x)\widetilde{D}_r(rc) \\ &\quad + (\widetilde{A}_r - \widetilde{A}_x)(rb)\widetilde{D}_r\widetilde{D}_x(rc) \\ &\quad + \tfrac{1}{2}\Delta x^2\widetilde{D}_r\widetilde{D}_x(rb)D_x^2(rc) - \tfrac{1}{2}\Delta r^2\widetilde{D}_r\widetilde{D}_x(rb)D_r^2(rc) \\ &\quad + \widetilde{D}_x(rc)\widetilde{A}_x\widetilde{D}_r(rb) - \widetilde{D}_r(rc)\widetilde{A}_r\widetilde{D}_x(rb). \end{aligned}$$

Here I is the identity operator and we have used the identities

$$\tilde{A}_x = \frac{1}{2}\Delta x^2 D_x^2 + I, \quad \tilde{A}_r = \frac{1}{2}\Delta r^2 D_r^2 + I$$

in the second equality of (A.5).

From (A.1), the first two terms on the right-hand side of (A.5) can be estimated by

$$|\widetilde{D}_r(rb)(I+\widetilde{A}_r)\widetilde{D}_x(rc)| \le Cr^2\left(|\widetilde{D}_r b| + \frac{|\widetilde{A}_r b|}{r}\right)\|\partial_x c\|_{L^\infty}, \tag{A.6}$$

$$|\widetilde{D}_x(rb)(I+\widetilde{A}_x)\widetilde{D}_r(rc)| \le Cr^2|\widetilde{D}_x b|\|\partial_r c + \frac{c}{r}\|_{L^\infty} \le Cr^2|\widetilde{D}_x b|(\|c\|_{0,0,0} + \|c\|_{1,1,0}). \tag{A.7}$$

From (A.3) and (A.4), we can similarly estimate the remaining terms in (A.5):

$$\begin{aligned}|(\widetilde{A}_r - \widetilde{A}_x)(rb)\widetilde{D}_r\widetilde{D}_x(rc)| &\le Cr^2\frac{(\widetilde{A}_r+\widetilde{A}_x)|b|}{r}\|\partial_x\partial_r(rc)\|_{L^\infty}\\ &\le Cr^2\frac{(\widetilde{A}_r+\widetilde{A}_x)|b|}{r}(\|c\|_{1,1,0} + \|c\|_{2,2,0}),\end{aligned} \tag{A.8}$$

$$|\frac{1}{2}\Delta x^2\widetilde{D}_r\widetilde{D}_x(rb)D_x^2(rc)| \le C\frac{(\Delta x)^2}{\Delta r}|\widetilde{A}_r(r\widetilde{D}_x(b))D_x^2(rc)| \le Cr^2\frac{\Delta r}{r}\widetilde{A}_r|\widetilde{D}_x b|\|c\|_{2,2,0}, \tag{A.9}$$

$$|\frac{1}{2}\Delta r^2\widetilde{D}_r\widetilde{D}_x(rb)D_r^2(rc)| \le C\Delta r|\widetilde{A}_r\widetilde{D}_x(rb)|\|\partial_r^2(rc)\|_{L^\infty} \le Cr^2\frac{\Delta r}{r}\widetilde{A}_r|\widetilde{D}_x b|\|\!|c|\!\|_{2,2,0}, \tag{A.10}$$

$$|\widetilde{A}_x\widetilde{D}_r(rb)\widetilde{D}_x(rc)| \le Cr^2|\widetilde{A}_x\left(\frac{1}{r}\widetilde{D}_r(rb)\right)|\|\partial_x c\|_{L^\infty} \le Cr^2\widetilde{A}_x\left(|\widetilde{D}_r b| + \frac{1}{r}\widetilde{A}_r|b|\right)\|c\|_{1,1,0}, \tag{A.11}$$

and

$$|\widetilde{A}_r\widetilde{D}_x(rb)\widetilde{D}_r(rc)| \le Cr^2\widetilde{A}_r|\widetilde{D}_x b|\|\!|c|\!\|_{1,1,0}. \tag{A.12}$$

From (A.6)–(A.12), we can estimate the weighted L^2 norm of $\frac{1}{r^2}J_h(rb,rc)$ by

$$\|\frac{1}{r^2}J_h(rb,rc)\|_{0,h} \le C\|\left(|\widetilde{D}_x b| + |\widetilde{D}_r b| + \frac{|b|}{r}\right)\|_{0,h}\|\!|c|\!\|_{2,2,0} \le C\|b\|_{1,h}\|\!|c|\!\|_{2,2,0}$$

and (5.14) follows. ∎

A.2. Local truncation error analysis—proof of Lemma 6. In this subsection, we proceed with the local truncation error estimate. All the assertions in Lemmas 7 to 10 are pointwise estimates on the grid points (x_i, r_j), $j \ge 1$. For brevity, we omit the indices (i,j) whenever it is obvious.

We start with the estimates of the diffusion terms in (5.3).

LEMMA 7. *If $a \in C_s^4(R\times\overline{R^+})$ and $\alpha_0, \beta_0 \in R$, we have*

$$r|(\nabla_h^2 - \nabla^2)a| \le C\left(\Delta x^2 + \Delta r^2\right)\frac{1}{(1+r)^{\alpha_0}(1+|x|)^{\beta_0}}\|\!|a|\!\|_{4,\alpha_0+2,\beta_0} \tag{A.13}$$

and

$$|(\nabla_h^2 - \nabla^2)a| \le C\left(\Delta x^2 + \Delta r^2\right)\frac{1}{r}\frac{1}{(1+r)^{\alpha_0}(1+|x|)^{\beta_0}}\|\!|a|\!\|_{4,\alpha_0+2,\beta_0}. \tag{A.14}$$

Proof. Since $a \in C_s^4(R \times \overline{R^+})$, the odd extension of a given by

$$\tilde{a}(x,r) = \begin{cases} a(x,r), & \text{if } r \geq 0, \\ -a(x,-r), & \text{if } r < 0, \end{cases}$$

is in $C^4(R^2)$. It follows that

$$\begin{aligned} \nabla_h^2 a &= \left(D_x^2 + D_r^2 + \frac{\widetilde{D}_r}{r} \right) a \\ &= \nabla^2 a + \frac{1}{12}\Delta x^2 \partial_x^4 a|_{(\xi,r)} + \Delta r^2 \left(\frac{1}{12}\partial_r^4 a|_{(x,\eta_1)} + \frac{1}{6}\frac{1}{r}(\partial_r^3 a)_{(x,\eta_2)} \right) \end{aligned} \tag{A.15}$$

is valid for all $j \geq 1$ with $\xi \in (x - \Delta x, x + \Delta x)$ and $\eta_1, \eta_2 \in (r - \Delta r, r + \Delta r)$.

Thus

$$\begin{aligned} & r|(\nabla_h^2 - \nabla^2)a| \\ \leq\ & C\left(\Delta x^2 + \Delta r^2\right)\left(r|\partial_x^4(r\tfrac{a}{r})|_{(\xi,r)}| + r|\partial_r^4(r\tfrac{a}{r})|_{(x,\eta_1)}| + |\partial_r^3(r\tfrac{a}{r})|_{(x,\eta_2)}| \right) \\ \leq\ & C\left(\Delta x^2 + \Delta r^2\right)\Big(\tfrac{r\|a\|_{4,\alpha_0+2,\beta_0}}{(1+r)^{\alpha_0+1}(1+|\xi|)^{\beta_0}} + \tfrac{r(\|a\|_{4,\alpha_0+2,\beta_0}+\|a\|_{3,\alpha_0+1,\beta_0})}{(1+\eta_1)^{\alpha_0+1}(1+|x|)^{\beta_0}} \\ & \qquad + \tfrac{\|a\|_{3,\alpha_0+1,\beta_0}+\|a\|_{2,\alpha_0,\beta_0}}{(1+\eta_2)^{\alpha_0}(1+|x|)^{\beta_0}} \Big) \\ \leq\ & C\left(\Delta x^2 + \Delta r^2\right) \tfrac{1}{(1+r)^{\alpha_0}(1+|x|)^{\beta_0}} \|\!|a|\!\|_{4,\alpha_0+2,\beta_0}. \end{aligned}$$

This gives (A.13), together with (A.14) as a direct consequence. ∎

Next we proceed with the estimates for the Jacobians, starting with their typical factors.

LEMMA 8. *For $a \in C_s^4(R \times \overline{R^+})$, $\alpha, \beta \in R$, we have*

$$\widetilde{D}_x\left(\frac{a}{r}\right) = \partial_x\left(\frac{a}{r}\right) + O(1)\Delta x^2 \frac{1}{(1+r)^\alpha (1+|x|)^\beta} \|\!|a|\!\|_{3,\alpha,\beta}, \tag{A.16}$$

$$\widetilde{D}_x(ra) = \partial_x(ra) + O(1) r^2 \Delta x^2 \frac{1}{(1+r)^\alpha (1+|x|)^\beta} \|\!|a|\!\|_{3,\alpha,\beta}, \tag{A.17}$$

$$\widetilde{D}_r\left(\frac{a}{r}\right) = \partial_r\left(\frac{a}{r}\right) + O(1)\frac{\Delta r^2}{r^3} \frac{1}{(1+r)^\alpha (1+|x|)^\beta} \|\!|a|\!\|_{3,\alpha+3,\beta}, \tag{A.18}$$

$$\widetilde{D}_r(ra) = \partial_r(ra) + O(1)\frac{\Delta r^2}{r} \frac{1}{(1+r)^\alpha (1+|x|)^\beta} \|\!|a|\!\|_{3,\alpha+3,\beta}. \tag{A.19}$$

Proof. We begin with (A.16) and (A.17).

Since

$$(\widetilde{D}_x - \partial_x) f = \frac{\Delta x^2}{6} \partial_x^3 f_{|(\xi,r)}, \quad \xi \in (x - \Delta x, x + \Delta x),$$

it follows that

$$\left|(\widetilde{D}_x - \partial_x)\left(\frac{a}{r}\right)\right| = \frac{\Delta x^2}{6}\left|\partial_x^3\left(\frac{a}{r}\right)\right|_{|(\xi,r)} \leq C\Delta x^2 \frac{1}{(1+r)^\alpha (1+|x|)^\beta} \|a\|_{3,\alpha,\beta}$$

and

$$|(\widetilde{D}_x - \partial_x)(ra)| = \frac{\Delta x^2}{6}\left|\partial_x^3\left(r^2\frac{a}{r}\right)_{|(\xi,r)}\right| \le Cr^2\Delta x^2\frac{1}{(1+r)^\alpha(1+|x|)^\beta}\|a\|_{3,\alpha,\beta}.$$

For (A.18) and (A.19), the estimate is more complicated due to our reflection boundary condition (4.8) and (4.9). We estimate for $j > 1$ and $j = 1$ separately.

When $j > 1$, we have

$$(\widetilde{D}_r - \partial_r)f = \frac{1}{6}\Delta r^2\partial_r^3 f|_{(x,\eta)}, \quad \eta \in (r - \Delta r, r + \Delta r).$$

Therefore

$$\left|(\widetilde{D}_r - \partial_r)\left(\frac{a}{r}\right)\right| = \frac{\Delta r^2}{6}\left|\partial_r^3\left(\frac{a}{r}\right)\right|_{(x,\eta)} \le C\frac{\Delta r^2}{r^3}\frac{1}{(1+r)^\alpha(1+|x|)^\beta}\|a\|_{3,\alpha+3,\beta}$$

and

$$\begin{aligned}|(\widetilde{D}_r - \partial_r)(ra)| &\le C\Delta r^2\left|\partial_r^3(r^2\tfrac{a}{r})\right|_{(x,\eta)}\\ &\le C\tfrac{\Delta r^2}{r}\tfrac{1}{(1+r)^\alpha(1+|x|)^\beta}(\|a\|_{3,\alpha+3,\beta} + \|a\|_{2,\alpha+2,\beta} + \|a\|_{1,\alpha+1,\beta}).\end{aligned}$$

When $j = 1$, we have

$$\left|\partial_r\left(\frac{a}{r}\right)\right|_{j=1} = C\frac{\Delta r^2}{r_1^3}r_1\left|\partial_r\left(\frac{a}{r}\right)\right|_{j=1} \le C\frac{\Delta r^2}{r_1^3}\frac{1}{(1+r_1)^\alpha(1+|x|)^\beta}\|a\|_{1,\alpha+1,\beta}.$$

In addition, since $r_1 = \frac{\Delta r}{2}$, we apply (4.9) to get

$$\left|\widetilde{D}_r\left(\frac{a}{r}\right)\right|_{j=1} = \left|\frac{\frac{a_2}{r_2} + \frac{a_1}{r_1}}{2\Delta r}\right| = \left|C\frac{\Delta r^2}{r_1^3}\left(\frac{a_2}{r_2} + \frac{a_1}{r_1}\right)\right| \le C\frac{\Delta r^2}{r_1^3}\frac{1}{(1+r_1)^\alpha(1+|x|)^\beta}\|a\|_{0,\alpha,\beta},$$

and (A.18) follows.

(A.19) can be proved similarly, as follows:

$$\widetilde{D}_r(ra)_{j=1} = \frac{\frac{3}{2}\Delta r a_2 + \frac{1}{2}\Delta r a_1}{2\Delta r} = \frac{3}{4}a_2 + \frac{1}{4}a_1,$$
$$|a_1| \le C\frac{\Delta r^2}{r_1}\left|\frac{a_1}{r_1}\right| \le C\frac{\Delta r^2}{r_1}\frac{1}{(1+r_1)^\alpha(1+|x|)^\beta}\|a\|_{0,\alpha,\beta},$$

and

$$|a_2| \le C\frac{\Delta r^2}{r_1}\left|\frac{a_2}{r_2}\right| \le C\frac{\Delta r^2}{r_1}\frac{1}{(1+r_1)^\alpha(1+|x|)^\beta}\|a\|_{0,\alpha,\beta}.$$

Therefore

$$\left|\widetilde{D}_r(ra)\right|_{j=1} \le C\frac{\Delta r^2}{r_1}\frac{1}{(1+r_1)^\alpha(1+|x|)^\beta}\|a\|_{0,\alpha,\beta}.$$

In addition,

$$|\partial_r(ra)|_{j=1} \le \left(r^2\left|\partial_r\left(\frac{a}{r}\right)\right| + 2r\left|\frac{a}{r}\right|\right)_{j=1} \le C\frac{\Delta r^2}{r_1}\frac{\|a\|_{1,\alpha+1,\beta} + \|a\|_{0,\alpha,\beta}}{(1+r_1)^\alpha(1+|x|)^\beta},$$

and (A.19) follows. ∎

We now continue with the pointwise estimate for the Jacobi terms $\frac{1}{r}|J_h(ra,rb) - J(ra,rb)|$ and $r|J_h\left(\frac{a}{r},rb\right) - J\left(\frac{a}{r},rb\right)|$. Since

(A.20)
$$\begin{aligned}\tfrac{3}{r^2}J_h(ra,rb) = \;& \widetilde{D}_x(\tfrac{a}{r})\widetilde{D}_r(rb) - \widetilde{D}_r(ra)\widetilde{D}_x(\tfrac{b}{r}) + \widetilde{D}_x\left(\tfrac{a}{r}\widetilde{D}_r(rb) - \tfrac{b}{r}\widetilde{D}_r(ra)\right)\\ & + \tfrac{1}{r^2}\widetilde{D}_r\left(r^2 b\widetilde{D}_x a - r^2 a\widetilde{D}_x b\right),\end{aligned}$$

(A.21)
$$\begin{aligned}3J_h\left(\tfrac{a}{r},rb\right) = \;& \widetilde{D}_x(\tfrac{a}{r})\widetilde{D}_r(rb) - \widetilde{D}_r(\tfrac{a}{r})\widetilde{D}_x(rb) + \widetilde{D}_x\left(\tfrac{a}{r}\widetilde{D}_r(rb) - rb\widetilde{D}_r(\tfrac{a}{r})\right)\\ & + \widetilde{D}_r\left(b\widetilde{D}_x a - a\widetilde{D}_x b\right),\end{aligned}$$

it suffices to estimate the terms in (A.20) and (A.21) individually. We summarize them as the following lemma.

LEMMA 9. *If $a, b \in C_s^4(R \times \overline{R^+})$ and $\alpha_1, \alpha_2, \beta_1, \beta_2 \in R$, then*

(A.22)
$$\begin{aligned}& r|\widetilde{D}_r(\tfrac{a}{r})\widetilde{D}_x(rb) - \partial_r(\tfrac{a}{r})\partial_x(rb)| + \tfrac{1}{r}|\widetilde{D}_r(rb)\widetilde{D}_x(ra) - \partial_r(rb)\partial_x(ra)|\\ & \le C(\Delta x^2 + \Delta r^2)\tfrac{1}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{3,\alpha_2+\frac{5}{2},\beta_2},\end{aligned}$$

(A.23)
$$\begin{aligned}& r|\widetilde{D}_x(\tfrac{a}{r}\widetilde{D}_r(rb)) - \partial_x(\tfrac{a}{r}\partial_r(rb))| + r|\widetilde{D}_x(ra\widetilde{D}_r(\tfrac{b}{r})) - \partial_x(ra\partial_r(\tfrac{b}{r}))|\\ & \le C(\Delta x^2 + \Delta r^2)\tfrac{1}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2},\end{aligned}$$

(A.24)
$$\begin{aligned}& r|\widetilde{D}_r(a\widetilde{D}_x b) - \partial_r(a\partial_x b)| + \tfrac{1}{r}|\widetilde{D}_r(r^2 a\widetilde{D}_x b) - \partial_r(r^2 a\partial_x b)|\\ & \le C(\Delta x^2 + \Delta r^2)\tfrac{1}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}.\end{aligned}$$

Proof. Since (A.16)–(A.19) are valid for any α, $\beta \in R$, we have

(A.25)
$$\widetilde{D}_x\left(\frac{a}{r}\right) = \partial_x\left(\frac{a}{r}\right) + O(1)\Delta x^2\frac{1}{(1+r)^{\alpha_1+\lambda}(1+|x|)^{\beta_1}}\|\!|a|\!\|_{3,\alpha_1+\lambda,\beta_1},$$

(A.26)
$$\widetilde{D}_x(ra) = \partial_x(ra) + O(1)r^2\Delta x^2\frac{1}{(1+r)^{\alpha_1+\lambda}(1+|x|)^{\beta_1}}\|\!|a|\!\|_{3,\alpha_1+\lambda,\beta_2},$$

(A.27)
$$\widetilde{D}_r\left(\frac{a}{r}\right) = \partial_r\left(\frac{a}{r}\right) + O(1)\frac{\Delta r^2}{r^3}\frac{1}{(1+r)^{\alpha_1+\lambda}(1+|x|)^{\beta_1}}\|\!|a|\!\|_{3,\alpha_1+\lambda+3,\beta_1},$$

(A.28)
$$\widetilde{D}_r(ra) = \partial_r(ra) + O(1)\frac{\Delta r^2}{r}\frac{1}{(1+r)^{\alpha_1+\lambda}(1+|x|)^{\beta_1}}\|\!|a|\!\|_{3,\alpha_1+\lambda+3,\beta_1},$$

and

(A.29)
$$\widetilde{D}_x\left(\frac{b}{r}\right) = \partial_x\left(\frac{b}{r}\right) + O(1)\Delta x^2\frac{1}{(1+r)^{\alpha_2+\mu}(1+|x|)^{\beta_2}}\|\!|b|\!\|_{3,\alpha_2+\mu,\beta_2},$$

(A.30)
$$\widetilde{D}_x(rb) = \partial_x(rb) + O(1)r^2\Delta x^2\frac{1}{(1+r)^{\alpha_2+\mu}(1+|x|)^{\beta_2}}\|\!|b|\!\|_{3,\alpha_2+\mu,\beta_2},$$

(A.31)
$$\widetilde{D}_r\left(\frac{b}{r}\right) = \partial_r\left(\frac{b}{r}\right) + O(1)\frac{\Delta r^2}{r^3}\frac{1}{(1+r)^{\alpha_2+\mu}(1+|x|)^{\beta_2}}\|\!|b|\!\|_{3,\alpha_2+\mu+3,\beta_2},$$

(A.32)
$$\widetilde{D}_r(rb) = \partial_r(rb) + O(1)\frac{\Delta r^2}{r}\frac{1}{(1+r)^{\alpha_2+\mu}(1+|x|)^{\beta_2}}\|\!|b|\!\|_{3,\alpha_2+\mu+3,\beta_2}$$

for any λ, $\mu \in R$. We apply (A.27), (A.30) with $\lambda = -\frac{1}{2}$, $\mu = \frac{5}{2}$ to get

$$\begin{aligned}
& r|\widetilde{D}_r(\tfrac{a}{r})\widetilde{D}_x(rb) - \partial_r(\tfrac{a}{r})\partial_x(rb)| \\
= \;& r|\widetilde{D}_r(\tfrac{a}{r})\widetilde{D}_x(rb) - \partial_r(\tfrac{a}{r})\widetilde{D}_x(rb) + \partial_r(\tfrac{a}{r})\widetilde{D}_x(rb) - \partial_r(\tfrac{a}{r})\partial_x(rb)| \\
= \;& O(|\widetilde{D}_x(rb)|)\tfrac{\Delta r^2}{r^2}\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}}{(1+r)^{\alpha_1-\frac{1}{2}}(1+|x|)^{\beta_1}} + O(|\partial_r(\tfrac{a}{r})|)r^3\Delta x^2\frac{\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_2+\frac{5}{2}}(1+|x|)^{\beta_2}}.
\end{aligned}$$

Moreover, since

$$r^3|\partial_r\left(\frac{a}{r}\right)| \le \frac{1}{(1+r)^{\alpha_1-\frac{5}{2}}(1+|x|)^{\beta_1}}\|a\|_{1,\alpha_1+\frac{1}{2},\beta_1}$$

and

$$|\widetilde{D}_x(rb)| = |\partial_x(rb)(\xi,r)| \le r^2\frac{1}{(1+r)^{\alpha_2+\frac{1}{2}}(1+|x|)^{\beta_2}}\|b\|_{1,\alpha_2+\frac{1}{2},\beta_2},$$

it follows that

$$\begin{aligned}
& r|\widetilde{D}_r(\tfrac{a}{r})\widetilde{D}_x(rb) - \partial_r(\tfrac{a}{r})\partial_x(rb)| \\
\le \;& C(\Delta x^2+\Delta r^2)\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{1,\alpha_2+\frac{1}{2},\beta_2}+\|a\|_{1,\alpha_1+\frac{1}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \qquad \text{(A.33)} \\
\le \;& C(\Delta x^2+\Delta r^2)\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}.
\end{aligned}$$

Similarly, from (A.32) and (A.25), we have

$$\begin{aligned}
& r|\widetilde{D}_x(\tfrac{a}{r})\widetilde{D}_r(rb) - \partial_x(\tfrac{a}{r})\partial_r(rb)| \\
= \;& r|\widetilde{D}_x(\tfrac{a}{r})\widetilde{D}_r(rb) - \widetilde{D}_x(\tfrac{a}{r})\partial_r(rb) + \widetilde{D}_x(\tfrac{a}{r})\partial_r(rb) - \partial_x(\tfrac{a}{r})\partial_r(rb)| \\
= \;& O(|\widetilde{D}_x(\tfrac{a}{r})|)\Delta r^2\frac{\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_2-\frac{1}{2}}(1+|x|)^{\beta_2}} + O(|\partial_r(rb)|)r\Delta x^2\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}}{(1+r)^{\alpha_1+\frac{5}{2}}(1+|x|)^{\beta_1}} \qquad \text{(A.34)} \\
\le \;& C\Delta r^2\frac{\|a\|_{1,\alpha_1+\frac{1}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} + C\Delta x^2\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{1,\alpha_2+\frac{1}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \\
\le \;& C(\Delta x^2+\Delta r^2)\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}.
\end{aligned}$$

The estimate (A.22) then follows from (A.33) and (A.34).

For (A.23), we have

$$\begin{aligned}
& \widetilde{D}_x(f\widetilde{D}_r g) - \partial_x(f\partial_r g) \qquad \text{(A.35)} \\
= \;& \widetilde{D}_x(f(\widetilde{D}_r-\partial_r)g) + (\widetilde{D}_x-\partial_x)(f\partial_r g) \\
= \;& \partial_x(f(\widetilde{D}_r-\partial_r)g)_{|(\xi_1,r)} + \tfrac{1}{6}\Delta x^2\partial_x^3(f\partial_r g)_{|(\xi_2,\eta)} \\
= \;& (\partial_x f)((\widetilde{D}_r-\partial_r)g)_{|(\xi_1,r)} + f((\widetilde{D}_r-\partial_r)\partial_x g)_{|(\xi_1,r)} + \tfrac{1}{6}\Delta x^2\partial_x^3(f\partial_r g)_{|(\xi_2,\eta)}.
\end{aligned}$$

We proceed with individual terms in (A.35), taking $f = \frac{a}{r}$ and $g = rb$. From (A.30) with $\mu = -\frac{1}{2}$, we have

$$\begin{aligned} r\left|(\partial_x \tfrac{a}{r})(\widetilde{D}_r - \partial_r)(rb)\right| &\le C|\partial_x(\tfrac{a}{r})|\Delta r^2 \tfrac{1}{(1+r)^{\alpha_2-\frac{1}{2}}(1+|x|)^{\beta_2}} \|\!|b|\!\|_{3,\alpha_2+\frac{5}{2},\beta_2} \\ &\le C\Delta r^2 \tfrac{1}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \|\!|a|\!\|_{1,\alpha_1+\frac{1}{2},\beta_1} \|\!|b|\!\|_{3,\alpha_2+\frac{5}{2},\beta_2}. \end{aligned}$$

Similarly, from (A.32)

$$\begin{aligned} & r\left|\tfrac{a}{r}(\widetilde{D}_r - \partial_r)\partial_x(rb)\right| \\ \le\ & C\Delta r^2 |\tfrac{a}{r}| \tfrac{1}{(1+r)^{\alpha_2+\frac{1}{2}}(1+|x|)^{\beta_2}} \|\!|\partial_x b|\!\|_{3,\alpha_2+\frac{7}{2},\beta_2} \\ \le\ & C\Delta r^2 \tfrac{1}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \|a\|_{0,\alpha_1-\frac{1}{2},\beta_1} \|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}, \\ & r\left|\Delta x^2 \partial_x^3 (\tfrac{a}{r}\partial_r(rb))_{|(x,\eta)}\right| \\ \le\ & C\Delta x^2 \left|r\partial_x^3\left(\tfrac{a}{r}\right)\partial_r(rb) + r\left(\tfrac{a}{r}\right)\partial_x^3\partial_r(rb)\right| \\ \le\ & C\Delta x^2 \tfrac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{1,\alpha_2+\frac{1}{2},\beta_2} + \|a\|_{0,\alpha_1-\frac{1}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \\ \le\ & C\Delta x^2 \tfrac{\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \end{aligned}$$

Therefore

$$r|\widetilde{D}_x\left(\frac{a}{r}\widetilde{D}_r(rb)\right) - \partial_x\left(\frac{a}{r}\partial_r(rb)\right)| \le C(\Delta x^2 + \Delta r^2)\frac{\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}.$$

Using the same argument as above, one can derive

$$r|\widetilde{D}_x\left(ra\widetilde{D}_r\left(\frac{b}{r}\right)\right) - \partial_x\left(ra\partial_r\left(\frac{b}{r}\right)\right)| \le C(\Delta x^2 + \Delta r^2)\frac{\|\!|a|\!\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}$$

and therefore (A.23) is proved.

We continue with (A.24). For the first term, we can write

$$\widetilde{D}_r(a\widetilde{D}_x b) - \partial_r(a\partial_x b) = \widetilde{D}_r(a(\widetilde{D}_x - \partial_x)b) + (\widetilde{D}_r - \partial_r)(a\partial_x b).$$

Since $a, b \in C_s^4(R \times \overline{R^+})$, by extending a, b to odd functions across $r = 0$, we see that the extended $a\widetilde{D}_x b$ is in $C^4(R^2)$; thus

$$\begin{aligned} \widetilde{D}_r(a(\widetilde{D}_x - \partial_x)b) &= \partial_r(a(\widetilde{D}_x - \partial_x)b)|_{(x,\eta)} \\ &= \left(\partial_r a(\widetilde{D}_x - \partial_x)b + a(\widetilde{D}_x - \partial_x)(\partial_r b)\right)|_{(x,\eta)} \\ &= \tfrac{\Delta x^2}{6}\left(\partial_r a|_{(x,\eta)}\partial_x^3 b|_{(\xi_1,\eta)} + a|_{(x,\eta)}\partial_x^3\partial_r b|_{(\xi_2,\eta)}\right) \end{aligned}$$

and therefore

$$r|\widetilde{D}_r(a(\widetilde{D}_x - \partial_x)b)| \le C\Delta x^2 \frac{\|\!|a|\!\|_{1,\alpha_1+\frac{1}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \tag{A.36}$$

Similarly, the extended $a\partial_x b$ is in $C^3(R^2)$, and thus we have

$$r|(\widetilde{D}_r-\partial_r)(a\partial_x b)| = r\frac{\Delta r^2}{6}\partial_r^3(a\partial_x b)|_{(x,\eta)} \le C\Delta r^2 \frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \tag{A.37}$$

From (A.36) and (A.37), we have the following estimate for the first term of (A.24):

$$r|\widetilde{D}_r(a\widetilde{D}_x b) - \partial_r(a\partial_x b)| \le C(\Delta x^2+\Delta r^2)\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \tag{A.38}$$

The second term in (A.24) can be treated similarly, as follows:

$$\frac{1}{r}\widetilde{D}_r(r^2a\widetilde{D}_x b) - \frac{1}{r}\partial_r(r^2a\partial_x b) = \frac{1}{r}\widetilde{D}_r(r^2a(\widetilde{D}_x-\partial_x)b) + \frac{1}{r}(\widetilde{D}_r-\partial_r)(r^2a\partial_x b). \tag{A.39}$$

Again, since the extensions of $r^2a(\widetilde{D}_x-\partial_x)b$ and $r^2a\partial_x b$ are both in $C^3(R^2)$, we can directly estimate these two terms by

(A.40)

$$\begin{aligned}
\tfrac{1}{r}\widetilde{D}_r(r^2a(\widetilde{D}_x-\partial_x)b) &= \tfrac{1}{r}\partial_r(r^2a(\widetilde{D}_x-\partial_x)b)_{(x,\eta)} \\
&= \tfrac{1}{r}\left(\Big(\partial_r(r^2a)(\widetilde{D}_x-\partial_x)b\Big)_{(x,\eta)} + \Big(r^2a(\widetilde{D}_x-\partial_x)(\partial_r b)\Big)_{(x,\eta)}\right) \\
&= C\Delta x^2\left(\big((r\partial_r a+2a)\partial_x^3 b\big)_{(\xi_1,\eta)} + \big(ra\partial_x^3(\partial_r b)\big)_{(\xi_2,\eta)}\right)
\end{aligned}$$

and

$$\frac{1}{r}(\widetilde{D}_r-\partial_r)(r^2a\partial_x b) = \frac{\Delta r^2}{r}\partial_r^3(r^2a\partial_x b)_{(x,\eta)} = \frac{\Delta r^2}{r}\partial_r^3\left(r^4\frac{a}{r}\partial_x(\frac{b}{r})\right)_{(x,\eta)}. \tag{A.41}$$

From (A.40) and (A.41), we have

$$\begin{aligned}
&|\tfrac{1}{r}\widetilde{D}_r(r^2a(\widetilde{D}_x-\partial_x)b)| \\
&\le C\Delta x^2\frac{\|a\|_{1,\alpha_1+\frac{1}{2},\beta_1}\|b\|_{3,\alpha_2+\frac{5}{2},\beta_2}+\|a\|_{0,\alpha_1-\frac{1}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}} \qquad \text{(A.42)} \\
&\le C\Delta x^2\frac{\|a\|_{1,\alpha_1+\frac{1}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}
\end{aligned}$$

and

$$\frac{1}{r}\left|(\widetilde{D}_r-\partial_r)(r^2a\partial_x b)\right| \le C\Delta r^2\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \tag{A.43}$$

From (A.39), (A.42), and (A.43), we conclude that

$$\left|\frac{1}{r}\widetilde{D}_r(r^2a\widetilde{D}_x b) - \frac{1}{r}\partial_r(r^2a\partial_x b)\right| \le C(\Delta x^2+\Delta r^2)\frac{\|a\|_{3,\alpha_1+\frac{5}{2},\beta_1}\|b\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}. \tag{A.44}$$

The estimates (A.38) and (A.44) imply (A.24). Thus the proof of Lemma 9 is completed. ∎

As a direct consequence of Lemma 9, we have the following pointwise estimate for the Jacobians.

LEMMA 10. *If* $a, b \in C_s^4(R \times \overline{R^+})$, *then*

$$\frac{1}{r}|J_h(ra,rb) - J(ra,rb)| \le C(\Delta x^2 + \Delta r^2)\frac{\|\!|a|\!\|_{4,\alpha_1+\frac{7}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}},$$

$$r|J_h\left(\frac{a}{r},rb\right) - J\left(\frac{a}{r},rb\right)| \le C(\Delta x^2 + \Delta r^2)\frac{\|\!|a|\!\|_{4,\alpha_1+\frac{7}{2},\beta_1}\|\!|b|\!\|_{4,\alpha_2+\frac{7}{2},\beta_2}}{(1+r)^{\alpha_1+\alpha_2}(1+|x|)^{\beta_1+\beta_2}}$$

for any $\alpha_1, \alpha_2, \beta_1, \beta_2 \in R$.

From (5.3), Lemma 7, and Lemma 10, we can easily derive (5.17)–(5.20). This completes the proof of Lemma 6. □

Acknowledgments. The authors would like to thank the anonymous referees and Dr. YinLiang Huang for their valuable suggestions that helped to improve this paper.

A RESTARTED KRYLOV SUBSPACE METHOD FOR THE EVALUATION OF MATRIX FUNCTIONS*

MICHAEL EIERMANN† AND OLIVER G. ERNST†

Abstract. We show how the Arnoldi algorithm for approximating a function of a matrix times a vector can be restarted in a manner analogous to restarted Krylov subspace methods for solving linear systems of equations. The resulting restarted algorithm reduces to other known algorithms for the reciprocal and the exponential functions. We further show that the restarted algorithm inherits the superlinear convergence property of its unrestarted counterpart for entire functions and present the results of numerical experiments.

Key words. matrix function, Krylov subspace approximation, Krylov projection method, restarted Krylov subspace method, linear system of equations, initial value problem

1. Introduction.

The evaluation of

$$f(A)\boldsymbol{b}, \qquad \text{where } A \in \mathbb{C}^{n\times n}, \boldsymbol{b} \in \mathbb{C}^n, \tag{1.1}$$

and $f : \mathbb{C} \supset D \to \mathbb{C}$ is a function for which $f(A)$ is defined, is a common computational task. Besides the solution of linear systems of equations, which involves the reciprocal function $f(\lambda) = 1/\lambda$, by far the most important application is the time evolution of a system under a linear operator, in which case $f(\lambda) = f_t(\lambda) = e^{t\lambda}$ and time acts as a parameter t. Other applications involving differential equations require the evaluation of (1.1) for the square root and trigonometric functions (see [8, 1]). Further applications include identification problems for semigroups involving the logarithm (see, e.g., [29]) and lattice quantum chromodynamics simulations requiring the evaluation of the matrix sign function (see [34] and the references therein).

In many of the applications mentioned above the matrix A is large and sparse or structured, typically resulting from discretization of an infinite-dimensional operator. In this case evaluating (1.1) by first computing $f(A)$ is usually unfeasible, so that most of the algorithms for the latter task (see, e.g., [18, 5]) cannot be used. The standard approach for approximating (1.1) directly is based on a Krylov subspace of A with initial vector $\boldsymbol{b}$ [8, 9, 28, 14, 17, 4, 19]. The advantage of this approach is that it requires A only for computing matrix-vector products and that, for smooth functions such as the exponential, it converges superlinearly [8, 28, 31, 17].

One shortcoming of the Krylov subspace approximation, however, lies in the fact that computing an approximation of (1.1) from a Krylov subspace $\mathcal{K}_m(A, \boldsymbol{b})$ of dimension m involves all the basis vectors of $\mathcal{K}_m(A, \boldsymbol{b})$, and hence these need to be stored. Memory constraints therefore often limit the size of the problem that can be solved, which is an issue especially when A is the discrete representation of a partial differential operator in three space dimensions. When A is Hermitian, the Hermitian Lanczos process allows the basis of $\mathcal{K}_m(A, \boldsymbol{b})$ to be constructed by a three-term recurrence. When solving linear systems of equations, this recurrence for the basis vectors

immediately translates to efficient update formulas for the approximation. This, however, is a consequence of the simple form of the reciprocal function and such update formulas are not available for general (nonrational) functions.

When solving non-Hermitian linear systems of equations by Krylov subspace approximation, a common remedy is to limit storage requirements by restarting the algorithm each time the Krylov space has reached a certain maximal dimension [26, 10]. The subject of this work is the extension of this restarting approach to general functions. How such a generalization may be accomplished is not immediately obvious, since the restarting approach for linear systems is based on solving successive residual equations to obtain corrections to the most recent approximation. The availability of a residual, however, is another property specific to problems where $f(A)\boldsymbol{b}$ solves an (algebraic or differential) equation.

The remainder of this paper is organized as follows: Section 2 recalls the definition and properties of matrix functions and their approximation in Krylov spaces, emphasizing the role of Hermite interpolation, and closes with an error representation formula for Krylov subspace approximations. In section 3 we introduce a new restarted Krylov subspace algorithm for the approximation of (1.1) for general functions f. We derive two mathematically equivalent formulations of the restarted algorithm, the second of which, while slightly more expensive, was found to be more stable in the presence of rounding errors.

In section 4 we show that, for the reciprocal and exponential functions, our restarted method reduces to the restarted full orthogonalization method (FOM; see [27]) and is closely related to an algorithm by Celledoni and Moret [4], respectively. We further establish that, for entire functions of order one (such as the exponential function), the superlinear convergence property of the Arnoldi/Lanczos approximation of (1.1) is retained by our restarted method. In section 5 we demonstrate the performance of the restarted method for several test problems.

2. Matrix functions and their Krylov subspace approximation. In this section we fix notation, provide some background material on functions of matrices and their approximation using Krylov subspaces, highlight the connection with Hermite interpolation, and derive a new representation formula for the error of Krylov subspace approximations of $f(A)\boldsymbol{b}$.

2.1. Functions of matrices. We recall the definition of functions of matrices (as given, e.g., in Gantmacher [15, Chapter 5]): Let $\Lambda(A) = \{\lambda_1, \lambda_2, \dots, \lambda_k\}$ denote the k distinct eigenvalues of $A \in \mathbb{C}^{n\times n}$ and let the minimal polynomial of A be given by

$$m_A(\lambda) = \prod_{j=1}^{k} (\lambda - \lambda_j)^{n_j} \in \mathcal{P}_K, \qquad \text{where } K = \sum_{j=1}^{k} n_j.$$

Given a complex-valued function f, the matrix $f(A)$ is defined if $f^{(r)}(\lambda_j)$ exists for $r = 0, 1, \dots, n_j - 1$; $j = 1, 2, \dots, k$. In this case $f(A) := q_{f,A}(A)$, where $q_{f,A} \in \mathcal{P}_{K-1}$ denotes the unique polynomial of degree at most $K-1$ which satisfies the K Hermite interpolation conditions

$$q_{f,A}^{(r)}(\lambda_j) = f^{(r)}(\lambda_j), \qquad r = 0, 1, \dots, n_j - 1,\ j = 1, 2, \dots, k. \tag{2.1}$$

In the remainder of the paper, we denote the unique polynomial q which interpolates f in the Hermite sense at a set of nodes $\{\vartheta_j\}_{j=1}^{k}$ with multiplicities n_j by $I_p f \in \mathcal{P}_{K-1}$,

$K = \sum_j n_j$, where $p \in \mathcal{P}_K$ is a (not necessarily monic) nodal polynomial with zeros ϑ_j of multiplicities n_j. In this notation, (2.1) reads

$$q_{f,A} = I_{m_A} f.$$

Our objective is the evaluation of $f(A)\boldsymbol{b}$ rather than $f(A)$, and this can possibly be achieved with polynomials of lower degree than $q_{f,A}$. To this end, let the minimal polynomial of $\boldsymbol{b} \in \mathbb{C}^n$ with respect to A be given by

$$m_{A,\boldsymbol{b}}(\lambda) = \prod_{j=1}^{\ell} (\lambda - \lambda_j)^{m_j} \in \mathcal{P}_L, \qquad \text{where } L = L(A,\boldsymbol{b}) = \sum_{j=1}^{\ell} m_j. \tag{2.2}$$

PROPOSITION 2.1. *Given a function f, a matrix $A \in \mathbb{C}^{n\times n}$ such that $f(A)$ is defined, and a vector $\boldsymbol{b} \in \mathbb{C}^n$ whose minimal polynomial with respect to A is given by* (2.2)*, there holds $f(A)\boldsymbol{b} = q_{f,A,\boldsymbol{b}}(A)\boldsymbol{b}$, where $q_{f,A,\boldsymbol{b}} := I_{m_{A,\boldsymbol{b}}} f \in \mathcal{P}_{L-1}$ denotes the unique Hermite interpolating polynomial determined by the conditions*

$$q_{f,A,\boldsymbol{b}}^{(r)}(\lambda_j) = f^{(r)}(\lambda_j), \qquad r = 0, 1, \ldots, m_j - 1,\ j = 1, 2, \ldots, \ell.$$

2.2. Krylov subspace approximations. We recall the definition of the mth Krylov subspace of $A \in \mathbb{C}^{n\times n}$ and $\mathbf{0} \neq \boldsymbol{b} \in \mathbb{C}^n$ given by

$$\mathcal{K}_m(A,\boldsymbol{b}) := \operatorname{span}\{\boldsymbol{b}, A\boldsymbol{b}, ..., A^{m-1}\boldsymbol{b}\} = \{q(A)\boldsymbol{b} \,:\, q \in \mathcal{P}_{m-1}\}.$$

By Proposition 2.1, $f(A)\boldsymbol{b}$ lies in $\mathcal{K}_L(A,\boldsymbol{b})$. The index $L = L(A,\boldsymbol{b}) \in \mathbb{N}$ (cf. (2.2)) is the smallest number for which $\mathcal{K}_L(A,\boldsymbol{b}) = \mathcal{K}_{L+1}(A,\boldsymbol{b})$. Note that for certain functions such as $f(\lambda) = 1/\lambda$, we have $f(A)\boldsymbol{b} \in \mathcal{K}_L(A,\boldsymbol{b}) \setminus \mathcal{K}_{L-1}(A,\boldsymbol{b})$; in general, however, $f(A)\boldsymbol{b}$ may lie in a space $\mathcal{K}_m(A,\boldsymbol{b})$ with $m < L$.[1]

In what follows, we consider a sequence of approximations $\boldsymbol{y}_m := q(A)\boldsymbol{b} \in \mathcal{K}_m(A,\boldsymbol{b})$ to $f(A)\boldsymbol{b}$ with polynomials $q \in \mathcal{P}_{m-1}$ which in some sense approximate f. The most popular of these approaches (see [28, 14, 17]), to which we shall refer as the *Arnoldi approximation*, is based on the Arnoldi decomposition of $\mathcal{K}_m(A,\boldsymbol{b})$,

$$AV_m = V_{m+1}\widetilde{H}_m = V_m H_m + \eta_{m+1,m}\boldsymbol{v}_{m+1}\boldsymbol{e}_m^\top. \tag{2.3}$$

Here, the columns of $V_m = [\boldsymbol{v}_1, \boldsymbol{v}_2, \ldots, \boldsymbol{v}_m]$ form an orthonormal basis of $\mathcal{K}_m(A,\boldsymbol{b})$ with $\boldsymbol{v}_1 = \boldsymbol{b}/\|\boldsymbol{b}\|$, $\widetilde{H}_m = [\eta_{j,\ell}] \in \mathbb{C}^{(m+1)\times m}$ as well as $H_m := [I_m, \mathbf{0}]\,\widetilde{H}_m \in \mathbb{C}^{m\times m}$ are unreduced upper Hessenberg matrices, and $\boldsymbol{e}_m \in \mathbb{R}^m$ denotes the mth unit coordinate vector. The Arnoldi approximation to $f(A)\boldsymbol{b}$ is then defined by

$$\boldsymbol{f}_m := \beta V_m f(H_m)\boldsymbol{e}_1, \qquad \text{where } \beta = \|\boldsymbol{b}\|.$$

The rationale behind this approximation is that H_m represents the compression of A onto $\mathcal{K}_m(A,\boldsymbol{b})$ with respect to the basis V_m and that $\boldsymbol{b} = \beta V_m \boldsymbol{e}_1$.

The non-Hermitian (or two-sided) Lanczos algorithm is another procedure for generating a decomposition of the form (2.3). In that case the columns of V_m still form a basis of $\mathcal{K}_m(A,\boldsymbol{b})$, albeit one that is, in general, not orthogonal, and the upper Hessenberg matrices $\widetilde{H}_m$ are tridiagonal (or block tridiagonal if a look-ahead

[1] For the exponential function it was shown in [28, Theorem 3.6] that $e^{tA}\boldsymbol{b} \in \mathcal{K}_m(A,\boldsymbol{b})$ for all $t \in \mathbb{R}$ if and only if $m \geq L$.

technique is employed). The associated approximation to $f(A)\boldsymbol{b}$ is again defined by $\boldsymbol{f}_m := \beta V_m f(H_m)\boldsymbol{e}_1$ (see, e.g., [14, 28, 17]). Both approximations $\boldsymbol{f}_m$, based either on the Arnoldi or Lanczos decomposition, result from an interpolation procedure: If $q \in \mathcal{P}_{m-1}$ denotes the polynomial which interpolates f in the Hermite sense on the spectrum of H_m (counting multiplicities), then

$$\boldsymbol{f}_m = \beta V_m f(H_m)\boldsymbol{e}_1 = \beta V_m q(H_m)\boldsymbol{e}_1 = q(A)\boldsymbol{b}, \qquad m = 1, 2, \ldots, L$$

(see [28, Theorem 3.3]).

For later applications, next we show that similar results hold true for more general decompositions of $\mathcal{K}_m(A, \boldsymbol{b})$. To this end, we introduce a sequence of ascending (not necessarily orthonormal) basis vectors $\{\boldsymbol{w}_m\}_{m=1}^L$ such that

$$\mathcal{K}_m(A, \boldsymbol{b}) = \operatorname{span}\{\boldsymbol{w}_1, \boldsymbol{w}_2, \ldots, \boldsymbol{w}_m\}, \qquad m = 1, 2, \ldots, L. \tag{2.4}$$

As is well known, there exists a unique unreduced upper Hessenberg matrix $H = [\eta_{j,m}] \in \mathbb{C}^{L\times L}$ such that, with $W := [\boldsymbol{w}_1, \boldsymbol{w}_2, \ldots, \boldsymbol{w}_L] \in \mathbb{C}^{n\times L}$, there holds $AW = WH$ and, for $m = 1, 2, \ldots, L-1$, we have

$$AW_m = W_{m+1}\widetilde{H}_m = W_m H_m + \eta_{m+1,m}\boldsymbol{w}_{m+1}\boldsymbol{e}_m^\top, \tag{2.5}$$

where $\widetilde{H}_m$ is the $(m+1)\times m$ leading submatrix of H, $H_m := [I_m, \boldsymbol{0}]\widetilde{H}_m$, and $W_m = [\boldsymbol{w}_1, \boldsymbol{w}_2, \ldots, \boldsymbol{w}_m]$. We shall refer to (2.5) as an *Arnoldi-like decomposition*[2] to distinguish it from a proper Arnoldi decomposition (2.3). We shall require the following lemma, which is a simple generalization of the corresponding result for (proper) Arnoldi decompositions (cf. [28, 23]).

LEMMA 2.2. *For any polynomial $q(\lambda) = \alpha_m\lambda^m + \cdots + \alpha_1\lambda + \alpha_0 \in \mathcal{P}_m$, the vector $q(A)\boldsymbol{b}$ may be represented in terms of the Arnoldi-like decomposition* (2.5) *as*

$$q(A)\boldsymbol{b} = \begin{cases} \beta\big[W_m q(H_m)\boldsymbol{e}_1 + \alpha_m\gamma_m\boldsymbol{w}_{m+1}\big], & m < L, \\ \beta W_L q(H_L)\boldsymbol{e}_1, & m \geq L, \end{cases} \tag{2.6}$$

where $\gamma_m := \prod_{j=1}^m \eta_{j+1,j}$ and $\beta\boldsymbol{w}_1 = \boldsymbol{b}$. In particular, for any $q \in \mathcal{P}_{m-1}$ there holds $q(A)\boldsymbol{b} = \beta W_m q(H_m)\boldsymbol{e}_1$.

The proof follows by verifying the assertion for monomials, taking account of the sparsity pattern of powers of a Hessenberg matrix (see, e.g., [12]).

We next introduce polynomial notation to describe Krylov subspaces. To each vector $\boldsymbol{w}_m$ of the nested basis (2.4) there corresponds a unique polynomial $w_{m-1} \in \mathcal{P}_{m-1}$ such that $\boldsymbol{w}_m = w_{m-1}(A)\boldsymbol{b}$. Via this correspondence, the Arnoldi-like recurrence (2.5) becomes

$$\begin{aligned} \lambda[w_0(\lambda), w_1(\lambda), \ldots, w_{m-1}(\lambda)] = {} & [w_0(\lambda), w_1(\lambda), \ldots, w_{m-1}(\lambda)]H_m \\ & + \eta_{m+1,m}[0, 0, \ldots, 0, w_m(\lambda)]. \end{aligned} \tag{2.7}$$

From this equation it is evident that each zero of w_m is an eigenvalue of H_m. Moreover, by differentiating (2.7), one observes that zeros of multiplicity ℓ are eigenvalues of H_m with Jordan blocks of dimension ℓ. Since H_m is an unreduced Hessenberg matrix and

[2] We mention that the related term *Krylov decomposition* introduced by Stewart in [32] refers to a decomposition of the form (2.5) without the restriction that the basis be ascending and, consequently, to a matrix H which is not necessarily Hessenberg.

hence nonderogatory, we conclude that the zeros of w_m coincide with the eigenvalues of H_m counting multiplicity.

LEMMA 2.3. *Let H_m be the unreduced upper Hessenberg matrix in* (2.5) *and* (2.7) *and let f be a function such that $f(H_m)$ is defined. Then a polynomial $q_{m-1} \in \mathcal{P}_{m-1}$ satisfies*

$$q_{m-1}(H_m) = f(H_m)$$

if and only if $q_{m-1} = I_{w_m} f$, i.e., if q_{m-1} interpolates f in the Hermite sense at the eigenvalues of H_m.

Proof. The proof follows directly from the definition of $f(H_m)$ and the fact that the zeros of w_m are the eigenvalues of H_m with multiplicity. ∎

We summarize the contents of Lemmata 2.2 and 2.3 as follows.

THEOREM 2.4. *Given the Arnoldi-like decomposition* (2.5) *and a function f such that $f(A)$ as well as $f(H_m)$ are defined, we denote by $q \in \mathcal{P}_{m-1}$ the unique polynomial which interpolates f at the eigenvalues of H_m. Then there holds*

$$\boldsymbol{f}_m := \beta V_m f(H_m)\boldsymbol{e}_1 = \beta V_m q(H_m)\boldsymbol{e}_1 = q(A)\boldsymbol{b}. \tag{2.8}$$

We shall refer to (2.8) as *the Krylov subspace approximation of $f(A)\boldsymbol{b}$ associated with the Arnoldi-like decomposition* (2.5). Note that (2.8) is merely a computational device for generating the Krylov subspace approximation of $f(A)\boldsymbol{b}$ without explicitly carrying out the interpolation process. This is an advantage whenever $f(H_m)\boldsymbol{e}_1$ for $m \ll n$ can be evaluated efficiently.

Remark 2.5. We also point out the following—somewhat academic—detail regarding finite termination: While Krylov subspace approximations $q(A)\boldsymbol{b}$ are defined for polynomials q of any degree, Arnoldi-like decompositions, and hence (2.8), are only available for $1 \le m \le L = L(A, \boldsymbol{b})$. At index $m = L$, the characteristic polynomial of $H_L = H$ coincides with the minimal polynomial $m_{A,\boldsymbol{b}}$ of $\boldsymbol{b}$ with respect to A (see (2.2)). In view of (2.8) and Proposition 2.1, we then have $\boldsymbol{f}_L = f(A)\boldsymbol{b}$. In this sense, Krylov subspace approximations of the form (2.8) respect the spectral distribution of A relevant for $\boldsymbol{b}$ and, in exact arithmetic, possess the finite termination property. This is in contrast to other approaches such as those based on Chebyshev or Faber expansions (see below).

Besides those generated by the Arnoldi or Lanczos processes, any ascending basis $\{\boldsymbol{w}_m\}_{m=1}^L$ of $\mathcal{K}_L(A, \boldsymbol{b})$ or, equivalently, any sequence of polynomials $\{w_{m-1}\}_{m=1}^L$ of exact degree $m-1$ may be used in the Arnoldi-like decomposition (2.5) or its polynomial counterpart (2.7), provided a means for obtaining the matrix $\widetilde{H}_L$ of recurrence coefficients is available. One such example is the sequence of kernel/quasi-kernel polynomials associated with the Arnoldi/Lanczos decomposition (see [13]), where the corresponding Hessenberg matrix is easily constructed from that of the original decomposition. Approximations based on quasi-kernel polynomials are discussed in [20]. Yet another approach—one which emphasizes the interpolation aspect of the Krylov subspace approximation—fixes a sequence of nodes

$$\begin{array}{lll} \vartheta_1^{(1)} & & \\ \vartheta_1^{(2)} & \vartheta_2^{(2)} & \\ \vartheta_1^{(3)} & \vartheta_2^{(3)} & \vartheta_3^{(3)} \\ \vdots & \vdots & \ddots \end{array}$$

and chooses the basis vectors $\boldsymbol{w}_m = w_{m-1}(A)\boldsymbol{b}$ as the associated nodal polynomials

$$w_{m-1}(\lambda) = \omega_{m-1}(\lambda - \vartheta_1^{(m)})(\lambda - \vartheta_2^{(m)}) \dots (\lambda - \vartheta_m^{(m)}), \qquad \omega_m \neq 0.$$

One possible choice of such a node sequence is the zeros of Chebyshev polynomials, in which case the nested basis vectors correspond to Chebyshev polynomials. Other choices of node sequences are explored in [19, 22, 20]. Note that, in view of Remark 2.5, such a basis choice, which is independent of A and $\boldsymbol{b}$, will generally destroy the finite termination property.

We also point out that, when $f(A)$ is defined, this need not be so for $f(H_m)$ for $m < L$. For the Arnoldi approximation, a sufficient condition ensuring this is that f, as a scalar function, be analytic in a neighborhood of the field of values of A. As a case in point, consider the FOM for solving a nonsingular system of linear equations $A\boldsymbol{x} = \boldsymbol{b}$. The solution is $f(A)\boldsymbol{b}$ with $f(\lambda) = 1/\lambda$ and, if the initial approximation is $\boldsymbol{x}_0 = \boldsymbol{0}$, the mth FOM iterate is simply the Arnoldi approximation $\boldsymbol{f}_m = \beta V_m H_m^{-1} \boldsymbol{e}_1$. There are well-known examples [3] in which $f(A)$, i.e., A^{-1}, is defined but for which H_m is singular for one or more of the indices $m = 1, \dots, L-1$, a phenomenon sometimes called a *Galerkin breakdown*.

2.3. An error representation. We conclude this section with a representation of the error of the Krylov subspace approximation of $f(A)\boldsymbol{b}$ based on any Arnoldi-like decomposition or, equivalently, any interpolatory approximation. We shall need the following notation: Given a function f and a set of nodes $\vartheta_1, \dots, \vartheta_m$ with associated nodal polynomial

$$p(\lambda) = (\lambda - \vartheta_1)(\lambda - \vartheta_2) \cdots (\lambda - \vartheta_m), \tag{2.9}$$

we denote the mth order divided difference of f with respect to the nodes $\{\vartheta_j\}_{j=1}^m$ by[3]

$$\mathbb{\Delta}_p f := \frac{f - I_p f}{p}. \tag{2.10}$$

THEOREM 2.6. *Given $A \in \mathbb{C}^{n\times n}$, $\boldsymbol{b} \in \mathbb{C}^n$, and a function f, let* (2.5) *be an Arnoldi-like decomposition of $\mathcal{K}_m(A, \boldsymbol{b})$ and let $w_m \in \mathcal{P}_{m-1}$ be the associated polynomial; cf.* (2.7)*. Then there holds*

$$f(A)\boldsymbol{b} - \beta W_m f(H_m)\boldsymbol{e}_1 = \beta\gamma_m [\mathbb{\Delta}_{w_m} f](A)\boldsymbol{w}_{m+1} \tag{2.11}$$

with γ_m as in Lemma 2.2*.*

Proof. We consider first an arbitrary set of nodes $\vartheta_1, \dots, \vartheta_m$ with associated nodal polynomial p as in (2.9). From the definition (2.10), there holds $f(\lambda) = [I_p f](\lambda) + [\mathbb{\Delta}_p f](\lambda)p(\lambda)$. Inserting A for λ in this identity and multiplying by $\boldsymbol{b}$, we obtain

$$f(A)\boldsymbol{b} = [I_p f](A)\boldsymbol{b} + [\mathbb{\Delta}_p f](A)p(A)\boldsymbol{b}.$$

Since $I_p f \in \mathcal{P}_{m-1}$, Lemma 2.2 yields $[I_p f](A)\boldsymbol{b} = \beta W_m [I_p f](H_m)\boldsymbol{e}_1$ and, since $p \in \mathcal{P}_m$ is monic, $p(A)\boldsymbol{b} = \beta W_m p(H_m)\boldsymbol{e}_1 + \beta\gamma_m \boldsymbol{w}_{m+1}$, giving

$$f(A)\boldsymbol{b} - \beta W_m [I_p f](H_m)\boldsymbol{e}_1 = \beta [\mathbb{\Delta}_p f](A)\big(W_m p(H_m)\boldsymbol{e}_1 + \gamma_m \boldsymbol{w}_{m+1}\big).$$

[3] The source of and justification for this notation can be found in [7].

Choosing p as the characteristic polynomial w_m of H_m, it follows that $w_m(H_m) = O$ by the Cayley–Hamilton theorem and, since $I_{w_m} f$ interpolates f at the eigenvalues of H_m, there also holds $[I_{w_m} f](H_m) = f(H_m)$ by Lemma 2.3. ∎

We interpret (2.11) as follows: Further improvement of a Krylov approximation $\boldsymbol{f}_m = \beta V_m f(H_m)\boldsymbol{e}_1$ could be achieved by approximating the error term

$$f(A)\boldsymbol{b} - \boldsymbol{f}_m = \widetilde{f}(A)\widetilde{\boldsymbol{b}}$$

with $\widetilde{f}(\lambda) := [\Delta_{w_m} f](\lambda)$ and $\widetilde{\boldsymbol{b}} := \beta\gamma_m \boldsymbol{w}_{m+1}$. Note that the modified function $\widetilde{f}$ has the same domain of analyticity as f and the vector $\widetilde{\boldsymbol{b}}$ points in the direction of the last vector in the Arnoldi-like decomposition.

3. A restarted Arnoldi approximation. For the remainder of the paper we shall restrict the discussion to the Arnoldi approximation of $f(A)\boldsymbol{b}$. To set this apart from a general Krylov subspace approximation (2.8) we denote the (orthonormal) Arnoldi basis vectors by $\boldsymbol{v}_1, \boldsymbol{v}_2, \ldots, \boldsymbol{v}_L$ and the Arnoldi decomposition by

$$AV_m = V_m H_m + \eta_{m+1,m}\boldsymbol{v}_{m+1}\boldsymbol{e}_m^\top, \qquad V_m = [\boldsymbol{v}_1, \boldsymbol{v}_2, \ldots, \boldsymbol{v}_m]$$

(cf. (2.3)). Our results apply to other Krylov subspace approximations with obvious modifications, some of which we shall point out.

3.1. Short recurrences are not enough. Besides the evaluation of $f(H_m)$, the computation of the mth Arnoldi approximation $\boldsymbol{f}_m = \beta V_m f(H_m)\boldsymbol{e}_1$ requires the Arnoldi basis V_m, which consists of m vectors of size n. As a consequence, even if the evaluation of $f(H_m)$ can be accomplished inexpensively, work and storage requirements incurred by V_m make this method impractical for moderate to large values of m. For $f(\lambda) = 1/\lambda$, i.e., when solving linear systems of equations, one can take advantage of the fact that the Arnoldi process reduces to the Hermitian Lanczos process when A is Hermitian. In this case the matrices H_m are Hermitian, hence tridiagonal, and three-term recurrence formulas can be derived for their characteristic polynomials w_m. (The same is true even in the non-Hermitian case when employing the non-Hermitian Lanczos process, possibly with look-ahead techniques.) If we interpolate $f(\lambda) = 1/\lambda$ at the zeros of the mth basis polynomial w_m, the resulting interpolating polynomial $q_{m-1} = I_{w_m} f$ satisfies

$$q_{m-1}(\lambda) = \frac{w_m(0) - w_m(\lambda)}{\lambda w_m(0)}, \tag{3.1}$$

and therefore q_{m-1} and hence also the approximation $\boldsymbol{f}_m$ obey a similar three-term recurrence. The relation (3.1) between the nodal and the interpolation polynomials can therefore be viewed as the basis for the efficiency of the conjugate gradient method and other polynomial acceleration methods such as Chebyshev iteration for solving linear systems of equations.

A relation analogous to (3.1) fails to hold for more complicated (nonrational) functions f such as the exponential function, and therefore short recurrences for the nodal polynomials do not translate into short recurrences for the interpolation polynomials. The computation of $\boldsymbol{f}_m$ therefore necessitates storing the full Arnoldi basis V_m also when A is Hermitian. It is therefore of interest to modify the Arnoldi approximation in a way that allows the construction of successively better approximations of $f(A)\boldsymbol{b}$

based on a sequence of Krylov spaces of small dimension.[4] Such *restarted Krylov subspace methods* are well known for the solution of linear systems of equations; see [26, 10].

3.2. Krylov approximation after Arnoldi restart. Consider two Krylov spaces of order m with Arnoldi decompositions

$$AV_m^{(1)} = V_m^{(1)} H_m^{(1)} + \eta_{m+1,m}^{(1)} \boldsymbol{v}_{m+1}^{(1)} \boldsymbol{e}_m^\top, \tag{3.2a}$$

$$AV_m^{(2)} = V_m^{(2)} H_m^{(2)} + \eta_{m+1,m}^{(2)} \boldsymbol{v}_{m+1}^{(2)} \boldsymbol{e}_m^\top, \tag{3.2b}$$

where $\boldsymbol{v}_1^{(1)} = \boldsymbol{b}/\beta$ and $\boldsymbol{v}_1^{(2)} = \boldsymbol{v}_{m+1}^{(1)}$, i.e., obtained from two cycles of the Arnoldi process applied to A, beginning with initial vector $\boldsymbol{b}$ and restarted after m steps with the last Arnoldi basis vector $\boldsymbol{v}_{m+1}^{(1)}$ from the first cycle. We note that the columns of $W_{2m} := [V_m^{(1)}, V_m^{(2)}]$ form a basis of $\mathcal{K}_{2m}(A, \boldsymbol{b})$, albeit not an orthonormal one, and we may combine the two proper Arnoldi decompositions (3.2) to the Arnoldi-like decomposition

$$AW_{2m} = W_{2m} H_{2m} + \eta_{m+1,m}^{(2)} \boldsymbol{v}_{m+1}^{(2)} \boldsymbol{e}_{2m}^\top, \tag{3.3}$$

where H_{2m} is the Hessenberg matrix

$$H_{2m} := \begin{bmatrix} H_m^{(1)} & O \\ \eta_{m+1,m}^{(1)} \boldsymbol{e}_1 \boldsymbol{e}_m^\top & H_m^{(2)} \end{bmatrix}. \tag{3.4}$$

Remark 3.1. We restart the Arnoldi process with $\boldsymbol{v}_{m+1}^{(1)}$, which is the most natural choice. We could, however, restart with any vector of the form

$$\widehat{\boldsymbol{v}}_{m+1} = V_m^{(1)} \boldsymbol{y} + y_{m+1} \boldsymbol{v}_{m+1}^{(1)} \in \mathcal{K}_{m+1}(A, \boldsymbol{b}) \setminus \mathcal{K}_m(A, \boldsymbol{b})$$

with a coefficient vector $\boldsymbol{y} = [y_1, y_2, \ldots, y_m]^\top \in \mathbb{C}^m$. In this case we must replace $H_m^{(1)}$ in (3.4) by the rank-one modification $H_m^{(1)} - (\eta_{m+1,m}^{(1)}/y_{m+1}) \boldsymbol{y} \boldsymbol{e}_m^\top$ and $\eta_{m+1,m}^{(1)}$ by $\eta_{m+1,m}^{(1)}/y_{m+1}$. It is conceivable that this could be used to emphasize certain directions such as Ritz approximations of certain eigenvectors as is done in popular restarting techniques for linear systems of equations [21] and eigenvalue calculations [30], but we shall not pursue this here.

Our objective is to compute the Krylov subspace approximation associated with (3.3) without reference to $V_m^{(1)}$. The former is defined as

$$\boldsymbol{f}_{2m} = [I_{w_{2m}} f](A)\boldsymbol{b} = \beta W_{2m} [I_{w_{2m}} f](H_{2m}) \boldsymbol{e}_1 = \beta W_{2m} f(H_{2m}) \boldsymbol{e}_1, \tag{3.5}$$

where w_{2m} is the nodal polynomial with zeros $\Lambda(H_m^{(1)}) \cup \Lambda(H_m^{(2)})$ with multiplicity. To evaluate the approximation (3.5), we note that $f(H_{2m})$ is of the form

$$f(H_{2m}) = \begin{bmatrix} f\big(H_m^{(1)}\big) & O \\ X_{2,1} & f\big(H_m^{(2)}\big) \end{bmatrix}, \qquad X_{2,1} \in \mathbb{C}^{m \times m}, \tag{3.6}$$

[4] Another remedy, well known from Lanczos-based eigenvalue computations (see [24, Chapter 13]), is to discard the basis vectors no longer needed in the recurrence and either recompute these or retrieve them from secondary storage when forming the approximation.

a consequence of the block triangular structure of H_{2m}, whereby (3.5) becomes

$$\boldsymbol{f}_{2m} = \beta V_m^{(1)} f(H_m^{(1)})\boldsymbol{e}_1 + \beta V_m^{(2)} X_{2,1}\boldsymbol{e}_1. \tag{3.7}$$

The first term on the right is the Arnoldi approximation with respect to $\mathcal{K}_m(A, \boldsymbol{b})$. If $X_{2,1}\boldsymbol{e}_1$ were computable, one could discard the basis vectors $V_m^{(1)}$ and use (3.7) to update the Arnoldi approximation, thus yielding the basis for a restarting scheme.

One conceivable approach is to observe that $X_{2,1}$ satisfies the Sylvester equation

$$H_m^{(2)}X_{2,1} - X_{2,1}H_m^{(1)} = \eta_{m+1,m}^{(1)}[f(H_m^{(2)})\boldsymbol{e}_1\boldsymbol{e}_m^\top - \boldsymbol{e}_1\boldsymbol{e}_m^\top f(H_m^{(1)})], \tag{3.8}$$

which follows from comparing the $(2,1)$ blocks of the identity $H_{2m}f(H_{2m}) = f(H_{2m})$ H_{2m}, and one could therefore proceed by solving (3.8). This approach, however, suffers from the shortcoming that the Sylvester equation (3.8) is only well conditioned if the spectra of $H_m^{(1)}$ and $H_m^{(2)}$ are well separated (cf. [16, section 15.3]). Since $H_m^{(1)}$ and $H_m^{(2)}$ are both compressions of the same matrix A, it is to be expected that at least some of their eigenvalues match very closely.

We shall instead derive a computable expression for $X_{2,1}\boldsymbol{e}_1$ directly by way of interpolation.

LEMMA 3.2. *Given two successive Arnoldi decompositions as in* (3.2)*, let* $w_m^{(1)}$*,* $w_m^{(2)}$*, and* w_{2m} *denote the monic nodal polynomials associated with* $\Lambda(H_m^{(1)})$*,* $\Lambda(H_m^{(2)})$*, and* $\Lambda(H_{2m}) = \Lambda(H_m^{(1)}) \cup \Lambda(H_m^{(2)})$*, respectively, with* H_{2m} *the upper Hessenberg matrix of the combined Arnoldi-like decomposition* (3.3)*. Then there holds*

$$[I_{w_{2m}}f](H_{2m})\boldsymbol{e}_1 = \begin{bmatrix} [I_{w_m^{(1)}}f]\big(H_m^{(1)}\big)\boldsymbol{e}_1 \\ \gamma_m^{(1)}[I_{w_m^{(2)}}(\Delta_{w_m^{(1)}}f)]\big(H_m^{(2)}\big)\boldsymbol{e}_1 \end{bmatrix}, \tag{3.9}$$

where $\gamma_m^{(1)} = \prod_{j=1}^m \eta_{j+1,j}^{(1)}$ *(cf. Lemma* 2.2*).*

Proof. Due to the block triangular structure of H_{2m} as given in (3.6), there holds

$$[I_{w_{2m}}f]\left(\begin{bmatrix} H_m^{(1)} & O \\ \eta_{m+1,m}^{(1)}\boldsymbol{e}_1\boldsymbol{e}_m^\top & H_m^{(2)} \end{bmatrix}\right) = \begin{bmatrix} [I_{w_{2m}}f]\big(H_m^{(1)}\big) & O \\ X_{2,1} & [I_{w_{2m}}f]\big(H_m^{(2)}\big) \end{bmatrix} \tag{3.10}$$

with $X_{2,1}$ as in (3.6). Next, we establish the polynomial identity

$$[I_{w_{2m}}f] = I_{w_m^{(1)}}f + I_{w_m^{(2)}}(\Delta_{w_m^{(1)}}f)\, w_m^{(1)}, \tag{3.11}$$

which can be seen by noting that both polynomials have the same degree $2m-1$ and interpolate f in the Hermite sense at the nodes $\Lambda(H_m^{(1)}) \cup \Lambda(H_m^{(1)})$. For nodes $\vartheta \in \Lambda(H_m^{(1)})$ this is so because $w_m^{(1)}(\vartheta) = 0$ and therefore

$$[I_{w_m^{(1)}}f](\vartheta) + [I_{w_m^{(2)}}(\Delta_{w_m^{(1)}}f)](\vartheta)\, w_m^{(1)}(\vartheta) = [I_{w_m^{(1)}}f](\vartheta) = f(\vartheta) = [I_{w_{2m}}f](\vartheta).$$

For nodes $\vartheta \in \Lambda(H_m^{(2)})$ we have

$$\begin{aligned}[I_{w_m^{(1)}}f](\vartheta) + [I_{w_m^{(2)}}(\Delta_{w_m^{(1)}}f)](\vartheta)\, w_m^{(1)}(\vartheta) &= [I_{w_m^{(1)}}f](\vartheta) + [\Delta_{w_m^{(1)}}f](\vartheta)\, w_m^{(1)}(\vartheta) \\ &= f(\vartheta) = [I_{w_{2m}}f](\vartheta)\end{aligned}$$

with the second equality following from the definition (2.10), and (3.11) is established. The assertion on the first block of the vector (3.9) is now verified by inserting the

matrix $H_m^{(1)}$ into the polynomials on either side of (3.11), noting that $w_m^{(1)}(H_m^{(1)}) = O$, and multiplying both sides of (3.10) by $\boldsymbol{e}_1$.

To verify the second block of (3.9), we use identity (3.11) to write

$$[I_{w_{2m}} f](H_{2m}) = M^{(1)} + M^{(2)} M^{(3)},$$

where

$$M^{(1)} := [I_{w_m^{(1)}} f](H_{2m}), \quad M^{(2)} := [I_{w_m^{(2)}}(\Delta_{w_m^{(1)}} f)](H_{2m}), \quad M^{(3)} := w_m^{(1)}(H_{2m}).$$

The block lower triangular structure of H_{2m} carries over to functions of H_{2m}, giving

$$M^{(i)} = \begin{bmatrix} M_{1,1}^{(i)} & O \\ M_{2,1}^{(i)} & M_{2,2}^{(i)} \end{bmatrix}, \qquad i = 1, 2, 3,$$

where in addition $M_{1,1}^{(3)} = w_m^{(1)}(H_m^{(1)}) = O$. In this notation the second block of (3.9) is given by

$$X_{2,1}\boldsymbol{e}_1 = M_{2,1}^{(1)}\boldsymbol{e}_1 + M_{2,2}^{(2)} M_{2,1}^{(3)}\boldsymbol{e}_1. \tag{3.12}$$

For the first term on the right, we have $M_{2,1}^{(1)}\boldsymbol{e}_1 = \mathbf{0}$ because, as the $(2,1)$-block of $M^{(1)} = [I_{w_m^{(1)}} f](H_{2m})$, a polynomial of degree $m-1$ in the Hessenberg matrix H_{2m}, $M_{2,1}^{(1)}$ has a zero first column. Next, again by the block lower triangular structure of H_{2m}, there holds $M_{2,2}^{(2)} = [I_{w_m^{(2)}}(\Delta_{w_m^{(1)}} f)](H_m^{(2)})$. Finally, we note that $M_{2,1}^{(3)}\boldsymbol{e}_1 = \gamma_m^{(1)}\boldsymbol{e}_1$. This follows in a similar way as the evaluation of $M_{2,1}^{(1)}\boldsymbol{e}_1$, but here $M^{(3)} = w_m^{(1)}(H_{2m})$ is a polynomial of degree m in the $2m \times 2m$ upper Hessenberg matrix H_{2m}. Again by the sparsity structure of powers of Hessenberg matrices, the first column of $M_{2,1}^{(3)}$ is a multiple of $\boldsymbol{e}_1$. Comparing coefficients reveals this multiple to be $\gamma_m^{(1)}$. Inserting these quantities in (3.12) establishes the second block of identity (3.9), and the proof is complete. ∎

Remark 3.3. We note that the same proof applies when the two Krylov spaces are of different dimensions m_1 and m_2.

Comparing coefficients in (3.7) and (3.9) reveals that $X_{2,1}\boldsymbol{e}_1 = \gamma_m^{(1)}[\Delta_{w_m^{(1)}} f]\big(H_m^{(2)}\big)\boldsymbol{e}_1$, and we summarize the resulting basic restart step in the following theorem.

THEOREM 3.4. *The Krylov subspace approximation* (3.5) *based on the Arnoldi-like decomposition* (3.3) *is given by*

$$\boldsymbol{f}_{2m} = \beta V_m^{(1)} f\big(H_m^{(1)}\big)\boldsymbol{e}_1 + \beta\gamma_m^{(1)} V_m^{(2)}[\Delta_{w_m^{(1)}} f]\big(H_m^{(2)}\big)\boldsymbol{e}_1. \tag{3.13}$$

Proof. The proof follows immediately from (3.5) upon inserting the representation for $[I_{w_{2m}} f](H_{2m})$ given in Lemma 3.2: Starting with (3.5), we obtain

$$\begin{aligned} \boldsymbol{f}_{2m} &= \beta W_{2m} f(H_{2m})\boldsymbol{e}_1 \\ &= \beta\left(V_m^{(1)}[I_{w_m^{(1)}} f]\big(H_m^{(1)}\big)\boldsymbol{e}_1 + V_m^{(2)}\gamma_m^{(1)}[I_{w_m^{(2)}}(\Delta_{w_m^{(1)}} f)]\big(H_m^{(2)}\big)\boldsymbol{e}_1\right) \\ &= \beta V_m^{(1)} f\big(H_m^{(1)}\big)\boldsymbol{e}_1 + \beta\gamma_m^{(1)} V_m^{(2)}[\Delta_{w_m^{(1)}} f]\big(H_m^{(2)}\big)\boldsymbol{e}_1, \end{aligned}$$

where the last equality follows from the interpolation properties of $I_{w_m^{(1)}}$ and $I_{w_m^{(2)}}$. ∎

3.3. The restarting algorithm. Theorem 3.4 suggests the following scheme for a Krylov approximation of $f(A)\boldsymbol{b}$ based on the restarted Arnoldi process with cycle length m: The first approximation $\boldsymbol{f}^{(1)}$ is simply the usual Arnoldi approximation with respect to the first Krylov space $\mathcal{K}_m(A, \boldsymbol{b})$, i.e., $\boldsymbol{f}^{(1)} = \beta V_m^{(1)} f(H_m^{(1)})\boldsymbol{e}_1$. The next Krylov space is generated with the initial vector $\boldsymbol{v}_{m+1}^{(1)}$ and, according to (3.13), the correction to $\boldsymbol{f}^{(1)}$ required to obtain the Krylov subspace approximation of $f(A)\boldsymbol{b}$ with respect to the Arnoldi-like decomposition (3.3) is given by

$$\boldsymbol{f}^{(2)} = \boldsymbol{f}^{(1)} + \beta\gamma_m^{(1)} V_m^{(2)} [\Delta_{w_m^{(1)}} f]\big(H_m^{(2)}\big)\boldsymbol{e}_1.$$

The effect of restarting is seen to be a modification of the function f to $\Delta_{w_m}^{(1)} f$ and a replacement of the vector $\boldsymbol{b}$ by $\beta\gamma_m^{(1)}\boldsymbol{v}_{m+1}^{(1)}$. Note that this is in line with the error representation (2.3) in that, after restarting, we are in fact approximating the error term and using this approximation as a correction. The computation of this update requires storing a representation of $\Delta_{w_m^{(1)}} f$ as well as the current approximation $\boldsymbol{f}^{(1)}$, but the Arnoldi basis $V_m^{(1)}$ can be discarded. Proceeding in this fashion, we arrive at the restarting scheme given in Algorithm 1.

ALGORITHM 1: RESTARTED ARNOLDI APPROXIMATION FOR $f(A)\boldsymbol{b}$

Given: $A, \boldsymbol{b}, f$
$f^{(0)} := f$, $\boldsymbol{f}^{(0)} := \boldsymbol{0}$, $\boldsymbol{b}^{(0)} := \boldsymbol{b}$, $\gamma^{(0)} := \|\boldsymbol{b}\|$.
for $k = 1, 2, \ldots$ *until convergence* **do**
  Compute the Arnoldi decomposition $AV_m^{(k)} = V_m^{(k)} H^{(k)} + \eta_{m+1,m}^{(k)} \boldsymbol{b}^{(k)} \boldsymbol{e}_m^\top$ of $\mathcal{K}_m(A, \boldsymbol{b}^{(k-1)})$.
  Update the approximation $\boldsymbol{f}^{(k)} := \boldsymbol{f}^{(k-1)} + \gamma^{(k-1)} V_m^{(k)} f^{(k-1)}(H_m^{(k)})\boldsymbol{e}_1$.
  $\gamma^{(k)} := \gamma^{(k-1)} \prod_{j=1}^{m} \eta_{j+1,j}^{(k)}$
  $f^{(k)} := \Delta_{w_m^{(k)}} f^{(k-1)}$, where $w_m^{(k)}$ is the characteristic polynomial of $H_m^{(k)}$.

Remark 3.5. Algorithm 1 is formulated for Krylov spaces of constant dimension m in each restart cycle, but this dimension can vary from cycle to cycle.

Although Algorithm 1 appears very attractive from a computational point of view, numerical experiments with a MATLAB implementation have revealed it to be afflicted with severe stability problems. The cause of this seems to be the difficulty of numerically computing interpolation polynomials of high degree (see also [33]).

We therefore turn to a slightly less efficient variant of our restarting scheme, which our numerical tests indicate to be free from these stability problems. The generic step of this second variant of the restarted Arnoldi algorithm proceeds as follows: After $k-1$ cycles of the algorithm, we may collect the entirety of Arnoldi decompositions in the $(k-1)$-fold Arnoldi-like decomposition

$$AW_{(k-1)m} = W_{(k-1)m} H_{(k-1)m} + \eta_{m+1,m}^{(k-1)} \boldsymbol{v}_{m+1}^{(k-1)} \boldsymbol{e}_{(k-1)m}^\top$$

with $W_{(k-1)m} = [V_m^{(1)} V_m^{(2)} \ldots V_m^{(k-1)}]$. Combining this with the Arnoldi decomposition

$$AV_m^{(k)} = V_m^{(k)} H_m^{(k)} + \eta_{m+1,m}^{(k)} \boldsymbol{v}_{m+1}^{(k)} \boldsymbol{e}_m^\top$$

of the next Krylov space $\mathcal{K}_m(A, \boldsymbol{v}_{m+1}^{(k-1)})$, we obtain the next Arnoldi-like decomposi-

tion

$$AW_{km} = W_{km}H_{km} + \eta^{(k)}_{m+1,m}\boldsymbol{v}^{(k)}_{m+1}\boldsymbol{e}_{km}^\top$$

with $W_{km} = [W_{(k-1)m}, V^{(k)}_m]$ and

$$H_{km} = \begin{bmatrix} H_{(k-1)m} & O \\ \eta^{(k-1)}_{m+1,m}\boldsymbol{e}_1\boldsymbol{e}^\top_{(k-1)m} & H^{(k)}_m \end{bmatrix}.$$

Denoting by w_{km} the characteristic polynomial of H_{km}, formula (2.11) for the Krylov subspace approximation with respect to an Arnoldi-like decomposition gives

$$\boldsymbol{f}^{(k)} = \beta W_{km} f(H_{km})\boldsymbol{e}_1 = \boldsymbol{f}^{(k-1)} + \beta V^{(k)}_m [f(H_{km})\boldsymbol{e}_1]_{(k-1)m+1:km}, \tag{3.14}$$

where the subscript in the last term is meant to refer to the vector with the last m components of $f(H_{km})\boldsymbol{e}_1$. (3.14) provides an alternative update formula for the restarted Arnoldi approximation. It is somewhat less efficient than that given in Algorithm 1 in that it requires storing H_{km} and the evaluation of $f(H_{km})$, but we have found it to be much stabler than the former. The second variant is summarized in Algorithm 2.

ALGORITHM 2: RESTARTED ARNOLDI APPROXIMATION FOR $f(A)\boldsymbol{b}$ (VARIANT 2)

Given: $A, \boldsymbol{b}, f$
$f^{(0)} := f$, $\boldsymbol{f}^{(0)} := \boldsymbol{0}$, $\boldsymbol{b}^{(0)} := \boldsymbol{b}$, $\beta := \|\boldsymbol{b}\|$.
for $k = 1, 2, \ldots$ *until convergence* **do**
  Compute the Arnoldi decomposition $AV^{(k)}_m = V^{(k)}_m H^{(k)}_m + \eta^{(k)}_{m+1,m}\boldsymbol{b}^{(k)}\boldsymbol{e}_m^\top$ of $\mathcal{K}_m(A, \boldsymbol{b}^{(k-1)})$.
  if $k = 1$ **then**
    $H_{km} := H^{(1)}_m$
  else
    $H_{km} := \begin{bmatrix} H_{(k-1)m} & O \\ \eta^{(k-1)}_{m+1,m}\boldsymbol{e}_1\boldsymbol{e}^\top_{(k-1)m} & H^{(k)}_m \end{bmatrix}$.
  Update the approximation $\boldsymbol{f}^{(k)} := \boldsymbol{f}^{(k-1)} + \beta V^{(k)}_m [f(H_{km})\boldsymbol{e}_1]_{(k-1)m+1:km}$.

4. Properties of the restarted Arnoldi algorithm.

4.1. Special cases. In this section we recover some known algorithms as special cases of the restarted Arnoldi approximation.

4.1.1. Linear systems of equations. We begin by showing that for $f(\lambda) = 1/\lambda$ we recover the well-known restarted FOM for solving linear systems of equations [27]. With $I_{w_m} f$ for this case given in (3.1), there results

$$[\mathbb{\Delta}_{w_m} f](\lambda) = \frac{1}{w_m(0)}\frac{1}{\lambda},$$

so that the representation (2.11) becomes

$$A^{-1}\boldsymbol{b} = \beta V_m H_m^{-1}\boldsymbol{e}_1 + \frac{\beta\gamma_m}{w_m(0)}A^{-1}\boldsymbol{v}_{m+1} = \boldsymbol{f}_m + \frac{\beta\gamma_m}{w_m(0)}A^{-1}\boldsymbol{v}_{m+1},$$

where $\boldsymbol{f}_m$ denotes the mth FOM iterate. The associated residual is therefore

$$\boldsymbol{r}_m = \boldsymbol{b} - A\boldsymbol{f}_m = \frac{\beta\gamma_m}{w_m(0)}\boldsymbol{v}_{m+1}, \tag{4.1}$$

which leads to

$$A^{-1}\boldsymbol{b} = \boldsymbol{f}_m + A^{-1}\boldsymbol{r}_m.$$

We conclude that in this case the exact correction $\boldsymbol{c}$ to the Arnoldi approximation $\boldsymbol{f}_m$ is the solution of the residual equation $A\boldsymbol{c} = \boldsymbol{r}_m$, leading to the problem of approximating $f(A)\boldsymbol{r}_m$, which in restarted FOM is carried out using a new Krylov space with initial vector $\boldsymbol{r}_m$. As an aside, we observe that (4.1) implies that the FOM residual norm can be expressed as

$$\|\boldsymbol{r}_m\| = \frac{\beta\gamma_m}{|w_m(0)|} = \frac{\beta\prod_{j=1}^{m}\eta_{j+1,j}}{|\det H_m|},$$

an expression first given in [4].

4.2. Initial value problems. We consider the initial value problem

$$\boldsymbol{y}'(t) = A\boldsymbol{y}(t), \quad \boldsymbol{y}(0) = \boldsymbol{b} \tag{4.2}$$

with $A \in \mathbb{C}^{n\times n}$, $\boldsymbol{b} \in \mathbb{C}^n$ (independent of t) with solution

$$\boldsymbol{y}(t) = f_t(A)\boldsymbol{b}, \qquad f_t(\lambda) = e^{t\lambda}. \tag{4.3}$$

The Arnoldi approximation of (4.3) with respect to (2.3) is given by

$$\boldsymbol{y}_m(t) = V_m\boldsymbol{u}(t), \qquad \boldsymbol{u}(t) = \beta e^{tH_m}\boldsymbol{e}_1, \quad \beta = \|\boldsymbol{b}\|. \tag{4.4}$$

As is easily verified, the associated approximation error $\boldsymbol{d}_m(t) := \boldsymbol{y}(t) - \boldsymbol{y}_m(t)$ as a function of t satisfies the initial value problem

$$(\partial_t - A)\boldsymbol{d}_m(t) = \boldsymbol{r}_m(t), \qquad \boldsymbol{d}_m(0) = \boldsymbol{0}, \tag{4.5}$$

in which the forcing term $\boldsymbol{r}_m(t)$, which plays the role of a residual, is given by

$$\boldsymbol{r}_m(t) := \eta_{m+1,m}\boldsymbol{e}_1^\top\boldsymbol{u}(t)\boldsymbol{v}_{m+1} = \beta\eta_{m+1,m}\boldsymbol{e}_m^\top e^{tH_m}\boldsymbol{e}_1\boldsymbol{v}_{m+1} =: \rho_m(t)\boldsymbol{v}_{m+1}. \tag{4.6}$$

In [4] (see also [19]) Celledoni and Moret propose a restarted Krylov subspace scheme for solving (4.2) based on the variation of constants formula

$$\boldsymbol{d}_m(t) = F_t(A)\boldsymbol{v}_{m+1}, \qquad F_t(\lambda) := \int_0^t e^{(t-s)\lambda}\rho_m(s)\,ds, \tag{4.7}$$

for the solution of the residual equation (4.5) using repeated Arnoldi approximations of $F_t(A)\boldsymbol{v}_{m+1}$ in a manner similar to Algorithm 1. We note that, in contrast to Algorithm 1, their method requires a time-stepping scheme in addition to the Krylov approximation. As the approximate solution (4.4) of (4.2) is an Arnoldi approximation, the error representation (4.7) must coincide with that given in (2.11). To provide more insight on the restarted Arnoldi approximation for solving initial value problems, we proceed to show explicitly that the two error representations are the same. The key is the proper treatment of the parameter t. Denoting the error representation (2.11) with $f = f_t$ by

$$\widetilde{\boldsymbol{d}}_m(t) = \beta\gamma_m[\Delta_{w_m}f_t](A)\boldsymbol{v}_{m+1}, \tag{4.8}$$

we prove the following result.

THEOREM 4.1. *The error representation* (4.8) *for the Arnoldi approximation of* (4.3) *as a function of* t *solves the initial value problem* (4.5).

Proof. The initial condition $\widetilde{\boldsymbol{d}}_m(0) = \mathbf{0}$ follows from the fact that $f_0 \equiv 1$ and, since this function is interpolated without error, the associated divided difference is zero.

To verify that $\widetilde{\boldsymbol{d}}_m$ solves the differential equation, note first that differentiating the interpolant of f_t with respect to the parameter t results in

$$\partial_t[I_{w_m} f_t] = I_{w_m}(\partial_t f_t). \tag{4.9}$$

This can be seen by writing the interpolant as

$$[I_{w_m} f_t](\lambda) = \sum_{j=1}^{k} \sum_{\ell=0}^{n_j-1} f_t^{(\ell)}(\vartheta_j)\, q_{j,\ell}(\vartheta_j), \qquad \sum_{j=1}^{k} n_j = m,$$

in terms of the Hermite basis polynomials $q_{j,\ell} \in \mathcal{P}_{m-1}$, characterized by

$$q_{j,\ell}^{(p)}(\vartheta_q) = \delta_{j,q}\,\delta_{\ell,p}, \qquad j,q = 1,2,\ldots,k, \qquad \ell,p = 0,1,\ldots,n_j-1,$$

and exchanging the order of differentiation. As a consequence of (4.9) and the fact that $(\partial_t f_t)(\lambda) = \lambda f_t(\lambda)$, we also have

$$\partial_t[\Lambda_{w_m} f_t] = \Lambda_{w_m}(\partial_t f_t) = \Lambda_{w_m}(g f_t), \qquad \text{where } g(\lambda) = \lambda.$$

The product formula for divided differences (see, e.g., [25, Theorem 1.3.3]) now yields

$$\partial_t[\Lambda_{w_m} f_t](\lambda) = \lambda[\Lambda_{w_m} f_t](\lambda) + \pi_{m-1}(t), \tag{4.10}$$

where $\pi_{m-1}(t)$ is the leading coefficient of $I_{w_m} f_t$. Inserting A for λ in the scalar equation (4.10) and multiplying by $\boldsymbol{v}_{m+1}$ now gives us

$$\begin{aligned}(\partial_t - A)\widetilde{\boldsymbol{d}}_m(t) &= \beta\gamma_m \Big(A[\Lambda_{w_m} f_t](A) + \pi_{m-1}(t) I - A[\Lambda_{w_m} f_t](A) \Big) \boldsymbol{v}_{m+1} \\ &= \beta\gamma_m \pi_{m-1}(t) \boldsymbol{v}_{m+1}.\end{aligned}$$

A comparison with (4.6) reveals that what remains to be shown is that

$$\frac{\gamma_m}{\eta_{m+1,m}} \pi_{m-1}(t) = \boldsymbol{e}_m^\top e^{tH_m} \boldsymbol{e}_1.$$

The term on the right is the entry at the $(m,1)$ position of the matrix $e^{tH_m} = [I_{w_m} f_t](H_m)$. Due to the sparsity pattern of powers of an upper Hessenberg matrix, this entry is given by

$$\prod_{j=1}^{m-1} \eta_{j+1,j} \pi_{m-1}(t) = \frac{\gamma_m}{\eta_{m+1,m}} \pi_{m-1}(t)$$

and the proof is complete. ∎

The uniqueness of the solution of (4.5) together with Theorem 4.1 now imply once more that $\widetilde{\boldsymbol{d}}_m(t) = \boldsymbol{d}_m(t)$. We emphasize again that our restarted Arnoldi method approximates these error terms directly without recourse to a time-stepping scheme.

4.3. Convergence. The full Arnoldi approximation is known to converge superlinearly for the exponential function, as shown in, e.g., [17, 8]. For the case of solving linear systems of equations, i.e., the Arnoldi approximation for the function $f(\lambda) = 1/\lambda$, it is known that restarting the process can degrade or even destroy convergence. In this section we show that, for sufficiently smooth functions, restarting the Arnoldi approximation preserves its superlinear convergence. We state the following result for entire functions of order one (cf. [2, section 2.1]), a class which includes the exponential function, and note that the result generalizes to other orders with minor modifications.

THEOREM 4.2. *Given $A \in \mathbb{C}^{n\times n}$ and an entire function f of order one, let $\{\vartheta_j^{(m)}\}_{j=1}^m, m \geq 1$, denote an arbitrary node sequence contained in the field of values $W(A)$ of A with associated nodal polynomials $w_m \in \mathcal{P}_m$. Then there exist constants C and γ which are independent of m such that*

$$\|f(A)\boldsymbol{b} - [I_{w_m} f](A)\boldsymbol{b}\| \leq C\frac{\gamma^{m-1}}{(m-1)!}\|\boldsymbol{b}\| \qquad \text{for all } m. \tag{4.11}$$

Proof. We recall the well-known Hermite representation theorem for the interpolation error (cf. [6, Theorem 3.6.1]): Let $\Gamma \subset \mathbb{C}$ be a contour which contains $W(A)$, and hence also the interpolation nodes, in its interior, which we denote by Ω. Then for all $\lambda \in \Omega$ we have

$$f(\lambda) - [I_{w_m} f](\lambda) = \frac{1}{2\pi i}\int_\Gamma \frac{f(t)}{t-\lambda}\frac{w_m(\lambda)}{w_m(t)}\,dt. \tag{4.12}$$

By replacing f with $f - p$ in (4.12), we obtain for arbitrary polynomials $p \in \mathcal{P}_{m-1}$ the identity

$$f(\lambda) - [I_{w_m} f](\lambda) = \frac{1}{2\pi i}\int_\Gamma \frac{f(t)-p(t)}{t-\lambda}\frac{w_m(\lambda)}{w_m(t)}\,dt.$$

Inserting A for λ on both sides, multiplying with $\boldsymbol{b}$, and taking norms gives

$$\|f(A)\boldsymbol{b} - [I_{w_m} f](A)\boldsymbol{b}\| = \frac{1}{2\pi}\left\|\int_\Gamma [f(t)-p(t)](tI-A)^{-1}\frac{w_m(A)}{w_m(t)}\,dt\,\boldsymbol{b}\right\|. \tag{4.13}$$

We now bound each factor of the integrand. For any unit vector $\boldsymbol{u} \in \mathbb{C}^n$, we have $\boldsymbol{u}^H A\boldsymbol{u} \in W(A)$, and thus, for all $t \in \Gamma$,

$$\operatorname{dist}(\Gamma, W(A)) \leq |t - \boldsymbol{u}^H A\boldsymbol{u}| = |\boldsymbol{u}^H(tI-A)\boldsymbol{u}| \leq \|(tI-A)\boldsymbol{u}\|.$$

For arbitrary $\boldsymbol{v} \in \mathbb{C}^n$, it follows that $\|(tI-A)\boldsymbol{v}\| \geq \operatorname{dist}(\Gamma, W(A))\|\boldsymbol{v}\|$ and therefore

$$\|(tI-A)^{-1}\| \leq \frac{1}{\operatorname{dist}(\Gamma, W(A))}. \tag{4.14}$$

Similarly, since the nodes $\vartheta_j^{(m)}$ are contained in $W(A)$ by assumption, we have

$$|w_m(t)| = |(t-\vartheta_1^{(m)})(t-\vartheta_2^{(m)})\cdots(t-\vartheta_m^{(m)})| \geq \operatorname{dist}(\Gamma, W(A))^m, \quad t \in \Gamma. \tag{4.15}$$

Moreover, with $r(A) := \max\{|\lambda| : \lambda \in W(A)\}$ denoting the numerical radius of A, we may bound $\|w_m(A)\|$ by

$$\|w_m(A)\| \leq \prod_{j=1}^m \|A - \vartheta_j I\| \leq \prod_{j=1}^m (\|A\| + \vartheta_j) \leq [3r(A)]^m, \tag{4.16}$$

which follows from the well-known inequality $\|A\| \leq 2r(A)$ and since $\vartheta_j^{(m)} \in W(A)$.

Thus, from (4.13), (4.14), (4.15), (4.16), and the fact that $p \in \mathcal{P}_{m-1}$ was arbitrary, we obtain the bound

$$\|f(A)\boldsymbol{b} - [I_{w_m} f](A)\boldsymbol{b}\| \leq \frac{\ell(\Gamma)}{2\pi} \frac{\inf_{p\in\mathcal{P}_{m-1}} \|f-p\|_{\infty,\Omega}\, [3r(A)]^m}{\operatorname{dist}(\Gamma, W(A))^{m+1}} \|\boldsymbol{b}\|,$$

where $\ell(\Gamma)$ denotes the length of the contour Γ and $\|\cdot\|_{\infty,\Omega}$ denotes the supremum norm on Ω. The assertion now follows from the convergence rate of best uniform approximation of entire functions of order one by polynomials. In particular, it is known (see [11]) that there exist constants $\widetilde{C}$ and $\widetilde{\gamma}$ such that

$$\inf_{p\in\mathcal{P}_{m-1}} \|f-p\|_{\infty,\Omega} \leq \widetilde{C} \frac{\widetilde{\gamma}^{m-1}}{(m-1)!}. \qquad \square$$

COROLLARY 4.3. *The restarted Arnoldi approximation converges superlinearly for entire functions of order one.*

Proof. This follows from Theorem 4.2 by noting that, for the Arnoldi approximation, the set of interpolation nodes for each restart cycle are Ritz values of A and therefore contained in $W(A)$. $\square$

5. Numerical experiments. In this section we demonstrate the behavior of the restarted Arnoldi approximation for the exponential function using several examples from the literature. All computations were carried out in MATLAB version 7.0 (R14) on a 1.6 GHz Power Mac G5 computer with 1.5 GB of RAM.

5.1. Three-dimensional heat equation. Our first numerical experiment is based on one from [14]: Consider the initial boundary value problem

$$\dot{u} - \Delta u = 0 \quad \text{on } (0,1)^3 \times (0,T), \tag{5.1a}$$

$$u(x,t) = 0 \quad \text{on } \partial(0,1)^3 \text{ for all } t \in [0,T], \tag{5.1b}$$

$$u(x,0) = u_0(x), \quad x \in (0,1)^3. \tag{5.1c}$$

When the Laplacian is discretized by the usual seven-point stencil on a uniform grid involving n interior grid points in each Cartesian direction, problem (5.1) reduces to the initial value problem

$$\begin{aligned} \dot{\boldsymbol{u}}(t) &= A\boldsymbol{u}(t), \quad t \in (0,T), \\ \boldsymbol{u}(0) &= \boldsymbol{u}_0, \end{aligned}$$

with an $N \times N$ matrix A ($N = n^3$) and an initial vector $\boldsymbol{u}_0$ consisting of the values $u_0(x)$ at the grid points x, the solution of which is given by

$$\boldsymbol{u}(t) = f_t(A)\boldsymbol{u}_0 = e^{tA}\boldsymbol{u}_0. \tag{5.2}$$

As in [14], we give the initial vector in terms of its expansion in eigenfunctions of the discrete Laplacian as

$$\boldsymbol{u}_0^{i,j,k} = \sum_{i',j',k'} \frac{1}{i'+j'+k'} \sin(ii'\pi h) \sin(jj'\pi h) \sin(kk'\pi h).$$

Here $h = 1/(n+1)$ is the mesh size and the triple indexing is relative to the lexicographic ordering of the mesh points in the unit cube.

TABLE 5.1

The full Arnoldi approximation applied to the three-dimensional heat equation with $h = 1/36$ and $t = 0.1 = n_{\text{steps}}\Delta t$. The dimension m of the Krylov spaces is chosen as the smallest to result in an error $\|\boldsymbol{e}\|_2$ less than 10^{-10} at $t = 0.1$.

TABLE 5.2

The restarted Arnoldi approximation applied to the three-dimensional heat equation with $h = 1/36$ and $t = 0.1$. The dimension m of the Krylov spaces is chosen to coincide with the runs in Table 5.1 and now the number of restarts k is chosen as the smallest to result in an error $\|\boldsymbol{e}\|_2$ less than 10^{-10} at $t = 0.1$.

Δt	k	m	Time [s]	$\|\boldsymbol{e}\|_2$
1e-1	2	51	10.2	2.22e-17
1e-1	2	36	5.2	3.61e-12
1e-1	3	29	5.0	7.78e-15
1e-1	4	22	4.1	9.54e-15
1e-1	6	13	2.2	4.37e-11
1e-1	7	11	1.8	1.29e-11
1e-1	10	8	1.7	7.01e-11
1e-1	12	7	1.6	3.27e-11

We first consider the case $n = 35$ and repeat a calculation in [14], where (5.2) is approximated at $t = 0.1$ using the unrestarted Arnoldi approximation. Writing the solution in the form $\boldsymbol{u}(t) = (e^{\Delta t A})^k \boldsymbol{u}_0$, where $k\Delta t = t$, one can compute the solution using k applications of the Arnoldi approximations involving the matrix $\Delta t A$, which has a smaller spectral interval than A and hence results in faster convergence. There is thus a tradeoff between using Krylov spaces of small dimension and having to take a small number of time steps of length Δt. The results in Table 5.1 show the execution times which result from fixing the time step Δt and using the smallest Krylov subspace dimension m which results in a Euclidean norm of less that 10^{-10} for the error vector $\boldsymbol{e}$ of the unrestarted Arnoldi approximation. We observe that using smaller time steps does allow one to use smaller Krylov spaces, but at a higher cost in terms of execution time.

We next consider the same problem, but instead of taking several time steps with the full Arnoldi approximation, we reduce the size of the Krylov spaces by restarting after every m steps. The results are given in Table 5.2. The dimension m of the Krylov spaces is chosen to coincide with the corresponding runs from Table 5.1, but now the number of restarts k is chosen as the smallest to result in an error less than 10^{-10}. Again there is a tradeoff between the size of the Krylov space and the number of restarts required until convergence. In contrast to Table 5.1, however, we note that the total execution times decrease rather than increase when smaller Krylov spaces are employed, in spite of the fact that this requires more restart cycles. Moreover, the longest execution time of the restarted variant is less than half of the shortest execution time of any of the full Arnoldi approximation runs.

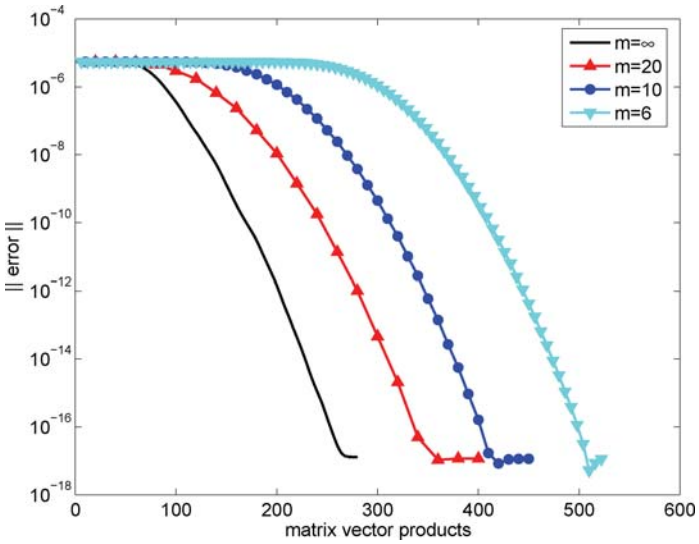

FIG. 5.1. *Error norm histories for the restarted Arnoldi approximation applied to the three-dimensional heat equation with $n = 50$, i.e., $N = 125\,000$, for several restart lengths m.*

TABLE 5.3
Execution times for the runs depicted in Figure 5.1: m denotes the restart length and k the number of restart cycles.

m	k	Time [s]
∞	1	1948
20	20	206
10	45	146
6	87	153

Finally, we consider the same problem for a finer discretization with $n = 50$, resulting in a matrix of dimension $N = 125\,000$. We apply the restarted Arnoldi approximation with restart lengths $m = 6, 10$, and 20 using the full Arnoldi approximation ($m = \infty$) as a reference. Each iteration is run until the accuracy no longer improves. The resulting error curves are shown in Figure 5.1, and the corresponding execution times in Table 5.3. We observe here that the method requires successively more restart cycles to converge as the restart length is decreased. Convergence, however, is merely delayed and is maintained down to the smallest restart length $m = 6$. In terms of execution time, there appears to be a point of diminishing returns using shorter and shorter restart lengths, as the shortest execution time was obtained for $m = 10$.

