respectively, where $\bar{v}$ is the complex conjugate of v. Then the weighted Sobolev spaces $H^s_\varpi(I)$ $(s = 0, 1, 2, \ldots)$ can be defined as usual with inner products, norms, and seminorms denoted by $(\cdot,\cdot)_{s,\varpi}$, $\|\cdot\|_{s,\varpi}$, and $|\cdot|_{s,\varpi}$, respectively. For real $s > 0$, $H^s_\varpi(I)$ is defined by space interpolation (cf. [20]). The subscript ϖ will be omitted from the notations in the case of $\varpi \equiv 1$. For simplicity, we denote $\partial_r^l v = \frac{d^l v}{dr^l}$, $l \geq 1$. We shall also use $(\cdot,\cdot)_\omega$ and $\|\cdot\|_\omega$ to denote the weighted inner product and the weighted L^2-norm, respectively, in two and three dimensions.

Let S be the unit circle in 2-D and the unit sphere in 3-D; we also use the nonisotropic periodic-type Sobolev space on $\Omega = S \times I$: $H^{s'}_p\big(S; H^s_\varpi(I)\big)$, $s' \geq 0$ (subscript p stands for periodicity in the θ-direction) with the norm

$$\|U\|_{H^{s'}_p(S;H^s_\varpi(I))} = \begin{cases} \Big(\sum_{|m|=0}^\infty (1+m^2)^{s'}\|\hat{u}_m\|^2_{s,\varpi}\Big)^{1/2} & \text{if } \ d = 2, \\ \Big(\sum_{m=0}^\infty \sum_{l=-m}^m (1+m)^{2s'}\|\hat{u}_{lm}\|^2_{s,\varpi}\Big)^{1/2} & \text{if } \ d = 3, \end{cases} \tag{1.8}$$

where $\{\hat{u}_m\}$ (resp., $\{\hat{u}_{lm}\}$) are the expansion coefficients of U in terms of Fourier (resp., spherical harmonic) basis, i.e.,

$$U = \sum_{|m|=0}^\infty \hat{u}_m e^{im\theta} \quad \text{or} \quad U = \sum_{m=0}^\infty \sum_{l=-m}^m \hat{u}_{lm} Y^l_m(\theta, \phi). \tag{1.9}$$

The norm of the Sobolev space $H^{s'}_p(S)$ on S can be defined in the same fashion by replacing the norm $\|\cdot\|_{s,\varpi}$ by the absolute value $|\cdot|$. In particular, we have

$$L^2_p(\Omega) = H^0_p(S, H^0_\varpi(I)) \ \text{ with } \ \varpi = r^{d-1}, \ \ d = 2, 3.$$

We assume that $a > 0$ is a fixed parameter representing the radius of the scatterer. Throughout this paper, we denote by c a generic positive constant which depends only on a and possibly on a fixed $k_0 > 0$. We use the expression $A \lesssim B$ to mean that $A \leq cB$.

2. Dirichlet-to-Neumann (DtN) map. The error analysis relies heavily on the properties of the DtN map which we investigate below.

2.1. Formulation of the DtN operator. We start with the 3-D case and consider an "auxiliary" exterior problem

$$\begin{cases} -\Delta U - k^2 U = 0 & \text{in } \Omega_{\text{ext}} := \mathbb{R}^3 \setminus \bar{B}, \\ U = \Psi & \text{on } \partial B, \end{cases} \tag{2.1}$$

where B is a ball of radius b. This problem can be solved analytically via separation of variables; namely, we can express its solution as

$$U(r,\theta,\phi) = \sum_{m=0}^{\infty} h_m^{(1)}(kr) \sum_{l=-m}^{m} \hat{u}_{lm} Y_m^l(\theta,\phi), \tag{2.2}$$

where $(r,\theta,\phi) \in [b,\infty) \times [0,2\pi) \times [0,\pi)$, $h_m^{(1)}(z)$ is the spherical Hankel function of the first kind of order m, and $\{Y_m^l\}$ are the spherical harmonic functions. To determine the coefficients $\{\hat{u}_{lm}\}$, we expand the Dirichlet boundary value Ψ on the sphere ∂B as

$$U(b,\theta,\phi) = \Psi(\theta,\phi) = \sum_{m=0}^{\infty} \sum_{l=-m}^{m} \hat{\psi}_{lm} Y_m^l(\theta,\phi). \tag{2.3}$$

Letting $r = b$ in (2.2) and comparing the coefficients of the two expansions yield that

$$\hat{u}_{lm} = \frac{\hat{\psi}_{lm}}{h_m^{(1)}(kb)} \quad \text{for} \quad m \geq |l| \geq 0. \tag{2.4}$$

Plugging it into (2.2) leads to the exact solution of (2.1):

$$U(r,\theta,\phi) = \sum_{m=0}^{\infty} \frac{h_m^{(1)}(kr)}{h_m^{(1)}(kb)} \sum_{l=-m}^{m} \hat{\psi}_{lm} Y_m^l(\theta,\phi). \tag{2.5}$$

Differentiating (2.5) with respect to r and setting $r = b$, we find

$$\partial_r U(b,\theta,\phi) = \sum_{m=0}^{\infty} k \frac{h_m^{(1)'}(kb)}{h_m^{(1)}(kb)} \sum_{l=-m}^{m} \hat{\psi}_{lm} Y_m^l(\theta,\phi). \tag{2.6}$$

Hence, the DtN map is defined explicitly as

$$T(U) = \frac{\partial U}{\partial \mathbf{n}}\Big|_{\partial B} = -\frac{\partial U}{\partial r}\Big|_{r=b} = -\sum_{m=0}^{\infty} k \frac{h_m^{(1)'}(kb)}{h_m^{(1)}(kb)} \sum_{l=-m}^{m} \hat{\psi}_{lm} Y_m^l(\theta,\phi), \tag{2.7}$$

where $\mathbf{n}$ is the outward normal of Ω_{ext}.

The counterpart of (2.1) in 2-D is

$$\begin{cases} -\Delta U - k^2 U = 0 & \text{in } \Omega_{\text{ext}} := \mathbb{R}^2 \setminus \bar{B}, \\ U = \Phi & \text{on } \partial B, \end{cases} \tag{2.8}$$

where B is a circle of radius b which can be solved analytically with the exact solution

$$U(r,\theta) = \sum_{|m|=0}^{\infty} \hat{u}_m H_m^{(1)}(kr) e^{\mathrm{i}m\theta} \quad \forall (r,\theta) \in [b,\infty) \times [0,2\pi). \tag{2.9}$$

Here $H_m^{(1)}(z)$ is the Hankel function of the first kind of order m. The coefficients $\{\hat{u}_m\}$ are determined by the boundary value $\Phi(\theta)$ with the expansion

$$U(b,\theta) = \Phi(\theta) = \sum_{|m|=0}^{\infty} \hat{\phi}_m e^{\mathrm{i}m\theta}. \tag{2.10}$$

Hence, letting $r = b$ in (2.9) and comparing the coefficients of the above two expansions lead to $\hat{u}_m = \hat{\phi}_m / H_m^{(1)}(kb)$. As a consequence, the exact solution of (2.8) is

$$U(r,\theta) = \sum_{|m|=0}^{\infty} \frac{H_m^{(1)}(kr)}{H_m^{(1)}(kb)} \hat{\phi}_m e^{\mathrm{i}m\theta} \quad \forall (r,\theta) \in [b,\infty) \times [0,2\pi). \tag{2.11}$$

The 2-D DtN map is given by

$$T(U) = \frac{\partial U}{\partial \mathbf{n}}\Big|_{\partial B} = -\frac{\partial U}{\partial r}\Big|_{r=b} = -\sum_{|m|=0}^{\infty} k \frac{H_m^{(1)'}(kb)}{H_m^{(1)}(kb)} \hat{\phi}_m e^{\mathrm{i}m\theta}. \tag{2.12}$$

By using the DtN map T and choosing b sufficiently large so that B contains both D and supp$F$, the original problem (1.1)–(1.2) with a Dirichlet boundary condition is reduced to:

$$\begin{cases} -\Delta U - k^2 U = F & \text{in } \Omega := B \cap \mathbb{R}^d \setminus \bar{D},\ d = 2,3, \\ U = \xi & \text{on } \partial D, \\ \partial_r U + TU = 0 & \text{on } \partial B. \end{cases} \tag{2.13}$$

To fix the idea, we prescribed a Dirichlet boundary condition on the scatterer D; other types of boundary conditions can be used as well.

2.2. Properties of the DtN kernel. In order to carry out a rigorous mathematical analysis for the problem (2.13), we need to study carefully the properties of the DtN kernel associated with (2.7) and (2.12), i.e., the properties of the coefficients:

$$\mathcal{T}_{m,\kappa} = \begin{cases} \dfrac{H_m^{(1)'}(\kappa)}{H_m^{(1)}(\kappa)} & \text{if } d = 2, \\ \dfrac{h_m^{(1)'}(\kappa)}{h_m^{(1)}(\kappa)} & \text{if } d = 3. \end{cases} \tag{2.14}$$

2.2.1. Behavior of the 3-D kernel. In this case, we have $\kappa > 0$ and $m \geq 0$. We recall that

$$h_m^{(1)}(\kappa) = j_m(\kappa) + \mathrm{i}y_m(\kappa) = \sqrt{\frac{\pi}{2\kappa}}J_{m+1/2}(\kappa) + \mathrm{i}\sqrt{\frac{\pi}{2\kappa}}Y_{m+1/2}(\kappa), \tag{2.15}$$

where J_ν and Y_ν (resp., j_ν and y_ν) are the Bessel (resp., spherical Bessel) functions of the first and second kinds, respectively, of order ν. Using the relevant properties of the Bessel functions (cf. [31]), one verifies that

$$\begin{aligned}\mathrm{Re}(\mathcal{T}_{m,\kappa}) &= \frac{m}{\kappa} - \frac{j_m(\kappa)j_{m+1}(\kappa) + y_m(\kappa)y_{m+1}(\kappa)}{\big|h_m^{(1)}(\kappa)\big|^2} \\ &= \frac{m}{\kappa} - \frac{J_{m+1/2}(\kappa)J_{m+3/2}(\kappa) + Y_{m+1/2}(\kappa)Y_{m+3/2}(\kappa)}{J_{m+1/2}^2(\kappa) + Y_{m+1/2}^2(\kappa)};\end{aligned} \tag{2.16a}$$

$$\mathrm{Im}(\mathcal{T}_{m,\kappa}) = \frac{1}{\kappa^2\big|h_m^{(1)}(\kappa)\big|^2} = \frac{2}{\pi\kappa}\frac{1}{J_{m+1/2}^2(\kappa) + Y_{m+1/2}^2(\kappa)}. \tag{2.16b}$$

An explicit expression of $\mathcal{T}_{m,\kappa}$ is given by Theorem 2.6.1 of [23]:

$$\mathcal{T}_{m,\kappa} = \mathrm{Re}(\mathcal{T}_{m,\kappa}) + \mathrm{i}\,\mathrm{Im}(\mathcal{T}_{m,\kappa}) = -\frac{P_m(\kappa)}{\kappa Q_m(\kappa)} + \frac{\mathrm{i}}{Q_m(\kappa)}, \tag{2.17}$$

where

$$\begin{aligned}P_m(\kappa) &= 1 + 2a_1^m\frac{1}{\kappa^2} + \cdots + (m+1)a_m^m\frac{1}{\kappa^{2m}}, \\ Q_m(\kappa) &= 1 + a_1^m\frac{1}{\kappa^2} + \cdots + a_m^m\frac{1}{\kappa^{2m}},\end{aligned} \tag{2.18}$$

with

$$a_j^m = \frac{(m+j)!(2j)!}{4^j(j!)^2(m-j)!}. \tag{2.19}$$

We now study the monotonic property of $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ with respect to m and κ. We observe from (2.17)–(2.19) that, for a fixed $m \geq 0$, $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is an *increasing* function of κ, as illustrated by Figure 2.1(b). However, for a given $\kappa > 0$, $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is a *decreasing* function of m, which follows from Nicholson's formula (see p. 444 of [31])

$$J_{m+1/2}^2(\kappa) + Y_{m+1/2}^2(\kappa) = \frac{8}{\pi^2}\int_0^{+\infty}\mathcal{K}_0(2\kappa\sinh t)\cosh\big((2m+1)t\big)dt, \tag{2.20}$$

where $\mathcal{K}_0(\xi) > 0$ is Kelvin's function defined by (A.2) in the appendix.

We next consider the bounds and asymptotic behavior of $\mathcal{T}_{m,\kappa}$. An immediate consequence of (2.17)–(2.19) is that

$$\mathrm{Re}(\mathcal{T}_{m,\kappa}) < 0, \qquad \mathrm{Im}(\mathcal{T}_{m,\kappa}) > 0, \tag{2.21}$$

which ensures the well-posedness of the problem (2.13) (cf. [11]). Moreover, we have the following bounds (see, e.g., p. 87 of [23]):

$$-\frac{m+1}{\kappa} \leq \mathrm{Re}(\mathcal{T}_{m,\kappa}) \leq -\frac{1}{\kappa}, \qquad 0 < \mathrm{Im}(\mathcal{T}_{m,\kappa}) \leq 1, \tag{2.22}$$

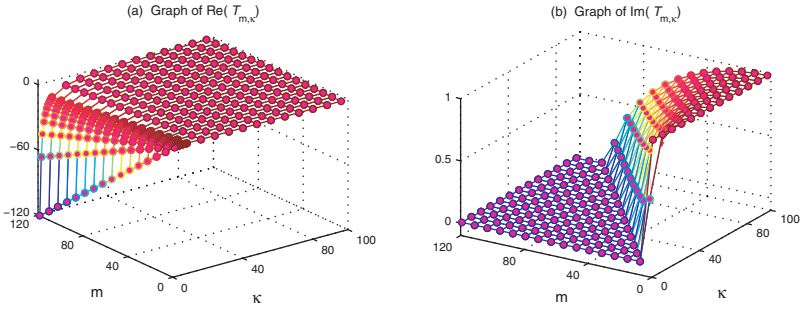

FIG. 2.1. *Graphs of* $\mathrm{Re}(\mathcal{T}_{m,\kappa})$ *and* $\mathrm{Im}(\mathcal{T}_{m,\kappa})$, *with* $(\kappa, m) \in [1{,}100] \times [0{,}120]$, *in the* 3-*D case.*

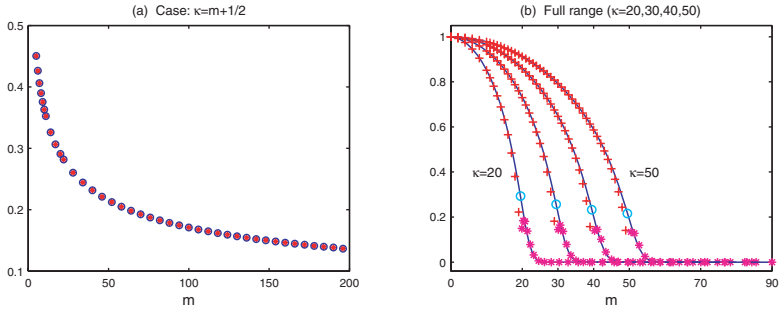

FIG. 2.2. (a) $\mathrm{Im}(\mathcal{T}_{m,m+1/2})$ ($\star$) *against* $E_{m,m+1/2}$ ($\circ$) *with* $m \in [1, 200]$; (b) $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ *(solid line) against* $E_{m,\kappa}$ ($+$ *for* $\kappa > m + 1/2$, ($\circ$) *for* $k = m + 1/2$, *and* ($\star$) *for* $\kappa < m + 1/2$), *with* $\kappa = 20, 30, 40, 50$.

in particular, by (2.17)–(2.19),

$$\mathrm{Re}(\mathcal{T}_{0,\kappa}) = -\frac{1}{\kappa}, \qquad \mathrm{Im}(\mathcal{T}_{0,\kappa}) = 1. \tag{2.23}$$

We now seek more precise estimates of $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ and proceed separately with three cases:

(i) $\kappa > m + 1/2$. We first recall the estimate (see p. 447 of [31])

$$\frac{2}{\pi\kappa} < J_\nu^2(\kappa) + Y_\nu^2(\kappa) < \frac{2}{\pi\sqrt{\kappa^2 - \nu^2}} \quad \text{if} \quad \frac{1}{2} \le \nu < \kappa, \tag{2.24}$$

which, together with (2.16b), implies that

$$E_{m,\kappa} := \frac{\sqrt{\kappa^2 - (m + 1/2)^2}}{\kappa} < \mathrm{Im}(\mathcal{T}_{m,\kappa}) < 1 \quad \text{if} \quad \kappa > m + \frac{1}{2}. \tag{2.25}$$

We observe from Figure 2.2 that the lower bound $E_{m,\kappa}$ provides an acceptable approximation to $\mathrm{Im}(\mathcal{T}_{m,\kappa})$.

(ii) $\kappa = m + 1/2$. Using the formulas (see p. 232 of [31])

$$J_\nu(\nu) = C_1\nu^{-1/3} + O(\nu^{-5/3}), \qquad Y_\nu(\nu) = -C_2\nu^{-1/3} + O(\nu^{-5/3}), \tag{2.26}$$

with

$$C_1 = \frac{\Gamma(1/3)}{2^{2/3}3^{1/6}\pi} \approx 0.4473, \quad C_2 = \frac{3^{1/3}\Gamma(1/3)}{2^{2/3}\pi} \approx 0.7748,$$

we obtain from (2.16b) that

$$\mathrm{Im}\big(\mathcal{T}_{m,m+1/2}\big) \sim C_\circ \big(m+1/2\big)^{-1/3} := E_{m,m+1/2}, \tag{2.27}$$

with $C_\circ = 2/\big(\pi(C_1^2+C_2^2)\big) \approx 0.7954$.

In Figure 2.2(a), we plot $\mathrm{Im}(\mathcal{T}_{m,m+1/2})$ against $E_{m,m+1/2}$ for $1 \le m \le 200$, which shows that, even for small m, the asymptotic estimate $C_\circ\big(m+1/2\big)^{-1/3}$ provides a very good approximation to $\mathrm{Im}\big(\mathcal{T}_{m,m+1/2}\big)$.

(iii) $\kappa < m+1/2$. By the asymptotic formulas (see p. 243 of [31])

$$J_\nu(\nu\mathrm{sech}\alpha) \sim \frac{e^{\nu(\tanh\alpha-\alpha)}}{\sqrt{2\pi\nu\tanh\alpha}}, \qquad Y_\nu(\nu\mathrm{sech}\alpha) \sim -\frac{e^{\nu(\alpha-\tanh\alpha)}}{\sqrt{\frac{1}{2}\pi\nu\tanh\alpha}}, \tag{2.28}$$

one verifies that for $m+1/2 = \kappa\cosh\alpha$, with $\alpha > 0$,

$$\mathrm{Im}(\mathcal{T}_{m,\kappa}) \sim \frac{2(2m+1)\tanh\alpha}{\kappa\big[e^{(2m+1)(\tanh\alpha-\alpha)} + 4e^{(2m+1)(\alpha-\tanh\alpha)}\big]} := E_{m,\kappa}. \tag{2.29}$$

Hence, $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ becomes exponentially small for large m. The exponential decay of $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is shown more clearly from the asymptotic estimate

$$\mathrm{Im}(\mathcal{T}_{m,\kappa}) \sim \Big(\frac{e\kappa}{2m+1}\Big)^{2m}, \quad m \gg \kappa, \tag{2.30}$$

which follows from formula 9.3.1 of [1]:

$$J_\nu(\kappa) \sim \frac{1}{\sqrt{2\pi\nu}}\Big(\frac{e\kappa}{2\nu}\Big)^{\nu}, \quad Y_\nu(\kappa) \sim -\frac{2}{\sqrt{\pi\nu}}\Big(\frac{e\kappa}{2\nu}\Big)^{-\nu}, \ \ \nu \gg \kappa. \tag{2.31}$$

We plot in Figure 2.2(b) the estimate $E_{m,\kappa}$ (defined in (2.25), (2.27), and (2.29)) versus $\mathrm{Im}(\mathcal{T}_{m,\kappa})$, with $\kappa = 20, 30, 40, 50$ and various m, which indicates that $E_{m,\kappa}$ provides an accurate picture of $\mathrm{Im}(\mathcal{T}_{m,\kappa})$.

2.2.2. Behavior of the 2-D kernel. The identity $H_{-\nu}^{(1)}(z) = e^{\nu\pi\mathrm{i}}H_\nu^{(1)}(z)$ and the definition (2.14) imply that

$$\mathcal{T}_{-m,\kappa} = \frac{H_{-m}^{(1)}{}'(\kappa)}{H_{-m}^{(1)}(\kappa)} = \frac{(-1)^m H_m^{(1)}{}'(\kappa)}{(-1)^m H_m^{(1)}(\kappa)} = \mathcal{T}_{m,\kappa}. \tag{2.32}$$

Hence, it suffices to consider $\mathcal{T}_{m,\kappa}$ with $m \ge 0$. Using the recursion formulas of the Bessel functions, one verifies that

$$\mathrm{Re}(\mathcal{T}_{m,\kappa}) = \frac{m}{\kappa} - \frac{J_m(\kappa)J_{m+1}(\kappa) + Y_m(\kappa)Y_{m+1}(\kappa)}{J_m^2(\kappa)+Y_m^2(\kappa)}; \tag{2.33a}$$

$$\mathrm{Im}(\mathcal{T}_{m,\kappa}) = \frac{2}{\pi\kappa}\frac{1}{|H_m^{(1)}(\kappa)|^2} = \frac{2}{\pi\kappa}\frac{1}{J_m^2(\kappa)+Y_m^2(\kappa)}. \tag{2.33b}$$

We observe that the 2-D kernel has an expression similar to that of the 3-D kernel (cf. (2.16)). In fact, they share similar properties and asymptotic behaviors except for $m = 0$ (comparison: Figure 2.1(a) versus Figure 2.3(a) and Figure 2.2(b) versus Figure 2.3(b)).

Indeed, we notice that the same monotonic property holds for the 2-D $\mathrm{Im}(\mathcal{T}_{m,\kappa})$:

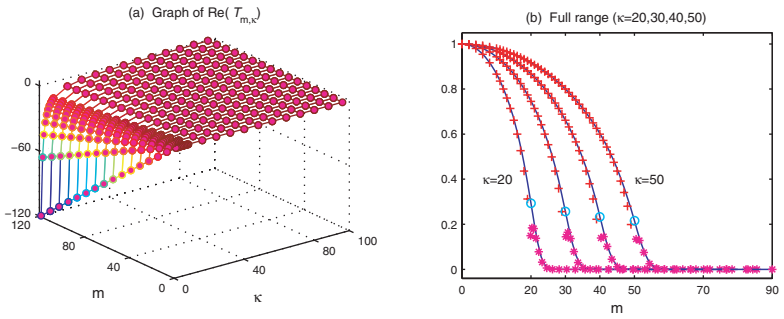

FIG. 2.3. (a) *Graph of* 2-*D* $\mathrm{Re}(\mathcal{T}_{m,\kappa})$, *with* $(\kappa, m) \in [1{,}100] \times [1{,}120]$; (b) 2-*D* $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ *(solid line) against* $E_{m,\kappa}$ *defined in* (2.35) (+ *for* $\kappa > m+1/2$, ○ *for* $\kappa = m+1/2$, *and* (⋆) *for* $\kappa < m+1/2$), *with* $\kappa = 20, 30, 40, 50$.

(i) For a given $m \geq 1$, $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is a strictly *increasing* function of κ, which follows from (2.33b) and the fact that $\kappa|H_m^{(1)}(\kappa)|^2$ is a strictly decreasing function of κ (cf. p. 446 of [31]);

(ii) for a fixed $\kappa > 0$, $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is a strictly *decreasing* function of m, which is a direct consequence of Nicholson's formula (A.3a).

As in (2.22), we have the following bound for the 2-D kernel (see the appendix for the proof):

$$0 < \mathrm{Im}(\mathcal{T}_{m,\kappa}) < 1, \ m \geq 1; \tag{2.34a}$$

$$-\frac{m}{\kappa} \leq \mathrm{Re}(\mathcal{T}_{m,\kappa}) \leq -\frac{1}{2\kappa}, \quad m \geq 1; \qquad -\frac{1}{2\kappa} \leq \mathrm{Re}(\mathcal{T}_{0,\kappa}) < 0; \tag{2.34b}$$

$$\mathrm{Im}(\mathcal{T}_{0,\kappa}) > 1 \ \ \forall \kappa > 0. \tag{2.34c}$$

As in the 3-D case, applying the general formulas (2.24), (2.26), and (2.28) to the 2-D $\mathrm{Im}(\mathcal{T}_{m,\kappa})$, we find that an accurate approximation for $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is

$$E_{m,\kappa} := \begin{cases} \sqrt{1 - m^2/\kappa^2} & \text{if } \ \kappa > m \geq 1, \\ C_\circ m^{-1/3} & \text{if } \ \kappa = m, \\ \dfrac{4m \tanh\alpha}{\kappa\left[e^{2m(\tanh\alpha - \alpha)} + 4e^{2m(\alpha - \tanh\alpha)}\right]} & \text{if } \ \kappa = m\,\mathrm{sech}\alpha, \ \alpha > 0, \end{cases} \tag{2.35}$$

where the constant $C_\circ$ is defined by (2.27).

In Figure 2.3(b), we plot $E_{m,\kappa}$ against $\mathrm{Im}(\mathcal{T}_{m,\kappa})$, which indicates that the estimate $E_{m,\kappa}$ gives an accurate picture of the behavior of $\mathrm{Im}(\mathcal{T}_{m,\kappa})$.

3. A priori estimates. In order to carry out error analysis for the spectral-Galerkin approximation to (1.7), we need to establish some a priori estimates for the solution of (1.7). Without loss of generality, we shall set $\xi = 0$ since the nonhomogeneous boundary condition at $r = a$ can be simply converted to a homogeneous one by subtracting a suitable function from the solution.

3.1. Dimension reduction. We now rewrite (1.7) with $\xi = 0$ in polar coordinates (r, θ) or spherical coordinates (r, θ, ϕ):

$$\begin{cases} -\Big(\dfrac{1}{r^{d-1}}\partial_r\big(r^{d-1}\partial_r U\big) + \dfrac{1}{r^2}\Delta_S U\Big) - k^2 U = F \quad \text{in } \Omega = (a,b) \times S, \\ U\big|_{r=a} = 0, \quad \big[\partial_r U + T(U)\big]\big|_{r=b} = \eta, \end{cases} \tag{3.1}$$

where

$$\Delta_S U = \begin{cases} \partial_\theta^2 U & \text{if } d=2, \\ \frac{1}{\sin^2\phi}\partial_\theta^2 U + \frac{1}{\sin\phi}\partial_\phi\big(\sin\phi\partial_\phi U\big) & \text{if } d=3, \end{cases} \tag{3.2}$$

and its eigenfunctions are the Fourier basis $\{e^{im\theta}\}$ (in 2-D) or the spherical harmonic functions $\{Y_m^l(\theta,\phi)\}$ (in 3-D), i.e.,

$$-\Delta_S e^{im\theta} = m^2 e^{im\theta}\ (d=2);\quad -\Delta_S Y_m^l(\theta,\phi) = m(m+1)Y_m^l(\theta,\phi)\ (d=3). \tag{3.3}$$

We shall denote

$$\beta_m = \begin{cases} m^2, & m=0,\pm1,\pm2,\ldots, \quad \text{if } d=2, \\ m(m+1), & m=0,1,2,\ldots, \quad \text{if } d=3. \end{cases} \tag{3.4}$$

Expanding the solution and given data in terms of the eigenfunctions of Δ_S :

$$\big(U,\ F,\ \eta\big) = \begin{cases} \sum_{|m|=0}^{\infty}\big(\hat{u}_m(r),\ \hat{f}_m(r),\ \hat{h}_m\big)e^{im\theta} & \text{if } d=2, \\ \sum_{m=0}^{\infty}\sum_{l=-m}^{m}\big(\hat{u}_{lm}(r),\ \hat{f}_{lm}(r),\ \hat{h}_{lm}\big)Y_m^l(\theta,\phi) & \text{if } d=3, \end{cases} \tag{3.5}$$

we find from (3.3) that the problem (3.1)–(3.2) is reduced to the following sequence of 1-dimensional equations (for brevity, we use u to denote $\hat{u}_m$ or $\hat{u}_{lm}$ and likewise for f and h below):

$$\begin{cases} -\dfrac{1}{r^{d-1}}\dfrac{d}{dr}\Big[r^{d-1}\dfrac{du}{dr}\Big] + \beta_m\dfrac{u}{r^2} - k^2 u = f, \quad r\in(a,b),\ d=2,3, \\ u(a)=0, \qquad u'(b) - kT_{m,k}u(b) = h, \end{cases} \tag{3.6}$$

where $T_{m,k}$ is derived from (2.7) and (2.12):

$$T_{m,k} = \begin{cases} \dfrac{H_m^{(1)\prime}(kb)}{H_m^{(1)}(kb)} & \text{if } d=2, \\ \dfrac{h_m^{(1)\prime}(kb)}{h_m^{(1)}(kb)} & \text{if } d=3. \end{cases} \tag{3.7}$$

Notice that $T_{m,k} = \mathcal{T}_{m,kb}$ (defined by (2.14)).

3.2. Variational formulation and a priori estimates. We denote the weight functions $\omega^\alpha(r) = r^\alpha$ and $\omega(r) = r$. Define the 1-D weighted space

$$X := X(d) = \big\{u\in H^1_{\omega^{d-1}}(I)\cap L^2_{\omega^{d-3}}(I):\ \ u(a)=0\big\}. \tag{3.8}$$

We define a bilinear form on $H_p^1(S;X)\times H_p^1(S;X)$:

$$\begin{aligned} \mathcal{B}(U,V) =& \big(\partial_r U,\partial_r V\big)_{\omega^{d-1}} + \big(\nabla_S U,\nabla_S V\big)_{\omega^{d-3}} - k^2\big(U,V\big)_{\omega^{d-1}} \\ &+ b^{d-1}\big\langle T(U)(\cdot),V(b,\cdot)\big\rangle_S, \end{aligned} \tag{3.9}$$

where $\langle\cdot,\cdot\rangle_S$ is the $L^2(S)$-inner product (cf. the appendix), and the gradient operator ∇_S is defined by

$$\nabla_S U = \begin{cases} \partial_\theta U & \text{if } d=2, \\ \Big(\frac{1}{\sin\theta}\partial_\theta U\Big)\vec{e}_\theta + \big(\partial_\phi U\big)\vec{e}_\phi & \text{if } d=3. \end{cases} \tag{3.10}$$

The variational formulation of (3.1) is as follows: Given $F \in L^2_{\omega^{d-1}}(\Omega)$ and $\eta \in L^2(S)$, find $U \in H^1_p(S;X)$ such that

$$\mathcal{B}(U,V) = (F,V)_{\omega^{d-1}} + b^{d-1}\big\langle \eta, V(b,\cdot)\big\rangle_S \quad \forall\, V \in H^1_p(S;X),\ \ d=2,3, \tag{3.11}$$

which admits a unique solution (see, e.g., [23]). The first main result of this paper is the following a priori estimates.

THEOREM 3.1. *Let U be the solution of* (3.11). *If $F \in L^2(\Omega)$ and $\eta \in L^2(S)$, then we have*

$$\|\nabla U\| + k\|U\|_\Omega \lesssim \Big(\sqrt{b^d} + \sqrt{b|I|}(kb)^{1/3}\Big)\|\eta\|_{L^2(S)} + (kb)^{1/3}|I|\|F\|, \tag{3.12}$$

where $|I| = b - a$.

The rest of this section is devoted to the proof of this estimate. Observe that, for each mode m or (l,m), the expansion coefficient $u = \hat{u}_m$ or $\hat{u}_{lm}$ (cf. (3.5)) satisfies the following reduced problem (i.e., the variational formulation of (3.6)–(3.7)):

$$\begin{aligned} &\text{Given } f \in L^2_{\omega^{d-1}}(I) \text{ and } h \in \mathbb{C}, \text{ find } u \in X \text{ such that}\\ &\mathcal{B}_m(u,v) = (f,v)_{\omega^{d-1}} + b^{d-1}h\overline{v(b)} \quad \forall v \in X,\ \ d=2,3, \end{aligned} \tag{3.13}$$

where $f = \hat{f}_m$ or $\hat{f}_{lm}$, $h = \hat{h}_m$ or $\hat{h}_{lm}$, and the sesquilinear form

$$\mathcal{B}_m(u,v) := (\partial_r u, \partial_r v)_{\omega^{d-1}} + \beta_m(u,v)_{\omega^{d-3}} - k^2(u,v)_{\omega^{d-1}} - kb^{d-1}T_{m,k}u(b)\overline{v(b)}, \tag{3.14}$$

where β_m is defined in (3.4).

An essential step is to derive a priori estimates for each $u = \hat{u}_m$ or $\hat{u}_{lm}$ and then combine these estimates to get the desired result for the original problem (3.11).

We have the following a priori estimate for the solution of (3.13)–(3.14).

LEMMA 3.1. *Let $|I| = b-a$ be the length of the interval $I = (a,b)$. If $f \in L^2_{\omega^{d-1}}(I)$, then given $k_0 > 0$, we have that, for $k \ge k_0$ and $d = 2,3$,*

$$\begin{aligned} &\|\partial_r u\|_{\omega^{d-1}} + \sqrt{\beta_m}\|u\|_{\omega^{d-3}} + k\|u\|_{\omega^{d-1}}\\ &\qquad \lesssim \big(\sqrt{b^d} + \sqrt{b|I|}C_{m,k}\big)|h| + C_{m,k}|I|\|f\|_{\omega^{d-1}}, \end{aligned} \tag{3.15}$$

where

$$C_{m,k} = \begin{cases} (kb)^{\frac{1}{3}} & \text{if} \quad |m| \le kb,\\ 1 & \text{if} \quad |m| > kb. \end{cases} \tag{3.16}$$

Proof. Some early work (cf. [12, 17, 18]) in this direction relies on the explicit form of Green's function which is very difficult, if not possible, to extend to more general cases. Our proof is based on an argument in [21, 10] (see also [30, 9]). More precisely, we take two test functions $v = u,\ (r-a)\partial_r u \in X$ in (3.13) successively to obtain a priori estimates without using Green's functions. In the following, $\varepsilon_j > 0$ $(j = 1,\dots,5)$ are some suitable real numbers.

We first take $v = u$ in (3.13). The imaginary and real parts are, respectively,

$$-kb^{d-1}\mathrm{Im}(T_{m,k})|u(b)|^2 = b^{d-1}\mathrm{Im}(h\overline{u(b)}) + \mathrm{Im}(f,u)_{\omega^{d-1}}, \tag{3.17a}$$

$$\begin{aligned} &\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m\|u\|^2_{\omega^{d-3}} - k^2\|u\|^2_{\omega^{d-1}} - kb^{d-1}\mathrm{Re}(T_{m,k})|u(b)|^2\\ &\qquad = b^{d-1}\mathrm{Re}(h\overline{u(b)}) + \mathrm{Re}(f,u)_{\omega^{d-1}}. \end{aligned} \tag{3.17b}$$

In order to derive an upper bound for $\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m \|u\|^2_{\omega^{d-3}}$, we proceed separately with two cases: (i) $d = 2,\ |m| > 0$ or $d = 3,\ m \geq 0$ and (ii) $d = 2,\ m = 0$. In the first case, we have from (2.22) and (2.34b) with $|m| \geq 1$ (note that $\kappa = kb$) that

$$\frac{1}{k|\mathrm{Re}(T_{m,k})|} \leq b \quad \text{for } d = 2,\ |m| > 0 \text{ or } d = 3,\ m \geq 0. \tag{3.18}$$

In what follows, we shall repeatedly use the inequality $2AB \leq \varepsilon A^2 + \frac{B^2}{\varepsilon}$ for all $A, B, \varepsilon > 0$.

Applying the Cauchy–Schwarz inequality to (3.17b) leads to

$$\begin{aligned} &\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m \|u\|^2_{\omega^{d-3}} - kb^{d-1}\mathrm{Re}(T_{m,k})|u(b)|^2 \\ &\qquad \leq k^2 \|u\|^2_{\omega^{d-1}} + \frac{kb^{d-1}|\mathrm{Re}(T_{m,k})|}{2}|u(b)|^2 + \frac{b^{d-1}}{2k|\mathrm{Re}(T_{m,k})|}|h|^2 \\ &\qquad\quad + \varepsilon_1 k^2 \|u\|^2_{\omega^{d-1}} + \frac{1}{4\varepsilon_1 k^2}\|f\|^2_{\omega^{d-1}}. \end{aligned} \tag{3.19}$$

Thus, by (3.18), the estimate (3.19) becomes (for $d = 2,\ |m| > 0$ or $d = 3,\ m \geq 0$)

$$\begin{aligned} &\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m \|u\|^2_{\omega^{d-3}} - \frac{kb^{d-1}\mathrm{Re}(T_{m,k})}{2}|u(b)|^2 \\ &\qquad \leq (1+\varepsilon_1) k^2 \|u\|^2_{\omega^{d-1}} + \frac{b^d}{2}|h|^2 + \frac{1}{4\varepsilon_1 k^2}\|f\|^2_{\omega^{d-1}}. \end{aligned} \tag{3.20}$$

To treat the only remaining case, (ii) $d = 2$ and $m = 0$, we apply the Cauchy–Schwarz inequality to (3.17a) and get that

$$\begin{aligned} kb\mathrm{Im}(T_{0,k})|u(b)|^2 \leq{}& \frac{kb\mathrm{Im}(T_{0,k})}{2}|u(b)|^2 + \frac{b}{2k\mathrm{Im}(T_{0,k})}|h|^2 \\ &+ \frac{\varepsilon_2 k\mathrm{Im}(T_{0,k})}{2}\|u\|^2_\omega + \frac{1}{2\varepsilon_2 k\mathrm{Im}(T_{0,k})}\|f\|^2_\omega, \end{aligned} \tag{3.21}$$

which implies that

$$k^2 b|u(b)|^2 \leq \varepsilon_2 k^2 \|u\|^2_\omega + \frac{b}{|\mathrm{Im}(T_{0,k})|^2}|h|^2 + \frac{1}{\varepsilon_2 |\mathrm{Im}(T_{0,k})|^2}\|f\|^2_\omega. \tag{3.22}$$

Thanks to (2.34c), we can rewrite the inequality (3.22) as

$$k^2 b|u(b)|^2 \leq \varepsilon_2 k^2 \|u\|^2_\omega + b|h|^2 + \frac{1}{\varepsilon_2}\|f\|^2_\omega. \tag{3.23}$$

We now apply the Cauchy–Schwarz inequality to (3.17b) (with $d = 2$ and $m = 0$) and use (3.23) to bound the term involving $|u(b)|^2$ to get

$$\begin{aligned} &\|\partial_r u\|^2_\omega + \beta_0 \|u\|^2_{\omega^{-1}} - kb\mathrm{Re}(T_{0,k})|u(b)|^2 \\ &\qquad \leq k^2 \|u\|^2_\omega + k^2 b|u(b)|^2 + \frac{b}{4k^2}|h|^2 + \frac{\varepsilon_1 k^2}{2}\|u\|^2_\omega + \frac{1}{2\varepsilon_1 k^2}\|f\|^2_\omega \\ &\qquad \leq (1+\varepsilon_1) k^2 \|u\|^2_\omega + cb|h|^2 + \frac{1}{\varepsilon_1}\|f\|^2_\omega, \end{aligned} \tag{3.24}$$

where we took $\varepsilon_2 = \varepsilon_1/2$ in (3.23). In view of (3.20) and (3.24), we have the following estimate which is valid for all cases:

$$\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m \|u\|^2_{\omega^{d-3}} \le (1+\varepsilon_1)k^2\|u\|^2_{\omega^{d-1}} + cb^d|h|^2 + c\|f\|^2_{\omega^{d-1}}. \tag{3.25}$$

Now the main difficulty is how to bound the term $k^2\|u\|^2_{\omega^{d-1}}$. To do this, we need to derive further estimates by testing (3.13) with another function. Using a standard regularity argument, one can easily verify that for $f \in L^2_{\omega^{d-1}}(I)$ the weak solution of (3.13) satisfies $(r-a)\partial_r u \in X$. Hence, we can take $v = 2(r-a)\partial_r u$ in (3.13), and after integration by parts and thanks to the identity

$$(u,v)_\omega + (v,u)_\omega = 2\mathrm{Re}(u,v)_\omega, \tag{3.26}$$

we find that the first three terms of the real part of (3.13) with $v = 2(r-a)\partial_r u$ are

$$\begin{aligned} 2\mathrm{Re}\big(\partial_r u, \partial_r((r-a)\partial_r u)\big)_{\omega^{d-1}} &= b^{d-1}|I||\partial_r u(b)|^2 \\ &\quad + \int_a^b \Big[(2-d) + (d-1)\frac{a}{r}\Big]|\partial_r u|^2 r^{d-1}dr; \end{aligned} \tag{3.27a}$$

$$\begin{aligned} 2\beta_m \mathrm{Re}\big(u, (r-a)\partial_r u\big)_{\omega^{d-3}} &= \beta_m b^{d-3}|I||u(b)|^2 \\ &\quad - \beta_m \int_a^b \Big[(d-2) - (d-3)\frac{a}{r}\Big]|u|^2 r^{d-3}dr; \end{aligned} \tag{3.27b}$$

$$\begin{aligned} -2k^2\mathrm{Re}(u, (r-a)\partial_r u)_{\omega^{d-1}} &= -k^2 b^{d-1}|I||u(b)|^2 \\ &\quad + k^2 \int_a^b \Big[d - (d-1)\frac{a}{r}\Big]|u|^2 r^{d-1}dr. \end{aligned} \tag{3.27c}$$

Accordingly, we find that the real part of (3.13) with $v = 2(r-a)\partial_r u$ becomes

$$\begin{aligned} &b^{d-1}|I|\Big(|\partial_r u(b)|^2 + \beta_m b^{-2}|u(b)|^2\Big) + a(d-1)\|\partial_r u\|^2_{\omega^{d-2}} \\ &\qquad + k^2\int_a^b \Big[d - (d-1)\frac{a}{r}\Big]|u|^2 r^{d-1}dr \\ &\le k^2 b^{d-1}|I||u(b)|^2 + (d-2)\|\partial_r u\|^2_{\omega^{d-1}} + \beta_m \int_a^b \Big[(d-2) + (3-d)\frac{a}{r}\Big]|u|^2 r^{d-3}dr \\ &\qquad + 2b^{d-1}|I|\big|\mathrm{Re}(h\overline{\partial_r u(b)})\big| + 2\big|\mathrm{Re}(f, (r-a)\partial_r u)_{\omega^{d-1}}\big|. \end{aligned} \tag{3.28}$$

Note that in the third term the factor $d - (d-1)\frac{a}{r} > 1$ for all $r \in (a,b)$, so we can use this term to bound $k^2\|u\|^2_{\omega^{d-1}}$ in (3.25).

By the Cauchy–Schwarz inequality, we can treat the last two terms at the right-hand side of (3.28) as, respectively,

$$2b^{d-1}|I|\big|\mathrm{Re}\big(h\overline{\partial_r u(b)}\big)\big| \le \frac{b^{d-1}|I|}{2}|\partial_r u(b)|^2 + 2b^{d-1}|I||h|^2, \tag{3.29}$$

and

$$2\big|\mathrm{Re}(f, (r-a)\partial_r u)_{\omega^{d-1}}\big| \le \varepsilon_3\|\partial_r u\|^2_{\omega^{d-1}} + \frac{|I|^2}{\varepsilon_3}\|f\|^2_{\omega^{d-1}}. \tag{3.30}$$

We now proceed separately for $d = 2$ and $d = 3$.

Case I: $d = 2$. In this case, a combination of (3.28)–(3.30) leads to

$$\begin{aligned} b|I|\Big(|\partial_r u(b)|^2 + \beta_m b^{-2}|u(b)|^2\Big) + a\|\partial_r u\|^2 + k^2\int_a^b \Big[2 - \frac{a}{r}\Big]|u|^2 r dr \\ \le k^2 b|I||u(b)|^2 + \Big(\varepsilon_3\|\partial_r u\|_\omega^2 + a\beta_m\|u\|_{\omega^{-2}}^2\Big) + \frac{b|I|}{2}|\partial_r u(b)|^2 \\ + 2b|I||h|^2 + \frac{|I|^2}{\varepsilon_3}\|f\|_\omega^2. \end{aligned} \tag{3.31}$$

Using (3.25) with $d = 2$, we have that, for $\varepsilon_3 < 1$ and for certain $\xi_1 \in (a, b)$,

$$\begin{aligned} \varepsilon_3\|\partial_r u\|_\omega^2 + a\beta_m\|u\|_{\omega^{-2}}^2 &\le \max\Big\{\varepsilon_3, \frac{a}{\xi_1}\Big\}\Big(\|\partial_r u\|_\omega^2 + \beta_m\|u\|_{\omega^{-1}}^2\Big) \\ &\le (1+\varepsilon_1)k^2\|u\|_\omega^2 + cb^2|h|^2 + c\|f\|_\omega^2. \end{aligned} \tag{3.32}$$

Hence, it remains to bound the term $k^2 b|I||u(b)|^2$ in (3.31).

(i) $|m| > kb$. In this case, the term $b|I|k^2|u(b)|^2$ can be absorbed by $b^{-1}|I|\beta_m|u(b)|^2$ at the left-hand side of (3.31). Hence, a combination of (3.31)–(3.32) leads to the desired result:

$$\begin{aligned} b|I|\Big(\frac{1}{2}|\partial_r u(b)|^2 + (\beta_m b^{-2} - k^2)|u(b)|^2\Big) + a\|\partial_r u\|^2 + Ck^2\|u\|_\omega^2 \\ \lesssim b^2|h|^2 + (1+|I|^2)\|f\|_\omega^2, \end{aligned} \tag{3.33}$$

where, with a suitable choice of ε_1, the constant

$$C = 1 - \frac{a}{\xi_2} - \varepsilon_1 > 0 \quad \text{for certain } \xi_2 \in (a, b). \tag{3.34}$$

(ii) $|m| \le kb$. Similar to the derivation of (3.22), we apply the Cauchy–Schwarz inequality to (3.17a):

$$k^2 b|I||u(b)|^2 \le \varepsilon_3|I|k^2\|u\|_\omega^2 + \frac{b|I|}{|\mathrm{Im}(T_{m,k})|^2}|h|^2 + \frac{|I|}{\varepsilon_3|\mathrm{Im}(T_{m,k})|^2}\|f\|_\omega^2. \tag{3.35}$$

Then a combination of the estimates (3.31), (3.32), and (3.35) leads to

$$\begin{aligned} b|I|\Big(\frac{1}{2}|\partial_r u(b)|^2 + \beta_m b^{-2}|u(b)|^2\Big) + a\|\partial_r u\|^2 + \widetilde{C}k^2\|u\|_\omega^2 \\ \lesssim C_{m,k}^{(1)}|h|^2 + C_{m,k}^{(2)}\|f\|_\omega^2, \end{aligned} \tag{3.36}$$

where, with a suitable choice of ε_1 and ε_3 and using the fact that $\mathrm{Im}(T_{m,k}) < 1$, the constants are

$$\begin{aligned} &\widetilde{C} = 1 - \frac{a}{\xi_3} - \varepsilon_1 - \varepsilon_3|I| > 0 \quad \text{for certain } \xi_3 \in (a, b), \\ &C_{m,k}^{(1)} = b^2 + \frac{b|I|}{|\mathrm{Im}(T_{m,k})|^2}, \\ &C_{m,k}^{(2)} = |I|^2 + \frac{|I|}{\varepsilon_3|\mathrm{Im}(T_{m,k})|^2} \lesssim |I|^2\Big(1 + \frac{1}{|\mathrm{Im}(T_{m,k})|^2}\Big). \end{aligned} \tag{3.37}$$

Notice that we have

$$\mathrm{Im}(T_{m,k}) \ge c(kb)^{-\frac{1}{3}} \quad \text{for } |m| \le kb, \tag{3.38}$$

since $\mathrm{Im}(T_{m,k})$ is a decreasing function of m and the estimate (2.35).

Therefore, the desired result (3.15) with $d = 2$ follows from (3.25), (3.33), and (3.36).

Case II: $d = 3$. In this case, a combination of (3.28)–(3.30) leads to

$$\begin{aligned} b^2|I|\big(|\partial_r u(b)|^2 + \beta_m b^{-2}|u(b)|^2\big) + 2a\|\partial_r u\|_\omega^2 + k^2\int_a^b \Big[3 - \frac{2a}{r}\Big]|u|^2 r dr \\ \le k^2 b^2|I||u(b)|^2 + \frac{b^2|I|}{2}|\partial_r u(b)|^2 + \Big(\|\partial_r u\|_{\omega^2}^2 + \beta_m\|u\|^2\Big) \\ + 2b^2|I||h|^2 + \frac{|I|^2}{\varepsilon_3}\|f\|_{\omega^2}^2. \end{aligned} \tag{3.39}$$

By (3.25),

$$\|\partial_r u\|_{\omega^2}^2 + \beta_m\|u\|^2 \le (1+\varepsilon_1)k^2\|u\|_{\omega^2}^2 + cb^3|h|^2 + c\|f\|_{\omega^2}^2. \tag{3.40}$$

The rest of the proof is essentially the same as that in the 2-D case. More precisely, we can derive the 3-D version of inequalities (3.33)–(3.38) with slightly different constants

$$\begin{aligned} C &= 2 - \frac{2a}{\xi_3} - \varepsilon_1 > 0, \quad \xi_3 \in (a,b), \quad \text{if } \ m \ge kb, \\ \tilde{C} &= 2 - \frac{2a}{\xi_3} - \varepsilon_1 - 2\varepsilon_3|I|, \quad \xi_3 \in (a,b), \quad \text{if } \ m < kb. \end{aligned} \tag{3.41}$$

Finally, since $\mathrm{Im}(T_{m,k})$ is a decreasing function of m and $\mathrm{Im}(T_{m,k}) = \mathrm{Im}(\mathcal{T}_{m,kb})$ (cf. (2.14) and (3.7)), the desired bound follows from (2.27) and (2.35). ∎

The proof of Theorem 3.1. Since the proof of the 2-D and 3-D cases is essentially the same, we prove only (3.12) with $d = 3$. Thanks to the orthogonality of the spherical harmonic functions, we deduce from Lemma 3.1 that

$$\begin{aligned} \|\nabla U\|^2 + k^2\|U\|^2 &\lesssim \|\partial_r U\|_{\omega^2}^2 + \|\nabla_S U\|^2 + k^2\|U\|_{\omega^2}^2 \\ &\lesssim \sum_{m=0}^{\infty}\sum_{l=-m}^{m}\Big(\|\partial_r \hat{u}_{lm}\|_{\omega^2}^2 + \beta_m\|\hat{u}_{lm}\|^2 + k^2\|\hat{u}_{lm}\|_{\omega^2}^2\Big) \\ &\lesssim \sum_{m=0}^{\infty}\sum_{l=-m}^{m}\Big(\big(\sqrt{b^3} + \sqrt{b|I|}C_{m,k}\big)^2|\hat{h}_{lm}|^2 + C_{m,k}^2|I|^2\|\hat{f}_{lm}\|_{\omega^2}^2\Big) \\ &\lesssim \sum_{m=0}^{\infty}\sum_{l=-m}^{m}\Big(\big(\sqrt{b^3} + \sqrt{b|I|}(kb)^{1/3}\big)^2\hat{h}_{lm}^2 + (kb)^{2/3}|I|^2\|\hat{f}_{lm}\|_{\omega^2}^2\Big) \\ &\lesssim \big(\sqrt{b^3} + \sqrt{b|I|}(kb)^{1/3}\big)^2\|\eta\|_{L^2(S)} + (kb)^{2/3}|I|^2\|F\|^2. \end{aligned}$$

This ends the proof.

4. Spectral-Galerkin approximation.

4.1. The spectral-Galerkin method and its well-posedness. Let P_N be the space of all complex polynomials of degree at most N on $\bar{I}$. Define $X_N := \big\{u \in P_N \ : \ u(a) = 0\big\}$ and

$$Y_M := \begin{cases} \mathrm{span}\big\{e^{\mathrm{i}m\theta} \ : \ -M \le m \le M\big\} & \text{if } \ d = 2, \\ \mathrm{span}\big\{Y_m^l(\theta,\phi) \ : \ 0 \le |l| \le m \le M\big\} & \text{if } \ d = 3, \end{cases} \tag{4.1}$$

where $\mathcal{B}(\cdot,\cdot)$ is defined in (3.9).

The spectral-Galerkin approximation to (3.11) is as follows:

$$\begin{aligned}&\text{Find } U_{MN} \in \mathcal{V}_{MN} := X_N \times Y_M \text{ such that}\\ &\mathcal{B}(U_{MN}, V_{MN}) = (F, V_{MN})_{\omega^{d-1}} + b^{d-1}\big\langle \eta, V_{MN}(b,\cdot)\big\rangle_S \quad \forall\, V_{MN} \in \mathcal{V}_{MN}.\end{aligned} \tag{4.2}$$

Since the sesquilinear form $\mathcal{B}(\cdot,\cdot)$ is not coercive in $\mathcal{V}_{MN} \times \mathcal{V}_{MN}$ even for small wave number k, an important issue is to prove the well-posedness of the discrete scheme (4.4).

Expanding the numerical solution and test function as

$$\big(U_{MN},\ V_{MN}\big) = \begin{cases} \sum_{|m|=0}^{M} \big(\hat{u}_m^N(r),\ \hat{v}_m^N(r)\big)e^{\mathrm{i}m\theta} & \text{if } d=2,\\ \sum_{m=0}^{M}\sum_{l=-m}^{m} \big(\hat{u}_{lm}^N(r),\ \hat{v}_{lm}^N(r)\big)Y_m^l(\theta,\phi) & \text{if } d=3,\end{cases} \tag{4.3}$$

one verifies that $u_N := \hat{u}_m^N$ or $\hat{u}_{lm}^N$ satisfies the reduced problem

$$\begin{cases} \text{Find } u_N \in X_N \text{ such that}\\ \mathcal{B}_m(u_N, v_N) = (f, v_N)_{\omega^{d-1}} + b^{d-1}h\overline{v_N(b)} \quad \forall v_N \in X_N,\ \ d=2,3,\end{cases} \tag{4.4}$$

where $\mathcal{B}_m(\cdot,\cdot)$ is defined in (3.14); for brevity, we denote $v_N := \hat{v}_m^N$ or v_{lm}^N, and f and h are the same as those in (3.13).

It is important to note that, unlike in the Galerkin finite-element method, the spectral-Galerkin approximation space X_N has the following property: *For $u_N \in X_N$, we have $(r-a)\partial_r u_N \in X_N$. Hence, the proof of Lemma* 3.1 *is also valid for the discrete system* (4.4). In particular, Theorem 3.1 holds with u_N in the place of u. As a consequence, the problem (4.4) has at most one solution. Since (4.4) is finite-dimensional, we then derive from a simple fact in linear algebra that the problem (4.4) admits a unique solution.

Therefore, following the same procedure as in the proof of Theorem 3.1 leads to the following result.

THEOREM 4.1. *If $F \in L^2(\Omega)$ and $\eta \in L^2(S)$, the problem* (4.2) *admits a unique solution satisfying*

$$\|\nabla U_{MN}\| + k\|U_{MN}\| \lesssim \Big(\sqrt{b^d} + \sqrt{b|I|}(kb)^{1/3}\Big)\|\eta\|_{L^2(S)} + (kb)^{1/3}|I|\|F\|. \tag{4.5}$$

4.2. Error estimates. In this part, we shall estimate the error between U (solution of (3.11)) and U_{MN} (solution of (4.2)). Our starting point is to analyze the error of 1-dimensional approximation (4.4).

4.2.1. Analysis of the 1-D scheme. In order to carry out the error analysis, we define the orthogonal projection ${}_0\pi_N^1 : X \to X_N$ by

$$\big(\partial_r(u - {}_0\pi_N^1 u),\ \partial_r v_N\big) = 0 \quad \forall v_N \in X_N. \tag{4.6}$$

For $s \geq 1$ and $s \in \mathbb{N}$, we introduce the weighted Sobolev space

$$B^s(I) := \big\{u \in L^2(I)\ :\ [(r-a)(b-r)]^{\frac{l-1}{2}}\partial_r^l u \in L^2(I),\ 1 \leq l \leq s\big\},$$

with the norm and seminorm

$$\begin{aligned}\|u\|_{B^s} &= \Big(\|u\|^2 + \sum_{l=1}^{s}\big\|[(r-a)(b-r)]^{\frac{l-1}{2}}\partial_r^l u\big\|^2\Big)^{\frac{1}{2}},\\ |u|_{B^s} &= \big\|[(r-a)(b-r)]^{\frac{s-1}{2}}\partial_r^s u\big\|.\end{aligned}$$

LEMMA 4.1. *For any $u \in X \cap B^s(I)$, with $s \geq 1$ and $s \in \mathbb{N}$,*

$$\|\partial_r({}_0\pi_N^1 u - u)\| + N|I|^{-1}\|{}_0\pi_N^1 u - u\| \lesssim N^{1-s}|u|_{B^s}. \tag{4.7}$$

Proof. This result is a direct consequence of the Legendre polynomial approximation (with a scaling and a direct extension to complex functions), which can be found, for instance, in [7], with an improvement of the weighted seminorm in the upper bound given by [14]. □

With the aid of Lemmas 3.1 and 4.1, we are able to obtain the following error estimates.

THEOREM 4.2. *Let u and u_N be, respectively, the solutions of* (3.13) *and* (4.4). *If $u \in X \cap B^s(I)$, with integer $s \geq 1$, then for $d = 2, 3$*

$$\begin{aligned}\|\partial_r(u - u_N)\|_{\omega^{d-1}} + \sqrt{\beta_m}\|u - u_N\|_{\omega^{d-3}} + k\|u - u_N\|_{\omega^{d-1}} \\ \lesssim C_\star(m, N, k; a, b, d)N^{1-s}|u|_{B^s},\end{aligned} \tag{4.8}$$

where

$$\begin{aligned}C_\star(m, N, k; a, b, d) :&= (1 + \sqrt{\beta_m})b^{(d-1)/2} + \sqrt{\beta_m}a^{\frac{d-3}{2}}|I|N^{-1} \\ &+ k^{1/3}(\sqrt{\beta_m}b^{3d/2-2}\sqrt{|I|}N^{-1/2} + |I|^2 b^{d/2}k^2 N^{-1}).\end{aligned} \tag{4.9}$$

Proof. Let $e_N = u_N - {}_0\pi_N^1 u$ and $\tilde{e}_N = u - {}_0\pi_N^1 u$. By (3.13) and (4.4),

$$\mathcal{B}_m(u - u_N, v_N) = 0 \quad \forall v_N \in X_N. \tag{4.10}$$

Then we derive from (3.14), (4.6), and (4.10) that for any $v_N \in X_N$

$$\begin{aligned}\mathcal{B}_m(e_N, v_N) =& \mathcal{B}_m(\tilde{e}_N, v_N) = \beta_m(\tilde{e}_N, v_N)_{\omega^{d-3}} \\ &- k^2(\tilde{e}_N, v_N)_{\omega^{d-1}} - kb^{d-1}T_{m,k}\tilde{e}_N(b)\overline{v_N(b)}.\end{aligned} \tag{4.11}$$

Hence, we can view (4.11) in the form of (3.13) with $u = e_N$, $h = -kb^{d-1}T_{m,k}\tilde{e}_N(b)$, $f = -k^2\tilde{e}_N$, and an additional term $\beta_m(\tilde{e}_N, v_N)_{\omega^{d-3}}$. As with the proof of Theorem 3.1, we take two different test functions $v_N = e_N, 2(r-a)\partial_r e_N \in X_N$ and treat the extra term as

$$\beta_m|(\tilde{e}_N, e_N)_{\omega^{d-3}}| \leq \varepsilon_6\beta_m\|e_N\|^2_{\omega^{d-3}} + \frac{\beta_m}{4\varepsilon_6}\|\tilde{e}_N\|^2_{\omega^{d-3}} \tag{4.12}$$

and

$$\begin{aligned}&2\beta_m|\big(\tilde{e}_N, (r-a)\partial_r e_N\big)_{\omega^{d-3}}| \leq 2\beta_m\Big\{b^{d-3}|I|\big|\tilde{e}_N(b)\overline{e_N(b)}\big| \\ &\quad + \big|\big(\partial_r\tilde{e}_N, (1 - ar^{-1})e_N\big)_{\omega^{d-2}}\big| + \big|\big(\tilde{e}_N, ((d-2) - a(d-3)r^{-1})e_N\big)_{\omega^{d-3}}\big|\Big\} \\ &\leq \varepsilon_7\beta_m b^{d-3}|I||e_N(b)|^2 + \frac{\beta_m b^{d-3}|I|}{\varepsilon_7}|\tilde{e}_N(b)|^2 + \varepsilon_8\beta_m\|e_N\|^2_{\omega^{d-3}} \\ &\quad + \frac{c\beta_m}{\varepsilon_8}\Big(\|\partial_r\tilde{e}_N\|^2_{\omega^{d-1}} + \|\tilde{e}_N\|^2_{\omega^{d-3}}\Big).\end{aligned} \tag{4.13}$$

Thus, choosing suitable constants $\{\varepsilon_j\}_{j=6}^8$ and following the same lines as for the proof of Theorem 3.1 (with $u = e_N$, $h = -kb^{d-1}T_{m,k}\tilde{e}_N(b)$, and $f = -k^2\tilde{e}_N$), we can

derive that

$$
\begin{aligned}
&\|\partial_r e_N\|^2_{\omega^{d-1}} + \beta_m \|e_N\|^2_{\omega^{d-3}} + k^2 \|e_N\|^2_{\omega^{d-1}} \\
&\quad \lesssim \beta_m \big(\|\partial_r \tilde{e}_N\|^2_{\omega^{d-1}} + \|\tilde{e}_N\|^2_{\omega^{d-3}}\big) + \beta_m b^{d-3} |I| |\tilde{e}_N(b)|^2 \\
&\qquad + k^2 b^{2(d-1)} |T_{m,k}|^2 \big(\sqrt{b^d} + \sqrt{b|I|} C_{m,k}\big)^2 |\tilde{e}_N(b)|^2 \\
&\qquad + k^4 |I|^2 C^2_{m,k} \|\tilde{e}_N\|^2_{\omega^{d-1}}.
\end{aligned} \tag{4.14}
$$

To estimate the term $|\tilde{e}_N(b)|$, we use the Sobolev inequality and Lemma 4.1 to obtain that

$$
|\tilde{e}_N(b)|^2 \lesssim \big(2 + |I|^{-1}\big) \|\tilde{e}_N\| \|\tilde{e}_N\|_1 \lesssim N^{1-2s} |I| |u|^2_{B^s}. \tag{4.15}
$$

Next, using the inequality $\|v\|^2_{\omega^\alpha} \le \max\{b^\alpha, a^\alpha\} \|v\|^2$ and Lemma 4.1 leads to

$$
\begin{aligned}
&\|\partial_r^\mu \tilde{e}_N\|^2_{\omega^{d-1}} \le b^{d-1} \|\partial_r^\mu \tilde{e}_N\|^2 \lesssim b^{d-1} |I|^{2-2\mu} N^{2\mu-2s} |u|^2_{B^s}, \quad \mu = 0, 1, \\
&\|\tilde{e}_N\|^2_{\omega^{d-3}} \le a^{d-3} \|\tilde{e}_N\|^2 \lesssim a^{d-3} |I|^2 N^{-2s} |u|^2_{B^s}.
\end{aligned} \tag{4.16}
$$

Hence, by the triangle inequality, (4.14)–(4.16), and Lemma 4.1, we have that

$$
\begin{aligned}
&\|\partial_r (u - u_N)\|^2_{\omega^{d-1}} + \beta_m \|u - u_N\|^2_{\omega^{d-3}} + k^2 \|u - u_N\|^2_{\omega^{d-1}} \\
&\quad \le \Big(\|\partial_r e_N\|^2_{\omega^{d-1}} + \beta_m \|e_N\|^2_{\omega^{d-3}} + k^2 \|e_N\|^2_{\omega^{d-1}}\Big) \\
&\qquad + \Big(\|\partial_r \tilde{e}_N\|^2_{\omega^{d-1}} + \beta_m \|\tilde{e}_N\|^2_{\omega^{d-3}} + k^2 \|\tilde{e}_N\|^2_{\omega^{d-1}}\Big) \\
&\quad \lesssim (1 + \beta_m) \|\partial_r \tilde{e}_N\|^2_{\omega^{d-1}} + \beta_m \|\tilde{e}_N\|^2_{\omega^{d-3}} + \beta_m b^{d-3} |I| |\tilde{e}_N(b)|^2 \\
&\qquad + k^2 b^{2(d-1)} |T_{m,k}|^2 \big(\sqrt{b^d} + \sqrt{b|I|} C_{m,k}\big)^2 |\tilde{e}_N(b)|^2 \\
&\qquad + k^4 |I|^2 C^2_{m,k} \|\tilde{e}_N\|^2_{\omega^{d-1}} \\
&\quad \lesssim C^*(m, N, k; a, b, d) N^{2-2s} |u|^2_{B^s},
\end{aligned} \tag{4.17}
$$

where

$$
\begin{aligned}
C^*(m, N, k; a, b, d) &:= (1 + \beta_m) b^{d-1} + \beta_m a^{d-3} |I|^2 N^{-2} \\
&\quad + \beta_m b^{d-3} |I|^2 N^{-1} + k^2 b^{2(d-1)} |T_{m,k}|^2 \big(\sqrt{b^d} + \sqrt{b|I|} C_{m,k}\big)^2 |I| N^{-1} \\
&\quad + k^4 |I|^4 b^{d-1} C^2_{m,k} N^{-2}.
\end{aligned} \tag{4.18}
$$

We now derive an upper bound for $C^*(m, N, k; a, b, d)$. Since by (2.22) and (2.34)

$$
|T_{m,k}|^2 \le 1 + \frac{(m+1)^2}{(kb)^2}
$$

and by (3.16) $C_{m,k} \lesssim (kb)^{1/3}$, we deduce that for $N \gg 1$

$$
\begin{aligned}
C^*(m, N, k; a, b, d) &\lesssim (1 + \beta_m) b^{d-1} + \beta_m a^{d-3} |I|^2 N^{-2} \\
&\quad + \beta_m b^{3d-4} |I| k^{2/3} N^{-1} + |I|^4 b^d k^{4+2/3} N^{-2}.
\end{aligned}
$$

This implies the desired result. ∎

Remark 4.1. Note that, in the error estimate (4.8), $N^{1-s}|u|_{B^s}$ is the best approximation error, and $k^2 N^{-1}$ in C_* is the so-called "pollution error" which is typical for the numerical approximations to the Helmholtz equation (cf. [4]). The extra term

$k^{1/3}$ in C_* is due to the asymptotic behavior of the DtN kernel (see section 2), and it is unlikely that this extra term can be removed.

Remark 4.2. To illustrate how the error behaves with respect to N, k, and b with $a > 0$ being fixed, we consider a typical oscillatory function $u(r) = e^{ikr} - e^{ika}$. Then, for any $s > 0$, we have

$$\begin{aligned} |u|^2_{B^s} &= \int_a^b |\partial_r^s u|^2 \big((r-a)(b-r)\big)^{s-1} dr \\ &\le k^{2s} \int_a^b \big((r-a)(b-r)\big)^{s-1} dr \lesssim k\Big(k\frac{b-a}{2}\Big)^{2s-1}. \end{aligned} \tag{4.19}$$

Plugging this into (4.8), we find that for this particular but typical solution we have that for any $s \ge 1$

$$\begin{aligned} &\|\partial_r(u-u_N)\|_{\omega^{d-1}} + \sqrt{\beta_m}\|u-u_N\|_{\omega^{d-3}} + k\|u-u_N\|_{\omega^{d-1}} \\ &\qquad \lesssim C_\star(m,N,k;a,b,d)k\sqrt{\frac{b-a}{2}}\Big(\frac{k(b-a)}{2N}\Big)^{1-s}. \end{aligned} \tag{4.20}$$

Hence, the error will decay exponentially as soon as $\frac{k(b-a)}{2N} < 1$, as opposed to the usual condition $\frac{kb}{2N} < 1$. Hence, we can significantly reduce the computational cost by choosing b as close to a as we wish (note, however, that, for scattering from a general obstacle $D = r > a + g(\theta)$ in 2-D or $D = r > a + g(\theta,\phi)$ in 3-D, we have to make sure that $b > a + \|g\|_{L^\infty}$).

With the above preparations, we are ready to perform the error analysis of the full scheme (4.2).

4.2.2. Multidimensional cases. To describe the error, we introduce the following nonisotropic Sobolev space:

$$\mathcal{H}^{s,s'}_{p,\omega^{d-1}}(\Omega) = L^2_p\big(S; B^s(I)\big) \cap H^{s'-1}_p\big(S; H^1_{\omega^{d-1}}(I)\big) \cap H^{s'}_p\big(S; L^2_{\omega^{d-3}}(I) \cap L^2_{\omega^{d-1}}(I)\big), \tag{4.21}$$

with $d = 2, 3$, $s, s' \ge 1$, and the norm

$$\begin{aligned} \big\|U\big\|_{\mathcal{H}^{s,s'}_{p,\omega}(\Omega)} =& \Big(\sum_{|m|=0}^{\infty} \Big[|\hat{u}_m|^2_{B^s} + (1+m^2)^{s'-1}\|\partial_r\hat{u}_m\|^2_\omega \\ &+ (1+m^2)^{s'}\big(\|\hat{u}_m\|^2_{\omega^{-1}} + \|\hat{u}_m\|^2_\omega\big)\Big]\Big)^{\frac{1}{2}}; \\ \big\|U\big\|_{\mathcal{H}^{s,s'}_{p,\omega^2}(\Omega)} =& \Big(\sum_{m=0}^{\infty}\sum_{l=-m}^{m} \Big[|\hat{u}_{lm}|^2_{B^s} + (1+m)^{2s'-s}\|\partial_r\hat{u}_{lm}\|^2_{\omega^2} \\ &+ (1+m)^{2s'}\big(\|\hat{u}_{lm}\|^2 + \|\hat{u}_{lm}\|^2_{\omega^2}\big)\Big]\Big)^{\frac{1}{2}}. \end{aligned} \tag{4.22}$$

THEOREM 4.3. *Let U and U_{MN} be the solutions of* (3.11) *and* (4.2)*, respectively. If $U \in L^2_p(S;X) \cap \mathcal{H}^{s,s'}_{p,\omega^{d-1}}(\Omega)$, with $d = 2,3$ and $s, s' \ge 1$, then we have*

$$\begin{aligned} &\|\nabla(U-U_{MN})\| + k\|U-U_{MN}\| \\ &\qquad \lesssim \Big(C_*(M,N,k;a,b,d)N^{1-s} + (1+kM^{-1})M^{1-s'}\Big)\big\|U\big\|_{\mathcal{H}^{s,s'}_{p,\omega^{d-1}}(\Omega)}, \end{aligned} \tag{4.23}$$

where

$$
\begin{aligned}
C_\star(M,N,k;a,b,d) :&= (1+M)b^{(d-1)/2} + Ma^{\frac{d-3}{2}}|I|N^{-1} \\
&\quad + k^{1/3}(Mb^{3d/2-2}\sqrt{|I|}N^{-1/2} + |I|^2 b^{d/2}k^2N^{-1}).
\end{aligned} \tag{4.24}
$$

Proof. Since the proof of $d = 2, 3$ is quite similar, we shall prove only the case $d = 2$. For notational convenience, let $E_{MN} = U - U_{MN}$ and $\hat{e}_m = \hat{u}_m - \hat{u}_m^N$. Thanks to the orthogonality of the Fourier series, we have that

$$
\begin{aligned}
\|\nabla E_{MN}\|^2 + k^2\|E_{MN}\|^2 &\lesssim \sum_{|m|=0}^{M}\Big(\|\partial_r\hat{e}_m\|_\omega^2 + m^2\|\hat{e}_m\|_{\omega^{-1}}^2 \\
&\quad + k^2\|\hat{e}_m\|_\omega^2\Big) + \sum_{|m|>M}\Big(\|\partial_r\hat{u}_m\|_\omega^2 + m^2\|\hat{u}_m\|_{\omega^{-1}}^2 + k^2\|\hat{u}_m\|_\omega^2\Big) := S_1^2 + S_2^2.
\end{aligned} \tag{4.25}
$$

Using Theorem 4.2 leads to

$$
\begin{aligned}
S_1 &\lesssim \Big(\max_{0\le|m|\le M}\{C_\star(m,\dots)\}\Big)N^{1-s}\Big(\sum_{|m|=0}^{M}|\hat{u}_m|_{B^s}^2\Big)^{\frac{1}{2}} \\
&\lesssim C_\star(M,N,k;a,b,d)N^{1-s}\big\|U\big\|_{\mathcal{H}^{s,s'}_{p,\omega}(\Omega)}.
\end{aligned} \tag{4.26}
$$

We treat S_2 as

$$
\begin{aligned}
S_2 &\lesssim M^{1-s'}\Big(\sum_{|m|>M} m^{2s'-2}\big(\|\partial_r\hat{u}_m\|_\omega^2 + m^2\|\hat{u}_m\|_{\omega^{-1}}^2\big)\Big)^{\frac{1}{2}} \\
&\quad + kM^{-s'}\Big(\sum_{|m|>M} m^{2s'}\|\hat{u}_m\|_\omega^2\Big)^{\frac{1}{2}} \\
&\lesssim \big(1 + kM^{-1}\big)M^{1-s'}\big\|U\big\|_{\mathcal{H}^{s,s'}_{p,\omega}(\Omega)}.
\end{aligned} \tag{4.27}
$$

Hence, a combination of (4.25)–(4.27) yields the desired result. ∎

5. Numerical results and discussions. We now present some numerical results to complement our error estimates for the spectral-Galerkin scheme (4.2). We consider the problem (3.1) in 2-D and take

$$
F(r,\theta) = 0, \quad \eta(\theta) = 0, \quad \xi(\theta) = H_m^{(1)}(ka)e^{im\theta}. \tag{5.1}
$$

In this case the exact solution is $U(r,\theta) = H_m^{(1)}(kr)e^{im\theta}$. Since for a given m, $e^{im\theta}$ can be exactly determined with the number of mode $M = N_\theta \ge 2m$, we will concentrate on the approximation behavior of our scheme with respect to the frequency k and the thickness of the annulus $b - a$.

In the first set of tests, we take $a = 1$ and $b = 2$. In Figure 5.1, we present the relative L^2-error versus the number of mode $N = N_r$ for a wide range of wave numbers. We note that, as soon as $N_r > k(b-a)/2$, the errors start to decay, for moderate to large wave numbers, the errors decay slowly until about $N_r \sim k(b-a)$, and finally, for $N_r > k(b-a)$, all errors converge to zero at an exponential rate.

In the second set of tests, we take $a = 1$ and $b = 1.25$. The results are plotted in Figure 5.2. We observe similar behaviors as in the first set except that now we have

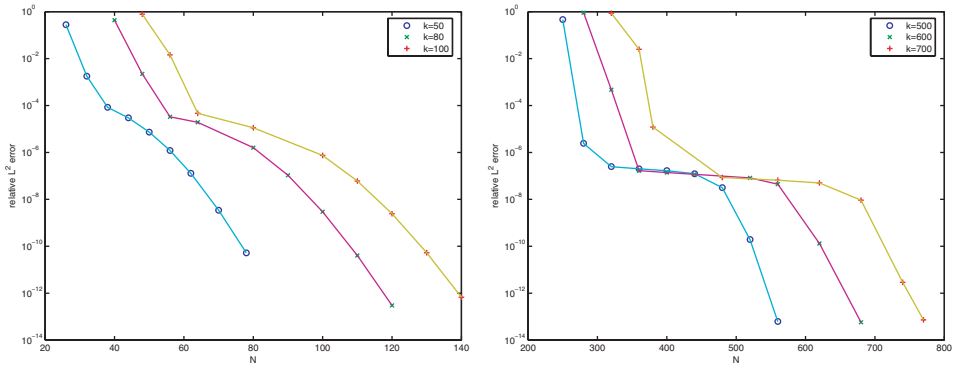

FIG. 5.1. *Relative L^2-error versus N_r as compared to an exact solution: $a = 1, b = 2$.*

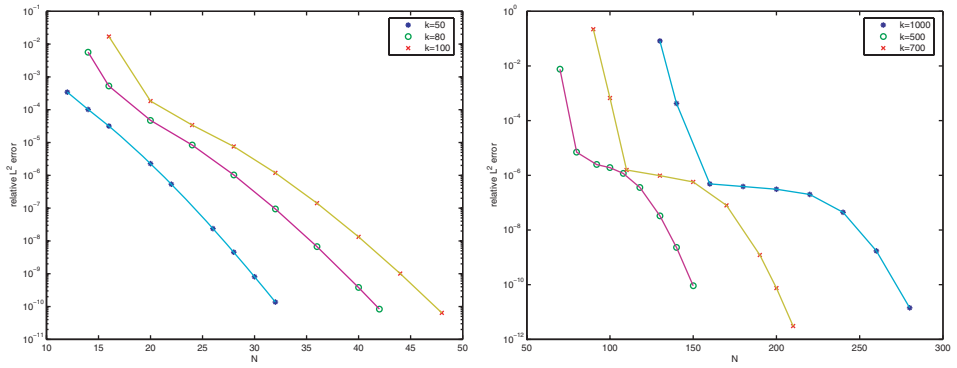

FIG. 5.2. *Relative L^2-error versus N_r as compared to an exact solution: $a = 1, b = 1.25$.*

$b - a = \frac{1}{4}$ and only about 1/4 of the modes are needed to achieve a similar accuracy. These behaviors are consistent with our error estimates (cf. Remark 4.2).

These results indicate that (i) the approximate solution U_{N_r,N_θ} will converge to the exact solution $U(r,\theta)$ exponentially fast as $N_r, N_\theta \to +\infty$ provided that all $F(r,\theta)$, $\xi(\theta)$, and $\eta(\theta)$ are analytic in Ω, and (ii) our numerical scheme is stable for large N_r and capable of providing accurate results for moderate to large wave numbers.

To summarize, we have presented a complete analysis for the spectral-Galerkin method to the Helmholtz equation in exterior domains. We first studied asymptotic behaviors of the Hankel functions which play essential roles for our error analysis. Using these asymptotic estimates, we then derived a priori estimates with explicit dependence on the wave number for both the continuous and the discrete problems. Finally, we performed an error analysis and derived error bounds with explicit dependence on the wave number. To the authors' best knowledge, our error estimates seem to be the first of their kind, i.e., with explicit dependence on the wave number for a numerical method on bounded obstacle scattering via the DtN map. A particular advantage of this approach, verified by our error estimates and numerical results, is that we can choose the artificial boundary very close to the scatterer while still maintaining the spectral accuracy.

Appendix A. The proof of (2.34). We first prove (2.34a). It is clear that, by (2.33b), $\mathrm{Im}(\mathcal{T}_{m,\kappa}) > 0$. On the other hand, since $\mathrm{Im}(\mathcal{T}_{m,\kappa})$ is a strictly increasing

(resp., decreasing) function of κ (resp., m), we have

$$\mathrm{Im}(\mathcal{T}_{m,\kappa}) \le \mathrm{Im}(\mathcal{T}_{1,\kappa}) < \mathrm{Im}(\mathcal{T}_{1,\infty}) = 1,$$

due to the asymptotic formula $|H_1^{(1)}(\kappa)|^2 \sim \frac{2}{\pi\kappa}$ for $\kappa \gg 1$ (see Formula 9.2.3 of [1]).

We now turn to the proof of (2.34b). Recall that the modified Bessel function of the second kind of order ν is defined by

$$\mathcal{K}_\nu(z) = \int_0^\infty e^{-z\cosh t}\cosh(\nu t)dt. \tag{A.1}$$

In particular, we have

$$\mathcal{K}_0(z) = \int_0^\infty e^{-z\cosh t}dt, \qquad \mathcal{K}_1(z) = -\mathcal{K}_0'(z). \tag{A.2}$$

By Formula (4) on p. 445 of [31],

$$J_m^2(\kappa) + Y_m^2(\kappa) = \frac{8}{\pi^2}\int_0^\infty \mathcal{K}_0(2\kappa\sinh t)\cosh(2mt)dt, \tag{A.3a}$$

$$\big[J_mJ_{m+1} + Y_mY_{m+1}\big](\kappa) = \frac{8}{\pi^2}\int_0^\infty \mathcal{K}_1(2\kappa\sinh t)\sinh\big((2m+1)t\big)dt. \tag{A.3b}$$

Using the identity $\mathcal{K}_1(z) = -\mathcal{K}_0'(z)$ and integration by parts leads to

$$\begin{aligned}\big[J_mJ_{m+1} + Y_mY_{m+1}\big](\kappa) &= -\frac{8}{\pi^2}\int_0^\infty \frac{\sinh\big((2m+1)t\big)}{2\kappa(\sinh t)'}d\Big(\mathcal{K}_0(2\kappa\sinh t)\Big)\\ &= -\frac{4}{\kappa\pi^2}\frac{\sinh\big((2m+1)t\big)}{\cosh t}\mathcal{K}_0(2\kappa\sinh t)\Big|_0^\infty\\ &\quad + \frac{4}{\kappa\pi^2}\int_0^\infty \mathcal{K}_0(2\kappa\sinh t)\Big(\frac{\sinh\big((2m+1)t\big)}{\cosh t}\Big)'dt\\ &= \frac{4}{\kappa\pi^2}\int_0^\infty \mathcal{K}_0(2\kappa\sinh t)\cosh(2mt)W_m(t)dt,\end{aligned}$$

where

$$W_m(t) = \frac{1}{\cosh(2mt)}\Big(\frac{\sinh\big((2m+1)t\big)}{\cosh t}\Big)'.$$

Note that in the last step we used the asymptotic formula (see Formula 9.7. 2 of [1])

$$\mathcal{K}_0(2\kappa\sinh t) \sim \sqrt{\frac{\pi}{2\kappa\sinh t}}e^{-2\kappa\sinh t} \sim e^{-\kappa e^t - t/2}, \qquad t \gg 1, \tag{A.4}$$

to claim that

$$\frac{\sinh\big((2m+1)t\big)}{\cosh t}\mathcal{K}_0(2\kappa\sinh t) \to 0 \quad \text{as } t \to \infty.$$

Using the identities of the hyperbolic functions, $W_m(t)$ can be written as

$$W_m(t) = 2m\big(1 + (\tanh t)\tanh(2mt)\big) + \mathrm{sech}^2 t, \quad 0 \le t < \infty. \tag{A.5}$$

We now seek the maximum and minimum values of $W_m(t)$. Taking the derivative of $W_m(t)$ yields

$$\begin{aligned} W_m'(t) &= 2m\big((\mathrm{sech}^2 t)\tanh(2mt) + 2m(\tanh t)\mathrm{sech}^2(2mt)\big) - 2(\tanh t)\mathrm{sech}^2 t \\ &= 2\big(m\tanh(2mt) - \tanh t\big)\mathrm{sech}^2 t + 4m^2(\tanh t)\mathrm{sech}^2(2mt). \end{aligned}$$

It is obvious that

$$m\tanh(2mt) - \tanh t > 0 \quad \forall t > 0,\ \forall m \geq 1.$$

Hence, $W_m(t)$ is an increasing function of t, and consequently,

$$2m + 1 = W_m(0) \leq W_m(t) \leq W_m(\infty) = 4m \quad \forall t \geq 0,\ \forall m \geq 1. \tag{A.6}$$

Therefore, for $m \geq 1$,

$$\frac{2m+1}{2\kappa} \leq \frac{J_m(\kappa)J_{m+1}(\kappa) + Y_m(\kappa)Y_{m+1}(\kappa)}{J_m^2(\kappa) + Y_m^2(\kappa)} \leq \frac{2m}{\kappa}, \tag{A.7}$$

which, together with (2.33a), yields the bounds

$$-\frac{m}{\kappa} \leq \mathrm{Re}(\mathcal{T}_{m,\kappa}) \leq -\frac{1}{2\kappa} \quad \text{for} \quad m \geq 1.$$

Finally, for $m = 0$, (A.5) implies that $0 < W_0(t) \leq 1$. Accordingly, we find that

$$-\frac{1}{2\kappa} \leq \mathrm{Re}(\mathcal{T}_{0,\kappa}) < 0.$$

It remains to prove (2.34c).

Let us first show that $\mathrm{Im}(\mathcal{T}_{0,\kappa})$ is a strictly decreasing function of κ. By (2.33b), it suffices to show that

$$f(x) := x|H_0^{(1)}(x)|^2 = x\big(J_0^2(x) + Y_0^2(x)\big), \quad x > 0,$$

is a strictly increasing function of x. Indeed, by (A.3a),

$$f(x) = \frac{8}{\pi^2}\int_0^\infty x\mathcal{K}_0(2x\sinh t)dt.$$

Differentiating it gives

$$f'(x) = \frac{8}{\pi^2}\int_0^\infty \big\{\mathcal{K}_0(2x\sinh t) + 2x\sinh t\ \mathcal{K}_0'(2x\sinh t)\big\}dt.$$

Integrating the second term by parts leads to

$$f'(x) = \frac{8}{\pi^2}\mathcal{K}_0(2x\sinh t)\tanh t\big|_0^\infty + \frac{8}{\pi^2}\int_0^\infty \mathcal{K}_0(2x\sinh t)\tanh^2 t dt.$$

Notice that the first term is zero due to the decay property of $\mathcal{K}_0$ (cf. (A.4)). Therefore, we have

$$f'(x) > 0 \quad \forall x > 0.$$

Finally, (2.34c) follows immediately from (2.33b) and the facts that $\mathrm{Im}(\mathcal{T}_{0,\kappa})$ is a strictly decreasing function of κ and $\kappa|H_0^{(1)}(\kappa)|^2 \to \frac{2}{\pi}$ as $\kappa \to \infty$.

This ends the proof of (2.34). ∎

FAST SEMI-LAGRANGIAN SCHEMES FOR THE EIKONAL EQUATION AND APPLICATIONS*

EMILIANO CRISTIANI† AND MAURIZIO FALCONE‡

Abstract. We introduce and analyze a fast version of the semi-Lagrangian algorithm for front propagation originally proposed in [M. Falcone, "The minimum time problem and its applications to front propagation," in *Motion by Mean Curvature and Related Topics*, A. Visintin and G. Buttazzo, eds., de Gruyter, Berlin, 1994, pp. 70–88]. The new algorithm is obtained using the local definition of the approximate solution typical of semi-Lagrangian schemes and redefining the set of "neighboring nodes" necessary for fast marching schemes. A new proof of convergence is needed since that definition produces a new *narrow band* centered at the interphase which is larger than the one used in fast marching methods based on finite differences. We show that the new algorithm converges to the viscosity solution of the problem and that its complexity is $O(N \log N_{nb})$, as it is for the fast marching method based on finite difference (N and N_{nb} being, respectively, the total number of nodes and the number of nodes in the *narrow band*). A new sufficient condition for the convergence of the standard finite difference fast marching method is also given. We present several tests comparing the two algorithms and other fast methods (e.g., fast sweeping) on a series of benchmarks which include the minimum time problem and the shape-from-shading problem.

Key words. front propagation, eikonal equation, semi-Lagrangian schemes, finite differences, fast marching methods

1. Introduction.

The level set method is a clever and rather simple way to describe an interface separating two or more regions with different physical phases. As is well known, the method describes the evolution of the front by a continuous representation function $u(x,t)$ which is negative in the domain Ω_t corresponding to one of the phases, positive outside that domain, and changes sign across the interfaces. A comprehensive introduction to the level set method as well as to several applications and references can be found in [19] and [32].

The level set method leads to a nonlinear first order PDE whenever the interface evolution is simply driven by a normal velocity and (possibly) a given advection term. More complicated types of evolution consider the normal velocity as a function of the curvature and/or of other geometric parameters of the interface, and this leads to second order nonlinear PDEs (or integrodifferential equations).

The typical model problem for an interface which evolves in the normal direction driven by a given scalar velocity $c(x) : \mathbb{R}^n \to \mathbb{R}$ leads to the first order Hamilton–Jacobi equation

$$\begin{cases} u_t(x,t) + c(x)|\nabla u(x,t)| = 0 & \text{for } x \in \mathbb{R}^n\,, \quad t \in (0,+\infty), \\ u(x,0) = u_0(x) & \text{for } x \in \mathbb{R}^n, \end{cases} \tag{1}$$

where the initial condition u_0 must be a representation function of the initial position of the front $\Gamma_0 = \partial\Omega_0$. Note that u_0 is unknown since Γ_0 is the only initial datum, so that the first step is usually to compute u_0. The above problem can be simplified when the evolution is monotone (increasing or decreasing), i.e., when either $\Omega_t \subset \Omega_{t+s}$ or the reverse inclusion are satisfied for any $t, s > 0$. For monotone types of evolution, it has been proved in [17] (see also [26]) that (1) can be replaced by the stationary equation

$$\begin{cases} c(x)|\nabla T(x)| = 1 & \text{for } x \in \mathbb{R}^n \backslash \Omega_0, \\ T(x) = 0 & \text{for } x \in \partial\Omega_0, \end{cases} \tag{2}$$

where we assume

$$c > 0 \tag{3}$$

and T represents the time needed to transfer a point $x \in \mathbb{R}^n \backslash \Omega_0$ to Ω_0 by appropriate dynamics (see below). In fact, the link between the two equations is simple: if T is the viscosity solution of (2), then $u(x,t) = T(x) - t$ is the viscosity solution of (1). It is worth noting that the second problem is easier to solve since it does not require the additional computation of u_0, which requires the solution of another Hamilton–Jacobi equation of type (2) to compute the (signed) distance function to Ω_0. Moreover, the knowledge of T gives a description of the interface for every time t using the fact that $\Gamma_t = \partial\Omega_t = \{x \in \mathbb{R}^n : T(x) = t\}$. On the other hand, (1) is preferable to its stationary version whenever it is needed to derive a high order scheme that has the same efficiency as the formally first order one (see, e.g., [1]). However, some results on high order methods for stationary first order Hamilton–Jacobi equations including (2) are available, e.g., in [15].

Note that the above stationary approach relies on the link between the propagations of fronts and the minimum time problem of control theory. In fact, as shown in [17], by the change of variable (Kružkov transform)

$$v(x) = 1 - e^{-T(x)} \tag{4}$$

we can transform (2) into the equation

$$\begin{cases} v(x) + \max\limits_{a \in B(0,1)} \{c(x)a \cdot \nabla v(x)\} = 1 & \text{for } x \in \mathbb{R}^n \backslash \Omega_0, \\ v(x) = 0 & \text{for } x \in \partial\Omega_0, \end{cases} \tag{5}$$

where $B(0,1)$ is the unit ball centered in 0. This is the Hamilton–Jacobi–Bellman equation of a minimum time problem for the dynamics

$$\begin{cases} \dot{y}(t) = -c(y)\alpha(t), & t \in (0, +\infty), \\ y(0) = x, \end{cases} \tag{6}$$

where $\alpha(\cdot) \in \mathcal{A} = \big\{\alpha(\cdot) : [0, +\infty) \to B(0,1) \subset \mathbb{R}^n, \text{ measurable}\big\}$. We will denote by $y(t; \alpha, x)$ the solution of the system corresponding to the control α and to the initial condition x. The usual requirement in order to have existence and uniqueness for the trajectories under the Carathéodory conditions is

$$c(x) \text{ Lipschitz continuous and bounded.} \tag{7}$$

Let us define the cost functional

$$J_x(\alpha(\cdot)) = \inf\left\{t : y(t;\alpha,x) \in \Omega_0\right\} \leq +\infty.$$

It is well known that the minimum time function

$$T(x) = \inf_{\alpha(\cdot)\in\mathcal{A}} J_x(\alpha(\cdot)) \tag{8}$$

is the unique viscosity solution of (2) (see, e.g., [2, 4]).

We will focus our attention on the numerical solution of (2). It should be noted that a fast marching method has a lower cost with respect to the corresponding classical iterative method (or fixed point method), which computes the solution on the whole grid at every iteration. The classical fast marching method based on finite differences (FM-FD) was proposed in [33] as an acceleration method for a monotone first order iterative finite difference scheme (see [7] for a second order version of the scheme and [8] for a general convergence result). Since semi-Lagrangian schemes have shown to be more accurate than the finite difference schemes corresponding to the same order, it is natural to extend the ideas behind the FM-FD method to this class of schemes. In the framework of semi-Lagrangian schemes several convergence results and a priori error estimates have been obtained via control arguments since these schemes correspond to a discrete version of the dynamic programming principle; see [2] and [13]. Moreover, these schemes do not require an explicit and restrictive CFL condition for stability (see [16]). It is interesting to note that the first tentative steps in this direction can be found in [38] using a different approximation scheme. More recently, a semi-Lagrangian scheme has been proposed by Sethian and Vladimirsky in [34] in a more general framework which includes anisotropic front propagation on unstructured grids.

Our main contribution here is to introduce and analyze a new fast marching version of a semi-Lagrangian scheme, for which a priori error estimates are available in [12], and to prove an upper bound on its computational cost. We will also review the basic features of the FM-FD method and give a complete proof of its convergence under an explicit CFL condition which guarantees that the scheme is always meaningful and there are no complex solutions. To our knowledge this condition appears for the first time in the literature; our proof is presented in the appendix. Lastly we will recall the fast sweeping method studied by Zhao [39] (see also [37, 20, 21, 27, 28] for other sweeping methods and extensions) and also provide a sweeping version of our algorithm. Further extensions and new applications of the scheme presented in this paper can be found in [9].

The paper is organized as follows. In section 2 we recall the basic features of the FM-FD method introduced in [33] to solve (2) when $c(x)$ has a constant sign in its domain of definition. An example which shows that the FM-FD scheme can produce complex solutions is given in the same section, and the proof of convergence under a new CFL condition which always guarantees real solutions is presented in the appendix. Section 3 is devoted to the presentation of the fast marching semi-Lagrangian method (FM-SL) for (5). Section 4 contains some properties of the FM-SL scheme that will be useful in establishing its convergence, which will be proved in section 5. In the same section we analyze the computational complexity, showing that the FM-SL scheme has a complexity of order $O(N\ln(N_{nb}))$, where N is the total number of nodes of our computational grid and N_{nb} is the number of nodes in the *narrow band* (bounded by N). In section 6 we also present other fast algorithms and

give the sweeping version of our method. Finally, section 7 is devoted to numerical tests and to comparisons between several FM schemes on a number of benchmarks.

2. The fast marching methods based on finite differences. The fast marching method has been introduced to reduce the computational effort needed to solve (2). The basic level set algorithm is based on a finite difference discretization and on an iterative procedure $T^{n+1} = F(T^n)$ which computes the approximate solution everywhere in $\mathbb{R}^n \setminus \Omega_0$ at every iteration. The FM-FD method instead follows the front concentrating the computational effort where it is needed, i.e., in a small neighborhood of the front, and it updates that neighborhood at every iteration to avoid useless computations. This is done by dividing the grid nodes into three subsets: *far* nodes, *accepted* nodes, and *narrow band* nodes. The narrow band nodes are the nodes where the computation actually takes place and their value can still change at the following iterations. The accepted nodes are those where the solution has been already computed and where the value cannot change in the following iterations. Finally, the far nodes are the remaining nodes where an approximate solution has never been computed. In physical terms, the far nodes are those in the space region which has never been touched by the front, the accepted nodes are those where the front has already passed through, and the narrow band nodes are, iteration by iteration, those lying in a neighborhood of the front.

The algorithm starts labeling as *accepted* only the nodes belonging to the initial front, i.e., belonging to $\Gamma_0 = \partial\Omega_0$, and ends only when all the nodes have been accepted. In this section, we will briefly sketch the FM-FD scheme for (2). In order to avoid cumbersome notation we will restrict the presentation to the case $n = 2$. In what follows, we will always consider the case of a positive normal velocity; i.e., we assume $c(x) > 0$ to guarantee a monotone (increasing) evolution of the front. The results in this section can be easily generalized to the n-dimensional case and to the case $c(x) < 0$.

We will take a square Q large enough to contain Ω_0; this is the domain where we want to compute T. Boundary conditions will be given on ∂Q and Γ_0 but, as a first step, we will consider the algorithm *without* boundary conditions on ∂Q. The implementation of boundary conditions in the scheme will be discussed in section 5.

We will assume that we are working on a structured grid of $M \times N$ nodes (x_i, y_j), $i = 1, \ldots, N$ and $j = 1, \ldots, M$. Δx and Δy will denote the (uniform) discretization steps, respectively, on the x and y axes. We will denote by $T_{i,j}$ and $c_{i,j}$, respectively, the values of T and c at (x_i, y_j).

Let us write (2) as

$$T_x^2 + T_y^2 = \frac{1}{c^2(x,y)}. \tag{9}$$

We replace the partial derivatives T_x and T_y by first order finite differences, and we choose for simplicity $M = N$ and $\Delta x = \Delta y$. It is well known that in order to obtain an approximation of the viscosity solution, an *up-wind* correction must be introduced. This leads to the equation

$$\begin{aligned} &\left(\max\left\{ \max\left\{ \frac{T_{i,j} - T_{i-1,j}}{\Delta x}, 0 \right\}, -\min\left\{ \frac{T_{i+1,j} - T_{i,j}}{\Delta x}, 0 \right\} \right\} \right)^2 \\ &+ \left(\max\left\{ \max\left\{ \frac{T_{i,j} - T_{i,j-1}}{\Delta x}, 0 \right\}, -\min\left\{ \frac{T_{i,j+1} - T_{i,j}}{\Delta x}, 0 \right\} \right\} \right)^2 = \frac{1}{c_{i,j}^2}. \end{aligned} \tag{10}$$

2.1. The FM-FD algorithm. Let us briefly recall the main definitions and steps of the FM-FD method.

DEFINITION 2.1 (neighboring nodes for the finite difference scheme). *Let* $X = (x_i, y_j)$ *be a node. We define the set of neighboring nodes to* X *as*

$$N_{FD}(X) = \Big\{(x_{i+1}, y_j), (x_{i-1}, y_j), (x_i, y_{j+1}), (x_i, y_{j-1})\Big\}.$$

These are the nodes appearing in the stencil of the first order finite difference discretization. The definition can be easily extended to the n-dimensional case.

Sketch of the FM-FD algorithm.

Initialization.

1. The nodes belonging to the initial front Γ_0 are located and labeled as *accepted*. Their value is set to $T = 0$ (they form the set $\widetilde{\Gamma}_0$).
2. The initial narrow band is defined taking the nodes belonging to $N_{FD}(\widetilde{\Gamma}_0)$, external to Γ_0. These nodes are labeled as *narrow band*, setting the value to $T = \frac{\Delta x}{c}$.
3. The remaining nodes are labeled as *far*, and their value is set to $T = +\infty$ (in practice, the maximum floating point number).

Main cycle.

1. Among all the nodes in the narrow band we search for the minimum value of T. Let us denote this node by A.
2. A is labeled as *accepted* and is removed from the *narrow band*.
3. The nodes in $N_{FD}(A)$ which are not accepted are labeled as *active*. If among these nodes there are nodes labeled as *far*, they are transferred to the narrow band.
4. The value of T in the active nodes is computed (or recomputed), solving the second order equation (10) and taking the largest root.
5. If the narrow band is not empty, go back to 1.

Note that the narrow band is a reasonable approximation of the level set of $T(x, y)$.

The main interest in the FM-FD method is that its computational cost is bounded. In fact, every node cannot be accepted more than one time and every node has just four neighbors, so the bound on the maximum number of times a single node can be recomputed is four. This corresponds to a computational cost of $O(N)$, where N is the total number of nodes. We should add to that cost the search for the minimum value of T among the nodes in the narrow band, which costs $O(\ln(N_{nb}))$, where N_{nb} is the number of nodes in the narrow band. In conclusion, the algorithm has a global cost of $O(N \ln(N_{nb}))$ operations (see [38, 32, 33] for further details on the computational cost). This is not the case for the usual iterative/fixed point algorithm since in that case the approximate solution is obtained in the limit and, in practice, no one knows when the stopping criterion will apply; i.e., the maximum number of iterations is virtually unbounded.

Let us observe that it is necessary to introduce some conditions or to modify the scheme in order to avoid inconsistencies due to the appearance of imaginary solutions. In fact, let us consider the discretization (10) and suppose that

$$T_{i,j} < T_{i+1,j}, \qquad T_{i,j} < T_{i,j-1}, \qquad T_{i,j} > T_{i-1,j}, \qquad T_{i,j} > T_{i,j+1}.$$

It is easy to check that (10) corresponds to

$$\left(\frac{T_{i,j} - T_{i-1,j}}{\Delta x}\right)^2 + \left(\frac{T_{i,j+1} - T_{i,j}}{\Delta x}\right)^2 = \frac{1}{c_{i,j}^2},$$

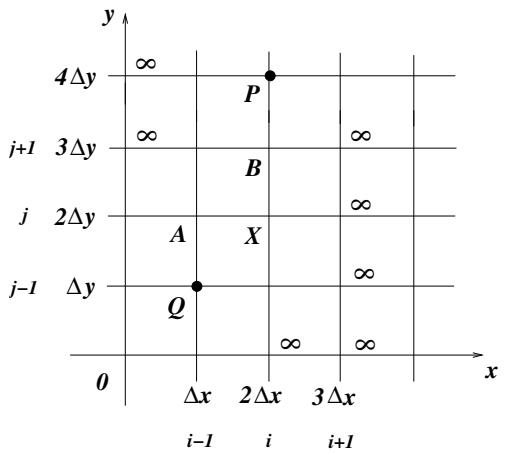

FIG. 1. *A configuration with complex roots.*

which gives

$$T_{i,j} = \frac{T_{i-1,j} + T_{i,j+1} \pm \sqrt{2\left(\frac{\Delta x}{c_{i,j}}\right)^2 - (T_{i-1,j} - T_{i,j+1})^2}}{2}. \tag{11}$$

We already noted that the term under the square root can be negative. Obviously this must be avoided since complex roots have no physical meaning. A situation where this occurs is the following example.

Consider the case where the initial front is the union of two points, i.e., $\Gamma_0 = P \cup Q$, $Q = (\Delta x, \Delta y)$ and $P = (2\Delta x, 4\Delta y)$ (see Figure 1). Let us consider the following velocity:

$$c(x,y) = \begin{cases} \varepsilon, & y \le \Delta y, \\ \varepsilon + \frac{1-\varepsilon}{\Delta y}(y - \Delta y), & \Delta y \le y \le 2\Delta y, \\ 1 - \frac{1-\varepsilon}{\Delta y}(y - 2\Delta y), & 2\Delta y \le y \le 3\Delta y, \\ \varepsilon, & y \ge 3\Delta y. \end{cases} \tag{12}$$

In this case the algorithm initializes the narrow band, computing a large value for B when ε is small and a small value for the node A which will be the first node accepted (after Γ_0). When the node X has to be computed, its value depends on $T(A)$ and $T(B)$. Since $c(X) = 1$ and $T(A) - T(B)$ is large (for ε small) the radicand in (11) will be negative (as numerical tests confirm).

This difficulty can be solved by either choosing the positive part of the radicand (as suggested in [22]) or changing discretization, as in [39]. However, both choices lead to a modification of the scheme, which can be difficult to handle when looking for theoretical results. We prefer to avoid changing the scheme, and we prove that under the CFL-like condition

$$\Delta x \le (\sqrt{2} - 1)\frac{c_{min}}{L_c} \tag{13}$$

the algorithm always computes *real* solutions at every node (here c_{min} is the minimum value of c, L_c is its Lipschitz constant, and again $\Delta x = \Delta y$). Condition (13) has a

clear meaning and allows us to give a proof of convergence to the viscosity solution. To our knowledge this is the first time this condition appears in the literature; a complete proof of the convergence result (Proposition 2.1) will be given in the appendix.

Let us denote by A the node in the narrow band where the minimum value of T is attained. The algorithm labels A as *accepted* and starts to compute the neighboring nodes which are not accepted.

PROPOSITION 2.1. *Let $X = (x_i, y_j) \in N_{FD}(A)$ be the node where the FM-FD method computes a solution. Let us assume that*

$$c_{min} = \min_{Q\setminus\Omega_0} c(x) > 0 \tag{14}$$

and that the following CFL-like condition holds true:

$$\Delta x \leq (\sqrt{2}-1)\frac{c_{min}}{L_c}, \tag{15}$$

where L_c denotes the Lipschitz constant of c. Then we have

$$T(A) \leq T(X) \leq T(A) + f_X, \tag{16}$$

where $f_X := \Delta x/c(X)$.

The above result is crucial in order to obtain convergence in a finite number of steps. In fact, it shows that the minimum value of the nodes in the narrow band (which is actually the only value accepted at every iteration) is exact within the consistency error of the scheme. An approximate value is considered to be exact if the algorithm cannot replace it with a strictly lower value at any of the following iterations.

3. The fast marching method based on the semi-Lagrangian scheme. We will study a fast marching version of the semi-Lagrangian scheme studied in [12] under the assumptions (3) and (7) that we will keep here. It was proved in [3] that the numerical scheme stems from a discrete version of the dynamic programming principle applied to (6); this leads to the equation

$$\begin{cases} w(x) = \min\limits_{a\in B(0,1)} \{\beta w(x - hc(x)a)\} + 1 - \beta & \text{for } x \in \mathbb{R}^n\setminus\Omega_0, \\ w(x) = 0 & \text{for } x \in \partial\Omega_0, \end{cases} \tag{17}$$

where $\beta = e^{-h}$, h is the time step for the (hidden) dynamics, and w is an approximation of v. We will consider for simplicity a structured grid G, denoting its nodes by x_i, $i = 1, \ldots, N$, i.e., $G = \{x_i,\ i = 1, \ldots, N\}$. Note that the same scheme can be implemented on an unstructured grid as in [31]. We write (17) at every node, obtaining

$$\begin{cases} w(x_i) = \min\limits_{a\in B(0,1)} \{\beta w(x_i - hc(x_i)a)\} + 1 - \beta & \text{for } x_i \in G\setminus\Omega_0, \\ w(x_i) = 0 & \text{for } x_i \in G \cap \Omega_0, \end{cases} \tag{18}$$

where we defined $w = 0$ also in the internal nodes of Γ_0. It has been shown in [12] that under our assumptions (3) and (7), equation (18) has a unique solution w in the class of piecewise linear functions ($\mathbb{P}_1$ in the finite element notation) defined on the grid. Let us note that by applying the Kružkov transform (4) to the equation, one can also treat the case when $c = 0$ since in that case the minimum time function to

the target (i.e., the initial configuration of the front in the front propagation problem) will have infinite value at some points, whereas v will always stay bounded by 1. This allows us to run the computations also for $c = 0$ and to treat problems with state constraints (as we will see in the last section).

We will always approximate the v variable and use the fact that the Kružkov transform is monotone. In fact, since $T_1 > T_2$ if and only if $v_1 > v_2$ we can work on the v variable without changing the rules for the update of the narrow band because the crucial point is to label as *accepted* the node in the narrow band, where T (or v) attains its minimum. The above rule guarantees that we will process the nodes in an ordering which corresponds to increasing values of v.

The idea which is behind the FM-SL method is rather simple: we follow the initialization and all the steps of the classical FM-FD method except the step where the value at the node x_i is actually computed. That step would require us to iterate until convergence the scheme

$$w(x_i) = \min_{a \in B(0,1)} \{\beta w(x_i - hc(x_i)a)\} + 1 - \beta, \tag{19}$$

so that the typical fixed point iteration is applied "locally" at every single node following the order indicated by the FM-FD method. We will prove that for a semi-Lagrangian scheme based on a piecewise linear space reconstruction, just a single iteration is needed to compute the exact (within the accuracy of the scheme) value at every node so that the computational effort is very limited and of the same order as the FM-FD method.

3.1. Fast minimum search in $B(0,1)$. We will start improving the minimum search which is typical of the semi-Lagrangian schemes. The search for a minimum in the unit ball $B(0,1)$ will be solved algebraically for a linear interpolation, which allows us to compute the values $w(x_i - hc(x_i)a)$ using the known values at the nodes. Clearly, a new algebraic solution must be obtained (if possible) for other high order interpolations. Let us just recall that for the standard semi-Lagrangian scheme the search for the minimum is usually restricted to a discretization of the unit ball $B(0,1)$ which takes into account r points (or *controls* in the minimum time terminology) $a_1, a_2, \ldots, a_k, \ldots, a_r \in B(0,1)$.

For example, one can construct a uniform grid on $\partial B(0,1)$ with step $\Delta\theta = 2\pi/r$. To find the minimum, for every a_k the value $w(x_i - hc(x_i)a_k)$ is actually computed by interpolation. Although the choice of the type and order of the interpolation is completely free, the most popular choices are *linear*, using the three values at the nodes which are closer to $x_i - hc(x_i)a_k$, and *bilinear*, using the four values of w at the vertices of the cell containing $x_i - hc(x_i)a_k$.

Once all the values for a_k, $k = 1, \ldots, r$, are computed the minimum is obtained by comparison. It is worth noting that this algorithm is quite slow and requires a high computational cost; however, it can be applied to every high order interpolation. Moreover, it should be noted that this minimization problem is quite difficult since we expect to have nondifferentiable or even discontinuous solutions (if state constraints/obstacles are present in the domain) and that the comparison algorithm is very simple to implement and reasonably fast in low dimension especially when the search for the minimum can be restricted to the boundary of $B(0,1)$ (as will be the case in many examples). However, other algorithms for the minimization of nonsmooth functions can be applied, and the interested reader can find in [6] and [14] recent improvements on the solution of this problem. These algorithms converge to

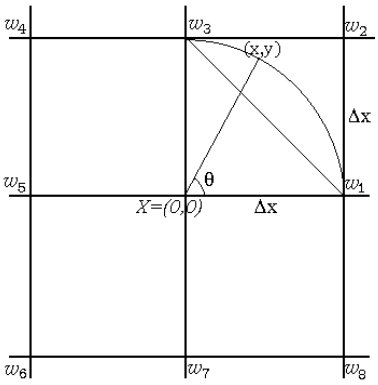

FIG. 2. *Search for optimal control.*

the minimum in the limit, so they cannot be applied here since we want to have an exact evaluation of the computational cost.

It is important to note that the time step h in (19) can vary at every node. We will denote by $h_i = h(x_i)$ the time step corresponding to the node x_i, by $c_i = c(x_i)$ the velocity at x_i, and by $\beta_i = e^{-h_i}$. When $c_i > 0$ it is always possible to choose

$$h_i = \frac{\Delta x}{c_i}. \tag{20}$$

In this way (19) can be written as

$$w(x_i) = \min_{a \in B(0,1)} \{\beta_i w(x_i - \Delta x\ a)\} + 1 - \beta_i. \tag{21}$$

In this situation, the nodes where $c_i = 0$ are actually treated apart from the other nodes: we just assign them the value $w = 1$ (which corresponds to $T = +\infty$) without any additional computation.

The method we propose here for the minimization problem has a low dimensional cost since for linear interpolation the search is restricted to the boundary of the unit ball. This is not a real restriction since, for our applications, the minimum in the unit ball is attained at the boundary. Later in this section we will show how this algorithm can be applied as a building block of our FM-SL scheme.

For simplicity, let us examine the situation in $\mathbb{R}^2$ considering a set of four cells each of side length Δx centered at the origin (see Figure 2). We want to compute the minimum of the function $w((0,0) - \Delta x\ a)$ for $a = (\cos\theta, \sin\theta)$ and $\theta \in [0, 2\pi)$. Let us introduce a vector $\mathbf{m} = (m_1, m_2, \ldots, m_8)$; the values of its components will be defined below. The minimum value for which we search will be given by $p = \min\{m_1, m_2, \ldots, m_8\}$.

Let us define the first four components of $\mathbf{m}$,

$$m_1 = w(\Delta x, 0)\,, \quad m_2 = w(0, \Delta x)\,, \quad m_3 = w(-\Delta x, 0)\,, \quad m_4 = w(0, -\Delta x),$$

and let us search for the minimum in every orthant.

Orthant I. Let w_1, w_2, and w_3 be the values of w corresponding, respectively, to the nodes $(\Delta x, 0)$, $(\Delta x, \Delta x)$, and $(0, \Delta x)$. The unique linear function $f(x, y)$ satisfying the conditions

$$f(\Delta x, 0) = w_1\,, \quad f(\Delta x, \Delta x) = w_2\,, \quad f(0, \Delta x) = w_3$$

is

$$f(x,y) = ax + by + c, \tag{22}$$

where

$$a = \left(\frac{w_2 - w_3}{\Delta x}\right), \qquad b = \left(\frac{w_2 - w_1}{\Delta x}\right), \qquad c = w_1 - w_2 + w_3.$$

Let us define the real function

$$F(\theta) = f(\Delta x \cos\theta, \Delta x \sin\theta) = a\Delta x \cos\theta + b\Delta x \sin\theta + c\,, \quad \theta \in [0, 2\pi) \tag{23}$$

and look for the minimum of $F(\theta)$ in the interval $(0, \pi/2)$. Note that the extreme values $\theta = 0$ and $\theta = \pi/2$ are not included since the values at the extrema of that interval have already been included in $\mathbf{m}$ (they are m_1 and m_2). By differentiating with respect to θ we obtain

$$F'(\theta) = 0 \Leftrightarrow \theta = \arctan(b/a).$$

The interesting case is when $w_2 < w_1$ and $w_2 < w_3$; otherwise the minimum is w_1 or w_3.

In this case, we get

$$a \neq 0\,, \quad b \neq 0\,, \quad b/a > 0\,, \quad \arctan(b/a) \in (0, \pi/2),$$

which means that the relative minimum is at $\theta_1^* = \arctan(b/a)$ and we set $m_5 = F(\theta_1^*)$.

If $w_2 \geq w_1$ or $w_2 \geq w_3$, we set $m_5 = +\infty$ (or the highest machine number).

Orthant II. Let w_3, w_4, and w_5 be the values of w, respectively, at the nodes $(0, \Delta x)$, $(-\Delta x, \Delta x)$, and $(-\Delta x, 0)$. The unique linear function $f(x, y)$ such that

$$f(0, \Delta x) = w_3\,, \quad f(-\Delta x, \Delta x) = w_4\,, \quad f(-\Delta x, 0) = w_5$$

is

$$f(x,y) = ax + by + c,$$

where

$$a = \left(\frac{w_3 - w_4}{\Delta x}\right), \qquad b = \left(\frac{w_4 - w_5}{\Delta x}\right), \qquad c = w_3 - w_4 + w_5.$$

Again we will consider the composite function $F(\theta)$ defined in (23), and we observe that it has a relative minimum in $(\pi/2, \pi)$ if and only if $w_4 < w_3$ and $w_4 < w_5$. In this case we have

$$a \neq 0\,, \quad b \neq 0\,, \quad b/a < 0\,, \quad \arctan(b/a) \in (-\pi/2, 0). \tag{24}$$

Since we are in the second orthant the value of θ where the minimum for F is attained is $\theta_2^* = \arctan(b/a) + \pi$. Proceeding as in the first orthant we set $m_6 = F(\theta_2^*)$.

If $w_4 \geq w_3$ or $w_4 \geq w_5$, we set $m_6 = +\infty$.

The analysis of the third and fourth orthants follows in the same way and will be skipped.

Once all the components of $\mathbf{m}$ have been set, we just compute $p = \min\{m_1, m_2, \ldots, m_8\}$ and substitute it in the expression

$$w(0,0) = \beta p + 1 - \beta. \tag{25}$$

This is done at every fixed point iteration until convergence. It is important to note that the above linear interpolation has a great advantage: the computation of the correct value of $w(0,0)$ does not require more than one iteration given the values at the neighboring nodes (along the axis directions and the diagonals) since $F(\theta)$ will not depend on $w(0,0)$. This property will *not* hold for other high-order interpolations, e.g., quadratic interpolation. Another advantage of linear interpolation with respect to the comparison of the values in a discrete unit ball is that it gives the exact value of the optimal direction at the cost corresponding to a discretization of $B(0,1)$ by just 8 directions.

3.2. The FM-SL scheme. This section is devoted to the presentation of the fast marching version of the SL-algorithm. For simplicity the presentation is given in $\mathbb{R}^2$, but the algorithm can be easily extended to $\mathbb{R}^n$. Let us start introducing the following definitions.

DEFINITION 3.1 (neighboring nodes for the SL scheme). *Let $X = (x_i, y_j)$ be a node of the grid. We define*

$$N_{FD}(X) = \Big\{(x_i, y_{j+1}), (x_i, y_{j-1}), (x_{i-1}, y_j), (x_{i+1}, y_j)\Big\},$$

$$D(X) = \Big\{(x_{i+1}, y_{j+1}), (x_{i+1}, y_{j-1}), (x_{i-1}, y_{j+1}), (x_{i-1}, y_{j-1})\Big\},$$

$$N_{SL}(X) = N_{FD}(X) \cup D(X).$$

The above definition is a natural extension of Definition 2.1 for the semi-Lagrangian scheme. According to the new definition, the nodes in the narrow band will also include the diagonal directions and not only the four directions N, S, E, W, as in the FM-FD method of section 2.

Sketch of the FM-SL algorithm.

Initialization (see Figure 3).

1. The nodes belonging to the initial front Γ_0 are located and labeled as *accepted*. Their value is set to $w = 0$. We will denote this set of nodes by $\widetilde{\Gamma}_0$.
2. The initial narrow band is defined according to the Definition 3.1, taking the nodes belonging to $N_{SL}(\widetilde{\Gamma}_0)$ external to Γ_0. These nodes are labeled as *narrow band*. Their value is set to $w = 1 - e^{-\frac{\Delta x}{c}}$ (which corresponds to $T = \Delta x/c$) if they belong to $N_{FD}(\widetilde{\Gamma}_0)$, or to $w = 1 - e^{-\frac{\sqrt{2}\Delta x}{c}}$ (which corresponds to $T = \sqrt{2}\Delta x/c$) if they belong to $D(\widetilde{\Gamma}_0)$.
3. We label as *far* all the remaining nodes of the grid; their value is set to $w = 1$ (which corresponds to the value $T = +\infty$).

Main cycle.

1. Among all the nodes in the narrow band we search for the minimum value of w. Let us denote this node by A.
2. The node A is labeled as *accepted* and is removed from the narrow band.
3. We label as *active* the nodes in $N_{SL}(A)$ which are not accepted. If there are far nodes, they are moved into the narrow band.

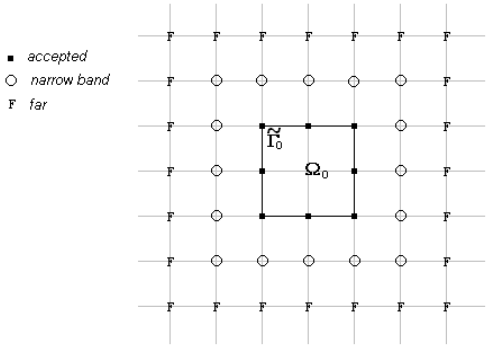

FIG. 3. *Initialization for FM-SL method, case* $c > 0$.

4. We compute (or recompute) the value w at the nodes belonging to $N_{FD}(A)$ which are active, iterating the fixed point operator

$$w(x_i) = \min_{a \in B(0,1)} \{\beta_i w(x_i - h_i c_i a)\} + 1 - \beta_i \,, \tag{26}$$

where $h_i c_i = \Delta x$. Note that just one iteration is needed, as we will see in the following sections. Then we compute by the same formula the value at the remaining active nodes in $N_{SL}(A) \setminus N_{FD}(A)$.
5. If the narrow band is empty, the algorithm stops; otherwise it goes back to step 1.

Although the algorithm advances the narrow band also in the diagonal directions, according to the new definition, it computes first the values at the neighboring nodes in the directions N, S, E, W (i.e., the finite difference directions) and then passes to the diagonal directions.

Some extensions: Obstacles, infinite velocity. We have seen that one can use our algorithm to deal with a front propagation with obstacles, i.e., regions where c vanishes. In [36, 18] the problem has been analyzed and several tests have been presented for a semi-Lagrangian method based on the linear interpolation, which treats the obstacle in a very simple way. The algorithm just assigns to the nodes belonging to an obstacle the value $w = 1$ in order to impose (indirectly and easily) a state constraints boundary conditions. In order to use the fast marching technique we just have to be careful and distinguish between nodes initialized to the value $w = 1$ because they are far and the ones to which was assigned the value $w = 1$ because they belong to an obstacle. In section 7 (Test 5) we will show a front propagating in the presence of obstacles.

Another interesting extension for applications to image processing is when the domain of computation contains points with infinite velocity. This is the case, for example, in the shape-from-shading problem when we have a point of maximal light intensity in the image (see, e.g., [29, 24]). Let us illustrate the idea which is behind our solution. Let x_{i_0} be a node such that

$$\lim_{x \to x_{i_0}} c(x) = +\infty.$$

Our equation $c(x)|\nabla T(x)| = 1$ can be written as

$$|\nabla T(x)| = g(x), \tag{27}$$

where $g(x) = 1/c(x)$. Clearly, (27) is a degenerate eikonal equation since g vanishes at x_{i_0}.

In order to compute $w(x_{i_0})$, we can set, according to (20), $h_{i_0} = 0$ and $\beta_{i_0} = 1$ and proceed as before, setting in (26)

$$h_{i_0} c_{i_0} = \Delta x. \tag{28}$$

Let us extend the function $h(x)$ outside the nodes in the domain $Q\backslash\Omega_0$. Our choice (28) can be justified by the fact that we would expect in our algorithm

$$\lim_{x\to x_{i_0}} c(x) = +\infty\,, \quad \lim_{x\to x_{i_0}} h(x) = 0, \quad \text{and} \quad \lim_{x\to x_{i_0}} c(x)h(x) = \Delta x.$$

Note that even if this argument is heuristic, it assigns to the node x_{i_0} the exact value for w. In fact, by (26), we get

$$w(x_{i_0}) = \min_{a\in B(0,1)} \{1w(x_{i_0} - \Delta x\ a)\} + 1 - 1 = w(x_{i_0} - \Delta x a^*),$$

where a^* is the *optimal control*. Since the front has an infinite velocity at x_{i_0} the minimum time of arrival on it coincides with the minimum time of arrival on the circle of radius Δx centered at x_{i_0}. In section 7 (Tests 6 and 7) we will show an application to a front propagation problem and to the shape-from-shading problem. It is interesting to note that theoretical results on discontinuous Hamiltonians can be found in [35] and [5].

4. Properties of the FM-SL scheme. We start with the following easy result on the semi-Lagrangian discretization.

PROPOSITION 4.1. *Let X be a node and assume that $w(X)$, defined by* (26), *is computed by interpolation using the three values $w^{(1)}$, $w^{(2)}$, $w^{(3)}$. Then*

$$w(X) \geq \min\left\{w^{(1)}, w^{(2)}, w^{(3)}\right\}. \tag{29}$$

Proof. Let $\beta = e^{-h}$, $h > 0$, and a^* be the optimal direction/control at X. The inequality

$$\beta w(X - h_i c_i a^*) + 1 - \beta \geq w(X - h_i c_i a^*)$$

is satisfied if and only if $w(X - h_i c_i a^*) \leq 1$. Since w is always less than or equal to 1 (due to the Kružkov transform) we have proved that

$$w(X) \geq w(X - h_i c_i a^*). \tag{30}$$

Since a simple property of linear interpolation guarantees that

$$\max\left\{w^{(1)}, w^{(2)}, w^{(3)}\right\} \geq w(X - h_i c_i a^*) \geq \min\left\{w^{(1)}, w^{(2)}, w^{(3)}\right\} \tag{31}$$

by (30) and (31) we end the proof. ∎

In order to prove that the fast marching version of our semi-Lagrangian scheme converges to the viscosity solution in a finite number of steps we have to prove first that the fast method for the minimum analyzed in section 3.1 matches the fast marching technique. This is necessary since the narrow band of the FM-SL method is larger than the narrow band of the FM-FD method as a consequence of the new definition of neighboring nodes. In particular we will show that the algorithm automatically

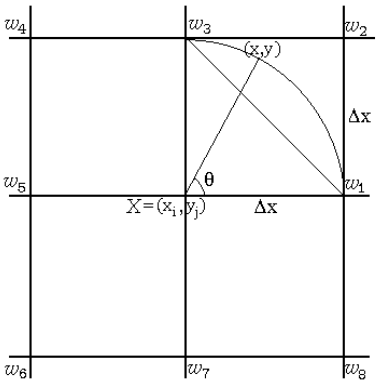

FIG. 4. *Analysis of the minimum in orthant I.*

rejects far nodes from the computation as in the standard up-wind finite difference discretization.

Let X be the node where we want to compute $w(X)$. Without loss of generality, we will assume that the optimal value is attained at a direction $\theta^* \in [0, \pi/2]$, i.e.,

$$a^* = (\cos\theta,\ \sin\theta)\,, \quad \theta \in [0, \pi/2]. \tag{32}$$

We will examine in detail all the possible configurations for this situation, which will be referred to in the following as the "minimum in orthant I" case (see Figure 4). For simplicity, let us assume $c > 0$ so that a node is labeled as *far* if and only if its value is $w = 1$.

PROPOSITION 4.2. *Let X be a node and let $w(X)$ be defined by* (26). *The value $w(X)$ will* not *be computed by interpolation using nodes labeled as* far.

Proof. Let us give the proof for the minimum in orthant I. The analysis for the other orthants is similar and can be easily obtained by symmetry arguments.

1. $w_1 = w_2 = w_3 = 1$: This configuration cannot occur. In fact, since the minimum is attained in orthant I we should have $w_4 = w_5 = w_6 = w_7 = w_8 = 1$. But this is not possible since we compute at X only when at least one of the nodes belonging to $N_{SL}(X)$ has been labeled as *accepted* in one of the previous iterations, and an accepted node must have a value lower than 1.
2. Among w_1, w_2, and w_3 there are two values equal to 1.
   (a) $w_1 = w_3 = 1$: this case cannot occur. In fact, since the minimum is attained in orthant I we must have $w_2 \leq w_1, w_3, w_4, \ldots, w_8$. The node that must be labeled as *accepted* is the one corresponding to the value w_2. This implies that the values w_1 and w_3 must be computed before X (see the sketch of the algorithm).
   (b) $w_1 = w_2 = 1$: the minimum value is w_3. A new iteration to compute $w(X)$ would not give a lower value, so the optimal value is obtained in just one iteration.
   (c) $w_2 = w_3 = 1$: the minimum value is w_1. Again, we will not get a lower value iterating, and the optimal value is obtained in just one iteration.
3. Among w_1, w_2, and w_3 only one value is equal to 1.
   (a) $w_2 = 1$: since f is linear the minimum will be attained by w_1 or w_3. The optimal value is obtained in just one iteration.
   (b) $w_1 = 1$, $w_3 \leq w_2$: the minimum is w_3.

(c) $w_1 = 1$, $w_3 > w_2$: this is the most delicate case since $w_2 < w_1, w_3$. The minimum for F will be attained at some $\theta^* \in (0, \pi/2)$. The value $w(X)$, obtained by linear interpolation, will not be correct since it depends on $w_1 = 1$, which is a conventional value. Moreover, note that a new iteration of the fixed point map at X will not make $w(X)$ decrease since w_1 is frozen and so is $w(X)$. If this case could occur, we would not get convergence to the correct value even in the limit on the number of iterations. Note that this difficulty can occur neither for the global semi-Lagrangian scheme where *all* the nodes are computed at the same iteration nor for the FM-FD method where the values corresponding to far nodes are not used in the stencil. The following argument shows that this case also cannot occur for the FM-SL scheme. Since $w_1 = 1$, the corresponding node is labeled as *far* at the current iteration. This implies that the nodes labeled as *accepted* at the previous iteration do not belong to $N_{SL}(w_1)$. As a consequence, w_2 belongs to the narrow band. By Proposition 4.1 we have $w(X) > w_2$. This implies that X cannot be labeled as *accepted* before the nodes corresponding to w_2. Once w_2 becomes accepted the algorithm computes w_1 and w_3 before computing $w(X)$ so that the values at nodes labeled as *far* will not contribute.

(d) $w_3 = 1$, $w_1 \leq w_2$: the minimum is w_1. The optimal value is obtained in just one iteration.

(e) $w_3 = 1$, $w_1 > w_2$: analogous to case (3c). □

5. Convergence of the FM-SL scheme in a finite number of steps. As for the FM-FD method we have to prove that the minimal value of the nodes of the narrow band cannot decrease if we iterate the fixed point operator; i.e., it coincides with the value obtained by the discrete operator working on all the nodes. As we have seen, the values at the nodes belonging to the narrow band are not accepted all together. Only the minimal value is accepted at every iteration (this is a very pessimistic choice which simplifies the theoretical result). The following proposition shows the bounds on the number of times that one node can be recomputed, and it is a building block for the convergence of the scheme.

PROPOSITION 5.1. *Let X be a node in the narrow band such that $w(X) = w_{old}(X)$. Let us assume that at the current iteration the algorithm needs to compute a new value $w_{new}(X)$ for X. Moreover, let us assume that at the current iteration the following property holds true:*

(33) *If A belongs to the narrow band and B is* accepted, *then $w(A) \geq w(B)$.*

The following properties hold:

1. *If the value $w_{old}(X)$ was computed at an iteration in which a grid point $A_1 \in N_{FD}(X)$ was labeled as* accepted, *then it is impossible that $w_{new}(X) < w_{old}(X)$.*
2. *If the value $w_{old}(X)$ was computed at an iteration in which a grid point $A_2 \in D(X)$ was labeled as* accepted, *then to the node X a new value $w_{new}(X) < w_{old}(X)$ can be assigned but it will always satisfy the inequality $w_{new}(X) \geq w(A_2)$.*

Proof. Let us start with the first statement.

1. Let us assume that when the value w_{old} was assigned to X the node A_1 was the (unique) node belonging to $N_{FD}(X)$, which had been labeled as *accepted*.

When the algorithm computed $w(X) = w_{old}(X)$ we certainly had

$$\min_{a \in \partial B(0,1)} w(X - \Delta x\ a) = w^* \leq w(A_1)$$

since there is a direction/control $\bar{a} \in \{(1,0),(0,1),(-1,0),(0,-1)\}$ such that $w(X - \Delta x\ \bar{a}) = w(A_1)$. The only possibility of having at X a value lower than $w_{old}(X)$ in the following iterations of the algorithm is that a value assigned to a node belonging to $N_{SL}(X)$ was lower than w^*. However, by Proposition 4.1 we know that this value cannot be computed using in the stencil the values at the nodes of the actual narrow band because they are all greater than $w(A_1) \geq w^*$, which has been accepted (as (33) assures). A lower value could be computed only using a stencil which contains nodes already accepted in one of the previous iterations since they all have values lower than $w(A_1)$. This is not possible since all the nodes which are neighbors of those accepted nodes have been computed already and they have a value greater than or equal to $w(A_1)$ since they have not been labeled as *accepted*.

2. Let us assume, for simplicity, that the node A_2 is the unique node belonging to $D(X)$ which has been labeled as *accepted* and let $w_{old}(X)$ be the value assigned at X at the same iteration. When a node $A_1 \in N_{FD}(X)$ has been labeled as *accepted* before A_2, the result holds true by the arguments of the above case 1.
   Let us assume that A_2 is the unique neighbor of X which has been labeled as *accepted*. Then we have

$$\min_{a \in \partial B(0,1)} w(X - \Delta x\ a) = w^* \geq w(A_2).$$

   It is always possible that using $w(A_2)$ one can obtain a new value $w_{new}(X)$ lower than $w_{old}(X)$. However, by (33) and Proposition 4.1 all the new values will be greater than or equal to $w(A_2)$; therefore $w_{new}(X) \geq w(A_2)$. □

Remark 5.1. Note that the previous proposition allows us to accelerate the algorithm. In fact, one can save CPU time by avoiding recomputing the values at the nodes corresponding to case 1. However, they cannot be labeled as *accepted* before their value is the minimum in the narrow band. An important consequence of Proposition 5.1 and the above observation is that every node can be computed at most 5 times; this is one of the reasons why the CPU time for FM-SL is slightly larger than that for the FM-FD method, where a node can be computed at most 4 times. We will see in the last section that the FM-SL method produces a more accurate approximation of the viscosity solution, which justifies a small increment in the CPU time.

The following result is an analogue of Proposition 2.1, and it is crucial to prove convergence in a finite number of steps.

PROPOSITION 5.2. *Let w be defined in* (26) *and let $w(X)$ be the value assigned at X at the same iteration when a node $Z \in N_{SL}(X)$ is labeled as* accepted. *Assume that*

$$c(x) \geq 0 \quad \textit{for any } \ x \in Q \backslash \Omega_0.$$

Then we have

$$w(X) \geq w(Z). \tag{34}$$

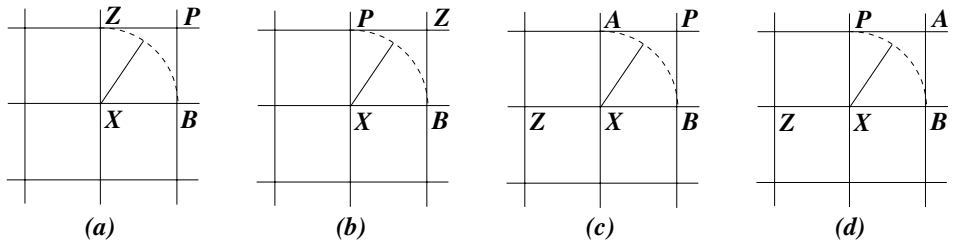

FIG. 5. *Four different configurations for Case* 2.

Proof. We examine all the cases corresponding to a minimum in orthant I (see Figure 4). The proof will be obtained by induction on the number of iterations of the algorithm.

At the first step the result holds true by our initialization.

Let us consider the nth step of the algorithm. The induction hypothesis implies that at the current iteration the values of nodes in the narrow band are greater than values of nodes labeled as accepted. Therefore (33) holds true, so we can apply Proposition 5.1. Our proof will be divided into three parts.

Case 1. $w_1, \ldots, w_8$ are narrow band or far (before Z is labeled as *accepted*).

If Z belongs to orthant I, we have seen by Proposition 4.1 that

$$w(X) \geq \min\{w_1, w_2, w_3\} = w(Z).$$

If Z does not belong to orthant I, we have

$$w(X) \geq \min\{w_1, w_2, w_3\} \geq w(Z)$$

since Z as been labeled as *accepted*.

Case 2. One node $w_1, \ldots, w_8$ is accepted (before Z is labeled as *accepted*).

Let us denote by P this node. When P was accepted the value at X was $w_{old}(X)$. Now the value at X has to be recomputed. We can only have one of the following situations:

1. P belongs to orthant I.
   (a) Z belongs to orthant I
      i. See Figure 5(a). By Proposition 5.1, Z and B cannot be assigned to a lower value after P became accepted, so $w_{new}(X) = w_{old}(X)$ and $w_{old}(X) \geq w(Z)$ since Z is the node chosen to be labeled as *accepted*.
      ii. See Figure 5(b). When Z is accepted the minimum is attained at P, and this implies again $w_{new}(X) = w_{old}(X)$.
   (b) Z does not belong to orthant I
      i. See Figure 5(c). In the iterations between the acceptance of P and that of Z the values $w(A)$ and $w(B)$ cannot be changed. Moreover, the minimum is attained in orthant I so we have $w_{new}(X) = w_{old}(X)$.
      ii. See Figure 5(d). We know that the value $w(A)$ has not been replaced, $w(B)$ cannot be lower than $w(P)$, and the minimum is attained in orthant I. Then the minimum is attained at P and $w_{new}(X) = w_{old}(X)$.

2. P does not belong to orthant I.
   Since the minimum is attained in orthant I this means that P has no effect on the computation at X and we are back to Case 1.

Case 3. More than one value among $w_1, \dots, w_8$ has been labeled as *accepted* (before Z is labeled as *accepted*).

This case can be solved by the arguments in Case 2. □

As for the FM-FD method (see [33]) we can now conclude that the value of the node which is labeled as *accepted* at every iteration cannot be decreased if we iterate the fixed point operator. In fact, let us denote this value w_{min}. Since all the nodes in the narrow band have values greater than w_{min}, the previous result implies that using those nodes we cannot assign to a node a value lower than w_{min}. In conclusion, the up-winding is respected and the value w_{min} can be considered exact since it cannot be improved on the same grid (of course it can be improved if we reduce the discretization steps).

Remark 5.2. The FM-SL scheme does not require a stability CFL-like condition, as required by the FM-FD scheme.

5.1. Convergence to the viscosity solution and conclusions. The semi-Lagrangian scheme is consistent, as has been proved, e.g., in [16]. Moreover, choosing $\Delta x = \Delta y$, we get that the local truncation error is $O(\Delta x)$.

We will prove that the solution computed by the FM-SL method is identical to the solution computed by the standard semi-Lagrangian scheme where the computation is repeated on every node of the grid until convergence. Naturally, if the two schemes compute the same values, convergence of the FM-SL method to the viscosity solution is just a consequence of that of the standard semi-Lagrangian scheme.

THEOREM 1. *Let* $(V_i)_{i=1,\dots,N}$ *be the matrix containing the final values on the* n*-dimensional grid and let*

$$V_i = F(V_{i-k}, \dots, V_{i+l}) \tag{35}$$

be the iteration corresponding to the numerical scheme. Let $\widehat{V}$ *be the matrix of the approximate solution corresponding to the fixed point iteration* (35) *and let* $\overline{V}$ *be the matrix containing the final values of the approximate solution corresponding to the fast marching technique applied to the* same *scheme (i.e., the result obtained when the narrow band is empty). Then* $\overline{V} = \widehat{V}$.

Proof. The two matrices coincide if and only if

$$\overline{V}_i = F(\overline{V}_{i-k}, \dots, \overline{V}_{i+l}) \quad \text{for any} \quad i = 1, \dots, N. \tag{36}$$

Assume the narrow band is empty and take $\overline{V}$ as initial guess for the fixed point technique; this will not change the solution since the value is computed by the same scheme. When all the nodes are accepted the equality (36) must hold for every i. In fact, if the equality is not true at one node, then its value can still be improved, implying that the list of narrow band or far nodes is not empty, which gives us a contradiction. □

The above results allow us to draw some conclusions about the order of complexity of the FM-SL scheme. The values $w(X)$ computed by (26) are an approximation of $v(X)$, which has been computed at most 5 times for every nodes. This means that the computational cost can be estimated as in the FM-FD scheme. One component is given by the cost of the heap-sort method to select the minimum value in the narrow band, and the other component is given by the computational cost at every node.

This globally gives a cost $O(N\log(N_{nb}))$, where N is the total number of nodes and N_{nb} the number of nodes in the narrow band (see [33]).

Since the values which have been labeled as *accepted* at every iteration cannot be improved by the global fixed point iteration, i.e., they coincide with the same values obtained by the global fixed point operator, the a priori error estimates in [12] are still valid for the solution obtained by the FM-SL method. In the last section we will present several tests which confirm these theoretical results.

Boundary conditions on ∂Q. We define outside Q a strip of ghost nodes where we set $w = 1$. If they enter the narrow band, at the end of the iteration, their value is set back to $w = 1$ to avoid their contributing to the computation of other internal nodes. When the minimal value on the nodes of the narrow band is 1, the ghost nodes will be the only nonaccepted nodes and we can stop the computation. In general, any constant larger than the maximum of the solution in Q can be used to assign the value at the ghost nodes (a typical choice is to set the solution to $+\infty$ if there is no a priori estimate on the solution).

Note that in our case, the normal velocity has always the same (positive) sign, so in the case of a constant velocity the front propagation starting from $\Gamma_0 \subset Q$ will hit the boundary of Q and both T and w are increasing approaching ∂Q. The values computed by the algorithm on the nodes of the boundary will always be lower than 1, and the choice of the above boundary condition is then well adapted to this situation. However, when c is variable or when there are obstacles in the domain we can also have a different situation: the front propagates more rapidly in some directions, and this could require enlarging the domain to get a correct solution to our problem. Finally, let us observe that the use of homogeneous Neumann boundary conditions is less appealing because it strongly affects the fronts near the boundary because all the level curves must be orthogonal to the boundary to satisfy $\nabla v(x)\cdot\eta(x) = 0$ for any $x \in \partial Q$ (here $\eta(x)$ denotes the exterior normal to Q).

6. Other fast schemes. As some authors have remarked, it is possible to improve the finite difference method. In the paper by Tsitsiklis [38] one can find an algorithm which can be parallelized directly with a complexity $O(N)$. There are at least two ways to accelerate convergence and/or reduce the CPU time:

1. Reduce the computational effort for the minimum search by accepting more than one node in the narrow band at every iteration (group marching method).
2. Avoid searching for the minimum value in the narrow band (fast sweeping method), obtaining convergence in more than one iteration.

We will briefly illustrate these two techniques.

Group marching. The group marching (GM) method has been introduced by Kim [22] to solve the eikonal equation on a structured grid by a discretization as that of FM-FD. Although we do not compare this algorithm with the others studied in the previous section, we will give a brief presentation of its main features for completeness. Let us denote by Γ the set of nodes belonging to the narrow band, and let us choose $\Delta x = \Delta y$. Define

$$T_{\Gamma,min} = \min\{T_{i,j} \mid (x_i, y_j) \in \Gamma\} \quad \text{and} \quad c_{\Gamma,\max} = \max\{c_{i,j} \mid (x_i, y_j) \in \Gamma\}.$$

The GM method labels as *accepted*, *all at once*, the nodes belonging to the set G defined by

$$G := \left\{(x_i, y_j) \in \Gamma \ : \ T_{i,j} \le T_{\Gamma,min} + \frac{\Delta x}{\sqrt{2}}\ \frac{1}{c_{\Gamma,\max}}\right\}. \tag{37}$$

At every iteration the update of the narrow band is obtained as in the FM-FD method, including the four neighbors of every node that have been labeled as *accepted*. It is clear that if the set G is large, the GM method can be much faster than the FM-FD method because more than one node at a time in accepted. On the other hand, it is rather difficult to give an estimate of the acceleration parameter since the cardinality of G depends on the values $\{T_{i,j} : (x_i, y_j) \in \Gamma\}$ and on the velocity of propagation. It could be that $G = \{T_{\Gamma,min}\}$, and this would imply a computational cost of $O(N \ln(N_{nb}))$ instead of getting $O(N)$, as one would expect by some tests in [22].

Fast sweeping. The fast sweeping (FS) method is based on an idea first introduced in [11] and was extensively analyzed in [39] and [37]. The crucial idea is that the algorithm sweeps the whole (two-dimensional) domain with four alternating orderings repeatedly,

$$(38) \qquad (1)\ i = 1, \dots, N\,,\ j = 1, \dots, M; \qquad (2)\ i = N, \dots, 1\,,\ j = 1, \dots, M;$$

$$(39) \qquad (3)\ i = N, \dots, 1\,,\ j = M, \dots, 1; \qquad (4)\ i = 1, \dots, N\,,\ j = M, \dots, 1$$

(where N and M are the number of nodes in each dimension), and it updates the value at a grid point only if the new value is smaller than the current one. This idea can be easily extended to n-dimensional domains.

Computing the values in this special ordering, the algorithm is able to follow simultaneously a family of characteristics in a certain direction. As proved in [39], the FS method converges in 2^n iterations, where n is the dimension of the problem if the initial front Γ_0 is just a point on the grid and the function c is constant. If those assumptions do not hold, the FS method has been shown to be of complexity $O(N)$ and to converge in a finite number of iterations although the bound for the number of iterations is not explicitly written out. See [27] for an extension on triangular meshes and an upper bound to the number of iterations needed by the FS method to reach convergence.

Let us note that the discretization used in [39] is the same as that used in the FM-FD method described in section 2, and that in any case the numerical evidence shows that the convergence is more rapid with respect to the classical iterative method.

The FS method has an easy extension to the semi-Lagrangian case. In fact, we can easily substitute the finite difference discretization by the semi-Lagrangian discretization maintaining the ordering in which nodes are visited. Obviously, we expect that at least in the case $c(x) \equiv$ const. the FS semi-Lagrangian scheme (FS-SL) can compute in four iterations exactly the same solution as FM-SL.

In the next section we run this algorithm in the case $c(x) \equiv 1$ with two different initial fronts and see that this intuition is actually true.

7. Numerical experiments. In this section we present some numerical experiments performed with MATLAB 7 on a PC equipped with a Pentium IV 2.80 GHz processor, 512 MB RAM.

The main goal is to compare the FM-FD method and the FM-SL method described in previous sections. We also compare these methods with the semi-Lagrangian iterative method and FS method based on a semi-Lagrangian discretization described in section 6. First, two tests are devoted to approximate the solution of model problems where we know the exact solution, so we can compute the L^∞ error and L^1 error. Other tests are devoted to solving more complicated problems and applications

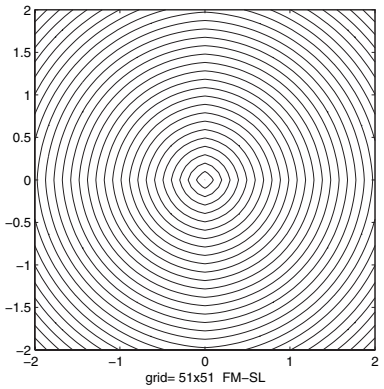

FIG. 6. *Level sets of $T(x)$ computed by the FM-SL method,* 51×51 *grid.*

in which the velocity function $c(x)$ does not satisfy standard assumptions such as Lipschitz continuity and boundedness.

If not specified otherwise, we choose $Q = [-2, 2]^2$ as our computational domain.

7.1. Tests on model problems. In the following tests we compare the exact solution T with the solution $\widehat{T}$ computed by the FM-FD method and the FM-SL method described above. Note that in the implementation of the FM-SL algorithm we have used the observation in Remark 5.1 to speed up the computation.

We compute

$$E_{\infty,\Delta x} = \max_{i,j} |T_{i,j} - \widehat{T}_{i,j}|\,, \qquad E_{1,\Delta x} = (\Delta x)^2 \sum_{i,j} |T_{i,j} - \widehat{T}_{i,j}| \tag{40}$$

and the rate of convergence r in some model problems in $\mathbb{R}^2$. We consider 51×51, 101×101, and 201×201 grids[1] corresponding, respectively, to $\Delta x = 0.08$, $\Delta x = 0.04$, and $\Delta x = 0.02$.

Since we know that there is a constant C such that

$$E_{p,\Delta x} \le C \Delta x^r \quad \text{and} \quad E_{p,\Delta x/2} \le C \left(\frac{\Delta x}{2}\right)^r, \qquad p = 1, \infty,$$

we obtain that the numerical rate of convergence is

$$r = \log_2 \left(\frac{E_{p,\Delta x}}{E_{p,\Delta x/2}}\right), \qquad p = 1, \infty.$$

Moreover, we compare these algorithms with the classical iterative semi-Lagrangian method in which we choose $\max_{i,j} |w_{i,j}^{(k)} - w_{i,j}^{(k-1)}| < \varepsilon$, $\varepsilon = 10^{-7}$, as the stopping criterion and with the FS-SL method performing just four iterations in different order.

Let us finally remark that in all cases condition (15) holds.

Test 1. $\Gamma_0 = (0, 0)$, $c(x, y) \equiv 1$. Exact solution: $T(x, y) = \sqrt{(x^2 + y^2)}$.

Results are summarized in Figure 6 and Table 1. As expected, in all cases errors reduce as Δx decreases. The numerical rate of convergence (Table 2) is in the interval $[0.5, 1]$ for both methods.

[1] In these grids there is a node corresponding to the point $(0, 0)$.

TABLE 2
Rate of convergence in L^∞ *and* L^1 *norms computed by errors in Table* 1.

Method	L^∞ $(0.08 \to 0.04)$	L^∞ $(0.04 \to 0.02)$	L^1 $(0.08 \to 0.04)$	L^1 $(0.04 \to 0.02)$
FM-FD	0.7342	0.7675	0.7132	0.7487
FM-SL	0.6895	0.7417	0.6831	0.7349

The FM-SL and semi-Lagrangian methods give exactly the same errors in accordance with Theorem 1, and they are also equal to the errors of FS-SL, as expected, since FS-SL converges in four iterations in the case c is constant. These errors number about half that of the FM-FD method, although both are first order methods. This is due to the fact that semi-Lagrangian discretization is able to follow every direction of the characteristic flow.

Both methods based on the fast marching technique are dramatically faster than the iterative semi-Lagrangian method. Nevertheless we want to note that only one iteration of the iterative scheme is less expensive with respect to the single iteration needed by fast marching–based algorithms. This is due to the fact that the narrow band technique requires that we (1) compute a minimum over nodes in the narrow band and (2) access the data in an almost random manner rather than in a systematic way along the loop indices (see [22]). Finally we note that the CPU time needed by the FM-SL method is slightly larger than the CPU time needed by the FM-FD method. This due to the fact that (1) the narrow band is bigger in the first method; and therefore the search for the minimum in the narrow band is more expensive; and (2) in the FM-SL method we need to compute the minimum over the unit ball $B(0,1)$.

Test 2. Γ_0 = unit square centered in $(-1,1)$ and rotated by $11.25^\circ \cup$ circle with radius $R = 0.5$ centered in $(0,-1) \cup$ square with side 0.4 centered in $(1.4, 1.4)$, $c(x,y) \equiv 1$. Exact solution: $T(x,y) =$ minimum between the distance function of the square rotated, the circle, and the square.

Results are summarized in Figure 7 and Table 3. In this test the shape of the initial front is much more complicated, but errors have the same behavior as in the previous simple Test 1, although the difference between errors is smaller.

TABLE 4
Rate of convergence in L^∞ and L^1 norms computed by errors in Table 3.

Method	L^∞ $(0.08 \to 0.04)$	L^∞ $(0.04 \to 0.02)$	L^1 $(0.08 \to 0.04)$	L^1 $(0.04 \to 0.02)$
FM-FD	0.6693	0.6642	0.9435	0.7434
FM-SL	1.0332	0.6714	0.8246	0.7218

FS-SL seems to be the best method. It has the smallest error and the CPU time is slightly larger than that of FM-FD. This is probably due to the fact that the structure of the narrow band is very complicated and is very large in terms of nodes.

Also in this case the rate of convergence (Table 4) is greater than 0.5.

7.2. Applications. In the following we try to use the FM-SL method in some classical applications of the eikonal equation such as the minimum time problem and shape-from-shading. We consider some cases not covered by the theory in which $c(x, y)$ is discontinuous, $c(x, y)$ vanishes in some regions (state constraints), and $c(x, y)$ has infinite values. We also consider the *anisotropic* case in which the velocity field c depends on (x, y) and on the control a. The results we obtained are very satisfactory even in these cases.

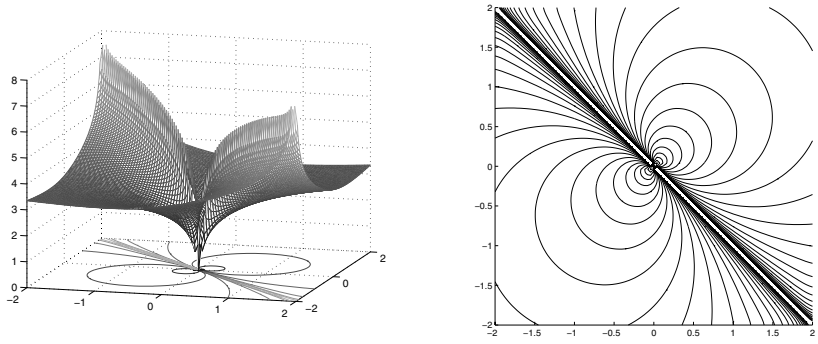

FIG. 8. *Value function T (left) and level sets of T (right).*

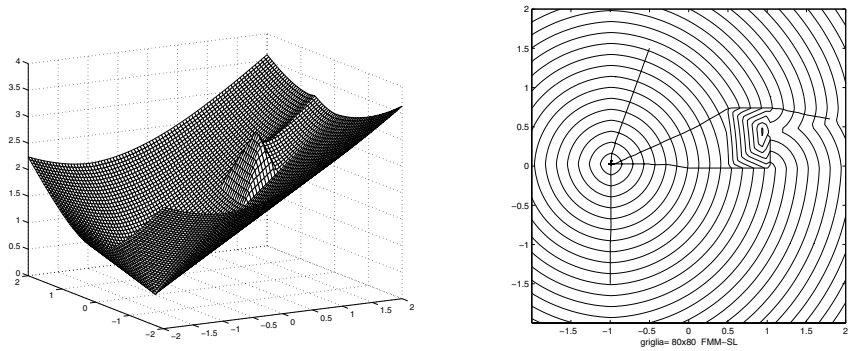

FIG. 9. *Value function T (left) and level sets of T with some optimal trajectories (right).*

Test 3: Nonconstant velocity. $\Gamma_0 = \partial B(0, \frac{\Delta x}{2})$, $c(x,y) = |x+y|$. In this case the velocity field is nonconstant. Figure 8 shows the value function $T(x,y)$ and level sets of T. On the line $x = -y$ the solution T is not defined since its correct value is $T = +\infty$. The FS-SL method needs 12 iterations to reach convergence and is more than three times slower than the FM-SL method on a 101×101 grid.

Test 4: Discontinuous vector field. $\Gamma_0 = (-1, 0)$.

$$c(x,y) = \begin{cases} 0.4, & (x,y) \in [0.5,1] \times [0,0.5], \\ 1 & \text{elsewhere.} \end{cases}$$

In this case the velocity field is discontinuous. Figure 9 shows the value function $T(x,y)$ and level sets of T. Figure 9 (right) also shows some optimal trajectories which start from four different points and reach the target Γ_0 in the minimum time with speed $c(x,y)$. The FS-SL method converges in 8 iterations.

Test 5: State constraint problem. $\Gamma_0 = (-1, -1)$.

$$c(x,y) = \begin{cases} 0, & (x,y) \in ([0,0.5] \times [-2,1.5]) \cup ([1,1.5] \times [-1.5,2]), \\ 1 & \text{elsewhere.} \end{cases}$$

In this test the velocity field vanishes in two different regions (the obstacles). Figure 10 shows the computational domain, the value function $T(x,y)$, and level sets of

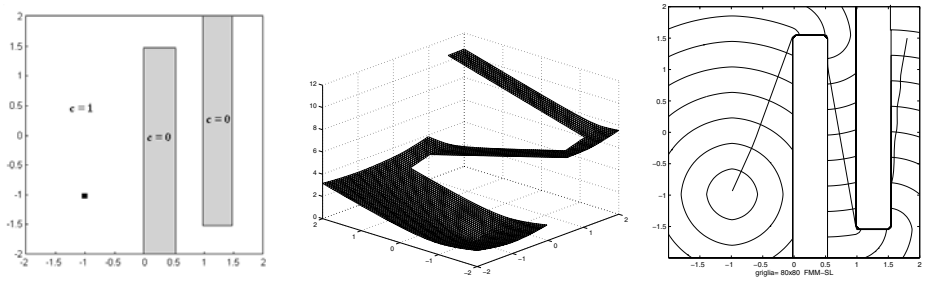

FIG. 10. *Domain of the equation (left), value function T (center), and level sets of T with one optimal trajectory (right).*

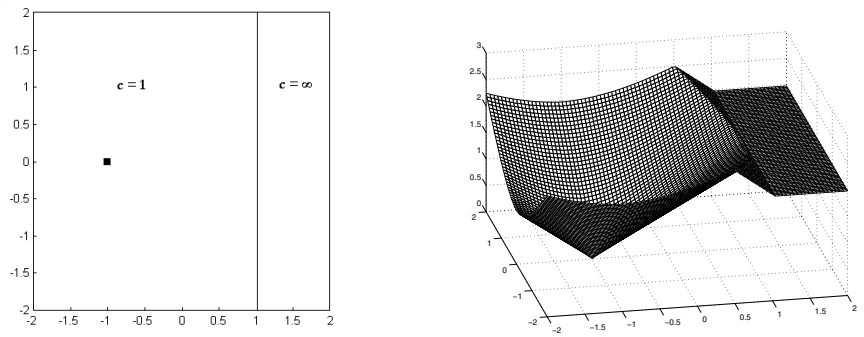

FIG. 11. *Domain of the equation (left) and value function T (right).*

T. Figure 10 (right) also shows one optimal trajectory which starts from the point $(1.8, 1.5)$ and reaches Γ_0 in the minimum time avoiding obstacles. We remark that since we use the Kružkov transform and compute v, we do not need to modify the numerical scheme to deal with state constraints. Also in this case the FS-SL method converges in 8 iterations.

Test 6: Infinite velocity. $\Gamma_0, = (-1, 0)$.

$$c(x,y) = \begin{cases} +\infty, & x \geq 1, \\ 1 & \text{elsewhere.} \end{cases}$$

In this case the front can propagate instantaneously in the region $R = \{x \geq 1\}$. It corresponds to the case of the following degenerate eikonal equation (see [30]):

$$|\nabla T(x,y)| = f(x,y) \quad \text{with } f = 0 \text{ in } R.$$

Figure 11 shows the computational domain and value function $T(x,y)$. In this test we used the technique described in section 3.2 in order to deal with this kind of vector field.

This technique allows us to reconstruct a perfect *flat* surface on R as the theory and the physical sense require. This technique can be very useful in shape-from-shading problems.

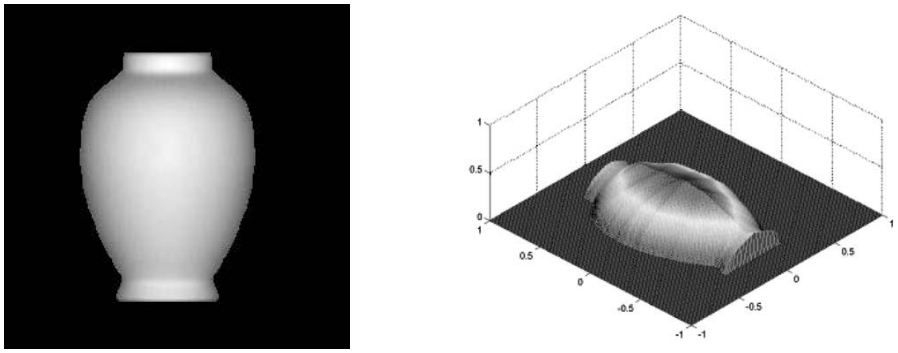

FIG. 12. *Initial image (left) and reconstructed surface (right).*

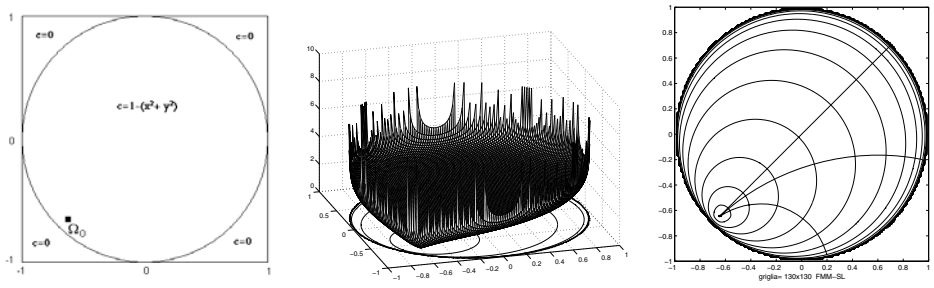

FIG. 13. *Domain of the equation (left), value function T (center), and level sets of T with some optimal trajectories (right).*

Test 7: Shape-from-shading. $Q = [-1,1]^2$, $\Gamma_0 =$ silhouette of a vase.

$$c(x,y) = \left(\sqrt{\frac{1}{I(x,y)^2} - 1}\right)^{-1}, \quad I(x,y) = \text{intensity light function.}$$

In this test we solve the shape-from-shading problem in the simple case of a vase. Figure 12 (left) shows the initial image and Figure 12 (right) shows the reconstructed surface. By the symmetry of the problem we guess that all characteristic curves start from the right and left sides of the image, so we can impose Dirichlet boundary condition just on the right and left sides of the domain and state constraints elsewhere as in [10] (see also [29, 24], where different boundary conditions are applied).

Test 8: Poincaré model. $Q = [-1,1]^2$, $\Gamma_0 = (-0.65, -0.65)$.

$$c(x,y) = \begin{cases} 1 - (x^2 + y^2), & x^2 + y^2 < 1, \\ 0 & \text{elsewhere.} \end{cases}$$

This example is an interesting application of the eikonal equation to the Poincaré model of the hyperbolic geometry. Figure 13 shows the computational domain, the value function $T(x,y)$, and level sets of T. The FS-SL method converges in 8 iterations.

As result of the particular choice of the velocity field (see [25]), the optimal trajectories of the associated minimum time problem correspond to the hyperbolic

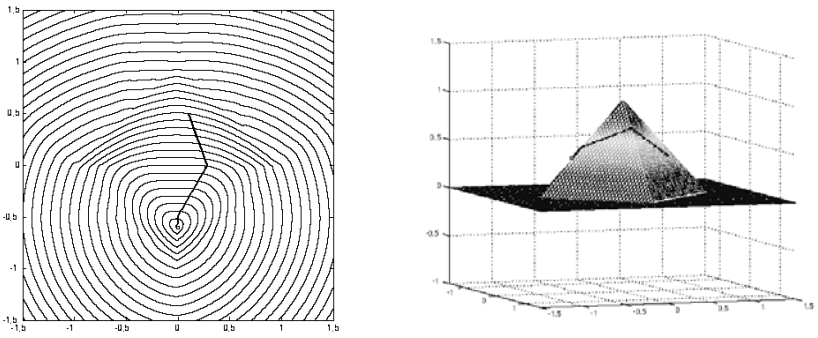

FIG. 14. *Level sets of T (left) and an optimal trajectory on the surface z (right).*

straight lines. Moreover, the level sets of T are hyperbolic circles with center Γ_0 (i.e., the sets of points which have the same hyperbolic distance from Γ_0).

Test 9: Geodesics on a nonsmooth surface. $Q = [-1.5, 1.5]^2, \Gamma_0 = (0, -0.6)$.

$$\text{Surface} : z(x,y) = \begin{cases} 1 - (|x| + |y|), & |x| + |y| < 1, \\ 0 & \text{elsewhere.} \end{cases}$$

In this case we want to solve a minimum time problem on a surface $z = z(x, y)$. The three-dimensional problem can be easily reduced to a two-dimensional problem modifying the velocity field according to the function z. In fact, if the intrinsic velocity on the surface in equal to 1, it can be shown (see [32, 23]) that the velocity of the corresponding two-dimensional problem becomes

$$c(x, y, a) = \frac{1}{\sqrt{1 + (\nabla z \cdot a)^2}}.$$

Figure 14 shows the level sets of T and the surface with an optimal trajectory on it. The starting point is $(0, 0.5)$.

We remark that the dependence of c on a changes the properties of the solution of the equation. In fact the equation for anisotropic front propagation is

$$\begin{cases} v(x) + \max\limits_{a \in B(0,1)} \{c(x,a)a \cdot \nabla v(x)\} = 1, & x \in \mathbb{R}^n \backslash \Omega_0, \\ v(x) = 0, & x \in \partial\Omega_0. \end{cases} \tag{41}$$

In this case the fast marching technique is no longer directly applicable (there is no guarantee that convergence is reached in just one iteration; see [34]). This is true for the FM-SL method too, but we stress that scheme (26) requires tiny modifications to deal with this kind of velocity field. Moreover, if we use the function w computed by the FM-SL method as a starting point of the iterative semi-Lagrangian scheme, we can reach convergence in very few iterations.

Appendix. Convergence of the FM-FD method in a finite number of steps.

Proof of Proposition 2.1. We will assume that B, C, and D are the neighbors of X which can have a label *accepted*, *narrow band,* or *far* (see Figure 15). We will

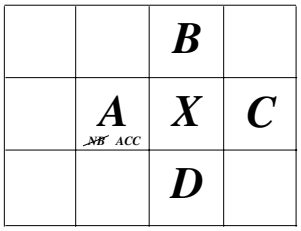

FIG. 15. *The neighboring nodes of* X.

prove the result by induction on the number of iterations of the algorithm. We will always assume

$$T(B) \leq T(D), \tag{42}$$

which is not restrictive since we can always switch the B and D.

In the first iteration we simply have $T(X) = 0 + f_X$ and (16) is satisfied. Let us consider the nth step of the algorithm. The induction hypothesis implies that at each iteration the values of nodes in the narrow band are greater than values of nodes labeled as *accepted* at the same iteration. Therefore, by construction we have that, given two nodes Y and Z,

$$\text{if } Y \text{ has become accepted before } Z, \text{ then } T(Y) \leq T(Z).$$

The proof will be divided into four cases.

Case 1. B is far. C and D are narrow band or far.

By assumption $T(B) = +\infty$, and since $T(B) \leq T(D)$ this implies that D must be far. Moreover, we have

$$T(C) \geq T(A)$$

since A has been chosen among all the nodes of the narrow band to become accepted. Also X must be far, since it has never been computed. Then by (10) we get

$$T(X) = T(A) + f_X. \tag{43}$$

Since $f_X > 0$, (43) implies

$$T(A) \leq T(X) \leq T(A) + f_X.$$

Case 2. B is narrow band. C and D are narrow band or far.

Also in this case X is far. We have

$$T(A) \leq T(B), \qquad T(A) \leq T(C)$$

since A is the minimal node in narrow band. Moreover, the assumption (42) implies that $T(X)$ will be computed by the values at A and B. From (10) we get

$$T(X) = \frac{T(A) + T(B) + \sqrt{2f_X^2 - (T(A) - T(B))^2}}{2} \tag{44}$$

and then

$$T(X) \geq \frac{T(A) + T(B)}{2} \geq \frac{T(A) + T(A)}{2} = T(A). \tag{45}$$

Since $T(X)$ solves

$$(T(X)-T(A))^2+(T(X)-T(B))^2=f_X^2$$

we have

$$(T(X)-T(A))^2\le f_X^2.$$

Since all the terms in the above equation are positive we conclude that

$$T(X)-T(A)\le f_X. \tag{46}$$

Case 3. B is accepted. C and D are narrow band or far.

This situation occurs when X has been already computed once (when B has been labeled as *accepted*). Let us denote its value by $T_{old}(X)$. The node X is then in the narrow band and has to be recomputed because A has just been labeled as *accepted*. Let us note that in the previous computation $T_{old}(X)$ has been computed according to the rules examined in Case 1 or 2. Then we have

$$T(B)\le T_{old}(X)\le T(B)+f_X.$$

Moreover $T(A)\le T_{old}(X)$ because A just became accepted and $T(B)\le T(A)$ since B became accepted before A (induction).

These inequalities imply

$$T(B)\le T(A)\le T_{old}(X)\le T(B)+f_X \tag{47}$$

and

$$0\le T(A)-T(B)\le f_X. \tag{48}$$

The value at X, which will be denoted by $T_{new}(X)$, will depend on $T(A)$ and $T(B)$.

By (48) and (47) we derive

$$\begin{aligned} T_{new}(X) &= \frac{T(A)+T(B)+\sqrt{2f_X^2-(T(A)-T(B))^2}}{2} \\ &\ge \frac{T(A)+(T(B)+f_X)}{2}\ge\frac{T(A)+T(A)}{2}=T(A) \end{aligned} \tag{49}$$

and

$$T_{new}(X)\le\frac{T(A)+T(B)+\sqrt{2}f_X}{2}\le T(A)+\frac{\sqrt{2}}{2}f_X\le T(A)+f_X.$$

Case 4. B is narrow band or far. C is accepted. D is narrow band or far.

In this case X has already been computed because it is a neighbor of C. It belongs to the narrow band and has a value $T_{old}(X)$. Besides

$$T(A)\le T_{old}(X) \tag{50}$$

since on the contrary X would have been chosen instead of A as the node to be accepted and

$$T(A)\le T(B) \tag{51}$$

for the same reason. Moreover we have $T(C) \leq T(A)$ by induction and $T(B) \leq T(D)$ by assumption. In conclusion, the nodes contributing to the computation of $T(X)$ are C and B or only C. The fact that A has been labeled as *accepted* has no effect on the computation so we are again in Case 1 or 2. This implies,

$$T(C) \leq T_{new}(X) \leq T(C) + f_X \leq T(A) + f_X.$$

Now we prove that $T_{new} \geq T(A)$. When $T_{old}(X)$ was computed the algorithm was in the Case 1 or 2, so

$$T(C) \leq T_{old}(X) \leq T(C) + f_X. \tag{52}$$

Moreover we have

$$T(C) \leq T(B) \tag{53}$$

by induction.

If $T(B) > T_{old}(X)$, then the node contributing to the computation of $T(X)$ is only C, so we have

$$T_{new}(X) = T(C) + f_X \geq T_{old}(X) \geq T(A).$$

Otherwise, if $T(B) \leq T_{old}(X)$, the nodes contributing to the computation of $T(X)$ are C and B.

Using this last assumption, (52), and (53) we have

$$\begin{aligned} T(C) \leq T(B) \leq T_{old}(X) \leq T(C) + f_X &\Rightarrow 0 \leq T(B) - T(C) \leq f_X \\ &\Rightarrow (T(B) - T(C))^2 \leq f_X^2. \end{aligned} \tag{54}$$

Moreover, by (50) and (52) we have

$$T(C) + f_X \geq T(A). \tag{55}$$

Computation of X leads to

$$\begin{aligned} T_{new}(X) &= \frac{T(C) + T(B) + \sqrt{2f_X^2 - (T(C) - T(B))^2}}{2} \\ &= \frac{(T(C) + f_X) - f_X + T(B) + \sqrt{2f_X^2 - (T(C) - T(B))^2}}{2}. \end{aligned} \tag{56}$$

Using (55), (54), and (51) we obtain

$$\begin{aligned} T_{new}(X) &\geq \frac{T(A) - f_X + T(B) + \sqrt{2f_X^2 - (T(C) - T(B))^2}}{2} \\ &\geq \frac{T(A) - f_X + T(B) + \sqrt{f_X^2}}{2} \geq \frac{T(A) + T(A)}{2} = T(A). \end{aligned} \tag{57}$$

Finally, let us remark that the cases when two or more nodes among B, C, and D are accepted can be treated as in the previous cases. Note that if D is accepted, then B must also be accepted since $T(B) \leq T(D)$.

To complete the proof, it is necessary to show that the expression appearing under the square root in the computation of $T(X)$ expressed as a function of its two

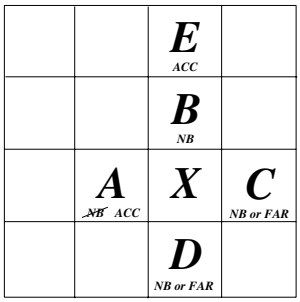

FIG. 16. *Proof that radicand is positive under the CFL-like condition* (15).

neighbors is nonnegative. Let us start by proving that the hypothesis (15) guarantees that

$$\frac{c(Z)}{c(Z')} \leq \sqrt{2} \tag{58}$$

for any couple of nodes Z and Z' such that

$$|Z - Z'| = \Delta x.$$

In fact, by assumption we have

$$|c(Z) - c(Z')| \leq L_c |Z - Z'|.$$

If $|Z - Z'| = \Delta x$, we have that

$$|c(Z) - c(Z')| \leq L_c \Delta x \leq (\sqrt{2} - 1) c_{min} \leq (\sqrt{2} - 1) c(Z'),$$

which implies

$$c(Z) - c(Z') \leq (\sqrt{2} - 1) c(Z')$$

and then

$$c(Z) \leq \sqrt{2}\, c(Z').$$

Let us examine the three cases where we need to show that the radicand is nonnegative.

Case 2. Since B is in the narrow band, there must be at least one neighbor belonging to accepted. Let E be this node (see Figures 16 and 1). Moreover, $T(A) \leq T(B)$ since A has been chosen to be labeled as *accepted* and $T(E) \leq T(A)$ because E became accepted before A. By the previous results, we get

$$T(E) \leq T(B) \leq T(E) + f_B,$$

which implies

$$T(A) \leq T(B) \leq T(E) + f_B \leq T(A) + f_B$$

and

$$0 \leq T(B) - T(A) \leq f_B. \tag{59}$$

Choosing $Z = X$ and $Z' = B$ in (58), we get

$$\frac{c(X)}{c(B)} \leq \sqrt{2}$$

and then

$$\sqrt{2} f_X \geq f_B. \tag{60}$$

Finally (59) and (60) imply

$$\sqrt{2} f_X \geq T(B) - T(A) \geq 0,$$

so we can conclude that

$$2 f_X^2 - (T(B) - T(A))^2 \geq 0.$$

Case 3 and 4. In these cases, (48) and (54) guarantee, respectively, that the expression appearing under the radicand is always positive. □

Let us show now that the value at the node which is labeled as *accepted* at every iteration is exact. Let us denote this value by T_{min}. Since all the nodes in the narrow band have values greater than T_{min}, the previous result implies that using those nodes we cannot assign to a node a value lower than T_{min}. In conclusion (see [33]), the up-winding is respected and the value T_{min} can be considered exact since it cannot be improved on the same grid (of course it can be improved if we reduce the discretization steps).

Note that Theorem 1 is valid also for the FM-FD method.

Acknowledgment. The authors wish to thank M. Sagona for helpful discussions on the FM-FD and FM-SL methods.

AN ERROR ESTIMATE FOR THE SIGNORINI PROBLEM WITH COULOMB FRICTION APPROXIMATED BY FINITE ELEMENTS*

PATRICK HILD† AND YVES RENARD‡

Abstract. The present paper is concerned with the unilateral contact model and the Coulomb friction law in linear elastostatics. We consider a mixed formulation in which the unknowns are the displacement field and the normal and tangential constraints on the contact area. The chosen finite element method involves continuous elements of degree one and continuous piecewise affine multipliers on the contact zone. A convenient discrete contact and friction condition is introduced in order to perform a convergence study. We finally obtain a first a priori error estimate under the assumptions ensuring the uniqueness of the solution to the continuous problem.

Key words. unilateral contact, Coulomb friction, uniqueness of solution, finite elements, a priori error estimate

Introduction. This study deals with the unilateral contact problem governed by the Coulomb friction law in linear elasticity. We consider a simplified model, the so-called static friction problem, which roughly corresponds to an incremental problem in the time discretized quasi-static model and whose solutions are also some particular equilibrium configurations of the dynamic problem.

From a mathematical point of view the early progress made on the static problem was accomplished in [15, 17]. These studies concerned the weak formulation of the problem. The first existence results were obtained in [39] for an infinite elastic strip. Thereafter, many existence results followed for general domains, in particular in [18] (see also the references quoted therein). These existence results hold for small friction coefficients, and uniqueness is not discussed. In fact, uniqueness does not hold in the general case, at least for large friction coefficients; see [26, 27]. More recently a first uniqueness result has been obtained in [41] with the assumption that a "regular" solution exists and that the friction coefficient is sufficiently small. Additionally, the so-called nonlocal Coulomb frictional models mollifying the normal stresses were introduced in [16] and developed in [14, 11, 31]. The smoothing map used in the nonlocal friction model allows one to obtain existence results for any friction coefficient. Moreover, uniqueness of a solution can also be established if the friction coefficient is small enough (see [16, 14, 11, 31]). The same type of result (existence for any friction coefficient and uniqueness for small friction coefficients) was obtained in [32, 33] for the normal compliance model, introduced in [40, 37].

From a numerical point of view, the finite element method is commonly used when approximating such frictional contact problems (see, e.g., [31, 24, 21, 35, 43]). It is well known that the finite element problem, associated with the continuous static

Coulomb friction model, always admits a solution and that the solution is unique if the friction coefficient is small enough. (Unfortunately the definition of small depends on the discretization parameter, and the bound ensuring uniqueness vanishes as the mesh is refined; see, e.g., [24].) The former result holds for any reasonable choice of the approximated contact and friction conditions (see [30]). Moreover, a first convergence study of the finite element problem towards the continuous model was accomplished in [22], where convergence was obtained under the assumptions ensuring the existence of a solution in [39] (i.e., small friction coefficient). This result proves the existence of a subsequence of discrete solutions converging towards a solution to the continuous problem. A similar result is obtained in [42] for the quasi-static model.

Our purpose is to carry out a convergence analysis and to obtain an a priori error estimate for a finite element discretization of the frictional contact conditions under the assumptions ensuring the uniqueness of a solution to the continuous problem obtained in [41]. As far as we know, this work presents the first error estimate with a convergence rate for this model.

Our paper is outlined as follows. Section 1 is concerned with the setting of the continuous problem, several equivalent weak formulations, and a presentation of the tools and techniques leading to the uniqueness result. In section 2 we consider a discretization of the problem with finite elements of degree one and continuous piecewise affine multipliers on the contact zone. We introduce a convenient discrete contact and friction condition which allows us to perform a convergence analysis and to obtain an a priori estimate of the discretization error with a quasi-optimal convergence rate of order $h^{1/2}$ in the energy norm under $H^{(3/2)+\varepsilon}$-regularity assumptions on the displacements.

1. The Signorini problem with Coulomb friction. Let $\Omega \subset R^d$ ($d = 2$ or 3) be a polygonal domain representing the reference configuration of a linearly elastic body whose boundary $\partial\Omega$ consists of three nonoverlapping open parts $\Gamma_{_N}$, $\Gamma_{_D}$, and $\Gamma_{_C}$ with $\overline{\Gamma_{_N}} \cup \overline{\Gamma_{_D}} \cup \overline{\Gamma_{_C}} = \partial\Omega$. We assume that the measures of $\Gamma_{_C}$ and $\Gamma_{_D}$ are positive and, in order to simplify that $\Gamma_{_C}$ is a straight line segment when $d = 2$ or a plane surface when $d = 3$. The body is submitted to a Neumann condition on $\Gamma_{_N}$ with a density of loads $F \in (L^2(\Gamma_{_N}))^d$, a Dirichlet condition on $\Gamma_{_D}$ (the body is assumed to be clamped on $\Gamma_{_D}$ to simplify), and to volume loads denoted $f \in (L^2(\Omega))^d$ in Ω. Finally, a unilateral contact condition with static Coulomb friction between the body and a flat rigid foundation holds on $\Gamma_{_C}$ (see Figure 1.1).

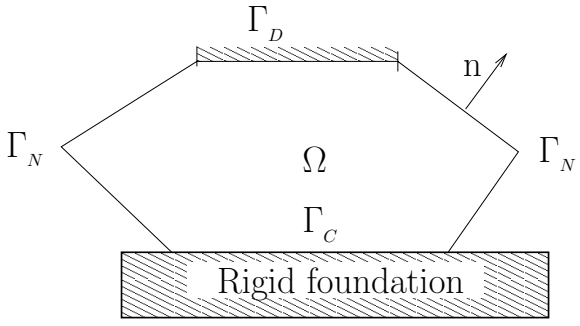

FIG. 1.1. *Elastic body* Ω *in frictional contact.*

The problem consists of finding the displacement field $u : \overline{\Omega} \to R^d$ satisfying

$$-\operatorname{div} \sigma(u) = f \quad \text{in } \Omega, \tag{1.1}$$

$$\sigma(u) = \mathcal{A}\varepsilon(u) \quad \text{in } \Omega, \tag{1.2}$$

$$\sigma(u)\mathrm{n} = F \quad \text{on } \Gamma_{_N}, \tag{1.3}$$

$$u = 0 \quad \text{on } \Gamma_{_D}, \tag{1.4}$$

where $\sigma(u)$ represents the stress tensor field, $\varepsilon(u) = (\nabla u + (\nabla u)^T)/2$ denotes the linearized strain tensor field, n stands for the outward unit normal to Ω on $\partial\Omega$, and $\mathcal{A}$ is the fourth order elastic coefficient tensor which satisfies the usual symmetry and ellipticity conditions and whose components are in $L^\infty(\Omega)$.

On $\Gamma_{_C}$, we decompose the displacement and the stress vector fields in normal and tangential components as follows:

$$u_{_N} = u.\mathrm{n}, \quad u_{_T} = u - u_{_N}\mathrm{n},$$

$$\sigma_{_N}(u) = (\sigma(u)\mathrm{n}).\mathrm{n}, \quad \sigma_{_T}(u) = \sigma(u)\mathrm{n} - \sigma_{_N}(u)\mathrm{n}.$$

The unilateral contact condition on $\Gamma_{_C}$ is expressed by the following complementary condition:

$$u_{_N} \le 0, \qquad \sigma_{_N}(u) \le 0, \qquad u_{_N}\sigma_{_N}(u) = 0, \tag{1.5}$$

where a vanishing gap between the elastic solid and the rigid foundation has been chosen in the reference configuration.

Denoting by $\mathcal{F} \ge 0$ the given friction coefficient on $\Gamma_{_C}$ (which is supposed constant for the sake of simplicity), the *static Coulomb friction* condition reads as

$$\text{if } \ u_{_T} = 0, \text{ then } |\sigma_{_T}(u)| \le -\mathcal{F}\sigma_{_N}(u), \tag{1.6}$$

$$\text{if } \ u_{_T} \ne 0, \text{ then } \sigma_{_T}(u) = \mathcal{F}\sigma_{_N}(u)\frac{u_{_T}}{|u_{_T}|}. \tag{1.7}$$

When $\mathcal{F} = 0$ the friction conditions (1.6)–(1.7) merely reduce to $\sigma_{_T}(u) = 0$ on $\Gamma_{_C}$.

1.1. Classical weak formulations. This section is devoted to the presentation of different and equivalent weak formulations of the Coulomb friction problem. Let us introduce the following Hilbert spaces:

$$V = \left\{ v \in (H^1(\Omega))^d, v = 0 \text{ on } \Gamma_{_D} \right\},$$

$$X = \left\{ v_{|_{\Gamma_{_C}}} : v \in V \right\} \subset (H^{1/2}(\Gamma_{_C}))^d,$$

$$X_{_N} = \left\{ v_{_N}|_{\Gamma_{_C}} : v \in V \right\}, \qquad X_{_T} = \left\{ v_{_T}|_{\Gamma_{_C}} : v \in V \right\},$$

and their topological dual spaces V', X', $X'_{_N}$, and $X'_{_T}$, endowed with their usual norms. Since $\Gamma_{_C}$ is a straight line segment ($d = 2$) or a plane surface ($d = 3$), we have $H^{1/2}_{00}(\Gamma_{_C}) \subset X_{_N} \subset H^{1/2}(\Gamma_{_C})$, $(H^{1/2}_{00}(\Gamma_{_C}))^{d-1}, \subset X_{_T} \subset (H^{1/2}(\Gamma_{_C}))^{d-1}$, which implies $X'_{_N} \subset H^{-1/2}(\Gamma_{_C})$ and $X'_{_T} \subset (H^{-1/2}(\Gamma_{_C}))^{d-1}$, where we denote by H^s the standard Sobolev spaces (see [1]). Classically, $H^{1/2}(\Gamma_{_C})$ is the space of the restrictions on $\Gamma_{_C}$

of traces on $\partial\Omega$ of functions in $H^1(\Omega)$, and $H^{-1/2}(\Gamma_C)$ is the dual space of $H^{1/2}_{00}(\Gamma_C)$, which is the space of the restrictions on Γ_C of functions in $H^{1/2}(\partial\Omega)$ vanishing outside Γ_C. We refer to [36, 1, 31] for a detailed presentation of trace operators and/or trace spaces.

The set of admissible displacements satisfying the noninterpenetration conditions on the contact zone is

$$K = \{v \in V, v_N \leq 0 \quad \text{a.e. on } \Gamma_C\}.$$

Take as given the following forms for any u and v in V:

$$a(u,v) = \int_\Omega \mathcal{A}\varepsilon(u) : \varepsilon(v)\, d\Omega,$$

$$l(v) = \int_\Omega f.v\, d\Omega + \int_{\Gamma_N} F.v\, d\Gamma,$$

which represent the virtual work of the elastic forces and of the external loads, respectively. If $\langle\cdot,\cdot\rangle_{X'_N,X_N}$ stands for the duality pairing between X'_N and X_N, then the "virtual work" of the friction forces is given by

$$j(\mathcal{F}\lambda_N, v_T) = -\langle \mathcal{F}\lambda_N, |v_T|\rangle_{X'_N,X_N}$$

for any $\lambda_N \in X'_N$ and $v_T \in X_T$. From the previous assumptions it follows that

$a(\cdot,\cdot)$ is a bilinear symmetric V-elliptic and continuous form on $V \times V$:
$\exists\ \alpha > 0, \exists\ M > 0, \quad a(v,v) \geq \alpha\|v\|^2_V, a(u,v) \leq M\|u\|_V\|v\|_V \quad \forall u, v \in V,$
$l(\cdot)$ linear continuous form on V, i.e., $\exists\ L > 0, \quad |l(v)| \leq L\|v\|_V \quad \forall v \in V.$

Moreover, $j(\mathcal{F}\lambda_N, v_T)$ is linear continuous with respect to λ_N and convex lower semicontinuous with regard to v_T if λ_N is a nonpositive element of X'_N (see, for instance, [2]).

Clearly $a(\cdot,\cdot)$ is an inner product on V, and the associated norm,

$$\|v\|_a = (a(v,v))^{1/2},$$

is equivalent to the usual norm of V:

$$\sqrt{\alpha}\|v\|_V \leq \|v\|_a \leq \sqrt{M}\|v\|_V \quad \forall v \in V.$$

The continuity constant of $l(\cdot)$ can also be given with respect to $\|\cdot\|_a$:

$$\exists\ L_a > 0, \quad |l(v)| \leq L_a\|v\|_a \quad \forall v \in V.$$

Constants L and L_a can be chosen such that

$$\sqrt{\alpha}L_a \leq L \leq \sqrt{M}L_a.$$

The weak formulation of problem (1.1)–(1.7) (written as an inequality), introduced in [15] (see also [17]), is

$$\text{(1.8)} \qquad \begin{cases} \text{Find } u \in K \text{ satisfying} \\ a(u, v-u) + j(\mathcal{F}\sigma_N(u), v_T) - j(\mathcal{F}\sigma_N(u), u_T) \geq l(v-u) \ \ \forall\ v \in K. \end{cases}$$

Introducing the stresses on the contact boundary as an unknown in the previous formulation, one obtains the following equivalent formulation (see [30]):

$$
\left\{
\begin{array}{l}
\text{Find } u \in V, \lambda_{_N} \in X_{_N}, \text{ and } \lambda_{_T} \in X_{_T} \text{ satisfying} \\
\\
a(u,v) = l(v) + \langle \lambda_{_N}, v_{_N} \rangle_{X'_{_N},X_{_N}} + \langle \lambda_{_T}, v_{_T} \rangle_{X'_{_T},X_{_T}} \quad \forall v \in V, \\
\\
u_{_N} \leq 0, \quad \langle \lambda_{_N}, v_{_N} - u_{_N} \rangle_{X'_{_N},X_{_N}} \geq 0 \quad \forall v_{_N} \in X_{_N}, v_{_N} \leq 0, \\
\\
\langle \lambda_{_T}, v_{_T} - u_{_T} \rangle_{X'_{_T},X_{_T}} + j(\mathcal{F}\lambda_{_N}, v_{_T}) - j(\mathcal{F}\lambda_{_N}, u_{_T}) \geq 0 \quad \forall v_{_T} \in X_{_T}.
\end{array}
\right. \tag{1.9}
$$

Inverting contact and friction relations, one also obtains the classical equivalent hybrid formulation (see [30]):

$$
\left\{
\begin{array}{l}
\text{Find } u \in V, \lambda_{_N} \in X_{_N}, \text{ and } \lambda_{_T} \in X_{_T} \text{ satisfying} \\
\\
a(u,v) = l(v) + \langle \lambda_{_N}, v_{_N} \rangle_{X'_{_N},X_{_N}} + \langle \lambda_{_T}, v_{_T} \rangle_{X'_{_T},X_{_T}} \quad \forall v \in V, \\
\\
\lambda_{_N} \in \Lambda_{_N}, \quad \langle \mu_{_N} - \lambda_{_N}, u_{_N} \rangle_{X'_{_N},X_{_N}} \geq 0 \quad \forall \mu_{_N} \in \Lambda_{_N}, \\
\\
\lambda_{_T} \in \Lambda_{_T}(\mathcal{F}\lambda_{_N}), \quad \langle \mu_{_T} - \lambda_{_T}, u_{_T} \rangle_{X'_{_T},X_{_T}} \geq 0 \quad \forall \mu_{_T} \in \Lambda_{_T}(\mathcal{F}\lambda_{_N}),
\end{array}
\right. \tag{1.10}
$$

where $\Lambda_{_N}$ and $\Lambda_{_T}(\mathcal{F}\lambda_{_N})$ denote the sets of admissible normal and tangential stresses:

$$
\Lambda_{_N} = \left\{ \lambda_{_N} \in X'_{_N} : \langle \lambda_{_N}, v_{_N} \rangle_{X'_{_N},X_{_N}} \geq 0 \ \ \forall v_{_N} \leq 0 \right\},
$$

$$
\Lambda_{_T}(\mathcal{F}\lambda_{_N}) = \left\{ \lambda_{_T} \in X'_{_T} : \langle \lambda_{_T}, v_{_T} \rangle_{X'_{_T},X_{_T}} + j(\mathcal{F}\lambda_{_N}, v_{_T}) \geq 0, \ \ \forall v_{_T} \in X_{_T} \right\}.
$$

It is easy to check that the multipliers $\lambda_{_N}$ and $\lambda_{_T}$ solving (1.9) and (1.10) satisfy $\lambda_{_N} = \sigma_{_N}(u)$ and $\lambda_{_T} = \sigma_{_T}(u)$ at least in a weak sense. The main difficulty in the existence and uniqueness analysis of (1.8), (1.9), or (1.10) comes from the coupling between the friction threshold $\mathcal{F}\sigma_{_N}(u)$ and the contact pressure $\sigma_{_N}(u)$.

Remark 1. The equivalence between problems (1.8) and (1.9) is easy to obtain here since the assumption $f \in L^2(\Omega)^d$ implies that a generalized Green formula holds (see [31], for instance). The proof can also be made directly as follows. A solution to problem (1.9) is obviously a solution to problem (1.8). Conversely, if u is solution to problem (1.8), then the map $X \ni v \longmapsto a(u, \Pi(v)) - l(\Pi(v))$ is linear continuous for any continuous lifting operator $\Pi : X \to V$. Thus there exists $\lambda \in X'$ such that $\langle \lambda, v \rangle_{X',X} = a(u, \Pi(v)) - l(\Pi(v))$ for all $v \in X$. It is easy to state that in fact $\langle \lambda, v \rangle_{X',X} = a(u,v) - l(v)$ for all $v \in V$, proving $a(u, \Pi(v|_{\Gamma_{_C}}) - v) - l(\Pi(v|_{\Gamma_{_C}}) - v) = 0$ for all $v \in V$. Indeed, $\Pi(v|_{\Gamma_{_C}}) - v$ has a vanishing trace on $\Gamma_{_C}$, and replacing successively $v - u$ by $(\Pi(v|_{\Gamma_{_C}}) - v + u) - u$ and by $(v - \Pi(v|_{\Gamma_{_C}}) + u) - u$ in the inequality of (1.8) leads to this result. The two inequalities of (1.9) result then from the replacement of $a(u, v-u) - l(v-u)$ by $\langle \lambda, v-u \rangle_{X',X}$ in the inequality of (1.8), separating normal and tangential components ($\Gamma_{_C}$ is straight here), and remarking that applying a Green formula, one has $\sigma_{_N}(u) = \lambda_{_N}$. The equivalence between (1.9) and (1.10) is developed in [30] by computing the Fenchel conjugate of $j(\mathcal{F}\sigma_{_N}, \cdot)$ and inverting the normal cone to K.

1.2. Neumann to Dirichlet operator. We introduce the Neumann to Dirichlet operator on Γ_C and its basic properties. This will allow us to restrict the contact and friction problem on Γ_C and obtain useful estimates.

Let $\lambda = (\lambda_N, \lambda_T) \in X'$. The solution u to

$$\left\{ \begin{array}{l} \text{Find } u \in V \text{ satisfying} \\ a(u,v) = l(v) + \langle \lambda, v \rangle_{X',X} \quad \forall\ v \in V \end{array} \right. \tag{1.11}$$

is unique (see [17]). So it is possible to define the operator

$$\begin{aligned} \mathbb{E} : X' &\longrightarrow X \\ \lambda &\longmapsto u_{|_{\Gamma_C}}. \end{aligned}$$

It is easy to check that the operator $\mathbb{E}$ is affine and continuous. We define the following norms on Γ_C relative to $a(\cdot,\cdot)$:

$$\|v\|_{a,\Gamma_C} = \inf_{w \in V,\ w_{|_{\Gamma_C}} = v} \|w\|_a,$$

$$\|v_N\|_{a,\Gamma_C} = \inf_{\substack{w \in V, \\ w_N = v_N \text{ on } \Gamma_C}} \|w\|_a = \inf_{\substack{w \in V, \\ w_N = v_N \text{ on } \Gamma_C}} \|w\|_{a,\Gamma_C},$$

$$\|v_T\|_{a,\Gamma_C} = \inf_{\substack{w \in V, \\ w_T = v_T \text{ on } \Gamma_C}} \|w\|_a = \inf_{\substack{w \in V, \\ w_T = v_T \text{ on } \Gamma_C}} \|w\|_{a,\Gamma_C},$$

$$\|\lambda\|_{-a,\Gamma_C} = \sup_{\substack{v \in X \\ v \neq 0}} \frac{\langle \lambda, v \rangle_{X',X}}{\|v\|_{a,\Gamma_C}} = \sup_{\substack{v \in V \\ v \neq 0}} \frac{\langle \lambda, v \rangle_{X',X}}{\|v\|_a},$$

$$\|\lambda_N\|_{-a,\Gamma_C} = \sup_{\substack{v_N \in X_N \\ v_N \neq 0}} \frac{\langle \lambda_N, v_N \rangle_{X'_N, X_N}}{\|v_N\|_{a,\Gamma_C}} = \|(\lambda_N, 0)\|_{-a,\Gamma_C},$$

$$\|\lambda_T\|_{-a,\Gamma_C} = \sup_{\substack{v_T \in X_T \\ v_T \neq 0}} \frac{\langle \lambda_T, v_T \rangle_{X'_T, X_T}}{\|v_T\|_{a,\Gamma_C}} = \|(0, \lambda_T)\|_{-a,\Gamma_C},$$

which are equivalent, respectively, to the norms in X and X':

$$\frac{\sqrt{\alpha}}{C_1} \|v\|_X \leq \|v\|_{a,\Gamma_C} \leq \sqrt{M}\gamma \|v\|_X,$$

$$\frac{\sqrt{\alpha}}{C_1} \|v_N\|_{X_N} \leq \|v_N\|_{a,\Gamma_C} \leq \sqrt{M}\gamma \|v_N\|_{X_N},$$

$$\frac{\sqrt{\alpha}}{C_1} \|v_T\|_{X_T} \leq \|v_T\|_{a,\Gamma_C} \leq \sqrt{M}\gamma \|v_T\|_{X_T},$$

$$\frac{1}{\sqrt{M}\gamma}\|\lambda\|_{X'} \leq \|\lambda\|_{-a,\Gamma_C} \leq \frac{C_1}{\sqrt{\alpha}}\|\lambda\|_{X'}.$$

One also has

$$\|v_N\|_{a,\Gamma_C} \leq \|v\|_{a,\Gamma_C}$$

and

$$\|\lambda_N\|_{-a,\Gamma_C} \leq C_\alpha \|\lambda\|_{-a,\Gamma_C}$$

with a constant $C_\alpha \leq C_1\gamma\sqrt{M/\alpha}$. (But a better estimate should be possible: following [19], C_α is close to 1 when the Poisson ratio is close to 0.)

With the previous norms, it is possible to state (see [41]) the following equalities, when $u = \mathbb{E}(\lambda)$ and $\overline{u} = \mathbb{E}(\overline{\lambda})$ are the solutions to problem (1.11):

$$\|u - \overline{u}\|_a = \|\mathbb{E}(\lambda) - \mathbb{E}(\overline{\lambda})\|_{a,\Gamma_C} = \|\lambda - \overline{\lambda}\|_{-a,\Gamma_C}. \tag{1.12}$$

1.3. Direct weak inclusion formulation. Let

$$K_N = \{v_N \in X_N : v_N \leq 0 \text{ a.e. on } \Gamma_C\}$$

be the set of admissible normal displacements on Γ_C. The normal cone in X'_N to K_N at $v_N \in X_N$ is defined as

$$N_{K_N}(v_N) = \left\{\mu_N \in X'_N : \langle \mu_N, w_N - v_N\rangle_{X'_N,X_N} \leq 0 \ \forall w_N \in K_N\right\} \qquad \text{if } v_N \in K_N,$$

and $N_{K_N}(v_N) = \emptyset$ if $v_N \notin K_N$. The subdifferential of $j(\mathcal{F}\lambda_N, .)$ (i.e., with respect to the second variable) at u_T is given by

$$\begin{aligned}&\partial_2 j(\mathcal{F}\lambda_N, u_T)\\ &= \left\{\mu_T \in X'_T : j(\mathcal{F}\lambda_N, v_T) \geq j(\mathcal{F}\lambda_N, u_T) + \langle \mu_T, v_T - u_T\rangle_{X'_T,X_T} \ \ \forall v_T \in X_T\right\}.\end{aligned}$$

With this notation, problem (1.8) can be written

$$\begin{cases} \text{Find } u \in V, \lambda_N \in X'_N, \text{ and } \lambda_T \in X'_T \text{ satisfying}\\ (u_N, u_T) = \mathbb{E}(\lambda_N, \lambda_T),\\ -\lambda_N \in N_{K_N}(u_N) \quad \text{in } X'_N,\\ -\lambda_T \in \partial_2 j(\mathcal{F}\lambda_N, u_T) \quad \text{in } X'_T. \end{cases} \tag{1.13}$$

More details resulting from this equivalence can be found in [34].

1.4. A uniqueness criterion. In [26, 27] some multisolutions of the problem (1.1)–(1.7) are exhibited for triangular or quadrangular domains. These multiple solutions involve either an infinite set of slipping solutions or two isolated (stick and separation) configurations. Note that these examples of nonuniqueness involve large friction coefficients (i.e., $\mathcal{F} > 1$) and tangential displacements with a constant sign on Γ_C. Actually, it seems that no multisolution has been detected for an arbitrary

small friction coefficient in the continuous case, although such a result exists for finite element approximations in [25], but for a variable geometry. The forthcoming partial uniqueness result is obtained in [41]: it defines some cases where it is possible to affirm that a solution to the Coulomb friction problem is in fact the unique solution. More precisely, if a regular solution to the Coulomb friction problem exists (here the term regular means, roughly speaking, that the transition is smooth when the slip direction changes) and if the friction coefficient is small enough, then this solution is the only one. We recall the main useful tools leading to that result.

LEMMA 1.1. *Let u and $\overline{u}$ be two solutions to problem* (1.8)*, and let λ and $\overline{\lambda}$ be the corresponding contact stresses on Γ_C. Then the following estimate holds:*

$$\|u-\overline{u}\|_a^2 = \|\lambda-\overline{\lambda}\|_{-a,\Gamma_C}^2 \le \langle \zeta-\lambda_T, \overline{u}_T-u_T\rangle_{X'_T,X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T).$$

Proof. From (1.12), the Green formula, and (1.5), we get

$$\begin{aligned}\|u-\overline{u}\|_a^2 = \|\lambda-\overline{\lambda}\|_{-a,\Gamma_C}^2 &= \left\langle \overline{\lambda}_N-\lambda_N, \overline{u}_N-u_N\right\rangle_{X'_N,X_N} + \left\langle \overline{\lambda}_T-\lambda_T, \overline{u}_T-u_T\right\rangle_{X'_T,X_T}\\ &\le \left\langle \overline{\lambda}_T-\lambda_T, \overline{u}_T-u_T\right\rangle_{X'_T,X_T}.\end{aligned}$$

Thus

$$\|u-\overline{u}\|_a^2 \le \left\langle (\overline{\lambda}_T-\zeta)+(\zeta-\lambda_T), \overline{u}_T-u_T\right\rangle_{X'_T,X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T).$$

The conclusion follows from (1.13) and the fact that $-\partial_2 j(\mathcal{F}\overline{\lambda}_N, .)$ is a monotone set-valued mapping. ∎

We now introduce the space of multipliers $M(X_T \to X_N)$ of the functions $\xi : \Gamma_C \to R^d$ satisfying $\xi.\mathrm{n} = 0$ a.e. on Γ_C and such that the following equivalent norms are finite:

$$\|\xi\|_{M(X_T\to X_N)} = \sup_{\substack{v_T\in X_T\\ v_T\neq 0}} \frac{\|\xi.v_T\|_{X_N}}{\|v_T\|_{X_T}}, \quad \text{and} \quad \|\xi\|_a = \sup_{\substack{v_T\in X_T\\ v_T\neq 0}} \frac{\|\xi.v_T\|_{a,\Gamma_C}}{\|v_T\|_{a,\Gamma_C}}.$$

Since Γ_C is assumed to be straight, $M(X_T \to X_N)$ contains for any $\varepsilon > 0$ the space $H^{1/2+\varepsilon}(\Gamma_C)$ when $d = 2$. When $d = 3$, $M(X_T \to X_N)$ contains $H^1(\Gamma_C) \cap L^\infty(\Gamma_C)$. (See [38] for a complete discussion on the theory of multipliers in a pair of Hilbert spaces.)

The partial uniqueness result is given assuming that $\lambda_T = \mathcal{F}\lambda_N\xi$, with $\xi \in M(X_T \to X_N)$. The product $\lambda_N\xi$ has to be understood in the sense that $\langle \lambda_N\xi, v_T\rangle_{X'_T,X_T} = \langle \lambda_N, \xi.v_T\rangle_{X'_N,X_N}$ for all $v_T \in X_T$. It is easy to see that this implies $|\xi| \le 1$ a.e. on the support of λ_N. More precisely, this implies that $\xi \in \mathrm{Dir}_T(u_T)$ a.e. on the support of λ_N, where $\mathrm{Dir}_T(.)$ is the subdifferential of the convex map $R^d \ni x \longmapsto |x_T|$. This means that it is possible to assume that $\xi \in \mathrm{Dir}_T(u_T)$ a.e. on Γ_C.

PROPOSITION 1.2. *Let u be a solution to problem* (1.8) *such that $\lambda_T = \mathcal{F}\lambda_N\xi$, with $\xi \in M(X_T \to X_N)$, $\xi \in Dir_T(u_T)$ a.e. on Γ_C, and $\mathcal{F} < (C_\alpha\|\xi\|_a)^{-1}$. Then u is the unique solution to problem* (1.8).

Proof. Let $\overline{u}$ be another solution to problem (1.8), where $\overline{\lambda}_N$ and $\overline{\lambda}_T$ denote the corresponding contact stresses on Γ_C. According to Lemma 1.1, we write

$$\|u-\overline{u}\|_a^2 \le \langle \zeta-\lambda_T, \overline{u}_T-u_T\rangle_{X'_T,X_T} \qquad \forall \zeta \in -\partial_2 j(\mathcal{F}\overline{\lambda}_N, u_T).$$

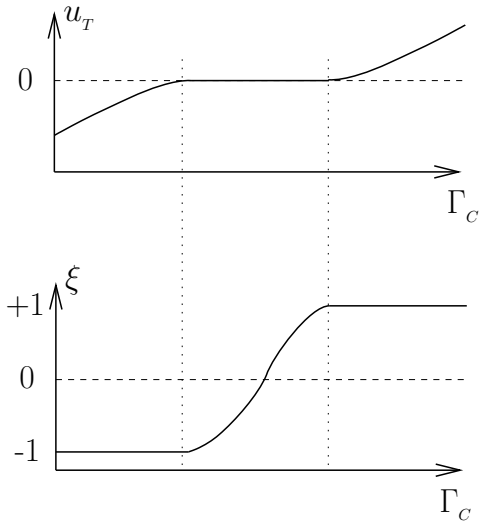

FIG. 1.2. *Example of a tangential displacement u_T and a possible corresponding multiplier ξ when $d = 2$.*

It is easy to see that a possible choice is $\zeta = \mathcal{F}\overline{\lambda}_N\xi$. Therefore

$$\begin{aligned}\|u-\overline{u}\|_a^2 \le \langle \mathcal{F}\xi(\overline{\lambda}_N-\lambda_N), \overline{u}_T-u_T\rangle_{X'_T,X_T} &\le \mathcal{F}\|\lambda_N-\overline{\lambda}_N\|_{-a,\Gamma_C}\|\xi.(u_T-\overline{u}_T)\|_{a,\Gamma_C}\\ &\le C_\alpha\mathcal{F}\|\xi\|_a\|\lambda-\overline{\lambda}\|_{-a,\Gamma_C}\|u-\overline{u}\|_a\\ &= C_\alpha\mathcal{F}\|\xi\|_a\|u-\overline{u}\|_a^2,\end{aligned}$$

which implies that $\overline{u} = u$ when $\mathcal{F} < (C_\alpha\|\xi\|_a)^{-1}$. □

In two space dimensions ($d = 2$), the case $\xi \equiv 1$ corresponds to a homogeneous sliding direction, and the previous result is complementary to the nonuniqueness results obtained in [26, 27].

As illustrated in Figure 1.2, when $d = 2$ the multiplier ξ has to vary from -1 to $+1$ each time the sign of the tangential displacement changes from negative to positive. The set $M(X_T \to X_N)$ does not contain any multiplier having a singularity of the first kind. Consequently, in order to satisfy the assumptions of Proposition 1.2, the tangential displacement of the solution u cannot pass from a negative value to a positive value and be zero at only a single point of Γ_C.

Remark 2. This remark deals with a more precise discussion concerning the assumption $\lambda_T = \mathcal{F}\lambda_N\xi$, $\xi \in M(X_T \to X_N)$, $\xi \in \mathrm{Dir}_T(u_T)$ and the cases where the assumption cannot be fulfilled independently of the regularity of the solution when $d = 2$. On the one hand, it is easy to show that the choice of ξ is unique at any point where $\lambda_N \neq 0$ or $u_T \neq 0$. In the first case $\xi = \lambda_T/(\mathcal{F}\lambda_N)$, in the second case $\xi = u_T/|u_T|$, and both expressions coincide when $\lambda_N \neq 0$ and $u_T \neq 0$. On the other hand, any $\xi \in [-1, 1]$ can be chosen at the points where $\lambda_N = u_T = 0$. So it remains to determine when ξ lies in $M(X_T \to X_N)$. If there are no points such that $\lambda_N = u_T = 0$ on Γ_C, then the condition $\xi \in M(X_T \to X_N)$ is linked to the regularity of u (in other words, if u is regular enough, then $\xi \in M(X_T \to X_N)$). If there are some points such that $\lambda_N = u_T = 0$, then it is easy to show that the continuity of ξ can be lost (whatever the regularity of u is) only if some of these points are isolated. A discussion

shows then that $\xi \notin M(X_T \to X_N)$ in three cases. The first one is when u_T passes from a negative to a positive value at such a point (note that this could also occur at a point which is separated from the foundation). The second case corresponds to a stick area surrounding such an isolated point and where the right and left limits of $\lambda_T/(\mathcal{F}\lambda_N)$ differ at this point (where $\lambda_T = \lambda_N = u_T = u_N = 0$). The third case is a combination of both previous cases: a side where $u_T \neq 0$, the other one with $u_T = 0$ and $\lambda_N \neq 0$, and a limit of $\lambda_T/(\mathcal{F}\lambda_N)$ which differs from $u_T/|u_T|$. If the solution is less regular, then other cases of nonfulfillment could appear, but we think that this assumption (which is needed to obtain the uniqueness of a solution to the continuous problem) takes into account many frictional contact configurations.

2. Finite element approximation. Let $V^h \subset V$ be a family of finite dimensional vector spaces indexed by h coming from a regular family $\mathcal{T}^h$ (see [9]) of triangulations of the domain Ω (h represents the largest diameter among all elements). We choose standard continuous and piecewise affine functions, i.e.,

$$V^h = \left\{ v^h \in (\mathcal{C}(\overline{\Omega}))^d, v^h{}_{|_T} \in P_1(T) \quad \forall T \in \mathcal{T}^h, v^h = 0 \text{ on } \Gamma_D \right\}. \tag{2.1}$$

Define

$$X_N^h = \left\{ v_N^h{}_{|_{\Gamma_C}} : v^h \in V^h \right\},$$

$$X_T^h = \left\{ v_T^h{}_{|_{\Gamma_C}} : v^h \in V^h \right\},$$

$$X^h = \left\{ v^h{}_{|_{\Gamma_C}} : v^h \in V^h \right\} = X_N^h \times X_T^h. \tag{2.2}$$

Identifying X_N^h and X_T^h with their dual spaces using the L^2 scalar product, we consider that X_N^h and X_T^h are also the finite-dimensional approximations of X_N' and X_T', respectively.

The finite element discretization of problem (1.10) becomes

$$\begin{cases} \text{Find } u^h \in V^h, \lambda_N^h \in X_N^h, \text{ and } \lambda_T^h \in X_T^h \text{ satisfying} \\ a(u^h, v^h) = l(v^h) + \displaystyle\int_{\Gamma_C} \lambda_N^h v_N^h \, d\Gamma + \int_{\Gamma_C} \lambda_T^h . v_T^h \, d\Gamma \quad \forall v^h \in V^h, \\ \lambda_N^h \in \Lambda_N^h, \quad \displaystyle\int_{\Gamma_C} (\mu_N^h - \lambda_N^h) u_N^h \, d\Gamma \geq 0 \quad \forall \mu_N^h \in \Lambda_N^h, \\ \lambda_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h), \quad \displaystyle\int_{\Gamma_C} (\mu_T^h - \lambda_T^h) . u_T^h d\Gamma \geq 0 \quad \forall \mu_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h), \end{cases} \tag{2.3}$$

where the approximations of Λ_N and $\Lambda_T(\mathcal{F}\lambda_N)$ have been chosen in the following way:

$$\Lambda_N^h = \Lambda_N \cap X_N^h, \tag{2.4}$$

$$\Lambda_T^h(\mathcal{F}\lambda_N^h) = \left\{ \lambda_T^h \in X_T^h : \int_{\Gamma_C} \lambda_T^h . v_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, v_T^h) \geq 0 \quad \forall v_T^h \in X_T^h \right\}. \tag{2.5}$$

To simplify our discussion, we assume afterwards that the mesh inherited on the contact zone is quasi-uniform (although there exist some less restrictive assumptions; see, e.g., [13]) of size h (to simplify). Another simplification is that we restrict ourselves to the two-dimensional case ($d = 2$), and we assume that the end points of Γ_C do not belong to $\overline{\Gamma_D}$ (in other words, $\overline{\Gamma_C} \cap \overline{\Gamma_D} = \emptyset$). More general cases will be discussed in some remarks at the end of the paper.

With this choice of discretization, the following discrete Babuška–Brezzi inf-sup condition holds (see, e.g., [12, 6]):

$$\inf_{\lambda^h \in X^h} \sup_{v^h \in V^h} \frac{\int_{\Gamma_C} \lambda^h . v^h d\Gamma}{\|v^h\|_a \|\lambda^h\|_{-a,\Gamma_C}} \geq c_{is} > 0, \tag{2.6}$$

where $c_{is} \leq 1$ is independent of h. As a consequence, problem (2.3) admits a solution for any friction coefficient, and the solution is unique for a sufficiently small friction coefficient (where the label "small" may depend on h) (see [30]).

The following lemma shows the relation between the hybrid formulation and the direct formulation of the friction condition in the discrete framework.

LEMMA 2.1. *For $\lambda_N^h \in \Lambda_N^h$, a pair $(\lambda_T^h, u_T^h) \in X_T^h \times X_T^h$ satisfies*

$$\lambda_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h), \quad \int_{\Gamma_C} (\mu_T^h - \lambda_T^h).u_T^h d\Gamma \geq 0 \quad \forall \mu_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h) \tag{2.7}$$

if and only if the pair satisfies

$$\int_{\Gamma_C} \lambda_T^h.(v_T^h - u_T^h)d\Gamma + j(\mathcal{F}\lambda_N^h, v_T^h) - j(\mathcal{F}\lambda_N^h, u_T^h) \geq 0 \quad \forall v_T^h \in X_T^h. \tag{2.8}$$

Proof. Let us first assume that (λ_T^h, u_T^h) satisfies (2.7). For an arbitrary choice $\xi \in \mathcal{F}\lambda_N^h \mathrm{Dir}_T(u_T^h)$ the map $v_T^h \longmapsto \int_{\Gamma_C} \xi.v_T^h d\Gamma$ is a linear form on X_T^h, and thus by the Riesz representation theorem there exists $\mu_T^h \in X_T^h$ such that $\int_{\Gamma_C} \mu_T^h.v_T^h d\Gamma = \int_{\Gamma_C} \xi.v_T^h d\Gamma$ for all $v_T^h \in X_T^h$. This μ_T^h satisfies $\int_{\Gamma_C} \mu_T^h.u_T^h d\Gamma = \int_{\Gamma_C} \mathcal{F}\lambda_N^h |u_T^h| d\Gamma = -j(\mathcal{F}\lambda_N^h, u_T^h)$, and μ_T^h is an element of $\Lambda_T^h(\mathcal{F}\lambda_N^h)$. Now considering this particular μ_T^h in (2.7) leads to

$$\int_{\Gamma_C} \lambda_T^h.u_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, u_T^h) \leq 0.$$

Together with the fact that λ_T^h is in $\Lambda_T^h(\mathcal{F}\lambda_N^h)$ this leads to the complementarity relation

$$\int_{\Gamma_C} \lambda_T^h.u_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, u_T^h) = 0,$$

which straightforwardly implies (2.8).

Conversely, let us assume that (λ_T^h, u_T^h) satisfies (2.8). Then choosing $v_T^h = 0$ in (2.8) gives $-\int_{\Gamma_C} \lambda_T^h.u_T^h d\Gamma - j(\mathcal{F}\lambda_N^h, u_T^h) \geq 0$, and choosing $v_T^h = 2u_T^h$ gives $\int_{\Gamma_C} \lambda_T^h.u_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, u_T^h) \geq 0$, which implies the complementarity relation

$$\int_{\Gamma_C} \lambda_T^h.u_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, u_T^h) = 0.$$

Taking this into account in (2.8) leads to

$$\int_{\Gamma_C} \lambda_T^h . v_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, v_T^h) \geq 0 \qquad \forall v_T^h \in X_T^h,$$

which implies $\lambda_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h)$. Now, from the complementarity relation and for all $\mu_T^h \in \Lambda_T^h(\mathcal{F}\lambda_N^h)$ one has

$$\int_{\Gamma_C} (\mu_T^h - \lambda_T^h).u_T^h d\Gamma = \int_{\Gamma_C} \mu_T^h.u_T^h d\Gamma + j(\mathcal{F}\lambda_N^h, u_T^h) \geq 0,$$

which implies (2.7). □

Remark 3. The equivalence given by this lemma is a classical result when it deals with the continuous problem. With the particular finite element discretization considered in this section, the result is still valid in the finite-dimensional case. One of the reasons is that the space of the multipliers has been chosen in such a way that it can represent the dual space of the discrete trace space X_T^h. But this result does not remain valid when a smaller space for the multipliers is chosen.

3. The error estimate.

THEOREM 3.1. *Let (u, λ) be the solution to problem* (1.8) *(for $d = 2$) such that $\lambda_T = \mathcal{F}\lambda_N\xi$, with $\xi \in M(X_T \to X_N)$, $\xi \in Dir_T(u_T)$ a.e. on Γ_C, and $\mathcal{F} < c_{is}(C_\alpha\|\xi\|_a)^{-1}$. Assume that $u \in (H^{(3/2)+\varepsilon}(\Omega))^2$ with $\varepsilon > 0$, and let (u^h, λ^h) be a solution to the discrete problem* (2.3). *Then there exists a constant $C > 0$ independent of h and u such that*

$$\|u - u^h\|_a + \|\lambda - \lambda^h\|_{-a,\Gamma_C} \leq Ch^{1/2}\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}. \tag{3.1}$$

Proof. Let $v^h \in V^h$. Then

$$\begin{aligned}
\|u - u^h\|_a^2 &= a(u - u^h, u - u^h) \\
&= a(u - u^h, u - v^h) + a(u, v^h - u^h) - a(u^h, v^h - u^h) \\
&= a(u - u^h, u - v^h) + \int_{\Gamma_C} \lambda_N (v_N^h - u_N^h)\, d\Gamma + \int_{\Gamma_C} \lambda_T.(v_T^h - u_T^h)\, d\Gamma \\
&\quad - \int_{\Gamma_C} \lambda_N^h (v_N^h - u_N^h)\, d\Gamma - \int_{\Gamma_C} \lambda_T^h.(v_T^h - u_T^h)\, d\Gamma \\
&= a(u - u^h, u - v^h) \\
&\quad + \int_{\Gamma_C} (\lambda_N - \lambda_N^h)(v_N^h - u_N)\, d\Gamma + \int_{\Gamma_C} (\lambda_T - \lambda_T^h).(v_T^h - u_T)\, d\Gamma \\
&\quad + \int_{\Gamma_C} (\lambda_N - \lambda_N^h)(u_N - u_N^h)\, d\Gamma + \int_{\Gamma_C} (\lambda_T - \lambda_T^h).(u_T - u_T^h)\, d\Gamma.
\end{aligned}$$

The continuous and discrete complementary conditions imply

$$\int_{\Gamma_C} \lambda_N u_N \, d\Gamma = \int_{\Gamma_C} \lambda_N^h u_N^h \, d\Gamma = 0.$$

Hence

$$\begin{aligned}\|u-u^h\|_a^2 = a(u-u^h,u-v^h)&\\ +\int_{\Gamma_C}(\lambda_N-\lambda_N^h)(v_N^h-u_N)\,d\Gamma+\int_{\Gamma_C}(\lambda_T-\lambda_T^h).(v_T^h-u_T)\,d\Gamma&\\ -\int_{\Gamma_C}\lambda_N u_N^h+\lambda_N^h u_N\,d\Gamma+\int_{\Gamma_C}(\lambda_T-\lambda_T^h).(u_T-u_T^h)\,d\Gamma.&\end{aligned}$$

Using the continuity of the bilinear form, we obtain

$$\begin{aligned}\|u-u^h\|_a^2 \le \|u-u^h\|_a\|u-v^h\|_a+\|\lambda-\lambda^h\|_{-a,\Gamma_C}\|u-v^h\|_{a,\Gamma_C}&\\ -\int_{\Gamma_C}\lambda_N u_N^h+\lambda_N^h u_N\,d\Gamma+\int_{\Gamma_C}(\lambda_T-\lambda_T^h).(u_T-u_T^h)\,d\Gamma.&\end{aligned}\tag{3.2}$$

Additionally, we consider the equilibrium equation. From $V^h\subset V$, we get

$$a(u,v^h)=l(v^h)+\int_{\Gamma_C}\lambda.v^h\,d\Gamma\qquad\forall\ v^h\in V^h.$$

Since

$$a(u^h,v^h)=l(v^h)+\int_{\Gamma_C}\lambda^h.v^h\,d\Gamma\qquad\forall\ v^h\in V^h,$$

we deduce by subtraction that

$$a(u-u^h,v^h)=\int_{\Gamma_C}(\lambda-\lambda^h).v^h\,d\Gamma\qquad\forall\ v^h\in V^h.$$

Consequently, for any $v^h\in V^h$ and any $\mu^h\in X^h$

$$\begin{aligned}\int_{\Gamma_C}(\lambda^h-\mu^h).v^h\,d\Gamma = a(u^h-u,v^h)+\int_{\Gamma_C}(\lambda-\mu^h).v^h\,d\Gamma&\\ \le(\|u-u^h\|_a+\|\lambda-\mu^h\|_{-a,\Gamma_C})\|v^h\|_a.&\end{aligned}$$

The mesh independent inf-sup condition (2.6) implies, for any $\mu^h\in X^h$,

$$c_{is}\|\lambda^h-\mu^h\|_{-a,\Gamma_C}\le\sup_{v^h\in V^h}\frac{\int_{\Gamma_C}(\lambda^h-\mu^h).v^h\,d\Gamma}{\|v^h\|_a}\le\|u-u^h\|_a+\|\lambda-\mu^h\|_{-a,\Gamma_C}.$$

By the triangular inequality we come to the conclusion that

$$\|\lambda-\lambda^h\|_{-a,\Gamma_C}\le\frac{1}{c_{is}}\|u-u^h\|_a+\left(1+\frac{1}{c_{is}}\right)\inf_{\mu^h\in X^h}\|\lambda-\mu^h\|_{-a,\Gamma_C}.\tag{3.3}$$

Keeping in mind that $u\in(H^{(3/2)+\varepsilon}(\Omega))^2$ with $\varepsilon>0$, so that $\lambda\in(L^2(\Gamma_C))^2$ according to the trace theorem, we choose $v^h=I^hu$, where I^h denotes the Lagrange interpolation operator mapping onto V^h, and $\mu^h=\pi^h\lambda$, where π^h represents the $(L^2(\Gamma_C))^2$-projection operator mapping onto X^h. As a consequence (see [7, 9, 13]) if $\varepsilon>0$ is small enough, we have

$$\inf_{v^h\in V^h}\|u-v^h\|_a\le Ch^{(1/2)+\varepsilon}\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}\tag{3.4}$$

and

$$\inf_{\mu^h \in X^h} \|\lambda - \mu^h\|_{-a,\Gamma_C} \leq Ch^{(1/2)+\varepsilon} \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}, \tag{3.5}$$

where C denotes here and afterwards a positive constant independent of h. We now estimate the terms in (3.2) coming from the contact approximation. Since $u_N \leq 0$ and $\lambda_N^h \leq 0$ on Γ_C, we deduce that the first term is nonpositive:

$$-\int_{\Gamma_C} \lambda_N^h u_N \, d\Gamma \leq 0. \tag{3.6}$$

In order to estimate the second term in (3.2) coming from the contact approximation we introduce a specific operator. Namely, $r^h : L^1(\Gamma_C) \mapsto X_N^h$ is the quasi-interpolation operator defined for any function v in $L^1(\Gamma_C)$ by

$$r^h v = \sum_{x \in N^h} \alpha_x(v) \psi_x,$$

where N^h represents the set of nodes of $\overline{\Gamma_C}$, ψ_x is the scalar basis function of X_N^h (defined on $\overline{\Gamma_C}$) at node x verifying $\psi_x(x') = \delta_{x,x'}$ for all $x' \in N^h$, and

$$\alpha_x(v) = \left(\int_{\Gamma_C} v \psi_x \, d\Gamma \right) \left(\int_{\Gamma_C} \psi_x \, d\Gamma \right)^{-1}.$$

Remark 4. It is straightforward to check that r^h is linear and that it preserves nonpositivity. It is also obvious that $r^h v^h \neq v^h$ when $v^h \in X_N^h$. This operator is different from Clément's (which consists of making local projections onto P_1 functions; see [10]), from Chen–Nochetto's (which uses local projections onto P_0 functions; see [8]), and from Ben Belgacem–Renard's (which consists of making local projections onto the convex cone of nonpositive P_1 functions; see [6]). The main particularity of the operator r^h, which directly follows from its definition, is that $r^h v^h \leq 0$ when $v^h \in X_N^h$ satisfies only "weak nonpositivity conditions"; i.e.,

$$\int_{\Gamma_C} \mu_N^h v^h d\Gamma \geq 0 \qquad \forall \mu_N^h \in \Lambda_N^h. \tag{3.7}$$

This property is not satisfied by the operators in [8] and [10]. Moreover, as we see hereafter, the approximation properties of r^h hold for any function without sign condition, contrary to the operator in [6].

The approximation properties of r^h are established in [28]. We recall them to render the proof of Theorem 3.1 self-contained. We first show the L^2-stability property of r^h.

LEMMA 3.2. *There is a positive constant C independent of h such that for any $v \in L^2(\Gamma_C)$ and any $E \in E_C^h$ (E_C^h denotes the set of closed edges lying in $\overline{\Gamma_C}$)*

$$\|r^h v\|_{L^2(E)} \leq C \|v\|_{L^2(\gamma_E)},$$

where $\gamma_E = \cup_{\{F \in E_C^h :\, F \cap E \neq \emptyset\}} F$.

Proof. Let γ_x be the support of the basis function ψ_x in Γ_C. Using the definition of $\alpha_x(v)$, the Cauchy–Schwarz inequality, and the uniform regularity of the mesh, we get

$$|\alpha_x(v)| \leq \|v\|_{L^2(\gamma_x)} \|\psi_x\|_{L^2(\gamma_x)} \|\psi_x\|_{L^1(\gamma_x)}^{-1} \leq Ch^{-\frac{1}{2}} \|v\|_{L^2(\gamma_x)}.$$

We obtain by a triangular inequality

$$\|r^h v\|_{L^2(E)} = \left\| \sum_{x \in N^h \cap E} \alpha_x(v) \psi_x \right\|_{L^2(E)} \leq C \|v\|_{L^2(\gamma_E)}. \qquad \square$$

The next lemma is concerned with the L^2-approximation properties of r^h.

LEMMA 3.3. *There is a positive constant C independent of h such that for any $v \in H^\eta(\Gamma_C)$, $0 \leq \eta \leq 1$, and any $E \in E_C^h$ (E_C^h denotes the set of closed edges lying in $\overline{\Gamma_C}$)*

$$\|v - r^h v\|_{L^2(E)} \leq C h^\eta \|v\|_{H^\eta(\gamma_E)}, \tag{3.8}$$

where $\gamma_E = \cup_{\{F \in E_C^h :\, F \cap E \neq \emptyset\}} F$.

Proof. When $\eta = 0$ the bound results from the previous lemma. Note that r^h preserves the constant functions on Γ_C. Let be given an arbitrary constant function $c(x) = c$, for all $x \in \Gamma_C$. From the definition of r^h, we may write, for any $v \in H^\eta(\Gamma_C)$,

$$v - r^h v = v - c - r^h(v - c).$$

Therefore by Lemma 3.2 we get

$$\|v - r^h v\|_{L^2(E)} \leq C \left(\|v - c\|_{L^2(E)} + \|v - c\|_{L^2(\gamma_E)} \right) \leq C \|v - c\|_{L^2(\gamma_E)} \quad \forall c \in R. \tag{3.9}$$

We then choose $c = \int_{\gamma_E} v(x)\, dx / |\gamma_E|$ in (3.9), where $|\gamma_E|$ denotes the length of γ_E. Then if $x \in \gamma_E$ and $0 < \eta < 1$, we have

$$\begin{aligned} v(x) - c &= |\gamma_E|^{-1} \int_{\gamma_E} v(x) - v(y)\, dy \\ &= |\gamma_E|^{-1} \int_{\gamma_E} \frac{v(x) - v(y)}{|x - y|^{\frac{1+2\eta}{2}}} |x - y|^{\frac{1+2\eta}{2}} dy. \end{aligned}$$

Using the Cauchy–Schwarz inequality, we deduce

$$\begin{aligned} \int_{\gamma_E} (v(x) - c)^2 dx &= |\gamma_E|^{-2} \int_{\gamma_E} \left(\int_{\gamma_E} \frac{v(x) - v(y)}{|x - y|^{\frac{1+2\eta}{2}}} |x - y|^{\frac{1+2\eta}{2}} dy \right)^2 dx \\ &\leq |\gamma_E|^{-2} \int_{\gamma_E} \left(\int_{\gamma_E} \frac{(v(x) - v(y))^2}{|x - y|^{1+2\eta}} dy \int_{\gamma_E} |x - y|^{1+2\eta} dy \right) dx \\ &\leq |\gamma_E|^{2\eta} \int_{\gamma_E} \int_{\gamma_E} \frac{(v(x) - v(y))^2}{|x - y|^{1+2\eta}}\, dy dx \\ &\leq C h^{2\eta} \|v\|^2_{H^\eta(\gamma_E)}. \end{aligned}$$

Hence the result.

If $x \in \gamma_E$ and $\eta = 1$, we have

$$v(x) - c = |\gamma_E|^{-1} \int_{\gamma_E} v(x) - v(y)\, dy = |\gamma_E|^{-1} \int_{\gamma_E} \int_y^x v'(t)\, dt dy.$$

Hence

$$|v(x) - c| \leq |\gamma_E|^{\frac{1}{2}} \|v'\|_{L^2(\gamma_E)}.$$

The result is then straightforward. ∎

End of the proof of Theorem 3.1. The second term coming from the contact approximation in (3.2) is handled as follows:

$$-\int_{\Gamma_C} \lambda_N u_N^h \, d\Gamma = -\int_{\Gamma_C} \lambda_N (u_N^h - r^h u_N^h) \, d\Gamma - \int_{\Gamma_C} \lambda_N \, r^h u_N^h \, d\Gamma.$$

According to (2.3), u_N^h satisfies a weak nonnegativity condition as in (3.7). From Remark 4 we deduce that $r^h u_N^h \leq 0$. Hence we have, for any small $\varepsilon > 0$,

$$\begin{aligned}
-\int_{\Gamma_C} \lambda_N u_N^h \, d\Gamma &\leq -\int_{\Gamma_C} \lambda_N (u_N^h - r^h u_N^h) \, d\Gamma \\
&\leq \|\lambda_N\|_{L^2(\Gamma_C)} \|u_N^h - r^h u_N^h\|_{L^2(\Gamma_C)} \\
&\leq \|\lambda_N\|_{L^2(\Gamma_C)} \|(u_N^h - u_N) - r^h(u_N^h - u_N)\|_{L^2(\Gamma_C)} \\
&\quad + \|\lambda_N\|_{L^2(\Gamma_C)} \|u_N - r^h u_N\|_{L^2(\Gamma_C)} \\
&\leq Ch^{1/2} \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2} \|u_N^h - u_N\|_{H^{1/2}(\Gamma_C)} \\
&\quad + Ch \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2} \|u_N\|_{H^1(\Gamma_C)}, \qquad (3.10)
\end{aligned}$$

where the trace theorem $\|\lambda_N\|_{L^2(\Gamma_C)} \leq C\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}$ (see [20]) and the estimates in Lemma 3.3 have been used. Putting together estimates (3.6) and (3.10) yields for any small $\varepsilon > 0$

$$\begin{aligned}
&-\int_{\Gamma_C} \lambda_N^h u_N + \lambda_N u_N^h \, d\Gamma \leq Ch^{1/2} \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2} \\
&\left(\|u - u^h\|_a + h^{1/2} \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2} \right). \qquad (3.11)
\end{aligned}$$

We now estimate the terms corresponding to the friction approximation in (3.2). From the assumptions in the theorem we write

$$\begin{aligned}
\int_{\Gamma_C} (\lambda_T - \lambda_T^h).(u_T - u_T^h) \, d\Gamma &= \int_{\Gamma_C} (\lambda_T - \mathcal{F}\lambda_N^h \xi).(u_T - u_T^h) \, d\Gamma \\
&\quad + \int_{\Gamma_C} (\mathcal{F}\lambda_N^h \xi - \lambda_T^h).(u_T - u_T^h) \, d\Gamma \\
&= \int_{\Gamma_C} \mathcal{F}(\lambda_N - \lambda_N^h)\xi.(u_T - u_T^h) \, d\Gamma \\
&\quad + \int_{\Gamma_C} (\mathcal{F}\lambda_N^h \xi - \lambda_T^h).(u_T - u_T^h) \, d\Gamma. \qquad (3.12)
\end{aligned}$$

The estimate of the first integral term in (3.12) gives

$$\int_{\Gamma_C} \mathcal{F}(\lambda_N - \lambda_N^h)\xi.(u_T - u_T^h) \, d\Gamma \leq C_\alpha \mathcal{F} \|\xi\|_a \|\lambda - \lambda^h\|_{-a,\Gamma_C} \|u - u^h\|_a.$$

The second integral term in (3.12) is written as follows:

$$\begin{aligned}
\int_{\Gamma_C} (\mathcal{F}\lambda_N^h \xi - \lambda_T^h).(u_T - u_T^h) \, d\Gamma &= \int_{\Gamma_C} \mathcal{F}\lambda_N^h \xi.(u_T - u_T^h) \, d\Gamma - \int_{\Gamma_C} \lambda_T^h.u_T \, d\Gamma \\
&\quad + \int_{\Gamma_C} \lambda_T^h.u_T^h \, d\Gamma.
\end{aligned}$$

Using the equivalent discrete friction conditions in (2.8), we obtain for any $v^h \in V^h$

$$\int_{\Gamma_C} (\mathcal{F}\lambda_N^h \xi - \lambda_T^h).(u_T - u_T^h)\,d\Gamma \le \int_{\Gamma_C} \mathcal{F}\lambda_N^h \xi.(u_T - u_T^h)\,d\Gamma - \int_{\Gamma_C} \lambda_T^h.u_T\,d\Gamma + \int_{\Gamma_C} \lambda_T^h.v_T^h\,d\Gamma - \int_{\Gamma_C} \mathcal{F}\lambda_N^h |v_T^h|\,d\Gamma + \int_{\Gamma_C} \mathcal{F}\lambda_N^h |u_T^h|\,d\Gamma.$$

Choosing $v_T^h = I^h u_T$ and since $\xi.u_T = |u_T|$, we obtain

$$\int_{\Gamma_C} (\mathcal{F}\lambda_N^h \xi - \lambda_T^h).(u_T - u_T^h)\,d\Gamma \le \int_{\Gamma_C} \lambda_T^h.(I^h u_T - u_T)\,d\Gamma + \int_{\Gamma_C} \mathcal{F}\lambda_N^h (|u_T^h| - \xi.u_T^h)\,d\Gamma + \int_{\Gamma_C} \mathcal{F}\lambda_N^h (|u_T| - |I^h u_T|)\,d\Gamma. \tag{3.13}$$

The estimate of the first term in (3.13) is achieved as follows by using the error estimates in [9]:

$$\int_{\Gamma_C} \lambda_T^h.(I^h u_T - u_T)\,d\Gamma = \int_{\Gamma_C} (\lambda_T^h - \lambda_T).(I^h u_T - u_T)\,d\Gamma + \int_{\Gamma_C} \lambda_T.(I^h u_T - u_T)\,d\Gamma \le Ch^{1/2}\|u\|_{(H^{3/2}(\Omega))^2}\Big(\|\lambda - \lambda^h\|_{-a,\Gamma_C} + h^{1/2}\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}\Big).$$

The estimate of the second term in (3.13) uses the fact that $\lambda_N^h \le 0$ and $|u_T^h| - \xi.u_T^h \ge 0$ so that

$$\int_{\Gamma_C} \mathcal{F}\lambda_N^h (|u_T^h| - \xi.u_T^h)\,d\Gamma \le 0.$$

Finally, the third term in (3.13) yields

$$\int_{\Gamma_C} \mathcal{F}\lambda_N^h (|u_T| - |I^h u_T|)\,d\Gamma \le \mathcal{F}\|\lambda_N^h\|_{L^2(\Gamma_C)}\||u_T| - |I^h u_T|\|_{L^2(\Gamma_C)} \le \mathcal{F}\|\lambda_N^h\|_{L^2(\Gamma_C)}\|u_T - I^h u_T\|_{L^2(\Gamma_C)} \le C\mathcal{F}\|\lambda_N^h\|_{L^2(\Gamma_C)} h\|u\|_{(H^{3/2}(\Omega))^2}.$$

Further, using the (global) $L^2(\Gamma_C)$-projection operator π_N^h onto X_N^h (the notation π^h stands for the $(L^2(\Gamma_C))^2$-projection operator onto X^h) and an inverse inequality (see, e.g., [7, 9, 13]), we write

$$\begin{aligned}\|\lambda_N^h\|_{L^2(\Gamma_C)} &\le \|\lambda_N^h - \pi_N^h\lambda_N\|_{L^2(\Gamma_C)} + \|\pi_N^h\lambda_N - \lambda_N\|_{L^2(\Gamma_C)} + \|\lambda_N\|_{L^2(\Gamma_C)} \\ &\le C\left(h^{-1/2}\|\lambda^h - \pi^h\lambda\|_{-a,\Gamma_C} + \|\lambda_N\|_{L^2(\Gamma_C)}\right) \\ &\le C\left(h^{-1/2}\|\lambda - \lambda^h\|_{-a,\Gamma_C} + \|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}\right).\end{aligned}$$

Therefore,

$$\int_{\Gamma_C} \mathcal{F}\lambda_N^h (|u_T| - |I^h u_T|)\,d\Gamma \le C\mathcal{F}h^{1/2}\|u\|_{(H^{3/2}(\Omega))^2} \left(\|\lambda - \lambda^h\|_{-a,\Gamma_C} + h^{1/2}\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}\right).$$

We come to the conclusion that the term dealing with the friction approximation in (3.2) is bounded as follows:

$$\begin{aligned}\int_{\Gamma_C} (\lambda_T - \lambda_T^h).(u_T - u_T^h)\, d\Gamma \le{}& C_\alpha \mathcal{F}\|\xi\|_a \|\lambda - \lambda^h\|_{-a,\Gamma_C} \|u - u^h\|_a \\ &+ C(1+\mathcal{F})h\|u\|^2_{(H^{(3/2)+\varepsilon}(\Omega))^2} \\ &+ C(1+\mathcal{F})h^{1/2}\|u\|_{(H^{3/2}(\Omega))^2}\|\lambda - \lambda^h\|_{-a,\Gamma_C}. \end{aligned} \tag{3.14}$$

Finally, the result is obtained by using (3.4)–(3.5) and putting together (3.2), (3.3), (3.11), and (3.14). ∎

Remark 5. The quasi-optimal rate of convergence of order 1/2 in the theorem does not depend on $\varepsilon > 0$. Actually we are not able to obtain a better convergence rate even if ε increases. A bit more regularity than $H^{3/2}$ is needed to apply the trace theorem, when writing $\|\lambda_N\|_{L^2(\Gamma_C)} \le C\|u\|_{(H^{(3/2)+\varepsilon}(\Omega))^2}$ (see [20]). The choice of the regularity assumptions $u \in (H^{(3/2)+\varepsilon}(\Omega))^2$ in the numerical analysis of contact problems is discussed in [4, Remark 2.4(i)] and [5, Remark 4.4]. If u is less regular than $H^{3/2}$, then the normal and tangential constraints cannot be expressed pointwise, and the frictional contact conditions cannot be simply written as in (1.5)–(1.7). In the frictionless case, when $u \in (H^\nu(\Omega))^2$ with $1 < \nu < 3/2$, the error analysis of a finite element approximation is achieved in [4]. Actually we are not able to extend these results to the frictional case.

Remark 6. If one (or both) end points of $\overline{\Gamma_C} = [x_0, x_n]$ is subjected to Dirichlet conditions, then the previous study can be extended with some modifications. Suppose, for instance, that $\overline{\Gamma_C} \cap \overline{\Gamma_D} = \{x_0\}$ and that the definition of V^h in (2.1) remains unchanged. If we still keep the same definition of X^h as in (2.2), then the estimate (3.5), does not hold in the general case. Thus we use a mortar approach introduced in [7]: denoting by $x_i, 0 \le i \le n$, the nodes on $\overline{\Gamma_C}$, we set

$$X_N^h = \left\{ \mu_N^h \in \mathcal{C}(\overline{\Gamma_C}), \mu_N^h{}_{|_{[x_i,x_{i+1}]}} \in P_1([x_i, x_{i+1}])\ \forall 1 \le i \le n-1, \mu_N^h{}_{|_{[x_0,x_1]}} \in P_0([x_0, x_1]) \right\}.$$

The particularity of this space is that the functions are constant on the extreme segment $[x_0, x_1]$. We choose the same kind of approximation for X_T^h, and we set $X^h = X_N^h \times X_T^h$. In this case the discrete Babuška–Brezzi inf-sup condition (2.6) still holds (see [3]). Moreover, estimate (3.5) remains valid (see [7, Lemma 4.1]). Keeping the same definitions of Λ_N^h and $\Lambda_T^h(\mathcal{F}\lambda_N^h)$ as in (2.4) and (2.5), we note that the equivalence in Lemma 2.1 still holds in this case since the dimensions of the multiplier and tangential displacement spaces are the same (see also Remark 1) and the inf-sup condition is satisfied. According to [30], problem (2.3) admits a solution for any friction coefficient, and the solution is unique for a sufficiently small friction coefficient. The following result is then obtained: if (u^h, λ^h) is a solution to (2.3), then estimate (3.1) is recovered.

Remark 7. In the three-dimensional case, the convergence result should hold (at least when $\overline{\Gamma_C} \cap \overline{\Gamma_D} = \emptyset$), and the main task would be to generalize the estimate (3.8).