5.2. Skew-symmetric problem. Our next example is taken from [17]. We consider a matrix A with 1001 equidistant eigenvalues in $[-20i, 20i]$. In contrast to [17], we choose A to be block diagonal and real (and not diagonal and complex) in order to avoid complex arithmetic, as follows:

$$
\begin{aligned}
&A = \operatorname{blockdiag}(B_0, B_1, \ldots, B_{500}) \in \mathbb{R}^{1001\times 1001},\\
&B_0 = 0,\\
&B_j = \tfrac{j}{25}\begin{bmatrix} 0 & 1 \\ -1 & 0 \end{bmatrix}, \quad j = 1, 2, \ldots, 500.
\end{aligned}
\tag{5.3}
$$

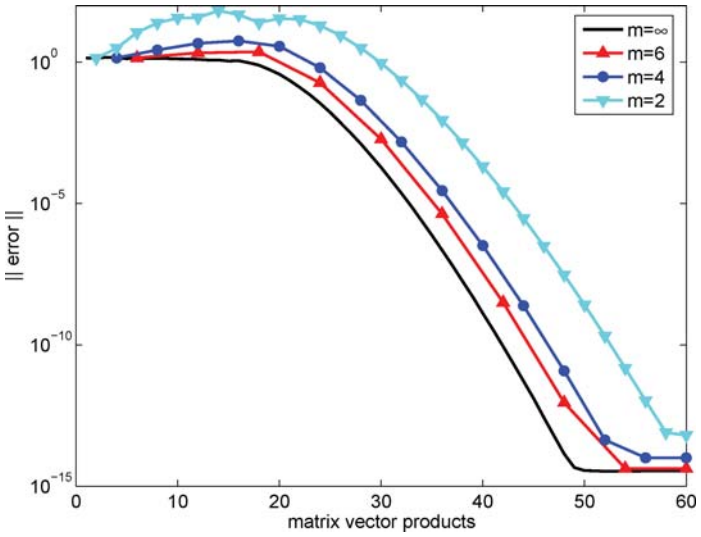

FIG. 5.2. *Error norm histories for the skew-symmetric problem of dimension* $n = 1001$.

The vector $\boldsymbol{b}$ is a random vector[5] of unit norm. The error curve of the full Arnoldi approximation ($m = \infty$) as well as those of the restarted Arnoldi approximation with restart lengths $m = 2, 4$, and 6 are shown in Figure 5.2.

We observe that the errors associated with the restarted Arnoldi approximations initially increase before tending to zero. We also observe that the final accuracy of the approximation deteriorates with decreasing restart length. This indicates that the restart length m is too small to "resolve" the spectral interval of A.

For an explanation, recall that the Arnoldi approximations $\boldsymbol{f}_m$ of $\exp(A)\boldsymbol{b}$ can be viewed as the result of an interpolation process: $\boldsymbol{f}_m = q_{m-1}(A)\boldsymbol{b}$, where q_{m-1} is an interpolating polynomial for the exponential function. For the unrestarted Arnoldi method, the interpolation nodes are the Ritz values of A with respect to $\mathcal{K}_m(A, \boldsymbol{b})$, which are approximately uniformly distributed over $[-20i, 20i]$ (cf. Figure 5.3, where the imaginary parts of the Ritz values are shown[6].) For the restarted Arnoldi method (with restart length m), however, the interpolation nodes are the collection of the Ritz values of A with respect to several Krylov spaces $\mathcal{K}_m\left(A, \boldsymbol{b}^{(j)}\right)$, $j = 0, 1, \ldots, k-1$ (after k restarts). These are far from uniformly distributed in $[-20i, 20i]$, but rather tend to accumulate at m discrete points (see Figure 5.3).

In the extreme case of restart length one, all interpolating nodes equal $\vartheta = 0$ (at least in exact arithmetic) and the interpolating polynomial $q_{k-1}(\lambda) = \sum_{j=0}^{k-1} \frac{1}{j!}\lambda^j$ is simply the truncated Taylor expansion of $\exp(\lambda)$. It is well known that, for $|\lambda| \gg 0$, intermediate partial sums are much larger than the final limit. An analogous statement holds for Hermite interpolating polynomials of the exponential function at too few nodes.

The phenomenon described above becomes more pronounced if we increase the spectral interval of A: Again, we consider the matrix A of (5.3), but now of dimension 10001 with equidistant eigenvalues in $[-200i, 200i]$. The resulting error curves for the restart lengths $m = 5, 10, 20$, and 40 are shown in Figure 5.4.

[5]Generated by the MATLAB syntax `randn('state',0); b = randn(1001,1)`

[6]Note that all Ritz values are purely imaginary because A is skew-symmetric and $\boldsymbol{b}$ is real.

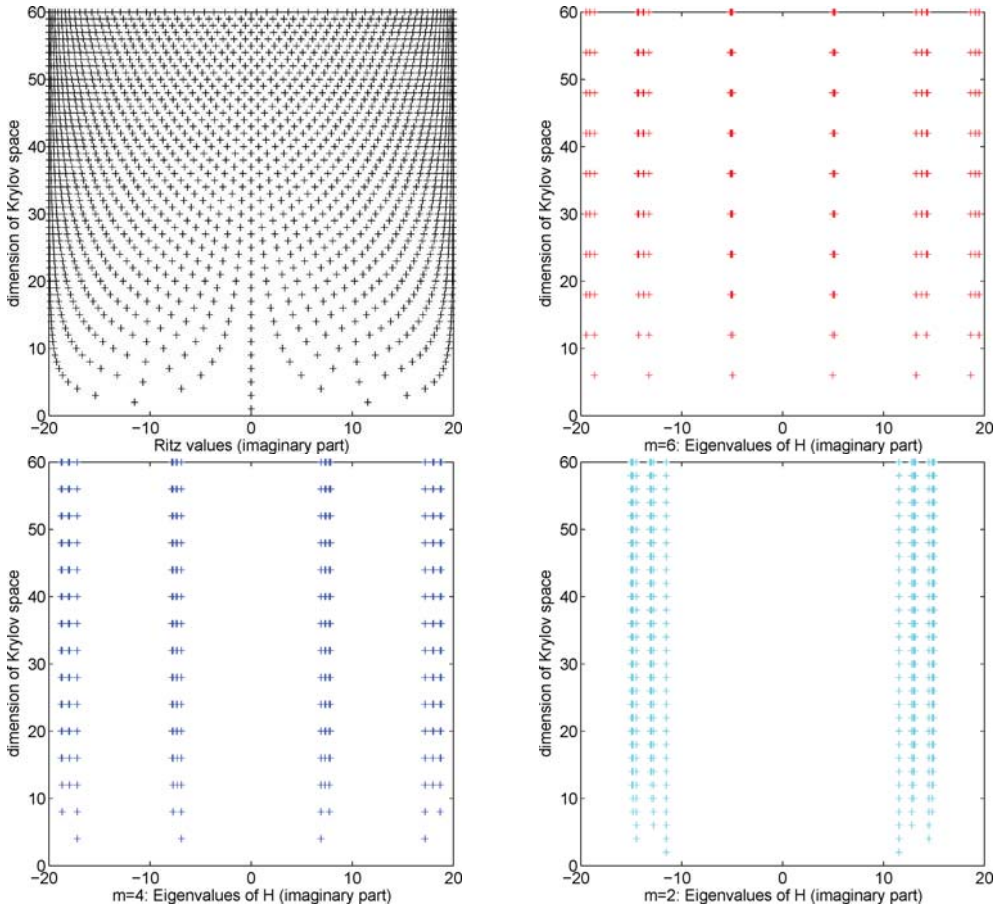

FIG. 5.3. *Interpolation nodes for the skew-symmetric problem of dimension* $n = 1001$.

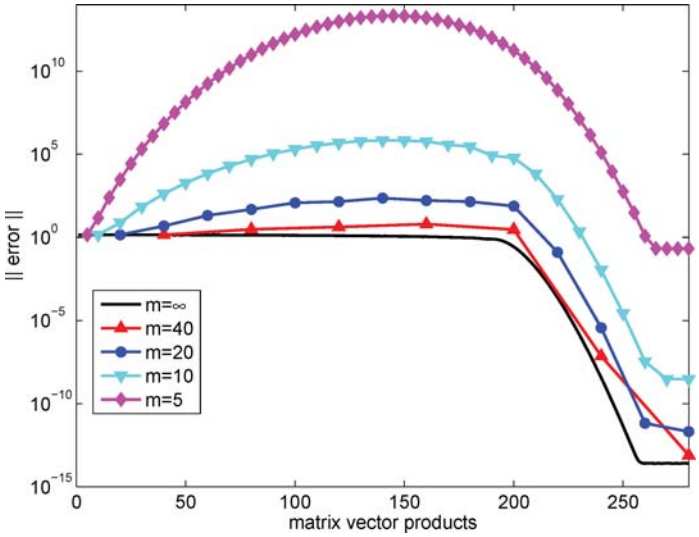

FIG. 5.4. *Error norm histories for the skew-symmetric problem of dimension* $n = 10001$.

TABLE 5.4
The restarted Arnoldi approximation applied to the skew-symmetric problem of dimension 10001*, for several restart lengths* m *(cf. Figure* 5.4*).*

m	Matrix vector products	Time[s]	Final accuracy	Largest error	Largest error / Final accuracy
∞	260	367	2.5e−14	1.4e+01 [1]	1.8e−14
40	280	48	7.8e−14	6.3e+01 [160]	1.2e−14
20	280	26	2.1e−12	2.3e+02 [140]	8.9e−15
10	270	16	2.9e−09	6.8e+05 [140]	4.3e−15
5	275	13	2.1e−01	2.2e+13 [145]	9.7e−15

Table 5.4 shows the number of matrix-vector products and the execution times which were required to reach a final accuracy for different restart length m. We also list the largest intermediate error (and after how many matrix-vector multiplications it is observed). Note that for every m the quotient of this largest error and the final accuracy approximately equals the machine precision of $2e-16$.

5.3. Convection-diffusion problem. Our final example is taken from [19, Example 6.1]: We consider the initial boundary value problem

$$\begin{aligned} \dot{u} - \Delta u + \tau_1 u_{x_1} + \tau_2 u_{x_2} &= 0 \quad \text{on } (0,1)^3 \times (0,T), \\ u(x,t) &= 0 \quad \text{on } \partial(0,1)^3 \text{ for all } t \in [0,T], \\ u(x,0) &= u_0(x), \quad x \in (0,1)^3. \end{aligned}$$

Discretizing the Laplacian by the usual seven-point stencil and the first-order derivatives, u_{x_1} and u_{x_2}, by central differences on a uniform grid with step size $h = 1/(n+1)$ leads—as in section 5.1—to an ordinary initial value problem

$$\begin{aligned} \dot{\boldsymbol{u}}(t) &= A\boldsymbol{u}(t), \quad t \in (0,T), \\ \boldsymbol{u}(0) &= \boldsymbol{u}_0 \end{aligned}$$

with the matrix

$$A = I_n \otimes [I_n \otimes C_1] + [B \otimes I_n + I_n \otimes C_2] \otimes I_n$$

of dimension $N = n^3$. Here,

$$B = \tfrac{1}{h^2}\text{tridiag}(1,-2,1), \;\; C_j = \tfrac{1}{h^2}\text{tridiag}(1+\mu_j, -2, 1-\mu_j), \;\; j = 1,2,$$

where $\mu_j = \tau_j h/2$. The nonsymmetric matrix A is a popular test matrix because its eigenvalues are explicitly known: If $|\mu_j| > 1$ (for at least one j), they are complex; more precisely (cf. [19]),

$$\begin{aligned} \Lambda(A) \subset \tfrac{1}{h^2}\,[-6 - 2\cos(\pi h)\,\mathrm{Re}(\theta),\; -6 + 2\cos(\pi h)\,\mathrm{Re}(\theta)] \\ \times \tfrac{1}{h^2}\,[-2i\cos(\pi h)\,\mathrm{Im}(\theta),\; 2i\cos(\pi h)\,\mathrm{Im}(\theta)] \end{aligned}$$

with $\theta = 1 + \sqrt{1-\mu_1^2} + \sqrt{1-\mu_2^2}$. As in [19], we choose $h = 1/16$, $\tau_1 = 96$, $\tau_2 = 128$ ($\tau_1 = \tau_2 = 320$) which leads to $\mu_1 = 3$, $\mu_2 = 4$ ($\mu_1 = \mu_2 = 10$), and approximate $e^{tA}\boldsymbol{b}$, where $t = h^2$ and $\boldsymbol{b} = [1,1,\ldots,1]^\top$. The resulting error norm histories are shown in Figure 5.5. In the second example we again observe transient error growth. We attribute this, as in the skew-symmetric example, to the sufficiently large imaginary parts of the eigenvalues of $h^2 A$, which lie in

$$[-8.0, -4.0] \times i[-13.1, 13.1] \quad \text{for} \quad \mu_1 = 3, \mu_2 = 4$$

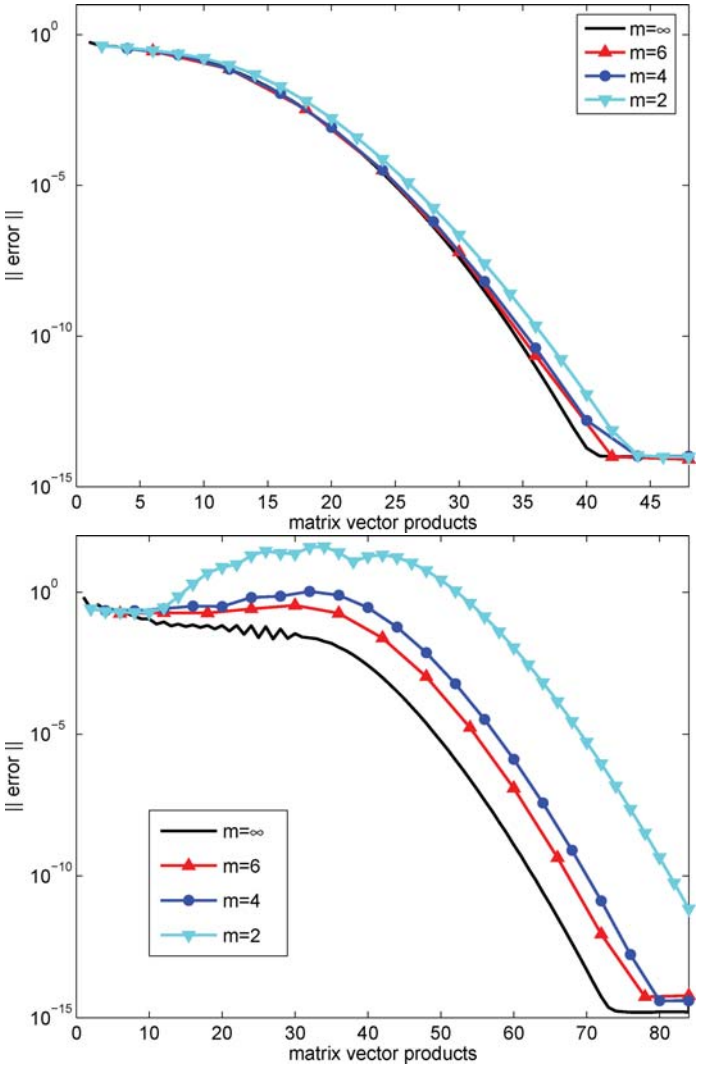

FIG. 5.5. *Error norm histories for the restarted Arnoldi approximation applied to the convection-diffusion problem with* $n = 15$*, i.e.,* $N = 3375$ *for several restart lengths* m*. As in* [19]*, we chose* $\mu_1 = 3$*,* $\mu_2 = 4$ *(top), and* $\mu_1 = \mu_2 = 10$ *(bottom).*

and

$$[-8.0, -4.0] \times i[-39.0, 39.0] \quad \text{for} \quad \mu_1 = \mu_2 = 10,$$

respectively.

6. Conclusions. We have shown how Krylov subspace methods for approximating $f(A)\boldsymbol{b}$ may be restarted. This permits the application of schemes like the Arnoldi approximation to very large matrices using a fixed amount of storage space. For functions f which are entire of order one, the restarted method retains the superlinear convergence property of the unrestarted method. In addition, we have identified the relationship of the restarted method to known algorithms in the cases $f(\lambda) = 1/\lambda$ and

$f_t(t\lambda) = e^{t\lambda}$. Moreover, we have demonstrated that the method performs well on several numerical examples from the literature. Related issues such as characterizing the convergence of the Arnoldi approximation using potential theoretic methods as well as yet more efficient implementations of the restarted algorithm will be the subject of future research.

DISCRETIZATION AND SIMULATION OF THE ZAKAI EQUATION*

EMMANUEL GOBET†, GILLES PAGÈS‡, HUYÊN PHAM‡, AND JACQUES PRINTEMS§

Abstract. This paper is concerned with numerical approximations for the stochastic partial differential Zakai equation of nonlinear filtering problems. The approximation scheme is based on the representation of the solutions as weighted conditional distributions. We first accurately analyze the error caused by an Euler-type scheme of time discretization. Sharp error bounds are calculated: we show that the rate of convergence is in general of order $\sqrt{\delta}$ (δ is the time step), but in the case when there is no correlation between the signal and the observation for the Zakai equation, the order of convergence becomes δ. This result is obtained by carefully employing techniques of Malliavin calculus. In a second step, we propose a simulation of the time discretization Euler scheme by a quantization approach. Formally, this consists in an approximation of the weighted conditional distribution by a conditional discrete distribution on finite supports. We provide error bounds and rate of convergence in terms of the number N of the grids of this support. These errors are minimal at some optimal grids which are computed by a recursive method based on Monte Carlo simulations. Finally, we illustrate our results with some numerical experiments arising from a correlated Kalman–Bucy filter.

1. Introduction.

We are interested in numerical approximation for the measure-valued process V governed by the following stochastic partial differential equations (SPDE) written in weak form: for all test functions $f \in C_b^2(\mathbb{R}^d)$,

$$\begin{aligned}\langle V_t, f\rangle = \langle \mu_0, f\rangle &+ \int_0^t \langle V_s, Lf\rangle ds \\ &+ \int_0^t \langle V_s, hf + \gamma^\intercal \nabla f\rangle . dW_s,\end{aligned} \tag{1.1}$$

where μ_0 is an initial probability measure. We denote by $\mathcal{M}(\mathbb{R}^d)$ the set of finite signed measures on $\mathbb{R}^d$. Here L is the second-order differential operator,

$$Lf(x) = \frac{1}{2}\sum_{i,j=1}^{d} a_{ij}(x)\partial^2_{x_i x_j} f(x) + \sum_{i=1}^{d} b_i(x)\partial_{x_i} f(x),$$

W is a q-dimensional Brownian motion, $a = (a_{ij})$ is a $d \times d$ matrix-valued function, $\gamma = (\gamma_{il})$ is a $d \times q$ matrix-valued function, $b = (b_i)$ is an $\mathbb{R}^d$-vector-valued function, and $h = (h_l)$ is an $\mathbb{R}^q$-vector-valued function defined on $\mathbb{R}^d$, in the form

$$\begin{aligned} a &= \sigma\sigma^\intercal + \gamma\gamma^\intercal, \\ b &= \beta + \gamma h, \end{aligned}$$

for some $d\times d$ matrix-valued function $\sigma=(\sigma_{ij})$ and $\mathbb{R}^d$-vector-valued function $\beta=(\beta_i)$ on $\mathbb{R}^d$. The transpose and the scalar product are, respectively, denoted by $^\intercal$ and a dot. The Euclidean norm of a vector is denoted $|.|$, and one uses the norm $|\sigma|=\sqrt{\mathrm{Tr}(\sigma\sigma^\intercal)}$ for a matrix σ.

When the distribution V_t admits a density $v(t,x)$, one may usually rewrite (1.1) in the following form:

$$dv(t,x)=\left(\frac{1}{2}\sum_{i,j=1}^{d}\partial^2_{x_ix_j}[a_{ij}(x)v(t,x)]-\sum_{i=1}^{d}\partial_{x_i}[b_i(x)v(t,x)]\right)dt + \left(h^\intercal(x)v(t,x)-\nabla[\gamma(x)v(t,x)]\right)dW_t. \tag{1.2}$$

Under appropriate conditions, it is proved in [21] that the solution V to (1.1) can be characterized through the following system of diffusions:

$$X_t = X_0+\int_0^t\beta(X_s)ds+\int_0^t\sigma(X_s)dB_s+\int_0^t\gamma(X_s)dW_s, \qquad X_0\rightsquigarrow\mu_0, \tag{1.3}$$

$$\xi_t=\exp(Z_t)=\exp\left(\int_0^t h(X_s).dW_s-\frac{1}{2}\int_0^t|h(X_s)|^2ds\right), \tag{1.4}$$

$$\langle V_t,f\rangle = E_W\left[f(X_t)\xi_t\right], \tag{1.5}$$

where B is an $\mathbb{R}^d$-Brownian motion independent of W, and E_W denotes the conditional expectation given W. We also denote by P_W the corresponding conditional probability.

Actually, (1.1) is the so-called Zakai equation arising from the nonlinear filtering problem: here, X given in (1.3) is a d-dimensional signal, and W is a q-dimensional observation process (with correlated noise when $\gamma\neq 0$) given by

$$W_t=\int_0^t h(X_s)ds+U_t,$$

on a probability space $(\Omega,\mathcal{F},P)$ equipped with filtration $(\mathcal{F}_t)$ under which B and U are independent Brownian motions. The nonlinear filtering problem consists in estimating the conditional distribution of X given W, i.e., we want to compute the measure-valued process π_t characterized by

$$\langle\pi_t,f\rangle=E^P[f(X_t)|\mathcal{F}_t^W],$$

where $\mathcal{F}_t^W$ is the filtration generated by the whole observation of W until t. Under suitable conditions, there exists a reference probability measure Q such that

$$\left.\frac{dP}{dQ}\right|_{\mathcal{F}_t}=\xi_t=\exp\left(\int_0^t h(X_s).dW_s-\frac{1}{2}\int_0^t|h(X_s)|^2ds\right),$$

and (B,W) are two independent Brownian motions under Q. By the Kallianpur–Striebel formula, we have

$$\langle\pi_t,f\rangle=\frac{\langle V_t,f\rangle}{\langle V_t,1\rangle},$$

where

$$\langle V_t, f\rangle = E_w^Q[f(X_t)\xi_t]$$

satisfies the Zakai equation (1.1). From now on, the symbol E will denote the expectation with respect to the probability Q.

1.1. A short discussion of related literature. Numerical approximations of the Zakai equation and more generally of SPDEs have been extensively studied in the literature. We cite the survey paper [17] and the references therein. Roughly summarizing, one may classify the following approaches:

– Approximations based on the analytic expression (1.2) vary from finite difference of finite elements methods, splitting up methods, or Galerkin's approximation. We cite, for instance, [33], [15], [16] for the finite difference method of the Zakai equation or SPDEs, and the recent paper [35] for the finite element method of SPDEs. For the splitting up method of the Zakai equation and SPDEs, see [4], [11], [23], [18]. See also [34] for a time discretization analysis of θ-schemes of parabolic-type SPDEs driven by a(n infinite-dimensional) Wiener process.

– A first algorithm based on some uniform quantization grids of the state process is mentioned in [20].

– Another point of view, developed and studied in [24] and [5], is based on the Wiener chaos decomposition of the solution to the Zakai equation. We mention also Wong–Zakai-type approximations considered in [19].

– The third approach is based on the probabilistic representation (1.5) of the solution as a weighted (or unnormalized) conditional distribution. For the Zakai equation of nonlinear filtering problem, papers [22] and [10] develop approximation methods by replacing the signal process by a finite state Markov chain on a uniform grid prescribed a priori. This method is somewhat equivalent to the finite difference method.

– The so-called particular Monte Carlo method is based on a particle approximation of the conditional distribution. It has recently given rise to extensive studies; see, for instance, [8], [6], [7] for the nonlinear filtering problem. We will compare some of our results to those obtained in [7] (in which the diffusion X does not depend on the observation process, i.e., $\gamma = 0$).

1.2. Contribution and organization of the paper. The first contribution of our work consists in accurately estimating the error due to time discretization on the conditional expectation (1.5). Without conditioning, classical results yield an error at most linear w.r.t. the time step δ (see, for instance, [3]). Here, the situation is unusual because of the conditional expectation, and our analysis makes clear the role of the correlation factor between the underlying process X and the observation process W. As concerns the proof, we use Malliavin calculus techniques, but the fact that we work conditionally to W induces some specific technicalities.

In a second part, we propose a simulation algorithm for the SPDE (1.1) based on an optimal quantization approach. Basically, this means a spatial discretization of the dynamics of the Euler time discretization (X_k, V_k) of (1.3)–(1.5) optimally fitted to its probabilistic features. To be more specific, we first recall some short background on optimal quantization of a random vector. Let $X : (\Omega, \mathcal{F}, P) \to \mathbb{R}^d$ be a random vector and let $\Gamma = \{x^1, \dots, x^N\}$ be a subset (or *grid*) of $\mathbb{R}^d$ having N elements. We approximate X by one of its Borel closest neighbor projections $\widehat{X}^\Gamma := \mathrm{Proj}_\Gamma(X)$ on Γ. Such a projection is canonically associated to a Voronoi tessellation $(C_i(\Gamma))_{1\le i\le N}$

that is a Borel partition of $\mathbb{R}^d$ satisfying for any $i = 1, \dots, N$

$$C_i(\Gamma) \subset \left\{ \xi \in \mathbb{R}^d : |\xi - x^i| = \min_j |\xi - x^j| \right\}.$$

Hence

$$\widehat{X}^\Gamma = \mathrm{Proj}_\Gamma(X) := \sum_{i=1}^N x^i \mathbf{1}_{\{X \in C_i(\Gamma)\}}.$$

As soon as $X \in L^p(\Omega, P, \mathbb{R}^d)$ the induced *L^p-quantization error* is given by

$$\|X - \widehat{X}^\Gamma\|_p = \left(E \min_{1 \le i \le N} |X - x^i|^p \right)^{\frac{1}{p}} < \infty.$$

The L^p-optimal N-quantization problem for X consists in finding a grid Γ^* which achieves the lowest L^p-quantization error among all grids of size at most N. Such an optimal grid does exist (see [14]), and its size is exactly N if the support of X is infinite; it is generally not unique (except in 1-dimension, where uniqueness holds when the distribution P_X of X has a log-concave density). The rate of convergence of the lowest L^p-quantization error as $N \to +\infty$ is ruled by the so-called Zador theorem (see [14]). For historical reasons, this theorem is usually stated with the pth power of the L^p-quantization error, known as the *L^p-distortion*.

THEOREM 1.1. *Assume that $X \in L^{p+\eta}(\Omega, P, \mathbb{R}^d)$ for some $\eta > 0$. Let f denote the probability density of the absolutely continuous part of its distribution P_X (f is possibly 0). Then,*

$$\lim_N \left(N^{\frac{p}{d}} \min_{|\Gamma| \le N} \|X - \widehat{X}^\Gamma\|_p^p \right) = J_{p,d} \|f\|_{\frac{d}{d+p}}.$$

The constant $J_{p,d}$ corresponds to the uniform distribution over $[0,1]^d$ and in that case the above $\lim_N$ also holds as an infimum.

The constant $J_{p,d}$ is unknown as soon as $d \ge 3$ although one knows that $J_{p,d} \sim (d/(2\pi e))^{\frac{p}{2}}$ as $d \to \infty$. This theorem says that the lowest L^p-quantization error goes to 0 at an $N^{-\frac{1}{d}}$-rate when $N \to \infty$. For more details about these results, we refer to [14] and the references therein.

From a computational viewpoint, no closed form is available for optimal quantization grids Γ^* except for some very specific 1-dimensional distributions like the uniform one. Several algorithms can be implemented to compute these optimal (or at least some efficient locally optimal) grids. Several of them rely on the differentiability of the L^p-distortion function as a function of the grid (viewed as an N-tuple of $(\mathbb{R}^d)^N$): if P_X is continuous, it is differentiable at any grid of size N and its gradient admits an integral representation with respect to the distribution of X. Consequently one may search for optimal grids by implementing a Newton–Raphson procedure (in 1-dimension) or a stochastic gradient descent (in d-dimension). These numerical aspects have been extensively investigated in [31] with special attention to the d-dim normal distribution. Efficient grids for these distributions are now available for many sizes in dimensions $d = 1$ up to 10 (which can be downloaded at www.quantification.finance-mathematique.com); the extension to the quantization of Markov chains, including its numerical aspects, has already been discussed in several papers for various fields

of applications, such as American option pricing, nonlinear filtering, or stochastic control (see, e.g., [1], [28], [30], or [29]).

We now briefly explain in this introduction how to apply the vector-quantization method to the Zakai SPDE (1.1). The process (X_k) is simply a time discretization of a diffusion independent of V. In particular, given an observation W, (X_k) can be easily simulated and the idea is to quantize optimally at each time step k the random vector X_k by a finite distribution $\hat{X}_k$. This provides in turn an approximation of (V_k) as the conditional distribution of $\hat{X}_k$, weighted by a Girsanov-like term.

Let us mention that this approach can be applied to a wider family of stochastic SPDEs, e.g., when the functions h and γ (and possibly β and σ in the diffusion process) depend upon V_t. This is the case of the stochastic McKean–Vlasov equation, where $h \equiv 0$ and $\gamma(x, V) = \int \bar{\gamma}(x, v)V(dv)$ (V positive measure). We refer to [13] for some theoretical and numerical developments on this equation.

Our main results concerning the rate of convergence can be summed up as follows. First we prove under some regularity assumptions that the error induced by a time discretization with step δ is in general of order $\sqrt{\delta}$, although in the case $\gamma = 0$ the order of convergence is improved to δ. As concerns spatial discretization error, we obtain $n^{\frac{3}{2}}/\bar{N}^{\frac{1}{d}}$ (where $\delta = T/n$ and $\bar{N} = N/n$ denotes the (average) size of the quantization grids used at every time step). Finally (when $\gamma \neq 0$), our global error term has the form

$$\frac{1}{\sqrt{n}} + \frac{n^{\frac{3}{2}}}{\bar{N}^{\frac{1}{d}}}.$$

Numerical experiments carried out in section 4 suggest that a significantly better space order holds true, such as (when $d = 1$) $\frac{c_1 + c_2 n + o(n)}{\bar{N}}$, where $c_2 \ll c_1$.

The finite element method applied to (1.2) would provide the same kind of rate (in [35] the Wiener process W is infinite-dimensional, which induces worst rates for time and space discretization). However, these methods require an implicit time integration in order to be stable. This requires us to invert an $N^d \times N^d$ linear system (even if it is sparse) at each time step, which becomes very expensive as the dimension d grows (say $d \geq 3$ or 4).

As concerns Monte Carlo methods based on interacting particles procedures like [8] or [6], the main difference of our approach in terms of complexity is that most parts of our computations (the quantization of the d-dimensional process X) can be made off-line. This compensates the dependency in d of its theoretical rate of convergence, at least in medium dimensions. Since the algorithm proposed here is similar to the quantized nonlinear filters developed in [28] from a computational point of view, we refer to the detailed discussion carried out in it.

The paper is organized as follows. Section 2 is devoted to the time discretization error of the SPDE (1.1). The above result is established using Malliavin calculus techniques. We describe precisely in section 3 the optimal quantization algorithm for the Zakai equation and we analyze the resulting error. Finally, we illustrate our results in section 4 with several simulations concerning the Zakai equation in the linear case.

2. Time discretization error. In this section, we study the error caused by a time discretization of the system (1.3)–(1.5) characterizing the solution to the SPDE (1.1) on a finite time interval $[0, T]$. We consider regular discretization times $t_k = k\delta$, $k = 0, \ldots, n$, where $\delta = T/n$ is the time step, and we denote $\phi(t) = \sup\{t_k : t_k \leq t\}$.

We then use an Euler scheme as follows:

$$\begin{aligned} X_t^\delta &= X_0 + \int_0^t \beta(X_{\phi(s)}^\delta)ds + \int_0^t \sigma(X_{\phi(s)}^\delta)dB_s + \int_0^t \gamma(X_{\phi(s)}^\delta)dW_s, \\ Z_t^\delta &= \int_0^t h(X_{\phi(s)}^\delta).dW_s - \frac{1}{2}\int_0^t |h(X_{\phi(s)}^\delta)|^2 ds, \\ \langle V_t^\delta, f\rangle &= E_W\left[f(X_t^\delta)\exp(Z_t^\delta)\right]. \end{aligned}$$

By denoting $\bar{X}_k = X_{t_k}^\delta$, $\bar{V}_k = V_{t_k}^\delta$, $\Delta\bar{B}_k = B_{t_k} - B_{t_{k-1}}$, $\Delta\bar{W}_k = W_{t_k} - W_{t_{k-1}}$, the Euler scheme reads at the discretization times t_k, $k = 0, \dots, n$,

$$\bar{X}_{k+1} = \bar{X}_k + \beta(\bar{X}_k)\delta + \sigma(\bar{X}_k)\Delta\bar{B}_{k+1} + \gamma(\bar{X}_k)\Delta\bar{W}_{k+1}, \tag{2.1}$$

$$\bar{X}_0 = X_0 \rightsquigarrow \mu_0, \tag{2.2}$$

$$\langle \bar{V}_k, f\rangle = E_W\left[f(\bar{X}_k)\exp\left(\sum_{j=0}^{k-1} g(\bar{X}_j, \Delta\bar{W}_{j+1})\right)\right], \tag{2.3}$$

where

$$g(x, \Delta\bar{W}) = h(x).\Delta\bar{W} - \frac{1}{2}|h(x)|^2\delta.$$

Denote by $\bar{P}_{k,W}(x, dx')$ the conditional probability of $\bar{X}_k$ given W and $\bar{X}_{k-1} = x$. From (2.1), we have

$$\bar{P}_{k,W}(x, dx') \rightsquigarrow \mathcal{N}\left(x + \beta(x)\delta + \gamma(x)\Delta\bar{W}_k, \delta\sigma(x)\sigma^\intercal(x)\right).$$

As usual, we set for any $f \in \mathcal{B}(\mathbb{R}^d)$ a set of bounded measurable functions on $\mathbb{R}^d$,

$$\bar{P}_{k,W} f(x) = E_W\left[f(\bar{X}_k)\middle|\, \bar{X}_{k-1} = x\right] = \int f(x')\bar{P}_{k,W}(x, dx'),$$

for any $x \in \mathbb{R}^d$. Hence, by the distribution of iterated conditional expectations, we have the following inductive formula for $\bar{V}_k$, $k = 0, \dots, n$:

$$\langle \bar{V}_{k+1}, f\rangle = \langle \bar{V}_k, \exp\left(g(., \Delta\bar{W}_{k+1})\right)\bar{P}_{k+1,W} f\rangle, \tag{2.4}$$

$$\bar{V}_0 = \mu_0. \tag{2.5}$$

We denote by $BL_1(\mathbb{R}^d)$ the unit ball of bounded Lipschitz functions on $\mathbb{R}^d$,

$$BL_1(\mathbb{R}^d) = \{f : \mathbb{R}^d \mapsto \mathbb{R} \text{ satisfying } |f(x)| \le 1 \text{ and } |f(x) - f(y)| \le |x - y| \ \forall\ x, y\},$$

and we consider the metric

$$\rho(V_1, V_2) = \sup\left\{|\langle V_1, f\rangle - \langle V_2, f\rangle|, \quad f \in BL_1(\mathbb{R}^d)\right\}$$

on $\mathcal{M}(\mathbb{R}^d)$ for any $V_1, V_2 \in \mathcal{M}(\mathbb{R}^d)$.

2.1. Main results. To simplify the following convergence analysis, we assume that the coefficients are very smooth and that they satisfy a uniform ellipticity condition.

(H1) (i) The functions β, σ, and γ are of class C^∞ with bounded derivatives.

(ii) The function h is of class C^∞ and is bounded, as are its derivatives.

(iii) For some $\epsilon_0 > 0$, one has $\sigma\sigma^\intercal(x) \geq \epsilon_0$ Id uniformly in x.

We recall some notation from [12]. We set $X_t^{\delta,\lambda} = X_t^\delta + \lambda(X_t - X_t^\delta)$ and $e^{\bar{Z}_T^\delta} = \int_0^1 e^{Z_T^\delta + \lambda(Z_T - Z_T^\delta)} d\lambda$. In addition, for any smooth function $a : \mathbb{R}^d \mapsto \mathbb{R}^{d'}$ we denote its derivative by a', which is $\mathbb{R}^{d'} \otimes \mathbb{R}^d$-valued. Finally, we repeatedly use the notation $a'(t) = \int_0^1 a'(X_t^{\delta,\lambda}) d\lambda$. Now, consider the unique solution of the linear equation $\mathcal{E}_t = \mathrm{Id} + \int_0^t \beta'(s)\mathcal{E}_s \, ds + \sum_{j=1}^d \int_0^t \sigma_j'(s)\mathcal{E}_s \, dB_s^j + \sum_{j=1}^q \int_0^t \gamma_j'(s)\mathcal{E}_s \, dW_s^j$ (as usual, σ_j and γ_j are the jth column of the matrix σ and γ). Then, Lemma 4.3 in [12] gives

$$
\begin{aligned}
X_t - X_t^\delta = \mathcal{E}_t \int_0^t \mathcal{E}_s^{-1} \Big\{ & [\beta(X_s^\delta) - \beta(X_{\phi(s)}^\delta)] \\
& - \sum_{j=1}^d \sigma_j'(s)[\sigma_j(X_s^\delta) - \sigma_j(X_{\phi(s)}^\delta)] \\
& - \sum_{j=1}^q \gamma_j'(s)[\gamma_j(X_s^\delta) - \gamma_j(X_{\phi(s)}^\delta)] \Big\} \, ds \\
& + \sum_{j=1}^d \mathcal{E}_t \int_0^t \mathcal{E}_s^{-1}[\sigma_j(X_s^\delta) - \sigma_j(X_{\phi(s)}^\delta)] \, dB_s^j \\
& + \sum_{j=1}^q \mathcal{E}_t \int_0^t \mathcal{E}_s^{-1}[\gamma_j(X_s^\delta) - \gamma_j(X_{\phi(s)}^\delta)] \, dW_s^j.
\end{aligned} \tag{2.6}
$$

For any $f \in BL_1(\mathbb{R}^d)$, we put $f_\delta(x) = E(f(x + \delta\tilde{B}_T))$, where $\tilde{B}$ is an extra d-dimensional Brownian motion independent on B and W. Clearly, f_δ is of class C_b^∞, $\|f_\delta\|_\infty + \sup_{x \neq y} \frac{|f_\delta(x) - f_\delta(y)|}{|x-y|} \leq C$, $\|f_\delta - f\|_\infty \leq C\delta$, both estimates being uniform in $BL_1(\mathbb{R}^d)$.

The main result of this section is the following.

THEOREM 2.1. *Assume* (H1). *For $f \in BL_1(\mathbb{R}^d)$, set*

$$
\begin{aligned}
A_1(f) &= -e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \left[\sum_{j=1}^q \int_0^T \left(\mathcal{E}_s^{-1} \int_{\phi(s)}^s \gamma_j'(X_r^\delta)\gamma(X_{\phi(r)}^\delta) dW_r \right) dW_s^j \right], \\
A_2(f) &= -e^{\bar{Z}_T^\delta} f(X_T) \left(\sum_{i=1}^q \int_0^T \left[\int_{\phi(s)}^s h_i'(X_r^\delta)\gamma(X_{\phi(r)}^\delta) dW_r \right] dW_s^i \right), \\
A_3(f) &= -\sum_{i,j=1}^q f(X_T) e^{\bar{Z}_T^\delta} \left(\int_0^T h_i'(s)\mathcal{E}_s \left(\int_0^s \mathcal{E}_r^{-1} \left[\int_{\phi(r)}^r \gamma_j'(X_u^\delta)\gamma(X_{\phi(u)}^\delta) dW_u \right] dW_r^j \right) dW_s^i \right), \\
A_4(f) &= \frac{1}{2} e^{\bar{Z}_T^\delta} f(X_T) \int_0^T \left[(\|h\|^2)'(s)\mathcal{E}_s \left(\sum_{j=1}^q \int_0^s \mathcal{E}_r^{-1} \left(\int_{\phi(r)}^r \gamma_j'(X_u^\delta)\gamma(X_{\phi(u)}^\delta) dW_u \right) dW_r^j \right) \right] ds.
\end{aligned}
$$

Then, one has

$$
\left\| \rho(V_T, V_T^\delta) \right\|_2 \leq C\delta + \sup_{f \in BL_1(\mathbb{R}^d)} \left\| E_W \left[A_1(f) + A_2(f) + A_3(f) + A_4(f) \right] \right\|_2,
$$

with

$$\sup_{f\in BL_1(\mathbb{R}^d)} \|E_W(A_1(f)+A_2(f)+A_3(f)+A_4(f))\|_2 \le C\sqrt{\delta}$$

for some constant C.

Remark 2.1. The fact that $\sqrt{\delta}$ is an upper bound for the error is clear, if we use classic L^p-estimates between X and X^δ. But we know that this argument involving pathwise errors is not optimal when errors on laws are considered [3]. The result above makes clear the role of the correlation in the error on conditional expectations.

1. When there is no correlation between signal and observation, i.e., $\gamma = 0$ (which is not really relevant in a filtering problem), the four terms $A_i(f)$, $i = 1, \dots, 4$, vanish and the rate of convergence for the approximation of V_T is of order δ, the time discretization step.

2. For constant function γ, the three contributions $A_1(f), A_3(f), A_4(f)$ vanish and there remains $A_2(f)$ of order $\sqrt{\delta}$ coming from the approximation of e^{Z_T}.

3. In the general case, the error will be inexorably of order $\sqrt{\delta}$. Indeed, main contributions in the error essentially behave like $\sum_{i=0}^{n-1}\int_{t_i}^{t_{i+1}}(W_s - W_{t_i})dW_s = \frac{1}{2}\sum_{i=0}^{n-1}\big([W_{t_{i+1}} - W_{t_i}]^2 - [t_{i+1} - t_i]\big)$, where the L^2-norm equals $C\sqrt{\delta}$.

2.2. Proof of Theorem 2.1. The proof relies on Malliavin calculus techniques: we refer the reader to [26], from which we borrow our notation. For technical reasons, it will be useful to work with the extended Wiener process

$$\mathcal{W} = \begin{pmatrix} B \\ \tilde{B} \\ W \end{pmatrix};$$

all the further Malliavin calculus computations are made relative to $\mathcal{W}$. Set $H = L^2([0,T],\mathbb{R}^{2d+q})$ and denote $\tilde{X}_t^{\delta,\lambda} = X_t^{\delta,\lambda} + \frac{\delta}{\sqrt{2}}\tilde{B}_t$. For $F \in \mathbb{D}^{1,p}$, we write $\mathcal{D}F = (\mathcal{D}^B F, \mathcal{D}^{\tilde{B}} F, \mathcal{D}^W F)$ for the components relative to the three Brownian motions B, $\tilde{B}$, and W; the partial Malliavin covariance matrix of F is denoted by $\gamma^F = \int_0^T [\mathcal{D}_t^B F, \mathcal{D}_t^{\tilde{B}} F, 0][\mathcal{D}_t^B F, \mathcal{D}_t^{\tilde{B}} F, 0]^\intercal dt = \int_0^T \mathcal{D}_t^B F[\mathcal{D}_t^B F]^\intercal dt + \int_0^T \mathcal{D}_t^{\tilde{B}} F[\mathcal{D}_t^{\tilde{B}} F]^\intercal dt$ (see section 2.1 in [26]). Following section 1.3 in [26], the Skorokhod integral, i.e., the adjoint operator of $\mathcal{D}$, is denoted by $\boldsymbol{\delta}$ (with a boldface symbol to avoid confusion with the time step δ). For a process u in the domain of $\boldsymbol{\delta}$, for its Skorokhod integral we write $\boldsymbol{\delta}(u)$ and $\int_0^T u_t \boldsymbol{\delta}\mathcal{W}_t$ as well.

As in section 4.5.2 of [12], a localization factor $\psi_T^\delta \in [0,1]$ will be needed in the control of residual terms to justify integration by parts formulas. It satisfies the following properties:

(a) For any integers k and p, $\psi_T^\delta \in \mathbb{D}^{k,p}$ and $\sup_\delta \|\psi_T^\delta\|_{\mathbb{D}^{k,p}} \le \frac{C}{T^q}$ for some $C, q \ge 0$.

(b) For any $k \ge 1$, there are $C, q \ge 0$ such that $P(\psi_T^\delta \ne 1) \le \frac{C}{T^q}\delta^k$.

(c) $\{\psi_T^\delta \ne 0\} \subset \{\forall \lambda \in [0,1] : \det(\gamma^{\tilde{X}_T^{\delta,\lambda}}) \ge \frac{1}{2}\det(\gamma^{X_T})\}$.

We omit the details of its tedious construction and we simply refer to [12] (we mention that the nondegeneracy condition (H1) (iii) is used to get the above estimates with $1/T^q$, but it could also be replaced by a hypoellipticity-type assumption). To prepare the proof, we now state a series of technical results (justified later) which will help to derive a suitable stochastic analysis conditionally on W.

LEMMA 2.1. *In the following,* $\Phi(W)$ *stands for a functional measurable w.r.t.* W*, which belongs to* $\mathbb{D}^\infty$.

(i) *For any random variable* $Y \in L^2$, $E_W(Y)$ *is the unique random variable satisfying the equality* $E(Y\Phi(W)) = E(E_W(Y)\Phi(W))$ *for any functional* $\Phi(W) \in \mathbb{D}^\infty$.

(ii) *For any* $\Phi(W) \in \mathbb{D}^\infty$ *and* $F \in \mathbb{D}^{1,2}$, *one has* $\Phi(W)F \in \mathbb{D}^{1,1}$, *with* $\mathcal{D}^B(\Phi(W)F) = \Phi(W)\mathcal{D}^B F$ *and* $\mathcal{D}^{\tilde{B}}(\Phi(W)F) = \Phi(W)\mathcal{D}^{\tilde{B}}F$.

(iii) *For* $\Phi(W)$ *and* G *in* $\mathbb{D}^\infty$, $g \in C_b^\infty$, *and any multi-index* α, *one has*

$$\begin{cases} E\left(\Phi(W)\partial^\alpha g(X_T)G\right) = E\left(\Phi(W)g(X_T)H_\alpha(X_T,G)\right), \\ \|H_\alpha(X_T,G)\|_2 \le C\dfrac{\|G\|_{\mathbb{D}^{k,p}}}{T^q} \end{cases} \tag{2.7}$$

for some integers k, p, q. *Furthermore, if* $G = 0$ *on* $\{\psi_T^\delta = 0\}$, *then for any* $\lambda \in [0,1]$, *one has*

$$\begin{cases} E(\Phi(W)\partial^\alpha g(\tilde{X}_T^{\delta,\lambda})G) = E(\Phi(W)g(\tilde{X}_T^{\delta,\lambda})H_\alpha(\tilde{X}_T^{\delta,\lambda},G)), \\ \|H_\alpha(\tilde{X}_T^{\delta,\lambda},G)\|_2 \le C\dfrac{\|G\|_{\mathbb{D}^{k,p}}}{T^q} \end{cases} \tag{2.8}$$

with some constants C, k, p, q *uniform in* δ, *and* $\lambda \in [0,1]$.

The result below is one of the keys of our error analysis. The estimates of order δ are rather surprising. Indeed, at first glance, each stochastic integral (for fixed r) in the left-hand side of (2.9) is of order $\sqrt{\delta}$, but the mean over r helps in improving this estimate to get δ, provided that the processes g and h satisfy some suitable controls. Its proof is postponed until the end of this section.

PROPOSITION 2.1. *For* $g \in \mathbb{D}^\infty(H)$ *and* $h \in \mathbb{D}^\infty(H)$, *one has*

$$\begin{aligned} \int_0^T g_r \left(\int_{\phi(r)}^r h_u \boldsymbol{\delta}\mathcal{W}_u \right) dr &= \int_0^T \left(\int_0^T g_r h_u \mathbf{1}_{\phi(r)\le u\le r} dr \right) \boldsymbol{\delta}\mathcal{W}_u \\ &\quad + \int_0^T \left(\int_0^T \mathcal{D}_u g_r \cdot h_u \mathbf{1}_{\phi(r)\le u\le r} dr \right) du, \end{aligned} \tag{2.9}$$

and the above random variable belongs to $\mathbb{D}^\infty$. *Under extra assumptions, both terms in the right-hand side (r.h.s.) above are of order* δ.

(i) *Assume that* $N_{k,p}(g) = \sum_{j=0}^k \left[E\left(\int_0^T \|\mathcal{D}^j g_r\|^p_{L^p([0,T]^j)} dr\right)\right]^{1/p} < +\infty$ *and* $N_{k,p}(h) < +\infty$ *for any* k *and* p. *Then, the first term in the r.h.s. of* (2.9) *is of order* δ *in* $\mathbb{D}^{k,p}$, *for any* $k \in \mathbb{N}$ *and* $p > 1$:

$$\left\| \int_0^T \left(\int_0^T g_r h_u \mathbf{1}_{\phi(r)\le u\le r} dr \right) \boldsymbol{\delta}\mathcal{W}_u \right\|_{\mathbb{D}^{k,p}} \le C\ N_{k+1,q}(g) N_{k+1,q}(h)\ \delta \tag{2.10}$$

for some constants C *and* q *depending only on* k *and* p.

(ii) *Assume that* $M_{k,p}(g) = \sum_{j=1}^k \sup_{0\le r\le T} \left[E\|\mathcal{D}^j g_r\|^p_{L^p([0,T]^j)}\right]^{1/p} < +\infty$ *and* $N_{k,p}(h) < +\infty$ *for any* k *and* p. *Then, the second term in the r.h.s. of* (2.9) *is of order* δ *in* $\mathbb{D}^{k,p}$, *for any* $k \in \mathbb{N}$ *and* $p \ge 1$:

$$\left\| \int_0^T \left(\int_0^T \mathcal{D}_u g_r \cdot h_u \mathbf{1}_{\phi(r)\le u\le r} dr \right) du \right\|_{\mathbb{D}^{k,p}} \le C\ M_{k+1,q}(g)\ N_{k,q}(h)\ \delta \tag{2.11}$$

for some constants C *and* q *depending only on* k *and* p.

Let us turn to the proof of Theorem 2.1. It consists in proving

$$E(\Phi(W)[f(X_T^\delta)e^{Z_T^\delta} - f(X_T)e^{Z_T}]) \tag{2.12}$$
$$= E(\Phi(W)e^{Z_T^\delta}[(f-f_\delta)(X_T^\delta) - (f-f_\delta)(X_T)])$$
$$+ E(\Phi(W)e^{Z_T^\delta}[f_\delta(X_T^\delta) - f_\delta(X_T)]) \tag{2.13}$$
$$+ E(\Phi(W)f(X_T)[e^{Z_T^\delta} - e^{Z_T}]) \tag{2.14}$$
$$= E(\Phi(W)[A_1(f) + A_2(f) + A_3(f) + A_4(f) + R])$$

for any functional $\Phi(W) \in \mathbb{D}^\infty$, with $\|R\|_2 = O(\delta)$ uniformly w.r.t. $f \in BL_1(\mathbb{R}^d)$. Since $\|f - f_\delta\|_\infty \le C\delta$ for $f \in BL_1(\mathbb{R}^d)$, the term (2.12) can be neglected in our expansion.

In the following computations, we simply write Φ instead of $\Phi(W)$.

2.2.1. Contribution (2.13). A Taylor's formula combined with (2.6) and Ito's formula between $\phi(s)$ and s gives

$$E(\Phi e^{Z_T^\delta}[f_\delta(X_T^\delta) - f_\delta(X_T)]) \tag{2.15}$$
$$= E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha^{0,0}(u)du\right]ds\right) \tag{2.16}$$
$$+ E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha^{0,1}(u)dB_u\right]ds\right) \tag{2.17}$$
$$+ E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha^{0,2}(u)dW_u\right]ds\right) \tag{2.18}$$
$$+ E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha^{1,0}(u)du\right]dB_s\right) \tag{2.19}$$
$$+ \sum_{i=1}^d E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u\right]dB_s^i\right) \tag{2.20}$$
$$+ \sum_{i=1}^d E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha_i^{1,2}(u)dW_u\right]dB_s^i\right) \tag{2.21}$$
$$+ E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha^{2,0}(u)du\right]dW_s\right) \tag{2.22}$$
$$+ \sum_{i=1}^q \sum_{j=1}^d E\left(\Phi e^{Z_T^\delta} f_\delta'(T)\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\left[\int_{\phi(s)}^s \alpha_{i,j}^{2,1}(u)dB_u^j\right]dW_s^i\right) + E(\Phi A_1(f)), \tag{2.23}$$

where coefficients $\alpha_\cdot^\cdot \in \mathbb{D}^\infty(H)$ with $N_{k,p}(\alpha_\cdot^\cdot) + M_{k,p}(\alpha_\cdot^\cdot) < +\infty$ for any k, p, uniformly w.r.t. δ (actually, this is a consequence of the stronger estimate $\sup_{r\in[0,T]} \|\mathcal{D}^k_{s_1,\dots,s_k}\alpha_\cdot^\cdot(r)\|_p < \infty$; see, e.g., [12]). For instance, one can easily check that $\alpha_{i,j}^{2,1}(u) = -\gamma_i'(X^\delta_{\phi(u)})\sigma_j(X^\delta_{\phi(u)})$.

Terms in the factor of Φ in (2.15), (2.18), (2.21) clearly satisfy $\|R\|_2 = O(\delta)$ (recall that $\|f'\|_\infty \le C$ uniformly in $f \in BL_1(\mathbb{R}^d)$).

The contributions (2.16) and (2.17) give a contribution of order δ in L^p-norm by an application of estimates (2.10)–(2.11).

Terms in (2.19) contain most of the difficulties that we have to face in this error analysis; here, we give detailed arguments ((2.20) is handled in the same way). Note that $f_\delta(x) = E(f_{\delta/\sqrt{2}}(x + \frac{\delta}{\sqrt{2}}\tilde{B}_T))$ as well for the derivatives; thus, each term of the sum in (2.19) equals

$$\int_0^1 d\lambda E\left(\Phi\psi_T^\delta e^{Z_T^\delta} f'_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\Big[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u\Big]dB_s^i\right) \tag{2.24}$$

$$+\int_0^1 d\lambda E\left(\Phi(1-\psi_T^\delta)e^{Z_T^\delta} f'_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\Big[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u\Big]dB_s^i\right). \tag{2.25}$$

Since $P(\psi_T^\delta \neq 1) \leq C\frac{\delta^2}{T^q}$, (2.25) provides a negligible contribution. Besides, if we transform the Ito integral w.r.t. B^i into a Lebesgue integral, using the duality relationship (see section 1.3 in [26]) and property (ii) of Lemma 2.1, we obtain that (2.24) can be rewritten in the form

$$\int_0^1 d\lambda E\left(\Phi\int_0^T \mathcal{D}_s^{B^i}[\psi_T^\delta e^{Z_T^\delta} f'_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\mathcal{E}_T]\mathcal{E}_s^{-1}\Big[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u\Big]ds\right)$$
$$= \sum_{\kappa:|\kappa|=1,2}\int_0^1 d\lambda E\left(\Phi\ \partial_x^\kappa f_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\int_0^T \alpha_{\kappa,i}^{1,1}(s)\Big[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u\Big]ds\right),$$

where the summation holds on differentiation multi-indices κ with length equal to 1 and 2. In addition, the coefficients $\alpha_{\kappa,i}^{1,1}$ and $\alpha_{\kappa,i}^{1,1}$ satisfy $N_{k,p}(\alpha_{\kappa,i}^{1,1}) + M_{k,p}(\alpha_{\kappa,i}^{1,1}) < +\infty$ for any k and p. If we put $G = \int_0^T \alpha_{\kappa,i}^{1,1}(s)[\int_{\phi(s)}^s \alpha_i^{1,1}(u)dB_u]ds$, we remark that $G \in \mathbb{D}^\infty$, that $G = 0$ if $\psi_T^\delta = 0$ because of the local property of the derivative operator (Proposition 1.3.7 in [26]), and that $\|G\|_{\mathbb{D}^{k,p}} \leq C\delta$ by applying Proposition 2.1. Thus, Lemma 2.1 completes the estimate, and the factor of Φ in (2.24) is of order δ in L^2-norm, uniformly w.r.t. $f \in BL_1(\mathbb{R}^d)$.

We now consider (2.22). As for (2.19), we introduce ψ_T^δ; the term with $1-\psi_T^\delta$ can be neglected as before. Using analogous computations as above, it is straightforward to see that we have to control

$$\int_0^1 d\lambda E\left(\Phi\psi_T^\delta e^{Z_T^\delta} f'_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\mathcal{E}_T \int_0^T \mathcal{E}_s^{-1}\Big[\int_{\phi(s)}^s \alpha_{i,j}^{2,1}(u)dB_u^j\Big]dW_s^i\right)$$
$$= \int_0^1 d\lambda \int_0^T\int_0^T E\Big(\mathcal{D}_u^{B^j}[\mathcal{D}_s^{W^i}[\Phi\psi_T^\delta e^{Z_T^\delta} f'_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\mathcal{E}_T]\mathcal{E}_s^{-1}]\mathbf{1}_{\phi(s)\leq u\leq s}\alpha_{i,j}^{2,1}(u)\Big)du\ ds$$
$$= \sum_{\kappa:|\kappa|=1,2}\int_0^1 d\lambda E\left(\Phi\ \partial_x^\kappa f_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})\int_0^T\int_0^T \hat{\alpha}_{i,j}^{\kappa,2,1}(s)\mathbf{1}_{\phi(s)\leq u\leq s}\alpha_{i,j}^{2,1}(u)du\ ds\right)$$

(2.26)

$$+\sum_{\kappa:|\kappa|=1,2}\int_0^1 d\lambda E\left(\int_0^T \mathcal{D}_s^{W^i}[\Phi\ \partial_x^\kappa f_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda})]\Big(\int_0^T \alpha_{i,j}^{\kappa,2,1}(s)\mathbf{1}_{\phi(s)\leq u\leq s}\alpha_{i,j}^{2,1}(u)du\Big)ds\right).$$

(2.27)

For (2.26), it is enough to apply (2.8) with $G = \int_0^T\int_0^T \hat{\alpha}_{i,j}^{\kappa,2,1}(s)\mathbf{1}_{\phi(s)\leq u\leq s}\alpha_{i,j}^{2,1}(u)du\ ds$, which clearly satisfies $\|G\|_{\mathbb{D}^{k,p}} \leq C\delta$; this proves the expected estimate of order δ. The same conclusion holds for each term in (2.27): indeed, they can be transformed in

$\int_0^1 d\lambda E(\Phi\ \partial_x^\kappa f_{\delta/\sqrt{2}}(\tilde{X}_T^{\delta,\lambda}) \int_0^T (\int_0^T \alpha_{i,j}^{\kappa,2,1}(s)\mathbf{1}_{\phi(s)\le u\le s}\alpha_{i,j}^{2,1}(u)du)\boldsymbol{\delta}W_s^i)$ and we conclude with Lemma 2.1.

2.2.2. Contribution (2.14). It can be decomposed as $E(\Phi f(X_T)[e^{Z_T^\delta}-e^{Z_T}]) = E(\Phi f(X_T)e^{\bar{Z}_T^\delta}[Z_T^\delta - Z_T])$, that is,

$$E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\int_0^T [h(X_{\phi(s)}^\delta) - h(X_s^\delta)].dW_s\right)\right) \tag{2.28}$$

$$+ E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\int_0^T [h(X_s^\delta) - h(X_s)].dW_s\right)\right) \tag{2.29}$$

$$- \frac{1}{2}E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\int_0^T [\|h\|^2(X_{\phi(s)}^\delta) - \|h\|^2(X_s^\delta)]ds\right)\right) \tag{2.30}$$

$$- \frac{1}{2}E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\int_0^T [\|h\|^2(X_s^\delta) - \|h\|^2(X_s)]ds\right)\right). \tag{2.31}$$

In what follows, the main idea is to use Ito's formula and the stochastic expansion (2.6) to expand the differences $h(X_{\phi(s)}^\delta) - h(X_s^\delta)$, $h(X_s^\delta) - h(X_s)$, and so on. It will raise iterated stochastic integrals and, as before, the ones for which conditional expectation w.r.t. W is of order $\sqrt{\delta}$ are essentially of type $\int_0^T \cdots (\int_{\phi(s)}^s \cdots dW_u)dW_s$ (and not $\int_0^T \cdots (\int_{\phi(s)}^s \cdots dB_u)dW_s$ or $\int_0^T \cdots (\int_{\phi(s)}^s \cdots dW_u)dB_s$).

We now go into detail. Since (2.28) can be rewritten as $E(\Phi f(X_T)e^{\bar{Z}_T^\delta}(\sum_{i=1}^q \int_0^T [h_i(X_{\phi(s)}^\delta) - h_i(X_s^\delta)]dW_s^i))$, it equals

$$-E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\sum_{i=1}^q \int_0^T \left[\int_{\phi(s)}^s h_i'(X_r^\delta)\beta(X_{\phi(r)}^\delta)dr\right]dW_s^i\right)\right) \tag{2.32}$$

$$-E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\sum_{i=1}^q \int_0^T \left[\int_{\phi(s)}^s h_i'(X_r^\delta)\sigma(X_{\phi(r)}^\delta)dB_r\right]dW_s^i\right)\right) \tag{2.33}$$

$$-E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\sum_{i=1}^q \int_0^T \left[\int_{\phi(s)}^s h_i'(X_r^\delta)\gamma(X_{\phi(r)}^\delta)dW_r\right]dW_s^i\right)\right). \tag{2.34}$$

The factor of Φ in (2.32) clearly satisfies the required estimate and can be neglected. The term (2.33) can also be discarded from the main part of the error using the same arguments as for (2.22). Finally, the term (2.34) gives $A_2(f)$.

Term (2.29). Owing to (2.6), $\sum_{i=1}^q E(\Phi f(X_T)e^{\bar{Z}_T^\delta}(\int_0^T [h_i(X_s^\delta) - h_i(X_s)]dW_s^i))$ equals

$$-\sum_{i=1}^q \sum_{j=1}^d E\left(\Phi f(X_T)e^{\bar{Z}_T^\delta}\left(\int_0^T h_i'(s)\mathcal{E}_s \times\left(\int_0^s \mathcal{E}_r^{-1}\left[\int_{\phi(r)}^r \sigma_j'(X_u^\delta)\sigma(X_{\phi(u)}^\delta)dB_u\right]dB_r^j\right)dW_s^i\right)\right)$$

$$
\begin{aligned}
&-\sum_{i=1}^{q}\sum_{j=1}^{d} E\Bigg(\Phi f(X_T)e^{\bar{Z}_T^\delta}\Bigg(\int_0^T h_i'(s)\mathcal{E}_s \\
&\qquad\qquad \times\Bigg(\int_0^s \mathcal{E}_r^{-1}\Bigg[\int_{\phi(r)}^r \sigma_j'(X_u^\delta)\gamma(X_{\phi(u)}^\delta)dW_u\Bigg]dB_r^j\Bigg)dW_s^i\Bigg)\Bigg) \\
&-\sum_{i,j=1}^{q} E\Bigg(\Phi f(X_T)e^{\bar{Z}_T^\delta}\Bigg(\int_0^T h_i'(s)\mathcal{E}_s \\
&\qquad\qquad \times\Bigg(\int_0^s \mathcal{E}_r^{-1}\Bigg[\int_{\phi(r)}^r \gamma_j'(X_u^\delta)\sigma(X_{\phi(u)}^\delta)dB_u\Bigg]dW_r^j\Bigg)dW_s^i\Bigg)\Bigg) \qquad (2.35) \\
&-\sum_{i,j=1}^{q} E\Bigg(\Phi f(X_T)e^{\bar{Z}_T^\delta}\Bigg(\int_0^T h_i'(s)\mathcal{E}_s \\
&\qquad\qquad \times\Bigg(\int_0^s \mathcal{E}_r^{-1}\Bigg[\int_{\phi(r)}^r \gamma_j'(X_u^\delta)\gamma(X_{\phi(u)}^\delta)dW_u\Bigg]dW_r^j\Bigg)dW_s^i\Bigg)\Bigg) + E(\Phi R) \qquad (2.36)
\end{aligned}
$$

with $\|R\|_2 = O(\delta)$ by estimates (2.10)–(2.11). The term (2.36) gives $A_3(f)$, while the other contributions can be neglected. To justify this assertion, let us consider, for instance, (2.35), with techniques being the same for the other ones. First, we can replace f by f_δ since $\|f - f_\delta\|_\infty \le C\delta$. Then, three applications of the duality relationship yield

$$
\begin{aligned}
&E\Bigg(\Phi f_\delta(X_T)e^{\bar{Z}_T^\delta}\Bigg(\int_0^T h_i'(s)\mathcal{E}_s\Bigg(\int_0^s \mathcal{E}_r^{-1}\Bigg[\int_{\phi(r)}^r \gamma_j'(X_u^\delta)\sigma(X_{\phi(u)}^\delta)dB_u\Bigg]dW_r^j\Bigg)dW_s^i\Bigg)\Bigg) \\
&\quad = \int_0^T\int_0^T\int_0^T E(\mathcal{D}_u^B[\mathcal{D}_r^{W^j}[\mathcal{D}_s^{W^i}[\Phi f_\delta(X_T)e^{\bar{Z}_T^\delta}]h_i'(s)\mathcal{E}_s]\mathcal{E}_r^{-1}] \\
&\qquad \cdot\gamma_j'(X_u^\delta)\sigma(X_{\phi(u)}^\delta)\mathbf{1}_{\phi(r)\le u\le r})du\ dr\ ds.
\end{aligned}
$$

The term inside the expectation can be split into a sum involving the derivative of Φ and of f. Presumably, the more difficult term to estimate is of the form

$$
\int_0^T\int_0^T\int_0^T E(\mathcal{D}_r^{W^j}[\mathcal{D}_s^{W^i}[\Phi\ \partial_x^\kappa f_\delta(X_T)]]\alpha(u,r,s)\mathbf{1}_{\phi(r)\le u\le r})du\ dr\ ds.
$$

We omit the details for the other ones, which are easier to handle. Two integrations by parts with fixed W (see (iii) in Lemma 2.1) show that it equals

$$
E\Bigg(\Phi\ \partial_x^\kappa f_\delta(X_T)\int_0^T\Bigg(\int_0^T\Bigg(\int_0^T \alpha(u,r,s)\mathbf{1}_{\phi(r)\le u\le r}du\Bigg)\boldsymbol{\delta}W_r^j\Bigg)\boldsymbol{\delta}W_s^i\Bigg).
$$

Then, we conclude using (2.7) with $\|\int_0^T(\int_0^T(\int_0^T \alpha(u,r,s)\mathbf{1}_{\phi(r)\le u\le r}du)\boldsymbol{\delta}W_r^j)\boldsymbol{\delta}W_s^i\|_{\mathbb{D}^{k,p}} \le C\delta$.

Term (2.30). It yields a contribution of order δ, by an application of Ito's formula and inequalities (2.10)–(2.11). At last, the term (2.31) is equal to $-\frac{1}{2}\int_0^T E(\Phi f(X_T)e^{\bar{Z}_T^\delta}[\|h\|^2(X_s^\delta) - \|h\|^2(X_s)])ds$; in this form, the analysis is analogous to that of (2.13) and we omit the details. It gives the contribution $A_4(f)$ and some residual terms of order δ.

2.2.3. Proof of Lemma 2.1. The two first statements are straightforward. Statement (i) immediately follows from the fact that any $\Phi(W) \in L^2$ can be approximated in L^2 by a sequence of $\mathbb{D}^\infty$-r.v. using the chaos expansion (see Theorem 1.1.1 in [26]). Statement (ii) is clear from the definition of $\mathbb{D}^{1,p}$, $\mathcal{D}^B$, and $\mathcal{D}^{\tilde{B}}$.

Statement (iii) is an integration by parts formula that puts the differentiation/integration only on B and $\tilde{B}$, but not on W. Its proof is an easy adaptation of Proposition 3.2.1 in [27]. The estimate (2.7) is standard using in particular $\|[\gamma^{X_T}]^{-1}\|_p \le \frac{C}{T^q}$ under the nondegeneracy condition (H1) (iii) (see Theorem 3.3.1 in [27]). We only prove (2.8), which is less usual because of the localization factor G. Using (ii), one obtains the following equalities:

$$[\mathcal{D}^B(\Phi(W)g(\tilde{X}_T^{\delta,\lambda})), \mathcal{D}^{\tilde{B}}(\Phi(W)g(\tilde{X}_T^{\delta,\lambda}))] = \Phi(W)g'(\tilde{X}_T^{\delta,\lambda})[\mathcal{D}^B\tilde{X}_T^{\delta,\lambda}, \mathcal{D}^{\tilde{B}}\tilde{X}_T^{\delta,\lambda}],$$

$$\int_0^T \mathcal{D}_t(\Phi(W)g(\tilde{X}_T^{\delta,\lambda}))[\mathcal{D}_t^B\tilde{X}_T^{\delta,\lambda}, \mathcal{D}_t^{\tilde{B}}\tilde{X}_T^{\delta,\lambda}, 0]^\intercal dt = \Phi(W)g'(\tilde{X}_T^{\delta,\lambda})\gamma^{\tilde{X}_T^{\delta,\lambda}}.$$

Note that $\gamma^{\tilde{X}_T^{\delta,\lambda}} \ge \frac{\delta^2}{2}\mathrm{Id}$ and thus $\gamma^{\tilde{X}_T^{\delta,\lambda}}$ is invertible (it is the purpose of the small perturbation of $X^{\delta,\lambda}$ with $\delta\tilde{B}/\sqrt{2}$). Then, the duality relationship leads to

$$\begin{aligned}
&E(\Phi(W)\partial_{x_i}g(\tilde{X}_T^{\delta,\lambda})G)\\
&= E\left(\int_0^T \mathcal{D}_t(\Phi(W)g(\tilde{X}_T^{\delta,\lambda}))[Ge^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^B\tilde{X}_T^{\delta,\lambda}, Ge^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^{\tilde{B}}\tilde{X}_T^{\delta,\lambda}, 0]^\intercal dt\right)\\
&= E\left(\Phi(W)g(\tilde{X}_T^{\delta,\lambda})\int_0^T [Ge^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^B\tilde{X}_T^{\delta,\lambda}, Ge^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^{\tilde{B}}\tilde{X}_T^{\delta,\lambda}, 0]\boldsymbol{\delta}\mathcal{W}_t\right).
\end{aligned}$$

For longer multi-index α, we iterate the procedure and construct $H_\alpha(\tilde{X}_T^{\delta,\lambda}, G)$ by the recurrence formula $H_{\alpha'+[e^i]^\intercal}(\tilde{X}_T^{\delta,\lambda}, G) = \int_0^T [H_{\alpha'}(\tilde{X}_T^{\delta,\lambda}, G)e^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^B\tilde{X}_T^{\delta,\lambda}, H_{\alpha'}(\tilde{X}_T^{\delta,\lambda}, G)e^i\cdot[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathcal{D}_t^{\tilde{B}}\tilde{X}_T^{\delta,\lambda}, 0]\boldsymbol{\delta}\mathcal{W}_t$. Concerning the estimation on $\|H_\alpha(\tilde{X}_T^{\delta,\lambda}, G)\|_2$, note first that since the derivative operator and the Skorokhod integral are local (see Propositions 1.3.6 and 1.3.7 in [26]), one has $H_\alpha(\tilde{X}_T^{\delta,\lambda}, G) = H_\alpha(\tilde{X}_T^{\delta,\lambda}, G)\mathbf{1}_{\psi_T^\delta>0}$ owing to the property on G. Using the standard inequality $\|H_\alpha(\tilde{X}_T^{\delta,\lambda}, G)\mathbf{1}_A\|_p \le C\|[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathbf{1}_A\|_{q_1}^{p_1}\|\tilde{X}_T^{\delta,\lambda}\|_{k_2,q_2}^{p_2}\|G\|_{\mathbb{D}^{k_3,q_3}}$ (Proposition 2.4 in [3]) combined with $\|[\gamma^{\tilde{X}_T^{\delta,\lambda}}]^{-1}\mathbf{1}_{\psi_T^\delta>0}\|_p \le \frac{C}{T^q}$ (take into account property (c) of ψ_T^δ; see section 2.2), we easily complete the expected estimation.

2.2.4. Proof of Proposition 2.1. To prove (2.9), take $\Psi \in \mathbb{D}^\infty$ and write using Fubini's theorem twice and the duality relationship alternatively as follows:

$$\begin{aligned}
E\left(\Psi\int_0^T g_r\left(\int_{\phi(r)}^r h_u\boldsymbol{\delta}\mathcal{W}_u\right)dr\right) &= \int_0^T E\left(\Psi g_r\left(\int_{\phi(r)}^r h_u\boldsymbol{\delta}\mathcal{W}_u\right)\right)dr\\
&= \int_0^T\int_0^T E\big(\mathcal{D}_u[\Psi g_r]\mathbf{1}_{\phi(r)\le u\le r}\cdot h_u\big)du\,dr\\
&= \int_0^T E\left(\mathcal{D}_u\Psi\cdot\int_0^T g_r h_u\mathbf{1}_{\phi(r)\le u\le r}dr\right)du
\end{aligned}$$

$$+\int_0^T E\left(\Psi\int_0^T \mathcal{D}_u g_r\cdot h_u \mathbf{1}_{\phi(r)\le u\le r}dr\right)du$$

$$= E\left(\Psi\int_0^T\left(\int_0^T g_r h_u \mathbf{1}_{\phi(r)\le u\le r}dr\right)\boldsymbol{\delta}\mathcal{W}_u\right)$$

$$+E\left(\Psi\int_0^T\left(\int_0^T \mathcal{D}_u g_r\cdot h_u \mathbf{1}_{\phi(r)\le u\le r}dr\right)du\right).$$

It is standard to check that $\int_0^T g_r(\int_{\phi(r)}^r h_u\boldsymbol{\delta}\mathcal{W}_u)dr$ belongs to $\mathbb{D}^\infty$ (see Lemma 1.3.4 in [26]). The original feature of our result is specifically related to (2.10) and (2.11). For this, we use the following general estimates, which we prove at the end.

LEMMA 2.2. *For appropriately defined random variables* $(g_{r,s}, h_{u,s}, g_{r,s,u})_{r,s,u}$, *we have*

(2.37)

$$\left[E\left(\int_{[0,T]^j}ds\int_0^T du\left|\int_0^T g_{r,s}h_{u,s}\mathbf{1}_{\phi(r)\le u\le r}dr\right|^2\right)^{p/2}\right]^{1/p}$$

$$\le C_{p,q}(T)\ \delta\left[E\left(\int_{[0,T]^{j+1}}|h_{u,s}|^q\ duds\right)\right]^{1/q}\left[E\left(\int_{[0,T]^{j+1}}|g_{r,s}|^q\ drds\right)\right]^{1/q},$$

$$\left[E\left(\int_{[0,T]^j}ds\int_0^T du\left|\int_0^T g_{r,s,u}h_{u,s}\mathbf{1}_{\phi(r)\le u\le r}dr\right|^2\right)^{p/2}\right]^{1/p}$$

(2.38)

$$\le C_{p,q}(T)\delta\left[E\left(\int_{[0,T]^{j+1}}|h_{u,s}|^q\ duds\right)\right]^{1/q}\sup_{0\le r\le T}\left[E\left(\int_{[0,T]^{j+1}}|g_{r,s,u}|^q\ dsdu\right)\right]^{1/q}$$

for q large enough.

We are now in a position to derive (2.10). Consider first $k=0$. To control the L^p-norms of the first term in the r.h.s. of (2.9), we invoke the continuity of the Skorokhod integral (Proposition 2.4.3 in [27]) to get

(2.39)

$$\left\|\int_0^T\left(\int_0^T g_r h_u\mathbf{1}_{\phi(r)\le u\le r}dr\right)\boldsymbol{\delta}\mathcal{W}_u\right\|_p \le C\left(\left\|\int_0^T g_r h_\cdot \mathbf{1}_{\phi(r)\le\cdot\le r}dr\right\|_{L^p(\Omega,H)}\right.$$

$$\left.+\left\|\int_0^T \mathcal{D}(g_r h_\cdot)\mathbf{1}_{\phi(r)\le\cdot\le r}dr\right\|_{L^p(\Omega,H^{\otimes 2})}\right).$$

From (2.37), we easily get that the first term above is bounded by $N_{0,q}(h)N_{0,q}(h)\delta$ for q large enough. With analogous computations, the second term in the r.h.s. of (2.39) is bounded by $CN_{1,q}(h)N_{1,q}(h)\delta$. Estimates (2.10) have been proved when $k=0$. For $k\ge 1$, the successive derivatives of the r.h.s. of (2.9) are standard to compute and can be expressed in a similar form as before. Then, analogous computations can be performed and this proves (2.10) for any k. The derivation of (2.11) is analogous, using in addition (2.38).

Proof of Lemma 2.2. The Cauchy–Schwarz inequality yields

$$\begin{aligned}
&\int_0^T du \left| \int_0^T g_{r,s,u} h_{u,s} \mathbf{1}_{\phi(r)\le u\le r} dr \right|^2 \\
&\quad \le \int_0^T du |h_{u,s}|^2 \left(\int_u^{\phi(u)+\delta} |g_{r,s,u}|\, dr \right)^2 \\
&\quad \le \left[\int_0^T du |h_{u,s}|^4 \right]^{1/2} \left[\int_0^T du \left(\int_u^{\phi(u)+\delta} |g_{r,s,u}|\, dr \right)^4 \right]^{1/2} \\
&\quad \le \delta^{3/2} \left[\int_0^T du |h_{u,s}|^4 \right]^{1/2} \left[\int_0^T du \int_u^{\phi(u)+\delta} |g_{r,s,u}|^4\, dr \right]^{1/2}.
\end{aligned}$$

If g does not depend on u, the last term above is bounded by $\delta^{1/2}[\int_0^T |g_{r,s}|^4\, dr]^{1/2}$. Then, the derivation of (2.37) is easy, using Hölder's inequalities. To obtain (2.38), i.e., when g depends on u, the previous computation to get the missing factor $\delta^{1/2}$ does not work directly; first, one has to integrate over s and ω, the other arguments remaining unchanged. ∎

3. Simulation of the Zakai equation and quantization error.

3.1. The quantization algorithm. In this section, we propose a quantization approach for the numerical implementation of formulas in (2.1), (2.3), and (2.5). Here, those formulas are written as

$$\begin{aligned}
\bar{X}_{k+1} &= \bar{X}_k + \beta(\bar{X}_k)\delta + \sigma(\bar{X}_k)\Delta\bar{B}_{k+1} + \gamma(\bar{X}_k)\Delta\bar{W}_{k+1} \\
&=: F_\delta(\bar{X}_k, \Delta\bar{B}_{k+1}, \Delta\bar{W}_{k+1}), \qquad (3.1)\\
\langle \bar{V}_{k+1}, f\rangle &= \langle \bar{V}_k, \exp\left(g(.,\Delta\bar{W}_{k+1})\right) \bar{P}_{k+1,W} f\rangle \qquad (3.2)
\end{aligned}$$

for $k = 0, \dots, n-1$, with

$$g(x,\Delta W) = h(x).\Delta W - \frac{1}{2}|h(x)|^2\delta, \qquad (3.3)$$

and $\bar{P}_{k+1,W}(x, dx')$ is a normal distribution with mean $x + \beta(x)\delta + \gamma(x)\Delta\bar{W}_{k+1}$ and variance $\sigma(x)\sigma^\intercal(x)\delta$.

We construct an approximation of $\bar{V}_k$ as follows. At each time t_k, $k = 0, \dots, n$, we are given the following grid $\Gamma_k = \{x_k^1, \dots, x_k^{N_k}\}$ of N_k points in $\mathbb{R}^d$, associated to Voronoi tessellations $C_i(\Gamma_k)$, $i = 1, \dots, N_k$:

$$C_i(\Gamma_k) = \left\{ u \in \mathbb{R}^d : |u - x_k^i| = \min_j |u - x_k^j| \right\}.$$

We then approximate the process $(\bar{X}_k)$ by the marginal quantized process $(\hat{X}_k)$ defined as

$$\hat{X}_k = \mathrm{Proj}_{\Gamma_k}(\bar{X}_k) := \sum_{i=1}^{N_k} x_k^i 1_{\{\bar{X}_k \in C_i(\Gamma_k)\}}.$$

We thus define the conditional probability $\hat{P}_{k,W}$ of $\hat{X}_k$ given $\hat{X}_{k-1}$ and W. In other words, $\hat{P}_{k,W}$ is a (random) probability transition matrix $\{\hat{p}_{k,W}^{ij},\ i = 1, \dots, N_{k-1}, j =$

$1, \dots, N_k\}$ characterized by

$$\hat{p}^{ij}_{k,W} = P_W\left[\hat{X}_k = x^j_k \middle| \hat{X}_{k-1} = x^i_{k-1}\right].$$

Finally, the random measure-valued process $(\bar{V}_k)$ is approximated by the discrete random measure process $(\hat{V}_k)$ defined by

$$\begin{aligned} \hat{V}_0 &= \text{law of} \hat{X}_0, \\ \langle \hat{V}_{k+1}, f\rangle &= \langle \hat{V}_k, \exp\left(g(.,\Delta\bar{W}_{k+1})\right)\hat{P}_{k+1,W} f\rangle. \end{aligned} \tag{3.4}$$

From an algorithmic viewpoint, this reads as

$$\hat{V}_k = \sum_{i=1}^{N_k} \hat{v}^i_k \delta_{x^i_k} \quad (\delta_x \text{ is the Dirac mass at } x)$$

for $k = 0, \dots, n$, where the weights $\hat{v}^i_k$ are computed in a forward induction as follows:

$$\begin{aligned} \hat{v}^i_0 = \hat{p}^i_0 &:= P[\hat{X}_0 = x^i_0] = P[\bar{X}_0 \in C_i(\Gamma_0)], \quad i = 1, \dots, N_0, \\ \hat{v}^j_{k+1} &= \sum_{i=1}^{N_k} \hat{v}^i_k \hat{p}^{ij}_{k+1,W} \exp\left(g(x^i_k, \Delta\bar{W}_{k+1})\right), \quad j = 1, \dots, N_{k+1}. \end{aligned}$$

The implementation of the above method requires optimally for each $k = 0, \dots, n$

- a grid Γ_k which minimizes the L^p-quantization error

$$\|\Delta_k\|_p = \|\bar{X}_k - \hat{X}_k\|_p$$

as well as an estimation of this error, and

- the weights of the joint distribution $(\hat{X}_{k-1}, \hat{X}_k)$ and marginal distribution $\hat{X}_{k-1}$,

$$\begin{aligned} \hat{r}^{ij}_{k,W} &= P_W\left[\hat{X}_k = x^j_k,\ \hat{X}_{k-1} = x^i_{k-1}\right] = P_W\left[\bar{X}_k \in C_j(\Gamma_k),\ \bar{X}_{k-1} \in C_i(\Gamma_{k-1})\right], \\ \hat{q}^i_{k-1,W} &= P_W\left[\hat{X}_{k-1} = x^i_k\right] = P_W\left[\bar{X}_{k-1} \in C_i(\Gamma_{k-1})\right] \end{aligned}$$

for $i = 1, \dots, N_{k-1}$, $j = 1, \dots, N_k$, so that

$$\hat{p}^{ij}_{k,W} = \frac{\hat{r}^{ij}_{k,W}}{\hat{q}^i_{k-1,W}}.$$

This program is achieved as follows:

– Monte Carlo simulation of M independent copies $(\bar{X}^{(m)}_0, \dots, \bar{X}^{(m)}_n)$, $m = 1, 2, \dots, M$, distributed according to $(\bar{X}_0, \dots, \bar{X}_n)$.

– Recursive optimization of the grids $\Gamma_0, \dots, \Gamma_n$ by a *competitive learning vector quantization* procedure and computation of the probability weights $\hat{r}^{ij}_{k,W}$ and $\hat{q}^i_{k-1,W}$, $k = 1, \dots, n$. As a byproduct, we also have an estimation of the L^2-quantization errors $\|\Delta_k\|_2$, $k = 0, \dots, n$.

3.2. Analysis of quantization error. The next theorem states an error estimation for the approximation of $\bar{V}_n$ under the following condition on the coefficients of the SDE X:

(H2) (i) The functions β, σ, and γ are Lipschitz.

(ii) The function h is bounded and Lipschitz.

THEOREM 3.1. *Under* (H2)*, for all* $p \in [1, +\infty)$ *and* $p' > p$*, there exists a positive real constant* $C_{p,p'}$ *such that*

$$\left\| \rho(\bar{V}_n, \hat{V}_n) \right\|_p \leq C_{p,p'} \frac{1}{\sqrt{\delta}} \sum_{k=0}^{n} \|\Delta_k\|_{p'} \qquad (\textit{with } \delta = T/n).$$

We first need the following classic result about the L^p-Lipschitz property of Euler schemes.

LEMMA 3.1. *Let* G_δ *be a functional in the form*

$$G_\delta(x, \varepsilon) = x + \delta B(x) + \sqrt{\delta}\, \Sigma(x)\varepsilon,$$

where B *and* Σ *are Lipschitz functions on* $\mathbb{R}^d$*, and* ε *is a Gaussian white noise. Then, for all* $p \in [1, \infty)$*, there exists a constant* C_p *such that for all* $x, x' \in \mathbb{R}^d$*,*

$$\|G_\delta(x, \varepsilon) - G_\delta(x', \varepsilon)\|_p \leq C_p(1 + \delta)|x - x'|.$$

We refer, e.g., to [30] for a detailed proof in a slightly more general setting where ε is only symmetric and lies in L^p.

One defines for every $k = 1, \ldots, n$ the operator $\bar{H}_{k,W}$ by

$$\bar{H}_{k,W}(f)(x) = \exp g(x, \Delta \bar{W}_k) \bar{P}_{k,W}(f)(x) \quad \forall f \in BL_1(\mathbb{R}^d),\ \forall x \in \mathbb{R}^d,$$

where g is defined by (3.3). One defines

$$\bar{H}_{0,W}(f) = \langle \mu_0, f \rangle.$$

One easily checks that (with the former notations)

$$\langle \bar{V}_k, f \rangle = E_W(\bar{H}_{k,W}(f)(\bar{X}_{k-1})) = \langle \bar{V}_{k-1}, \bar{H}_{k,W}(f) \rangle$$

so that, for every $k = 0, \ldots, n$,

$$\langle \bar{V}_k, f \rangle \ = \ (\bar{H}_{0,W} \circ \bar{H}_{1,W} \circ \cdots \circ \bar{H}_{k,W})(f).$$

This equality can be written either in forward or backward recursive form. The backward form will be an important tool for proofs:

$$\begin{aligned} \bar{U}_{n,W} f &:= f, \\ \bar{U}_{k-1,W} f &:= \bar{H}_{k,W}(\bar{U}_{k,W} f), \qquad k = 1, \ldots n. \end{aligned} \tag{3.5}$$

Then, one checks *using the Markov property and the iterated conditional expectation rule* that

$$\bar{U}_{0,W} f = \langle \bar{V}_n, f \rangle.$$

For every $k = 1, \dots, n$, one approximates the operator $\bar{H}_{k,W}$ by its natural quantized counterpart $\widehat{H}_{k,W}$ defined on the grid $\Gamma_{k-1} = \{x_{k-1}^1, \dots, x_{k-1}^i, \dots, x_{k-1}^{N_{k-1}}\}$ by

$$\widehat{H}_{k,W}(f)(x_{k-1}^i) := \exp g(x_{k-1}^i, \Delta\bar{W}_k) \sum_j f(x_k^j) P_W(\widehat{X}_k = x_k^j \mid \widehat{X}_{k-1} = x_{k-1}^i)$$

so that

$$\widehat{H}_{k,W}(f)(\widehat{X}_{k-1}) = \exp g(\widehat{X}_{k-1}, \Delta\bar{W}_k)\, E_W(f(\widehat{X}_k) \mid \widehat{X}_{k-1}).$$

Then, one sets

$$\widehat{H}_{0,W}(f) := \sum_j f(x_0^j) P_W(\widehat{X}_0 = x_0^j).$$

We then notice that the approximation of $\bar{V}_k$ defined in (3.4) satisfies the following:

$$\langle \widehat{V}_k, f\rangle = (\widehat{H}_{0,W} \circ \widehat{H}_{1,W} \circ \cdots \circ \widehat{H}_{k,W})(f), \quad k = 1, \dots, n. \tag{3.6}$$

Once again, this equality can be read in backward form as follows:

$$\begin{aligned} &\widehat{U}_{n,W} f(x_n^i) := f(x_n^i), \quad i = 1, \dots, N_n, \\ &\widehat{U}_{k-1,W} f(x_{k-1}^i) := \widehat{H}_{k,W}(\widehat{U}_{k,W} f)(x_{k-1}^i), \quad i = 1, \dots, N_{k-1}, \ \ k = 1, \dots n, \end{aligned} \tag{3.7}$$

so that

$$\langle \widehat{V}_n, f\rangle = \widehat{U}_{0,W} f. \tag{3.8}$$

The proof is designed as follows: we wish to establish a backward induction between the error terms $\|\bar{U}_{k,W} f(\bar{X}_k) - \widehat{U}_{k,W} f(\widehat{X}_k)\|_p$ at successive times k and $k+1$ involving the quantization error $\|\bar{X}_{k+1} - \hat{X}_{k+1}\|_p$ of the Euler scheme. Unfortunately a naive approach makes the final error explode because of successive use of the Hölder inequality. So we are led to introduce a process $\bar{Y}_k$ starting at $\bar{X}_0$ but produced by a *biased* dynamics $G_{\delta,p}$ (instead of F_δ) which corresponds to a step-by-step discrete Girsanov (implicit) change of probability. Thus we can simultaneously take advantage of the martingale property of the Doléans exponential and of the independence property of the increments $\Delta\bar{W}_k$; it makes it possible not to use the Hölder inequality at a crucial step (see (3.15) below), which would cause an explosion of the constants. Finally, we use a revert Girsanov change of probability to come back to the quantization error of the original dynamics $(\bar{X}_k)$.

Proof of Theorem 3.1. We will assume for convenience that $\delta = T/n \in (0, 1]$ throughout the proof.

Step 1 (backward induction on the error $\|\bar{U}_{k,W} f(\bar{Y}_k) - \widehat{U}_{k,W} f(\widehat{Y}_k)\|_p$). Set temporarily

$$\begin{aligned} G_{\delta,p}(y, v, w) &:= F_\delta(y, v, w + p\delta h(y)) \\ &= y + \delta(\beta(y) + p\gamma(y)h(y)) + \sigma(y)v + \gamma(y)w, \\ \bar{Y}_k &:= G_{\delta,p}(\bar{Y}_{k-1}, \Delta\bar{B}_k, \Delta\bar{W}_k), \quad k \geq 1, \\ \bar{Y}_0 &= X_0, \\ \widetilde{Y}_k &:= F_\delta(\bar{Y}_{k-1}, \Delta\bar{B}_k, \Delta\bar{W}_k), \quad k \geq 1. \end{aligned}$$

Let $\bar{\mathcal{F}}_k$ denote the σ-field $\sigma(\Delta\bar{B}_\ell, \Delta\bar{W}_\ell, \ell = 1, \dots, k)$. Set, for every $k = 0, \dots, n$,

$$\hat{Y}_k := \mathrm{Proj}_{\Gamma_k}(\bar{Y}_k) \quad \text{and} \quad \widehat{\widetilde{Y}}_k := \mathrm{Proj}_{\Gamma_k}(\widetilde{Y}_k).$$

With these notations, one checks that for every $f \in BL_1(\mathbb{R}^d)$,

$$\bar{H}_{k,W}(f)(\bar{Y}_{k-1}) = \exp g(\bar{Y}_{k-1}, \Delta\bar{W}_k) E_W(f(\widetilde{Y}_k) \,|\, \bar{Y}_{k-1}) \tag{3.9}$$

and

$$\widehat{H}_{k,W}(f)(\widehat{Y}_{k-1}) = \exp g(\bar{Y}_{k-1}, \Delta\bar{W}_k) E_W(f(\widehat{\widetilde{Y}}_k) \,|\, \hat{Y}_{k-1}). \tag{3.10}$$

Consequently

$$\begin{aligned}
&\bar{U}_{k-1,W} f(\bar{Y}_{k-1}) - \widehat{U}_{k-1,W} f(\widehat{Y}_{k-1}) \\
&\quad = \bar{H}_{k,W}(\bar{U}_{k,W} f)(\bar{Y}_{k-1}) - \widehat{H}_{k,W}(\widehat{U}_{k,W} f)(\widehat{Y}_{k-1}) \\
&\quad = (\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) - E_w\big((\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) \,|\, \widehat{Y}_{k-1}\big) \\
&\qquad + E_w\big(\bar{H}_{k,W}(\bar{U}_{k,W} f)(\bar{Y}_{k-1}) - \widehat{H}_{k,W}(\widehat{U}_{k,W} f)(\widehat{Y}_{k-1}) \,|\, \widehat{Y}_{k-1}\big).
\end{aligned}$$

Let us deal with the above two terms successively. The random vector $\widehat{Y}_{k-1}$ being a function of $\bar{Y}_{k-1}$ and conditional expectation $E(\,.\,|\,W, \widehat{Y}_{k-1})$ being an L^p-contraction, one gets

$$\begin{aligned}
&\big\|\bar{U}_{k-1,W} f(\bar{Y}_{k-1}) - E_w\big((\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) | \widehat{Y}_{k-1}\big)\big\|_p \\
&\quad \le \big\|(\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) - (\bar{U}_{k-1,W} f)(\widehat{Y}_{k-1})\big\|_p \\
&\qquad + \big\|E_w\big((\bar{U}_{k-1,W} f)(\widehat{Y}_{k-1}) - (\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) \,|\, \widehat{Y}_{k-1}\big)\big\|_p \\
&\quad \le 2\big\|(\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) - (\bar{U}_{k-1,W} f)(\widehat{Y}_{k-1})\big\|_p.
\end{aligned}$$

Consequently, using the expressions (3.9) and (3.10) and once again the contraction property and the $\sigma(\bar{Y}_{k-1})$-measurability of $\hat{Y}_{k-1}$ yields

$$\begin{aligned}
&\big\|\bar{U}_{k-1,W} f(\bar{Y}_{k-1}) - \widehat{U}_{k-1,W} f(\widehat{Y}_{k-1})\big\|_p \\
&\quad \le 2\big\|(\bar{U}_{k-1,W} f)(\bar{Y}_{k-1}) - (\bar{U}_{k-1,W} f)(\widehat{Y}_{k-1})\ \big\|_p \\
&\qquad + \big\|e^{g(\bar{Y}_{k-1}, \Delta\bar{W}_k)}(\bar{U}_{k,W} f)(\widetilde{Y}_k) - e^{g(\widehat{Y}_{k-1}, \Delta\bar{W}_k)}(\widehat{U}_{k,W} f)(\widehat{\widetilde{Y}}_k)\big\|_p
\end{aligned} \tag{3.11}$$

(when $p = 2$, the 2 factor can be deleted). Let us deal now with the second term of the sum in the r.h.s. First note that

$$\begin{aligned}
&\big\|e^{g(\bar{Y}_{k-1}, \Delta\bar{W}_k)}(\bar{U}_{k,W} f)(\widetilde{Y}_k) - e^{g(\widehat{Y}_{k-1}, \Delta\bar{W}_k)}(\widehat{U}_{k,W} f)(\widehat{\widetilde{Y}}_k)\big\|_p \\
&\quad = \big\| \exp g(\bar{Y}_{k-1}, \Delta\bar{W}_k)\big(\bar{U}_{k,W} f(\widetilde{Y}_k) - \exp\big(g(\widehat{Y}_{k-1}, \Delta\bar{W}_k) \\
&\qquad - g(\bar{Y}_{k-1}, \Delta\bar{W}_k)\big)\widehat{U}_{k,W} f(\widehat{\widetilde{Y}}_k)\big)\big\|_p.
\end{aligned}$$

Set $L_p(\delta) := \exp\left((p-1)\|h\|_\infty^2\, \delta/2\right)$. A change of variable "à la Girsanov" yields for every nonnegative Borel function Θ and every $p \in (1, +\infty)$

$$\begin{aligned}
&\big\|\exp\left(g(\bar{Y}_{k-1}, \Delta\bar{W}_k)\right)\Theta(\bar{Y}_{k-1}, \Delta\bar{B}_k, \Delta\bar{W}_k)\big\|_p^p \\
&\quad \le (L_p(\delta))^p E\left(\exp\left(ph(\bar{Y}_{k-1}).\Delta\bar{W}_k - p^2|h(\bar{Y}_{k-1})|^2\delta/2\right)\Theta^p(\bar{Y}_{k-1}, \Delta\bar{B}_k, \Delta\bar{W}_k)\right) \\
&\quad \le (L_p(\delta))^p E\left(\Theta^p(\bar{Y}_{k-1}, \Delta\bar{B}_k, \Delta\bar{W}_k + p\delta h(\bar{Y}_{k-1}))\right)
\end{aligned}$$

so that

$$\begin{aligned}(3.12)\qquad &\left\|\exp\left(g(\bar{Y}_{k-1},\Delta\bar{W}_k)\right)\Theta(\bar{Y}_{k-1},\Delta\bar{B}_k,\Delta\bar{W}_k)\right\|_p\\ &\quad\le L_p(\delta)\|\Theta(\bar{Y}_{k-1},\Delta\bar{B}_k,\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\|_p.\end{aligned}$$

Applying the above inequality with $\Theta(y,v,w)=(\bar{U}_{k,W}f)(G_{\delta,p}(y,v,w))$ leads to

$$\begin{aligned}&\left\|e^{g(\bar{Y}_{k-1},\Delta\bar{W}_k)}(\bar{U}_{k,W}f)(\widetilde{Y}_k)-e^{g(\widehat{Y}_{k-1},\Delta\bar{W}_k)}(\widehat{U}_{k,W}f)(\widehat{\widetilde{Y}}_k)\right\|_p\\ &\le L_p(\delta)\Big\|\big(\bar{U}_{k,W}f(\bar{Y}_k)-\exp\big(g(\widehat{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\\ &\qquad -g(\bar{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\big)\widehat{U}_{k,W}f(\widehat{Y}_k)\big)\Big\|_p\\ &\le L_p(\delta)\left\|\bar{U}_{k,W}f(\bar{Y}_k)-\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_p\\ &\quad+L_p(\delta)\Big\|\big(1-\exp\big(g(\widehat{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\\ &\qquad -g(\bar{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\big)\big)\widehat{U}_{k,W}(f)(\widehat{Y}_k)\Big\|_p\\ &\le L_p(\delta)\left\|\bar{U}_{k,W}f(\bar{Y}_k)-\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_p\\ &\quad+L_p(\delta)\Big\|1-\exp\big(g(\widehat{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\\ &\qquad -g(\bar{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\big)\Big\|_{rp}\left\|\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_{sp},\end{aligned}\qquad(3.13)$$

where $r>1$ and $s=\frac{r}{r-1}$ are conjugate Hölder exponents. Now

$$\left\|\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_{sp}=\left\|\exp g(\widehat{Y}_k,\Delta\bar{W}_k)\,\widehat{U}_{k+1,W}f(\widehat{Y}_k)\right\|_{sp}.$$

Applying (3.12) (with sp) yields

$$\left\|\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_{sp}\le L_{sp}(\delta)\left\|\widehat{U}_{k+1,W}f(\widehat{Y}_{k+1}^{(sp)})\right\|_{sp}$$

for some $\bar{\mathcal{F}}_{k+1}$-measurable random vector $\widehat{Y}_{k+1}^{(sp)}$ which we have no need to specify (since f is bounded). One derives by induction that

$$\begin{aligned}(3.14)\qquad \left\|\widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_{sp}&\le(L_{sp}(\delta))^{n-k}\left\|\widehat{U}_{n,W}f(\widehat{Y}_n^{(sp)})\right\|_{sp}\\ &\le(L_{sp}(\delta))^{n-k}\|f\|_\infty\le C_{p,r,\|h\|_\infty,T}\|f\|_\infty\end{aligned}$$

with $K_{p,r,\|h\|_\infty,T}=\exp\left((sp-1)\|h\|_\infty^2T/2\right)$.

Let us deal now with the L^{rp}-norm of the exponential term. First, temporarily set $\widehat{\Delta}_k(h):=h(\widehat{Y}_k)-h(\bar{Y}_k)$. Then, standard computations show that

$$\begin{aligned}&\left\|1-\exp\Big(g(\widehat{Y}_{k-1},\Delta\bar{W}_k+p\,\delta\,h(\bar{Y}_{k-1}))-g(\bar{Y}_{k-1},\Delta\bar{W}_k+p\delta h(\bar{Y}_{k-1}))\Big)\right\|_{rp}\\ &\quad=\left\|1-\exp\Big((p-1)\delta h(\bar{Y}_{k-1}).\widehat{\Delta}_{k-1}(h)+\widehat{\Delta}_{k-1}(h)\Delta\bar{W}_k-|\widehat{\Delta}_{k-1}(h)|^2\delta/2\Big)\right\|_{rp}.\end{aligned}$$

Now using the elementary inequality $|e^x - 1| \le |x| e^{x_+}$, where $x_+ := \max(x, 0)$, and the fact that $x \mapsto x_+$ is nondecreasing yields

$$\begin{aligned}
&\big\|1 - \exp\big(g(\widehat{Y}_{k-1}, \Delta\bar{W}_k + p\,\delta\,h(\bar{Y}_{k-1})) - g(\bar{Y}_{k-1}, \Delta\bar{W}_k + p\delta h(\bar{Y}_{k-1}))\big)\big\|_{rp} \\
&\quad \le \big\| |\widehat{\Delta}_{k-1}(h)|(p-1)\delta h(\bar{Y}_{k-1}) + \Delta\bar{W}_k \\
&\qquad - (\widehat{\Delta}_{k-1}(h))\delta/2| \exp(2(p-1)\delta\|h\|_\infty^2 + 2\|h\|_\infty |\Delta\bar{W}_k|)\big\|_{rp} \\
&\quad \le L_{4p-3}(\delta)\sqrt{\delta}[h]_{\mathrm{Lip}} \big\| |\bar{Y}_{k-1} - \widehat{Y}_{k-1}|((p-1)\sqrt{\delta}\|h\|_\infty + |Z_k| + \|h\|_\infty\sqrt{\delta}) \\
&\qquad \times \exp(2\|h\|_\infty\sqrt{\delta}|Z_k|)\big\|_{rp},
\end{aligned}$$

where $Z_k := \frac{\Delta\bar{W}_k}{\sqrt{\delta}}$ is an $\mathcal{N}(0; I_d)$ random vector *independent* of $\bar{\mathcal{F}}_{k-1}$. Finally,

$$\begin{aligned}
&\big\|1 - \exp\big(g(\widehat{Y}_{k-1}, \Delta\bar{W}_k + p\delta h(\bar{Y}_{k-1})) - g(\bar{Y}_{k-1}, \Delta\bar{W}_k + p\delta h(\bar{Y}_{k-1}))\big)\big\|_{rp} \\
&\qquad \le C_{p,r,\delta,\|h\|_\infty,T}\sqrt{\delta}[h]_{\mathrm{Lip}}\big\|\widehat{Y}_{k-1} - \bar{Y}_{k-1}\big\|_{rp} \qquad (3.15)
\end{aligned}$$

with

$$C_{p,r,\delta,\|h\|_\infty,T} = L_{4p-3}(\delta)\big\|\big((p-1)\sqrt{\delta}\|h\|_\infty + |Z| + \sqrt{\delta}\|h\|_\infty\big)\exp\big(2\|h\|_\infty\sqrt{\delta}|Z|\big)\big\|_{rp}.$$

(Note that this real constant is increasing as a function of δ.) Plugging the estimates in (3.15) and (3.14) into (3.13) yields for every $k = 1, \dots, n$

$$\begin{aligned}
&\big\|e^{g(\bar{Y}_{k-1},\Delta\bar{W}_k)}(\bar{U}_{k,W}f)(\widetilde{Y}_k) - e^{g(\widehat{Y}_{k-1},\Delta\bar{W}_k)}(\widehat{U}_{k,W}f)(\widehat{\widetilde{Y}}_k)\big\|_p \\
&\qquad \le L_p(\delta)\big\|\bar{U}_{k,W}f(\bar{Y}_k) - \widehat{U}_{k,W}f(\widehat{Y}_k)\big\|_p + B(\delta)\big\|\bar{Y}_{k-1} - \widehat{Y}_{k-1}\big\|_{rp} \qquad (3.16)
\end{aligned}$$

with $B(\delta) := C_{p,r,\|h\|_\infty,T}\sqrt{\delta}[h]_{Lip}\|f\|_\infty$ (with $C_{p,r,\|h\|_\infty,T} = C_{p,r,1,\|h\|_\infty,T}K_{p,r,\|h\|_\infty,T}$ $L_p(1)$).

Now let us pass to the first term in the r.h.s. of (3.11). Let $(\bar{Y}_\ell^{k,y})_{\ell=k,\dots,n}$ be the sequence obtained by iterating $G_{p,\delta}(., \Delta\bar{B}_\ell, \Delta\bar{W}_\ell)$ from y at time $\ell = k$, i.e.,

$$\forall\, \ell \in \{k+1, \dots, n\}, \qquad \bar{Y}_\ell^{k,y} = G_{p,\delta}(\bar{Y}_{\ell-1}^{k,y}, \Delta\bar{B}_\ell, \Delta\bar{W}_\ell), \quad \bar{Y}_k^{k,y} := y.$$

The same proof as above shows that, for any couple (Z_{k-1}, Z'_{k-1}) of $\bar{\mathcal{F}}_{k-1}$-measurable L^p-integrable random variables,

$$\begin{aligned}
&\big\|(\bar{U}_{k-1,W}f)(Z_{k-1}) - (\bar{U}_{k-1,W}f)(Z'_{k-1})\ \big\|_p \\
&\quad \le L_p(\delta)\big\|\bar{U}_{k,W}(\bar{Y}_k^{k-1,Z_{k-1}}) - \bar{U}_{k,W}(\bar{Y}_k^{k-1,Z'_{k-1}})\big\|_p \\
&\qquad + B(\delta)\big\|\bar{Y}_{k-1}^{k-1,Z_{k-1}} - \bar{Y}_{k-1}^{k-1,Z'_{k-1}}\big\|_{rp},
\end{aligned}$$

so that by induction

$$\begin{aligned}
&\Big\|(\bar{U}_{k-1,W}f)(\bar{Y}_{k-1}) - (\bar{U}_{k-1,W}f)(\widehat{Y}_{k-1})\ \Big\|_p \\
&\quad \le B(\delta)\sum_{\ell=k}^{n}(L_p(\delta))^{\ell-k}\Big\|\bar{Y}_{\ell-1}^{k-1,\bar{Y}_{k-1}} - \bar{Y}_{\ell-1}^{k-1,\widehat{Y}_{k-1}}\Big\|_{rp} \\
&\qquad + (L_p(\delta))^{n+1-k}[f]_{\mathrm{Lip}}\Big\|\bar{Y}_n^{k-1,\bar{Y}_{k-1}} - \bar{Y}_n^{k-1,\widehat{Y}_{k-1}}\Big\|_{rp}.
\end{aligned}$$

Now, Lemma 3.1 (applied to $G_{\delta,p}$) implies the existence of a real constant $C_{rp} > 0$ such that

$$\left\|\bar{Y}_\ell^{k-1,\bar{Y}_{k-1}} - \bar{Y}_\ell^{k-1,\widehat{Y}_{k-1}}\right\|_{rp} \le (1 + C_{rp}\delta)^{\ell+1-k}\left\|\bar{Y}_{k-1} - \widehat{Y}_{k-1}\right\|_{rp}.$$

Setting $L'_{p,r}(\delta) = L_p(\delta)(1 + C_{rp}\delta)$ finally yields for every $k = 1, \dots, n$

$$\left\|(\bar{U}_{k-1,W}f)(\bar{Y}_{k-1}) - (\bar{U}_{k-1,W}f)(\widehat{Y}_{k-1})\ \right\|_p \le C(\delta)\left\|\bar{Y}_{k-1} - \widehat{Y}_{k-1}\right\|_{2p}$$

with

$$C(\delta) = L_p(T)e^{C_{rp}}\left(C_{p,r,\|h\|_\infty,T}\frac{[h]_{\mathrm{Lip}}\|f\|_\infty\sqrt{\delta}}{L'_{p,r}(\delta) - 1} + [f]_{\mathrm{Lip}}\right) \tag{3.17}$$

$$\le L_p(T)e^{C_{rp}}\left(C'_{p,r,\|h\|_\infty,T}\frac{[h]_{\mathrm{Lip}}\|f\|_\infty}{\sqrt{\delta}} + [f]_{\mathrm{Lip}}\right). \tag{3.18}$$

Plugging (3.16) and (3.17) into (3.11) finally yields the induction

$$\begin{aligned}\left\|\bar{U}_{k-1,W}f(\bar{Y}_{k-1}) - \widehat{U}_{k-1,W}f(\widehat{Y}_{k-1})\right\|_p &\le L_p(\delta)\left\|\bar{U}_{k,W}f(\bar{Y}_k) - \widehat{U}_{k,W}f(\widehat{Y}_k)\right\|_p \\ &\quad + A(\delta)\left\|\bar{Y}_{k-1} - \widehat{Y}_{k-1}\right\|_{rp}\end{aligned}$$

with

$$\begin{aligned}A(\delta) = B(\delta) + 2\,C(\delta) &\le C''_{p,r,\|h\|_\infty,T}\left([h]_{\mathrm{Lip}}\|f\|_\infty\left(\sqrt{\delta} + \frac{1}{\sqrt{\delta}}\right) + [f]_{\mathrm{Lip}}\right) \\ &\le \frac{C_{p,r,\|h\|_\infty,[h]_{\mathrm{Lip}},\|f\|_\infty,[f]_{\mathrm{Lip}},T}}{\sqrt{\delta}}\end{aligned}$$

since $\delta \in (0, 1]$. A new induction leads to

$$\begin{aligned}\left\|\langle\bar{V}_n, f\rangle - \langle\hat{V}_n, f\rangle\right\|_p &= \left\|\bar{U}_{0,W}f(\bar{X}_0) - \widehat{U}_{0,W}f(\widehat{X}_0)\right\|_p \\ &= \left\|\bar{U}_{0,W}f(\bar{Y}_0) - \widehat{U}_{0,W}f(\widehat{Y}_0)\right\|_p \\ &\le A(\delta)\sum_{k=0}^{n}(L_p(\delta))^k\|\bar{Y}_k - (\widehat{U}_{n,W}f)(\widehat{Y}_n)\|_{rp} \\ &\quad + (L_p(\delta))^n\|(\bar{U}_{n,W}f)(\bar{Y}_n) - \widehat{Y}_k\|_p \\ &\le \frac{C_{p,r,\|h\|_\infty,[h]_{\mathrm{Lip}},\|f\|_\infty,[f]_{\mathrm{Lip}},T}}{\sqrt{\delta}}\sum_{k=0}^{n}\|\bar{Y}_k - \widehat{Y}_k\|_{rp} \\ &\quad + L_p(T)[f]_{\mathrm{Lip}}\|\bar{Y}_n - \widehat{Y}_n\|_{rp}.\end{aligned} \tag{3.19}$$

Step 2 (global revert Girsanov transform). Now, we aim to come back to $\bar{X}_k$ by introducing a revert Girsanov transform:

$$\|\bar{Y}_k - \widehat{Y}_k\|_{rp}^{rp} = E(Z_k(Z_k)^{-1}|\bar{Y}_k - \widehat{Y}_k|^{rp}),$$

where

$$Z_k = \exp\left(-\sum_{\ell=1}^{k} ph(\bar{Y}_{\ell-1}).\Delta\bar{W}_\ell - p^2|h(\bar{Y}_{\ell-1})|^2\frac{\delta}{2}\right).$$

It follows that

$$E(Z_k(Z_k)^{-1}|\bar{Y}_k - \widehat{Y}_k|^{rp}) = E\left(\exp\left(\sum_{\ell=1}^{k} ph(\bar{X}_{\ell-1}).\Delta\bar{W}_\ell - p^2|h(\bar{X}_{\ell-1})|^2\frac{\delta}{2}\right)|\bar{X}_k - \widehat{X}_k|^{rp}\right)$$

so that by the Hölder inequality applied with two conjugate exponents r', $s' > 1$,

$$\begin{aligned}\|\bar{Y}_k - \widehat{Y}_k\|_{rp}^{rp} &\le \left(E\exp\left(\sum_{\ell=1}^{k} s'ph(\bar{X}_{\ell-1}).\Delta\bar{W}_\ell - s'p^2|h(\bar{X}_{\ell-1})|^2\delta/2\right)\right)^{1/s'} \\ &\quad \cdot \left(E|\bar{X}_k - \widehat{X}_k|^{rr'p}\right)^{1/r'} \\ &\le \exp\left(k(s'-1)p^2\|h\|_\infty^2\delta/2\right)\|\bar{X}_k - \widehat{X}_k\|_{rr'p}^{rp}.\end{aligned}$$

Finally,

$$\|\bar{Y}_k - \widehat{Y}_k\|_{rp} \le \exp\left(kp\|h\|_\infty^2\delta/4\right)\|\bar{X}_k - \widehat{X}_k\|_{4p} \le C_{p,r,r',\|h\|_\infty,T}\|\bar{X}_k - \widehat{X}_k\|_{rr'p}.$$

One completes the proof by setting $r = r' = \sqrt{p'/p} > 1$ and plugging this last inequality into (3.19). □

3.3. Global error. Combining the results established in the former sections, we obtain the following result.

THEOREM 3.2. *Assume* (H1)–(H2). *Let* $p' > 2$ *and let* $N \ge n \ge 1$. *Assume that for every* $k \in \{0, \dots, n\}$, Γ_k *is an* $L^{p'}$*-optimal grid of size* $[N/(n+1)]$ *for* X_k. *There exists a real constant* C (*depending on* p' *but not* n) *such that*

$$\|\rho(V_T, \widehat{V}_n)\|_2 \le C\left(\frac{1}{n^\theta} + \frac{n^{\frac{3}{2}}}{\bar{N}^{\frac{1}{d}}}\right) \tag{3.20}$$

with $\theta = 0$ *if* $\gamma \equiv 0$ *and* $\theta = 1/2$ *otherwise, and* $\bar{N} = N/n$.

Proof. Combining results obtained in Theorems 2.1 and 3.1 yields the following:

$$\|\rho(V_T, \widehat{V}_n)\|_2 \le C\left(\frac{1}{n^\theta} + \sqrt{\delta}\sum_{k=0}^{n}\|\Delta_k\|_{p'}\right),$$

where $\Delta_k = X_k - \widehat{X}_k = X_k - \mathrm{Proj}_{\Gamma_k}(X_k)$. It follows from the nonparametric version of Zador's theorem, recently established in [25], that for every $p, \delta > 0$ there exists a universal real constant $C_{p,\delta}$ such that for every $N \ge 1$ and every $\mathbb{R}^d$-valued random vector Y,

$$\min_{\Gamma\subset\mathbb{R}^d, |\Gamma|\le N}\|Y - \widehat{Y}^\Gamma\|_p \le C_{p,\delta}\|Y\|_{p+\delta}N^{-\frac{1}{d}}.$$

Applying this result to our framework yields (with $\delta = 1$)

$$\begin{aligned}\sum_{k=0}^{n}\|\Delta\|_{p'} &\le C_{p'}\sup_n\max_{0\le k\le n}\|\bar{X}_k\|_{p'+1}(n+1)(N/(n+1))^{\frac{1}{d}} \\ &\le Cn^{\frac{3}{2}}(N/n)^{-\frac{1}{d}},\end{aligned}$$

where C is a finite real constant since we know that (b and σ, γ having at most linear growth) the family of Euler schemes $((\bar{X}_k)_{0\le k\le n})_{n\ge 1}$ satisfies $\sup_n \max_{0\le k\le n} \|\bar{X}_k\|_r < +\infty$ for any $r > 0$. □

Remark 3.1. • The $n^{\frac{3}{2}}$ in the spatial error term of (3.20) is most likely not optimal (see section 4). It probably comes from the specific technicalities induced by quantization. It corresponds, e.g., to the rate obtained for the "quenched error" in [7]. As shown by our numerical experiments, the spatial error term most likely behaves as $O(n \times (N/n)^{-\frac{1}{d}})$ or $O((N/n)^{-\frac{1}{d}})$, depending on some stability conditions between n and $\bar{N}$ (see section 4 for a detailed explanation).

• As an example, one can compare our error rate with that obtained in [7] (in the $\gamma \equiv 0$ setting) where an error bound is of the form

$$\frac{1}{n} + \sqrt{\frac{n}{M}},$$

where M denotes the number of Monte Carlo trials obtained under some regularity assumptions on the diffusion coefficients h and f (regardless of the dimension). In this case, M can be compared with our N/n, i.e., the mean value of points per time layers in our algorithm.

4. Numerical simulations and estimation of the rates of convergence. Since the expression of the global error given by (3.20) does not separate clearly the time and space parameters, we will try in this section to investigate separately the rate of convergence in time and in space in the following (linear) case:

$$\begin{aligned} \beta(x) = (A - \Gamma H)x, \quad h(x) = Hx, \\ \gamma(x) = \Gamma, \quad \sigma(x) = \Sigma, \end{aligned}$$

where A, Γ, Σ, and H are constant matrices of appropriate dimensions. We also suppose that μ_0 is a Gaussian law with mean m_0 and covariance matrix R_0. Then it is well known that the solution to the Zakai equation (1.1) is explicitly given by

$$\langle V_t, f\rangle = \left[\int f(\hat{m}_t + R(t)^{\frac{1}{2}}x)\frac{\exp\left(-\frac{1}{2}|x|^2\right)}{(2\pi)^{\frac{d}{2}}}dx\right]\langle V_t, 1\rangle, \tag{4.1}$$

where $R(t)$ is the solution to the Riccati equation

$$\begin{aligned} \frac{dR}{dt} &= AR + RA^\intercal + \Sigma\Sigma^\intercal + \Gamma\Gamma^\intercal - (RH^\intercal + \Gamma)(HR + \Gamma^\intercal), \\ R(0) &= R_0; \end{aligned} \tag{4.2}$$

$\hat{m}_t$ is the solution of

$$\begin{aligned} d\hat{m}_t &= A\hat{m}_t dt + (RH^\intercal + \Gamma)(dW_t - H\hat{m}_t dt), \\ \hat{m}_0 &= m_0; \end{aligned} \tag{4.3}$$

and

$$\langle V_t, 1\rangle = \exp\left(\int_0^t H\hat{m}_s.dW_s - \frac{1}{2}\int_0^t |H\hat{m}_s|^2 ds\right). \tag{4.4}$$

In other words, the normalized measure π_t defined by

$$\langle \pi_t, f \rangle = \frac{\langle V_t, f \rangle}{\langle V_t, 1 \rangle}$$

is a Gaussian distribution with mean $\hat{m}_t$ and variance $R(t)$.

We now introduce the quantized normalized filter for a given function $f \in BL_1(\mathbb{R})$ as

$$\langle \hat{\pi}_k^\delta, f \rangle := \frac{\langle \hat{V}_k, f \rangle}{\langle \hat{V}_k, 1 \rangle}, \quad k = 0, \dots, n,$$

where we have emphasized the dependence of the filter in $\delta = T/n$ by a superscript. The unnormalized filters $\hat{V}_k$ are computed according to algorithm (3.4).

The exact normalized filter is approximated owing to (4.1) using the following method. Since R is an explicitly known function (solution of (4.2)), it is sufficient to approximate $\hat{m}_t$, the solution of the SDE (4.3) with a refined Euler scheme of step, as

$$\delta_{ref} = \frac{T}{1024} \ll \delta.$$

Indeed, for each path of the observation W, (4.3) and (4.4) are discretized as

$$\bar{m}_{l+1} = \bar{m}_l + \delta_{ref} A \bar{m}_l + (R(l\delta_{ref})H^\intercal + \Gamma)(W_{(l+1)\delta_{ref}} - W_{l\delta_{ref}} - H\bar{m}_l \delta_{ref}), \tag{4.5}$$

$$\bar{Z}_{l+1} = \bar{Z}_l + H\bar{m}_l.(W_{(l+1)\delta_{ref}} - W_{l\delta_{ref}}) - \frac{1}{2}|H\bar{m}_l|^2\delta_{ref}, \quad \bar{\xi}_l = \exp(\bar{Z}_l), \tag{4.6}$$

and thus a very close approximation of the exact normalized filter, in the sense that it can be considered as the exact solution as long as δ remains considerably larger than δ_{ref}, is

$$\langle \pi_{l\delta_{ref}}^{\delta_{ref}}, f \rangle := \int f(\bar{m}_l + R(l\delta_{ref})^{\frac{1}{2}} x) \frac{\exp\left(-\frac{1}{2}|x|^2\right)}{(2\pi)^{\frac{d}{2}}} dx,$$

where $R(t)$ is computed owing to an exact quadrature formula.

We now estimate the rate of convergence of the scheme with respect to the spatial and time discretization. In order to smooth undesirable time oscillations of the error, we focus on the following temporal mean of the quadratic quantization error for the normalized filter, namely

$$\mathrm{Err}(\delta, \bar{N}) = \frac{1}{n} E \sum_{k=0}^{n} \left| \langle \hat{\pi}_k^\delta, f \rangle - \langle \pi_{t_k}^{\delta_{ref}}, f \rangle \right|^2, \tag{4.7}$$

where $t_k = k\delta = l(k)\delta_{ref}$ and $\bar{N} = N/n$ denotes the mean number of points per time layers. Then $\mathrm{Err}(\delta, \bar{N})$ is simply an approximation of the squared $L^2([0,T], dt)$-norm of the error.

We test the error for the following test functions:

$$f_0(x) = x, \quad f_1(x) = \exp(-x^2), \quad f_2(x) = \exp(-x). \tag{4.8}$$

The expectation in (4.7) is computed by a Monte Carlo method with $M = 100$ trajectories of the observations W.

The parameters of our simulations are

$$\Sigma = 1, \quad B = -0.5, \quad H = 1, \quad T = 1.$$

Such a choice of parameters is motivated by the fact that it provides values for $R(t)$ that are not too small. Otherwise, there would not be enough points around $m_0 = 0$ to be able to "capture" the behavior of the signal around its mean 0.

We will also change the model a bit and consider the following equations:

$$\begin{cases} dX_t = BX_t\,dt + \Sigma\,dB_t + \Gamma dW_t, \\ \\ dW_t = HX_t dt + \varepsilon dU_t. \end{cases} \tag{4.9}$$

The formulas above need to be changed as follows: $\Gamma \rightsquigarrow \varepsilon\Gamma$ and $H \rightsquigarrow H/\varepsilon$. The reason for introducing this new degree of freedom on the noise level may look paradoxical since small ε will provide large errors. But precisely, these large errors make it possible to display the rate of convergence more efficiently than with $\varepsilon = 1$, which produces smaller errors. Let us take the example of the spatial order. Indeed, we will see that as the discretization parameters $\bar{N}$ get larger and larger the error $\mathrm{Err}(\delta, \bar{N})$ is decreasing as a function of $\bar{N}$ until some threshold, depending a priori on δ and on the number M of observations (i.e., paths of W). Beyond this threshold, the error becomes more or less constant because the difference with the exact solution will be of the same order of the temporal discretization. Subsequently the sum of the two errors will become indistinguishable from the temporal one. Therefore, a small ε will provide bigger errors and so we will have more relevant points before reaching this threshold.

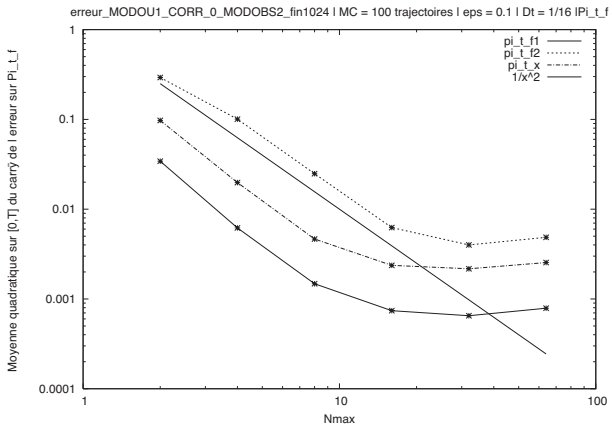
• *Estimation of the spatial discretization rate.* We first estimate the spatial rate of convergence in the case $\Gamma = 0$ (no correlation between the signal process X and the observation process W). For four values of $n = 1/\delta \in \{16, 32, 64, 256\}$, we estimate $\bar{N} \mapsto Err(\delta, \bar{N})$ with $\bar{N} = 2^{-\ell}$, $\ell = 1, \ldots, 7$. As a first step, for each value of n and of $\bar{N}$, we compute an optimal quantization $(\hat{X}_k)_k$ of the Euler scheme $(\bar{X}_k)_k$ of (4.9) (which is a version of (3.1)), according to the algorithm described in subsection 3.1. Then, for each test function f in (4.8) and each observation path of W, we compute recursively $\langle \hat{V}_k^\delta, f\rangle$ and $\langle \hat{V}_k^\delta, 1\rangle$ using (3.4) and then $\langle \hat{\pi}_k^\delta, f\rangle$. On the other hand, we compute the exact solutions using (4.5), and finally we compute $Err(\delta, \bar{N})$ as defined by (4.7) by summing up over the M trajectories sampled from the observation process W.

Note that since $\Gamma = 0$, the quantization optimization procedure of $(X_k)_k$ is a one-shot process which does not depend on the observations W.

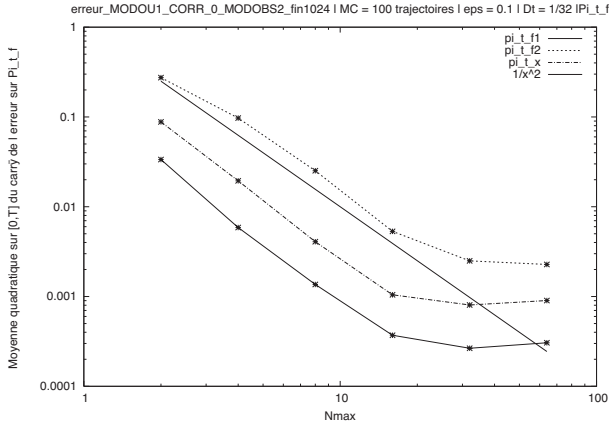
The results are summarized in Figures 1 and 2. It seems to have two regimes of convergence when $\bar{N}$ becomes larger. On the one hand, Figure 1 displays the error (4.7) for low values of n. It seems that its square root behaves like $O(1/\bar{N})$ for the three values of n before a threshold depending (linearly) on n; after that the error remains unchanged.

On the other hand, for high values of n (but still below $n_{ref} = 1024$), Figure 2 suggests a slower rate of convergence in $O((\bar{N})^{-\mathbf{1/2}})$.

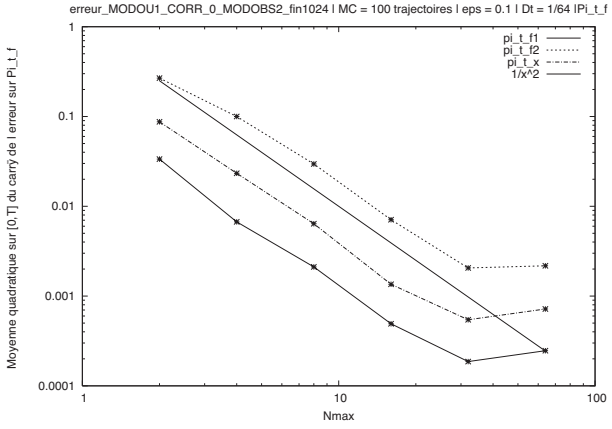
This suggests, keeping in mind (3.20) and Remark 3.1, a decomposition of the



(a) $n = 16$



(b) $n = 32$



(c) $n = 64$

FIG. 1. *Error* $Err(\delta, \bar{N})$ *as a function of* $\bar{N}$ *for several time discretizations* n. *The straight line depicts* $\bar{N} \mapsto 1/\bar{N}^2$, *and the dashed lines denote the errors computed with the different functions* (4.8). *Here* $\varepsilon = 0.1$.

global error of the form

$$\frac{C_1}{n} + \frac{C_2(n)}{\bar{N}},$$

where $C_1 > 0$ and $C_2(n) = C_2 + c_2 n + o(n)$ with $C_2 > 0$, $c_2 > 0$, and $c_2 \ll C_2$.

For low values of n, C_2 remains constant and hence we get, obviously,

$$\frac{C_1}{n} \leq \frac{C_2}{\bar{N}} \Longleftrightarrow \bar{N} \leq Cn = \bar{N}_1^*(n),$$

and thus we get an order $O(1/\bar{N})$.

For high values of n, the linear part of C_2 becomes larger and hence we get, obviously, in the same manner

$$\frac{C_1}{n} \leq \frac{c_2 n}{\bar{N}} \Longleftrightarrow \bar{N} \leq C' n^2 = \bar{N}_2^*(n),$$

and hence we have the order $O((\bar{N})^{-1/2})$.

In fact, this emphasizes that the scheme needs some stability criterion involving n and $\bar{N}$ in order to converge at the true rate $O(1/\bar{N})$.

The quantization step of the algorithm can also be the cause of this rate. Indeed, during the quantization optimization of the signal X, we need to simulate at each time step an Euler increment of X in (4.9). This simulation is used to compute the weights of the "quantization tree" of X (weight of the Voronoi cells and the transition probabilities) and to process the optimization. Here the Euler increment of X, namely $\Sigma\sqrt{\delta}\,\chi$, where χ denotes a real valued normal random variable, becomes very small as n grows; and so it is when $n = 256$. This implies that the Euler increment will mainly "hit" the closest cell in the upper time layer (not to mention the ability of a random number generator to simulate the tail of distributions). Consequently, the transition

probabilities are not computed accurately enough, given the size of the simulation, and can explain the downgrading of the rate of convergence in time. One can conclude this experiment by saying that there is a CFL involving the mean spatial unit length and the time step parameter and a second CFL involving the time discretization parameter and the size of the simulation (this one has been precisely analyzed in [2]).

These results clarify Remark 3.1 concerning the improvement of Theorem 3.1.

• *Estimation of the time discretization rate of convergence.* Now we look for the rate of convergence with respect to δ. For that purpose, we use $\bar{N} = 100$ quantization points in each time layer. The rate of convergence in time will be estimated with

$$\Gamma \in \{0, 0.5\}, \quad \varepsilon \in \{0.1, 0.5, 1.0\}, \quad \delta = 2^{-m}, \quad m = 1, \dots, 8.$$

Let us see now why we used the normalized filter instead of the unnormalized one. In Figure 3 are displayed typical examples of graphs $k \mapsto \langle \hat{V}_k^\delta, f \rangle$, $t \mapsto \langle V_t, f \rangle$, $k \mapsto \langle \hat{\pi}_k^\delta, x \rangle$, and $t \mapsto \langle \pi_t, x \rangle$ for $\Gamma = 0$, $\varepsilon = 0.1$, $\delta = 1/256$, and $\bar{N} = N_n = 100$. The exact filters are still computed using (4.5) and (4.6). We verify on that example that the normalized filter seems to be better computed than the unnormalized one. It explains why we did not use the unnormalized version of the error. Indeed, for such a level of noise for the observations ($\varepsilon = 0.1$), the unnormalized filter $\langle \hat{V}_k^\delta, f \rangle$ has very large values. This is true for all tested functions f and all time discretizations $\delta = 1/n$. Furthermore, it is also true on all sampled trajectories of W (not all depicted). Therefore, it is difficult for numerical reasons to compute errors based on $\langle \hat{V}_k^\delta, f \rangle$ for $\varepsilon = 0.1$.

Let us consider first the uncorrelated case ($\Gamma = 0$). Figure 4 shows the error plotted against the time step in a log-log scale for f given by (4.8). We can see again that for a given fixed ε, the time error decreases until a threshold and then remains flat. We also see that this threshold grows as the inverse of the noise level ε. Before reaching this threshold, for every ε and every function f, the rate seems to be of order $\delta = 1/n$ as established in Theorem 2.1.

Let us emphasize that, once again in this case, the quantization procedure does not depend on the observations. Therefore, it can be carried out *off-line*. This is no longer true in the correlated case. Then (e.g., if $\Gamma = 0.5$), we will have to compute $M = 100$ quantizations (one per observation path) of the signal $(X_k)_k$ for every $n \in \{2, 4, 8, 16, 32, 64, 128, 256\}$, i.e., 800 optimal grids. The previous study in the uncorrelated case seems to indicate that we need a small level of noise on the observations in order to display a rate with a significant number of time steps. This is why we have chosen $\varepsilon = 0.1$ for the simulations. Figure 5 shows the errors obtained as a function of n in a log-log scale for the functions (4.8). The rates of convergence are the same in each case. A linear regression seems to indicate a rate of $O(n^{-3/4})$ which is better than the $O(n^{-1/2})$ stated in Theorem 2.1. An explanation of this unexpected behavior could be the following one. The constant in the factor of the term $n^{-1/2}$ is presumably very small compared to the one associated to n^{-1}; thus, small values of n make an intermediate rate of convergence appear, while the rate $n^{-1/2}$ would be observed for larger n (in the asymptotic regime).

ON A PARALLEL ROBIN-TYPE NONOVERLAPPING DOMAIN DECOMPOSITION METHOD*

LIZHEN QIN† AND XUEJUN XU†

Abstract. In recent years, a nonoverlapping Robin-type domain decomposition method (DDM) for the finite element discretization systems of the second order elliptic equations, which is based on using Robin-type boundary conditions as information transmission conditions on the subdomain interfaces, has been developed and analyzed since it was first proposed by P. L. Lions in [*On the Schwarz alternating method* III: *A variant for nonoverlapping subdomains*, in Proceedings of the 3rd International Symposium on Domain Decomposition Methods for Partial Differential Equations, SIAM, Philadelphia, PA, 1990, pp. 202–223]. However, the convergence rate of this DDM with many subdomains remains open when the lower term of equations vanishes. This open problem will be considered in this paper. The convergence rate is almost $1 - O(h^{1/2}H^{-1/2})$ in certain cases—for example, the case of a small number of subdomains, where h is the mesh size and H is the size of subdomain. In order to get the desirous convergence results, two mathematics skills are introduced in this paper; one is complexification of real linear space and the other is the spectral radius formula.

Key words. nonconforming finite elements, nonoverlapping domain decomposition, convergence rate, geometric convergence

1. Introduction.

The Robin-type nonoverlapping domain decomposition method (DDM), which is based on using Robin-type boundary conditions as information transmission conditions on the subdomain interfaces, has become an increasingly important tool for solving the following second order elliptic equations:

$$\begin{cases} -\sum\limits_{i,j} \frac{\partial}{\partial x_i}(a_{ij}(x)\frac{\partial u}{\partial x_j}) + b(x)u &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega. \end{cases}$$

The idea of employing Robin-type boundary conditions as interface conditions was first proposed by P. L. Lions in [21]. Recently there have been several theoretical analyses and applications of this DDM; cf. [1], [2], [8], [9], [13], [14], [15], [19], [23], [10], [16], [17], [18], [20], and [11] for details. In [17], Gander, Halpern, and Nataf considered the second elliptic problems in the case of the two subdomains. It is first pointed out by them that the optimal choice of relaxation parameter was $O(h^{-1/2})$ and the convergence rate $1-O(h^{1/2})$ can be achieved in this special case. In this paper, we will discuss the second order elliptic problems in the case of many subdomains.

Compared with other DDMs, this method has several advantages. First, the iterative procedure is very simple. Second, in contrast to other procedures, it need not to solve global problems. So the iterative procedure is much more highly parallel than others. Last, by the results in [22] and in this paper, we know that the convergence

rate of this method is $1 - O(h^{1/2}H^{-1/2})$ in certain cases, where h is the size of the mesh and H is the size of the subdomain, which is much better than that of the Schwarz DDMs with small overlapping. Based on the analysis in [12] and [4], we know that the realistic convergence rate is only $1 - O(hH^{-1})$ for the additive and multiplicative Schwarz DDMs.

In the case of $b(x) \geq b > 0$, the lower term is positive strictly. The analysis of this method has been highly developed. In [6], [7], Deng proved that this method was convergent. The result in [7] claims that the convergence of this method is geometric and the convergence rate is $1 - O(h)$. This result had been improved in [22], which tells us this convergence rate could be $1-O(h^{1/2}H^{-1/2})$. Meanwhile counterexamples constructed in [22] show that the convergence rate cannot be improved in general.

However, the analysis for convergence is much harder when the lower term vanishes, i.e., $b(x) = 0$. In [6], [7], Deng proved that this method was also convergent in this case, but he was not able to tell us the convergence rate. In [22], we showed that the convergence rate was $1 - O(h^{1/2}H^{-1/2})$ if at least one face of each subdomain belongs to the boundary of domain. But for the general domain decomposition with interior subdomains, the analysis of the convergence rate remains open.

In this paper, we get the convergence rate in general in the case when the lower term vanishes. We will show that the convergence rate can be $1 - O(C^N h^{1/2}H^{-1/2})$, where $C \in (0, 1)$ and N is a geometric parameter which will be introduced in section 4. The convergence rate will be $1-O(h^{1/2}H^{-1/2})$ when N is not large. The numerical experiments in this paper support our theoretical results. Our proof is based on the energy method. The energy method was first proposed by P. L. Lions in [21] and has been developed in [6] and [7]. We will introduce two other techniques for obtaining the convergence rate in this paper; one is the complexification of real linear space and the other is the spectral radius formula.

The outline of this paper is as follows. In section 2, we will introduce the model problem and some basic results of this method. The analysis of this paper is based on two skills; one is the complexification of real linear space and the other is the spectral radius formula. We will introduce them in section 3. In section 4, we will introduce some geometric aspects of domain decomposition. In section 5, we prove our main result, Theorem 5.1. Finally, in section 6, we will give some numerical results to support our theory.

2. Model problem and preliminaries. We consider the following model problem:

$$\left\{ \begin{array}{rcll} -\Delta u & = & f & \text{in } \Omega, \\ u & = & 0 & \text{on } \partial\Omega, \end{array} \right. \tag{2.1}$$

where Ω is a bounded polyhedral domain in $R^d (d = 2, 3)$, $f \in L^2(\Omega)$.

Partition Ω into nonoverlapping subdomains $\Omega_i (i = 1, \ldots, K)$ quasi-uniformly and regularly. Then the domain decomposition iterative procedure can be written as follows (cf. [7] for details):

$$\left\{ \begin{array}{rcll} -\Delta u_i^n & = & f & \text{in } \Omega_i, \\ \frac{\partial u_i^n}{\partial \nu_i} + \lambda_{ij} u_i^n & = & g_{ij}^n & \text{on } \gamma_{ij}, \quad j \in N(i), \\ u_i^n & = & 0 & \text{on } \Gamma_i, \\ g_{ij}^{n+1} & = & 2\lambda_{ij} u_j^n - g_{ji}^n, & \end{array} \right. \tag{2.2}$$

where $\Gamma_i = \partial\Omega_i \bigcap \partial\Omega$, $\gamma_{ij} = \partial\Omega_i \bigcap \partial\Omega_j$, $\lambda_{ij} = \lambda_{ji} > 0$ are parameters,

$$N(i) = \{j \neq i \mid |\gamma_{ij}| > 0\}, \tag{2.3}$$

and $|\gamma_{ij}|$ is the measure of γ_{ij}.

This algorithm was first proposed by P. L. Lions in [21] and then improved by Deng in [6]. It can be accelerated by using Krylov methods via a substructuring of this algorithm.

Let $\mathcal{T}_h$ be a quasi-uniform and regular finite element triangulation of Ω. The mesh size is h. Let X be a nonconforming Crouzeix–Raviart finite element space over $\mathcal{T}_h$ (cf. [5]). The function of X vanishes at every freedom on $\partial\Omega$.

Denote N_h as the set of all interior nodal points, i.e., N_h contains all midpoints of interior edges ($d = 2$) or barycenters of interior faces ($d = 3$) of elements.

Let $X_i = X|_{\Omega_i}$. Define $X_i^0 \subseteq X_i$ whose functions vanish at every freedom on $\partial\Omega_i$.

Next we define two spaces Y_i and Y_{ij} on $\partial\Omega_i$ and γ_{ij}, respectively. Define Y_i to be a piecewise constant space on triangulation $\mathcal{T}_{\partial\Omega_i}$, where $\mathcal{T}_{\partial\Omega_i}$ is the triangulation of $\partial\Omega_i \setminus \partial\Omega$ inherited from $\mathcal{T}_h$, i.e., $\mathcal{T}_{\partial\Omega_i} = \mathcal{T}_h|_{\partial\Omega_i \setminus \partial\Omega}$. Furthermore let $Y_{ij} = Y_i|_{\gamma_{ij}}$.

All above spaces are equipped with the L^2 norm denoted by $\|\cdot\|_0$. Denote the L^2 inner product by $\langle\cdot,\cdot\rangle$. X can also be equipped with norms $|\cdot|_{1,h}$ and $\|\cdot\|_{1,h}$, where

$$|v|_{1,h}^2 = \sum_{T\in\mathcal{T}_h} \int_T |\nabla v|^2,$$

$$\|v\|_{1,h,\Omega_i}^2 = |v|_{1,h,\Omega_i}^2 + H^{-2}\|v\|_{0,\Omega_i}^2,$$

$$\|v\|_{1,h}^2 = \sum_{i=1}^{K} \|v\|_{1,h,\Omega_i}^2.$$

Define π_i and π_{ij} to be linear operators from X_i to Y_i and Y_{ij}, respectively. $\forall v_i \in X_i$, $\pi_i v_i \in Y_i$ and

$$\pi_i v_i|_\tau \equiv v_i(p) \quad \forall \tau \in \mathcal{T}_{\partial\Omega_i},$$

where p is the midpoint of $\tau(d = 2)$ or the barycenter of $\tau(d = 3)$, and $\pi_{ij} v_i \in Y_{ij}$ is defined to be $\pi_i v_i|_{\gamma_{ij}}$.

Conversely, we define S_i and S_{ij} to be linear operators from Y_i and Y_{ij} to X_i, respectively. $\forall w_i \in Y_i$, let $S_i w_i \in X_i$ and

$$S_i w_i = \begin{cases} w_i & \text{freedom on } \partial\Omega_i, \\ 0 & \text{other freedom.} \end{cases}$$

$\forall w_{ij} \in Y_{ij}$, we also define $S_{ij} w_{ij} \in X_i$ and

$$S_{ij} w_{ij} = \begin{cases} w_{ij} & \text{freedom on } \gamma_{ij}, \\ 0 & \text{other freedom.} \end{cases}$$

Note that $\pi_i v_i \neq v_i|_{\partial\Omega_i}$, $S_i w_i|_{\partial\Omega_i} \neq w_i$ in general. However,

$$v_i - S_i \pi_i v_i \in X_i^0, \tag{2.4}$$

$$\pi_i S_i = Id_i, \qquad \pi_{ij} S_{ij} = Id_{ij}, \tag{2.5}$$

where Id_i and Id_{ij} are identity operators on Y_i and Y_{ij}, respectively. By (2.5), we know that both π_i and π_{ij} are surjective. Furthermore, we have the following lemma.

LEMMA 2.1.

$$\|\pi_{ij}v_i\|_{0,\gamma_{ij}} \le C\|v_i|_{\gamma_{ij}}\|_{0,\gamma_{ij}} \quad \forall v_i \in X_i,$$

$$\|S_{ij}w_{ij}\|_{0,\Omega_i} \le Ch^{1/2}\|w_{ij}\|_0,$$

$$|S_{ij}w_{ij}|_{1,h,\Omega_i} \le Ch^{-1/2}\|w_{ij}\|_0 \quad \forall w_{ij} \in Y_{ij},$$

where C is a constant independent of h.

Proof. The first inequality can be verified by direct computation.

By scaling arguments, we have

$$\begin{aligned}\|S_{ij}w_{ij}\|_{0,\Omega_i} &\le Ch^{d/2}\Big(\sum_{p\in\Omega_i\bigcap N_h}(S_{ij}w_{ij})(p)^2\Big)^{1/2}\\ &= Ch^{d/2}\Big(\sum_{p\in\gamma_{ij}\bigcap N_h} w_{ij}(p)^2\Big)^{1/2}\\ &\le Ch^{1/2}\|w_{ij}\|_{0,\gamma_{ij}},\end{aligned}$$

where $d = 2, 3$ is the dimension of domain Ω. Using the inverse inequality,

$$|S_{ij}w_{ij}|_{1,h,\Omega_i} \le Ch^{-1}\|S_{ij}w_{ij}\|_{0,\Omega_i},$$

we get the last two inequalities. ∎

The discrete finite element approximation of (2.1) is to find $\hat{u} \in X$ such that

$$a(\hat{u}, v) = f(v) \quad \forall v \in X, \tag{2.6}$$

where

$$\begin{aligned}a(\hat{u}, v) &= \sum_{T\in\mathcal{T}_h}\int_T \nabla u\cdot\nabla v,\\ f(v) &= \int_\Omega fv.\end{aligned}$$

Let

$$a_i(\cdot,\cdot) = a(\cdot,\cdot)|_{X_i}, \qquad f_i(\cdot) = f(\cdot)|_{X_i}.$$

The discrete finite element version of (2.2) can be written as follows:

$$\begin{cases} a_i(u_i^n, v) + \sum\limits_{j\in N(i)}\lambda_{ij}\int_{\gamma_{ij}}\pi_{ij}u_i^n\cdot\pi_{ij}v &=& \int_{\Omega_i} fv + \sum\limits_{j\in N(i)}\int_{\gamma_{ij}} g_{ij}^n\cdot\pi_{ij}v,\\ g_{ij}^{n+1} &=& 2\lambda_{ij}\pi_{ji}u_j^n - g_{ji}^n. \end{cases} \tag{2.7}$$

Remark 2.1. $\forall u, v \in X_i$,

$$\int_{\gamma_{ij}}\pi_{ij}u\cdot\pi_{ij}v = \sum_{p\in\gamma_{ij}\bigcap N_h} u(p)v(p)|s_p|,$$

where s_p is the element face with p as its barycenter and $|s_p|$ is the measure of s_p. In [7], $\int_{\gamma_{ij}}\pi_{ij}u\cdot\pi_{ij}v$ is replaced by $\sum_{p\in\gamma_{ij}\bigcap N_h} u(p)v(p)|s_p|$ in (2.7). In fact, these two iterative procedures are equivalent.

DEFINITION 2.2. *Let $\hat{u}$ be the finite element solution and u^n be the solution of the nth iterative step, respectively. If*

$$\|u^n - \hat{u}\| \le CL^n \|u^0 - \hat{u}\|, \tag{2.8}$$

where $\|\cdot\|$ is the certain norm, $L \in [0,1)$, and C is independent of n, then this is geometric convergence. L is the convergence rate.

It is well known that $\hat{u}$ can be approximated by the procedure (2.7). The following theorem will tell us that $\hat{u}$ is the fixed point of (2.7). Its proof can be found in [22].

THEOREM 2.3. *If $\hat{u}$ is the solution of* (2.6) *and $\lambda_{ij} = \lambda_{ji} > 0$, then there exists $\hat{g}_{ij} \in Y_{ij}$ such that*

$$a_i(\hat{u}, v) + \sum_{j \in N(i)} \lambda_{ij} \int_{\gamma_{ij}} \pi_{ij}\hat{u}_i \cdot \pi_{ij} v_i = f_i(v) + \sum_{j \in N(i)} \int_{\gamma_{ij}} \hat{g}_{ij} \cdot \pi_{ij} v_i, \tag{2.9}$$

where $\hat{u}_i = \hat{u}|_{\Omega_i}$, $v = (v_1, \ldots, v_k) \in \prod_{i=1}^K X_i$,

$$\hat{g}_{ij} = 2\lambda_{ij}\pi_{ji}\hat{u}_j - \hat{g}_{ji}. \tag{2.10}$$

Define W to be a subspace of $\prod_{i=1}^K X_i \times \prod_{i=1}^K Y_i$ such that $(e_1, \ldots, e_K, \varepsilon_1, \ldots, \varepsilon_k) \in W$ if and only if $\forall v_i \in X_i$

$$a_i(e_i, v_i) + \sum_{j \in N(i)} \lambda_{ij} \int_{\gamma_{ij}} \pi_{ij} e_i \cdot \pi_{ij} v_i = \sum_{j \in N(i)} \int_{\gamma_{ij}} \varepsilon_{ij} \cdot \pi_{ij} v_i, \tag{2.11}$$

where $\varepsilon_{ij} = \varepsilon_i|_{\gamma_{ij}} \in Y_{ij}$.

Define A to be a linear operator of W. $\forall (e_1, \ldots, e_K, \varepsilon_1, \ldots, \varepsilon_k)$,

$$A(e_1, \ldots, e_K, \varepsilon_1, \ldots, \varepsilon_k) = (\tilde{e}_1, \ldots, \tilde{e}_K, \tilde{\varepsilon}_1, \ldots, \tilde{\varepsilon}_k), \tag{2.12}$$

where

$$\tilde{\varepsilon}_{ij} = 2\lambda_{ij}\pi_{ji} e_j - \varepsilon_{ji}.$$

$\tilde{e}_i$ is determined by $(\tilde{\varepsilon}_1, \ldots, \tilde{\varepsilon}_k)$ and (2.11).

Define

$$e_i^n = u_i^n - \hat{u}_i, \varepsilon_i^n = g_i^n - \hat{g}_i,$$

and

$$\varepsilon_{ij}^n = \varepsilon_i^n|_{\gamma_{ij}} = g_{ij}^n - \hat{g}_{ij}.$$

By Theorem 2.3 and (2.12), we get a corollary immediately.

COROLLARY 2.4. *$(e^n, \varepsilon^n) \in W$; i.e., (e^n, ε^n) satisfies* (2.11). *Moreover,*

$$(e^{n+1}, \varepsilon^{n+1}) = A(e^n, \varepsilon^n). \tag{2.13}$$

Proof. Subtracting (2.7) by (2.9), we get

$$a_i(e_i^n, v_i) + \sum_{j \in N(i)} \lambda_{ij} \int_{\gamma_{ij}} \pi_{ij} e_i^n \cdot \pi_{ij} v_i = \sum_{j \in N(i)} \int_{\gamma_{ij}} \varepsilon_{ij}^n \cdot \pi_{ij} v_i,$$

so $(e^n, \varepsilon^n) \in W$.

By Theorem 2.3, we have

$$\varepsilon_{ij}^{n+1} = g_{ij}^{n+1} - \hat{g}_{ij} = 2\lambda_{ij}\pi_{ji}e_j^n - \varepsilon_{ji}^n.$$

Thus we deduce (2.13) from the definition of A. ∎

We need the trace theorem and the Poincaré inequality for nonconforming finite element space in order to get the convergence rate. First, we introduce the Sarkis' isomorphism between the Crouzeix–Raviart nonconforming element space and the Courant conforming element space (see [24, Isomorphism 1, Lemmas 3, 4, and 5, and Isomorphism 2]).

LEMMA 2.5 (Sarkis' isomorphism). *Suppose γ_{ij} is a face (when $d = 2$, a face is an edge) of subdomain Ω_i; then $\forall u \in X_i$, there is a piecewise linear function $\tilde{u} \in H^1(\Omega_i)$ such that*

$$c|u|_{1,h,\Omega_i} \le |\tilde{u}|_{1,\Omega_i} \le C|u|_{1,h,\Omega_i},$$

$$c\|u\|_{1,h,\Omega_i} \le \|\tilde{u}\|_{1,\Omega_i} \le C\|u\|_{1,h,\Omega_i},$$

$$\int_{\gamma_{ij}} \tilde{u} = \int_{\gamma_{ij}} u,$$

and if γ_{ik} is an arbitrary face of Ω_i, then

$$c\|u|_{\gamma_{ik}}\| \le \|\tilde{u}|_{\gamma_{ik}}\| \le C\|u|_{\gamma_{ik}}\|,$$

where c and C are constants independent of h and the diameter of Ω_i.

Proof. Proofs of the first two inequalities and equality can be found in [24, Lemmas 3, 4, and 5]. The last inequality can be verified by direct computation thanks to the construction of $\tilde{u}$ and the equivalence between the L^2 norm and the L^2 discrete norm. ∎

The following theorem is a Poincaré–Friedrichs inequality (cf. [3, (1.1)] and [24, Lemma 4]. It can be proved by using equivalence norm of quotient spaces (see [5, the proof of Theorem 3.1.1] and the scaling argument.

THEOREM 2.6 (Poincaré–Friedrichs inequality). *If the diameter of each subdomain Ω_i $(i = 1, \ldots, K)$ is $O(H)$, and γ_{ij} is a face of Ω_i, then $\forall \tilde{u} \in H^1(\Omega_i)$, we have*

$$\|\tilde{u}\|_{0,\Omega_i}^2 \le CH^2|\tilde{u}|_{1,\Omega_i}^2 + CH^{2-d}\left(\int_{\gamma_{ij}} \tilde{u}\right)^2,$$

where $d = 2, 3$ is the dimension of Ω_i and C is a constant independent of Ω_i.

Furthermore, we can get a special trace theorem of Crouzeix–Raviart element space.

LEMMA 2.7 (special trace theorem). *If the diameter of each subdomain Ω_i $(i = 1, \ldots, K)$ is $O(H)$, γ_{ij}, and γ_{ik} are two faces of Ω_i, then $\forall v_i \in X_i$ we have*

$$\|\pi_{ik}v_i\|_{0,\gamma_{ik}}^2 \le CH|v_i|_{1,h,\Omega_i}^2 + C\|\pi_{ij}v_i\|_{0,\gamma_{ij}}^2,$$

where C is a constant independent of Ω_i.

Proof. By Lemma 2.5, there is a $\tilde{v}_i \in H^1(\Omega_i)$ such that

$$c|v_i|_{1,h,\Omega_i} \le |\tilde{v}_i|_{1,\Omega_i} \le C|v_i|_{1,h,\Omega_i},$$

$$\int_{\gamma_{ij}} \tilde{v}_i = \int_{\gamma_{ij}} v_i,$$

and

$$c\|v_i|_{\gamma_{ik}}\| \le \|\tilde{v}_i|_{\gamma_{ik}}\| \le C\|v_i|_{\gamma_{ik}}\|.$$

As a result, we have

$$\begin{aligned}
\|\pi_{ik}v_i\|^2_{0,\gamma_{ik}} &\le C\|v_i|_{\gamma_{ik}}\|^2_{0,\gamma_{ik}} \\
&\le C\|\tilde{v}_i|_{\gamma_{ik}}\|^2_{0,\gamma_{ik}} \\
&\le CH|\tilde{v}_i|^2_{1,\Omega_i} + CH^{-1}\|\tilde{v}_i\|^2_{0,\Omega_i} \\
&\le CH|\tilde{v}_i|^2_{1,\Omega_i} + CH^{1-d}\left(\int_{\gamma_{ij}} \tilde{v}_i\right)^2 \\
&\le CH|v_i|^2_{1,h,\Omega_i} + CH^{1-d}\left(\int_{\gamma_{ij}} v_i\right)^2,
\end{aligned}$$

where we have used Lemma 2.1, the trace theorem for $H^1(\Omega_i)$, and Theorem 2.6 in the first, third, and fourth inequalities, respectively. By the definition of π_{ij}, we know that

$$\int_{\gamma_{ij}} v_i = \int_{\gamma_{ij}} \pi_{ij}v_i;$$

then

$$\begin{aligned}
\|\pi_{ik}v_i\|^2_{0,\gamma_{ik}} &\le CH|v_i|^2_{1,h,\Omega_i} + CH^{1-d}\left(\int_{\gamma_{ij}} \pi_{ij}v_i\right)^2 \\
&\le CH|v_i|^2_{1,h,\Omega_i} + C\|\pi_{ij}v_i\|^2_{0,\gamma_{ij}}. \qquad \square
\end{aligned}$$

3. Some results in linear space. In this section we will introduce some notions and skills in linear space, such as complexification and the spectral radius formula which will play important roles in the following analysis.

We will consider $\|A^n\|$ in order to get the convergence rate, where A is the operator of linear space W defined in (2.12). If V is a complex linear space and T is a complex linear operator of V, then we have the following well-known spectral radius formula:

$$\lim_{n\to\infty} \|T^n\|^{1/n} = \rho(T),$$

where $\rho(T)$ is the spectral radius of T. So we can estimate $\|T^n\|$ in terms of $\rho(T)$. Unfortunately, W is a real linear space and A is a real linear operator while the spectral radius formula does not hold in the real case in general. So the complexification of a real linear space and a real linear operator is necessary.

Constructing the complexification of a real linear space is just like constructing a complex number field by a real number field.

DEFINITION 3.1. *Suppose V is a real n dimensional linear space; we call the tensor product space $C \otimes V$ the complexification of V, where C is the complex number field or one dimensional complex linear space. In other words, $C \otimes V$ is a complex n dimensional space such that*

$$C \otimes V = \{x + \sqrt{-1}y | x, y \in V\}.$$

Then $C \otimes V$ has the following addition and scalar multiplication properties:

$$(x_1 + \sqrt{-1}y_1) + (x_2 + \sqrt{-1}y_2) = (x_1 + x_2) + \sqrt{-1}(y_1 + y_2),$$

$$(a + \sqrt{-1}b)(x + \sqrt{-1}y) = (ax - by) + \sqrt{-1}(bx + ay), \quad a + \sqrt{-1}b \in C.$$

LEMMA 3.2. *Suppose V is a real linear space equipped with inner product $\langle \cdot, \cdot \rangle$; then we can define an inner product of $C \otimes V$ such that*

$$\langle x_1 + \sqrt{-1}y_1, x_2 + \sqrt{-1}y_2 \rangle = \langle x_1, x_2 \rangle + \langle y_1, y_2 \rangle - \sqrt{-1}\langle x_1, y_2 \rangle + \sqrt{-1}\langle y_1, x_2 \rangle.$$

If $\| \cdot \|$ is the norm induced by the inner product, then

$$\|x + \sqrt{-1}y\|^2 = \|x\|^2 + \|y\|^2.$$

The proof of this lemma will be presented in the appendix.

Remark 3.1. As for the semi-innerproduct, i.e., $\langle x, x \rangle \geq 0$ and may be equal to 0 even when $x \neq 0$, the counterpart conclusion of Lemma 3.2 also holds. In this case the semi-innerproduct will induce a seminorm. The proof of this conclusion is similar to that of Lemma 3.2.

Remark 3.2. From now on, all norms and seminorms in this paper can be induced by innerproducts and semi-innerproducts.

DEFINITION 3.3. *If V is a real linear space and T is a real linear operator of V, we define a complex linear operator $1 \otimes T$ of $C \otimes V$ such that*

$$1 \otimes T(x + \sqrt{-1}y) = Tx + \sqrt{-1}Ty.$$

We call $1 \otimes T$ the complexification of T. For convenience, we also denote $1 \otimes T$ by $\bar{T}$.

LEMMA 3.4. *If V is a real linear space and T_1, T_2 are real linear operators of V, then*

$$(1 \otimes T_1)(1 \otimes T_2) = 1 \otimes (T_1 T_2).$$

In particular,

$$1 \otimes (T^n) = (1 \otimes T)^n;$$

we denote $1 \otimes (T^n)$ or $(1 \otimes T)^n$ by $\bar{T}^n$.

We will prove this lemma in the appendix.

LEMMA 3.5. *If V is a finite dimensional real linear space equipped with an innerproduct, and T is a real linear operator of V, then*

$$\|\bar{T}\| = \|T\|.$$

This lemma will also be proved in the appendix.

Now let us discuss the linear space W and the linear operator A defined in (2.12) again. Our main skill to deal with $\|A^n\|$ is that $\|A^n\|$ is dominated by $\rho(\bar{A})$, where $\rho(\bar{A})$ is the spectral radius of $\bar{A}$, the complexification of A. In other words, we use the following lemma.

LEMMA 3.6. *If W is equipped with an innerproduct and*

$$\rho(\bar{A}) \leq 1 - R, \quad R \in (0, 1),$$

then for all positive integer number n, there is a constant C independent of n such that

$$\|A^n\| \leq C(1 - R/2)^n.$$

Proof. By Lemmas 3.4 and 3.5, we know that

$$\|A^n\| = \|\bar{A}^n\|.$$

Since $\bar{A}$ is a complex linear operator of the complex linear space $C \otimes W$, then by the spectral radius formula,

$$\lim_{n\to\infty} \|\bar{A}^n\|^{1/n} = \rho(\bar{A}).$$

So $\forall \varepsilon > 0$, there is an integer N such that when $n > N$, we have

$$\|\bar{A}^n\|^{1/n} \leq \rho(\bar{A}) + \varepsilon,$$

or

$$\|\bar{A}^n\| \leq (\rho(\bar{A}) + \varepsilon)^n.$$

Choose a constant $C > 1$ such that

$$\|\bar{A}^n\| \leq C(\rho(\bar{A}) + \varepsilon)^n$$

for $n = 1, \ldots, N$. Then $\forall\ n$,

$$\|A^n\| = \|\bar{A}^n\| \leq C(\rho(\bar{A}) + \varepsilon)^n.$$

Letting $\varepsilon = R/2$, we get the conclusion, where C is independent of n, although it may depend on R. ∎

Besides the complexification of W and A, we will also use those of other real linear spaces such as X_i, and Y_i, and other real linear operators such as π_{ij}.

4. Some geometric aspects of domain decomposition. Our analysis depends on the geometric aspects of subdomain decomposition. Now we introduce some notions and an assumption.

We define a sequence of sets D_i whose elements are subdomains by induction:

$$D_1 = \{\Omega_i | \text{at least one face of } \Omega_i \text{ belongs to } \partial\Omega\},$$

$$D_{r+1} = \{\Omega_i | \Omega_i \notin D_r, \Omega_i \text{ share one face with some } \Omega_j \in D_r \text{ at least}\}.$$

Now we define a geometric parameter of subdomain decomposition.

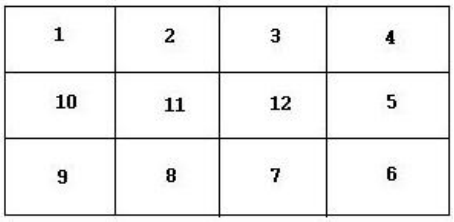

FIG. 1.

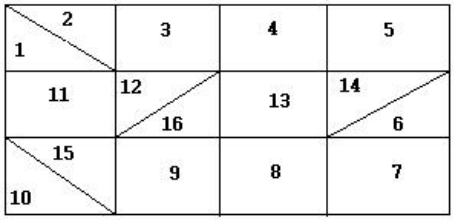

FIG. 2.

DEFINITION 4.1. *There is an integer N such that $\bigcup_{i=1}^{N} D_i$ contains all subdomains of Ω and we call N the winding number of domain decomposition.*

For example (see Figure 1), the integer i in each subdomain means that this subdomain is Ω_i. So

$$D_1 = \{\Omega_i | i = 1, \ldots, 10\},$$

$$D_2 = \{\Omega_{11}, \Omega_{12}\},$$

and winding number $N = 2$.

See also Figure 2:

$$D_1 = \{\Omega_i | i = 1, \ldots, 11\},$$

$$D_2 = \{\Omega_i | i = 12, \ldots, 16\},$$

and winding number N is also 2.

For convenience, we denote a subdomain belongs to D_r by Ω_{i^r}.

DEFINITION 4.2. *$\forall \Omega_{i^r} \in D_r$, we call a set*

$$P = \{\Omega_{i^1}, \ldots, \Omega_{i^r}\} \subseteq \bigcup_{i=1}^{r} D_r$$

a path connecting Ω_{i^r} with the boundary provided that $\Omega_{i^r} \in P$ and $P \cap D_k$ $(k = 1, \ldots, r)$ has exact one element.

Of course, the path connecting Ω_{i^r} with the boundary may not be unique. For example (see Figure 1), Ω_{11} has three paths, $\{\Omega_2, \Omega_{11}\}$, $\{\Omega_8, \Omega_{11}\}$, and $\{\Omega_{10}, \Omega_{11}\}$.

Now we make an assumption on the domain decomposition.

ASSUMPTION 4.1. *The domain decomposition satisfies the following two conditions.*

(1) *For each Ω_i, there is a path connecting Ω_i with the boundary. Then we assign this path to Ω_i.*

(2) *If* $\Omega_i, \Omega_j \in D_r$ *and* $\Omega_i \neq \Omega_j$, *then the path assigned to* Ω_i *has no intersection with that assigned to* Ω_j.

See Figure 2. We assign $\{\Omega_{11}, \Omega_{12}\}$, $\{\Omega_4, \Omega_{13}\}$, $\{\Omega_6, \Omega_{14}\}$, $\{\Omega_{10}, \Omega_{15}\}$, and $\{\Omega_9, \Omega_{16}\}$, to $\Omega_{11}, \ldots, \Omega_{15}$, respectively. Each pair has no intersection.

Remark 4.1. It is necessary to point out that Assumption 4.1 is not strict at all. It is almost not an assumption because most domain decompositions are satisfied by it.

Remark 4.2. The relations among N, H, and number of subdomains are delicate. N must be small provided that H is not small or the number of subdomains is small. However, N will not be large necessarily when H is small or the number of subdomains is large. A case in point is that the domain Ω is a strip. For example, decompose a narrow rectangle domain into 4×25 small rectangles uniformly. Then the number of subdomains is 100 while N is 2.

5. Convergence rate. Now we state and prove the main theorem of this paper. We define

$$\|(e^n, \varepsilon^n)\|^2 = \sum_{i=1}^{K} \|e_i^n\|_{1,h,\Omega_i}^2 + \sum_{i=1}^{K} \|\varepsilon_i^n\|_{0,\partial\Omega_i}^2. \tag{5.1}$$

THEOREM 5.1. *If domain decomposition satisfies Assumption* 4.1, *choose* $\lambda_{ij} = \lambda = O(h^{-1/2}H^{-1/2})$ $\forall i,\ j$; *then*

$$\|(e^n, \varepsilon^n)\| \leq C_2(1 - C_1(C_0)^N h^{1/2} H^{-1/2})^n \|(e^0, \varepsilon^0)\|, \tag{5.2}$$

where N *is the winding number of the domain decomposition,* $C_0 \in (0,1)$ *and* $C_1 > 0$ *are constants independent of* h, H, N, *and* n, *and* C_2 *is a positive constant independent of* n.

Remark 5.1. Counterexamples have been constructed in [22] to show that the convergence rate of this method can never be better than $1 - O(h^{1/2}H^{-1/2})$. The convergence rate, $1 - O(h^{1/2}H^{-1/2})$, can only be attained if we choose $\lambda_{ij} = \lambda = O(h^{-1/2}H^{-1/2})$ $\forall i,\ j$ when at least one face of each subdomain belongs to $\partial\Omega$. (See [22, sections 4 and 5] for details.) So we choose $\lambda = O(h^{-1/2}H^{-1/2})$ here.

Remark 5.2. If the winding number N is small, it can be seen from (5.2) that the convergence rate is $1 - O(h^{1/2}H^{-1/2})$. But when the winding number N goes up, the convergence rate of the DDM will deteriorate.

From now on, let $\lambda = O(h^{-1/2}H^{-1/2})$. We define a new norm over the space $\prod_{i=1}^{k} Y_i$, that is, $\forall \varepsilon \in \prod_{i=1}^{k} Y_i$,

$$\|\varepsilon\|_*^2 = \lambda^{-1}\|\varepsilon\|_0^2, \quad \|\varepsilon_{ij}\|_*^2 = \lambda^{-1}\|\varepsilon_{ij}\|_0^2. \tag{5.3}$$

Some lemmas are needed to prove Theorem 5.1.

LEMMA 5.2. *If* $(\bar{e}, \bar{\varepsilon}) \in C \otimes W$, $j, k \in N(i)$, *then*

$$\|\bar{\varepsilon}_{ik}\|_*^2 \leq C(h^{-1/2}H^{1/2}|\bar{e}_i|_{1,h,\Omega_i}^2 + h^{-1/2}H^{-1/2}\|\bar{\pi}_{ij}\bar{e}_i\|_{0,\gamma_{ij}}^2),$$

where $\bar{\pi}_{ij}$ *is the complexification of* π_{ij} *just as in Definition* 3.1 *and* C *is independent of* h *and* H.

Proof. Suppose

$$(\bar{e}, \bar{\varepsilon}) = (\tilde{e}, \tilde{\varepsilon}) + \sqrt{-1}(\hat{e}, \hat{\varepsilon}),$$

where $(\tilde{e},\tilde{\varepsilon}),(\hat{e},\hat{\varepsilon}) \in W$; then by Lemma 3.2 and Remark 3.1,

$$\|\bar{\varepsilon}_{ik}\|_*^2 = \|\tilde{\varepsilon}_{ik}\|_*^2 + \|\hat{\varepsilon}_{ik}\|_*^2,$$

$$|\bar{e}_i|_{1,h,\Omega_i}^2 = |\tilde{e}_i|_{1,h,\Omega_i}^2 + |\hat{e}_i|_{1,h,\Omega_i}^2,$$

and

$$\|\bar{\pi}_{ij}\bar{e}_i\|_{0,\gamma_{ij}}^2 = \|\pi_{ij}\tilde{e}_i\|_{0,\gamma_{ij}}^2 + \|\pi_{ij}\hat{e}_i\|_{0,\gamma_{ij}}^2.$$

So we need only to verify that $\forall (e,\varepsilon) \in W$, we have

$$\|\varepsilon_{ik}\|_*^2 \le C(h^{-1/2}H^{1/2}|e_i|_{1,h,\Omega_i}^2 + h^{-1/2}H^{-1/2}\|\pi_{ij}e_i\|_{0,\gamma_{ij}}^2).$$

By Lemma 2.7, we know that

$$\|\pi_{ik}e_i\|_{0,\gamma_{ik}}^2 \le CH|e_i|_{1,h,\Omega_i}^2 + C\|\pi_{ij}e_i\|_{0,\gamma_{ij}}^2. \tag{5.4}$$

Since $(e,\varepsilon) \in W$, replace V_i in (2.11) by $S_{ij}\varepsilon_{ij}$, and we have

$$\begin{aligned}
\|\epsilon_{ik}\|_0^2 &= \int_{\gamma_{ik}} \varepsilon_{ik}\cdot\pi_{ik}S_{ik}\varepsilon_{ik} \\
&= a_i(e_i, S_{ik}\varepsilon_{ik}) + \lambda\int_{\gamma_{ik}} \pi_{ik}e_i\cdot\epsilon_{ik} \\
&\le |e_i|_{1,h,\Omega_i}|S_{ik}\epsilon_{ik}|_{1,h,\Omega_i} + \lambda\|\pi_{ik}e_i\|_{0,\gamma_{ik}}\|\varepsilon_{ik}\|_0 \\
&\le Ch^{-1/2}|e_i|_{1,h,\Omega_i}\|\varepsilon_{ik}\|_0 + C\lambda(H^{1/2}|e_i|_{1,h,\Omega_i} + \|\pi_{ij}e_i\|_{0,\gamma_{ij}})\|\varepsilon_{ik}\|_0 \\
&\le C(h^{-1/2} + \lambda H^{1/2})|e_i|_{1,h,\Omega_i}\|\varepsilon_{ik}\|_0 + C\lambda\|\pi_{ij}e_i\|_{0,\gamma_{ij}}\|\varepsilon_{ik}\|_0.
\end{aligned}$$

Here we have used (2.5) in the first and second equalities and Lemma 2.1 and (5.4) in the second inequality, respectively. Then

$$\|\epsilon_{ik}\|_0^2 \le C(h^{-1/2} + \lambda H^{1/2})^2|e_i|_{1,h,\Omega_i}^2 + C\lambda^2\|\pi_{ij}e_i\|_{0,\gamma_{ij}}^2,$$

or

$$\|\epsilon_{ik}\|_*^2 \le C(\lambda^{-1/2}h^{-1/2} + \lambda^{1/2}H^{1/2})^2|e_i|_{1,h,\Omega_i}^2 + C\lambda\|\pi_{ij}e_i\|_{0,\gamma_{ij}}^2.$$

Since $\lambda = O(h^{-1/2}H^{-1/2})$, we finish the proof. ∎

LEMMA 5.3. *If $(\bar{e},\bar{\varepsilon}) \in C \otimes W$ is an eigenvector of $\bar{A}$ such that $\bar{A}(\bar{e},\bar{\varepsilon}) = \sigma(\bar{e},\bar{\varepsilon})$, then*

$$\bar{\varepsilon} \neq 0, \quad |\sigma| \le 1, \tag{5.5}$$

$$\sigma\bar{\varepsilon}_{ij} = 2\lambda\bar{\pi}_{ji}\bar{e}_j - \bar{\varepsilon}_{ji}, \tag{5.6}$$

$$|\sigma|^2\|\bar{\varepsilon}\|_*^2 = \|\bar{\varepsilon}\|_*^2 - 4a(\bar{e},\bar{e}), \tag{5.7}$$

where $|\sigma|$ is modulus of σ.

Proof. By the definition of A, (2.12), and Definition 3.3, we get (5.6) immediately. We can conclude that $\bar{\varepsilon} \neq 0$. Otherwise, if $\bar{\varepsilon} = 0$, by (2.11), we know $\bar{e} = 0$, so $(\bar{e},\bar{\varepsilon}) = 0$. However, since $(\bar{e},\bar{\varepsilon})$ is an eigenvector, then $(\bar{e},\bar{\varepsilon}) \neq 0$. This is a contradiction.

Suppose

$$(\bar{e},\bar{\varepsilon}) = (\tilde{e},\tilde{\varepsilon}) + \sqrt{-1}(\hat{e},\hat{\varepsilon}),$$

where $(\tilde{e},\tilde{\varepsilon}),(\hat{e},\hat{\varepsilon}) \in W$; then

$$\|\sigma\bar{\varepsilon}_{ij}\|_0^2 = \|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon}_{ji}\|_0^2 + \|2\lambda\pi_{ji}\hat{e}_j - \hat{\varepsilon}_{ji}\|_0^2,$$

or

$$|\sigma|^2\|\bar{\varepsilon}_{ij}\|_*^2 = \|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon}_{ji}\|_*^2 + \|2\lambda\pi_{ji}\hat{e}_j - \hat{\varepsilon}_{ji}\|_*^2, \tag{5.8}$$

$$\|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon}_{ji}\|_*^2 = \|\tilde{\varepsilon}_{ji}\|_*^2 - 4\langle\pi_{ji}\tilde{e}_j, \tilde{\varepsilon}_{ji} - \lambda\pi_{ji}\tilde{e}_j\rangle,$$

$$\begin{aligned}
&\sum_{1\le i<j\le K}(\|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon}_{ji}\|_*^2 + \|2\lambda\pi_{ij}\tilde{e}_i - \tilde{\varepsilon}_{ij}\|_*^2)\\
&= \sum_{\substack{1\le i<j\le K\\ j\in N(i)}}(\|\tilde{\epsilon}_{ij}\|_*^2 + \|\tilde{\epsilon}_{ji}\|_*^2 - 4\langle\pi_{ji}\tilde{e}_j, \tilde{\epsilon}_{ji} - \lambda\pi_{ji}\tilde{e}_j\rangle|_{\gamma_{ji}} - 4\langle\pi_{ij}\tilde{e}_i, \tilde{\epsilon}_{ij} - \lambda\pi_{ij}\tilde{e}_i\rangle|_{\gamma_{ij}})\\
&= \sum_{i=1}^K\sum_{j\in N(i)}\|\tilde{\epsilon}_{ij}\|_*^2 - 4\sum_{i=1}^K\sum_{j\in N(i)}\langle\pi_{ij}\tilde{e}_i, \tilde{\epsilon}_{ij} - \lambda\pi_{ij}\tilde{e}_i\rangle|_{\gamma_{ij}}.
\end{aligned}$$

Since $(\tilde{e},\tilde{\varepsilon}) \in W$, by (2.11),

$$\sum_{j\in N(i)}\langle\pi_{ij}\tilde{e}_i, \tilde{\epsilon}_{ij} - \lambda\pi_{ij}\tilde{e}_i\rangle|_{\gamma_{ij}} = a_i(\tilde{e}_i,\tilde{e}_i).$$

Then

$$\sum_{1\le i<j\le K}(\|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon_{ji}}\|_*^2 + \|2\lambda\pi_{ij}\tilde{e}_i - \tilde{\varepsilon_{ij}}\|_*^2) = \|\tilde{\varepsilon}\|_*^2 - 4a(\tilde{e},\tilde{e}).$$

Similarly, we also have

$$\sum_{1\le i<j\le K}(\|2\lambda\pi_{ji}\hat{e}_j - \hat{\varepsilon_{ji}}\|_*^2 + \|2\lambda\pi_{ij}\hat{e}_i - \hat{\varepsilon_{ij}}\|_*^2) = \|\hat{\varepsilon}\|_*^2 - 4a(\hat{e},\hat{e}).$$

So

$$\begin{aligned}
&|\sigma|^2\|\bar{\varepsilon}\|_*^2\\
&= \sum_{1\le i<j\le K}(|\sigma|^2\|\bar{\varepsilon}_{ij}\|_*^2 + |\sigma|^2\|\bar{\varepsilon}_{ji}\|_*^2)\\
&= \sum_{1\le i<j\le K}(\|2\lambda\pi_{ji}\tilde{e}_j - \tilde{\varepsilon_{ji}}\|_*^2 + \|2\lambda\pi_{ij}\tilde{e}_i - \tilde{\varepsilon_{ij}}\|_*^2)\\
&\quad + \sum_{1\le i<j\le K}(\|2\lambda\pi_{ji}\hat{e}_j - \hat{\varepsilon_{ji}}\|_*^2 + \|2\lambda\pi_{ij}\hat{e}_i - \hat{\varepsilon_{ij}}\|_*^2)\\
&= \|\tilde{\varepsilon}\|_*^2 - 4a(\tilde{e},\tilde{e}) + \|\hat{\varepsilon}\|_*^2 - 4a(\hat{e},\hat{e})\\
&= \|\bar{\varepsilon}\|_*^2 - 4a(\bar{e},\bar{e}).
\end{aligned}$$

Thus we get (5.7).

We know $|\sigma| \le 1$ since $a(\bar{e},\bar{e}) \ge 0$ and $\bar{\varepsilon} \ne 0$. ∎

Remark 5.3. By a similar argument in the proof of Lemma 5.3, we can prove the following important equality,

$$\|\epsilon^{n+1}\|_*^2 = \|\epsilon^n\|_*^2 - 4a(e^n, e^n). \tag{5.9}$$

This equality discloses the convergence behavior of this method explicitly.

LEMMA 5.4. *If $(\bar{e},\bar{\varepsilon})$ is an eigenvector of $\bar{A}$ such that $\bar{A}(\bar{e},\bar{\varepsilon}) = \sigma(\bar{e},\bar{\varepsilon})$, $\sigma \ne 0$, $j \in N(i)$, then*

$$\|\bar{\pi}_{ij}\bar{e}_i\|_0^2 \le C|\sigma|^{-2}h^{1/2}H^{1/2}\|\bar{\varepsilon}_{ji}\|_*^2 + C|\sigma|^{-2}\|\bar{\pi}_{ji}\bar{e}_j\|_0^2,$$

where C is a constant independent of h and H.

Proof. By (5.6), we have

$$|\sigma|^2\|\bar{\varepsilon}_{ij}\|_0^2 \le C\lambda^2\|\bar{\pi}_{ji}\bar{e}_j\|_0^2 + C\|\bar{\varepsilon}_{ji}\|_0^2$$

or

$$\|\bar{\varepsilon}_{ij}\|_*^2 \le C|\sigma|^{-2}\lambda\|\bar{\pi}_{ji}\bar{e}_j\|_0^2 + C|\sigma|^{-2}\|\bar{\varepsilon}_{ji}\|_*^2. \tag{5.10}$$

On the other hand, also by (5.6), we know

$$2\lambda\bar{\pi}_{ij}\bar{e}_i = \sigma\bar{\varepsilon}_{ji} + \bar{\varepsilon}_{ij};$$

then

$$\lambda^2\|\bar{\pi}_{ij}\bar{e}_i\|_0^2 \le C|\sigma|^2\|\bar{\varepsilon}_{ji}\|_0^2 + C\|\bar{\varepsilon}_{ij}\|_0^2,$$

and

$$\begin{aligned}\lambda\|\bar{\pi}_{ij}\bar{e}_i\|_0^2 &\le C|\sigma|^2\|\bar{\varepsilon}_{ji}\|_*^2 + C\|\bar{\varepsilon}_{ij}\|_*^2\\ &\le C|\sigma|^2\|\bar{\varepsilon}_{ji}\|_*^2 + C|\sigma|^{-2}\lambda\|\bar{\pi}_{ji}\bar{e}_j\|_0^2 + C|\sigma|^{-2}\|\bar{\varepsilon}_{ji}\|_*^2\\ &\le C2|\sigma|^{-2}\|\bar{\varepsilon}_{ji}\|_*^2 + C|\sigma|^{-2}\lambda\|\bar{\pi}_{ji}\bar{e}_j\|_0^2,\end{aligned}$$

where we have used (5.10) and the fact that $|\sigma| \le 1$ in the second and third inequalities, respectively. As a result,

$$\|\bar{\pi}_{ij}\bar{e}_i\|_0^2 \le C|\sigma|^{-2}\lambda^{-1}\|\bar{\varepsilon}_{ji}\|_*^2 + C|\sigma|^{-2}\|\bar{\pi}_{ji}\bar{e}_j\|_0^2.$$

Recall that $\lambda = O(h^{-1/2}H^{-1/2})$, and we get the conclusion. ∎

LEMMA 5.5. *If $\Omega_{i^r} \in D_r$ and there is a path $\{\Omega_{i^1},\dots,\Omega_{i^r}\}$ connecting Ω_{i^r} with boundary, then for all eigenvectors $(\bar{e},\bar{\varepsilon})$ such that $\bar{A}(\bar{e},\bar{\varepsilon}) = \sigma(\bar{e},\bar{\varepsilon})$, $\sigma \ne 0$,we have*

$$\begin{aligned}&\|\bar{\varepsilon}_{i^rk}\|_*^2\\ &\le C_3h^{-1/2}H^{1/2}|\bar{e}_{i^r}|_{1,h,\Omega_{i^r}}^2 + (C_3)^3 2|\sigma|^{-2}h^{-1/2}H^{1/2}|\bar{e}_{i^{r-1}}|_{1,h,\Omega_{i^{r-1}}}^2\\ &\quad + \cdots + (C_3)^{2r-1}(2|\sigma|^{-2})^{r-1}h^{-1/2}H^{1/2}|\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2,\end{aligned}$$

where $C_3 > 1$ is independent of h, H, and the choice of eigenvector $(\bar{e},\bar{\varepsilon})$.

Proof. We verify it by induction on r.

By Lemma 5.2, Lemma 5.4, and (5.4), we know that there is a constant $C_3 > 1$ such that $\forall j,k \in N(i)$, the following three inequalities hold:

$$\|\bar{\pi}_{ik}\bar{e}_i\|_{0,\gamma_{ik}}^2 \le C_3H|\bar{e}_i|_{1,h,\Omega_i}^2 + C_3\|\bar{\pi}_{ij}\bar{e}_i\|_{0,\gamma_{ij}}^2, \tag{5.11}$$

$$\|\bar{\varepsilon}_{ik}\|_*^2 \le C_3 h^{-1/2} H^{1/2} |\bar{e}_i|_{1,h,\Omega_i}^2 + C_3 h^{-1/2} H^{-1/2} \|\bar{\pi}_{ij}\bar{e}_i\|_{0,\gamma_{ij}}^2, \tag{5.12}$$

$$\|\bar{\pi}_{ij}\bar{e}_i\|_0^2 \le C_3 |\sigma|^{-2} h^{1/2} H^{1/2} \|\bar{\varepsilon}_{ji}\|_*^2 + C_3 |\sigma|^{-2} \|\bar{\pi}_{ji}\bar{e}_j\|_0^2. \tag{5.13}$$

It is necessary to point out that C_3 is independent of h, H, and the choice of eigenvector $(\bar{e}, \bar{\varepsilon})$.

When $r = 1$, i.e., $\Omega_{i^1} \in D_1$, there is at least one face of Ω_{i^1} belonging to $\partial\Omega$. Let this face play the role of γ_{ij} in (5.11) and (5.12); since $\bar{\pi}\bar{e}_{i^1}$ vanishes on this face, we have

$$\|\bar{\pi}_{i^1 k}\bar{e}_{i^1}\|_0^2 \le C_3 H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2, \tag{5.14}$$

$$\|\bar{\varepsilon}_{i^1 k}\|_*^2 \le C_3 h^{-1/2} H^{1/2} |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2. \tag{5.15}$$

So the conclusion holds in the case of $r = 1$.

When $r = 2$, i.e., $\Omega_{i^2} \in D_2$, there is a path $\{\Omega_{i^1}, \Omega_{i^2}\}$. So on one hand we can apply (5.11), (5.12), and (5.13) to Ω_{i^2}; on the other hand we can also use the hypothesis of induction (5.14) and (5.15) since Ω_{i^1} must belong to D_1.

By (5.13), (5.15), and (5.14) we have

$$\begin{aligned} \|\bar{\pi}_{i^2 i^1}\bar{e}_{i^2}\|_0^2 &\le C_3 |\sigma|^{-2} h^{1/2} H^{1/2} \|\bar{\varepsilon}_{i^1 i^2}\|_*^2 + C_3 |\sigma|^{-2} \|\bar{\pi}_{i^1 i^2}\bar{e}_{i^1}\|_0^2 \\ &\le (C_3)^2 |\sigma|^{-2} H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2 + (C_3)^2 |\sigma|^{-2} H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2 \\ &= (C_3)^2 2 |\sigma|^{-2} H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2. \end{aligned} \tag{5.16}$$

By (5.11) and (5.16), we have $\forall k \in N(i^2)$

$$\begin{aligned} &\|\bar{\pi}_{i^2 k}\bar{e}_{i^2}\|_0^2 \\ &\le C_3 H |\bar{e}_{i^2}|_{1,h,\Omega_{i^2}}^2 + C_3 \|\bar{\pi}_{i^2 i^1}\bar{e}_{i^2}\|_0^2 \\ &\le C_3 H |\bar{e}_{i^2}|_{1,h,\Omega_{i^2}}^2 + (C_3)^3 2 |\sigma|^{-2} H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2. \end{aligned} \tag{5.17}$$

By (5.12) and (5.16), we also get

$$\begin{aligned} &\|\bar{\varepsilon}_{i^2 k}\|_*^2 \\ &\le C_3 h^{-1/2} H^{1/2} |\bar{e}_{i^2}|_{1,h,\Omega_{i^2}}^2 + C_3 h^{-1/2} H^{-1/2} \|\bar{\pi}_{i^2 i^1}\bar{e}_{i^2}\|_0^2 \\ &\le C_3 h^{-1/2} H^{1/2} |\bar{e}_{i^2}|_{1,h,\Omega_{i^2}}^2 + (C_3)^3 2 |\sigma|^{-2} h^{-1/2} H^{1/2} |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2. \end{aligned} \tag{5.18}$$

So the conclusion also holds for $r = 2$.

In general, if the conclusion holds for $r - 1$, we consider the case of r. We know there is a path $\{\Omega_{i^1}, \ldots, \Omega_{i^{r-1}}, \Omega_{i^r}\}$. We can get the estimation for Ω_{i^r} by using (5.11), (5.12), (5.13), and the conclusion for $r - 1$ since $\{\Omega_{i^1}, \ldots, \Omega_{i^{r-1}}\}$ is a path connecting $\Omega_{i^{r-1}}$ with the boundary. In other words, we can get $\forall k \in N(i^r)$

$$\begin{aligned} &\|\bar{\pi}_{i^r k}\bar{e}_{i^r}\|_0^2 \\ &\le C_3 H |\bar{e}_{i^r}|_{1,h,\Omega_{i^r}}^2 + (C_3)^3 2 |\sigma|^{-2} H |\bar{e}_{i^{r-1}}|_{1,h,\Omega_{i^{r-1}}}^2 \\ &\quad + \cdots + (C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} H |\bar{e}_{i^1}|_{1,h,\Omega_{i^1}}^2, \end{aligned}$$

$$\begin{aligned}&\|\bar{\varepsilon}_{i^r k}\|_*^2\\ &\le C_3 h^{-1/2} H^{1/2} |\bar{e}_{i^r}|^2_{1,h,\Omega_{i^r}} + (C_3)^3 2|\sigma|^{-2} h^{-1/2} H^{1/2} |\bar{e}_{i^{r-1}}|^2_{1,h,\Omega_{i^{r-1}}}\\ &\quad + \cdots + (C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} h^{-1/2} H^{1/2} |\bar{e}_{i^1}|^2_{1,h,\Omega_{i^1}}.\end{aligned}$$

Thus we get the conclusion in general. □

Now we are in a position to prove the main theorem.

Proof of Theorem 5.1. By Corollary 2.4, we know

$$\|(e^n, \varepsilon^n)\| \le \|A^n\| \|(e^0, \varepsilon^0)\|. \tag{5.19}$$

In addition, by Lemma 3.6, we need only to estimate $\rho(\bar{A})$. This is our main task.

Suppose $(\bar{e}, \bar{\varepsilon})$ is an eigenvector of $\bar{A}$ and $\sigma \neq 0$ is certain eigenvalue. By the condition (1) of Assumption 4.1, $\forall \Omega_{i^r} \in D_r$, Ω_{i^r} has a path $\{\Omega_{i^1}, \Omega_{i^2}, \ldots, \Omega_{i^r}\}$. By Lemma 5.5, $\forall k \in N(i^r)$,

$$\begin{aligned}&\|\bar{\varepsilon}_{i^r k}\|_*^2\\ &\le C_3 h^{-1/2} H^{1/2} |\bar{e}_{i^r}|^2_{1,h,\Omega_{i^r}} + (C_3)^3 2|\sigma|^{-2} h^{-1/2} H^{1/2} |\bar{e}_{i^{r-1}}|^2_{1,h,\Omega_{i^{r-1}}}\\ &\quad + \cdots + (C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} h^{-1/2} H^{1/2} |\bar{e}_{i^1}|^2_{1,h,\Omega_{i^1}}.\end{aligned}$$

We assume each Ω_i has at most M faces. So

$$\begin{aligned}&\sum_{k\in N(i^r)} \|\bar{\varepsilon}_{i^r k}\|_*^2\\ &\le MC_3 h^{-1/2} H^{1/2} |\bar{e}_{i^r}|^2_{1,h,\Omega_{i^r}} + M(C_3)^3 2|\sigma|^{-2} h^{-1/2} H^{1/2} |\bar{e}_{i^{r-1}}|^2_{1,h,\Omega_{i^{r-1}}}\\ &\quad + \cdots + M(C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} h^{-1/2} H^{1/2} |\bar{e}_{i^1}|^2_{1,h,\Omega_{i^1}}.\end{aligned}$$

By the condition (2) of Assumption 4.1, we have

$$\begin{aligned}&\sum_{\Omega_{i^r}\in D_r} \sum_{j\in N(i^r)} \|\bar{\varepsilon}_{i^r j}\|_*^2\\ &\le MC_3 h^{-1/2} H^{1/2} \sum_{\Omega_{i^r}\in D_r} |\bar{e}_{i^r}|^2_{1,h,\Omega_{i^r}}\\ &\quad + M(C_3)^3 2|\sigma|^{-2} h^{-1/2} H^{1/2} \sum_{\Omega_{i^{r-1}}\in D_{r-1}} |\bar{e}_{i^{r-1}}|^2_{1,h,\Omega_{i^{r-1}}}\\ &\quad + \cdots + M(C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} h^{-1/2} H^{1/2} \sum_{\Omega_{i^1}\in D_1} |\bar{e}_{i^1}|^2_{1,h,\Omega_{i^1}}.\end{aligned} \tag{5.20}$$

Summing up all subdomains by (5.20), we get

$$\begin{aligned}\|\bar{\varepsilon}\|_*^2 &= \sum_{r=1}^{N} \sum_{\Omega_{i^r}\in D_r} \sum_{j\in N(i^r)} \|\bar{\varepsilon}_{i^r j}\|_*^2\\ &\le Mh^{-1/2} H^{1/2} \sum_{r=1}^{N} (C_3)^{2r-1} (2|\sigma|^{-2})^{r-1} a(\bar{e}, \bar{e})\\ &\le (C_1)^{-1} |\sigma|^{-2N} (2(C_3)^2)^N h^{-1/2} H^{1/2} a(\bar{e}, \bar{e}),\end{aligned}$$

where C_1 is independent of h, H, N, and the choice of eigenvector $(\bar{e}, \bar{\varepsilon})$. By (5.7), we have

$$\begin{aligned}|\sigma|^2\|\bar{\varepsilon}\|_*^2 &= \|\bar{\varepsilon}\|_*^2 - 4a(\bar{e},\bar{e})\\ &\le \|\bar{\varepsilon}\|_*^2 - 4C_1|\sigma|^{2N}(2(C_3)^2)^{-N}h^{1/2}H^{-1/2}\|\bar{\varepsilon}\|_*^2.\end{aligned}$$

Moreover, by (5.5), $\bar{\varepsilon} \neq 0$, so

$$|\sigma|^2 \le 1 - 4C_1|\sigma|^{2N}(2(C_3)^2)^{-N}h^{1/2}H^{-1/2}.$$

If $|\sigma|^2 > 1/2$, then

$$|\sigma|^2 \le 1 - 4C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2}.$$

As a result,

$$|\sigma|^2 \le \max\{1/2, 1 - 4C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2}\}.$$

Since

$$1 - 4C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2} \ge 1/2,$$

when h tends to 0, we get

$$|\sigma|^2 \le 1 - 4C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2}.$$

Thus

$$|\sigma| \le (1 - 4C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2})^{1/2} \le 1 - 2C_1(4(C_3)^2)^{-N}h^{1/2}H^{-1/2}.$$

Let $C_0 = (4(C_3)^2)^{-1}$; then

$$\rho(\bar{A}) \le 1 - 2C_1(C_0)^N h^{1/2}H^{-1/2}, \tag{5.21}$$

where $C_0 \in (0,1)$ and C_1 are independent of h, H, and N.

By Lemma 3.6, (5.19), and (5.21) we finish this proof. ∎

6. Numerical experiments. Now we carry out some numerical experiments to check the convergence behavior of this method. We find that this method converges quickly when the winding number N is not very large. But the convergence rate will deteriorate when the winding number N goes up.

The domain in which our problems are defined is $[0, L \times H] \times [0, M \times H]$. We decompose the domain into $L \times M$ subdomains. Each subdomain is a square whose edge length is H. The problem is (2.1) and the exact solution u is $x(x - L \times H)y(y - M \times H)$. We triangulate the domain uniformly and the mesh size is h.

We will consider four cases. In these cases, $L \times M$ is 10×2, 5×3, 5×5, and 7×7, respectively. The winding numbers of these four cases are 1, 2, 3, and 4, respectively. In addition we will modify H in each case.

We choose the initial guess $g_{ij}^0 = 0$ in each case (see (2.7)). The stop criterion is $\|u^n - u\|_\infty \le 10^{-4}$. The iteration number is n. Let the initial error be $e^0 = \|u^0 - u\|_\infty$ and the final one be $e^n = \|u^n - u\|_\infty$. Since the iteration number n is dependent on e^0, we compare the convergence speed to the convergence rate $(e^n/e^0)^{1/n}$ instead of n. The smaller $(e^n/e^0)^{1/n}$ is, the quicker the convergence will be.

In this paper, we choose the relaxation parameter $\lambda = O(h^{-1/2}H^{-1/2})$ in theory. Here we denote $h^{-1/2}H^{-1/2}$ by λ_0. We search the optimal parameter λ_{opt} in each experiment. We find that $\lambda_{opt}/\lambda_0 \approx 0.2$. Table 1 displays the numerical results.

It is seen from the table that the convergence rate of the DDM converges quickly when the winding number is not very large, but it will deteriorate when the winding number N goes up. This numerical result confirms our theoretical investigation.

TABLE 1

$L \times M$	N	h	H	λ_{opt}/λ_0	n	e^n	$(e^n/e^0)^{1/n}$
10×2	1	0.01	0.3	0.24	8	$6.6749e-5$	0.3805
		0.01	0.2	0.25	6	$6.4250e-5$	0.3623
5×3	2	0.01	0.3	0.20	10	$7.3636e-5$	0.4965
		0.01	0.2	0.25	7	$4.0014e-5$	0.4250

		0.01	0.2	0.20	10	$6.6438e-5$	0.5166
7×7	4	0.01	0.3	0.13	24	$6.7312e-5$	0.6688
		0.01	0.2	0.16	18	$3.9613e-5$	0.6214

7. Conclusion. The Robin-type nonoverlapping DDM is a convenient, applicable, and highly parallel tool for solving the second order elliptic partial differential equations. The convergence rate is $1-O(h^{1/2}H^{-1/2})$ in certain cases when the lower term of the equation is strictly positive (see [22]). In this paper, we point out the convergence rate is $1-O((C_0)^N h^{1/2}H^{-1/2})$ when the lower term of the equation vanishes. Here h is size of mesh, H is the size of subdomain, and N is the winding number of domain decomposition (see Definition 4.1). $C_0 \in (0,1)$ is independent of h, H, and N. The numerical results in this paper support our theory. Given the fact claimed in [22] that the convergence rate of this method cannot be better than $1-O(h^{1/2}H^{-1/2})$ whether or not the lower term is positive definite strictly, the result in this paper is also sharp.

Appendix. Now we give the proofs of Lemmas 3.2, 3.4, and 3.5.

Proof of Lemma 3.2. It is easy to check that

$$\langle x+\sqrt{-1}y, x+\sqrt{-1}y\rangle \geq 0,$$

where the equality holds if and only if $x+\sqrt{-1}y=0$, and

$$\langle x_1+\sqrt{-1}y_1, x_2+\sqrt{-1}y_2\rangle = \overline{\langle x_2+\sqrt{-1}y_2, x_1+\sqrt{-1}y_1\rangle},$$

where $\bar{z}$ means the conjugate complex number of z. Moreover

$$\begin{aligned}&\langle (x_1+\sqrt{-1}y_1)+(x_3+\sqrt{-1}y_3), x_2+\sqrt{-1}y_2\rangle\\ &= \langle x_1+\sqrt{-1}y_1, x_2+\sqrt{-1}y_2\rangle + \langle x_3+\sqrt{-1}y_3, x_2+\sqrt{-1}y_2\rangle,\end{aligned}$$

$$\langle (a+\sqrt{-1}b)(x_1+\sqrt{-1}y_1), x_2+\sqrt{-1}y_2\rangle = (a+\sqrt{-1}b)\langle x_1+\sqrt{-1}y_1, x_2+\sqrt{-1}y_2\rangle.$$

So we have defined an inner product of complex linear space $C\otimes V$. Meanwhile

$$\|x+\sqrt{-1}y\|^2 = \langle x+\sqrt{-1}y, x+\sqrt{-1}y\rangle = \langle x,x\rangle + \langle y,y\rangle = \|x\|^2+\|y\|^2. \qquad \square$$

Proof of Lemma 3.4.

$$\begin{aligned}(1\otimes T_1)(1\otimes T_2)(x+\sqrt{-1}y) &= (1\otimes T_1)(T_2x+\sqrt{-1}T_2y)\\ &= T_1T_2x+\sqrt{-1}T_1T_2y\\ &= 1\otimes(T_1T_2)(x+\sqrt{-1}y),\end{aligned}$$

so we get the conclusion. $\square$

Proof of Lemma 3.5. By Lemma 3.2,

$$\|\bar{T}\|^2 = \sup_{x+\sqrt{-1}y\neq 0} \frac{\|\bar{T}(x+\sqrt{-1}y)\|^2}{\|x+\sqrt{-1}y\|^2} = \sup_{x+\sqrt{-1}y\neq 0} \frac{\|Tx\|^2+\|Ty\|^2}{\|x\|^2+\|y\|^2}$$
$$\leq \sup_{x+\sqrt{-1}y\neq 0} \frac{\|T\|^2\|x\|^2+\|T\|^2\|y\|^2}{\|x\|^2+\|y\|^2} = \|T\|^2,$$

so

$$\|\bar{T}\| \leq \|T\|.$$

On the other hand, we know there is a vector $x_0 \in V$ such that $\|x_0\| = 1$ and $\|Tx_0\| = \|T\|$, and also by Lemma 3.2,

$$\|\bar{T}\|^2 \geq \frac{\|\bar{T}(x_0+\sqrt{-1}x_0)\|^2}{\|x_0+\sqrt{-1}x_0\|^2} = \frac{2\|Tx_0\|^2}{2\|x_0\|^2} = \|T\|^2.$$

So $\|\bar{T}\| = \|T\|$. □

Acknowledgment. We thank the anonymous referees for many constructive comments and suggestions which led to an improved presentation of this paper.

STRONG TRACTABILITY OF QUASI-MONTE CARLO QUADRATURE USING NETS FOR CERTAIN BANACH SPACES*

RONG-XIAN YUE† AND FRED J. HICKERNELL‡

Abstract. We consider multivariate integration in the weighted spaces of functions with mixed first derivatives bounded in L_p norms and the weighted coefficients introduced via ℓ_q norms, where $p, q \in [1, \infty]$. The integration domain may be bounded or unbounded. The worst-case error and randomized error are investigated for quasi-Monte Carlo quadrature rules. For the worst-case setting the quadrature rule uses deterministic $((T_u), s)$-sequences in base b, and for the randomized setting the quadrature rule uses randomly scrambled digital $((T_u), m, s)$-nets in base b. Sufficient conditions are found under which multivariate integration is strongly tractable in the worst-case and randomized settings, respectively. Similar results hold for the Banach spaces of finite-order weights. Results presented in this article extend and improve upon those found previously.

Key words. weighted integration, quasi-Monte Carlo quadrature, strong tractability

1. Introduction.

In many practical problems arising in statistics [FW94, Gen92], finance [PT96], and physics [Kei96], one often needs to approximate the integral of a function $f(\mathbf{x})$ over the s-dimensional unit cube,

$$I(f) = \int_{[0,1]^s} f(\mathbf{x}) d\mathbf{x}, \tag{1}$$

or over a bounded or unbounded s-dimensional box D with a nonnegative weight function $\rho(\mathbf{x})$,

$$I_\rho(f) = \int_D f(\mathbf{x}) \rho(\mathbf{x}) d\mathbf{x}. \tag{2}$$

It is assumed in this article that D is an s-dimensional box of the form

$$D = \overline{(\mathbf{a}, \mathbf{b})} := \overline{(a_1, b_1)} \times \cdots \times \overline{(a_s, b_s)} \subseteq R^s, \tag{3}$$

where each of the $\overline{(a_k, b_k)}$ may possibly be a finite, semi-infinite, or infinite interval. In addition, the weight function $\rho(\mathbf{x})$ is assumed to have product form

$$\rho(\mathbf{x}) = \prod_{k=1}^{s} \rho_k(x_k) \tag{4}$$

for nonnegative functions ρ_k, which are assumed to be probability density functions on (a_k, b_k) for simplicity. After a suitable transformation, the integration problem in (2) can be written as the form in (1). We call integration in (1) the classical problem. In this article we concentrate mainly on the classical problem, and then extend the results to the general problem.

For the classical problem with large s the integral is often approximated by algorithms of the following form:

$$Q_n(f) = \frac{1}{n} \sum_{j=0}^{n-1} f(\mathbf{x}^j), \tag{5}$$

where the point set $P = \{\mathbf{x}^0, \mathbf{x}^1, \ldots, \mathbf{x}^{n-1}\}$ is carefully chosen from the unit cube $[0,1]^s$. In this article P is chosen by quasi-Monte Carlo and randomized quasi-Monte Carlo methods known as (T, m, s)-nets and (T, s)-sequences [Nie92, Chapter 4] and their scrambled versions [Owe95]. For fixed dimension s, quasi-Monte Carlo methods are usually considered to be more accurate than Monte Carlo methods, but for Monte Carlo methods it can be much easier to estimate accuracy. Randomized Monte Carlo methods combine the best of Monte Carlo and quasi-Monte Carlo methods [Owe95, Owe97a, Owe97b, Owe98, YM99, HY00, HHY04].

It is interesting to investigate the performance of quasi-Monte Carlo and randomized quasi-Monte Carlo methods for high or very high dimensional integration. This problem is related to the concepts of tractability and strong tractability [SW98]. Tractability means that one can reduce the initial error by a factor $\varepsilon \in (0,1)$ by using a number of function values which are polynomial in s and ε^{-1}. Strong tractability means that the number of samples is independent of s and depends polynomially on ε^{-1}. The smallest (or the infimum of) power of ε^{-1} is called the strong exponent of tractability. See [SW98] for a more precise description of tractability and strong tractability.

Strong tractability for integration is related to the class of integrands. There have been a few investigations in recent years concentrating on the strong tractability problem of quasi-Monte Carlo and randomized quasi-Monte Carlo methods based on (T, m, s)-nets and (T, s)-sequences for reproducing kernel Hilbert spaces [DP05, Wan03, YH01, YH05].

However, as pointed out in [Slo02], it is necessary to consider integration problems for Banach spaces of functions since the reproducing kernel Hilbert space methods are too restrictive for some classes of problems. For example, integrals from mathematical finance are typically with respect to probability measures over unbounded domains. After mapping to the unit cube most problems of this kind yield integrands whose derivatives are integrable, *but not square integrable*.

Consider the European put option as a simple one-dimensional example. The payoff is given by

$$g(z) = \max(K - S_0 \exp\{(r - \sigma^2/2)\tau + \sigma\sqrt{\tau} z\}, 0),$$

where S_0 is the initial asset price, τ is the time to maturity, r is the interest rate, σ is the volatility, K is the strike price, and z is a random variable with the standard Gaussian distribution, $\Phi(z)$. The fair price of the option is the mean or expected value of the payoff, i.e., $\int_{-\infty}^{\infty} g(z)\Phi'(z)\,dz = \int_0^1 f(x)\,dx$, where $f(x) = g(\Phi^{-1}(x))$. The integral in terms of x after a variable transformation is the classical integration

problem. The integral of the pth power of the first derivative of f is

$$\int_0^1 |f'(x)|^p \, dx = \int_{-\infty}^{\infty} |g'(z)|^p [\Phi'(z)]^{1-p} \, dz$$
$$= (2\pi)^{(p-1)/2} \int_{-\infty}^{\infty} |g'(z)|^p e^{(p-1)z^2/2} \, dz.$$

For the example in question $g'(z)$ decays exponentially to zero as $z \to -\infty$, is zero for z large enough, and has a jump discontinuity where $g(z)$ becomes positive. Thus, $g'(z)$ is p-integrable for all $p \geq 1$; however, due to the term $[\Phi'(z)]^{1-p}$, the function f' is integrable, but not square integrable. In fact, it is not p-integrable for any $p > 1$. The same conclusion holds if other fatter tailed distributions, such as the variance-gamma, are substituted for the Gaussian distribution.

Therefore, a fundamental difficulty arises in applying the Hilbert space results to such problems. Recently, there have been some studies of the tractability problem for weighted integration based on general quadrature rules and lattice rules for weighted Banach spaces of functions whose mixed partial derivatives are bounded in L_p norms for $p \in [1, \infty]$; see [HSW04a, HSW04b, HSW04c]. We think that it is also interesting to consider the quadrature rules that use (T, m, s)-nets and (T, s)-sequences for these spaces.

This article studies the tractability problems for weighted Banach spaces of integrands, in which two quasi-Monte Carlo rules are considered. One uses *deterministic* Niederreiter (T, s)-sequences, and another uses *randomly scrambled* Niederreiter digital (T, m, s)-nets. We refer to [Nie88] for Niederreiter sequences and [Nie92, Chapter 4; NX01, Chapter 8] for constructions of digital nets. For *deterministic* Niederreiter sequence rules we assume that the integrands f lie in a weighted Banach space, $\mathcal{F}^{(1)}_{p,q,\gamma,s}$, of functions whose mixed *anchored* first derivatives are bounded in L_p norms, and the weighted coefficients, $\gamma = \{\gamma_k\}_k$, are introduced via ℓ_q norms over the index u, where $p, q \in [1, \infty]$. This space is the same as that in [HSW04b]. For the *randomly scrambled* Niederreiter net rules, the class of integrands is a weighted Banach space, $\mathcal{F}^{(2)}_{p,q,\gamma,s}$, of functions whose *unanchored* mixed first derivatives are bounded in L_p norms and the weighted coefficients, $\gamma = \{\gamma_k\}_k$, are introduced via ℓ_q norms, where $p, q \in [1, \infty]$.

Note that the spaces $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ and $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ have the same smoothness. But the space $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ works technically better for the worst-case setting, and the space $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ works technically better for the randomized setting.

The reason for using Niederreiter sequences is that Niederreiter sequences are telescoping; i.e., to obtain a sequence in dimension $s + 1$, it suffices to add the last component x^j_{s+1} to the term of the s-dimensional sequence $(x^j_1, \ldots, x^j_s)$ for $j = 1, 2, \ldots$. Moreover, for any nonempty subset u of $\{1, \ldots, s\}$, the projection of the s-dimensional Niederreiter (T, s)-sequence onto the axes in u forms a $|u|$-dimensional Niederreiter sequence with quality parameter [Nie88]

$$T_u = \sum_{k \in u} [\deg(g_k) - 1], \tag{6}$$

where $g_1, \ldots, g_s$ denote the first s monic irreducible polynomials over the finite field F_b. This allows us to write the Niederreiter sequence and net as $((T_u), s)$-sequence and $((T_u), m, s)$-net, respectively, where (T_u) denotes a $(2^s - 1)$-dimensional vector of the quality parameters corresponding to all nonempty subsets u of $\{1, \ldots, s\}$. From

[Nie92, Wan03] one has the following upper bound on $\deg(g_k)$:

$$\deg(g_k) \le \log_b k + \log_b \log_b(k+b) + 2, \quad k = 1, 2, \ldots. \tag{7}$$

These properties make Niederreiter sequences suitable for tractability studies.

Note that very similar properties hold for some other sequences, such as Sobol sequences [Sob67, Sob69], Halton sequences [Hal60, HW02], generalized Niederreiter sequences [Nie92, Tez95], and certain constructions by Niederreiter and Xing [NX01]. Hence results very similar to the one presented in this article hold for those sequences. For instance, the Sobol sequence (in base 2) also has the telescopic property. And for any nonempty subset u of $\{1, \ldots, s\}$, the projection of the s-dimensional Sobol (T, s)-sequence onto the axes in u forms a $|u|$-dimensional Sobol sequence with quality parameter [Sob67]

$$T_u = \sum_{k \in u} [\deg(P_k) - 1],$$

where $P_1, \ldots, P_s$ denote the first s primitive polynomials. From [Sob69, Wan03] the degree $\deg(P_k)$ can be bounded by

$$\deg(P_k) \le \log_2 k + \log_2 \log_2(k+1) + \log_2 \log_2 \log_2(k+3) + C, \quad k = 1, 2, \ldots,$$

where C is a constant independent of k and s. Hence very similar strong tractability results to the one presented for Niederreiter sequences hold for Sobol sequences but the sufficient conditions are slightly stronger.

The main results of this article are Theorems 1 to 4, which provide sufficient conditions on strong tractability for $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ in the worst-case setting and $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ in the randomized setting. These results are summarized in Table 1, where p^* and q^* denote the conjugates of p and q, i.e.,

$$\frac{1}{p} + \frac{1}{p^*} = 1, \quad \frac{1}{q} + \frac{1}{q^*} = 1.$$

The asymptotic orders of the quadrature errors are given under the assumption that the sufficient condition for strong tractability holds. The parameter ϵ is an arbitrary positive number. For comparison, related results in [HSW04b, Wan03, YH05] are also listed in the table.

The following points are worth noting about these results:

(i) The spaces considered in [Wan03] are the weighted reproducing kernel Hilbert spaces, and the original weights γ_k in [Wan03] are the square of our weights. Therefore, the space in [Wan03] in which the weights are replaced with γ_k^2 becomes $\mathcal{F}^{(1)}_{2,2,\gamma,s}$. Our results substantially extend and improve upon the results of [Wan03] by considering more general spaces of integrands and deriving weaker sufficient conditions for strong tractability.