Remark 8. If $\mathcal{F} = 0$, then the continuous problem admits a unique solution. Choosing then the same approximation method as in (2.3) (therefore $\lambda_T^h = 0$ and the discrete solution is unique) and accomplishing the convergence analysis has led to an upper bound of the error of order $h^{1/2}$ under H^2-regularity hypotheses (see [6]). The estimate obtained in the present paper improves the bound in [6], since we obtain the

same convergence rate with fewer regularity assumptions ($H^{(3/2)+\varepsilon}$ with ε arbitrary small instead of H^2). Moreover, we observe that there is no loss of convergence when the friction terms are added. Nevertheless we mention that there exists in the frictionless case a standard finite element approximation, which leads to an upper bound of the error of order $h^{3/4}$ under H^2-regularity hypotheses (see [24, 23]) and of order h with some additional assumptions concerning the finiteness of transition points between contact and separation (see [29]). Actually we are not able to extend these results to the frictional case.

Remark 9. Note that we do not prove that the solution to the discrete problem is unique under the assumptions of Theorem 3.1. This seems to be an open question which is actually under investigation. Note also that this possible loss of uniqueness would not be embarrassing in the a priori error analysis of Theorem 3.1. As a matter of fact, even if there are multiple solutions to the discrete problem, any solution would converge towards the unique solution of the continuous model. Additionally, the bound ensuring uniqueness in Proposition 1.2 is $\mathcal{F} < (C_\alpha \|\xi\|_a)^{-1}$, and we establish the error estimate only for $\mathcal{F} < c_{is}(C_\alpha \|\xi\|_a)^{-1}$. It should be interesting to see whether or not it is possible to prove an error estimate for all the uniqueness cases of Proposition 1.2.

Conclusion. This work is a contribution to the numerical analysis of the unilateral contact problem governed by Coulomb's law of friction in elastostatics. As far as we know, this study establishes a first error estimate with a convergence rate for this model. From the previous remarks we can reasonably conclude that the present convergence analysis could be generalized in many directions.

SUPERCONVERGENT DERIVATIVE RECOVERY FOR LAGRANGE TRIANGULAR ELEMENTS OF DEGREE p ON UNSTRUCTURED GRIDS*

RANDOLPH E. BANK†, JINCHAO XU‡, AND BIN ZHENG‡

Abstract. In this paper, we develop a postprocessing derivative recovery scheme for the finite element solution u_h on general unstructured but shape regular triangulations. In the case of continuous piecewise polynomials of degree $p \geq 1$, by applying the global L^2 projection (Q_h) and a smoothing operator (S_h), the recovered pth derivatives ($S_h^m Q_h \partial^p u_h$) superconverge to the exact derivatives ($\partial^p u$). Based on this technique we are able to derive a local error indicator depending only on the geometry of corresponding element and the $(p+1)$st derivatives approximated by $\partial S_h^m Q_h \partial^p u_h$. We provide several numerical examples illustrating the effectiveness of our schemes. We also observe that higher order elements are likely to require more conservative refinement strategies to create meshes corresponding to optimal orders of convergence.

Key words. superconvergence, derivative recovery, a posteriori error estimates

1. Introduction.

In this work we introduce a derivative recovery scheme for Lagrange triangular elements of degree p. It is an extension of the gradient recovery scheme for linear elements proposed by Bank and Xu [3]. The recovered pth derivatives are shown to be superconvergent to the exact ones for general shape regular meshes. Due to the superconvergent property of this scheme, some a posteriori error estimates and local error indicators can be derived for mesh adaptation.

The recovery techniques for finite element analysis have been studied extensively in the literature [6, 7, 10, 12, 13, 16, 17]. The main goal of the recovery techniques is to construct better approximations of the solution function or derivative using certain postprocessing procedures. Typically these techniques involve some kind of local or global averaging, including local or global L^2 projection. Due to the superconvergence property, recovery techniques are often used to construct a posteriori error estimators (see, e.g., [5, 11, 14, 15, 18]) which are asymptotically exact. For the literature regarding superconvergence analysis of recovery techniques, we refer to [3] and the references therein.

Most recovery schemes are concerned only with the recovery of the gradient, the finite element solution itself, and the second order derivatives. There was also some work on the recovery of higher order derivatives on uniform grids (see, e.g., [4]). It is the purpose of the current work to recover $(p+1)$st derivatives for Lagrange elements of degree $p \geq 1$ on unstructured grids.

Our development has two major components. First, we develop a postprocessing derivative recovery scheme for the finite element solution u_h on general shape regular triangulations. In particular, in section 2 of this paper we compute $S_h^m Q_h \partial^p u_h$, where S_h is an appropriate smoothing operator, $m \in \{1, 2, \dots\}$ is the number of smoothing steps, and Q_h is the L^2 projection operator. The recovered pth derivatives superconverge to the exact ones. In the case of a small number of smoothing steps (the most interesting case), Theorem 2.5 shows that

$$\|\partial^p u - S_h^m Q_h \partial^p u_h\|_{0,\Omega} \lesssim h \left(m h^{1/2} + \left[\frac{\kappa - 1}{\kappa} \right]^m \right) \left(\|u\|_{p+2,\Omega} + |u|_{p+1,\infty,\Omega} \right).$$

Here $\kappa > 1$ is a constant independent of h and u.

The second major component, presented in section 3 of this paper, is the development of a posteriori error estimates based on the derivative recovery scheme. As an example, we discuss quadratic finite elements in detail. For the case of quadratic elements, we define our local error indicator as

$$\epsilon_\tau = \frac{1}{12} \prod_{k=1}^{3} \left(\ell_{k+1} \partial_{k+1} - \ell_{k-1} \partial_{k-1} \right) \bar{u}_3 \phi_0 + \frac{1}{12} \sum_{k=1}^{3} \ell_k^3 \partial_k^3 \bar{u}_3 \phi_k,$$

where $\bar{u}_3$ is any cubic polynomial with third derivatives equal to $\partial S_h^m Q_h \partial^2 u_h$, ℓ_k are the edge lengths of the triangular element, and ϕ_k's are hierarchical basis functions for the 4-dimensional space of cubic polynomials that are zero at the vertices and midpoints of the element. Note that the above local error indicator depends only on the geometry of the corresponding element and the gradients of the recovered second order derivatives.

The rest of this paper is organized as follows: In section 2, we describe our derivative scheme and give superconvergence estimates of the pth derivatives for shape regular meshes. In section 3, we develop and analyze our a posteriori error estimate. Finally, in section 4, we present several numerical examples, involving both uniform and adaptively refined (nonuniform) meshes, with some solutions that satisfy our smoothness assumptions and some that do not. In the latter case, we observe that high order elements require conservative refinement strategies to create meshes corresponding to optimal orders of convergence.

2. A derivative recovery scheme for shape regular triangulations. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with Lipschitz boundary $\partial\Omega$.[1] For simplicity of exposition, we assume that Ω is a polygon. Let $\mathcal{V}_h^{(p)}$ denote the finite element space consisting of C^0 piecewise polynomials of degree p associated with a shape regular triangulation $\mathcal{T}_h$, and let $u_h \in \mathcal{V}_h^{(p)}$ be the finite element approximation to a (possibly nonlinear) second order elliptic boundary value problem.

We analyze a superconvergent approximation to the pth order derivatives of u. This approximation is generated by applying the global L^2 projection operator Q_h and a multigrid smoothing operator S_h to the discrete pth order derivatives of the finite element solution u_h, and it can be represented as $S_h^m Q_h \partial_h^p u_h$.

We first recall that the L^2 projection $Q_h u \in \mathcal{V}_h^{(1)}$ of a given function $u \in L^2(\Omega)$ is defined by solving the variational problem

$$(Q_h u, v_h) = (u, v_h) \; \forall \; v_h \in \mathcal{V}_h^{(1)}. \tag{2.1}$$

Here $(\cdot, \cdot)$ denotes the inner product on $L^2(\Omega)$.

[1] It is easy to see that our theory in this paper is also valid for domains with cracks, such as the slit domain in the third example of section 4.

Consider the following bilinear form:

$$a(u,v) = (\nabla u, \nabla v) + (u,v). \tag{2.2}$$

By the Riesz representation theorem, $a(\cdot,\cdot)$ induces a bounded linear operator $A_h : \mathcal{V}_h^{(1)} \to \mathcal{V}_h^{(1)}$ uniquely determined by

$$(A_h u_h, v_h) = a(u_h, v_h) \; \forall \; u_h, v_h \in \mathcal{V}_h^{(1)},$$

and it follows that the operator A_h is symmetric with respect to the L^2-inner product. We further notice that the discrete operator A_h is symmetric positive definite on the finite dimensional space $\mathcal{V}_h^{(1)}$ and

$$\lambda \equiv \rho(A_h) \simeq \mathcal{O}(h^{-2}).$$

Using A_h, we introduce the smoothing operator S_h defined by

$$S_h = I - \lambda^{-1} A_h.$$

The usual multigrid convergence function

$$f(\alpha,\beta) = \frac{\alpha^\alpha \beta^\beta}{(\alpha+\beta)^{(\alpha+\beta)}} = \sup_{x\in[0,1]} x^\alpha (1-x)^\beta,$$

$\alpha, \beta > 0$, plays an important role [3].

For convenience in notation, we let $\partial^p u$ denote some pth order derivative of u and $\partial^p u_h$ denote some discrete pth order derivative of u_h. We also use the notation $\|\cdot\|'_{p,\Omega}$ to indicate the discrete norm $\sum_{K\in\mathcal{T}_h} \|\cdot\|_{p.K}$. We now state and prove some preliminary lemmas leading to the main Theorem 2.5 in this section.

LEMMA 2.1. *For any $z \in \mathcal{V}_h^{(1)}$, $u \in H^{p+2}(\Omega)$,*

$$\|(I - S_h^m)z\|_{0,\Omega} \lesssim mh(\|z - \partial^p u\|_{1,\Omega} + h\|u\|_{p+2,\Omega} + h^{1/2}|u|_{p+1,\partial\Omega}).$$

Proof. We note, from the definition of S_h, that

$$\begin{aligned}
\|(I - S_h^m)z\|_{0,\Omega} &= \lambda^{-1}\|(I - S_h^m)(I - S_h)^{-1} A_h z\|_{0,\Omega} \\
&\le \lambda^{-1} \max_{s\in[0,1]} [(1-s^m)(1-s)^{-1}] \|A_h z\|_{0,\Omega} \\
&\le \lambda^{-1} m \|A_h z\|_{0,\Omega} \\
&\lesssim mh^2 \|A_h z\|_{0,\Omega}.
\end{aligned}$$

Let $w = A_h z$. By definition,

$$(w,\varphi) = (\nabla z, \nabla\varphi) + (z,\varphi) \tag{2.3}$$

for all $\varphi \in \mathcal{V}_h^{(1)}$. We take $\varphi = w$ in (2.3),

$$\|w\|_{0,\Omega}^2 = (w,w) = (\nabla z, \nabla w) + (z,w).$$

We estimate the terms on the right-hand side

$$\begin{aligned}
(\nabla z, \nabla w) &= (\nabla(z - \partial^p u), \nabla w) + (\nabla \partial^p u, \nabla w) \\
&\lesssim \|\nabla(z - \partial^p u)\|_{0,\Omega} \|\nabla w\|_{0,\Omega} - (\triangle \partial^p u, w) + \int_{\partial\Omega} \nabla \partial^p u \cdot n w ds \\
&\lesssim h^{-1} \|\nabla(z - \partial^p u)\|_{0,\Omega} \|w\|_{0,\Omega} + \|u\|_{p+2,\Omega} \|w\|_{0,\Omega} + |u|_{p+1,\partial\Omega} \|w\|_{0,\partial\Omega} \\
&\lesssim (h^{-1}\|z - \partial^p u\|_{1,\Omega} + \|u\|_{p+2,\Omega} + h^{-1/2}|u|_{p+1,\partial\Omega}) \|w\|_{0,\Omega}.
\end{aligned}$$

Also

$$\begin{aligned}(z,w) &= (z-\partial^p u, w) + (\partial^p u, w)\\ &\lesssim (\|z-\partial^p u\|_{0,\Omega} + \|u\|_{p,\Omega})\|w\|_{0,\Omega}.\end{aligned}$$

Thus for $z \in \mathcal{V}_h^{(1)}$,

$$\|A_h z\|_{0,\Omega} = \|w\|_{0,\Omega} \lesssim h^{-1}\|z-\partial^p u\|_{1,\Omega} + \|u\|_{p+2,\Omega} + h^{-1/2}|u|_{p+1,\partial\Omega},$$

completing the proof. ∎

LEMMA 2.2 ([3]). *Suppose that for $v \in \mathcal{V}_h^{(1)}$ and some $0 < \alpha \le 1$ we have*

$$\|v\| \le \omega(h,v),$$
$$\|v\|_{-\alpha} \equiv \|A_h^{-\alpha/2} v\| \le (\mathcal{C}h)^\alpha \omega(h,v).$$

Then

$$\|S_h^m v\| \le \varepsilon_m\, \omega(h,v),$$

where

$$\varepsilon_m = \begin{cases} \kappa^{\alpha/2} f(m,\alpha/2) \lesssim m^{-\alpha/2} & \text{for } m > (\kappa-1)\alpha/2,\\ [(\kappa-1)/\kappa]^m & \text{for } m \le (\kappa-1)\alpha/2,\end{cases}$$

and $\kappa = (\mathcal{C}h)^2\lambda$.

Proof. See Lemma 2.3 of [3]. ∎

LEMMA 2.3. *Let $w|_K \in H^p(K) \cap W^{p-1,\infty}(K)$ for all $K \in \mathcal{T}_h$. Then, for $1/2 < \alpha \le 1$,*

$$\|S_h^m Q_h \partial^p w\|_{0,\Omega} \lesssim \varepsilon_m (h^{-1}\|w\|'_{p-1,\Omega} + \|w\|'_{p,\Omega} + h^{-\alpha}\|w\|'_{p-1,\infty,\Omega}),$$

with ε_m defined as in Lemma 2.2.

Proof. Our plan is to apply Lemma 2.2 to $v = Q_h\partial^p w$. Note that

$$\|v\|_{-\alpha} = \|Q_h\partial^p w\|_{-\alpha} = \sup_{\phi\in\mathcal{V}_h^{(1)}} \frac{(Q_h\partial^p w,\phi)}{\|\phi\|_\alpha} = \sup_{\phi\in\mathcal{V}_h^{(1)}} \frac{(\partial^p w,\phi)}{\|\phi\|_\alpha}.$$

Here $\|\phi\|_\alpha \equiv \|A_h^{\alpha/2}\phi\|$. Using integration by parts,

$$\begin{aligned}(\partial^p w,\phi) &= -(\partial^{p-1}w, \partial\phi) + \sum_{K\in\mathcal{T}_h}\int_{\partial K} \partial^{p-1} w\phi n_i ds\\ &\le \|w\|'_{p-1,\Omega}\|\phi\|_{1,\Omega} + \|w\|'_{p-1,\infty,\Omega}\|\phi\|_{\alpha,\Omega}\\ &\lesssim (h^{\alpha-1}\|w\|'_{p-1,\Omega} + \|w\|'_{p-1,\infty,\Omega})\|\phi\|_{\alpha,\Omega}.\end{aligned}$$

Thus

$$\|v\|_{-\alpha} \lesssim h^\alpha \omega(h,v),$$

with $\omega(h,v) = h^{-1}\|w\|'_{p-1,\Omega} + \|w\|'_{p,\Omega} + h^{-\alpha}\|w\|'_{p-1,\infty,\Omega}$.

Since

$$\|v\|_{0,\Omega} \le \|\partial^p w\|'_{0,\Omega} \le \omega(h,v),$$

the desired estimate now follows from Lemma 2.2. ∎

LEMMA 2.4. *Let $u \in H^{p+2}(\Omega) \cap W^{p+1,\infty}(\Omega)$. Then for any $v_h \in \mathcal{V}_h^{(p)}$ and $1/2 < \alpha \leq 1$ we have*

$$\|\partial^p u - S_h^m Q_h \partial^p v_h\|_{0,\Omega} \lesssim mh^{3/2}(h^{1/2}\|u\|_{p+2,\Omega} + |u|_{p+1,\partial\Omega}) + \varepsilon_m(h^{-1}\|u - v_h\|'_{p-1,\Omega} + h^{-\alpha}\|u - v_h\|'_{p-1,\infty,\Omega}),$$

with ε_m defined as in Lemma 2.2.

Proof. By the triangle inequality,

$$\|\partial^p u - S_h^m Q_h \partial^p v_h\|_{0,\Omega} \leq \|(I - Q_h)\partial^p u\|_{0,\Omega} + \|(I - S_h^m)Q_h\partial^p u\|_{0,\Omega} + \|S_h^m Q_h \partial^p (u - v_h)\|_{0,\Omega}.$$

By standard arguments, the first term

$$\|(I - Q_h)\partial^p u\|_{0,\Omega} \lesssim h^2\|u\|_{p+2,\Omega}.$$

The second term is estimated by Lemma 2.1. For the third term, we apply Lemma 2.3. ∎

In the case in which $v_h = u_h \in \mathcal{V}_h^{(p)} \cap H_0^1(\Omega)$ is the finite element approximation to $u \in H_0^1(\Omega)$, the boundary terms vanish and

$$\|\partial^p u - S_h^m Q_h \partial^p u_h\|_{0,\Omega} \lesssim h(mh + \varepsilon_m)\|u\|_{p+2,\Omega}.$$

In the more general case, we have the following theorem based on the results developed in this section.

THEOREM 2.5. *Let $u \in H^{p+2}(\Omega) \cap W^{p+1,\infty}(\Omega)$ and $u_h \in \mathcal{V}_h^{(p)}$ be an approximation of u satisfying*

$$\|u - u_h\|'_{p-1,\Omega} \lesssim h^2|u|_{p+1,\Omega},$$

$$\|u - u_h\|'_{p-1,\infty,\Omega} \lesssim h^2|\log h||u|_{p+1,\infty,\Omega}.$$

Then

$$\|\partial^p u - S_h^m Q_h \partial^p u_h\|_{0,\Omega} \lesssim h(mh^{1/2} + \varepsilon_m)(\|u\|_{p+2,\Omega} + |u|_{p+1,\infty,\Omega}),$$

where ε_m is defined as in Lemma 2.2 and $1/2 < \alpha < 1$.

We can easily derive the following estimate for $(p+1)$st order derivatives with the help of Theorem 2.5.

THEOREM 2.6. *Assume the hypotheses of Theorem 2.5 are satisfied. Then*

$$\|\partial(\partial^p u - S_h^m Q_h \partial^p u_h)\|_{0,\Omega} \lesssim (mh^{1/2} + \varepsilon_m)(\|u\|_{p+2,\Omega} + |u|_{p+1,\infty,\Omega}),$$

where ε_m is defined as in Lemma 2.2 and $1/2 < \alpha < 1$.

Proof. Let $z = I_h \partial^p u \in \mathcal{V}_h^{(1)}$. Then

$$\begin{aligned}\|\partial(\partial^p u - S_h^m Q_h \partial^p u_h)\|_{0,\Omega} &\leq \|\partial(\partial^p u - z)\|_{0,\Omega} + \|\partial(z - S_h^m Q_h \partial^p u_h\|)_{0,\Omega} \\ &\lesssim h\|u\|_{p+2,\Omega} + h^{-1}\|z - S_h^m Q_h \partial^p u_h\|_{0,\Omega} \\ &\lesssim h\|u\|_{p+2,\Omega} + h^{-1}(\|z - \partial^p u\|_{0,\Omega} + \|\partial^p u - S_h^m Q_h \partial^p u_h\|_{0,\Omega}) \\ &\lesssim (mh^{1/2} + \varepsilon_m)(\|u\|_{p+2,\Omega} + |u|_{p+1,\infty,\Omega}).\end{aligned}$$ ∎

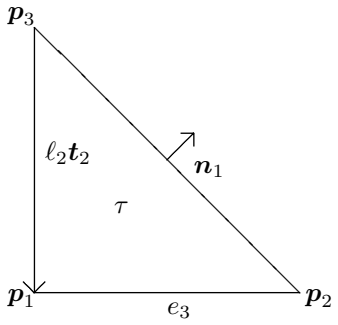

FIG. 3.1. *Parameters associated with the triangle* τ.

3. A posteriori error estimates. We begin with a description of our a posteriori error estimator. Our approach follows the development in [3] for the case of piecewise linear finite elements. For the general case of Lagrange elements of degree p, our goal is to find an expression for the error that involves only (approximate) derivatives of order $p+1$ of u and known parameters describing the geometry of a given element τ. Let a canonical element $\tau \in \mathcal{T}_h$ have vertices $\boldsymbol{p}_k^t = (x_k, y_k)$, $1 \le k \le 3$, oriented counterclockwise, and corresponding linear nodal basis functions (barycentric coordinates) $\{\psi_k\}_{k=1}^3$. Let $\{e_k\}_{k=1}^3$ denote the edges of element τ, $\{\boldsymbol{n}_k\}_{k=1}^3$ the unit outward normal vectors, $\{\boldsymbol{t}_k\}_{k=1}^3$ the unit tangent vectors with counterclockwise orientation, and $\{\ell_k\}_{k=1}^3$ the edge lengths (see Figure 3.1).

As an example, we now restrict attention to quadratic finite elements, since it is the quadratic space that is used in the numerical illustrations. We first seek an expression for $\hat{u}_3 - u_2$ on τ, where u_2 is the quadratic Lagrange interpolant and $\hat{u}_3$ is the cubic hierarchical extension. Thus $\hat{u}_3 - u_2$ is a cubic polynomial vanishing at vertices and edge midpoints of τ. A hierarchical basis for this 4-dimensional space is given by

$$\phi_0 = \psi_1\psi_2\psi_3,$$
$$\phi_k = \psi_{k-1}\psi_{k+1}(\psi_{k+1} - \psi_{k-1}),$$

for $1 \le k \le 3$, and $(k-1, k, k+1)$ is a cyclic permutation of $(1, 2, 3)$. Let $\partial_k u$ denote the directional derivative in the direction $\boldsymbol{t}_k$. Then

$$\hat{u}_3 - u_2 = \frac{1}{12}\prod_{k=1}^{3}\left(\ell_{k+1}\partial_{k+1} - \ell_{k-1}\partial_{k-1}\right)\hat{u}_3\phi_0 + \frac{1}{12}\sum_{k=1}^{3}\ell_k^3\partial_k^3\hat{u}_3\phi_k. \tag{3.1}$$

Equation (3.1) can be verified using the identities

$$\psi_1 + \psi_2 + \psi_3 = 1,$$
$$\nabla\psi_1 + \nabla\psi_2 + \nabla\psi_3 = 0,$$
$$\ell_1\boldsymbol{t}_1 + \ell_2\boldsymbol{t}_2 + \ell_3\boldsymbol{t}_3 = 0,$$
$$\begin{pmatrix}\ell_1\boldsymbol{t}_1^t\\ \ell_2\boldsymbol{t}_2^t\\ \ell_3\boldsymbol{t}_3^t\end{pmatrix}\begin{pmatrix}\nabla\psi_1 & \nabla\psi_2 & \nabla\psi_3\end{pmatrix} = \begin{pmatrix}0 & -1 & 1\\ 1 & 0 & -1\\ -1 & 1 & 0\end{pmatrix}.$$

In our local error indicator, we simply approximate the third derivatives needed to compute the directional derivatives appearing in (3.1) by

$$
\begin{aligned}
\partial_{xxx}\hat{u}_3 &\approx \alpha_\tau \partial_x S_h^m Q_h \partial_{xx} u_h, \\
\partial_{xxy}\hat{u}_3 &\approx \frac{\alpha_\tau}{2}(\partial_y S_h^m Q_h \partial_{xx} u_h + \partial_x S_h^m Q_h \partial_{xy} u_h), \\
\partial_{xyy}\hat{u}_3 &\approx \frac{\alpha_\tau}{2}(\partial_y S_h^m Q_h \partial_{xy} u_h + \partial_x S_h^m Q_h \partial_{yy} u_h), \\
\partial_{yyy}\hat{u}_3 &\approx \alpha_\tau \partial_y S_h^m Q_h \partial_{yy} u_h,
\end{aligned}
\tag{3.2}
$$

where $\alpha_\tau > 0$ is a constant described below. Let $\bar{u}_3$ be any cubic polynomial with third derivatives given by the right-hand sides of (3.2). Then our local error indicator is given by

$$
\epsilon_\tau = \frac{1}{12}\prod_{k=1}^{3}\left(\ell_{k+1}\partial_{k+1} - \ell_{k-1}\partial_{k-1}\right)\bar{u}_3\phi_0 + \frac{1}{12}\sum_{k=1}^{3}\ell_k^3\partial_k^3\bar{u}_3\phi_k. \tag{3.3}
$$

The normalization constant α_τ is chosen such that

$$
\begin{aligned}
|\epsilon_\tau|_{2,\tau}^2 = \|(I - S_h^m Q_h)\partial_{xx}^2 u_h\|_{0,\tau}^2 + 2\|(I - S_h^m Q_h)\partial_{xy}^2 u_h\|_{0,\tau}^2 \\
+ \|(I - S_h^m Q_h)\partial_{yy}^2 u_h\|_{0,\tau}^2 \equiv |u_h - R(u_h)|_{2,\tau}^2.
\end{aligned}
$$

Normally we expect that $\alpha_\tau \approx 1$, which is likely to be the case in regions where the third derivatives of the true solution are well defined. Near singularities, u is not smooth, and we anticipate difficulties in estimating the third derivatives. For elements near such singularities, α_τ provides a heuristic for partly compensating for poor approximation. Note that ϵ_τ is a cubic polynomial on each element depending only on the geometry of τ and the approximate third derivatives derived from our superconvergent approximations.

In the general case, $\hat{u}_{p+1} - u_p$ on element τ is a polynomial of degree $p+1$ that is zero at the degrees of freedom defining u_p. One can express this polynomial in terms of hierarchical basis functions depending on the geometry of τ and the derivatives of order $p+1$ of $\hat{u}_{p+1}$. The derivatives can be approximated by $\partial S_h^m Q_h \partial^p u_h$ as in the example above. This yields a polynomial ϵ_τ of degree $p+1$ for each element. The local error indicator η_τ is given by

$$
\eta_\tau = \|\nabla \epsilon_\tau\|_{0,\tau}. \tag{3.4}
$$

Since ϵ_τ is a discontinuous piecewise polynomial on all of Ω, we can also formally approximate errors in global norms and other functionals using ϵ_τ. For example,

$$
\begin{aligned}
\|u - u_h\|_{0,\Omega}^2 &\approx \sum_\tau \|\epsilon_\tau\|_{0,\tau}^2, \\
|u - u_h|_{1,\Omega}^2 &\approx \sum_\tau |\epsilon_\tau|_{1,\tau}^2 = \sum_\tau \eta_\tau^2.
\end{aligned}
$$

In the case of $|\cdot|_{1,\Omega}$ there is a bit of theory. In particular,

$$|u-u_h|_{1,\Omega} \le |u-\hat{u}_{p+1}|_{1,\Omega} + |u_p-u_h|_{1,\Omega} + |u_p-\hat{u}_{p+1}|_{1,\Omega}, \tag{3.5}$$

$$|u_p-\hat{u}_{p+1}|_{1,\Omega} \le |u-\hat{u}_{p+1}|_{1,\Omega} + |u_p-u_h|_{1,\Omega} + |u-u_h|_{1,\Omega}. \tag{3.6}$$

Suppose $|u-u_h|_{1,\Omega} \ge ch^p$, and $|u-\hat{u}_{p+1}|_{1,\Omega} \le Ch^{p+1}$. Then if $|u_p-u_h|_{1,\Omega}$ is also higher order, estimates (3.5)–(3.6) show $|u_p-\hat{u}_{p+1}|_{1,\Omega}$ to be an asymptotically exact estimate for $|u-u_h|_{1,\Omega}$. Such superapproximation results for $|u_p-u_h|_{1,\Omega}$ are known for $p=1,2$; see [2, 3, 8]. However, superapproximation estimates for $|u_p-u_h|_{1,\Omega}$ are not yet known to hold for $p \ge 3$; see [9]. For general p, estimate (3.5) can be replaced by

$$|u-u_h|_{1,\Omega} \le C\left(|u-\hat{u}_{p+1}|_{1,\Omega} + |\hat{u}_{p+1}-u_p|_{1,\Omega}\right) \tag{3.7}$$

due to the best approximation property for the energy norm and norm comparability of $|\!|\!|\cdot|\!|\!|_\Omega$ and $|\cdot|_{1,\Omega}$. Here we may lose asymptotic exactness but still have a useful upper bound for the error. Insofar as we know, the lower bound for $p>2$ is still an open question, as are general norms and functionals. Nonetheless, this informal analysis suggests that the error indicators η_τ will provide a useful and reliable basis for adaptive meshing algorithms.

4. Numerical experiments. We now present some numerical illustrations of our recovery scheme in the cases of uniform and adaptively refined (nonuniform) meshes. The gradient recovery scheme and a posteriori error estimate described above for the case of continuous piecewise quadratic elements were implemented in the PLTMG package [1], which was then used for our numerical experiments. The experiments were done on a dual Opteron Linux workstation, using the *g77* compiler and double precision arithmetic. We reprise some experiments given in [3] for the case of continuous piecewise linear finite elements.

In our first example, we consider the solution of the problem

$$\begin{aligned} -\Delta u &= f \qquad \text{in } \Omega=(0,1)\times(0,1),\\ u &= g \qquad \text{on } \partial\Omega, \end{aligned}$$

where f and g are chosen such that $u=\mathrm{e}^{x+y}$ is the exact solution. This is a very smooth solution that satisfies all of the assumptions of our theory. Here we will compare the recovery scheme with $m=2$ smoothing steps for the case of uniform and adaptive meshes. We begin with a uniform 3×3 mesh consisting of eight right triangles as shown in Figure 4.1. Elements in Figure 4.1 are colored according to size; this allows one to obtain some impression of the structure of highly refined meshes with many elements, even if individual elements can no longer be resolved.

In Tables 4.1–4.2, we record the results of the computation. We give the error as a function of the number of elements, choosing targets for the adaptive refinement procedure to produce adaptive meshes with similar numbers of elements to the uniform refinement case. Note that the dimension of the quadratic finite element space is approximately $2\,nt$, where nt is the number of elements reported in the tables. Other

values are defined as follows:

$$L2 = \|u - u_h\|_{0,\Omega},$$
$$\widetilde{L2} = \|\epsilon_h\|_{0,\Omega},$$
$$EF_0 = \frac{\|\epsilon_h\|_{0,\Omega}}{\|u - u_h\|_{0,\Omega}},$$
$$H1 = |u - u_h|_{1,\Omega},$$
$$\widetilde{H1} = |\epsilon_h|_{1,\Omega},$$
$$EF_1 = \frac{|\epsilon_h|_{1,\Omega}}{|u - u_h|_{1,\Omega}},$$
$$H2 = |u - u_h|_{2,\Omega},$$
$$\widetilde{H2} = |u - R(u_h)|_{2,\Omega},$$
$$EF_2 = \frac{|R(u_h) - u_h|_{2,\Omega}}{|u - u_h|_{2,\Omega}}.$$

For each type of norm, we made a least squares fit of the data to a function of the form $F(N) = CN^{-p/2}$ to estimate the order of convergence p. All integrals were approximated using a 12-point order 7 quadrature formula applied to each triangle.

We note here the superconvergence of the second derivatives and effectivity ratios that are close to one. Despite the lack of a complete theory, error estimates $\widetilde{L2}$ and $\widetilde{H1}$ are also quite accurate, and the orders of convergence are optimal in all three norms (and superconvergent for the recovered second derivatives).

In our second example, we consider the nonlinear problem

$$\begin{aligned} -\nabla \cdot (a\nabla u) + \mathrm{e}^u &= f \qquad \text{in } \Omega = (0,1) \times (0,1), \\ u &= 0 \qquad \text{on } \partial\Omega, \end{aligned}$$

where a is the 2×2 diagonal matrix

$$a = \begin{pmatrix} .01 & \\ & 1 \end{pmatrix}.$$

The function f is chosen such that $u = x(1-x)^3 y^5 (1-y)$ is the exact solution. We repeat the same computations as in the first example, with uniform and adaptive meshes. The uniform meshes are identical to those of the first example. Some of the adaptive meshes are shown in Figure 4.2. The numerical results are summarized in Tables 4.3–4.4.

This problem is more difficult than the first in several respects. The diffusion is anisotropic, and the operator is nonlinear. The solution is smooth but generally has larger derivatives than the first example. Nonetheless, we see a similar behavior of the gradient recovery scheme and a posteriori error estimate.

In our third example, we consider the problem

$$\begin{aligned} -\Delta u &= 0 \qquad \text{in } \Omega, \\ u &= g \qquad \text{on } \partial\Omega_1, \\ u_n &= 0 \qquad \text{on } \partial\Omega_2, \end{aligned}$$

where Ω is a circle of radius one centered at the origin, and with a crack along the positive x-axis $0 \le x \le 1$. The boundary $\partial\Omega_2$ is the bottom edge of the crack, and $\partial\Omega_1 = \partial\Omega \setminus \partial\Omega_2$. The function g is chosen such that the exact solution is $u = r^{1/4}\sin(\theta/4)$, the leading term of the singularity associated with the interior angle of 2π and change in boundary conditions at the origin. In Figure 4.3 we illustrate the initial mesh and several of the uniformly and adaptively refined meshes.

Convergence results for uniform and adaptive refinement are reported in Tables 4.5–4.6. The solution u is not smooth in this case ($u \in H^{5/4-\epsilon}(\Omega)$), and this is reflected in the results. In particular, both $H2$ and $\widetilde{H2}$ should be infinite and are computed as finite only because of numerical quadrature. Despite this singularity, the resulting error approximations ϵ_τ still provided useful information and formed a reliable basis for adaptive refinement.

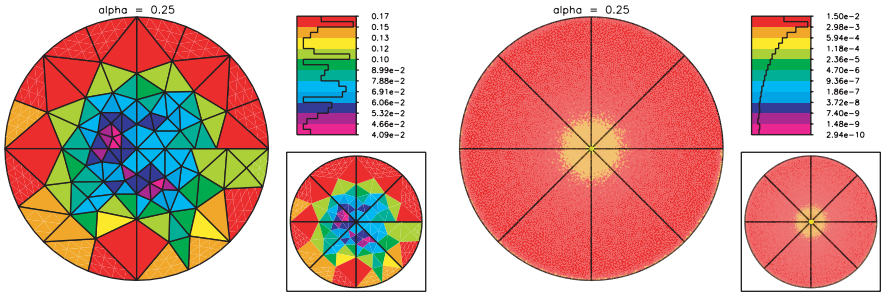

FIG. 4.4. *Left: Adaptive refinement with* $nt = 136$. *Right: Adaptive refinement with* $nt = 130586$. *Elements are colored according to size.*

For the case of uniform refinement, the 0.25 order of convergence of the gradient coincides with the smoothness of the solution. The effectivity ratios for all cases show a lack of asymptotic exactness. EF_1, although not approaching unity, still seems under control, reflecting the analysis (3.5)–(3.7). On the other hand, EF_0 seems very poorly controlled, indicating that $\|\epsilon_\tau\|_{0,\Omega}$ is not a very reliable estimate for $\|u-u_h\|_{0,\Omega}$.

For the adaptive meshes, the order of convergence improves and seems to be approaching order one for the gradient and order two for the solution. This is suboptimal for quadratic elements. This was not due to poor error indicators but rather to an overly aggressive refinement strategy. In the adaptive refinement procedure implemented in PLTMG, all elements are placed on a heap with the element having the largest error at the root. The root element is then selected for refinement. When an element is refined, it is removed from the heap, and its child elements are added to the heap. This of course requires the child elements to have error indicators. These are constructed using derivative values inherited from the parent and their own geometry information. Thus a single element might undergo several levels of refinement during a given adaptive step. Using old derivative information for new elements will generally fail to be optimal after sufficiently many levels of refinement.

In PLTMG, the amount of refinement allowed in a given refinement step is governed by the user by specifying a target number of vertices in the refined mesh. In this example, we chose a strategy that increased the number of vertices by roughly a factor of four in each refinement step in order to closely match the size of problems generated by uniform refinement. If there are too many levels of refinement of individual elements before the problem is resolved, the resulting mesh might be lower quality, as was the case in this example. On the other hand, frequently assembling and resolving the global finite element equations results in higher quality adaptive meshes but at a much greater cost. Since the appropriate compromise is likely to be highly problem-dependent, in PLTMG it is up to the user to choose the proper balance.

For this example, we solved this problem adaptively a second time, this time specifying that the number of vertices should be increased by a factor of roughly two between resolves rather than four. We report the results in Table 4.7. Here we see the near optimal rate of convergence for both $L2$ and $H1$. In other respects, the data are quite similar to Table 4.6. Meshes corresponding to the adaptive meshes in Figure 4.3 are shown in Figure 4.4.

It is interesting to note that a refinement factor of four caused no problems in the case of a similar experiment performed in the case $p = 1$ in [3]. For $p = 2$ the refinement is much sharper in the region of the singularity, and it was this increase in sharpness that required a less aggressive refinement strategy. Even higher order

A FAMILY OF C^0 FINITE ELEMENTS FOR KIRCHHOFF PLATES I: ERROR ANALYSIS*

L. BEIRÃO DA VEIGA†, J. NIIRANEN‡, AND R. STENBERG‡

Abstract. A new finite element formulation for the Kirchhoff plate model is presented. The method is a displacement formulation with the deflection and the rotation vector as unknowns, and it is based on ideas stemming from a stabilized method for the Reissner–Mindlin model [R. Stenberg, in *Asymptotic Methods for Elastic Structures*, P. Ciarlet, L. Trabucho, and J. M. Viano, eds., de Gruyter, Berlin, 1995] and a method to treat a free boundary [P. Destuynder and T. Nevers, *RAIRO Modél. Math. Anal. Numér.*, 22 (1988), pp. 217–242]. Optimal a priori and a posteriori error estimates are derived.

Key words. finite elements, Kirchhoff plate model, free boundary, a priori error analysis, a posteriori error analysis

1. Introduction.

A conforming finite element method for the Kirchhoff plate-bending problem requires a C^1-continuity and hence leads to methods that are rarely used in practice. Instead, either a nonconforming method is used or the model is abandoned in favor of the Reissner–Mindlin model. For the latter, there exist several families of methods that have rigorously been shown to be free from locking and optimally convergent.

A natural idea is to consider the Kirchhoff model as the limit of the Reissner–Mindlin model when the plate thickness approaches zero and to use a good Reissner–Mindlin element with the thickness (after a scaling, see below) representing the parameter when penalizing the Kirchhoff constraint. In this approach, there are two obstacles. First, for a free boundary, this leads to a method which is not consistent. This inconsistency significantly reduces the convergence rate of the method. In the literature, this point is often ignored since mostly the clamped case is considered. A remedy to this was developed by Destuynder and Nevers, who showed that the consistency is obtained by adding a term penalizing the tangential Kirchhoff condition along the free boundary [7]. Even if this modification has been done, there remains a second drawback. In order for the solution to the penalized formulation to be close to the exact solution, the penalty parameter should be large. This, however, leads to an ill-conditioned discrete system.

The free boundary inconsistency of the limit problem is closely related to the strong boundary layer of the Reissner–Mindlin plate problem with free boundaries. For Reissner–Mindlin plates, the presence of free boundaries significantly reduces the regularity of the solution and hence decreases the convergence rate of finite element approximations [1, 10, 5]. In [5, 2], the regularity of the solution has been improved by modifying the boundary conditions for free boundaries. These modifications imitate the boundary conditions of the Kirchhoff model as well as couple the variational

spaces for the deflection and the rotation through the tangential Kirchhoff constraint along free boundaries. Adopting the modified boundary conditions on the discrete level it has been proved in [5, 2] that a set of finite element methods maintain their optimal order of convergence in the free boundary case. However, it can be seen as a drawback that all of these methods follow the mixed formulation with the shear force as an additional unknown. For positive values of the thickness parameter t, as usual, the corresponding displacement formulations can be achieved by condensing the shear force from the formulation. For the limit case $t = 0$, however, this possibility is excluded due to the nominator t^2 of the factor penalizing the Kirchhoff condition. For this reason, applying these methods for Kirchhoff plates requires a mixed formulation with the additional shear force degrees of freedom.

Our aim in the present paper is to present a family of Kirchhoff plate-bending elements which follows the displacement formulation and for which the convergence rate is optimal even in the presence of free boundaries. The method is a formulation combining the ideas from the stabilized method for Reissner–Mindlin plates presented in [13] and the treatment of the free boundary presented in [7]. Altough the method resembles the one with the linked interpolation technique in [2] for Reissner–Mindlin plates, it has been independently derived for the Kirchhoff plate problem with free boundaries. The family includes "simple low-order" elements, and it is well-conditioned. In the second part [3] of this paper, we give the results of numerical tests and a more detailed and constructive motivation for the method (cf. [4] as well).

The paper is organized as follows. In the next section, we describe the plate-bending problem, and in section 3, we introduce the new family of finite elements. In section 4, an a priori error analysis is derived. This analysis leads to optimal results, with respect both to the regularity of the solution and to the polynomial degree used. In section 5, an a posteriori error analysis is performed. We derive a local error indicator which is shown to be both reliable and efficient.

2. The Kirchhoff plate-bending problem. We consider the problem of bending of an isotropic linearly elastic plate and assume that the undeformed plate midsurface is described by a given convex polygonal domain $\Omega \subset \mathbb{R}^2$. The plate is considered to be clamped on the part Γ_{C} of its boundary $\partial\Omega$, simply supported on the part $\Gamma_{\mathrm{S}} \subset \partial\Omega$, and free on $\Gamma_{\mathrm{F}} \subset \partial\Omega$. The deflection and transversal load are denoted by w and g, respectively.

In what follows, we indicate with $\mathcal{V}$ the set of all corner points in Γ_{F}. Moreover, $\boldsymbol{n}$ and $\boldsymbol{s}$ represent the unit outward normal and the unit counterclockwise tangent to the boundary, respectively. Finally, for points $x \in \mathcal{V}$, we introduce the following notation. We indicate with $\boldsymbol{n}_1$ and $\boldsymbol{s}_1$ the unit vectors corresponding, respectively, to $\boldsymbol{n}$ and $\boldsymbol{s}$ on one of the two edges forming the boundary angle at x; with $\boldsymbol{n}_2$ and $\boldsymbol{s}_2$ we indicate the ones corresponding to the other edge. Note that which of the two edges correspond to the subscript 1 or 2 is not relevant.

The classical Kirchhoff plate-bending model is then given by the biharmonic partial differential equation

$$\mathsf{D}\Delta^2 w = g \qquad \text{in } \Omega, \tag{2.1}$$

the boundary conditions

$$\begin{aligned}
&w = 0, && \frac{\partial w}{\partial \boldsymbol{n}} = 0 && \text{on } \Gamma_{\mathrm{C}},\\
&w = 0, && \boldsymbol{n}\cdot\boldsymbol{M}\boldsymbol{n} = 0 && \text{on } \Gamma_{\mathrm{S}},\\
&\boldsymbol{n}\cdot\boldsymbol{M}\boldsymbol{n} = 0, && \frac{\partial}{\partial \boldsymbol{s}}\big(\boldsymbol{s}\cdot\boldsymbol{M}\boldsymbol{n}\big) + (\mathbf{div}\,\boldsymbol{M})\cdot\boldsymbol{n} = 0 && \text{on } \Gamma_{\mathrm{F}},
\end{aligned} \tag{2.2}$$

and the corner conditions

$$\big(\boldsymbol{s}_1 \cdot \boldsymbol{M}\boldsymbol{n}_1\big)(x) = \big(\boldsymbol{s}_2 \cdot \boldsymbol{M}\boldsymbol{n}_2\big)(x) \qquad \forall x \in \mathcal{V}. \tag{2.3}$$

Here

$$\mathsf{D} = \frac{\mathsf{E}t^3}{12(1-\nu^2)} \tag{2.4}$$

is the bending rigidity, with E, ν being the Young modulus and the Poisson ratio for the material, respectively. Note that for the shear modulus G it holds that

$$\mathsf{G} = \frac{\mathsf{E}}{2(1+\nu)}. \tag{2.5}$$

The moment tensor is given by

$$\boldsymbol{M}(\nabla w) = \mathsf{D}\big((1-\nu)\boldsymbol{\varepsilon}(\nabla w) + \nu \mathrm{div}(\nabla w)\boldsymbol{I}\big), \tag{2.6}$$

with the symmetric gradient $\boldsymbol{\varepsilon}$, and the shear force by

$$\boldsymbol{Q} = -\mathbf{div}\, \boldsymbol{M}. \tag{2.7}$$

Note that the independence of the Poisson ratio ν in the differential equation (2.1) is a consequence of cancellations when substituting (2.6) and (2.7) into the equilibrium equation

$$-\mathrm{div}\, \boldsymbol{Q} = g. \tag{2.8}$$

For the analysis below, it will be convenient to perform a scaling of the problem by assuming that the load is given by $g = \mathsf{G}t^3 f$, with f fixed. Then the differential equation (2.1) becomes independent of the plate thickness:

$$\frac{1}{6(1-\nu)}\Delta^2 w = f \qquad \text{in } \Omega. \tag{2.9}$$

Furthermore, we use the following scaled moment tensor $\boldsymbol{m}$:

$$\boldsymbol{M}(\nabla w) = \mathsf{G}t^3 \boldsymbol{m}(\nabla w), \tag{2.10}$$

and the shear force $\boldsymbol{q}$ is defined by

$$\boldsymbol{Q} = \mathsf{G}t^3 \boldsymbol{q}. \tag{2.11}$$

The unknowns in our finite element method will be the approximations to the deflection and its gradient, the rotation $\boldsymbol{\beta} = \nabla w$. With this as a new unknown, our problem can be written as the system of partial differential equations

$$\nabla w - \boldsymbol{\beta} = \mathbf{0}, \tag{2.12}$$

$$-\mathrm{div}\, \boldsymbol{q} = f, \tag{2.13}$$

$$\boldsymbol{L}\boldsymbol{\beta} + \boldsymbol{q} = \mathbf{0} \qquad \text{in } \Omega, \tag{2.14}$$

the boundary conditions

$$w = 0,\ \boldsymbol{\beta} = \mathbf{0} \qquad \text{on } \Gamma_{\mathrm{C}}, \tag{2.15}$$

$$w = 0,\ \boldsymbol{\beta}\cdot\boldsymbol{s} = 0,\ \boldsymbol{n}\cdot\boldsymbol{m}(\boldsymbol{\beta})\boldsymbol{n} = 0 \qquad \text{on } \Gamma_{\mathrm{S}}, \tag{2.16}$$

$$\frac{\partial w}{\partial \boldsymbol{s}} - \boldsymbol{\beta}\cdot\boldsymbol{s} = 0,\ \boldsymbol{n}\cdot\boldsymbol{m}(\boldsymbol{\beta})\boldsymbol{n} = 0,\ \frac{\partial}{\partial \boldsymbol{s}}\big(\boldsymbol{s}\cdot\boldsymbol{m}(\boldsymbol{\beta})\boldsymbol{n}\big) - \boldsymbol{q}\cdot\boldsymbol{n} = 0 \text{ on } \Gamma_{\mathrm{F}}, \tag{2.17}$$

and the corner conditions

$$\big(\boldsymbol{s}_1\cdot\boldsymbol{m}(\boldsymbol{\beta})\boldsymbol{n}_1\big)(x) = \big(\boldsymbol{s}_2\cdot\boldsymbol{m}(\boldsymbol{\beta})\boldsymbol{n}_2\big)(x) \qquad \forall x\in\mathcal{V}. \tag{2.18}$$

The operator $\boldsymbol{L}$ is defined as

$$\boldsymbol{L}\boldsymbol{\beta} = \mathbf{div}\,\boldsymbol{m}(\boldsymbol{\beta}), \tag{2.19}$$

and the scaled bending moment is considered as a function of the rotation:

$$\boldsymbol{m}(\boldsymbol{\beta}) = \frac{1}{6}\left(\boldsymbol{\varepsilon}(\boldsymbol{\beta}) + \frac{\nu}{1-\nu}\mathrm{div}\,\boldsymbol{\beta}\,\boldsymbol{I}\right). \tag{2.20}$$

In what follows, we will often write $\boldsymbol{m}$ instead of $\boldsymbol{m}(\boldsymbol{\beta})$. We further denote

$$a(\boldsymbol{\beta},\boldsymbol{\eta}) = (\boldsymbol{m}(\boldsymbol{\beta}),\boldsymbol{\varepsilon}(\boldsymbol{\eta})). \tag{2.21}$$

In order to neglect plate rigid movements and the related technicalities, we will in what follows assume that the one-dimensional measure of Γ_{C} is positive.

3. The finite element formulation. In this section, we will introduce our finite element method. Even if our method is stable for all choices of finite element spaces, we will, for simplicity, present it for triangular elements and for the polynomial degrees that yield an optimal convergence rate. Hence, let a regular family of triangular meshes on Ω be given. For the integer $k\geq 1$, we then define the discrete spaces

$$W_h = \{v\in W \ \mid\ v_{|K}\in P_{k+1}(K)\ \ \forall K\in\mathcal{C}_h\}, \tag{3.1}$$

$$\boldsymbol{V}_h = \{\boldsymbol{\eta}\in\boldsymbol{V} \ \mid\ \boldsymbol{\eta}_{|K}\in[P_k(K)]^2\ \ \forall K\in\mathcal{C}_h\}, \tag{3.2}$$

with

$$W = \left\{v\in H^1(\Omega)\,|\,v = 0 \text{ on } \Gamma_{\mathrm{C}}\cup\Gamma_{\mathrm{S}}\right\}, \tag{3.3}$$

$$\boldsymbol{V} = \left\{\boldsymbol{\eta}\in[H^1(\Omega)]^2\,|\,\boldsymbol{\eta} = \boldsymbol{0} \text{ on } \Gamma_{\mathrm{C}},\ \boldsymbol{\eta}\cdot\boldsymbol{s} = 0 \text{ on } \Gamma_{\mathrm{S}}\right\}. \tag{3.4}$$

Here $\mathcal{C}_h$ represents the set of all triangles K of the mesh, and $P_k(K)$ is the space of polynomials of degree k on K. In what follows, we will indicate with h_K the diameter of each element K, while h will indicate the maximum size of all of the elements in the mesh. Furthermore, we will indicate with E a general edge of the triangulation and with h_E the length of E. The set of all edges lying on the free boundary Γ_{F} we denote by $\mathcal{F}_h$.

Before introducing the method, we state the following result which trivially follows from classical scaling arguments and the coercivity of the form a.

LEMMA 3.1. *There exist positive constants C_I and C_I' such that*

$$C_I\sum_{K\in\mathcal{C}_h} h_K^2\|\boldsymbol{L}\boldsymbol{\phi}\|_{0,K}^2 \leq a(\boldsymbol{\phi},\boldsymbol{\phi}) \qquad \forall\boldsymbol{\phi}\in\boldsymbol{V}_h, \tag{3.5}$$

$$C_I'\sum_{E\in\mathcal{F}_h} h_E\,\|m_{ns}(\boldsymbol{\phi})\|_{0,E}^2 \leq a(\boldsymbol{\phi},\boldsymbol{\phi}) \qquad \forall\boldsymbol{\phi}\in\boldsymbol{V}_h, \tag{3.6}$$

where the operator $m_{ns}(\boldsymbol{\phi}) = \boldsymbol{s} \cdot \boldsymbol{m}(\boldsymbol{\phi})\boldsymbol{n}$, *with* $\boldsymbol{n}, \boldsymbol{s}$, *being the unit outward normal and the unit counterclockwise tangent to the edge* E, *respectively, and with* $\boldsymbol{m}$ *defined in* (2.20).

Let two real numbers γ and α be assigned: $\gamma > 2/C_I'$ and $0 < \alpha < C_I/4$. Then the discrete problem reads as follows.

Method 3.1. Find $(w_h, \boldsymbol{\beta}_h) \in W_h \times \boldsymbol{V}_h$, such that

$$\mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) = (f, v) \qquad \forall (v, \boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h, \tag{3.7}$$

where the form $\mathcal{A}_h$ is defined as

$$\mathcal{A}_h(z, \boldsymbol{\phi}; v, \boldsymbol{\eta}) = \mathcal{B}_h(z, \boldsymbol{\phi}; v, \boldsymbol{\eta}) + \mathcal{D}_h(z, \boldsymbol{\phi}; v, \boldsymbol{\eta}), \tag{3.8}$$

with

$$\begin{aligned} \mathcal{B}_h(z, \boldsymbol{\phi}; v, \boldsymbol{\eta}) &= a(\boldsymbol{\phi}, \boldsymbol{\eta}) - \sum_{K \in \mathcal{C}_h} \alpha h_K^2 (\boldsymbol{L}\boldsymbol{\phi}, \boldsymbol{L}\boldsymbol{\eta})_K \\ &\quad + \sum_{K \in \mathcal{C}_h} \frac{1}{\alpha h_K^2} (\nabla z - \boldsymbol{\phi} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\phi}, \nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta})_K \end{aligned} \tag{3.9}$$

and

$$\begin{aligned} \mathcal{D}_h(z, \boldsymbol{\phi}; v, \boldsymbol{\eta}) &= \langle m_{ns}(\boldsymbol{\phi}), [\nabla v - \boldsymbol{\eta}] \cdot \boldsymbol{s} \rangle_{\Gamma_{\mathrm{F}}} + \langle [\nabla z - \boldsymbol{\phi}] \cdot \boldsymbol{s}, m_{ns}(\boldsymbol{\eta}) \rangle_{\Gamma_{\mathrm{F}}} \\ &\quad + \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \langle [\nabla z - \boldsymbol{\phi}] \cdot \boldsymbol{s}, [\nabla v - \boldsymbol{\eta}] \cdot \boldsymbol{s} \rangle_E \end{aligned} \tag{3.10}$$

for all $(z, \boldsymbol{\phi}), (v, \boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h$. Here $\langle \cdot, \cdot \rangle_{\Gamma_{\mathrm{F}}}$ and $\langle \cdot, \cdot \rangle_E$ denote the L^2-inner products on Γ_{F} and E, respectively.

The bilinear form $\mathcal{B}_h$ constitutes the Reissner–Mindlin method of [13] with the thickness t set equal to zero, while the additional form $\mathcal{D}_h$ is introduced in order to avoid the convergence deterioration in the presence of free boundaries.

Furthermore, we introduce the discrete shear force

$$\boldsymbol{q}_{h|K} = \frac{1}{\alpha h_K^2} (\nabla w_h - \boldsymbol{\beta}_h - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\beta}_h)_{|K} \quad \forall K \in \mathcal{C}_h. \tag{3.11}$$

We note that, due to (2.14) and (2.12), it holds that

$$\boldsymbol{q}_{|K} = \frac{1}{\alpha h_K^2} (\nabla w - \boldsymbol{\beta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\beta})_{|K} \quad \forall K \in \mathcal{C}_h, \tag{3.12}$$

and hence it follows that the definition (3.11) is consistent with the exact shear force.

For simplicity, in the rest of this section we assume that the deflection w belongs to $H^3(\Omega)$; this is a very reasonable assumption, as discussed at the end of this section. Note as well that, with some additional technical work involving the appropriate Sobolev spaces and their duals, such an assumption could probably be avoided. The following result states the consistency of the method.

THEOREM 3.2. *The solution* $(w, \boldsymbol{\beta})$ *of the problem* (2.14)–(2.18) *satisfies*

$$\mathcal{A}_h(w, \boldsymbol{\beta}; v, \boldsymbol{\eta}) = (f, v) \qquad \forall (v, \boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h. \tag{3.13}$$

Proof. The definition of the bilinear forms in Method 3.1, recalling (2.14) and the expression (3.12), give

$$\begin{aligned}\mathcal{B}_h(w,\boldsymbol{\beta};v,\boldsymbol{\eta}) &= a(\boldsymbol{\beta},\boldsymbol{\eta}) - \sum_{K\in\mathcal{C}_h} \alpha h_K^2(\boldsymbol{L}\boldsymbol{\beta},\boldsymbol{L}\boldsymbol{\eta})_K \\ &\quad + \sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}(\nabla w - \boldsymbol{\beta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\beta}, \nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta})_K \\ &= a(\boldsymbol{\beta},\boldsymbol{\eta}) + \sum_{K\in\mathcal{C}_h} \alpha h_K^2(\boldsymbol{q},\boldsymbol{L}\boldsymbol{\eta})_K + \sum_{K\in\mathcal{C}_h} (\boldsymbol{q}, \nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta})_K \\ &= a(\boldsymbol{\beta},\boldsymbol{\eta}) + (\boldsymbol{q}, \nabla v - \boldsymbol{\eta}). \qquad (3.14)\end{aligned}$$

First, by the definition (2.21), then integrating by parts on each triangle, and finally using the regularity of the functions involved, and the boundary conditions (2.15), (2.16) on Γ_{C}, Γ_{S}, respectively, we get

$$\begin{aligned}a(\boldsymbol{\beta},\boldsymbol{\eta}) + (\boldsymbol{q}, \nabla v - \boldsymbol{\eta}) &= (\boldsymbol{m}(\boldsymbol{\beta}), \boldsymbol{\varepsilon}(\boldsymbol{\eta})) + (\boldsymbol{q}, \nabla v - \boldsymbol{\eta}) \\ &= -(\boldsymbol{L}\boldsymbol{\beta} + \boldsymbol{q}, \boldsymbol{\eta}) + \langle \boldsymbol{m}(\boldsymbol{\beta})\cdot\boldsymbol{n}, \boldsymbol{\eta}\rangle_{\Gamma_{\mathrm{F}}} - (\operatorname{div}\boldsymbol{q}, v) + \langle \boldsymbol{q}\cdot\boldsymbol{n}, v\rangle_{\Gamma_{\mathrm{F}}}. \qquad (3.15)\end{aligned}$$

Recalling (2.14) and (2.13), the identity above becomes

$$a(\boldsymbol{\beta},\boldsymbol{\eta}) + (\boldsymbol{q}, \nabla v - \boldsymbol{\eta}) = (f, v) + \langle \boldsymbol{m}(\boldsymbol{\beta})\cdot\boldsymbol{n}, \boldsymbol{\eta}\rangle_{\Gamma_{\mathrm{F}}} + \langle \boldsymbol{q}\cdot\boldsymbol{n}, v\rangle_{\Gamma_{\mathrm{F}}}, \qquad (3.16)$$

while using the boundary conditions of (2.17) on Γ_{F} and integration by parts along the boundary finally leads to

$$a(\boldsymbol{\beta},\boldsymbol{\eta}) + (\boldsymbol{q}, \nabla v - \boldsymbol{\eta}) = (f, v) - \langle m_{ns}(\boldsymbol{\beta}), [\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_{\Gamma_{\mathrm{F}}}. \qquad (3.17)$$

Due to (2.17), we have

$$\begin{aligned}\mathcal{D}_h(w,\boldsymbol{\beta};v,\boldsymbol{\eta}) &= \langle m_{ns}(\boldsymbol{\beta}), [\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_{\Gamma_{\mathrm{F}}} + \langle [\nabla w - \boldsymbol{\beta}]\cdot\boldsymbol{s}, m_{ns}(\boldsymbol{\eta})\rangle_{\Gamma_{\mathrm{F}}} \\ &\quad + \sum_{E\in\mathcal{F}_h} \frac{\gamma}{h_E}\langle [\nabla w - \boldsymbol{\beta}]\cdot\boldsymbol{s}, [\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_E \\ &= \langle m_{ns}(\boldsymbol{\beta}), [\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_{\Gamma_{\mathrm{F}}}. \qquad (3.18)\end{aligned}$$

The result now directly follows from (3.14), (3.17), and (3.18). ∎

Remark 3.1. If the Reissner–Mindlin method of [13] without the additional form $\mathcal{D}_h$ is employed by setting $t = 0$, then in the presence of a free boundary we obtain

$$\mathcal{B}_h(w,\boldsymbol{\beta};v,\boldsymbol{\eta}) = (f, v) + \langle m_{ns}(\boldsymbol{\beta}), [\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_{\Gamma_{\mathrm{F}}} \qquad \forall (v,\boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h. \qquad (3.19)$$

Therefore, this would lead to an inconsistent method. We return to this in Remark 4.1 below.

4. Stability and a priori error estimates. For $(v,\boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h$, we introduce the following mesh-dependent norms:

$$|(v,\boldsymbol{\eta})|_h^2 = \sum_{K\in\mathcal{C}_h} h_K^{-2}\|\nabla v - \boldsymbol{\eta}\|_{0,K}^2, \qquad (4.1)$$

$$\|v\|_{2,h}^2 = \|v\|_1^2 + \sum_{K\in\mathcal{C}_h} |v|_{2,K}^2 + \sum_{E\in\mathcal{I}_h} h_E^{-1}\left\| \left[\!\left[\frac{\partial v}{\partial \boldsymbol{n}} \right]\!\right] \right\|_{0,E}^2 + \sum_{E\subset\Gamma_{\mathrm{C}}} h_E^{-1}\left\| \frac{\partial v}{\partial \boldsymbol{n}} \right\|_{0,E}^2, \qquad (4.2)$$

$$|||(v,\boldsymbol{\eta})|||_h = \|\boldsymbol{\eta}\|_1 + \|v\|_{2,h} + |(v,\boldsymbol{\eta})|_h, \qquad (4.3)$$

where $[\![\cdot]\!]$ represents the jump operator and $\mathcal{I}_h$ denotes the edges lying in the interior of the domain Ω.

In [12], the following lemma is proved.

LEMMA 4.1. *There exists a positive constant C such that*

$$\|v\|_{2,h} \le C\big(\|\boldsymbol{\eta}\|_1 + \|v\|_1 + |(v,\boldsymbol{\eta})|_h\big) \qquad \forall (v,\boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h. \tag{4.4}$$

Using the Poincaré inequality and the previous lemma, the following equivalence easily follows.

LEMMA 4.2. *There exists a positive constant C such that*

$$C|||(v,\boldsymbol{\eta})|||_h \le \|\boldsymbol{\eta}\|_1 + |(v,\boldsymbol{\eta})|_h \le |||(v,\boldsymbol{\eta})|||_h \quad \forall (v,\boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h. \tag{4.5}$$

We now have the following stability estimate.

THEOREM 4.3. *Let $0 < \alpha < C_I/4$ and $\gamma > 2/C_I'$. Then there exists a positive constant C such that*

$$\mathcal{A}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta}) \ge C|||(v,\boldsymbol{\eta})|||_h^2 \quad \forall (v,\boldsymbol{\eta}) \in W_h \times \boldsymbol{V}_h. \tag{4.6}$$

Proof. Using the first inverse estimate of Lemma 3.1 we get

$$\begin{aligned}
&\mathcal{B}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta}) \\
&\quad = a(\boldsymbol{\eta},\boldsymbol{\eta}) - \sum_{K\in\mathcal{C}_h} \alpha h_K^2 \|\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2 + \sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2 \\
&\quad \ge \left(1 - \frac{\alpha}{C_I}\right) a(\boldsymbol{\eta},\boldsymbol{\eta}) + \sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2. \qquad (4.7)
\end{aligned}$$

Next, using locally the arithmetic-geometric mean inequality with the constant γ/h_E then the second inverse inequality of Lemma 3.1, we get

$$\begin{aligned}
&\mathcal{D}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta}) \\
&\quad = \sum_{E\in\mathcal{F}_h} \Big(2\langle m_{ns}(\boldsymbol{\eta}), [\nabla v - \boldsymbol{\eta}]\cdot \boldsymbol{s}\rangle_E + \frac{\gamma}{h_E}\|[\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\|_{0,E}^2\Big) \\
&\quad \ge \sum_{E\in\mathcal{F}_h} \Big(-\frac{\gamma}{h_E}\|[\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\|_{0,E}^2 - \gamma^{-1}h_E\,\|m_{ns}(\boldsymbol{\eta})\|_{0,E}^2 + \frac{\gamma}{h_E}\|[\nabla v - \boldsymbol{\eta}]\cdot\boldsymbol{s}\|_{0,E}^2\Big) \\
&\quad = -\sum_{E\in\mathcal{F}_h} \gamma^{-1}h_E\,\|m_{ns}(\boldsymbol{\eta})\|_{0,E}^2 \\
&\quad \ge -\frac{\gamma^{-1}}{C_I'}\,a(\boldsymbol{\eta},\boldsymbol{\eta}) \ge -\frac{1}{2}\,a(\boldsymbol{\eta},\boldsymbol{\eta}). \qquad (4.8)
\end{aligned}$$

Joining (4.7) with (4.8) and using Korn's inequality we then obtain

$$\begin{aligned}
&\mathcal{B}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta}) + \mathcal{D}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta}) \\
&\quad \ge \left(\frac{1}{2} - \frac{\alpha}{C_I}\right) a(\boldsymbol{\eta},\boldsymbol{\eta}) + \sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2 \\
&\quad \ge C\Big(\|\boldsymbol{\eta}\|_1^2 + \sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2\Big). \qquad (4.9)
\end{aligned}$$

From the triangle inequality, again the inverse estimate of Lemma 3.1, and the boundedness of the bilinear form a, it follows that

$$\begin{aligned}
&\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}\|_{0,K}^2\\
&\quad\le 2\left(\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2+\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2\right)\\
&\quad\le 2\left(\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2+\sum_{K\in\mathcal{C}_h} \alpha h_K^2\|\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2\right)\\
&\quad\le C\left(\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2+a(\boldsymbol{\eta},\boldsymbol{\eta})\right)\\
&\quad\le C\left(\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2+\|\boldsymbol{\eta}\|_1^2\right),
\end{aligned}\tag{4.10}$$

which combined with (4.9) gives

$$\mathcal{A}_h(v,\boldsymbol{\eta};v,\boldsymbol{\eta})\ge C\big(\|\boldsymbol{\eta}\|_1^2+|(v,\boldsymbol{\eta})|_h^2\big).\tag{4.11}$$

The result then follows from the norm equivalence of Lemma 4.2. ∎

We can now derive the error estimates for the method. We note that the assumptions of the theorem are supposed to be valid for the further results below as well and hence are not repeated in what follows.

THEOREM 4.4. *Let $0<\alpha<C_I/4$ and $\gamma>2/C_I'$. Let $(w,\boldsymbol{\beta})$ be the exact solution of the problem, and let $(w_h,\boldsymbol{\beta}_h)$ be the approximate solution obtained with Method* 3.1. *Suppose that $w\in H^{s+2}(\Omega)$, with $1\le s\le k$. Then it holds that*

$$|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_h\le Ch^s\|w\|_{s+2}.\tag{4.12}$$

Proof. Step 1. Let $(w_I,\boldsymbol{\beta}_I)\in W_h\times\boldsymbol{V}_h$ be the usual Lagrange interpolants to w and $\boldsymbol{\beta}$, respectively. Using first the stability result of Theorem 4.3 and then the consistency result of Theorem 3.2, one has the existence of a pair

$$(v,\boldsymbol{\eta})\in W_h\times\boldsymbol{V}_h,\qquad |||(v,\boldsymbol{\eta})|||_h\le C\tag{4.13}$$

such that

$$\begin{aligned}
|||(w_h-w_I,\boldsymbol{\beta}_h-\boldsymbol{\beta}_I)|||_h&\le\mathcal{A}_h(w_h-w_I,\boldsymbol{\beta}_h-\boldsymbol{\beta}_I;v,\boldsymbol{\eta})\\
&=\mathcal{A}_h(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I;v,\boldsymbol{\eta}),
\end{aligned}\tag{4.14}$$

where we recall that $\mathcal{A}_h=\mathcal{B}_h+\mathcal{D}_h$.

Step 2. For the $\mathcal{B}_h$-part, we have

$$\begin{aligned}
\mathcal{B}_h(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I;v,\boldsymbol{\eta})&=a(\boldsymbol{\beta}-\boldsymbol{\beta}_I,\boldsymbol{\eta})-\sum_{K\in\mathcal{C}_h}\alpha h_K^2(\boldsymbol{L}(\boldsymbol{\beta}-\boldsymbol{\beta}_I),\boldsymbol{L}\boldsymbol{\eta})_K\\
&+\sum_{K\in\mathcal{C}_h}\frac{1}{\alpha h_K^2}(\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)-\alpha h_K^2\boldsymbol{L}(\boldsymbol{\beta}-\boldsymbol{\beta}_I),\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta})_K.
\end{aligned}\tag{4.15}$$

Due to the first inverse inequality of Lemma 3.1, we get

$$\left(\sum_{K\in\mathcal{C}_h} h_K^2\|\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2\right)^{1/2} \le C|||(v,\boldsymbol{\eta})|||_h \tag{4.16}$$

and

$$\left(\sum_{K\in\mathcal{C}_h} \frac{1}{\alpha h_K^2}\|\nabla v-\boldsymbol{\eta}-\alpha h_K^2\boldsymbol{L}\boldsymbol{\eta}\|_{0,K}^2\right)^{1/2} \le C|||(v,\boldsymbol{\eta})|||_h. \tag{4.17}$$

Using these bounds in (4.15) and recalling (4.13), we obtain

$$\begin{aligned}&\mathcal{B}_h(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I;v,\boldsymbol{\eta})\\ &\quad\le C\left(|||(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I)|||_h+\left(\sum_{K\in\mathcal{C}_h} h_K^2|\boldsymbol{\beta}-\boldsymbol{\beta}_I|_{2,K}^2\right)^{1/2}\right).\end{aligned} \tag{4.18}$$

Substituting the definition of the norm (4.3) in (4.18), using the triangle inequality, and finally applying the classical interpolation estimates, it easily follows that

$$\mathcal{B}_h(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I;v,\boldsymbol{\eta}) \le Ch^s\big(\|w\|_{s+2}+\|\boldsymbol{\beta}\|_{s+1}\big). \tag{4.19}$$

Step 3. For the $\mathcal{D}_h$-part in (4.14), we have, by the definition (3.10),

$$\begin{aligned}\mathcal{D}_h(w-w_I,\boldsymbol{\beta}-\boldsymbol{\beta}_I;v,\boldsymbol{\eta}) &= \langle m_{ns}(\boldsymbol{\beta}-\boldsymbol{\beta}_I),[\nabla v-\boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_{\Gamma_F}\\ &\quad+\langle[\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)]\cdot\boldsymbol{s},m_{ns}(\boldsymbol{\eta})\rangle_{\Gamma_F}\\ &\quad+\sum_{E\in\mathcal{F}_h}\frac{\gamma}{h_E}\langle[\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)]\cdot\boldsymbol{s},[\nabla v-\boldsymbol{\eta}]\cdot\boldsymbol{s}\rangle_E\\ &=: T_1+T_2+T_3.\end{aligned} \tag{4.20}$$

Scaling arguments give

$$\|[\nabla v-\boldsymbol{\eta}]\cdot\boldsymbol{s}\|_{0,E}^2 \le \|\nabla v-\boldsymbol{\eta}\|_{0,E}^2 \le Ch_{K(E)}^{-1}\|\nabla v-\boldsymbol{\eta}\|_{0,K(E)}^2 \tag{4.21}$$

for all $E\in\mathcal{F}_h$, where $K(E)$ is the triangle with E as an edge. The l^2-Cauchy–Schwarz inequality, the bound (4.21), and the norm definition (4.3) now give

$$\begin{aligned}T_1 &\le \left(\sum_{E\in\mathcal{F}_h} h_{K(E)}\|m_{ns}(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2}\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}^{-1}\|[\nabla v-\boldsymbol{\eta}]\cdot\boldsymbol{s}\|_{0,E}^2\right)^{1/2}\\ &\le C\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}\|m_{ns}(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2}|||(v,\boldsymbol{\eta})|||_h.\end{aligned} \tag{4.22}$$

Recalling the bound (4.13), classical polynomial interpolation properties give

$$T_1 \le C\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}\|m_{ns}(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2} \le Ch^s\|\boldsymbol{\beta}\|_{s+1}. \tag{4.23}$$

Again, by scaling we have

$$\|m_{ns}(\boldsymbol{\eta})\|_{0,E}^2 \leq h_{K(E)}^{-1}|\boldsymbol{\eta}|_{1,K(E)}^2 \qquad \forall E \in \mathcal{F}_h. \tag{4.24}$$

The l^2-Cauchy–Schwarz inequality, this bound, and the norm definition (4.3) give

$$\begin{aligned} T_2 &\leq \left(\sum_{E\in\mathcal{F}_h} h_{K(E)}^{-1}\|\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2}\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}\|m_{ns}(\boldsymbol{\eta})\|_{0,E}^2\right)^{1/2} \\ &\leq C\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}^{-1}\|\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2} |||(v,\boldsymbol{\eta})|||_h. \end{aligned} \tag{4.25}$$

Recalling the bound (4.13), classical polynomial interpolation estimates give

$$\begin{aligned} T_2 &\leq C\left(\sum_{E\in\mathcal{F}_h} h_{K(E)}^{-1}\|\nabla(w-w_I)-(\boldsymbol{\beta}-\boldsymbol{\beta}_I)\|_{0,E}^2\right)^{1/2} \\ &\leq Ch^s\big(\|\boldsymbol{\beta}\|_{s+1}+\|w\|_{s+2}\big). \end{aligned} \tag{4.26}$$

The bound for T_3 follows by combining the same techniques used for T_1 and T_2; we get

$$T_3 \leq Ch^s\big(\|\boldsymbol{\beta}\|_{s+1}+\|w\|_{s+2}\big). \tag{4.27}$$

Now, joining all of the bounds (4.14), (4.19), (4.20), (4.23), (4.26), and (4.27) we obtain

$$|||(w_h-w_I,\boldsymbol{\beta}_h-\boldsymbol{\beta}_I)|||_h \leq Ch^s\big(\|\boldsymbol{\beta}\|_{s+1}+\|w\|_{s+2}\big). \tag{4.28}$$

The triangle inequality and the classical polynomial interpolation estimates (recalling that $\boldsymbol{\beta}=\nabla w$) then yield

$$|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_h \leq Ch^s\big(\|\boldsymbol{\beta}\|_{s+1}+\|w\|_{s+2}\big) \leq Ch^s\|w\|_{s+2}. \tag{4.29}$$

Note that the result holds for real values of the regularity parameter s since the interpolation results used above are valid for real values of s. ∎

Remark 4.1. As noted in Remark 3.1, the limiting Reissner–Mindlin method (i.e., without the additional correction $\mathcal{D}_h$) is inconsistent. Regardless of the solution regularity and the polynomial degree k, the inconsistency term can be bounded only with the order $O(h^{1/2})$. As is well known (see, for example, [10]), the inconsistency error is a lower bound for the error of finite element methods. As a consequence, the numerical scheme will not converge with a rate better than $h^{1/2}$ if $\Gamma_{\mathrm{F}} \neq \emptyset$. This observation is also confirmed by the numerical tests shown in [3]. See [6] for other numerical tests regarding this issue. Note further that this boundary inconsistency term is connected not only to the formulation in [13] but is common to any other Kirchhoff method which follows a "Reissner–Mindlin limit" approach.

For the shear force, the practical norm to use is the discrete negative norm

$$\|\boldsymbol{r}\|_{-1,h} = \left(\sum_{K\in\mathcal{C}_h} h_K^2\|\boldsymbol{r}\|_{0,K}^2\right)^{1/2}. \tag{4.30}$$

Since we assume that $w \in H^{s+2}(\Omega)$, with $s \geq 1$, we have $\boldsymbol{q} \in [L^2(\Omega)]^2$, and from the estimates above the lemma immediately follows.

LEMMA 4.5. *It holds that*

$$\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,h} \leq Ch^s \|w\|_{s+2}. \tag{4.31}$$

From this follows a norm estimate in the dual to the space

$$\boldsymbol{V}_* = \left\{ \boldsymbol{\eta} \in [H^1(\Omega)]^2 \mid \boldsymbol{\eta} = \boldsymbol{0} \text{ on } \Gamma_{\mathrm{C}},\ \boldsymbol{\eta} \cdot \boldsymbol{s} = 0 \text{ on } \Gamma_{\mathrm{F}} \cup \Gamma_{\mathrm{S}} \right\}, \tag{4.32}$$

i.e., in the norm

$$\|\boldsymbol{r}\|_{-1,*} = \sup_{\boldsymbol{\eta} \in \boldsymbol{V}_*} \frac{\langle \boldsymbol{r}, \boldsymbol{\eta} \rangle}{\|\boldsymbol{\eta}\|_1}. \tag{4.33}$$

We have the following result.

LEMMA 4.6. *It holds that*

$$\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*} \leq Ch^s \|w\|_{s+2}. \tag{4.34}$$

Proof. The proof is essentially an application of the "Pitkäranta–Verfürth trick" (see [11, 14]). By the definition of the norm $\|\cdot\|_{-1,*}$ there exists a function $\boldsymbol{\eta} \in \boldsymbol{V}_*$ such that

$$\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*} \leq (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta}), \qquad \|\boldsymbol{\eta}\|_1 \leq C. \tag{4.35}$$

Using a Clément-type interpolant we can find a piecewise linear function $\boldsymbol{\eta}_I \in \boldsymbol{V}_*$ such that it holds that

$$h_K^{s-1} \|\boldsymbol{\eta} - \boldsymbol{\eta}_I\|_{s,K} \leq C \|\boldsymbol{\eta}\|_{1,K} \leq C', \quad s = 0, 1, \tag{4.36}$$

for all $K \in \mathcal{C}_h$. Using the Cauchy–Schwarz inequality, the bound (4.36) with $s = 0$, and the definition (4.30), it follows that

$$\begin{aligned} (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta}) &= (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta} - \boldsymbol{\eta}_I) + (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta}_I) \\ &\leq C \|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,h} + (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta}_I). \end{aligned} \tag{4.37}$$

Note that $\boldsymbol{\eta}_I$ is in both $\boldsymbol{V}_h$ and $\boldsymbol{V}_*$; moreover, $\boldsymbol{L}\boldsymbol{\eta}_I = \boldsymbol{0}$ on each element K of $\mathcal{C}_h$. As a consequence, using (3.7), (3.11), (3.12), and Theorem 3.2, it follows that

$$\begin{aligned} (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\eta}_I) &= a(\boldsymbol{\beta} - \boldsymbol{\beta}_h, \boldsymbol{\eta}_I) + \langle [\nabla w_h - \boldsymbol{\beta}_h)] \cdot \boldsymbol{s}, M_{ns}(\boldsymbol{\eta}_I) \rangle_{\Gamma_{\mathrm{F}}} \\ &=: T_1 + T_2. \end{aligned} \tag{4.38}$$

Due to the continuity of the bilinear form and using bound (4.36) with $s = 1$, it immediately follows that

$$T_1 \leq C \|\boldsymbol{\beta} - \boldsymbol{\beta}_h\|_1 \leq C |||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_h. \tag{4.39}$$

Using first the Cauchy–Schwarz inequality, then the Agmon inequality, and finally the bound (4.36) with $s = 1$, Lemma 3.1, and the definition (4.3), we get

$$\begin{aligned} T_2 &\leq \left(\sum_{E \in \mathcal{F}_h} h_E^{-1} \|\nabla w_h - \boldsymbol{\beta}_h)\|_{0,E}^2 \right)^{1/2} \left(\sum_{E \in \mathcal{F}_h} h_E \|M_{ns}(\boldsymbol{\eta}_I)\|_{0,E}^2 \right)^{1/2} \\ &\leq \left(\sum_{K \in \mathcal{C}_h} h_K^{-2} \|\nabla w_h - \boldsymbol{\beta}_h)\|_{0,K}^2 \right)^{1/2} \|\boldsymbol{\eta}_I\|_1 \\ &\leq C |||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_h, \end{aligned} \tag{4.40}$$

where in the last inequality we implicitly used the relation $\nabla w - \boldsymbol{\beta} = \mathbf{0}$. Combining (4.35), (4.37) with (4.38), (4.39), and (4.40), it follows that

$$\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*} \leq C\big(\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,h} + |||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_h\big). \tag{4.41}$$

Joining (4.41) and (4.31) and using Theorem 4.4 the proposition immediately follows. ∎

The regularity of the solution to the Kirchhoff plate problems for convex polygonal domains, with all three main types of boundary conditions, is very case-dependent. We refer, for example, to the work [9], in which a rather complete study is accomplished. Note that if $f \in H^{-1}(\Omega)$, in most cases of interest, the regularity condition $w \in H^3(\Omega)$ is indeed achieved.

Note further that with classical duality arguments and technical calculations it is possible to derive the error bound

$$\|w - w_h\|_1 \leq Ch^{s+1}\|w\|_{s+2}, \tag{4.42}$$

if the regularity estimate

$$\|w\|_3 \leq C\|f\|_{-1} \tag{4.43}$$

holds. Moreover, if $k \geq 2$ and the regularity estimate

$$\|w\|_4 \leq C\|f\|_0 \tag{4.44}$$

is satisfied, then it holds that

$$\|w - w_h\|_0 \leq Ch^{s+2}\|w\|_{s+2}. \tag{4.45}$$

5. A posteriori error estimates. In this section, we prove the reliability and the efficiency for an a posteriori error estimator for our method. To this end, we introduce

$$\tilde{\eta}_K^2 := h_K^4\|f + \operatorname{div} \boldsymbol{q}_h\|_{0,K}^2 + h_K^{-2}\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2, \tag{5.1}$$

$$\eta_E^2 := h_E^3\|[\![\boldsymbol{q}_h \cdot \boldsymbol{n}]\!]\|_{0,E}^2 + h_E\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}^2, \tag{5.2}$$

$$\eta_{S,E}^2 := h_E\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}^2, \tag{5.3}$$

$$\eta_{F,E}^2 := h_E\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}^2 + h_E^3\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h) - \boldsymbol{q}_h \cdot \boldsymbol{n}\right\|_{0,E}^2, \tag{5.4}$$

where h_E denotes the length of the edge E and $[\![\cdot]\!]$ represents the jump operator (which is assumed to be equal to the function value on boundary edges). Further, for a triangle $K \in \mathcal{C}_h$ we denote the sets of edges lying in the interior of Ω, on Γ_{S}, and on Γ_{F}, by $I(K)$, $S(K)$, and $F(K)$, respectively. By $\mathcal{S}_h$ we denote the set of all edges on Γ_{S} and by $\mathcal{I}_h$ the ones lying in the interior of the domain.

Given any element $K \in \mathcal{C}_h$, let the local error indicator be

$$\eta_K := \left(\tilde{\eta}_K^2 + \frac{1}{2}\sum_{E\in I(K)}\eta_E^2 + \sum_{E\in S(K)}\eta_{S,E}^2 + \sum_{E\in F(K)}\eta_{F,E}^2\right)^{1/2}. \tag{5.5}$$

Finally, the global error indicator is defined as

$$\eta := \left(\sum_{K\in\mathcal{C}_h}\eta_K^2\right)^{1/2}. \tag{5.6}$$

Remark 5.1. It is worth noting that, by the definition (3.11),

$$(\boldsymbol{q}_h + \boldsymbol{L}\boldsymbol{\beta}_h)_{|K} = \frac{1}{\alpha h_K^2}(\nabla w_h - \boldsymbol{\beta}_h)_{|K} \qquad \forall K \in \mathcal{C}_h, \tag{5.7}$$

which is the reason why there appear no terms of the kind $\|\boldsymbol{q}_h + \boldsymbol{L}\boldsymbol{\beta}_h\|_{0,K}$ in the error estimator. We note as well that scaling arguments give

$$\sum_{E\in\mathcal{F}_h} h_E^{-1}\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,E}^2 \le C \sum_{K\in\mathcal{C}_h} h_K^{-2}\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2, \tag{5.8}$$

which is the reason why there appear no boundary terms of the kind $\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,E}$.

5.1. Upper bound. In order to derive the reliability of the method we need the following saturation assumption.

Assumption 5.1. Given a mesh $\mathcal{C}_h$, let $\mathcal{C}_{h/2}$ be the mesh obtained by splitting each triangle $K \in \mathcal{C}_h$ into four triangles connecting the edge midpoints. Let $(w_{h/2}, \boldsymbol{\beta}_{h/2})$ be the discrete solution corresponding to the mesh $\mathcal{C}_{h/2}$. We assume that there exists a constant ρ, $0 < \rho < 1$, such that

$$\begin{aligned} &|||(w - w_{h/2}, \boldsymbol{\beta} - \boldsymbol{\beta}_{h/2})|||_{h/2} + \|\boldsymbol{q} - \boldsymbol{q}_{h/2}\|_{-1,*} \\ &\qquad \le \rho\big(|||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_h + \|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*}\big), \end{aligned} \tag{5.9}$$

where by $|||\cdot|||_{h/2}$ we indicate the mesh-dependent norm with respect to the new mesh $\mathcal{C}_{h/2}$.

In what follows, we will need the following result.

LEMMA 5.1. *Let, for $v \in W_{h/2}$, the local seminorm be*

$$|v|_{2,h/2,K} = \left(\sum_{K'\in\mathcal{C}_{h/2},\ K'\subset K} |v|_{2,K'}^2\right)^{1/2}. \tag{5.10}$$

Then there is a positive constant C such that for all $v \in W_{h/2}$ there exists $v_I \in W_h$ with the bound

$$\|v - v_I\|_{0,K} + h_K^{1/2}\|v - v_I\|_{0,\partial K} \le C h_K^2 |v|_{2,h/2,K} \qquad \forall K \in \mathcal{C}_h. \tag{5.11}$$

Moreover, v_I interpolates v at all of the vertices of the triangulation $\mathcal{C}_{h/2}$.

Proof. We choose v_I as the only function in $H^1(\Omega)$ such that

$$\begin{aligned} &v_{I|K} \in P_2(K) \qquad \forall K \in \mathcal{C}_h, \\ &v_I(x) = v(x) \qquad \forall x \in \mathcal{V}_{h/2}, \end{aligned} \tag{5.12}$$

where $\mathcal{V}_{h/2}$ represents the set of all of the vertices of $\mathcal{C}_{h/2}$. Note that it is trivial to check that $v_I \in W_h$ for all $k \ge 1$. Observing that

$$|v|_{2,h/2,K} + \sum_{x\in\mathcal{V}_{h/2}\cap K} |v(x)|, \qquad v \in W_{h/2}, K \in \mathcal{C}_h, \tag{5.13}$$

is indeed a norm on the finite-dimensional space of the functions $v \in W_{h/2}$ restricted to K, the result follows applying the classical scaling argument. ∎

For simplicity, in what follows we will treat the case $\Gamma_{\mathrm{S}} = \emptyset$, the general case following with identical arguments as the ones that follow. We have the following preliminary result.

THEOREM 5.2. *It holds that*

$$|||(w_{h/2} - w_h, \boldsymbol{\beta}_{h/2} - \boldsymbol{\beta}_h)|||_{h/2} \leq C\eta. \tag{5.14}$$

Proof. Step 1. Due to the stability of the discrete formulation, proved in Theorem 4.3, there exists a couple $(v, \boldsymbol{\eta}) \in W_{h/2} \times \boldsymbol{V}_{h/2}$ such that

$$|||(v, \boldsymbol{\eta})|||_{h/2} \leq C \tag{5.15}$$

and

$$|||(w_{h/2} - w_h, \boldsymbol{\beta}_{h/2} - \boldsymbol{\beta}_h)|||_{h/2} \leq \mathcal{A}_{h/2}(w_{h/2} - w_h, \boldsymbol{\beta}_{h/2} - \boldsymbol{\beta}_h; v, \boldsymbol{\eta}). \tag{5.16}$$

Furthermore, we have

$$\mathcal{A}_{h/2}(w_{h/2}, \boldsymbol{\beta}_{h/2}; v, \boldsymbol{\eta}) = (f, v). \tag{5.17}$$

Step 2. Simple calculations and the definition (3.11) give

$$\begin{aligned}
\mathcal{B}_{h/2}(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) &= a(\boldsymbol{\beta}_h, \boldsymbol{\eta}) - \sum_{K \in \mathcal{C}_{h/2}} \alpha h_K^2 (\boldsymbol{L}\boldsymbol{\beta}_h, \boldsymbol{L}\boldsymbol{\eta})_K \\
&\quad + \sum_{K \in \mathcal{C}_{h/2}} \frac{1}{\alpha h_K^2} (\nabla w_h - \boldsymbol{\beta}_h - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\beta}_h, \nabla v - \boldsymbol{\eta} - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\eta})_K \\
&= a(\boldsymbol{\beta}_h, \boldsymbol{\eta}) - \sum_{K \in \mathcal{C}_{h/2}} (\nabla w_h - \boldsymbol{\beta}_h, \boldsymbol{L}\boldsymbol{\eta})_K + \sum_{K \in \mathcal{C}_{h/2}} (\boldsymbol{q}_h, \nabla v - \boldsymbol{\eta})_K \\
&\quad + R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) \\
&= \mathcal{B}_h(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) + R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}),
\end{aligned} \tag{5.18}$$

where $\boldsymbol{q}_h$ is defined as in (3.11), i.e., based on the coarser mesh, and

$$\begin{aligned}
R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) &= \sum_{K \in \mathcal{C}_{h/2}} \frac{1}{\alpha h_K^2} (\nabla w_h - \boldsymbol{\beta}_h, \nabla v - \boldsymbol{\eta})_K \\
&\quad - \sum_{K \in \mathcal{C}_h} \frac{1}{\alpha h_K^2} (\nabla w_h - \boldsymbol{\beta}_h, \nabla v - \boldsymbol{\eta})_K.
\end{aligned} \tag{5.19}$$

The last term on the right-hand side is well defined since $\nabla v - \boldsymbol{\eta}$ is piecewise L^2-regular.

Let now $\mathcal{F}_{h/2}$ indicate the set of all edges of $\mathcal{C}_{h/2}$ lying on Γ_{F}. Adding and subtracting the difference between the two forms, it then follows that

$$\mathcal{D}_{h/2}(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) = \mathcal{D}_h(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) + R_2(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}), \tag{5.20}$$

where

$$\begin{aligned}
R_2(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) &= \sum_{E \in \mathcal{F}_{h/2}} \frac{\gamma}{h_E} \langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\nabla v - \boldsymbol{\eta}] \cdot \boldsymbol{s} \rangle_E \\
&\quad - \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\nabla v - \boldsymbol{\eta}] \cdot \boldsymbol{s} \rangle_E
\end{aligned} \tag{5.21}$$

and where the first member on the right-hand side is indeed well defined due to the piecewise regularity of $(v, \boldsymbol{\eta})$. We will denote

$$R(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) = R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) + R_2(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}). \tag{5.22}$$

Joining (5.17)–(5.21) then yields

$$\mathcal{A}_{h/2}(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) = \mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) + R(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}). \tag{5.23}$$

Step 3. Let $v_I \in W_h$ be the interpolant defined in Lemma 5.1, and let $\boldsymbol{\eta}_I \in \boldsymbol{V}_h$ be the piecewise linear interpolant to $\boldsymbol{\eta}$. First, we have

$$\mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v_I, \boldsymbol{\eta}_I) = (f, v_I). \tag{5.24}$$

This, together with (5.17) and (5.23), gives

$$\begin{aligned}
&\mathcal{A}_{h/2}(w_{h/2} - w_h, \boldsymbol{\beta}_{h/2} - \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) \\
&\quad = \mathcal{A}_{h/2}(w_{h/2}, \boldsymbol{\beta}_{h/2}; v, \boldsymbol{\eta}) - \mathcal{A}_{h/2}(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) \\
&\quad = \mathcal{A}_{h/2}(w_{h/2}, \boldsymbol{\beta}_{h/2}; v, \boldsymbol{\eta}) - \mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) - R(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}) \\
&\quad = (f, v - v_I) - \mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v - v_I, \boldsymbol{\eta} - \boldsymbol{\eta}_I) - R(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta}). \qquad (5.25)
\end{aligned}$$

Step 4. Next, we bound the last terms above. Recalling that $\mathcal{C}_{h/2}$ is a subdivision of $\mathcal{C}_h$, the Cauchy–Schwarz inequality, (4.3), and (5.15) give

$$\begin{aligned}
|R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta})| &\le 2 \left| \sum_{K \in \mathcal{C}_{h/2}} \frac{1}{\alpha h_K^2} (\nabla w_h - \boldsymbol{\beta}_h, \nabla v - \boldsymbol{\eta})_K \right| \\
&\le 2 \left(\sum_{K \in \mathcal{C}_{h/2}} \frac{1}{h_K^2} \|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2 \right)^{1/2} \left(\sum_{K \in \mathcal{C}_{h/2}} \frac{1}{h_K^2} \|\nabla v - \boldsymbol{\eta}\|_{0,K}^2 \right)^{1/2} \\
&\le C \left(\sum_{K \in \mathcal{C}_{h/2}} \frac{1}{h_K^2} \|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2 \right)^{1/2}. \qquad (5.26)
\end{aligned}$$

Using scaling and arguments similar to those already adopted in (5.26) it can be checked that

$$|R_2(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta})| \le C \left(\sum_{K \in \mathcal{C}_{h/2}} \frac{1}{h_K^2} \|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2 \right)^{1/2}. \tag{5.27}$$

Combining (5.26) and (5.27) we get

$$|R(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta})| \le |R_1(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta})| + |R_2(w_h, \boldsymbol{\beta}_h; v, \boldsymbol{\eta})| \le C\eta. \tag{5.28}$$

Step 5. Next, we expand, substitute the expression (3.11) for $\boldsymbol{q}_h$, and regroup the terms:

$$
\begin{aligned}
&(f, v - v_I) - \mathcal{A}_h(w_h, \boldsymbol{\beta}_h; v - v_I, \boldsymbol{\eta} - \boldsymbol{\eta}_I) \\
&= (f, v - v_I) - \Big\{ a(\boldsymbol{\beta}_h, \boldsymbol{\eta} - \boldsymbol{\eta}_I) - \sum_{K \in \mathcal{C}_h} \alpha h_K^2 \big(\boldsymbol{L}\boldsymbol{\beta}_h, \boldsymbol{L}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big)_K \\
&\qquad + \sum_{K \in \mathcal{C}_h} \frac{1}{\alpha h_K^2} \big(\nabla w_h - \boldsymbol{\beta}_h - \alpha h_K^2 \boldsymbol{L}\boldsymbol{\beta}_h, \nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I) - \alpha h_K^2 \boldsymbol{L}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big)_K \\
&\qquad + \big\langle m_{ns}(\boldsymbol{\beta}_h), [\nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I)] \cdot \boldsymbol{s} \big\rangle_{\Gamma_{\mathrm{F}}} + \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, m_{ns}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big\rangle_{\Gamma_{\mathrm{F}}} \\
&\qquad + \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I)] \cdot \boldsymbol{s} \big\rangle_E \Big\} \\
&= (f, v - v_I) - \Big\{ a(\boldsymbol{\beta}_h, \boldsymbol{\eta} - \boldsymbol{\eta}_I) - \sum_{K \in \mathcal{C}_h} \alpha h_K^2 \big(\boldsymbol{L}\boldsymbol{\beta}_h + \boldsymbol{q}_h, \boldsymbol{L}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big)_K \\
&\qquad + \big(\boldsymbol{q}_h, \nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big) \\
&\qquad + \big\langle m_{ns}(\boldsymbol{\beta}_h), [\nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I)] \cdot \boldsymbol{s} \big\rangle_{\Gamma_{\mathrm{F}}} + \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, m_{ns}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big\rangle_{\Gamma_{\mathrm{F}}} \\
&\qquad + \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\nabla(v - v_I) - (\boldsymbol{\eta} - \boldsymbol{\eta}_I)] \cdot \boldsymbol{s} \big\rangle_E \Big\} \\
&= \Big\{ (f, v - v_I) - \big(\boldsymbol{q}_h, \nabla(v - v_I) \big) - \big\langle m_{ns}(\boldsymbol{\beta}_h), [\nabla(v - v_I)] \cdot \boldsymbol{s} \big\rangle_{\Gamma_{\mathrm{F}}} \\
&\qquad - \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\nabla(v - v_I)] \cdot \boldsymbol{s} \big\rangle_E \Big\} \\
&\qquad - \Big\{ a(\boldsymbol{\beta}_h, \boldsymbol{\eta} - \boldsymbol{\eta}_I) - \sum_{K \in \mathcal{C}_h} \alpha h_K^2 \big(\boldsymbol{L}\boldsymbol{\beta}_h + \boldsymbol{q}_h, \boldsymbol{L}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big)_K - \big(\boldsymbol{q}_h, \boldsymbol{\eta} - \boldsymbol{\eta}_I \big) \\
&\qquad - \big\langle m_{ns}(\boldsymbol{\beta}_h), [\boldsymbol{\eta} - \boldsymbol{\eta}_I] \cdot \boldsymbol{s} \big\rangle_{\Gamma_{\mathrm{F}}} + \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, m_{ns}(\boldsymbol{\eta} - \boldsymbol{\eta}_I) \big\rangle_{\Gamma_{\mathrm{F}}} \\
&\qquad - \sum_{E \in \mathcal{F}_h} \frac{\gamma}{h_E} \big\langle [\nabla w_h - \boldsymbol{\beta}_h] \cdot \boldsymbol{s}, [\boldsymbol{\eta} - \boldsymbol{\eta}_I] \cdot \boldsymbol{s} \big\rangle_E \Big\} \\
&=: A - B.
\end{aligned}
\tag{5.29}
$$

Step 6. In the part A above, integration by parts and using the fact that $v(x) = v_I(x)$ at the corner points $x \in \mathcal{V}$ yields

$$
\begin{aligned}
&(f, v - v_I) - \big(\boldsymbol{q}_h, \nabla(v - v_I) \big) - \big\langle m_{ns}(\boldsymbol{\beta}_h), [\nabla(v - v_I)] \cdot \boldsymbol{s} \big\rangle_{\Gamma_{\mathrm{F}}} \\
&\qquad = (f + \operatorname{div} \boldsymbol{q}_h, v - v_I) + \left\langle \frac{\partial}{\partial \boldsymbol{s}} m_{ns}(\boldsymbol{\beta}_h) - \boldsymbol{q}_h \cdot \boldsymbol{n}, v - v_I \right\rangle_{\Gamma_{\mathrm{F}}}.
\end{aligned}
\tag{5.30}
$$

The separate terms are then estimated as follows, using the Cauchy–Schwarz inequal-

ity and Lemma 5.1:

$$\begin{aligned}
\big|(f+\operatorname{div}\boldsymbol{q}_h, v-v_I)\big| &= \left|\sum_{K\in\mathcal{C}_h}(f_h+\operatorname{div}\boldsymbol{q}_h, v-v_I)_K\right| \\
&\le \left(\sum_{K\in\mathcal{C}_h} h_K^4\|f+\operatorname{div}\boldsymbol{q}_h\|_{0,K}^2\right)^{1/2}\left(\sum_{K\in\mathcal{C}_h} h_K^{-4}\|v-v_I\|_{0,K}^2\right)^{1/2} \\
&\le C\left(\sum_{K\in\mathcal{C}_h} h_K^4\|f+\operatorname{div}\boldsymbol{q}_h\|_{0,K}\right)^{1/2}\left(\sum_{K\in\mathcal{C}_h}|v|_{2,h/2,K}^2\right)^{1/2} \\
&\le C\left(\sum_{K\in\mathcal{C}_h}\tilde{\eta}_K^2\right)^{1/2} \qquad (5.31)
\end{aligned}$$

and

$$\begin{aligned}
\left|\left\langle\frac{\partial}{\partial\boldsymbol{s}}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}, v-v_I\right\rangle_{\Gamma_F}\right| &= \left|\sum_{E\in\mathcal{F}_h}\left\langle\frac{\partial}{\partial\boldsymbol{s}}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}, v-v_I\right\rangle_E\right| \\
&\le \left(\sum_{E\in\mathcal{F}_h} h_E^3\left\|\frac{\partial}{\partial\boldsymbol{s}}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E}^2\right)^{1/2}\left(\sum_{E\in\mathcal{F}_h} h_E^{-3}\|v-v_I\|_{0,E}^2\right)^{1/2} \\
&\le C\left(\sum_{E\in\mathcal{F}_h}\eta_{F,E}^2\right)^{1/2}\left(\sum_{K\in\mathcal{C}_h}|v|_{2,h/2,K}^2\right)^{1/2} \\
&\le C\left(\sum_{E\in\mathcal{F}_h}\eta_{F,E}^2\right)^{1/2}. \qquad (5.32)
\end{aligned}$$

The last term in A is readily estimated by scaling estimates and Lemma 5.1:

$$\begin{aligned}
&\left|\sum_{E\in\mathcal{F}_h}\frac{\gamma}{h_E}\big\langle[\nabla w_h-\boldsymbol{\beta}_h]\cdot\boldsymbol{s}, [\nabla(v-v_I)]\cdot\boldsymbol{s}\big\rangle_E\right| \\
&\quad\le \left(\sum_{E\in\mathcal{F}_h} h_E^{-1}\|\nabla w_h-\boldsymbol{\beta}_h\|_{0,E}^2\right)^{1/2}\left(\sum_{E\in\mathcal{F}_h} h_E^{-1}\|\nabla(v-v_I)\|_{0,E}^2\right)^{1/2} \\
&\quad\le C\left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\|\nabla w_h-\boldsymbol{\beta}_h\|_{0,K}^2\right)^{1/2}\left(\sum_{E\in\mathcal{F}_h} h_E^{-3}\|v-v_I\|_{0,E}^2\right)^{1/2} \\
&\quad\le C\left(\sum_{K\in\mathcal{C}_h}\tilde{\eta}_K^2\right)^{1/2}\left(\sum_{K\in\mathcal{C}_h}|v|_{2,h/2,K}^2\right)^{1/2} \le C\left(\sum_{K\in\mathcal{C}_h}\tilde{\eta}_K^2\right)^{1/2}. \qquad (5.33)
\end{aligned}$$

Collecting (5.30)–(5.33) we obtain

$$\big|A\big| \le C\eta. \qquad (5.34)$$

Step 7. We will now estimate the term B. The following terms are directly estimated as the similar terms above:

$$\begin{aligned}&\left|\langle[\nabla w_h-\boldsymbol{\beta}_h]\cdot\boldsymbol{s},m_{ns}(\boldsymbol{\eta}-\boldsymbol{\eta}_I)\rangle_{\Gamma_{\mathrm{F}}}\right|+\left|\sum_{E\in\mathcal{F}_h}\frac{\gamma}{h_E}\langle[\nabla w_h-\boldsymbol{\beta}_h]\cdot\boldsymbol{s},[\boldsymbol{\eta}-\boldsymbol{\eta}_I]\cdot\boldsymbol{s}\rangle_E\right|\\ &\qquad\le C\eta.\end{aligned}\tag{5.35}$$

Since $\boldsymbol{\eta}_I$ is piecewise linear, it holds that $\boldsymbol{L}\boldsymbol{\eta}_{I|K}=\mathbf{0}$. The inverse estimate then gives

$$\begin{aligned}&\left|\sum_{K\in\mathcal{C}_h}\alpha h_K^2\big(\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h,\boldsymbol{L}(\boldsymbol{\eta}-\boldsymbol{\eta}_I)\big)_K\right|=\left|\sum_{K\in\mathcal{C}_h}\alpha h_K^2\big(\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h,\boldsymbol{L}\boldsymbol{\eta}\big)_K\right|\\ &\quad\le C\left(\sum_{K\in\mathcal{C}_h}\alpha h_K^2\|\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h\|_{0,K}^2\right)^{1/2}\|\boldsymbol{\eta}\|_1\\ &\quad\le C\eta,\end{aligned}\tag{5.36}$$

where we in the last step used (5.7). The final step in estimating the term B is to integrate by parts, use the Cauchy–Schwarz inequality, interpolation estimates, and again (5.7):

$$\begin{aligned}&\big|a(\boldsymbol{\beta}_h,\boldsymbol{\eta}-\boldsymbol{\eta}_I)-\big(\boldsymbol{q}_h,\boldsymbol{\eta}-\boldsymbol{\eta}_I\big)-\big\langle m_{ns}(\boldsymbol{\beta}_h),[\boldsymbol{\eta}-\boldsymbol{\eta}_I]\cdot\boldsymbol{s}\big\rangle_{\Gamma_{\mathrm{F}}}\big|\\ &\quad=\Bigg|-\sum_{K\in\mathcal{C}_h}(\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h,\boldsymbol{\eta}-\boldsymbol{\eta}_I)+\sum_{E\in\mathcal{I}_h}\langle[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!],\boldsymbol{\eta}-\boldsymbol{\eta}_I\rangle_E\\ &\qquad+\langle m_{nn}(\boldsymbol{\beta}_h),[\boldsymbol{\eta}-\boldsymbol{\eta}_I]\cdot\boldsymbol{n}\rangle_{\Gamma_{\mathrm{S}}\cup\Gamma_{\mathrm{F}}}\Bigg|\\ &\quad\le\sum_{K\in\mathcal{C}_h}\|\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h\|_{0,K}\|\boldsymbol{\eta}-\boldsymbol{\eta}_I\|_{0,K}+\sum_{E\in\mathcal{I}_h}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}\|\boldsymbol{\eta}-\boldsymbol{\eta}_I\|_{0,E}\\ &\qquad+\sum_{E\in\mathcal{S}_h\cup\mathcal{F}_h}\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}\|\boldsymbol{\eta}-\boldsymbol{\eta}_I\|_{0,E}\\ &\quad\le C\eta.\end{aligned}\tag{5.37}$$

Collecting (5.35)–(5.37) we obtain

$$\big|B\big|\le C\eta.\tag{5.38}$$

Step 8. The asserted estimate now follows from (5.16), (5.25), (5.28), (5.29), (5.34), and (5.38). ∎

We also have the following lemma for the shear force.

LEMMA 5.3. *It holds that*

$$\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,*}\le C\big(|\!|\!|(w_{h/2}-w_h,\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h)|\!|\!|_{h/2}+\eta\big).\tag{5.39}$$

Proof. We start by observing that, referring to the definition (3.11) and its "$h/2$" counterpart, $\boldsymbol{q}_h$ and $\boldsymbol{q}_{h/2}$ are defined on different meshes and therefore with different h_K^2 coefficients. However, recalling that the size ratio between the two meshes is bounded, it is easy to check that an opportune splitting and the triangle inequality

give

$$\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|^2_{-1,h}\le C\left(\sum_{K\in\mathcal{C}_{h/2}}\|\nabla(w_{h/2}-w_h)-(\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h)\|^2_{0,K}\right.$$

$$\left.+\sum_{K\in\mathcal{C}_h}\|\nabla w_h-\boldsymbol{\beta}_h\|^2_{0,K}+\sum_{K\in\mathcal{C}_{h/2}}h_K^2\|\boldsymbol{L}\boldsymbol{\beta}_{h/2}-\boldsymbol{L}\boldsymbol{\beta}_h\|^2_{0,K}\right). \tag{5.40}$$

The first and the last term in (5.40) can be bounded in terms of the $|||\cdot|||_{h/2}$ norm, simply using the definition (4.3) and the inverse inequality

$$h_K^2\|\boldsymbol{L}\boldsymbol{\beta}_{h/2}-\boldsymbol{L}\boldsymbol{\beta}_h\|^2_{0,K}\le C\|\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h\|^2_{1,K}. \tag{5.41}$$

Therefore, recalling the definition (5.1), we get

$$\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,h}\le C\big(|||(w_{h/2}-w_h,\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h)|||_{h/2}+\eta\big). \tag{5.42}$$

The transition from the $\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,h}$ norm to the $\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,*}$ norm is accomplished by using the "Pitkäranta–Verfürth trick" with steps almost identical to those used in Lemma 4.5, which are therefore omitted. ∎

Joining Theorem 5.2 and Lemma 5.3 gives the following a posteriori upper bound for the method.

THEOREM 5.4. *It holds that*

$$|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_h+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*}\le C\eta. \tag{5.43}$$

Proof. Theorem 5.2 combined with Lemma 5.3 trivially gives

$$|||(w_{h/2}-w_h,\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h)|||_{h/2}+\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,*}\le C\eta. \tag{5.44}$$

From the saturation assumption it follows that

$$|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h/2}+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*}$$

$$\le\frac{1}{1-\rho}\big(|||(w_{h/2}-w_h,\boldsymbol{\beta}_{h/2}-\boldsymbol{\beta}_h)|||_{h/2}+\|\boldsymbol{q}_{h/2}-\boldsymbol{q}_h\|_{-1,*}\big), \tag{5.45}$$

and hence the assertion follows from (5.44). ∎

5.2. Lower bound. In this section, we prove the efficiency of the error estimator. Given any edge E of the triangulation, we define ω_E as the set of all of the triangles $K\in\mathcal{C}_h$ that have E as an edge. Given any $K\in\mathcal{C}_h$, we define ω_K as the set of all of the triangles in $\mathcal{C}_h$ that share an edge with K. We then have the following lemma [8].

LEMMA 5.5. *Given any edge E of the triangulation $\mathcal{C}_h$, let $P_k(E)$ be the space of polynomials of degree at most k on E. There exists a linear operator*

$$\Pi_E\ :\ P_k(E)\longrightarrow H^2_0(\omega_E) \tag{5.46}$$

such that for all $p_k\in P_k(E)$ it holds that

$$C_1\|p_k\|^2_{0,E}\le\langle p_k,\Pi_E(p_k)\rangle_E\le\|p_k\|^2_{0,E}, \tag{5.47}$$

$$\|\Pi_E(p_k)\|_{0,\omega_E}\le C_2h_E^{1/2}\|p_k\|_{0,E}, \tag{5.48}$$

where the positive constants C_i above depend only on k and the minimum angle of the triangles in $\mathcal{C}_h$.

Next, we define a local counterpart of the negative norm defined in (4.33) for the shear force.

$$\|\boldsymbol{r}\|_{-1,*,\omega_K} = \sup_{\substack{\boldsymbol{\eta}\in V_* \\ \boldsymbol{\eta}=\boldsymbol{0} \text{ in } \Omega\setminus\omega_K}} \frac{\langle \boldsymbol{r},\boldsymbol{\eta}\rangle}{\|\boldsymbol{\eta}\|_1}. \tag{5.49}$$

We then have the following reliability result.

THEOREM 5.6. *It holds that*

$$\eta_K \le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_K} + \|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_K} + h_K^2\|f-f_h\|_{0,\omega_K}\big), \tag{5.50}$$

where f_h is some approximation of the load f. Here $|||\cdot|||_{h,\omega_K}$ and $\|\cdot\|_{0,\omega_K}$ represent, respectively, the standard restrictions of the norms $|||\cdot|||_h$ and $\|\cdot\|_0$ to the domain ω_K.

Proof. The proof of the theorem consists of bounding separately all of the addenda of η_K in (5.5).

Step 1. We first bound the terms of $\tilde{\eta}_K^2$ in (5.1). Considering the right-hand side of (5.50), the triangle inequality immediately shows that it is sufficient to bound the term $h_K^2\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K}$.

Given any $K\in\mathcal{C}_h$, let b_K indicate the standard third-order polynomial bubble function on K, scaled such that $\|b_K\|_{L^\infty(K)}=1$. Given $K\in\mathcal{C}_h$, let now $\varphi_K\in H_0^2(K)$ be defined as

$$\varphi_K = (f_h+\operatorname{div}\boldsymbol{q}_h)\, b_K^2. \tag{5.51}$$

The standard scaling arguments then easily show that

$$\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K}^2 \le C(f_h+\operatorname{div}\boldsymbol{q}_h,\varphi_K)_K, \tag{5.52}$$

$$\|\varphi_K\|_{0,K} \le C\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K}. \tag{5.53}$$

For the first term in $\tilde{\eta}_K^2$, the equilibrium equation (2.13) and integration by parts give

$$\begin{aligned} h_K^2\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K}^2 &\le Ch_K^2(f_h+\operatorname{div}\boldsymbol{q}_h,\varphi_K)_K \\ &= Ch_K^2\big((f+\operatorname{div}\boldsymbol{q}_h,\varphi_K)_K + (f_h-f,\varphi_K)_K\big) \\ &= Ch_K^2\big((-\operatorname{div}\boldsymbol{q}+\operatorname{div}\boldsymbol{q}_h,\varphi_K)_K + (f_h-f,\varphi_K)_K\big) \\ &= Ch_K^2\big((\boldsymbol{q}_h-\boldsymbol{q},\nabla\varphi_K)_K + (f_h-f,\varphi_K)_K\big). \end{aligned} \tag{5.54}$$

We note, in particular, that $\nabla\varphi_K\in\boldsymbol{V}_*$ and $\nabla\varphi_K=\boldsymbol{0}$ in $\Omega\setminus K$. Therefore, the duality inequality and the Cauchy–Schwarz inequality followed by the inverse inequality and the bound (5.53) lead to the estimate

$$\begin{aligned} &Ch_K^2\big((\boldsymbol{q}_h-\boldsymbol{q},\nabla\varphi_K)_K + (f_h-f,\varphi_K)\big) \\ &\quad\le C\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,K}\, h_K^2\|\nabla\varphi_K\|_{1,K} + Ch_K^2\|f-f_h\|_{0,K}\|\varphi_K\|_{0,K} \\ &\quad\le C\big(\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,K} + h_K^2\|f-f_h\|_{0,K}\big)\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K}. \end{aligned} \tag{5.55}$$

Combining now (5.54) with (5.55) gives

$$h_K^2\|f_h+\operatorname{div}\boldsymbol{q}_h\|_{0,K} \le C\big(\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,K} + h_K^2\|f-f_h\|_{0,K}\big). \tag{5.56}$$

The second term of $\tilde{\eta}_K^2$ in (5.1) can be directly bounded by using the Kirchhoff condition (2.12) with the definitions (4.1)–(4.3):

$$\begin{aligned} h_K^{-1}\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K} &= h_K^{-1}\|\nabla(w - w_h) - (\boldsymbol{\beta} - \boldsymbol{\beta}_h)\|_{0,K}^2 \\ &\le |||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_{h,K}. \end{aligned} \tag{5.57}$$

Step 2. We next bound the terms of η_E^2 in (5.2). Given now $E \in I(K)$, an edge of the element K lying in the interior of Ω, let

$$\boldsymbol{\varphi}_E = \Pi_E([\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]), \tag{5.58}$$

where, with a little abuse of notation, the operator Π_E is intended as applied on each single component. Then, from (5.47) with integration by parts, it follows that

$$\begin{aligned} h_E^{1/2}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}^2 &\le Ch_E^{1/2}\langle [\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!], \boldsymbol{\varphi}_E\rangle_E \\ &= Ch_E^{1/2}\big((\boldsymbol{L}\boldsymbol{\beta}_h, \boldsymbol{\varphi}_E)_{\omega_E} + (\boldsymbol{m}(\boldsymbol{\beta}_h), \nabla\boldsymbol{\varphi}_E)_{\omega_E}\big), \end{aligned} \tag{5.59}$$

where we recall that ω_E was defined at the start of this section. Integration by parts and the equation (2.14) immediately lead to the identity

$$(\boldsymbol{m}(\boldsymbol{\beta}), \nabla\boldsymbol{\varphi}_E)_{\omega_E} = -(\boldsymbol{L}\boldsymbol{\beta}, \boldsymbol{\varphi}_E)_{\omega_E} = (\boldsymbol{q}, \boldsymbol{\varphi}_E)_{\omega_E}, \tag{5.60}$$

which, applied to (5.59), gives

$$\begin{aligned} &h_E^{1/2}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}^2 \\ &\quad\le Ch_E^{1/2}\big((\boldsymbol{L}\boldsymbol{\beta}_h + \boldsymbol{q}, \boldsymbol{\varphi}_E)_{\omega_E} + (\boldsymbol{m}(\boldsymbol{\beta}_h) - \boldsymbol{m}(\boldsymbol{\beta}), \nabla\boldsymbol{\varphi}_E)_{\omega_E}\big) \\ &\quad= Ch_E^{1/2}\big((\boldsymbol{L}\boldsymbol{\beta}_h + \boldsymbol{q}_h, \boldsymbol{\varphi}_E)_{\omega_E} + (\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\varphi}_E)_{\omega_E} \\ &\qquad+(\boldsymbol{m}(\boldsymbol{\beta}_h) - \boldsymbol{m}(\boldsymbol{\beta}), \nabla\boldsymbol{\varphi}_E)_{\omega_E}\big). \end{aligned} \tag{5.61}$$

Next, we bound the three terms on the right-hand side of (5.61). For the first term, the identity (5.7), the Cauchy–Schwarz inequality, the definition (5.58), and the bound (5.48) give

$$\begin{aligned} &h_E^{1/2}(\boldsymbol{L}\boldsymbol{\beta}_h + \boldsymbol{q}_h, \boldsymbol{\varphi}_E)_{\omega_E} \\ &\quad\le C\left(\sum_{K\subset\omega_E} h_K^{-2}\|\nabla w_h - \boldsymbol{\beta}_h\|_{0,K}^2\right)^{1/2} \|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E} \\ &\quad\le C\,|||(w - w_h, \boldsymbol{\beta} - \boldsymbol{\beta}_h)|||_{h,\omega_E}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}. \end{aligned} \tag{5.62}$$

For the second term on the right-hand side of (5.61), we note that $\boldsymbol{\varphi}_E \in \boldsymbol{V}_*$ and $\boldsymbol{\varphi}_E = \boldsymbol{0}$ in $\Omega\backslash\omega_E$. Therefore, the duality inequality and the definition (5.58) combined with the bound (5.48) give

$$\begin{aligned} h_E^{1/2}(\boldsymbol{q} - \boldsymbol{q}_h, \boldsymbol{\varphi}_E)_{\omega_E} &\le h_E^{1/2}\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*,\omega_E}\|\boldsymbol{\varphi}_E\|_{1,\omega_E} \\ &\le C\|\boldsymbol{q} - \boldsymbol{q}_h\|_{-1,*,\omega_E}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}. \end{aligned} \tag{5.63}$$

For the third term of (5.61), the Cauchy–Schwarz inequality, then the inverse inequality, and finally (5.58) combined with the bound (5.48) lead to the estimate

$$\begin{aligned} h_E^{1/2}(\boldsymbol{m}(\boldsymbol{\beta}_h) - \boldsymbol{m}(\boldsymbol{\beta}), \nabla\boldsymbol{\varphi}_E)_{\omega_E} &\le C\|\boldsymbol{\beta} - \boldsymbol{\beta}_h\|_{1,\omega_E}\, h_K^{-1/2}\|\boldsymbol{\varphi}_E\|_{0,\omega_E} \\ &\le C\|\boldsymbol{\beta} - \boldsymbol{\beta}_h\|_{1,\omega_E}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E}. \end{aligned} \tag{5.64}$$

Now, by combining (5.62), (5.63), and (5.64) with (5.61) it follows that

$$h_E^{1/2}\|[\![\boldsymbol{m}(\boldsymbol{\beta}_h)\boldsymbol{n}]\!]\|_{0,E} \le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E} + \|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}\big). \tag{5.65}$$

The remaining term of η_E^2 is bounded with similar arguments; with the notation

$$\varphi_E = \Pi_E([\![\boldsymbol{q}_h\cdot\boldsymbol{n}]\!]), \tag{5.66}$$

the identity

$$-(\operatorname{div}\boldsymbol{q},\varphi_E)_{\omega_E} = (\boldsymbol{q},\nabla\varphi_E)_{\omega_E} \tag{5.67}$$

with (5.54) implies

$$\begin{aligned} h_E^{1/2}\|[\![\boldsymbol{q}\cdot\boldsymbol{n}]\!]\|_{0,E}^2 &\le Ch_E^{1/2}\langle[\![\boldsymbol{q}\cdot\boldsymbol{n}]\!],\varphi_E\rangle_E \\ &\le Ch_E^{1/2}\big((f-f_h,\varphi_E)_{\omega_E} + (\boldsymbol{q}_h-\boldsymbol{q},\nabla\varphi_E)_{\omega_E}\big). \end{aligned} \tag{5.68}$$

Finally, we note that $\nabla\varphi_E \in \boldsymbol{V}_*$ and $\nabla\varphi_E = \boldsymbol{0}$ in $\Omega\backslash\omega_E$. Therefore,

$$h_E^{3/2}\|[\![\boldsymbol{q}_h\cdot\boldsymbol{n}]\!]\|_{0,E} \le C\big(\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E} + h_K^2\|f-f_h\|_{0,\omega_E}\big). \tag{5.69}$$

Step 3. Third, we bound the only term of $\eta_{S,E}^2$ in (5.3) which appears in $\eta_{F,E}^2$ as well. Given now a triangulation edge E in $S(K)\cup F(K)$, let

$$\varphi_E = \Pi_E(m_{nn}(\boldsymbol{\beta}_h)). \tag{5.70}$$

Due to (5.47) and (2.19), integration by parts gives (here $\boldsymbol{\nabla}$ denotes the tensor-valued gradient applied to a vector-valued function)

$$\begin{aligned} h_E^{1/2}\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}^2 &\le h_E^{1/2}\langle m_{nn}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\rangle_E \\ &= h_E^{1/2}\langle \boldsymbol{m}_n(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\boldsymbol{n}\rangle_E \\ &= h_E^{1/2}\big((\boldsymbol{m}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\boldsymbol{\nabla}(\varphi_E\boldsymbol{n}))_{\omega_E} + (\boldsymbol{L}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\boldsymbol{n})_{\omega_E}\big), \end{aligned} \tag{5.71}$$

where $\boldsymbol{n}$ is, as usual, the chosen normal unit vector to E. For the first term, using the Cauchy–Schwarz inequality, then the inverse inequality, and finally the bound (5.48), we easily get

$$\begin{aligned} h_E^{1/2}(\boldsymbol{m}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\boldsymbol{\nabla}(\varphi_E\boldsymbol{n}))_{\omega_E} &\le h_E^{1/2}\|\boldsymbol{\beta}-\boldsymbol{\beta}_h\|_{1,\omega_E}\|\boldsymbol{\nabla}(\varphi_E\boldsymbol{n})\|_{0,\omega_E} \\ &\le C\|\boldsymbol{\beta}-\boldsymbol{\beta}_h\|_{1,\omega_E}\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}. \end{aligned} \tag{5.72}$$

For the second term in (5.71), recalling (2.14) we have

$$\begin{aligned} &h_E^{1/2}(\boldsymbol{L}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\boldsymbol{n})_{\omega_E} \\ &\quad = h_E^{1/2}(\boldsymbol{L}\boldsymbol{\beta}_h+\boldsymbol{q}_h,\varphi_E\boldsymbol{n})_{\omega_E} + h_E^{1/2}(\boldsymbol{q}-\boldsymbol{q}_h,\varphi_E\boldsymbol{n})_{\omega_E}. \end{aligned} \tag{5.73}$$

Observing now that $\varphi_E\boldsymbol{n} \in \boldsymbol{V}_*$ and $\varphi_E\boldsymbol{n} = \boldsymbol{0}$ in $\Omega\backslash\omega_E$, the two terms on the right-hand side of (5.73) can be bounded with the same arguments used above, respectively, in (5.62) and (5.63). Omitting the details, we therefore get

$$\begin{aligned} h_E^{1/2}(\boldsymbol{L}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\boldsymbol{n})_{\omega_E} &\le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E} \\ &\quad + \|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}\big)\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}. \end{aligned} \tag{5.74}$$

From (5.71), (5.72), and (5.74) we get

$$h_E^{1/2}\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E} \le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E} + \|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}\big). \tag{5.75}$$

Step 4. Finally, we bound the last term of $\eta_{F,E}^2$ in (5.4). Given now a triangulation edge E in $F(K)$, let

$$\varphi_E = \Pi_E\left(\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h) - \boldsymbol{q}_h\cdot\boldsymbol{n}\right). \tag{5.76}$$

Using (5.47) and recalling (2.17), we obtain

$$\begin{aligned} &h_E^{3/2}\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h) - \boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E}^2 \\ &\quad\le h_E^{3/2}\left(\left\langle\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\right\rangle_E + \langle[\boldsymbol{q}-\boldsymbol{q}_h]\cdot\boldsymbol{n},\varphi_E\rangle_E\right). \end{aligned} \tag{5.77}$$

For the first term, integration by parts on the edge and simple algebra give

$$\begin{aligned} h_E^{3/2}\left\langle\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\varphi_E\right\rangle_E &= h_E^{3/2}\langle m_{ns}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E\cdot\boldsymbol{s}\rangle_E \\ &= h_E^{3/2}\big(\langle\boldsymbol{m}(\boldsymbol{\beta}-\boldsymbol{\beta}_h)\boldsymbol{n},\nabla\varphi_E\rangle_E - \langle m_{nn}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E\cdot\boldsymbol{n}\rangle_E\big). \end{aligned} \tag{5.78}$$

Using again integration by parts, the first term in (5.78) can be written as

$$\begin{aligned} &h_E^{3/2}\langle\boldsymbol{m}(\boldsymbol{\beta}-\boldsymbol{\beta}_h)\boldsymbol{n},\nabla\varphi_E\rangle_E \\ &\quad= h_E^{3/2}\big(\boldsymbol{L}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E)_{\omega_E} + \langle\boldsymbol{m}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\boldsymbol{\nabla}\nabla\varphi_E)_{\omega_E}\big). \end{aligned} \tag{5.79}$$

The second term in (5.77), again due to integration by parts and recalling (2.13), is instead equivalent to

$$\begin{aligned} h_E^{3/2}\langle[\boldsymbol{q}-\boldsymbol{q}_h]\cdot\boldsymbol{n},\varphi_E\rangle_E &= h_E^{3/2}\big(\boldsymbol{q}-\boldsymbol{q}_h,\nabla\varphi_E)_{\omega_E} \\ &\quad -(f_h+\operatorname{div}\boldsymbol{q}_h,\varphi_E)_{\omega_E} - (f-f_h,\varphi_E)_{\omega_E}\big). \end{aligned} \tag{5.80}$$

For the first term, due to (2.14) and (3.11), we now have

$$\begin{aligned} &h_E^{3/2}(\boldsymbol{q}-\boldsymbol{q}_h,\nabla\varphi_E)_{\omega_E} \\ &\quad= h_E^{3/2}\big(\boldsymbol{L}(\boldsymbol{\beta}_h-\boldsymbol{\beta}),\nabla\varphi_E)_{\omega_E} - \frac{1}{\alpha h_{\omega_E}^2}(\nabla w_h-\boldsymbol{\beta}_h,\nabla\varphi_E\big)_{\omega_E}, \end{aligned} \tag{5.81}$$

where h_{ω_E} is the size of the triangle ω_E. Combining all of the identities from (5.77) to (5.81), it follows that

$$\begin{aligned} &h_E^{3/2}\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h) - \boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E}^2 \\ &\quad\le h_E^{3/2}\Bigg((\boldsymbol{m}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\boldsymbol{\nabla}\nabla\varphi_E)_{\omega_E} - (m_{nn}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E\cdot\boldsymbol{n}\rangle_E \\ &\qquad-\frac{1}{\alpha h_{\omega_E}^2}(\nabla w_h-\boldsymbol{\beta}_h,\nabla\varphi_E)_{\omega_E} - (f_h+\operatorname{div}\boldsymbol{q}_h,\varphi_E)_{\omega_E} \\ &\qquad-(f-f_h,\varphi_E)_{\omega_E}\Bigg). \end{aligned} \tag{5.82}$$

For the second term on the right-hand side of (5.82), recalling (2.17), using the Cauchy–Schwarz inequality and the bound (5.75), we have

$$\begin{aligned} h_E^{3/2}\langle m_{nn}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E\cdot\boldsymbol{n}\rangle_E &\le h_E^{1/2}\|m_{nn}(\boldsymbol{\beta}_h)\|_{0,E}\, h_E\|\nabla\varphi_E\|_{0,E} \\ &\le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E}+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}\big)h_E\|\nabla\varphi_E\|_{0,E}, \end{aligned} \tag{5.83}$$

which, using the inverse inequality and the bound (5.48), gives

$$\begin{aligned} h_E^{3/2}\langle m_{nn}(\boldsymbol{\beta}-\boldsymbol{\beta}_h),\nabla\varphi_E\cdot\boldsymbol{n}\rangle_E &\le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E} \\ &\quad+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}\big)\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E}. \end{aligned} \tag{5.84}$$

The remaining terms on the right-hand side of (5.82) can all be bounded using the Cauchy–Schwarz inequality, the inverse inequality, and the bounds (5.56), (5.48) as already shown for the similar previous cases. Without showing all of the details, we finally get

$$\begin{aligned} &h_E^{3/2}\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E}^2 \\ &\quad\le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E}+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E} \\ &\qquad+h_K^2\|f-f_h\|_{0,K}\big)\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E} \end{aligned} \tag{5.85}$$

or, trivially,

$$\begin{aligned} &h_E^{3/2}\left\|\frac{\partial}{\partial s}m_{ns}(\boldsymbol{\beta}_h)-\boldsymbol{q}_h\cdot\boldsymbol{n}\right\|_{0,E} \\ &\quad\le C\big(|||(w-w_h,\boldsymbol{\beta}-\boldsymbol{\beta}_h)|||_{h,\omega_E}+\|\boldsymbol{q}-\boldsymbol{q}_h\|_{-1,*,\omega_E}+h_K^2\|f-f_h\|_{0,K}\big). \end{aligned} \tag{5.86}$$

Recalling now the definitions for η_K in (5.1) and the local negative norm in (5.49), the proposition is proved. ∎

ANALYSIS OF THE COUPLING OF PRIMAL AND DUAL-MIXED FINITE ELEMENT METHODS FOR A TWO-DIMENSIONAL FLUID-SOLID INTERACTION PROBLEM*

GABRIEL N. GATICA†, ANTONIO MÁRQUEZ‡, AND SALIM MEDDAHI§

Abstract. This paper deals with a time-harmonic fluid-solid interaction problem posed in the plane. More precisely, we apply the coupling of primal and dual-mixed finite element methods to compute both the pressure of the scattered wave in the linearized fluid and the elastic vibrations that take place in the solid elastic body. To this end, we solve a transmission problem holding between the cross-section of the infinitely long cylinder representing the obstacle and an annular region surrounding it. The novelty of our method lies in the use of a dual-mixed variational formulation in the obstacle, while maintaining the usual primal formulation in the fluid. In other words, we introduce a stress-pressure formulation of the problem instead of the traditional displacement-pressure encountered in the literature. As a consequence, one of the transmission conditions becomes essential, and hence we enforce it weakly by means of a Lagrange multiplier. Next, we apply the abstract framework developed in a recent work by A. Buffa, prove that our coupled variational formulation is well posed, and define the corresponding discrete scheme by using PEERS in the solid domain and standard Lagrange finite elements in the fluid domain. Then we show that the resulting Galerkin scheme is uniquely solvable and convergent and derive optimal error estimates. Finally, we illustrate our analysis with some results from computational experiments.

Key words. mixed finite elements, Helmholtz equation, elastodynamic equation

1. Introduction.

In this paper we develop a coupled primal/dual-mixed finite element method for a time-harmonic fluid-solid interaction problem in the plane. We consider an elastic body occupying a region Ω_s and assume that it is subject to a given incident wave that travels in the fluid surrounding it. Actually, we suppose here that the fluid occupies an annular region Ω_f whose exterior boundary Γ is located far from the obstacle (the solid body) and impose on this artificial closed curve a boundary condition that imitates the behavior of the scattered field at infinity. Thus, our model problem is posed in a bounded region. Concerning the numerical solution of this kind of fluid-solid interaction problem, we remark that they have deserved some attention recently from the FEM and BEM-FEM communities. However, to the best of our knowledge, all the methods rely on a displacement formulation of the linear elasticity equation posed in Ω_s (see, e.g., [8, 24, 27, 28] and the references cited therein). However, it is also known that the stress in the solid and the pressure in the fluid usually have more physical interest than the displacement and the velocity,

respectively. Therefore, instead of that classical approach, our goal in this paper is to employ a dual-mixed variational formulation for plane elasticity in the obstacle and keep the usual primal formulation in the linearized fluid region. In this way, the stress tensor in Ω_s and the linearized fluid pressure p, which solves the Helmholtz equation in Ω_f, constitute our main unknowns. In addition, since one of the transmission conditions becomes essential, we enforce it weakly by means of a Lagrange multiplier. We remark that, as compared with the stress-velocity formulation, this turns out to be an advantageous feature of the present approach. In fact, if that formulation were employed, both transmission conditions would be essential and then two Lagrange multipliers would be required.

Now, it is important to point out that in the Helmholtz and elastodynamics equations there is a zero order term with a "wrong" sign that causes the loss of ellipticity of the operators arising from the corresponding primal formulations. Nevertheless, the compactness of the embedding $H^1(\Omega_s) \hookrightarrow L^2(\Omega_s)$ allows one to use successfully a Fredholm alternative to analyze its solvability. On the other hand, the usual dual-mixed formulation is more intricate since it does not fit in any classical theory for proving well-posedness. In particular, a strategy based on elaborated duality arguments is developed in [16] for dealing with this difficulty in the case of the Helmholtz equation. In the present paper we apply a different approach. First of all, in contrast to the usual dual-mixed formulation, the elastodynamic equation is used here to eliminate the original unknown given by the displacement field $\mathbf{u}$. This leads to a method that is equivalent (both at the continuous and the discrete levels) to the standard dual-mixed formulation (see [1]), which has the advantage of reducing the number of unknowns. However, the elimination of $\mathbf{u}$ yields to a formulation that, though having the typical mixed structure, does not satisfy the hypotheses of the Babuška–Brezzi theory. In addition, since the canonical embedding $\mathbf{H}(\mathbf{div}; \Omega_s) \hookrightarrow [L^2(\Omega_s)]^2$ is not compact, it is not possible to employ a Fredholm alternative, at least for the original form of the resulting variational formulation.

In order to circumvent the above difficulties, we take advantage of a recent technique essentially developed for electromagnetism (see [11] and the references cited therein). In fact, a successful strategy has been developed there to deal with a similar noncoercive bilinear form arising in the study of Maxwell equations. Actually, Buffa [11] succeeded in setting up this technique in a general framework. We extend here the range of application of this methodology by using it for the dual-mixed formulation described above. More precisely, we show that a judicious decomposition of $\mathbf{H}(\mathbf{div}; \Omega_s)$ renders suitable the application of a Fredholm alternative for the analysis of the whole coupled problem. The corresponding discrete scheme is defined with PEERS elements in the obstacle and the traditional first order Lagrange finite elements in the fluid domain. The stability and convergence of this Galerkin method also relies on a stable decomposition of the finite element space used to approximate the stress variable. Now, if the stress-velocity formulation were applied then, besides the second Lagrange multiplier on the interface, the discrete system would employ the Raviart–Thomas subspace in the fluid, which involves many more degrees of freedom than the first order Lagrange finite elements. Therefore, since the pressure and not the velocity is the variable of interest in the acoustic medium (fluid), this additional computational effort does not seem to be worthy at all.

The remainder of the paper is organized as follows. In sections 2 and 3 we give a brief description of the fluid-solid interaction problem and derive its coupled variational formulation. In section 4, we show that the resulting saddle point problem is

well posed. The corresponding Galerkin scheme is analyzed in section 5. Finally, in section 6 we provide results from numerical experiments that confirm our theoretical assertions. We end this section with some notation to be used below. Since in what follows we deal with complex valued functions, we let $\mathbb{C}$ be the set of complex numbers, use the symbol $\imath$ for $\sqrt{-1}$, and denote by $\overline{z}$ and $|z|$ the conjugate and modulus, respectively, of each $z \in \mathbb{C}$. In addition, given any Hilbert space U, U^2 and $U^{2\times 2}$ denote, respectively, the space of vectors and tensors of order 2 with entries in U. In particular, $\mathbf{I}$ is the identity matrix of $\mathbb{C}^{2\times 2}$, and given $\boldsymbol{\tau} := (\tau_{ij})$, $\boldsymbol{\zeta} := (\zeta_{ij}) \in \mathbb{C}^{2\times 2}$, we define as usual the transpose tensor $\boldsymbol{\tau}^{\mathtt{t}} := (\tau_{ji})$, the trace $\mathrm{tr}(\boldsymbol{\tau}) := \sum_{i=1}^{2} \tau_{ii}$, the deviator tensor $\boldsymbol{\tau}^{\mathtt{d}} := \boldsymbol{\tau} - \frac{1}{2}\,\mathrm{tr}(\boldsymbol{\tau})\,\mathbf{I}$, the tensor product $\boldsymbol{\tau} : \boldsymbol{\zeta} := \sum_{i,j=1}^{2} \tau_{ij}\,\zeta_{ij}$, and the conjugate tensor $\overline{\boldsymbol{\tau}} := (\overline{\tau}_{ij})$. Finally, in what follows we utilize the standard terminology for Sobolev spaces and norms, employ $\mathbf{0}$ to denote a generic null vector, and use C and c, with or without subscripts, bars, tildes or hats, to denote generic constants independent of the discretization parameters, which may take different values at different places.

2. The fluid-solid interaction problem. We consider an incident acoustic wave upon a bounded elastic body (obstacle) fully surrounded by a fluid, and are interested in determining both the response of both the body and the scattered wave. The obstacle is supposed to be an infinitely long cylinder parallel to the x_3-axis whose cross-section is Ω_s. The boundary of Ω_s is denoted by Σ. We assume that the incident wave and the volume force acting on the body exhibit a time-harmonic behavior with $e^{-\imath\,\omega\,t}$ ansatz and phasors p_i and $\mathbf{f}$, respectively, so that p_i satisfies the Helmholtz equation in $\mathbb{R}^2\backslash\Omega_s$. Hence, as we assume that the phenomenon is invariant under a translation in the x_3-direction, we may consider a bidimensional interaction problem posed in the frequency domain. In this way, and since we plan to employ a mixed variational formulation in the solid, our main unknowns become the phasor $\boldsymbol{\sigma} : \Omega_s \to \mathbb{C}^{2\times 2}$ of the Cauchy stress tensor, the phasor $\mathbf{u} : \Omega_s \to \mathbb{C}^2$ of the displacement field, and the phasor of the total (incident + scattered) pressure $p : \mathbb{R}^2\backslash\Omega_s \to \mathbb{C}$.

The fluid is assumed to be perfect, compressible, and homogeneous, with mass density ρ_f and wave number $\kappa_f := \frac{\omega}{v_0}$, where v_0 is the speed of sound in the linearized fluid. In addition, the solid is supposed to be isotropic and linearly elastic with mass density ρ_s and Lamé constants μ and λ, which means, in particular, that the corresponding constitutive equation is given by

$$\boldsymbol{\sigma} \,=\, \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}) \qquad \text{in } \Omega_s\,, \tag{2.1}$$

where $\boldsymbol{\varepsilon}(\mathbf{u}) := \frac{1}{2}\,(\nabla\mathbf{u} + (\nabla\mathbf{u})^{\mathtt{t}})$ is the strain tensor of small deformations, ∇ is the gradient tensor, and $\mathcal{C}$ is the elasticity operator given by Hooke's law, that is,

$$\mathcal{C}\,\boldsymbol{\zeta} \;:=\; \lambda\,\mathrm{tr}(\boldsymbol{\zeta})\,\mathbf{I} \,+\, 2\,\mu\,\boldsymbol{\zeta} \qquad \forall\,\boldsymbol{\zeta} \,\in\, [L^2(\Omega_s)]^{2\times 2}\,, \quad \boldsymbol{\zeta} \,=\, \boldsymbol{\zeta}^{\mathtt{t}}\,. \tag{2.2}$$

Consequently, under the hypotheses of small oscillations, in both the solid and the fluid, the unknowns $\boldsymbol{\sigma}$, $\mathbf{u}$, and p satisfy the following equations:

$$\begin{aligned} \boldsymbol{\sigma} \,&=\, \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}) && \text{in } \Omega_s\,, \\ \mathbf{div}(\boldsymbol{\sigma}) \,+\, \rho_s\,\omega^2\,\mathbf{u} \,&=\, -\,\mathbf{f} && \text{in } \Omega_s\,, \\ \Delta p \,+\, \kappa_f^2\,p \,&=\, 0 && \text{in } \mathbb{R}^2\backslash\Omega_s\,, \end{aligned} \tag{2.3}$$

together with the transmission conditions

$$\begin{aligned} \boldsymbol{\sigma}\boldsymbol{\nu} &= -p\boldsymbol{\nu} \quad \text{on } \Sigma\,, \\ \rho_f\,\omega^2\,\mathbf{u}\cdot\boldsymbol{\nu} &= \frac{\partial p}{\partial \boldsymbol{\nu}} \quad \text{on } \Sigma \end{aligned} \tag{2.4}$$

and the behavior at infinity given by

$$p - p_i \;=\; O(\mathtt{r}^{-1/2}) \tag{2.5}$$

and

$$\frac{\partial (p-p_i)}{\partial \mathtt{r}} \;-\; \imath\,\kappa_f\,(p-p_i) \;=\; o(\mathtt{r}^{-1/2})\,, \tag{2.6}$$

as $\mathtt{r} := \|\mathbf{x}\| \to +\infty$, uniformly for all directions $\frac{\mathbf{x}}{\|\mathbf{x}\|}$. Hereafter, **div** stands for the usual divergence operator div acting on each row of the tensor, $\|\mathbf{x}\|$ is the euclidean norm of a vector $\mathbf{x} := (x_1, x_2)^{\mathtt{t}} \in \mathbb{R}^2$, and $\boldsymbol{\nu}$ denotes the unit outward normal on Σ. The second and third equations of (2.3) correspond to the elastodynamic and acoustic equations in time-harmonic regime, respectively, whereas the transmission conditions given in (2.4) represent the equilibrium of forces and the equality of the normal displacements of the solid and fluid. Equation (2.6) is known as the Sommerfeld radiation condition.

On the other hand, it is important to remark, as a consequence of (2.5) and (2.6), that the outgoing waves are absorbed by the far field. Motivated by this fact, and aiming to obtain a suitable simplification of our model problem, we now introduce a sufficiently large circle Γ centered at the origin, define Ω_f as the annular domain bounded by Σ and Γ (see Figure 2.1), and consider the Robin boundary condition:

$$\frac{\partial p}{\partial \boldsymbol{\nu}} \;-\; \imath\,\kappa_f\,p \;=\; g \;:=\; \frac{\partial p_i}{\partial \boldsymbol{\nu}} \;-\; \imath\,\kappa_f\,p_i \quad \text{on } \Gamma\,, \tag{2.7}$$

where $\boldsymbol{\nu}$ denotes also the unit outward normal on Γ. Actually, in order to avoid introducing later a nonconforming Galerkin scheme, we may simply think of Γ as the polygonal curve resulting after joining with straight lines the points defining a uniform partition of the given circle. Alternatively, we could take Γ as an arbitrary closed curve sufficiently far away from Σ and consider the Dirichlet boundary condition

$$p \;=\; p_i \quad \text{on } \Gamma\,. \tag{2.8}$$

It is worth mentioning here that, irrespectively of the boundary condition chosen on Γ, the main idea is to reduce the original problem posed in $\mathbb{R}^2$ to an interaction problem on the bounded domain $\Omega_s \cup \Sigma \cup \Omega_f$. Nevertheless, we also remark that the Sommerfeld condition seems to be the most suitable choice since it shows a higher order of approximation (as $\mathtt{r} \to +\infty$) and constitutes the right condition guaranteeing the uniqueness of the exterior Helmholtz problem. Another possibility, which will be reported in a separate work, is to employ the boundary integral equation method in the unbounded region $\mathbb{R}^2 \backslash \overline{\Omega_s \cup \Omega_f}$. Further techniques, including Dirichlet-to-Neumann mappings, infinite elements, and PML approaches, are also available in the literature (see, e.g., [3, 7, 12, 13, 18, 19, 22] and the references therein).

Therefore, throughout the rest of the paper we assume the Robin boundary condition (2.7) and, given $\mathbf{f} \in [L^2(\Omega_s)]^2$ and $g \in H^{-1/2}(\Gamma)$, consider the following fluid-solid

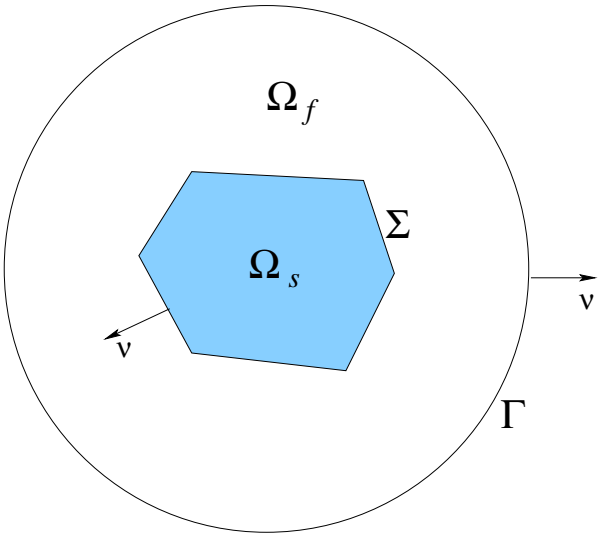

FIG. 2.1. *Geometry of the interaction problem.*

interaction problem: Find $\boldsymbol{\sigma} \in \mathbf{H}(\mathbf{div}; \Omega_s)$, $\mathbf{u} \in [L^2(\Omega_s)]^2$, and $p \in H^1(\Omega_f)$ such that the following hold in the distributional sense:

$$
\begin{aligned}
\boldsymbol{\sigma} &= \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}) && \text{in } \Omega_s\,,\\
\mathbf{div}(\boldsymbol{\sigma}) + \kappa_s^2\,\mathbf{u} &= -\,\mathbf{f} && \text{in } \Omega_s\,,\\
\Delta p + \kappa_f^2\, p &= 0 && \text{in } \Omega_f\,,\\
\boldsymbol{\sigma}\boldsymbol{\nu} &= -\,p\boldsymbol{\nu} && \text{on } \Sigma\,,\\
\rho_f\,\omega^2\,\mathbf{u}\cdot\boldsymbol{\nu} &= \frac{\partial p}{\partial \boldsymbol{\nu}} && \text{on } \Sigma\,,\\
\frac{\partial p}{\partial \boldsymbol{\nu}} - \imath\,\kappa_f\, p &= g && \text{on } \Gamma\,,
\end{aligned}
\tag{2.9}
$$

where the wave number κ_s of the solid is defined by $\sqrt{\rho_s}\,\omega$.

3. The continuous variational formulation. In this section we employ primal and dual-mixed approaches in the fluid Ω_f and the solid Ω_s, respectively, to derive the full continuous variational formulation of (2.9). In fact, we first multiply the acoustic equation by $q \in H^1(\Omega_f)$, integrate by parts, and use the Robin boundary condition, to obtain

$$
\int_{\Omega_f} \nabla p\cdot\nabla q - \kappa_f^2 \int_{\Omega_f} pq + \left\langle \frac{\partial p}{\partial \boldsymbol{\nu}}, q \right\rangle_{\Sigma} - \imath\,\kappa_f \int_{\Gamma} pq = \langle g, q\rangle_{\Gamma}\,,
\tag{3.1}
$$

where, given $\mathcal{S} \in \{\Sigma, \Gamma\}$, $\langle\cdot,\cdot\rangle_{\mathcal{S}}$ stands for the duality pairing of $H^{-1/2}(\mathcal{S})$ and $H^{1/2}(\mathcal{S})$ with respect to the $L^2(\mathcal{S})$-inner product. Next, we use the second transmission condition and replace $\frac{\partial p}{\partial \boldsymbol{\nu}}$ by $\rho_f\,\omega^2\,\mathbf{u}\cdot\boldsymbol{\nu}$ on Σ, introduce the auxiliary unknown

$$
\boldsymbol{\varphi} := \mathbf{u}|_{\Sigma} \in [H^{1/2}(\Sigma)]^2\,,
$$

and divide by $\rho_f\,\omega^2$, whence (3.1) becomes

$$\frac{1}{\rho_f\,\omega^2}\int_{\Omega_f}\nabla p\cdot\nabla q\,-\,\frac{\kappa_f^2}{\rho_f\,\omega^2}\int_{\Omega_f}pq\,+\,\langle q\boldsymbol{\nu},\boldsymbol{\varphi}\rangle_\Sigma\,-\,\imath\,\frac{\kappa_f}{\rho_f\,\omega^2}\int_\Gamma pq \\ =\,\frac{1}{\rho_f\,\omega^2}\langle g,q\rangle_\Gamma\,, \tag{3.2}$$

where $\langle\,\cdot,\cdot\,\rangle_\Sigma$ denotes, from now on, the duality pairing of $[H^{-1/2}(\Sigma)]^2$ and $[H^{1/2}(\Sigma)]^2$ with respect to the $[L^2(\Sigma)]^2$-inner product.

On the other hand, in order to derive the mixed variational formulation in the solid Ω_s, we follow the usual procedure (see [1] and [31]) and introduce the rotation

$$\boldsymbol{\gamma}\,:=\,\frac{1}{2}(\nabla\mathbf{u}-(\nabla\mathbf{u})^{\mathtt{t}})\,\in\,[L^2(\Omega_s)]^{2\times2}_{\mathtt{asym}}$$

as a further unknown, where $[L^2(\Omega_s)]^{2\times2}_{\mathtt{asym}}$ denotes the space of asymmetric tensors with entries in $L^2(\Omega_s)$. In this way, the constitutive equation can be rewritten in the form

$$\mathcal{C}^{-1}\,\boldsymbol{\sigma}\,=\,\boldsymbol{\varepsilon}(\mathbf{u})\,=\,\nabla\mathbf{u}\,-\,\boldsymbol{\gamma}\,,$$

which, multiplying by $\boldsymbol{\tau}\in\mathbf{H}(\mathbf{div};\,\Omega_s)$ and integrating by parts, yields

$$\int_{\Omega_s}\mathcal{C}^{-1}\,\boldsymbol{\sigma}:\boldsymbol{\tau}\,+\,\int_{\Omega_s}\mathbf{u}\cdot\mathbf{div}(\boldsymbol{\tau})\,-\,\langle\boldsymbol{\tau}\boldsymbol{\nu},\boldsymbol{\varphi}\rangle_\Sigma\,+\,\int_{\Omega_s}\boldsymbol{\tau}:\boldsymbol{\gamma}\,=\,0\,. \tag{3.3}$$

Then from the elastodynamic equation we get

$$\mathbf{u}\,=\,-\,\frac{1}{\kappa_s^2}\,\big(\,\mathbf{f}\,+\,\mathbf{div}(\boldsymbol{\sigma})\big)\,, \tag{3.4}$$

which, replaced back into (3.3), gives

$$\int_{\Omega_s}\mathcal{C}^{-1}\,\boldsymbol{\sigma}:\boldsymbol{\tau}\,-\,\frac{1}{\kappa_s^2}\int_{\Omega_s}\mathbf{div}(\boldsymbol{\sigma})\cdot\mathbf{div}(\boldsymbol{\tau})\,-\,\langle\boldsymbol{\tau}\boldsymbol{\nu},\boldsymbol{\varphi}\rangle_\Sigma\,+\,\int_{\Omega_s}\boldsymbol{\tau}:\boldsymbol{\gamma} \\ =\,\frac{1}{\kappa_s^2}\int_{\Omega_s}\mathbf{f}\cdot\mathbf{div}(\boldsymbol{\tau})\,. \tag{3.5}$$

Finally, the symmetry of $\boldsymbol{\sigma}$ and the first transmission condition on Σ (see (2.4) or (2.9)) are imposed weakly through the relations

$$\int_{\Omega_s}\boldsymbol{\sigma}:\boldsymbol{\eta}\,=\,0\qquad\forall\,\boldsymbol{\eta}\,\in\,[L^2(\Omega_s)]^{2\times2}_{\mathtt{asym}} \tag{3.6}$$

and

$$\langle p\boldsymbol{\nu}\,+\,\boldsymbol{\sigma}\boldsymbol{\nu},\boldsymbol{\psi}\rangle_\Sigma\,=\,0\qquad\forall\,\boldsymbol{\psi}\,\in\,[H^{1/2}(\Sigma)]^2\,. \tag{3.7}$$

It is clear from (3.2) and (3.7), as already announced in the introduction, that the transmission conditions on Σ, say $\frac{\partial p}{\partial\boldsymbol{\nu}}\,=\,\rho_f\,\omega^2\,\mathbf{u}\cdot\boldsymbol{\nu}$ and $p\boldsymbol{\nu}\,=\,-\,\boldsymbol{\sigma}\boldsymbol{\nu}$, are natural and essential, respectively. In particular, the trace $\boldsymbol{\varphi}\,:=\,\mathbf{u}|_\Sigma\,\in\,[H^{1/2}(\Sigma)]^2$ constitutes the Lagrange multiplier associated with (3.7). If dual-mixed formulations were employed

in the solid and in the fluid, then both transmission conditions would be essential and therefore, besides $\mathbf{u}|_\Sigma$, the trace $p|_\Sigma$ would be required as a second Lagrange multiplier.

Now, adding (3.2) and (3.5), and subtracting (3.7) from (3.6), we arrive at the following variational formulation of (2.9): Find $((\boldsymbol{\sigma},p),(\boldsymbol{\varphi},\boldsymbol{\gamma})) \in \mathbf{H}\times\mathbf{Q}$ such that

$$\begin{aligned} A((\boldsymbol{\sigma},p),(\boldsymbol{\tau},q)) + B_1((\boldsymbol{\tau},q),(\boldsymbol{\varphi},\boldsymbol{\gamma})) &= F(\boldsymbol{\tau},q) \quad \forall\,(\boldsymbol{\tau},q)\in\mathbf{H}\,, \\ B_2((\boldsymbol{\sigma},p),(\boldsymbol{\psi},\boldsymbol{\eta})) &= 0 \qquad\quad \forall\,(\boldsymbol{\psi},\boldsymbol{\eta})\in\mathbf{Q}\,, \end{aligned} \tag{3.8}$$

where $\mathbf{H}$ and $\mathbf{Q}$ are the product spaces

$$\mathbf{H} := \mathbf{H}(\mathbf{div};\Omega_s)\times H^1(\Omega_f)\,, \quad \mathbf{Q} := [H^{1/2}(\Sigma)]^2\times[L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}}\,, \tag{3.9}$$

$F:\mathbf{H}\to\mathbb{C}$ is the linear functional

$$F(\boldsymbol{\tau},q) := \frac{1}{\kappa_s^2}\int_{\Omega_s}\mathbf{f}\cdot\mathbf{div}(\boldsymbol{\tau}) + \frac{1}{\rho_f\,\omega^2}\,\langle g,q\rangle_\Gamma \qquad \forall\,(\boldsymbol{\tau},q)\in\mathbf{H}\,, \tag{3.10}$$

and $A:\mathbf{H}\times\mathbf{H}\to\mathbb{C}$, $B_1:\mathbf{H}\times\mathbf{Q}\to\mathbb{C}$, and $B_2:\mathbf{H}\times\mathbf{Q}\to\mathbb{C}$ are the bilinear forms defined by

$$\begin{aligned} A((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) &:= \int_{\Omega_s}\mathcal{C}^{-1}\,\boldsymbol{\zeta}:\boldsymbol{\tau} - \frac{1}{\kappa_s^2}\int_{\Omega_s}\mathbf{div}(\boldsymbol{\zeta})\cdot\mathbf{div}(\boldsymbol{\tau}) + \frac{1}{\rho_f\,\omega^2}\int_{\Omega_f}\nabla r\cdot\nabla q \\ &\quad - \frac{\kappa_f^2}{\rho_f\,\omega^2}\int_{\Omega_f} rq - \imath\,\frac{\kappa_f}{\rho_f\,\omega^2}\int_\Gamma rq \qquad \forall\,(\boldsymbol{\zeta},r),\,(\boldsymbol{\tau},q)\in\mathbf{H}\,, \end{aligned} \tag{3.11}$$

$$B_1((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) := \langle q\boldsymbol{\nu} - \boldsymbol{\tau}\boldsymbol{\nu},\boldsymbol{\psi}\rangle_\Sigma + \int_{\Omega_s}\boldsymbol{\tau}:\boldsymbol{\eta}\,, \tag{3.12}$$

and

$$B_2((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) := -\langle q\boldsymbol{\nu}+\boldsymbol{\tau}\boldsymbol{\nu},\boldsymbol{\psi}\rangle_\Sigma + \int_{\Omega_s}\boldsymbol{\tau}:\boldsymbol{\eta} \tag{3.13}$$

for all $(\boldsymbol{\tau},q)\in\mathbf{H}$, $(\boldsymbol{\psi},\boldsymbol{\eta})\in\mathbf{Q}$. It is easy to see that F, A, B_1, and B_2 are all bounded with constants depending on ω, ρ_f, ρ_s, κ_f, and κ_s, in the case of F and A, and constants independent of the physical parameters for B_1 and B_2. Concerning the form A, we also observe from (2.2) that the inverse operator $\mathcal{C}^{-1}$ reduces to

$$\mathcal{C}^{-1}\,\boldsymbol{\zeta} := \frac{1}{2\,\mu}\,\boldsymbol{\zeta} - \frac{\lambda}{4\,\mu\,(\lambda+\mu)}\,\mathrm{tr}(\boldsymbol{\zeta})\,\mathbf{I} \qquad \forall\,\boldsymbol{\zeta}\in[L^2(\Omega_s)]^{2\times 2}\,, \tag{3.14}$$

which implies that

$$\int_{\Omega_s}\mathcal{C}^{-1}\,\boldsymbol{\zeta}:\boldsymbol{\tau} = \frac{1}{2\,\mu}\int_{\Omega_s}\boldsymbol{\zeta}^{\mathtt{d}}:\boldsymbol{\tau}^{\mathtt{d}} + \frac{1}{4\,(\lambda+\mu)}\int_{\Omega_s}\mathrm{tr}(\boldsymbol{\zeta})\,\mathrm{tr}(\boldsymbol{\tau}) \tag{3.15}$$

for all $\boldsymbol{\zeta},\,\boldsymbol{\tau}\in[L^2(\Omega_s)]^{2\times 2}$, and hence

$$\int_{\Omega_s}\mathcal{C}^{-1}\,\boldsymbol{\zeta}:\overline{\boldsymbol{\zeta}} \;\geq\; \frac{1}{2\mu}\,\|\boldsymbol{\zeta}^{\mathtt{d}}\|^2_{[L^2(\Omega_s)]^{2\times 2}} \qquad \forall\,\boldsymbol{\zeta}\in[L^2(\Omega_s)]^{2\times 2}\,. \tag{3.16}$$

This estimate will be useful for our analysis below.

We end this section by commenting that, instead of eliminating the displacement $\mathbf{u}$ by means of (3.4), the classical method for the mixed formulation of the elasticity problem keeps this unknown in (3.3) and incorporates the equation

$$\int_{\Omega_s} \mathbf{v} \cdot \mathbf{div}(\boldsymbol{\sigma}) + \kappa_s^2 \int_{\Omega_s} \mathbf{u} \cdot \mathbf{v} = - \int_{\Omega_s} \mathbf{f} \cdot \mathbf{v} \,,$$

which arises after multiplying the elastodynamic equation by a test function $\mathbf{v} \in [L^2(\Omega_s]^2$. However, the resulting variational formulation does not fit into the framework of any of the available theories for proving well-posedness, and hence a different approach, such as the one proposed in the present paper, must be adopted. An alternative technique, which makes extensive use of duality arguments, was developed in [16] for the coupling of a mixed variational formulation and the boundary integral equation method when applied to an exterior Helmholtz problem in the plane.

4. Analysis of the continuous variational formulation. In this section we proceed analogously to [11] and employ a suitable decomposition of $\mathbf{H}(\mathbf{div}; \Omega_s)$ to show that (3.8) becomes a compact perturbation of a well-posed problem. First, we need to consider an elasticity problem in Ω_s with Neumann boundary conditions. Then this auxiliary problem yields the definition of an associated operator, which is employed to obtain the above-mentioned decomposition.

4.1. Preliminaries. Let $\mathbb{RM}(\Omega_s)$ be the space of rigid body motions in Ω_s, that is,

$$\mathbb{RM}(\Omega_s) := \left\{ \mathbf{v} : \Omega_s \to \mathbb{C}^2 \,:\, \mathbf{v}(\mathbf{x}) = \begin{pmatrix} a \\ b \end{pmatrix} + c \begin{pmatrix} x_2 \\ -x_1 \end{pmatrix} \right.$$
$$\left. \forall\, \mathbf{x} := \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \in \Omega_s \,,\; a,\, b \,,\, c \in \mathbb{C} \right\},$$

and let $\mathbf{M} : [L^2(\Omega_s)]^2 \to \mathbb{RM}(\Omega_s)$ be the $[L^2(\Omega_s)]^2$-orthogonal projector. Then, given $\boldsymbol{\tau} \in \mathbf{H}(\mathbf{div}; \Omega_s)$, we let $(\tilde{\boldsymbol{\sigma}}, \tilde{\mathbf{u}}, \tilde{\boldsymbol{\gamma}}) \in \mathbf{H}(\mathbf{div}; \Omega_s) \times (\mathbf{I} - \mathbf{M})([L^2(\Omega_s)]^2) \times [L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}}$ be the unique solution (see [1], [9, Theorem 9.2.30], [15]) of the dual-mixed variational formulation of the boundary value problem

$$\tilde{\boldsymbol{\sigma}} = \mathcal{C}\, \boldsymbol{\varepsilon}(\tilde{\mathbf{u}}) \,, \quad \mathbf{div}\, \tilde{\boldsymbol{\sigma}} = (\mathbf{I} - \mathbf{M})(\mathbf{div}\, (\boldsymbol{\tau})) \quad \text{in } \Omega_s \,, \quad \tilde{\boldsymbol{\sigma}}\, \boldsymbol{\nu} = \mathbf{0} \quad \text{on } \Sigma \,, \tag{4.1}$$

where $\tilde{\boldsymbol{\gamma}} := \frac{1}{2}(\nabla \tilde{\mathbf{u}} - (\nabla \tilde{\mathbf{u}})^{\mathtt{t}})$ denotes the auxiliary unknown named rotation, $\mathcal{C}\, \boldsymbol{\varepsilon}(\tilde{\mathbf{u}})$ is defined according to (2.2), and $\mathbf{I}$ stands for a generic identity operator. Owing to the regularity result for the elasticity problem with Neumann boundary conditions (see, e.g., [20, 21]), we know that there exists $\epsilon > 0$ such that

$$(\tilde{\boldsymbol{\sigma}}, \tilde{\mathbf{u}}, \tilde{\boldsymbol{\gamma}}) \in [H^{\epsilon}(\Omega_s)]^{2\times 2} \times [H^{1+\epsilon}(\Omega_s)]^2 \times [H^{\epsilon}(\Omega_s)]^{2\times 2} \tag{4.2}$$

and

$$\|\tilde{\boldsymbol{\sigma}}\|_{[H^{\epsilon}(\Omega_s)]^{2\times 2}} + \|\tilde{\mathbf{u}}\|_{[H^{1+\epsilon}(\Omega_s)]^2} + \|\tilde{\boldsymbol{\gamma}}\|_{[H^{\epsilon}(\Omega_s)]^{2\times 2}} \leq C\, \|\mathbf{div}(\boldsymbol{\tau})\|_{[L^2(\Omega_s)]^2} \,. \tag{4.3}$$

We now introduce the linear operator

$$\begin{aligned} \mathbf{P} : \mathbf{H}(\mathbf{div}; \Omega_s) &\to \mathbf{H}(\mathbf{div}; \Omega_s), \\ \boldsymbol{\tau} &\to \mathbf{P}(\boldsymbol{\tau}) := \tilde{\boldsymbol{\sigma}} \end{aligned} \tag{4.4}$$

and observe from (4.1) that

$$\begin{aligned} \mathbf{div}\,\mathbf{P}(\boldsymbol{\tau}) \,&=\, (\mathbf{I}-\mathbf{M})(\mathbf{div}\,(\boldsymbol{\tau})) \quad \text{in } \Omega_s\,, \\ \mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\tau}) \,&=\, \mathbf{M}(\mathbf{div}\,(\boldsymbol{\tau})) \quad \text{in } \Omega_s\,, \end{aligned} \tag{4.5}$$

and

$$\mathbf{P}(\boldsymbol{\tau})\,\boldsymbol{\nu} \,=\, \mathbf{0} \quad \text{on } \Sigma\,. \tag{4.6}$$

Then, using the continuous dependence result for (4.1), we find that

$$\|\mathbf{P}(\boldsymbol{\tau})\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)} \,\leq\, C\,\|\mathbf{div}(\boldsymbol{\tau})\|_{[L^2(\Omega_s)]^2} \qquad \forall\,\boldsymbol{\tau}\,\in\,\mathbf{H}(\mathbf{div};\,\Omega_s)\,,$$

which shows that $\mathbf{P}$ is bounded. Moreover, it is easy to see that $\mathbf{P}$ is actually a linear projection, and hence

$$\mathbf{H}(\mathbf{div};\,\Omega_s) \,=\, \mathbf{P}(\mathbf{H}(\mathbf{div};\,\Omega_s)) \,\oplus\, (\mathbf{I}-\mathbf{P})(\mathbf{H}(\mathbf{div};\,\Omega_s))\,. \tag{4.7}$$

Finally, it is clear from (4.2) and (4.3) that $\mathbf{P}(\boldsymbol{\tau}) \,\in\, [H^{\epsilon}(\Omega_s)]^{2\times 2}$ and

$$\|\mathbf{P}(\boldsymbol{\tau})\|_{[H^{\epsilon}(\Omega_s)]^{2\times 2}} \,\leq\, C\,\|\mathbf{div}(\boldsymbol{\tau})\|_{[L^2(\Omega_s)]^2} \qquad \forall\,\boldsymbol{\tau}\,\in\,\mathbf{H}(\mathbf{div};\,\Omega_s)\,. \tag{4.8}$$

4.2. Well-posedness of the continuous formulation. In order to show that our coupled problem (3.8) is well posed, we now employ the stable decomposition (4.7) to reformulate (3.8) in a more suitable form. We begin by observing, according to (4.5), (4.6), the symmetry of $\mathbf{P}(\boldsymbol{\tau})$, and the fact that $\nabla\mathbf{v} \,\in\, [L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}}$ for all $\mathbf{v} \,\in\, \mathbb{RM}(\Omega_s)$, that for all $\boldsymbol{\zeta}$, $\boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\,\Omega_s)$ there holds

$$\begin{aligned} \int_{\Omega_s} \mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})\cdot\mathbf{div}\,\mathbf{P}(\boldsymbol{\tau}) \,&=\, \int_{\Omega_s} \mathbf{M}(\mathbf{div}(\boldsymbol{\zeta}))\cdot\mathbf{div}\,\mathbf{P}(\boldsymbol{\tau}) \\ &=\, -\int_{\Omega_s} \nabla\mathbf{M}(\mathbf{div}(\boldsymbol{\zeta})) : \mathbf{P}(\boldsymbol{\tau}) \,+\, \langle\,\mathbf{P}(\boldsymbol{\tau})\boldsymbol{\nu}, \mathbf{M}(\mathbf{div}(\boldsymbol{\zeta}))\,\rangle_{\Sigma} \,=\, 0\,. \end{aligned} \tag{4.9}$$

Then, writing $\boldsymbol{\zeta} \,=\, \mathbf{P}(\boldsymbol{\zeta}) + (\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})$ and $\boldsymbol{\tau} \,=\, \mathbf{P}(\boldsymbol{\tau}) + (\mathbf{I}-\mathbf{P})(\boldsymbol{\tau})$ in (3.11), using the identity (4.9), and adding and subtracting the terms

$$\int_{\Omega_s} \mathcal{C}^{-1}\,\mathbf{P}(\boldsymbol{\zeta}) : \mathbf{P}(\boldsymbol{\tau})\,, \quad \int_{\Omega_s} \mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})\cdot\mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\tau})\,, \quad \text{and} \quad \frac{1}{\rho_f\,\omega^2}\int_{\Omega_f} rq\,,$$

we find that A can be decomposed as

$$A((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) \,=\, A_0((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) \,+\, K_0((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) \tag{4.10}$$

for all $(\boldsymbol{\zeta},r)\,,(\boldsymbol{\tau},q) \,\in\, \mathbf{H}$, where $A_0 : \mathbf{H}\times\mathbf{H} \to \mathbb{C}$ and $K_0 : \mathbf{H}\times\mathbf{H} \to \mathbb{C}$ are the bounded and symmetric bilinear forms given by

(4.11)

$$\begin{aligned} A_0((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) \,:=\, &-\int_{\Omega_s} \mathcal{C}^{-1}\,\mathbf{P}(\boldsymbol{\zeta}) : \mathbf{P}(\boldsymbol{\tau}) \,-\, \frac{1}{\kappa_s^2}\int_{\Omega_s} \mathbf{div}\,\mathbf{P}(\boldsymbol{\zeta})\cdot\mathbf{div}\,\mathbf{P}(\boldsymbol{\tau}) \\ &+\int_{\Omega_s} \mathcal{C}^{-1}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}) : (\mathbf{I}-\mathbf{P})(\boldsymbol{\tau}) + \int_{\Omega_s} \mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})\cdot\mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\tau}) \\ &+\frac{1}{\rho_f\,\omega^2}\int_{\Omega_f} \nabla r\cdot\nabla + \frac{1}{\rho_f\,\omega^2}\int_{\Omega_f} rq - \imath\,\frac{\kappa_f}{\rho_f\,\omega^2}\int_{\Gamma} rq\,, \end{aligned}$$

and

(4.12)

$$K_0((\boldsymbol{\zeta},r),(\boldsymbol{\tau},q)) := 2\int_{\Omega_s}\mathcal{C}^{-1}\,\mathbf{P}(\boldsymbol{\zeta}):\mathbf{P}(\boldsymbol{\tau}) + \int_{\Omega_s}\mathcal{C}^{-1}\,\mathbf{P}(\boldsymbol{\zeta}):(\mathbf{I}-\mathbf{P})(\boldsymbol{\tau}) + \int_{\Omega_s}\mathcal{C}^{-1}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}):\mathbf{P}(\boldsymbol{\tau}) - \left(1+\frac{1}{\kappa_s^2}\right)\int_{\Omega_s}\mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})\cdot\mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\tau}) - \frac{(1+\kappa_f^2)}{\rho_f\,\omega^2}\int_{\Omega_f} rq\,.$$

On the other hand, we easily deduce from (3.12) and (3.13) that B_1 and B_2 can be decomposed as

$$B_1((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) = B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) + K_1((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) \tag{4.13}$$

and

$$B_2((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) = B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) - K_1((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) \tag{4.14}$$

for all $(\boldsymbol{\tau},q)\in\mathbf{H}$, $(\boldsymbol{\psi},\boldsymbol{\eta})\in\mathbf{Q}$, where $B_0:\mathbf{H}\times\mathbf{H}\to\mathbb{C}$ and $K_1:\mathbf{H}\times\mathbf{H}\to\mathbb{C}$ are the bounded bilinear forms defined by

$$B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) := -\langle\boldsymbol{\tau}\,\boldsymbol{\nu},\boldsymbol{\psi}\rangle_\Sigma + \int_{\Omega_s}\boldsymbol{\tau}:\boldsymbol{\eta} \tag{4.15}$$

and

$$K_1((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta})) := \langle q\boldsymbol{\nu},\boldsymbol{\psi}\rangle_\Sigma\,. \tag{4.16}$$

Next, we let $\mathbf{A}_0:\mathbf{H}\to\mathbf{H}$, $\mathbf{B}_0:\mathbf{H}\to\mathbf{Q}$, $\mathbf{K}_0:\mathbf{H}\to\mathbf{H}$, and $\mathbf{K}_1:\mathbf{H}\to\mathbf{Q}$ be the linear and bounded operators induced by the corresponding bilinear forms. In addition, we let $\mathbf{B}_0^*:\mathbf{Q}\to\mathbf{H}$ and $\mathbf{K}_1^*:\mathbf{Q}\to\mathbf{H}$ be the associated adjoint operators and denote by $\mathbf{F}$ the Riesz representant of F. Hence, using these notations and taking into account the decompositions (4.10), (4.13), and (4.14), our variational formulation (3.8) can be rewritten as the following operator equation: Find $((\boldsymbol{\sigma},p),(\boldsymbol{\varphi},\boldsymbol{\gamma}))\in\mathbf{H}\times\mathbf{Q}$ such that

$$\begin{pmatrix}\mathbf{A}_0 & \mathbf{B}_0^*\\ \mathbf{B}_0 & \mathbf{0}\end{pmatrix}\begin{pmatrix}(\boldsymbol{\sigma},p)\\(\boldsymbol{\varphi},\boldsymbol{\gamma})\end{pmatrix} + \begin{pmatrix}\mathbf{K}_0 & \mathbf{K}_1^*\\ -\mathbf{K}_1 & \mathbf{0}\end{pmatrix}\begin{pmatrix}(\boldsymbol{\sigma},p)\\(\boldsymbol{\varphi},\boldsymbol{\gamma})\end{pmatrix} = \begin{pmatrix}\mathbf{F}\\\mathbf{0}\end{pmatrix}. \tag{4.17}$$

Throughout the rest of this section we prove that the matrix operators on the left-hand side of (4.17) become invertible and compact, respectively.

The following two lemmas are needed to prove the continuous inf-sup condition for B_0. In particular, we notice that Lemma 4.1 provides a right inverse of the normal traces of functions in $\mathbf{H}(\mathbf{div};\Omega_s)$.

LEMMA 4.1. *There exists a bounded and linear operator* $\mathbf{S}:[H^{-1/2}(\Sigma)]^2\to\mathbf{H}(\mathbf{div};\Omega_s)$ *such that*

$$\mathbf{S}(\boldsymbol{\xi})\,\boldsymbol{\nu} = -\boldsymbol{\xi}\quad \text{on } \Sigma\qquad \forall\,\boldsymbol{\xi}\in[H^{-1/2}(\Sigma)]^2\,.$$

Proof. Given $\boldsymbol{\xi}:=(\xi_1,\xi_2)^{\mathtt{t}}\in[H^{-1/2}(\Sigma)]^2$, we let $\mathbf{S}(\boldsymbol{\xi}):=\nabla\mathbf{z}$ where $\mathbf{z}\in[H^1(\Omega_s)]^2$ is the unique weak solution, up to a constant vector in $\mathbb{C}^2$, of the boundary value problem with Neumann boundary conditions

$$-\Delta\,\mathbf{z} = \frac{1}{|\Omega_s|}\,(\langle\xi_1,1\rangle_\Sigma,\langle\xi_2,1\rangle_\Sigma)^{\mathtt{t}}\quad\text{in }\Omega_s\,,\quad \nabla\mathbf{z}\,\boldsymbol{\nu} = -\boldsymbol{\xi}\quad\text{on }\Sigma\,. \tag{4.18}$$

It follows easily that $\mathbf{S}(\boldsymbol{\xi})$ belongs to $\mathbf{H}(\mathbf{div};\Omega_s)$ and satisfies the required conditions. In particular, the fact that $\mathbf{div}(\mathbf{S}(\boldsymbol{\xi})) = -\frac{1}{|\Omega_s|}\,(\langle\xi_1,1\rangle_\Sigma,\langle\xi_2,1\rangle_\Sigma)^{\mathtt{t}}$ in Ω_s and the continuous dependence result for (4.18) imply the boundedness of $\mathbf{S}$. ∎

LEMMA 4.2. *There exists a bounded and linear operator* $\mathbf{T} : [L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}} \to \mathbf{H}(\mathbf{div};\Omega_s)$ *such that*

$$\mathbf{T}(\boldsymbol{\eta})\,\boldsymbol{\nu} = 0 \quad \text{on } \Sigma \quad \text{and} \quad \frac{1}{2}\left(\mathbf{T}(\boldsymbol{\eta}) - \mathbf{T}(\boldsymbol{\eta})^{\mathtt{t}}\right) = \boldsymbol{\eta} \qquad \forall\,\boldsymbol{\eta} \in [L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}}\,.$$

Proof. The proof is a slight variation of the proof of Lemma 4.4 in [17] (see also Lemma 4.2 in [6]). ∎

We are now in a position to prove that B_0 satisfies the continuous inf-sup condition.

LEMMA 4.3. *There exists* $C_1 > 0$ *such that*

$$\sup_{\substack{(\boldsymbol{\tau},q)\in\mathbf{H}\\(\boldsymbol{\tau},q)\neq\mathbf{0}}} \frac{|\,B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta}))\,|}{\|(\boldsymbol{\tau},q)\|_{\mathbf{H}}} \geq C_1\,\|(\boldsymbol{\psi},\boldsymbol{\eta})\|_{\mathbf{Q}} \qquad \forall\,(\boldsymbol{\psi},\boldsymbol{\eta}) \in \mathbf{Q}\,. \tag{4.19}$$

Proof. Given $(\boldsymbol{\psi},\boldsymbol{\eta}) \in \mathbf{Q}$, we consider the linear operators $\mathbf{S}$ and $\mathbf{T}$ defined in the previous lemmas and observe from the definition of B_0 (cf. (4.15)) that

$$B_0((\mathbf{S}(\boldsymbol{\xi}),0),(\boldsymbol{\psi},\boldsymbol{\eta})) := \langle\boldsymbol{\xi},\boldsymbol{\psi}\rangle_\Sigma + \int_{\Omega_s}\mathbf{S}(\boldsymbol{\xi}) : \boldsymbol{\eta} \qquad \forall\,\boldsymbol{\xi} \in [H^{-1/2}(\Sigma)]^2$$

and

$$B_0((\mathbf{T}(\overline{\boldsymbol{\eta}}),0),(\boldsymbol{\psi},\boldsymbol{\eta})) := \int_{\Omega_s}\mathbf{T}(\overline{\boldsymbol{\eta}}) : \boldsymbol{\eta} = \int_{\Omega_s}\frac{1}{2}\left(\mathbf{T}(\overline{\boldsymbol{\eta}}) - \mathbf{T}(\overline{\boldsymbol{\eta}})^{\mathtt{t}}\right) : \boldsymbol{\eta} = \|\boldsymbol{\eta}\|^2_{[L^2(\Omega_s)]^{2\times 2}}\,.$$

Then, employing the boundedness of $\mathbf{S}$ and $\mathbf{T}$, respectively, we find that

$$\begin{aligned}
&\sup_{\substack{(\boldsymbol{\tau},q)\in\mathbf{H}\\(\boldsymbol{\tau},q)\neq\mathbf{0}}} \frac{|\,B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta}))\,|}{\|(\boldsymbol{\tau},q)\|_{\mathbf{H}}} \geq \sup_{\substack{\boldsymbol{\xi}\in[H^{-1/2}(\Sigma)]^2\\\boldsymbol{\xi}\neq\mathbf{0}}} \frac{|\,B_0((\mathbf{S}(\boldsymbol{\xi}),0),(\boldsymbol{\psi},\boldsymbol{\eta}))\,|}{\|(\mathbf{S}(\boldsymbol{\xi}),0)\|_{\mathbf{H}}} \\
&= \sup_{\substack{\boldsymbol{\xi}\in[H^{-1/2}(\Sigma)]^2\\\boldsymbol{\xi}\neq\mathbf{0}}} \frac{\left|\,\langle\boldsymbol{\xi},\boldsymbol{\psi}\rangle_\Sigma + \displaystyle\int_{\Omega_s}\mathbf{S}(\boldsymbol{\xi}) : \boldsymbol{\eta}\,\right|}{\|\mathbf{S}(\boldsymbol{\xi})\|_{\mathbf{H}(\mathbf{div};\Omega_s)}} \geq \frac{1}{\|\mathbf{S}\|}\,\|\boldsymbol{\psi}\|_{[H^{1/2}(\Sigma)]^2} - \|\boldsymbol{\eta}\|_{[L^2(\Omega_s)]^{2\times 2}}
\end{aligned} \tag{4.20}$$

and

$$\begin{aligned}
&\sup_{\substack{(\boldsymbol{\tau},q)\in\mathbf{H}\\(\boldsymbol{\tau},q)\neq\mathbf{0}}} \frac{|\,B_0((\boldsymbol{\tau},q),(\boldsymbol{\psi},\boldsymbol{\eta}))\,|}{\|(\boldsymbol{\tau},q)\|_{\mathbf{H}}} \geq \frac{|\,B_0((\mathbf{T}(\overline{\boldsymbol{\eta}}),0),(\boldsymbol{\psi},\boldsymbol{\eta}))\,|}{\|(\mathbf{T}(\overline{\boldsymbol{\eta}}),0)\|_{\mathbf{H}}} \\
&= \frac{\|\boldsymbol{\eta}\|^2_{[L^2(\Omega_s)]^{2\times 2}}}{\|\mathbf{T}(\overline{\boldsymbol{\eta}})\|_{\mathbf{H}(\mathbf{div};\Omega_s)}} \geq \frac{1}{\|\mathbf{T}\|}\,\|\boldsymbol{\eta}\|_{[L^2(\Omega_s)]^{2\times 2}}\,.
\end{aligned} \tag{4.21}$$

The estimates (4.20) and (4.21) imply (4.19) and complete the proof. ∎

Our next goal, according to the well-known Babuška–Brezzi theory, is to prove that $\mathbf{A}_0$ is an isomorphism on the kernel of $\mathbf{B}_0$. To this end, we now introduce the decomposition

$$\mathbf{H}(\mathbf{div};\Omega_s) = \mathbf{H}_0(\mathbf{div};\Omega_s) \oplus \mathbb{C}\,\mathbf{I}\,, \tag{4.22}$$

where

$$\mathbf{H}_0(\mathbf{div};\Omega_s) := \left\{ \boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s) : \quad \int_{\Omega_s} \mathrm{tr}(\boldsymbol{\tau}) = 0 \right\}. \tag{4.23}$$

This means that for any $\boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s)$ there exist unique $\boldsymbol{\tau}_0 \in \mathbf{H}_0(\mathbf{div};\Omega_s)$ and $d \in \mathbb{C}$ given by $d := \frac{1}{2\,|\Omega_s|}\int_{\Omega_s} \mathrm{tr}(\boldsymbol{\tau})$, where $|\Omega_s|$ denotes the measure of Ω_s, such that $\boldsymbol{\tau} = \boldsymbol{\tau}_0 + d\,\mathbf{I}$.

The inequalities provided by the following three lemmas will be crucial in our subsequent analysis. We notice that Lemma 4.5 corresponds to Lemma 2.2 in [14], whose proof, being short and simple, is recalled here for the sake of completeness.

LEMMA 4.4. *There exists $c_1 > 0$, depending only on Ω_s, such that*

$$c_1 \,\|\boldsymbol{\tau}_0\|^2_{[L^2(\Omega_s)]^{2\times 2}} \le \|\boldsymbol{\tau}^{\mathtt{d}}\|^2_{[L^2(\Omega_s)]^{2\times 2}} + \|\mathbf{div}(\boldsymbol{\tau})\|^2_{[L^2(\Omega_s)]^2} \quad \forall\, \boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s)\,. \tag{4.24}$$

Proof. See Lemma 3.1 in [2] or Proposition 3.1 of Chapter IV in [10]. ∎

LEMMA 4.5. *There exists $c_2 > 0$, depending only on Ω_s, such that*

$$c_2\,\|\boldsymbol{\tau}\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} \le \|\boldsymbol{\tau}_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} \quad \forall\, \boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s) \quad \textit{such that} \quad \boldsymbol{\tau}\boldsymbol{\nu} = \mathbf{0} \quad \textit{on } \Sigma\,. \tag{4.25}$$

Proof. Given $\boldsymbol{\tau} = \boldsymbol{\tau}_0 + d\,\mathbf{I} \in \mathbf{H}(\mathbf{div};\Omega_s)$, with $\boldsymbol{\tau}_0 \in \mathbf{H}_0(\mathbf{div};\Omega_s)$ and $d \in \mathbb{C}$, and such that $\boldsymbol{\tau}\boldsymbol{\nu} = \mathbf{0}$ on Σ, we note that $d\,\boldsymbol{\nu} = -\,\boldsymbol{\tau}_0\,\boldsymbol{\nu}$ on Σ, and hence, using the trace theorem of $\mathbf{H}(\mathbf{div};\Omega_s)$,

$$|d|\,\|\boldsymbol{\nu}\|_{[H^{-1/2}(\Sigma)]^2} = \|\boldsymbol{\tau}_0\boldsymbol{\nu}\|_{[H^{-1/2}(\Sigma)]^2} \le \tilde{c}_2\,\|\boldsymbol{\tau}_0\|_{\mathbf{H}(\mathbf{div};\Omega_s)}\,.$$

This inequality and the fact that $\|\boldsymbol{\tau}\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} = \|\boldsymbol{\tau}_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} + 2\,d^2\,|\Omega_s|$ imply (4.25). ∎

LEMMA 4.6. *Let $\Xi := (\mathbf{I} - 2\,\mathbf{P}) : \mathbf{H}(\mathbf{div};\Omega_s) \to \mathbf{H}(\mathbf{div};\Omega_s)$. Then there exists $C > 0$, depending on μ, c_1, c_2, κ_s, ρ_f, and ω^2, such that for each $(\boldsymbol{\zeta}, r) \in \mathbf{H}$ there holds*

$$\begin{aligned} &\mathrm{Re}\left\{ A_0((\boldsymbol{\zeta}, r), (\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})) \right\} \\ &\quad \ge C \left\{ \|\mathbf{P}(\boldsymbol{\zeta})\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|r\|^2_{H^1(\Omega_f)} \right\}, \end{aligned} \tag{4.26}$$

where $(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})_0$ is the $\mathbf{H}_0(\mathbf{div};\Omega_s)$-component of $(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})$.

Proof. Using that $\mathbf{P}$ is a projector, we easily observe that

$$\mathbf{P}\,\Xi(\boldsymbol{\zeta}) = -\,\mathbf{P}(\boldsymbol{\zeta}) \quad \text{and} \quad (\mathbf{I}-\mathbf{P})\,\Xi(\boldsymbol{\zeta}) = (\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}) \qquad \forall\, \boldsymbol{\zeta} \in \mathbf{H}(\mathbf{div};\Omega_s)\,, \tag{4.27}$$

and hence, according to the definition of A_0 (cf. (4.11)), we obtain

$$\begin{aligned} A_0((\boldsymbol{\zeta}, r), (\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})) &:= \int_{\Omega_s} \mathcal{C}^{-1}\,\mathbf{P}(\boldsymbol{\zeta}) : \overline{\mathbf{P}(\boldsymbol{\zeta})} + \frac{1}{\kappa_s^2}\int_{\Omega_s} \mathbf{div}\,\mathbf{P}(\boldsymbol{\zeta}) \cdot \overline{\mathbf{div}\,\mathbf{P}(\boldsymbol{\zeta})} \\ &+ \int_{\Omega_s} \mathcal{C}^{-1}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}) : \overline{(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})} + \int_{\Omega_s} \mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}) \cdot \overline{\mathbf{div}\,(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta})} \\ &+ \frac{1}{\rho_f\,\omega^2}\int_{\Omega_f} \|\nabla r\|^2 + \frac{1}{\rho_f\,\omega^2}\int_{\Omega_f} |r|^2 - \imath\,\frac{\kappa_f}{\rho_f\,\omega^2}\int_{\Gamma} |r|^2 \end{aligned} \tag{4.28}$$

for all $(\boldsymbol{\zeta}, r) \in \mathbf{H}$. It follows that

$$\begin{aligned}\mathrm{Re}\Big\{ A_0((\boldsymbol{\zeta}, r), (\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})) \Big\} &:= \int_{\Omega_s} \mathcal{C}^{-1}\, \mathbf{P}(\boldsymbol{\zeta}) : \overline{\mathbf{P}(\boldsymbol{\zeta})} + \frac{1}{\kappa_s^2} \int_{\Omega_s} \mathbf{div}\, \mathbf{P}(\boldsymbol{\zeta}) \cdot \overline{\mathbf{div}\, \mathbf{P}(\boldsymbol{\zeta})} \\ &+ \int_{\Omega_s} \mathcal{C}^{-1}\, (\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta}) : \overline{(\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta})} + \int_{\Omega_s} \mathbf{div}\, (\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta}) \cdot \overline{\mathbf{div}\, (\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta})} \\ &+ \frac{1}{\rho_f\, \omega^2}\, \|r\|^2_{H^1(\Omega_f)}\,,\end{aligned}$$

which, applying (3.16) and Lemmas 4.4 and 4.5, yields (4.26). Note that Lemma 4.5 cannot be applied to $(\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta})$ since its normal trace does not necessarily vanish on Σ. ∎

The weak coercivity of A_0 is established next.

LEMMA 4.7. *Let* $\mathbf{V}$ *be the kernel of* $\mathbf{B}_0$*, that is,*

$$\mathbf{V} := \{\, (\boldsymbol{\tau}, q) \in \mathbf{H} : \quad B_0((\boldsymbol{\tau}, q), (\boldsymbol{\psi}, \boldsymbol{\eta})) = 0 \qquad \forall\, (\boldsymbol{\psi}, \boldsymbol{\eta}) \in \mathbf{Q} \,\}\,.$$

Then there exists $C > 0$ *such that*

$$\sup_{\substack{(\boldsymbol{\tau}, q) \in \mathbf{V} \\ (\boldsymbol{\tau}, q) \neq \mathbf{0}}} \frac{|\, A_0((\boldsymbol{\zeta}, r), (\boldsymbol{\tau}, q))\,|}{\|(\boldsymbol{\tau}, q)\|_{\mathbf{H}}} \geq C\, \|(\boldsymbol{\zeta}, r)\|_{\mathbf{H}} \qquad \forall\, (\boldsymbol{\zeta}, r) \in \mathbf{V}\,. \tag{4.29}$$

In addition, there holds

$$\sup_{(\boldsymbol{\zeta}, r) \in \mathbf{V}} |\, A_0((\boldsymbol{\zeta}, r), (\boldsymbol{\tau}, q))\,| > 0 \qquad \forall\, (\boldsymbol{\tau}, q) \in \mathbf{V}\,,\, (\boldsymbol{\tau}, q) \neq \mathbf{0}\,. \tag{4.30}$$

Proof. From the definition of B_0 (cf. (4.15)) we find that $\mathbf{V} = V \times H^1(\Omega_f)$, where

$$V := \{\, \boldsymbol{\zeta} \in \mathbf{H}(\mathbf{div}; \Omega_s) : \quad \boldsymbol{\zeta} = \boldsymbol{\zeta}^{\mathtt{t}} \quad \text{in } \Omega_s \quad \text{and} \quad \boldsymbol{\zeta}\, \boldsymbol{\nu} = 0 \quad \text{on } \Sigma \,\}\,.$$

In addition, it is easy to see that $\Xi(\boldsymbol{\zeta}) \in V$ for each $\boldsymbol{\zeta} \in V$. In fact, the symmetry of $\Xi(\boldsymbol{\zeta})$ follows from that of $\boldsymbol{\zeta}$ and $\mathbf{P}(\boldsymbol{\zeta})$ (cf. (4.4)), whereas the identity (4.6) guarantees that $\Xi(\boldsymbol{\zeta})\, \boldsymbol{\nu} = \mathbf{0}$ on Σ. Then, applying Lemma 4.5 to $(\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta})$, we deduce from (4.26) that there exists $C > 0$, depending on μ, c_1, c_2, κ_s, ρ_f, and ω^2, such that

$$\begin{aligned}&\mathrm{Re}\Big\{ A_0((\boldsymbol{\zeta}, r), (\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})) \Big\} \\ &\qquad \geq C \Big\{ \|\mathbf{P}(\boldsymbol{\zeta})\|^2_{\mathbf{H}(\mathbf{div}; \Omega_s)} + \|(\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta})\|^2_{\mathbf{H}(\mathbf{div}; \Omega_s)} + \|r\|^2_{H^1(\Omega_f)} \Big\}\end{aligned} \tag{4.31}$$

for each $(\boldsymbol{\zeta}, r) \in \mathbf{V}$. Therefore, using the stability of the decomposition (4.7), the fact that $\|(\boldsymbol{\zeta}, r)\|_{\mathbf{H}} = \|(\overline{\boldsymbol{\zeta}}, \overline{r})\|_{\mathbf{H}}$, and the boundedness of Ξ, we deduce from (4.31) that

$$\mathrm{Re}\Big\{ A_0((\boldsymbol{\zeta}, r), (\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})) \Big\} \geq C\, \|(\boldsymbol{\zeta}, r)\|^2_{\mathbf{H}} \geq C\, \|(\Xi(\overline{\boldsymbol{\zeta}}), \overline{r})\|_{\mathbf{H}}\, \|(\boldsymbol{\zeta}, r)\|_{\mathbf{H}} \tag{4.32}$$

for each $(\boldsymbol{\zeta}, r) \in \mathbf{V}$, which implies the inf-sup condition (4.29). Finally, the symmetry of A_0 and the estimate (4.32) yield the inf-sup condition (4.30) and complete the proof. ∎

LEMMA 4.8. *The operators* $\mathbf{K}_0 : \mathbf{H} \to \mathbf{H}$ *and* $\mathbf{K}_1 : \mathbf{H} \to \mathbf{Q}$ *are compact.*

Proof. We begin by recalling (cf. (4.8)) that there exists $\epsilon > 0$ such that $\mathbf{P}(\boldsymbol{\tau}) \in [H^{\epsilon}(\Omega_s)]^{2\times 2}$ for all $\boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s)$, which, according to the compact imbedding $H^{\epsilon}(\Omega_s) \overset{c}{\hookrightarrow} L^2(\Omega_s)$, yields the compactness of $\mathbf{P} : \mathbf{H}(\mathbf{div};\Omega_s) \to [L^2(\Omega_s)]^{2\times 2}$. It follows that $\mathbf{P}^* : [L^2(\Omega_s)]^{2\times 2} \to \mathbf{H}(\mathbf{div};\Omega_s)$, $\mathbf{P}^*\,\mathcal{C}^{-1}\,\mathbf{P}$, $(\mathbf{I}-\mathbf{P})^*\,\mathcal{C}^{-1}\,\mathbf{P}$, and $\mathbf{P}^*\,\mathcal{C}^{-1}\,(\mathbf{I}-\mathbf{P})$ are all compact, which shows that the operator associated to the first three terms defining K_0 (cf. (4.12)) becomes compact as well. Certainly, we have also used here that $\mathcal{C}^{-1} : [L^2(\Omega_s)]^{2\times 2} \to [L^2(\Omega_s)]^{2\times 2}$ (cf. (3.14)) is continuous. Next, because of the second identity in (4.5), the fourth term on the right-hand side of (4.12) constitutes a finite rank operator, whereas for the last one it suffices to apply the compact imbedding of $H^1(\Omega_f)$ into $L^2(\Omega_f)$.

Finally, the continuous mapping $q \in H^1(\Omega_f) \to q\boldsymbol{\nu} \in [L^2(\Sigma)]^2$ and the compact imbedding $H^{1/2}(\Sigma) \overset{c}{\hookrightarrow} L^2(\Sigma)$ imply the compactness of $\mathbf{K}_1 : \mathbf{H} \to \mathbf{Q}$ (cf. (4.16)). ∎

We are able now to establish the main result of this section.

THEOREM 4.1. *Assume that the homogeneous problem associated to* (3.8) *has only the trivial solution. Then, given* $\mathbf{f} \in [L^2(\Omega_s)]^2$ *and* $g \in H^{-1/2}(\Gamma)$, *there exists a unique solution* $((\boldsymbol{\sigma},p),(\boldsymbol{\varphi},\boldsymbol{\gamma})) \in \mathbf{H}\times\mathbf{Q}$ *to* (3.8) (*equivalently* (4.17)). *In addition, there exists* $C > 0$ *such that*

$$\|((\boldsymbol{\sigma},p),(\boldsymbol{\varphi},\boldsymbol{\gamma}))\|_{\mathbf{H}\times\mathbf{Q}} \;\leq\; C\left\{\,\|\mathbf{f}\|_{[L^2(\Omega_s)]^2} \;+\; \|g\|_{H^{-1/2}(\Gamma)}\,\right\}. \tag{4.33}$$

Proof. It suffices to observe that the left-hand side of (4.17) constitutes a Fredholm operator of index zero. In fact, Lemmas 4.3 and 4.7 imply that $\left(\begin{smallmatrix}\mathbf{A}_0 & \mathbf{B}_0^* \\ \mathbf{B}_0 & \mathbf{0}\end{smallmatrix}\right)$ is an isomorphism, and Lemma 4.8 yields the compactness of $\left(\begin{smallmatrix}\mathbf{K}_0 & \check{\mathbf{K}}_1^* \\ -\mathbf{K}_1 & \mathbf{0}\end{smallmatrix}\right)$. ∎

5. Analysis of the primal/dual-mixed finite element method. In this section we introduce a Galerkin approximation of (3.8) and prove its well-posedness.

5.1. Preliminaries. We first let $\{\mathcal{T}_h\}_{h>0} := \{\mathcal{T}_{h_s}\}_{h_s>0} \cup \{\mathcal{T}_{h_f}\}_{h_f>0}$, where $\{\mathcal{T}_{h_s}\}_{h_s\geq 0}$ and $\{\mathcal{T}_{h_f}\}_{h_f>0}$ are regular families of triangulations of the polygonal regions $\bar{\Omega}_s$ and $\bar{\Omega}_f$, respectively, by triangles T of diameter h_T with mesh sizes $h_s := \max\{\,h_T : T \in \mathcal{T}_{h_s}\,\}$, $h_f := \max\{\,h_T : T \in \mathcal{T}_{h_f}\,\}$, and $h := \max\{h_s,h_f\}$, and such that the vertices of $\{\mathcal{T}_{h_s}\}_{h_s>0}$ and $\{\mathcal{T}_{h_f}\}_{h_f>0}$ coincide on Σ. Also, for reasons that will become clear below, we introduce an independent partition $\{\hat{\Sigma}_1,\hat{\Sigma}_2,\ldots,\hat{\Sigma}_m\}$ of the interface Σ and denote $\hat{h} := \max\{\,|\hat{\Sigma}_j| : j \in \{1,\ldots,m\}\,\}$. Then we define the finite element subspaces $H_h^{\boldsymbol{\sigma}}$, H_h^p, $Q_{\hat{h}}^{\boldsymbol{\varphi}}$, and $Q_h^{\boldsymbol{\gamma}}$ for the unknowns $\boldsymbol{\sigma}$, p, $\boldsymbol{\varphi}$, and $\boldsymbol{\gamma}$ of (3.8), respectively, as follows:

$$H_h^{\boldsymbol{\sigma}} := \Big\{\boldsymbol{\tau}_h \in \mathbf{H}(\mathbf{div};\Omega_s) :\; \boldsymbol{\tau}_{h,i}|_T \in \mathbb{R}\mathbb{T}_0(T)^{\mathtt{t}} \oplus \mathbb{P}_0(T)\,\mathbf{curl}^{\mathtt{t}}\,b_T \quad \forall\, i\in\{1,2\}\,,\quad \forall\, T \in \mathcal{T}_{h_s}\Big\}, \tag{5.1}$$

$$H_h^p := \left\{q_h \in \mathbf{C}(\bar{\Omega}_f) :\; q_h|_T \in \mathbb{P}_1(T) \quad \forall\, T \in \mathcal{T}_{h_f}\right\}, \tag{5.2}$$

$$Q_{\hat{h}}^{\boldsymbol{\varphi}} := \left\{\boldsymbol{\psi}_{\hat{h}} \in [\mathbf{C}(\Sigma)]^2 :\; \boldsymbol{\psi}_{\hat{h}}|_{\hat{\Sigma}_j} \in [\mathbb{P}_1(\hat{\Sigma}_j)]^2 \quad \forall\, j\in\{1,\ldots,m\}\right\}, \tag{5.3}$$

$$Q_h^{\boldsymbol{\gamma}} := \left\{\begin{pmatrix} 0 & \eta_h \\ -\eta_h & 0\end{pmatrix} :\; \eta_h \in \mathbf{C}(\bar{\Omega}_s)\,,\quad \eta_h|_T \in \mathbb{P}_1(T) \quad \forall\, T \in \mathcal{T}_{h_s}\right\}, \tag{5.4}$$

where $\boldsymbol{\tau}_{h,i}$ is the ith row of $\boldsymbol{\tau}_h$, $\mathbb{RT}_0(T)$ is the local Raviart–Thomas space of order 0 (cf. [10, 30]), b_T is the usual cubic bubble function on $T \in \mathcal{T}_{h_s}$, $\mathbf{curl}^{\mathtt{t}}\, b_T := (\frac{\partial b_T}{\partial x_2}, -\frac{\partial b_T}{\partial x_1})$, $\mathbf{C}(\cdot)$ stands for the space of continuous functions on the corresponding domain, and, given an integer $\ell \geq 0$ and a subset $\mathcal{K}$ of $\mathbb{R}^2$, $\mathbb{P}_\ell(\mathcal{K})$ denotes the space of polynomials defined in $\mathcal{K}$ of total degree $\leq \ell$. In addition, in what follows we will also need the following spaces:

$$\tilde{H}_h^{\boldsymbol{\sigma}} := \{\tilde{\boldsymbol{\tau}}_h \in H_h^{\boldsymbol{\sigma}} : \ \tilde{\boldsymbol{\tau}}_h\, \boldsymbol{\nu} = \mathbf{0} \quad \text{on } \Sigma\}\,, \tag{5.5}$$

$$E_h^{\boldsymbol{\sigma}} := \{\boldsymbol{\tau}_h \in \mathbf{H}(\mathbf{div};\Omega_s) : \ \boldsymbol{\tau}_{h,i}|_T \in \mathbb{RT}_0(T)^{\mathtt{t}} \quad \forall\, i \in \{1,2\}\,, \quad \forall\, T \in \mathcal{T}_{h_s}\}\,, \tag{5.6}$$

and

$$Q_h^{\mathbf{u}} := \left\{\mathbf{v}_h \in [L^2(\Omega_s)]^2 : \ \mathbf{v}_h|_T \in [\mathbb{P}_0(T)]^2 \quad \forall\, T \in \mathcal{T}_{h_s}\right\}. \tag{5.7}$$

We remark that $H_h^{\boldsymbol{\sigma}} \times Q_h^{\mathbf{u}} \times Q_h^{\boldsymbol{\gamma}}$ constitutes the well-known PEERS introduced in [1] for a mixed finite element approximation of the linear elasticity problem in the plane.

Next, given $\delta \in (0,1]$, we let $\mathcal{E}_h : [H^\delta(\Omega_s)]^{2\times 2} \cap \mathbf{H}(\mathbf{div};\Omega_s) \to E_h^{\boldsymbol{\sigma}}$ be the usual equilibrium interpolation operator (see [10, 30]), which is characterized by the identities

$$\mathbf{div}(\mathcal{E}_h(\boldsymbol{\tau})) = \mathcal{P}_h(\mathbf{div}(\boldsymbol{\tau})) \quad \text{and} \quad \int_e \mathcal{E}_h(\boldsymbol{\tau})\boldsymbol{\nu} = \int_e \boldsymbol{\tau}\boldsymbol{\nu} \quad \text{for every edge } e \text{ of } \mathcal{T}_{h_s}\,, \tag{5.8}$$

where $\mathcal{P}_h : [L^2(\Omega_s)]^2 \to Q_h^{\mathbf{u}}$ is the $[L^2(\Omega_s)]^2$-orthogonal projector. Since $E_h^{\boldsymbol{\sigma}} \subseteq H_h^{\boldsymbol{\sigma}}$, we note that $\mathcal{E}_h$ can also be considered as acting from $[H^\delta(\Omega_s)]^2 \cap \mathbf{H}(\mathbf{div};\Omega_s)$ into $H_h^{\boldsymbol{\sigma}}$. In particular, the second identity in (5.8) implies that $\mathcal{E}_h(\boldsymbol{\tau}) \in \tilde{H}_h^{\boldsymbol{\sigma}}$ for each $\boldsymbol{\tau} \in [H^\delta(\Omega_s)]^2 \cap \mathbf{H}(\mathbf{div};\Omega_s)$ such that $\boldsymbol{\tau}\,\boldsymbol{\nu} = \mathbf{0}$ on Σ. On the other hand, it is well known (see, e.g., Theorem 3.16 of [23]) that $\mathcal{E}_h$ satisfies

$$\begin{aligned} &\|\boldsymbol{\tau} - \mathcal{E}_h(\boldsymbol{\tau})\|_{[L^2(\Omega_s)]^{2\times 2}} \\ &\leq C\, h^\delta \left\{|\boldsymbol{\tau}|_{[H^\delta(\Omega_s)]^{2\times 2}} + \|\mathbf{div}(\boldsymbol{\tau})\|_{[L^2(\Omega_s)]^2}\right\} \quad \forall\, \boldsymbol{\tau} \in [H^\delta(\Omega_s)]^{2\times 2} \cap \mathbf{H}(\mathbf{div};\Omega_s). \end{aligned} \tag{5.9}$$

Moreover, in order to establish the global approximation properties of our finite element subspaces, we now let $\Pi_h : H^1(\Omega_f) \to H_h^p$, $\mathcal{Q}_{\hat{h}} : [H^{1/2}(\Sigma)]^2 \to Q_{\hat{h}}^{\boldsymbol{\varphi}}$, and $\mathcal{R}_h : [L^2(\Omega_s)]^{2\times 2} \to Q_h^{\boldsymbol{\gamma}}$ be the corresponding orthogonal projectors with respect to the natural norms of each space. Then we have (see [4, 10, 30]) the following:

($\mathrm{AP}_h^{\boldsymbol{\sigma}}$) For each $\delta \in (0,1]$ and for each $\boldsymbol{\tau} \in [H^\delta(\Omega_s)]^{2\times 2}$, with $\mathbf{div}(\boldsymbol{\tau}) \in [H^\delta(\Omega_s)]^2$, there holds

$$\|\boldsymbol{\tau} - \mathcal{E}_h(\boldsymbol{\tau})\|_{\mathbf{H}(\mathbf{div};\Omega_s)} \leq C\, h^\delta \left\{\|\boldsymbol{\tau}\|_{[H^\delta(\Omega_s)]^{2\times 2}} + \|\mathbf{div}(\boldsymbol{\tau})\|_{[H^\delta(\Omega_s)]^2}\right\}.$$

(AP_h^p) For each $s \in [1,2]$ and for each $q \in H^s(\Omega_f)$, there holds

$$\|q - \Pi_h(q)\|_{H^1(\Omega_f)} \leq C\, h^{s-1}\, \|q\|_{H^s(\Omega_f)}\,.$$

($\mathrm{AP}_{\hat{h}}^{\boldsymbol{\varphi}}$) For each $t \in \left[\frac{1}{2}, \frac{3}{2}\right]$ and for each $\boldsymbol{\psi} \in [H^t(\Sigma)]^2$, there holds

$$\|\boldsymbol{\psi} - \mathcal{Q}_{\hat{h}}(\boldsymbol{\psi})\|_{[H^{1/2}(\Sigma)]^2} \leq C\, \hat{h}^{t-1/2}\, \|\boldsymbol{\psi}\|_{[H^t(\Sigma)]^2}\,.$$

($\mathrm{AP}_h^{\boldsymbol{\gamma}}$) For each $s \in [0,1]$ and for each $\boldsymbol{\eta} \in [H^s(\Omega_s)]^{2\times 2} \cap [L^2(\Omega_s)]^{2\times 2}_{\mathtt{asym}}$, there holds

$$\|\boldsymbol{\eta} - \mathcal{R}_h(\boldsymbol{\eta})\|_{[L^2(\Omega_s)]^{2\times 2}} \,\leq\, C\, h^s\, \|\boldsymbol{\eta}\|_{[H^s(\Omega_s)]^{2\times 2}}\,.$$

($\mathrm{AP}_h^{\mathbf{u}}$) For each $t \in [0,1]$ and for each $\mathbf{v} \in [H^t(\Omega_s)]^2$, there holds

$$\|\mathbf{v} - \mathcal{P}_h(\mathbf{v})\|_{[L^2(\Omega_s)]^2} \,\leq\, C\, h^t\, \|\mathbf{v}\|_{[H^t(\Omega_s)]^2}\,.$$

Note that ($\mathrm{AP}_h^{\boldsymbol{\sigma}}$) is actually a straightforward consequence of (5.8), (5.9), and ($\mathrm{AP}_h^{\mathbf{u}}$).

We now let

$$\mathbf{H}_h \,:=\, H_h^{\boldsymbol{\sigma}} \times H_h^p\,, \qquad \mathbf{Q}_{\hat{h},h} \,:=\, Q_{\hat{h}}^{\boldsymbol{\varphi}} \times Q_h^{\boldsymbol{\gamma}} \tag{5.10}$$

and define the primal/dual-mixed finite element scheme associated to our coupled problem (3.8) as follows: Find $((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h)) \in \mathbf{H}_h \times \mathbf{Q}_{\hat{h},h}$ such that

(5.11)

$$\begin{aligned} A((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\tau}_h, q_h)) + B_1((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h)) &= F(\boldsymbol{\tau}_h, q_h) \quad \forall\, (\boldsymbol{\tau}_h, q_h) \in \mathbf{H}_h\,, \\ B_2((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h)) &= 0 \qquad\qquad \forall\, (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}\,. \end{aligned}$$

5.2. Well-posedness of the primal/dual-mixed finite element method. In this section we prove the well-posedness of our primal/dual-mixed finite element scheme (5.11). To this end, as established by a classical result on projection methods for Fredholm operators of index zero (see, e.g., Theorem 13.7 in [25]), it suffices to show that the Galerkin scheme associated to the isomorphism $\left(\begin{smallmatrix} \mathbf{A}_0 & \mathbf{B}_0^* \\ \mathbf{B}_0 & \mathbf{0} \end{smallmatrix}\right)$ is well posed. Therefore, in what follows we prove that A_0 and B_0 (cf. (4.11), (4.15)) satisfy the corresponding inf-sup conditions on the finite element subspace $\mathbf{H}_h \times \mathbf{Q}_{\hat{h},h}$, thus providing the discrete analogues of Lemmas 4.3 and 4.7.

We begin with the following preliminary estimate.

LEMMA 5.1. *There exists $C_1 > 0$, independent of h and $\hat{h}$, such that for each $(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}$ there holds*

$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h) \in \mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h) \neq \mathbf{0}}} \frac{|\, B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \,\geq\, C_1\, \|\boldsymbol{\eta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}\,. \tag{5.12}$$

Proof. Given $(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}$, we apply Theorem 4.5 in [26] (see also Lemma 4.4 in [1]) and deduce the existence of $\boldsymbol{\zeta}_h \in H_h^{\boldsymbol{\sigma}}$ such that $\boldsymbol{\zeta}_h\, \boldsymbol{\nu} = \mathbf{0}$ on Σ, $\mathbf{div}(\boldsymbol{\zeta}_h) = \mathbf{0}$ in Ω_s, and

$$|\, B_0((\boldsymbol{\zeta}_h, 0), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,| \,=\, \left| \int_{\Omega_s} \boldsymbol{\zeta}_h : \boldsymbol{\eta}_h \right| \,\geq\, C\, \|\boldsymbol{\zeta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}\, \|\boldsymbol{\eta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}\,,$$

which yields (5.12) and finishes the proof. ∎

Next, we follow the analysis in [5] and introduce the subspace of $[H^{-1/2}(\Sigma)]^2$ given by the piecewise constant functions. In other words, if $\{\Sigma_1, \Sigma_2, \ldots, \Sigma_n\}$ is the partition on Σ induced by the triangulation $\mathcal{T}_h$, we define

$$Q_h^{\boldsymbol{\xi}} \,:=\, \left\{ \boldsymbol{\xi}_h \in [L^2(\Sigma)]^2 :\; \boldsymbol{\xi}_h|_{\Sigma_j} \in [\mathbb{P}_0(\Sigma_j)]^2 \quad \forall j \in \{1, \ldots, n\} \right\}\,,$$

which satisfies the following approximation property (see [4, 29]):

($\mathrm{AP}_h^{\boldsymbol{\xi}}$) For each $s \in (-\frac{1}{2}, \frac{1}{2}]$ and for each $\boldsymbol{\xi} \in [H^s(\Sigma)]^2$ there exists $\boldsymbol{\xi}_h \in Q_h^{\boldsymbol{\xi}}$ such that

$$\|\boldsymbol{\xi} - \boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2} \,\leq\, C\, h^{s+1/2}\, \|\boldsymbol{\xi}\|_{[H^s(\Sigma)]^2}\,.$$

Also, we assume that $\{\Sigma_1, \Sigma_2, \ldots, \Sigma_n\}$ and $\{\hat{\Sigma}_1, \hat{\Sigma}_2, \ldots, \hat{\Sigma}_m\}$ are uniformly regular, which means that there exist $C, \hat{C} > 0$, independent of h and $\hat{h}$, such that $|\Sigma_j| \geq C\, h$ for all $j \in \{1, \ldots, n\}$ and $|\hat{\Sigma}_j| \geq \hat{C}\, \hat{h}$ for all $j \in \{1, \ldots, m\}$, for all $h, \hat{h} > 0$. These conditions yield the inverse inequalities for the spaces $Q_h^{\boldsymbol{\xi}}$ and $Q_{\hat{h}}^{\boldsymbol{\varphi}}$ (see [4, 29]), respectively; that is, for any real numbers s and t with $-\frac{1}{2} \leq s \leq t \leq 0$, there exists $c > 0$ such that

$$\|\boldsymbol{\xi}_h\|_{[H^t(\Sigma)]^2} \;\leq\; c\, h^{s-t}\, \|\boldsymbol{\xi}_h\|_{[H^s(\Sigma)]^2} \qquad \forall\, \boldsymbol{\xi}_h \in Q_h^{\boldsymbol{\xi}}\,, \tag{5.13}$$

and for any real numbers s and t with $0 \leq s \leq t \leq 1$, there exists $c > 0$ such that

$$\|\boldsymbol{\psi}_{\hat{h}}\|_{[H^t(\Sigma)]^2} \;\leq\; c\, \hat{h}^{s-t}\, \|\boldsymbol{\psi}_{\hat{h}}\|_{[H^s(\Sigma)]^2} \qquad \forall\, \boldsymbol{\psi}_{\hat{h}} \in Q_{\hat{h}}^{\boldsymbol{\varphi}}\,. \tag{5.14}$$

The following lemma establishes a second preliminary estimate.

LEMMA 5.2. *There exist $C_0 \in\,]0, 1[$ and $C_2 > 0$, independent of h and $\hat{h}$, such that for all $h \leq C_0\, \hat{h}$ and for each $(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}$, there holds*

$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h) \in \mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h) \neq \mathbf{0}}} \frac{|\, B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \;\geq\; C_2\, \|\boldsymbol{\psi}_{\hat{h}}\|_{[H^{1/2}(\Sigma)]^2} \;-\; \|\boldsymbol{\eta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}\,. \tag{5.15}$$

Proof. Given $\boldsymbol{\xi}_h \in Q_h^{\boldsymbol{\xi}}$, we consider the discrete analogue of (4.18) (cf. proof of Lemma 4.1) and let $\mathbf{z} \in [H^1(\Omega_s)]^2$ be the unique weak solution, up to an element in $[\mathbb{P}_0(\Omega_s)]^2$, of the boundary value problem with Neumann boundary conditions:

$$-\,\Delta \mathbf{z} \;=\; \frac{1}{|\Omega_s|} \int_{\Sigma} \boldsymbol{\xi}_h \quad \text{in } \Omega_s\,, \qquad \nabla \mathbf{z}\, \boldsymbol{\nu} \;=\; -\,\boldsymbol{\xi}_h \quad \text{on } \Sigma\,.$$

Since $Q_h^{\boldsymbol{\xi}} \subseteq [L^2(\Sigma)]^2$, the corresponding regularity result (see, e.g., [20, 21]) implies that $\mathbf{z} \in [H^{1+\delta}(\Omega_s)]^2$ for each $\delta \in \left[0, \frac{1}{2}\right]$, and

$$\|\mathbf{z}\|_{[H^{1+\delta}(\Omega_s)]^2} \;\leq\; C\, \|\boldsymbol{\xi}_h\|_{[H^{-1/2+\delta}(\Sigma)]^2}\,. \tag{5.16}$$

Then we let $\boldsymbol{\zeta} := \nabla \mathbf{z}$ in Ω_s and observe that

$$\mathbf{div}(\boldsymbol{\zeta}) \;=\; -\,\frac{1}{|\Omega_s|} \int_{\Sigma} \boldsymbol{\xi}_h \quad \text{in } \Omega_s \quad \text{and} \quad \boldsymbol{\zeta}\boldsymbol{\nu} \;=\; -\,\boldsymbol{\xi}_h \quad \text{on } \Sigma\,. \tag{5.17}$$

In addition, using (5.16) and (5.17), we obtain

$$\|\boldsymbol{\zeta}\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)} \leq C \|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2} \quad \text{and} \quad \|\boldsymbol{\zeta}\|_{[H^{\delta}(\Omega_s)]^{2\times 2}} \leq C \|\boldsymbol{\xi}_h\|_{[H^{-1/2+\delta}(\Sigma)]^2}. \tag{5.18}$$

Now, according to the characterization (5.8), there holds $\mathbf{div}(\mathcal{E}_h(\boldsymbol{\zeta})) = \mathbf{div}(\boldsymbol{\zeta}) = -\frac{1}{|\Omega_s|} \int_{\Sigma} \boldsymbol{\xi}_h$ in Ω_s and $\mathcal{E}_h(\boldsymbol{\zeta})\, \boldsymbol{\nu} = \boldsymbol{\zeta}\boldsymbol{\nu} = -\,\boldsymbol{\xi}_h$ on Σ. It follows from (5.9) and (5.18) that

$$\begin{aligned}
\|\mathcal{E}_h(\boldsymbol{\zeta})\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)} \;&\leq\; \|\boldsymbol{\zeta} - \mathcal{E}_h(\boldsymbol{\zeta})\|_{[L^2(\Omega_s)]^{2\times 2}} \;+\; \|\boldsymbol{\zeta}\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)} \\
&\leq\; C\, \left\{\, h^{\delta}\, |\boldsymbol{\zeta}|_{[H^{\delta}(\Omega_s)]^{2\times 2}} \;+\; \|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2} \,\right\} \\
&\leq\; C\, \left\{\, h^{\delta}\, \|\boldsymbol{\xi}_h\|_{[H^{-1/2+\delta}(\Sigma)]^2} \;+\; \|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2} \,\right\},
\end{aligned}$$

which, applying the inverse inequality (5.13), yields

$$\|\mathcal{E}_h(\boldsymbol{\zeta})\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)} \;\leq\; \hat{C}\, \|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2}\,.$$

Therefore, given $(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}$, we find that

$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h)\in \mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h)\neq \mathbf{0}}} \frac{|\, B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \geq \frac{|\, B_0((\mathcal{E}_h(\boldsymbol{\zeta}), 0), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|\mathcal{E}_h(\boldsymbol{\zeta})\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)}}$$

$$= \frac{\Big|\, \langle \boldsymbol{\xi}_h\,,\, \boldsymbol{\psi}_{\hat{h}}\rangle_{\Sigma} + \displaystyle\int_{\Omega} \mathcal{E}_h(\boldsymbol{\zeta}) : \boldsymbol{\eta}_h \,\Big|}{\|\mathcal{E}_h(\boldsymbol{\zeta})\|_{\mathbf{H}(\mathbf{div};\,\Omega_s)}} \geq \frac{1}{\hat{C}}\, \frac{|\, \langle \boldsymbol{\xi}_h, \boldsymbol{\psi}_{\hat{h}}\rangle_{\Sigma}\,|}{\|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2}} - \|\boldsymbol{\eta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}$$

for all $\boldsymbol{\xi}_h \in Q_h^{\boldsymbol{\xi}}$, and hence

(5.19)
$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h)\in \mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h)\neq \mathbf{0}}} \frac{|\, B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \geq \frac{1}{\hat{C}} \sup_{\substack{\boldsymbol{\xi}_h\in Q_h^{\boldsymbol{\xi}} \\ \boldsymbol{\xi}_h\neq \mathbf{0}}} \frac{|\, \langle \boldsymbol{\xi}_h, \boldsymbol{\psi}_{\hat{h}}\rangle_{\Sigma}\,|}{\|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2}} - \|\boldsymbol{\eta}_h\|_{[L^2(\Omega_s)]^{2\times 2}}\,.$$

Since the normal trace on Σ is well defined and continuous from $[H^{\delta}(\Omega_s)]^{2\times 2} \cap \mathbf{H}(\mathbf{div};\,\Omega_s)$ onto $[H^{-1/2+\delta}(\Sigma)]^2$ for $\delta \neq \frac{1}{2}$, we now apply the vector version of Lemma 3.3 in [5], making use of the approximation property $(\mathrm{AP}_h^{\boldsymbol{\xi}})$ and the inverse inequality (5.14), and deduce that there exist $C_0 \in\,]0,1[$ and $\tilde{C}_2 > 0$, independent of h and $\hat{h}$, such that for all $h \leq C_0\, \hat{h}$ there holds

$$\sup_{\substack{\boldsymbol{\xi}_h\in Q_h^{\boldsymbol{\xi}} \\ \boldsymbol{\xi}_h\neq \mathbf{0}}} \frac{|\, \langle \boldsymbol{\xi}_h, \boldsymbol{\psi}_{\hat{h}}\rangle_{\Sigma}\,|}{\|\boldsymbol{\xi}_h\|_{[H^{-1/2}(\Sigma)]^2}} \geq \tilde{C}_2\, \|\boldsymbol{\psi}_{\hat{h}}\|_{[H^{1/2}(\Sigma)]^2}\,. \tag{5.20}$$

In this way, (5.19) and (5.20) yield the required estimate and complete the proof. ∎

The discrete inf-sup condition for B_0 can be established now as a straightforward consequence of Lemmas 5.1 and 5.2.

LEMMA 5.3. *Let $C_0 \in\,]0,1[$ be the constant provided by Lemma 5.2. Then there exists $\beta > 0$, independent of h and $\hat{h}$, such that for all $h \leq C_0\, \hat{h}$ and for each $(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h}$, there holds*

$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h)\in \mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h)\neq \mathbf{0}}} \frac{|\, B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \geq \beta\, \|(\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h)\|_{\mathbf{H}}\,.$$

Proof. It suffices to add (5.12) and (5.15), the latter multiplied by $C_1/2$. ∎

It remains to establish the discrete weak coercivity of A_0. To this end, we now introduce the following discrete approximation of the operator $\mathbf{P}$ (cf. (4.4)):

$$\begin{aligned} \mathbf{P}_h : \mathbf{H}(\mathbf{div};\,\Omega_s) &\to \tilde{H}_h^{\boldsymbol{\sigma}}, \\ \boldsymbol{\tau} &\to \mathbf{P}_h(\boldsymbol{\tau}) := \tilde{\boldsymbol{\sigma}}_h\,, \end{aligned} \tag{5.21}$$

where $(\tilde{\boldsymbol{\sigma}}_h, \tilde{\mathbf{u}}_h, \tilde{\boldsymbol{\gamma}}_h) \in \tilde{H}_h^{\boldsymbol{\sigma}} \times (Q_h^{\mathbf{u}} \cap \mathbb{RM}(\Omega_s)^{\perp}) \times Q_h^{\gamma}$ is the mixed finite element approximation of $(\tilde{\boldsymbol{\sigma}}, \tilde{\mathbf{u}}, \tilde{\boldsymbol{\gamma}})$ (cf. section 4.1) (see also [15] for details). In particular, we easily find that for each $\boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\,\Omega_s)$ there holds

$$\mathbf{P}_h(\boldsymbol{\tau})\,\boldsymbol{\nu} = \mathbf{0} \quad \text{on } \Sigma \qquad \text{and} \qquad \int_{\Omega_s} \mathbf{P}_h(\boldsymbol{\tau}) : \tilde{\boldsymbol{\eta}}_h = 0 \quad \forall\, \tilde{\boldsymbol{\eta}}_h \in Q_h^{\gamma}\,. \tag{5.22}$$

In addition, one can show that there exist $C > 0$, independent of h, such that

$$\begin{aligned} &\|\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}_h\|_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|\tilde{\mathbf{u}} - \tilde{\mathbf{u}}_h\|_{[L^2(\Omega_s)]^2} + \|\tilde{\boldsymbol{\gamma}} - \tilde{\boldsymbol{\gamma}}_h\|_{[L^2(\Omega_s)]^{2\times 2}} \\ &\qquad \leq \tilde{C}\Big\{\|(\mathbf{I}-\mathcal{E}_h)(\tilde{\boldsymbol{\sigma}})\|_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|(\mathbf{I}-\mathcal{P}_h)(\tilde{\mathbf{u}})\|_{[L^2(\Omega_s)]^2} \\ &\qquad\qquad + \|(\mathbf{I}-\mathcal{R}_h)(\tilde{\boldsymbol{\gamma}})\|_{[L^2(\Omega_s)]^{2\times 2}}\Big\}. \end{aligned} \tag{5.23}$$

Hence, we are in a position to estimate

$$\|\mathbf{P}(\boldsymbol{\tau}_h) - \mathbf{P}_h(\boldsymbol{\tau}_h)\|_{\mathbf{H}(\mathbf{div};\Omega_s)} = \|\tilde{\boldsymbol{\sigma}} - \tilde{\boldsymbol{\sigma}}_h\|_{\mathbf{H}(\mathbf{div};\Omega_s)} \quad \text{for each} \quad \boldsymbol{\tau}_h \in H_h^{\boldsymbol{\sigma}}.$$

More precisely, we have the following result.

LEMMA 5.4. *Let $\epsilon > 0$ be the parameter defining the regularity of the solution of (4.1). Then there exists $C > 0$, independent of h, such that*

$$\|\mathbf{P}(\boldsymbol{\tau}_h) - \mathbf{P}_h(\boldsymbol{\tau}_h)\|_{\mathbf{H}(\mathbf{div};\Omega_s)} \leq C\, h^{\epsilon}\, \|\mathbf{div}(\boldsymbol{\tau}_h)\|_{[L^2(\Omega_s)]^2} \qquad \forall\, \boldsymbol{\tau}_h \in H_h^{\boldsymbol{\sigma}}. \tag{5.24}$$

Proof. It suffices to show that the right-hand side of (5.23) is bounded by $C\, h^{\epsilon}\, \|\mathbf{div}(\boldsymbol{\tau}_h)\|_{[L^2(\Omega_s)]^2}$. Indeed, using $(\mathrm{AP}_h^{\mathbf{u}})$, $(\mathrm{AP}_h^{\boldsymbol{\gamma}})$, and the regularity estimate (4.3), we easily find that

$$\begin{aligned} &\|(\mathbf{I}-\mathcal{P}_h)(\tilde{\mathbf{u}})\|_{[L^2(\Omega_s)]^2} + \|(\mathbf{I}-\mathcal{R}_h)(\tilde{\boldsymbol{\gamma}})\|_{[L^2(\Omega_s)]^{2\times 2}} \\ &\quad \leq C\Big\{ h\, \|\tilde{\mathbf{u}}\|_{[H^1(\Omega_s)]^2} + h^{\epsilon}\, \|\tilde{\boldsymbol{\gamma}}\|_{[H^{\epsilon}(\Omega_s)]^{2\times 2}}\Big\} \leq C\, h^{\epsilon}\, \|\mathbf{div}(\boldsymbol{\tau}_h)\|_{[L^2(\Omega_s)]^2}. \end{aligned} \tag{5.25}$$

Now, we observe that a straight application of $(\mathrm{AP}_h^{\boldsymbol{\sigma}})$ to $\|(\mathbf{I}-\mathcal{E}_h)(\tilde{\boldsymbol{\sigma}})\|_{\mathbf{H}(\mathbf{div};\Omega_s)}$ yields the expression $h^{\delta}\, \|\mathbf{div}(\tilde{\boldsymbol{\sigma}})\|_{[H^{\delta}(\Omega_s)]^2}$, which does not provide the expected estimate, and hence a different procedure must be employed. In fact, it is clear from (4.1), with $\boldsymbol{\tau}_h$ instead of $\boldsymbol{\tau}$, that

$$\mathbf{div}(\tilde{\boldsymbol{\sigma}}) = (\mathbf{I}-\mathbf{M})(\mathbf{div}(\boldsymbol{\tau}_h)) \quad \text{in } \Omega_s, \tag{5.26}$$

which, applying (5.9), (4.3), and the boundedness of $\mathbf{M}$, leads to

$$\begin{aligned} &\|(\mathbf{I}-\mathcal{E}_h)(\tilde{\boldsymbol{\sigma}})\|_{[L^2(\Omega_s)]^{2\times 2}} \\ &\leq C\, h^{\epsilon}\Big\{|\tilde{\boldsymbol{\sigma}}|_{[H^{\epsilon}(\Omega_s)]^{2\times 2}} + \|\mathbf{div}(\tilde{\boldsymbol{\sigma}})\|_{[L^2(\Omega_s)]^2}\Big\} \leq C\, h^{\epsilon}\, \|\mathbf{div}(\boldsymbol{\tau}_h)\|_{[L^2(\Omega_s)]^2}. \end{aligned} \tag{5.27}$$

Next, it follows from (5.8) and (5.26) that

$$\begin{aligned} &\|\mathbf{div}(\tilde{\boldsymbol{\sigma}}) - \mathbf{div}(\mathcal{E}_h(\tilde{\boldsymbol{\sigma}}))\|_{[L^2(\Omega_s)]^2} \\ &= \|(\mathbf{I}-\mathcal{P}_h)(\mathbf{div}(\tilde{\boldsymbol{\sigma}}))\|_{[L^2(\Omega_s)]^2} = \|(\mathbf{I}-\mathcal{P}_h)(\mathbf{M}(\mathbf{div}(\boldsymbol{\tau}_h)))\|_{[L^2(\Omega_s)]^2}, \end{aligned}$$

whence $(\mathrm{AP}_h^{\mathbf{u}})$, the fact that all the norms in $\mathbb{RM}(\Omega_s)$ are equivalent (with constants certainly independent of h), and the boundedness of $\mathbf{M}$ imply that

$$\begin{aligned} \|\mathbf{div}(\tilde{\boldsymbol{\sigma}}) - \mathbf{div}(\mathcal{E}_h(\tilde{\boldsymbol{\sigma}}))\|_{[L^2(\Omega_s)]^2} &\leq C\, h\, \|\mathbf{M}(\mathbf{div}(\boldsymbol{\tau}_h))\|_{[H^1(\Omega_s)]^2} \\ &\leq C\, h\, \|\mathbf{M}(\mathbf{div}(\boldsymbol{\tau}_h))\|_{[L^2(\Omega_s)]^2} \leq C\, h\, \|\mathbf{div}(\boldsymbol{\tau}_h)\|_{[L^2(\Omega_s)]^2}. \end{aligned} \tag{5.28}$$

In this way, (5.27) and (5.28) give the required estimate for $\|(\mathbf{I}-\mathcal{E}_h)(\tilde{\boldsymbol{\sigma}})\|_{\mathbf{H}(\mathbf{div};\Omega_s)}$, which, together with (5.25) and (5.23), yields (5.24) and finishes the proof. ∎

We now recall from [14] the following result, which is the discrete analogue of Lemma 4.5, and whose proof applies the decomposition (4.22)–(4.23) and the approximation property $(\mathrm{AP}^{\boldsymbol{\varphi}}_{\hat{h}})$.

LEMMA 5.5. *Let* $V_{\hat{h}} := \{\, \boldsymbol{\tau} \in \mathbf{H}(\mathbf{div};\Omega_s) : \langle \boldsymbol{\tau}\boldsymbol{\nu}, \boldsymbol{\psi}_{\hat{h}} \rangle_\Sigma = 0 \ \text{for all}\ \boldsymbol{\psi}_{\hat{h}} \in Q^{\boldsymbol{\varphi}}_{\hat{h}} \,\}$. *Then there exist positive constants* C, h_0, *independent of* h, *such that for each* $\hat{h} \le h_0$ *there holds*

$$C\,\|\boldsymbol{\tau}\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} \ \le\ \|\boldsymbol{\tau}_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} \qquad \forall\, \boldsymbol{\tau} \in V_{\hat{h}}\,, \tag{5.29}$$

where $\boldsymbol{\tau} = \boldsymbol{\tau}_0 + d\,\mathbf{I}$, *with* $\boldsymbol{\tau}_0 \in \mathbf{H}_0(\mathbf{div};\Omega_s)$ *and* $d \in \mathbb{C}$.

Proof. See Lemma 4.4 in [14]. □

Actually, Lemma 4.4 in [14] establishes the estimate (5.29) for the subspace

$$V_{\hat{h}} := \{\, \boldsymbol{\tau}_h \in H^{\boldsymbol{\sigma}}_h : \langle \boldsymbol{\tau}_h\boldsymbol{\nu}, \boldsymbol{\psi}_{\hat{h}} \rangle_\Sigma = 0 \quad \forall\, \boldsymbol{\psi}_{\hat{h}} \in Q^{\boldsymbol{\varphi}}_{\hat{h}} \,\}\,.$$

Nevertheless, it is easy to see that the same proof is valid for $V_{\hat{h}}$ as defined here in Lemma 5.5.

The discrete weak coercivity of A_0 can be proved now.

LEMMA 5.6. *Let* $\mathbf{V}_{h,\hat{h}}$ *be the discrete kernel of* $\mathbf{B}_0$, *that is,*

$$\mathbf{V}_{h,\hat{h}} := \left\{ (\boldsymbol{\tau}_h, q_h) \in \mathbf{H}_h :\ B_0((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h)) = 0 \qquad \forall\, (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h) \in \mathbf{Q}_{\hat{h},h} \right\},$$

and let $h_0 > 0$ *be the constant provided by Lemma* 5.5. *Then there exist* C, $h_1 > 0$, *independent of* h *and* $\hat{h}$, *such that for each* $\hat{h} \le h_0$ *and for each* $h \le h_1$ *there holds*

$$\sup_{\substack{(\boldsymbol{\tau}_h, q_h) \in \mathbf{V}_{h,\hat{h}} \\ (\boldsymbol{\tau}_h, q_h) \neq \mathbf{0}}} \frac{|\, A_0((\boldsymbol{\zeta}_h, r_h), (\boldsymbol{\tau}_h, q_h))\,|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \ \ge\ C\,\|(\boldsymbol{\zeta}_h, r_h)\|_{\mathbf{H}} \qquad \forall\, (\boldsymbol{\zeta}_h, r_h) \in \mathbf{V}_{h,\hat{h}}\,. \tag{5.30}$$

In addition, for each $\hat{h} \le h_0$ *and for each* $h \le h_1$ *there holds*

$$\sup_{(\boldsymbol{\zeta}_h, r_h) \in \mathbf{V}_{h,\hat{h}}} |\, A_0((\boldsymbol{\zeta}_h, r_h), (\boldsymbol{\tau}_h, q_h))\,| \ >\ 0 \qquad \forall\, (\boldsymbol{\tau}_h, q_h) \in \mathbf{V}_{h,\hat{h}}\,,\ (\boldsymbol{\tau}_h, q_h) \neq \mathbf{0}\,. \tag{5.31}$$

Proof. Let us introduce the linear and bounded operator $\Xi_h := (\mathbf{I} - 2\,\mathbf{P}_h) : H^{\boldsymbol{\sigma}}_h \to H^{\boldsymbol{\sigma}}_h$. It follows from Lemma 5.4 that

$$\|\Xi(\boldsymbol{\zeta}_h) - \Xi_h(\boldsymbol{\zeta}_h)\|_{\mathbf{H}(\mathbf{div};\Omega_s)} \ \le\ C\,h^\epsilon\,\|\mathbf{div}(\boldsymbol{\zeta}_h)\|_{[L^2(\Omega_s)]^2} \ \le\ C\,h^\epsilon\,\|\boldsymbol{\zeta}_h\|_{\mathbf{H}(\mathbf{div};\Omega_s)}$$

for all $\boldsymbol{\zeta}_h \in H^{\boldsymbol{\sigma}}_h$, and hence, using the boundedness of A_0 and the inequality (4.26) (cf. Lemma 4.6), we find that for each $(\boldsymbol{\zeta}_h, r_h) \in \mathbf{H}_h$ there holds

$$\begin{aligned}
&\left|\, \mathrm{Re}\left\{ A_0((\boldsymbol{\zeta}_h, r_h), (\Xi_h(\overline{\boldsymbol{\zeta}}_h), \overline{r}_h)) \right\} \right| \\
&\quad \ge \left|\, \mathrm{Re}\left\{ A_0((\boldsymbol{\zeta}_h, r_h), (\Xi(\overline{\boldsymbol{\zeta}}_h), \overline{r}_h)) \right\} \right| - C\,h^\epsilon\,\|(\boldsymbol{\zeta}_h, r_h)\|^2_{\mathbf{H}} \\
&\quad \ge C \left\{ \|\mathbf{P}(\boldsymbol{\zeta}_h)\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|(\mathbf{I} - \mathbf{P})(\boldsymbol{\zeta}_h)_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} + \|r_h\|^2_{H^1(\Omega_f)} \right\} \\
&\qquad - C\,h^\epsilon\,\|(\boldsymbol{\zeta}_h, r_h)\|^2_{\mathbf{H}}\,.
\end{aligned} \tag{5.32}$$

Now, from the definition of B_0 (cf. (4.15)) we see that $\mathbf{V}_{h,\hat{h}} = V_{h,\hat{h}} \times H^p_h$, where

$$V_{h,\hat{h}} := V_{\hat{h}} \ \cap\ \left\{ \boldsymbol{\tau}_h \in H^{\boldsymbol{\sigma}}_h :\ \int_{\Omega_s} \boldsymbol{\tau}_h : \boldsymbol{\eta}_h = 0 \quad \forall\, \boldsymbol{\eta}_h \in Q^\gamma_h \right\}.$$

Then it is clear that $(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}_h) \in V_{\hat{h}}$ for each $\boldsymbol{\zeta}_h \in V_{h,\hat{h}}$, and therefore Lemma 5.5 implies that for each $\hat{h} \leq h_0$ there holds

$$\|(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}_h)_0\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)} \geq c\,\|(\mathbf{I}-\mathbf{P})(\boldsymbol{\zeta}_h)\|^2_{\mathbf{H}(\mathbf{div};\Omega_s)}\,.$$

Thus, replacing the above estimate back into (5.32), and using the stability of the decomposition (4.7), we deduce the existence of $h_1 > 0$ such that for each $\hat{h} \leq h_0$ and for each $h \leq h_1$ there holds

$$\begin{aligned} &\left| \mathrm{Re}\left\{ A_0((\boldsymbol{\zeta}_h, r_h), (\Xi_h(\overline{\boldsymbol{\zeta}}_h), \overline{r}_h)) \right\} \right| \\ &\quad \geq C\,\|(\boldsymbol{\zeta}_h, r_h)\|^2_{\mathbf{H}} \geq C\,\|(\Xi_h(\overline{\boldsymbol{\zeta}}_h), \overline{r}_h)\|_{\mathbf{H}}\,\|(\boldsymbol{\zeta}_h, r_h)\|_{\mathbf{H}} \end{aligned} \tag{5.33}$$

for each $(\boldsymbol{\zeta}_h, r_h) \in \mathbf{V}_{h,\hat{h}}$, where the boundedness of Ξ_h has also been used in the last inequality. In this way, since (5.22) implies that $\Xi_h(\boldsymbol{\tau}_h) \in V_{h,\hat{h}}$ for each $\boldsymbol{\tau}_h \in V_{h,\hat{h}}$, the discrete inf-sup condition (5.30) follows straightforwardly from (5.33). In addition, the symmetry of A_0 and the estimate (5.33) yield the discrete inf-sup condition (5.31) and complete the proof. ∎

The following theorem establishes the well-posedness and convergence of the discrete scheme (5.11).