(ii) The setting in [YH05] is the *randomized worst case*, and the quadrature rule is based on a randomly scrambled Niederreiter sequence. Moreover, the weighted Sobolev–Hilbert spaces, $\mathcal{H}^{\mathrm{SH}}_{s,\gamma}$, are nearly the same as $\mathcal{F}^{(1)}_{2,2,\gamma,s}$. The sufficient condition there for strong tractability is somewhat weaker than the one in the present article. We do not know yet whether the condition for the worst-case setting in this article can be weakened or not.

TABLE 1
Summary results in the present article and [HSW04b, Wan03, YH05].

Setting	Article	Space	Rule	Sufficient condition for strong tractability	Error
Worst case	Present	$\mathcal{F}^{(1)}_{p,q,\gamma,s}$	sequence	$\sum_{k=1}^{\infty} \gamma_k^a k \ln k < \infty$ $(1 \le a \le q^*)$	$\mathcal{O}(n^{-1/a+\epsilon})$
Worst case	[HSW04b]	$\mathcal{F}^{(1)}_{p,q,\gamma,s}$	lattice	$\sum_{k=1}^{\infty} \gamma_k^a < \infty$ $(1 \le a \le q^*)$	$\mathcal{O}(n^{-1/a+\epsilon})$
Worst case	[Wan03]	$\mathcal{F}^{(1)}_{2,2,\gamma,s}$	sequence	$\sum_{k=1}^{\infty} \gamma_k k \ln k < \infty$	$\mathcal{O}(n^{-1+\epsilon})$
Randomized worst case	[YH05]	$\mathcal{H}^{\mathrm{SH}}_{s,\gamma}$	sequence	$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^2 < \infty$	$\mathcal{O}(n^{-1+\epsilon})$
Randomized	Present	$\mathcal{F}^{(2)}_{p,q,\gamma,s}$	net	$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^2 < \infty$ $(1 \le p \le \infty)$	$\mathcal{O}(n^{-1+\epsilon})$
				$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^3 < \infty$ $(2 \le p \le \infty)$	$\mathcal{O}(n^{-3/2+\epsilon})$
Randomized	[YH05]	$\mathcal{H}^{\mathrm{SH}}_{s,\gamma}$	net	$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^3 < \infty$	$\mathcal{O}(n^{-3/2+\epsilon})$

(iii) Compared with the lattice rules in [HSW04b], our sufficient condition for digital sequences in the worst-case setting is somewhat more stringent. In fact, we can conclude that our condition $\sum_{k=1}^{\infty} \gamma_k^a k \ln k < \infty$ $(1 \le a \le q^*)$ is roughly equivalent to $\sum_{k=1}^{\infty} \gamma_k^{a/2} < \infty$ $(1 \le a \le q^*)$ from the following Lemma 1, provided that $\gamma_1 \ge \gamma_2 \ge \cdots \ge 0$.

(iv) As far as we are aware, there have been few studies on randomized settings in literature. Sloan and Woźniakowski [SW01] studied the randomized error of the classical Monte Carlo algorithm for weighted Korobov spaces. Yue and Hickernell [YH05] studied the randomized error of the quasi-Monte Carlo algorithm based on scrambled Niederreiter nets and sequences for weighted Sobolev–Hilbert spaces. The result of the randomized error for $p = q = 2$ in this article is the same as that of [YH05]. Therefore, the results of this article extend the result of [YH05] by considering more general spaces of integrands.

(v) Compared with the condition with $a = 1$ in the worst-case setting for $\mathcal{F}^{(1)}_{p,q,\gamma,s}$, the condition in the randomized setting for $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ is weaker for $p \ge 1$. However, the results in the randomized setting are just for Niederreiter digital nets, unlike Niederreiter sequences in the worst-case setting.

LEMMA 1. *Let* $\{\gamma_k\}$ *be a nonnegative nonincreasing sequence, and let* λ_k *be a sequence satisfying*

$$\tilde{c}_{r,\delta} k^{r-\delta} \le \lambda_k \le c_{r,\delta} k^{r+\delta} \quad \forall \delta \in \left(0, \frac{1}{r}\right), \quad k = 1, 2, \ldots,$$

where $\tilde{c}_{r,\delta}$ and $c_{r,\delta}$ are two nonnegative constants depending only on r and δ. Then

$$\tilde{L}_{r,\delta}\left[\sum_{k=1}^{\infty}\gamma_k^{\frac{a(1+\delta)}{1+r}}\right]^{\frac{1+r}{1+\delta}} \le \sum_{k=1}^{\infty}\gamma_k^a\lambda_k \le L_{r,\delta}\left[\sum_{k=1}^{\infty}\gamma_k^{\frac{a(1-r\delta)}{1+r}}\right]^{\frac{1+r}{1-r\delta}},$$

where $\tilde{L}_{r,\delta}$ and $L_{r,\delta}$ are two nonnegative constants depending only on r and δ.

The proof of Lemma 1 is given in the appendix.

The article proceeds as follows: Section 2 considers the strong tractability of quasi-Monte Carlo rules that use deterministic Niederreiter sequences for the classical problem. Section 3 considers strong tractability of quasi-Monte Carlo rules that use the randomly scrambled Niederreiter digital nets for the classical problem. Section 4 extends the strong tractability results for the classical problem to the weighted integration over a general domain. Some concluding remarks are given in section 5, where it is shown that similar results to the one presented in previous sections hold for the Banach spaces of finite-order weights.

2. Tractability in worst-case settings for the classical problem. In this section, we deal with the strong tractability problem of multivariate integration using the deterministic Niederreiter sequence for the *classical problem*. We first introduce the spaces of our integrands, which are defined as in [HSW04a]. We briefly recall the definition as follows.

For a given $p \in [1,\infty]$, let $\mathcal{H}_{p,k}$ be the space of absolutely continuous functions $h : [0,1] \to R$ with p-integrable first derivatives, i.e., $h'(x) \in L_p([0,1])$. Let $\mathcal{H}_p^s = \otimes_{k=1}^s \mathcal{H}_{p,k}$ be the space consisting of linear combinations of functions of the following tensor product form:

$$f : [0,1]^s \to R \quad \text{and} \quad f(\mathbf{x}) = \prod_{k=1}^{s} h_k(x_k) \text{ with } h_k \in \mathcal{H}_{p,k}.$$

Take a sequence $\gamma = \{\gamma_k\}_k$ of positive numbers, and let $\gamma_\emptyset = 1$ and $\gamma_u = \prod_{k\in u}\gamma_k$ for nonempty subset $u \subseteq \{1,\dots,s\}$. Let $\mathbf{c}$ be a fixed point in $[0,1]^s$ and define the mixed *anchored* first derivative $f'_{u,\mathbf{c}}$ of $f(\mathbf{x})$ for any nonempty subset u by

$$f'_{u,\mathbf{c}}(\mathbf{x}_u) := \left(\prod_{k\in u}\frac{\partial}{\partial x_k}\right) f(\mathbf{x}_u, \mathbf{c}_{\bar{u}}),$$

where $(\mathbf{x}_u, \mathbf{c}_{\bar{u}})$ denotes the s-dimensional vector whose kth component is x_k if $k \in u$, and is c_k if $k \in \bar{u}$. Given an additional parameter $q \in [1,\infty]$, define the space $\mathcal{F}_{p,q,\gamma,s}^{(1)}$ to be the completion of $\mathcal{H}_p^s$ with respect to the norm

$$\|f\|_{p,q,\gamma,s} := \begin{cases} \left(\displaystyle\sum_{u\subseteq\{1,\dots,s\}} \gamma_u^{-q}\|f'_{u,\mathbf{c}}\|_{L_p}^q\right)^{1/q} & \text{for } q < \infty, \\ \displaystyle\max_{u\subseteq\{1,\dots,s\}}\{\gamma_u^{-1}\|f'_{u,\mathbf{c}}\|_{L_p}\} & \text{for } q = \infty, \end{cases} \tag{8}$$

where the sum is over all 2^s subsets of coordinates of $[0,1]^s$, and $f'_{\emptyset,\mathbf{c}} = f(\mathbf{c})$.

For the significance of the weights γ_k we refer to, e.g., [SW98, NW01] and note that in some articles, including [SW98, NW01, Wan03], $p = q = 2$ and the definition of $\|\cdot\|_{2,2,\gamma,s}$ uses γ_u^{-1} instead of γ_u^{-2}. Hence, our weights γ_k in (8) for $p = q = 2$ are the square roots of those in [SW98, NW01, Wan03].

For the weighted Banach space $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ defined above, the worst-case error of the quasi-Monte Carlo quadrature Q_n is defined as

$$e^{\mathrm{wo}}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s}) := \sup_{\|f\|_{p,q,\gamma,s}\le 1} |I(f) - Q_n(f)|. \tag{9}$$

An expression for $e^{\mathrm{wo}}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s})$ is given in [HSW04a], in which the functions $M_u(\mathbf{x}, \mathbf{t})$ are important. For each $k \in \{1, \dots, s\}$ let

$$M_k(x,t) := \begin{cases} 1 & \text{if } c_k \le t < x, \\ -1 & \text{if } x \le t < c_k, \\ 0 & \text{otherwise,} \end{cases}$$

and for each subset u of $\{1, \dots, s\}$ let

$$M_u(\mathbf{x}_u, \mathbf{t}_u) := \prod_{k\in u} M_k(x_k, t_k)$$

with the convention that $M_\emptyset \equiv 1$. It is shown in [HSW04c] that

$$f(\mathbf{x}) = \sum_{u\subseteq\{1,\dots,s\}} \int_{[0,1]^u} f'_{u,\mathbf{c}}(\mathbf{t}_u) M_u(\mathbf{x}_u, \mathbf{t}_u) d\mathbf{t}_u.$$

Define

$$h_u(\mathbf{t}_u) := I(M_u(\cdot, \mathbf{t}_u)) - Q_n(M_u(\cdot, \mathbf{t}_u)). \tag{10}$$

When $\mathbf{c} = \mathbf{1}$, then $h_u(\mathbf{t}_u)$ has the following expression:

$$h_u(\mathbf{t}_u) = \mathrm{vol}([\mathbf{0}, \mathbf{t}_u)) - \frac{1}{n}\sum_{j=0}^{n-1} 1_{[\mathbf{0},\mathbf{t}_u)}(\mathbf{x}_u^j). \tag{11}$$

For the case where $\mathbf{c}$ is in the interior of the unit cube $[0,1]^s$, $h_u(\mathbf{t}_u)$ has a similar expression replacing the cube $[\mathbf{0}, \mathbf{t}_u)$ by a certain box, which is described below. Note that the anchor $\mathbf{c} \in (0,1)^s$ partitions the unit cube $[0,1]^s$ into 2^s quadrants. Given a $\mathbf{t} = (t_1, \dots, t_s)^T$ in one of these quadrants, let $B(\mathbf{t}; \mathbf{c})$ denote the box with one corner at $\mathbf{t}$ and the opposite corner given by the unique vertex of $[0,1]^s$ that lies in the same quadrant as $\mathbf{t}$. Then $h_u(\mathbf{t}_u)$ can be expressed as

$$h_u(\mathbf{t}_u) = \mathrm{vol}(B_u(\mathbf{t}_u; \mathbf{c}_u)) - \frac{1}{n}\sum_{j=0}^{n-1} 1_{B_u(\mathbf{t}_u;\mathbf{c}_u)}(\mathbf{x}_u^j), \tag{12}$$

where $B_u(\mathbf{t}_u; \mathbf{c}_u)$ is the projection of $B(\mathbf{t}; \mathbf{c})$ onto the axes in u.

In terms of the functions h_u the worst-case error $e^{\rm wo}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s})$ in (9) is given by [HSW04a]

$$e^{\rm wo}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s}) = \begin{cases} \left(\sum_{u \neq \emptyset} \gamma_u^{q^*} \|h_u\|_{L_{p^*}}^{q^*} \right)^{1/q^*} & \text{for } q > 1, \\ \max_{u \neq \emptyset} \{\gamma_u \|h_u\|_{L_{p^*}}\} & \text{for } q = 1, \end{cases} \tag{13}$$

where p^* and q^* are the conjugates of p and q, respectively.

The result in the following lemma will be used several times in the proofs of the main theorems in this article.

LEMMA 2. *Let $\alpha, \beta, \theta > 0$ and $\tau \geq 1$. For the first n points of a Niederreiter $((T_u), s)$-sequence in base b, define*

$$\Phi(\alpha, \beta, \theta, \tau) := \sum_{\emptyset \neq u \subseteq 1,\ldots,s} \gamma_u^{\alpha} b^{\beta T_u} (\theta \ln(\tau n))^{|u|}. \tag{14}$$

If the γ_k satisfy

$$\sum_{k=1}^{\infty} \gamma_k^{\alpha} (k \ln k)^{\beta} < \infty, \tag{15}$$

then for any fixed $\epsilon > 0$ there exists a constant C_ϵ independent of s and n such that

$$\Phi(\alpha, \beta, \theta, \tau) \leq C_\epsilon n^{\epsilon}.$$

Proof. This lemma can be proved by an argument similar to that used in [Wan03, Theorem 4]. □

Now we can proceed to prove the strong tractability result of multivariate integration using Niederreiter sequences in the worst-case setting.

THEOREM 1. *Assume $p, q \in [1, \infty]$. Let $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ be the Banach space of functions f with norm* (8)*. Assume that the quasi-Monte Carlo quadrature Q_n uses a Niederreiter $((T_u), s)$-sequence in a prime power base b. If*

$$\sum_{k=1}^{\infty} \gamma_k^{a} k \ln k < \infty \tag{16}$$

for any $a \in [1, q^*]$, then the corresponding integration is strongly tractable in the worst-case setting, and for any fixed $\epsilon > 0$ there exists a constant C independent of s and n such that

$$e^{wo}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s}) \leq C n^{-1/a+\epsilon}. \tag{17}$$

Proof. It follows from the expression in (13) for the worst-case error and the fact $\|h_u\|_{L_{p^*}} \leq \|h_u\|_{L_\infty}$ for any $p^* \in [1, \infty]$ that it is sufficient to consider the case with $p^* = \infty$. For the case of $\mathbf{c} = \mathbf{1}$,

$$\|h_u\|_{L_\infty} = \sup_{\mathbf{t}_u \in [0,1]^u} \left| \mathrm{vol}([\mathbf{0}, \mathbf{t}_u)) - \frac{1}{n} \sum_{j=0}^{n-1} 1_{[\mathbf{0}, \mathbf{t}_u)}(\mathbf{x}_u^j) \right| = D^*_{u,\infty}(P)$$

due to the expression (11), where $D^*_{u,\infty}(P)$ is the local *star discrepancy* of P corresponding to the subset u. Note that if $\{\mathbf{x}^j\}_{j\geq 0}$ is a Niederreiter $((T_u),s)$-sequence in base b, then its projection onto the axes in u is a Niederreiter $(T_u,|u|)$-sequence in base b, where T_u is as given by (6). It follows from [Wan03, Lemma 1] that

$$D^*_{u,\infty}(P) \leq n^{-1} b^{T_u} (\theta \ln(bn))^{|u|},$$

where $\theta = b/\ln b$. Noting that $\|h_u\|_{L_\infty} = D^*_{u,\infty}(P) \leq 1$, we then have the following for $q \in [1,\infty]$ and any $\tilde{a} \in [1, q^*]$:

$$\begin{aligned}\left(\sum_u \gamma_u^{q^*} \|h_u\|^{q^*}_{L_\infty}\right)^{1/q^*} &\leq \left(\sum_u \gamma_u^{q^*} \|h_u\|^{\tilde{a}}_{L_\infty}\right)^{1/q^*} \leq \left(\sum_u \gamma_u^{q^*/\tilde{a}} \|h_u\|_{L_\infty}\right)^{\tilde{a}/q^*} \\ &\leq n^{-\tilde{a}/q^*} \left(\sum_u \gamma_u^{q^*/\tilde{a}} b^{T_u} (\theta \ln(bn))^{|u|}\right)^{\tilde{a}/q^*} \\ &= n^{-\tilde{a}/q^*} [\Phi(q^*/\tilde{a}, 1, \theta, b)]^{\tilde{a}/q^*}.\end{aligned}$$

Set $a = q^*/\tilde{a}$, and then $a \in [1, q^*]$ since $1 \leq \tilde{a} \leq q^*$. It follows from (13) that

$$e^{\mathrm{wo}}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s}) \leq n^{-1/a} [\Phi(a, 1, \theta, b)]^{1/a}.$$

Applying Lemma 2 to $\Phi(a,1,\theta,b)$ gives the upper bound (17) for $e^{\mathrm{wo}}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s})$ if condition (16) holds.

For the case with $\mathbf{c}$ in the interior of the unit cube $[0,1]^s$, from expression (12) we have

$$\begin{aligned}\|h_u\|_{L_\infty} &= \sup_{\mathbf{t}_u \in [0,1]^u} \left| \mathrm{vol}(B_u(\mathbf{t}_u; \mathbf{c}_u)) - \frac{1}{n} \sum_{j=0}^{n-1} 1_{B_u(\mathbf{t}_u;\mathbf{c}_u)}(\mathbf{x}^j_u) \right| \\ &\leq \sup_{J_u} \left| \mathrm{vol}(J_u) - \frac{1}{n} \sum_{j=0}^{n-1} 1_{J_u}(\mathbf{x}^j_u) \right| = D_{u,\infty}(P),\end{aligned}$$

where J_u denotes subintervals of $[0,1]^s$ of the form $\prod_{k\in u}[\alpha_k, \beta_k)$, and $D_{u,\infty}(P)$ is the local *extreme discrepancy* (or *unanchored discrepancy*) of P corresponding to the subset u. From Proposition 2.4 in [Nie92] we have

$$D_{u,\infty}(P) \leq 2^{|u|} D^*_{u,\infty}(P).$$

Then the upper bound for $e^{\mathrm{wo}}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s})$ follows from the previous argument for $\mathbf{c} = \mathbf{1}$.

Note that the initial error in multivariate integration in the space $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ is

$$e^{\mathrm{wo}}(0, \mathcal{F}^{(1)}_{p,q,\gamma,s}) = \left(\sum_{u \subseteq \{1,\ldots,s\}} \gamma_u^{q^*} \|\mathrm{vol}(B_u(\cdot; \mathbf{c}_u))\|^{q^*}_{L_{p^*}} \right)^{1/q^*}.$$

By the definition of $B_u(\mathbf{t}_u; \mathbf{c}_u)$ it can be verified that

$$\begin{aligned}\|\mathrm{vol}(B_u(\cdot;\mathbf{c}_u))\|_{L_{p^*}}^{p^*} &= \sum_{v\subseteq u}\left(\prod_{k\in v}\int_0^{c_k} t_k^{p^*}\,dt_k\right)\left(\prod_{k\in u-v}\int_{c_k}^1 (1-t_k)^{p^*}\,dt_k\right)\\ &= (p^*+1)^{-|u|}\sum_{v\subseteq u}\left(\prod_{k\in v} c_k^{p^*+1}\right)\left(\prod_{k\in u-v}(1-c_k)^{p^*+1}\right)\\ &= (p^*+1)^{-|u|}\prod_{k\in u}\left[c_k^{p^*+1}+(1-c_k)^{p^*+1}\right].\end{aligned}$$

It follows that

$$\begin{aligned}e^{\mathrm{wo}}(0,\mathcal{F}^{(1)}_{p,q,\gamma,s}) &= \left[\sum_{u\subseteq\{1,\dots,s\}}\gamma_u^{q^*}(p^*+1)^{-|u|q^*/p^*}\prod_{k\in u}\left(c_k^{p^*+1}+(1-c_k)^{p^*+1}\right)^{q^*/p^*}\right]^{1/q^*}\\ &= \prod_{k=1}^{s}\left[1+\gamma_k^{q^*}(p^*+1)^{-q^*/p^*}\left(c_k^{p^*+1}+(1-c_k)^{p^*+1}\right)^{q^*/p^*}\right]^{1/q^*},\end{aligned}$$

which is uniformly bounded in s under condition (16). From this factor and the upper bound for the worst-case error above, we assert that the multivariate integration is strongly tractable in the worst-case setting. This concludes the proof. □

Remark 1. From Theorem 1 the following facts are observed:

(i) If condition (16) holds for $a = 1$, then the worst-case error is $O(n^{-1+\epsilon})$, and in the case with $p = q = 2$, this result is the same as that obtained in [Wan03] for reproducing kernel Hilbert spaces. Therefore, our result in Theorem 1 is an extension of that in [Wan03] to arbitrary p and q.

(ii) Although the convergence rate for $a > 1$ is smaller than that for $a = 1$, by introducing the number $a \in (1, q^*]$, the sequence of weights $\{\gamma_k\}_k$ is transformed at the same time and the strong tractability condition is weaker. Therefore, when considering the question of strong tractability, this theorem allows one to accept a lower convergence rate in turn for less restrictive conditions on the weights. This was done in [HSW04b].

3. Tractability in randomized settings for the classical problem. In this section we consider the strong tractability problem of integration using randomly scrambled Niederreiter digital net rules in randomized settings for the classical problem. The function spaces $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ defined below have slightly different norms than $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ considered in the previous section although the smoothness assumptions are the same. The reason for this is that the arguments for the randomized setting are different from that used in the previous section. In analyzing the randomized error, the mean square error of the quadrature rule is expressed in terms of Fourier coefficients of the integrand under the orthogonormal system of multivariate Haar wavelets. By making use of integration by parts, each of the Fourier coefficients is expressed by an integral of the product of two functions: one is the unanchored mixed first derivative of the integral, and another is defined via the Haar wavelet.

For $p \in [1,\infty]$ let $\mathcal{H}_p^s$ be defined as in the previous section. Given an additional parameter $q \in [1,\infty]$ and a sequence $\gamma = \{\gamma_k\}_k$ of positive numbers, $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ is defined

to be the completion of $\mathcal{H}_p^s$ with respect to the norm

$$\|f\|_{p,q,\gamma,s} := \begin{cases} \left(\sum_{u \subseteq \{1,\ldots,s\}} \gamma_u^{-q} \|f'_u\|_{L_p}^q \right)^{1/q} & \text{for } q < \infty, \\ \max_{u \subseteq \{1,\ldots,s\}} \{\gamma_u^{-1} \|f'_u\|_{L_p}\} & \text{for } q = \infty, \end{cases} \tag{18}$$

where $\gamma_\emptyset = 1$, $\gamma_u = \prod_{k \in u} \gamma_k$, the derivative $f'_u(\mathbf{x})$ for $u \neq \emptyset$ is defined by

$$f'_u(\mathbf{x}) := \left(\prod_{k \in u} \frac{\partial}{\partial x_k} \right) f(\mathbf{x}),$$

and $f'_\emptyset(\mathbf{x})$ denotes $f(\mathbf{x})$. For $p = q = 2$ the space becomes the Sobolev space considered in section 3.1 of [SW01].

For the weighted Banach spaces defined above, we define the randomized error of the quadrature rule Q_n as

$$e^{\mathrm{ra}}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s}) := \sup_{\|f\|_{p,q,\gamma,s} \leq 1} \sqrt{E|I(f) - Q_n(f)|^2}, \tag{19}$$

where the expectation E is taken with respect to the random samples.

In what follows, we first give some background about the randomly scrambled digital sequences and Haar wavelets. Then we deal with the randomized error of the quadrature rules.

3.1. Randomly scrambled digital sequences. The sequence $\{\mathbf{x}^j\}_{j \geq 0}$ of points in the unit cube $[0,1]^s$ is generated in the following way, which is called scrambling [Owe95, Owe00]. Let $b \geq 2$ be a prime power base. The kth component of the jth point $\mathbf{x}^j = (x_1^j, \ldots, x_s^j)^T$ is determined by the b-ary expression

$$x_k^j = \frac{x_{jk1}}{b} + \frac{x_{jk2}}{b^2} + \cdots.$$

Here, the digits x_{jkl} are generated by

$$\begin{pmatrix} x_{jk1} \\ x_{jk2} \\ \vdots \end{pmatrix} = \boldsymbol{L}_k \boldsymbol{C}_k \begin{pmatrix} j_1 \\ j_2 \\ \vdots \end{pmatrix} + \mathbf{e}_k \bmod b, \quad k = 1, \ldots, s,$$

where $(j_1, j_2, \ldots)^T$ is the vector of b-ary digits of $j \in Z_+$, i.e., $j = j_1 + j_2 b + j_3 b^2 + \cdots$, the $\boldsymbol{C}_k$ are the prescribed $\infty \times \infty$ generator matrices, the $\boldsymbol{L}_k$ are lower triangular $\infty \times \infty$ scrambling matrices, and the $\mathbf{e}_k$ are $\infty \times 1$ digital shifts. The scrambling matrices and shifts are chosen randomly.

Choosing the first $n = b^m$, $m \in Z_+$, points of a digital sequence in base b gives a digital net in base b. The quality of the digital net is defined below.

For a vector $\boldsymbol{\ell} = (\ell_1, \ell_2, \ldots)^T \in Z_+^\infty$ with $\|\boldsymbol{\ell}\|_1 := \sum_\alpha \ell_\alpha < \infty$, let $\boldsymbol{C}(\boldsymbol{\ell})$ be the $\|\boldsymbol{\ell}\|_1 \times \infty$ matrix formed by the first ℓ_1 rows of $\boldsymbol{C}_1$ followed by the first ℓ_2 rows of $\boldsymbol{C}_2$, etc. For any integer $m \in Z_+$ let $\boldsymbol{C}(\boldsymbol{\ell}, m)$ denote the $\|\boldsymbol{\ell}\|_1 \times m$ matrix formed by the first m columns of $\boldsymbol{C}(\boldsymbol{\ell})$. Define

$$T_u := \min\{T \geq 0 : \ \mathrm{rank}(\boldsymbol{C}(\boldsymbol{\ell}, m)) = \|\boldsymbol{\ell}\|_1 \ \forall m, \forall \boldsymbol{\ell} \text{ with } U(\boldsymbol{\ell}) \subseteq u, \|\boldsymbol{\ell}\|_1 = m - T\}.$$

Smaller values of T_u correspond to better nets. Note that the quality measure introduced here is the same as the T_u in (6). See [Owe95, Owe00] for a more detailed explanation of the scrambled scheme, and [Nie92, Chapter 4; NX01, Chapter 8] for constructions of digital nets and sequences.

3.2. Haar wavelets. To deal with the randomized error of the randomly scrambled digital net rules, we use Haar wavelets. Multidimensional Haar wavelets are tensor products of one-dimensional wavelets. We refer to [Wal02, Chapter 5] for one-dimensional Haar wavelets and to [Ent97, Ent98] for earlier work on Haar wavelets and nets.

We first introduce some notation. For any $\nu \in Z_+$ define the function

$$\lg(\nu) := \begin{cases} \lfloor \log_b(\nu) \rfloor + 1 & \text{if } \nu > 0, \\ 0 & \text{if } \nu = 0, \end{cases}$$

which means that the base b representation of ν has $\lg(\nu)$ digits if one ignores leading zeros. Let $\tilde{\nu}$ denote the leading digit of ν when written in base b, and define

$$z_\nu := \nu b^{1-\lg(\nu)} - \tilde{\nu}.$$

For any $\boldsymbol{\nu} = (\nu_1, \ldots, \nu_s)^T \in Z_+^s$ define

$$\lg(\boldsymbol{\nu}) := (\lg(\nu_1), \ldots, \lg(\nu_s))^T, \quad \mathbf{z}_{\boldsymbol{\nu}} := (z_{\nu_1}, \ldots, z_{\nu_s})^T.$$

Also, let $U(\boldsymbol{\nu})$ denote the set of all k for which $\nu_k > 0$ and let $|U(\boldsymbol{\nu})|$ denote the cardinality of $U(\boldsymbol{\nu})$. Moreover, for $u \subseteq \{1, \ldots, s\}$ let $\mathbf{1}_u$ denote the s-dimensional vector whose kth component is 1 for $k \in u$ and 0 otherwise. For any $\mathbf{x} = (x_1, \ldots, x_s)^T, \mathbf{y} = (y_1, \ldots, y_s)^T \in [0,1]^s$, and $\boldsymbol{\ell} = (\ell_1, \ldots, \ell_s)^T \in Z_+^s$, let $\delta(\mathbf{x}, \mathbf{y}, \boldsymbol{\ell}) = 1$ if the first ℓ_k digits of x_k and y_k are the same for all $k = 1, \ldots, s$, and let $\delta(\mathbf{x}, \mathbf{y}, \boldsymbol{\ell}) = 0$ otherwise.

Multidimensional Haar wavelets $\psi_{\boldsymbol{\nu}}(\mathbf{x})$ for $\boldsymbol{\nu} \in Z_+^s$ are piecewise constant functions, which are defined as

$$\psi_{\boldsymbol{\nu}}(\mathbf{x}) := b^{(\|\lg(\boldsymbol{\nu})\|_1 - |U(\boldsymbol{\nu})|)/2} \exp\left(\frac{2\pi i}{b} \sum_{k=1}^{s} \tilde{\nu}_k x_{\bullet k \lg(\nu_k)}\right) \delta(\mathbf{x}, \mathbf{z}_{\boldsymbol{\nu}}, \lg(\boldsymbol{\nu}) - \mathbf{1}_{U(\boldsymbol{\nu})}), \tag{20}$$

where $x_{\bullet k\ell}$ denotes the ℓth b-ary digit of the kth component of $\mathbf{x}$, and $i := \sqrt{-1}$. Note that the support of $\psi_{\boldsymbol{\nu}}$ is a box, $S(\boldsymbol{\nu})$, of volume $b^{|U(\boldsymbol{\nu})| - \|\lg(\boldsymbol{\nu})\|_1}$. In fact,

$$S(\boldsymbol{\nu}) = \prod_{k \in U(\boldsymbol{\nu})} \left[z_{\nu_k}, z_{\nu_k} + b^{1-\lg(\nu_k)} \right) \times [0,1)^{\{1,\ldots,s\} \setminus U(\boldsymbol{\nu})}. \tag{21}$$

It is known that $\{\psi_{\boldsymbol{\nu}}(\mathbf{x})\}_{\boldsymbol{\nu}}$ is a sequence of complex-valued, integrable, orthogonormal basis functions. Any $f \in L_2([0,1]^s)$ can be represented as an infinite series

$$f(\mathbf{x}) = \sum_{\boldsymbol{\nu}} F(\boldsymbol{\nu}) \psi_{\boldsymbol{\nu}}(\mathbf{x}), \quad \mathbf{x} \in [0,1]^s, \tag{22}$$

where the $F(\boldsymbol{\nu})$ are Fourier coefficients given by

$$F(\boldsymbol{\nu}) := \int_{[0,1]^s} f(\mathbf{x}) \overline{\psi_{\boldsymbol{\nu}}(\mathbf{x})} d\mathbf{x}; \tag{23}$$

here $\overline{\psi_{\boldsymbol{\nu}}(\mathbf{x})}$ denotes the complex conjugate of $\psi_{\boldsymbol{\nu}}(\mathbf{x})$. The following facts will play an important role in our randomized error analysis. For each $\nu \in Z_+$ and any $x \in [0,1]$ let

$$\xi_\nu(x) := \int_0^x \overline{\psi_\nu(t)}dt.$$

For each $\boldsymbol{\nu} \in Z_+^s$ and any $\mathbf{x} \in [0,1]^s$ let

$$\xi_{\boldsymbol{\nu}}(\mathbf{x}) := \prod_{k \in U(\boldsymbol{\nu})} \xi_{\nu_k}(x_k). \tag{24}$$

Note that the support of $\xi_{\boldsymbol{\nu}}$ is the same as that of $\psi_{\boldsymbol{\nu}}$.

The following upper bounds on the different norms of $\xi_{\boldsymbol{\nu}}$ can be verified by immediate calculations, which are omitted here.

LEMMA 3. *For each* $\boldsymbol{\nu} \in Z_+^s$,

$$\begin{aligned}
&\|\xi_{\boldsymbol{\nu}}\|_{L_1} \le 2^{-|U(\boldsymbol{\nu})|} b^{-3(\|lg(\boldsymbol{\nu})\|_1 - |U(\boldsymbol{\nu})|)/2},\\
&\|\xi_{\boldsymbol{\nu}}\|_{L_2} \le 3^{-|U(\boldsymbol{\nu})|/2} b^{-\|lg(\boldsymbol{\nu})\|_1 + |U(\boldsymbol{\nu})|},\\
&\|\xi_{\boldsymbol{\nu}}\|_{L_\infty} \le b^{-(\|lg(\boldsymbol{\nu})\|_1 - |U(\boldsymbol{\nu})|)/2}.
\end{aligned}$$

3.3. Upper bounds for the randomized error. This subsection will give upper bounds for the randomized error defined in (19) for different values of $p \in [1,\infty]$, and find sufficient conditions under which multivariate integration using the randomly scrambled Niederreiter digital nets is strongly tractable in the randomized setting.

LEMMA 4. *Let* $\psi_{\boldsymbol{\nu}}(\mathbf{x})$, $\boldsymbol{\nu} \in Z_+^s$, *be the Haar wavelets defined by* (20), *and let* Q_n *be the quasi-Monte Carlo quadrature that uses randomly scrambled digital nets with* $n = b^m$, $m \in Z_+$. *By* $\mathrm{MSE}(Q_n, f)$ *denote the mean square error of the approximation* Q_n, *i.e.,*

$$\mathrm{MSE}(Q_n, f) = E|I(f) - Q_n(f)|^2.$$

Then for any $f \in L_2([0,1]^s)$

$$\begin{aligned}
\mathrm{MSE}(Q_n, f) &= \sum_{\boldsymbol{\nu} \ne \mathbf{0}} |F(\boldsymbol{\nu})|^2 E[Q_n(\psi_{\boldsymbol{\nu}}) Q_n(\overline{\psi_{\boldsymbol{\nu}}})]\\
&\le \sum_{\boldsymbol{\nu}: \|lg(\boldsymbol{\nu})\|_1 + T_U(\boldsymbol{\nu}) > m} |F(\boldsymbol{\nu})|^2 3^{|U(\boldsymbol{\nu})|} b^{T_{U(\nu)} - m},
\end{aligned} \tag{25}$$

where the $F(\boldsymbol{\nu})$ *are the coefficients of* f *under the Haar wavelets.*

Proof. Making use of the expansion in (22) and noting that $F(\mathbf{0}) = I(f)$ yields

$$I(f) - Q_n(f) = -\frac{1}{n} \sum_{j=0}^{n-1} \sum_{\boldsymbol{\nu} \ne \mathbf{0}} F(\boldsymbol{\nu}) \psi_{\boldsymbol{\nu}}(\mathbf{x}^j) = -\sum_{\boldsymbol{\nu} \ne \mathbf{0}} F(\boldsymbol{\nu}) Q_n(\psi_{\boldsymbol{\nu}}),$$

and then

$$|I(f) - Q_n(f)|^2 = \sum_{\boldsymbol{\nu} \ne \mathbf{0}} \sum_{\boldsymbol{\omega} \ne \mathbf{0}} F(\boldsymbol{\nu}) \overline{F(\boldsymbol{\omega})} Q_n(\psi_{\boldsymbol{\nu}}) Q_n(\overline{\psi_{\boldsymbol{\omega}}}).$$

It is proved in [HD04, Lemma 10] that for scrambled digital nets

$$\begin{aligned} E[Q_n(\psi_{\boldsymbol{\nu}})Q_n(\overline{\psi_{\boldsymbol{\omega}}})] &= 0 \quad \text{for } \boldsymbol{\nu} \neq \boldsymbol{\omega}, \\ E[Q_n(\psi_{\boldsymbol{\nu}})Q_n(\overline{\psi_{\boldsymbol{\nu}}})] &= 0 \quad \text{for } \|\mathrm{lg}(\boldsymbol{\nu})\|_1 + T_{U(\boldsymbol{\nu})} \le m, \\ E[Q_n(\psi_{\boldsymbol{\nu}})Q_n(\overline{\psi_{\boldsymbol{\nu}}})] &\le 3^{|U(\boldsymbol{\nu})|} b^{T_{U(\boldsymbol{\nu})}-m} \quad \text{for } \|\mathrm{lg}(\boldsymbol{\nu})\|_1 + T_{U(\boldsymbol{\nu})} > m. \end{aligned}$$

The results in (25) then follow immediately from the facts mentioned above. ∎

For $f \in \mathcal{F}^{(2)}_{p,q,\gamma,s}$, by making use of integration by parts we can express the Fourier coefficients $F(\boldsymbol{\nu})$ in terms of the functions $\xi_{\boldsymbol{\nu}}$ defined in (24) as follows:

$$F(\boldsymbol{\nu}) = (-1)^{|U(\boldsymbol{\nu})|} \int_{S(\boldsymbol{\nu})} \xi_{\boldsymbol{\nu}}(\mathbf{x}) f'_{U(\boldsymbol{\nu})}(\mathbf{x}) d\mathbf{x}, \tag{26}$$

where $S(\boldsymbol{\nu})$ is the support of $\xi_{\boldsymbol{\nu}}$ given in (21). By Hölder's inequality applied to (26),

$$|F(\boldsymbol{\nu})| \le \|f'_{U(\boldsymbol{\nu})}\|_{L_p,S(\boldsymbol{\nu})} \|\xi_{\boldsymbol{\nu}}\|_{L_{p^*}}, \tag{27}$$

where

$$\|f'_{U(\boldsymbol{\nu})}\|_{L_p,S(\boldsymbol{\nu})} := \left(\int_{S(\boldsymbol{\nu})} |f'_{U(\boldsymbol{\nu})}(\mathbf{x})|^p d\mathbf{x}\right)^{1/p}, \quad \|\xi_{\boldsymbol{\nu}}\|_{L_{p^*}} := \left(\int_{[0,1]^s} |\xi_{\boldsymbol{\nu}}(\mathbf{x})|^{p^*} d\mathbf{x}\right)^{1/p^*}.$$

It follows from (25) that

$$\begin{aligned} \mathrm{MSE}(Q_n, f) &\le n^{-1} \sum_{\boldsymbol{\nu}:\|\mathrm{lg}(\boldsymbol{\nu})\|_1 + T_{U(\boldsymbol{\nu})} > m} \|f'_{U(\boldsymbol{\nu})}\|^2_{L_p,S(\boldsymbol{\nu})} \|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}} 3^{|U(\boldsymbol{\nu})|} b^{T_{U(\boldsymbol{\nu})}} \\ &= n^{-1} \sum_{u \neq \emptyset} \sum_{\substack{\boldsymbol{\nu}:\, U(\boldsymbol{\nu})=u, \\ \|\mathrm{lg}(\boldsymbol{\nu})\|_1 + T_u > m}} 3^{|u|} b^{T_u} \|f'_u\|^2_{L_p,S(\boldsymbol{\nu})} \|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}}. \end{aligned} \tag{28}$$

For simplicity in notation, we define $\mathcal{L}_{u,m}$ as the set of s-dimensional vector $\boldsymbol{\ell}$ with integer components $\ell_k > 0$ for $k \in u$, $\ell_k = 0$ for $k \in \bar{u}$, and $\|\boldsymbol{\ell}\|_1 > m - T_u$, and for each $\boldsymbol{\ell}$ define $\mathcal{N}_{u,\boldsymbol{\ell}}$ as the set of s-dimensional integer vector $\boldsymbol{\nu}$ with $U(\boldsymbol{\nu}) = u$ and $\mathrm{lg}(\boldsymbol{\nu}) = \boldsymbol{\ell}$, i.e.,

$$\mathcal{L}_{u,m} := \{\boldsymbol{\ell} = (\ell_1, \ldots, \ell_s)^T : \|\mathrm{lg}(\boldsymbol{\ell})\|_1 > m - T_u,\, \ell_k > 0\, \forall k \in u,\, \ell_k = 0\, \forall k \in \bar{u}\}, \tag{29}$$

$$\mathcal{N}_{u,\boldsymbol{\ell}} := \{\boldsymbol{\nu} = (\nu_1, \ldots, \nu_s)^T : U(\boldsymbol{\nu}) = u,\, \mathrm{lg}(\boldsymbol{\nu}) = \boldsymbol{\ell}\}. \tag{30}$$

The inner sum in the last expression in (28) can be written as follows:

$$\Psi_{u,m,p} := \sum_{\boldsymbol{\ell} \in \mathcal{L}_{u,m}} \sum_{\boldsymbol{\nu} \in \mathcal{N}_{u,\boldsymbol{\ell}}} 3^{|u|} b^{T_u} \|f'_u\|^2_{L_p,S(\boldsymbol{\nu})} \|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}}. \tag{31}$$

Then (28) becomes

$$\mathrm{MSE}(Q_n, f) \le n^{-1} \sum_{u \neq \emptyset} \Psi_{u,m,p}. \tag{32}$$

Before stating the main results for the randomized strong tractability, we give the following lemma that will be used in the proof of Theorem 2. This lemma can be proved by the binomial theory.

LEMMA 5. *Let m, t, r, and b be integers with $m \geq t \geq 0$, $r \geq 1$, and $b \geq 2$. Then for $\eta \in (0, \infty)$*

$$\Omega(\eta, m, t, r) := \sum_{l=m-t+1}^{\infty} \binom{l-1}{r-1} b^{-\eta l} < \left(\frac{b^{\eta} m}{b^{\eta}-1}\right)^{r} b^{-\eta(m-t)}. \tag{33}$$

THEOREM 2. *Let $p, q \in [1, \infty]$. Let $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ be the Banach space of functions with norm* (18). *Let Q_n be the quasi-Monte Carlo quadrature that uses randomly scrambled Niederreiter digital $((T_u), m, s)$-nets in prime power base b.*

(i) *For $p \in [1, \infty]$, if*

$$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^2 < \infty, \tag{34}$$

then the corresponding integration is strongly tractable in the randomized setting, and for any fixed $\epsilon > 0$, there exists a constant C independent of s and n such that

$$e^{ra}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s}) \leq C n^{-1+\epsilon}. \tag{35}$$

(ii) *In particular, for $p \in [2, \infty]$, if*

$$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^3 < \infty, \tag{36}$$

then the corresponding integration is strongly tractable in the randomized setting, and for any fixed $\epsilon > 0$, there exists a constant C independent of s and n such that

$$e^{ra}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s}) \leq C n^{-\frac{3}{2}+\epsilon}. \tag{37}$$

Proof. For item (i), we first note that $\mathcal{F}^{(2)}_{p,q,\gamma,s} \subseteq \mathcal{F}^{(2)}_{2,q,\gamma,s}$ for any $p > 2$, and then

$$e^{\mathrm{ra}}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s}) \leq e^{\mathrm{ra}}(Q_n, \mathcal{F}^{(2)}_{2,q,\gamma,s}) \quad \forall p > 2. \tag{38}$$

Hence it is sufficient to consider the case $p \in [1, 2]$. In this case we have $p^* \in (1, \infty]$ and

$$\|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}} \leq \|\xi_{\boldsymbol{\nu}}\|^2_{L_\infty} \leq b^{-\|\mathrm{lg}(\boldsymbol{\nu})\|_1 + |U(\boldsymbol{\nu})|}$$

by Lemma 3. Then by the definition (31) of $\Psi_{u,m,p}$,

$$\begin{aligned} \Psi_{u,m,p} &\leq \sum_{\boldsymbol{\ell} \in \mathcal{L}_{u,m}} \sum_{\boldsymbol{\nu} \in \mathcal{N}_{u,\boldsymbol{\ell}}} (3b)^{|u|} b^{T_u - \|\boldsymbol{\ell}\|_1} \|f'_u\|^2_{L_p, S(\boldsymbol{\nu})} \|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}} \\ &\leq (3b)^{|u|} b^{T_u} \sum_{\boldsymbol{\ell} \in \mathcal{L}_{u,m}} b^{-\|\boldsymbol{\ell}\|_1} \left(\sum_{\boldsymbol{\nu} \in \mathcal{N}_{u,\boldsymbol{\ell}}} \int_{S(\boldsymbol{\nu})} |f'_u(\mathbf{x})|^p d\mathbf{x} \right)^{\frac{2}{p}}, \end{aligned} \tag{39}$$

where the last inequality holds due to $\frac{2}{p} \geq 1$. By the definition of the support $S(\boldsymbol{\nu})$ in (21), for a fixed $|s|$-dimensional vector $\boldsymbol{\ell} = (\ell_1, \ldots, \ell_s)^T$ with $\ell_k > 0$ for $k \in u$ and $\ell_k = 0$ for $k \in \bar{u}$ we have

$$\sum_{\boldsymbol{\nu} \in \mathcal{N}_{u,\boldsymbol{\ell}}} \int_{S(\boldsymbol{\nu})} |f'_u(\mathbf{x})|^p d\mathbf{x} = (b-1)^{|u|} \int_{[0,1]^s} |f'_u(\mathbf{x})|^p d\mathbf{x} = (b-1)^{|u|} \|f'_u\|^p_{L_p}. \tag{40}$$

Moreover, note that for a given positive integer l with $l > m - T_u$ there is a total number $\binom{l-1}{|u|-1}$ of the vectors $\boldsymbol{\ell}$ in $\mathcal{L}_{u,\boldsymbol{\ell}}$ such that $\|\boldsymbol{\ell}\|_1 = l$. Therefore, (39) becomes

$$\begin{aligned}\Psi_{u,m,p} &\le \|f'_u\|^2_{L_p}[3b(b-1)]^{|u|}b^{T_u}\sum_{l=m-T_u+1}^{\infty}\binom{l-1}{|u|-1}b^{-\frac{p}{2}l} \\ &= \|f'_u\|^2_{L_p}[3b(b-1)]^{|u|}b^{T_u}\Omega(1,m,T_u,|u|),\end{aligned} \tag{41}$$

where Ω is as defined in Lemma 5. Making use of the inequality in Lemma 5 and the fact $m = \log_b n = \ln n/\ln b$ in (41) yields

$$\Psi_{u,m,p} \le n^{-1}\|f'_u\|^2_{L_p}b^{2T_u}(\theta_1 \ln n)^{|u|}, \tag{42}$$

where $\theta_1 = 3b^2/\ln b$. Applying this inequality to (32) we have

$$\mathrm{MSE}(Q_n, f) \le n^{-2}\sum_{u\ne\emptyset}\|f'_u\|^2_{L_p}b^{2T_u}(\theta_1 \ln n)^{|u|}.$$

Therefore, for $q \in [1,\infty]$, by Hölder's inequality and the definition of norm in (18) we have the following:

$$\begin{aligned}\mathrm{MSE}(Q_n, f) &\le n^{-2}\left[\sum_{u\ne\emptyset}\left(\gamma_u^{-2}\|f'_u\|^2_{L_p}\right)^q\right]^{\frac{1}{q}}\left[\sum_{u\ne\emptyset}\left(\gamma_u^2 b^{2T_u}(\theta_1\ln n)^{|u|}\right)^{q^*}\right]^{\frac{1}{q^*}} \\ &\le n^{-2}\|f\|^2_{p,q,\gamma,s}\left[\sum_{u\ne\emptyset}\left(\gamma_u^2 b^{2T_u}(\theta_1\ln n)^{|u|}\right)^{q^*}\right]^{\frac{1}{q^*}} \\ &\le n^{-2}\|f\|^2_{p,q,\gamma,s}\sum_{u\ne\emptyset}\gamma_u^2 b^{2T_u}(\theta_1\ln n)^{|u|} \\ &= n^{-2}\|f\|^2_{p,q,\gamma,s}\Phi(2,2,\theta_1,1),\end{aligned}$$

where Φ is defined by (14). It follows from Lemma 2 that for any fixed $\epsilon > 0$, there exists a constant C independent of s and n such that

$$e^{\mathrm{ra}}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s}) = \sup_{\|f\|_{p,q,\gamma,s}\le 1}\sqrt{\mathrm{MSE}(Q_n,f)} \le Cn^{-1+\epsilon}$$

under condition (34).

We now consider the initial error in the space $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ with $p \in [1,2]$. Note from (27) and Lemma 3 that

$$\begin{aligned}|F(0)|^2 &\le \sum_{\boldsymbol{\nu}}|F(\boldsymbol{\nu})|^2 \le \sum_u\sum_{\boldsymbol{\nu}:U(\boldsymbol{\nu})=u}\|f'_u\|^2_{L_p,S(\boldsymbol{\nu})}\|\xi_{\boldsymbol{\nu}}\|^2_{L_{p^*}} \\ &\le \sum_u\sum_{\boldsymbol{\ell}_u}\sum_{\boldsymbol{\nu}:\lg(\boldsymbol{\nu})=\boldsymbol{\ell}_u} b^{|u|-\|\boldsymbol{\ell}_u\|_1}\|f'_u\|^2_{L_p,S(\boldsymbol{\nu})} \\ &\le \sum_u\sum_{\boldsymbol{\ell}_u} b^{|u|-\|\boldsymbol{\ell}_u\|_1}\left(\sum_{\boldsymbol{\nu}:\lg(\boldsymbol{\nu})=\boldsymbol{\ell}_u}\int_{S(\boldsymbol{\nu})}|f'_u(\mathbf{x})|^p d\mathbf{x}\right)^{\frac{2}{p}} \\ &= \sum_u\sum_{\boldsymbol{\ell}_u}[b(b-1)]^{|u|}b^{-\|\boldsymbol{\ell}_u\|_1}\|f'_u\|^2_{L_p},\end{aligned}$$

where $\boldsymbol{\ell}_u$ denotes the s-dimensional integer vector with components $\ell_k > 0$ for $k \in u$ and $\ell_k = 0$ for $k \in \bar{u}$. Because

$$\sum_{\boldsymbol{\ell}_u} b^{-\|\boldsymbol{\ell}_u\|_1} = \sum_{l=|u|}^{\infty} \binom{l-1}{|u|-1} b^{-l} = (b-1)^{-|u|},$$

we then have

$$\begin{aligned}
|F(0)|^2 &\le \sum_u \|f_u'\|_{L_p}^2 b^{|u|} \\
&\le \left[\sum_u \left(\gamma_u^{-2}\|f_u'\|_{L_p}^2\right)^q\right]^{\frac{1}{q}} \left[\sum_u \left(\gamma_u^2 b^{2|u|}\right)^{q^*}\right]^{\frac{1}{q^*}} \\
&\le \|f\|_{p,q,\gamma,s}^2 \prod_{k=1}^{s} \left(1 + (b\gamma_k)^{2q^*}\right)^{\frac{1}{q^*}}.
\end{aligned}$$

Therefore,

$$e^{\mathrm{wo}}(0, \mathcal{F}_{p,q,\gamma,s}^{(1)}) = \sup_{\|f\|_{p,q,\gamma,s}\le 1} |F(0)| \le \prod_{k=1}^{s} \left(1 + (b\gamma_k)^{2q^*}\right)^{\frac{1}{q^*}},$$

which is uniformly bounded in s under condition (34). It follows that the multivariate integration is strongly tractable in the randomized setting.

As for item (ii), it is also sufficient to consider the case $p = 2$ due to (38). For $p = 2$ ($p^* = 2$), from (31), (40), and Lemma 3 we have

$$\begin{aligned}
\Psi_{u,m,2} &\le b^{2|u|+T_u} \sum_{\boldsymbol{\ell}\in\mathcal{L}_{u,m}} \sum_{\boldsymbol{\nu}\in\mathcal{N}_{u,\boldsymbol{\ell}}} b^{-2\|\boldsymbol{\ell}\|_1} \|f_u'\|_{L_2,S(\boldsymbol{\nu})}^2 \\
&= b^{2|u|+T_u} \sum_{\boldsymbol{\ell}\in\mathcal{L}_{u,m}} b^{-2\|\boldsymbol{\ell}\|_1} (b-1)^{|u|} \|f_u'\|_{L_2}^2 \\
&= \|f_u'\|_{L_2}^2 [b^2(b-1)]^{|u|} b^{T_u} \sum_{l=m-T_u+1}^{\infty} \binom{l-1}{|u|-1} b^{-2l} \\
&= \|f_u'\|_{L_2}^2 [b^2(b-1)]^{|u|} b^{T_u} \Omega(2, m, T_u, |u|).
\end{aligned}$$

From Lemma 5 we then have

$$\Psi_{u,m,2} \le n^{-2} \|f_u'\|_{L_2}^2 (\theta_2 \ln n)^{|u|} b^{3T_u},$$

where $\theta_2 = b^4/[(b+1)\ln b]$. Therefore, from (32),

$$\mathrm{MSE}(Q_n, f) \le n^{-3} \sum_{u\ne\emptyset} \|f_u'\|_{L_2}^2 b^{3T_u} (\theta_2 \ln n)^{|u|}.$$

For $q \in [1, \infty]$, by Hölder's inequality

$$\begin{aligned}
\mathrm{MSE}(Q_n, f) &\le n^{-3} \|f\|_{2,q,\gamma,s}^2 \left[\sum_{u\ne\emptyset} \left(\gamma_u^2 b^{3T_u} (\theta_2 \ln n)^{|u|}\right)^{q^*}\right]^{\frac{1}{q^*}} \\
&\le n^{-3} \|f\|_{2,q,\gamma,s}^2 \sum_{u\ne\emptyset} \gamma_u^2 b^{3T_u} (\theta_2 \ln n)^{|u|} \\
&= n^{-3} \|f\|_{2,q,\gamma,s}^2 \Phi(2, 3, \theta_2, 1).
\end{aligned}$$

Applying Lemma 2 to $\Phi(2,3,\theta_2,1)$ gives the desired result for the case $p=2$ and then for $p\in(2,\infty]$. This completes the proof for the theorem. □

Remark 2. For different values of p in $[2,\infty]$, we have two kinds of sufficient conditions for strong tractability in the randomized setting. The convergence rates are different under these two conditions. The condition under which the rate is higher is a little bit stronger.

Remark 3. The results in Theorem 2 are just for randomly scrambled Niederreiter digital nets but not for sequences. The difficulty for randomly scrambled sequences is the calculation of the expectation $E[Q_n(\psi_{\boldsymbol{\nu}})Q_n(\overline{\psi_{\boldsymbol{\nu}}})]$.

4. Weighted integration over a general domain. In this section, we extend the results presented in the previous two sections to the weighted integration problem over a general domain in (3), i.e., $D=\overline{(a_1,b_1)}\times\cdots\times\overline{(a_s,b_s)}$ and the general weight function ρ defined in (4).

4.1. Worst-case error analysis. The general problem for the worst case of integration can be reduced to the classical problem with domain $[0,1]^s$ and uniform weight $\rho\equiv 1$. Specifically, we define the following transformations:

$$W_k(x):=\int_{a_k}^{x}\rho_k(z)dz,\quad k=1,\dots,s. \tag{43}$$

Then $W_k:\overline{(a_k,b_k)}\to[0,1]$ is onto and increasing. Define

$$\boldsymbol{W}(\mathbf{x})=(W_1(x_1),\dots,W_s(x_s))^T$$

and $\mathbf{d}=\boldsymbol{W}(\mathbf{c})$ for a given anchor $\mathbf{c}\in D$. By $\boldsymbol{W}^{-1}$ denote the inverse transformation of $\boldsymbol{W}$.

By these transformations the integral $I_\rho(f)=\int_D f(\mathbf{x})\rho(\mathbf{x})d\mathbf{x}$ may be written as

$$\int_{[0,1]^s} g(\mathbf{y})d\mathbf{y},\quad \text{where}\quad g(\mathbf{y})=f(\boldsymbol{W}^{-1}(\mathbf{y})). \tag{44}$$

Let $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ be the weighted Banach space of functions defined on D with the corresponding norm of the form (8). The worst-case error

$$e^{\mathrm{wo}}(Q_n,\mathcal{F}^{(1)}_{p,q,\gamma,s})=\sup_{\|f\|_{p,q,\gamma,s}\le 1}|I_\rho(f)-Q_n(f)|$$

is still of the form (13) [HSW04a], where

$$h_u(\mathbf{t}_u)=I_\rho(M_u(\cdot,\mathbf{t}_u))-Q_n(M_u(\cdot,\mathbf{t}_u)),\quad \mathbf{t}_u\in D_u:=\prod_{k\in u}\overline{(a_k,b_k)}.$$

Denote the $|u|$-dimensional vectors $\mathbf{d}_u=(W_k(c_k))_{k\in u}$, $\mathbf{y}_u=(W_k(t_k))_{k\in u}$, $\mathbf{z}_u^j=(W_k(x_k^j))_{k\in u}$. By u_- denote the subset of u containing those indices k for which $t_k<c_k$. Then $h_u(\mathbf{t}_u)$ can be expressed as

$$h_u(\mathbf{t}_u)=(-1)^{u_-}\left[\mathrm{vol}(B_u(\mathbf{y}_u,\mathbf{d}_u))-\frac{1}{n}\sum_{j=0}^{n-1}1_{B_u(\mathbf{y}_u,\mathbf{d}_u)}(\mathbf{z}_u^j)\right],$$

where B_u is defined as in section 2. It follows that for $p \in [1,\infty]$ with conjugate p^*

$$\begin{aligned}\|h_u\|_{L_{p^*}} &= \left(\int_{D_u} |h_u(\mathbf{t}_u)|^{p^*} \rho_u(\mathbf{t}_u) d\mathbf{t}_u\right)^{\frac{1}{p^*}} \\ &= \left(\int_{[0,1]^u} \left|\mathrm{vol}(B_u(\mathbf{y}_u,\mathbf{d}_u)) - \frac{1}{n}\sum_{j=0}^{n-1} 1_{B_u(\mathbf{y}_u,\mathbf{d}_u)}(\mathbf{z}_u^j)\right|^{p^*} d\mathbf{y}_u\right)^{\frac{1}{p^*}} \\ &= D_{u,p^*}(\mathbf{z}^0,\ldots,\mathbf{z}^{n-1}),\end{aligned}$$

which is the *local L_{p^*} anchored discrepancy* of the point set $\{\mathbf{z}^0,\ldots,\mathbf{z}^{n-1}\}$. It is known that [Nie92]

$$D_{u,p^*}(\mathbf{z}^0,\ldots,\mathbf{z}^{n-1}) \le \kappa D^*_{u,\infty}(\mathbf{z}^0,\ldots,\mathbf{z}^{n-1}),$$

where $\kappa = 1$ if $\mathbf{d} = \boldsymbol{W}(\mathbf{c}) = \mathbf{1}$ and $\kappa = 2^{|u|}$ if $\mathbf{d} = \boldsymbol{W}(\mathbf{c})$, is in the interior of the unit cube $[0,1]^s$. Therefore, we have the following strong tractability result immediately following from Theorem 1.

THEOREM 3. *Let $p, q \in [1,\infty]$ and $\mathcal{F}^{(1)}_{p,q,\gamma,s}$ be defined as in section 2 for functions on the domain $D = \overline{(\mathbf{a},\mathbf{b})}$. Assume that $\{\mathbf{z}^j\}_{j\ge 0}$ is a Niederreiter $((T_u),s)$-sequence in base b, and $\{\mathbf{x}^j\}_{j\ge 0}$ is the transformed sequence according to the transformations in* (43)*. If*

$$\sum_{k=1}^{\infty} \gamma_k^a k \ln k < \infty$$

for any $a \in [1,q^*]$, then the corresponding integration is strongly tractable in the worst-case setting, and for any fixed $\epsilon > 0$, where C is some constant independent of s and n such that

$$e^{wo}(Q_n, \mathcal{F}^{(1)}_{p,q,\gamma,s}) \le C n^{-\frac{1}{a}+\epsilon}.$$

4.2. Randomized error analysis. Here we note that the assumption, $\|f\|_{p,q,\gamma,s} < \infty$, in the space $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ defined in section 3 might be too restrictive when D is unbounded. To alleviate this problem, we consider a modification following the approach from [HSW04b].

Consider a transformation of variables

$$\mathbf{y} = \boldsymbol{W}(\mathbf{x}) = (W_1(x_1),\ldots,W_s(x_s))^T,$$

where each W_k is a cumulative distribution function on interval (a_k,b_k) with density $w_k(x_k) = W_k'(x_k)$. Then integral $I_\rho(f) = \int_D f(\mathbf{x})\rho(\mathbf{x})d\mathbf{x}$ may be written as

$$\int_{[0,1]^s} g(\mathbf{y})d\mathbf{y}, \quad \text{where} \quad g(\mathbf{y}) = f(\boldsymbol{W}^{-1}(\mathbf{y}))\phi(\boldsymbol{W}^{-1}(\mathbf{y})), \tag{45}$$

$$\phi(\mathbf{x}) = \frac{\rho(\mathbf{x})}{w(\mathbf{x})}, \quad \text{and} \quad w(\mathbf{x}) = \prod_{k=1}^{s} w_k(x_k).$$

See [HSW04b] for a discussion about the necessity of introducing $w(\mathbf{x})$.

We now suppose that $\{\mathbf{z}^0, \dots, \mathbf{z}^{n-1}\}$ is a randomly scrambled digital net, and the integral of g in (45) is approximated by $n^{-1}\sum_{j=0}^{n-1} g(\mathbf{z}^j)$. This is equivalent to the rule

$$Q_n(f) = \frac{1}{n}\sum_{j=0}^{n-1} f(\boldsymbol{W}^{-1}(\mathbf{z}^j))\phi(\boldsymbol{W}^{-1}(\mathbf{z}^j)) \tag{46}$$

for $I_\rho(f)$. By Lemma 4 the error of this approximation has the following upper bound:

$$\sum_{\boldsymbol{\nu}:\|\lg(\boldsymbol{\nu})\|_1+T_{U(\boldsymbol{\nu})}>m} |G(\boldsymbol{\nu})|^2 3^{|U(\boldsymbol{\nu})|} b^{T_{U(\boldsymbol{\nu})}-m},$$

where the $G(\boldsymbol{\nu})$ are the Fourier coefficients of $g(\mathbf{y}) = f(\boldsymbol{W}^{-1}(\mathbf{y}))\phi(\boldsymbol{W}^{-1}(\mathbf{y}))$ under the Haar wavelets $\psi_{\boldsymbol{\nu}}$. In terms of $\xi_{\boldsymbol{\nu}}$ defined in (24) $G(\boldsymbol{\nu})$ can be expressed as

$$G(\boldsymbol{\nu}) = (-1)^{|U(\boldsymbol{\nu})|}\int_{S(\boldsymbol{\nu})} \xi_{\boldsymbol{\nu}}(\mathbf{y}) g'_{U(\boldsymbol{\nu})}(\mathbf{y})\,d\mathbf{y},$$

where $S(\boldsymbol{\nu})$ is the support of the wavelet $\psi_{\boldsymbol{\nu}}$, which is given in (21). Now for each nonempty subset $u \subseteq \{1, \dots, s\}$,

$$g'_u(\mathbf{y}) = \frac{1}{w_u(\boldsymbol{W}^{-1}(\mathbf{y}))}\left.\frac{\partial^{|u|}(f\phi)(\mathbf{x})}{\partial \mathbf{x}_u}\right|_{\mathbf{x}=\boldsymbol{W}^{-1}(\mathbf{y})},$$

where $f\phi$ just denotes the multiplication of the two functions, and $w_u(\mathbf{x}) = \prod_{k\in u} w_k(x_k)$. Applying Hölder's inequality yields the following:

$$\begin{aligned}|G(\boldsymbol{\nu})| \le{}& \left(\int_{S(\boldsymbol{\nu})} \left|\left.\frac{\partial^{|u|}(f\phi)(\mathbf{x})}{\partial \mathbf{x}_u}\right|_{\mathbf{x}=\boldsymbol{W}^{-1}(\mathbf{y})} \frac{1}{w_u(\boldsymbol{W}^{-1}(\mathbf{y}))}\right|^p d\mathbf{y}\right)^{\frac{1}{p}} \\ &\times \left(\int_{[0,1]^s} |\xi_{\boldsymbol{\nu}}(\mathbf{y})|^{p^*} d\mathbf{y}\right)^{\frac{1}{p^*}}.\end{aligned}$$

Define the norm

$$\|f\|_{p,q,\gamma,s,\rho,w} := \begin{cases} \left(\displaystyle\sum_{u\subseteq\{1,\dots,s\}} \gamma_u^{-q}\|(f\rho/w)'_u w_u^{-1}\|_{L_p}^q\right)^{\frac{1}{q}} & \text{for } q<\infty, \\ \displaystyle\max_{u\subseteq\{1,\dots,s\}} \left\{\gamma_u^{-1}\|(f\rho/w)'_u w_u^{-1}\|_{L_p}\right\} & \text{for } q=\infty. \end{cases} \tag{47}$$

Then we modify the space $\mathcal{F}^{(2)}_{p,q,\gamma,s}$ to $\mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}$, i.e., we let $\mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}$ be the weighted Banach space of all absolutely continuous functions f defined on D with $\|f\|_{p,q,\gamma,s,\rho,w} < \infty$. The randomized error is defined as

$$e^{\mathrm{ra}}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}) := \sup_{\|f\|_{p,q,\gamma,s,\rho,w}\le 1} \sqrt{E|I_\rho(f) - Q_n(f)|^2}.$$

From Theorem 2 we have the strong tractability results of integration over the general domain in the randomized setting.

THEOREM 4. *Consider the integration problem of approximating integral* (2) *by rule* (46) *with randomly scrambled Niederreiter digital nets in base b. Let* $\mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}$ *be defined as above.*

(i) *For* $p \in [1,\infty]$, *if*

$$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^2 < \infty,$$

then the corresponding integration is strongly tractable in the randomized setting, and for any fixed $\epsilon > 0$, *where* C *is some constant independent of* s *and* n *such that*

$$e^{ra}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}) \le C n^{-1+\epsilon}.$$

(ii) *In particular, for* $p \in [2,\infty]$, *if*

$$\sum_{k=1}^{\infty} \gamma_k^2 (k \ln k)^3 < \infty,$$

then the corresponding integration is strongly tractable in the randomized setting, and for any fixed $\epsilon > 0$, *where* C *is some constant independent of* s *and* n *such that*

$$e^{ra}(Q_n, \mathcal{F}^{(2)}_{p,q,\gamma,s,\rho,w}) \le C n^{-\frac{3}{2}+\epsilon}.$$

5. Concluding remarks. We have considered the strong tractability problems for multivariate integration using deterministic and randomly scrambled Niederreiter sequences. The spaces of integrands are weighted Banach spaces with parameters p, q, γ, s. The definitions of these spaces are slightly different in the worst-case and randomized settings. The main results of this article are summarized below.

Each of the conditions we found for strong tractability in worst-case and randomized settings is of the form $\sum_{k=1}^{\infty} \gamma_k^{\alpha} (k \ln k)^{\beta} < \infty$ for some positive numbers α and β. The values of α and β are determined by p or q. The larger α and smaller β imply weaker conditions of strong tractability. In the worst-case setting, the parameter p has little influence on the convergence rate of the worst-case error; however, the parameter q plays a significant role in determining strong tractability. In the randomized setting, only the parameter p plays a significant role in determining both strong tractability and convergence rate of the randomized error.

The factors $(k \ln k)^{\beta}$ in each term of the summation in the strong tractability conditions come from the quality parameter vector (T_u) of a Niederreiter sequence due to its telescopic property. These factors make the strong tractability conditions in this article slightly stronger than the conditions on integration using lattice rules. It is shown in [HSW04b, Theorem 3] that integration using lattice rules for the weighted Banach spaces is strongly tractable under the condition that $\sum_{k=1}^{\infty} \gamma_k^a < \infty$ for $a \in [1, q^*]$, and the convergence rate of the worst-case error is $O(n^{-1/a+\epsilon})$. We do not know yet whether integration using Niederreiter sequences is strongly tractable under the same condition as using lattice rules, but this is an interesting question worth pursuing.

The functions considered in this article depend on successive variables. We associate the first variable x_1 to the weight γ_1, the second variable x_2 to the weight γ_2, the variables $\mathbf{x}_u$ to the weights $\gamma_u = \prod_{k \in u} \gamma_k$, and so on. Although dimension-dependent weights are sometimes used in practice, we have some philosophical difficulties with

them. What this means is that a function that just depends on, say, the first five variables, could have its norm decrease as the nominal dimension, s, changes just because the weights change. On the other hand, weights not in product form are important; see, e.g., the work of [SWW04] and others on finite-order weights and tractability. We observe that each of the results in Theorems 1 to 4 holds for the Banach spaces of finite-order weights after a modification to the sufficient condition. This modification can be made according to the following lemma, compared with the proofs of Theorems 1 to 4.

LEMMA 6. *Let the finite-order weights $\{\gamma_{s,u}\}$ be of order d^*, i.e.,*

$$d^* = \min\{d : \gamma_{s,u} = 0 \quad \forall s \ \text{ and } \ \forall u \text{ with } |u| > d\}.$$

Let $\alpha, \beta, \theta > 0$ and $\tau \geq 1$. For the first n points of a Niederreiter $((T_u), s)$-sequence in base b, define

$$\Phi(\alpha, \beta, \theta, \tau) := \sum_{\emptyset \neq u \subseteq \{1,\dots,s\}, |u| \leq d^*} \gamma_{s,u}^{\alpha} b^{\beta T_u} (\theta \ln(\tau n))^{|u|}. \tag{48}$$

If the weights $\{\gamma_{s,u}\}$ satisfy

$$M_{\alpha,\beta} := \sup_{s=1,2,\cdots} \sum_{\emptyset \neq u \subseteq \{1,\dots,s\}, |u| \leq d^*} \gamma_{s,u}^{\alpha} \prod_{k \in u} [k \ln(k+b)]^{\beta} < \infty, \tag{49}$$

then for any fixed $\epsilon > 0$ there exists a constant C_ϵ independent of s and n such that

$$\Phi(\alpha, \beta, \theta, \tau) \leq C_\epsilon n^{\epsilon}.$$

Proof. From (6), (7), and (49) we have

$$\begin{aligned}
\Phi(\alpha, \beta, \theta, \tau) &\leq \sum_{\emptyset \neq u \subseteq \{1,\dots,s\}, |u| \leq d^*} \left(\tilde{\theta} \ln(\tau n)\right)^{|u|} \gamma_{s,u}^{\alpha} \prod_{k \in u} [k \ln(k+b)]^{\beta} \\
&= \sum_{r=1}^{d^*} \left(\tilde{\theta} \ln(\tau n)\right)^{r} \sum_{|u|=r} \gamma_{s,u}^{\alpha} \prod_{k \in u} [k \ln(k+b)]^{\beta} \leq M_{\alpha,\beta} \sum_{r=1}^{d^*} \left(\tilde{\theta} \ln(\tau n)\right)^{r},
\end{aligned}$$

where $\tilde{\theta} = \theta(b/\ln b)^{\beta}$. For any fixed $\epsilon > 0$ define

$$B_\epsilon = \max_{r=1,2,\dots,d^*} \left[r! (\tilde{\theta}/\epsilon)^r \right],$$

and we then have

$$\Phi(\alpha, \beta, \theta, \tau) \leq M_{\alpha,\beta} B_\epsilon \sum_{r=1}^{d^*} \frac{(\epsilon \ln(\tau n))^r}{r!} \leq M_{\alpha,\beta} B_\epsilon e^{\epsilon \ln(\tau n)} = C_\epsilon n^{\epsilon},$$

where $C_\epsilon = M B_\epsilon$. This completes the proof for the lemma. ∎

Therefore, we have the following modification:

1. For the Banach space, $\mathcal{F}_{p,q,\gamma,s}^{(1)}$, of finite-order weights $\gamma = \{\gamma_{s,u}\}$ with order d^*, condition (16) is modified by

$$M_{a,1} = \sup_{s=1,2,\cdots} \sum_{\emptyset \neq u \subseteq \{1,\dots,s\}, |u| \leq d^*} \gamma_{s,u}^{a} \prod_{k \in u} [k \ln(k+b)] < \infty.$$

2. For the Banach space, $\mathcal{F}^{(2)}_{p,q,\gamma,s}$, of finite-order weights $\gamma = \{\gamma_{s,u}\}$ with order d^*, conditions (34) and (36) are modified by

$$M_{2,2} = \sup_{s=1,2,\cdots} \sum_{\emptyset \neq u \subseteq \{1,\ldots,s\}, |u| \leq d^*} \gamma_{s,u}^2 \prod_{k \in u} [k \ln(k+b)]^2 < \infty$$

and

$$M_{2,3} = \sup_{s=1,2,\cdots} \sum_{\emptyset \neq u \subseteq \{1,\ldots,s\}, |u| \leq d^*} \gamma_{s,u}^2 \prod_{k \in u} [k \ln(k+b)]^3 < \infty,$$

respectively.

Appendix: Proof of Lemma 1. First we have

$$\sup_k \{\gamma_k^\beta k\} \leq \sum_{k=1}^\infty \gamma_k^\beta \quad \forall \beta > 0,$$

since for any integer $K > 0$

$$\sum_{k=1}^\infty \gamma_k^\beta \geq \sum_{k=1}^K \gamma_k^\beta \geq K \gamma_K^\beta.$$

Now for any $\delta, \delta' > 0$ applying the assumption on λ_k we have

$$\begin{aligned}\sum_{k=1}^\infty \gamma_k^a \lambda_k &\leq \sup_k \left\{ \gamma_k^{\frac{ar(1+\delta)}{1+r}} c_{r,\delta} k^{r+\delta'} \right\} \sum_{k=1}^\infty \gamma_k^{\frac{a(1-r\delta)}{1+r}} \\ &\leq \sum_{k=1}^\infty \gamma_k^a c_{r,\delta'} k^{r+\delta'} = \sum_{k=1}^\infty c_{r,\delta'} k^{r+\delta'} \gamma_k^{\frac{ar(1+\delta)}{1+r}} \gamma_k^{\frac{a(1-r\delta)}{1+r}}.\end{aligned}$$

We choose δ' such that $r + \delta' = r(1+\delta)/(1-r\delta)$, and then we have

$$\sup_k \left\{ \gamma_k^{\frac{ar(1+\delta)}{1+r}} k^{r+\delta'} \right\} = \left[\sup_k \gamma_k^{\frac{a(1-r\delta)}{1+r}} k \right]^{\frac{r(1+\delta)}{1-r\delta}} \leq \left[\sum_{k=1}^\infty \gamma_k^{\frac{a(1-r\delta)}{1+r}} \right]^{\frac{r(1+\delta)}{1-r\delta}}.$$

It follows that

$$\sum_{k=1}^\infty \gamma_k^a \lambda_k \leq c_{r,\delta'} \left[\sum_{k=1}^\infty \gamma_k^{\frac{a(1-r\delta)}{1+r}} \right]^{\frac{r(1+\delta)}{1-r\delta}+1},$$

which gives the right-hand side of the desired result.

As for the left-hand side of the desired result, we write for any $\delta > 0$

$$\sum_{k=1}^\infty \gamma_k^{\frac{a(1+\delta)}{1+r}} = \sum_{k=1}^\infty \gamma_k^{\frac{a(1+\delta)}{1+r}} k^{\frac{(r-\delta)(1+\delta)}{1+r}} k^{\frac{(\delta-r)(1+\delta)}{1+r}}.$$

Applying Hölder's inequality yields

$$\begin{aligned}\sum_{k=1}^\infty \gamma_k^{\frac{a(1+\delta)}{1+r}} &\leq \left[\sum_{k=1}^\infty \gamma_k^a k^{r-\delta} \right]^{\frac{1+\delta}{1+r}} \left[\sum_{k=1}^\infty k^{\frac{(1+\delta)(\delta-r)}{r-\delta}} \right]^{\frac{r-\delta}{1+r}} \\ &= \left[\sum_{k=1}^\infty \gamma_k^a k^{r-\delta} \right]^{\frac{1+\delta}{1+r}} \left[\sum_{k=1}^\infty k^{-(1+\delta)} \right]^{\frac{r-\delta}{1+r}}.\end{aligned}$$

Noting that $\sum_{k=1}^{\infty} k^{-(1+\delta)} < \infty$ and applying the assumption on λ_k again yields

$$\sum_{k=1}^{\infty} \gamma_k^{\frac{a(1+\delta)}{1+r}} \le \left[\sum_{k=1}^{\infty} \gamma_k^a \lambda_k\right]^{\frac{1+\delta}{1+r}} \hat{c}_{r,\delta},$$

which gives the left-hand side of the desired result. The proof of Lemma 1 is complete. □

LOCAL LINEARIZATION METHOD FOR NUMERICAL INTEGRATION OF DELAY DIFFERENTIAL EQUATIONS*

J. C. JIMENEZ†, L. M. PEDROSO†, F. CARBONELL†, AND V. HERNANDEZ†

Abstract. In this paper, a new approach for the numerical computation of delay differential equations (DDEs) is introduced. The essential idea consists of obtaining numerical integrators that use a code expressly developed for linear DDEs, in contrast with the conventional approach of using a code for ordinary differential equations. Specifically, two numerical schemes of this new class of integrators are proposed and their numerical viability analyzed. It includes the estimation of the convergence rate, the evaluation of the computational cost of the schemes, and a simulation study. It is proved that these one-step explicit integrators converge uniformly with order two to the solution of nonlinear DDEs and are able to integrate stiff equations in a satisfactory way with low computational cost.

Key words. delay differential equations, local linearization methods, numerical integrators

1. Introduction.

In recent years interest has increased in the numerical solution of delay differential equations (DDEs) with constant delay. Such interest was motivated by their applicability in the mathematical modeling of several physical, chemical, and biological processes, where they provide the best and sometimes the only realistic simulation of the observable phenomena [7, 17, 30].

There exists a variety of such numerical integrators, which essentially have two main ingredients [2]: (1) the emulation of the method of the steps in order to obtain piecewise ordinary differential equations (ODEs), and (2) the application of a variable step-size ODE code with a suitable approximation of the retarded solutions. Examples include the schemes proposed in [8, 21, 23, 25, 27, 33, 34, 41], which use several ODE codes (e.g., Euler, Runge–Kutta, multisteps, and local linearization (LL)) and several ways to approximate the retarded solutions (e.g., polynomial functions, θ-methods, continuous extensions of Runge–Kutta, and LL methods). Although the convergence and linear stability of these methods have been well studied, it is not the case of the preserving qualitative features of such methods [2]. It is well known [13, 39] that, in general, conventional numerical integrators for ODEs do not preserve the dynamical properties of the original ODEs. Therefore, it is expected that the numerical integrators for DDEs derived from the above-mentioned ODE codes do not preserve the dynamic properties of the original DDEs either.

It is also well known that for the stability analysis of ODEs, as well as for DDEs, there are two main techniques [2]: (1) the Lyapunov theory, and (2) the stability theory in first approximation. The latter, simpler one is based on the local linearization of the differential equations. This kind of linearization is also the main component of the so-called LL integrators for ODEs. In recent papers [26, 15], it has been shown that this type of scheme preserves the dynamical properties of the original equations

†Instituto de Cibernética Matemática y Físisca, Calle 15 No. 551 entre C y D, Vedado, La Habana 10400, Cuba (jcarlos@icmf.inf.cu, liuva@icmf.inf.cu, felix@icmf.inf.cu, vivky@icmf.inf.cu).

much better than the conventional numerical integrators. For instance, under quite general conditions, they do not have spurious equilibrium points and preserve the local stability of the exact solution at hyperbolic equilibrium points and periodic orbits. On the other hand, this linearization approach has been the key for the construction of efficient and stable numerical schemes for the integration and estimation of various classes of random dynamical systems (see [28, 29, 36, 37] and the references therein). Specifically, in the framework of stochastic and random differential equations, simulations studies have shown that the LL integrators have similar stability properties to the conventional implicit integrators with the computational efficiency of the explicit ones (see, for instance, [5, 10, 9]). In addition, in the framework of the nonlinear filtering problems the LL filters have similar features (see, for instance, [35]). In all cases, the piecewise linearization of the vector fields that define the differential equations to be integrated is the keystone in the construction of the LL integrators and, at the same time, the main difference with the conventional numerical integrators (which are typically derived from a primary expansion of the unknown solution in power series). Thus, the application of this LL approach for the integration of DDEs is also attractive.

The goal of this paper is to study the numerical viability of the LL approach for defining a new type of numerical integrators for DDEs, leaving the qualitative analysis of them for a future paper. The essential ideas of this approach are (1) approximate linearly the vector field of the DDE in order to obtain a piecewise linear DDE, and (2) compute the solution of such linear equations by the variation-of-constants formula with a suitable approximation of the retarded solutions.

The paper is organized as follow. In section 2, the LL method is introduced and two numerical schemes are proposed. In section 3, the convergence of the method is studied, while in the last section a simulation study is carried out in order to illustrate the performance of the method.

2. LL method. Let $\mathbf{f} : \mathbb{R} \times \mathbb{R}^m \times \mathbb{R}^m \longrightarrow \mathbb{R}^m$ be a differentiable function and let $\mathbf{x}(t)$ be the solution of the m-dimensional DDE

$$\frac{d\mathbf{x}(t)}{dt} = \mathbf{f}\left(t, \mathbf{x}(t), \mathbf{x}_t(-\tau)\right), \quad t \in [t_0, T], \tag{2.1}$$

$$\mathbf{x}_{t_0}(s) = \varphi(s), \quad s \in [-\tau, 0], \tag{2.2}$$

at the point $t \in [t_0 - \tau, T]$, where $\tau > 0$ is a constant delay, $\varphi : [-\tau, 0] \longrightarrow \mathbb{R}^m$ is a given initial function, and $\mathbf{x}_t : [-\tau, 0] \longrightarrow \mathbb{R}^m$ is the segment function defined as

$$\mathbf{x}_t(s) := \mathbf{x}(t+s), \quad s \in [-\tau, 0],$$

for all $t \in [t_0, T]$. Lipschitz and smoothness conditions on the function $\mathbf{f}$ are also assumed in order to ensure a unique solution for (2.1)–(2.2).

Let $(t)_h = \{t_0 < t_1 < \cdots < t_n < \cdots \leq T\}$ be a partition of the time interval $[t_0, T]$ such that

$$\sup_n (t_{n+1} - t_n) \leq h < 1, \tag{2.3}$$

and define

$$n_t := \max\{n = 0, 1, 2, \ldots, : t_n \leq t \text{ and } t_n \in (t)_h\}$$

for $t \in [t_0, T]$. Throughout this paper it will be assumed that condition $h < \tau$ holds.

Suppose that, for all $t_n \in (t)_h$, $\mathbf{y}_n \in \mathbb{R}^m$ is a point close to $\mathbf{x}(t_n)$. For all $t \in [t_0, T]$, let $\widetilde{\mathbf{y}}_t : [-\tau, 0] \longrightarrow \mathbb{R}^m$ be a segment function that approximates to $\mathbf{x}_t$, such that $\widetilde{\mathbf{y}}_{t_n}(0) = \mathbf{y}_n$ for all $t_n \in (t)_h$.

In addition, let us consider the first order Taylor expansion of the function $\mathbf{f}$ around the point $(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))$,

$$\begin{aligned}\mathbf{f}(s, \mathbf{u}, \mathbf{v}) \approx \mathbf{f}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau)) + \mathbf{f}_x(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))(\mathbf{u} - \mathbf{y}_n) \\ + \mathbf{f}_{x_t}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))(\mathbf{v} - \widetilde{\mathbf{y}}_{t_n}(-\tau)) + \mathbf{f}_t(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))(s - t_n)\end{aligned}$$

for $s \in \mathbb{R}$ and $\mathbf{u}, \mathbf{v} \in \mathbb{R}^m$, where $\mathbf{f}_x$, $\mathbf{f}_{x_t}$, and $\mathbf{f}_t$ denote the partial derivatives of $\mathbf{f}$ with respect to the variables $\mathbf{x}$, $\mathbf{x}_t$, and t, respectively. Taking into account that $\mathbf{f}$ can be linearly approximated by its first order Taylor expansion, the solution of (2.1)–(2.2) can be locally approximated on each interval $[t_n, t_{n+1})$ by the solution of the linear DDE

$$\begin{aligned}\frac{d\mathbf{z}(t)}{dt} &= \mathbf{A}_n\mathbf{z}(t) + \mathbf{B}_n\mathbf{z}_t(-\tau) + \mathbf{c}_n t - \mathbf{c}_n t_n + \mathbf{d}_n \\ &\quad -\mathbf{A}_n\mathbf{y}_n - \mathbf{B}_n\widetilde{\mathbf{y}}_{t_n}(-\tau),\ t \in [t_n, t_{n+1}), \\ \mathbf{z}_{t_n}(s) &= \widetilde{\mathbf{y}}_{t_n}(s), \quad s \in [-\tau, 0],\end{aligned} \tag{2.4}$$

which is given by [20]

$$\begin{aligned}\mathbf{z}(t) = e^{\mathbf{A}_n(t-t_n)}\Big\{\mathbf{y}_n + \int_0^{t-t_n} e^{-\mathbf{A}_n u}(\mathbf{B}_n(\widetilde{\mathbf{y}}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(-\tau)) + \mathbf{c}_n u + \mathbf{d}_n \\ - \mathbf{A}_n\mathbf{y}_n)du\Big\},\end{aligned} \tag{2.5}$$

where $\mathbf{A}_n = \mathbf{f}_x(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))$, $\mathbf{B}_n = \mathbf{f}_{x_t}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))$ are constant matrices, $\mathbf{c}_n = \mathbf{f}_t(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))$, $\mathbf{d}_n = \mathbf{f}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}_{t_n}(-\tau))$ are constant vectors, and $t_n, t_{n+1} \in (t)_h$. Further, by using the identity

$$\int_0^{\Delta} e^{-\mathbf{A}_n u}du\ \mathbf{A}_n = -(e^{-\mathbf{A}_n\Delta} - \mathbf{I}), \qquad \Delta \geq 0, \tag{2.6}$$

and simple rules from the integral calculus, the above expression can be conveniently rewritten as

$$\mathbf{z}(t) = \mathbf{y}_n + \Phi(t_n, \mathbf{y}_n, t - t_n; \widetilde{\mathbf{y}}_{t_n}), \tag{2.7}$$

where

$$\begin{aligned}\Phi(t_n, \mathbf{y}_n, t - t_n; \widetilde{\mathbf{y}}_{t_n}) = \int_0^{t-t_n} e^{\mathbf{A}_n(t-t_n-u)}(\mathbf{B}_n(\widetilde{\mathbf{y}}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(-\tau)) + \mathbf{d}_n)du \\ + \int_0^{t-t_n}\int_0^{u} e^{\mathbf{A}_n(t-t_n-u)}\mathbf{c}_n dr du.\end{aligned} \tag{2.8}$$

In this way, by setting $\mathbf{y}_0 = \mathbf{x}(t_0)$ and iteratively evaluating the expression (2.7) at t_{n+1} (for $n = 0, 1, \dots$) a sequence of points

$$\mathbf{y}_{n+1} = \mathbf{y}_n + \Phi(t_n, \mathbf{y}_n, t_{n+1} - t_n; \widetilde{\mathbf{y}}_{t_n})$$

can be obtained as an approximation to the solution $\mathbf{x}$ of (2.1)–(2.2) at each point $t_{n+1} \in (t)_h$. This just defines the local linear discretization of a DDE. More precisely, we have the following definition.

DEFINITION 2.1. *For a time discretization $(t)_h$, the local linear discretization of the solution of* (2.1)–(2.2) *at each point $t_{n+1} \in (t)_h$ is defined by the recursive expression*

$$\mathbf{y}_{n+1} = \mathbf{y}_n + \Phi(t_n, \mathbf{y}_n, t_{n+1} - t_n; \widetilde{\mathbf{y}}_{t_n}), \tag{2.9}$$

where $\widetilde{\mathbf{y}}_{t_n} : [-\tau, 0] \longrightarrow \mathbb{R}^m$ is a segment function that approximate to $\mathbf{x}_{t_n}$, such that $\widetilde{\mathbf{y}}_{t_n}(0) = \mathbf{y}_n$.

Moreover, an approximation for $\mathbf{x}$ in the whole interval $[t_0 - \tau, T]$ is stated in the definition below.

DEFINITION 2.2. *For a time discretization $(t)_h$, the local linear approximation of the solution of* (2.1)–(2.2) *is defined by the function*

$$\mathbf{y}(t) = \mathbf{y}_{n_t} + \Phi(t_{n_t}, \mathbf{y}_{n_t}, t - t_{n_t}; \widetilde{\mathbf{y}}_{t_{n_t}}) \tag{2.10}$$

for all $t \in [t_0, T]$ and by

$$\mathbf{y}(t) = \varphi(t)$$

for $t \in [t_0 - \tau, t_0]$. Here, $\mathbf{y}_{n_t}$ denotes the LL discretization (2.9) *at n_t, and $\widetilde{\mathbf{y}}_{t_{n_t}}$ is the segment function of Definition* 2.1.

In addition, for $t \in [t_0, T]$, let $\mathbf{y}_t : [-\tau, 0] \longrightarrow \mathbb{R}^m$ be the segment function defined as

$$\mathbf{y}_t(s) := \mathbf{y}(t + s),\ s \in [-\tau, 0],$$

where $\mathbf{y}(t + s)$ is the LL approximation (2.10) evaluated at the point $t + s$.

It is clear that the LL approximation is a continuous function that coincides with the LL discretization at each point of the time discretization $(t)_h$.

As can be noted from the definition, to compute the LL discretization at the time t_{n+1}, a suitable approximation $\widetilde{\mathbf{y}}_{t_n}$ to $\mathbf{x}_{t_n}$ is assumed to be given. Based on the choice of such an approximation, different kinds of LL schemes could be defined. In the following subsections, two LL schemes will be introduced.

2.1. Natural LL scheme. Let us consider the numerical scheme that is defined in a natural way by taking $\widetilde{\mathbf{y}}_t(s)$ as the LL approximation $\mathbf{y}_t(s)$ for all $s \in [-\tau, 0]$ and $t + s \in [t_0, T]$. Specifically, the scheme shall be defined through the expression (2.9) with $\widetilde{\mathbf{y}}_{t_n} \equiv \mathbf{y}_{t_n}$ for all $t_n \in (t)_h \setminus t_0$, and $\widetilde{\mathbf{y}}_{t_0}(s) \equiv \widetilde{\varphi}(s)$ for all $s \in [-\tau, 0]$, where $\widetilde{\varphi}$ is an approximation to φ that shall be defined below.

In this subsection, and only here, it is assumed that the points in the time discretization $(t)_h$ are equidistant, i.e., $t_{n+1} - t_n = h = \frac{\tau}{N_0}$, for a fixed $N_0 \in \mathbb{N}_+$.

Consider the times t_n, $n = 0, \ldots, N_0$, for which $t_0 \le t_n \le t_0 + \tau$, and denote $s_n = t_n - \tau$. Suppose that in the interval $[s_n, s_{n+1}]$, the initial function φ in (2.2) can be exponentially approximated by the function

$$\widetilde{\varphi}(s_n + u) = \varphi(s_n) + \mathbf{L} e^{\mathbf{T}_n u} \mathbf{R}, \quad u \in [0, h], \tag{2.11}$$

where $\mathbf{T}_n$, $\mathbf{L}$, and $\mathbf{R}$ are certain constant matrices such that $\mathbf{L} e^{\mathbf{T}_n u} \mathbf{R} \in \mathbb{R}^m$. For instance, when $\varphi(s_n + u)$ is approximated by the interpolating polynomial $\sum_{i=0}^{p} \alpha_{i,n} u^i$

these matrices can be chosen as

$$\mathbf{T}_n = \begin{pmatrix} \mathbf{0}_{m\times m} & p!\alpha_{p,n} & (p-1)!\alpha_{p-1,n} & \cdots & 2\alpha_{2,n} & \alpha_{1,n} \\ 0 & 0 & 1 & \cdots & 0 & 0 \\ 0 & 0 & 0 & \ddots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \ddots & 1 & 0 \\ 0 & 0 & \cdots & 0 & 0 & 1 \\ 0 & 0 & \cdots & 0 & 0 & 0 \end{pmatrix} \in \mathbb{R}^{(m+p)\times(m+p)},$$

$\mathbf{L} = (\mathbf{I}_m, \mathbf{0}_{m\times p})$, and $\mathbf{R}^\intercal = (\mathbf{0}_{1\times m+p-1}, 1)$, where the coefficients $\alpha_{i,n}$ are obtained from interpolating conditions. The statement above is straightforwardly derived from Lemma 6.1 in the appendix and the expression

$$\sum_{i=0}^{p} \alpha_{i,n} u^i = \alpha_{0,n} + \int_0^u \alpha_{1,n} ds + \sum_{i=2}^{p} i!\alpha_{i,n} \int_0^u \int_0^{s_1} \cdots \int_0^{s_{i-1}} ds_i ds_{i-1} \ldots ds_1, \tag{2.12}$$

with $\alpha_{0,n} = \varphi(s_n)$.

Taking into account that $\widetilde{\mathbf{y}}_{t_n}(u-\tau) = \widetilde{\varphi}(s_n + u)$ it follows that

$$\Phi(t_n, \mathbf{y}_n, h; \widetilde{\mathbf{y}}_{t_n}) = \int_0^h e^{\mathbf{A}_n(h-u)}(\mathbf{B}_n\mathbf{L}e^{\mathbf{T}_n u}\mathbf{R} + \mathbf{d}_n)du + \int_0^h \int_0^u e^{\mathbf{A}_n(h-u)}\mathbf{c}_n dr du,$$

which, by (2.6), can be rewritten as

$$\begin{aligned}\Phi(t_n, \mathbf{y}_n, h; \widetilde{\mathbf{y}}_{t_n}) = &\int_0^h \int_0^u e^{\mathbf{A}_n(h-u)}\mathbf{B}_n\mathbf{L}e^{\mathbf{T}_n r}\mathbf{T}_n\mathbf{R}dr du + \int_0^h e^{\mathbf{A}_n(h-u)}\mathbf{B}_n\mathbf{L}\mathbf{R}du \\ &+ \int_0^h e^{\mathbf{A}_n(h-u)}\mathbf{d}_n du + \int_0^h \int_0^u e^{\mathbf{A}_n(h-u)}\mathbf{c}_n dr du.\end{aligned}$$

Now, since $\mathbf{L}\mathbf{R} = \mathbf{0}_{m\times 1}$, by Lemma 6.1 it is obtained that

$$\Phi(t_n, \mathbf{y}_n, h; \widetilde{\mathbf{y}}_{t_n}) = \mathbf{L}_0 e^{\mathbf{T}_{0,n}h}\mathbf{R}_0,$$

where

$$\mathbf{T}_{0,n} = \begin{pmatrix} \mathbf{A}_n & \mathbf{B}_n\mathbf{L} & \mathbf{c}_n & \mathbf{d}_n \\ 0 & \mathbf{T}_n & 0 & \mathbf{T}_n\mathbf{R} \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad t_n \in [t_0, t_0+\tau],$$

$\mathbf{L}_0 = (\mathbf{I}_m, \mathbf{0}_{m\times m+p+2})$, and $\mathbf{R}_0^\intercal = (\mathbf{0}_{1\times 2m+p+1}, 1)$. Therefore, for $t_0 \le t_n \le t_0+\tau$, the expression

$$\mathbf{y}_{n+1} = \mathbf{y}_n + \mathbf{L}_0 e^{\mathbf{T}_{0,n}h}\mathbf{R}_0, \quad n = 0, \ldots, N_0 - 1,$$

defines an LL discretization, while the expression

$$\mathbf{y}(t) = \mathbf{y}_{n_t} + \mathbf{L}_0 e^{\mathbf{T}_{0,n}(t-t_{n_t})}\mathbf{R}_0, \quad n = 0, \ldots, N_0 - 1, \tag{2.13}$$

defines an LL approximation for all $t \in [t_0, t_0+\tau]$.

Taking into account the analogy between the expressions (2.13) and (2.11), the procedure above can be used to extend the LL approximation to $t_0+\tau \le t_n \le t_0+2\tau$,

and so on. In this way, for $t_0 + k\tau \le t_n \le t_0 + (k+1)\,\tau$ with $k = 1, 2, \ldots,$ we obtain the expression

$$\mathbf{y}_{n+1} = \mathbf{y}_n + \mathbf{L}_k e^{\mathbf{T}_{k,n} h} \mathbf{R}_k, \quad n = kN_0, \ldots, (k+1)N_0 - 1,$$

which defines the natural LL scheme. Here, the matrices $\mathbf{T}_{k,n}$, $\mathbf{L}_k$, and $\mathbf{R}_k$ are recursively defined by

$$\mathbf{T}_{k,n} = \begin{pmatrix} \mathbf{A}_n & \mathbf{B}_n\mathbf{L}_{k-1} & \mathbf{c}_n & \mathbf{d}_n \\ 0 & \mathbf{T}_{k-1,n} & 0 & \mathbf{T}_{k-1,n}\mathbf{R}_{k-1} \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad t_n \in [t_0 + k\tau, t_0 + (k+1)\tau],$$

$\mathbf{L}_k = (\mathbf{L}_{k-1}, \mathbf{0}_{m+2})$, and $\mathbf{R}_k^\intercal = (\mathbf{0}_{1\times m+2}, \mathbf{R}_{k-1}^\intercal)$.

Note that the natural LL scheme produces the exact solution of linear DDEs with polynomial or exponential initial condition. Thus, obviously, the numerical solution provided by it preserves the stability properties of linear DDEs. However, observe also that the dimension of the matrices $\mathbf{T}_{k,n}$ increases with k, which increases the computational cost of the scheme when $\tau \ll T$. In this case, the use of Krylov subspace methods [22] to compute these high dimensional exponential matrices are highly recommended in order to reduce the computational cost of the natural LL scheme.

2.2. Polynomial LL scheme. Let us consider a piecewise polynomial approximation $\widetilde{\mathbf{y}}_{t_n}(s)$ to $\mathbf{y}_{t_n}(s)$ for all $s \in [-\tau, 0]$ defined in such a way that $\widetilde{\mathbf{y}}_{t_n}(0) = \mathbf{y}_{t_n}(0)$ and

$$\widetilde{\mathbf{y}}_{t_n}(u - \tau) = \alpha_{0,n} + \sum_{i=1}^{p} \alpha_{i,n} u^i, \quad u \in [0, h_n], \tag{2.14}$$

where the coefficients $\alpha_{i,n}$ are obtained from either interpolating or smoothness conditions, $h_n = t_{n+1} - t_n$ and $t_{n+1}, t_n \in (t)_h$.[1] By taking into account the integral representation (2.12) for polynomials and that $\widetilde{\mathbf{y}}_{t_n}(-\tau) = \alpha_{0,n}$, the function Φ can be rewritten as

$$\begin{aligned}\Phi(t_n, \mathbf{y}_n, h_n; \widetilde{\mathbf{y}}_{t_n}) = &\int_0^{h_n} e^{\mathbf{A}_n(h_n - u)} \mathbf{d}_n du + \int_0^{h_n}\int_0^{u} e^{\mathbf{A}_n(h_n-u)} \left(\mathbf{c}_n + \mathbf{B}_n\alpha_{1,n}\right) ds du \\ &+ \sum_{i=2}^{p} (i!\alpha_{i,n}) \int_0^{h_n}\int_0^{u}\int_0^{s_1} \cdots \int_0^{s_{i-1}} e^{\mathbf{A}_n(h_n-u)} \mathbf{B}_n ds_i ds_{i-1} \ldots ds_1 du.\end{aligned}$$

Then, from Lemma 6.1 it follows that

$$\Phi(t_n, \mathbf{y}_{t_n}, h_n; \widetilde{\mathbf{y}}_{t_n}) = \mathbf{L} e^{\mathbf{T}_n h_n} \mathbf{R},$$

where $\mathbf{T}_n \in \mathbb{R}^{(m+p+1)\times(m+p+1)}$ is given by

$$\mathbf{T}_n = \begin{pmatrix} \mathbf{A}_n & p!\mathbf{B}_n\alpha_{p,n} & (p-1)!\mathbf{B}_n\alpha_{p-1,n} & \cdots & 2\mathbf{B}_n\alpha_{2,n} & \mathbf{c}_n + \mathbf{B}_n\alpha_{1,n} & \mathbf{d}_n \\ 0 & 0 & 1 & \cdots & 0 & 0 & 0 \\ 0 & 0 & 0 & \ddots & \vdots & \vdots & \vdots \\ \vdots & \vdots & \vdots & \ddots & 1 & 0 & 0 \\ 0 & 0 & 0 & \cdots & 0 & 1 & 0 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 1 \\ 0 & 0 & 0 & \cdots & 0 & 0 & 0 \end{pmatrix},$$

[1] Note that no specification for the piecewise polynomial $\widetilde{\mathbf{y}}_{t_n}$ is given for $s \in (h_{n+1} - \tau, 0)$.

$\mathbf{L} = (\mathbf{I}_m, \mathbf{0}_{m\times p+1})$, and $\mathbf{R}^\intercal = (\mathbf{0}_{1\times m+p}, 1)$. Therefore, for all $t_n \in (t)_h$, the expression

$$\mathbf{y}_{n+1} = \mathbf{y}_n + \mathbf{L}e^{\mathbf{T}_n h_n}\mathbf{R} \tag{2.15}$$

defines the polynomial LL scheme.

Note that, in contrast to the natural LL scheme, the polynomial LL scheme is defined in terms of a matrix exponential of fixed dimension for all t_n. Therefore, this scheme is computationally feasible and its numerical implementation is reduced to using a convenient algorithm to compute matrix exponentials, e.g., those based on rational Padé approximations [18], the Schur decomposition [18], or Krylov subspace methods [22] (for a recent review see [38]). The selection of one of them will mainly depend on the size and structure of the matrices $\mathbf{T}_n$. For instance, for many low-dimensional systems of equations it is enough to use the algorithm developed in [40], which takes advantage of the special structure of the matrices $\mathbf{T}_n$, whereas for large systems of equations the Krylov subspace methods are strongly recommended.

2.3. LL schemes for equations with multiple delays. Let $\mathbf{f} : \mathbb{R} \times \prod_{i=1}^{d+1} \mathbb{R}^m \longrightarrow \mathbb{R}^m$ be a differentiable function. Consider the m-dimensional DDE with d constant delays defined by

$$\begin{aligned} &\frac{d\mathbf{x}(t)}{dt} = \mathbf{f}\left(t, \mathbf{x}(t), \mathbf{x}_t(-\tau_1), \ldots, \mathbf{x}_t(-\tau_d)\right), \quad t \in [t_0, T], \\ &\mathbf{x}_{t_o}(s) = \varphi(s), \quad s \in [-\tau, 0], \end{aligned}$$

where $\varphi : [-\tau, 0] \longrightarrow \mathbb{R}^m$ is a given initial function with $\tau = \max_{i=1,\ldots,d}\{\tau_i\}$, and $\tau_i > 0$, $i = 1, \ldots, d$, are constant delays. $\mathbf{x}_t$ is a segment function defined as at the beginning of section 2.

By following the same ideas of the previous subsections, the definitions of the LL discretization and LL approximation are easily extended to equations with multiple delays. In this case, the expressions (2.9) and (2.10) are also obtained but with Φ defined by the form

$$\begin{aligned} \Phi(t_n, \mathbf{y}_n, h_n; \widetilde{\mathbf{y}}^1_{t_n}, \ldots, \widetilde{\mathbf{y}}^d_{t_n}) = &\int_0^{h_n} e^{\mathbf{A}_n(h_n-u)}\left(\sum_{i=1}^{d}\mathbf{B}^i_n(\widetilde{\mathbf{y}}^i_{t_n}(u-\tau_i) - \widetilde{\mathbf{y}}^i_{t_n}(-\tau_i)) + \mathbf{d}_n\right)du \\ &+ \int_0^{h_n}\int_0^{u} e^{\mathbf{A}_n(h_n-u)}\mathbf{c}_n dr du, \end{aligned} \tag{2.16}$$

where $\widetilde{\mathbf{y}}^i_{t_n} : [-\tau_i, 0] \longrightarrow \mathbb{R}^m$ is the segment function defined by

$$\widetilde{\mathbf{y}}^i_{t_n}(s) := \widetilde{\mathbf{y}}^i(t_n + s), \quad s \in [-\tau_i, 0],$$

and $\widetilde{\mathbf{y}}^i : [t_n - \tau_i, t_n] \longrightarrow \mathbb{R}^m$ is a suitable approximation to $\mathbf{x}(t)$ for all $t \in [t_n - \tau_i, t_n]$ such that $\widetilde{\mathbf{y}}^i(t_n) = \mathbf{y}_n$. In expression (2.16), $t_n, t_{n+1} \in (t)_h$, $h_n = t_{n+1} - t_n$,

$$\mathbf{A}_n = \mathbf{f}_x(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}^1_{t_n}(-\tau_1), \ldots, \widetilde{\mathbf{y}}^d_{t_n}(-\tau_d)),\ \mathbf{B}^i_n = \mathbf{f}_{x_t(-\tau_i)}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}^1_{t_n}(-\tau_1), \ldots, \widetilde{\mathbf{y}}^d_{t_n}(-\tau_d))$$

are constant matrices and

$$\mathbf{c}_n = \mathbf{f}_t(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}^1_{t_n}(-\tau_1), \ldots, \widetilde{\mathbf{y}}^d_{t_n}(-\tau_d)), \quad \mathbf{d}_n = \mathbf{f}(t_n, \mathbf{y}_n, \widetilde{\mathbf{y}}^1_{t_n}(-\tau_1), \ldots, \widetilde{\mathbf{y}}^d_{t_n}(-\tau_d))$$

are constant vectors. $\mathbf{f}_t$, $\mathbf{f}_x$, and $\mathbf{f}_{x_t(-\tau_i)}$ denote, respectively, the partial derivatives of $\mathbf{f}$ with respect to the variables t, $\mathbf{x}$, and $\mathbf{x}_t(-\tau_i)$.

In this way, the LL schemes proposed in the subsections above are easily extended to DDEs with multiple delays.