THEOREM 5.1. *Assume that the homogeneous problem associated to* (3.8) *has only the trivial solution. Let* $C_0 \in]0,1[$ *and* h_0, $h_1 > 0$ *be the constants provided by Lemmas* 5.2, 5.5, *and* 5.6, *respectively. Then there exist* $\tilde{h}_0 \in]0, h_0]$ *and* $\tilde{h}_1 \in]0, h_1]$ *such that for each* $\hat{h} \leq \tilde{h}_0$ *and for each* $h \leq \min\{\tilde{h}_1, C_0\,\hat{h}\}$, *the primal/dual-mixed finite element scheme* (5.11) *has a unique solution* $((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h)) \in \mathbf{H}_h \times \mathbf{Q}_{\hat{h},h}$. *In addition, there exist* C_1, $C_2 > 0$, *independent of* h *and* $\hat{h}$, *such that*

$$\begin{aligned} &\|((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h))\|_{\mathbf{H}\times\mathbf{Q}} \\ &\quad \leq C_1 \sup_{\substack{(\boldsymbol{\tau}_h, q_h)\in\mathbf{H}_h \\ (\boldsymbol{\tau}_h, q_h)\neq\mathbf{0}}} \frac{|F(\boldsymbol{\tau}_h, q_h)|}{\|(\boldsymbol{\tau}_h, q_h)\|_{\mathbf{H}}} \leq C_1 \left\{ \|\mathbf{f}\|_{[L^2(\Omega_s)]^2} + \|g\|_{H^{-1/2}(\Gamma)} \right\} \end{aligned} \tag{5.34}$$

and

$$\begin{aligned} &\|((\boldsymbol{\sigma}, p), (\boldsymbol{\varphi}, \boldsymbol{\gamma})) - ((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h))\|_{\mathbf{H}\times\mathbf{Q}} \\ &\leq C_2 \inf_{((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\in\mathbf{H}_h\times\mathbf{Q}_{\hat{h},h}} \|((\boldsymbol{\sigma}, p), (\boldsymbol{\varphi}, \boldsymbol{\gamma})) - ((\boldsymbol{\tau}_h, q_h), (\boldsymbol{\psi}_{\hat{h}}, \boldsymbol{\eta}_h))\|_{\mathbf{H}\times\mathbf{Q}}\,. \end{aligned} \tag{5.35}$$

Furthermore, if there exists $\delta \in (0,1]$ *such that* $\boldsymbol{\sigma} \in [H^\delta(\Omega_s)]^{2\times 2}$, $\mathbf{div}(\boldsymbol{\sigma}) \in [H^\delta(\Omega_s)]^2$, $p \in H^{1+\delta}(\Omega_f)$, $\boldsymbol{\varphi} \in [H^{1/2+\delta}(\Sigma)]^2$, *and* $\boldsymbol{\gamma} \in [H^\delta(\Omega_s)]^{2\times 2}$, *then there holds*

$$\begin{aligned} &\|((\boldsymbol{\sigma}, p), (\boldsymbol{\varphi}, \boldsymbol{\gamma})) - ((\boldsymbol{\sigma}_h, p_h), (\boldsymbol{\varphi}_{\hat{h}}, \boldsymbol{\gamma}_h))\|_{\mathbf{H}\times\mathbf{Q}} \leq C_3\,\hat{h}^\delta\,\|\boldsymbol{\varphi}\|_{[H^{1/2+\delta}(\Sigma)]^2} \\ &+ C_3\,h^\delta \left\{ \|\boldsymbol{\sigma}\|_{[H^\delta(\Omega_s)]^{2\times 2}} + \|\mathbf{div}(\boldsymbol{\sigma})\|_{[H^\delta(\Omega_s)]^2} + \|p\|_{H^{1+\delta}(\Omega_f)} + \|\boldsymbol{\gamma}\|_{[H^\delta(\Omega_s)]^{2\times 2}} \right\}, \end{aligned} \tag{5.36}$$

with a constant $C_3 > 0$, *independent of* h *and* $\hat{h}$.

Proof. Thanks to Lemmas 5.3 and 5.6, the proof of the first part is a direct application of Theorem 13.7 in [25], whereas the rate of convergence (5.36) follows directly from the Cea estimate (5.35) and the approximation properties $(\mathrm{AP}^{\boldsymbol{\sigma}}_h)$, (AP^{p}_h), $(\mathrm{AP}^{\boldsymbol{\varphi}}_{\hat{h}})$, and $(\mathrm{AP}^{\boldsymbol{\gamma}}_h)$ (cf. section 5.1). ∎

6. Numerical results. In this section we present an example illustrating the performance of the primal/dual-mixed finite element scheme (5.11) on a finite sequence of uniform triangulations of the domain. We begin by introducing additional notation. The variable N stands for the number of degrees of freedom defining the finite element subspaces $\mathbf{H}_h$ and $\mathbf{Q}_{\hat{h},h}$, and the individual errors are denoted by

$$\mathsf{e}(\boldsymbol{\sigma}) := \|\boldsymbol{\sigma} - \boldsymbol{\sigma}_h\|_{\mathbf{H}(\mathbf{div};\Omega_s)}, \quad \mathsf{e}(p) := \|p - p_h\|_{H^1(\Omega_f)},$$

$$\mathsf{e}(\boldsymbol{\varphi}) := \|\boldsymbol{\varphi} - \boldsymbol{\varphi}_{\hat{h}}\|_{[H^{1/2}(\Sigma)]^2}, \quad \text{and} \quad \mathsf{e}(\boldsymbol{\gamma}) := \|\boldsymbol{\gamma} - \boldsymbol{\gamma}_h\|_{[L^2(\Omega_s)]^{2\times 2}}.$$

Also, we let $r(\boldsymbol{\sigma})$, $r(p)$, $r(\boldsymbol{\varphi})$, and $r(\boldsymbol{\gamma})$ be the experimental rates of convergence given by

$$r(\boldsymbol{\sigma}) := \frac{\log(\mathsf{e}(\boldsymbol{\sigma})/\mathsf{e}'(\boldsymbol{\sigma}))}{\log(h/h')}, \quad r(p) := \frac{\log(\mathsf{e}(p)/\mathsf{e}'(p))}{\log(h/h')},$$

$$r(\boldsymbol{\varphi}) := \frac{\log(\mathsf{e}(\boldsymbol{\varphi})/\mathsf{e}'(\boldsymbol{\varphi}))}{\log(h/h')}, \quad \text{and} \quad r(\boldsymbol{\gamma}) := \frac{\log(\mathsf{e}(\boldsymbol{\gamma})/\mathsf{e}'(\boldsymbol{\gamma}))}{\log(h/h')},$$

where h and h' denote two consecutive mesh sizes with corresponding errors e and e'.

We consider the domains $\Omega_s :=]-0.3, 0.3[^2$ and $\Omega_f := \mathbf{B}(\mathbf{0}, 1) \setminus \Omega_s$, where $\mathbf{B}(\mathbf{0}, 1)$ is the unit circle, and take the parameters $\omega = 10$, $\rho_s = \rho_f = \lambda = \mu = 1$, whence $\kappa_f = 1$ and $\kappa_s = 10$. On the other hand, let K_0, K_1, and K_2 be the modified Bessel functions of the second kind and order 0, 1, and 2, respectively, and let $H_0^{(1)}$ be the Hankel function of the first kind and order 0. Then we choose the data $\mathbf{f}$ and g so that the exact solution of (2.9) is given by

$$\mathbf{u}(\mathbf{x}) = \begin{pmatrix} \dfrac{1}{2\pi}\,\psi(\mathbf{x}) - \dfrac{(x_1-1)^2}{r_1^2}\,\chi(\mathbf{x}) \\ \\ -\dfrac{(x_1-1)\,x_2}{r_1^2}\,\chi(\mathbf{x}) \end{pmatrix} \quad \forall\, \mathbf{x} \in \Omega_s, \quad p(\mathbf{x}) = H_0^{(1)}(\omega\,|\mathbf{x}|) \quad \forall\, \mathbf{x} \in \Omega_f,$$

where

$$\psi(\mathbf{x}) := K_0(\imath\,\omega\, r_1) + \frac{1}{\imath\,\omega\, r_1}\left(K_1(\imath\,\omega\, r_1) - \frac{1}{\sqrt{3}}\,K_1\left(\frac{\imath\,\omega\, r_1}{\sqrt{3}}\right)\right),$$

$$r_1 := \sqrt{(x_1-1)^2 + x_2^2}, \quad \text{and} \quad \chi(\mathbf{x}) := K_2(\imath\,\omega\, r_1) - \frac{1}{3}\,K_2\left(\frac{\imath\,\omega\, r_1}{\sqrt{3}}\right).$$

Actually, $\mathbf{u}$ is the fundamental solution, centered at $(1, 0)$, of the elastodynamic equation, which yields $\mathbf{f} = \mathbf{0}$ in Ω_s, and p is the fundamental solution, centered at the origin, of the Helmholtz equation in Ω_f. In this way, $(\mathbf{u}, p)$ is the solution of (2.9) with nonhomogeneous transmission conditions on Σ and suitable boundary conditions on Γ.

The numerical results shown below were obtained on a Pentium Xeon computer with dual processors, using a MATLAB code. According to the requirements established in our main theorem, Theorem 5.1, for the mesh sizes h and $\hat{h}$, and since the constant C_0 mentioned there is not explicitly known, we simply put a vertex of the

0.0082	175630	0.173E-01	0.99	0.710E-02	1.03	0.296E-03	1.70	0.255E-03	1.34
0.0061	310084	0.131E-01	0.96	0.530E-02	1.01	0.187E-03	1.59	0.181E-03	1.18

independent partition $\{\hat{\Sigma}_1, \hat{\Sigma}_2, \ldots, \hat{\Sigma}_m\}$ every two vertices of $\mathcal{T}_h$ on Σ (see Figure 6.1, where the vertices of $\{\hat{\Sigma}_1, \hat{\Sigma}_2, \ldots, \hat{\Sigma}_m\}$ are marked with bullets). As we will see below, this choice works out well in the present example. In addition, there is no need to take sufficiently small values of $\hat{h}$ and h (as technically suggested by the inequalities $\hat{h} \leq \tilde{h}_0$ and $h \leq \tilde{h}_1$ in Theorem 5.1) since the resulting discrete schemes all become well posed for the degrees of freedom employed.

In Table 6.1 we present the convergence history of our example for a sequence of quasi-uniform triangulations of the computational domain $\bar{\Omega}_s \cup \bar{\Omega}_f$. We see there that the dominant error is given by $\mathsf{e}(\boldsymbol{\sigma})$, which is actually a quite frequent fact in many mixed finite element schemes. We also remark that the rate of convergence $O(h)$ predicted by Theorem 5.1 (when $\delta = 1$) is attained for all the unknowns. Moreover, we observe that at some stages the convergence of $\mathsf{e}(\boldsymbol{\varphi})$ and $\mathsf{e}(\boldsymbol{\gamma})$ is even faster than $O(h)$, which could mean either a superconvergence phenomenon of these unknowns or a special feature of this particular example. Finally, we display real and imaginary parts of some components of the exact and approximate solutions (for $N = 43,140$) in Figures 6.2 and 6.3, from which we notice that they are indistinguishable from each other.

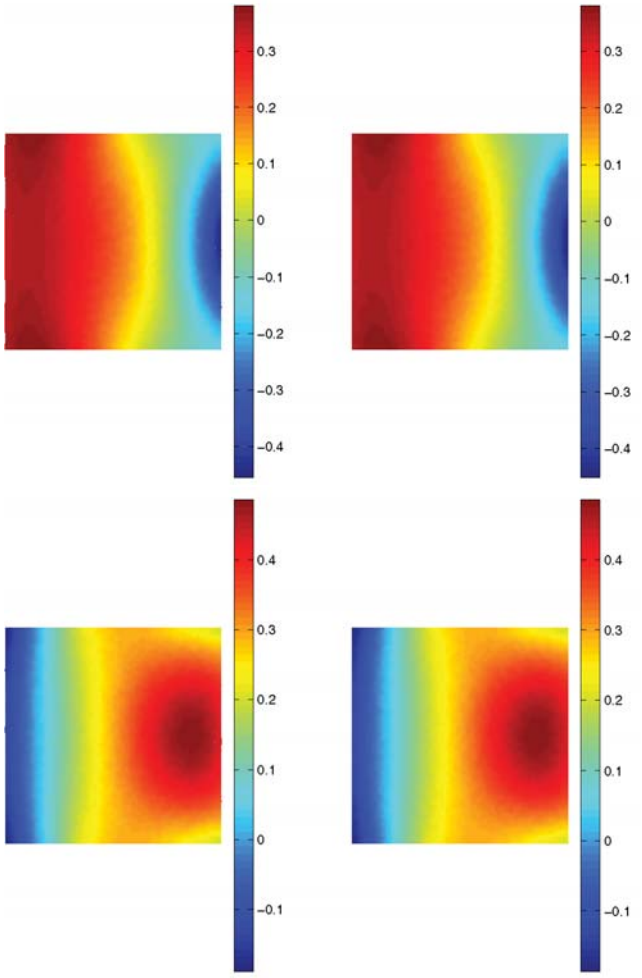

FIG. 6.2. *Approximate (left) and exact (right) real and imaginary parts of* $\boldsymbol{\sigma}_{11}$.

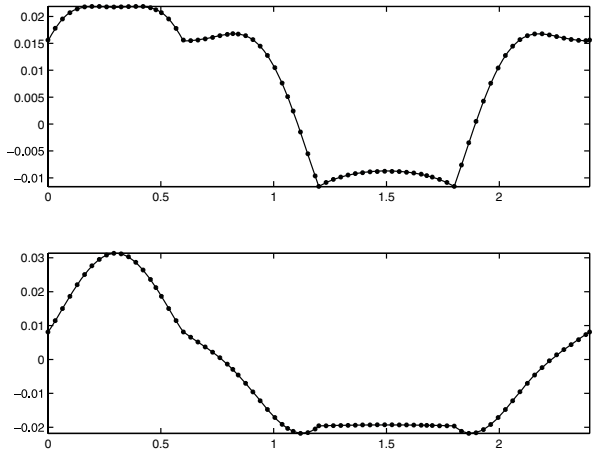

FIG. 6.3. *Approximate (dots) and exact (solid line) real and imaginary parts of* $\boldsymbol{\varphi}_1$.

HIGH-ORDER RELAXATION SCHEMES FOR NONLINEAR DEGENERATE DIFFUSION PROBLEMS*

FAUSTO CAVALLI†, GIOVANNI NALDI†, GABRIELLA PUPPO‡, AND MATTEO SEMPLICE†

Abstract. Several relaxation approximations to partial differential equations have been recently proposed. Examples include conservation laws, Hamilton–Jacobi equations, convection-diffusion problems, and gas dynamics problems. The present paper focuses on diffusive relaxation schemes for the numerical approximation of nonlinear parabolic equations. These schemes are based on a suitable semilinear hyperbolic system with relaxation terms. High-order methods are obtained by coupling ENO and weighted essentially nonoscillatory (WENO) schemes for space discretization with implicit-explicit (IMEX) schemes for time integration. Error estimates and a convergence analysis are developed for semidiscrete schemes with a numerical analysis for fully discrete relaxed schemes. Various numerical results in one and two dimensions illustrate the high accuracy and good properties of the proposed numerical schemes, also in the degenerate case. These schemes can be easily implemented on parallel computers and applied to more general systems of nonlinear parabolic equations in two- and three-dimensional cases.

Key words. parabolic problems, relaxation schemes, high-order accuracy, porous media equation, WENO reconstruction

1. Introduction.

Relaxation approximations to nonlinear partial differential equations have been introduced in [22] (conservation laws) and [28] (degenerate diffusion) and later studied also in [2, 1, 21, 25, 29, 27]. The main idea is to approximate the original partial differential equation with a suitable semilinear hyperbolic system with stiff relaxation terms. As the relaxation parameter $\varepsilon \to 0$, the solution of the system converges to the solution of the original partial differential equation.

Moreover, appropriate numerical schemes for the relaxation system yield accurate numerical approximations to the original equation or system when the relaxation rate ϵ is sufficiently small. Numerically, the main advantage of solving the relaxation model over the original conservation law lies in the simple linear structure of characteristic fields and in the fact that the lower-order term is localized. In particular, the semilinear nature of the relaxation system gives a new way to develop numerical schemes that are simple, general, and Riemann solver free [20, 22].

The aim of this work is to analyze, from both a theoretical and a computational point of view, relaxation schemes for the numerical approximation of the following nonlinear degenerate diffusion problem:

$$\frac{\partial u}{\partial t} = D\Delta(p(u)), \quad x \in \mathbb{R}^d,\ t > 0, \tag{1.1}$$

with initial data $u(x,0) = u_0(x) \in L^1(\mathbb{R}^d)$. $D > 0$ is a diffusivity coefficient. As

usual, we will assume $p : \mathbb{R} \to \mathbb{R}$ to be nondecreasing and Lipschitz continuous [36]. The equation is degenerate if $p(0) = 0$, and the set of points where $u(x)$ becomes 0 is called the interface.

In the case $p(u) = u^m$, $m > 1$, the previous equation is the *porous media equation*, which describes the flow of a gas through a porous interface according to some constitutive relation like Darcy's law in order to link the velocity of the gas and its pressure. With this choice of p, the diffusion coefficient mu^{m-1} vanishes at the points where $u = 0$. Thus the porous media equation is necessarily degenerate for compactly supported initial data [3], and the interfaces exhibit a finite speed of propagation. The degeneracy of the diffusion terms makes the dynamics of the interfaces difficult to study from both the theoretical and the numerical point of view. In general the numerical analysis of (1.2) is difficult for at least two reasons: the appearance of singularities for compactly supported solutions and the growth of the size of the support as time increases (*retention property*).

A common numerical technique to approximate (1.1) involves implicit discretization in time: It requires, at each time step, the solution of a nonlinear algebraic system, which can be singular on the interface. Another possibility is to linearize the nonlinear problem in order to take advantage of efficient linear solvers. For example, linear approximation schemes based on the so-called nonlinear Chernoff formula with a suitable relaxation parameter have been studied in [6, 26, 30, 31]. Other linear approximation schemes have been introduced by Jäger, Kačur, and Handlovičová [19, 23]. Also, a new scheme based on the maximum principle and on a perturbation and regularization approach was proposed by Pop and Yong in [33]. In the more general convection-diffusion case other approaches were investigated in the work of Evje and Karlsen [16], based on a suitable splitting of the convection and the diffusion operators, with a front tracking method for the advection term and implicit numerical integration of the latter. This approach limits the achievable order of accuracy and requires nonlinear solvers for the elliptic part.

A relaxation system to approximate degenerate parabolic equations was proposed originally in [28], inspired by kinetic schemes for the Carleman model. The convergence of the analytical solutions of the relaxation system to those of the partial differential equation is proven in [25], for the $u_t - (u^m)_{xx} = 0$ equation with $m > 0$ (porous media and fast-diffusion equations). The numerical integration of the relaxation system is performed at the macroscopic level, leading to the schemes proposed in [29, 27], where the kinetic derivation of the relaxation system is not relevant any more.

Natalini and coworkers proposed a kinetic approach to the numerical integration of conservation laws [2] and of convection-diffusion problems [7, 1]. Their work is based on a Bhatnagar–Gross–Krook (BGK) approximation which, despite being inspired by the work of Kurz and McKean as [28], is different at the kinetic level, as detailed in [24].

The aim of the present work is to obtain high-order numerical schemes in time and space for the integration of (1.1), following and developing the ideas of [27]. While in [27], the main focus is the development of suitable relaxation systems for several partial differential equations, here we will concentrate on the numerical analysis of the schemes resulting from the relaxation system. In particular we prove the convergence of the semidiscrete scheme, study the stability (linear and nonlinear) of the fully discrete scheme, and propose the construction of high-order extensions. In order to obtain higher-order methods, we couple ENO and weighted essentially nonoscillatory (WENO) schemes for space discretization and implicit-explicit (IMEX) schemes for time advancement. The schemes we obtain avoid both operator splitting techniques and implicit nonlinear solvers.

We point out that, despite the fact that high-order schemes may not reach their order of convergence due to the loss of regularity of the solution during the evolution, they are nevertheless interesting for error reduction when the number of grid points is fixed or until discontinuities develop (both cases arise, for example, in nonlinear filtering in image analysis [37]).

Note that the relaxation system we consider, following [27], can be obtained also as a three velocity model in the BGK approach of [24]. However, in the present case we are interested in the relaxed scheme, i.e., the $\varepsilon = 0$ limit of a numerical scheme for the relaxation system. For this reason, the numerical scheme we propose is different from those of [1], as described in the following section.

Our approach allows us to obtain numerical schemes for (1.1) that are easy to implement and suited for parallel coding, even in the multidimensional case and for more general and complex problems, such as oil recovery problems [15].

Equation (1.1) is a particular case of the more general convection diffusion equation

$$\frac{\partial u}{\partial t} + \operatorname{div} f(u) = D\Delta(p(u)), \quad x \in \mathbb{R}^d,\ t > 0. \tag{1.2}$$

The approach described in this paper can be extended to this more general case, introducing an additional equation to allow the relaxation of the convective term. However, this can be achieved in several ways, leading to different numerical schemes for the partial differential equation (1.2). The stability and efficiency of these schemes can differ wildly and will be the subject of further work [11].

The paper is organized as follows. Section 2 is devoted to the introduction of our relaxation schemes. The stability and error estimates of the semidiscrete scheme are provided in section 3. In section 4 we consider the fully discrete relaxed scheme with a nonlinear stability analysis and the extension to the multidimensional case. We also study parabolic problems in a bounded domain $\Omega \subset \mathbb{R}^d$ with Neumann boundary conditions. Finally, the implementation of the method as well as the results of several numerical experiments are discussed in section 5.

2. Relaxation approximation of nonlinear diffusion. The schemes proposed in the present work are based on the idea at the basis of the well-known relaxation schemes for hyperbolic conservation laws [22]. In the case of the nonlinear diffusion operator, an additional variable $\vec{v}(x,t) \in \mathbb{R}^d$ and a positive parameter ε are introduced, obtaining the following relaxation system:

$$\begin{cases} \dfrac{\partial u}{\partial t} + \operatorname{div}(\vec{v}) = 0, \\ \dfrac{\partial \vec{v}}{\partial t} + \dfrac{D}{\varepsilon}\nabla p(u) = -\dfrac{1}{\varepsilon}\vec{v}. \end{cases} \tag{2.1}$$

Formally, in the small relaxation limit, $\varepsilon \to 0^+$, system (2.1) approximates to leading order (1.1). Next, we remove the nonlinear term from the second equation, as in standard relaxation schemes, introducing a variable $w(x,t) \in \mathbb{R}$ and rewriting the system as:

$$\begin{cases} \dfrac{\partial u}{\partial t} + \operatorname{div}(\vec{v}) = 0, \\ \dfrac{\partial \vec{v}}{\partial t} + \dfrac{D}{\varepsilon}\nabla w = -\dfrac{1}{\varepsilon}\vec{v}, \\ \dfrac{\partial w}{\partial t} + \operatorname{div}(\vec{v}) = -\dfrac{1}{\varepsilon}(w - p(u)). \end{cases} \tag{2.2}$$

Formally, as $\varepsilon \to 0^+$, $w \to p(u)$, $v \to -D\nabla p(u)$, and the original diffusion equation (1.1) is recovered. As a matter of fact, this convergence can be justified rigorously by the results of section 3 of [7], since the relaxation system (2.2) can be seen as a particular case of the BGK system in [7]. Hence we are guaranteed that the solutions of (2.2) converge to the solutions of the degenerate parabolic equation when $\varepsilon \to 0^+$.

For the numerical integration of (2.2) one has to deal with the stiff characteristic velocities due to the term $\nabla(w)/\varepsilon$. In [1], the authors propose two possible methods: either choose ε dependent of the space discretization h or consider $\varepsilon = 0$ and use a splitting technique. Instead, we introduce a suitable parameter φ and rewrite the system (2.2) as

$$\begin{cases} \dfrac{\partial u}{\partial t} + \operatorname{div}(\vec{v}) = 0, \\ \dfrac{\partial \vec{v}}{\partial t} + \varphi^2 \nabla w = -\dfrac{1}{\varepsilon}\vec{v} + \left(\varphi^2 - \dfrac{D}{\varepsilon}\right)\nabla w, \\ \dfrac{\partial w}{\partial t} + \operatorname{div}(\vec{v}) = -\dfrac{1}{\varepsilon}(w - p(u)). \end{cases} \tag{2.3}$$

We anticipate here that we intend to integrate implicitly the terms on the right-hand side of system (2.3), so that we can consider the case $\varepsilon = 0$ without being limited by the stiffness of the problem. In particular, in the relaxed case (i.e., $\varepsilon = 0$), the stiff source terms can be integrated by solving a system that is already in a suitable triangular form and does not require iterative solvers.

In the previous system the parameter ε has physical dimensions of time and represents the so-called relaxation time. Furthermore, w has the same dimensions as u, while each component of $\vec{v}$ has the dimension of u times a velocity; finally φ is a velocity. The inverse of ε gives the rate at which v decays onto $-\nabla p(u)$ in the evolution of the variable $\vec{v}$ governed by the stiff second equation of (2.3).

Equations (2.3) form a semilinear hyperbolic system with a stiff source term. The characteristic velocities of the hyperbolic part are given by $0, \pm\varphi$. The parameter φ allows one to "move" the stiff terms $\frac{D}{\varepsilon}\nabla p(u)$ to the right-hand side, without losing the hyperbolicity of the system.

We point out that degenerate parabolic equations often model physical situations with free boundaries or discontinuities: We expect that schemes for hyperbolic systems will be able to reproduce faithfully these details of the solution. One of the main properties of (2.3) consists in the semilinearity of the system; that is, all of the nonlinearities are in the (stiff) source terms, while the differential operator is linear. Hence, the solution of the convective part requires neither Riemann solvers nor the computation of the characteristic structure at each time step, since the eigenstructure of the system is constant in time. Moreover, the relaxation approximation does not exploit the form of the nonlinear function p, and hence it gives rise to a numerical scheme that, to a large extent, is independent of it, resulting in a very versatile tool.

3. The semidiscrete scheme. System (2.3) can be written in the form:

$$z_t + \operatorname{div} f(z) = \frac{1}{\varepsilon} g(z), \tag{3.1}$$

where

$$z = \begin{pmatrix} u \\ v \\ w \end{pmatrix}, \qquad f(z) = \begin{bmatrix} v^T \\ \Phi^2 w \\ v^T \end{bmatrix}, \qquad g(z) = \begin{pmatrix} 0 \\ -v + (\varphi^2\varepsilon - D)\nabla w \\ p(u) - w \end{pmatrix}, \tag{3.2}$$

and Φ^2 is the $d \times d$ identity matrix times the scalar φ^2. We start discretizing the system in time using, for simplicity, a uniform time step Δt. Let $z^n(x) = z(x, t^n)$, with $t^n = n\Delta t$. Since (3.1) involves both stiff and nonstiff terms, it is a natural idea to employ different time-discretization strategies for each of them, as in [4, 32]. In this work we integrate (3.1) with a Runge–Kutta IMEX scheme [32], obtaining the following semidiscrete formulation:

$$z^{n+1} = z^n - \Delta t \sum_{i=1}^{\nu} \tilde{b}_i \mathrm{div} f(z^{(i)}) + \frac{\Delta t}{\varepsilon} \sum_{i=1}^{\nu} b_i g(z^{(i)}), \tag{3.3}$$

where the $z^{(i)}$'s are the stage values of the Runge–Kutta scheme which are given by

$$z^{(i)} = z^n - \Delta t \sum_{k=1}^{i-1} \tilde{a}_{i,k} \mathrm{div} f(z^{(k)}) + \frac{\Delta t}{\varepsilon} \sum_{k=1}^{i} a_{i,k} g(z^{(k)}), \tag{3.4}$$

where $\tilde{b}_i$, $\tilde{a}_{ij}$ and b_i, a_{ij} denote the coefficients of the explicit and implicit Runge–Kutta schemes, respectively. We assume that the implicit scheme is of the diagonally implicit type. To find the $z^{(i)}$'s it is necessary in principle to solve a nonlinear system of equations which, however, can be easily decoupled. The system for the first stage $z^{(1)}$ at time t^n is

$$\begin{pmatrix} u^{(1)} \\ v^{(1)} \\ w^{(1)} \end{pmatrix} = \begin{pmatrix} u^n \\ v^n \\ w^n \end{pmatrix} + \frac{\Delta t}{\varepsilon} a_{11} \begin{pmatrix} 0 \\ -v^{(1)} + (\varphi^2\varepsilon - D)\nabla w^{(1)} \\ p(u^{(1)}) - w^{(1)} \end{pmatrix}. \tag{3.5}$$

The first equation yields $u^{(1)} = u^n$; substituting in the third equation, we immediately find $w^{(1)}$; and finally, substituting $w^{(1)}$ in the second equation, we compute $v^{(1)}$. In other words, the system can be written in triangular form. For the following stage values, by grouping the already computed terms in the vector $B^{(i)}$ given by

$$B^{(i)} = z^n - \Delta t \sum_{k=1}^{i-1} \tilde{a}_{i,k} \mathrm{div} f(z^{(k)}) + \frac{\Delta t}{\varepsilon} \sum_{k=1}^{i-1} a_{i,k} g(z^{(k)}), \tag{3.6}$$

the new stage values are given by

$$\begin{pmatrix} u^{(i)} \\ v^{(i)} \\ w^{(i)} \end{pmatrix} = B^{(i)} + \frac{\Delta t}{\varepsilon} a_{ii} \begin{pmatrix} 0 \\ -v^{(i)} + (\varphi^2\varepsilon - D)\nabla w^{(i)} \\ p(u^{(i)}) - w^{(i)} \end{pmatrix}, \tag{3.7}$$

which is again a triangular system. In the numerical tests, we will apply IMEX schemes of order 1, 2, and 3.

Following [22] we set $\varepsilon = 0$, thus obtaining the so-called *relaxed scheme*. The computation of the first stage reduces to

$$\begin{aligned} u^{(1)} &= u^n, \\ w^{(1)} &= p(u^{(1)}), \\ v^{(1)} &= -D\nabla w^{(1)}. \end{aligned} \tag{3.8}$$

For the following stages the first equation is

$$u^{(i)} = u^n - \Delta t \sum_{k=1}^{i-1} \tilde{a}_{i,k} \mathrm{div} v^{(k)}. \tag{3.9}$$

In the other equations the convective terms are dominated by the source terms, and thus $v^{(i)}$ and $w^{(i)}$ are given by

$$\begin{aligned} v^{(i)} &= -D \nabla w^{(i)}, \\ w^{(i)} &= p(u^{(i)}). \end{aligned} \tag{3.10}$$

We see that only the explicit part of the Runge–Kutta method is involved in the updating of the solution. Then, in the relaxed schemes we use only the explicit part of the tableaux. In particular we consider second- and third-order strongly stable Runge–Kutta (SSRK) schemes [17], namely,

`IMEX1` (1^{st} order)

0	
1	

`IMEX2` (2^{nd} order)

0	0	
1	0	
$\frac{1}{2}$	$\frac{1}{2}$	

`IMEX3` (3^{rd} order)

0	0	0	
1	0	0	
$\frac{1}{4}$	$\frac{1}{4}$	0	
$\frac{1}{6}$	$\frac{1}{6}$	$\frac{2}{3}$	

In [10] we studied the increase in efficiency obtained by using suitable strongly stable Runge–Kutta schemes.

3.1. Convergence of the semidiscrete relaxed scheme. The aim of this section is to show the L^1 convergence of the solution of the semidiscrete in time relaxed scheme defined by (3.8), (3.9), and (3.10). We will extend the theorem proved in [6], where only the case of forward Euler time stepping was considered. In this section, for the sake of simplicity, we set $D = 1$.

Theorem 3.1 proves that the numerical solution of the relaxed scheme converges to the solution of (1.1). The proof does not make explicit use of the convergence of the solutions of the relaxation system (2.3) to the solutions of (1.1).

Eliminating v from (3.8) and (3.9) using (3.10), we rewrite the relaxed scheme as

$$\begin{aligned} u^{(1)} &= u^n, \\ w^{(1)} &= p(u^n) \end{aligned} \tag{3.11}$$

for the first stage, and

$$\begin{aligned} u^{(i)} &= u^n + \Delta t \sum_{k=1}^{i-1} \tilde{a}_{i,k} \Delta w^{(k)}, \\ w^{(i)} &= p(u^{(i)}) \end{aligned} \tag{3.12}$$

for subsequent stages. We recall that a Runge–Kutta scheme for the ordinary differential equation $y' = R(y)$ can also be written in the form [17]

$$\begin{aligned} y^{(1)} &= y^n, \\ y^{(i)} &= \sum_{k=1}^{i-1} \alpha_{ik} \left(y^{(k)} + \Delta t \frac{\beta_{ik}}{\alpha_{ik}} R(y^{(k)}) \right), \qquad i = 2, \ldots, \nu, \end{aligned} \tag{3.13}$$

where $y^{n+1} = y^{(\nu)}$. For consistency, $\sum_{k=1}^{i-1} \alpha_{ik} = 1$ for every $i = 1, \ldots, \nu$. Moreover we assumed that $\alpha_{ik} \geq 0$ and $\beta_{ik} \geq 0$ and that $\alpha_{ik} = 0$ implies $\beta_{ik} = 0$. Under these assumptions, each stage value $y^{(i)}$ can be written as a convex combination of forward Euler steps. This remark allows us to study the convergence of the Runge–Kutta scheme in terms of the convergence of the explicit forward Euler scheme applied to the nonlinear diffusion problem.

This latter was studied in [6] via a nonlinear semigroup argument. In the following we review the approach of [6], and next we extend the proof to the case of a ν-stages explicit Runge–Kutta scheme.

3.1.1. The forward Euler case. We wish to solve the evolution equation

$$\frac{du}{dt} + Lp(u) = 0, \qquad u(\cdot, t = 0) = u_0, \tag{3.14}$$

on the domain Ω, where $L = -\Delta$ and $p : \mathbb{R} \to \mathbb{R}$ is a nondecreasing locally Lipschitz function such that $p(0) = 0$. Under these hypotheses, the nonlinear operator $Au = Lp(u)$ with domain $D(A) = \{u \in L^1(\Omega) : p(u) \in D(L)\}$ is m-accretive in $L^1(\Omega)$; that is, for all $\varphi \in \mathrm{L}^1(\Omega)$ and for all $\lambda > 0$ there exists a unique solution $u \in D(A)$ such that $u + \lambda Lp(u) = \varphi$ and the application defined by $\varphi \mapsto u$ is a contraction [14].

Moreover $D(A)$ is dense in $L^1(\Omega)$, so it follows that

$$S_A(t)u_0 = \lim_{m\to\infty} \left(\mathbb{I} + \frac{t}{m}A\right)^{-m} u_0 \tag{3.15}$$

is a contraction semigroup on $L^1(\Omega)$ and $S_A(t)u_0$ is the generalized solution of (3.14) in the sense of Crandall–Liggett [14]. Let $S(t)$ be the linear contraction semigroup generated by $-L$; that is, $u(t) = S(t)u_0$ is the solution of the initial value problem $u_t = -L(u)$ and $u(\cdot, t = 0) = u_0$. The algorithm proposed in [6] is

$$\frac{u^{n+1} - u^n}{\tau} + \left[\frac{\mathbb{I} - S(\sigma_\tau)}{\sigma_\tau}\right] p(u^n) = 0, \tag{3.16}$$

where τ is the time step and $\sigma_\tau \downarrow 0$. This can be written as

$$u^{n+1} = F_E(\tau)u^n, \quad \text{where } F_E(\tau)\varphi = \varphi + \frac{\tau}{\sigma_\tau}\left[S(\sigma_\tau) - \mathbb{I}\right] p(\varphi). \tag{3.17}$$

Hence

$$u^n = (F_E(\tau))^n u_0. \tag{3.18}$$

The proof in [6] is based on the following argument. Note that formally $S(\sigma_\tau)\varphi \sim e^{-\sigma_\tau L}\varphi$. Let $t = \tau n$ and

$$\begin{aligned} u(t) &= \left[\mathbb{I} + \frac{t}{n\sigma_\tau}\left(S(\sigma_\tau) - \mathbb{I}\right) \circ p\right]^n u_0 \\ &= \left[\mathbb{I} + \frac{t}{n\sigma_\tau}\left(e^{-\sigma_\tau L} - \mathbb{I}\right) \circ p\right]^n u_0 \qquad \text{if } \sigma_\tau \to 0 \\ &= \left[\mathbb{I} - \frac{t}{n} L \circ p\right]^n u_0 \\ &\to S_A(u_0) \qquad \text{when } n \to \infty. \end{aligned} \tag{3.19}$$

The convergence proof requires that $\mu\frac{\tau}{\sigma_\tau} \leq 1$, where μ is the Lipschitz constant of $p(u)$. We point out that σ_τ is linked to the spatial approximation of the operator L, and in our scheme this requirement is reflected in the stability condition of the fully discrete scheme (see section 4).

3.1.2. Runge–Kutta schemes. Now we are going to prove convergence for the case of a ν-stages Runge–Kutta scheme.

Let $t > 0$ and $\tau = t/n$, with $n \geq 1$; let $\sigma_\tau : (0,\infty) \to (0,\infty)$ be a function such that $\lim_{\tau\to 0} \sigma_\tau = 0$.

$$\begin{aligned} &u^{(1)} = u^n, \\ &u^{(i)} = \sum_{k=1}^{i-1} \alpha_{ik} \left[u^{(k)} + \tau \frac{\beta_{ik}}{\alpha_{ik}} A(u^{(k)}) \right], \qquad i = 2, \dots, \nu, \end{aligned} \tag{3.20}$$

and proceeding as in (3.19), this becomes

$$\begin{aligned} &u^{(1)} = u^n, \\ &u^{(i)} = \sum_{k=1}^{i-1} \alpha_{ik} \left[u^{(k)} + \tau \frac{\beta_{ik}}{\alpha_{ik}} (S(\sigma_\tau) - \mathbb{I}) \circ p(u^{(k)}) \right], \qquad i = 2, \dots, \nu, \\ &u^{n+1} = u^{(\nu)}. \end{aligned} \tag{3.21}$$

We now extend (3.17) to the Runge–Kutta scheme defined by (3.21). Define, for $\phi \in L^1(\Omega)$,

$$\begin{aligned} &F^{(1)}(\tau)\phi = \phi, \\ &F^{(i)}(\tau)\phi = \sum_{k=1}^{i-1} \alpha_{ik} F^{(k)}(\tau)\phi + \frac{\tau\beta_{ik}}{\sigma_\tau} \left[S(\sigma_\tau) - \mathbb{I} \right] p(F^{(k)}(\tau)\phi), \\ &F(\tau)\phi = F^{(\nu)}(\tau)\phi, \end{aligned} \tag{3.22}$$

and therefore

$$u^n(t) = [F(\tau)]^n u_0. \tag{3.23}$$

Let $u(t)$ be the generalized solution of (3.14). The following theorem proves the convergence of the semidiscrete solution to $u(t)$.

THEOREM 3.1. *Assume $u^0 \in L^\infty(\Omega)$, and $\|u^0\|_\infty = M$; let p be a nondecreasing Lipschitz continuous function on $[-M, M]$ with Lipschitz constant μ. Assume that the following conditions hold:*

$$\begin{cases} \alpha_{ik} \geq 0, \\ \beta_{ik} \geq 0, \\ \alpha_{ik} = 0 \Rightarrow \beta_{ik} = 0, \\ \displaystyle\sum_{k=1}^{i-1} \alpha_{ik} = 1 \ \textit{(consistency)}, \\ \dfrac{\mu\tau}{\sigma_\tau} \leq \min \dfrac{\alpha_{ik}}{\beta_{ik}} \quad \textit{for } \tau > 0, \alpha_{ik} \neq 0 \qquad \textit{(stability)}, \end{cases} \tag{3.24}$$

and then $\lim_{n\to\infty} u^n(t) = u(t)$ in L^1. Moreover the convergence is uniform for t in any given bounded interval.

The proof follows the steps of [6]: First we show that u^n verifies a maximum principle (Lemma 3.2) and that F is a contraction (Lemma 3.3), and finally we apply the nonlinear Chernoff formula [8].

LEMMA 3.2. *If* (3.24) *is verified, then* $-M \le u^n \le M$ *for all* n.

Proof. We argue by induction on n: We assume that $-M \le u^n \le M$, and we show that $-M \le u^{n+1} \le M$. Let

$$u^{(i)} = F^{(i)}(\tau)u^n. \tag{3.25}$$

Since $u^{n+1} = u^{(\nu)}$, it suffices to prove that $-M \le u^{(i)} \le M$ for $i = 1, \dots, \nu$. We prove this by induction on i. When $i = 1$, the statement is true thanks to the induction hypothesis on n and being $F^{(1)} = \mathbb{I}$. Let's assume that $-M \le u^{(i-1)} \le M$ holds; we are going to show that

$$-M \le u^{(i)} = F^{(i)}(\tau)u^n \le M. \tag{3.26}$$

The function $s \mapsto \alpha_{ik}s - \frac{\tau\beta_{ik}}{\sigma_\tau}p(s)$ is nondecreasing thanks to (3.24) and the hypotheses on the function p. By the induction hypothesis on i, we have that for $k = 1, \dots, i-1$

$$-\alpha_{ik}M - \frac{\tau\beta_{ik}}{\sigma_\tau}p(-M) \le \alpha_{ik}u^{(k)} - \frac{\tau\beta_{ik}}{\sigma_\tau}p(u^{(k)}) \le \alpha_{ik}M - \frac{\tau\beta_{ik}}{\sigma_\tau}p(M). \tag{3.27}$$

Using again the induction hypothesis on i and recalling that p is nondecreasing, since S is a contraction in L^∞ [6] and $p(-M) \le p(u^{(k)}) \le p(M)$,

$$p(-M) \le S\left(p(u^{(k)})\right) \le p(M). \tag{3.28}$$

Multiplying the last equation by $\frac{\tau\beta_{ik}}{\sigma_\tau}$ and summing it to (3.27), we get

$$-\alpha_{ik}M \le \alpha_{ik}u^{(k)} + \frac{\tau\beta_{ik}}{\sigma_\tau}(S - \mathbb{I})p(u^{(k)}) \le \alpha_{ik}M, \qquad k = 1, \dots, i-1. \tag{3.29}$$

Summing for $k = 1, \dots, i-1$ and using the consistency relation of (3.24):

$$-M \le \sum_{k=1}^{i-1} \alpha_{ik}u^{(k)} + \frac{\tau\beta_{ik}}{\sigma_\tau}(S - \mathbb{I})p(u^{(k)}) \le M. \tag{3.30}$$

In particular this is valid when $i = \nu$, proving that $-M \le u^{(n+1)} \le M$. ∎

Now we can replace p by $\overline{p}$, where $\overline{p} = p$ in $-M \le x \le M$, $\overline{p} = p(M)$ for $x \ge M$, and $\overline{p} = p(-M)$ for $x \le -M$: The algorithm is the same, and in what follows we can assume that p is Lipschitz continuous with constant μ on all $\mathbb{R}$.

LEMMA 3.3. *If the hypotheses of Theorem* 3.1 *hold, then* $F(\tau)$ *is a contraction on* $L^1(\Omega)$, *i.e.,*

$$\|F(\tau)\phi - F(\tau)\psi\|_1 \le \|\phi - \psi\|_1 \qquad \forall \psi, \phi \in L^1. \tag{3.31}$$

Proof. We start showing that the result holds for a single forward Euler step. Recalling the definition of F_E from (3.17)

$$\begin{aligned} \|F_E(\tau)\phi - F_E(\tau)\psi\|_1 &\le \frac{\tau}{\sigma_\tau}\left\|S(\sigma_\tau)[p(\phi) - p(\psi)]\right\|_1 + \left\|(\phi - \psi) - \frac{\tau}{\sigma_\tau}[p(\phi) - p(\psi)]\right\|_1 \\ &\le \frac{\tau}{\sigma_\tau}\left\|p(\phi) - p(\psi)\right\|_1 + \left\|\left(\phi - \frac{\tau}{\sigma_\tau}p(\phi)\right) - \left(\psi - \frac{\tau}{\sigma_\tau}p(\psi)\right)\right\|_1 \\ &= \left\|\phi - \psi\right\|_1, \end{aligned} \tag{3.32}$$

where we used the contractivity of S. The last equality relies on the fact that p and the function $x \mapsto x - \frac{\tau}{\sigma_\tau} p(x)$ are nondecreasing, which in turn is guaranteed by the stability condition, which in this case reduces to $\mu\tau/\sigma_\tau \leq 1$ [6].

In the general case we have

$$\begin{aligned} \|F^{(i)}(\tau)\phi - F^{(i)}(\tau)\psi\|_1 &\leq \sum_{k=1}^{i-1} \alpha_{ik} \left\| F_E\left(\frac{\tau\beta_{ik}}{\alpha_{ik}}\right) F^{(k)}(\tau)\phi - F_E\left(\frac{\tau\beta_{ik}}{\alpha_{ik}}\right) F^{(k)}(\tau)\psi \right\|_1 \\ &\leq \sum_{k=1}^{i-1} \alpha_{ik} \left\| F^{(k)}(\tau)\phi - F^{(k)}(\tau)\psi \right\|_1 \qquad (3.33) \\ &\leq \|\phi - \psi\|_1 . \end{aligned}$$

In the second inequality we used the contractivity of F_E and the stability condition, while in the third one we apply an induction argument on the contractivity of $F^{(k)}$, the positivity constraint on α_{ik} and β_{ik}, as well as the consistency condition $\sum_k \alpha_{ik} = 1$. Setting $i = \nu$ yields the result. □

Proof of Theorem 3.1. Let ψ_τ and ψ be, respectively,

$$\psi_\tau = \left(I + \frac{\lambda}{\tau}(I - F(\tau))\right)^{-1} \phi \qquad \text{and} \qquad \psi = (I + \lambda A)^{-1}\phi. \qquad (3.34)$$

The function ψ exists since the operator A is m-accretive, whereas the existence of the function ψ_τ is guaranteed by the following fixed-point argument. Let

$$G(y) = \frac{1}{1+\eta}\phi + \frac{\eta}{\eta+1} F(\tau) y,$$

where $\phi \in \mathrm{L}^1$, $y \in \overline{D(A)}$, and $\eta \geq 0$. We have

$$\|G(y) - G(x)\| = \frac{\eta}{\eta+1}\|F(\tau)y - F(\tau)x\| \leq \frac{\eta}{\eta+1}\|y - x\|$$

since F is a contraction, as proved in Lemma 3.3. Thus G is also a contraction, and therefore it possesses a unique fixed point which coincides with ψ_τ.

We want to show that

$$\psi_\tau \to \psi \qquad \text{in } \mathrm{L}^1$$

as $\tau \to 0$ for each fixed $\lambda > 0$. Let

$$\phi_\tau = \psi + \frac{\lambda}{\tau}(\mathbb{I} - F(\tau))\psi.$$

We want to estimate $\psi_\tau - \psi$ in terms of $\phi_\tau - \phi$.

$$\phi_\tau - \phi = \left(1 + \frac{\lambda}{\tau}\right)(\psi - \psi_\tau) - \frac{\lambda}{\tau}(F(\tau)\psi - F(\tau)\psi_\tau),$$

Therefore

$$\left(1 + \frac{\lambda}{\tau}\right)(\psi - \psi_\tau) - (\phi_\tau - \phi) = \frac{\lambda}{\tau}(F(\tau)\psi - F(\tau)\psi_\tau),$$

and, by taking norms and using the fact that F is a contraction, we have

$$\left|\left(1+\frac{\lambda}{\tau}\right)\|\psi-\psi_\tau\|-\|\phi_\tau-\phi\|\right| \le \left\|\left(1+\frac{\lambda}{\tau}\right)(\psi-\psi_\tau)-(\phi_\tau-\phi)\right\| \le \frac{\lambda}{\tau}\|\psi-\psi_\tau\|.$$

In particular

$$\left(1+\frac{\lambda}{\tau}\right)\|\psi-\psi_\tau\|-\|\phi_\tau-\phi\| \le \frac{\lambda}{\tau}\|\psi-\psi_\tau\|,$$

and therefore $\|\psi-\psi_\tau\| \le \|\phi-\phi_\tau\|$.

Now we estimate $\|\phi-\phi_\tau\|$ in the simple case of a forward Euler scheme. Note that

$$\phi-\phi_\tau = \lambda A\psi - \frac{\lambda}{\tau}(\mathbb{I}-F(\tau))\psi,$$

and thus $\|\phi-\phi_\tau\|$ measures a sort of consistency error. For a single forward Euler step, $F=F_E$, where F_E is defined in (3.17). Thus

$$\|\phi-\phi_\tau\| = \lambda\left\|A\psi-\frac{1}{\sigma_\tau}(\mathbb{I}-S(\sigma_\tau))p(\psi)\right\| \to 0 \tag{3.35}$$

as $\tau\to 0$ since $\frac{\mathbb{I}-S(\sigma_\tau)}{\sigma_\tau}p(\psi)\to Lp(\psi)=A\psi$.

The more general case of a ν-stages Runge–Kutta scheme can be carried out by induction following the procedure already applied in the proofs of the previous lemmas.

We now use Theorem 3.2 of [8], which, specialized to our case, can be written as follows. Assume that $F(\tau):\mathrm{L}^1\to\mathrm{L}^1$ for $\tau>0$ is a family of contractions. Assume further that an m-accretive operator A is given, and let $S(t)$ be the semigroup generated by A. Assume further that the family $F(\tau)$ and the operator A are linked by the following formula:

$$\psi_\tau = \left(I+\frac{\lambda}{\tau}(I-F(\tau))\right)^{-1}\phi \to \psi = (I+\lambda A)^{-1}\phi \tag{3.36}$$

for each $\phi\in\mathrm{L}^1$. Then

$$\lim_{n\to\infty} F\left(\frac{t}{n}\right)^n \phi = S(t)\phi \qquad \forall\phi\in\mathrm{L}^1. \qquad \square$$

4. Fully discrete relaxed scheme. In order to complete the description of the scheme, we need to specify the space discretization. We will use discretizations based on finite differences, in order to avoid cell coupling due to the source terms.

Note that the IMEX technique reduces the integration to a cascade of relaxation and transport steps. The former are the implicit parts of (3.5) and (3.7), while the transport steps appear in the evaluation of the explicit terms $B^{(i)}$ in (3.6). Since (3.5) and (3.7) involve only local operations, the main task of the space discretization is the evaluation of $\mathrm{div}(f)$, where we will exploit the linearity of f in its arguments.

4.1. One-dimensional scheme. Let us introduce a uniform grid on $[a,b]\subset\mathbb{R}$, $x_j = a-\frac{h}{2}+jh$ for $j=1,\dots,n$, where $h=(b-a)/n$ is the grid spacing and n the number of cells. The fully discrete scheme may be written as

$$z_j^{n+1} = z_j^n - \Delta t\sum_{i=1}^{\nu}\tilde{b}_i\left(F^{(i)}_{j+1/2}-F^{(i)}_{j-1/2}\right)+\frac{\Delta t}{\varepsilon}\sum_{i=1}^{\nu}b_i g(z_j^{(i)}), \tag{4.1}$$

where $F^{(i)}_{j+1/2}$ are the numerical fluxes, which are the only items we still need to specify. For convergence it is necessary to write the scheme in conservation form. Thus, following [34], we introduce the function $\hat{F}$ such that

$$f(z(x,t)) = \frac{1}{h}\int_{x-h/2}^{x+h/2} \hat{F}(s,t)\mathrm{d}s \quad \Rightarrow \frac{\partial f}{\partial x}(z(x_j,t)) = \frac{1}{h}\left(\hat{F}(x_{j+1/2},t) - \hat{F}(x_{j-1/2},t)\right).$$

The numerical flux function $F_{j+1/2}$ must approximate $\hat{F}(x_{j+1/2})$.

In order to compute the numerical fluxes, for each stage value, we reconstruct boundary extrapolated data $z^{(i)\pm}_{j+1/2}$ with a nonoscillatory interpolation method from the point values $z^{(i)}_j$ of the variables at the center of the cells. Next we apply a monotone numerical flux to these boundary-extrapolated data.

To minimize numerical viscosity we choose the Godunov flux, which in the present case of a linear system of equations reduces to the upwind flux. In order to select the upwind direction we write the system in characteristic form. The characteristic variables relative to the eigenvalues $\varphi, -\varphi, 0$ (in one space dimension φ reduces to a scalar parameter) are, respectively,

$$U = \frac{\varphi w + v}{2\varphi}, \qquad V = \frac{\varphi w - v}{2\varphi}, \qquad W = u - w. \tag{4.2}$$

Note that $u = U + V + W$. Therefore the numerical flux in characteristic variables is $F_{j+1/2} = (\varphi U^-_{j+1/2}, -\varphi V^+_{j+1/2}, 0)$.

The accuracy of the scheme depends on the accuracy of the reconstruction of the boundary-extrapolated data. For a first-order scheme we use a piecewise constant reconstruction such that $U^-_{j+1/2} = U_j$ and $V^+_{j+1/2} = V_{j+1}$. For higher-order schemes, we use ENO or WENO reconstructions of appropriate accuracy [35].

For $\varepsilon \to 0$ we obtain the relaxed scheme. Recall from (3.10) that the relaxation steps reduce to

$$w^{(i)}_j = p(u^{(i)}_j), \qquad v^{(i)}_j = -D\widehat{\nabla} w^{(i)}_j, \tag{4.3}$$

where $\widehat{\nabla}$ is a suitable approximation of the one-dimensional gradient operator. Thus the transport steps need to be applied only to $u^{(i)}$

$$u^{(i)}_j = u^n_j - \lambda \sum_{k=1}^{i-1} \tilde{a}_{i,k}\left[\varphi\left(U^{(k)-}_{j+1/2} - U^{(k)-}_{j-1/2}\right) - \varphi\left(V^{(k)+}_{j+1/2} - V^{(k)+}_{j-1/2}\right)\right]. \tag{4.4}$$

Finally, taking the last stage value and going back to conservative variables,

$$\begin{aligned} u^{n+1}_j = u^n_j - \frac{\lambda}{2}\sum_{i=1}^{\nu} \tilde{b}_i \Big(& [v^{(i)-}_{j+1/2} + v^{(i)+}_{j+1/2} - (v^{(i)-}_{j-1/2} + v^{(i)+}_{j-1/2})] \\ & + \varphi[w^{(i)-}_{j+1/2} - w^{(i)+}_{j+1/2} - (w^{(i)-}_{j-1/2} - w^{(i)+}_{j-1/2})]\Big). \end{aligned} \tag{4.5}$$

We wish to emphasize that the scheme reduces to the time advancement of the single variable u. Although the scheme is based on a system of three equations, the construction is used only to select the correct upwinding for the fluxes of the relaxed scheme, and the computational cost of each time step remains moderate.

4.2. Nonlinear stability for the first-order scheme. The relaxed scheme in the first-order case reduces to:

$$u_j^{n+1} = u_j^n + \frac{\lambda}{2}\left(\partial_x p(u^n)|_{j+1} - \partial_x p(u^n)|_{j-1}\right) + \frac{\lambda}{2}\varphi\left(p(u_{j+1}^n) - 2p(u_j^n) + p(u_{j-1}^n)\right). \tag{4.6}$$

We wish to compute the restrictions on λ and φ so that the scheme is total variation nonincreasing. We select the centered finite difference formula to approximate the partial derivatives of $p(u)$; we drop the index n and write p_j for $p(u_j^n)$. Define $\Delta_{j+1/2} = \frac{p_{j+1}-p_j}{u_{j+1}-u_j}$, and observe that these quantities are always nonnegative since p is nondecreasing. We obtain

$$\begin{aligned}
\mathrm{TV}(u^{n+1}) &= \sum_j |u_j^{n+1} - u_{j-1}^{n+1}| \\
&\le \sum_j \left\{ \frac{\lambda}{4h}\Delta_{j+3/2}|u_{j+2} - u_{j+1}| + \frac{\lambda}{2}\varphi\Delta_{j+1/2}|u_{j+1} - u_j| \right. \\
&\qquad + \left(1 - \lambda\left(\frac{1}{2h} + \varphi\right)\Delta_{j-1/2}\right)|u_j - u_{j-1}| \\
&\qquad \left. + \frac{\lambda}{2}\varphi\Delta_{j-3/2}|u_{j-1} - u_{j-2}| + \frac{\lambda}{4h}\Delta_{j-5/2}|u_{j-2} - u_{j-3}| \right\}
\end{aligned} \tag{4.7}$$

provided that

$$\left(1 - \lambda\left(\frac{1}{2h} + \varphi\right)\Delta_{j-1/2}\right) \ge 0 \qquad \forall j. \tag{4.8}$$

Assuming that the data have compact support, we can rescale all sums and finally get $\mathrm{TV}(u^{n+1}) \le \mathrm{TV}(u^n)$. Taking into account the Lipschitz condition on p, the scheme is total variation stable provided that (4.8) is satisfied, i.e., that

$$\Delta t \le \frac{2h^2}{\mu}\frac{1}{1+2h\varphi} \simeq \frac{(2-\delta)}{\mu}h^2, \tag{4.9}$$

where δ vanishes as h does. We point out that the stability condition is of the parabolic type. Finally, we observe that, using one-sided approximations for the partial derivatives of p in the scheme (4.6), one gets a stability condition involving the relation $\varphi > 1/h$. This would reintroduce in the scheme the constraint due to the stiffness in the convective term that prompted the introduction of φ in (2.3).

4.3. Linear stability. We study the linear stability of the schemes based on (4.3), (4.4), and (4.5) in the case when $p(u) = u$, by von Neumann analysis. We substitute the discrete Fourier modes $u_j^n = \rho^n e^{i(jk/N)}$ into the scheme, where k is the wave number and N the number of cells. We set $\xi = k/N$ and compute the amplification factor $Z(\xi)$ such that $u_j^{n+1} = Z(\xi)u_j^n$. We can consider ξ as a continuous variable, since the amplification factors for various choices of N all lie on the curves obtained considering the variable $\xi \in [0, 2\pi]$.

First we consider the same scheme studied in the previous section, for comparison purposes. Using piecewise constant reconstructions in space and forward Euler time integration, the amplification factor is $Z(\xi) = 1 + M(\xi)$, where

$$M(\xi) = \frac{\lambda}{h}\left(\cos(\xi) - 1\right)\left(\cos(\xi) + 1 + h\varphi\right).$$

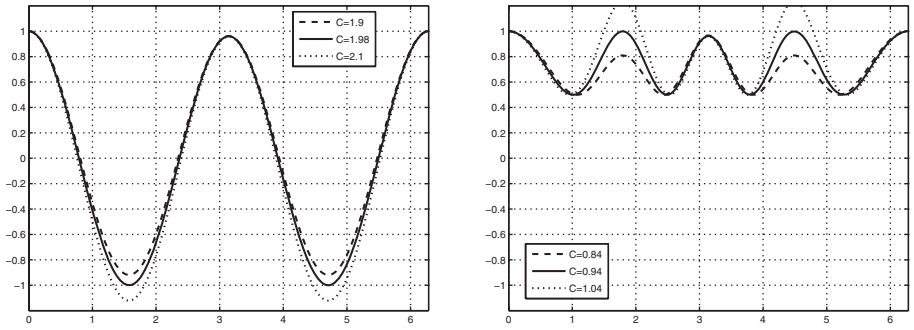

FIG. 4.1. *Amplification factor for upwind spatial reconstruction coupled with forward Euler (left) and for upwind second-order spatial reconstruction coupled with second-order time integration (right).*

$M(\xi)$ takes maximum value 0 and attains its minimum at the point ξ^* such that $\cos(\xi^*) = -\varphi h/2$. Stability requires that $M(\xi^*) \geq -2$, i.e.,

$$1 + \frac{\lambda}{h}\left(\frac{\varphi^2 h^2}{4} - 1\right) - \lambda\varphi\left(\frac{\varphi h}{2} + 1\right) \geq -1,$$

and, recalling that $\lambda = \Delta t/h$,

$$\Delta t \leq \frac{2h^2}{\left(1 + \frac{\varphi h}{2}\right)^2} \simeq 2\,(1 - \varphi h)\,h^2. \tag{4.10}$$

This gives a CFL condition of the form $\Delta t \leq 2(1-\delta)h^2$, where $\delta = O(h\varphi)$ (see Figure 4.1). These results are in very good agreement with those of the nonlinear analysis performed in the previous section.

Now we consider higher-order spatial reconstructions coupled with forward Euler time stepping. M takes the form

$$M(\xi, \gamma) = \frac{\lambda}{h}\left[f_1(\cos(\xi)) + \gamma f_2(\cos(\xi))\right],$$

where $\gamma = h\varphi$. Since γ is small, we compute the critical points ξ^* of $M(\xi, 0)$. For stability we thus require that $-2 \leq M(\xi^*, \gamma) \leq 0$.

We consider a piecewise linear and a WENO reconstruction. The first one is computed along characteristic variables using the upwind slope, while the gradient of $p(u)$ is computed with centered differences. The WENO reconstruction is fifth-order accurate and is obtained by setting to 1 the smoothness indicators, and the gradient of $p(u)$ is computed with the fourth-order centered difference formula.

For the piecewise linear reconstruction, we have that

$$M(\xi) = -\frac{\lambda}{h}\left[(\cos^2(\xi) - 1)(\cos(\xi) - 2) + h\varphi(\cos(\xi) - 1)^2\right],$$

and therefore

$$\Delta t \leq \frac{2h^2}{\frac{20+14\sqrt{7}}{27} + \frac{8+2\sqrt{7}}{9}\varphi h} \simeq 0.94(1 - 1.44\varphi h)h^2.$$

TABLE 4.1

	RK1	RK2	RK3
P-wise constant	2	2	2.51
P-wise linear	0.94	0.94	
WENO5	0.79	0.79	1

For the WENO reconstruction $M(\xi, \gamma)$ can be easily computed, and we get

$$\Delta t \leq 0.79(1 - 0.13\varphi h)h^2.$$

Now we wish to extend our results to the case of higher-order Runge–Kutta schemes. Since both the equation and the scheme are linear, the amplification factors for the Runge–Kutta schemes of orders 2 and 3 used here are, respectively,

$$Z_{(2)}(\xi) = 1 + M(\xi) + \frac{M(\xi)^2}{2},$$
$$Z_{(3)}(\xi) = 1 + M(\xi) + \frac{M(\xi)^2}{2} + \frac{M(\xi)^3}{6},$$

where $M(\xi)$ is the function appearing in the amplification factor relevant to the chosen spatial reconstruction. We have that

$$Z'_{(2)}(\xi) = M'(\xi)(1 + M(\xi)),$$
$$Z'_{(3)}(\xi) = M'(\xi)\left(1 + M(\xi) + \frac{M(\xi)^2}{2}\right),$$

and therefore the critical points are the points ξ^* such that $M'(\xi^*) = 0$.

In the Runge–Kutta 2 case the stability constraint $\|Z_{(2)}(\xi^*)\| \leq 1$ reduces to the CFL condition for the forward Euler scheme. For Runge–Kutta 3, $\|Z_{(3)}(\xi^*)\| \leq 1$, provided that

$$M(\xi^*) \geq \tilde{s} \simeq -2.51.$$

Notice that this is less restrictive than the Euler and second-order Runge–Kutta schemes for which the stability requirement is $M(\xi^*) \geq -2$.

For the third-order Runge–Kutta scheme with linearized WENO of order 5, we have

$$\Delta t \leq \frac{-\tilde{s}h^2}{2.51 + 0.33\varphi h} \simeq (1 - .1325\varphi h)h^2.$$

Table 4.1 summarizes the stability results obtained in this section by listing the values of the constant C that appears in the stability restriction $\Delta t \leq C(1 - C_1\varphi h)h^2$. Figures 4.1 and 4.2 contain the amplification factors $Z(\xi)$ for $\varphi = 1$ and $h = 10^{-2}$ for various choices of spatial reconstructions and time integration schemes. Each of them contains the curve corresponding to the value of C reported in Table 4.1 and two other close-by values.

4.4. Boundary conditions. Different boundary conditions can be implemented. Here we describe how to implement Neumann boundary conditions, considering for simplicity the one-dimensional case.

We first add g ghost points on each side of the computational domain $[a, b]$, where g depends on the order of the spatial reconstruction. We find a polynomial $q(x)$ of

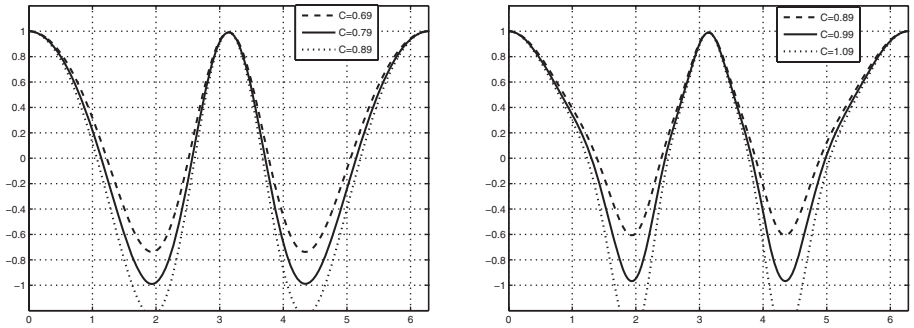

FIG. 4.2. *Amplification factors Z for WENO reconstructions of order* 5 *coupled with first-order (left) and third-order (right) time integration.*

degree d passing through the points (x_i, u_i) for $i = 1, \dots, d$ and having a prescribed derivative at the boundary point $x_{1/2} = a$. (The degree d is determined by the accuracy of the scheme that one wants to obtain and should match the degree of the reconstruction procedures used to obtain $U_j^{\pm}$ and $V_j^{\pm}$.) This polynomial is then used to set the values $u_{-i} = q(x_{-i})$ of the ghost points for $i = 0, 1, g-1$. One operates similarly at the right edge of the computational domain.

We also used periodic boundary conditions, which can be implemented with an obvious choice of the values u_i at the ghost points.

4.5. Multidimensional scheme. An appropriate numerical approximation of (2.3) in $\mathbb{R}^d$ that generalizes the scheme described in section 4.1 can be obtained by additive dimensional splitting. We consider the relaxed scheme, i.e., $\varepsilon = 0$, and for the sake of simplicity, let us focus on the square domain $[a, b] \times [a, b] \subset \mathbb{R}^2$. Here we shall describe the generalization of the scheme defined by (4.3), (4.2), (4.4), and (4.5) to the case of two space dimensions.

Without loss of generality, we consider a uniform grid in $[a, b] \times [a, b] \subset \mathbb{R}^2$ such that $\vec{x}_{i,j} = (x_i, y_j) = (a - h/2, a - h/2) + i(h, 0) + j(0, h)$ for $i, j = 1, 2, \dots, n$ and $h = (b - a)/n$.

In the present case, u and w are one-dimensional variables, while $\vec{v} = (v_{(1)}, v_{(2)})$ is now a field in $\mathbb{R}^2$. First we observe that the relaxation steps (4.3) are easily generalized for $d > 1$. For the transport steps, one has to evolve in time the system

$$\frac{\partial}{\partial t}\begin{pmatrix} u \\ v_{(1)} \\ v_{(2)} \\ w \end{pmatrix} + \frac{\partial}{\partial x}\begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & \varphi^2 \\ 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{bmatrix}\begin{pmatrix} u \\ v_{(1)} \\ v_{(2)} \\ w \end{pmatrix} + \frac{\partial}{\partial y}\begin{bmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \varphi^2 \\ 0 & 0 & 1 & 0 \end{bmatrix}\begin{pmatrix} u \\ v_{(1)} \\ v_{(2)} \\ w \end{pmatrix} = 0. \tag{4.11}$$

The semidiscretization in space of the above equation can be written as

$$\frac{\partial z_{i,j}}{\partial t} = -\frac{1}{h}\left(F_{i+1/2,j} - F_{i-1/2,j}\right) - \frac{1}{h}\left(G_{i,j+1/2} - G_{i,j-1/2}\right),$$

where F and G are the numerical fluxes in the x and the y direction, respectively, and can be written as

$$F_{i+1/2,j} = F(z^+_{i+1/2,j}, z^-_{i+1/2,j}), \qquad G_{i,j+1/2} = G(z^+_{i,j+1/2}, z^-_{i,j+1/2}).$$

The fluxes in the two directions are computed separately. We illustrate the computation of the flux F along the x direction. We note that only the field $v_{(1)}$ appears in

the differential operator along this direction. The third component of the flux is zero, and thus we have three independent characteristic variables, namely,

$$U_{(1)} = \frac{\varphi w + v_1}{2\varphi}, \qquad V_{(1)} = \frac{\varphi w - v_1}{2\varphi}, \qquad W = u - w,$$

which correspond, respectively, to the eigenvalues $\varphi, -\varphi, 0$. At this point the numerical fluxes can be easily evaluated by upwinding. We proceed similarly for the numerical flux G that depends on the characteristic variables $U_{(2)}, V_{(2)}, W$.

Denote by $U^{\pm}_{i+1/2,j}$ the reconstructions of $U_{(1)}(\cdot, y_j)$ at the point $(x_i + h/2, y_j)$. This involves a reconstruction of the restriction of $U_{(1)}$ to the line $y = y_i$ and can be obtained with any of the one-dimensional techniques mentioned in section 4.1. Similarly, denote by $U^{\pm}_{i,j+1/2}$ the reconstructions of $U_{(2)}(x_i, \cdot)$ at the point $(x_i, y_j + h/2)$. Now, (4.4) and (4.5) become, respectively,

$$u^{(l)}_{i,j} = u^n_{i,j} - \lambda \sum_{m=1}^{l-1} \tilde{a}_{l,m} \Big[\varphi \left(U^{(m)-}_{i+1/2,j} - U^{(m)-}_{i-1/2,j} \right) - \varphi \left(V^{(m)+}_{i+1/2,j} - V^{(m)+}_{i-1/2,j} \right) \varphi \left(U^{(m)-}_{i,j+1/2} - U^{(m)-}_{i,j-1/2} \right) - \varphi \left(V^{(m)+}_{i,j+1/2} - V^{(m)+}_{i,j-1/2} \right) \Big] \tag{4.12}$$

and

$$u^{n+1}_{i,j} = u^n_{i,j} - \lambda \sum_{l=1}^{\nu} \varphi \tilde{b}_l \Big[\left(U^{(l)-}_{i+1/2,j} - V^{(l)+}_{i+1/2,j} \right) - \left(U^{(l)-}_{i-1/2,j} - V^{(l)+}_{i-1/2,j} \right) \left(U^{(l)-}_{i,j+1/2} - V^{(l)+}_{i,j+1/2} \right) - \left(U^{(l)-}_{i,j-1/2} - V^{(l)+}_{i,j-1/2} \right) \Big]. \tag{4.13}$$

The generalization to $d > 2$ and rectangular domains is now trivial. We stress once again that no two-dimensional reconstruction is used, but only d one-dimensional reconstructions are needed. Finally, boundary conditions can be implemented directionwise with the same techniques used in the one-dimensional case.

5. Numerical results. We performed several numerical tests of our relaxed schemes. First we tested convergence for a linear diffusion equation with periodic and Neumann boundary conditions for initial data giving rise to smooth solutions. Next, numerical tests were also performed on the porous media equation $u_t = (u^m)_{xx}$, $m = 2, 3$, in both one and two dimensions.

5.1. Linear diffusion. For the first test we considered the linear problem

$$\begin{cases} \dfrac{\partial u}{\partial t}(x,t) = \dfrac{\partial^2 u}{\partial x^2} u(x,t), & x \in [0,1], \\ u(x,0) = u_0(x), & x \in [0,1]. \end{cases}$$

First we used periodic boundary conditions with $u_0(x) = \cos(2\pi x)$, so that $u(x,t) = \cos(2\pi x) e^{-4\pi^2 t}$ is an exact solution. Then we used Neumann boundary conditions $u_x(0) = u_x(1) = 1$ with initial data $u_0(x) = x + cos(2\pi x)$, so that $u(x,t) = x + \cos(2\pi x) e^{-4\pi^2 t}$ is an exact solution.

We tested the numerical schemes defined by (4.2), (4.3), (4.4), and (4.5) with various degrees of accuracy for the spatial reconstructions and time-stepping operators. We used ENO spatial reconstructions of degrees from 2 to 6 and WENO reconstructions of degrees 3 and 5. The time-stepping procedures chosen are IMEX

Runge–Kutta schemes of section 3 of accuracy chosen to match the accuracy of the spatial reconstruction. Since stability forces the parabolic restriction $\Delta t \leq Ch^2$, an IMEX scheme of order m was coupled with a spatial ENO/WENO reconstruction of accuracy p such that $p \leq 2m$, obtaining a scheme of order p.

We computed the numerical solution of the diffusion equation with final time $t = 0.05$ with $N = 40, 80, 160, 320, 640$ grid points and computed the L^1 norm of the difference between the numerical and the exact solution. The results are in Table 5.1 for the periodic boundary conditions and Table 5.2 for the Neumann boundary conditions. One can see that the expected convergence rates are reached, even if the combination of the WENO reconstruction of accuracy 3 and the IMEX scheme of second order reach the predicted error reduction only on very fine grids.

5.2. Porous media equation. On the porous media equation (1.1) with $p(u) = u^m$ we performed a test proposed in [18]. We took $m = 2, 3$ and initial data of class

C^1 as follows:

$$u(x,0) = \begin{cases} \cos^2(\pi x/2), & |x| \le 1, \\ 0, & |x| > 1. \end{cases} \tag{5.1}$$

The computational domain is $\{|x| \le 3\} \subset \mathbb{R}$, and the boundary conditions are periodic; the CFL constant is taken as $C = 0.25$.

Since the initial data have compact support and are Lipschitz continuous, the solution will be of compact support for every $t \ge 0$ but will develop a discontinuity in u_x at some finite time $\tau > 0$ (see [3]).

As was shown in [3], the solution with the initial condition we chose has a front that does not move for $t < 0.034$. We therefore chose a final time of the simulation $t_{\text{fin}} = 0.03$ to prevent the formation of the singularity of u_x from affecting the order of convergence. We used as a reference solution the one obtained numerically with $N = 4860$ grid points and computed the L^1 norms of the errors of the solutions with $N = 60, 180, 540, 1620$ grid points. The results are presented in Table 5.3.

First of all one verifies that the degree of regularity of the solution poses a limit on the order of convergence of the schemes: Therefore the schemes we tested perform at best as third-order schemes, as confirmed by the data in Table 5.3. Still, high-order schemes yield a smaller error on a given grid. This can be of practical importance in problems where one does not have the freedom of choosing the number of grid points, as in digital image analysis, where nonlinear degenerate diffusion equations are sometimes used as filters for contour enhancement (see [5]).

In Figure 5.1 we show the numerical solution for the porous media equation with $p(u) = u^2$ and $p(u) = u^3$, with the initial data (5.1) and $t \in [0, 2]$. It can be appreciated that a front (i.e., a discontinuity of $\frac{\partial u}{\partial x}$) develops at a finite time and then it travels at finite speed.

We present a numerical simulation for the two-dimensional porous media equation (1.1) with $p(u) = u^2$. We chose an initial data $u_0(x, y)$ given by two bumps with periodic boundary conditions on $[-10, 10] \times [-10, 10]$. The large domain ensures that the compact support of the solution is still contained in the computational domain

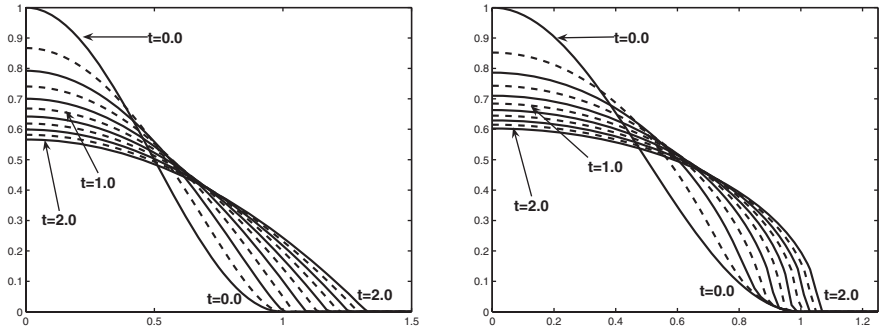

FIG. 5.1. *Snapshots of the numerical solutions for the porous media equation with* $p(u) = u^2$ *(left) and* $p(u) = u^3$ *(right). Initial data are chosen according to* (5.1)*, and the numerical solutions are represented at times* $t = 0, 0.2, \ldots, 2.0$*. FIG. 5.2. *The numerical solution of the porous media equation on a square regular grid with compactly supported initial data. From top left to bottom right, we show the numerical solution at times* $t = 0, 0.5, 1.0, 4.0$*.*

at the final time of the calculation. The numerical approximation at different time levels is shown in Figure 5.2.

We can note that the symmetries of the initial data are preserved and the solution seems to be unaffected by the dimensional splitting of the two-dimensional scheme.

6. Conclusions. We have proposed and analyzed relaxed schemes for nonlinear degenerate parabolic equations.

We considered a relaxation system similar to the one used in [29, 27] but focused on the relaxed schemes that are obtained by taking the relaxation parameter $\varepsilon = 0$. By using suitable discretizations in space and time, namely, ENO/WENO nonoscillatory reconstructions for numerical fluxes and IMEX Runge–Kutta schemes for time

integration, we have obtained a class of high-order schemes. We proved a convergence theorem for the semidiscrete scheme using the nonlinear Chernoff formula; furthermore we obtained stability results for the fully discrete schemes. Our computational tests suggest that our schemes converge with the predicted rate and exhibit a high resolution of propagating fronts.

Finally, we point out that these schemes can be easily implemented on parallel computers. Some preliminary results and details are reported in [12]. In particular the schemes involve only linear matrix-vector operations, and the execution time scales linearly when increasing the number of processors.

Our numerical approach can be easily extended to more general problems. The case of degenerate reaction-diffusion equations will appear in [13]. The treatment of convection-diffusion equations requires the introduction of an additional equation to relax the convection terms. A preliminary study appears in [9], while some of these applications will appear in a forthcoming paper [11].

NUMERICAL APPROXIMATION OF A QUASI-NEWTONIAN STOKES FLOW PROBLEM WITH DEFECTIVE BOUNDARY CONDITIONS*

VINCENT J. ERVIN† AND HYESUK LEE†

Abstract. In this article we study the numerical approximation of a quasi-Newtonian Stokes flow problem where only the flow rates are specified at the inflow and outflow boundaries. A variational formulation of the problem, using Lagrange multipliers to enforce the stated flow rates, is given. The existence and the uniqueness to the continuous, and discrete, variational formulations of the solution are shown. An error analysis for the numerical approximation is also given. Numerical computations are included which demonstrate the approximation scheme studied.

Key words. quasi-Newtonian Stokes flow, defective boundary condition, power law fluid

1. Introduction.

In this paper we investigate the numerical approximation of a quasi-Newtonian Stokes flow problem with defective boundary conditions. Such problems arise in modeling viscoelastic fluid flow. Several examples are given in section 2.1. For well-posedness of a Newtonian fluid flow problem suitable boundary conditions are required to uniquely define the solution. Perhaps the simplest of these is to specify the velocity at each point on the boundary of the domain. Often what is assumed is that the flow is *fully developed* at the inflow and outflow boundaries, which justifies a parabolic flow profile at these boundaries. Typically a *no slip* (i.e., velocity $= \mathbf{0}$) is assumed along the other portions of the boundary of the domain. However, in many physical problems the assumption of fully developed flow at the inflow and outflow is either unreasonable or highly questionable. Usually what is known in physical fluid flow problems are the various inflow and outflow flow rates.

In [6] Formaggia et al. discuss the defective boundary condition problem for the time-dependent Navier–Stokes equation. They introduce a Lagrange multiplier approach to enforce flow constraints at the inflow and outflow portions of the boundary. For the steady-state Stokes problem, they show the existence and the uniqueness of the solution for flow rates imposed using the Lagrange multiplier formulation. Herein we extend this work to analyze a quasi-Newtonian Stokes flow problem subject to specified inflow and outflow flow rates. We establish the existence and the uniqueness of the solution for the continuous and discrete variational problems and present an error analysis for the numerical approximation.

Initially it is, perhaps, somewhat perplexing to note that, for the uniqueness of the solution to the variational problem for (i) the Dirichlet problem, we require that $\acute{d}$ (the dimension of the space) conditions be specified at each point on the boundary, whereas (ii) the defective boundary condition problem requires only that a single scalar be specified at inflow and outflow boundaries (and $\acute{d}$ conditions at

†Department of Mathematical Sciences, Clemson University, Clemson, SC 29634-0975 (vjervin@clemson.edu, hklee@clemson.edu).

other boundary points). This seeming anomaly is explained in Lemma 2.1 (see also [6, Proposition 2.1] and [12, p. 341]). Specifically, the variational formulation for the defective boundary condition problem implicity imposes that across each of the inflow and outflow boundaries the total stress normal to the boundaries is a constant, and the extra stress lying in the surface of the inflow and outflow boundaries is zero.

In [12] Heywood, Rannacher, and Turek also investigated the defective boundary condition problem for the time-dependent Navier–Stokes equations. They considered both the case of specified flow rates at the inflow and outflow boundaries and also the case of the mean specified pressure at the inflow and outflow boundaries. For the specified flow-rate problem, the formulation they considered (and proved the existence of a steady-state solution) involved the construction of suitable *flux-carrier* vector functions.

The numerical approximation of the quasi-Newtonian Stokes flow problem with homogeneous boundary conditions has been previously studied in several papers [2, 5, 8, 14, 17].

This paper is organized as follows. In sections 2.1 and 2.2 we describe the model problem, state our assumptions on the model, and introduce appropriate mathematical notation. We show in section 2.3 that the corresponding variational formulation, in which the flow rate boundary conditions are weakly imposed using Lagrange multipliers, is well-posed. A numerical approximation scheme is presented in section 3, and its solution shown to exist. A priori error estimates for the numerical approximation are derived in section 4. Numerical results are presented in section 5.

2. Mathematical model. Motivated by physical considerations we consider the numerical approximation of a three-field, quasi-Newtonian Stokes flow problem with fixed flow-rate boundary conditions.

2.1. Problem specification. Let Ω denote a bounded domain in $\mathbb{R}^{\acute{d}}$, $\acute{d} = 2$ or 3, whose boundary $\partial\Omega$ is decomposed into the union of Γ and several disjoint sections $S_1, S_2, \ldots, S_m$, $m \geq 2$. See Figure 2.1.

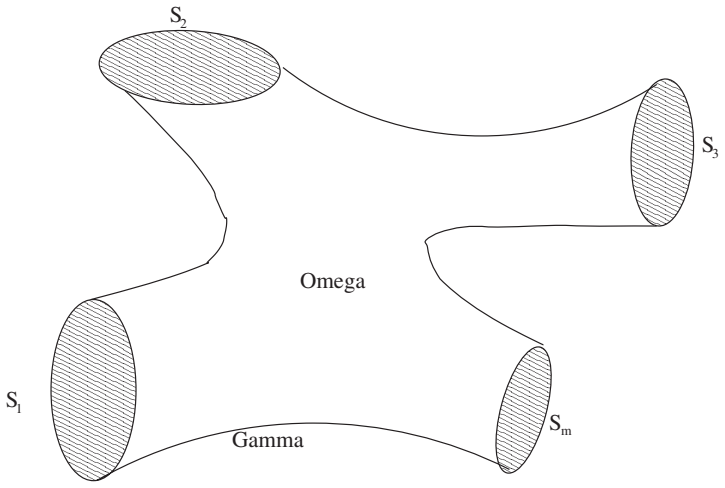

FIG. 2.1. *Illustration of the flow domain.*

We are interested in the numerical approximation of

$$\sigma = g(\mathbf{u}) \text{ in } \Omega, \tag{2.1}$$

$$-\nabla \cdot \sigma + \nabla p = \mathbf{f} \text{ in } \Omega, \tag{2.2}$$

$$\nabla \cdot \mathbf{u} = 0 \text{ in } \Omega, \tag{2.3}$$

$$\mathbf{u} = 0 \text{ on } \Gamma, \tag{2.4}$$

subject to the specified flow rates across the surfaces S_i:

$$\int_{S_i} \mathbf{u} \cdot \mathbf{n}\, ds = Q_i \text{ for } i = 1, \ldots, m. \tag{2.5}$$

We use $\mathbf{n}$ to denote the outward (from Ω) normal to the surface.

Because of the incompressibility condition (2.3) it follows that

$$\sum_{i=1}^{m} Q_i = 0. \tag{2.6}$$

Note that (2.1)–(2.5) can only determine the pressure p up to an arbitrary constant. Below, we fix this constant by requiring p to have mean value 0 over Ω.

The general form of the (algebraic) constitutive equation we assume in our analysis (see A1, A2, A3, in section 2.2) is motivated by the study of fluids having a *power law* constitutive equation, i.e.,

$$\sigma = \nu_0 |d(\mathbf{u})|^{r-2} d(\mathbf{u}), \quad \nu_0 > 0, \quad 1 < r < 2, \tag{2.7}$$

where σ denotes the extra stress tensor, $\mathbf{u}$ the fluid velocity, and $d(\mathbf{u}) := (\nabla \mathbf{u} + \nabla \mathbf{u}^T)/2$ the rate of deformation tensor.

The power law model has been used to model the viscosity of many polymeric solutions and melts over a considerable range of shear rates [11].

Other constitutive equations having a similar form to the power law model include [3, 14, 15]:

(i) *Ladyzhenskaya law* [13]

$$\sigma = \nu_0 + \nu_1 |\nabla \mathbf{u}|^{r-2} d(\mathbf{u}), \quad \nu_0 \geq 0, \nu_1 > 0, r > 1, \tag{2.8}$$

used in modeling fluids with large stresses; and

(ii) *Carreau law*

$$\sigma = \nu_0 \left(1 + |d(\mathbf{u})|^2\right)^{(r-2)/2} d(\mathbf{u}), \quad \nu_0 > 0, r \geq 1, \tag{2.9}$$

used in modeling viscoplastic flows and creeping flow of metals.

2.2. Notation/assumptions. We made the following assumptions regarding the constitutive equation (2.1) for the stress σ:

A1. $g(\mathbf{u})$ is (formally) uniquely invertible to obtain

$$d(\mathbf{u}) = \breve{g}(\sigma)\sigma, (\text{ or } \nabla \mathbf{u} = \breve{g}(\sigma)\sigma)$$

and the inverse is continuous. For $G(\sigma) := \breve{g}(\sigma)\sigma$,

A2.

$$(G(s) - G(t)) : (s - t) \geq c|s - t|^{r'} \qquad \forall s, t \in \mathbb{R}^{\acute{d} \times \acute{d}}, \tag{2.10}$$

A3.

$$|G(s) - G(t)| \leq M\left(|s| + |t|\right)^{r'-2}|s-t|, \qquad \forall s,t \in \mathbb{R}^{\acute{d}\times\acute{d}}. \tag{2.11}$$

For $r \in \mathbb{R}, r > 1$, we denote its unitary conjugate by r', satisfying $r^{-1} + r'^{-1} = 1$.

For problems of physical interest, $1 < r \leq 2$, e.g., shear thinning fluids. We therefore assume that $1 < r \leq 2$ and, consequently, $2 \leq r' < \infty$.

Properties A2 and A3 imply that $G(\cdot)$ is strongly monotone and Lipschitz continuous for bounded arguments [4].

We remark that differential constitutive models for viscoelastic fluids, such as the Oldroyd-B or Giesekus models, do not satisfy A1–A3.

Used in the analysis below are the following function spaces and norms:

$$T := \left(L^{r'}(\Omega)\right)^{\acute{d}\times\acute{d}}_{sym} = \left\{\tau = (\tau_{ij}); \tau_{ij} = \tau_{ji}; \tau_{ij} \in L^{r'}(\Omega); i,j = 1,\ldots,\acute{d}\right\},$$

with norm $\|\tau\|_T := (\int_\Omega |\tau|^{r'} d\Omega)^{1/r'}$, and

$$X := \left\{\mathbf{v} \in \left(W^{1,r}(\Omega)\right)^{\acute{d}} : \mathbf{v}|_\Gamma = \mathbf{0}\right\},$$

with $W^{k,p}(\Omega)$ denoting the usual Sobolev space notation. We take for the norm on X, $\|v\|_X := \left(\int_\Omega |d(\mathbf{v})|^r d\Omega\right)^{1/r}$, which is equivalent to the usual $\|\cdot\|_{W^{1,r}}$ norm by the Poincaré–Friedrichs lemma:

$$P := L^{r'}_0(\Omega) = \left\{q \in L^{r'}(\Omega) : \int_\Omega q d\Omega = 0\right\},$$

with norm $\|q\|_P := (\int_\Omega |q|^{r'} d\Omega)^{1/r'}$.

We use V_X to denote the subspace of X defined by

$$V_X := \left\{\mathbf{v} \in X : \int_\Omega q\nabla\cdot\mathbf{v} d\Omega + \sum_{i=1}^m \beta_i \int_{S_i} \mathbf{v}\cdot\mathbf{n} ds = 0 \ \forall (q,\beta) \in P \times \mathbb{R}^m\right\}$$

and let

$$V_T := \left\{\tau \in T : \int_\Omega \tau : d(\mathbf{v}) d\Omega = 0 \ \forall \mathbf{v} \in V_X\right\}.$$

For a Banach space Y, Y' denotes its dual space with associated norm $\|\cdot\|_{Y'}$. For σ, τ tensors and $\mathbf{u}$, $\mathbf{v}$ vectors, we use : and $\cdot$ to denote the scalar quantities $\sigma : \tau := \sum_{i=1}^{\acute{d}}\sum_{j=1}^{\acute{d}} \sigma_{ij}\tau_{ij}$ and $\mathbf{u}\cdot\mathbf{v} := \sum_{i=1}^{\acute{d}} \mathbf{u}_i\mathbf{v}_i$, respectively. We use $(\cdot,\cdot)$ to denote the L^2 inner product for functions (scalar, vector, or tensor) over Ω and $\langle\cdot,\cdot\rangle$ to denote the duality pairing between a function space and its dual space.

2.3. Lagrange multiplier approach. We consider the following variational formulation to (2.1)–(2.5): *Given* $\mathbf{f} \in X'$, $Q \in \mathbb{R}^m$, *determine* $(\sigma,\mathbf{u},p,\lambda) \in T \times X \times P \times \mathbb{R}^m$, *such that*

$$a(\sigma,\tau) - b(\tau,\mathbf{u}) = 0 \quad \forall \tau \in T, \tag{2.12}$$

$$b(\sigma,\mathbf{v}) - s(\mathbf{v},(p,\lambda)) = \langle \mathbf{f},\mathbf{v}\rangle \quad \forall \mathbf{v} \in X, \tag{2.13}$$

$$s(\mathbf{u},(q,\beta)) = \sum_{i=1}^m Q_i\beta_i \quad \forall (q,\beta) \in P \times \mathbb{R}^m, \tag{2.14}$$

where

$$a(\sigma,\tau) := \int_\Omega \breve{g}(\sigma)\sigma : \tau d\Omega, \tag{2.15}$$

$$b(\tau,\mathbf{u}) := \int_\Omega \tau : d(\mathbf{u})d\Omega, \tag{2.16}$$

$$s(\mathbf{v},(p,\lambda)) := \int_\Omega p\nabla\cdot\mathbf{v}d\Omega + \sum_{i=1}^m \lambda_i \int_{S_i} \mathbf{v}\cdot\mathbf{n}ds. \tag{2.17}$$

The *Lagrange multiplier* $\lambda \in \mathbb{R}^m$ is introduced to include the flow constraints (2.5) in the variational formulation, see [1, 6, 10].

Equivalence of the differential equations and variational formulations. The variational formulation is obtained by multiplying the differential equations by sufficiently smooth functions, integrating over the domain, and, where appropriate, applying Green's theorem. The constraint equations are imposed weakly using Lagrange multipliers. For a smooth solution the steps used in deriving the variational equations can be reversed to show that (2.1)–(2.5) are satisfied. In addition we have that a smooth solution of (2.12)–(2.14) satisfies the following additional boundary conditions (see [6]).

For $\mathbf{n}$ the outward normal on S_i, express the extra stress vector on S_i, $\sigma\cdot\mathbf{n}$, as

$$\sigma\cdot\mathbf{n} = s_n\mathbf{n} + \mathbf{s}_T,$$

where $s_n = (\sigma\cdot\mathbf{n})\cdot\mathbf{n}$ and $\mathbf{s}_T = \sigma\cdot\mathbf{n} - s_n\mathbf{n}$. The scalar s_n represents the magnitude of the extra stress in the outward normal direction to S_i, and $\mathbf{s}_T$ is the component of the extra stress vector which lies in the plane of S_i.

LEMMA 2.1. *Any smooth solution of* (2.12)–(2.14) *satisfies the additional boundary conditions*

$$-p + s_n|_{S_i} = \lambda_i \text{ and } \mathbf{s}_T|_{S_i} = \mathbf{0}, \quad i = 1,\dots,m. \tag{2.18}$$

Proof. The proof follows as in [6]. □

Remark. The equations (2.1)–(2.5) do not uniquely define a solution but rather a set of solutions. The variational formulation (2.12)–(2.14) chooses a solution from the solution set. Specifically, (2.12)–(2.14) chooses *the solution* which satisfies (2.18). A different variational formulation may result in a different selection for *the solution* from the solution set. (See, for example, [6].)

Unique solvability of (2.12)–(2.14). There are two main steps in showing that (2.12)–(2.14) is uniquely solvable. Step 1 involves showing that the (2.12)–(2.14) can be reduced to an equivalent problem involving only σ. Step 2 demonstrates that the stress is uniquely solvable. Used in step 1 is the following lemma.

LEMMA 2.2 (see [9, Remark 4.2, p. 61]). *Let* $(X,\|\cdot\|_X)$ *and* $(M,\|\cdot\|_M)$ *be two reflexive Banach spaces. Let* $(X',\|\cdot\|_{X'})$ *and* $(M',\|\cdot\|_{M'})$ *be their corresponding dual spaces. Let* $B : X \to M'$ *be a linear continuous operator and* $B' : M'' \to X'$ *the dual operator of* B. *Let* $V = ker(B)$ *be the kernel of* B; *we denote by* $V^o \subset X'$ *the polar set of* $V : V^o = \{x' \in X', \langle x', v\rangle = 0\ \forall v \in V\}$ *and* $\dot{B} : X/V \to M'$ *the quotient operator associated with* B. *The following three properties are equivalent:*

(i) $\exists c > 0$ *such that*

$$\inf_{q\in M}\sup_{v\in X}\frac{\langle Bv,q\rangle}{\|q\|_M\|v\|_X} \geq c;$$

(ii) *B' is an isomorphism from M'' onto V^o and*

$$\|B'q\|_{X'} \geq C_B\|q\|_{M''} \ \forall q \in M'';$$

(iii) *$\dot{B}$ is an isomorphism from X/V onto M' and*

$$\|\dot{B}\dot{v}\|_{M'} \geq C_B\|\dot{v}\|_{X/V} \ \forall \dot{v} \in X/V.$$

As the first part of step 1, we show that (p, λ) can be eliminated from (2.12)–(2.14). To do this we use the following *inf-sup* condition. (See also [18].)

LEMMA 2.3. *There exists $C_{PRX} > 0$ such that*

$$\inf_{(q,\beta)\in P\times\mathbb{R}^m} \sup_{\mathbf{u}\in X} \frac{s(\mathbf{u},(q,\beta))}{\|\mathbf{u}\|_X\|(q,\beta)\|_{P\times\mathbb{R}^m}} \geq C_{PRX}, \tag{2.19}$$

where $\|(q,\beta)\|_{P\times\mathbb{R}^m} := \|q\|_P + \|\beta\|_{\mathbb{R}^m}$.

Proof. Fix $(q,\beta) \in P \times \mathbb{R}^m$, and let

$$\hat{q} = \frac{|q|^{r'/r-1}q}{\|q\|_P^{r'-1}}, \quad \hat{\beta} = \frac{\beta}{\|\beta\|_{\mathbb{R}^m}}. \tag{2.20}$$

Note that $(q,\hat{q}) = \|q\|_P$, $\|\hat{q}\|_{P'} = 1$, $\hat{\beta}\cdot\beta = \|\beta\|_{\mathbb{R}^m}$, and $\|\hat{\beta}\|_{\mathbb{R}^m} = 1$.

Next, we introduce $\delta \in \mathbb{R}$ and $h \in W^{1-1/r,r}(\partial\Omega)$, a piecewise constant function, defined by

$$h = \begin{cases} \hat{\beta}_i/\mathtt{meas}(S_i) & \text{on} \quad S_i, i = 1,\dots,m, \\ 0 & \text{on} \quad \Gamma, \end{cases} \tag{2.21}$$

$$\delta = \left(\int_{\partial\Omega} h ds - \int_\Omega \hat{q} d\Omega\right)/\mathtt{meas}(\Omega). \tag{2.22}$$

From [7, p. 127], given $f \in L^r(\Omega), \mathbf{a} \in W^{1-1/r,r}(\partial\Omega), 1 < r < \infty$, satisfying

$$\int_\Omega f d\Omega = \int_{\partial\Omega} \mathbf{a}\cdot\mathbf{n} ds, \tag{2.23}$$

there exists $\mathbf{v} \in W^{1,r}(\Omega)$ such that

$$\nabla\cdot\mathbf{v} = f \text{ in } \Omega, \tag{2.24}$$

$$\mathbf{v} = \mathbf{a} \text{ on } \partial\Omega, \tag{2.25}$$

$$\text{with } \|\mathbf{v}\|_{W^{1,r}(\Omega)} \leq C\left(\|f\|_{L^r(\Omega)} + \|\mathbf{a}\|_{W^{1-1/r,r}(\partial\Omega)}\right). \tag{2.26}$$

Let $f = \hat{q} + \delta$, and, for $\{\mathbf{n}, \mathbf{t}_i, i = 1,\dots \acute{d}-1\}$ denoting an orthonormal system on $\partial\Omega$, let $\mathbf{a}$ be defined by

$$\begin{cases} \mathbf{a}\cdot\mathbf{n} &= h, \\ \mathbf{a}\cdot\mathbf{t}_i &= 0,\ i = 1,\dots \acute{d}-1. \end{cases}$$

Remark. The choice of the constant δ guarantees that the compatibility condition $\int_\Omega f d\Omega = \int_{\partial\Omega} \mathbf{a}\cdot\mathbf{n} ds$ is satisfied.

We have that

$$\|\hat{q}\|_{W^{0,r}(\Omega)} = 1 \text{ (by construction)}, \tag{2.27}$$

$$\|\mathbf{a}\|_{W^{1-1/r,r}(\partial\Omega)} \leq C_1\|\hat{\beta}\|_{\mathbb{R}^m} = C_1 \tag{2.28}$$

(by the equivalence of finite dimensional norms).

Also,

$$\int_\Omega \hat{q} d\Omega \leq \|\hat{q}\|_{P'} \|1\|_P = C_2, \tag{2.29}$$

$$\int_{\partial\Omega} h ds \leq \|\hat{\beta}\|_{\mathbb{R}^m} \|\mathbf{1}\|_{\mathbb{R}^m} = C_3, \tag{2.30}$$

and thus $\|\delta\|_{W^{0,r}(\Omega)} \leq C_4$.

With $\mathbf{u}$ denoting the solution of (2.24)–(2.26), we have that $\mathbf{u} \in X$ and satisfies

$$\|\mathbf{u}\|_{W^{1,r}(\Omega)} \leq C(1 + C_4 + C_1) \leq C_5. \tag{2.31}$$

Hence,

$$\begin{aligned} s(\mathbf{u}, (q, \beta)) &= (\nabla \cdot \mathbf{u}, q) + \sum_{i=1}^m \beta_i \int_{S_i} \mathbf{u} \cdot \mathbf{n} ds \\ &= (\hat{q} + \delta, q) + \hat{\beta} \cdot \beta \\ &= \|q\|_P + \|\beta\|_{\mathbb{R}^m} \\ &= \|(q, \beta)\|_{P \times \mathbb{R}^m}, \end{aligned}$$

as $(\delta, q) = 0$ for $q \in P (= L_0^{r'}(\Omega))$. Thus,

$$\sup_{\mathbf{u} \in X} \frac{s(\mathbf{u}, (q, \beta))}{\|(q, \beta)\|_{P \times \mathbb{R}^m} \|\mathbf{u}\|_{W^{1,r}(\Omega)}} \geq \frac{1}{C_5},$$

from which (2.19) directly follows. ∎

We now state and prove the existence and the uniqueness of the solution to (2.12)–(2.14).

THEOREM 2.1. *Given $\mathbf{f} \in X'$ and $Q \in \mathbb{R}^m$, there exists a unique $(\sigma, \mathbf{u}, p, \lambda) \in T \times X \times P \times \mathbb{R}^m$ satisfying* (2.12)–(2.14).

Proof. From Lemmas 2.3 and 2.2(i), (iii), with the associations $X = X$, $M = P \times \mathbb{R}^m$, $B : X \to (P \times \mathbb{R}^m)'$ defined by

$$B(\mathbf{v}) := s(\mathbf{v}, (\cdot, \cdot)),$$

$V = ker(B)$, we have that there exists $\dot{\mathbf{u}} \in X/V$ such that

$$s(\dot{\mathbf{u}}, (q, \beta)) = \sum_{i=1}^m Q_i \beta_i \quad \forall (q, \beta) \in P \times \mathbb{R}^m,$$

with $\|\dot{\mathbf{u}}\|_{X/V} \leq 1/C_s \|Q\|_{\mathbb{R}^m}$.

Note: $\|\dot{\mathbf{u}}\|_{X/V} := \inf_{\mathbf{v} \in \dot{\mathbf{u}}} \|\mathbf{v}\|_X$.

As the cosets in X/V are closed, we can choose $\mathbf{u}_s \in \dot{\mathbf{u}}$ such that

$$\|\mathbf{u}_s\|_X = \|\dot{\mathbf{u}}\|_{X/V} \leq 1/C_s \|Q\|_{\mathbb{R}^m}. \tag{2.32}$$

Let $\mathbf{u} = \tilde{\mathbf{u}} + \mathbf{u}_s$. Then, solving (2.12)–(2.14) is equivalent to: *Find $\sigma \in X, \tilde{\mathbf{u}} \in V_X$, such that*

$$a(\sigma, \tau) - b(\tau, \tilde{\mathbf{u}}) = b(\tau, \mathbf{u}_s) \quad \forall \tau \in T, \tag{2.33}$$

$$b(\sigma, \mathbf{v}) = \langle \mathbf{f}, \mathbf{v} \rangle \quad \forall \mathbf{v} \in V_X. \tag{2.34}$$

Now note that, for $\mathbf{v} \in X$ and $\tau = |d(\mathbf{v})|^{r-2}d(\mathbf{v}) \in T$, $\|\tau\|_T = \|\mathbf{v}\|_X^{r/r'}$ and

$$\frac{b(\tau, \mathbf{v})}{\|\tau\|_T} = \frac{\|\mathbf{v}\|_X^r}{\|\mathbf{v}\|_X^{r/r'}} = \|\mathbf{v}\|_X.$$

Thus

$$\inf_{\mathbf{v}\in X} \sup_{\tau \in T} \frac{b(\tau, \mathbf{v})}{\|\tau\|_T \|\mathbf{v}\|_X} \geq 1, \tag{2.35}$$

i.e., $b(\tau, \mathbf{v})$ satisfies an inf-sup condition over $X \times T$.

As above, there exists $\sigma_b \in T$ such that

$$\begin{aligned} b(\sigma_b, \mathbf{v}) &= \langle \mathbf{f}, \mathbf{v} \rangle \quad \forall \mathbf{v} \in X, \\ \text{with } \|\sigma_b\|_T &\leq \frac{1}{C_b}\|\mathbf{f}\|_{X'}. \end{aligned} \tag{2.36}$$

Let $\sigma = \tilde{\sigma} + \sigma_b$. Then, solving (2.33), (2.34) is equivalent to: *Find $\tilde{\sigma} \in V_T$, such that*

$$a(\tilde{\sigma} + \sigma_b, \tau) = b(\tau, \mathbf{u}_s) \quad \forall \tau \in V_T. \tag{2.37}$$

From assumptions A2 and A3 we have that $G(\tau) : V_T \to V_T'$ is a continuous, coercive, strictly monotone operator on a real, separable, reflexive Banach space [16]. Hence, there exists a unique $\tilde{\sigma} \in V_T$ satisfying (2.37). This then also uniquely determines $\sigma \in T$.

The inf-sup condition (2.35), together with (2.33), uniquely determines $\tilde{\mathbf{u}} \in V_X$ and hence also $\mathbf{u} = \tilde{\mathbf{u}} + \mathbf{u}_s \in X$.

Finally, the inf-sup condition (2.19) and the equation (2.13) uniquely determine $p \in P$ and $\lambda \in \mathbb{R}^m$. ∎

We now establish a bound for $\|\sigma\|_T$, which we use below in section 4 in deriving a priori estimates for the numerical approximation. Estimates for $\mathbf{u}$, p, and λ can also be derived.

COROLLARY 2.1. *For $\sigma \in T$ satisfying* (2.12)–(2.14) *we have that there exists $C > 0$ such that*

$$\|\sigma\|_T \leq C(\|\mathbf{f}\|_{X'} + \|Q\|_{\mathbb{R}^m}^{r/r'}). \tag{2.38}$$

Proof. From (2.37), with the choice $\tau = \tilde{\sigma}$, we have

$$\begin{aligned} a(\tilde{\sigma} + \sigma_b, \tilde{\sigma}) &= b(\tilde{\sigma}, \mathbf{u}_s) \\ &\leq 2^{-r'}\epsilon\|\tilde{\sigma}\|_T^{r'} + C\|\mathbf{u}_s\|_X^r \\ &\leq 2^{-r'}\epsilon\left(\|\tilde{\sigma} + \sigma_b\|_T + \|\sigma_b\|_T\right)^{r'} + C\|\mathbf{u}_s\|_X^r \\ &\leq \epsilon\|\tilde{\sigma} + \sigma_b\|_T^{r'} + \epsilon\|\sigma_b\|_T^{r'} + C\|\mathbf{u}_s\|_X^r. \end{aligned} \tag{2.39}$$

Using assumption (2.10),

$$\begin{aligned} a(\tilde{\sigma} + \sigma_b, \tilde{\sigma}) &= \int_\Omega \breve{g}(\tilde{\sigma} + \sigma_b)(\tilde{\sigma} + \sigma_b) : \tilde{\sigma} d\Omega \\ &= \int_\Omega \breve{g}(\tilde{\sigma} + \sigma_b)(\tilde{\sigma} + \sigma_b) : (\tilde{\sigma} + \sigma_b) - \int_\Omega \breve{g}(\tilde{\sigma} + \sigma_b)(\tilde{\sigma} + \sigma_b) : \sigma_b d\Omega \\ &\geq \int_\Omega c|\tilde{\sigma} + \sigma_b|^{r'} d\Omega - \|G(\tilde{\sigma} + \sigma_b)\|_{L^r}\|\sigma_b\|_T \\ &\geq c\|\tilde{\sigma} + \sigma_b\|_T^{r'} - \frac{c}{2M^r}\|G(\tilde{\sigma} + \sigma_b)\|_{L^r}^r - C\|\sigma_b\|_T^{r'}. \end{aligned} \tag{2.40}$$

We use (2.11) to estimate the second term on the right-hand side (RHS) of (2.40):

$$\begin{aligned}\|G(\tilde{\sigma}+\sigma_b)\|_{L^r}^r = \int_\Omega |G(\tilde{\sigma}+\sigma_b)|^r d\Omega &\leq M^r \int_\Omega \left((|\tilde{\sigma}+\sigma_b|+0)^{r'-2} |\tilde{\sigma}+\sigma_b - 0| \right)^r d\Omega \\ &= M^r \int_\Omega |\tilde{\sigma}+\sigma_b|^{(r'-1)r} d\Omega \\ &= M^r \int_\Omega |\tilde{\sigma}+\sigma_b|^{r'} d\Omega \\ &= M^r \|\tilde{\sigma}+\sigma_b\|_T^{r'}. \end{aligned} \tag{2.41}$$

Combining (2.39)–(2.41) we have that

$$\left(\frac{c}{2}-\epsilon\right) \|\tilde{\sigma}+\sigma_b\|_T^{r'} \leq C \left(\|\sigma_b\|_T^{r'} + \|\mathbf{u}_s\|_X^r \right).$$

As $\sigma = \tilde{\sigma} + \sigma_b$, and using the estimates (2.32) and (2.36), we obtain (2.38). ∎

3. Discrete approximation. We now describe the discrete approximation problem corresponding to (2.12)–(2.14) and show that the problem is well-defined. Analogous to the continuous problem the existence and the uniqueness for the discrete problem rely on the approximating spaces satisfying suitable inf-sup conditions.

We begin by describing the finite element approximation framework used in the analysis.

Let $\Omega \subset \mathbb{R}^{\acute{d}} (\acute{d} = 2, 3)$ be a polygonal domain, and let $\mathcal{T}_h$ be a triangulation of Ω made of triangles (in $\mathbb{R}^2$) or tetrahedrals (in $\mathbb{R}^3$). Thus, the computational domain is defined by

$$\Omega = \cup K; \quad K \in T_h.$$

We assume that there exist constants c_1, c_2 such that

$$c_1 h \leq h_K \leq c_2 \rho_K,$$

where h_K is the diameter of triangle (tetrahedral) K, ρ_K is the diameter of the greatest ball (sphere) included in K, and $h = \max_{K \in \mathcal{T}_h} h_K$. Let $P_k(A)$ denote the space of polynomials on A of degree no greater than k. Then we define the finite element spaces as follows:

$$T_h := \left\{ \tau \in T \cap C(\bar{\Omega})^{2\times 2} : \tau|_K \in P_l(K) \; \forall K \in \mathcal{T}_h \right\}, \tag{3.1}$$

$$X_h := \left\{ \mathbf{v} \in X \cap C(\bar{\Omega})^2 : \mathbf{v}|_K \in P_k(K) \; \forall K \in \mathcal{T}_h \right\}, \tag{3.2}$$

$$P_h := \left\{ q \in P \cap C(\bar{\Omega}) : q|_K \in P_n(K) \; \forall K \in \mathcal{T}_h \right\}. \tag{3.3}$$

We assume that the velocity-stress and the pressure-velocity spaces satisfy the following (typical) discrete inf-sup condition: *There exist constants C_{XTh}, $C_{PXh} > 0$ such that*

$$\inf_{\mathbf{v} \in X_h} \sup_{\tau \in T_h} \frac{b(\tau, \mathbf{v})}{\|\tau\|_T \|\mathbf{v}\|_X} \geq C_{XTh}, \tag{3.4}$$

$$\inf_{q \in P_h} \sup_{\mathbf{v} \in X_h} \frac{\int_\Omega q \nabla \cdot \mathbf{v} dA}{\|q\|_P \|\mathbf{v}\|_X} \geq C_{PXh}. \tag{3.5}$$

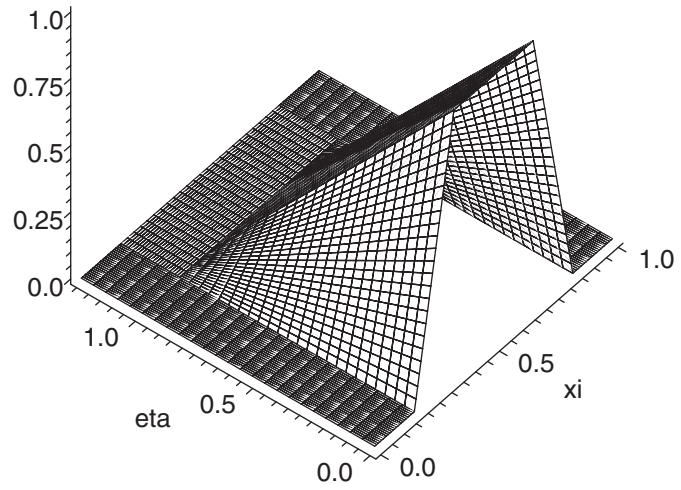

FIG. 3.1. *Plot of* g_i/β_i.

Discrete approximation problem. Given $\mathbf{f} \in X'$, and $Q \in \mathbb{R}^m$, determine $(\sigma_h, \mathbf{u}_h, p_h, \lambda_h) \in T_h \times X_h \times P_h \times \mathbb{R}^m$ such that

$$a(\sigma_h, \tau_h) - b(\tau_h, \mathbf{u}_h) = 0 \quad \forall \tau_h \in T_h, \tag{3.6}$$

$$b(\sigma_h, \mathbf{v}_h) - s(\mathbf{v}_h, (p_h, \lambda_h)) = \langle \mathbf{f}, \mathbf{v}_h \rangle \quad \forall \mathbf{v}_h \in X_h, \tag{3.7}$$

$$s(\mathbf{u}_h, (q_h, \beta_h)) = \sum_{i=1}^{m} Q_i \beta_i \quad \forall (q_h, \beta_h) \in P_h \times \mathbb{R}^m. \tag{3.8}$$

For the analysis a more general inf-sup condition than that given in (3.5) is needed. This is established using the following two lemmas. (See also [18].)

LEMMA 3.1. *There exists* $C_{RXh} > 0$ *such that*

$$\inf_{\beta \in \mathbb{R}^m} \sup_{\mathbf{v}_h \in X_h} \frac{\sum_{i=1}^{m} \beta_i \int_{S_i} \mathbf{v}_h \cdot \mathbf{n} ds}{\|\mathbf{v}_h\|_X \|\beta\|_{\mathbb{R}^m}} \geq C_{RXh}. \tag{3.9}$$

Outline of proof. From inspection of (3.9) we see that we would like to choose $\mathbf{v}_h \in X_h$ such that $\mathbf{v}_h \cdot \mathbf{n} = \beta_i$ on each S_i, and $\|\mathbf{v}_h\|_X \leq c\|\beta\|_{\mathbb{R}^m}$. This is done by constructing a suitable $\mathbf{v}_{h,i}$, with $\mathbf{v}_{h,i}|_{S_j} = \mathbf{0}, j \neq i$, and then letting $\mathbf{v}_h = \sum_i \mathbf{v}_{h,i}$.

We focus our attention on a single S_i. We will assume that on S_i, $\mathbf{n}(x) \cdot \mathbf{n}(y) \geq c > 0$ at all points $x, y \in S_i$ for which $\mathbf{n}$ is defined. (That is, on S_i the normal $\mathbf{n}$ does not vary by more than 90 degrees. If the normal does vary by more than 90 degrees, consider the surface as two surfaces.)

For ease of explanation, consider S_i as a straight line segment from $(0,0)$ to $(|S_i|, 0)$. Fix a *depth* d_i such that the rectangle $\mathcal{R}$ with vertices $(|S_i|/6, 0)$, $(5|S_i|/6, 0)$, $(5|S_i|/6, d_i)$, $(|S_i|/6, d_i)$ lies in Ω. Introduce the labeling of the following points: $A := (|S_i|/6, 0)$, $B := (5|S_i|/6, 0)$, $C := (5|S_i|/6, d_i)$, $D := (|S_i|/6, d_i)$, $E := (|S_i|/3, 0)$, $F := (2|S_i|/3, 0)$, $G := (2|S_i|/3, d_i)$, and $H := (|S_i|/3, d_i)$.

Let $\tilde{\mathbf{n}} = \mathbf{n}|_{(|S_i|/2,0)}$ and g_i be the continuous, piecewise bilinear, function defined by $g_i|_{E,F} = \beta_i$, and $g_i|_{A,B,C,D,G,H} = 0$. (See Figure 3.1. In Figure 3.1, xi $= x/|S_i|$, and eta $= y/d$.).

We define the function $\tilde{\mathbf{v}}_i$ as $\tilde{\mathbf{v}}_i|_{\Omega\setminus\mathcal{R}} = \mathbf{0}$, and $\tilde{\mathbf{v}}_i|_{\mathcal{R}} = g_i\tilde{\mathbf{n}}$. Then

$$\beta_i \int_{S_i} \tilde{\mathbf{v}}_i \cdot \mathbf{n} ds = \beta_i \int_E^F (\beta_i \tilde{\mathbf{n}}) \cdot \mathbf{n} ds \geq c_i \beta_i^2 |S_i|/3.$$

Also,

$$\begin{aligned}\|\tilde{\mathbf{v}}_i\|_X &= \left(\int_{\mathcal{R}} |\tilde{\mathbf{v}}_i|^r dA + \int_{\mathcal{R}} |\nabla \tilde{\mathbf{v}}_i|^r dA \right)^{1/r} \\ &= |\beta_i| \left((r+2) d_i |S_i|/(3(r+1)^2) + 6^{r-2} 2 d_i/(|S_i|^{r-1}(r+1)) \right. \\ &\qquad \left. + (6r+7)|S_i|/(18(r+1)d_i^{r-1}) \right)^{1/r}.\end{aligned}$$

Now there exists h_0 such that for all $h \leq h_0$ there exists $\mathbf{v}_{h,i} \in \mathcal{T}_h$ such that $\|\tilde{\mathbf{v}}_i - \mathbf{v}_{h,i}\|_\infty \leq c_i\beta_i/6$ and $\|\tilde{\mathbf{v}}_i - \mathbf{v}_{h,i}\|_X \leq |\beta_i|$. Then

$$\begin{aligned}\frac{\sum_{i=1}^m \beta_i \int_{S_i} \mathbf{v}_h \cdot \mathbf{n} ds}{\|\mathbf{v}_h\|_X} \geq \frac{\sum_{i=1}^m \beta_i \int_{S_i} \mathbf{v}_{h,i} \cdot \mathbf{n} ds}{\sum_{i=1}^m \|\mathbf{v}_{h,i}\|_X} &\geq \frac{\sum_{i=1}^m \left(\beta_i \int_{S_i} \tilde{\mathbf{v}}_i \cdot \mathbf{n} ds - c_i \beta_i^2 |S_i|/6 \right)}{\sum_{i=1}^m \left(\|\tilde{\mathbf{v}}_i\|_X + \|\tilde{\mathbf{v}}_i - \mathbf{v}_{h,i}\|_X \right)} \\ &\geq \frac{\sum_{i=1}^m c_i \beta_i^2 |S_i|/6}{\sum_{i=1}^m \hat{c}_i |\beta_i|} \geq C\|\beta\|,\end{aligned}$$

from which (3.9) then follows. □

LEMMA 3.2. *For h sufficiently small, there exists $C_{PRXh} > 0$ such that*

$$\inf_{(q_h,\beta)\in P_h\times\mathbb{R}^m} \sup_{\mathbf{v}_h \in X_h} \frac{s(\mathbf{v}_h, (q_h,\beta))}{\|\mathbf{v}_h\|_X \|(q,\beta)\|_{P\times\mathbb{R}^m}} \geq C_{PRXh}. \tag{3.10}$$

Proof. Let $(p_h, \beta) \in P_h \times \mathbb{R}^m$. From Lemma 3.1, there exists $\hat{\mathbf{u}}_h \in X_h$ such that

$$\|\hat{\mathbf{u}}_h\|_X = \|\beta\|_{\mathbb{R}^m} \quad \text{and} \quad \frac{\sum_{i=1}^m \beta_i \int_{S_i} \hat{\mathbf{u}}_h \cdot \mathbf{n} ds}{\|\hat{\mathbf{u}}_h\|_X} \geq c_1 \|\beta\|_{\mathbb{R}^m}. \tag{3.11}$$

Let $X_h^0 := \{\mathbf{v}_h \in X_h : \mathbf{v}_h|_{\partial\Omega} = \mathbf{0}\}$, and consider the (discrete) power law problem: *Determine $\tilde{\mathbf{u}}_h \in X_h^0, \tilde{p}_h \in P_h$ such that*

$$(|d(\tilde{\mathbf{u}}_h)|^{r-2} d(\tilde{\mathbf{u}}_h), d(\mathbf{v})) - (\tilde{p}_h, \nabla \cdot \mathbf{v}) = 0 \quad \forall \mathbf{v} \in X_h^0, \tag{3.12}$$

$$(q, \nabla \cdot \tilde{\mathbf{u}}_h) = (q, \|p_h\|_P^{1-r'/r} |p_h|^{r'/r-1} p_h - \nabla \cdot \hat{\mathbf{u}}_h) \quad \forall q \in P_h. \tag{3.13}$$

Note that $\|p_h\|_P^{1-r'/r} |p_h|^{r'/r-1} p_h - \nabla \cdot \hat{\mathbf{u}}_h \in L^r(\Omega)$.

The existence and the uniqueness of $\tilde{\mathbf{u}}_h \in X_h^0, \tilde{p}_h \in P_h$ satisfying (3.12), (3.13) follow analogous to the proof of Theorem 2.1. (See also [9, 2]).

From (3.12), (3.13) with the choices $\mathbf{v} = \tilde{\mathbf{u}}_h$ and $q = \tilde{p}_h$,

$$\begin{aligned}\|\tilde{\mathbf{u}}_h\|_X^r = (|d(\tilde{\mathbf{u}}_h)|^{r-2} d(\tilde{\mathbf{u}}_h), d(\tilde{\mathbf{u}}_h)) &= (\tilde{p}_h, \nabla \cdot \tilde{\mathbf{u}}_h) \\ &= (\tilde{p}_h, \|p_h\|_P^{1-r'/r} |p_h|_P^{r'/r-1} p_h - \nabla \cdot \hat{\mathbf{u}}_h) \\ &\leq \|\tilde{p}_h\|_P \left(\|p_h\|_P^{1-r'/r} \| |p_h|_P^{r'/r-1} p_h \|_{L^r} + \|\nabla \cdot \hat{\mathbf{u}}_h\|_{L^r} \right) \\ &\leq \|\tilde{p}_h\|_P \left(\|p_h\|_P + C\|\hat{\mathbf{u}}_h\|_X \right) \\ &= \|\tilde{p}_h\|_P \left(\|p_h\|_P + \|\beta\|_{\mathbb{R}^m} \right). \qquad (3.14)\end{aligned}$$

Also, from the inf-sup condition for spaces X_h^0 and P_h we have

$$\begin{aligned} c\|\tilde{p}_h\|_P &\le \sup_{\mathbf{v}\in X_h^0} \frac{(\tilde{p}_h, \nabla\cdot\mathbf{v})}{\|\mathbf{v}\|_X} \\ &= \sup_{\mathbf{v}\in X_h^0} \frac{(|d(\tilde{\mathbf{u}}_h)|^{r-2}d(\tilde{\mathbf{u}}_h), d(\mathbf{v}))}{\|\mathbf{v}\|_X} \\ &\le \sup_{\mathbf{v}\in X_h^0} \frac{(\||d(\tilde{\mathbf{u}}_h)|^{r-2}d(\tilde{\mathbf{u}}_h)\|_{L^{r'}}\|d(\mathbf{v})\|_{L^r}}{\|\mathbf{v}\|_X} \\ &= \||d(\tilde{\mathbf{u}}_h)|^{r-2}d(\tilde{\mathbf{u}}_h)\|_{L^{r'}} \\ &= \|\tilde{\mathbf{u}}_h\|_X^{r/r'}. \end{aligned} \tag{3.15}$$

Combining (3.14) and (3.15) we have the estimate

$$\|\tilde{\mathbf{u}}_h\|_X \le \left(\|p_h\|_P + C\|\beta\|_{\mathbb{R}^m}\right). \tag{3.16}$$

Let $\mathbf{u}_h = \tilde{\mathbf{u}}_h + \hat{\mathbf{u}}_h$. Then, using (3.13) and (3.11),

$$\begin{aligned} s(\mathbf{u}_h,(p_h,\beta)) &= \int_\Omega p_h\nabla\cdot\tilde{\mathbf{u}}_h d\Omega + \int_\Omega p_h\nabla\cdot\hat{\mathbf{u}}_h d\Omega + \sum_{i=1}^m \beta_i\int_{S_i}\tilde{\mathbf{u}}_h\cdot\mathbf{n}ds \\ &\quad + \sum_{i=1}^m \beta_i\int_{S_i}\hat{\mathbf{u}}_h\cdot\mathbf{n}ds \\ &= \int_\Omega p_h\|p_h\|_P^{1-r'/r}|p_h|^{r'/r-1}p_h d\Omega + \sum_{i=1}^m \beta_i\int_{S_i}\hat{\mathbf{u}}_h\cdot\mathbf{n}ds \\ &\ge c\left(\|p_h\|_P^2 + \|\beta\|_{\mathbb{R}^m}^2\right). \end{aligned} \tag{3.17}$$

Thus, using (3.11), (3.16), we have

$$\begin{aligned} \sup_{\mathbf{v}_h\in X_h}\frac{s(\mathbf{v}_h,(p_h,\beta))}{\|\mathbf{v}_h\|_X} &\ge \frac{s(\mathbf{u}_h,(p_h,\beta))}{\|\mathbf{u}_h\|_X} \\ &\ge C\left(\|p_h\|_P + \|\beta\|_{\mathbb{R}^m}\right), \end{aligned}$$

from which (3.10) immediately follows. ∎

We now state and prove the existence and the uniqueness of solutions to (3.6)–(3.8).

THEOREM 3.1. *Given $\mathbf{f}\in X'$ and $Q\in\mathbb{R}^m$, there exists a unique $(\sigma_h,\mathbf{u}_h,p_h,\lambda_h)\in T_h\times X_h\times P_h\times\mathbb{R}^m$ satisfying* (3.6)–(3.8). *In addition,*

$$\|\sigma_h\|_T \le C(\|\mathbf{f}\|_{X'} + \|Q\|_{\mathbb{R}^m}^{r/r'}). \tag{3.18}$$

Proof. With the inf-sup conditions given in (3.4) and (3.10) the proof of existence follows exactly as for the continuous problem in Theorem 2.1. Similarly, the norm estimate for σ_h follows as that for σ given in Corollary 2.1. ∎

4. A priori error estimate. In this section we derive an error estimate for the error in the approximation $(\sigma_h,\mathbf{u}_h,p_h,\lambda_h)$ satisfying (3.6)–(3.8) and $(\sigma,\mathbf{u},p,\lambda)$ satisfying (2.12)–(2.14).

The proof of the estimates gives in Theorem 4.1 follows along the same lines as the proofs for the existence and uniqueness, except for the error estimates we work

backwards. The procedure to establish the existence and uniqueness was to reduce the problem to an equivalent problem for σ (or σ_h) on a subspace of the solution space. To obtain the error estimates we begin by considering the determining equations for σ_h, u_h, over a subspace. Using the coercivity and continuity assumptions (2.10), (2.11), an error estimate for $\|\sigma - \sigma_h\|$ over the subspace is constructed. We then show that the estimate over the subspace can be extended to the entire solution space.

Useful in the analysis below is the following inf-sup condition which follows from (3.4) and (3.10).

LEMMA 4.1. *For h sufficiently small, there exists a constant $C_{XTPRh} > 0$ such that*

$$\inf_{\mathbf{v}\in X_h} \sup_{(\tau,q,\beta)\in T_h\times P_h\times\mathbb{R}^m} \frac{b(\tau,\mathbf{v}) - s(\mathbf{v},(q,\beta))}{\|(\tau,q,\beta)\|_{T\times P\times\mathbb{R}^m}\|\mathbf{v}\|_X} \geq C_{XTPRh}, \tag{4.1}$$

where $\|(\tau,q,\beta)\|_{T\times P\times\mathbb{R}^m} := \|\tau\|_T + \|q\|_P + \|\beta\|_{\mathbb{R}^m}$.

Proof. For $\mathbf{v} \in X_h$, from (3.4) there exists τ_v such that

$$b(\tau_v,\mathbf{v}) \geq \frac{C_{XTh}}{2}\|\tau_v\|_T\|\mathbf{v}\|_X. \tag{4.2}$$

We now consider two cases. First, if $s(\mathbf{v},(q,\beta)) = 0$ for all $(q,\beta) \in P_h\times\mathbb{R}^m$, then (4.1) follows immediately from (4.2). Otherwise, from the definition of $s(\mathbf{v},(q,\beta))$, there exists $(q_v,\beta_v) \in P_h \times \mathbb{R}^m$ such that $s(\mathbf{v},(q_v,\beta_v)) < 0$ and $\|(q_v,\beta_v)\|_{P_h\times\mathbb{R}^m} = \|\tau_v\|_T$. Thus,

$$\begin{aligned}\sup_{(\tau,q,\beta)\in T_h\times P_h\times\mathbb{R}^m} \frac{b(\tau,\mathbf{v}) - s(\mathbf{v},(q,\beta))}{\|(\tau,q,\beta)\|_{T\times P\times\mathbb{R}^m}} &\geq \frac{b(\tau_v,\mathbf{v}) - s(\mathbf{v},(q_v,\beta_v))}{\|(\tau_v,q_v,\beta_v)\|_{T\times P\times\mathbb{R}^m}}\\ &\geq \frac{C_{XTh}\|\tau_v\|_T\|\mathbf{v}\|_X}{2(\|\tau_v\|_T + \|\tau_v\|_T)},\end{aligned}$$

from which (4.2) then follows. ∎

THEOREM 4.1. *For $(\sigma,\mathbf{u},p,\lambda)$ satisfying (2.12)–(2.14) and $(\sigma_h,\mathbf{u}_h,p_h,\lambda_h)$ satisfying (3.6)–(3.8), for h sufficiently small, we have that there exists a constant $C > 0$ such that*

$$\begin{aligned}\|\sigma - \sigma_h\|_T^{r'} \leq C\Bigg(&\inf_{\tau_h\in T_h}\left(\|\sigma-\tau_h\|_T^r + \|\sigma-\tau_h\|_T^{r'}\right)\\ &+ \inf_{\mathbf{v}_h\in X_h}\|\mathbf{u}-\mathbf{v}_h\|_X^r + \inf_{q_h\in P_h}\|p-q_h\|_P^{r'}\Bigg),\end{aligned} \tag{4.3}$$

$$\|\mathbf{u}-\mathbf{u}_h\|_X \leq C\left(\|\sigma-\sigma_h\|_T + \inf_{\mathbf{v}_h\in X_h}\|\mathbf{u}-\mathbf{v}_h\|_X\right), \tag{4.4}$$

$$\|p-p_h\|_P + \|\lambda-\lambda_h\|_{\mathbb{R}^m} \leq C\left(\|\sigma-\sigma_h\|_T + \inf_{q_h\in P_h}\|p-q_h\|_P\right). \tag{4.5}$$

Proof. We have that $(\sigma_h,\mathbf{u}_h,p_h,\lambda_h)$ satisfies

$$a(\sigma_h,\tau_h) - b(\tau_h,\mathbf{u}_h) = 0 \quad \forall\tau_h \in T_h, \tag{4.6}$$

$$b(\sigma_h,\mathbf{v}_h) - s(\mathbf{v}_h,(p_h,\lambda_h)) = \langle\mathbf{f},\mathbf{v}_h\rangle \quad \forall\mathbf{v}_h \in X_h, \tag{4.7}$$

$$s(\mathbf{u}_h,(q_h,\beta_h)) = \sum_{i=1}^m Q_i\beta_i \quad \forall(q_h,\beta) \in P_h\times\mathbb{R}^m. \tag{4.8}$$

Introduce the affine subspaces $\tilde{X}_h \subset X_h$, $\tilde{K}_h$ defined by

$$\tilde{X}_h := \left\{ \mathbf{v}_h \in X_h : s(\mathbf{v}_h, (q_h, \beta)) = \sum_{i=1}^{m} Q_i \beta_i \quad \forall (q_h, \beta_h) \in P_h \times \mathbb{R}^m \right\}, \tag{4.9}$$

$$\tilde{K}_h := \{ \tau_h \in T_h : b(\tau_h, \mathbf{v}_h) - s(\mathbf{v}_h, (p_h, \lambda_h)) = \langle \mathbf{f}, \mathbf{v}_h \rangle \quad \forall \mathbf{v}_h \in \tilde{X}_h \}. \tag{4.10}$$

Note that $\sigma_h \in \tilde{K}_h$ and $\mathbf{u}_h \in \tilde{X}_h$.

From (2.10), (2.11) we have

$$\begin{aligned} c\|\sigma - \sigma_h\|_T^{r'} &\le a(\sigma, \sigma - \sigma_h) - a(\sigma_h, \sigma - \sigma_h) \\ &= a(\sigma, \sigma - \tau_h) - a(\sigma_h, \sigma - \tau_h) + a(\sigma, \tau_h - \sigma_h) - a(\sigma_h, \tau_h - \sigma_h) \\ &\le \int_\Omega M(|\sigma| + |\sigma_h|)^{r'-2} |\sigma - \sigma_h||\sigma - \tau_h| d\Omega + a(\sigma, \tau_h - \sigma_h) - a(\sigma_h, \tau_h - \sigma_h). \end{aligned} \tag{4.11}$$

Now, noting that $1 < r \le 2$, and hence $r'/r \ge 1$,

$$\begin{aligned} &\int_\Omega M(|\sigma| + |\sigma_h|)^{r'-2} |\sigma - \sigma_h||\sigma - \tau_h| d\Omega \\ &\quad \le \left(\int_\Omega M^r (|\sigma| + |\sigma_h|)^{(r'-2)r} |\sigma - \tau_h|^r d\Omega \right)^{1/r} \|\sigma - \sigma_h\|_T \\ &\quad \le \epsilon \|\sigma - \sigma_h\|_T^{r'} + C M^r \int_\Omega 2^{(r'-2)r} \left(|\sigma|^{(r'-2)r} + |\sigma_h|^{(r'-2)r} \right) |\sigma - \tau_h|^r d\Omega \\ &\quad \le \epsilon \|\sigma - \sigma_h\|_T^{r'} \\ &\qquad + C \left(\int_\Omega \left(|\sigma|^{(r'-2)r} + |\sigma_h|^{(r'-2)r} \right)^{r'/(r'-r)} d\Omega \right)^{(r'-r)/r'} \left(\int_\Omega |\sigma - \tau_h|^{r'} d\Omega \right)^{r/r'} \\ &\quad \le \epsilon \|\sigma - \sigma_h\|_T^{r'} + C \left(\|\sigma\|_T^{r'} + \|\sigma_h\|_T^{r'} \right)^{(r'-r)/r'} \|\sigma - \tau_h\|_T^r \\ &\quad \le \epsilon \|\sigma - \sigma_h\|_T^{r'} + C \|\sigma - \tau_h\|_T^r. \end{aligned} \tag{4.12}$$

With the choice $\tau_h \in \tilde{K}_h$, using (2.12) and (4.6),

$$\begin{aligned} a(\sigma, \tau_h - \sigma_h) - a(\sigma_h, \tau_h - \sigma_h) &= b(\tau_h - \sigma_h, \mathbf{u}) - b(\tau_h - \sigma_h, \mathbf{u}_h) \\ &= b(\tau_h - \sigma_h, \mathbf{u}) \quad (\text{since } \tau_h \text{ and } \sigma_h \text{ are in } \tilde{K}_h) \\ &= b(\tau_h - \sigma_h, \mathbf{u} - \mathbf{v}_h) \quad (\text{for } \mathbf{v}_h \in \tilde{X}_h) \\ &= \int_\Omega (\tau_h - \sigma_h) : d(\mathbf{u} - \mathbf{v}_h) d\Omega \\ &= \int_\Omega (\sigma - \sigma_h) : d(\mathbf{u} - \mathbf{v}_h) d\Omega \\ &\qquad + \int_\Omega (\tau_h - \sigma) : d(\mathbf{u} - \mathbf{v}_h) d\Omega \\ &\le \|\sigma - \sigma_h\|_T \|\mathbf{u} - \mathbf{v}_h\|_X + \|\sigma - \tau_h\|_T \|\mathbf{u} - \mathbf{v}_h\|_X \\ &\le \epsilon \|\sigma - \sigma_h\|_T^{r'} + C \left(\|\sigma - \tau_h\|_T^{r'} + \|\mathbf{u} - \mathbf{v}_h\|_X^r \right). \end{aligned} \tag{4.13}$$

Combining (4.11)–(4.13) gives an error bound for $\|\sigma - \sigma_h\|_T$ in terms of the *best approximations* of σ and $\mathbf{u}$ in the sets $\tilde{K}_h$ and $\tilde{X}_h$, respectively. Next we show that we can *lift* these best approximations from $\tilde{K}_h$ and $\tilde{X}_h$ to $T_h \times X_h$. This is done in two steps: first, *lifting* from $\tilde{K}_h$ to $\tilde{W}_h$ and then using the discrete inf-sup condition to go from $\tilde{W}_h$ to $T_h \times X_h$.

Let

$$\begin{aligned}\tilde{W}_h &:= \{(\tau_h, q_h) \in T_h \times P_h : b(\tau_h, \mathbf{v}_h) - s(\mathbf{v}_h, (q_h, \lambda_h)) \\ &= \langle \mathbf{f}, \mathbf{v}_h \rangle \ \ \forall \mathbf{v}_h \in X_h\}. \end{aligned} \tag{4.14}$$

Note that if (τ_h, q_h) is in $\tilde{W}_h$, then τ_h is in $\tilde{K}_h$. Hence,

$$\inf_{\tau_h \in K_h} \|\sigma - \tau_h\|_T \leq \inf_{(\tau_h, q_h) \in \tilde{W}_h} \|(\sigma, p) - (\tau_h, q_h)\|_{T \times P}. \tag{4.15}$$

From the inf-sup conditions (4.1) we have that there exist operators $\Pi_1 : T \to T_h$ and $\Pi_2 : P \to P_h$ such that

$$b(\tau - \Pi_1 \tau, \mathbf{v}_h) - s(\mathbf{v}_h, (q - \Pi_2 q, \lambda_h)) = 0 \quad \forall \mathbf{v}_h \in X_h \tag{4.16}$$

and

$$\|(\Pi_1 \tau, \Pi_2 q)\|_{T \times P} \leq \tilde{C} \|(\tau, q)\|_{T \times P} \ \ \forall (\tau, q) \in T \times P. \tag{4.17}$$

Consider $(\tau_h, q_h) \in T_h \times P_h$, and introduce $\tilde{\sigma} := \tau_h - \Pi_1(\tau_h - \sigma)$ and $\tilde{p} := q_h - \Pi_2(q_h - p)$. Then for all $\mathbf{v}_h \in X_h$

$$\begin{aligned} b(\tilde{\sigma}, \mathbf{v}_h) - s(\mathbf{v}_h, (\tilde{p}, \lambda_h)) &= b(\sigma, \mathbf{v}_h) - s(\mathbf{v}_h, (p, \lambda_h)) \\ &= \langle \mathbf{f}, \mathbf{v}_h \rangle, \end{aligned}$$

which implies $(\tilde{\sigma}, \tilde{p}) \in \tilde{W}_h$.

Also, using (4.17),

$$\begin{aligned} \|(\tilde{\sigma}, \tilde{p}) - (\tau_h, q_h)\|_{T \times P} &= \|(\Pi_1(\sigma - \tau_h), \Pi_2(p - q_h)\|_{T \times P} \\ &\leq \tilde{C} \|(\sigma - \tau_h, p - q_h)\|_{T \times P}. \end{aligned} \tag{4.18}$$

With $(\tilde{\sigma}, \tilde{p})$ as defined above, using (4.17), (4.18), and the triangle inequality,

$$\begin{aligned} \inf_{(\tau_h, q_h) \in \tilde{W}_h} \|(\sigma, p) - (\tau_h, q_h)\|_{T \times P} &\leq \inf_{(\tau_h, q_h) \in T_h \times P_h} \|(\sigma, p) - (\tilde{\sigma}, \tilde{p})\|_{T \times P} \\ &\leq \inf_{(\tau_h, q_h) \in T_h \times P_h} (\|(\sigma, p) - (\tau_h, q_h)\|_{T \times P} + \|(\tilde{\sigma}, \tilde{p}) - (\tau_h, q_h)\|_{T \times P}) \\ &\leq (1 + \tilde{C}) \inf_{(\tau_h, q_h) \in T_h \times P_h} \|(\sigma, p) - (\tau_h, q_h)\|_{T \times P}. \end{aligned} \tag{4.19}$$

Using an analogous argument with the inf-sup condition (3.10) it is straightforward to show that

$$\inf_{\mathbf{v}_h \in \tilde{X}_h} \|\mathbf{u} - \mathbf{v}_h\|_X \leq C \inf_{\mathbf{v}_h \in X_h} \|\mathbf{u} - \mathbf{v}_h\|_X. \tag{4.20}$$

Combining (4.11)–(4.13), (4.15), (4.19), and (4.20), we then have

$$\begin{aligned} \|\sigma - \sigma_h\|_T^{r'} \leq C \Bigg(&\inf_{\tau_h \in T_h} \left(\|\sigma - \tau_h\|_T^r + \|\sigma - \tau_h\|_T^{r'} \right) + \inf_{\mathbf{v}_h \in X_h} \|\mathbf{u} - \mathbf{v}_h\|_X^r \\ &+ \inf_{q_h \in P_h} \|p - q_h\|_P^{r'} \Bigg). \end{aligned}$$

To obtain the error estimate for the velocity we use (3.4). We have that

$$\begin{aligned} C_{XTh}\|\mathbf{u}_h - \mathbf{v}_h\|_X &\le \sup_{\tau_h \in T_h} \frac{b(\tau_h, \mathbf{u}_h - \mathbf{v}_h)}{\|\tau_h\|_T} \\ &= \sup_{\tau_h \in T_h} \frac{b(\tau_h, \mathbf{u}_h - \mathbf{u}) + b(\tau_h, \mathbf{u} - \mathbf{v}_h)}{\|\tau_h\|_T} \\ &\le \sup_{\tau_h \in T_h} \frac{a(\sigma_h, \tau_h) - a(\sigma, \tau_h)}{\|\tau_h\|_T} + \|\mathbf{u} - \mathbf{v}_h\|_X. \end{aligned} \tag{4.21}$$

Proceeding as in the estimate (4.12), we have that

$$\begin{aligned} a(\sigma_h, \tau_h) - a(\sigma, \tau_h) &= \int_\Omega (\breve{g}(\sigma_h)\sigma_h - \breve{g}(\sigma)\sigma) : \tau_h d\Omega \\ &\le \int_\Omega M \left(|\sigma_h| + |\sigma|\right)^{r'-2} |\sigma - \sigma_h| : \tau_h d\Omega \\ &\le C\|\sigma - \sigma_h\|_T \|\tau_h\|_T. \end{aligned} \tag{4.22}$$

Combining (4.21) and (4.22) yields

$$\|\mathbf{u}_h - \mathbf{v}_h\|_X \le C\left(\|\sigma - \sigma_h\|_T + \|\mathbf{u} - \mathbf{v}_h\|_X\right).$$

An application of the triangle inequality then establishes (4.4).

The error estimate for the pressure and the "Lagrange multipliers" is obtained using the inf-sup condition (3.10), the trace theorem, and the equivalence of norms in $\mathbb{R}^m$. We have that

$$\begin{aligned} C_{PRXh}\left(\|p_h - q_h\|_P + \|\lambda_h - \beta_h\|_{\mathbb{R}^m}\right) &\le \sup_{\mathbf{v}_h \in X_h} \frac{s(\mathbf{v}_h, (p_h - q_h, \lambda_h - \beta_h))}{\|\mathbf{v}_h\|_X} \\ &= \sup_{\mathbf{v}_h \in X_h} \frac{s(\mathbf{v}_h, (p_h - p, \lambda_h - \lambda)) + s(\mathbf{v}_h, (p - q_h, \lambda - \beta_h))}{\|\mathbf{v}_h\|_X} \\ &\le \sup_{\mathbf{v}_h \in X_h} \frac{b(\sigma, \mathbf{v}_h) - b(\sigma_h, \mathbf{v}_h)}{\|\mathbf{v}_h\|_X} \\ &\quad + \sup_{\mathbf{v}_h \in X_h} \frac{\int_\Omega (p - q_h)\nabla \cdot \mathbf{v}_h d\Omega + \sum_{i=1}^m (\lambda_i - \beta_{h,i}) \int_{S_i} \mathbf{v}_h \cdot \mathbf{n} ds}{\|\mathbf{v}_h\|_X} \\ &\le \sup_{\mathbf{v}_h \in X_h} \frac{\int_\Omega (\sigma - \sigma_h) : d(\mathbf{v}_h) d\Omega}{\|\mathbf{v}_h\|_X} + C\left(\|p - q_h\|_P + \|\lambda - \beta_h\|_{\mathbb{R}^m}\right) \\ &\le \|\sigma - \sigma_h\|_T + C\left(\|p - q_h\|_P + \|\lambda - \beta_h\|_{\mathbb{R}^m}\right). \end{aligned}$$

Estimate (4.5) then follows using the triangle inequality. ∎

Remark. As $\mathbf{u}_h$ exactly satisfies the specified flow rates, the error in the Lagrange multipliers does not appear in the error estimate for $\|\mathbf{u} - \mathbf{u}_h\|_X$.

COROLLARY 4.1. *For* $(\sigma, \mathbf{u}, p, \lambda) \in (W^{l+1,r'})^{\acute{d}\times\acute{d}} \times \left(W^{k+1,r}\right)^{\acute{d}} \times W^{n+1,r'} \times \mathbb{R}^m$ *satisfying* (2.12)–(2.14) *and* $(\sigma_h, \mathbf{u}_h, p_h, \lambda_h)$ *satisfying* (3.6)–(3.8) *(with* T_h, X_h, P_h *defined in* (3.1)–(3.3)*), for* h *sufficiently small, we have with* $\tilde{l} := \min\{(l+1)r/r', kr/r', n+1\}$ *that*

$$\|\sigma - \sigma_h\|_T + \|\mathbf{u} - \mathbf{u}_h\|_X + \|p - q_h\|_P + \|\lambda - \beta_h\|_{\mathbb{R}^m} \le Ch^{\tilde{l}}. \tag{4.23}$$

Proof. Estimate (4.23) follows from (4.3)–(4.5) and the approximating properties of continuous piecewise polynomials. (Note that, by assumption, $r \le r'$.) ∎

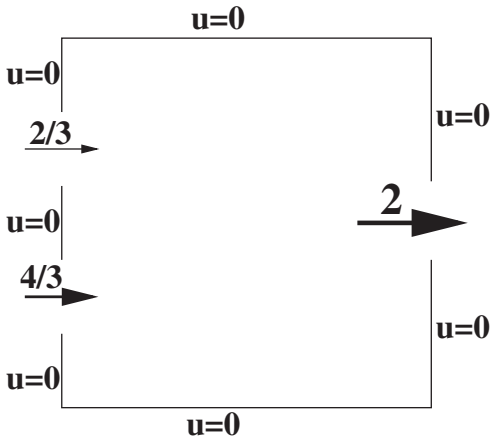

FIG. 5.1. *The flow problem.*

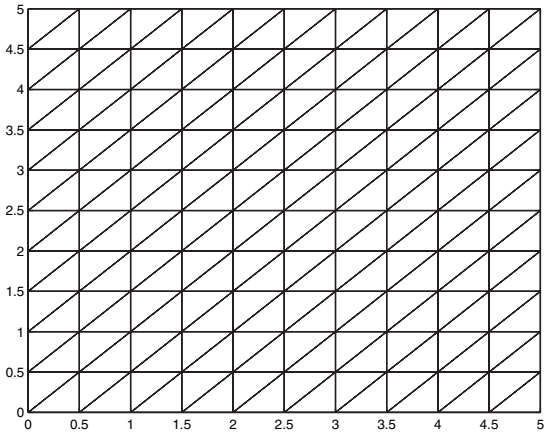

FIG. 5.2. *The second computational mesh,* $h = 1/2$.

5. Numerical computations. In this section we present numerical results, obtained using MATLAB, for a flow problem subject (only) to specified flow-rate conditions at the inflow and outflow boundaries. Along the other boundaries we impose the usual nonslip condition for the fluid velocity. In order to demonstrate the theoretical results derived in section 4 we consider a simple model problem of flow in a square domain $(0\,5) \times (0\,5)$, with inflow boundaries $x = 0$, $1 < y < 2$ and $x = 0$, $3 < y < 4$ and an outflow boundary at $x = 5$, $2 < y < 3$. The inflow rates were specified to be $4/3$ and $2/3$, respectively, with the outflow rate corresponding given as 2. (See Figure 5.1.)

Computations were performed on a sequence of four meshes, with each mesh a uniform refinement (each triangle subdivided into four similar/smaller triangles) of the preceding mesh. The second computational mesh is shown in Figure 5.2. The approximating nonlinear system was solved using a Newton method. For the approximation of the velocity and pressure we used continuous piecewise quadratic and continuous piecewise linear finite elements, respectively (i.e., the Taylor–Hood pair). For the approximation of the stress we used continuous piecewise linear finite elements.

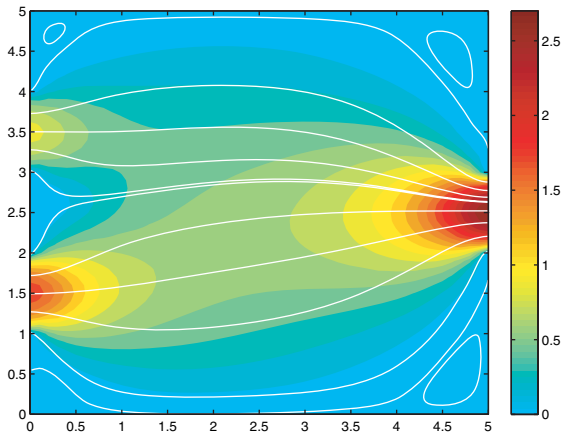

FIG. 5.3. *Plot of the magnitude of the velocity and streamlines for $r = 2$.*

TABLE 5.2
Norms of the velocity and stress for $r = 3/2$.

	$\|\nabla \mathbf{u}_h\|_{L^{3/2}}$	$\|\nabla(\mathbf{u}_h - \mathbf{u}_{2h})\|_{L^{3/2}}$	$\tilde{\alpha}_{\mathbf{u}}$	$\|\sigma_h\|_{L^3}$	$\|\sigma_h - \sigma_{2h}\|_{L^3}$	$\tilde{\alpha}_{\sigma}$
$h = 1$	8.680			1.758		
$h = 1/2$	8.664	4.710		1.995	1.279	
$h = 1/4$	8.531	2.607	0.85	2.063	0.871	0.55
$h = 1/8$	8.526	1.469	0.83	2.249	0.697	0.32

For the constitutive equation of the fluid we considered the power law equation (2.7), which, in the notation of (2.15), is rewritten as

$$d(\mathbf{u}) = \nu_0^{1-r'} |\sigma|^{r'-2} \sigma = \breve{g}(\sigma)\sigma. \tag{5.1}$$

Presented in Table 5.1 and Figure 5.3 are the results of the computations for the parameter $r = 2$ ($r' = 2$), and in Table 5.2 and Figure 5.4 are the results of the computations for the parameter $r = 3/2$ ($r' = 3$).

Assuming the convergence rate for the velocity is $\alpha_{\mathbf{u}}$, i.e., $\|\nabla(\mathbf{u} - \mathbf{u}_h)\|_{L^r} \sim C h^{\alpha_{\mathbf{u}}}$, we compute the experimental convergence rate for the velocity using

$$\|\nabla(\mathbf{u}_h - \mathbf{u}_{2h})\|_{L^r} \le \|\nabla(\mathbf{u} - \mathbf{u}_h)\|_{L^r} + \|\nabla(\mathbf{u} - \mathbf{u}_{2h})\|_{L^r} \sim \tilde{C} h^{\alpha_{\mathbf{u}}}.$$

$$\text{Therefore} \qquad \tilde{\alpha}_{\mathbf{u}} = \log\left(\|\nabla(\mathbf{u}_h - \mathbf{u}_{2h})\|_{L^r} / \|\nabla(\mathbf{u}_{2h} - \mathbf{u}_{4h})\|_{L^r}\right) / \log(2). \tag{5.2}$$

$$\text{Similarly} \qquad \tilde{\alpha}_{\sigma} = \log\left(\|\sigma_h - \sigma_{2h}\|_{L^{r'}} / \|\sigma_{2h} - \sigma_{4h}\|_{L^{r'}}\right) / \log(2). \tag{5.3}$$

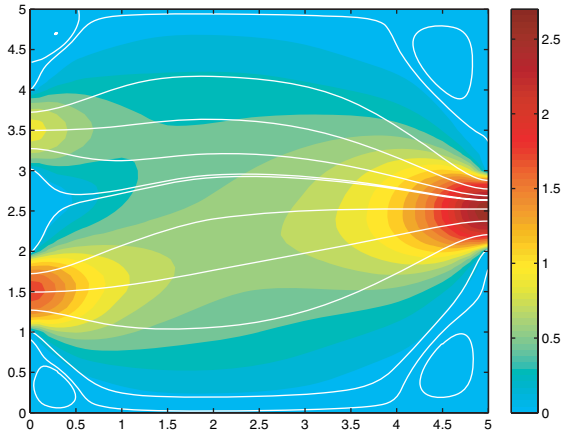

FIG. 5.4. *Plot of the magnitude of the velocity and streamlines for* $r = 3/2$.

The case $r = 2$ $(r' = 2)$. For the case $r = 2$ $(r' = 2)$ the constitutive equation describes a "Newtonian" fluid and the problem becomes a (linear) three-field Stokes problem with defective boundary conditions. As in this case $\sigma = \nu_0 d(\mathbf{u}) = \nu_0/2(\nabla \mathbf{u} + (\nabla \mathbf{u})^T)$, and we are constructing a piecewise linear approximation for the σ and a piecewise quadratic approximation for $\mathbf{u}$, we expect that $\tilde{\alpha}_{\mathbf{u}} \approx \tilde{\alpha}_\sigma$, as observed in Table 5.1. The fact that $\tilde{\alpha}_{\mathbf{u}} \approx \tilde{\alpha}_\sigma \neq 2$ is due to the lack of regularity of $\mathbf{u}$ and σ, attributable to the singular behavior of $\nabla \mathbf{u}$ and σ at the corners of the inflow and outflow boundaries.

The case $r = 3/2$ $(r' = 3)$. Note that for this case the velocity is in $(W^{1,3/2}(\Omega))^2$ and the stress in $(L^3(\Omega))^4_{sym}$. Also, we have that $\sigma = \nu_0 |d(\mathbf{u})|^{-0.5} d(\mathbf{u})$.

The a priori error estimates presented in Theorem 4.1 are dominated by the term $\|\sigma - \tau_h\|_T^r$ on the RHS of (4.3). If this term was not present, the a priori estimate would represent the *best approximation error* (for appropriately chosen approximation spaces for $\sigma_h, \mathbf{u}_h, p_h$). The computations in Table 5.2 are consistent with the approximations being *best approximations* (see below). This may be due to the fact that the behavior of the computational results are preasymptotic or that the estimates in Theorem 4.1 are not optimal.

At the end points of the inflow/outflow boundaries $\nabla \mathbf{u}$ will be singular. Assuming that at these points $\nabla \mathbf{u}$ has a point singularity of the form $\rho^{-s}, 0 < s < 1$, where ρ denotes the distance from the singular point, and $\mathbf{u}_I$ is a continuous piecewise quadratic interpolant of $\mathbf{u}$, then we expect that

$$\begin{aligned}
\|\nabla(\mathbf{u} - \mathbf{u}_I)\|_{L^r} &\sim \left(\int_{B(0,h)} (\rho^{-s})^r dA + \int_{B(0,R)\setminus B(0,h)} (h^2 \rho^{-s-2})^r dA \right)^{1/r} \\
&= \left(\int_{\theta=0}^{\pi} \int_{\rho=0}^{h} \rho \rho^{-sr} d\rho d\theta + \int_{\theta=0}^{\pi} \int_{\rho=h}^{R} \rho h^{2r} \rho^{-(s+2)r} d\rho d\theta \right)^{1/r} \\
&\sim C h^{(2-rs)/r}, \\
\text{(5.4)} \qquad \text{i.e.,} \quad \alpha_{\mathbf{u}} &= (2 - rs)/r.
\end{aligned}$$

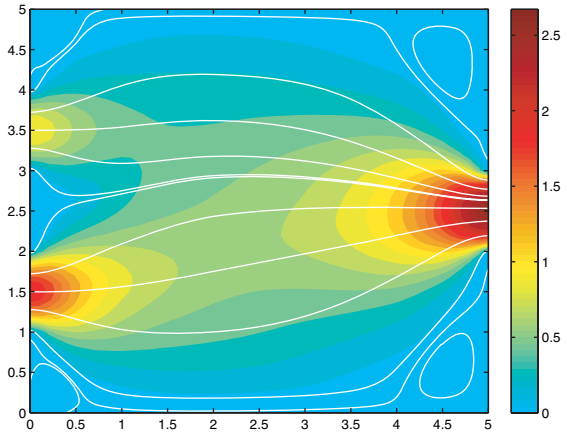

FIG. 5.5. *Plot of the magnitude of the velocity and streamlines for $r = 3/2$ with parabolic inflow boundary conditions and a "do nothing" outflow boundary condition.*

From (2.7), and for σ_I a continuous piecewise linear interpolant of σ, we would expect that

$$\begin{aligned}\|\sigma - \sigma_I\|_{L^{r'}} &\sim \left(\int_{B(0,h)} \left((\rho^{-s})^{r-2} \rho^{-s} \right)^{r'} dA \right. \\ &\qquad \left. + \int_{B(0,R)\setminus B(0,h)} \left(h^2 (\rho^{-s})^{r-2} \rho^{-s-2} \right)^{r'} dA \right)^{1/r'} \\ &\sim Ch^{(2-rs)/r'}, \\ \text{i.e.,} \quad \alpha_\sigma &= (2-rs)/r'. \end{aligned} \tag{5.5}$$

For $r = 3/2$, $r' = 3$, from (5.4),(5.5) we have that $\alpha_{\mathbf{u}}/\alpha_\sigma = r'/r = 2$, which is consistent with the computations in Table 5.2.

Comparing Figures 5.3 and 5.4, the flow fields corresponding to $r = 2$ and $r = 3/2$, respectively, we observe (as expected) the larger vortices in the upper and lower right-hand corners of Ω for the case $r = 3/2$. The magnitude of $\mathbf{u}(x, y) = [u_1(x, y), u_2(x, y)]$ plotted in Figures 5.3 and 5.4 was calculated via $|\mathbf{u}(x, y)| = (u_1(x, y)^r + u_2(x, y)^r)^{1/r}$.

For comparison, in Figure 5.5 is the flow field for the case $r = 3/2$, where we specify parabolic velocity inflow profiles (with inflow rates 4/3 and 2/3, respectively) and a "do nothing" (i.e., $\sigma - pI = \mathbf{0}$) outflow boundary condition. The flow field looks very similar to that in Figure 5.4 where the flow rates were imposed using the Lagrange multiplier approach. The values for the velocity seminorm and the stress norm in Figure 5.5 are 8.718 and 2.081, respectively, compared to 8.531 and 2.063 in Figure 5.4.

EXPLICIT CONSTRUCTIONS OF QUASI-MONTE CARLO RULES FOR THE NUMERICAL INTEGRATION OF HIGH-DIMENSIONAL PERIODIC FUNCTIONS*

JOSEF DICK†

Abstract. In this paper, we give explicit constructions of point sets in the s-dimensional unit cube yielding quasi-Monte Carlo algorithms which achieve the optimal rate of convergence of the worst-case error for numerically integrating high-dimensional periodic functions. In the classical measure P_α of the worst-case error introduced by Korobov, the convergence, for every even integer $\alpha \geq 1$, is of $\mathcal{O}(N^{-\min(\alpha,d)}(\log N)^{s\alpha-2})$, where d is a parameter of the construction which can be chosen arbitrarily large and N is the number of quadrature points. This convergence rate is known to be the best possible up to some $\log N$ factors. We prove the result for the deterministic and also a randomized setting. The construction is based on a suitable extension of digital (t, m, s)-nets over the finite field $\mathbb{Z}_b$.

1. Introduction.

Korobov [11] and independently Hlawka [9] introduced a quadrature formula which is suited for numerically integrating high-dimensional periodic functions. More precisely, we want to approximate the high-dimensional integral $\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}$ (where f is assumed to be periodic with period 1 in each coordinate) by a quasi-Monte Carlo rule, i.e., an equal weight quadrature rule $Q_{N,s}(f) = N^{-1}\sum_{n=0}^{N-1} f(\boldsymbol{x}_n)$, where $\boldsymbol{x}_0, \ldots, \boldsymbol{x}_{N-1} \in [0,1]^s$ are the quadrature points. Specifically, Korobov and Hlawka suggested using a quadrature rule of the form $Q_{N,\boldsymbol{g},s}(f) = N^{-1}\sum_{n=0}^{N-1} f(\{n\boldsymbol{g}/N\})$, where for a vector of real numbers $\boldsymbol{x} = (x_1, \ldots, x_s)$ we define $\{\boldsymbol{x}\}$ as the fractional part of each component of $\boldsymbol{x}$, i.e., $\{x_j\} = x_j - \lfloor x_j \rfloor = x_j \pmod 1$, and where $\boldsymbol{g} \in \mathbb{Z}^s$ is an integer vector. The quadrature rule $Q_{N,\boldsymbol{g},s}$ is called *lattice rule*, and $\boldsymbol{g}$ is called the generating vector (of the lattice rule). The monographs [10, 12, 17, 25] deal partly or entirely with the approximation of such integrals. (Note that the assumption that the integrand f is periodic is not really a restriction since there are transformations which transform nonperiodic functions into periodic ones such that the smoothness of the integrand is preserved; see, for example, [25].)

To analyze the properties of a quadrature rule, one considers then the worst-case error $\sup_{f\in B_{\mathcal{H}}} |\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} - Q_{N,s}(f)|$, where $B_{\mathcal{H}}$ denotes some class of functions. In the classical theory, the class ε_α^s of periodic functions has been considered where one demands that the absolute values of the Fourier coefficients of the function decay sufficiently fast (see [10, 12, 25, 17]). This leads us to the classical measure of the quality of lattice rules $P_\alpha = \sup_{f\in\varepsilon_\alpha^s} \left|\int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} - Q_{N,s}(f)\right|$, which then for a

lattice rule with generating vector $\boldsymbol{g} = (g_1, \dots, g_s)$ can also be written as

$$P_\alpha = P_\alpha(\boldsymbol{g}, N) = \sum_{\substack{\boldsymbol{h} \in \mathbb{Z}^s \setminus \{\boldsymbol{0}\} \\ \boldsymbol{h} \cdot \boldsymbol{g} \equiv 0 \pmod N}} |\bar{\boldsymbol{h}}|^{-\alpha},$$

where $\boldsymbol{h} = (h_1, \dots, h_s)$, $\boldsymbol{h} \cdot \boldsymbol{g} = h_1 g_1 + \cdots + h_s g_s$, and $|\bar{\boldsymbol{h}}| = \prod_{j=1}^s \max(1, |h_j|)$. (Later on in this paper, we prefer to use the more contemporary notation of reproducing kernel Hilbert spaces, in our case so-called Korobov spaces (see section 2.3), but as is well understood (and as is also shown in section 2.3) the results also apply to the classical problem.)

By averaging over all generating vectors $\boldsymbol{g}$, several existence results for good lattice rules which achieve $P_\alpha = \mathcal{O}(N^{-\alpha}(\log N)^{\alpha s})$ have been shown; see [10, 11, 12, 18, 17, 25]. By a lower bound of Sharygin [24], this convergence is also known to be essentially the best possible, as he showed that the worst-case error is at least of order $N^{-\alpha}(\log N)^{s-1}$. But, except for dimension $s = 2$, no explicit generating vectors $\boldsymbol{g}$ which yield a small worst-case error are known. For $s \geq 3$, one relies on a computer search to find good generating vectors $\boldsymbol{g}$, and many such search algorithms have been introduced and analyzed, especially recently; see [11, 26, 27, 32].

On the other hand, one can of course also use some other quadrature rule $Q_{N,s}(f) = \sum_{n=0}^{N-1} \omega_n f(\boldsymbol{x}_n)$ to numerically integrate functions in the class ε_α^s. In this case, the worst-case error in the class ε_α^s for a quadrature rule with weights $\omega_0, \dots, \omega_{N-1}$ and points $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}\} \subset [0,1)^s$ is given by

$$P_\alpha(\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}\}) = \sum_{n,m=0}^{N-1} \omega_n \omega_m \sum_{\boldsymbol{h} \in \mathbb{Z}^s \setminus \{\boldsymbol{0}\}} \frac{\mathrm{e}^{2\pi \mathrm{i} \boldsymbol{h} \cdot (\boldsymbol{x}_n - \boldsymbol{x}_m)}}{|\bar{\boldsymbol{h}}|^\alpha}. \tag{1.1}$$

An explicit construction of such point sets was introduced by Niederreiter (see [14, Theorem 5.3]) and is called Kronecker sequence. Here the idea is to choose the quadrature points of the form $\{\boldsymbol{z}k\}$, $k = 1, 2, \dots$, where $\boldsymbol{z}$ is an s-dimensional vector of certain irrational numbers (for example, one can choose $\boldsymbol{z} = (\sqrt{p_1}, \dots, \sqrt{p_s})$, where $p_1, \dots, p_s$ are distinct prime numbers). Depending on the smoothness α, certain points will be used more than once; see [14]. In practice, problems can occur because of the finite precision of computers making it impossible to use points whose coordinates are all irrational numbers.

Another construction of quadrature rules is due to Smolyak [29] and is nowadays called a sparse grid; see also [7]. Those quadrature rules are sums over certain products of differences of one-dimensional quadrature rules. In principle, any one-dimensional quadrature rule can be chosen as a basis, leading to different quadrature rules. In many cases, the weights ω_n of such quadrature rules are not known explicitly but can be precomputed. But even if the underlying one-dimensional quadrature rule has only positive weights, it is possible that some weights in Smolyak's quadrature rules are negative, which can have a negative impact on the stability of the quadrature formula. In general, quadrature formulas for which all weights are equal and $\sum_{n=0}^{N-1} \omega_n = 1$, that is, $\omega_n = N^{-1}$ for all $n = 0, \dots, N-1$, are to be preferred. As mentioned above, such quadrature rules are called quasi-Monte Carlo rules, to which we now switch for the remainder of the paper.

As the weights for quasi-Monte Carlo rules are given by N^{-1}, the focus lies on the choice of the quadrature points. Constructions of quadrature points have been introduced with the aim to distribute the points as evenly as possible over the unit cube. An explicit construction of well-distributed point sets in the unit cube has been

introduced by Sobol [30]. A similar construction was established by Faure [6] before Niederreiter [16] (see also [17]) introduced the general concept of (t, m, s)-nets and (t, s)-sequences and the construction scheme of digital (t, m, s)-nets and digital (t, s)-sequences. For such point sets, it has been shown that the star discrepancy (which is a measure of the distribution properties of a point set) is $\mathcal{O}(N^{-1}(\log N)^{s-1})$; see [17]. From this result, it follows that those point sets yield quasi-Monte Carlo algorithms which achieve a convergence of $\mathcal{O}(N^{-2}(\log N)^{2s-2})$ for functions in the class ε_α^s for all $\alpha \geq 2$. This result holds in the deterministic and randomized setting.

For smoother functions, though, i.e., larger values of α in the class ε_α^s, one can expect higher order convergence. For example, if the partial derivatives up to order two are square integrable, then one would expect an integration error of $\mathcal{O}(N^{-4}(\log N)^{c(s)})$, for some $c(s) > 0$ depending only on s, in the function class ε_α^s, and, in general, if the mixed partial derivatives up to order $\alpha/2$ exist and are square integrable, then one would expect an integration error in ε_α^s of $\mathcal{O}(N^{-\alpha}(\log N)^{c(s,\alpha)})$, for some $c(s, \alpha) > 0$ depending only on s and α. But until now (t, m, s)-nets and (t, s)-sequences have only been shown to yield a convergence of at best $\mathcal{O}(N^{-2}(\log N)^{2s-2})$ (or $\mathcal{O}(N^{-3+\delta})$ for any $\delta > 0$ if one uses a randomization method called scrambling; see [22]) in ε_α^s, even if the integrands satisfy stronger smoothness assumptions.

In this paper, we show that a modification of digital (t, m, s)-nets and digital (t, s)-sequences introduced by Niederreiter [16, 17] yields point sets which achieve the optimal rate of convergence of the worst-case error $P_{2\alpha} = \mathcal{O}(N^{-2\min(\alpha,d)}(\log N)^{2s\alpha-2})$ for any integer $\alpha \geq 1$ and where $d \in \mathbb{N}$ is a parameter of the construction which can be chosen arbitrarily large. We, too, use the digital construction scheme introduced by Niederreiter [16, 17] for the construction of (t, m, s)-nets and (t, s)-sequences, but our analysis of the worst-case error shows that the t-value does not provide enough information about the point set. Hence we generalize the definition of digital (t, m, s)-nets and digital (t, s)-sequences to suit our needs. This leads us to the definition of digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences. For $\alpha = \beta = 1$, those definitions reduce to the case introduced by Niederreiter but are different for $\alpha > 1$. Subsequently, we prove that quasi-Monte Carlo rules based on digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences achieve the optimal rate of convergence. Further we give explicit constructions of digital $(t, \alpha, \min(\alpha, d), m, s)$-nets and digital $(t, \alpha, \min(\alpha, d), s)$-sequences, where $d \in \mathbb{N}$ is a parameter of the construction which can be chosen arbitrarily large.

Digital $(t, 2, 2, m, s)$-nets and digital $(t, 2, 2, s)$-sequences over $\mathbb{Z}_b$ (i.e., where $\alpha = \beta = 2$) can also be used for nonperiodic function spaces where one uses randomly shifted and then folded point sets using the baker's transformation (see [3]). Our analysis and error bounds for $\alpha = 2$ here also apply for the case considered in [3] (with different constants though), hence yielding useful constructions also for nonperiodic function spaces where one uses the baker's transformation. Using a digital (t, α, m, s)-net with a scrambling algorithm (see [22]), on the other hand, does not improve the performance in nonperiodic spaces compared to (t, m, s)-nets.

In the following we summarize some properties of the quadrature rules:

- The quadrature rules introduced in this paper are equal weight quadrature rules which achieve the optimal rate of convergence up to some $\log N$ factors, and we show the result for deterministic and randomly digitally shifted quadrature rules. The upper bound for the randomized quadrature rules even improves upon the best known upper bound (more precisely, the power of the $\log N$ factor) for lattice rules for the worst-case error in ε_α^s for all dimensions $s \geq 2$ and even integers $\alpha \geq 2$ (compare Corollary 6.5 to Theorem 2 in [18]).

- The construction of the underlying point set is explicit.
- They automatically adjust themselves to the optimal rate of convergence in the class $\varepsilon^s_{2\alpha}$ as long as α is an integer such that $\alpha \le d$, where d is a parameter of the construction which can be chosen arbitrarily large.
- The underlying point set is extensible in the dimension as well as in the number of points; i.e., one can always add some coordinates or points to an existing point set such that the quality of the point set is preserved.
- Tractability and strong tractability results (see [28]) can be obtained for weighted Korobov spaces.

The outline of the paper is as follows. In the next section we introduce the necessary tools, namely, Walsh functions, the digital construction scheme upon which the construction of the point set is based on and Korobov spaces. Further we also introduce the worst-case error in those Korobov spaces, and we give a representation of this worst-case error for digital nets in terms of the Walsh coefficients of the reproducing kernel. In section 3, we give the definition of digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences. Further we prove some propagation rules for those digital nets and sequences. In section 4, we give explicit constructions of digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences, and we prove some upper bounds on the t-value. We then show, in section 5, that quasi-Monte Carlo rules based on those digital nets and sequences achieve the optimal rate of convergence of the worst-case error in the Korobov spaces. The results are based on entirely deterministic point sets. Section 6 finally deals with randomly digitally shifted digital (t, α, β, m, s)-nets and (t, α, β, s)-sequences, and we show similar results for the mean square worst-case error in the Korobov space for this setting. The appendix is devoted to the analysis of the Walsh coefficients of the Walsh series representation of $B_{2\alpha}(|x-y|)$, where $B_{2\alpha}$ is the Bernoulli polynomial of degree 2α. In the last section, we give a concrete example of a digital $(t, \alpha, \alpha, m, s)$-net where we compute the t-value by hand.

2. Preliminaries. In this section we introduce the necessary tools for the analysis of the worst-case error and the construction of the point sets. In the following, let $\mathbb{N}$ denote the set of natural numbers, and let $\mathbb{N}_0$ denote the set of nonnegative integers.

2.1. Walsh functions. In the following, we define Walsh functions in base $b \ge 2$ which are the main tool of analyzing the worst-case error. First we give the definition for the one-dimensional case.

DEFINITION 2.1. *Let $b \ge 2$ be an integer and represent $k \in \mathbb{N}_0$ in base b, $k = \kappa_{a-1} b^{a-1} + \cdots + \kappa_0$, with $\kappa_i \in \{0, \ldots, b-1\}$. Further let $\omega_b = \mathrm{e}^{2\pi \mathrm{i}/b}$. Then the kth Walsh function ${}_b\mathrm{wal}_k : [0,1) \to \{1, \omega_b, \ldots, \omega_b^{b-1}\}$ in base b is given by*

$$ {}_b\mathrm{wal}_k(x) = \omega_b^{x_1\kappa_0 + \cdots + x_a\kappa_{a-1}}, $$

for $x \in [0,1)$ with base b representation $x = x_1 b^{-1} + x_2 b^{-2} + \cdots$ (unique in the sense that infinitely many of the x_i are different from $b-1$).

DEFINITION 2.2. *For dimension $s \ge 2$, $\boldsymbol{x} = (x_1, \ldots, x_s) \in [0,1)^s$, and $\boldsymbol{k} = (k_1, \ldots, k_s) \in \mathbb{N}_0^s$, we define ${}_b\mathrm{wal}_{\boldsymbol{k}} : [0,1)^s \to \{1, \omega_b, \ldots, \omega_b^{b-1}\}$ by*

$$ {}_b\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \prod_{j=1}^{s} {}_b\mathrm{wal}_{k_j}(x_j). $$

As we will always use Walsh functions in base b, we will in the following often write wal instead of ${}_b$wal.

We introduce some notation. By $\oplus$ we denote the digitwise addition modulo b; i.e., for $x = \sum_{i=w}^{\infty} x_i b^{-i}$ and $y = \sum_{i=w}^{\infty} y_i b^{-i}$ we define

$$x \oplus y = \sum_{i=w}^{\infty} z_i b^{-i},$$

where $z_i \in \{0, \dots, b-1\}$ is given by $z_i \equiv x_i + y_i \pmod b$, and let $\ominus$ denote the digitwise subtraction modulo b. In the same manner we also define a digitwise addition and digitwise subtraction for nonnegative integers based on the b-adic expansion. For vectors in $[0,1)^s$ or $\mathbb{N}_0^s$, the operations $\oplus$ and $\ominus$ are carried out componentwise. Throughout the paper, we always use base b for the operations $\oplus$ and $\ominus$. Further we call $x \in [0,1)$ a b-adic rational if it can be written in a finite base b expansion.

In the following proposition we summarize some basic properties of Walsh functions.

PROPOSITION 2.3.

1. *For all $k, l \in \mathbb{N}_0$ and all $x, y \in [0,1)$, with the restriction that if x, y are not b-adic rationals, then $x \oplus y$ is not allowed to be a b-adic rational, we have*

$$\mathrm{wal}_k(x) \cdot \mathrm{wal}_l(x) = \mathrm{wal}_{k \oplus l}(x), \quad \mathrm{wal}_k(x) \cdot \mathrm{wal}_k(y) = \mathrm{wal}_k(x \oplus y).$$

2. *We have*

$$\int_0^1 \mathrm{wal}_0(x)\,\mathrm{d}x = 1 \quad \textit{and} \quad \int_0^1 \mathrm{wal}_k(x) = 0 \ \textit{if } k > 0.$$

3. *For all $\boldsymbol{k}, \boldsymbol{l} \in \mathbb{N}_0^s$ we have the following orthogonality properties:*

$$\int_{[0,1)^s} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) \mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} = \begin{cases} 1 & \textit{if } \boldsymbol{k} = \boldsymbol{l}, \\ 0 & \textit{otherwise.} \end{cases}$$

4. *For any $f \in \mathcal{L}_2([0,1)^s)$ and any $\boldsymbol{\sigma} \in [0,1)^s$ we have*

$$\int_{[0,1)^s} f(\boldsymbol{x} \oplus \boldsymbol{\sigma})\,\mathrm{d}\boldsymbol{x} = \int_{[0,1)^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x}.$$

5. *For any integer $s \geq 1$ the system $\{\mathrm{wal}_{\boldsymbol{k}} : \boldsymbol{k} = (k_1, \dots, k_s), k_1, \dots, k_s \geq 0\}$ is a complete orthonormal system in $\mathcal{L}_2([0,1)^s)$.*

The proofs of 1–3 are straightforward, and for a proof of the remaining items see [2] or [31] for more information.

2.2. The digital construction scheme. The construction of the point set used here is based on the digital construction scheme introduced by Niederreiter; see [17].

DEFINITION 2.4. *Let integers $m, s \geq 1$ and $b \geq 2$ be given. Let R_b be a commutative ring with identity such that $|R_b| = b$, and let $\mathbb{Z}_b = \{0, \dots, b-1\}$. Let $C_1, \dots, C_s \in R_b^{m \times m}$, with $C_j = (c_{j,k,l})_{1 \leq k,l \leq m}$. Further, let $\psi_l : \mathbb{Z}_b \to R_b$ for $l = 0, \dots, m-1$ and $\mu_{j,k} : R_b \to \mathbb{Z}_b$ for $j = 1, \dots, s$ and $k = 1, \dots, m$ be bijections.*

For $n = 0, \dots, b^m - 1$ let $n = \sum_{l=0}^{m-1} a_l(n) b^l$, with all $a_l(n) \in \mathbb{Z}_b$, be the base b digit expansion of n. Let $\vec{n} = (\psi_0(a_0(n)), \dots, \psi_{m-1}(a_{m-1}(n)))^T$, and let $\vec{y}_j = (y_{j,1}, \dots, y_{j,m})^T = C_j \vec{n}$ for $j = 1, \dots, s$. Then we define $x_{j,n} = \mu_{j,1}(y_{j,1}) b^{-1} + \cdots + \mu_{j,m}(y_{j,m}) b^{-m}$ for $j = 1, \dots, s$ and $n = 0, \dots, b^m - 1$, and the nth point $\boldsymbol{x}_n$ is then given by $\boldsymbol{x}_n = (x_{1,n}, \dots, x_{s,n})$. The point set $\{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{b^m-1}\}$ is called a digital net (over R_b) (with generating matrices $C_1, \dots, C_s$).

For $m = \infty$ we obtain a sequence $\{\boldsymbol{x}_0, \boldsymbol{x}_1, \dots\}$, which is called a digital sequence (over R_b) (with generating matrices $C_1, \dots, C_s$).

Niederreiter's concept of a digital (t, m, s)-net and a digital (t, s)-sequence will appear as a special case in section 3. Apart from sections 3 and 4, where we state the results using Definition 2.4 in the general form, we use only a special case of Definiton 2.4, where we assume that b is a prime number, we choose R_b the finite field $\mathbb{Z}_b$, and the bijections ψ_l and $\mu_{j,k}$ from $\mathbb{Z}_b$ to $\mathbb{Z}_b$ are all chosen to be the identity map.

We remark that, throughout the paper when Walsh functions wal, digitwise addition $\oplus$, digitwise subtraction $\ominus$, or digital nets are used in conjunction with each other, we always use the same base b for each of those operations.

2.3. Korobov space. Historically the function class ε_α^s has been used. In this paper, we use a more contemporary notation by replacing the function class ε_α^s with a reproducing kernel Hilbert space $\mathcal{H}_\alpha$ called the Korobov space. The worst-case error expression (1.1) will almost be the same for both function classes, and hence the results apply for both cases.

A reproducing kernel Hilbert space $\mathcal{H}$ over $[0,1)^s$ is a Hilbert space with inner product $\langle \cdot, \cdot \rangle$ which allows a function $K : [0,1)^s \to \mathbb{R}$ such that $K(\cdot, \boldsymbol{y}) \in \mathcal{H}$, $K(\boldsymbol{x}, \boldsymbol{y}) = K(\boldsymbol{y}, \boldsymbol{x})$, and $\langle f, K(\cdot, \boldsymbol{y}) \rangle = f(\boldsymbol{y})$ for all $\boldsymbol{x}, \boldsymbol{y} \in [0,1)^s$ and all $f \in \mathcal{H}$. For more information on reproducing kernel Hilbert spaces, see [1]; for more information on reproducing kernel Hilbert spaces in the context of numerical integration, see, for example, [4, 28].

The Korobov space $\mathcal{H}_\alpha$ is a reproducing kernel Hilbert space of periodic functions. Its reproducing kernel is given by

$$K_\alpha(\boldsymbol{x}, \boldsymbol{y}) = \sum_{\boldsymbol{h} \in \mathbb{Z}^s} \frac{\mathrm{e}^{2\pi \mathrm{i} \boldsymbol{h} \cdot (\boldsymbol{x} - \boldsymbol{y})}}{|\bar{\boldsymbol{h}}|^{2\alpha}},$$

where $\alpha > 1/2$ and $|\bar{\boldsymbol{h}}| = \prod_{j=1}^s \max(1, |h_j|)$. The inner product in the space $\mathcal{H}_\alpha$ is given by

$$\langle f, g \rangle_\alpha = \sum_{\boldsymbol{h} \in \mathbb{Z}^s} |\bar{\boldsymbol{h}}|^{2\alpha} \hat{f}(\boldsymbol{h}) \hat{g}(\boldsymbol{h}), \tag{2.1}$$

where

$$\hat{f}(\boldsymbol{h}) = \int_{[0,1)^s} f(\boldsymbol{x}) \mathrm{e}^{-2\pi \mathrm{i} \boldsymbol{h} \cdot \boldsymbol{x}} \, \mathrm{d}\boldsymbol{x}$$

are the Fourier coefficients of f. The norm is given by $\|f\|_\alpha = \langle f, f \rangle_\alpha^{1/2}$.

Note that for α a natural number and any $x \in (0,1)$ we have

$$B_{2\alpha}(x) = \frac{(-1)^{\alpha+1} (2\alpha)!}{(2\pi)^{2\alpha}} \sum_{h \neq 0} \frac{\mathrm{e}^{2\pi \mathrm{i} h x}}{|h|^{2\alpha}},$$

where $B_{2\alpha}$ is the Bernoulli polynomial of degree 2α. Hence, for α a natural number we can write

$$K_\alpha(\boldsymbol{x}, \boldsymbol{y}) = \prod_{j=1}^s \left(1 + \sum_{h \neq 0} \frac{\mathrm{e}^{2\pi \mathrm{i} h (x_j - y_j)}}{|h|^{2\alpha}} \right) = \prod_{j=1}^s \left(1 - (-1)^\alpha \frac{(2\pi)^{2\alpha}}{(2\alpha)!} B_{2\alpha}(|x_j - y_j|) \right).$$

Let now

$$K_\alpha(x,y) = 1 + \sum_{h\neq 0} \frac{\mathrm{e}^{2\pi \mathrm{i} h(x-y)}}{|h|^{2\alpha}} = 1 - (-1)^\alpha \frac{(2\pi)^{2\alpha}}{(2\alpha)!} B_{2\alpha}(|x-y|). \tag{2.2}$$

Then we have

$$K_\alpha(\boldsymbol{x},\boldsymbol{y}) = \prod_{j=1}^{s} K_\alpha(x_j,y_j),$$

where $\boldsymbol{x} = (x_1,\ldots,x_s)$ and $\boldsymbol{y} = (y_1,\ldots,y_s)$. Hence the Korobov space is a tensor product of one-dimensional reproducing kernel Hilbert spaces.

Though $\alpha > 1/2$ can in general be any real number, we restrict ourselves to integers $\alpha \geq 1$ for most of this paper. The bounds on the integration error for $\mathcal{H}_\alpha$, with $\alpha \geq 1$ a real number, still apply when one replaces α with $\lfloor \alpha \rfloor$, as in this case the unit ball of $\mathcal{H}_\alpha$ given by $\{f \in \mathcal{H}_\alpha : \|f\|_\alpha \leq 1\}$ is contained in the unit ball $\{f \in \mathcal{H}_{\lfloor\alpha\rfloor} : \|f\|_{\lfloor\alpha\rfloor} \leq 1\}$ of $\mathcal{H}_{\lfloor\alpha\rfloor}$ as $\|f\|_{\lfloor\alpha\rfloor} \leq \|f\|_\alpha$. Hence it follows that integration in the space $\mathcal{H}_\alpha$ is easier than integration in the space $\mathcal{H}_{\lfloor\alpha\rfloor}$.

In general, the worst-case error $e(P,\mathcal{H})$ for multivariate integration in a normed space $\mathcal{H}$ over $[0,1]^s$ with norm $\|\cdot\|$ using a point set P is given by

$$e(P,\mathcal{H}) = \sup_{f\in\mathcal{H},\|f\|\leq 1} \left| \int_{[0,1]^s} f(\boldsymbol{x})\,\mathrm{d}\boldsymbol{x} - Q_P(f) \right|,$$

where $Q_P(f) = N^{-1}\sum_{\boldsymbol{x}\in P} f(\boldsymbol{x})$ and $N = |P|$ is the number of points in P. If $\mathcal{H}$ is a reproducing kernel Hilbert space with reproducing kernel K, we will write $e(P,K)$ instead of $e(P,\mathcal{H})$. It is known that (see, for example, [28])

$$e^2(P,K) = \int_{[0,1)^{2s}} K(\boldsymbol{x},\boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y} - \frac{2}{N}\sum_{n=0}^{N-1}\int_{[0,1)^s} K(\boldsymbol{x}_n,\boldsymbol{y})\,\mathrm{d}\boldsymbol{y} + \frac{1}{N^2}\sum_{n,l=0}^{N-1} K(\boldsymbol{x}_n,\boldsymbol{x}_l), \tag{2.3}$$

where $P = \{\boldsymbol{x}_0,\ldots,\boldsymbol{x}_{N-1}\}$. Hence for the Korobov space $\mathcal{H}_\alpha$ we obtain

$$e^2(P,K_\alpha) = -1 + \frac{1}{N^2}\sum_{n,h=0}^{N-1} K_\alpha(\boldsymbol{x}_n,\boldsymbol{x}_h). \tag{2.4}$$

Therefore it follows that $e^2(P,K_\alpha) = P_{2\alpha}$, and hence our results also apply to the classical setting introduced by Korobov [11].

It follows from Proposition 2.3 that K_α can be represented by a Walsh series, i.e., let

$$K_\alpha(\boldsymbol{x},\boldsymbol{y}) = \sum_{\boldsymbol{k},\boldsymbol{l}\in\mathbb{N}_0^s} r_{b,\alpha}(\boldsymbol{k},\boldsymbol{l})\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})\overline{\mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{y})}, \tag{2.5}$$

where

$$r_{b,\alpha}(\boldsymbol{k},\boldsymbol{l}) = \int_{[0,1)^{2s}} K_\alpha(\boldsymbol{x},\boldsymbol{y})\overline{\mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x})}\mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{y})\,\mathrm{d}\boldsymbol{x}\,\mathrm{d}\boldsymbol{y}.$$

As the kernel K_α is a product of one-dimensional kernels, it follows that $r_{b,\alpha}(\boldsymbol{k},\boldsymbol{l}) = \prod_{j=1}^s r_{b,\alpha}(k_j,l_j)$, where $\boldsymbol{k} = (k_1,\ldots,k_s)$ and $\boldsymbol{l} = (l_1,\ldots,l_s)$ and

$$r_{b,\alpha}(k,l) = \int_0^1\int_0^1 K_\alpha(x,y)\overline{\mathrm{wal}_k(x)}\mathrm{wal}_l(y)\,\mathrm{d}x\,\mathrm{d}y.$$

For a digital net with generating matrices $C_1, \dots, C_s$, let $\mathcal{D} = \mathcal{D}(C_1, \dots, C_s)$ be the dual net given by

$$\mathcal{D} = \{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\} : C_1^T \vec{k}_1 + \cdots + C_s^T \vec{k}_s = \vec{0}\},$$

where for $\boldsymbol{k} = (k_1, \dots, k_s)$, with $k_j = \kappa_{j,0} + \kappa_{j,1} b + \cdots$, we set $\vec{k}_j = (\kappa_{j,0}, \dots, \kappa_{j,m-1})^T$. Further, for $\emptyset \neq u \subseteq \{1, \dots, s\}$ let $\mathcal{D}_u = \mathcal{D}((C_j)_{j \in u})$. We have the following theorem.

THEOREM 2.5. *Let $C_1, \dots, C_s \in \mathbb{Z}_b^{m \times m}$ be the generating matrices of a digital net P_{b^m}, and let $\mathcal{D}$ denote the dual net. Then for any $\alpha > 1/2$ the square worst-case error in $\mathcal{H}_\alpha$ is given by*

$$e^2(P_{b^m}, K_\alpha) = \sum_{\boldsymbol{k},\boldsymbol{l} \in \mathcal{D}} r_{b,\alpha}(\boldsymbol{k}, \boldsymbol{l}).$$

Proof. From (2.4) and (2.5) it follows that

$$e^2(P_{b^m}, K_\alpha) = -1 + \sum_{\boldsymbol{k},\boldsymbol{l} \in \mathbb{N}_0^s} r_{b,\alpha}(\boldsymbol{k}, \boldsymbol{l}) \frac{1}{b^{2m}} \sum_{\boldsymbol{x},\boldsymbol{y} \in P_{b^m}} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) \overline{\mathrm{wal}_{\boldsymbol{l}}(\boldsymbol{y})}.$$

In [4] it was shown that

$$\frac{1}{b^m} \sum_{\boldsymbol{x} \in P_{b^m}} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}) = \begin{cases} 1 & \text{if } \boldsymbol{k} \in \mathcal{D} \cup \{\boldsymbol{0}\}, \\ 0 & \text{otherwise.} \end{cases}$$

Hence we have

$$e^2(P_{b^m}, K_\alpha) = -1 + \sum_{\boldsymbol{k},\boldsymbol{l} \in \mathcal{D} \cup \{\boldsymbol{0}\}} r_{b,\alpha}(\boldsymbol{k}, \boldsymbol{l}).$$

In the following we will show that $r_{b,\alpha}(\boldsymbol{0}, \boldsymbol{0}) = 1$ and $r_{b,\alpha}(\boldsymbol{0}, \boldsymbol{k}) = r_{b,\alpha}(\boldsymbol{k}, \boldsymbol{0}) = 0$ if $\boldsymbol{k} \neq \boldsymbol{0}$ from which the result then follows. Note that it is enough to show those identities for the one-dimensional case. We have $\mathrm{wal}_0(x) = 1$ for all $x \in [0, 1)$, and hence

$$\begin{aligned} r_{b,\alpha}(0, k) &= \int_0^1 \int_0^1 \left(1 + \sum_{h \in \mathbb{Z} \setminus \{0\}} |h|^{-2\alpha} \mathrm{e}^{2\pi \mathrm{i} h(x-y)}\right) \mathrm{wal}_k(y) \, \mathrm{d}x \, \mathrm{d}y \\ &= \int_0^1 \mathrm{wal}_k(y) \, \mathrm{d}y + \int_0^1 \sum_{h \in \mathbb{Z} \setminus \{0\}} |h|^{-2\alpha} \int_0^1 \mathrm{e}^{2\pi \mathrm{i} h x} \, \mathrm{d}x \, \mathrm{e}^{-2\pi \mathrm{i} h y} \mathrm{wal}_k(y) \, \mathrm{d}y \\ &= \int_0^1 \mathrm{wal}_k(y) \, \mathrm{d}y. \end{aligned}$$

It now follows from Proposition 2.3 that $r_{b,\alpha}(0, 0) = 1$ and $r_{b,\alpha}(0, k) = 0$ for $k > 0$. The result for $r_{b,\alpha}(k, 0)$ can be obtained in the same manner. Hence the result follows. ∎

In the following lemma we obtain a formula for the Walsh coefficients $r_{b,\alpha}$.

LEMMA 2.6. *Let $b \geq 2$ be an integer, and let $\alpha > 1/2$ be a real number. The Walsh coefficients $r_{b,\alpha}(k, l)$ for $k, l \in \mathbb{N}$ are given by*

$$r_{b,\alpha}(k, l) = \sum_{h \in \mathbb{Z} \setminus \{0\}} \frac{\overline{\beta_{h,k}} \beta_{h,l}}{|h|^{2\alpha}},$$

where $\beta_{h,k} = \int_0^1 \mathrm{e}^{-2\pi \mathrm{i} h x} \mathrm{wal}_k(x) \, \mathrm{d}x$.

Proof. We have

$$r_{b,\alpha}(k,l) = \int_0^1 \int_0^1 \sum_{h\in\mathbb{Z}\setminus\{0\}} |h|^{-2\alpha} \mathrm{e}^{2\pi \mathrm{i} h(x-y)} \overline{\mathrm{wal}_k(x)} \mathrm{wal}_l(y)\,\mathrm{d}x\,\mathrm{d}y$$
$$= \sum_{h\in\mathbb{Z}\setminus\{0\}} |h|^{-2\alpha} \int_0^1 \mathrm{e}^{2\pi \mathrm{i} hx} \overline{\mathrm{wal}_k(x)}\,\mathrm{d}x \int_0^1 \mathrm{e}^{-2\pi \mathrm{i} hy} \mathrm{wal}_l(y)\,\mathrm{d}y.$$

The result follows. □

It is difficult to calculate the exact value of $r_{b,\alpha}(k,l)$ in general, but for our purposes it is enough to obtain an upper bound. Note that $r_{b,\alpha}(k,k)$ is a nonnegative real number.

LEMMA 2.7. *Let $b \geq 2$ be an integer, and let $\alpha > 1/2$ be a real number. The Walsh coefficients $r_{b,\alpha}(k,l)$ for $k,l \in \mathbb{N}$ are bounded by*

$$|r_{b,\alpha}(k,l)|^2 \leq r_{b,\alpha}(k,k) r_{b,\alpha}(l,l).$$

Proof. Using Lemma 2.6 we obtain

$$|r_{b,\alpha}(k,l)|^2 \leq \left(\sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{|\beta_{h,k}||\beta_{h,l}|}{|h|^{2\alpha}} \right)^2 \leq \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{|\beta_{h,k}|^2}{|h|^{2\alpha}} \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{|\beta_{h,l}|^2}{|h|^{2\alpha}}$$
$$= r_{b,\alpha}(k,k) r_{b,\alpha}(l,l).$$

The result follows. □

In the following we will write $r_{b,\alpha}(k)$ instead of $r_{b,\alpha}(k,k)$ and also $r_{b,\alpha}(\boldsymbol{k})$ instead of $r_{b,\alpha}(\boldsymbol{k},\boldsymbol{k})$.

LEMMA 2.8. *Let $C_1,\dots,C_s \in \mathbb{Z}_b^{m\times m}$ be the generating matrices of a digital net P_{b^m}, and let $\mathcal{D}$ denote the dual net. Then for any natural number α the worst-case error in $\mathcal{H}_\alpha$ is bounded by*

$$e(P_{b^m}, K_\alpha) \leq \sum_{\boldsymbol{k}\in\mathcal{D}} \sqrt{r_{b,\alpha}(\boldsymbol{k})}.$$

Proof. From Theorem 2.5 and Lemma 2.7 it follows that

$$e^2(P_{b^m}, K_\alpha) \leq \sum_{\boldsymbol{k},\boldsymbol{l}\in\mathcal{D}} |r_{b,\alpha}(\boldsymbol{k},\boldsymbol{l})| \leq \left(\sum_{\boldsymbol{k}\in\mathcal{D}} \sqrt{r_{b,\alpha}(\boldsymbol{k},\boldsymbol{k})} \right)^2,$$

and hence the result follows. □

For $\alpha \geq 1$ a natural number we can write the reproducing kernel in terms of Bernoulli polynomials of degree 2α. Then for $k \geq 1$ we have

$$r_{b,\alpha}(k) = (-1)^{\alpha+1} \frac{(2\pi)^{2\alpha}}{(2\alpha)!} \int_0^1 \int_0^1 B_{2\alpha}(|x-y|) \overline{\mathrm{wal}_k(x)} \mathrm{wal}_k(y)\,\mathrm{d}x\,\mathrm{d}y.$$

Note that the Bernoulli polynomials of even degree 2α are of the form

$$B_{2\alpha}(x) = c_\alpha x^{2\alpha} + c_{\alpha-1} x^{2(\alpha-1)} + \cdots + c_0 + c x^{2\alpha-1}$$

for some rational numbers $c_\alpha,\dots,c_0,c$, with $c_\alpha, c \neq 0$. Let

$$I_j(k) = \int_0^1 \int_0^1 |x-y|^j \overline{\mathrm{wal}_k(x)} \mathrm{wal}_k(y)\,\mathrm{d}x\,\mathrm{d}y. \tag{2.6}$$

As mentioned above, $r_{b,\alpha}(k)$ is a real number such that $r_{b,\alpha}(k) \geq 0$ for all $k \geq 1$ and $\alpha > 1/2$; hence, it follows that for any natural number α we have

$$r_{b,\alpha}(k) \leq \frac{(2\pi)^{2\alpha}}{(2\alpha)!} \left(|c_\alpha I_{2\alpha}(k)| + |c_{\alpha-1} I_{2(\alpha-1)}(k)| + \cdots + |c_0 I_0(k)| + |c I_{2\alpha-1}| \right).$$

Using Lemmas 8.2 and 8.5 from the appendix we obtain the following lemma.

LEMMA 2.9. *Let $b, \alpha \in \mathbb{N}$, with $b \geq 2$. For $k \in \mathbb{N}$, with $k = \kappa_1 b^{a_1 - 1} + \cdots + \kappa_\nu b^{a_\nu - 1}$, where $\nu \geq 1$, $\kappa_1, \ldots, \kappa_\nu \in \{1, \ldots, b-1\}$, and $1 \leq a_\nu < \cdots < a_1$, let $q_{b,\alpha}(k) = b^{-a_1 - \cdots - a_{\min(\nu,\alpha)}}$. Then for any natural number α and any natural number $b \geq 2$ there exists a constant $C_{b,\alpha} > 0$ which depends only on b and α such that*

$$r_{b,\alpha}(k) \leq C_{b,\alpha}^2 \, q_{b,\alpha}^2(k) \quad \text{for all } k \geq 1.$$

Let now $q_{b,\alpha}(0) = 1$. For $\boldsymbol{k} = (k_1, \ldots, k_s) \in \mathbb{N}_0^s$ we define $q_{b,\alpha}(\boldsymbol{k}) = \prod_{j=1}^s q_{b,\alpha}(k_j)$. We have the following lemma.

LEMMA 2.10. *Let $m \geq 1$, $b \geq 2$, and $\alpha \geq 2$ be natural numbers, and let $\mathcal{D}^*_{b^m,u} = \mathcal{D}_u \cap \{1, \ldots, b^m - 1\}^{|u|}$. Then we have*

$$\begin{aligned}
&\sum_{\boldsymbol{k} \in \mathcal{D}} \sqrt{r_{b,\alpha}(\boldsymbol{k})} \\
&\leq \sum_{\emptyset \neq u \subseteq \{1,\ldots,s\}} (1 + b^{-\alpha m} C_{b,\alpha}(\alpha + b^{-2}))^{s-|u|} C_{b,\alpha}^{|u|} (1 + \alpha + b^{-2})^{|u|} Q^*_{b,m,u,\alpha}(C_1, \ldots, C_s) \\
&\quad + (1 + b^{-\alpha m} C_{b,\alpha}(\alpha + b^{-2}))^s - 1,
\end{aligned}$$

where $C_{b,\alpha}$ is the constant from Lemma 2.9 and where

$$Q^*_{b,m,u,\alpha}(C_1, \ldots, C_s) = \sum_{\boldsymbol{k} \in \mathcal{D}^*_{b^m,u}} q_{b,\alpha}(\boldsymbol{k}).$$

Proof. Every $\boldsymbol{k} \in \mathbb{N}_0^s$ can be uniquely written in the form $\boldsymbol{k} = \boldsymbol{h} + b^m \boldsymbol{l}$, with $\boldsymbol{h} \in \{0, \ldots, b^m - 1\}^s$ and $\boldsymbol{l} \in \mathbb{N}_0^s$. Let $\mathcal{D}_{b^m} = \mathcal{D} \cap \{0, \ldots, b^m - 1\}^s$. Then we have

$$\sum_{\boldsymbol{k} \in \mathcal{D}} \sqrt{r_{b,\alpha}(\boldsymbol{k})} = \sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \sqrt{r_{b,\alpha}(b^m \boldsymbol{l})} + \sum_{\boldsymbol{h} \in \mathcal{D}_{b^m}} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \sqrt{r_{b,\alpha}(\boldsymbol{h} + b^m \boldsymbol{l})}.$$

For the first sum we have

$$\sum_{\boldsymbol{l} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} \sqrt{r_{b,\alpha}(b^m \boldsymbol{l})} = -1 + \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \sqrt{r_{b,\alpha}(b^m \boldsymbol{l})} = -1 + \left(\sum_{l=0}^\infty \sqrt{r_{b,\alpha}(b^m l)} \right)^s.$$

By using Lemma 8.8 from the appendix and Lemma 2.9 we obtain that

$$\sum_{l=0}^\infty \sqrt{r_{b,\alpha}(b^m l)} = 1 + b^{-\alpha m} \sum_{l=1}^\infty \sqrt{r_{b,\alpha}(l)} \leq 1 + b^{-\alpha m} C_{b,\alpha} \sum_{l=1}^\infty q_{b,\alpha}(l).$$

We need to show that $\sum_{l=1}^\infty q_{b,\alpha}(l) \leq \alpha + b^{-2}$. Let $l = l_1 b^{c_1 - 1} + \cdots + l_\nu b^{c_\nu - 1}$ for some $\nu \geq 1$, with $1 \leq c_\nu < \cdots < c_1$ and $l_1, \ldots, l_\nu \in \{1, \ldots, b-1\}$. First we consider the sum over all those l for which $1 \leq \nu \leq \alpha$. This part of the sum is bounded by

$$\sum_{\nu=1}^\alpha (b-1)^\nu \sum_{c_1=\nu}^\infty \sum_{c_2=\nu-1}^{c_1-1} \cdots \sum_{c_\nu=1}^{c_{\nu-1}-1} b^{-c_1 - \cdots - c_\nu} \leq \sum_{\nu=1}^\alpha (b-1)^\nu \left(\sum_{c=1}^\infty b^{-c} \right)^\nu = \alpha.$$

If $\nu > \alpha$, we have $q_{b,\alpha}(l) = q_{b,\alpha}(l')$ for $l = l_1 b^{c_1-1} + \cdots + l_\nu b^{c_\nu - 1}$ and where $l' = l'(l) = l_1 b^{c_1-1} + \cdots + l_\alpha b^{c_\alpha - 1}$. Thus we only need to sum over all l' (i.e., natural numbers with exactly α digits) and for given l' multiply it with the number of l which yield the same l', which is $b^{c_\alpha - 1} - 1$ (and which we bound in the following by $b^{c_\alpha - 1}$). We have

$$\begin{aligned}
&(b-1)^\alpha \sum_{c_1=\alpha+1}^{\infty} \sum_{c_2=\alpha}^{c_1-1} \cdots \sum_{c_\alpha=2}^{c_{\alpha-1}-1} b^{-c_1-\cdots-c_\alpha} b^{c_\alpha-1} \\
&= b^{-1}(b-1)^\alpha \sum_{c_1=\alpha+1}^{\infty} \sum_{c_2=\alpha}^{c_1-1} \cdots \sum_{c_{\alpha-1}=3}^{c_{\alpha-2}-2} (c_{\alpha-1}-2) b^{-c_1-\cdots-c_{\alpha-1}} \\
&\le b^{-3}(b-1)^\alpha \left(\sum_{c=1}^{\infty} b^{-c} \right)^{\alpha-2} \sum_{c=1}^{\infty} c b^{-c} \\
&= \frac{1}{b^2}.
\end{aligned}$$

Thus we obtain $\sum_{l=1}^{\infty} q_{b,\alpha}(l) \le \alpha + b^{-2}$.

Further we have

$$\sum_{\boldsymbol{h} \in \mathcal{D}_{b^m}} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \sqrt{r_{b,\alpha}(\boldsymbol{h} + b^m \boldsymbol{l})} = \sum_{\boldsymbol{h} \in \mathcal{D}_{b^m}} \prod_{j=1}^{s} \sum_{l=0}^{\infty} \sqrt{r_{b,\alpha}(h_j + b^m l)},$$

where $\boldsymbol{h} = (h_1, \ldots, h_s)$. By using Lemma 8.8 from the appendix and Lemma 2.9 we obtain

$$\sum_{l=0}^{\infty} \sqrt{r_{b,\alpha}(b^m l)} = 1 + b^{-\alpha m} C_{b,\alpha} \sum_{l=1}^{\infty} q_{b,\alpha}(l) \le 1 + b^{-\alpha m} C_{b,\alpha} (\alpha + b^{-2}).$$

Let now $0 < h_j < b^m$. From Lemma 2.9 we obtain

$$\sqrt{r_{b,\alpha}(h_j + b^m l)} \le C_{b,\alpha} q_{b,\alpha}(h_j + b^m l) \le C_{b,\alpha} q_{b,\alpha}(h_j) q_{b,\alpha}(l).$$

From above we have $\sum_{l=0}^{\infty} q_{b,\alpha}(l) \le 1 + \alpha + b^{-2}$ and hence

$$\sum_{l=0}^{\infty} \sqrt{r_{b,\alpha}(h_j + b^m l)} \le q_{b,\alpha}(h_j) C_{b,\alpha} \sum_{l=0}^{\infty} q_{b,\alpha}(l) \le C_{b,\alpha} (1 + \alpha + b^{-2}) q_{b,\alpha}(h_j).$$

Thus we obtain

$$\begin{aligned}
&\sum_{\boldsymbol{h} \in \mathcal{D}_{b^m}} \sum_{\boldsymbol{l} \in \mathbb{N}_0^s} \sqrt{r_{b,\alpha}(\boldsymbol{h} + b^m \boldsymbol{l})} \\
&= \sum_{\emptyset \ne u \subseteq \{1,\ldots,s\}} \sum_{\boldsymbol{h}_u \in \mathcal{D}^*_{b^m,u}} \prod_{j \in u} \sum_{l=0}^{\infty} \sqrt{r_{b,\alpha}(h_j + b^m l)} \prod_{j \notin u} \sum_{l=0}^{\infty} \sqrt{r_{b,\alpha}(b^m l)} \\
&\le \sum_{\emptyset \ne u \subseteq \{1,\ldots,s\}} (1 + b^{-\alpha m} C_{b,\alpha} (\alpha + b^{-2}))^{s-|u|} C_{b,\alpha}^{|u|} (1 + \alpha + b^{-2})^{|u|} \sum_{\boldsymbol{h}_u \in \mathcal{D}^*_{b^m,u}} \prod_{j \in u} q_{b,\alpha}(h_j),
\end{aligned}$$

where $\boldsymbol{h}_u = (h_j)_{j \in u}$. The result follows. ∎

In [24] it was shown that the square worst-case error for numerical integration in the Korobov space can at best be of $\mathcal{O}(N^{-2\alpha}(\log N)^{s-1})$, where N is the number of quadrature points. Hence Lemma 2.10 shows that it is enough to consider only $Q^*_{b,m,u,\alpha}(C_1,\dots,C_s)$ in order to investigate the convergence rate of digitally shifted digital nets.

3. $(t,\boldsymbol{\alpha},\boldsymbol{\beta},m,s)$-nets and $(t,\boldsymbol{\alpha},\boldsymbol{\beta},s)$-sequences. The t-value of a (t,m,s)-net is a quality parameter for the distribution properties of the net. A low t-value yields well-distributed point sets, and it has been shown (see, for example, [5, 17]) that a small t-value also guarantees a small worst-case error for integration in Sobolev spaces for which the partial first derivatives are square integrable.

In the following we will show how the definition of the t-value needs to be modified in order to obtain faster convergence rates for periodic Sobolev spaces for which the partial derivatives up to order α are square integrable. It is the aim of this definition to translate the problem of minimizing the worst-case error into an algebraical problem concerning the generating matrices. (This definition can therefore also be used in a computer search algorithm, where one could, for example, search for the polynomial lattice with the smallest $t(\alpha)$-value which, in turn, yields a small worst-case error for integration of periodic functions.)

For natural numbers $\alpha \geq 1$, Lemma 2.9 suggests defining the following metric $\mu_{b,\alpha}(\boldsymbol{k},\boldsymbol{l}) = \mu_{b,\alpha}(\boldsymbol{k} \ominus \boldsymbol{l})$ on $\mathbb{N}_0^s$ which is an extension of the metric introduced in [15]; see also [23] (for $\alpha = 1$ we basically obtain the metric in [15, 23]). Here $\mu_{b,\alpha}(0) = 0$ and for $k \in \mathbb{N}$, with $k = \kappa_\nu b^{a_\nu - 1} + \cdots + \kappa_1 b^{a_1 - 1}$, where $1 \leq a_\nu < \cdots < a_1$ and $\kappa_i \in \{1,\dots,b-1\}$, let $\mu_{b,\alpha}(k) = a_1 + \cdots + a_{\min(\alpha,\nu)}$. For a $\boldsymbol{k} \in \mathbb{N}_0^s$, with $\boldsymbol{k} = (k_1,\dots,k_s)$, let $\mu_{b,\alpha}(\boldsymbol{k}) = \mu_{b,\alpha}(k_1) + \cdots + \mu_{b,\alpha}(k_s)$. Then we have $q_{b,\alpha}(\boldsymbol{k}) = b^{-\mu_{b,\alpha}(\boldsymbol{k})}$. Hence in order to obtain a small worst-case error in the Korobov space $\mathcal{H}_\alpha$, we need digital nets for which $\min\{\mu_{b,\alpha}(\boldsymbol{k}) : \boldsymbol{k} \in \mathcal{D}\}$ is large. We can translate this property into a linear independence property of the row vectors of the generating matrices $C_1,\dots,C_s$. We have the following definition.

DEFINITION 3.1. *Let $m, \alpha \geq 1$ be natural numbers, let $0 < \beta \leq \alpha$ be a real number, and let $0 \leq t \leq \beta m$ be a natural number. Let R_b be a ring with b elements, and let $C_1,\dots,C_s \in R_b^{m\times m}$, with $C_j = (c_{j,1},\dots,c_{j,m})^T$. If for all $1 \leq i_{j,\nu_j} < \cdots < i_{j,1} \leq m$, where $0 \leq \nu_j \leq m$ for all $j = 1,\dots,s$, with*

$$i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha)} \leq \beta m - t,$$

the vectors

$$c_{1,i_{1,\nu_1}},\dots,c_{1,i_{1,1}},\dots,c_{s,i_{s,\nu_s}},\dots,c_{s,i_{s,1}}$$

are linearly independent over R_b, then the digital net which has generating matrices $C_1,\dots,C_s$ is called a digital (t,α,β,m,s)-net over R_b. Further we call a digital (t,α,α,m,s)-net over R_b a digital (t,α,m,s)-net over R_b.

If t is the smallest nonnegative integer such that the digital net generated by $C_1,\dots,C_s$ is a digital (t,α,β,m,s)-net, then we call the digital net a strict digital (t,α,β,m,s)-net or a strict digital (t,α,m,s)-net if $\alpha = \beta$.

A concrete example of a digital (t,α,β,m,s)-net, where we also calculate the exact t-value by hand, is given in section 7.

Remark 1. Using duality theory (see [19]) it follows that for every digital (t,α,β,m,s)-net we have $\min_{\boldsymbol{k}\in\mathcal{D}} \mu_{b,\alpha}(\boldsymbol{k}) > \beta m - t$, and for a strict digital (t,α,β,m,s)-net we have $\min_{\boldsymbol{k}\in\mathcal{D}} \mu_{b,\alpha}(\boldsymbol{k}) = \beta m - t + 1$. Hence digital (t,α,β,m,s)-nets with high quality have a large value of $\beta m - t$.

DEFINITION 3.2. *Let $\alpha \geq 1$ and $t \geq 0$ be integers, and let $0 < \beta \leq \alpha$ be a real number. Let R_b be a ring with b elements, and let $C_1, \ldots, C_s \in R_b^{\infty \times \infty}$, with $C_j = (c_{j,1}, c_{j,2}, \ldots)^T$. Further let $C_{j,m}$ denote the left upper $m \times m$ submatrix of C_j. If for all $m > t/\beta$ the matrices $C_{1,m}, \ldots, C_{s,m}$ generate a digital (t, α, β, m, s)-net, then the digital sequence with generating matrices $C_1, \ldots, C_s$ is called a digital (t, α, β, s)-sequence over R_b. Further we call a digital (t, α, α, s)-sequence over R_b a digital (t, α, s)-sequence over R_b.*

If t is the smallest nonnegative integer such that the digital sequence generated by $C_1, \ldots, C_s$ is a digital (t, α, β, s)-sequence, then we call the digital sequence a strict digital (t, α, β, s)-sequence or a strict digital (t, α, s)-sequence if $\alpha = \beta$.

Remark 2. Note that the definition of a digital $(t, 1, m, s)$-net coincides with the definition of a digital (t, m, s)-net and the definition of a digital $(t, 1, s)$-sequence coincides with the definition of a digital (t, s)-sequence as defined by Niederreiter [17]. Further note that the t-value depends on α and β, i.e., $t = t(\alpha, \beta)$ or $t = t(\alpha)$ if $\alpha = \beta$.

In the following theorem we establish some propagation rules.

THEOREM 3.3. *Let P be a digital (t, α, β, m, s)-net over a ring R_b, and let S be a digital (t, α, β, s)-sequence over a ring R_b. Then we have the following:*

(i) *P is a digital $(t', \alpha, \beta', m, s)$-net for all $1 \leq \beta' \leq \beta$ and all $t \leq t' \leq \beta' m$, and S is a digital (t', α, β', s)-sequence for all $1 \leq \beta' \leq \beta$ and all $t \leq t'$.*

(ii) *P is a digital $(t', \alpha', \beta', m, s)$-net for all $1 \leq \alpha' \leq m$, and S is a digital (t', α', β', s)-sequence for all $\alpha' \geq 1$, where $\beta' = \beta \min(\alpha, \alpha')/\alpha$ and $t' = \lceil t \min(\alpha, \alpha')/\alpha \rceil$.*

(iii) *Any digital (t, α, m, s)-net is a digital $(\lceil t\alpha'/\alpha \rceil, \alpha', m, s)$-net for all $1 \leq \alpha' \leq \alpha$, and every digital (t, α, s)-sequence is a digital $(\lceil t\alpha'/\alpha \rceil, \alpha', s)$-sequence for all $1 \leq \alpha' \leq \alpha$.*

Proof. Note that it follows from Definition 3.2 that we need to prove the result only for digital nets.

The first part follows trivially. To prove the second part choose an α' such that $\alpha' \geq 1$. Then choose arbitrary $1 \leq i_{j,\nu_j} < \cdots < i_{j,1} \leq m$, with $0 \leq \nu_j \leq m$, such that

$$i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha')} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha')} \leq m\beta \frac{\min(\alpha, \alpha')}{\alpha} - \left\lceil t \frac{\min(\alpha, \alpha')}{\alpha} \right\rceil.$$

We need to show that the vectors

$$c_{1,i_{1,\nu_1}}, \ldots, c_{1,i_{1,1}}, \ldots, c_{s,i_{s,\nu_s}}, \ldots, c_{s,i_{s,1}}$$

are linearly independent over R_b. This is certainly the case as long as

$$i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha)} \leq \beta m - t.$$

Indeed we have

$$\begin{aligned}
&i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha)} \\
&\leq \frac{\alpha}{\min(\alpha, \alpha')} (i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha')} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha')}) \\
&\leq m\beta - \frac{\alpha}{\min(\alpha, \alpha')} \left\lceil t \frac{\min(\alpha, \alpha')}{\alpha} \right\rceil \\
&\leq m\beta - t,
\end{aligned}$$

and hence the second part follows. The third part is just a special case of the second part. ∎

Remark 3. Note that by choosing $\alpha' = 1$ in part (iii) of Theorem 3.3 it follows that digital (t, α, m, s)-nets and digital (t, α, s)-sequences are also well-distributed point sets if the value of t is small; see [17].

4. Explicit constructions of digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences. In this section we show how suitable digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences can be constructed.

Let $d \geq 1$, and let $C_1, \ldots, C_{sd}$ be the generating matrices of a digital (t, m, sd)-net. Note that many explicit examples of such generating matrices are known; see, for example, [6, 17, 20, 30] and the references therein. For the construction of a (t, α, β, m, s)-net any of the above mentioned explicit constructions can be used, but, as will be shown below, the quality of the (t, α, β, m, s)-net obtained depends on the quality of the underlying digital (t, m, sd)-net on which our construction is based.

Let $C_j = (c_{j,1}, \ldots, c_{j,m})^T$ for $j = 1, \ldots, sd$; i.e., $c_{j,l}$ are the row vectors of C_j. Now let the matrix $C_j^{(d)}$ be made of the first rows of the matrices $C_{(j-1)d+1}, \ldots, C_{jd}$, then the second rows of $C_{(j-1)d+1}, \ldots, C_{jd}$, and so on, until $C_j^{(d)}$ is an $m \times m$ matrix, i.e., $C_j^{(d)} = (c_{j,1}^{(d)}, \ldots, c_{j,m}^{(d)})^T$, where $c_{j,l}^{(d)} = c_{u,v}$, with $l = (v-j)d + u$, $1 \leq v \leq m$, and $(j-1)d < u \leq jd$ for $l = 1, \ldots, m$ and $j = 1, \ldots, s$. In the following we will show that the matrices $C_1^{(d)}, \ldots, C_s^{(d)}$ are the generating matrices of a digital $(t, \alpha, \min(\alpha, d), m, s)$-net.

THEOREM 4.1. *Let $d \geq 1$ be a natural number, and let $C_1, \ldots, C_{sd}$ be the generating matrices of a digital (t', m, sd)-net over some ring R_b with b elements. Let $C_1^{(d)}, \ldots, C_s^{(d)}$ be defined as above. Then for any $\alpha \geq 1$ the matrices $C_1^{(d)}, \ldots, C_s^{(d)}$ are generating matrices of a digital $(t, \alpha, \min(\alpha, d), m, s)$-net over R_b, with*

$$t = \min(\alpha, d)\, t' + \left\lceil \frac{s(d-1)\min(\alpha, d)}{2} \right\rceil.$$

Proof. Let $C_j^{(d)} = (c_{j,1}^{(d)}, \ldots, c_{j,m}^{(d)})^T$ for $j = 1, \ldots, s$, and further let the integers $i_{1,1}, \ldots, i_{1,\nu_1}, \ldots, i_{s,1}, \ldots, i_{s,\nu_s}$ be such that $1 \leq i_{j,\nu_j} < \cdots < i_{j,1} \leq m$ and

$$i_{1,1} + \cdots + i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,1} + \cdots + i_{s,\min(\nu_s,\alpha)} \leq \min(\alpha, d)m - t.$$

We need to show that the vectors

$$c_{1,i_{1,1}}^{(d)}, \ldots, c_{1,i_{1,\nu_1}}^{(d)}, \ldots, c_{s,i_{s,1}}^{(d)}, \ldots, c_{s,i_{s,\nu_s}}^{(d)}$$

are linearly independent over R_b. For $j = 1, \ldots, s$ let $U_j = \{c_{j,i_{j,\nu_j}}^{(d)}, \ldots, c_{j,i_{j,1}}^{(d)}\}$. The vectors in the set U_j stem from the matrices $C_{(j-1)d+1}, \ldots, C_{jd}$. For $j = 1, \ldots, s$ and $d_j = (j-1)d + 1, \ldots, jd$ let e_{d_j} denote the largest index such that $(e_{d_j} - j)d + d_j \in \{i_{j,\nu_j}, \ldots, i_{j,1}\}$, and if for some d_j there is no such e_{d_j}, we set $e_{d_j} = 0$ (basically this means e_{d_j} is the largest integer such that $c_{d_j, e_{d_j}} \in U_j$).

Let $d \leq \alpha$; then we have $d((e_{(j-1)d+1} - 1)_+ + \cdots + (e_{jd} - 1)_+) + \sum_{l=1}^{L_j} l \leq i_{j,1} + \cdots + i_{j,\min(\nu_j,d)}$, where $(x)_+ = \max(x, 0)$ and $L_j = |\{(j-1)d+1 \leq d_j \leq jd : e_{d_j} > 0\}|$. Hence we have

$$\begin{aligned} &d((e_{(j-1)d+1} - 1)_+ + \cdots + (e_{jd} - 1)_+) + \sum_{l=1}^{L_j} l \\ &= d(e_{(j-1)d+1} + \cdots + e_{jd}) - L_j d + L_j(L_j + 1)/2 \\ &\geq d(e_{(j-1)d+1} + \cdots + e_{jd}) - \frac{d(d-1)}{2}. \end{aligned} \tag{4.1}$$

Thus it follows that

$$d(e_1+\cdots+e_{sd}) \le \sum_{j=1}^{s}(i_{j,1}+\cdots+i_{j,\min(\nu_j,\alpha)}) + s\frac{d(d-1)}{2} \le dm - t + s\frac{d(d-1)}{2},$$

and therefore

$$e_1+\cdots+e_{sd} \le m - \frac{t}{d} + s\frac{d-1}{2} \le m - t'.$$

Thus it follows from the (t', m, sd)-net property of the digital net generated by $C_1, \dots, C_{sd}$ that the vectors $c^{(d)}_{1,i_{1,1}}, \dots, c^{(d)}_{1,i_{1,\nu_1}}, \dots, c^{(d)}_{s,i_{s,1}}, \dots, c^{(d)}_{s,i_{s,\nu_s}}$ are linearly independent.

Let now $d > \alpha$. Then we have $d((e_{(j-1)d+1}-1)_+ + \cdots + (e_{jd}-1)_+) + \sum_{l=1}^{L_j} l \le i_{j,1}+\cdots+i_{j,\min(\nu_j,\alpha)} + (d-\alpha)i_{j,\min(\nu_j,\alpha)}$, where again $L_j = |\{(j-1)d+1 \le d_j \le jd : e_{d_j} > 0\}|$. Hence we can use inequality (4.1) again. Note that $i_{1,\min(\nu_1,\alpha)} + \cdots + i_{s,\min(\nu_s,\alpha)} \le m - t/\alpha$, and hence we have

$$\sum_{j=1}^{s}(i_{j,1}+\cdots+i_{j,\min(\nu_j,\alpha)}+(d-\alpha)i_{j,\min(\nu_j,\alpha)}) \le \alpha m - t + (d-\alpha)(m-t/\alpha) = dm - dt/\alpha.$$

Thus it follows that

$$\begin{aligned} d(e_1+\cdots+e_{sd}) &\le \sum_{j=1}^{s}(i_{j,1}+\cdots+i_{j,\min(\nu_j,\alpha)}+(d-\alpha)i_{j,\min(\nu_j,\alpha)}) + s\frac{d(d-1)}{2} \\ &\le dm - \frac{dt}{\alpha} + s\frac{d(d-1)}{2}, \end{aligned}$$

and therefore

$$e_1+\cdots+e_{sd} \le m - \frac{t}{\alpha} + s\frac{d-1}{2} \le m - t'.$$

Thus it follows from the (t', m, sd)-net property of the digital net generated by $C_1, \dots, C_{sd}$ that the vectors $c^{(d)}_{1,i_{1,1}}, \dots, c^{(d)}_{1,i_{1,\nu_1}}, \dots, c^{(d)}_{s,i_{s,1}}, \dots, c^{(d)}_{s,i_{s,\nu_s}}$ are linearly independent, and hence the result follows. □

In section 7 we use this construction method to construct a digital $(3, 2, 4, 2)$-net over $\mathbb{Z}_2$.

Note that the construction and Theorem 4.1 can easily be extended to (t, α, β, s)-sequences. Indeed, let $d \ge 1$, and let $C_1, \dots, C_{sd}$ be the generating matrices of a digital (t, sd)-sequence. Again many explicit generating matrices are known; see, for example, [6, 17, 20, 30]. Let $C_j = (c_{j,1}, c_{j,2}, \dots)^T$ for $j = 1, \dots, sd$; i.e., $c_{j,l}$ are the row vectors of C_j. Now let the matrix $C^{(d)}_j$ be made of the first rows of the matrices $C_{(j-1)d+1}, \dots, C_{jd}$, then the second rows of $C_{(j-1)d+1}, \dots, C_{jd}$, and so on, i.e.,

$$C^{(d)}_j = (c_{(j-1)d+1,1}, \dots, c_{jd,1}, c_{(j-1)d+1,2}, \dots, c_{jd,2}, \dots)^T.$$

The following theorem states that the matrices $C^{(d)}_1, \dots, C^{(d)}_s$ are the generating matrices of a digital $(t, \alpha, \min(\alpha, d), s)$-sequence.

THEOREM 4.2. *Let $d \ge 1$ be a natural number, and let $C_1, \dots, C_{sd}$ be the generating matrices of a digital (t', sd)-sequence over some ring R_b with b elements. Let*

$C_1^{(d)}, \dots, C_s^{(d)}$ *be defined as above. Then for any* $\alpha \geq 1$ *the matrices* $C_1^{(d)}, \dots, C_s^{(d)}$ *are generating matrices of a digital* $(t, \alpha, \min(\alpha, d), s)$*-sequence over* R_b*, with*

$$t = \min(\alpha, d)\, t' + \left\lceil \frac{s(d-1)\min(\alpha, d)}{2} \right\rceil.$$

The last result shows that (t, α, β, m, s)-nets indeed exist for any $0 < \beta \leq \alpha$ and for m arbitrarily large. We have even shown that digital (t, α, β, m, s)-nets exist which are extensible in m and s. This can be achieved by using an underlying (t', sd)-sequence which is itself extensible in m and s. If the t'-value of the original (t', m, s)-net or (t', s)-sequence is known explicitly, then we also know the t-value of the digital (t, α, β, m, s)-net or (t, α, β, s)-sequence. Furthermore it has also been shown how such digital nets can be constructed in practice.

In the following we investigate for which values of t, α, s, b digital (t, α, s)-sequences over $\mathbb{Z}_b$ exist. We need some further notation (see also [21, Definition 8.2.15]).

DEFINITION 4.3. *For given integers* $s, \alpha \geq 1$ *and prime number* b *let* $d_b(s, \alpha)$ *be the smallest value of* t *such that a* (t, α, s)*-sequence over* $\mathbb{Z}_b$ *exists.*

We have the following bound on $d_b(s, \alpha)$.

COROLLARY 4.4. *Let* $s, \alpha \geq 1$ *be integers and* b *be a prime number. Then we have*

$$\alpha \left(\frac{s}{b} - 1 - \log_b \frac{(b-1)s + b + 1}{2} \right) + 1$$
$$\leq d_b(s, \alpha) \leq \alpha(s-1)\frac{3b-1}{b-1} - \alpha \frac{(2b+4)\sqrt{s-1}}{\sqrt{b^2-1}} + 2\alpha + s\frac{\alpha(\alpha-1)}{2}.$$

Proof. The lower bound follows from part (iii) of Theorem 3.3 by choosing $\alpha' = 1$ and using a lower bound on the t-value for (t, s)-sequences (see [20]). The upper bound follows from Theorem 4.2 by choosing $d = \alpha$ and using Theorem 8.4.4 of [21]. □

5. A bound on the worst-case error in $\mathcal{H}_\alpha$ for digital (t, α, β, m, s)-nets and digital (t, α, β, s)-sequences. In this section we prove an upper bound on the worst-case error for integration in the Korobov space $\mathcal{H}_\alpha$ using digital (t, α, β, m, s)-nets and (t, α, β, s)-sequences.

LEMMA 5.1. *Let* $\alpha \geq 2$ *be a natural number, let* b *be prime, and let* $C_1, \dots, C_s \in \mathbb{Z}_b^{m \times m}$ *be the generating matrices of a digital* (t, α, β, m, s)*-net over* $\mathbb{Z}_b$*, with* $m > t/\beta$*. Then we have*

$$Q^*_{b,m,u,\alpha}(C_1, \dots, C_s) \leq 2b^{|u|\alpha} b^{-\beta m + t} (\beta m + 2)^{|u|\alpha - 1},$$

where $Q^*_{b,m,u,\alpha}$ *is defined in Lemma* 2.10*.*

Proof. We obtain a bound on $Q^*_{b,m,\{1,\dots,s\},\alpha}$; for all other subsets u, the bound can be obtained using the same arguments.

We first partition the set $\mathcal{D}^*_{b^m,\{1,\dots,s\}}$ into parts where the highest digits of k_j are prescribed, and we count the number of solutions of $C_1^T \vec{k}_1 + \cdots + C_s^T \vec{k}_s = \vec{0}$. For $j = 1, \dots, s$ let now $i_{j,\alpha} < \cdots < i_{j,1} \leq m$, with $i_{j,1} \geq 1$. Note that we now allow $i_{j,l} < 1$, in which case the contributions of those $i_{j,l}$ are to be ignored. This notation is adopted in order to avoid considering many special cases. Now we define

$$\mathcal{D}^*_{b^m,\{1,\dots,s\}}(i_{1,1}, \dots, i_{1,\alpha}, \dots, i_{s,1}, \dots, i_{s,\alpha})$$
$$= \{\boldsymbol{k} \in \mathcal{D}^*_{b^m,\{1,\dots,s\}} : k_j = \lfloor \kappa_{j,1} b^{i_{j,1}-1} + \cdots + \kappa_{j,\alpha} b^{i_{j,\alpha}-1} + l_j \rfloor, \text{ with } 0 \leq l_j < b^{i_{j,\alpha}-1}$$
$$\text{and } 1 \leq \kappa_{j,l} < b \text{ for } j = 1, \dots, s\},$$

where $\lfloor\cdot\rfloor$ just means that the contributions of $i_{j,l} < 1$ are to be ignored. Then we have

$$Q^*_{b,m,\{1,\dots,s\},\alpha}(C_1,\dots,C_s) = \sum_{i_{1,1}=1}^{m} \cdots \sum_{i_{1,\alpha}=1}^{i_{1,\alpha-1}-1} \cdots \sum_{i_{s,1}=1}^{m} \cdots \sum_{i_{s,\alpha}=1}^{i_{s,\alpha-1}-1} \frac{|\mathcal{D}^*_{b^m,\{1,\dots,s\}}(i_{1,1},\dots,i_{1,\alpha},\dots,i_{s,1},\dots,i_{s,\alpha})|}{b^{i_{1,1}+\cdots+i_{1,\alpha}+\cdots+i_{s,1}+\cdots+i_{s,\alpha}}}. \tag{5.1}$$

Some of the sums above can be empty, in which case we just set the corresponding summation index $i_{j,l} = 0$.

Note that by the (t,α,β,m,s)-net property we have

$$|\mathcal{D}^*_{b^m,\{1,\dots,s\}}(i_{1,1},\dots,i_{1,\alpha},\dots,i_{s,1},\dots,i_{s,\alpha})| = 0$$

as long as $i_{1,1}+\cdots+i_{1,\alpha}+\cdots+i_{s,1}+\cdots+i_{s,\alpha} \le \beta m - t$. Hence let now $0 \le i_{1,1},\dots,i_{s,\alpha} \le m$ be given such that $i_{1,1},\dots,i_{s,1} \ge 1$, $i_{j,\alpha} < \cdots < i_{j,1} \le m$ for $j = 1,\dots,s$ and where if $i_{j,l} < 1$ we set $i_{j,l} = 0$ and $i_{1,1}+\cdots+i_{1,\alpha}+\cdots+i_{s,1}+\cdots+i_{s,\alpha} > \beta m - t$. We now need to estimate $|\mathcal{D}^*_{b^m,\{1,\dots,s\}}(i_{1,1},\dots,i_{1,\alpha},\dots,i_{s,1},\dots,i_{s,\alpha})|$; that is, we need to count the number of $\boldsymbol{k} \in \mathcal{D}^*_{b^m,\{1,\dots,s\}}$ with $k_j = \lfloor \kappa_{j,1} b^{i_{j,1}-1} + \cdots + \kappa_{j,\alpha} b^{i_{j,\alpha}-1} + l_j \rfloor$ such that $C_1^T \vec{k}_1 + \cdots + C_s^T \vec{k}_s = \vec{0}$.

There are at most $(b-1)^{\alpha s}$ choices for $\kappa_{1,1},\dots,\kappa_{s,\alpha}$ (we write at most because if $i_{j,l} < 1$, then the corresponding $\kappa_{j,l}$ does not have any effect and therefore need not to be included). Let now $1 \le \kappa_{1,1},\dots,\kappa_{s,\alpha} < b$ be given, and define

$$\vec{g} = \kappa_{1,1} c^T_{1,i_{1,1}} + \cdots + \kappa_{1,\alpha} c^T_{1,i_{1,\alpha}} + \cdots + \kappa_{s,1} c^T_{s,i_{s,1}} + \cdots + \kappa_{s,\alpha} c^T_{s,i_{s,\alpha}},$$

where we set $c^T_{j,l} = 0$ if $l < 1$. Further let

$$B = (c^T_{1,1},\dots,c^T_{1,i_{1,\alpha}-1},\dots,c^T_{s,1},\dots,c^T_{s,i_{s,\alpha}-1}).$$

Now the task is to count the number of solutions $\vec{l}$ of $B\vec{l} = \vec{g}$. As long as the columns of B are linearly independent, the number of solutions can at most be 1. By the (t,α,β,m,s)-net property this is certainly the case if (we write $(x)_+ = \max(x,0)$)

$$\begin{aligned}(i_{1,\alpha}-1)_+ + \cdots + (i_{1,\alpha}-\alpha)_+ + \cdots + (i_{s,\alpha}-1)_+ + \cdots + (i_{s,\alpha}-\alpha)_+ &\\ \le \alpha(i_{1,\alpha}+\cdots+i_{s,\alpha}) &\\ \le \beta m - t,&\end{aligned}$$

that is, as long as

$$i_{1,\alpha}+\cdots+i_{s,\alpha} \le \frac{\beta m - t}{\alpha}.$$

Let now $i_{1,\alpha}+\cdots+i_{s,\alpha} > \frac{\beta m - t}{\alpha}$. Then by considering the rank of the matrix B and the dimension of the space of solutions of $B\vec{l} = \vec{0}$, it follows that the number of solutions of $B\vec{l} = \vec{g}$ is smaller or equal to $b^{i_{1,\alpha}+\cdots+i_{s,\alpha}-\lfloor(\beta m-t)/\alpha\rfloor}$. Thus we have

$$|\mathcal{D}^*_{b^m,\{1,\dots,s\}}(i_{1,1},\dots,i_{1,\alpha},\dots,i_{s,1},\dots,i_{s,\alpha})| \le \begin{cases} 0 & \text{if } \sum_{j=1}^{s}\sum_{l=1}^{\alpha} i_{j,l} \le \beta m - t, \\ (b-1)^{\alpha s} & \text{if } \sum_{j=1}^{s}\sum_{l=1}^{\alpha} i_{j,l} > \beta m - t \\ & \text{and } \sum_{j=1}^{s} i_{j,\alpha} \le \frac{\beta m - t}{\alpha}, \\ (b-1)^{\alpha s} b^{i_{1,\alpha}+\cdots+i_{s,\alpha}-\lfloor(\beta m-t)/\alpha\rfloor} & \text{if } \sum_{j=1}^{s}\sum_{l=1}^{\alpha} i_{j,l} > \beta m - t \\ & \text{and } \sum_{j=1}^{s} i_{j,\alpha} > \frac{\beta m - t}{\alpha}. \end{cases}$$

We estimate the sum (5.1) now. Let S_1 be the sum in (5.1) where $i_{1,1}+\cdots+i_{s,\alpha} > \beta m - t$ and $i_{1,\alpha}+\cdots+i_{s,\alpha} \le \frac{\beta m-t}{\alpha}$. For an $l > \beta m - t$ let $A_1(l)$ denote the number of admissible choices of $i_{1,1},\dots,i_{s,\alpha}$ such that $l = i_{1,1}+\cdots+i_{s,\alpha}$. Then we have

$$S_1 = (b-1)^{\alpha s} \sum_{l=\beta m-t+1}^{\alpha s m} \frac{A_1(l)}{b^l}.$$

We have $A_1(l) \le \binom{l+s\alpha-1}{s\alpha-1}$, and hence we obtain

$$S_1 \le (b-1)^{s\alpha} \sum_{l=\beta m-t+1}^{\infty} \binom{l+s\alpha-1}{s\alpha-1} \frac{1}{b^l} \le b^{s\alpha} b^{-\beta m+t-1} \binom{\beta m-t+s\alpha}{s\alpha-1},$$

where the last inequality follows from a result by Matoušek [13, Lemma 2.18]; see also [5, Lemma 6].

Let S_2 be the part of (5.1) for which $i_{1,1}+\cdots+i_{s,\alpha} > \beta m-t$ and $i_{1,\alpha}+\cdots+i_{s,\alpha} > \frac{\beta m-t}{\alpha}$; i.e., we have

$$\begin{aligned} S_2 &= (b-1)^{s\alpha} \sum_{i_{1,1}=1}^{m} \cdots \sum_{i_{1,\alpha}=1}^{i_{1,\alpha-1}-1} \cdots \sum_{i_{s,1}=1}^{m} \cdots \sum_{i_{s,\alpha}=1}^{i_{s,\alpha-1}-1} \frac{b^{-\lfloor(\beta m-t)/\alpha\rfloor}}{b^{i_{1,1}+\cdots+i_{1,\alpha-1}+\cdots+i_{s,1}+\cdots+i_{s,\alpha-1}}} \\ &\le \frac{m^s(b-1)^{s\alpha}}{b^{\lfloor(\beta m-t)/\alpha\rfloor}} \sum_{i_{1,1}=1}^{m} \cdots \sum_{i_{1,\alpha-1}=1}^{i_{1,\alpha-2}-1} \cdots \sum_{i_{s,1}=1}^{m} \cdots \sum_{i_{s,\alpha-1}=1}^{i_{s,\alpha-2}-1} \frac{1}{b^{i_{1,1}+\cdots+i_{1,\alpha-1}+\cdots+i_{s,1}+\cdots+i_{s,\alpha-1}}}, \end{aligned} \tag{5.2}$$

where in the first line above we have the additional conditions $i_{1,1}+\cdots+i_{s,\alpha} > \beta m-t$ and $i_{1,\alpha}+\cdots+i_{s,\alpha} > \frac{\beta m-t}{\alpha}$. From the last inequality and $i_{1,\alpha-l}+\cdots+i_{s,\alpha-l} > i_{1,\alpha}+\cdots+i_{s,\alpha}$ for $l = 1,\dots,\alpha-1$, it follows that $i_{1,1}+\cdots+i_{1,\alpha-1}+\cdots+i_{s,1}+\cdots+i_{s,\alpha-1} \ge \lfloor(\beta m-t)(1-\alpha^{-1})\rfloor + 1$. Let $A_2(l)$ denote the number of admissible choices of $i_{1,1},\dots,i_{1,\alpha-1},\dots,i_{s,1},\dots,i_{s,\alpha-1}$ such that $l = i_{1,1}+\cdots+i_{1,\alpha-1}+\cdots+i_{s,1}+\cdots+i_{s,\alpha-1}$. Note that we have $A_2(l) \le \binom{l+s(\alpha-1)-1}{s(\alpha-1)-1}$. Then we have

$$\begin{aligned} S_2 &\le \frac{m^s(b-1)^{s\alpha}}{b^{\lfloor(\beta m-t)/\alpha\rfloor}} \sum_{l=\lfloor(\beta m-t)(1-\alpha^{-1})\rfloor+1}^{\infty} \binom{l+s(\alpha-1)-1}{s(\alpha-1)-1} \frac{1}{b^l} \\ &\le \frac{m^s(b-1)^{s\alpha}}{b^{\lfloor(\beta m-t)/\alpha\rfloor}} \frac{b^{\lceil(\beta m-t)/\alpha\rceil}}{(1-b^{-1})^{s(\alpha-1)} b^{\beta m-t+1}} \binom{\lfloor(\beta m-t)(1-\alpha^{-1})\rfloor + s(\alpha-1)}{s(\alpha-1)-1}, \end{aligned}$$

where the last inequality follows again from a result by Matoušek [13, Lemma 2.18]; see also [5, Lemma 6]. Hence we have

$$S_2 \le m^s b^{s\alpha} b^{-\beta m+t} \binom{\lfloor(\beta m-t)(1-\alpha^{-1})\rfloor + s(\alpha-1)}{s(\alpha-1)-1}.$$

Note that we have $Q^*_{b,m,\alpha,\{1,\dots,s\}}(C_1,\dots,C_s) = S_1 + S_2$. Let $a \ge 1$ and $b \ge 0$ be integers; then we have

$$\binom{a+b}{b} = \prod_{i=1}^{b} \left(1+\frac{a}{i}\right) \le (1+a)^b.$$

Therefore we obtain $S_1 \le b^{s\alpha} b^{-\beta m+t-1}(\beta m-t+2)^{s\alpha-1}$ and $S_2 \le b^{s\alpha} b^{-\beta m+t} m^s (\beta m - t+2)^{s(\alpha-1)-1}$. Thus we have

$$Q^*_{b,m,\alpha,\{1,\dots,s\}}(C_1,\dots,C_s) \le 2b^{s\alpha} b^{-\beta m+t}(\beta m+2)^{s\alpha-1},$$

from which the result follows. □

The following theorem is an immediate consequence of Lemmas 2.10 and 5.1.

THEOREM 5.2. *Let b be prime, let $\alpha \ge 2$ be a natural number, and let $C_1,\dots,C_s \in \mathbb{Z}_b^{m\times m}$ be the generating matrices of a digital (t,α,β,m,s)-net over $\mathbb{Z}_b$, with $m > t/\beta$. Then the worst-case error in the Korobov space $\mathcal{H}_\alpha$ is bounded by*

$$e_{b,m,\alpha}(C_1,\dots,C_s) \le \frac{2\left(1+b^{-\alpha m}C_{b,\alpha}(\alpha+b^{-2})+C_{b,\alpha}(1+\alpha+b^{-2})(\beta m+2)^\alpha\right)^s}{b^{\beta m-t}(\beta m+2)} + (1+b^{-\alpha m}C_{b,\alpha}(\alpha+b^{-2}))^s - 1,$$

where $C_{b,\alpha} > 0$ is the constant in Lemma 2.9.