3. Convergence analysis. For the sake of simplicity, in this section it is assumed that there is a single delay. Suppose also that the initial function φ in (2.2) satisfies the boundedness and Lipschitz conditions

$$\sup_{-\tau\le s\le 0}\|\varphi(s)\|\le M_0 \tag{3.1}$$

and

$$\|\varphi(s_2)-\varphi(s_1)\|\le M_1(s_2-s_1) \tag{3.2}$$

for $-\tau\le s_1\le s_2\le 0$; and the function $\mathbf{f}$ in (2.1) and its first partial derivatives satisfy the Lipschitz conditions

$$\|\mathbf{f}(t,\mathbf{u}_1,\mathbf{v}_1)-\mathbf{f}(t,\mathbf{u}_2,\mathbf{v}_2)\|\le\lambda_0(\|\mathbf{u}_1-\mathbf{u}_2\|+\|\mathbf{v}_1-\mathbf{v}_2\|), \tag{3.3}$$

$$\|\mathbf{f}_{\mathbf{x}}(t,\mathbf{u}_1,\mathbf{v}_1)-\mathbf{f}_{\mathbf{x}}(t,\mathbf{u}_2,\mathbf{v}_2)\|\le\lambda_1(\|\mathbf{u}_1-\mathbf{u}_2\|+\|\mathbf{v}_1-\mathbf{v}_2\|), \tag{3.4}$$

$$\|\mathbf{f}_{\mathbf{x}_t}(t,\mathbf{u}_1,\mathbf{v}_1)-\mathbf{f}_{\mathbf{x}_t}(t,\mathbf{u}_2,\mathbf{v}_2)\|\le\lambda_2(\|\mathbf{u}_1-\mathbf{u}_2\|+\|\mathbf{v}_1-\mathbf{v}_2\|), \tag{3.5}$$

$$\|\mathbf{f}_t(t,\mathbf{u}_1,\mathbf{v}_1)-\mathbf{f}_t(t,\mathbf{u}_2,\mathbf{v}_2)\|\le\lambda_3(\|\mathbf{u}_1-\mathbf{u}_2\|+\|\mathbf{v}_1-\mathbf{v}_2\|) \tag{3.6}$$

for all $\mathbf{u}_1,\mathbf{u}_2,\mathbf{v}_1,\mathbf{v}_2\in\mathbb{R}^m$, $t\in\mathbb{R}$. Further, suppose that $\mathbf{f}$ and its first and second partial derivatives satisfy the linear growth and boundedness conditions

$$\|\mathbf{f}(t,\mathbf{u},\mathbf{v})\|+\|\mathbf{f}_t(t,\mathbf{u},\mathbf{v})\|\le K_0(1+\|\mathbf{u}\|+\|\mathbf{v}\|), \tag{3.7}$$

$$\|\mathbf{f}_{\mathbf{x}}(t,\mathbf{u},\mathbf{v})\|+\|\mathbf{f}_{\mathbf{x}_t}(t,\mathbf{u},\mathbf{v})\|\le K_1, \tag{3.8}$$

and

$$\begin{aligned}&\|f_{\mathbf{xx}}(t,\mathbf{u},\mathbf{v})\|+\|f_{\mathbf{xx}_t}(t,\mathbf{u},\mathbf{v})\|+\|f_{\mathbf{x}_t\mathbf{x}_t}(t,\mathbf{u},\mathbf{v})\|\\&+\|f_{tt}(t,\mathbf{u},\mathbf{v})\|+\|f_{t\mathbf{x}}(t,\mathbf{u},\mathbf{v})\|+\|f_{t\mathbf{x}_t}(t,\mathbf{u},\mathbf{v})\|\le K_2\end{aligned} \tag{3.9}$$

for all $\mathbf{u},\mathbf{v}\in\mathbb{R}^m$, $t\in\mathbb{R}$.

3.1. Local truncation error. In this subsection, the local truncation error of the LL discretization shall be derived. With that proposal the next two lemmas shall be used. The first one establishes a uniform bound and Lipschitz condition for the solution of the DDE, whereas the second one states a Lipschitz-type condition for the function Φ with respect to its second and fourth arguments.

LEMMA 3.1. *Assuming that conditions* (3.1), (3.2), *and* (3.7) *hold, there exist positive constants* C_0 *and* C_1 *such that*

$$\sup_{t_0-\tau\le t\le T}\|\mathbf{x}(t)\|\le C_0 \tag{3.10}$$

and

$$\|\mathbf{x}(s_2)-\mathbf{x}(s_1)\|\le C_1(s_2-s_1) \tag{3.11}$$

hold for $t_0-\tau\le s_1\le s_2\le T$, *where* $\mathbf{x}$ *is the solution of* (2.1)–(2.2).

Proof. From the integral form of (2.1)–(2.2) it follows that

$$\|\mathbf{x}(t)\|\le\|\varphi(0)\|+\int_{t_0}^{t}\|\mathbf{f}\left(s,\mathbf{x}\left(s\right),\mathbf{x}_s(-\tau)\right)\|\,ds,\quad t\ge t_0,$$

which by conditions (3.1) and (3.7) leads to

$$\|\mathbf{x}(t)\| \leq M_0 + \int_{t_0}^{t} K_0(1 + \|\mathbf{x}(s)\| + \|\mathbf{x}_s(-\tau)\|)ds.$$

Hence

$$\sup_{t_0-\tau\leq u\leq t} \|\mathbf{x}(u)\| \leq M_0 + \int_{t_0}^{t} K_0\left(1 + 2\sup_{t_0-\tau\leq u\leq s} \|\mathbf{x}(u)\|\right)ds,$$

and (3.10) follows from the Gronwall inequality.

On the other hand, for $t_0 - \tau \leq s_1 \leq s_2 \leq t_0$ inequality (3.11) follows from condition (3.2), whereas for $t_0 \leq s_1 \leq s_2 \leq T$ we obtain

$$\begin{aligned}\|\mathbf{x}(s_2) - \mathbf{x}(s_1)\| &\leq \int_{s_1}^{s_2} \|\mathbf{f}(s, \mathbf{x}(s), \mathbf{x}_s(-\tau))\| ds \\ &\leq (s_2 - s_1)K_0\left(1 + \sup_{s_1\leq s\leq s_2} (\|\mathbf{x}(s)\| + \|\mathbf{x}_s(-\tau)\|)\right),\end{aligned}$$

which by (3.10) gives

$$\|\mathbf{x}(s_2) - \mathbf{x}(s_1)\| \leq K_0(1 + 2C_0)(s_2 - s_1),$$

and so we conclude the proof. □

LEMMA 3.2. *Let $t_n, t_{n+1} \in (t)_h$ and $h_n = t_{n+1} - t_n$. Under conditions* (3.1)–(3.8)*, there exists a positive constant P such that*

$$\begin{aligned}&\|\Phi(t_n, \mathbf{v}, h_n; \mathbf{z}_{t_n}) - \Phi(t_n, \mathbf{x}(t_n), h_n; \mathbf{x}_{t_n})\| \\ &\quad\leq h_n P\left(\|\mathbf{v} - \mathbf{x}(t_n)\| + \sup_{s\in[0,h_n]} \|\mathbf{z}_{t_n}(s-\tau) - \mathbf{x}_{t_n}(s-\tau)\|\right),\end{aligned}$$

where $\mathbf{x}$ is the solution of (2.1)–(2.2)*, Φ is defined as in* (2.8)*, $\mathbf{v} \in \mathbb{R}^m$,$\mathbf{z}_{t_n} : [-\tau, 0] \longrightarrow \mathbb{R}^m$ is a segment function defined as*

$$\mathbf{z}_{t_n}(s) := \mathbf{z}(t_n + s),\ \ s \in [-\tau, 0],$$

and $\mathbf{z} : [t_n - \tau, t_n] \longrightarrow \mathbb{R}^m$ is a function.

Proof. Define

$$R_n := \Phi(t_n, \mathbf{v}, h_n; \mathbf{z}_{t_n}) - \Phi(t_n, \mathbf{x}(t_n), h_n; \mathbf{x}_{t_n}),$$

which in turn can be written as

$$\begin{aligned}R_n = &\int_0^{h_n} e^{\mathbf{A}_n(h_n-u)}(\mathbf{B}_n(\mathbf{z}_{t_n}(u-\tau) - \mathbf{z}_{t_n}(-\tau)) + u\mathbf{c}_n + \mathbf{d}_n)du \\ &- \int_0^{h_n} e^{\overline{\mathbf{A}}_n(h_n-u)}(\overline{\mathbf{B}}_n(\mathbf{x}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(-\tau)) + u\overline{\mathbf{c}}_n + \overline{\mathbf{d}}_n)du,\end{aligned}$$

where $\mathbf{A}_n = \mathbf{f}_{\mathbf{x}}(t_n, \mathbf{v}, \mathbf{z}_{t_n}(-\tau))$, $\mathbf{B}_n = \mathbf{f}_{\mathbf{x}_t}(t_n, \mathbf{v}, \mathbf{z}_{t_n}(-\tau))$, $\overline{\mathbf{A}}_n = \mathbf{f}_{\mathbf{x}}(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$, $\overline{\mathbf{B}}_n = \mathbf{f}_{\mathbf{x}_t}(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$ are constant matrices and $\mathbf{c}_n = \mathbf{f}_t(t_n, \mathbf{v}, \mathbf{z}_{t_n}(-\tau))$, $\mathbf{d}_n = \mathbf{f}(t_n, \mathbf{v}, \mathbf{z}_{t_n}(-\tau))$, $\overline{\mathbf{c}}_n = \mathbf{f}_t(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$, $\overline{\mathbf{d}}_n = \mathbf{f}(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$ are constant vectors.

By using Lemma 6.3 in the appendix we obtain

$$\begin{aligned}\|R_n\| \leq & \int_0^{h_n} \left\| e^{\mathbf{A}_n(h_n-u)} - e^{\overline{\mathbf{A}}_n(h_n-u)} \right\| \left(\left\| \overline{\mathbf{B}}_n \right\| \|\mathbf{x}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(-\tau)\| + u \|\overline{\mathbf{c}}_n\| + \left\| \overline{\mathbf{d}}_n \right\| \right) du \\ & + \int_0^{h_n} \left\| e^{\mathbf{A}_n(h_n-u)} \right\| \left(\left\| \mathbf{B}_n \mathbf{z}_{t_n}(-\tau) - \overline{\mathbf{B}}_n \mathbf{x}_{t_n}(-\tau) \right\| + u \|\mathbf{c}_n - \overline{\mathbf{c}}_n\| + \left\| \mathbf{d}_n - \overline{\mathbf{d}}_n \right\| \right. \\ & \left. + \left\| \mathbf{B}_n \mathbf{z}_{t_n}(u-\tau) - \overline{\mathbf{B}}_n \mathbf{x}_{t_n}(u-\tau) \right\| \right) du.\end{aligned}$$

From the finite increments inequality, conditions (3.8), (3.4), and constraint (2.3) it is follows that

$$\begin{aligned}\left\| e^{\mathbf{A}_n(h_n-u)} - e^{\overline{\mathbf{A}}_n(h_n-u)} \right\| &\leq e^{K_1 h_n} h_n \left\| \mathbf{A}_n - \overline{\mathbf{A}}_n \right\| \\ &\leq e^{K_1} \lambda_1 h_n \Gamma_n,\end{aligned}$$

where

$$\Gamma_n = \|\mathbf{v} - \mathbf{x}(t_n)\| + \sup_{u \in [0,h_n]} \|\mathbf{z}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(u-\tau)\|.$$

In addition, from Lemmas 6.3 and 3.1 and conditions (3.5) and (3.8) it is follows that

$$\begin{aligned}\left\| \mathbf{B}_n \mathbf{z}_{t_n}(u-\tau) - \overline{\mathbf{B}}_n \mathbf{x}_{t_n}(u-\tau) \right\| &\leq \|\mathbf{B}_n\| \|\mathbf{z}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(u-\tau)\| \\ &\quad + \left\| \mathbf{B}_n - \overline{\mathbf{B}}_n \right\| \|\mathbf{x}_{t_n}(u-\tau)\| \\ &\leq (K_1 + \lambda_2 C_0)\, \Gamma_n\end{aligned}$$

for all $u \in [0, h_n]$. By using the two previous inequalities, Lemma 3.1, and conditions (3.3), (3.6), (3.7), and (3.8) we obtain

$$\begin{aligned}\|R_n\| &\leq \Gamma_n \int_0^{h_n} e^{K_1} \lambda_1 h_n (2K_1 C_0 + K_0(1+2C_0)u + K_0(1+2C_0)) du \\ &\quad + \Gamma_n \int_0^{h_n} e^{K_1} (2(K_1 + \lambda_2 C_0) + \lambda_0 + \lambda_3 u) du \\ &\leq h_n P\, \Gamma_n,\end{aligned}$$

where $P = 2e^{K_1}\lambda_1 (K_1 C_0 + K_0(1+2C_0)) + e^{K_1}(2(K_1 + \lambda_2 C_0) + \lambda_0 + \lambda_3)$. Constraint (2.3) has also been used to obtain P. □

Let us denote by L_{n+1} the local truncation error of the LL discretization at t_{n+1}, i.e.,

$$L_{n+1} = \|\mathbf{x}(t_{n+1}) - \mathbf{x}(t_n) - \Phi(t_n, \mathbf{x}(t_n), h_n; \widetilde{\mathbf{y}}_{t_n})\|, \tag{3.12}$$

where $t_n, t_{n+1} \in (t)_h$, $h_n = t_{n+1} - t_n$, $\mathbf{x}$ is the solution of (2.1)–(2.2), and $\Phi, \widetilde{\mathbf{y}}_{t_n}$ are defined as in Definition 2.1.

THEOREM 3.3. *Suppose that conditions* (3.1)–(3.9) *hold. Then*

$$L_{n+1} \leq L h_n^3 + P h_n \sup_{s \in [0,h_n]} \|\widetilde{\mathbf{y}}_{t_n}(s-\tau) - \mathbf{x}_{t_n}(s-\tau)\|,$$

where L and P are positive constants.

Proof. Let $\mathbf{u}$ and $\mathbf{v}$ be the solutions of the nonautonomous ODEs

$$\begin{aligned} \frac{d\mathbf{u}(t)}{dt} &= \mathbf{f}(t, \mathbf{u}(t), \mathbf{x}_t(-\tau)), \quad t \in [t_n, t_{n+1}], \\ \mathbf{u}(t_n) &= \mathbf{x}(t_n), \end{aligned} \tag{3.13}$$

and

$$\begin{aligned} \frac{d\mathbf{v}(t)}{dt} &= \mathbf{g}(t, \mathbf{v}(t), \mathbf{x}_t(-\tau)), \quad t \in [t_n, t_{n+1}], \\ \mathbf{v}(t_n) &= \mathbf{x}(t_n), \end{aligned}$$

respectively, where function $\mathbf{g}$ is the first order Taylor expansion of the function $\mathbf{f}$ around the point $(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$. That is,

$$\mathbf{g}(t, \mathbf{v}(t), \mathbf{x}_t(-\tau)) = \mathbf{A}_n \left(\mathbf{v}\left(t\right) - \mathbf{x}\left(t_n\right)\right) + \mathbf{B}_n \left(\mathbf{x}_t\left(-\tau\right) - \mathbf{x}_{t_n}\left(-\tau\right)\right) + \mathbf{c}_n(t - t_n) + \mathbf{d}_n,$$

where $\mathbf{A}_n = \mathbf{f}_{\mathbf{x}}(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$, $\mathbf{B}_n = \mathbf{f}_{\mathbf{x}_t}(t_n, \mathbf{x}\left(t_n\right), \mathbf{x}_{t_n}\left(-\tau\right))$ are constant matrices and $\mathbf{c}_n = \mathbf{f}_t(t_n, \mathbf{x}\left(t_n\right), \mathbf{x}_{t_n}\left(-\tau\right))$, $\mathbf{d}_n = \mathbf{f}(t_n, \mathbf{x}(t_n), \mathbf{x}_{t_n}(-\tau))$ are constant vectors. In addition, let

$$\begin{aligned} \varepsilon &:= \sup_{t \in [t_n, t_{n+1}]} \left\| \frac{d\mathbf{v}(t)}{dt} - \mathbf{f}(t, \mathbf{v}(t), \mathbf{x}_t(-\tau)) \right\| \\ &= \sup_{t \in [t_n, t_{n+1}]} \left\| \mathbf{g}(t, \mathbf{v}(t), \mathbf{x}_t(-\tau)) - \mathbf{f}(t, \mathbf{v}(t), \mathbf{x}_t(-\tau)) \right\|. \end{aligned} \tag{3.14}$$

By applying the Taylor formulae with Lagrange remainder for functions defined on a Banach space [12] and condition (3.9) we obtain

$$\varepsilon \leq \frac{3}{2} K_2 \sup_{t \in [t_n, t_{n+1}]} (\|t - t_n\|^2 + \|\mathbf{v}(t) - \mathbf{v}\left(t_n\right)\|^2 + \|\mathbf{x}_t(-\tau) - \mathbf{x}_{t_n}(-\tau)\|^2).$$

Moreover, by using Lemma 3.1, conditions (3.7)–(3.8), and constraint (2.3) we obtain

$$\begin{aligned} \|\mathbf{v}(t) - \mathbf{v}\left(t_n\right)\| &= \|\Phi(t_n, \mathbf{v}\left(t_n\right), t - t_n; \mathbf{x}_{t_n})\| \\ &\leq \int_0^{t-t_n} \left\| e^{\mathbf{A}_n(t-t_n-u)} \right\| (\|\mathbf{d}_n\| + \|\mathbf{c}_n\| u) du \\ &\quad + \int_0^{t-t_n} \left\| e^{\mathbf{A}_n(t-t_n-u)} \right\| \|\mathbf{B}_n\| \, \|\mathbf{x}_{t_n}\left(u - \tau\right) - \mathbf{x}_{t_n}\left(-\tau\right)\| \, du \\ &\leq C_2 h_n, \end{aligned}$$

where $C_2 = 2e^{K_1}(K_0(1 + 2C_0) + K_1 C_0)$. However, Lemma 3.1 also implies that

$$\|\mathbf{x}_t(-\tau) - \mathbf{x}_{t_n}(-\tau)\| \leq C_1 h_n.$$

Therefore,

$$\varepsilon \leq \frac{3}{2} K_2 (1 + C_2^2 + C_1^2) h_n^2.$$

Now, by applying Lemma 6.2 to the functions $\mathbf{u}$ and $\mathbf{v}$ (i.e., by using (3.13) and (3.14) for the first and second differential inequality in that lemma, respectively) it is obtained that

$$\|\mathbf{u}(t) - \mathbf{v}(t)\| \leq \frac{\varepsilon}{\lambda_0} (e^{\lambda_0 (t - t_n)} - 1)$$

for $t \in [t_n, t_{n+1}]$. Moreover, from the mean value theorem it follows that

$$(e^{\lambda_0(t-t_n)} - 1) \leq \lambda_0 e^{\lambda_0(t-t_n)}(t - t_n),$$

which implies that

$$\|\mathbf{u}(t) - \mathbf{v}(t)\| \leq \varepsilon e^{\lambda_0(t-t_n)}(t - t_n).$$

Taking into account that $\mathbf{u} \equiv \mathbf{x}$ in $[t_n, t_{n+1}]$ and that

$$\mathbf{v}(t) \equiv \mathbf{x}(t_n) + \Phi\left(t_n, \mathbf{x}\left(t_n\right), t - t_n; \mathbf{x}_{t_n}\right)$$

we obtain

$$\begin{aligned} l_{n+1} &= \|\mathbf{x}\left(t_{n+1}\right) - \mathbf{x}\left(t_n\right) - \Phi(t_n, \mathbf{x}\left(t_n\right), h_n; \mathbf{x}_{t_n})\| \\ &\leq L h_n^3, \end{aligned}$$

with $L = \frac{3}{2}K_2(1 + C_2^2 + C_1^2)e^{\lambda_0}$. Constraint (2.3) has been again used to obtain L.

The proof is completed by applying Lemma 3.2 to the second term of the inequality

$$L_{n+1} \leq l_{n+1} + \|\Phi(t_n, \mathbf{x}\left(t_n\right), h_n; \widetilde{\mathbf{y}}_{t_n}) - \Phi(t_n, \mathbf{x}\left(t_n\right), h_n; \mathbf{x}_{t_n})\|. \qquad \square$$

3.2. Uniform convergence. The main result of this subsection is stated in the following theorem.

THEOREM 3.4. *For $t \in [t_0, T]$, let $\mathbf{y}_t : [-\tau, 0] \longrightarrow \mathbb{R}^m$ be the segment function defined as*

$$\mathbf{y}_t(s) := \mathbf{y}(t + s), \quad s \in [-\tau, 0],$$

where $\mathbf{y}(t + s)$ is the LL approximation of the DDE (2.1)–(2.2) at the point $t + s$. Further, let $\widetilde{\mathbf{y}}_{t_n} : [-\tau, 0] \longrightarrow \mathbb{R}^m$ be a segment function defined as

$$\widetilde{\mathbf{y}}_{t_n}(s) := \widetilde{\mathbf{y}}(t_n + s), \quad s \in [-\tau, 0],$$

where $\widetilde{\mathbf{y}}(t_n + s)$ is an approximation of $\mathbf{y}(t_n + s)$ such that

$$\sup_{u \in [0, h_n]} \|\mathbf{y}_{t_n}(u - \tau) - \widetilde{\mathbf{y}}_{t_n}(u - \tau)\| \leq C_r h_n^r \tag{3.15}$$

and $\widetilde{\mathbf{y}}_{t_n}(0) = \mathbf{y}(t_n)$ for all $t_n \in (t)_h$, with $C_r > 0$ and $r \in \mathbb{N}_+$. Then, under conditions (3.1)–(3.9), there exists a positive constant M such that

$$\|\mathbf{x}\left(t\right) - \mathbf{y}\left(t\right)\| \leq M h^{\min\{2,r\}}$$

for every $t \in [t_0 - \tau, T]$, where $\mathbf{x}$ is the solution of (2.1)–(2.2).

Proof. Suppose that the numerical integration has reached t_n and let E_n be a uniform bound on $\|\mathbf{x}\left(t\right) - \mathbf{y}\left(t\right)\|$ for every $t \in [t_0 - \tau, t_n]$.

By definition of LL approximation

$$\begin{aligned} \mathbf{x}\left(t\right) - \mathbf{y}\left(t\right) = \mathbf{x}(t) - \mathbf{y}\left(t_n\right) - \Phi(t_n, \mathbf{y}\left(t_n\right), t - t_n; \widetilde{\mathbf{y}}_{t_n}) + \mathbf{x}(t_n) - \mathbf{x}\left(t_n\right) \\ + \Phi(t_n, \mathbf{x}\left(t_n\right), t - t_n; \widetilde{\mathbf{y}}_{t_n}) - \Phi(t_n, \mathbf{x}\left(t_n\right), t - t_n; \widetilde{\mathbf{y}}_{t_n}) \end{aligned}$$

for $t \in [t_n, t_{n+1}]$, and thus

$$\|\mathbf{x}(t) - \mathbf{y}(t)\| \leq \|\mathbf{x}(t_n) - \mathbf{y}(t_n)\| + L_{n+1} + R_{n+1}, \tag{3.16}$$

where L_{n+1} denotes the local truncation error (3.12) and

$$R_{n+1} = \|\Phi(t_n, \mathbf{x}(t_n), t - t_n; \widetilde{\mathbf{y}}_{t_n}) - \Phi(t_n, \mathbf{y}(t_n), t - t_n; \widetilde{\mathbf{y}}_{t_n})\|.$$

Taking into account that

$$\begin{aligned} \sup_{u\in[0,h_n]} \|\widetilde{\mathbf{y}}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(u-\tau)\| &\leq \sup_{u\in[0,h_n]} \|\mathbf{x}_{t_n}(u-\tau) - \mathbf{y}_{t_n}(u-\tau)\| \\ &\quad + \sup_{u\in[0,h_n]} \|\mathbf{y}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(u-\tau)\| \\ &\leq E_n + C_r h_n^r \end{aligned} \tag{3.17}$$

we obtain

$$L_{n+1} \leq L h_n^3 + h_n P\,(E_n + C_r h_n^r) \tag{3.18}$$

and

$$\begin{aligned} R_{n+1} &\leq \|\Phi(t_n, \mathbf{x}(t_n), t - t_n; \widetilde{\mathbf{y}}_{t_n}) - \Phi(t_n, \mathbf{x}(t_n), t - t_n; \mathbf{x}_{t_n})\| \\ &\quad + \|\Phi(t_n, \mathbf{x}(t_n), t - t_n; \mathbf{x}_{t_n}) - \Phi(t_n, \mathbf{y}(t_n), t - t_n; \widetilde{\mathbf{y}}_{t_n})\| \\ &\leq h_n P \left\{ \|\mathbf{x}(t_n) - \mathbf{y}(t_n)\| + 2 \sup_{u\in[0,h_n]} \|\widetilde{\mathbf{y}}_{t_n}(u-\tau) - \mathbf{x}_{t_n}(u-\tau)\| \right\} \\ &\leq h_n P(3E_n + 2C_r h_n^r) \end{aligned} \tag{3.19}$$

for $t \in [t_n, t_{n+1}]$. Here, (3.15), Theorem 3.3, and Lemma 3.2 were used to derive (3.17), (3.18), and (3.19).

Thus, from (3.16), (3.18), and (3.19) and constraint (2.3) we obtain

$$\|\mathbf{x}(t) - \mathbf{y}(t)\| \leq (1 + hP_1)\, E_n + L_1 h^{\min\{3, r+1\}},$$

where $P_1 = 4P$ and $L_1 = L + 3PC_r$. Note that this expression gives an error bound for all $t \in [t_n, t_{n+1}]$. Therefore, by definition of E_n, that bound also holds for $t \in [t_0, t_n]$. Thus,

$$E_{n+1} \leq (1 + hP_1)\, E_n + L_1 h^{\min\{3, r+1\}}.$$

Finally, by induction, the last inequality implies that

$$\begin{aligned} E_{n+1} &\leq \frac{((1 + hP_1)^{n+1} - 1)}{hP_1}\; L_1 h^{\min\{3, r+1\}} \\ &\leq M\; h^{\min\{2, r\}}, \end{aligned}$$

where $M = L_1(e^{P_1(T-t_0)} - 1)/P_1$. This completes the proof. □

Thus, we are ready to analyze the convergence rate of the two LL schemes introduced in the previous section. Denote by $\mathcal{C}^r[-\tau, 0]$ the class of functions on $[-\tau, 0]$ with continuous derivatives up to order r, and by $\overline{\mathcal{C}}^r[-\tau, 0]$ the class of functions with continuous r-derivatives everywhere in $[-\tau, 0]$ except at a finite number of points.

For the natural LL scheme it is obvious that $\max_{u\in[0,h_n]} \|\mathbf{y}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(u-\tau)\| = 0$ for all $t_n \in (t)_h$ whenever the initial condition φ is either a piecewise polynomial or an exponential function. However, if $\varphi \in \mathcal{C}^r[-\tau, 0]$, the function φ can be approximated by a piecewise interpolating polynomial of order r and so condition (3.15) holds for all $t_n \in (t)_h \cap [t_0, t_0+\tau]$, and $\max_{u\in[0,h_n]} \|\mathbf{y}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(u-\tau)\| = 0$ for all $t_n \in (t)_h \cap [t_0+\tau, T]$. Thus, in the first case the order of convergence of the natural LL scheme is two, while in the second case it is $\min\{2, r\}$.

However, for the polynomial LL schemes, the convergence analysis is not so simple. Note that the first derivative of the LL approximation $\mathbf{y}$ satisfies (2.4) for each $t \in [t_n, t_{n+1})$, and thus its rth derivative is not continuous at all of the points $t_n \in (t)_h$ for all $r \in \mathbb{N}_+$. That is, $\mathbf{y}_t \in \overline{\mathcal{C}}^r[-\tau, 0]$. Therefore, the conventional results from the approximation theory are not straightforward applicable and additional results are needed. For example, the next theorem deals with the case of interpolating polynomials for $\mathbf{y}$.

THEOREM 3.5. *Let $\widetilde{\mathbf{y}}$ be the order r polynomial that interpolate $\mathbf{y}$ in r points s_i on $[t_n-\tau, t_{n+1}-\tau]$ for each $t_n \in (t)_h$. Then*

$$\sup_{u\in[0,h_n]} \|\mathbf{y}_{t_n}(u-\tau) - \widetilde{\mathbf{y}}_{t_n}(u-\tau)\| \le C_{r,n} h_n^r,$$

where

$$C_{r,n} = D_r \left(1 + \sup_{u\in[0,h_n]} \|\lambda_r(u+t_n-\tau)\|\right) \sup_{u\in[0,h_n]} \left\| \frac{d^r \mathbf{y}_{t_n}}{ds^r}(u-\tau) \right\|.$$

Here, $\lambda_r(t) = \sum_{i=1}^r |\prod_{j\neq i}(t-s_j)/\prod_{j\neq i}(s_i-s_j)|$ is the well-known Lebesgue function [14], *$\frac{d^r \mathbf{y}_{t_n}}{ds^r}(u-\tau)$ denotes the rth derivative of $\mathbf{y}_{t_n}$ evaluated at $(u-\tau)$, and D_r is a positive constant depending only on r.*

Proof. Let $\mathcal{P}_r$ be the space of polynomials of order r on $[t_n-\tau, t_{n+1}-\tau]$. Then, by Theorem XII.5 in [14] for the polynomial approximation of functions with continuous derivatives on a bounded interval except at a finite number of points, there exists $\mathbf{p} \in \mathcal{P}_r$ such that

$$\|\mathbf{y}-\mathbf{p}\|_\infty \le D_r \left\| \frac{d^r \mathbf{y}}{dt^r} \right\|_\infty (t_{n+1}-t_n)^r, \tag{3.20}$$

where $\|.\|_\infty$ denotes the uniform norm on $[t_n-\tau, t_{n+1}-\tau]$ and D_r is a positive constant depending only on r.

Let $I_r\mathbf{y}(t)$ be an order r polynomial that interpolates $\mathbf{y}$ in r points s_i on $[t_n-\tau, t_{n+1}-\tau]$. Taking into account the Lagrange form

$$I_r\mathbf{y}(t) = \sum_{i=1}^r \mathbf{y}(s_i) l_i(t), \text{ with } l_i(t) = \prod_{j\neq i}(t-s_j)/\prod_{j\neq i}(s_i-s_j)$$

of that polynomial, it is follows that

$$\|I_r\mathbf{y}\|_\infty \le \|\mathbf{y}\|_\infty \|\lambda_r\|_\infty, \tag{3.21}$$

where $\lambda_r(t) = \sum_{i=1}^r |l_i(t)|$ is the Lebesgue function.

Now, by taking into account that $I_r\mathbf{p} = \mathbf{p}$ for all $\mathbf{p} \in \mathcal{P}_r$, and using the inequalities (3.20) and (3.21) we obtain

$$\begin{aligned} \|\mathbf{y} - I_r\mathbf{y}\|_\infty &\le \|\mathbf{y}-\mathbf{p}\|_\infty + \|I_r(\mathbf{p}-\mathbf{y})\|_\infty \\ &\le (1+\|\lambda_r\|_\infty)\|\mathbf{p}-\mathbf{y}\|_\infty \\ &\le C_{r,n} h_n^r. \end{aligned}$$

The proof is completed by noting that $\widetilde{\mathbf{y}} \equiv I_r \mathbf{y}$. ∎

In this way, if $C_{r,n}$ were bounded for all n, Theorems 3.4 and 3.5 would imply the order of convergence $\min\{2, r\}$ for the interpolating polynomial LL schemes. Accordingly, the polynomial LL scheme (2.15) with linear interpolation would provide the best performance with respect to the trade-off between convergence rate and computational cost. For this kind of LL approximation, the next theorem states an upper bound for its second derivative in such a way that condition (3.15) in Theorem 3.4 holds for $r = 2$.

THEOREM 3.6. *For all $t_n \in (t)_h$, let*

$$\widetilde{\mathbf{y}}_{t_n}(u - \tau) = \alpha_{0,n} + \alpha_{1,n} u, \quad \text{with } u \in [0, h_n],$$

be a piecewise linear interpolant of $\mathbf{y}$, where $\alpha_{0,n} = \mathbf{y}_{t_n}(-\tau)$ and $\alpha_{1,n} = (\mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau))/h_n$. Then

$$\sup_{u \in [0, h_n]} \|\lambda_2(u + t_n - \tau)\| = 1,$$

and, under conditions (3.7)–(3.8)*, we obtain*

$$\sup_{u \in [0, h_n]} \left\| \frac{d^2 \mathbf{y}_{t_n}}{ds^2}(u - \tau) \right\| \leq M,$$

where M is a constant independent of n.

Proof. By definition

$$\begin{aligned} \lambda_2(u + t_n - \tau) &= \left| \frac{u + t_n - t_{n+1}}{t_n - t_{n+1}} \right| + \left| \frac{u}{t_{n+1} - t_n} \right| \\ &= \frac{t_{n+1} - t_n - u}{t_{n+1} - t_n} + \frac{u}{t_{n+1} - t_n} \\ &= 1 \end{aligned}$$

for $u \in [0, h_n]$, which implies the first assertion of the theorem.

To prove the second one, the boundedness and Lipschitz condition for the LL approximation $\mathbf{y}$ shall be derived first and afterward bounds for the first and second derivatives of $\mathbf{y}$.

From the definition of LL approximation

$$\mathbf{y}(t) = \mathbf{y}(t_0) + \sum_{n=0}^{n_t - 1} \Phi(t_n, \mathbf{y}_n, h_n; \widetilde{\mathbf{y}}_{t_n}) + \Phi(t_{n_t}, \mathbf{y}_{n_t}, t - t_{n_t}; \widetilde{\mathbf{y}}_{t_{n_t}}),$$

where

$$\Phi(t_n, \mathbf{y}_n, t - t_n; \widetilde{\mathbf{y}}_{t_n}) = \int_0^{t - t_n} e^{\mathbf{A}_n (t - t_n - u)} \left(\mathbf{B}_n (\mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau)) \frac{u}{h_n} + \mathbf{d}_n + \mathbf{c}_n u \right) du$$

with $\mathbf{A}_n = \mathbf{f}_x(t_n, \mathbf{y}_n, \mathbf{y}_{t_n}(-\tau))$, $\mathbf{B}_n = \mathbf{f}_{x_t}(t_n, \mathbf{y}_n, \mathbf{y}_{t_n}(-\tau))$, $\mathbf{c}_n = \mathbf{f}_t(t_n, \mathbf{y}_n, \mathbf{y}_{t_n}(-\tau))$, and $\mathbf{d}_n = \mathbf{f}(t_n, \mathbf{y}_n, \mathbf{y}_{t_n}(-\tau))$ for all $t_n \in (t)_h$.

Now, by using conditions (3.7)–(3.8) and constraint (2.3) it follows that

$$\begin{aligned}
R_n(t) &= \|\Phi(t_n, \mathbf{y}_n, t-t_n; \widetilde{\mathbf{y}}_{t_n})\| \\
&\leq \int_0^{t-t_n} \left\| e^{\mathbf{A}_n(t-t_n-u)} \right\| \left(\|\mathbf{B}_n\| \left\| \mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau) \right\| \left\| \frac{u}{h_n} \right\| + \|\mathbf{d}_n\| + \|\mathbf{c}_n\| u \right) du \\
&\leq e^{K_1} K_1 \int_0^{t-t_n} \left\| \mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau) \right\| du \\
&\quad + e^{K_1} K_0 \int_0^{t-t_n} (1 + \|\mathbf{y}_n\| + \|\mathbf{y}_{t_n}(-\tau)\|)(1+u) du \\
&\leq 2e^{K_1} K_1 \int_{t_n}^{t} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du \\
&\quad + (1+h_n) e^{K_1} K_0 \int_{t_n}^{t} \left(1 + 2 \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \right) du. \qquad (3.22)
\end{aligned}$$

In this way,

$$\begin{aligned}
\|\mathbf{y}(t)\| &\leq \|\mathbf{y}(t_0)\| + \sum_{n=0}^{n_t-1} R_n(h_n) + R_{n_t}(t-t_{n_t}) \\
&\leq \|\mathbf{y}(t_0)\| + 2e^{K_1} \sum_{n=0}^{n_t-1} \left(K_1 \int_{t_n}^{t_{n+1}} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du \right. \\
&\quad \left. + K_0 \int_{t_n}^{t_{n+1}} (1 + 2 \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\|) du \right) + 2e^{K_1} \left(K_1 \int_{t_{n_t}}^{t} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du \right. \\
&\quad \left. + K_0 \int_{t_{n_t}}^{t} (1 + 2 \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\|) du \right) \\
&\leq \|\mathbf{y}(t_0)\| + 2e^{K_1} \left(K_1 \int_{t_0}^{t} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du + K_0 \int_{t_0}^{t} (1 + 2 \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\|) du \right) \\
&\leq M_1 + M_2 \int_{t_0}^{t} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du,
\end{aligned}$$

where $M_1 = \|\mathbf{y}(t_0)\| + 2e^{K_1} K_0 (T - t_0)$ and $M_2 = 2e^{K_1}(K_1 + 2K_0)$. Therefore

$$\sup_{t_0-\tau \leq s \leq t} \|\mathbf{y}(s)\| \leq M_1 + M_2 \int_{t_0}^{t} \sup_{t_0-\tau \leq s \leq u} \|\mathbf{y}(s)\| \, du.$$

Now, by applying the Gronwall inequality we obtain

$$\sup_{t_0-\tau \leq t \leq T} \|\mathbf{y}(t)\| \leq M_3, \qquad (3.23)$$

where $M_3 = M_1 M_2 e^{M_2(T-t_0)}$ is a positive constant.

Let $s_2 = t_{n_{s_2}} + \Delta_2$ and $s_1 = t_{n_{s_1}} + \Delta_1$ be two points in $[t_0, T]$ such that $s_2 \geq s_1$. Thus,

$$\begin{aligned}\mathbf{y}(s_2) - \mathbf{y}(s_1) = {} & \Phi(t_{n_{s_1}}, \mathbf{y}_{n_{s_1}}, h_{n_{s_1}}; \widetilde{\mathbf{y}}_{t_{n_{s_1}}}) - \Phi(t_{n_{s_1}}, \mathbf{y}_{n_{s_1}}, \Delta_1; \widetilde{\mathbf{y}}_{t_{n_{s_1}}}) \\ & + \sum_{n=n_{s_1}+1}^{n_{s_2}-1} \Phi(t_n, \mathbf{y}_n, h_n; \widetilde{\mathbf{y}}_{t_n}) + \Phi(t_{n_{s_2}}, \mathbf{y}_{n_{s_2}}, \Delta_2; \widetilde{\mathbf{y}}_{t_{n_{s_2}}}).\end{aligned}$$

From (3.22) it is straightforward to obtain

$$\|\Phi(t_n, \mathbf{y}_n, h_n; \widetilde{\mathbf{y}}_{t_n})\| = M_4 h_n,$$

where $M_4 = 2e^{K_1}(K_1 M_3 + K_0(1 + 2M_3))$, while the inequality

$$\left\|\Phi(t_{n_{s_1}}, \mathbf{y}_{n_{s_1}}, h_{n_{s_1}}; \widetilde{\mathbf{y}}_{t_{n_{s_1}}}) - \Phi(t_{n_{s_1}}, \mathbf{y}_{n_{s_1}}, \Delta_1; \widetilde{\mathbf{y}}_{t_{n_{s_1}}})\right\| \leq M_4(h_{n_{s_1}} - \Delta_1)$$

can be derived by following the same steps used to obtain (3.22). Then

$$\begin{aligned}\|\mathbf{y}(s_2) - \mathbf{y}(s_1)\| &\leq M_4 \left(h_{n_{s_1}} - \Delta_1 + \sum_{n=n_{s_1}+1}^{n_{s_2}-1} h_n + \Delta_2 \right) \\ &\leq M_4 \left(t_{n_{s_1}+1} - t_{n_{s_1}} - \Delta_1 + \sum_{n=n_{s_1}+1}^{n_{s_2}-1} (t_{n+1} - t_n) + s_2 - t_{n_{s_2}} \right) \\ &\leq M_4(s_2 - s_1). \qquad (3.24)\end{aligned}$$

By definition, for each $t_n \in (t)_h$, the LL approximation $\mathbf{y}$ satisfies the linear DDE (2.4), which can be written in terms of the nonautonomous ODE

$$\begin{aligned}\frac{d\mathbf{z}\,(t)}{dt} &= \mathbf{g}^n(t, \mathbf{z}(t)), \quad t \in [t_n, t_{n+1}), \qquad (3.25) \\ \mathbf{z}(t_n) &= \widetilde{\mathbf{y}}_{t_n}(0),\end{aligned}$$

where

$$\begin{aligned}\mathbf{g}^n(t, \mathbf{z}(t)) = {} & \mathbf{A}_n \mathbf{z}(t) + \mathbf{B}_n(\mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau)) \frac{(t - t_n)}{h_n} \\ & + \mathbf{c}_n(t - t_n) + \mathbf{d}_n - \mathbf{A}_n \mathbf{y}_n.\end{aligned}$$

Hence,

$$\begin{aligned}\left\|\frac{d\mathbf{z}\,(t)}{dt}\right\| &= \|\mathbf{g}^n(t, \mathbf{z}(t))\| \\ &\leq 2(\|\mathbf{A}_n\| + \|\mathbf{B}_n\|) \sup_{t_0 - \tau \leq t \leq T} \|\mathbf{y}\,(t)\| + \|\mathbf{c}_n h_n + \mathbf{d}_n\|\end{aligned}$$

for all $t \in [t_n, t_{n+1})$. However, from conditions (3.7)–(3.8) and constraint (2.3) it is

obtained that

$$\begin{aligned}\|\mathbf{c}_n h_n + \mathbf{d}_n\| &\leq (1+h_n)K_0\Big(1+2\sup_{t_0-\tau\leq t\leq T}\|\mathbf{y}\,(t)\|\Big)\\ &\leq 2K_0(1+2M_3)\end{aligned}$$

and $\|\mathbf{A}_n\|+\|\mathbf{B}_n\| \leq K_1$. Thus, by taking into account that $\mathbf{z}(t) \equiv \mathbf{y}(t)$ for $t \in [t_n, t_{n+1})$ and $t_n, t_{n+1} \in (t)_h$, it is obtained that

$$\sup_{t_n\leq t\leq t_{n+1}}\left\|\frac{d\mathbf{y}\,(t)}{dt}\right\| \leq M_5, \tag{3.26}$$

where $M_5 = 2K_1M_3 + 2K_0(1+2M_3)$ is a positive constant independent of n.

Now, by taking the derivative in (3.25) we obtain

$$\frac{d^2\mathbf{z}\,(t)}{dt^2} = \mathbf{g}_t^n(t,\mathbf{z}(t)) + \mathbf{g}_{\mathbf{z}}^n(t,\mathbf{z}(t))\frac{d\mathbf{z}\,(t)}{dt},$$

where $\mathbf{g}_t^n$ and $\mathbf{g}_{\mathbf{z}}^n$ denote the partial derivatives of $\mathbf{g}^n$ with respect to t and $\mathbf{z}$, respectively. Thus,

$$\left\|\frac{d^2\mathbf{z}\,(t)}{dt^2}\right\| \leq \|\mathbf{g}_t^n(t,\mathbf{z}(t))\| + \|\mathbf{g}_{\mathbf{z}}^n(t,\mathbf{z}(t))\|\left\|\frac{d\mathbf{z}\,(t)}{dt}\right\| \tag{3.27}$$

for $t \in [t_n, t_{n+1})$. From conditions (3.7)–(3.8) and (3.23)–(3.24) it follows that

$$\begin{aligned}\|\mathbf{g}_t^n(u,\mathbf{z}(u))\| &\leq \frac{1}{h_n}\|\mathbf{B}_n\|\left\|\mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau)\right\| + \|\mathbf{c}_n\|\\ &\leq \frac{1}{h_n}K_1\left\|\mathbf{y}_{t_{n+1}}(-\tau) - \mathbf{y}_{t_n}(-\tau)\right\| + K_0\Big(1+2\sup_{t_0-\tau\leq t\leq T}\|\mathbf{y}\,(t)\|\Big)\\ &\leq K_1M_4 + K_0(1+2M_3) \qquad (3.28)\end{aligned}$$

and

$$\|\mathbf{g}_{\mathbf{z}}^n(u,\mathbf{z}(u))\| \leq K_1 \tag{3.29}$$

for $u \in [t_n, t_{n+1}]$. Finally, by using (3.26), (3.28), and (3.29) in (3.27), and by taking into account that $\mathbf{z}(t) \equiv \mathbf{y}(t)$ for $t \in [t_n, t_{n+1})$ and $t_n, t_{n+1} \in (t)_h$, we obtain

$$\sup_{t_n\leq t\leq t_{n+1}}\left\|\frac{d^2\mathbf{y}\,(t)}{dt^2}\right\| \leq M_6,$$

where $M_6 = K_1(M_4+M_5) + K_0(1+2M_3)$ is a positive constant independent of n. Thus, the proof is complete. □

4. Simulation results. In this section the performance of the LL method is illustrated by means of numerical simulations. To do so, we shall use the polynomial LL scheme (2.15) with linear interpolation and fixed step-size h. Specifically, in each interval $[t_n - \tau_i, t_{n+1} - \tau_i]$, the LL approximation $\mathbf{y}$ is approximated by the function

$$\widetilde{\mathbf{y}}\left(t_n + s - \tau_i\right) = \mathbf{y}\left(t_n - \tau_i\right) + \alpha_{1,n}^i s$$

with $s \in [0, h]$ and $\alpha_{1,n}^i = \left(\mathbf{y}\left(t_{n+1} - \tau_i\right) - \mathbf{y}\left(t_n - \tau_i\right)\right)/h$ for each delay τ_i; and the LL scheme is defined by the iteration

$$\mathbf{y}_{t_{n+1}} = \mathbf{y}_{t_n} + \mathbf{h}(\mathbf{y}_{t_n}) \tag{4.1}$$

for all $t_n \in (t)_h$, where the vector $\mathbf{h}(\mathbf{y}_{t_n})$ is obtained from the expression

$$\begin{bmatrix} \mathbf{F} & \mathbf{g}_1 & \mathbf{h}(\mathbf{y}_{t_n}) \\ 0 & 1 & \mathbf{g}_2 \\ 0 & 0 & 1 \end{bmatrix} = e^{h\mathbf{T}_n}$$

with

$$\mathbf{T}_n = \begin{bmatrix} \mathbf{A}_n & \mathbf{c}_n + \sum_{i=1}^{d} \mathbf{B}_n^i \alpha_{1,n}^i & \mathbf{d}_n \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{bmatrix} \in \mathbb{R}^{(m+2)\times(m+2)}.$$

Here, the matrix $e^{h\mathbf{T}_n}$ is computed by the rational Padé approximation with the "scaling and squaring" procedure (see Algorithm 11.3.1 in [18] for details).

Two DDEs with a variety of complexity were selected. This includes nonlinear equations with single and multiple delays, with low order discontinuities, and stiff equations.

Example 1. The first example is an epidemic model due to Cooke [31]. It describes the fraction of a population that is infected by a virus at time t through the equation

$$\frac{dx\left(t\right)}{dt} = bx\left(t-7\right)\left(1 - x\left(t\right)\right) - cx\left(t\right), \quad t \in [0, 70]. \tag{4.2}$$

Here b and c are positive constants. If $b > c$, then the solution $x\left(t\right) = 1 - c/b$ is an equilibrium point. The equation is integrated for $b = 2$, $c = 1$ and initial condition function $x\left(t\right) = 0.8$ for $t \in [-7, 0]$.

Figure 4.1 shows the numerical solution converging to the equilibrium point. Figure 4.2 shows the maximum errors of the LL scheme (4.1) in the computation of the solution of (4.2) in $(t)_h$ for $h = 0.1$, 0.01, 0.001 and the straight line that fits these points in the minimum square sense. The slope of that line is 2, which agrees with the theoretical estimate obtained in the previous section. For a "true" solution we used the trajectory obtained by the LL scheme with $h = 0.00001$. For a comparison, Figure 4.2 also shows the results obtained by the polynomial LL scheme with first and third order interpolating polynomial $\widetilde{\mathbf{y}}$, i.e., schemes of the form (2.15) with $p = 0$ and $p = 2$, respectively. In each case, the slope of their respective lines are 1 and 2, which also agrees with the theoretical estimate.

Example 2. The second example is the stiff DDE proposed in [6] to describe the dynamic of an antiviral immune response. The disease dynamic is governed by the

system of ten-dimensional DDEs,

$$
\begin{aligned}
\frac{dx_1}{dt} &= a_1 x_2 + a_2 a_3 x_2 x_7 - a_4 x_1 x_{10} - a_5 x_1 - a_6 x_1 (a_7 - x_2 - x_3),\\
\frac{dx_2}{dt} &= a_8 x_1 (a_7 - x_2 - x_3) - a_3 x_2 x_7 - a_9 x_2,\\
\frac{dx_3}{dt} &= a_3 x_2 x_7 + a_9 x_2 - a_{10} x_3,\\
\frac{dx_4}{dt} &= a_{11} a_{12} x_1 - a_{13} x_4,\\
\frac{dx_5}{dt} &= a_{14}((1 - x_3/a_7) a_{15} x_4(t - \tau_1) x_5(t - \tau_1) - x_4 x_5) - a_{16} x_4 x_5 x_7 + a_{17}(a_{18} - x_5),\\
\frac{dx_6}{dt} &= a_{19}((1 - x_3/a_7) a_{20} x_4(t - \tau_2) x_6(t - \tau_2) - x_4 x_6) - a_{21} x_4 x_6 x_8 + a_{22}(a_{23} - x_6),\\
\frac{dx_7}{dt} &= a_{24}((1 - x_3/a_7) a_{25} x_4(t - \tau_3) x_5(t - \tau_3) x_7(t - \tau_3) - x_4 x_5 x_7) - a_{26} x_2 x_7\\
&\quad + a_{27}(a_{28} - x_7),\\
\frac{dx_8}{dt} &= a_{29}((1 - x_3/a_7) a_{30} x_4(t - \tau_4) x_6(t - \tau_4) x_8(t - \tau_4) - x_4 x_6 x_8) + a_{31}(a_{32} - x_8),\\
\frac{dx_9}{dt} &= a_{33}(1 - x_3/a_7) a_{34} x_4(t - \tau_5) x_6(t - \tau_5) x_8(t - \tau_5) + a_{35}(a_{36} - x_9),\\
\frac{dx_{10}}{dt} &= a_{37} x_9 - a_{38} x_{10} x_1 - a_{39} x_{10},
\end{aligned}
$$

with five time delays $\tau_1 = \tau_2 = 0.6$, $\tau_3 = \tau_4 = 2$, and $\tau_5 = 3$, and initial conditions $x_1(t) = 2.9 \times 10^{-16}$, $x_2(t) = x_3(t) = x_4(t) = 0$, $x_5(t) = a_{18}$, $x_6(t) = a_{23}$, $x_7(t) = a_{28}$, $x_8(t) = a_{32}$, $x_9(t) = a_{36}$, and $x_{10}(t) = a_{36} a_{37} a_{39}$ for all $t \in [-\tau_5, 0]$. The parameters a_i are given in Table 4.1.

That equation has been used as a test example to compare the performance of numerical integrators in the case of multidimensional stiff equations with multiple delays. It has been reported in [6] that a number of them fail to produce a numerical solution after $t = 110$ because the appearance of sharp picks in the solution. Figure 4.3 illustrates this problem. In this case, the explicit continuous extension Runge–Kutta $(2, 3)$ scheme with step-size $h = 0.01$ was used.

On the contrary, Figure 4.4 shows the numerical solution until $t = 150$ obtained

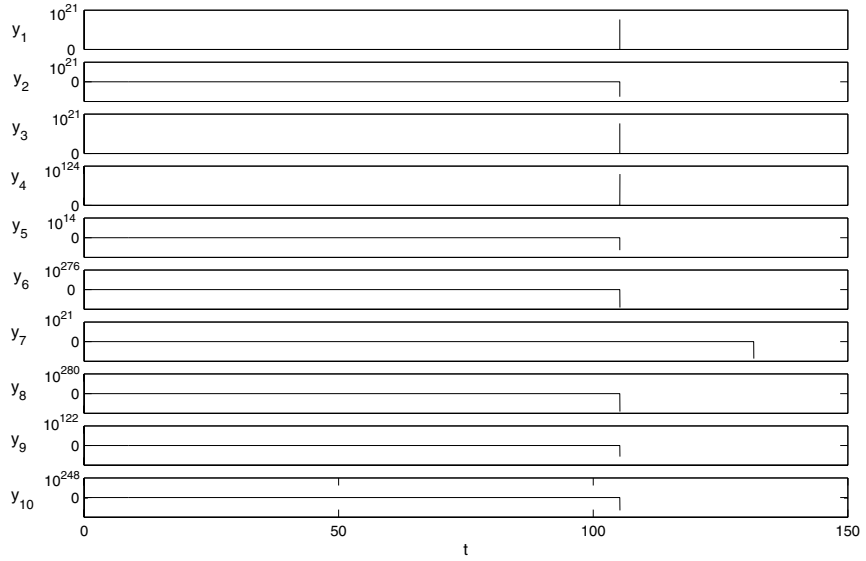

FIG. 4.3. *Approximate solution of Example* 2 *computed by the continuous extension Runge–Kutta* $(2,3)$ *scheme with step-size* $h = 0.01$.

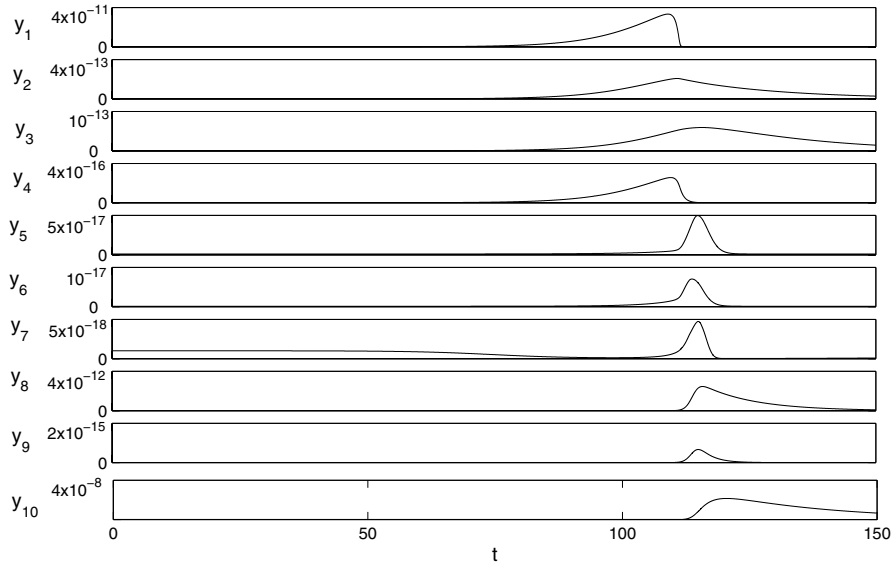

FIG. 4.4. *Approximate solution of Example* 2 *computed by the LL scheme* (4.1) *with step-size* $h = 0.01$.

TABLE 4.2
Maximum of the relative errors (%) produced by the LL scheme (4.1) in the integration of Example 2 on the interval $[0, 150]$ with different step-size h.

h/x	1	2	3	4	5	6	7	8	9	10
0.1	17.86	0.0377	0.0478	0.7256	0.3140	0.5269	1.3753	0.6410	0.6258	1.7621
0.01	0.13	0.0004	0.0035	0.0780	0.0031	0.0054	0.0120	0.0730	0.0071	0.0132

by the LL scheme (4.1) with the same step-size. Table 4.2 presents the maximum of the relative errors of the LL scheme in $(t)_h$ versus h for each variable. For a "true" solution we used the trajectory obtained by the LL scheme with $h = 0.00001$. The time for computing such a solution (until $t = 100$) was 1.7 times longer than the time used by the Runge–Kutta scheme mentioned above. Thus, no small step-size is necessary to integrate that equation with an adequate precision and computational cost, which reveals the potential of the LL method to integrate stiff DDEs.

5. Conclusions. The local linearization approach for the numerical integration of DDEs was introduced and two numerical schemes were considered. The first one, called the natural LL scheme, preserves the stability of multidimensional linear DDEs with multiple delays, but its computational cost is high in the case that the smallest delay of the DDE is much lower than the final integration time. On the contrary, according to the simulation study carried out, the computational cost of the polynomial LL scheme is comparable to the cost of the conventional explicit integrators but with the advantage of integrating stiff systems. This last result agrees with similar performances of the LL integrators of other classes of differential equations (ordinary, random, and stochastic). The two LL schemes proposed in this paper are explicit and have second order of convergence. Nevertheless, high order schemes of this family can also be derived by just following the same ideas that have been used to construct high order LL integrators for ODEs and SDEs [15, 16].

6. Appendix. The following result is a generalization of Theorem 1 in [40].

LEMMA 6.1 (Theorem 1 in [11]). *Let n, d_1, $d_2, \ldots, d_n$ be positive integers and $\mathbf{A}$ an $n \times n$ block triangular matrix defined by*

$$\mathbf{A} = \begin{pmatrix} \mathbf{A}_{11} & \mathbf{A}_{12} & \ldots & \mathbf{A}_{1n} \\ \mathbf{0} & \mathbf{A}_{22} & \ldots & \mathbf{A}_{2n} \\ \mathbf{0} & \mathbf{0} & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{A}_{nn} \end{pmatrix},$$

where $(\mathbf{A}_{lj})$ are $d_l \times d_j$ matrices, with $l, j = 1, \ldots, n$. Then for $t \geqslant 0$

$$e^{\mathbf{A}t} = \begin{pmatrix} \mathbf{B}_{11}(t) & \mathbf{B}_{12}(t) & \ldots & \mathbf{B}_{1n}(t) \\ \mathbf{0} & \mathbf{B}_{22}(t) & \ldots & \mathbf{B}_{2n}(t) \\ \mathbf{0} & \mathbf{0} & \ddots & \vdots \\ \mathbf{0} & \mathbf{0} & \mathbf{0} & \mathbf{B}_{nn}(t) \end{pmatrix},$$

with

$$\mathbf{B}_{ll}(t) = e^{\mathbf{A}_{ll}t}, \quad l = 1, \ldots, n,$$
$$\mathbf{B}_{lj}(t) = \int_0^t \mathbf{M}^{(l,j)}(t, s_1) ds_1, \quad l = 1, \ldots, n-1, j = l+1,$$

$$\mathbf{B}_{lj}(t) = \int_0^t \mathbf{M}^{(l,j)}(t,s_1)ds_1 + \sum_{k=1}^{j-l-1} \int_0^t\int_0^{s_1} \cdots \int_0^{s_k} \sum_{l<i_1<\cdots<i_k<j} \mathbf{M}^{(l,i_1,\ldots,i_k,j)}(t,s_1,\ldots,s_{k+1})ds_{k+1}\ldots ds_1,$$
$$l = 1,\ldots,n-2,\ j = l+2,\ldots,n,$$

where, for any multi-index $(i_1,\ldots,i_k) \in \mathbb{N}^k$ *and vector* $(s_1,\ldots,s_k) \in \mathbb{R}^k$*, the matrices* $\mathbf{M}^{(i_1,\ldots,i_k)}(s_1,\ldots,s_k)$ *are defined by*

$$\mathbf{M}^{(i_1,\ldots,i_k)}(s_1,\ldots,s_k) = \left(\prod_{r=1}^{k-1} e^{\mathbf{A}_{i_r i_r}(s_r - s_{r+1})}\mathbf{A}_{i_r i_{r+1}}\right) e^{\mathbf{A}_{i_k i_k} s_k}.$$

The thesis of the next lemma is known as the fundamental inequality in the framework of ODEs.

LEMMA 6.2 (fundamental inequality; Theorem 2 in [24, p. 6]). *Let* $\mathbf{f}(t,\mathbf{x}) : [t_0,t_1] \times D \longrightarrow \mathbb{R}^m$, $D \subset \mathbb{R}^m$*, be a continuous function that satisfies*

$$\|\mathbf{f}(t,\mathbf{x}) - \mathbf{f}(t,\mathbf{y})\| \le \lambda_0 \|\mathbf{x}-\mathbf{y}\|, \qquad \lambda_0 \ge 0,$$

for all $t \in [t_0,t_1]$ *and* $\mathbf{x},\mathbf{y} \in D$*. Let* $\mathbf{u}(t)$ *and* $\mathbf{v}(t)$ *be functions such that*

$$\left\| \frac{d\mathbf{u}(t)}{dt} - \mathbf{f}(t,\mathbf{u}(t)) \right\| \le \varepsilon_1,$$
$$\left\| \frac{d\mathbf{v}(t)}{dt} - \mathbf{f}(t,\mathbf{v}(t)) \right\| \le \varepsilon_2$$

for all $t \in [t_0,t_1]$*. Set*

$$\mathbf{p}(t) = \mathbf{u}(t) - \mathbf{v}(t) \qquad \text{and} \qquad \varepsilon = \varepsilon_1 + \varepsilon_2.$$

Then

$$\|\mathbf{p}(t)\| \le e^{\lambda_0(t-t_0)} \|\mathbf{p}(t_0)\| + \frac{\varepsilon}{\lambda_0}(e^{\lambda_0(t-t_0)} - 1)$$

for all $t \in [t_0,t_1]$.

LEMMA 6.3. *Let* $\mathbf{A}$, $\mathbf{C}$ *be* $n \times m$ *matrices, and let* $\mathbf{B}$, $\mathbf{D}$ *be* $m \times r$ *matrices. Then*

$$\|\mathbf{AB} - \mathbf{CD}\| \le \|\mathbf{A}-\mathbf{C}\| \|\mathbf{D}\| + \|\mathbf{A}\| \|\mathbf{B}-\mathbf{D}\|.$$

Proof. The lemma is obtained by applying the triangular inequality to the identity $\mathbf{AB} - \mathbf{CD} = (\mathbf{A}-\mathbf{C})\mathbf{D} + \mathbf{A}(\mathbf{B}-\mathbf{D})$. ∎

IMPROVED SIMULATION FOR THE KILLED BROWNIAN MOTION IN A CONE*

STÉPHANE MENOZZI†

Abstract. In this paper, we first give an error expansion of the weak error associated to a discretely killed Brownian motion in a cone that writes as an intersection of half spaces. We exploit this result to derive an original correction method to improve the initial convergence rate. This method is based on the sensitivity of the underlying Dirichlet problem w.r.t. the domain and turns out to be a numerically cheaper and sharper alternative to standard extrapolation techniques.

Key words. discretely killed Brownian motion, nonsmooth domains, overshoot above the boundary, domain correction

1. Introduction: Statement of the problem. Let $(X_t)_{t\in[0,T]}$ be a d-dimensional diffusion process. For a real valued functional ψ of the process, the numerical estimation of $Q_T := \mathbb{E}[\psi\big((X_t)_{t\in[0,T]}\big)]$ arises in a large class of problems. In financial mathematics, Q_T corresponds to the price of an option with possibly path-dependent pay-off ψ if one assumes the dynamics of the underlying asset is given by X; see, e.g., [KS98]. For some ψ, Q_T is also the probabilistic representation of the solution of a linear PDE. This is the well-known Feynman–Kac formula; see [Fre85]. In this context, the probabilistic approximation is particularly adapted in large dimensions.

Concerning the numerical estimation of Q_T, the easiest case is $\psi\big((X_t)_{t\in[0,T]}\big) = f(X_T)$, i.e. when Q_T corresponds to the price of a European option with pay-off f or to the solution of a Cauchy problem in a PDE setting. This problem has been analyzed in detail by Talay and Tubaro [TT90] and then by Bally and Talay [BT96a], [BT96b]. These works provide an expansion of the weak error when the process is discretized with the Euler scheme.

We are going to deal with the trickier case $\psi\big((X_t)_{t\in[0,T]}\big) = f(X_T)\mathbf{1}_{\forall t\in[0,T]:\ X_t\in D}$, D being a given domain (i.e., an open connected subset) of $\mathbb{R}^d$. This is an irregular functional of the path. In this framework, Q_T corresponds to the price of a barrier option (see Andersen and Brotherton-Ratcliffe [ABR96] for references on the subject) or to the solution of a Cauchy–Dirichlet problem. Assuming the domain is smooth, Gobet and the author [Gob00], [GM04] obtained bounds for the weak error associated to the discretely killed Euler scheme but no error expansion. In this work, we derive an error expansion for the special case of the Brownian motion (Black–Scholes setting) and an intersection of half spaces (nonsmooth domains). Even though this context can seem quite restrictive, it already induces a major difficulty w.r.t. the previous works. Namely, for the proofs one has to handle the singularities of the heat kernel in a cone.

Let $(X_t)_{t\in[0,T]}$ be a d-dimensional Brownian motion (BM) with dynamics

$$X_t = x + \mu t + \sigma W_t \tag{1.1}$$

with fixed initial data x and terminal time T. Here W is a standard d-dimensional BM defined on a filtered probability space $(\Omega, \mathcal{F}, (\mathcal{F}_t)_{t\in[0,T]}, \mathbb{P})$ with the usual assumptions on $(\mathcal{F}_t)_{t\in[0,T]}$. We assume $\sigma\sigma^*$ to be positive definite.

Let D be a domain of $\mathbb{R}^d$. Define $\tau := \inf\{t \geq 0 : X_t \notin D\}$. Consider a regular time mesh of the interval $[0,T]$ with N time steps, $(t_i = ih)_{i\in[\![0,N]\!]}$, $h = T/N$ being the step size. Introduce $\tau^N := \inf\{t_i \geq 0 : X_{t_i} \notin D\}$. For a measurable nonnegative function f and an initial point $x \in D$, denoting $\mathbb{E}_x[.] = \mathbb{E}[.|X_0 = x]$, we refer to the quantity

$$\mathrm{Err}(T, h, f, x) = \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau^N > T}] - \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau > T}]$$

as the weak error associated to the discrete time killing of X w.r.t. the domain D. Note that since $\tau^N > \tau$ a.s., $\mathrm{Err}(T, h, f, x) \geq 0$.

The discrete approximation of the exit time allows us to define a simple Monte Carlo procedure to estimate the previous quantity. In this context, $\mathrm{Err}(T, h, f, x)$ can thus be seen as the error associated to the discretization of the exit time.

Let us first recall some controls on $\mathrm{Err}(T, h, f, x)$ given in the literature. In [GM04] and Chapter I of [Men04], we proved, in the wider framework of killed diffusion processes approximated by their corresponding Euler schemes, that for smooth domains and functions f satisfying either some support condition w.r.t. D or some smoothness properties and compatibility conditions, one had that $\mathrm{Err}(T, h, f, x)$ was upper and lower bounded at order $1/2$ w.r.t. h. We also showed in [GM05] that, for a large class of Itô processes, the upper bound holds true for an intersection of smooth domains.

Still in [GM04], we stated an expansion and correction result for $\mathrm{Err}(T, h, f, x)$ in the special case of the half space in a Brownian framework. In this work, we extend these results to the case of an intersection of half spaces which is of particular interest in mathematical finance since the domain of a multiasset barrier option is often defined as a product domain.

Let $D \subset \mathbb{R}^d$ be a domain of the form $D = \cap_{i=1}^m D^i$, $m \in [\![1, d]\!]$, where the $(D^i)_{i\in[\![1,m]\!]}$ are d-dimensional half spaces with nonempty intersection. Under suitable smoothness properties up to the boundary for $v(t, x) := \mathbb{E}_x[f(X_{T-t})\mathbf{1}_{\tau > T-t}]$, we obtain an error expansion at order $\frac{1}{2}$ w.r.t. h for $\mathrm{Err}(T, h, f, x)$.

As emphasized in [GM04], the leading term in the weak error is still the one associated to the overshoot of the killed process above the boundary (the overshoot being defined as the distance to the boundary of the process when it exits the domain).

In the special case of Brownian motion, for half spaces or intersections of half spaces forming a cone, we are able to obtain the asymptotic distribution of the overshoot, extending previous results obtained by Siegmund [Sie79]. To derive the error expansion we then use usual techniques based on Taylor's expansions. The smoothness of v is needed for this last step. From a theoretical point of view, the main difficulty is analytical and consists in having good smoothness properties of v up to the boundary of a nonsmooth domain.

From a numerical point of view, the error expansion is the preliminary step for a procedure that aims to improve the convergence rate. A standard one in this framework is the Romberg extrapolation; see Talay and Tubaro [TT90] and section 3 for details.

In this paper, we propose an alternative correction method based on the recent work of Costantini, El Karoui, and Gobet [CKG03] concerning the sensitivity of the Dirichlet problem w.r.t. the domain. Unlike the Romberg extrapolation, we do not need to refine the time step and thus the procedure is computationally cheaper. Note also that the empirical variance associated to the Monte Carlo estimator is by construction smaller. We simply proceed to the simulation w.r.t. a more constrained domain. Namely, instead of killing the process when it exits from D at one of the discretization times, we kill it when it leaves $D_h := \cap_{i=1}^m D_h^i,\ D_h^i := \{y \in \mathbb{R}^d : y - C_i\sqrt{h}n_i \in D^i\}$, where n_i denotes the inner unit normal associated to the half space D^i. We will see that, for suitable positive constants C_i, this new choice of discrete time killing allows us to remove the leading term in the error development.

We mention that in a one-dimensional setting, both the expansion result and the correction procedure could be derived by direct computations from the work of Broadie, Glasserman, and Kou [BGK99].

For the sake of completeness, let us also mention that concerning the weak approximation of killed or reflected diffusion processes, another approach to improve the initial convergence rate can be found in Gobet [Gob01]. The techniques introduced therein strongly rely on some explicit transition probabilities for the Brownian motion in a half space and cannot be easily adapted to the orthant case.

Outline of the paper. We state our main results in section 2. Numerical results are presented in section 3. They confirm that the correction procedure is rather accurate and also numerically extends to a wider context for the underlying processes and domains. The proofs of the main results are developed in section 4. In section 5 we give some smoothness properties of v in nonsmooth domains. We conclude in section 6 evoking possible extensions and open problems. Appendices A and B are respectively devoted to the proofs of technical points concerning the asymptotic behavior of the overshoot and the killed heat kernel in a nonsmooth domain.

2. Main results.

2.1. Current working assumptions. We suppose our domain satisfies the following assumption:

(D) $D = \cap_{j=1}^m D^j\ \forall j \in [\![1,m]\!],\ D^j := \{y \in \mathbb{R}^d : y_j > b_0^j\}$, where $m \in [\![1,d]\!]$.

We introduce the following:

(BM) The d-dimensional process $(X_s)_{s\geq 0}$ has the form $X_s := x + \sigma_0 W_s$, where W is a standard d-dimensional BM and $\sigma_0\sigma_0^* = \begin{pmatrix} \Sigma & 0 \\ 0 & \mathbf{I}_{d-m} \end{pmatrix}$ is assumed to be positive definite and Σ is a correlation matrix with coefficients $(\rho_{ij})_{(i,j)\in[\![1,m]\!]^2}$. The integer $m \in [\![1,d]\!]$ is the same as in assumption **(D)**.

Suppose **(BM)**, **(D)** are in force. For a given positive measurable function f we define $\forall (t,y) \in [0,T]\times\mathbb{R}^d,\ v(t,y) := \mathbb{E}_y[f(X_{T-t})\mathbf{1}_{\tau>T-t}]$.

In the following, for an open set $U \subset \mathbb{R}^d$ we denote by $C_b^{k+\alpha}(\bar{U}), k \in \mathbf{N}^*,\ \alpha \in (0,1)$, the space of functions possessing k bounded and uniformly α-Hölder continuous spatial derivatives in $\bar{U}$. We also introduce $C_b^{k/2+\alpha/2,k+\alpha}([0,T]\times\bar{U}), k \in \mathbf{N}^*,\ \alpha \in (0,1)$, the space of functions possessing k bounded and uniformly α-Hölder continuous spatial derivatives in $[0,T]\times\bar{U}$ and $\lfloor k/2 \rfloor$ bounded and uniformly $(\mathbf{1}_{k=1}+\alpha)/2$-Hölder continuous time derivatives in $[0,T]\times\bar{U}$. Continuity is intended w.r.t. the parabolic metric; i.e., $\forall (P,Q) = ((t,x),(t',x')) \in ([0,T]\times\bar{U})^2,\ d(P,Q) = (|t-t'|+|x-x'|^2)^{1/2}$.

Now, under **(BM)**, **(D)**, we assume the following:

(S) The function f vanishes on the boundary. The associated function v belongs

to $C_b^{1/2+\alpha/2,1+\alpha}([0,T]\times\bar{D})\cap C^{1,2}([0,T)\times D)$, $\alpha>0$; i.e., there exists a constant $C>0$, s.t.

$$\sup_{\substack{(x,\,y)\,\in\,\bar{D}^2,\\(s,\,t)\,\in\,[0,\,T]^2}}\frac{|\nabla v(s,x)-\nabla v(t,y)|}{|s-t|^{\alpha/2}+|x-y|^{\alpha}}+\sup_{(s,\,t)\,\in\,[0,\,T]^2,\ x\,\in\,\bar{D}}\frac{|v(s,x)-v(t,x)|}{|s-t|^{\frac{1+\alpha}{2}}}\leq C.$$

$$|v|_{\infty,[0,T]\times\bar{D}}+|\nabla v|_{\infty,[0,T]\times\bar{D}}+$$

In particular, **(S)** means that the function f is at least $C_b^{1+\alpha}(\bar{D})$. We specify in section 5 sufficient conditions on f to obtain **(S)** in special cases.

We mention that the previous assumptions on f, i.e., that it is a smooth function vanishing on the boundary, are essentially technical. Numerically speaking they seem to have little influence; see section 3 for details.

2.2. Statement of the main theorems.

THEOREM 2.1 (error expansion for the correlated Brownian motion in an orthant). *Assume* **(BM)**, **(D)**, *and* **(S)**. *For h small enough the error writes*

$$Err(T,h,f,x)=C_1\sqrt{h}+o(\sqrt{h})$$

with $C_1=C_0\sum_{i=1}^m\mathbb{E}_x[\mathbf{1}_{\tau^i\leq T,\wedge_{j\in[\![1,m]\!]\setminus\{i\}}\tau^j>\tau^i}(\partial_{y_i}v(\tau^i,X_{\tau^i}))]$, $\tau^i:=\inf\{s\geq 0: X_s^i=b_0^i\}$, $C_0=\frac{\mathbb{E}_0[s_{\tau^+}^2]}{2\mathbb{E}_0[s_{\tau^+}]}$, *where* $s_0:=0,\forall n\geq 1, s_n:=\sum_{i=1}^n G^i$, *the G^i being i.i.d. standard centered normal variables and* $\tau^+:=\inf\{n\geq 0: s_n>0\}$.

One knows from [Sie79] and [AGP95] that $\frac{\mathbb{E}_0[s_{\tau^+}^2]}{2\mathbb{E}_0[s_{\tau^+}]}=-\frac{\zeta(1/2)}{\sqrt{2\pi}}=0.5823\ldots$, where ζ denotes Riemann's Zeta function.

Under our current assumptions **(BM)**, **(D)**, **(S)**, the next theorem improves the accuracy of the numerical procedure by removing the term of order $\frac{1}{2}$ in the error. For this, the simulation of $(X_{t_i})_{0\leq i\leq N}$ is performed in a modified domain, namely, $D^h:=\{y\in\mathbb{R}^d:\forall i\in[\![1,m]\!],\ y_i>b_0^i+C_0\sqrt{h}\}$ instead of $D:=\{y\in\mathbb{R}^d:\forall i\in[\![1,m]\!],\ y_i>b_0^i\}$.

We denote $\tau_{D^h}^N$ (resp., τ_{D^h}) the discrete (resp., continuous) exit time from this domain D^h.

THEOREM 2.2. *Assume* **(BM)**, **(D)**, **(S)**. *For h small enough we have*

$$Err'(T,h,f,x):=\mathbb{E}_x[f(X_T)\mathbf{1}_{\tau_{D^h}^N>T}]-\mathbb{E}_x[f(X_T)\mathbf{1}_{\tau>T}]=o(\sqrt{h}).$$

Remark 2.1. Consider now the more general case $X_s=x+\mu s+\sigma W_s, D:=\{x\in\mathbb{R}^d:(Ax)_i>b_i\ \forall i\in[\![1,m]\!]\}$, where $A=(a_1\ a_2\ \ldots\ a_m)^*$ is of rank m. Using Girsanov's theorem and a rotation of coordinates using a matrix Λ (with the ith row equal to $\frac{\sigma^*a_i}{\|\sigma^*a_i\|}$ for $i\in[\![1,m]\!]$ and the remaining rows forming an orthonormal basis of $\{\mathrm{Span}((\sigma^*a_j)_{j\in[\![1,m]\!]})\}^{\perp}$) preserving the Wiener measure, one obtains that for a Borelian bounded function f

$$\mathrm{Err}(T,h,f,x)=\mathbb{E}_0[f_0^x(\check{W}_T)(\mathbf{1}_{\tau_{D_0^x}^N>T}-\mathbf{1}_{\tau_{D_0^x}>T})],$$

where $\check{W}$ is a centered d-dimensional Brownian motion with covariance matrix $\sigma_0\sigma_0^*=\begin{pmatrix}\Sigma & 0\\ 0 & \mathbf{I}_{d-m}\end{pmatrix}$, and $\forall(i,j)\in[\![1,m]\!]^2$, $\Sigma_{ij}=\langle\sigma^*a_i,\sigma^*a_j\rangle/(\|\sigma^*a_i\|\|\sigma^*a_j\|)$. The domain D_0^x writes $D_0^x:=\cap_{j=1}^m D_0^{x,j}$, where $\forall\ j\in[\![1,m]\!]$, $D_0^{x,j}:=\{y\in\mathbb{R}^d:\ y_j>b_0^{x,j}\}$, $b_0^{x,j}=$

$\frac{b_j - a_j \cdot x}{\|\sigma^* a_j\|}$. Denoting $\tau_{D_0^{x,j}} := \inf\{s \geq 0 : \check{W}_s \notin D_0^{x,j}\}$, $\tau^N_{D_0^{x,j}} := \inf\{s_i \geq 0 : \check{W}_{s_i} \notin D_0^{x,j}\}$, we have $\tau_{D_0^x} := \wedge_{j=1}^m \tau_{D_0^{x,j}}, \tau^N_{D_0^x} := \wedge_{j=1}^m \tau^N_{D_0^{x,j}}$. The function f_0^x writes $f_0^x(y) = \exp(\sigma^{-1}\mu \cdot \Lambda^{-1} y - \frac{\|\sigma^{-1}\mu\|^2}{2} T) f(x + \sigma\Lambda^{-1} y)$.

Introduce, $\forall (t,y) \in [0,T] \times D_0^x$, $v_0^x(t,y) = \mathbb{E}_y[f_0^x(\check{W}_{T-t}) \mathbf{1}_{\tau_{D_0^x} > T-t}]$. If assumption **(S)** is fulfilled by v_0^x (one could weaken the boundedness condition in **(S)** to an exponential growth condition), then the former error expansion remains valid. We can as in the previous theorem remove the leading term of the error by simulating w.r.t. $D^h := \{x \in \mathbb{R}^d : (Ax)_i > (b + C_0 e\sqrt{h})_i,\ i \in [\![1,m]\!]\}$, $e = (\|\sigma^* a_1\|, \ldots, \|\sigma^* a_m\|)^*$.

Remark 2.2. In the half space case, i.e., for $m = 1$, the above transformation illustrates that the problem is essentially one-dimensional. This last aspect still holds true for a domain delimited by parallel hyperplanes. This is the reason why we did not take this case into consideration in **(D)**.

3. Numerical results. In this section we provide some numerical tests and compare the method from Theorem 2.2 with the usual Romberg correction that we briefly recall.

From Theorem 2.1, we derive $\frac{1}{\sqrt{2}-1}\mathbb{E}[f(X_T)(\sqrt{2}\mathbf{1}_{\tau^{2N} > T} - \mathbf{1}_{\tau^N > T})] - \mathbb{E}[f(X_T)\mathbf{1}_{\tau > T}] = o(\sqrt{h})$. The Romberg extrapolation technique consists in approximating by a Monte Carlo method the first term in the left-hand side of the previous equation.

We point out that our correction is numerically less expensive than the Romberg procedure that requires refining the time step. The Monte Carlo estimator deriving from Theorem 2.2 also has by construction a smaller empirical variance.

Bidimensional cone. We consider a two-dimensional risky asset following the Black–Scholes–Merton dynamics, $S_t^1 = S_0^1 \exp(\sigma_1 W_t^1 + (r - \frac{\sigma_1^2}{2})t)$, $S_t^2 = S_0^2 \exp(\sigma_2(\rho W_t^1 + (1-\rho^2)^{1/2} W_t^2) + (r - \frac{\sigma_2^2}{2})t)$, where $W = (W^1, W^2)$ is a standard bidimensional BM. For a fixed final time T, a given strike K, and threshold B, put $D := \{(s_1, s_2) \in \mathbb{R}^2 : s_1 > B, s_2 > B\}$. We are interested in computing $\mathbb{E}[e^{-rT}\mathbf{1}_{\tau > T}\varphi(S_T)]$, where φ is a smooth approximation of the indicator function that one expects in the case of a digital barrier option. We take $\varphi(s) := \mathbf{1}^\star_{K,\varepsilon}(s_1)\mathbf{1}^\star_{K,\varepsilon}(s_2)$ with $\mathbf{1}^\star_{K,\varepsilon}(s_1) = 0$ if $s_1 \leq K - \varepsilon$, $\mathbf{1}^\star_{K,\varepsilon}(s_1) = 1$ if $s_1 \geq K$, and in between we use the smooth interpolating function $\mathbf{1}^\star_{K,\varepsilon}(s_1) = 10\varepsilon^{-3}(s_1 - (K-\varepsilon))^3 - 15\varepsilon^{-4}(s_1 - (K-\varepsilon))^4 + 6\varepsilon^{-5}(s_1 - (K-\varepsilon))^5$. As soon as $K > B + \varepsilon$, the previous function φ satisfies conditions that guarantee **(S)** is fulfilled up to an exponential growth condition; see assumption **(F)**, section 5.2, Proposition 5.3, and Remark 2.1.

For $r = .04$, $\sigma_1 = \sigma_2 = .3$, $\rho = .5$, $S_0^1 = S_0^2 = 100 = K$, $B = 90$, $T = 1$, $\varepsilon = 5$ we compute the standard Monte Carlo approximation, the Romberg approximation, and the correction proposed in Theorem 2.2 for 10^6 paths (see Figure 1). The reference value has been computed with 10^6 paths and 15000 times steps with the Monte Carlo procedure.

The width of the 95% confidence interval is essentially equal to 1.5 10^{-3}. Furthermore we also observe that the associated empirical variance is lower than the one of the Romberg extrapolation.

From a numerical point of view a natural question concerns the behavior of the $o(\sqrt{h})$ appearing in Theorem 2.2. We have not experimentally emphasized a constant exponent; anyhow it turns out that the numerical rest is smaller than $O(h^{3/2})$.

Experiments in higher dimensions. Set $d \in \mathbf{N}^*, d > 2$. Let $X_s = x + \sigma_0 W_s$, where W is a d-dimensional standard BM and $\forall (i,j) \in [\![1,d]\!]^2$, $(\sigma_0 \sigma_0^*)_{ij} = \mathbf{1}_{i=j} +$

FIG. 2.

$\frac{\alpha}{d-1}\mathbf{1}_{i\neq j}, \alpha \in [0,1)$, so that $\sigma_0\sigma_0^*$ has dominant diagonal and is thus positive definite. We take $D := \{x \in \mathbb{R}^d : x_i > 0 \; \forall i \in [\![1,d]\!]\}$ and we are interested in approximating the quantity $\mathbb{E}_x[f(X_T)\mathbf{1}_{\tau>T}]$, where $\forall x \in D,\ f(x) = \prod_{i=1}^d \mathbf{1}_{K<S_0^i \exp(sx_i)}$. Here $S_0 \in \mathbb{R}^d$ is a fixed vector and s is a fixed scale factor. Note that f is not as smooth as required in **(S)**.

The results in Figure 2 have been obtained with $d = 5$, $T = 1$, $K = 100$, $\alpha = s =$

$.05$, $S_0^i = 95\exp(sx_i)$, $x_i = .85\ \forall i \in [\![1,d]\!]$. The reference value has been computed with the standard Monte Carlo procedure for 2×10^6 paths and 2×10^4 steps. We used 10^6 paths for the other Monte Carlo computations.

The size of the 95% confidence interval is essentially equal to $1.5\ 10^{-3}$.

Even though we are not under the assumptions of the main theorems, the correction technique gives a good result. It is still sharper and provides smaller empirical variance than the Romberg extrapolation.

Numerical correction in a non-Brownian setting. We introduce in this section an algorithm that aims to extend the correction method of Theorem 2.2 to the diffusion case and to a wider class of domains. Namely, we assume in the following that D is a Lipschitz domain. In particular, the inner normal unit is defined a.e. on ∂D. Let $(X_s)_{s\geq 0}$ be a diffusion process with dynamics

$$X_t = x + \int_0^t b(X_s)ds + \int_0^t \sigma(X_s)dW_s, \tag{3.1}$$

where b,σ are bounded and Lipschitz continuous. We approximate it by its Euler scheme $X_t^N = x + \int_0^t b(X_{\phi(s)}^N)ds + \int_0^t \sigma(X_{\phi(s)}^N)dW_s$, $\phi(s) := \inf\{t_i \geq 0 : t_i \leq s < t_{i+1}\}$ and define the discrete exit time $\tau^N := \inf\{t_i \geq 0 : X_{t_i}^N \notin D\}$. Note that the Euler scheme is locally in time nothing else but a Brownian motion with constant drift and diffusion coefficients. Thus, on the set $\tau^N > t_i$, $i \in [\![0, N-1]\!]$, and for $X_{t_i}^N$ in a neighborhood of the boundary s.t. $\Pi_{\partial D}$ is a.e. well defined, mimicking the procedure introduced in Theorem 2.2, we heuristically extend the correction by killing the Euler scheme in t_{i+1} whenever it is outside $D_h(X_{t_i}^N) := D\backslash V_{\partial D}(C_0\sqrt{h}\|\sigma^*(X_{t_i}^N)n(\Pi_{\partial D}(X_{t_i}^N))\|)$, where $\forall a>0, V_{\partial D}(a) := \{y\in\mathbb{R}^d : d(y,\partial D)\leq a\}$.

From an algorithmic point of view, the computation of $n(\Pi_{\partial D}(X_{t_i}^N))$ can be very demanding. Anyhow, on $\{\tau^N > t_i\}$ for a given $\eta > 0$ s.t. $X_{t_i}^N \in D\backslash V_{\partial D}(h^{1/2-\eta})$ we derive from Bernstein's inequality (cf. Lemma 4.1) and standard computations that $\mathbb{P}[\tau^N = t_{i+1}|\mathcal{F}_{t_i}] \leq C\exp(-ch^{-\eta})$. It is therefore useless to refine the simulation procedure for those events.

We sum up this heuristic correction in the following algorithm.

Algorithm 3.1 (empirical correction in a diffusion framework).

- *Assume X follows the dynamics of* (3.1).
- *Fix $\eta > 0$ and set*

(i) $X_0^N = x$.

(ii) $\forall i \in [\![0, N-1]\!]$ *s.t.* $\tau^N > t_i$, $X_{t_{i+1}}^N := X_{t_i}^N + b(X_{t_i}^N)h + \sigma(X_{t_i}^N)(W_{t_{i+1}} - W_{t_i})$.

- If $X_{t_i} \in V_{\partial D}(h^{1/2-\eta})$ *and* $X_{t_{i+1}} \notin D_h(X_{t_i}^N)$*:* Kill the path.
- If $X_{t_i} \notin V_{\partial D}(h^{1/2-\eta})$ *and* $X_{t_{i+1}} \notin D$*:* Kill the path (rare event).
- If $i+1 \neq N$ *and no killing, iterate step* (ii).

We first give some results that illustrate that the proposed extension has a good numerical behavior. Namely, we take $b(x) = (b^i(x))_{i\in[\![1,d]\!]} = (\sin(x_i))_{i\in[\![1,d]\!]}, \sigma(x) = (\sigma^{ij}(x))_{(i,j)\in[\![1,d]\!]^2} = (\mathbf{1}_{i=j} + \sin(x_i)/(2(d-1))\mathbf{1}_{j\neq i})_{(i,j)\in[\![1,d]\!]^2}$ in (3.1) and a domain corresponding to a hypercube. For $f(x) = 1$ (corresponding to the estimation of the complementary distribution function of the exit time), $d = 3$, $D = (-1, 1.5)\times(-1.5, 1)\times(-2, 2.5)$, $T = 1$, $X_0 = 0$, we compute a reference value using the Romberg technique with $N = 12000$ and 2×10^6 paths. We obtain for 10^6 paths the results in Figure 3.

The size of the 95% confidence interval is still essentially equal to $1.5\ 10^{-3}$. For

FIG. 3.

this example, our correction is significantly more accurate.

We conclude this subsection giving a less favorable case. Take X a standard bidimensional BM, $D = B(0,1) \subset \mathbb{R}^2$, and $f(y) = (\frac{1}{2} - \|y\|^2)^+$. The 95% confidence interval associated to the reference value computed for $N_{MCR} = 2 \times 10^6, N_R = 14400$ by a standard Monte Carlo method is $I_C(N_{MCR}, N_R) = [.0203672, .0204871]$.

With $N_{MC} = 10^6$ paths, the previous correction algorithm gives the following:

	$N = 15$	$N = 30$	$N = 60$
$I_C(N_{MC}, N)$	[.019911, .0202323]	[.01999915, .020314]	[.0200514, .0203743]

	$N = 120$	$N = 240$	$N = 480$
$I_C(N_{MC}, N)$	[.0200527, .0203756]	[.0199975, .0203202]	[.0199531, .0202749]

Even though most of the intervals $I_C(N_{MC}, N)$ do not intersect $I_C(N_{MCR}, N_R)$, they are quite close to it. This is promising because the computational time employed to get the above estimates is significantly reduced w.r.t. to the one needed to obtain $I_C(N_{MCR}, N_R)$. Furthermore, the fact that the quantity to estimate is small brings additional numerical difficulty.

4. Proof of the main results.

4.1. Additional notation and usual controls. For smooth functions $g(t,x)$, the notation $H_g(t,x)$ stands for the Hessian matrix of g w.r.t. x. Time derivatives are denoted by $\partial_t^\beta g(t,x),\ \beta \in \mathbf{N}^*$.

We will keep the same notation C (or C') for all finite, nonnegative constants which will appear in our computations: they may depend on D, T, σ_0, or f, but they will not depend on the number of time steps N and the initial value x. We reserve the notation c and c' for constants that are also independent of T and f. Other possible dependences for the constants are explicitly indicated.

In the following $O_{pol}(h)$ (resp., $O(h)$) stands for every quantity $R(h)$ such that

$\forall n \in \mathbf{N}$, for some $C > 0$, one has $|R(h)| \leq Ch^n$ (resp., $|R(h)| \leq Ch$) (uniformly in x).

LEMMA 4.1 (Bernstein's inequality). *Assume* **(BM)**. *Consider two stopping times S, S' upper bounded by T with $0 \leq S' - S \leq \Delta \leq T$. Then for any $p \geq 1$, there are some constants $c > 0$ and C, such that for any $\eta \geq 0$, one has a.s.*

$$\mathbb{P}[\sup_{t\in[S,S']} \|X_t - X_S\| \geq \eta \mid \mathcal{F}_S] \leq C \exp\left(-c\frac{\eta^2}{\Delta}\right),$$
$$\mathbb{E}[\sup_{t\in[S,S']} \|X_t - X_S\|^p \mid \mathcal{F}_S] \leq C\Delta^{p/2}.$$

For a proof of the first inequality we refer to Chapter 3, section 3 in [RY99]. The other inequality easily follows from the first one or from the BDG inequalities.

4.2. Proof of Theorem 2.1 (expansion result). Let us briefly outline the scheme of the proof. First, we write the error as a sum of increments of the function v. Using Taylor expansions, we then introduce the overshoot terms of the process in the previous development (the overshoot being defined as the distance of the process to the domain when it exits the domain). We finally conclude using the asymptotic independence of the rescaled overshoot, as well as its integrability properties, and the discrete exit time.

Step 1: Decomposition of the error. Recalling that the function v vanishes on D^c, we write

$$\begin{aligned}\mathrm{Err}(T,h,f,x) &= \mathbb{E}_x[v(T\wedge\tau^N, \Pi_{\bar{D}}(X_{T\wedge\tau^N}))] - v(0,x)\\ &= \sum_{i=0}^{N-1} \mathbb{E}_x[\big(v(t_{i+1}\wedge\tau^N, \Pi_{\bar{D}}(X_{t_{i+1}\wedge\tau^N})) - v(t_i\wedge\tau^N, \Pi_{\bar{D}}(X_{t_i\wedge\tau^N}))\big)]\\ &= \sum_{i=0}^{N-1} \mathbb{E}_x[\mathbf{1}_{\tau^N > t_i}\big(v(t_{i+1}, \Pi_{\bar{D}}(X_{t_{i+1}})) - v(t_i, X_{t_i})\big)].\end{aligned}$$

Introduce $\forall t \in [0,T), \tau_t := \inf\{s \geq t : X_s \notin D\}$. Recall also that the function v satisfies the PDE

$$\begin{cases} (\partial_t v + \frac{1}{2}\mathrm{tr}(H_v \sigma_0 \sigma_0^*))(t,y) = 0,\ (t,y) \in [0,T)\times D,\\ v(t,.)|_{\partial D} = 0, t \in [0,T],\ v(T,y) = f(y),\ y \in \bar{D}.\end{cases} \tag{4.1}$$

Hence, $(v(s\wedge\tau_t, X_{s\wedge\tau_t}))_{s\in[t,T]}$ is a martingale. We have

$$\mathrm{Err}(T,h,f,x) = \sum_{i=0}^{N-1} \mathbb{E}_x[\mathbf{1}_{\tau^N > t_i}\mathbf{1}_{\tau_{t_i} < t_{i+1}}(v(t_{i+1}, \Pi_{\bar{D}}(X_{t_{i+1}})) - v(\tau_{t_i}, X_{\tau_{t_i}}))].$$

Define now $\forall j \in [\![1,m]\!]$, $\tau_t^j := \inf\{s \geq t : X_s^j = b_0^j\}$. Since $\mathbb{P}[\tau_{t_i}^j = \tau_{t_i}^k | \mathcal{F}_{t_i}] = 0$, $j \neq k$, one gets $\mathbb{P}[X_{t_{i+1}} \notin D|\mathcal{F}_{t_i}] = \sum_{j=1}^m \mathbb{E}[\mathbf{1}_{\tau_{t_i} < t_{i+1}, \tau_{t_i} = \tau_{t_i}^j} \mathbb{P}[X_{t_{i+1}} \notin D | \mathcal{F}_{\tau_{t_i}^j}]|\mathcal{F}_{t_i}]$ $\geq \frac{1}{2}\mathbb{P}[\tau_{t_i} < t_{i+1}|\mathcal{F}_{t_i}]$. Hence,

$$\sum_{i=0}^{N-1} \mathbb{P}_x[\tau^N > t_i, \tau_{t_i} \leq t_{i+1}] \leq 2\sum_{i=0}^{N-1} \mathbb{P}_x[\tau^N = t_{i+1}] \leq 2. \tag{4.2}$$

This last identity will be frequently used from now on to isolate the remainders; see, e.g., the last equality below.

Using **(S)** and Lemma 4.1 we obtain

$$\mathrm{Err}(T,h,f,x)=\sum_{i=0}^{N-1}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i,\tau_{t_i}<t_{i+1}}\{\nabla v(\tau_{t_i},X_{\tau_{t_i}})\cdot(\Pi_{\bar D}(X_{t_{i+1}})-X_{\tau_{t_i}})$$
$$+o(h^{1/2})\}]=\sum_{i=0}^{N-1}\sum_{j=1}^{m}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i,\tau^j_{t_i}<t_{i+1},\tau_{t_i}=\tau^j_{t_i}}\partial_{x_j}v(\tau^j_{t_i},X_{\tau^j_{t_i}})(X^j_{t_{i+1}}-b^j_0)^+]+o(h^{1/2}).$$

For the last equality we used the explicit expression of the projection on $\bar D$, namely, $\Pi_{\bar D}(y)=(b^1_0+(y_1-b^1_0)^+,\dots,b^m_0+(y_m-b^m_0)^+,y_{m+1},\dots,y_d)$ and also that $\forall(j,k)\in[\![1,m]\!]^2,\ j\neq k,\ \forall s\in[0,T],\ \partial_{x_k}v(s,y)|_{y\in\mathbb{R}^d:y_j=b^j_0}=0$. This is a simple consequence of the fact that v vanishes on D^c. By symmetry, assumption **(S)**, and the previous arguments we derive

$$\mathrm{Err}(T,h,f,x)=\sum_{j=1}^{m}\mathbb{E}_x[\mathbf{1}_{\tau^N\le T}\partial_{x_j}v(\tau^N,\Pi_{\bar D}(X_{\tau^N}))(X^j_{\tau^N}-b^j_0)^-]+R+o(h^{1/2}),\tag{4.3}$$

where

$$|R|:=\left|\sum_{i=0}^{N-1}\sum_{j=1}^{m}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i}\mathbf{1}_{\tau^j_{t_i}<t_{i+1},\tau_{t_i}\neq\tau^j_{t_i}}\partial_{x_j}v(\tau^j_{t_i},\Pi_{\bar D}(X_{\tau^j_{t_i}}))(X^j_{t_{i+1}}-b^j_0)^-]\right|$$
$$\le C\sqrt{h}\sum_{i=0}^{N-1}\sum_{j=1}^{m}\sum_{k\in[\![1,m]\!],\ k\neq j}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i}\mathbf{1}_{\tau^j_{t_i}<t_{i+1},\tau_{t_i}=\tau^k_{t_i}}|\partial_{x_j}v(\tau^j_{t_i},\Pi_{\bar D}(X_{\tau^j_{t_i}}))|].$$

Define $\forall\eta>0$, $V^{jk}(h^\eta):=\{y\in\mathbb{R}^d:|y_l-b^l_0|\le h^\eta,\ l\in\{j,k\}\}$. Put also $\mathcal{CO}^{jk}:=\{y\in\mathbb{R}^d:y_l=b^l_0,\ l\in\{j,k\}\}$. In short, $V^{jk}(h^\eta)$ is a neighborhood of width h^η of the corner $\mathcal{CO}^{jk}$. Note that $\forall(t,y)\in[0,T]\times\mathcal{CO}^{jk}\cap\bar D,\ \nabla v(t,y)=0$. Thus, from Lemma 4.1, assumption **(S)**, and (4.2) we derive that for h small enough

$$|R|\le C\sqrt{h}\sum_{i=0}^{N-1}\sum_{j=1}^{m}\sum_{k\in[\![1,m]\!],\ k\neq j}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i}\mathbf{1}_{X_{t_i}\in V^{jk}(h^{1/4})}\mathbf{1}_{\tau^j_{t_i}<t_{i+1},\tau_{t_i}=\tau^k_{t_i}}$$
$$\times|\partial_{x_j}v(\tau^j_{t_i},\Pi_{\bar D}(X_{\tau^j_{t_i}}))-\partial_{x_j}v(\tau^j_{t_i},\Pi_{\bar D}(\Pi_{\mathcal{CO}^{jk}}(X_{\tau^j_{t_i}})))|]+O_{pol}(h)$$
$$\le C\sqrt{h}\sum_{i=0}^{N-1}\sum_{j=1}^{m}\sum_{k\in[\![1,m]\!],\ k\neq j}\mathbb{E}_x[\mathbf{1}_{\tau^N>t_i}\mathbf{1}_{X_{\tau^j_{t_i}}\in V^{jk}(h^{1/8})}\mathbf{1}_{\tau^j_{t_i}<t_{i+1},\tau_{t_i}=\tau^k_{t_i}}$$
$$\times|X_{\tau^j_{t_i}}-\Pi_{\mathcal{CO}^{jk}}(X_{\tau^j_{t_i}})|^\alpha]+O_{pol}(h)=O(h^{\frac12+\frac{\alpha}{8}}):=o(h^{1/2}).$$

Plugging this last estimate into (4.3), we have

$$\mathrm{Err}(T,h,f,x)=\sum_{j=1}^{m}\mathbb{E}_x[\mathbf{1}_{\tau^N\le T}\partial_{x_j}v(\tau^N,\Pi_{\bar D}(X_{\tau^N}))(X^j_{\tau^N}-b^j_0)^-]+o(h^{1/2})$$
$$:=\sum_{j=1}^{m}E_j+o(h^{1/2}).\tag{4.4}$$

Remark 4.1. We emphasize that, up to now, we have not used the specific Brownian dynamics of the process X. The expansion (4.4) is valid for the error associated to the discretization of a diffusion process approximated by its discretely killed Euler scheme, provided that the process is nonadherent to the boundary and that **(S)** is fulfilled for the associated function v.

Step 2: Use of the asymptotic independence of the hitting time and the overshoot in the Brownian case. We now detail the asymptotic behavior of E_1. The other terms could be handled in exactly the same way. The following lemma, whose proof is postponed to Appendix A and strongly relies on the Brownian setting, is the main tool needed.

LEMMA 4.2. *Assume* **(BM)**, **(D)**. *Put* $\forall i \in [\![1,m]\!]$, $\tau^i := \inf\{t \geq 0 : X_t^i = b_0^i\}$, $\tau^{N,i} := \inf\{t_j := jh \geq 0 : X_{t_j}^i \leq b_0^i\}$. *One has* $\forall y \in \mathbb{R}^{+,*}$,

$$\mathbb{P}_x[\sqrt{h}^{-1}(X_{\tau^N}^1 - b_0^1)^- \geq y, \tau^N \leq t, \tau^{N,1} \leq \wedge_{i=2}^m \tau^{N,i}] \underset{N}{\longrightarrow} (1-H(y))\mathbb{P}_x[\tau^1 \leq t, \tau^1 < \wedge_{i=2}^m \tau^i],$$

where, using the notation of Theorem 2.1, $H(y) := (\mathbb{E}_0[s_{\tau^+}])^{-1}\int_0^y dz \mathbb{P}_0[s_{\tau^+} > z]$. *The limit is uniform on* $[0,T]$.

In order to isolate the rescaled overshoot $Z_N := \sqrt{h}^{-1}(X_{\tau^N}^1 - b_0^1)^-$ in E_1, we rewrite the components $X^2, \ldots, X^m$, of the correlated part of X in terms of X^1 and an additional correlated $(m-1)$-dimensional BM $\tilde{X}$ independent of X^1 and $(X^i)_{i\in[\![m+1,d]\!]}$. Namely, $\forall i \in [\![2,m]\!]$, $X_s^i = \rho_{1i}X_s^1 + (1-\rho_{1i}^2)^{1/2}\tilde{X}_s^{i-1}$, $\tilde{X}_0^{i-1} = (x_0^i - \rho_{1i}x_0^1)/(1-\rho_{1i}^2)^{1/2}$. Set also $(\rho_{1.}X_s^1 + (1-\rho_{1.}^2)^{1/2}\tilde{X}_s^{\cdot,-1})^{2,m} := (\rho_{12}X_s^1 + (1-\rho_{12}^2)^{1/2}\tilde{X}_s^1, \ldots, \rho_{1m}X_s^1 + (1-\rho_{1m}^2)^{1/2}\tilde{X}_s^{m-1}) = (X_s^2, \ldots, X_s^m) := X_s^{2,m}$, $X_s^{m+1,d} := (X_s^{m+1}, \ldots, X_s^d)$.

For notational convenience we introduce $\forall y \in \mathbb{R}^{d-1}$, $\Pi_{\bar{D}^{2,d}}(y) := (b_0^2 + (y_1 - b_0^2)^+, \ldots, b_0^m + (y_{m-1} - b_0^m)^+, y_m, \ldots, y_{d-1})$. The term E_1, defined in (4.4), writes

$$\begin{aligned}
&E_1 = \sqrt{h}\mathbb{E}_x[Z_N \mathbf{1}_{\tau^N \leq T}\partial_{x_1} v(\tau^N, b_0^1, \Pi_{\bar{D}^{2,d}}((\rho_{1.}(b_0^1 - \sqrt{h}Z_N)\\
&+(1-\rho_{1.}^2)^{1/2}\tilde{X}_{\tau^N}^{\cdot,-1})^{2,m}, X_{\tau^N}^{m+1,d}))]\\
&= \sqrt{h}\mathbb{E}_x[Z_N \mathbf{1}_{\tau^N \leq T}\partial_{x_1} v(\tau^N, b_0^1, \Pi_{\bar{D}^{2,d}}((\rho_{1.}b_0^1 + (1-\rho_{1.}^2)^{1/2}\tilde{X}_{\tau^N}^{\cdot,-1})^{2,m}, X_{\tau^N}^{m+1,d}))] + R_1,
\end{aligned}$$

where

$$\begin{aligned}
R_1 := \sqrt{h}\mathbb{E}_x[Z_N \mathbf{1}_{\tau^N \leq T}\big(&\partial_{x_1} v(\tau^N, b_0^1, \Pi_{\bar{D}^{2,d}}((\rho_{1.}(b_0^1 - \sqrt{h}Z_N)\\
&+(1-\rho_{1.}^2)^{1/2}\tilde{X}_{\tau^N}^{\cdot,-1})^{2,m}, X_{\tau^N}^{m+1,d}))\\
&-\partial_{x_1} v(\tau^N, b_0^1, \Pi_{\bar{D}^{2,d}}((\rho_{1.}b_0^1 + (1-\rho_{1.}^2)^{1/2}\tilde{X}_{\tau^N}^{\cdot,-1})^{2,m}, X_{\tau^N}^{m+1,d})))].
\end{aligned}$$

Under **(S)** the function $\partial_{x_1} v$ is continuous and bounded. Proposition 6 from [GM04] gives the uniform integrability of Z_N on the event $\tau^{N,1} \leq T$. We thus derive from Lemma 4.2 by convergence in law that for h small enough

$$E_1 = \sqrt{h}\mathbb{E}[Z]\mathbb{E}_x[\mathbf{1}_{\tau^1 \leq T, \wedge_{j=2}^m \tau^j > \tau^1}\partial_{x_1} v(\tau^1, X_{\tau^1})] + o(\sqrt{h}) + R_1,$$

where the distribution function of Z is given by H defined in Lemma 4.2. Recalling that $\mathbb{E}[Z] = \frac{\mathbb{E}[s_{\tau^+}^2]}{2\mathbb{E}[s_{\tau^+}]} = C_0$, we obtain $E_1 = \sqrt{h}C_0\mathbb{E}[\mathbf{1}_{\tau^1 \leq T, \wedge_{j=2}^m \tau^j > \tau^1}\partial_{x_1} v(\tau^1, X_{\tau^1})] + o(\sqrt{h}) + R_1$. Now, from assumption **(S)** we have $|R_1| \leq Ch^{\frac{1+\alpha}{2}}\mathbb{E}_x[Z_N^{1+\alpha}\mathbf{1}_{\tau^{N,1} \leq T}]$. Thus, by Proposition 6 in [GM04] we have $R_1 = O(h^{\frac{1+\alpha}{2}})$, which completes the proof.