Remark 4. By the lower bound of Sharygin [24] we have that the worst-case error in the Korobov space $\mathcal{H}_\alpha$ is at most $\mathcal{O}(N^{-\alpha}(\log N)^{s-1})$. Hence it follows from Theorem 5.2 that for a digital (t,α,β,m,s)-net with $\beta > \alpha$ we must have $t = \mathcal{O}((\beta-\alpha)m)$. Thus in order to avoid having a t-value which grows with m, we added the restriction $\beta \le \alpha$ in Definition 3.1. Further, this also implies that a digital (t,α,β,s)-sequence with $t < \infty$ cannot exist if $\beta > \alpha$; hence, $\beta \le \alpha$ is in this case a consequence of the definition rather than a restriction.

Remark 5. Lemma 2.8 also holds for digital nets which are digitally shifted by an arbitrary digital shift $\boldsymbol{\sigma} \in [0,1)^s$, and hence it follows that Theorem 5.2 also holds in a more general form, namely, for all digital (t,α,β,m,s)-nets which are digitally shifted.

Theorem 5.2 shows that we can obtain the optimal convergence rate for natural numbers $\alpha \ge 2$ by using a digital (t,α,m,s)-net. The constructions previously proposed (for example, by Sobol, Faure, Niederreiter, or Niederreiter–Xing) have only been shown to be $(t,1,m,s)$-nets, and it has been proven that they achieve a convergence of the worst-case error of $\mathcal{O}(N^{-1}(\log N)^{s-1})$.

We can use Theorem 5.2 to obtain the following corollary.

COROLLARY 5.3. *Let b be prime, and let $C_1^{(d)},\dots,C_s^{(d)} \in \mathbb{Z}_b^{\infty\times\infty}$ be the generating matrices of a digital $(t(a),a,\min(a,d),s)$-sequence S over $\mathbb{Z}_b$ for any integer $a \ge 1$. Then for any real $\alpha \ge 1$ there is a constant $C'_{b,s,\alpha} > 0$, depending only on b,s, and α, such that the worst-case error in the Korobov space $\mathcal{H}_\alpha$ using the first $N = b^m$ points of S is bounded by*

$$e_{b,m,\alpha}(C_1^{(d)},\dots,C_s^{(d)}) \le C'_{b,s,\alpha} b^{t(\lfloor\alpha\rfloor)} \frac{(\log N)^{s\lfloor\alpha\rfloor-1}}{N^{\min(\lfloor\alpha\rfloor,d)}}.$$

Remark 6. The above corollary shows that digital $(t,\alpha,\min(\alpha,d),s)$-sequences constructed in section 4 achieve the optimal convergence (apart from maybe some $\log N$ factor) of $P_{2\alpha}$ of $\mathcal{O}(N^{-2\alpha}(\log N)^{2s\alpha-2})$ as long as α is an integer such that $1 \le \alpha \le d$. If $\alpha > d$, we obtain a convergence of $\mathcal{O}(N^{-2d}(\log N)^{2s\alpha-2})$.

6. A bound on the mean square worst-case error in $\mathcal{H}_\alpha$ for digital (t,α,β,m,s)-nets and digital (t,α,β,s)-sequences. To combine the advantages of random quadrature points with those of deterministic quadrature points, one

sometimes uses a combination of those two methods; see, for example, [5, 8, 13, 22]. The idea is to use a random element which preserves the essential properties of a deterministic point set. We call the expectation value of the square worst-case error of such randomized point sets the mean square worst-case error.

6.1. Randomization. In the following we introduce a randomization scheme called digital shift (see [4, 13]). Let $P_N = \{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}\} \subseteq [0,1)^s$, with $\boldsymbol{x}_n = (x_{1,n}, \dots, x_{s,n})$ and $x_{j,n} = x_{j,n,1}b^{-1} + x_{j,n,2}b^{-2} + \cdots$ for $n = 0, \dots, N-1$ and $j = 1, \dots, s$. Let $\sigma_{j,1}, \sigma_{j,2}, \ldots \in \{0,1\}$ be independently and identically distributed (i.i.d.) for $j = 1, \dots, s$. Then the randomly digitally shifted point set $P_{N,\boldsymbol{\sigma}} = \{\boldsymbol{z}_0, \dots, \boldsymbol{z}_{N-1}\}$, $\boldsymbol{z}_n = (z_{1,n}, \dots, z_{s,n})$ using a digital shift, is then given by

$$z_{j,n} = (x_{j,n,1} \oplus \sigma_{j,1})b^{-1} + (x_{j,n,2} \oplus \sigma_{j,2})b^{-2} + \cdots$$

for $j = 1, \dots, s$ and $n = 0, \dots, N-1$, where $x_{j,n,k} \oplus \sigma_{j,n} = x_{j,n,k} + \sigma_{j,n} \pmod b$ (note that all additions of the digits are carried out in the finite field $\mathbb{Z}_b$). Subsequently let $P_N = \{\boldsymbol{x}_0, \dots, \boldsymbol{x}_{N-1}\}$, and let $P_{N,\boldsymbol{\sigma}}$ be the digitally shifted point set P_N using the randomization just described.

6.2. The mean square worst-case error in the Korobov space. In this section we will analyze the expectation value of $e^2(P_{N,\boldsymbol{\sigma}}, K_\alpha)$, which we denote by $\tilde{e}^2(P_N, K_\alpha) = \mathbb{E}[e^2(P_{N,\boldsymbol{\sigma}}, K_\alpha)]$, with respect to the random digital shift described above. We call $\tilde{e}^2(P_N, K_\alpha)$ the mean square worst-case error.

From (2.4) and the linearity of the expectation operator we have

$$\tilde{e}^2(P_N, K_\alpha) = \mathbb{E}[e^2(P_{N,\boldsymbol{\sigma}}, K_\alpha)] = -1 + \frac{1}{N^2} \sum_{n,l=0}^{N-1} \prod_{j=1}^{s} \mathbb{E}[K_\alpha(z_{j,n}, z_{j,l})].$$

In order to compute $\mathbb{E}[K_\alpha(z_{j,n}, z_{j,l})]$ we need the following lemma, which, in a very similar form, was already shown in [5, Lemma 3]. Hence we omit a proof.

LEMMA 6.1. *Let $x_1, x_2 \in [0,1)$, and let $z_1, z_2 \in [0,1)$ be the points obtained after applying an i.i.d. random digital shift to x_1 and x_2. Then we have*

$$\mathbb{E}[\mathrm{wal}_k(z_1)\overline{\mathrm{wal}_l(z_2)}] = \begin{cases} \mathrm{wal}_k(x_1)\overline{\mathrm{wal}_k(x_2)} & \text{if } k = l, \\ 0 & \text{otherwise.} \end{cases}$$

Recall that

$$K_\alpha(x_1, x_2) = \sum_{k,l=0}^{\infty} r_{b,\alpha}(k,l)\mathrm{wal}_k(x_1)\overline{\mathrm{wal}_l(x_2)},$$

where

$$r_{b,\alpha}(k,l) = \int_0^1 \int_0^1 K_\alpha(x_1, x_2)\overline{\mathrm{wal}_k(x_1)}\mathrm{wal}_l(x_2)\,\mathrm{d}x_1\,\mathrm{d}x_2.$$

Let z_1, z_2 be obtained by applying an i.i.d. random digital shift to x_1, x_2. Using Lemma 6.1 and the linearity of expectation we obtain

$$\mathbb{E}[K_\alpha(z_1, z_2)] = \sum_{k=0}^{\infty} r_{b,\alpha}(k)\mathrm{wal}_k(x_1)\overline{\mathrm{wal}_k(x_2)},$$

where $r_{b,\alpha}(k) = r_{b,\alpha}(k,k)$ and $r_{b,\alpha}(0) = 1$.

Therefore we obtain

$$\mathbb{E}[e^2(P_{N,\boldsymbol{\sigma}}, K_\alpha)] = -1 + \frac{1}{N^2} \sum_{n,l=0}^{N-1} \prod_{j=1}^{s} \sum_{k=0}^{\infty} r_{b,\alpha}(k) \mathrm{wal}_k(x_{j,n}) \overline{\mathrm{wal}_k(x_{j,l})}.$$

Further we have

$$\prod_{j=1}^{s} \sum_{k=0}^{b^m-1} r_{b,\alpha}(k) \mathrm{wal}_k(x_{j,n}) \overline{\mathrm{wal}_k(x_{j,l})} = 1 + \sum_{\boldsymbol{k} \in \{0,\ldots,b^m-1\}^s \setminus \{\boldsymbol{0}\}} r_{b,\alpha}(\boldsymbol{k}) \mathrm{wal}_k(\boldsymbol{x}_n \ominus \boldsymbol{x}_l),$$

where we write $r_{b,\alpha}(\boldsymbol{k}) = \prod_{j=1}^{s} r_{b,\alpha}(k_j)$ for $\boldsymbol{k} = (k_1, \ldots, k_s)$. We have shown the following theorem.

THEOREM 6.2. *Let $b \geq 2$ be a natural number, and let $\alpha > 1/2$ be a real number. Then the mean square worst-case error for integration in the Korobov space $\mathcal{H}_\alpha$ using the point set P_N randomized by a digital shift is given by*

$$\mathbb{E}[e^2(P_{N,\boldsymbol{\sigma}}, K_\alpha)] = \sum_{\boldsymbol{k} \in \mathbb{N}_0^s \setminus \{\boldsymbol{0}\}} r_{b,\alpha}(\boldsymbol{k}) \frac{1}{N^2} \sum_{n,l=0}^{N-1} \mathrm{wal}_k(\boldsymbol{x}_n \ominus \boldsymbol{x}_l).$$

In the following we closer investigate the mean square worst-case error for digital nets randomized with a digital shift.

Subsequently we will often write $\tilde{e}^2_{b,m,\alpha}(C_1, \ldots, C_s)$ to denote the mean square worst-case error $\mathbb{E}[e(P_{b^m,\boldsymbol{\sigma}}, K_\alpha)]$, where P_{b^m} is a digital net with generating matrices $C_1, \ldots, C_s$ and b^m points and $P_{b^m,\boldsymbol{\sigma}}$ is the digital net P_{b^m} randomized with a digital shift.

THEOREM 6.3. *Let $m \geq 1$, b be a prime number, and $\alpha > 1/2$ be a real number. The mean square worst-case error in the Korobov space $\mathcal{H}_\alpha$ using a randomly digitally shifted digital net over $\mathbb{Z}_b$ with generating matrices $C_1, \ldots, C_s \in \mathbb{Z}_b^{m \times m}$ is given by*

$$\tilde{e}^2_{b,m,\alpha}(C_1, \ldots, C_s) = \sum_{\boldsymbol{k} \in \mathcal{D}} r_{b,\alpha}(\boldsymbol{k}).$$

Proof. In [4] it was shown that

$$\frac{1}{b^{2m}} \sum_{n,l=0}^{b^m-1} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_n \ominus \boldsymbol{x}_l) = \frac{1}{b^m} \sum_{n=0}^{b^m-1} \mathrm{wal}_{\boldsymbol{k}}(\boldsymbol{x}_n) = \begin{cases} 1 & \text{if } \boldsymbol{k} \in \mathcal{D} \cup \{\boldsymbol{0}\}, \\ 0 & \text{otherwise.} \end{cases}$$

Hence the result follows from Theorem 6.2. ∎

Remark 7. Theorems 2.5 and 6.3 now imply that

$$\tilde{e}_{b,m,\alpha}(C_1, \ldots, C_s) = \sqrt{\sum_{\boldsymbol{k} \in \mathcal{D}} r_{b,\alpha}(\boldsymbol{k})} \leq \sqrt{\sum_{\boldsymbol{k},\boldsymbol{l} \in \mathcal{D}} r_{b,\alpha}(\boldsymbol{k},\boldsymbol{l})} = e(P_{b^m}, K_\alpha);$$

i.e., the root mean square worst-case error is always smaller than the worst-case error; see also Remark 5.

Remark 5 and also the above Remark 7 imply that the bounds on the worst-case error also hold for the root mean square worst-case error. On the other hand, following the proofs for the bound on the worst-case error using the criterion for the root mean square worst-case error yields a better bound. We outline the results subsequently.

Following the proof of Lemma 2.10 we obtain

$$\sum_{\boldsymbol{k}\in\mathcal{D}} r_{b,\alpha}(\boldsymbol{k}) \le \sum_{\emptyset\ne u\subseteq\{1,\dots,s\}} (1+b^{-2\alpha m}\bar{C}_{b,\alpha}^2)^{s-|u|}(C_{b,\alpha}^2+\bar{C}_{b,\alpha}^2)^{|u|} \sum_{\boldsymbol{k}\in\mathcal{D}^*_{b^m,u}} q_{b,\alpha}^2(\boldsymbol{k}) + (1+b^{-2\alpha m}\bar{C}_{b,\alpha}^2)^s - 1,$$

where $C_{b,\alpha}$ is the constant from Lemma 2.9 and

$$\bar{C}_{b,\alpha} = C_{b,\alpha}\sqrt{b^{-1}+(b^2-b)^{-1}\prod_{c=3}^{\alpha+1}(b^{2c}-b^{2(c-1)})^{-1}}. \tag{6.1}$$

The sum $\sum_{\boldsymbol{k}\in\mathcal{D}^*_{b^m,u}} q_{b,\alpha}^2(\boldsymbol{k})$ can now be bounded using almost the same arguments as in the proof of Lemma 5.1. Doing this one can obtain that for a digital (t,α,β,m,s)-net we have

$$\sum_{\boldsymbol{k}\in\mathcal{D}^*_{b^m,u}} q_{b,\alpha}^2(\boldsymbol{k}) \le (2b)^{|u|\alpha} b^{-2(\beta m-t)+1}(\beta m-t+1)^{|u|\alpha-1}.$$

Hence we obtain the following theorem.

THEOREM 6.4. *Let b be prime, let $\alpha\ge 1$ be an integer, and let $C_1,\dots,C_s\in\mathbb{Z}_b^{m\times m}$ be the generating matrices of a digital (t,α,β,m,s)-net over $\mathbb{Z}_b$, with $m>t/\beta$. Then the mean square worst-case error in the Korobov space $\mathcal{H}_\alpha$ is bounded by*

$$\tilde{e}_{b,m,\alpha}^2(C_1,\dots,C_s) \le \frac{\left(1+b^{-2\alpha m}\bar{C}_{b,\alpha}^2+(2b)^\alpha(C_{b,\alpha}^2+\bar{C}_{b,\alpha}^2)(\beta m-t+1)^\alpha\right)^s-(1+b^{-2\alpha m}\bar{C}_{b,\alpha}^2)^s}{b^{2(\beta m-t)-1}(\beta m-t+1)} + (1+b^{-2\alpha m}\bar{C}_{b,\alpha}^2)^s-1,$$

where $C_{b,\alpha}>0$ is the constant in Lemma 2.9 and the constant $\bar{C}_{b,\alpha}>0$ is given by (6.1).

We can use Theorem 6.4 to obtain the following corollary.

COROLLARY 6.5. *Let b be prime, and let $C_1^{(d)},\dots,C_s^{(d)}\in\mathbb{Z}_b^{\infty\times\infty}$ be the generating matrices of a digital $(t(a),a,\min(a,d),s)$-sequence S over $\mathbb{Z}_b$ for any integer $a\ge 1$. Then for any real $\alpha\ge 1$ there is a constant $C''_{b,s,\alpha}>0$, depending only on b,s, and α, such that the root mean square worst-case error in the Korobov space $\mathcal{H}_\alpha$ using the first $N=b^m$ points of S is bounded by*

$$\tilde{e}_{b,m,\alpha}(C_1^{(d)},\dots,C_s^{(d)}) \le C''_{b,s,\alpha} b^{t(\lfloor\alpha\rfloor)}\frac{(\log N)^{(s\lfloor\alpha\rfloor-1)/2}}{N^{\min(\lfloor\alpha\rfloor,d)}}.$$

Remark 8. The above corollary shows that the digital $(t,\alpha,\min(\alpha,d),s)$-sequences constructed in section 4 achieve the optimal convergence of $P_{2\alpha}$ of $\mathcal{O}(N^{-2\alpha}(\log N)^{s\alpha-1})$ as long as α is an integer such that $1\le\alpha\le d$. (This convergence is the best possible for $\alpha=1$ by the lower bound in [24].) If $\alpha>d$, we obtain a convergence of $\mathcal{O}(N^{-2d}(\log N)^{s\alpha-1})$.

Using the construction of Theorem 4.1 or 4.2 it follows that $t(a)$ also depends on the choice of d. Hence choosing a large value of d also increases the constant factor $b^{t(\lfloor\alpha\rfloor)}$ in Corollaries 5.3 and 6.5.

7. Some examples of digital (t, α, m, s)-nets over $\mathbb{Z}_2$. In this section we give a simple example to show how the nets described in this paper can be constructed. We use the construction method outlined in section 4.

7.1. Example of a digital $(0, 2, m, 1)$-net over $\mathbb{Z}_2$. First we use the so-called Hammersley net as the underlying digital net, which is a $(0, m, 2)$-net over $\mathbb{Z}_2$. The generating matrices for this net are given by

$$C_1 = \begin{pmatrix} 1 & 0 & \dots & 0 \\ 0 & \ddots & \ddots & \vdots \\ \vdots & \ddots & \ddots & 0 \\ 0 & \dots & 0 & 1 \end{pmatrix} \text{ and } C_2 = \begin{pmatrix} 0 & \dots & 0 & 1 \\ \vdots & \iddots & \iddots & 0 \\ 0 & \iddots & \iddots & \vdots \\ 1 & 0 & \dots & 0 \end{pmatrix}. \tag{7.1}$$

Now we use the construction method of section 4 to construct the matrix $C_1^{(2)}$, i.e., $d = 2$ in this case. The first row of $C_1^{(2)}$ is the first row of C_1, the second row of $C_1^{(2)}$ is the first row of C_2, the third row of $C_1^{(2)}$ is the second row of C_1, the fourth row of $C_1^{(2)}$ is the second row of C_2, and so on. Assume that C_1, C_2 are $m \times m$ matrices, where m is even. Then we obtain

$$C_1^{(2)} = \begin{pmatrix} 1 & 0 & \dots & \dots & \dots & \dots & \dots & 0 \\ 0 & \dots & \dots & \dots & \dots & \dots & 0 & 1 \\ 0 & 1 & 0 & \dots & \dots & \dots & \dots & 0 \\ 0 & \dots & \dots & \dots & \dots & 0 & 1 & 0 \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots & \dots & \dots & \dots \\ 0 & \dots & 0 & 1 & 0 & \dots & \dots & 0 \\ 0 & \dots & \dots & 0 & 1 & 0 & \dots & 0 \end{pmatrix}.$$

So, for example, if $m = 4$, we obtain

$$C_1^{(2)} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \end{pmatrix}. \tag{7.2}$$

The matrix $C_1^{(2)}$ is of course nonsingular, and therefore the point set one obtains consists of just equidistant points starting with 0.

Assume that m is even. Then the digital net which one obtains from $C_1^{(2)}$ is a digital $(0, 1, m, 1)$-net over $\mathbb{Z}_2$, and, at the same time, it is also a digital $(0, 2, m, 1)$-net. Note that using the bound from Theorem 4.1 we obtain a t-value of 1, but by closer investigation using Definition 3.1 one can see that the properties also hold for $t = 0$. Hence the t-value obtained from Theorem 4.1 is not necessarily strict even if the value of the underlying digital net is strict.

7.2. Example of a digital $(t, 2, 4, 2)$-net over $\mathbb{Z}_2$. Consider the digital $(1, 4, 4)$-net over $\mathbb{Z}_2$ with generating matrices given by C_1, C_2 above and

$$C_3 = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 0 & 1 \\ 0 & 0 & 1 & 1 \\ 0 & 0 & 0 & 1 \end{pmatrix} \text{ and } C_4 = \begin{pmatrix} 0 & 1 & 1 & 0 \\ 1 & 1 & 0 & 1 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.$$

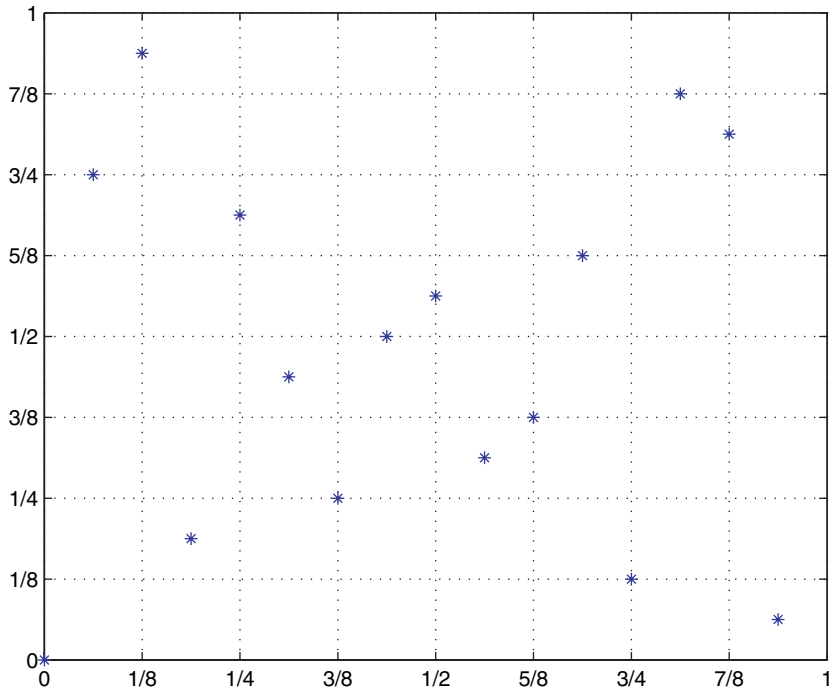

FIG. 7.1. *A digital* $(3,2,4,2)$*-net over* $\mathbb{Z}_2$.

Then $C_1^{(2)}$ is given by (7.2), and $C_2^{(2)}$ is given by

$$C_2^{(2)} = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 0 & 1 & 1 & 0 \\ 0 & 1 & 0 & 1 \\ 1 & 1 & 0 & 1 \end{pmatrix}.$$

Using the digital construction scheme we obtain the points

$$(0,0),(\tfrac{1}{2},\tfrac{9}{16}),(\tfrac{1}{8},\tfrac{15}{16}),(\tfrac{5}{8},\tfrac{3}{8}),(\tfrac{1}{16},\tfrac{3}{4}),(\tfrac{9}{16},\tfrac{5}{16}),(\tfrac{3}{16},\tfrac{3}{16}),(\tfrac{11}{16},\tfrac{5}{8}),$$
$$(\tfrac{1}{4},\tfrac{11}{16}),(\tfrac{3}{4},\tfrac{1}{8}),(\tfrac{3}{8},\tfrac{1}{4}),(\tfrac{7}{8},\tfrac{13}{16}),(\tfrac{5}{16},\tfrac{7}{16}),(\tfrac{13}{16},\tfrac{7}{8}),(\tfrac{7}{16},\tfrac{1}{2}),(\tfrac{15}{16},\tfrac{1}{16}),$$

which are shown in Figure 7.1.

It can be checked that this digital net is a digital $(1,1,4,2)$-net, i.e., a digital $(1,4,2)$-net (the first two rows of $C_1^{(2)}$ and the first two rows of $C_2^{(2)}$ are linearly dependent, so the t-value cannot be 0 when $\alpha = 1$).

Now we investigate the t-value when $\alpha = 2$. First note that Theorem 4.1 yields a t-value of 4 for $\alpha = 2$ ($d = s = 2$). Further the t-value cannot be 2 in this case: We need to consider all cases where $i_{1,1} + i_{1,\min(\nu_1,2)} + i_{2,1} + i_{2,\min(\nu_2,2)} \le \alpha m - t = 2 \cdot 4 - 2 = 6$, with $0 \le \nu_1, \nu_2 \le 4$. But by choosing $i_{1,1} = i_{2,1} = 2$ and $i_{1,2} = i_{2,2} = 1$ we obtain the first two rows of C_1 and the first two rows of C_2, and as those 4 rows are linearly dependent it follows that the t-value cannot be 2. Now let us check whether a t-value of 3 is possible: We need to have $i_{1,1} + i_{1,\min(\nu_1,2)} + i_{2,1} + i_{2,\min(\nu_2,2)} \le 5$; hence, $\nu_1, \nu_2 \ge 2$ is not possible (because then we would have $i_{1,1} + i_{1,2} + i_{2,1} + i_{2,2} \ge 2+1+2+1 > 5$). Further the conditions are satisfied if either $\nu_1 = 0$ or $\nu_2 = 0$ as the matrices $C_1^{(2)}$

and $C_2^{(2)}$ are nonsingular. If $\nu_1 > 2$, then $i_{1,1} \geq 3$, $i_{1,2} \geq 2$, and hence $i_{1,1} + i_{1,2} \geq 5$, and we can only get $i_{1,1} + i_{1,\min(\nu_1,2)} + i_{2,1} + i_{2,\min(\nu_2,2)} \leq 5$ if $\nu_2 = 0$. Hence if either $\nu_1 > 2$ or $\nu_2 > 2$, the properties are also satisfied. Thus we are left with the following three cases: $(\nu_1, \nu_2) = (1, 1)$, $(\nu_1, \nu_2) = (1, 2)$, and $(\nu_1, \nu_2) = (2, 1)$.

Now let $\nu_1 = \nu_2 = 1$. Then we need to take one row of each matrix $C_1^{(2)}$ and $C_2^{(2)}$ such that the sum of their row indices is smaller or equal to 5 and check whether those two rows are linearly independent. It can be checked that this is always the case: Let $C_j^{(2)} = (c_{j,1}^\top, c_{j,2}^\top, c_{j,3}^\top, c_{j,4}^\top)$; i.e., $c_{j,k}$ denotes the kth row of $C_j^{(2)}$. Then the pairs of vectors $(c_{1,k}, c_{2,l})$, where $k + l \leq 5$, are always linearly independent for all admissible choices of k and l (i.e., $c_{1,k} \neq c_{2,l}$).

Consider now $\nu_1 = 1$ and $\nu_2 = 2$; i.e., we take one row from $C_1^{(2)}$ and two rows from $C_2^{(2)}$ such that the sum of the row indices does not exceed 5. Note that $i_{2,2}$ has to be 1; otherwise, $i_{2,1} + i_{2,2} \geq 5$ and $i_{1,1}$ cannot even be 1. As $i_{1,1} \geq 1$ and $i_{2,1} \geq 2$, the only choices left are $i_{1,1} = 1$, $i_{2,1} = 2, 3$ and $i_{1,1} = 2$, $i_{2,1} = 2$. So we need to check whether the triplets $(c_{1,1}, c_{2,1}, c_{2,2})$, $(c_{1,1}, c_{2,1}, c_{2,3})$, and $(c_{1,2}, c_{2,1}, c_{2,2})$ are all linearly independent, which upon inspection can be seen to be the case.

The case $\nu = 2$ and $\nu = 1$ can also be checked as the previous case. In this case all of the relevant sets of vectors are also always linearly independent; hence, a t-value of 3 is possible for $\alpha = 2$; i.e., the digital net above is a (strict) digital $(3, 2, 4, 2)$-net.

The classical t-value (i.e., $\alpha = 1$) of this digital net is not as good as, for example, the t-value of the Hammersley net (which is 0). On the other hand, it can be checked that for $\alpha = 2$ the t-value of the Hammersley net where $m = 4$ is 4, and hence for this case it is worse than the t-value of the digital net constructed above.

As a last example let us consider the Hammersley net again for arbitrary $m \geq 1$, i.e., with the $m \times m$ generating matrices given by (7.1). As, for example, the first row of C_1 and the last row of C_2 are the same (and therefore linearly dependent), we must have $\beta m - t < m + 1$ for all $\alpha \geq 1$ (for $\alpha = 1$ we can still choose $\beta = 1$ and $t = 0$, and hence the Hammersley net achieves the optimal t-value, but for $\alpha > 1$ we have seen in section 4 that there are better constructions). It is sensible to choose β such that we can have a t-value which is independent of m (for example, this is the case when one considers sequences and which is also the motivation for introducing those parameters; for digital nets it would of course also make sense to just state the value of $\beta m - t$ and m instead of t, β, and m). This means that $\beta \leq 1$, and as β indicates the convergence rate one can obtain, it follows that one cannot expect to obtain a convergence rate beyond $(b^m)^{-1+\delta}$ (for an arbitrary small $\delta > 0$) when using a Hammersley net.

8. Appendix: Some lemmas. We need the following lemmas.

LEMMA 8.1. *Let $j \geq 1$, $a \geq 0$, $b \geq 2$, and $0 \leq u, v < b^a$, with $u \neq v$. Then we have*

$$\int_{u/b^a}^{(u+1)/b^a} \int_{u/b^a}^{(u+1)/b^a} |x - y|^j \, \mathrm{d}x \, \mathrm{d}y = \frac{2}{b^{a(j+2)}(j+1)(j+2)}$$

and

$$\int_{u/b^a}^{(u+1)/b^a} \int_{v/b^a}^{(v+1)/b^a} |x - y|^j \, \mathrm{d}x \, \mathrm{d}y = \frac{2j!}{b^{a(j+2)}} \sum_{l=0}^{\lfloor j/2 \rfloor} \frac{|u - v|^{j-2l}}{(j-2l)!(2l+2)!}.$$

Proof. We have

$$\int_{u/b^a}^{(u+1)/b^a}\int_{u/b^a}^{(u+1)/b^a} |x-y|^j \,\mathrm{d}x\,\mathrm{d}y = \int_0^{1/b^a}\int_0^{1/b^a} |x-y|^j \,\mathrm{d}x\,\mathrm{d}y$$
$$= \frac{1}{b^{a(j+2)}}\int_0^1\int_0^1 |x-y|^j \,\mathrm{d}x\,\mathrm{d}y.$$

We divide the last double integral in two parts, and we have

$$\int_0^1\int_0^1 |x-y|^j \,\mathrm{d}x\,\mathrm{d}y = \int_0^1\int_0^y (y-x)^j \,\mathrm{d}x\,\mathrm{d}y + \int_0^1\int_y^1 (x-y)^j \,\mathrm{d}x\,\mathrm{d}y.$$

We calculate the first part and obtain

$$\int_0^1\int_0^y (y-x)^j \,\mathrm{d}x\,\mathrm{d}y = \frac{1}{j+1}\int_0^1 y^{j+1}\,\mathrm{d}y = \frac{1}{(j+1)(j+2)},$$

and the second part is given by

$$\int_0^1\int_y^1 (x-y)^j \,\mathrm{d}x\,\mathrm{d}y = \frac{1}{j+1}\int_0^1 (1-y)^{j+1}\,\mathrm{d}y = \frac{1}{(j+1)(j+2)}.$$

Hence we have

$$\int_0^1\int_0^1 |x-y|^j \,\mathrm{d}x\,\mathrm{d}y = \frac{2}{(j+1)(j+2)}.$$

For the second part we have

$$\int_{u/b^a}^{(u+1)/b^a}\int_{v/b^a}^{(v+1)/b^a} |x-y|^j \,\mathrm{d}x\,\mathrm{d}y = \int_0^{1/b^a}\int_{|u-v|/b^a}^{(|u-v|+1)/b^a} |x-y|^j \,\mathrm{d}x\,\mathrm{d}y$$
$$= \frac{1}{b^{a(j+2)}}\int_0^1\int_{|u-v|}^{|u-v|+1} (x-y)^j \,\mathrm{d}x\,\mathrm{d}y,$$

where now $|u-v|\geq 1$. We have

$$\int_0^1\int_{|u-v|}^{|u-v|+1} (x-y)^j \,\mathrm{d}x\,\mathrm{d}y = \frac{1}{j+1}\int_0^1 \left((|u-v|+1-y)^{j+1} - (|u-v|-y)^{j+1}\right)\,\mathrm{d}y$$
$$= \frac{2|u-v|^{j+2} - (|u-v|+1)^{j+2} - (|u-v|-1)^{j+2}}{(j+1)(j+2)}.$$

The result follows by simplifying the sum in the numerator. □

LEMMA 8.2. *Let $k\geq 1$ be given by $k=\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}$ for some $\nu\geq 1$, $\kappa_{a_1-1},\ldots,\kappa_{a_\nu-1}\in\{1,\ldots,b-1\}$, and $1\leq a_\nu<\cdots<a_1$. For any even $0\leq j<2\nu$ we have $I_j(k)=0$.*

Proof. The result for $j=0$ follows from Proposition 2.3 and (2.6). It was shown in [4, Appendix A] that

$$x = \frac{1}{2} + \sum_{c=1}^{\infty}\sum_{\tau=1}^{b-1} \frac{1}{b^c(\mathrm{e}^{-2\pi\mathrm{i}\tau/b}-1)}\mathrm{wal}_{\tau b^{c-1}}(x),$$

and hence

$$|x-y|^j = \left(\sum_{c=1}^{\infty}\sum_{\tau=1}^{b-1}\frac{1}{b^c(\mathrm{e}^{-2\pi\mathrm{i}\tau/b}-1)}(\mathrm{wal}_{\tau b^{c-1}}(y)-\mathrm{wal}_{\tau b^{c-1}}(x))\right)^j$$
$$= \sum_{c_1,\ldots,c_j=1}^{\infty}\frac{1}{b^{c_1+\cdots+c_j}}\prod_{i=1}^{j}\sum_{\tau=1}^{b-1}\frac{\mathrm{wal}_{\tau b^{c_i-1}}(y)-\mathrm{wal}_{\tau b^{c_i-1}}(x)}{\mathrm{e}^{-2\pi\mathrm{i}\tau/b}-1}.$$

Let

$$A_k(c_1,\ldots,c_j)=\int_0^1\int_0^1\prod_{i=1}^{j}\sum_{\tau=1}^{b-1}\frac{\mathrm{wal}_{\tau b^{c_i-1}}(y)-\mathrm{wal}_{\tau b^{c_i-1}}(x)}{\mathrm{e}^{-2\pi\mathrm{i}\tau/b}-1}\overline{\mathrm{wal}_k(x)}\mathrm{wal}_k(y)\,\mathrm{d}x\,\mathrm{d}y.$$

Then we have

$$I_j(k)=\sum_{c_1,\ldots,c_j=1}^{\infty}\frac{A_k(c_1,\ldots,c_j)}{b^{c_1+\cdots+c_j}}.$$

We have

$$\prod_{i=1}^{j}\sum_{\tau=1}^{b-1}\frac{\mathrm{wal}_{\tau b^{c_i-1}}(y)-\mathrm{wal}_{\tau b^{c_i-1}}(x)}{\mathrm{e}^{-2\pi\mathrm{i}\tau/b}-1}$$
$$=\sum_{\tau_1,\ldots,\tau_j=1}^{b-1}\prod_{i=1}^{j}(\mathrm{e}^{-2\pi\mathrm{i}\tau_j/b}-1)^{-1}\sum_{u\subseteq\{1,\ldots,j\}}(-1)^{|u|}\prod_{i\in u}\mathrm{wal}_{\tau_i b^{c_i-1}}(y)\prod_{i\notin u}\mathrm{wal}_{\tau_i b^{c_i-1}}(x)$$
$$=\sum_{\tau_1,\ldots,\tau_j=1}^{b-1}\prod_{i=1}^{j}(\mathrm{e}^{-2\pi\mathrm{i}\tau_j/b}-1)^{-1}\sum_{u\subseteq\{1,\ldots,j\}}(-1)^{|u|}\mathrm{wal}_{C_{u,\tau}}(y)\mathrm{wal}_{C_{\{1,\ldots,j\}\setminus u,\tau}}(x),$$

where $C_{u,\tau}=\sum_{i\in u}\tau_i b^{c_i-1}$, and hence

$$A_k(c_1,\ldots,c_j)$$
$$=\sum_{\tau_1,\ldots,\tau_j=1}^{b-1}\prod_{i=1}^{j}(\mathrm{e}^{-2\pi\mathrm{i}\tau_j/b}-1)^{-1}\sum_{u\subseteq\{1,\ldots,j\}}(-1)^{|u|}$$
$$\int_0^1\int_0^1\mathrm{wal}_{C_{u,\tau}}(y)\mathrm{wal}_{C_{\{1,\ldots,j\}\setminus u,\tau}}(x)\overline{\mathrm{wal}_k(x)}\mathrm{wal}_k(y)\,\mathrm{d}x\,\mathrm{d}y$$
$$=\sum_{\tau_1,\ldots,\tau_j=1}^{b-1}\prod_{i=1}^{j}(\mathrm{e}^{-2\pi\mathrm{i}\tau_j/b}-1)^{-1}$$
$$\sum_{u\subseteq\{1,\ldots,j\}}(-1)^{|u|}\int_0^1\mathrm{wal}_{C_{u,\tau}\oplus k}(y)\,\mathrm{d}y\int_0^1\mathrm{wal}_{C_{\{1,\ldots,j\}\setminus u,\tau}\ominus k}(x)\,\mathrm{d}x.$$

Note that if $\nu > j/2$, we have either $C_{u,\tau}\oplus k\neq 0$ or $C_{\{1,\ldots,j\}\setminus u,\tau}\ominus k\neq 0$, and hence $A_k(c_1,\ldots,c_j)=0$. The result now follows. □

Let $\sigma_p(n) = \sum_{h=1}^{n-1} h^p$. It is known that

$$\sigma_p(n) = \sum_{h=0}^{p} \frac{B_h}{h!} \frac{p!}{(p+1-h)!} n^{p+1-h}, \tag{8.1}$$

where $B_0, B_1, \ldots$ are the Bernoulli numbers (in particular, $B_0 = 1$, $B_1 = -1/2$, and $B_2 = 1/6$).

LEMMA 8.3. *Let $b \geq 2$, $1 \leq d \leq a$, and $k = \kappa_{d-1} b^{d-1} + \cdots + \kappa_0$, where $\kappa_{d-1} \in \{1, \ldots, b-1\}$, $\kappa_{d-2}, \ldots, \kappa_0 \in \{0, \ldots, b-1\}$, $m = m_{a-1} b^{a-1} + \cdots + m_0$, and $n = n_{a-1} b^{a-1} + \cdots + n_0$. Then we have*

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} \mathrm{wal}_k((n \ominus m)/b^a) = b^{2a-d} \left(\frac{1}{2} + \frac{1}{\mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}/b} - 1} \right) - \frac{b^a}{2},$$

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n) \mathrm{wal}_k((n \ominus m)/b^a) = b^{3a-2d} \left(\frac{1}{6} - \frac{1}{2 \sin^2(\kappa_{d-1} \pi/b)} \right) - \frac{b^a}{6},$$

and

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n) = \frac{1}{6}(b^{3a} - b^a).$$

Proof. In order to obtain a formula for the first sum, let $m' = m_{a-1} b^{a-1} + \cdots + m_{a-d+1} b^{a-d+1}$, $m'' = m_{a-d-1} b^{a-d-1} + \cdots + m_0$, $n' = n_{a-1} b^{a-1} + \cdots + n_{a-d+1} b^{a-d+1}$, and $n'' = n_{a-d-1} b^{a-d-1} + \cdots + n_0$. First consider the case where $m' > n'$ and arbitrary m'', n''. We have

$$\sum_{n_{a-d}=0}^{b-1} \sum_{m_{a-d}=0}^{b-1} \mathrm{e}^{2\pi \mathrm{i}(\kappa_0(n_{a-1}-m_{a-1}) + \cdots + \kappa_{d-1}(n_{a-d}-m_{a-d}))/b} = 0,$$

as $\sum_{m=0}^{b-1} \mathrm{e}^{2\pi \mathrm{i} \kappa m/b} = 0$ for all $\kappa = 1, \ldots, b-1$. Thus we only need to consider the case where $m' = n'$, for which case we have

$$\mathrm{e}^{2\pi \mathrm{i}(\kappa_0(n_{a-1}-m_{a-1}) + \cdots + \kappa_{d-1}(n_{a-d}-m_{a-d}))/b} = \mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}(m_{a-d}-n_{a-d})/b}.$$

This part is now given by

$$b^{d-1} \sum_{n''=0}^{b^{a-d}-1} \sum_{m''=0}^{b^{a-d}-1} \sum_{n_{a-d}=0}^{b-1} \sum_{m_{a-d}=0}^{b-1} \mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}(n_{a-d}-m_{a-d})/b}, \tag{8.2}$$

where we have the additional assumption $m_{a-d} b^{a-d} + m'' > n_{a-d} b^{a-d} + n''$. First consider the case where $m_{a-d} > n_{a-d}$. This part of (8.2) is given by

$$\begin{aligned} b^{d-1} \sum_{n''=0}^{b^{a-d}-1} \sum_{m''=0}^{b^{a-d}-1} \sum_{n_{a-d}=0}^{b-2} \sum_{m_{a-d}=n_{a-d}+1}^{b-1} & \mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}(n_{a-d}-m_{a-d})/b} \\ &= b^{d-1} b^{2(a-d)} \sum_{n_{a-d}=0}^{b-2} \sum_{m_{a-d}=n_{a-d}+1}^{b-1} \mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}(n_{a-d}-m_{a-d})/b} \\ &= \frac{b^{2a-d}}{\mathrm{e}^{2\pi \mathrm{i} \kappa_{d-1}/b} - 1}. \end{aligned}$$

Now consider the case where $m_{a-d} = n_{a-d}$. In this case we have the assumption that $m'' > n''$, and hence this part of (8.2) is given by

$$b^d \sum_{n''=0}^{b^{a-d}-2} \sum_{m''=n''+1}^{b^{a-d}-1} 1 = \frac{1}{2}\left(b^{2a-d} - b^a\right).$$

Thus (8.2) is given by

$$\frac{b^{2a-d}}{\mathrm{e}^{2\pi \mathrm{i}\kappa_{d-1}/b} - 1} + \frac{1}{2}\left(b^{2a-d} - b^a\right),$$

and the first result follows.

For the second sum let again $m' = m_{a-1}b^{a-1} + \cdots + m_{a-d+1}b^{a-d+1}$, $m'' = m_{a-d-1}b^{a-d-1} + \cdots + m_0$, $n' = n_{a-1}b^{a-1} + \cdots + n_{a-d+1}b^{a-d+1}$, and also $n'' = n_{a-d-1}b^{a-d-1} + \cdots + n_0$. First consider the case where $m' > n'$ and arbitrary m'', n''. We have

$$\begin{aligned}
&\sum_{n_{a-d}=0}^{b-1} \sum_{m_{a-d}=0}^{b-1} (m-n)\mathrm{e}^{2\pi \mathrm{i}(\kappa_0(n_{a-1}-m_{a-1})+\cdots+\kappa_{d-1}(n_{a-d}-m_{a-d}))/b} \\
&= \sum_{n_{a-d}=0}^{b-1} \sum_{m_{a-d}=0}^{b-1} (m_{a-d}-n_{a-d})\mathrm{e}^{2\pi \mathrm{i}(\kappa_0(n_{a-1}-m_{a-1})+\cdots+\kappa_{d-1}(n_{a-d}-m_{a-d}))/b} \\
&= 0,
\end{aligned}$$

as $\sum_{m=0}^{b-1} \mathrm{e}^{2\pi \mathrm{i}\kappa m/b} = 0$ for all $\kappa = 1, \ldots, b-1$.

Thus we are left with the case where $m' = n'$. We have

$$\mathrm{e}^{2\pi \mathrm{i}(\kappa_0(n_{a-1}-m_{a-1})+\cdots+\kappa_{d-1}(n_{a-d}-m_{a-d}))/b} = \mathrm{e}^{2\pi \mathrm{i}\kappa_{d-1}(m_{a-d}-n_{a-d})/b}.$$

Hence this part is given by

(8.3)

$$b^{d-1} \sum_{n_{a-d}=0}^{b-1} \sum_{m_{a-d}=0}^{b-1} \sum_{n''=0}^{b^{a-d}-1} \sum_{m''=0}^{b^{a-d}-1} (m''-n''+b^{a-d}(m_{a-d}-n_{a-d}))\mathrm{e}^{2\pi \mathrm{i}\kappa_{d-1}(n_{a-d}-m_{a-d})/b},$$

where we have the additional assumption $m_{a-d}b^{a-d} + m'' > n_{a-d}b^{a-d} + n''$. First consider the case where $m_{a-d} > n_{a-d}$. This part of (8.3) is given by

$$\begin{aligned}
&b^{d-1} \sum_{0 \le n_{a-d} < m_{a-d} < b} \sum_{m'',n''=0}^{b^{a-d}-1} (m''-n''+b^{a-d}(m_{a-d}-n_{a-d}))\mathrm{e}^{2\pi \mathrm{i}\kappa_{d-1}(n_{a-d}-m_{a-d})/b} \\
&\qquad = b^{d-1}b^{3(a-d)} \sum_{n_{a-d}=0}^{b-2} \sum_{m_{a-d}=n_{a-d}+1}^{b-1} (m_{a-d}-n_{a-d})\mathrm{e}^{2\pi \mathrm{i}\kappa_{d-1}(n_{a-d}-m_{a-d})/b} \\
&\qquad = -\frac{b^{3a-2d}}{2\sin^2(\kappa_{d-1}\pi/b)}.
\end{aligned}$$

Now consider the case where $m_{a-d} = n_{a-d}$. In this case we have the assumption that $m'' > n''$, and hence this part of (8.3) is given by

$$b^d \sum_{n''=0}^{b^{a-d}-2} \sum_{m''=n''+1}^{b^{a-d}-1} (m'' - n'') = \frac{b^d}{6}(b^{3(a-d)} - b^{a-d}).$$

(This result can be obtained using (8.1); see the proof of the third part below.) Thus (8.3) is given by

$$-\frac{b^{3a-2d}}{2\sin^2(\kappa_{d-1}\pi/b)} + \frac{b^d}{6}(b^{3(a-d)} - b^{a-d}),$$

and the second result follows.

The third result can easily be verified by using (8.1). Indeed we have

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n) = \sum_{n=0}^{b^a-2} \sum_{m=1}^{b^a-1-n} m = \sum_{n=0}^{b^a-2} \sigma_1(b^a - n) = \frac{1}{2} \sum_{n=0}^{b^a-2} ((b^a-n)^2 - (b^a-n)).$$

The last sum can be written as $\frac{1}{2}\sum_{n=1}^{b^a}(n^2-n) = \frac{1}{2}(\sigma_2(b^a+1) - \sigma_1(b^a+1))$, and by using (8.1) again the result follows. □

LEMMA 8.4. *Let $j \geq 0$, $\nu \geq 1$, $1 \leq a_\nu < \cdots < a_1 \leq a$, and $k = \kappa_{a_1-1}b^{a_1-1} + \cdots + \kappa_{a_\nu-1}b^{a_\nu-1}$, where $\kappa_{a_1-1}, \ldots, \kappa_{a_\nu-1} \in \{1, \ldots, b-1\}$. Then we have*

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n)^j = b^a \sigma_j(b^a) - \sigma_{j+1}(b^a) \leq \frac{b^{a(j+2)}}{(j+1)(j+2)}$$

and

$$\left| \sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n)^j \operatorname{wal}_k((n \ominus m)/b^a) \right| \leq C_{b,j} b^{(j+2)a - 2(a_1+\cdots+a_{\min(\nu, \lceil j/2 \rceil)})}$$

for some constant $C_{b,j} > 0$ which is independent of ν, a, and $a_1, \ldots, a_\nu$.

Proof. We have

$$\sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n)^j = \sum_{n=1}^{b^a-1} (b^a - n) n^j = b^a \sigma_j(b^a) - \sigma_{j+1}(b^a),$$

and by using (8.1) it follows that

$$\begin{aligned} &b^a \sigma_j(b^a) - \sigma_{j+1}(b^a) \\ &= b^{a(j+2)} \left(\sum_{h=0}^{j} B_h \left(\frac{j!}{h!(j+1-h)!} - \frac{(j+1)!}{h!(j+2-h)!} \right) b^{-ah} - B_{j+1} b^{-a(j+1)} \right) \\ &\leq b^{a(j+2)} B_0 \frac{1}{(j+1)(j+2)}, \end{aligned}$$

from which the first part follows as $B_0 = 1$.

For $j = 0, 1$ the second part immediately follows from Lemma 8.3. Let now $j \geq 2$, and assume the result holds for all $j-1, \ldots, 1, 0$.

Let $m = m_{a-1}b^{a-1} + \cdots + m_0$ and $n = n_{a-1}b^{a-1} + \cdots + n_0$. In order to obtain a bound on

$$\left| \sum_{n=0}^{b^a-2} \sum_{m=n+1}^{b^a-1} (m-n)^j \mathrm{e}^{2\pi \mathrm{i}(\kappa_{a_1-1}(n_{a-a_1}-m_{a-a_1})+\cdots+\kappa_{a_\nu-1}(n_{a-a_\nu}-m_{a-a_\nu}))/b} \right|, \tag{8.4}$$

we first sum over the digits m_{a-a_1} and n_{a-a_1}.

Let $m' = m_{a-1}b^{a-1}+\cdots+m_{a-a_1+1}b^{a-a_1+1}$, $n' = n_{a-1}b^{a-1}+\cdots+n_{a-a_1+1}b^{a-a_1+1}$, $m'' = m_{a-a_1-1}b^{a-a_1-1} + \cdots + m_0$, and $n'' = n_{a-a_1-1}b^{a-a_1-1} + \cdots + n_0$. We consider two cases, namely, where $m' > n'$ and where $m' = n'$.

For $m' = n'$ we have either $m_{a-a_1} > n_{a-a_1}$ or $m_{a-a_1} = n_{a-a_1}$ and $m'' > n''$, as $m > n$. First let $m_{a-a_1} > n_{a-a_1}$. We have b^{a_1-1} choices for $m' = n'$, and the sum over the digits m_{a-a_1}, n_{a-a_1} with $m_{a-a_1} > n_{a-a_1}$ can be written as one sum so that the part of (8.4) where $m' = n'$ is given by

$$\begin{aligned}
&b^{a_1-1} \left| \sum_{n''=0}^{b^{a-a_1}-1} \sum_{m''=0}^{b^{a-a_1}-1} \sum_{\tau=1}^{b-1} (b-\tau)(\tau b^{a-a_1} + m'' - n'')^j \mathrm{e}^{-2\pi \mathrm{i}\kappa_{a_1-1}\tau/b} \right| \\
&\leq b^{a_1-1} \sum_{n''=0}^{b^{a-a_1}-1} \sum_{m''=0}^{b^{a-a_1}-1} \sum_{\tau=1}^{b-1} (b-\tau)(\tau b^{a-a_1} + m'' - n'')^j \\
&\leq C''_{b,j} b^{a_1} b^{(j+2)(a-a_1)},
\end{aligned}$$

for some constant $C''_{b,j} > 0$ which depends only on b and j. Hence this part satisfies the bound. Now let $m_{a-a_1} = n_{a-a_1}$; then we have $m'' > n''$, and hence the part of (8.4) where $m' = n'$ and $m_{a-a_1} = n_{a-a_1}$ is given by

$$b^{a_1} \sum_{n''=0}^{b^{a-a_1}-1} \sum_{m''=n''+1}^{b^{a-a_1}-1} (m''-n'')^j \leq \frac{b^{a_1} b^{(j+2)(a-a_1)}}{(j+1)(j+2)},$$

where the inequality was already obtained in the first part of this proof. Hence also this part satisfies the bound.

Now we consider the part of (8.4) where $m' > n'$. We have

$$\begin{aligned}
&\sum_{m_{a-a_1}, n_{a-a_1}=0}^{b-1} (m'-n'+b^{a-a_1}(m_{a-a_1}-n_{a-a_1})+m''-n'')^j \mathrm{e}^{2\pi \mathrm{i}\kappa_{a_1-1}(n_{a-a_1}-m_{a-a_1})/b} \\
&= b(m'-n'+m''-n'')^j + \sum_{\tau=1}^{b-1} (b-\tau)[\mathrm{e}^{-2\pi \mathrm{i}\kappa_{a_1-1}\tau/b}(m'-n'+\tau b^{a-a_1}+m''-n'')^j \\
&\quad + \mathrm{e}^{2\pi \mathrm{i}\kappa_{a_1-1}\tau/b}(m'-n'-\tau b^{a-a_1}+m''-n'')^j] \\
&= b(m'-n'+m''-n'')^j + \sum_{u=0}^{j} \binom{j}{u} (m'-n'+m''-n'')^{j-u} b^{u(a-a_1)} E_u,
\end{aligned} \tag{8.5}$$

where

$$E_u = \sum_{\tau=1}^{b-1} (b-\tau)[\mathrm{e}^{-2\pi \mathrm{i}\kappa_{a_1-1}\tau/b}\tau^u + \mathrm{e}^{2\pi \mathrm{i}\kappa_{a_1-1}\tau/b}(-\tau)^u].$$

It can be checked that $E_0 = -b$ and $E_1 = 0$. Hence (8.5) is given by

$$\sum_{u=2}^{j} \binom{j}{u} (m' - n' + m'' - n'')^{j-u} b^{u(a-a_1)} E_u,$$

and hence the result follows from the induction assumption or the first part. □

LEMMA 8.5. *Let $k \ge 1$ be given by $k = \kappa_{a_1-1} b^{a_1-1} + \cdots + \kappa_{a_\nu-1} b^{a_\nu-1}$ for some $\nu \ge 1$, $1 \le a_\nu < \cdots < a_1$, and $\kappa_{a_1-1}, \ldots, \kappa_{a_\nu-1} \in \{1, \ldots, b-1\}$. Then for $j \ge 1$ we have*

$$|I_j(k)| \le \frac{\bar{C}_{b,j}}{b^{2(a_1+\cdots+a_{\min(\nu,\lceil j/2 \rceil)})}}$$

for some constant $\bar{C}_{b,j} > 0$ which depends only on b and j.

Proof. Let $k = \kappa_{a-1} b^{a-1} + \cdots + \kappa_0$, where now $a = a_1$, $u = u_{a-1} b^{a-1} + \cdots + u_0$, and $v = v_{a-1} b^{a-1} + \cdots + v_0$. Then we have

$$\begin{aligned} I_j(k) &= \int_0^1 \int_0^1 |x-y|^j \overline{\mathrm{wal}_k(x)} \mathrm{wal}_k(y) \,\mathrm{d}x \,\mathrm{d}y \\ &= \sum_{u=0}^{b^a-1} \sum_{v=0}^{b^a-1} \mathrm{e}^{2\pi \mathtt{i}(\kappa_0(u_{a-1}-v_{a-1})+\cdots+\kappa_{a-1}(u_0-v_0))} \int_{u/b^a}^{(u+1)/b^a} \int_{v/b^a}^{(v+1)/b^a} |x-y|^j \,\mathrm{d}x \,\mathrm{d}y. \end{aligned}$$

For $u = v$ we have $\mathrm{e}^{2\pi \mathtt{i}(\kappa_0(u_{a-1}-v_{a-1})+\cdots+\kappa_{a-1}(u_0-v_0))} = 1$. Using Lemma 8.1 it follows that this part in the above sum is given by

$$\frac{2}{b^{a(j+1)}(j+1)(j+2)}.$$

Hence it remains to calculate

$$\begin{aligned} &\sum_{u=0}^{b^a-1} \sum_{\substack{v=0 \\ u \ne v}}^{b^a-1} \mathrm{e}^{2\pi \mathtt{i}(\kappa_0(u_{a-1}-v_{a-1})+\cdots+\kappa_{a-1}(u_0-v_0))} \int_{u/b^a}^{(u+1)/b^a} \int_{v/b^a}^{(v+1)/b^a} |x-y|^j \,\mathrm{d}x \,\mathrm{d}y \\ &= 2 \sum_{u=0}^{b^a-2} \sum_{v=u+1}^{b^a-1} \mathrm{e}^{2\pi \mathtt{i}(\kappa_0(u_{a-1}-v_{a-1})+\cdots+\kappa_{a-1}(u_0-v_0))} \frac{2j!}{b^{a(j+2)}} \sum_{i=0}^{\lfloor j/2 \rfloor} \frac{|u-v|^{j-2i}}{(j-2i)!(2i+2)!} \\ &= \frac{4j!}{b^{a(j+2)}} \sum_{i=0}^{\lfloor j/2 \rfloor} \frac{1}{(j-2i)!(2i+2)!} \sum_{u=0}^{b^a-2} \sum_{v=u+1}^{b^a-1} \frac{\mathrm{e}^{2\pi \mathtt{i}(\kappa_0(u_{a-1}-v_{a-1})+\cdots+\kappa_{a-1}(u_0-v_0))}}{(v-u)^{2i-j}}, \end{aligned}$$

where we used Lemma 8.1. The absolute value of the inner double sum can now be bounded using Lemma 8.4, and hence the result follows. □

LEMMA 8.6. *Let $b \ge 2$ be an integer, and let $\alpha > 1/2$ be a real number. Then we have*

$$\sum_{k=1}^{\infty} r_{b,\alpha}(k) = 2\zeta(2\alpha),$$

where $\zeta(2\alpha) = \sum_{h=1}^{\infty} h^{-2\alpha}$.

Proof. Let $h \in \mathbb{Z} \setminus \{0\}$, and let $f_h(x) = \mathrm{e}^{2\pi \mathrm{i} h x}$. The Walsh coefficients $\hat{f}_h(k)$ of the function f_h are then given by $\hat{f}_h(k) = \int_0^1 f_h(x)\overline{\mathrm{wal}_k(x)}\,\mathrm{d}x$. It follows that $|\hat{f}_h(k)|^2 = |\beta_{h,k}|^2$, where $\beta_{h,k}$ was defined in Lemma 2.6. Using Parseval's equality we obtain

$$\sum_{k=1}^{\infty} |\beta_{h,k}|^2 = \sum_{k=1}^{\infty} |\hat{f}_h(k)|^2 = \int_0^1 |f_h(x)|^2\,\mathrm{d}x = \int_0^1 1\,\mathrm{d}x = 1.$$

Hence we have

$$\sum_{k=1}^{\infty} r_{b,\alpha}(k) = \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{1}{|h|^{2\alpha}} \sum_{k=1}^{\infty} |\beta_{h,k}|^2 = \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{1}{|h|^{2\alpha}} = 2\zeta(2\alpha).$$

The result follows. □

LEMMA 8.7. *Let* $k = \kappa_{a_1-1}b^{a_1-1} + \cdots + \kappa_{a_\nu-1}b^{a_\nu-1}$, *with* $1 \le a_\nu < \cdots < a_1$, *let* $\kappa_{a_1-1}, \ldots, \kappa_{a_\nu-1} \in \{1, \ldots, b-1\}$. *Then*

$$\beta_{h,\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}} = \sum_{\substack{h_1,\ldots,h_\nu\in\mathbb{Z},h_l\equiv\kappa_{a_l-1} \pmod b\\ h=h_1b^{a_1-1}+\cdots+h_\nu b^{a_\nu-1}}} \frac{b^\nu}{(2\pi\mathrm{i})^\nu} \prod_{l=1}^{\nu} \frac{1-\mathrm{e}^{2\pi\mathrm{i}h_l/b}}{h_l}.$$

Proof. First we consider $k = \kappa_{a-1}b^{a-1}$, with $\kappa_{a-1} \in \{1, \ldots, b-1\}$. Let $x = \frac{x_1}{b} + \frac{x_2}{b^2} + \cdots$, and then we have $\mathrm{wal}_k(x) = \mathrm{e}^{2\pi\mathrm{i}\kappa_{a-1}x_a/b}$. Note that $\mathrm{wal}_k(x)$ is constant in the intervals $[u/b^a, (u+1)/b^a)$ for $0 \le u < b^a$. Let $u = u_{a-1}b^{a-1} + \cdots + u_0$. Then for any $h \in \mathbb{Z} \setminus \{0\}$ we have

$$\begin{aligned}
\beta_{h,k} &= \sum_{u=0}^{b^a-1} \mathrm{e}^{2\pi\mathrm{i}\kappa_{a-1}u_0/b} \int_{u/b^a}^{(u+1)/b^a} \mathrm{e}^{-2\pi\mathrm{i}hx}\,\mathrm{d}x\\
&= \sum_{u=0}^{b^a-1} \mathrm{e}^{2\pi\mathrm{i}\kappa_{a-1}u_0/b} \frac{\mathrm{e}^{-2\pi\mathrm{i}h(u+1)/b^a} - \mathrm{e}^{-2\pi\mathrm{i}hu/b^a}}{-2\pi\mathrm{i}h}\\
&= \frac{1-\mathrm{e}^{-2\pi\mathrm{i}h/b^a}}{2\pi h\mathrm{i}} \sum_{u_0=0}^{b-1} \cdots \sum_{u_{a-1}=0}^{b-1} \mathrm{e}^{2\pi\mathrm{i}\kappa_{a-1}u_0/b} \mathrm{e}^{-2\pi\mathrm{i}h(u_{a-1}/b+\cdots+u_0/b^a)}\\
&= \frac{1-\mathrm{e}^{-2\pi\mathrm{i}h/b^a}}{2\pi h\mathrm{i}} \sum_{u_0=0}^{b-1} \mathrm{e}^{2\pi\mathrm{i}u_0(\kappa_{a-1}/b-h/b^a)} \sum_{u_1=0}^{b-1} \mathrm{e}^{-2\pi\mathrm{i}u_1h/b^{a-1}} \cdots \sum_{u_{a-1}=0}^{b-1} \mathrm{e}^{-2\pi\mathrm{i}u_{a-1}h/b}.
\end{aligned}$$

Let now $h \in \mathbb{Z}\setminus\{0\}$, let $h = h_{c-1}b^{c-1} + \cdots + h_0$, and set $h_c = h_{c+1} = \cdots = 0$. If $h > 0$, we assume that $h_i \in \{0, \ldots, b-1\}$, and if $h < 0$, we assume that $h_i \in \{-b+1, \ldots, 0\}$ for all $i \ge 0$. If $h_0 \ne 0$, then $\sum_{u_{a-1}=0}^{b-1} \mathrm{e}^{-2\pi\mathrm{i}u_{a-1}h/b} = 0$, and hence $\beta_{h,\kappa_{a-1}b^{a-1}} = 0$. If $h_0 = 0$, then $\sum_{u_{a-1}=0}^{b-1} \mathrm{e}^{-2\pi\mathrm{i}u_{a-1}h/b} = b$. In general, if for an $0 \le i < a-1$ we have $h_i \ne 0$, then $\beta_{h,\kappa_{a-1}b^{a-1}} = 0$. Further, if $h_i = 0$ for $0 \le i \le a-1$, then we also have $\beta_{h,\kappa_{a-1}b^{a-1}} = 0$. Hence, in order to obtain $\beta_{h,\kappa_{a-1}b^{a-1}} \ne 0$ we must have $h_0 = \cdots = h_{a-2} = 0$ and $\kappa_{a-1} - h_{a-1} \equiv 0 \pmod b$. In this case we have

$$\beta_{h,\kappa_{a-1}b^{a-1}} = \frac{1-\mathrm{e}^{-2\pi\mathrm{i}h_{a-1}/b}}{2\pi h\mathrm{i}} b^a,$$

where $h = h_{a-1}b^{a-1} + h_a b^a + \cdots$, with $h_{a-1} \equiv \kappa_{a-1} \pmod b$. We can also write

$$\beta_{hb^{a-1},\kappa_{a-1}b^{a-1}} = \frac{b(1-\mathrm{e}^{-2\pi \mathtt{i} h/b})}{2\pi \mathtt{i} h},$$

with $h \in \mathbb{Z}$ such that $h \equiv \kappa_{a-1} \pmod b$.

We can interpret $\beta_{h,k} = \int_0^1 \mathrm{e}^{-2\pi \mathtt{i} hx} \mathrm{wal}_k(x)\,\mathrm{d}x$ as the Fourier coefficients of the kth Walsh function; hence, it follows that

$$\mathrm{wal}_k(x) = \sum_{h\in\mathbb{Z}} \beta_{h,k} \mathrm{e}^{2\pi \mathtt{i} hx}.$$

Let now $k = \kappa_{a_1-1}b^{a_1-1} + \cdots + \kappa_{a_\nu-1}b^{a_\nu-1}$ for some $1 \le a_\nu < \cdots < a_1$. Then we have

$$\begin{aligned}
&\mathrm{wal}_{\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}}(x)\\
&= \mathrm{wal}_{\kappa_{a_1-1}b^{a_1-1}}(x)\cdots \mathrm{wal}_{\kappa_{a_\nu-1}b^{a_\nu-1}}(x)\\
&= \sum_{h_1\in\mathbb{Z}} \beta_{h_1,\kappa_{a_1-1}b^{a_1-1}} \mathrm{e}^{2\pi \mathtt{i} h_1 x} \cdots \sum_{h_\nu\in\mathbb{Z}} \beta_{h_\nu,\kappa_{a_\nu-1}b^{a_\nu-1}} \mathrm{e}^{2\pi \mathtt{i} h_\nu x}\\
&= \sum_{h_1,\ldots,h_\nu\in\mathbb{Z}} \beta_{h_1,\kappa_{a_1-1}b^{a_1-1}} \cdots \beta_{h_\nu,\kappa_{a_\nu-1}b^{a_\nu-1}} \mathrm{e}^{2\pi \mathtt{i}(h_1+\cdots+h_\nu)x}.
\end{aligned}$$

On the other hand, we have

$$\mathrm{wal}_{\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}}(x) = \sum_{h\in\mathbb{Z}\setminus\{0\}} \beta_{h,\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}} \mathrm{e}^{2\pi \mathtt{i} hx}.$$

On comparing the last two equations we obtain that $\beta_{h,\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}} = 0$ if either $b^{a_1-1} \not| h$ or $h \not\equiv \kappa_{a_1-1} \pmod{b^{a_1-1}}$. Now let $h \in \mathbb{Z}$ such that $b^{a_1-1} | h$ and $h \equiv \kappa_{a_1-1} \pmod{b^{a_1-1}}$. Then we have

$$\begin{aligned}
&\beta_{h,\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}}\\
&= \sum_{\substack{h_1,\ldots,h_\nu\in\mathbb{Z}, h_l\equiv\kappa_{a_l-1} \pmod b\\ h=h_1b^{a_1-1}+\cdots+h_\nu b^{a_\nu-1}}} \beta_{h_1b^{a_1-1},\kappa_{a_1-1}b^{a_1-1}} \cdots \beta_{h_\nu b^{a_\nu-1},\kappa_{a_\nu-1}b^{a_\nu-1}}\\
&= \sum_{\substack{h_1,\ldots,h_\nu\in\mathbb{Z}, h_l\equiv\kappa_{a_l-1} \pmod b\\ h=h_1b^{a_1-1}+\cdots+h_\nu b^{a_\nu-1}}} \frac{b^\nu}{(2\pi\mathtt{i})^\nu} \prod_{l=1}^{\nu} \frac{1-\mathrm{e}^{2\pi \mathtt{i} h_l/b}}{h_l},
\end{aligned}$$

and the result follows. □

LEMMA 8.8. *For $k \ge 1$, $b \ge 2$, $m \ge 1$, and $\alpha > 1/2$ we have*

$$r_{b,\alpha}(kb^m) = b^{-2\alpha m} r_{b,\alpha}(k).$$

Proof. First note that $\beta_{h,\kappa_{a_1-1}b^{m+a_1-1}+\cdots+\kappa_{a_\nu-1}b^{m+a_\nu-1}} = 0$ if $b^m \not| h$. Further it follows from the previous lemma that

$$\beta_{hb^m,\kappa_{a_1-1}b^{m+a_1-1}+\cdots+\kappa_{a_\nu-1}b^{m+a_\nu-1}} = \beta_{h,\kappa_{a_1-1}b^{a_1-1}+\cdots+\kappa_{a_\nu-1}b^{a_\nu-1}},$$

and hence by Lemma 2.6 we have

$$r_{b,\alpha}(kb^m) = \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{|\beta_{hb^m,kb^m}|^2}{|hb^m|^{2\alpha}} = b^{-2\alpha m} \sum_{h\in\mathbb{Z}\setminus\{0\}} \frac{|\beta_{h,k}|^2}{|h|^{2\alpha}} = b^{-2\alpha m} r_{b,\alpha}(k).$$

The result follows. □

A MASS AND MAGNETIZATION CONSERVATIVE AND ENERGY-DIMINISHING NUMERICAL METHOD FOR COMPUTING GROUND STATE OF SPIN-1 BOSE–EINSTEIN CONDENSATES*

WEIZHU BAO† AND HANQUAN WANG‡

Abstract. In this paper, a mass (or normalization) and magnetization conservative and energy-diminishing numerical method is presented for computing the ground state of spin-1 (or $F = 1$ spinor) Bose–Einstein condensates (BECs). We begin with the coupled Gross–Pitaevskii equations, and the ground state is defined as the minimizer of the energy functional under two constraints on the mass and magnetization. By constructing a continuous normalized gradient flow (CNGF) which is mass and magnetization conservative and energy-diminishing, the ground state can be computed as the steady state solution of the CNGF. The CNGF is then discretized by the Crank–Nicolson finite difference method with a proper way to deal with the nonlinear terms, and we prove that the discretization is mass and magnetization conservative and energy-diminishing in the discretized level. Numerical results of the ground state and their energy of spin-1 BECs are reported to demonstrate the efficiency of the numerical method.

Key words. spin-1 Bose–Einstein condensate, coupled Gross–Pitaevskii equations, ground state, continuous normalized gradient flow, mass and magnetization conservative, energy-diminishing

1. Introduction.

Since its realization in dilute bosonic atomic gases [2, 13, 9], the atomic Bose–Einstein condensate (BEC) has been produced and studied extensively in the laboratory [28, 29, 16] and has provided a successful testing ground of theoretical studies of quantum many-body systems [28, 29]. In earlier BEC experiments, atoms were spatially confined with magnetic traps, which essentially freeze the atomic internal degrees of freedom [2, 13, 9]. Most studies were thus focused on scalar models, i.e., single-component quantum degenerate gases [12]. One of the most important recent developments in BECs was the study of spin-1 condensates (of atoms with hyperfine quantum number $F = 1$) [17, 27, 34, 10, 31], and they were realized in experiments recently using both ^{23}Na and ^{87}Rb [24, 35]. In fact, the emergence of the spin-1 BEC [19, 20, 24] has created opportunities for understanding degenerate gases with internal degrees of freedom [21, 22, 17, 18, 14, 25, 26, 32, 37].

At temperature T much smaller than the critical condensate temperature T_c [23], a spin-1 BEC is well described by the three-component wave function $\Psi = (\psi_1(\mathbf{x}, t), \psi_0(\mathbf{x}, t), \psi_{-1}(\mathbf{x}, t))^T$ whose evolution is governed by the coupled Gross–Pitaevskii equations (GPEs) [23, 17, 18, 38, 36]:

$$i\hbar\partial_t\psi_1(\mathbf{x},t) = \left[-\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{x}) + (c_0+c_2)\left(|\psi_1|^2+|\psi_0|^2\right) + (c_0-c_2)|\psi_{-1}|^2\right]\psi_1$$
$$+c_2\bar{\psi}_{-1}\psi_0^2, \tag{1.1}$$
$$i\hbar\partial_t\psi_0(\mathbf{x},t) = \left[-\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{x}) + (c_0+c_2)\left(|\psi_1|^2+|\psi_{-1}|^2\right) + c_0|\psi_0|^2\right]\psi_0$$
$$+2c_2\psi_{-1}\bar{\psi}_0\psi_1, \tag{1.2}$$
$$i\hbar\partial_t\psi_{-1}(\mathbf{x},t) = \left[-\frac{\hbar^2}{2m}\nabla^2 + V(\mathbf{x}) + (c_0+c_2)\left(|\psi_{-1}|^2+|\psi_0|^2\right) + (c_0-c_2)|\psi_1|^2\right]\psi_{-1}$$
$$+c_2\psi_0^2\bar{\psi}_1. \tag{1.3}$$

Here $\mathbf{x} = (x,y,z)^T$ is the Cartesian coordinate vector, $\hbar$ is the Planck constant, m is the atomic mass, and $V(\mathbf{x})$ is the external trapping potential. When a harmonic trap potential is considered,

$$V(\mathbf{x}) = \frac{m}{2}(\omega_x^2x^2 + \omega_y^2y^2 + \omega_z^2z^2), \tag{1.4}$$

with ω_x, ω_y, and ω_z being the trap frequencies in the x-, y-, and z-directions, respectively. $\bar{f}$ and $\mathrm{Re}(f)$ denote the conjugate and the real part of the function f, respectively. $c_0 = 4\pi\hbar^2(a_0+2a_2)/3m$ and $c_2 = 4\pi\hbar^2(a_2-a_0)/3m$ denote constants of the mean-field (spin-independent) and spin-exchange interaction, respectively, with a_j the s-wave scattering lengths for the channel of total hyperfine spin j ($j = 0, 2$). The wave function is normalized according to

$$\|\Psi\|^2 := \int_{\mathbb{R}^3}|\Psi(\mathbf{x},t)|^2\,d\mathbf{x} = \int_{\mathbb{R}^3}\sum_{j=-1}^{1}|\psi_j(\mathbf{x},t)|^2\,d\mathbf{x} := \sum_{j=-1}^{1}\|\psi_j\|^2 = N, \tag{1.5}$$

where N is the total number of particles in the condensate.

By introducing the dimensionless variables $t \to t/\omega_m$, with $\omega_m = \min\{\omega_x,\omega_y,\omega_z\}$, and $\mathbf{x} \to \mathbf{x}\ a_s$, with $a_s = \sqrt{\frac{\hbar}{m\omega_m}}$, $\psi_j \to \sqrt{N}\psi_j/a_s^{3/2}$ ($j = -1, 0, 1$), we get the dimensionless coupled GPEs from (1.1)–(1.3) as [38, 39, 36]:

$$i\partial_t\psi_1(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_1|^2+|\psi_0|^2\right) + (\beta_n-\beta_s)|\psi_{-1}|^2\right]\psi_1$$
$$+\beta_s\bar{\psi}_{-1}\psi_0^2, \tag{1.6}$$
$$i\partial_t\psi_0(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_1|^2+|\psi_{-1}|^2\right) + \beta_n|\psi_0|^2\right]\psi_0$$
$$+2\beta_s\psi_{-1}\bar{\psi}_0\psi_1, \tag{1.7}$$
$$i\partial_t\psi_{-1}(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_{-1}|^2+|\psi_0|^2\right) + (\beta_n-\beta_s)|\psi_1|^2\right]\psi_{-1}$$
$$+\beta_s\psi_0^2\bar{\psi}_1, \tag{1.8}$$

where $\beta_n = \frac{N\,c_0}{a_s^3\hbar\omega_m} = \frac{4\pi N(a_0+2a_2)}{3a_s}$, $\beta_s = \frac{N\,c_2}{a_s^3\hbar\omega_m} = \frac{4\pi N(a_2-a_0)}{3a_s}$, and $V(\mathbf{x}) = \frac{1}{2}(\gamma_x^2x^2 + \gamma_y^2y^2 + \gamma_z^2z^2)$, with $\gamma_x = \frac{\omega_x}{\omega_m}$, $\gamma_y = \frac{\omega_y}{\omega_m}$, and $\gamma_z = \frac{\omega_z}{\omega_m}$. Similar as those in the single-component BEC [29, 1, 7, 3, 6], in the disk-shaped condensation, i.e., $\omega_x \approx \omega_y$ and $\omega_z \gg \omega_x$ ($\Longleftrightarrow \gamma_x = 1$, $\gamma_y \approx 1$, and $\gamma_z \gg 1$, with $\omega_m = \omega_x$), the three-dimensional (3D) coupled GPEs (1.6)–(1.8) can be reduced to 2D coupled GPEs, and in the cigar-shaped condensation, i.e., $\omega_y \gg \omega_x$ and $\omega_z \gg \omega_x$ ($\Longleftrightarrow \gamma_x = 1$, $\gamma_y \gg 1$, and $\gamma_z \gg 1$,

with $\omega_m = \omega_x$), the 3D coupled GPEs (1.6)–(1.8) can be reduced to 1D coupled GPEs. Thus here we consider the dimensionless coupled GPEs in d dimensions ($d = 1, 2, 3$):

$$i\partial_t\psi_1(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_1|^2+|\psi_0|^2\right) + (\beta_n-\beta_s)|\psi_{-1}|^2\right]\psi_1$$
$$+\beta_s\bar{\psi}_{-1}\psi_0^2, \tag{1.9}$$

$$i\partial_t\psi_0(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_1|^2+|\psi_{-1}|^2\right) + \beta_n|\psi_0|^2\right]\psi_0$$
$$+2\beta_s\psi_{-1}\bar{\psi}_0\psi_1, \tag{1.10}$$

$$i\partial_t\psi_{-1}(\mathbf{x},t) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\psi_{-1}|^2+|\psi_0|^2\right) + (\beta_n-\beta_s)|\psi_1|^2\right]\psi_{-1}$$
$$+\beta_s\psi_0^2\bar{\psi}_1. \tag{1.11}$$

Here $V(\mathbf{x})$ is a real-valued potential whose shape is determined by the type of system under investigation; $\beta_n \propto N$ and $\beta_s \propto N$ correspond to the dimensionless mean-field (spin-independent) and spin-exchange interaction, respectively. Three important invariants of (1.9)–(1.11) are the *mass* (or normalization) of the wave function

$$N(\Psi(\cdot,t)) := \|\Psi(\cdot,t)\|^2 := \int_{\mathbb{R}^d}\sum_{j=-1}^{1}|\psi_j(\mathbf{x},t)|^2\,d\mathbf{x} \equiv N(\Psi(\cdot,0)) = 1, \qquad t \ge 0, \tag{1.12}$$

the *magnetization* (with $-1 \le M \le 1$)

$$M(\Psi(\cdot,t)) := \int_{\mathbb{R}^d}\left[|\psi_1(\mathbf{x},t)|^2 - |\psi_{-1}(\mathbf{x},t)|^2\right]d\mathbf{x} \equiv M(\Psi(\cdot,0)) = M, \tag{1.13}$$

and the energy per particle

$$E(\Psi(\cdot,t)) = \int_{\mathbb{R}^d}\Bigg\{\sum_{j=-1}^{1}\left(\frac{1}{2}|\nabla\psi_j|^2 + V(\mathbf{x})|\psi_j|^2\right) + (\beta_n-\beta_s)|\psi_1|^2|\psi_{-1}|^2$$
$$+\frac{\beta_n}{2}|\psi_0|^4 + \frac{\beta_n+\beta_s}{2}\left[|\psi_1|^4+|\psi_{-1}|^4+2|\psi_0|^2\left(|\psi_1|^2+|\psi_{-1}|^2\right)\right]$$
$$+\beta_s\left(\bar{\psi}_{-1}\psi_0^2\bar{\psi}_1 + \psi_{-1}\bar{\psi}_0^2\psi_1\right)\Bigg\}\,d\mathbf{x} \equiv E(\Psi(\cdot,0)), \qquad t \ge 0. \tag{1.14}$$

The ground state of a spin-1 BEC is defined as the minimizer of the following nonconvex minimization problem:

Find ($\Phi_g \in S$) such that

$$E_g := E(\Phi_g) = \min_{\Phi\in S} E(\Phi), \tag{1.15}$$

where the nonconvex set S is defined as

$$S = \left\{\Phi = (\phi_1,\phi_0,\phi_{-1})^T \mid \|\Phi\| = 1,\ \int_{\mathbb{R}^d}\left[|\phi_1(\mathbf{x})|^2 - |\phi_{-1}(\mathbf{x})|^2\right] = M,\ E(\Phi) < \infty\right\}. \tag{1.16}$$

When $\beta_n \ge 0$, $\beta_n \ge |\beta_s|$, and $\lim_{|\mathbf{x}|\to\infty} V(\mathbf{x}) = \infty$, the existence of a minimizer of the nonconvex minimization problem (1.15) follows from the standard theory [33].

For understanding the uniqueness question note that $E(\alpha \cdot \Phi_g) = E(\Phi_g)$ for all $\alpha = \left(e^{i\theta_1}, e^{i\theta_0}, e^{i\theta_{-1}}\right)^T$, with $\theta_1 + \theta_{-1} = 2\theta_0$. Thus additional constraints have to be introduced to show the uniqueness.

One of the fundamental problems in theoretical study of a spin-1 BEC is to find its ground state so as to compare the numerical results with experimental observations and to prepare initial data for studying the dynamics of a spin-1 BEC. Due to the facts that there are three components in the wave function Φ in (1.15) and that there are only two constraints in (1.16), it is not obvious that the most powerful and popular imaginary time method [11, 1, 3, 4, 5, 8, 7] used for computing the ground state of a single-component BEC could be extended to this case directly. The reason is that, in the projection step, we need to determine three parameters but have only two equations from the two constraints. However, in physics literatures, they still use the imaginary time method for computing the ground state of a spin-1 BEC by introducing a random variable to choose the three projection parameters in the projection step [38]. Of course, this is not a determinate and efficient way to compute the ground state of a spin-1 BEC due to the choice of the random variable. In fact, to our knowledge, there is no efficient and determinate numerical method for computing the ground state of a spin-1 BEC in the literature yet. The aim of this paper is to propose such a numerical method.

The paper is organized as follows. In section 2, we first introduce the Euler–Lagrange equations (or time-independent coupled GPEs) associated to the minimization problem (1.15) and then construct a continuous normalized gradient flow (CNGF) such that the ground state of a spin-1 BEC is the steady state solution of this CNGF. In section 3, the CNGF is discretized in space and time with a proper way to treat the nonlinear terms, and we prove that the discretization is mass and magnetization conservative and energy-diminishing. In section 4, numerical results are reported to demonstrate the efficiency of our numerical method. Finally, some conclusions are drawn in section 5.

2. A continuous normalized gradient flow. In this section, we will introduce the Euler–Lagrange equations associated to the minimization problem (1.15) and construct a continuous normalized gradient flow for computing the ground state of a spin-1 BEC.

2.1. Euler–Lagrange equations. In order to find the Euler–Lagrange equations associated to the minimization problem (1.15), we define the Lagrangian

$$\mathcal{L}(\Phi, \mu, \lambda) := E(\Phi) - \mu\left(\|\phi_1\|^2 + \|\phi_0\|^2 + \|\phi_{-1}\|^2 - 1\right) - \lambda\left(\|\phi_1\|^2 - \|\phi_{-1}\|^2 - M\right). \tag{2.1}$$

Differentiating (2.1) with respect to $\bar{\phi}_1$, $\bar{\phi}_0$, and $\bar{\phi}_{-1}$, respectively, we get the following Euler–Lagrange equations:

$$\begin{aligned}(\mu+\lambda)\,\phi_1(\mathbf{x}) = &\left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\phi_1|^2 + |\phi_0|^2\right) + (\beta_n-\beta_s)|\phi_{-1}|^2\right]\phi_1 \\ &+\beta_s\bar{\phi}_{-1}\phi_0^2 := H_1\phi_1,\end{aligned} \tag{2.2}$$

$$\begin{aligned}\mu\,\phi_0(\mathbf{x}) = &\left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\phi_1|^2 + |\phi_{-1}|^2\right) + \beta_n|\phi_0|^2\right]\phi_0 \\ &+2\beta_s\phi_{-1}\bar{\phi}_0\phi_1 := H_0\phi_0,\end{aligned} \tag{2.3}$$

$$(\mu-\lambda)\,\phi_{-1}(\mathbf{x}) = \left[-\frac{1}{2}\nabla^2 + V(\mathbf{x}) + (\beta_n+\beta_s)\left(|\phi_{-1}|^2+|\phi_0|^2\right) + (\beta_n-\beta_s)|\phi_1|^2\right]\phi_{-1}$$

$$+\beta_s\phi_0^2\bar{\phi}_1 := H_{-1}\phi_{-1}. \tag{2.4}$$

Here μ and λ are the Lagrange multipliers (or chemical potentials) of the coupled GPEs (2.2)–(2.4). In addition, (2.2)–(2.4) is also a nonlinear eigenvalue problem with two constraints:

$$\|\Phi\|^2 := \int_{\mathbb{R}^d} |\Phi(\mathbf{x})|^2\,d\mathbf{x} = \int_{\mathbb{R}^d}\sum_{j=-1}^{1}|\phi_j(\mathbf{x})|^2\,d\mathbf{x} := \sum_{j=-1}^{1}\|\phi_j\|^2 = 1, \tag{2.5}$$

$$\|\phi_1\|^2 - \|\phi_{-1}\|^2 := \int_{\mathbb{R}^d}\left[|\phi_1(\mathbf{x})|^2 - |\phi_{-1}(\mathbf{x})|^2\right]d\mathbf{x} = M. \tag{2.6}$$

In fact, the nonlinear eigenvalue problem (2.2)–(2.4) can be also obtained from the coupled GPEs (1.9)–(1.11) by plugging $\psi_j(\mathbf{x},t) = e^{-i\mu_j t}\phi_j(\mathbf{x})$ $(j=1,0,-1)$ with $\mu_1=\mu+\lambda$, $\mu_0=\mu$, and $\mu_{-1}=\mu-\lambda$. Thus it is also called time-independent coupled GPEs. In physics literatures, any eigenfunction Φ of the nonlinear eigenvalue problem (2.2)–(2.4) under the constraints (2.5) and (2.6) whose energy is larger than the energy of the ground state is called an excited state of the coupled GPEs (1.9)–(1.11).

When $V(\mathbf{x})$ is chosen as a harmonic oscillator potential, following the idea in [12, 29] for a single-component BEC, we have the following virial theorem for a spin-1 BEC.

LEMMA 2.1. *Suppose $\Phi \in S$ is an eigenfunction of the nonlinear eigenvalue problem* (2.2)–(2.4). *When $V(\mathbf{x})$ is chosen as a harmonic oscillator potential, i.e., it is a quadratic form in* $\mathbf{x}$, *we have*

$$2\,E_{\rm kin}(\Phi) - 2\,E_{\rm pot}(\Phi) + d\,E_{\rm int}(\Phi) = 0, \tag{2.7}$$

where $E_{\rm kin}$, $E_{\rm pot}$, and $E_{\rm int}$ are the kinetic energy, potential energy, and interaction energy, respectively, and are defined as

$$E_{\rm kin}(\Phi) = \frac{1}{2}\int_{\mathbb{R}^d}\sum_{j=-1}^{1}|\nabla\phi_j|^2\,d\mathbf{x}, \qquad E_{\rm pot}(\Phi) = \int_{\mathbb{R}^d}\sum_{j=-1}^{1}V(\mathbf{x})|\phi_j|^2\,d\mathbf{x}, \tag{2.8}$$

$$E_{\rm int}(\Phi) = \int_{\mathbb{R}^d}\Big[\frac{\beta_n+\beta_s}{2}\Big(|\phi_1|^4+|\phi_{-1}|^4+2|\phi_0|^2\left(|\phi_1|^2+|\phi_{-1}|^2\right)\Big)$$

$$+(\beta_n-\beta_s)|\phi_1|^2|\phi_{-1}|^2 + \frac{\beta_n}{2}|\phi_0|^4 + \beta_s\left(\bar{\phi}_{-1}\phi_0^2\bar{\phi}_1 + \phi_{-1}\bar{\phi}_0^2\phi_1\right)\Big]\,d\mathbf{x}. \tag{2.9}$$

Proof. Suppose $\Phi_e \in S$ is an eigenfunction of the nonlinear eigenvalue problem (2.2)–(2.4), and we define a trial function $\Phi_\varepsilon \in S$ as

$$\Phi_\varepsilon(\mathbf{x}) = (1+\varepsilon)^{d/2}\Phi_e\left((1+\varepsilon)\mathbf{x}\right), \qquad \mathbf{x}\in\mathbb{R}^d. \tag{2.10}$$

Plugging Φ_ε into the energy functional in (1.14), change of variables, we obtain

$$E(\Phi_\varepsilon(\mathbf{x})) = E\left((1+\varepsilon)^{d/2}\Phi_e\left((1+\varepsilon)\mathbf{x}\right)\right)$$

$$= (1+\varepsilon)^2 E_{\rm kin}\left(\Phi_e(\mathbf{x})\right) + \frac{1}{(1+\varepsilon)^2}E_{\rm pot}\left(\Phi_e(\mathbf{x})\right) + (1+\varepsilon)^d E_{\rm int}\left(\Phi_e(\mathbf{x})\right). \tag{2.11}$$

Differentiating (2.11) with respect to ε, we get

$$\frac{dE(\Phi_\varepsilon)}{d\varepsilon} = 2(1+\varepsilon)E_{\rm kin}\left(\Phi_e\right) - \frac{2}{(1+\varepsilon)^3}E_{\rm pot}\left(\Phi_e\right) + d(1+\varepsilon)^{d-1}E_{\rm int}\left(\Phi_e\right). \tag{2.12}$$

Since Φ_e is also a critical point of the energy functional $E(\Phi)$ over the set S, we get (2.7) from (2.12) by setting $\varepsilon = 0$ and noticing $\Phi_{\varepsilon=0}(\mathbf{x}) = \Phi_e(\mathbf{x})$ in (2.10). ∎

2.2. A continuous normalized gradient flow. In order to compute the ground state of a spin-1 BEC in (1.15) numerically, we construct the following CNGF:

$$\partial_t \phi_1(\mathbf{x},t) = \left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - (\beta_n+\beta_s)\left(|\phi_1|^2+|\phi_0|^2\right) - (\beta_n-\beta_s)|\phi_{-1}|^2\right]\phi_1$$

$$-\beta_s\bar{\phi}_{-1}\phi_0^2 + [\mu_\Phi(t)+\lambda_\Phi(t)]\,\phi_1 = -H_1\,\phi_1 + [\mu_\Phi(t)+\lambda_\Phi(t)]\,\phi_1, \tag{2.13}$$

$$\partial_t \phi_0(\mathbf{x},t) = \left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - (\beta_n+\beta_s)\left(|\phi_1|^2+|\phi_{-1}|^2\right) - \beta_n|\phi_0|^2\right]\phi_0$$

$$-2\beta_s\phi_{-1}\bar{\phi}_0\phi_1 + \mu_\Phi(t)\,\phi_0 = -H_0\,\phi_0 + \mu_\Phi(t)\,\phi_0, \tag{2.14}$$

$$\partial_t \phi_{-1}(\mathbf{x},t) = \left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - (\beta_n+\beta_s)\left(|\phi_{-1}|^2+|\phi_0|^2\right) - (\beta_n-\beta_s)|\phi_1|^2\right]\phi_{-1}$$

$$-\beta_s\phi_0^2\bar{\phi}_1 + [\mu_\Phi(t)-\lambda_\Phi(t)]\,\phi_{-1} = -H_{-1}\,\phi_{-1} + [\mu_\Phi(t)-\lambda_\Phi(t)]\,\phi_{-1}. \tag{2.15}$$

Here $\mu_\Phi(t)$ and $\lambda_\Phi(t)$ are chosen such that the above CNGF is mass (or normalization) and magnetization conservative, and they are given as

$$\mu_\Phi(t) = \frac{R_\Phi(t)D_\Phi(t) - M_\Phi(t)F_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)}, \qquad \lambda_\Phi(t) = \frac{N_\Phi(t)F_\Phi(t) - M_\Phi(t)D_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)}, \tag{2.16}$$

with

$$N_\Phi(t) = \int_{\mathbb{R}^d}\left[|\phi_{-1}(\mathbf{x},t)|^2 + |\phi_0(\mathbf{x},t)|^2 + |\phi_1(\mathbf{x},t)|^2\right]d\mathbf{x}, \tag{2.17}$$

$$M_\Phi(t) = \int_{\mathbb{R}^d}\left[|\phi_1(\mathbf{x},t)|^2 - |\phi_{-1}(\mathbf{x},t)|^2\right]\,d\mathbf{x}, \tag{2.18}$$

$$R_\Phi(t) = \int_{\mathbb{R}^d}\left[|\phi_1(\mathbf{x},t)|^2 + |\phi_{-1}(\mathbf{x},t)|^2\right]\,d\mathbf{x}, \tag{2.19}$$

$$\begin{aligned} D_\Phi(t) = \int_{\mathbb{R}^d}\Bigg\{ &\sum_{j=-1}^{1}\left(\frac{1}{2}|\nabla\phi_j|^2 + V(\mathbf{x})|\phi_j|^2\right) + 2(\beta_n-\beta_s)|\phi_1|^2|\phi_{-1}|^2 + \beta_n|\phi_0|^4 \\ &+(\beta_n+\beta_s)\Big[|\phi_1|^4 + |\phi_{-1}|^4 + 2|\phi_0|^2\left(|\phi_1|^2+|\phi_{-1}|^2\right)\Big] \\ &+2\beta_s\left(\bar{\phi}_{-1}\phi_0^2\bar{\phi}_1 + \phi_{-1}\bar{\phi}_0^2\phi_1\right)\Bigg\}\,d\mathbf{x}, \end{aligned} \tag{2.20}$$

$$\begin{aligned} F_\Phi(t) = \int_{\mathbb{R}^d}\Bigg\{ &\frac{1}{2}\left(|\nabla\phi_1|^2 - |\nabla\phi_{-1}|^2\right) + V(\mathbf{x})\left(|\phi_1|^2 - |\phi_{-1}|^2\right) \\ &+(\beta_n+\beta_s)\Big[|\phi_1|^4 - |\phi_{-1}|^4 + |\phi_0|^2\left(|\phi_1|^2 - |\phi_{-1}|^2\right)\Big]\Bigg\}\,d\mathbf{x}. \end{aligned} \tag{2.21}$$

For the above CNGF, we have the following.

THEOREM 2.2. *For any given initial data*

$$\Phi(\mathbf{x},0) = (\phi_1(\mathbf{x},0),\phi_0(\mathbf{x},0),\phi_{-1}(\mathbf{x},0))^T := \Phi^{(0)}(\mathbf{x}), \qquad \mathbf{x}\in\mathbb{R}^d, \tag{2.22}$$

satisfying

$$N_\Phi(t=0) := N_{\Phi^{(0)}} = 1, \qquad M_\Phi(t=0) := M_{\Phi^{(0)}} = M, \tag{2.23}$$

the CNGF (2.13)–(2.15) *is mass and magnetization conservative and energy-diminishing, i.e.,*

$$N_\Phi(t) \equiv N_\Phi(t=0) = 1, \qquad M_\Phi(t) \equiv M_\Phi(t=0) = M, \qquad t \geq 0, \tag{2.24}$$

$$E\left(\Phi(\cdot,t)\right) \leq E\left(\Phi(\cdot,s)\right) \qquad \text{for any } t \geq s \geq 0. \tag{2.25}$$

Proof. Differentiating (2.17) with respect to t and noticing (2.13)–(2.15), we have

$$\begin{aligned}
\frac{dN_\Phi(t)}{dt} &= \frac{d}{dt}\int_{\mathbb{R}^d}\sum_{j=-1}^{1}|\phi_j(\mathbf{x},t)|^2\,d\mathbf{x} = \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\Big[\bar\phi_j\,\partial_t\phi_j + \phi_j\,\partial_t\bar\phi_j\Big]\,d\mathbf{x}\\
&= \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\Big(-\bar\phi_j H_j\phi_j - \phi_j\bar H_j\bar\phi_j\Big)d\mathbf{x} + 2\left[\mu_\Phi(t)+\lambda_\Phi(t)\right]\|\phi_1\|^2\\
&\quad +2\mu_\Phi(t)\|\phi_0\|^2 + 2\left[\mu_\Phi(t)-\lambda_\Phi(t)\right]\|\phi_{-1}\|^2\\
&= 2\mu_\Phi(t)\left(\|\phi_1\|^2+\|\phi_0\|^2+\|\phi_{-1}\|^2\right) + 2\lambda_\Phi(t)\left(\|\phi_1\|^2-\|\phi_{-1}\|^2\right)\\
&\quad -\int_{\mathbb{R}^d}\sum_{j=-1}^{1}\bar\phi_j H_j\phi_j\,d\mathbf{x} - \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\phi_j\bar H_j\bar\phi_j\,d\mathbf{x}.
\end{aligned} \tag{2.26}$$

From (2.13)–(2.15) and (2.20), integrating by parts, we have

$$D_\Phi(t) = \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\bar\phi_j H_j\phi_j\,d\mathbf{x} = \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\phi_j\bar H_j\bar\phi_j\,d\mathbf{x}. \tag{2.27}$$

Plugging (2.27) into (2.26) and noticing (2.16), (2.17), and (2.18), we obtain

$$\begin{aligned}
\frac{dN_\Phi(t)}{dt} &= 2\mu_\Phi(t)N_\Phi(t) + 2\lambda_\Phi(t)M_\Phi(t) - 2D_\Phi(t)\\
&= 2N_\Phi(t)\frac{R_\Phi(t)D_\Phi(t) - M_\Phi(t)F_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)} + 2M_\Phi(t)\frac{N_\Phi(t)F_\Phi(t) - M_\Phi(t)D_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)}\\
&\quad -2D_\Phi(t)\\
&= 2D_\Phi(t) - 2D_\Phi(t) \equiv 0, \qquad t \geq 0.
\end{aligned} \tag{2.28}$$

Thus the first part in (2.24) can be obtained from (2.28) immediately. Similarly, differentiating (2.18) with respect to t, noticing (2.13), (2.15), (2.16), and (2.21), and integrating by parts, we obtain

$$\begin{aligned}
\frac{dM_\Phi(t)}{dt} &= \frac{d}{dt}\int_{\mathbb{R}^d}\Big[|\phi_1(\mathbf{x},t)|^2 - |\phi_{-1}(\mathbf{x},t)|^2\Big]\,d\mathbf{x}\\
&= \int_{\mathbb{R}^d}\Big[\bar\phi_1\,\partial_t\phi_1 + \phi_1\,\partial_t\bar\phi_1 - \bar\phi_{-1}\,\partial_t\phi_{-1} - \phi_{-1}\,\partial_t\bar\phi_{-1}\Big]d\mathbf{x}\\
&= \int_{\mathbb{R}^d}\Big[-\bar\phi_1\,H_1\phi_1 - \phi_1\,\bar H_1\bar\phi_1 + \bar\phi_{-1}\,H_{-1}\phi_{-1} + \phi_{-1}\,\bar H_{-1}\bar\phi_{-1}\Big]d\mathbf{x}\\
&\quad +2\left[\mu_\Phi(t)+\lambda_\Phi(t)\right]\|\phi_1\|^2 - 2\left[\mu_\Phi(t)-\lambda_\Phi(t)\right]\|\phi_{-1}\|^2\\
&= 2\mu_\Phi(t)\left(\|\phi_1\|^2-\|\phi_{-1}\|^2\right) + 2\lambda_\Phi(t)\left(\|\phi_1\|^2+\|\phi_{-1}\|^2\right)\\
&\quad -\int_{\mathbb{R}^d}\Big[\bar\phi_1\,H_1\phi_1 - \bar\phi_{-1}\,H_{-1}\phi_{-1}\Big]\,d\mathbf{x} - \int_{\mathbb{R}^d}\Big[\phi_1\,\bar H_1\bar\phi_1 - \phi_{-1}\,\bar H_{-1}\bar\phi_{-1}\Big]d\mathbf{x}.
\end{aligned} \tag{2.29}$$

From (2.13)–(2.15) and (2.21), integrating by parts, we have

$$F_\Phi(t) = \int_{\mathbb{R}^d} \left[\bar\phi_1\ H_1\phi_1 - \bar\phi_{-1}\ H_{-1}\phi_{-1}\right] d\mathbf{x} = \int_{\mathbb{R}^d} \left[\phi_1\ \bar H_1\bar\phi_1 - \phi_{-1}\ \bar H_{-1}\bar\phi_{-1}\right] d\mathbf{x}. \tag{2.30}$$

Plugging (2.30) into (2.29) and noticing (2.16), (2.18), and (2.19), we obtain

$$\begin{aligned}\frac{dM_\Phi(t)}{dt} &= 2\mu_\Phi(t)M_\Phi(t) + 2\lambda_\Phi(t)R_\Phi(t) - 2F_\Phi(t)\\ &= 2M_\Phi(t)\frac{R_\Phi(t)D_\Phi(t) - M_\Phi(t)F_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)} + 2R_\Phi(t)\frac{N_\Phi(t)F_\Phi(t) - M_\Phi(t)D_\Phi(t)}{N_\Phi(t)R_\Phi(t) - M_\Phi^2(t)}\\ &\quad -2F_\Phi(t)\\ &= 2F_\Phi(t) - 2F_\Phi(t) \equiv 0, \qquad t \ge 0. \end{aligned} \tag{2.31}$$

Thus the second part in (2.24) can be obtained from (2.31) immediately. Finally, differentiating (1.14) (with $\Psi = \Phi$) with respect to t and integrating by parts, we have

$$\begin{aligned}\frac{dE(\Phi(t))}{dt} &= \frac{d}{dt}\int_{\mathbb{R}^d}\left\{\sum_{j=-1}^{1}\left(\frac{1}{2}|\nabla\phi_j|^2 + V(\mathbf{x})|\phi_j|^2\right) + (\beta_n - \beta_s)|\phi_1|^2|\phi_{-1}|^2\right.\\ &\quad + \frac{\beta_n}{2}|\phi_0|^4 + \frac{\beta_n+\beta_s}{2}\left[|\phi_1|^4 + |\phi_{-1}|^4 + 2|\phi_0|^2\left(|\phi_1|^2 + |\phi_{-1}|^2\right)\right]\\ &\quad \left. + \beta_s\left(\bar\phi_{-1}\phi_0^2\bar\phi_1 + \phi_{-1}\bar\phi_0^2\phi_1\right)\right\} d\mathbf{x}\\ &= \int_{\mathbb{R}^d}\sum_{j=-1}^{1}\left[\partial_t\phi_j\bar H_j\bar\phi_j + \partial_t\bar\phi_j H_j\phi_j\right]\ d\mathbf{x}. \end{aligned} \tag{2.32}$$

Plugging (2.13)–(2.15) into (2.32) and noticing (2.28) and (2.31), we obtain

$$\begin{aligned}\frac{dE(\Phi(t))}{dt} &= \int_{\mathbb{R}^d}\left[-2|\partial_t\phi_{-1}|^2 + \left(\mu_\Phi(t) - \lambda_\Phi(t)\right)\partial_t|\phi_{-1}|^2 - 2|\partial_t\phi_0|^2 + \mu_\Phi(t)\partial_t|\phi_0|^2\right.\\ &\quad \left. -2|\partial_t\phi_1|^2 + \left(\mu_\Phi(t) + \lambda_\Phi(t)\right)\partial_t|\phi_1|^2\right] d\mathbf{x}\\ &= \mu_\Phi(t)\int_{\mathbb{R}^d}\partial_t\left[|\phi_1|^2 + |\phi_0|^2 + |\phi_{-1}|^2\right] d\mathbf{x} + \lambda_\Phi(t)\int_{\mathbb{R}^d}\partial_t\left[|\phi_1|^2 - |\phi_{-1}|^2\right] d\mathbf{x}\\ &\quad -2\int_{\mathbb{R}^d}\left[|\partial_t\phi_{-1}|^2 + |\partial_t\phi_0|^2 + |\partial_t\phi_1|^2\right] d\mathbf{x}\\ &= \mu_\Phi(t)\frac{dN_\Phi(t)}{dt} + \lambda_\Phi(t)\frac{dM_\Phi(t)}{dt} - 2\int_{\mathbb{R}^d}\left[|\partial_t\phi_{-1}|^2 + |\partial_t\phi_0|^2 + |\partial_t\phi_1|^2\right] d\mathbf{x}\\ &= -2\int_{\mathbb{R}^d}\left[|\partial_t\phi_{-1}|^2 + |\partial_t\phi_0|^2 + |\partial_t\phi_1|^2\right] d\mathbf{x} \le 0, \qquad t \ge 0. \end{aligned} \tag{2.33}$$

Thus the inequality (2.25) can be obtained from (2.33) immediately. ∎

Using an argument similar to that in [33], when $V(\mathbf{x}) \ge 0$ for all $\mathbf{x} \in \mathbb{R}^d$, $\beta_n \ge 0$, $\beta_n \ge |\beta_s|$, and $\Phi_0 \in S$, we may get that as $t \to \infty$, Φ approaches to a steady state solution, which is a critical point of the energy functional $E(\Phi)$ over the set S. When the initial data Φ_0 in (2.22) for the CNGF (2.13)–(2.15) are chosen properly, e.g., its energy is less than that of the first excited state, the ground state Φ_g can be obtained from the steady state solution of the CNGF (2.13)–(2.15), i.e.,

$$\Phi_g(\mathbf{x}) = \lim_{t\to\infty}\Phi(\mathbf{x}, t), \qquad \mathbf{x} \in \mathbb{R}^d. \tag{2.34}$$

3. Mass and magnetization conservative and energy-diminishing numerical discretization. In this section, we present a mass and magnetization conservative and energy-diminishing scheme to discretize the continuous normalized gradient flow (2.13)–(2.15) for computing the ground state of a spin-1 BEC.

3.1. Semidiscretization in time. Choose a time step $k = \Delta t > 0$, and set $t_n = n\Delta t$ for $n = 0, 1, 2, \ldots$. Let $\Phi^n(\mathbf{x}) = (\phi_1^n(\mathbf{x}), \phi_0^n(\mathbf{x}), \phi_{-1}^n(\mathbf{x}))^T$ be the approximation of $\Phi(\mathbf{x}, t_n)$, and denote $\Phi^{n+1/2}(\mathbf{x}) = (\phi_1^{n+1/2}(\mathbf{x}), \phi_0^{n+1/2}(\mathbf{x}), \phi_{-1}^{n+1/2}(\mathbf{x}))^T$ defined as

$$\phi_j^{n+1/2} := \phi_j^{n+1/2}(\mathbf{x}) = \frac{1}{2}\left[\phi_j^{n+1}(\mathbf{x}) + \phi_j^n(\mathbf{x})\right], \qquad j = -1, 0, 1. \tag{3.1}$$

Consider the following implicit semidiscretization scheme for the CNGF (2.13)–(2.15):

$$\begin{aligned}\frac{\phi_1^{n+1}(\mathbf{x}) - \phi_1^n(\mathbf{x})}{\Delta t} = &\left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - \frac{\beta_n + \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)\right.\\ &\left.-\frac{\beta_n - \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2\right)\right]\phi_1^{n+1/2}\\ &-\frac{\beta_s}{2}\left[\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2\right]\bar{\phi}_{-1}^{n+1/2} + \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right]\phi_1^{n+1/2},\end{aligned} \tag{3.2}$$

$$\begin{aligned}\frac{\phi_0^{n+1}(\mathbf{x}) - \phi_0^n(\mathbf{x})}{\Delta t} = &\left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - \frac{\beta_n + \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2\right)\right.\\ &\left.-\frac{\beta_n}{2}\left(|\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)\right]\phi_0^{n+1/2} - \beta_s\left(\phi_{-1}^{n+1}\phi_1^{n+1} + \phi_{-1}^n\phi_1^n\right)\bar{\phi}_0^{n+1/2}\\ &+\mu_\Phi^{n+1/2}\phi_0^{n+1/2},\end{aligned} \tag{3.3}$$

$$\begin{aligned}\frac{\phi_{-1}^{n+1}(\mathbf{x}) - \phi_{-1}^n(\mathbf{x})}{\Delta t} = &\left[\frac{1}{2}\nabla^2 - V(\mathbf{x}) - \frac{\beta_n + \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)\right.\\ &\left.-\frac{\beta_n - \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2\right)\right]\phi_{-1}^{n+1/2}\\ &-\frac{\beta_s}{2}\left[\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2\right]\bar{\phi}_1^{n+1/2} + \left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right]\phi_{-1}^{n+1/2}.\end{aligned} \tag{3.4}$$

Here $\mu_\Phi^{n+1/2}$ and $\lambda_\Phi^{n+1/2}$ are chosen such that the above discretization is mass (or normalization) and magnetization conservative, and they are given as

$$\begin{aligned}\mu_\Phi^{n+1/2} &= \frac{R_\Phi^{n+1/2}D_\Phi^{n+1/2} - M_\Phi^{n+1/2}F_\Phi^{n+1/2}}{N_\Phi^{n+1/2}R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2},\\ \lambda_\Phi^{n+1/2} &= \frac{N_\Phi^{n+1/2}F_\Phi^{n+1/2} - M_\Phi^{n+1/2}D_\Phi^{n+1/2}}{N_\Phi^{n+1/2}R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2},\end{aligned} \tag{3.5}$$

with

$$N_\Phi^{n+1/2} = \int_{\mathbb{R}^d} \left[|\phi_{-1}^{n+1/2}(\mathbf{x})|^2 + |\phi_0^{n+1/2}(\mathbf{x})|^2 + |\phi_1^{n+1/2}(\mathbf{x})|^2 \right] d\mathbf{x}, \tag{3.6}$$

$$M_\Phi^{n+1/2} = \int_{\mathbb{R}^d} \left[|\phi_1^{n+1/2}(\mathbf{x})|^2 - |\phi_{-1}^{n+1/2}(\mathbf{x})|^2) \right] d\mathbf{x}, \tag{3.7}$$

$$R_\Phi^{n+1/2} = \int_{\mathbb{R}^d} \left[|\phi_1^{n+1/2}(\mathbf{x})|^2 + |\phi_{-1}^{n+1/2}(\mathbf{x})|^2) \right] d\mathbf{x}, \tag{3.8}$$

$$\begin{aligned} D_\Phi^{n+1/2} = \int_{\mathbb{R}^d} \Bigg\{ & \sum_{j=-1}^{1} \left(\frac{1}{2} |\nabla \phi_j^{n+1/2}|^2 + V(\mathbf{x}) |\phi_j^{n+1/2}|^2 \right) + \frac{\beta_n}{2} \left(|\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) |\phi_0^{n+1/2}|^2 \\ & + \frac{\beta_n - \beta_s}{2} \left[\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 \right) |\phi_1^{n+1}|^2 + \left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 \right) |\phi_{-1}^{n+1}|^2 \right] \\ & + \beta_s \mathrm{Re} \Big(\phi_{-1}^{n+1/2} [\left(\bar{\phi}_0^{n+1} \right)^2 + \left(\bar{\phi}_0^n \right)^2] \phi_1^{n+1/2} \\ & + \left(\bar{\phi}_0^{n+1/2} \right)^2 \left(\phi_{-1}^{n+1} \phi_1^{n+1} + \phi_{-1}^n \phi_1^n \right) \Big) \\ & + \frac{\beta_n + \beta_s}{2} \Big[\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) |\phi_1^{n+1/2}|^2 \\ & + \left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) |\phi_{-1}^{n+1/2}|^2 \\ & + \left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 \right) |\phi_0^{n+1/2}|^2 \Big] \Bigg\} d\mathbf{x}, \end{aligned} \tag{3.9}$$

$$\begin{aligned} F_\Phi^{n+1/2} = \int_{\mathbb{R}^d} \Bigg\{ & \frac{1}{2} \left(|\nabla \phi_1^{n+1/2}|^2 - |\nabla \phi_{-1}^{n+1/2}|^2 \right) + V(\mathbf{x}) \left(|\phi_1^{n+1/2}|^2 - |\phi_{-1}^{n+1/2}|^2 \right) \\ & + \frac{\beta_n - \beta_s}{2} \left[\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 \right) |\phi_1^{n+1/2}|^2 - \left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 \right) |\phi_{-1}^{n+1/2}|^2 \right] \\ & + \frac{\beta_n + \beta_s}{2} \Big[\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) |\phi_1^{n+1/2}|^2 \\ & - \left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) |\phi_{-1}^{n+1/2}|^2 \Big] \Bigg\} d\mathbf{x}. \end{aligned} \tag{3.10}$$

For the above semidiscretization (3.2)–(3.4), we have the following.

THEOREM 3.1. *For any given time step $\Delta t > 0$ and initial data $\Phi^{(0)}(\mathbf{x})$ in* (2.22) *satisfying* (2.23), *the semidiscretization* (3.2)–(3.4) *is mass and magnetization conservative and energy-diminishing, i.e.,*

$$N_\Phi^{n+1} := N_\Phi(t_{n+1}) \equiv N_\Phi(t_0 = 0) = N_{\Phi^{(0)}} = 1, \tag{3.11}$$

$$M_\Phi^{n+1} := M_\Phi(t_{n+1}) \equiv M_\Phi(t_0 = 0) = M_{\Phi^{(0)}} = M, \tag{3.12}$$

$$E\left(\Phi^{n+1}\right) \le E\left(\Phi^n\right) \le \cdots \le E\left(\Phi^0\right) = E(\Phi^{(0)}), \qquad n = 0, 1, 2, \ldots. \tag{3.13}$$

Proof. Multiplying (3.2) by $2\bar{\phi}_1^{n+1/2} = \bar{\phi}_1^{n+1} + \bar{\phi}_1^n$, integrating over $\mathbb{R}^d$, and integrating by parts, we have

$$\begin{aligned}\|\phi_1^{n+1}\|^2 = -2\Delta t \int_{\mathbb{R}^d} \Bigg[& \frac{1}{2}|\nabla\phi_1^{n+1/2}|^2 + \frac{\beta_n - \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2\right)|\phi_1^{n+1/2}|^2 \\ & + \frac{\beta_n + \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)|\phi_1^{n+1/2}|^2 + V(\mathbf{x})|\phi_1^{n+1/2}|^2 \\ & + \frac{\beta_s}{2}\bar{\phi}_{-1}^{n+1/2}\left[\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2\right]\bar{\phi}_1^{n+1/2}\Bigg] d\mathbf{x} \\ & + 2\Delta t\left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right]\|\phi_1^{n+1/2}\|^2 + \|\phi_1^n\|^2 + \int_{\mathbb{R}^d}\left[\bar{\phi}_1^{n+1}\phi_1^n - \bar{\phi}_1^n\phi_1^{n+1}\right] d\mathbf{x}. \end{aligned} \tag{3.14}$$

Summing (3.14) with its conjugate and then dividing both sides by 2, we obtain

$$\begin{aligned}\|\phi_1^{n+1}\|^2 = -2\Delta t \int_{\mathbb{R}^d} \Bigg\{ & \frac{1}{2}|\nabla\phi_1^{n+1/2}|^2 + \frac{\beta_n - \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2\right)|\phi_1^{n+1/2}|^2 \\ & + \frac{\beta_n + \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)|\phi_1^{n+1/2}|^2 + V(\mathbf{x})|\phi_1^{n+1/2}|^2 \\ & + \frac{\beta_s}{2}\,\mathrm{Re}\left(\phi_{-1}^{n+1/2}\left[\left(\bar{\phi}_0^{n+1}\right)^2 + \left(\bar{\phi}_0^n\right)^2\right]\phi_1^{n+1/2}\right)\Bigg\} d\mathbf{x} \\ & + \|\phi_1^n\|^2 + 2\Delta t\left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right]\|\phi_1^{n+1/2}\|^2. \end{aligned} \tag{3.15}$$

Applying the same procedure to (3.3) by multiplying $2\bar{\phi}_0^{n+1/2} = \bar{\phi}_0^{n+1} + \bar{\phi}_0^n$, we get

$$\begin{aligned}\|\phi_0^{n+1}\|^2 = -2\Delta t \int_{\mathbb{R}^d} \Bigg\{ & \frac{1}{2}|\nabla\phi_0^{n+1/2}|^2 + V(\mathbf{x})|\phi_0^{n+1/2}|^2 + \frac{\beta_n}{2}\left(|\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)|\phi_0^{n+1/2}|^2 \\ & + \frac{\beta_n + \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2\right)|\phi_0^{n+1/2}|^2 \\ & + \beta_s\,\mathrm{Re}\left(\left(\bar{\phi}_0^{n+1/2}\right)^2\left(\phi_{-1}^{n+1}\phi_1^{n+1} + \phi_{-1}^n\phi_1^n\right)\right)\Bigg\} d\mathbf{x} \\ & + \|\phi_0^n\|^2 + 2\Delta t\,\mu_\Phi^{n+1/2}\,\|\phi_0^{n+1/2}\|^2. \end{aligned} \tag{3.16}$$

Applying the same procedure to (3.4) by multiplying $2\bar{\phi}_{-1}^{n+1/2} = \bar{\phi}_{-1}^{n+1} + \bar{\phi}_{-1}^n$, we have

$$\begin{aligned}\|\phi_{-1}^{n+1}\|^2 = -2\Delta t \int_{\mathbb{R}^d} \Bigg\{ & \frac{1}{2}|\nabla\phi_{-1}^{n+1/2}|^2 + \frac{\beta_n - \beta_s}{2}\left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2\right)|\phi_{-1}^{n+1/2}|^2 \\ & + \frac{\beta_n + \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2\right)|\phi_{-1}^{n+1/2}|^2 + V(\mathbf{x})|\phi_{-1}^{n+1/2}|^2 \\ & + \frac{\beta_s}{2}\,\mathrm{Re}\left(\phi_{-1}^{n+1/2}\left[\left(\bar{\phi}_0^{n+1}\right)^2 + \left(\bar{\phi}_0^n\right)^2\right]\phi_1^{n+1/2}\right)\Bigg\} d\mathbf{x} \\ & + \|\phi_{-1}^n\|^2 + 2\Delta t\left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right]\|\phi_{-1}^{n+1/2}\|^2. \end{aligned} \tag{3.17}$$

Summing (3.15), (3.16), and (3.17) and noticing (3.9), (3.6), and (3.7), we get

$$\begin{aligned}
N_\Phi^{n+1} &= \|\phi_1^{n+1}\|^2 + \|\phi_0^{n+1}\|^2 + \|\phi_{-1}^{n+1}\|^2 \\
&= N_\Phi^n - 2\Delta t\, D_\Phi^{n+1/2} + 2\Delta t \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right] \|\phi_1^{n+1/2}\|^2 \\
&\quad +2\Delta t\, \mu_\Phi^{n+1/2} \|\phi_0^{n+1/2}\|^2 + 2\Delta t \left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right] \|\phi_{-1}^{n+1/2}\|^2 \\
&= N_\Phi^n - 2\Delta t\, D_\Phi^{n+1/2} + 2\Delta t\, \mu_\Phi^{n+1/2} \left[\|\phi_1^{n+1/2}\|^2 + \|\phi_0^{n+1/2}\|^2 + \|\phi_{-1}^{n+1/2}\|^2\right] \\
&\quad +2\Delta t\, \lambda_\Phi^{n+1/2} \left[\|\phi_1^{n+1/2}\|^2 - \|\phi_{-1}^{n+1/2}\|^2\right] \\
&= N_\Phi^n - 2\Delta t\, D_\Phi^{n+1/2} + 2\Delta t\, \mu_\Phi^{n+1/2}\, N_\Phi^{n+1/2} + 2\Delta t\, \lambda_\Phi^{n+1/2}\, M_\Phi^{n+1/2}. \qquad (3.18)
\end{aligned}$$

Plugging (3.5) into (3.18), we obtain

$$\begin{aligned}
N_\Phi^{n+1} &= N_\Phi^n - 2\Delta t\, D_\Phi^{n+1/2} + 2\Delta t\, N_\Phi^{n+1/2}\, \frac{R_\Phi^{n+1/2} D_\Phi^{n+1/2} - M_\Phi^{n+1/2} F_\Phi^{n+1/2}}{N_\Phi^{n+1/2} R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2} \\
&\quad +2\Delta t\, M_\Phi^{n+1/2}\, \frac{N_\Phi^{n+1/2} F_\Phi^{n+1/2} - M_\Phi^{n+1/2} D_\Phi^{n+1/2}}{N_\Phi^{n+1/2} R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2} \\
&= N_\Phi^n - 2\Delta t\, D_\Phi^{n+1/2} + 2\Delta t\, D_\Phi^{n+1/2} \\
&= N_\Phi^n, \qquad n = 0, 1, 2, \ldots. \qquad (3.19)
\end{aligned}$$

Thus the mass conservation in (3.11) can be obtained from (3.19) by induction. Subtracting (3.17) from (3.15) and noticing (3.10), (3.6), and (3.8), we have

$$\begin{aligned}
M_\Phi^{n+1} &= \|\phi_1^{n+1}\|^2 - \|\phi_{-1}^{n+1}\|^2 \\
&= \|\phi_1^n\|^2 - \|\phi_{-1}^n\|^2 - 2\Delta t\, F_\Phi^{n+1/2} + 2\Delta t \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right] \|\phi_1^{n+1/2}\|^2 \\
&\quad -2\Delta t \left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right] \|\phi_{-1}^{n+1/2}\|^2 \\
&= M_\Phi^n - 2\Delta t\, F_\Phi^{n+1/2} + 2\Delta t \mu_\Phi^{n+1/2} \left[\|\phi_1^{n+1/2}\|^2 - \|\phi_{-1}^{n+1/2}\|^2\right] \\
&\quad +2\Delta t\, \lambda_\Phi^{n+1/2} \left[\|\phi_1^{n+1/2}\|^2 + \|\phi_{-1}^{n+1/2}\|^2\right] \\
&= M_\Phi^n - 2\Delta t\, F_\Phi^{n+1/2} + 2\Delta t\, \mu_\Phi^{n+1/2} M_\Phi^{n+1/2} + 2\Delta t\, \lambda_\Phi^{n+1/2} R_\Phi^{n+1/2}. \qquad (3.20)
\end{aligned}$$

Plugging (3.5) into (3.20), we obtain

$$\begin{aligned}
M_\Phi^{n+1} &= M_\Phi^n - 2\Delta t\, F_\Phi^{n+1/2} + 2\Delta t\, M_\Phi^{n+1/2}\, \frac{R_\Phi^{n+1/2} D_\Phi^{n+1/2} - M_\Phi^{n+1/2} F_\Phi^{n+1/2}}{N_\Phi^{n+1/2} R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2} \\
&\quad +2\Delta t\, R_\Phi^{n+1/2}\, \frac{N_\Phi^{n+1/2} F_\Phi^{n+1/2} - M_\Phi^{n+1/2} D_\Phi^{n+1/2}}{N_\Phi^{n+1/2} R_\Phi^{n+1/2} - \left(M_\Phi^{n+1/2}\right)^2} \\
&= M_\Phi^n - 2\Delta t\, F_\Phi^{n+1/2} + 2\Delta t\, F_\Phi^{n+1/2} \\
&= M_\Phi^n, \qquad n = 0, 1, 2, \ldots. \qquad (3.21)
\end{aligned}$$

Thus the magnetization conservation in (3.12) can be obtained from (3.21) by induction. To prove the energy-diminishing property (3.13), multiplying (3.2) by $\hat{\phi}_1^{n+1/2} :=$

$\bar{\phi}_1^{n+1} - \bar{\phi}_1^n$, integrating over $\mathbb{R}^d$, and integrating by parts, we have

$$\begin{aligned}\frac{\|\phi_1^{n+1} - \phi_1^n\|^2}{\Delta t} = &- \int_{\mathbb{R}^d} \left[\frac{1}{2} \nabla \phi_1^{n+1/2} \cdot \nabla \hat{\phi}_1^{n+1/2} + \frac{\beta_s}{2} \bar{\phi}_{-1}^{n+1/2} \left(\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2 \right) \hat{\phi}_1^{n+1/2} \right. \\ &+ V(\mathbf{x}) \phi_1^{n+1/2} \hat{\phi}_1^{n+1/2} + \frac{\beta_n - \beta_s}{2} \left(|\phi_{-1}^{n+1}|^2 + |\phi_{-1}^n|^2 \right) \phi_1^{n+1/2} \hat{\phi}_1^{n+1/2} \\ &\left. + \frac{\beta_n + \beta_s}{2} \left(|\phi_1^{n+1}|^2 + |\phi_1^n|^2 + |\phi_0^{n+1}|^2 + |\phi_0^n|^2 \right) \phi_1^{n+1/2} \hat{\phi}_1^{n+1/2} \right] d\mathbf{x} \\ &+ \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2} \right] \int_{\mathbb{R}^d} \phi_1^{n+1/2} \hat{\phi}_1^{n+1/2} \, d\mathbf{x}. \end{aligned} \tag{3.22}$$

Summing (3.22) with its conjugate, we obtain

$$\begin{aligned}\frac{2}{\Delta t} \|\phi_1^{n+1} - \phi_1^n\|^2 = &- \int_{\mathbb{R}^d} \left[\frac{1}{2} |\nabla \phi_1^{n+1}|^2 + V(\mathbf{x}) |\phi_1^{n+1}|^2 + \frac{\beta_n - \beta_s}{2} |\phi_{-1}^{n+1}|^2 |\phi_1^{n+1}|^2 \right. \\ &+ \frac{\beta_n + \beta_s}{2} \left(|\phi_1^{n+1}|^2 + |\phi_0^{n+1}|^2 \right) |\phi_1^{n+1}|^2 - \frac{1}{2} |\nabla \phi_1^n|^2 - V(\mathbf{x}) |\phi_1^n|^2 \\ &- \frac{\beta_n - \beta_s}{2} |\phi_{-1}^n|^2 |\phi_1^n|^2 - \frac{\beta_n + \beta_s}{2} \left(|\phi_1^n|^2 + |\phi_0^n|^2 \right) |\phi_1^n|^2 \\ &+ \frac{\beta_n + \beta_s}{2} \left[\left(|\phi_1^n|^2 + |\phi_0^n|^2 \right) |\phi_1^{n+1}|^2 - \left(|\phi_1^{n+1}|^2 + |\phi_0^{n+1}|^2 \right) |\phi_1^n|^2 \right] \\ &+ \frac{\beta_n - \beta_s}{2} \left[|\phi_{-1}^n|^2 |\phi_1^{n+1}|^2 - |\phi_{-1}^{n+1}|^2 |\phi_1^n|^2 \right] \\ &\left. + \beta_s \operatorname{Re} \left(\bar{\phi}_{-1}^{n+1/2} \left(\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2 \right) \left(\bar{\phi}_1^{n+1} - \bar{\phi}_1^n \right) \right) \right] d\mathbf{x} \\ &+ \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2} \right] \left(\|\phi_1^{n+1}\|^2 - \|\phi_1^n\|^2 \right). \end{aligned} \tag{3.23}$$

Here we use

$$\begin{aligned}&\phi_1^{n+1/2} \left(\bar{\phi}_1^{n+1} - \bar{\phi}_1^n \right) + \bar{\phi}_1^{n+1/2} \left(\phi_1^{n+1} - \phi_1^n \right) \\ &= \frac{1}{2} \left[\left(\phi_1^{n+1} + \phi_1^n \right) \left(\bar{\phi}_1^{n+1} - \bar{\phi}_1^n \right) + \left(\bar{\phi}_1^{n+1} + \bar{\phi}_1^n \right) \left(\phi_1^{n+1} - \phi_1^n \right) \right] \\ &= |\phi_1^{n+1}|^2 - |\phi_1^n|^2, \end{aligned} \tag{3.24}$$

and

$$\nabla \phi_1^{n+1/2} \cdot \nabla \left(\bar{\phi}_1^{n+1} - \bar{\phi}_1^n \right) + \nabla \bar{\phi}_1^{n+1/2} \cdot \nabla \left(\phi_1^{n+1} - \phi_1^n \right) = |\nabla \phi_1^{n+1}|^2 - |\nabla \phi_1^n|^2. \tag{3.25}$$

Applying the same procedure to (3.3) by multiplying $\bar{\phi}_0^{n+1} - \bar{\phi}_0^n$, we get

$$\begin{aligned}\frac{2}{\Delta t} \|\phi_0^{n+1} - \phi_0^n\|^2 = &- \int_{\mathbb{R}^d} \left[\frac{1}{2} |\nabla \phi_0^{n+1}|^2 + V(\mathbf{x}) |\phi_0^{n+1}|^2 + \frac{\beta_n}{2} |\phi_0^{n+1}|^4 \right. \\ &+ \frac{\beta_n + \beta_s}{2} \left(|\phi_1^{n+1}|^2 + |\phi_{-1}^{n+1}|^2 \right) |\phi_0^{n+1}|^2 - \frac{1}{2} |\nabla \phi_0^n|^2 - V(\mathbf{x}) |\phi_0^n|^2 \\ &- \frac{\beta_n}{2} |\phi_0^n|^4 - \frac{\beta_n + \beta_s}{2} \left(|\phi_1^n|^2 + |\phi_{-1}^n|^2 \right) |\phi_0^n|^2 \\ &+ \frac{\beta_n + \beta_s}{2} \left[\left(|\phi_1^n|^2 + |\phi_{-1}^n|^2 \right) |\phi_0^{n+1}|^2 - \left(|\phi_1^{n+1}|^2 + |\phi_{-1}^{n+1}|^2 \right) |\phi_0^n|^2 \right] \\ &\left. + \beta_s \operatorname{Re} \left(\left(\phi_{-1}^{n+1} \phi_1^{n+1} + \phi_{-1}^n \phi_1^n \right) \left((\bar{\phi}_0^{n+1})^2 - (\bar{\phi}_0^n)^2 \right) \right) \right] d\mathbf{x} \\ &+ \mu_\Phi^{n+1/2} \left(\|\phi_0^{n+1}\|^2 - \|\phi_0^n\|^2 \right). \end{aligned} \tag{3.26}$$

Applying the same procedure to (3.4) by multiplying $\bar{\phi}_{-1}^{n+1} - \bar{\phi}_{-1}^{n}$, we get

$$\begin{aligned}
\frac{2}{\Delta t}\|\phi_{-1}^{n+1} - \phi_{-1}^{n}\|^2 = &- \int_{\mathbb{R}^d} \Big[\frac{1}{2}|\nabla\phi_{-1}^{n+1}|^2 + V(\mathbf{x})|\phi_{-1}^{n+1}|^2 + \frac{\beta_n - \beta_s}{2}|\phi_{-1}^{n+1}|^2|\phi_1^{n+1}|^2 \\
&+ \frac{\beta_n + \beta_s}{2}\left(|\phi_{-1}^{n+1}|^2 + |\phi_0^{n+1}|^2\right)|\phi_{-1}^{n+1}|^2 - \frac{1}{2}|\nabla\phi_{-1}^{n}|^2 - V(\mathbf{x})|\phi_{-1}^{n}|^2 \\
&- \frac{\beta_n - \beta_s}{2}|\phi_{-1}^{n}|^2|\phi_1^{n}|^2 - \frac{\beta_n + \beta_s}{2}\left(|\phi_{-1}^{n}|^2 + |\phi_0^{n}|^2\right)|\phi_{-1}^{n}|^2 \\
&+ \frac{\beta_n + \beta_s}{2}\Big[\left(|\phi_{-1}^{n}|^2 + |\phi_0^{n}|^2\right)|\phi_{-1}^{n+1}|^2 - \left(|\phi_{-1}^{n+1}|^2 + |\phi_0^{n+1}|^2\right)|\phi_{-1}^{n}|^2\Big] \\
&+ \frac{\beta_n - \beta_s}{2}\Big[|\phi_1^{n}|^2|\phi_{-1}^{n+1}|^2 - |\phi_1^{n+1}|^2|\phi_{-1}^{n}|^2\Big] \\
&+ \beta_s\,\mathrm{Re}\left(\bar{\phi}_1^{n+1/2}\left(\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^{n}\right)^2\right)\left(\bar{\phi}_{-1}^{n+1} - \bar{\phi}_{-1}^{n}\right)\right)\Big]\,d\mathbf{x} \\
&+ \left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right]\left(\|\phi_{-1}^{n+1}\|^2 - \|\phi_{-1}^{n}\|^2\right). \qquad (3.27)
\end{aligned}$$

Adding (3.23), (3.26), and (3.27) and noticing (3.19), (3.21), and (1.14) with $\Psi = \Phi^{n+1}$ and $\Psi = \Phi^n$, respectively, we have

$$\begin{aligned}
E(\Phi^{n+1}) &= E(\Phi^n) - \frac{2}{\Delta t}\left[\|\phi_1^{n+1} - \phi_1^n\|^2 + \|\phi_0^{n+1} - \phi_0^n\|^2 + \|\phi_{-1}^{n+1} - \phi_{-1}^n\|^2\right] \\
&\quad + \left[\mu_\Phi^{n+1/2} + \lambda_\Phi^{n+1/2}\right]\left(\|\phi_1^{n+1}\|^2 - \|\phi_1^n\|^2\right) + \mu_\Phi^{n+1/2}\left(\|\phi_0^{n+1}\|^2 - \|\phi_0^n\|^2\right) \\
&\quad + \left[\mu_\Phi^{n+1/2} - \lambda_\Phi^{n+1/2}\right]\left(\|\phi_{-1}^{n+1}\|^2 - \|\phi_{-1}^n\|^2\right) \\
&= E(\Phi^n) - \frac{2}{\Delta t}\left[\|\phi_1^{n+1} - \phi_1^n\|^2 + \|\phi_0^{n+1} - \phi_0^n\|^2 + \|\phi_{-1}^{n+1} - \phi_{-1}^n\|^2\right] \\
&\quad + \mu_\Phi^{n+1/2}\left[\|\phi_1^{n+1}\|^2 + \|\phi_0^{n+1}\|^2 + \|\phi_{-1}^{n+1}\|^2 - \|\phi_1^n\|^2 - \|\phi_0^n\|^2 - \|\phi_{-1}^n\|^2\right] \\
&\quad + \lambda_\Phi^{n+1/2}\left[\|\phi_1^{n+1}\|^2 - \|\phi_{-1}^{n+1}\|^2 - \|\phi_1^n\|^2 + \|\phi_{-1}^n\|^2\right] \\
&= E(\Phi^n) - \frac{2}{\Delta t}\left[\|\phi_1^{n+1} - \phi_1^n\|^2 + \|\phi_0^{n+1} - \phi_0^n\|^2 + \|\phi_{-1}^{n+1} - \phi_{-1}^n\|^2\right] \\
&\quad + \mu_\Phi^{n+1/2}\left[N_\Phi^{n+1} - N_\Phi^n\right] + \lambda_\Phi^{n+1/2}\left[M_\Phi^{n+1} - M_\Phi^n\right] \\
&= E(\Phi^n) - \frac{2}{\Delta t}\left[\|\phi_1^{n+1} - \phi_1^n\|^2 + \|\phi_0^{n+1} - \phi_0^n\|^2 + \|\phi_{-1}^{n+1} - \phi_{-1}^n\|^2\right] \\
&\le E(\Phi^n), \qquad n = 0, 1, 2, \ldots. \qquad (3.28)
\end{aligned}$$

Here we use

$$\begin{aligned}
&\beta_s\,\mathrm{Re}\Big(\left[\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2\right]\left[\bar{\phi}_{-1}^{n+1/2}\left(\bar{\phi}_1^{n+1} - \bar{\phi}_1^n\right) + \bar{\phi}_1^{n+1/2}\left(\bar{\phi}_{-1}^{n+1} - \bar{\phi}_{-1}^n\right)\right] \\
&\qquad + \left(\phi_{-1}^{n+1}\phi_1^{n+1} + \phi_{-1}^n\phi_1^n\right)\left((\bar{\phi}_0^{n+1})^2 - (\bar{\phi}_0^n)^2\right)\Big) \\
&= \beta_s\,\mathrm{Re}\Big(\left[\left(\phi_0^{n+1}\right)^2 + \left(\phi_0^n\right)^2\right]\left(\bar{\phi}_1^{n+1}\bar{\phi}_{-1}^{n+1} - \bar{\phi}_1^n\bar{\phi}_{-1}^n\right) \\
&\qquad + \left(\phi_{-1}^{n+1}\phi_1^{n+1} + \phi_{-1}^n\phi_1^n\right)\left((\bar{\phi}_0^{n+1})^2 - (\bar{\phi}_0^n)^2\right)\Big) \\
&= \beta_s\left[\phi_{-1}^{n+1}\phi_1^{n+1}(\bar{\phi}_0^{n+1})^2 + \bar{\phi}_{-1}^{n+1}\bar{\phi}_1^{n+1}(\phi_0^{n+1})^2\right] \\
&\qquad - \beta_s\left[\phi_{-1}^{n}\phi_1^{n}(\bar{\phi}_0^{n})^2 + \bar{\phi}_{-1}^{n}\bar{\phi}_1^{n}(\phi_0^{n})^2\right]. \qquad (3.29)
\end{aligned}$$

Thus (3.13) can be obtained from (3.28) immediately. ∎

3.2. A fully discretized method. For simplicity of notation, we introduce a fully discretized method for the CNGF (2.13)–(2.15) truncated into a bounded interval $\Omega = [a, b]$ (with $|a|$ and $|b|$ sufficiently large) in the case of one spatial dimension ($d = 1$) with homogeneous Dirichlet boundary conditions

$$\phi_j(a,t) = \phi_j(b,t) = 0, \qquad t \geq 0, \quad j = 1, -0, 1. \tag{3.30}$$

Generalizations to a higher dimension are straightforward for tensor product grids, and the results remain valid without modifications. For $d = 1$, we choose the spatial mesh size $h = \Delta x > 0$, with $\Delta x = (b-a)/L$ and L is an even positive integer. The grid points are defined as $x_l = a + l\,h$ for $l = 0, 1, \cdots, L$, and let $\Phi_l^n = (\phi_{1,l}^n, \phi_{0,l}^n, \phi_{-1,l}^n)^T$ be the numerical approximation of $\Phi(x_j, t_n)$ and Φ_h^n the solution vector at time $t = t_n$ with components Φ_l^n. In addition, denote $\Phi_l^{n+1/2} = (\phi_{1,l}^{n+1/2}, \phi_{0,l}^{n+1/2}, \phi_{-1,l}^{n+1/2})^T$, with $\phi_{j,l}^{n+1/2}$ defined as

$$\phi_{j,l}^{n+1/2} := \frac{1}{2}\left[\phi_{j,l}^{n+1} + \phi_{j,l}^{n}\right], \qquad j = -1, 0, 1, \quad l = 0, 1, 2, \ldots, L. \tag{3.31}$$

Here we propose a full discretization for the CNGF (2.13)–(2.15) in 1D, for $1 \leq l \leq L-1$ and $n \geq 0$, as

$$\begin{aligned}
\frac{\phi_{1,l}^{n+1} - \phi_{1,l}^{n}}{\Delta t} &= \frac{\phi_{1,l+1}^{n+1/2} - 2\phi_{1,l}^{n+1/2} + \phi_{1,l-1}^{n+1/2}}{2h^2} - \frac{\beta_n - \beta_s}{2}\left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2\right)\phi_{1,l}^{n+1/2} \\
&\quad - \left[\frac{\beta_n + \beta_s}{2}\left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2\right) + V(x_l)\right]\phi_{1,l}^{n+1/2} \\
&\quad - \frac{\beta_s}{2}\bar{\phi}_{-1,l}^{n+1/2}\left[\left(\phi_{0,l}^{n+1}\right)^2 + \left(\phi_{0,l}^{n}\right)^2\right] + \left[\mu_{\Phi,h}^{n+1/2} + \lambda_{\Phi,h}^{n+1/2}\right]\phi_{1,l}^{n+1/2},
\end{aligned} \tag{3.32}$$

$$\begin{aligned}
\frac{\phi_{0,l}^{n+1} - \phi_{0,l}^{n}}{\Delta t} &= \frac{\phi_{0,l+1}^{n+1/2} - 2\phi_{0,l}^{n+1/2} + \phi_{0,l-1}^{n+1/2}}{2h^2} - \frac{\beta_n}{2}\left(|\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2\right)\phi_{0,l}^{n+1/2} \\
&\quad - \left[\frac{\beta_n + \beta_s}{2}\left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 + |\phi_{-,l}^{n+1}|^2 + |\phi_{-,l}^{n}|^2\right) + V(x_l)\right]\phi_{0,l}^{n+1/2} \\
&\quad - \beta_s\left(\phi_{-1,l}^{n+1}\phi_{1,l}^{n+1} + \phi_{-1,l}^{n}\phi_{1,l}^{n}\right)\bar{\phi}_{0,l}^{n+1/2} + \mu_{\Phi,h}^{n+1/2}\phi_{0,l}^{n+1/2},
\end{aligned} \tag{3.33}$$

$$\begin{aligned}
\frac{\phi_{-1,l}^{n+1} - \phi_{-1,l}^{n}}{\Delta t} &= \frac{\phi_{-1,l+1}^{n+1/2} - 2\phi_{-1,l}^{n+1/2} + \phi_{-1,l-1}^{n+1/2}}{2h^2} - \frac{\beta_n - \beta_s}{2}\left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2\right)\phi_{-1,l}^{n+1/2} \\
&\quad - \left[\frac{\beta_n + \beta_s}{2}\left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2\right) + V(x_l)\right]\phi_{-1,l}^{n+1/2} \\
&\quad - \frac{\beta_s}{2}\bar{\phi}_{1,l}^{n+1/2}\left[\left(\phi_{0,l}^{n+1}\right)^2 + \left(\phi_{0,l}^{n}\right)^2\right] + \left[\mu_{\Phi,h}^{n+1/2} - \lambda_{\Phi,h}^{n+1/2}\right]\phi_{-1,l}^{n+1/2}.
\end{aligned} \tag{3.34}$$

Again, here $\mu_{\Phi,h}^{n+1/2}$ and $\lambda_{\Phi,h}^{n+1/2}$ are chosen such that the above discretization is mass (or normalization) and magnetization conservative, and they are given as

$$\begin{aligned}
\mu_{\Phi,h}^{n+1/2} &= \frac{R_{\Phi,h}^{n+1/2} D_{\Phi,h}^{n+1/2} - M_{\Phi,h}^{n+1/2} F_{\Phi,h}^{n+1/2}}{N_{\Phi,h}^{n+1/2} R_{\Phi,h}^{n+1/2} - \left(M_{\Phi,h}^{n+1/2}\right)^2}, \\
\lambda_{\Phi,h}^{n+1/2} &= \frac{N_{\Phi,h}^{n+1/2} F_{\Phi,h}^{n+1/2} - M_{\Phi,h}^{n+1/2} D_{\Phi,h}^{n+1/2}}{N_{\Phi,h}^{n+1/2} R_{\Phi,h}^{n+1/2} - \left(M_{\Phi,h}^{n+1/2}\right)^2},
\end{aligned} \tag{3.35}$$

with

$$N_{\Phi,h}^{n+1/2} = \sum_{l=0}^{L-1} h \left[|\phi_{-1,l}^{n+1/2}|^2 + |\phi_{0,l}^{n+1/2}|^2 + |\phi_{1,l}^{n+1/2}|^2 \right], \tag{3.36}$$

$$M_{\Phi,h}^{n+1/2} = \sum_{l=0}^{L-1} h \left[|\phi_{1,l}^{n+1/2}|^2 - |\phi_{-1,l}^{n+1/2}|^2 \right], \tag{3.37}$$

$$R_{\Phi,h}^{n+1/2} = \sum_{l=0}^{L-1} h \left[|\phi_{1,l}^{n+1/2}|^2 + |\phi_{-1,l}^{n+1/2}|^2 \right], \tag{3.38}$$

$$\begin{aligned} D_{\Phi,h}^{n+1/2} = h \sum_{l=0}^{L-1} \Bigg\{ & \sum_{j=-1}^{1} \left(\frac{1}{2h^2} |\phi_{j,l+1}^{n+1/2} - \phi_{j,l}^{n+1/2}|^2 + V(x_l) |\phi_{j,l}^{n+1/2}|^2 \right) \\ & + \frac{\beta_n - \beta_s}{2} \left[\left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 \right) |\phi_{1,l}^{n+1}|^2 + \left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 \right) |\phi_{-1,l}^{n+1}|^2 \right] \\ & + \beta_s \mathrm{Re} \Big(\phi_{-1,l}^{n+1/2} \big[\left(\bar{\phi}_{0,l}^{n+1} \right)^2 + \left(\bar{\phi}_{0,l}^{n} \right)^2 \big] \phi_{1,l}^{n+1/2} + \left(\bar{\phi}_{0,l}^{n+1/2} \right)^2 \big(\phi_{-1,l}^{n+1} \phi_{1,l}^{n+1} \\ & + \phi_{-1,l}^{n} \phi_{1,l}^{n} \big) \Big) + \frac{\beta_n + \beta_s}{2} \left[\left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2 \right) |\phi_{1,l}^{n+1/2}|^2 \right. \\ & + \frac{\beta_n}{2} \left(|\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2 \right) |\phi_{0,l}^{n+1/2}|^2 + \left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 \right. \\ & \left. \left. + |\phi_{0,l}^{n}|^2 \right) |\phi_{-1,l}^{n+1/2}|^2 + \left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 + |\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 \right) |\phi_{0,l}^{n+1/2}|^2 \right] \Bigg\}, \end{aligned} \tag{3.39}$$

$$\begin{aligned} F_{\Phi,h}^{n+1/2} = h \sum_{l=0}^{L-1} \Bigg\{ & \frac{1}{2h^2} \left(|\phi_{1,l+1}^{n+1/2} - \phi_{1,l}^{n+1/2}|^2 - |\phi_{-1,l+1}^{n+1/2} - \phi_{-1,l}^{n+1/2}|^2 \right) + V(x_l) |\phi_{1,l}^{n+1/2}|^2 \\ & + \frac{\beta_n - \beta_s}{2} \left[\left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 \right) |\phi_{1,l}^{n+1/2}|^2 - \left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 \right) |\phi_{-1,l}^{n+1/2}|^2 \right] \\ & + \frac{\beta_n + \beta_s}{2} \left[\left(|\phi_{1,l}^{n+1}|^2 + |\phi_{1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2 \right) |\phi_{1,l}^{n+1/2}|^2 - V(x_l) |\phi_{-1,l}^{n+1/2}|^2 \right. \\ & \left. - \left(|\phi_{-1,l}^{n+1}|^2 + |\phi_{-1,l}^{n}|^2 + |\phi_{0,l}^{n+1}|^2 + |\phi_{0,l}^{n}|^2 \right) |\phi_{-1,l}^{n+1/2}|^2 \right] \Bigg\}. \end{aligned} \tag{3.40}$$

The homogeneous Dirichlet boundary conditions (3.30) are discretized as

$$\phi_{1,0}^{n+1} = \phi_{1,L}^{n+1} = \phi_{0,0}^{n+1} = \phi_{0,L}^{n+1} = \phi_{-1,0}^{n+1} = \phi_{-1,L}^{n+1} = 0, \qquad n = 0, 1, 2, \ldots. \tag{3.41}$$

The initial conditions (2.22) in 1D are discretized as

$$\phi_{j,l}^{0} = \phi_j(x_l, 0) = \phi_j^{(0)}(x_l), \qquad j = -1, 0, 1, \quad l = 0, 1, 2, \ldots, L. \tag{3.42}$$

For the above full discretization (3.32)–(3.34), we have the following.

THEOREM 3.2. *For any given time step $\Delta t > 0$ and mesh size $h > 0$ as well as initial data $\Phi^{(0)}(\mathbf{x})$ in* (2.22) *satisfying* (2.23)*, the full discretization* (3.32)–(3.34) *for the*

CNGF (2.13)–(2.15) *is mass and magnetization conservative and energy-diminishing, i.e.,*

$$N_{\Phi,h}^n := h\sum_{l=0}^{L-1}\sum_{j=-1}^{1}|\phi_{j,l}^n|^2 \equiv N_{\Phi,h}^0 := h\sum_{l=0}^{L-1}\sum_{j=-1}^{1}|\phi_j^{(0)}(x_l)|^2,$$

$$M_{\Phi,h}^n := h\sum_{l=0}^{L-1}\left[|\phi_{1,l}^n|^2 - |\phi_{-1,l}^{n+1}|^2\right] \equiv M_{\Phi,h}^0 := h\sum_{l=0}^{L-1}\left[|\phi_1^{(0)}(x_l)|^2 - |\phi_{-1}^{(0)}(x_l)|^2\right],$$

$$E_{\Phi,h}^n \le E_{\Phi,h}^{n-1} \le \cdots \le E_{\Phi,h}^0, \quad n = 0,1,2,\ldots, \tag{3.43}$$

where the discretized energy functional is defined as

$$\begin{aligned} E_{\Phi,h}^n = h\sum_{l=0}^{L-1}\Bigg\{ &\sum_{j=-1}^{1}\left(\frac{1}{2h^2}|\phi_{j,l+1}^n - \phi_{j,l}^n|^2 + V(x_l)|\phi_{j,l}^n|^2\right) + (\beta_n - \beta_s)|\phi_{1,l}^n|^2|\phi_{-1,l}^n|^2 \\ &+\frac{\beta_n}{2}|\phi_{0,l}^n|^4 + \frac{\beta_n+\beta_s}{2}\left[|\phi_{1,l}^n|^4 + |\phi_{-1,l}^n|^4 + 2|\phi_{0,l}^n|^2\left(|\phi_{1,l}^n|^2 + |\phi_{-1,l}^n|^2\right)\right] \\ &+\beta_s\left(\bar{\phi}_{-1,l}^n\left(\phi_{0,l}^n\right)^2\bar{\phi}_{1,l}^n + \phi_{-1,l}^n\left(\bar{\phi}_{0,l}\right)^2\phi_{1,l}^n\right)\Bigg\}. \end{aligned} \tag{3.44}$$

Proof. The proof is similar as that for Theorem 3.1 except that we need to replace integrating over $\mathbb{R}^d$ by summation over $0 \le l \le L-1$ and notice

$$\sum_{l=0}^{L-1}\left(\phi_{j,l+1}^{n+1/2} - 2\phi_{j,l}^{n+1/2} + \phi_{j,l-1}^{n+1/2}\right)\, g_l = \sum_{l=0}^{L-1}\left(\phi_{j,l+1}^{n+1/2} - \phi_{j,l}^{n+1/2}\right)\left(g_{l+1} - g_l\right) \tag{3.45}$$

for any g_l $(l = 0,1,2,\ldots,L)$ with $g_0 = g_L = 0$. The details are omitted here. ∎

Remark 3.1. For solving the nonlinear system (3.32)–(3.34), different iterative numerical methods in the literature can be applied. Here we use an efficient way which is easy to be extended to 2D and 3D to solve it iteratively by treating the linear terms implicitly and the nonlinear terms explicitly at each iterative step. For (3.32), the iterative method reads

$$\begin{aligned} \frac{\phi_{1,l}^{n+1,m+1} - \phi_{1,l}^n}{\Delta t} = &\frac{\phi_{1,l+1}^{n+1/2,m+1} - 2\phi_{1,l}^{n+1/2,m+1} + \phi_{1,l-1}^{n+1/2,m+1}}{2h^2} - \alpha_1\,\phi_{1,l}^{n+1,m+1} \\ &+\alpha_1\,\phi_{1,l}^{n+1,m} - \frac{\beta_n - \beta_s}{2}\left(|\phi_{-1,l}^{n+1,m}|^2 + |\phi_{-1,l}^n|^2\right)\phi_{1,l}^{n+1/2,m} \\ &-\left[\frac{\beta_n+\beta_s}{2}\left(|\phi_{1,l}^{n+1,m}|^2 + |\phi_{1,l}^n|^2 + |\phi_{0,l}^{n+1,m}|^2 + |\phi_{0,l}^n|^2\right) + V(x_l)\right]\phi_{1,l}^{n+1/2,m} \\ &-\frac{\beta_s}{2}\bar{\phi}_{-1,l}^{n+1/2,m}\left[\left(\phi_{0,l}^{n+1,m}\right)^2 + \left(\phi_{0,l}^n\right)^2\right] + \left[\mu_{\Phi,h}^{n+1/2,m} + \lambda_{\Phi,h}^{n+1/2,m}\right]\phi_{1,l}^{n+1/2,m}, \end{aligned} \tag{3.46}$$

where $\phi_{1,l}^{n+1,m}$ is the approximation of $\phi_{1,l}^{n+1}$ at the mth iterative step, with $\phi_{1,l}^{n+1,0} = \phi_{1,l}^n$, $\phi_{1,l}^{n+1/2,m+1} := \frac{1}{2}[\phi_{1,l}^{n+1,m+1} + \phi_{1,l}^n]$ and $\phi_{1,l}^{n+1/2,m} := \frac{1}{2}[\phi_{1,l}^{n+1,m} + \phi_{1,l}^n]$ $(j = 0,1,2,\ldots,L)$, and α_1 is a stabilization factor such that the iterative method converges as fast as possible [4]. The other two equations (3.33) and (3.34) can be dealt with in a similar way.

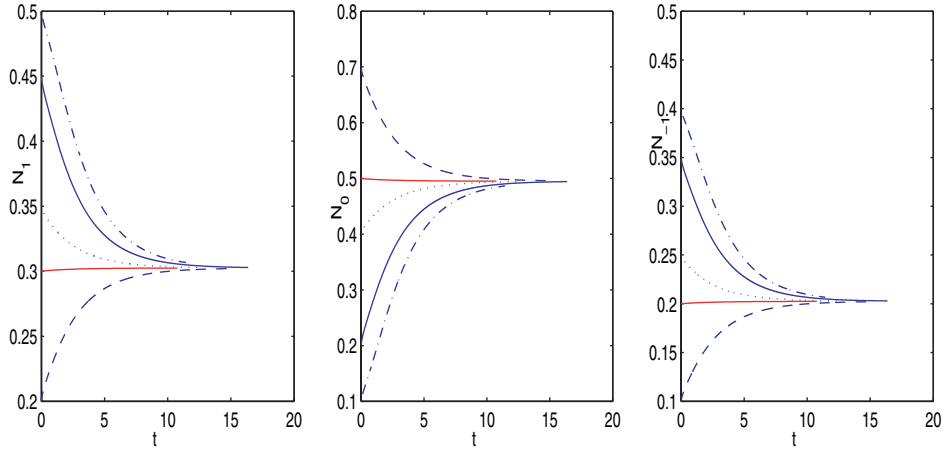

FIG. 1. *Time evolution of* $N_1 = \|\phi_1(\cdot,t)\|^2$ *(left),* $N_0 = \|\phi_0(\cdot,t)\|^2$ *(middle), and* $N_{-1} = \|\phi_{-1}(\cdot,t)\|^2$ *(right) for the full discretization* (3.32)–(3.34) *with* $\beta_n = 87.16$ *and* $\beta_s = -1.7481$ *to analyze the convergence of different initial data in* (4.2) *with* $\alpha = 0.1$ *(dotted-dashed line),* $\alpha = 0.2$ *(solid line),* $\alpha = 0.4$ *(dotted line),* $\alpha = 0.5$ *(horizontal line), and* $\alpha = 0.7$ *(dashed line), respectively.*

4. Numerical results. In this section, we will first study how to choose the initial data in (2.22) for computing the ground state and then test the energy-diminishing property and accuracy of our numerical method. Finally, we apply the method to compute the ground state of a spin-1 BEC with harmonic potential. In our computations, the ground state is reached by using the numerical method (3.32)–(3.34) when $\|\Phi_h^{n+1} - \Phi_h^n\| \le \varepsilon := 10^{-6}$.

In our computations, we choose $d = 1$, $V(x) = x^2/2$, $\beta_n = 0.08716N$, and $\beta_s = -0.0017481N$ in (2.13)–(2.15), with N the number of particles in the condensate. The values for the interaction strengths β_n and β_s correspond to the experimental setup with parameters as follows [34, 24, 25]: $\hbar = 1.054 \times 10^{-34}$[J s], $m = 1.443 \times 10^{-25}$[kg], $\omega_x = 2\pi$[Hz], $\omega_y = 2\pi \times 20\pi\sqrt{2}$[Hz], $\omega_z = 2\pi \times 20\pi\sqrt{2}$[Hz], $a_0 = 5.5$[nm]$= 5.5 \times 10^{-9}$[m], and $a_2 = 5.182$[nm]$= 5.182 \times 10^{-9}$[m], which implies $a_s = \sqrt{\hbar/m\omega_x} = 0.7624 \times 10^{-6}$, $\beta_n \approx \frac{4\pi(a_0+2a_2)N}{3a_s}\frac{\sqrt{\omega_y\omega_z}}{2\pi\omega_x} = 0.08716N$, and $\beta_s \approx \frac{4\pi(a_2-a_0)N}{3a_s}\frac{\sqrt{\omega_y\omega_z}}{2\pi\omega_x} = -0.0017481N$.

4.1. Choice of initial data and energy diminishing. Here we test that the converged solution is independent of different choices of the initial data in (2.22). In order to do so, we take $M = 0.1$ in (2.24) and choose the initial data in (2.22) as

$$\phi_1^{(0)}(x) = \sqrt{0.5(1+M-\alpha)}\frac{1}{\pi^{1/4}}e^{-x^2/2}, \qquad \phi_0^{(0)}(x) = \frac{\sqrt{\alpha}}{\pi^{1/4}}e^{-x^2/2}, \tag{4.1}$$

$$\phi_{-1}^{(0)}(x) = \sqrt{0.5(1-M-\alpha)}\frac{1}{\pi^{1/4}}e^{-x^2/2}, \qquad -\infty < x < \infty, \tag{4.2}$$

where α is a parameter to be determined. We solve the problem (2.13)–(2.15) by our discretization (3.32)–(3.34) on $[-16, 16]$ with time step $\Delta t = 0.01$ and mesh size $h = 1/16$ for different values of α in (4.2). Figure 1 plots the time evolution of $N_j(t) := \|\phi_j(\cdot,t)\|^2$ $(j = 1, 0, -1)$ for different choices of α in (4.2). In addition, Figure 2 shows the time evolution of mass N and magnetization M as well as energy E of our method for the problem with $\alpha = 0.1$ in the initial data (4.1)–(4.2).

From Figure 1 and additional results not shown here, we can see that the converged solution is independent of the choices of initial data in (2.22). In fact, other

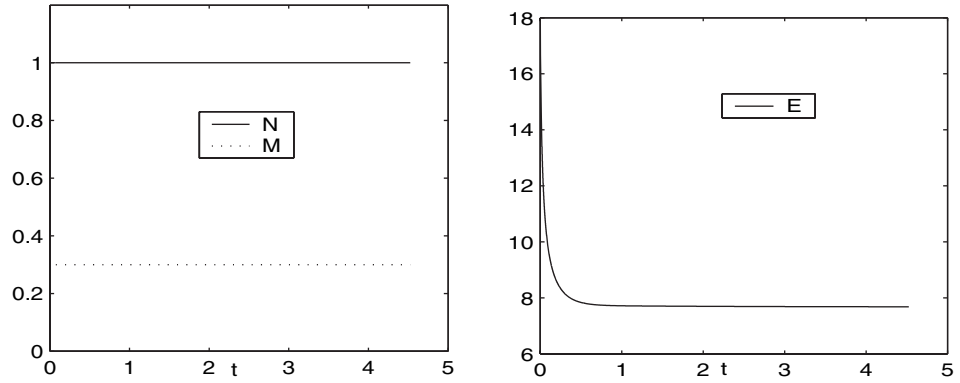

FIG. 2. *Time evolution of the mass N and magnetization M (left) and energy E (right) for the discretization* (3.32)–(3.34) *with* $\beta_n = 87.16$ *and* $\beta_s = -1.7481$ *and initial data* (4.2) *with* $\alpha = 0.1$.

TABLE 1
Spatial error analysis of the ground state for different mesh sizes h and number of particles N in the condensate with fixed magnetization $M = 0.3$.

N	$h = 1/2$	$h = 1/4$	$h = 1/8$	$h = 1/16$	$h = 1/32$
0	1.3336E-2	3.2999E-3	8.0E-4	2.0E-4	5.0E-5
10	4.3021E-3	1.1145E-3	2.5794E-4	6.0940E-5	1.1990E-5
100	1.9063E-3	5.1658E-4	1.3568E-4	2.9750E-5	6.7299E-6

10000	8.9626E-4	1.8109E-4	4.4159E-5	1.0589E-5	2.1599E-6
30000	6.4606E-4	2.5697E-4	8.5889E-5	3.6030E-5	1.1980E-5

types of initial data are also tested. From our experiments, when $\beta_s \le 0$, for any $\phi_1^{(0)} \ge 0$, $\phi_0^{(0)} \ge 0$, and $\phi_{-1}^{(0)} \ge 0$ in (2.22) satisfying (2.23), we always get the unique positive ground state solution of (1.15). In addition, from Figure 2, the mass N and magnetization M are conserved (cf. Figure 2, left), and energy E is diminishing (cf. Figure 2, right) when time t increases, which confirm the results in Theorem 3.2.

4.2. Accuracy test. Here we test the accuracy of our numerical method (3.32)–(3.34) for computing the ground state of a spin-1 BEC. We choose $M = 0.3$ in (2.24) and $\alpha = 0.1$ in (4.1)–(4.2). For a given set of parameters, the "exact" ground state solution Φ_g is obtained by our numerical method with mesh size $h = 1/64$. Let Φ_g^h be the numerical solution obtained by our method with mesh size h. Table 1 lists the error $\|\Phi_g - \Phi_g^h\|$ for different mesh sizes h and number of particles N in the condensate.

From Table 1, we can see that the full discretization (3.32)–(3.34) is second order in space for computing the ground state of a spin-1 BEC.

4.3. Applications. Now we report the ground state of a spin-1 BEC computed by our numerical method (3.32)–(3.34) for different parameter regimes. In this subsection, the initial data are always taken as in (4.1)–(4.2) with $\alpha = 0.3$, and the bounded computational interval is taken as $[-32, 32]$. We choose mesh size $h = 1/16$ and time step $\Delta t = 0.01$ in (3.32)–(3.34) in our computation.

First, we report the energy of the ground state and study conservation law (2.7) of our numerical ground state. Table 2 shows the numerical kinetic energy $E_{\rm kin}^h := E_{\rm kin}(\Phi_g^h)$ (with Φ_g^h is the numerical ground state), potential energy $E_{\rm pot}^h := E_{\rm pot}(\Phi_g^h)$, interaction energy $E_{\rm int}^h := E_{\rm int}(\Phi_g^h)$, total energy $E_g^h := E(\Phi_g^h)$, and the error $e^h =$

TABLE 2

Different energies of the ground state for different numbers of particles N in the condensate with fixed magnetization $M = 0.2$.

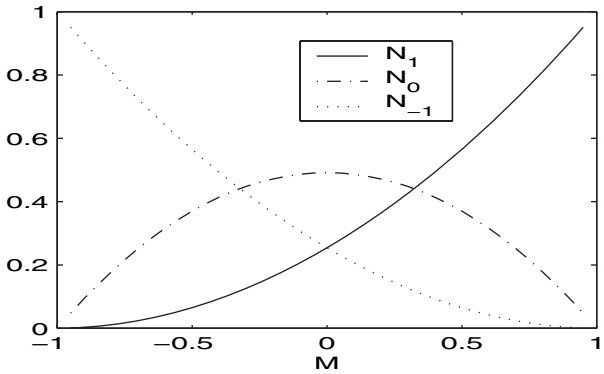

FIG. 3. *Mass of the three components of the ground state, i.e., $N_j = \|\phi_j\|^2$ $(j = 1, 0, -1)$, of a spin-1 BEC with a fixed number of particles $N = 1000$ for different magnetizations $-1 < M < 1$.*

$2E^h_{\rm kin} - 2E^h_{\rm pot} - E^h_{\rm int}$, with magnetization $M = 0.2$ for different numbers of particles N in the condensate.

From Table 2, we can see that, when the number of particles N in the condensate increases, the total energy, potential energy, and interaction energy increases, too, where the kinetic energy decreases. In addition, the relation (2.7) for different energies of the ground state is kept very well in our numerical results.

Second, we report the ground state wave functions for different magnetizations M and numbers of particles N in the condensate. Figures 3 and 4 plot the mass of the three components and wave functions of the ground states of a spin-1 BEC with a fixed number of particles $N = 1000$ in the condensate for different magnetizations M, respectively. In addition, Figure 5 depicts the wave functions of the ground state of a spin-1 BEC with fixed magnetization $M = 0.1$ for different numbers of particles N in the condensate.

From Figure 3, we can see that, for a fixed number of particles N in the condensate, when the magnetization M increases from -1 to 1, the mass N_1 increases from 0 to 1, the mass N_{-1} decreases from 1 to 0, and the mass N_0 increases from 0 to its maximum when $-1 \le M \le 0$, attains its maximum when $M = 0$, and decreases from its maximum to 0 when $0 \le M \le 1$. From Figures 4 and 5, we can see that the ground states are positive functions when $\beta_s \le 0$.

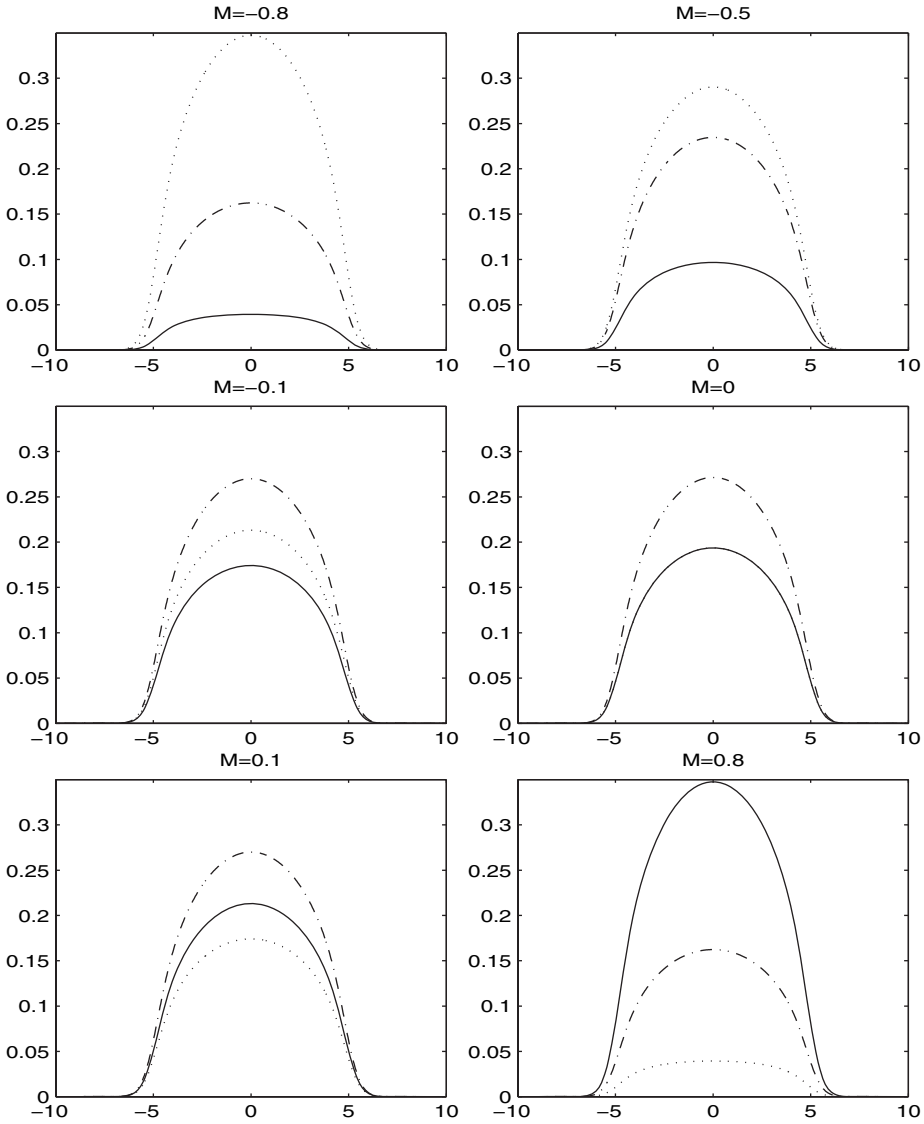

FIG. 4. *Wave functions of the ground state, i.e., $\phi_1(x)$ (solid line), $\phi_0(x)$ (dashed-dotted line), and $\phi_{-1}(x)$ (dotted line), of a spin-1 BEC with a fixed number of particles $N = 1000$ in the condensate for different magnetizations $M = -0.8, -0.5, -0.1, 0, 0.1, 0.8$.*

5. Conclusion. We have proposed an efficient and determinate numerical method for computing the ground state of a spin-1 BEC. By constructing a CNGF which is mass and magnetization conservative and energy-diminishing, the ground state of a spin-1 BEC can be computed as the steady state solution of the CNGF. The CNGF was then discretized in space by the finite difference method and in time by the Crank–Nicolson method with a proper way to deal with the nonlinear terms, and we proved rigorously that the discretization is mass and magnetization conservative and energy-diminishing in the discretized level. Numerical results were reported to demonstrate the efficiency of our new numerical method for computing the ground

METHODS FOR RELIABLE TOPOLOGY CHANGES FOR PERIMETER-REGULARIZED GEOMETRIC INVERSE PROBLEMS*

BENJAMIN HACKL†

Abstract. This paper is devoted to the incorporation of topological derivativelike expansions into level set methods for perimeter-regularized geometric inverse problems. The expansions are done up to the second order with respect to the Lebesgue measure of the symmetric difference. They provide simpler shape functionals, still including the perimeter, and therefore allow the construction of steepest descent- and Newton-type algorithms to force topology changes during the level set evolution. Numerous numerical examples are provided that show the strong and also the weak points of the newly developed algorithms.

Key words. geometric inverse problems, perimeter regularization, topological derivatives, level set methods

1. Introduction.

Identification of unknown geometries via minimizing appropriate objective functionals is a challenging task, appearing in various applications ranging from topology optimization (cf. Bendsøe and Sigmund [11], Bourdin and Chambolle [12]) over image processing (cf. Tsai and Osher [46]) to inverse problems (cf. Burger and Osher [18], Habib and Hyeonbae [29]). Later it got very common to use level set methods (cf. Osher and Fedkiw [40], Litman, Lesselier, and Santosa [36]) whose velocities depend on shape derivatives (cf. Delfour and Zolésio [22]) to solve such geometric problems. For several optimization problems, these level set methods were successfully applied to compute optimal geometries without a priori knowledge of the number of connected components (cf. Burger [13, 15], Dorn, Miller, and Rapport [23], Hintermüller and Ring [33], Ito, Kunisch, and Li [34], Santosa et al. [36, 41, 42]).

Level set methods are gradientlike methods that allow a simple and flexible geometry representation and evolution. Hence the topologies can only split, merge, and vanish during the level set evolution. A sudden appearance of a new component during the evolution is not possible. Due to the fact that level set methods just evolve the boundary of a geometry, they may easily get stuck in local minima. Theoretical constructed examples prove this, but it is even observed practically (cf. Allaire, Jouve, and Toader [3, 4], Burger, Hackl, and Ring [16]).

Recently a new concept called topological derivatives (cf. Eschenauer et al. [24, 25], Sokolowski and Żochowski [43, 44]) was developed. In this concept one considers the variation of an objective functional with respect to the introduction of infinitesimally small holes at a certain point. The topological derivative then indicates whether it is favorable to introduce a hole at this point or not. Already the definition of the topological derivative suggests an algorithm that was successfully applied to several problems (cf. Amstutz et al. [7, 8, 9], Guillaume and Idris [27], Guzina and Bonnet

[28], Masmoudi et al. [9, 37]). Also algorithms based just on topological derivatives may get stuck in local minima. This is mainly due to their "disability" to reduce the number of connected components.

Hence several authors (cf. Allaire, de Gournay, and Toader [2], Burger, Hackl, and Ring [16], Hintermüller [32], Wang, Mei, and Wang [47]) tried successfully to combine classical level set methods with the concept of topological derivatives. There are basically two ideas about how to combine these methods. One idea is to add an additional source term to the right-hand side of the level set methods. This additional source term depends on the topological derivative and is defined in the whole domain. Therefore the modified level set methods allow also for the addition of new components. The second idea is to restart the level set evolution after some fixed time (or due to some stopping criteria). The initial value of the restart is determined via the topological derivative at the last time step. The rationale behind both ideas is to fulfill the combined necessary optimality condition for shape and topological derivatives (see Sokolowski and Żochowski [45]).

Nonetheless there are still some problems. First, in geometric inverse problems one usually uses perimeter regularization, which is not topological differentiable at all. Second, topological derivatives are just indicators. They do not provide information about the size and shape of the preferable topology change which actually decreases the cost functional.

By means of an ill-posed, PDE-constraint inverse shape identification problem we are going to construct local approximations of the perimeter-regularized objective functional such that:

- we can provide local error estimates of first (respectively, second) order with respect to the Lebesgue measure of the symmetric difference;
- the approximated shape functionals are either not PDE-constraint (first order approximation) or the PDE constraint becomes simpler (second order approximation); and
- in the limit, Lebesgue measure to zero, we retrieve the topological derivative of the original problem.

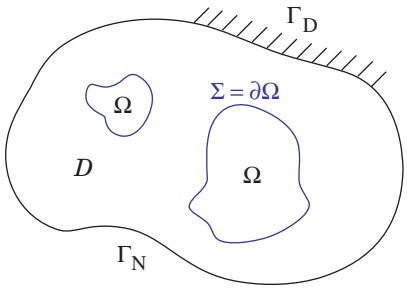
Minimizing the approximated shape functionals will allow one to construct algorithms of the steepest descent type (first order approximation) and the Newton type (second order approximation). Up to provided error estimates every minimizer of the approximated shape functional guarantees a descent of the original perimeter-regularized objective functional. This is in contrast to most methods relying on topological derivatives. Like in the functional analytic framework, the numerical minimization of the first order approximation is less expensive than the second order approximation but also provides less accurate error estimates close to the solution.

Model problem. Let $\mathcal{D} \subset \mathbb{R}^d$ be some bounded open Lipschitz set, and let $\Omega \in \mathcal{F}_L(\mathcal{D})$, with $\mathcal{F}_L(\mathcal{D}) = \big\{\Omega \subset \operatorname{cl}(\mathcal{D}) \,\big|\, \Omega \text{ open and measurable}\big\}$. Consider the partial differential equation

$$\begin{aligned} -\Delta u + c_\Omega\, u &= f && \text{in } \mathcal{D}, \\ \frac{\partial u}{\partial n} &= h && \text{on } \Gamma_N, \\ u &= g && \text{on } \Gamma_D, \end{aligned} \tag{1.1}$$

where $c_\Omega = \underline{c} + (\overline{c} - \underline{c})\chi_\Omega$ and χ_Ω is the characteristic function of Ω. Furthermore assume that the source term $f \in L^2(\mathcal{D})$, the Neumann boundary term h is in $H^{-\frac{1}{2}}(\Gamma_N)$, and the Dirichlet term g is in $H^{\frac{1}{2}}(\Gamma_D) = H^1(\mathcal{D})|_{\Gamma_D}$. For every set $\Omega \in \mathcal{F}_L(\mathcal{D})$ the

partial differential equation (1.1) provides an unique solution $u \in H^1(\mathcal{D})$.



Now let $\Gamma_M \subset \mathcal{D}$ be some open set or $\Gamma_M \subset \Gamma_N$ with positive $(d-1)$-dimensional Lebesgue measure. Denote by $\hat{u}$ measurements of $u|_{\Gamma_M}$ restricted to Γ_M with possible additional Gaussian noise bounded in the L^2-norm. The geometric inverse problem is to identify the set $\Omega \in \mathcal{F}_L(\mathcal{D})$ from measurements $\hat{u}$.

In general the solution to the above geometric inverse problem is not stable. A stabilized approximation of the original problem is the minimization of the perimeter-regularized least squares functional

$$J_\alpha(\Omega) = \frac{1}{2}\int_{\Gamma_M} |u - \hat{u}|^2 \, ds + \alpha \mathrm{Per}\big(\Omega\big), \tag{1.2}$$

where α acts as regularization parameter and is chosen in dependence of the noise level of the measurements $\hat{u}$. Note that the perimeter of a set is defined by

$$\mathrm{Per}\big(\Omega\big) = |\chi_\Omega|_{\mathrm{BV}(\mathcal{D})} = \sup_{\substack{\phi \in C_0^1(\mathcal{D},\mathbb{R}^d) \\ \|\phi\|_\infty \le 1}} \int_{\mathcal{D}} \chi_\Omega \mathrm{div}\phi \, dx \,.$$

The regularization property of the perimeter and the choice of the parameter α will not be dealt with in this paper (cf. Ben Ameur, Burger, and Hackl [10] for a detailed analysis). Only the appearance of the perimeter in the minimization functional will be in the focus in the following, since it prevents the application of known solution methods based on topological derivatives.

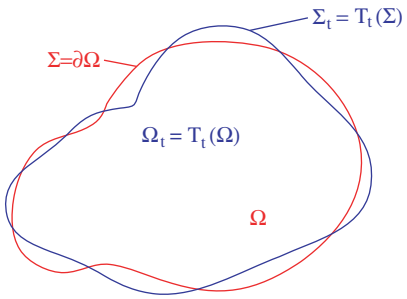
Notation. We denote by $L^p(\mathcal{D})$ the space of functions on Ω whose pth power is integrable, with $H^k(\mathcal{D})$ the Sobolev space of k-times differentiable functions whose derivatives up to order k are in $L^2(\mathcal{D})$. Note that the space $H^k(\mathcal{D})$ is a Hilbert space. Furthermore we abbreviate by $H^1_{D,0}(\mathcal{D}) \subset H^1(\mathcal{D})$ the function space with boundary values zero at the boundary $\Gamma_D \subset \partial\mathcal{D}$. We often use the notation $\preceq$, which means $\le$ up to a multiplicative constant that does not depend on the important properties. With ∂_u we denote the partial derivative with respect to u. Finally we denote with $\tilde{\Omega}\Delta\Omega = (\tilde{\Omega} \setminus \Omega) \cup (\Omega \setminus \tilde{\Omega}) = (\tilde{\Omega} \cup \Omega) \setminus (\tilde{\Omega} \cap \Omega)$ the symmetric difference of sets.

The paper is organized as follows: In section 2 we provide the shape and the topological derivative for the objective functional (1.2). Then, based on the proof of the topological derivative, we provide in section 3 the first and second order approximations, in volume and perimeter, of the objective functional (1.2). The first and second order approximations allow one to construct steepest descent (respectively, Newton-) type iterations which allow topology changes. Details about the numerical implementation of level set methods and the newly suggested steepest descent- as well as Newton-type iterations are provided in section 4. In section 5 we provide

some numerical examples to show the applicability and performance of the methods suggested in this paper. Finally we draw the conclusion in section 6.

2. Shape and topological derivatives. In this section we recall two different concepts of shape (geometry) perturbations and consider the sensitivity of the shape functional (1.2) with respect to these perturbations. The first perturbation is a pure boundary perturbation moving a shape (geometry) in a velocity field V. This approach results in the concept of shape derivatives. For a comprehensive introduction to this topic we refer to Delfour and Zolésio [22]. The second perturbation changes the topology of the shape (geometry) by introducing a fixed additional shape with varying size and position. The sensitivity of the shape functional (1.2) with respect to the size of the newly introduced shape results in the concept of topological derivatives, which were first introduced by Eschenauer et al. [24, 25] and by Céa et al. [19] in the context of topology optimization and made mathematically rigorous by Sokolowski and Żochowski [43, 44].

2.1. Shape derivatives. Shape derivatives for geometric problems allow one to characterize extrema and yield directions of steepest descent. They take the role of *Gateaux* and *Fréchet derivatives* in a functional analytic framework.



The basic idea is to define a perturbation of a domain Ω (piecewise C^2) via the time evolution of Ω in a vector field $V : \mathbb{R}_0^+ \times \mathbb{R}^d \to \mathbb{R}^d$, with

$$\begin{aligned} &\exists\, \tau > 0 \,\forall\, x \in \mathbb{R}^d \,:\, V(.,x) \in C([0,\tau], \mathbb{R}^d) \\ &\exists\, L > 0 \,\forall\, x, y \in \mathbb{R}^d \,: \\ &\quad \|V(.,y) - V(.,x)\|_{C([0,\tau],\mathbb{R}^d)} \leq L|y - x|\,. \end{aligned} \tag{2.1}$$

Then the perturbed domain is set to $\Omega_t(V) = T_t(\Omega, V)$, where $T_t(., V)$ is the solution map (the flow) of the dynamical system

$$\begin{aligned} \frac{dT_t(x,V)}{dt} &= V(t, T_t(x,V)), \\ T_0(x,V) &= x. \end{aligned} \tag{2.2}$$

With these perturbations we are able to define the Eulerian semiderivative of a shape functional $J(\Omega)$ as

$$J'(\Omega)[V] = \frac{d}{dt} J(T_t(\Omega, V))\big|_{t=0}.$$

When this semiderivative is linear and continuous for all velocities $V = t\theta$, with $\theta \in C^{0,1}(\mathcal{D}, \mathbb{R}^d)$, we call the shape functional $J(\Omega)$ shape differentiable.

A basic structure theorem (cf. Novruzi and Pierre [38], Delfour and Zolésio [22]) proves that the shape derivative depends only on $V|_{\partial\Omega}$. Furthermore, for smooth shapes, the perturbation vector field V can be decomposed into a normal and a tangential component on $\partial\Omega$, where the tangential component leaves Ω invariant. Hence the shape derivative is independent of the tangential component, and we obtain

$$J'(\Omega)[V] = J'(\Omega)[(V.n)n].$$

In the case that $J(\Omega)$ is an objective functional in a minimization problem a necessary condition for the shape Ω to be optimal is

$$\forall\, V \,:\, J'(\Omega)[V] \,=\, 0.$$

When the shape derivative is not zero we can construct a velocity V such that the objective functional decreases. This allows the construction of gradientlike descent algorithms as level set methods (see section 4.1).

To calculate the shape derivative of the shape functional J_α (1.2) we need the shape derivative of domain (respectively, boundary) integrals and the solution of the partial differential equation (1.1). These derivatives are well known in the literature (cf. Delfour and Zolésio [22] for shape derivatives of domain and boundary integrals and Hettlich and Rundell [31] for the shape derivative of (1.1)), and we just state them in the following theorems.

THEOREM 2.1 (shape derivative domain and boundary integrals). *Let Ω be an open, bounded measurable domain of class C^2 with boundary $\Sigma = \partial\Omega$, and assume that $V \in C^0\big([0,\tau], C^1_{\rm loc}(\mathbb{R}^d,\mathbb{R}^d)\big)$ fulfill (2.1). Furthermore assume $\varphi \in C\big(0,\tau, W^1_{\rm loc}(\mathbb{R}^d) \cap C^1(0,\tau, H^2_{\rm loc}(\mathbb{R}^d))\big)$. Then the semiderivative of the shape functionals*

$$J_D(\Omega_t) \,:=\, \int_{T_t(\Omega,V)} \varphi(t)\,dx, \qquad J_B(\Sigma_t) \,:=\, \int_{T_t(\Sigma,V)} \varphi(t)\,ds$$

at $t = 0$ are given by

$$J'_D(\Omega)[V(0)] = \int_\Omega \frac{d\varphi}{dt}(0)\,dx + \int_\Sigma \varphi(0)V(0).n\,ds,$$

$$J'_B(\Gamma)[V(0)] = \int_\Sigma \frac{d\varphi}{dt}(0) + \Big(\frac{\partial\varphi(0)}{\partial n} + \kappa\varphi(0)\Big)V(0).n\,ds\,,$$

where κ is the mean curvature of Σ.

THEOREM 2.2. *Let Ω be a domain with C^1 boundary and the velocity field V be as in the previous theorem. Then the solution u of (1.1) is shape differentiable and its shape derivative is characterized by the unique solution $u' = u'(\Omega)[V(0)]$ to the transmission problem*

$$\begin{array}{lll}
-\Delta u' + c_\Omega\, u' = 0 & & \text{in } \Omega \cup \mathcal{D} \setminus \overline{\Omega},\\
\Big[\!\Big[\dfrac{\partial u'}{\partial n}\Big]\!\Big] & = -\big[\!\big[c_\Omega\big]\!\big] V(0).n & \text{on } \partial\Omega,\\
\big[\!\big[u'\big]\!\big] & = 0 & \text{on } \partial\Omega,\\
\dfrac{\partial u'}{\partial n} & = 0 & \text{on } \Gamma_N,\\
u' & = 0 & \text{on } \Gamma_D,
\end{array} \tag{2.3}$$

where $[\![\,.\,]\!]$ denotes the jump across the interface $\partial\Omega$.

Summing up, the shape derivative of the objective functional J_α (1.2) is given as

$$J'_\alpha(\Omega)[V(0)] = \int_{\Gamma_M} u'[V(0)](u-\hat{u})\,ds + \alpha \int_{\partial\Omega} \kappa V(0).n\,ds.$$

We can simplify this shape derivative when we introduce the adjoint state w

$$\begin{aligned} &-\Delta w + c_\Omega\, w = -\chi_{\Gamma_M}(u-\hat{u}), && \text{respectively,} && 0, && \text{in } \mathcal{D},\\ &\frac{\partial w}{\partial n} = 0, && \text{respectively,} && -\chi_{\Gamma_M}(u-\hat{u}), && \text{on } \Gamma_N,\\ &w = 0 && && && \text{on } \Gamma_D. \end{aligned} \tag{2.4}$$

The shape derivative of the objective functional $J_\alpha(\Omega)$ finally gets

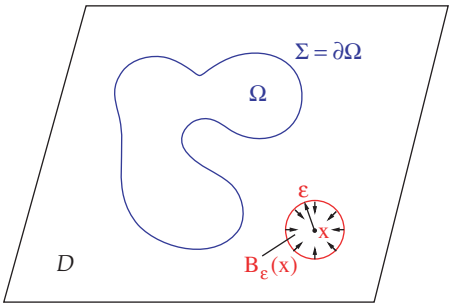
$$J'_\alpha(\Omega)[V(0)] = \int_{\partial\Omega} ([\![c_\Omega]\!]uw + \alpha\kappa)V(0).n\,ds. \tag{2.5}$$

First note that we just solve two partial differential equations, namely, (1.1) and (2.4), to calculate the shape derivative. Second, the first order necessary condition for optimal shapes Ω requires for all V : $J'_\alpha(\Omega)[V(0)] = 0$. Hence $(uw + \alpha\kappa) = 0$ on $\partial\Omega$. If this is not the case, we can construct a velocity such that $J'_\alpha(\Omega)[V(0)] < 0$. For example, take $V = -(uw + \alpha\kappa)n$, but other choices are possible (cf. Burger [14]).

2.2. Topological derivatives. In contrast to *shape derivatives* where one considers variations of a shape, *topological derivatives* aim for variations of the topology. The basic idea of the topological derivative is to add a small sphere with center x and radius ϵ to the domain Ω and consider the variation of the objective functional $J(\Omega \cup B_\epsilon(x))$ with respect to the radius of this sphere. Note that different shapes than spheres are possible and might result in different values of the derivatives.

DEFINITION 2.3 (topological derivative). *Let $J : \Omega \subset \mathbb{R}^d \to \mathbb{R}$ be an objective functional. Then the topological derivative is defined as the limit (if it exists)*

$$d_\tau J(x) := \lim_{\epsilon \to 0^+} \frac{J(\Omega \cup B_\epsilon(x)) - J(\Omega)}{|B_\epsilon(x)|}. \tag{2.6}$$



A negative topological derivative $d_\tau J(x) < 0$ indicates that it might be reasonable to add a small sphere at point x to reduce the objective functional. It is also possible to subtract material, i.e., take the set-minus instead of adding material, i.e., the union in (2.6).

In practice, topology changes forced by the topological derivative are neither spherical nor infinitesimally small. Most methods are based on a threshold criteria such as (4.3). This is opposed to functional analytic methods, where the finite step sizes are usually based on higher order estimates (remainder estimates) or line search methods, still guaranteeing descent in the objective functional. For a line searchlike idea in combination with topological derivatives, see Hintermüller [32]. In the framework of topological, asymptotic higher order estimates are used by Cedio-Fengya, Moskow, and Vogelius [20] and Habib and Hyeonbae [29]. To the best knowledge of the author, higher order estimates, although available, are not used for algorithms based on topological derivatives. One reason might be that higher order estimates for topological derivatives would just allow for a finite number of disjoint small holes (cf. Cedio-Fengya, Moskow, and Vogelius [20]).

Nonetheless the practical experience by most authors, using the topological derivative as an indicator, is rather positive. Therefore let us calculate the topological derivative for our objective functional (1.2). First of all consider the topological derivative of the perimeter $\mathrm{Per}\big(\Omega\big)$:

$$d_\tau \mathrm{Per}\big(\Omega\big) = \lim_{\epsilon\to 0} \frac{\mathrm{Per}\big(B_\epsilon(x)\big)}{|B_\epsilon(x)|} \simeq \lim_{\epsilon\to 0} \frac{\epsilon^{d-1}}{\epsilon^d} = \infty.$$

Hence the perimeter is not topologically differentiable. In practical applications one usually neglects this fact and calculates the topological derivative of the objective functional without the perimeter, i.e., for $J_0(\Omega)$. This derivative is already well known (see Amstutz [6]). Nonetheless we provide a detailed proof that is based on Hölder estimates, Sobolev embedding, and regularity results for elliptic partial differential equations. Parts of the proof will play a crucial role in the rest of the paper. Let us first state Sobolev's embedding theorem (cf. Adams [1])

THEOREM 2.4 (Sobolev embedding). *Let ω be a Lipschitz domain in $\mathbb{R}^d$, $m \in \mathbb{N}_0$.*
$d > 2m$: $H^m(\omega) \hookrightarrow L^q(\omega)$ for $2 \le q \le \frac{2d}{d-2m}$,
$d = 2m$: $H^m(\omega) \hookrightarrow L^q(\omega)$ for $2 \le q < \infty$,
$d < 2m$: $H^m(\omega) \hookrightarrow C\big(\mathrm{cl}(\omega)\big)$.

Based on the Caccioppoli inequality we cite an interior regularity result for elliptic partial differential equations (cf. Giaquinta [26]) that applies to (1.1) and (2.4).

THEOREM 2.5 (interior regularity). *Let $A_{ij} \in C^{0,1}(\mathcal{D})$ be strictly elliptic and $f \in L^2(\mathcal{D})$ and u be a weak solution to the linear elliptic equation*

$$-\partial_i\big(A_{ij}\partial_j u\big) = f;$$

then $u \in H^2_{\mathrm{loc}}(\mathcal{D})$ and even more

$$\|u\|^2_{H^2([\mathcal{D}]^\eta)} \le C(d)\left(\|f\|^2_{L^2(\mathcal{D})} + \frac{1}{\eta^2}\|\nabla u\|^2_{L^2(\mathcal{D})}\right), \tag{2.7}$$

where $\eta > 0$ and $[\mathcal{D}]^\eta := \mathrm{cl}\big(\mathrm{int}\{x \in \mathcal{D} | \mathrm{dist}(x, \partial\mathcal{D}) \ge \eta\}\big)$.

The strength of the above interior regularity result is that it is independent of the boundary conditions and the regularity of the domain $\mathcal{D}$ at the price that it is valid only in the interior of the domain $\mathcal{D}$. This allows us to deal with Lipschitz domains $\mathcal{D}$ and arbitrary mixed boundaries; i.e., $g \in H^{\frac{1}{2}}(\Gamma_D), h \in H^{-\frac{1}{2}}(\Gamma_N)$ are arbitrary in (1.1). Therefore we need not bother about corner singularities. The drawback for this convenience is that we need to restrict Ω to be a subset of $[\mathcal{D}]^\eta$.

In our application $u, w \in H^1(\mathcal{D})$ are solutions to the elliptic partial differential equations (1.1), (2.4). Therefore $\|u\|_{H^1(\mathcal{D})}$ and $\|w\|_{H^1(\mathcal{D})}$ can be estimated by

$$\begin{aligned}\|u\|^2_{H^1(\mathcal{D})} &\preceq \|f\|^2_{H^{-1}(\mathcal{D})} + \|g\|^2_{H^{\frac{1}{2}}(\Gamma_D)} + \|h\|^2_{H^{-\frac{1}{2}}(\Gamma_N)},\\ \|w\|_{H^1(\mathcal{D})} &\preceq \|u-\hat{u}\|_{L^2(\Gamma_M)}.\end{aligned}$$

When we plug this into the interior regularity result (2.7) we achieve

$$\begin{aligned}\|u\|^2_{H^2([\mathcal{D}]^\eta)} &\leq C(\eta,d,\mathcal{D})\big(\|f\|^2_{L^2(\mathcal{D})} + \|g\|^2_{H^{\frac{1}{2}}(\Gamma_D)} + \|h\|^2_{H^{-\frac{1}{2}}(\Gamma_N)}\big),\\ \|w\|_{H^2([\mathcal{D}]^\eta)} &\leq C(\eta,d,\mathcal{D})\|u-\hat{u}\|_{L^2(\Gamma_M)}.\end{aligned}$$

Note that, if it is not an option to restrict $\Omega \subset [\mathcal{D}]^\eta$, one needs to restrict instead $\mathcal{D} \in C^1$, $g \in H^{\frac{3}{2}}(\Gamma_D)$, $h \in H^{\frac{1}{2}}(\Gamma_N)$, and g, h compatible such that the outer regularity result applies (cf. Giaquinta [26]):

$$\begin{aligned}&\|u\|_{H^2(\mathcal{D})} \leq C(d,\mathcal{D})\big(\|f\|_{L^2(\mathcal{D})} + \|g\|_{H^{\frac{3}{2}}(\Gamma_D)} + \|h\|_{H^{\frac{1}{2}}(\Gamma_N)}\big),\\ &\|w\|_{H^2(\mathcal{D})} \leq C(d,\mathcal{D})\|u-\hat{u}\|_{L^2(\Gamma_M)}, \quad \text{respectively,} \quad \|w\|_{H^{\frac{3}{2}}(\mathcal{D})} \leq C(d,\mathcal{D})\|u-\hat{u}\|_{L^2(\Gamma_M)}.\end{aligned}$$

Finally, before we calculate the topological derivative, let us recall the direct (1.1) and the adjoint (2.4) partial differential equations but in their weak form.

Direct problem.

$$\langle \nabla u, \nabla v\rangle + \langle c_\Omega u, v\rangle = \langle f, v\rangle + \langle h, v\rangle_{H^{-\frac{1}{2}}(\Gamma_N)\times H^{\frac{1}{2}}(\Gamma_N)} \qquad \forall\, v \in H^1_{0,D}(\mathcal{D}). \tag{2.8}$$

Adjoint problem.

$$\langle \nabla v, \nabla w\rangle + \langle c_\Omega v, w\rangle = -\partial_u J_0(\Omega)[v] = -\langle u-\hat{u}, v\rangle_{L^2(\Gamma_M)} \qquad \forall\, v \in H^1_{0,D}(\mathcal{D}). \tag{2.9}$$

In the following we will often use the topologically perturbed domain $\tilde{\Omega}$ and the corresponding solution $\tilde{u}$ of (1.1).

PROPOSITION 2.6. *For $\eta > 0$ and every point $x \in [\mathcal{D}]^\eta \setminus \partial\Omega$ the topological derivative of the shape functional* (1.2) *with $\alpha = 0$ is given by*

$$d_\tau J_0(\Omega)(x) = -2(\chi_\Omega - \tfrac{1}{2})(\overline{c} - \underline{c})u(x)w(x).$$

Proof. Let $\tilde{\Omega}$, $\Omega \subset [\mathcal{D}]^\eta$ be arbitrary domains with positive Lebesgue measure, and consider the first order Taylor expansion of the objective functional J_0 with respect to the state u:

$$J_0(\tilde{\Omega}) - J_0(\Omega) = \partial_u J_0(\Omega)[\tilde{u}-u] + \mathcal{O}\big(\|\tilde{u}-u\|^2_{H^1(\mathcal{D})}\big).$$

$\|\tilde{u}-u\|_{H^1(\mathcal{D})} \preceq |\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{2d}}$: We subtract the two determining partial differential equations for u (respectively, $\tilde{u}$) and rearrange the terms to get

$$\begin{aligned}\langle \nabla(\tilde{u}-u), \nabla v\rangle + \langle c_{\tilde{\Omega}}(\tilde{u}-u), v\rangle &\overset{(1.1)}{=} -\langle (c_{\tilde{\Omega}} - c_\Omega)u, v\rangle\\ &\overset{\text{Hölder } \frac{1}{r}+\frac{1}{p}+\frac{1}{q}=1}{\leq} |\overline{c}-\underline{c}||\tilde{\Omega}\Delta\Omega|^{\frac{1}{r}}\|u\|_{L^p(\tilde{\Omega}\Delta\Omega)}\|v\|_{L^q(\tilde{\Omega}\Delta\Omega)}.\end{aligned}$$

To minimize r we use the interior regularity result $u \in H^2([\mathcal{D}]^\eta)$ and $v \in H^1(\mathcal{D})$ and apply Sobolev's embedding theorem to conclude $p \leq \infty$:

$$q \leq \begin{cases} \frac{2d}{d-2} & d=3\\ <\infty & d=2\end{cases} \quad\Rightarrow\quad r \geq \begin{cases} \frac{2d}{d+2} & d=3\\ >1 & d=2.\end{cases}$$

Finally the Lax Milgram lemma provides us with the desired result

$$\|\tilde{u} - u\|_{H^1(\mathcal{D})} \preceq |\overline{c} - \underline{c}||\tilde{\Omega}\Delta\Omega|^{\frac{1}{r}} \|u\|_{H^2([\mathcal{D}]^\eta)}.$$

$\partial_u J_0(\Omega)[\tilde{u} - u] = \langle (c_{\tilde{\Omega}} - c_\Omega)u, w\rangle + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{d}}\big)$: We just use the definition of the adjoint problem (2.4) and afterwards (1.1) for $\tilde{u}$ and u to get

$$\begin{aligned}\partial_u J_0(\Omega)[\tilde{u} - u] &\overset{(2.4)}{=} -\langle \nabla(\tilde{u} - u), \nabla w\rangle - \langle c_\Omega(\tilde{u} - u), w\rangle \overset{(1.1)}{=} \langle (c_{\tilde{\Omega}} - c_\Omega)\tilde{u}, w\rangle \\ &= \langle (c_{\tilde{\Omega}} - c_\Omega)u, w\rangle + \langle (c_{\tilde{\Omega}} - c_\Omega)(\tilde{u} - u), w\rangle.\end{aligned}$$

For the term $\langle (c_{\tilde{\Omega}} - c_\Omega)(\tilde{u} - u), w\rangle$ we proceed as above, but this time we consider $(\tilde{u} - u) \in H^1_{0,D}(\mathcal{D})$ and $w \in H^2([\mathcal{D}]^\eta)$. Therefore we get, with r as above, the estimate

$$\partial_u J_0(\Omega)[\tilde{u} - u] = \langle (c_{\tilde{\Omega}} - c_\Omega)u, w\rangle + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{\frac{1}{r}} |\overline{c} - \underline{c}| \|\tilde{u} - u\|_{H^1(\mathcal{D})} \|w\|_{H^2([\mathcal{D}]^\eta)}\big).$$

Summing up all of the estimates we get

$$J_0(\tilde{\Omega}) - J_0(\Omega) \leq \langle (c_{\tilde{\Omega}} - c_\Omega)u, w\rangle + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{d}}\big). \tag{2.10}$$

Now set $\tilde{\Omega} = B_\epsilon(x) \cup \Omega$ and perform the limit according to the definition of the topological derivative. In general the limit can be deduced from the Lebesgue differentiation theorem (cf. Giaquinta [26]) almost everywhere, but due to the fact that u, $w \in H^2([\mathcal{D}^\eta]) \hookrightarrow C([\mathcal{D}]^\eta)$ it is even more obvious. ∎

Like the shape derivative (2.5), the topological derivative depends on the solution u of (1.1) and the adjoint w (2.4) only, which is standard for adjoint methods. Moreover, both derivatives are the same, which is not true in general but holds, up to a constant, for surprisingly many cases.

3. Topological expansions up to the first and second orders. In the previous section we introduced two concepts of geometry derivatives. *Shape derivatives* take the role of the Gateux and Fréchet derivatives in a functional analytic framework and allow Taylor expansions with remainder estimates in proper shape metrics such as the Courant metric. Shape derivatives are even suitable for perimeter-regularized objective functionals. This is different for *topological derivatives*. They provide Taylor expansion with respect to the size parameter ϵ (see Definition 2.3) but not with respect to shape metrics such as the L^1-metric (Lebesgue measure), and they are not suitable for perimeter-regularized problems. Therefore the goal of this section is to overcome these, remedy, and provide Taylor expansions of first and second order with respect to the L^1-metric. To allow also for perimeter-regularized problems we need to add to the Taylor expansion an additional dominating first order term depending on the perimeter of the symmetric difference of the two objects. The rational of this extra term is the general inequality

$$\big|\mathrm{Per}\big(\tilde{\Omega}\big) - \mathrm{Per}\big(\Omega\big)\big| \leq \mathrm{Per}\big(\tilde{\Omega}\Delta\Omega\big). \tag{3.1}$$

With a Taylor expansion at hand we are able to construct, like in the functional analytic framework, steepest descent- and Newton-type algorithms to reduce the shape objective functional $J_\alpha(\Omega)$.

3.1. First order topological expansion. A closer look at the proof of the topological derivative (Proposition 2.6), more precisely, (2.10) together with (3.1), shows that we already have the desired topological estimate.

PROPOSITION 3.1. *Let $\tilde{\Omega}, \Omega \in \mathcal{F}_L([\mathcal{D}]^\eta)$; then the objective functional $J_\alpha(\Omega)$ (1.2) with state u given by (1.1) has the first order topological expansion*

$$J_\alpha(\tilde{\Omega}) - J_\alpha(\Omega) \leq \langle (c_{\tilde{\Omega}} - c_\Omega)u, w\rangle + \alpha \mathrm{Per}\big(\tilde{\Omega}\Delta\Omega\big) + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{2}}\big)\,. \tag{3.2}$$

Our aim is to minimize the objective functional $J_\alpha(\Omega)$ (1.2) with respect to the geometry Ω. Hence, when we already have an initial guess Ω_k we can improve it and calculate a new geometry Ω_{k+1} such that we reduce the objective functional $J_\alpha(\Omega_k)$, when we solve the auxiliary minimization problem

$$\Omega_{k+1} = \operatorname*{argmin}_{\Omega \in \mathcal{F}_L([\mathcal{D}]^\eta)} \langle (c_\Omega - c_{\Omega_k})u, w\rangle + \alpha \mathrm{Per}\big(\Omega\Delta\Omega_k\big) + c\big(|\Omega\Delta\Omega_k|^{<\frac{d+2}{2}}\big)\,. \tag{3.3}$$

The constant c is a consequence of the embedding and regularity results and can in principle be estimated. Algorithmically it seems more favorable to perform a trust region approach and vary c until the predicted decrease of the objective functional $J_\alpha(\Omega)$ is close to the actual decrease.

The minimization problem (3.3) already suggests a steepest descent-type algorithm to solve the original minimization problem of $J_\alpha(\Omega)$. We are more interested to solve (3.3) just once for every restart in the level set methods to force systematically reliable topology changes that decrease the objective functional $J_\alpha(\Omega)$. Therefore we prove that the minimization problem (3.3) has a solution which is not necessarily unique.

PROPOSITION 3.2. *Let $\alpha > 0$ and $\mathrm{Per}\big(\Omega_k\big) < \infty$; then the minimization problem (3.3) has a solution in the finite perimeter (Caccioppoli) sets.*

Proof. For every $\Omega \in \mathcal{F}_L([\mathcal{D}]^\eta)$ with a finite objective functional in the minimization problem (3.3) we conclude from $\alpha > 0$ that $\mathrm{Per}\big(\Omega\Delta\Omega_k\big) < \infty$. Therefore we can restrict $\Omega \in \mathcal{F}_L([\mathcal{D}]^\eta)$ to finite perimeter sets. Next we observe that $c_\Omega - c_{\Omega_k} = -2(\overline{c} - \underline{c})\big(\chi_{\Omega_k} - \frac{1}{2}\big)\chi_{\Omega\Delta\Omega_k}$. This allows one to replace the minimization problem (3.3) over Ω by a minimization problem over $\Omega\Delta\Omega_k$ and therefore an equivalent reformulation in $\mathrm{BV}(\mathcal{D}, \{0,1\})$:

$$\min_{p \in \mathrm{BV}(\mathcal{D},\{0,1\})} \Big\langle -2(\overline{c} - \underline{c})(\chi_{\Omega_k} - \tfrac{1}{2})uw, p\Big\rangle + \alpha |p|_{\mathrm{BV}(\mathcal{D})} + c\big(|p|^{<\frac{d+2}{2}}_{L^1(\mathcal{D})}\big)\,.$$

Now take a minimizing sequence $p_i \in \mathrm{BV}(\mathcal{D}, \{0,1\})$ which is due to $\alpha > 0$ uniformly bounded in $\|\,.\,\|_{\mathrm{BV}(\mathcal{D})}$. Therefore there exists a BV weak-* limit $p \in \mathrm{BV}(\mathcal{D})$. Due to the compact embedding $\mathrm{BV}(\mathcal{D}) \hookrightarrow^c L^1(\mathcal{D})$ (cf. Ambrosio, Fusco, and Pallara [5, Corollary 3.49]), the weak-* limit is also a strong limit in $L^1(\mathcal{D})$. Consequently we conclude $p \in \mathrm{BV}(\mathcal{D}, \{0,1\})$. Finally, the lower semicontinuity of $|\,.\,|_{\mathrm{BV}(\mathcal{D})}$ in the functions of bounded variation $\mathrm{BV}(\mathcal{D})$ guarantees that p is a solution to the above minimization problem formulated in $\mathrm{BV}(\mathcal{D}, \{0,1\})$, and therefore $\Omega_{k+1} = \big(\Omega_k \setminus \{p = 1\}\big) \cup \{(1 - \chi_{\Omega_k})p = 1\}$ is a minimizer for (3.3). ∎

Note that the minimizer to (3.3) might be Ω_k itself; i.e., no topology change is favorable to generate a guaranteed descent in the objective functional $J_\alpha(\Omega)$. This happens when the perimeter term dominates the first order term, i.e., when the topology changes get too small or when the topology is already the optimum of $J_\alpha(\Omega)$.

3.2. Second order topological expansion. The first order topological expansion in the L^1-metric was based mainly on a first order Taylor expansion of the objective functional $J_0(\Omega)$ with respect to the state u. We follow this strategy for the second order topological expansion. To allow a proper estimation of the second order terms we need to introduce an auxiliary partial differential equation.

Linearized problem.

$$\begin{aligned} -\Delta u^{\mathrm{lin}}(\tilde{\Omega}) + c_\Omega u^{\mathrm{lin}}(\tilde{\Omega}) &= -(c_{\tilde{\Omega}} - c_\Omega)u && \text{in } \mathcal{D}, \\ \frac{\partial u^{\mathrm{lin}}}{\partial n}(\tilde{\Omega}) &= 0 && \text{on } \Gamma_N, \\ u^{\mathrm{lin}}(\tilde{\Omega}) &= 0 && \text{on } \Gamma_D. \end{aligned}$$

We will indeed need the weak form of the linearized problem, which is given by

$$\langle \nabla u^{\mathrm{lin}}(\tilde{\Omega}), \nabla v\rangle + \langle c_\Omega u^{\mathrm{lin}}(\tilde{\Omega}), v\rangle = -\langle (c_{\tilde{\Omega}} - c_\Omega)u, v\rangle \qquad \forall\, v \in H^1_{0,D}(\mathcal{D}). \tag{3.4}$$

The reason why we denote the above partial differential equation linearized problem of (1.1) is that, when we consider (1.1) in a functional analytic setting with $c_\Omega \in L^2(\mathcal{D})$, the above formula would be its linearization.

PROPOSITION 3.3. *Let $\alpha > 0$ and $\mathrm{Per}(\Omega_k) < \infty$; then the objective functional $J_\alpha(\Omega)$ (1.2) with state u given by (1.1) has the second order topological expansion*

$$\begin{aligned} J_\alpha(\tilde{\Omega}) - J_\alpha(\Omega) \quad \le \quad & \big\langle (c_{\tilde{\Omega}} - c_\Omega)\big(u + u^{\mathrm{lin}}(\tilde{\Omega})\big), w\big\rangle + \tfrac{1}{2}\partial_u^2 J_0(\Omega)[u^{\mathrm{lin}}(\tilde{\Omega})]^2 \\ & + \alpha \mathrm{Per}\big(\tilde{\Omega}\Delta\Omega\big) + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{<\frac{d+4}{d}}\big). \end{aligned} \tag{3.5}$$

Proof. First we start to do a Taylor expansion up to the second order for the unregularized objective functional $J_0(\Omega)$ with respect to the state u:

$$\begin{aligned} J_0(\tilde{\Omega}) - J_0(\Omega) \quad = \quad & \partial_u J_0(\Omega)[\tilde{u} - u] + \tfrac{1}{2}\partial_u^2 J_0(\Omega)[u^{\mathrm{lin}}(\tilde{\Omega})]^2 \\ & + \partial_u^2 J_0(\Omega)[\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})][u^{\mathrm{lin}}(\tilde{\Omega})] \\ & + \tfrac{1}{2}\partial_u^2 J_0(\Omega)[\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})]^2 + \mathcal{O}\big(\|\tilde{u} - u\|^3_{H^1(\mathcal{D})}\big). \end{aligned}$$

Again we estimate the higher order terms in the second and third rows by the L^1-metric $|\tilde{\Omega}\Delta\Omega|$, where we use $\|\partial_u^2 J_0(\Omega)\| \preceq 1$. Then we reformulate the terms in the first row. Several times we will use that $u, w \in H^2([\mathcal{D}]^\eta)$ (Theorem 2.5), Sobolev's embedding theorem, Hölder's inequality, and the Lax Milgram lemma.

$\|u^{\mathrm{lin}}(\tilde{\Omega})\|_{H^1(\mathcal{D})} \preceq |\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{2d}}$: With r, p, q as in the proof of Proposition 2.6 we have

$$\begin{aligned} \langle \nabla u^{\mathrm{lin}}(\tilde{\Omega}), \nabla v\rangle + \langle c_\Omega u^{\mathrm{lin}}(\tilde{\Omega}), v\rangle &= -\langle (c_{\tilde{\Omega}} - c_\Omega)u, v\rangle \\ &\overset{\text{Hölder } \frac{1}{r}+\frac{1}{p}+\frac{1}{q}=1}{\preceq} (\overline{c} - \underline{c})|\tilde{\Omega}\Delta\Omega|^{\frac{1}{r}}\|u\|_{L^p(\tilde{\Omega}\Delta\Omega)}\|v\|_{L^q(\tilde{\Omega}\Delta\Omega)} \\ &\overset{\text{Theorem 2.4}}{\preceq} (\overline{c} - \underline{c})|\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{2d}}\|u\|_{H^2([\mathcal{D}]^\eta)}\|v\|_{H^1(\mathcal{D})}. \end{aligned}$$

$\|\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})\|_{H^1(\mathcal{D})} \preceq |\tilde{\Omega}\Delta\Omega|^{<\frac{d+6}{2d}}$: First note that due to Sobolev's embedding theorem $H^1(\mathcal{D}) \hookrightarrow L^q(\mathcal{D})$, with

$$q \le \begin{cases} \frac{2d}{d-2} & d = 3 \\ < \infty & d = 2. \end{cases}$$

Then we apply Lax Milgram's lemma to the following term:

$$\begin{aligned} \langle \nabla(\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})), \nabla v\rangle + \langle c_\Omega(\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})), v\rangle &\overset{(1.1)\ \&\ (3.4)}{=} -\langle (c_{\tilde{\Omega}} - c_\Omega)(\tilde{u} - u), v\rangle \\ &\overset{\text{Hölder } \frac{1}{p}+\frac{2}{q}=1}{\preceq} |\tilde{\Omega}\Delta\Omega|^{\frac{1}{p}}\|\tilde{u} - u\|_{L^q(\tilde{\Omega}\Delta\Omega)}\|v\|_{L^q(\tilde{\Omega}\Delta\Omega)} \\ &\overset{\text{Theorem 2.4}}{\preceq} |\tilde{\Omega}\Delta\Omega|^{<\frac{2}{d}}\|\tilde{u} - u\|_{H^1(\mathcal{D})}\|v\|_{H^1(\mathcal{D})} \\ &\overset{\text{Proposition 2.6}}{\preceq} |\tilde{\Omega}\Delta\Omega|^{<\frac{d+6}{2d}}\|u\|_{H^2([\mathcal{D}]^\eta)}\|v\|_{H^1(\mathcal{D})}. \end{aligned}$$

$$\partial_u J_0(\Omega)[\tilde{u}-u] = \langle (c_{\tilde{\Omega}} - c_\Omega)(u + u^{\mathrm{lin}}(\tilde{\Omega})), w\rangle + \mathcal{O}\big(|\tilde{\Omega}\Delta\Omega|^{<\frac{d+4}{d}}\big):$$

$$\begin{aligned}\partial_u J_0(\Omega)[\tilde{u}-u] &\overset{(2.4)}{=} -\langle \nabla(\tilde{u}-u), \nabla w\rangle - \langle c_\Omega(\tilde{u}-u), w\rangle \overset{(1.1)}{=} \langle (c_{\tilde{\Omega}} - c_\Omega)\tilde{u}, w\rangle \\ &= \langle (c_{\tilde{\Omega}} - c_\Omega)(u + u^{\mathrm{lin}}(\tilde{\Omega})), w\rangle + \langle (c_{\tilde{\Omega}} - c_\Omega)(\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})), w\rangle.\end{aligned}$$

Finally we need to to estimate the term $\langle (c_{\tilde{\Omega}} - c_\Omega)(\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})), w\rangle$ following the same arguments and with the same choice for r, p, q as in Proposition 2.6:

$$\begin{aligned}\dots &\overset{\text{Hölder } \frac{1}{r}+\frac{1}{p}+\frac{1}{q}=1}{\leq} && |\tilde{\Omega}\Delta\Omega|^{\frac{1}{r}} |\overline{c} - \underline{c}| \|\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})\|_{L^q(\mathcal{D})} \|w\|_{L^p(\mathcal{D})} \\ &\overset{\text{Theorem 2.4}}{\preceq} && |\tilde{\Omega}\Delta\Omega|^{<\frac{d+2}{2d}} |\overline{c} - \underline{c}| \|\tilde{u} - u - u^{\mathrm{lin}}(\tilde{\Omega})\|_{H^1(\mathcal{D})} \|w\|_{H^2([\mathcal{D}]^\eta)}.\end{aligned}$$

The perimeter term we estimate as in the first order topological expansion. ∎

With the second order expansion at hand we can improve an initial geometry Ω_k, such that the objective functional $J_\alpha(\Omega)$ decreases, when we solve the partial differential equation constraint minimization problem

(3.6)
$$\Omega_{k+1} = \operatorname*{argmin}_{\Omega\in\mathcal{F}_L([\mathcal{D}]^\eta)} \langle (c_\Omega - c_{\Omega_k})(u + u^{\mathrm{lin}}(\Omega)), w\rangle + \tfrac{1}{2}\partial_u^2 J_\alpha(\Omega_k)[u^{\mathrm{lin}}(\Omega)]^2 + \alpha \mathrm{Per}\big(\Omega\Delta\Omega_k\big).$$

The constraint minimization problem is similar to a Newton-type step. Later we will use the solution to the minimization problem to force a topology change in level set methods. Before that, we prove that the constraint minimization problem (3.6) has a solution which is not necessarily unique.

PROPOSITION 3.4. *Let $\alpha > 0$ and $\mathrm{Per}\big(\Omega_k\big) < \infty$; then the minimization problem* (3.6) *has a solution in the finite perimeter (Caccioppoli) sets.*

Proof. First we note that $u^{\mathrm{lin}}(\Omega)$ is uniformly bounded in $H^1(\mathcal{D})$. Therefore also the objective functional of the constraint minimization problem (3.6) is uniformly bounded from below. Hence every $\Omega \in \mathcal{F}_L([\mathcal{D}]^\eta)$ with a finite objective functional of the constraint minimization problem (3.6) has a finite perimeter, i.e., $\mathrm{Per}\big(\Omega\big) < \infty$. As in Proposition 3.2 we conclude from $c_\Omega - c_{\Omega_k} = -2(\chi_{\Omega_k} - \frac{1}{2})\chi_{\Omega\Delta\Omega_k}$ that also $u^{\mathrm{lin}}(\Omega)$ (3.4) just depends on $\Omega\Delta\Omega_k$. Therefore we can again reformulate the minimization problem (3.6) over Ω to a minimization over $\Omega\Delta\Omega_k$ and then switch to $\mathrm{BV}(\mathcal{D}, \{0,1\})$:

$$\min_{p\in\mathrm{BV}(\mathcal{D},\{0,1\})} \big\langle -2(\overline{c} - \underline{c})(\chi_{\Omega_k} - \tfrac{1}{2}) w(u + u^{\mathrm{lin}}(p)), p\big\rangle + \tfrac{1}{2}\partial_u^2 J_\alpha(\Omega_k)[u^{\mathrm{lin}}(p)]^2 + \alpha|p|_{\mathrm{BV}}.$$

Note that $u^{\mathrm{lin}}(p)$ solves for all $v \in H^1_{0,D}(\mathcal{D})$:

$$\langle \nabla u^{\mathrm{lin}}(p), \nabla v\rangle + \langle c_{\Omega_k} u^{\mathrm{lin}}(p), v\rangle = \big\langle -2(\overline{c} - \underline{c})(\chi_{\Omega_k} - \tfrac{1}{2}) p u_{\Omega_k}, v\big\rangle.$$

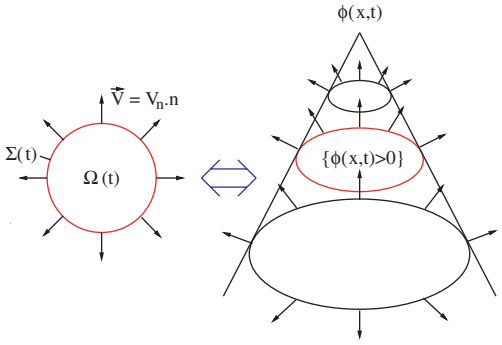
Following the arguments of Proposition 3.2 provides a minimizing sequence $p_i \in \mathrm{BV}(\mathcal{D}, \{0,1\})$ converging weak* to $p \in \mathrm{BV}(\mathcal{D})$ and strongly in $L^1(\mathcal{D})$. From the strong convergence of $p_i \to p$ in $L^1(\mathcal{D})$ and Lax Milgram's lemma, we conclude strong convergence of $u^{\mathrm{lin}}(p_i) \to u^{\mathrm{lin}}(p)$ in $H^1(\mathcal{D})$. Finally we deduce from the lower semicontinuity of $|\,.\,|_{\mathrm{BV}}$ that $p \in \mathrm{BV}(\mathcal{D}, \{0,1\})$ is a minimizer, and therefore $\Omega_{k+1} = \big(\Omega_k \setminus \{p = 1\}\big) \cup \{(1 - \chi_{\Omega_k})p = 1\}$ is a minimizer of (3.6). ∎

In principle, minimization problem (3.6) is as difficult as the original problem, but first we do not need to solve it too accurately; it is enough to correct the first order solution. Second, it might be much easier to construct efficient solvers for problems with the partial differential equation constraint that are linear in $\chi_{\Omega\Delta\Omega_k}$. For example, in imaging it is possible to reformulate problems in $\mathrm{BV}(\{0,1\})$ to problems in $\mathrm{BV}([0,1])$ (cf. Burger and Hintermüller [17]). Furthermore there is a well-developed theory for BV regularization for linear problems, linear in χ_Ω (cf. Osher et al. [39]).

4. Numerical solution. In this section we provide a brief introduction into level set methods (cf. Osher and Fedkiw [40]). Then we use the so-called phase I/II method (cf. Allaire et al. [2], Burger, Hackl, and Ring [16], Hintermüller [32]) to incorporate the steepest descent- (3.3) (respectively, the Newton-) type (3.6) step into level set methods. Furthermore we provide details about how we solved the minimization problems (3.3) and (3.6) numerically.

4.1. Level set methods. The main idea of level set methods is to represent an evolving front $\Sigma(t) = \partial\Omega(t)$ as the zero level set of a continuous function, i.e.,

$$\begin{aligned}\Omega(t) &= \big\{x \in \mathcal{D} \,\big|\, \phi(x,t) > 0\big\},\\ \Sigma(t) &= \big\{x \in \mathcal{D} \,\big|\, \phi(x,t) = 0\big\}.\end{aligned}$$



The geometric motion of the level set with normal velocity $\vec{V} = V_n.n$ can equivalently be described by the propagation of the level set function ϕ which solves the Hamilton–Jacobi equation

$$\frac{\partial\phi}{\partial t} - V_n|\nabla\phi| = 0 \qquad \text{in } \mathbb{R}^d \times \mathbb{R}^+. \tag{4.1}$$

The Hamilton–Jacobi equation (4.1) for ϕ is the analogon to the flow equation (2.2).

As already mentioned in section 2.1 the crucial point is an appropriate choice of the velocity, such that the objective functional $J_\alpha(\Omega)$ (1.2) decreases. This resembles the classical speed method in shape optimization (cf. Delfour and Zolésio [22]). The weak formulation via the level set methods allows for more general evolutions and for topological changes such as splitting, merging, and vanishing of domains.

From the shape derivative $J'_\alpha(\Omega)[V_n]$ of the objective functional (1.2)

$$J'_\alpha(\Omega)[V_n] = \int_{\partial\Omega} \big([\![c_\Omega]\!]uw + \alpha\kappa\big)V_n\,ds,$$

we can deduce normal velocities V_n such that the objective functional (1.2) decreases. The simplest choice would be $V_n = -\big([\![c_\Omega]\!]uw + \alpha\kappa\big)$. This choice results in a very regular velocity. According to Burger [14] a preconditioned velocity $V_n \in H^{-\frac{1}{2}}(\partial\Omega)$ is more appropriate and results into faster convergence. This $H^{-\frac{1}{2}}(\partial\Omega)$ velocity can be set to $V_n = [\![\frac{\partial\psi}{\partial n}]\!]$, where ψ solves the subproblem

$$\langle\psi, v\rangle = -\left\langle [\![c_\Omega]\!]uw + \alpha\kappa, \left[\!\!\left[\frac{\partial v}{\partial n}\right]\!\!\right]\right\rangle_{\partial\Omega} \qquad \forall\, v \in H^1_0(\mathcal{D}).$$

We solve the level set equation (4.1) with a standard fifth order weighted ENO scheme for the spatial and a third order explicit Runge–Kutta scheme for the time discretization (cf. Jiang and Peng [35]).

4.2. Phase I/II algorithm. In Burger, Hackl, and Ring [16] the topological derivatives were incorporated as an extra source term in the level set methods:

$$\frac{\partial \phi}{\partial t} - V_n|\nabla \phi| + \mathcal{S} = 0, \qquad V_n = V_n\big(J'_\alpha(\Omega)\big), \quad \mathcal{S} = \mathcal{S}\big(d_\tau J_0(\Omega)\big).$$

An inherent time step control in the level set methods guaranteed that the topological change was such that the objective function decreased. Another method suggested by Allaire et al. [2], Burger, Hackl, and Ring [16], and Hintermüller [32] is to restart the level set evolution after a fixed time (or due to clever criteria) with an initial level set function generated by the last time step plus the topological change due to the topological derivatives. This algorithm was phrased phase I/II algorithm by Hintermüller [32], where phase I corresponds to the algorithm for the topology change and phase II to the classical level set evolution. Let us put this into a more mathematical formulation: Let $(T_k)_{k\in\mathbb{N}_0}$ be a series of time steps, either fixed or generated due to a termination criterion in the level set evolution. Set $\phi_{-1}(T_{-1})$ to an initial guess (usually no material or material everywhere). Then the phase I/II algorithm is given by

$$\begin{aligned} \phi_k(t=0) \qquad\qquad &= \mathcal{S}(d_\tau J_0(\Omega_{k-1}), \phi_{k-1}(T_{k-1})), \\ \frac{\partial \phi_k}{\partial t} + V_n(J'_\alpha)|\nabla \phi_k| &= 0, \end{aligned}$$

where $\mathcal{S}(.,.)$ describes phase I; i.e., the algorithm that forces other topology changes than splitting, merging, and vanishing. Most implementations of phase I do not use higher order estimates for the topological derivative and force a topology change whenever the topological derivative is negative or smaller than a certain threshold criterion as (4.3). Therefore the objective functional $J_\alpha(\Omega)$ and even $J_0(\Omega)$ might increase. Exceptional to this practice is the line searchlike algorithm proposed by Hintermüller [32] that guarantees descent in $J_0(\Omega)$. An extension of the line search algorithm to problems with perimeter constraints $J_\alpha(\Omega)$ is possible with the methods developed in this paper.

The idea is to use the first (respectively, second) order topological expansion to construct phase I and therefore guarantee a decrease in the objective functional $J_\alpha(\Omega)$.

Phase I. $\mathcal{S}(J_\alpha, \phi_{k-1}(T_{k-1})) := b_{\Omega_k}$; Ω_k solution to (3.3) (respectively, (3.6)). With b_Ω we denoted the signed distance function defined by

$$b_\Omega(x) = \inf_{y\in\Omega} |x-y| - \inf_{y\in C(\Omega)} |x-y|.$$

In the following we describe briefly how we solve (3.3) (respectively, (3.6)) numerically.

Steepest descent-type topology changes. First we recall the auxiliary minimization problem (3.3) in its equivalent reformulation given, in Proposition 3.2:

(4.2)
$$\Omega_{k+1}\Delta\Omega_k = \operatorname*{argmin}_{\Omega\Delta\Omega_k\in\mathcal{F}_L([\mathcal{D}]^\eta)} \underbrace{\langle d_\tau J_0(\Omega_k), \chi_{\Omega\Delta\Omega_k}\rangle + \alpha \mathrm{Per}\big(\Omega\Delta\Omega_k\big) + c|\Omega\Delta\Omega_k|^{<\frac{d+2}{2}}}_{=:\mathcal{G}^1_{\Omega_k}(\Omega\Delta\Omega_k)},$$

where we used that $d_\tau J_0(\Omega_k) = -2(\overline{c}-\underline{c})(\chi_{\Omega_k}-\frac{1}{2})uw$. Ω_{k+1} is then given by $\Omega_{k+1} = \Omega_k \backslash (\Omega_{k+1}\Delta\Omega_k) \cup (C(\Omega_k)\cap(\Omega_{k+1}\Delta\Omega_k))$. As soon as the solutions to the direct problem u (1.1) and the adjoint problem w (2.4) are given, we can solve the minimization problem (4.2) without solving further partial differential equations. Furthermore note that the objective functional in the auxiliary minimization problem (3.3) over Ω was not continuous due to the term $\mathrm{Per}\big(\Omega\Delta\Omega_k\big)$. This is not the case any more for the objective functional $\mathcal{G}^1(\Omega\Delta\Omega_k)$, which is even shape differentiable:

$$\mathcal{G}^1_{\Omega_k}{}'(\Omega\Delta\Omega_k)[V] = \int_{\partial(\Omega\Delta\Omega_k)} \left(d_\tau J_0(\Omega_k) + c\left(< \frac{d+2}{2} \right) |\Omega\Delta\Omega_k|^{<\frac{d}{2}} + \alpha\kappa \right) V.n \, ds.$$

This allows us to use level set methods to solve the minimization problem (4.2). An obvious choice for the velocity is $V_n = -\big(d_\tau J_0(\Omega_k) + c\big(< \frac{d+2}{2}\big)|\tilde{\Omega}\Delta\Omega|^{<\frac{d}{2}} + \alpha\kappa\big)$. To provide an appropriate initial guess either we solve the minimization problem (3.3) for $\alpha = 0$ or we use the classical guess

$$\big\{\chi_{\Omega_k} d_\tau J_0(\Omega_k) < r \min(\underline{m}_{\chi_{\Omega_k}}, 0)\big\} \cup \big\{(1-\chi_{\Omega_k}) d_\tau J_0(\Omega_k) < r \min(\underline{m}_{1-\chi_{\Omega_k}}, 0)\big\}, \tag{4.3}$$

with $\underline{m}_\chi = -\| \min(\chi d_\tau J_0(\Omega_k), 0)\|_{L^\infty(\mathcal{D})}$ and $r \in [0,1]$.

Note that the solution to the minimization problem (4.2) with $\alpha = 0$ needs to fulfill

$$d_\tau J_0(\Omega_k)|_{\partial(\Omega\Delta\Omega_k)} + c\left(< \frac{d+2}{d} \right) |\Omega\Delta\Omega_k|^{<\frac{d}{2}} = 0.$$

Therefore we are searching for a level set of $-\big(> \frac{d}{c(d+2)}\big) d_\tau J_0(\Omega_k)$ whose enclosed volume to the power of $< \frac{d}{2}$ coincides with the value of the level set. The volume $|\Omega\Delta\Omega_k|$ enclosed by the level set $-\big(> \frac{d}{c(d+2)}\big) d_\tau J_0(\Omega_k)$ is monotonically (not necessarily continuously) decreasing to zero. Therefore a simple bisection algorithm can provide an outer (inner) approximation for the minimization problem (3.3) with $\alpha = 0$. This can be used as the initial guess for the above minimization problem with $\alpha \neq 0$.

Both the classical guess as well as the solution to the above minimization problem with $\alpha = 0$ are based on the level set of the topological derivative. In our numerical implementation we use the classical guess with $r = 0.7$. Both guesses might provide many topology changes at once and/or very rough topologies which might increase the original objective functional J_α. Therefore they are usually not very well suited as an initial guess for level set methods applied to the original problem (cf. Hackl [30]).

Newton-type topology changes. First we recall the minimization problem (3.6) but in its equivalent reformulation developed in Proposition 3.4:

$$\Omega_{k+1}\Delta\Omega_k = \operatorname*{argmin}_{\Omega\Delta\Omega_k \in \mathcal{F}_L([\mathcal{D}]^\eta)} \underbrace{\begin{array}{c} \langle -2(\overline{c}-\underline{c})(\chi_{\Omega_k}-\frac{1}{2})(u+u^{\mathrm{lin}}(\Omega\Delta\Omega_k))w, \chi_{\Omega\Delta\Omega_k}\rangle \\ +\frac{1}{2}\partial_u^2 J_\alpha(\Omega_k)[u^{\mathrm{lin}}(\Omega\Delta\Omega_k)]^2 + \alpha\mathrm{Per}\big(\Omega\Delta\Omega_k\big) \end{array}}_{=:\mathcal{G}^2_{\Omega_k}(\Omega)} . \tag{4.4}$$

Note that here $u^{\mathrm{lin}}(\Omega\Delta\Omega_k)$ is equivalently defined by for all $v \in H^1_{0,D}(\mathcal{D})$:

$$\langle \nabla u^{\mathrm{lin}}(\Omega\Delta\Omega_k), \nabla v\rangle + \langle c_\Omega u^{\mathrm{lin}}(\Omega\Delta\Omega_k), v\rangle = \langle 2(\overline{c}-\underline{c})(\chi_{\Omega_k}-\tfrac{1}{2})\chi_{\Omega\Delta\Omega_k} u_k, v\rangle.$$

Minimization problem (4.4) has a partial differential equation as a constraint. Hence it is as difficult to treat as the original minimization problem of $J_\alpha(\Omega)$ (1.2).

One might argue that there is no point in solving the Newton-type minimization problem but to just perform phase I with the steepest descent-type method and then proceed with the level set evolution of the original minimization problem with objective functional J_α. This argument is true because we do not have efficient solvers at hand that exploit the special structure of the constraint minimization problem where the partial differential equation constraint is $u^{\mathrm{lin}}(\Omega\Delta\Omega_k)$ is linear in $\chi_{\Omega\Delta\Omega_k}$. Algorithms that aim in this direction are known in imaging (cf. Burger and Hintermüller [17], Osher et al. [39]) but are not yet applicable to our problem. Furthermore note that the above argument would also apply to Newton's method in a functional analytic setting. There it is known that Newton-type iterations have quadratic convergence rates, whereas steepest descent-type iterations have linear rates. The better convergence comes at the price that one Newton iteration is usually computationally much more expansive than one steepest descent-type iteration. This effect is especially observed in minimization problems with partial differential equations as a constraint. Here the steepest descent-type methods often perform equally well, in terms of total computational time consumed, as Newton-type methods.

Our task is to solve the above shape optimization problem, and clearly we could use level set methods for that. To distinguish phase I with Newton-type iterations from phase II we decided to use a phase field approach to solve the above minimization problem. Again it might be much more efficient to apply this approach directly to the original shape optimization problem (see Hackl [30] for a comparison of these methods), but this is not the point of this paper. We focus on the expansion of first and second orders and show their applicability.

The phase field approach is based on the equivalent formulation of the above minimization problem in the space $\mathrm{BV}(\mathcal{D},\{0,1\})$ that we already met in the proof of Proposition 3.4. In the phase field approach the minimization problem, formulated in $\mathrm{BV}(\mathcal{D},\{0,1\})$, is relaxed, in the framework of Γ-convergence (cf. Bourdin and Chambolle [12]) to a Hilbert space problem, namely:

$$p_{k+1} = \operatorname*{argmin}_{p\in H_0^1(\mathcal{D})} \left\langle -2(\overline{c}-\underline{c})(\chi_{\Omega_k}-\tfrac{1}{2})w(u+u^{\mathrm{lin}}(p)),p\right\rangle + \tfrac{1}{2}\partial_u^2 J_0(\Omega_k)[u^{\mathrm{lin}}(p)]^2 + \left(\epsilon\|\nabla p\|^2_{L^2(\mathcal{D})} + \frac{\alpha^2}{\epsilon}\int_{\mathcal{D}} W_N(p)\,dx\right).$$

$W_N(.)$ is a normalized double well potential, with $W_N(0)=W_N(1)=0$, $W_N(s)>0, s\in\mathbb{R}\setminus\{0,1\}$, and $2\int_0^1\sqrt{W_N(s)}\,ds=1$.

The double well potential on one hand forces p to approach $\{0,1\}$ when $\epsilon\to 0$, whereas the H^1-seminorm of p requires smooth solutions. With $\epsilon\to 0$ the H^1-seminorm term forces the solution to switch smoothly from 0 to 1 in an ϵ-region. Altogether these two terms approximate with $\epsilon\to 0$ the perimeter term. The minimization problem is now posed in a Hilbert space setting, and one can use steepest descent- or Newton-type methods to solve this problem. For our numerical tests we chose

$$W_N(s) = \begin{cases} \left(\frac{4}{\pi}\right)^2 s(1-s) & s\in[0,1],\\ \infty & \text{otherwise,}\end{cases}$$

and perform a Gauss–Newton algorithm implemented as SQP. For details about the implementation of the phase field method see Hackl [30]. We will discuss only briefly the choice of ϵ.

From the theoretical point of view ϵ should be very small to approximate the original problem best, but numerically there needs to be a relation that connects $\frac{\epsilon}{\alpha}$ to the mesh size h. Practical experience led us to set this relation to

$$\frac{\epsilon}{\alpha} = \tau h, \qquad \tau \geq 2.$$

Furthermore when we start the optimization with a very small ϵ, then the double well potential provides a too-strict restriction, and the algorithm cannot perform topology changes other than merging, splitting, and vanishing. In this case the algorithm behaves more like classical level set methods, and therefore it is better to use a level set method, due to its clear, reliable, and simple implementation. Hence ϵ should be chosen large at the beginning of the iterations to allow for easy topology changes and get gradually closer to the smallest possible value for ϵ to get sharp interfaces.

Final remark. In our implementation for both the steepest descent- as well as the Newton-type phase I algorithms, we ensured that only the level set method (phase II) is responsible for evolving the boundary $\partial\Omega$. We did this by minimizing (4.2), (3.6) over $\Omega\Delta\Omega_k \in \mathcal{F}_L\big([\mathcal{D}]^\eta \cap [\partial\Omega_k]^\eta\big)$ instead of $\Omega\Delta\Omega_k \in \mathcal{F}_L([\mathcal{D}]^\eta)$. The main reason for that is that we believe that phase I should be responsible for topology changes only. The evolution of the boundary $\partial\Omega_k$ is usually much more efficient and reliable using level set methods (phase II). As a side effect of this restriction we have the equality $\mathrm{Per}\big(\Omega\big) - \mathrm{Per}\big(\Omega_k\big) = \mathrm{Per}\big(\Omega\Delta\Omega_k\big)$ instead of the inequality (3.1).

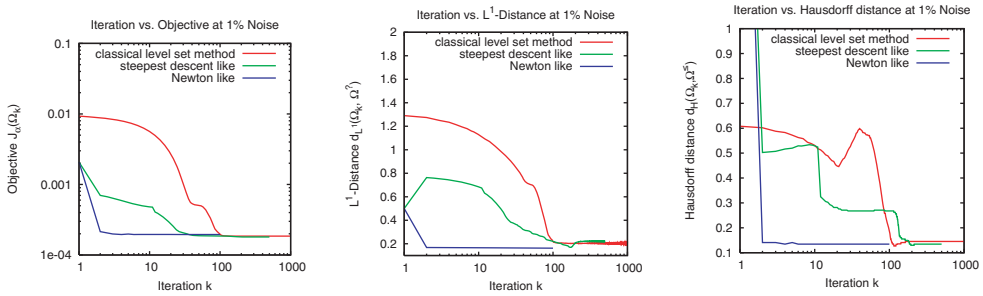
5. Numerical results. In this section we compare the classical level set method to the level set method proposed in this paper that incorporates steepest descent-type (4.2) and Newton-type (4.4) topology changes. For a comparison to other methods see Hackl [30]. We just restrict our attention to problems with more than one connected component, namely, to the identification of two ellipses and of an elliptic hole in another ellipse. The two ellipse case we consider for full measurements, i.e., $\Gamma_M = \mathcal{D}$, as well as for boundary measurements, i.e., $\Gamma_M = \Gamma_N$. Just the elliptic hole in an ellipse case we consider for full measurements only.

We perform all numerical tests on a fixed domain $\mathcal{D} = [-1, 1]^2$. To avoid inverse crime (cf. Colton and Kress [21, p. 133]), we generate the data on a different grid (finer mesh and higher order basis functions) and perturb it with 1% Gaussian noise, measured in the $\|\,.\,\|_{L^2(\Gamma_M)}$-norm. We use 1% noise because we expect the numerical error of our discretization to be of the same magnitude.

We provide graphs (Figures 5.1, 5.2, 5.3) that show the iteration number versus objective functional $J_\alpha(\Omega_k)$, L^1-distance $d_{L^1}(\Omega_k, \Omega^\dagger)$, and Hausdorff distance $d_H(\Omega_k, \Omega^\dagger)$:

$$\begin{aligned} d_{L^1}(\Omega, \tilde{\Omega}) &:= |\Omega\Delta\tilde{\Omega}|, \\ d_H(\Omega, \tilde{\Omega}) &:= \max\big(\, \sup_{x\in\Omega} \inf_{y\in\tilde{\Omega}} |x-y|, \sup_{y\in\tilde{\Omega}} \inf_{x\in\Omega} |x-y| \,\big). \end{aligned}$$

To visualize the evolution of the geometry for each algorithm, we present a series of pictures (see Figures 5.4, 5.5, 5.6), starting with the first iteration up to the final solution (note the iteration numbers in each row do not coincide). The pictures are arranged such that each column represents the evolution for one algorithm: namely, the left column represents the classical level set method, the middle column represents the level set method with incorporated steepest descent-type topology change, and the right column represents the level set method with incorporated Newton type topology change.



(a) Iteration vs. Objective (b) Iteration vs. L^1-Distance (c) Iteration vs. Hausdorff

FIG. 5.1. *Two ellipses,* $\Gamma_M = \mathcal{D}$*: Iteration vs.* $J_\alpha(\Omega_i)$, $d_{L^1}(\Omega_i, \Omega^\dagger)$, $d_H(\Omega_i, \Omega^\dagger)$.

Finally we present in Table 5.1 the numbers of iterations needed for each method to get to the final solution, the corresponding values of the objective functional, the L^1-distance and the Hausdorff-distance, as well as the number of needed partial differential equation solver calls. For Newton-type phase I steps we solve a Newton system, implemented as SQP with an additional feasibility step. In our implementation one SQP call is approximately equivalent to 11 partial differential equation calls, when using also sparse direct solvers for the SQP system.

Our theoretic results for the topological derivative (Theorem 2.6) as well as for the steepest descent-type (3.3) and the Newton-type (3.6) topology changes are valid just inside the domain $\mathcal{D}$, and all constants depend on the distance to the boundary $\partial\mathcal{D}$.

(c) Two ellipses, $\Gamma_M = \Gamma_N$.

This was due to the use of the interior regularity result (Theorem 2.5). Therefore we restrict our algorithm to the domain $[\mathcal{D}]^{0.1} = [-0.9, 0.9]^2$. Furthermore we perform phase I just on the set $[\mathcal{D}]^{0.1} \cap [\partial\Omega_k]^{0.1}$ to guarantee a disjoint set of influence for phases I and II.

Our objective functional $J_\alpha(\Omega)$ incorporates perimeter regularization. To get a proper choice for the regularization parameter α we chose α such that the classical level set method, started at the exact solution (with 1% noisy data), does not iterate away from the exact solution too far. A too-large α would not allow us to achieve topology changes in our algorithms, and a too-small α does not regularize the problem enough. We found $\alpha = 10^{-5}\|\hat{u}\|^2_{L^2(\Gamma_M)}$ to be a proper choice for all examples.