Remark 4.2. The controls in the previous proof as well as the residual terms appearing in the computations are locally uniform w.r.t. the domain D.

Remark 4.3. To conclude this section, we would like to emphasize that the main difficulty in applying the previous theorem consists in finding conditions on f that guarantee that **(S)** is fulfilled. We provide some sufficient conditions in section 5 but in all generality this is far from easy.

4.3. Proof of Theorem 2.2 (correction result). In this subsection we detail how the arguments from Costantini, El Karoui, and Gobet (see [CKG03]) can be employed to prove our correction result. We write

$$\begin{aligned}\mathrm{Err}'(T,h,f,x) &= \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau^N_{D^h}>T}] - \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau_{D^h}>T}]\\ &+\mathbb{E}_x[f(X_T)\mathbf{1}_{\tau_{D^h}>T}] - \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau>T}] := E_1+E_2.\end{aligned}$$

From Remark 4.2 we derive that one could show just like in Theorem 2.1 that even though the domain depends on h we have $E_1 = C_1\sqrt{h} + o(\sqrt{h})$, where C_1 denotes the constant introduced in the quoted theorem. For E_2 we adapt some ideas from [CKG03] concerning the sensitivity of the Dirichlet problem w.r.t. the domain.

For a given $c \in \mathbb{R}^d$, let us denote $\forall \eta > 0,\ D_\eta := \{y \in \mathbb{R}^d : y - \eta c \in D\}$. We define $\tau_{D_\eta} := \inf\{s > 0 : X_s \notin D_\eta\}$ and we introduce $\forall\ x \in D$ the mapping $\mathcal{J}_c^x : \eta \longrightarrow \mathbb{E}_x[f(X_T)\mathbf{1}_{\tau_{D_\eta}>T}]$. We show below that under the assumptions of Theorem 2.2, the mapping $\mathcal{J}_c^x$ is differentiable in $\eta = 0$ and for $c = (\underbrace{1,\dots,1}_{m},\underbrace{0,\dots,0}_{d-m})$, one has

$$\begin{aligned}\partial_\eta \mathcal{J}_c^x(\eta)|_{\eta=0} &= -\mathbb{E}_x[\nabla v(\tau, X_\tau).c\mathbf{1}_{\tau<T}]\\ &= -\sum_{i=1}^{m}\mathbb{E}_x[\partial_{x_i} v(\tau^i, X_{\tau^i})\mathbf{1}_{\tau^i\le T,\wedge_{j\neq i}\tau^j>\tau^i}].\end{aligned} \tag{4.5}$$

From (4.5) we then derive that $E_2 = \mathcal{J}_c^x(C_0\sqrt{h}) - \mathcal{J}_c^x(0) = \partial_\eta \mathcal{J}_c^x(0)C_0\sqrt{h} + o(\sqrt{h}) = -C_1\sqrt{h} + o(\sqrt{h})$ which proves the theorem.

Proof of (4.5). Let us define $X_s^\eta := X_s - \eta c,\ \tau^{D,\eta} = \inf\{s > 0 : X_s^\eta \notin D\}$. Note that $\tau_{D_\eta} = \tau^{D,\eta}$. Denoting $\Delta_\eta := \mathbb{E}_x[f(X_T^\eta + \eta c)\mathbf{1}_{\tau^{D,\eta}>T}] - v(0,x)$, we have to identify the limit of Δ_η/η as $\eta \longrightarrow 0$. We have

$$\begin{aligned}\Delta_\eta &= \mathbb{E}_x[f(X_T^\eta + \eta c)\mathbf{1}_{\tau^{D,\eta}>T}] - \mathbb{E}_x[f(X_T^\eta)\mathbf{1}_{\tau^{D,\eta}>T}]\\ &+\mathbb{E}_x[f(X_T^\eta)\mathbf{1}_{\tau^{D,\eta}>T} - v(T\wedge\tau^{D,\eta}, X_{T\wedge\tau^{D,\eta}})]\\ &+\mathbb{E}_x[v(T\wedge\tau^{D,\eta}, X_{T\wedge\tau^{D,\eta}})] - v(0,x) := \Delta_{\eta,1}+\Delta_{\eta,2}+\Delta_{\eta,3}.\end{aligned}$$

Since $(M_t)_{t\in[0,T]} := (v(t\wedge\tau, X^{0,x}_{t\wedge\tau}))_{t\in[0,T]}$ is a martingale and $\tau^{D,\eta} < \tau$, we readily get $\Delta_{\eta,3} = 0$.

Note that $f(X_T^\eta)\mathbf{1}_{\tau^{D,\eta}>T} = v(T\wedge\tau^{D,\eta}, X^\eta_{T\wedge\tau^{D,\eta}})$. One also has $\tau_{D_\eta} \underset{\eta\longrightarrow 0,\ \text{a.s}}{\longrightarrow} \tau$. From assumption **(S)**, v is continuously differentiable. Thus, one gets $\lim_{\eta\longrightarrow 0}\Delta_{\eta,2}/\eta = -\mathbb{E}_x[\nabla v(T\wedge\tau, X_{T\wedge\tau}).c]$.

On the other hand, since we assumed f to be continuously differentiable we obtain $\lim_{\eta\longrightarrow 0}\Delta_{\eta,1}/\eta = \mathbb{E}_x[\nabla f(X_T).c\ \mathbf{1}_{\tau>T}]$. Recalling $\forall x \in \bar{D},\ v(T,x) = f(x)$ we write

$$\partial_\eta \mathcal{J}_c^x(\eta)|_{\eta=0} = -\mathbb{E}_x\big[\big(\nabla v(T\wedge\tau, X_{T\wedge\tau}) - \nabla f(X_T)\mathbf{1}_{\tau>T}\big).c\big] = -\mathbb{E}_x[\mathbf{1}_{\tau\le T}\nabla v(\tau, X_\tau).c]$$

which for $c = (\underbrace{1,\dots,1}_{m},\underbrace{0,\dots,0}_{d-m})$ proves (4.5). ∎

Remark 4.4. We mention that in the special case of a half space, an alternative proof based on the explicit expression of the hitting time densities is possible; see Chapter III of [Men04].

5. Some smoothness properties of v under (D): Sufficient conditions to fulfill (S). In the whole section we assume **(BM)**, **(D)**. We deal only with the case $d \geq 2, m \geq 2$. Indeed, for $m = 1$ the domain D is smooth and standard results, based on the explicit expression of the density of the killed BM, can be used to derive the required smoothness in **(S)**.

This section is divided into two parts. In subsection 5.1 we recall the explicit expression of the killed heat kernel under **(D)** and also state a control of its derivatives in dimension 2. Using these results and some standard PDE techniques we then derive in subsection 5.2 some sufficient conditions to get **(S)** when $d = m = 2$.

5.1. Explicit expression of the heat kernel under (D) and associated controls. Note first that

$$\mathbb{P}_x[\tau > t, X_t \in [y, y + dy)]/dy = |\det(\sigma_0^{-1})|\mathbb{P}_{\tilde{x}}[\tilde{\tau} > t, \tilde{X}_t \in [z, z + dz)]/dz, \tag{5.1}$$

where $\tilde{x} = \sigma_0^{-1}x,\ z = \sigma_0^{-1}y,\ \tilde{X}_t = \tilde{x} + W_t$ with W standard BM, $\tilde{D} := \{z \in \mathbb{R}^d : (\sigma_0 z)_i > b_0^i\}$, and $\tilde{\tau} := \inf\{s \geq 0 : \tilde{X}_s \notin \tilde{D}\}$.

Equation (5.1) gives the expression of the killed density of X under **(D)** in function of the density of the killed standard BM in a convex cone $\tilde{D}$ that writes as an intersection of half spaces. The domain $\tilde{D}$ is piecewise C^∞ and hence the trace of the cone on the unit sphere $\mathbb{S}^{d-1}$ with center at the vertex of $\tilde{D}$ is a normal domain in the sense of Chavel [Cha84] (see definition on page 16 of this reference). Denoting this trace by $\Gamma := \tilde{D} \cap \mathbb{S}^{d-1}$, we derive from page 169 of the above reference that we have a Sturm–Liouville spectral decomposition of the Laplace–Beltrami operator for the elliptic Dirichlet problem on Γ; i.e., the normalized eigenfunctions $(m_j)_{j\in\mathbf{N}^*}$ of $\Delta_{\mathbb{S}^{d-1}}$ form an orthonormal basis of $L^2(\Gamma)$ and the eigenvalues $(\lambda_j)_{j\in\mathbf{N}^*}$ are s.t. $0 < \lambda_1 < \lambda_2 \leq \lambda_3 \leq \cdots \uparrow +\infty$.

As a direct consequence of (2.2) in Bañuelos and Smits [BS97], we derive the following proposition.

PROPOSITION 5.1. *Let $\tilde{D}$ be a cone with origin 0 that writes as a nonempty intersection of half spaces. One has*

$$\begin{aligned}
&\forall (t, x, y) \in \mathbb{R}^{+*} \times \tilde{D}^2,\ x = r\theta,\ y = \rho\eta,\ (\theta, \eta) \in (\mathbb{S}^{d-1})^2,\ (\rho, r) \in (\mathbb{R}^{+*})^2,\\
&\mathbb{P}_x[\tilde{X}_t \in dy, \tilde{\tau} > t] = \frac{e^{-\frac{\rho^2+r^2}{2t}}}{t(\rho r)^{\frac{d}{2}-1}} \sum_{j=1}^{+\infty} I_{\nu_j}\left(\frac{\rho r}{t}\right) m_j(\theta) m_j(\eta) \rho^{d-1} d\rho d\sigma(\eta)\\
&:= \mathbf{q_t}(\mathbf{x}, \mathbf{y})\mathbf{dy},\ \nu_j = (\lambda_j + (\tfrac{d}{2} - 1)^2)^{1/2},
\end{aligned}$$

where λ_j (resp., m_j) are the eigenvalues (resp., the normalized eigenfunctions) of $\Delta_{\mathbb{S}^{d-1}}$ on Γ for the elliptic Dirichlet problem and I_ν denotes the modified Bessel function of order ν.

Remark 5.1. The result of Proposition 5.1 is standard in the bidimensional case. It is in that case a simple extension of the well-known method of images that consists, for special angles, in writing the killed heat kernel as a suitable sum of standard Gaussian kernels alternating heat sources and sinks in order to satisfy the boundary conditions. We refer to Carslaw and Jaeger [CJ59] or to Iyengar [Iye85] for details.

Remark 5.2. In the special case $d = m = 2$ the eigenvalues (resp., the normalized eigenfunctions) write $\lambda_j = (\pi j/\omega)^2$ (resp., $m_j(\theta) = \sqrt{\frac{2}{\omega}} \sin(\frac{\pi j}{\omega} \arg(\theta))$), where $\omega \in (0, 2\pi)$ is the angle of the cone. For $m > 2$, we do not have such an explicit expression, but analysis techniques (see Weyl's lemma [Cha84, p. 172]) give some controls on the behavior of these eigenvalues; see also Remark B.2.

LEMMA 5.2 (radial control of the derivatives when $\mathbf{d = m = 2}$). *For a given* $\omega \in (0, \pi)$, *let* $\tilde{D} := \{x = (r\cos\theta, r\sin\theta) \in \mathbb{R}^2 : r > 0,\ \theta \in (0, \omega)\}$. *Note that* $\tilde{D}$ *is a convex cone.* $\forall\ R > 0, T > 0$, *there exist positive constants* $C := C(R, T), c, \xi$ *s.t.* $\forall (t, x, y) \in (0, T] \times (\tilde{D} \cap B(0, R)) \times \tilde{D}$, $x = (r\cos\theta, r\sin\theta)$, $y = (\rho\cos\eta, \rho\sin\eta)$, $(\theta, \eta) \in (0, \omega)^2$, $(\rho, r) \in (\mathbb{R}^{+*})^2$, *one has*

$$q_t(x, y) + |\partial_t q_t(x, y)| + |\nabla_x q_t(x, y)| \le \frac{C}{t^\xi} \exp\left(-c\frac{|r - \rho|^2}{t}\right)$$

and $\exists \alpha_0 := \alpha_0(\omega) > 0$,

$$\sup_{(x,\, x') \,\in\, (\tilde{D} \,\cap\, B(0,\, R))^2} \frac{|\nabla q_t(x, y) - \nabla q_t(x', y)|}{|x - x'|^{\alpha_0}} \le \frac{C}{t^\xi} \exp\left(-c\frac{|r - \rho|^2 \wedge |r' - \rho|^2}{t}\right).$$

The proof of the above lemma is postponed to Appendix B.

5.2. Derivation of (S) when $d = m = 2$. In Remark 5.1 we mentioned that for special angles of the cone, one could express the killed heat kernel q in terms of a sum of standard Gaussian kernels. To be precise, this can be done when the angle of the cone writes $\omega = \pi/m_0, m_0 \in \mathbf{N}^*$. For our original problem (4.1), one can establish a connection between the killed heat kernel q and the density of the killed BM in the orthant thanks to (5.1). One therefore deduces that for some particular correlation coefficients, corresponding to angles that have the previous form, under suitable assumptions on the final condition f one has the "usual" smoothness properties for the solution v of problem (4.1), and hence **(S)** is satisfied. We now give a smoothness result for the solution v of (4.1) for general correlation coefficients. Using the notation of section 2.1, we introduce the following assumption:

(F) The function $f \in C_b^{2+\alpha}(\bar{D})$, $\alpha > 0$, $f|_{\partial D} = \mathrm{Tr}(H_f \sigma_0 \sigma_0^*)|_{\partial D} = 0$, and $d(\mathrm{supp}(f), b_0) \ge 2\varepsilon > 0$.

PROPOSITION 5.3. *Assume* **(D)**, **(BM)**, **(F)**. *For* $D := \{x \in \mathbb{R}^2 : x_1 > b_0^1, x_2 > b_0^2\}$, $\sigma_0\sigma_0^* = \begin{pmatrix} 1 & \rho \\ \rho & 1 \end{pmatrix}$, $\rho \in (-1, 1)$, *there exists* $\alpha' > 0$ *s.t. the unique solution* v *of* (4.1) *belongs to* $C_b^{1/2+\alpha'/2, 1+\alpha'}([0, T] \times \bar{D})$. *In particular,* **(S)** *is satisfied.*

Proof. From Proposition 5.1 we derive that problem (4.1) has a unique solution $v \in C^{1,2}([0, T) \times D) \cap C_b^0([0, T] \times \bar{D})$, where $C_b^0([0, T] \times \bar{D})$ denotes the space of bounded continuous functions on $[0, T] \times \bar{D}$.

Let us now note that as a consequence of the support condition in **(F)** and the radial control of Lemma 5.2 there exists $\alpha_0 > 0$ s.t. $v \in C_b^{1/2+\alpha_0/2, 1+\alpha_0}([0, T] \times B(b_0, \varepsilon) \cap \bar{D})$. Choose now D_1 to be a C^3 domain s.t. $d(\bar{D}_1, b_0) \ge \varepsilon/3 > 0$ and $\{x \in \mathbb{R}^2 : |x - b_0| \ge \varepsilon, x \in \partial D\} = \{x \in \mathbb{R}^2 : |x - b_0| \ge \varepsilon, x \in \partial D_1\}$. From the techniques used in Chapter IV of Friedman [Fri64] to prove the boundary Schauder estimates and Theorem 5.2 in Chapter 4 in [LSU68], we derive that $v \in C_b^{1+\alpha/2, 2+\alpha}([0, T] \times \bar{D}_1)$. Put $\alpha' := \alpha \wedge \alpha_0$. The proof is complete. □

6. Conclusion. In this paper we obtained an expansion result for the weak error in the special case of a discretely killed Brownian motion in an orthant provided

we had smoothness properties of the solution of the underlying Cauchy–Dirichlet problem. We exploited the explicit asymptotic distribution of the overshoot above the boundary that had previously been characterized as the leading term of the weak error; see [GM04]. Finally, the correction method we introduced has given promising results. A natural question concerns its possible extension to a wider framework than the Brownian one. The theoretical analysis of Algorithm 3.1 introduced to this end will concern further research.

The main motivation that led us to deal with conical cases comes from mathematical finance. Indeed, with multiassets, one often defines the domain of a barrier option as a product domain. For the moment we are only able to treat in whole generality the case of bidimensional domains in a Black–Scholes framework.

Concerning further extensions in bigger dimensions, the key point concerns the smoothness properties of the underlying function $v(t,x) = \mathbb{E}_x[f(X_{T-t})\mathbf{1}_{\tau>T-t}]$. Anyhow, for some special angles, or equivalently for special correlation coefficients, we can extend the method of images to express the transition density as a sum of standard Gaussian kernels. In that case, under suitable assumptions on f, we have the usual smoothness properties on v, and both the expansion and correction results hold true.

Let us mention that the proof of the main results would work if v had a uniform Hölder continuous first spatial derivative with exponential growth only in a neighborhood of the boundary. This could allow us to relax the boundedness assumption on f.

Appendix A. Asymptotic behavior of the overshoot. This section is dedicated to the proof of Lemma 4.2 introduced in section 4.2 concerning the asymptotic behavior of the overshoot. In the following, we freely use the notation introduced in Theorem 2.1 and Lemma 4.2.

A.1. Asymptotic independence of the overshoot and the exit time. We first state a one-dimensional result due to Siegmund [Sie79].

LEMMA A.1 (asymptotic independence of the overshoot and the discrete exit time). *Let W be a standard linear BM. Put $x > 0$ and consider the domain $D :=]-\infty, x[$. We have for any $y \geq 0$*

$$\lim_{h \longrightarrow 0} \mathbb{P}_0[\tau^N \leq t, (W_{\tau^N} - x) \leq y\sqrt{h}] = \mathbb{P}_0[\tau \leq t] H(y). \tag{A.1}$$

The limit is uniform in $t \in [0,T]$.

Proof. Equation (A.1) is a direct consequence of Lemma 3 in [Sie79] for a fixed t. We derive the uniformity on $[0,T]$ using Dini-like arguments noting that the left-hand side of (A.1) defines a sequence of (discontinuous) increasing functions and that the simple limit is continuous (see, e.g., problem 7.2.3 in [Die71] or subsection A.2). ∎

From now on, we assume $m \geq 2$ and proceed to the proof.

Proof of Lemma 4.2. Let us first show that $\forall (t,y) \in [0,T] \times \mathbb{R}^{+,*}$, $\zeta_N(t) := \mathbb{P}_x[\sqrt{h}^{-1}(X^1_{\tau^{N,1}} - b^1_0)^- \geq y, \tau^N \leq t, \tau^{N,1} \leq \wedge_{i=2}^m \tau^{N,i}] \underset{N}{\longrightarrow} (1 - H(y))\mathbb{P}_x[\tau^1 \leq t, \wedge_{i=2}^m \tau^i > \tau^1] := \zeta(t)$. We write

$$\begin{aligned} \zeta_N(t) &= \mathbb{P}_x[\sqrt{h}^{-1}(X^1_{\tau^{N,1}} - b^1_0)^- \geq y, \tau^{N,1} \leq t] \\ &\quad -\mathbb{P}_x[\sqrt{h}^{-1}(X^1_{\tau^{N,1}} - b^1_0)^- \geq y, \tau^{N,1} \leq t, \tau^{N,1} > \wedge_{i=2}^m \tau^{N,i}] \\ &:= (\zeta^1_N - \zeta^2_N)(t). \end{aligned} \tag{A.2}$$

From Lemma A.1 one gets

$$\zeta_N^1(t) \underset{N}{\longrightarrow} \zeta^1(t) := (1-H(y))\mathbb{P}_x[\tau^1 \le t] \tag{A.3}$$

uniformly on $[0,T]$. Let us turn to the control of ζ_N^2. As a consequence of the strong Markov property of X, we have

$$\begin{aligned}\zeta_N^2(t) &= \mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m \tau^{N,i} \le t}\mathbf{1}_{\tau^{N,1}>\wedge_{i=2}^m \tau^{N,i}}\mathbb{P}[\sqrt{h}^{-1}(X^1_{\tau^{N,1}} - b_0^1)^- \ge y, \tau^{N,1} \le t | \mathcal{F}_{\wedge_{i=2}^m \tau^{N,i}}]] \\ &:= \mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m \tau^{N,i} \le t}\mathbf{1}_{\tau^{N,1}>\wedge_{i=2}^m \tau^{N,i}}\xi_N(X^1_{\wedge_{i=2}^m \tau^{N,i}}, \wedge_{i=2}^m \tau^{N,i}, t)]\end{aligned}$$

with $\xi_N(X^1_{\wedge_{i=2}^m \tau^{N,i}}, \wedge_{i=2}^m \tau^{N,i}, t) = \mathbb{P}_{X^1_{\wedge_{i=2}^m \tau^{N,i}}}[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}} - b_0^1)^- \ge y, \tilde{\tau}^{N,1} \le t - \wedge_{i=2}^m \tau^{N,i}]$, where $(\tilde{X}^1_t)_{t\ge 0}$ is a standard BM with starting point $X^1_{\wedge_{i=2}^m \tau^{N,i}}$ and $\tilde{\tau}^{N,1} := \inf\{t_i := ih \ge 0 : \tilde{X}^1_{t_i} \le b_0^1\}$.

For a given arbitrary compact interval $\mathcal{K} := [\underline{\mathcal{K}}, \overline{\mathcal{K}}] \subset (b_0^1, +\infty)$ we split $\zeta_N^2(t)$ into two parts.

$$\begin{aligned}\zeta_N^2(t) &= \mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m \tau^{N,i} \le t}\mathbf{1}_{\tau^{N,1}>\wedge_{i=2}^m \tau^{N,i}}\mathbf{1}_{X^1_{\wedge_{i=2}^m \tau^{N,i}} \in \mathcal{K}}\xi_N(X^1_{\wedge_{i=2}^m \tau^{N,i}}, \wedge_{i=2}^m \tau^{N,i}, t)] \\ &+ \mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m \tau^{N,i} \le t}\mathbf{1}_{\tau^{N,1}>\wedge_{i=2}^m \tau^{N,i}}\mathbf{1}_{X^1_{\wedge_{i=2}^m \tau^{N,i}} \notin \mathcal{K}}\xi_N(X^1_{\wedge_{i=2}^m \tau^{N,i}}, \wedge_{i=2}^m \tau^{N,i}, t)] \\ &:= \zeta_N^{21}(t) + \zeta_N^{22}(t).\end{aligned}$$

Fix $\varepsilon > 0$. We now show that one can choose $\mathcal{K}(\varepsilon),\ N_0 := N_0(\varepsilon, \mathcal{K}(\varepsilon))$ s.t. for $N \ge N_0$,

$$\zeta_N^2(t) = (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t] + O(\varepsilon). \tag{A.4}$$

Control of $\zeta_N^{21}(t)$. Write first

$$\begin{aligned}\zeta_N^{21}(t) &= \Big(\zeta_N^{21}(t) - (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t, X^1_{\wedge_{i=2}^m \tau^i} \in \mathcal{K}]\Big) \\ &\quad + (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t] - R(t,\mathcal{K}),\end{aligned}$$

where $R(t,\mathcal{K}) = (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t, X^1_{\wedge_{i=2}^m \tau^i} \notin \mathcal{K}]$. Note that

$$\begin{aligned}0 \le R(t,\mathcal{K}) &\le \mathbb{P}_x\big[\wedge_{i=2}^m \tau^i \le T, X^1_{\wedge_{i=2}^m \tau^i} \ge \overline{\mathcal{K}}\big] \\ &\quad + \mathbb{P}_x\big[\wedge_{i=2}^m \tau^i \le T, X^1_{\wedge_{i=2}^m \tau^i} \in (b_0^1, \underline{\mathcal{K}}]\big] := R_1(\overline{\mathcal{K}}) + R_2(\underline{\mathcal{K}}).\end{aligned}$$

Lemma 4.1 readily gives $R_1(\overline{\mathcal{K}}) \le C\exp(-c\frac{(\overline{\mathcal{K}}-x_1)^2}{T})$. On the other hand, $R_2(\underline{\mathcal{K}}) \underset{\underline{\mathcal{K}} \longrightarrow b_0^1}{\longrightarrow} 0$. Hence, for $\varepsilon > 0$ we can choose $\mathcal{K} = \mathcal{K}(\varepsilon)$ s.t.

$$\begin{aligned}\zeta_N^{21}(t) &= \Big(\zeta_N^{21}(t) - (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t, X^1_{\wedge_{i=2}^m \tau^i} \in \mathcal{K}]\Big) \\ &\quad + (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t] + O(\varepsilon) \\ &:= \delta_N(t) + (1-H(y))\mathbb{P}_x[\wedge_{i=2}^m \tau^i < \tau^1, \tau^1 \le t] + O(\varepsilon).\end{aligned}$$

For the term $\delta_N(t)$ we introduce the following lemma whose proof is postponed to the end of the section.

LEMMA A.2. *Let $\tilde{X}^1$ be a standard BM with starting point $\tilde{x}$ in a given compact interval $\mathcal{K} = [\underline{\mathcal{K}}, \overline{\mathcal{K}}] \subset (b_0^1, +\infty)$. Then*

$$\mathbb{P}_{\tilde{x}}[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}} - b_0^1)^- \ge y, \tilde{\tau}^{N,1} \le u] \underset{N}{\longrightarrow} (1-H(y))\mathbb{P}_{\tilde{x}}[\tilde{\tau}^1 \le u]$$

uniformly on $(\tilde{x},u)\in\mathcal{K}\times[0,T]$.

From Lemma A.2, $\forall\varepsilon>0,\ \exists\tilde{N}_0:=\tilde{N}_0(\mathcal{K}(\varepsilon),\varepsilon)$, s.t. $N\geq\tilde{N}_0$

$$\begin{aligned}
&\delta_N(t)=(1-H(y))\Big\{\mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m\tau^{N,i}\leq t}\mathbf{1}_{\wedge_{i=2}^m\tau^{N,i}<\tau^{N,1}}\mathbf{1}_{X^1_{\wedge_{i=2}^m\tau^{N,i}}\in\mathcal{K}}\\
&\times\mathbb{P}_{X^1_{\wedge_{i=2}^m\tau^{N,i}}}[\tilde{\tau}^1\leq t-\wedge_{i=2}^m\tau^{N,i}]]-\mathbb{P}_x[\wedge_{i=2}^m\tau^i<\tau^1,\tau^1\leq t,X^1_{\wedge_{i=2}^m\tau^i}\in\mathcal{K}]\Big\}+O(\varepsilon)\\
&:=(1-H(y))\Big(\mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m\tau^{N,i}\leq t}\mathbf{1}_{\wedge_{i=2}^m\tau^{N,i}<\tau^{N,1}}\mathbf{1}_{X^1_{\wedge_{i=2}^m\tau^{N,i}}\in\mathcal{K}}\xi_t(X^1_{\wedge_{i=2}^m\tau^{N,i}},\wedge_{i=2}^m\tau^{N,i})]\\
&-\mathbb{E}_x[\mathbf{1}_{\wedge_{i=2}^m\tau^i\leq t}\mathbf{1}_{\wedge_{i=2}^m\tau^i<\tau^1}\mathbf{1}_{X^1_{\wedge_{i=2}^m\tau^i}\in\mathcal{K}}\xi_t(X^1_{\wedge_{i=2}^m\tau^i},\wedge_{i=2}^m\tau^i)]\Big)+O(\varepsilon).
\end{aligned}$$

Note that $\xi_t(x,u):=\mathbb{P}_x[\tilde{\tau}\leq t-u]$ is continuous in $(x,u)\in(b_0^1,+\infty)\times[0,t]$. Recall that $\tau^{N,i}\xrightarrow[N]{\text{a.s}}\tau^i,\ i\in[\![1,m]\!]$, and by continuity $X^1_{\wedge_{i=2}^m\tau^{N,i}}\xrightarrow[N]{\text{a.s}}X^1_{\wedge_{i=2}^m\tau^i}$. One can check that the law of $(\tau^1,\wedge_{i=2}^m\tau^i,X^1_{\wedge_{i=2}^m\tau^i})$ is absolutely continuous w.r.t. the Lebesgue measure. We thus derive by convergence in law that for N large enough

$$\delta_N(t)\ =\ O(\varepsilon),\ \zeta_N^{21}(t)=(1-H(y))\mathbb{P}_x[\wedge_{i=2}^m\tau^i<\tau^1,\tau^1\leq t]+O(\varepsilon). \tag{A.5}$$

Control of $\zeta_N^{22}(t)$. The arguments we use to control this term are quite similar to those introduced to treat the terms $R_1(\overline{\mathcal{K}}),R_2(\underline{\mathcal{K}})$ above.

Indeed, since $\xi_N\in[0,1]$ one gets

$$\begin{aligned}
\zeta_N^{22}(t)\ &\leq\ \mathbb{P}_x[\wedge_{i=2}^m\tau^{N,i}\leq T,X^1_{\wedge_{i=2}^m\tau^{N,i}}\geq\overline{\mathcal{K}}]+\mathbb{P}_x[\wedge_{i=2}^m\tau^{N,i}\leq T,X^1_{\wedge_{i=2}^m\tau^{N,i}}\in(b_0^1,\underline{\mathcal{K}}]]\\
&:=\ R_1^N(\overline{\mathcal{K}})+R_2^N(\underline{\mathcal{K}}).
\end{aligned}$$

From Lemma 4.1 we get $R_1^N(\overline{\mathcal{K}})\leq C\exp(-c\frac{(\overline{\mathcal{K}}-x_1)^2}{T})$. The previous choice of $\overline{\mathcal{K}}$ gives $R_1^N(\overline{\mathcal{K}})=O(\varepsilon)$. Write now $R_2^N(\underline{\mathcal{K}}):=(R_2^N(\underline{\mathcal{K}})-R_2(\underline{\mathcal{K}}))+R_2(\underline{\mathcal{K}})$. On the one hand, the former choice of $\underline{\mathcal{K}}$ yields $R_2(\underline{\mathcal{K}})=O(\varepsilon)$. On the other hand, for the difference $(R_2^N-R_2)(\underline{\mathcal{K}})$, since $\tau^{N,i}\xrightarrow[N]{\text{a.s}}\tau^i,\ i\in[\![2,m]\!],\ X^1_{\wedge_{i=2}^m\tau^{N,i}}\xrightarrow[N]{\text{a.s}}X^1_{\wedge_{i=2}^m\tau^i}$, with the same arguments we employed to control $\delta_N(t)$, we derive by convergence in law $\exists N_0:=N_0(\underline{\mathcal{K}},\varepsilon),\ N\geq N_0,\ |(R_2^N-R_2)(\underline{\mathcal{K}})|\leq\varepsilon$. Hence, for $N:=N(\mathcal{K},\varepsilon)$ large enough, we write $\zeta_N^{22}(t)=O(\varepsilon)$ which together with (A.5) gives (A.4). From (A.4), (A.3), and (A.2) we derive the simple convergence of ζ_N to ζ for a fixed $t\in[0,T]$.

The uniformity in $t\in[0,T]$ derives from the fact that $\zeta_N(t)$ is a cumulative distribution function with continuous limit; see also the arguments at the beginning of the proof of Lemma A.1. □

A.2. Proof of Lemma A.2. Let us define $\forall(x,u)\in(\mathcal{K}:=[\underline{\mathcal{K}},\overline{\mathcal{K}}])\times[0,T],\ \underline{\mathcal{K}}>b_0^1,\ \Psi_N(x,u)=\mathbb{P}_x[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}}-b_0^1)^-\geq y,\tilde{\tau}^{N,1}\leq u]$. For a fixed $x\in\mathcal{K}$, Lemma A.1 yields that $\Psi_N(x,u)\xrightarrow[N]{}(1-H(y))\mathbb{P}_x[\tau^1\leq u]:=\Psi(x,u)$ uniformly on $u\in[0,T]$. Let us now show that for a fixed $u\in[0,T]$ we have the uniform convergence w.r.t. $x\in\mathcal{K}$. Write

$$\begin{aligned}
&\Psi_N(x,u)=\mathbb{P}_x[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}}-b_0^1)^-\geq y]-\mathbb{P}_x[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}}-b_0^1)^-\geq y,\tilde{\tau}^{N,1}>u]\\
&:=\Psi_N^1(x)-\Psi_N^2(x,u).
\end{aligned}$$

With the notation of Theorem 2.1, introducing $\forall a \geq 0, \bar{\tau}_a := \inf\{n \in \mathbf{N} : s_n > a\}$, we write $\Psi_N^1(x) = \mathbb{P}_x[\sqrt{h}^{-1}(\tilde{X}^1_{\tilde{\tau}^{N,1}} - b_0^1)^- \geq y] = \mathbb{P}_0[(s_{\bar{\tau}_{(x-b_0^1)/\sqrt{h}}} - (x-b_0^1)/\sqrt{h}) \geq y]$. Equation (19) from [Sie79] gives $\lim_{b\to\infty} \mathbb{P}_0[s_{\bar{\tau}_b} - b \geq y] = 1 - H(y)$. Hence, $\Psi_N^1(x) \underset{N}{\longrightarrow} (1 - H(y))$ uniformly on $x \in \mathcal{K}$. We develop Ψ_N^2 like in the proof of Lemma 3 from the same reference, controlling that we can isolate uniform rests. Recalling $\phi(u) := \inf\{t_i \geq 0 : t_i \leq u < t_{i+1}\}$, we get

$$\begin{aligned}\Psi_N^2(x,u) &= \mathbb{P}[(s_{\bar{\tau}_{(x-b_0^1)/\sqrt{h}}} - (x-b_0^1)/\sqrt{h}) \geq y, \bar{\tau}_{(x-b_0^1)/\sqrt{h}} > \phi(u)/h] \\ &= \int_0^\infty \mathbb{P}[\bar{\tau}_{(x-b_0^1)/\sqrt{h}} > \phi(u)/h, (x-b_0^1)/\sqrt{h} - s_{\phi(u)/h} \in [z, z+dz)] \\ &\quad \times \mathbb{P}[s_{\bar{\tau}_z} - z \geq y].\end{aligned}$$

We split the above integral into three terms $\Psi_N^{21}, \Psi_N^{22}, \Psi_N^{23}$ respectively associated to the intervals $(0, \varepsilon(x-b_0^1)/\sqrt{h})$, $(\varepsilon(x-b_0^1)/\sqrt{h}, (x-b_0^1)/(\varepsilon\sqrt{h}))$, $((x-b_0^1)/(\varepsilon\sqrt{h}), \infty)$ for an arbitrary $\varepsilon \in (0,1)$. One has

$$\begin{aligned}\Psi_N^{21}(x,u) &\leq \mathbb{P}\left[\frac{(1-\varepsilon)(x-b_0^1)}{\sqrt{h}\sqrt{\phi(u)/h}} \leq \mathcal{N}(0,1) \leq \frac{x-b_0^1}{\sqrt{h}\sqrt{\phi(u)/h}}\right] \\ &\leq \mathbb{P}\left[\frac{(1-\varepsilon)(x-b_0^1)}{T^{1/2}} \leq \mathcal{N}(0,1) \leq \frac{x-b_0^1}{T^{1/2}}\right] \leq \tfrac{C\varepsilon(\overline{\mathcal{K}}-b_0^1)}{T^{1/2}}\end{aligned}$$

uniformly for $x \in \mathcal{K}$. We also have

$$\begin{aligned}\Psi_N^{23}(x,u) &\leq \mathbb{P}\left[\mathcal{N}(0,1) \leq (1-\varepsilon^{-1})\frac{x-b_0^1}{\phi(u)^{1/2}}\right] \leq \mathbb{P}\left[\mathcal{N}(0,1) \leq (1-\varepsilon^{-1})\frac{\underline{\mathcal{K}}-b_0^1}{T^{1/2}}\right] \\ &\leq \frac{CT^{1/2}}{\underline{\mathcal{K}}-b_0^1}\frac{\varepsilon}{1-\varepsilon},\end{aligned}$$

which is still uniform w.r.t. $x \in \mathcal{K}$. From these computations we derive that for N large enough, $\Psi_N^{22}(x,u) = (1-H(y))\mathbb{P}_x[\tilde{\tau}^{N,1} > u] + O(\varepsilon)$, where the rest is uniform w.r.t. $\mathcal{K}$. It therefore remains to show $\mathbb{P}_x[\tilde{\tau}^{N,1} > u] := \gamma_N(u,x) \underset{N}{\longrightarrow} \gamma(u,x) := \mathbb{P}_x[\tilde{\tau}^1 > u]$ uniformly on $\mathcal{K}$. We note that $1 - \gamma_N(u,x) = \mathbb{P}_0[\sup_{i\in[\![0,\phi(u)/h]\!]} \tilde{X}^1_{t_i} \geq (x-b_0^1)]$ is decreasing in x, so that $\gamma_N(u,.)$ is increasing. Since the simple limit is continuous, we derive the uniformity using the same arguments as in the proof of Lemma A.1.

Now, we have shown that for a fixed parameter $x \in \mathcal{K}$, $u \in [0,T]$, we have the uniform convergence w.r.t. the other. Let us now show the joint uniform convergence. The limit Ψ is uniformly continuous on $\mathcal{K} \times [0,T]$. This reads

(A.6)
$$\forall \varepsilon > 0, \exists \eta := \eta(\varepsilon), \forall (x,x') \times (t,t') \in \mathcal{K}^2 \times [0,T]^2,\ |t-t'| + |x-x'| \leq \eta, \\ |\Psi(x,t) - \Psi(x',t')| \leq \varepsilon.$$

In particular, $|t-t'| \leq \eta \Rightarrow \sup_{x\in\mathcal{K}} |\Psi(x,t) - \Psi(x,t')| \leq \varepsilon$. Let us now consider a regular grid $\Lambda := \{s_i\}_{i\in[\![1,a]\!]}$ of $[0,T]$ with step $s = s_{i+1} - s_i \leq \eta$. Since for a fixed $t \in [0,T]$ we have uniform convergence in space,

(A.7) $$\forall \varepsilon > 0,\ \exists \tilde{N}_0 = \max_{i\in[\![1,a]\!]} \tilde{N}_0(s_i),\ N \geq \tilde{N}_0,\ \sup_{i\in[\![1,a]\!]} \sup_{x\in\mathcal{K}} |\Psi_N(x,s_i) - \Psi(x,s_i)| \leq \varepsilon.$$

Noting that both $\Psi_N(x,.), \Psi(x,.)$ are increasing functions we derive from (A.6), (A.7)

$$\begin{array}{l}\forall t \in [s_i, s_{i+1}],\ \Psi(x,s_i) - \Psi(x,s_{i+1}) + \Psi(x,s_{i+1}) - \Psi_N(x,s_{i+1}) \\ \leq \Psi(x,t) - \Psi_N(x,t) \leq \Psi(x,s_{i+1}) - \Psi(x,s_i) + \Psi(x,s_i) - \Psi_N(x,s_i), \\ \forall \varepsilon > 0, \exists N_0,\ N \geq N_0,\ \sup_{t\in[0,T]} \sup_{x\in\mathcal{K}} |\Psi(x,t) - \Psi_N(x,t)| \leq \varepsilon,\end{array}$$

which shows the joint uniformity and completes the proof.

Appendix B. Results about the killed heat kernel: Proof of Lemma 5.2. One of the key tools in the proof of the lemma is the following identity:

$$\forall x > 0,\ \forall \mu > \nu \geq 0,\ I_\mu(x) < I_\nu(x). \tag{B.1}$$

Relation (B.1) was proved by Jones in [Jon68]. From identity 9.6.34 in Abramowitz and Stegun we also get that $\exp(z) = I_0(z) + 2\sum_{n=1}^{\infty} I_n(z)$. Hence, from the explicit expression of the killed heat kernel (see Proposition 5.1 and Remark 5.2) and recalling that $\nu_n := n\pi/\omega > n$, (B.1) yields

$$q_t(x,y) \leq \frac{2\exp(-\frac{r^2+\rho^2}{2t})}{t\omega} \sum_{n=1}^{\infty} I_{\nu_n}\left(\frac{r\rho}{t}\right) \leq \frac{2\exp(-\frac{r^2+\rho^2}{2t})}{t\omega} \sum_{n=1}^{\infty} I_n\left(\frac{r\rho}{t}\right) \leq \frac{\exp(-\frac{|r-\rho|^2}{2t})}{t\omega}.$$

Put $A_t := \sum_{n=1}^{\infty} \partial_t(\sin(\nu_n\theta)\sin(\nu_n\eta) I_{\nu_n}\left(\frac{r\rho}{t}\right))$. From the recurrence relations on modified Bessel functions (see formula 9.6.26 in [AS72]) one gets $|A_t| \leq \frac{r\rho}{2t^2}\sum_{n=1}^{\infty}(I_{\nu_n+1} + I_{\nu_n-1})\left(\frac{r\rho}{t}\right) \leq C\frac{r\rho}{t^2}\exp\left(\frac{r\rho}{t}\right)$. Thus,

$$\begin{array}{rcl}\exp\left(-\frac{r^2+\rho^2}{2t}\right)|A_t| & \leq & C\frac{r\rho}{t^2}\exp\left(-\frac{|r-\rho|^2}{2t}\right) \leq C(\frac{R^2}{t^2} + \frac{R|r-\rho|}{t^2})\exp\left(-c\frac{|r-\rho|^2}{2t}\right) \\ & \leq & C(\frac{R^2}{t^2} + \frac{R}{t^{3/2}})\exp\left(-c\frac{|r-\rho|^2}{t}\right) \leq \frac{C}{t^\xi}\exp\left(-c\frac{|r-\rho|^2}{t}\right),\end{array}$$

which gives the result for the time derivative.

The boundedness and Hölder continuity of the gradient is somehow trickier to obtain. Let us show these properties for the partial derivative of the heat kernel w.r.t. the first parameter. They could be obtained for the other one exactly in the same way. Bare hand calculations yield

$$\begin{array}{rcl}\partial_{x_1} q_t(x,y) & = & -\frac{x_1}{t} q_t(x,y) + \frac{\rho}{t^2\omega}\exp\left(-\frac{r^2+\rho^2}{2t}\right)\sum_{n=1}^{\infty}\sin(\nu_n\eta) \\ & & \times\left\{\sin((\nu_n-1)\theta) I_{\nu_n-1}\left(\frac{r\rho}{t}\right) + \sin((\nu_n+1)\theta) I_{\nu_n+1}\left(\frac{r\rho}{t}\right)\right\}.\end{array}$$

The previous arguments give the stated control for $|\partial_{x_1} q_t(x,y)|$.

Now, the most "singular" term in the expression of $\partial_{x_1} q_t(x,y)$ is the one involving the modified Bessel functions of lowest order. Thus, we have to prove the Hölder continuity of

$$\begin{array}{rcl} g_t(x,y) & := & \frac{\rho}{t^2\omega}\exp\left(-\frac{r^2+\rho^2}{2t}\right)\sum_{n=1}^{\infty}\sin(\nu_n\eta)\sin((\nu_n-1)\theta) I_{\nu_n-1}\left(\frac{r\rho}{t}\right) \\ & := & \frac{\rho}{t^2\omega}\exp\left(-\frac{r^2+\rho^2}{2t}\right) B_t(x,y).\end{array}$$

Still by direct computation we get that

$$|\nabla_x B_t(x,y)| \leq \frac{C\rho}{t}\left\{\exp\left(\frac{r\rho}{t}\right) + \sum_{n=1}^{\infty} I_{\nu_n-2}\left(\frac{r\rho}{t}\right)\right\}.$$

Now, since $z \in \mathbb{R}^{+*}$, from equation 9.6.20 in [AS72]

$$I_\nu(z) = \frac{1}{\pi}\int_0^\pi \exp(z\cos(\gamma))\cos(\nu\gamma)d\gamma - \frac{\sin(\nu\pi)}{\pi}\int_0^\infty \exp(-z\cosh(t)-\nu t)dt.$$

From this expression it is easily seen that $\forall n \in \mathbf{N},\ z>0,\ I_n(z) = I_{-n}(z)$, and $\forall \nu > 0,\ \forall \varepsilon > 0$

$$\begin{aligned}&|I_\nu - I_{-\nu}|(z) \le C\int_0^\infty \exp(-z\cosh(t))\exp(\nu t)dt\\ &= C\int_0^1 \exp\left(-\frac{z}{2}(u^{-1}+u)\right)u^{-(1+\nu)}du \le Cz^{-(\nu+\varepsilon)}\int_0^1 u^{-(1-\varepsilon)}du \le \frac{C}{\varepsilon}z^{-(\nu+\varepsilon)}.\end{aligned}$$

Thus, for all $\varepsilon > 0$

$$|\nabla_x B_t(x,y)| \le \frac{C\rho}{t}\left\{\exp\left(\frac{r\rho}{t}\right) + \varepsilon^{-1}\left(\frac{r\rho}{t}\right)^{-(2-\nu_1+\varepsilon)}\mathbf{1}_{\nu_1<2}\right\}. \tag{B.2}$$

Take $(x,x') \in (B(0,R)\cap\tilde{D})^2$, s.t. $r<r'$. For $\alpha_0 \in (0,1]$ to be specified later on,

$$\begin{aligned}&\tfrac{|g_t(x,y)-g_t(x',y)|}{|x-x'|^{\alpha_0}} \le \tfrac{\rho}{t^2\omega}\exp\left(-\tfrac{\rho^2}{2t}\right)\left[\left|\exp\left(-\tfrac{r'^2}{2t}\right)-\exp\left(-\tfrac{r^2}{2t}\right)\right||B_t(x,y)|\right.\\ &\left.+\exp\left(-\tfrac{r'^2}{2t}\right)|B_t(x',y)-B_t(x,y)|\right]\times|x-x'|^{-\alpha_0} := (A_t^1+A_t^2)(x,x').\end{aligned}$$

Recalling that $|x-x'| \ge |r-r'|$ and $|B_t(x,y)| \le C\exp\left(\frac{r\rho}{t}\right)$ we derive

$$\begin{aligned}A_t^1(x,x') &\le \tfrac{C\rho}{t^3}\exp\left(-\tfrac{\rho^2}{2t}\right)\sup_{s\in[r,r']}\exp\left(-\tfrac{s^2}{2t}\right)|r-r'|^{1-\alpha_0}\times\exp\left(\tfrac{r\rho}{t}\right)\\ &\le \tfrac{C}{t^\xi}\exp\left(-c\tfrac{|r-\rho|^2}{t}\right).\end{aligned} \tag{B.3}$$

We also have $A_t^2(x,x') \le \frac{C\rho}{t^2}\exp(-\frac{r'^2+\rho^2}{2t})\sup_{u\in[0,1]}|\nabla_x B_t(ux+(1-u)x',y)||x-x'|^{1-\alpha_0}$. Hence, from (B.2) we get

$$\begin{aligned}A_t^2(x,x') \le \tfrac{C\rho^2}{t^3}\exp\left(-\tfrac{r'^2+\rho^2}{2t}\right)&\left\{\exp\left(\tfrac{r'\rho}{t}\right)+\varepsilon^{-1}\left(\tfrac{r\rho}{t}\right)^{-(2-\nu_1+\varepsilon)}\mathbf{1}_{\nu_1<2}\right\}\\ &\times|x-x'|^{1-\alpha_0}.\end{aligned}$$

If $\nu_1 \ge 2$, the above control together with (B.3) give the statement of the proposition with $\alpha_0 = 1$; i.e., the gradient is Lipschitz continuous. So from now on, we consider the case $\nu_1 < 2$.

If $|x-x'| \le r$, we derive from the previous expression that for $\nu_1 > \varepsilon$

$$\begin{aligned}A_t^2(x,x') &\le \tfrac{C}{(1\wedge\varepsilon)t^\xi}\exp\left(-c\tfrac{|r'-\rho|^2}{t}\right)(1+r^{1-\alpha_0-(2-\nu_1+\varepsilon)})\\ &\le \tfrac{C}{(1\wedge\varepsilon)t^\xi}\exp\left(-c\tfrac{|r'-\rho|^2}{t}\right)(1+r^{\nu_1-1-\varepsilon-\alpha_0}).\end{aligned} \tag{B.4}$$

On the other hand, if $|x-x'|>r$, we write

$$
\begin{aligned}
A_t^2(x,x') &\leq \tfrac{C\rho}{t^2}\exp\left(-\tfrac{r'^2+\rho^2}{2t}\right)|B_t(x,y)-B_t(x',y)|\times|x-x'|^{-\alpha_0}\\
&\leq \tfrac{C\rho}{t^2}\exp\left(-\tfrac{r'^2+\rho^2}{2t}\right)\Big(\textstyle\sum_{n=1}^{\infty}(\nu_n-1)I_{\nu_n-1}\left(\tfrac{r\rho}{t}\right)\\
&\quad+\textstyle\sum_{n=1}^{\infty}\left|I_{\nu_n-1}\left(\tfrac{r\rho}{t}\right)-I_{\nu_n-1}\left(\tfrac{r'\rho}{t}\right)\right|\Big)\times|x-x'|^{-\alpha_0}\\
&:= \tfrac{C\rho}{t^2}\exp\left(-\tfrac{r'^2+\rho^2}{2t}\right)(D_t^1+D_t^2).
\end{aligned}
\tag{B.5}
$$

From the recurrence relations on modified Bessel functions, see equation 9.6.26 in [AS72], and since $|x-x'|>r$ one gets

$$
\begin{aligned}
D_t^1 &\leq \tfrac{Cr\rho}{t}\textstyle\sum_{n\geq 1}(I_{\nu_n-2}+I_{\nu_n})\left(\tfrac{r\rho}{t}\right)r^{-\alpha_0}\leq \tfrac{Cr^{1-\alpha_0}\rho}{(1\wedge\varepsilon)t}\exp\left(\tfrac{\rho r}{t}\right)\left\{\left(\tfrac{r\rho}{t}\right)^{-(2-\nu_1+\varepsilon)}+1\right\}\\
&\leq \tfrac{C}{1\wedge\varepsilon}\exp\left(\tfrac{r\rho}{t}\right)\left\{\tfrac{\rho}{t}+\left(\tfrac{\rho}{t}\right)^{\nu_1-1-\varepsilon}r^{\nu_1-1-\varepsilon-\alpha_0}\right\}.
\end{aligned}
\tag{B.6}
$$

Recall now formula 9.6.18 from [AS72]; i.e.,

$$
\forall\nu>-1/2,\ I_\nu(z)=\frac{(\frac{1}{2}z)^\nu}{\pi^{1/2}\Gamma(\nu+\frac{1}{2})}\int_{-1}^{1}(1-u^2)^{\nu-1/2}\cosh(zu)du.
$$

Hence,

$$
\begin{aligned}
D_t^2 &\leq C\left\{\left|I_{\nu_1-1}\left(\tfrac{r\rho}{t}\right)-I_{\nu_1-1}\left(\tfrac{r'\rho}{t}\right)\right|+\tfrac{\rho|r-r'|}{t}\exp\left(\tfrac{r'\rho}{t}\right)\right\}|x-x'|^{-\alpha_0}\\
&\leq C\left\{\left(\tfrac{\rho}{t}\right)^{\nu_1-1}|r^{\nu_1-1}-r'^{\nu_1-1}|+\left(\tfrac{\rho}{t}\right)^{\nu_1}|r-r'|+\tfrac{\rho|r-r'|}{t}\right\}\exp\left(\tfrac{r'\rho}{t}\right)|r-r'|^{-\alpha_0}\\
&\leq C\left\{\left(\tfrac{\rho}{t}\right)^{\nu_1-1}|r-r'|^{\nu_1-1-\alpha_0}+\left(\tfrac{\rho}{t}\right)^{\nu_1}+\tfrac{\rho}{t}\right\}\exp\left(\tfrac{r'\rho}{t}\right).
\end{aligned}
\tag{B.7}
$$

Plugging (B.6) and (B.7) into (B.5) we derive that for $|x-x'|>r$

$$
A_t^2(x,x')\leq\frac{C}{(1\wedge\varepsilon)t^\xi}\exp\left(-c\frac{|r'-\rho|^2}{t}\right)\left\{1+|r-r'|^{\nu_1-1-\alpha_0}+r^{\nu_1-1-\varepsilon-\alpha_0}\right\}.
\tag{B.8}
$$

Take now $\varepsilon>0$ s.t. $\nu_1-1-\varepsilon>0$. Set $\alpha_0=\nu_1-1-\varepsilon$. From (B.4) and (B.8) the proof is complete.

Remark B.1. The spectral theory suggests our previous Hölder constant for the gradient is somehow optimal. Indeed, if ϕ_1 denotes the first eigenfunction of the elliptic Dirichlet problem for the Laplacian in a bidimensional truncated cone of angle ω and vertex 0, we have from Example 4.6.5 in Davies [Dav89] that $\phi_1(x)=O(r^{\nu_1})$, $\nu_1=\pi/\omega$ when $x\longrightarrow 0$ nontangentially, and the heat kernel also writes $q_t(x,y)=\sum_{i=1}^{\infty}\exp(-E_it)\phi_i(x)\phi_i(y)$, where the $(E_i)_{i\in\mathbf{N}^*}$ are the eigenvalues of the Laplacian in the truncated cone ($0<E_1\leq E_2\leq\cdots\uparrow\infty$) and the $(\phi_i)_{i\in\mathbf{N}^*}$ the orthonormal eigenfunctions.

The spectral decomposition of the heat kernel also suggests that we cannot expect more spatial smoothness than that of the elliptic problem. A general study of this kind

of problem is far from easy. A Sobolev approach can be found in Dauge [Dau88] and Kozlov, Maz'ya, and Rossmann [KMR97]. The possible application of their arguments to the parabolic case will concern further research.

Remark B.2. The control of the time derivative stated in Lemma 5.2 holds true up to $d = 4$ without major changes in the proof. The main tool needed is Weyl's asymptotic lemma that gives some controls on the behavior of the eigenfunctions that appear in Proposition 5.1; see [Cha84, p. 172]. The remaining computations are rather similar to the previous ones.

A UNIFIED APPROACH FOR UZAWA ALGORITHMS*

CONSTANTIN BACUTA†

Abstract. We present a unified approach in analyzing Uzawa iterative algorithms for saddle point problems. We study the classical Uzawa method, the augmented Lagrangian method, and two versions of inexact Uzawa algorithms. The target application is the Stokes system, but other saddle point systems, e.g., arising from mortar methods or Lagrange multipliers methods, can benefit from our study. We prove convergence of Uzawa algorithms and find optimal rates of convergence in an abstract setting on finite- or infinite-dimensional Hilbert spaces. The results can be used to design multilevel or adaptive algorithms for solving saddle point problems. The discrete spaces do not have to satisfy the LBB stability condition.

Key words. Uzawa algorithms, saddle point system, multilevel methods, augmented Lagrangian method, Stokes problem

1. Introduction.

In this paper, we provide a unified approach for Uzawa methods for linear saddle point systems. Such systems arise in solving various partial differential equations (PDEs) or systems of PDEs at the continuous level or at the discrete level. Typical examples of such PDEs are second-order elliptic problems, Stokes equations, and elasticity problems. We analyze the classical Uzawa Method (UM) [1], the augmented Lagrangian Uzawa method (ALUM) [14], the inexact Uzawa method (IUM) [7, 13], and a modified (or multilevel) inexact Uzawa method (MIUM) under a general approach on abstract Hilbert spaces. The motivation for considering abstract versions of Uzawa algorithms on infinite-dimensional Hilbert spaces is that the analysis at the continuous level of an algorithm for solving a PDE gives the right strategy for discretizing the PDE. In addition, the convergence factors of certain multilevel or adaptive algorithms for solving saddle point systems depend on the stability parameters of the continuous problem, and in many cases the discrete LBB stability condition is not required to be satisfied (see [4, 12] or section 6). Next, we formulate the general framework of the saddle point problem to be studied in this paper and indicate the way the paper is organized.

We let $\mathbf{V}$ and P be two Hilbert spaces with inner products $a(\cdot,\cdot)$ and $(\cdot,\cdot)$, with the corresponding induced norms $|\cdot|_{\mathbf{V}} = |\cdot| = a(\cdot,\cdot)^{1/2}$ and $\|\cdot\|_P = \|\cdot\| = (\cdot,\cdot)^{1/2}$. The dual parings on $\mathbf{V}^* \times \mathbf{V}$ and $P^* \times P$ are denoted by $\langle\cdot,\cdot\rangle$ and $(\cdot,\cdot)$, respectively. Here, $\mathbf{V}^*$ and P^* denote the dual of $\mathbf{V}$ and P, respectively. We identify P^* and P as Hilbert spaces so that $(\cdot,\cdot)$ represents both the inner product on P and the duality between P^* and P. In applications to Stokes systems, $\mathbf{V} = (H_0^1)^d (d = 2, 3, \dots)$, P is a subspace of L^2 of codimension one and $(\cdot,\cdot)$ is the standard inner product on L^2. Next, we consider that $b(\cdot,\cdot)$ is a continuous bilinear form on $\mathbf{V} \times P$, satisfying the

†Department of Mathematical Sciences, University of Delaware, 501 Ewing Hall, Newark, DE 19716 (bacuta@math.udel.edu).

inf-sup condition. More precisely, we assume that

$$\inf_{p\in P}\sup_{\mathbf{v}\in\mathbf{V}}\frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|}=m>0 \tag{1.1}$$

and

$$\sup_{p\in P}\sup_{\mathbf{v}\in\mathbf{V}}\frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|}=M<\infty. \tag{1.2}$$

For $f\in\mathbf{V}^*$, $g\in P^*$, we consider the following variational problem:
Find $(\mathbf{u},p)\in\mathbf{V}\times P$ such that

$$\begin{array}{lcll} a(\mathbf{u},\mathbf{v}) & + & b(\mathbf{v},p) & =\langle\mathbf{f},\mathbf{v}\rangle \quad \text{for all } \mathbf{v}\in\mathbf{V},\\ b(\mathbf{u},q) & & & =(g,q) \quad \text{for all } q\in P. \end{array} \tag{1.3}$$

It is known that the above variational problem has a unique solution for any $f\in\mathbf{V}^*$, $g\in P^*$ (see [9, 10, 15] or Lemma 2.1). With the forms a and b, we associate two linear operators $A:V\to V^*$ and $B:V\to P$ defined by

$$\langle A\mathbf{u},\mathbf{v}\rangle=a(\mathbf{u},\mathbf{v}) \quad \text{for all } \mathbf{u},\mathbf{v}\in\mathbf{V}$$

and

$$(B\mathbf{u},q)=b(\mathbf{u},q) \quad \text{for all } \mathbf{u}\in\mathbf{V},\ q\in P.$$

Let $B^*:P\to V^*$ be the dual operator of B defined by

$$\langle B^*q,\mathbf{v}\rangle=(q,B\mathbf{v})=(B\mathbf{v},q)=b(\mathbf{v},q) \quad \text{for all } \mathbf{v}\in\mathbf{V},\ q\in P.$$

The problem (1.3) is equivalent to the following problem:
Find $(\mathbf{u},p)\in\mathbf{V}\times P$ such that

$$\begin{array}{lcll} A\mathbf{u} & + & B^*p & =\mathbf{f},\\ B\mathbf{u} & & & =g. \end{array} \tag{1.4}$$

In this framework, we analyze Uzawa algorithms for solving the system (1.3) or (1.4). We consider that the form a gives the inner product and the norm on $\mathbf{V}$. A more general case of (1.3) is considered in [9, 10, 15]. Our particular assumptions for the form a give rise to a simplified analysis. For the general case, we obtain sharp convergence estimates only in terms of the two constants m and M.

The rest of the paper is organized as follows. In section 2, we analyze the convergence of the classical Uzawa algorithm. The augmented Lagrangian Uzawa method is analyzed in section 3 (Fortin and Glowinski [14]). In section 4, we shall investigate the convergence of the inexact Uzawa algorithm (Bramble, Pasciak, and Vassilev [7] and Elman and Golub [13]) in the above abstract framework. Applications to discretizations on stable pairs are presented in section 5. A modified inexact Uzawa algorithm with applications in constructing multilevel methods and adaptive methods for solving (1.3) is illustrated in section 6. In section 7, we present applications of our abstract results to the Stokes system.

2. The abstract Uzawa algorithm. We begin this section with two lemmas which provide basic properties of norms and operators introduced in section 1. The proofs are based on the Riesz representation theorem (see, e.g., [20]). For completeness, we include the proofs.

LEMMA 2.1. *The operator $A : V \to V^*$ is invertible and the Schur complement operator $BA^{-1}B^* : P \to P$ is symmetric and a positive definite operator satisfying*

$$(BA^{-1}B^*p, p) = \sup_{\mathbf{v}\in\mathbf{V}} \frac{b(\mathbf{v}, p)^2}{|\mathbf{v}|^2}, \tag{2.1}$$

$$m^2\|p\|^2 \le (BA^{-1}B^*p, p) \le M^2\|p\|^2, \quad p \in P. \tag{2.2}$$

Consequently, the problem (1.3) *(or* (1.4)*) has a unique solution.*

Proof. From the definition of A, we get that A is a bounded injective operator. Using the Riesz representation theorem, it follows that A is also a surjective operator. Let us further note that A satisfies

$$\langle A\mathbf{u}, \mathbf{v}\rangle = a(\mathbf{u}, \mathbf{v}) = a(\mathbf{v}, \mathbf{u}) = \langle A\mathbf{v}, \mathbf{u}\rangle,$$

and the changes of variable $A\mathbf{u} = \mathbf{u}^*$ and $A\mathbf{v} = \mathbf{v}^*$ lead to

$$\langle \mathbf{u}^*, A^{-1}\mathbf{v}^*\rangle = \langle \mathbf{v}^*, A^{-1}\mathbf{u}^*\rangle, \quad \mathbf{u}^*, \mathbf{v}^* \in \mathbf{V}^*. \tag{2.3}$$

Using (2.3), we obtain

$$\begin{aligned}(BA^{-1}B^*p, q) &= \langle B^*q, A^{-1}B^*p\rangle = \langle B^*p, A^{-1}B^*q\rangle \\ &= (BA^{-1}B^*q, p) = (p, BA^{-1}B^*q), \quad p, q \in P.\end{aligned}$$

To prove (2.1), we let $p \in P$ be fixed and consider the following problem:

Find $\mathbf{u} \in \mathbf{V}$ such that

$$a(\mathbf{u}, \mathbf{v}) = b(\mathbf{v}, p) \qquad \text{for all } \mathbf{v} \in \mathbf{V}. \tag{2.4}$$

Since the functional $\mathbf{v} \to b(\mathbf{v}, p)$ is continuous on $\mathbf{V}$, by the Riesz representation theorem we have that the unique solution $\mathbf{u}$ of (2.4) satisfies

$$a(\mathbf{u}, \mathbf{u}) = \|\mathbf{v} \to b(\mathbf{v}, p)\|^2_{\mathbf{V}^*} = \sup_{\mathbf{v}\in\mathbf{V}} \frac{b(\mathbf{v}, p)^2}{|\mathbf{v}|^2}. \tag{2.5}$$

On the other hand, from (2.4) we have

$$A\mathbf{u} = B^*p \ \text{ or } \ \mathbf{u} = A^{-1}B^*p$$

and

$$a(\mathbf{u}, \mathbf{u}) = \langle A\mathbf{u}, \mathbf{u}\rangle = \langle B^*p, A^{-1}B^*p\rangle = (p, BA^{-1}B^*p). \tag{2.6}$$

Thus, (2.1) follows from (2.5) and (2.6). The estimate (2.2) follows imediately from (2.1), (1.1), and (1.2).

To prove the existence and uniqueness of (1.3) (or (1.4)), we substitute $\mathbf{u}$ from the first equation of (1.4) into the second equation of (1.4). The resulting equation in p,

$$BA^{-1}B^*p = BA^{-1}\mathbf{f} - g,$$

has a unique solution due to the fact that $BA^{-1}B^* : P \to P$ is symmetric and a positive definite operator. ∎

Remark 2.2. From the general theory of symmetric operators and Lemma 2.1, we have that $\sigma(BA^{-1}B^*) \subset [m^2, M^2]$ and $m^2, M^2 \in \sigma(BA^{-1}B^*)$. In the finite-dimensional case, m^2 and M^2 are the extreme eigenvalues of the Schur complement $BA^{-1}B^*$.

LEMMA 2.3. *The following norm estimates are valid:*

$$\|\phi\|^2_{\mathbf{V}^*} = a(A^{-1}\phi, A^{-1}\phi) = |A^{-1}\phi|^2, \quad \phi \in \mathbf{V}^*, \tag{2.7}$$

$$\|A\mathbf{u}\|_{\mathbf{V}^*} = |\mathbf{u}|, \quad \mathbf{u} \in \mathbf{V}, \tag{2.8}$$

$$\|B^*q\|_{\mathbf{V}^*} = |A^{-1}B^*q| = (BA^{-1}B^*q, q)^{1/2} \le M\|q\|, \quad q \in P, \tag{2.9}$$

$$\|B\| = M, \quad \textit{hence} \quad \|B\mathbf{u}\| \le M\ |\mathbf{u}|, \quad \mathbf{u} \in \mathbf{V}. \tag{2.10}$$

Proof. By the Riesz representation theorem, we have that for any $\phi \in \mathbf{V}^*$ the problem

Find $\mathbf{u} \in \mathbf{V}$ such that

$$\langle A\mathbf{u}, \mathbf{v}\rangle = a(\mathbf{u}, \mathbf{v}) = \langle \phi, \mathbf{v}\rangle \qquad \text{for all } \ \mathbf{v} \in \mathbf{V} \tag{2.11}$$

has a unique solution, and the solution $\mathbf{u}$ satisfies

$$a(\mathbf{u}, \mathbf{u}) = \sup_{\mathbf{v}\in\mathbf{V}} \frac{\langle \phi, \mathbf{v}\rangle^2}{a(\mathbf{v}, \mathbf{v})} = \|\phi\|^2_{\mathbf{V}^*}. \tag{2.12}$$

From (2.11), we have that $\mathbf{u} = A^{-1}\phi$, which combined with (2.12) gives (2.7). The equality (2.8) is a consequence of (2.7), and (2.9) follows from (2.8) and (2.2). The last estimate follows from the definition of B and the assumption in (1.2). ∎

Next, we present the Uzawa algorithm [1] for solving the solution of the abstract problem (1.3). Given a parameter $\alpha > 0$, called a relaxation parameter, the Uzawa algorithm for approximating the solution $(\mathbf{u}, p)$ of (1.3) can be described as follows.

ALGORITHM 2.4 (Uzawa method (UM)). *Let p_0 be any approximation for p, and for $k = 1, 2, \ldots,$ construct $(\mathbf{u}_k, p_k)$ by*

$$\begin{aligned} a(\mathbf{u}_k, \mathbf{v}) &= (\mathbf{f}, \mathbf{v}) - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}, \\ p_k &= p_{k-1} + \alpha(B\mathbf{u}_k - g). \end{aligned} \tag{2.13}$$

The convergence of the UM is discussed for particular cases in, e.g., [10, 14, 15, 17]. It shows that the UM is convergent for small enough α and that the convergence rate is the same as the convergence rate of the Richardson iterative methods for the Schur complement $BA^{-1}B^*$. For completeness, we include the proof.

THEOREM 2.5. *Let $(\mathbf{u}, p)$ be the solution of (1.3) and let $(\mathbf{u}_k, p_k)$ be the sequence of approximations built by the UM (2.13). Then, the following holds.*

(i) *The sequences $\mathbf{u} - \mathbf{u}_k$ and $p - p_k$ satisfy*

$$\begin{aligned} a(\mathbf{u} - \mathbf{u}_k, \mathbf{u} - \mathbf{u}_k)^{1/2} &\le M\ \|p - p_{k-1}\|, \\ \|p - p_k\| &\le \|I - \alpha BA^{-1}B^*\|\ \|p - p_{k-1}\|. \end{aligned}$$

(ii) *For $\alpha < \frac{2}{M^2}$, the UM is convergent and*

$$\|I - \alpha BA^{-1}B^*\| = \max\{|1 - \alpha m^2|, |1 - \alpha M^2|\} < 1.$$

(iii) *For* $\alpha = \frac{1}{M^2}$, *the convergence factor is* $\|I - \alpha BA^{-1}B^*\| = 1 - \frac{m^2}{M^2}$.
(iv) *The optimal convergence factor is achieved for*

$$\alpha_{opt} = \frac{2}{M^2 + m^2} \quad \textit{and} \quad \|I - \alpha_{opt} BA^{-1}B^*\| = \frac{M^2 - m^2}{M^2 + m^2}.$$

Proof. From the first equation of (1.3) and the first equation of (2.13), we have that

$$a(\mathbf{u} - \mathbf{u}_k, \mathbf{v}) = b(\mathbf{v}, p_{k-1} - p) \qquad \text{for all } \mathbf{v} \in \mathbf{V}. \tag{2.14}$$

The above relation implies

$$\begin{aligned} |\mathbf{u} - \mathbf{u}_k|^2 &= a(\mathbf{u} - \mathbf{u}_k, \mathbf{u} - \mathbf{u}_k) = (BA^{-1}B^*(p_{k-1} - p), (p_{k-1} - p)) \\ &\leq M^2 \|p_{k-1} - p\|^2, \end{aligned}$$

which proves the first part of (i). From the second equation of (1.4) and the second equation of (2.13), we have that

$$p - p_k = p - p_{k-1} + \alpha B(\mathbf{u} - \mathbf{u}_k).$$

Combining with (2.14), we get

$$p - p_k = (I - \alpha BA^{-1}B^*)(p - p_{k-1}), \tag{2.15}$$

which gives the second part of (i). From Lemma 2.1, we have that $(I - \alpha BA^{-1}B^*)$ is a symmetric operator, and for any $p \in$P, $p \neq 0$,

$$1 - \alpha M^2 \leq \frac{((I - \alpha BA^{-1}B^*)p, p)}{\|p\|^2} \leq 1 - \alpha m^2,$$

which justifies part (ii). The rest of the proof follows from (ii). ∎

3. Augmented Lagrangian Uzawa algorithm. The main idea of the augmented Lagrangian method, introduced by Fortin and Glowinski [14], is to use the constraint condition for the variable p and another tuning parameter $\rho > 0$ in order to improve the convergence factor of the Uzawa algorithm. We will consider the approach for abstract Hilbert spaces $\mathbf{V}$ and P and prove sharp convergence estimates for the corresponding Uzawa algorithm.

Let $(\mathbf{u}, p)$ be the solution of the variational problem (1.3). Then, from the second equation of (1.4), we have that

$$(B\mathbf{u}, B\mathbf{v}) = (g, B\mathbf{v}), \quad \mathbf{v} \in \mathbf{V}.$$

Thus, for any $\rho > 0$, $(\mathbf{u}, p)$ is also a solution of

$$\begin{array}{ll} a(\mathbf{u}, \mathbf{v}) + \rho(B\mathbf{u}, B\mathbf{v}) + b(\mathbf{v}, p) &= \langle \mathbf{f}, \mathbf{v} \rangle + \rho(g, B\mathbf{v}), \\ b(\mathbf{u}, q) &= (g, q). \end{array} \tag{3.1}$$

Using the notation

$$a_\rho(\mathbf{u}, \mathbf{v}) := a(\mathbf{u}, \mathbf{v}) + \rho(B\mathbf{u}, B\mathbf{v}) \text{ and } \mathbf{f}_\rho := \mathbf{f} + \rho B^* g,$$

we have that

$$\begin{array}{ll} a_\rho(\mathbf{u}, \mathbf{v}) + b(\mathbf{v}, p) &= \langle \mathbf{f}_\rho, \mathbf{v} \rangle, \quad \mathbf{v} \in \mathbf{V}, \\ b(\mathbf{u}, q) &= (g, q), \quad q \in P. \end{array} \tag{3.2}$$

With the form a_ρ, we associate the linear operator $A_\rho : V \to V^*$,

$$\langle A_\rho \mathbf{u}, \mathbf{v}\rangle = a_\rho(\mathbf{u}, \mathbf{v}) \qquad \text{for all } \mathbf{u}, \mathbf{v} \in \mathbf{V}.$$

Thus, an equivalent form of (3.2) is

$$\begin{aligned} A_\rho \mathbf{u} + B^* p &= \mathbf{f}_\rho, \\ B\mathbf{u} &= g. \end{aligned} \tag{3.3}$$

Since $a_\rho(\cdot,\cdot)$ and $a(\cdot,\cdot)$ give rise to equivalent norms on $\mathbf{V}$, we have that (3.2) (or (3.3)) has a unique solution. Consequently, problems (1.3) and (3.2) are equivalent. In what follows, the Uzawa algorithm applied to (3.2) will be called the augmented Lagrangian Uzawa method (ALUM).

Given a relaxation parameter $\alpha > 0$, the augmented Lagrangian Uzawa algorithm for approximating the solution $(\mathbf{u}, p)$ of (1.3) is as follows.

ALGORITHM 3.1 (ALUM). *Let p_0 be any approximation for p, and for $k = 1, 2, \ldots,$ construct $(\mathbf{u}_k, p_k)$ by*

$$\begin{aligned} a_\rho(\mathbf{u}_k, \mathbf{v}) &= (\mathbf{f}_\rho, \mathbf{v}) - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}, \\ p_k &= p_{k-1} + \alpha(B\mathbf{u}_k - g). \end{aligned}$$

To study the convergence of (3.1), we shall calculate first

$$M_\rho := \sup_{p\in P} \sup_{\mathbf{v}\in\mathbf{V}} \frac{b(\mathbf{v}, p)}{\|p\|(a_\rho(\mathbf{v}, \mathbf{v}))^{1/2}} \tag{3.4}$$

and

$$m_\rho := \inf_{p\in P} \sup_{\mathbf{v}\in\mathbf{V}} \frac{b(\mathbf{v}, p)}{\|p\|(a_\rho(\mathbf{v}, \mathbf{v}))^{1/2}}. \tag{3.5}$$

THEOREM 3.2. *For any $\rho > 0$, we have*

$$BA_\rho^{-1}B^* = \left(\rho I + (BA^{-1}B^*)^{-1}\right)^{-1}, \tag{3.6}$$

$$M_\rho^2 = \frac{1}{\rho + \frac{1}{M^2}} \quad \textit{and} \quad m_\rho^2 = \frac{1}{\rho + \frac{1}{m^2}}. \tag{3.7}$$

Proof. To prove (3.6), we need two identities. First, we note that for any invertible linear operator $C : P \to P$ such that $I + \rho C$ is also invertible, we have

$$\left(\rho I + C^{-1}\right)^{-1} = C - \rho C(I + \rho C)^{-1}C. \tag{3.8}$$

This can be proved by checking that the proposed inverse verifies the algebraic definition of the inverse. The second identity is based on the Sherman–Morrison–Woodbury formula and can be proved again just by algebraic manipulations:

$$(A + \rho B^* B)^{-1} = A^{-1} - \rho A^{-1}B^*(I + \rho BA^{-1}B^*)^{-1}BA^{-1}. \tag{3.9}$$

From (3.9), we get

$$\begin{aligned} B(A + \rho B^* B)^{-1}B^* = {} & BA^{-1}B^* \\ & - \rho BA^{-1}B^*(I + \rho BA^{-1}B^*)^{-1}BA^{-1}B^*. \end{aligned} \tag{3.10}$$

If we take $C = BA^{-1}B^*$ in (3.8) and combine it with (3.10), we obtain (3.6). To verify (3.7), we notice that by applying Lemma 2.1 with a_ρ instead of a we have

$$\sup_{\mathbf{v}\in\mathbf{V}} \frac{b(\mathbf{v},p)^2}{\|p\|^2\ a_\rho(\mathbf{v},\mathbf{v})} = (BA_\rho^{-1}B^*p,p), \quad p\in P. \tag{3.11}$$

Thus, we get

$$\begin{aligned} M_\rho^2 &= \sup_{p\in P} \frac{(BA_\rho^{-1}B^*p,p)}{(p,p)} = \sup_{p\in P} \frac{\left((\rho I + (BA^{-1}B^*)^{-1}\ )^{-1}p,p\right)}{(p,p)} \\ &= \frac{1}{\inf\limits_{q\in P} \frac{((\rho I+(BA^{-1}B^*)^{-1})q,q)}{(q,q)}} = \frac{1}{\rho + \inf\limits_{q\in P} \frac{((BA^{-1}B^*)^{-1}q,q)}{(q,q)}} \\ &= \left(\rho + \frac{1}{\sup\limits_{r\in P} \frac{(BA^{-1}B^*r,r)}{(r,r)}}\right)^{-1} = \left(\rho + \frac{1}{M^2}\right)^{-1}. \end{aligned}$$

Here, we have used the changes of variable $(\rho I + (BA^{-1}B^*)^{-1}\ )^{-1/2}p = q$ and $(BA^{-1}B^*)^{-1/2}q = r$. The proof for m_ρ is similar. ∎

The above result gives formulas for the inf-sup and sup-sup constants for the ALUM in terms of m, M, and ρ. In applications, the constant m is more difficult to obtain. The following theorem gives the convergence rate of the ALUM.

THEOREM 3.3. *Let* $(\mathbf{u},p)$ *be the solution of* (1.3) *and let* $(\mathbf{u}_k,p_k)$ *be the sequence of approximations built by Algorithm* 3.1. *Then, the following holds true:*

(i) *The sequences* $\mathbf{u}-\mathbf{u}_k$ *and* $p-p_k$ *satisfy*

$$\begin{aligned} &a_\rho(\mathbf{u}-\mathbf{u}_k,\mathbf{u}-\mathbf{u}_k)^{1/2} \le M_\rho\ \|p-p_{k-1}\|, \\ &\|p-p_k\| \le \|I-\alpha BA_\rho^{-1}B^*\|\ \|p-p_{k-1}\|. \end{aligned}$$

(ii) *For* $\alpha < \frac{2}{M_\rho^2}$, *the ALUM is convergent and*

$$\|I-\alpha BA_\rho^{-1}B^*\| = \max\{|1-\alpha m_\rho^2|, |1-\alpha M_\rho^2|\} < 1.$$

(iii) *For* $\alpha = \frac{1}{M_\rho^2}$, *the convergence factor is*

$$\|I-\alpha BA_\rho^{-1}B^*\| = \left(1-\frac{m^2}{M^2}\right)\frac{1}{m^2\rho+1}.$$

(iv) *The optimal convergence factor is achieved for* $\alpha_{opt} = \frac{2}{M_\rho^2+m_\rho^2}$ *and*

$$\|I-\alpha_{opt}BA_\rho^{-1}B^*\| = \frac{M_\rho^2-m_\rho^2}{M_\rho^2+m_\rho^2} = \left(1-\frac{m^2}{M^2}\right)\frac{1}{2m^2\rho+1+m^2/M^2}.$$

Proof. The result is a direct consequence of Theorem 2.5 and (3.7). ∎

A similar result for the discrete version of the Stokes system can be found in [19]. As it was pointed out in [14] and [19], the choice of a very large ρ improves on the rate of convergence of the ALUM, but at the same time, the operator A_ρ becomes more difficult to invert. For the continuous and discrete Stokes system, estimates for the convergence factor of the ALUM were recently obtained by Nochetto and Pyo in [16]. The question raised in [16] on how much we can improve the rate of convergence of the ALUM if information about the spectral value m is available can be easily answered now by comparing part (iii) and part (iv) of Theorem 3.3 or Theorem 7.1.

4. Inexact Uzawa method. Throughout the rest of the paper we will keep the notation and assumptions of section 2. In this section, following the ideas in [7, 13], we shall introduce and investigate the convergence of an abstract inexact Uzawa algorithm where the exact solve of the elliptic problem (the action of A^{-1}) is replaced by an approximation process, which might not be a linear operator. We describe the approximate inverse of A as a map $C : \mathbf{V}^* \to \mathbf{V}$ which, for $\phi \in \mathbf{V}^*$, returns an approximation of $\xi = A^{-1}\phi$ such that

$$|C\phi - A^{-1}\phi|_{\mathbf{V}} \leq \delta \|\phi\|_{\mathbf{V}^*} \qquad \text{for all } \phi \in \mathbf{V}^* \tag{4.1}$$

for some $\delta \in (0,1)$. We notice here that (4.1) is a strong condition for the infinite-dimensional case. The condition can be weakened by requiring to be satisfied only for certain values $\phi \in \mathbf{V}^*$. If $\mathbf{V}$ and P are finite-dimensional spaces, then C can be considered as a linear or nonlinear process for inverting A and (4.1) is a reasonable assumption (see [7]). One example of nonlinear process C is the approximate inverse associated with the preconditioned conjugate gradient algorithm. A practical case would be to consider $C\phi = \xi_{num}$, where ξ_{num} is the numerical approximation of ξ defined by

$$a(\xi, \mathbf{v}) = \langle \phi, \mathbf{v} \rangle \qquad \text{for all } v \in \mathbf{V}.$$

In any case, if $A\xi = \phi$ and $C\phi$ is defined by $C\phi = \xi_{ap}$, an approximation of ξ, then, according to (2.7), the assumption (4.1) is equivalent to

$$|\xi_{ap} - \xi|_{\mathbf{V}} \leq \delta |\xi|_{\mathbf{V}} \qquad \text{for all } \xi \in \mathbf{V}. \tag{4.2}$$

The inexact Uzawa algorithm for approximating the solution $(\mathbf{u}, p)$ of (1.3) is as follows.

ALGORITHM 4.1 (inexact Uzawa method (IUM)). *Let* $(\mathbf{u}_0, p_0)$ *be any approximation for* $(\mathbf{u}, p)$*, and for* $k = 1, 2, \ldots,$ *construct* $(\mathbf{u}_k, p_k)$ *by*

$$\begin{aligned} \mathbf{u}_k &= \mathbf{u}_{k-1} + C(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1}), \\ p_k &= p_{k-1} + \alpha(B\mathbf{u}_k - g). \end{aligned}$$

Before we study the stability and convergence rate of Algorithm 4.1 we shall introduce the following notation. For $k = 0, 1, \ldots,$ let $e_k^{\mathbf{u}} = \mathbf{u} - \mathbf{u}_k$, $e_k^p = p - p_k$, and

$$E_k = \begin{pmatrix} |e_k^{\mathbf{u}}| \\ \|e_k^p\| \end{pmatrix}.$$

Let

$$\mathbf{M} := \begin{pmatrix} \delta & M(1+\delta) \\ \alpha M \delta & \gamma + \alpha M^2 \delta \end{pmatrix},$$

where $\gamma := \|I - \alpha B A^{-1} B^*\| = \max\{|1 - \alpha m^2|, |1 - \alpha M^2|\}$. On $\mathbf{R}^2$ we introduce the inner product $[\cdot, \cdot]_w$ defined by

$$\left[\begin{pmatrix} x_1 \\ x_2 \end{pmatrix}, \begin{pmatrix} y_1 \\ y_2 \end{pmatrix} \right]_w = w_1 x_1 y_1 + w_2 x_2 y_2,$$

where w_1, w_2 are any two positive numbers such that

$$\frac{w_1}{w_2} = \frac{\alpha\delta}{1+\delta},$$

and δ is a positive number such that (4.1) is satisfied. We note that $\mathbf{M}$ is symmetric with respect to the $[\cdot,\cdot]_w$ inner product. We will denote the norm induced by $[\cdot,\cdot]_w$ with $\|\cdot\|_w$.

THEOREM 4.2. *Let $0 < \alpha < 2/M^2$ and assume that C satisfies* (4.1) *with*

$$\delta < \frac{1-\gamma}{1-\gamma+2\alpha M^2}. \tag{4.3}$$

Then, the IUM converges. If r is the spectral radius of the matrix $\mathbf{M}$, then $0 < r < 1$ and

$$\|E_k\|_w \leq \ r^k \ \|E_0\|_w, \quad k = 1, 2, \ldots . \tag{4.4}$$

Proof. We follow the proof of a similar result in [7] for the finite-dimensional case. From the first equation of (1.4) and the first equation of Algorithm 4.1, we have

$$\begin{aligned} e_k^{\mathbf{u}} &= e_{k-1}^{\mathbf{u}} - C(Ae_{k-1}^{\mathbf{u}} + B^* e_{k-1}^p) \\ &= (A^{-1} - C)(Ae_{k-1}^{\mathbf{u}} + B^* e_{k-1}^p) - A^{-1}B^* e_{k-1}^p. \end{aligned} \tag{4.5}$$

From the second equation of (1.4) and the second equation of Algorithm 4.1, we get

$$e_k^p = e_{k-1}^p + \alpha B e_k^{\mathbf{u}}. \tag{4.6}$$

If we substitute $e_k^{\mathbf{u}}$ from (4.5) into (4.6), then

$$e_k^p = (I - \alpha B A^{-1} B^*) e_{k-1}^p + \alpha B (A^{-1} - C)(Ae_{k-1}^{\mathbf{u}} + B^* e_{k-1}^p). \tag{4.7}$$

From (4.5) and (4.7), by the triangle inequality, and from the estimates (2.9) and (2.10) and the assumption (4.1), we obtain

$$|e_k^{\mathbf{u}}| \leq \delta \ |e_{k-1}^{\mathbf{u}}| + M(1+\delta) \ \|e_{k-1}^p\|$$

and

$$\|e_k^p\| \leq \alpha M \delta \ |e_{k-1}^{\mathbf{u}}| + (\gamma + \alpha M^2 \delta) \|e_{k-1}^p\|.$$

Using the notation introduced above, we have

$$E_k \leq \mathbf{M} \ E_{k-1}, \tag{4.8}$$

where

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \leq \begin{pmatrix} y_1 \\ y_2 \end{pmatrix}$$

means $x_1 \leq y_1$ and $x_2 \leq y_2$. From (4.8), we deduce

$$E_k \leq \mathbf{M}^k \ E_0. \tag{4.9}$$

Since $\mathbf{M}$ is symmetric with respect to $[\cdot,\cdot]_w$-inner product, we have

$$\|E_k\|_w^2 = [E_k, E_k]_w \leq [\mathbf{M}^k \ E_0, \mathbf{M}^k \ E_0]_w = [\mathbf{M}^{2k} \ E_0, E_0]_w \leq r^{2k} \ \|E_0\|_w^2,$$

which proves (4.2). To complete the proof, we have to show that $r \in (0,1)$, provided that $0 < \alpha < 2/M^2$ and (4.3) holds. The characteristic equation of the matrix $\mathbf{M}$ is

$$\lambda^2 - \lambda(\delta + \gamma + \alpha M^2 \delta) + \delta(\gamma - \alpha M^2) = 0.$$

Since $\mathbf{M}$ has positive entries, the characteristic equation has real roots and the largest (positive) root agrees with the spectral radius of $\mathbf{M}$. Consequently,

$$r = \frac{1}{2}\left(\delta + \gamma + \alpha M^2\delta + \sqrt{(\delta+\gamma+\alpha M^2\delta)^2 - 4\delta(\gamma - \alpha M^2)}\right).$$

Using that $\gamma = \max\{|1-\alpha m^2|, |1-\alpha M^2|\}$ and $\alpha \in (0, 2/M^2)$, it is easy to verify that the function $\delta \to r = r(\delta)$ is an increasing function on $(0,1)$ and that $r = 1$ for

$$\delta = \delta_0 := \frac{1-\gamma}{1-\gamma+2\alpha M^2}. \tag{4.10}$$

This completes the proof of the theorem. □

Remark 4.3. For $0 < \alpha \leq \frac{2}{M^2+m^2}$ we have that $\gamma = 1 - \alpha m^2$ and the threshold δ_0 becomes

$$\delta_0 = \frac{m^2}{m^2 + 2M^2},$$

which is independent of α. For $\frac{2}{M^2+m^2} \leq \alpha < \frac{2}{M^2}$ we have that $\gamma = \alpha M^2 - 1$ and the threshold δ_0 becomes

$$\delta_0 = \frac{2 - \alpha M^2}{2 + \alpha M^2}.$$

Nevertheless, the optimal (maximal) value of δ_0 as the function of $\alpha \in [\frac{2}{M^2+m^2}, \frac{2}{M^2})$ is $\delta_0 = \frac{m^2}{m^2+2M^2}$ and is achieved for $\alpha = \frac{2}{M^2+m^2}$. Thus, a good choice for α (independent of m) is $\alpha = 1/M^2$. In this case we still have $\delta_0 = \frac{m^2}{m^2+2M^2}$.

Remark 4.4. We can apply the IUM for the augmented Lagrangian formulation. The only changes in Algorithm 4.1 is that A is replaced by A_ρ and $\mathbf{f}$ is replaced by $\mathbf{f}_\rho$. The convergence analysis follows from Theorem 4.2. Let us further notice that in this case $|e_k^{\mathbf{u}}|^2 = a_\rho(e_k^{\mathbf{u}}, e_k^{\mathbf{u}})$ and for $\alpha = 1/M_\rho^2$ the threshold δ_0 which assures convergence for the IUM is

$$\delta_0(\rho) = \frac{m_\rho^2}{m_\rho^2 + 2M_\rho^2} = \frac{m^2 + \rho m^2 M^2}{m^2 + 2M^2 + 3\rho m^2 M^2} \to \frac{1}{3} \quad \text{as} \quad \rho \to \infty.$$

Thus, if the IUM for the augmented Lagrangian formulation is applied with sufficiently large ρ, $\alpha = 1/M_\rho^2$ and with the approximation operator C satisfying

$$\|C - A_\rho^{-1}\| \leq \delta_0(\rho) < 1/3,$$

then the method converges.

Remark 4.5. A different approach in analyzing the IUM in the finite-dimensional case is presented by Cheng in [11]. From his analysis for $\alpha = 1$ and $M = 1$, it follows that the IUM converges (with a different estimate for the convergence factor), under the weaker assumption that $\delta < \delta_0 = 1/3$. Cheng's result for the infinite-dimensional case seems not to have been investigated. A positive answer for this problem would be an interesting result, since in practice it is difficult to estimate the spectral value m.

5. Discretization with the inf-sup condition. In this section we assume that the variational form of a PDE (or system of PDEs) leads to (1.3) and let $\mathbf{V}_h$ and P_h be two finite-dimensional spaces, $\mathbf{V}_h \subset \mathbf{V}$, $P_h \subset P$, with good approximation properties. We further assume that

$$\inf_{p\in P_h} \sup_{\mathbf{v}\in\mathbf{V}_h} \frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|} = m(h) > 0 \text{ and } \sup_{p\in P_h} \sup_{\mathbf{v}\in\mathbf{V}_h} \frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|} = M(h). \tag{5.1}$$

For an overview of numerical methods for solving saddle point systems, we refer the reader to the recently published review paper [5] by Benzi, Golub, and Liesen.

From Lemma 2.1 and Remark 2.2 we see that $m(h), M(h)$ are the lowest and the largest eigenvalues of the Schur complement $B_h A_h^{-1} B_h^*$ associated with the discrete spaces $\mathbf{V}_h$ and P_h. Then (see, e.g., [9, 15]), the discrete variational problem

Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times P_h$ such that

$$\begin{array}{lcll} a(\mathbf{u}_h,\mathbf{v}) & + & b(\mathbf{v},p_h) & = \langle \mathbf{f},\mathbf{v}\rangle, \quad \mathbf{v}\in\mathbf{V}_h, \\ b(\mathbf{u}_h,q) & & & = (g,q), \quad q\in P_h, \end{array} \tag{5.2}$$

has a unique solution and

$$|\mathbf{u}-\mathbf{u}_h| + \|p-p_h\| \le c\left(\inf_{\mathbf{v}\in\mathbf{V}_h} |\mathbf{u}-\mathbf{v}| + \inf_{q\in P_h} \|p-q\|\right),$$

where c is a constant depending only on $m(h)$ and $M(h)$. In this case, the exact or inexact Uzawa algorithms can be applied for the discrete variational problem (5.2) on $\mathbf{V}_h \times P_h$; see, e.g., [7]. The convergence factors depend on $m(h)$ and $M(h)$ and could deteriorate as $h \to 0$ if the pair $(\mathbf{V}_h, P_h)$ is not stable. We recall here that a pair $(\mathbf{V}_h, P_h)$, or more precisely a family of pairs $\{(\mathbf{V}_h, P_h)\}_h$, is called stable if $m(h)$ defined in (5.1) satisfies

$$m(h) \ge m > 0,$$

with m independent of h. In the next section we use the inexact Uzawa algorithm at the continuous level to construct algorithms which avoid building stable pairs $(\mathbf{V}_h, P_h)$.

6. Modified inexact Uzawa method. Eliminating the discrete inf-sup condition. We shall apply the IUM to construct discrete approximations $(\mathbf{u}_k, p_k) \in (\mathbf{V}_k, P_k)$, where $\mathbf{V}_k \subset \mathbf{V}$ and $P_k \subset P$ are finite-dimensional spaces such that the pairs $(\mathbf{V}_k, P_k)$ do not have to be stable pairs.

The algorithm proposed in this section can be used for building multilevel or adaptive methods for solving the system (1.3). Adaptive methods for saddle point problems have been the subject for recent research in numerical analysis (see, e.g., [12, 4]). Our new approach, combined with standard techniques of a posteriori error estimate theory, could lead to new and efficient adaptive algorithms for solving saddle point systems. To describe our new algorithm, we assume that a sequence of nested subspaces,

$$\mathbf{V}_0 \subset \mathbf{V}_1 \subset \mathbf{V}_2 \subset \cdots \subset \mathbf{V},$$

was determined and for $k = 1, 2, \ldots$, a linear or nonlinear process $C_k : \mathbf{V}^* \to \mathbf{V}_k$ approximating A^{-1} is available such that for a fixed $\phi \in \mathbf{V}^*$, $C_k\phi \in \mathbf{V}_k$ is an approximation of $\xi = A^{-1}\phi$. To construct a good approximate inverse $C_k : \mathbf{V}^* \to \mathbf{V}_k$

one might need to increase the space $\mathbf{V}_{k-1}$ to a space with better approximation properties using an adaptive method. Thus, the embedding assumption $\mathbf{V}_{k-1} \subset \mathbf{V}_k$ is needed. On the other hand, in the proposed algorithms, the variable p is updated at the continuous level and no inversion is used. Thus, the P_k's are just subsets of the space P and do not have to be nested.

The modified inexact Uzawa algorithm for approximating the solution $(\mathbf{u}, p)$ of (1.3) can be stated now as follows.

ALGORITHM 6.1 (modified inexact Uzawa method (MIUM)). *Let $\mathbf{u}_0 \in \mathbf{V}_0$ be any approximation for $\mathbf{u}$ and let $p_0 \in P$ be any approximation for p. For $k = 1, 2, \ldots$, construct $(\mathbf{u}_k, p_k)$, with $\mathbf{u}_k \in \mathbf{V}_k$, by*

$$\begin{aligned} \mathbf{u}_k &= \mathbf{u}_{k-1} + C_k(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1}), \\ p_k &= p_{k-1} + \alpha(B\mathbf{u}_k - g). \end{aligned} \tag{6.1}$$

THEOREM 6.2. *Let $0 < \alpha < 2/M^2$, $\gamma = \max\{|1 - \alpha m^2|, |1 - \alpha M^2|\} = \|I - \alpha B A^{-1} B^*\|$, and assume that for $k = 1, 2, \ldots, C_k$ satisfies*

$$\|(C_k - A^{-1})(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1})\|_{\mathbf{V}} \leq \delta \|(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1})\|_{\mathbf{V}^*}, \tag{6.2}$$

with

$$\delta < \frac{1 - \gamma}{1 - \gamma + 2\alpha M^2}. \tag{6.3}$$

Then, the MIUM converges and the convergence rate is given by (4.4).

Proof. It is similar to the proof of Theorem 4.2. ∎

We notice here that, for a fixed α, the threshold δ which assures the convergence of the MIUM depends only on the constants m and M. In the case $g = 0$, we have $p_k \in P_k := B\mathbf{V}_k$. Nevertheless, no matter the choice of the spaces $\mathbf{V}_k, P_k$, the pairs $(\mathbf{V}_k, P_k)$ do not have to be stable pairs.

For the rest of this section, the first equation in (6.1) will be considered in a variational form as follows. Let $\mathbf{d}_k \in \mathbf{V}_k$ be the solution of

$$a(\mathbf{d}_k, \mathbf{v}) = \langle f, \mathbf{v} \rangle - a(\mathbf{u}_{k-1}, v) - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}_k. \tag{6.4}$$

Take $\tilde{\mathbf{d}}_k := C_k(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1})$ to be an approximation of $\mathbf{d}_k$. For example, $\tilde{\mathbf{d}}_k$ could be a numerical approximation of $\mathbf{d}_k$. Let us assume that $\mathbf{D}_{k-1} \in \mathbf{V}$ is the solution of the continuous problem

$$a(\mathbf{D}_{k-1}, \mathbf{v}) = \langle f, \mathbf{v} \rangle - a(\mathbf{u}_{k-1}, v) - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}. \tag{6.5}$$

From the Riesz representation theorem

$$\|(\mathbf{f} - A\mathbf{u}_{k-1} - B^* p_{k-1})\|_{\mathbf{V}^*} = |\mathbf{D}_{k-1}|_{\mathbf{V}}.$$

Thus, the assumption (6.2) can be rewritten as

$$|\tilde{\mathbf{d}}_k - \mathbf{D}_{k-1}|_{\mathbf{V}} \leq \delta \, |\mathbf{D}_{k-1}|_{\mathbf{V}}. \tag{6.6}$$

Since $\mathbf{d}_k \in \mathbf{V}_k$ is the Galerkin approximation of $\mathbf{D}_{k-1} \in \mathbf{V}$, we have that $|\mathbf{d}_k|_{\mathbf{V}} \leq |\mathbf{D}_{k-1}|_{\mathbf{V}}$. A sufficient condition for the assumption (6.2) is

$$|\tilde{\mathbf{d}}_k - \mathbf{D}_{k-1}|_{\mathbf{V}} \leq \delta \, |\mathbf{d}_k|_{\mathbf{V}}. \tag{6.7}$$

6.1. Multilevel exact Uzawa. In this subsection we assume that the problem (6.4) can be solved exactly on $\mathbf{V}_k$, i.e., $\tilde{\mathbf{d}}_k = \mathbf{d}_k$. Then, $\mathbf{u}_k = \mathbf{u}_{k-1} + \mathbf{d}_k$ and consequently,

$$a(\mathbf{u}_k, \mathbf{v}) = \langle f, \mathbf{v}\rangle - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}_k.$$

If $\mathbf{U}_{k-1} \in \mathbf{V}$ satisfies

$$a(\mathbf{U}_{k-1}, \mathbf{v}) = \langle f, \mathbf{v}\rangle - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V},$$

then $\mathbf{D}_{k-1} = \mathbf{U}_{k-1} - \mathbf{u}_{k-1}$ and (6.6) is equivalent to

$$|\mathbf{u}_k - \mathbf{U}_{k-1}|_{\mathbf{V}} \le \delta\ |\mathbf{u}_{k-1} - \mathbf{U}_{k-1}|_{\mathbf{V}}. \tag{6.8}$$

If $\eta_k > 0$ is a computable estimator for $|\mathbf{u}_k - \mathbf{U}_{k-1}|_{\mathbf{V}}$, i.e.,

$$|\mathbf{u}_k - \mathbf{U}_{k-1}|_{\mathbf{V}} \le \eta_k, \tag{6.9}$$

then, using (6.7), we get that a sufficient condition for (6.8) is

$$\eta_k \le \delta\ |\mathbf{u}_k - \mathbf{u}_{k-1}|_{\mathbf{V}}. \tag{6.10}$$

ALGORITHM 6.3 (multilevel exact Uzawa). *Let $p_0 \in P$ be any approximation for p. For $k = 1, 2, \ldots$, construct $(\mathbf{u}_k, p_k)$, with $\mathbf{u}_k \in \mathbf{V}_k$, by*

$$\begin{aligned} a(\mathbf{u}_k, \mathbf{v}) &= \langle f, \mathbf{v}\rangle - b(\mathbf{v}, p_{k-1}), \quad \mathbf{v} \in \mathbf{V}_k, \\ p_k &= p_{k-1} + \alpha(B\mathbf{u}_k - g). \end{aligned}$$

As a consequence of Theorem 6.2 we have the following.

COROLLARY 6.4. *Let $0 < \alpha < 2/M^2$, $\gamma = \|I - \alpha BA^{-1}B^*\|$, and assume that (6.8) or (6.9)–(6.10) are satisfied with $\delta < \frac{1-\gamma}{1-\gamma+2\alpha M^2}$. Then, the multilevel exact Uzawa algorithm converges and the convergence rate is given by (4.4).*

6.2. Multilevel inexact Uzawa. In this subsection, we assume that the problem (6.4) can be solved on each $\mathbf{V}_k$ with an absolute error $\epsilon_k \in [0, \delta)$, i.e.,

$$|\mathbf{d}_k - \tilde{\mathbf{d}}_k|_{\mathbf{V}} \le \epsilon_k |\mathbf{d}_k|_{\mathbf{V}}. \tag{6.11}$$

If $\eta_k > 0$ is a computable estimator for $|\mathbf{d}_k - \mathbf{D}_{k-1}|_{\mathbf{V}}$, i.e.,

$$|\mathbf{d}_k - \mathbf{D}_{k-1}|_{\mathbf{V}} \le \eta_k, \tag{6.12}$$

then a computable sufficient condition for (6.6) is

$$\eta_k \le \frac{\delta - \epsilon_k}{1 + \epsilon_k}\ |\tilde{\mathbf{d}}_k|_{\mathbf{V}}. \tag{6.13}$$

Indeed, from (6.7) and (6.11)–(6.13) and the triangle inequality we have

$$\begin{aligned} |\tilde{\mathbf{d}}_k - \mathbf{D}_{k-1}|_{\mathbf{V}} &\le |\mathbf{d}_k - \mathbf{D}_{k-1}|_{\mathbf{V}} + |\mathbf{d}_k - \tilde{\mathbf{d}}_k|_{\mathbf{V}} \\ &\le \eta_k + \epsilon_k |\mathbf{d}_k|_{\mathbf{V}} \le \frac{\delta_k - \epsilon_k}{1 + \epsilon_k}\ |\tilde{\mathbf{d}}_k|_{\mathbf{V}} + \epsilon_k |\mathbf{d}_k|_{\mathbf{V}} \\ &\le \frac{\delta_k - \epsilon_k}{1 + \epsilon_k}(1 + \epsilon_k)|\mathbf{d}_k|_{\mathbf{V}} + \epsilon_k |\mathbf{d}_k|_{\mathbf{V}} = \delta_k |\mathbf{d}_k|_{\mathbf{V}} \le \delta_k\ |\mathbf{D}_{k-1}|_{\mathbf{V}}. \end{aligned}$$

We conclude this subsection with a corollary and some remarks.

COROLLARY 6.5. *Let $0 < \alpha < 2/M^2$, $\gamma = \|I - \alpha BA^{-1}B^*\|$, and let $\mathbf{d}_k, \tilde{\mathbf{d}}_k$ satisfy (6.11)–(6.13) with $\delta < \frac{1-\gamma}{1-\gamma+2\alpha M^2}$. Then, the MIUM converges and the convergence rate is given by (4.4).*

6.3. Multilevel and adaptive interpretation of the inexact Uzawa algorithm. We note that the modified inexact Uzawa algorithm can be interpreted as a multilevel algorithm. We consider that a sequence $\{\mathbf{M}_k\}$ of approximating subspaces of $\mathbf{V}$ is constructed such that $\mathbf{M}_k$ is strictly larger than $\mathbf{M}_{k-1}$ and that $\mathbf{M}_k$ is built from $\mathbf{M}_{k-1}$ by a uniform refinement strategy (see, e.g., [3, 6, 8, 19]). Based on this existing sequence of nested subspaces of $\mathbf{V}$, we can now build a sequence $\{\mathbf{V}_k\}$ so that (6.6) holds as follows.

Take $\mathbf{V}_0 = \mathbf{M}_0$, and for any positive integer k, assuming that $\mathbf{V}_{k-1} = \mathbf{M}_j$ is known, define $\mathbf{V}_{k+i} := \mathbf{M}_j$ for $i = 0, 1, \ldots$ as long as (6.13) is satisfied for k replaced by $k+i$. In other words, we update $\mathbf{u}_{k-1}$ without enlarging the space $\mathbf{V}_{k-1}$ as long as (6.13) is satisfied. When (6.13) fails to hold, we solve for the $\mathbf{u}_k$ on the next discrete level space.

The modified inexact Uzawa algorithm can be also interpreted as an adaptive method. We construct the sequence $\{\mathbf{V}_k\}$ (so that (6.6) holds) by starting with a subspace $\mathbf{V}_0$ of $\mathbf{V}$ with good approximation properties and by building the sequence $\{\mathbf{V}_k\}_{k\geq 1}$ in a similar manner. If (6.13) fails to hold for $\mathbf{V}_k = \mathbf{V}_{k-1}$, then the new discrete space $\mathbf{V}_k$ is constructed by using an adaptive strategy which assures that (6.13) and consequently (6.6) hold.