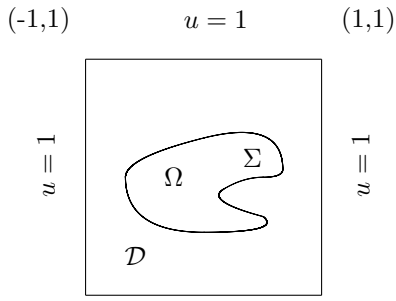
As an initial guess we take for all of our test examples a circle with radius $r = 0.7$ and centered at the origin $(0, 0)$ for the classical level set method, while we started with no material for the level set method incorporating steepest descent-type (respectively, Newton-type) topological changes.

For the level set method incorporating a steepest descent-type topology change we solve (4.2) after every 10th classical level set iterations, while for Newton-type topology changes we solve (4.4) after every 50th classical level set iteration.

In our implementation we did not implement any termination criteria except a maximal number of iterations. This is because our implementation of the L^1-distance and Hausdorff distance are not accurate enough to allow classical termination criteria from optimization terminate when $d_{L^1}(\Omega_{k+1}, \Omega_k)$ is small enough. The number of iterations needed to get to the optimum was estimated in a postprocessing step looking for the minimum in the L^1-distance $d_{L^1}(\Omega_k, \Omega^\dagger)$.

5.1. Full measurements $\Gamma_M = \mathcal{D}$. In this section we consider the identification of two ellipses and an ellipse with an elliptic hole from full measurements, i.e., $\Gamma_M = \mathcal{D}$. The full measurement case is mildly ill-posed, something like twice differentiation, and provides a lot of data. Therefore we can expect good results for all algorithms. Most challenging is probably the ellipse with an elliptic hole. For this case we expect that the classical level set method does not perform a topology change.

The partial differential equations (1.1), (2.4) are described by



$$
\begin{aligned}
-\Delta u + \chi_\Omega u &= 0 && \text{in } \mathcal{D},\\
u &= 1 && \text{on } \Gamma_D,\\
\frac{\partial u}{\partial n} &= 0 && \text{on } \Gamma_N,\\
-\Delta w + \chi_\Omega w &= -(u-\hat{u}) && \text{in } \mathcal{D},\\
w &= 0 && \text{on } \Gamma_D,\\
\frac{\partial w}{\partial n} &= 0 && \text{on } \Gamma_N.
\end{aligned}
$$

Measurements.

$$
\begin{aligned}
\hat{u} &= u|_{\mathcal{D}} + 1\%\ \text{noise} \quad \text{in } L^2(\mathcal{D}),\\
J_\alpha(\Omega) &= \tfrac{1}{2}\|u-\hat{u}\|^2_{L^2(\mathcal{D})} + \alpha \mathrm{Per}\big(\Omega\big).
\end{aligned}
$$

Due to the Dirichlet boundary conditions $u = 1$ on $\partial\mathcal{D}$ the solution $u(\Omega^\dagger)$ is close to the solution of the system without material $u(\emptyset) = 1$. Hence the subproblem (3.4) approximates the original problem (1.1) quite well, and we can expect that the level set method, incorporating Newton-type topology changes, performs very well. Indeed we will see that already the first solution to (3.6) provides a very good initial guess and predicts the correct topology of the desired geometry.

Two ellipses, $\boldsymbol{\Gamma_M = \mathcal{D}}$. We compare the classical level set method to a level set method incorporating a steepest descent-type topology change (4.2) and a level set method incorporating a Newton-type topology change (4.4). As expected all three methods perform very well and approximate the exact geometry quite accurately (Figure 5.4, last row).

Classical level set method (Figure 5.4, 1st column). The algorithm performs very well and even realizes the necessary topology change, by splitting. The number of iterations needed to approach the solution is moderate (see Table 5.1a). The distance to the exact geometry in both the L^1- and the Hausdorff metrics is reasonably small (see Figure 5.1).

Steepest descent-type topology change (Figure 5.4, 2nd column). The classical level set method incorporated into the steepest descent-type topology changes (4.2) does not predict the correct topology within the first solution to (4.2). It needs a second call (Figure 5.4, 2nd row, 2nd column) to generate a further topology change. Even when this topology change does not result in a substantial decrease in the objective functional (Figure 5.1a), the topological change can be observed in the jump of the Hausdorff distance $d_H(\Omega_k, \Omega^\dagger)$ (Figure 5.1c). Interestingly this topology change adds two new geometries at the correct position but does not try to reduce the wrong geometry. Further calls of (3.3) do not cause any changes of the geometry. The only topology change that occurs happens during the level set evolution where the above two geometries merge together. Even when the level set method incorporating a steepest descent-type topology change almost reaches the minimum of the objective functional $J_\alpha(\Omega)$ before the classical level set method (Figure 5.1a), it needs more iterations until it stays at the final geometry (see Table 5.1a).

Newton-type topology change (Figure 5.4, 3rd column). The first Newton-type topology change (3.6) already predicts the correct topology (Figure 5.4, 1st row, 3rd column). Also the objective functional $J_\alpha(\Omega)$ as well as the L^1- and Hausdorff distances (see Figure 5.1) get very close to their optimum and need just a few correction steps with the classical level set method. This is not too unexpected because the subproblem (3.4) approximates the nonlinear partial differential equation (1.1) very accurately. Although the number of iterations to approach the solution is very low,

note that one solution of (3.6) is more expansive (see Table 5.1a). Nonetheless the phase I/II with Newton-type topology changes is significantly faster than the other methods discussed above.

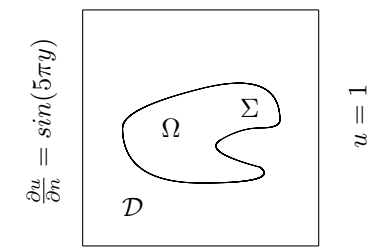
Elliptic hole in ellipse, $\boldsymbol{\Gamma_M = \mathcal{D}}$. This geometry is more challenging, and we expect that the classical level set method gets stuck in a local minima and does not predict the correct geometry. Here the power of the other two methods should show up. Again the subproblem (3.4) approximates the original partial differential equation (1.1) very well, and we can expect that the level set method incorporating Newton-type topology changes perform very well within the first solution of (3.6).

Classical level set method (Figure 5.5, 1st column). During the level set evolution the topology does not change although the objective functional $J_\alpha(\Omega)$ (Figure 5.2a) gets close to its minimum. Nonetheless the identified geometry does not look too bad (visually). The number of iterations doubled but is still moderate (see Table 5.1b).

Steepest-descent type topology change (Figure 5.5, 2nd column). As before the steepest descent-type topology change (3.3) does not generate the correct topology within its first call but needs two calls (Figure 5.5, 2nd row, 2nd column). Further solver calls of (3.3) do not force further changes. Hence after the second solution call of (3.3) we evolve the geometry just by the classical level set method. This can be observed in the L^1-distance as well as in the Hausdorff distance (Figures 5.2b, 5.2c) which have a jump at iteration 12. We are at the final solution at approximately 40 level set iterations, which makes an equivalent, due to 3 times calling a solver for (3.3), of 50 classical level set iterations in total (see Table 5.1b). In this test the steepest descent-type topology change results into the fastest solution.

Newton-type topology change (Figure 5.5, 3rd column). Again the first call to the Newton-type topology change (4.4) already predicts the topology correct (see Figure 5.5, 1st row, 3rd column). This time the objective functional $J_\alpha(\Omega)$ as well as the L^1- and Hausdorff distances (Figure 5.2) are not yet too close to their optimum. Hence we additionally need 20–40 classical level set iteration to end at the final solution. Summing up the level set iterations and the SQP equivalent for one solution of (4.4), the total cost is about 75–95 classical level set iterations. Therefore the algorithm is severely faster than the classical level set method but takes twice the time of the level set method incorporating steepest descent-type topology changes (see Table 5.1b).

5.2. Boundary neasurements $\boldsymbol{\Gamma_M = \Gamma_N}$. Finally we consider the identification of two ellipses from just one set of boundary measurements, i.e., $\Gamma_M = \Gamma_N$. To deal with boundary measurements we have to change slightly our boundary conditions for the partial differential equations (1.1), (2.4), namely,



$$
\begin{aligned}
-\Delta u + \chi_\Omega u &= 0 && \text{in } \mathcal{D},\\
u &= 1 && \text{on } \Gamma_D,\\
\frac{\partial u}{\partial n} &= h && \text{on } \Gamma_N,\\
-\Delta w + \chi_\Omega w &= 0 && \text{in } \mathcal{D},\\
w &= 0 && \text{on } \Gamma_D,\\
\frac{\partial w}{\partial n} &= -(u-\hat{u}) && \text{on } \Gamma_N.
\end{aligned}
$$

Measurements.

$$
\begin{aligned}
\hat{u} &= u|_{\Gamma_N} + 1\% \text{ noise} \quad \text{in } L^2(\Gamma_N),\\
J_\alpha(\Omega) &= \tfrac{1}{2}\|u-\hat{u}\|^2_{L^2(\Gamma_N)} + \alpha \mathrm{Per}\big(\Omega\big).
\end{aligned}
$$

Geometric inverse problems with boundary measurements are supposed to be severely ill-posed. Severely ill-posed problems are extremely challenging to every algorithm, and usually one cannot expect too good results for them. Especially topology changes are extremely difficult to achieve. We expect that the classical level set method is not able to perform the desired topology change, even when it managed it for the full measurements case.

Due to the Neumann boundary conditions the solution u to the above system is not close to the solution $u(\emptyset) = 1$ (solution without material). Hence the subproblem (3.4) does not approximate the original problem (1.1) very well (when starting with no material). As a consequence of this the first step of a Newton-type topology change (4.4) shall not perform as good as in the full measurement cases.

Two ellipses $\boldsymbol{\Gamma_M = \Gamma_N}$. Once more we compare the classical level set method to a level set method incorporating a steepest descent-type topology change (4.2) and a level set method incorporating a Newton-type topology change (4.4).

Classical level set method (Figure 5.6, 1st column). As predicted, the classical level set method does not split. Nonetheless the finally identified geometry does not look too bad (visually). The number of iterations needed, until it approaches its optimum, is very high, but this is not uncommon for severely ill-posed problems. Although we do not get the correct topology, the objective functional $J_\alpha(\Omega)$ (Figure 5.3a) gets close to its minimum.

Steepest descent-type topology change (Figure 5.6, 2nd column). As before the classical level set method incorporating steepest descent-type topology changes (4.2) does not predict the correct topology within the first solution to (4.2). Iterating further and calculating several times the solution to (4.2), the algorithm forces further topology changes, some of them correctly located, some of them not (Figure 5.6, 1st column). Nonetheless the objective functional $J_\alpha(\Omega)$ decreases, as predicted by the theory. After many iterations the algorithm stops with four nonconnected components, where two are correctly located and the others are not.

Newton-type topology change (Figure 5.6, 3rd column). Finally we consider the classical level set method incorporating Newton-type topology changes (4.4). Already the first calculation of the solution to (4.4) predicts the correct number of connected components, and later solution calls of (4.4) do not force any additional topology changes. As for the steepest descent-type topology changes, the first solution to (4.4) does not look too good, but it is enough for the classical level set method to approach the exact solution. For the final result presented in Figure 5.6, 3rd column, 4th row, the objective functional and also the L^1- and Hausdorff distances (Figure 5.3) would decrease further. Hence, iterating further would still improve the result. Nonetheless we terminated the algorithm, because the number of iterations is already very high, and we can already see from Figure 5.6, 3rd column, that the algorithm behaves better than the two other.

6. Conclusion. In this paper we presented a way to generalize the notion of topological derivatives such that we can also deal with perimeter-regularized objective functionals. The generalization allows one to formulate auxiliary minimization problems similar to steepest descent-type and Newton-type minimization problems, such that a descent in the objective functional is guaranteed. This is in contrast to classical topological derivatives, where one gets just an indicator of where to force topology changes, but the indicator does not guarantee a descent in the objective functional.

We incorporated this generalization of topological derivatives into the classical level set method and showed by means of some examples its applicability. While, in some cases, the classical level set method failed to predict the correct topology, the suggested level set methods with incorporated steepest descent-type and Newton-type topology changes succeed to get the correct topology or at least forced topology changes.

The numerical results for the specific example presented in this paper were quite promising, and an extension to more complicated problems might be of interest.

Acknowledgments. I thank Dr. Martin Burger (University of Linz) for many useful discussions. My gratitude goes also to the two anonymous referees whose comments improved the presentation of the paper severely.

CONVERGENCE ANALYSIS OF A MIXED FINITE VOLUME SCHEME FOR AN ELLIPTIC-PARABOLIC SYSTEM MODELING MISCIBLE FLUID FLOWS IN POROUS MEDIA*

CLAIRE CHAINAIS-HILLAIRET† AND JÉRÔME DRONIOU‡

Abstract. We study a finite volume discretization of a strongly coupled elliptic-parabolic PDE system describing miscible displacement in a porous medium. We discretize each equation by a finite volume scheme which allows a wide variety of unstructured grids (in any space dimension) and gives strong enough convergence for handling the nonlinear coupling of the equations. We prove the convergence of the scheme as the time and space steps go to 0. Finally, we provide numerical results to demonstrate the efficiency of the proposed numerical scheme.

Key words. finite volume methods, porous medium, miscible fluid flow, convergence analysis, numerical tests

1. Introduction.

1.1. Miscible displacement in porous media.

The mathematical model for the single-phase miscible displacement of one fluid by another in a porous medium, in the case where the fluids are considered incompressible, is an elliptic-parabolic coupled system [2, 4]. Let Ω be a bounded domain of $\mathbb{R}^d$ ($d = 2$ or 3) representing the reservoir and let $(0,T)$ be the time interval. The unknowns of the problem are p the pressure in the mixture, $\mathbf{U}$ its Darcy velocity, and c the concentration of the invading fluid.

We denote by $\Phi(x)$ and $\mathbf{K}(x)$ the porosity and the absolute permeability tensor of the porous medium, $\mu(c)$ the viscosity of the fluid mixture, $\widehat{c}$ the injected concentration, and q^+ and q^- the injection and the production source terms. If we neglect gravity, the model reads

$$\begin{cases} \operatorname{div}(\mathbf{U}) = q^+ - q^- & \text{in } (0,T)\times\Omega, \\ \mathbf{U} = -\dfrac{\mathbf{K}(x)}{\mu(c)}\nabla p & \text{in } (0,T)\times\Omega, \end{cases} \tag{1}$$

$$\Phi(x)\partial_t c - \operatorname{div}(D(x,\mathbf{U})\nabla c - c\mathbf{U}) + q^- c = q^+\widehat{c} \quad \text{in } (0,T)\times\Omega, \tag{2}$$

where D is the diffusion-dispersion tensor including molecular diffusion and mechanical dispersion

$$D(x,\mathbf{U}) = \Phi(x)\Big(d_m\mathbf{I} + |\mathbf{U}|\Big(d_l E(\mathbf{U}) + d_t(\mathbf{I} - E(\mathbf{U}))\Big)\Big) \tag{3}$$

with $\mathbf{I}$ the identity matrix, d_m the molecular diffusion, d_l and d_t the longitudinal and transverse dispersion coefficients, and $E(\mathbf{U}) = (\frac{\mathbf{U}_i\mathbf{U}_j}{|\mathbf{U}|^2})_{1\le i,j\le d}$. Laboratory experiments have found that the longitudinal dispersivity d_l is much greater than the transverse dispersivity d_t and that the diffusion coefficient is very small by comparison.

In reservoir simulation, the boundary $\partial\Omega$ is typically impermeable. Therefore, if $\mathbf{n}$ denotes the exterior normal to $\partial\Omega$, the system (1)–(2) is supplemented with no flow boundary conditions:

$$\begin{cases} \mathbf{U}\cdot\mathbf{n} = 0 & \text{on } (0,T)\times\partial\Omega, \\ D(x,\mathbf{U})\nabla c\cdot\mathbf{n} = 0 & \text{on } (0,T)\times\partial\Omega. \end{cases} \tag{4}$$

An initial condition is also prescribed:

$$c(x,0) = c_0(x) \text{ in } \Omega. \tag{5}$$

Because of the homogeneous Neumann boundary conditions on $\mathbf{U}$, the injection and production source terms have to satisfy the compatibility condition $\int_\Omega q^+(\cdot,x)\ dx = \int_\Omega q^-(\cdot,x)\ dx$ in $(0,T)$, and since the pressure is defined only up to an arbitrary constant, we normalize p by the following condition:

$$\int_\Omega p(\cdot,x)\ dx = 0 \quad \text{in } (0,T). \tag{6}$$

The viscosity μ is usually determined by the following mixing rule

$$\mu(c) = \mu(0)\Big(1 + \Big(M^{1/4} - 1\Big)c\Big)^{-4} \text{ in } [0,1], \tag{7}$$

where $M = \frac{\mu(0)}{\mu(1)}$ is the mobility ratio (μ can be extended to $\mathbb{R}$ by letting $\mu = \mu(0)$ on $(-\infty,0)$ and $\mu = \mu(1)$ on $(1,\infty)$). The porosity Φ and the permeability $\mathbf{K}$ are in general assumed to be bounded from above and from below by positive constants (or positive multiples of $\mathbf{I}$ for the tensor $\mathbf{K}$).

In [15], Feng proved the existence of a weak solution to the problem (1)–(7) in the two-dimensional case and with $d_l \ge d_t > 0$ and $d_m > 0$. This result has been generalized by Chen and Ewing in [3] to the three-dimensional case and with gravity effects and various boundary conditions. At high flow velocities the effects of mechanical dispersion are much greater than those of molecular diffusion. Therefore, Amirat and Ziani studied in [1] the asymptotic behavior of the weak solution as d_m goes to 0 and proved the existence of a weak solution in the case where $d_m = 0$.

From a numerical point of view, various methods have already been developed for this problem. In general the pressure equation is discretized by a finite element method. However, the key point is that equation (2) on c is a convection-dominated equation, which is not well adapted to the discretization by finite difference or finite element methods. Douglas, Ewing, and Wheeler [6] used a mixed finite element method for the pressure equation and a Galerkin finite element method for the concentration equation. In [19], Russell introduced a modified method of characteristic for the resolution of (2), while (1) is solved by a finite element method. Then, Ewing, Russell, and Wheeler [10] combined a mixed finite element method for (1) and a modified method of characteristic for (2). In [20, 21], the authors also used a mixed

finite element method for (1) but developed an Eulerian Lagrangian localized adjoint method for (2).

Convergence of numerical schemes to (1)–(7) (or connected problems) has already been studied (see, e.g., [5, 6, 11, 12, 17]). But, to the best of our knowledge, these proofs of convergence are based on a priori error estimates, which need regularity assumptions on the solution $(p, \mathbf{U}, c)$ to the continuous problem. Such regularity does not seem provable in general, such as if we take a discontinuous permeability tensor (which is expected in field applications; see [20]).

Finite volume methods are well adapted to the discretization of conservation laws; see, for instance, the reference book by Eymard, Gallouët, and Herbin [13]. They provide efficient numerical schemes for elliptic equations as well as for convection-dominated parabolic equations. However, because of the anisotropic diffusion in (1) (due to $\mathbf{K}(x)$) and of the dispersion terms in (2)–(3), the standard four-point finite volume schemes cannot be used here. Besides, as said above, (2) is convection-dominated and, therefore, a good approximation of $\mathbf{U}$ is needed in the discretization of (2) in order to obtain admissible numerical results. In [9], Droniou and Eymard recently proposed a mixed finite volume scheme which handles anisotropic heterogeneous diffusion problems on any grid and precisely provides, for equations such as (1), good approximations of $\mathbf{U}$; this scheme is therefore a natural candidate to discretize such coupled problems as (1)–(7), especially as it has been shown to behave well from a numerical point of view.

In this paper, we extend the mixed finite volume scheme of [9] to a system, presented in section 1.2, which generalizes (1)–(7). Section 2 contains the definition of the scheme and the statement of the main results: existence and uniqueness of an approximate solution and its convergence to the solution of the continuous problem as the time and space steps tend to 0. A priori estimates on the approximate solution are established in section 3, and in section 4 we prove the existence and uniqueness of the solution to our scheme. The proof of convergence is presented in section 5, under no regularity assumption on the solution to the continuous problem. Section 6 presents some numerical experiments to demonstrate the efficiency of our numerical scheme. Section 7 is an appendix containing a few technical results.

1.2. Formulation of the problem and assumptions. Let us now rewrite the problem (1)–(7) under the following synthesized and more general form (notice that, from now on, we use letters with bar accents to denote the exact solutions, and we use letters without bar accents to denote approximate solutions):

$$(8)\quad \begin{cases} \operatorname{div}(\bar{\mathbf{U}}) = q^+ - q^- \ \text{ in } (0,T)\times\Omega, & \bar{\mathbf{U}} = -A(\cdot,\bar c)\nabla \bar p \ \text{ in } (0,T)\times\Omega, \\ \displaystyle\int_\Omega \bar p(\cdot,x)\,dx = 0 \ \text{ in } (0,T), & \bar{\mathbf{U}}\cdot\mathbf{n} = 0 \ \text{ on } (0,T)\times\partial\Omega, \end{cases}$$

$$(9)\quad \begin{cases} \Phi\partial_t \bar c - \operatorname{div}(D(\cdot,\bar{\mathbf{U}})\nabla\bar c) + \operatorname{div}(\bar c\bar{\mathbf{U}}) + q^-\bar c = q^+\widehat{c} & \text{in } (0,T)\times\Omega, \\ \bar c(0,\cdot) = c_0 & \text{in } \Omega, \\ D(\cdot,\bar{\mathbf{U}})\nabla\bar c\cdot\mathbf{n} = 0 & \text{on } (0,T)\times\partial\Omega. \end{cases}$$

In what follows, we assume that Ω is a convex polygonal bounded domain of $\mathbb{R}^d$, $T>0$, and the following:

$$(10)\quad \begin{aligned} &(q^+,q^-)\in L^\infty(0,T;L^2(\Omega)) \text{ are nonnegative,} \\ &\int_\Omega q^+(\cdot,x)\,dx = \int_\Omega q^-(\cdot,x)\,dx \text{ a.e. in } (0,T), \end{aligned}$$

$A : \Omega \times \mathbb{R} \to M_d(\mathbb{R})$ is a Carathéodory function satisfying the following:

$$\exists \alpha_A > 0\,,\ \exists \Lambda_A > 0 \text{ such that, for a.e. } x \in \Omega, \text{ all } s \in \mathbb{R}, \text{ and all } \xi \in \mathbb{R}^d, \tag{11}$$
$$A(x,s)\xi \cdot \xi \geq \alpha_A |\xi|^2 \text{ and } |A(x,s)| \leq \Lambda_A,$$

$D : \Omega \times \mathbb{R}^d \to M_d(\mathbb{R})$ is a Carathéodory function satisfying the following:

$$\exists \alpha_D > 0\,,\ \exists \Lambda_D > 0 \text{ such that, for a.e. } x \in \Omega, \text{ all } \mathbf{W} \in \mathbb{R}^d, \text{ and all } \xi \in \mathbb{R}^d, \tag{12}$$
$$D(x,\mathbf{W})\xi \cdot \xi \geq \alpha_D (1 + |\mathbf{W}|)|\xi|^2 \text{ and } |D(x,\mathbf{W})| \leq \Lambda_D (1 + |\mathbf{W}|),$$

$$\Phi \in L^\infty(\Omega) \text{ and there exists } \Phi_* > 0 \text{ such that } \Phi_* \leq \Phi \leq \Phi_*^{-1} \text{ a.e. in } \Omega, \tag{13}$$

$$\widehat{c} \in L^\infty((0,T) \times \Omega) \text{ satisfies } 0 \leq \widehat{c} \leq 1 \text{ a.e. in } (0,T) \times \Omega, \tag{14}$$

$$c_0 \in L^\infty(\Omega) \text{ satisfies } 0 \leq c_0 \leq 1 \text{ a.e. in } \Omega. \tag{15}$$

Remark 1.1. Since $E(\mathbf{U}) = \left(\mathbf{U}_i \mathbf{U}_j / |\mathbf{U}|^2\right)_{1 \leq i,j \leq d}$ is the orthogonal projector on $\mathbb{R}\mathbf{U}$, the model in section 1.1 satisfies this assumptions with $\alpha_D = \phi_* \inf(d_m, d_l, d_t)$ and $\Lambda_D = \phi_*^{-1} \sup(d_m, d_l, d_t)$.

As Φ does not depend on t, the following definition (similar to the one in [15]) of weak solution to (8)–(9) makes sense.

DEFINITION 1.1. *Under assumptions* (10)–(15), *a weak solution to* (8)–(9) *is* $(\bar{p}, \bar{\mathbf{U}}, \bar{c})$ *such that* $\bar{p} \in L^\infty(0,T; H^1(\Omega))$, $\bar{\mathbf{U}} \in L^\infty(0,T; L^2(\Omega))^d$, $\bar{c} \in L^\infty(0,T; L^2(\Omega)) \cap L^2(0,T; H^1(\Omega))$,

$$\int_\Omega \bar{p}(t,\cdot) = 0 \text{ for a.e. } t \in (0,T)\,, \quad \bar{\mathbf{U}} = -A(\cdot,\bar{c})\nabla \bar{p} \text{ a.e. in } (0,T) \times \Omega,$$
$$\forall \varphi \in C^\infty([0,T] \times \overline{\Omega})\,,\ -\int_0^T \int_\Omega \bar{\mathbf{U}} \cdot \nabla \varphi = \int_0^T \int_\Omega (q^+ - q^-)\varphi\,,$$
$$\forall \psi \in C_c^\infty([0,T) \times \overline{\Omega})\,,\ -\int_0^T \int_\Omega \Phi \bar{c} \partial_t \psi + \int_0^T \int_\Omega D(\cdot, \bar{\mathbf{U}}) \nabla \bar{c} \cdot \nabla \psi - \int_0^T \int_\Omega \bar{c} \bar{\mathbf{U}} \cdot \nabla \psi$$
$$+ \int_0^T \int_\Omega q^- \bar{c} \psi - \int_\Omega \Phi c_0 \psi(0,\cdot) = \int_0^T \int_\Omega q^+ \widehat{c} \psi.$$

2. Scheme and main results. Let us first define the notion of admissible mesh of Ω and some notation associated with it.

DEFINITION 2.1. *Let* Ω *be a convex polygonal bounded domain in* $\mathbb{R}^d$. *An admissible mesh of* Ω *is given by* $\mathcal{D} = (\mathcal{M}, \mathcal{E})$, *where the following hold:*

(i) $\mathcal{M}$ *is a finite family of nonempty disjoint convex polygonal domains in* Ω *(the "control volumes") such that* $\overline{\Omega} = \cup_{K \in \mathcal{M}} \overline{K}$.

(ii) $\mathcal{E}$ *is a finite family of disjoint subsets of* $\overline{\Omega}$ *(the "edges" of the mesh), such that, for all* $\sigma \in \mathcal{E}$, *there exists an affine hyperplane* E *of* $\mathbb{R}^d$ *and* $K \in \mathcal{M}$ *verifying that* $\sigma \subset \partial K \cap E$ *and* σ *is a nonempty open convex subset of* E. *We assume that, for all* $K \in \mathcal{M}$, *there exists a subset* $\mathcal{E}_K$ *of* $\mathcal{E}$ *such that* $\partial K = \cup_{\sigma \in \mathcal{E}_K} \overline{\sigma}$. *We also assume that, for all* $\sigma \in \mathcal{E}$, *either* $\sigma \subset \partial\Omega$ *or* $\overline{\sigma} = \overline{K} \cap \overline{L}$ *for some* $(K,L) \in \mathcal{M} \times \mathcal{M}$.

The d-dimensional measure of a control volume K is denoted by $\mathrm{m}(K)$, and the $(d-1)$-dimensional measure of an edge σ by $\mathrm{m}(\sigma)$; in the integral signs, γ denotes the measure on the edges. If $\sigma \in \mathcal{E}_K$, then $\mathbf{n}_{K,\sigma}$ is the unit normal to σ outward to K. In the case where $\sigma \in \mathcal{E}$ satisfies $\overline{\sigma} = \overline{K} \cap \overline{L}$ for $(K,L) \in \mathcal{M} \times \mathcal{M}$, we denote $\sigma = K|L$ (K and L are then called "neighboring control volumes"). We define the set of interior (resp., boundary) edges as $\mathcal{E}_{\rm int} = \{\sigma \in \mathcal{E};\ \sigma \not\subset \partial\Omega\}$ (resp., $\mathcal{E}_{\rm ext} = \{\sigma \in \mathcal{E};\ \sigma \subset \partial\Omega\}$). For all $K \in \mathcal{M}$ and all $\sigma \in \mathcal{E}$, $\mathbf{x}_K$ and $\mathbf{x}_\sigma$ are the respective barycenters of K and σ.

The size of a mesh $\mathcal{D}$ is $\mathrm{size}(\mathcal{D}) = \sup_{K\in\mathcal{M}} \mathrm{diam}(K)$. The following quantity measures the regularity of the mesh

$$\mathrm{regul}(\mathcal{D}) = \sup\left\{ \max\left(\frac{\mathrm{diam}(K)^d}{\rho_K^d}, \mathrm{Card}(\mathcal{E}_K) \right) \ ;\ K \in \mathcal{M} \right\},$$

where, for $K \in \mathcal{M}$, ρ_K is the supremum of the radius of the balls contained in K. The definition of $\mathrm{regul}(\mathcal{D})$ implies that, if ω_d is the volume of the unit ball in $\mathbb{R}^d$, for all $K \in \mathcal{M}$,

$$\mathrm{diam}(K)^d \le \mathrm{regul}(\mathcal{D})\rho_K^d \le \frac{\mathrm{regul}(\mathcal{D})}{\omega_d}\mathrm{m}(K)\,. \tag{16}$$

Remark 2.1. We ask for very few geometrical constraints on the mesh of Ω. This is particularly important since, in real-world problems, meshes used in basin and reservoir simulations can be quite irregular and not admissible in the usual finite element or finite volume senses (see [14]).

Our scheme is based on the mixed finite volume scheme introduced in [9] and, for elliptic equations, [8]. Its main goal is to handle a wide variety of grids for heterogeneous and anisotropic operators while giving strong convergence of approximate gradients. Therefore, this scheme applied to (8) provides a strong approximation of $\bar{\mathbf{U}}$, which can then be used in the discretization of the convective term $\mathrm{div}(\bar{c}\bar{\mathbf{U}})$ in the parabolic equation.

The idea is to consider, besides unknowns which approximate the functions $(\bar{p}, \bar{c})$, unknowns which approximate the gradients of these functions, as well as unknowns which stand for the fluxes associated with the differential operators. Thus, if $\mathcal{D}$ is an admissible mesh of Ω and $k > 0$ is a time step (we always choose time steps such that $N_k = T/k$ is an integer), we consider, for all $n = 1, \dots, N_k$ and all $K \in \mathcal{M}$, unknowns $(p_K^n, \mathbf{v}_K^n)$ which stand for approximate values of $(\bar{p}, \nabla\bar{p})$ on $[(n-1)k, nk) \times K$ and numbers $F_{K,\sigma}^n$ (for $\sigma \in \mathcal{E}_K$) which stand for approximate values of $-\int_\sigma \bar{\mathbf{U}} \cdot \mathbf{n}_{K,\sigma}\, d\gamma$ on $[(n-1)k, nk)$. Similarly, the unknowns $(c_K^n, \mathbf{w}_K^n)$ approximate $(\bar{c}, \nabla\bar{c})$ on $[(n-1)k, nk) \times K$ and the numbers $G_{K,\sigma}^n$ (for $\sigma \in \mathcal{E}_K$) approximate $\int_\sigma D(\cdot, \bar{\mathbf{U}})\nabla\bar{c} \cdot \mathbf{n}_{K,\sigma}\, d\gamma$ on $[(n-1)k, nk)$.

The quantities $q_K^{+,n}$, $q_K^{-,n}$, and $\widehat{c}_K^n$ denote the mean values of q^+, q^-, and $\widehat{c}$ on $[(n-1)k, nk) \times K$, and Φ_K, c_K^0, $A_K(s)$, and $D_K(\xi)$ are the mean values of Φ, c_0, $A(\cdot, s)$, and $D(\cdot, \xi)$ on K. We also take positive numbers $(\nu_K)_{K\in\mathcal{M}}$. The scheme for (8) reads as follows: for all $n = 1, \dots, N_k$,

$$\begin{aligned} \mathbf{v}_K^n \cdot (\mathbf{x}_\sigma - \mathbf{x}_K) + \mathbf{v}_L^n \cdot (\mathbf{x}_L - \mathbf{x}_\sigma) + \nu_K \mathrm{m}(K) F_{K,\sigma}^n - \nu_L \mathrm{m}(L) F_{L,\sigma}^n \\ = p_L^n - p_K^n \quad \forall \sigma = K|L \in \mathcal{E}_{\rm int}, \end{aligned} \tag{17}$$

$$F_{K,\sigma}^n + F_{L,\sigma}^n = 0 \quad \forall \sigma = K|L \in \mathcal{E}_{\rm int}\,, \tag{18}$$

$$\mathbf{U}_K^n = -A_K(c_K^{n-1})\mathbf{v}_K^n \quad \forall K \in \mathcal{M}\,, \tag{19}$$

$$\mathrm{m}(K)\mathbf{U}_K^n = -\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K) \quad \forall K \in \mathcal{M}\,, \tag{20}$$

$$-\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n = \mathrm{m}(K)q_K^{+,n} - \mathrm{m}(K)q_K^{-,n} \quad \forall K \in \mathcal{M}\,, \tag{21}$$

$$\sum_{K\in\mathcal{M}} \mathrm{m}(K)p_K^n = 0\,, \tag{22}$$

$$F_{K,\sigma}^n = 0 \quad \forall K \in \mathcal{M}\,,\ \forall \sigma \in \mathcal{E}_K \cap \mathcal{E}_{\mathrm{ext}}\,. \tag{23}$$

Denoting by $(-F_{K,\sigma}^n)^+$ and $(-F_{K,\sigma}^n)^-$ the positive and negative parts of $-F_{K,\sigma}^n$, the scheme for (9) reads as follows: for all $n = 1, \ldots, N_k$,

$$\begin{aligned}\mathbf{w}_K^n \cdot (\mathbf{x}_\sigma - \mathbf{x}_K) + \mathbf{w}_L^n \cdot (\mathbf{x}_L - \mathbf{x}_\sigma) + \nu_K \mathrm{m}(K) G_{K,\sigma}^n - \nu_L \mathrm{m}(L) G_{L,\sigma}^n \\ = c_L^n - c_K^n \quad \forall \sigma = K|L \in \mathcal{E}_{\mathrm{int}}\,,\end{aligned} \tag{24}$$

$$G_{K,\sigma}^n + G_{L,\sigma}^n = 0 \quad \forall \sigma = K|L \in \mathcal{E}_{\mathrm{int}}\,, \tag{25}$$

$$\mathrm{m}(K)D_K(\mathbf{U}_K^n)\mathbf{w}_K^n = \sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K) \quad \forall K \in \mathcal{M}\,, \tag{26}$$

$$\begin{aligned}\mathrm{m}(K)\Phi_K \frac{c_K^n - c_K^{n-1}}{k} - \sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n + \sum_{\substack{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}} \\ \sigma = K|L}} \left[(-F_{K,\sigma}^n)^+ c_K^n - (-F_{K,\sigma}^n)^- c_L^n\right] \\ + \mathrm{m}(K)q_K^{-,n} c_K^n = \mathrm{m}(K)q_K^{+,n}\widehat{c}_K^n \quad \forall K \in \mathcal{M}\,,\end{aligned} \tag{27}$$

$$G_{K,\sigma}^n = 0 \quad \forall K \in \mathcal{M}\,,\ \forall \sigma \in \mathcal{E}_K \cap \mathcal{E}_{\mathrm{ext}}\,. \tag{28}$$

Let us explain why each equation of this scheme is quite natural.

- If we take $\nu_K = 0$, (17) and (24) state that $\mathbf{v}_K^n$ ($\approx \nabla\bar{p}$) and $\mathbf{w}_K^n$ ($\approx \nabla\bar{c}$) are "discrete gradients" of p_K^n ($\approx \bar{p}$) and c_K^n ($\approx \bar{c}$). The penalization using the fluxes (i.e., with $\nu_K > 0$) is added to ensure the stability of the scheme.
- Equations (18) and (25) state the conservation of the fluxes, and (23) and (28) translate the no flow boundary conditions.
- Equations (21) and (27) come from the integration on a control volume and on a time step of the PDEs in (8) and (9). Notice that, as usual, we have chosen a time-implicit scheme for the convection-diffusion equation with an upwind discretization of the convective term.
- Equations (19) and (22) are expressions of $\bar{\mathbf{U}} = -A(\cdot,\bar{c})\nabla\bar{p}$ and $\int_\Omega \bar{p}(t,\cdot) = 0$.
- Equations (20) and (26) come from the reconstruction formula given in Lemma 7.1, since $F_{K,\sigma}^n$ and $G_{K,\sigma}^n$ are approximations of the fluxes of $-\bar{\mathbf{U}}$ and $D(\cdot,\bar{\mathbf{U}})\nabla\bar{c}$.

In the following, if $a = (a_K^n)_{n=1,\dots,N_k\,,\,K\in\mathcal{M}}$ is a family of numbers (or vectors), we use a to denote the piecewise constant function on $[0,T)\times\Omega$ which is equal to a_K^n on $[(n-1)k, nk)\times K$. Similarly, for a fixed n, $a^n = (a_K^n)_{K\in\mathcal{M}}$ is identified with the function on Ω which takes the constant value a_K^n on the control volume K. Hence p denotes both the family $(p_K^n)_{n=1,\dots,N_k\,,\,K\in\mathcal{M}}$ and the corresponding function on $[0,T)\times\Omega$. We also denote by F and G the families $(F_{K,\sigma}^n)_{n=1,\dots,N_k\,,\,K\in\mathcal{M}\,,\,\sigma\in\mathcal{E}_K}$ and $(G_{K,\sigma}^n)_{n=1,\dots,N_k\,,\,K\in\mathcal{M}\,,\,\sigma\in\mathcal{E}_K}$.

THEOREM 2.1. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$ and let $T>0$. Assume* (10)–(15) *hold. Let $\mathcal{D}$ be an admissible mesh of Ω and $k>0$ such that T/k is an integer. Then there exists a unique solution $(p,\mathbf{v},\mathbf{U},F,c,\mathbf{w},G)$ to* (17)–(28).

THEOREM 2.2. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$ and let $T>0$. Assume* (10)–(15) *hold. Let $\nu_0>0$ and $\beta\in(2-2d, 4-2d)$. Let $(\mathcal{D}_m)_{m\geq 1}$ be a sequence of admissible meshes of Ω such that* $\mathrm{size}(\mathcal{D}_m)\to 0$ *as $m\to\infty$ and* $(\mathrm{regul}(\mathcal{D}_m))_{m\geq 1}$ *is bounded; assume that there exists C_1 such that, for all $m\geq 1$,*

$$\forall K,L\in\mathcal{M}_m \text{ neighboring control volumes, } \mathrm{diam}(K)^{2-\beta-d}\leq C_1\mathrm{diam}(L)^{d-2}. \tag{29}$$

For all $K\in\mathcal{M}_m$, we take $\nu_K=\nu_0\mathrm{diam}(K)^\beta$. Let $k_m>0$ be such that $N_{k_m}=T/k_m$ is an integer and $k_m\to 0$ as $m\to\infty$, and denote by $(p^m,\mathbf{v}^m,\mathbf{U}^m,F^m,c^m,\mathbf{w}^m,G^m)$ the solution to (17)–(28) *with $\mathcal{D}=\mathcal{D}_m$ and $k=k_m$. Then, up to a subsequence, as $m\to\infty$,*

$$\begin{aligned}
&p^m\to\bar p && \text{weakly-}* \text{ in } L^\infty(0,T;L^2(\Omega)) \text{ and strongly in } L^p(0,T;L^q(\Omega))\\
&&& \text{for all } p<\infty \text{ and all } q<2;\\
&\mathbf{v}^m\to\nabla\bar p && \text{weakly-}* \text{ in } L^\infty(0,T;L^2(\Omega))^d \text{ and strongly in } L^2((0,T)\times\Omega)^d;\\
&\mathbf{U}^m\to\bar{\mathbf{U}} && \text{weakly-}* \text{ in } L^\infty(0,T;L^2(\Omega))^d \text{ and strongly in } L^2((0,T)\times\Omega)^d;\\
&c^m\to\bar c && \text{weakly-}* \text{ in } L^\infty(0,T;L^2(\Omega)) \text{ and strongly in } L^p(0,T;L^q(\Omega))\\
&&& \text{for all } p<\infty \text{ and all } q<2;\\
&\mathbf{w}^m\to\nabla\bar c && \text{weakly in } L^2((0,T)\times\Omega)^d,
\end{aligned}$$

where $(\bar p,\bar{\mathbf{U}},\bar c)$ is a weak solution to (8)–(9).

Remark 2.2. As usual in finite volume schemes, we do not assume the existence of a solution to the continuous problem; this existence is obtained as a byproduct of the proof of convergence. In particular, this means that, contrary to [5] or [11], the convergence of the mixed finite volume scheme is proved here under no regularity assumption on the solution to (8)–(9). The convergence occurs only up to a subsequence because, with such a lack of regularity, the uniqueness of the solution is not known (see [15]); in the case where the solution is unique (for instance, under suitable regularity assumptions), then the whole sequence converges.

Remark 2.3. Note that, since $4-\beta-2d\geq 0$, one way to satisfy (29) is to ask that $\mathrm{diam}(K)\leq C_2\mathrm{diam}(L)$ for all neighboring control volumes K and L of a mesh. But (29) allows more freedom on the meshes (for example, if $d=1$ and $\beta\in(0,1]$ or if $d=2$ and $\beta\in(-2,0)$, then (29) is always satisfied).

3. The a priori estimates. We prove a priori estimates on the solution to the scheme.

PROPOSITION 3.1. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$ and let $T>0$. Assume* (10)–(11) *hold. Let $\mathcal{D}$ be an admissible mesh of Ω such that* $\mathrm{regul}(\mathcal{D})\leq\theta$ *for some $\theta>0$, and let $k>0$ be such that $N_k=T/k$ is an integer. Let*

$(\nu_K)_{K\in\mathcal{M}}$ be a family of positive numbers such that, for some $\nu_0 > 0$ and $\beta \geq 2-2d$, $\nu_K \leq \nu_0 \mathrm{diam}(K)^\beta$ for all $K \in \mathcal{M}$. Then there exists C_3 only depending on d, Ω, θ, β, ν_0, α_A, and Λ_A such that, for any numbers $(c_K^{n-1})_{n=1,\dots,N_k,\, K\in\mathcal{M}}$, any solution $(p, \mathbf{v}, \mathbf{U}, F)$ to (17)–(23) satisfies

$$\|p\|^2_{L^\infty(0,T;L^2(\Omega))} + \|\mathbf{v}\|^2_{L^\infty(0,T;L^2(\Omega))^d} + \|\mathbf{U}\|^2_{L^\infty(0,T;L^2(\Omega))^d} + \sup_{n=1,\dots,N_k} \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2 \leq C_3 \|q^+ - q^-\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

Proof. Let $n \in [1, N_k]$. Multiply (21) by p_K^n, sum over all control volumes, and gather by edges using (18). Thanks to (23), the terms involving boundary edges disappear, and this leads to

$$\sum_{\sigma=K|L\in\mathcal{E}_{\mathrm{int}}} F^n_{K,\sigma}(p^n_L - p^n_K) = \sum_{K\in\mathcal{M}} \mathrm{m}(K)(q_K^{+,n} - q_K^{-,n})p_K^n = \int_\Omega (q^{+,n} - q^{-,n})p^n,$$

where $q^{+,n}(\cdot) - q^{-,n}(\cdot) = \frac{1}{k}\int_{(n-1)k}^{nk} q^+(t,\cdot) - q^-(t,\cdot)\,dt$. Substituting (17) into this equality and gathering by control volumes (still using (18) and (23)), we deduce

$$\begin{aligned}\int_\Omega (q^{+,n} - q^{-,n})p^n &= \sum_{\sigma=K|L\in\mathcal{E}_{\mathrm{int}}} F^n_{K,\sigma}\left(\mathbf{v}_K^n \cdot (\mathbf{x}_\sigma - \mathbf{x}_K) + \mathbf{v}_L^n \cdot (\mathbf{x}_L - \mathbf{x}_\sigma)\right) \\ &\quad + \sum_{\sigma=K|L\in\mathcal{E}_{\mathrm{int}}} F^n_{K,\sigma}\left(\nu_K \mathrm{m}(K) F^n_{K,\sigma} - \nu_L \mathrm{m}(L) F^n_{L,\sigma}\right) \\ &= \sum_{K\in\mathcal{M}} \mathbf{v}_K^n \cdot \sum_{\sigma\in\mathcal{E}_K} F^n_{K,\sigma}(\mathbf{x}_\sigma - \mathbf{x}_K) + \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2. \end{aligned} \tag{30}$$

Thanks to (20), (19), and hypothesis (11), we find

$$\|q^{+,n} - q^{-,n}\|_{L^2(\Omega)} \|p^n\|_{L^2(\Omega)} \geq \alpha_A \|\mathbf{v}^n\|^2_{L^2(\Omega)^d} + \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2. \tag{31}$$

We notice that (17) is exactly (61) for $(p^n, \mathbf{v}^n, F^n)$. Hence, since p^n satisfies (22), we can apply the discrete Poincaré–Wirtinger inequality given in Lemma 7.2 to get

$$\|p^n\|_{L^2(\Omega)} \leq C_4 \left(\|\mathbf{v}^n\|_{L^2(\Omega)^d} + \left(\sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \mathrm{diam}(K)^{2d-2} \nu_K^2 \mathrm{m}(K) |F^n_{K,\sigma}|^2 \right)^{\frac{1}{2}} \right),$$

where C_4 depends only on d, Ω, and θ. By choice of ν_K, we have $\mathrm{diam}(K)^{2d-2}\nu_K \leq \nu_0 \mathrm{diam}(K)^{2d-2+\beta}$; but $2d-2+\beta \geq 0$, and thus $\mathrm{diam}(K)^{2d-2}\nu_K \leq \nu_0 \mathrm{diam}(\Omega)^{2d-2+\beta}$. Hence

$$\|p^n\|_{L^2(\Omega)} \leq C_5 \left(\|\mathbf{v}^n\|_{L^2(\Omega)^d} + \left(\sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2 \right)^{\frac{1}{2}} \right), \tag{32}$$

where C_5 depends only on d, Ω, θ, β, and ν_0. Substituting this into (31), we obtain

$$\alpha_A \|\mathbf{v}^n\|^2_{L^2(\Omega)^d} + \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2 \leq C_5 \|q^{+,n} - q^{-,n}\|_{L^2(\Omega)} \|\mathbf{v}^n\|_{L^2(\Omega)^d} + C_5 \|q^{+,n} - q^{-,n}\|_{L^2(\Omega)} \left(\sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2 \right)^{\frac{1}{2}}.$$

Using Young's inequality, this gives the desired bound on $\mathbf{v}$ and F and, coming back to (32), the bound on p. The bound on $\mathbf{U}$ derives from the one on $\mathbf{v}$, since A is bounded (see (11)). ∎

PROPOSITION 3.2. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$ and let $T>0$. Assume (10) and (12)–(15) hold. Let $\mathcal{D}$ be an admissible mesh of Ω, and let $k>0$ be such that $N_k = T/k$ is an integer. Let $(\nu_K)_{K\in\mathcal{M}}$ be a family of positive numbers. Assume that $F = (F^n_{K,\sigma})_{n=1,\dots,N_k,\, K\in\mathcal{M},\, \sigma\in\mathcal{E}_K}$ satisfies (18), (21), and (23), and let $\mathbf{U} = (\mathbf{U}^n_K)_{n=1,\dots,N_k,\, K\in\mathcal{M}}$ be a family of vectors in $\mathbb{R}^d$. Then there exists C_6 depending only on d, Ω, T, α_D, and Φ_* such that any solution $(c,\mathbf{w},G)$ to (24)–(28) satisfies*

$$\|c\|^2_{L^\infty(0,T;L^2(\Omega))} + \|\mathbf{w}\|^2_{L^2((0,T)\times\Omega)^d} + \| \, |\mathbf{U}|^{1/2} \, |\mathbf{w}| \, \|^2_{L^2((0,T)\times\Omega)}$$
$$+ \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |G^n_{K,\sigma}|^2 \le C_6 \|c_0\|^2_{L^2(\Omega)} + C_6 \|q^+\|^2_{L^\infty(0,T;L^2(\Omega))}.$$

Proof. Multiply (27) by c^n_K and sum over all control volumes. Noting that $(c^n_K - c^{n-1}_K)c^n_K \ge \frac{1}{2}\left((c^n_K)^2 - (c^{n-1}_K)^2\right)$ and using (25) to gather by edges (no boundary term remains thanks to (28)), we obtain, since $\Phi_K \ge 0$,

$$\frac{1}{2k}\sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K\left((c^n_K)^2 - (c^{n-1}_K)^2\right) + \sum_{\substack{\sigma\in\mathcal{E}_{\rm int}\\ \sigma=K|L}} G^n_{K,\sigma}(c^n_L - c^n_K) + \sum_{K\in\mathcal{M}} \mathrm{m}(K) q^{-,n}_K (c^n_K)^2$$
$$+ \sum_{K\in\mathcal{M}} \sum_{\substack{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\rm int}\\ \sigma=K|L}} \left[(-F^n_{K,\sigma})^+ c^n_K - (-F^n_{K,\sigma})^- c^n_L\right] c^n_K \le \sum_{K\in\mathcal{M}} \mathrm{m}(K) |q^{+,n}_K \widehat{c}^n_K| \, |c^n_K|. \tag{33}$$

Let us denote by $\mathcal{T}$ the fourth term of the inequality. Gathering by edges and using (18), which implies $(-F^n_{L,\sigma})^+ = (-F^n_{K,\sigma})^-$ and $(-F^n_{L,\sigma})^- = (-F^n_{K,\sigma})^+$, yields

$$\mathcal{T} = \sum_{\sigma=K|L\in\mathcal{E}_{\rm int}} \left[(-F^n_{K,\sigma})^+ (c^n_K(c^n_K - c^n_L)) + (-F^n_{K,\sigma})^- (c^n_L(c^n_L - c^n_K))\right].$$

But $c^n_K(c^n_K - c^n_L) \ge \frac{1}{2}\left((c^n_K)^2 - (c^n_L)^2\right)$ and $c^n_L(c^n_L - c^n_K) \ge \frac{1}{2}\left((c^n_L)^2 - (c^n_K)^2\right)$, hence

$$\mathcal{T} \ge \frac{1}{2} \sum_{\sigma=K|L\in\mathcal{E}_{\rm int}} \left[(-F^n_{K,\sigma})^+ - (-F^n_{K,\sigma})^-\right]\left((c^n_K)^2 - (c^n_L)^2\right)$$
$$\ge \frac{1}{2} \sum_{\sigma=K|L\in\mathcal{E}_{\rm int}} -F^n_{K,\sigma}\left((c^n_K)^2 - (c^n_L)^2\right),$$

which gives, gathering by control volumes and using (18), (23), and (21),

$$\mathcal{T} \ge \frac{1}{2}\sum_{K\in\mathcal{M}} (c^n_K)^2 \left(-\sum_{\sigma\in\mathcal{E}_K} F^n_{K,\sigma}\right) \ge \frac{1}{2}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(c^n_K)^2(q^{+,n}_K - q^{-,n}_K).$$

Since

$$\frac{1}{2}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(c^n_K)^2(q^{+,n}_K - q^{-,n}_K) + \sum_{K\in\mathcal{M}} \mathrm{m}(K) q^{-,n}_K (c^n_K)^2$$
$$= \frac{1}{2}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(q^{+,n}_K + q^{-,n}_K)(c^n_K)^2 \ge 0$$

(because q^+ and q^- are nonnegative), we deduce from (33) that

$$\frac{1}{2k}\sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K\left((c_K^n)^2-(c_K^{n-1})^2\right)+\sum_{\sigma=K|L\in\mathcal{E}_{\rm int}} G_{K,\sigma}^n(c_L^n-c_K^n)$$

$$\leq \sum_{K\in\mathcal{M}} \mathrm{m}(K)|q_K^{+,n}\widehat{c}_K^n|\,|c_K^n|. \tag{34}$$

Using (24) and gathering by control volumes, we get, thanks to (25), (28), and (26),

$$\sum_{\substack{\sigma\in\mathcal{E}_{\rm int}\\ \sigma=K|L}} G_{K,\sigma}^n(c_L^n-c_K^n)=\sum_{K\in\mathcal{M}}\mathbf{w}_K^n\cdot\sum_{\sigma\in\mathcal{E}_K}G_{K,\sigma}^n(\mathbf{x}_\sigma-\mathbf{x}_K)+\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)|G_{K,\sigma}^n|^2$$

$$=\sum_{K\in\mathcal{M}}\mathrm{m}(K)D_K(\mathbf{U}_K^n)\mathbf{w}_K^n\cdot\mathbf{w}_K^n+\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)|G_{K,\sigma}^n|^2. \tag{35}$$

We then use (12) and plug the corresponding lower bound into (34), which we multiply by k and sum over $n=1,\dots,N$ (for some $N\in[1,N_k]$); since $|\widehat{c}|\leq 1$, this leads to

$$\frac12\sum_{K\in\mathcal{M}}\mathrm{m}(K)\Phi_K\left((c_K^N)^2-(c_K^0)^2\right)+\alpha_D\sum_{n=1}^N k\sum_{K\in\mathcal{M}}\mathrm{m}(K)(1+|\mathbf{U}_K^n|)|\mathbf{w}_K^n|^2$$

$$+\sum_{n=1}^N k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)|G_{K,\sigma}^n|^2\leq T\|q^+\|_{L^\infty(0,T;L^2(\Omega))}\|c\|_{L^\infty(0,T;L^2(\Omega))}. \tag{36}$$

This gives in particular, by (13) and the definition of $(c_K^0)_{K\in\mathcal{M}}$,

$$\frac{\Phi_*}{2}\sum_{K\in\mathcal{M}}\mathrm{m}(K)(c_K^N)^2\leq\frac{\Phi_*^{-1}}{2}\|c_0\|_{L^2(\Omega)}^2+\frac{T^2}{\Phi_*}\|q^+\|_{L^\infty(0,T;L^2(\Omega))}^2+\frac{\Phi_*}{4}\|c\|_{L^\infty(0,T;L^2(\Omega))}^2.$$

Since $\|c\|_{L^\infty(0,T;L^2(\Omega))}^2=\sup_{r=1,\dots,N_k}\sum_{K\in\mathcal{M}}\mathrm{m}(K)(c_K^r)^2$, this inequality, valid for all $1\leq N\leq N_k$, gives the estimate on $\|c\|_{L^\infty(0,T;L^2(\Omega))}$. Plugged into (36), it gives the desired bounds on $\mathbf{w}$, $|\mathbf{U}|^{1/2}\,|\mathbf{w}|$ and G. ∎

4. Existence and uniqueness of numerical solutions. In this section, we prove Theorem 2.1. Note first that (17)–(23) and (24)–(28) are decoupled systems: at time step n, the knowledge of c_K^{n-1} (or of c_K^0 if $n=1$) shows that (17)–(23) is a linear system for $(p^n,\mathbf{v}^n,\mathbf{U}^n,(F_{K,\sigma}^n)_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$; once this system is solved, $\mathbf{U}^n$ is known and (24)–(28) becomes a linear system for $(c^n,\mathbf{w}^n,(G_{K,\sigma}^n)_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$. Hence, to prove Theorem 2.1 we only need to show that these linear systems are solvable.

Let us first consider the system on $(c^n,\mathbf{w}^n,(G_{K,\sigma}^n)_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$. By (25) and (28), we can consider that there is only one flux by interior edge and this system therefore has $(d+1)\mathrm{Card}(\mathcal{M})+\mathrm{Card}(\mathcal{E}_{\rm int})$ unknowns, with as many remaining equations ((26) gives $d\mathrm{Card}(\mathcal{M})$ equations, (27) another $\mathrm{Card}(\mathcal{M})$ equations, and (24) the last $\mathrm{Card}(\mathcal{E}_{\rm int})$ equations). Hence, this first system is a square system. Assume that $(c^n,\mathbf{w}^n,(G_{K,\sigma}^n)_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$ is a solution with a null right-hand side, i.e., with $c^{n-1}=\widehat{c}^n=0$; then (34) and (35) show that this solution is null, and therefore that this system is invertible.

Without the relation (22) and since we can eliminate $\mathbf{U}^n$ by (19), the system on $(p^n,\mathbf{v}^n,\mathbf{U}^n,(F_{K,\sigma}^n)_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$ also has $(d+1)\mathrm{Card}(\mathcal{M})+\mathrm{Card}(\mathcal{E}_{\rm int})$ unknowns

and the same number of equations. However, it is not invertible since its kernel clearly contains $(\mathcal{C},0,0,0)$, where $\mathcal{C}\in\mathbb{R}^{\mathrm{Card}(\mathcal{M})}$ is any constant vector; in fact, the estimates in the preceding section show that these vectors fully describe the kernel of ((17)–(21), (23)): if $(p^n,\mathbf{v}^n,\mathbf{U}^n,(F^n_{K,\sigma})_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$ belongs to this kernel, then $(p^n-\mathcal{C},\mathbf{v}^n,\mathbf{U}^n,(F^n_{K,\sigma})_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})$, where $\mathcal{C}$ is a constant vector such that (22) holds with $p^n-\mathcal{C}$, satisfies (17)–(23) with $q^{+,n}-q^{-,n}=0$, and is therefore null by Proposition 3.1, which shows that $(p^n,\mathbf{v}^n,\mathbf{U}^n,(F^n_{K,\sigma})_{K\in\mathcal{M},\sigma\in\mathcal{E}_K})=(\mathcal{C},0,0,0)$.

Summing (21) over K and using (18) and (23), we obtain that a necessary condition for ((17)–(21), (23)) to have a solution is $\sum_{K\in\mathcal{M}}\mathrm{m}(K)q_K^{n,+}-\mathrm{m}(K)q_K^{n,-}=0$. Since the kernel of the square system ((17)–(21), (23)) has dimension 1, this condition is also sufficient, and is clearly satisfied by the data we consider thanks to (10). We can therefore always find a solution to ((17)–(21), (23)) and, in view of the kernel of this system, (22) then selects one and only one solution.

Remark 4.1. As said above, at each time step the scheme (17)–(28) can be decoupled in two successive linear systems, (17)–(23) and then (24)–(28), each one with size $(d+1)\mathrm{Card}(\mathcal{M})+\mathrm{Card}(\mathcal{E}_{\mathrm{int}})$. However, it is possible to proceed to an algebraic elimination which leads to smaller sparse linear systems, following [18] for the mixed finite element method and [9] for the mixed finite volume method for anisotropic diffusion problems.

The computation of $(p,\mathbf{v},\mathbf{U},F)$ at each time step reduces to the resolution of a linear system of size $\mathrm{Card}(\mathcal{E}_{\mathrm{int}})$, while the computation of $(c,\mathbf{w},G)$ demands the resolution of a linear system of size $\mathrm{Card}(\mathcal{M})+\mathrm{Card}(\mathcal{E}_{\mathrm{int}})$ (the size of this last system cannot be reduced to $\mathrm{Card}(\mathcal{E}_{\mathrm{int}})$ because of the upwind and implicit discretization of the convective term $\mathrm{div}(c\mathbf{U})$).

5. Proof of the convergence of the scheme. In this section, we prove Theorem 2.2. To simplify the notation, we drop the index m and thus prove the desired convergence as $\mathrm{size}(\mathcal{D})\to 0$ and $k\to 0$, with $\mathrm{regul}(\mathcal{D})$ bounded and (29) uniformly satisfied for all considered meshes. Under these assumptions, Propositions 3.1 and 3.2 give estimates which are uniform with respect to the meshes and time steps.

5.1. Compactness of the concentration. We prove the strong compactness of the concentration.

LEMMA 5.1. *Under the assumptions of Theorem* 2.2, c *is relatively compact in* $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$.

Proof. We first construct an affine interpolant $\widetilde{c}$ of c and prove, thanks to Aubin's theorem, the relative compactness of this interpolant in a weaker space. We then deduce the compactness of c in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$. ∎

Step 1. An affine interpolant of c.

We define $\widetilde{c}:[0,T)\times\Omega\to\mathbb{R}$ as, for all $n=1,\dots,N_k$ and all $t\in[(n-1)k,nk)$,

$$\widetilde{c}(t,\cdot)=\frac{t-(n-1)k}{k}c_K^n+\frac{nk-t}{k}c_K^{n-1}\quad\text{on } K.$$

The estimates of Proposition 3.2 and the definition of $(c_K^0)_{K\in\mathcal{M}}$ ensure the bound of $\|\widetilde{c}\|_{L^\infty(0,T;L^2(\Omega))}$. For all $n=1,\dots,N_k$ and all $t\in[(n-1)k,nk)$, we have $\partial_t\widetilde{c}(t,\cdot)=\frac{c_K^n-c_K^{n-1}}{k}$ on K. Hence, denoting by $\Phi_{\mathcal{D}}$ the piecewise constant function on Ω equal to Φ_K on K and taking $\varphi\in C_c^2(\Omega)$, we deduce from (27) that if φ_K is the mean value

of φ on K,

$$\begin{aligned}\int_\Omega \Phi_{\mathcal{D}}(x)\partial_t\widetilde{c}(t,x)\varphi(x)\,dx &= \sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K \frac{c_K^n - c_K^{n-1}}{k}\varphi_K \\ &= \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n\varphi_K - \sum_{K\in\mathcal{M}} \mathrm{m}(K) q_K^{-,n} c_K^n \varphi_K + \sum_{K\in\mathcal{M}} \mathrm{m}(K) q_K^{+,n}\widehat{c}_K^n\varphi_K \\ &\quad - \sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} \left[(-F_{K,\sigma}^n)^+ c_K^n - (-F_{K,\sigma}^n)^- c_L^n\right]\varphi_K. \end{aligned} \tag{37}$$

Let us denote by T_1, T_3, T_4, and T_2 the four terms on the right-hand side of this equality. In the following, C_i denote constants which do not depend on k, $\mathcal{D}$, n, K, or φ; we induce $C_c^2(\Omega)$ with the norm $\|\varphi\| = \sup_{x\in\Omega}\left(|\varphi(x)| + |\nabla\varphi(x)| + |D^2\varphi(x)|\right)$.

Since $\mathbf{x}_K$ is the barycenter of K and φ is regular we have $\varphi(\mathbf{x}_\sigma) - \varphi_K = \nabla\varphi(\mathbf{x}_K)\cdot(\mathbf{x}_\sigma - \mathbf{x}_K) + R_{K,\sigma}$ for all $\sigma\in\mathcal{E}_K$, with $|R_{K,\sigma}| \le C_7\|\varphi\|\mathrm{diam}(K)^2$. Hence,

$$\varphi_L - \varphi_K = \nabla\varphi(\mathbf{x}_K)\cdot(\mathbf{x}_\sigma - \mathbf{x}_K) + \nabla\varphi(\mathbf{x}_L)\cdot(\mathbf{x}_L - \mathbf{x}_\sigma) + R_{K,\sigma} - R_{L,\sigma}. \tag{38}$$

Using this equality and gathering by control volumes, we get

$$\begin{aligned} -T_1 &= \sum_{\sigma=K|L\in\mathcal{E}_{\mathrm{int}}} G_{K,\sigma}^n(\varphi_L - \varphi_K) \\ &= \sum_{K\in\mathcal{M}} \nabla\varphi(\mathbf{x}_K)\cdot\sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K) + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n R_{K,\sigma} \\ &= \sum_{K\in\mathcal{M}} \mathrm{m}(K)\nabla\varphi(\mathbf{x}_K)\cdot D_K(\mathbf{U}_K^n)\mathbf{w}_K^n + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n R_{K,\sigma}. \end{aligned} \tag{39}$$

On one hand, thanks to (12) and to the estimate on $\mathbf{U}$ in $L^\infty(0,T;L^2(\Omega))^d$ (which gives in particular an estimate in $L^\infty(0,T;L^1(\Omega))^d$), we have

$$\begin{aligned}\left|\sum_{K\in\mathcal{M}} \mathrm{m}(K)\nabla\varphi(\mathbf{x}_K)\cdot D_K(\mathbf{U}_K^n)\mathbf{w}_K^n\right| &\le C_8\|\varphi\|\sum_{K\in\mathcal{M}} \mathrm{m}(K)(1+|\mathbf{U}_K^n|)\,|\mathbf{w}_K^n| \\ &\le C_9\|\varphi\|\left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(1+|\mathbf{U}_K^n|)|\mathbf{w}_K^n|^2\right)^{\frac12}. \end{aligned} \tag{40}$$

On the other hand, using $|R_{K,\sigma}| \le C_7\|\varphi\|\mathrm{diam}(K)^2$ and the Cauchy–Schwarz inequality, we get

$$\begin{aligned}&\left|\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G_{K,\sigma}^n R_{K,\sigma}\right| \\ &\quad\le C_7\|\varphi\|\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K\mathrm{m}(K)|G_{K,\sigma}^n|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\frac{\mathrm{diam}(K)^4}{\nu_K\mathrm{m}(K)}\right)^{\frac12} \\ &\quad\le C_{10}\|\varphi\|\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K\mathrm{m}(K)|G_{K,\sigma}^n|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\mathrm{diam}(K)^{4-2d-\beta}\mathrm{m}(K)\right)^{\frac12} \end{aligned} \tag{41}$$

because (16) and the definition of ν_K imply

$$\frac{\mathrm{diam}(K)^4}{\nu_K \mathrm{m}(K)} = \mathrm{m}(K)\frac{\mathrm{diam}(K)^{4-\beta}}{\nu_0 \mathrm{m}(K)^2} \le \frac{1}{\nu_0}\left(\frac{\mathrm{regul}(\mathcal{D})}{\omega_d}\right)^2 \mathrm{m}(K)\mathrm{diam}(K)^{4-2d-\beta}. \tag{42}$$

But $4-2d-\beta \ge 0$ and thus $\mathrm{diam}(K)^{4-2d-\beta} \le \mathrm{diam}(\Omega)^{4-2d-\beta}$. Using this in (41) and substituting the result along with (40) into (39), we deduce the final estimate:

$$\begin{aligned} |T_1| &\le C_{11}\|\varphi\| \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(1+|\mathbf{U}_K^n|)|\mathbf{w}_K^n|^2\right)^{\frac12} \\ &\quad + C_{11}\|\varphi\| \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|G_{K,\sigma}^n|^2\right)^{\frac12}. \end{aligned} \tag{43}$$

For $\sigma = K|L$, set $b_{K,\sigma}^n = (-F_{K,\sigma}^n)^+ c_K^n - (-F_{K,\sigma}^n)^- c_L^n$. By (18), we have $b_{K,\sigma}^n = -b_{L,\sigma}^n$. Hence, using (38) and gathering by control volumes, we get

$$\begin{aligned} T_2 &= \sum_{\sigma=K|L\in\mathcal{E}_{\mathrm{int}}} b_{K,\sigma}^n(\varphi_L - \varphi_K) \\ &= \sum_{K\in\mathcal{M}} \nabla\varphi(\mathbf{x}_K)\cdot \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} b_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K) + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} b_{K,\sigma}^n R_{K,\sigma}. \end{aligned}$$

But $b_{K,\sigma}^n = -F_{K,\sigma}^n c_K^n + (-F_{K,\sigma}^n)^-(c_K^n - c_L^n)$ and thus, by (23) and (20),

$$T_2 = -\sum_{K\in\mathcal{M}} c_K^n \nabla\varphi(\mathbf{x}_K)\cdot \sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K) + T_5 = \sum_{K\in\mathcal{M}} \mathrm{m}(K) c_K^n \nabla\varphi(\mathbf{x}_K)\cdot\mathbf{U}_K^n + T_5$$

with

$$T_5 = \sum_{K\in\mathcal{M}} \nabla\varphi(\mathbf{x}_K)\cdot \sum_{\substack{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}\\ \sigma=K|L}} (-F_{K,\sigma}^n)^-(c_K^n - c_L^n)(\mathbf{x}_\sigma - \mathbf{x}_K) + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} b_{K,\sigma}^n R_{K,\sigma}.$$

Let us estimate T_5. The corresponding calculations will be useful later in the proof of the convergence of the concentration. We have

$$\begin{aligned} |T_5| &\le \|\varphi\| \sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} |F_{K,\sigma}^n|\,|c_K^n - c_L^n|\mathrm{diam}(K) \\ &\quad + C_7\|\varphi\| \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} |b_{K,\sigma}^n|\mathrm{diam}(K)^2. \end{aligned} \tag{44}$$

But (24) entails

$$|c_K^n - c_L^n| \le |\mathbf{w}_K^n|\mathrm{diam}(K) + |\mathbf{w}_L^n|\mathrm{diam}(L) + \nu_K \mathrm{m}(K)|G_{K,\sigma}^n| + \nu_L \mathrm{m}(L)|G_{L,\sigma}^n|$$

and thus, using $|F_{K,\sigma}^n| = |F_{L,\sigma}^n|$ whenever $\sigma = K|L$,

$$\begin{aligned} |b_{K,\sigma}^n| &\le |F_{K,\sigma}^n|\,|c_K^n| + |F_{K,\sigma}^n|\,|\mathbf{w}_K^n|\mathrm{diam}(K) + |F_{K,\sigma}^n|\,|\mathbf{w}_L^n|\mathrm{diam}(L) \\ &\quad + \nu_K \mathrm{m}(K)|F_{K,\sigma}^n|\,|G_{K,\sigma}^n| + \nu_L \mathrm{m}(L)|F_{L,\sigma}^n|\,|G_{L,\sigma}^n|. \end{aligned}$$

Substituting these two estimates into (44) and bounding $\mathrm{diam}(K)$ either by $\mathrm{diam}(\Omega)$ or $\mathrm{size}(\mathcal{D})$, we get

$$
\begin{aligned}
|T_5| \le{}& C_{12}\|\varphi\| \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} |F^n_{K,\sigma}|\ (|\mathbf{w}^n_K| + |c^n_K|)\,\mathrm{diam}(K)^2 \\
&+ C_{12}\|\varphi\| \sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} |F^n_{K,\sigma}|\,|\mathbf{w}^n_L|\mathrm{diam}(K)\mathrm{diam}(L) \\
&+ C_{12}\|\varphi\|\mathrm{size}(\mathcal{D}) \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|\,|G^n_{K,\sigma}| \\
&+ C_{12}\|\varphi\|\mathrm{size}(\mathcal{D}) \sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} \nu_L \mathrm{m}(L)|F^n_{L,\sigma}|\,|G^n_{L,\sigma}|. \qquad (45)
\end{aligned}
$$

We successively apply the Cauchy–Schwarz inequality, the fact that $\mathrm{regul}(\mathcal{D})$ is bounded, inequality (42), and the estimates on F from Proposition 3.1. This yields

$$
\begin{aligned}
&\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} |F^n_{K,\sigma}|\ (|\mathbf{w}^n_K| + |c^n_K|)\,\mathrm{diam}(K)^2 \\
&\le C_{13}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)\mathrm{diam}(K)^{4-2d-\beta}(|\mathbf{w}^n_K| + |c^n_K|)^2\right)^{\frac12} \\
&\le C_{14}\mathrm{size}(\mathcal{D})^{\frac{4-2d-\beta}{2}}\left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(|\mathbf{w}^n_K| + |c^n_K|)^2\right)^{\frac12}. \qquad (46)
\end{aligned}
$$

Then we note that (thanks to (23))

$$
\sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} \nu_L \mathrm{m}(L)|F^n_{L,\sigma}|\,|G^n_{L,\sigma}| = \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|\,|G^n_{K,\sigma}| \qquad (47)
$$

and, with the estimates on F from Proposition 3.1, we get

$$
\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|\,|G^n_{K,\sigma}| \le C_{15}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|G^n_{K,\sigma}|^2\right)^{\frac12}. \qquad (48)
$$

Using the fact that $\nu_K = \nu_0\mathrm{diam}(K)^\beta$ and inequalities (16) and (29),we get

$$
\begin{aligned}
&\sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} |F^n_{K,\sigma}|\,|\mathbf{w}^n_L|\mathrm{diam}(K)\mathrm{diam}(L) \\
&\le \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\sum_{\substack{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}\\ \sigma=K|L}} \frac{\mathrm{diam}(K)^2\mathrm{diam}(L)^2}{\nu_K \mathrm{m}(K)}|\mathbf{w}^n_L|^2\right)^{\frac12} \\
&\le C_{16}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\left(\sum_{L\in\mathcal{M}}|\mathbf{w}^n_L|^2\sum_{\substack{\sigma\in\mathcal{E}_L\cap\mathcal{E}_{\mathrm{int}}\\ \sigma=L|K}}\mathrm{diam}(K)^{2-\beta-d}\mathrm{diam}(L)^2\right)^{\frac12} \\
&\le C_{17}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\left(\sum_{L\in\mathcal{M}} \mathrm{m}(L)|\mathbf{w}^n_L|^2\right)^{\frac12}.
\end{aligned}
$$

Finally, gathering (45), (46), (47), (48), and this last inequality, it yields

$$
\begin{aligned}
|T_5| &= \left| T_2 - \sum_{K\in\mathcal{M}} \mathrm{m}(K) c_K^n \nabla\varphi(\mathbf{x}_K)\cdot \mathbf{U}_K^n \right| \\
&\le C_{18}\|\varphi\|\mathrm{size}(\mathcal{D})^{\frac{4-2d-\beta}{2}} \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(|\mathbf{w}_K^n| + |c_K^n|)^2 \right)^{\frac12} \\
&\quad + C_{18}\|\varphi\| \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F_{K,\sigma}^n|^2 \right)^{\frac12} \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)|\mathbf{w}_K^n|^2 \right)^{\frac12} \\
&\quad + C_{18}\|\varphi\|\mathrm{size}(\mathcal{D}) \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |G_{K,\sigma}^n|^2 \right)^{\frac12}. \qquad (49)
\end{aligned}
$$

Thanks to the $L^\infty(0,T;L^2(\Omega))$ estimates on c and $\mathbf{U}$, we also have

$$
\begin{aligned}
\left| \sum_{K\in\mathcal{M}} \mathrm{m}(K) c_K^n \nabla\varphi(\mathbf{x}_K)\cdot \mathbf{U}_K^n \right| &\le \|\varphi\| \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)|c_K^n|^2 \right)^{\frac12} \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)|\mathbf{U}_K^n|^2 \right)^{\frac12} \\
&\le C_{19}\|\varphi\|,
\end{aligned}
$$

and, using the bound on the fluxes $F_{K,\sigma}^n$ from Proposition 3.1, the final estimate on T_2 reads

$$
\begin{aligned}
|T_2| &\le C_{20}\|\varphi\| + C_{20}\|\varphi\| \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(|\mathbf{w}_K^n| + |c_K^n|)^2 \right)^{\frac12} \\
&\quad + C_{20}\|\varphi\| \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |G_{K,\sigma}^n|^2 \right)^{\frac12}. \qquad (50)
\end{aligned}
$$

The estimates on T_3 and T_4 are straightforward, thanks to the $L^\infty(0,T;L^2(\Omega))$-bound on c; plugging (43) and (50) into (37), we obtain, for all $n = 1,\dots,N_k$ and all $t\in[(n-1)k, nk)$,

$$
\begin{aligned}
&\left| \int_\Omega \Phi_{\mathcal{D}}(x)\partial_t\widetilde{c}(t,x)\varphi(x)\,dx \right| \\
&\le C_{21}\|\varphi\| \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(1+|\mathbf{U}_K^n|)|\mathbf{w}_K^n|^2 \right)^{\frac12} + C_{21}\|\varphi\| \left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |G_{K,\sigma}^n|^2 \right)^{\frac12} \\
&\quad + C_{21}\|\varphi\| + C_{21}\|\varphi\| \left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)(|\mathbf{w}_K^n| + |c_K^n|)^2 \right)^{\frac12}.
\end{aligned}
$$

Since this inequality is satisfied for all $\varphi\in C_c^2(\Omega)$ and $\Phi_{\mathcal{D}}$ does not depend on t, this gives an estimate on $\|\partial_t(\Phi_{\mathcal{D}}\widetilde{c})(t,\cdot)\|_{(C_c^2(\Omega))'}$ which, squared, leads to

$$
\begin{aligned}
\|\partial_t(\Phi_{\mathcal{D}}\widetilde{c})(t,\cdot)\|_{(C_c^2(\Omega))'}^2 &\le C_{22}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(1+|\mathbf{U}_K^n|)|\mathbf{w}_K^n|^2 + C_{22} \\
&\quad + C_{22}\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|G_{K,\sigma}^n|^2 + C_{22}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(|\mathbf{w}_K^n| + |c_K^n|)^2
\end{aligned}
$$

for all $n = 1, \dots, N_k$ and all $t \in [(n-1)k, nk)$. Integrating this last inequality on $t \in [(n-1)k, nk)$ and summing over $n = 1, \dots, N_k$, we prove, thanks to the estimates of Proposition 3.2, that $\partial_t(\Phi_{\mathcal{D}}\widetilde{c})$ is bounded in $L^2(0,T;(C_c^2(\Omega))')$.

Noting that $\Phi_{\mathcal{D}}\widetilde{c}$ is bounded in $L^\infty(0,T;L^2(\Omega))$ (because $\widetilde{c}$ is bounded in this space and $\Phi_{\mathcal{D}}$ is bounded in $L^\infty(\Omega)$), and since $L^2(\Omega)$ is continuously embedded in $(C_c^2(\Omega))'$ (via the natural embedding $f \to (\varphi \to \int_\Omega f\varphi)$), this shows that $\Phi_{\mathcal{D}}\widetilde{c}$ is bounded in $H^1(0,T;(C_c^2(\Omega))')$. But $C_c^2(\Omega)$ is compactly and densely embedded in $C_0(\Omega)$, and, by duality, $(C_0(\Omega))'$ (the space of bounded measures on Ω) is compactly embedded in $(C_c^2(\Omega))'$. Since $L^2(\Omega)$ is continuously embedded in $(C_0(\Omega))'$ (via an embedding which is compatible with the preceding one), the embedding of $L^2(\Omega)$ in $(C_c^2(\Omega))'$ is in fact compact. Hence, by Aubin's compactness theorem we deduce that $\Phi_{\mathcal{D}}\widetilde{c}$ is relatively compact in $C([0,T];(C_c^2(\Omega))')$.

Step 2. Conclusion.

For all $n = 1, \dots, N_k$ and $t \in [(n-1)k, nk)$, we have $\Phi_{\mathcal{D}}c(t,\cdot) = \Phi_{\mathcal{D}}\widetilde{c}(nk,\cdot)$ on Ω (these functions are both equal to $\Phi_K c_K^n$ on each $K \in \mathcal{M}$). We also know (see, e.g., [7]) that $H^1(0,T;(C_c^2(\Omega))')$ is continuously embedded in $C^{1/2}([0,T];(C_c^2(\Omega))')$ (the space of 1/2-Hölder continuous functions $[0,T] \to (C_c^2(\Omega))'$). Hence, $\Phi_{\mathcal{D}}\widetilde{c}$ is also bounded in $C^{1/2}([0,T];(C_c^2(\Omega))')$ and there exists C_{23} not depending on k or $\mathcal{D}$ such that, for all $n = 1, \dots, N_k$ and all $t \in [(n-1)k, nk)$,

$$\|\Phi_{\mathcal{D}}c(t,\cdot) - \Phi_{\mathcal{D}}\widetilde{c}(t,\cdot)\|_{(C_c^2(\Omega))'} = \|\Phi_{\mathcal{D}}\widetilde{c}(nk,\cdot) - \Phi_{\mathcal{D}}\widetilde{c}(t,\cdot)\|_{(C_c^2(\Omega))'} \le C_{23}\sqrt{k}.$$

This means that, as $k \to 0$, $\Phi_{\mathcal{D}}c - \Phi_{\mathcal{D}}\widetilde{c} \to 0$ in $L^\infty(0,T;(C_c^2(\Omega))')$; since $\Phi_{\mathcal{D}}\widetilde{c}$ is relatively compact in this space, we deduce that $\Phi_{\mathcal{D}}c$ is also relatively compact in this same space, and thus in particular in $L^1(0,T;(C_c^2(\Omega))')$.

Let $n = 1, \dots, N_k$ and $t \in [(n-1)k, nk)$. By (24), Lemma 7.3 gives, for all ω relatively compact in Ω and all $|\xi| < \operatorname{dist}(\omega, \mathbb{R}^d \backslash \Omega)$,

$$\begin{aligned}\|c(t,\cdot+\xi) - c(t,\cdot)\|_{L^1(\omega)} &\le C_{24}|\xi| \sum_{K\in\mathcal{M}} \mathrm{m}(K)|\mathbf{w}_K^n| \\ &\quad + C_{24}|\xi| \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \operatorname{diam}(K)^{d-1}\nu_K \mathrm{m}(K)|G_{K,\sigma}^n|.\end{aligned}$$

Integrating on $t \in [(n-1)k, nk)$ and summing over $n = 1, \dots, N_k$, this implies that

$$\begin{aligned}&\|c(\cdot,\cdot+\xi) - c\|_{L^1((0,T)\times\omega)} \\ &\le C_{24}|\xi|\,\|\mathbf{w}\|_{L^1((0,T)\times\Omega)^d} + C_{24}|\xi| \left(\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \operatorname{diam}(K)^{2d-2}\nu_K \mathrm{m}(K)\right)^{\frac12} \\ &\qquad\qquad \times \left(\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K)|G_{K,\sigma}^n|^2\right)^{\frac12} \\ &\le C_{25}|\xi| + C_{25}|\xi| \left(\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \operatorname{diam}(K)^{2d-2+\beta}\mathrm{m}(K)\right)^{\frac12}\end{aligned}$$

thanks to the estimates of Proposition 3.2. But $2d-2+\beta \ge 0$ and $\operatorname{diam}(K)^{2d-2+\beta} \le \operatorname{diam}(\Omega)^{2d-2+\beta}$. Hence, we see that $\|c(\cdot,\cdot+\xi) - c\|_{L^1((0,T)\times\omega)} \to 0$ as $\xi \to 0$, independent of k or $\mathcal{D}$.

Since $\Phi_{\mathcal{D}}$ is bounded in $L^\infty(\Omega)$ and c is bounded in $L^\infty(0,T;L^2(\Omega))$, we have

$$\begin{aligned}
&\|(\Phi_{\mathcal{D}}c)(\cdot,\cdot+\xi)-\Phi_{\mathcal{D}}c\|_{L^1((0,T)\times\omega)}\\
&\qquad=\|\Phi_{\mathcal{D}}(\cdot+\xi)(c(\cdot,\cdot+\xi)-c)+(\Phi_{\mathcal{D}}(\cdot+\xi)-\Phi_{\mathcal{D}})c\|_{L^1((0,T)\times\omega)}\\
&\qquad\le C_{26}\|c(\cdot,\cdot+\xi)-c\|_{L^1((0,T)\times\omega)}+C_{27}\|\Phi_{\mathcal{D}}(\cdot+\xi)-\Phi_{\mathcal{D}}\|_{L^2(\omega)},
\end{aligned}$$

where C_{26} and C_{27} do not depend on $\mathcal{D}$ or k. But it is classical that $\Phi_{\mathcal{D}}\to\Phi$ in $L^2(\Omega)$ as $\mathrm{size}(\mathcal{D})\to 0$ and thus $\|\Phi_{\mathcal{D}}(\cdot+\xi)-\Phi_{\mathcal{D}}\|_{L^2(\omega)}\to 0$ as $\xi\to 0$, independent of $\mathcal{D}$. We therefore obtain $\|(\Phi_{\mathcal{D}}c)(\cdot,\cdot+\xi)-\Phi_{\mathcal{D}}c\|_{L^1((0,T)\times\omega)}\to 0$ as $\xi\to 0$, independent of k or $\mathcal{D}$. Since $\Phi_{\mathcal{D}}c$ is relatively compact in $L^1(0,T;(C_c^2(\Omega))')$, Lemma 7.5 then shows that $\Phi_{\mathcal{D}}c$ is relatively compact in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$.

Up to a subsequence as $k\to 0$ and $\mathrm{size}(\mathcal{D})\to 0$, $\Phi_{\mathcal{D}}c\to f$ in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$. Using again the fact that $\Phi_{\mathcal{D}}\to\Phi$ in $L^2(\Omega)$ we also have, up to another subsequence, $\Phi_{\mathcal{D}}\to\Phi$ a.e. on Ω; moreover, $\Phi_{\mathcal{D}}\ge\Phi_*>0$ and thus $\frac{1}{\Phi_{\mathcal{D}}}$ stays bounded on Ω (independent of $\mathcal{D}$) and converges a.e. to $\frac{1}{\Phi}$. The Lebesgue dominated convergence theorem then shows that $c=\frac{1}{\Phi_{\mathcal{D}}}\Phi_{\mathcal{D}}c\to\frac{1}{\Phi}f$ in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$, which concludes the proof. ∎

In what follows, we extract a sequence such that c converges in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$ to some $\bar c$.

5.2. Convergence of the pressure. Let us now turn to the convergence of $(p,\mathbf{v},\mathbf{U})$. By Proposition 3.1, we can assume, up to a subsequence, that $p\to\bar p$ weakly-$*$ in $L^\infty(0,T;L^2(\Omega))$ and that $\mathbf{v}\to\bar{\mathbf{v}}$ weakly-$*$ in $L^\infty(0,T;L^2(\Omega))^d$. Since $\int_\Omega p(t,\cdot)=0$ for all $t\in(0,T)$, it is quite clear that $\int_\Omega\bar p(t,\cdot)=0$ for a.e. $t\in(0,T)$. By choice of ν_K and thanks to the estimate on F in Proposition 3.1 and the fact that $2d-2+\beta>0$, we have

$$\begin{aligned}
&\sum_{n=1}^{N_k}k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{d-1}\nu_K\mathrm{m}(K)|F^n_{K,\sigma}|\\
&\le\left(\sum_{n=1}^{N_k}k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}(K)\right)^{\frac12}\left(\sum_{n=1}^{N_k}k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{2d-2}\nu_K^2\mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\\
&\le C_{28}\left(\sup_{n=1,\dots,N_k}\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{2d-2+\beta}\nu_K\mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\\
&\le C_{29}\,\mathrm{size}(\mathcal{D})^{\frac{2d-2+\beta}{2}}. \qquad (51)
\end{aligned}$$

Hence, Lemma 7.4 shows that $\bar p\in L^2(0,T;H^1(\Omega))$ and that $\nabla\bar p=\bar{\mathbf{v}}$, so that $\bar p\in L^\infty(0,T;H^1(\Omega))$. Let $A_{\mathcal{D}}:\Omega\times\mathbb{R}\to M_d(\mathbb{R})$ be the function defined by $A_{\mathcal{D}}(x,s)=A_K(s)$ whenever $s\in\mathbb{R}$ and x belongs to $K\in\mathcal{M}$. We also define $\check c:(0,T)\times\Omega\to\mathbb{R}$ by $\check c=c_K^{n-1}$ on $[(n-1)k,nk)\times K$ ($n=1,\dots,N_k$ and $K\in\mathcal{M}$); noticing that $\check c=c_K^0\in[0,1]$ on $[0,k[\times K$ and that $\check c=c(\cdot-k,\cdot)$ on $[k,T[\times\Omega$, it is clear that $\check c\to\bar c$ in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$ as $k\to 0$ and $\mathrm{size}(\mathcal{D})\to 0$. We have $\mathbf{U}=-A_{\mathcal{D}}(\cdot,\check c)\mathbf{v}$ and thus, for all $\mathbf{Z}\in L^2((0,T)\times\Omega)^d$, $\int_0^T\int_\Omega\mathbf{Z}\cdot\mathbf{U}=\int_0^T\int_\Omega-A_{\mathcal{D}}(\cdot,\check c)^T\mathbf{Z}\cdot\mathbf{v}$. Applying Lemma 7.6 (with $-A^T$ instead of A, $u^m=\check c$, and $\mathbf{Z}^m$ constant equal to $\mathbf{Z}$), and since $\mathbf{v}$ converges to $\nabla\bar p$ weakly in $L^2((0,T)\times\Omega)^d$, we obtain that $\int_0^T\int_\Omega\mathbf{Z}\cdot\mathbf{U}\to\int_0^T\int_\Omega-A(\cdot,\bar c)^T\mathbf{Z}\cdot\nabla\bar p$, which proves that $\mathbf{U}\to\bar{\mathbf{U}}=-A(\cdot,\bar c)\nabla\bar p$ weakly in $L^2((0,T)\times\Omega)^d$ (since $\mathbf{U}$ is bounded in $L^\infty(0,T;L^2(\Omega))^d$, the convergence also holds weakly-$*$ in this space).

Let us now prove that $\bar{p}$ is the weak solution to (8) with $\bar{c}$ fixed as given above. Let $\varphi \in C^\infty([0,T]\times\overline{\Omega})$ and define $\varphi^n(x) = \frac{1}{k}\int_{(n-1)k}^{nk}\varphi(t,x)\,dt$ for $n = 1,\dots,N_k$. Multiply (21) by $\varphi^n(\mathbf{x}_K)$, sum over all control volumes, and, using (18) and (23), gather by edges; this gives

$$\sum_{K\in\mathcal{M}} \mathrm{m}(K)(q_K^{+,n} - q_K^{-,n})\varphi^n(\mathbf{x}_K) = \sum_{\sigma=K|L\in\mathcal{E}_{\rm int}} F_{K,\sigma}^n(\varphi^n(\mathbf{x}_L) - \varphi^n(\mathbf{x}_K)).$$

However, since φ is regular, we have

$$\begin{aligned}\varphi^n(\mathbf{x}_L) - \varphi^n(\mathbf{x}_K) &= \nabla\varphi^n(\mathbf{x}_K)\cdot(\mathbf{x}_\sigma - \mathbf{x}_K) + \nabla\varphi^n(\mathbf{x}_L)\cdot(\mathbf{x}_L - \mathbf{x}_\sigma)\\ &\quad + R_{K,\sigma}^n - R_{L,\sigma}^n\\ &\text{with } |R_{K,\sigma}^n| \le C_{30}\mathrm{diam}(K)^2\,,\end{aligned} \tag{52}$$

where C_{30} does not depend on n, $\sigma = K|L$, k, or $\mathcal{D}$. Therefore,

$$\begin{aligned}\sum_{K\in\mathcal{M}} \mathrm{m}(K)(q_K^{+,n} - q_K^{-,n})\varphi^n(\mathbf{x}_K) &= \sum_{K\in\mathcal{M}} \nabla\varphi^n(\mathbf{x}_K)\cdot\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n(\mathbf{x}_\sigma - \mathbf{x}_K)\\ &\quad + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n R_{K,\sigma}^n\\ &= -\sum_{K\in\mathcal{M}} \mathrm{m}(K)\nabla\varphi^n(\mathbf{x}_K)\cdot\mathbf{U}_K^n + \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n R_{K,\sigma}^n.\end{aligned} \tag{53}$$

If $\varphi_{k,\mathcal{D}}$ and $\Psi_{k,\mathcal{D}}$ denote the functions on $[0,T)\times\Omega$ which are equal to $\varphi^n(\mathbf{x}_K)$ and to $\nabla\varphi^n(\mathbf{x}_K)$ on $[(n-1)k, nk)\times K$, it is clear that $\varphi_{k,\mathcal{D}}\to\varphi$ and $\Psi_{k,\mathcal{D}}\to\nabla\varphi$ uniformly on $(0,T)\times\Omega$ as $k\to 0$ and $\mathrm{size}(\mathcal{D})\to 0$; multiplying (53) by k and summing over $n = 1,\dots,N_k$, we obtain

$$\int_0^T\int_\Omega (q^+ - q^-)\varphi_{k,\mathcal{D}} = -\int_0^T\int_\Omega \Psi_{k,\mathcal{D}}\cdot\mathbf{U} + \sum_{n=1}^{N_k} k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n R_{K,\sigma}^n. \tag{54}$$

Adapting the proof of (41) to F by using Proposition 3.1, we get

$$\begin{aligned}\left|\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}^n R_{K,\sigma}^n\right| &\le C_{31}\left(\sum_{K\in\mathcal{M}} \mathrm{m}(K)\mathrm{diam}(K)^{4-2d-\beta}\right)^{\frac{1}{2}}\\ &\le C_{32}\ \mathrm{size}(\mathcal{D})^{\frac{4-2d-\beta}{2}}.\end{aligned} \tag{55}$$

Hence, by the weak convergence of $\mathbf{U}$, we can pass to the limit in (54) and find $\int_0^T\int_\Omega(q^+ - q^-)\varphi = -\int_0^T\int_\Omega \nabla\varphi\cdot\bar{\mathbf{U}}$; since this equation is satisfied for all $\varphi\in C^\infty([0,T]\times\overline{\Omega})$, this concludes the proof that $\bar{p}$ is the weak solution to (8) for the given $\bar{c}$ (limit of c).

We now want to prove the strong convergence of $\mathbf{v}$ to $\nabla\bar{p}$ in $L^2((0,T)\times\Omega)^d$. To do so, we use (20) and (19) in (30), which we then multiply by k and sum over $n = 1,\dots,N_k$; this leads to

$$\int_0^T\int_\Omega (q^+ - q^-)p = \int_0^T\int_\Omega A(\cdot,\breve{c})\mathbf{v}\cdot\mathbf{v} + \sum_{n=1}^{N_k} k\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K \mathrm{m}(K)|F_{K,\sigma}^n|^2. \tag{56}$$

Dropping the last term (which is nonnegative), the weak convergence of p gives, since $\bar{p}$ is a solution to (8),

$$\limsup_{k\to 0\,,\ \mathrm{size}(\mathcal{D})\to 0} \int_0^T \int_\Omega A(\cdot,\check{c})\mathbf{v}\cdot\mathbf{v} \le \int_0^T \int_\Omega (q^+ - q^-)\bar{p} = \int_0^T \int_\Omega A(\cdot,\bar{c})\nabla\bar{p}\cdot\nabla\bar{p} \tag{57}$$

(the last equality is obtained using $\bar{p}$ as a test function in (8), which is possible since the weak formulation of (8) is in fact valid with test functions in $L^1(0,T;H^1(\Omega))$). We now write, thanks to (11),

$$\begin{aligned}\alpha_A \int_0^T \int_\Omega |\mathbf{v}-\nabla\bar{p}|^2 &\le \int_0^T \int_\Omega A(\cdot,\check{c})(\mathbf{v}-\nabla\bar{p})\cdot(\mathbf{v}-\nabla\bar{p})\\ &= \int_0^T \int_\Omega A(\cdot,\check{c})\mathbf{v}\cdot\mathbf{v} - \int_0^T \int_\Omega A(\cdot,\check{c})\mathbf{v}\cdot\nabla\bar{p} - \int_0^T \int_\Omega A(\cdot,\check{c})\nabla\bar{p}\cdot\mathbf{v}\\ &\quad + \int_0^T \int_\Omega A(\cdot,\check{c})\nabla\bar{p}\cdot\nabla\bar{p}. \end{aligned}\tag{58}$$

Up to a subsequence, we can assume that $\check{c}\to\bar{c}$ a.e. on $(0,T)\times\Omega$, and (11) then gives $A(\cdot,\check{c})\nabla\bar{p}\to A(\cdot,\bar{c})\nabla\bar{p}$ and $A(\cdot,\check{c})^T\nabla\bar{p}\to A(\cdot,\bar{c})^T\nabla\bar{p}$ strongly in $L^2((0,T)\times\Omega)^d$. Hence, the weak convergence of $\mathbf{v}$ to $\nabla\bar{p}$ allows us to pass to the limit in the second and third terms on the right-hand side of (58); the last term on this right-hand side obviously converges and (57) therefore gives

$$\begin{aligned}\limsup_{k\to 0\,,\ \mathrm{size}(\mathcal{D})\to 0} \alpha_A \int_0^T \int_\Omega |\mathbf{v}-\nabla\bar{p}|^2 &\le \limsup_{k\to 0\,,\ \mathrm{size}(\mathcal{D})\to 0} \int_0^T \int_\Omega A(\cdot,\check{c})\mathbf{v}\cdot\mathbf{v}\\ &\quad - \int_0^T \int_\Omega A(\cdot,\bar{c})\nabla\bar{p}\cdot\nabla\bar{p} \le 0\,,\end{aligned}$$

which concludes the proof of the strong convergence of $\mathbf{v}$ to $\nabla\bar{p}$ in $L^2((0,T)\times\Omega)^d$. The strong convergence of $\mathbf{U}$ in the same space is then a consequence of Lemma 7.6, of the equality $\mathbf{U} = -A_{\mathcal{D}}(\cdot,\check{c})\mathbf{v}$, and of the strong convergence of $\mathbf{v}$.

We conclude by proving that, up to subsequence and as $k\to 0$ and $\mathrm{size}(\mathcal{D})\to 0$, $p(t)\to\bar{p}(t)$ in $L^1_{\mathrm{loc}}(\Omega)$ for a.e. $t\in(0,T)$. Since p is bounded in $L^\infty(0,T;L^2(\Omega))$, and thus in $L^\infty(0,T;L^1_{\mathrm{loc}}(\Omega))$, this a.e. convergence and Vitali's theorem imply the convergence in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$, and, using once again the bound on p in $L^\infty(0,T;L^2(\Omega))$, we deduce the strong convergences stated in Theorem 2.2.

As $\mathbf{v}$ converges in $L^2(0,T;L^2(\Omega))^d$, we can assume that, up to a subsequence, $\mathbf{v}(t)\to\nabla\bar{p}(t)$ in $L^2(\Omega)^d$ for a.e. $t\in(0,T)$. Take a t_0 for which this convergence holds, and such that $\int_\Omega \bar{p}(t_0)=0$; we now prove, using the method of proof by contradiction, that $p(t_0)\to\bar{p}(t_0)$ in $L^1_{\mathrm{loc}}(\Omega)$ (along the same subsequence as the one chosen for $\mathbf{v}$, which thus does not depend on t_0). If this convergence does not hold, then we can assume, up to a new subsequence, that, for some $\eta>0$, $\mathrm{d}_1(p(t_0),\bar{p}(t_0))\ge\eta$, where d_1 is the distance in $L^1_{\mathrm{loc}}(\Omega)$. By (17), $(p(t_0),\mathbf{v}(t_0),F^{n(t_0,k)})\in L_\nu(\mathcal{D})$ (where $n(t_0,k)$ is such that $(n(t_0,k)-1)k\le t_0<n(t_0,k)k$) and Proposition 3.1 proves, with the help of the Cauchy–Schwarz inequality, that $M_1(\mathcal{D},\nu,F^{n(t_0,k)})$ (defined in Lemma 7.3) stays bounded; hence, since $p(t_0)$ is bounded in $L^2(\Omega)$ (see again Proposition 3.1), Lemma 7.3 and Kolmogorov's compactness theorem show that, up to a subsequence, $p(t_0)$ converges to some P strongly in $L^1_{\mathrm{loc}}(\Omega)$ and weakly in $L^2(\Omega)$. By (22), it is

clear that $\int_\Omega P = 0$ (use the weak convergence in $L^2(\Omega)$). Applying Lemma 7.4 to the functions constant in time $(u, \mathbf{r}) = (p(t_0), \mathbf{v}(t_0))$ and to the fluxes $H = F^{n(t_0,k)}$, the estimates in Proposition 3.1 allow us to see that (64) is satisfied and thus that $\nabla P = \nabla \bar{p}(t_0)$ (because $\mathbf{v}(t_0) \to \nabla \bar{p}(t_0)$); hence, since $\int_\Omega \bar{p}(t_0) = 0$, we deduce that $P = \bar{p}(t_0)$, and therefore that $p(t_0) \to \bar{p}(t_0)$ in $L^1_{\rm loc}(\Omega)$. Since the subsequence along which this convergence holds has been extracted from a sequence which satisfies $\mathrm{d}_1(p(t_0), \bar{p}(t_0)) \geq \eta$, this gives the contradiction we sought.

Remark 5.1. From the strong convergence of $\mathbf{v}$ and the a.e. convergence of $\check{c}$, we have $\int_0^T \int_\Omega A(\cdot, \check{c})\mathbf{v}\cdot\mathbf{v} \to \int_0^T \int_\Omega A(\cdot, \bar{c})\nabla\bar{p}\cdot\nabla\bar{p} = \int_0^T \int_\Omega (q^+ - q^-)\bar{p}$. Hence, (56) implies

$$\lim_{k\to 0\,,\ \mathrm{size}(\mathcal{D})\to 0} \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |F^n_{K,\sigma}|^2 = 0. \tag{59}$$

5.3. Convergence of the concentration. Let us now turn to the convergence of $(c, \mathbf{w})$. By the estimates of Proposition 3.2, the convergence of c to $\bar{c}$ holds not only in $L^1(0,T; L^1_{\rm loc}(\Omega))$, but also in $L^\infty(0,T; L^2(\Omega))$ weak-$*$ and strongly in $L^p(0,T; L^q(\Omega))$ for all $p < \infty$ and $q < 2$. Up to a subsequence, we can assume that $\mathbf{w} \to \bar{\mathbf{w}}$ weakly in $L^2((0,T)\times\Omega)^d$. Thanks to the estimates on G from Proposition 3.2, the analogue of (51) reads

$$\sum_{k=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \mathrm{diam}(K)^{d-1} \nu_K \mathrm{m}(K) |G^n_{K,\sigma}| \leq C_{33} \mathrm{size}(\mathcal{D})^{\frac{2d-2+\beta}{2}} \to 0 \ \text{ as } \mathrm{size}(\mathcal{D}) \to 0.$$

Hence, by (24) and Lemma 7.4, we have $\bar{c} \in L^2(0,T; H^1(\Omega))$ and $\bar{\mathbf{w}} = \nabla\bar{c}$. We now prove that $\bar{c}$ is a solution to (9), with $\bar{\mathbf{U}}$ the strong limit of $\mathbf{U}$ found in section 5.2. Let $\psi \in C^\infty_c([0,T)\times\overline{\Omega})$ and, for $n = 1, \ldots, N_k$, $\psi^n(x) = \frac{1}{k}\int_{(n-1)k}^{nk} \psi(t,x)\,dt$. We multiply (27) by $k\psi^n(\mathbf{x}_K)$ and sum over all $K \in \mathcal{M}$ and over $n = 1, \ldots, N_k$; this gives $T_6 + T_7 + T_8 + T_9 = T_{10}$. Let us study the limit of each of these terms as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$.

5.3.1. Limit of T_6. We have, since $\psi^{N_k} = \psi^{N_k+1} = 0$ for k small enough (the support of ψ does not touch $t = T$),

$$\begin{aligned} T_6 &= \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K \frac{c^n_K - c^{n-1}_K}{k} \psi^n(\mathbf{x}_K) \\ &= \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K c^n_K \frac{\psi^n(\mathbf{x}_K) - \psi^{n+1}(\mathbf{x}_K)}{k} - \sum_{K\in\mathcal{M}} \mathrm{m}(K)\Phi_K c^0_K \psi^1(\mathbf{x}_K) \\ &= \int_0^T \int_\Omega \Phi c \zeta_{k,\mathcal{D}} - \int_\Omega \Phi_{\mathcal{D}} c_0 \pi_{k,\mathcal{D}}, \end{aligned}$$

where $\Phi_{\mathcal{D}} = \Phi_K$ on K (as before), $\zeta_{k,\mathcal{D}} = \frac{\psi^n(\mathbf{x}_K) - \psi^{n+1}(\mathbf{x}_K)}{k}$ on $[(n-1)k, nk)\times K$, and $\pi_{k,\mathcal{D}} = \psi^1_K$ on K ($n = 1, \ldots, N_k$ and $K \in \mathcal{M}$). By regularity of ψ, it is clear that $\zeta_{k,\mathcal{D}} \to -\partial_t\psi$ uniformly on $(0,T)\times\Omega$ and $\pi_{k,\mathcal{D}} \to \psi(0,\cdot)$ uniformly on Ω; we also recall that $\Phi_{\mathcal{D}} \to \Phi$ strongly in $L^2(\Omega)$. The weak-$*$ convergence of c in $L^\infty(0,T; L^2(\Omega))$ then implies $T_6 \to -\int_0^T \int_\Omega \Phi\bar{c}\partial_t\psi - \int_\Omega \Phi c_0 \psi(0,\cdot)$.

5.3.2. Limit of T_7. Making use of manipulations which should be, at this stage, familiar to the reader, we get, using (52) with $\varphi = \psi$ and letting $\Psi_{k,\mathcal{D}}$ be the function on $[0,T)\times\Omega$ equal to $\nabla\psi^n(\mathbf{x}_K)$ on $[(n-1)k, nk)\times K$,

$$\begin{aligned}
T_7 &= -\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}\psi^n(\mathbf{x}_K)\\
&= \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \nabla\psi^n(\mathbf{x}_K)\cdot\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}(\mathbf{x}_\sigma-\mathbf{x}_K) + \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}R^n_{K,\sigma}\\
&= \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K) D_K(\mathbf{U}^n_K)\mathbf{w}^n_K\cdot\nabla\psi^n(\mathbf{x}_K) + \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}R^n_{K,\sigma}\\
&= \int_0^T\int_\Omega \mathbf{w}\cdot D(\cdot,\mathbf{U})^T\Psi_{k,\mathcal{D}} + \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}R^n_{K,\sigma}. \qquad (60)
\end{aligned}$$

However, thanks to the estimates on G from Proposition 3.2, the analogue of (55) reads

$$\left|\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K} G^n_{K,\sigma}R^n_{K,\sigma}\right| \le C_{34}\ \mathrm{size}(\mathcal{D})^{\frac{4-2d-\beta}{2}} \to 0 \quad \text{as } \mathrm{size}(\mathcal{D})\to 0.$$

Since $\mathbf{U}\to\bar{\mathbf{U}}$ strongly in $L^2((0,T)\times\Omega)^d$, hypothesis (12) classically implies that $D(\cdot,\mathbf{U})\to D(\cdot,\bar{\mathbf{U}})$ strongly in $L^2((0,T)\times\Omega)^{d\times d}$. Since $\Psi_{k,\mathcal{D}}\to\nabla\psi$ uniformly on $(0,T)\times\Omega$, we deduce that $D(\cdot,\mathbf{U})^T\Psi_{k,\mathcal{D}}\to D(\cdot,\bar{\mathbf{U}})^T\nabla\psi$ in $L^2((0,T)\times\Omega)^d$ and the weak convergence of $\mathbf{w}$ to $\nabla\bar{c}$ allows us to pass to the limit in (60), and we get $T_7\to\int_0^T\int_\Omega D(\cdot,\bar{\mathbf{U}})\nabla\bar{c}\cdot\nabla\psi$.

5.3.3. Limit of T_8. The term T_8 is built by writing $-kT_2$ (introduced in the proof of Lemma 5.1) with $\psi^n(\mathbf{x}_K)$ instead of ψ_K and summing over n, that is,

$$T_8 = \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}}\sum_{\sigma=K|L\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{int}}} \left[(-F^n_{K,\sigma})^+c^n_K - (-F^n_{L,\sigma})^-c^n_L\right]\psi^n(\mathbf{x}_K).$$

In the proof of Lemma 5.1, the estimate (49) on T_2 has been proved for test functions φ in $C^2_c(\Omega)$, but it is also valid for test functions in $C^2(\overline{\Omega})$; in the same way, it is still valid if we use, in the definition of T_2, $\varphi(\mathbf{x}_K)$ rather than the mean value of φ on K (because (52) is similar to (38) without requiring $\mathbf{x}_K$ to be the barycenter of K). Therefore,

$$\begin{aligned}
&\left|T_8 + \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K)c^n_K\mathbf{U}^n_K\cdot\nabla\psi^n(\mathbf{x}_K)\right|\\
&\quad\le C_{35}\ \mathrm{size}(\mathcal{D})^{\frac{4-2d-\beta}{2}} \sum_{n=1}^{N_k} k\left(\sum_{K\in\mathcal{M}}\mathrm{m}(K)(|\mathbf{w}^n_K|+|c^n_K|)^2\right)^{\frac12}\\
&\qquad + C_{35}\sum_{n=1}^{N_k} k\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)|F^n_{K,\sigma}|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\mathrm{m}(K)|\mathbf{w}^n_K|^2\right)^{\frac12}\\
&\qquad + C_{35}\ \mathrm{size}(\mathcal{D})\sum_{n=1}^{N_k} k\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)|G^n_{K,\sigma}|^2\right)^{\frac12}
\end{aligned}$$

and, using the Cauchy–Schwarz inequality, the estimates of Proposition 3.2, and (59), this right-hand side tends to 0 as $k \to 0$ and size$(\mathcal{D}) \to 0$. With the same $\Psi_{k,\mathcal{D}}$ as before, we have $\sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K) c_K^n \mathbf{U}_K^n \cdot \nabla\psi^n(\mathbf{x}_K) = \int_0^T \int_\Omega c\mathbf{U} \cdot \Psi_{k,\mathcal{D}}$, and we therefore can pass to the limit (using the weak convergence of c in $L^2((0,T)\times\Omega)$, the strong convergence of $\mathbf{U}$ in $L^2((0,T)\times\Omega)^d$, and the uniform convergence of $\Psi_{k,\mathcal{D}}$ on $(0,T)\times\Omega$) to obtain $T_8 \to -\int_0^T \int_\Omega \bar{c}\bar{\mathbf{U}} \cdot \nabla\psi$.

5.3.4. Limits of T_9 and T_{10}. We have, with $\psi_{k,\mathcal{D}}$ equal to $\psi^n(\mathbf{x}_K)$ on $[(n-1)k, nk) \times K$,

$$T_9 = \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K) q_K^{-,n} c_K^n \psi^n(\mathbf{x}_K) = \int_0^T \int_\Omega q^- c\psi_{k,\mathcal{D}} \to \int_0^T \int_\Omega q^- \bar{c}\psi.$$

It is also easy to pass to the limit in

$$T_{10} = \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K) q_K^{+,n} \widehat{c}_K^n \psi^n(\mathbf{x}_K) = \int_0^T \int_\Omega q^+ \widehat{c}_{k,\mathcal{D}} \psi_{k,\mathcal{D}}$$

once we notice that, as for $\Phi_\mathcal{D}$, the function $\widehat{c}_{k,\mathcal{D}}$ equal to $\widehat{c}_K^n$ on $[(n-1)k, nk) \times K$ converges to $\widehat{c}$ in $L^2((0,T)\times\Omega)$. Hence, $T_{10} \to \int_0^T \int_\Omega q^+ \widehat{c}\psi$.

Gathering the preceding convergences in $T_6 + T_7 + T_8 + T_9 = T_{10}$, we deduce that $\bar{c}$ is a weak solution to (9) with the function $\bar{\mathbf{U}}$ being the limit of $\mathbf{U}$.

6. Numerical results. In this section, we illustrate the behavior of the mixed finite volume scheme by applying it to the system (1)–(7), which describes the miscible displacement of one fluid by another in a porous medium. Some of the tests cases come from [20], where an ELLAM-MFEM scheme is used, and our results compare very well to the ones in this reference. In practice, for the implementation of the numerical scheme we have used the hybrid method mentioned in Remark 4.1.

In all the test cases, the spatial domain is $\Omega = (0,1000) \times (0,1000)$ ft^2 and the time period is $[0, 3600]$ days. The injection well is located at the upper-right corner $(1000, 1000)$ with an injection rate $q^+ = 30$ ft^2/day and an injection concentration $\hat{c} = 1.0$. The production well is located at the lower-left corner $(0,0)$ with a production rate $q^- = 30$ ft^2/day. The viscosity of the oil is $\mu(0) = 1.0$ cp, the porosity of the medium is specified as $\Phi(x) = 0.1$, and the initial concentration is $c_0(x) = 0$.

Remark 6.1. Although this does not entirely satisfy the assumptions of our theoretical study, the wells can be considered as Dirac masses; from the point of view of numerical tests, we saw no difference between using Dirac masses for q^+ and q^- or approximations of such masses by functions with small support (which would be admissible in the theoretical study).

The mesh of the domain is partitioned into 928 triangles of maximal edge length 50 ft. We take as time step $k = 36$ days, but the scheme still works with greater time steps (indeed, the discretization is implicit in time and does not require any stability condition). In fact, if we use the same time step $k = 360$ days as in [20], we obtain numerical results close to the ones in this reference but, since the computational times are in any case very short (less than 3 seconds per time step on a personal computer), we choose the smaller time step $k = 36$ days to show more accurate results with respect to the exact solution. As noticed in [9], the choice of ν_K has very little impact on the numerical outcomes and any small value for the penalization gives good results; we therefore take $\nu_K \mathrm{m}(K) = 10^{-6}$ for all K. Note that for $10^{-10} \le \nu_K \mathrm{m}(K) \le 10^{-2}$,

the numerical results are similar. For each test case, we present the surface plot and/or the contour plot of the concentration c, the interesting physical quantity, at $t = 3$ years (≈ 30 time steps) and $t = 10$ years (≈ 100 time steps).

Remark 6.2. Notice that our scheme preserves the discrete mass, that is, for $n = 1, \dots, N_k$,

$$\int_\Omega \phi(x)c^n(x)\,dx + \int_{(n-1)k}^{nk}\int_\Omega q^-(t,x)c^n(x)\,dxdt = \int_\Omega \phi(x)c^{n-1}(x)\,dx + \int_{(n-1)k}^{nk}\int_\Omega q^+(t,x)\widehat{c}^n(x)\,dxdt$$

(this is obtained by summing (27) over all $K \in \mathcal{M}$ and using (25) and (28) to cancel the terms involving $G^n_{K,\sigma}$ and (18) to cancel the terms involving $F^n_{K,\sigma}$). This is of essential importance in the applications.

Remark 6.3. We also notice that, in all the following numerical tests, the computed values of the concentration remain in $[0, 1]$. This is, however, only a numerical verification, not a proof (but, thanks to assumption (11), these bounds are not needed to prove the convergence of the mixed finite volume scheme—and in fact, since the computed c remains in $[0, 1]$, the implementation of the scheme does not require extending μ outside of $[0, 1]$). The mixed finite volume method has many advantages: it works on very general meshes (which can be useful in petroleum engineering; see [14]); it ensures strong convergence of the discrete gradients (and therefore convergence of the scheme for the fully coupled system with minimal regularity assumptions on the data); it can be easily implemented. But the counterpart is that, though the *continuous* concentration remains in $[0, 1]$ (see [3] or [15]), we did not prove such bounds for the *approximate* concentration; they are just verified in numerical experiments (such is also the case for other numerical methods; see, e.g., [12, 17, 20]).

Test 1. For this test case, we assume that the porous medium is homogeneous and isotropic: the permeability tensor is diagonal and constant, $\mathbf{K} = 80\mathbf{I}$. The mobility ratio between the resident and the injected fluids is $M = 1$, so that the viscosity is constant, $\mu(c) = 1.0$ cp.

We assume that $\Phi d_m = 1.0$ ft^2/day, $\Phi d_l = 5.0$ ft, and $\Phi d_t = 0.5$ ft. This means that the diffusion effects will be considerably greater than the dispersion effects, which is in fact unrealistic.

The surface plot and the contour plot of the concentration c at $t = 3$ years and $t = 10$ years are shown in Figure 1. As expected, the Darcy velocity is radial and the contour plots are circular until the invading fluid reaches the production well (see at $t = 3$ years). When the production well is reached, the invading fluid continues to fill the whole domain until $c = 1$.

Test 2. The permeability tensor is still diagonal and constant, $\mathbf{K} = 80\mathbf{I}$. The adverse mobility ratio is $M = 41$ and the viscosity $\mu(c)$ now really depends on c.

We assume that there is no molecular diffusion $\Phi d_m = 0.0$ ft^2/day and that $\Phi d_l = 5.0$ ft and $\Phi d_t = 0.5$ ft. This means that we take into account dispersion effects, which is realistic.

This test case is presented in [20] and permits us to see the macroscopic fingering phenomenon. Indeed, the viscosity $\mu(c)$ rapidly changes across the fluid interface. It induces rapid changes of the Darcy velocity $\mathbf{U}$, and the difference between the longitudinal and the transverse dispersivity coefficients implies that the fluid flow is much faster along the diagonal direction. Such effects can be seen on the surface and contour plots in Figure 2.

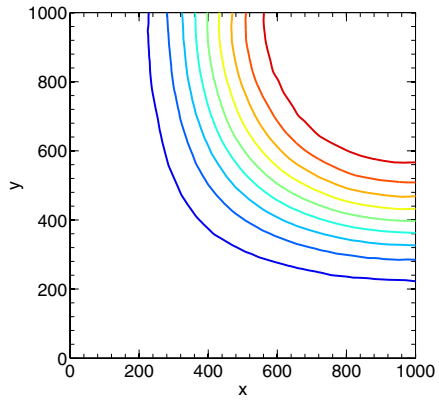
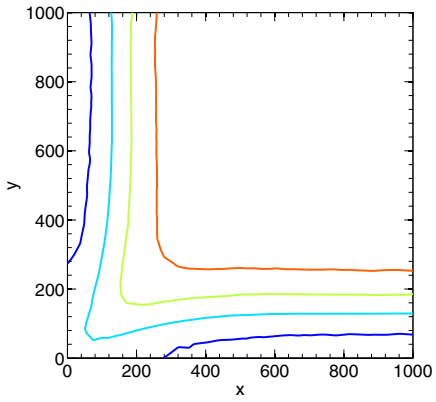
Surface plot at $t = 10$ years



Contour plot at $t = 3$ years



Contour plot at $t = 10$ years

FIG. 1. *Concentration of the invading component in Test* 1.

Remark 6.4. Although this test (as well as Tests 3 and 4) does not satisfy our theoretical assumptions (because $d_m = 0$), we present its results to show that the mixed finite volume scheme is robust and can numerically handle more general cases than the ones admitted in the theoretical study, and also to compare it with other existing schemes for the same equations (note that there is no theoretical study of convergence whatsoever in [20] or [21]).

Test 3. In this test case, we consider that the permeability tensor is still diagonal but discontinuous: $\mathbf{K} = 80\mathbf{I}$ on the subdomain $(0, 1000) \times (0, 500)$ and $\mathbf{K} = 20\mathbf{I}$ on the subdomain $(0, 1000) \times (500, 1000)$. The adverse mobility ratio, the molecular diffusion, the longitudinal and the transverse dispersivities are the same as in Test 2.

The lower half domain has a larger permeability than the upper half domain. Therefore, when the invading fluid reaches the lower half domain, it "prefers" to pass through this domain rather than through the domain with lower permeability. As expected, we also notice that the upper half domain is, overall, less invaded than in Test 2. These effects are illustrated by the contour plots of c in Figure 3.

Test 4. In this last test case, the permeability tensor has the form $\mathbf{K} = \kappa(x)\mathbf{I}$ with $\kappa(x) = 80$ except on the four square subdomains $(200, 400) \times (200, 400)$, $(600, 800) \times (200, 400)$, $(200, 400) \times (600, 800)$, and $(600, 800) \times (600, 800)$, where $\kappa(x) = 20$. The

adverse mobility ratio is $M = 41$, and we take $\Phi d_m = 0.0$ ft^2/day, $\Phi d_l = 5.0$ ft, and $\Phi d_t = 0.5$ ft.

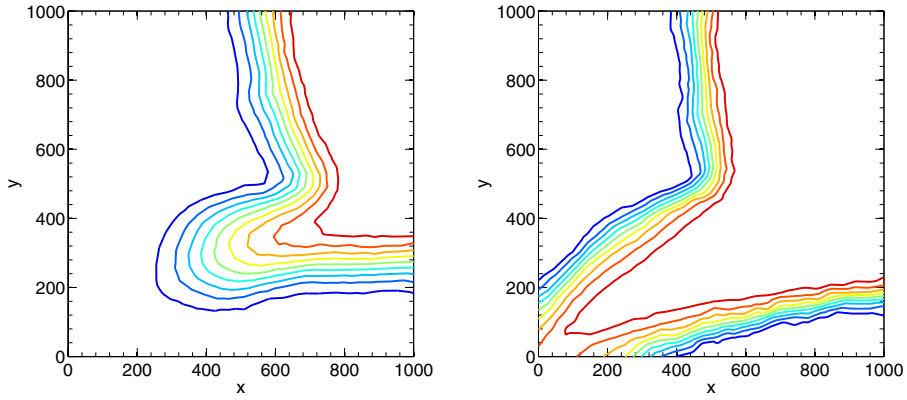
Figure 4 shows the contour plot of the concentration at $t = 3$ years and $t = 10$ years. The subdomains where the permeability is lower can easily be seen in the figures. We note that the area occupied by the invading fluid at $t = 10$ years is in this case larger than in Test 2, where the permeability was homogeneous.

7. Appendix.

7.1. A magical lemma. The proof of the following lemma (a very simple application of Stokes's formula) can be found in [9].

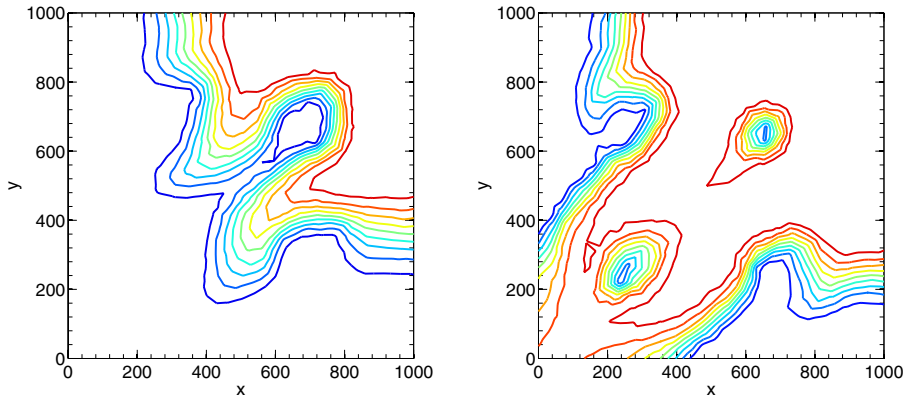
LEMMA 7.1. *Let K be a nonempty polygonal convex domain in $\mathbb{R}^d$. For $\sigma \in \mathcal{E}_K$, we define $\mathbf{x}_\sigma$ as the center of gravity of σ, and $\mathbf{n}_{K,\sigma}$ as the unit normal to σ outward to K. Then, for all vector $\mathbf{e} \in \mathbb{R}^d$ and for all point $\mathbf{x}_K \in \mathbb{R}^d$, we have* $\mathrm{m}(K)\mathbf{e} = \sum_{\sigma\in\mathcal{E}_K} \mathrm{m}(\sigma)\mathbf{e}\cdot\mathbf{n}_{K,\sigma}(\mathbf{x}_\sigma - \mathbf{x}_K)$, *where* $\mathrm{m}(K)$ *is the d-dimensional measure of K and* $\mathrm{m}(\sigma)$ *is the $(d-1)$-dimensional measure of σ.*

7.2. Lemmas on discrete gradients. For $\mathcal{D}$ an admissible mesh of Ω and $\nu = (\nu_K)_{K\in\mathcal{M}}$ a family of positive numbers, we denote by $L_\nu(\mathcal{D})$ the space of $(u, \mathbf{r}, H)$, with $u = (u_K)_{K\in\mathcal{M}}$ a family of numbers, $\mathbf{r} = (\mathbf{r}_K)_{K\in\mathcal{M}}$ a family of vectors, and



Contour plot at $t = 3$ years Contour plot at $t = 10$ years

FIG. 3. *Concentration of the invading component in Test* 3.



Contour plot at $t = 3$ years Contour plot at $t = 10$ years

FIG. 4. *Concentration of the invading component in Test* 4.

$H = (H_{K,\sigma})_{K\in\mathcal{M},\,\sigma\in\mathcal{E}_K}$ a family of numbers, such that, for all $\sigma = K|L \in \mathcal{E}_{\rm int}$,

$$\mathbf{r}_K \cdot (\mathbf{x}_\sigma - \mathbf{x}_K) + \mathbf{r}_L \cdot (\mathbf{x}_L - \mathbf{x}_\sigma) + \nu_K \mathrm{m}(K) H_{K,\sigma} - \nu_L \mathrm{m}(L) H_{L,\sigma} = u_L - u_K \tag{61}$$

(note that u and $\mathbf{r}$ are also identified with the corresponding functions on Ω constant on each control volume K). The following lemmas are the counterparts for Neumann boundary conditions of lemmas stated in [9] or [8] in the case of Dirichlet boundary conditions.

LEMMA 7.2. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$, $\mathcal{D}$ an admissible mesh of Ω such that* $\mathrm{regul}(\mathcal{D}) \le \theta$ *for some $\theta > 0$, and $\nu = (\nu_K)_{K\in\mathcal{M}}$ a family of positive numbers. Then there exists C_{36} depending only on d, Ω, and θ such that, for all $(u, \mathbf{r}, H) \in L_\nu(\mathcal{D})$ satisfying $\int_\Omega u = 0$,*

$$\|u\|_{L^2(\Omega)} \le C_{36} \left(\|\mathbf{r}\|_{L^2(\Omega)^d} + M_2(\mathcal{D}, \nu, H) \right)$$

with $M_2(\mathcal{D}, \nu, H) = \left(\sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \mathrm{diam}(K)^{2d-2} \nu_K^2 \mathrm{m}(K) |H_{K,\sigma}|^2 \right)^{\frac{1}{2}}$.

Proof. Let w be the weak solution of $-\Delta w = u$ on Ω with homogeneous Neumann boundary conditions on $\partial\Omega$ (such a w exists thanks to the fact that $\int_\Omega u = 0$) and null mean value. Since Ω is convex, it is well known (see [16]) that $w \in H^2(\Omega)$ and that there exists C_{37} depending only on d and Ω such that $\|w\|_{H^2(\Omega)} \le C_{37}\|u\|_{L^2(\Omega)}$.

We multiply each equation of (61) by $\int_\sigma \nabla w\cdot \mathbf{n}_{K,\sigma}\,d\gamma$, sum over the interior edges, gather by control volumes, and use that $\int_\sigma \nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma = 0$ whenever $\sigma\in\mathcal{E}_{\rm ext}$; this gives

$$\begin{aligned}(62)\qquad &\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathbf{r}_K\cdot(\mathbf{x}_\sigma-\mathbf{x}_K)\int_\sigma \nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma\\ &\qquad+\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)H_{K,\sigma}\int_\sigma\nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma = \|u\|^2_{L^2(\Omega)}.\end{aligned}$$

Since $\mathrm{regul}(\mathcal{D})\le\theta$, [8, Lemma 8.1] gives C_{38} depending only on d, Ω, and θ such that

$$\left|\int_\sigma \nabla w\,d\gamma\cdot\mathbf{n}_{K,\sigma}\right|^2 \le \left|\int_\sigma\nabla w\,d\gamma\right|^2 \le \frac{C_{38}\mathrm{m}(\sigma)}{\mathrm{diam}(K)}\|w\|^2_{H^2(K)}.$$

Using the Cauchy–Schwarz inequality, we deduce, since $\mathrm{Card}(\mathcal{E}_K)\le\mathrm{regul}(\mathcal{D})\le\theta$ for all $K\in\mathcal{M}$,

$$\begin{aligned}&\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathbf{r}_K\cdot(\mathbf{x}_\sigma-\mathbf{x}_K)\int_\sigma\nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma\\ &\le\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}(K)|\mathbf{r}_K|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\frac{\mathrm{diam}(K)^2}{\mathrm{m}(K)}\left|\int_\sigma\nabla w\,d\gamma\cdot\mathbf{n}_{K,\sigma}\right|^2\right)^{\frac12}\\ &\le(C_{38}\theta)^{\frac12}\left(\sum_{K\in\mathcal{M}}\mathrm{m}(K)|\mathbf{r}_K|^2\right)^{\frac12}\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\frac{\mathrm{diam}(K)\mathrm{m}(\sigma)}{\mathrm{m}(K)}\|w\|^2_{H^2(K)}\right)^{\frac12}.\end{aligned}$$

We have, if $\sigma\in\mathcal{E}_K$, $\mathrm{m}(\sigma)\le\omega_{d-1}\mathrm{diam}(K)^{d-1}$ (where ω_{d-1} is the volume of the unit ball in $\mathbb{R}^{d-1}$); thus, by (16), $\frac{\mathrm{diam}(K)\mathrm{m}(\sigma)}{\mathrm{m}(K)}\le\frac{\mathrm{regul}(\mathcal{D})\omega_{d-1}}{\omega_d}$ and we obtain

$$(63)\quad\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathbf{r}_K\cdot(\mathbf{x}_\sigma-\mathbf{x}_K)\int_\sigma\nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma\le\frac{\theta^{\frac32}\sqrt{C_{38}\omega_{d-1}}}{\sqrt{\omega_d}}\|\mathbf{r}\|_{L^2(\Omega)^d}\|w\|_{H^2(\Omega)}.$$

The Cauchy–Schwarz inequality also gives

$$\begin{aligned}&\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)H_{K,\sigma}\int_\sigma\nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma\\ &\le\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{2d-2}\nu_K^2\mathrm{m}(K)|H_{K,\sigma}|^2\right)^{\frac12}\\ &\qquad\qquad\times\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\frac{\mathrm{m}(K)}{\mathrm{diam}(K)^{2d-2}}\left|\int_\sigma\nabla w\cdot\mathbf{n}_{K,\sigma}\,d\gamma\right|^2\right)^{\frac12}\\ &\le\sqrt{C_{38}}\,M_2(\mathcal{D},\nu,H)\left(\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\frac{\mathrm{m}(\sigma)\mathrm{m}(K)}{\mathrm{diam}(K)^{2d-1}}\|w\|^2_{H^2(K)}\right)^{\frac12}.\end{aligned}$$

Since $\frac{\mathrm{m}(\sigma)\mathrm{m}(K)}{\mathrm{diam}(K)^{2d-1}} \le \omega_{d-1}\omega_d$, this inequality and (63) plugged in (62) conclude the proof, since $\|w\|_{H^2(\Omega)} \le C_{37}\|u\|_{L^2(\Omega)}$. ∎

LEMMA 7.3. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$, $\mathcal{D}$ an admissible mesh of Ω such that* $\mathrm{regul}(\mathcal{D}) \le \theta$ *for some $\theta > 0$, and $\nu = (\nu_K)_{K\in\mathcal{M}}$ a family of positive numbers. Let ω be relatively compact in Ω. Then there exists C_{39} depending only on d, Ω, ω, and θ such that, for all $(u, \mathbf{r}, H) \in L_\nu(\mathcal{D})$ and all $|\xi| < \mathrm{dist}(\omega, \mathbb{R}^d\backslash\Omega)$,*

$$\|u(\cdot+\xi) - u\|_{L^1(\omega)} \le C_{39}\left(\|\mathbf{r}\|_{L^1(\Omega)^d} + M_1(\mathcal{D},\nu,H)\right)|\xi|,$$

where $M_1(\mathcal{D},\nu,H) = \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{d-1}\nu_K\mathrm{m}(K)|H_{K,\sigma}|$.

We leave to the reader the proof of Lemma 7.3, counterpart of Lemma 3.2 in [9].

LEMMA 7.4. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$ and let $T > 0$. Let $(\mathcal{D}_m)_{m\ge1}$ be a sequence of admissible meshes of Ω such that* $\mathrm{size}(\mathcal{D}_m) \to 0$ *as $m \to \infty$ and* $(\mathrm{regul}(\mathcal{D}_m))_{m\ge1}$ *is bounded. We also take, for all $m \ge 1$, $k_m > 0$ such that $N_{k_m} = T/k_m$ is an integer and $k_m \to 0$ as $m \to \infty$, and $\nu_m = (\nu_{m,K})_{K\in\mathcal{M}_m}$ a family of positive numbers.*

For all $m \ge 1$ and all $n = 1, \dots, N_{k_m}$, we take $(u^{m,n}, \mathbf{r}^{m,n}) = (u_K^{m,n}, \mathbf{r}_K^{m,n})_{K\in\mathcal{M}_m}$ and a family $H^{m,n} = (H_{K,\sigma}^{m,n})_{K\in\mathcal{M}_m,\,\sigma\in\mathcal{E}_K}$ such that $(u^{m,n}, \mathbf{r}^{m,n}, H^{m,n}) \in L_{\nu_m}(\mathcal{D}_m)$. We let $(u^m, \mathbf{r}^m)$ be the functions on $[0,T)\times\Omega$ equal to $(u_K^{m,n}, \mathbf{r}_K^{m,n})$ on $[(n-1)k, nk)\times K$ (for $n = 1, \dots, N_{k_m}$ and $K \in \mathcal{M}_m$).

Assume that, as $m \to \infty$, $u^m \to \bar{u}$ weakly in $L^2((0,T)\times\Omega)$, $\mathbf{r}^m \to \bar{\mathbf{r}}$ weakly in $L^2((0,T)\times\Omega)^d$, and

$$\sum_{n=1}^{N_{k_m}} k_m \sum_{K\in\mathcal{M}_m}\sum_{\sigma\in\mathcal{E}_K}\mathrm{diam}(K)^{d-1}\nu_{m,K}\mathrm{m}(K)|H_{K,\sigma}^{m,n}| \to 0. \tag{64}$$

Then $\bar{u} \in L^2(0,T;H^1(\Omega))$ and $\nabla\bar{u} = \bar{\mathbf{r}}$.

Proof. We first simplify the notation by dropping the index m; hence, we denote $\mathcal{D} = \mathcal{D}_m$, $k = k_m$, $u = u^m$, $\mathbf{r} = \mathbf{r}^m$, $H_{K,\sigma}^n = H_{K,\sigma}^{m,n}$, and we are interested in the convergence of quantities as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$.

To prove the lemma, we just need to show that $\nabla\bar{u} = \bar{\mathbf{r}}$ in the sense of the distributions on $(0,T)\times\Omega$. Let $\varphi \in C_c^\infty((0,T)\times\Omega)$ and $\mathbf{e} \in \mathbb{R}^d$; we multiply each equation (61) on $(u^n, \mathbf{r}^n, H^n)$ by $\int_{(n-1)k}^{nk}\int_\sigma \varphi\mathbf{e}\cdot\mathbf{n}_{K,\sigma}\,d\gamma$. We then sum over all the edges and, using $\mathbf{n}_{K,\sigma} = -\mathbf{n}_{L,\sigma}$ if $\sigma = K|L \in \mathcal{E}_{\mathrm{int}}$, we gather by control volumes. Thanks to the fact that $\int_{(n-1)k}^{nk}\int_\sigma \varphi\mathbf{e}\cdot\mathbf{n}_{K,\sigma}\,d\gamma = 0$ if $\sigma \in \mathcal{E}_{\mathrm{ext}}$, we can freely introduce the terms corresponding to boundary edges (which are otherwise not present). Finally summing over $n = 1, \dots, N_k$, we obtain

$$\begin{aligned}&\sum_{n=1}^{N_k}\sum_{K\in\mathcal{M}}\mathbf{r}_K^n\cdot\sum_{\sigma\in\mathcal{E}_K}\int_{(n-1)k}^{nk}\int_\sigma \varphi\mathbf{e}\cdot\mathbf{n}_{K,\sigma}\,d\gamma(\mathbf{x}_\sigma - \mathbf{x}_K)\\ &+\sum_{n=1}^{N_k}\sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\nu_K\mathrm{m}(K)H_{K,\sigma}^n\int_{(n-1)k}^{nk}\int_\sigma \varphi\mathbf{e}\cdot\mathbf{n}_{K,\sigma}\,d\gamma = -\int_0^T\int_\Omega u\mathrm{div}(\varphi\mathbf{e}).\end{aligned} \tag{65}$$

By convergence of u, this right-hand side tends, as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$, to $-\int_0^T\int_\Omega \bar{u}\mathrm{div}(\varphi\mathbf{e})$. Let us denote by T_{11} and T_{12} the two terms on the left-hand side of this equality.

We have, since φ is bounded and $\mathrm{m}(\sigma) \le \omega_{d-1}\mathrm{diam}(K)^{d-1}$ if $\sigma \in \mathcal{E}_K$,

$$|T_{12}| \le \|\varphi\|_\infty \omega_{d-1} \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K} \nu_K \mathrm{m}(K) |H^n_{K,\sigma}| \mathrm{diam}(K)^{d-1}$$

and thus, by assumption, $T_{12} \to 0$ as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$. We now compare T_{11} with

$$T_{13} = \sum_{n=1}^{N_k} \sum_{K\in\mathcal{M}} \mathbf{r}^n_K \cdot \int_{(n-1)k}^{nk} \sum_{\sigma\in\mathcal{E}_K} \mathrm{m}(\sigma) \left(\frac{1}{\mathrm{m}(K)} \int_K \varphi\, \mathbf{e} \right) \cdot \mathbf{n}_{K,\sigma} (\mathbf{x}_\sigma - \mathbf{x}_K).$$

Since φ is regular, we have C_{40} depending only on φ such that

$$|T_{11} - T_{13}| \le C_{40} \mathrm{size}(\mathcal{D}) \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} |\mathbf{r}^n_K| \sum_{\sigma\in\mathcal{E}_K} \mathrm{m}(\sigma) \mathrm{diam}(K).$$

Using the fact that $\mathrm{regul}(\mathcal{D})$ stays bounded and that $\mathrm{m}(\sigma) \le \omega_{d-1}\mathrm{diam}(K)^{d-1}$, we get

$$|T_{11} - T_{13}| \le C_{41} \mathrm{size}(\mathcal{D}) \sum_{n=1}^{N_k} k \sum_{K\in\mathcal{M}} \mathrm{m}(K) |\mathbf{r}^n_K| = C_{41} \mathrm{size}(\mathcal{D}) \|\mathbf{r}\|_{L^1((0,T)\times\Omega)^d}.$$

Since $\mathbf{r}$ is bounded in $L^2((0,T)\times\Omega)^d$, this shows that $T_{11} - T_{13} \to 0$ as $\mathrm{size}(\mathcal{D}) \to 0$. Using Lemma 7.1 with $\frac{1}{\mathrm{m}(K)} \int_K \varphi(t,\cdot)\, \mathbf{e}$ instead of $\mathbf{e}$, we get

$$T_{13} = \sum_{n=1}^{N_k} \sum_{K\in\mathcal{M}} \mathbf{r}^n_K \cdot \int_{(n-1)k}^{nk} \int_K \varphi\, \mathbf{e} = \int_0^T \int_\Omega \mathbf{r} \cdot \varphi\, \mathbf{e} \longrightarrow \int_0^T \int_\Omega \bar{\mathbf{r}} \cdot \varphi\, \mathbf{e}$$

as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$. Hence, the limit of (65) as $k \to 0$ and $\mathrm{size}(\mathcal{D}) \to 0$ gives $\int_0^T \int_\Omega \bar{\mathbf{r}} \cdot \varphi\, \mathbf{e} = -\int_0^T \int_\Omega \bar{u} \mathrm{div}(\varphi \mathbf{e})$, which concludes the proof. ∎

7.3. A compactness lemma. The following lemma, whose proof is inspired by classical proofs of Kolmogorov's or Aubin's compactness theorems, mixes a weak time-compactness and a space-equicontinuity property to obtain a strong time-space compactness.

LEMMA 7.5. *Let Ω be a bounded domain in $\mathbb{R}^d$, let $T > 0$, and let $A \subset L^1(0,T; L^1_{\mathrm{loc}}(\Omega))$. If A is relatively compact in $L^1(0,T;(C^2_c(\Omega))')$ and if, for all ω relatively compact in Ω,*

$$\sup_{u\in A} \|u(\cdot,\cdot+\xi) - u\|_{L^1((0,T)\times\omega)} \to 0 \quad \text{as } |\xi| \to 0,$$

then A is relatively compact in $L^1(0,T; L^1_{\mathrm{loc}}(\Omega))$.

Proof. Let ω be relatively compact in Ω and take $(\rho_\mu)_{0<\mu<\mathrm{dist}(\omega,\mathbb{R}^d\setminus\Omega)}$ smoothing kernels on $\mathbb{R}^d$ such that $\mathrm{supp}(\rho_\mu)$ is included in the ball of center 0 and radius μ. For $u \in A$, let $u_\mu = u * \rho_\mu$ (the convolution being only on the space variable), which is defined on $(0,T)\times\omega$.

We first prove that, for all μ, $A_\mu = \{u_\mu,\ u \in A\}$ is relatively compact in $L^1((0,T)\times\omega)$. Let $(u^n_\mu)_{n\ge1}$ be a sequence in A_μ. Since $(u^n)_{n\ge1}$ lies in A, it is relatively

compact in $L^1(0,T;(C_c^2(\Omega))')$ and we can assume, up to a subsequence, that it converges in this space. We then have, for all $(t,x)\in(0,T)\times\omega$, since $\mathrm{supp}(\rho_\mu(x-\cdot))\subset\Omega$ by choice of μ,

$$|u_\mu^n(t,x)-u_\mu^m(t,x)| = \left|\int_\Omega (u^n(t,y)-u^m(t,y))\rho_\mu(x-y)\,dx\right|$$
$$\le \|u^n(t,\cdot)-u^m(t,\cdot)\|_{(C_c^2(\Omega))'}\|\rho_\mu(x-\cdot)\|_{C_c^2(\Omega)}.$$

Hence, integrating on $x\in\omega$ and $t\in(0,T)$, we find C_μ depending on μ but not on n or m such that $\|u_\mu^n-u_\mu^m\|_{L^1((0,T)\times\omega)}\le C_\mu\|u^n-u^m\|_{L^1(0,T;(C_c^2(\Omega))')}$, which shows that $(u_\mu^n)_{n\ge1}$ converges in $L^1((0,T)\times\omega)$ since $(u^n)_{n\ge1}$ converges in $L^1(0,T;(C_c^2(\Omega))')$. Hence, for all $\mu\in(0,\mathrm{dist}(\omega,\mathbb{R}^d\backslash\Omega))$, A_μ is relatively compact in $L^1((0,T)\times\omega)$.

Let us now conclude. It is sufficient to show that $\sup_{u\in A}\|u-u_\mu\|_{L^1((0,T)\times\omega)}$ goes to 0 as $\mu\to0$. Indeed, once this is done, we get $A\subset A_\mu+B_{L^1((0,T)\times\omega)}(0,\delta(\mu))$ with $\delta(\mu)\to0$ as $\mu\to0$, which clearly shows, since A_μ is precompact in $L^1((0,T)\times\omega)$, that A is also precompact (and thus relatively compact) in this space. Let $u\in A$, $t\in(0,T)$, and $x\in\omega$; we have $|u(t,x)-u_\mu(t,x)|\le\int_{B(0,\mu)}|u(t,x)-u(t,x-y)|\rho_\mu(y)\,dy$ and thus, integrating on $x\in\omega$ and $t\in(0,T)$,

$$\|u-u_\mu\|_{L^1((0,T)\times\omega)}\le\int_{B(0,\mu)}\int_0^T\int_\omega|u(t,x)-u(t,x-y)|\,dtdx\,\rho_\mu(y)\,dy$$
$$\le\sup_{|y|\le\mu}\int_0^T\int_\omega|u(t,x)-u(t,x-y)|\,dtdx,$$

and the proof is concluded. ∎

7.4. A technical lemma. The proof of the following technical lemma is left to the reader.

LEMMA 7.6. *Let Ω be a convex polygonal bounded domain in $\mathbb{R}^d$, let $T>0$, and let $A:\Omega\times\mathbb{R}\to M_d(\mathbb{R})$ be a Carathéodory bounded matrix-valued function. Let $(\mathcal{D}_m)_{m\ge1}$ be a sequence of admissible meshes of Ω such that $\mathrm{size}(\mathcal{D}_m)\to0$ as $m\to\infty$, and let $k_m>0$ be such that $N_{k_m}=T/k_m$ is an integer and $k_m\to0$ as $m\to\infty$.*

Let $u^m=(u_K^{m,n})_{n=1,\dots,N_{k_m},\,K\in\mathcal{M}}$ be a function on $(0,T)\times\Omega$, constant on each $[(n-1)k,nk)\times K$ ($n=1,\dots,N_{k_m}$, $K\in\mathcal{M}_m$). We assume that $u^m\to\bar u$ in $L^1(0,T;L^1_{\mathrm{loc}}(\Omega))$ as $m\to\infty$. Let $\mathbf{Z}^m\in L^2((0,T)\times\Omega)^d$, which converges to $\bar{\mathbf{Z}}$ in $L^2((0,T)\times\Omega)^d$ as $m\to\infty$. Define $A_{\mathcal{D}_m}:\Omega\times\mathbb{R}\to M_d(\mathbb{R})$ by $A_{\mathcal{D}_m}(x,s)=\frac{1}{\mathrm{m}(K)}\int_K A(y,s)\,dy$ whenever x belongs to $K\in\mathcal{M}_m$.

Then $A_{\mathcal{D}_m}(\cdot,u^m)\mathbf{Z}^m\to A(\cdot,\bar u)\bar{\mathbf{Z}}$ in $L^2((0,T)\times\Omega)^d$ as $m\to\infty$.

ANALYSIS OF DIRECT THREE-DIMENSIONAL PARABOLIC PANEL METHODS*

PHILIPPE PONCET†

Abstract. Adherence boundary conditions for time dependent partial differential equations, via Chorin algorithm, can be reduced to a parabolic problem with Robin–Fourier boundary conditions in the three-dimensional context. In the spirit of panel methods, one establishes an integral formulation whose key point is the estimation of the potential density, introducing a kind of panel method for tangential kinematic boundary conditions. This paper discusses explicit estimations of this density in the general case of an arbitrarily shaped three-dimensional body, which leads to a fast numerical scheme. An error analysis is also provided, involving body smoothness, the Hölder exponent of the density, and whether the body presents torsion or not.

Key words. numerical analysis, boundary value problems, integral representation, fundamental solutions, parabolic equations, growth of solutions

1. Introduction.

Numerical techniques aimed at solving partial differential equations involving kinematic boundary conditions, such as the Navier–Stokes equations, have been viewed from many perspectives. These kinematic boundary conditions usually rely on zero velocity field on bodies when considering viscous flows. Despite the fact that these conditions are all mathematically of homogeneous Dirichlet type, fixing velocity value at boundaries, such vectorial boundary conditions have very different meanings physically, depending on the velocity component: while the zero normal component of velocity field on a body is linked to a no-slip-through property, or impermeability, the zero tangential components come from an adherence property, or no-slip condition, not required for ideal fluids relevant to the Euler equations.

The present article focuses on the integral formulation of adherence properties, which is related to a parabolic problem via the Chorin algorithm (instead of elliptic for classical panel methods). We present for the first time the numerical analysis of an ad hoc density evaluation, commonly known as the fastest way to ensure adherence properties.

It is now generally recognized that integral methods provide powerful tools to enforce numerically such boundary conditions. Concerning the normal conditions of velocity, the most common discrete integral technique, known as the "panel method," was pioneered by Hess [18, 19] in the 1970s and consists in using a formulation close to electromagnetism [26], that is, in finding a potential of the form

$$\phi(x) = \int_{\partial\Omega} K(x,y)q(y)\mathrm{d}\sigma(y). \tag{1.1}$$

In this equation (1.1), K is a Green function, whose expression is $(4\pi|x-y|)^{-1}$ in the full space $\mathbb{R}^3$, and q is the density function, defined over domain boundary and

solution of the following integral equation:

$$-\frac{q(x)}{2}+\int_{\partial\Omega} n_x\cdot\nabla K(x,y)\,q(y)\,\mathrm{d}\sigma(y)=g(x), \tag{1.2}$$

where n_x denotes the normal field to $\partial\Omega$ and g is a given function depending on the problem considered. The velocity is then obtained by differentiation of this potential. Proofs of regularity and well-posedness properties of related discrete operators can be found in the existing literature (see [34], for example). This usually leads to solving a large linear system of the size of the boundary discretization [21], which can be nevertheless efficiently preconditioned [16]. The order of convergence can be under control and possibly high [3, 4, 35]. In order to speed up the computation, a way to proceed is to use multipole methods [15, 33, 17], which are by definition well adapted for Lagrangian or pointwise formulations [2]. Another way is to provide an estimate of density, which limits convergence order but dramatically decreases computational time since only potential evaluation remains to be computed [13].

The tangential part of kinematic boundary conditions is a completely different matter. In the fluid dynamics context, these conditions are related physically to viscous effects, modeled by the Laplacian operator in the Navier–Stokes equations, which makes them of parabolic type, as opposed to the Euler equations, which are hyperbolic. Since the 1980s, several numerical schemes aimed at splitting apart linearity and nonlinearity have been proposed and implemented in various fields of physics and mathematical physics, in order to use well-fitted numerical techniques taking into account the linearity, or lack thereof.

These splitting techniques, also known as fractional step algorithms, can be basically of first order, or second order when based on the Strang formula, or higher order by using more general Trotter permutation formulae. Splitting the Navier–Stokes equations [22] over a time step leads one to consider successively the Euler equation with only its natural no-slip-though boundary condition, and then a Stokes equation with full no-slip conditions [9]. In its vorticity formulation, the Stokes problem can be reduced to a heat equation, possibly vectorial for three-dimensional configurations, with kinematic boundary conditions [8] relying only on tangential components. From a physical point of view, this heat equation takes into account both near-wall adherence properties and viscous effects in the whole fluid.

Lighthill's model states that these kinematic no-slip conditions for a fluid result from vorticity production on solid boundaries [29]. This production of vorticity has been viewed from many perspectives, involving Dirichlet conditions [7, 37] or Neumann conditions [23, 24], usually constrained by Kelvin's theorem to satisfy conservation of circulation. It has been shown that Neumann conditions are well adapted for nonstationary flows for two-dimensional problems [8, 25] or three-dimensional problems in the half-space [9], i.e., without curvature. It has been recently put forward that three-dimensional vortical boundary conditions involve the Robin–Fourier condition [11].

By using linearity of the heat equation, it can be split without any approximation into an equation with a generally nonzero initial condition and homogeneous boundary conditions, and another equation with zero initial condition and Robin–Fourier boundary conditions, which can be written as

$$\begin{cases} \dfrac{\partial\omega}{\partial t}-\nu\Delta\omega=0 \text{ in } \ \Omega\times]0,T[,\\ \omega(x,0)=0 \ \text{ on } \ \Omega,\\ \nu\,\mathcal{L}_x\omega(x,t)=F(x,t) \ \text{ on } \ \partial\Omega\times]0,T[, \end{cases} \tag{1.3}$$

where Ω is an open set of $\mathbb{R}^3$, F is a boundary source, ν is the diffusion coefficient, and $\mathcal{L}$, the differential operator defining Robin–Fourier boundary conditions, can be written as

$$\mathcal{L}_x = \beta(x)\mathrm{Id} + n(x)\cdot\nabla, \tag{1.4}$$

where $n(x)$ denotes the inward normal field to $\partial\Omega$ and β denotes a continuous and bounded function from $\partial\Omega$ to $\mathbb{R}$, bounded by β_0 (i.e., $|\beta(x)| < \beta_0$ for all $x \in \partial\Omega$). Throughout the present paper, Ω is supposed to be an open set such that $\partial\Omega$ is a two-dimensional submanifold of $\mathbb{R}^3$, of class $\mathcal{C}^{2+\lambda}$, and the source F is supposed to be a bounded and continuous function on $\partial\Omega \times [0,T]$. The solution of this heat equation can be found in its integral formulation:

$$\omega(x,t) = \int_0^t \int_{\partial\Omega} G_{\xi,\tau}(x,t)\widetilde{\mu}(\xi,\tau)\mathrm{d}\sigma(\xi)\mathrm{d}\tau, \tag{1.5}$$

where σ is a measure on $\partial\Omega$ induced by the Lebesgue measure and $G_{\xi,\tau}$ is the parametrix [20, 27], which is, in the case of an isotropic heat equation, simply the following three-dimensional Gaussian function:

$$G_{\xi,\tau}(x,t) = \widehat{G}(x-\xi,\nu(t-\tau)) \ \text{ with } \ \widehat{G}(x,\eta) = \frac{e^{-x^2/4\eta}}{(4\pi\eta)^{3/2}}, \tag{1.6}$$

whose standard deviation is $\sqrt{2\nu(t-\tau)}$. The density field $\widetilde{\mu}$ defined on $\partial\Omega$ is the solution of the following Volterra-type integral equation:

$$-\frac{1}{2}\widetilde{\mu}(x,t) + \nu\int_0^t \int_{\partial\Omega} \mathcal{L}_x G_{\xi,\tau}(x,t)\,\widetilde{\mu}(\xi,\tau)\mathrm{d}\sigma(\xi)\mathrm{d}\tau = F(x,t), \tag{1.7}$$

which admits a unique continuous and bounded solution over $\partial\Omega \times [0,T]$ under some minimalistic hypothesis of smoothness, discussed in [14]. Existence, uniqueness, and regularity of solutions of the heat equation and this integral equation have been intensively treated in the literature, many results being summarized in [14] and [28].

Joint equations (1.5)–(1.7) are similar in spirit to (1.1)–(1.2), with both providing a potential aimed at satisfying boundary conditions, and could be named "parabolic panel method." Nevertheless, such a panel method involves fully time dependent densities, which is a function of two variables (instead of one in (1.5)). Moreover, the integrodifferential operator in (1.7) is twice integrated, in time and space. These two remarks make joint equations (1.5)–(1.7) much more difficult to handle than classical panel methods and lead to a much higher degree of computational complexity.

Fast algorithms estimating density $\widetilde{\mu}$ are consequently of fundamental interest in order to make the integral method usable in practice, especially in a three-dimensional context. A way to obtain a fast algorithm is to estimate analytically the density $\widetilde{\mu}$ as a function of the source F, viscosity ν, time t, the coefficients of operator $\mathcal{L}$, and local invariants of $\partial\Omega$ such as its curvature.

Carrying out density estimation from (1.7) has been performed for two-dimensional bodies [24] and for the three-dimensional case of the half-plane [9] (which comes directly via a tensorialization for the two-dimensional case). Nevertheless, the existing literature either considers pure Neumann boundary conditions or simply neglects curvature effects, sometimes involving some hypothesis on nondependency on time (usually not mathematically valid) and in any case not followed by any mathematical analysis on the order of the method.

The present paper provides such an analysis for the more general problem of Robin–Fourier boundary conditions and a class of noncompact domains, in establishing, proving, and illustrating that the early behavior of the density can be explicitly given by the following formula:

$$\widetilde{\mu}(x,t) = \frac{-2F(x,t)}{1 + 2\left(\bar{\kappa}(x) - \beta(x)\right)\sqrt{\nu t/\pi}} + \mathcal{O}(t^{\gamma}), \tag{1.8}$$

where $\bar{\kappa}(x)$ is the mean curvature of $\partial\Omega$ in x, and where γ can reach different values among $]1/2, 3/2]$ in the present study, depending on regularity of $\partial\Omega$ and whether or not $\partial\Omega$ presents torsion. This result can then be used directly as a numerical scheme in formula (1.5), its order being led by the value of γ.

One can notice that Neumann boundary conditions can lead to qualitatively good results at high Reynolds numbers since the relative curvature $\bar{\kappa}\sqrt{\nu}$ tends toward 0. Nevertheless, the Dirichlet part of the Robin–Fourier boundary conditions is linked to the boundary curvatures [11], and is of the same order of the mean curvature effect, as shown in formula (1.8) above. Studying the full Robin–Fourier conditions is consequently of fundamental importance for engineering concerns on viscous flows, especially since the research community finds new interests in micro- and nanotechnologies, which involve small scales where viscous effects are potentially dominant. In this context, neglecting curvature can lead to dramatic errors in numerical simulation of fluids, especially when considering nonstationary dynamics whose prediction requires direct numerical simulation. Moreover, even for macroscopic devices, some new generation Lagrangian schemes such as vortex in cell (VIC) (see [10]) or smooth particle hydrodynamics (SPH) (see [6]) are very stable and can be used with large time steps. Consequently, this enlarges numerical viscous scales, which are of order $\sqrt{\nu\delta t}$ (where δt is the time step), and makes the curvature effects orders of magnitude stronger than standard numerical methods, such as spectral or finite element schemes, whose time scales are limited due to strong stability conditions related to transport terms.

The outline of the paper is as follows. Section 2 provides various preliminary properties. Section 2.1 gives a few well-known properties of fundamental solutions of the heat equation, results more or less already established in the literature. A few conditions are then set in section 2.2 in order to provide a good environment for differential and integral calculus for the following sections. In section 2.3, we show that integral calculus restricted to a local area is an accurate approximation of the global calculus at any order of time. This section also extends a classical result on Hölder continuity of the double heat layer to a class of noncompact manifolds. Section 3 provide convergence results and error estimations of geometrical approximation when the integrodifferential operator is computed on the local quadratic osculating manifold instead of the manifold itself. Section 4 shows that the heat layer of unit density on the best quadratic approximation of the surface can be determined at its main order with error estimation. Finally, section 5 presents the achievement of the present work, and Theorem 5.1 shows that the value of the approximated heat layer obtained in section 5 is a valid value at the first order in time. Theorem 5.3 shows that sufficiently smooth torsionless manifolds allow one to reach order 3/2. The link between these results is displayed in Figure 1. Sections 6 and 7 give several examples illustrating some statements of previous sections, in cylindrical and toroidal geometries, respectively. These examples show that estimates given by Theorems 5.1 and 5.3 are optimal and describe their application to kinematic boundary conditions.

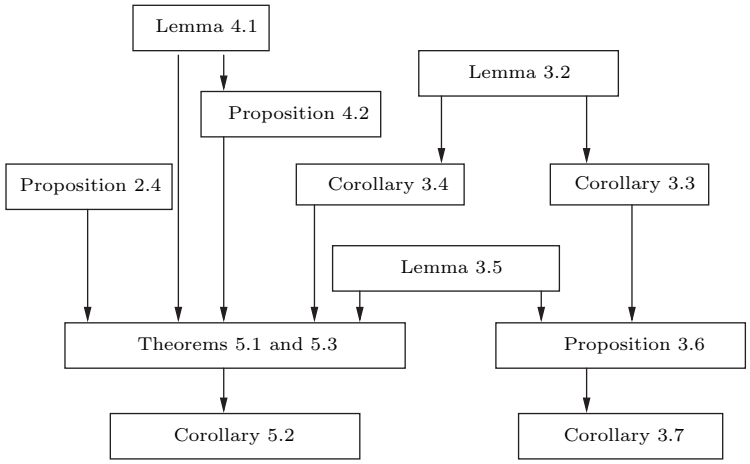

FIG. 1. *Relations between results leading to Theorems* 5.1 *and* 5.3 *(Lemma* 3.1 *and Proposition* 2.3 *are often involved in different proofs).*

2. Preliminary work. This section presents well-known results on parabolic problems in section 2.1 and the hypotheses that are required for the present study in section 2.2. Accuracy of domain restriction is then analyzed in section 2.3, with a specific proof valid for noncompact manifolds.

2.1. Well-known results. One first introduces Friedman's notion of Hölder continuity for parabolic problems: a function ω is said to be ϑ-Hölder continuous over $\Omega \times [0,T]$ if there exist two constants C and ϑ, independent of x, y, t, and s, such that

$$|\omega(x,t) - \omega(y,s)| \leqslant C \left(|x-y|^{\vartheta} + |\nu(t-s)|^{\vartheta/2} \right) \tag{2.1}$$

for all (x,t) and (y,s) in $\overline{\Omega} \times [0,T]$, where $|\cdot|$ denotes both the Euclidean norm of $\mathbb{R}^3$ and the absolute value, depending on the context.

Throughout the paper, $|\cdot|$ will be used for the Euclidean norm in $\mathbb{R}^n$ (absolute value when $n = 1$), $\|\cdot\|$ for norms of functions, and $|||\cdot|||$ for linear operators (not necessarily Euclidean for double and triple norms, but $\mathbb{L}^\infty$ norm most times and $\mathbb{L}^1$ occasionally).

The integral operator is of fundamental interest for the present study, since its value at the leading order is the effect of curvature. It is a double layer of density f with respect to the heat kernel and depends on surface location and time (on $\partial\Omega \times [0,T]$):

$$\widetilde{\mathcal{H}}(x,t)f = \nu \int_0^t \int_{\partial\Omega} \mathcal{L}_x G_{\xi,\tau}(x,t)\, f(\xi,\tau) \mathrm{d}\sigma(\xi) \mathrm{d}\tau \tag{2.2}$$

for any density f bounded and continuous on $\partial\Omega \times [0,T]$.

Furthermore, from [31] and Theorem 4 of Chapter 5 of [14], one gets the following result.

COROLLARY 2.1. *Under the notation above, if f is a continuous and bounded function on $\partial\Omega \times [0,T]$, and $\partial\Omega$ is a compact two-dimensional submanifold of $\mathbb{R}^3$ of class $\mathcal{C}^{1+\lambda}$, then $\widetilde{\mathcal{H}}(x,t)f$, as a function of x and t, is ϑ-Hölder continuous on $\partial\Omega \times [0,T]$ for any exponent satisfying $\vartheta < 2\min(\lambda,1)/3$.*

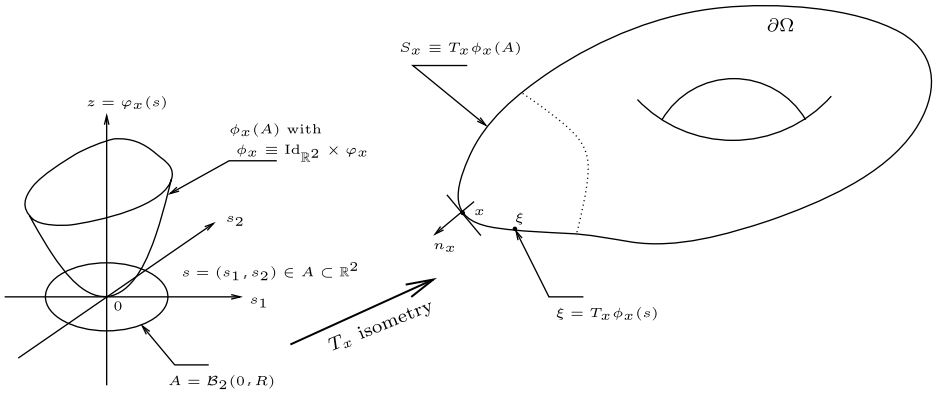

FIG. 2. *Geometrical setup and main notation.*

Nevertheless, for a manifold of class at least $\mathcal{C}^2$, this corollary gives that $\widetilde{\mathcal{H}}(x,t)f$ is ϑ-Hölder continuous for any exponent less than $2/3$. In our context, one can go further than this result. Indeed, Corollary 2.1 is independent of the dimension of space and is valid for manifolds presenting less regularity (i.e., manifolds of class $\mathcal{C}^{1+\lambda}$) than our present considerations. In the present context, set up in section 2.2, the following proposition (more general than Corollary 2.1) holds.

PROPOSITION 2.2. *Let $\widetilde{\mathcal{H}}$ be the integrodifferential operator defined by formula* (2.2). *Under conditions* (C1)–(C5), *with $\beta : \partial\Omega \to \mathbb{R}$ and $f : \partial\Omega \times [0,T] \to \mathbb{R}$ two bounded and, respectively, ϑ_β- and ϑ_f-Hölder continuous functions, we have that $\widetilde{\mathcal{H}}(\cdot,\cdot)f$ is ϑ^*-Hölder continuous with any $\vartheta^* = \min(1-\varepsilon, \vartheta_\beta, \vartheta_f)$ for all $\varepsilon > 0$.*

One can see with this proposition that the maximum Hölder exponent is bounded by the density's, which forbids us from deducting regularity of $\widetilde{\mu}$ from the regularity of $\widetilde{\mathcal{H}}$.

Moreover, Proposition 2.2 shows that the regularity of the density depends on the manifold considered, on the regularity of the source, and on the regularity of the coefficient defining the Dirichlet part of the boundary condition (i.e., the three are involved and arise at the same order in the regularity analysis). The regularity consequently has to be analyzed case by case and will not be discussed in the present paper. To proceed, one can refer to [36] and references therein or [5, 1].

2.2. Geometrical setup and conditions. In order to provide pertinent computations, one assumes that the following condition is satisfied:

(C1) $\partial\Omega$ is a two-dimensional differentiable submanifold of $\mathbb{R}^3$, of class $\mathcal{C}^{2+\lambda}$.

This condition means that $\partial\Omega$ is locally the graph of a function φ_x of class $\mathcal{C}^{2+\lambda}(\Pi_x, \mathbb{R}^3)$, where Π_x is the tangential plan of $\partial\Omega$ in x. One denotes by $T_x : \mathbb{R}^3 \to \mathbb{R}^3$ the affine operator that changes 0 into x and $\mathbb{R}^2 \times \{0\}$ into Π_x.

Consequently, for any $x \in \partial\Omega$, there exists a function φ_x defined in a neighborhood A_x of 0 satisfying $\varphi_x(0) = 0$ and $\nabla\varphi_x(0) = 0$ such that

$$T_x\left(A_x \times \varphi_x(A_x)\right) \subset \partial\Omega.$$

One can notice that the bijective application T_x is a composition of a translation and a rotation; thus its Jacobian is identically equal to 1, and consequently one can integrate indifferently over $\partial\Omega$ or over $T_x^{-1}\partial\Omega$.

This sets up notation for the local description of $\partial\Omega$ around x as a graph of functions φ_x of class $C^{2+\lambda}(\mathbb{R}^2, \mathbb{R})$, as displayed in Figure 2. One recalls that being

of class $C^{m+\lambda}(\mathbb{R}^2,\mathbb{R})$, with $0<\lambda\leqslant 1$, means that φ_x is of class $C^m(\mathbb{R}^2,\mathbb{R})$ and all its mth order partial derivatives are λ-Hölder continuous. This means that for any $x\in\partial\Omega$, there exist two constants C_x and C'_x such that locally one has

$$\left|\varphi_x(s)-\frac{1}{2}\,{}^t sK_x s\right| \;\leqslant\; C_x\,|s|^{2+\lambda} \quad\text{and}\quad \left|\nabla\varphi_x(s)-K_x s\right| \;\leqslant\; C'_x\,|s|^{1+\lambda}, \tag{2.3}$$

where K_x is the Hessian matrix of φ_x in $0=T_x^{-1}(x)$.

One then requires the following conditions on the globality of bounds defined above:

(C2) There exists $R>0$ such that domain definition A_x of applications φ_x contains $\mathcal{B}_2(0,R)$ for all $x\in\partial\Omega$.

(C3) The spectral radius of the Hessian K_x of ϕ_x in 0 is bounded independently of $x\in\partial\Omega$, and its upper bound is denoted ρ_0.

(C4) There exist two constants C and C' such that for any $x\in\partial\Omega$, one has $C_x\leqslant C$ and $C'_x\leqslant C'$.

Note that these hypotheses do not imply a lack of generality but provide some restrictions on smoothness (condition (C1)) and mapping orientation and size (conditions (C2) and (C4)). One can also notice that $\partial\Omega$ being the boundary of an open set Ω and condition (C1) imply that $\partial\Omega$ is an oriented manifold and thus the existence of an inward normal field n to $\partial\Omega$. Condition (C3) eliminates, for example, spiraloids or clothoidal surfaces whose curvature tends to infinity.

For convenience, one sets up the notation $\phi_x=\mathrm{Id}_{\mathbb{R}^2}\times\varphi_x$, which gives that

$$S_x\equiv T_x\phi_x\left(\mathcal{B}_2(0,R)\right)\subset\partial\Omega. \tag{2.4}$$

This local parameterization of $\partial\Omega$ gives the following integration formula:

$$\int_{S_x} f(\xi)\mathrm{d}\sigma(\xi)=\int_{\mathcal{B}_2(0,R)} f\circ T_x\circ\phi_x(s)\,|N_x(s)|\,\mathrm{d}s, \tag{2.5}$$

where

$$N_x(s)=\frac{\partial\phi_x}{s_1}(s)\wedge\frac{\partial\phi_x}{s_2}(s)$$

is the normal field induced by the parameterization ϕ_x, its Euclidean norm being the Jacobian of the parameterization and satisfying

$$|N_x(s)|=\sqrt{1+|\nabla\varphi_x(s)|}, \tag{2.6}$$

where $|\cdot|$ denotes the Euclidean norm in $\mathbb{R}^3$. Note that T_x is not involved in this Jacobian because $|\partial_{s_1}T_x\circ\phi_x\wedge\partial_{s_1}T_x\circ\phi_x|=|\partial_{s_1}\phi_x\wedge\partial_{s_1}\phi_x|=|N_x(s)|$.

A few direct consequences of conditions (C1)–(C4) can then be stated.

PROPOSITION 2.3. *Under conditions* (C1)–(C4), *one has the following:*

(P1) *N_x, the Jacobian of the parameterization by ϕ_x, is bounded independently of x, and its bound is denoted M_1.*

(P2) *There exists a constant M_2 such that*

$$|(x-\xi)\cdot n_x|\leqslant M_2|x-\xi|^2\quad\forall x,\xi\in\partial\Omega. \tag{2.7}$$

Proof. Let x be a point of $\partial\Omega$. By (2.3), one gets

$$|\nabla\varphi_x(s)| \leqslant |K_x s| + C'_x|s|^{1+\lambda} \leqslant \rho_0 R + C' R^{1+\lambda}.$$

Setting $M_1 = \sqrt{1 + (\rho_0 + C'R^\lambda)^2 R^2}$ finishes the proof of assertion (P1).

Furthermore, for all ξ in $\partial\Omega \cap \mathcal{B}_3(x,R) \subset T_x\phi_x(\mathcal{B}_2(0,R))$ where R is defined by condition (C2), one has $\xi = T_x\phi_x(s)$ with $\phi_x = \mathrm{Id}_{\mathbb{R}^2} \times \varphi_x$, and $T_x^{-1}n(x) = -e_3$. Consequently, one has $(\xi - x)\cdot n(x) = \varphi_x(s) - \varphi_x(0) = \varphi_x(s)$ and by condition (C3) and by definition of class $\mathcal{C}^{2+\lambda}$, one gets

$$|(\xi - x)\cdot n(x)| = |\varphi_x(s)| \leqslant \frac{\rho_0}{2}|s|^2 + C|s|^{2+\lambda} \leqslant \left(\frac{\rho_0}{2} + C\,R^\lambda\right)|s|^2.$$

For any ξ not in $\partial\Omega \cap \mathcal{B}_3(x,R)$, one has $|(\xi - x)\cdot n_x| \leqslant |\xi - x| \leqslant (\xi - x)^2/R$. Setting $M_2 = \max(C\,R^\lambda + \rho_0/2, 1/R)$ finishes the proof. □

Part (P1) of the proposition will often be useful for calculus through the maps, while part (P2) implies that the operator $\widetilde{\mathcal{H}}(x,t)f$ is bounded over $\partial\Omega \times [0,T]$, which in itself is useful for showing that the $\widetilde{\mathcal{H}}$ is Hölder continuous.

Moreover, one needs a last condition of measure growth of $\partial\Omega$:

(C5) There exist two positive constants C and k such that for any $x \in \partial\Omega$, the measure of the part of $\partial\Omega$ in the spherical strips $\mathcal{B}_3(x,(n+1)R) \setminus \mathcal{B}_3(x,nR)$ does not grow faster than $e^{k\,n^2}$; that is,

$$\sigma\left(\left\{\xi \in \partial\Omega \;/\; nR \leqslant |\xi - x| < (n+1)R\right\}\right) \leqslant C\,e^{k\,n^2} \quad \forall x \in \partial\Omega. \tag{2.8}$$

Condition (C5) is satisfied as soon as $\partial\Omega$ is compact, and provides useful majorations and controllable error estimates of map restriction when $\partial\Omega$ is not compact.

As a concluding note on conditions (C1)–(C5), let us remark that they are not very restrictive and do not lead to a lack of generality on the kind of surfaces considered. Their most significant effect is that they limit size and orientation of the maps and provide a good environment for integral calculus in the next sections.

2.3. Error estimation of the restriction to a map. The definition of $\widetilde{\mathcal{H}}$ involves a Gaussian function whose standard deviation tends to zero when t tends to zero (smaller than $\sqrt{2\nu t}$). Even if a Gaussian is not compactly supported, it decreases quickly, and its significant values are very localized. Consequently, thanks to limiting the final time T of the heat equation (which is not a limitation in practice), we can consider the integral over one map,

$$S_x \equiv T_x\phi_x(\mathcal{B}_2(0,R)) \subset \partial\Omega \subset \mathbb{R}^3, \tag{2.9}$$

instead of the whole surface $\partial\Omega$, and provide an error analysis thanks to the fast decreasing of Gaussian functions. One can introduce the heat layer restricted to $S_x \subset \partial\Omega$ as

$$\widetilde{\mathcal{H}}_{S_x}(x,t)f = \nu \int_0^t \int_{S_x} \mathcal{L}_x G_{\xi,\tau}(x,t)\, f(\xi,\tau)\mathrm{d}\sigma(\xi)\mathrm{d}\tau$$

for any continuous and bounded function $f : \partial\Omega \times [0,T] \to \mathbb{R}$, and the error due to the restriction on $S_x \subset \partial\Omega$ as

$$\widetilde{\mathcal{H}}_{_{err}}(x,t)f = \left(\widetilde{\mathcal{H}}(x,t) - \widetilde{\mathcal{H}}_{S_x}(x,t)\right) f = \nu \int_0^t \int_{\partial\Omega\setminus S_x} \mathcal{L}_x G_{\xi,\tau}(x,t)\, f(\xi,\tau)\mathrm{d}\sigma(\xi)\mathrm{d}\tau.$$

By setting $\eta = \nu(t-\tau)$, one gets

$$\frac{|\widetilde{\mathcal{H}}_{err}(x,t)f|}{\|f\|_\infty} \leqslant \int_0^{\nu t} \int_{\partial\Omega\setminus S_x} \left|\beta(x) - \frac{(x-\xi)\cdot n(x)}{2\eta}\right| \widehat{G}(x-\xi,\eta)\mathrm{d}\sigma(\xi)\mathrm{d}\eta.$$

One can now show that the error due to the restriction to a map can then be neglected at any order. The following integral calculus features the parametric approach of the present paper.

First, by condition (C2) there exists R, such that for all $x \in \partial\Omega$, one has $s = T_x^{-1}(\xi)$ for all ξ in the neighborhood S_x of x and the inequality

$$|s|^2 \leqslant |s|^2 + \varphi_x(s)^2 = |T_x\phi_x(s) - T_x(0)|^2 = |\xi - x|^2 < R^2$$

and, consequently, the inclusions

$$\partial\Omega \cap \mathcal{B}_3(x,R) \subset T_x\phi_x(\mathcal{B}_2(0,R)) = S_x \subset \partial\Omega$$

which imply directly

$$\partial\Omega \setminus S_x = \partial\Omega \setminus T_x\phi_x(\mathcal{B}_2(0,R)) \subset \partial\Omega \setminus \mathcal{B}_3(x,R) \subset \partial\Omega. \tag{2.10}$$

Error estimate $|\widetilde{\mathcal{H}}_{err}(x,t)f|$ is thus majorated by

$$\|f\|_\infty \int_0^{\nu t} \int_{\partial\Omega\setminus\mathcal{B}_3(x,R)} \left|\beta(x) - \frac{(x-\xi)\cdot n(x)}{2\eta}\right| \widehat{G}(x-\xi,\eta)\mathrm{d}\sigma(\xi)\mathrm{d}\eta, \tag{2.11}$$

which implies, due to part (P2) of Proposition 2.3, the following majoration:

$$\|f\|_\infty \int_0^{\nu t} \left(|\beta(x)| + M_2\frac{|x-\xi|^2}{2\eta}\right) \int_{\partial\Omega\setminus\mathcal{B}_3(x,R)} \widehat{G}(x-\xi,\eta)\mathrm{d}\sigma(\xi)\mathrm{d}\eta. \tag{2.12}$$

Second, and this notation will be used throughout the paper, one has for all positive x and α,

$$x^\alpha e^{-x} \leqslant L_\alpha e^{-x/2} \quad \text{with} \quad L_\alpha = (2\alpha)^\alpha e^{-\alpha}. \tag{2.13}$$

It follows from (2.13) that expression (2.12) is majorated by

$$\|f\|_\infty (\beta_0 + L_1M_2) \int_0^{\nu t} \int_{\partial\Omega\setminus\mathcal{B}_3(x,R)} \frac{e^{-|x-\xi|^2/8\eta}}{(4\pi\eta)^{3/2}}\, \mathrm{d}\sigma(\xi)\, \mathrm{d}\eta. \tag{2.14}$$

If $\partial\Omega$ is compact, then (2.14) is majorated by

$$\|f\|_\infty (\beta_0 + L_1M_2)\, \sigma(\partial\Omega) \int_0^{\nu t} \frac{e^{-R^2/8\eta}}{(4\pi\eta)^{3/2}}\, \mathrm{d}\eta, \tag{2.15}$$

which is finally majorated by

$$\|f\|_\infty 2\sqrt{2}\, L_{3/2}\, \frac{\beta_0 + M_2L_1}{R^3\pi^{3/2}}\, e^{-R^2/16\nu t}\, \nu t\, \sigma(\partial\Omega). \tag{2.16}$$

If $\partial\Omega$ is not compact, there is more work to be done, and one has to consider condition (C5) on maximal admissible growth of measures of $\partial\Omega$ contained in successive spherical strips, which leads to the same result. Indeed, one has the disjoint decomposition

$$\partial\Omega = (\partial\Omega \cap \mathcal{B}_3(x,R)) \cup \left[\bigcup_{n\in\mathbb{N}^*} (\partial\Omega \cap (\mathcal{B}_3(0,(n+1)R) \setminus \mathcal{B}_3(0,nR))) \right];$$

thus

$$\partial\Omega \setminus \mathcal{B}_3(x,R) = \bigcup_{n\in\mathbb{N}^*} (\partial\Omega \cap (\mathcal{B}_3(0,(n+1)R) \setminus \mathcal{B}_3(0,nR)))\,,$$

and one can build a majoration of (2.14) by the use of condition (C5):

$$\|f\|_\infty C \int_0^{\nu t} (\beta_0 + L_1 M_2) \left(\sum_{j\in\mathbb{N}^*} \frac{e^{-j^2R^2/8\eta}}{8\pi^{3/2}\eta^{3/2}}\, e^{j^2 k} \right) \mathrm{d}\eta \tag{2.17}$$

with C depending only on $\partial\Omega$. Equation (2.17) is itself majorated for νt sufficiently small, i.e., for $\nu t \leqslant R^2/8k$, where k depends only on $\partial\Omega$, by

$$\|f\|_\infty C\ (\beta_0 + L_1 M_2) \int_0^{\nu t} \frac{1}{8\pi^{3/2}\eta^{3/2}} \left(\sum_{j\in\mathbb{N}^*} \exp\left\{ -j^2 \left(\frac{R^2}{8\eta} - k \right) \right\} \right) \mathrm{d}\eta. \tag{2.18}$$

Now noticing that $j \leqslant j^2$ and that $k - R^2/8\eta \leqslant -R^2/16\eta$ for $\nu t \leqslant R^2/16k$, one gets another majoration of (2.18) by

$$\|f\|_\infty C\ (\beta_0 + L_1 M_2) \int_0^{\nu t} \frac{1}{8\pi^{3/2}\eta^{3/2}} \frac{1}{1 - e^{-R^2/16\eta}}\, e^{-R^2/16\eta}\ \mathrm{d}\eta. \tag{2.19}$$

Noticing also that $e^{-R^2/16\eta} \leqslant 1/2$ for $\eta \leqslant R^2/16\ln 2$, one gets

$$\|f\|_\infty C\ (\beta_0 + L_1 M_2) \int_0^{\nu t} \frac{e^{-R^2/16\eta}}{4\pi^{3/2}\eta^{3/2}}\ \mathrm{d}\eta, \tag{2.20}$$

which gives the final majoration for $\nu t \leqslant R^2/16k^a st$ with $k^* = \max(\ln 2,\, k)$, i.e., for t sufficiently small:

$$\|f\|_\infty 16\, C\, L_{3/2}\, \frac{\beta_0 + L_1 M_2}{\pi^{3/2} R^3}\, e^{-R^2/32\nu t} \nu t. \tag{2.21}$$

Equation (2.16) holds when $\partial\Omega$ is a compact manifold, and is extended to the noncompact case by means of (2.21). From these equations, one gets the following proposition.

PROPOSITION 2.4. *Under conditions* (C1)–(C5) *and previous notation, there exists a constant C independent of x and t such that*

$$\frac{|\widetilde{\mathcal{H}}_{err,\mathcal{B}_2(\zeta,R)}(x,t)f|}{\|f\|_\infty} \leqslant \frac{|\widetilde{\mathcal{H}}_{err,A}(x,t)f|}{\|f\|_\infty} \leqslant C\,\|f\|_\infty\, e^{-R^2/32\nu t} \nu t = \mathcal{O}(t^\infty) \tag{2.22}$$

for t sufficiently small and for all $x \in \partial\Omega$ and any $f \in \mathbb{L}^\infty(\partial\Omega)$.

$$
\begin{array}{ccc}
-\frac{1}{2}\widetilde{\mu}(x,t)+\widetilde{\mathcal{H}}(x,t)\widetilde{\mu}=F(x,t) & \xrightarrow{\text{param.}} & \mu_x^\flat(s,t)=\widetilde{\mu}(T_x\phi_x(s),t) \\
\Big\downarrow \text{restr. on } S_x & & \\
-\frac{1}{2}\mu^\natural(x,t)+\widetilde{\mathcal{H}}_{S_x}(x,t)\mu^\natural=F(x,t) & \xrightarrow{\text{param.}} & \mu_x(s,t)=\mu^\natural(T_x\phi_x(s),t) \\
\Updownarrow & & \\
-\frac{1}{2}\mu_x(0,t)+\mathcal{H}(x,t)\mu_x=F(x,t) & & \\
\Big\downarrow \text{approx. on } \overline{S_x} & & \\
-\frac{1}{2}\overline{\mu}_x(0,t)+\overline{\mathcal{H}}(x,t)\overline{\mu}_x=F(x,t) & \xrightarrow{\text{param.}} & \overline{\mu}_x(s,t)=\mu^\sharp(T_x\phi_x(s),t).
\end{array}
$$

FIG. 3. *Different integrodifferential operators and associated integral equations and densities involved in the surface potential analysis.*

3. Geometrical approximation. It has been shown in section 2.3 that only a local analysis of the heat layer is required to obtain the development in early time of the heat layer at any order, since the Gaussian kernel has significant values very locally.

The local parameterizations of the manifold and its quadratic osculating manifold are set up in sections 3.1 and 3.2, respectively, and we give a few approximation lemmas in section 3.3 that will be useful in proving convergence in section 3.4 and providing error estimates of truncations to get the final results.

The process of parameterization and approximation can be split into two different steps as shown in Figure 3, which should be read as follows. First one considers the original integral equation of solution $\widetilde{\mu}$, whose parameterization is denoted $\mu_x^\flat$ in a neighborhood of origin whose image is a neighborhood $S_x \subset \partial\Omega$ of x.

The map-restricted heat layer $\widetilde{\mathcal{H}}_{S_x}$ is introduced in section 3.1 and defines a new integral equation whose solution is denoted $\mu^\natural$ and its parameterization μ_x, which is itself the solution of an integral equation involving $\mathcal{H}$, the restricted heat layer acting on parameterizations, i.e., such that

$$\widetilde{\mathcal{H}}_{S_x}(x,t)\mu^\natural=\mathcal{H}(x,t)\mu_x.$$

The portion of surface S_x is then approximated by its best quadratic approximant $\overline{S_x}$ in section 3.2, which induces a heat layer on the surface approximant denoted $\overline{\mathcal{H}}$, and another integral equation involving this operator acting on parameterizations, whose solution is denoted $\overline{\mu}_x : A \to \mathbb{R}$. This solution corresponds to a density $\mu^\sharp : \partial\Omega \to \mathbb{R}$.

While the relation between densities $\widetilde{\mu}$ and $\mu^\natural$ is quite obvious by means of proposition 2.4, the link between $\mu^\natural$ and $\mu^\sharp$ is less obvious and requires an analysis of approximation relations between the associated integral operators. The convergence of densities is established in section 3.4, especially in Proposition 3.6.

3.1. Local parameterization of the surface. The two-dimensional manifold $\partial\Omega$ is described by its maps, which are themselves defined by means of the description of $\partial\Omega$ by graphs of functions φ_x, given in (2.4), which reads as follows:

$$T_x\phi_x \equiv T_x(\mathrm{Id}_{\mathbb{R}^2}\times\varphi_x) : A=\mathcal{B}(0,R)\subset\mathbb{R}^2 \longrightarrow T_x\phi_x(A)\equiv S_x\subset\partial\Omega. \tag{3.1}$$

A density $\widetilde{f} : \partial\Omega \to \mathbb{R}$ can be restricted on a map as

$$\begin{array}{rccc} \widetilde{f}: & S_x \subset \partial\Omega \subset \mathbb{R}^3 \times [0,T] & \longrightarrow & \mathbb{R} \times [0,T], \\ & (\xi, t) & \longmapsto & \widetilde{f}(\xi, t). \end{array} \tag{3.2}$$

One can introduce the local parameterization f in space of $\widetilde{f}$ through $T_x\phi_x$ in a neighborhood S_x of x in $\partial\Omega$, so that $\xi = T_x\phi_x(s)$, which gives

$$\begin{array}{rccl} f: & A \times [0,T] & \longrightarrow & \mathbb{R} \times [0,T], \\ & (s,t) & \longmapsto f(s,t) & = \widetilde{f}(T_x \circ \phi_x(s), t) \\ & & & = \widetilde{f}\left(T_x\left(s_1, s_2, \varphi_x(s)\right), t\right), \end{array} \tag{3.3}$$

where $A \equiv \mathcal{B}_2(0,R) \subset \mathbb{R}^2$.

One also considers the double heat layer restricted to a map acting on parameterizations of densities, defined consequently by

$$\mathcal{H}(x,t)f = \widetilde{\mathcal{H}}_{S_x}(x,t)\widetilde{f} = \nu \int_0^t \int_A \mathcal{L}_x G_{T_x\phi_x(s),\tau}(x,t) f(s,\tau) |N_x(s)| \mathrm{d}s\mathrm{d}\tau, \tag{3.4}$$

where

$$N_x(s) = \frac{\partial \phi_x}{s_1}(s) \wedge \frac{\partial \phi_x}{s_2}(s)$$

and $|N(s)|$ denotes its Euclidean norm in $\mathbb{R}^3$. This Jacobian calculus holds since the Jacobian of T_x is identically equal to 1 and gives

$$|N_x(s)| = \sqrt{1 + |\nabla\varphi_x(s)|^2}, \tag{3.5}$$

which is bounded with respect to x over $\partial\Omega$ by Proposition 2.3(P1). One can notice that the Gaussian functions are spherically symmetric; thus the equalities

$$\begin{aligned} G_{T_x\phi_x(s),\tau}(x,t) &= G_{\phi_x(s),\tau}(T_x^{-1}x, t) = G_{\phi_x(s),\tau}(0,t) \\ &= G_{0,0}(\phi_x(s), t-\tau) = \widehat{G}\left(\phi_x(s), \nu(t-\tau)\right) \\ &= \frac{e^{-(s^2+\varphi_x(s)^2)/4\nu(t-\tau)}}{(4\pi\nu(t-\tau))^{3/2}} \end{aligned}$$

hold because $\phi_x = \mathrm{Id}_{\mathbb{R}^2} \times \varphi_x$.

Since one has $\varphi_x(0) = 0$ and $\nabla\varphi_x(0) = 0$, this leads, by means of (2.3), to

$$\varphi_x(s) = \frac{1}{2}\, {}^t s\, K_x\, s\, + \mathcal{O}(s^{2+\lambda}), \tag{3.6}$$

where K_x is the symmetric 2×2 curvature matrix of $\partial\Omega$ in x, in the spirit of the two-dimensional approach of [24].

3.2. Local approximation of the surface. In order to provide a local analysis on an explicitly known surface, and to estimate the error related to geometrical approximation, one considers the second order approximation of $\partial\Omega$ in a neighborhood S_x of $x \in \partial\Omega$. This means we introduce the quadratic form

$$\overline{\varphi}_x(s) = \frac{1}{2}\, {}^t s\, K_x\, s$$

and all the related quantities, as displayed in Figure 4:

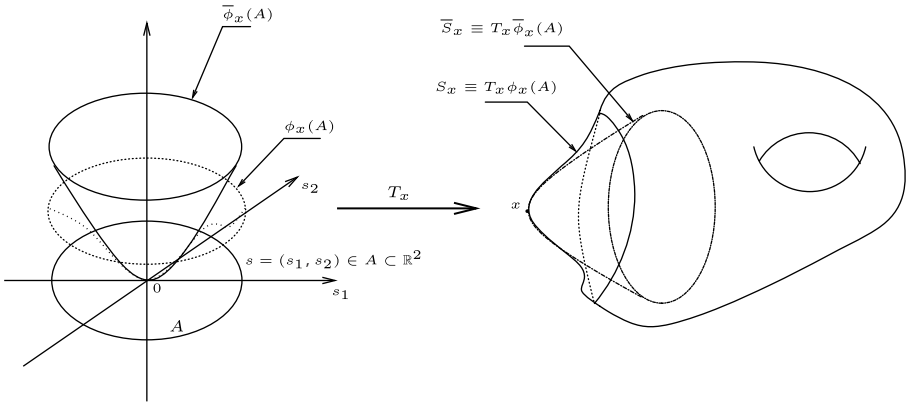

FIG. 4. *Context and notation of surface approximation.*

- $\overline{\phi}_x = T_x \circ (\mathrm{Id}_{\mathbb{R}^2} \times \overline{\varphi}_x)$,
- $\overline{S_x} = T_x\overline{\phi}_x(A)$, the quadratic approximant of S_x,
- $\overline{\mathcal{H}}(x,t)$, the integral operator defined over $\overline{S_x}$,
- $\overline{N}_x(s) = \partial_{s_1}\overline{\phi}_x \wedge \partial_{s_2}\overline{\phi}_x$, the Jacobian of this parameterization, which verifies

$$|\overline{N}_x(s)| = \sqrt{1 + |\nabla\varphi_x(s)|^2} = \sqrt{1 + |K_x s|^2}, \tag{3.7}$$

- $\overline{\mu}_x : A \to \mathbb{R}$, the parameterized solution of the integral equation

$$-\overline{\mu}_x(0,t) + 2\overline{\mathcal{H}}(x,t)\overline{\mu}_x = F(x,t), \tag{3.8}$$

  which defines the density $\mu^\sharp : \partial\Omega \to \mathbb{R}$ by $\mu^\sharp(x,t) = \overline{\mu}_x(0,t)$.

Furthermore, the boundary operator $\mathcal{L}_x$ defining the Robin–Fourier condition can be written as $\beta(x)\mathrm{Id} + n(x)\cdot\nabla$. The gradient of the Gaussian kernel satisfies

$$\nabla_x G_{\xi,\tau}(x,t) = -\frac{x-\xi}{2\nu(t-\tau)} G_{\xi,\tau}(x,t);$$

thus

$$\mathcal{L}_x G_{\xi,\tau}(x,t) = \left(\beta(x) - \frac{(x-\xi)\cdot n(x)}{2\nu(t-\tau)}\right) G_{\xi,\tau}(x,t). \tag{3.9}$$

Moreover, the gradient $\nabla\varphi_x(0) = 0$ implies $T_x^{-1}n(x) = -e_3$, and since the scalar product is conserved by rotation/translation (i.e., by operator T_x), one gets

$$\begin{aligned} -(x-\xi)\cdot n(x) &= (T_x\phi_x(s) - T_x\phi_x(0))\cdot n(x) \\ &= (\mathrm{Id}_{\mathbb{R}^2} \times \varphi_x)(s)\cdot(-be_3) = -\varphi_x(s) \end{aligned}$$

for all $\xi = T_x\phi_x(s) = T_x(\mathrm{Id}_{\mathbb{R}^2} \times \varphi_x)(s) \in S_x$, i.e., for all $s \in A = \mathcal{B}_2(0,R)$.

For a function $f : A \to \mathbb{R}$, one has consequently

$$\mathcal{H}(x,t)f = \tag{3.10}$$

$$\nu\int_0^t\int_A \left(\beta(x) - \frac{\varphi_x(s)}{2\nu(t-\tau)}\right) G_{0,\tau}\left(\phi_x(s),t\right) f(T_x\phi_x(s),\tau)\ \sqrt{1+|\nabla\varphi_x(s)|^2}\ \mathrm{d}s\mathrm{d}\tau,$$

and similarly, one gets

(3.11)

$$\overline{\mathcal{H}}(x,t)f = \nu \int_0^t \int_A \left(\beta(x) - \frac{\overline{\varphi}_x(s)}{2\nu(t-\tau)}\right) G_{0,\tau}\left(\overline{\phi}_x(s),t\right) f(T_x\phi_x(s),\tau)\ \sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}\ \mathrm{d}s\mathrm{d}\tau.$$

For practical considerations in the estimation of the integrals defined above and their related quantities, one will often need a purely computational result, which is given to increase readability.

LEMMA 3.1 (integral majoration). *There exists a constant C_0 independent of t such that for $R \geqslant 0$ and $k > 0$, the majoration*

$$\Gamma^{R,k}_{\alpha,\eta}(\tau) = \int_0^\tau \int_R^\infty \frac{r^\alpha + u^{\alpha/2}}{u^\eta} e^{-r^2/ku}\, r\, \mathrm{d}r\, \mathrm{d}u \leqslant C_0\, e^{-R^2/2k\tau}\, \tau^{2-\eta+\alpha/2}$$

holds when $\eta - \alpha/2 < 2$, i.e., when the integral is convergent.

Consequently, $\Gamma^{R,k}_{\alpha,\eta}(\tau) = \mathcal{O}(\tau^{2-\eta+\alpha/2})$ if $R = 0$, and $\Gamma^{R,k}_{\alpha,\eta}(\tau) = \mathcal{O}(\tau^\infty)$ otherwise.

Proof. One has

$$r\, \frac{r^\alpha + u^{\alpha/2}}{u^\eta} e^{-r^2/ku} \leqslant C\, r\, u^{\alpha/2-\eta} e^{-r^2/2ku}$$

with $C = 1 + L_{\alpha/2} k^{\alpha/2}$, and consequently

$$\begin{aligned}\int_R^\infty \frac{r^\alpha + u^{\alpha/2}}{u^\eta} e^{-r^2/ku}\, r\, \mathrm{d}r &\leqslant C\, k\, u^{\alpha/2+1-\eta} \int_R^\infty \frac{2r}{2ku} e^{-r^2/2ku}\, \mathrm{d}r \\ &= C\, k\, u^{\alpha/2+1-\eta} e^{-R^2/2ku}.\end{aligned}$$

Integral (3.1) is then majorated by

$$\Gamma^{R,k}_{\alpha,\eta}(\tau) \leqslant\ C\, k \int_0^\tau u^{\alpha/2+1-\eta} e^{-R^2/2ku} \mathrm{d}u \leqslant\ C_0\, e^{-R^2/2k\tau}\, \tau^{2-\eta+\alpha/2}$$

with

$$C_0 = \frac{k\, C}{2-\eta+\alpha/2} > 0.$$

The comment on order is then obvious. ∎

The question now is how great an error is made in the integral operator when the surface $\partial\Omega$ is approximated by its best osculating quadratic surface, and how the error on the integral operator is related to the error on the solution μ_x.

3.3. Approximation lemma. In this section we exhibit in Lemma 3.5 the convergence rate of $\overline{\mathcal{H}}$ toward $\mathcal{H}$ in time variable when the surface $\partial\Omega$ is replaced by its best quadratic approximation. This lemma requires preliminary results in Lemmas 3.2 and 3.1. The result of Lemma 3.5 is used in the next sections and also implies the convergence of $\overline{\mu}_x$ toward μ_x with the same rate, as explained in Proposition 3.6.

One can define the usual norms considered herein. The simple norm $|\cdot|$ denotes the Euclidean norm of $\mathbb{R}^3$, and the maximum double norm denotes the usual $\mathbb{L}^\infty$ norm over $\partial\Omega$ or $\partial\Omega \times [0,T]$, depending on the context.

The triple norm of linear operator applies to the integrodifferential operators defined above. Indeed, for any $(x,t) \in \partial\Omega \times [0,T]$, $\mathcal{H}(x,t)$ is a linear operator that verifies $|\mathcal{H}(x,t)f| \leqslant \|f\|_\infty |\mathcal{H}(x,t)1|$ for any bounded function f, with equality for f identically equal to 1. One then gets

$$|||\mathcal{H}(x,t)|||_\infty = \sup_{f \in \mathbb{L}^\infty(A)\setminus\{0\}} \frac{|\mathcal{H}(x,t)f|}{\|f\|_\infty} = \sup_{\|f\|_\infty = 1} |\mathcal{H}(x,t)f| = |\mathcal{H}(x,t)1|. \tag{3.12}$$

The triple norm $|||\overline{\mathcal{H}}(x,t)|||_\infty$ is itself a function of x and t, whose $\mathbb{L}^\infty$ norm over $\partial\Omega$ is defined as

$$||||\mathcal{H}(\cdot,t)||||_\infty = ||\ x \mapsto |||\mathcal{H}(x,t)|||_\infty\ ||_\infty = \sup_{x\in\partial\Omega} |||\overline{\mathcal{H}}(x,t)|||_\infty = \sup_{x\in\partial\Omega} |\mathcal{H}(x,t)1|. \tag{3.13}$$

LEMMA 3.2. *Let $f_t : A\times[0,T] \to \mathbb{R}$ be a function, possibly depending on $t \in [0,T]$, such that there exist two constants $\alpha \geqslant 0$ and C_f independent of t satisfying*

$$|f_t(s,\tau)| \leqslant C_f \left(|s|^\alpha + |\nu(t-\tau)|^{\alpha/2} \right)$$

for all $(s,\tau) \in A\times[0,t]$. Under the hypothesis (C1)–(C4) *of section* 2.2, *with $\mathcal{H}$ defined by formula* (3.10), *there exists a constant C_0 such that for any $x \in \partial\Omega$, one has*

$$\mathcal{H}(x,t)f_t = C_0\, t^{(\alpha+1)/2}.$$

Proof. The portion of surface S_x is the image by the isometry T_x of the graph of φ_x over the two-dimensional ball $A = \mathcal{B}_2(0,R)$, with

$$\varphi_x(s) = \frac{1}{2}\, {}^t s\, K_x\, s\ + \mathcal{O}(s^{2+\lambda})$$

since $\partial\Omega$ is a manifold of class $\mathcal{C}^{2+\lambda}$. One has, through the map $T_x\phi_x$,

$$\mathcal{H}(x,t)f_t = \nu \int_0^t \int_A \left(\beta(x) - \frac{\varphi_x(s)}{2\nu(t-\tau)} \right) G_{0,\tau}\left(\phi_x(s),t\right) f(s,\tau)\, |N_x(s)|\, \mathrm{d}s\mathrm{d}\tau \tag{3.14}$$

with

$$|N_x(s)| = \sqrt{1+|\nabla\varphi_x(s)|^2} \leqslant M_1$$

and

$$|\varphi_x(s)| \leqslant \left| \frac{1}{2}\, {}^t s\, K_x\, s \right| + C\,|s|^{2+\lambda} \leqslant \left(\frac{\rho_0}{2} + C\,R^\lambda \right)\, s^2, \tag{3.15}$$

where M_1, ρ_0, and C are the constants introduced, respectively, in Proposition 2.3(P1), condition (C3), and condition (C4).

One gets consequently, assuming $C_1 = (\rho_0/2 + C\,R^\lambda)$ and $u = \nu t$,

$$|\mathcal{H}(x,t)f_t| \leqslant$$
$$M_1 \int_0^{\nu t} \int_A \left(\beta_0 + C_1 \frac{|s|^2}{2u} \right) \frac{1}{(4\pi u)^{3/2}} \exp\left(-\frac{|s|^2 + ({}^t s K_x s)^2}{4u} \right)\, f_t(s,\tau)\, \mathrm{d}s\mathrm{d}\tau. \tag{3.16}$$

Now noticing that $({}^t sKs)^2 \geqslant 0$, assuming $r = |s|$, and applying the Hölder-like hypothesis on f_t, one has an axisymmetric expression that integrates into

$$|\mathcal{H}(x,t)f_t| \leqslant \frac{2\,C_f\,M_1}{\sqrt{\pi}} \int_0^{\nu t} \int_0^R \left(\beta_0 + C_1 \frac{r^2}{2u}\right) \frac{r^\alpha + u^{\alpha/2}}{(4u)^{3/2}}\, e^{-r^2/4u}\, r\,\mathrm{d}r\mathrm{d}\tau. \tag{3.17}$$

Using relation (2.13) that gives $x\,e^{-x} \leqslant L_1 e^{-x/2}$, the result follows from Lemma 3.1:

$$|\mathcal{H}(x,t)f_t| \leqslant \frac{C_f\,M_1}{4\sqrt{\pi}}\,(\beta_0 + 2L_1C_1)\,\Gamma^{0,8}_{\alpha,3/2}(t) = \mathcal{O}(t^{1/2+\alpha/2}).$$

Note that $C_0 = C_f\,M_1\,(\beta_0 + 2L_1C_1)\,/4\sqrt{\pi}$ depends neither on $x \in \partial\Omega$ nor on $t \in [0,T]$. ∎

One first has to notice that this result holds when $\alpha = 0$, which provides a useful majoration of $\mathcal{H}(x,t)f$ when f is only bounded, that is to say, majoration of $\mathcal{H}(x,t)1$, and directly gives that

$$|||\mathcal{H}(x,t)|||_\infty = O(t^{1/2}) \tag{3.18}$$

for any $(x,t) \in \partial\Omega \times [0,T]$.

One can also notice that the final majorant in the proof is not dependent on x, and applying this again to the unity function, one can extend result (3.18) into

$$||||\mathcal{H}(\cdot,t)||||_\infty = ||\, x \mapsto |||\mathcal{H}(x,t)|||_\infty\,||_\infty = O(t^{1/2}). \tag{3.19}$$

Another important result is that the lemma also holds for $\overline{\mathcal{H}}(x,t)$, which is a special case with the function $\varphi_x = \overline{\varphi}_x$ of class $\mathcal{C}^\infty$ so a fortiori $\mathcal{C}^3$, with a constant C set to 0 in (3.15). This gives that there exists a constant C such that

$$||||\overline{\mathcal{H}}(\cdot,t)||||_\infty \leqslant C\,t^{1/2} \tag{3.20}$$

and consequently the following corollary.

COROLLARY 3.3. *Let $\overline{\mathcal{H}}$ be the operator defined by formula* (3.11). *Then, under the hypothesis of Lemma* 3.2, *for t sufficiently small, one has $||||\overline{\mathcal{H}}(\cdot,t)||||_\infty < 1/2$.*

From Lemma 3.2, one also has the following property valid on $S_x \subset \partial\Omega$.

COROLLARY 3.4. *Let $Z_{x,t}$ be a function over $S_x \times [0,T]$ such that there exist two constants $\alpha \geqslant 0$ and C_Z independent of x, y, t, and τ satisfying*

$$|Z_{x,t}(y,\tau)| \leqslant C_Z \left(|x-y|^\alpha + |\nu(t-\tau)|^{\alpha/2}\right)$$

for all $(y,\tau) \in S_x \times [0,t]$ and $(x,t) \in \partial\Omega \times [0,T]$. Under the hypothesis (C1)–(C4) *of section* 2.2, *there exists a constant C_0 such that for any $x \in \partial\Omega$, one has*

$$\widetilde{\mathcal{H}}_{S_x}(x,t)Z_{x,t} = C_0\,t^{(\alpha+1)/2}.$$

Proof. Let $Z^\natural_{x,t}$ be the parameterization of Z through the map $T_x\phi_x$:

$$Z^\natural_{x,t}(s,\tau) = Z_{x,t}(T_x\phi_x(s),\tau),$$

which gives $\widetilde{\mathcal{H}}_{S_x}(x,t)Z_{x,t} = \mathcal{H}(x,t)Z^\natural_{x,t}$. One then has

$$|Z^\natural_{x,t}(s,\tau)| \leqslant C_Z \left(|T_x\phi_x(s) - x|^\alpha + |\nu(t-\tau)|^{\alpha/2}\right) \leqslant C_0 \left(|s|^\alpha + |\nu(t-\tau)|^{\alpha/2}\right)$$

since T_x is an isometry and $|\phi_x(s)|^2 = |s|^2 + |\varphi_x(s)|^2 \leqslant (1 + C_1^2R^2)|s|^2$, which leads to set $C_0 = C_Z\sqrt{1 + C_1^2R^2}$. One can then apply Lemma 3.2. ∎

3.4. Geometrical convergence. Now we present the following stability lemma of fundamental importance.

LEMMA 3.5 ($\mathcal{H}-\overline{\mathcal{H}}$ estimation). *Under the hypothesis* (C1)–(C4) *of section* 2.2, $\partial\Omega$ *being a two-dimensional manifold of class* $\mathcal{C}^{2+\lambda}$, $0<\lambda\leqslant 1$, *there exists a constant* C_0 *independent of* t *such that*

$$||||\mathcal{H}(\cdot,t)-\overline{\mathcal{H}}(\cdot,t)||||_\infty=\sup_{x\in\partial\Omega}|||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty\leqslant\ C_0\,t^{(1+\lambda)/2}.$$

Proof. The proof of this lemma uses more or less the same technique as the proof of Lemma 3.2. One chooses an $x\in\partial\Omega$ and gets for a bounded function over $S_x\subset\partial\Omega$

$$|\mathcal{H}(x,t)f-\overline{\mathcal{H}}(x,t)f|\leqslant\|f\|_\infty|\mathcal{H}(x,t)1-\overline{\mathcal{H}}(x,t)1|$$

with equality for $f\equiv 1$, and consequently

$$|||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty=|\mathcal{H}(x,t)1-\overline{\mathcal{H}}(x,t)1|.$$

It remains to build an accurate majoration of this quantity independent of x.

Operators $\mathcal{H}(x,t)$ and $\overline{\mathcal{H}}(x,t)$ are defined by formulas (3.10) and (3.11), which give

$$|||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty=\left|\int_0^{\nu t}\int_A\gamma(s,u)\widehat{G}\left(\phi_x(s),u\right)-\overline{\gamma}(s,u)\widehat{G}\left(\overline{\phi}_x(s),u\right)\,\mathrm{d}s\mathrm{d}u\right|,$$

where $u=\nu(t-\tau)$, and

$$\gamma(s,u)=\left(\beta_x-\frac{\varphi_x(s)}{2u}\right)\sqrt{1+|\nabla\varphi_x(s)|^2}$$

and

$$\overline{\gamma}(s,u)=\left(\beta_x-\frac{\overline{\varphi}_x(s)}{2u}\right)\sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}.$$

Moreover, $\widehat{G}\left(\overline{\phi}_x(s),u\right)$ and $\widehat{G}\left(\phi_x(s),u\right)$ are both majorated by $e^{-|s|^2/4u}/(4\pi u)^{3/2}$, and thus

$$|||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty\leqslant\int_0^{\nu t}\int_{\mathbb{R}^2}\left|\gamma(s,u)-\overline{\gamma}(s,u)\right|\frac{e^{-|s|^2/4u}}{(4\pi u)^{3/2}}\,\mathrm{d}s\mathrm{d}u. \tag{3.21}$$

The graph approximation, by means of condition (C4), satisfies

$$\left|\varphi_x(s)-\overline{\varphi}_x(s)\right|\ \leqslant\ C\,|s|^{2+\lambda}. \tag{3.22}$$

Moreover, the gradients satisfy $\nabla\overline{\varphi}_x(s)=K_xs$, and there exists a constant C' such that $|\nabla\varphi_x(s)-K_xs|\leqslant C'\,|s|^{1+\lambda}$; thus

$$|\nabla\varphi_x(s)-\nabla\overline{\varphi}_x(s)|^2\leqslant C'|s|^{2+2\lambda}. \tag{3.23}$$

One can do the following decomposition relying on the triangular inequality:

$$\left|\gamma(s,u)-\overline{\gamma}(s,u)\right|\leqslant K_1+K_2$$

with

$$K_1 = \left| \left(\beta_x - \frac{\varphi_x(s)}{2u}\right)\sqrt{1+|\nabla\varphi_x(s)|^2} - \left(\beta_x - \frac{\varphi_x(s)}{2u}\right)\sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}\ \right|$$

and

$$K_2 = \left| \left(\beta_x - \frac{\varphi_x(s)}{2u}\right)\sqrt{1+|\nabla\overline{\varphi}_x(s)|^2} - \left(\beta_x - \frac{\overline{\varphi}_x(s)}{2u}\right)\sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}\ \right|.$$

The first part K_1 can be majorated by

$$K_1 \leqslant \left(\beta_0 + \left|\frac{\varphi_x(s)}{2u}\right|\right)\left|\sqrt{1+|\nabla\varphi_x(s)|^2}\ -\ \sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}\ \right|, \tag{3.24}$$

and the second by

$$K_2 \leqslant \frac{1}{2u}\left|\varphi_x(s) - \overline{\varphi}_x(s)\right|\ \sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}, \tag{3.25}$$

which, noticing that $|\nabla\varphi_x(s)| = |K_x s| \leqslant \rho_0 R \leqslant \rho_0 R + C' R^{1+\lambda}$, gives (see proof of Proposition 2.3(P1))

$$K_2 \leqslant M_1 \frac{\left|\varphi_x(s) - \overline{\varphi}_x(s)\right|}{2u} \leqslant M_1 C'\,\frac{|s|^{2+\lambda}}{2u}. \tag{3.26}$$

Furthermore, the triangular inequality

$$|\nabla\varphi_x(s)|^2 \leqslant |\nabla\overline{\varphi}_x(s)|^2 + |\nabla\varphi_x(s) - \nabla\overline{\varphi}_x(s)|^2$$

implies

$$\sqrt{1+|\nabla\varphi_x(s)|^2} \leqslant \sqrt{1+|\nabla\overline{\varphi}_x(s)|^2 + |\nabla\varphi_x(s) - \nabla\overline{\varphi}_x(s)|^2}. \tag{3.27}$$

Now one can notice that the epigraph of $-\sqrt{x}$ is convex; thus for any $a > 0$ one has $\sqrt{a+x} \leqslant \sqrt{a} + x/2\sqrt{a}$ for all $x \in [-a, +\infty[$. This implies

$$\sqrt{1+|\nabla\varphi_x(s)|^2} \leqslant \sqrt{1+|\nabla\overline{\varphi}_x(s)|^2} + \frac{|\nabla\varphi_x(s) - \nabla\overline{\varphi}_x(s)|^2}{2\sqrt{1+|\nabla\overline{\varphi}_x(s)|^2}}. \tag{3.28}$$

This leads to a majoration of (3.24) using (3.23):

$$K_1 \leqslant \frac{C'}{2}\left(\beta_0 + \left|\frac{\varphi_x(s)}{2u}\right|\right)|s|^{2+2\lambda}. \tag{3.29}$$

Since one has $|\varphi_\varsigma(s)| \leqslant (\rho_0 + C\,R^\lambda)|s|^2$, one finally has the majoration

$$\left|\gamma(s,u) - \overline{\gamma}(s,u)\right| \leqslant \frac{C'}{2}\left(\beta_0 + (\rho_0 + C\,R^\lambda)\frac{|s|^2}{2u}\right)|s|^{2+2\lambda} + M_1 C'\,\frac{|s|^{2+\lambda}}{2u}. \tag{3.30}$$

Integral (3.21) can then be majorated by applying Lemma 3.1 and majoration obtained by (3.30). Indeed, one can set $r = |s|$ and apply Lemma 3.1 with $R = 0$. This gives

$$|||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty \leqslant \frac{C'\beta_0}{8\sqrt{\pi}}\Gamma^{0,4}_{2+2\lambda,3/2}(t)+\frac{C'\beta_0}{16\sqrt{\pi}}(\rho_0+C\,R^\lambda)\Gamma^{0,4}_{4+2\lambda,5/2}(t) + \frac{M_1C'}{8\sqrt{\pi}}\Gamma^{0,4}_{2+\lambda,5/2}(t)=\mathcal{O}(t^{(1+\lambda)/2}). \qquad \square \tag{3.31}$$

PROPOSITION 3.6 (geometrical convergence). *Under the previous notation and conditions* (C1)–(C4), *with* $\mathcal{H}$ *and* $\overline{\mathcal{H}}$ *defined, respectively, by formulas* (3.10) *and* (3.11), *and for* t *sufficiently small, the densities* $\mu^\natural$ *and* $\mu^\sharp$ *defined in section* 3 *satisfy*

$$\frac{\|\mu^\natural(\cdot,t)-\mu^\sharp(\cdot,t)\|_\infty}{\|\mu^\natural(\cdot,t)\|_\infty} \leqslant \frac{2}{1-2||||\overline{\mathcal{H}}(\cdot,t)||||_\infty}\,||||\mathcal{H}(\cdot,t)-\overline{\mathcal{H}}(\cdot,t)||||_\infty. \tag{3.32}$$

Proof. Let $\mu^\natural$, introduced in section 3, be the solution of the integral equation involving the localized integrodifferential operator (see also Figure 3),

$$-\frac{1}{2}\mu^\natural(x,t)+\widetilde{\mathcal{H}}_{S_x}\mu^\natural = F(x,t), \tag{3.33}$$

whose solution $\mu^\natural$, bounded over $\partial\Omega$, has a local parameterization μ_x on A by $\mu_x(s,t)=\mu^\natural(T_x\phi_x(s),t)$. The integral equation (3.33) is then equivalent to

$$-\frac{1}{2}\mu_x(0,t)+\mathcal{H}(x,t)\mu_x = F(x,t). \tag{3.34}$$

The S_x-localized integrodifferential operator $\mathcal{H}$ acting on parameterized densities can then be defined on an approximated surface $\overline{S_x}$, which leads to the integral equation

$$-\frac{1}{2}\overline{\mu}_x(0,t)+\overline{\mathcal{H}}(x,t)\overline{\mu}_x = F(x,t) \tag{3.35}$$

of solution $\overline{\mu}_x : A\times[0,T]\to\mathbb{R}$, which is the parameterization of the density $\mu^\sharp(x,t)=\overline{\mu}_x(0,t)$. The functions μ_x and $\overline{\mu}_x$ are both defined on the same domain A but represent densities on two different surfaces, $S_x\subset\partial\Omega$ and $\overline{S_x}$.

One can then write, subtracting (3.34) and (3.35),

$$\begin{aligned}\frac{\mu_x(s,t)-\overline{\mu}_x(s,t)}{2} &= \mathcal{H}(x,t)\mu_x-\overline{\mathcal{H}}(x,t)\overline{\mu}_x\\ &= \mathcal{H}(x,t)\mu_x-\overline{\mathcal{H}}(x,t)\mu_x+\overline{\mathcal{H}}(x,t)\mu_x-\overline{\mathcal{H}}(x,t)\overline{\mu}_x\end{aligned}$$

and

$$\frac{|\mu_x(s,t)-\overline{\mu}_x(s,t)|}{2} \leqslant |||\mathcal{H}(x,t)-\overline{\mathcal{H}}(x,t)|||_\infty\,\|\mu_x\|_\infty+|||\overline{\mathcal{H}}(x,t)|||_\infty\,\|\mu_x-\overline{\mu}_x\|_\infty, \tag{3.36}$$

where the $\mathbb{L}^\infty$-norm of densities is taken over A. One can notice that

$$\|\mu_x\|_\infty=\sup_{s\in A}|\mu_x(s)|=\sup_{\xi\in S_x}|\mu^\natural(\xi)|\leqslant\sup_{\xi\in\partial\Omega}|\mu^\natural(\xi)|=\|\mu^\natural\|_\infty$$

and also that $\|\mu_x-\overline{\mu}_x\|_\infty\leqslant\|\mu^\natural-\mu^\sharp\|_\infty$.

Taking the maximum of x over $\partial\Omega$ for the triple norms in (3.36) and applying it to $s = 0$ gives

(3.37)
$$|\mu^\natural(x,t) - \mu^\sharp(x,t)| \leqslant 2\,||||\mathcal{H}(\cdot,t) - \overline{\mathcal{H}}(\cdot,t)||||_\infty\,\|\mu^\natural\|_\infty + 2\,||||\overline{\mathcal{H}}(\cdot,t)||||_\infty\,\|\mu^\natural - \mu^\sharp\|_\infty.$$

The right-hand side of (3.37) is independent of x; thus one can take the maximum of x over $\partial\Omega$ on the left-hand side and get

$$\left(1 - 2\,||||\overline{\mathcal{H}}(\cdot,t)||||_\infty\right)\,\|\mu^\natural - \mu^\sharp\|_\infty \leqslant 2\,||||\mathcal{H}(\cdot,t) - \overline{\mathcal{H}}(\cdot,t)||||_\infty\,\|\mu^\natural\|_\infty. \tag{3.38}$$

Finally, by Corollary 3.3 of Lemma 3.2, one has $||||\overline{\mathcal{H}}(\cdot,t)||||_\infty < 1/2$, which finishes the proof. ∎

This proposition leads directly to the order of convergence when $\partial\Omega$ is sufficiently smooth, when used with Lemma 3.5

COROLLARY 3.7. *Under the hypothesis of Proposition* 3.6, *if* $\partial\Omega$ *is a manifold of class* $\mathcal{C}^{2+\lambda}$, $0 < \lambda \leqslant 1$, *then there exists a constant* C_0 *independent of* t *such that*

$$\|\mu^\natural(\cdot,t) - \mu^\sharp(\cdot,t)\|_\infty \leqslant C\,t^{(1+\lambda)/2}. \tag{3.39}$$

This means that a manifold of class $\mathcal{C}^3$ allows us to reach order 1 in density convergence when locally approximating the surface by its best quadratic osculating surface.

4. Leading order of $\overline{\mathcal{H}}$. We have shown in last section that the best parabolic approximation of the surface leads at least to first order in the approximation of the density, which is enough to carry out the main contribution of the curvature effect to the solution.

LEMMA 4.1. *Under conditions* (C1)–(C4) *and previous notation, we consider the integral*

$$\mathcal{H}_0(x,t) = \int_0^{\nu t}\int_{\mathbb{R}^2}\left(\beta_x - \frac{{}^t s K_x s}{4u}\right)\frac{e^{-(|s|^2 + {}^t s K_x s/2)/4u}}{(4\pi u)^{3/2}}\,\mathrm{d}s\,\mathrm{d}u. \tag{4.1}$$

Then $\overline{\mathcal{H}}(x,t)1 = \mathcal{H}_0(x,t) + \mathcal{O}\left(t^{3/2}\right)$, *with* $\overline{\mathcal{H}}(x,t)$ *defined by* (3.11).

Proof. We first introduce the integral

$$H_1(x,t) = \int_0^{\nu t}\int_{\mathbb{R}^2}\left(\beta_x - \frac{{}^t s K_x s}{4u}\right)\frac{e^{-(|s|^2 + ({}^t s K_x s)^2/4)/4u}}{(4\pi u)^{3/2}}\sqrt{1 + |K_x s|^2}\,\mathrm{d}s\,\mathrm{d}u \tag{4.2}$$

with ${}^t s K_x s/2 = \overline{\varphi}_x(s)$. We then get

$$|\overline{\mathcal{H}}(x,t)1 - H_1(x,t)| \leqslant \frac{M_1}{4\sqrt{\pi}}\int_0^{\nu t}\int_R^{+\infty}\left(\beta_0 + \frac{|\overline{\varphi}_x(s)|}{2u}\right)\frac{e^{-|s|^2/4u}}{u^{3/2}}\,r\,\mathrm{d}r,$$

where $|\overline{\varphi}_x(s)| \leqslant \rho_0|s|^2/2$, which gives

$$|\overline{\mathcal{H}}(x,t)1 - H_1(x,t)| \leqslant \frac{M_1}{4\sqrt{\pi}}(\beta_0 + \rho_0 L_1)\,\Gamma^{R,8}_{0,3/2}(t). \tag{4.3}$$

One can now focus on the estimation of $\mathcal{H}_1(x,t) - H_0(x,t)$. The difference between the two operators lies in the Jacobian $N_x(s)$, which is not present in the definition of $\mathcal{H}_0(x,t)$. One has

$$|\mathcal{H}_1(x,t) - H_0(x,t)| \leqslant \frac{\beta_0 + \rho_0 L_1}{4\sqrt{\pi}}\int_0^{\nu t}\int_0^{+\infty}\frac{e^{-|s|^2/8u}}{u^{3/2}}\left(\sqrt{1 + \rho_0^2 r^2} - 1\right)r\,\mathrm{d}r,$$

which gives, since $\sqrt{1+\alpha} \leqslant 1 + \alpha/2$ for any $\alpha \geqslant -1$,

$$|\mathcal{H}_1(x,t) - H_0(x,t)| \leqslant \frac{\rho_0^2}{8\sqrt{\pi}}(\beta_0 + \rho_0 L_1)\,\Gamma^{0,8}_{2,3/2}(t). \tag{4.4}$$

Applying triangular inequality and noticing that $\Gamma^{R,8}_{0,3/2}(t) + \Gamma^{0,8}_{2,3/2}(t) = \mathcal{O}\left(t^{3/2}\right)$ finishes the proof the lemma. □

Now that the integrals $\overline{\mathcal{H}}(x,t)1$ and $\mathcal{H}_0(x,t)$ are linked and are an approximation of one another at an order higher than surface approximation (see Lemma 3.5), one can focus on the estimation of $\mathcal{H}_0(x,t)$.

PROPOSITION 4.2. *Under conditions* (C1)–(C4) *and* $\mathcal{H}_0(x,t)$ *defined by* (4.1), *one has uniformly*

$$\mathcal{H}_0(x,t) = \left(\beta_x - \frac{\mathsf{tr}(K_x)}{2}\right)\sqrt{\frac{\nu t}{\pi}} + \mathcal{O}\left(t^{3/2}\right). \tag{4.5}$$

Proof. We begin to write the curvature matrix K_x as

$$K_x = \begin{bmatrix} \kappa_1 & \kappa_0 \\ \kappa_0 & \kappa_2 \end{bmatrix}.$$

By means of the cylindrical change of variable $s = (r\cos\theta,\, r\sin\theta)$, the integral (4.1) becomes

$$\mathcal{H}_0(x,t) = \int_0^{2\pi}\int_0^{\nu t}\int_0^{\infty}\left(\beta_x - \frac{r^2 m(\theta)}{4u}\right)\frac{e^{-(r^2+r^4 m(\theta)^2/4)/4u}}{(4\pi u)^{3/2}}\, r\,\mathrm{d}r\,\mathrm{d}u\,\mathrm{d}\theta, \tag{4.6}$$

where $m(\theta) = \kappa_1\cos^2\theta + \kappa_2\sin^2\theta + \kappa_0\cos\theta\sin\theta$. Now posing $(r,u) = (\xi\zeta, \zeta^2/4)$, associated with a Jacobian $\zeta^2/2$, one gets

$$\mathcal{H}_0(x,t) = \frac{1}{2\pi^{3/2}}\int_0^{2\pi}\int_0^{2\sqrt{\nu t}}\int_0^{\infty}\gamma(\xi,\zeta,\theta,x,t)\,\mathrm{d}\xi\,\mathrm{d}\zeta\,\mathrm{d}\theta$$

with

$$\gamma(\xi,\zeta,\theta,x,t) = (\xi\beta_x - \xi^3 m(\theta))\exp\left\{-\xi^2\left(1 + \frac{\xi^2\zeta^2 m(\theta)^2}{4}\right)\right\}, \tag{4.7}$$

which is infinitely differentiable in variables ξ, ζ, and θ.

Since for any positive constants a and b, the function $f(\zeta) = e^{-a-b\zeta^2}$ satisfies $f'(0) = 0$ and f'' is bounded over $\mathbb{R}^+$, there exists $\zeta_0 \in [0,\zeta]$ such that

$$f(\zeta) = f(0) + \zeta^2 f''(\zeta_0)/2.$$

In order to make a Taylor development of γ in ζ valid, one has to exhibit the bounds of f'' with respect to coefficients a, b, and c. Indeed, one has

$$f''(\zeta) = (4b^2\zeta^2 - 2b)e^{-a-b\zeta^2};$$

thus

$$|f''(\zeta)| \leqslant 2be^{-a}(1 + 2b\zeta^2)e^{-b\zeta^2} \leqslant 4be^{-a}. \tag{4.8}$$

Applying this result with $a = \xi^2$ and $b = \xi^4 m(\theta)^2/4$ to the exponential part of (4.7), and using majoration (2.13), one gets

$$\left|\exp\left\{-\xi^2\left(1+\frac{\xi^2\zeta^2 m(\theta)^2}{4}\right)\right\}-1\right| \leqslant \zeta^2\xi^4 m(\theta)^2 e^{-\xi^2} \leqslant L_2\,\zeta^2\, m(\theta)^2 e^{-\xi^2/2}.$$

Consequently, one has

$$\left|\gamma(\xi,\zeta,\theta,x,t) - (\xi\beta_x - \xi^3 m(\theta))e^{-\xi^2}\right| \leqslant L_2\left(\beta_0\xi + |m(\theta)|\xi^3\right)\zeta^2 m(\theta)^2 e^{-\xi^2/2}, \tag{4.9}$$

which is itself majorated, using again formula (2.13), by

$$\sqrt{2}\,L_2\left(L_{1/2}\beta_0 + 2L_{3/2}|m(\theta)|\right)\zeta^2 m(\theta)^2 e^{-\xi^2/4}.$$

Now noticing that

$$\begin{aligned}|m(\theta)| &\leqslant |\kappa_1| + |\kappa_0| + |\kappa_0| + |\kappa_2| \\ &\leqslant 2\max\left(|\kappa_1| + |\kappa_0|, |\kappa_0| + |\kappa_2|\right) = 2|||K_x|||_1 \leqslant 2\sqrt{2}|||K_x|||_2 \leqslant 2\sqrt{2}\rho_0,\end{aligned}$$

where $|||\cdot|||$ is the standard norm for linear operators, and setting

$$C = 8\sqrt{2}\,L_2\left(L_{1/2}\beta_0 + 4L_{3/2}\rho_0\right)\rho_0^2, \tag{4.10}$$

one gets

$$\left|\gamma(\xi,\zeta,\theta,x,t) - (\xi\beta_x - \xi^3 m(\theta))e^{-\xi^2}\right| \leqslant C\,\zeta^2\, e^{-\xi^2/4}, \tag{4.11}$$

whose right-hand side is variable separated and integrates obviously into

$$\int_0^{2\pi}\int_0^{2\sqrt{\nu t}}\int_0^{\infty} \zeta^2\, e^{-\xi^2/4}\,\mathrm{d}\xi\,\mathrm{d}\zeta\,\mathrm{d}\theta = \frac{16\pi^{3/2}}{3}(\nu t)^{3/2}, \tag{4.12}$$

and consequently

$$\left|\mathcal{H}_0(x,t) - \frac{\sqrt{\nu t}}{\pi^{3/2}}\int_0^{2\pi}\int_0^{\infty}(\xi\beta_x - \xi^3 m(\theta))e^{-\xi^2}\,\mathrm{d}\xi\,\mathrm{d}\theta\right| \leqslant \frac{8C}{3}(\nu t)^{3/2}. \tag{4.13}$$

Moreover, one has

$$\int_0^{2\pi} m(\theta)\,\mathrm{d}\theta = \pi\kappa_1 + \pi\kappa_2 = \pi\,\mathrm{tr}(K_x), \tag{4.14}$$

and thus

$$\left|\mathcal{H}_0(x,t) - \sqrt{\frac{\nu t}{\pi}}\int_0^{\infty}(2\xi\beta_x - \xi^3(\kappa_1+\kappa_2))e^{-\xi^2}\,\mathrm{d}\xi\right| \leqslant \frac{8C}{3}(\nu t)^{3/2} \tag{4.15}$$

with

$$\int_0^{\infty}(2\xi\beta_x - \xi^3(\kappa_1+\kappa_2))e^{-\xi^2}\,\mathrm{d}\xi = \beta_x - \frac{\kappa_1+\kappa_2}{2},$$

which concludes the proof. □

5. Curvature effect on the whole surface. From all the previous sections we can give now the following result.

THEOREM 5.1. *Let Ω be an open set of $\mathbb{R}^3$ such that $\partial\Omega$ is a two-dimensional manifold of class $\mathcal{C}^{2+\lambda}$, $0 < \lambda \leqslant 1$, satisfying conditions* (C1)–(C5), *and $\mathcal{L}_x$ is a Robin–Fourier differential operator $\mathcal{L}_x = \beta(x)\mathrm{Id} + n(x)\cdot\nabla$ with β bounded over $\partial\Omega$ and $n(x)$ the inward normal to $\partial\Omega$ in x. Let also $\widetilde{\mathcal{H}}$ be the following integrodifferential operator:*

$$\widetilde{\mathcal{H}}(x,t)f = \nu \int_0^t \int_{\partial\Omega} \mathcal{L}_x G_{\xi,\tau}(x,t)\, f(\xi,\tau)\mathrm{d}\sigma(\xi)\mathrm{d}\tau \tag{5.1}$$

for all continuous and bounded functions $f : \partial\Omega \times [0,T] \to \mathbb{R}$. If the density $\widetilde{\mu}$ is α-Hölder continuous, then

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \left[\widetilde{\mu}(x,t)\ \left(\beta(x) - \bar{\kappa}(x)\right)\right]\sqrt{\frac{\nu t}{\pi}} + \mathcal{O}(t^{(1+\gamma)/2}), \tag{5.2}$$

where $\gamma = \min(\alpha,\lambda)$ and $\bar{\kappa}(x)$ is the mean curvature of $\partial\Omega$ in x.

Proof. Let $\widetilde{\mu}$ be a density that is supposed α-Hölder continuous with $\alpha \in]0,\,1]$. One can introduce the function $Z_{x,t}$ defined by

$$Z_{x,t}\ :\ (y,\tau) \mapsto Z_{x,t}(y,\tau) = \widetilde{\mu}(y,\tau) - \widetilde{\mu}(x,t) \tag{5.3}$$

with the following property:

$$|Z_{x,t}(y,\tau)| = |\widetilde{\mu}(y,\tau) - \widetilde{\mu}(x,t)| \leqslant C_Z\left(|x-y|^\alpha + |\nu(t-\tau)|^{\alpha/2}\right). \tag{5.4}$$

One then gets

$$\widetilde{\mathcal{H}}_{S_x}(x,t)Z_{x,t} = \widetilde{\mathcal{H}}_{S_x}(x,t)\widetilde{\mu} - \widetilde{\mu}(x,t)\widetilde{\mathcal{H}}_{S_x}(x,t)1.$$

By Corollary 3.4 of Lemma 3.2, one gets that there exists a constant C_1 independent of x and t such that

$$|\widetilde{\mathcal{H}}_{S_x}(x,t)Z_{x,t}| = |\widetilde{\mathcal{H}}_{S_x}(x,t)\widetilde{\mu} - \widetilde{\mu}(x,t)\widetilde{\mathcal{H}}_{S_x}(x,t)1| \leqslant C_1 t^{(\alpha+1)/2} \tag{5.5}$$

with $\widetilde{\mathcal{H}}_{S_x}(x,t)1 = \mathcal{H}(x,t)1$, and thus

$$\left|\widetilde{\mathcal{H}}_{S_x}(x,t)1 - \overline{\mathcal{H}}(x,t)1\right| \leqslant C_2 t^{(1+\lambda)/2} \tag{5.6}$$

by Lemma 3.5,

$$\left|\overline{\mathcal{H}}(x,t)1 - \mathcal{H}_0(x,t)\right| \leqslant C_3 t^{3/2} \tag{5.7}$$

by Lemma 4.1, and also

$$\left|\mathcal{H}_0(x,t) - (\beta_x - \bar{\kappa}(x))\sqrt{\nu t/\pi}\right| \leqslant C_4 t^{3/2} \tag{5.8}$$

by Proposition 4.2, where $\bar{\kappa}(x) = \mathrm{tr}K_x/2$ is the mean curvature of $\partial\Omega$ in x.

Joining together (5.5), (5.6), (5.7), and (5.8) gives

$$\left|\widetilde{\mathcal{H}}_{S_x}(x,t)\widetilde{\mu} - (\beta_x - \bar{\kappa}(x))\,\widetilde{\mu}(x,t)\sqrt{\nu t/\pi}\right| \leqslant C_5 t^{(\gamma+1)/2} \tag{5.9}$$

with $\gamma = \min(\alpha, \lambda)$ and $C_5 = C_1 T^{(\alpha-\gamma)/2} + C_2 T^{(\lambda-\gamma)/2} + (C_3 + C_4) T^{2-\gamma/2}$. Noticing that

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \widetilde{\mathcal{H}}_{S_x}(x,t)\widetilde{\mu} + \mathcal{O}(t^\infty) \tag{5.10}$$

by Proposition 2.4 gives the final result. □

First of all, it is necessary to remark that Theorem 5.1 gives the early behavior of the solution, as mentioned in section 1.

COROLLARY 5.2. *Let $\partial\Omega$ be a two-dimensional manifold of class $\mathcal{C}^3$ and let F be a bounded function over $\partial\Omega \times [0,T]$ such that the solution $\widetilde{\mu}$ of the integral equation*

$$-\frac{1}{2}\widetilde{\mu}(x,t) + \widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = F(x,t) \tag{5.11}$$

is bounded and $(1-\varepsilon)$-Hölder continuous with the Hölder exponent satisfying $0 \leqslant \varepsilon < 1$. Under the notation and hypothesis of Theorem 5.1*, one has*

$$\widetilde{\mu}(x,t) = \frac{-2F(x,t)}{1 + 2\left(\bar{\kappa}(x) - \beta(x)\right)\sqrt{\nu t/\pi}} + \mathcal{O}(t^{1-\varepsilon/2}). \tag{5.12}$$

Furthermore, one can build a result in a smoother context concerning torsion-free surfaces.

THEOREM 5.3. *Let Ω be an open set of $\mathbb{R}^3$ such that $\partial\Omega$ is a two-dimensional manifold of class $\mathcal{C}^{3+\lambda^*}$ without torsion, with $0 < \lambda^* \leqslant 1$, satisfying conditions* (C1)–(C5). *Let β and F be two functions bounded, respectively, over $\partial\Omega$ and $\partial\Omega \times [0,T]$ such that the solution $\widetilde{\mu}$ of the integral equation* (5.11) *is of class $\mathcal{C}^{1+\alpha}(\partial\Omega \times [0,T])$ and bounded. Then the solution $\widetilde{\mu}$ of* (5.11) *satisfies*

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \left[\widetilde{\mu}(x,t)\ \left(\beta(x) - \bar{\kappa}(x)\right)\right]\sqrt{\frac{\nu t}{\pi}} + \mathcal{O}(t^{1+\gamma/2}), \tag{5.13}$$

where $\gamma = \min(\alpha, \lambda^*)$ and $\bar{\kappa}(x)$ is the mean curvature of $\partial\Omega$ in x.

Proof. In the context of a manifold smoother than $\mathcal{C}^3$, there exist two constants C_x and C'_x such that

$$\left|\varphi_x(s) - \frac{1}{2}\,{}^t s K_x s - \frac{1}{6}\,T_x^{ijk} s_i s_j s_k\right| \ \leqslant\ C_x\,|s|^{3+\lambda} \tag{5.14}$$

and

$$\left|\nabla\varphi_x(s) - K_x s - \frac{1}{2}\,{}^t s(\mathcal{T}_x : e_\cdot)s\right| \ \leqslant\ C'_x\,|s|^{2+\lambda}, \tag{5.15}$$

where $\mathcal{T}_x$ is the torsion tensor of φ_x in 0 defined as

$$\mathcal{T}_x^{ijk} = \frac{\partial^3\varphi_x}{\partial s_i \partial s_j \partial s_k}(0)$$

and $\mathcal{T}_x^{ijk} s_i s_j s_k$ is its associated cubic form. The torsion tensor can be contracted with the vectors of canonical basis e_k, such that the kth component of $\mathcal{T}_x : e_\cdot$ is the matrix $\mathcal{T}_x : e_k$ associated to the quadratic form ${}^t s(\mathcal{T}_x : e_k)s$. This can be equivalently stated, using again the Einstein notation, as

$${}^t s(\mathcal{T}_x : e_\cdot)s = (\mathcal{T}_x : e_\cdot)^{ij} s_i s_j = \mathcal{T}_x^{ijk} s_i s_j e_k.$$

This statement is also equivalent to the symmetric formulation $(E^*)^{\otimes 3} \equiv E \otimes E^* \otimes E^*$ with $E = \mathbb{R}^2$.

Constants C_x and C'_x can be assumed to be bounded independently of x over $\partial\Omega$, and in the case of a torsion-free surface (for example, cylinders and spheres are torsion-free), the torsion tensor is identically equal to 0, which leads to majorations of the same kind as those of equations (2.3) with majorants $C|s|^{3+\lambda^*}$ and $C'|s|^{2+\lambda^*}$, respectively, for the gradients. In this context, Lemma 3.5 holds with $\lambda = 1 + \lambda^* \in]0, 2]$, which gives that

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \mathcal{H}(x,t)\mu_x^\flat + \mathcal{O}(t^\infty) = \overline{\mathcal{H}}(x,t)\mu_x^\flat + \mathcal{O}(t^{1+\lambda^*/2}) \tag{5.16}$$

with $\mu_x^\flat(s,\tau) = \widetilde{\mu}(T_x\phi_x(s),\tau)$.

Moreover, thanks to greater regularity of the density through the maps, one can write the following development:

$$\begin{aligned}\mu_x^\flat(s,\tau) = \mu_x^\flat(0,t) + R_{x,t}(s,\tau) - \nu(t-\tau)\frac{\partial \mu_x^\flat}{\partial \tau}\Big|_{0,t} \\ + \mathcal{O}\left(|s|^{1+\alpha} + |s|u^{\alpha/2}\right) + \mathcal{O}\left(|s|^\alpha u + u^{1+\alpha/2}\right)\end{aligned} \tag{5.17}$$

with $R_{x,t}(s,\tau) = s \cdot \nabla\mu_x^\flat(0,t)$ and $u = \nu|t-\tau|$.

By oddness, one has $\overline{\mathcal{H}}(x,t)R_{x,t} = 0$, and one can easily establish upon proof of Lemma 3.2 that

$$\left|\overline{\mathcal{H}}(x,t)[|s|^a(\nu(t-\tau))^b]\right| \leqslant \frac{2\,M_1}{\sqrt{\pi}} \int_0^{\nu t}\int_0^R \left(\beta_0 + \frac{\rho_0}{2}\,\frac{r^2}{2u}\right) \frac{r^a u^b e^{-r^2/4u}}{8u^{3/2}}\, r\,\mathrm{d}r\mathrm{d}\tau, \tag{5.18}$$

which gives

$$\left|\overline{\mathcal{H}}(x,t)[|s|^a(\nu(t-\tau))^b]\right| \leqslant C_1\,\Gamma^{0,8}_{a,3/2-b} = \mathcal{O}(t^{1/2+b+a/2}) \tag{5.19}$$

with $C_1 = M_1(\beta_0 + L_1\rho_0)/4\sqrt{\pi}$. This implies that $|\overline{\mathcal{H}}(x,t)[\nu(t-\tau)]| = \mathcal{O}(t^{3/2})$; thus (5.17) reads as

$$\mu_x^\flat(s,\tau) \;= \mu_x^\flat(0,t) + \mathcal{O}(t^\eta) \tag{5.20}$$

with $\eta = \min(3/2, 1+\alpha/2, 3/2+\alpha/2) = 1+\alpha/2$. Combining this with (5.16) gives

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \overline{\mathcal{H}}(x,t)\mu_x^\flat + \mathcal{O}(t^{1+\lambda^*/2}) = \mu_x^\flat(0,t)\overline{\mathcal{H}}(x,t)1 + \mathcal{O}(t^{1+\lambda^*/2}) + \mathcal{O}(t^{1+\alpha/2}). \tag{5.21}$$

By Lemma 4.1 and Proposition 4.2, one has

$$\left|\overline{\mathcal{H}}(x,t)1 - (\beta_x - \bar{\kappa}(x))\,\sqrt{\nu t/\pi}\right| = \mathcal{O}(t^{3/2}), \tag{5.22}$$

and consequently (5.21) leads to

$$\widetilde{\mathcal{H}}(x,t)\widetilde{\mu} = \widetilde{\mu}(x,t)\overline{\mathcal{H}}(x,t)1 + \mathcal{O}(t^{1+\gamma/2}) = \widetilde{\mu}(x,t)\,(\beta_x - \bar{\kappa}(x))\,\sqrt{\nu t/\pi} + \mathcal{O}(t^{1+\gamma/2}) \tag{5.23}$$

with $\gamma = \min(\lambda^*, \alpha)$. □

Note that Theorem 5.3 is not an extension of Theorem 5.1, because a function can be more regular than Hölder continuous (even with an exponent 1) and less than $\mathcal{C}^1$ (for example, $\sqrt{t}$). Moreover, one can notice that this result is useful only as a

kind of regularity estimation of the integrodifferential operator $\widetilde{\mathcal{H}}$, since the density obtained as the solution of the original integral equation (5.11) exhibits a square-root singularity in the general case (see Corollary 5.2) and consequently cannot be $\mathcal{C}^1$.

Furthermore, a direct corollary of this result is that if the density is $\mathcal{C}^2(\partial\Omega\times[0,T])$, which is in practice a restrictive condition, and if the manifold $\partial\Omega$ is $\mathcal{C}^4$, then the error is of order 3/2. This fact is illustrated in section 6.2 with a constant density and a cylinder.

6. Cylindrical examples. In this section we provide a few canonical examples showing the contribution of the curvature effect on the solution.

Example 6.1 puts the problem of boundary source in the more general context of enforcing boundary conditions. Examples 6.2 and 6.3 describe, respectively, the cases of the spanwise and azimuthal components of the cylinder. A numerical application of kinematic boundary conditions is then provided in section 6.4.

6.1. Splitting the full heat equation. The method presented herein can be very useful when a scheme that does not control boundary conditions is used. Indeed, the problem

$$\left\{\begin{array}{l} \dfrac{\partial\omega}{\partial t}-\nu\Delta\omega=g \ \text{ in } \ \Omega\times]0,T[,\\ \omega(x,0)=\omega_0(x) \ \text{ on } \ \Omega,\\ \nu\,\mathcal{L}_x\omega(x,t)=F(x,t) \ \text{ on } \ \partial\Omega\times]0,T[\end{array}\right. \tag{6.1}$$

can be solved in the inner part of Ω by a numerical method not consistent on boundaries (or leading to a prohibitive computational cost when consistent), i.e., approximating the problem

$$\left\{\begin{array}{l} \dfrac{\partial\omega}{\partial t}-\nu\Delta\omega=g \ \text{ in } \ \Omega\times]0,T[,\\ \omega(x,0)=\omega_0(x) \ \text{ on } \ \Omega \end{array}\right. \tag{6.2}$$

with arbitrary boundary conditions. Then one can measure the error on boundaries

$$q(x,t)=\nu\mathcal{L}_x\omega(x,t)$$

and use the present integral method to give explicitly (without the cost of another partial differential equation to solve) the solution of

$$\left\{\begin{array}{l} \dfrac{\partial\omega}{\partial t}-\nu\Delta\omega=0 \ \text{ in } \ \Omega\times]0,T[,\\ \omega(x,0)=0 \ \text{ on } \ \Omega,\\ \nu\,\mathcal{L}_x\omega(x,t)=F(x,t)-q(x,t) \ \text{ on } \ \partial\Omega\times]0,T[, \end{array}\right. \tag{6.3}$$

which is then approximated (at the appropriate order coming from Theorem 5.1 or Theorem 5.3) by

$$\omega(x,t)\simeq\int_0^t\int_{\partial\Omega}\frac{-2F(\xi,\tau)+2q(\xi,\tau)}{1+2\left(\bar\kappa(\xi)-\beta(\xi)\right)\sqrt{\nu\tau/\pi}}\,\frac{e^{-(x-\xi)^2/4\nu(t-\tau)}}{\left(4\pi\nu(t-\tau)\right)^{3/2}}\,\mathrm{d}\sigma(\xi)\mathrm{d}\tau, \tag{6.4}$$

which can itself be computed by a time quadrature (for t sufficiently small, typically for a time step when used in a numerical context) over a surface integral, using, for example, the midpoint rule:

$$\omega(x,t) \simeq \int_{\partial\Omega} \frac{-2t\,F(\xi,t/2)+2t\,q(\xi,t/2)}{1+2\,(\bar\kappa(\xi)-\beta(\xi))\,\sqrt{\nu t/2\pi}}\,\frac{e^{-(x-\xi)^2/2\nu t}}{(2\pi\nu t)^{3/2}}\,\mathrm{d}\sigma(\xi). \tag{6.5}$$

Note that the time quadrature based on an implicit Euler scheme is singular, while an explicit Euler scheme does not take curvature into account, despite the fact of being only first order.

Moreover, in order to provide more accuracy, this technique can be repeated on smaller intervals of time. The drawback in segmenting the time interval is that it reduces standard deviation of the Gaussian, which can possibly make the scheme underresolved, especially for three-dimensional computations. This approach, which couples the present integral method and a particle strength exchange (PSE) scheme (see [12]), has been successfully used for three-dimensional flow computations in [32], where boundary effects are the dominant effect.

Furthermore, one can also notice that (6.2)–(6.3) can be naturally parallelized if (6.2) is solved for homogeneous boundary conditions (i.e., $q=0$). Using this density estimation also provides a way to correct lack of regularity at the grid interface when performing domain decomposition at minimal cost.

6.2. The spanwise invariant cylinder. Let $\mathcal{B}_2(0,r)$ be the open ball of center 0 and radius r in $\mathbb{R}^2$, let $\Omega=\mathbb{R}^2\setminus\mathcal{B}_2(0,r)\times\mathbb{R}$ be an infinitely long cylindrical body of $\mathbb{R}^3$, and let $\mathcal{C}=\partial\mathcal{B}_2(0,r)$.

One considers the heat equation and the spanwise component of its solution, which is related to a pure Neumann boundary condition. One then gets the spanwise heat layer of unity:

$$\widetilde{\mathcal{H}}_z(x,t)1=\nu\int_0^t\int_{\partial\Omega} n_x\cdot\nabla G_{\xi,\tau}(x,t)\mathrm{d}\sigma(\xi)\mathrm{d}\tau.$$

Since the configuration is axisymmetric and spanwise invariant, one can set $x=(r,0,0)$ and $\xi=(r\cos\theta,r\sin\theta,0)$ without loss of generality. By means of integration in the spanwise direction, one gets

$$\begin{aligned}\widetilde{\mathcal{H}}_z(x,t)1&=-\nu\int_0^t\int_{\mathcal{C}}\frac{1}{4\pi\nu(t-\tau)}\,\frac{n_x\cdot(x-\xi)}{2\nu(t-\tau)}\,\exp\left(-\frac{(x-\xi)^2}{4\nu(t-\tau)}\right)\mathrm{d}\sigma(\xi)\mathrm{d}\tau\\&=-\frac{1}{\pi}\int_0^{\nu t}\int_{-\pi}^{\pi}\frac{r}{8u^2}(1-\cos\theta)\,\exp\left(-\frac{\left[(\cos\theta-1)^2+\sin^2\theta\right]r^2}{4u}\right)r\mathrm{d}\theta\mathrm{d}u\end{aligned}$$

with $u=\nu(t-\tau)$. Noticing the symmetry around $\theta=0$, one gets by parity

$$\widetilde{\mathcal{H}}_z(x,t)1=-\frac{r^2}{2\pi}\int_0^{\nu t}\int_0^1\frac{y}{u^2}\exp\left(-\frac{y\,r^2}{u}\right)\frac{1}{\sqrt{y(1-y)}}\,\mathrm{d}y\mathrm{d}u$$

with $y=(1-\cos\theta)/2$, which integrates successively into

$$\widetilde{\mathcal{H}}_z(x,t)1=-\frac{1}{2\pi}\int_0^1\frac{e^{-y\,r^2/\nu t}}{\sqrt{y(1-y)}}\,\mathrm{d}y=-\frac{1}{2}e^{-r^2/2\nu t}\,\mathrm{I}_0\left(\frac{r^2}{2\nu t}\right),$$

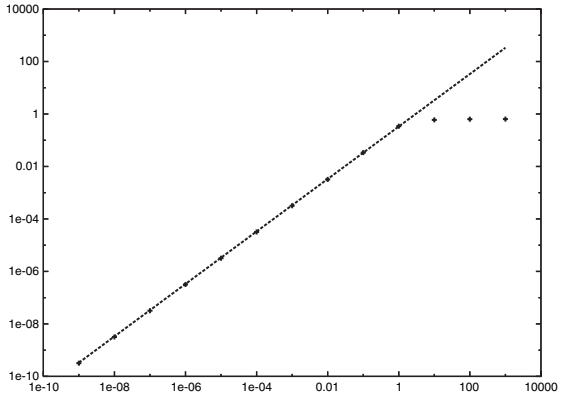

FIG. 5. *Numerical values of heat layer $\widetilde{\mathcal{H}}_z(x,t)f_x$ with respect to time t (dashed line represents the function $t/3$).*

where I_0 is the modified Bessel function of first kind (i.e., the solution of $x^2y'' + xy' - x^2y = 0$ with $y(0) = 1$ and $y'(0) = 0$). Since the mean curvature of $\partial\Omega$ is $\bar{\kappa} = 1/2r$, and noticing that

$$\lim_{x\to+\infty} \sqrt{x}\, e^{-x}\mathrm{I}_0(x) = \frac{1}{\sqrt{2\pi}},$$

one finally has that $\widetilde{\mathcal{H}}_z(x,t)1$ is equivalent to $-\bar{\kappa}\sqrt{\nu t/\pi}$ when t tends to 0, as expected by Lemma 4.2 and Theorem 5.1. One can notice that the present computation is performed on the exact surface $\partial\Omega$ instead of an approximation.

Moreover, in the present case, the density is smooth and the hypothesis of Theorem 5.3 holds; thus one can expect a full 3/2 order of convergence. Indeed, a cylinder presents no torsion, and one can show that

$$\lim_{x\to+\infty} \left(\sqrt{x}\, e^{-x}\mathrm{I}_0(x) - \frac{1}{\sqrt{2\pi x}}\right) x^{3/2} = \frac{1}{8\sqrt{2\pi}},$$

which proves the 3/2 order of heat layer error on both the exact surface and its quadratic approximation. This example illustrate the statement of Theorem 5.3, i.e., that no torsion implies no error at first order in time for a constant source.

In order to exhibit the limit convergence order of Theorem 5.1, one has to choose an example for which Theorem 5.3 is not valid. Since the cylinder is torsion-free, one has to choose a density which is 1-Hölder continuous without being differentiable. The Euclidean norm satisfies this condition, and using the notation already set above, one considers the density

$$f_x(\xi,\tau) = |x - \xi| = 2r\sqrt{y};$$

thus evaluating the heat layer at point x gives

$$\widetilde{\mathcal{H}}_z(x,t)f_x = -\frac{r}{\pi}\int_0^1 \frac{e^{-y\,r^2/\nu t}}{\sqrt{1-y}}\,\mathrm{d}y. \tag{6.6}$$

Integrating this integral symbolically is more difficult than the previous ones (though possible using erf functions). Figure 5 shows a certified 15-digit evaluation of the integral expression (6.6) with respect to time t. This actually exhibits a first order convergence since $f_x(x,t) = 0$, and consequently $\widetilde{\mathcal{H}}_z(x,t)f_x = f_x(x,t) + \mathcal{O}(t)$.

6.3. Vectorial kinematic boundary conditions and integral formulation of Chorin's algorithm in the cylinder case. In this section, one applies the present density estimation to Chorin's algorithm in the parabolic context (initially proposed in an hyperbolic context [7]), in the case of a circular cylinder.

Let $u : \Omega \times [0,T] \to \mathbb{R}^3$ be a velocity field satisfying the Stokes equations, and let ω be its associated vorticity field defined by $\omega = \mathrm{curl} u$ and satisfying the diffusion problem with kinematic boundary conditions:

$$\left\{ \begin{array}{l} \dfrac{\partial \omega}{\partial t} - \nu \Delta \omega = 0 \ \text{ in } \ \Omega \times]0,T[, \\ u(x,t) = 0 \ \text{ on } \ \partial\Omega \times]0,T[, \\ \omega(x,0) = \omega_0(x) \ \text{ on } \ \Omega. \end{array} \right. \tag{6.7}$$

While computing ω from u is obvious, building u from ω is more difficult. In the full space $\Omega = \mathbb{R}^3$, one can use the three-dimensional Green kernel $G(x) = (4\pi|x|)^{-1}$ through the Biot–Savart law

$$u = \nabla G \,\hat{*}\, \omega = \int_{\mathbb{R}^3} \nabla G(\cdot - x) \wedge \omega(x)\, \mathrm{d}x. \tag{6.8}$$

In the presence of boundaries, one can use symmetrizations of Biot–Savart laws around $\partial\Omega$ or more rigorously consider the single-layer integral formulation of (6.7) shown in [10]. Nevertheless, integral techniques are much less useful for this problem than the one presented herein, since the Green kernel and its gradient decrease much more slowly than Gaussian functions. A more competitive approach to computing the velocity from the vorticity is to introduce the Poisson equation on stream function with appropriate boundary conditions (see [30]) and eventually additional quantities such as potential stream to uncouple components of the three-dimensional Poisson equation (see [11]). In any case, it is possible to consider the operator $\mathcal{A}$, in the appropriate functional space, associating a velocity field $u = \mathcal{A}\omega$ to a vorticity field ω, satisfying $\mathrm{curl} u = \omega$ and $\mathrm{div} u = 0$ on Ω and $u \cdot n_x = 0$ on $\partial\Omega$.

One considers the infinitely long circular cylinder Ω of axis e_z and radius R, whose other tangential vector is denoted e_θ and whose normal vector is denoted e_r (that is, the standard cylindrical coordinates).

Applying Chorin's method (whose convergence is proved in [8] in the case of the Stokes equation and its rotational formulation), this problem can be reduced to two parabolic problems with Neumann and Robin–Fourier (see [11]) boundary conditions. The first has homogeneous boundary conditions, which in cylindrical coordinates reads as

$$\left\{ \begin{array}{l} \dfrac{\partial \omega^1}{\partial t} - \nu \Delta \omega^1 = 0 \ \text{ in } \ \Omega \times]0,T[, \\ \omega^1(x,0) = \omega_0(x) \ \text{ on } \ \Omega, \\ \nu \dfrac{\partial \omega^1_z}{\partial n} = 0 \ \text{ on } \ \partial\Omega \times]0,T[, \\ \nu \dfrac{\omega^1_\theta}{R} + \dfrac{\partial \omega^1_\theta}{\partial n} = 0 \ \text{ on } \ \partial\Omega \times]0,T[, \\ \omega^1_r = 0 \ \text{ on } \ \partial\Omega \times]0,T[, \end{array} \right. \tag{6.9}$$

whose divergence-free and no-slip-through associated velocity field $u^1 = \mathcal{A}\omega^1$ presents a priori nonzero tangential values (u^1 is usually called spurious velocity). One then considers a second diffusion problem with zero initial condition,

$$\left\{\begin{array}{l} \dfrac{\partial \omega^2}{\partial t} - \nu \Delta \omega^2 = 0 \ \text{ in } \ \Omega \times]0,T[, \\ \omega^2(x,0) = 0 \ \text{ on } \ \Omega, \\ \nu \dfrac{\partial \omega_z^2}{\partial n} = -\dfrac{\partial u_\theta}{\partial t} \ \text{ on } \ \partial\Omega \times]0,T[, \\ \nu \dfrac{\omega_\theta^2}{R} + \dfrac{\partial \omega_\theta^2}{\partial n} = \dfrac{\partial u_z}{\partial t} \ \text{ on } \ \partial\Omega \times]0,T[, \\ \omega_r^2 = 0 \ \text{ on } \ \partial\Omega \times]0,T[, \end{array}\right. \tag{6.10}$$

which allows us to link asymptotically (see [8]) the solution of (6.7) to the solutions of (6.9)–(6.10):

$$\omega^1(t) + \omega^2(t) = \omega(t) + \mathcal{O}(t). \tag{6.11}$$

One can immediately notice that problem (6.10) is a heat equation with a zero initial condition and a vectorial Robin–Fourier boundary condition, on which one can apply component by component the density estimation presented herein, as long as boundary conditions are expressed in a basis in which the fundamental solution of heat equation is still Gaussian. One can thus introduce the matrix

$$K = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \ N = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}, \text{ and } \ \Gamma_\theta = \begin{bmatrix} \cos\theta & \sin\theta & 0 \\ -\sin\theta & \cos\theta & 0 \\ 0 & 0 & 1 \end{bmatrix} \tag{6.12}$$

so that in the canonical basis $\omega = (\omega_x, \omega_y, \omega_z)$, the boundary operator of equation (6.10) reads as

$$\mathcal{L}_x \omega = \Gamma_{-\theta} K \, \Gamma_\theta \frac{\omega}{R} + \Gamma_{-\theta} N \, \Gamma_\theta \frac{\partial \omega}{\partial n} \tag{6.13}$$

when expressed at point $x = (R\cos\theta, R\sin\theta, z)$. This allows us to write the boundary conditions of (6.10) under the form

$$\nu \, \mathcal{L}_x \omega = \frac{\partial u}{\partial t} \wedge n_x. \tag{6.14}$$

One can use Theorem 5.1 and get by linearity

$$\widetilde{\mathcal{H}}(x,t) f \simeq \Gamma_{-\theta} \left(K - \frac{N}{2} \right) \Gamma_\theta \frac{f(x,t)}{R} \tag{6.15}$$

because the mean curvature of the cylinder in $\kappa = 1/2R$. Since the density of the potential giving ω satisfies the integral equation $\widetilde{\mu} - 2\widetilde{\mathcal{H}}\widetilde{\mu} = -2\partial_t u \wedge n$, one gets

$$\widetilde{\mu}(x,t) \simeq -2\Gamma_{-\theta} \left(\mathrm{Id} - \frac{\sqrt{\nu t/\pi}}{R}(2K - N) \right)^{-1} \Gamma_\theta \, \frac{\partial u}{\partial t} \wedge n_x \tag{6.16}$$

at the appropriate order, depending only on regularity of u since the cylinder is a $\mathcal{C}^\infty$ differentiable manifold.

Setting $\varepsilon = \sqrt{\nu t/\pi}/R$, (6.16) reads as

$$\widetilde{\mu}(x,t) \simeq -2\Gamma_{-\theta} P^{-1} \Gamma_\theta \frac{\partial u}{\partial t} \wedge n_x, \quad \text{where} \quad P = \begin{bmatrix} 1-2\varepsilon & 0 & 0 \\ 0 & 1-\varepsilon & 0 \\ 0 & 0 & 1+\varepsilon \end{bmatrix}. \tag{6.17}$$

This matrix P is obvious to inverse, as long as t is sufficiently small. One can notice that curvature effects are of different signs for ω_θ and ω_z due to the Dirichlet part in the azimuthal direction.

Note also that if one considers only the z direction (for a two-dimensional problem), the density estimation (6.17) can be written as

$$\widetilde{\mu}_z(x,t) \simeq \frac{+2}{1 + \frac{1}{R}\left(\sqrt{\nu t/\pi}\right)} \frac{\partial u_\theta}{\partial t}(x,t). \tag{6.18}$$

6.4. Numerical example of kinematic boundary conditions. One considers the diffusion problem with time-periodic unknown $\omega : \Omega \times]0, 2\pi] \mapsto \mathbb{R}^3$, still defined in a cylindrical domain Ω, and kinematic boundary conditions:

$$\begin{cases} \dfrac{\partial \omega}{\partial t} - \nu \Delta \omega = 0 \quad \text{in} \quad \Omega \times]0, 2\pi], \\ u(x,t) = \cos t \; e_\theta(x) \quad \text{on} \quad \partial\Omega \times]0, 2\pi], \end{cases} \tag{6.19}$$

where the velocity field $u(x,t)$ is built from ω by $u = \mathcal{A}\omega$, where operator $\mathcal{A}$ is based on formula (6.8), or by using a hybrid technique (see [11]).

Note that this problem is slightly more general than the one in the last section, because one has nonhomogeneous kinematic boundary conditions, whose main implication is that spurious velocity vanishes toward boundary value. Indeed, it has been shown (see [24]) that the parabolic problem

$$\begin{cases} \dfrac{\partial \omega}{\partial t} - \nu \Delta \omega = 0 \quad \text{in} \quad \Omega \times]0, 2\pi], \\ \nu \dfrac{\partial \omega_z}{\partial n}(x,t) = -\dfrac{\partial u_\theta}{\partial t}(x,t) = \sin t \quad \text{on} \quad \partial\Omega \times]0, 2\pi], \\ \nu \dfrac{\partial \omega_\theta}{\partial n}(x,t) = \dfrac{\partial u_z}{\partial t}(x,t) = 0 \quad \text{on} \quad \partial\Omega \times]0, 2\pi], \\ \omega_r = 0 \quad \text{on} \quad \partial\Omega \times]0, 2\pi] \end{cases} \tag{6.20}$$

approximates well problem (6.19) in this particular context (i.e., when residual velocities coming from (6.20) with homogeneous conditions vanish toward $\partial_t u$ as stated above). One can notice that the solution is then invariant in z and θ.

Then let the functions

$$\begin{cases} K^+(r) = \mathfrak{Re}\left(Ke_0(cr)\right) + \mathfrak{Im}\left(Ke_0(cr)\right), \\ K^-(r) = \mathfrak{Re}\left(Ke_0(cr)\right) - \mathfrak{Im}\left(Ke_0(cr)\right) \end{cases}$$

be based on Kelvin functions (sometimes also called Thompson functions), with $c = 1/\sqrt{\nu}$. The function

$$\omega^*(r,t) = \left(\alpha K^-(r) - \beta K^+(r)\right)\cos t - \left(\alpha K^+(r) + \beta K^-(r)\right)\sin t$$

is then a time-periodic solution of $\partial_t\omega - \nu\Delta\omega = 0$. Setting $A = c\sqrt{2}/2|\,Ke_1(c)\,|$ helps to check that $\beta - i\alpha = Ke_1(c)/A$ is the only pair of parameters that makes $\omega^* e_z$ satisfy (6.20).

Let us consider (6.20) over a time step $]t_n, t_{n+1}[$ with $t_n = n\delta t$ and its initial value denoted $\omega^n(x)$. The initial value for $n = 0$ is set with the exact solution $\omega_z^0(x) = \omega^*(|x|, t_n)$ and other components of ω^0 set to zero.

Playing with linearity of the heat equation (without approximation), (6.20) can be solved in two steps over $]t_n, t_{n+1}[$. The first step is the computation of the solution with arbitrary boundary conditions, in practice using a second order PSE scheme on a grid with a uniform cylindrical lattice (see [11]). The second step is the enforcement of the boundary condition, in the spirit of section 6.1.

Nevertheless, one can notice that truncated PSE schemes are consistent with a flux and can be tuned to provide homogeneous Neumann boundary conditions. The flux error denoted q in section 6.1 can consequently be set to 0 in equations (6.3)–(6.5). The two steps can be naturally parallelized, and the second step can be computed with the integral scheme presented herein in the pure Neumann boundary condition context, which, using formula (6.18), reads as

$$\omega_z(x, t_n + \delta t) \simeq \omega_z(x, t_n) - 2\int_0^{\delta t}\int_{\partial\Omega} \frac{G_{\xi,\tau}(x, \delta t)}{1 + \frac{1}{R}(\sqrt{\nu\tau/\pi})}\,\sin(t_n + \tau)\,\mathrm{d}\sigma(\xi)\mathrm{d}\tau,$$

where R is the cylinder radius, without any action on other components since 0 is solution. Note that Theorem 5.3 is valid only at $t_n = 0$; thus this density evaluation is first order (from Corollary 5.2). One can then use a time quadrature to compute $\omega(x, t_{n+1})$, such as using the midpoint rule (see (6.5) with $q = 0$).

This one-dimensional reducible example allows us to compare the three-dimensional algorithm presented herein with the two-dimensional algorithm from [24] given for Neumann boundary conditions, and compare both of them with the exact solution. These three quantities are plotted in Figure 6 at times $t = 0.75$, 1, 1.5, and 2. The curves show a good agreement qualitatively, but the main result is that the algorithm allows us to enforce very well the kinematic boundary conditions: the residual velocity (rebuilt from vorticity ω by the operator $\mathcal{A}$ defined in section 6.3) is close to 10^{-6}, and this code was run in simple precision.

7. Toroidal examples. This section aims to illustrate the optimality of the convergence ratio obtained by Theorem 5.1. In order to proceed, one has to consider an example for which Theorem 5.3 is not valid.

The differences in the hypotheses of Theorems 5.1 and 5.3 lead us to consider either a nondifferentiable 1-Hölder continuous function on a torsion-free surface (the case already studied in section 6.2), or a smooth function density defined on a surface presenting torsion (i.e., whose tensor of map third derivatives is not identically zero).

In order to build such a surface and analyze properties of the integrodifferential operator $\widetilde{\mathcal{H}}$ on it, one considers the heat equation with pure Neumann boundary conditions:

$$\left\{\begin{array}{l} \dfrac{\partial\omega}{\partial t} - \nu\Delta\omega = 0 \ \text{ in } \ \Omega\times]0, \delta t], \\ \nu\,\dfrac{\partial\omega}{\partial n}(x,t) = F(x,t) \ \text{ on } \ \partial\Omega\times]0,\delta t], \\ \omega(x,0) = 0 \ \text{ on } \ \partial\Omega, \end{array}\right. \tag{7.1}$$

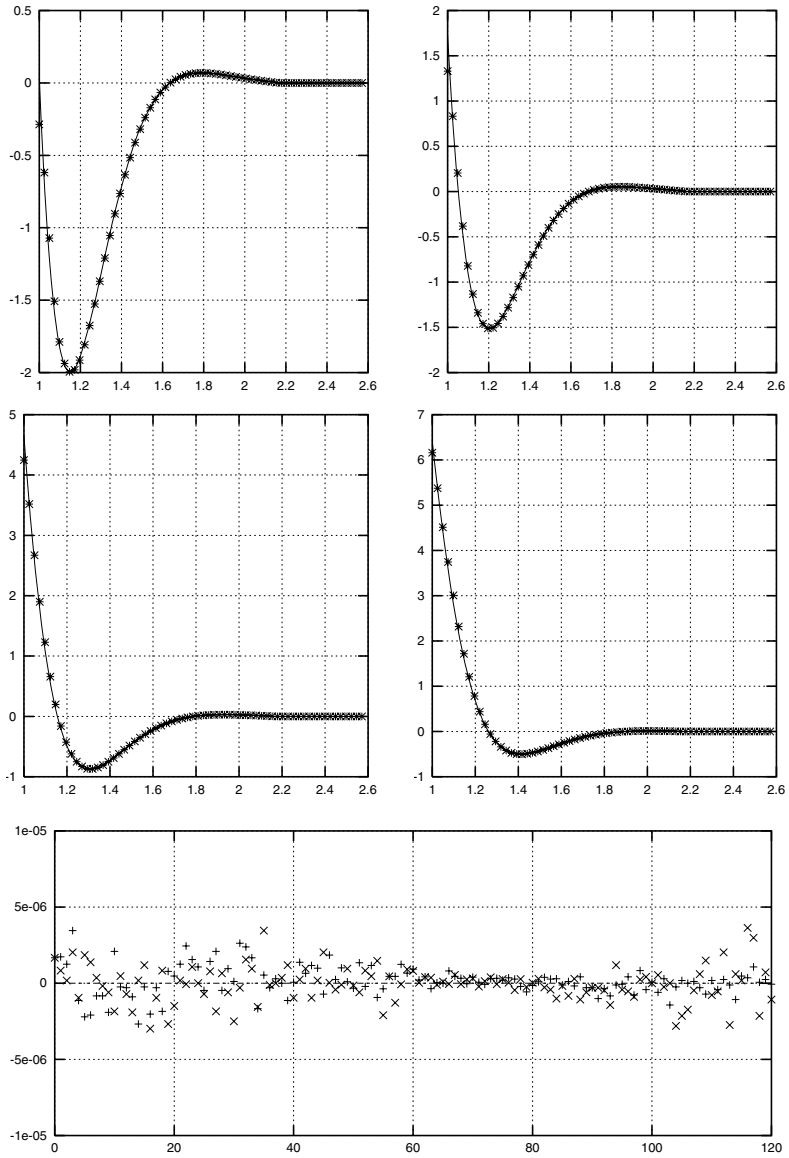

FIG. 6. *Numerical solutions compared to the exact axisymmetric and time-periodic solution of the heat equation at times* $t = 0.75, 1.0, 1.5, 2.0$*, with exact solution (–), three-dimensional scheme (+), and two-dimensional scheme (×) from* [24]*. Bottom: residual tangential velocity versus time step number* n *(time step* $\delta t = 0.025$*).*

where $\partial\Omega$ is successively the usual torus in section 7.1 and then modified with harmonic perturbations introducing torsion in sections 7.2 and 7.3. Large and small wavelength perturbations are involved, generating, respectively, a "twisted" and a "rippled" torus.

Instead of solving the heat equation, we will discuss properties of the related operator $\widetilde{\mathcal{H}}$ defined by formula (2.2), which reads as follows:

$$\widetilde{\mathcal{H}}(x,t)1 = -\frac{\nu}{16\pi^{3/2}} \int_0^t \int_{\partial\Omega} \frac{(x-\xi)\cdot n_x}{\big(\nu(t-\tau)\big)^{5/2}} e^{-|x-\xi|^2/4\nu(t-\tau)} \mathrm{d}\sigma(\xi)\mathrm{d}\tau. \tag{7.2}$$

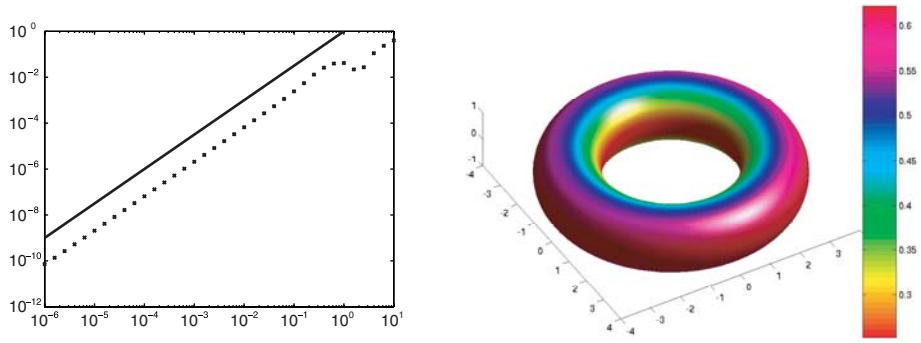

FIG. 7. *Right: plot of this surface, with color being the curvature coefficient given by formula* (7.12). *Left: pointwise error of the estimate of* $\widetilde{\mathcal{H}}(x,t)1$ *in* $\theta_0 = \pi/2$ *versus* νt ($\times$ *is formula* (7.13), *and the solid line is* $(\nu t)^{3/2}$).

7.1. The torsionless torus. One sets two radii r and $R > r$, and two angles $\theta \in [-\pi, \pi[$ and $\zeta \in [-\pi, \pi[$, both defined modulo 2π. The torus $\mathbb{T}$ is then the image of these domains by the function

$$f(\theta,\zeta) = \big((R + r\cos\theta)\cos\zeta, (R + r\cos\theta)\sin\zeta, r\sin\theta\big)\,, \tag{7.3}$$

which satisfies

$$\left\| \frac{\partial f}{\partial \theta} \wedge \frac{\partial f}{\partial \zeta} \right\|_2 = r\, I_\theta \quad \text{with} \quad I_\theta = (R + r\cos\theta) > 0. \tag{7.4}$$

The resulting surface is shown in Figure 7.

One can consider the points on the $\zeta = 0$ section, defined by

$$x = f(\theta_0, 0) = \big(I_{\theta_0}, 0, r\sin\theta_0\big)\,, \tag{7.5}$$

as arbitrary points of the surface without loss of generality, since the torus is globally ζ-invariant. The normal vector to $\mathbb{T}$ in x is then

$$n_x = (\cos\theta_0, 0, \sin\theta_0)\,. \tag{7.6}$$

Moreover, in order to describe a neighborhood of x, one also defines

$$\xi = f(\theta,\zeta) = \big(I_\theta\cos\zeta, I_\theta\sin\zeta, r\sin\theta\big)\,. \tag{7.7}$$

The integrodifferential operator defined by formula (7.2) reads as

$$\widetilde{\mathcal{H}}(x,t)1 = -\frac{1}{2\pi^{3/2}} \int_0^{4\nu t} \int_{\partial\Omega} \frac{(x-\xi)\cdot n_x}{u^{5/2}} e^{-|x-\xi|^2/u} \mathrm{d}\sigma(\xi)\mathrm{d}u \tag{7.8}$$

for $u = 4\nu(t-\tau)$. In order to obtain a two-dimensional integral calculus, one can set

$$U_t(\theta,\zeta) = \frac{(x - \xi(\theta,\zeta))^2}{4\nu t} \tag{7.9}$$

so that

$$\int_0^{4\nu t} e^{-(x-\xi(\theta,\zeta))^2/u} u^{-5/2}\,\mathrm{d}u = \frac{\mathrm{E}\left(U_t(\theta,\zeta)^{1/2}\right) - U_t(\theta,\zeta)^{1/2} e^{-U_t(\theta,\zeta)}}{U_t(\theta,\zeta)^{3/2}}\,(4\nu t)^{3/2}, \tag{7.10}$$

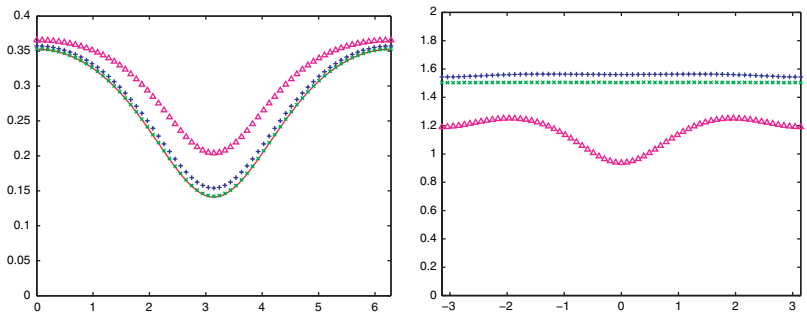

FIG. 8. *Convergence of estimates for the torsionless torus. Left: uniform convergence of* $(\nu\delta t)^{-1/2}\widetilde{\mathcal{H}}(x,\delta t)1$ *toward* $\bar\kappa(x)/\sqrt{\pi}$ *versus angle* θ_0. *Right: resulting numerical order* $N(\nu\delta t,\theta_0)$ *obtained by formula* (7.14) *versus angle* θ_0. *Legend:* $\triangle$ *is* $\nu\delta t = 1$, $+$ *is* $\nu\delta t = 0.1$, *and* $\times$ *is* $\nu\delta t = 0.01$.

where E is the scaled erf complementary function defined by

$$\mathrm{E}(x) = -\int_x^{+\infty} e^{-z^2}\mathrm{d}z = \frac{\sqrt{\pi}}{2}(\mathrm{erf}(x) - 1).$$

This leads to a new expression for $\widetilde{\mathcal{H}}(x,t)1$:

(7.11)
$$-\frac{r}{(4\pi\nu t)^{3/2}}\int_0^{\pi}\int_{\theta_0-\pi}^{\theta_0+\pi}\frac{\mathrm{E}\left(U_t(\theta,\zeta)^{1/2}\right) - U_t(\theta,\zeta)^{1/2}e^{-U_t(\theta,\zeta)}}{U_t(\theta,\zeta)^{3/2}}\,(x-\xi(\theta,\zeta))\cdot n_x\, I_\theta\,\mathrm{d}\theta\mathrm{d}\zeta.$$

This two-dimensional integral is then computed by a fifth order Gauss–Legendre quadrature formula with 2000^3 elements, once the singularity in $(\theta_0, 0)$ has been smoothed by setting $\theta = \theta_0 \pm \hat\theta^s$ and $\zeta = \hat\zeta^s$ with $s = 3$.

It can be shown (but is not developed herein) that the mean curvature in $x = f(\theta,\zeta)$ is given by

$$\bar\kappa(x) = \frac{1}{2}\left(\frac{1}{r} + \frac{\cos\theta}{R + r\cos\theta}\right). \tag{7.12}$$

Theorem 5.3 then predicts, since the torus is a $\mathcal{C}^\infty$ torsionless two-dimensional submanifold of $\mathbb{R}^3$, that

$$\widetilde{\mathcal{H}}(x,t)1 - \bar\kappa(x)\sqrt{\frac{\nu t}{\pi}} = \mathcal{O}(t^{3/2}). \tag{7.13}$$

One verifies that this 3/2 order is reached with the computation of the difference of the two expressions above for $x = \pi/2$. The left-hand picture in Figure 7 shows that indeed the difference scales as $t^{3/2}$. In order to measure the convergence more uniformly, one introduces the numerical order of convergence $N(t)$ defined by

$$N(\nu\delta t,\theta_0) = \log_{10}\left(\frac{\widetilde{\mathcal{H}}(x,\delta t)1 - \bar\kappa(x)\sqrt{\frac{\nu\delta t}{\pi}}}{\widetilde{\mathcal{H}}(x,\delta t/10)1 - \bar\kappa(x)\sqrt{\frac{\nu\delta t/10}{\pi}}}\right) \tag{7.14}$$

with $x = f(\theta_0, 0)$ chosen on the $\zeta = 0$ section (which is the generality since this torus is ζ-invariant). This function is plotted in the right-hand graph of Figure 8 and shows a convergence toward the 3/2 order everywhere. The convergence order suggested by Theorem 5.3 is consequently optimal.

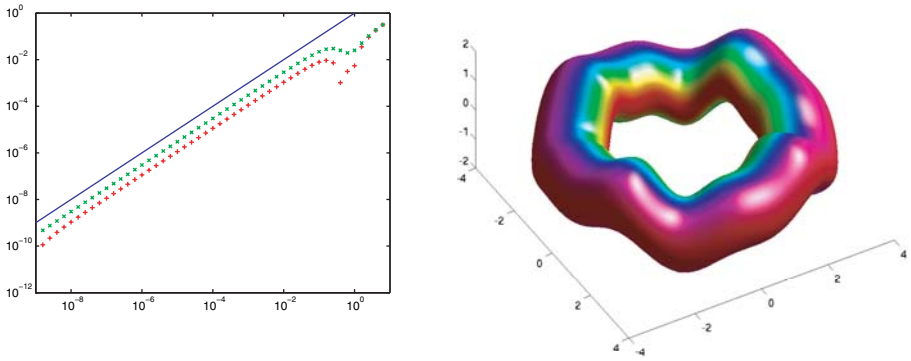

FIG. 9. *Right: plot of the twisted torus (color is the same as for Figure* 7*). Left: pointwise error of the estimate of* $\widetilde{\mathcal{H}}(x,t)1$ *versus* νt *(*$\times$ *is formula* (7.13) *for* $\theta_0 = \pi/4$, $+$ *is formula* (7.13) *for* $\theta_0 = \pi/2$, *and the solid line is* νt*).*

7.2. The "twisted" torus. In order to introduce torsion effects to the geometry, one considers two strictly positive numbers $\bar{A}$ and $\bar{m}$ and the function

$$g(\zeta) = \bar{A}\,(2\sin(\bar{m}\zeta) - \sin(2\bar{m}\zeta))\,, \tag{7.15}$$

which satisfies $g(0) = g'(0) = g''(0) = 0$ and $g'''(0) = 6\bar{A}\bar{m}^3 \neq 0$.

The surface defined by

$$f(\theta,\zeta) + g(\zeta)e_z \tag{7.16}$$

with $\bar{A} = 0.2$ and $\bar{m} = 4$ (where e_z denotes the third vector of the canonical basis of $\mathbb{R}^3$) is called herein the "twisted" torus and is plotted in Figures 9 and 10.

It presents nonzero torsion everywhere on the section $\zeta = 0$, except for $\theta_0 = 0$ and $\theta_0 = \pi$ for which the mapping is tangential (thus introduces no torsion), without changing curvature, slope, and location of this section when compared to the torsionless torus discussed in the last section (note that in this case the Jacobian is not as obvious as before and is thus not explicitly given herein).

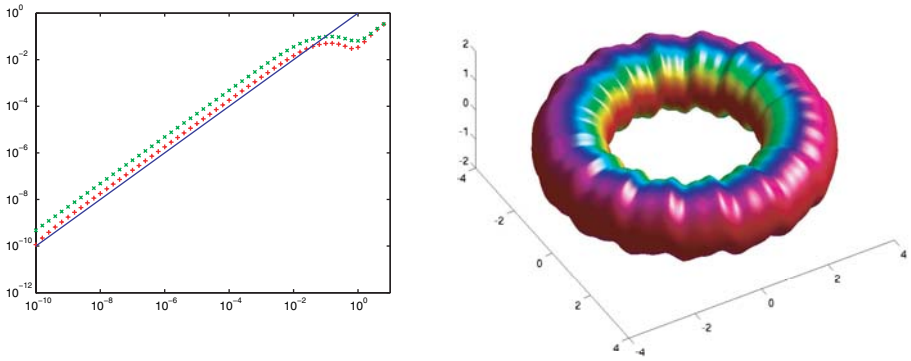

FIG. 11. *Right: plot of the rippled torus (color is the same as for Figure 7). Left: pointwise error of the estimate of* $\widetilde{\mathcal{H}}(x,t)1$ *versus* νt *(*$\times$ *is formula* (7.13) *for* $\theta_0 = \pi/4$, $+$ *is formula* (7.13) *for* $\theta_0 = \pi/2$, *and the solid line is* νt*).*

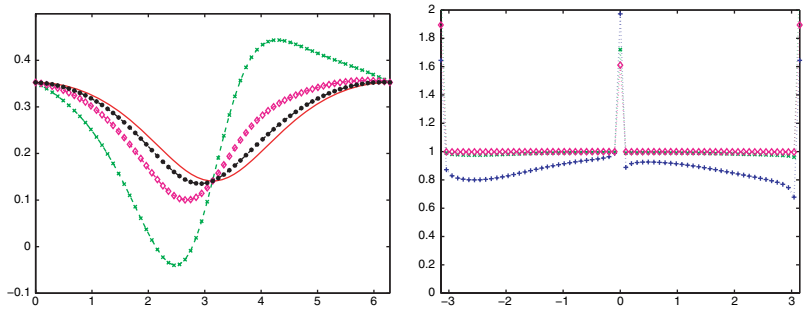

FIG. 12. *Convergence of estimate for the rippled torus. Left: uniform convergence of* $(\nu\delta t)^{-1/2}\widetilde{\mathcal{H}}(x,\delta t)1$ *toward* $\bar{\kappa}(x)/\sqrt{\pi}$ *versus angle* θ_0*. Right: resulting numerical order* $N(\nu\delta t, \theta_0)$ *obtained by formula* (7.14) *versus angle* θ_0*. Legend:* $+$ *is* $\nu\delta t = 10^{-2}$, $\times$ *is* $\nu\delta t = 10^{-3}$, $\triangle$ *is* $\nu\delta t = 10^{-4}$, *and* $*$ *is* $\nu\delta t = 10^{-5}$.

According to Theorem 5.1 and the strong need in Theorem 5.3 of the torsion-free surface to reach order 3/2, one expects in the present case to observe a first order convergence rate, except for the singular value of θ_0 mentioned above.

7.3. The "rippled" torus. In this section one considers the same kind of torus as in section 7.2, with perturbation parameters chosen as $\bar{A} = 0.05$ and $\bar{m} = 16$. This example provides a torsion 16 times stronger than the previous one, which makes torsion effects even clearer. Indeed, one can see in Figure 11 that convergence is globally first order, as observed for the twisted torus, but with a shift of accuracy due to stronger torsion effects.

Figure 12 shows that the first order is induced by a broken symmetry led by the torsion tensor, but also that the order is still constant over the section, except for $\theta_0 = 0$ for which the torsion effect is tangential; thus it does not act on body torsion and allows a 3/2 convergence order at this special point.

8. Conclusion. In this article, we have proved that the solution of the heat equation whose sources are provided only at boundaries can be explicited analytically up to order 3/2, exhibiting a square root in time depending on the boundary curvature

and the Dirichlet part of the Robin–Fourier coefficients of the boundary conditions. The solution is expressed in its integral formulation, involving a Gaussian kernel and a surface density. Most of the present study focuses on properties of this density.

The main result obtained herein is that since the density is analytically provided, one gets a very fast estimation of the solution of the heat equation for early times. This leads to a fast numerical scheme for kinematic boundary conditions or in addition to a scheme not satisfying algebraically the Robin–Fourier boundary condition.

The order depends on whether the manifold defining the domain boundary is torsionless or not, and on the manifold and the density regularities. Since small times are considered, the Gaussian kernel of the heat equation has small standard deviation, and thus its effect is localized (if not compactly supported). Therefore classical results have been extended to a class of noncompact manifolds, satisfying a few properties denoted (C1)–(C5).

We first discussed the error estimation due to restriction and then the error resulting from the substitution of the manifold by its best quadratic approximant. The error coming from the flattening process was also discussed, obtaining finally an integral expression which can be symbolically carried out.

Several applications illustrate that the limit convergence rates given by Theorems 5.1 and 5.3 are optimal. As examples, we investigate numerically the two- and three-dimensional cylinders, whose different eigenvectors of the curvature matrix induce density anisotropy. These cylindrical examples allow us to show the effect of density regularity on the double heat layer. The effect of manifold torsion is finally investigated for smoothly perturbated toroidal manifolds.

Acknowledgments. The author thanks Georges-Henri Cottet and Petros Koumoutsakos for their helpful contribution in the early work leading to the three-dimensional results.

THE FINITE ELEMENT APPROXIMATION OF THE NONLINEAR POISSON–BOLTZMANN EQUATION*

LONG CHEN†, MICHAEL J. HOLST‡, AND JINCHAO XU§

Abstract. A widely used electrostatics model in the biomolecular modeling community, the nonlinear Poisson–Boltzmann equation, along with its finite element approximation, are analyzed in this paper. A regularized Poisson–Boltzmann equation is introduced as an auxiliary problem, making it possible to study the original nonlinear equation with delta distribution sources. A priori error estimates for the finite element approximation are obtained for the regularized Poisson–Boltzmann equation based on certain quasi-uniform grids in two and three dimensions. Adaptive finite element approximation through local refinement driven by an a posteriori error estimate is shown to converge. The Poisson–Boltzmann equation does not appear to have been previously studied in detail theoretically, and it is hoped that this paper will help provide molecular modelers with a better foundation for their analytical and computational work with the Poisson–Boltzmann equation. Note that this article apparently gives the first rigorous convergence result for a numerical discretization technique for the nonlinear Poisson–Boltzmann equation with delta distribution sources, and it also introduces the first provably convergent adaptive method for the equation. This last result is currently one of only a handful of existing convergence results of this type for nonlinear problems.

Key words. nonlinear Poisson–Boltzmann equation, finite element methods, a priori and a posteriori error estimate, convergence of adaptive methods

1. Introduction.

In this paper, we shall design and analyze finite element approximations of a widely used electrostatics model in the biomolecular modeling community, the nonlinear Poisson–Boltzmann equation (PBE):

$$-\nabla \cdot (\varepsilon \nabla \tilde{u}) + \bar{\kappa}^2 \sinh(\tilde{u}) = \sum_{i=1}^{N_m} q_i \delta_i \quad \text{in } \mathbb{R}^d,\ d = 2, 3, \tag{1.1}$$

where the dielectric ε and the modified Debye–Hückel parameter $\bar{\kappa}$ are piecewise constants in domains Ω_m (the domain for the biomolecule of interest) and Ω_s (the domain for a solvent surrounding the biomolecule), and $\delta_i := \delta(x - x_i)$ is a Dirac distribution at point x_i. The importance of (1.1) in biomolecular modeling is well-established; cf. [14, 44] for thorough discussions. Some analytical solutions are known,

but only for unrealistic structure geometries, and usually only for linearizations of the equation; cf. [30] for a collection of these solutions and for references to the large amount of literature on analytical solutions to the PBE and similar equations. The current technological advances are more demanding and require the solution of highly nonlinear problems in complicated geometries. To this end, numerical methods, including the finite element method, are widely used to solve the nonlinear PBE [30, 31, 5, 6, 45, 19, 57].

The main difficulties for the rigorous analysis and provably good numerical approximation of solutions to the nonlinear Poisson–Boltzmann equation include: (1) Dirac distribution sources, (2) exponential rapid nonlinearities, and (3) discontinuous coefficients. We shall address these difficulties in this paper. To deal with the δ distribution sources, we decompose $\tilde{u}$ as an unknown function in H^1 and a known singular function, namely,

$$\tilde{u} = u + G, \qquad \text{with } G = \sum_{i=1}^{N_m} G_i,$$

where G_i is the fundamental solution of $-\varepsilon_m \Delta G_i = q_i \delta_i$ in $\mathbb{R}^d$. Substituting this decomposition into the PBE, we then obtain the so-called regularized Poisson–Boltzmann equation (RPBE):

$$-\nabla \cdot (\varepsilon \nabla u) + \bar{\kappa}^2 \sinh(u + G) = \nabla \cdot ((\varepsilon - \varepsilon_m)\nabla G) \quad \text{in } \mathbb{R}^d,\ d = 2, 3.$$

The singularities of the δ distributions are transferred to G, which then exhibits degenerate behavior at each $\{x_i\} \subset \Omega_m$. At those points, both $\sinh G(x_i)$ and $\nabla G(x_i)$ exhibit blowup. However, since G is known analytically, one avoids having to build numerical approximations to G. Moreover, both of the coefficients $\bar{\kappa}$ and $\varepsilon - \varepsilon_m$ are zero inside Ω_m where the blowup behavior arises. Due to this cutoff nature of coefficients, we obtain a well-defined nonlinear second-order elliptic equation for the regularized solution u with a source term in H^{-1}. We will show that it also admits a unique solution $u \in H^1$, even though the original solution $\tilde{u} \notin H^1$ due to the singularities present in G.

Singular function expansions are a common technique in applied and computational mathematics for this type of singularity; this type of expansion has been previously proposed for the Poisson–Boltzmann equation in [59] and was shown (empirically) to allow for more accurate finite difference approximations. In their work, the motivation for the technique was the poor discrete approximation of arbitrarily placed delta distributions using only the fixed corners of uniform finite difference meshes. In the present work, our interest is in developing finite element methods using completely unstructured meshes, so we are able to place the delta distributions precisely where they should be and do not have this problem with approximate delta function placement. Our motivation here for considering a singular function expansion is rather that the solution to the Poisson–Boltzmann equation is simply not smooth enough to either analyze or approximate using standard methods without using some sort of two-scale or multiscale expansion that represents the nonsmooth part of the solution analytically. In fact, it will turn out that expanding the solution into the sum of three functions, namely, a known singular function, an unknown solution to a linear auxiliary problem, and an unknown solution to a second nonlinear auxiliary problem, is the key to establishing some fundamental results and estimates for the continuous

problem and is also the key to developing a complete approximation theory for the discrete problem as well as provably convergent nonadaptive and adaptive numerical methods.

Starting with some basic results on existence, uniqueness, and a priori estimates for the continuous problem, we analyze the finite element discretization and derive discrete analogues of the continuous results to show that discretization leads to a well-posed discrete problem. Using maximum principles for the continuous and discrete problems, we derive a priori L^∞-estimates for the continuous and discrete solutions to control the nonlinearity, allowing us to obtain a priori error estimates for our finite element approximation of the form

$$\|u - u_h\|_1 \lesssim \inf_{v_h \in V_D^h} \|u - v_h\|_1,$$

where V_D^h is the linear finite element subspace defined over quasi-uniform triangulations with a certain boundary condition, and u_h is the finite element approximation of u in V_D^h. The result is *quasi-optimal* in the sense it implies that the finite element approximation to the RPBE is within a constant of being the best approximation from the subspace V_D^h. After establishing these results for finite element approximations, we describe an adaptive approximation algorithm that uses mesh adaptation through local refinement driven by a posteriori error estimates. The adaptive algorithm can be viewed as a mechanism for dealing with the primary remaining difficulty in the RPBE, namely, the discontinuities of the coefficients across the interface between the solvent and the molecular regions. Finally, we shall prove that our adaptive finite element method will produce a sequence of approximations that converges to the solution of the continuous nonlinear PBE. This last result is one of only a handful of existing results of this type for nonlinear elliptic equations (the others being [24, 49, 15]).

The outline of this paper is as follows. In section 2, we give a brief derivation and overview of the Poisson–Boltzmann equation. In section 3, we derive a regularized form of the Poisson–Boltzmann equation by using a singular function expansion. In section 4, we give some basic existence and uniqueness results for the RPBE. In section 5, we derive an a priori L^∞-estimate for the continuous problem. After introducing finite element methods for the RPBE, in section 6 we derive an analogous a priori L^∞-estimate for the discrete problem, and based on this we obtain a quasi-optimal a priori error estimate for the finite element approximation. In section 7, we describe the adaptive algorithm, present an a posteriori error estimate, and prove a general convergence result for the algorithm. In the last section, we summarize our work and give further remarks on the practical aspects using results in the present paper.

2. The Poisson–Boltzmann equation. In this section we shall give a brief introduction to the nonlinear Poisson–Boltzmann equation. A detailed derivation can be found in [48, 30].

The nonlinear PBE, a second-order nonlinear partial differential equation, is fundamental to Debye–Hückel continuum electrostatic theory [22]. It determines a dimensionless potential around a charged biological structure immersed in a salt solution. The PBE arises from the Gauss law, represented mathematically by the Poisson equation, which relates the electrostatic potential Φ in a dielectric to the charge density ρ:

$$-\nabla \cdot (\varepsilon \nabla \Phi) = \rho,$$

where ε is the dielectric constant of the medium and here is typically piecewise constant. Usually it jumps by one or two orders of magnitude at the interface between

the charged structure (a biological molecular or membrane) and the solvent (a salt solution). The charge density ρ consist of two components: $\rho = \rho_{\text{macro}} + \rho_{\text{ion}}$. For the macromolecule, the charge density is a summation of δ distributions at N_m point charges in the point charge behavior, i.e.,

$$\rho_{\text{macro}}(x) = \sum_{i=1}^{N_m} q_i \delta(x - x_i), \qquad q_i = \frac{4\pi e_c^2}{\kappa_B T} z_i,$$

where $\kappa_B > 0$ is the Boltzmann constant, T is the temperature, e_c is the unit of charge, and z_i is the amount of charge.

For the mobile ions in the solvent, the charge density ρ_{ion} cannot be given in a deterministic way. Instead it will be given by the Boltzmann distribution. If the solvent contains N types of ions, of valence Z_i and of bulk concentration c_i, then a Boltzmann assumption about the equilibrium distribution of the ions leads to

$$\rho_{\text{ion}} = \sum_{i=1}^{N} c_i Z_i e_c \exp\left(-Z_i \frac{e_c \Phi}{\kappa_B T}\right).$$

For a symmetric $1:1$ electrolyte, $N = 2$, $c_i = c_0$, and $Z_i = (-1)^i$, which yields

$$\rho_{\text{ion}} = -2c_0 e_c \sinh\left(\frac{e_c \Phi}{\kappa_B T}\right).$$

We can now write the PBE for modeling the electrostatic potential of a solvated biological structure. Let us denote the molecule region by $\Omega_m \subset \mathbb{R}^d$ and consider the solvent region $\Omega_s = \mathbb{R}^d \backslash \bar{\Omega}_m$. We use $\tilde{u}$ to denote the dimensionless potential and $\bar{\kappa}^2$ to denote the modified Debye–Hückel parameter (which is a function of the ionic strength of the solvent). The nonlinear Poisson–Boltzmann equation is then

$$-\nabla \cdot (\varepsilon \nabla \tilde{u}) + \bar{\kappa}^2 \sinh(\tilde{u}) = \sum_{i=1}^{N_m} q_i \delta_i \quad \text{in } \mathbb{R}^d, \tag{2.1}$$

$$\tilde{u}(\infty) = 0, \tag{2.2}$$

where

$$\varepsilon = \begin{cases} \varepsilon_m & \text{if} \quad x \in \Omega_m, \\ \varepsilon_s & \text{if} \quad x \in \Omega_s, \end{cases} \qquad \text{and} \qquad \bar{\kappa} = \begin{cases} 0 & \text{if} \quad x \in \Omega_m, \\ \sqrt{\varepsilon_s}\kappa > 0 & \text{if} \quad x \in \Omega_s. \end{cases}$$

It has been determined empirically that $\varepsilon_m \approx 2$ and $\varepsilon_s \approx 80$. The structure itself (e.g., a biological molecule or a membrane) is represented implicitly by ε and $\bar{\kappa}$, as well as explicitly by the N_m point charges $q_i = z_i e_c$ at the positions x_i. The charge positions are located in the strict interior of the molecular region Ω_m. A physically reasonable mathematical assumption is that all charge locations obey the following lower bound on their distance to the solvent region Ω_s for some $\sigma > 0$:

$$|x - x_i| \geq \sigma \quad \forall x \in \Omega_s, \quad i = 1, \ldots, N_m. \tag{2.3}$$

In some models employing the PBE, there is a third region Ω_l (the Stern layer [11]), a layer between Ω_m and Ω_s. In the presence of a Stern layer, the parameter σ in (2.3)

increases in value. Our analysis and results can be easily generalized to this case as well.

Some analytical solutions of the nonlinear PBE are known, but only for unrealistic structure geometries and usually only for linearizations of the equation; cf. [30] for a collection of these solutions and for references to the large amount of literature on analytical solutions to the PBE and similar equations. However, the problem is highly nonlinear. Surface potentials of the linear and the nonlinear PBE differ by over an order of magnitude [45]. Hence, using the nonlinear version of the PBE model is fundamentally important to accurately describe physical effects, and access to reliable and accurate numerical approximation techniques for the nonlinear PBE is critically important in this research area.

We finish this section by making some remarks about an alternative equivalent formulation of the PBE. It is well known (cf. [48, 30]) that the PBE is formally equivalent to a coupling of two equations for the electrostatic potential in different regions Ω_m and Ω_s through the boundary interface. In fact, this equivalence can be rigorously justified; some results of this type will appear in [29]. Inside Ω_m, there are no ions. Thus the equation is simply the Poisson equation

$$-\nabla \cdot (\varepsilon_m \nabla \tilde{u}) = \sum_{i=1}^{N_m} q_i \delta_i \quad \text{in } \Omega_m.$$

In the solvent region Ω_s, there are no atoms. Thus the density is given purely by the Boltzmann distribution

$$-\nabla \cdot (\varepsilon_s \nabla \tilde{u}) + \bar{\kappa}^2 \sinh(\tilde{u}) = 0 \quad \text{in } \Omega_s.$$

These two equations are coupled together through the boundary conditions on the interface $\Gamma := \partial\Omega_m = \partial\Omega_s \cap \Omega_m$:

$$[\tilde{u}]_\Gamma = 0, \quad \text{and} \quad \left[\varepsilon \frac{\partial \tilde{u}}{\partial n_\Gamma}\right]_\Gamma = 0,$$

where $[f]|_\Gamma = \lim_{t\to 0} f(x + t n_\Gamma) - f(x - t n_\Gamma)$, with n_Γ being the unit outward normal direction of interface Γ. We will assume Γ to be sufficiently smooth, say, of class C^2.

Solving the individual subdomain systems and coupling them through the boundary, in the spirit of a nonoverlapping domain decomposition method, is nontrivial due to the complicated boundary conditions and subdomain shapes. Approaches such as mortar-based finite element methods to solve the coupled equations for linear or nonlinear PBE can be found in [19, 52].

3. Regularization of the continuous problem. In this section, we shall introduce a regularized version of the nonlinear PBE for both analysis and discretization purposes. We first transfer the original equation posed on the whole space to a truncated domain using an artificial boundary condition taken from an approximate analytical solution. Then we use the fundamental solution in the whole space to get rid of the singularities caused by δ distributions. We shall mainly focus on more difficult problems in three dimensions. Formulation and results in two dimensions are similar and relatively easy.

Let $\Omega \subset \mathbb{R}^3$ with a convex and Lipschitz-continuous boundary $\partial\Omega$, and $\Omega_m \subset \Omega$. In the numerical simulation, for simplicity, we usually choose Ω to be a ball or cube

containing a molecule region. The solvent region is chosen as $\Omega_s \cap \Omega$ and will be still denoted by Ω_s. On $\partial\Omega$ we choose the boundary condition $\tilde{u} = g$, with

$$g = \left(\frac{e_c^2}{k_B T}\right) \sum_{i=1}^{N_i} \frac{e^{-\kappa|x-x_i|}}{\varepsilon_s |x - x_i|}. \tag{3.1}$$

The boundary condition is usually taken to be induced by a known analytical solution to one of several possible simplifications of the linearized PBE. Far from the molecule, such analytical solutions provide a highly accurate boundary condition approximation for the general nonlinear PBE on a truncation of $\mathbb{R}^3$. For example, (3.1) arises from the use of the Green's function for the Helmholtz operator arising from linearizations of the Poisson–Boltzmann operator, where a single constant global dielectric value of ε_s is used to generate the approximate boundary condition. (This is the case of a rod-like molecule approximation; cf. [30].) Another approach to handling the boundary condition more accurately is to solve the PBE with boundary conditions such as (3.1) on a large Ω (with a coarse mesh) and then solve it in a smaller Ω (with a fine mesh) with the boundary condition provided by the earlier coarse mesh solution. The theoretical justification of this approach can be found at [28] using the two-grid theory [54]. We are not going to discuss more on the choice of the boundary condition in this paper.

Employing (3.1) we obtain the nonlinear PBE on a truncated domain:

$$-\nabla \cdot (\varepsilon \nabla \tilde{u}) + \bar{\kappa}^2 \sinh(\tilde{u}) = \sum_{i=1}^{N_m} q_i \delta_i \qquad \text{in } \Omega, \tag{3.2}$$

$$\tilde{u} = g \qquad \text{on } \partial\Omega. \tag{3.3}$$

This is, in most respects, a standard boundary-value problem for a nonlinear second-order elliptic partial differential equation. However, the right side contains a linear combination of δ distributions, which individually and together are not in $H^{-1}(\Omega)$; thus we cannot apply standard techniques such as classical potential theory. This has at times been the source of some confusion in the molecular modeling community, especially with respect to the design of convergent numerical methods. More precisely, we will see shortly that the solution to the nonlinear Poisson–Boltzmann equation is simply not globally smooth enough to expect standard numerical methods (currently used by most PBE simulators) to produce approximations that converge to the solution to the PBE in the limit of mesh refinement.

In order to gain a better understanding of the properties of solutions to the nonlinear PBE, primarily so that we can design new provably convergent numerical methods, we shall propose a decomposition of the solution to separate out the singularity caused by the δ distributions. This decomposition will turn out to be the key idea that will allow us to design discretization techniques for the nonlinear PBE which have provably good approximation properties and, based on this, also design a new type of adaptive algorithm which is provably convergent for the nonlinear PBE.

We now give this decomposition. It is well known that the function

$$G_i = \frac{q_i}{\varepsilon_m} \frac{1}{|x - x_i|}$$

solves the equation

$$-\nabla \cdot (\varepsilon_m \nabla G_i) = q_i \delta_i \quad \text{in } \mathbb{R}^3.$$

We thus decompose the unknown $\tilde{u}$ as an unknown smooth function u and a known singular function G:

$$\tilde{u} = u + G,$$

with

$$G = \sum_{i=1}^{N_m} G_i. \tag{3.4}$$

Substituting the decomposition into (3.2), we then obtain

$$-\nabla \cdot (\varepsilon \nabla u) + \bar{\kappa}^2 \sinh(u+G) = \nabla \cdot ((\varepsilon - \varepsilon_m)\nabla G) \qquad \text{in } \Omega, \tag{3.5}$$

$$u = g - G \qquad \text{on } \partial\Omega, \tag{3.6}$$

and call it the RPBE. The singularities of the δ distribtuions are transferred to G, which then exhibits degenerate behavior at each $\{x_i\} \subset \Omega_m$. At those points, both $\sinh G(x_i)$ and $\nabla G(x_i)$ exhibit blowup. However, since G is known analytically, one avoids having to build numerical approximations to G. Moreover, both of the coefficients $\bar{\kappa}$ and $\varepsilon - \varepsilon_m$ are zero inside Ω_m, where the blowup behavior arises. Due to this cutoff nature of coefficients, the RPBE is a mathematically well defined nonlinear second-order elliptic equation for the regularized solution u with the source term in H^{-1}. We give a fairly standard argument in the next section to show that it also admits a unique solution $u \in H^1$, even though the original solution $\tilde{u} \notin H^1$ due to the singularities present in G. In the remainder of the paper we shift our focus to establishing additional estimates and developing an approximation theory to guide the design of convergent methods, both nonadaptive and adaptive.

Before moving on, it is useful to note that, away from $\{x_i\}$, the function G is smooth. In particular, we shall make use of the fact that $G \in C^\infty(\Omega_s) \cap C^\infty(\Gamma) \cap C^\infty(\partial\Omega)$ in the later analysis. Also, a key technical tool will be a further decomposition of the regularized solution u into linear and nonlinear parts, $u = u^l + u^n$, where u^l satisfies

$$-\nabla \cdot (\varepsilon \nabla u^l) = \nabla \cdot ((\varepsilon - \varepsilon_m)\nabla G) \qquad \text{in } \Omega, \tag{3.7}$$

$$u^l = 0 \qquad \text{on } \partial\Omega, \tag{3.8}$$

and where u^n satisfies

$$-\nabla \cdot (\varepsilon \nabla u^n) + \bar{\kappa}^2 \sinh(u^n + u^l + G) = 0 \qquad \text{in } \Omega, \tag{3.9}$$

$$u^n = g - G \qquad \text{on } \partial\Omega. \tag{3.10}$$

4. Existence and uniqueness. In this section we shall discuss the existence and uniqueness of the solution of the continuous RPBE. The arguments we use in this section appear essentially in [30], except there the PBE was artificially regularized by replacing the delta distributions with H^{-1}-approximations directly rather than being regularized through a singular function expansion. A different analysis from that appearing below, giving a more precise characterization of the particular function spaces involved and containing various auxiliary results such as the rigorous equivalence of different PBE formulations, will appear in [29].

We first write out the weak formulation. Since $\Delta G = 0$ away from $\{x_i\}$, through integration by parts we get the weak formulation of RPBE: Find

$$u \in M := \{v \in H^1(\Omega) \,|\, e^v, e^{-v} \in L^2(\Omega_s), \text{ and } v = g - G \text{ on } \partial\Omega\}$$

such that

$$A(u,v) + (B(u),v) + \langle f_G, v\rangle = 0 \quad \forall v \in H_0^1(\Omega), \tag{4.1}$$

where

- $A(u,v) = (\varepsilon\nabla u, \nabla u)$,
- $(B(u),v) = (\bar{\kappa}^2 \sinh(u+G), v)$, and
- $\langle f_G, v\rangle = \int_\Omega (\varepsilon - \varepsilon_m)\nabla G \cdot \nabla v$.

Let us define the energy on M:

$$E(w) = \int_\Omega \frac{\varepsilon}{2}|\nabla w|^2 + \bar{\kappa}^2 \cosh(w+G) + \langle f_G, w\rangle.$$

It is easy to characterize the solution of (4.1) as the minimizer of the energy.

LEMMA 4.1. *If u is the solution of the optimization problem, i.e.,*

$$E(u) = \inf_{w\in M} E(w),$$

then u is the solution of (4.1).

Proof. For any $v \in H_0^1(\Omega)$ and any $t \in \mathbb{R}$, the function $F(t) = E(u+tv)$ attains the minimal point at $t = 0$, and thus $F'(0) = 0$, which gives the desired result. ∎

We now recall some standard variational analysis on the existences of the minimizer. In what follows we suppose S is a set in some Banach space V with norm $\|\cdot\|$, and $J(u)$ is a functional defined on S. S is called *weakly sequential compact* if, for any sequence $\{u_k\} \subset S$, there exists a subsequence $\{u_{k_i}\}$ such that $u_{k_i} \rightharpoonup u \in S$, where $\rightharpoonup$ stands for the convergence in the weak topology. For any $u_k \rightharpoonup u$, if $J(u_k) \to J(u)$, we say J is *weakly continuous* at u; if

$$J(u) \le \liminf_{k\to\infty} J(u_k),$$

we say J is *weakly lower semicontinuous* (w.l.s.c.) at u. The following theorem can be proved by the definition easily.

THEOREM 4.2. *If*

1. *S is weakly sequential compact, and*
2. *J is weakly lower semicontinuous on S,*

then there exists $u \in S$ such that

$$J(u) = \inf_{w\in S} J(w).$$

We shall give conditions for the weakly sequential compactness and weakly lower semicontinuity. First we use the fact that a bounded set in a reflexive Banach space is weakly sequential compact.

LEMMA 4.3. *One has the following results:*

1. *The closed unit ball in a reflexive Banach space V is weakly sequential compact.*
2. *If $\lim_{\|v\|\to\infty} J(v) = \infty$, then*

$$\inf_{w\in V} J(w) = \inf_{w\in S} J(w).$$

The next lemma concerns when the functional is w.l.s.c. The proof can be found at [58].

LEMMA 4.4. *If J is a convex functional on a convex set S and J is Gâteaux differentiable, then J is w.l.s.c. on S.*

Now we are in the position to establish the existence and uniqueness of solutions to the RPBE.

THEOREM 4.5. *There exists a unique $u \in M \subset H^1(\Omega)$ such that*

$$E(u) = \inf_{w \in M} E(w).$$

Proof. It is easy to see $E(w)$ is differentiable in M with

$$\langle DE(u), v\rangle = A(u,v) + (B(u), v) + \langle f_G, v\rangle.$$

To prove the existence of the minimizer, we need only to verify that

1. M is a convex set,
2. E is convex on M, and
3. $\lim_{\|v\|_1 \to \infty} E(v) = \infty$.

The verification of (1) is easy and thus skipped here. (2) comes from the convexity of functions x^2 and $\cosh(x)$. Indeed E is *strictly* convex. (3) is a consequence of the inequality

$$E(v) \geq C(\varepsilon, \bar{\kappa})\|v\|_1^2 + C(G, g), \tag{4.2}$$

which can be proved as following. First, by Young's inequality we have for any $\delta > 0$

$$\langle f_G, v\rangle \leq \varepsilon_s \|\nabla G\|_{\Omega_s} \|\nabla v\|_{\Omega_s} \leq \frac{1}{\delta}\|\nabla G\|_{\Omega_s}^2 + \delta \varepsilon_s^2 \|\nabla_v\|_{\Omega_s}^2.$$

Since $\cosh(x) \geq 0$, we have then $E(v) \geq C(\varepsilon, \bar{\kappa})\|\nabla v\|^2 - (1/\delta)\|\nabla G\|_{\Omega_s}^2$, where we can ensure $C(\varepsilon, \bar{\kappa}) > 0$ if δ is chosen to be sufficiently small. Then using norm equivalence on M, we get (4.2). The uniqueness of the minimizer comes from the strict convexity of E. ∎

5. Continuous a priori L^∞-estimates. In this section, we shall derive a priori L^∞-estimates of the solution of the RPBE. The main result of this section is the following theorem.

THEOREM 5.1. *Let u be the weak solution of RPBE in $H^1(\Omega)$. Then u is also in $L^\infty(\Omega)$.*

Note that we cannot apply the analysis of [32, 33] directly to the RPBE, since the right side $f_G \in H^{-1}(\Omega)$ and does not lie in $L^\infty(\Omega)$ as required for use of these results. We shall overcome this difficulty through further decomposition of u into linear and nonlinear parts.

Let $u = u^l + u^n$, where $u^l \in H_0^1(\Omega)$ satisfies the linear elliptic equation (the weak form of (3.7)–(3.8))

$$A(u^l, v) + \langle f_G, v\rangle = 0 \quad \forall v \in H_0^1(\Omega) \tag{5.1}$$

and where $u^n \in M$ satisfies the nonlinear elliptic equation (the weak form of (3.9)–(3.10))

$$A(u^n, v) + (B(u^n + u^l), v) = 0 \quad \forall v \in H_0^1(\Omega). \tag{5.2}$$

Theorem 5.1 then follows from the estimates of u^l and u^n in Lemmas 5.2 and 5.3; cf. (5.3) and (5.4).

LEMMA 5.2. *Let u^l be the weak solution of* (5.1). *Then*

$$u^l \in L^\infty(\Omega). \tag{5.3}$$

Proof. Since $\Delta G = 0$ in Ω_s, using integral by parts we can rewrite the functional f_G as

$$\langle f_G, v\rangle = ((\varepsilon - \varepsilon_m)\nabla G, \nabla v) = \left([\varepsilon]\frac{\partial G}{\partial n_\Gamma}, v\right)_\Gamma,$$

where $[\varepsilon] = \varepsilon_s - \varepsilon_m$ is the jump of ε at the interface. We shall still use f_G to denote the smooth function $[\varepsilon]\frac{\partial G}{\partial n_\Gamma}$ on Γ.

It is easy to see that the linear equation (5.1) is the weak formulation of the elliptic interface problem

$$-\nabla\cdot(\varepsilon\nabla u^l) = 0 \text{ in } \Omega \quad [u^l] = 0,\ \left[\varepsilon\frac{\partial u^l}{\partial n}\right] = f_G \text{ on } \Gamma, \quad \text{and } u = 0 \text{ on } \partial\Omega.$$

Since $f_G \in C^\infty(\Gamma)$ and $\Gamma \in C^2$, by the regularity result of the elliptic interface problem [4, 12, 20, 42], we have $u^l \in H^2(\Omega_m)\cap H^2(\Omega_s)\cap H_0^1(\Omega)$. In particular by the embedding theorem we conclude that $u^l \in L^\infty(\Omega)$. ∎

To derive a similar estimate for the nonlinear part u^n, we define

$$\alpha' = \arg\max_c \left(\bar\kappa^2\sinh(c + \sup_{x\in\Omega_s}(u^l + G)) \le 0\right), \qquad \alpha = \min\left(\alpha', \inf_{\partial\Omega}(g - G)\right),$$
$$\beta' = \arg\min_c \left(\bar\kappa^2\sinh(c + \inf_{x\in\Omega_s}(u^l + G)) \ge 0\right), \qquad \beta = \max\left(\beta', \sup_{\partial\Omega}(g - G)\right).$$

The next lemma gives the a priori L^∞-estimate of u^n.

LEMMA 5.3. *Let u^n be the weak solution of* (5.2). *Then $\alpha \le u^n \le \beta$, and thus*

$$u^n \in L^\infty(\Omega). \tag{5.4}$$

Proof. We use a cutoff-function argument similar to that used in [32]. Since the boundary condition $g - G \in C^\infty(\partial\Omega)$, we can find a $u_D \in H^1(\Omega)$ such that $u_D = g - G$ on $\partial\Omega$ in the trace sense, or more precisely

$$Tu_D = g - G,$$

where $T : \Omega \mapsto \partial\Omega$ is the trace operator. Then the solution can be written $u^n = u_D + u_0$, with $u_0 \in H_0^1(\Omega)$. Let $\overline{\phi} = (u^n - \beta)^+ = \max(u^n - \beta, 0)$ and $\underline{\phi} = (u^n - \alpha)^- = \min(u^n - \alpha, 0)$. Then from

$$0 \le \overline{\phi} = (u^n - \beta)^+ = (u_D + u_0 - \beta)^+ \le (u_D - \beta)^+ + u_0^+,$$
$$0 \ge \underline{\phi} = (u^n - \alpha)^- = (u_D + u_0 - \alpha)^- \ge (u_D - \alpha)^- + u_0^-,$$

and

$$0 \le T\overline{\phi} \le T(u_D - \beta)^+ + Tu_0^+ = 0,$$
$$0 \ge T\underline{\phi} \ge T(u_D - \alpha)^- + Tu_0^- = 0,$$

we conclude that both $\overline{\phi}, \underline{\phi} \in H_0^1(\Omega)$. Thus for either $\phi = \overline{\phi}$ or $\phi = \underline{\phi}$, we have

$$(\varepsilon\nabla u^n, \nabla\phi) + (\bar\kappa^2\sinh(u^n + u^l + G), \phi) = 0.$$

Note that $\overline{\phi} \geq 0$ in Ω and its support is the set $\overline{\mathcal{Y}} = \{x \in \bar{\Omega} \,|\, u^n(x) \geq \beta\}$. On $\overline{\mathcal{Y}}$, we have

$$\bar{\kappa}^2 \sinh(u^n + u^l + G) \geq \bar{\kappa}^2 \sinh\left(\beta' + \inf_{x \in \Omega_s} (u^l + G)\right) \geq 0.$$

Similarly, $\underline{\phi} \leq 0$ in Ω with support set $\underline{\mathcal{Y}} = \{x \in \bar{\Omega} \,|\, u^n(x) \leq \alpha\}$. On $\underline{\mathcal{Y}}$, we now have

$$\bar{\kappa}^2 \sinh(u^n + u^l + G) \leq \bar{\kappa}^2 \sinh\left(\alpha' + \inf_{x \in \Omega_s} (u^l + G)\right) \leq 0.$$

Together this implies

$$0 \geq (\varepsilon \nabla u^n, \nabla \phi) = (\varepsilon \nabla (u^n - \beta), \nabla \phi) = \varepsilon \|\nabla \phi\|^2 \geq 0$$

for either $\phi = \overline{\phi}$ or $\phi = \underline{\phi}$. Using the Poincare inequality we have finally

$$0 \leq \|\phi\| \lesssim \|\nabla \phi\| \leq 0,$$

giving $\phi = 0$, again for either $\phi = \overline{\phi}$ or $\phi = \underline{\phi}$. Thus $\alpha \leq u^n \leq \beta$ in Ω. ∎

6. Finite element methods for the regularized Poisson–Boltzmann equation. In this section we shall discuss the finite element discretization of RPBE using linear finite element spaces V_D^h and prove the existence and uniqueness of the finite element approximation u_h. Furthermore, under some assumptions on the grids we shall derive a priori L^∞-estimates for u_h and use these to prove that u_h is a quasi-optimal approximation of u in the H^1 norm in the sense that

$$\|u - u_h\|_1 \lesssim \inf_{v_h \in V_D^h} \|u - v_h\|_1. \tag{6.1}$$

While the term on the left in (6.1) is in general difficult to analyze, the term on the right represents the fundamental question addressed by classical approximation theory in normed spaces, of which much is known. To bound the term on the right from above, one picks a function in V_D^h which is particularly easy to work with, namely, a nodal or generalized interpolant of u, and then one employs standard techniques in interpolation theory. Therefore, it is clear that the importance of approximation results such as (6.1) are that they completely separate the details of the Poisson–Boltzmann equation from the approximation theory, making available all known results on finite element interpolation of functions in Sobolev spaces (cf. [21]).

Now we assume Ω can be triangulated exactly (e.g., Ω is a cube) with a shape regular and conforming (in the sense of [21]) triangulation $\mathcal{T}_h$. Here $h = h_{\max}$ represents the mesh size which is the maximum diameter of elements in the triangulation. We further assume in the triangulation that the discrete interface Γ_h approximates the known interface Γ to the second order, i.e., $d(\Gamma, \Gamma_h) \leq Ch^2$.

Given such a triangulation $\mathcal{T}_h$ of Ω, we construct the linear finite element space $V^h := \{v \in H^1(\Omega), v|_\tau \in \mathcal{P}_1(\tau)\ \forall \tau \in \mathcal{T}_h\}$. Since the boundary condition $g - G \in C^\infty(\partial\Omega)$, we can find a $u_D \in H^1(\Omega)$ such that $u_D = g - G$ on $\partial\Omega$ in the trace sense. Then the solution can be uniquely written as $u = u_D + u_0$, with $u_0 \in H_0^1$. Thus we will use $H_D^1(\Omega) := H_0^1(\Omega) + u_D$ to denote the affine space with a specified boundary condition and $V_D^h = V^h \cap H_D^1(\Omega)$ to denote the finite element affine space of $H_D^1(\Omega)$. Similarly $V_0^h = V^h \cap H_0^1(\Omega)$. Here to simplify the analysis the boundary condition is assumed to be represented exactly.

Recall that the weak form of RPBE is

$$\text{Find } u \in H_D^1(\Omega) \text{ such that (s.t.) } A(u,v)+(B(u),v)+\langle f_G, v\rangle = 0 \ \ \forall v \in H_0^1(\Omega). \tag{6.2}$$

We are interested in the quality of the finite element approximation:

$$\text{Find } u_h \in V_D^h \quad \text{s.t. } A(u_h, v_h) + (B(u_h), v_h) + \langle f_G, v\rangle = 0 \ \ \forall v_h \in V_0^h. \tag{6.3}$$

It is easy to show that the finite element approximation u_h is the minimizer of E in V_D^h, i.e., $E(u_h) = \inf_{v_h \in V_D^h} E(v_h)$. Then the existence and uniqueness follows from section 3 since V_D^h is convex. As in the continuous setting, it will be convenient to split the discrete solution to the RPBE into linear and nonlinear parts $u_h = u_h^l + u_h^n$, where u_h^l and u_h^n satisfy, respectively,

$$\text{Find } u_h^l \in V_0^h \text{ s.t. } A(u_h^l, v_h) + \langle f_G, v\rangle = 0 \ \ \forall v_h \in V_0^h, \tag{6.4}$$

$$\text{Find } u_h^n \in V_D^h \text{ s.t. } A(u_h^n, v_h) + \langle B(u_h^n + u_h^l), v_h\rangle = 0 \ \ \forall v_h \in V_0^h. \tag{6.5}$$

6.1. Quasi-optimal a priori error estimate. We begin with the following properties of the bilinear form A and and operator B.

LEMMA 6.1. 1. *The bilinear form $A(u,v)$ satisfies the coercivity and continuity conditions. That is, for $u, v \in H^1(\Omega)$*

$$\|u\|_1^2 \lesssim A(u,u), \quad \textit{and} \quad A(u,v) \lesssim \|u\|_1 \|v\|_1.$$

2. *The operator B is monotone in the sense that*

$$(B(u) - B(v), u - v) \geq \bar{\kappa}^2 \|u - v\|^2 \geq 0.$$

3. *The operator B is bounded in the sense that for $u, v \in L^\infty(\Omega), w \in L^2(\Omega)$,*

$$(B(u) - B(v), w) \leq C\|u - v\|\|w\|.$$

Proof. The proof of (1) and (2) is straightforward. We now prove (3). By the mean value theorem, there exists $\theta \in (0,1)$ such that

$$B(u) - B(v) = \bar{\kappa}^2 \cosh(\theta u + (1-\theta)v + G)(u - v).$$

Then by the convexity of cosh and the fact that $u, v \in L^\infty(\Omega), G \in C^\infty(\Omega_s)$, we get

$$\|\cosh(\theta u + (1-\theta)v + G)\|_{\infty,\Omega_s} \leq \|\cosh(u + G)\|_{\infty,\Omega_s} + \|\cosh(v + G)\|_{\infty,\Omega_s} \leq C.$$

The desired result then follows since $B(\cdot)$ is nonzero only in Ω_s. ∎

THEOREM 6.2. *Let u and u_h be the solution of RPBE and its finite element approximation, respectively. When u_h is uniformly bounded, we have*

$$\|u - u_h\|_1 \lesssim \inf_{v_h \in V^h} \|u - v_h\|_1.$$

Proof. By the definition, the error $u - u_h$ satisfies

$$A(u - u_h, w_h) + (B(u) - B(u_h), w_h) = 0 \quad \forall w_h \in V_0^h.$$

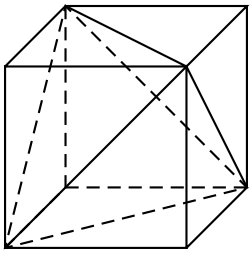

FIG. 6.1. *Divide a cube into* 5 *tetrahedra.*

We then have, for any $v_h \in V_D^h$,

$$\begin{aligned}\|u-u_h\|_1^2 &\lesssim A(u-u_h,u-u_h) = A(u-u_h,u-v_h)+A(u-u_h,v_h-u_h)\\ &\lesssim \|u-u_h\|_1\|u-v_h\|_1 - (B(u)-B(u_h),v_h-u_h).\end{aligned}$$

The second term on the right side is estimated by

$$\begin{aligned}-(B(u)-B(u_h),v_h-u_h) &= -(B(u)-B(u_h),u-u_h)+(B(u)-B(u_h),u-v_h)\\ &\le (B(u)-B(u_h),u-v_h)\\ &\lesssim \|u-u_h\|_1\|u-v_h\|_1.\end{aligned}$$

Here we make use of the monotonicity of B in the second step and the boundness of B in the third step. In summary we obtain for any $v_h \in V_D^h$

$$\|u-u_h\|_1 \lesssim \|u-v_h\|_1,$$

which leads to the desired result by taking the infimum. ∎

6.2. Discrete a priori L^∞-estimates. We now derive L^∞-estimates of the finite element approximation u_h. To this end, we have to put assumptions on the grid. Let (a_{ij}) denote the matrix of the elliptic operator $(\varepsilon\nabla u,\nabla v)$, i.e., $a_{i,j} = A(\varphi_i,\varphi_j)$. Two nodes i and j are adjacent if there is an edge connecting them.

(A1) The off-diagonal term $a_{i,j}$, i,j are adjacent, satisfies

$$a_{i,j} \le -\frac{\rho}{h^2}\sum_{e_{i,j}\subset T}|T|, \quad \text{with } \rho > 0.$$

We now give example grids satisfying (A1). In three dimensions, to simplify the generation of the grid, we choose Ω as a cube and divide into small cubes with length h. For each small cube, we divide it into 5 tetrahedra; see Figure 6.1 for a prototype of the triangulation of one cube. Neighbor cubes are triangulated in the same fashion (with different reflection to make the triangulation conforming). By the formula of the local stiffness matrix in [33, 55], it is easy to verify that the grids will satisfy assumption (A1). We comment that the uniform grid obtained by dividing each cube into 6 tetrahedra will not satisfy the assumption (A1), since in this case if i,j are vertices of diagonal of some cube, then $a_{ij} = 0$.

THEOREM 6.3. *In general dimension $\mathbb{R}^d, d \ge 2$, with assumption* (A1) *and h sufficiently small, the finite element approximation u_h of RPBE satisfies*

$$\|u_h\|_\infty \le C,$$

where C is independent of h.

Proof. We shall use the decomposition $u_h = u_h^n + u_h^l$. By the regularity result [42], we know $u^l \in B^{3/2}_{2,\infty}(\Omega)$ and thus obtain a priori estimate on quasi-uniform grids

$$\|u^l - u_h^l\|_\infty \le C h_{\max}^s \le C \mathrm{diam}(\Omega)^s \quad \text{for some } s \in (0, 3/2).$$

This implies that $\|u_h^l\|_\infty \le \|u^l\|_\infty + \|u^l - u_h^l\|_\infty \le C$ is uniformly bounded with respect to $h_{\max}$. The estimate of u_h^n follows from Theorem 3.3 in [33], where the grid assumption (A1) is used. ∎

In two dimensions, we can relax the assumption on the grid and obtain a similar result. Later we will see that, due to this relaxation, the local refinement in two dimensions is pretty simple.

(A1′) The off-diagonal terms $a_{i,j} \le 0, j \ne i$; i.e., the stiffness matrix corresponding to $A(\cdot,\cdot)$ is an M-matrix.

THEOREM 6.4. *For a two-dimensional triangulation satisfying* (A1′)*, the finite element approximation u_h of RPBE is bounded, i.e.,*

$$\|u_h\|_\infty \le C.$$

Proof. Similarly $\|u_h^l\|_\infty \le C$ is uniformly bounded. In two dimensions the estimate of u_h^n follows from Theorem 3.1 in [33], where the grid assumption (A1) is used. ∎

7. Convergence of adaptive finite element approximation. In this section, we shall follow the framework presented in [50, 51] to derive an a posteriori error estimate. Furthermore we shall present an adaptive method through local refinement based on this error estimator and prove that it will converge. The a priori L^∞-estimates of the continuous and discrete problems derived in the previous sections play an important role here.

7.1. A posteriori error estimate. There are several approaches to adaptive error control, among which the one based on a posteriori error estimation is usually the most effective and most general. Although most existing work on a posteriori estimates has been for linear problems, extensions to the nonlinear case can be made through linearization. For example, consider the nonlinear problem

$$F(u) = 0, \quad F \in C^1(\mathcal{B}_1, B_2^*), \tag{7.1}$$

where the Banach spaces $\mathcal{B}_1$ and $\mathcal{B}_2$ are, e.g., Sobolev spaces and where $\mathcal{B}^*$ denotes the dual space of $\mathcal{B}$. Consider now also a discretization of (7.1)

$$F_h(u_h) = 0, \quad F_h \in C^0(U_h, V_h^*), \tag{7.2}$$

where $U_h \subset \mathcal{B}_1$ and $V_h \subset \mathcal{B}_2$. For the RPBE and a finite element discretization, the function spaces would be taken to be $\mathcal{B}_1 = \mathcal{B}_2 = H_0^1(\Omega)$. The nonlinear residual $F(u_h)$ can be used to estimate the error through the use of a linearization inequality

$$C_1 \|F(u_h)\|_{\mathcal{B}_2^*} \le \|u - u_h\|_{\mathcal{B}_1} \le C_2 \|F(u_h)\|_{\mathcal{B}_2^*}. \tag{7.3}$$

See, for example, [50] for a proof of this linearization result under weak assumptions on F. The estimator is then based on an upper bound on the dual norm of the nonlinear residual on the right in (7.3).

In this section, to show the main idea, we will assume $F_h(u_h) = F(u_h)$ by making the following assumption on the grid.

(A2) The smooth interface Γ is replaced by its discrete approximation Γ_h such that ε and $\bar{\kappa}$ are piecewise constants on each element of the triangulation $\mathcal{T}_h$.

In our setting of the weak formulation, we need to estimate $\|F(u_h)\|_{-1,\Omega}$. To this end, we first introduce quite a bit of notation. We assume that the d-dimensional domain Ω has been exactly triangulated with a set $\mathcal{T}_h$ of shape-regular d-simplices (the finite dimension d is arbitrary, not restricted to $d \leq 3$, throughout this discussion). A family of simplices will be referred to here as shape-regular in the sense of [21].

It will be convenient to introduce the following notation:

$$
\begin{array}{lcl}
\mathcal{T}_h & = & \text{the set of shape-regular simplices triangulating the domain } \Omega. \\
\mathcal{N}(\tau) & = & \text{the union of faces contained in simplex set } \tau \text{ lying on } \partial\Omega. \\
\mathcal{I}(\tau) & = & \text{the union of faces contained in simplex set } \tau \text{ not in } \mathcal{N}(\tau). \\
\mathcal{F}(\tau) & = & \mathcal{N}(\tau) \cup \mathcal{I}(\tau). \\
\mathcal{F} & = & \cup_{\tau \in \mathcal{T}_h} \mathcal{F}(\tau). \\
\omega_\tau & = & \bigcup \{ \tilde{\tau} \in \mathcal{T}_h \mid \tau \bigcap \tilde{\tau} \neq \varnothing, \text{ where } \tau \in \mathcal{T}_h \}. \\
\omega_S & = & \bigcup \{ \tilde{\tau} \in \mathcal{T}_h \mid S \bigcap \tilde{\tau} \neq \varnothing, \text{ where } S \in \mathcal{F} \}. \\
h_\tau & = & \text{the diameter of the simplex } \tau. \\
h_S & = & \text{the diameter of the face } S.
\end{array}
$$

When the argument to one of the face set functions $\mathcal{N}$, $\mathcal{I}$, or $\mathcal{F}$ is in fact the entire set of simplices, we will leave off the explicit dependence on $\mathcal{S}$ without danger of confusion. Finally, we will also need some notation to represent discontinuous jumps in function values across faces interior to the triangulation. For any face $S \in \mathcal{N}$, let n_S denote the unit outward normal; for any face $S \in \mathcal{I}$, take n_S to be an arbitrary (but fixed) choice of one of the two possible face normal orientations. Now, for any $v \in L^2(\Omega)$ such that $v \in C^0(\tau)\ \forall \tau \in \mathcal{T}_h$, define the *jump function*:

$$
[v]_S(x) = \lim_{t \to 0^+} v(x + t n_S) - \lim_{t \to 0^-} v(x - t n_S).
$$

We now define our a posteriori error estimator

$$
\eta_\tau^2(u_h) = h_\tau^2 \|B(u_h)\|_{0,\tau}^2 + \frac{1}{2} \sum_{S \in \mathcal{I}(\tau)} h_S \| \left[n_S \cdot (\varepsilon \nabla u_h + (\varepsilon - \varepsilon_m) \nabla G) \right]_S \|_{0,S}^2, \tag{7.4}
$$

and the oscillation

$$
\operatorname{osc}_\tau^2(u_h) = h_\tau^4 \left(\|\nabla u_h\|_{0,\tau}^2 + \|\nabla G\|_{0,\tau}^2 \right). \tag{7.5}
$$

THEOREM 7.1. *Let $u \in H^1(\Omega)$ be a weak solution of the RPBE and u_h be the finite element approximation with a grid satisfying assumptions* (A1) *and* (A2)*. There exist two constants depending only on the shape regularity of $\mathcal{T}_h$ such that*

$$
\|u - u_h\|_1^2 \leq C_1\, \eta_h^2 + C_2 \operatorname{osc}_h^2, \tag{7.6}
$$

where

$$
\eta_h^2 := \sum_{\tau \in \mathcal{T}_h} \eta_\tau^2(u_h), \quad \textit{and} \quad \operatorname{osc}_h^2 := \sum_{\tau \in \mathcal{T}_h \cap \Omega_s} \operatorname{osc}_\tau^2(u_h).
$$

Proof. We shall apply the general estimate in [51, Chapter 2] (see also [50]) to

$$
\underline{a}(x, u, \nabla u) = \varepsilon \nabla u + (\varepsilon - \varepsilon_m) \nabla G, \quad \text{and} \quad b(x, u, \nabla u) = -\bar{\kappa}^2 \sinh(u + G).
$$

We then use the following facts to get the desired result:

- $\nabla \cdot (\varepsilon \nabla u_h) \mid_\tau = 0 \ \forall \tau \in \mathcal{T}_h$ by the assumption (A2) of the grid;
- $\nabla \cdot ((\varepsilon - \varepsilon_m)\nabla G) \mid_\tau = 0 \ \forall \tau \in \mathcal{T}_h$ since $\Delta G(x) = 0$ if $x \notin \{x_i\}$.
- For $\tau \in \mathcal{T}_h \cap \Omega_s$, let $\bar{u}_h$ and $\bar{G}$ denote the average of u_h and G over τ, respectively. We then have

$$\begin{aligned} \| \sinh(u_h + G) - \sinh(\bar{u}_h + \bar{G})\|_{0,\tau} &\le |\cosh(\xi)| \|u_h - \bar{u}_h + G - \bar{G}\|_{0,\tau} \\ &\le C h_\tau^2 (\|\nabla u_h\|_{0,\tau} + \|\nabla G\|_{0,\tau}). \end{aligned}$$

  Here we use the L^∞-estimates of u and u_h to conclude that $|\cosh(\xi)| \le C$ and the standard error estimate for $\|u_h - \bar{u}_h\|_{0,\tau}$ and $\|G - \bar{G}\|_{0,\tau}$. ∎

We give some remarks on our error estimator and the oscillation term. First, using (4.2) one can easily show that $\|\nabla u_h\|_{0,\Omega} \le C$ uniformly with respect to h and thus $\mathrm{osc}_\tau = O(h_\tau^2)$. Comparing to the order of $\eta_\tau = O(h_\tau)$, the error estimator η_τ will dominate in the upper bound. Second, in (7.4) the jump of $[n_S \cdot (\varepsilon - \varepsilon_m)\nabla G]_S \neq 0$ only if $S \in \Gamma_h$. This additional term with order $O([\varepsilon])$ will emphasize the elements around the interface where the refinement most occurs.

Although it is clear that the upper bound is the key to bounding the error, the lower bound can also be quite useful; it can help to ensure that the adaptive procedure does not do too much work by overrefining an area where it is unnecessary. Again using the general framework for the a posteriori error estimate in [50, 51], we have the following lower bound result.

THEOREM 7.2. *There exists two constants C_3, C_4 depending only on the shape regularity of $\mathcal{T}_h$ such that*

$$\eta_\tau^2(u_h) \le C_3 \|u - u_h\|_{1,\omega_\tau}^2 + C_4 \sum_{\tilde{\tau} \in \omega_\tau \cap \Omega_s} \mathrm{osc}_{\tilde{\tau}}^2(u_h) \quad \forall \tau \in \mathcal{T}_h.$$

7.2. Marking and refinement strategy. Given an initial triangulation $\mathcal{T}_0$, we shall generate a sequence of nested conforming triangulations $\mathcal{T}_k$ using the following loop:

$$\textbf{SOLVE} \ \rightarrow \ \textbf{ESTIMATE} \rightarrow \ \textbf{MARK} \ \rightarrow \ \textbf{REFINE}. \tag{7.7}$$

More precisely to get $\mathcal{T}_{k+1}$ from $\mathcal{T}_k$ we first solve the discrete equation to get u_k on $\mathcal{T}_k$. The error is estimated using u_k and used to mark a set of triangles that are to be refined. Triangles are refined in such a way that the triangulation is still shape-regular and conforming.

We have discussed the step **ESTIMATE** in detail, and we shall not discuss the step **SOLVE**, which deserves a separate investigation. We assume that the solutions of the finite-dimensional problems can be solved to any accuracy efficiently. Examples of such optimal solvers are the multigrid method or the multigrid-based preconditioned conjugate gradient method [53, 13, 27, 56]. In particular we refer to [1, 2] for recent work on adaptive grids in three dimensions and [31, 30] for solving the PBE with inexact Newton methods.

We now present the marking strategy which is crucial for our adaptive methods. We shall focus on one iteration of loop (7.7) and thus use $\mathcal{T}_H$ for the coarse mesh and $\mathcal{T}_h$ for the refined mesh. Quantities related to those meshes will be distinguished by a subscript H or h, respectively.

Let $\theta_i, i = 1, 2$ be two numbers in $(0, 1)$.

1. Mark $\mathcal{M}_{1,H}$ such that

$$\sum_{\tau \in \mathcal{M}_{1,H}} \eta_\tau^2(u_H) \ge \theta_1 \sum_{\tau \in \mathcal{T}_H} \eta_\tau^2(u_H).$$

2. If

$$\operatorname{osc}_H \geq \eta_H \tag{7.8}$$

or

$$C_4 \sum_{\tilde{\tau}\in\cup_{\tau\in M_H}\omega_\tau} \operatorname{osc}_\tau^2(u_H) \geq \frac{1}{2}\sum_{\tau\in\mathcal{M}_H}\eta_\tau^2(u_H), \tag{7.9}$$

then extend $\mathcal{M}_{1,H}$ to $\mathcal{M}_{2,H}$ such that

$$\sum_{\tau\in\mathcal{M}_{2,H}} \operatorname{osc}_\tau^2(u_H) \geq \theta_2 \sum_{\tau\in\mathcal{T}_H} \operatorname{osc}_\tau^2(u_H).$$

Unlike the marking strategy for reducing oscillation in the adaptive finite element methods in [37, 38], in the second step, we put a switch (7.8)–(7.9). In our setting, the oscillation $\operatorname{osc}_H = O(H^2)$ is in general a high-order term. The marking step (2) is seldom applied.

In the **REFINE** step, we need to carefully choose the rule for dividing the marked triangles such that the mesh obtained by this dividing rule is still conforming and shape-regular. Such refinement rules include red and green refinement [7], longest refinement [41, 40], and newest vertex bisection [43, 35, 36]. For the **REFINE** step, we are going to impose the following assumptions.

(A3) Each $\tau \in \mathcal{M}_H$, as well as each of its faces, contains a node of $\mathcal{T}_h$ in its interior.

(A4) Let $\mathcal{T}_h$ be a refinement of $\mathcal{T}_H$ such that the corresponding finite element spaces are nested, i.e., $V^H \subset V^h$.

With those assumptions, we can have the discrete lower bound between two nested grids. Let $\mathcal{T}_H$ be a shape-regular triangulation, and let $\mathcal{T}_h$ be a refinement of $\mathcal{T}_H$ obtained by local refinement of marked elements set $\mathcal{M}_H$. The assumption (A3) is known as the *interior nodes property* in [38]. Such a requirement ensures that the refined finite element space V^h is fine enough to capture the difference of solutions.

THEOREM 7.3. *Let $\mathcal{T}_H$ be a shape-regular triangulation, and let $\mathcal{T}_h$ be a refinement of $\mathcal{T}_H$ obtained by some local refinement methods of marked elements set $\mathcal{M}_H$, such that it satisfies assumptions* (A3) *and* (A4). *Then there exist two constants, depending only on the shape regularity of $\mathcal{T}_H$, such that*

$$\eta_\tau^2(u_H) \leq C_3\|u_h - u_H\|_{1,\omega_\tau}^2 + C_4 \sum_{\tilde{\tau}\in\omega_\tau} \operatorname{osc}_{\tilde{\tau}}^2(u_H) \quad \forall \tau \in \mathcal{M}_H. \tag{7.10}$$

Proof. The proof is standard using the discrete bubble functions on τ and each face $S \in \partial\tau$. ∎

7.3. Convergence analysis. We shall prove that the repeating of loop (7.7) will produce a convergent solution u_k to u. The convergent analysis of the adaptive finite element method is an active topic. In the literature it is mainly restricted to the linear equations [17, 47, 16, 37, 25, 9, 38, 34, 26, 8]. The convergence analysis for the nonlinear equation is relatively rare [24, 49, 15].

LEMMA 7.4. *Let $\mathcal{T}_H$ and $\mathcal{T}_h$ satisfy assumptions* (A1)–(A4). *Then there exist two constants depending only on the shape regularity of $\mathcal{T}_H$ such that*

$$\|u - u_H\|_1^2 \leq C_5\|u_h - u_H\|_1^2 + C_6 \operatorname{osc}_H^2.$$

When (7.8) *and* (7.9) *do not hold, we have a stronger inequality*

$$\|u - u_H\|_1^2 \le C_7 \|u_h - u_H\|_1^2,$$

where C_7 *depends only on the shape regularity of* $\mathcal{T}_H$.

Proof. By the upper bound and marking strategy

$$\begin{aligned}\|u - u_H\|_1^2 &\le C_1\eta_H^2 + C_2\mathrm{osc}_H^2 \\ &\le C_1\theta_1^{-1}\sum_{\tau\in\mathcal{M}_{1,H}}\eta_\tau^2(u_H) + C_2\,\mathrm{osc}_H^2 \\ &\le C_5\|u_h - u_H\|_1^2 + C_6\,\mathrm{osc}_H^2,\end{aligned}$$

with

$$C_5 = C_1\theta_1^{-1}C_3^{-1}, \quad \text{and} \quad C_6 = (C_2 + 2C_3^{-1}C_4).$$

If (7.8) does not hold, i.e., $\mathrm{osc}_H \le \eta_H$, the first inequality becomes

$$\|u - u_H\|_1^2 \le (C_1 + C_2)\eta_H^2.$$

If (7.9) does not hold, we can easily modify the lower bound (7.10) as

$$\sum_{\tau\in\mathcal{M}_{1,H}}\eta_\tau^2(u_H) \le 2C_3\|u_h - u_H\|_1^2.$$

Then the inequality follows similarly. ∎

For $\tau_h \subset \tau_H$, let $h_{\tau_h} = \gamma H_{\tau_H}$, with $\gamma \in (0,1)$. The next lemma shows that even the oscillation is not small; there is also a reduction result. For the marked set $\mathcal{M}_H \subset \mathcal{T}_H$, we shall use $\overline{\mathcal{M}_H}$ to denoted the refined elements in $\mathcal{T}_h$.

LEMMA 7.5. *If* $\mathcal{M}_{2,H}\backslash\mathcal{M}_{1,H} \notin \varnothing$, *there exist* ρ_1, ρ_2 *such that*

$$\mathrm{osc}_h^2 \le \rho_1\,\mathrm{osc}_H^2 + \rho_2\|u_h - u_H\|_1^2.$$

Proof.

$$\begin{aligned}\mathrm{osc}_h^2 &\le \sum_{\tau\in\mathcal{T}_h}\mathrm{osc}_\tau^2(u_H) + C\sum_{\tau\in\mathcal{T}_h}(h_\tau^4\|\nabla(u_h - u_H)\|_\tau^2) \\ &\le \sum_{\tau_h\in\overline{\mathcal{M}}_{2,H}}\mathrm{osc}_\tau^2(u_H) + \sum_{\tau_h\in\mathcal{T}_h\backslash\overline{\mathcal{M}}_{2,H}}\mathrm{osc}_\tau^2(u_H) + Ch^2\|\nabla(u_h - u_H)\|^2 \\ &\le \gamma^2\sum_{\tau_H\in\mathcal{M}_{2,H}}\mathrm{osc}_\tau^2(u_H) + \sum_{\tau_H\in\mathcal{T}_H\backslash\mathcal{M}_{2,H}}\mathrm{osc}_\tau^2(u_H) + Ch^2\|\nabla(u_h - u_H)\|^2 \\ &\le \mathrm{osc}_H^2 + (\gamma^2 - 1)\sum_{\tau_H\in\mathcal{M}_{2,H}}\mathrm{osc}_\tau^2(u_H) + Ch^2\|\nabla(u_h - u_H)\|^2 \\ &\le \rho_1\,\mathrm{osc}_H^2 + \rho_2\|u_h - u_H\|_1^2,\end{aligned}$$

with $\rho_1 = 1 - (1-\gamma^2)/\theta_2 \in (0,1)$, and $\rho_2 = Ch^2$. ∎

We shall choose θ_2 sufficiently close to 1 and $h_{\max} < 1/c$ to ensure $\rho_i \in (0,1), i = 1,2$.

For the nonlinear problem, we do not have the orthogonality in H^1 norms. But we shall use the trivial identity

$$E(u_H) - E(u) = E(u_H) - E(u_h) + E(u_h) - E(u). \tag{7.11}$$

The following lemma proves the equivalence of energy error and error in H^1 norm. Again the L^∞ norm estimate of u and u_h is crucial.

LEMMA 7.6. *If both $\mathcal{T}_h$ and $\mathcal{T}_H$ satisfy the assumption* (A1)*, then*

- $E(u_h) - E(u) \simeq \|u_h - u\|_1^2$;
- $E(u_H) - E(u) \simeq \|u_H - u\|_1^2$;
- $E(u_H) - E(u_h) \simeq \|u_H - u_h\|_1^2$.

Proof. By the Taylor expansion

$$E(u_H) - E(u_h) = \langle DE(u_h), u_H - u_h\rangle + (D^2E(\xi)(u_H - u_h), u_H - u_h).$$

The first term is zero since u_h is the minimizer. The desired result follows from the bound

$$\bar{\kappa}^2 \le \|D^2E(\xi)\|_\infty = \bar{\kappa}^2 \|\cosh(\xi + G)\|_{\infty,\Omega_s} \le C.$$

Other inequalities follow from the same line. ∎

Our adaptive finite element methods (AFEMs) consist of the iteration of loop (7.7) with the estimate, marking, and refinement parts discussed before. Also the grids generated by the algorithm will satisfy assumptions (A1)–(A4). Hereafter we replace the subscript h by an iteration counter called k and introduce some notation to simplify the proof. Let u_k be the solution in the kth iteration, $\delta_k := E(u_k) - E(u)$, $d_k = E(u_k) - E(u_{k+1})$, and $o_k = \mathrm{osc}^2(u_k)$

THEOREM 7.7. *The adaptive method using loop* (7.7) *will produce a convergent approximation in the sense that*

$$\lim_{k\to 0} \|u - u_k\|_1 = 0.$$

Proof. By Lemma 7.6, we need only to show $\delta^k \to 0$ as $k \to 0$. We first discuss the easier case: When osc_H is the high-order term in the sense that the inequalities (7.8) and (7.9) do not hold, we have the error reduction

$$\|u - u_H\|_1^2 \le C\|u_h - u_H\|^2.$$

Using Lemma 7.5 and (7.11), we have

$$E(u_H) - E(u) \le C(E(u_H) - E(u_h)),$$

which is equivalent to $\delta_H \le C\delta_H - C\delta_h$. Then $\delta_h \le (1 - 1/C)\delta_H$, and thus

$$\delta^k \le \alpha^k \delta^0, \quad \text{with } \alpha = (1 - 1/C) \in (0, 1).$$

When the oscillation is not small, i.e., (7.8) or (7.9) holds, we can get only

$$\Lambda_1\delta_k \le d_k + \Lambda_2 o_k, \quad \text{with } \Lambda_1 \in (0, 1). \tag{7.12}$$

We shall use techniques from [34] to prove the convergence. Recall that we have

$$\delta_{k+1} = \delta_k - d_k. \tag{7.13}$$

For any $\beta \in (0, 1)$, $\beta \times (7.12) + (7.13)$ gives

$$\delta_{k+1} \le \alpha\delta_k + \beta\Lambda_2 o_k - (1 - \beta)d_k, \quad \text{with } \alpha = (1 - \beta\Lambda_1) \in (0, 1). \tag{7.14}$$

Recall that we have

$$o_{k+1} \le \rho_1 o_k + \rho_2 d_k. \tag{7.15}$$

Let $\gamma = (1-\beta)/\rho_2$; (7.15) $\times\, \gamma$ + (7.14) gives

$$\delta_{k+1} + \gamma o_{k+1} \le \alpha \delta_k + (\beta \Lambda_2 + \rho_1 \gamma) o_k.$$

Let $1 > \mu > \rho_1$. We choose

$$\beta = \frac{\frac{\mu-\rho_1}{\rho_2}}{\Lambda_2 + \frac{\mu-\rho_1}{\rho_2}} \in (0,1)$$

to get

$$\delta_{k+1} + \gamma o_{k+1} \le \max(\alpha, \mu)(\delta_k + \gamma o_k),$$

which also implies the convergence of our AFEM. ∎

8. Summary and concluding remarks. In this article we have established a number of basic theoretical results for the nonlinear Poisson–Boltzmann equation and for its approximation using finite element methods. We began by showing that the problem is well-posed through the use of an auxiliary or *regularized* version of the equation and then established a number of basic estimates for the solution to the regularized problem. The Poisson–Boltzmann equation does not appear to have been previously studied in detail theoretically, and it is hoped that this paper, together with a more complete analysis of the continuous PDE solution theory to appear in [29], will help provide molecular modelers with a better theoretical foundation for their analytical and computational work with the Poisson–Boltzmann equation. The bulk of this article then focused on designing a numerical discretization procedure based on the regularized problem and on establishing rigorously that the discretization procedure converged to the solution to the original (nonregularized) nonlinear Poisson–Boltzmann equation. Based on these results, we also designed an adaptive finite element approximation procedure and then gave a fairly involved technical argument showing that this adaptive procedure also converges in the limit of mesh refinement. This article apparently gives the first convergence result for a numerical discretization technique for the nonlinear Poisson–Boltzmann equation with delta distribution sources, and it also introduces the first provably convergent adaptive method for the equation. This last result is one of only a handful of convergence results of this type for nonlinear elliptic equations (the others being [24, 49, 15]).

Several of the theoretical results in the paper rest on some basic assumptions on the underlying simplex mesh partitioning of the domain, namely, assumptions (A1)–(A4); we now make a few comments on these assumptions. To begin, we required a refinement procedure that would preserve the L^∞ norm estimate of u_h. Meeting this requirement in the two-dimensional setting is relatively easy; one can choose Ω as a square and start with a uniform mesh of a square. For the refinement methods, one can use longest edge or newest vertex bisection. Subdivisions obtained by these two methods contain only one type of triangle: isosceles right triangles. Thus the assumption (A1′) always holds. In the three-dimensional setting, this is more tricky. Bisection will introduce some obtuse angles in the refined elements. One needs to use a three-dimensional analogue of red-green refinement [10]. However, this will not produce nested subspaces; i.e., assumption (A4) is invalid. For convergence analysis

based on red-green refinement, we could use the technique in [46] to relax the assumption (A4). Since this will only add technical difficulties but does not exhibit principally new phenomena, we omit them here. Another approach to relax the assumption (A1) is to use pointwise a posteriori error estimates developed in [39] for monotone semilinear equations. We can start with a quasi-uniform triangulation and refine the triangulation according to the pointwise a posteriori error estimator to make sure $\|u - u_h\|_\infty \leq C$. Then together with the L^∞ norm estimate of u, by the triangulation inequality $\|u_h\|_\infty \leq \|u\|_\infty + \|u - u_h\|_\infty \leq C$, we have the control of $\|u_h\|_\infty$. Note that the pointwise a posteriori error estimates developed in [39] are for elliptic-type equations with continuous coefficients. To use this approach we need to adapt the estimate for the jump coefficients case which will be a further research topic.

Assumption (A2) is needed to approximate the interface well in an a priori manner. Of course, one can include this approximation effect into the a posteriori error estimate (namely, the term $\|F(u_h) - F_h(u_h)\|$) and use this to drive local refinement to improve the approximation to the desired level for the assumption or use the strategy for the oscillation to include it in the refinement loop. However, we note that, since the interface is known a priori from, e.g., x-ray crystallography information, we do not need to solve the equation (which is generally the more expensive route) to solve this problem; we view this as primarily a mesh generation problem. Robust algorithms to produce well-shaped tetrahedral meshes which are constrained to exactly match some interior embedded two-manifold are available in the literature; for example, see [18, 3]. A simple algorithm can be based entirely on local refinement with the marking and refinement strategy, but without having to solve the PBE to produce error indicators: If the element cross the interface, then it gets refined. This strategy was employed in [5].

After this work was done, we learned that the assumption (A3) is not needed for the convergence of adaptive finite element methods for a linear elliptic equation. As an ongoing project, we are extending it to the nonlinear Poisson–Boltzmann equation.

Finally, we make some remarks on the practical realization of a convergent discretization procedure based on the two-way (or three-way) expansion into a known singular function and solution(s) of an associated regularized version of the problem. Methods for building high-quality approximate solutions of the regularized nonlinear PBE, either by solving (3.5)–(3.6) at once or by solving for the linear and nonlinear pieces separately by solving (5.1)–(5.2) and then adding the solutions together, are well-understood. The techniques described in [28], taken together with the approximation framework and the adaptive algorithm proposed in the present article, moves us a step closer to the goal of a complete optimal solution to this problem, in terms of approximation quality for a given number of degrees of freedom, computational complexity of solving the corresponding discrete equations, and the storage requirements of the resulting algorithms. What remains is simply the cost of evaluating the singular function G in forming the source terms in (3.5) or (5.1). The source terms are evaluated using numerical quadrature schemes: sampling the integrand at specially chosen discrete points in each element and then summing the results up using an appropriate weighting. This is equivalent to computing all pairwise interactions between the collection of quadrature points (a fixed constant number of points per simplex) and the number of charges forming G. Given that G is typically formed from at most a few thousand charges, the algorithm evaluating G at the quadrature points should scale linearly with the number of quadrature points, which is a (small) constant multiple of the number of simplices. This can be accomplished using techniques such distance-classing and fast multiple-type methods.

OVERLAPPING ADDITIVE SCHWARZ PRECONDITIONERS FOR ELLIPTIC PROBLEMS WITH DEGENERATE LOCALLY ANISOTROPIC COEFFICIENTS*

SVEN BEUCHLER† AND SERGEY V. NEPOMNYASCHIKH‡

Abstract. In this paper, we consider degenerate and locally anisotropic boundary value problems on the unit square. These problems are discretized by piecewise linear finite elements on a triangular mesh of isosceles right triangles. The system of linear algebraic equations is solved by a preconditioned gradient method using a domain decomposition preconditioner with overlap. We prove that the condition number of the preconditioned system is bounded by a constant independent of the discretization parameter. Moreover, the preconditioning operation requires $\mathcal{O}(N)$ operations, where N is the number of unknowns. Several numerical experiments show the performance of the proposed method.

Key words. solution of discretized equations, finite elements, domain decomposition

1. Introduction.

In this paper, we investigate the degenerate and locally anisotropic boundary value problem

$$\begin{aligned} -\omega_1^2(y)u_{xx} - \omega_2^2(x)u_{yy} &= f \quad \text{in } \Omega = (0,1)^2, \\ u &= 0 \quad \text{on } \partial\Omega \end{aligned} \tag{1.1}$$

with some strongly monotonic increasing and bounded weight functions $\omega_i : [0,1] \mapsto \mathbb{R}$ satisfying $\omega_1(0)\omega_2(0) = 0$.

In the past, degenerate problems have been considered relatively rarely. One reason is the unphysical behavior of the partial differential equation (PDE), which is quite unusual in technical applications. One work focusing on this type of PDE is the book of Kufner and Sändig [13]. Nowadays, problems of this type are becoming more and more popular because there are stochastic PDEs of a similar structure. An example of an isotropic degenerate stochastic PDE is the elliptic part of the Black–Scholes PDE [18].

An example of a locally anisotropic degenerate elliptic problem is the solver related to the problem of the subdomains for the p-version of the finite element method (FEM) using quadrilateral elements. This solver can be interpreted as the h-version FEM-discretization matrix of problem (1.1) with $\omega_1(\xi) = \omega_2(\xi) = \xi$. We refer the reader to [1], [12] for more details.

The discretization of (1.1) using the h-version of the FEM leads to a linear system of algebraic equations

$$\mathcal{K}\underline{u} = \underline{f}. \tag{1.2}$$

It is well known from the literature that preconditioned conjugate gradient (PCG) methods with domain decomposition (DD) preconditioners are among the most efficient iterative solvers for systems of type (1.2); see, e.g., [7], [14], [10], [20], [15]. In this paper, we will propose and analyze overlapping DD preconditioners.

The type of overlapping DD preconditioners presented in this paper was originally developed in [17] for problems with jumping coefficients; see also the recent research for highly jumping coefficients in [19], [9]. In our recent paper [4], we analyzed these overlapping DD preconditioners for isotropic degenerate problems. In most cases, the optimality of this method has been shown. Here, we adapt these techniques to problem (1.1). For tensor product discretizations, we will prove the optimality of the method. Moreover, this method can easily be extended to more general h-version FEM discretizations, too.

Only a limited number of papers have investigated fast solvers for degenerate elliptic problems. The paper [6] deals with the Laplacian in two dimensions in polar coordinates. In the paper [8], multigrid methods for some other types of degenerate problems are proposed. Multigrid solvers for finite element discretizations of (1.1) have been investigated in [1]; see also [2]. However, the convergence of the V-cycle was not yet proved. The paper [12] develops nonoverlapping DD preconditioners for $\omega_1(\xi) = \omega_2(\xi) = \xi$. The paper [5] proposes wavelet methods for several classes of degenerate elliptic problems on the unit square. One of them is problem (1.1) under the restriction $\lim_{\xi\to 0+} \frac{\xi^3}{\omega_i^2(\xi)} = 0$, $i = 1, 2$, on the weight functions. Moreover, a fast direct solver based on eigenvalue computations combined with the fast Fourier transform and solving tridiagonal systems can be designed if at least one of the weight functions ω_i, $i = 1, 2$, is assumed to be constant on $(0, 1)$ and if a tensor product discretization is used.

The remaining part of this paper is organized as follows. In section 2, we introduce the reader to our problem and to our notation. The preconditioners are defined in section 3; moreover, the main theorems with the condition number estimates are stated. In section 4, we formulate some auxiliary results from the additive Schwarz method (ASM), which are required for the proofs of our main theorems given in section 5. In section 6, we present some numerical experiments which show the performance of the presented methods.

Throughout this paper, the integer k denotes the level number. For two real symmetric and positive definite $n \times n$ matrices A, B, the relation $A \preceq B$ means that $A - cB$ is negative definite, where $c > 0$ is a constant independent of n. The relation $A \sim B$ means $A \preceq B$ and $B \preceq A$, i.e., the matrices A and B are spectrally equivalent. The parameter c denotes a generic constant. The isomorphism between a function $u = \sum_i u_i \psi_i \in L^2$ and the corresponding vector of coefficients $\underline{u} = [u_i]_i$ in the basis $[\Psi] = [\psi_1, \psi_2, \ldots]$ is denoted by $u = [\Psi]\underline{u}$. The Greek letters μ and ν stand for pairs of integers (μ_1, μ_2) and (ν_1, ν_2), respectively. The closure of an open set M is denoted by $\overline{M}$.

2. Setting of the problem. In this paper, we investigate the following boundary value problem. Let $\Omega = (0, 1)^2$.

Find $u \in \mathbb{H}_{\mathcal{D},0} := \{u \in L_2(\Omega) : \int_\Omega (\nabla u)^T \mathcal{D} \nabla u < \infty, u\,|_{\partial\Omega} = 0\}$ such that

$$a(u, v) := \int_\Omega (\nabla v)^T D \nabla u = (f, v) \quad \forall v \in \mathbb{H}_{\mathcal{D},0} \tag{2.1}$$

with the coefficient matrix $\mathcal{D}(x, y) = \left[\begin{smallmatrix} \omega_1^2(y) & 0 \\ 0 & \omega_2^2(x) \end{smallmatrix}\right]$ and weight functions ω_i, $i = 1, 2$,

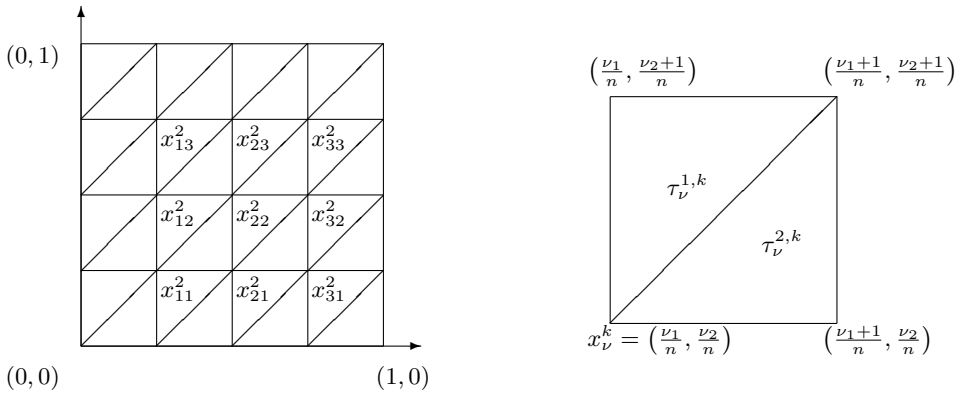

FIG. 2.1. *Mesh for the finite element method for $k = 2$ (left); notation of the triangles (right).*

which satisfy the following assumption.

ASSUMPTION 2.1. *The functions $\omega_i : [0,1] \mapsto \mathbb{R}$, $i = 1, 2$,*

- *are monotonically increasing;*
- *are continuous; and*
- *satisfy the estimate*

$$\omega_i(2\xi) \le c_\omega \omega_i(\xi) \quad \forall \xi \in \left(0, \frac{1}{2}\right] \tag{2.2}$$

with some constants $c_\omega > 0$.

We discretize problem (2.1) by piecewise linear finite elements on the regular Cartesian grid consisting of congruent, isosceles, and right triangles. For this purpose, some notation is introduced. Let k be the level of approximation and $n = 2^k$. Let $x^k_\nu = \left(\frac{\nu_1}{n}, \frac{\nu_2}{n}\right)$, where $\nu = (\nu_1, \nu_2) \in \{0, 1, \ldots, n\}^2$. The domain Ω is divided into congruent, isosceles, and right triangles $\tau^{s,k}_\nu$, where $\nu \in \{0, 1, \ldots, n-1\}^2$ and $s = 1, 2$; see Figure 2.1. The triangle $\tau^{1,k}_\nu$ has the three vertices $\left(\frac{\nu_1}{n}, \frac{\nu_2}{n}\right), \left(\frac{\nu_1+1}{n}, \frac{\nu_2+1}{n}\right)$, and $\left(\frac{\nu_1}{n}, \frac{\nu_2+1}{n}\right)$, and $\tau^{2,k}_\nu$ has the three vertices $\left(\frac{\nu_1}{n}, \frac{\nu_2}{n}\right), \left(\frac{\nu_1+1}{n}, \frac{\nu_2+1}{n}\right)$, and $\left(\frac{\nu_1+1}{n}, \frac{\nu_2}{n}\right)$; see Figure 2.1. Piecewise linear finite elements are used on the mesh $T_k = \{\tau^{s,k}_\nu\}_{\nu \in \{0,1,\ldots,n-1\}^2, s \in \{1,2\}}$. The subspace of piecewise linear functions ϕ^k_ν with

$$\phi^k_\nu \in H^1_0(\Omega),\ \phi^k_\nu\,|_{\tau^{s,k}_\mu} \in \mathbb{P}_1(\tau^{s,k}_\mu)$$

is denoted by $\mathbb{V}_k$, where $\mathbb{P}_1$ is the space of polynomials of degree ≤ 1. A basis of $\mathbb{V}_k$ is the system of the usual hat-functions $\Phi_k = \{\phi^k_\nu\}_{\nu \in \mathcal{I}_n}$ with $\mathcal{I}_n = \{(\nu_1, \nu_2) \in \mathbb{N}^2, \nu_1, \nu_2 \le n-1\}$ uniquely defined by

$$\phi^k_\nu(x^k_\mu) = \delta_{\nu\mu}$$

and $\phi^k_\nu \in \mathbb{V}_k$, where $\delta_{\nu\mu}$ is the Kronecker delta for multi-indices. Now, we can formulate the discretized problem.

Find $u^k \in \mathbb{V}_k$ such that

$$a(u^k, v^k) = (f, v^k) \quad \forall v^k \in \mathbb{V}_k \tag{2.3}$$

holds. Problem (2.3) is equivalent to solving the system of linear algebraic equations

$$K_k \underline{u}_k = \underline{f}_k, \tag{2.4}$$

where $K_k = \left[a(\phi_\nu^k, \phi_\mu^k)\right]_{\nu,\mu\in\mathcal{I}_n}$, $\underline{u}_k = [u_\nu]_{\nu\in\mathcal{I}_n}$, and $\underline{f}_k = \left[(f, \phi_\mu^k)\right]_{\mu\in\mathcal{I}_n}$. The size of the matrix K_k is $N \times N$ with $N = (n-1)^2$.

3. Definition of the preconditioners. In this section, we define the overlapping preconditioners for the matrix K_k (2.3). We distinguish between two cases:

- the weight function ω_1 is assumed to be constant;
- both weight functions satisfy $\omega_i(0) = 0$, $i = 1, 2$.

3.1. The case $\omega_1(\xi) = 1$. We introduce the following notation. Let

- $\Omega_{i,x} = (2^{-1-i}, 2^{-i}) \times (0,1)$, $i = 0, \dots, k-2$, be a strip of width 2^{-i-1};
- $\Omega_{k-1,x} = (0, 2^{-k+1}) \times (0,1)$ be a strip of width 2^{-k+1}, i.e., $2h$;
- $\Gamma_{i,x} = \{2^{-i}\} \times (0,1)$, $i = 1, \dots, k-1$, be the interface of two neighboring stripes;
- $\tilde{\Omega}_{j,x} = \operatorname{int}(\bigcup_{i=j}^{k-1} \overline{\Omega_{i,x}}) = (0, 2^{-i}) \times (0,1)$ be a strip of width 2^{-i}; and
- $n_j = 2^{k-j} - 1$ be the number of interior grid points in $\tilde{\Omega}_{j,x}$ in the x-direction, $N_j = (n-1)n_j$ the total number of interior grid points, and $n_k = -1$.

Moreover, let

$$\varepsilon_{2,j} = \left(\omega_2\left(2^{-j}\right)\right)^2.$$

Figure 3.1 displays a sketch with the notation for $k = 4$.

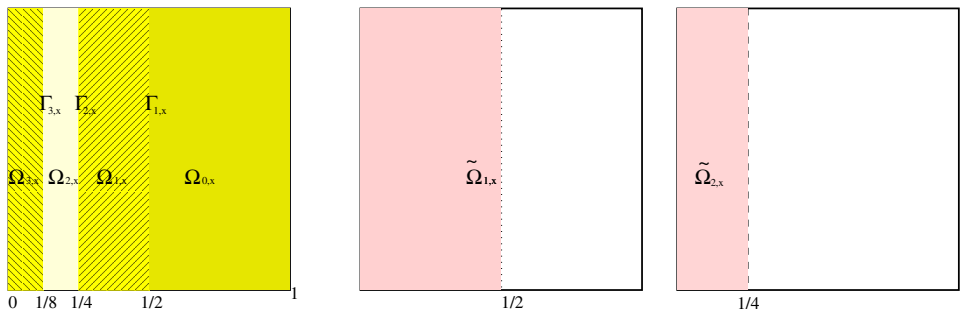

FIG. 3.1. *Notation for $k = 4$.*

We will develop two overlapping additive Schwarz preconditioners with inexact subproblem solvers. For the first preconditioner, we split the domain Ω into the substripes $\{\tilde{\Omega}_{i,x}\}_{i=0}^{k-1}$. On $\{\tilde{\Omega}_{i,x}\}_{i=0}^{k-1}$, we choose the constant diffusion matrix $\operatorname{argsup}_{(x,y)\in\tilde{\Omega}_{j,x}} \mathcal{D}(x,y)$, i.e., the componentwise supremum of the original diffusion matrix $\mathcal{D}$. For the second preconditioner, we consider the domain decomposition into $\{\overline{\Omega_{i,x}} \cup \overline{\Omega_{i+1,x}}\}_{i=0}^{k-2}$ and into $\Omega_{k-1,x}$. The construction of the diffusion matrix is similar to the first preconditioner.

For the correct mathematical definition of the preconditioners, we introduce the bilinear form

$$a_j(u,v) = \int_{\tilde{\Omega}_{j,x}} (\nabla u)^T \begin{bmatrix} 1 & 0 \\ 0 & \varepsilon_{2,j} \end{bmatrix} \nabla v, \quad j = 0, \dots, k-1. \tag{3.1}$$

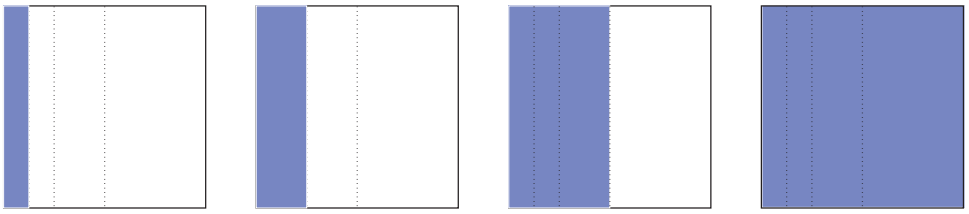

FIG. 3.2. *Computational domains for C (3.4), Θ_3, Θ_2, Θ_1, and Θ_0, and corresponding diffusion matrices for $\omega_2^2(\xi) = \xi^2$ (from left to right).*

This is a bilinear form with constant coefficients on $\tilde{\Omega}_{j,x}$. Let C_j be the stiffness matrix

$$C_j = \left[a_j(\phi_\mu^k, \phi_\nu^k)\right]_{\mu,\nu\in I_j}, \quad j = 0, \dots, k-1, \tag{3.2}$$

$$\text{with} \quad I_j = \left\{\nu \in \mathbb{N}^2 : \frac{1}{n}\nu \in \tilde{\Omega}_{j,x}\right\} = \{(\nu_1, \nu_2) \in \mathbb{N}^2 : \nu_1 \le n_j, \nu_2 \le n_0\}$$

corresponding to the bilinear form $a_j(\cdot,\cdot)$. Finally, let

$$\Theta_j = \begin{bmatrix} C_j & \mathbf{0} \\ \mathbf{0} & \mathbf{0}_{N-N_j} \end{bmatrix} \in \mathbb{R}^{N\times N} \tag{3.3}$$

be the corresponding global assembled stiffness matrix. The computational domains for Θ_j are displayed in Figure 3.2.

Then we define

$$C^{-1} = \sum_{j=0}^{k-1} \Theta_j^+ \tag{3.4}$$

as a first preconditioner for K_k, where B^+ denotes the pseudoinverse of a matrix B. Note that the locally anisotropic diffusion matrix $\mathcal{D}(x,y)$ is hidden in the matrix Θ_j.

This preconditioner turns out not to be optimal; see Theorem 3.2. To develop an optimal preconditioner, we have to modify C. Therefore, let

$$C_{j,mod} = \left[\int_{\overline{\Omega}_{j+1,x}\cup\overline{\Omega}_{j,x}} \nabla\phi_\mu^k \cdot \begin{bmatrix} 1 & 0 \\ 0 & \varepsilon_{2,j} \end{bmatrix} \nabla\phi_\nu^k\right]_{\mu,\nu\in I_{j,mod}} \tag{3.5}$$

$$\begin{aligned}\text{with} \quad I_{j,mod} &= \left\{\nu \in \mathbb{N}^2 : \frac{1}{n}\nu \in \operatorname{int}(\overline{\Omega}_{j+1,x} \cup \overline{\Omega}_{j,x})\right\} \\ &= \{(\nu_1, \nu_2) \in \mathbb{N}^2 : n_{j+2} + 2 \le \nu_1 \le n_j, \nu_2 \le n_0\}.\end{aligned}$$

This is the discretized operator on $\overline{\Omega_{j+1,x}} \cup \overline{\Omega_{j,x}}$ with Dirichlet boundary conditions at all edges. Moreover, let

$$\Theta_{j,mod} = \begin{bmatrix} \mathbf{0}_{N_{j+2}+n_0} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & C_{j,mod} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0}_{N-N_j} \end{bmatrix} \in \mathbb{R}^{N\times N}, \quad j = 0, \dots, k-2,$$

be the corresponding assembled matrix; see Figure 3.3 for the computational domains.

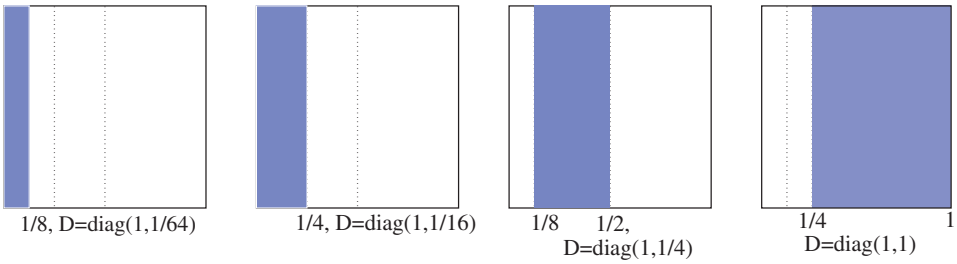

FIG. 3.3. *Computational domains for C_{mod} (3.6), Θ_3, $\Theta_{2,mod}$, $\Theta_{1,mod}$, and $\Theta_{0,mod}$, and corresponding diffusion matrices for $\omega_2^2(\xi) = \xi^2$ (from left to right).*

The second overlapping preconditioner for K_k is defined as

$$C_{mod}^{-1} = \sum_{j=0}^{k-2} \Theta_{j,mod}^{+} + \Theta_{k-1}^{+}. \tag{3.6}$$

Then we can formulate the following theorem.

THEOREM 3.1. *Let C_{mod} be defined via (3.6) and let $\mathcal{D}(x,y) = \left[\begin{smallmatrix} 1 & 0 \\ 0 & \omega_2^2(x) \end{smallmatrix}\right]$. Then the matrix C_{mod}^{-1} is symmetric positive definite and satisfies $K_k \sim C_{mod}$.*

Proof. A detailed proof is given in subsection 5.2. ∎

Concerning the first preconditioner (3.4), we can now prove the following result.

THEOREM 3.2. *Let C be defined via (3.4) and let $\mathcal{D}(x,y) = \left[\begin{smallmatrix} 1 & 0 \\ 0 & \omega_2^2(x) \end{smallmatrix}\right]$. Then the spectral equivalence relations $\frac{1}{k} K_k \leq C \preceq K_k$ hold.*

Proof. The proof is given in subsection 5.3. ∎

3.2. The general case. In addition to the notation of subsection 3.1, we define the following:

- $\Omega_{i,y} = (0,1) \times (2^{-1-i}, 2^{-i})$, $i = 0, \ldots, k-2$.
- $\Omega_{k-1,y} = (0,1) \times (0, 2^{-k+1})$.
- $\tilde{\Omega}_{j,y} = \operatorname{int}\left(\bigcup_{i=j}^{k-1} \overline{\Omega_{i,y}}\right) = (0,1) \times (0, 2^{-i})$.
- $\Omega_{jj'} = \operatorname{int}((\overline{\Omega_{j,x}} \cup \overline{\Omega_{j+1,x}}) \cap (\overline{\Omega}_{j',y} \cup \overline{\Omega}_{j'+1,y}))$ for $j, j' = 0, \ldots, k-2$. Note that $\Omega_{jj'} = (2^{-2-j}, 2^{-j}) \times (2^{-2-j'}, 2^{-j'})$ for $j, j' \leq k-3$.
- Moreover, let

$$\varepsilon_{1,j} = \left(\omega_1\left(2^{-j}\right)\right)^2.$$

Again, we will define two preconditioners. In comparison to the preconditioners of subsection 3.1, we use the domain decomposition in both directions. More precisely, we introduce the bilinear form

$$b_{j,j'}(u,v) = \int_{\tilde{\Omega}_{j,x} \cap \tilde{\Omega}_{j',y}} \nabla u \cdot \begin{bmatrix} \varepsilon_{1,j'} & 0 \\ 0 & \varepsilon_{2,j} \end{bmatrix} \nabla v, \quad j', j = 0, \ldots, k-1.$$

For $j = 0, \ldots, k-1$, let $B_{j,j'}$ be the stiffness matrix

$$B_{j,j'} = \left[b_{j,j'}(\phi_\mu^k, \phi_\nu^k)\right]_{\mu,\nu \in J_{j,j'}} \quad \text{with}$$

$$J_{j,j'} = \{\nu \in \mathbb{N}^2, \frac{1}{n}\nu \in \tilde{\Omega}_{j,x} \cap \tilde{\Omega}_{j',y}\} = \{(\nu_1, \nu_2) \in \mathbb{N}^2, \nu_1 \leq n_j, \nu_2 \leq n_{j'}\},$$

corresponding to the bilinear form $b_{j,j'}(\cdot,\cdot)$ with Dirichlet boundary conditions at all edges.

The corresponding global assembled stiffness matrices is denoted by the matrix $\Upsilon_{j,j'} \in \mathbb{R}^{N\times N}$. Then we define

$$B^{-1} = \sum_{j=0}^{k-1}\sum_{j'=0}^{k-1} \Upsilon^{+}_{j,j'} \tag{3.7}$$

as a first preconditioner for K_k. Note that the locally anisotropic diffusion matrix $\mathcal{D}(x,y)$ is hidden in the matrix $\Upsilon_{j,j'}$. This gives us a nonoptimal preconditioner; see Theorem 3.4. Moreover, we introduce an optimal preconditioner. For $0 \le j, j' \le k-2$, let

$$B_{j,j',mod} = \left[\int_{\Omega_{jj'}} \nabla\phi^k_\mu \cdot \begin{bmatrix} \varepsilon_{1,j'} & 0 \\ 0 & \varepsilon_{2,j} \end{bmatrix} \nabla\phi^k_\nu\right]_{\mu,\nu\in J_{j,j',mod}} \quad \text{with} \tag{3.8}$$

$$\begin{aligned} J_{j,j',mod} &= \left\{\nu \in \mathbb{N}^2, \frac{1}{n}\nu \in \Omega_{jj'}\right\} \\ &= \{(\nu_1,\nu_2) \in \mathbb{N}^2, n_{j+2}+2 \le \nu_1 \le n_j, n_{j'+2}+2 \le \nu_2 \le n_{j'}\}. \end{aligned}$$

This matrix is the finite element discretization matrix of an operator with piecewise constant coefficients on $\Omega_{jj'} = (\overline{\Omega_{j+1,x}} \cup \overline{\Omega_{j,x}}) \cap (\overline{\Omega_{j'+1,y}} \cup \overline{\Omega_{j',y}})$ and Dirichlet boundary conditions at all edges. For $j, j' \le k-2$, the corresponding global assembled stiffness matrices are denoted by the matrices $\Upsilon_{j,j',mod} \in \mathbb{R}^{N\times N}$. If $j = k-1$ or $j' = k-1$, we set

$$\Upsilon_{j,j',mod} = \Upsilon_{j,j'}.$$

The corresponding computational domains for the matrices $\Upsilon_{j,j'}$ are displayed in Figure 3.4.

The second overlapping preconditioner for K_k is defined as

$$B^{-1}_{mod} = \sum_{j=0}^{k-1}\sum_{j'=0}^{k-1} \Upsilon^{+}_{j,j',mod}. \tag{3.9}$$

THEOREM 3.3. *Let B_{mod} be defined via (3.9) and let $\mathcal{D}(x,y) = \left[\begin{smallmatrix} \omega_1^2(y) & 0 \\ 0 & \omega_2^2(x) \end{smallmatrix}\right]$. Then the matrix B^{-1}_{mod} is symmetric positive definite and satisfies $K_k \sim B_{mod}$.*

Proof. The proof is given in subsection 5.4. ∎

Concerning the first preconditioner (3.7), we can prove the following result.

THEOREM 3.4. *Let B be defined via (3.7) and let $\mathcal{D}(x,y) = \left[\begin{smallmatrix} \omega_1^2(y) & 0 \\ 0 & \omega_2^2(x) \end{smallmatrix}\right]$. Then the spectral equivalence relations $\frac{1}{k^2}K_k \le B \preceq K_k$ hold.*

Proof. The proof is similar to the proof of Theorem 3.2. ∎

Remark 3.5. We can replace the matrices $B_{j,j',mod}$ in (3.8) by

$$B_{j,j',var} = \left[\int_{\Omega_{jj'}} \nabla\phi^k_\mu \cdot \begin{bmatrix} \omega_1^2(y) & 0 \\ 0 & \omega_2^2(x) \end{bmatrix} \nabla\phi^k_\nu\right]_{\mu,\nu\in J_{j,j',mod}}.$$

Let $\Upsilon_{j,j',var}$ be the assembled matrices and

$$B^{-1}_{var} = \sum_{j=0}^{k-1}\sum_{j'=0}^{k-1} \Upsilon^{+}_{j,j',var}.$$

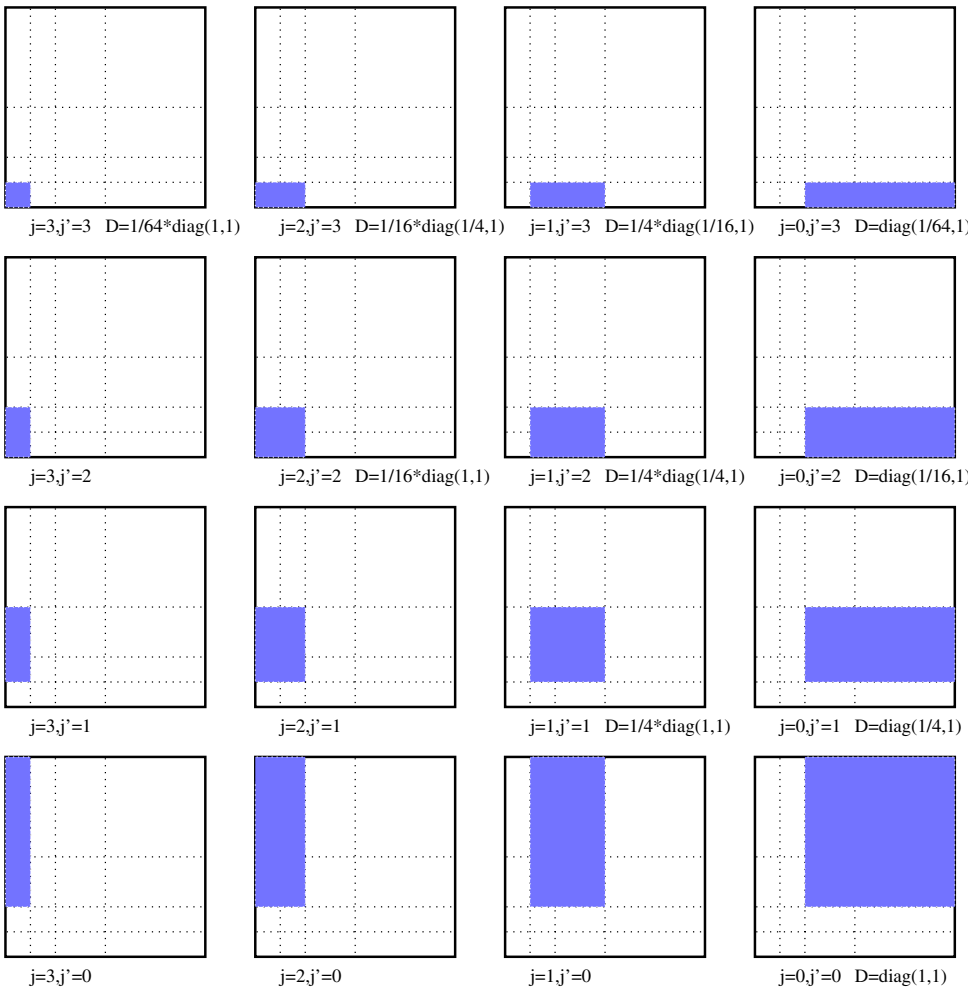

FIG. 3.4. *Corresponding domains $\Omega_{jj'}$ and diffusion matrices with weight functions $\omega_i^2(\xi) = \xi^2$ for $\Upsilon_{j,j',mod}$, $i = 1, 2$.*

Due to (2.2), we have $B_{j,j',var} \sim B_{j,j',mod}$, which gives $B_{mod} \sim B_{var}$. In the preconditioner B_{var}, we now have an operator with variable coefficients. However, the constants do not change too much since we have the estimate

$$\sup_{x_1,x_2 \in (\overline{\Omega}_{j,x} \cup \overline{\Omega}_{j+1,x})} \frac{\omega_2^2(x_1)}{\omega_2^2(x_2)} \leq c_\omega^4$$

from our assumption (2.2).

3.3. Computational aspects. In this subsection, we investigate the preconditioning operation $\mathcal{C}^{-1}\underline{w}$ for the preconditioners (3.4), (3.6), (3.7), and (3.9). We present algorithms to perform this preconditioning operation in optimal arithmetical complexity.

Let us start with the case $\omega_1(\xi) = 1$. Here, we have developed the preconditioners

$$C^{-1} = \sum_{j=0}^{k-1} \Theta_j^+$$

(see (3.4)) and

$$C_{mod}^{-1} = \sum_{j=0}^{k-2} \Theta_{j,mod}^+ + \Theta_{k-1}^+$$

(see (3.6)). In both cases, we have to solve systems of linear algebraic equations with the discretization of an operator with constant coefficients on a rectangle using triangular finite elements. The corresponding operators are now

$$-\varepsilon_j^2 u_{xx} - u_{yy} \tag{3.10}$$

with some numbers $0 < \varepsilon_j \leq 1$. The computational domains are displayed in Figures 3.2 and 3.3. These domains are the same as for the preconditioners C and C_{mod} of [4].

Using multigrid preconditioners combined with a line smoother, optimal solvers for Θ_j and $\Theta_{j,mod}$ can easily be designed; see [11]. The line smoother is necessary to remove the anisotropy of the operator. It can be shown that the multigrid preconditioner with line smoother and V-cycle is an optimal method independent of the parameter ε_j [11]. With the same arguments as in the isotropic case (see [4]), we can prove that the cost for the operations $\underline{w} = C^{-1}\underline{r}$ and $\underline{w} = C_{mod}^{-1}\underline{r}$ depends linearly on the number of unknowns.

In the general case, the application of the preconditioning operations $B^{-1}\underline{r}$ (3.7) and $B_{mod}^{-1}\underline{r}$ (3.9) implies again the solution of systems of linear algebraic equations with discretizations of operators of type (3.10). However, these systems have to be solved on the smaller subdomains $(\overline{\Omega}_{j,x} \cup \overline{\Omega}_{j+1,x}) \cap (\overline{\Omega}_{j',y} \cup \overline{\Omega}_{j'+1,y})$; see Figure 3.4 for $k = 4$. The structure of the diffusion matrices are displayed below each of the 16 panels for the weight functions $\omega_i^2(\xi) = \xi^2$, $i = 1, 2$. The diffusion matrices are isotropic for $j \approx j'$ and globally anisotropic elsewhere. Therefore, a multigrid algorithm or multigrid preconditioner with line smoother should be used as a solution method for $|j - j'| \gg 1$. Similarly as for the preconditioners C (3.4) and C_{mod} (3.6), the optimality of the preconditioning operations $B^{-1}\underline{r}$ and $B_{mod}^{-1}\underline{r}$ can be shown.

Summarizing, we now have to solve globally anisotropic problems with constant coefficients instead of locally anisotropic problems with changing directions of the anisotropy. This is much simpler than the original problem since solvers for the problem with constant coefficients are known in the literature. However, this method cannot remove the anisotropic behavior of the problem.

4. Some preliminaries. In this section, we formulate some auxiliary results from ASM which are necessary to prove our main results. The proofs can be found in the literature.

4.1. Preliminaries from ASM. The first result is a general result for preconditioned ASM.

LEMMA 4.1. *Let $\mathbb{H}$ be a Hilbert space with the scalar product $(\cdot, \cdot)$. Moreover, let $\mathbb{H}_i$, $i = 1, \ldots, m$, be subspaces of $\mathbb{H}$ such that*

$$\mathbb{H} = \mathbb{H}_1 + \mathbb{H}_2 + \cdots + \mathbb{H}_m.$$

Let $\mathcal{A} : \mathbb{H} \mapsto \mathbb{H}$ be a linear, self-adjoint, bounded, and positive definite operator and let

$$(u, v)_{\mathcal{A}} = (\mathcal{A}u, v) \quad \forall u, v \in \mathbb{H}.$$

We denote by P_i, $i = 1, \ldots, m$, the orthogonal projection operators from $\mathbb{H}$ onto $\mathbb{H}_i$ with respect to the scalar product $(\cdot, \cdot)_{\mathcal{A}}$. We assume that for any $u \in \mathbb{H}$ there exists a decomposition $u = u_1 + \cdots + u_m$ such that

$$c_1 \sum_{i=1}^{m} (u_i, u_i)_{\mathcal{A}} \leq (u, u)_{\mathcal{A}} \tag{4.1}$$

with a positive constant c_1. Moreover, let c_2 be some positive constant such that

$$\sum_{i=1}^{m} (P_i u, u)_{\mathcal{A}} \leq c_2 \, (u, u)_{\mathcal{A}} \quad \forall u \in \mathbb{H}. \tag{4.2}$$

Also, let $\mathcal{B}_i : \mathbb{H}_i \mapsto \mathbb{H}_i$, $i = 1, \ldots, m$, be some self-adjoint and surjective operators such that

$$c_3 \, (\mathcal{B}_i u_i, u_i) \leq (\mathcal{A} P_i u_i, P_i u_i) \leq c_4 \, (\mathcal{B}_i u_i, u_i) \quad \forall u_i \in \mathbb{H}_i, \; i = 1, \ldots, m. \tag{4.3}$$

Let $\mathcal{B}^{-1} = \mathcal{B}_1^{+} + \cdots + \mathcal{B}_m^{+}$, where $\mathcal{B}_i^{+}$ denotes the pseudoinverse operator of $\mathcal{B}_i$. Then

$$c_1 c_3 \left(\mathcal{A}^{-1} u, u\right) \leq \left(\mathcal{B}^{-1} u, u\right) \leq c_2 c_4 \left(\mathcal{A}^{-1} u, u\right) \quad \forall u \in \mathbb{H}.$$

Proof. The proof can be found in [16]. ∎

The second result is a technical result for some overlapping preconditioners, in which the domain is split into stripes as displayed in Figure 3.1. First, let us introduce some notation which is similar to the notation in Figure 3.1.

- Let

  $$\overline{\Omega} = \bigcup_{j=0}^{k-1} \overline{\Omega}_j$$

  be a domain Ω which is decomposed into stripes Ω_i, i.e.,

  $$\Omega_i \cap \Omega_j = \emptyset \quad \text{for } i \neq j, \quad \overline{\Omega}_i \cap \overline{\Omega}_j = \begin{cases} \Gamma_i, & i = j + 1, \\ \Gamma_j, & i = j - 1, \\ \overline{\Omega}_i, & i = j, \\ \emptyset, & |i - j| \geq 2, \end{cases}$$

  and let $\overline{\Omega}_{k-1} \cap \partial\Omega = \Gamma_k$.
- Let τ_k be a triangulation of Ω which is admissible to the decomposition of Ω into Ω_i.
- Let $\Phi_k = [\phi_i]_{i=1}^{N}$ be the basis of hat-functions according to the triangulation τ_k and let $\mathbb{V}_k = \text{span}\Phi_k$ be the corresponding finite element space.
- Let $a(\cdot, \cdot) : \mathbb{V}_k \times \mathbb{V}_k \mapsto \mathbb{R}$ be a symmetric and positive definite bilinear form and let

  $$\|u\|_{a,\Omega} = a(u, u)$$

  be the energetic norm. In the same way, let

  $$\|u\|_{a,\tilde{\Omega}} = a \mid_{\tilde{\Omega}} (u, u)$$

  be the restriction of the norm onto some subdomain $\tilde{\Omega} \subset \Omega$.

- For $j = 0, \ldots, k-2$, let $\mathbb{Y}_j = \{u \in \mathbb{V}_k : \text{supp } u \subset \overline{\Omega}_j \cup \overline{\Omega}_{j+1}\}$ be the restriction of the finite element space $\mathbb{V}_k$ onto $\overline{\Omega}_j \cup \overline{\Omega}_{j+1}$ with Dirichlet boundary conditions at the boundaries Γ_j and Γ_{j+2}. For $j = k-1$, we set $\mathbb{Y}_{k-1} = \{u \in \mathbb{V}_k : \text{supp } u \subset \overline{\Omega}_{k-1}\}$.
- Let

$$\|w\|^2_{\Gamma_j,\text{left}} = \min_{\substack{u\in\mathbb{V}_k \\ u|_{\Gamma_j}=w \\ u|_{\Gamma_{j+1}}=0}} \|u\|^2_{a,\Omega_j} \quad \text{and} \tag{4.4}$$

$$\|w\|^2_{\Gamma_j,\text{right}} = \min_{\substack{u\in\mathbb{V}_k \\ u|_{\Gamma_j}=w \\ u|_{\Gamma_{j-1}}=0}} \|u\|^2_{a,\Omega_{j-1}}$$

  be the left and right trace norms on Γ_j.
- Let $\mathcal{T}_{j,\text{left}} : \mathbb{V}_k\,|_{\Gamma_j} \mapsto \mathbb{V}_k\,|_{\Omega_j}$ and $\mathcal{T}_{j,\text{right}} : \mathbb{V}_k\,|_{\Gamma_j} \mapsto \mathbb{V}_k\,|_{\Omega_{j-1}}$ be the minimal energetic extension operators from Γ_j to Ω_j and Ω_{j-1}, i.e.,

$$\|w\|_{\Gamma_j,\text{left}} = \|\mathcal{T}_{j,\text{left}} w\|_{a,\Omega_j} \quad \text{and} \quad \|w\|_{\Gamma_j,\text{right}} = \|\mathcal{T}_{j,\text{right}} w\|_{a,\Omega_{j-1}}.$$

THEOREM 4.2. *In addition to the above assumptions, let us assume that there exists an integer j_0 such that the following hold:*

- *There exists a constant $\gamma < 1$, which is independent of the discretization parameter and j, such that*

$$a(\mathcal{T}_{j,\text{left}} u, \mathcal{T}_{j+1,\text{right}} v) \le \gamma \|u\|_{\Gamma_j,\text{left}} \|v\|_{u,\Gamma_{j+1},\text{right}} \quad \forall j = 0, \ldots, j_0,\ \ \forall u \in \mathbb{Y}_j\,|_{\Gamma_j},\ \forall v \in \mathbb{Y}_{j+1}\,|_{\Gamma_{j+1}}. \tag{4.5}$$

- *There exists a constant $q_0 < 1$ and a constant c_2, which are independent of j and the discretization parameter, such that*

$$q_0^{-1} \|w\|^2_{\Gamma_j,\text{left}} \le \|w\|^2_{\Gamma_j,\text{right}} \le c_2 \|w\|^2_{\Gamma_j,\text{left}} \quad \forall w, \quad j = j_0. \tag{4.6}$$

- *There exists a constant c_1, which is independent of the discretization parameter, such that*

$$c_1^{-1} \|w\|^2_{\Gamma_j,\text{left}} \le \|w\|^2_{\Gamma_j,\text{right}} \le c_2 \|w\|^2_{\Gamma_j,\text{left}} \quad \forall w, \quad \forall j = j_0+1, \ldots, k-1. \tag{4.7}$$

Then there exists a decomposition $u = \sum_{j=0}^{k-1} u_j$ with $u_j \in \mathbb{Y}_j$ such that

$$c_L^2 \sum_{j=0}^{k-1} a(u_j, u_j) \le a(u,u) \quad \forall u \in \mathbb{V}_k.$$

The constant $c_L > 0$ depends only on γ, c_1, c_2, and q_0. Moreover, for all decompositions of $u = \sum_{j=0}^{k-1} u_j$ with $u_j \in \mathbb{Y}_j$, the estimate

$$a(u,u) \le\ 2 \sum_{j=0}^{k-1} a(u_j, u_j) \quad \forall u \in \mathbb{V}_k$$

holds.

Proof. The proof can be found in [4]. ∎

Next, we construct a bilinear form $a_p(\cdot,\cdot)$ with piecewise constant coefficients which is spectrally equivalent to the original bilinear form $a(\cdot,\cdot)$; cf. (2.1). This idea has originally been developed in [12]. For $i = 1, 2$, let

$$\chi_i^2(\xi) = \varepsilon_{i,j}, \quad \xi \in (2^{-j-1}, 2^{-j}) \quad \text{with} \quad \varepsilon_{i,j} := \omega_i^2(2^{-j}) \tag{4.8}$$

be a piecewise constant coefficient function and let

$$a_p(u,v) := \int_\Omega (\nabla v)^T \begin{bmatrix} \chi_1^2(y) & 0 \\ 0 & \chi_2^2(x) \end{bmatrix} \nabla u \tag{4.9}$$

be the corresponding bilinear form. Moreover, we define the energetic norm

$$\|u\|_p^2 := a_p(u,u) \quad \forall u \in \mathbb{V}_k \tag{4.10}$$

with respect to the bilinear form $a_p(\cdot,\cdot)$. The stiffness matrix with respect to the basis Φ_k is denoted by $K_{k,p}$, i.e.,

$$K_{k,p} = [a_p(\phi_{il}, \phi_{i'l'})]_{(i,i'),(l,l')=(1,1)}^{n_0,n_0}. \tag{4.11}$$

LEMMA 4.3. *Let us assume that the weight functions ω_i, $i = 1, 2$, satisfy Assumption* 2.1. *Then we have*

$$a(u,u) \le a_p(u,u) \le 2c_\omega^2\, a(u,u) \quad \forall u \in \mathbb{V}_k.$$

The constant c_ω is from (2.2).

Proof. The proof is similar to the proof of Lemma 4.3 in [4]. ∎

Remark 4.4.

- In the case of the weight function $\omega_i^2(\xi) = \xi^\alpha$ with $\alpha > 0$, we have $c_\omega^2 = 2^\alpha$.
- A direct consequence of (2.4), (4.11), and Lemma 4.3 is the spectral equivalence estimate

$$\frac{1}{2} c_\omega^{-2} K_{k,p} \le K_k \le K_{k,p}.$$

4.2. Some estimates for tridiagonal matrices. Finally, some estimates for tridiagonal matrices with constant main and subdiagonals are required. For a fixed integer m and some positive parameter κ, we introduce

$$F_m = \begin{bmatrix} 2+\kappa & -1 & & & 0 \\ -1 & 2+\kappa & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2+\kappa & -1 \\ 0 & & & -1 & 2+\kappa \end{bmatrix} \in \mathbb{R}^{m-1\times m-1},$$

$$\tilde{F}_m = \begin{bmatrix} 1+\frac{\kappa}{2} & e_1^T \\ e_1 & F_m \end{bmatrix} \in \mathbb{R}^{m\times m}, e_1 = (1,0,\ldots,0)^T \in \mathbb{R}^{m-1\times 1}, \tag{4.12}$$

and the real number

$$q = 1 + \frac{\kappa}{2} + \frac{1}{2}\sqrt{\kappa(\kappa+4)}. \tag{4.13}$$

We prove the following lemma.

LEMMA 4.5. *Let F_m and $\tilde{F}_m$ be defined via* (4.12). *Then the following assertions are valid:*

- *The determinant of F_m satisfies the equation*

$$\det F_{m+1} = \frac{q^{m+2} - q^{-m}}{q^2 - 1} = q^{-m} \sum_{i=0}^{m} q^{2i}. \tag{4.14}$$

- *Let $s_m = 1 + \frac{\kappa}{2} - e_1^T F_m^{-1} e_1$ be the Schur complement of $\tilde{F}_m$ with respect to the first row and column. Then*

$$s_m = \frac{\kappa}{2} + \frac{1 + q^{2m-1}}{1 + q + \cdots + q^{2m-1}}. \tag{4.15}$$

Moreover, the estimate

$$\frac{\kappa}{2} + \frac{1}{m} \leq s_m \leq \frac{\kappa}{2} + \frac{1}{m} \frac{1 + q^{2m-1}}{2\sqrt{q^{2m-1}}} \tag{4.16}$$

holds.

- *Let $\hat{s}_m = e_1^T F_m^{-1} e_m$, $e_m = (0, \ldots, 0, 1)^T$. Then*

$$|\hat{s}_m| = \frac{1}{\det F_{m-1}}. \tag{4.17}$$

- *Let $\gamma_m = \frac{|\hat{s}_m|}{s_m}$. Then*

$$\gamma_m \leq \frac{2}{q^{m-1}}. \tag{4.18}$$

Proof. Relation (4.14) is a consequence of the following recursion:

$$\begin{aligned} \det F_m &= (2 + \kappa) \det F_{m-1} - \det F_{m-2}, \\ \det F_0 &= 1, \ \det F_1 = 2 + \kappa. \end{aligned}$$

The solution of this linear recursion of second order gives the first assertion. The second relation follows from the first one by the geometric series

$$1 + q^2 + \cdots + q^{2m} = \frac{q^{2m+2} - 1}{q^2 - 1}.$$

To prove relation (4.15), we compute the Schur complement by using Cramer's rule and (4.14) explicitly. Since

$$e_1^T F_M^{-1} e_1 = (F_m^{-1})_{(1,1)} = \frac{\det F_{m-1}}{\det F_m},$$

we conclude

$$s_m = \frac{\kappa}{2} + \frac{\det F_m - \det F_{m-1}}{\det F_m}.$$

We simplify the second summand with (4.14) and obtain

$$\det F_m - \det F_{m-1} = q^{-m+1} \sum_{i=0}^{2m-2} (-q)^i = q^{-m+1} \frac{q^{2m-1} + 1}{1 + q}. \tag{4.19}$$

Hence,

$$\frac{\det F_m - \det F_{m-1}}{\det F_m} = \frac{1+q^{2m-1}}{1+q+\cdots+q^{2m-1}}, \tag{4.20}$$

which proves (4.15). To prove (4.16), we start from (4.15) and use the convexity of the function $f:(1,\infty)\mapsto\mathbb{R}$ given by $f(x)=q^x$ for $q>1$. Then we have

$$\begin{aligned} 1+q^{2m-1} &\geq q+q^{2m-2},\\ 1+q^{2m-1} &\geq q^2+q^{2m-3},\\ &\vdots \quad \vdots\\ 1+q^{2m-1} &\geq q^{m-1}+q^m. \end{aligned}$$

Summing up over all inequalities yields

$$\frac{1+q^{2m-1}}{1+q+\cdots+q^{2m-1}} \geq \frac{1}{m},$$

which proves the lower estimate. For the upper estimate, the inequality of the mean values between arithmetical and geometrical means is used. Then we have

$$1+q+\cdots+q^{2m-1} \geq 2m\sqrt[2m]{q\cdot q^2\cdot\ldots\cdot q^{2m-1}} = 2m\sqrt{q^{2m-1}}.$$

This proves the lower estimate of (4.16).

The proof of (4.17) is similar to the proof of (4.15).

For the proof of (4.18), we use relations (4.15), (4.17) and equation (4.19). We obtain

$$\gamma_m = \frac{|\hat{s}_m|}{s_m} \leq \frac{1}{\det F_m - \det F_{m-1}} = \frac{q^{m-1}(1+q)}{q^{2m-1}+1} \leq \frac{1+q}{qq^{m-1}}.$$

Since $\frac{1+q}{q}\leq 2$ for $q\geq 1$, the assertion (4.18) follows, which proves the lemma. ∎

The next lemma gives some asymptotic estimates for the Schur complement s_m and the constant γ_m.

LEMMA 4.6.

- *Let $m\geq\max\{\frac{1}{\sqrt{\kappa}},2\}$. Then we have*

$$\gamma_m < \frac{20}{21}. \tag{4.21}$$

- *Let $2\leq m\leq\frac{1}{\sqrt{\kappa}}$ and $m\in\mathbb{N}$. Then the estimate*

$$\frac{1}{m} \leq s_m \leq \frac{9}{5}\frac{1}{m} \tag{4.22}$$

is valid.

Proof. To prove the first assertion, we use (4.13) and obtain

$$q^{m-1} = \left(1+\frac{\kappa}{2}+\frac{1}{2}\sqrt{\kappa(\kappa+4)}\right)^{m-1} \geq \left(1+\frac{\kappa}{2}+\sqrt{\kappa}\right)^{m-1}.$$

With $m \geq \frac{1}{\sqrt{\kappa}}$, we can conclude that

$$q^{m-1} \geq \left(1 + \frac{1}{2m^2} + \frac{1}{m}\right)^{m-1}.$$

The series $\{a_m\}_m$ given by $a_m = (1 + \frac{1}{2m^2} + \frac{1}{m})^{m-1}$ is monotonically increasing and satisfies $\lim_{m\to\infty} a_m = e$. Moreover, $a_m \geq \frac{21}{10}$ for $m \geq 4$. This gives

$$q^{m-1} \geq \frac{21}{10}.$$

Using (4.18), the assertion follows for $m \geq 4$. The case $m = 2$ implies that $\kappa \geq \frac{1}{4}$ and $q \geq \frac{13}{8}$. A direct computation shows

$$\gamma_2 \leq \frac{5}{6} < \frac{20}{21}.$$

A similar proof can be given for $m = 3$.

To prove the second assertion, we start with $\kappa < m^{-2}$. With the arguments we used above, we have

$$q^{2m-1} \leq \left(1 + \frac{1}{2m^2} + \frac{1}{m}\right)^{2m-1} \leq e^2.$$

Moreover, the function $f : [1, \infty) \mapsto \mathbb{R}$ given by

$$f(x) = \frac{1+x}{\sqrt{x}} = \left(\sqrt[4]{x} - \frac{1}{\sqrt[4]{x}}\right)^2 - 2$$

is monotonically increasing for $x \geq 1$. Hence, we can estimate

$$\frac{1 + q^{2m-1}}{\sqrt{q^{2m-1}}} \leq \frac{1 + e^2}{e}.$$

Now, we insert this estimate into (4.16) and can conclude that

$$\frac{1}{m} \leq s_m \leq \frac{\kappa}{2} + \frac{1}{m}\frac{1 + q^{2m-1}}{2\sqrt{q^{2m-1}}} \leq \frac{1}{m}\left(\frac{1}{2m} + \frac{1 + e^2}{2e}\right) \leq \frac{1}{m}\left(\frac{1}{4} + \frac{31}{20}\right) = \frac{9}{5m}.$$

This proves the lemma. ∎

5. Condition number estimates. In this section, we prove the central theorems of this paper. The proofs exploit the tensor product structure of the problems and use some auxiliary results from the one-dimensional case. The results for the one-dimensional case are presented in subsection 5.1. The proofs of Theorems 3.1, 3.2, and 3.3 are presented in subsections 5.2, 5.3, and 5.4, respectively.

5.1. Some one-dimensional auxiliary results. In this subsection, we prove some auxiliary results for the corresponding one-dimensional case. We start with the definition of a corresponding bilinear form and discretization matrices.

For $n = 2^k$ and $i = 1, 2$, let $I_{n-1} \in \mathbb{R}^{n-1\times n-1}$,

$$T_{n-1} = \begin{bmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ & & & -1 & 2 \end{bmatrix} \in \mathbb{R}^{n-1\times n-1} \quad \text{and} \tag{5.1}$$

$$M_{\omega_i} = \operatorname{diag}(d_s)_{s=1}^{n-1} \quad \text{with} \quad d_s = \begin{cases} \varepsilon_{i,j} & \text{if} \quad 2^{k-j-1} < s < 2^{k-j}, \\ \frac{1}{2}(\varepsilon_{i,j} + \varepsilon_{i,j-1}) & \text{if} \quad 2^{k-j} = s, \end{cases} \tag{5.2}$$

be the identity, the unweighted Laplacian in one dimension, and a scaled weighted mass matrix with piecewise constant coefficients, respectively. The coefficients $\varepsilon_{i,j}$ are defined via (4.8).

Since T_{n_0} is the one-dimensional Laplacian, we introduce linear finite elements on the equidistant mesh $\mathcal{M}_n = \bigcup_{s=0}^{n-1} \tau_s^n$, where $\tau_s^n = \left(\frac{s}{n}, \frac{s+1}{n}\right)$. The one-dimensional hat-functions on this mesh,

$$\phi_s^n(x) = \begin{cases} nx - (s-1) & \text{on } \tau_{s-1}^n, \\ (s+1) - nx & \text{on } \tau_s^n, \\ 0 & \text{otherwise,} \end{cases} \qquad s = 1, \dots, n-1, \tag{5.3}$$

are a basis of the finite element space $\mathbb{X}_n = \operatorname{span}[\phi_s^n]_{s=1}^{n-1} = \operatorname{span}[\Phi_1]$. Let $\lambda > 0$. Then the matrix $T_{n-1} + \lambda M_{\omega_i}$ defines a coercive bilinear form $a_1(\cdot,\cdot)$ on $\mathbb{X}_n$, i.e.,

$$\underline{u}^T (T_{n-1} + \lambda M_{\omega_i}) \underline{v} = a_1([\Phi_1]\underline{u}, [\Phi_1]\underline{v}) := \frac{1}{n} \int_0^1 u'(x) v'(x)\, \mathrm{d}x + \sum_{s=1}^{n-1} \rho_{i,s} u\left(\frac{s}{n}\right) v\left(\frac{s}{n}\right) \tag{5.4}$$

with $\rho_{i,s} = \frac{1}{2}\lambda(\chi_i^2|_{\tau_{s-1}^n} + \chi_i^2|_{\tau_s^n})$, $i = 1, 2$. Due to the symmetry and positive definiteness of the matrix $T_{n-1} + \lambda M_{\omega_i}$, the bilinear form $a_1(\cdot,\cdot)$ is symmetric and coercive.

For $j = 0, \dots, k-2$, let $\Omega_j = \left(2^{-j-1}, 2^{-j}\right)$ and $\Omega_{k-1} = (0, 2^{k-1})$. Moreover, we introduce

$$\begin{aligned} \tilde{\mathbb{W}}_j &= \operatorname{span}\{\phi_i^n\}_{i=n_{j+1}+2}^{n_j}, \quad j = 0, \dots, k-1, \quad \text{and} \\ \mathbb{W}_j &= \operatorname{span}\{\phi_i^n\}_{i=n_{j+2}+2}^{n_j}, \quad j = 0, \dots, k-2, \quad \mathbb{W}_{k-1} = \tilde{\mathbb{W}}_{k-1}, \end{aligned}$$

where n_j is defined in subsection 3.1. Due to this definition, the spaces $\mathbb{W}_j$ and $\tilde{\mathbb{W}}_j$ are formed by those finite element functions of $\mathbb{X}_n$ which have support inside $\overline{\Omega_{j+1,x}} \cup \overline{\Omega_{j,x}}$ and $\overline{\Omega_{j,x}}$, respectively.

LEMMA 5.1. *There exists a decomposition $u = \sum_{j=0}^{k-1} u_j$ with $u_j \in \mathbb{W}_j$ such that*

$$a_1(u,u) \geq c^2 \sum_{j=0}^{k-1} a_1(u_j, u_j) \quad \forall u \in \mathbb{X}_n.$$

The constant $c^2 > 0$ does not depend on n and ρ_i.

Proof. We adapt the notation of Theorem 4.2, i.e., let $\Gamma_{j+1} = \overline{\Omega}_{j+1} \cup \overline{\Omega}_j$ and

$$\|w\|^2_{\Gamma_j,\text{left}} = \min_{\substack{u\in\mathbb{X}_n \\ u|_{\Gamma_j}=w \\ u|_{\Gamma_{j+1}}=0}} \|u\|^2_{a_1,\Omega_j} \quad \text{and} \quad \|w\|^2_{\Gamma_j,\text{right}} = \min_{\substack{u\in\mathbb{X}_n \\ u|_{\Gamma_j}=w \\ u|_{\Gamma_{j-1}}=0}} \|u\|^2_{a_1,\Omega_{j-1}} \tag{5.5}$$

be the left and right trace norms on Γ_j. Moreover, the minimal energy extension operators with respect to $a_1(\cdot,\cdot)$ from Γ_j to Ω_j and Ω_{j-1} are denoted by $\mathcal{T}_{j,\text{left}}$ and $\mathcal{T}_{j,\text{right}}$, respectively. Since the coefficients of the bilinear form $a_1(\cdot,\cdot)$ are constant on Ω_j and the discretization is symmetric with respect to the left and right boundaries, we have

$$\|w\|^2_{\Gamma_j,\text{left}} = \|w\|^2_{\Gamma_{j+1},\text{right}} \quad \forall w \in \mathbb{R} \tag{5.6}$$

for which the minima in (5.5) are achieved.

We now fix a stripe Ω_j. A simple computation shows

$$\left[a_1\left|_{\Omega_j}(\phi^n_l, \phi^n_{l'})\right]^{n_j}_{l,l'=n_{j+1}+2} = T_{m_j-1} + \kappa_{i,j} I_{m_j-1}, \quad i = 1,2, \tag{5.7}$$

with $m_j = 2^{k-j-1}$ and $\kappa_{i,j} = \varepsilon_{i,j}\lambda$; i.e., this matrix has the structure of the matrix F_m (4.12) with $m = m_j$ and $\kappa = \kappa_{i,j}$, $i = 1,2$. So, it is possible to apply the results about the matrix F_m. Due to the properties of the Schur complement, we have

$$\|w\|^2_{\Gamma_j,\text{left}} = \|w\|^2_{\Gamma_{j+1},\text{right}} = w^2 s_{m_j} \quad \forall w \in \mathbb{R} \tag{5.8}$$

with s_{m_j} defined via (4.15). A simple computation shows

$$a_1(\mathcal{T}_{j,\text{left}} u, \mathcal{T}_{j+1,\text{right}} v) = u \hat{s}_{m_j} v \quad \forall u, v \in \mathbb{R} \tag{5.9}$$

with $\hat{s}_{m_j}$ of (4.17). Hence, we can conclude that

$$\gamma^2_{m_j} = \max_{\substack{u,v\in\mathbb{R}\\ u,v\neq 0}} \frac{a_1(\mathcal{T}_{j,\text{left}} u, \mathcal{T}_{j+1,\text{right}} v)}{\|u\|_{\Gamma_j,\text{left}} \|v\|_{\Gamma_{j+1},\text{right}}} = \frac{\hat{s}_{m_j}}{s_{m_j}}. \tag{5.10}$$

The series $\{m_j\}_{j=0}^{k-1}$ is monotonically decreasing by definition. The series $\{\kappa_{i,j}\}_{j=0}^{k-1}$ is monotonically decreasing by Assumption 2.1. Hence, the series $\{m_j \kappa^2_{i,j}\}_{j=0}^{k-1}$ is monotonically decreasing, too. Consequently, there exists a number $j_0 \in \{-1, 0, \ldots, k\}$ such that

$$m_j \geq \kappa^{-2}_{i,j} \quad \forall j \leq j_0 \quad \text{and} \quad m_j \leq \kappa^{-2}_{i,j} \quad \forall j > j_0, i = 1,2. \tag{5.11}$$

Now, we verify the assumptions of Theorem 4.2. Using (5.10) and (4.21), we have

$$\gamma^2_{m_j} \leq \frac{20}{21} \quad \text{for} \quad j < j_0.$$

This gives (4.5). Using (5.8) and (4.22), the lower estimate in (4.7) follows with

$$q = \frac{9}{10} < 1 \quad \text{for} \quad j > j_0.$$

The estimates (4.6) and the upper estimate in (4.7) are a consequence of Assumption 2.1; i.e., the weight function before the mass matrix does not vary too much on two neighboring stripes. Using Theorem 4.2, the assertion follows. ∎

We now define an overlapping preconditioner of the type (3.6), (3.9) for the matrix

$$A_\lambda = \lambda M_{\omega_i} + T_{n_0}, \quad \lambda > 0. \tag{5.12}$$

First, we have to introduce some auxiliary matrices. For $j = 0, \dots, k-2$, let

$$M_{i,j} = \begin{bmatrix} \mathbf{0}_{n_{j+2}+1} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & \varepsilon_{i,j} I_{n_j - n_{j+2}-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0}_{n_0 - n_j} \end{bmatrix} \in \mathbb{R}^{n_0 \times n_0},\ i = 1, 2,$$

$$T_{j,n_0} = \begin{bmatrix} \mathbf{0}_{n_{j+2}+1} & \mathbf{0} & \mathbf{0} \\ \mathbf{0} & T_{n_j - n_{j+2}-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} & \mathbf{0}_{n_0 - n_j} \end{bmatrix} \in \mathbb{R}^{n_0 \times n_0},$$

where $\varepsilon_{i,j}$ is defined via (4.8). For $j = k-1$, we set

$$M_{i,k-1} = \begin{bmatrix} \varepsilon_{i,k-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0}_{n_0-1} \end{bmatrix} \in \mathbb{R}^{n_0 \times n_0},\ i = 1, 2, \quad T_{j,n_0} = \begin{bmatrix} 2 & \mathbf{0} \\ \mathbf{0} & \mathbf{0}_{n_0-1} \end{bmatrix} \in \mathbb{R}^{n_0 \times n_0}.$$

Now, we can define

$$C_1^{-1} = \sum_{j=0}^{k-1} (\lambda M_{i,j} + T_{j,n-1})^+ \tag{5.13}$$

as a preconditioner for A_λ. Now, we are able to formulate the final lemma.

LEMMA 5.2. *For $i = 1, 2$ and $\lambda > 0$, let A_λ and C_1 be defined via* (5.12) *and* (5.13)*, respectively. Then $c_1 C_1 \le A_\lambda \le c_2 C_1$. The constants do not depend on the structure of the weight functions ω_i or the parameter λ.*

Proof. We apply Lemma 4.1 with the bilinear form $(\cdot,\cdot)_{\mathcal{A}} = a_1(\cdot,\cdot)$ and verify the assumptions (4.1), (4.2), and (4.3). The space splitting implies $\beta = 2$ (cf. Theorem 4.2), which proves (4.2). Relation (4.1) follows from Lemma 5.1.

The bilinear form $a_1(\cdot,\cdot)$ (5.4) is the sum of two terms—a stiffness term and a mass term. The coefficient before the stiffness term is constant. The coefficient before the mass term is piecewise constant, i.e., $\varepsilon_{i,j}$ on Ω_j, $i = 1, 2$. Hence, the maximum of the coefficients on $\overline{\Omega}_j \cup \overline{\Omega}_{j+1}$ is $\varepsilon_{i,j}$, and the minimum is $\varepsilon_{i,j+1}$. In the preconditioner C_1 (5.13), the coefficient on $\overline{\Omega}_j \cup \overline{\Omega}_{j+1}$ is replaced by $\varepsilon_{i,j}$. Assumption 2.1 implies that the ratio of coefficients $\varepsilon_{i,j+1}^{-1}\varepsilon_{i,j}$ is bounded. This gives (4.3) and proves the lemma for the matrix C_1. ∎

5.2. The proof of Theorem 3.1. Now, we prove Theorem 3.1.

Proof. Due to Lemma 4.3, it suffices to show the result for the matrix $K_{k,p}$ (4.11). A simple computation shows that

$$K_{k,p} = T_{n_0} \otimes M_{\omega_2} + I_{n_0} \otimes T_{n_0},$$

where the matrices T_n and M_{ω_2} are defined via (5.1) and (5.2). Since the matrix T_{n_0} is symmetric and positive definite, we have

$$T_{n_0} = Q^T \Lambda Q \quad \text{with} \quad Q^T Q = I_{n_0},\ \Lambda = \operatorname{diag}[\lambda_i]_i, \quad \lambda_i > 0.$$

Hence,

$$\begin{aligned} K_{k,p} &= (Q^T \otimes I_{n_0})(\Lambda \otimes M_{\omega_2} + I_{n_0} \otimes T_{n_0})(Q \otimes I_{n_0}) \\ &= (Q^T \otimes I_{n_0})\operatorname{blockdiag}\left[\lambda_i M_{\omega_2} + T_{n_0}\right]_i (Q \otimes I_{n_0}). \end{aligned}$$

We now apply Lemma 5.2 and obtain

$$\begin{aligned}
K_{k,p}^{-1} &= (Q^T \otimes I_{n_0})\text{blockdiag}\left[(\lambda_i M_{\omega_2} + T_{n_0})^{-1}\right]_i (Q \otimes I_{n_0}) \\
&\sim (Q^T \otimes I_{n_0})\text{blockdiag}\left[\sum_{j=0}^{k-1}(\lambda_i M_j + T_{j,n_0})^+\right]_i (Q \otimes I_{n_0}) \\
&= (Q^T \otimes I_{n_0})\sum_{j=0}^{k-1}(\Lambda \otimes M_j + I_{n_0} \otimes T_{j,n_0})^+ (Q \otimes I_{n_0}) \\
&= \sum_{j=0}^{k-1}\left((Q^T \otimes I_{n_0})(\Lambda \otimes M_j + I_{n_0} \otimes T_{j,n_0})(Q \otimes I_{n_0})\right)^+ \\
&= \sum_{j=0}^{k-1}(T_{n_0} \otimes M_j + I_{n_0} \otimes T_{j,n_0})^+ = C_{mod}^{-1},
\end{aligned}$$

which proves the result. ∎

5.3. The proof of Theorem 3.2. The proof of Theorem 3.2 requires the following auxiliary result about block matrices.

LEMMA 5.3. *Let* $A = \left[\begin{smallmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{smallmatrix}\right]$ *be a symmetric positive definite matrix and* $C_0 = \left[\begin{smallmatrix} A_{11}^{-1} & \mathbf{0} \\ \mathbf{0} & \mathbf{0} \end{smallmatrix}\right]$. *Then we have* $C_0 \le A^{-1}$.

Proof. Since A is positive definite, A is nonsingular. The inverse of A can be expressed by

$$A^{-1} = \begin{bmatrix} A_{11}^{-1} + A_{11}^{-1}A_{12}S^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1}A_{21}A_{11}^{-1} & S^{-1} \end{bmatrix},$$

where $S = A_{22} - A_{21}A_{11}^{-1}A_{12}$ denotes the Schur complement. The matrix

$$A^{-1} - C_0 = \begin{bmatrix} A_{11}^{-1}A_{12}S^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}S^{-1} \\ -S^{-1}A_{21}A_{11}^{-1} & S^{-1} \end{bmatrix} = \begin{bmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{bmatrix}$$

is positive semidefinite since $B_{22} = S^{-1}$ is positive definite and $B_{11} - B_{12}B_{22}^{-1}B_{21} = \mathbf{0}$. This proves the lemma. ∎

Now, we are able to prove Theorem 3.2.

Proof. We start with the proof of the lower inequality. We apply Lemma 4.1 for the bilinear forms $(\cdot,\cdot)_{\mathcal{A}} = a(\cdot,\cdot)$ and $(\mathcal{B}_i\cdot,\cdot) = a_i(\cdot,\cdot)$, $i = 0,\dots,k-1$; see (3.1). We verify the assumptions $(\mathcal{A}P_iu_i, P_iu_i) \le c_4\,(\mathcal{B}_iu_i, u_i)$ (see (4.3)) and $\sum_{i=0}^{k-1}(P_iu,u)_{\mathcal{A}} \le c_2\,(u,u)_{\mathcal{A}}$ (see (4.2)) of this lemma. The monotonicity of the weight function gives $c_4 = 1$ in (4.3). The space splitting into k subspaces implies $c_2 = k$ in (4.2). Using Lemma 4.1, we have $C^{-1} \le kK_k^{-1}$, which proves the lower estimate.

To prove the upper estimate, we note that $C_j = \left[\begin{smallmatrix} * & \\ * & C_{j,mod}^{*} \end{smallmatrix}\right] > 0$; cf. the definition of the matrices C_j and $C_{j,mod}$ in (3.2) and (3.5), respectively. Lemma 5.3 implies $\Theta_{j,mod}^{+} \le \Theta_j^{+}$. Using (3.4) and (3.6), we conclude that $C_{mod}^{-1} \le C^{-1}$, or, equivalently, $C \le C_{mod}$. By Theorem 3.1, we obtain $C \le C_{mod} \preceq K_k$. ∎

5.4. The proof of Theorem 3.3.

Proof. As in the previous case, we use the tensor product structure of the stiffness matrices K_k and $K_{k,p}$ (4.11). Due to Lemma 4.3, it suffices to prove $B_{mod}^{-1} \sim K_{k,p}$. A simple computation shows that

$$K_{k,p} = T_{n_0} \otimes M_{\omega_2} + M_{\omega_1} \otimes T_{n_0};$$

see (5.1) and (5.2) for the definition of the involved matrices. Since M_{ω_1} and T_{n_0} are symmetric and positive definite matrices, we can conclude

$$M_{\omega_1}^{-1/2} T_{n_0} M_{\omega_1}^{-1/2} = \tilde{Q}^T \tilde{\Lambda} \tilde{Q} \quad \text{with} \quad \tilde{Q}^T \tilde{Q} = I_{n_0},\ \tilde{\Lambda} = \operatorname{diag}[\tilde{\lambda}_i]_i, \quad \tilde{\lambda}_i > 0.$$

This gives

$$\begin{aligned} K_{k,p} &= (M_{\omega_1}^{1/2} \tilde{Q} \otimes I_{n_0})(\tilde{\Lambda} \otimes M_{\omega_2} + I_{n_0} \otimes T_{n_0})(\tilde{Q}^T M_{\omega_1}^{1/2} \otimes I_{n_0}) \\ &= (M_{\omega_1}^{1/2} \tilde{Q} \otimes I_{n_0}) \operatorname{blockdiag} \left[\tilde{\lambda}_i M_{\omega_2} + T_{n_0} \right]_i (\tilde{Q}^T M_{\omega_1}^{1/2} \otimes I_{n_0}). \end{aligned}$$

Using Lemma 5.2, we can conclude

$$(\tilde{\lambda}_i M_{\omega_2} + T_{n_0})^{-1} \sim \sum_{j=0}^{k-1} (\tilde{\lambda}_i M_{2,j} + T_{j,n_0})^+.$$

Hence, we can proceed with the estimates

$$\begin{aligned} K_{k,p}^{-1} &\sim (M_{\omega_1}^{-1/2} \tilde{Q} \otimes I_{n_0}) \operatorname{blockdiag} \left[\sum_{j=0}^{k-1} (\tilde{\lambda}_i M_{2,j} + T_{j,n_0})^+ \right]_i (\tilde{Q}^T M_{\omega_1}^{-1/2} \otimes I_{n_0}) \\ &= (M_{\omega_1}^{-1/2} \tilde{Q} \otimes I_{n_0}) \left[\sum_{j=0}^{k-1} \tilde{\Lambda} \otimes M_{2,j} + I_{n_0} \otimes T_{j,n_0} \right] (\tilde{Q}^T M_{\omega_1}^{-1/2} \otimes I_{n_0}) \\ &= \sum_{j=0}^{k-1} (T_{n_0} \otimes M_{2,j} + M_{\omega_1} \otimes T_{j,n_0})^+ := \sum_{j=0}^{k-1} C_{3,j}^+. \end{aligned} \tag{5.14}$$

In a second step, we derive a preconditioner for $C_{3,j}$. With the same tensor product arguments as above, we obtain

$$C_{3,j}^+ \sim \sum_{j'=0}^{k-1} (T_{j',n_0} \otimes M_{2,j} + M_{1,j'} \otimes T_{j,n_0})^+ \tag{5.15}$$

uniformly for all $j = 0, \ldots, k-1$. Combining (5.14) and (5.15), we have

$$K_{k,p}^{-1} \sim \sum_{j=0}^{k-1} \sum_{j'=0}^{k-1} (T_{j',n_0} \otimes M_{2,j} + M_{1,j'} \otimes T_{j,n_0})^+ = B_{mod}^{-1},$$

which proves the result. ∎

6. Numerical experiments. In this section, we present some numerical experiments.

6.1. The case $\omega_1(\xi) = 1$. In a first experiment, we investigate the preconditioner C (3.4). Figure 6.1 displays the maximal and minimal eigenvalues of the matrix $C^{-1}K_{k,p}$ for different weight functions. The minimal eigenvalue of the matrix $C^{-1}K_{k,p}$ is bounded from below by a positive constant for all types of investigated weight functions. The constants are very close to 1. The maximal eigenvalue is about k on level k.

In a second experiment, we investigate the preconditioner C_{mod} (3.6). In comparison to the first preconditioner, this preconditioner is optimal. Figure 6.2 displays

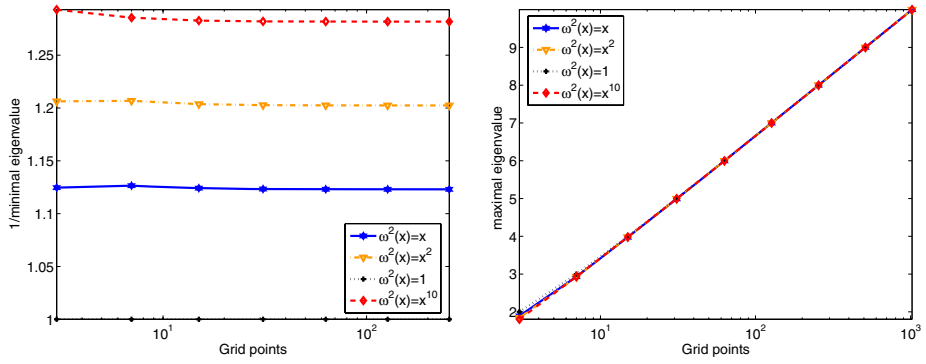

FIG. 6.1. *Eigenvalue bounds with the preconditioner* (3.4): *minimal eigenvalue (left), maximal eigenvalue (right).*

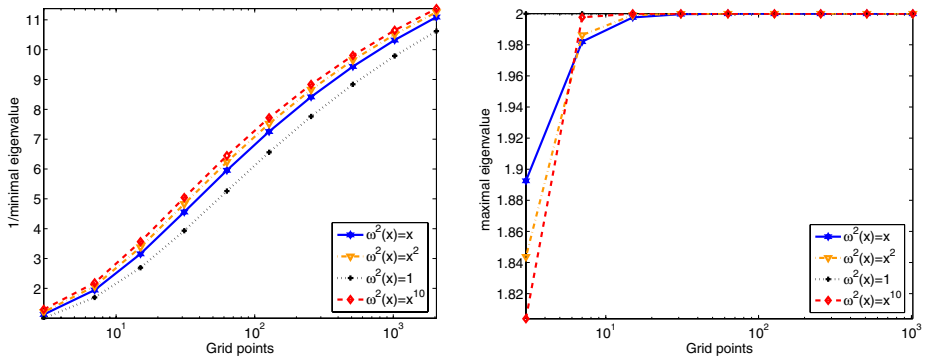

FIG. 6.2. *Eigenvalue bounds with the modified preconditioner* (3.6): *minimal eigenvalue (left), maximal eigenvalue (right).*

the maximal and minimal eigenvalues for the matrix $C_{mod}^{-1}K_{k,p}$ with the modified preconditioner (3.6) for different weight functions. The minimal eigenvalue of the matrix $C_{mod}^{-1}K_{k,p}$ is bounded from below by a positive constant for all types of investigated weight functions. The maximal eigenvalue is bounded from above by a constant of 2. The asymptotically optimal behavior can be seen only for relatively high level numbers. Thus, the condition number of $C^{-1}K_{k,p}$ is lower for $k \leq 10$ than the condition number of $C_{mod}^{-1}K_{k,p}$, although the condition number of $C_{mod}^{-1}K_{k,p}$ grows logarithmically, whereas the condition number of $C^{-1}K_{k,p}$ is bounded.

Finally, we investigated the preconditioners for the matrix K_k. The results for the minimal eigenvalue of the matrices $C^{-1}K_k$ and $C_{mod}^{-1}K_k$ are displayed in Figure 6.3, left and right panels, respectively. For the maximal eigenvalues, the results are the same as for the matrix K_k; i.e., the maximal eigenvalue of the matrix $C^{-1}K_k$ is about k, whereas the maximal eigenvalue of the matrix $C_{mod}^{-1}K_k$ is about 2.

Considering the minimal eigenvalue, the results are different. The results for the matrix $C_{mod}^{-1}K_k$ are comparable with the results for the matrix $C_{mod}^{-1}K_{k,p}$ if the weight function is not $\omega_2^2(\xi) = \xi^{10}$. Then an additional factor of about 2.5 can be seen. The minimal eigenvalue $C^{-1}K_k$ has the expected (pessimistic) additional factor of $2 \cdot 2^{\alpha}$ of Lemma 4.3 compared with the minimal eigenvalue $C^{-1}K_{k,p}$. Summarizing, the preconditioner C_{mod} (3.6) should be preferred for the matrix K_k with a weight function $\omega_2^2(\xi) = \xi^{\alpha}$, $\alpha > 1$.

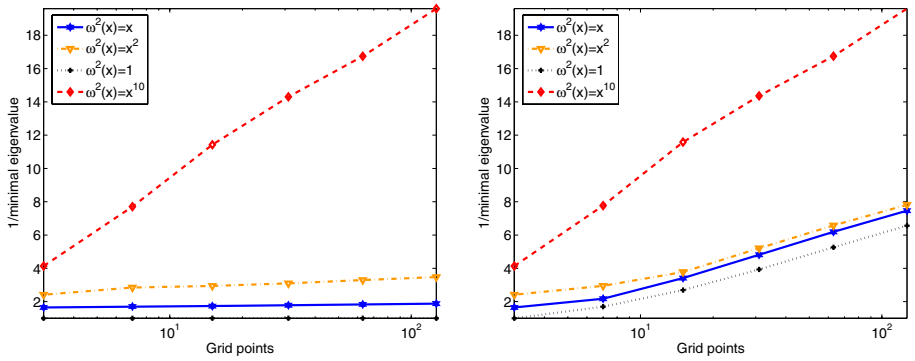

FIG. 6.3. *Minimal eigenvalue of the matrix $C^{-1}K_k$ (left) and minimal eigenvalue of the matrix $C_{mod}^{-1}K_k$ (right).*

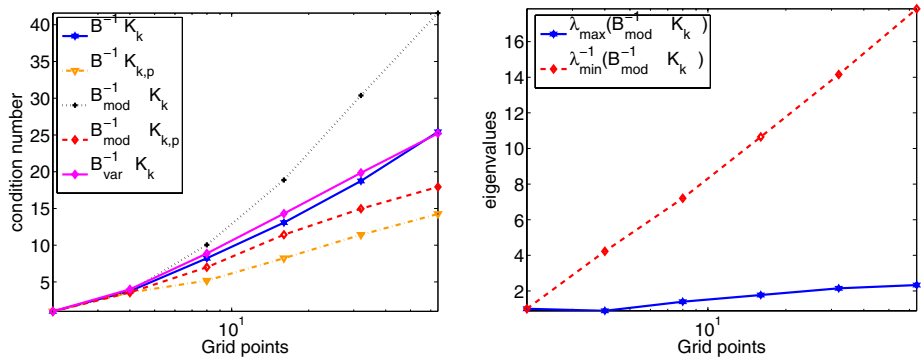

FIG. 6.4. *Condition numbers for the general case (left), eigenvalue bounds for $B_{mod}^{-1}K_k$ (right).*

6.2. The general case. In this subsection, we consider the systems

$$K_k\underline{u} = \underline{f} \quad \text{and} \quad K_{k,p}\underline{u} = \underline{f}.$$

In all experiments, we choose the weight functions $\omega_i^2(\xi) = \xi^2$, $i = 1, 2$. Figure 6.4 displays the condition number of $\mathcal{C}^{-1}K$ for five combinations of $\mathcal{C} = \{B, B_{mod}, B_{var}\}$ and $K = \{K_k, K_{k,p}\}$. The best results are obtained for the matrix $K_{k,p}$ with a piecewise constant coefficient function. Then the condition number is moderately increasing for both preconditioners. For the matrix K_k with the smooth coefficient function, the results are not as good as in the previous case if we take a preconditioner with constant coefficients. The preconditioner with variable but smooth coefficients B_{var} of Remark 3.5 behaves better.

In particular for $B_{mod}^{-1}K_k$ (3.9), an additional factor of about 4 can be seen, which arises from the estimates of Lemma 4.3. The eigenvalue bounds of $B_{mod}^{-1}K_k$ and $B_{var}^{-1}K_k$ are similar to those for the preconditioner C_{mod} (3.6) (cf. Figures 6.3 and 6.2), where the asymptotics can be seen only for relatively high level numbers. Hence, the nonoptimal preconditioner B (3.7) should be preferred for moderate level numbers of $k = 5, 6, 7$.

Finally, we investigate the iterations of the PCG method with the preconditioner B (3.7). In all experiments, we have taken a randomly chosen right-hand side and a

TABLE 6.1
PCG iterations for the systems $K_k\underline{u} = \underline{f}$ and $K_{k,p}\underline{u} = \underline{f}$ with the preconditioner B (3.7).

Level	3	4	5	6	7	8	9	10
K_k	16	21	25	29	33	37	40	43
$K_{k,p}$	16	20	25	30	34	38	41	43

relative accuracy of 10^{-5}. The results for both systems are displayed in Table 6.1. From the results, a slight increase of the iteration numbers can be seen. Since this preconditioner is not optimal (cf. Theorem 3.4), the growth of the PCG numbers is not surprising. The PCG iterations are about the same for the matrix K_k with continuous weight function and the matrix $K_{k,p}$ with piecewise constant weight function.

7. Concluding remarks. We will conclude the paper with a remark about an application for the p-version of the FEM in three dimensions. Using the basis of the integrated Legendre polynomials $\{\hat{L}_i\}_{i=2}^{p}$, it has been proved in [3] that the element stiffness matrix for odd polynomial degree p with respect to the interior bubbles is spectrally equivalent to the matrix

$$\begin{aligned} K_{pv} &= P^T \text{blockdiag}\,[T_n \otimes T_n \otimes M_\omega + T_n \otimes M_\omega \otimes T_n + M_\omega \otimes T_n \otimes T_n]_{i=1}^{8}\, P \\ &=: P^T \text{blockdiag}\,[K_3]_{i=1}^{8}\, P, \end{aligned}$$

where T_n is the matrix (5.1) of dimension $\frac{p-1}{2}$, M_ω is the matrix (5.2) with the weight function $\omega^2(\xi) = \xi^2$, and P is a permutation matrix. In [5], an optimal solver for K_{pv} based on wavelets has been derived.

Another preconditioner C_3 for K_3 can be developed in the same way as for K_k in (3.9) and (3.7). With the same tensor product arguments as in the proof of Theorem 3.3 presented in subsection 5.4, the optimality of the estimate $C_3 \sim K_{3,k}$ is proved. Using a fast Fourier transform for the remaining problem, we obtain a second fast solver for the block of the interior bubbles in the p-version of the FEM using hexahedral elements.

SPECTRAL ANALYSIS OF NONSYMMETRIC QUASI-TOEPLITZ MATRICES WITH APPLICATIONS TO PRECONDITIONED MULTISTEP FORMULAS*

DANIELE BERTACCINI† AND FABIO DI BENEDETTO‡

Abstract. The eigenvalue spectrum of a class of nonsymmetric preconditioned matrices arising in time-dependent partial differential equations is analyzed and discussed. The matrices generated by the underlying numerical integrators are small rank perturbations of block Toeplitz matrices; circulant-like preconditioners based on the former are considered. The eigenvalue distribution of the preconditioned matrix influences often crucially the convergence of Krylov iterative accelerators. Due to several reasons (lack of symmetry, band structure, and coefficients depending on the size) the classical approach based on smooth generating functions gives very little insight here. Therefore, to characterize the eigenvalues, a *difference equation* approach exploiting the band Toeplitz and circulant patterns generalizing the well-known results of Trench is proposed.

Key words. circulant preconditioners, nonsymmetric Toeplitz matrices, eigenvalues, difference equations, linear systems of time-step integrators, linear multistep formulas, boundary value problems

1. Introduction.

In this paper we focus on small rank perturbations of block nonsymmetric Toeplitz matrices preconditioned by circulant approximations introduced in [3, 4, 7].

An $n \times n$ matrix $A_n = (a_{j,k})$ is said to be *Toeplitz* if $a_{j,k} = a_{j-k}$, $j, k = 1, \ldots, n$, i.e., A_n is constant along its diagonals, and quasi-Toeplitz if it is a small rank perturbation of a Toeplitz matrix. $\breve{A}_n$ is *circulant* if it is Toeplitz and its diagonals satisfy $\breve{a}_{n-j} = \breve{a}_{-j}$. The circulant matrices $\breve{A}_n$ are diagonalized by the Fourier matrix $F = (F_{j,k})$, $F_{j,k} = e^{2\pi \mathbf{i} jk/n}/\sqrt{n}$, $j, k = 0, \ldots, n-1$, and $\mathbf{i}$ is the imaginary unit; see [19]. Circulant matrices are easily and efficiently invertible using the fast Fourier transform (FFT), as in [16].

Perturbations of block nonsymmetric Toeplitz matrices arise in the numerical approximation of time-dependent partial differential equations (PDEs) by generalizations of implicit multistep formulas used in boundary value form [20, 1, 14]. The techniques considered here could be adapted to other discretization schemes based on finite differences for PDEs.

Other circulant-like matrices used in the PDE context can be found in [8].

As explained in section 2.1, the matrices of the underlying linear systems can be written as follows:

$$M = A \otimes I - h\, B \otimes J, \tag{1.1}$$

where A and B are $n \times n$ small rank perturbations of band Toeplitz matrices whose entries are given by the coefficients of the scheme involved, I is the identity, and J is an $m \times m$ matrix which can be large and sparse. More precisely, J is the Jacobian matrix of a system of equations discretized in space by finite differences; see [4] for details.

Unfortunately, when m and/or n are (even moderately) large, iterative solvers for (1.1), used without preconditioners or with general purpose preconditioners, such as those based on incomplete factorizations, often converge very slowly or not at all; see [4, section 5]. In general, direct methods cannot exploit the block structure of (1.1).

Preconditioners introduced in [4] take into account this structure. They are block-circulant and, in compact form, can be written as

$$P = \breve{A} \otimes I - h\, \breve{B} \otimes \tilde{J}, \tag{1.2}$$

where $\breve{A}$ and $\breve{B}$ are circulant-like approximations for A, B, respectively, and $\tilde{J}$ is a suitable approximation for J. Their performance has been tested in several papers [4, 5, 17].

The distribution of the eigenvalues of the matrices M and $P^{-1}M$ can influence the convergence of iterations of Krylov subspace methods. This is the case, e.g., if the condition number of the eigenvector matrix is moderate; see [22].

Tables of the condition number $\kappa_2(X)$ of the eigenvector matrix X for the (left) preconditioned matrix $P^{-1}M$ and related discussions can be found in [9], showing that eigenvalues can give reasonable information in our setting. Similar conclusions hold true for the nonpreconditioned case for most of the methods considered here. More details are reported in section 6.

A theoretical investigation of the eigenvalues is hard because, in general, P and M are nonsymmetric and nonsymmetrizable. Moreover, as explained in section 3 an analysis of the eigenvalues based on the generating function of the underlying Toeplitz matrices is not feasible here, although very meaningful for Hermitian matrices [16, 23].

These difficulties motivate us to a "direct" analysis, based on the generalized eigenvalue problem

$$M\, u = \lambda\, P\, u.$$

The tools used here are completely different from those in previous works such as [10], [7], or [25]. In particular, we cannot write $\breve{A}$, $\breve{B}$ as small rank perturbations of A, B.

By using instead linear difference equation theory and generalizing Trench's approach [33, 34], we derive closed formulas and first-order expansions for λ as a function of the time step h and of the eigenvalues of the Jacobian matrix J. This characterization involves the roots of a sparse polynomial whose degree is related to the size of A and B.

Our estimates are explicitly computed for some well-known 2-step integrators and compared with the "true" eigenvalues approximated by Matlab. The approach seems very useful for spectrum localization and is not too expensive provided that A and B have moderate size or an efficient rootfinder is associated with our technique.

The paper is organized as follows. Section 2 introduces the problem and the main circulant preconditioning techniques. In section 3 we discuss the relevant literature for spectral analysis, and we explain in more detail the motivation of our work. Section 4 is devoted to the spectral analysis, from the general case to the 2-step case study. In section 5 we describe two classical PDE examples, representing the test problems for our experiments of section 6.

2. Preliminaries. Let us consider a model problem based on a first-order initial-boundary value time-dependent partial differential equation

$$\begin{cases} \dfrac{\partial u}{\partial t} & = \mathcal{L}(u) + f, \quad x \in \mathbf{D}, \\ \mathcal{G}(u) & = g, \qquad\quad x \in \partial\mathbf{D}, \\ u & = u_0, \qquad\quad t = t_0, x \in \mathbf{D}, \end{cases} \tag{2.1}$$

where $\mathbf{D}$ is an open domain in $\mathbb{R}^N$, $N \geq 1$, and $\mathcal{L}$ is a differential operator, nonlinear in u in general. Equations (2.1) are *evolutionary* because they describe evolving phenomena and combine differentiation with respect to both space and time. For simplicity, we will focus on linear operators $\mathcal{L}$ and $\mathcal{G}$. However, most of the techniques considered here can be applied to a more general nonlinear framework by recalling that often numerical codes linearize the nonlinear algebraic equations by using a quasi-Newton step; see [21].

2.1. Linear multistep formulas in boundary value form. In the following, a brief description of a generalization of linear multistep formulas is given.

If the partial differential equation (2.1) is first discretized in space, we obtain a system of ordinary differential equations (ODEs). Such a system can be very large and is treated by means of a numerical method for ODEs.

Here we focus on linear multistep formulas applied in boundary value form (see [1, 14]), which generalize classical implicit linear multistep formulas by using both initial and boundary conditions even in the presence of an initial value problem. Such schemes have a relatively long history (see, e.g., [20, 1]) and can be very useful in some communities where "time" has no special orientation (see an example of these problems in the work by Shirley referred to in [26]).

More precisely, we suppose that (2.1), with solution $u(x,t)$, has been discretized in space on a certain grid Ω_τ, with mesh width $\tau > 0$, to yield a *semidiscrete* system

$$y'(t) = F(t, y(t)), \quad t_0 \leq t \leq t_s, \quad y(t_0) \text{ given}, \tag{2.2}$$

with $y(t) = (u_j(t))_{j=1}^m$, m being related to the number of grid points in space, and, for unidimensional spatial domain $\mathbf{D}$, i.e., $N = 1$ in (2.1), $u_j(t)$ approximates $u(x_j, t)$ at some x_j, $j = 1, \ldots, m$. The contribution of the discretized boundary conditions is enclosed in F. In order to approximate $u(x,t)$ on Ω_τ for $t = t_0, t_1, \ldots, t_s$, an appropriate temporal mesh, we apply an ODE method with step size $h > 0$.

Using the shortened notation $F_{n+i} = F(t_{n+i}, y_{n+i})$, $i = 0, \ldots, k$, if y_n approximates $y(t_n)$, linear multistep formulas in boundary value form are given by

$$\sum_{i=0}^{k} \alpha_i y_{n+i} = h \sum_{i=0}^{k} \beta_i F_{n+i}, \quad n = 0, \ldots, s-k, \tag{2.3}$$

where $y_0 = y(t_0)$ is provided by initial conditions of (2.1), while $y_1, \ldots, y_{\nu-1}$ and $y_{s-k+\nu+1}, \ldots, y_s$, computed at the mesh points $t_0, \ldots, t_{\nu-1}$, $t_{s-k+\nu+1}, \ldots, t_s$, are determined by using other difference formulas, usually of the same order of (2.3). In practical use, we couple three sets of formulas: $\nu - 1$ for $y_1, \ldots, y_{\nu-1}$, $s - k + 1$ with the coefficients as (2.3) and $k - \nu$ for $y_{s-k+\nu+1}, \ldots, y_s$. We note that the formulas of the first and third sets are still based on linear multistep finite differences expressions as (2.3), but each one has different coefficients (and is independent from those in (2.3)), while all formulas in the second set, based on (2.3), share the same coefficients $\alpha_0, \ldots, \alpha_k$, $\beta_0, \ldots, \beta_k$.

As announced, we simplify the notation; i.e., we suppose F linear, $F(t, y(t)) = J\,y(t) + g(t)$, where $J \in \mathbb{R}^{m\times m}$ and g is a vector-valued function of t. The underlying discrete boundary value problem can be solved by forming the following linear system:

$$\begin{aligned} &Mz = b, \quad M = A \otimes I_m - B \otimes (h\,J), \quad z^T = \left(y_0^T, y_1^T, \ldots, y_s^T\right), \\ &b = e_1 \otimes y_0 + h(B \otimes I_m)g, \quad g^T = (g(t_0)^T \ldots g(t_s)^T), \end{aligned} \tag{2.4}$$

where A, B are $(s+1)\times(s+1)$ real-valued quasi-Toeplitz nonsymmetric matrices and e_1 is the first column of the identity matrix. In practice, we accommodate the coefficients α_j, $\alpha_j^{(r)}$, $\quad j = 0, \ldots, k, \quad r = 1, \ldots, \nu-1, s-k+\nu+1, \ldots, s$ in A and β_j, $\beta_j^{(r)}$, $\quad j = 0, \ldots, k, \quad r = 1, \ldots, \nu-1, s-k+\nu+1, \ldots, s$ in B such that we can look at A as $\hat{A} + R_A$ and B as $\hat{B} + R_B$, $\hat{A}$ and $\hat{B}$ Toeplitz matrices with stencil

$$\left(0 \ldots 0\ \alpha_0 \ldots \underline{\alpha_\nu} \ldots \alpha_k 0 \ldots 0\right)$$

and

$$\left(0 \ldots 0\ \beta_0 \ldots \underline{\beta_\nu} \ldots \beta_k 0 \ldots 0\right),$$

respectively. The underlined element is the one on the main diagonal, and R_A and R_B have nonzero elements at most in their $\nu \times (k+1)$ upper left and $(k-\nu)\times(k+1)$ lower right corners.

The additional work needed for the solution of the discrete problems (2.4) with respect to those for the solution of implicit standard linear multistep formulas (i.e., used with only initial values) is justified by better stability and order properties; see [14, 4] for details and discussions.

More on the matrices A, B, and M generated by the schemes above can be found in [7, 6]. Examples of matrices A, B, and M for 2-step formulas will be given in what follows.

2.2. A review of block-circulant preconditioners. We noted in [4] that, in d dimensions, $d > 1$, when a fine enough spatial discretization is used in (2.1), direct methods are often not feasible to solve linear systems (2.4). Iterative methods are mandatory when the discrete problem is generated by a three-dimensional or even two-dimensional differential model (2.1). In [3, 4] Krylov subspace methods were proposed to solve (2.4). However, without preconditioning, the convergence can be very slow or iterations do not converge at all. Therefore, in [3, 4] a preconditioning strategy based on circulant matrices was introduced (see also [16]). Thus, other approximations were introduced in [5, 8]; see [8] for a more comprehensive bibliography. By left preconditioning we mean solving the equivalent nonsymmetric linear system

$$P^{-1}Mx = P^{-1}b \tag{2.5}$$

instead of $Mx = b$. Right preconditioning is obtained by considering

$$MP^{-1}y = b, \quad x = P^{-1}y.$$

Note that matrices MP^{-1} and $P^{-1}M$ are similar and hence share the same eigenvalues. Since we are interested in the eigenvalues of (2.5), our analysis is based entirely on left preconditioning.

In what follows, some block-circulant and block-circulant-like preconditioners for (2.4) are briefly reviewed.

Let us consider the following approximation of the matrix M:

$$P = \breve{A} \otimes I_m - h\breve{B} \otimes \tilde{J}, \tag{2.6}$$

where $\tilde{J}$ is a suitable approximation of the Jacobian matrix or the Jacobian itself. $\breve{A}$, $\breve{B}$ are circulant matrices whose entries are derived from the coefficients of the main method (2.3) as follows:

$$\begin{aligned} &\breve{A} = circ(\breve{a}),\ \breve{a}_j = c_{j,1}(s)\alpha_{j+\nu} + c_{j,2}(s)\alpha_{j+\nu-(s+1)}, \\ &\breve{B} = circ(\breve{b}),\ \breve{b}_j = c_{j,3}(s)\beta_{j+\nu} + c_{j,4}(s)\beta_{j+\nu-(s+1)}, j = 0, \ldots, s, \end{aligned} \tag{2.7}$$

where $circ(\cdot)$ denotes the circulant matrix having the first column specified in the argument, and the $c_{j,i}(s)$, $i = 1, \ldots, 4$, $j = 0, \ldots, s$, are linear in j. It is understood that α_j (β_j) is zero for $j < 0$ or $j > k$ in (2.7), so that the sparsity of A, B implies that of $\breve{A}$, $\breve{B}$. The coefficients $c_{i,j}(s)$ in (2.7) are chosen in such a way that $\breve{A}$, $\breve{B}$ are suitable approximations of A, B in (2.4), respectively.

The approximation of A, B with T. Chan's *optimal circulant preconditioner* (see [18]) requires that

$$c_{j,1}(s) = c_{j,3}(s) = 1 - \frac{j}{s+1},\ \text{and}\ c_{j,2}(s) = c_{j,4}(s) = \frac{j}{s+1}, j = 0, \ldots, s, \tag{2.8}$$

while for Strang's *natural (or simple) circulant preconditioner* (see [29])

$$\begin{aligned} &c_{j,1}(s) = c_{j,3}(s) = 1, \quad j = 0, \ldots, \left\lfloor \frac{s+1}{2} \right\rfloor, \\ &c_{j,2}(s) = c_{j,4}(s) = 1, \quad j = \left\lfloor \frac{s+1}{2} \right\rfloor + 1, \ldots, s, \quad c_{j,i}(s) = 0 \text{ otherwise.} \end{aligned}$$

On the other hand, if we consider, instead of (2.8), the following definition of the coefficients $c_{j,i}(s)$ for $\breve{A}$ and $\breve{B}$:

$$c_{j,1}(s) = c_{j,3}(s) = 1 + \frac{j}{s+1}, \quad c_{j,2}(s) = c_{j,4}(s) = \frac{j}{s+1}, \quad j = 0, \ldots, s, \tag{2.9}$$

we get the so-called P-circulant approximations which, used in (2.6), gives the P-circulant (block) preconditioner, introduced in [3, 4]. The latter definition avoids singularity problems which are sometimes typical of the former choices.

In [3, 4] and in [17] it was shown that both the P-circulant and generalized Strang preconditioned systems can be effective to accelerate the convergence. Unfortunately, when the Jacobian matrix J has some small (or zero) eigenvalues, the simple circulant or Strang preconditioner can be severely ill-conditioned or even singular (see [3, 4, 5]). An analysis of the spectrum for the preconditioned matrix based on simple circulant approximations can be found in [10]. However, we stress that the tools used here are completely different from those in the former. In particular, we cannot write anymore $\breve{A}$, $\breve{B}$ as small rank perturbations of A, B, respectively.

Therefore, we will focus on preconditioners (2.6) based on T. Chan's and the P-circulant approximations in the following discussions. Practical examples for the matrices A, B, $\breve{A}$, $\breve{B}$, M, and P can be found below.

Another approximation which was found effective (but is not considered here) is based on $\{\omega\}$-circulant approximations for matrices A and B in (2.4); see [8]. In

particular, $\breve{A}$, $\breve{B}$ are $\{\omega\}$-circulant matrices approximating A and B, respectively. The $\{\omega\}$-circulant matrices are Toeplitz matrices whose first entry of a row is given by multiplying the last entry of the preceding row by $\omega = \exp(\mathbf{i}\theta)$; see [19] for more details. Notice that the $\{1\}$-circulant matrices ($\theta = 0$) are just circulant matrices (and therefore generate simple or Strang's approximations for a given Toeplitz matrix), while $\{-1\}$-circulant matrices ($\theta = \pi$) are skew-circulant matrices.

We observe that various trigonometric approximations can be combined. For example, $\{\omega\}$-P-circulant preconditioners can be defined by using (2.9) to give the first row of the related $\{\omega\}$-circulant approximation. A similar combination can be made by using T. Chan's optimal circulant matrices. Moreover, it is straightforward to observe that P-circulant approximations can be seen as $\{\omega\}$-circulant preconditioners with $\theta = 0$, whose entries are defined as in (2.9). More comments on these generalizations can be found in [8].

2.3. Dahlquist's hypothesis. In the proposed eigenvalue analysis for the preconditioned linear systems (2.5), unless otherwise specified, we choose $J = \mu$ (i.e., a scalar) in (2.2), where $\mu \in \mathbb{C}^- := \{\lambda \in \mathbb{C} : \mathrm{Re}\lambda \leq 0\}$ ("Dahlquist's hypothesis"). It is customary to consider this scalar problem in the linear stability theory for ODEs. The parameter μ can be any eigenvalue of the Jacobian matrix J of the given PDE, supposed diagonalizable. Indeed, notice that, supposing J diagonalizable, we have

$$J = VDV^{-1}, \quad D = \mathrm{diag}(\mu_1, \ldots, \mu_m).$$

This framework is not restrictive for our analysis since

$$M = A \otimes I_m - hB \otimes \left(VDV^{-1}\right) = (I_{s+1} \otimes V)(A \otimes I_m - hB \otimes D)(I_{s+1} \otimes V^{-1}).$$

Assuming that the preconditioner is based on the exact Jacobian, a similar expression can be derived for P. Let us write

$$M(q) = A - qB, \quad P(q) = \breve{A} - q\breve{B}, \quad q = h\mu.$$

It is straightforward to observe that the eigenvalues of the preconditioned/transformed linear system (2.5) are given by the union of the eigenvalues of the finite sequence of matrices

$$\{P(q)^{-1}M(q)\}_q, \quad q = h\mu_i, \quad i = 1, \ldots, m.$$

Just to have an idea of the matrix structures, we sketch below the explicit expression of $M(q)$ and $P(q)$ for the particular example of a 2-step generalized Adams–Moulton method in connection to a P-circulant preconditioner, with an additional final condition given by the implicit Euler method:

$$M(q) = \begin{pmatrix} 1 & 0 & & & \\ -1 & 1 & 0 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 1 & 0 \\ & & & -1 & 1 \end{pmatrix} - q \cdot \begin{pmatrix} \frac{2}{3} & -\frac{1}{12} & & & \\ \frac{5}{12} & \frac{2}{3} & -\frac{1}{12} & & \\ & \ddots & \ddots & \ddots & \\ & & \frac{5}{12} & \frac{2}{3} & -\frac{1}{12} \\ & & & 0 & 1 \end{pmatrix},$$

$$P(q) = \begin{pmatrix} 1 & 0 & & & -\frac{s}{s+1} \\ -\frac{s}{s+1} & 1 & 0 & & \\ & \ddots & \ddots & \ddots & \\ & & -\frac{s}{s+1} & 1 & 0 \\ 0 & & & -\frac{s}{s+1} & 1 \end{pmatrix} - q \cdot \begin{pmatrix} \frac{2}{3} & \breve{b}_1 & & & \breve{b}_s \\ \breve{b}_s & \frac{2}{3} & \breve{b}_1 & & \\ & \ddots & \ddots & \ddots & \\ & & \breve{b}_s & \frac{2}{3} & \breve{b}_1 \\ \breve{b}_1 & & & \breve{b}_s & \frac{2}{3} \end{pmatrix},$$

where $\breve{b}_1 = -\frac{s+2}{12(s+1)}, \breve{b}_s = \frac{5s}{12(s+1)}$.

We recall that the underlying generalizations of Adams–Moulton formulas, which should be used only as implicit methods with one initial (given) and one final condition, are (i) A-stable not only for $k = 2$ but for arbitrarily high-order $k+1$ and (ii) all formulas preserve important properties such as the time reversal symmetry and the Hamiltonian function; see [14]. Note that if we use the usual 2-step Adams–Moulton formula, we should supply another starting value y_1.

3. Motivation of the work. From now on, we will assume Dahlquist's hypothesis (see section 2.3) in order to simplify the theoretical analysis.

Understanding the behavior of iterative solvers for (2.4) requires the knowledge of the following features:

1. How does the spectrum of M depend on the discretization parameters? For instance, for which values of q (both involving the time step and the Jacobian of the PDE) can we ensure that the spectrum lies in $\mathbb{C}^+ := \{\lambda \in \mathbb{C} : \mathrm{Re}\lambda > 0\}$? Can we exclude the pathological situation where M is singular?
2. When a suitable preconditioner is applied, we know that the spectrum of $P^{-1}M$ is clustered; see, e.g., [23]. But which localization of the cluster (and of the outliers, if present) should be expected? Again, how does that localization depend on q?

Concerning the first issue, the literature contains plenty of spectral results involving Toeplitz matrices (see, e.g., [12, 13]), even though the nonsymmetric case is more difficult to treat (surprisingly, smoothness of the generating function can be a disadvantage: see [32]). In particular, this difficulty arises in our setting, where generating functions are trigonometric polynomials, and the accurate localization results typical for Hermitian matrices are no longer applicable. Moreover, such results are of the asymptotic type and require a critical assumption: *the entries of M must not depend on the size*. In other words, as the size varies we obtain a finite section of a *fixed* infinite matrix. This is not our case, since varying s (the size of matrices A and B and $s = O(h^{-1})$) gives a different value of q in M.

The only known results we can apply concern mainly algorithms for computation of a few eigenvalues (in [2]) or a theoretical analysis of the "pencil" $A - qB$ (in the sense of generalized eigenvalues) in [14]: in the latter book we can find conditions on q for which M is nonsingular, that is, a partial answer to our questions raised above.

In summary, to the best of our knowledge, *a general theoretical characterization of the eigenvalues of $M = A - qB$ as functions of q is still lacking*. The underlying algebraic setting is the (standard) eigenvalue problem for nonsymmetric Toeplitz matrices with small rank corrections.

Concerning the second issue, some mathematical tools for the spectral analysis of $P^{-1}M$ have been proposed in the literature (see, e.g., [4, 10, 17, 25]), but they all assume that $M - P$ has small rank. This is true for some choices of P (such as Strang's preconditioner and a few extensions), but several other important instances (such as T. Chan's or P-circulant approximations) give rise to matrices $M - P$ whose rank is usually full.

Therefore, *appropriate tools for the analysis of the case where P differs from M by more than a matrix whose rank is small*[1] *are still unknown.* An exception is provided in the Hermitian case, not of interest in this context. The underlying algebraic setting is the *generalized* eigenvalue problem for nonsymmetric Toeplitz matrices with small rank corrections.

The following sections will attempt to give some answers to the open questions discussed so far.

4. Spectral analysis. From now on we focus on the generalized eigenvalue problem for nonsymmetric quasi-Toeplitz matrices:

$$M(q)u = \lambda P(q)u, \qquad u \neq 0. \tag{4.1}$$

The standard eigenproblem falls into this notation by making the formal assumption $P(q) = I$ (in this section we are interested just in the *structure* of the matrices involved).

The lack of symmetry and the band structure imply that the classical approach based on generating functions gives very little insight here (see the results presented in [32]). Therefore, the best way to characterize eigenvalues (and potentially eigenvectors) by exploiting the band Toeplitz pattern seems to be the *difference equation* approach, proposed by Trench [33] for the standard, pure Toeplitz case.

Let the $s+1$ equations of (4.1), as well as the entries of u, be indexed from 0 to s; the indices from ν to $s-k+\nu$ correspond to the rows of $M(q)$ and $P(q)$ not affected by the low rank correction and containing all of the coefficients of the main method. The resulting relations

$$\sum_{i=0}^{k}(\alpha_i - q\beta_i)u_{i+j} = \lambda\sum_{i=0}^{k}(\breve{a}_{i-\nu} - q\breve{b}_{i-\nu})u_{i+j}, \quad j = 0, \ldots, s-k$$

(where we assume a periodic pattern for $\breve{a}_i$ and $\breve{b}_i$, whenever a subscript is out of range), can be treated as linear k-order homogeneous difference equations with constant coefficients. The first and last rows of (4.1) will provide us with initial and final conditions.

The eigenvector u is a nonzero solution of the difference problem and therefore can be characterized in terms of the algebraic *characteristic equation* of degree k:

$$\pi(z) - \lambda\breve{\pi}(z) = 0, \quad \pi(z) := \sum_{i=0}^{k}(\alpha_i - q\beta_i)z^i, \ \breve{\pi}(z) := \sum_{i=0}^{k}(\breve{a}_{i-\nu} - q\breve{b}_{i-\nu})z^i \tag{4.2}$$

(notice that $\breve{\pi}(z)$ simplifies into z^ν in the standard problem).

From now on we assume that, for each eigenvalue λ, all of the roots $z_1(\lambda), \ldots, z_k(\lambda)$ of the characteristic equation are distinct (otherwise, λ is called *defective* [34], but this pathological situation occurs just in isolated cases and for specific values of s). In this case, each component of the solution of the difference equation has the form

$$u_j = \sum_{l=1}^{k} c_l z_l(\lambda)^j, \quad j = 0, \ldots, s, \tag{4.3}$$

for suitable coefficients $c_1, \ldots, c_k$ determined by the boundary conditions.

[1] In the sense that s is supposed large with respect to the band of the Toeplitz matrices involved, and the rank is not depending on s.

More specifically, the first ν and the last $k-\nu$ rows of (4.1) represent additional conditions on the sequence u_j. In the standard problem, we have ν *initial* and $k-\nu$ *final* conditions since just the first and last entries of u are involved, respectively. In the generalized problem, the circulant structure of $P(q)$ determines a mixing of initial and final entries in all of these k equations, but for simplicity we keep the same terminology.

Substituting (4.3) into the mentioned equations, we obtain k homogeneous relations involving the unknown coefficients $c_1, \dots, c_k$, which can be put in matrix form as follows:

$$\begin{aligned} K_{\text{in}}(z_1(\lambda), \dots, z_k(\lambda))c = 0, \\ K_{\text{fin}}(z_1(\lambda), \dots, z_k(\lambda))c = 0, \end{aligned} \tag{4.4}$$

where $K_{\text{in}} \in \mathbb{C}^{\nu \times k}$, $K_{\text{fin}} \in \mathbb{C}^{(k-\nu)\times k}$ and we have emphasized the dependence of these Vandermonde-like matrices on the roots of the characteristic equation. The trivial solution $c = 0$ would imply $u = 0$ and therefore must be discarded; hence the square matrix

$$K(z_1(\lambda), \dots, z_k(\lambda)) := \begin{pmatrix} K_{\text{in}} \\ K_{\text{fin}} \end{pmatrix} \tag{4.5}$$

must be singular. Its (vanishing) determinant can be regarded as a function of λ having the same zeros of the characteristic polynomial of (4.1).

An alternative parameterization with respect to the roots $z_j(\lambda)$ can be useful for a different characterization of λ.

Let ζ be one of the roots, say, $z_1(\lambda)$. From one point of view, ζ is a function of λ, but it is understood that λ can be retrieved as well from ζ by means of the characteristic equation

$$\lambda(\zeta) = \frac{\pi(\zeta)}{\breve{\pi}(\zeta)} \qquad (\lambda(\zeta) = \zeta^{-\nu}\pi(\zeta) \text{ in the standard case}); \tag{4.6}$$

we remark that *any* root gives the same value of λ. The other roots can be expressed in terms of λ by inverting some elementary symmetric functions. For example, in the generalized problem with $k = 2$ and $\nu = 1$, the easiest way is to consider the ratio between the constant term and the leading coefficient in (4.2)

$$\frac{\alpha_0 - q\beta_0 - \lambda(\breve{a}_s - q\breve{b}_s)}{\alpha_2 - q\beta_2 - \lambda(\breve{a}_1 - q\breve{b}_1)} = z_1(\lambda)z_2(\lambda),$$

whence, after the substitution $\lambda = \lambda(\zeta)$ given in (4.6),

$$z_2(\lambda) = \zeta^{-1}\frac{(\alpha_0 - q\beta_0)\breve{\pi}(\zeta) - (\breve{a}_s - q\breve{b}_s)\pi(\zeta)}{(\alpha_2 - q\beta_2)\breve{\pi}(\zeta) - (\breve{a}_1 - q\breve{b}_1)\pi(\zeta)} =: \zeta_2(\zeta). \tag{4.7}$$

In general, we can assume that we have explicit functions $\zeta_2(\zeta), \dots, \zeta_k(\zeta)$ that replace $z_2(\lambda), \dots, z_k(\lambda)$ in the matrix K of (4.5). Thus

$$\det K(\zeta, \zeta_2(\zeta), \dots, \zeta_k(\zeta)) =: \det(\zeta; q)$$

is a function of the single complex variable ζ, containing q as a parameter.

TABLE 4.1
Coefficients for some 2-step formulas.

Type	α_0	α_1	α_2	β_0	β_1	β_2
Midpoint (MP)	-1	0	1	0	2	0
Simpson (S)	-1	0	1	$\frac{1}{3}$	$\frac{4}{3}$	$\frac{1}{3}$
Adams–Moulton (AM)	-1	1	0	$\frac{5}{12}$	$\frac{2}{3}$	$-\frac{1}{12}$

As we will see in specific examples, the analysis of the function $\det(\zeta; q)$ can be sometimes reduced to the study of a sparse polynomial, which makes feasible a first-order analysis (perhaps a direct computation) of its roots $\zeta(q)$. Finally, the relation (4.6) allows us to obtain a knowledge of λ from that of $\zeta(q)$.

Remark 4.1. $\det(\zeta; q)$ has a number of redundant roots that should be discarded in order to simplify the analysis. Some of them are "spurious" values for which $\zeta = \zeta_j(\zeta)$ or $\zeta_j(\zeta) = \zeta_l(\zeta)$, with $j \neq l$ (the matrix K turns out to have two equal columns), violating the assumption of distinct roots. Furthermore, if ζ is a root of $\det(\zeta; q)$, then $\zeta_2(\zeta), \ldots, \zeta_k(\zeta)$ are roots as well, and they all give the same eigenvalue λ. In summary, since there are $s+1$ eigenvalues, we expect to find $k(s+1)$ roots of $\det(\zeta; q)$, plus the spurious roots (whose number cannot be estimated a priori, in general).

Remark 4.2. Once the behavior of $\zeta(q)$ has been obtained, in principle this can be used also for the study of eigenvectors: the key relation is (4.3), and the main issue would be the behavior (in terms of q) of the coefficients $c_1, \ldots, c_k$. This problem is not treated in the present paper, where we are interested only in the eigenvalues $\lambda(q)$.

4.1. A case study: 2-step formulas. In this paper, we focus on 2-step methods as the principal (or main) scheme (2.3) for a linear multistep formula in boundary value form, with one initial condition and one final condition provided by an implicit Euler scheme. For those methods, we have

$$k = 2, \nu = 1,$$

and Dahlquist's hypothesis of section 2.3 allows us to assume that

$$A = \begin{pmatrix} \alpha_1 & \alpha_2 & & & 0 \\ \alpha_0 & \alpha_1 & \alpha_2 & & \\ & \ddots & \ddots & \ddots & \\ & & \alpha_0 & \alpha_1 & \alpha_2 \\ & & & -1 & 1 \end{pmatrix}, \quad B = \begin{pmatrix} \beta_1 & \beta_2 & & & \\ \beta_0 & \beta_1 & \beta_2 & & \\ & \ddots & \ddots & \ddots & \\ & & \beta_0 & \beta_1 & \beta_2 \\ & & & 0 & 1 \end{pmatrix}, \tag{4.8}$$

where parameters are given in Table 4.1 for the most common cases.

Circulant approximations for A and B are given by

$$\breve{A} = \begin{pmatrix} \breve{a}_0 & \breve{a}_1 & & & \breve{a}_s \\ \breve{a}_s & \breve{a}_0 & \breve{a}_1 & & \\ & \ddots & \ddots & \ddots & \\ & & \breve{a}_s & \breve{a}_0 & \breve{a}_1 \\ \breve{a}_1 & & & \breve{a}_s & \breve{a}_0 \end{pmatrix}, \quad \breve{B} = \begin{pmatrix} \breve{b}_0 & \breve{b}_1 & & & \breve{b}_s \\ \breve{b}_s & \breve{b}_0 & \breve{b}_1 & & \\ & \ddots & \ddots & \ddots & \\ & & \breve{b}_s & \breve{b}_0 & \breve{b}_1 \\ \breve{b}_1 & & & \breve{b}_s & \breve{b}_0 \end{pmatrix}, \tag{4.9}$$

where the examples for its entries considered here are shown in Table 4.2.

TABLE 4.2
Entries for the preconditioner $P = P(q)$.

Type	$\breve{a}_0$	$\breve{a}_1$	$\breve{a}_s$	$\breve{b}_0$	$\breve{b}_1$	$\breve{b}_s$
MP, P-circ	0	$\frac{s+2}{s+1}$	$-\frac{s}{s+1}$	2	0	0
S, P-circ	0	$\frac{s+2}{s+1}$	$-\frac{s}{s+1}$	$\frac{4}{3}$	$\frac{s+2}{3(s+1)}$	$\frac{s}{3(s+1)}$
AM, Chan	1	0	$-\frac{s}{s+1}$	$\frac{2}{3}$	$-\frac{s}{12(s+1)}$	$\frac{5s}{12(s+1)}$
AM, P-circ	1	0	$-\frac{s}{s+1}$	$\frac{2}{3}$	$-\frac{s+2}{12(s+1)}$	$\frac{5s}{12(s+1)}$

We are not interested in T. Chan's approximation for the midpoint and Simpson methods, since it becomes singular in such cases [7, p. 1819].

The characteristic equation (4.2) has a quadratic form, with

$$\pi(z) = \gamma_0 + \gamma_1 z + \gamma_2 z^2 \qquad (\gamma_i := \alpha_i - q\beta_i),$$

$$\breve{\pi}(z) = \breve{g}_s + \breve{g}_0 z + \breve{g}_1 z^2 \qquad (\breve{g}_i := \breve{a}_i - q\breve{b}_i);$$

its roots ζ and ζ_2 are then related through (4.7), where we observe that the numerator vanishes for $\zeta = 0$, whereas the denominator loses its quadratic term. Hence we define

$$N(\zeta) := \frac{\gamma_0\breve{\pi}(\zeta) - \breve{g}_s\pi(\zeta)}{\zeta}, \quad D(\zeta) := \gamma_2\breve{\pi}(\zeta) - \breve{g}_1\pi(\zeta),$$

which are both linear polynomials such that

$$\zeta_2(\zeta) = \frac{N(\zeta)}{D(\zeta)}. \tag{4.10}$$

In light of Remark 4.1, we know that the function $\det(\zeta; q)$ has two spurious roots for which $\zeta = \zeta_2$, satisfying the quadratic equation $N(\zeta) - \zeta D(\zeta) = 0$; hence we know in advance that $N(\zeta) - \zeta D(\zeta)$ exactly divides $\det(\zeta; q)$.

In order to form the explicit expression of $\det(\zeta; q)$, first we must compute the 2×2 matrix

$$K(\zeta, \zeta_2) = \begin{pmatrix} \gamma_{\text{in}}(\zeta) & \gamma_{\text{in}}(\zeta_2) \\ \gamma_{\text{fin}}(\zeta) & \gamma_{\text{fin}}(\zeta_2) \end{pmatrix},$$

where $\gamma_{\text{in}}(\cdot)$ and $\gamma_{\text{fin}}(\cdot)$ are suitable polynomials obtained by imposing boundary conditions on the main difference equation.

More precisely, since $k = 2$ and $\nu = 1$, we have just one initial condition (the first equation in (4.1))

$$\gamma_1 u_0 + \gamma_2 u_1 = \lambda(\breve{g}_0 u_0 + \breve{g}_1 u_1 + \breve{g}_s u_s)$$

and one final condition (the last of (4.1))

$$-u_{s-1} + (1-q)u_s = \lambda(\breve{g}_1 u_0 + \breve{g}_s u_{s-1} + \breve{g}_0 u_s),$$

where u_j given by (4.3),

$$u_j = c_1\zeta^j + c_2\zeta_2^j,$$

should be substituted.

This way we obtain two homogeneous equations in the unknowns c_1, c_2, whose coefficients contribute to the matrix K. For instance, the coefficient of c_1 in the initial condition is

$$\gamma_{\text{in}}(\zeta) = \gamma_1 + \gamma_2\zeta - \lambda(\breve{g}_0 + \breve{g}_1\zeta + \breve{g}_s\zeta^s),$$

whereas that in the final condition is

$$\gamma_{\text{fin}}(\zeta) = -\zeta^{s-1} + (1-q)\zeta^s - \lambda(\breve{g}_1 + \breve{g}_s\zeta^{s-1} + \breve{g}_0\zeta^s).$$

The same holds for c_2 with ζ_2 in place of ζ; it must be remembered that

$$\lambda(\zeta) = \frac{\pi(\zeta)}{\breve{\pi}(\zeta)} = \frac{\pi(\zeta_2)}{\breve{\pi}(\zeta_2)}. \tag{4.11}$$

Some further algebraic manipulations give the following compact formulas:

$$\gamma_{\text{in}}(z) = \pi_0(z) - \frac{\pi(z)}{\breve{\pi}(z)}\mathcal{R}[z^s\breve{\pi}], \quad \gamma_{\text{fin}}(z) = z^{s-2}\pi_s(z) - \frac{\pi(z)}{\breve{\pi}(z)}\mathcal{R}[z^{s-1}\breve{\pi}],$$

where the notation $\mathcal{R}[P]$ means the s-degree remainder of P modulo $z^{s+1}-1$, and

$$\pi_0(z) := \frac{\pi(z) - \pi(0)}{z}, \quad \pi_s(z) := (1-q)z^2 - z.$$

A useful simplification arises by observing that in light of (4.11) λ needs not to be evaluated in ζ_2 when we form the second column of K. Therefore, the determinant is given by

$$\det(\zeta; q) = \gamma_{\text{in}}(\zeta)\gamma_{\text{fin}}(\zeta_2) - \gamma_{\text{in}}(\zeta_2)\gamma_{\text{fin}}(\zeta),$$

where

$$\gamma_{\text{in}}(\zeta_2) = \pi_0(\zeta_2) - \frac{\pi(\zeta)}{\breve{\pi}(\zeta)}Q_s(\zeta_2)$$

and

$$\gamma_{\text{fin}}(\zeta_2) = \zeta_2^{s-2}\pi_s(\zeta_2) - \frac{\pi(\zeta)}{\breve{\pi}(\zeta)}\tilde{Q}_s(\zeta_2),$$

with suitable s-degree polynomials Q_s and $\tilde{Q}_s$; the substitution (4.10) shows that $\det(\zeta; q)$ is a rational function whose denominator is $\breve{\pi}(\zeta)^2 D(\zeta)^s$. From the linearity of N and D, the function

$$d(\zeta; q) := \breve{\pi}(\zeta)^2 D(\zeta)^s \det(\zeta; q) \tag{4.12}$$

is a $(2s+4)$-degree polynomial in ζ, for which $N(\zeta) - \zeta D(\zeta)$ is a known exact divisor. Its significant roots occur in pairs $(\zeta(q), \zeta_2(q))$, each of them providing a unique value of $\lambda(q)$.

The formulas derived so far simplify very much if we are concerned with the nonpreconditioned case: it suffices to put formally $\breve{\pi}(z) := z$, so that

$$\zeta_2 = \frac{\gamma_0}{\gamma_2 \zeta}, \quad \gamma_{\text{in}}(z) := \pi_0(z) - \frac{\pi(z)}{z} = -\frac{\gamma_0}{z}, \quad \gamma_{\text{fin}}(z) := z^{s-2}(\pi_s(z) - z\pi(z)),$$

whence

$$\det(\zeta; q) = -\gamma_2 \zeta_2^{s-1}(\pi_s(\zeta_2) - \zeta_2 \pi(\zeta_2)) + \gamma_2 \zeta^{s-1}(\pi_s(\zeta) - \zeta\pi(\zeta));$$

here the denominator is just ζ^{s+2}, and the spurious roots of $d(\zeta; q) := \zeta^{s+2} \det(\zeta; q)$ are $\pm\sqrt{\gamma_0/\gamma_2}$.