7. Applications to the Stokes system. We consider the stationary Stokes equations

$$\begin{array}{lll} -\Delta \mathbf{u} & -\nabla p & = \mathbf{f} \quad \text{in } \Omega, \\ \operatorname{div} \mathbf{u} & & = g \quad \text{in } \Omega, \end{array} \tag{7.1}$$

with vanishing Dirichlet boundary condition $\mathbf{u} = 0$ on $\partial\Omega$ and g satisfying the constraint

$$\int_\Omega g \, dx = 0.$$

In this section we apply the abstract Uzawa results presented in the previous sections to solve (7.1).

Let $\mathbf{V} := (H_0^1(\Omega))^d$, $d = 2$ or $= 3$, and

$$P = L_0^2(\Omega) := \left\{ h \in L^2(\Omega) | \int_\Omega h \, dx = 0 \right\}.$$

We assume that $\mathbf{f} \in (L^2(\Omega))^d$ and $g \in L^2(\Omega)$. The variational formulation of (7.1) becomes

Find $\mathbf{u} \in \mathbf{V}, p \in P$ such that

$$\begin{array}{lll} (\nabla \mathbf{u}, \nabla \mathbf{v}) & +(\operatorname{div} \mathbf{v}, p) & = (\mathbf{f}, \mathbf{v}), \quad \mathbf{v} \in \mathbf{V}. \\ (\operatorname{div} \mathbf{u}, q) & & = (g, q), \quad q \in P, \end{array} \tag{7.2}$$

where $(\cdot, \cdot)$ represents the standard L^2-inner product. We will denote by $a(\cdot, \cdot)$ and $b(\cdot, \cdot)$ the bilinear forms

$$a(\mathbf{u}, \mathbf{v}) := (\nabla \mathbf{u}, \nabla \mathbf{v}) = \sum_{i=1}^{d} (\nabla \mathbf{u}_i, \nabla \mathbf{v}_i)$$

and

$$b(\mathbf{v}, p) := (\operatorname{div} \mathbf{v}, p), \quad \mathbf{v} \in \mathbf{V}, p \in P.$$

We note that, for Ω smooth enough, we have

$$a(\mathbf{u},\mathbf{v}) := (\nabla\mathbf{u},\nabla\mathbf{v}) = (\operatorname{curl}\mathbf{u},\operatorname{curl}\mathbf{v}) + (\operatorname{div}\mathbf{u},\operatorname{div}\mathbf{v}), \quad \mathbf{u},\mathbf{v}\in\mathbf{V}. \tag{7.3}$$

We denote the norm induced by a with $|\cdot|_{\mathbf{V}}$ or $|\cdot|$. The norm on P is the L^2-standard norm and is simply denoted by $\|\cdot\|$. With the above notation, the variational formulation of (7.1) becomes (1.3).

It is known that for Ω smooth enough, the following LBB condition holds. More precisely, we have

$$\inf_{p\in P}\sup_{\mathbf{v}\in\mathbf{V}}\frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|} = c_0 > 0. \tag{7.4}$$

On the other hand, from (7.3) we get that

$$\sup_{p\in P}\sup_{\mathbf{v}\in\mathbf{V}}\frac{b(\mathbf{v},p)}{\|p\|\ |\mathbf{v}|} = 1. \tag{7.5}$$

We notice that for the Stokes problem the operator $A:\mathbf{V}\to\mathbf{V}^*$ consists of d copies of $-\Delta : H_0^1(\Omega)\to H^{-1}(\Omega)$, $B\mathbf{v} = \operatorname{div}\mathbf{v}$, $B^*p = -\nabla p$, and for $\rho>0$,

$$a_\rho(\mathbf{u},\mathbf{v}) := a(\mathbf{u},\mathbf{v}) + \rho(\operatorname{div}\mathbf{u},\operatorname{div}\mathbf{v}), \quad \mathbf{u},\mathbf{v}\in\mathbf{V}.$$

The next two theorems are direct consequences of Theorems 2.5 and 3.3, respectively.

THEOREM 7.1. *Let* $(\mathbf{u},p)$ *be the solution of* (7.2) *and let* $(\mathbf{u}_k,p_k)$ *be the sequence of approximations built by the UM* (2.13). *Then the statements* (i)–(iv) *of Theorem* 2.5 *hold with* $m = c_0$ *and* $M = 1$.

THEOREM 7.2. *Let* $(\mathbf{u},p)$ *be the solution of* (7.2) *and let* $(\mathbf{u}_k,p_k)$ *be the sequence of approximations built by the ALUM* (3.1). *Then the statements* (i)–(iv) *of Theorem* 3.3 *hold with* $m = c_0$ *and* $M = 1$.

According to section 5, both the UM and ALUM can be applied to any discretization of (7.2), provided that $(\mathbf{V_h},P_h)$, with $\mathbf{V_h}\subset\mathbf{V}$ and $P_h\subset P$, is a stable pair. Let us assume that a fixed pair $(\mathbf{V}_h,P_h)$ satisfies the discrete inf-sup and sup-sup conditions with constants $m(h) = c_d > 0$ and $M(h) = 1$. If $Q_h : P\to P_h$ is the L^2-orthogonal projection, then, with the new spaces, the operators associated with the forms a and b are A_h and B_h, respectively, where $A_h : \mathbf{V}_h\to\mathbf{V}_h^*$ consists of d copies of the discrete Laplacian and $B_h\mathbf{v} = Q_h\operatorname{div}\mathbf{v}$. Thus, the update for the pressure becomes

$$p_k = p_{k-1} + \alpha\ Q_h(\operatorname{div}\mathbf{u}_k - g).$$

The analysis of the discrete versions of the UM and the ALUM can be carried on similarly. The only difference in describing the convergence of the two algorithms for the discrete case is that c_0 in Theorems 7.1 and 7.2 is replaced by c_d.

The inexact Uzawa algorithm can be also applied for the discretization of (7.2) on $(\mathbf{V_h},\mathbf{P_h})$ (see, e.g., [7]). Taking for example $C_h : \mathbf{V}_h^*\to\mathbf{V}_h$ to be a preconditioner for A_h such that (4.1) is satisfied with $\delta < \frac{c_d^2}{2+c_d^2}$, we have that the IUM converges for any $\alpha\in(0,2)$. We can also apply the inexact Uzawa algorithm for the augmented Lagrangian Uzawa formulation on $(\mathbf{V_h},\mathbf{P_h})$ (see Remark 4.4).

According to Corollary 6.5, the MIUM for solving (7.2) can be also applied for any $\delta < c_0^2/(2+c_0^2)$. The main difficulty in doing so is to find the sequence of spaces $\{\mathbf{V}_k\}$ such that (6.6) or (6.13) is satisfied. Residual-type a posteriori estimators η_k (see, e.g., [2], [18]) could be involved in finding the right sequence $\{\mathbf{V}_k\}$. Constructing and testing multilevel or adaptive algorithms for solving the Stokes system based on the MIUM remains a challenging new problem and is a subject for future work.

8. Conclusion. The paper gives a unified analysis approach of various Uzawa-like algorithms for solving continuous or discrete saddle point problems. The convergence condition and the convergence factors depend upon the extreme spectral bounds of the Schur complement $BA^{-1}B^*$ only. To the best of our knowledge, the result concerning the optimal convergence factor of the ALUM for the infinite-dimensional case is new. The analysis of the modified inexact Uzawa algorithm at the continuous level, which was introduced in section 6, gives a general strategy for solving saddle point systems. Our inexact Uzawa algorithm is similar to the algorithm for solving the Stokes system presented in [4]. The differences are in the way the error bounds are imposed (see (6.6), (6.13)) and the way the pressure is updated. Our analysis, combined with standard techniques of a posteriori error estimates, could lead to new and efficient adaptive algorithms for solving saddle point systems. The main difficulty in implementing concrete algorithms based on the MIUM is finding error estimators η_k such that the conditions (6.6) or (6.13) are satisfied. Finding spaces $\{\mathbf{V}_k\}$ such that conditions similar to (6.6) are satisfied will be the focus of our future work.

Acknowledgment. The author would like to thank the two reviewers for the valuable suggestions towards improving this paper.

DISCONTINUOUS GALERKIN FINITE ELEMENT APPROXIMATION OF NONLINEAR NON-FICKIAN DIFFUSION IN VISCOELASTIC POLYMERS*

BÉATRICE RIVIÈRE† AND SIMON SHAW‡

Abstract. We consider discrete schemes for a nonlinear model of non-Fickian diffusion in viscoelastic polymers. The model is motivated by, but not the same as, that proposed by Cohen, White, and Witelski in *SIAM J. Appl. Math.*, 55 (1995), pp. 348–368. The spatial discretization is effected with both the symmetric and nonsymmetric interior penalty discontinuous Galerkin finite element method, and the time discretization is of Crank–Nicolson type. We also discuss two means of handling the nonlinearity: either implicitly, which requires the solution of nonlinear equations at each time level, or through a linearization based on extrapolating from previous time levels. The same optimal orders of convergence are proven in both cases and, to verify this, some numerical results are also given for the linearized scheme.

Key words. non-Fickian diffusion, viscoelasticity, finite element method, error estimates

1. Introduction.

In [24] Thomas and Windle demonstrated by experiment that the diffusion of organic penetrants into glassy polymers does not obey the classical Fick's law. At moderate temperatures the profile of diffusing penetrant (methanol in their case) forms a steep front which travels at a constant speed into the polymer. In [25] they developed a model for this "anomalous" diffusion in terms of an ordinary differential equation for the fractional swelling of the polymer.

However, in order to have more predictive value, a mathematical model for this behavior in the form of a partial differential equation is more desirable. Such a model has been proposed by Cohen, White, and Witelski in [6] (see also the references therein). Recognizing that viscoelastic stress relaxation effects are significant in polymers, they add such a term to Fick's law and drive this stress through a nonlinear relaxation equation which is adjoined to the diffusion equation. Solving the system then results in a heat equation with a nonlinear viscoelastic memory term in the form of a Volterra integral—typical of continuum models of polymers (see, e.g., [8] for polymer theory and [14] for a similar model of heat conduction).

In terms of the underlying physics, it seems that high levels of penetrant concentration can cause a *rubber-glass phase change*. The polymer's viscoelastic properties change dramatically across this transition layer, and this can cause sharp fronts to develop in the diffusing penetrant.

The model proposed in [6] seems to be difficult to handle in terms of obtaining estimates and so, as a stepping stone to that model, we deal here with a simpler version which involves a vector of stresses in the diffusion equation, rather than (as

in [6]) the gradient of a scalar stress. The reason this is a simplification can be better explained once we have seen the equations.

Our model is as follows. For an open bounded domain $\Omega \subset \mathbb{R}^d$ ($d = 2$ or 3) and a time interval $I := (0, T)$, for some $T > 0$, we want to find the "concentration," $u\colon \Omega \times I \to \mathbb{R}$, and viscoelastic stress, $\boldsymbol{\sigma}\colon \Omega \times I \to \mathbb{R}^d$, such that in $\Omega \times I$,

$$u_t(t) - \nabla \cdot D\nabla u(t) = f(t) + \nabla \cdot K\boldsymbol{\sigma}(t), \tag{1}$$

$$\boldsymbol{\sigma}_t(t) + \gamma(u)\boldsymbol{\sigma}(t) = \mu\nabla u(t), \tag{2}$$

where $\boldsymbol{\sigma} = (\sigma_1, \ldots, \sigma_d)^T$. These are subject to the initial conditions,

$$u(\boldsymbol{x}, 0) = \breve{u}(\boldsymbol{x}) \qquad \text{and} \qquad \boldsymbol{\sigma}(\boldsymbol{x}, 0) = \breve{\boldsymbol{\sigma}}(\boldsymbol{x}), \tag{3}$$

and the boundary conditions,

$$\begin{aligned} &u(\boldsymbol{x}, t) = 0 \text{ on } \Gamma_D \times I \qquad \text{and} \\ &(D\nabla u(\boldsymbol{x}, t) + K\boldsymbol{\sigma}(\boldsymbol{x}, t)) \cdot \boldsymbol{n}(\boldsymbol{x}) = g(\boldsymbol{x}, t) \text{ on } \Gamma_N \times I, \end{aligned} \tag{4}$$

where $\Gamma_D \cup \Gamma_N = \partial\Omega$, $\Gamma_D \cap \Gamma_N = \varnothing$, Γ_N has outward normal $\boldsymbol{n}$, and Γ_D is closed with positive surface measure. Note that in (1) and (2), and usually below, we drop the $\boldsymbol{x}$ dependence.

In [6] the vector of stresses, $\boldsymbol{\sigma}$, is replaced by the gradient of a scalar stress, $\nabla\sigma$. Our model is a simplification because, in weak form, we can generate the term $(\boldsymbol{\sigma}, \nabla u)$ in both equations and therefore easily merge them as a starting point for estimates. This is clearly illustrated below in Theorem 1.1.

In our equations D, K, and μ are positive constants. Also, the nonlinear function

$$\gamma(u) = \frac{1}{2}(\gamma_R + \gamma_G) + \frac{1}{2}(\gamma_R - \gamma_G)\tanh\left(\frac{u - u_{RG}}{\Delta}\right), \tag{5}$$

with constants $\gamma_R \gg \gamma_G > 0$, models the sharp change in material properties across the *rubber-glass transition*. The sharpness of the change is controlled by the positive constant Δ, and the location of the change is controlled by the constant transition concentration u_{RG}. Regions where $u \ll u_{RG}$ correspond to the "glassy" phase while regions where $u \gg u_{RG}$ are "rubbery." When u is in or near a Δ-neighborhood of u_{RG} the polymer is in a nebulous phase transition state.

Since this simplified model is motivated by a diffusion problem we have continued to refer to u as a concentration. However, because the underlying physics may have been lost in the simplification, it may not actually have the correct physical properties.

We note that

$$0 < \gamma_G \leqslant \gamma(y) \leqslant \gamma_R \qquad \forall y \in \mathbb{R} \tag{6}$$

and

$$\gamma'(y) = \frac{\gamma_R - \gamma_G}{2\Delta}\operatorname{sech}^2\left(\frac{y - u_{RG}}{\Delta}\right), \tag{7}$$

so that

$$0 \leqslant \gamma'(y) \leqslant C'_\gamma := \frac{\gamma_R - \gamma_G}{2\Delta} \qquad \forall y \in \mathbb{R}. \tag{8}$$

Also,

$$\gamma''(y) = -\left(\frac{\gamma_R - \gamma_G}{\Delta^2}\right) \tanh\left(\frac{y - u_{RG}}{\Delta}\right) \operatorname{sech}^2\left(\frac{y - u_{RG}}{\Delta}\right),$$

which gives

$$|\gamma''(y)| \leqslant C''_\gamma := \frac{\gamma_R - \gamma_G}{\Delta^2} \qquad \forall y \in \mathbb{R}. \tag{9}$$

We also note that we can solve (2) to get

$$\boldsymbol{\sigma}(t) = \breve{\boldsymbol{\sigma}} e^{-\int_0^t \gamma(u(\xi))\, d\xi} + \mu \int_0^t e^{-\int_s^t \gamma(u(\xi))\, d\xi} \nabla u(s)\, ds \tag{10}$$

and use this in (1) to arrive at (assuming $\breve{\boldsymbol{\sigma}} = \mathbf{0}$)

$$u_t(t) - \nabla \cdot D\nabla u(t) = f(t) + \nabla \cdot \mu K \int_0^t e^{-\int_s^t \gamma(u(\xi))\, d\xi} \nabla u(s)\, ds. \tag{11}$$

We recognize this as a parabolic partial differential equation with a nonlinear Volterra-type memory term typical of that arising in viscoelasticity theory. We could work directly with this formulation in constructing our numerical approximation, but we prefer to work with the system, (1) with (2), since we then need not be concerned with the discretization of the Volterra integral. Also, representing viscoelasticity through evolution equations for internal variables is often preferred to the use of Volterra integrals. See, for example, [11, 10, 3]. It is important to realize that introducing internal variables does not introduce more unknowns and lead to a more complex scheme than would result from using the Volterra formulation directly. In the latter case the "history" in the Volterra integral needs to be stored and updated at each time step. This is exactly analogous to storing the previous value of the internal variable and then updating it through a time-stepping scheme.

This is the third in a series of papers extending the (spatially) *discontinuous Galerkin (DG) finite element method (FEM)* to viscoelasticity problems. In [16] we considered an elliptic stress analysis problem with memory and in [17] we extended this to a second-order hyperbolic problem with memory. Both of these deal only with linear problems, but below we "complete the set" by considering a parabolic problem and including a physically relevant nonlinearity.

DG methods offer several advantages. The lack of continuity constraints between the local approximations allows for an easy implementation of mesh adaptivity. Unlike the classical continuous FEM, the DG method can handle unstructured nonconforming meshes with several hanging nodes per edge (or face). In addition, increasing the polynomial degree does not require any major modification of the software. It is relatively easy as well to have polynomial degrees that vary from one mesh element to the next. Finally, one inherent property of DG methods is the local mass conservation. While this property is essential in many flow and transport problems, it remains to be seen that local mass conservation is important for non-Fickian polymer diffusion problems. A deeper numerical investigation is needed. This will be the object of future work.

The layout of this article is as follows. In section 2 the equations are spatially discretized using an interior penalty DG FEM, and we consider both the symmetric and nonsymmetric variants. The time discretization is a standard Crank–Nicolson

method with a choice of treatments for the nonlinear term. Either this term is approximated in an implicit way, which involves a nonlinear equation set at each time level, or it is handled by extrapolating the current approximation of u to the current time level from the two previous time levels (similarly to [5]). Special care is needed at the first time step, but we can show optimal second-order convergence in each case. The error estimates are contained in section 3 and some numerical experiments are given in section 4. We finish with some comments regarding our model and approach in section 5, as well as discuss the potential for extending this work to Cohen, White, and Witelski's model.

For background on the DG FEM we refer the reader to [18, 21, 9, 20], and for the numerical analysis of generic parabolic problems with memory we refer the reader to [5, 12, 23, 26, 13] (but there are many others).

However, apart from [17], we are not aware of any error analysis for numerical approximations to viscoelasticity problems where the Volterra integral is replaced with internal variable evolution equations, such as (2).

Our notation is standard. For $\omega \subseteq \bar{\Omega}$ we use $(\cdot,\cdot)_\omega$ to denote the $L_2(\omega)$ inner product and simply write $(\cdot,\cdot)$ when $\omega = \Omega$. Also, we use $\|\cdot\|_{p,\omega}$ to denote the $H^p(\omega)$ norm and write $\|\cdot\|_m$ as an abbreviation for $\|\cdot\|_{m,\Omega}$.

We set $\boldsymbol{H}^p(\Omega) := (H^p(\Omega))^d$, but in the notation just described we do not distinguish between inner products and norms on $H^p(\Omega)$ (as used for u) and inner products and norms on $\boldsymbol{H}^p(\Omega)$ (as used for $\boldsymbol{\sigma}$).

Since our functions are time dependent we take the usual approach of thinking of them as maps from I to some underlying Banach space, X. For $1 \leqslant p < \infty$ the $L_p(0,t;X)$ norms are given by

$$\|v\|_{L_p(0,t;X)} := \left(\int_0^t \|v(t)\|_X^p \, dt\right)^{1/p},$$

with the usual "ess sup" modification when $p = \infty$.

To finish this introduction we derive a stability estimate for this problem; the proof is a model of how to proceed with the estimates for the discrete scheme that follows. To begin we note that if

$$V := \{v \in H^1(\Omega) \colon v = 0 \text{ on } \Gamma_D\},$$

then a variational formulation of (1)–(2) is as follows: find maps $u \colon I \to V$ and $\boldsymbol{\sigma} \colon I \to \boldsymbol{L}_2(\Omega)$ such that

$$(12)\quad (u_t(t), v) + (D\nabla u(t), \nabla v) + (K\boldsymbol{\sigma}(t), \nabla v) = L(t; v) \qquad \forall v \in V,$$

$$(13)\quad (\boldsymbol{\sigma}_t(t) + \gamma(u)\boldsymbol{\sigma}(t), \boldsymbol{w}) = (\mu\nabla u(t), \boldsymbol{w}) \qquad \forall \boldsymbol{w} \in \boldsymbol{L}_2(\Omega),$$

where

$$(14)\qquad L(t; v) := (f(t), v) + (g(t), v)_{\Gamma_N}.$$

We can now state a basic stability estimate which does not require Gronwall's lemma.

THEOREM 1.1 (basic stability). *There exists a constant $C > 0$, independent of T, such that, if $(u, \boldsymbol{\sigma})$ is a solution of (12), (13), then*

$$\|u(t)\|_0^2 + \|\boldsymbol{\sigma}(t)\|_0^2 + \int_0^t \left(\|D^{1/2}\nabla u(s)\|_0^2 + \|\boldsymbol{\sigma}(s)\|_0^2\right) ds \leqslant C\left(\|\breve{u}\|_0^2 + \|\breve{\boldsymbol{\sigma}}\|_0^2 + \|f\|_{L_2(0,t;L_2(\Omega))}^2 + \|g\|_{L_2(0,t;L_2(\Gamma_N))}^2\right)$$

for all $t > 0$.

Proof. Choose $v = u$ in (12) and $\boldsymbol{w} = (K/\mu)\boldsymbol{\sigma}(t)$ in (13) and add the resulting equations to get

$$\begin{aligned}(u_t(t), u(t)) + (D\nabla u(t), \nabla u(t)) + (K\boldsymbol{\sigma}(t), \nabla u(t))\\ + \frac{K}{\mu}(\boldsymbol{\sigma}_t(t), \boldsymbol{\sigma}(t)) + \frac{K}{\mu}(\gamma(u)\boldsymbol{\sigma}(t), \boldsymbol{\sigma}(t)) - (K\boldsymbol{\sigma}(t), \nabla u(t))\\ = (f(t), u(t)) + (g(t), u(t))_{\Gamma_N}.\end{aligned}$$

Hence, using Poincaré's inequality

$$\begin{aligned}\frac{d}{dt}\|u(t)\|_0^2 + \frac{K}{\mu}\frac{d}{dt}\|\boldsymbol{\sigma}(t)\|_0^2 + 2\|D^{1/2}\nabla u(t)\|_0^2 + \frac{2K}{\mu}(\gamma(u)\boldsymbol{\sigma}(t), \boldsymbol{\sigma}(t))\\ \leqslant 2C\|f(t)\|_0\|D^{1/2}\nabla u(t)\|_0 + 2C\|g(t)\|_{0,\Gamma_N}\|D^{1/2}\nabla u(t)\|_0\\ \leqslant 2C^2\|f(t)\|_0^2 + 2C^2\|g(t)\|_{0,\Gamma_N}^2 + \|D^{1/2}\nabla u(t)\|_0^2.\end{aligned}$$

Integrating then gives

$$\begin{aligned}\|u(t)\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}(t)\|_0^2 + \int_0^t \left(\|D^{1/2}\nabla u(s)\|_0^2 + \frac{2K\gamma_G}{\mu}\|\boldsymbol{\sigma}(s)\|_0^2\right) ds\\ \leqslant \|\breve{u}\|_0^2 + \frac{K}{\mu}\|\breve{\boldsymbol{\sigma}}\|_0^2 + 2C^2\left(\|f\|_{L_2(0,t;L_2(\Omega))}^2 + \|g\|_{L_2(0,t;L_2(\Gamma_N))}^2\right).\end{aligned}$$

This concludes the proof. ∎

Last in this section, we recall Young's inequality in the form

$$ab \leqslant \frac{a^p}{p\epsilon^p} + \frac{\epsilon^q b^q}{q} \tag{15}$$

for all $a, b \geqslant 0$, $\epsilon > 0$, and $p, q \in (1, \infty)$ such that $1/p + 1/q = 1$.

2. The numerical scheme. The first step is to establish notation for the spatial discretization. Let $\mathcal{E}_h = \{E\}$ be a nondegenerate quasiuniform subdivision of Ω, where E is a triangle if $d = 2$, or a tetrahedron if $d = 3$. The nondegeneracy requirement is that there exists $\rho > 0$ such that if $h_E = \operatorname{diam}(E)$, then E contains a ball of radius ρh_E in its interior. Let $h = \max\{h_E : E \in \mathcal{E}_h\}$; the quasiuniformity requirement is that there exists $\tau > 0$ such that $h/h_E \leqslant \tau$ for all $E \in \mathcal{E}_h$. We denote by Γ_h the set of interior edges (faces for $d = 3$) of $\mathcal{E}_h$. With each edge (or face) e, we associate a unit normal vector $\boldsymbol{n}_e$. For a boundary edge e, $\boldsymbol{n}_e$ is taken to be the unit outward vector normal to $\partial\Omega$.

We now define the average and the jump operators. For each of the interior edges, suppose that e is shared by E_1^e and E_2^e such that $\boldsymbol{n}_e$ points from E_1^e to E_2^e and for a boundary edge, suppose that e belongs to E_1^e. We define the averaging operator $\{\cdot\}$ by

$$\{w\} := \begin{cases} \frac{1}{2}(w|_{E_1^e})|_e + \frac{1}{2}(w|_{E_2^e})|_e & \text{if } e \subset \Omega,\\ (w|_{E_1^e})|_e & \text{if } e \subset \partial\Omega \end{cases}$$

and the jump operator $[\cdot]$ by

$$[w] := \begin{cases} (w|_{E_1^e})|_e - (w|_{E_2^e})|_e & \text{if } e \subset \Omega,\\ (w|_{E_1^e})|_e & \text{if } e \subset \partial\Omega. \end{cases}$$

The distinction between $[\cdot]$ and $-[\cdot]$ can be made because each edge e_a has a unit normal associated with it. The "direction" in which the jump takes place is unimportant.

These operators are well defined if $w|_{E_a^i} \in H^{\frac{1}{2}+\epsilon}(E_a^i)$ for $i = 1, 2$ and $\epsilon > 0$. Below, we use $|e|$ to denote the $(d-1)$-dimensional surface measure of the edge/face e. We also frequently use the estimate, $|e| \leqslant Ch^{d-1}$ which arises as a consequence of our assumptions.

Define the broken spaces for any integer $r > 0$ as

$$\begin{aligned}
\mathcal{D}_r(\mathcal{E}_h) &= \{v \in L_2(\Omega) : v|_E \in \mathbb{P}_r(E) \quad \forall E \in \mathcal{E}_h\},\\
\boldsymbol{\mathcal{D}}_r(\mathcal{E}_h) &= \mathcal{D}_r(\mathcal{E}_h)^d,\\
H^n(\mathcal{E}_h) &= \{v \in L_2(\Omega) : v|_E \in H^n(E) \quad \forall E \in \mathcal{E}_h\}.
\end{aligned}$$

For these finite element spaces we have the following interpolation-error estimates. If $v \in H^n(\mathcal{E}_h) \cap C(\bar{\Omega})$ and $\mu = \min\{r+1, n\}$ then there is an interpolant $\hat{v} \in \mathcal{D}_r(\mathcal{E}_h) \cap C(\bar{\Omega})$ such that for each $E \in \mathcal{E}_h$,

$$\|v - \hat{v}\|_{m,E} \leqslant Ch_E^{\mu-m}\|v\|_{n,E} \qquad \text{for } n \geqslant m \geqslant 0, \tag{16}$$

$$\|v - \hat{v}\|_{m,\gamma} \leqslant Ch_E^{\mu-m-1/2}\|v\|_{n,E} \qquad \text{for } m = 0, 1 \text{ and } n \geqslant m, \tag{17}$$

where $\gamma \subseteq \partial E$.

Define the bilinear forms

$$J_0^{\delta,\beta}(w,v) = \sum_{e\in\Gamma_h\cup\Gamma_D} \frac{\delta}{|e|^\beta}\int_e [w][v] \qquad \text{for } \beta \geqslant (d-1)^{-1},$$

$$\begin{aligned}
A(w,v) = \sum_E \int_E D\nabla w\cdot\nabla v + J_0^{\delta,\beta}(w,v) - \sum_{e\in\Gamma_h\cup\Gamma_D}\int_e \{D\nabla w\cdot \boldsymbol{n}_e\}[v]\\
+ \kappa\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e \{D\nabla v\cdot \boldsymbol{n}_e\}[w].
\end{aligned}$$

Here κ is a switch: we set $\kappa = 1$ to obtain the nonsymmetric DG scheme, and $\kappa = -1$ to obtain the symmetric scheme. Following from these definitions are the norm and seminorm

$$\|v\|_{\mathcal{A}} := \left(|v|_{\mathcal{E}}^2 + J_0^{\delta,\beta}(v,v)\right)^{\frac{1}{2}} \qquad \text{and} \qquad |v|_{\mathcal{E}} := \left(\sum_{E\in\mathcal{E}_h}\int_E D\nabla v\cdot\nabla v\, dE\right)^{\frac{1}{2}}.$$

We will need the following estimates.

LEMMA 2.1. *We have*

$$\|v\|_0 \leqslant C_f\|v\|_{\mathcal{A}} \qquad \forall v \in H^1(\mathcal{E}_h) \tag{18}$$

and

$$\|v\|_{0,\Gamma_N} \leqslant C_g h^{-1/2}\|v\|_{\mathcal{A}} \qquad \forall v \in \mathcal{D}_r(\mathcal{E}_h),$$

for constants C_f and C_g, independent of h.

Proof. For the first inequality we refer to [9, Lemma 6.2], and for the second inequality we use the first one with Sobolev interpolation to get

$$\|v\|_{0,\Gamma_N}^2 = \sum_{e\in\Gamma_N}\|v\|_{0,e}^2 \leqslant C\sum_E h^{-1}\|v\|_{0,E}\|\nabla v\|_{0,E} \leqslant Ch^{-1}(C_f^2 + D^{-1})\|v\|_{\mathcal{A}}^2.$$

This completes the proof. ∎

We note that if $u(t) \in C(\bar{\Omega})$ for each t, then

$$(u_t(t), v) + A(u(t), v) = L(t; v) - \sum_E (K\boldsymbol{\sigma}(t), \nabla v)_E + \sum_{e \in \Gamma_h \cup \Gamma_D} \int_e \{K\boldsymbol{\sigma}(t) \cdot \boldsymbol{n}_e\}[v] \qquad \forall v \in \mathcal{D}_r(\mathcal{E}_h), \tag{19}$$

and

$$(\boldsymbol{\sigma}_t(t) + \gamma(u)\boldsymbol{\sigma}(t), \boldsymbol{w}) = \sum_E (\mu \nabla u(t), \boldsymbol{w})_E \qquad \forall \boldsymbol{w} \in \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h). \tag{20}$$

The first of these arises by elementwise partial integration and "adding zero" (see, e.g., [21]).

To construct a fully discrete approximation we set $k = T/N$ for some $N \in \mathbb{N}$, and write $t_i = ik$. To ease notation we define

$$\partial_t w_i := \frac{w(t_i) - w(t_{i-1})}{k} \qquad \text{and} \qquad \bar{w}_i := \frac{w(t_i) + w(t_{i-1})}{2}.$$

The fully discrete approximations, u^h and $\boldsymbol{\sigma}^h$, to u and $\boldsymbol{\sigma}$ are continuous and piecewise linear in time, and discontinuous in space. We set $u_i^h := u^h(t_i)$ and $\boldsymbol{\sigma}_i^h := \boldsymbol{\sigma}^h(t_i)$.

An issue is how to handle the nonlinearity, $\gamma(u)$, in the numerical scheme. We offer two possibilities by approximating $\gamma(u)|_{(t_{i-1},t_i)}$ by $\gamma(\mathcal{B}_{i,n}u^h)$ for $n = 1$ or 2, where

$$\mathcal{B}_{i,1}u^h := \bar{u}_i^h \qquad \text{and} \qquad \mathcal{B}_{i,2}u^h := \mathcal{E}_i u^h,$$

with $\mathcal{E}_i$ an extrapolation operator defined by

$$\mathcal{E}_i u^h := \begin{cases} u_0^h & \text{for } i = 1; \\ \frac{3}{2}u_{i-1}^h - \frac{1}{2}u_{i-2}^h & \text{for } i = 2, \ldots, N. \end{cases}$$

In the first case we approximate $\gamma(u)|_{(t_{i-1},t_i)}$ by taking the true average, $\bar{u}_i^h$, of the discrete solution. This will result in a nonlinear system to be solved at each time level. To linearize this system, the second method linearly extrapolates to the average based on the two previous solutions. This is not possible at the first time step and so this first step will require special treatment in the error estimation. This extrapolation technique is widely used in coupled flow and transport problems such as miscible displacement. See, for example, [7] and [19].

The fully discrete approximations (i.e., for $n = 1$ or 2) are based on sampling (19) and (20) at the temporal midpoints, $t_{i-1/2}$. They are defined as follows: for each $i = 1, 2, \ldots, N$, find a pair $\{u_i^h, \boldsymbol{\sigma}_i^h\} \in \mathcal{D}_r(\mathcal{E}_h) \times \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h)$ such that

$$(\partial_t u_i^h, v) + A(\bar{u}_i^h, v) = L_i(v) - \sum_E (K\bar{\boldsymbol{\sigma}}_i^h, \nabla v)_E + \sum_{e \in \Gamma_h \cup \Gamma_D} \int_e \{K\bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\}[v] \qquad \forall v \in \mathcal{D}_r(\mathcal{E}_h), \tag{21}$$

and

$$(\partial_t \boldsymbol{\sigma}_i^h + \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^h, \boldsymbol{w}) = \sum_E (\mu \nabla \bar{u}_i^h, \boldsymbol{w})_E \qquad \forall \boldsymbol{w} \in \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h), \tag{22}$$

where

$$L_i(v) := \frac{1}{2}\Big(L(t_i; v) + L(t_{i-1}; v)\Big),$$

and the discrete initial data are given by

$$\begin{aligned} (u_0^h, v) &= (\breve{u}, v) && \forall v \in \mathcal{D}_r(\mathcal{E}_h), \\ (\boldsymbol{\sigma}_0^h, \boldsymbol{w}) &= (\breve{\boldsymbol{\sigma}}, \boldsymbol{w}) && \forall \boldsymbol{w} \in \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h). \end{aligned}$$

We now give a stability estimate for this discrete approximation and note that Gronwall's lemma is not used. We also note that the "h^{-1}" factor appearing in front of the boundary term is a weakness in the proof and is not observed in computations. It appears that the removal of this factor is an open problem (although, see Remark 3.6 later).

THEOREM 2.2 (discrete basic stability). *If $\beta \geqslant (d-1)^{-1}$ and $h \leqslant \hat{h}$ we have for $m = 1, 2, \ldots, N$ that*

$$\begin{aligned} \|u_m^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_m^h\|_0^2 + C^\star k \sum_{i=1}^m \left(\|\bar{u}_i^h\|_{\mathcal{A}}^2 + 2K\|\bar{\boldsymbol{\sigma}}_i^h\|_0^2\right) \\ \leqslant \|\breve{u}\|_0^2 + \frac{K}{\mu}\|\breve{\boldsymbol{\sigma}}\|_0^2 + 6k\sum_{i=1}^m \left(C_f^2\|\bar{f}_i\|_0^2 + C_g^2 h^{-1}\|\bar{g}_i\|_{0,\Gamma_N}^2\right), \end{aligned}$$

provided that

$$\delta \geqslant 3C\hat{h}^{(d-1)\beta-1}\max\left\{\frac{4D}{1-C^\star}, \frac{\mu K}{2\gamma_G - 2\mu C^\star}\right\},$$

where $C^\star < \min\{1, \gamma_G/\mu\}$ is some chosen positive constant, C is independent of h, and C_f and C_g are those in Lemma 2.1.

Proof. Choose $v = \bar{u}_i^h$ in (21) and $\boldsymbol{w} = (K/\mu)\bar{\boldsymbol{\sigma}}_i^h$ in (22) and note that

$$\begin{aligned} (\partial_t u_i^h, \bar{u}_i^h) &= \frac{1}{2k}\|u_i^h\|_0^2 - \frac{1}{2k}\|u_{i-1}^h\|_0^2, \\ (\partial_t \boldsymbol{\sigma}_i^h, \bar{\boldsymbol{\sigma}}_i^h) &= \frac{1}{2k}\|\boldsymbol{\sigma}_i^h\|_0^2 - \frac{1}{2k}\|\boldsymbol{\sigma}_{i-1}^h\|_0^2, \\ A(\bar{u}_i^h, \bar{u}_i^h) &= \sum_E (D\nabla\bar{u}_i^h, \nabla\bar{u}_i^h)_E + J_0^{\delta,\beta}(\bar{u}_i^h, \bar{u}_i^h) \\ &\qquad + (\kappa - 1)\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e \{D\nabla\bar{u}_i^h \cdot \boldsymbol{n}_e\}[\bar{u}_i^h]. \end{aligned}$$

Adding the two resulting equations then gives

$$\begin{aligned} &\frac{1}{2k}\|u_i^h\|_0^2 - \frac{1}{2k}\|u_{i-1}^h\|_0^2 + \frac{K}{2k\mu}\|\boldsymbol{\sigma}_i^h\|_0^2 - \frac{K}{2k\mu}\|\boldsymbol{\sigma}_{i-1}^h\|_0^2 + \|\bar{u}_i^h\|_{\mathcal{A}}^2 + \frac{K}{\mu}(\gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^h, \bar{\boldsymbol{\sigma}}_i^h) \\ &\quad = L_i(\bar{u}_i^h) - (\kappa-1)\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e \{D\nabla\bar{u}_i^h \cdot \boldsymbol{n}_e\}[\bar{u}_i^h] + \sum_{e\in\Gamma_h\cup\Gamma_D}\int_e \{K\bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\}[\bar{u}_i^h], \end{aligned}$$

and summing over $i = 1, \ldots, m$ and multiplying by $2k$ yields

$$\begin{aligned} &\|u_m^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_m^h\|_0^2 + 2k\sum_{i=1}^m \|\bar{u}_i^h\|_{\mathcal{A}}^2 + 2k\sum_{i=1}^m \frac{K}{\mu}(\gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^h, \bar{\boldsymbol{\sigma}}_i^h) \\ &\quad = \|u_0^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_0^h\|_0^2 + 2k\sum_{i=1}^m L_i(\bar{u}_i^h) + I + II, \end{aligned}$$

where

$$I = 2k \sum_{i=1}^{m} \sum_{e \in \Gamma_h \cup \Gamma_D} \int_e \{K \bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\} [\bar{u}_i^h],$$
$$II = 2k \sum_{i=1}^{m} (1-\kappa) \sum_{e \in \Gamma_h \cup \Gamma_D} \int_e \{D \nabla \bar{u}_i^h \cdot \boldsymbol{n}_e\} [\bar{u}_i^h].$$

Now, using $\|\bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\|_{0,\partial E} \leqslant C h^{-1/2} \|\bar{\boldsymbol{\sigma}}_i^h\|_{0,E}$ and recalling that $|e| \leqslant C h^{d-1}$, for I we have

$$\begin{aligned}
|I| &\leqslant 2k \sum_{i=1}^{m} \sum_{e \in \Gamma_h \cup \Gamma_D} K \|\{\bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\}\|_{0,e} \|[\bar{u}_i^h]\|_{0,e}, \\
&\leqslant 2\epsilon_1 k \sum_{i=1}^{m} \sum_{e \in \Gamma_h \cup \Gamma_D} K^2 \left(\frac{|e|^\beta}{\delta} \right) \|\{\bar{\boldsymbol{\sigma}}_i^h \cdot \boldsymbol{n}_e\}\|_{0,e}^2 + \frac{k}{2\epsilon_1} \sum_{i=1}^{m} \sum_{e \in \Gamma_h \cup \Gamma_D} \left(\frac{\delta}{|e|^\beta} \right) \|[\bar{u}_i^h]\|_{0,e}^2, \\
&\leqslant 2\epsilon_1 k \sum_{i=1}^{m} \frac{K^2 C h^{(d-1)\beta - 1}}{\delta} \|\bar{\boldsymbol{\sigma}}_i^h\|_0^2 + \frac{k}{2\epsilon_1} \sum_{i=1}^{m} J_0^{\delta,\beta}(\bar{u}_i^h, \bar{u}_i^h).
\end{aligned}$$

Similarly, since $|\kappa - 1| \leqslant 2$,

$$\begin{aligned}
|II| &\leqslant 4k \sum_{i=1}^{m} \sum_{e \in \Gamma_h \cup \Gamma_D} \left(\frac{|e|^\beta}{\delta} \right)^{1/2} \|\{D \nabla \bar{u}_i^h \cdot \boldsymbol{n}_e\}\|_{0,e} \left(\frac{\delta}{|e|^\beta} \right)^{1/2} \|[\bar{u}_i^h]\|_{0,e}, \\
&\leqslant 2\epsilon_2 k \sum_{i=1}^{m} \sum_{E} \frac{D C h^{(d-1)\beta - 1}}{\delta} \|D^{1/2} \nabla \bar{u}_i^h\|_{0,E}^2 + \frac{2k}{\epsilon_2} \sum_{i=1}^{m} J_0^{\delta,\beta}(\bar{u}_i^h, \bar{u}_i^h).
\end{aligned}$$

With these we arrive at

$$\begin{aligned}
&\|u_m^h\|_0^2 + \frac{K}{\mu} \|\boldsymbol{\sigma}_m^h\|_0^2 + \left(2 - \frac{1}{2\epsilon_1} - \frac{2}{\epsilon_2} \right) k \sum_{i=1}^{m} \|\bar{u}_i^h\|_{\mathcal{A}}^2 + 2k \sum_{i=1}^{m} \frac{K}{\mu} (\gamma(\mathcal{B}_{i,n} u^h) \bar{\boldsymbol{\sigma}}_i^h, \bar{\boldsymbol{\sigma}}_i^h) \\
&\quad \leqslant \|u_0^h\|_0^2 + \frac{K}{\mu} \|\boldsymbol{\sigma}_0^h\|_0^2 + 2k \left| \sum_{i=1}^{m} L_i(\bar{u}_i^h) \right| \\
&\qquad + 2k \sum_{i=1}^{m} \frac{C h^{(d-1)\beta - 1}}{\delta} \left(K^2 \epsilon_1 \|\bar{\boldsymbol{\sigma}}_i^h\|_0^2 + D \epsilon_2 \|\bar{u}_i^h\|_{\mathcal{A}}^2 \right).
\end{aligned}$$

Now, using Lemma 2.1,

$$\begin{aligned}
2k \left| \sum_{i=1}^{m} L_i(\bar{u}_i^h) \right| &= k \left| \sum_{i=1}^{m} \left(L(t_i; \bar{u}_i^h) + L(t_{i-1}; \bar{u}_i^h) \right) \right| \\
&= k \left| \sum_{i=1}^{m} \left((f(t_i), \bar{u}_i^h) + (f(t_{i-1}), \bar{u}_i^h) + (g(t_i), \bar{u}_i^h)_{\Gamma_N} + (g(t_{i-1}), \bar{u}_i^h)_{\Gamma_N} \right) \right| \\
&= 2k \left| \sum_{i=1}^{m} \left((\bar{f}_i, \bar{u}_i^h) + (\bar{g}_i, \bar{u}_i^h)_{\Gamma_N} \right) \right| \\
&\leqslant 2k \sum_{i=1}^{m} C_f \|\bar{f}_i\|_0 \|\bar{u}_i^h\|_{\mathcal{A}} + 2k \sum_{i=1}^{m} C_g h^{-1/2} \|\bar{g}_i\|_{0,\Gamma_N} \|\bar{u}_i^h\|_{\mathcal{A}}
\end{aligned}$$

$$\leqslant \epsilon_3 k \sum_{i=1}^{m} C_f^2 \|\bar{f}_i\|_0^2 + \epsilon_3 k \sum_{i=1}^{m} C_g^2 h^{-1} \|\bar{g}_i\|_{0,\Gamma_N}^2 + \frac{2k}{\epsilon_3} \sum_{i=1}^{m} \|\bar{u}_i^h\|_{\mathcal{A}}^2.$$

With this and (6), we now have

$$\begin{aligned}
\|u_m^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_m^h\|_0^2 + \left(2 - \frac{1}{2\epsilon_1} - \frac{2}{\epsilon_2} - \frac{2}{\epsilon_3}\right) k \sum_{i=1}^{m} \|\bar{u}_i^h\|_{\mathcal{A}}^2 + 2k \sum_{i=1}^{m} \frac{K\gamma_G}{\mu} \|\bar{\boldsymbol{\sigma}}_i^h\|_0^2 \\
\leqslant \|u_0^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_0^h\|_0^2 + \epsilon_3 k \sum_{i=1}^{m} \Big(C_f^2 \|\bar{f}_i\|_0^2 + C_g^2 h^{-1} \|\bar{g}_i\|_{0,\Gamma_N}^2 \Big) \\
+ 2k \sum_{i=1}^{m} \frac{C h^{(d-1)\beta - 1}}{\delta} \left(K^2 \epsilon_1 \|\bar{\boldsymbol{\sigma}}_i^h\|_0^2 + D\epsilon_2 \|\bar{u}_i^h\|_{\mathcal{A}}^2 \right).
\end{aligned}$$

Setting $\epsilon_2 = \epsilon_3 = 6$ and $\epsilon_1 = 3/2$ means that we can write this as

$$\begin{aligned}
\|u_m^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_m^h\|_0^2 + \left(1 - \frac{12DC\hat{h}^{(d-1)\beta-1}}{\delta}\right) k \sum_{i=1}^{m} \|\bar{u}_i^h\|_{\mathcal{A}}^2 \\
+ \left(\frac{\gamma_G}{\mu} - \frac{3KC\hat{h}^{(d-1)\beta-1}}{2\delta}\right) 2Kk \sum_{i=1}^{m} \|\bar{\boldsymbol{\sigma}}_i^h\|_0^2 \\
\leqslant \|u_0^h\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\sigma}_0^h\|_0^2 + 6k \sum_{i=1}^{m} \Big(C_f^2 \|\bar{f}_i\|_0^2 + C_g^2 h^{-1} \|\bar{g}_i\|_{0,\Gamma_N}^2 \Big),
\end{aligned}$$

and choosing some positive constant $C^\star < \min\{1, \gamma_G/\mu\}$ and requiring that

$$\delta \geqslant 3C\hat{h}^{(d-1)\beta-1} \max\left\{ \frac{4D}{1 - C^\star}, \frac{\mu K}{2\gamma_G - 2\mu C^\star} \right\},$$

we arrive at the theorem. ∎

Since this is a finite dimensional problem, we can infer existence from uniqueness in the linear case where $n = 2$. Since this is the more practical of the two algorithms we are content with this. Also, at least for the original model of Cohen et al., [6], it seems from [2] that such analysis for the nonlinear problem is highly nontrivial.

THEOREM 2.3 (discrete existence and uniqueness). *Under the conditions of Theorem* 2.2*, the discrete solution exists for* $n = 2$ *and is unique.*

REMARK 2.4. *The condition that* δ *"be large enough" in Theorem* 2.2 *can be removed in the nonsymmetric case,* $\kappa = 1$*, by requiring a small enough time step,* k*. To see this note that the term* II *in the proof vanishes and that the second term in the bound for* I *can be moved to the left with an appropriate choice of* ϵ_1*. After applying the triangle inequality to* $\|\bar{\boldsymbol{\sigma}}_i^h\|_0^2$*, the term* $\|\boldsymbol{\sigma}_m^h\|_0^2$ *can also be moved to the left if* k *is small enough, and the remaining terms are bounded by a discrete Gronwall inequality.*

3. Error estimate. In this section we derive error estimates for our schemes encompassing the cases $\kappa = \pm 1$ and $n = 1$ or 2. First we need some standard Taylor series estimates, and it is convenient to define

$$\Delta_i v := \frac{v_t(t_i) + v_t(t_{i-1})}{2} - \frac{v(t_i) - v(t_{i-1})}{k},$$

which we recognize as (the negative of) the error in the trapezium rule.

LEMMA 3.1 (Taylor estimates). *Whenever v has the indicated regularity we have positive constants, C, independent of h and k such that*

$$\|v(t_{i-1/2}) - \bar{v}_i\|_0 \leqslant Ck^{3/2}\|v_{tt}\|_{L_2(t_{i-1},t_i;L_2(\Omega))}, \tag{23}$$

$$\|v(k/2) - v(0)\|_0 \leqslant Ck\|v_t\|_{L_\infty(0,k/2;L_2(\Omega))}, \tag{24}$$

$$\left\|v(t_{i-1/2}) - \frac{3v(t_{i-1}) - v(t_{i-2})}{2}\right\|_0 \leqslant Ck^{3/2}\|v_{tt}\|_{L_2(t_{i-2},t_{i-1/2};L_2(\Omega))}, \tag{25}$$

$$\|v_t(t_{i-1/2}) - \partial_t v_i\|_0 \leqslant Ck^{3/2}\|v_{ttt}\|_{L_2(t_{i-1},t_i;L_2(\Omega))}, \tag{26}$$

and

$$\|\Delta_i v\|_0 \leqslant Ck^{3/2}\|v_{ttt}\|_{L_2(t_{i-1},t_i;L_2(\Omega))}, \tag{27}$$

from the Peano kernel theorem applied to the trapezoidal rule for numerical integration.

We define

$$\chi_i := u_i^h - u^\perp(t_i), \qquad \boldsymbol{\eta}_i := \boldsymbol{\sigma}_i^h - \boldsymbol{\sigma}^*(t_i),$$
$$\xi(t_i) := u(t_i) - u^\perp(t_i), \qquad \boldsymbol{\theta}(t_i) := \boldsymbol{\sigma}(t_i) - \boldsymbol{\sigma}^*(t_i),$$

where $\boldsymbol{\sigma}^* \in \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h)$ is the nodal interpolant to $\boldsymbol{\sigma}$, and $u^\perp \in \mathcal{D}_r(\mathcal{E}_h)$ is the elliptic projection of u defined by

$$A(u^\perp, v) = A(u, v) \qquad \forall v \in \mathcal{D}_r(\mathcal{E}_h). \tag{28}$$

PROPOSITION 3.2 (estimates for the elliptic projection). *If $u \in C(\bar{\Omega})$ and $u^\perp \in \mathcal{D}_r(\mathcal{E}_h)$ is defined through* (28) *for $\kappa = \pm 1$, we have for $m = 0, 1, 2, \ldots$ and $t \geq 0$ that*

$$\left\|\frac{\partial^m}{\partial t^m}\Big(u(t) - u^\perp(t)\Big)\right\|_{\mathcal{A}} \leqslant Ch^s \left\|\frac{\partial^m u}{\partial t^m}(t)\right\|_{s+1}, \tag{29}$$

$$\left\|\frac{\partial^m}{\partial t^m}\Big(u(t) - u^\perp(t)\Big)\right\|_0 \leqslant Ch^s \left\|\frac{\partial^m u}{\partial t^m}(t)\right\|_{s+1}, \tag{30}$$

$$\left\|\frac{\partial^m u^\perp}{\partial t^m}(t)\right\|_{\mathcal{A}} \leqslant C \left\|\frac{\partial^m u}{\partial t^m}(t)\right\|_2, \tag{31}$$

whenever $\partial^m u(t)/\partial t^m \in H^{s+1}(\Omega)$ and $1 \leqslant s \leqslant r$.

When $m = 0$ the proof of (29) is given in [21] (the "NIPG" scheme) for the nonsymmetric case, $\kappa = 1$, and can be readily established for $\kappa = -1$ by similar arguments. The nonoptimal (30) then follows from (29) and (18) (an optimal L_2 estimate is also given in [21], but we do not need it here). The stability estimate, (31), follows from

$$\|u^\perp(t)\|_{\mathcal{A}} \leqslant \|u(t) - u^\perp(t)\|_{\mathcal{A}} + \|u(t)\|_{\mathcal{A}},$$

along with (29) (with $s = 1$) and the fact that $[u(t)] = 0$. The estimates then follow for $m \geqslant 1$ by differentiating (28).

For use later, we note also that

$$\|\boldsymbol{\sigma}^*(t)\|_{\boldsymbol{L}_\infty(\Omega)} \leqslant C\|\boldsymbol{\sigma}(t)\|_{\boldsymbol{L}_\infty(\Omega)}. \tag{32}$$

The next result is a lemma that deals with the error generated by the nonlinear term.

LEMMA 3.3 (nonlinearity error). *For $n = 1$ or 2 we have*

$$\begin{aligned}
&\left|\left((\overline{(\gamma(u)\boldsymbol{\sigma})_i}) - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*, \bar{\boldsymbol{\eta}}_i\right)\right| \\
&\quad\leqslant \frac{Ch^{2r}}{\epsilon}\left(\|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{H}^r(\Omega))} + \|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\|u\|^2_{L_\infty(0,T;H^{r+1}(\Omega))}\right) \\
&\qquad + \frac{Ck^3}{\epsilon}\left(\|(\gamma(u)\boldsymbol{\sigma})_{tt}\|^2_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))} + \|\boldsymbol{\sigma}_{tt}\|^2_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}\right) \\
&\qquad\quad + \frac{C}{\epsilon}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\|\chi_{i-1}\|_0^2 \\
&+ \begin{cases}
\dfrac{C}{\epsilon}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\left(k^3\|u_{tt}\|^2_{L_2(t_{i-1},t_i;H^2(\Omega))} + \|\chi_i\|_0^2\right) + \dfrac{\gamma_G\epsilon}{2}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \\
\qquad \textit{for } n = 1,\ i = 1,\dots,N, \\[2ex]
\dfrac{Ck^2}{\epsilon}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\|u_t\|^2_{L_\infty(0,k/2;H^2(\Omega))} + \dfrac{\gamma_G\epsilon}{2}\|\boldsymbol{\eta}_1\|_0^2 + \dfrac{\gamma_G\epsilon}{2}\|\boldsymbol{\eta}_0\|_0^2 \\
\qquad \textit{for } n = 2,\ i = 1, \\[2ex]
\dfrac{C}{\epsilon}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\left(k^3\|u_{tt}\|^2_{L_2(t_{i-2},t_{i-1/2};H^2(\Omega))} + \|\chi_{i-2}\|_0^2\right) + \dfrac{\gamma_G\epsilon}{2}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \\
\qquad \textit{for } n = 2,\ i = 2,\dots,N,
\end{cases}
\end{aligned}$$

for a constant C independent of h, k, and ϵ and for all $\epsilon > 0$.

Proof. We have, from (23) in Lemma 3.1,

$$\begin{aligned}
\left|\left((\overline{\gamma(u)\boldsymbol{\sigma}(t_i)}) - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*, \bar{\boldsymbol{\eta}}_i\right)\right| &\leqslant \|\bar{\boldsymbol{\eta}}_i\|_0\Big(\|\overline{\gamma(u)\boldsymbol{\sigma}(t_i)} - \gamma(u(t_{i-1/2}))\boldsymbol{\sigma}(t_{i-1/2})\|_0 \\
&\quad + \|\gamma(u(t_{i-1/2}))\boldsymbol{\sigma}(t_{i-1/2}) - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*\|_0\Big), \\
&\leqslant Ck^{3/2}\|(\gamma(u)\boldsymbol{\sigma})_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}\|\bar{\boldsymbol{\eta}}_i\|_0 \\
&\quad + \|\bar{\boldsymbol{\eta}}_i\|_0\Big(\|\gamma(u(t_{i-1/2}))(\boldsymbol{\sigma}(t_{i-1/2}) - \bar{\boldsymbol{\sigma}}_i^*)\|_0 \\
&\quad + \|\gamma(u(t_{i-1/2})) - \gamma(\mathcal{B}_{i,n}u^h)\|_0\|\bar{\boldsymbol{\sigma}}_i^*\|_{\boldsymbol{L}_\infty(\Omega)}\Big), \\
&\leqslant Ck^{3/2}\|(\gamma(u)\boldsymbol{\sigma})_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}\|\bar{\boldsymbol{\eta}}_i\|_0 \\
&\quad + \gamma_R\|\bar{\boldsymbol{\eta}}_i\|_0\Big(\|\boldsymbol{\sigma}(t_{i-1/2}) - \bar{\boldsymbol{\sigma}}_i\|_0 + \|\bar{\boldsymbol{\sigma}}_i - \bar{\boldsymbol{\sigma}}_i^*\|_0\Big) \\
&\quad + C'_\gamma\|\bar{\boldsymbol{\eta}}_i\|_0\|\bar{\boldsymbol{\sigma}}_i^*\|_{\boldsymbol{L}_\infty(\Omega)}\|u(t_{i-1/2}) - \mathcal{B}_{i,n}u^h\|_0,
\end{aligned}$$

where we observed, using (8), that

$$\begin{aligned}
\|\gamma(u(t_{i-1/2})) - \gamma(\mathcal{B}_{i,n}u^h)\|_0 &= \left\|\int_0^1 \gamma'(su(t_{i-1/2}) + (1-s)\mathcal{B}_{i,n}u^h)\,ds\ (u(t_{i-1/2}) \right. \\
&\qquad \left. - \mathcal{B}_{i,n}u^h)\right\|_0 \\
&\leqslant C'_\gamma\|u(t_{i-1/2}) - \mathcal{B}_{i,n}u^h\|_0.
\end{aligned}$$

Using (23), (24), and (25) from Lemma 3.1, along with (16) and (32), we therefore

arrive at

$$\begin{aligned}\left|\left(\overline{(\gamma(u)\boldsymbol{\sigma}(t_i))}-\gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*,\bar{\boldsymbol{\eta}}_i\right)\right| &\leqslant Ck^{3/2}\|(\gamma(u)\boldsymbol{\sigma})_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}\|\bar{\boldsymbol{\eta}}_i\|_0\\ &\quad+\gamma_R\|\bar{\boldsymbol{\eta}}_i\|_0\left(Ck^{3/2}\|\boldsymbol{\sigma}_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}+Ch^r\|\boldsymbol{\sigma}\|_{L_\infty(0,T;\boldsymbol{H}^r(\Omega))}\right)\\ &\quad+C\|\bar{\boldsymbol{\eta}}_i\|_0\|\boldsymbol{\sigma}\|_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\|u(t_{i-1/2})-\mathcal{B}_{i,n}u^h\|_0.\end{aligned}$$

Now, using Proposition 3.2,

$$\begin{aligned}\|u(t_{i-1/2})-\mathcal{B}_{i,n}u^h\|_0 &\leqslant \|u(t_{i-1/2})-u^\perp(t_{i-1/2})\|_0+\|u^\perp(t_{i-1/2})-\mathcal{B}_{i,n}u^\perp\|_0\\ &\quad+\|\mathcal{B}_{i,n}u^\perp-\mathcal{B}_{i,n}u^h\|_0,\\ &\leqslant Ch^r\|u\|_{L_\infty(0,T;H^{r+1}(\Omega))}+\|u^\perp(t_{i-1/2})-\mathcal{B}_{i,n}u^\perp\|_0+\|\mathcal{B}_{i,n}\chi\|_0,\end{aligned}$$

and this is as far as we can get without distinguishing between $n=1$ and $n=2$.

So, first, for $n=1$ we have

$$\begin{aligned}\|u(t_{i-1/2})-\mathcal{B}_{i,1}u^h\|_0 &\leqslant Ch^r\|u\|_{L_\infty(0,T;H^{r+1}(\Omega))}+Ck^{3/2}\|u_{tt}\|_{L_2(t_{i-1},t_i;H^2(\Omega))}\\ &\quad+\frac{1}{2}\|\chi_i\|_0+\frac{1}{2}\|\chi_{i-1}\|_0,\end{aligned}$$

where we used (23) from Lemma 3.1 and (30) with $m=0$.

Second, using (24) from Lemma 3.1, in the case $n=2$ we have when $i=1$ that

$$\|u(t_{i-1/2})-\mathcal{B}_{i,2}u^h\|_0\leqslant Ch^r\|u\|_{L_\infty(0,T;H^{r+1}(\Omega))}+Ck\|u_t\|_{L_\infty(0,k/2;H^2(\Omega))}+\|\chi_0\|_0,$$

while if $i>1$, with (25) from Lemma 3.1,

$$\begin{aligned}\|u(t_{i-1/2})-\mathcal{B}_{i,2}u^h\|_0 &\leqslant Ch^r\|u\|_{L_\infty(0,T;H^{r+1}(\Omega))}+Ck^{3/2}\|u_{tt}\|_{L_2(t_{i-2},t_{i-1/2};H^2(\Omega))}\\ &\quad+\frac{3}{2}\|\chi_{i-1}\|_0+\frac{1}{2}\|\chi_{i-2}\|_0.\end{aligned}$$

Assembling these estimates then gives

$$\begin{aligned}&\left|\left(\overline{((\gamma(u)\boldsymbol{\sigma})_i)}-\gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*,\bar{\boldsymbol{\eta}}_i\right)\right|\\ &\quad\leqslant Ck^{3/2}\Big(\|(\gamma(u)\boldsymbol{\sigma})_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}+\gamma_R\|\boldsymbol{\sigma}_{tt}\|_{L_2(t_{i-1},t_i;\boldsymbol{L}_2(\Omega))}\Big)\|\bar{\boldsymbol{\eta}}_i\|_0\\ &\qquad+Ch^r\Big(\|\boldsymbol{\sigma}\|_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\|u\|_{L_\infty(0,T;H^{r+1}(\Omega))}+\gamma_R\|\boldsymbol{\sigma}\|_{L_\infty(0,T;\boldsymbol{H}^r(\Omega))}\Big)\|\bar{\boldsymbol{\eta}}_i\|_0\\ &\qquad+\|\bar{\boldsymbol{\eta}}_i\|_0\|\boldsymbol{\sigma}\|_{L_\infty(0,T;\boldsymbol{L}_\infty(\Omega))}\times\begin{cases}Ck^{3/2}\|u_{tt}\|_{L_2(t_{i-1},t_i;H^2(\Omega))}+\frac{1}{2}\|\chi_i\|_0+\frac{1}{2}\|\chi_{i-1}\|_0\\ \qquad\text{for } n=1,\ i\geqslant 1;\\ Ck\|u_t\|_{L_\infty(0,k/2;H^2(\Omega))}+\|\chi_0\|_0\\ \qquad\text{for } n=2,\ i=1;\\ Ck^{3/2}\|u_{tt}\|_{L_2(t_{i-2},t_{i-1/2};H^2(\Omega))}\\ \qquad+\frac{3}{2}\|\chi_{i-1}\|_0+\frac{1}{2}\|\chi_{i-2}\|_0\\ \qquad\text{for } n=2,\ i>1.\end{cases}\end{aligned}$$

Several applications of Young's inequality then complete the proof. ∎

Before giving the error estimate we recall from, e.g., [1, Theorem 4.12] that if $\Omega \subset \mathbb{R}^d$ for $d = 2$ or 3 satisfies a cone condition, then $\|v\|_{L_\infty(\Omega)} \leqslant C\|v\|_m$ for $m > d/2$. Moreover,

$$H^1(\Omega) \hookrightarrow L_q(\Omega) \qquad \text{for} \qquad \begin{cases} 2 \leqslant q < \infty & \text{if } d = 2, \\ 2 \leqslant q \leqslant 6 & \text{if } d = 3, \end{cases} \tag{33}$$

and then $\|v\|_{L_q(\Omega)} \leqslant C\|v\|_1$ for all $v \in H^1(\Omega)$. Also, if $(X, \|\cdot\|_X)$ is a Banach space then, for $v\colon I \to X$, we have

$$\|v\|_{L_\infty(0,\tau;X)} \leqslant C(\tau)\Big(\|v(0)\|_X + \|v_t\|_{L_p(0,\tau;X)}\Big) \qquad \forall \tau \in \bar{I} \tag{34}$$

and for $1 \leqslant p \leqslant \infty$.

Now we can state the error estimate. The regularity requirements stated in this are given simply as they appear in the proof and in Lemma 3.3. We return to this point later.

THEOREM 3.4 (error estimate). *Let $\hat{h} \leqslant diam(\Omega)$ and $\hat{k} \leqslant T$ be positive constants and for $r \geqslant 1$ assume that $\breve{u} \in H^{r+1}(\Omega)$, $\breve{\boldsymbol{\sigma}} \in \boldsymbol{H}^r(\Omega)$,*

- *$u \in W^1_\infty(I; H^{r+1}(\Omega)) \cap H^2(I; H^2(\Omega)) \cap H^3(I; L_2(\Omega))$,*
- *$\boldsymbol{\sigma} \in L_\infty(I; \boldsymbol{L}_\infty(\Omega)) \cap W^1_\infty(I; \boldsymbol{H}^r(\Omega)) \cap H^3(I; \boldsymbol{L}_2(\Omega))$,*
- *$(\gamma(u)\boldsymbol{\sigma})_{tt} \in L_2(I; \boldsymbol{L}_2(\Omega))$;*

then for $\beta \geqslant (d-1)^{-1}$, $h \leqslant \hat{h}$, $\hat{h}^{(d-1)\beta-1}/\delta$ small enough (for $n = 1$ and 2), and $k \leqslant \hat{k}$, where $\hat{k}$ is small enough (for $n = 1$ only), we have a positive constant, C, independent of h and k such that

$$\|u(t_m) - u^h_m\|_0 + \|\boldsymbol{\sigma}(t_m) - \boldsymbol{\sigma}^h_m\|_0 + \left(k\sum_{i=1}^m \|\bar{u}_i - \bar{u}^h_i\|^2_{\mathcal{A}} + \|\bar{\boldsymbol{\sigma}}_i - \bar{\boldsymbol{\sigma}}^h_i\|^2_0\right)^{1/2} \leqslant C(h^r + k^2)$$

for each $m = 1, \ldots, N$.

Proof. We average (19) between t_i and t_{i-1} and subtract it from (21), and do the same with (20) and (22). Adding the results of these then gives an error equation,

$$\begin{aligned}(\partial_t\chi_i, v) + (\partial_t\boldsymbol{\eta}_i, \boldsymbol{w}) + A(\bar{\chi}_i, v) &= (\Delta_i u, v) + (\Delta_i\boldsymbol{\sigma}, \boldsymbol{w}) + (\partial_t\xi_i, v) + (\partial_t\boldsymbol{\theta}_i, \boldsymbol{w}) + A(\bar{\xi}_i, v) \\ &\quad - \sum_E (K\bar{\boldsymbol{\eta}}_i, \nabla v)_E + \sum_E (K\bar{\boldsymbol{\theta}}_i, \nabla v)_E \\ &\quad + \sum_E (\mu\nabla\bar{\chi}_i, \boldsymbol{w})_E - \sum_E (\mu\nabla\bar{\xi}_i, \boldsymbol{w})_E \\ &\quad + \sum_{e\in\Gamma_h\cup\Gamma_D} \int_e \{K\bar{\boldsymbol{\eta}}_i \cdot \boldsymbol{n}_e\}[v] - \sum_{e\in\Gamma_h\cup\Gamma_D} \int_e \{K\bar{\boldsymbol{\theta}}_i \cdot \boldsymbol{n}_e\}[v] \\ &\quad + (\overline{\gamma(u)\boldsymbol{\sigma}(t_i)} - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}^h_i, \boldsymbol{w}) \qquad \forall v \in \mathcal{D}_r(\mathcal{E}_h) \text{ and } \forall \boldsymbol{w} \in \boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h).\end{aligned}$$

We now choose $v = \bar{\chi}_i$ and $\boldsymbol{w} = (K/\mu)\bar{\boldsymbol{\eta}}_i$, multiply by $2k$, and sum over $i = 1, \ldots, m \leqslant N$ to get

$$\begin{aligned}\|\chi_m\|^2_0 + \frac{K}{\mu}\|\boldsymbol{\eta}_m\|^2_0 + 2k\sum_{i=1}^m \|\bar{\chi}_i\|^2_{\mathcal{A}} + 2k\sum_{i=1}^m \frac{K}{\mu}(\gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\eta}}_i, \bar{\boldsymbol{\eta}}_i) \\ = \|\chi_0\|^2_0 + \frac{K}{\mu}\|\boldsymbol{\eta}_0\|^2_0 + 2k\sum_{i=1}^m (\Delta_i u, \bar{\chi}_i) + 2k\sum_{i=1}^m \frac{K}{\mu}(\Delta_i\boldsymbol{\sigma}, \bar{\boldsymbol{\eta}}_i)\end{aligned}$$

$$
\begin{aligned}
&+ 2k\sum_{i=1}^m(\partial_t\xi_i,\bar\chi_i) + 2k\sum_{i=1}^m A(\bar\xi_i,\bar\chi_i) + \frac{2Kk}{\mu}\sum_{i=1}^m(\partial_t\boldsymbol{\theta}_i,\bar{\boldsymbol{\eta}}_i)\\
&+ 2k\sum_{i=1}^m\sum_E(K\bar{\boldsymbol{\theta}}_i,\nabla\bar\chi_i)_E - 2k\sum_{i=1}^m\sum_E(K\nabla\bar\xi_i,\bar{\boldsymbol{\eta}}_i)_E\\
&+ 2k\sum_{i=1}^m(1-\kappa)\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e\{D\nabla\bar\chi_i\cdot\boldsymbol{n}_e\}[\bar\chi_i]\\
&+ 2k\sum_{i=1}^m\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e\{K\bar{\boldsymbol{\eta}}_i\cdot\boldsymbol{n}_e\}[\bar\chi_i] - 2k\sum_{i=1}^m\sum_{e\in\Gamma_h\cup\Gamma_D}\int_e\{K\bar{\boldsymbol{\theta}}_i\cdot\boldsymbol{n}_e\}[\bar\chi_i]\\
&+ \frac{2Kk}{\mu}\sum_{i=1}^m(\overline{\gamma(u)\boldsymbol{\sigma}(t_i)} - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*,\bar{\boldsymbol{\eta}}_i),\\
&= T_1+\cdots+T_{13}.
\end{aligned}
$$

We now take each term in turn. By the $L_2(\Omega)$ projection we have $(\chi_0,v)=(\xi(0),v)$ for all $v\in\mathcal{D}_r(\mathcal{E}_h)$, which, from (30), results in

$$|T_1| = \|\chi_0\|_0^2 \leqslant \|\xi(0)\|_0^2 \leqslant Ch^{2r}\|\breve{u}\|_{r+1}^2.$$

Similarly, we have $(\boldsymbol{\eta}_0,\boldsymbol{w})=(\boldsymbol{\theta}(0),\boldsymbol{w})$ for all $\boldsymbol{w}\in\boldsymbol{\mathcal{D}}_{r-1}(\mathcal{E}_h)$ and, from (16), this gives

$$|T_2| = \|\boldsymbol{\eta}_0\|_0^2 \leqslant \|\boldsymbol{\theta}(0)\|_0^2 \leqslant Ch^{2r}\|\breve{\boldsymbol{\sigma}}\|_r^2.$$

For T_3 and T_4 we appeal to (27) from Lemma 3.1 and (18) to get

$$|T_3| \leqslant \frac{Ck}{\epsilon_3}\sum_{i=1}^m\|\Delta_i u\|_0^2 + \epsilon_3 k\sum_{i=1}^m\|\bar\chi_i\|_{\mathcal{A}}^2 \leqslant \frac{Ck^4}{\epsilon_3}\|u_{ttt}\|_{L_2(0,t_m;L_2(\Omega))}^2 + \epsilon_3 k\sum_{i=1}^m\|\bar\chi_i\|_{\mathcal{A}}^2,$$

and

$$
\begin{aligned}
|T_4| &\leqslant \frac{Kk}{\mu\gamma_G\epsilon_4}\sum_{i=1}^m\|\Delta_i\boldsymbol{\sigma}\|_0^2 + \epsilon_4 k\sum_{i=1}^m\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2,\\
&\leqslant \frac{Ck^4}{\epsilon_4}\|\boldsymbol{\sigma}_{ttt}\|_{L_2(0,t_m;\boldsymbol{L}_2(\Omega))}^2 + \epsilon_4 k\sum_{i=1}^m\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2.
\end{aligned}
$$

Using (18), (30), and (26) from Lemma 3.1, we have for T_5 that

$$
\begin{aligned}
|T_5| &\leqslant \frac{Ck}{\epsilon_5}\sum_{i=1}^m\left(\|\partial_t\xi_i - \xi_t(t_{i-1/2})\|_0^2 + \|\xi_t(t_{i-1/2})\|_0^2\right) + \epsilon_5 k\sum_{i=1}^m\|\bar\chi_i\|_{\mathcal{A}}^2,\\
&\leqslant \frac{Ck^4}{\epsilon_5}\|u_{ttt}\|_{L_2(0,t_m;H^2(\Omega))} + \frac{Ct_mh^{2r}}{\epsilon_5}\|u_t\|_{L_\infty(0,t_m;H^{r+1}(\Omega))}^2 + \epsilon_5 k\sum_{i=1}^m\|\bar\chi_i\|_{\mathcal{A}}^2,
\end{aligned}
$$

where we used (18) and (31) to get $\|\xi_{ttt}\|_0\leqslant C\|u_{ttt}\|_2$.

Now, $T_6=0$ from (28) and for T_7 we argue similarly as for T_5 and obtain

$$
\begin{aligned}
|T_7| &\leqslant \frac{Kk}{\mu\gamma_G\epsilon_7}\sum_{i=1}^m\|\partial_t\boldsymbol{\theta}_i\|_0^2 + \epsilon_7 k\sum_{i=1}^m\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2,\\
&\leqslant \frac{Ck^4}{\epsilon_7}\|\boldsymbol{\sigma}_{ttt}\|_{L_2(0,t_m;\boldsymbol{L}_2(\Omega))} + \frac{Ct_mh^{2r}}{\epsilon_7}\|\boldsymbol{\sigma}_t\|_{L_\infty(0,t_m;\boldsymbol{H}^r(\Omega))}^2 + \epsilon_7 k\sum_{i=1}^m\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2,
\end{aligned}
$$

where we used the estimate $\|\boldsymbol{\theta}_{ttt}\|_0 \leqslant C\|\boldsymbol{\sigma}_{ttt}\|_0$. For T_8,

$$|T_8| \leqslant \frac{Ck}{\epsilon_8 D^2}\sum_{i=1}^m \|\bar{\boldsymbol{\theta}}_i\|_0^2 + \epsilon_8 k\sum_{i=1}^m \|\bar{\chi}_i\|_{\mathcal{A}}^2 \leqslant \frac{Ct_m h^{2r}}{\epsilon_8}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,t_m;\boldsymbol{H}^r(\Omega))} + \epsilon_8 k\sum_{i=1}^m \|\bar{\chi}_i\|_{\mathcal{A}}^2,$$

and for T_9,

$$\begin{aligned}|T_9| &\leqslant 2k\sum_{i=1}^m \frac{K}{D}\|\bar{\xi}_i\|_{\mathcal{A}}\|\bar{\boldsymbol{\eta}}_i\|_0 \leqslant \frac{k}{\epsilon_9}\sum_{i=1}^m \frac{\mu K}{\gamma_G D^2}\|\bar{\xi}_i\|_{\mathcal{A}}^2 + \epsilon_9 k\sum_{i=1}^m \frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2,\\ &\leqslant \frac{Ct_m h^{2r}}{\epsilon_9}\|u\|^2_{L_\infty(0,t_m;H^{r+1}(\Omega))} + \epsilon_9 k\sum_{i=1}^m \frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2.\end{aligned}$$

We now note that $T_{10} = 0$ if $\kappa = 1$ (the nonsymmetric scheme) and in general we have

$$\begin{aligned}|T_{10}| &\leqslant 2(1-\kappa)k\sum_{i=1}^m \sum_{e\in\Gamma_h\cup\Gamma_D}\left(\frac{|e|^\beta}{\delta}\right)^{1/2}\|\{D\nabla\bar{\chi}_i\cdot\boldsymbol{n}_e\}\|_{0,e}\left(\frac{\delta}{|e|^\beta}\right)^{1/2}\|[\bar{\chi}_i]\|_{0,e},\\ &\leqslant 2(1-\kappa)k\sum_{i=1}^m \frac{Ch^{(d-1)\beta/2-1/2}}{\delta^{1/2}}\|D^{1/2}\nabla\bar{\chi}_i\|_0\ J_0^{\delta,\beta}(\bar{\chi}_i,\bar{\chi}_i)^{1/2},\\ &\leqslant (1-\kappa)\epsilon_{10}k\sum_{i=1}^m \frac{Ch^{(d-1)\beta-1}}{\delta}\|\bar{\chi}_i\|_{\mathcal{A}}^2 + \frac{(1-\kappa)k}{\epsilon_{10}}\sum_{i=1}^m \|\bar{\chi}_i\|_{\mathcal{A}}^2.\end{aligned}$$

For T_{11} a similar argument produces

$$|T_{11}| \leqslant \epsilon_{11}k\sum_{i=1}^m \frac{Ch^{(d-1)\beta-1}}{\delta}\|\bar{\boldsymbol{\eta}}_i\|_0^2 + \frac{k}{\epsilon_{11}}\sum_{i=1}^m \|\bar{\chi}_i\|_{\mathcal{A}}^2,$$

and, for T_{12},

$$\begin{aligned}|T_{12}| &\leqslant \epsilon_{12}k\sum_{i=1}^m \frac{Ch^{(d-1)\beta}}{\delta}\left(\sum_E \|\bar{\boldsymbol{\theta}}_i\|_{L_2(\partial E)}\right)^2 + \frac{k}{\epsilon_{12}}\sum_{i=1}^m J_0^{\delta,\beta}(\bar{\chi}_i,\bar{\chi}_i),\\ &\leqslant \frac{Ct_m\epsilon_{12}h^{2r-1+(d-1)\beta}}{\delta}\|\boldsymbol{\sigma}\|^2_{L_\infty(0,t_m;\boldsymbol{H}^r(\Omega))} + \frac{k}{\epsilon_{12}}\sum_{i=1}^m J_0^{\delta,\beta}(\bar{\chi}_i,\bar{\chi}_i).\end{aligned}$$

Setting $\epsilon_{10} = 2$ and choosing

$$\epsilon_3+\epsilon_5+\epsilon_8+\frac{1}{\epsilon_{12}} = \frac{1}{4}, \qquad \epsilon_4+\epsilon_7+\epsilon_9 = 1, \qquad \text{and} \qquad \epsilon_{11} = 4,$$

we then assemble these estimates and obtain

$$\begin{aligned}\|\chi_m\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\eta}_m\|_0^2 &+ \left(\frac{1}{2} - \frac{4C\hat{h}^{(d-1)\beta-1}}{\delta}\right)k\sum_{i=1}^m \|\bar{\chi}_i\|_{\mathcal{A}}^2\\ &+ \left(1 - \frac{4\mu C\hat{h}^{(d-1)\beta-1}}{\delta K\gamma_G}\right)k\sum_{i=1}^m \frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2\\ &\leqslant C(h^{2r}+k^4) + \frac{2kK}{\mu}\sum_{i=1}^m \left|\left(\overline{\gamma(u)\boldsymbol{\sigma}(t_i)} - \gamma(\mathcal{B}_{i,n}u^h)\bar{\boldsymbol{\sigma}}_i^*, \bar{\boldsymbol{\eta}}_i\right)\right|,\end{aligned}$$

where we recalled that $\beta \geqslant (d-1)^{-1}$. Now we make several appeals to Lemma 3.3. First, when $n = 1$ we have, for $k \leq \hat{k}$, that

$$\left(1 - \frac{C\hat{k}}{\epsilon}\right)\|\chi_m\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\eta}_m\|_0^2 + \left(\frac{1}{2} - \frac{4C\hat{h}^{(d-1)\beta-1}}{\delta}\right)k\sum_{i=1}^{m}\|\bar{\chi}_i\|_{\mathcal{A}}^2 + \left(1 - \frac{4\mu C\hat{h}^{(d-1)\beta-1}}{\delta K\gamma_G} - \epsilon\right)k\sum_{i=1}^{m}\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \leqslant C(h^{2r}+k^4) + \frac{Ck}{\epsilon}\sum_{i=0}^{m-1}\|\chi_i\|_0^2.$$

Choosing $\epsilon = 1/2$, $\hat{k}$, and $\hat{h}^{(d-1)\beta-1}/\delta$ small enough, an application of Gronwall's lemma then results in

$$\|\chi_m\|_0^2 + \|\boldsymbol{\eta}_m\|_0^2 + k\sum_{i=1}^{m}\|\bar{\chi}_i\|_{\mathcal{A}}^2 + k\sum_{i=1}^{m}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \leqslant C(h^{2r}+k^4).$$

Second, for the linearized scheme where $n = 2$, we have by Lemma 3.3 for $m = 1$ and with $\epsilon = (2\gamma_G k)^{-1}$ that

$$\|\chi_1\|_0^2 + \frac{K}{2\mu}\|\boldsymbol{\eta}_1\|_0^2 + \left(\frac{1}{2} - \frac{4C\hat{h}^{(d-1)\beta-1}}{\delta}\right)k\|\bar{\chi}_1\|_{\mathcal{A}}^2 + \left(1 - \frac{4\mu C\hat{h}^{(d-1)\beta-1}}{\delta K\gamma_G}\right)k\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_1\|_0^2 \leqslant C(h^{2r}+k^4) + Ck^2\|\chi_0\|_0^2 + C\|\boldsymbol{\eta}_0\|_0^2.$$

Now use the estimates given above for T_1 and T_2 and again select $\hat{h}^{(d-1)\beta-1}/\delta$ small enough to get

$$\|\chi_1\|_0^2 + \|\boldsymbol{\eta}_1\|_0^2 + k\|\bar{\chi}_1\|_{\mathcal{A}}^2 + k\|\bar{\boldsymbol{\eta}}_1\|_0^2 \leqslant C(h^{2r}+k^4).$$

On the other hand, for $m > 1$ we estimate the first term in the sum (corresponding to $i = 1$) in T_{13} by choosing $\epsilon = 1/k$ in Lemma 3.3 and then use the estimates just obtained. For the remaining terms we choose $\epsilon = 1/2$. With empty sums set to zero, we then have for $m = 2, 3, 4, \ldots$ that

$$\|\chi_m\|_0^2 + \frac{K}{\mu}\|\boldsymbol{\eta}_m\|_0^2 + \left(\frac{1}{2} - \frac{4C\hat{h}^{(d-1)\beta-1}}{\delta}\right)k\sum_{i=1}^{m}\|\bar{\chi}_i\|_{\mathcal{A}}^2 + \left(\frac{1}{2} - \frac{4\mu C\hat{h}^{(d-1)\beta-1}}{\delta K\gamma_G}\right)k\sum_{i=1}^{m}\frac{K\gamma_G}{\mu}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \leqslant C(h^{2r}+k^4) + Ck\sum_{i=2}^{m-1}\|\chi_i\|_0^2,$$

by the same estimates for the initial conditions as used previously. Once again, we choose $\hat{h}^{(d-1)\beta-1}/\delta$ small enough and use Gronwall's lemma to arrive at

$$\|\chi_m\|_0^2 + \|\boldsymbol{\eta}_m\|_0^2 + k\sum_{i=1}^{m}\|\bar{\chi}_i\|_{\mathcal{A}}^2 + k\sum_{i=1}^{m}\|\bar{\boldsymbol{\eta}}_i\|_0^2 \leqslant C(h^{2r}+k^4).$$

We now see that this inequality holds for all $m \in \{1, \ldots, N\}$ in both of the cases

$n = 1$ and $n = 2$. By the triangle inequality we then have

$$\begin{aligned}\|u(t_m) - u_m^h\|_0 + \|\boldsymbol{\sigma}(t_m) - \boldsymbol{\sigma}_i^h\|_0 + \left(k\sum_{i=1}^m \|\bar{u}(t_i) - \bar{u}_i^h\|_{\mathcal{A}}^2\right)^{1/2} \\ + \left(k\sum_{i=1}^m \|\bar{\boldsymbol{\sigma}}(t_i) - \bar{\boldsymbol{\sigma}}_i^h\|_0^2\right)^{1/2} \\ \leqslant \|\xi(t_m)\|_0 + \|\boldsymbol{\theta}(t_m)\|_0 + \left(k\sum_{i=1}^m \|\bar{\xi}(t_i)\|_{\mathcal{A}}^2\right)^{1/2} + \left(k\sum_{i=1}^m \|\bar{\boldsymbol{\theta}}(t_i)\|_0^2\right)^{1/2} \\ + \|\chi(t_m)\|_0 + \|\boldsymbol{\eta}(t_m)\|_0 + \left(k\sum_{i=1}^m \|\bar{\chi}(t_i)\|_{\mathcal{A}}^2\right)^{1/2} + \left(k\sum_{i=1}^m \|\bar{\boldsymbol{\eta}}(t_i)\|_0^2\right)^{1/2},\end{aligned}$$

and our estimates, along with (16) and (30) and the fact that $(a^2 + b^2)^{1/2} \leqslant a + b$ for $a, b \geqslant 0$, then complete the proof. □

Note that due to the much larger number of terms involved this proof used Gronwall's inequality, unlike the proof of Theorem 2.2. It is possible that more careful estimation could remove the need for an exponentially large "Gronwall constant" in the error estimate, but we leave this as a problem for another time.

If we replace the $\mathcal{D}_r(\mathcal{E}_h)$-approximation of u by a standard conforming piecewise polynomial finite element space containing the essential boundary condition, then the DG FEM schemes presented above reduce to a standard continuous Galerkin (CG) FEM. An error estimate of the form presented in Theorem 3.4 then continues to hold (as a special case).

COROLLARY 3.5. *For a CG finite element approximation of the problem we also have*

$$\|u(t_m) - u_m^h\|_0 + \|\boldsymbol{\sigma}(t_m) - \boldsymbol{\sigma}_m^h\|_0 + \left(k\sum_{i=1}^m \|\bar{u}_i - \bar{u}_i^h\|_{\mathcal{A}}^2 + \|\bar{\boldsymbol{\sigma}}_i - \bar{\boldsymbol{\sigma}}_i^h\|_0^2\right)^{1/2} \leqslant C(h^r + k^2)$$

for each $m = 1, \ldots, N$.

REMARK 3.6. *If* $(u, \boldsymbol{\sigma})$ *is a solution of* (12), (13), *then we could use Theorems* 1.1 *and* 3.4 *to show that*

$$\|u_m^h\|_0^2 + \|\boldsymbol{\sigma}_m^h\|_0^2 \leq C(u).$$

This would follow from the triangle inequality and is the closest we can get to a stability estimate. However, to get "data" on the right-hand side we would need stability estimates on higher derivatives of the exact solutions.

Theorem 3.4 naturally contains some regularity assumptions on both u and $\boldsymbol{\sigma}$. Since, via (10), we can replace the system (1) and (2) by the single (11) we can expect that the regularity of σ can be tied into that of u. In this direction, for the case of piecewise linear spatial approximation ($r = 1$), we have the following claim (see [15] for details).

PROPOSITION 3.7. *For* $r = 1$ *the regularity requirements of Theorem* 3.4 *can be replaced by*

$$\begin{aligned}u \in H^2(I; H^2(\Omega)) \cap L_1(I; W_\infty^1(\Omega)) \cap L_\infty(I; W_4^1(\Omega)) \cap W_8^1(I; L_8(\Omega)) \\ \cap W_4^2(I; L_4(\Omega)) \cap H^3(I; L_2(\Omega)) \cap H^1(I; W_4^1(\Omega))\end{aligned}$$

and $\breve{\boldsymbol{\sigma}} \in \boldsymbol{L}_\infty(\Omega) \cap \boldsymbol{H}^1(\Omega)$.

4. Numerical experiments. We anticipate that the linearized scheme is the one that is of most interest and so first quote from [4] just a few numerical results to illustrate Theorem 3.4 in the case $r = 1$. The data common to these first results are $D = K = \mu = 1$, $\gamma_R = 10$, $\gamma_G = 0.1$, $\Delta = 0.1$, $\Omega = (0,1)^2$, and $I = (0,T)$ for $T = 1$, and in each case the loads and boundary conditions are designed so that the problem has a known exact solution. (To achieve this we added a function $\boldsymbol{h} = \boldsymbol{h}(\boldsymbol{x},t)$ to the right of (2).) The resulting errors,

$$\mathcal{E} := k \sum_{i=1}^{N} \left(\|\bar{u}_i - \bar{u}_i^h\|_{\mathcal{A}}^2, + \|\bar{\boldsymbol{\sigma}}_i - \bar{\boldsymbol{\sigma}}_i^h\|_0^2 \right)^{1/2},$$

are tabulated along with the estimated order of convergence (EOC). In the tables, M denotes a uniform $M \times M$ space mesh and N is the number of time intervals.

Table 1 shows results for the solutions

$$u(\boldsymbol{x},t) = t \sin(2\pi x) \sin(2\pi y), \qquad \boldsymbol{\sigma}(\boldsymbol{x},t) = t \begin{pmatrix} \sin(2\pi x) \\ \cos(2\pi y) \end{pmatrix}$$

in the case $\Gamma_D = \{x = 0 \text{ or } y = 0\}$ when $u_{RG} = 0.5$. In this case there is no time discretization error and we observe $O(h)$ convergence.

On the other hand, for the solutions

$$u(\boldsymbol{x},t) = t^3 x, \qquad \boldsymbol{\sigma}(\boldsymbol{x},t) = t^2 \begin{pmatrix} 1 \\ 1 \end{pmatrix},$$

there is no space discretization error and for $\Gamma_D = \{x = 0\}$ with $u_{RG} = 0.5$ we observe, in Table 2, $O(k^2)$ convergence.

Cohen, White, and Witelski's model [6] produces solutions which exhibit very sharp changes in u, and these fronts become steeper as time advances. It seems that the near-discontinuity in u is driven by the fact that their scalar stress equation is

$$\sigma_t + \gamma(u)\sigma = \mu u,$$

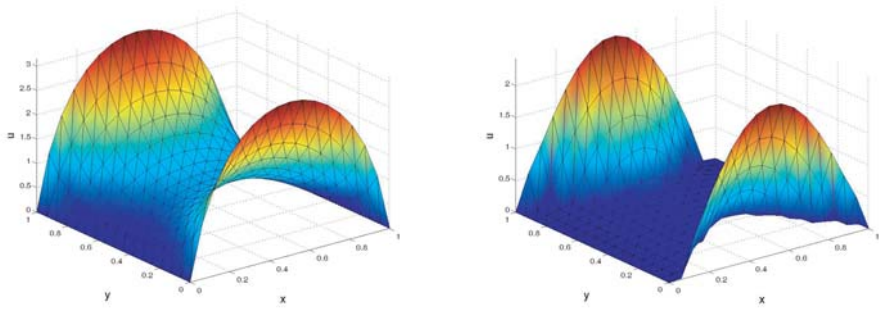

FIG. 1. *Computed surfaces showing* u *at* $t = 10$ *for the data* $\Omega := (0,1)^2$, $f = 0$, $g = 1$, $\Gamma_N := \{y = 0 \text{ or } y = 1\}$, $\breve{u} = -0.5x(x-1)$, $\breve{\boldsymbol{\sigma}} = \mathbf{0}$, $D = 10^{-1}$, $K = 10^{-4}$, $\mu = 10^4$, $\Delta = 10^{-3}$, *and* $u_{RG} = 0.5$. *The figure on the left corresponds to* $\gamma_R = \gamma_G = 5000$ *and the one on the right to* $\gamma_R = 10^4$ *and* $\gamma_G = 10^{-3}$.

whereas ours is a vector equation given by (2) and has the gradient of u on the right. Because of this, solutions to our model exhibit sharp changes in ∇u rather than u itself, and we illustrate this in Figure 1 (16×16 elements, 50 time steps, $\beta = 2$, $\delta = 10^2$, $\kappa = -1$).

The surface plot on the left corresponds to linear non-Fickian behavior where we choose $\gamma_G = \gamma_R$ so as to remove the nonlinear term in (5). The figure on the right shows the effect of the nonlinearity when $\gamma_R \gg \gamma_G$, and we can see steep changes in ∇u.

5. Conclusion. The numerical experiments support the error estimate in Theorem 3.4 and so we conclude that the linearization derived from the extrapolation is an effective method of approximating the solution to this type of problem. Also, on examining the estimates in Lemma 3.3, we see that the linearized scheme does not require any additional regularity assumptions. Hence, we conclude that it should always be preferred over the nonlinear scheme.

As we mentioned earlier in section 1, our model is a simplification of the original model proposed in [6]. Nonetheless, preliminary numerical experiments (not included here) with the CG FEM indicate that it is capable of capturing the same basic phenomena of steep traveling fronts. An error analysis for the model in [6] is currently being undertaken and, when this is complete, we expect to give more extensive numerical demonstrations for both models.

On a closing note, the problem we have studied is a generalization of a parabolic analogue to the dynamic solids problem considered in [17] to the case of nonlinear relaxation time. It is an ongoing project to extend our results to the dynamic case and to other types of nonlinearities (see, for example, the nonlinear relaxation time discussed in [22]).

AN $H^1(\mathcal{P}^h)$-COERCIVE DISCONTINUOUS GALERKIN FORMULATION FOR THE POISSON PROBLEM: 1D ANALYSIS*

K. G. VAN DER ZEE†, E. H. VAN BRUMMELEN†, AND R. DE BORST†

Abstract. Coercivity of the bilinear form in a continuum variational problem is a fundamental property for finite-element discretizations: By the classical Lax–Milgram theorem, any conforming discretization of a coercive variational problem is stable; i.e., discrete approximations are well-posed and possess unique solutions, irrespective of the specifics of the underlying approximation space. Based on the prototypical one-dimensional Poisson problem, we establish in this work that most concurrent discontinuous Galerkin formulations for second-order elliptic problems represent instances of a generic conventional formulation and that this generic formulation is noncoercive. Consequently, all conventional discontinuous Galerkin formulations are a fortiori noncoercive, and typically their well-posedness is contingent on approximation-space-dependent stabilization parameters. Moreover, we present a new symmetric nonconventional discontinuous Galerkin formulation based on element Green's functions and the data local to the edges. We show that the new discontinuous Galerkin formulation is coercive on the broken Sobolev space $H^1(\mathcal{P}^h)$, viz., the space of functions that are elementwise in the H^1 Sobolev space. The coercivity of the new formulation is supported by calculations of discrete inf-sup constants, and numerical results are presented to illustrate the optimal convergence behavior in the energy-norm and in the $L_2(\Omega)$-norm.

1. Introduction.

The recent renewal of interest in discontinuous Galerkin (DG) methods for second-order elliptic boundary value problems can be attributed to twofold reasons. First, DG methods provide robust finite-element discretizations for hyperbolic conservation laws, as the interelement discontinuities enable an extension of Godunov's method for finite-volume methods. However, to extend these techniques to singularly perturbed elliptic problems, an appropriate treatment for the elliptic part of the operator is required. Second, the absence of interelement-continuity constraints renders DG methods ideally suited for hp adaptivity, e.g., based on a posteriori error estimation; see, for instance, [1, 8]. A comprehensive overview of the historical development of DG methods is provided in [7].

A framework for analyzing DG formulations for elliptic problems has recently been erected in [2]. Although the analysis in [2] clarifies basic properties of the different formulations, it does not seem to warrant a clear preference. The literature on DG methods for elliptic problems is dominated by formulations that possess edge terms composed of linear combinations of the jumps and averages of the test and trial functions and their normal derivatives. That is, denoting by u and v the test and trial functions, and by $[\![\cdot]\!]$ and $\{\cdot\}$ the jump and average of $(\cdot)$ at an interelement edge, these formulations contain terms conforming to $\{\partial_n u\}[\![v]\!]$, $[\![u]\!][\![v]\!]$, $[\![\partial_n u]\!][\![\partial_n v]\!]$, etc., where ∂_n represents the normal derivative. We refer to such formulations as

conventional DG formulations and to the corresponding edge terms as *conventional edge terms*. Symmetric examples of such formulations are the *global element method* (GEM; see [10, 12]) and the *interior penalty* DG formulation (IPDG; cf. [2, 10, 12]). Nonsymmetric examples are the celebrated *Baumann and Oden* DG formulation (BODG [3]), the *stabilized* DG formulation (SDG [14]), the *nonsymmetric interior penalty* DG formulation (NIPDG [13]), and the family of formulations considered by Larson and Niklasson (LNDG [9]).

The essential deficiency of conventional DG formulations is that their bilinear form is not *strongly coercive* (and simultaneously continuous) on a continuum (infinite-dimensional) broken space, in contrast to the bilinear form in the classical continuous Galerkin (CG) formulation. For conciseness, we say that these methods are *noncoercive*. In particular, this implies that finite-element approximations can be ill-posed, despite well-posedness of the underlying continuum problem. Furthermore, a sequence of nested stable approximations need not converge monotonously, as the constants in the error-estimates are approximation-space-dependent, and cannot be bounded uniformly. Conventional DG formulations can be coercive on *discrete* approximation spaces. However, this generally requires stability parameters which increase unboundedly as the approximation space is refined. For example, for broken polynomial spaces the stability parameters are typically proportional to a monomial of the polynomial degree. Moreover, conventional DG formulations are in general subject to the assumption that the solution resides in $H^2(\Omega)$, whereas a formulation allowing solutions in $H^1(\Omega)$ would be more natural from the classical CG formulation perspective.[1]

Nonsymmetric conventional DG formulations can be well-posed without stability parameters. However, such formulations derive their well-posedness from *weak coercivity*. Moreover, for nonsymmetric formulations the error converges suboptimally in the $L_2(\Omega)$-norm for even-degree broken polynomial spaces. It has been conjectured that this behavior emanates from the nonsymmetry of the formulation; see [3, 9, 10].

Alternatively, DG formulations can be constructed by introducing *nonconventional edge terms*. We remark that the support of such terms is not necessarily restricted to the edges. Examples of such DG formulations are the *lift-operator-based* schemes in [2]. These include, among others, the *Bassi and Rebay* DG formulation (BRDG [4, 5]) and the *local* DG formulation (LDG [6]). However, lift-operators are explicitly defined using a discrete (finite-element) space. As a consequence, the continuum formulation with lift-operators, although consistent at a discrete level, is inconsistent at the continuum level. Therefore, for each approximation space, the edge-traces need to be lifted accordingly and the extension to a consistent continuum formulation is nonobvious.

A recent example of another nonconventional formulation is the discontinuous finite-element formulation based on second-order derivatives in [15]. This formulation resembles a least-squares form. However, it is based on second-order derivatives, thereby implicitly restricting the admissible functions to $H^2(\Omega)$ and, moreover, it is unknown if the bilinear form is simultaneously coercive and continuous.

In this paper, we first establish on the basis of the prototypical one-dimensional Poisson problem that a conventional DG formulation with a coercive bilinear form is *nonexistent*. We then present a new nonconventional symmetric DG formulation based on *element Green's functions* and the data local to the edges. The essential advantage of our new DG formulation is that it is *coercive* on the (infinite-dimensional)

[1] More precisely, only $H^{3/2+\epsilon}(\Omega)$ regularity is required. This ensures that the edge terms in conventional DG formulations are well defined.

broken Sobolev space $H^1(\mathcal{P}^{\mathsf{h}})$, the space of functions that are elementwise in the H^1 Sobolev space. On account of its coercivity, approximations of the new formulation inherit their well-posedness from the continuum formulation; i.e., well-posedness of the approximation problem is ensured for any approximation space and, in particular, for the usual broken polynomial spaces. Furthermore, optimal error estimates hold with constants that can be bounded uniformly independent of the specifics of the approximation space. Finally, we demonstrate that the new DG formulation is equivalent with the classical CG formulation, thus allowing solutions in $H^1(\Omega)$.

The contents of this paper are arranged as follows: section 2 presents the elliptic model problem, viz., the Poisson problem. Furthermore, mathematical preliminaries for DG formulations of the Poisson problem are given. Section 3 reviews elementary existence and uniqueness theorems for linear variational problems, to establish the differences between coercivity and weak coercivity, and to furnish the basis for our analysis in the ensuing sections. In section 4 we present the generic conventional DG formulation, and we prove its noncoerciveness. In section 5 we introduce the new DG formulation and we demonstrate its coercivity. Furthermore, we establish its equivalence with the classical CG formulation. Numerical results are presented in section 6. The coercivity of the new formulation is supported by calculations of discrete inf-sup constants. Moreover, the convergence behavior in the energy-norm and in the $L_2(\Omega)$-norm is investigated. Finally, section 7 contains concluding remarks.

2. Problem statement. In this work, we shall restrict ourselves to the simplest prototypical model problem for second-order elliptic boundary value problems, viz., the linear one-dimensional *Poisson* problem.

2.1. Poisson problem. Let $\Omega \subset \mathbb{R}$ be a bounded open interval. Its two-point boundary $\partial\Omega$ consists of two disjoint parts, $\Gamma_{\mathcal{D}}$ (nonempty) and $\Gamma_{\mathcal{N}}$ (possibly empty) on which Dirichlet and Neumann boundary conditions are imposed, respectively. The unit normal n at the boundary $\partial\Omega$ is defined to be outward with respect to the interval Ω.

Within this one-dimensional setting, we formulate the Poisson problem: Given an arbitrary $\bar{u} \in H^1(\Omega)$ with $\bar{u} = g_{\mathcal{D}}$ on $\Gamma_{\mathcal{D}}$,

$$\boxed{\begin{aligned}&\text{Find } u = \bar{u} + u_0 \in \bar{u} + H^1_{0,\mathcal{D}}(\Omega) : \\ &\qquad\qquad \mathscr{B}_{\mathrm{c}}(u_0, v) = \mathscr{L}_{\mathrm{c}}(v) \qquad \forall v \in H^1_{0,\mathcal{D}}(\Omega)\ ,\end{aligned}} \tag{2.1}$$

where the bilinear form $\mathscr{B}_{\mathrm{c}} : H^1(\Omega) \times H^1(\Omega) \to \mathbb{R}$ and the linear functional $\mathscr{L}_{\mathrm{c}} : H^1(\Omega) \to \mathbb{R}$ are defined as

$$\mathscr{B}_{\mathrm{c}}(u, v) := \int_\Omega \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}\,\mathrm{d}x\ , \tag{2.2a}$$

$$\mathscr{L}_{\mathrm{c}}(v) := \int_\Omega fv\,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{N}}} \big(g_{\mathcal{N}} v\big)_e - \mathscr{B}_{\mathrm{c}}(\bar{u}, v)\ . \tag{2.2b}$$

We define $H^1_{0,\mathcal{D}}(\Omega)$ to be the subspace of functions in the Sobolev space $H^1(\Omega)$ which vanish on the Dirichlet boundary $\Gamma_{\mathcal{D}}$, i.e.,

$$H^1_{0,\mathcal{D}}(\Omega) := \{u \in H^1(\Omega) : u = 0 \text{ on } \Gamma_{\mathcal{D}}\}\ .$$

For $f \in L_2(\Omega)$, Problem (2.1) possesses a unique solution $u \in H^2(\Omega)$ which, moreover,

uniquely solves the boundary value problem

$$\boxed{\begin{aligned} -\frac{\mathrm{d}^2 u}{\mathrm{d}x^2} &= f && \text{in } \Omega\ , \qquad (2.3a)\\ u &= g_{\mathcal{D}} && \text{on } \Gamma_{\mathcal{D}}\ , \qquad (2.3b)\\ \partial_n u &= g_{\mathcal{N}} && \text{on } \Gamma_{\mathcal{N}}\ , \qquad (2.3c) \end{aligned}}$$

where $\partial_n(\cdot)$ denotes the normal derivative $\frac{\mathrm{d}}{\mathrm{d}n}(\cdot)$.

The variational problem (2.1) constitutes the classical CG formulation of the Poisson problem. It is *well-posed* (stable); i.e., there *exists* a *unique* solution $u \in H^1(\Omega)$ which, moreover, depends continuously on the auxiliary data. The well-posedness follows from the classical Lax–Milgram theorem on account of *coercivity* of the bilinear functional $\mathscr{B}_{\mathrm{c}}(\cdot,\cdot)$; see section 3. A *conforming approximation* to the *continuum* problem (2.1) is obtained by replacing $H^1_{0,\mathcal{D}}(\Omega)$ by a closed, generally finite-dimensional, *sub*space $\widehat{H}^1_{0,\mathcal{D}}(\Omega) \subset H^1_{0,\mathcal{D}}(\Omega)$. The corresponding approximate solution $\widehat{u} \in \bar{u} + \widehat{H}^1_{0,\mathcal{D}}(\Omega)$ can be extracted by solving the following *approximate* problem:

$$\boxed{\begin{aligned} &\text{Find } \widehat{u} = \bar{u} + \widehat{u}_0 \in \bar{u} + \widehat{H}^1_{0,\mathcal{D}}(\Omega) : \\ &\qquad\qquad \mathscr{B}_{\mathrm{c}}(\widehat{u}_0, v) = \mathscr{L}_{\mathrm{c}}(v) \qquad \forall v \in \widehat{H}^1_{0,\mathcal{D}}(\Omega)\ . \end{aligned}} \qquad (2.4)$$

As the coercivity of the underlying continuum problem transfers to the approximate problem, the approximate problem is automatically well-posed irrespective of the specifics of the approximation space $\widehat{H}^1_{0,\mathcal{D}}(\Omega)$. This is a particularly favorable property which enables, for example, subsequent stable approximations in an hp-adaptive finite element procedure. We emphasize that coercivity is generally lost in a DG formulation.

2.2. Broken Sobolev spaces. To facilitate the ensuing consideration of DG formulations, we introduce a *finite-element partition*. Let $\mathcal{P}^{\mathsf{h}} := \mathcal{P}^{\mathsf{h}}(\Omega)$ denote such a partition of the interval Ω; i.e., $\mathcal{P}^{\mathsf{h}}$ is a finite collection of open nonoverlapping subintervals (*elements*) K, such that

$$\Omega = \mathrm{int}\left(\bigcup_{K \in \mathcal{P}^{\mathsf{h}}} \overline{K} \right) .$$

The mesh parameter h associated with $\mathcal{P}^{\mathsf{h}}$ is defined as

$$\mathsf{h} := \max_{K \in \mathcal{P}^{\mathsf{h}}} h_K\ ,$$

where h_K is the length of element K. The set of all (element) *edges*, $\Gamma := \Gamma(\mathcal{P}^{\mathsf{h}})$, can be divided into complementary subsets:

$$\Gamma = \Gamma_{\mathcal{D}} \cup \Gamma_{\mathcal{N}} \cup \Gamma_{\mathcal{I}}\ ,$$

where $\Gamma_{\mathcal{I}} := \Gamma_{\mathcal{I}}(\mathcal{P}^{\mathsf{h}})$ is the set of *interior* edges. We define a unit normal n_e at each edge $e \in \Gamma$. This normal coincides with the unit outward normal of Ω for *boundary* edges $e \in \partial\Omega = \Gamma_{\mathcal{D}} \cup \Gamma_{\mathcal{N}}$ and we set $n_e := -1$ for interior edges $e \in \Gamma_{\mathcal{I}}$. For example, if e is an interior edge then we have $(\partial_n u)_e = \frac{\mathrm{d}u}{\mathrm{d}n}\big|_e = -\frac{\mathrm{d}u}{\mathrm{d}x}\big|_e$. We will further denote by $\mathcal{K}_e$ the set of elements sharing edge $e \in \Gamma$, that is,

$$\mathcal{K}_e := \left\{ K \in \mathcal{P}^{\mathsf{h}} : \partial K \cap e = e \right\} .$$

Note that for boundary and interior edges e, the set $\mathcal{K}_e$ contains one element and two elements, respectively.

The functional setting of DG formulations is provided by the so-called (partition $\mathcal{P}^{\mathsf{h}}$ dependent) *broken Sobolev spaces* $H^m(\mathcal{P}^{\mathsf{h}})$ [10]. For any positive integer m, the broken Sobolev space $H^m(\mathcal{P}^{\mathsf{h}})$ is defined as

$$H^m(\mathcal{P}^{\mathsf{h}}) := \{v \in L_2(\Omega) : v\big|_K \in H^m(K)\ \forall K \in \mathcal{P}^{\mathsf{h}}\}\ ; \tag{2.5}$$

in other words, $H^m(\mathcal{P}^{\mathsf{h}})$ consists of functions for which the restriction to each element $K \in \mathcal{P}^{\mathsf{h}}$ is in $H^m(K)$. Equipped with the broken inner product

$$(u,v)_{H^m(\mathcal{P}^{\mathsf{h}})} := \sum_{K\in\mathcal{P}^{\mathsf{h}}} (u,v)_{H^m(K)}\ ,$$

$H^m(\mathcal{P}^{\mathsf{h}})$ is a Hilbert space. The corresponding norm will be denoted $\|\cdot\|_{H^m(\mathcal{P}^{\mathsf{h}})}$. Note that functions in a broken Sobolev space are generally discontinuous at the interior edges.

Functions in $H^1(\mathcal{P}^{\mathsf{h}})$ have traces on Γ. These are single-valued at boundary edges and double-valued at interior edges. To handle the traces, we introduce for each boundary edge $e \in \partial\Omega$ the usual boundary trace $(\cdot)_e$ as

$$u_e := \lim_{s\downarrow 0} u(e - n_e\, s)\ ,$$

and we introduce for each interior edge $e \in \Gamma_{\mathcal{I}}$ the $\pm$-trace, $(\cdot)_e^{\pm}$, as

$$u_e^{\pm} := \lim_{s\downarrow 0} u(e \pm s)\ .$$

Furthermore, we define the *average* $\{\cdot\}_e$ and the *jump* $[\![\cdot]\!]_e$ for each interior edge $e \in \Gamma_{\mathcal{I}}$ in the usual manner:

$$\begin{aligned} \{u\}_e &:= \tfrac{1}{2}(u_e^+ + u_e^-)\ , \\ [\![u]\!]_e &:= u_e^+ - u_e^-\ . \end{aligned}$$

These trace operators are bounded in $\mathbb{R}$ for functions in $H^1(\mathcal{P}^{\mathsf{h}})$; that is, trace inequalities hold.

2.3. DG formulations of the Poisson problem. Let $H := H(\mathcal{P}^{\mathsf{h}})$ be a broken space subordinate to the partition $\mathcal{P}^{\mathsf{h}}$ and $\widehat{H} := \widehat{H}(\mathcal{P}^{\mathsf{h}}) \subset H(\mathcal{P}^{\mathsf{h}})$ a finite-dimensional subspace. The generic form of a continuum DG formulation is given by the following abstract Galerkin variational problem:

$$\boxed{\begin{array}{l}\text{Find } u \in H : \\ \qquad\qquad \mathscr{B}(u,v) = \mathscr{L}(v) \qquad \forall v \in H\ .\end{array}} \tag{2.6}$$

Clearly, the continuum DG formulation should be consistent with the Poisson problem; i.e., the solution of (2.1) must comply with (2.6). The generic form of the corresponding approximate DG problem is given by

$$\boxed{\begin{array}{l}\text{Find } \widehat{u} \in \widehat{H} : \\ \qquad\qquad \mathscr{B}(\widehat{u},v) = \mathscr{L}(v) \qquad \forall v \in \widehat{H}\ .\end{array}} \tag{2.7}$$

We will refer to the broken space associated with a particular DG problem as its *DG space*.

The conventional approach to constructing consistent DG formulations premises that $f \in L_2(\Omega)$ and, accordingly, $u \in H^2(\Omega) \subset H^2(\mathcal{P}^{\mathsf{h}}) \subset H$. Multiplication of (2.3a) with $v \in H$, integration on Ω, and elementwise integration by parts then yield

$$\sum_{K\in\mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}\,\mathrm{d}x - \sum_{e\in\Gamma_{\mathcal{I}}} \left(\partial_n u[\![v]\!]\right)_e - \sum_{e\in\Gamma_{\mathcal{D}}} \left((\partial_n u)v\right)_e = \int_\Omega fv\,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}}v\right)_e \quad \forall v \in H\ .$$

For $u \in H^2(\Omega)$, $(\partial_n u)_e$ is well defined for $e \in \Gamma_{\mathcal{I}}$. However, for u in the DG space H, $(\partial_n u)_e$ is not uniquely defined at the interior edges. Therefore, $(\partial_n u)_e$ is conventionally replaced by $\{\partial_n u\}_e$. On account of $\{\partial_n u\}_e = (\partial_n u)_e$ for $u \in H^2(\Omega)$, this replacement preserves consistency. In addition, the bilinear form can be augmented with other products of edge values and/or edge derivatives, for instance, $\{\partial_n v\}_e[\![u]\!]_e$ for $e \in \Gamma_{\mathcal{I}}$. Most concurrent DG formulations are the result of such an augmentation and, accordingly, we will refer to such augmentations as *conventional edge terms*, and to the corresponding variational statements as *conventional* DG formulations. A precise definition is provided in section 4. Alternatively, the bilinear form can be endowed with other consistency-preserving edge terms, e.g., based on lift operators [4,5,6]. We collectively refer to such terms as *nonconventional edge terms*.

The above exposition furnishes the context for the problem considered in this paper. Our first objective is to establish that all conventional DG formulations are necessarily noncoercive, in contrast to the classical CG formulation. Conventional DG formulations are contingent on weak coercivity for their well-posedness. However, at variance with coercivity, weak coercivity does not transfer to subspaces and, consequently, well-posedness of the continuum DG formulation does not generally imply well-posedness of corresponding approximate DG problems. Moreover, we introduce a new nonconventional symmetric DG formulation based on *element Green's functions* that is coercive on the broken Sobolev space $H^1(\mathcal{P}^{\mathsf{h}})$.

3. Existence and uniqueness theorems for linear variational problems. In this section we review elementary existence theorems pertaining to the well-posedness of linear variational problems. These theorems form the basis for our analysis in section 4 and section 5. Furthermore, a priori error estimates are given for Galerkin approximations.

Section 3.1 is concerned with the generalized Lax–Milgram theorem. This theorem provides the fundament for the classical Lax–Milgram theorem in section 3.2.

3.1. The generalized Lax–Milgram theorem. The generalized Lax–Milgram theorem gives necessary and sufficient conditions for the well-posedness of a generic linear variational problem. Its proof can be found in [11,16].[2]

THEOREM 1 (generalized Lax–Milgram). *Let H be a real Hilbert space with corresponding norm $\|\cdot\|_H$. Consider a continuous bilinear form $\mathscr{B} : H \times H \to \mathbb{R}$; i.e., there exists a positive constant c_b such that*

$$|\mathscr{B}(u,v)| \le c_b\|u\|_H\|v\|_H \qquad \forall u, v \in H\ .$$

[2]The necessity of (3.1) is shown in [16].

If and only if $\mathscr{B}(\cdot,\cdot)$ is weakly coercive on $H \times H$, i.e., there exists a constant $\gamma > 0$ such that

$$\inf_{u\in H\setminus\{0\}} \sup_{v\in H\setminus\{0\}} \frac{\mathscr{B}(u,v)}{\|u\|_H \|v\|_H} \geq \gamma \,, \tag{3.1a}$$

$$\sup_{u\in H} \mathscr{B}(u,v) > 0 \qquad \forall v \in H \setminus \{0\} \,, \tag{3.1b}$$

then for every continuous linear functional $\mathscr{L} : H \to \mathbb{R}$, problem (2.6) *has a unique solution $u \in H$.*

Inequality (3.1a) is known as the *inf-sup condition*, and the supremum over all numbers γ in compliance with (3.1a) is referred to as the *inf-sup constant*.

Let $\widehat{H} \subset H$ be a closed subspace associated with an approximate variational problem. As a closed subspace of a Hilbert space is itself a Hilbert space, well-posedness of the approximate problem on $\widehat{H}$ is settled identically by Theorem 1 with H replaced by $\widehat{H}$. The corresponding inf-sup constant $\widehat{\gamma}$ then generally depends on the approximation space $\widehat{H}$, i.e., $\widehat{\gamma} := \widehat{\gamma}(\widehat{H})$. Moreover, if the approximate problem is well-posed, its solution $\widehat{u} \in \widehat{H}$ complies with the a priori estimate

$$\|u - \widehat{u}\|_H \leq (1+c_b/\widehat{\gamma}) \inf_{v\in\widehat{H}} \|u - v\|_H \,. \tag{3.2}$$

It is to be noted that weak coercivity on $H \times H$ does not imply weak coercivity on $\widehat{H} \times \widehat{H}$. Therefore, well-posedness of the continuum problem does not imply well-posedness of corresponding approximate problems. On account of the dependence of $\widehat{\gamma}$ on $\widehat{H}$, it moreover holds that if we consider a sequence of asymptotically dense nested approximation spaces $\widehat{H}^{(1)} \subset \widehat{H}^{(2)} \subset \cdots \subseteq H$, $\widehat{H}^{(m)} \to H$ as $m \to \infty$, then the corresponding approximations $\widehat{u}^{(m)}$ need not converge, or need not converge monotonously.

3.2. The classical Lax–Milgram theorem. A theorem on the well-posedness of linear Galerkin variational problems with more restrictive conditions and stronger implications is provided by the classical Lax–Milgram theorem (see, e.g., [11, 16]).

THEOREM 2 (classical Lax–Milgram). *Let $\mathscr{B} : H \times H \to \mathbb{R}$ be a continuous, (strongly) coercive bilinear form on H; i.e., there exists a positive constant κ such that*

$$|\mathscr{B}(u,u)| \geq \kappa \|u\|_H^2 \qquad \forall u \in H \,. \tag{3.3}$$

Then for every continuous linear functional $\mathscr{L} : H \to \mathbb{R}$, the variational problem (2.6) *possesses a unique solution $u \in H$.*

Coercivity on H is a sufficient condition for weak coercivity on $H \times H$. As coercivity transfers to subspaces $\widehat{H} \subset H$, it holds that well-posedness of the continuum problem implies well-posedness of approximate problems based on conforming subspaces. Moreover, the subspace approximation $\widehat{u} \in \widehat{H}$ satisfies the a priori estimate

$$\|u - \widehat{u}\|_H \leq c_b/\kappa \inf_{v\in\widehat{H}} \|u - v\|_H \,, \tag{3.4}$$

where c_b and κ denote the continuity and coercivity constant of the bilinear form on $H \times H$, respectively. It is to be noted that the constants in (3.4) are independent of the approximation space. Hence, if $\widehat{H}^{(2)} \subset H$ is a larger approximation space than $\widehat{H}^{(1)} \subset \widehat{H}^{(2)}$, then the error (measured in $\|\cdot\|_H$) of the corresponding approximate

solution $\widehat{u}^{(2)} \in \widehat{H}^{(2)}$ is at most equal to that of the approximate solution $\widehat{u}^{(1)} \in \widehat{H}^{(1)}$. In particular, this implies that if we consider a sequence of asymptotically dense nested approximation spaces $\widehat{H}^{(1)} \subset \widehat{H}^{(2)} \subset \cdots \subseteq H$ and $\widehat{H}^{(m)} \to H$ as $m \to \infty$, then the error $\|u - \widehat{u}^{(m)}\|_H$ converges monotonously to 0 as m increases.

Let us consider an arbitrary variational continuum problem. Under the condition of coercivity of the bilinear form, conforming approximate problems are well-posed if the continuum problem is well-posed. The premise of coercivity not only provides a sufficient condition; it is also *necessary*.

PROPOSITION 3. *Consider a continuous linear functional $\mathscr{L} : H \to \mathbb{R}$ and continuous bilinear form $\mathscr{B} : H \times H \to \mathbb{R}$. If and only if $\mathscr{B}(\cdot,\cdot)$ is coercive on H, then well-posedness of the continuum problem* (2.6) *implies well-posedness of the approximate problem* (2.7).

Proof. (i) Forward implication: By Theorem 2, coercivity on H ensures that the continuum problem (2.6) and the approximate problem (2.7) are well-posed.

(ii) Reverse implication: We show the proof by contradiction. We assume that $\mathscr{B}(\cdot,\cdot)$ is weakly coercive on $H \times H$, but not coercive, and then construct a subspace $\widehat{H} \subset H$ in which the approximate problem is ill-posed. As H is a closed space, noncoercivity implies the existence of a $\bar{u} \in H \setminus \{0\}$ such that $\mathscr{B}(\bar{u},\bar{u}) = 0$. Taking the approximate space as the one-dimensional space $\widehat{H} = \operatorname{span}\{\bar{u}\}$, it follows that

$$\inf_{u \in \widehat{H}\setminus\{0\}} \sup_{v \in \widehat{H}\setminus\{0\}} \frac{\mathscr{B}(u,v)}{\|u\|_H \|v\|_H} = \frac{\mathscr{B}(\bar{u},\bar{u})}{\|\bar{u}\|_H^2} = 0 \,;$$

i.e., weak coercivity does not hold on $\widehat{H} \times \widehat{H}$. By Theorem 1 weak coercivity on $\widehat{H} \times \widehat{H}$ is necessary for well-posedness of the approximate problem. ∎

4. Conventional DG formulations. This section is concerned with an analysis of the generic properties of conventional DG formulations. To this end, we introduce a generic consistent conventional DG formulation in section 4.1. Section 4.2 establishes the existence of well-posed conventional DG formulations. Section 4.3 proves that consistent conventional DG formulations are necessarily noncoercive.

4.1. Generic conventional DG formulation. Consider the following bilinear form $\mathscr{B}_\Lambda(\cdot,\cdot)$ and linear functional $\mathscr{L}_\Lambda(\cdot)$:[3]

$$\mathscr{B}_\Lambda(u,v) := \sum_{K \in \mathcal{P}^h} \int_K \frac{\mathrm{d}u}{\mathrm{d}x} \frac{\mathrm{d}v}{\mathrm{d}x} \,\mathrm{d}x + \sum_{e \in \Gamma} \left(\boldsymbol{u}^\mathsf{T} \Lambda \boldsymbol{v}\right)_e \,, \tag{4.1a}$$

$$\mathscr{L}_\Lambda(v) := \int_\Omega f v \,\mathrm{d}x + \sum_{e \in \Gamma_\mathcal{D}} \left(g_\mathcal{D} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e + \sum_{e \in \Gamma_\mathcal{N}} \left(g_\mathcal{N} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e \,, \tag{4.1b}$$

[3]For notational transparency, in a composition of terms with a subscript $(\cdot)_e$, we suppress the subscript of the individual terms and append it to enclosing parentheses. For example, $(g_\mathcal{D} \bar{\Lambda} \bar{\boldsymbol{v}})_e$ is to be interpreted as $g_{\mathcal{D}e} \bar{\Lambda}_e \bar{\boldsymbol{v}}_e$. Moreover, we occasionally suppress the subscript $(\cdot)_e$ entirely if the dependence is apparent from the context.

where boldfaced variables, such as $\boldsymbol{v}$, and boldfaced overlined variables, such as $\bar{\boldsymbol{v}}$, denote (column-) vectors containing values at edge e according to

$$\boldsymbol{v}_e := \begin{cases} \big(h^{-\frac{1}{2}}\,[\![v]\!],\ h^{\frac{1}{2}}\,\{\partial_n v\},\ h^{\frac{1}{2}}\,[\![\partial_n v]\!],\ h^{-\frac{1}{2}}\,\{v\}\big)_e^{\mathsf{T}}\,, & e\in\Gamma_{\mathcal{I}}\,,\\ \big(h^{-\frac{1}{2}}\,v,\ h^{\frac{1}{2}}\,\partial_n v\big)_e^{\mathsf{T}}\,, & e\in\partial\Omega\,, \end{cases} \tag{4.2a}$$

$$\bar{\boldsymbol{v}}_e := \begin{cases} \big(h^{-1}\,v,\ \partial_n v\big)_e^{\mathsf{T}}\,, & e\in\Gamma_{\mathcal{D}}\,,\\ \big(v,\ h\,\partial_n v\big)_e^{\mathsf{T}}\,, & e\in\Gamma_{\mathcal{N}}\,. \end{cases} \tag{4.2b}$$

The matrices $\Lambda_e\in\mathbb{R}^{4\times4}$ ($e\in\Gamma_{\mathcal{I}}$), and $\Lambda_e\in\mathbb{R}^{2\times2}$, $\bar{\Lambda}_e\in\mathbb{R}^{1\times2}$ ($e\in\partial\Omega$) specify bilinear relations between edge values and edge derivatives of u and v. A conventional edge term can now be precisely defined as any term in the bilinear form conforming to $(\boldsymbol{u}^{\mathsf{T}}\Lambda\boldsymbol{v})_e$ for all $e\in\Gamma$, and any term in the linear form conforming to $(g_{\mathcal{D}}\bar{\Lambda}\bar{\boldsymbol{v}})_e$ for $e\in\Gamma_{\mathcal{D}}$ or $(g_{\mathcal{N}}\bar{\Lambda}\bar{\boldsymbol{v}})_e$ for $e\in\Gamma_{\mathcal{N}}$.

The constants $h:\Gamma\to\mathbb{R}$ in (4.2) are local mesh parameters introduced to minimize the mesh dependence of the matrices. Typically, for $e\in\Gamma_{\mathcal{I}}$, h_e is set to the average of the lengths of the elements sharing edge e and for $e\in\partial\Omega$ it is set to half the length of the element contiguous to edge e; i.e.,

$$h_e = \tfrac{1}{2}\sum_{K\in\mathcal{K}_e} h_K \qquad \forall e\in\Gamma\,. \tag{4.3}$$

To provide a functional setting for conventional DG formulations, we introduce the norm $\|\cdot\|_{H_\Lambda}$,

$$\|u\|_{H_\Lambda}^2 := \sum_{K\in\mathcal{P}^{\mathsf{h}}} |u|_{1,K}^2 + \sum_{e\in\Gamma}\big(\boldsymbol{u}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{u}\big)_e\,, \tag{4.4}$$

where the seminorm $|\cdot|_{1,K}$ is defined by

$$|u|_{1,K}^2 := \int_K \Big(\frac{\mathrm{d}u}{\mathrm{d}x}\Big)^2\,\mathrm{d}x\,,$$

and $\mathrm{D}_\Lambda(=\mathrm{D}_{\Lambda_e})$ is a diagonal matrix in $\mathbb{R}^{4\times4}$ for $e\in\Gamma_{\mathcal{I}}$ and in $\mathbb{R}^{2\times2}$ for $e\in\partial\Omega$ with diagonal entries

$$(\mathrm{D}_\Lambda)_{ii} := \textstyle\sum_j\big(\big|(\mathrm{S}_\Lambda)_{ij}\big|+\big|(\mathrm{A}_\Lambda)_{ij}\big|\big) \quad\text{with}\quad \mathrm{S}_\Lambda := \tfrac{1}{2}\big(\Lambda+\Lambda^{\mathsf{T}}\big),\quad \mathrm{A}_\Lambda := \tfrac{1}{2}\big(\Lambda-\Lambda^{\mathsf{T}}\big); \tag{4.5}$$

i.e., D_Λ is obtained from Λ by lumping the absolute values of its symmetric part S_Λ and its antisymmetric part A_Λ to the diagonal.[4] The matrices Λ and D_Λ are then related by

$$\begin{aligned} \big|\boldsymbol{u}^{\mathsf{T}}\Lambda\boldsymbol{v}\big| &= \big|\textstyle\sum_{i,j}\boldsymbol{u}_i(\mathrm{S}_{\Lambda ij}+\mathrm{A}_{\Lambda ij})\boldsymbol{v}_j\big| \le \sum_{i,j}|\boldsymbol{u}_i|\,(|\mathrm{S}_{\Lambda ij}|+|\mathrm{A}_{\Lambda ij}|)\,|\boldsymbol{v}_j|\\ &\le \sqrt{\textstyle\sum_{i,j}(|\mathrm{S}_{\Lambda ij}|+|\mathrm{A}_{\Lambda ij}|)\boldsymbol{u}_i^2}\sqrt{\textstyle\sum_{i,j}(|\mathrm{S}_{\Lambda ij}|+|\mathrm{A}_{\Lambda ij}|)\boldsymbol{v}_j^2} = \sqrt{\boldsymbol{u}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{u}}\,\sqrt{\boldsymbol{v}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{v}}\,. \end{aligned} \tag{4.6}$$

[4]Strictly speaking, $\|\cdot\|_{H_\Lambda}$ is a norm only if $(\mathrm{D}_\Lambda)_{11}>0$ for $e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}$. This implies that the bilinear form incorporates $[\![u]\!]_e$ and/or $[\![v]\!]_e$ on $\Gamma_{\mathcal{I}}$ and u_e and/or v_e on $\Gamma_{\mathcal{D}}$. However, in Proposition 4 it will be shown that any consistent formulation necessarily contains such terms. Hence, there is no loss of generality in proceeding under the assumption that $\|\cdot\|_{H_\Lambda}$ provides a norm.

The second inequality in (4.6) follows from the discrete Schwartz inequality, viz., $\sum |x_i y_i| \leq \sqrt{\sum x_i^2}\,\sqrt{\sum y_i^2}$. We now define the space H_Λ as the completion of $H^2(\mathcal{P}^\mathsf{h})$ under norm $\|\cdot\|_{H_\Lambda}$:

$$\boxed{H_\Lambda := H_\Lambda(\mathcal{P}^\mathsf{h}) = \overline{H^2(\mathcal{P}^\mathsf{h})}^{\|\cdot\|_{H_\Lambda}}\ .} \tag{4.7}$$

The Hilbert space H_Λ defined in this manner provides the appropriate space for the generic conventional DG formulation:

$$\boxed{\begin{array}{l}\text{Find } u \in H_\Lambda : \\ \qquad\qquad \mathscr{B}_\Lambda(u,v) = \mathscr{L}_\Lambda(v) \qquad \forall v \in H_\Lambda\ .\end{array}} \tag{4.8}$$

The appropriateness of H_Λ is rigorously settled in section 4.2. Let us note that H_Λ is a generalization of the space used in [3].

4.2. Well-posedness results for the continuum formulation. Under certain conditions on the matrices Λ and $\bar{\Lambda}$, (4.8) provides a consistent, well-posed weak formulation of (2.3). The proposition below specifies necessary and sufficient conditions on the matrices Λ and $\bar{\Lambda}$ for consistency with (2.3).

PROPOSITION 4 (consistency of conventional DG). *If and only if the matrices* Λ, $\bar{\Lambda}$ *are of the form*

$$\Lambda_e = \begin{pmatrix} \alpha & \delta & \gamma^\mathrm{u} & \zeta^1 \\ -1 & 0 & 0 & 0 \\ \gamma^\mathrm{l} & \varepsilon & \beta & \zeta^2 \\ 0 & 0 & 0 & 0 \end{pmatrix}_e \qquad \forall e \in \Gamma_\mathcal{I}\ , \tag{4.9a}$$

$$\Lambda_e = \begin{pmatrix} \alpha & \delta \\ -1 & 0 \end{pmatrix}_e\ , \quad \bar{\Lambda}_e = \begin{pmatrix} \alpha & \delta \end{pmatrix}_e \qquad \forall e \in \Gamma_\mathcal{D}\ , \tag{4.9b}$$

$$\Lambda_e = \begin{pmatrix} 0 & 0 \\ \varepsilon & \beta \end{pmatrix}_e\ , \quad \bar{\Lambda}_e = \begin{pmatrix} \varepsilon{+}1 & \beta \end{pmatrix}_e \qquad \forall e \in \Gamma_\mathcal{N} \tag{4.9c}$$

for certain fixed parameters $\alpha_e, \beta_e, \gamma_e^\mathrm{u}, \gamma_e^\mathrm{l}, \delta_e, \varepsilon_e, \zeta_e^1, \zeta_e^2 \in \mathbb{R}$ *(for all* $e \in \Gamma$*), then the corresponding conventional DG formulation* (4.8) *is consistent with* (2.3)*; i.e., the solution* $u \in H^2(\Omega) \subset H_\Lambda$ *of* (2.3) *complies with* (4.8)*.*

Proof. (i) Forward implication: Let $u \in H^2(\Omega)$ solve (2.3). Multiplying (2.3a) by an arbitrary $v \in H_\Lambda$, integrating on Ω, and invoking integration by parts, elementwise, we obtain

$$\sum_{K\in\mathcal{P}^\mathsf{h}} \int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}\,\mathrm{d}x = \int_\Omega fv\,\mathrm{d}x + \sum_{e\in\Gamma_\mathcal{I}} \big(\partial_n u[\![v]\!]\big)_e + \sum_{e\in\partial\Omega} \big((\partial_n u)v\big)_e\ . \tag{4.10}$$

From (4.1a) and (4.10) it follows that

$$\mathscr{B}_\Lambda(u,v) = \int_\Omega fv\,\mathrm{d}x + \sum_{e\in\Gamma_\mathcal{I}} \big(\partial_n u[\![v]\!]\big)_e + \sum_{e\in\Gamma_\mathcal{D}\cup\Gamma_\mathcal{N}} \big((\partial_n u)v\big)_e + \sum_{e\in\Gamma} \big(\boldsymbol{u}^\mathsf{T}\Lambda\boldsymbol{v}\big)_e\ . \tag{4.11}$$

The boundary conditions (2.3b) and (2.3c) imply that $u_e = (g_\mathcal{D})_e$ for $e \in \Gamma_\mathcal{D}$ and $(\partial_n u)_e = (g_\mathcal{N})_e$ for $e \in \Gamma_\mathcal{N}$. Moreover, on account of the C^1-continuity of functions

in $H^2(\Omega)$, the solution u complies with $[\![u]\!]_e = [\![\partial_n u]\!]_e = 0$ and $\{\partial_n u\}_e = (\partial_n u)_e$ for $e \in \Gamma_{\mathcal{I}}$. Hence, upon replacing Λ in (4.11) with (4.9), we obtain

$$\mathscr{B}_\Lambda(u,v) = \int_\Omega fv \,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{D}}} \left(\alpha g_{\mathcal{D}} v/h + \delta g_{\mathcal{D}} \partial_n v\right)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}} v + \varepsilon g_{\mathcal{N}} v + \beta h g_{\mathcal{N}} \partial_n v\right)_e .$$

By (4.1b) and (4.9), for any $v \in H_\Lambda$,

$$\mathscr{L}_\Lambda(v) = \int_\Omega fv \,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{D}}} \left(\alpha g_{\mathcal{D}} v/h + \delta g_{\mathcal{D}} \partial_n v\right)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}} v + \varepsilon g_{\mathcal{N}} v + \beta h g_{\mathcal{N}} \partial_n v\right)_e ,$$

and, hence, $\mathscr{B}_\Lambda(u,v) = \mathscr{L}_\Lambda(v)$ for all $v \in H_\Lambda$.

(ii) Reverse implication: By (4.1b), (4.8), and (4.11),

$$\sum_{e\in\Gamma_{\mathcal{I}}} \left(\partial_n u [\![v]\!]\right)_e + \sum_{e\in\partial\Omega} \left((\partial_n u)v\right)_e + \sum_{e\in\Gamma} \left(\boldsymbol{u}^{\mathsf{T}} \Lambda \boldsymbol{v}\right)_e = \sum_{e\in\Gamma_{\mathcal{D}}} \left(g_{\mathcal{D}} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e \quad \forall v \in H_\Lambda .$$

Upon rearranging the summations, replacing $\boldsymbol{u}_e$ according to its definition (4.2), and invoking the boundary conditions in (2.3) and $[\![u]\!]_e = [\![\partial_n u]\!]_e = 0$, $\{\partial_n u\}_e = (\partial_n u)_e$, and $\{u\}_e = u_e$ for $e \in \Gamma_{\mathcal{I}}$, we obtain

(4.12)
$$\sum_{e\in\Gamma_{\mathcal{I}}} \left(\partial_n u [\![v]\!] + (0,\ h^{\frac{1}{2}}\partial_n u, 0,\ h^{-\frac{1}{2}} u)\Lambda \boldsymbol{v}\right)_e + \sum_{e\in\Gamma_{\mathcal{D}}} \left((\partial_n u)v + (h^{-\frac{1}{2}} g_{\mathcal{D}},\ h^{\frac{1}{2}}\partial_n u)\Lambda \boldsymbol{v}\right)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}} v + (h^{-\frac{1}{2}} u,\ h^{\frac{1}{2}} g_{\mathcal{N}})\Lambda \boldsymbol{v}\right)_e = \sum_{e\in\Gamma_{\mathcal{D}}} \left(g_{\mathcal{D}} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \left(g_{\mathcal{N}} \bar{\Lambda} \bar{\boldsymbol{v}}\right)_e$$

for all $v \in H_\Lambda$. Selecting a $v \in H_\Lambda$ such that $[\![v]\!]_e = 1$ for some edge $e \in \Gamma_{\mathcal{I}}$ and such that all other edge terms vanish, we obtain the identity

$$\left(\partial_n u + (\partial_n u)\Lambda_{21} + u\Lambda_{41}/h\right)_e = 0 .$$

Therefore, $(\Lambda_{21})_e = -1$ and $(\Lambda_{41})_e = 0$. Similarly, by making appropriate choices for the test function $v \in H_\Lambda$ in (4.12), the precise form (4.9) can be established. ∎

To establish the conditions on the matrices $\Lambda, \bar{\Lambda}$ in (4.9) for well-posedness, we appeal to the generalized Lax–Milgram theorem, Theorem 1. In particular, we establish the conditions for continuity of $\mathscr{L}_\Lambda(\cdot)$, and for continuity and weak coercivity of $\mathscr{B}_\Lambda(\cdot,\cdot)$. Continuity of the bilinear form is in fact independent of the precise form of Λ. This is asserted by the following proposition.

PROPOSITION 5 (continuity of $\mathscr{B}_\Lambda$). *The bilinear form $\mathscr{B}_\Lambda(\cdot,\cdot)$ given in* (4.1a) *is continuous on H_Λ, i.e.,*

$$|\mathscr{B}_\Lambda(u,v)| \le c_b \|u\|_{H_\Lambda} \|v\|_{H_\Lambda} \qquad \forall u, v \in H_\Lambda ,$$

with continuity constant $c_b = 1$.

Proof. First, note that

$$|\mathscr{B}_\Lambda(u,v)| \le \sum_{K\in\mathcal{P}^{\mathsf{h}}} \int_K \left|\frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}\right| \mathrm{d}x + \sum_{e\in\Gamma} \left|\boldsymbol{u}^{\mathsf{T}} \Lambda \boldsymbol{v}\right|_e .$$

From the Schwarz inequality and (4.6) it follows that

$$|\mathscr{B}_\Lambda(u,v)| \leq \sum_{K\in\mathcal{P}^\mathrm{h}} |u|_{1,K}\,|v|_{1,K} + \sum_{e\in\Gamma} \left(\sqrt{\boldsymbol{u}^\mathsf{T}\mathrm{D}_\Lambda\boldsymbol{u}}\sqrt{\boldsymbol{v}^\mathsf{T}\mathrm{D}_\Lambda\boldsymbol{v}}\,\right)_e .$$

Application of the discrete Schwarz inequality then yields

$$|\mathscr{B}_\Lambda(u,v)| \leq \left(\sum_{K\in\mathcal{P}^\mathrm{h}} |u|^2_{1,K} + \sum_{e\in\Gamma} \left(\boldsymbol{u}^\mathsf{T}\mathrm{D}_\Lambda\boldsymbol{u}\right)_e\right)^{1/2} \left(\sum_{K\in\mathcal{P}^\mathrm{h}} |v|^2_{1,K} + \sum_{e\in\Gamma} \left(\boldsymbol{v}^\mathsf{T}\mathrm{D}_\Lambda\boldsymbol{v}\right)_e\right)^{1/2} . \qquad \square$$

In a similar manner it can be shown that for all $f \in [H_\Lambda]'$, $\mathscr{L}_\Lambda(\cdot)$ is a continuous functional on H_Λ. Hence, it remains to derive the conditions on the matrices Λ_e in (4.9) which yield $\mathscr{B}_\Lambda(\cdot,\cdot)$ weakly coercive on $H_\Lambda \times H_\Lambda$. Sufficient conditions for weak coercivity are established in Proposition 6. As the proof is rather elaborate, it is transferred to Appendix A.

PROPOSITION 6 (weak coercivity of $\mathscr{B}_\Lambda$). *If the parameters in the matrices Λ_e in* (4.9) *satisfy the algebraic conditions*

$$\left.\begin{array}{ll} & \alpha \in \mathbb{R}, \\ & \beta,\gamma^\mathrm{u},\gamma^\mathrm{l},\delta,\varepsilon \in \mathbb{R}: \\ & \quad \beta,\gamma^\mathrm{u},\gamma^\mathrm{l},\varepsilon = 0 \ \wedge\ 4 > |\delta| \neq 0, \\ & \textit{or} \quad \delta\beta - \varepsilon\gamma^\mathrm{u} \neq 0 \ \wedge\ 4 > \tfrac{1}{2}|\delta+1| + \tfrac{1}{2}|\delta-1| + |\varepsilon|, \\ & \zeta^1,\zeta^2 = 0 \end{array}\right\} \quad \forall e \in \Gamma_\mathcal{I} , \tag{4.13a}$$

$$\alpha \in \mathbb{R}, \quad 4 > |\delta| \neq 0 \qquad \forall e \in \Gamma_\mathcal{D} , \tag{4.13b}$$

$$\beta \in \mathbb{R}, \quad \varepsilon = 0 \qquad \forall e \in \Gamma_\mathcal{N} , \tag{4.13c}$$

then the corresponding bilinear form $\mathscr{B}_\Lambda(\cdot,\cdot)$ in (4.1a) *is weakly coercive on $H_\Lambda \times H_\Lambda$ with an inf-sup constant $\gamma_\Lambda > 0$.*

Let us note that $\{\delta : 4 > |\delta|\} = \{\delta : 4 > \frac{1}{2}|\delta+1| + \frac{1}{2}|\delta-1|\}$. Proposition 6 generalizes the proof of weak coercivity of the BODG in [3] to any consistent conventional DG formulation. We remark that although the conditions in (4.13) are unrestrictive, they can in fact be further weakened.

In conclusion, by the generalized Lax–Milgram theorem, Theorem 1, if the matrices Λ, $\bar{\Lambda}$ conform to (4.9) and (4.13), then for every $f \in [H_\Lambda]'$ the corresponding conventional DG formulation (4.8) is well-posed and consistent with (2.3). In Table 1, we have summarized the parameter choices for several conventional DG formulations

TABLE 1
Parameters in the matrices Λ, $\bar{\Lambda}$ in (4.9) *for several conventional DG formulations.*

DG formulation		α	β	$\gamma^\mathrm{u},\gamma^\mathrm{l}$	δ	ε	ζ^1,ζ^2
GEM	[10, 12]	0	0	0	-1	0	0
IPDG	[2, 10, 12]	α	0	0	-1	0	0
BODG	[3]	0	0	0	1	0	0
NIPDG	[13]	α	0	0	1	0	0
SDG	[14]	0	β	0	1	0	0
LNDG	[9]	α	0	0	δ	0	0

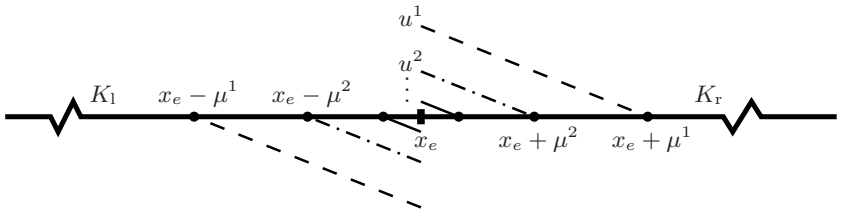

FIG. 1. *Example of a Cauchy sequence* $\{u^i\}$ *in* H_Λ *satisfying* (4.15).

that have appeared in the literature. It can be verified that all formulations, except LNDG, satisfy immediately the conditions in (4.13). LNDG requires the auxiliary condition $4 > |\delta| \neq 0$.

4.3. Noncoercivity of consistent conventional DG formulations. The exposition in section 3 motivates the pursuit of a consistent formulation that is coercive on H_Λ, rather than only weakly coercive. However, the proposition below asserts that a coercive consistent conventional DG formulation is nonexistent; i.e., of the DG formulations in compliance with (4.9), none is coercive.

PROPOSITION 7 (noncoercivity of $\mathscr{B}_\Lambda$). *The bilinear form* $\mathscr{B}_\Lambda(\cdot,\cdot)$ *in* (4.1a) *with* Λ *subject to the consistency requirement* (4.9) *is noncoercive on* H_Λ*; i.e., a positive constant* κ *such that*

$$|\mathscr{B}_\Lambda(u,u)| \geq \kappa \|u\|^2_{H_\Lambda} \qquad \forall u \in H_\Lambda \tag{4.14}$$

is nonexistent.

Proof. We show the existence of a Cauchy sequence $\{u^i\}$ in H_Λ such that $\mathscr{B}_\Lambda(u^i,u^i) \to 0$ and $\|u^i\|_{H_\Lambda} \to c \geq 1$ as $i \to \infty$. Consider an interior edge $e \in \Gamma_\mathcal{I}$ and the left and right elements $K_\mathrm{l}, K_\mathrm{r} \in \mathcal{K}_e$ contiguous to this edge.[5] The Cauchy sequence is chosen such that its elements $u^i \in H_\Lambda$ have local support ($\mathrm{supp}(u^i) \subset \overline{K_\mathrm{l} \cup K_\mathrm{r}}$ with strict inclusion) and, moreover,

$$|u^i|_{1,K_\mathrm{l}}, |u^i|_{1,K_\mathrm{r}} \to 0\,, \tag{4.15a}$$

$$\{u^i\}_e = 0\,,\ [\![u^i]\!]_e \to 0\,, \tag{4.15b}$$

$$h_e^{\frac{1}{2}}\{u^i_n\}_e = 1\,,\ [\![u^i_n]\!]_e = 0\,. \tag{4.15c}$$

An example of a sequence satisfying (4.15) is the sequence $u^1, u^2, \ldots$ depicted in Figure 1. The support of u^i is the closed interval in $\mathbb{R}$ with length $2\mu^i$ centered at e. The length of the support set forms a Cauchy sequence $\{\mu^i\}$ in $\mathbb{R}$ with limit $\lim_{i\to\infty} \mu^i = 0$. Moreover, within the support set, u^i is an asymmetric, piecewise linear function.

From the consistency conditions (4.9) on Λ_e and the properties (4.15) of the sequence $\{u^i\}$ it follows that

$$\begin{aligned}\mathscr{B}_\Lambda(u^i,u^i) &= |u^i|^2_{1,K_\mathrm{l}} + |u^i|^2_{1,K_\mathrm{r}} + \begin{pmatrix} h^{-\frac{1}{2}}[\![u^i]\!] & 1 & 0 & 0\end{pmatrix}_e \begin{pmatrix} \alpha & \delta & \gamma^\mathrm{u} & \zeta^1 \\ -1 & 0 & 0 & 0 \\ \gamma^\mathrm{l} & \varepsilon & \beta & \zeta^2 \\ 0 & 0 & 0 & 0 \end{pmatrix}_e \begin{pmatrix} h^{-\frac{1}{2}}[\![u^i]\!] \\ 1 \\ 0 \\ 0 \end{pmatrix}_e \\ &= |u^i|^2_{1,K_\mathrm{l}} + |u^i|^2_{1,K_\mathrm{r}} + \left(\alpha[\![u^i]\!]^2/h + (\delta-1)h^{-\frac{1}{2}}[\![u^i]\!]\right)_e\,,\end{aligned}$$

[5] If there are no interior edges ($\Gamma_\mathcal{I} = \emptyset$), a proof of noncoercivity can be established similarly by considering a Dirichlet boundary edge.

and, hence, $\mathscr{B}_\Lambda(u^i,u^i)\to 0$ as $i\to\infty$. Furthermore, the norm of u^i reduces to

$$\begin{aligned}\|u^i\|^2_{H_\Lambda} &= |u^i|^2_{1,K_\mathrm{l}} + |u^i|^2_{1,K_\mathrm{r}} + \begin{pmatrix} h^{-\frac{1}{2}}[\![u^i]\!] & 1 & 0 & 0\end{pmatrix}_e \begin{pmatrix} (\mathrm{D}_\Lambda)_{11} & 0 & 0 & \cdots \\ 0 & (\mathrm{D}_\Lambda)_{22} & & \\ 0 & & \ddots & \\ \vdots & & & \end{pmatrix}_e \begin{pmatrix} h^{-\frac{1}{2}}[\![u^i]\!] \\ 1 \\ 0 \\ 0 \end{pmatrix}_e \\ &= |u^i|^2_{1,K_\mathrm{l}} + |u^i|^2_{1,K_\mathrm{r}} + \big((\mathrm{D}_\Lambda)_{11}[\![u^i]\!]^2/h + (\mathrm{D}_\Lambda)_{22}\big)_e\,.\end{aligned}$$

Thus, as $i\to\infty$,

$$\|u^i\|^2_{H_\Lambda} \to (\mathrm{D}_\Lambda)_{22} = \big(\tfrac{1}{2}|\delta{+}1| + \tfrac{1}{2}|\delta{-}1| + |\varepsilon|\big)_e \geq 1\,.$$

The identity follows by replacing $(\mathrm{D}_\Lambda)_{22}$ in accordance with (4.5) and (4.9a). ∎

5. A new symmetric DG formulation with $H^1(\mathcal{P}^\mathsf{h})$-coercivity. In this section we present a new *nonconventional* coercive symmetric DG formulation based on element Green's functions. Section 5.1 presents the variational formulation. In section 5.2 we establish continuity properties of the corresponding bilinear and linear forms. Finally, in section 5.3 we demonstrate consistency and, most importantly, well-posedness on account of coercivity on $H^1(\mathcal{P}^\mathsf{h})$.

5.1. Weak formulation with element Green's functions. By Proposition 7, a coercive DG formulation must contain nonconventional edge terms. Below, we present a formulation based on *element Green's functions*.

Consider an edge $e\in\Gamma_\mathcal{I}\cup\Gamma_\mathcal{D}$, and a contiguous element $K\in\mathcal{K}_e$. The two-point boundary of K is denoted by $\partial K=\{e,\bar{e}\}$. With the pair (K,e) we associate a function $\phi_{K,e}:K\to\mathbb{R}$ by the auxiliary boundary-value problem

$$-\frac{\mathrm{d}^2\phi_{K,e}}{\mathrm{d}x^2} = 0 \qquad \text{in } K, \tag{5.1a}$$

$$\phi_{K,e} = \begin{cases} -n_e\,n_K & \text{on } e\,, \\ 0 & \text{on } \bar{e}\,, \end{cases} \tag{5.1b}$$

where n_K is the unit outward normal of K. For each edge e and each $K\in\mathcal{K}_e$, the solutions of (5.1) are linear functions on K; see Figure 2. Specifically, $\phi_{K,e}$ corresponds to the element *Dirichlet-to-Neumann Green's function* for the one-dimensional Laplacian. To corroborate this assertion, we multiply (5.1a) with $u\in H^2(K)$ and integrate on K. Upon performing integration by parts twice, and invoking the boundary conditions (5.1b), we obtain

$$(\partial_n u)_e = \int_K -\frac{\mathrm{d}^2u}{\mathrm{d}x^2}\,\phi_{K,e}\,\mathrm{d}x - \sum_{\{e,\bar{e}\}}\Big(u\,\frac{\mathrm{d}\phi_K}{\mathrm{d}x}\,n_K\Big)\,,$$

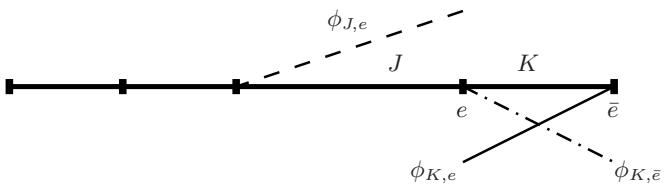

FIG. 2. *Several solutions of auxiliary problem* (5.1).

which shows that the "Neumann value" $\partial_n u$ at e is readily expressed in terms of the Laplacian and "Dirichlet" values of u at e and $\bar{e}$.

For each edge $e \in \Gamma_{\mathcal{I}} \cup \Gamma_{\mathcal{D}}$ we define the functionals $\Phi_e : H^1(\mathcal{P}^{\mathsf{h}}) \to \mathbb{R}$ and $\bar{\Phi}_e : [H^1_{0,\mathcal{D}}(\Omega)]' \to \mathbb{R}$ as

$$\Phi_e(u) := \sum_{K \in \mathcal{K}_e} \theta_{K,e} \int_K \frac{\mathrm{d}u}{\mathrm{d}x} \frac{\mathrm{d}\phi_{K,e}}{\mathrm{d}x} \, \mathrm{d}x \,, \tag{5.2a}$$

$$\bar{\Phi}_e(f) := \sum_{K \in \mathcal{K}_e} \theta_{K,e} \int_K f \phi_{K,e} \, \mathrm{d}x \,. \tag{5.2b}$$

The functionals constitute weighted combinations of contributions of elements that share edge e. The partition-dependent constants $\theta_{K,e} \in \mathbb{R}$ (for $K \in \mathcal{K}_e$) are defined as

$$\theta_{K,e} := h_K / \sum_{J \in \mathcal{K}_e} h_J \,. \tag{5.3}$$

Trivially, $\theta_{K,e} = 1$ for $e \in \Gamma_{\mathcal{D}}$, $K \in \mathcal{K}_e$. It is to be noted that the following partition-of-unity property holds:

$$\sum_{K \in \mathcal{K}_e} \theta_{K,e} = 1 \qquad \forall e \in \Gamma_{\mathcal{I}} \cup \Gamma_{\mathcal{D}} \,. \tag{5.4}$$

Equations (5.2)–(5.4) enable us to condense the new DG formulation into the following variational problem:

(5.5) Find $u \in H^1(\mathcal{P}^{\mathsf{h}})$:

$$\mathscr{B}_{\Phi}(u,v) = \mathscr{L}_{\Phi}(v) \qquad \forall v \in H^1(\mathcal{P}^{\mathsf{h}}) \,,$$

where

$$\begin{aligned} \mathscr{B}_{\Phi}(u,v) := {} & \sum_{K \in \mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}u}{\mathrm{d}x} \frac{\mathrm{d}v}{\mathrm{d}x} \, \mathrm{d}x + \sum_{e \in \Gamma_{\mathcal{I}}} \Big(\alpha [\![u]\!][\![v]\!]/h + [\![u]\!] \Phi(v) + \Phi(u) [\![v]\!] \Big)_e \\ & + \sum_{e \in \Gamma_{\mathcal{D}}} \Big(\alpha uv/h + u\Phi(v) + \Phi(u) v \Big)_e \,, \end{aligned} \tag{5.6a}$$

$$\begin{aligned} \mathscr{L}_{\Phi}(v) := {} & \int_\Omega f v \, \mathrm{d}x + \sum_{e \in \Gamma_{\mathcal{I}}} \Big(\bar{\Phi}(f) [\![v]\!] \Big)_e \\ & + \sum_{e \in \Gamma_{\mathcal{D}}} \Big(\alpha g_{\mathcal{D}} v/h + g_{\mathcal{D}} \Phi(v) + \bar{\Phi}(f) v \Big)_e + \sum_{e \in \Gamma_{\mathcal{N}}} \big(g_{\mathcal{N}} v \big)_e \,. \end{aligned} \tag{5.6b}$$

Note that in a composition of terms with a subscript $(\cdot)_e$, we adhere to the standing notational convention that the subscript of the individual terms is suppressed and appended to the enclosing parenthesis instead.

Let us allude to the fact that the edge terms involving Φ and $\bar{\Phi}$ are nonconventional. The parameters $\alpha_e \in \mathbb{R}$ ($e \in \Gamma_{\mathcal{I}} \cup \Gamma_{\mathcal{D}}$) are associated with conventional edge terms, viz., jumps of u and v at edge e. The rationale for adding these terms is elucidated by the coercivity analysis in section 5.3. The local mesh parameter h_e can in principle be selected in a similar manner as in conventional DG formulations; cf. (4.3). In what follows, we stipulate only that $h_e \leq \frac{1}{2} \sum_{K \in \mathcal{K}_e} h_K$.

5.2. Continuity properties of $\mathscr{B}_\Phi$ and $\mathscr{L}_\Phi$. To facilitate the ensuing analysis, we equip $H^1(\mathcal{P}^\mathsf{h})$ with the energy norm $\|\!|\cdot|\!\|$ according to

$$\|\!|u|\!\|^2 := \sum_{K\in\mathcal{P}^\mathsf{h}} |u|^2_{1,K} + \sum_{e\in\Gamma_\mathcal{I}} \big(\llbracket u\rrbracket^2/h\big)_e + \sum_{e\in\Gamma_\mathcal{D}} \big(u^2/h\big)_e \,.$$

The norm $\|\!|\cdot|\!\|$ is equivalent to $\|\cdot\|_{H^1(\mathcal{P}^\mathsf{h})}$. We then have the following proposition.

PROPOSITION 8 (continuity of $\mathscr{B}_\Phi$). *The bilinear form $\mathscr{B}_\Phi(\cdot,\cdot)$ given in* (5.6a) *is continuous on $H^1(\mathcal{P}^\mathsf{h})$, i.e.,*

$$|\mathscr{B}_\Phi(u,v)| \le c_b \|\!|u|\!\|\|\!|v|\!\| \qquad \forall u,v\in H^1(\mathcal{P}^\mathsf{h}) \,,$$

with, in particular, continuity constant $c_b = \max\big\{2, 1+\max_{e\in\Gamma_\mathcal{I}\cup\Gamma_\mathcal{D}} \alpha_e\big\}$.

Proof. First note that

$$|\mathscr{B}_\Phi(u,v)| \le \sum_{K\in\mathcal{P}^\mathsf{h}} \int_K \Big|\frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x}\Big|\,\mathrm{d}x + \sum_{e\in\Gamma_\mathcal{I}} \Big(\alpha\big|\llbracket u\rrbracket\llbracket v\rrbracket\big|/h + \big|\llbracket u\rrbracket\Phi(v)\big| + \big|\Phi(u)\llbracket v\rrbracket\big|\Big)_e + \sum_{e\in\Gamma_\mathcal{D}} \Big(\alpha\big|uv\big|/h + \big|u\Phi(v)\big| + \big|\Phi(u)v\big|\Big)_e \,.$$

Application of the Schwarz inequality to the first term and subsequent application of the discrete Schwarz inequality yield

$$|\mathscr{B}_\Phi(u,v)| \le \Bigg(\sum_{K\in\mathcal{P}^\mathsf{h}} |u|^2_{1,K} + \sum_{e\in\Gamma_\mathcal{I}} \Big((1+\alpha)\llbracket u\rrbracket^2/h + h\,\Phi(u)^2\Big)_e + \sum_{e\in\Gamma_\mathcal{D}} \Big((1+\alpha)u^2/h + h\,\Phi(u)^2\Big)_e\Bigg)^{1/2} \Big(\cdots\Big)^{1/2} \,,$$

where the dots $(\cdots)$ represent an identical term with u replaced by v. Moreover, by consecutively applying the inequality

$$\big(\theta x + (1-\theta)y\big)^2 \le \theta x^2 + (1-\theta)y^2 \,, \qquad x,y\in\mathbb{R}\,,\ 0\le\theta\le 1\,,$$

the Schwarz inequality, the identity $|\phi_{K,e}|^2_{1,K} = 1/h_K$ for the $|\cdot|_{1,K}$ norm of $\phi_{K,e}$, definition (5.3), and $h_e \le \frac{1}{2}\sum_{K\in\mathcal{K}_e} h_K$, we derive the following important inequality:

$$\Phi_e(u)^2 = \Big(\sum_{K\in\mathcal{K}_e} \theta_{K,e}\int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}\phi_{K,e}}{\mathrm{d}x}\,\mathrm{d}x\Big)^2 \le \sum_{K\in\mathcal{K}_e} \theta_{K,e}\Big(\int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}\phi_{K,e}}{\mathrm{d}x}\,\mathrm{d}x\Big)^2 \le \sum_{K\in\mathcal{K}_e} \theta_{K,e}|u|^2_{1,K}|\phi_{K,e}|^2_{1,K} \le \sum_{K\in\mathcal{K}_e}\Big(\sum_{J\in\mathcal{K}_e} h_J\Big)^{-1}|u|^2_{1,K} \le \frac{1}{2h_e}\sum_{K\in\mathcal{K}_e}|u|^2_{1,K} \,. \tag{5.7}$$

Therefore,

$$|\mathscr{B}_\Phi(u,v)| \le \left(\sum_{K\in\mathcal{P}^\mathsf{h}} |u|_{1,K}^2 + \sum_{e\in\Gamma_\mathcal{I}} \left((1+\alpha)[\![u]\!]^2/h + \tfrac{1}{2}\textstyle\sum_{K\in\mathcal{K}_e} |u|_{1,K}^2 \right)_e \right.$$
$$\left. + \sum_{e\in\Gamma_\mathcal{D}} \left((1+\alpha)u^2/h + \tfrac{1}{2}\textstyle\sum_{K\in\mathcal{K}_e} |u|_{1,K}^2 \right)_e \right)^{1/2} \left(\cdots \right)^{1/2}$$
$$\le \left(2 \sum_{K\in\mathcal{P}^\mathsf{h}} |u|_{1,K}^2 + \sum_{e\in\Gamma_\mathcal{I}} \left((1+\alpha)[\![u]\!]^2/h \right)_e \right.$$
$$\left. + \sum_{e\in\Gamma_\mathcal{D}} \left((1+\alpha)u^2/h \right)_e \right)^{1/2} \left(\cdots \right)^{1/2} . \qquad \square$$

Before addressing the continuity of the linear form $\mathscr{L}_\Phi(\cdot)$, we introduce a function splitting in $H^1(\mathcal{P}^\mathsf{h})$. For any $v \in H^1(\mathcal{P}^\mathsf{h})$, we define its *discontinuous part* $v^\mathrm{d} := v^\mathrm{d}(v) \in H^1(\mathcal{P}^\mathsf{h})$ as

$$v^\mathrm{d} = \sum_{e\in\Gamma_\mathcal{I}} \left([\![v]\!]_e \textstyle\sum_{K\in\mathcal{K}_e} \theta_{K,e} \mathfrak{E}_K(-\phi_{K,e}) \right) + \sum_{e\in\Gamma_\mathcal{D}} \left(v_e \textstyle\sum_{K\in\mathcal{K}_e} \theta_{K,e} \mathfrak{E}_K(-\phi_{K,e}) \right) ,$$

where we have introduced the trivial-extension operators $\mathfrak{E}_K : H^1(K) \to H^1(\mathcal{P}^\mathsf{h})$,

$$\mathfrak{E}_K(\phi) = \begin{cases} \phi & \text{in } K , \\ 0 & \text{in } \Omega \setminus K . \end{cases}$$

Note that v^d is an elementwise linear function. The *continuous part* $v^\mathrm{c} := v^\mathrm{c}(v) \in H^1_{0,\mathcal{D}}(\Omega)$ is now defined as the completion of the splitting

$$v^\mathrm{c} = v - v^\mathrm{d} \qquad \forall v \in H^1(\mathcal{P}^\mathsf{h}) . \tag{5.8}$$

To corroborate that v^d and v^c indeed represent the discontinuous and the continuous parts of v, respectively, we note that

$$[\![v^\mathrm{d}]\!]_e = [\![v]\!]_e , \qquad [\![v^\mathrm{c}]\!]_e = 0 \qquad \forall e \in \Gamma_\mathcal{I} , \tag{5.9a}$$
$$v_e^\mathrm{d} = v_e , \qquad v_e^\mathrm{c} = 0 \qquad \forall e \in \Gamma_\mathcal{D} , \tag{5.9b}$$
$$v_e^\mathrm{d} = 0 , \qquad v_e^\mathrm{c} = v_e \qquad \forall e \in \Gamma_\mathcal{N} . \tag{5.9c}$$

In Figure 3, we illustrate for an example function v the corresponding v^d and v^c.

PROPOSITION 9 (continuity of $\mathscr{L}_\Phi$). *For $f \in [H^1_{0,\mathcal{D}}(\Omega)]'$, the linear functional $\mathscr{L}_\Phi(\cdot)$ in* (5.6b) *is continuous on $H^1(\mathcal{P}^\mathsf{h})$.*

Proof. First note that

$$\sum_{e\in\Gamma_\mathcal{I}} \left(\bar{\Phi}(f)[\![v]\!] \right)_e + \sum_{e\in\Gamma_\mathcal{D}} \left(\bar{\Phi}(f)v \right)_e = \sum_{e\in\Gamma_\mathcal{I}} \left([\![v]\!]_e \textstyle\sum_{K\in\mathcal{K}_e} \theta_{K,e} \int_K f\phi_{K,e} \,\mathrm{d}x \right)$$
$$+ \sum_{e\in\Gamma_\mathcal{D}} \left(v_e \textstyle\sum_{K\in\mathcal{K}_e} \theta_{K,e} \int_K f\phi_{K,e} \,\mathrm{d}x \right) = \int_\Omega f(-v^\mathrm{d}) \,\mathrm{d}x . \tag{5.10}$$

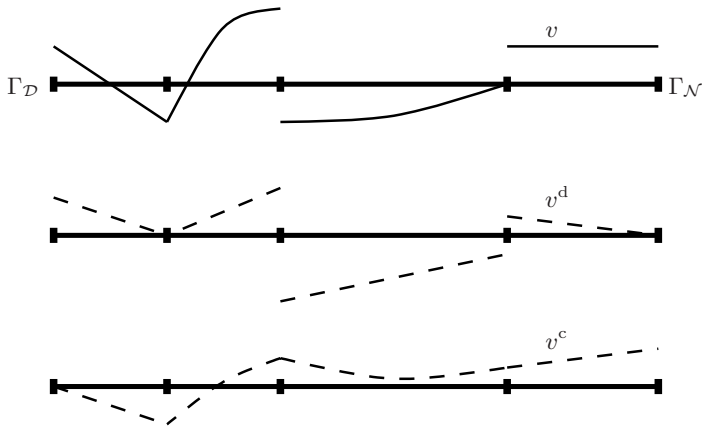

FIG. 3. *Illustration of v^{d} and v^{c} for an example function $v \in H^1(\mathcal{P}^{\mathsf{h}})$ on a domain for which the left boundary is $\Gamma_{\mathcal{D}}$ and the right boundary is $\Gamma_{\mathcal{N}}$.*

As $v - v^{\mathrm{d}} = v^{\mathrm{c}}$, we obtain for $\mathscr{L}_{\Phi}(v)$

$$\mathscr{L}_{\Phi}(v) = \int_{\Omega} f v^{\mathrm{c}} \,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(\alpha g_{\mathcal{D}} v/h + g_{\mathcal{D}}\Phi(v)\Big)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \big(g_{\mathcal{N}} v\big)_e \,, \tag{5.11}$$

which can be bounded as follows

$$|\mathscr{L}_{\Phi}(v)| \le \left| \int_{\Omega} f v^{\mathrm{c}} \,\mathrm{d}x \right| + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(|g_{\mathcal{D}}|\big(\alpha|v|/h + |\Phi(v)|\big)\Big)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \big(|g_{\mathcal{N}}||v|\big)_e.$$

Since $v^{\mathrm{c}} \in H^1_{0,\mathcal{D}}(\Omega)$, the first term is bounded for $f \in [H^1_{0,\mathcal{D}}(\Omega)]'$. The other terms can also be bounded using (5.7) and the usual trace inequalities. ∎

5.3. Well-posedness results for the continuum formulation. At variance with conventional DG formulations, the new DG formulation is consistent with the more general Poisson problem (2.1).

PROPOSITION 10 (consistency with classical CG formulation). *For all f in the dual space $[H^1_{0,\mathcal{D}}(\Omega)]'$, the DG formulation* (5.5) *is consistent with* (2.1)*, i.e., if $u \in H^1(\Omega)$ is the solution of* (2.1)*, then u satisfies* (5.5).

Proof. Let $u \in H^1(\Omega)$ solve (2.1) and let v be an arbitrary function in $H^1(\mathcal{P}^{\mathsf{h}})$. On account of $[\![u]\!]_e = 0$ for $e \in \Gamma_{\mathcal{I}}$ and $u = g_{\mathcal{D}}$ on $\Gamma_{\mathcal{D}}$, it follows from (5.6a) that

$$\mathscr{B}_{\Phi}(u,v) = \sum_{K\in\mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v}{\mathrm{d}x} \,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{I}}} \Big(\Phi(u)[\![v]\!]\Big)_e + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(\alpha g_{\mathcal{D}} v/h + g_{\mathcal{D}}\Phi(v) + \Phi(u)v\Big)_e \,.$$

Moreover, in analogy with (5.10), it holds that

$$\sum_{e\in\Gamma_{\mathcal{I}}} \Big(\Phi(u)[\![v]\!]\Big)_e + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(\Phi(u)v\Big)_e = \sum_{K\in\mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}(-v^{\mathrm{d}})}{\mathrm{d}x} \,\mathrm{d}x \quad \forall u, v \in H^1(\mathcal{P}^{\mathsf{h}}) \,. \tag{5.12}$$

As $v - v^{\mathrm{d}} = v^{\mathrm{c}}$, we obtain

$$\mathscr{B}_{\Phi}(u,v) = \int_{\Omega} \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v^{\mathrm{c}}}{\mathrm{d}x}\,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(\alpha g_{\mathcal{D}} v/h + g_{\mathcal{D}}\Phi(v)\Big)_e\,,$$

where the sum of integrals is replaced by an integral over Ω, which is admissible because $u \in H^1(\Omega)$ and $v^{\mathrm{c}} \in H^1_{0,\mathcal{D}}(\Omega)$. Recalling from (2.1) that

$$\int_{\Omega} \frac{\mathrm{d}u}{\mathrm{d}x}\frac{\mathrm{d}v^{\mathrm{c}}}{\mathrm{d}x}\,\mathrm{d}x = \int_{\Omega} f v^{\mathrm{c}}\,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{N}}} \big(g_{\mathcal{N}} v^{\mathrm{c}}\big)_e\,,$$

we finally obtain from (5.9c) that

$$\mathscr{B}_{\Phi}(u,v) = \int_{\Omega} f v^{\mathrm{c}}\,\mathrm{d}x + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(\alpha g_{\mathcal{D}} v/h + g_{\mathcal{D}}\Phi(v)\Big)_e + \sum_{e\in\Gamma_{\mathcal{N}}} \big(g_{\mathcal{N}} v\big)_e\,.$$

Hence, $\mathscr{B}_{\Phi}(u,v)$ can be identified with $\mathscr{L}_{\Phi}(v)$ according to (5.11) for all $v \in H^1(\mathcal{P}^{\mathsf{h}})$. ∎

We remark that consistency can be established for any choice of $\theta_{K,e}$ in the operators Φ and $\bar{\Phi}$ in (5.2), provided that the partition-of-unity property (5.4) holds.

A fundamental property of the bilinear form $\mathscr{B}_{\Phi}(\cdot,\cdot)$ in (5.6a) is its *coercivity* on $H^1(\mathcal{P}^{\mathsf{h}})$.

PROPOSITION 11 (coercivity of $\mathscr{B}_{\Phi}$). *If the parameter $\alpha_e > 1$ for all $e \in \Gamma_{\mathcal{I}} \cup \Gamma_{\mathcal{D}}$, then the bilinear form $\mathscr{B}_{\Phi}(\cdot,\cdot)$ in* (5.6a) *is coercive on $H^1(\mathcal{P}^{\mathsf{h}})$, i.e.,*

$$|\mathscr{B}_{\Phi}(u,u)| \geq \kappa |\!|\!| u |\!|\!|^2 \qquad \forall u \in H^1(\mathcal{P}^{\mathsf{h}})\,,$$

with, in particular, coercivity constant

$$\kappa = \min_{e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}} \tfrac{1}{2}\Big((\alpha_e - 1) + 2 - \sqrt{(\alpha_e-1)^2+4}\Big) \in (0,1). \tag{5.13}$$

Note that α_e can be chosen such that κ in (5.13) is bounded away from 0.

Proof. Consider an arbitrary $u \in H^1(\mathcal{P}^{\mathsf{h}})$. We show that there exists a κ in the interval $0 < \kappa < 1$ such that $\mathscr{B}_{\Phi}(u,u) - \kappa |\!|\!| u |\!|\!|^2 \geq 0$. First, we observe that

$$\begin{aligned}\mathscr{B}_{\Phi}(u,u) - \kappa |\!|\!| u |\!|\!|^2 = (1-\kappa) \sum_{K\in\mathcal{P}^{\mathsf{h}}} |u|^2_{1,K} + \sum_{e\in\Gamma_{\mathcal{I}}} \Big((\alpha-\kappa)[\![u]\!]^2/h + 2[\![u]\!]\Phi(u)\Big)_e \\ + \sum_{e\in\Gamma_{\mathcal{D}}} \Big((\alpha-\kappa)u^2/h + 2u\Phi(u)\Big)_e\,.\end{aligned}$$

Application of the Young inequality yields

$$\begin{aligned}\mathscr{B}_{\Phi}(u,u) - \kappa |\!|\!| u |\!|\!|^2 \geq (1-\kappa) \sum_{K\in\mathcal{P}^{\mathsf{h}}} |u|^2_{1,K} \\ + \sum_{e\in\Gamma_{\mathcal{I}}} \left((\alpha-\kappa)[\![u]\!]^2/h - \frac{[\![u]\!]^2}{(1-\kappa)h} - (1-\kappa)h\,\Phi(u)^2\right)_e \\ + \sum_{e\in\Gamma_{\mathcal{D}}} \left((\alpha-\kappa)u^2/h \quad - \frac{u^2}{(1-\kappa)h} - (1-\kappa)h\,\Phi(u)^2\right)_e\,.\end{aligned}$$

We now invoke (5.7) to obtain

$$\begin{aligned}\mathscr{B}_{\Phi}(u,u)-\kappa|\!|\!|u|\!|\!|^2 \geq (1-\kappa)\sum_{K\in\mathcal{P}^{\mathsf{h}}}|u|^2_{1,K} \\ +\sum_{e\in\Gamma_{\mathcal{I}}}\left(\left(\alpha-\kappa-\tfrac{1}{1-\kappa}\right)[\![u]\!]^2/h-\tfrac{1}{2}(1-\kappa)\textstyle\sum_{K\in\mathcal{K}_e}|u|^2_{1,K}\right)_e \\ +\sum_{e\in\Gamma_{\mathcal{D}}}\left(\left(\alpha-\kappa-\tfrac{1}{1-\kappa}\right)u^2/h\quad-\tfrac{1}{2}(1-\kappa)\textstyle\sum_{K\in\mathcal{K}_e}|u|^2_{1,K}\right)_e .\end{aligned}$$

The summations over the elements cancel, except for the contributions of elements contiguous to Neumann boundaries, and, hence,

(5.14)
$$\begin{aligned}\mathscr{B}_{\Phi}(u,u)-\kappa|\!|\!|u|\!|\!|^2 \geq \sum_{e\in\Gamma_{\mathcal{I}}}\left(\left(\alpha-\kappa-\tfrac{1}{1-\kappa}\right)[\![u]\!]^2/h\right)_e+\sum_{e\in\Gamma_{\mathcal{D}}}\left(\left(\alpha-\kappa-\tfrac{1}{1-\kappa}\right)u^2/h\right)_e \\ +\tfrac{1}{2}(1-\kappa)\sum_{e\in\Gamma_{\mathcal{N}}}\sum_{K\in\mathcal{K}_e}|u|^2_{1,K} .\end{aligned}$$

If $\alpha_e>1$ for all $e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}$ and κ complies with (5.13), then $\alpha_e-\kappa-\frac{1}{1-\kappa}\geq 0$ for all $e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}$. Furthermore, for $0<\kappa<1$ the final term in the right member of (5.14) is nonnegative and, therefore, $\mathscr{B}_{\Phi}(u,u)-\kappa|\!|\!|u|\!|\!|^2\geq 0$. ∎

By the classical Lax–Milgram theorem, Theorem 2, we can now conclude that if $\alpha_e>1$ for all $e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}$, then for all $f\in[H^1_{0,\mathcal{D}}(\Omega)]'$ the new DG formulation (5.5) is well-posed and consistent with (2.1). Moreover, by virtue of the coercivity of the new DG formulation, conforming approximations in $H^1(\mathcal{P}^{\mathsf{h}})$ inherit their well-posedness from the continuum formulation, and optimal error estimates hold with uniformly bounded constants.

6. Numerical experiments. In this section we present numerical results for the new DG formulation. First, we investigate the sharpness of the estimate of the coercivity constant (5.13) by means of discrete inf-sup calculations. Next, we illustrate the optimal convergence behavior of the new formulation in appropriate norms.

6.1. Discrete inf-sup calculations. The estimate of the coercivity constant κ in (5.13) represents a lower bound. That is, a $\bar{\kappa}>\kappa$ possibly exists such that $|\mathscr{B}_{\Phi}(u,u)|\geq\bar{\kappa}|\!|\!|u|\!|\!|^2$ for all $u\in H^1(\mathcal{P}^{\mathsf{h}})$. An upper bound to the coercivity constant can be determined by establishing the discrete coercivity constant, viz., the coercivity constant in a finite-dimensional subspace $\widehat{H}\subset H^1(\mathcal{P}^{\mathsf{h}})$, according to

$$\widehat{\kappa}:=\widehat{\kappa}(\widehat{H})=\inf_{u\in\widehat{H}\setminus\{0\}}\frac{\mathscr{B}_{\Phi}(u,u)}{|\!|\!|u|\!|\!|^2} .$$

For a symmetric bilinear form on a finite-dimensional subspace $\widehat{H}$, the coercivity constant coincides with the discrete inf-sup constant

$$\widehat{\gamma}:=\widehat{\gamma}(\widehat{H})=\inf_{u\in\widehat{H}\setminus\{0\}}\sup_{v\in\widehat{H}\setminus\{0\}}\frac{\mathscr{B}_{\Phi}(u,v)}{|\!|\!|u|\!|\!|\;|\!|\!|v|\!|\!|} ,$$

which can be determined numerically by means of the procedure in [10]. Note that the discrete coercivity constants pertaining to a sequence of nested subspaces $\widehat{H}^{(1)}\subset$

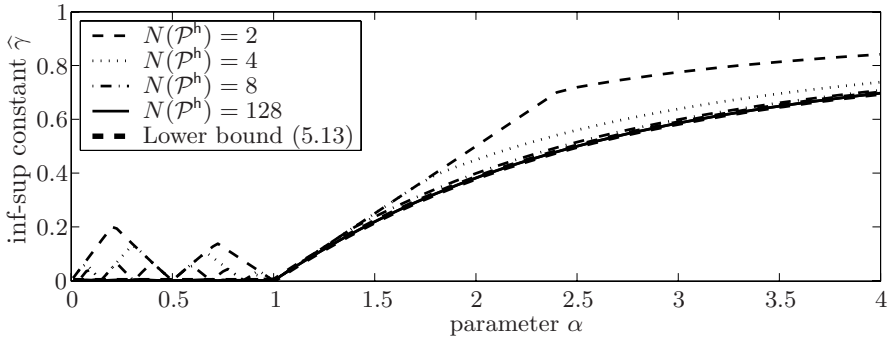

FIG. 4. *Discrete inf-sup constant $\widehat{\gamma}$ versus the parameter α for broken polynomial spaces on uniform partitions with $N(\mathcal{P}^{\mathsf{h}})$ elements. The inf-sup constant $\widehat{\gamma}$ is p independent.*

$\widehat{H}^{(2)} \subset \cdots \subseteq H^1(\mathcal{P}^{\mathsf{h}})$ form a nonincreasing sequence $\widehat{\kappa}^{(1)} \geq \widehat{\kappa}^{(2)} \geq \cdots \geq \bar{\kappa}$. Hence, the discrepancy between the discrete inf-sup constants corresponding to a sequence of nested subspaces and the estimate (5.13) provides a measure of the sharpness of the estimate.

To assess the sharpness of (5.13), we compute the discrete inf-sup constant of the bilinear form in the new DG formulation (5.5) for the Poisson problem on the open unit domain $\Omega = (0,1)$ with Dirichlet boundary conditions, i.e., $\partial\Omega = \Gamma_{\mathcal{D}} = \{0,1\}$. We restrict ourselves to uniform partitions $\mathcal{P}^{\mathsf{h}}$ of $N(\mathcal{P}^{\mathsf{h}})$ elements, and finite-dimensional approximation spaces consisting of broken polynomials with a uniform distribution of the polynomial degree p:

$$\widehat{H} = \mathbb{P}^{\mathsf{p}}(\mathcal{P}^{\mathsf{h}}) := \left\{ u \in L_2(\Omega) : u|_K \in \mathbb{P}^{\mathsf{p}}(K) \; \forall K \in \mathcal{P}^{\mathsf{h}} \right\}.$$

Moreover, we use a uniform distribution of the parameter α_e (=: α) for all $e \in \Gamma_{\mathcal{D}} \cup \Gamma_{\mathcal{I}}$.

The results are displayed in Figure 4. In addition, the figure plots the lower bound κ according to (5.13). The numerical results convey that the computed inf-sup constants are independent of the polynomial degree p (results not displayed). They do, however, depend on $N(\mathcal{P}^{\mathsf{h}})$ and α. It appears that for large $N(\mathcal{P}^{\mathsf{h}})$ the discrete inf-sup constants indeed converge to the lower bound and, hence, the estimate of the coercivity constant κ in (5.13) is apparently sharp.

6.2. Error convergence behavior. We consider the new DG formulation for the Poisson problem (5.5) on the open unit domain $\Omega = (0,1)$ with homogeneous Dirichlet boundary conditions. The prescribed data f is selected such that the solution is $u(x) = \sin(\pi x)$. We consider uniform partitions $\mathcal{P}^{\mathsf{h}}$ with $N(\mathcal{P}^{\mathsf{h}})$ elements. The approximation spaces $\widehat{H}$ are the same as used in the inf-sup calculations above.

Figure 5 plots the error in the approximations. The figure indicates that the approximate solutions $\widehat{u}$ are pointwise exact at the interior and boundary edges. This behavior is characteristic for the classical CG method (2.4). Similarly, it can be proven that if $\mathbb{P}^1(\mathcal{P}^{\mathsf{h}}) \subset \widehat{H}$, i.e., if the approximation space contains the piecewise linear functions, then the DG approximation exhibits the same behavior. In Appendix B we elaborate the pointwise exactness for approximations to the new DG formulation (5.5). In particular, the pointwise exactness implies that

$$\widehat{u} \in \widehat{H} \cap \{ u \in H^1(\Omega) : u = g_{\mathcal{D}} \text{ on } \Gamma_{\mathcal{D}} \}. \tag{6.1}$$

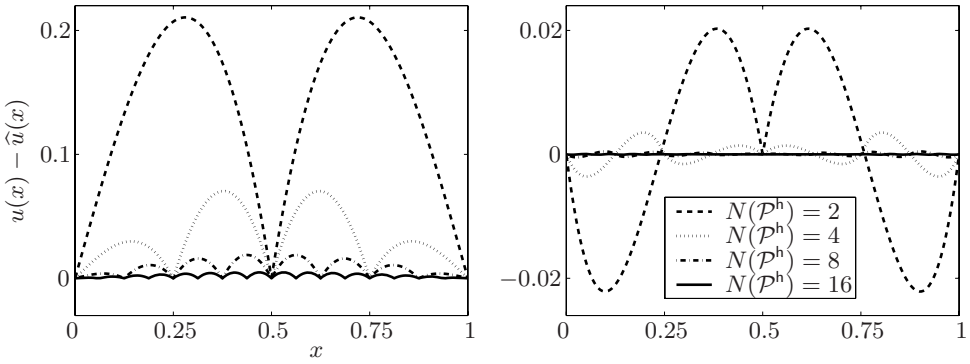

FIG. 5. *Pointwise error for broken polynomial spaces of order* $\mathsf{p} = 1$ *(left) and* $\mathsf{p} = 2$ *(right) on uniform partitions with* $N(\mathcal{P}^{\mathsf{h}})$ *elements.*

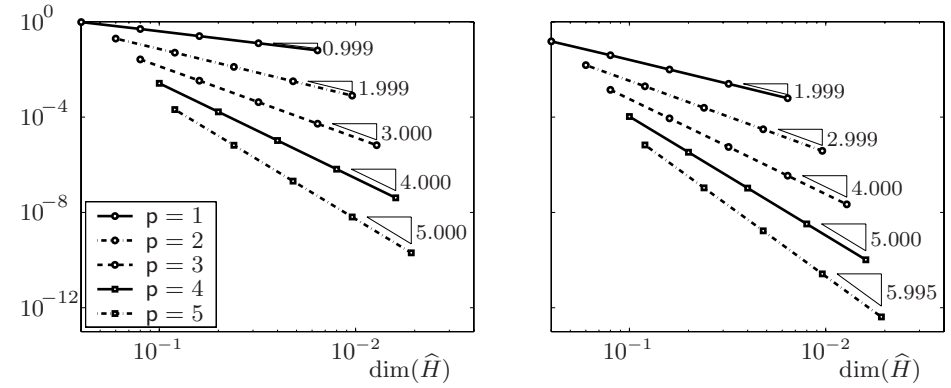

FIG. 6. *Error in the energy-norm (left),* $|\!|\!| u - \hat{u} |\!|\!|$*, and in the* $L^2(\Omega)$*-norm (right),* $\|u - \hat{u}\|_{L_2(\Omega)}$*, versus the dimension of the approximation space* $\dim(\widehat{H})$ *for broken polynomial spaces of order* $\mathsf{p} = 1, \ldots, 5$ *on uniform partitions.*

Moreover, $\widehat{u}$ is then identical to the approximate solution of the classical CG formulation (2.4) on $\widehat{H}^1_{0,\mathcal{D}}(\Omega) = \widehat{H} \cap H^1_{0,\mathcal{D}}(\Omega)$ with $\bar{u} \in \mathbb{P}^1(\Omega)$. Another implication is that the approximations are independent of the parameters α_e (provided that $\alpha_e > 1$ so that the approximate problem is well posed), because the terms associated with α_e vanish from the formulation; cf. Eqs. (5.5) and (5.6).

Figure 6 plots the energy-norm and the $L_2(\Omega)$-norm of the error versus the dimension of the approximation space, $\dim(\widehat{H}) := (\mathsf{p}+1)N(\mathcal{P}^{\mathsf{h}})$, for polynomial orders $\mathsf{p} = 1, 2, \ldots, 5$. The figures corroborate the optimal convergence behavior of the new DG formulation in both norms.

7. Conclusions. We established on the basis of the prototypical Poisson problem that most concurrent DG finite-element methods for second-order elliptic differential equations can be condensed into a generic conventional DG formulation. By means of this generic formulation, we showed that a coercive conventional DG formulation is nonexistent. Conventional DG formulations are contingent on weak coercivity for their well-posedness. However, as weak coercivity does not transfer to subspaces, well-posedness of the continuum problem does not generally imply well-posedness of approximate problems based on conforming subspaces.

We then presented a new nonconventional symmetric DG formulation that is coercive on the broken Sobolev space $H^1(\mathcal{P}^{\mathsf{h}})$. The new formulation is based on element Green's functions and the data local to the edges. On account of its coercivity, conforming approximations of the new formulation inherit their well-posedness from the continuum formulation, and optimal error estimates hold with approximation-space-independent constants. Furthermore, the new DG formulation is consistent with the classical CG formulation in that it admits solutions in $H^1(\mathcal{P}^{\mathsf{h}}) \supset H^1(\Omega)$, rather than $H^2(\mathcal{P}^{\mathsf{h}})$ which is common for conventional DG formulations.

We derived a lower bound for the coercivity constant of the bilinear form in the new formulation. The sharpness of this estimate was confirmed by means of numerical computations of discrete inf-sup constants. Furthermore, numerical experiments were conducted to assess the convergence behavior of the new formulation. The results corroborate that the formulation yields optimal convergence in the energy-norm and in the $L^2(\Omega)$-norm. Moreover, the results demonstrate that discrete approximations in subspaces that contain the piecewise linear functions are identical to classical CG approximations.

It is anticipated that the main attributes of the proposed DG formulation can be extended to higher-dimensional settings. Essentially, the Green's function provides a decomposition of the broken space into the continuous functions and their orthogonal complement. This decomposition can be used to construct a bilinear form that is both consistent and coercive. The generalization of the Green's function to higher dimensions is complex, but there is no fundamental obstacle that precludes such a generalization.

Appendix A. Proof of Proposition 6. The proof is supported by the following lemma.

LEMMA 12. *If there exist a linear continuous operator $v_{(\cdot)} : H_\Lambda \to H_\Lambda$ dependent only on the edge values $\boldsymbol{u}_e$, and a constant $c_1 > \frac{1}{2}$, such that*

$$\big(\Lambda(\boldsymbol{u} + \boldsymbol{v_u})\big)_e = c_1 \big(\mathrm{D}_\Lambda \boldsymbol{u}\big)_e \,, \tag{A.1a}$$

$$\tfrac{1}{2} \sum_{K\in\mathcal{P}^{\mathsf{h}}} |v_u|^2_{1,K} \le \sum_{e\in\Gamma} \big(\boldsymbol{u}^{\mathsf{T}} \mathrm{D}_\Lambda \boldsymbol{u}\big)_e \,, \tag{A.1b}$$

$$\|v_u\|_{H_\Lambda} \le c_\Lambda \|u\|_{H_\Lambda} \tag{A.1c}$$

for all $e \in \Gamma$, then $\mathscr{B}_\Lambda(\cdot,\cdot)$ satisfies the inf-sup condition on $H_\Lambda \times H_\Lambda$.

Note that (A.1c) just expresses the continuity of the operator $v_{(\cdot)}$. Bold-faced variables and the matrix D_Λ are defined in (4.2) and (4.5), respectively.

Proof. By the Young inequality and (A.1a) and (A.1b) it holds that

$$\begin{aligned}
\mathscr{B}_\Lambda(u, u+v_u) &= \sum_{K\in\mathcal{P}^{\mathsf{h}}} \Big(|u|^2_{1,K} + \textstyle\int_K u' v_u' \,\mathrm{d}x \Big) + \sum_{e\in\Gamma} \big(\boldsymbol{u}^{\mathsf{T}} \Lambda(\boldsymbol{u} + \boldsymbol{v_u})\big)_e \\
&\ge \sum_{K\in\mathcal{P}^{\mathsf{h}}} \Big((1 - \tfrac{1}{2\epsilon}) |u|^2_{1,K} - \tfrac{\epsilon}{2} |v_u|^2_{1,K} \Big) + c_1 \sum_{e\in\Gamma} \big(\boldsymbol{u}^{\mathsf{T}} \mathrm{D}_\Lambda \boldsymbol{u}\big)_e \\
&\ge (1 - \tfrac{1}{2\epsilon}) \sum_{K\in\mathcal{P}^{\mathsf{h}}} |u|^2_{1,K} + (c_1 - \epsilon) \sum_{e\in\Gamma} \big(\boldsymbol{u}^{\mathsf{T}} \mathrm{D}_\Lambda \boldsymbol{u}\big)_e
\end{aligned}$$

for all $\epsilon > 0$. Recalling the definition of $\|\cdot\|_{H_\Lambda}$ according to (4.4), we note that for all $c_1 > \frac{1}{2}$ there exists an $\epsilon > \frac{1}{2}$ such that $\mathscr{B}_\Lambda(u, u+v_u) \ge (c_1 - \epsilon)\|u\|^2_{H_\Lambda} > 0$. Using

this in the inf-sup condition, we obtain

$$\sup_{v\in H_\Lambda\setminus\{0\}} \frac{\mathscr{B}_\Lambda(u,v)}{\|u\|_{H_\Lambda}\|v\|_{H_\Lambda}} \geq \frac{\mathscr{B}_\Lambda(u,u+v_u)}{\|u\|_{H_\Lambda}\|u+v_u\|_{H_\Lambda}} \geq \frac{(c_1-\epsilon)\|u\|^2_{H_\Lambda}}{\|u\|_{H_\Lambda}\big(\|u\|_{H_\Lambda}+\|v_u\|_{H_\Lambda}\big)}$$
$$\geq \frac{c_1-\epsilon}{1+c_\Lambda} > 0\,. \qquad \square$$

To prove that the inf-sup condition (3.1a) holds, we establish that under the conditions (4.13) there exists an operator $v_{(\cdot)} : H_\Lambda \to H_\Lambda$ in compliance with the premises of Lemma 12. The existence is verified by construction. Simple linear algebra conveys that if and only if the parameters in the matrices Λ_e in (4.9) satisfy

$$\left.\begin{aligned} \delta\beta-\varepsilon\gamma^{\mathrm{u}}\neq 0 \quad \text{or} \quad \beta,\gamma^{\mathrm{u}},\gamma^{\mathrm{l}},\delta,\varepsilon=0 \\ \zeta^1,\zeta^2=0 \end{aligned}\right\} \quad \forall e\in\Gamma_{\mathcal{I}}\,, \tag{A.2a}$$

$$\delta\neq 0 \qquad \forall e\in\Gamma_{\mathcal{D}}\,, \tag{A.2b}$$

$$\varepsilon=0 \qquad \forall e\in\Gamma_{\mathcal{N}}\,, \tag{A.2c}$$

then for each $u\in H_\Lambda$, (A.1a) admits a (nonunique) solution $(\boldsymbol{v}_u)_e$ for any $c_1\in\mathbb{R}$. Thus, (A.1a) yields the values of v_u at the edges $e\in\Gamma$. The kernel of the matrix Λ in (A.1a) accommodates arbitrary $\{v_u\}_e$ for $e\in\Gamma_{\mathcal{I}}$ and arbitrary $(v_u)_e$ for $e\in\Gamma_{\mathcal{N}}$. We set $(v_u)_e=0$ for $e\in\Gamma_{\mathcal{N}}$.

To facilitate the proof, we introduce an auxiliary operator $\bar{v}_{(\cdot)}$ from H_Λ to $\mathbb{P}^1(\mathcal{P}^{\mathsf{h}})$, viz., the space of piecewise linear functions on the partition $\mathcal{P}^{\mathsf{h}}$. The operator $\bar{v}_{(\cdot)}$ associates with each $u\in H_\Lambda$ the function $\bar{v}_u\in\mathbb{P}^1(\mathcal{P}^{\mathsf{h}})$ such that

$$\begin{aligned} [\![\bar{v}_u]\!]_e &= [\![v_u]\!]_e && \forall e\in\Gamma_{\mathcal{I}}\,,\\ \big(\bar{v}_u\big)_e &= \big(v_u\big)_e && \forall e\in\Gamma_{\mathcal{D}}\,,\\ \big(\bar{v}_u\big)_e &= 0 && \forall e\in\Gamma_{\mathcal{N}}\,, \end{aligned}$$

with $[\![v_u]\!]_e$ the previously determined jumps at edges. Specifically, we define $\bar{v}_u$ as

$$\lim_{K\ni x\to e}\big(\bar{v}_u\big|_K\big)(x) = \begin{cases} \frac{1}{2}n_e\,n_K h_K [\![v_u]\!]_e/h_e & \forall e\in\partial K\cap\Gamma_{\mathcal{I}}\,,\\ \frac{1}{2}h_K(v_u)_e/h_e & \forall e\in\partial K\cap\Gamma_{\mathcal{D}}\,,\\ 0 & \forall e\in\partial K\cap\Gamma_{\mathcal{N}}\,. \end{cases} \tag{A.3}$$

We can now define $v_{(\cdot)}$ as the map $u\to v_u$, where v_u is the limit of a Cauchy sequence $\{v_u^i\}$ in H_Λ with the properties

$$\begin{aligned} v_u^i\big|_K &\to \bar{v}_u\big|_K && \text{in } H^1(K) && \forall K\in\mathcal{P}^{\mathsf{h}}\,,\\ [\![\partial_n v_u^i]\!]_e &\to [\![\partial_n v_u]\!]_e && \text{in } \mathbb{R} && \forall e\in\Gamma_{\mathcal{I}}\,,\\ \{\partial_n v_u^i\}_e &\to \{\partial_n v_u\}_e && \text{in } \mathbb{R} && \forall e\in\Gamma_{\mathcal{I}}\,,\\ \big(\partial_n v_u^i\big)_e &\to \big(\partial_n v_u\big)_e && \text{in } \mathbb{R} && \forall e\in\partial\Omega\,, \end{aligned}$$

where $\{\partial_n v_u\}_e$ and $[\![\partial_n v_u]\!]_e$ refer to the previously determined average derivatives and derivative jumps at edges. Such a Cauchy sequence can be constructed in a similar manner as the sequence in the proof of Proposition 7. The operator $v_{(\cdot)}$ thus defined complies with (A.1a).

To ascertain that $v_{(\cdot)}$ satisfies (A.1b), we note that by (4.9) and (A.2), the second equation in the linear system (A.1a) yields

$$\big(h^{-\frac{1}{2}}[\![v_u]\!]\big)_e = -\big(h^{-\frac{1}{2}}[\![u]\!] + c_1(D_\Lambda)_{22}\, h^{\frac{1}{2}}\{\partial_n u\}\big)_e \qquad \forall e \in \Gamma_{\mathcal{I}}\,, \tag{A.4a}$$

$$\big(h^{-\frac{1}{2}} v_u\big)_e = -\big(h^{-\frac{1}{2}} u \quad + c_1(D_\Lambda)_{22}\, h^{\frac{1}{2}}\partial_n u \quad \big)_e \qquad \forall e \in \Gamma_{\mathcal{D}}\,, \tag{A.4b}$$

with, in particular,

$$1 \le \big((D_\Lambda)_{22}\big)_e = \begin{cases} \big(\frac{1}{2}|\delta+1| + \frac{1}{2}|\delta-1| + |\varepsilon|\big)_e & \forall e \in \Gamma_{\mathcal{I}}\,, \\ \big(\frac{1}{2}|\delta+1| + \frac{1}{2}|\delta-1|\big)_e & \forall e \in \Gamma_{\mathcal{D}}\,. \end{cases} \tag{A.5}$$

Equations (A.3) and (A.4) yield

$$\begin{aligned} \left|\frac{\mathrm{d}\bar{v}_u}{\mathrm{d}x}\Big|_K\right|^2 &= \left|\sum_{e\in\partial K} \big(\bar{v}_u|_K\, n_K\big)_e / h_K\right|^2 \le 2\sum_{e\in\partial K} \big(\bar{v}_u|_K\big)_e^2 / h_K^2 \\ &\le \sum_{e\in\partial K\cap\Gamma_{\mathcal{I}}} \tfrac{1}{2}\Big([\![u]\!]/h + c_1(\mathrm{D}_\Lambda)_{22}\{\partial_n u\}\Big)_e^2 + \sum_{e\in\partial K\cap\Gamma_{\mathcal{D}}} \tfrac{1}{2}\Big(u/h + c_1(\mathrm{D}_\Lambda)_{22}\partial_n u\Big)_e^2 . \end{aligned}$$

From the relation $h_e = \frac{1}{2}\sum_{K\in\mathcal{K}_e} h_K$ in (4.3) it follows that

$$\begin{aligned} \tfrac{1}{2}\sum_{K\in\mathcal{P}^{\mathsf{h}}} |\bar{v}_u|_{1,K}^2 &\le \tfrac{1}{2}\sum_{K\in\mathcal{P}^{\mathsf{h}}} h_K \Big(\textstyle\sum_{e\in\partial K\cap\Gamma_{\mathcal{I}}} \frac{1}{2}\Big([\![u]\!]/h + c_1(\mathrm{D}_\Lambda)_{22}\{\partial_n u\}\Big)_e^2 \\ &\qquad + \textstyle\sum_{e\in\partial K\cap\Gamma_{\mathcal{D}}} \frac{1}{2}\Big(u/h + c_1(\mathrm{D}_\Lambda)_{22}\partial_n u\Big)_e^2\Big) \\ &\le \sum_{e\in\Gamma_{\mathcal{I}}} \Big([\![u]\!]^2/h + c_1^2(\mathrm{D}_\Lambda)_{22}^2 h\{\partial_n u\}^2\Big)_e \\ &\qquad + \sum_{e\in\Gamma_{\mathcal{D}}} \Big(u^2/h + c_1^2(\mathrm{D}_\Lambda)_{22}^2 h(\partial_n u)^2\Big)_e \\ &\le \max\Big\{1, c_1^2 \max_{e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}} \big((\mathrm{D}_\Lambda)_{22}\big)_e\Big\} \sum_{e\in\Gamma} \big(\boldsymbol{u}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{u}\big)_e\,. \end{aligned}$$

Moreover, under the conditions (4.13) it holds that

$$\begin{aligned} \big(4 > \tfrac{1}{2}|\delta+1| + \tfrac{1}{2}|\delta-1| + |\varepsilon| \;\wedge\; \varepsilon \neq 0\big) \quad \text{or} \quad \big(4 > |\delta| \neq 0 \;\wedge\; \varepsilon = 0\big) \qquad & \forall e \in \Gamma_{\mathcal{I}}\,, \\ 4 > |\delta| \qquad & \forall e \in \Gamma_{\mathcal{D}}\,. \end{aligned}$$

Inequality (A.5) then yields $1 \le \max_{e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}}((\mathrm{D}_\Lambda)_{22})_e < 4$. As $v_u^i|_K \to \bar{v}_u^i|_K$ in $H^1(\mathcal{P}^{\mathsf{h}})$ as $i\to\infty$, there exists a $c_1 > \frac{1}{2}$ such that $c_1^2 \max_{e\in\Gamma_{\mathcal{I}}\cup\Gamma_{\mathcal{D}}}((\mathrm{D}_\Lambda)_{22})_e < 1$ and hence (A.1b) holds.

To establish (A.1c), we denote by Λ^- the (square) generalized inverse for the matrix Λ in equation (A.1a). We can then write

$$\boldsymbol{v_u} = \Lambda^-(c_1\mathrm{D}_\Lambda - \Lambda)\boldsymbol{u}\,,$$

and, thus,

$$\boldsymbol{v_u}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{v_u} = \big\|\mathrm{D}_\Lambda^{\frac{1}{2}}\Lambda^-(c_1\mathrm{D}_\Lambda - \Lambda)\boldsymbol{u}\big\|^2 \le \underbrace{\big\|\mathrm{D}_\Lambda^{\frac{1}{2}}\Lambda^-(c_1\mathrm{D}_\Lambda - \Lambda)\mathrm{D}_\Lambda^{-\frac{1}{2}}\big\|^2}_{=:\mathcal{C}_2} \big(\boldsymbol{u}^{\mathsf{T}}\mathrm{D}_\Lambda\boldsymbol{u}\big)\,,$$

where $\|\cdot\|$ represents the usual Euclidian vector norm, and the corresponding matrix norm. Condition (A.1c) can then be verified straightforwardly:

$$\|v_u\|_{H_\Lambda}^2 = \sum_{K\in\mathcal{P}^\mathsf{h}} |v_u|_{1,K}^2 + \sum_{e\in\Gamma} \left(\boldsymbol{v_u}^\mathsf{T} \mathrm{D}_\Lambda \boldsymbol{v_u}\right)_e \leq (2+c_2) \sum_{e\in\Gamma} \left(\boldsymbol{u}^\mathsf{T} \mathrm{D}_\Lambda \boldsymbol{u}\right)_e \leq (2+c_2)\|u\|_{H_\Lambda}^2 \ .$$

The second condition for weak coercivity of $\mathscr{B}_\Lambda(\cdot,\cdot)$, i.e.,

$$\sup_{u\in H_\Lambda} \mathscr{B}_\Lambda(u,v) > 0 \qquad \forall v \in H_\Lambda \setminus \{0\} \ ,$$

is easily established by means of the relation $\mathscr{B}_\Lambda(u,v) = \mathscr{B}_{\Lambda^\mathsf{T}}(v,u)$. Under the conditions in (4.13), we can construct an operator $u_{(\cdot)} : H_\Lambda \to H_\Lambda$, in a similar manner as the operator $v_{(\cdot)}$ above, such that

$$\sup_{u\in H_\Lambda} \mathscr{B}_{\Lambda^\mathsf{T}}(v,u) \geq \mathscr{B}_{\Lambda^\mathsf{T}}(v, v+u_v) > 0 \ .$$

Appendix B. Pointwise exactness of approximations. In this section we establish that the new DG formulation is pointwise exact on all edges $\Gamma = \Gamma_\mathcal{I} \cup \partial\Omega$ if the discrete approximation space contains the piecewise linear polynomials, i.e., $\mathbb{P}^1(\mathcal{P}^\mathsf{h}) \subseteq \widehat{H} \subset H^1(\mathcal{P}^\mathsf{h})$.

Let $\widehat{u} \in \widehat{H}$ be the solution of the approximation problem $\mathscr{B}_\Phi(\widehat{u},v) = \mathscr{L}_\Phi(v)$ for all $v \in \widehat{H}$. First, we show that the jumps of $\widehat{u}$ are zero and that the Dirichlet boundary traces comply with the Dirichlet boundary condition, i.e.,

$$\llbracket \widehat{u} \rrbracket_e = 0 \quad \forall e \in \Gamma_\mathcal{I} \ , \qquad \widehat{u} = g_\mathcal{D} \quad \text{on } \Gamma_\mathcal{D} \ . \tag{B.1}$$

Consider an arbitrary edge $\bar{e} \in \Gamma_\mathcal{I} \cup \Gamma_\mathcal{D}$. We construct a discontinuous test function $w = w(\bar{e}) \in \mathbb{P}^1(\mathcal{P}^\mathsf{h})$ such that $w^\mathrm{c} = 0$, $w^\mathrm{d} = w$ (cf. section 5.2 for the splitting $v = v^\mathrm{c} + v^\mathrm{d}$ into a continuous and a discontinuous part), and

$$\begin{aligned} \alpha\llbracket w \rrbracket/h + \Phi(w) &= 0 \qquad && \forall e \in \Gamma_\mathcal{I} \setminus \{\bar{e}\} \ , \\ \alpha w/h + \Phi(w) &= 0 && \forall e \in \Gamma_\mathcal{D} \setminus \bar{e} \ , \\ \alpha\llbracket w \rrbracket/h + \Phi(w) &= 1 && \text{if } \bar{e} \in \Gamma_\mathcal{I} \ , \\ \alpha w/h + \Phi(w) &= 1 && \text{if } \bar{e} \in \Gamma_\mathcal{D} \ . \end{aligned} \tag{B.2}$$

It can be shown that the system of equations (B.2) admits a unique solution under the (sufficient) condition $\alpha_e > 1$. This condition is satisfied by assumption; see Proposition 11. As $w \in \mathbb{P}^1(\mathcal{P}^\mathsf{h}) \subset \widehat{H}$, it holds that $\mathscr{B}_\Phi(\widehat{u},w) = \mathscr{L}_\Phi(w)$. From (5.11), (5.12), and $w = 0$ on $\Gamma_\mathcal{N}$, it follows that

$$\sum_{e\in\Gamma_\mathcal{I}} \Big(\big(\alpha\llbracket w \rrbracket/h + \Phi(w)\big) \llbracket \widehat{u} \rrbracket \Big)_e + \sum_{e\in\Gamma_\mathcal{D}} \Big(\big(\alpha w/h + \Phi(w)\big) \big(\widehat{u} - g_\mathcal{D}\big) \Big)_e = 0 \ .$$

Equation (B.1) now follows straightforwardly from the conditions (B.2).

We next establish that $\widehat{u}$ is exact on Neumann edges $\Gamma_\mathcal{N}$. Let $e_\mathcal{N}$ denote the Neumann edge and $e_\mathcal{D}$ the complementary Dirichlet edge. Further, let $\varphi_\mathcal{N} \in H^1_{0,\mathcal{D}}(\Omega)$ be the linear function which is $|\Omega|$ at $e_\mathcal{N}$ and which vanishes at $e_\mathcal{D}$. Using $\varphi_\mathcal{N}$ in (2.1), we obtain for the exact solution

$$u(e_\mathcal{N}) = \int_\Omega f\varphi_\mathcal{N} \,\mathrm{d}x + g_\mathcal{D}(e_\mathcal{D}) + |\Omega| g_\mathcal{N}(e_\mathcal{N}) \ . \tag{B.3}$$

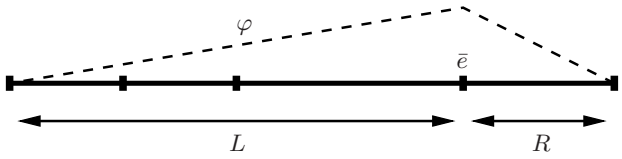

FIG. 7. *Global Green's function φ with respect to edge $\bar{e}$.*

Moreover, as $\varphi_{\mathcal{N}} \in \mathbb{P}^1(\mathcal{P}^{\mathsf{h}}) \subset \widehat{H}$, it holds that $\mathscr{B}_{\Phi}(\widehat{u}, \varphi_{\mathcal{N}}) = \mathscr{L}_{\Phi}(\varphi_{\mathcal{N}})$. On account of $[\![\varphi_{\mathcal{N}}]\!]_e = [\![\widehat{u}]\!]_e = 0$ for $e \in \Gamma_{\mathcal{I}}$, $\varphi_{\mathcal{N}}(e_{\mathcal{D}}) = 0$, and $\widehat{u}(e_{\mathcal{D}}) = g_{\mathcal{D}}(e_{\mathcal{D}})$, this implies

$$\sum_{K \in \mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}\widehat{u}}{\mathrm{d}x} \frac{\mathrm{d}\varphi_{\mathcal{N}}}{\mathrm{d}x} \, \mathrm{d}x = \int_\Omega f \varphi_{\mathcal{N}} \, \mathrm{d}x + |\Omega| g_{\mathcal{N}}(e_{\mathcal{N}}) \, .$$

The left side evaluates to $\widehat{u}(e_{\mathcal{N}}) - \widehat{u}(e_{\mathcal{D}})$, which is identical to $\widehat{u}(e_{\mathcal{N}}) - g_{\mathcal{D}}(e_{\mathcal{D}})$ by virtue of the previously established coincidence of $\widehat{u}(e_{\mathcal{D}})$ and $g_{\mathcal{D}}(e_{\mathcal{D}})$. We then conclude from (B.3) that $\widehat{u}(e_{\mathcal{N}}) = u(e_{\mathcal{N}})$.

Finally, we establish that $\widehat{u}$ is exact on interior edges $\Gamma_{\mathcal{I}}$. We consider an arbitrary edge $\bar{e} \in \Gamma_{\mathcal{I}}$ and define $L = L(\bar{e})$ and $R = R(\bar{e})$ to be the open subsets of Ω left and right of edge $\bar{e}$; see Figure 7. Furthermore, we define $\varphi = \varphi(\bar{e}) \in H^1_{0,\mathcal{D}}(\Omega)$ to be the global Green's function corresponding to $\bar{e}$, viz., a hat function for which the jump in the derivative at $\bar{e}$ equals -1. Inserting φ in (2.1), we obtain the following relation for the exact solution at edge $\bar{e}$:

$$u(\bar{e}) = \int_\Omega f\varphi \, \mathrm{d}x + \sum_{e \in \Gamma_{\mathcal{D}}} \vartheta(e) g_{\mathcal{D}}(e) + \sum_{e \in \Gamma_{\mathcal{N}}} \vartheta(e) u(e) \, , \tag{B.4}$$

where $\vartheta(e) := |R|/|\Omega|$ if e is a left edge, and $\vartheta(e) := |L|/|\Omega|$ if e is a right edge. Moreover, the identity $\mathscr{B}_{\Phi}(\widehat{u}, \varphi) = \mathscr{L}_{\Phi}(\varphi)$ yields

$$\sum_{K \in \mathcal{P}^{\mathsf{h}}} \int_K \frac{\mathrm{d}\widehat{u}}{\mathrm{d}x} \frac{\mathrm{d}\varphi}{\mathrm{d}x} \, \mathrm{d}x = \int_\Omega f\varphi \, \mathrm{d}x \, .$$

The left side evaluates to $\widehat{u}(e) - \sum_{e \in \partial\Omega} \vartheta(e) \widehat{u}(e)$. As $\widehat{u}$ is exact on the boundary edges, we finally conclude from (B.4) that $\widehat{u}(e) = u(e)$.

Acknowledgment. The authors thank Dr. Marc Gerritsma for his careful review of the manuscript and the many helpful comments.