It is important to observe that $d(\zeta; q)$ is a *sparse* polynomial, which makes a first-order analysis feasible.

We sketch below the essential formulas arising for the specific examples under consideration, which represent the individual instances of (4.10) for ζ_2, (4.12) for $d(\zeta; q)$, and (4.6) for $\lambda(q) := \lambda(\zeta(q))$. In the preconditioned cases, polynomials N and D have been scaled by a constant common factor σ which has been explicitly reported; hence the true expression of $d(\zeta; q)$ should be multiplied by σ^s, but obviously this correction has no influence on the roots and will not be considered in the subsequent analysis.

Nonpreconditioned matrices $M(q)$.

Midpoint (MP).

$$\zeta_2 = -\frac{1}{\zeta},$$
$$d(\zeta; q) = (-1)^s((1+q)\zeta + 1) + \zeta^{2s+3}(1 + q - \zeta),$$
$$\lambda(\zeta(q)) = \zeta(q) - 2q - \frac{1}{\zeta(q)}.$$

Simpson (S).

$$\zeta_2 = \frac{\gamma}{\zeta}, \quad \gamma := \frac{q/3 + 1}{q/3 - 1},$$
$$d(\zeta; q) = \gamma^{s+1}\left(\frac{q}{3} - 1\right)\left(1 + \frac{q}{3} + \left(1 + \frac{q}{3}\right)\zeta + \frac{q}{3\gamma}\zeta^2\right),$$
$$- \zeta^{2s+2}\left(\frac{q}{3} - 1\right)\left(\frac{q}{3} + \left(1 + \frac{q}{3}\right)\zeta + \left(\frac{q}{3} - 1\right)\zeta^2\right),$$
$$\lambda(\zeta(q)) = \left(1 - \frac{q}{3}\right)\zeta(q) - \frac{4}{3}q - \left(1 + \frac{q}{3}\right)/\zeta(q).$$

Adams–Moulton (AM).

$$\zeta_2 = \frac{\gamma}{\zeta}, \quad \gamma := -5 - \frac{12}{q},$$
$$d(\zeta; q) = \gamma^{s-1}\left(1 + \frac{5}{12}q\right)\left(\gamma\left(1 + \frac{5}{12}q\right) - \frac{1}{3}\gamma q\zeta + \frac{5}{12}q\zeta^2\right)$$
$$+ \zeta^{2s+2}\frac{q^2}{36}\left(\frac{5}{4} - \zeta - \frac{1}{4}\zeta^2\right),$$
$$\lambda(\zeta(q)) = \frac{q}{12}\zeta(q) + 1 - \frac{2}{3}q - \left(1 + \frac{5}{12}q\right)/\zeta(q).$$

Preconditioned matrices $P(q)^{-1}M(q)$.

MP, P-circulant.

$$\sigma = -\frac{s+1}{2}, \quad N(\zeta) = q - \zeta, \quad D(\zeta) = 1 + q\zeta, \quad \zeta_2 = \frac{N(\zeta)}{D(\zeta)},$$

$$\begin{aligned} d(\zeta;q) = {} & \frac{2\pi(\zeta)}{s+1}(N-\zeta D)\left[-\left(1-\frac{1}{s+1}\right)\zeta^s N^s + \left(1+\frac{1}{s+1}\right)D^s\right] \\ & + \left(1-\frac{1}{(s+1)^2}\right)\pi(\zeta)^2[N^s - (\zeta D)^s] \\ & - \frac{2(1+q)\breve{\pi}(\zeta)}{s+1}[N^{s+1} - (\zeta D)^{s+1}] + \frac{4}{(s+1)^2}[N^{s+2} - (\zeta D)^{s+2}], \end{aligned}$$

$$\pi(\zeta) = \zeta^2 - 2q\zeta - 1, \quad \breve{\pi}(\zeta) = \pi(\zeta) + \frac{1}{s+1}(\zeta^2+1), \quad \lambda(\zeta(q)) = \frac{\pi}{\breve{\pi}}.$$

S, P-circulant.

$$\sigma = -\frac{9(s+1)}{2}, \quad N(\zeta) = (3+q)(2q+(q-3)\zeta), \quad D(\zeta) = (3-q)(q+3+2q\zeta),$$

$$\begin{aligned} d(\zeta;q) = {} & \pi(\zeta)(N-\zeta D)(\breve{g}_1 D^{s-1}\phi_1 + \breve{g}_s(\zeta N)^{s-1}\psi_0) \\ & - \left(\breve{g}_1\breve{g}_s\pi(\zeta)^2 + \frac{2D\psi_0}{9(s+1)}\right)[N^s - (\zeta D)^s] - \frac{2\psi_1}{9(s+1)}[N^{s+1} - (\zeta D)^{s+1}] \end{aligned}$$

($\breve{g}_i := \breve{a}_i - q\breve{b}_i$, where $\breve{a}_i$ and $\breve{b}_i$ are given by Table 4.2),

$$\pi(\zeta) = \zeta - 1 - \frac{q}{12}(\zeta^2 - 8\zeta - 5), \quad \breve{\pi}(\zeta) = \pi(\zeta) + \frac{1}{s+1}\left(\frac{q}{12}\zeta^2 + 1 + \frac{5}{12}q\right).$$

4.2. A first-order analysis. The parameterization of λ as a function of q obtained so far allows us to investigate the behavior of the eigenvalues for q small.

We recall that $q = h\mu$, where h is the time discretization step and μ represents any eigenvalue of the Jacobian matrix J in (2.4) related to the space discretization. Thus, a small value of q is a physically meaningful situation, occurring whenever, e.g., the Jacobian matrix has eigenvalues with a small modulus (as in the examples sketched in section 5) and/or a small time step is used. A particular care is required in the latter instance: we stress that $s \to \infty$ as $h \to 0$, so that the polynomial $d(\zeta;q)$ raises its degree, increasing the number of the roots $\zeta(q)$. However, the insights given by the first-order analysis are generally in good agreement with the localization of λ, as we will see in the numerical experiments of section 6.

In what follows, we present a first-order expansion of $\lambda(q)$ centered in zero for all of the three nonpreconditioned methods (MP, S, AM) and for two preconditioners (P-circulant approximations for MP and AM).

The starting point is the continuity of polynomial roots with respect to coefficients (provided that the degree remains constant). Hence $\zeta(q)$ is very close to $\zeta(0)$ for small q, and its first-order dependence on q can be made explicit.

In the MP method, $\zeta = \zeta(0)$ is a root of $d(\zeta;0) = (-1)^s(1+\zeta) + \zeta^{2s+3}(1-\zeta)$, and therefore

$$|\zeta|^{2s+3} = \left|\frac{1+\zeta}{1-\zeta}\right|.$$

Squaring both sides of the previous equation and letting $\zeta = \rho e^{\mathbf{i}\theta}$, after some algebraic manipulations, we get

$$\cos\theta = \frac{1+\rho^2}{2\rho}\cdot\frac{\rho^{4s+6}-1}{\rho^{4s+6}+1}. \tag{4.13}$$

(4.13) is the equation, in polar coordinates, of a curve containing all of the roots $\zeta(0)$ and lying in the following region of the complex plane:

$$\Omega = \left\{\theta \in \left(\frac{\pi}{2}, \frac{3}{2}\pi\right), \rho < 1\right\} \cup \left\{|\theta| < \frac{\pi}{2}, \rho > 1\right\} \cup \{\pm\mathbf{i}\},$$

where $\pm\mathbf{i}$ are exactly the spurious roots for which $\zeta = \zeta_2$.

Therefore, $\lambda(0)$ can be localized through the transformation $\lambda = \zeta - 1/\zeta$ of the previous curve. In particular, since $\mathrm{Re}\lambda = (\rho - 1/\rho)\cos\theta$, it is straightforward to observe that $\mathrm{Re}\lambda > 0$ whenever $\zeta \in \Omega$ (except for the spurious roots). By continuity, we have the useful result that the eigenvalues of M lie on $\mathbb{C}^+$ for q small enough. We recall that projection methods such as GMRES or BiCGstab show often a faster convergence behavior whenever the matrix of the linear systems we have to solve has all eigenvalues in one half-plane; see [22].

If we are interested in a deeper analysis, we can check that the roots $\zeta(0)$ are distinct and therefore

$$\zeta(q) \doteq \zeta(0) + \zeta'(0)q,$$

where $\doteq$ denotes a first-order approximation of the function on the left-hand side. Therefore,

$$\lambda(q) \doteq \zeta(0) - \frac{1}{\zeta(0)} + \left[\zeta'(0) + \frac{\zeta'(0)}{\zeta(0)^2} - 2\right] q;$$

the explicit expression of $\zeta'(0)$, if desired, can be retrieved from the classical theory on the conditioning of zeros of polynomials (see, e.g., [30, section 5.8]).

The Simpson method has a quite similar analysis. In addition, since the matrix A is the same as the previous case, the zero-order terms of $\zeta(q)$ and $\lambda(q)$ are exactly equal to the corresponding ones for MP. On the other hand, the first-order expansion for S has a different expression, which is reported below:

$$\lambda(q) \doteq \zeta(0) - \frac{1}{\zeta(0)} + \left[\zeta'(0) + \frac{\zeta'(0)}{\zeta(0)^2} - \frac{4}{3} - \frac{\zeta(0)}{3} - \frac{1}{3\zeta(0)}\right] q,$$

where $\zeta'(0)$ is different from the MP method.

The analysis of the AM method shows a further complication with respect to the previous cases. It is evident that $d(\zeta; q)$ loses several degrees when q goes to zero, so that many roots $\zeta(q)$ become infinite. Hence we are not able to predict the behavior of $\lambda(q)$, unless we apply an appropriate change of variable. For this purpose, let

$$\xi := q^{1/2}\zeta, \quad \beta := \gamma q,$$

and rewrite the polynomial d in terms of the new variable ξ. We obtain

$$\begin{aligned} q^s d(\xi; q) = \beta^{s-1}\left(1 + \frac{5}{12}q\right)\left(\beta\left(1 + \frac{5}{12}q\right) - \frac{1}{3}\beta q^{1/2}\xi + \frac{5}{12}q\xi^2\right) \\ + \xi^{2s+2}/36\left(\frac{5}{4}q - q^{1/2}\xi - \frac{1}{4}\xi^2\right), \end{aligned}$$

whence $\xi(q) \doteq \xi(0) + \xi'(0)q^{1/2}$, where $\xi(0)$ solves the equation

$$(-12)^s - \xi^{2s+4}/144 = 0,$$

that is, $\xi(0) = 2\sqrt{3}\exp(\mathbf{i}(\frac{l\pi}{s+2} + \frac{\pi}{2}))$, $l = 1, \ldots, s+1$. Other values of the index l would give spurious roots or already obtained values of λ. Taking into account the change of variable, the behaviors of ζ and λ are, respectively,

$$\zeta(q) \doteq \xi(0)q^{-1/2} + \xi'(0),$$

$$\lambda(q) \doteq 1 + \frac{\mathbf{i}}{\sqrt{3}}\cos\frac{l\pi}{s+2}q^{1/2} + \left[\frac{\xi'(0)}{12} + \frac{\xi'(0)}{\xi(0)^2} - \frac{2}{3}\right] q.$$

Hence, for small values of q, the eigenvalues of M are close to a vertical segment on $\mathbb{C}^+$ with the midpoint placed at 1.

The main difficulty arising in the preconditioned case is given by the presence of the spurious divisor $N - \zeta D$ in all instances of $d(\zeta; q)$. In order to perform the analysis, it is worth considering the quotient $\hat{d}(\zeta; q) := d(\zeta; q)/(N - \zeta D)$, studied for $q \approx 0$. Let

$$F_m(\zeta; q) := \frac{N^m - (\zeta D)^m}{N - \zeta D} = \sum_{j=0}^{m-1} N^j (\zeta D)^{m-j-1};$$

this expression appears in almost all of the terms of $\hat{d}(\zeta; q)$ and will determine the first-order behavior of the significant roots.

Concerning the P-circulant preconditioner for the MP method, for $q = 0$ we have $N(\zeta) = -\zeta$, $D(\zeta) = 1$. Therefore,

$$F_m(\zeta; 0) = \zeta^{m-1} \sum_{j=0}^{m-1} (-1)^j = \begin{cases} \zeta^{m-1} & \text{if } m \text{ is odd,} \\ 0 & \text{otherwise.} \end{cases}$$

Thus, the zero-order localization of the roots $\zeta(q)$ strictly depends on the parity of s: more specifically, when s is odd they solve the equation

$$\begin{aligned} &(\zeta^2 - 1)\zeta^{s+1} + \frac{2}{s+1}(\zeta^2 - 1)(\zeta^{2s} + 1) \\ &+ \frac{1}{(s+1)^2}[4\zeta^{s+1} - (\zeta^2 - 1)\zeta^{s-1} + 2(\zeta^2 - 1)(1 - \zeta^{2s})] = 0, \end{aligned}$$

and when s is even the equation becomes

$$(\zeta^2 - 1)(1 - \zeta^s - \zeta^{2s}) + \frac{1}{s+1}[(\zeta^2 - 1)(\zeta^{2s} + 1) - (\zeta^2 + 1)\zeta^s] = 0.$$

For q very small, the eigenvalues of $P^{-1}M$ can be estimated from the roots $\zeta = \zeta(0)$ through the relation

$$\lambda(0) = \frac{\zeta^2 - 1}{\zeta^2 - 1 + \dfrac{1}{s+1}(\zeta^2 + 1)}.$$

After more heavy computations we are able to obtain the first-order terms in the expansions of $\zeta(q)$ and $\lambda(q)$. In section 6 we will present explicit estimates based on the formulas derived so far and compare them with values obtained numerically.

The difficulties found in the analysis of the AM method arise in the P-circulant preconditioned case as well. Many ingredients of $d(\zeta; q)$ degenerate for $q = 0$: among others, polynomials $N(\zeta), D(\zeta), \pi(\zeta)$, and $\breve{\pi}(\zeta)$ drop their degree. This causes several roots $\zeta(q)$ to go to infinity: also here we need a suitable change of variable.

Let $\xi := q\zeta$, and rewrite all of the polynomials $N, D, \pi, \breve{\pi}, \phi_i, \psi_i (i = 0, 1)$ in terms of the new variable, in particular,

$$N(\xi) = \left(1 + \frac{5}{12}q\right)\left(1 - \frac{2}{3}q + \frac{1}{6}\xi\right), \quad D(\xi) = \frac{1}{12}\left[\left(1 - \frac{2}{3}q\right)\xi - q\left(2 + \frac{5}{6}q\right)\right].$$

The "clean" polynomial $\hat{d}$ takes the following expression after some algebra:

$$\hat{d}(\xi; q) = q^{-s-1}\breve{d}(\xi; q),$$

where $\check{d}$ has constant degree $2s+2$ (independently on q) and its zero-order form is

$$\check{d}(\xi;0) = \left(-\frac{1}{s+1}\right)^s \xi^{s+1}\left\{-\frac{1}{12^{s+1}(s+1)}\left[\xi^{s-3}(12+2\xi)^2+\xi^{s+1}\right] - \left(1-\frac{1}{s+1}\right)\left(1+\frac{1}{12}\xi\right)\left(1+\frac{1}{6}\xi\right)^s\right\}.$$

Notice that $s+1$ roots of $\check{d}$ are distinct and behave as $\xi(q) \doteq \xi(0)+\xi'(0)q$, whence

$$\zeta(q) \doteq \xi(0)q^{-1}+\xi'(0).$$

These are the roots going to infinity, associated with the values of $\lambda(q)$ with

$$\lambda(0) = \frac{12+\xi(0)}{12+\xi(0)\left(1-\dfrac{1}{s+1}\right)};$$

the same eigenvalues are associated with the corresponding "dual" roots given by $\zeta_2 = N(\xi)/D(\xi)$ which are finite for $q=0$, as a direct look at N and D shows. Through the transformation $\xi = q\zeta_2$ we find the remaining $s+1$ roots of $\check{d}$, which collapse at the origin.

We will compare these results with numerical estimates for this setting as well; see section 6.

5. Model problems. As a first benchmark of our analysis, we consider two simple model problems which encompass two important types of spectra for their Jacobian matrices: real and negative and pure imaginary eigenvalues, respectively. Only one-dimensional (1D) problems are considered, but extensions to 2D and 3D cases are straightforward and not necessary in our setting.

Diffusion equation. As a typical example of a problem whose Jacobian matrix has negative (real) eigenvalues, we report the variable coefficient 1D diffusion equation with homogeneous Dirichlet boundary conditions at both ends. Let $a = a(x) \geq 0$ be a suitably smooth function.

$$\begin{cases} u_t - c(a\,u_x)_x = 0, & x \in [0, x_{\max}], t \in (0,T], \\ u(0,t) = u(x_{\max},t) = 0 & t \in (0,T], \\ u(x,0) = g(x), & x \in [0, x_{\max}]. \end{cases} \tag{5.1}$$

Discretizing the operator $\partial/\partial x$ in (5.1) with centered differences and step size $\Delta x = x_{\max}/(m+1)$ gives a sequence of systems of ODEs parameterized by Δx whose mth element is given by

$$\begin{cases} y'(t) = T_m y(t), & t \in [0,T], \\ y(0) = \eta, & \eta = (g(x_1)\dots g(x_m))^T, \end{cases} \tag{5.2}$$

where $x_j = j\Delta x$ and

$$T_m = \frac{c}{(\Delta x)^2}\begin{pmatrix} a_1 & b_1 & & \\ b_1 & \ddots & \ddots & \\ & \ddots & \ddots & b_{m-1} \\ & & b_{m-1} & a_m \end{pmatrix}, \tag{5.3}$$

where

$$a_j = -(a(x_{j-1/2}) + a(x_{j+1/2})), \quad b_j = a(x_{j+1/2}).$$

The Jacobian matrix T_m is $m \times m$ symmetric, tridiagonal, and weakly diagonally dominant with negative diagonal entries. From an extensive study performed in [15, 28] we get for each eigenvalue μ_j of T_m the bounds

$$-\frac{4c}{(\Delta x)^2} \max_x\{a(x)\} \le \mu_j \le -\frac{c\pi^2}{(x_{\max})^2} \min_x\{a(x)\}.$$

Note that, as Δx tends to zero, the systems of differential equations (5.2) become increasingly stiff, spreading the eigenvalues of the Jacobian matrix T_m along an interval in $(-4c \max_x\{a\}/(\Delta x)^2, 0)$ whose left boundary tends to $-\infty$ with $O((\Delta x)^{-2})$.

More precisely, the spectrum is equally distributed [31] as the values of the bivariate function $a(x)f(\theta)$, where

$$f(\theta) = \frac{2c}{(\Delta x)^2}(\cos(\theta) - 1), \quad \theta \in (-\pi, \pi),$$

is the so-called "generating function" related to the constant-coefficient version of the problem. As stated in [27, 24], if $a(x)$ has a zero at the origin of order α, the smallest eigenvalue shows an asymptotic behavior like $(\Delta x)^2/m^{\max(2,\alpha)}$.

Transport equation. The linear 1D transport equation with periodic boundary conditions and constant coefficient $c > 0$ in its simplest form reads:

$$\begin{cases} u_t + c\, u_x = 0, \\ u(x,0) = g(x), & x \in [0,\pi], \\ u(\pi,t) = u(0,t), & t \in [0,2\pi]. \end{cases} \tag{5.4}$$

Discretizing the partial derivative $\partial/\partial x$ with central differences and step size $\Delta x = \pi/m$, $x_j = j\Delta x$ gives a sequence of systems of ODEs parameterized by Δx whose mth element is given by

$$\begin{cases} y'(t) = C_m y(t), & t \in [0,2\pi], \\ y(0) = \eta, & \eta = (g(x_0) \dots\ g(x_{m-1}))^T, \end{cases} \tag{5.5}$$

with

$$C_m = \frac{c}{2\Delta x} \begin{pmatrix} 0 & -1 & & & 1 \\ 1 & \ddots & \ddots & & \\ & \ddots & \ddots & \ddots & \\ & & \ddots & \ddots & -1 \\ -1 & & & 1 & 0 \end{pmatrix}. \tag{5.6}$$

The matrix C_m is circulant $m \times m$ with generating function

$$\tilde{f}(\theta) = \frac{c}{2\Delta x}\left(e^{-\mathbf{i}\theta} - e^{\mathbf{i}\theta} - e^{-\mathbf{i}(m-1)\theta} + e^{\mathbf{i}(m-1)\theta}\right) = \frac{-\mathbf{i}c\,(\sin\theta - \sin(m-1)\theta)}{\Delta x}, \tag{5.7}$$

where $\theta \in (-\pi, \pi)$. Therefore, the eigenvalues of C_m are distributed as $\tilde{f}(\theta)$ in (5.7) and lie in the purely imaginary (closed) interval

$$[-2\mathbf{i}c/\Delta x, 2\mathbf{i}c/\Delta x],$$

which becomes wider as $O(1/\Delta x)$ as we refine the discretization. This implies that a finer mesh for the time-step integrator is required to resolve the (oscillatory) solution as Δx (the step for the discretization in space) decreases to zero.

An explicit expression of the spectrum of C_m can be obtained by observing that

$$C_m = F\Lambda F^*, \tag{5.8}$$

where Λ is a diagonal matrix containing the eigenvalues μ_j of C_m and F is the Fourier matrix; see, e.g., [19]. Thus, from the expression of the eigenvalues of a circulant matrix, we have

$$\mu_j = -\frac{2\mathbf{i}c}{\Delta x}\left(\sin\frac{2\pi j}{m}\right), \quad j = 0, \ldots, m-1,$$

i.e., the generating function computed in the points $\theta_j = 2\pi j/m$, $j = 0, \ldots, m-1$, as usual.

It is worth noting that the Jacobian matrices for both of the proposed model problems are normal and therefore can be diagonalized by unitary matrices. This feature is useful in order to use the bounds for the convergence of a Krylov accelerator which uses the preconditioners analyzed here; see [9, Theorems 3.1 and 3.2]. In particular, by applying the cited results, for the underlying problems we can predict convergence in at most $O(\log s)$ (preconditioned) iterations.

6. Numerical estimates and comparisons. We compare the results of zero- and of some first-order approximations presented in section 4.2 with the eigenvalues computed by Matlab's QR method for the model problems in section 5. We do not report plots generated by Simpson's formula because they are very similar to those related to the midpoint formula.

In all tests, unless specified otherwise, we consider $s = m = 100$, $c = 1$, $T = 2\pi$, $x_{\max} = \pi$, $t_0 = 0$. The Jacobian matrix J is taken, in light of Dahlquist's hypothesis, as the smallest eigenvalue (in modulus) for each one of the model problems considered in the previous section. In the variable diffusion model problem, the diffusion function is of the form $a(x) = x^k$, $k > 0$ integer; i.e., it has a zero in the origin of multiplicity k. However, a similar eigenvalue distribution of the preconditioned and nonpreconditioned problems has been observed even in the absence of zeros on the real axis for various functions such as $a(x) = x^k + \epsilon$, where $\epsilon > 0$ is a small constant, varying with $O(m^{-1})$. We stress that, in both cases, eigenvalues of the Jacobian matrix (5.3), are negative, but some of them go to zero as the space discretization gets refined. On the other hand, the same asymptotic behavior holds for some nonzero eigenvalues of the Jacobian matrix (5.6), although the transport equation has constant coefficients.

Results of some tests are reported in Figures 6.1 (nonpreconditioned case), 6.2, and 6.3 (preconditioned case). In all three cases, the condition number $\kappa_2(X)$ of the eigenvector matrix X is modest. Therefore GMRES' convergence is well described by the eigenvalues.

Note that in all tests we get that even just zero-order approximations can give reasonable information on the qualitative behavior of the eigenvalues related to the smallest eigenvalues (in modulus) of the Jacobian matrix of the differential problem both in the nonpreconditioned and in the preconditioned cases, for variable and constant coefficient equations, provided that the mesh for the discretization in space is fine enough.

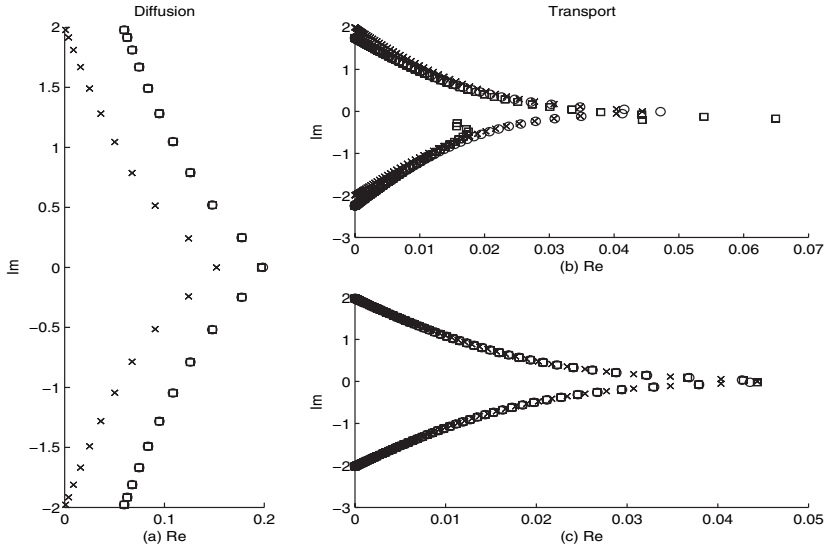

FIG. 6.1. *MP method, smallest eigenvalue (in modulus) for* (a) *the diffusion equation with* $a(x) = x^4$, $s = 20$, $m = 20$ *giving* $\kappa_2(X) \approx 7$, (b) *the transport equation,* $s = 100$, $m = 100$, $c = 1$ *giving* $\kappa_2(X) \approx 28$, *and* (c) *the same equation with* $c = 0.1$ *giving* $\kappa_2(X) \approx 28$; *x=order* 0, *o=eig*(M), $\square$*=order* 1 *approximations.*

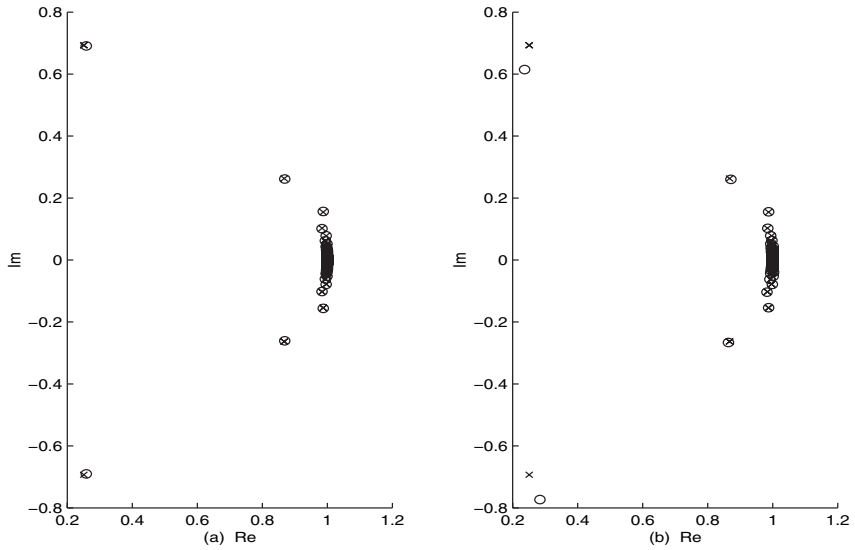

FIG. 6.2. *MP method with* P*-circulant preconditioning, smallest eigenvalue (in modulus) for* (a) *the diffusion equation with* $a(x) = x^4$, $s = 100$, $m = 100$ *and* (b) *the transport equation,* $s = 100$, $m = 100$; *+=order 0, o=eig*$(P^{-1}M)$ *approximations.*

In order to emphasize the effect of the first-order approximations with respect to zero order, just in Figure 6.1 (left) we use a rougher mesh with $s = m = 20$ for the midpoint formula without using preconditioning.

It is surprising that, for the transport equation (upper right plot in Figure 6.1), the order 1 approximation gives worse approximations than order 0 for some eigen-

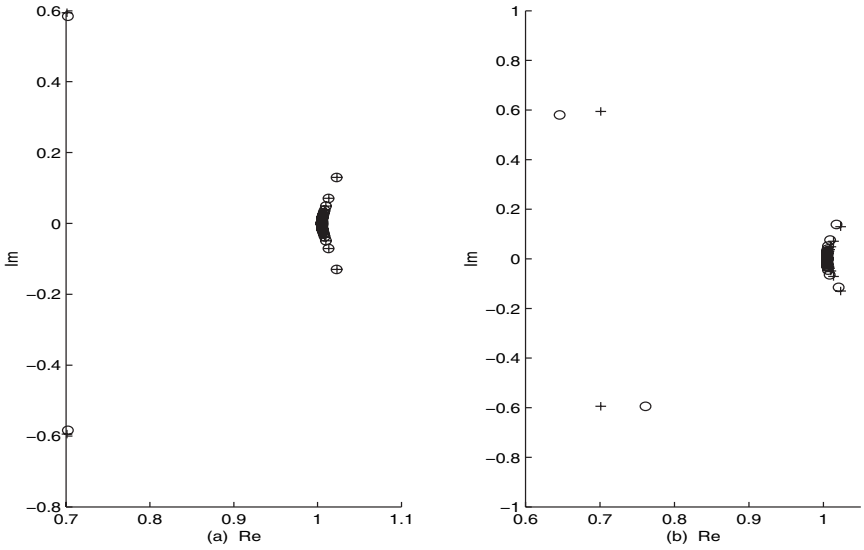

FIG. 6.3. *Adams–Moulton with* P*-circulant preconditioning, smallest eigenvalue (in modulus) for* (a) *the diffusion equation with* $a(x) = x^4$, $s = 100$, $m = 100$ *and* (b) *the transport equation,* $s = 100$, $m = 100$*; +=order 0, o=eig*$(P^{-1}M)$ *approximations.*

values: the "wrong" values come from roots $\zeta(0)$ very close to the real axis (the same occurs for the derivatives $\zeta'(0)$, $\zeta''(0)$, etc.). This phenomenon is probably explained by observing that q is pure imaginary in this setting, so that in the power series $\sum_{j=0}^{+\infty} \zeta^{(j)}(0)q^j$ just the even terms contribute to refine the real part, as well as the odd terms are related only to the imaginary part; this way the convergence radius of the series could be reduced, and the actual value of q could fall outside the region of analyticity. On the other hand, continuity still holds so that order 0 is always meaningful.

Our conjecture is confirmed by the lower right plot in Figure 6.1, where we have simply set $c = 0.1$: q has been divided by a factor of 10, and order 1 estimates become again more accurate than order 0.

For these moderate dimensions, every $\zeta(0)$ has been computed through the Matlab function `roots`. If one is interested in locating the spectrum of much larger matrices, we suggest the use of more efficient rootfinders specifically designed for sparse polynomials, such as MPSolve proposed in [11].

AN INTERPOLATION ERROR ESTIMATE ON ANISOTROPIC MESHES IN $\mathcal{R}^n$ AND OPTIMAL METRICS FOR MESH REFINEMENT*

WEIMING CAO†

Abstract. In this paper, we extend the work in [W. Cao, *Math. Comp.*, to appear] to functions of n dimensions. We measure the anisotropic behavior of higher-order derivative tensors by the "largest" (in certain sense) ellipse/ellipsoid contained in the level curve/surface of the polynomial for directional derivatives. Given the anisotropic measure for the interpolated functions, we derive an error estimate for piecewise polynomial interpolations on meshes that are quasi-uniform under a given metric. By using the inertia properties for matrix eigenvalues [R. C. Thompson, *J. Math. Anal. Appl.*, 58 (1977), pp. 572–577] and Hölder's inequality, we can identify the optimal mesh metrics leading to the smallest error bound in various norms. Furthermore, we develop a dimensional reduction method to find the anisotropic measure approximately. We present two numerical examples for linear and quadratic interpolation on various anisotropic meshes generated with the optimal mesh metrics developed in this paper. Numerical results show that the smallest interpolation error is attained exactly on meshes optimal for the corresponding error norm as predicted.

Key words. interpolation error, anisotropic mesh, anisotropic measure, aspect ratio, mesh alignment, mesh metric

1. Introduction.

It is well known in mesh generation and finite element analysis communities that in order to minimize linear interpolation errors, the eigenvalues and eigenvectors of Hessian matrices can be used to determine the element aspect ratio and mesh alignment direction for anisotropic mesh generation or refinement; see, e.g., [3, 4, 11, 13, 15, 19, 21, 23, 24]. In the case of quadratic or higher-order interpolations, the error is determined by the third- or higher-order partial derivatives of the interpolated functions. Measuring their anisotropic behavior is the key for anisotropic mesh design and refinement [2]. In particular, in order to determine an ideal element orientation and aspect ratio, one needs to define the "principal direction" and the "strength" to characterize the anisotropic behavior of the derivative tensors. In a previous paper [6], the author developed a method to measure the orientation and anisotropic ratio of the higher-order derivative tensors for two-dimensional functions. The technique is based on decomposing the homogeneous polynomials for directional derivatives into the product of linear and nonnegative quadratic polynomials. Then the anisotropic measure is defined by the directions of the lines and ellipses corresponding to those factors. An interpolation error estimate is further derived on anisotropic meshes that are quasi-uniform under given metrics. Optimal mesh metrics can be identified to minimize the error bound in various norms.

In this paper, we extend the work in [6] to functions of n dimensions. The difficulty in making such an extension is that it is generally impossible to factor a homogeneous polynomial in three or higher dimensions into the product of linear and nonnegative

quadratic functions. However, the idea in [6], which characterizes the anisotropic behavior of derivative tensors by the largest ellipse contained in the level curve of the polynomial for directional derivatives (see Remark 2.1 in [6]), is still valid in higher dimensions. Algebraically, for any positive integer k, let $\nabla^{k+1}u(\boldsymbol{x}) = \nabla(\nabla^k u)(\boldsymbol{x})$ be the $(k+1)$th-order tensor for the partial derivatives of function u at a point $\boldsymbol{x}$. We may characterize its anisotropic behavior by a suitable $n \times n$ positive definite matrix Q satisfying the following constraint:

$$|(\boldsymbol{\xi} \cdot \nabla)^{k+1} u(\boldsymbol{x})| \leq |\boldsymbol{\xi} \cdot Q\boldsymbol{\xi}|^{\frac{k+1}{2}} \qquad \forall \boldsymbol{\xi} \in \mathcal{R}^n.$$

Based on the anisotropic measure of the interpolated functions, we derive an error estimate for the higher-order polynomial interpolation on meshes that are quasi-uniform under a given mesh metric. The error bound involves the same convergence rate with respect to the number of elements as in classical results on quasi-uniform meshes under Euclidean metrics. However, the constant in the error bound depends on an interplay between the anisotropic mesh (through the mesh metric) and the anisotropic behavior of $\nabla^{k+1}u$, which can be much smaller than that in the classical error bound. Furthermore, by using the inertia properties of matrix eigenvalues proved by Thompson [26] and Hölder's inequality, we show that the smallest bound for the $W^{m,p}$-error of kth-order interpolations is attained when the metric is defined as

$$M_{k+1,m,p} = c(\lambda_{max}(Q))^{\frac{mp}{(k+1-m)p+n}} |\det(Q)|^{-\frac{1}{(k+1-m)p+n}} \cdot Q,$$

where $\lambda_{max}(Q)$ is the largest eigenvalue of the matrix Q measuring the anisotropic behavior of $\nabla^{k+1}u$. In the case of linear interpolation ($k = 1$), Q can be chosen as $Q = [(\nabla^2 u)^2]^{1/2} + \delta \cdot I_n$, where δ is a user-specified small parameter and I_n is the identity matrix. Then the above optimal metric for minimizing the L^p-error (i.e., with $m = 0$) is identical to that presented in Chen, Sun, and Xu [7]. In the case of higher-order interpolations, the optimal choice of Q relies on a constrained minimization. We develop a dimensional reduction method to find an approximate Q to measure the anisotropic behavior of $\nabla^{k+1}u$. To test the optimality of the proposed mesh metrics, we generated various anisotropic meshes using the black-box anisotropic mesh generator `bamg` [3, 16] supplied with the metric $M_{k+1,m,p}$. We compare various error norms for linear and quadratic interpolations in two dimensions. It is found in all the cases that the smallest error norm is attained exactly with meshes based on the corresponding optimal mesh metric. We also present a three-dimensional example to demonstrate that the smallest error norms are attained at the best aspect ratios, as expected.

An outline of this paper is as follows. In section 2 we present the error estimate for interpolations on anisotropic meshes that are quasi-uniform under a given metric. The metrics leading to the smallest error bounds (in various norms) are identified. In section 3 we introduce the notion of anisotropic measure of higher-order derivative tensors, and present a dimension reduction algorithm to determine the measure approximately. In section 4 we present two numerical examples demonstrating the optimality of the proposed mesh metrics. We conclude the paper with some discussion.

2. Error estimates on anisotropic meshes.

2.1. Basic assumptions and lemmas. We introduce in this subsection some assumptions regarding the anisotropic behaviors of the meshes and the higher-order derivative tensors of the interpolated functions, and list several lemmas needed for

deriving the interpolation error estimates. Denote by $\{\mathcal{T}_N\}$ a family of triangulations of a polygonal domain $\Omega \in \mathcal{R}^n$ into simplicial elements (see [9]). Here N represents the total number of elements. We study the error estimates for piecewise polynomial interpolations over a class of anisotropic meshes $\{\mathcal{T}_N\}$ that are quasi-uniform under a given metric. More specifically, let M be a Riemannian metric on Ω. For each element $\tau \in \mathcal{T}_N$, define M_τ to be the average of M over τ, i.e.,

$$M_\tau = \frac{1}{|\tau|}\int_\tau M(\boldsymbol{x})d\boldsymbol{x}.$$

Since M_τ is an $n \times n$ symmetric positive definite matrix, we may express it in its eigen-decomposition form,

$$M_\tau = \ T_\tau \cdot D_\tau \cdot T_\tau', \tag{1}$$

where $D_\tau = \mathrm{diag}(d_1, d_2, \ldots, d_n)$ is composed of all the eigenvalues of M_τ, and T_τ is the orthogonal matrix composed of all the eigenvectors. Define

$$F_\tau = T_\tau D_\tau^{-\frac{1}{2}}. \tag{2}$$

Clearly $(M_\tau)^{-1} = F_\tau \cdot F_\tau'$. Let $\boldsymbol{x}_c$ be the center of element τ. Define an affine mapping $\tilde{\boldsymbol{x}} = F_\tau^{-1}(\boldsymbol{x} - \boldsymbol{x}_c)$. Then τ is transformed into a simplex element $\tilde{\tau}$ with its center at the origin. We call a family of triangulations $\{\mathcal{T}_N\}$ quasi-uniform under metric M if there exist positive constants c_1 and c_2 independent of N such that

(i) for all $\tau \in \mathcal{T}_N$, the smallest internal angle of $\tilde{\tau} = F_\tau^{-1}(\tau - \boldsymbol{x}_c)$ is bounded from below by c_1, i.e., $\tilde{\tau}$ is shape regular; and
(ii) $\max_{\tau\in\mathcal{T}_N} |\tilde{\tau}| \le c_2 \min_{\tau\in\mathcal{T}_N} |\tilde{\tau}|$.

Note that if $\{\mathcal{T}_N\}$ is quasi-uniform under metric M, then the geometric features of the mesh are determined by M. Specifically, the element size (area/volume) is proportional to $|\det(M)|^{-1/n}$, the element aspect ratio is proportional to $1/\sqrt{d_1} : 1/\sqrt{d_2} : \cdots : 1/\sqrt{d_n}$, and the element orientation (or mesh alignment) is determined by the directions of the eigenvectors of M. Indeed, some anisotropic mesh generators, such as `bamg` developed by Borouchaki et al. [3] and Hecht [16], take user-specified metrics to control directly the anisotropic behaviors of the meshes.

We also would like to point out that not all anisotropic meshes can be considered as quasi-uniform under suitable metrics. For instance, the mesh in Figure 1 is anisotropic. But it cannot be quasi-uniform under any metric, since for a quasi-uniform mesh there is at most a fixed number of neighboring elements next to each vertex; otherwise the metric would be singular at certain points. For general meshes in n dimensions, a necessary condition for a family of triangulations being quasi-uniform under a metric is that there is an upper limit for the number of neighboring elements at each element interface (i.e., vertex, edge, and face). We call it the *limited connectivity condition* for anisotropic meshes.

In order to derive the continuous form of the interpolation error estimate, we make an assumption on the smoothness of the mesh metric M.

Assumption A. Let M be a given Riemannian metric on Ω. There exists $\delta > 0$ such that for any neighborhood $\mathcal{N}_{\boldsymbol{z}}$ of any $\boldsymbol{z} \in \Omega$ with radius (under metric M) less than δ, the following is true for all $\boldsymbol{x} \in \mathcal{N}_{\boldsymbol{z}}$:

$$c_1\ \boldsymbol{\xi} \cdot \bar{M}\boldsymbol{\xi}\ \le\ \boldsymbol{\xi} \cdot M(\boldsymbol{x})\boldsymbol{\xi}\ \le\ c_2\ \boldsymbol{\xi} \cdot \bar{M}\boldsymbol{\xi} \qquad \forall \boldsymbol{\xi} \in \mathcal{R}^n, \tag{3}$$

where $\bar{M}$ is the average of M over $\mathcal{N}_{\boldsymbol{z}}$.

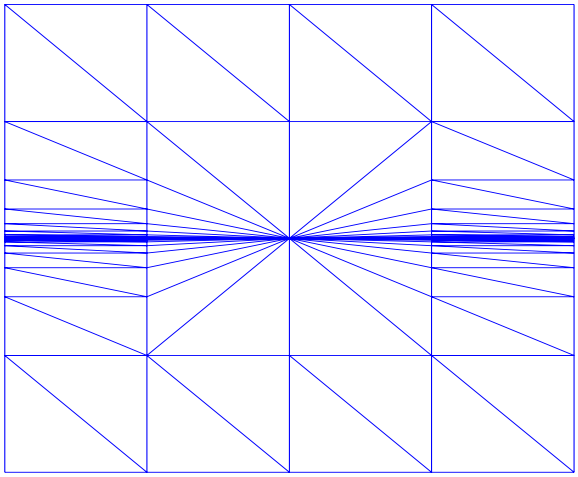

FIG. 1. *An example of anisotropic meshes that are not quasi-uniform under any metric.*

This assumption means that the metric M is equivalent to its local average over a sufficiently small neighborhood of each point. It basically requires the continuity of M. Indeed, if M is uniformly continuous over Ω, the above assumption holds obviously.

LEMMA 2.1. *Let M be a metric on Ω satisfying Assumption* A. *Let $F(\boldsymbol{x})F'(\boldsymbol{x}) = [M(\boldsymbol{x})]^{-1}$ be the decomposition of its inverse as given in* (2). *For any neighborhood $\mathcal{N}_{\boldsymbol{z}}$ of $\boldsymbol{z} \in \Omega$ with radius less than δ, we have for all $\boldsymbol{x} \in \mathcal{N}_{\boldsymbol{z}}$ that*

$$\|F^{-1}(\boldsymbol{x})\bar{F}\| \le \sqrt{c_2}, \qquad \|\bar{F}^{-1}F(\boldsymbol{x})\| \le 1/\sqrt{c_1}, \tag{4}$$

and that

$$(c_1)^n \,|\det(\bar{M})| \;\le\; \det(M(\boldsymbol{x})) \;\le\; (c_2)^n \,|\det(\bar{M})|, \tag{5}$$

where $\bar{M}$ is the average of M over $N_{\boldsymbol{z}}$, $\bar{F}\bar{F}' = \bar{M}^{-1}$ is the decomposition of $\bar{M}^{-1}$, and $\|\cdot\|$ stands for the 2-norm of matrices.

Proof. It is easy to see that

$$\|F^{-1}(\boldsymbol{x})\bar{F}\| = \max_{\boldsymbol{\xi}\in\mathcal{R}^n} \frac{\|F^{-1}(\boldsymbol{x})\bar{F}\boldsymbol{\xi}\|}{\|\boldsymbol{\xi}\|} \;=\; \left[\max_{\boldsymbol{\xi}\in\mathcal{R}^n} \frac{(\bar{F}\boldsymbol{\xi})\cdot M(\boldsymbol{x})(\bar{F}\boldsymbol{\xi})}{\boldsymbol{\xi}\cdot\boldsymbol{\xi}}\right]^{1/2}$$

$$= \left[\max_{\boldsymbol{\xi}\in\mathcal{R}^n} \frac{\boldsymbol{\xi}\cdot M(\boldsymbol{x})\boldsymbol{\xi}}{(\bar{F}^{-1}\boldsymbol{\xi})\cdot(\bar{F}^{-1}\boldsymbol{\xi})}\right]^{1/2} \;=\; \left[\max_{\boldsymbol{\xi}\in\mathcal{R}^n} \frac{\boldsymbol{\xi}\cdot M(\boldsymbol{x})\boldsymbol{\xi}}{\boldsymbol{\xi}\cdot\bar{M}\boldsymbol{\xi}}\right]^{1/2} \;\le\; \sqrt{c_2},$$

and similarly for the second inequality in (4). To show (5), we note that $c_i\boldsymbol{\xi}\cdot\bar{M}\boldsymbol{\xi} = 1$ $(i = 1, 2)$ and $\boldsymbol{\xi}\cdot M(\boldsymbol{x})\boldsymbol{\xi} = 1$ are three ellipsoids in $\mathcal{R}^n$, with their volumes being $\frac{\pi^{[\frac{n}{2}]}}{\Gamma(1+\frac{n}{2})}\cdot(c_i)^{-\frac{n}{2}}\cdot|\det(\bar{M})|^{-1/2}$, $i = 1, 2$, and $\frac{\pi^{[\frac{n}{2}]}}{\Gamma(1+\frac{n}{2})}|\det(M(\boldsymbol{x}))|^{-1/2}$, respectively. Here $[\frac{n}{2}]$ represents the integer part of $\frac{n}{2}$, and Γ is the Gamma function. Assumption A means that ellipsoid $\boldsymbol{\xi}\cdot M(\boldsymbol{x})\boldsymbol{\xi} = 1$ lies in between ellipsoids $c_i\boldsymbol{\xi}\cdot\bar{M}\boldsymbol{\xi} = 1$ $(i = 1, 2)$. Thus (5) follows easily from the ordering of their volumes. ∎

Because the error for polynomial interpolations of degree k is determined by the $(k+1)$th derivative tensor $\nabla^{k+1}u$ of the interpolated functions u, we make an assumption on its anisotropic behavior.

Assumption B. For each $\boldsymbol{x} \in \Omega$, there exists a positive definite matrix $Q(\boldsymbol{x})$ such that

$$|(\boldsymbol{\xi} \cdot \nabla)^{k+1} u(\boldsymbol{x})| \le |\boldsymbol{\xi} \cdot Q(\boldsymbol{x}) \boldsymbol{\xi}|^{\frac{k+1}{2}} \qquad \forall \boldsymbol{\xi} \in \mathcal{R}^n. \tag{6}$$

Note that $p_{k+1}(\boldsymbol{\xi}) \equiv (\boldsymbol{\xi} \cdot \nabla)^{k+1} u(\boldsymbol{x})$ is a homogeneous polynomial of $\boldsymbol{\xi}$ of degree $k+1$. For $\|\boldsymbol{\xi}\| = 1$, $p_{k+1}(\boldsymbol{\xi})$ is simply the $(k+1)$th-order directional derivative at $\boldsymbol{x}$ along $\boldsymbol{\xi}$. The right-hand side is also a homogeneous function of $\boldsymbol{\xi}$. Thus, geometrically Assumption B is equivalent to saying that at each $\boldsymbol{x}$, the ellipse/ellipsoid $\boldsymbol{\xi} \cdot Q\boldsymbol{\xi} = 1$ is contained in the level curve/surface $|p_{k+1}(\boldsymbol{\xi})| = 1$ for directional derivatives.

Some choices of Q can be made readily. For instance, if one is only interested in isotropic mesh refinement, then we may choose $Q(\boldsymbol{x}) = |||\nabla^{k+1} u(\boldsymbol{x})||| \cdot I_n$, where

$$|||\nabla^{k+1} u(\boldsymbol{x})||| = \max_{\|\boldsymbol{\xi}\|=1} |(\boldsymbol{\xi} \cdot \nabla)^{k+1} u|$$

is the largest $(k+1)$th-order directional derivative at $\boldsymbol{x}$, and I_n is the $n \times n$ identity matrix. This choice corresponds to defining Q by the largest circle/sphere contained in the level curve/surface. In the case of $k = 1$ (i.e., linear interpolation), Q can be chosen as

$$Q = abs(\nabla^2 u) + \delta \cdot I_n,$$

where $abs(A) = [A^T A]^{1/2}$ is the symmetric matrix of the same eigenvectors as matrix A, but of eigenvalues equal to the absolute eigenvalues of A. δ is a small positive constant to avoid Q from being degenerate in case $\nabla^2 u(\boldsymbol{x})$ becomes singular. Such a Q is called the majorization matrix for the Hessian $\nabla^2 u$ in Chen, Sun, and Xu [7].

In order to reflect accurately the anisotropic behavior of $\nabla^{k+1} u$ at $\boldsymbol{x}$, the matrix $Q(\boldsymbol{x})$ in (6) should be chosen as "small" (in certain sense) as possible. Also, its choice should be invariant under translation and rotation transforms of the coordinates, since the anisotropic behavior is so. The best choice will depend on how Assumption B is used. For minimizing the interpolation error in various norms, we present in section 3.1 an ideal choice of Q. We also present in section 3.2 an algorithm to find an approximate Q that characterizes roughly the anisotropic behavior of $\nabla^{k+1} u$.

Next, we list two lemmas regarding the anisotropic behavior of $\nabla^{k+1} u$ under affine transforms.

LEMMA 2.2. *Let* $|\alpha| = \sum \alpha_i$ *for any multi-index* $\alpha = (\alpha_1, \ldots, \alpha_n)$ *of nonnegative integers. For any integer* $k \ge 0$, $\sum_{|\alpha|=k+1} |\partial^\alpha u|$ *is equivalent to* $|||\nabla^{k+1} u|||$.

Proof. Define

$$\bar{\mathcal{P}}_{k+1} = \left\{ v(\boldsymbol{\xi}) = \sum_{|\alpha|=k+1} C_\alpha (\xi_1)^{\alpha_1} \cdots (\xi_n)^{\alpha_n} \;\middle|\; \forall C_\alpha \in R \right\}.$$

The $\bar{\mathcal{P}}_{k+1}$ is a finite-dimensional linear space. It is easy to verify that

$$\|v\|_{\bar{\mathcal{P}}_{k+1}} = \max_{\|\boldsymbol{\xi}\|=1} |v(\boldsymbol{\xi})|$$

is a norm on $\bar{\mathcal{P}}_{k+1}$. Indeed, if $\|v\|_{\bar{\mathcal{P}}_{k+1}} = 0$, then for any $\boldsymbol{\xi} \ne \mathbf{0}$, $|v(\boldsymbol{\xi})| = \|\boldsymbol{\xi}\|^{k+1} \cdot |v(\boldsymbol{\xi}/\|\boldsymbol{\xi}\|)| = 0$, thus $v \equiv 0$ and $\|\cdot\|_{\bar{\mathcal{P}}_{k+1}}$ is a norm.

On the other hand, $\sum_{|\alpha|=k+1} |C_\alpha|$ is clearly also a norm on $\bar{\mathcal{P}}_{k+1}$. Hence it is equivalent to $\|v\|_{\bar{\mathcal{P}}_{k+1}}$. Now, for $p_{k+1}(\boldsymbol{\xi}) = (\boldsymbol{\xi} \cdot \nabla)^{k+1} u \in \bar{\mathcal{P}}_{k+1}$, since its coefficients

C_α are multiples of $\partial^\alpha u$ with fixed positive constants, therefore $\sum_{|\alpha|=k+1} |\partial^\alpha u|$ is equivalent to $\sum_{|\alpha|=k+1} |C_\alpha|$, and to $\max_{\|\boldsymbol{\xi}\|=1} |p_{k+1}(\boldsymbol{\xi})| = |||\nabla^{k+1} u|||$, too. ∎

LEMMA 2.3. *Let $\boldsymbol{x} = F_\tau(\tilde{\boldsymbol{x}}) + \boldsymbol{x}_c$ be the affine mapping from $\tilde\tau$ to τ, and define $\tilde u(\tilde{\boldsymbol{x}}) = u(F_\tau(\tilde{\boldsymbol{x}}) + \boldsymbol{x}_c)$. Denote by $\tilde\nabla$ the gradient operator with respect to $\tilde{\boldsymbol{x}}$. Then under Assumption* B *we have*

$$|||\tilde\nabla^{k+1} \tilde u(\tilde{\boldsymbol{x}})||| \le \|F_\tau' Q F_\tau\|^{\frac{k+1}{2}}.$$

Proof. Let $\tilde p_{k+1}(\boldsymbol{\xi}) = (\boldsymbol{\xi}\cdot\tilde\nabla)^{k+1}\tilde u(\tilde{\boldsymbol{x}})$. By the fact that F_τ is constant, it follows from the chain rule for derivatives that $\tilde\nabla = F_\tau'\nabla$ and $\tilde p_{k+1}(\boldsymbol{\xi}) = [\boldsymbol{\xi}\cdot(F_\tau'\nabla)]^{k+1} u(\boldsymbol{x}) = p_{k+1}(F_\tau\boldsymbol{\xi})$. Hence Assumption B implies that

$$|||\tilde\nabla^{k+1}\tilde u(\tilde{\boldsymbol{x}})||| = \max_{\|\boldsymbol{\xi}\|=1} |p_{k+1}(F_\tau\boldsymbol{\xi})| \le \max_{\|\boldsymbol{\xi}\|=1} |(F_\tau\boldsymbol{\xi})' Q (F_\tau\boldsymbol{\xi})|^{\frac{k+1}{2}} = \|F_\tau' Q F_\tau\|^{\frac{k+1}{2}}. \qquad ∎$$

Finally, in order to minimize the interpolation errors and to select the optimal mesh metrics, we need the following inertial properties for matrix eigenvalues established in [26] by Thompson and an elementary inequality.

LEMMA 2.4. *Let A be an $n\times n$ symmetric matrix with eigenvalues $\alpha_1 \ge \cdots \ge \alpha_n \ge 0$, and let S be a nonsingular matrix with singular values $s_1 \ge \cdots \ge s_n$. Denote the eigenvalues of $B = S^* A S$ by $\beta_1 \ge \cdots \ge \beta_n$. Then $\beta_{i+j-n} \ge s_i^2 \alpha_j$ for all $1 \le i, j \le n$ with $i + j > n$. In particular, $\lambda_{max}(B) = \beta_1 \ge \max_{1\le i\le n}(s_i)^2 \alpha_{n+1-i}$.*

LEMMA 2.5. *Let $0 < \lambda_1 \le \lambda_2 \le \cdots \le \lambda_n$ and $0 \le \alpha < 1$. For $\boldsymbol{t} = (t_1, t_2, \ldots, t_n)$, let*

$$f(\boldsymbol{t}) = |t_n|^\alpha \cdot \max_{1\le i\le n} \frac{\lambda_i}{t_i}.$$

Then f attains its infimum on the set

$$\mathcal{K} \;=\; \{\; \boldsymbol{t} \in \mathcal{R}^n \mid 0 < t_1 \le t_2 \le \cdots \le t_n, \;\; \textit{and } \Pi_{i=1}^n t_i = 1 \;\}$$

if and only if $\frac{\lambda_i}{t_i} = \text{const.}$ for all i.

Proof. First we show that f attains its infimum on $\mathcal{K}$. Let $\{\boldsymbol{t}^{(k)}\}$ be a sequence in $\mathcal{K}$ such that $\lim f(\boldsymbol{t}^{(k)}) = \inf_{\boldsymbol{t}\in\mathcal{K}} f(\boldsymbol{t}) < \infty$. Clearly $\{\boldsymbol{t}^{(k)}\}$ must be bounded; otherwise there exists a subsequence $\{\boldsymbol{t}^{(k')}\}$ whose nth components $t_n^{(k')} \to \infty$, while its ith components $t_i^{(k')} \to 0$ for some i, which would imply $f(\boldsymbol{t}^{(k)}) \to \infty$. Therefore, $\{\boldsymbol{t}^{(k)}\}$ is bounded and has a cluster point $\boldsymbol{t}^* \in \mathcal{K}$ with $f(\boldsymbol{t}^*) = \inf_{\boldsymbol{t}\in\mathcal{K}} f(\boldsymbol{t})$.

Next we show that

$$\frac{\lambda_i}{t_i^*} \le \frac{\lambda_n}{t_n^*} \qquad \forall i. \tag{7}$$

Suppose otherwise; then there exists $m \le n-1$ such that

$$\max_{1\le i\le n} \frac{\lambda_i}{t_i^*} = \frac{\lambda_m}{t_m^*} > \frac{\lambda_j}{t_j^*} \qquad \forall j \ge m+1.$$

For each $j \ge m+1$, since $\lambda_m \le \lambda_j$, we must have $t_m^* < t_j^*$. Let $\beta > 1$ and define $\tilde{\boldsymbol{t}} = (\tilde t_1, \tilde t_2, \ldots, \tilde t_n)$ with

$$\tilde t_i \;=\; \begin{cases} \beta^{1/m} t_i^* & \text{if } i \le m, \\ \beta^{-1/(n-m)} t_i^* & \text{if } i \ge m+1. \end{cases}$$

For β close enough to 1, we have $\tilde{\boldsymbol{t}} \in \mathcal{K}$ and

$$\begin{aligned} f(\tilde{\boldsymbol{t}}) &= \beta^{-\alpha/(n-m)} \\ &\quad \cdot \max\left[\beta^{-1/m} \cdot (t_n^*)^\alpha \max_{1\le i\le m} \frac{\lambda_i}{t_i^*}, \beta^{-1/(n-m)} \cdot (t_n^*)^\alpha \max_{m+1\le i\le n} \frac{\lambda_i}{t_i^*} \right] \\ &< f(\boldsymbol{t}^*). \end{aligned}$$

Finally we prove that

$$\frac{\lambda_i}{t_i^*} = \text{const.} \qquad \forall i. \tag{8}$$

Note that $\Pi_{i=1}^n t_i^* = 1$. It follows from (7) that

$$\Pi_{i=1}^n \lambda_i \le \left(\frac{\lambda_n}{t_n^*}\right)^n,$$

which implies

$$t_n^* \le \left(\Pi_{i=1}^n \frac{\lambda_n}{\lambda_i}\right)^{1/n}.$$

In particular, "=" in the above inequality holds if and only if (8) is satisfied. Thus

$$\inf_{\boldsymbol{t}\in\mathcal{K}} f(\boldsymbol{t}) = f(\boldsymbol{t}^*) = \lambda_n (t_n^*)^{\alpha-1} \ge \lambda_n \left(\Pi_{i=1}^n \frac{\lambda_n}{\lambda_i}\right)^{\frac{\alpha-1}{n}},$$

and "=" holds if and only if (8) is satisfied. □

2.2. Error estimate and optimal mesh metrics. We first recall some classical results for the interpolation error estimates under Euclidean metrics. Let k be a positive integer. Denote by P_k the set of all the polynomials of $\boldsymbol{x} \in \mathcal{R}^n$ of total degree less than or equal to k. Let Π_k be an interpolation operator whose restriction on each element preserves P_k. It is well known that on any shape regular element τ, and for any $0 \le m \le k$ and $p, q \in [1, \infty]$

$$|u - \Pi_k u|_{m,p,\tau} \le c|\tau|^{(k+1-m)/n+1/p-1/q} |u|_{k+1,q,\tau}, \tag{9}$$

provided that

$$W^{k+1,q}(\tau) \hookrightarrow C^s(\tau) \qquad \text{and} \qquad W^{k+1,q}(\tau) \hookrightarrow W^{m,p}(\tau), \tag{10}$$

where s is the highest degree of derivatives used in defining the interpolation Π_k. See, e.g., Theorem 3.1.5 of [9].

If we further assume that $\{\mathcal{T}_N\}$ is a family of quasi-uniform triangulations, i.e., all $\tau \in \mathcal{T}_N$, for all N, are shape regular and

$$\max_{\tau\in\mathcal{T}_N} |\tau| \le c \min_{\tau\in\mathcal{T}_N} |\tau|,$$

then we have globally

$$\left(\sum_{\forall \tau\in\mathcal{T}_N} |u - \Pi_k u|_{m,p,\tau}^p\right)^{1/p} \le cN^{-(k+1-m)/n-1/p+1/q} |u|_{k+1,q,\Omega}. \tag{11}$$

Now we present the main theorem of this paper on interpolation error estimates for anisotropic meshes.

THEOREM 2.1. *Let M be a Riemannian metric on Ω satisfying Assumption* A, *and let $F(\boldsymbol{x})\ F'(\boldsymbol{x}) = (M(\boldsymbol{x}))^{-1}$ be the decomposition of its inverse at each $\boldsymbol{x} \in \Omega$. Let $\{\mathcal{T}_N\}$ be a family of triangulations of Ω that is quasi-uniform under metric M. Let k be a positive integer, and let Π_k be an interpolation operator whose restriction on each element preserves P_k. For any function u satisfying Assumption* B, *any $0 \le m \le k$, and $p \in [1, \infty]$ satisfying* (10), *we have*

(12)

$$\left(\sum_{\tau \in \mathcal{T}_N} |u - \Pi_k u|^p_{m,p,\tau} \right)^{1/p}$$

$$\le\ cN^{-(k+1-m)/n} \left\{ \int_\Omega |\det(M)|^{\frac{1}{2}} \right\}^{(k+1-m)/n} \left\{ \int_\Omega \|F^{-1}\|^{mp} \|F' Q F\|^{\frac{(k+1)p}{2}} \right\}^{1/p}.$$

Furthermore, among all the Riemannian metrics, the optimal bound of the above estimate is attained when M is defined to be

$$M_{k+1,m,p} \ \equiv\ c(\lambda_{max}(Q))^{\frac{mp}{(k+1-m)p+n}} |\det(Q)|^{-\frac{1}{(k+1-m)p+n}} \cdot Q. \tag{13}$$

If $\{\mathcal{T}_N\}$ is quasi-uniform under $M_{k+1,m,p}$, we have

$$\left(\sum_{\tau \in \mathcal{T}_N} |u - \Pi_k u|^p_{m,p,\tau} \right)^{1/p} \tag{14}$$

$$\le\ cN^{-(k+1-m)/n} \parallel |\lambda_{max}(Q)|^{\frac{m}{2}} |\det(Q)|^{\frac{k+1-m}{2n}} \|_{L^{np/[(k+1-m)p+n]}(\Omega)}.$$

Proof. Consider an element $\tau \in \mathcal{T}_N$. Denote by M_τ the average of M over τ, and let F_τ be defined as in (2). By the fact that (see [9])

$$\sum_{|\alpha|=m} |\partial^\alpha v(\boldsymbol{x})| \le c \|F_\tau^{-1}\|^m \cdot \sum_{|\alpha|=m} |\partial^\alpha \tilde{v}(\tilde{\boldsymbol{x}})| \qquad \forall v,$$

we have

$$\begin{aligned} |u - \Pi_k u|^p_{m,p,\tau} &= \int_{\tilde{\tau}} \sum_{|\alpha|=m} |\partial^\alpha (u - \Pi_k u)(\boldsymbol{x})|^p \, d\tilde{\boldsymbol{x}} \\ &\le c\, \frac{|\tau|}{|\tilde{\tau}|}\ \|F_\tau^{-1}\|^{mp}\ |\tilde{u} - \tilde{\Pi}_k \tilde{u}|^p_{m,p,\tilde{\tau}}. \end{aligned}$$

Because $\tilde{\tau}$ is shape regular, we have from the classical error estimate (9) that

$$|\tilde{u} - \tilde{\Pi}_k \tilde{u}|_{m,p,\tilde{\tau}} \le c |\tilde{\tau}|^{(k+1-m)/n}\ |\tilde{u}|_{k+1,p,\tilde{\tau}},$$

which implies that

$$|u - \Pi_k u|^p_{m,p,\tau} \le c|\tau|\, |\tilde{\tau}|^{(k+1-m)p/n-1}\, \|F_\tau^{-1}\|^{mp} |\tilde{u}|^p_{k+1,p,\tilde{\tau}}.$$

It follows from Lemmas 2.2 and 2.3 that

$$\sum_{|\alpha|=k+1} |\partial^\alpha \tilde{u}(\tilde{\boldsymbol{x}})| \;\le\; c\,|\|\tilde{\nabla}^{k+1}\tilde{u}(\tilde{\boldsymbol{x}})|\| \;\le\; c\,\|F_\tau' Q(\boldsymbol{x}) F_\tau\|^{\frac{k+1}{2}}.$$

Hence

$$\begin{aligned}|u-\Pi_k u|^p_{m,p,\tau} &\le c|\tau|\,|\tilde{\tau}|^{(k+1-m)p/n-1}\,\|F_\tau^{-1}\|^{mp}\int_\tau \|F_\tau' Q(\boldsymbol{x})F_\tau\|^{\frac{(k+1)p}{2}}\cdot\det\left(\frac{\partial\tilde{\boldsymbol{x}}}{\partial\boldsymbol{x}}\right)\,d\boldsymbol{x}\\ &\le c|\tilde{\tau}|^{(k+1-m)p/n}\,\|F_\tau^{-1}\|^{mp}\int_\tau \|F_\tau' Q(\boldsymbol{x})F_\tau\|^{\frac{(k+1)p}{2}}\,d\boldsymbol{x}.\end{aligned}$$

Now we write F_τ on the right-hand side of the above inequality in terms of $M(\boldsymbol{x})$ directly. For each $\boldsymbol{x}\in\tau$, decompose $M(\boldsymbol{x})$ into its eigenvalues and eigenvectors as

$$M(\boldsymbol{x}) = T(\boldsymbol{x})\cdot D(\boldsymbol{x})\cdot T'(\boldsymbol{x}), \tag{15}$$

where $D(\boldsymbol{x})$ is the diagonal matrix composed of all the eigenvalues $d_1(\boldsymbol{x})\le d_2(\boldsymbol{x})\le\cdots\le d_n(\boldsymbol{x})$ and T is the orthogonal matrix composed of all the eigenvectors. Define also $F(\boldsymbol{x}) = T(\boldsymbol{x})D(\boldsymbol{x})^{-\frac{1}{2}}$ as in (2). Then by Assumption A about the smoothness of M, we have from Lemma 2.1 that

$$\begin{aligned}\|F_\tau' Q(\boldsymbol{x})F_\tau\| &\le \|(F^{-1}(\boldsymbol{x})F_\tau)'\cdot(F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x}))\cdot(F^{-1}(\boldsymbol{x})F_\tau)\|\\ &\le \|F^{-1}(\boldsymbol{x})F_\tau\|^2\cdot\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\|\\ &\le c\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\|\end{aligned}$$

and

$$\|F_\tau^{-1}\| \le \|F_\tau^{-1}F(\boldsymbol{x})\|\cdot\|F^{-1}(\boldsymbol{x})\| \le c\|F^{-1}(\boldsymbol{x})\|.$$

Therefore,

$$|u-\Pi_k u|^p_{m,p,\tau} \le c|\tilde{\tau}|^{(k+1-m)p/n}\int_\tau \|F^{-1}(\boldsymbol{x})\|^{mp}\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\|^{\frac{(k+1)p}{2}}\,d\boldsymbol{x}. \tag{16}$$

Summing up the above inequality for all $\tau\in\mathcal{T}_N$, we find that

$$\begin{aligned}&\sum_{\tau\in\mathcal{T}_N}|u-\Pi_k u|^p_{m,p,\tau}\\ &\quad\le c\left(\max_{\tau\in\mathcal{T}_N}|\tilde{\tau}|\right)^{(k+1-m)p/n}\int_\Omega \|F^{-1}(\boldsymbol{x})\|^{mp}\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\|^{\frac{(k+1)p}{2}}\,d\boldsymbol{x}.\end{aligned} \tag{17}$$

Now we estimate $|\tilde{\tau}|$. Note that $\tilde{\tau} = F_\tau^{-1}(\tau-\boldsymbol{x}_c)$ and $\det(F_\tau^{-1}) = |\det(M_\tau)|^{1/2}$. By the assumption that $\{\mathcal{T}_N\}$ is quasi-uniform under metric M, the sizes of all $\tilde{\tau}$'s are of the same order. Hence,

$$\begin{aligned}\max_{\tau\in\mathcal{T}_N}|\tilde{\tau}| &\le cN^{-1}\sum_{\tau\in\mathcal{T}_N}|\tilde{\tau}| = cN^{-1}\textstyle\sum_{\tau\in\mathcal{T}_N}\displaystyle\int_\tau|\det(F_\tau^{-1})|\,d\boldsymbol{x}\\ &= cN^{-1}\textstyle\sum_{\tau\in\mathcal{T}_N}\displaystyle\int_\tau|\det(M_\tau)|^{1/2}\,d\boldsymbol{x}\\ &\le cN^{-1}\textstyle\sum_{\tau\in\mathcal{T}_N}\displaystyle\int_\tau|\det(M(\boldsymbol{x}))|^{1/2}\,d\boldsymbol{x}\\ &= cN^{-1}\int_\Omega|\det(M(\boldsymbol{x}))|^{1/2}\,d\boldsymbol{x},\end{aligned}$$

where in the last inequality we used (5) in Lemma 2.1. Putting the above inequality into (17), we have the error estimate (12).

Next, we consider for what metric M the error bound on the right-hand side of (12) is the smallest. We determine M through its eigenvalues and eigenvectors. Since they are independent of each other, we proceed in three steps as follows. First, for any $\boldsymbol{x} \in \Omega$ and a given set of eigenvalues of $M(\boldsymbol{x})$, we determine the orthogonal matrix $T(\boldsymbol{x})$ so that the integrands on the right-hand side of (12) are the smallest possible. Then we determine the ratios among the eigenvalues to further minimize the integrands. Finally, the optimal distribution of $\det(M)$ on Ω is determined such that the error bound in (12) is minimized.

First, for fixed $\boldsymbol{x}$ we write $Q(\boldsymbol{x})$ in its eigen-decomposition form,

$$Q(\boldsymbol{x}) = S(\boldsymbol{x}) \cdot \mathrm{diag}(\lambda_1, \lambda_2, \ldots, \lambda_n) \cdot S'(\boldsymbol{x}),$$

where $0 < \lambda_1 \le \lambda_2 \le \cdots \le \lambda_n$ are eigenvalues of $Q(\boldsymbol{x})$ and S is the orthogonal matrix composed of all its eigenvectors. Applying Lemma 2.4 on the inertia properties of matrix eigenvalues (with $A = Q(x)$, $S = F(x)$, $\alpha_i = \lambda_{n+1-i}$, and $s_i = (d_i)^{-1/2}$), we have

$$\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\| \;=\; \lambda_{\max}(F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})) \;\ge\; \max_{1\le i\le n}\{\lambda_i/d_i\}.$$

Moreover, the equality in the above relation is attained when $T(\boldsymbol{x}) = S(\boldsymbol{x})$. Thus, we conclude that

$$\min_{\forall T} \|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\| = \max_{1\le i\le n}\{\lambda_i/d_i\},$$

and the minimum value is attained at $T(\boldsymbol{x}) = S(\boldsymbol{x})$. Since $\|F^{-1}(\boldsymbol{x})\| = (d_n)^{1/2}$ is independent of T, then for the integrand $\|F^{-1}(\boldsymbol{x})\|^{mp}\|F'(\boldsymbol{x})Q(\boldsymbol{x})F(\boldsymbol{x})\|^{\frac{(k+1)p}{2}}$, this choice of $T(\boldsymbol{x})$ is also optimal, with the minimum value

$$(d_n)^{\frac{mp}{2}} \left[\max_{1\le i\le n}\{\lambda_i/d_i\}\right]^{\frac{(k+1)p}{2}}. \tag{18}$$

Now we consider minimizing (18) with respect to the ratios among eigenvalues of $M(\boldsymbol{x})$. For fixed $\det(M) = \Pi_{i=1}^n d_i$, it follows from Lemma 2.5 that the expression in (18) achieves its minimum if and only if

$$\lambda_i/d_i = \frac{1}{\mu} \qquad \forall i = 1, 2, \ldots, n,$$

where μ depends on $\boldsymbol{x}$ and will be determined later. This implies that $d_i = \mu \cdot \lambda_i$ for all i, and

$$M(\boldsymbol{x}) \;=\; \mu(\boldsymbol{x}) \cdot Q(\boldsymbol{x}). \tag{19}$$

The minimum value of (18) is

$$\mu^{-\frac{(k+1-m)p}{2}}(\lambda_n)^{\frac{mp}{2}}. \tag{20}$$

This is the smallest possible value of the integrand in (17) at $\boldsymbol{x}$ for all possible $T(\boldsymbol{x})$ and different ratios among $d_i(\boldsymbol{x})$, $i = 1, 2, \ldots, n$. With this optimal choice, the error

estimate (12) becomes

$$\sum_{\tau\in\mathcal{T}_N} |u-\Pi_k u|^p_{m,p,\tau} \tag{21}$$
$$\leq\ cN^{-(k+1-m)p/n}\left\{\int_\Omega \mu^{\frac{n}{2}}\,|\det(Q)|^{\frac{1}{2}}\right\}^{(k+1-m)p/n}\cdot\int_\Omega \mu^{-\frac{(k+1-m)p}{2}}(\lambda_n)^{\frac{mp}{2}}.$$

Finally, we determine the distribution of μ on Ω to minimize the right-hand side of the above error estimate. Let $\alpha=(k+1-m)p/n$, and let

$$f=\mu^{\frac{n}{2}}\cdot|\det(Q)|^{\frac{1}{2}},$$
$$g=\mu^{-\frac{(k+1-m)p}{2}}\cdot(\lambda_n)^{\frac{mp}{2}}.$$

Then the integrals on the right-hand side of (21) are $[\int f]^\alpha[\int g]$. It follows from Hölder's inequality that

$$\begin{aligned}\left\{\left[\int f\right]^\alpha\cdot\left[\int g\right]\right\}^{1/(\alpha+1)} &= \left[\int f\right]^{\alpha/(\alpha+1)}\cdot\left[\int g\right]^{1/(\alpha+1)}\\ &= \|f^{\frac{\alpha}{\alpha+1}}\|_{L^{(\alpha+1)/\alpha}}\cdot\|g^{\frac{1}{\alpha+1}}\|_{L^{\alpha+1}}\\ &\geq \int f^{\frac{\alpha}{\alpha+1}}\cdot g^{\frac{1}{\alpha+1}},\end{aligned}$$

and the equality holds if and only if f is a constant multiple of g. In this case

$$\mu=c(\lambda_n)^{\frac{mp}{(k+1-m)p+n}}|\det(Q)|^{-\frac{1}{(k+1-m)p+n}}, \tag{22}$$

and the metric M becomes

$$M=\mu\cdot Q=c(\lambda_n)^{\frac{mp}{(k+1-m)p+n}}|\det(Q)|^{-\frac{1}{(k+1-m)p+n}}\cdot Q.$$

With this optimal choice of metric M, we have the smallest error bound

$$\sum_{\tau\in\mathcal{T}_N} |u-\Pi_k u|^p_{m,p,\tau} \leq cN^{-\frac{(k+1-m)p}{n}}\left[\int\mu^{\frac{n}{2}}|\det(Q)|^{\frac{1}{2}}\right]^{\alpha+1} \tag{23}$$
$$\leq cN^{-\frac{(k+1-m)p}{n}}\left\{\int_\Omega(\lambda_n)^{\frac{mp}{2(\alpha+1)}}\,|\det(Q)|^{\frac{\alpha}{2(\alpha+1)}}\right\}^{\alpha+1}.$$

Let $\beta=\frac{p}{\alpha+1}=\frac{np}{(k+1-m)p+n}$. Then we may write the above inequality in the following form:

$$\left(\sum_{\tau\in\mathcal{T}_N} |u-\Pi_k u|^p_{m,p,\tau}\right)^{1/p} \leq cN^{-\frac{k+1-m}{n}}\left\{\int_\Omega[\,(\lambda_n)^{\frac{m}{2}}|\det(Q)|^{\frac{\alpha}{2p}}\,]^\beta\right\}^{1/\beta} \tag{24}$$
$$= cN^{-\frac{k+1-m}{n}}\left\|(\lambda_n)^{\frac{m}{2}}|\det(Q)|^{\frac{k+1-m}{2n}}\right\|_{L^{np/[(k+1-m)p+n]}(\Omega)}.$$

This completes the proof of the theorem. □

Remark 2.1. Theorem 2.1 covers the error estimate on isotropic meshes as a special case. Indeed, if we choose $Q(\boldsymbol{x}) = c\,|\|\nabla^{k+1}u(\boldsymbol{x})\|\|^{\frac{2}{k+1}} \cdot I_n$, then the optimal metric $M_{k+1,m}$ based on Q becomes $c\,|\|\nabla^{k+1}u\|\|^{\frac{2p}{(k+1-m)p+n}} \cdot I_n$, and that $\{\mathcal{T}_N\}$ is quasi-uniform under $M_{k+1,m,p}$ implies it is isotropic. In this case, error estimate (14) is reduced to

$$\left(\sum_{\tau\in\mathcal{T}_N} |u-\Pi_k u|^p_{m,p,\tau}\right)^{\frac{1}{p}} \;\le\; c\,N^{-\frac{k+1-m}{n}}\;|u|_{k+1,np/[(k+1-m)p+n],\Omega}.$$

The above error bound is sharper than estimate (11) with $q = p$, since $L^p(\Omega) \subset L^{\frac{np}{(k+1-m)p+n}}$ due to $m \le k$.

Remark 2.2. In the case of $k = 1$, namely for linear interpolation, we may choose $Q = abs(\nabla^2 u)+\delta\cdot I_n$, where $\delta > 0$ is a small parameter to avoid Q from being singular. In this case, the optimal metrics and error estimate with $m = 0$ (i.e., for L^p-error) stated in Theorem 2.1 are identical to those in [7] by Chen, Sun, and Xu. They are also identical to those in [18] by Huang. For the case of $k \ge 2$, error estimates and mesh metrics are also derived in [17, 18] based on the sum of the Hessians of $(k-1)$th partial derivatives. It is shown in our previous study [5] that metrics based on the sum of the Hessians can be problematic for general anisotropic meshes; see Remark 3 in [5] for details.

Remark 2.3. It is easy to see that if $\{\mathcal{T}_N\}$ is quasi-uniform under the optimal metric $M_{k+1,m,p}$, then estimate (16) for the $W^{m,p}(\tau)$-seminorm of the error is of the same magnitude on each element. In other words, $M_{k+1,m,p}$ is a matrix which makes the $W^{m,p}$-error evenly distributed over all elements. Therefore, the optimal metrics and meshes follow also the so-called equidistribution principle. This principle has been used extensively to justify the selection of optimal or nearly optimal meshes; see, e.g., [12, 18, 22].

3. Measuring the anisotropic behavior of $\nabla^{k+1}u(\boldsymbol{x})$.

3.1. Definition of anisotropic measure of $\nabla^{k+1}u(\boldsymbol{x})$. It is seen from Theorem 2.1 that a good interpolation error estimate relies on a proper matrix Q in Assumption B that characterizes the anisotropic behavior of $\nabla^{k+1}u$ at each point. In order to produce as tight as possible an error estimate, we need to measure as accurately as possible the anisotropic behavior of $\nabla^{k+1}u$. Note that the optimal error bound (14) is determined by the function $|\lambda_{max}(Q(\boldsymbol{x}))|^{\frac{m}{2}}\,|\det(Q(\boldsymbol{x}))|^{\frac{k+1-m}{2n}}$, where $Q(\boldsymbol{x})$ is a positive definite matrix satisfying Assumption B. Therefore, to produce the tightest error bound, we choose matrix $Q(\boldsymbol{x})$ in (13) and (14) to be $Q_{k+1,m}$, the solution of the following minimization problem:

$$\min_{Q\in\mathcal{V}_{k+1}(\boldsymbol{x})} |\lambda_{max}(Q)|^{\frac{m}{2}}\,|\det(Q)|^{\frac{k+1-m}{2n}}, \tag{25}$$

where $\mathcal{V}_{k+1}(\boldsymbol{x})$ is the set of all $n\times n$ symmetric positive definite matrices Q that satisfy

$$|p_{k+1}(\boldsymbol{\xi})| = |(\boldsymbol{\xi}\cdot\nabla)^{k+1}u(\boldsymbol{x})| \le (\boldsymbol{\xi}\cdot Q\boldsymbol{\xi})^{\frac{k+1}{2}} \qquad \forall\boldsymbol{\xi}\in\mathcal{R}^n. \tag{26}$$

We call $Q_{k+1,m}$ an *anisotropic measure* of $\nabla^{k+1}u(\boldsymbol{x})$. It depends not only on k, the interpolation degree, but also on the index m, which is associated with the norm used to measure the error. In the special case of $m = 0$ (i.e., for L^p-error estimates), the

above problem is reduced to minimizing $\det(Q)$ for all $Q \in \mathcal{V}_{k+1}(\boldsymbol{x})$. Geometrically, for any symmetric positive definite matrix Q, the level curve/surface $\boldsymbol{\xi} \cdot Q\boldsymbol{\xi} = 1$ is an ellipse/ellipsoid of area/volume proportional to $|\det(Q)|^{-1/2}$, and $Q \in \mathcal{V}_{k+1}(\boldsymbol{x})$ implies that this level curve/surface is enclosed in that of $|p_{k+1}(\boldsymbol{\xi})| = 1$. Thus the solution $Q_{k+1,m}$ to (25) corresponds to the largest ellipse/ellipsoid (in area/volume) contained in $|p_{k+1}(\boldsymbol{\xi})| = 1$.

The above definition of $Q_{k+1,m}$ based on constrained minimization formulation is not quite convenient for theoretical study and practical use. We may change it into an unconstrained problem. For this purpose, we write the eigen-decomposition of each $Q \in \mathcal{V}_{k+1}(\boldsymbol{x})$ in the form

$$Q = \nu \cdot S\ \Lambda\ S'. \tag{27}$$

Without loss of generality, we assume $\nu = |\det(Q)|^{\frac{1}{n}}$ and

$$\Lambda = \mathrm{diag}(a_1, a_2, \ldots,\ a_{n-1}, [\Pi_{i=1}^{n-1} a_i]^{-1})$$

with $0 < a_1 \le a_2 \le \cdots \le a_{n-1} \le [\Pi_{i=1}^{n-1} a_i]^{-1}$. Clearly, minimization with respect to all Q is equivalent to minimization with respect to all a_i, $\nu > 0$, and all $n \times n$ orthogonal matrices S. Note that $\det(Q) = \nu^n$ and the largest eigenvalue of Q is $\lambda_{max}(Q) = \nu \cdot [\Pi_{i=1}^{n-1} a_i]^{-1}$. The objective function in (25) is indeed

$$|\lambda_{max}(Q)|^{\frac{m}{2}} \cdot |\det(Q)|^{\frac{k+1-m}{2n}} = \nu^{\frac{k+1}{2}} \cdot |\Pi_{i=1}^{n-1} a_i|^{-\frac{m}{2}},$$

and the constraint $Q \in \mathcal{V}_{k+1}(\boldsymbol{x})$ becomes

$$|p_{k+1}(\boldsymbol{\xi})| \ \le\ [\ \nu\ (S'\boldsymbol{\xi}) \cdot \Lambda(S'\boldsymbol{\xi})\ ]^{\frac{k+1}{2}} \qquad \forall \boldsymbol{\xi} \in \mathcal{R}^n.$$

This condition is equivalent to

$$|p_{k+1}(S\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})| \ \le\ \nu^{\frac{k+1}{2}} \cdot \|\boldsymbol{\eta}\|^{k+1} \qquad \forall \boldsymbol{\eta} \in \mathcal{R}^n.$$

Since p_{k+1} is a homogeneous polynomial of degree $k+1$, it is further equivalent to

$$|p_{k+1}(S\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})| \le \nu^{\frac{k+1}{2}} \qquad \forall \boldsymbol{\eta} \in \mathcal{R}^n \text{ with } \|\boldsymbol{\eta}\| = 1.$$

Hence we conclude that the following ν value is optimal:

$$\nu = \left[\ \max_{\|\boldsymbol{\eta}\|=1} |p_{k+1}(S\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})|\ \right]^{\frac{2}{k+1}}, \tag{28}$$

with which the constraint $Q \in \mathcal{V}_{k+1}(\boldsymbol{x})$ is automatically satisfied. Now the constrained minimization problem (25) is reduced to finding the minimum of

$$(\Pi_{i=1}^{n-1} a_i)^{-\frac{m}{2}} \cdot \max_{\|\boldsymbol{\eta}\|=1} |p_{k+1}(S\Lambda^{-\frac{1}{2}}\eta)| \tag{29}$$

with respect to all $0 < a_1 \le a_2 \le \cdots \le a_{n-1} \le [\Pi_{i=1}^{n-1} a_i]^{-1}$ and all orthogonal matrices S.

It is possible that the minimization problem (29) does not have a solution, or problem (25) has a solution with some $\lambda_i = 0$. In this case, Q becomes singular, and the optimal metrics $M_{k+1,m,p}$ based on it will lead to elements of infinitely large aspect

ratio. In order to avoid such a degenerate mesh metric in practice, we put a cap on the ratios of the eigenvalues of Q. More precisely, we may restrict $\lambda_{min}(Q)/\lambda_{max}(Q) \geq \delta$, where $\delta \in (0,1]$ is a user-specified parameter. This requirement is guaranteed when $a_i \in [\delta^{\frac{1}{n}}, \delta^{-\frac{n-1}{n}}]$ for all $1 \leq i \leq n-1$. Therefore, we may seek the minimizer to (29) over all $\delta^{\frac{1}{n}} \leq a_1 \leq a_2 \leq \cdots \leq a_{n-1} \leq [\Pi_{n=1}^{n-1}]^{-1} \leq \delta^{-\frac{n-1}{n}}$ and all orthogonal S. Since the set of all these a_i's and T's is compact, and the objective function in (29) is continuous with respect to its variables, a positive definite minimizer $Q_{k+1,m}$ is guaranteed to exist for any specified $0 < \delta \leq 1$.

Examples. We present two examples to explain the definition of $Q_{k+1,m}$. First we consider the simplest case, $n = 2, k = 1$, which corresponds to linear interpolation in $\mathcal{R}^2$. Without loss of generality, suppose

$$\nabla^2 u = R_\phi \cdot \begin{bmatrix} \mu_1 & \\ & \mu_2 \end{bmatrix} R_\phi^T$$

with $|\mu_1| \leq |\mu_2|$, where R_ϕ is the matrix of rotation by angle ϕ counterclockwise. Let

$$Q = \nu \cdot R_\psi \cdot \begin{bmatrix} a & \\ & a^{-1} \end{bmatrix} R_\psi^T$$

with $0 < a \leq a^{-1}$ or $a \in (0,1]$. Then $Q_{k+1,m}$ is defined by the solution (a_*, ψ_*) to the following problem:

$$\min_{a \in (0,1], \psi \in [0,2\pi]} \left\{ a^{-\frac{m}{2}} \cdot \max_{\|\boldsymbol{\eta}\|=1} |p_2(R_\psi \Lambda^{-\frac{1}{2}} \boldsymbol{\eta})| \right\}. \tag{30}$$

Note that

$$\max_{\|\boldsymbol{\eta}\|=1} |p_2(R_\psi \Lambda^{-\frac{1}{2}} \boldsymbol{\eta})| \;=\; \max_{\|\boldsymbol{\xi}\|=1} \frac{|p_2(R_\psi \boldsymbol{\xi})|}{\|\Lambda^{\frac{1}{2}} \boldsymbol{\xi}\|^2}.$$

Using the polar coordinates for $\boldsymbol{\xi} \in \mathcal{R}^2$, the objective function of (30) can be written as $a^{-\frac{m}{2}} \cdot \max_{t \in [0,2\pi]} J(a, \psi, t)$, where

$$J(a, \psi, t) \equiv \left| \frac{\mu_1 \cos^2(t - \phi + \psi) + \mu_2 \sin^2(t - \phi + \psi)}{a \cdot \cos^2 t + a^{-1} \cdot \sin^2 t} \right|. \tag{31}$$

When $\mu_1 \cdot \mu_2 \geq 0$, we can show that

$$\max_{t \in [0,2\pi]} J(a, \psi, t) \geq \max_{t \in [0,2\pi]} J(a, \phi, t) \qquad \forall \psi \in [0, 2\pi]. \tag{32}$$

Indeed, it is easy to see that

$$\max_{t \in [0,2\pi]} J(a, \phi, t) = \max_{t \in [0,2\pi]} \left| \frac{\mu_1 \cos^2 t + \mu_2 \sin^2 t}{a \cdot \cos^2 t + a^{-1} \cdot \sin^2 t} \right| = \max(|\mu_1 \cdot a^{-1}|,\ |\mu_2 \cdot a|)$$

since $J(a, \phi, t)$ is a rational function of $\cos^2 t \in [0,1]$. On the other hand,

$$\max_{t \in [0,2\pi]} J(a, \psi, t) \geq J(a, \psi, 0) = \left| \frac{\mu_1 \cos^2(\phi - \psi) + \mu_2 \sin^2(\phi - \psi)}{a} \right| \geq |\mu_1 \cdot a^{-1}|$$

since $|\mu_1| \le |\mu_2|$, and similarly

$$\max_{t\in[0,2\pi]} J(a,\psi,t) \ge J\left(a,\psi,\phi-\psi+\frac{\pi}{2}\right)$$
$$= \left|\frac{\mu_2}{a\cdot\sin^2(\phi-\psi)+a^{-1}\cdot\cos^2(\phi-\psi)}\right| \ge |\mu_2\cdot a|$$

since $a \le 1$. Therefore, we conclude that

$$\min_{a\in(0,1],\psi\in[0,2\pi]}\left\{a^{-\frac{m}{2}}\cdot\max_{\|\boldsymbol{\eta}\|=1}|p_2(R_\psi\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})|\right\}$$
$$= \min_{a\in(0,1]}\left\{a^{-\frac{m}{2}}\cdot\max(|\mu_1\cdot a^{-1}|,|\mu_2\cdot a|)\right\}, \tag{33}$$

where the minimum is attained at $\psi = \phi$. Furthermore, since $m \le k = 1$, the minimizer for the right-hand side of the above equation is

$$a = \sqrt{\left|\frac{\mu_1}{\mu_2}\right|},$$

which implies by (28) that

$$\nu = \sqrt{|\mu_1\cdot\mu_2|} \tag{34}$$

and

$$Q_{k+1,m} = R_\phi\cdot\begin{bmatrix}|\mu_1| & \\ & |\mu_2|\end{bmatrix}R_\phi^T = abs(\nabla^2 u). \tag{35}$$

In the case of $\mu_1\cdot\mu_2 < 0$, (32) is not true in general. However, our numerical calculation shows that in this case the minimum of (30) is still attained at $a = \sqrt{|\mu_1/\{\mu_2\}|}$ and $\psi = \phi$, which results in the same ν and Q as in (34) and (35).

This example confirms from another perspective that the conventional choice is optimal by using the eigenvalues and eigenvectors of the Hessian matrix to characterize its anisotropic behavior in mesh generation and refinement for linear interpolation or linear elements; see [3, 4, 7, 8, 11, 13, 17, 18].

Our second example is for $u = \frac{1}{6}xy^2$ in $\mathcal{R}^2$ and $k = 2$ (quadratic interpolation). In this example, $p_3(\boldsymbol{\xi}) = \xi\eta^2$. Matrix Q can be determined as in (27) with a and ψ being the minimizer to the following problem:

$$\min_{a\in(0,1],\psi\in[0,2\pi]}\left\{a^{-\frac{m}{2}}\cdot\max_{\|\boldsymbol{\eta}\|=1}|p_3(R_\psi\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})|\right\}. \tag{36}$$

For each $a > 0$, it can be shown numerically that

$$\max_{\|\boldsymbol{\eta}\|=1}|p_3(\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})| \le \max_{\|\boldsymbol{\eta}\|=1}|p_3(R_\psi\Lambda^{-\frac{1}{2}}\boldsymbol{\eta})| \qquad \forall\psi\in[0,2\pi].$$

Thus $\psi = 0$ is an optimal solution, with minimum value $a^{-(m-1)/2}\max_t|\cos t\cdot\sin^2 t| = \frac{2\sqrt{3}}{9}a^{-(m-1)/2}$. In this case, problem (36) is reduced to $\min_{a\in(0,1]}\frac{2\sqrt{3}}{9}a^{-(m-1)/2}$. For $m = 0$, which corresponds to L^p-error estimates, the optimal a is 0; while for $m = 1$

(corresponding to H^1-error estimates), any positive $a \leq 1$ is optimal. The optimal ν value is $\frac{\sqrt[3]{4}}{3}$.

Applying Theorem 2.1 to the quadratic interpolation of $u = \frac{1}{6}xy^2$, we see that the L^2-error bound can be driven to 0 if we increase the aspect ratio of the elements while keeping their area fixed and alignment direction fixed along the x-axis. The H^1-error bound does not change (since $|\lambda_{max}(Q)|^{\frac{m}{2}} |\det(Q)|^{\frac{k+1}{2}}$ is a constant independent of a), which implies that using highly anisotropic triangles does not help reduce the H^1-error. This conclusion coincides with the study in [5] based on the exact formula for the quadratic interpolation errors; see Remark 2 in [5].

3.2. Estimate of the anisotropic measure: A dimension reduction method. The definition of the anisotropic measure for $\nabla^{k+1}u$ in the previous subsection involves a nonlinear minimization (25) with respect to the matrix Q. Solving this problem could be expensive in practice. Here we describe a method to find a suboptimal solution to the minimization problem, and give an approximate Q for the anisotropic measure.

Let $\lambda_1, \lambda_2, \ldots, \lambda_n$ be the eigenvalues (in ascending order) of Q, and $\boldsymbol{v}_1, \boldsymbol{v}_2, \ldots, \boldsymbol{v}_n$ be the corresponding eigenvectors. Notice that the objective function in (25), $|\lambda_{max}(Q)|^{\frac{m}{2}} |\det(Q)|^{\frac{k+1-m}{2n}}$, is the product of the eigenvalues of Q. We determine an approximate Q by choosing successively $(\lambda_i, \boldsymbol{v}_i)$ for $i = n, n-1, \ldots, 1$, such that each λ_i is the smallest possible to have constraint (26) hold. More precisely, we first choose λ_n as

$$\lambda_n = |||\nabla^{k+1}u|||^{\frac{2}{k+1}} = \left[\max_{\|\boldsymbol{\xi}\|=1} |p_{k+1}(\boldsymbol{\xi})| \right]^{\frac{2}{k+1}};$$

i.e., $|\lambda_n|^{\frac{k+1}{2}}$ is the largest $(k+1)$th-order directional derivative of u. The corresponding eigenvector $\boldsymbol{v}_n$ is chosen as the unit vector along which the $(k+1)$th directional derivative is the largest, i.e.,

$$\boldsymbol{v}_n = \arg \max_{\|\boldsymbol{\xi}\|=1} |p_{k+1}(\boldsymbol{\xi})|.$$

To determine the rest $n-1$ eigenpairs, let $\tilde{\boldsymbol{v}}_1, \ldots, \tilde{\boldsymbol{v}}_{n-1}$ be a set of orthonormal bases for the orthogonal complement of $span\{\boldsymbol{v}_n\}$ in $\mathcal{R}^n$. Then any $\boldsymbol{\xi} \in \mathcal{R}^n$ can be expressed as

$$\boldsymbol{\xi} = \sum_{i=1}^{n-1} \zeta_i \tilde{\boldsymbol{v}}_i + z\boldsymbol{v}_n$$

for some $\boldsymbol{\zeta} = [\zeta_1, \ldots, \zeta_{n-1}]' \in \mathcal{R}^{n-1}$ and $z \in \mathcal{R}$. Furthermore, let

$$T_{n-1} = \begin{bmatrix} \tilde{\boldsymbol{v}}_1' \\ \vdots \\ \tilde{\boldsymbol{v}}_{n-1}' \end{bmatrix} \cdot [\boldsymbol{v}_1, \ldots, \boldsymbol{v}_{n-1}], \qquad D_{n-1} = \begin{bmatrix} \lambda_1 & & \\ & \ddots & \\ & & \lambda_{n-1} \end{bmatrix},$$

and

$$Q_{n-1} = T_{n-1} D_{n-1} T_{n-1}'.$$

Then

$$\boldsymbol{\xi} \cdot Q\boldsymbol{\xi} = \boldsymbol{\zeta} \cdot Q_{n-1}\boldsymbol{\zeta} + \lambda_n z^2,$$

and constraint (26) is reduced to

$$\boldsymbol{\zeta}\cdot Q_{n-1}\boldsymbol{\zeta} \;\geq\; h(\boldsymbol{\zeta},z) \;\equiv \left|p_{k+1}\left(\sum_{i=1}^{n-1}\zeta_i\tilde{\boldsymbol{v}}_i + z\boldsymbol{v}_n\right)\right|^{\frac{2}{k+1}} - \lambda_n z^2 \qquad \forall\boldsymbol{\zeta}\in\mathcal{R}^{n-1}, \forall z\in\mathcal{R}.$$

This condition can be expressed equivalently as

$$\boldsymbol{\zeta}\cdot Q_{n-1}\boldsymbol{\zeta} \;\geq\; g(\boldsymbol{\zeta}) \;\equiv\; \max_{z\in\mathcal{R}} h(\boldsymbol{\zeta},z) \qquad \forall\boldsymbol{\zeta}\in\mathcal{R}^{n-1}. \tag{37}$$

It is easy to verify that $g(\boldsymbol{\zeta})$ is a homogeneous function of $\boldsymbol{\zeta}$. Indeed, for any $t\in\mathcal{R}$,

$$g(t\boldsymbol{\zeta}) \;=\; \max_{z\in\mathcal{R}} h(t\boldsymbol{\zeta},z) \;=\; \max_{z\in\mathcal{R}} h(t\boldsymbol{\zeta},tz) \;=\; \max_{z\in\mathcal{R}} t^2 h(\boldsymbol{\zeta},z) \;=\; t^2 g(\boldsymbol{\zeta}).$$

Therefore, to determine Q_{n-1} under constraint (37) is similar to the original problem to determine Q under constraint (26), except the former is of one dimension less than the later. We may repeat this process $n-1$ times to arrive at a one-dimensional problem, whose solution is ready to work out.

In practice, the evaluation of $g(\boldsymbol{\zeta})$ in the constraint (37) can be carried out by checking the critical points of $h(\boldsymbol{\zeta},z)$ in the z direction. Indeed, for given $\boldsymbol{\zeta}$,

$$\frac{\partial}{\partial z}p_{k+1}(\boldsymbol{\xi}) = (k+1)(\boldsymbol{\xi}\cdot\nabla)^k(\tilde{\boldsymbol{v}}_n\cdot\nabla)u.$$

Thus the critical points (excluding those making $p_{k+1}=0$, which are clearly not among the maxima of $h(\boldsymbol{\zeta},z)$) satisfy the following equation:

$$|p_{k+1}(\boldsymbol{\xi})|^{\frac{1-k}{k+1}}(\boldsymbol{\xi}\cdot\nabla)^k(\tilde{\boldsymbol{v}}_n\cdot\nabla)u = \lambda_n z.$$

It is equivalent to

$$\left[\ (\boldsymbol{\xi}\cdot\nabla)^k(\tilde{\boldsymbol{v}}_n\cdot\nabla)u\ \right]^{k+1} = (\lambda_n z)^{k+1}\cdot\left[\ (\boldsymbol{\xi}\cdot\nabla)^{k+1}u\ \right]^{k-1},$$

which is a polynomial equation for z of degree $k(k+1)$.

Remark 3.1. For two-dimensional problems ($n=2$), the author developed in [5, 6] a method to define a matrix Q_{k+1} characterizing the anisotropic behavior $\nabla^{k+1}u$ by using the factors of polynomial $p_{k+1}(\boldsymbol{\xi})$ for directional derivatives. For the cases of $k=1,2$, it can be shown that Q_{k+1} given in [5, 6] is equivalent to the matrix Q produced by the dimension reduction algorithm described here. For $k\geq 3$, we believe they are still equivalent. However, it is yet to be verified.

4. Numerical results. In this section, we present some numerical results to compare the error in various norms for interpolations based on anisotropic meshes generated with the optimal metric $M_{k+1,m,p}$ developed in Theorem 2.1.

Two-dimensional example. We consider linear and quadratic interpolations of the following function on $\Omega=[0,1]^2$:

$$u(x,y) = x^2+y^2+x^3+y^3+\exp(-K\ (y-d_1(x))^2)+\exp(-K\ (y-d_2(x))^2), \tag{38}$$

where $K=10000$ and

$$d_1(x) = -x(x-a)/[2(1-a)]+1, \qquad \text{with } a=1.25;$$
$$d_2(x) = (x-b)(x-c)/[2(1-b)(1-c)], \qquad \text{with } b=0.2, c=1.25.$$

This function u has steep layers around two parabolas $y = d_i(x)$, $i = 1, 2$.

We calculate exactly all the second and third partial derivatives of u and determine matrix Q for measuring their anisotropic behaviors by using the dimension reduction algorithm described in section 3.2. Then we form the mesh metric $M_{k+1,m,p}$ according to (13), which is optimal for minimizing an upper bound of the $W^{m,p}$-norm of the interpolation error $e = u - \Pi_k u$. The constant multiple c in (13) is used to control the total number of elements.

We use the two-dimensional mesh generator `bamg` (bidimensional anisotropic mesh generator) developed by Borouchaki et al. [3] and Hecht [16] to create the anisotropic meshes. This package accepts a user-defined metric to create and refine an anisotropic mesh that is quasi-uniform under the given metric. We choose the following parameter setting in all our experiments:

```
"-NoRescaling -NbSmooth 5 -hmax 0.02 -hmin 0.0000005 -ratio 0
    -nbv 100000 -v 9"
```

In order to make the anisotropic mesh as uniform as possible under metric $M_{k+1,m,p}$, we call `bamg` iteratively with the metrics recalculated over the updated mesh. The final mesh is the one after 20 iterations for all the cases, where there is little change of the mesh and the interpolation error.

We consider specifically the linear ($k = 1$) and quadratic ($k = 2$) interpolations, and measure the errors in (i) L^1-norm ($m = 0, p = 1$), (ii) L^2-norm ($m = 0, p = 2$), (iii) L^∞-norm ($m = 0, p = \infty$), and (iv) H^1-seminorm ($m = 1, p = 2$). These error norms are calculated using numerical quadratures based on 7 and 28 Fekete points for

linear and quadratic interpolations, respectively; see [25]. We list in Tables 1 and 2 the linear and quadratic interpolation errors in four norms, and display in Figures 2 and 3 the anisotropic meshes (of about 4,000 elements). Several observations are clearly at hand. (a) In all the cases, the smallest $W^{m,p}$-norm of the interpolation error is obtained when the mesh is generated according to the optimal metric $M_{k+1,m,p}$. This indicates not only the optimality of the metric $M_{k+1,m,p}$ stated in Theorem 2.1, but also that the matrix Q produced by the dimension reduction algorithm characterizes fairly accurately the anisotropic behavior of $\nabla^{k+1}u$. (b) When the number of elements is quadrupled (i.e., the element length scale is halved), the interpolation error is reduced by a factor 2^{k+1-m} as predicted in the error estimate. (c) The mesh metrics and the anisotropic meshes ideal for linear interpolation are not necessarily good for quadratic interpolation, and vice versa.

Three-dimensional example. We present here an example for the quadratic interpolation in three dimensions. Consider the following function on $\Omega = [0,1]^3$:

$$u(x,y,z) = x^3 + (\mu_1 y)^3 + (\mu_2 z)^3, \tag{39}$$

where $\mu_1 = 10, \mu_2 = 30$. For this function, $\nabla^3 u$ is constant over all Ω. By using the dimension reduction algorithm, it is easy to find the matrix Q that characterizes the anisotropic behavior of $\nabla^3 u$ as follows:

$$Q = \begin{bmatrix} 1 & & \\ & \mu_1 & \\ & & \mu_2 \end{bmatrix}.$$

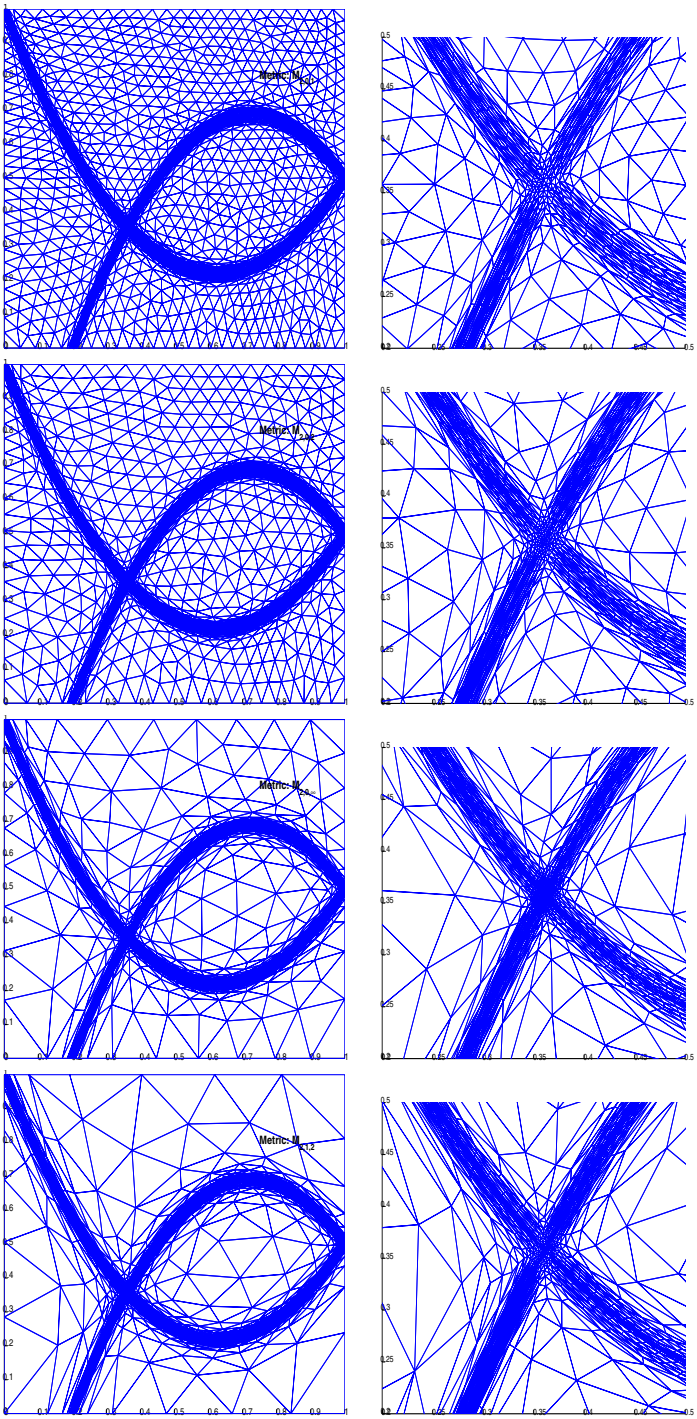

FIG. 2. *Anisotropic meshes that are quasi-uniform under respective metrics $M_{2,m,p}$ and their closeup views.*

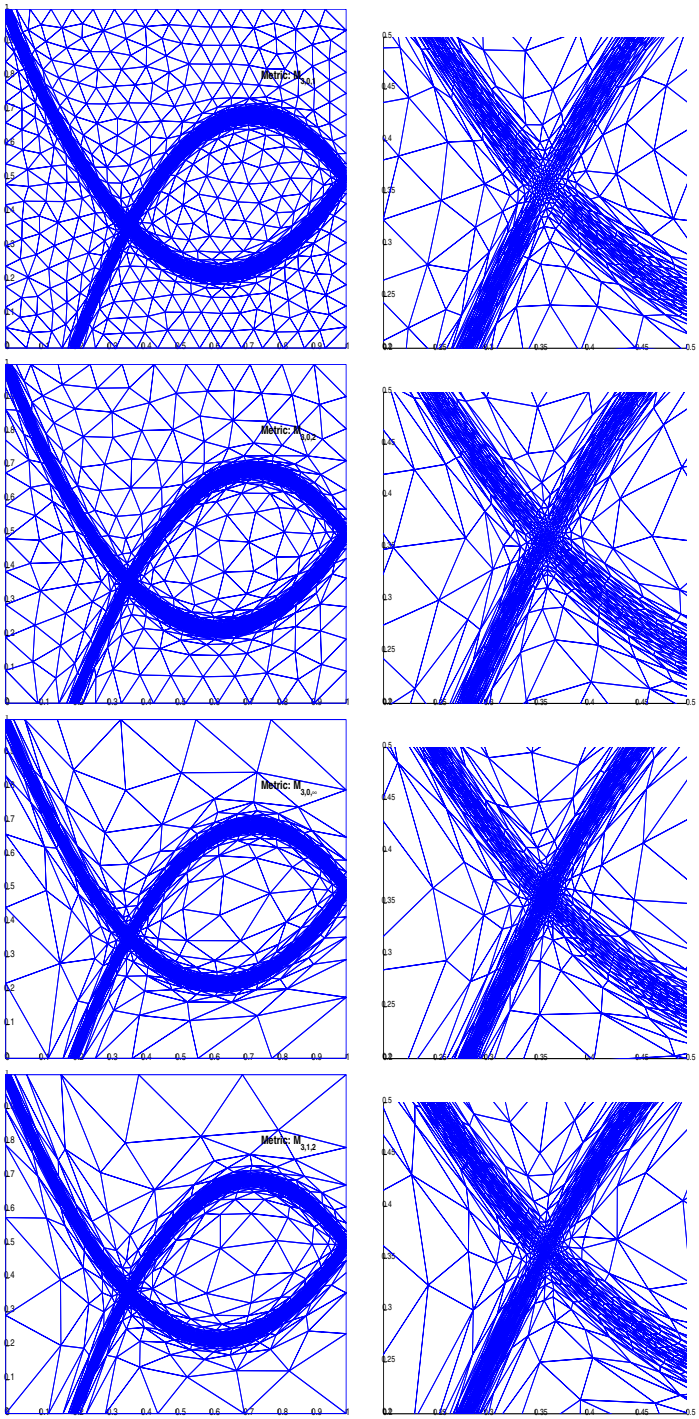

FIG. 3. *Anisotropic meshes that are quasi-uniform under respective metrics* $M_{3,m,p}$ *and their closeup views.*

The optimal mesh metric $M_{k+1,m,p}$ is a constant multiple of the above matrix. Thus in an anisotropic mesh that is quasi-uniform under $M_{k+1,m,p}$ all elements must be of about the same volume, and all elements must have approximately the same length scale $1 : \frac{1}{\mu_1} : \frac{1}{\mu_2}$ in x, y, and z directions. We create meshes of a specified length scale $1 : \frac{1}{L_y} : \frac{1}{L_z}$ in the following way. First we generate a quasi-uniform tetrahedral mesh using a three-dimensional Delaunay generator `gmsh` developed by Geuzaine and Remacle [14] over a rectangular box $[0,1] \times [0, L_y] \times [0, L_z]$. Then it is scaled in y and z directions by factors L_y and L_z to obtain the anisotropic mesh on Ω. When $L_x = \mu_1$ and $L_y = \mu_2$, the obtained mesh is quasi-uniform under $M_{k+1,m,p}$. This mesh should also be the minimizer for the $W^{m,p}$-error of interpolation Π_k (in this example, $M_{k+1,m,p}$ is identical for all m, k, and p). We calculate the error norms by using a quadrature formula with 24 points supplied by [10], which is exact for numerical integration of polynomials of degree less than or equal to 6. We vary L_y between $1 \sim 20$ and L_z between $10 \sim 40$ to obtain meshes of different aspect ratios, while keeping the total number of elements around $40,000$ (by setting the characteristic length `lc` in `gmsh` to be $0.05\sqrt[3]{L_y L_z}$).

We display in Figure 4 the error contour plots against L_y and L_z in the cases of

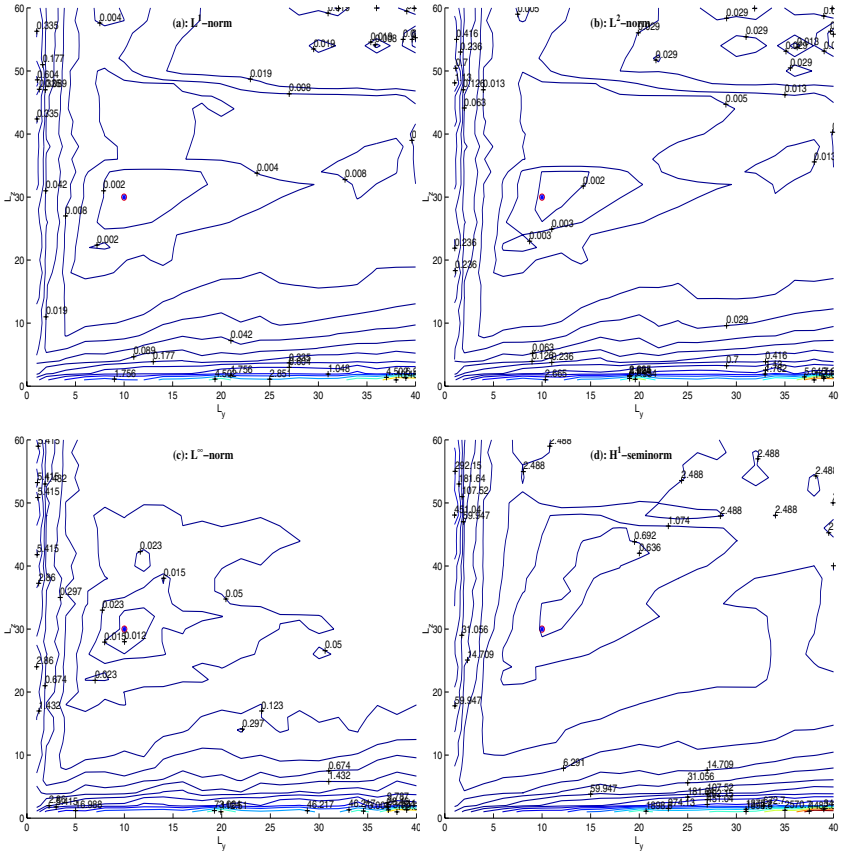

FIG. 4. *Contour plot of the* (a) L^1, (b) L^2, (c) L^∞, *and* (d) H^1 *errors with respect to various element aspect ratios* $1 : \frac{1}{L_y} : \frac{1}{L_z}$. *The star-circle mark at* $(10, 30)$ *indicates the optimal aspect ratio predicted by the error estimates.*

$m = 0, p = 1, 2, \infty$, and $m = 1, p = 2$. It is noted that the smallest interpolation error is achieved when the element aspect ratio is approximately equal to $1 : \frac{1}{\mu_1} : \frac{1}{\mu_2}$ in all four cases. This indicates the optimality of the metric $M_{k+1,m,p}$. It is also noted that the error is relatively insensitive to variation of the length scales in y and z directions when they are close to the optimal values. We believe this is because the anisotropic behavior of $\nabla^3 u$ in this example is relatively "mild." For interpolated functions of stronger anisotropic behaviors, the improvement by using the optimal mesh metrics can be more drastic. Due to the lack of a reliable anisotropic mesh generator in three dimensions, we are unable to test the optimality of $M_{k+1,m,p}$ for u with variable $\nabla^3 u$.

5. Conclusion and discussions. In the previous sections, we presented an error estimate for higher-order interpolations over anisotropic meshes in $\mathcal{R}^n$. It involves an interplay of the mesh features controlled by a given mesh metric and the anisotropic measures of the higher-order derivative tensors of interpolated functions. Based on the error estimate, we were able to identify the optimal mesh metrics leading to the smallest error bound for a subset of interpolated functions exhibiting similar anisotropic behaviors. Numerical results indicate that the meshes generated according to the optimal metrics produce the smallest interpolation error in the corresponding norms.

A critical component in applying the error estimate for anisotropic mesh generation or refinement is to measure the anisotropic behavior of higher-order derivative tensors. We define such a measure by the "largest" ellipse/ellipsoid contained in the level curve for directional derivatives. To avoid solving the minimization problem for defining the anisotropic measure, we developed a dimension reduction algorithm to produce the measure approximately.

The practical application of the results in this paper is always associated with the development of a reliable and efficient anisotropic mesh generator. While there have been many two-dimensional packages available (`bamg` is clearly among the best of them), general three-dimensional anisotropic meshing packages are yet to be developed and tested. Also, it is natural to apply the results in this paper to quadratic and higher-order finite element methods for solving PDEs. To this end, one needs to recover the higher-order derivatives of the PDEs solution from its numerical approximation. While there have been extensive studies along this direction for isotropic triangulations and linear elements [1, 20, 27, 28], the analysis and application for higher-order elements on anisotropic meshes are yet to be developed.

AN INF-SUP STABLE AND RESIDUAL-FREE BUBBLE ELEMENT FOR THE OSEEN EQUATIONS*

LEOPOLDO P. FRANCA†, VOLKER JOHN‡, GUNAR MATTHIES§, AND LUTZ TOBISKA¶

Abstract. We investigate the residual-free bubble method for the linearized incompressible Navier–Stokes equations. Starting with a nonconforming inf-sup stable element pair for approximating the velocity and pressure, we enrich the velocity space by discretely divergence-free bubble functions to handle the influence of strong convection. An important feature of the method is that the stabilization does not generate an additional coupling between the mass equation and the momentum equation as is the case for the streamline upwind Petrov–Galerkin method applied to equal-order interpolation. Furthermore, the discrete solution is piecewise divergence-free, a property which is useful for the mass balance in transport equations coupled with the incompressible Navier–Stokes equations.

Key words. stabilized finite elements, Navier–Stokes equations, nonconforming finite elements

1. Introduction.

Finite element approximations of the Oseen equations need stability for advective-dominated flows and compatibility between the velocity and pressure spaces. The latter is also necessary for the Stokes flow.

Starting with the streamline upwind Petrov–Galerkin (SUPG) stabilization of Brooks and Hughes [9] for the advective term, this idea has been extended to the Stokes equations in [21], where a stabilized method is proposed accommodating low equal-order interpolation to be stable and convergent. This formulation circumvents the need to abide by inf-sup condition for many interpolations. In an attempt to get the stability features of these works, a method is proposed in [14] that at the same time is advective stable and overcomes the inf-sup restrictions of the standard Galerkin method. The analysis of these SUPG-type stabilizations, including the case of equal-order interpolations, can be found in [31]. The drawback of these methods is that various terms need to be added to the weak formulation. Residual-based stabilization methods which use inf-sup stable pairs of elements reduce the number of terms which have to be added to the Galerkin formulation [17, 25]. However, there is still a strong coupling of the form $(\nabla p, (\mathbf{b} \cdot \nabla)\mathbf{v}_h)$ which is difficult to handle, and an optimal L^2 error estimate for the pressure is missing in [17]. Several attempts have been made to relax the strong coupling of velocity and pressure and to introduce symmetric versions of the stabilizing terms; for an overview see [5]. Local projection-type methods have

been introduced for the Stokes problem in [2], extended to the transport equation in [3], and analyzed for low-order discretizations of the Oseen equations in [4]. They are designed for equal-order interpolation and allow a separation of the velocity and pressure in the stabilization terms. The disadvantage is that the finite element stencil is less compact than for the SUPG-type stabilization. They also suffer from the weak fulfillment of the incompressiblity constraint which is important for mass conservation in a transport equation coupled with the Navier–Stokes problem. In the edge-oriented stabilization technique, introduced in [10], we find the same problem of a much wider stencil which needs also some special data structure or an implicit defect correction.

Our method of enriching the velocity space of an inf-sup stable pair of finite elements by discretely divergence-free functions will always suppress additional coupling terms in the discrete formulation and lead to a separation of the velocity and pressure in the stabilization terms. Due to the use of inf-sup stable finite element pairs, the computed velocity field is always discretely divergence-free. As a first step in this paper, we analyze the simplest version of such an enrichment method, the Crouzeix–Raviart element of lowest order, i.e., piecewise linear nonconforming velocity and piecewise constant pressure approximations.

The plan of the paper is as follows. In section 2, the weak formulation of the Oseen equations and its Galerkin discretization is considered. Next, in section 3, we apply the residual-free bubble approach and highlight the advantages of using discretely divergence-free enrichments. The relation to the classical SUPG method is studied in section 4. Finally, an a priori error estimate for an approximate residual-free bubble method is derived in section 5. A numerical test example confirms the convergence rates.

Notations. We use the Sobolev spaces $W^{k,p}(D)$, $H^k(D) = W^{k,2}(D)$, $H_0^k(D)$, $L^2(D) = H^0(D)$, and write $\mathbf{W}^{k,p}(D)$, $\mathbf{H}^k(D)$, $\mathbf{H}_0^k(D)$, $\mathbf{L}^2(D)$ for their vector-valued versions. The norms and seminorms in the scalar and vector-valued versions of $W^{k,p}(D)$ are denoted by $\|\cdot\|_{k,p,D}$ and $|\cdot|_{k,p,D}$, respectively [12]. To simplify the notation, we drop D if $D = \Omega$ and p if $p = 2$. Moreover, we introduce the broken H^1 seminorm and norm for piecewise H^1 functions defined on a triangulation $\mathcal{T}_h$ by

$$|v|_{1,h} := \left(\sum_{K \in \mathcal{T}_h} |v|_{1,K}^2 \right)^{1/2}, \qquad \|v\|_{1,h} := \left(|v|_{1,h}^2 + \|v\|_0^2 \right)^{1/2}.$$

2. A linearized Navier–Stokes model. We consider the steady linearized Navier–Stokes model given by

$$-\nu \Delta \mathbf{u} + (\mathbf{b} \cdot \nabla)\mathbf{u} + \nabla p = \mathbf{f} \qquad \text{in } \Omega \subset \mathbb{R}^d, \tag{2.1}$$

$$\nabla \cdot \mathbf{u} = \mathbf{0} \qquad \text{in } \Omega, \tag{2.2}$$

$$\mathbf{u} = \mathbf{0} \qquad \text{on } \Gamma = \partial\Omega, \tag{2.3}$$

where $\mathbf{b} \in \mathbf{W}^{1,\infty}(\Omega)$ with $\nabla \cdot \mathbf{b} = 0$ in Ω, $\mathbf{f} \in \mathbf{L}^2(\Omega)$, and Ω denotes a bounded domain in $\mathbb{R}^d$ with $d = 2$ or $d = 3$. Homogeneous Dirichlet boundary conditions are considered for simplicity of presentation. The extension to nonhomogeneous Dirichlet boundary conditions is straightforward when the boundary data are interpolated in the space of restrictions of discretely divergence-free functions. For smooth boundary data, this is always possible and requires only additional technical details which do not lead to further insight into the method. The weak formulation of (2.1)–(2.3) reads:

Find $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that for all $(\mathbf{v}, q) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$,

$$a(\mathbf{u}, \mathbf{v}) + b(\mathbf{u}, \mathbf{v}) - (p, \nabla \cdot \mathbf{v}) + (q, \nabla \cdot \mathbf{u}) = (\mathbf{f}, \mathbf{v}), \tag{2.4}$$

where the bilinear forms a and b are defined by

$$a(\mathbf{u}, \mathbf{v}) := \nu(\nabla \mathbf{u}, \nabla \mathbf{v}), \quad b(\mathbf{u}, \mathbf{v}) := ((\mathbf{b} \cdot \nabla)\mathbf{u}, \mathbf{v}) \quad \forall \mathbf{u}, \mathbf{v} \in \mathbf{H}_0^1(\Omega), \tag{2.5}$$

$(\cdot, \cdot)$ denotes the inner product in $L^2(\Omega)$ or its vector-valued and tensor-valued versions, and

$$L_0^2(\Omega) = \{q \in L^2(\Omega) \ : \ (q, 1) = 0\}.$$

The property

$$b(\mathbf{v}, \mathbf{v}) = ((\mathbf{b} \cdot \nabla)\mathbf{v}, \mathbf{v}) = \frac{1}{2}(\mathbf{b} \cdot \nabla(\mathbf{v} \cdot \mathbf{v}), 1) = -\frac{1}{2}(\nabla \cdot \mathbf{b}, \mathbf{v} \cdot \mathbf{v}) = 0 \qquad \forall \mathbf{v} \in \mathbf{H}_0^1(\Omega)$$

of the bilinear form b guarantees that the Lax–Milgram lemma can be applied in the subspace of divergence-free functions. A unique pressure in $L_0^2(\Omega)$ follows from the Babuška–Brezzi condition for the pair $(\mathbf{H}_0^1(\Omega), L_0^2(\Omega))$ [18]. Therefore, there is a unique solution $(\mathbf{u}, p)$ of (2.4) for all positive ν.

For the finite element approximation, we use the nonconforming P_1^{nc}/P_0 element pair of Crouzeix–Raviart [13]. Let $\mathcal{T}_h$ be a regular decomposition of the domain $\Omega \subset \mathbb{R}^d$ into d-dimensional simplices $K \in \mathcal{T}_h$, where the mesh parameter h represents the maximum diameter of the elements $K \in \mathcal{T}_h$. We denote by $\mathcal{E}_h$ the set of all $(d-1)$-dimensional faces E of cells $K \in \mathcal{T}_h$. We choose for any face $E \in \mathcal{E}_h$ a unit normal $\mathbf{n}_E$ with an arbitrary but fixed orientation where $\mathbf{n}_E$ on boundary faces is the outer unit normal of Ω. We will write $\mathbf{n}_K$ for the outer unit normal with respect to the cell K. For a scalar piecewise continuous function ψ, the jump $[\psi]_E$ and the average $\{\psi\}_E$ on a face E are defined by

$$[\psi]_E := \begin{cases} (\psi|_K)|_E - (\psi|_{\widetilde{K}})|_E & \text{if} \quad E \not\subset \Gamma, \\ (\psi|_K)|_E & \text{if} \quad E \subset \Gamma, \end{cases}$$

$$\{\psi\}_E := \begin{cases} \frac{1}{2}\left((\psi|_K)|_E + (\psi|_{\widetilde{K}})|_E\right) & \text{if} \quad E \not\subset \Gamma, \\ \frac{1}{2}(\psi|_K)|_E & \text{if} \quad E \subset \Gamma, \end{cases}$$

where K and $\widetilde{K}$ are chosen such that $E = \partial K \cap \partial \widetilde{K}$ and $\mathbf{n}_K = \mathbf{n}_E$.

Note that the definition of the jump and the average on a boundary face corresponds to that on an inner face when extending the functions outside of Ω by zero. Furthermore, we have the relation

$$[\varphi\psi]_E = [\varphi]_E\{\psi\}_E + \{\varphi\}_E[\psi]_E$$

on both inner and boundary faces E. The jump and the average of vector-valued functions are defined in a componentwise manner.

Now our approximate spaces $\mathbf{V}_h \approx \mathbf{H}_0^1(\Omega)$ and $Q_h \approx L_0^2(\Omega)$ can be defined to be

$$\mathbf{V}_h := \left\{\mathbf{v}_h \in \mathbf{L}^2(\Omega) \ : \ \mathbf{v}_h\Big|_K \in P_1(K)^d \ \forall K \in \mathcal{T}_h, \ \int_E [\mathbf{v}_h]_E \, d\gamma = 0 \ \forall E \in \mathcal{E}_h\right\}, \tag{2.6}$$

$$Q_h := \left\{q_h \in L_0^2(\Omega) \ : \ q_h\Big|_K \in P_0(K) \ \forall K \in \mathcal{T}_h\right\}, \tag{2.7}$$

where $P_n(K)$ is the set of all polynomials on K of degree less than or equal to n. Note that a function $\mathbf{v}_h \in \mathbf{V}_h$—in general—is discontinuous across the inner faces E and does not vanish on the boundary.

Now, we introduce the discrete bilinear forms elementwise to be

$$a_h(\mathbf{u}_h, \mathbf{v}_h) := \nu \sum_{K\in\mathcal{T}_h} (\nabla_h \mathbf{u}_h, \nabla_h \mathbf{v}_h)_K, \tag{2.8}$$

$$b_h(\mathbf{u}_h, \mathbf{v}_h) := \sum_{K\in\mathcal{T}_h} ((\mathbf{b}\cdot\nabla_h)\mathbf{u}_h, \mathbf{v}_h)_K - \sum_{E\in\mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{u}_h]_E, \{\mathbf{v}_h\}_E\rangle_E\,. \tag{2.9}$$

Here, the discrete versions of the gradient and the divergence operators, ∇ and $\nabla\cdot$, respectively, are understood in the following sense:

$$(\nabla_h \mathbf{v}_h)\big|_K := \nabla\left(\mathbf{v}_h\big|_K\right) \quad \forall \mathbf{v}_h \in \mathbf{V}_h,\ \forall K \in \mathcal{T}_h,$$

$$(\nabla_h \cdot \mathbf{v}_h)\big|_K := \nabla\cdot\left(\mathbf{v}_h\big|_K\right) \quad \forall \mathbf{v}_h \in \mathbf{V}_h,\ \forall K \in \mathcal{T}_h,$$

and $\langle\cdot,\cdot\rangle_E$ denotes the inner product in $L^2(E)$ and its vector-valued versions. To simplify the notation, we briefly write ∇ instead of ∇_h in expressions like (2.8) and (2.9). Clearly, we have

$$a_h(\mathbf{u}, \mathbf{v}) = a(\mathbf{u}, \mathbf{v}), \quad b_h(\mathbf{u}, \mathbf{v}) = b(\mathbf{u}, \mathbf{v}), \quad \mathbf{u}, \mathbf{v} \in \mathbf{H}^1(\Omega).$$

The additional term in the elementwise-defined bilinear form b_h (compare (2.9)) vanishes for $\mathbf{v}_h \in \mathbf{H}^1(\Omega)$. For functions $\mathbf{v}_h$ belonging to our nonconforming finite element space $\mathbf{V}_h$, it guarantees that we have

$$\begin{aligned} b_h(\mathbf{v}_h, \mathbf{v}_h) &= \frac{1}{2}\sum_{K\in\mathcal{T}_h} ((\mathbf{b}\cdot\nabla)(\mathbf{v}_h\cdot\mathbf{v}_h), 1)_K - \sum_{E\in\mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{v}_h]_E, \{\mathbf{v}_h\}_E\rangle_E \\ &= \sum_{E\in\mathcal{E}_h} \left(\frac{1}{2}\langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{v}_h\cdot\mathbf{v}_h]_E, 1\rangle_E - \langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{v}_h]_E, \{\mathbf{v}_h\}_E\rangle_E\right) = 0, \end{aligned}$$

in analogy to $b(\mathbf{v}, \mathbf{v}) = 0$ for all $\mathbf{v} \in \mathbf{H}^1_0(\Omega)$.

The standard Galerkin finite element method reads:

Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ such that for all $(\mathbf{v}_h, q_h) \in \mathbf{V}_h \times Q_h$,

$$a_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(\mathbf{u}_h, \mathbf{v}_h) - (p_h, \nabla_h\cdot\mathbf{v}_h) + (q_h, \nabla_h\cdot\mathbf{u}_h) = (\mathbf{f}, \mathbf{v}_h). \tag{2.10}$$

The finite element pair $(\mathbf{V}_h, Q_h)$ satisfies the discrete inf-sup stability condition

$$\exists \beta_0 > 0 \quad \forall q_h \in Q_h: \qquad \beta_0 \|q_h\|_0 \le \sup_{\mathbf{v}_h\in\mathbf{V}_h} \frac{(q_h, \nabla_h\cdot\mathbf{v}_h)}{|\mathbf{v}_h|_{1,h}}; \tag{2.11}$$

see [6, 13]. As a result, we have the unique solvability of (2.10). Error estimates which do not take into consideration the size of ν are standard, e.g., in the energy norm we have

$$\nu^{1/2}|\mathbf{u} - \mathbf{u}_h|_{1,h} + \|p - p_h\|_0 \le C(\nu)\ h\ (|u|_2 + |p|_1) \tag{2.12}$$

with a constant $C(\nu)$ depending on ν. We are interested in the case of small ν (high Reynolds numbers) in which numerical experiments show the need for stabilization [11, 29, 30]. In the next section, we will follow the concept of residual-free bubble stabilizations, which has been already successfully applied to scalar convection-diffusion equations [1, 7, 8, 16].

3. Residual-free bubble method. Let us enrich the velocity space $\mathbf{V}_h$ by the space of residual-free bubbles

$$\mathbf{B}_h := \bigoplus_{K \in \mathcal{T}_h} \mathbf{H}_0^1(K)$$

and denote the enriched space by $\mathbf{V}_{RFB}$. Since a piecewise linear function which vanishes at the boundary of each cell is identically zero, we conclude $\mathbf{V}_{RFB} = \mathbf{V}_h \oplus \mathbf{B}_h$. The pair $(\mathbf{V}_{RFB}, Q_h)$ satisfies the discrete inf-sup stability (2.11) as well. Note that a function from the bubble space $\mathbf{B}_h$ is discretely divergence-free since we have, for all $q_h \in Q_h,\ \mathbf{v}_B \in \mathbf{B}_h$,

$$(q_h, \nabla_h \cdot \mathbf{v}_B) = \sum_{K \in \mathcal{T}_h} q_h\big|_K (1, \nabla \cdot \mathbf{v}_B)_K = \sum_{K \in \mathcal{T}_h} q_h\big|_K \langle 1, \mathbf{v}_B \cdot \mathbf{n}_K \rangle_{\partial K} = 0.$$

In this sense the inf-sup stability will not be improved by enriching $\mathbf{V}_h$ by $\mathbf{B}_h$. Each element $\mathbf{u}_{RFB} \in \mathbf{V}_{RFB}$ can be uniquely represented in the form

$$\mathbf{u}_{RFB} = \mathbf{u}_h + \mathbf{u}_B \quad \text{with } \mathbf{u}_h \in \mathbf{V}_h,\ \mathbf{u}_B \in \mathbf{B}_h.$$

The Galerkin approximation of (2.4) with respect to the pair $(\mathbf{V}_{RFB}, Q_h)$ reads:

Find $(\mathbf{u}_h, \mathbf{u}_B, p_h) \in \mathbf{V}_h \times \mathbf{B}_h \times Q_h$ such that

$$a_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(\mathbf{u}_B, \mathbf{v}_h) - (p_h, \nabla_h \cdot \mathbf{v}_h) = (\mathbf{f}, \mathbf{v}_h) \quad \forall \mathbf{v}_h \in \mathbf{V}_h, \tag{3.1}$$

$$a_h(\mathbf{u}_B, \mathbf{v}_B) + b_h(\mathbf{u}_B, \mathbf{v}_B) + b_h(\mathbf{u}_h, \mathbf{v}_B) = (\mathbf{f}, \mathbf{v}_B) \quad \forall \mathbf{v}_B \in \mathbf{B}_h, \tag{3.2}$$

$$(q_h, \nabla_h \cdot \mathbf{u}_h) = 0 \qquad \forall q_h \in Q_h. \tag{3.3}$$

Note that in deriving (3.1)–(3.3) we have taken into consideration the orthogonality property

$$\begin{aligned} a_h(\mathbf{v}_B, \mathbf{w}_h) = a_h(\mathbf{w}_h, \mathbf{v}_B) &= \nu \sum_{K \in \mathcal{T}_h} (\nabla \mathbf{w}_h, \nabla \mathbf{v}_B)_K \\ &= \nu \sum_{K \in \mathcal{T}_h} \left(\left\langle \frac{\partial \mathbf{w}_h}{\partial \mathbf{n}_K}, \mathbf{v}_B \right\rangle_{\partial K} - (\Delta \mathbf{w}_h, \mathbf{v}_B)_K \right) = 0 \end{aligned}$$

and the property that $\mathbf{u}_B$ and $\mathbf{v}_B$ are discretely divergence-free. Equation (3.2) can be considered to define $\mathbf{u}_B$ as a functional of $\mathbf{u}_h$. In order to find a representation for $\mathbf{u}_B$, we define $M(\mathbf{u}_h)$, $F(\mathbf{f}) \in \mathbf{B}_h$ as the solutions of the problems:

Find $M(\mathbf{u}_h),\ F(\mathbf{f}) \in \mathbf{B}_h$ such that for all $\mathbf{v}_B \in \mathbf{B}_h$,

$$a_h(M(\mathbf{u}_h), \mathbf{v}_B) + b_h(M(\mathbf{u}_h), \mathbf{v}_B) = -b_h(\mathbf{u}_h, \mathbf{v}_B),$$

$$a_h(F(\mathbf{f}), \mathbf{v}_B) + b_h(F(\mathbf{f}), \mathbf{v}_B) = (\mathbf{f}, \mathbf{v}_B).$$

Then, the solution $\mathbf{u}_B$ of (3.2) can be represented in the form $\mathbf{u}_B = M(\mathbf{u}_h) + F(\mathbf{f})$. Elimination of $\mathbf{u}_B$ from (3.1) gives the residual-free bubble method for solving (2.4):

Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ such that

$$a_{RFB}(\mathbf{u}_h, \mathbf{v}_h) - (p_h, \nabla_h \cdot \mathbf{v}_h) = l_{RFB}(\mathbf{v}_h) \qquad \forall \mathbf{v}_h \in \mathbf{V}_h, \tag{3.4}$$

$$(q_h, \nabla_h \cdot \mathbf{u}_h) = 0 \qquad \forall q_h \in Q_h, \tag{3.5}$$

where

$$a_{RFB}(\mathbf{u}_h, \mathbf{v}_h) = a_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(\mathbf{u}_h, \mathbf{v}_h) + b_h(M(\mathbf{u}_h), \mathbf{v}_h), \tag{3.6}$$

$$l_{RFB}(\mathbf{v}_h) = (\mathbf{f}, \mathbf{v}_h) - b_h(F(\mathbf{f}), \mathbf{v}_h). \tag{3.7}$$

The difficulty in realizing the *exact* residual-free method (3.4)–(3.5) is that we have to evaluate the terms $b_h(M(\mathbf{u}_h), \mathbf{v}_h)$ and $b_h(F(\mathbf{f}), \mathbf{v}_h)$, which essentially means solving an infinite-dimensional problem. Therefore, in practice some sort of approximation is used. We mention in particular the following approaches:

- stabilizing subgrid methods [8],
- pseudo-residual-free bubble method [7],
- two-level and three-level approaches [15, 16, 19, 20].

In the following we will reformulate the method (3.4)–(3.5) by looking at the constant coefficient case.

4. Relation to other stabilized methods. The case of continuous P_1 pressure and velocity approximations on triangles has been considered in [28]; for a systematic study on quadrilaterals with a continuous Q_1 pressure approximation and a sufficiently large velocity space see [24]. In that paper the fully nonlinear case of the Navier–Stokes equations has also been considered.

In the following we consider a discretization within the space $(\mathbf{V}_h \times Q_h)$, i.e., nonconforming piecewise linear velocity and piecewise constant pressure approximations. Let us assume that $\mathbf{b}$ and $\mathbf{f}$ are constants. Moreover, let $\varphi_K \in H_0^1(K)$ be the solution of the scalar convection-diffusion problem

$$-\nu\Delta\varphi_K + \mathbf{b}\cdot\nabla\varphi_K = 1 \text{ in } K, \quad \varphi_K = 0 \text{ on } \partial K.$$

Then, we obtain

$$M(\mathbf{u}_h)\Big|_K = -(\mathbf{b}\cdot\nabla)\mathbf{u}_h\Big|_K \varphi_K, \quad F(\mathbf{f})\Big|_K = \mathbf{f}\Big|_K \varphi_K.$$

The terms which appear in (3.6)–(3.7), in addition to the standard Galerkin approach, become

$$\begin{aligned} b_h(M(\mathbf{u}_h), \mathbf{v}_h) &= \sum_{K\in\mathcal{T}_h} ((\mathbf{b}\cdot\nabla)M(\mathbf{u}_h), \mathbf{v}_h)_K - \sum_{E\in\mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E[M(\mathbf{u}_h)]_E, \{\mathbf{v}_h\}_E\rangle_E \\ &= -\sum_{K\in\mathcal{T}_h} ((\mathbf{b}\cdot\nabla)\mathbf{v}_h, M(\mathbf{u}_h))_K \\ &= \sum_{K\in\mathcal{T}_h} ((\mathbf{b}\cdot\nabla)\mathbf{v}_h, (\mathbf{b}\cdot\nabla)\mathbf{u}_h\ \varphi_K)_K \\ &= \sum_{K\in\mathcal{T}_h} \tau_K((\mathbf{b}\cdot\nabla)\mathbf{v}_h, (\mathbf{b}\cdot\nabla)\mathbf{u}_h)_K, \end{aligned}$$

$$
\begin{aligned}
-b_h(F(\mathbf{f}),\mathbf{v}_h) &= -\sum_{K\in\mathcal{T}_h}((\mathbf{b}\cdot\nabla)F(\mathbf{f}),\mathbf{v}_h)_K + \sum_{E\in\mathcal{E}_h}\langle \mathbf{b}\cdot\mathbf{n}_E[F(\mathbf{f})]_E,\{\mathbf{v}_h\}_E\rangle_E \\
&= \sum_{K\in\mathcal{T}_h}((\mathbf{b}\cdot\nabla)\mathbf{v}_h,F(\mathbf{f}))_K \\
&= \sum_{K\in\mathcal{T}_h}((\mathbf{b}\cdot\nabla)\mathbf{v}_h,\mathbf{f}\,\varphi_K)_K \\
&= \sum_{K\in\mathcal{T}_h}\tau_K((\mathbf{b}\cdot\nabla)\mathbf{v}_h,\mathbf{f})_K,
\end{aligned}
$$

since $M(\mathbf{u}_h),\ F(\mathbf{f})\in\mathbf{B}_h$ where

$$\tau_K = \frac{1}{|K|}\int_K \varphi_K\,dx.$$

Thus, the exact residual-free bubble method for constant $\mathbf{b}$ and $\mathbf{f}$ is equal to:

Find $(\mathbf{u}_h,p_h)\in\mathbf{V}_h\times Q_h$ such that

$$\tilde{a}_{RFB}(\mathbf{u}_h,\mathbf{v}_h)-(p_h,\nabla_h\cdot\mathbf{v}_h)=\tilde{l}_{RFB}(\mathbf{v}_h)\qquad\forall\mathbf{v}_h\in\mathbf{V}_h, \tag{4.1}$$

$$(q_h,\nabla_h\cdot\mathbf{u}_h)=0\qquad\forall q_h\in Q_h, \tag{4.2}$$

where

$$\tilde{a}_{RFB}(\mathbf{u}_h,\mathbf{v}_h)=a_h(\mathbf{u}_h,\mathbf{v}_h)+b_h(\mathbf{u}_h,\mathbf{v}_h)+\sum_{K\in\mathcal{T}_h}\tau_K((\mathbf{b}\cdot\nabla)\mathbf{u}_h,(\mathbf{b}\cdot\nabla)\mathbf{v}_h)_K,$$

$$\tilde{l}_{RFB}(\mathbf{v}_h)=(\mathbf{f},\mathbf{v}_h)+\sum_{K\in\mathcal{T}_h}\tau_K(\mathbf{f},(\mathbf{b}\cdot\nabla)\mathbf{v}_h)_K.$$

Since on each $K\in\mathcal{T}_h$ it holds that $-\nu\Delta\mathbf{u}_h+\nabla p_h=0$, the method corresponds to the SUPG method analyzed in [26] for the fully nonlinear case of the Navier–Stokes equations. However, the influence of small ν on the error constants has not been investigated in that paper.

5. Error estimate for the generalized Oseen equations. We now turn to estimates with Reynolds-number-independent constants. It has been shown in a series of papers [22, 23, 27] that for nonconforming finite element discretizations applied to scalar convection-diffusion equations, one has to add certain jump terms to the discretization to recover the error estimates of the SUPG method known for conforming finite elements. Therefore, we expect to meet the same situation in the more complex problem of linearized Navier–Stokes equations and add

$$j_h(\mathbf{u}_h,\mathbf{v}_h):=\sum_{E\in\mathcal{E}_h}\gamma_E\langle[\mathbf{u}_h]_E,[\mathbf{v}_h]_E\rangle_E$$

with positive constants γ_E to the discrete formulation. In the case of a scalar convection-diffusion equation it turns out that it is enough to choose $\gamma_E\sim 1$ (see [22]), but due to the coupling with the pressure we have to choose γ_E differently; see Lemma 5.2. Note that the solution $(\mathbf{u},p)\in\mathbf{H}_0^1(\Omega)\times L_0^2(\Omega)$ satisfies $[\mathbf{u}]_E=0$ and consequently $j_h(\mathbf{u},\mathbf{v})=0$ for all $\mathbf{v}\in\mathbf{H}_0^1(\Omega)+\mathbf{V}_h$.

We shall consider and analyze the case of the generalized Oseen equations,

$$-\nu\Delta\mathbf{u} + (\mathbf{b}\cdot\nabla)\mathbf{u} + \sigma\mathbf{u} + \nabla p = \mathbf{f}, \quad \nabla\cdot\mathbf{u} = \mathbf{0} \quad \text{in } \Omega, \quad \mathbf{u} = \mathbf{0} \quad \text{on } \Gamma = \partial\Omega$$

which appears as a result of time discretizations of the nonstationary Navier–Stokes equations with $\sigma = (1/\Delta t)$. Its weak formulation reads:

Find $(\mathbf{u}, p) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$ such that for all $(\mathbf{v}, q) \in \mathbf{H}_0^1(\Omega) \times L_0^2(\Omega)$,

$$a^\sigma(\mathbf{u}, \mathbf{v}) + b(\mathbf{u}, \mathbf{v}) - (p, \nabla\cdot\mathbf{v}) + (q, \nabla\cdot\mathbf{u}) = (\mathbf{f}, \mathbf{v}), \tag{5.1}$$

where the bilinear form $a(\cdot,\cdot)$ in (2.4) has been replaced by the bilinear form

$$a^\sigma(\mathbf{u}, \mathbf{v}) := \nu(\nabla\mathbf{u}, \nabla\mathbf{v}) + \sigma(\mathbf{u}, \mathbf{v}).$$

Let us introduce the following notations:

$$\begin{aligned} A\left((\mathbf{u}, p), (\mathbf{v}, q)\right) &= a_h^\sigma(\mathbf{u}, \mathbf{v}) + b_h(\mathbf{u}, \mathbf{v}) + j_h(\mathbf{u}, \mathbf{v}) + \sum_{K\in\mathcal{T}_h} \tau_K((\mathbf{b}\cdot\nabla)\mathbf{u}, (\mathbf{b}\cdot\nabla)\mathbf{v})_K \\ &\quad - (p, \nabla_h\cdot\mathbf{v}) + (q, \nabla_h\cdot\mathbf{u}), \\ L\left((\mathbf{v}, q)\right) &= (\mathbf{f}, \mathbf{v}) + \sum_{K\in\mathcal{T}_h} \tau_K(\mathbf{f}, (\mathbf{b}\cdot\nabla)\mathbf{v})_K \end{aligned}$$

with $a_h^\sigma(\cdot,\cdot)$ being the discrete analogue of $a^\sigma(\cdot,\cdot)$, more precisely

$$a_h^\sigma(\mathbf{u}_h, \mathbf{v}_h) := \sum_{K\in\mathcal{T}_h} (\nu(\nabla\mathbf{u}_h, \nabla\mathbf{v}_h)_K + \sigma(\mathbf{u}_h, \mathbf{v}_h)_K) \quad \forall \mathbf{u}_h, \mathbf{v}_h \in \mathbf{V}_h + \mathbf{H}_0^1(\Omega).$$

The discrete problem to be studied now becomes:

Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ such that for all $(\mathbf{v}_h, q_h) \in \mathbf{V}_h \times Q_h$,

$$A\left((\mathbf{u}_h, p_h), (\mathbf{v}_h, q_h)\right) = L\left((\mathbf{v}_h, q_h)\right). \tag{5.2}$$

The bilinear form $A(\cdot,\cdot)$ generates a norm on the product space $\mathbf{V}_h \times Q_h$

$$\begin{aligned} |||(\mathbf{v}, q)||| = \Bigg(&\nu|\mathbf{v}|_{1,h}^2 + \sigma\|\mathbf{v}\|_0^2 + (\nu+\sigma)\|q\|_0^2 \\ &+ j_h(\mathbf{v}, \mathbf{v}) + \sum_{K\in\mathcal{T}_h} \tau_K\|(\mathbf{b}\cdot\nabla)\mathbf{v}\|_{0,K}^2 \Bigg)^{1/2}. \end{aligned}$$

First we show an inf-sup condition for the bilinear form $A(\cdot,\cdot)$ on the product space $\mathbf{V}_h \times Q_h$.

LEMMA 5.1. *Assume that* $\max(\nu, \sigma, \tau_K, \gamma_E h_E) \le C$. *Then, there is a positive constant* β *independent of* $\nu > 0$ *such that for all* $(\mathbf{v}_h, q_h) \in \mathbf{V}_h \times Q_h$,

$$|||(\mathbf{v}_h, q_h)||| \le \frac{1}{\beta} \sup_{(\mathbf{w}_h, r_h)\in\mathbf{V}_h\times Q_h} \frac{A\left((\mathbf{v}_h, q_h), (\mathbf{w}_h, r_h)\right)}{|||(\mathbf{w}_h, r_h)|||}. \tag{5.3}$$

Proof. Let us consider an arbitrary $(\mathbf{v}_h, q_h) \in \mathbf{V}_h \times Q_h$. Choosing $(\mathbf{w}_h, r_h) = (\mathbf{v}_h, q_h)$, we have

$$\begin{aligned} &A\big((\mathbf{v}_h, q_h), (\mathbf{v}_h, q_h)\big) \\ &\quad = \nu|\mathbf{v}_h|_{1,h}^2 + \sigma\|\mathbf{v}_h\|_0^2 + j_h(\mathbf{v}_h, \mathbf{v}_h) + \sum_{K\in\mathcal{T}_h} \tau_K\|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2 \end{aligned} \tag{5.4}$$

due to the property $b_h(\mathbf{v}_h, \mathbf{v}_h) = 0$ which has been shown in section 2.

Now let us consider another choice of $(\mathbf{w}_h, r_h)$. For any $q_h \in Q_h$ the discrete Babuška–Brezzi condition (2.11) guarantees the existence of a function $\mathbf{v}_{q_h} \in \mathbf{V}_h$ such that

$$(\nabla_h \cdot \mathbf{v}_{q_h}, q_h) = -(q_h, q_h), \qquad \|\mathbf{v}_{q_h}\|_{1,h} \leq C\|q_h\|_0.$$

Thus, by choosing $(\mathbf{w}_h, r_h) = (\mathbf{v}_{q_h}, 0)$ we obtain

$$\begin{aligned} A\left((\mathbf{v}_h, q_h), (\mathbf{v}_{q_h}, 0)\right) &= \|q_h\|_0^2 + a_h^\sigma(\mathbf{v}_h, \mathbf{v}_{q_h}) + b_h(\mathbf{v}_h, \mathbf{v}_{q_h}) + j_h(\mathbf{v}_h, \mathbf{v}_{q_h}) \\ &\quad + \sum_{K \in \mathcal{T}_h} \tau_K((\mathbf{b}\cdot\nabla)\mathbf{v}_h, (\mathbf{b}\cdot\nabla)\mathbf{v}_{q_h})_K. \end{aligned} \tag{5.5}$$

Now, the second term on the right-hand side of (5.5) can be bounded as follows:

$$\begin{aligned} |a_h^\sigma(\mathbf{v}_h, \mathbf{v}_{q_h})| &\leq C\ (\nu|\mathbf{v}_h|_{1,h} + \sigma\|\mathbf{v}_h\|_0)\ \|q_h\|_0 \\ &\leq C\ \left(\nu^2|\mathbf{v}_h|_{1,h}^2 + \sigma^2\|\mathbf{v}_h\|_0^2\right) + \frac{1}{8}\|q_h\|_0^2. \end{aligned}$$

Elementwise integration by parts of the third term on the right-hand side of (5.5) gives

$$\begin{aligned} b_h(\mathbf{v}_h, \mathbf{v}_{q_h}) &= \sum_{E \in \mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E, [\mathbf{v}_h \cdot \mathbf{v}_{q_h}]_E\rangle_E - \sum_{K \in \mathcal{T}_h} ((\mathbf{b}\cdot\nabla)\mathbf{v}_{q_h}, \mathbf{v}_h)_K \\ &\quad - \sum_{E \in \mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{v}_h]_E, \{\mathbf{v}_{q_h}\}_E\rangle_E \\ &= \sum_{E \in \mathcal{E}_h} \langle \mathbf{b}\cdot\mathbf{n}_E[\mathbf{v}_{q_h}]_E, \{\mathbf{v}_h\}_E\rangle_E - \sum_{K \in \mathcal{T}_h} ((\mathbf{b}\cdot\nabla)\mathbf{v}_{q_h}, \mathbf{v}_h)_K. \end{aligned}$$

Let $\omega(E)$ denote the union of the cells K sharing a common face E. For any $\mathbf{v}_h \in V_h$ we have

$$\|[\mathbf{v}_h]_E\|_{0,E} \leq C\, h_E^{1/2}|\mathbf{v}_h|_{1,h,\omega(E)}, \qquad \|\{\mathbf{v}_h\}_E\|_{0,E} \leq C\, h_E^{-1/2}\|\mathbf{v}_h\|_{0,\omega(E)},$$

from which

$$|b_h(\mathbf{v}_h, \mathbf{v}_{q_h})| \leq C\,|\mathbf{v}_{q_h}|_{1,h}\,\|\mathbf{v}_h\|_0 \leq C\,\|q_h\|_0\,\|\mathbf{v}_h\|_0 \leq C\,\|\mathbf{v}_h\|_0^2 + \frac{1}{8}\|q_h\|_0^2$$

follows. Similarly, for the fourth term on the right-hand side of (5.5) we obtain

$$\begin{aligned} j_h(\mathbf{v}_h, \mathbf{v}_{q_h}) &\leq C \sum_{E \in \mathcal{E}_h} \gamma_E\|[\mathbf{v}_h]_E\|_{0,E}\, h_E^{1/2}|\mathbf{v}_{q_h}|_{1,h,\omega(E)} \\ &\leq C \sum_{E \in \mathcal{E}_h} \gamma_E^2 h_E\|[\mathbf{v}_h]_E\|_{0,E}^2 + \frac{1}{8}\|q_h\|_0^2. \end{aligned}$$

Finally, the fifth term on the right-hand side of (5.5) is estimated by

$$\begin{aligned} \left|\sum_{K \in \mathcal{T}_h} \tau_K((\mathbf{b}\cdot\nabla)\mathbf{v}_h, (\mathbf{b}\cdot\nabla)\mathbf{v}_{q_h})_K\right| &\leq \sum_{K \in \mathcal{T}_h} \tau_K\|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}\|(\mathbf{b}\cdot\nabla)\mathbf{v}_{q_h}\|_{0,K} \\ &\leq C \sum_{K \in \mathcal{T}_h} \tau_K^2\|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2 + \frac{1}{8}\|q_h\|_0^2. \end{aligned}$$

Combining the inequalities and taking into consideration that ν, τ_K, and $\gamma_E h_E$ are bounded from above, we get from (5.5)

$$A\big((\mathbf{v}_h, q_h), (\mathbf{v}_{q_h}, 0)\big) \geq \frac{1}{2}\|q_h\|_0^2$$

$$- C_1 \left[\nu|\mathbf{v}_h|_{1,h}^2 + \|\mathbf{v}_h\|_0^2 + j_h(\mathbf{v}_h, \mathbf{v}_h) + \sum_{K\in\mathcal{T}_h} \tau_K \|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2\right]. \tag{5.6}$$

Multiplying this inequality by $(\nu+\sigma)$, using the estimate $\nu+\sigma \leq C$ to bound

$$(\nu+\sigma)\nu|\mathbf{v}_h|_{1,h}^2 \leq C\nu|\mathbf{v}_h|_{1,h}^2,$$
$$(\nu+\sigma) j_h(\mathbf{v}_h, \mathbf{v}_h) \leq C j_h(\mathbf{v}_h, \mathbf{v}_h),$$
$$(\nu+\sigma)\sum_{K\in\mathcal{T}_h} \tau_K \|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2 \leq C \sum_{K\in\mathcal{T}_h} \tau_K \|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2,$$

and hiding the $\nu\|\mathbf{v}_h\|_0^2$ term by the discrete Poincaré's inequality

$$(\nu+\sigma)\|\mathbf{v}_h\|_0^2 = \nu\|\mathbf{v}_h\|_0^2 + \sigma\|\mathbf{v}_h\|_0^2 \leq C\nu|\mathbf{v}_h|_{1,h}^2 + \sigma\|\mathbf{v}_h\|_0^2,$$

we end up with

$$A\big((\mathbf{v}_h, q_h), ((\nu+\sigma)\mathbf{v}_{q_h}, 0)\big) \geq \frac{\nu+\sigma}{2}\|q_h\|_0^2$$

$$- C_2 \left[\nu|\mathbf{v}_h|_{1,h}^2 + \sigma\|\mathbf{v}_h\|_0^2 + j_h(\mathbf{v}_h, \mathbf{v}_h) + \sum_{K\in\mathcal{T}_h} \tau_K \|(\mathbf{b}\cdot\nabla)\mathbf{v}_h\|_{0,K}^2\right]. \tag{5.7}$$

From (5.4) and (5.7) we get for $(\mathbf{w}_h, r_h) := (1-\alpha)(\mathbf{v}_h, q_h) + \alpha((\nu+\sigma)\mathbf{v}_{q_h}, 0)$,

$$A\big((\mathbf{v}_h, q_h), (\mathbf{w}_h, r_h)\big) \geq \frac{\alpha}{2}|||(\mathbf{v}_h, q_h)|||^2 \tag{5.8}$$

with $\alpha = 2/(2C_2+3) \in (0,1)$. Moreover, analyzing each individual term in the triple norm, we can show that

$$|||(\mathbf{v}_{q_h}, 0)||| \leq C\|\mathbf{v}_{q_h}\|_{1,h} \leq C\|q_h\|_0,$$

and with $\nu+\sigma \leq C\sqrt{\nu+\sigma}$ we conclude that

$$\begin{aligned} |||(\mathbf{w}_h, r_h)||| &\leq (1-\alpha)|||(\mathbf{v}_h, q_h)||| + \alpha(\nu+\sigma)|||(\mathbf{v}_{q_h}, 0)||| \\ &\leq C_3|||(\mathbf{v}_h, q_h)||| \end{aligned}$$

follows. Thus, we obtain (5.3) with $\beta = \alpha/(2C_3)$. ∎

Remark. Note that for $\sigma > 0$ we have control over the L^2 norm of the velocity and the pressure *uniformly with respect to* ν. However, for $\sigma = 0$ we lose this uniform L^2 norm control. In this case, the pressure is only controlled by $\nu^{1/2}\|\cdot\|_0$. Taking into consideration Poincaré's inequality we see that the velocity is also controlled by $\nu^{1/2}\|\cdot\|_0$. This behavior, that the case $\sigma > 0$ leads to a uniform (with respect to ν) control of the L^2 norm of velocity and pressure, can be also observed in other stabilized methods; see, for example, [11].

Let the weak solution of the generalized Oseen equations belong additionally to $\mathbf{H}^2(\Omega) \times H^1(\Omega)$. Our formulation admits the following consistency property, where the parameter choice satisfies the assumption of Lemma 5.1.

LEMMA 5.2. *Let* $(\mathbf{u}, p) \in (\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)) \times (L_0^2(\Omega) \cap H^1(\Omega))$ *be the weak solution of* (5.1) *and let* $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ *be the discrete solution of* (5.2). *Then, the consistency error can be represented in the form*

$$\begin{aligned} R(\mathbf{u}, p; \mathbf{w}_h, r_h) :&= A\left((\mathbf{u} - \mathbf{u}_h, p - p_h), (\mathbf{w}_h, r_h)\right) \\ &= \sum_{E \in \mathcal{E}_h} \left\{ \left\langle \nu \frac{\partial \mathbf{u}}{\partial \mathbf{n}_E}, [\mathbf{w}_h]_E \right\rangle_E - \langle p, [\mathbf{w}_h]_E \cdot \mathbf{n}_E \rangle_E \right\} \\ &\quad + \sum_{K \in \mathcal{T}_h} \tau_K (\nu \Delta \mathbf{u} - \sigma \mathbf{u} - \nabla p, (\mathbf{b} \cdot \nabla) \mathbf{w}_h)_K. \end{aligned}$$

Furthermore, assume that $\tau_K \sim h_K^2$ *and* $\gamma_E \sim h_E^{-1}$. *Then, there is a positive constant* C *independent of* ν *such that*

$$|R(\mathbf{u}, p; \mathbf{w}_h, r_h)| \leq C\, h (\|\mathbf{u}\|_2 + \|p\|_1)\, |||(\mathbf{w}_h, r_h)||| \quad \forall (\mathbf{w}_h, r_h) \in \mathbf{V}_h \times Q_h.$$

Proof. The representation follows by testing the strong form of the problem with $\mathbf{w}_h$ and $(\mathbf{b} \cdot \nabla)\mathbf{w}_h$, respectively, elementwise integration by parts, and taking into consideration the definition of $A(\cdot, \cdot)$, (5.1), and (5.2). Following [13] we have

$$\left| \sum_{E \in \mathcal{E}_h} \left\langle \nu \frac{\partial \mathbf{u}}{\partial \mathbf{n}_E}, [\mathbf{w}_h]_E \right\rangle_E \right| \leq C\, h \nu \|\mathbf{u}\|_2\, |\mathbf{w}_h|_{1,h} \leq C\, h \|\mathbf{u}\|_2\, |||(\mathbf{w}_h, r_h)|||,$$

$$\left| \sum_{E \in \mathcal{E}_h} \langle p, [\mathbf{w}_h]_E \cdot \mathbf{n}_E \rangle_E \right| \leq Ch \|p\|_1\, |\mathbf{w}_h|_{1,h},$$

which shows that the second estimate does not lead to the desired estimate with a ν independent constant. Therefore, we bound the term in a different way as follows:

$$\begin{aligned} \left| \sum_{E \in \mathcal{E}_h} \langle p, [\mathbf{w}_h]_E \cdot \mathbf{n}_E \rangle_E \right| &\leq C \sum_{E \in \mathcal{E}_h} \gamma_E^{-1/2} h_E^{1/2} |p|_{1,h,\omega(E)}\ \gamma_E^{1/2} \|[\mathbf{w}_h]_E\|_{0,E} \\ &\leq Ch \|p\|_1 \sqrt{j_h(\mathbf{w}_h, \mathbf{w}_h)}. \end{aligned}$$

Concerning the last term of the consistency error, we get

$$\begin{aligned} &\left| \sum_{K \in \mathcal{T}_h} \tau_K (\nu \Delta \mathbf{u} - \sigma \mathbf{u} - \nabla p, (\mathbf{b} \cdot \nabla) \mathbf{w}_h)_K \right| \\ &\qquad \leq \sum_{K \in \mathcal{T}_h} \tau_K^{1/2} \left(\|\mathbf{u}\|_{2,K} + \|p\|_{1,K}\right)\ \tau_K^{1/2} \|(\mathbf{b} \cdot \nabla) \mathbf{w}_h\|_{0,K} \\ &\qquad \leq Ch \left(\|\mathbf{u}\|_2 + \|p\|_{1,K}\right) \left(\sum_{K \in \mathcal{T}_h} \tau_K \|(\mathbf{b} \cdot \nabla) \mathbf{w}_h\|_{0,K}^2 \right)^{1/2}. \end{aligned}$$

Summarizing the individual estimates we obtain the statement of the lemma. ∎

Next we shall investigate the interpolation error. First, note that a discretely divergence-free function is divergence-free on each cell K. Indeed, if χ_K denotes the characteristic function of K, $|K|$ and $|\Omega|$ denoting the measure of K and Ω, respectively, we conclude for a discretely divergence-free function $\mathbf{v}_h \in \mathbf{V}_h$ that the function $\nabla_h \cdot \mathbf{v}_h$ is piecewise constant and, thus, by setting $q_h = \chi_K - |K|/|\Omega| \in Q_h$,

$$\begin{aligned} 0 = (q_h, \nabla_h \cdot \mathbf{v}_h) &= (1, \nabla_h \cdot \mathbf{v}_h)_K - \frac{|K|}{|\Omega|}(1, \nabla_h \cdot \mathbf{v}_h)_\Omega \\ &= |K| \left(\nabla \cdot \mathbf{v}_h\big|_K\right) - \frac{|K|}{|\Omega|} \sum_{K \in \mathcal{T}_h} \langle 1, \mathbf{v}_h \cdot \mathbf{n}_K \rangle_{\partial K} \\ &= |K| \left(\nabla \cdot (\mathbf{v}_h\big|_K)\right). \end{aligned}$$

LEMMA 5.3. *The canonical interpolant $\mathbf{I}_h : \mathbf{H}_0^1(\Omega) \to \mathbf{V}_h$ defined by*

$$\frac{1}{|E|} \int_E (\mathbf{I}_h \mathbf{v} - \mathbf{v}) \, ds = \mathbf{0} \qquad \forall E \in \mathcal{E}_h$$

satisfies

$$(q_h, \nabla_h \cdot \mathbf{I}_h \mathbf{v}) = (q_h, \nabla \cdot \mathbf{v}) \qquad \forall\, q_h \in Q_h,\ \mathbf{v} \in \mathbf{H}_0^1(\Omega), \tag{5.9}$$

$$\|\mathbf{v} - \mathbf{I}_h \mathbf{v}\|_{0,K} + h_K |\mathbf{v} - \mathbf{I}_h \mathbf{v}|_{1,K} \le C\, h_K^2\, |\mathbf{v}|_{2,K} \qquad \forall\, \mathbf{v} \in \mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega). \tag{5.10}$$

Proof. For the proof see [13]. ∎

LEMMA 5.4. *Let $(\mathbf{u}, p) \in (\mathbf{H}_0^1(\Omega) \cap \mathbf{H}^2(\Omega)) \times (L_0^2(\Omega) \cap H^1(\Omega))$ be the weak solution of (5.1) and let $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times Q_h$ be the discrete solution of (5.2). Assume that $\tau_K \sim h_K^2$ and $\gamma_E \sim h_E^{-1}$. Then, for the canonical interpolant $\mathbf{I}_h : \mathbf{H}_0^1(\Omega) \to \mathbf{V}_h$ and the L^2 projection $J_h : L_0^2(\Omega) \to Q_h$ there is a constant C independent of ν such that*

$$|A\left((\mathbf{u} - \mathbf{I}_h \mathbf{u}, p - J_h p), (\mathbf{w}_h, r_h)\right)| \le C\, h (\|\mathbf{u}\|_2 + \|p\|_1)\, |||(\mathbf{w}_h, r_h)||| \tag{5.11}$$

for all $(\mathbf{w}_h, r_h) \in \mathbf{V}_h \times Q_h$.

Proof. Taking into consideration the definition of $|||\cdot|||$, we estimate each term in $A(\cdot,\cdot)$ separately. The estimate

$$|a_h^\sigma(\mathbf{u} - \mathbf{I}_h \mathbf{u}, \mathbf{w}_h)| \le C\, h\, \|\mathbf{u}\|_2\, |||(\mathbf{w}_h, r_h)|||$$

is standard. Using elementwise integration by parts, we obtain

$$b_h(\mathbf{u} - \mathbf{I}_h \mathbf{u}, \mathbf{w}_h) = \sum_{E \in \mathcal{E}_h} \langle \mathbf{b} \cdot \mathbf{n}_E [\mathbf{w}_h]_E, \{\mathbf{u} - \mathbf{I}_h \mathbf{u}\}_E \rangle_E - \sum_{K \in \mathcal{T}_h} (\mathbf{u} - \mathbf{I}_h \mathbf{u}, (\mathbf{b} \cdot \nabla) \mathbf{w}_h)_K$$

(see also the proof of Lemma 5.1). The first term on the right-hand side is estimated by

$$\begin{aligned} &\Big| \sum_{E \in \mathcal{E}_h} \langle \mathbf{b} \cdot \mathbf{n}_E [\mathbf{w}_h]_E, \{\mathbf{u} - \mathbf{I}_h \mathbf{u}\}_E \rangle_E \Big| \\ &\qquad \le C \sum_{E \in \mathcal{E}_h} \gamma_E^{-1/2} h_E^{3/2} \|\mathbf{u}\|_{2,\omega(E)}\, \gamma_E^{1/2} \|[\mathbf{w}_h]_E\|_{0,E} \\ &\qquad \le C\, h^2\, \|\mathbf{u}\|_2 \sqrt{j_h(\mathbf{w}_h, \mathbf{w}_h)} \end{aligned}$$

and the second one by

$$\left|\sum_{K\in\mathcal{T}_h}(\mathbf{u}-\mathbf{I}_h\mathbf{u},(\mathbf{b}\cdot\nabla)\mathbf{w}_h)_K\right| \le C\sum_{K\in\mathcal{T}_h}\tau_K^{-1/2}h_K^2\|\mathbf{u}\|_{2,K}\,\tau_K^{1/2}\|(\mathbf{b}\cdot\nabla)\mathbf{w}_h\|_{0,K}$$

$$\le C\,h\,\|\mathbf{u}\|_2\left(\sum_{K\in\mathcal{T}_h}\tau_K\|(\mathbf{b}\cdot\nabla)\mathbf{w}_h\|_{0,K}^2\right)^{1/2}.$$

The next expression is

$$|j_h(\mathbf{u}-\mathbf{I}_h\mathbf{u},\mathbf{w}_h)| \le C\sum_{E\in\mathcal{E}_h}\gamma_E^{1/2}h_E^{3/2}\|\mathbf{u}\|_{2,\omega(E)}\;\gamma_E^{1/2}\|[\mathbf{w}_h]_E\|_{0,E}$$

$$\le C\,h\,\|\mathbf{u}\|_2\,\sqrt{j_h(\mathbf{w}_h,\mathbf{w}_h)}$$

followed by

$$\sum_{K\in\mathcal{T}_h}\tau_K\big((\mathbf{b}\cdot\nabla)(\mathbf{u}-\mathbf{I}_h\mathbf{u}),(\mathbf{b}\cdot\nabla)\mathbf{w}_h\big)_K \le C\,h^2\,\|\mathbf{u}\|_2\left(\sum_{K\in\mathcal{T}_h}\tau_K\|(\mathbf{b}\cdot\nabla)\mathbf{w}_h\|_{0,K}^2\right)^{1/2}.$$

The orthogonality of the L^2 projection J_h and the property that any discretely divergence-free function is divergence-free on each cell yield that the last two terms become zero; i.e.,

$$(p-J_hp,\nabla_h\cdot\mathbf{w}_h)=0 \qquad \forall\mathbf{w}_h\in\mathbf{V}_h,$$

$$(r_h,\nabla_h\cdot(\mathbf{u}-\mathbf{I}_h\mathbf{u}))=0 \qquad \forall r_h\in Q_h.$$

Collecting all estimates, we get the statement of the lemma. ∎

THEOREM 5.5. *Let* $(\mathbf{u},p)\in(\mathbf{H}_0^1(\Omega)\cap\mathbf{H}^2(\Omega))\times(L_0^2(\Omega)\cap H^1(\Omega))$ *be the weak solution of* (5.1) *and let* $(\mathbf{u}_h,p_h)\in\mathbf{V}_h\times Q_h$ *be the discrete solution of* (5.2). *Assume that* $\tau_K\sim h_K^2$ *and* $\gamma_E\sim h_E^{-1}$. *Then, there is a positive constant* C *independent of* ν *such that*

$$|||(\mathbf{u}-\mathbf{u}_h,p-p_h)||| \le C\,h\,(\|\mathbf{u}\|_2+\|p\|_1). \tag{5.12}$$

Proof. Starting with Lemma 5.1 we have

$$|||(\mathbf{u}_h-\mathbf{I}_h\mathbf{u},p_h-J_hp)||| \le \frac{1}{\beta}\sup_{(\mathbf{w}_h,r_h)\in\mathbf{V}_h\times Q_h}\frac{A((\mathbf{u}_h-\mathbf{I}_h\mathbf{u},p_h-J_hp),(\mathbf{w}_h,r_h))}{|||(\mathbf{w}_h,r_h)|||}$$

$$\le \frac{1}{\beta}\sup_{(\mathbf{w}_h,r_h)\in\mathbf{V}_h\times Q_h}\frac{A((\mathbf{u}_h-\mathbf{u},p_h-p),(\mathbf{w}_h,r_h))}{|||(\mathbf{w}_h,r_h)|||}$$

$$+\frac{1}{\beta}\sup_{(\mathbf{w}_h,r_h)\in\mathbf{V}_h\times Q_h}\frac{A((\mathbf{u}-\mathbf{I}_h\mathbf{u},p-J_hp),(\mathbf{w}_h,r_h))}{|||(\mathbf{w}_h,r_h)|||}.$$

Now, the first term can be bounded by Lemma 5.2 and the second one by Lemma 5.4. It remains to apply the triangle inequality

$$|||(\mathbf{u}-\mathbf{u}_h,p-p_h)||| \le |||(\mathbf{u}-\mathbf{I}_h\mathbf{u},p-J_hp)||| + |||(\mathbf{u}_h-\mathbf{I}_h\mathbf{u},p_h-J_hp)|||$$

and the approximation properties of the interpolation operators $\mathbf{I}_h$ and J_h. ∎

Remark. According to the definition of the triple norm we have for $\sigma > 0$ an additional control *uniformly with respect to* ν over the L^2 norm of the velocity and the pressure. For $\sigma = 0$ we lose this control for $\nu \to 0$.

Remark. In the SUPG method the additional stabilizing term

$$\sum_{K \in \mathcal{T}_h} \gamma_K (\nabla \cdot \mathbf{u}_h, \nabla \cdot \mathbf{v}_h)_K$$

is often used [17, 31]. In our case of the Crouzeix–Raviart element, discretely divergence-free functions are piecewise divergence-free, therefore this term vanishes.

Remark. Often the SUPG parameter in the SUPG method is chosen in the advective regime as $\tau_K \sim h_K$, which is the correct choice for equal-order interpolation [9, 14, 31]. However, using inf-sup stable elements with different-order interpolation in the SUPG method, we have to take $\tau_K \sim h_K^2$ [5].

Numerical test. We consider the generalized Oseen equations (5.2) in $\Omega = (0,1)^2$ with the prescribed solution

$$\mathbf{u} = \begin{pmatrix} 2x^2(1-x)^2y(1-y)(1-2y) \\ -2y^2(1-y)^2x(1-x)(1-2x) \end{pmatrix}, \quad p = x^3 + y^3 - 0.5,$$

the convection field

$$\mathbf{b} = \begin{pmatrix} \sin(x)\sin(y) \\ \cos(x)\cos(y) \end{pmatrix},$$

and with the parameters $\nu = 10^{-3}$, $\sigma = 100$. The choice of σ corresponds to a length of the time step of 0.01 in the nonstationary Navier–Stokes equations.

The coarsest grid in the computations (level 0) consists of two triangles with the common edge from $(0,0)$ to $(1,1)$. On level 7, the system has 98 816 velocity degrees of freedom (including Dirichlet nodes) and 32 768 pressure degrees of freedom.

Results for different choices of the parameter γ_E in the jump term $j_h(\mathbf{u}_h, \mathbf{v}_h)$ are presented in Tables 5.1 and 5.2. In Table 5.1, computations without this jump term ($\gamma_E = 0$) and with the appropriate choice ($\gamma_E = 1$) known from scalar convection-diffusion equations (cf. [22]) are given. It can be observed that the order of convergence with respect to the natural norms for the Oseen equations is far below the optimal one in the convection-dominated regime; even an increase of errors occurs. However, optimal orders are obtained for the choice $\gamma_E = 1/h_E$, which is in agreement with our theoretical results presented in this section; see Table 5.2. In addition, the optimal order of convergence in the $|||\cdot|||$ norm, (5.12), can be seen.

A NEW STICKY PARTICLE METHOD FOR PRESSURELESS GAS DYNAMICS*

ALINA CHERTOCK†, ALEXANDER KURGANOV‡, AND YURII RYKOV§

Abstract. We first present a new sticky particle method for the system of pressureless gas dynamics. The method is based on the idea of sticky particles, which seems to work perfectly well for the models with point mass concentrations and strong singularity formations. In this method, the solution is sought in the form of a linear combination of δ-functions, whose positions and coefficients represent locations, masses, and momenta of the particles, respectively. The locations of the particles are then evolved in time according to a system of ODEs, obtained from a weak formulation of the system of PDEs. The particle velocities are approximated in a special way using global conservative piecewise polynomial reconstruction technique over an auxiliary Cartesian mesh. This velocities correction procedure leads to a desired interaction between the particles and hence to clustering of particles at the singularities followed by the merger of the clustered particles into a new particle located at their center of mass. The proposed sticky particle method is then analytically studied. We show that our particle approximation satisfies the original system of pressureless gas dynamics in a weak sense, but only within a certain residual, which is rigorously estimated. We also explain why the relevant errors should diminish as the total number of particles increases. Finally, we numerically test our new sticky particle method on a variety of one- and two-dimensional problems as well as compare the obtained results with those computed by a high-resolution finite-volume scheme. Our simulations demonstrate the superiority of the results obtained by the sticky particle method that accurately tracks the evolution of developing discontinuities and does not smear the developing δ-shocks.

Key words. nonstrictly hyperbolic systems of conservation laws, pressureless gas dynamics, mass concentration, strong singularities, δ-shock, sticky particle method

1. Introduction.

We consider the Euler equations of pressureless gas dynamics:

$$\mathbf{w}_t + \nabla_{\mathbf{x}} \cdot (\mathbf{u} \otimes \mathbf{w}) = \mathbf{0}. \tag{1.1}$$

Here, $\mathbf{x} := (x, y, \ldots)$ is an n-dimensional vector of spatial variables, $\mathbf{u} := (u, v, \ldots)$ is the corresponding velocity vector, and $\mathbf{w} \equiv (w^1, w^2, w^3, \ldots)^T := (\rho, \rho u, \rho v, \ldots)^T$ is the $(n+1)$-dimensional vector of unknown function, where ρ is the density.

This system arises in the modeling of the formation of large-scale structures in the universe [24]. It can be formally obtained as the limit of the isotropic Euler equations of gas dynamics as pressure tends to zero or as the macroscopic limit of a Boltzmann equation when the Maxwellian has zero temperature.

This author's work was supported in part by Russian Foundation for Basic Research grant 030100189 and by Program 01 of the Division of Mathematical Sciences of the Russian Academy of Sciences.

Even in the simplest one-dimensional (1-D) case, the system (1.1), which can be rewritten as

$$\begin{cases} \rho_t + (\rho u)_x = 0, \\ (\rho u)_t + (\rho u^2)_x = 0, \end{cases} \tag{1.2}$$

is mathematically challenging since it is nonstrictly hyperbolic and its Jacobian is not diagonalizable. For smooth solutions, the system (1.2) is equivalent to

$$\rho_t + (\rho u)_x = 0, \tag{1.3}$$

$$u_t + u u_x = 0. \tag{1.4}$$

Notice that (1.4) is the inviscid Burgers equation, which is, in fact, decoupled from (1.3). It is well known that the solution of the initial-value problem associated with (1.4), as long as it stays smooth, can be easily obtained by the method of characteristics. The density ρ can then be determined from (1.3), which becomes a linear transport equation. However, if the initial velocity $u(x,0)$ is not monotone increasing, the characteristics will intersect within a finite time, and the solution will lose its initial smoothness, and thus it must be understood in a weak sense. As in the general theory of weak solutions of hyperbolic systems of conservation laws, one has to introduce discontinuity lines. Let $x = \xi(t)$ be such a line and assume that the solution accepts finite values $u^{\pm} := u(\xi(t) \pm 0, t)$ and $\rho^{\pm} := \rho(\xi(t) \pm 0, t)$ from both sides of discontinuity. The jumps then must satisfy the Rankine–Hugoniot conditions, namely,

$$\begin{cases} \xi'(t)\,(\rho^+ - \rho^-) = \rho^+ u^+ - \rho^- u^-, \\ \xi'(t)\,(\rho^+ u^+ - \rho^- u^-) = \rho^+ \left(u^+\right)^2 - \rho^- \left(u^-\right)^2. \end{cases}$$

After eliminating ξ' from this system, one obtains $\rho^+ \rho^- \left(u^+ - u^-\right)^2 = 0$, which implies $u^+ = u^-$. Therefore, in order to support the shock discontinuity in the velocity field, the density must have a stronger (than a shock) singularity at $x = \xi'(t)$. Since in the Burgers equation, the characteristic lines impinge each other and thus, as part of the system (1.2), cause a mass concentration at the velocity discontinuity line, resulting in the formation of a δ-type singularity in the density field there.

The two-dimensional (2-D) version of (1.1) reads as

$$\begin{cases} \rho_t + (\rho u)_x + (\rho v)_y = 0, \\ (\rho u)_t + (\rho u^2)_x + (\rho u v)_y = 0, \\ (\rho v)_t + (\rho u v)_x + (\rho v^2)_y = 0. \end{cases} \tag{1.5}$$

Compared to the 1-D case, solutions of the 2-D system have a similar but essentially more sophisticated mechanism of singularities formation due to the dimensionality factor: strong singularities may now be formed either along surfaces or at separate points (we expect that in the three space dimensions the situation is even more complex). The system (1.5) has been intensively studied at the theoretical level (see, e.g., [2, 4, 6, 7, 8, 20, 21]). However, no more or less complete analytical results concerning the existence and uniqueness of solutions in the 2-D case are available. This is primarily related to the difficulties in the theoretical description of the collision of 2-D shocks. (See section 3.2 for an extensive numerical study of this phenomenon.)

Formation and further evolution of singular shocks, their interactions as well as the emergence of vacuum states, make development of numerical methods for the

system (1.1) a challenging problem. A numerical method based on the movement of a system of particles was introduced in [19]. Several finite-volume [17], kinetic [2, 3, 5], and relaxation [1] methods have been recently proposed. These methods are able to reasonably accurately capture δ-shocks, but their applicability is rather limited; for example, most of these methods do not work well for problems where the velocities change sign in regions where the density varies smoothly [17].

We develop a simple, efficient, and low-dissipative sticky particle method for pressureless gas dynamics. The derivation of our method is based on a weak formulation of the system (1.5) and can be viewed as a practical implementation of the sticky particle method from [4]. We first approximate $\mathbf{w}$ by a collection of N particles, located at $(x_i^N(t), y_i^N(t))$, $i = 1, \dots, N$, at time t, and carrying fixed masses and momenta. The particle locations are then evolved according to the corresponding system of ODEs, derived by plugging the particle approximation into a weak form of (1.1). In order to prevent the situation, in which approaching particles simply pass by each other without any interaction (such an undesirable situation is obviously impossible in the 1-D case, but is almost unavoidable in the 2-D case), we divide the computational domain into a set of auxiliary cells and compute the total mass and momenta in each cell. The particle velocities are then approximated using the global conservative piecewise polynomial interpolants of ρ, ρu, and ρv, constructed over an auxiliary Cartesian mesh. This way an interaction of all particles located in the same cell is guaranteed. When the particles get even closer to each other, we unite them into a new particle, located at the center of mass of the original clustered particles. The mass (momentum) of the new particle is simply the sum of the masses (corresponding momenta) of the replaced particles, and the velocities of the new particle are uniquely determined from the conservation requirements. This particle merger procedure results in mass concentration, which is an essential property of pressureless gases.

We would like to note that our 2-D sticky particle method can be extended to any number of space dimensions in a rather straightforward manner. In this paper, we restrict our consideration to the 1-D and 2-D cases only, since, to the best of our knowledge, no analytical results on three-dimensional (3-D) pressureless gas dynamics system are available, and it is therefore hard to set up convincing 3-D numerical experiments.

We test our method on a number of 1-D and 2-D numerical examples, in which we compare the results obtained by the new (nondissipative) sticky particle method and by the (dissipative) second-order central-upwind scheme from [11]. The latter scheme is a high-resolution Godunov-type finite-volume method that belongs to a family of central schemes, which may serve as "black-box" solvers for multidimensional hyperbolic systems of conservation laws. The prototype of modern central schemes is the first-order Lax–Friedrichs scheme [9, 16], which is the most universal method for solving (multidimensional systems of) time-dependent PDEs. However, its excessive numerical dissipation prevents sharp resolution and therefore in practice one has to use higher-order schemes. The first high-resolution nonoscillatory central scheme—the second-order Nessyahu–Tadmor scheme—was proposed in [18]. The amount of numerical dissipation present in projection-evolution central schemes was further reduced by incorporating some more upwinding information on local speeds of propagation into the evolution step [12, 14] (the resulting schemes thus have been referred to as central-upwind schemes) and, more recently, by enhancing the accuracy of the projection step [11, 13]. We note that the only upwinding information required by the central-upwind schemes is the eigenvalues of the Jacobians, and therefore application of these schemes to nonstrictly hyperbolic systems like (1.5) is straightforward.

The paper is organized as follows. We start in section 2 by introducing the new sticky particle method for the system (1.5). We then describe, in section 2.1, the velocity correction procedure and, in section 2.2, an algorithm of the unification of clustering particles. The main analytical result in section 2.3 is Theorem 2.1, where we show that even though our particle solution fails to satisfy (1.1) in a weak sense defined in [21], the relevant errors can be rigorously estimated. We then provide a heuristic justification why these errors tend to zero as $N \to \infty$. We conclude in section 3 with several 1-D and 2-D numerical examples and demonstrate that the new method accurately tracks the evolution of developing discontinuities. We also compare solutions computed by the sticky particle method with the corresponding solutions computed using the second-order semidiscrete central-upwind scheme, developed in [11, 12, 14]. A brief description of the central-upwind scheme for the pressureless gas dynamics system (1.5) is provided in Appendix A.

2. Derivation of the sticky particle method. We consider the system (1.1) subject to the compactly supported (or periodic) initial data,

$$\mathbf{w}(\mathbf{x},0) \equiv (\rho(\mathbf{x},0), \rho u(\mathbf{x},0), \rho v(\mathbf{x},0))^T, \quad \mathbf{x} := (x,y)^T, \tag{2.1}$$

and look for the solution of the initial-value problem (1.1), (2.1) in the particle form,

$$\mathbf{w}^N(\mathbf{x},t) = \sum_{i=1}^{N} \boldsymbol{\alpha}_i(t)\delta(\mathbf{x} - \mathbf{x}_i^N(t)),\ \mathbf{x}_i^N := (x_i^N, y_i^N)^T,\ \boldsymbol{\alpha}_i = (m_i, m_i u_i, m_i v_i)^T. \tag{2.2}$$

Here, N is a total number of particles, $\mathbf{x}_i^N(t)$ is the location of the ith particle at time t, and $m_i, m_i u_i$, and $m_i v_i$ are its mass, the x-, and the y-momenta, respectively.

In order to study the particle time evolution, we plug (2.2) into the weak formulation of the system (1.1),

$$\int_0^\infty \iint_{\mathbb{R}^2} \left\{\mathbf{w}^N \cdot [\boldsymbol{\varphi}_t + u\boldsymbol{\varphi}_x + v\boldsymbol{\varphi}_y]\right\} d\mathbf{x}dt - \iint_{\mathbb{R}^2} \mathbf{w}^N(\mathbf{x},0)\cdot\boldsymbol{\varphi}(\mathbf{x},0)\,d\mathbf{x} = 0, \tag{2.3}$$

where $\boldsymbol{\varphi}$ is an arbitrary C_0^1 test function. As a result, (2.3) reduces to

$$\sum_{i=1}^{N} \int_0^\infty \boldsymbol{\alpha}_i(t)\cdot\left\{\boldsymbol{\varphi}_t + u\boldsymbol{\varphi}_x + v\boldsymbol{\varphi}_y\right\}\Big|_{(\mathbf{x},t)=(\mathbf{x}_i^N(t),t)} dt - \sum_{i=1}^{N} \boldsymbol{\alpha}_i(0)\cdot\boldsymbol{\varphi}(\mathbf{x}_i^N(0),0) = 0, \tag{2.4}$$

which should be satisfied for any $\boldsymbol{\varphi}$. Evolving particle locations according to the following system of ODEs:

$$\frac{dx_i^N(t)}{dt} = u(\mathbf{x}_i^N(t),t), \quad \frac{dy_i^N(t)}{dt} = v(\mathbf{x}_i^N(t),t), \qquad i = 1,\dots,N, \tag{2.5}$$

and integrating by parts, we rewrite (2.4) as

$$\sum_{i=1}^{N} \int_0^\infty \frac{d\boldsymbol{\alpha}_i(t)}{dt}\cdot\boldsymbol{\varphi}(\mathbf{x}_i^N(t),t)\,dt = 0.$$

The last equation implies

$$\frac{d\boldsymbol{\alpha}_i(t)}{dt} = 0, \quad i = 1,\dots,N, \tag{2.6}$$

that is, the particle weights remain constant in time. Thus, the weights can be determined from the initial conditions, for instance, in the following manner. We divide the computational domain Ω into N subdomains Ω_i, $i = 1, \dots, N$, and place an ith particle with

$$\boldsymbol{\alpha}_i := \iint\limits_{\Omega_i} \mathbf{w}(\mathbf{x}, 0)\, d\mathbf{x}$$

into the center of Ω_i, denoted by $\mathbf{x}_i^N(0) \equiv (x_i^N(0), y_i^N(0))$, which will serve as initial data for the ODE system (2.5).

2.1. Particle velocities. In order to be able to solve the system of ODEs (2.5), one would need to recover the particle velocities at any given time moment. The simplest (and the least dissipative) way to compute the velocities is to divide the corresponding particle momenta by its mass, that is, by taking

$$u_i \equiv u(\mathbf{x}_i^N(t), t) := \frac{m_i u_i}{m_i}, \quad v_i \equiv v(\mathbf{x}_i^N(t), t) := \frac{m_i v_i}{m_i}. \tag{2.7}$$

In fact, this means that every particle travels with constant velocity until it collides with another particle (see section 2.2). This approach can be rigorously justified through the weak formulation (2.3) and it seems to work perfectly in the 1-D case, in which collision of approaching particles is unavoidable. However, in the 2-D case, the probability of collision of two particles approaching the same singularity curve is zero unless a special symmetry in initial particle locations has been imposed (see Example 5 in section 3.2).

We propose an alternative way of particle velocities reconstruction, which is independent of an initial placement of particles. Our approach is based on a global piecewise polynomial reconstruction technique, which is widely used in finite-volume framework (see Appendix A and the references therein). To adopt this technique to a mesh-free particle method we introduce an auxiliary Cartesian grid (which may vary in time). The grid should be adapted to the particle distribution so that the number of particles in every cell is about the same. In our numerical experiments, we have used the simplest strategy: we have adapted the auxiliary grid to the initial (uniform) particle distribution only by taking the size of the cells to be twice larger than the distance between the particles. A more sophisticated adaptation strategy may lead to more accurate results, but its optimization may substantially increase the complexity of the proposed sticky particle method.

Taking a simple uniform auxiliary grid, $x_j \equiv j\Delta x$, $y_k \equiv k\Delta y$, we first compute the cell averages of the conserved quantities at time t,

$$\bar{\mathbf{w}}_{j,k}(t) = \frac{1}{\Delta x \Delta y} \sum_{i:\, \mathbf{x}_i^N(t) \in I_{j,k}} \boldsymbol{\alpha}_i, \qquad I_{j,k} = [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}] \times [y_{k-\frac{1}{2}}, y_{k+\frac{1}{2}}]. \tag{2.8}$$

Using these cell averages, we then reconstruct a nonoscillatory piecewise polynomial interpolant of an appropriate order of accuracy, denoted by

$$\widetilde{\mathbf{w}}(\mathbf{x}, t) := (w^1(\mathbf{x}, t), w^2(\mathbf{x}, t), w^3(\mathbf{x}, t))^T,$$

which is used to compute the particle velocities,

$$u_i := \frac{\widetilde{w}^2(\mathbf{x}_i^N(t), t)}{\widetilde{w}^1(\mathbf{x}_i^N(t), t)}, \quad v_i := \frac{\widetilde{w}^3(\mathbf{x}_i^N(t), t)}{\widetilde{w}^1(\mathbf{x}_i^N(t), t)}. \tag{2.9}$$

Notice that in order to ensure that no mass (momentum) is artificially lost (created) at this step, the reconstruction must be performed in a conservative manner, namely, one should guarantee that

$$\sum_{i:\,\mathbf{x}_i^N(t)\in I_{j,k}} \widetilde{\mathbf{w}}(\mathbf{x}_i^N(t),t)=\bar{\mathbf{w}}_{j,k}(t).$$

We achieve the conservation (in fact, while the mass is conserved exactly, only approximate momentum conservation is guaranteed; see the computation in section 2.3) by taking $\widetilde{\mathbf{w}}$ to be a second-order accurate piecewise linear reconstruction centered at the center of mass of the particles located in the $I_{j,k}$ cell,

$$\begin{aligned}\widetilde{\mathbf{w}}(x,y,t)=\bar{\mathbf{w}}_{j,k}&+(\mathbf{s}_x)_{j,k}(x-x_{j,k}^{\mathrm{CM}}(t))\\&+(\mathbf{s}_y)_{j,k}(y-y_{j,k}^{\mathrm{CM}}(t))\quad\text{for}\quad(x,y)\in I_{j,k},\end{aligned}\tag{2.10}$$

where the coordinates of the center of mass are

$$x_{j,k}^{\mathrm{CM}}(t):=\frac{\displaystyle\sum_{i:\,\mathbf{x}_i^N(t)\in I_{j,k}} m_i x_i^N(t)}{\displaystyle\sum_{i:\,\mathbf{x}_i^N(t)\in I_{j,k}} m_i},\quad y_{j,k}^{\mathrm{CM}}(t):=\frac{\displaystyle\sum_{i:\,\mathbf{x}_i^N(t)\in I_{j,k}} m_i y_i^N(t)}{\displaystyle\sum_{i:\,\mathbf{x}_i^N(t)\in I_{j,k}} m_i},\tag{2.11}$$

and the slopes $(\mathbf{s}_x)_{j,k}$ and $(\mathbf{s}_y)_{j,k}$ are (at least) first-order approximations of the derivatives $\mathbf{w}_x(x_{j,k}^{\mathrm{CM}}(t),y_{j,k}^{\mathrm{CM}}(t))$ and $\mathbf{w}_y(x_{j,k}^{\mathrm{CM}}(t),y_{j,k}^{\mathrm{CM}}(t))$, respectively.

Finally, in order to ensure a nonoscillatory nature of the reconstruction (2.10), the slopes $(\mathbf{s}_x)_{j,k}$ and $(\mathbf{s}_y)_{j,k}$ should be computed using a nonlinear limiter. In our numerical experiments, we have used the minmod limiter applied in the following way.

Let us take, for example, the first component of $\mathbf{w}$ (density) and consider the four planes, denoted by $\pi_{j,k}^{\mathrm{NE}},\pi_{j,k}^{\mathrm{NW}},\pi_{j,k}^{\mathrm{SE}},\pi_{j,k}^{\mathrm{SW}}$, that pass through the following four triplets of points:

$$\begin{aligned}\pi_{j,k}^{\mathrm{NE}}&:\left\{(x_{j,k}^{\mathrm{CM}},y_{j,k}^{\mathrm{CM}},\bar{w}_{j,k}^1),\,(x_{j,k+1}^{\mathrm{CM}},y_{j,k+1}^{\mathrm{CM}},\bar{w}_{j,k+1}^1),\,(x_{j+1,k}^{\mathrm{CM}},y_{j+1,k}^{\mathrm{CM}},\bar{w}_{j+1,k}^1)\right\},\\ \pi_{j,k}^{\mathrm{NW}}&:\left\{(x_{j,k}^{\mathrm{CM}},y_{j,k}^{\mathrm{CM}},\bar{w}_{j,k}^1),\,(x_{j,k+1}^{\mathrm{CM}},y_{j,k+1}^{\mathrm{CM}},\bar{w}_{j,k+1}^1),\,(x_{j-1,k}^{\mathrm{CM}},y_{j-1,k}^{\mathrm{CM}},\bar{w}_{j-1,k}^1)\right\},\\ \pi_{j,k}^{\mathrm{SE}}&:\left\{(x_{j,k}^{\mathrm{CM}},y_{j,k}^{\mathrm{CM}},\bar{w}_{j,k}^1),\,(x_{j,k-1}^{\mathrm{CM}},y_{j,k-1}^{\mathrm{CM}},\bar{w}_{j,k-1}^1),\,(x_{j+1,k}^{\mathrm{CM}},y_{j+1,k}^{\mathrm{CM}},\bar{w}_{j+1,k}^1)\right\},\\ \pi_{j,k}^{\mathrm{SW}}&:\left\{(x_{j,k}^{\mathrm{CM}},y_{j,k}^{\mathrm{CM}},\bar{w}_{j,k}^1),\,(x_{j,k-1}^{\mathrm{CM}},y_{j,k-1}^{\mathrm{CM}},\bar{w}_{j,k-1}^1),\,(x_{j-1,k}^{\mathrm{CM}},y_{j-1,k}^{\mathrm{CM}},\bar{w}_{j-1,k}^1)\right\}\end{aligned}\tag{2.12}$$

(the dependence of $\{x_{j,k}^{\mathrm{CM}}\}$ and $\{y_{j,k}^{\mathrm{CM}}\}$ on t has been omitted here for briefness). We then denote the gradients of these planes by $((\pi_x)_{j,k}^{\mathrm{NE}},(\pi_y)_{j,k}^{\mathrm{NE}})^T$, $((\pi_x)_{j,k}^{\mathrm{NW}},(\pi_y)_{j,k}^{\mathrm{NW}})^T$, etc., and take the first component of the slopes in (2.10) to be

$$\begin{aligned}(s_x^1)_{j,k}&=\mathrm{minmod}\left((\pi_x)_{j,k}^{\mathrm{NE}},(\pi_x)_{j,k}^{\mathrm{NW}},(\pi_x)_{j,k}^{\mathrm{SE}},(\pi_x)_{j,k}^{\mathrm{SW}}\right),\\ (s_y^1)_{j,k}&=\mathrm{minmod}\left((\pi_y)_{j,k}^{\mathrm{NE}},(\pi_y)_{j,k}^{\mathrm{NW}},(\pi_y)_{j,k}^{\mathrm{SE}},(\pi_y)_{j,k}^{\mathrm{SW}}\right),\end{aligned}\tag{2.13}$$

where the minmod function is defined by

$$\text{minmod}(c_1,c_2,\ldots) := \begin{cases} \min(c_1,c_2,\ldots) & \text{if } \ c_i>0 \ \forall i,\\ \max(c_1,c_2,\ldots) & \text{if } \ c_i<0 \ \forall i,\\ 0 & \text{otherwise.}\end{cases} \tag{2.14}$$

The reconstructions for the other two fields of $\mathbf{w}$ (momenta) are obtained in a similar way.

Remarks.

1. It may happen that one of the planes in (2.12) is perpendicular to the (x,y)-plane or is not uniquely determined. Then this plane is not taken into account, and its gradient is excluded from the formulae for the slopes in (2.13).
2. As was mentioned in section 1, our velocity recovery procedure ensures that there is an interaction between the particles, located inside the same auxiliary grid cell. As is illustrated in our numerical experiments (see section 3.2), this leads to the desired clustering of particles at the singularities.

2.2. Unification of clustering particles. A major drawback of particle methods is that, in general, their resolution and efficiency significantly deteriorate when too many particles cluster near the same point at the singularity. To prevent such an undesired situation, we unite clustering particles according to the following algorithm. We choose a certain critical distance d_{cr} and as soon as the distance between any two particles gets smaller than the critical distance, we unite them into a new "heavier" particle.

Let us assume that at some time t, the distance between the ith and the jth particles, $|\mathbf{x}_i(t)-\mathbf{x}_j(t)|$, is smaller than d_{cr}. We then replace these two particles with a new one of the following total mass and momenta:

$$\boldsymbol{\alpha}_{\text{new}} = \boldsymbol{\alpha}_i + \boldsymbol{\alpha}_j, \tag{2.15}$$

located at the center of mass of the replaced particles, namely,

$$\mathbf{x}^N_{\text{new}} = \frac{m_i\mathbf{x}^N_i + m_j\mathbf{x}^N_j}{m_i+m_j}. \tag{2.16}$$

The velocities of the new particle are determined according to the procedure in section 2.1. After completing the replacement process (2.15)–(2.16), we check whether any other two particles are to be united, and if not, the remaining set of particles is further evolved in time according to (2.2), (2.5), (2.9) until another particle clustering occurs. Then, the unification procedure is repeated, and so forth.

Remark. The critical distance d_{cr} should be chosen experimentally. In all our numerical examples, except for Example 4, this distance was taken a quarter of a minimal initial distance between the particles (note that the initial distribution of particles is rather uniform in every numerical example below). In Example 4, d_{cr} was made proportional to the size of the shrinking support of the solution.

We would also like to stress that our numerical experiments clearly indicate that the presented sticky particle method does not seem to be sensitive to the choice of d_{cr}.

2.3. On convergence of the sticky particle method. In previous sections, a sequence of approximate solutions $\{\mathbf{w}^N\}_{N=1}^{\infty}$ of the system (1.1) for a fixed time interval $[0,T]$ has been constructed based on the dynamics of moving particles. In this section, we show that the measures $\mathbf{w}^N$ do not satisfy (1.1) in a weak sense.

Nevertheless, in Theorem 2.1, we obtain rigorous estimates for relevant errors and further discuss the heuristic justification why these errors tend to zero as $N \to \infty$.

In order to exactly formulate the theorem, let us first describe the interactions of moving particles in detail. Consider a time interval $[t_1, t_2] \subset [0, T]$, some number p of moving particles, and a time moment t_0 such that the particles evolve according to the ODE system (2.5)–(2.6) for $t \in [t_1, t_0)$ and $t \in (t_0, t_2]$, while at time t_0 the particles either coalesce (Case I) or change the velocities according to (2.9) (Case II).

For the considered group of p particles, $\mathcal{P}$, with the total mass

$$M := \sum_{i \in \mathcal{P}} m_i,$$

we introduce the following notation.

- Prior to $t = t_0$ we denote by
  $\boldsymbol{\alpha}_i = (m_i, m_i u_i, m_i v_i)^T$: weights of the particles,
  $(x_i(t), y_i(t))$: their locations at time $t < t_0$,
  $(x_i^0, y_i^0) = (x_i(t_0), y_i(t_0))$: final locations of the particles at time $t = t_0$.
- At $t = t_0$ the considered p particles either
  − coalesce (Case I) and then we denote by
  $\boldsymbol{\alpha} = (M, MU, MV)$: weights of the newly formed particle of mass M,
  $U = \dfrac{\sum_{i \in \mathcal{P}} m_i u_i}{\sum_{i \in \mathcal{P}} m_i}$ and $V = \dfrac{\sum_{i \in \mathcal{P}} m_i v_i}{\sum_{i \in \mathcal{P}} m_i}$: its x- and y-velocities,
  $(X_0, Y_0) = (X(t_0), Y(t_0))$: its initial position at time $t = t_0$,
  $(X(t), Y(t))$: its location at time $t > t_0$;
  or
  − undergo the velocities correction (Case II) and then we denote by
  $\widetilde{\boldsymbol{\alpha}}_i = (m_i, m_i \widetilde{u}_i, m_i \widetilde{v}_i)^T$: new weights of the original p particles,
  $(x_i(t), y_i(t))$: their locations, which are not instantaneously affected by the velocities correction procedure and thus change continuously.

We also denote by $\left(x^{\mathrm{CM}}(t), y^{\mathrm{CM}}(t)\right)$ the location of the center of mass of the considered group of p particles,

$$x^{\mathrm{CM}}(t) = \frac{\sum\limits_{i \in \mathcal{P}} m_i x_i(t)}{\sum\limits_{i \in \mathcal{P}} m_i}, \quad y^{\mathrm{CM}}(t) = \frac{\sum\limits_{i \in \mathcal{P}} m_i y_i(t)}{\sum\limits_{i \in \mathcal{P}} m_i}. \tag{2.17}$$

Let us call by *the event with respect to Case* I the situation when some number of particles coalesce at some time moment and at some location. Suppose E_{C1} is the set of such events, and denote by N_{C1} the number of such events that take place in the computational domain within the specified time interval. It is obvious that, in general, N_{C1} is less than the initial number of particles N since each possible merging reduces the number of particles by at least one.

Let us call by *the event with respect to Case* II the situation when the velocities of a particle change according to (2.9) at some time moment. Suppose E_{C2} is the set of such events, and denote by N_{C2} the number of such events that take place in the computational domain within the specified time interval. Notice that all existing particles, whose total number is always less than or equal to N, can undergo the velocity correction procedure at every time step. The minimal distance between the particles is controlled by the particle unification procedure and is thus proportional to $1/\sqrt{N}$. Due to the CFL condition, the size of each time step is proportional to the

minimal distance between the particles. Therefore, the total number of time steps in our 2-D sticky particle method is proportional to $\sqrt{N}$, and hence $N_{\mathrm{C2}} \lesssim N^{3/2}$.

We are now ready to formulate the following theorem.

THEOREM 2.1. *Let* $\mathbf{R}$ *be the residual of the particle solution* $\mathbf{w}^N$*, that is, let* $\mathbf{w}^N$ *satisfy the equation*

$$\mathbf{w}_t + (u\mathbf{w})_x + (v\mathbf{w})_y = \mathbf{R}(x,y,z)$$

in the weak sense defined in [21, *Definition* 1] *for any time interval* $[t_1,t_2] \subset [0,T]$.

If the slopes $(\mathbf{s}_x)_{j,k}$ *and* $(\mathbf{s}_y)_{j,k}$ *in the piecewise linear reconstruction* (2.9) *are set to be* 0 *in all cells* $I_{j,k}$*, then the size of the residual can be estimated by*

$$|\mathbf{R}| \le C\varepsilon \sum_{E_{\mathrm{C1}}\cup E_{\mathrm{C2}}} \left(\frac{\sum\limits_{i<l} m_i m_l \left(|u_i-u_l|+|v_i-v_l|\right)}{\sum\limits_{l} m_l} + \varepsilon \sum_i m_i \left(1+|u_i|+|v_i|\right) \right), \tag{2.18}$$

where the summation is taken over the particles that participate in the specific event from E_{C1} *or* E_{C2}*, and* $\varepsilon := \sqrt{(\Delta x)^2+(\Delta y)^2}$ *is the diameter of the auxiliary grid cell, which is assumed to tend to* 0 *as* $N \to \infty$.

In the case where the slopes $(\mathbf{s}_x)_{j,k}$ *and* $(\mathbf{s}_y)_{j,k}$ *in* (2.9) *are defined according to formulae* (2.10)–(2.12)*, the estimate* (2.18) *is also true, provided the following bound*

$$\left|(s_x^r)_{j,k}\left(x_i - x_{j,k}^{\mathrm{CM}}\right) + (s_y^r)_{j,k}\left(y_i - y_{j,k}^{\mathrm{CM}}\right)\right| \le C\varepsilon \bar{w}_{j,k}^r, \quad r=1,2,3, \tag{2.19}$$

is true at each auxiliary $I_{j,k}$ *cell and for each particle such that* $(x_i,y_i) \in I_{j,k}$*. Here,* $x_{j,k}^{\mathrm{CM}}$ *and* $y_{j,k}^{\mathrm{CM}}$*, given by* (2.11)*, are the coordinates of the center of mass of the particles, located in* $I_{j,k}$ *at the time moment when the velocity correction procedure is performed.*

Remark. The conditions (2.19) are rather technical. It is clear that for the reconstruction (2.10)–(2.14) they hold in smooth parts of the solution (away from vacuum), where all the slopes are bounded. In the nonsmooth parts of the solution and near vacuum, the conditions (2.19) represent a certain nonoscillatory requirement, which may or may not be satisfied by the reconstruction (2.10)–(2.14).

Proof. We start by observing that there is a finite number (which may be proportional to N) of time moments in the interval $[0,T]$ at which some particle velocities change according to either Case I or Case II. Therefore, it is enough to consider such time intervals $[t_1,t_2]$ that contain only a single moment $t=t_0$ of the velocities change.

Let us next fix a test function, $\boldsymbol{\psi} \equiv (\psi^1,\psi^2,\psi^3)^T \in C_0^1(\mathbb{R}^2)$ and consider the following two sets of time moments:

$$\mathcal{T}_1 := \{t_{1_i} \in [t_1,t_0], i=1,\dots,q_1\} \quad \text{and} \quad \mathcal{T}_2 := \{t_{2_i} \in [t_0,t_2], i=1,\dots,q_2\},$$

such that some particle either enters or leaves the domain

$$\Phi := \operatorname{supp}\psi^1 \cup \operatorname{supp}\psi^2 \cup \operatorname{supp}\psi^3 \tag{2.20}$$

at these times.

Notice that it suffices to consider the sets $\mathcal{T}_1$ and $\mathcal{T}_2$ to be finite. If not, then the supports of functions ψ^i, $i=1,2,3$, can be placed into larger convex sets Λ_i and the functions ψ^i can be extended to Λ_i by zero. As has been mentioned above, there is only a finite number of time moments in the interval $[0,T]$ at which some particle velocities change according to either Case I or Case II. Between these time moments

all the particles freely move along straight lines and, due to the convexity of Λ_i, they can intersect the boundaries of Λ_i at most twice. Therefore, replacing $\operatorname{supp}\psi^i$ with Λ_i in (2.20) will make $\mathcal{T}_1$ and $\mathcal{T}_2$ finite.

The conservation laws are thus satisfied in any time interval $[t_{1_i}, t_{1_{i+1}}]$ or $[t_{2_k}, t_{2_{k+1}}]$ since no velocities correction procedures are performed and since the test function $\boldsymbol{\psi}$ vanishes at the points where particles enter or leave the domain Φ. Hence, it is enough to consider only the particles dynamics in the time interval $[\max_i t_{1_i}, \min_k t_{2_k}]$, such that at time $t = \max_i t_{1_i}$ there are p particles (from $\mathcal{P}$) inside the domain Φ and no particles enter or leave Φ until $t = \min_k t_{2_k}$. In order to simplify the notation, we again denote such interval by $[t_1, t_2]$.

Case I. First, we suppose that the particle formed at the time moment $t = t_0$ stays inside the domain Φ. We then plug the particle solution (2.2) into the weak formulation (in the sense of [21, Definition 1]) of (1.1) over the time interval $[t_1, t_2]$ to compute the residuals for the equations of mass and momenta conservation.

- From the *mass conservation* equation we obtain

$$\begin{aligned}
&\int_{t_1}^{t_0} \left\{ \sum_{i\in\mathcal{P}} \left[\psi_x^1(x_i(\tau), y_i(\tau)) m_i u_i + \psi_y^1(x_i(\tau), y_i(\tau)) m_i v_i \right] \right\} d\tau \\
&+ \int_{t_0}^{t_2} \left\{ \psi_x^1(X(\tau), Y(\tau)) MU + \psi_y^1(X(\tau), Y(\tau)) MV \right\} d\tau \\
&= \int_{t_1}^{t_0} \frac{d}{d\tau} \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(\tau), y_i(\tau))\, d\tau + \int_{t_0}^{t_2} \frac{d}{d\tau} M\psi^1(X(\tau), Y(\tau))\, d\tau \\
&= M\psi^1(X(t_2), Y(t_2)) - \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(t_1), y_i(t_1)) + R^1,
\end{aligned}$$

where

$$R^1 = \sum_{i\in\mathcal{P}} m_i \psi^1(x_i^0, y_i^0) - M\psi^1(X_0, Y_0). \tag{2.21}$$

Rewriting (2.21), using the Taylor expansion about (X_0, Y_0) and taking into account (2.17) for $t = t_0$, we arrive at

$$\begin{aligned}
R^1 &= \sum_{i\in\mathcal{P}} m_i \left[\psi^1(x_i^0, y_i^0) - \psi^1(X_0, Y_0) \right] \\
&= \sum_{i\in\mathcal{P}} m_i \left[\psi_x^1(X_0, Y_0) \left(x_i^0 - X_0 \right) + \psi_y^1(X_0, Y_0) \left(y_i^0 - Y_0 \right) + \mathcal{O}(\varepsilon^2) \right] \\
&= \psi_x^1(X_0, Y_0) \left[\sum_{i\in\mathcal{P}} m_i x_i^0 - MX_0 \right] + \psi_y^1(X_0, Y_0) \left[\sum_{i\in\mathcal{P}} m_i y_i^0 - MY_0 \right] + M \cdot \mathcal{O}(\varepsilon^2) \\
&= M \cdot \mathcal{O}(\varepsilon^2). \qquad (2.22)
\end{aligned}$$

- From the *x-momentum conservation* equation we obtain

$$\begin{aligned}
&\int_{t_1}^{t_0} \left\{ \sum_{i\in\mathcal{P}} \left[\psi_x^2(x_i(\tau), y_i(\tau)) u_i \cdot m_i u_i + \psi_y^2(x_i(\tau), y_i(\tau)) v_i \cdot m_i u_i \right] \right\} d\tau \\
&+ \int_{t_0}^{t_2} \left\{ \psi_x^2(X(\tau), Y(\tau)) U \cdot MU + \psi_y^2(X(\tau), Y(\tau)) V \cdot MU \right\} d\tau
\end{aligned}$$

$$= \int_{t_1}^{t_0} \frac{d}{d\tau} \sum_{i\in\mathcal{P}} m_i u_i \psi^2(x_i(\tau), y_i(\tau))\, d\tau + \int_{t_0}^{t_2} \frac{d}{d\tau} MU\psi^2(X(\tau), Y(\tau))\, d\tau$$
$$= MU\psi^2(X(t_2), Y(t_2)) - \sum_{i\in\mathcal{P}} m_i u_i \psi^2(x_i(t_1), y_i(t_1)) + R^2,$$

where

$$R^2 = \sum_{i\in\mathcal{P}} m_i u_i \psi^2(x_i^0, y_i^0) - MU\psi^2(X_0, Y_0). \tag{2.23}$$

We now rewrite (2.23) and use the Taylor expansion about (X_0, Y_0) and (2.17) to obtain

$$R^2 = \sum_{i\in\mathcal{P}} m_i u_i \left[\psi^2(x_i^0, y_i^0) - \psi^2(X_0, Y_0)\right]$$
$$= \sum_{i\in\mathcal{P}} m_i u_i \left[\psi_x^2(X_0, Y_0)\left(x_i^0 - X_0\right) + \psi_y^2(X_0, Y_0)\left(y_i^0 - Y_0\right) + \mathcal{O}(\varepsilon^2)\right]$$
$$= \psi_x^2(X_0, Y_0)\left[\sum_{i\in\mathcal{P}} m_i u_i x_i^0 - MUX_0\right] + \psi_y^2(X_0, Y_0)\left[\sum_{i\in\mathcal{P}} m_i u_i y_i^0 - MUY_0\right] + MU\cdot\mathcal{O}(\varepsilon^2)$$
$$= \psi_x^2(X_0, Y_0)\left[\sum_{i\in\mathcal{P}} m_i u_i x_i^0 - \frac{\sum\limits_{i\in\mathcal{P}} m_i u_i \cdot \sum\limits_{l\in\mathcal{P}} m_l x_l^0}{\sum\limits_{l\in\mathcal{P}} m_l}\right]$$
$$+ \psi_y^2(X_0, Y_0)\left[\sum_{i\in\mathcal{P}} m_i u_i y_i^0 - \frac{\sum\limits_{i\in\mathcal{P}} m_i u_i \cdot \sum\limits_{l\in\mathcal{P}} m_l y_l^0}{\sum\limits_{l\in\mathcal{P}} m_l}\right] + MU\cdot\mathcal{O}(\varepsilon^2).$$

Then, taking into account that

$$\sum_{i\in\mathcal{P}} m_i u_i x_i^0 - \frac{\sum\limits_{i\in\mathcal{P}} m_i u_i \cdot \sum\limits_{l\in\mathcal{P}} m_l x_l^0}{\sum\limits_{l\in\mathcal{P}} m_l} = \frac{\sum\limits_{i,l\in\mathcal{P}} \left(m_l m_i u_i x_i^0 - m_i m_l u_i x_l^0\right)}{\sum\limits_{l\in\mathcal{P}} m_l}$$
$$= \frac{\sum\limits_{i,l\in\mathcal{P}} m_i m_l u_i \left(x_i^0 - x_l^0\right)}{\sum\limits_{l\in\mathcal{P}} m_l} = \frac{\sum\limits_{i,l\in\mathcal{P}:i<l} \left[m_i m_l u_i \left(x_i^0 - x_l^0\right) + m_l m_i u_l \left(x_l^0 - x_i^0\right)\right]}{\sum\limits_{l\in\mathcal{P}} m_l}$$
$$= \frac{\sum\limits_{i,l\in\mathcal{P}:i<l} m_i m_l \left(x_i^0 - x_l^0\right)(u_i - u_l)}{\sum\limits_{l\in\mathcal{P}} m_l},$$

we end up with

$$R^2 = \psi_x^2(X_0, Y_0)\frac{\sum\limits_{i,l\in\mathcal{P}:i<l} m_i m_l (x_i^0 - x_l^0)(u_i - u_l)}{\sum\limits_{l\in\mathcal{P}} m_l}$$
$$+ \psi_y^2(X_0, Y_0)\frac{\sum\limits_{i,l\in\mathcal{P}:i<l} m_i m_l (y_i^0 - y_l^0)(u_i - u_l)}{\sum\limits_{l\in\mathcal{P}} m_l} + MU\cdot\mathcal{O}(\varepsilon^2). \tag{2.24}$$

• In a similar manner, we consider the third component of the residual,

$$R^3 = \sum_{i\in\mathcal{P}} m_i v_i \psi^3(x_i^0, y_i^0) - MV\psi^3(X_0, Y_0), \tag{2.25}$$

and then from the *y-momentum conservation* equation derive

$$\begin{aligned} R^3 = {} & \psi_x^3(X_0, Y_0) \frac{\sum\limits_{i,l\in\mathcal{P}:i<l} m_i m_l (x_i^0 - x_l^0)(v_i - v_l)}{\sum\limits_{l\in\mathcal{P}} m_l} \\ & + \psi_y^3(X_0, Y_0) \frac{\sum\limits_{i,l\in\mathcal{P}:i<l} m_i m_l (y_i^0 - y_l^0)(v_i - v_l)}{\sum\limits_{l\in\mathcal{P}} m_l} + MV\cdot\mathcal{O}(\varepsilon^2). \end{aligned} \tag{2.26}$$

Finally, combining formulae (2.22), (2.24), and (2.26) and using the fact that the distance between (x_i^0, y_i^0) and (x_l^0, y_l^0) is less than $d_{cr} < \varepsilon$, we immediately conclude with the desired estimate (2.18).

Remark. Recall that formulae (2.22), (2.24), and (2.26) were derived under the assumption that the particle formed at $t = t_0$ stays inside the domain Φ. If not, then $\boldsymbol{\psi}(X_0, Y_0) = \mathbf{0}$ and all the particles from $\mathcal{P}$ lie within the distance $d_{cr} < \varepsilon$ from the boundary of $\boldsymbol{\psi}$. Thus the estimate (2.18) follows (as can be seen from formulae (2.21), (2.23), and (2.25)) since $\boldsymbol{\psi} \in C_0^1(\mathbb{R}^2)$ and $|\boldsymbol{\psi}(x_i^0, y_i^0)| < C\varepsilon^2$ for all $(x_i^0, y_i^0) \in \mathcal{P}$.

Case II. As in Case I, we plug the particle solution (2.2) into the weak formulation (in the sense of [21, Definition 1]) of (1.1) over the time interval $[t_1, t_2]$ to compute the corresponding residuals. However, since the set of particles participating in the velocities correction procedure at time $t = t_0$, described in section 2.1, coincides (in general) with the set of all existing particles (including the ones lying outside the domain Φ), the residuals computation is carried out as follows.

• From the *mass conservation* equation we obtain

$$\begin{aligned} & \int_{t_1}^{t_0} \left\{ \sum_{i\in\mathcal{P}} \left[\psi_x^1(x_i(\tau), y_i(\tau)) m_i u_i + \psi_y^1(x_i(\tau), y_i(\tau)) m_i v_i \right] \right\} d\tau \\ & + \int_{t_0}^{t_2} \left\{ \sum_{i\in\mathcal{P}} \left[\psi_x^1(x_i(\tau), y_i(\tau)) m_i \widetilde{u}_i + \psi_y^1(x_i(\tau), y_i(\tau)) m_i \widetilde{v}_i \right] \right\} d\tau \\ & = \int_{t_1}^{t_0} \frac{d}{d\tau} \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(\tau), y_i(\tau))\, d\tau + \int_{t_0}^{t_2} \frac{d}{d\tau} \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(\tau), y_i(\tau))\, d\tau \\ & = \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(t_2), y_i(t_2)) - \sum_{i\in\mathcal{P}} m_i \psi^1(x_i(t_1), y_i(t_1)). \end{aligned}$$

Unlike Case I, the particle trajectories are now continuous within the time interval $[t_1, t_2]$ because only particle velocities may change at $t = t_0$. Therefore, the first component of the residual is

$$R^1 = \sum_{i\in\mathcal{P}} m_i \psi^1(x_i^0, y_i^0) - \sum_{i\in\mathcal{P}} m_i \psi^1(x_i^0, y_i^0) = 0. \tag{2.27}$$

• From the *x-momentum conservation* equation we obtain

$$\int_{t_1}^{t_0} \left\{ \sum_{i\in\mathcal{P}} \left[\psi_x^2(x_i(\tau), y_i(\tau)) u_i \cdot m_i u_i + \psi_y^2(x_i(\tau), y_i(\tau)) v_i \cdot m_i u_i \right] \right\} d\tau$$

$$
\begin{aligned}
&+\int_{t_0}^{t_2}\left\{\sum_{i\in\mathcal{P}}\left[\psi_x^2(x_i(\tau),y_i(\tau))\widetilde{u}_i\cdot m_i\widetilde{u}_i+\psi_y^2(x_i(\tau),y_i(\tau))\widetilde{v}_i\cdot m_i\widetilde{u}_i\right]\right\}d\tau\\
&=\int_{t_1}^{t_0}\frac{d}{d\tau}\sum_{i\in\mathcal{P}}m_iu_i\psi^2(x_i(\tau),y_i(\tau))\,d\tau+\int_{t_0}^{t_2}\frac{d}{d\tau}\sum_{i\in\mathcal{P}}m_i\widetilde{u}_i\psi^2(x_i(\tau),y_i(\tau))\,d\tau\\
&=\sum_{i\in\mathcal{P}}m_i\widetilde{u}_i\psi^2(x_i(t_2),y_i(t_2))-\sum_{i\in\mathcal{P}}m_iu_i\psi^2(x_i(t_1),y_i(t_1))+R^2,
\end{aligned}
$$

where

$$
R^2=\sum_{i\in\mathcal{P}}\psi^2(x_i^0,y_i^0)(m_iu_i-m_i\widetilde{u}_i). \tag{2.28}
$$

Note that the summation in (2.28) is taken over the particles located in the domain Φ, which consists of a certain number of auxiliary cells (or their parts) $I_{j,k}$. Thus, the residual R^2 can be written as the sum of residuals in each cell $I_{j,k}$ that contains (at least) one particle and has a nonempty intersection with Φ. Let us now consider such a cell, denote the set of particles, located in it at time moment $t=t_0$, by $\mathcal{P}_{j,k}$, and the residual in this cell by $R^2_{j,k}$.

Applying the Taylor expansion about the center of mass $(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k})$ given by (2.11) yields

$$
\begin{aligned}
R^2_{j,k}=&\sum_{i\in\mathcal{P}_{j,k}}\Big[\psi^2\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)+\psi^2_x\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)\left(x_i^0-x^{\rm CM}_{j,k}\right)\\
&\qquad+\psi^2_y\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)\left(y_i^0-y^{\rm CM}_{j,k}\right)+\mathcal{O}(\varepsilon^2)\Big]m_i(u_i-\widetilde{u}_i)\\
=&\left[\psi^2\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)+\mathcal{O}(\varepsilon^2)\right]\sum_{i\in\mathcal{P}_{j,k}}m_i(u_i-\widetilde{u}_i)\\
&+\psi^2_x\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)\sum_{i\in\mathcal{P}_{j,k}}m_i(u_i-\widetilde{u}_i)\left(x_i^0-x^{\rm CM}_{j,k}\right)\\
&+\psi^2_y\left(x^{\rm CM}_{j,k},y^{\rm CM}_{j,k}\right)\sum_{i\in\mathcal{P}_{j,k}}m_i(u_i-\widetilde{u}_i)\left(y_i^0-y^{\rm CM}_{j,k}\right).
\end{aligned}
\tag{2.29}
$$

Next, we consider each sum on the right-hand side (RHS) of (2.29) separately. For the first sum, use formulae (2.8)–(2.10) to rewrite

$$
\begin{aligned}
&\sum_{i\in\mathcal{P}_{j,k}}m_i(u_i-\widetilde{u}_i)=\sum_{i\in\mathcal{P}_{j,k}}m_i\left[u_i-\frac{\bar{w}^2_{j,k}+\left(s^2_x\right)_{j,k}\left(x_i^0-x^{\rm CM}_{j,k}\right)+\left(s^2_y\right)_{j,k}\left(y_i^0-y^{\rm CM}_{j,k}\right)}{\bar{w}^1_{j,k}+\left(s^1_x\right)_{j,k}\left(x_i^0-x^{\rm CM}_{j,k}\right)+\left(s^1_y\right)_{j,k}\left(y_i^0-y^{\rm CM}_{j,k}\right)}\right]\\
&=\sum_{i\in\mathcal{P}_{j,k}}m_i\left\{u_i-\frac{1}{\bar{w}^1_{j,k}}\left[\bar{w}^2_{j,k}+\left(s^2_x\right)_{j,k}\left(x_i^0-x^{\rm CM}_{j,k}\right)+\left(s^2_y\right)_{j,k}\left(y_i^0-y^{\rm CM}_{j,k}\right)\right]\right.\\
&\left.\times\left[1+\frac{\left(s^1_x\right)_{j,k}\left(x_i^0-x^{\rm CM}_{j,k}\right)+\left(s^1_y\right)_{j,k}\left(y_i^0-y^{\rm CM}_{j,k}\right)}{\bar{w}^1_{j,k}}\right]^{-1}\right\}.
\end{aligned}
\tag{2.30}
$$

Taking into account (2.19), the last term in (2.30) is equal to

$$
1-\frac{\left(s^1_x\right)_{j,k}\left(x_i^0-x^{\rm CM}_{j,k}\right)+\left(s^1_y\right)_{j,k}\left(y_i^0-y^{\rm CM}_{j,k}\right)}{\bar{w}^1_{j,k}}+\mathcal{O}(\varepsilon^2),
$$

and thus

$$\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)=\frac{1}{\bar{w}^1_{j,k}}\Bigg\{\bar{w}^1_{j,k}\sum_{i\in\mathcal{P}_{j,k}} m_iu_i$$
$$-\sum_{i\in\mathcal{P}_{j,k}} m_i\Bigg[\bar{w}^2_{j,k}-\frac{\bar{w}^2_{j,k}}{\bar{w}^1_{j,k}}\left(\left(s^1_x\right)_{j,k}\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)+\left(s^1_y\right)_{j,k}\left(y^0_i-y^{\mathrm{CM}}_{j,k}\right)\right)$$
$$+\left(s^2_x\right)_{j,k}\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)+\left(s^2_y\right)_{j,k}\left(y^0_i-y^{\mathrm{CM}}_{j,k}\right)+\bar{w}^2_{j,k}\mathcal{O}(\varepsilon^2)\Bigg]\Bigg\}.$$

Finally, using the definition of cell averages (2.8) and the fact that the center of mass $(x^{\mathrm{CM}}_{j,k},y^{\mathrm{CM}}_{j,k})$ satisfies (2.11), we obtain

$$\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)=\frac{1}{\bar{w}^1_{j,k}}\Bigg\{\sum_{i\in\mathcal{P}_{j,k}} m_i\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)\left[\frac{\bar{w}^2_{j,k}}{\bar{w}^1_{j,k}}\left(s^1_x\right)_{j,k}-\left(s^2_x\right)_{j,k}\right]$$
$$+\sum_{i\in\mathcal{P}_{j,k}} m_i\left(y^0_i-y^{\mathrm{CM}}_{j,k}\right)\left[\frac{\bar{w}^2_{j,k}}{\bar{w}^1_{j,k}}\left(s^1_y\right)_{j,k}-\left(s^2_y\right)_{j,k}\right]+\bar{w}^2_{j,k}\mathcal{O}(\varepsilon^2)\sum_{i\in\mathcal{P}_{j,k}} m_i\Bigg\}$$
$$=\Delta x\Delta y\bar{w}^2_{j,k}\mathcal{O}(\varepsilon^2)=\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\cdot\mathcal{O}(\varepsilon^2). \tag{2.31}$$

Remark. Note that if $\left(\mathbf{s}_x\right)_{j,k}=\left(\mathbf{s}_y\right)_{j,k}=\mathbf{0}$, then the RHS of (2.31) vanishes and $\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)=0$. Otherwise, one has an approximate x-momentum conservation only.

We next consider the second sum on the RHS of (2.29) and in a similar manner obtain

$$\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)=\frac{1}{\bar{w}^1_{j,k}}\Bigg\{\bar{w}^1_{j,k}\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)$$
$$-\sum_{i\in\mathcal{P}_{j,k}} m_i\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)\Bigg(\bar{w}^2_{j,k}+\left[\left(s^2_x\right)_{j,k}-\frac{\bar{w}^2_{j,k}}{\bar{w}^1_{j,k}}\left(s^1_x\right)_{j,k}\right]\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)$$
$$+\left[\left(s^2_y\right)_{j,k}-\frac{\bar{w}^2_{j,k}}{\bar{w}^1_{j,k}}\left(s^1_y\right)_{j,k}\right]\left(y^0_i-y^{\mathrm{CM}}_{j,k}\right)+\bar{w}^2_{j,k}\mathcal{O}(\varepsilon^2)\Bigg)\Bigg\}$$
$$=\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)+\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\cdot\mathcal{O}(\varepsilon^2). \tag{2.32}$$

Then, using the definition of the center of mass (2.11) we rewrite the first term on the RHS of (2.32) as

$$\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\left(x^0_i-x^{\mathrm{CM}}_{j,k}\right)=\sum_{i\in\mathcal{P}_{j,k}} m_iu_ix^0_i-\frac{\sum\limits_{i\in\mathcal{P}_{j,k}} m_iu_i\sum\limits_{l\in\mathcal{P}_{j,k}} m_lx^0_l}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}$$
$$=\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}}\left(m_lm_iu_ix^0_i-m_im_lu_ix^0_l\right)}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}=\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}:i<l} m_im_l\left(x^0_i-x^0_l\right)(u_i-u_l)}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l},$$

and conclude with

(2.33)
$$\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)\left(x_i^0-x_{j,k}^{\rm CM}\right)=\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}:i<l} m_im_l\left(x_i^0-x_l^0\right)(u_i-u_l)}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}+\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\cdot\mathcal{O}(\varepsilon^2).$$

The estimate on the third sum on the RHS of (2.29) is completely analogous:

(2.34)
$$\sum_{i\in\mathcal{P}_{j,k}} m_i(u_i-\widetilde{u}_i)\left(y_i^0-y_{j,k}^{\rm CM}\right)=\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}:i<l} m_im_l\left(y_i^0-y_l^0\right)(u_i-u_l)}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}+\sum_{i\in\mathcal{P}_{j,k}} m_iu_i\cdot\mathcal{O}(\varepsilon^2).$$

We now substitute (2.31), (2.33), and (2.34) into (2.29) and sum up all $R^2_{j,k}$ to end up with the following estimate:

$$|R^2|\le C\varepsilon\sum_{j,k}\left(\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}:i<l} m_im_l|u_i-u_l|}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}+\varepsilon\sum_{i\in\mathcal{P}_{j,k}} m_i|u_i|\right). \tag{2.35}$$

• A similar estimate on R^3 is obtained from the *y-momentum conservation* equation,

$$|R^3|\le C\varepsilon\sum_{j,k}\left(\frac{\sum\limits_{i,l\in\mathcal{P}_{j,k}:i<l} m_im_l|v_i-v_l|}{\sum\limits_{l\in\mathcal{P}_{j,k}} m_l}+\varepsilon\sum_{i\in\mathcal{P}_{j,k}} m_i|v_i|\right). \tag{2.36}$$

Finally, adding up (2.27), (2.35), and (2.36), and considering velocity corrections occurring in different auxiliary cells to be different events from the set $E_{\rm C2}$, we obtain the estimate (2.18) in Case II.

This completes the proof of the theorem since in our 2-D sticky particle method the only contributions to the residual $\mathbf{R}$ come from the particle interactions enforced by the merger (Case I) and velocity correction (Case II) procedures. □

Remark. Note that as has been shown in the proof (see the estimate (2.31) and the remark after it), the use of the second-order reconstruction (2.10) results in additional errors in momenta conservation equations compared with the first-order ($(\mathbf{s}_x)_{j,k}=(\mathbf{s}_y)_{j,k}=0$ for all j,k) approach. However, a more accurate velocity reconstruction typically leads to a more accurate particle dynamics, while the momenta conservation errors and their contributions to the corresponding residuals (the second terms on the RHS of (2.35) and (2.36)) are relatively small.

We conclude this section with a brief discussion of the result established in Theorem 2.1, which provides us with an estimate on the size of the residual. We view this result as a step toward the convergence proof of the proposed 2-D sticky particle method. Completing the proof would require obtaining more precise estimates on the residual, which, in general, may be rather difficult. However, according to the conjecture in [21], the following scenario of mass concentration occurs. Let us first mention that the system (1.5) has straight bicharacteristic lines, which usually intersect at some time moment (analogously to the 1-D case) and form curves in the (x,y)-plane (their representation in the (t,x,y)-space is not a characteristic surface, but a surface defined by a generalization of the Hugoniot relations) with a finite mass distributed

along the curves as a δ-function. These curves then start to impinge each other and form the singularities with finite masses at separate points. The collisions of the curves take place, in general, transversally, but no rigorous theoretical description of such a solution behavior is available. Assuming now that solutions of (1.5) have such a structure (this assumption has also been supported by the numerical experiments reported in section 3.2, Examples 7, 8a, and 8b), it is possible to show that $|\mathbf{R}| \to 0$ as $N \to \infty$.

Indeed, following the above scenario when particles coalesce (Case I) they form curves with finite masses. In this case, the differences $|u_i - u_l|$ and $|v_i - v_l|$ are finite, the considered cluster of particles $\mathcal{P}$ merges into a particle with mass $\sim \varepsilon$, while other, nonclustered, particles have masses $\sim \varepsilon^2$. Also, $m_l \sim \varepsilon^2$ and $|\mathcal{P}| \sim 1/\varepsilon$. Thus, $\sum_{l\in\mathcal{P}} m_l \sim \varepsilon$, $\sum_{i,l\in\mathcal{P}:i<l} m_i m_l \sim \varepsilon^3$, and hence one gets $|\mathbf{R}| \sim \varepsilon^3 \cdot N_{\mathrm{C1}}$. Finally, $N_{\mathrm{C1}} < C/\varepsilon^2$ since it is bounded by the total number of particles N, and thus we obtain that $|\mathbf{R}| \sim \varepsilon$, which tends to zero as N tends to infinity.

We now consider the situation of "pure" Case 2, when only the velocities correction procedure is performed and no particles coalesce. In this case, taking into account that the corrected velocities are also close and masses of particles are of order ε^2, one has $|\mathbf{R}| \sim \varepsilon^4 \cdot N_{\mathrm{C2}}$. But, as has been mentioned before, $N_{\mathrm{C2}} \sim N^{3/2} \sim 1/\varepsilon^3$, and thus we obtain that $|\mathbf{R}| \sim \varepsilon$ in Case II as well.

We hope that the presented heuristic convergence arguments can be "upgraded" to a rigorous convergence proof and we plan to do so in forthcoming papers.

3. Numerical examples. In this section, we test the new sticky particle (SP) method presented in section 2 on a number of 1-D and 2-D numerical examples. We also compare solutions computed by the particle method with the corresponding solutions computed using the second-order semidiscrete central-upwind (CU) scheme, developed in [11, 12, 14]. A brief description of the CU scheme for the pressureless gas dynamics system (1.5) is provided in Appendix A. Numerical time integration has been performed using the strong stability preserving Runge–Kutta method [10].

Note that in all the examples below, we do not reconstruct point values of the computed density from its particle distribution at the final time but rather plot the total mass m of each particle. For the purpose of fair comparison, the solutions computed by the finite-volume CU scheme are always presented in a similar way, that is, we plot the total mass in each cell rather than the corresponding cell averages.

3.1. One-dimensional examples. The following four examples are devoted to the 1-D system (1.2). A 1-D version of our SP method can be easily deduced from its 2-D formulation in section 2.

Example 1. In the first numerical test, taken from [5], we solve the system (1.2) subject to the following Riemann initial data:

$$(\rho(x,0), u(x,0)) = \begin{cases} (1.00, \quad 0.5) & \text{if } \ x < 0, \\ (0.25, -0.4) & \text{if } \ x > 0. \end{cases} \tag{3.1}$$

In this example, a δ-shock develops immediately and propagates with speed 0.2.

We take $\Delta x = 0.005$ for the CU scheme and the initial uniform distribution of particles, placed Δx away from each other, for the SP method. In Figure 1, the particle/cell masses and the corresponding velocities, computed by both the SP method and the CU scheme, are plotted at time $t = 0.5$. Note that because of the point mass concentration occurring at the δ-shock, the masses are presented in the logarithmic scale so that a more detailed structure of the solution can be seen.

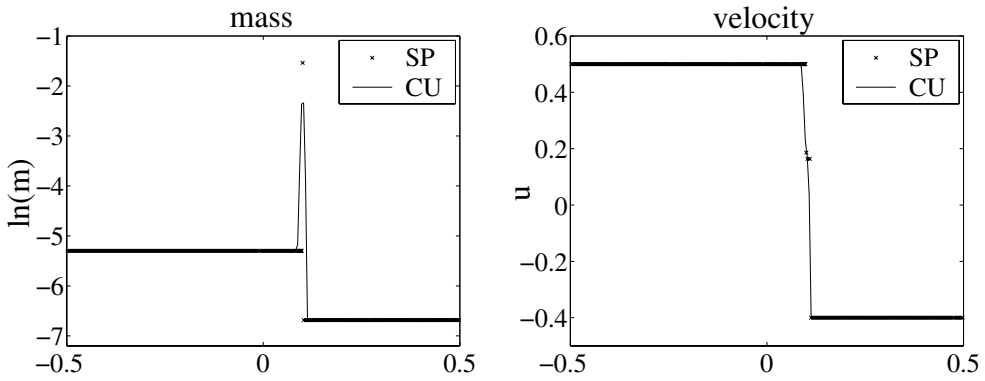

FIG. 1. *Solution of* (1.2), (3.1) *computed by the SP method and the CU scheme.*

Figure 1 demonstrates that both schemes are able to capture the δ-shock with the correct propagation speed, but one can clearly see the superiority of the results obtained by the SP method, which does not smear the δ-shock.

Example 2. We consider a test problem of the collision of two compactly supported clouds. The initial data, prescribed at $t = -1$, are taken from [17],

$$(\rho(x,-1),u(x,-1)) = \begin{cases} (2,\ \ 1) & \text{if} \quad -2 < x < -1, \\ (1,-1) & \text{if} \quad\ \ 1 < x < 5, \\ (0,\ \ 0) & \text{otherwise.} \end{cases} \tag{3.2}$$

The two clouds collide at time $t = 0$. The left cloud is fully accelerated into the δ-wave at about $t \approx 1.21$ and the right cloud is fully accelerated at about $t \approx 4.25$. We use a uniform spatial grid with $\Delta x = 0.0125$ for the CU scheme. The SP method is started with 400 particles, placed only in the intervals $[-2,-1]$ and $[1,5]$, where the dust is initially present. Figures 2 and 3 show the particle/cell masses (in the logarithmic scale) at times $t = -1$, -0.5, 0, 0.5, 1, 1.5, 3.5, and 6. As one can observe, both methods give the same correct location of the δ-wave. However, both the δ-wave and the contact discontinuities computed by the CU scheme are smeared over a number of cells, while the resolution achieved by the SP method is almost perfect. We note that the mass computed by the SP method is concentrated in a single point by time $t = 6$.

Example 3. In this example, we demonstrate an interaction of two singular shocks by numerically solving the system (1.2) subject to the following initial data:

$$(\rho(x,0),u(x,0)) = \begin{cases} (0.25,1.00) & \text{if} \ -2.75 < x < -0.75, \\ (0.25,0.50) & \text{if} \ -0.75 < x < 0.5, \\ (1.00,-1.00) & \text{if} \quad\ \ 0.5 < x < 1.5, \\ (0.00,0.00) & \text{otherwise.} \end{cases} \tag{3.3}$$

In Figure 4, we plot the particle/cell masses (in the logarithmic scale) computed by both the SP method and the CU scheme at times $t = 0$, 0.5, 1, 1.5, 2, and 2.5. We start the SP method with $N = 425$ particles, which are uniformly distributed in the interval $[-2.75, 1.5]$. For the CU scheme, we use a uniform spatial grid with $\Delta x = 0.01$. Again, one can clearly see that the SP method outperforms the finite-volume CU scheme by far.

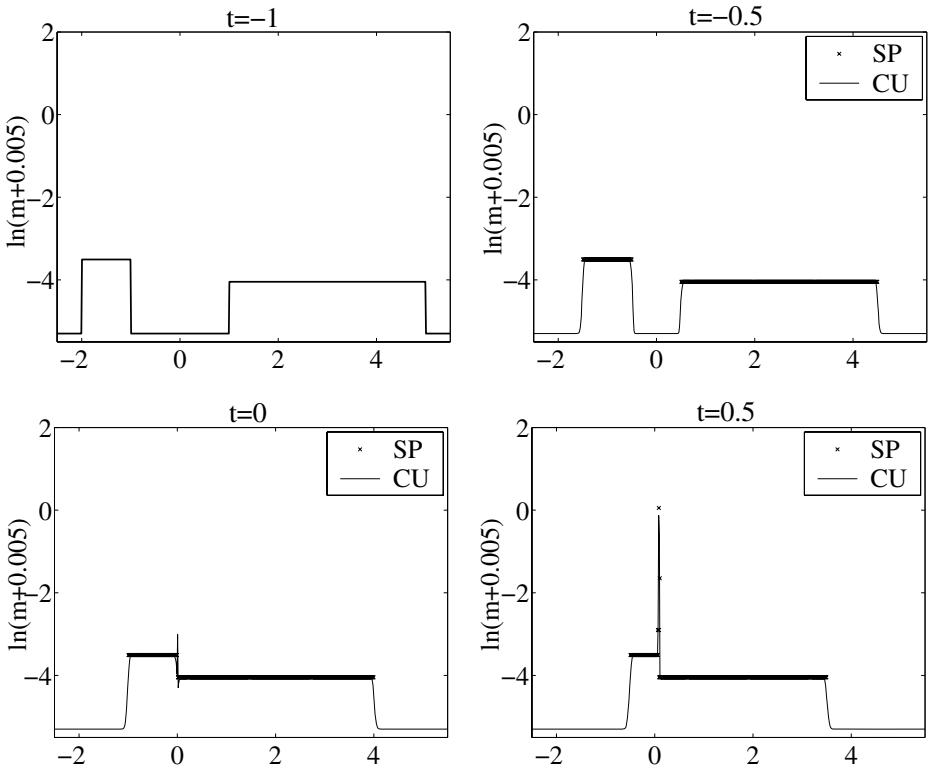

FIG. 2. *Solution (masses) of* (1.2), (3.2) *computed by the SP method and the CU scheme.*

Example 4. The last 1-D example is devoted to a problem where the velocity u changes its sign in the region with varying density. This significantly increases the level of complexity of the problem due to a special way the singularity forms, as demonstrated below.

We consider the system (1.2) subject to the smooth initial data:

(3.4)
$$\rho(x,0) = \begin{cases} 2-\sin x & \text{if } -\pi \le x \le \pi, \\ 0 & \text{otherwise,} \end{cases} \qquad u(x,0) = \begin{cases} 1-x & \text{if } -\pi \le x \le \pi, \\ 0 & \text{otherwise,} \end{cases}$$

for which the exact solution can be found analytically as follows. A continuous part of the solution is obtained by the method of characteristics:

$$u(X(t),t) = 1 - x_0, \qquad \rho(X(t),t) = \frac{2-\sin x_0}{1-t}, \tag{3.5}$$

where

$$X(t) = x_0 + t(1-x_0) \tag{3.6}$$

is the characteristic line starting at $x = x_0$. Obviously, the solution (3.5)–(3.6) is valid in the domain bounded by the characteristics $X_-(t) = -\pi + t(1+\pi)$ and $X_+(t) = \pi + t(1-\pi)$ and thus exists until $t = 1$ only; see Figure 5.

As t approaches 1, the density tends to infinity, more and more mass is concentrated near the point $x = 1$, and therefore one can anticipate a massive particle

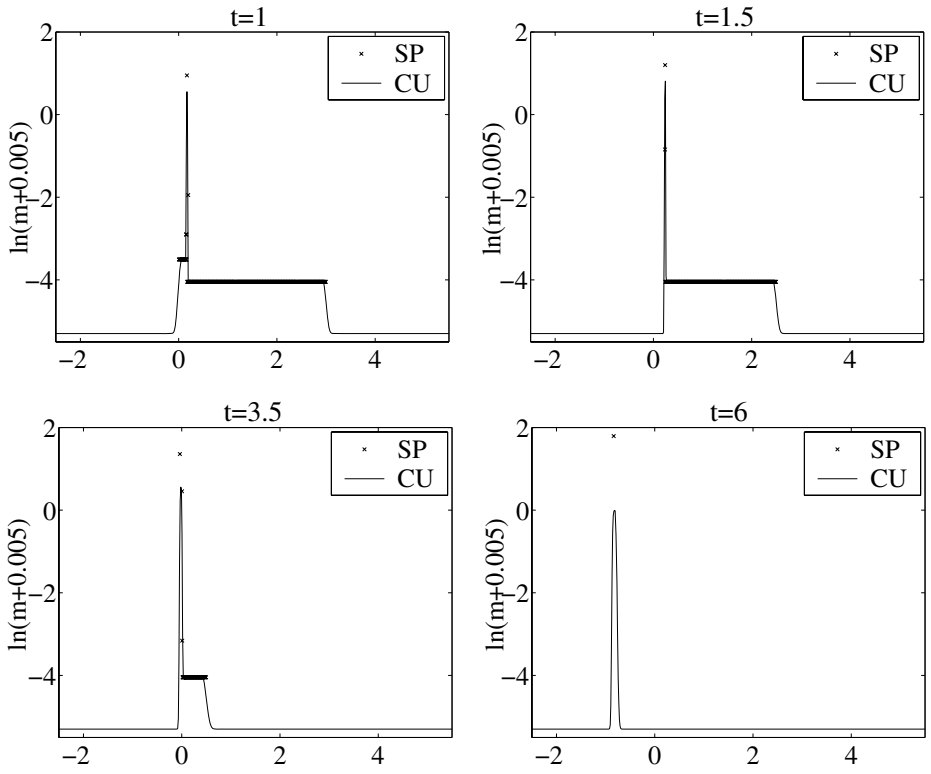

FIG. 3. *Solution (masses) of* (1.2), (3.2) *computed by the SP method and the CU scheme.*

formation at this point. In order to determine a singular part of the solution of (1.2), (3.4) we use the variational representation of the generalized solution of pressureless gas dynamics equations introduced in [8]. To this end, we consider the function

$$F(x_0) \equiv F(x_0;x,t) := \int_0^{x_0} [s - x + t\,u(s,0)]\,\rho(s,0)\,ds = \int_0^{x_0} [s - x + t\,(1-s)]\,(2-\sin s)\,ds, \tag{3.7}$$

and according to [8], the smoothness of the solution depends on a number of points at which the global minimum of F is attained. If F has only one global minimum point, then the solution is continuous at (x,t); otherwise the solution develops a shock discontinuity in velocity and a δ-shock in density there. In the latter case, suppose that there exists a set of points $\{x_0^1, x_0^2, \ldots\}$ at which F assumes its global minimum, and denote $x_0^- := \min\{x_0^1, x_0^2, \ldots\}$ and $x_0^+ := \max\{x_0^1, x_0^2, \ldots\}$. Then the left and right values of ρ and u at (x,t) are computed from (3.5) with $x_0 = x_0^-$ and $x_0 = x_0^+$, respectively. In addition, the δ-function singularity at this point ("a massive particle") has the following mass and momentum:

$$M = \int_{x_0^-}^{x_0^+} \rho(s,0)\,ds, \qquad I = \int_{x_0^-}^{x_0^+} u(s,0)\rho(s,0)\,ds, \tag{3.8}$$

and according to mass and momentum conservation, the speed of the massive particle

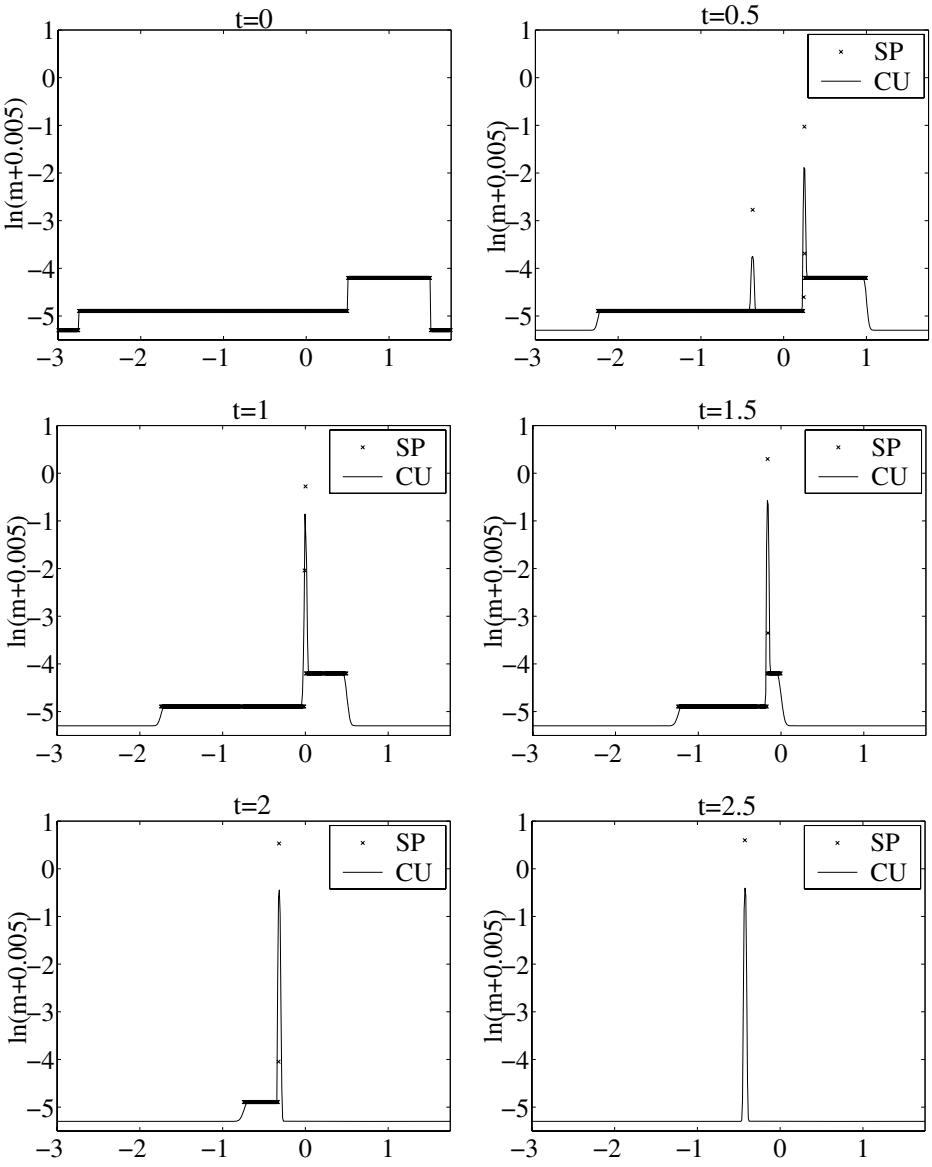

FIG. 4. *Solution (masses) of* (1.2), (3.3) *computed by the SP method and the CU scheme.*

is

$$\frac{dX}{dt} = \frac{I}{M}. \tag{3.9}$$

For the problem under consideration, the singularity is first formed at the point $(x,t) = (1,1)$, and for $t \geq 1$, the global minimum of F is attained at two points only: $x_0^- = -\pi$ and $x_0^+ = \pi$. Therefore, by $t = 1$ all the mass is concentrated in one massive particle with the mass $M = 4\pi$ and the momentum $I = 6\pi$ (according to (3.8)), and the movement of this particle is described, according to (3.9), by the formula $X(t) = (3t-1)/2$, $t \geq 1$; see Figure 5.

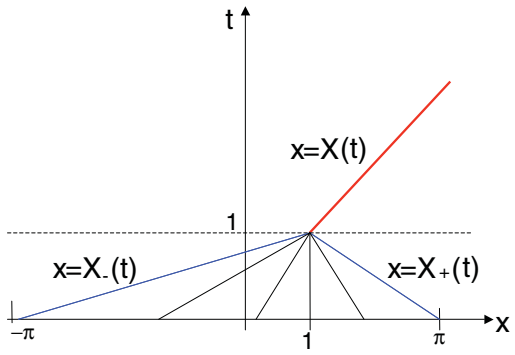

FIG. 5. *Characteristics diagram for the initial-value problem* (1.2), (3.4).

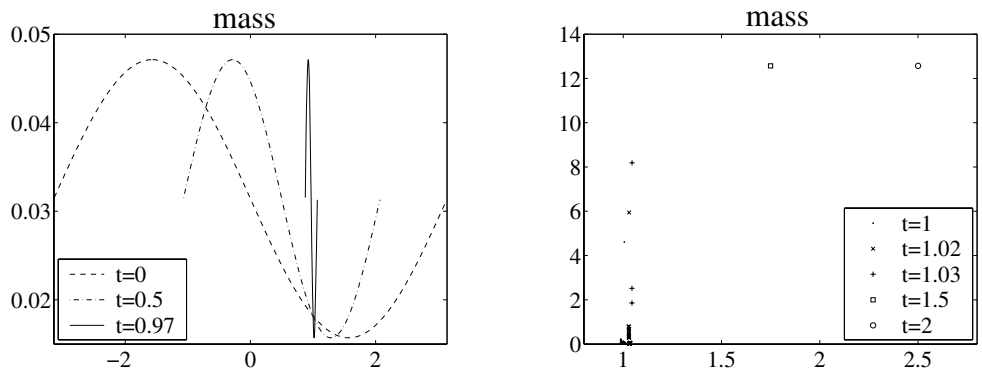

FIG. 6. *Solution (masses) of* (1.2), (3.4) *computed by the SP method for* $t < 1$ *(left), when the solution is smooth inside its shrinking support, and for* $t \geq 1$ *(right), when the total mass* $M = 4\pi$ *is concentrated in one particle, propagating with the constant speed* $I/M = 3/2$. *Note that due to a certain arbitrariness in the selection of the unification parameter* $d_{\rm cr}$, *the final collapse of the numerical solution occurs at a slightly later time* $t \approx 1.03$.

We now turn to the presentation of our numerical results. We start the SP simulations with 400 particles uniformly distributed over the interval $[-\pi, \pi]$. In Figure 6, we plot the particle masses computed by the SP method only, since the CU scheme could not be applied to this problem at large times ($t \sim 1$ and larger). We note that, as indicated in [17], other finite-volume methods are likely to fail to capture the solution of the initial-value problem (1.2), (3.4) as well.

3.2. Two-dimensional examples.

Example 5. We start by numerically solving the 2-D analogue of the 1-D problem considered in Example 1, namely, we solve the system (1.5) in the square domain $[-1, 1] \times [-1, 1]$ subject to the 1-D Riemann initial data, artificially extended to two space dimensions:

$$(\rho(x, y, 0), u(x, y, 0), v(x, y, 0)) = \begin{cases} (1.00, \ \ 0.5, \ 0) & \text{if } \ x < 0, \\ (0.25, -0.4, \ 0) & \text{if } \ x > 0. \end{cases} \tag{3.10}$$

The purpose of this simple example is to demonstrate the failure of the "standard" velocity recovery procedure (2.7) and the ability of the alternative procedure (2.9), developed in section 2.1, to force the desired interaction of nearby particles.

Recall that in this example a δ-shock develops immediately at the line $x = 0$ and then propagates to the right with speed 0.2. As has been already mentioned, the probability of collision of two particles approaching the same singularity curve in two dimensions is, in general, zero, and therefore using formula (2.7) for computing velocities requires a special symmetric setting of the initial locations of particles; see Figure 7 (left). Obviously, if at time $t = 0$ the particles are placed as shown in Figure 7 (right) and if the unification parameter is reasonably small ($d_{\rm cr} < \Delta y/2$), the particles moving from the left and from the right will never interact and the δ-shock will not be captured numerically. We note that for a more complicated, truly 2-D initial data it may be impossible to impose any kind of symmetry, so the situation with the data as in Figure 7 (right) is generic.

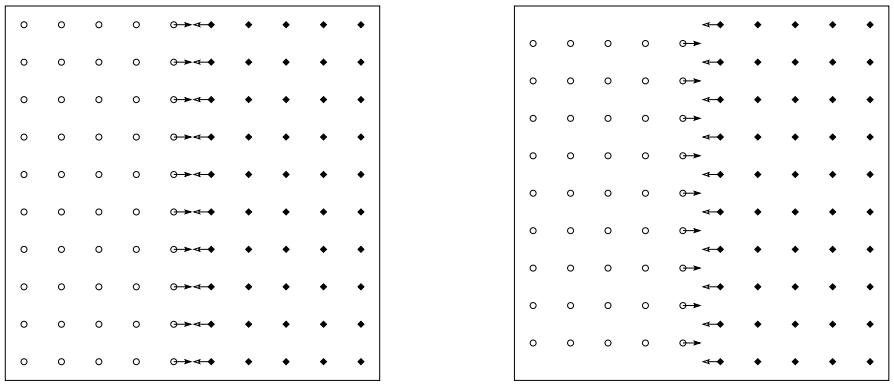

FIG. 7. *Initial locations of particles in Example* 5*: symmetric (left) and asymmetric (right) cases.*

On the other hand, the velocity recovery procedure (2.9) ensures an interaction between particles independently of their initial placement. In Figures 8 and 9, we show the masses and x-velocities of the particles at time $t = 0.5$. They are computed by the SP method with the initial locations of particles as in Figure 7 (left) and Figure 7 (right), respectively. As one can see, in both cases the SP method combined with the velocity recovery procedure (2.9) leads to the desired clustering of particles at the singularity. Moreover, the resolution achieved in the case of asymmetric initial particle distribution is almost as good as in the symmetric case.

Example 6. Next, we turn to genuinely 2-D problems. First, consider the system (1.5) subject to the following initial data:

$$(\rho(x,y,0), u(x,y,0), v(x,y,0)) = \begin{cases} (2,2,1) & \text{if } (x,y) \in \Omega, \\ (0,0,0) & \text{if } (x,y) \in \partial\Omega, \\ (1,0,0) & \text{otherwise,} \end{cases} \tag{3.11}$$

where $\Omega = \{x < 0,\, y < 1\} \cup \{x > 0,\, y > 0,\, x^2 + y^2 < 1\} \cup \{y < 0,\, 0 < x < 1\}$. The initial location of the discontinuity $\partial\Omega$ is shown in Figure 10. According to [21], the exact solution of the initial-value problem (1.5), (3.11) develops a δ-shock in density,

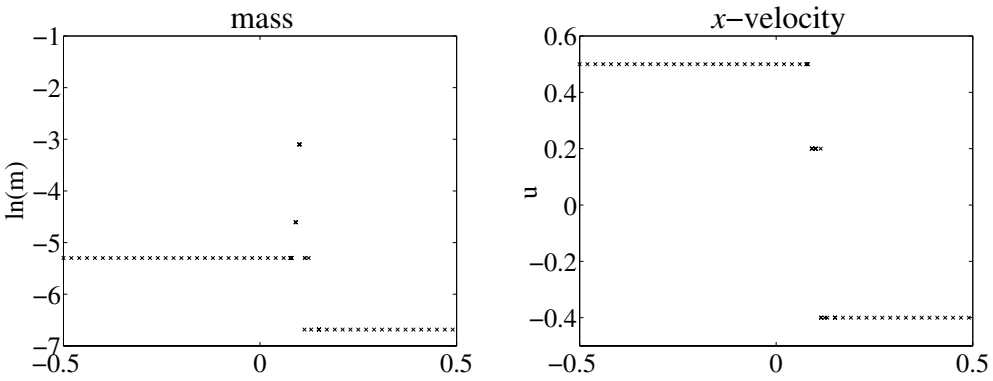

FIG. 8. *Side view on the solution of* (1.5), (3.10) *computed by the SP method. The initial location of particles is shown in Figure* 7 *(left).*

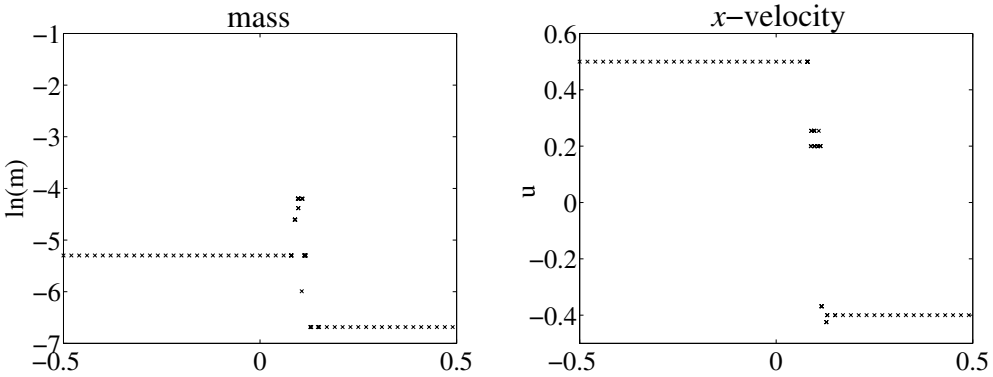

FIG. 9. *Side view on the solution of* (1.5), (3.10) *computed by the SP method. The initial location of particles is shown in Figure* 7 *(right).*

and the evolution of the shock curve is described by the following system of ODEs:

$$\begin{cases} \dfrac{dX}{dt} = u_- \dfrac{\sqrt{\rho_-}}{\sqrt{\rho_-}+\sqrt{\rho_+}} = \dfrac{2\sqrt{2}}{\sqrt{2}+1}, \\ \dfrac{dY}{dt} = v_- \dfrac{\sqrt{\rho_-}}{\sqrt{\rho_-}+\sqrt{\rho_+}} = \dfrac{\sqrt{2}}{\sqrt{2}+1}, \end{cases} \tag{3.12}$$

where $(\rho_-, u_-, v_-) := (2, 2, 1)$ are the initial values inside the domain Ω and $\rho_+ := 1$ is the initial value of the density on the other side of the initial shock curve.

Numerically, we restrict the initial data (3.11) to the finite domain $[-4, 4]\times[-4, 4]$ and consider the following initial-boundary value problem: (1.5), (3.11) together with the solid wall boundary conditions. The numerical solutions, computed by the SP method at time $t = 2$ with 50×50 and 100×100 initially uniformly distributed particles, are plotted in Figure 10. The size of each point in the figure is proportional to the mass accumulated in the particle located there. The exact solution of the initial-boundary value problem is not known, but in the domain $[0, 4] \times [-2, 4]$ it coincides with the solution of the original initial-value problem (1.5), (3.11), and as can be clearly seen in Figure 10, the SP method accurately tracks the evolution of

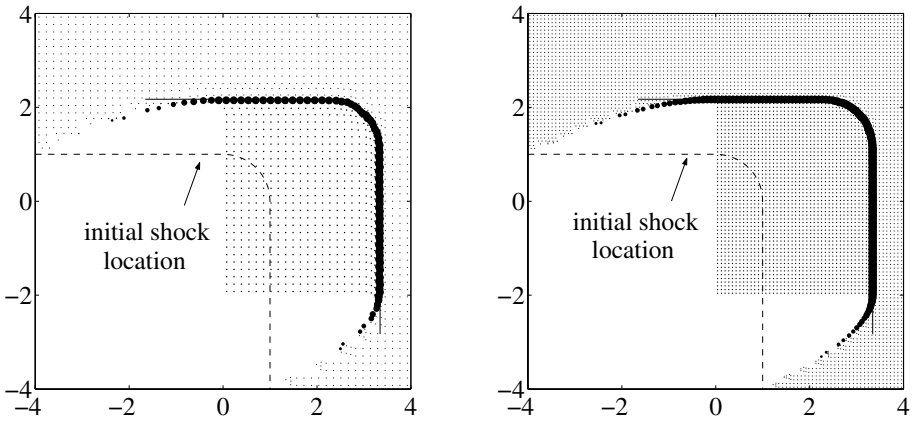

FIG. 10. *Top view on the solution (masses) of* (1.5), (3.11) *computed by the SP method with* 50×50 *(left) and* 100×100 *(right) particles. The solid line is obtained from the initial shock curve (the dashed line) by the evolution according to* (3.12).

the corresponding part of the shock curve described by (3.12). Outside the domain $[0,4] \times [-2,4]$, the solution is obviously affected by the boundedness of the cloud, but the obtained numerical solution looks reasonable, as supported by the performed mesh refinement study.

Example 7. Next, we consider an example with nonzero mass and momenta at the initial shock curve. We numerically solve the system (1.5) subject to the following initial data:

$$(\rho(\mathbf{x},0), u(\mathbf{x},0), v(\mathbf{x},0)) = \begin{cases} (2,2,2) & \text{if } \mathbf{x} \in \Omega, \\ (10\,\delta(\mathrm{dist}(\mathbf{x},\partial\Omega)),2,1) & \text{if } \mathbf{x} \in \partial\Omega, \\ (2,0,0) & \text{otherwise,} \end{cases} \tag{3.13}$$

where $\mathbf{x} \equiv (x,y)$ and the domain Ω is the same as in Example 6: $\Omega = \{x<0,\, y<1\} \cup \{x>0,\, y>0,\, x^2+y^2<1\} \cup \{y<0,\, 0<x<1\}$. In the practical implementation, we replace the δ-function along the curve $\partial\Omega$ with its approximation by a step function; namely, we take

$$\rho(\mathbf{x},0) = \begin{cases} \dfrac{10\sqrt{2}}{\sqrt{(\Delta x)^2+(\Delta y)^2}} & \text{if } \mathrm{dist}(\mathbf{x},\partial\Omega) \le \dfrac{\sqrt{(\Delta x)^2+(\Delta y)^2}}{2\sqrt{2}}, \\ 2 & \text{otherwise.} \end{cases}$$

The numerical solutions at time $t = 1.5$ obtained using the SP method with 101×101 particles (initially uniformly distributed) and the CU scheme with $\Delta x = \Delta y = 0.08$ are plotted in Figures 11 and 12. Note that the maximal mass value of the solution obtained by the CU scheme is 0.6299 while the maximal mass obtained by the SP method is 2.7009. As before, the size of each point in the figures is proportional to the mass accumulated in the particle located there.

Even though a complete structure of the exact solution of the initial-value problem (1.5), (3.13) is not available, the obtained solution behavior has been expected (see the discussion at the end of section 2). It is instructive to compare the computed numerical solution with theoretical results presented in [21]. According to [21], if

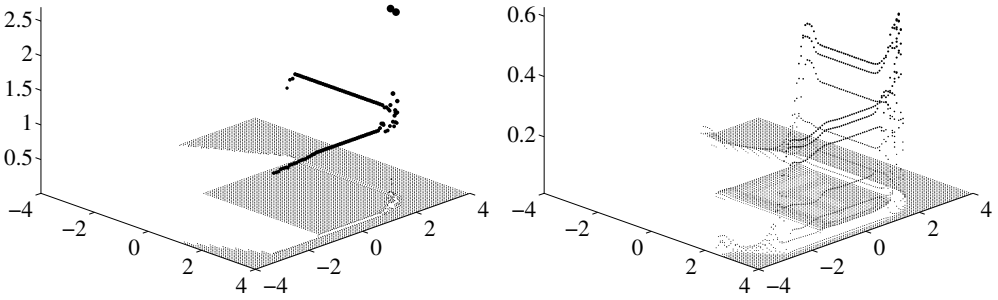

FIG. 11. *Solution (masses) of* (1.5), (3.13) *computed by the SP method (left) and the CU scheme (right).*

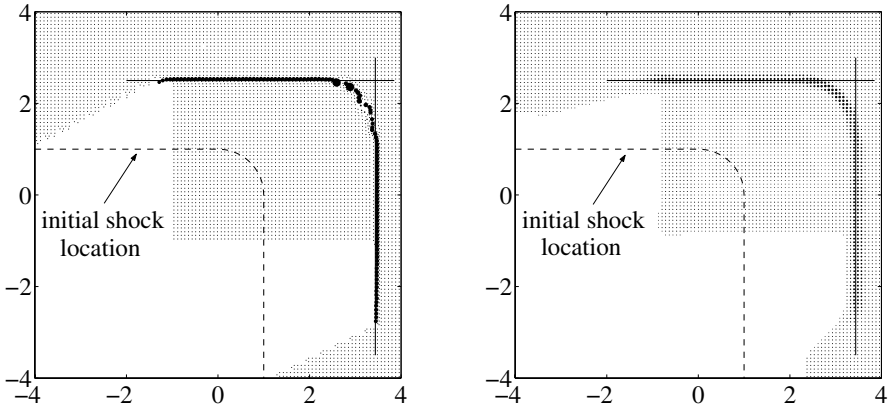

FIG. 12. *Top view on the solution (masses) of* (1.5), (3.13) *computed by the SP method (left) and the CU scheme (right). The solid lines are obtained from the initial shock curve (the dashed line) by the evolution according to* (3.14).

initially a shock curve with mass distribution P_0 and velocities (U_0, V_0) is located along the line $x_0(l) = C \equiv \text{const}$, $y_0(l) = l$, then its location at a later time is given by

$$\begin{cases} x = C + \left[\dfrac{u}{2} - \dfrac{\left(\frac{1}{2}u - U_0\right) P_0}{\rho u t + P_0}\right] t, \\ uy - vx = \dfrac{(uV_0 - vU_0)P_0}{\rho u} \ln\left(1 + \dfrac{\rho u t}{P_0}\right) + ul - vC, \end{cases} \tag{3.14}$$

where ρ, u, and v are the density and the corresponding velocities inside the domain. If we now consider a part of the initial shock curve $\partial\Omega$, namely, $x_0 = 1$, $y_0 = l$, $0 \le l \le 1$, and substitute the corresponding values of $P_0 = 10$, $U_0 = 2$, $V_0 = 1$, and $\rho = u = v = 2$ into the first formula in (3.14), we obtain that at time $t = 1.5$ the shock line should be located at $x = 3.4375$. Similarly, it can be shown that the initial shock line $x_0 = l$, $y_0 = 1$, $0 \le l \le 1$ should move to $y = 2.5$ by the time $t = 1.5$. As one can see from Figure 12, both methods accurately track the evolution of the corresponding

parts of the shock curve: in this figure, the horizontal solid line ($y = 2.5$) and the vertical solid line ($x = 3.4375$) represent the exact shock locations, while the dots are used to plot the numerical solution obtained by the SP method (left) and the CU scheme (right). One can clearly observe a much better resolution of the discontinuity achieved by the SP method.

Example 8. We now consider the system (1.5) subject to the following initial data:

$$(\rho(\mathbf{x},0),u(\mathbf{x},0),v(\mathbf{x},0)) = \begin{cases} (2,2,1) & \text{if } \mathbf{x}\in\Omega_1,\\ (2,1,2) & \text{if } \mathbf{x}\in\Omega_2,\\ (2,\eta,\eta) & \text{if } \mathbf{x}\in\Omega_3,\\ (0,0,0) & \text{if } \mathbf{x}\in\partial\Omega_1\cup\partial\Omega_2\cup\partial\Omega_3,\\ (1,0,0) & \text{otherwise,}\end{cases} \tag{3.15}$$

where $\Omega_1 = \{x < 0,\ x/2+1 < y < 1\}$, $\Omega_2 = \{y < 0,\ y/2+1 < x < 1\}$, and $\Omega_3 = \{x < 0,\ y < x/2+1\}\cup\{x > 0,\ y > 0,\ x^2+y^2 < 1\}\cup\{y < 0,\ x < y/2+1\}$. The initial locations of the discontinuities are shown in Figures 13 and 16. As in the previous two examples, we restrict the initial data (3.15) to the finite domain $[-4,4]\times[-4,4]$ and supplement the initial-value problem (1.5), (3.15) with the solid wall boundary conditions.

Example 8a. We first take $\eta = 1$ in (3.15). In this case, δ-shocks are immediately formed along the initial shock curves. Then, they propagate and develop stronger δ-type singularities at two points, which later merge into a single one in the upper right corner of the computational domain (as in the previous numerical example, the exact solution of the initial-value problem (1.5), (3.15) is not available, but the obtained solution behavior is in line with our expectations; see the discussion at the end of section 2).

We apply the SP method with initially uniformly distributed 100×100 particles and present the solutions, computed at times $t = 2$ and $t = 4$, in Figures 13 and 14. Once again, the size of each point in the figures is proportional to the mass accumulated in the particle located there. For comparison purposes, we also apply the CU scheme with $\Delta x = \Delta y = 0.08$ to the same initial-boundary value problem. The obtained solution, presented in Figure 15 (left), clearly demonstrates that the resolution achieved by the SP method is by far superior. However, since the exact solution of this test problem is unavailable and since there is a very big discrepancy between the solutions computed by the SP and CU methods, we also apply the CU scheme on a much finer grid with $\Delta x = \Delta y = 0.02$. The obtained solution, shown in Figure 15 (right), looks more like the SP solution in Figure 14 (right), but the resolution is still not as high as the one achieved by our SP method; compare, for instance, the maximal mass values—7.2927, 3.9223, and 1.0205—of the solutions, computed by the SP method, the CU scheme on the fine grid, and the CU scheme on the coarse grid, respectively.

Example 8b. Next, we take $\eta = 2-1/\sqrt{2}$ in (3.15). In this case, we observe a more clear structure of the formed δ-shocks, which then interact with two contact waves. This interaction, as in Example 8a, leads to formation of strong singularities. Such a structure—strong singularities emerging from δ-shock curves—is anticipated as a typical one for 2-D pressureless gases; see the discussion at the end of section 2. See also [21] and the references therein.

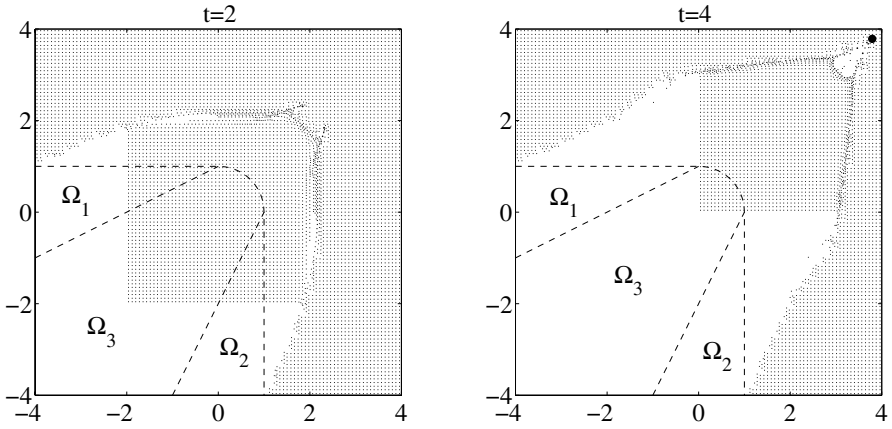

FIG. 13. *Top view on the solution (masses) of* (1.5), (3.15) *with* $\eta = 1$ *at* $t = 2$ *(left) and* $t = 4$ *(right) computed by the SP method. The dashed lines represent the initial location of discontinuities.*

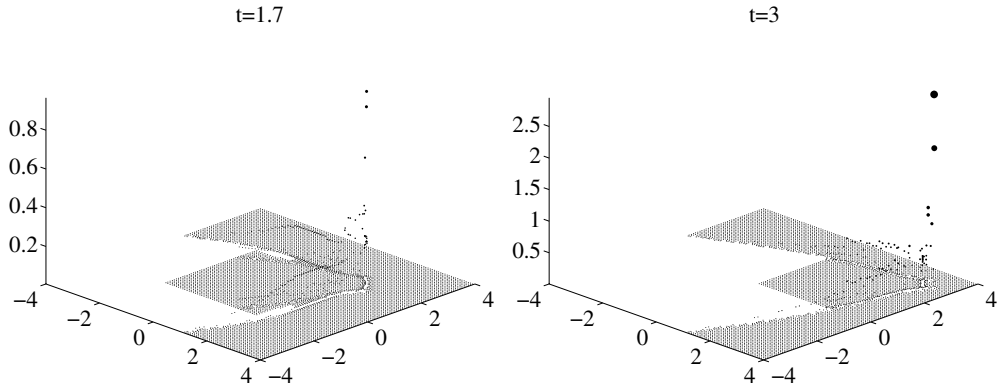

FIG. 17. *Solution (masses) of* (1.5), (3.15) *with* $\eta = 2 - 1/\sqrt{2}$ *at* $t = 1.7$ *(left) and* $t = 3$ *(right) computed by the SP method.*

We apply the SP method with initially uniformly distributed 100×100 particles and present the solutions, computed at times $t = 1.7$ and $t = 3$, in Figures 16 and 17. As before, the size of each point in these figures is proportional to the mass accumulated in the particle located there. We compare the SP solution, presented in Figure 17 (right), with the solution computed by the CU scheme with $\Delta x = \Delta y = 0.08$, which is plotted in Figure 18 (left). One can clearly see the superiority of the results achieved by the SP method. We also apply the CU scheme on a much finer grid with $\Delta x = \Delta y = 0.02$. The obtained solution, shown in Figure 18 (right), looks more like the SP solution in Figure 17 (right), but the resolution is still not as high as the one achieved by the SP method; compare, as before, the maximal mass values—2.9529, 1.7261, and 0.4724—of the solutions, computed by the SP method, the CU scheme on the fine grid, and the CU scheme on the coarse grid, respectively.

Example 9. Finally, we consider the system (1.5) subject to the initial data taken from [1, 23]. In this example, $\rho(x, 0)$ is a Gaussian field, shown in Figures 19 and 20 (a detailed description of its generation can be found in [23, section 5.1]) and

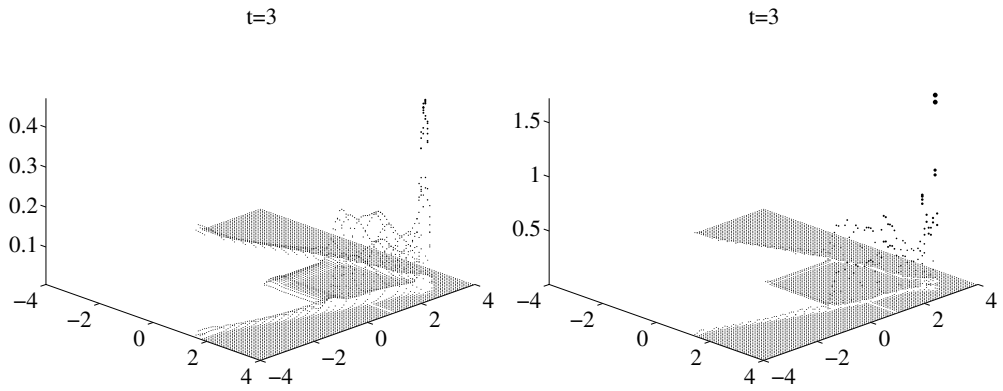

FIG. 18. *Solution (masses) of* (1.5), (3.15) *with* $\eta = 2 - 1/\sqrt{2}$ *at* $t = 3$ *computed by the CU scheme with* $\Delta x = \Delta y = 0.08$ *(left) and* $\Delta x = \Delta y = 0.02$ *(right).*

the initial velocity vector is the solution of the following elliptic problem:

$$\text{(3.16)} \qquad \begin{cases} u = -\phi_x, \\ v = -\phi_y, \\ \Delta\phi = 4\pi G(\rho - \bar{\rho}) \quad \text{in } \Omega = [0, 251] \times [0, 251], \end{cases}$$

where G is the gravitational constant and $\bar{\rho} = \frac{1}{|\Omega|} \int_\Omega \rho \, dx \, dy$. All the boundary conditions are assumed to be periodic. These 2-D physical data are derived from large-scale structure simulations related to the cosmological model of Zeldovich [24]. In Figures 19 and 20, we observe the formation of the large-scale structures computed by the SP method and the CU scheme, respectively. We use a uniform spatial grid with $\Delta x = \Delta y = 1$ for the CU scheme and the uniform initial distribution of 251×251 particles. In order to compare the results, the total mass of each cell computed by the CU scheme has been recalculated at the location of particles. Again, the size of each point in Figures 19 and 20 is proportional to the total mass at this point, that is, bigger points correspond to larger masses. As one can see, for small times both schemes produce very similar results, while for larger times a numerical diffusion present in the CU scheme "takes over" (compare the corresponding results at times $t = 4000$ and $t = 15000$ in Figures 19 and 20). In fact, the maximum mass accumulated at one point by the SP method is about 15 times larger than the one accumulated by the CU scheme. We also would like to point out that, as a result of unification of clustering particles, the number of particles is decreasing in time and therefore the efficiency of the SP method is increasing. For instance, the number of particles at times $t = 1000$, 4000, and 15000 is 2767, 1068, and 454, respectively, while computations using the CU scheme are being performed on a 251×251 grid for all times. This also results in much smaller runtime for the SP method compared to the CU scheme.

4. Concluding remarks. We have presented a new sticky particle (SP) method for the system of Euler equations of pressureless gas dynamics that arises in the modeling of the formation of large-scale structures in the universe. The main feature of interest in this problem is the formation of strong singularities (δ-functions along the surfaces as well as at separate points) and the emergence of vacuum states, and therefore particle methods seem to be a natural choice for numerical simulations of such models. The proposed SP method has been studied both analytically and numerically.

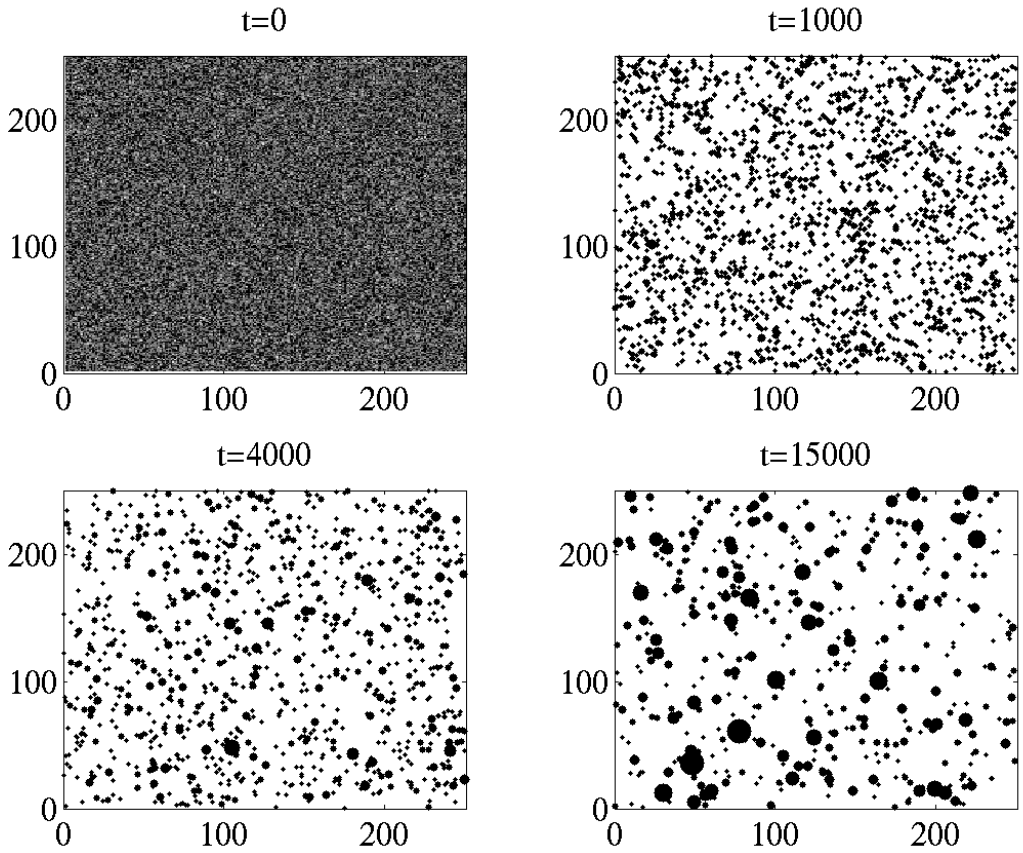

FIG. 19. *Top view on the solution (masses) of* (1.5), (3.16) *computed by the SP method at different times.*

It has been shown that the particle approximation satisfies the original system of pressureless gas dynamics in a weak sense, but only within a certain residual, which has been rigorously estimated. It has also been explained why the relevant errors should diminish as the total number of particles increases. Numerical experiments in one and two space dimensions have been performed (3-D extension of the SP method is out of scope of this paper, but it can be carried out rather straightforwardly). The SP method has been compared to the second-order CU scheme. Our numerical experiments clearly demonstrate the superiority of results obtained by the SP method, which seems to be a robust, accurate, and efficient alternative to existing numerical methods for pressureless gas dynamics.

Appendix A. Semidiscrete central-upwind schemes for pressureless gas dynamics. Here, we briefly describe semidiscrete CU schemes for the 2-D system of pressureless gas dynamics (1.5), which can be written in the following flux-vector form:

$$\mathbf{w}_t + \mathbf{f}(\mathbf{w})_x + \mathbf{g}(\mathbf{w})_y = 0,$$

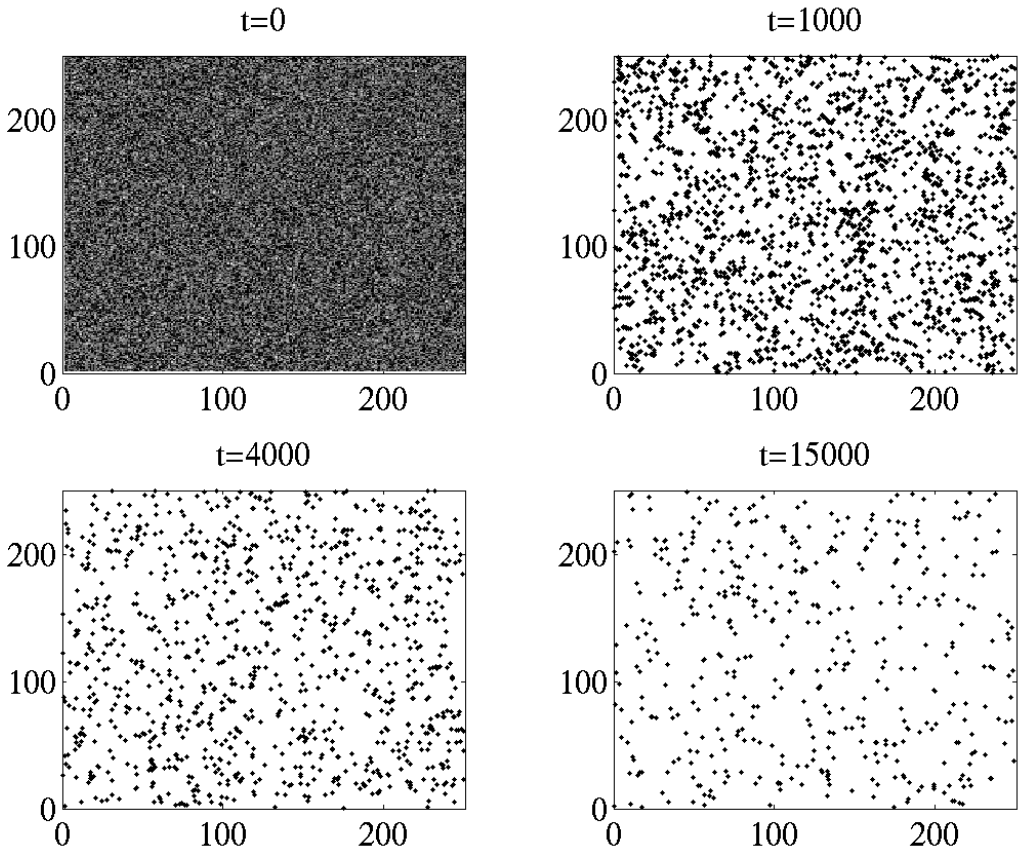

FIG. 20. *Top view on the solution (masses) of* (1.5), (3.16) *computed by the CU scheme at different times.*

where

$$\mathbf{w} := \begin{pmatrix} \rho \\ \rho u \\ \rho v \end{pmatrix}, \quad \mathbf{f}(\mathbf{w}) := \begin{pmatrix} \rho u \\ \rho u^2 \\ \rho uv \end{pmatrix}, \quad \mathbf{g}(\mathbf{w}) := \begin{pmatrix} \rho v \\ \rho uv \\ \rho v^2 \end{pmatrix}.$$

We consider a uniform spatial grid $x_\mu := \mu\Delta x$, $y_\nu := \nu\Delta y$, and denote the computed quantities, the cell averages, by

$$\bar{\mathbf{w}}_{j,k}(t) := \frac{1}{\Delta x \Delta y} \iint\limits_{I_{j,k}} \mathbf{w}(\xi,\eta,t)\,d\eta\,d\xi, \quad I_{j,k} := [x_{j-\frac{1}{2}}, x_{j+\frac{1}{2}}] \times [y_{k-\frac{1}{2}}, y_{k+\frac{1}{2}}].$$

The cell averages are evolved in time according to the semidiscrete CU scheme

$$\frac{d}{dt}\bar{\mathbf{w}}_{j,k}(t) = -\frac{H^x_{j+\frac{1}{2},k}(t) - H^x_{j-\frac{1}{2},k}(t)}{\Delta x} - \frac{H^y_{j,k+\frac{1}{2}}(t) - H^y_{j,k-\frac{1}{2}}(t)}{\Delta y},$$

where the numerical fluxes $H^x_{j+\frac12,k}$ and $H^y_{j,k+\frac12}$ are given by (see [11] for the derivation)

(A.1)
$$H^x_{j+\frac12,k}=\frac{a^+_{j+\frac12,k}\mathbf{f}(\mathbf{w}^{\rm E}_{j,k})-a^-_{j+\frac12,k}\mathbf{f}(\mathbf{w}^{\rm W}_{j+1,k})}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}}+a^+_{j+\frac12,k}a^-_{j+\frac12,k}\left[\frac{\mathbf{w}^{\rm W}_{j+1,k}-\mathbf{w}^{\rm E}_{j,k}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}}-\mathbf{q}^x_{j+\frac12,k}\right]$$

and

(A.2)
$$H^y_{j,k+\frac12}=\frac{b^+_{j,k+\frac12}\mathbf{g}(\mathbf{w}^{\rm N}_{j,k})-b^-_{j,k+\frac12}\mathbf{g}(\mathbf{w}^{\rm S}_{j,k+1})}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}}+b^+_{j,k+\frac12}b^-_{j,k+\frac12}\left[\frac{\mathbf{w}^{\rm S}_{j,k+1}-\mathbf{w}^{\rm N}_{j,k}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}}-\mathbf{q}^y_{j,k+\frac12}\right].$$

Note that all the quantities in (A.1) and (A.2) depend on t, but we will omit this dependence in order to simplify the notation.

In (A.1)–(A.2), the point values $\mathbf{w}^{E(W,S,N)}$ are to be computed from a conservative, nonoscillatory piecewise polynomial reconstruction of an appropriate order. For example, the second-order CU scheme would employ a piecewise linear reconstruction

$$\widetilde{\mathbf{w}}(x,y,t)=\bar{\mathbf{w}}_{j,k}(t)+(\mathbf{w}_x)_{j,k}(x-x_j)+(\mathbf{w}_y)_{j,k}(y-y_k)\quad\text{for}\quad(x,y)\in I_{j,k},\tag{A.3}$$

and the corresponding point values will be

$$\mathbf{w}^{\rm E(W)}_{j,k}:=\bar{\mathbf{w}}_{j,k}(t)\pm\frac{\Delta x}{2}(\mathbf{w}_x)_{j,k},\quad \mathbf{w}^{\rm N(S)}_{j,k}:=\bar{\mathbf{w}}_{j,k}(t)\pm\frac{\Delta y}{2}(\mathbf{w}_y)_{j,k}.$$

To ensure a nonoscillatory property of this reconstruction and thus of the second-order CU scheme, the slopes in (A.3) should be computed with the help of a nonlinear limiter. In our numerical experiments, we have used a one-parameter family of the *minmod* limiters [15, 18, 22]:

$$(\mathbf{w}_x)_{j,k}=\text{minmod}\left(\theta\frac{\bar{\mathbf{w}}_{j+1,k}-\bar{\mathbf{w}}_{j,k}}{\Delta x},\ \frac{\bar{\mathbf{w}}_{j+1,k}-\bar{\mathbf{w}}_{j-1,k}}{2\Delta x},\ \theta\frac{\bar{\mathbf{w}}_{j,k}-\bar{\mathbf{w}}_{j-1,k}}{\Delta x}\right),$$
$$(\mathbf{w}_y)_{j,k}=\text{minmod}\left(\theta\frac{\bar{\mathbf{w}}_{j,k+1}-\bar{\mathbf{w}}_{j,k}}{\Delta y},\ \frac{\bar{\mathbf{w}}_{j,k+1}-\bar{\mathbf{w}}_{j,k-1}}{2\Delta y},\ \theta\frac{\bar{\mathbf{w}}_{j,k}-\bar{\mathbf{w}}_{j,k-1}}{\Delta y}\right),$$

where $\theta\in[1,2]$, and the multivariate minmod function is defined by (2.14). Notice that larger θ's correspond to less dissipative but, in general, more oscillatory limiters (we have used $\theta=1.5$ in all the reported numerical experiments).

Since all the eigenvalues of the Jacobians $\frac{\partial\mathbf{f}}{\partial\mathbf{w}}$ and $\frac{\partial\mathbf{g}}{\partial\mathbf{w}}$ are of multiplicity 3 and are equal to u and v, respectively, the one-sided local speeds in (A.1)–(A.2) are easy to estimate:

$$a^+_{j+\frac12,k}:=\max\left\{u^{\rm W}_{j+1,k},u^{\rm E}_{j,k},0\right\},\quad a^-_{j+\frac12,k}:=\min\left\{u^{\rm W}_{j+1,k},u^{\rm E}_{j,k},0\right\},$$
$$b^+_{j,k+\frac12}:=\max\left\{v^{\rm S}_{j,k+1},v^{\rm N}_{j,k},0\right\},\quad b^-_{j,k+\frac12}:=\min\left\{v^{\rm S}_{j,k+1},v^{\rm N}_{j,k},0\right\}.$$

Finally, $\mathbf{q}^x_{j+\frac12,k}$ and $\mathbf{q}^y_{j,k+\frac12}$ are the "antidiffusion" terms that help to reduce numerical dissipation present at nonoscillatory central schemes [11]:

$$\mathbf{q}^x_{j+\frac12,k}=\text{minmod}\left(\frac{\mathbf{w}^{\rm NW}_{j+1,k}-\mathbf{w}^{\rm int}_{j+\frac12,k}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}},\frac{\mathbf{w}^{\rm int}_{j+\frac12,k}-\mathbf{w}^{\rm NE}_{j,k}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}},\right.$$
$$\left.\frac{\mathbf{w}^{\rm SW}_{j+1,k}-\mathbf{w}^{\rm int}_{j+\frac12,k}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}},\frac{\mathbf{w}^{\rm int}_{j+\frac12,k}-\mathbf{w}^{\rm SE}_{j,k}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}}\right),$$

$$\mathbf{q}^y_{j,k+\frac12}=\text{minmod}\left(\frac{\mathbf{w}^{\text{SW}}_{j,k+1}-\mathbf{w}^{\text{int}}_{j,k+\frac12}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}},\frac{\mathbf{w}^{\text{int}}_{j,k+\frac12}-\mathbf{w}^{\text{NW}}_{j,k}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}},\right.$$
$$\left.\frac{\mathbf{w}^{\text{SE}}_{j,k+1}-\mathbf{w}^{\text{int}}_{j,k+\frac12}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}},\frac{\mathbf{w}^{\text{int}}_{j,k+\frac12}-\mathbf{w}^{\text{NE}}_{j,k}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}}\right),$$

where

$$\mathbf{w}^{\text{int}}_{j+\frac12,k}=\frac{a^+_{j+\frac12,k}\mathbf{w}^{\text{W}}_{j+1,k}-a^-_{j+\frac12,k}\mathbf{w}^{\text{E}}_{j,k}-\left\{\mathbf{f}(\mathbf{w}^{\text{W}}_{j+1,k})-\mathbf{f}(\mathbf{w}^{\text{E}}_{j,k})\right\}}{a^+_{j+\frac12,k}-a^-_{j+\frac12,k}},$$
$$\mathbf{w}^{\text{int}}_{j,k+\frac12}=\frac{b^+_{j,k+\frac12}\mathbf{w}^{\text{S}}_{j,k+1}-b^-_{j,k+\frac12}\mathbf{w}^{\text{N}}_{j,k}-\left\{\mathbf{g}(\mathbf{w}^{\text{S}}_{j,k+1})-\mathbf{g}(\mathbf{w}^{\text{N}}_{j,k})\right\}}{b^+_{j,k+\frac12}-b^-_{j,k+\frac12}},$$

and the point values at the cell corners are

$$\mathbf{w}^{\text{NE(NW)}}_{j,k}:=\bar{\mathbf{w}}_{j,k}(t)\pm\frac{\Delta x}{2}(\mathbf{w}_x)_{j,k}+\frac{\Delta y}{2}(\mathbf{w}_y)_{j,k},$$
$$\mathbf{w}^{\text{SE(SW)}}_{j,k}:=\bar{\mathbf{w}}_{j,k}(t)\pm\frac{\Delta x}{2}(\mathbf{w}_x)_{j,k}-\frac{\Delta y}{2}(\mathbf{w}_y)_{j,k}.$$

CENTRAL DISCONTINUOUS GALERKIN METHODS ON OVERLAPPING CELLS WITH A NONOSCILLATORY HIERARCHICAL RECONSTRUCTION*

YINGJIE LIU†, CHI-WANG SHU‡, EITAN TADMOR§, AND MENGPING ZHANG¶

Abstract. The central scheme of Nessyahu and Tadmor [*J. Comput. Phys.*, 87 (1990), pp. 408–463] solves hyperbolic conservation laws on a staggered mesh and avoids solving Riemann problems across cell boundaries. To overcome the difficulty of excessive numerical dissipation for small time steps, the recent work of Kurganov and Tadmor [*J. Comput. Phys.*, 160 (2000), pp. 241–282] employs a variable control volume, which in turn yields a semidiscrete nonstaggered central scheme. Another approach, which we advocate here, is to view the staggered meshes as a collection of overlapping cells and to realize the computed solution by its overlapping cell averages. This leads to a simple technique to avoid the excessive numerical dissipation for small time steps [Y. Liu, *J. Comput. Phys.*, 209 (2005), pp. 82–104]. At the heart of the proposed approach is the evolution of *two* pieces of information per cell, instead of one cell average which characterizes all central and upwind Godunov-type finite volume schemes. Overlapping cells lend themselves to the development of a central-type discontinuous Galerkin (DG) method, following the series of works by Cockburn and Shu [*J. Comput. Phys.*, 141 (1998), pp. 199–224] and the references therein. In this paper we develop a central DG technique for hyperbolic conservation laws, where we take advantage of the redundant representation of the solution on overlapping cells. The use of redundant overlapping cells opens new possibilities beyond those of Godunov-type schemes. In particular, the central DG is coupled with a novel reconstruction procedure which removes spurious oscillations in the presence of shocks. This reconstruction is motivated by the moments limiter of Biswas, Devine, and Flaherty [*Appl. Numer. Math.*, 14 (1994), pp. 255–283] but is otherwise different in its hierarchical approach. The new hierarchical reconstruction involves a MUSCL or a second order ENO reconstruction in each stage of a multilayer reconstruction process without characteristic decomposition. It is compact, easy to implement over arbitrary meshes, and retains the overall preprocessed order of accuracy while effectively removing spurious oscillations around shocks.

Key words. central scheme, discontinuous Galerkin method, ENO scheme, MUSCL scheme, TVD scheme

1. Introduction. The first order Godunov and Lax–Friedrichs (LxF) schemes are, respectively, the forerunners for the large classes of upwind and central high-resolution schemes for nonlinear conservation laws and related equations. The Godunov scheme captures shock waves monotonically in narrow transition layers. It is based on evolving a piecewise cell average representation of the solution by evaluating the fluxes at the boundaries of each cell which are obtained from the solution of (approximate) Riemann problems along the boundary interfaces. Various higher order generalizations of Godunov scheme have been developed since the mid 1970s. They employ higher order piecewise polynomials which are reconstructed from the evolving cell averages "in the direction of smoothness." We mention here the notable examples of the high-resolution upwind FCT, MUSCL, TVD, PPM, ENO, and WENO schemes [8, 49, 19, 16, 20, 35], and this list is far from complete. The use of intricate Riemann solvers can be avoided at the expense of using the more diffusive LxF scheme. The excessive numerical dissipation can be reduced significantly, however, when higher order piecewise polynomial reconstructions are used in conjunction with the staggered formulation of the LxF scheme. The central scheme of Nessyahu and Tadmor (NT) [40] provides such a second order generalization of the staggered LxF scheme. It is based on the same piecewise linear reconstructions of cell averages used with upwind schemes, yet the solution of (approximate) Riemann problems is avoided. High-resolution generalizations of the NT scheme were developed since the 1990s as the class of central schemes in, e.g., [43, 3, 22, 21, 36, 6, 25, 2, 27, 28, 32], and here too the list is far from complete. The relaxation scheme of Jin and Xin [23] provides another approach which leads to a staggered central stencil for solving nonlinear conservation laws.

Being free of the (eigenstructure of) the underlying Riemann problems, central schemes provide black-box–type methods for the approximate solution of nonlinear hyperbolic conservation laws and other closely related equations [5]. Essentially, one only needs to supply the flux functions. But the staggered high order central schemes of order, say, $r > 1$ still share one disadvantage with the original LxF scheme, namely, the amplitude of their numerical viscosity of order $\mathcal{O}((\Delta x)^{r+1}/\Delta t)$. It excludes the use of small time steps, Δt, which are too small relative to the spatial grid size Δx. The problem lies with the space-time control volumes which are staggered "$\Delta x/2$-away" from each other. (Similar difficulties occur with the two-dimensional (2D) conservative front tracking method which was overcome by Glimm et al. in [17] using space-time cells instead of rezoning.) This problem was addressed by Kurganov and Tadmor who introduced, in [28], a new type of central scheme whose numerical viscosity is independent of $\mathcal{O}(1/\Delta t)$). This was achieved by using variable control volumes so that cells are staggered only "$\mathcal{O}(\Delta t)$-away" from each other. The latest version of the central-upwind scheme has been recently derived in [26]. It allows implementation of central schemes with arbitrarily small time step, and, in particular, it yields a semidiscrete formulation which can be conveniently integrated by ODE solvers, e.g., the strong stability preserving (SSP) Runge–Kutta methods of [45]; consult, e.g., [18]. Similar advantages of a semidiscrete formulation can be achieved when a local LxF building block is used over nonstaggered meshes; see, e.g., Shu and Osher [45, 46] and Liu and Osher [34]. The upwind and central schemes mentioned so far share one thing in common—they evolve *one* piece of information per cell, that is, the cell average. Upwind schemes use Riemann solvers, while central schemes use simpler quadrature rules. For higher accuracy, they both employ piecewise polynomial representation of the solution which is reconstructed from these cell averages.

In [38], Y. Liu introduced an alternative technique for controlling the numerical

dissipation of central schemes. The main idea is to evolve the solution over *overlapping cells*. That is, two sets of cell averages are realized over interlacing grids. The solution is then represented as a convex combination—an "$\mathcal{O}(\Delta t)$-weighted" combination of these overlapping cell averages. The resulting scheme has a numerical viscosity which is independent of $\mathcal{O}(1/\Delta t)$, and as such it admits a semidiscrete formulation which can be integrated using SSP methods. The use of overlapping cells, however, is fundamentally different in that it evolves *two* independent quantities for each given cell, that is, the two overlapping subcell averages. The use of overlapping cells opens many new possibilities. For example, instead of the usual reconstructions such as MUSCL and (W)ENO, overlapping cells offer a more efficient approach for high-resolution: by adding the two subcell averages, we recover the evolution of a full cell average, where by taking their difference, we independently evolve an approximate slope, rather than reconstructing it from neighboring averages. This makes feasible the use of the central discontinuous Galerkin (DG) approach over overlapping cells, following the series of works by Cockburn and Shu [13, 14, 15]. Thus, in particular, the use of overlapping cells yields the versatility of finite element (Galerkin) methods which can be easily formulated on general unstructured meshes with any formal order, since no reconstruction is involved. In this paper, we further develop the staggered central DG method introduced in [37] for solving hyperbolic conservation laws. Numerical tests are performed up to third order accuracy on uniform staggered meshes in one and two dimensions. Stability analysis and error estimates, and extension of the method for time-dependent and steady state convection-diffusion equations, constitute ongoing work and will be reported in the future. Here, one does not reconstruct a piecewise-polynomial representation of the solution; rather it is part of the evolution of higher moments. Still, a nonlinear limiting procedure is necessary to reduce spurious oscillations for high order methods. We introduce here such a general nonoscillatory procedure, the so-called hierarchical reconstruction, interesting in its own right, which is closely related to the moment limiters of Biswas, Devine, and Flaherty [7] and to the earlier work of Cockburn and Shu [13]. Since this limiting procedure requires only linear reconstructions using information from adjacent cells without characteristic decomposition, it can be easily implemented for any shapes of the cells and hence is practical also for unstructured meshes or even dynamically moving meshes (e.g., Tang and Tang [47]), although we do not pursue it in this paper. We refer the reader to [3] and the references therein for a systematic study of central schemes on unstructured grids using the framework of discontinuous finite elements.

This paper is organized as follows. In section 2, we briefly describe the central finite volume scheme on overlapping cells as the background. The natural extension to the central DG scheme on overlapping cells is discussed in section 3. In subsection 3.1 we study the numerical convergence rate for a number of linear and nonlinear equations having smooth solutions. In section 4, we introduce a general nonoscillatory hierarchical reconstruction procedure and use it as a limiter for the central DG scheme on overlapping cells to control spurious oscillations in the presence of shocks. Numerical results testing the accuracy of the proposed schemes are included in sections 3 and 4. Additional numerical results are presented in section 5. Concluding remarks and a plan for future work are included in section 6.

2. Central schemes on overlapping cells. Consider the scalar one-dimensional (1D) conservation law

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \qquad (x,t) \in \mathcal{R} \times (0,T). \tag{2.1}$$

Set $\{x_i := x_0 + i\Delta x\}$, let $C_{i+1/2} := [x_i, x_{i+1})$ be a uniform partition of $\mathcal{R}$, and let $\{\overline{U}^n_{i+1/2}\}$ denote the set of approximate cell averages $\overline{U}^n_{i+1/2} \approx (1/\Delta x)\int_{C_{i+1/2}} u(x,t^n)dx$. Similarly, we set $D_i := [x_{i-1/2}, x_{i+1/2})$ as the dual partition and let $\{\overline{V}^n_i\}$ denote the corresponding set of approximate cell averages $\overline{V}^n_i \approx (1/\Delta x)\int_{D_i} u(x,t^n)dx$. Starting with these two piecewise-constant approximations,[1]

$$\sum_i \overline{U}^n_{i+1/2}\mathbf{1}_{C_{i+1/2}}(x) \quad \text{and} \quad \sum_i \overline{V}^n_i \mathbf{1}_{D_i}(x),$$

we proceed to compute our approximate solution at the next time level, $t^{n+1} := t^n + \Delta t^n$. To this end, we reconstruct two higher order nonoscillatory piecewise-polynomial approximations,

$$U^n(x) = \sum_i U_{i+1/2}(x)\mathbf{1}_{C_{i+1/2}}(x) \quad \text{and} \quad V^n(x) = \sum_i V_i(x)\mathbf{1}_{D_i}(x),$$

with breakpoints at x_i, $i = 0, \pm1, \pm2, \dots$, and, respectively, at $x_{i+1/2}$, $i = 0, \pm1, \pm2, \dots$. These piecewise polynomials should be conservative in the sense that $\int_{C_{j+1/2}} U^n(x)dx = \Delta x\overline{U}^n_{j+1/2}$ and $\int_{D_j} V^n(x)dx = \Delta x\overline{V}^n_j$ for all j's. There are large libraries for such conservative, accurate, and nonoscillatory reconstructions; we refer, for example, to the second order example of MUSCL [48], the third order example of [36], the well-known class of high order (W)ENO reconstructions [20, 44], etc. Following Nessyahu and Tadmor [40], the central scheme associated with these piecewise polynomials reads

$$\overline{V}^{n+1}_i = \frac{1}{\Delta x}\int_{D_i} U^n(x)dx - \frac{\Delta t^n}{\Delta x}\Big[f(U^{n+\frac12}(x_{i+1/2})) - f(U^{n+\frac12}(x_{i-1/2}))\Big], \tag{2.2a}$$

$$\overline{U}^{n+1}_{i+1/2} = \frac{1}{\Delta x}\int_{C_{i+1/2}} V^n(x)dx - \frac{\Delta t^n}{\Delta x}\Big[f(V^{n+\frac12}(x_{i+1})) - f(V^{n+\frac12}(x_i))\Big]. \tag{2.2b}$$

To guarantee second order accuracy, the right-hand sides of (2.2a), (2.2b) require the approximate values of $U^{n+\frac12}(x_{j+1/2}) \approx u(x_{j+1/2}, t^{n+\frac12})$ and $V^{n+\frac12}(x_j) \approx u(x_j, t^{n+\frac12})$ to be evaluated at the midpoint $t + \Delta t^n/2$. Replacing the midpoint rule with higher order quadratures yields higher order accuracy; see, e.g., [36, 6].

The central NT scheme (2.2) and its higher order generalizations provide effective high-resolution "black-box" solvers to a wide variety of nonlinear conservation laws. However, when Δt is very small, e.g., with $\Delta t = \mathcal{O}\big((\Delta x)^2\big)$ as required by the CFL condition for convection-diffusion equations, the numerical dissipation of the NT schemes becomes excessively large. The excessive dissipation is due to the staggered grids where, at each time step, cell averages are shifted $\Delta x/2$-away from each other: indeed, at the extreme of $f(u) \equiv 0$, the central scheme (2.2) is reduced to reaveraging at every time step. To address this difficulty, Kurganov and Tadmor [28] suggested removing this excessive dissipation by using staggered grids which are shifted only $\mathcal{O}(\Delta t)$-away from each other. This amounts to using control volumes of width $\mathcal{O}(\Delta t)$ so that the resulting schemes admit a semidiscrete limit as $\Delta t \to 0$, the so-called "central-upwind" schemes introduced in [28] and further generalized in [27]. Liu [38] introduced another modification of the NT scheme which removes its $\mathcal{O}(1/\Delta t)$ dependency of numerical dissipation. In this approach, one takes advantage of the *redundant*

[1] Here and below, $\mathbf{1}_\Omega(x)$ denotes the characteristic function of Ω.

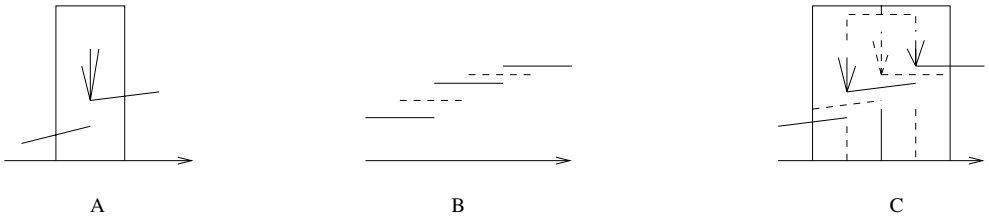

FIG. 1. (A) *NT scheme;* (B) 1*D overlapping cells;* (C) *overlapping cells create self-similarity for the grid over time and allow a convex combination of the overlapping cell averages to control the numerical dissipation.*

representation of the solution over overlapping cells, $\overline{V}_i^n$ and $\overline{U}_{i+1/2}^n$. The idea is to use an $\mathcal{O}(\Delta t)$-dependent weighted average of $\overline{U}_{i+1/2}^n$ and $\overline{V}_i^n$. In fact the difference between them is the local dissipation error. To simplify our discussion, we momentarily give up on second order accuracy in time, setting $U^{n+\frac{1}{2}} = U^n$ and $V^{n+\frac{1}{2}} = V^n$ in (2.2a) and (2.2b). The resulting first order forward-Euler formulation of the new central scheme (consult Figure 1) reads

$$\overline{V}_i^{n+1} = \theta\Big(\frac{1}{\Delta x}\int_{D_i} U^n(x)dx\Big) + (1-\theta)\overline{V}_i^n - \frac{\Delta t^n}{\Delta x}\Big[f(U^n(x_{i+1/2})) - f(U^n(x_{i-1/2}))\Big], \tag{2.3a}$$

$$\overline{U}_{i+1/2}^{n+1} = \theta\Big(\frac{1}{\Delta x}\int_{C_{i+1/2}} V^n(x)dx\Big) + (1-\theta)\overline{U}_{i+1/2}^n - \frac{\Delta t^n}{\Delta x}\Big[f(V^n(x_{i+1})) - f(V^n(x_i))\Big]. \tag{2.3b}$$

Here $\theta := \Delta t^n/\Delta\tau^n$, where $\Delta\tau^n$ is an upper bound for the time step, dictated by the CFL condition. We refer the readers to [40] and [38] for more details to facilitate the full understanding of the sketches in Figure 1. Note that when $\theta = 1$, (2.3a), (2.3b) is reduced to the first order, forward-Euler–based version of the NT scheme (2.2a), (2.2b). Moreover, writing

$$\theta\Big(\frac{1}{\Delta x}\int_{D_i} U^n(x)dx\Big) + (1-\theta)\overline{V}_i^n = \overline{V}_i^n + \frac{\Delta t^n}{\Delta\tau^n}\Big(\frac{1}{\Delta x}\int_{D_i} U^n(x)dx - \overline{V}_i^n\Big),$$

and recalling that $\Delta\tau^n = \mathcal{O}(\Delta x)$ due to the CFL restriction, it follows that the local dissipative error now has a prefactor of order Δt^n, and hence the cumulative error will be independent of $\mathcal{O}(\Delta t)$. The reduced dissipation allows us to pass to a semidiscrete formulation: subtracting $\overline{V}_i^n$ and $\overline{U}_{i+1/2}^n$ from both sides, multiplying by $\frac{1}{\Delta t^n}$, and then passing to the limit as $\Delta t^n \to 0$, we end up with

$$\frac{d}{dt}\overline{V}_i(t^n) = \frac{1}{\Delta\tau^n}\left(\frac{1}{\Delta x}\int_{D_i} U^n(x)dx - \overline{V}_i^n\right) - \frac{1}{\Delta x}\Big[f(U^n(x_{i+1/2})) - f(U^n(x_{i-1/2}))\Big], \tag{2.4a}$$

$$\frac{d}{dt}\overline{U}_{i+1/2}(t^n) = \frac{1}{\Delta\tau^n}\left(\frac{1}{\Delta x}\int_{C_{i+1/2}} V^n(x)dx - \overline{U}_{i+1/2}^n\right) - \frac{1}{\Delta x}\Big[f(V^n(x_{i+1})) - f(V^n(x_i))\Big]. \tag{2.4b}$$

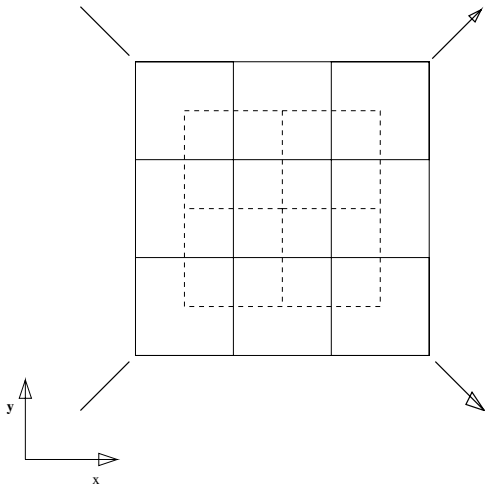

FIG. 2. *2D overlapping cells formed by collapsing the staggered dual cells on two adjacent time levels to one time level.*

The spatial accuracy of the semidiscrete central scheme (2.4) is dictated by the order of the reconstruction $U^n(x)$ and $V^n(x)$. The SSP Runge–Kutta methods yield the matching high order discretization in time.

We conclude this section by quoting [38] regarding the nonoscillatory behavior of the central scheme (2.4), which is quantified here in terms of the total-variation-diminishing (TVD) property; see, e.g., [19].

THEOREM 1. *Consider the central schemes* (2.2) *and* (2.3) *which are set with the same initial values* $\overline{V}_i^n$ *and* $\overline{U}_{i+1/2}^n$ *at* $t = t^n$. *If the NT scheme is TVD, then so is the central scheme* (2.3).

There are two reconstruction procedures for overlapping cells: one is the standard procedure to reconstruct the two classes of cell averages $\{\overline{V}_i^n : i = 0, \pm 1, \pm 2, \ldots\}$ and $\{\overline{U}_{i+1/2}^n : i = 0, \pm 1, \pm 2, \ldots\}$; the other couples these two classes for reconstruction of the final representation of the solution. Thus, this approach is redundant. At the same time, numerical examples in [38] have shown that by coupling the reconstructions, redundancy does provide improved resolution when compared with the one-cell average evolution approach of Godunov-type schemes.

3. A central discontinuous Galerkin method on overlapping cells for conservation laws. Following the general strategy of the DG methods (see, e.g., Lesaint and Raviart [31], Cockburn [10], and Cockburn and Shu [13, 15]), the central-type DG method on overlapping cells can be derived [37]. Consider the system of conservation laws

$$\frac{\partial u_k}{\partial t} + \nabla_{\mathbf{x}} \cdot \mathbf{f}_k(\mathbf{u}) = 0, \qquad (\mathbf{x}, t) \in \mathcal{R}^d \times (0, T), \quad k = 1, \ldots, m, \tag{3.1}$$

where $\mathbf{u} = (u_1, \ldots, u_m)^\top$. For simplicity, assume a uniform staggered rectangular mesh, depicted in Figure 2, for the 2D case, and we note that a similar formulation is used for irregular staggered meshes, e.g., the Voronoi mesh consisting of a triangular mesh and its dual.

Let $\{C_{I+1/2}\}$, $I = (i_1, i_2, \ldots, i_d)$, be a partition of R^d into uniform square cells, depicted by solid lines in Figure 2, and tagged by their cell centroids at the *half*

integers, $\mathbf{x}_{I+1/2} := (I+1/2)\Delta x$. Let $\mathcal{M}$ denote the set of piecewise polynomials of degree r on the cells $\{C_{I+1/2}\}$; no continuity is assumed across cell boundaries. Let $\{D_I\}$ be the dual mesh which consists of a $\Delta x/2$ shift of the $C_{I+1/2}$'s, depicted by dashed lines in Figure 2. Let $\mathbf{x}_I$ be the cell centroid of the cell D_I and let $\mathcal{N}$ denote the set of piecewise polynomials of degree r over the cells $\{D_I\}$; again, no continuity is assumed across the cell boundary. The weak formulation of (3.1) over these cells reads

$$\frac{d}{dt}\int_{C_{I+1/2}} u_k\phi d\mathbf{x} = \int_{C_{I+1/2}} \mathbf{f}_k\cdot\nabla_{\mathbf{x}}\phi d\mathbf{x} - \int_{\partial C_{I+1/2}} (\mathbf{f}_k\cdot\mathbf{n})\phi ds \quad \forall\phi\in\mathcal{M},\ k=1,\dots,m, \tag{3.2a}$$

$$\frac{d}{dt}\int_{D_I} u_k\psi d\mathbf{x} = \int_{D_I} \mathbf{f}_k\cdot\nabla_{\mathbf{x}}\psi d\mathbf{x} - \int_{\partial D_I} (\mathbf{f}_k\cdot\mathbf{n})\psi ds \quad \forall\psi\in\mathcal{N},\ k=1,\dots,m, \tag{3.2b}$$

where $\mathbf{n}$ is the unit outer normal of the corresponding cell and ϕ and ψ are test functions. As in the 1D setup, we let

$$\mathbf{U}^n(\mathbf{x}) = \sum_{I+1/2} \mathbf{U}^n_{I+1/2}(\mathbf{x})\mathbf{1}_{C_{I+1/2}}(\mathbf{x}) \in \mathcal{M} \quad \text{and} \quad \mathbf{V}^n(\mathbf{x}) = \sum_I \mathbf{V}^n_I(\mathbf{x})\mathbf{1}_{D_I}(\mathbf{x}) \in \mathcal{N}$$

denote two representations of the numerical solution, approximating $\mathbf{u}(\cdot,t^n)$ over the two overlapping grids, $\{C_{I+1/2}\}$ and $\{D_I\}$. Observe that each of the two vector functions, $\mathbf{U}^n$ with smooth pieces supported on the $C_{I+1/2}$'s and $\mathbf{V}^n$ with smooth pieces supported on the D_I's, consists of m components

$$\mathbf{U}^n(\mathbf{x}) = (U^n_1(\mathbf{x}),\dots,U^n_m(\mathbf{x}))^\top \quad \text{and} \quad \mathbf{V}^n(\mathbf{x}) = (V^n_1(\mathbf{x}),\dots,V^n_m(\mathbf{x}))^\top.$$

Given these conservative, accurate, and nonoscillatory approximations at t^n we proceed to compute the approximate solution at the next time level, $t^{n+1} = t^n + \Delta t^n$. To this end, the exact solution $\mathbf{u}(\mathbf{x},t^n)$ of (3.1) in the right-hand side of (3.2a) is replaced by $\mathbf{V}^n(\mathbf{x}) = (V^n_1,\dots,V^n_m)^\top$; similarly, for the right-hand side of (3.2b) we use the approximate solution $\mathbf{U}^n(\mathbf{x}) = (U^n_1,\dots,U^n_m)^\top$. Further, time derivatives on the left are replaced by forward-Euler time differencing where we use the same type of θ-weighting of the $\mathbf{U}^n$'s and the $\mathbf{V}^n$'s as in (2.3a), (2.3b). In the resulting central DG method one seeks piecewise polynomials $\{\mathbf{U}^{n+1}_{I+1/2}\}\in\mathcal{M}$ and $\{\mathbf{V}^{n+1}_I\}\in\mathcal{N}$ such that for all I's,

$$\begin{aligned}\int_{C_{I+1/2}} U^{n+1}_k(\mathbf{x})\phi(\mathbf{x})d\mathbf{x} &= \theta\int_{C_{I+1/2}} V^n_k(\mathbf{x})\phi(\mathbf{x})d\mathbf{x} + (1-\theta)\int_{C_{I+1/2}} U^n_k(\mathbf{x})\phi(\mathbf{x})d\mathbf{x}\\ &+ \Delta t^n\int_{C_{I+1/2}} \mathbf{f}_k(\mathbf{V}^n(\mathbf{x}))\cdot\nabla_{\mathbf{x}}\phi d\mathbf{x}\\ &- \Delta t^n\int_{\partial C_{I+1/2}} (\mathbf{f}_k(\mathbf{V}^n(\mathbf{x}))\cdot\mathbf{n})\phi(\mathbf{x})ds \quad \forall\phi\in\mathcal{M},\ k=1,\dots,m,\end{aligned} \tag{3.3a}$$

$$\int_{D_I} V_k^{n+1}(\mathbf{x})\psi(\mathbf{x})d\mathbf{x} = \theta \int_{D_I} U_k^n(\mathbf{x})\psi(\mathbf{x})d\mathbf{x} + (1-\theta)\int_{D_I} V_k^n(\mathbf{x})\psi(\mathbf{x})d\mathbf{x}$$
$$+ \Delta t^n \int_{D_I} \mathbf{f}_k(\mathbf{U}^n(\mathbf{x}))\cdot\nabla_{\mathbf{x}}\psi(\mathbf{x})d\mathbf{x} \tag{3.3b}$$
$$- \Delta t^n \int_{\partial D_I} (\mathbf{f}_k(\mathbf{U}^n(\mathbf{x}))\cdot\mathbf{n})\psi(\mathbf{x})ds \quad \forall\psi\in\mathcal{N},\ k=1,\dots,m.$$

Here $\theta = \Delta t^n/\Delta\tau^n \le 1$, $\Delta\tau^n$ is the maximum time step size determined by the CFL restriction, and $\Delta t^n = t^{n+1} - t^n$ is the current time step size. $\Delta\tau^n$ = (CFL factor) × Δx/(maximum characteristic speed), where the CFL factor should be less than 1/2. At time t^n, $\Delta\tau^n$ is first chosen with a certain CFL factor, then Δt^n has the freedom to take any value in $(0, \Delta\tau^n]$ without introducing excessive dissipation. The smaller $\Delta\tau^n$ is chosen, the larger the numerical dissipation is. We find in numerical experiments that setting $\Delta\tau^n$ with CFL factor 0.4 is robust. In some numerical tests with fewer interactions of discontinuities, we can choose larger $\Delta\tau^n$. This forward-Euler step is going to be used in an SSP Runge–Kutta method of desired order. For the pure hyperbolic problem, Δt^n can be chosen as large as possible, i.e., $\Delta t^n = \Delta\tau^n$ for efficiency.

The resulting central DG is the 2D analogue of the 1D central scheme (2.4). And as in the 1D case, the semidiscrete version of (3.3) can be obtained; higher order Runge–Kutta time discretization can be used to match the high order accuracy of the spatial reconstructions. We conclude with the semidiscrete central DG approximation of (3.1) such that for all admissible test functions ϕ and ψ and all I's,

$$\frac{d}{dt}\int_{C_{I+1/2}} U_k\phi d\mathbf{x} = \frac{1}{\Delta\tau}\int_{C_{I+1/2}} (V_k(\mathbf{x}) - U_k(\mathbf{x}))\phi(\mathbf{x})d\mathbf{x}$$
$$+ \int_{C_{I+1/2}} \mathbf{f}_k(\mathbf{V}(\mathbf{x}))\cdot\nabla_{\mathbf{x}}\phi d\mathbf{x} \tag{3.4a}$$
$$- \int_{\partial C_{I+1/2}} (\mathbf{f}_k(\mathbf{V}(\mathbf{x}))\cdot\mathbf{n})\phi(\mathbf{x})ds \quad \forall\phi\in\mathcal{M},\ k=1,\dots,m,$$
$$\frac{d}{dt}\int_{D_I} V_k\psi d\mathbf{x} = \frac{1}{\Delta\tau}\int_{D_I} (U_k(\mathbf{x}) - V_k(\mathbf{x}))\psi(\mathbf{x})d\mathbf{x}$$
$$+ \int_{D_I} \mathbf{f}_k(\mathbf{U}(\mathbf{x}))\cdot\nabla_{\mathbf{x}}\psi(\mathbf{x})d\mathbf{x} \tag{3.4b}$$
$$- \int_{\partial D_I} (\mathbf{f}_k(\mathbf{U}(\mathbf{x}))\cdot\mathbf{n})\psi(\mathbf{x})ds \quad \forall\psi\in\mathcal{N},\ k=1,\dots,m.$$

For example, consider the piecewise quadratic element in two dimensions; see, e.g., Figure 2. We use the third order SSP Runge–Kutta method [45] to discretize (3.4) in time, which ends up with calling the forward-Euler step (3.3) three times. Let cell $C_{I+1/2}$ as in (3.3a) be the cell bounded by solid lines in the center of Figure 2, and let

$$\begin{aligned} U_{I+1/2}(x - x_{I+1/2}, y - y_{I+1/2}) = {} & U_{I+1/2}(0,0) + \partial_x U_{I+1/2}(0,0)(x - x_{I+1/2}) \\ & + \partial_y U_{I+1/2}(0,0)(y - y_{I+1/2}) \\ & + \frac{1}{2}\partial_{xx} U_{I+1/2}(0,0)(x - x_{I+1/2})^2 \\ & + \partial_{xy} U_{I+1/2}(0,0)(x - x_{I+1/2})(y - y_{I+1/2}) \\ & + \frac{1}{2}\partial_{yy} U_{I+1/2}(0,0)(y - y_{I+1/2})^2 \end{aligned}$$

be $U_k^{n+1}|_{C_{I+1/2}}$, i.e., $U_k^{n+1}(\mathbf{x})$ restricted in cell $C_{I+1/2}$, where $(x_{I+1/2}, y_{I+1/2})$ is the cell centroid of cell $C_{I+1/2}$. There are six coefficients to be determined in this polynomial in cell $C_{I+1/2}$, namely,

$$U_{I+1/2}(0,0),\ \partial_x U_{I+1/2}(0,0),\ \partial_y U_{I+1/2}(0,0),$$
$$\frac{1}{2}\partial_{xx} U_{I+1/2}(0,0),\ \partial_{xy} U_{I+1/2}(0,0),\ \frac{1}{2}\partial_{yy} U_{I+1/2}(0,0).$$

By letting

$$\phi(\mathbf{x}) = 1,\ x - x_{I+1/2},\ y - y_{I+1/2},\ (x - x_{I+1/2})^2,$$
$$(x - x_{I+1/2})(y - y_{I+1/2}),\ \text{or}\ (y - y_{I+1/2})^2,$$

we obtain six linear equations in (3.3a) to solve for $U_{I+1/2}(x - x_{I+1/2},\, y - y_{I+1/2})$. The last two integrals in (3.3a) can be approximated by Gaussian quadratures, such as the three-point Gaussian quadrature for line integrals. The other integrals on the right-hand side of (3.3a) can be evaluated exactly.

3.1. Numerical errors for smooth solutions. In this subsection we study the convergence rate for a number of equations having smooth solutions. The examples are computed by linear schemes described previously without using any limiter.

Example 1. Let us start with the following linear transport equation with periodic boundary conditions:

$$u_t + a u_x = 0, \qquad (x,t) \in (0,2) \times (0,2), \tag{3.5}$$
$$u(x,0) = 1 + \sin(\pi x), \qquad x \in (0,2),$$

where $a = 1$ by default.

The test results at $T = 2$ for the P^1 (piecewise linear) version of the central DG scheme on overlapping cells (3.4) are listed in Table 1, with second order Runge–Kutta time discretization. The CFL factor is 0.4 for choosing $\Delta\tau$ and the actual time step size Δt is chosen with $\theta = 0.9$. It can be seen that the expected second order accuracy is achieved. Similar results for the 2D Burgers equation can be found in Table 2. The results for the P^2 (piecewise quadratic) version of the scheme (3.4) for the linear convection equation (3.5) are listed in Table 3, with a third order TVD

Runge–Kutta time discretization [45]. The results for the same equation with $a = 0$ are listed in Table 4, in which the first row is computed with the previously chosen Δt and the second row is computed with $\Delta t = \Delta x^2$. We observe that the staggered dissipation error does not increase with a diminishing time step size. We remark that for this special case with $a = 0$, the $\Delta\tau$ can be chosen as $+\infty$, since there is no CFL restriction on the stability time step. With this choice of $\Delta\tau$, our scheme will maintain exactly the initial condition for this degenerated PDE. If we choose a finite $\Delta\tau^n$ anyway, then the initial solution may not be maintained exactly. As to the order of accuracy, we can see that the expected third order accuracy is achieved in Table 3, and fourth order accuracy, which is one order higher than expected, is achieved in Table 4.

Example 2. We test the scheme for the Burgers equation $u_t + (\frac{1}{2}u^2)_x = 0$, $u(x, 0) = \frac{1}{4} + \frac{1}{2}\sin(\pi x)$. The errors are shown in Table 5 at the final time $T = 0.1$ when the solution is still smooth.

Example 3. We conduct a convergence test for the P^1 version of the scheme (3.4) on a 2D problem [11] which is the Burgers equation with periodic initial data: $u_t + (\frac{1}{2}u^2)_x + (\frac{1}{2}u^2)_y = 0$ on $[-1, 1] \times [-1, 1]$, $u(x, y, 0) = \frac{1}{4} + \frac{1}{2}\sin(\pi(x + y))$. The numerical solutions are computed at the final time $T = 0.1$ when the exact solution is still smooth. The CFL factor is 0.4 for choosing $\Delta\tau$ and the actual time step size Δt is chosen with $\theta = 0.9$. The errors are shown in Table 2. Again we observe the expected second order accuracy. Further we test the P^2 version of scheme for the 2D Burgers equation. The errors are shown in Table 6 at the final time $T = 0.1$.

Example 4. The solution of the 2D Burgers equation may contain linear waves; hence we also test the scheme on another 2D equation $u_t + (\frac{1}{2}u^2)_x + (\frac{1}{4}u^4)_y = 0$, $u(x, 0) = \frac{1}{4} + \frac{1}{2}\sin(\pi(x + y))$. The accuracy of the numerical solution is shown at $T = 0.1$ in Table 7.

P^2 *version of the central DG scheme* (3.4) *for the* 2*D nonlinear equation.*

Δx	1/4	1/8	1/16	1/32	1/64
L_1 *error*	5.35E-3	5.75E-4	6.80E-5	7.81E-6	9.77E-7
order	-	3.22	3.08	3.12	3.00
L_∞ *error*	2.57E-3	3.16E-4	8.00E-5	1.10E-5	1.53E-6
order	-	3.02	1.98	2.86	2.85

It seems that for all these cases the expected third order accuracy is achieved for the P^2 version of scheme, at least for the L_1 errors.

4. A general nonoscillatory hierarchical reconstruction procedure. Compared to finite volume schemes which evolve only cell averages over time, DG methods compute and evolve a high order polynomial in each cell. The challenge lies in determining how to take advantage of the extra information provided by the DG method in each cell and use it in the limiting process where the solution is nonsmooth. The first idea is given by Cockburn and Shu [13] for the DG method which limits the variation between a cell edge value and its cell average by the differences between the cell averages of the current and neighboring cells. The higher Legendre moments are truncated in a cell if nonsmoothness is detected. This process is shown to be total variation bounded in the means. A generalization is introduced in Biswas, Devine, and Flaherty [7], which detects the nonsmoothness in higher degree moments and applies the limiting when necessary from higher to lower moments. In Qiu and Shu [42, 41], a high order WENO reconstruction is used as a limiter for the so-called troubled cells, where the polynomial defined at Gaussian points is reconstructed from a WENO procedure and is projected back to the finite element space to replace the one computed by the DG method. In [41], the Hermite WENO reconstruction takes not only cell averages of a function, but also cell averages of its first order derivatives in order to obtain a compact reconstruction. A similar strategy is used in our nonoscillatory hierarchical reconstruction, where cell averages of various orders of derivatives of a function are to be calculated and used in the reconstruction of linear polynomials at each stage. Our limiting procedure is closely related to that of [7]. Our departure from [7] begins with a different point of view, where the approximation in each cell is viewed as a high degree polynomial, instead of the combination of orthogonal Legendre polynomials advocated in [7]. Instead of a limiting procedure which is trying to set an acceptable range for the coefficient of the Legendre moments (by using the coefficients of lower degree moments), we reconstruct the *complete set* of coefficients of the m-degree polynomial terms, using a nonoscillatory conservative reconstruction which involves previous reconstructed terms of degrees above m. The resulting, so-called *hierarchical reconstruction* algorithm is easy to implement in a multidimensional setting, and there is no need to transform an irregular mesh cell into a rectangular one or use a dimension-by-dimension extension of a 1D limiter. It

is essentially independent of the shapes of mesh cells and is compact because of the conservative nonoscillatory linear reconstruction (such as the MUSCL or second order ENO reconstruction; see [1] for an implementation for unstructured meshes) used at each stage. We now give the details of this reconstruction procedure. For simplicity we discuss only the scalar case. For systems a component-by-component extension is applied without characteristic decomposition.

From scheme (3.4) with the SSP Runge–Kutta methods, we obtain numerical solutions $U^n(\mathbf{x})$ and $V^n(\mathbf{x})$ at time t^n. To simplify the notation we drop the superscript n and write

$$U(\mathbf{x}) = \sum_{I+1/2} U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})\mathbf{1}_{C_{I+1/2}}(\mathbf{x}) \in \mathcal{M},$$
$$V(\mathbf{x}) = \sum_{I} V_I(\mathbf{x}-\mathbf{x}_I)\mathbf{1}_{D_I}(\mathbf{x}) \in \mathcal{N},$$

recalling that $\mathbf{x}_{I+1/2}$ and $\mathbf{x}_I$ are centroids of cells $C_{I+1/2}$ and D_I, respectively; $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ and $V_I(\mathbf{x}-\mathbf{x}_I)$ are the polynomials (of degree r) in cells $C_{I+1/2}$ and D_I, respectively.[2] The task is to reconstruct a "limited" version of these polynomials, retaining high-resolution and removing spurious oscillations. In the following, we discuss a hierarchical reconstruction procedure for recomputing the polynomial $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ by using polynomials in cells adjacent to cell $C_{I+1/2}$. For convenience these adjacent cells are renamed as the set $\{C_J\}$ (which contain cells $C_{I+1/2}$, D_I, etc.), and the polynomials (of degree r) supported on them are thus renamed as $\{U_J(\mathbf{x}-\mathbf{x}_J)\}$, respectively, where $\mathbf{x}_J$ is the cell centroid of cell C_J. We write $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ in terms of its Taylor expansion,

$$U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}) = \sum_{m=0}^{r}\sum_{|\mathbf{m}|=m}\frac{1}{\mathbf{m}!}U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})(\mathbf{x}-\mathbf{x}_{I+1/2})^{\mathbf{m}},$$

where $\frac{1}{\mathbf{m}!}U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$ are the coefficients which participate in its typical m-degree terms,

$$\sum_{|\mathbf{m}|=m}\frac{1}{\mathbf{m}!}U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})(\mathbf{x}-\mathbf{x}_{I+1/2})^{\mathbf{m}}, \qquad |\mathbf{m}| = 0,\dots,r,$$

$\mathbf{m} = (m_1, m_2, \dots, m_d)$ is the multi-index,

$$|\mathbf{m}| = \sum_{i=1}^{d} m_i, \quad \mathbf{m}! = \prod_{i=1}^{d} m_i!, \quad U^{(\mathbf{m})}_{I+1/2}(\mathbf{x}) = \partial^{m_d}_{x_d}\cdots\partial^{m_1}_{x_1}U_{I+1/2}(\mathbf{x}),$$

and $\mathbf{x} = (x_1, \dots, x_d)$. The following hierarchical reconstruction describes a procedure to compute the new coefficients,

$$\frac{1}{\mathbf{m}!}\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0}), \qquad m = r, r-1, \dots, 0,$$

in $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, iterating from the highest to the lowest degree terms.

[2] These polynomials could be oscillatory. There could be other methods to compute these polynomials such as a finite volume reconstruction from cell averages.

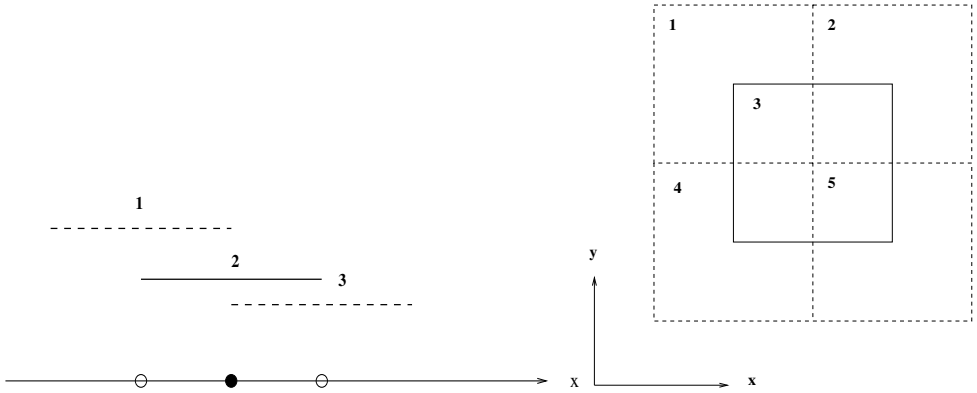

FIG. 3. *Left:* 1*D nonoscillatory hierarchical reconstruction for cell* 2 *involves only overlapping cells* 1, 2, *and* 3. *Right:* 2*D nonoscillatory hierarchical reconstruction for cell* 3 *involves only overlapping cells* 1, 2, 3, 4, *and* 5.

4.1. An example for piecewise quadratic finite element space in one dimension. Suppose $U_j(x-x_j) = U_j(0)+U_j'(0)(x-x_j)+\frac{1}{2}U_j''(0)(x-x_j)^2$, $j = 1, 2, 3$, are given at cells C_1, C_2, and C_3, respectively (see Figure 3, left), where x_j is the center of cell C_j. These polynomials could be oscillatory if located near a discontinuity of the weak solution. The following algorithm computes a new value for each coefficient in the polynomial defined on cell C_2 in order to reduce the oscillation while keeping the accuracy (in the smooth area) and resolution.

Step 1. (1) Take the first derivative for them to obtain $L_j(x - x_j) = U_j'(0) + U_j''(0)(x - x_j)$, $j = 1, 2, 3$.

(2) Calculate the cell average of $L_j(x - x_j)$ on cell C_j to obtain $\overline{L}_j = U_j'(0)$, $j = 1, 2, 3$.

(3) With the three cell averages one can apply a MUSCL or second order ENO procedure to reconstruct a nonoscillatory linear polynomial in cell C_2. The slope of this new linear polynomial corresponds to the slope $U_2''(0)$ of the original linear polynomial $L_2(x-x_2)$ in cell C_2 and is denoted by $\widetilde{U}_2''(0)$. The details can be explained as follows.

Using the technique of [1], let the new linear polynomial $\widetilde{L}_2(x - x_2)$ in cell C_2 be determined by solving

$$\frac{1}{|C_j|}\int_{C_j} \widetilde{L}_2(x - x_2)dx = \overline{L}_j, \quad j = 1, 2. \tag{4.1}$$

We now obtain the slope of $\widetilde{L}_2(x - x_2)$, which is only a candidate for the new value of $U_2''(0)$. The set of cells $\{C_1, C_2\}$ chosen by C_j in (4.1) is called a stencil for cell C_2. We can similarly determine another candidate for the new value of $U_2''(0)$ by solving (4.1) with C_j chosen from another stencil $\{C_2, C_3\}$ of cells. Finally we let

$$\widetilde{U}_2''(0) = \text{minmod}\big(\text{ candidates of } U_2''(0)\ \big),$$

where

$$\text{minmod}\{c_1, c_2, \ldots, c_m\} = \begin{cases} \min\{c_1, c_2, \ldots, c_m\} & \text{if } c_1, c_2, \ldots, c_m > 0, \\ \max\{c_1, c_2, \ldots, c_m\} & \text{if } c_1, c_2, \ldots, c_m < 0, \\ 0, & \text{otherwise.} \end{cases}$$

TABLE 8
P^2 version of the central DG scheme (3.4) *with the hierarchical reconstruction Algorithm* 1 *for the Burgers equation. MUSCL is used in Algorithm* 1.

Δx	1/10	1/20	1/40	1/80	1/160
L_1 *error*	4.24E-4	5.33E-5	6.71E-6	8.44E-7	1.07E-7
order	-	2.99	2.99	2.99	2.98
L_∞ *error*	5.13E-4	6.20E-5	7.38E-6	1.29E-6	2.66E-7
order	-	3.05	3.07	2.52	2.28

TABLE 9
P^2 version of the central DG scheme (3.4) *with the hierarchical reconstruction Algorithm* 1 *for the Burgers equation. Second order ENO is used in Algorithm* 1.

Δx	1/10	1/20	1/40	1/80	1/160
L_1 *error*	4.51E-4	5.36E-5	6.85E-6	8.54E-7	1.08E-7
order	-	3.07	2.97	3.00	2.98
L_∞ *error*	5.24E-4	6.17E-5	1.03E-5	1.81E-6	3.27E-7
order	-	3.09	2.58	2.51	2.47

This is a MUSCL reconstruction. To use the second order ENO reconstruction, we replace the minmod function by the following minmod_2 function:

$$\text{minmod}_2\{c_1, c_2, \ldots, c_m\} = c_j \quad \text{if } |c_j| = \min\{|c_1|, |c_2|, \ldots, |c_m|\}.$$

In order to find the new value $\widetilde{U}_2'(0)$ for $U_2'(0)$ by using the above MUSCL or second order ENO reconstruction, we need to find the cell averages of the linear part $U_2(0) + U_2'(0)(x - x_2)$ on cell C_2 and its neighbors C_1 and C_3.

Step 2. (1) Compute the cell average of $U_j(x - x_j)$ on cell C_j to obtain $\overline{U_j}$, $j = 1, 2, 3$.

(2) Compute the cell average of the polynomial $\widetilde{R}_2(x - x_2) = \frac{1}{2}\widetilde{U}_2''(0)(x - x_2)^2$ on cell C_j to obtain $\overline{R}_j$, $j = 1, 2, 3$.

(3) Redefine $\overline{L}_j = \overline{U_j} - \overline{R}_j$, $j = 1, 2, 3$. *These are the approximate cell averages of the linear part $U_2(0) + U_2'(0)(x - x_2)$ on cells C_1, C_2, and C_3.*

(4) Similar to Step 1, we solve (4.1) to obtain a linear polynomial in cell C_2. The slope of this linear polynomial corresponds to the slope $U_2'(0)$ of the linear polynomial $U_2(0)+U_2'(0)(x-x_2)$ and is only a candidate for the new value of $U_2'(0)$. Another candidate can be obtained by solving (4.1) with C_j chosen from another stencil $\{C_2, C_3\}$ of cells. Finally let

$$\widetilde{U}_2'(0) = \text{minmod}\big(\text{ candidates of } U_2'(0)\ \big).$$

For the second order ENO reconstruction, the minmod function can be replaced by the minmod_2 function. To keep the cell average invariant, we let the new value for $U_2(0)$ be $\widetilde{U}_2(0) = \overline{L}_2$.

The convergence test results with Algorithm 1 for Example 2 can be found in Tables 8 and 9. We observe that the order of accuracy is maintained, although (as expected for any limiter) the magnitude of the error is increased for the same mesh (see Table 5 for a comparison).

4.2. Hierarchical reconstruction—General description. In the following, we discuss a hierarchical reconstruction procedure for recomputing the polynomial $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ by using polynomials in cells adjacent to cell $C_{I+1/2}$. Recall that these adjacent cells are renamed as the set $\{C_J\}$ and the polynomials (of degree r)

supported on them are thus renamed as $\{U_J(\mathbf{x}-\mathbf{x}_J)\}$, respectively. The following hierarchical reconstruction describes a procedure to compute the new coefficients,

$$\frac{1}{\mathbf{m}!}\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0}), \qquad m=r,r-1,\dots,0,$$

in $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, iterating from the highest to the lowest degree terms.

To reconstruct $\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$, we first compute many *candidates* of $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$ (sometimes still denoted as $\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$ with specification), and we then let the new coefficient for $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$ be

$$\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0}) = F\big(\text{ candidates of } U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})\ \big),$$

where F is a convex limiter of its arguments, e.g., the minmod function.

In order to find these candidates of $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$, $|\mathbf{m}|=m$, we take an $(m-1)$th order partial derivative of $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ and denote it by

$$\partial^{m-1}U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}) = L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}) + R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}),$$

where $L_{I+1/2}$ is the linear part and $R_{I+1/2}$ contains all second and higher degree terms of $\partial^{m-1}U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$. Clearly, every coefficient in the first degree terms of $L_{I+1/2}$ is in the set $\{U^{(\mathbf{m})}_{I+1/2}(\mathbf{0}) : |\mathbf{m}|=m\}$. And for every $\mathbf{m}$ subject to $|\mathbf{m}|=m$, one can always take some $(m-1)$th order partial derivatives of $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ so that $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$ is a coefficient in the first degree terms of $L_{I+1/2}$. Thus, a "candidate" for a coefficient in the first degree terms of $L_{I+1/2}$ is the candidate for the corresponding $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$.

In order to find the candidates for all the coefficients in the first degree terms of $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, we only need to know the cell averages of $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ on $d+1$ distinct mesh cells adjacent to cell $C_{I+1/2}$, recalling that d is the spatial dimension. Assume $C_{J_0}, C_{J_1}, \dots, C_{J_d} \in \{C_J\}$ are these cells and $\overline{L}_{J_0}, \overline{L}_{J_1}, \dots, \overline{L}_{J_d}$ are the corresponding cell averages. The set of these $d+1$ cells with the associated cell averages is called a *stencil*. Let a linear polynomial $\widetilde{L}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ be determined by

$$\frac{1}{|C_{J_l}|}\int_{C_{J_l}} \widetilde{L}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})d\mathbf{x} = \overline{L}_{J_l}, \quad l=0,1,\dots,d. \tag{4.2}$$

Then the coefficients in the first degree terms of $\widetilde{L}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ will be the candidates for the corresponding coefficients of $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$. Therefore, a stencil located near cell $C_{I+1/2}$ will determine a set of candidates for all coefficients in the first degree terms of $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$. The key is to determine the new approximate cell averages of $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ on the cells of $\{C_J\}$, which is outlined by the following algorithm.

ALGORITHM 1.

Step 1. *Suppose* $r \geq 2$. *For* $m=r,r-1,\dots,2$, *do the following:*

(a) *Take an* $(m-1)$*th order partial derivative for each of* $\{U_J(\mathbf{x}-\mathbf{x}_J)\}$ *to obtain polynomials* $\{\partial^{m-1}U_J(\mathbf{x}-\mathbf{x}_J)\}$, *respectively. In particular, denote* $\partial^{m-1}U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}) = L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2}) + R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, *where* $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *is the linear part of* $\partial^{m-1}U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *and* $R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *is the remainder.*

(b) *Calculate the cell averages of* $\{\partial^{m-1}U_J(\mathbf{x}-\mathbf{x}_J)\}$ *on cells* $\{C_J\}$ *to obtain* $\{\overline{\partial^{m-1}U_J}\}$, *respectively.*

(c) *Let* $\widetilde{R}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *be the* $R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *with its coefficients replaced by the corresponding new coefficients.*[3] *Calculate the cell averages of* $\widetilde{R}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *on cells* $\{C_J\}$ *to obtain* $\{\overline{R}_J\}$, *respectively.*

(d) *Let* $\overline{L}_J=\overline{\partial^{m-1}U_J}-\overline{R}_J$ *for all* J.

(e) *Form stencils out of the new approximate cell averages* $\{\overline{L}_J\}$ *by using a nonoscillatory finite volume MUSCL or second order ENO strategy. Each stencil will determine a set of candidates for the coefficients in the first degree terms of* $L_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, *which are also candidates for the corresponding* $U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$*'s,* $|\mathbf{m}|=m$.

(f) *Repeat from* (a) *to* (e) *until all possible combinations of the* $(m-1)$*th order partial derivatives are taken. Then the candidates for all coefficients in the* m*th degree terms of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *have been computed. For each of these coefficients, say* $\frac{1}{\mathbf{m}!}U^{(\mathbf{m})}_{I+1/2}(\mathbf{0})$, $|\mathbf{m}|=m$, *let the new coefficient* $\widetilde{U}^{(\mathbf{m})}_{I+1/2}(\mathbf{0})=F(\text{candidates of}\,U^{(\mathbf{m})}_{I+1/2}(\mathbf{0}))$.

Step 2. *In order to find the new coefficients in the zeroth and first degree terms of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$, *we perform the procedure of Step* 1(a)–(f) *with* $m=1$, *and make sure that the new approximate cell average* $\overline{L}_{I+1/2}$ *is in each of the stencils, which ensures that the cell average of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *on cell* $C_{I+1/2}$ *is not changed with the new coefficients. The new coefficient in the zeroth degree term of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *is* $\overline{L}_{I+1/2}$, *which ensures that the cell average of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *in cell* $C_{I+1/2}$ *is invariant with the new coefficients. At this stage all new coefficients of* $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ *have been found.*

Remarks. 1. The coefficients of the polynomials can be updated after Algorithm 1 has been applied to all mesh cells, or at the mth stage when all new coefficients for those in the mth degree terms of all polynomials have been computed (in this case, $\{\overline{\partial^0 U_J}\}$ used in Step 2 should be the cell averages of the original polynomials to ensure that they are invariant). The latter case is supposed to be more diffusive. In numerical experiments we find their results are about the same. All numerical results presented in this paper are performed with the former implementation.

2. One motivation for us to develop this hierarchical reconstruction is that the limiting for the DG scheme on nonstaggered meshes is different from that for scheme (3.4). For the usual DG scheme the time evolution of the cell averages is completely determined by the fluxes; however, in (3.4), cell interior values are also involved. We find in numerical experiments that the moment limiter [7] does not work as robustly for scheme (3.4) as it does for the DG scheme on nonstaggered meshes. The proposed hierarchical reconstruction process is quite general and could be useful for conventional DG or even finite volume schemes. These will be explored in the future.

3. Scheme (3.4) with Algorithm 1 and with piecewise linear elements is identical to the second order central scheme on overlapping cells [38].

4. It is more efficient to apply the hierarchical reconstruction process only in places where it is needed by using nonsmoothness detectors (see, e.g., [42, 9]). This will be explored in the future.

[3] At this stage, we have already found new values for all coefficients in the terms of $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ of degree above m. These coefficients remain in $R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ (after taking an $(m-1)$th order partial of $U_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$). When they are replaced by their corresponding new values, $R_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$ becomes $\widetilde{R}_{I+1/2}(\mathbf{x}-\mathbf{x}_{I+1/2})$. See Step 2(2) in section 4.1 as an example.

The most important point is that even though the linear reconstruction used in Algorithm 1 is only second order accurate, the approximation order of accuracy of a polynomial in a cell is unaffected by the algorithm, and we have the following condition.

CONDITION 1. *Let* $\{\mathbf{x}_{J_0}, \mathbf{x}_{J_1}, \ldots, \mathbf{x}_{J_d}\}$ *be the* $d+1$ *cell centroids of a stencil. Then there is a point among them, say* $\mathbf{x}_{J_0}$*, such that the matrix* $A = \frac{1}{\Delta x}[\mathbf{x}_{J_1} - \mathbf{x}_{J_0}, \mathbf{x}_{J_2} - \mathbf{x}_{J_0}, \ldots, \mathbf{x}_{J_d} - \mathbf{x}_{J_0}]$ *is nonsingular. Further, there is a constant* $\alpha > 0$ *independent of* Δx *such that* $||A^{-1}|| \le \alpha$.

In two dimensions, this condition means that $\mathbf{x}_{J_0}, \mathbf{x}_{J_1}, \mathbf{x}_{J_2}$ are not along a straight line. Further, the angle between the line passing $\mathbf{x}_{J_0}, \mathbf{x}_{J_1}$ and the line passing $\mathbf{x}_{J_0}, \mathbf{x}_{J_2}$ has a positive lower bound independent of Δx. This condition is satisfied for stencils such as $\{C_3, C_1, C_2\}$, $\{C_3, C_2, C_5\}$, $\{C_3, C_5, C_4\}$, and $\{C_3, C_4, C_1\}$ in Figure 3 (right), and is not satisfied for $\{C_1, C_3, C_5\}$.

THEOREM 2. *Suppose* $\{U_J(\mathbf{x} - \mathbf{x}_J)\}$ *in Algorithm* 1 *approximate a* C^{r+1} *function* $u(\mathbf{x})$ *with pointwise error* $\mathcal{O}\big((\Delta x)^{r+1}\big)$ *within their respective cell* $\{C_J\}$*, and all cells in* $\{C_J\}$ *are contained in a circle centered at* $\mathbf{x}_{I+1/2}$ *with radius* $\mathcal{O}(\Delta x)$*. Let the* $d+1$ *cell centroids in every stencil used in Algorithm* 1 *satisfy Condition* 1*. Then after the application of Algorithm* 1*, the polynomial* $\widetilde{U}_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$*, i.e.,* $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ *with its coefficients replaced by the corresponding new values, also approximates the function* $u(\mathbf{x})$ *with pointwise error* $\mathcal{O}\big((\Delta x)^{r+1}\big)$ *within cell* $C_{I+1/2}$*. The cell average of* $\widetilde{U}_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ *on cell* $C_{I+1/2}$ *is the same as that of* $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$.

Proof. From the assumption we know that the coefficients in the mth degree terms of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$, $0 \le m \le r$, are the $(r-m+1)$th order approximation to the corresponding coefficients of the Taylor expansion of $u(\mathbf{x})$ at $\mathbf{x}_{I+1/2}$.

Assume that when starting to compute new values for the coefficients of the mth degree terms of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$, $1 \le m \le r$, all the computed new values (if there are any) for the coefficients of the lth degree terms ($m < l \le r$, if they exist) of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ are their $(r-l+1)$th order approximations. In fact, when $m = r$, there are no new coefficients which have been computed at Step 1(a). However, the following argument will show that the new coefficients computed at Step 1(f) for coefficients of the rth degree terms of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ are their first order approximations.

Let $L_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2}) = c_0 + \mathbf{c}_1 \cdot (\mathbf{x} - \mathbf{x}_{I+1/2})$ in Step 1(a) and let $\widehat{L}(\mathbf{x}) = \widehat{c}_0 + \widehat{\mathbf{c}}_1 \cdot (\mathbf{x} - \mathbf{x}_{I+1/2})$ be the corresponding linear part in the Taylor expansion of the same (as for U_J) $(m-1)$th partial derivative of $u(x)$ at $\mathbf{x}_{I+1/2}$. Therefore c_0 and $\mathbf{c}_1$ approximate $\widehat{c}_0$ and $\widehat{\mathbf{c}}_1$ to the order of $\mathcal{O}\big((\Delta x)^{r-m+2}\big)$ and $\mathcal{O}\big((\Delta x)^{r-m+1}\big)$, respectively. Also from the above assumptions it is easy to see that $\overline{L}_J = \overline{\partial^{m-1} U_J} - \overline{R}_J$ in Step 1(d) approximates the cell average of $\widehat{L}(\mathbf{x})$ on cell C_J to the order of $O(\Delta x^{r-m+2})$ for all cells C_J adjacent to cell $C_{I+1/2}$.

Reconstructing $\widetilde{L}_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2}) = \widetilde{c}_0 + \widetilde{\mathbf{c}}_1 \cdot (\mathbf{x} - \mathbf{x}_{I+1/2})$ from a stencil $C_{J_0}, C_{J_1}, \ldots, C_{J_d} \in \{C_J\}$ entails finding $\widetilde{c}_0$ and $\widetilde{\mathbf{c}}_1$ that satisfy the equations (see (4.2))

$$\begin{aligned} \frac{1}{|C_{J_l}|} \int_{C_{J_l}} (\widetilde{c}_0 + \widetilde{\mathbf{c}}_1 \cdot (\mathbf{x} - \mathbf{x}_{I+1/2})) d\mathbf{x} &= \widetilde{c}_0 + \widetilde{\mathbf{c}}_1 \cdot (\mathbf{x}_{J_l} - \mathbf{x}_{I+1/2}) \\ &= \overline{L}_{J_l} = \widehat{c}_0 + \widehat{\mathbf{c}}_1 \cdot (\mathbf{x}_{J_l} - \mathbf{x}_{I+1/2}) \\ &\quad + \mathcal{O}\big((\Delta x)^{r-m+2}\big), \end{aligned} \tag{4.3}$$

where $\mathbf{x}_{J_l}$ is the cell centroid of cell C_{J_l}, $l = 0, \ldots, d$. The solutions are candidates for c_0 and $\mathbf{c}_1$, respectively. Subtracting the first equation ($l = 0$) from the rest of the

equations in (4.3), we can obtain

$$A^T(\widetilde{\mathbf{c}}_1 - \widehat{\mathbf{c}}_1) = \mathcal{O}\big((\Delta x)^{r-m+1}\big),$$

where $A = \frac{1}{\Delta x}[\mathbf{x}_{J_1} - \mathbf{x}_{J_0}, \mathbf{x}_{J_2} - \mathbf{x}_{J_0}, \ldots, \mathbf{x}_{J_d} - \mathbf{x}_{J_0}]$. From Condition 1, $||A^{-1}||$ is bounded independently of Δx. We conclude that the candidate

$$\widetilde{\mathbf{c}}_1 = \widehat{\mathbf{c}}_1 + \mathcal{O}\big((\Delta x)^{r-m+1}\big). \tag{4.4}$$

Also since $||\mathbf{x}_{J_l} - \mathbf{x}_{I+1/2}|| = \mathcal{O}(\Delta x)$, $l = 0, 1, \ldots, d$, by substituting the estimate of the candidate $\widetilde{\mathbf{c}}_1$ back into one of the equations of (4.3), we obtain that the candidate

$$\widetilde{c}_0 = \widehat{c}_0 + \mathcal{O}\big((\Delta x)^{r-m+2}\big). \tag{4.5}$$

Since the function F used in Step 1(f) is a convex combination of its arguments, it does not change the approximation order of its arguments. Therefore estimate (4.4) implies that the new values for coefficients of the mth degree terms of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ are their $(r-m+1)$th order approximations. Estimate (4.4) moves the induction till $m = 1$ and estimate (4.5) implies that in Step 2 the new value for the coefficient of the zeroth degree term of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ is its $O(\Delta x^{r+1})$ approximation. Step 2 clearly ensures that the cell average of $U_{I+1/2}(\mathbf{x} - \mathbf{x}_{I+1/2})$ on cell $C_{I+1/2}$ is unchanged with the new coefficients. The proof is now complete.

4.3. Implementation for piecewise quadratic finite element space in two dimensions. Suppose on cell C_j (see Figure 3, right) a quadratic polynomial is given as

$$\begin{aligned} U_j(x - x_j, y - y_j) = {} & U_j(0,0) + \partial_x U_j(0,0)(x - x_j) + \partial_y U_j(0,0)(y - y_j) \\ & + \frac{1}{2}\partial_{xx} U_j(0,0)(x - x_j)^2 \\ & + \partial_{xy} U_j(0,0)(x - x_j)(y - y_j) + \frac{1}{2}\partial_{yy} U_j(0,0)(y - y_j)^2, \end{aligned}$$

where (x_j, y_j) is the cell centroid of cell C_j, $j = 1, 2, \ldots, 5$.

According to Step 1 of Algorithm 1, take the first partial derivative with respect to x for them to obtain $L_j(x - x_j,\ y - y_j) = \partial_x U_j(0,0) + \partial_{xx} U_j(0,0)(x - x_j) + \partial_{xy} U_j(0,0)(y - y_j)$, $j = 1, 2, \ldots, 5$. Calculate the cell average of $L_j(x - x_j,\ y - y_j)$ on cell C_j to obtain $\overline{L}_j = \partial_x U_j(0,0)$, $j = 1, 2, \ldots, 5$ (note that $R_3(x - x_3,\ y - y_3) \equiv 0$). With the five new approximate cell averages $\{\overline{L}_j : j = 1, 2, \ldots, 5\}$, one can apply a MUSCL or a second order ENO procedure to reconstruct a nonoscillatory linear polynomial

$$\widetilde{L}_3(x - x_3, y - y_3) = \partial_x \widetilde{U}_3(0,0) + \partial_{xx} \widetilde{U}_3(0,0)(x - x_3) + \partial_{xy} \widetilde{U}_3(0,0)(y - y_3)$$

in cell C_3. For example, one can form the four stencils $\{C_3, C_1, C_2\}$, $\{C_3, C_2, C_5\}$, $\{C_3, C_5, C_4\}$, and $\{C_3, C_4, C_1\}$. For the first stencil, solve the following equations for $\partial_{xx} \widetilde{U}_3(0,0)$ and $\partial_{xy} \widetilde{U}_3(0,0)$:

$$\begin{aligned} \frac{1}{|C_j|}\int_{C_j} \widetilde{L}_3(x - x_3, y - y_3)\,dx\,dy &= \overline{L}_3 + \partial_{xx} \widetilde{U}_3(0,0)(x_j - x_3) + \partial_{xy} \widetilde{U}_3(0,0)(y_j - y_3) \\ &= \overline{L}_j, \end{aligned}$$

TABLE 10
P^2 version of the central DG scheme (3.4) with the hierarchical reconstruction Algorithm 1 for the 2D Burgers equation. Second order ENO is used in Algorithm 1.

Δx	1/4	1/8	1/16	1/32	1/64
L_1 *error*	8.00E-2	1.24E-2	1.58E-3	1.92E-4	2.40E-5
order	-	2.69	2.97	3.04	3.00
L_∞ *error*	4.90E-2	9.85E-3	1.68E-3	2.01E-4	2.68E-5
order	-	2.31	2.55	3.06	2.91

$j = 1, 2$; similarly for other stencils. We obtain two sets of candidates for $\partial_{xx}U_3(0,0)$ and $\partial_{xy}U_3(0,0)$, respectively. By taking the first partial derivative with respect to y for $U_j(x - x_j,\ y - y_j)$, $j = 1, 2, \ldots, 5$, we similarly obtain a set of candidates for $\partial_{yy}U_3(0,0)$ and enlarge the set of candidates for $\partial_{xy}U_3(0,0)$. Putting all candidates for $\partial_{xx}U_3(0,0)$ into the arguments of the minmod (or minmod_2) function, we obtain the new coefficient $\partial_{xx}\widetilde{U}_3(0,0)$ for $\partial_{xx}U_3(0,0)$. Applying the same procedure, we obtain new coefficients $\partial_{xy}\widetilde{U}_3(0,0)$ and $\partial_{yy}\widetilde{U}_3(0,0)$.

According to Step 2 of Algorithm 1, we compute the cell average of $U_j(x - x_j,\ y - y_j)$ on cell C_j to obtain $\overline{U_j}$, $j = 1, 2, \ldots, 5$, and compute cell averages of the polynomial

$$\widetilde{R}_3(x - x_3, y - y_3) = \frac{1}{2}\partial_{xx}\widetilde{U}_3(0,0)(x - x_3)^2 + \partial_{xy}\widetilde{U}_3(0,0)(x - x_3)(y - y_3) + \frac{1}{2}\partial_{yy}\widetilde{U}_3(0,0)(y - y_3)^2$$

on cell $C_1, C_2, \ldots, C_5$ to obtain $\overline{R}_1, \overline{R}_2, \ldots, \overline{R}_5$, respectively. Redefine $\overline{L}_j = \overline{U_j} - \overline{R}_j$, $j = 1, 2, \ldots, 5$. The same MUSCL or second order ENO procedure as described previously can be applied to the five cell averages $\{\overline{L}_j : j = 1, 2, \ldots, 5\}$ to obtain the new coefficients $\partial_x\widetilde{U}_3(0,0)$ and $\partial_y\widetilde{U}_3(0,0)$. Finally let the new coefficient $\widetilde{U}_3(0,0) = \overline{L}_3$.

The convergence test results with Algorithm 1 for Example 3 can be found in Table 10. We again observe that the order of accuracy is maintained, although (as expected for any limiter) the magnitude of the error is increased for the same mesh (see Table 6 for a comparison).

5. Additional numerical examples. Scheme (3.4) with the piecewise rth degree polynomial space is referred to as CO-DG-$(r+1)$, where "C" stands for "central" and "O" stands for "overlapping cells." When the hierarchical reconstruction Algorithm 1 is applied, it is referred to as CO-DG-hr1-$(r+1)$. To specify whether a linear MUSCL (with the minmod limiter) or ENO (with the minmod_2 limiter) reconstruction is used in Algorithm 1, we refer it as CO-DG-hr1m-$(r+1)$ or CO-DG-hr1e-$(r+1)$, respectively.

The corresponding (up to third order) TVD Runge–Kutta time discretization methods [45] are applied to the above schemes. Only the solution in one class of the overlapping cells is shown in the graphs throughout this section. For systems of equations, the componentwise extensions of the scalar schemes (without characteristic decomposition) have been used in all the computations.

Example 5. We compute the Euler equation with Lax's initial data. $u_t + f(u)_x = 0$ with $u = (\rho, \rho v, E)^T$, $f(u) = (\rho v, \rho v^2 + p, v(E + p))^T$, $p = (\gamma - 1)(E - \frac{1}{2}\rho v^2)$, $\gamma = 1.4$. Initially, the density ρ, momentum ρv, and total energy E are 0.445, 0.311, and 8.928 in $(0, 0.5)$, and are 0.5, 0, and 1.4275 in $(0.5, 1)$. The computed results by CO-DG-hr1e-3 and CO-DG-hr1m-3 are shown at $T = 0.16$ in Figure 4, with $\Delta x = 1/200$,

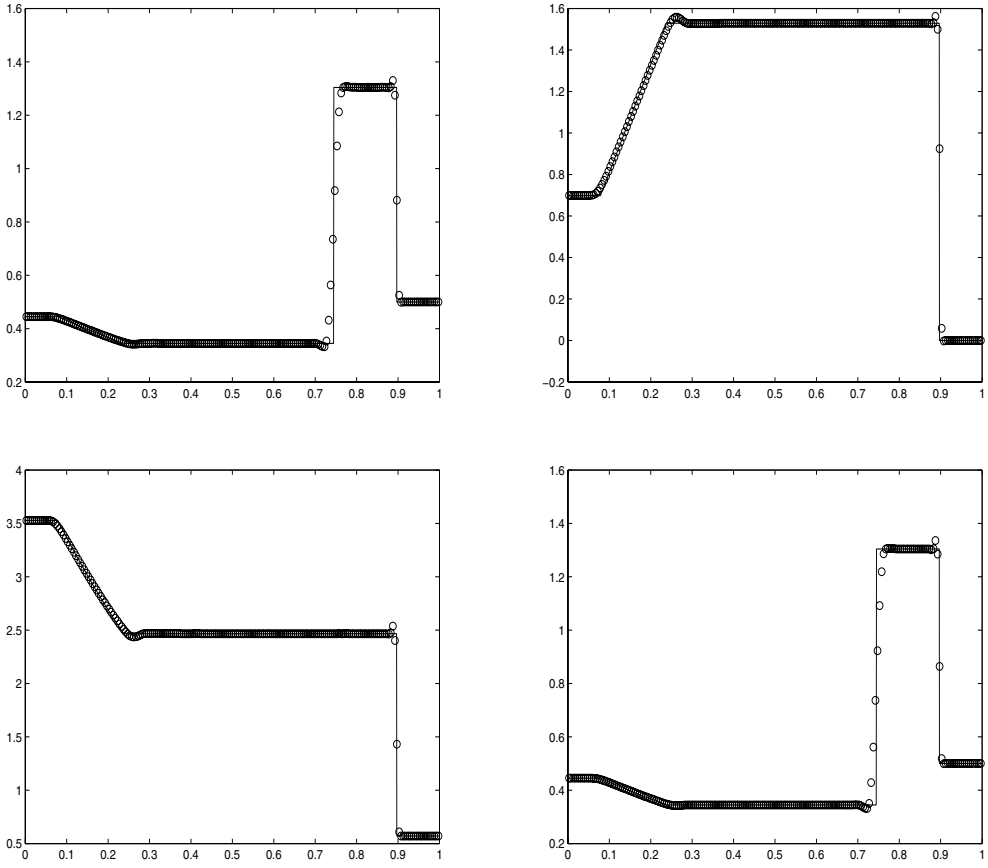

FIG. 4. *Lax's problem,* $\Delta x = 1/200$. *From left to right, top to bottom,* (1) *density (CO-DG-hr*1*e*-3*);* (2) *velocity (CO-DG-hr*1*e*-3*);* (3) *pressure (CO-DG-hr*1*e*-3*);* (4) *density (CO-DG-hr*1*m*-3*).*

$\Delta\tau^n$ chosen with a CFL factor 0.4, $\Delta t^n = 0.5\Delta\tau^n$. The solid line reference solutions are analytic solutions to the Riemann problem. We observe that the resolution is quite good with very small over/undershoots. The only concern is that the contact discontinuity is much more smeared than that of the regular third order DG scheme with a total variation bounded limiter (Figure 20 in [12]). We hope to improve this performance by reducing the usage of the reconstruction limiter through a troubled-cell indicator in future work.

Example 6. The Woodward and Colella blast wave problem [50] for the Euler equation computed by CO-DG-hr1e-3. Initially, the density, momentum, and total energy are $1, 0, 2500$ in $(0, 0.1)$; $1, 0, 0.025$ in $(0.1, 0.9)$; and $1, 0, 250$ in $(0.9, 1)$. The density, velocity, and pressure profiles are plotted in Figure 5 for $T = 0.01$ and $T = 0.038$. The solid line reference solutions are computed by a third order central scheme on overlapping cells [38] on a much refined mesh ($\Delta x = 1/2000$). $\Delta\tau^n$ is chosen with a CFL factor 0.4, $\Delta t^n = \frac{1}{2}\Delta\tau^n$. We observe stable results with good resolution for this very demanding problem in terms of numerical stability.

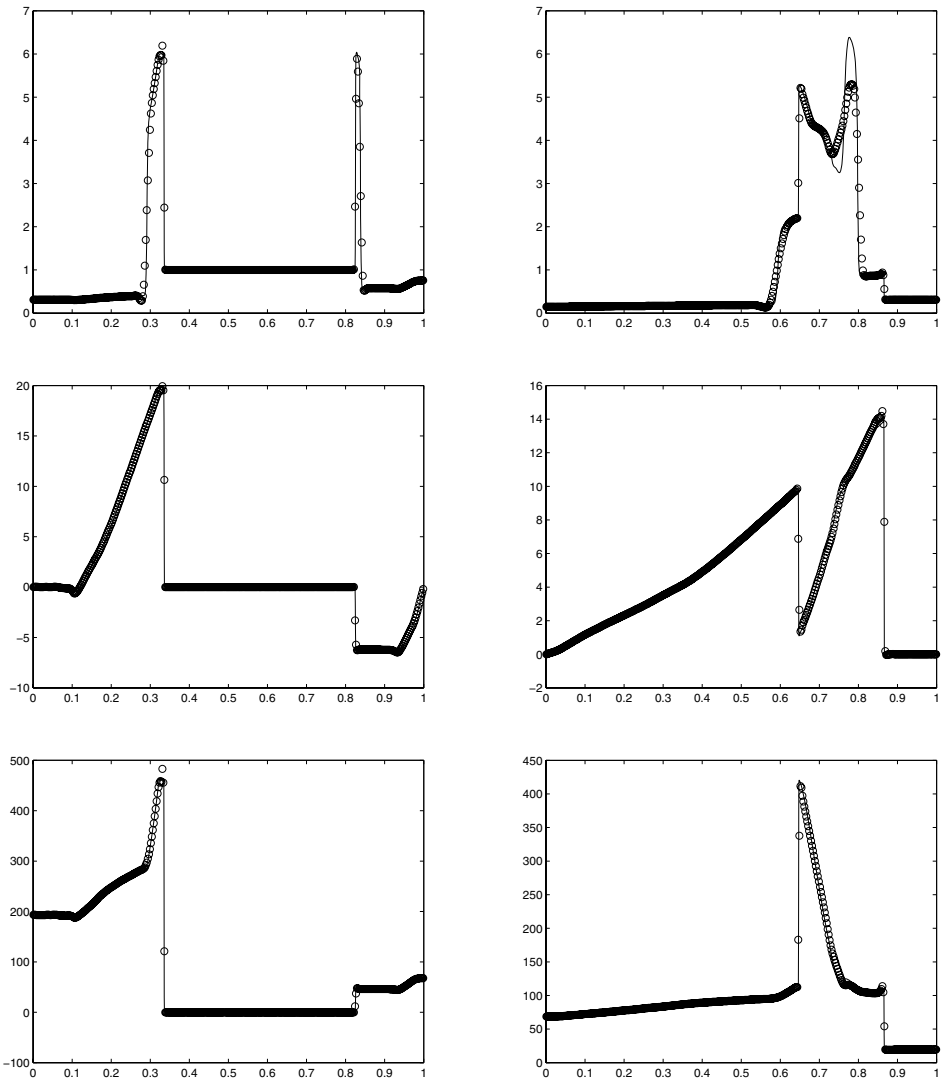

FIG. 5. *Woodward and Colella blast wave problem computed by CO-DG-hr*1*e*-3, $\Delta x = 1/400$. *Top: density; middle: velocity; bottom: pressure. Left:* $T = 0.01$. *Right:* $T = 0.038$.

Example 7. Shu–Osher problem [46]. It is the Euler equation with an initial data

$$(\rho, v, p) = (3.857143,\ 2.629369,\ 10.333333) \quad \text{for } x < -4,$$
$$(\rho, v, p) = (1 + 0.2\sin(5x),\ 0,\ 1) \quad \text{for } x \geq -4.$$

The density profiles are plotted at $T = 1.8$, with $\Delta x = 1/40$; see Figure 6. $\Delta\tau^n$ is chosen with a CFL factor 0.5, $\Delta t^n = 0.5\Delta\tau^n$. The solid line is the numerical solution on a fine mesh ($\Delta x = 1/200$) computed by a central scheme on overlapping cells [38]. We observe very good resolution for this example. In order to see the resolution of the 2D nonoscillatory hierarchical reconstruction algorithm, we put the Shu–Osher problem to a 2D domain $[-5, 5] \times [0, 0.25]$ and solve the 2D Euler equation. Initially

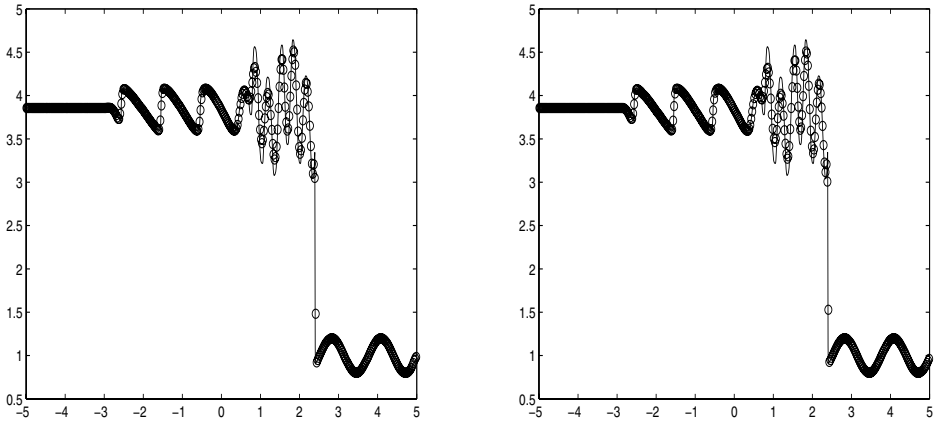

FIG. 6. *Shu–Osher problem,* $\Delta x = 1/40$. *Left: CO-DG-dr*1*m*-3. *Right: CO-DG-hr*1*e*-3.

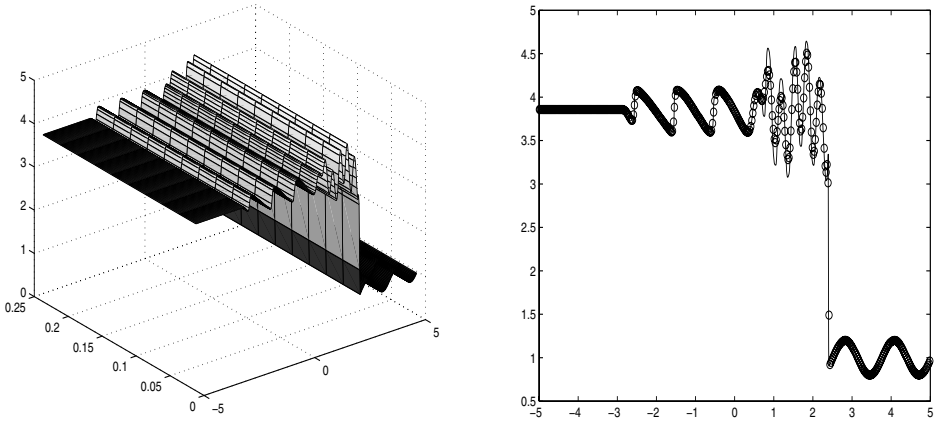

FIG. 7. *Shu–Osher problem in two dimensions,* $\Delta x = \Delta y = 1/40$. *CO-DG-hr*1*e*-3. *Left: density in the xy plane. Right: density along the line* $y = 0.25/3$.

the density variation is only along the x direction. The density profiles at $T = 1.8$ are plotted in Figure 7.

Example 8. 2D Riemann problem [29] for the Euler equation computed by CO-DG-hr1e-3. The 2D Euler equation can be written as

$$\mathbf{u}_t + \mathbf{f}(\mathbf{u})_x + \mathbf{g}(\mathbf{u})_y = 0, \quad \mathbf{u} = (\rho, \rho u, \rho v, E)^T, \quad p = (\gamma - 1)(E - \tfrac{1}{2}\rho(u^2 + v^2)),$$
$$\mathbf{f}(\mathbf{u}) = (\rho u, \rho u^2 + p, \rho uv, u(E + p))^T, \quad \mathbf{g}(\mathbf{u}) = (\rho v, \rho uv, \rho v^2 + p, v(E + p))^T,$$

where $\gamma = 1.4$. The computational domain is $[0, 1] \times [0, 1]$. The initial states are constants within each of the 4 quadrants. Counterclockwise from the upper right quadrant, they are labeled (ρ_i, u_i, v_i, p_i), $i = 1, 2, 3, 4$. Initially, $\rho_1 = 1.1$, $u_1 = 0$, $v_1 = 0$, $p_1 = 1.1$; $\rho_2 = 0.5065$, $u_2 = 0.8939$, $v_2 = 0$, $p_2 = 0.35$; $\rho_3 = 1.1$, $u_3 = 0.8939$, $v_3 = 0.8939$, $p_3 = 1.1$; and $\rho_4 = 0.5065$, $u_4 = 0$, $v_4 = 0.8939$, $p_4 = 0.35$. The density

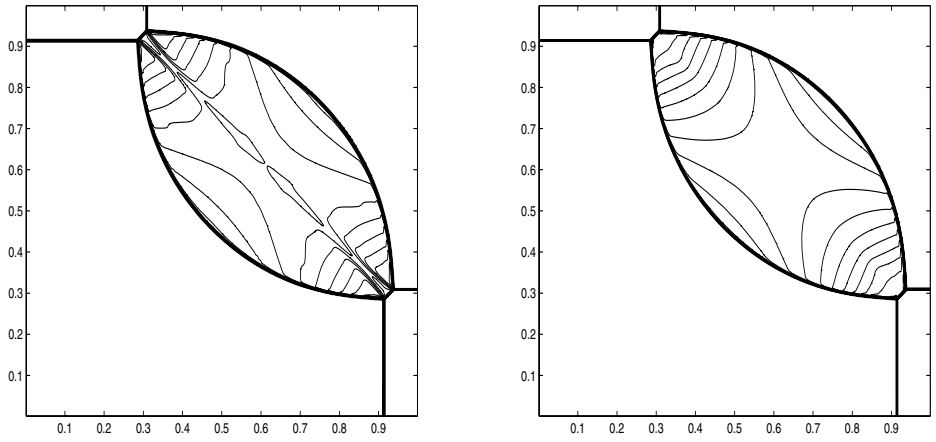

FIG. 8. *A 2D Riemann problem* [29] *computed by CO-DG-hr1e-3.* $\Delta x = \Delta y = 1/400$*, Left: density. Right: pressure.*

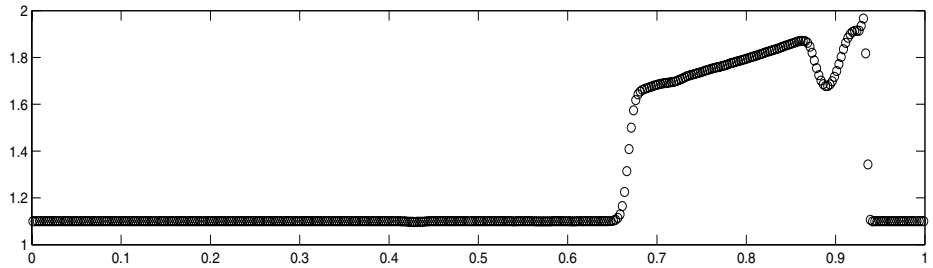

FIG. 9. *A 2D Riemann problem* [29]. *Density profile along* $y = 1/3$.

and pressure profiles are plotted at $T = 0.25$ in Figure 8, with 30 equally spaced contours. The numerical resolution is quite good for this problem. The density profile along $y = 1/3$ is plotted in Figure 9. There is no oscillation near the discontinuities.

Example 9. Double Mach reflection [50] computed by CO-DG-hr1e-3. A planar Mach 10 shock is incident on an oblique wedge at a $\pi/3$ angle. The air in front of the shock has density 1.4, pressure 1, and velocity 0. The boundary condition is described in [50]. The density and pressure profiles are plotted at $T = 0.2$ in Figure 10, with 30 equally spaced contours. $\Delta x = \Delta y = 1/120$, $\Delta\tau^n$ chosen with a CFL factor 0.4, $\Delta t^n = 0.99\Delta\tau^n$. We can see in the lower graph (the cross section density profile along $y = 1/3$) that the computed result is nonoscillatory.

6. Concluding remarks and a plan for future work. In this paper we have developed a central DG method based on staggered overlapping cells, with a numerical viscosity which stays bounded when the time step size goes to zero. Time discretization is via the standard TVD Runge–Kutta method. We have also developed a multilayer hierarchical reconstruction procedure and used it as a limiter for our central DG scheme. The limiter is able to maintain the original order of accuracy and can effectively control spurious oscillations for discontinuous solutions. In future

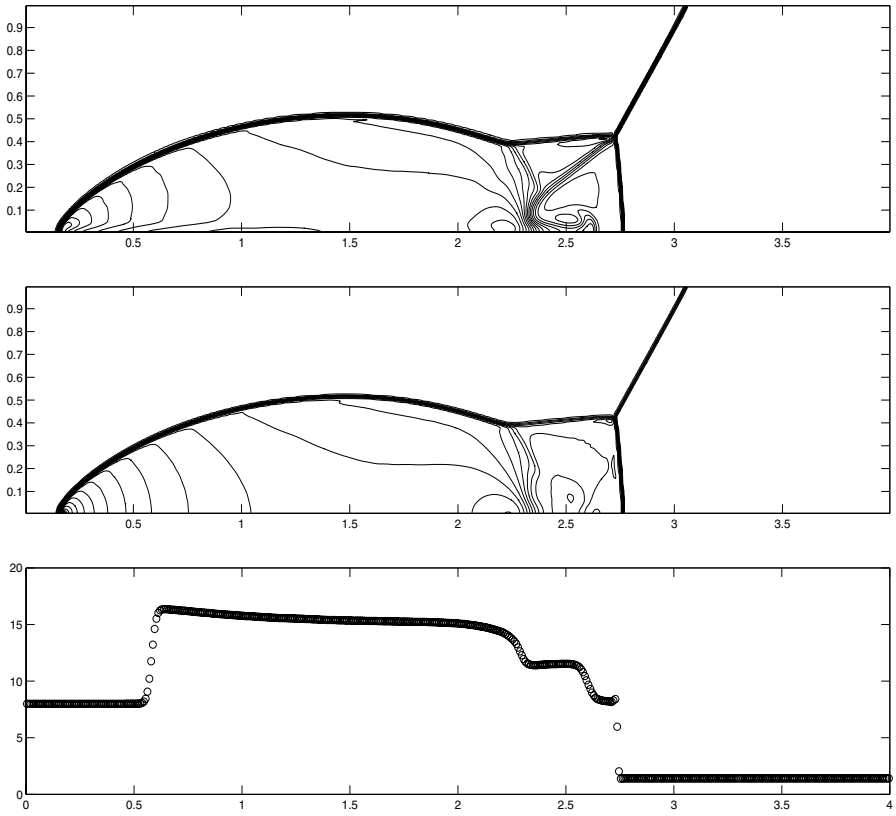

FIG. 10. *Double Mach reflection computed by CO-DG-hr*1*e*-3, $\Delta x = \Delta y = 1/120$. *Top: density contours. Middle: pressure contours. Bottom: density cut along the line* $y = 1/3$.

work we will generalize the method to convection-diffusion equations, improve the limiter by applying troubled-cell indicators, and also study further the hierarchical reconstruction procedure as a limiter for the regular DG methods and finite volume schemes. A stability analysis and error estimates for the central DG scheme as well as a comparison between the regular DG and central DG schemes will also be performed.

The examples reported in the paper are aimed to show the flexibility of the new approach to use with a Runge–Kutta method, and its capability to handle small time steps, without introducing excessive numerical dissipation. The more efficient way to overcome the small time step restriction with the presence of a diffusion term is to use implicit-explicit time discretization, e.g., Ascher, Ruuth, and Spiteri [4], Kennedy and Carpenter [24], and Liotta, Romano, and Russo [33], which treats the advection part explicitly and the diffusion part implicitly, thus avoiding the $O(\Delta x^2)$ stability restriction on the time step due to the diffusion term; another way would be to use a fast explicit Runge–Kutta solver, e.g., Lebedev [30] or Medovikov [39].

Even though in all the numerical examples the reconstruction is performed componentwisely, we have also performed some preliminary tests on the nonoscillatory hierarchical reconstruction with local characteristic decomposition and have not found any significant difference. We plan to conduct more careful study on this subject in the future.

MONOTONIC PARAREAL CONTROL FOR QUANTUM SYSTEMS*

YVON MADAY†, JULIEN SALOMON‡, AND GABRIEL TURINICI§

Abstract. Following encouraging experimental results in quantum control, numerical simulations have known significant improvements through the introduction of efficient optimization algorithms. Yet, the computational cost still prevents using these procedures for high-dimensional systems often present in quantum chemistry. Using parareal framework, we present here a time parallelization of these schemes which allows us to reduce significantly their computational cost while still finding convenient controls.

Key words. quantum control, monotonic schemes, optimal control, parareal scheme, time parallelization

1. Introduction.

In the last decade, quantum control has witnessed significant developments including encouraging experimental results [5, 6, 9, 15, 16, 23, 24, 29, 36]. At the computational level [7, 25], the introduction of the monotonic algorithms of Krotov (by Tannor [31]), Zhu and Rabitz [37], or the unified form of Maday and Turinici [21] allows us to design efficient methods to obtain laser fields controlling the molecular dynamics. On the other hand, parareal scheme (that stands for parallelization in real time) has shown a convenient efficiency in the case of the Schrödinger equation; see, e.g., [2, 33]. In what follows, we combine these two approaches by using monotonic algorithms as the inner loop of a time-parallelization procedure.

Let us first briefly present the model and the corresponding optimal control framework used in this paper. Consider a quantum system described by its wavefunction $\psi(x,t)$, also called *state* in what follows. Here "x" $\in \Omega$ denotes the relevant spatial coordinates (the symbol x will often be omitted in what follows for reason of simplicity). The operator $V(x)$ is the potential part. The dynamics of this system is characterized by its internal Hamiltonian:

$$H(x) = H_0 + V(x).$$

In this equation H_0, the kinetic part, could be

$$H_0 = -\frac{1}{2}\sum_{n=1}^{p}\frac{1}{m_n}\Delta_{r_n},$$

where p is the number of particles considered, m_n their masses, and Δ_{r_n} the Laplace operator with respect to their coordinates.

§CEREMADE, Université Paris Dauphine, Pl. du Maréchal Lattre de Tassigny, 75775 Paris Cedex 16, France (gabriel.turinici@dauphine.fr).

A way to control such a system is to light it with a laser pulse. We denote by $\varepsilon(t)$ the intensity of this control field. The contribution of this parameter is taken into account by introducing a perturbative term in the Hamiltonian which then reads $H(x) - \mu(x)\varepsilon(t)$. The evolution of $\psi^\varepsilon(x,t)$ is governed by the Schrödinger equation (we work in atomic units, i.e., $\hbar = 1$):

$$\left\{ \begin{array}{rcl} i\frac{\partial}{\partial t}\psi^\varepsilon(x,t) & = & (H(x) - \mu(x)\varepsilon(t))\psi^\varepsilon(x,t), \\ \psi^\varepsilon(x,0) & = & \psi_{init}(x), \end{array} \right. \tag{1.1}$$

where ψ_{init} is the initial condition for ψ^ε subject to the constraint:

$$\|\psi_{init}\|_{L^2(\Omega)} = 1.$$

Since H is self-adjoint, from (1.1) the norm of the state is constant with respect to the time. In the numerical simulations, the ground state, i.e., a unitary eigenvector of H associated with the lowest eigenvalue, is generally taken as initial condition.

The optimal control framework can then be applied to this bilinear control system to design relevant control fields. The quality of the pulse is evaluated via a cost functional. A general example of such a function is

$$J(\varepsilon) = \|\psi^\varepsilon(T) - \psi_{target}\|^2_{L^2(\Omega)} + \int_0^T \alpha(t)\varepsilon^2(t)dt, \tag{1.2}$$

where T is the total time of control, α a positive function, and ψ_{target} a target state which has to be reached.

At the minimum of the cost functional J, the Euler–Lagrange critical point equations are satisfied; a standard way to write these equations is to use a Lagrange multiplier $\chi^\varepsilon(x,t)$ called *adjoint state*. The following critical point equations are thus obtained [37]:

$$\left\{ \begin{array}{l} i\frac{\partial}{\partial t}\psi^\varepsilon(x,t) = (H(x) - \varepsilon(t)\mu(x))\psi^\varepsilon(x,t), \\ \psi^\varepsilon(x,0) = \psi_{init}(x), \end{array} \right. \tag{1.3}$$

$$\left\{ \begin{array}{l} i\frac{\partial}{\partial t}\chi^\varepsilon(x,t) = (H(x) - \varepsilon(t)\mu(x))\chi^\varepsilon(x,t), \\ \chi^\varepsilon(x,T) = \psi_{target}(x), \end{array} \right. \tag{1.4}$$

$$\alpha(t)\varepsilon(t) = -Im\langle\chi^\varepsilon(t)|\mu|\psi^\varepsilon(t)\rangle, \tag{1.5}$$

where A is an operator on $L^2(\Omega)$ and $\langle f|A|g\rangle = \int_\Omega \overline{f(x)}A(g)(x)dx$.

Numerous optimization procedures exist to compute iteratively sequences $(\varepsilon^k)_{k\in\mathbf{N}}$ that approximate the solution of (1.3)–(1.5). The common feature of these algorithms is that they involve repeated resolutions of Schrödinger equations (1.3) and (1.4), which induce a heavy computational time cost. Depending on their order, the mere computation of ε^k can also be time consuming due to the high nonlinearity of the cost functional. In order to reduce the computation time, some time parallelization of the resolution of (1.3)–(1.5) can be done. A standard method consists of subdividing the interval $[0,T]$ into subintervals and to compute iteratively the corresponding adequate initial conditions for parallel resolution on each subinterval. This approach is also the base of the multiple shooting methods (see [22, sect. 17.1] and, e.g., [8]). In [10] a comparison between these methods shows that the parareal algorithms can be recast as a multiple shooting algorithm where the Jacobian matrix is approached by a finite difference method on a coarse grid.

Another body of related literature was introduced in the pioneering works of Hackbush; see [11, 12] and also [14, 19, 35]. The parareal method corresponds to a two-level multigrid with a larger coarsening rate and an unusual smoother which corresponds to a single phase of a bicolor relaxation scheme.

Such time parallelization procedures have already been associated to optimization procedures to tackle control problems, e.g., in the case of ordinary differential equations [13], or linear control of hyperbolic [17], or parabolic evolution equations [4, 34]. On the contrary, we present here a new method to treat the bilinear optimal control of the Schrödinger equation (1.1), and consider a particular decomposition of J in sub-cost functionals corresponding to the time subdivision. In this framework, an iterative optimization procedure is designed that converges to a critical point of J.

The paper is organized as follows: parareal optimal control settings corresponding to our quantum control problem is presented in section 2. In section 3, we give an algorithm achieving a parallel in time optimization. We prove the convergence of this procedure towards a critical point of a discrete version of the cost functional J in section 4 and we finally give some numerical results in section 5.

2. Parareal control setting. Throughout this section the control field ε is either a function of $L^2([0,T])$ or its corresponding time discretization.

2.1. Main features of the parallelization. Following Lions, Maday, and Turinici [18], we now introduce the necessary concepts and tools involved in the time parallelization proposed by the parareal approach.

2.1.1. Subdivision of $[0,T]$ and virtual controls. Let $N \geq 1$ be an integer. In order to design the time parallelized optimization procedure, we introduce a subdivision of $[0,T]$:

$$[0,T] = \bigcup_{\ell=0}^{N-1} [T_\ell, T_{\ell+1}],$$

with $T_0 = 0$ and $T_N = T$. Consider also a set $\Lambda = (\lambda_\ell)_{\ell=1,\dots,N-1} \in \left(L^2(\Omega)\right)^{N-1}$. In what follows, Λ will be called the set of *virtual controls*. For notational simplicity, we will also denote by λ_0 the initial state ψ_{init} and by λ_N the target state ψ_{target}. The resolution of (1.1) is now substituted by the resolution of the N problems:

$$\left\{ \begin{array}{rcl} i\frac{\partial}{\partial t}\psi_\ell^{\varepsilon_\ell}(x,t) & = & (H(x) - \varepsilon_\ell(t)\mu(x))\psi_\ell^{\varepsilon_\ell}(x,t), \\ \psi_\ell^{\varepsilon_\ell}(x,T_\ell) & = & \lambda_\ell(x), \quad \ell = 0,\dots,N-1, \end{array} \right. \tag{2.1}$$

where ε_ℓ is the restriction of ε to $[T_\ell, T_{\ell+1}]$ (with $\ell = 0,\dots,N-1$). By (2.1), $\psi_\ell^{\varepsilon_\ell}$ also depends on λ_ℓ. In order to simplify the notations, we omit this dependence. The solution of (2.1) coincides to that of (1.1) if and only if

$$\forall \ell = 0,\dots,N-1, \qquad \psi_\ell^{\varepsilon_\ell}(x,T_{\ell+1}) = \lambda_{\ell+1}(x). \tag{2.2}$$

The parareal framework provides different methods to iteratively compute a solution Λ^* of (2.1)–(2.2).

2.1.2. Coarse and fine propagators. Suppose that the numerical simulation of (1.1) can be realized both by a coarse propagator and a fine propagator. Because the use of the coarse propagator is considered to be cheap, it can be used for the

resolution of (1.1) over the whole interval of control $[0, T]$. On the contrary, the fine propagator will only be used for parallel resolutions on $[T_\ell, T_{\ell+1}]$.

The analysis of the algorithm presented below requires that the L^2-norm of the finely approximated solution be constant with respect to the time (as is the case for the exact solution of (1.1)). Because of its numerical accuracy, we choose to consider the Strang-second-order split-operator solver [3, 30], that fulfills this property. Let us present it in some detail.

Consider two parameters of the time discretization n and $\delta t = \frac{T}{n}$, and define $n_0 = 0 < n_1 < \cdots < n_\ell < \cdots < n_N = n$, the time indexes associated with $(T_\ell)_{\ell=0,\ldots,N}$. Let us also introduce, for $\ell = 0, \ldots, N-1$, $j = n_\ell, \ldots, n_{\ell+1}-1$, the discretized control field $\varepsilon_{\ell,j}$ and for $\ell = 0, \ldots, N-1$, $j = n_\ell, \ldots, n_{\ell+1}$, the discretized state $\psi^{\varepsilon_\ell}_{\ell,j}$ that stand, respectively, for approximations of $\varepsilon_\ell(j\delta t)$ and $\psi^{\varepsilon_\ell}_\ell(j\delta t)$. The time discretization of (2.1) is given by

$$\left\{ \begin{array}{rcl} \psi^{\varepsilon_\ell}_{\ell,j+1} & = & e^{\frac{H_0\delta t}{2i}} e^{\frac{V-\mu\varepsilon_{\ell,j}}{i}\delta t} e^{\frac{H_0\delta t}{2i}} \psi^{\varepsilon_\ell}_{\ell,j}, \quad j = n_\ell, \ldots, n_{\ell+1}-1, \\ \psi^{\varepsilon_\ell}_{\ell,n_\ell} & = & \lambda_\ell, \quad \ell = 0, \ldots, N-1. \end{array} \right. \tag{2.3}$$

We refer the reader to [20] for additional details about the corresponding full discretization.

Remark 1. Though we focus on the Strang-second-order split-operator scheme, the methodology presented in this paper can be adapted to other time discretizations. Indeed, the analysis done below requires only that the norm of the wavefunction be preserved during the propagation.

2.1.3. Parareal strategy. Parareal algorithms aim at computing in parallel on each subinterval the solution of evolution equations such as (1.1). To do this, they propose various iterative methods to update the virtual controls after each parallel propagation. The purpose of what follows is to define an updated algorithm that allows one to couple the parareal approach with an optimization procedure of quantum control.

2.2. Parareal cost functionals. Let $\Lambda = (\lambda_\ell)_{\ell=1,\ldots,N-1}$ be a set of virtual controls and $(\psi^{\varepsilon_\ell}_\ell)_{\ell=0,\ldots,N-1}$ the corresponding time discretized solutions of the parallel propagations (2.3), with $\psi^{\varepsilon_\ell}_\ell = (\psi^{\varepsilon_\ell}_{\ell,j})_{j=n_\ell,\ldots,n_{\ell+1}}$. In order to design a formulation combining optimal control and parareal framework, let us also consider the following cost functional:

$$J_\parallel(\varepsilon, \Lambda) = \sum_{\ell=0}^{N-1} \beta_\ell \|\psi^{\varepsilon_\ell}_{\ell,n_{\ell+1}} - \lambda_{\ell+1}\|^2_{L^2(\Omega)} + \delta t \sum_{\ell=0}^{N-1} \sum_{j=n_\ell}^{n_{\ell+1}-1} \alpha_j \varepsilon^2_{\ell,j}, \tag{2.4}$$

where $\beta_\ell = \frac{n}{n_{\ell+1}-n_\ell}$ and α_j is an approximation $\alpha(j\delta t)$. This cost functional can be decomposed as follows:

$$J_\parallel(\varepsilon, \Lambda) = \sum_{\ell=0}^{N-1} \beta_\ell J_\ell(\varepsilon_\ell, \lambda_\ell, \lambda_{\ell+1}),$$

where J_ℓ are the *parareal cost functionals*:

$$J_\ell(\varepsilon_\ell, \lambda_\ell, \lambda_{\ell+1}) = \|\psi^{\varepsilon_\ell}_{\ell,n_{\ell+1}} - \lambda_{\ell+1}\|^2_{L^2(\Omega)} + \delta t \sum_{j=n_\ell}^{n_{\ell+1}-1} \alpha'_{\ell,j} \varepsilon^2_{\ell,j},$$

with:

$$\alpha'_{\ell,j} = \frac{\alpha_j}{\beta_\ell}. \tag{2.5}$$

Note that the optimization problems defined on $[T_\ell, T_{\ell+1}]$ via J_ℓ are similar to the initial control problem on $[0,T]$ corresponding to (1.2).

3. Monotonic parareal algorithm. Our aim is to optimize $J_\parallel(\varepsilon,\Lambda)$ with respect to its two variables. We first present the main features of our algorithm and then give further details on each step.

3.1. Structure of the algorithm. To couple parareal framework and the control optimization, we propose the following methodology: given $\nu > 0$, consider the termination criterion $c(\varepsilon) = J(\varepsilon) + \nu \sum_{\ell=0}^{N-2} |\varepsilon_{\ell,n_{\ell+1}-1} - \varepsilon_{\ell+1,n_{\ell+1}}|^2$. Given an initial control field ε^k and a tolerance $tol \geq 0$, the computation of ε^{k+1} is done as follows:

1. If $c(\varepsilon^k) \leq tol$, then stop.
2. Compute a coarse solution $\psi^k = \psi^{\varepsilon^k}$ of (1.3).
3. Compute a coarse solution $\chi^k = \chi^{\varepsilon^k}$ of (1.4).
4. Using ψ^k and χ^k, compute Λ^k, which optimizes $J_\parallel(\varepsilon^k,\Lambda)$ with respect to Λ.
5. On each interval $[T_\ell, T_{\ell+1}]$, compute in parallel some control field ε_ℓ^{k+1}, which optimizes the cost functionals $J_\ell(\varepsilon_\ell, \lambda_\ell^k, \lambda_{\ell+1}^k)$ with respect to ε_ℓ.
6. Define ε^{k+1} as the concatenation of the control fields ε_ℓ^{k+1}.
7. Assign $k \leftarrow k+1$. Return to step 1.

This algorithm is similar to an alternate direction descent algorithm, in the sense that it alternatively optimizes $J_\parallel(\varepsilon,\Lambda)$ with respect to Λ and to ε.

Of course, to take advantage of the time parallelization, steps 2 and 3 of the previous algorithm are to be computed using the coarse propagator, whereas step 5 can be done simultaneously and by fine propagations.

Remark 2. Solving (1.4) exploits in an essential manner the time-reversibility of the Schrödinger equation. Further work is required to extend this algorithm to nonreversible cases.

3.2. Virtual controls definition. We present in this section some results which will enable us to achieve efficiently step 4 of the monotonic parareal algorithm. As we do not intend to deal with the coarse propagator properties, we will consider in this section that steps 2 and 3 are done with the split-operator method presented in section 2.1.2, with the (small) time step δt. Even though this is not what we want to do ultimately, the results below keep a practical interest since the most expensive part of the algorithm is the update of the control field which will be done in parallel. Thus, given a control field $\varepsilon = (\varepsilon_j)_{j=0,\dots,n-1}$, the states $\psi^\varepsilon = (\psi_j^\varepsilon)_{j=0,\dots,n}$ and the adjoint states $\chi^\varepsilon = (\chi_j^\varepsilon)_{j=0,\dots,n}$ are computed by

$$\left\{ \begin{array}{rcl} \psi_{j+1}^\varepsilon & = & e^{\frac{H_0\delta t}{2i}} e^{\frac{V-\mu\varepsilon_j}{i}\delta t} e^{\frac{H_0\delta t}{2i}} \psi_j^\varepsilon, \\ \psi_0^\varepsilon & = & \psi_{init}, \end{array} \right. \tag{3.1}$$

$$\left\{ \begin{array}{rcl} \chi_{j-1}^\varepsilon & = & e^{-\frac{H_0\delta t}{2i}} e^{-\frac{V-\mu\varepsilon_{j-1}}{i}\delta t} e^{-\frac{H_0\delta t}{2i}} \chi_j^\varepsilon, \\ \chi_n^\varepsilon & = & \psi_{target}. \end{array} \right. \tag{3.2}$$

For reasons of simplicity, we use in what follows the following notation:

$$\mathcal{F}_{j,j'}^\varepsilon \psi_j^\varepsilon = \psi_{j'}^\varepsilon,$$

where $0 \le j, j' \le n$ are two (time) indices, and $\psi^\varepsilon = (\psi_j^\varepsilon)_{j=0,\dots,n}$ is the solution of (3.1). We still denote by J the time discretized cost functional corresponding to (1.2):

$$J(\varepsilon) = \|\psi_n^\varepsilon - \psi_{target}\|^2_{L^2(\Omega)} + \delta t \sum_{j=0}^{n-1} \alpha_j \varepsilon_j^2. \tag{3.3}$$

The following theorem provides the optimal choice of virtual controls Λ.

THEOREM 3.1. *With the previous notations, let us define* $\Lambda^\varepsilon = (\lambda_\ell^\varepsilon)_{\ell=1,\dots,N-1}$ *by*

$$\lambda_\ell^\varepsilon = (1-\gamma_\ell)\psi_{n_\ell}^\varepsilon + \gamma_\ell \chi_{n_\ell}^\varepsilon, \tag{3.4}$$

where $\gamma_\ell = \frac{n_\ell}{n}$. *Then*

$$\Lambda^\varepsilon = \operatorname{argmin}_\Lambda (J_\parallel(\varepsilon, \Lambda)). \tag{3.5}$$

Moreover, we have

$$J_\parallel(\varepsilon, \Lambda^\varepsilon) = J(\varepsilon).$$

Proof. For a given $\Lambda = (\lambda_\ell)_{\ell=1,\dots,N-1}$, let us first prove that $J(\varepsilon)$ is a lower bound for $J_\parallel(\varepsilon, \Lambda)$. The Cauchy–Schwarz inequality gives

$$\sum_{\ell=0}^{N-1} \beta_\ell \|\psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}\|^2_{L^2(\Omega)} = \left(\sum_{\ell=0}^{N-1} \frac{1}{\beta_\ell}\right) \sum_{\ell=0}^{N-1} \beta_\ell \|\psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}\|^2_{L^2(\Omega)} \tag{3.6}$$

$$\ge \left(\sum_{\ell=0}^{N-1} \|\psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}\|_{L^2(\Omega)}\right)^2. \tag{3.7}$$

Recalling that $\mathcal{F}^\varepsilon$ is a unitary operator, we have

$\forall \ell = 1, \dots, N-1,$

$$\begin{aligned} \|\psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}\|_{L^2(\Omega)} &= \|\mathcal{F}^\varepsilon_{n_\ell,n_{\ell+1}}(\lambda_\ell) - \lambda_{\ell+1}\|_{L^2(\Omega)} \\ &= \big\|\mathcal{F}^\varepsilon_{n_{\ell+1},n}\big(\mathcal{F}^\varepsilon_{n_\ell,n_{\ell+1}}(\lambda_\ell) - \lambda_{\ell+1}\big)\big\|_{L^2(\Omega)} \\ &= \|\mathcal{F}^\varepsilon_{n_\ell,n}(\lambda_\ell) - \mathcal{F}^\varepsilon_{n_{\ell+1},n}(\lambda_{\ell+1})\|_{L^2(\Omega)}. \end{aligned} \tag{3.8}$$

Hence

$$\begin{aligned} \sum_{\ell=0}^{N-1} \|\psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}\|_{L^2(\Omega)} &= \sum_{\ell=0}^{N-1} \|\mathcal{F}^\varepsilon_{n_\ell,n}(\lambda_\ell) - \mathcal{F}^\varepsilon_{n_{\ell+1},n}(\lambda_{\ell+1})\|_{L^2(\Omega)} \\ &\ge \|\mathcal{F}^\varepsilon_{0,n}(\psi_{init}) - \psi_{target}\|_{L^2(\Omega)}. \end{aligned} \tag{3.9}$$

Combining (3.9) and (3.6) we obtain, since $\mathcal{F}^\varepsilon_{0,n}(\psi_{init}) = \psi_n^\varepsilon$,

$$J_\parallel(\varepsilon, \Lambda) \ge J(\varepsilon).$$

By (3.4), we have

$$\begin{aligned} \psi_{\ell,n_{\ell+1}}^{\varepsilon_\ell} - \lambda_{\ell+1}^\varepsilon &= \mathcal{F}^\varepsilon_{n_\ell,n_{\ell+1}}(\lambda_\ell^\varepsilon) - \lambda_{\ell+1}^\varepsilon \\ &= \mathcal{F}^\varepsilon_{n_\ell,n_{\ell+1}}\big((1-\gamma_\ell)\psi_{n_\ell}^\varepsilon + \gamma_\ell \chi_{n_\ell}^\varepsilon\big) - \big((1-\gamma_{l+1})\psi_{n_{\ell+1}}^\varepsilon + \gamma_{\ell+1}\chi_{n_{\ell+1}}^\varepsilon\big) \\ &= (\gamma_{\ell+1} - \gamma_\ell)\big(\psi_{n_{\ell+1}}^\varepsilon - \chi_{n_{\ell+1}}^\varepsilon\big). \end{aligned} \tag{3.10}$$

Hence,

$$\|\psi^{\varepsilon_\ell}_{\ell,n_{\ell+1}} - \lambda^{\varepsilon}_{\ell+1}\|_{L^2(\Omega)} = \frac{1}{\beta_\ell}\|\psi^{\varepsilon}_n - \psi_{target}\|_{L^2(\Omega)}.$$

Combining this equality with (2.4), we obtain the following:

$$\begin{aligned} J_{\|}(\varepsilon,\Lambda^\varepsilon) &= \sum_{\ell=0}^{N-1}\frac{1}{\beta_\ell}\|\psi^\varepsilon_n - \psi_{target}\|^2_{L^2(\Omega)} + \delta t\sum_{\ell=0}^{N-1}\sum_{j=n_\ell}^{n_{\ell+1}-1}\alpha_j\varepsilon^2_{\ell,j}, \\ &= \|\psi^\varepsilon_n - \psi_{target}\|^2_{L^2(\Omega)} + \delta t\sum_{\ell=0}^{N-1}\sum_{j=n_\ell}^{n_{\ell+1}-1}\alpha_j\varepsilon^2_{\ell,j}, \end{aligned} \tag{3.11}$$

and the theorem follows. ∎

Remark 3. The trajectory $\left((1-\frac{j}{N})\psi^\varepsilon_j + \frac{j}{N}\chi^\varepsilon_j\right)_{j=0,\dots,n}$ is an ideal trajectory that reaches exactly the target ψ_{target}. The choice $\Lambda = \Lambda^\varepsilon$ is equivalent to define the virtual controls on this trajectory. This interpretation is closely related to the concept of reference trajectory tracking: through the introduction of the parareal cost functionals, the initial problem is transformed into $N-1$ optimization problems that aim to minimize on each subinterval the distance between the current trajectory and this ideal (unknown) trajectory.

Remark 4. An alternative definition for Λ can be

$$\lambda_\ell = \frac{(1-\gamma_\ell)\psi^\varepsilon_{n_\ell} + \gamma_\ell\chi^\varepsilon_{n_\ell}}{\|(1-\gamma_\ell)\psi^\varepsilon_{n_\ell} + \gamma_\ell\chi^\varepsilon_{n_\ell}\|_{L^2(\Omega)}}, \tag{3.12}$$

which has the advantage that the norms of the virtual controls are preserved. Furthermore, it can be proved that λ corresponds to a critical point of $J_{\|}(\varepsilon,\Lambda)$ under the constraint

$$\forall \ell = 1,\dots,N-1, \quad \|\lambda_\ell\|_{L^2(\Omega)} = 1.$$

3.3. Monotonic schemes. Let us now describe a practical implementation of step 5 of the monotonic parareal algorithm. Given a set of virtual controls $\Lambda = (\lambda_\ell)_{\ell=1,\dots,N-1}$ (recall that $\lambda_0 = \psi_0$ and $\lambda_N = \psi_{target}$), the parareal cost functional J_ℓ reads

$$\begin{aligned} J_\ell(\varepsilon_\ell,\lambda_\ell,\lambda_{\ell+1}) &= \|\lambda_\ell\|^2_{L^2(\Omega)} + \|\lambda_{\ell+1}\|^2_{L^2(\Omega)} - 2Re\langle\psi_{\ell,n_{\ell+1}},\lambda_{\ell+1}\rangle \\ &\quad + \delta t\sum_{j=n_\ell}^{n_{\ell+1}-1}\alpha'_{\ell,j}\varepsilon^2_{\ell,j}, \quad \ell = 0,\dots,N-1. \end{aligned} \tag{3.13}$$

The first two terms of J_ℓ will not change during the optimization of ε. An efficient way to minimize cost functionals of the form $\widetilde{J}(\varepsilon) = -2Re\langle\psi(T),\psi_{target}\rangle + \int_0^T\alpha(t)\varepsilon^2(t)dt$ associated with the Schrödinger equation is to use monotonic schemes [21, 37].

In our case, the time discretized monotonic scheme corresponding to (3.13) can be defined by the following procedure.

Let us consider $(\delta,\eta) \in [0,2[\times[0,2[$ and introduce the notations

$$\widetilde{\chi}_{\ell,j} = e^{\frac{H_0\delta t}{2i}}\chi_{\ell,j}, \quad \breve{\psi}_{\ell,j} = e^{\frac{H_0\delta t}{2i}}\psi_{\ell,j}, \quad \breve{\chi}_{\ell,j} = e^{-\frac{H_0\delta t}{2i}}\chi_{\ell,j}, \quad \widetilde{\psi}_{\ell,j} = e^{-\frac{H_0\delta t}{2i}}\psi_{\ell,j},$$

and $\mu^*(h)$, an approximation of μ, defined by

$$\mu^*(h) = \frac{e^{-i\mu h\delta t} - Id}{-ih\delta t}, \tag{3.14}$$

where Id is the identity operator.

Given a control field ε^k, its restriction ε^k_ℓ to the interval $[T_\ell, T_{\ell+1}]$ and the corresponding $\psi^k_\ell = (\psi^k_{\ell,j})_{j=n_\ell,\dots,n_{\ell+1}}$ are defined iteratively by

$$\begin{cases} \psi^k_{\ell,j+1} &= e^{\frac{H_0\delta t}{2i}} e^{\frac{V-\mu\varepsilon^k_{\ell,j}}{i}\delta t} e^{\frac{H_0\delta t}{2i}} \psi^k_{\ell,j}, \quad j = n_\ell, \dots, n_{\ell+1}-1, \\ \psi^k_{\ell,n_\ell} &= \lambda_\ell, \quad \ell = 0, \dots, N-1. \end{cases} \tag{3.15}$$

The computation of ε^{k+1}_ℓ is performed as follows:

1. For $\ell = 0, \dots, N-1$, compute iteratively an intermediate control field $\widetilde{\varepsilon}^k_\ell$ and its corresponding adjoint state χ^k_ℓ by

$$\chi^k_{\ell,j} = e^{-\frac{H_0\delta t}{2i}} e^{\frac{-V+\mu\widetilde{\varepsilon}^k_{\ell,j}}{i}\delta t} e^{-\frac{H_0\delta t}{2i}} \chi^k_{\ell,j+1}, \quad j = n_\ell, \dots, n_{\ell+1}-1, \tag{3.16}$$

where $\widetilde{\varepsilon}^k_{\ell,j}$ is such that

$$\widetilde{\varepsilon}^k_{\ell,j} = (1-\eta)\varepsilon^k_{\ell,j} - \frac{\eta}{\alpha'_{\ell,j}} Im\langle \breve{\chi}^k_{\ell,j+1} | \mu^*(\varepsilon^k_{\ell,j} - \widetilde{\varepsilon}^k_{\ell,j}) | \widetilde{\psi}^k_{\ell,j+1} \rangle, \tag{3.17}$$

with the final condition

$$\chi^k_{\ell,n_{\ell+1}} = \lambda_{\ell+1}.$$

2. For $\ell = 0, \dots, N-1$, compute iteratively the control field ε^{k+1}_ℓ and its corresponding state ψ^{k+1}_ℓ by

$$\psi^{k+1}_{\ell,j+1} = e^{\frac{H_0\delta t}{2i}} e^{\frac{V-\mu\varepsilon^{k+1}_{\ell,j}}{i}\delta t} e^{\frac{H_0\delta t}{2i}} \psi^{k+1}_{\ell,j}, \quad j = n_\ell, \dots, n_{\ell+1}-1,$$

where $\varepsilon^{k+1}_{\ell,j}$ is such that

$$\varepsilon^{k+1}_{\ell,j} = (1-\delta)\widetilde{\varepsilon}^k_{\ell,j} - \frac{\delta}{\alpha'_{\ell,j}} Im\langle \widetilde{\chi}^k_j | \mu^*(\varepsilon^{k+1}_{\ell,j} - \widetilde{\varepsilon}^k_{\ell,j}) | \breve{\psi}^{k+1}_{\ell,j} \rangle, \tag{3.18}$$

with the initial condition

$$\psi^{k+1}_{\ell,n_\ell} = \lambda_\ell. \tag{3.19}$$

The implicit equations (3.17) and (3.18) are solved independently for $\widetilde{\varepsilon}^k_{\ell,j}$ and $\varepsilon^{k+1}_{\ell,j}$, respectively, at each time step by a Newton method (all other parameters involved are known). We refer the reader to [20] for a proof of the existence of solutions and further details on this scheme.

In what follows, the initial value ε^0 of the monotonic scheme is considered fixed. An important property of this algorithm is given in the following theorem [21].

THEOREM 3.2. *For any $\eta, \delta \in [0,2]$ the algorithm given in* (3.16)–(3.19) *is well defined and converges monotonically in the sense that*

$$\forall \ell = 0, \dots, N-1,$$

$$J_\ell(\varepsilon_\ell^{k+1}, \lambda_\ell, \lambda_{\ell+1}) - J_\ell(\varepsilon_\ell^{k}, \lambda_\ell, \lambda_{\ell+1}) = -\delta t \sum_{j=n_\ell}^{n_{\ell+1}-1} \alpha'_{\ell,j} (\varepsilon_{j,\ell}^{k+1} - \varepsilon_{j,\ell}^{k})^2 \leq 0. \tag{3.20}$$

This optimization procedure can be done in parallel on each interval $[T_\ell, T_{\ell+1}]$. Consequently, the computations can be carried out with fine propagators $\mathcal{F}^{\varepsilon_\ell^{k+1}}$.

Remark 5. As was the case for step 4 (see Remark 3), this step of the algorithm is also linked to the concept of reference trajectory tracking: in the monotonic schemes, the control field $\widetilde{\varepsilon}_{\ell,j1}^{k}$ (resp., $\varepsilon_{\ell,j}^{k+1}$) is chosen such that the distance between the current states and adjoint state $\|\psi_{\ell,j}^{k} - \chi_{\ell,j}^{k}\|_{L^2(\Omega)}$ (resp., $\|\psi_{\ell,j+1}^{k+1} - \chi_{\ell,j+1}^{k}\|_{L^2(\Omega)}$) decreases at each time step. We refer the reader to [28, 32] for details about the relationship between the monotonic schemes and local tracking algorithms.

Remark 6. Note that several iterations of this scheme can be done during step 5 of the monotonic parareal algorithm, especially in case of slow convergence (see Table 5.1 in section 5.4 for numerical results about it).

The algorithm is schematically depicted in Figure 3.1.

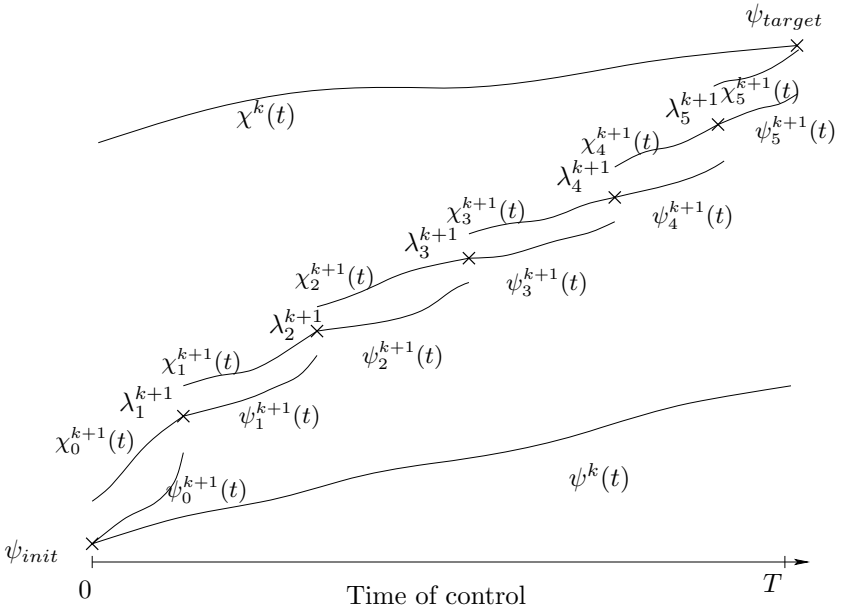

FIG. 3.1. *Symbolic representation of one iteration of the monotonic parareal algorithm. The optimization is achieved in parallel on each subinterval $[T_\ell, T_{\ell+1}]$. The virtual controls λ_ℓ^k are updated at each iteration.*

3.4. Monotonicity of the algorithm. The combination of the two previous strategies allows us to define

$$\Lambda^k = \Lambda^{\varepsilon^k}$$

and ε^{k+1} as the concatenation of the sequence $(\varepsilon_\ell^{k+1})_{\ell=0,\dots,N-1}$. We have thus obtained a global monotonic algorithm since

$$J(\varepsilon^{k+1}) = J_\parallel(\varepsilon^{k+1}, \Lambda^{k+1}) \leq J_\parallel(\varepsilon^{k+1}, \Lambda^k) \leq J_\parallel(\varepsilon^k, \Lambda^k) = J(\varepsilon^k).$$

4. Convergence of the algorithm. The convergence of the sequence $(\varepsilon^k)_{k\in\mathbf{N}}$ defined by the previous algorithm is described in the next theorem.

THEOREM 4.1. *Given an initial control field ε^0, consider the sequence $(\varepsilon^k)_{k\in\mathbf{N}}$ obtained by the algorithm (3.16)–(3.19), where the coarse propagator in steps 2–3 is taken to be the same as the fine propagator. The sequence $(\varepsilon^k)_{k\in\mathbf{N}}$ converges towards a critical point of J.*

Proof. Since the proof is very similar to that presented in [26], we give only a brief overview.

Denote by C_J the set of critical points of J. Using the previous notations, this set reads

$$C_J = \left\{\varepsilon /\ \forall j = 0,\dots,N-1,\ Im\langle\widetilde{\chi}_j^\varepsilon|\mu|\breve{\psi}_j^\varepsilon\rangle + \alpha_j\varepsilon_j = 0\right\}. \tag{4.1}$$

Let C_{ε^0} be the set of limit points of $(\varepsilon^k)_{k\in\mathbf{N}}$.

Since $\|\lambda_0^k\|_{L^2(\Omega)} = \|\lambda_N^k\|_{L^2(\Omega)} = 1$, (3.4) implies that

$$\forall \ell = 0,\dots,N, \quad \|\lambda_\ell^k\|_{L^2(\Omega)} \leq 1.$$

It can then be proved by induction that (see [20, Theorem 3])

$$\forall k \in \mathbf{N}, \quad \forall j = 0,\dots,n-1, \quad |\varepsilon_j^k| \leq M, \tag{4.2}$$

with

$$M = \max\left(\|\varepsilon^0\|_\infty, \max\left(1, \frac{\delta}{2-\delta}, \frac{\eta}{2-\eta}\right)\frac{\|\mu\|_*}{\min_{j=1,\dots,n-1}(\alpha_j)}\right), \tag{4.3}$$

where $\|\mu\|_*$ denotes the operator norm of μ and $\|\varepsilon^0\|_\infty = \max_{j=0,\dots,n-1}(|\varepsilon_j^0|)$. Consider now a converging subsequence $(\varepsilon^{k_p})_{p\in\mathbf{N}}$ and its limit $\varepsilon^\infty \in C_{\varepsilon^0}$. The corresponding state $\psi^{\varepsilon^{k_p}} = \psi^{k_p}$ and adjoint state $\chi^{\varepsilon^{k_p}} = \chi^{k_p}$ defined by (3.1) and (3.2) converge, respectively, towards $\psi^{\varepsilon^\infty}$ and $\chi^{\varepsilon^\infty}$. By (3.4), the sequence $(\Lambda_p^k)_{p\in\mathbf{N}}$ converges towards $\Lambda^{\varepsilon^\infty}$. Then, a similar proof indicates that $(\psi_\ell^{k_p})_{p\in\mathbf{N}}$ and $(\chi_\ell^{k_p})_{p\in\mathbf{N}}$ converge towards $\psi_\ell^{\varepsilon^\infty}$ and $\chi_\ell^{\varepsilon^\infty}$. Thanks to the similar structures of J_ℓ and J, one can adapt the proof of Lemma 3.3 in [26] which shows that

$$\forall \ell = 0,\dots,N-1, \quad \forall j = n_\ell,\dots,n_{\ell+1}-1, \quad Im\langle\widetilde{\chi}_{\ell,j}^{\varepsilon^\infty}|\mu|\breve{\psi}_{\ell,j}^{\varepsilon^\infty}\rangle + \alpha'_{\ell,j}\varepsilon_{\ell,j}^\infty = 0. \tag{4.4}$$

Another use of (3.4) proves that

$$\forall \ell = 0,\dots,N-1, \quad \forall j = n_\ell,\dots,n_{\ell+1}-1, \quad \frac{1}{\beta_\ell} Im\langle\widetilde{\chi}_{\ell,j}^{\varepsilon^\infty}|\mu|\breve{\psi}_{\ell,j}^{\varepsilon^\infty}\rangle = Im\langle\widetilde{\chi}_j^{\varepsilon^\infty}|\mu|\breve{\psi}_j^{\varepsilon^\infty}\rangle. \tag{4.5}$$

Combining (4.4) and (4.5) with (2.5), we obtain that

$$C_{\varepsilon^0} \subset C_J. \tag{4.6}$$

Since $(J(\varepsilon^k))_{k\in\mathbf{N}}$ is a bounded (by $2 + \max_{j=0,\dots,n-1}(\alpha_j)TM$) monotonic sequence, it converges towards a limit denoted by l_{ε^0}.

We are now in the position to reproduce the analysis in Theorem 4.5 of [26] which shows that

$$\exists \theta \in \left]0, \frac{1}{2}\right], \exists \kappa > 0, \exists k_0 \in \mathbf{N} / \ \forall k \geq k_0,$$
$$(l_{\varepsilon^0} - J(\varepsilon^k))^\theta - (l_{\varepsilon^0} - J(\varepsilon^{k+1}))^\theta \geq \kappa \|\varepsilon^{k+1} - \varepsilon^k\|_2, \tag{4.7}$$

where $\|.\|_2$ denotes the usual Euclidean norm on $\mathbf{R}^n$. Hence, the sequence $(\varepsilon^k)_{k\in\mathbf{N}}$ is a Cauchy sequence and by (4.6) the theorem follows. □

5. Numerical results.

5.1. Model. In order to test the performance of the algorithm, a case already treated in the literature has been considered. The system is a molecule of HCN modelled as a rigid rotator. We refer the reader to [1, 27] for numerical details concerning this system. The goal is to control the orientation of the system; this is expressed through the requirement that $\|\psi(T) - \psi_{target}\|_{L^2(\Omega)}$ is minimized, where the target function ψ_{target} corresponds to an orientated state.

5.2. Propagators. All the propagations are done through a Strang-second-order split-operator type as, e.g., in (3.15). The coarse propagator, corresponding to (3.1) and (3.2), is used with a large time step, whereas the fine propagator, as it appears in (3.18) and (3.17), is used with a small time step. The ratio of these two time steps is 10. We have observed that a renormalization (3.12) slightly reduces the speed of convergence, but has no effect on the converged control fields.

5.3. Numerical convergence. Let us present some results concerning the convergence of the monotonic parareal algorithm.

5.3.1. Evolution of $(\varepsilon^k)_{k\in\mathbf{N}}$. In a first test, $N = 10$ identical subintervals are considered to parallelize the algorithm. Figures 5.1–5.3 show a typical evolution of the sequence $(\varepsilon^k)_{k\in\mathbf{N}}$ computed by our algorithm. Figure 5.4 represents the control field obtained without parallelization by a monotonic algorithm applied to J. Note that the discontinuities that are visible on Figure 5.1 and even on Figure 5.2 disappear as the number of iteration increases.

5.3.2. Variation of the number of subintervals. The control field obtained at the numerical convergence appears to be independent of the number N of subintervals. This is coherent with Theorem 4.1 which claims that the limit depends only on the initial cost functional J. In order to evaluate the effect of N on the convergence of the algorithm, we have run the algorithm for different values of this parameter. Figure 5.5 shows the evolution of the cost functional values for $N = 1, 2, 5, 10, 50, 100$. The convergence speed decreases when N becomes larger. One has thus to find an optimum between the acceleration obtained by parallelization and the reduction of the convergence speed induced by it. This compromise depends on the choice of the coarse and fine propagators. In our case, the parallel optimizations and the coarse propagations allow us to reach a satisfactory cost functional value with an actual gain in "wall-clock" time roughly equal to 7. We have not sought to optimize the coarse and the fine propagators for these numerical tests. In particular, a coarser propagator should improve this result.

5.4. About the full efficiency. Consider again $N = 10$ identical subintervals. An ideal time parallelization should divide the computational time by 10. In order to

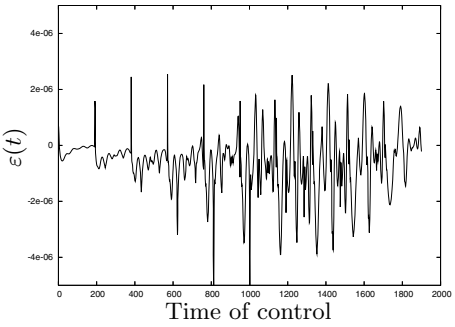

FIG. 5.1. *Field of control obtained after one iteration.*

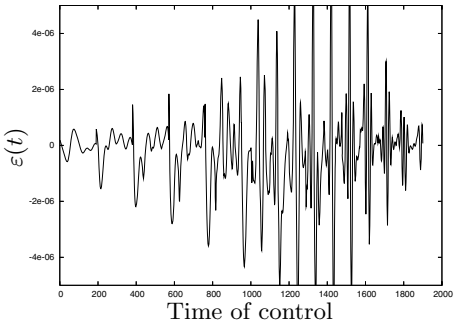

FIG. 5.2. *Field of control obtained after* 10 *iterations.*

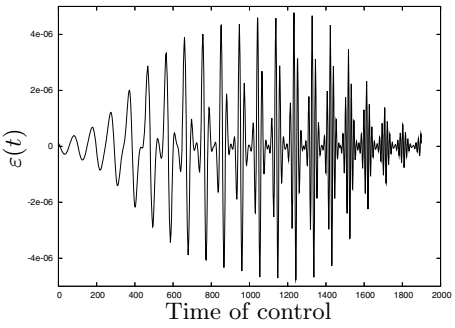

FIG. 5.3. *Field of control obtained after* 250 *iterations. In such nonlinear equations the typical number of iterations is in the range* 10^2–10^4 [1, 27].

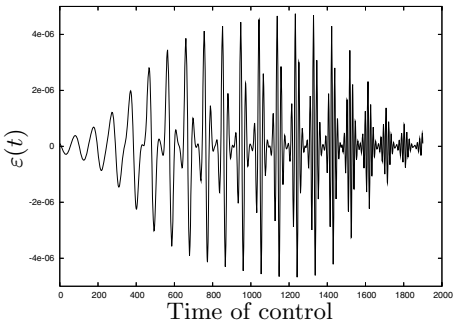

FIG. 5.4. *Field of control obtained by a nonparallelized monotonic algorithm (i.e., with* $N = 1$*) after* 250 *iterations.*

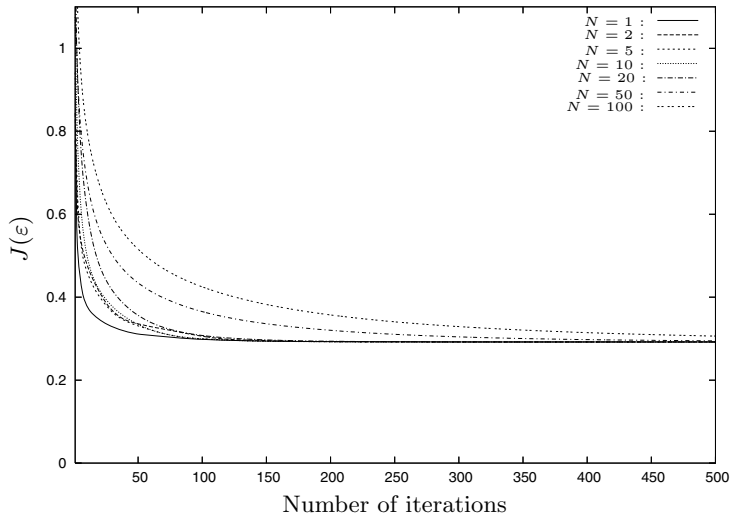

FIG. 5.5. *Evolution of the cost functional value during the first* 500 *iterations.*

TABLE 5.1

Results obtained for several subiterations of the monotonic schemes (3.16)–(3.19) *during step* 5 *of the monotonic parareal algorithm.*

	k	m	Comp. time	$J(\varepsilon^k)$
Case 0	100	1	$100.10.T_f$	0.2983
Case 1	100	1	$100.(T_f + T_C)$	0.2986
Case 2	50	2	$50.(2T_f + T_C)$	0.3062
Case 3	25	4	$25.(4T_f + T_C)$	0.3295

approach such a full efficiency, a strategy would be to increase the parallel computations (step 5) with respect to the coarse propagations (steps 2 and 3 of the algorithm). In this perspective, the influence on the convergence of the number of iterations (denoted by m) of the monotonic algorithm (3.17)–(3.18) done during step 5 has been tested (see Remark 6). Let us denote by k the number of iterations of the monotonic parareal algorithm, by T_f the computational time of one iteration of the monotonic algorithm in a subinterval, and by T_C the computational time of both step 2 and step 3. Table 5.1 summarizes the cases that have been tested.

Case 0 corresponds to the nonparallelized monotonic algorithm (i.e., with $N = 1$) computed with the fine propagator. Figure 5.6 shows that the best strategy corresponds to case 1. Further work is needed to reach the full efficiency (corresponding in our case to a computational time close to $100.T_f$).

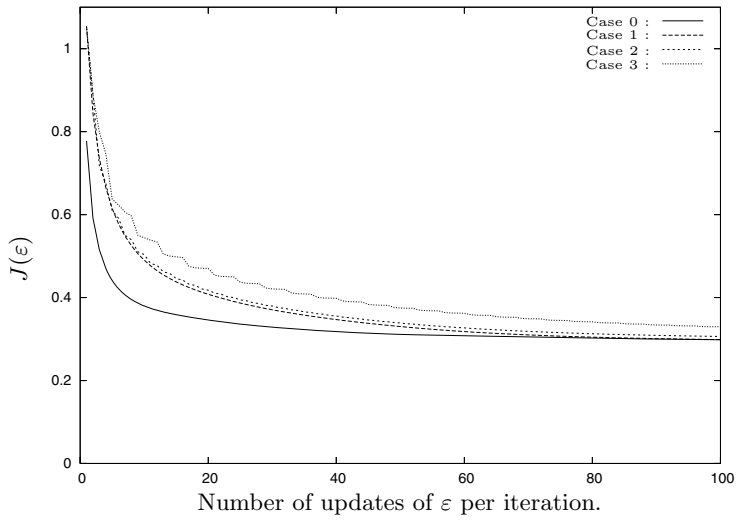

FIG. 5.6. *Evolutions of the cost functional values for different values of* m.

NODAL AUXILIARY SPACE PRECONDITIONING IN H(curl) AND H(div) SPACES*

RALF HIPTMAIR† AND JINCHAO XU‡

Abstract. In this paper, we develop and analyze a general approach to preconditioning linear systems of equations arising from conforming finite element discretizations of $\mathbf{H}(\mathbf{curl},\Omega)$- and $\mathbf{H}(\mathrm{div},\Omega)$-elliptic variational problems. The preconditioners exclusively rely on solvers for discrete Poisson problems. We prove mesh-independent effectivity of the preconditioners by using the abstract theory of auxiliary space preconditioning. The main tools are discrete analogues of so-called regular decomposition results in the function spaces $\mathbf{H}(\mathbf{curl},\Omega)$ and $\mathbf{H}(\mathrm{div},\Omega)$. Our preconditioner for $\mathbf{H}(\mathbf{curl},\Omega)$ is similar to an algorithm proposed in [R. Beck, *Algebraic Multigrid by Component Splitting for Edge Elements on Simplicial Triangulations*, Tech. rep. SC 99-40, ZIB, Berlin, Germany, 1999].

Key words. auxiliary space preconditioning, fictitious space preconditioning, $\mathbf{H}(\mathbf{curl})$ and $\mathbf{H}(\mathrm{div})$, edge and face finite elements, algebraic multigrid

DOI. 10.1137/060660588

1. Introduction.

On a polyhedron Ω, scaled such that $\mathrm{diam}(\Omega) = 1$, we consider the variational problems

$$\mathbf{u} \in \mathcal{H}(\mathbf{curl}): \quad (\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v})_0 + \tau\,(\mathbf{u},\mathbf{v})_0 = (\mathbf{f},\mathbf{v})_0 \quad \forall \mathbf{v} \in \mathcal{H}(\mathbf{curl},\Omega), \tag{1.1}$$

$$\mathbf{u} \in \mathcal{H}(\mathrm{div}): \quad (\mathrm{div}\,\mathbf{u}, \mathrm{div}\,\mathbf{v})_0 + \tau\,(\mathbf{u},\mathbf{v})_0 = (\mathbf{f},\mathbf{v})_0 \quad \forall \mathbf{v} \in \mathcal{H}(\mathrm{div},\Omega), \tag{1.2}$$

where $\mathbf{f}$ is a vector field in $(L^2(\Omega))^3$ and $\tau \geq 0$. We admit both homogeneous natural and essential boundary conditions; that is, $\mathcal{H}(\mathrm{div},\Omega)$ and $\mathcal{H}(\mathbf{curl},\Omega)$ can stand for either $\mathbf{H}(\mathbf{curl},\Omega)$ and $\mathbf{H}(\mathrm{div},\Omega)$ or $\mathbf{H}_0(\mathbf{curl},\Omega)$ and $\mathbf{H}_0(\mathrm{div},\Omega)$, respectively. The parameter τ controls the relative weight of the second and zero order terms in the bilinear forms.

More generally, the bilinear forms of (1.1) and (1.2) could feature spatially varying coefficients. So far, our theoretical analysis can take into account variations in the coefficients only very crudely. Thus, for the sake of simplicity, we have decided to focus on the constant coefficient case. Variable coefficients will be covered in some numerical experiments.

Variational problems of the form (1.1) and (1.2) arise in different applications, for instance, in

- (1.1) as a variational formulation of the eddy current model in computational electromagnetics [9], and
- (1.2) in the context of equivalent operator preconditioning for mixed finite element and first order system least squares (FOSLS) schemes for second order elliptic problems [3].

Geometric multigrid approaches to discrete linear problems arising from the Galerkin finite element discretization of (1.1) and (1.2) are well known [2, 4, 19, 22]. They supply mesh-independent iterative solvers and preconditioners, provided a hierarchy of uniformly shape regular meshes is available. Algebraic multigrid (AMG) methods that dispense with this requirement have been proposed in [7, 33], but they noticeably deteriorate on fine meshes, let alone permit a comprehensive theoretical analysis. The auxiliary space approach [38] allows us to harness powerful and asymptotically optimal AMG methods developed for discrete second order elliptic boundary value problems in order to get fast iterative solvers for discretized $\mathbf{H}(\mathbf{curl},\Omega)$- and $\mathbf{H}(\mathrm{div},\Omega)$-elliptic problems. As these auxiliary discrete second order elliptic boundary value problems arise from the use of Lagrangian finite elements, which are known as nodal finite elements in computational electromagnetism [10], we have tagged this special auxiliary space technique as *nodal*.

There is a close relationship between the variational problems (1.1) and (1.2) (cf. [20, section 2]) which allows a fairly parallel treatment of both. Thus we opt for a unified presentation, starting from an abstract variational problem

$$\mathbf{u}\in\mathcal{H}(\mathsf{D},\Omega):\quad a(\mathbf{u},\mathbf{v}):=(\mathsf{D}\mathbf{u},\mathsf{D}\mathbf{v})_0+\tau\,(\mathbf{u},\mathbf{v})_0=f(\mathbf{v})\quad\forall\mathbf{u},\mathbf{v}\in\mathcal{H}(\mathsf{D},\Omega), \tag{1.3}$$

where f is a continuous linear functional on the Hilbert space $\mathcal{H}(\mathsf{D},\Omega)$. Relating (1.3) to (1.1) and (1.2) discloses the meaning of D, f, and $\mathcal{H}(\mathsf{D},\Omega)$; see also Table 3.1. The bilinear form $a(\cdot,\cdot)$ induces the *energy norm*

$$\|\mathbf{v}\|_A^2:=a(\mathbf{v},\mathbf{v}),\quad \mathbf{v}\in\mathcal{H}(\mathsf{D},\Omega), \tag{1.4}$$

which is merely a seminorm, if $\tau=0$. The energy norm is closely related to the Hilbert space norm on $\mathcal{H}(\mathsf{D},\Omega)$

$$\|\mathbf{v}\|_{\mathcal{H}(\mathsf{D},\Omega)}^2:=\|\mathsf{D}\mathbf{v}\|_{L^2(\Omega)}^2+\|\mathbf{v}\|_{L^2(\Omega)}^2,\qquad \mathbf{v}\in\mathcal{H}(\mathsf{D},\Omega). \tag{1.5}$$

The principal challenge confronted in the development of preconditioners for discretized versions of (1.1) and (1.2) is the presence of a large kernel of D: in contrast to the case $\mathsf{D}=\mathbf{grad}$, these kernels have infinite dimension for $\mathsf{D}=\mathbf{curl}$ (comprising, e.g., all gradients) and $\mathsf{D}=\mathrm{div}$ (comprising, e.g., all rotations). This entails a separate treatment of these kernels by the preconditioner, which can exploit the fact that in suitable **curl**- and div-conforming finite element spaces the kernels possess a convenient representation through potentials. On the complement of the kernel the variational problem should display strong ellipticity and be amenable to standard elliptic preconditioning techniques; cf. the reasoning in [19, section 3] and [5, section 5].

Roughly speaking, on the complement of the kernels, the differential operators underlying (1.1) and (1.2) can be expected to be spectrally equivalent to a second order differential operator applied to the components of the vector fields. However, using a discrete second order differential operator as preconditioner is not possible immediately, because it does not fit the **curl**- and div-conforming finite element space. This is why we need the auxiliary space preconditioning technology [38] to link the finite element spaces on which (1.3) is discretized and the vectorial $H^1(\Omega)$-conforming finite elements that underlie the preconditioning operator.

The main rationale for pursuing this method in [5] was that the evaluation of the preconditioner boils down to inverting discrete scalar second order elliptic operators approximately. Fast AMG methods for this purpose abound; see [36, Appendix A]. Thus, AMG codes can be harnessed for $\mathbf{H}(\mathbf{curl},\Omega)$- and $\mathbf{H}(\mathrm{div},\Omega)$-elliptic problems.

The principal idea underlying our approach can be gleaned from the understanding that stable space decompositions are at the heart of preconditioners for symmetric positive definite variational problems; see section 2 for further explanations. Results that we have dubbed regular decompositions provide fundamental stable splittings for the spaces $\mathcal{H}(\mathsf{D},\Omega)$; see section 3 for details. For instance, for the space $\mathbf{H}_0(\mathbf{curl},\Omega)$ we have a stable splitting

$$\mathbf{H}_0(\mathbf{curl},\Omega) = (H^1_0(\Omega))^3 + \mathbf{grad}\, H^1_0(\Omega).$$

This suggests that a preconditioner for $\mathbf{H}_0(\mathbf{curl},\Omega)$-elliptic variational problem can be based on solving $H^1_0(\Omega)$-elliptic variational problems. However, to make this idea work, the splittings have to be adapted to the discrete setting. Thus, in sections 5 and 6 we establish stable discrete regular decompositions and corresponding norm equivalences. This yields the desired preconditioners, whose implementation will be discussed in section 7. In the end, we supplement the asymptotic theoretical estimate with numerical studies of the performance of the preconditioners. We refer the reader to [27,28] for more numerical results.

2. Auxiliary space preconditioning: Abstract theory. In this section, we give a self-contained description of preconditioning techniques based on fictitious or auxiliary spaces as developed in [18,31,38].

Let V stand for a real Hilbert space with inner product $a(\cdot,\cdot)$ and (energy) norm $\|\cdot\|_A$. The fictitious space method targets linear variational problems

$$u \in V: \quad a(u,v) = f(v) \quad \forall v \in V. \tag{2.1}$$

Its main building blocks are

1. a *fictitious space* $\bar{V}$, that is, another real Hilbert space equipped with the inner product $\overline{a}(\cdot,\cdot)$, which induces the norm $\|\cdot\|_{\bar{\mathsf{A}}}$, and
2. a continuous and surjective linear transfer operator $\Pi : \bar{V} \mapsto V$.

We tag dual spaces by $'$ and adjoint operators by *, and we use angle brackets for duality pairings. Then, writing $\mathsf{A} : V \mapsto V'$ and $\bar{\mathsf{A}} : \bar{V} \mapsto \bar{V}'$ for the isomorphisms associated with $a(\cdot,\cdot)$ and $\overline{a}(\cdot,\cdot)$, respectively, the fictitious space preconditioner is given by

$$\mathsf{B} = \Pi \circ \bar{\mathsf{A}}^{-1} \circ \Pi^* : V' \mapsto V. \tag{2.2}$$

Obviously, the operator B is associated with a symmetric bilinear form on the dual space V'. The next lemma confirms that this form is actually positive definite, which renders B a valid preconditioner.

LEMMA 2.1. *If $\Pi : \bar{V} \mapsto V$ is surjective, then the operator B is an isomorphism.*

Proof. Π being surjective means that it is an open mapping and Π^* is injective. As $\overline{a}$ is positive definite, we infer

$$\langle \varphi, \mathsf{B}\varphi \rangle_{V'\times V} = \left\langle \Pi^*\varphi, \bar{\mathsf{A}}^{-1}\Pi^*\varphi \right\rangle_{\bar{V}'\times\bar{V}} > 0 \quad \forall \varphi \in V' \setminus \{0\}.$$

From this we conclude the assertion of the theorem. ∎

The next theorem is known as the *fictitious space lemma* [31], for which we provide the elementary proof for the sake of completeness.

THEOREM 2.2 (fictitious space lemma). *Assume that Π is surjective and*

$$\exists c_0 > 0: \quad \forall v \in V: \quad \exists \bar{v} \in \bar{V}: \quad v = \Pi\bar{v} \quad \wedge \quad \|\bar{v}\|_{\bar{\mathsf{A}}} \le c_0 \|v\|_A, \tag{2.3}$$

$$\exists c_1 > 0: \quad \|\Pi\bar{v}\|_A \le c_1 \|\bar{v}\|_{\bar{\mathsf{A}}} \quad \forall \bar{v} \in \bar{V}. \tag{2.4}$$

Then

$$c_0^{-2}\,\|v\|_A^2 \le a(\mathsf{BA}v,v) \le c_1^2\,\|v\|_A^2 \quad \forall v\in V. \tag{2.5}$$

Proof. The proof makes use of only the Cauchy–Schwarz inequality:

$$\begin{aligned} a(\mathsf{BA}v,v) &\le a(\mathsf{BA}v,\mathsf{BA}v)^{1/2}a(v,v)^{1/2}\\ &= a(\Pi\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v,\Pi\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v)^{1/2}\,\|v\|_A\\ &\le c_1\,\overline{a}(\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v,\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v)^{1/2}\,\|v\|_A\\ &= c_1\,\left\langle\Pi^*\mathsf{A}v,\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v\right\rangle_{\bar V'\times\bar V}^{1/2}\,\|v\|_A = c_1\,a(\mathsf{BA}v,v)^{1/2}\,\|v\|_A\,. \end{aligned}$$

Next, we rely on the assumption (2.3) and get

$$\begin{aligned} a(v,v) &= \langle\mathsf{A}v,\Pi\bar v\rangle_{V'\times V} = \langle\Pi^*\mathsf{A}v,\bar v\rangle_{\bar V'\times\bar V} = \overline{a}(\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v,\bar v)\\ &\le \overline{a}(\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v,\bar{\mathsf{A}}^{-1}\Pi^*\mathsf{A}v)^{1/2}\,\|\bar v\|_{\bar{\mathsf{A}}} \le c_0\,a(\mathsf{BA}v,v)^{1/2}\,\|v\|_A\,. \end{aligned}$$

∎

From (2.5) we immediately get an estimate for the spectral condition number of the preconditioned operator A:

$$\kappa(\mathsf{BA}) := \frac{\lambda_{\max}(\mathsf{BA})}{\lambda_{\min}(\mathsf{BA})} \le (c_0c_1)^2. \tag{2.6}$$

Corollary 2.3. *Under the assumptions of the previous theorem, we have the following estimate for the spectral condition number:*

$$\kappa((\Pi\bar{\mathsf{B}}\Pi^*)\mathsf{A}) \le \kappa(\bar{\mathsf{B}}\bar{\mathsf{A}})(c_0c_1)^2,$$

where $\bar{\mathsf{B}}:\bar V'\mapsto\bar V$ *is supposed to be a preconditioner for* $\bar{\mathsf{A}}$.

Proof. This result is a consequence of the obvious inequality

$$\kappa((\Pi\bar B\Pi^*)\mathsf{A}) \le \kappa(\bar B\bar{\mathsf{A}})\kappa(\mathsf{BA}).$$ ∎

The auxiliary space method as pioneered in [38] can be viewed as a fictitious space approach relying on the special choice

$$\bar V = V\times W_1\times\cdots\times W_J, \tag{2.7}$$

where $W_1,\dots,W_J$, $J\in\mathbb{N}$, are Hilbert spaces endowed with inner products $\overline{a}_j(\cdot,\cdot)$, $j=1,\dots,J$. They provide the so-called auxiliary spaces.

A distinctive feature of the auxiliary space method is the presence of V in (2.7), but as a component of $\bar V$ the space V will be equipped with an inner product $s(\cdot,\cdot)$ different from $a(\cdot,\cdot)$. The operator $\mathsf{S}:V\mapsto V'$ induced by $s(\cdot,\cdot)$ on V is usually called the *smoother*. In other words, the auxiliary space method adopts the fictitious space approach with the inner product

$$\overline{a}(\bar v,\bar v) := s(v_0,v_0)+\sum_{j=1}^J\overline{a}_j(w_j,w_j), \quad \begin{array}{l}\bar v=(v_0,w_1,\dots,w_J)\in\bar V,\\ v_0\in V,\,w_j\in W_j.\end{array} \tag{2.8}$$

Furthermore, for each W_j we need a linear transfer operator $\Pi_j : W_j\mapsto V$, from which we build the surjective operator

$$\Pi := \begin{pmatrix} Id & & & \\ & \Pi_1 & & \\ & & \ddots & \\ & & & \Pi_J \end{pmatrix} : \bar V\mapsto V. \tag{2.9}$$

Now, all components of the auxiliary space preconditioner are in place and the formula (2.2) becomes

$$\mathsf{B} = \mathsf{S}^{-1} + \sum_{j=1}^{J} \Pi_j \circ \bar{\mathsf{A}}_j^{-1} \circ \Pi_j^*. \tag{2.10}$$

The verification of the assumptions of Theorem 2.2 for the preconditioner boils down to three steps.

1. Find bounds $c_j > 0$ for norms of the transfer operators Π_j:

$$\|\Pi_j w_j\|_A \le c_j \overline{a}(w_j, w_j)^{1/2}, \quad w_j \in W_j. \tag{2.11}$$

2. Investigate the continuity of S^{-1}:

$$\exists c_s > 0 : \quad \|v\|_A \le c_s s(v,v)^{1/2} \quad \forall v \in V. \tag{2.12}$$

3. Establish that for every $v \in V$ there are $v_0 \in V$ and $w_j \in W_j$ such that $v = v_0 + \sum_{j=1}^{J} \Pi_j w_j$ and

$$s(v_0, v_0) + \sum_{j=1}^{J} \overline{a}_j(w_j, w_j) \le c_0^2 \|v\|_A^2, \tag{2.13}$$

where $c_0 > 0$ should be small and independent of v.

Then, the assertion of Theorem 2.2 translates to

$$\kappa(\mathsf{BA}) \le c_0^2 (c_s^2 + c_1^2 + \cdots + c_J^2). \tag{2.14}$$

It goes without saying that in the spirit of Corollary 2.3, the bilinear forms $\overline{a}_j$ on the auxiliary spaces W_j can be replaced with spectrally equivalent bilinear forms $\bar{b}_j$; i.e., we may use preconditioners $\bar{\mathsf{B}}_j$ for the operators $\bar{\mathsf{A}}_j$. The impact of this approximation can be gauged as in Corollary 2.3.

In the applications we have in mind all the spaces will be finite element spaces and will feature bases comprised of locally supported functions. Plugging basis functions into the bilinear forms $a(\cdot,\cdot)$ and $\overline{a}_j(\cdot,\cdot)$, we obtain the Galerkin matrices $\mathbf{A} \in \mathbb{R}^{N,N}$, $N := \dim V$, $\overline{\mathbf{A}}_j \in \mathbb{R}^{N_j,N_j}$, $N_j := \dim W_j$. The smoother is provided by local relaxation procedures: for instance, if Jacobi smoothing is used, an algebraic representation of the associated operator S is given by the diagonal part $\mathbf{D}_A$ of the matrix $\mathbf{A}$. Hence, the algebraic version of the preconditioner from (2.10) reads

$$\mathbf{B} = \mathbf{D}_A^{-1} + \sum_{j=1}^{J} \mathbf{P}_j \overline{\mathbf{A}}_j^{-1} \mathbf{P}_j^T, \tag{2.15}$$

where $\mathbf{P}_j \in \mathbb{R}^{N,N_j}$ is the matrix representation of Π_j. When using symmetric Gauss–Seidel smoothing $\mathbf{D}_A^{-1}$ has to be replaced with $\mathbf{L}_A^{-1} + \mathbf{L}_A^{-T} - \mathbf{L}_A^{-1}\mathbf{A}\mathbf{L}_A^{-T}$, where $\mathbf{L}_A$ stands for the lower triangular part of (the symmetric matrix) $\mathbf{A}$.

Remark 1. Naturally, we can also try to apply the successive subspace correction idea [37] to the multiple auxiliary spaces to obtain the following iterative method for the operator equation $\mathsf{A}u = f$, $f \in V'$:

$$u \leftarrow u + \mathsf{S}^{-1}(f - \mathsf{A}u), \qquad u \leftarrow u + \Pi_j \bar{\mathsf{B}}_j \Pi_j^*(f - \mathsf{A}u), \quad 1 \le j \le J. \tag{2.16}$$

It is easy to see that a sufficient condition for the convergence of this successive auxiliary space method is

$$\lambda_{\max}(\bar{\mathsf{B}}_j \bar{\mathsf{A}}_j) \leq \frac{\omega}{c_j}, \qquad 1 \leq j \leq J, \tag{2.17}$$

for some $0 < \omega < 2$. Under the above conditions, the convergence rate of the iteration (2.16) depends only on c_0, c_s, c_j $(1 \leq j \leq J)$, ω, and J.

3. Regular decompositions. The abstract theory of the previous section has identified the uniform stability of decompositions (cf. (2.13)) as a key prerequisite of successful auxiliary space preconditioning. This connects well with the pivotal role of certain stable decomposition in the analysis of variational problems linked with $\mathbf{H}(\mathbf{curl}, \Omega)$ and $\mathbf{H}(\mathrm{div}, \Omega)$ [6,12,14]. In the subsequent discussion, to avoid topological obstructions, we restrict ourselves to "simple" domains.

ASSUMPTION 3.1. *We assume that Ω is homotopy equivalent to a ball.*

This makes it possible to use *potential representations* for the kernels of the differential operators.

LEMMA 3.1 (exact sequence property).

$$\textit{Assumption } 3.1 \quad \Rightarrow \quad \begin{array}{l} \mathbf{H}(\mathbf{curl}\,0, \Omega) := \{\mathbf{v} \in \mathbf{H}(\mathbf{curl}, \Omega) : \mathbf{curl}\,\mathbf{v} = 0\} = \mathbf{grad}\, H^1(\Omega), \\ \mathbf{H}_0(\mathbf{curl}\,0, \Omega) := \{\mathbf{v} \in \mathbf{H}_0(\mathbf{curl}, \Omega) : \mathbf{curl}\,\mathbf{v} = 0\} = \mathbf{grad}\, H^1_0(\Omega), \\ \mathbf{H}(\mathrm{div}\,0, \Omega) := \{\mathbf{v} \in \mathbf{H}(\mathrm{div}, \Omega) : \mathrm{div}\,\mathbf{v} = 0\} = \mathbf{curl}\,\mathbf{H}(\mathbf{curl}, \Omega), \\ \mathbf{H}_0(\mathrm{div}\,0, \Omega) := \{\mathbf{v} \in \mathbf{H}_0(\mathrm{div}, \Omega) : \mathrm{div}\,\mathbf{v} = 0\} = \mathbf{curl}\,\mathbf{H}_0(\mathbf{curl}, \Omega). \end{array}$$

In the unifying framework, this lemma can be recast into

$$\text{Assumption } 3.1 \quad \Rightarrow \quad \mathcal{H}(\mathsf{D}0, \Omega) := \{\mathbf{v} \in \mathcal{H}(\mathsf{D}, \Omega) : \mathsf{D}\mathbf{v} = 0\} = \mathsf{D}^- \mathcal{H}(\mathsf{D}^-, \Omega), \tag{3.1}$$

where D^- is the differential operator characterizing the *potential* space $\mathcal{H}(\mathsf{D}^-, \Omega)$; see the "translation table" Table 3.1.

TABLE 3.1
Translation table for unifying notational framework, generic case.

D	$\mathcal{H}(\mathsf{D}, \Omega)$	D^-	$\mathcal{H}(\mathsf{D}^-, \Omega)$	D^+	$\boldsymbol{\mathcal{H}}^1$
grad	$H^1(\Omega)$ $H^1_0(\Omega)$	Id	$\{\mathrm{const}\}$ $\{0\}$	**curl**	$H^1(\Omega)$ $H^1_0(\Omega)$
curl	$\mathbf{H}(\mathbf{curl}, \Omega)$ $\mathbf{H}_0(\mathbf{curl}, \Omega)$	**grad**	$H^1(\Omega)$ $H^1_0(\Omega)$	div	$(H^1(\Omega))^3$ $(H^1_0(\Omega))^3$
div	$\mathbf{H}(\mathrm{div}, \Omega)$ $\mathbf{H}_0(\mathrm{div}, \Omega)$	**curl**	$\mathbf{H}(\mathbf{curl}, \Omega)$ $\mathbf{H}_0(\mathbf{curl}, \Omega)$	0	$(H^1(\Omega))^3$ $(H^1_0(\Omega))^3$

Remark 2. If Assumption 3.1 fails to hold, De Rham cohomology theory teaches that the potential representations will be available only up to contributions from cohomology spaces of a small and finite dimension. They will not matter much for the overall performance of a preconditioner, and so we decided to forgo a discussion of general topologies.

The starting point for the development of the auxiliary space preconditioners presented in this paper is theoretical results that, roughly speaking, state that the gap between $(H^1(\Omega))^3$ and $\mathcal{H}(\mathsf{D}, \Omega)$ can be bridged by contributions from the kernel of D. A rigorous statement is made by the following so-called regular decomposition

results. In light of the unified treatment we aim for, operators with similar function will be denoted alike, though they are different in **curl**- and div-contexts, respectively.

LEMMA 3.2 (existence of regular vector potentials [21, Lemma 2.5]). *There is a continuous mapping* $\mathsf{L} : \{\mathbf{v} \in \mathbf{H}(\mathrm{div}, \mathbb{R}^3), \mathrm{div}\,\mathbf{v} = 0\} \mapsto (H^1(\mathbb{R}^3))^3$ *such that* $\mathbf{curl}\,\mathsf{L}v = v$ *and* $\mathrm{div}\,\mathsf{L}v = 0$.

LEMMA 3.3 (regular decomposition of $\mathbf{H}(\mathbf{curl}, \Omega)$ [21, Lemma 2.4]). *There are continuous maps* $\mathsf{R} : \mathbf{H}(\mathbf{curl}, \Omega) \mapsto (H^1(\Omega))^3$, $\mathsf{Z} : \mathbf{H}(\mathbf{curl}, \Omega) \mapsto H^1(\Omega)$ *such that* $\mathsf{R} + \mathbf{grad} \circ \mathsf{Z} = \mathsf{Id}$ *on* $\mathbf{H}(\mathbf{curl}, \Omega)$ *and* $\mathsf{R}u = 0 \Leftrightarrow \mathbf{curl}\,u = 0$.

LEMMA 3.4 (regular decomposition of $\mathbf{H}_0(\mathbf{curl}, \Omega)$ [32, section 2]). *There are continuous linear operators* $\mathsf{R} : \mathbf{H}_0(\mathbf{curl}, \Omega) \mapsto (H^1_0(\Omega))^3$, $\mathsf{Z} : \mathbf{H}_0(\mathbf{curl}, \Omega) \mapsto H^1_0(\Omega)$ *such that* $\mathsf{R} + \mathbf{grad} \circ \mathsf{Z} = \mathsf{Id}$ *on* $\mathbf{H}_0(\mathbf{curl}, \Omega)$ *and* $\mathsf{R}u = 0 \Leftrightarrow \mathbf{curl}\,u = 0$.

COROLLARY 3.5. *Both operators* R *introduced in Lemmas* 3.3 *and* 3.4 *satisfy*

$$\exists C = C(\Omega) > 0 : \quad \|\mathsf{R}\mathbf{v}\|_{H^1(\Omega)} \leq C \|\mathbf{curl}\,\mathbf{v}\|_{L^2(\Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathbf{curl}).$$

LEMMA 3.6 (existence of regular velocity fields, [17, Corollary 2.4]). *There is a continuous linear operator* $\mathsf{K} : L^2_0(\Omega) := \{\mathbf{v} \in L^2(\Omega), \int_\Omega \mathbf{v}\,\mathrm{d}\boldsymbol{x} = 0\} \mapsto (H^1_0(\Omega))^3$ *such that* $\mathrm{div} \circ \mathsf{K} = \mathsf{Id}$ *on* $L^2_0(\Omega)$.

LEMMA 3.7 (regular decomposition of $\mathbf{H}(\mathrm{div}, \Omega)$). *There are continuous linear operators* $\mathsf{R} : \mathbf{H}(\mathrm{div}, \Omega) \mapsto (H^1(\Omega))^3$, $\mathsf{Z} : \mathbf{H}(\mathrm{div}, \Omega) \mapsto (H^1(\Omega))^3$ *such that* $\mathsf{R} + \mathbf{curl} \circ \mathsf{Z} = \mathsf{Id}$ *on* $\mathbf{H}(\mathrm{div}, \Omega)$ *and* $\mathsf{R}u = 0 \Leftrightarrow \mathrm{div}\,u = 0$.

Proof. For $u \in \mathbf{H}(\mathrm{div}, \Omega)$ perform a trivial extension by zero of $\mathrm{div}\,u$ to an element of $L^2(\mathbb{R}^3)$. By elementary Fourier transform techniques (see [17, section 3.3]) we establish the existence of $w \in \mathbf{H}(\mathrm{div}, \mathbb{R}^3)$ such that $\mathrm{div}\,w = \mathrm{div}\,u$ on Ω. Lemma 3.1 finishes the proof. ∎

LEMMA 3.8 (regular decomposition of $\mathbf{H}_0(\mathrm{div}, \Omega)$). *There are continuous linear operators* $\mathsf{R} : \mathbf{H}_0(\mathrm{div}, \Omega) \mapsto (H^1_0(\Omega))^3$, $\mathsf{Z} : \mathbf{H}_0(\mathrm{div}, \Omega) \mapsto (H^1_0(\Omega))^3$ *such that* $\mathsf{R} + \mathbf{curl} \circ \mathsf{Z} = \mathsf{Id}$ *on* $\mathbf{H}_0(\mathrm{div}, \Omega)$ *and* $\mathsf{R}u = 0 \Leftrightarrow \mathrm{div}\,u = 0$.

Proof. Observe that $\mathrm{div}\,\mathbf{H}_0(\mathrm{div}, \Omega) \subset L^2_0(\Omega)$ and use Lemmas 3.6 and 3.1. ∎

COROLLARY 3.9. *Both operators* R *introduced in Lemmas* 3.7 *and* 3.8 *satisfy*

$$\exists C = C(\Omega) > 0 : \quad \|\mathsf{R}\mathbf{v}\|_{H^1(\Omega)} \leq C \|\mathrm{div}\,\mathbf{v}\|_{L^2(\Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathrm{div}).$$

Using the operator symbols from Table 3.1, we can summarize the above assertions in the following lemma.

LEMMA 3.10 (stable regular decomposition).

$$\begin{array}{l} \exists \mathsf{R} \in L(\mathcal{H}(\mathsf{D}, \Omega), \boldsymbol{\mathcal{H}}^1), \\ \exists \mathsf{Z} \in L(\mathcal{H}(\mathsf{D}, \Omega), \mathcal{H}(\mathsf{D}^-, \Omega)), \\ \exists C = C(\Omega) > 0 \end{array} : \quad \begin{cases} \mathsf{R} + \mathsf{D}^- \circ \mathsf{Z} = \mathsf{Id} \quad \text{on } \mathcal{H}(\mathsf{D}, \Omega), \\ \|\mathsf{R}\mathbf{v}\|_{H^1(\Omega)} \leq C \|\mathsf{D}\mathbf{v}\|_{L^2(\Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathsf{D}, \Omega), \\ \|\mathsf{Z}\mathbf{v}\|_{\mathcal{H}(\mathsf{D}^-, \Omega)} \leq C \|\mathbf{v}\|_{\mathcal{H}(\mathsf{D}, \Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathsf{D}, \Omega). \end{cases}$$

Proof. The assertion about R rephrases those of Corollaries 3.5 and 3.9. Then

$$\begin{aligned} \left\|\mathsf{D}^-\mathsf{Z}\mathbf{v}\right\|_{L^2(\Omega)} &\leq \|\mathsf{R}\mathbf{v}\|_{L^2(\Omega)} + \|\mathbf{v}\|_{L^2(\Omega)} \\ &\leq C \|\mathsf{R}\mathbf{v}\|_{H^1(\Omega)} + \|\mathbf{v}\|_{L^2(\Omega)} \leq C \|\mathsf{D}\mathbf{v}\|_{L^2(\Omega)} + \|\mathbf{v}\|_{L^2(\Omega)}, \end{aligned}$$

and the estimate for the norm $\|\cdot\|_{\mathcal{H}(\mathsf{D}^-, \Omega)}$ can be inferred from the fact that $\mathsf{D}^- : \mathcal{H}(\mathsf{D}^-, \Omega) \mapsto L^2(\Omega)$ has closed range. ∎

In light of the fictitious space lemma Theorem 2.2, the result of Lemma 3.10 can be read as follows (we refer the reader to Table 3.1 for the meaning of $\boldsymbol{\mathcal{H}}^1$ and write

$(Id - \boldsymbol{\Delta}) : \boldsymbol{\mathcal{H}}^1 \mapsto (\boldsymbol{\mathcal{H}}^1)'$ for the (second order elliptic) operator associated with the inner product of $\boldsymbol{\mathcal{H}}^1$): the regular decomposition confirms that

$$\mathsf{B} := \mathsf{I} \circ (\mathsf{Id} - \boldsymbol{\Delta})^{-1} \circ \mathsf{I}^* + \mathsf{D}^- \circ (\mathsf{Id} + (\mathsf{D}^-)^* \mathsf{D}^-)^{-1} \circ (\mathsf{D}^-)^* \tag{3.2}$$

will supply a "preconditioner" for the operator $\mathsf{A} : \mathcal{H}(\mathsf{D}, \Omega) \mapsto \mathcal{H}(\mathsf{D}, \Omega)'$ induced by the bilinear form of (1.3). Here, I designates the trivial injection $\mathsf{I} : \boldsymbol{\mathcal{H}}^1 \mapsto \mathcal{H}(\mathsf{D}, \Omega)$ arising from the continuous embedding $\boldsymbol{\mathcal{H}}^1 \subset \mathcal{H}(\mathsf{D}, \Omega)$. Applying Theorem 2.2 and (2.6) and recalling that $\|\boldsymbol{\Psi}\|_{\mathcal{H}(\mathsf{D},\Omega)} \leq \|\boldsymbol{\Psi}\|_{H^1(\Omega)}$, $\boldsymbol{\Psi} \in \mathcal{H}(\mathsf{D}^-, \Omega)$, and $\|\mathsf{D}^- \varphi\|_{\mathcal{H}(\mathsf{D},\Omega)} \leq \|\varphi\|_{\mathcal{H}(\mathsf{D}^-,\Omega)}$, $\varphi \in \mathcal{H}(\mathsf{D}^-, \Omega)$, we readily conclude for $\tau = 1$

$$\kappa(\mathsf{BA}) \leq \|\mathsf{R}\|^2 + \|\mathsf{Z}\|^2 . \tag{3.3}$$

Of course, "preconditioning" an operator equation set in infinite-dimensional function spaces is hardly relevant for practical computations. Hence, the main objective of this paper is to get a discrete version of the above result.

Remark 3. All the above regular decompositions are global in the sense that the estimates of Corollaries 3.9 and 3.5 do not hold on subsets of Ω.

Remark 4. The regular decompositions outlined above have been widely used in functional analysis and numerical analysis connected with $\mathcal{H}(\mathsf{D}, \Omega)$. In the study of function spaces and traces, some of them first appeared in [6] and were later used in [12, 15]. They have found their way into the theoretical analysis of multilevel methods [22,26], domain decomposition methods [32], and boundary element methods [23].

A major shortcoming of the regular decompositions summarized in Lemma 3.10 is their lack of $L^2(\Omega)$-stability. This is obviously guaranteed in the case of the classical $L^2(\Omega)$-orthogonal Helmholtz decomposition

$$\mathcal{H}(\mathsf{D}, \Omega) = \mathcal{H}(\mathsf{D}0, \Omega) \oplus \mathcal{H}(\mathsf{D}0, \Omega)^{\perp}. \tag{3.4}$$

However, the $L^2(\Omega)$-orthogonal complement generally fails to belong to $H^1(\Omega)$ or $(H^1(\Omega))^3$, respectively. According to [17, section 3.4] this can only be taken for granted if $-\Delta$ with suitable homogeneous Dirichlet or Neumann boundary conditions is 2-*regular* on Ω (see [1] for details). We will refer to this situation as *the* 2-*regular case*. Conversely, Table 3.1 gives the meaning of the symbols in the *generic case*.

Remark 5. Convexity of Ω will ensure the 2-regular case. Moreover, for a convex Ω, formulas (2.8) and (2.3) in [16] involve the estimate

$$|\mathsf{R}\mathbf{v}|_{H^1(\Omega)} \leq \|\mathsf{D}\mathbf{v}\|_{L^2(\Omega)} , \tag{3.5}$$

where $|\cdot|_{H^1(\Omega)}$ designates the componentwise $H^1(\Omega)$-seminorm of a vector field.

However, use of the Helmholtz decomposition (3.4) entails relaxing the boundary conditions in $\mathcal{H}(\mathsf{D}^-, \Omega)$, when boundary conditions are imposed on $\mathcal{H}(\mathsf{D}, \Omega)$. More precisely, in the 2-regular case the following slightly modified meanings of the notation from Table 3.1 will be assumed. They are given in Table 3.2, where

$$\mathbf{H}^1_t(\Omega) := (H^1(\Omega))^3 \cap \mathbf{H}_0(\mathbf{curl}, \Omega), \qquad \mathbf{H}^1_n(\Omega) := (H^1(\Omega))^3 \cap \mathbf{H}_0(\mathrm{div}, \Omega).$$

With (3.4) in mind, in the 2-regular case, the operators Z and R from Lemma (3.10) can be chosen to satisfy

$$\left\|\mathsf{D}^- \mathsf{Z}\mathbf{v}\right\|^2_{L^2(\Omega)} + \|\mathsf{R}\mathbf{v}\|^2_{L^2(\Omega)} = \|\mathbf{v}\|^2_{L^2(\Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathsf{D}, \Omega). \tag{3.6}$$

TABLE 3.2
Symbols with altered meaning in the 2-regular case.

D	$\mathcal{H}(\mathsf{D},\Omega)$	D^-	$\mathcal{H}(\mathsf{D}^-,\Omega)$	D^+	$\boldsymbol{\mathcal{H}}^1$
curl	$\mathbf{H}_0(\mathbf{curl},\Omega)$	**grad**	$H^1_0(\Omega)$	div	$\mathbf{H}^1_t(\Omega)$
div	$\mathbf{H}_0(\mathrm{div},\Omega)$	**curl**	$\mathbf{H}_0(\mathbf{curl},\Omega)$	0	$\mathbf{H}^1_n(\Omega)$

In particular, Z and $\mathsf{D}^- \circ \mathsf{Z}$ turn out to be the $L^2(\Omega)$-orthogonal projections parallel to $\mathcal{H}(\mathsf{D}0,\Omega)$ and onto $\mathcal{H}(\mathsf{D}0,\Omega)$, respectively. The estimates of Corollaries 3.9 and 3.5 remain valid [1, section 2]. Thus, in the 2-regular case, Lemma 3.10 still holds with operators Z and R satisfying (3.6).

Remark 6. If Ω is a *polyhedron* (i.e., has flat faces), then we learn from Theorem 2.3 in [16] that

$$\|\mathbf{curl}\,\mathbf{u}\|^2_{L^2(\Omega)} + \|\mathrm{div}\,\mathbf{u}\|^2_{L^2(\Omega)} = \|\mathbf{grad}\,\mathbf{u}\|^2_{L^2(\Omega)} \quad \forall \mathbf{u} \in \mathbf{H}^1_t(\Omega) \cup \mathbf{H}^1_n(\Omega). \tag{3.7}$$

Whenever the definition of R is based on the Helmholtz decomposition it will map into either $\mathbf{H}^1_t(\Omega)$ or $\mathbf{H}^1_n(\Omega)$ in the 2-regular case. Thus, we conclude that on a polyhedron in the 2-regular case

$$\|\mathsf{R}\mathbf{v}\|_{H^1(\Omega)} \le \|\mathbf{v}\|_{\mathcal{H}(\mathsf{D},\Omega)} \quad \forall \mathbf{v} \in \mathcal{H}(\mathsf{D},\Omega) \quad \Rightarrow \quad \|\mathsf{R}\| = 1. \tag{3.8}$$

4. Finite element spaces. Essentially, the analysis of this paper applies to all the finite element subspaces of $\mathbf{H}(\mathbf{curl},\Omega)$ and $\mathbf{H}(\mathrm{div},\Omega)$ that can be viewed as discrete differential forms. This includes the so-called first and second families of edge elements [29, 30] and Raviart–Thomas elements and the Brezzi–Douglas–Marini (BDM) elements [11, Chapter 4]. To keep the presentation focused, we discuss only the lowest order cases.

Examples for the lowest order $\mathcal{H}(\mathsf{D},\Omega)$-conforming finite element spaces on a tetrahedral mesh $\mathcal{T}_h$ of Ω are listed in Table 4.1. They can be defined by

$$V_h(\mathbf{grad}) := \left\{ v_h \in \begin{matrix} H^1(\Omega) \\ H^1_0(\Omega) \end{matrix} \;:\; v_{h|K}(\mathbf{x}) = a + \mathbf{b}\cdot\mathbf{x},\, a \in \mathbb{R}, \mathbf{b} \in \mathbb{R}^3,\ \forall K \in \mathcal{T}_h \right\},$$

$$V_h(\mathbf{curl}) := \left\{ \mathbf{v}_h \in \begin{matrix} \mathbf{H}(\mathbf{curl},\Omega) \\ \mathbf{H}_0(\mathbf{curl},\Omega) \end{matrix} \;:\; \mathbf{v}_{h|K}(\mathbf{x}) = \mathbf{a} + \mathbf{x}\times\mathbf{b},\, \mathbf{a},\mathbf{b} \in \mathbb{R}^3,\ \forall K \in \mathcal{T}_h \right\},$$

$$V_h(\mathrm{div}) := \left\{ \mathbf{v}_h \in \begin{matrix} \mathbf{H}(\mathrm{div},\Omega) \\ \mathbf{H}_0(\mathrm{div},\Omega) \end{matrix} \;:\; \mathbf{v}_{h|K}(\mathbf{x}) = \mathbf{a} + \beta\mathbf{x},\, \mathbf{a} \in \mathbb{R}^3, \beta \in \mathbb{R}, \forall K \in \mathcal{T}_h \right\}.$$

$$V_h(0) := \left\{ v_h \in \begin{matrix} L^2(\Omega) \\ L^2_0(\Omega) \end{matrix} \;:\; v_{h|K}(\mathbf{x}) = a,\, a \in \mathbb{R},\ \forall K \in \mathcal{T}_h \right\}.$$

For a thorough discussion the reader is referred to [21, Chapter 3] and [29]. Resorting to a unified notation, we use the symbol $V_h(\mathsf{D})$ for these spaces. Its concrete meaning in different contexts is specified in Table 4.1.

A fundamental property of these families of finite element spaces is that they permit a discrete counterpart of (3.1):

$$\text{Assumption 3.1} \quad \Rightarrow \quad V_h(\mathsf{D}0) := \{\mathbf{v}_h \in V_h(\mathsf{D}) :\ \mathsf{D}\mathbf{v}_h = 0\} = \mathsf{D}^- V_h(\mathsf{D}^-). \tag{4.1}$$

TABLE 4.1

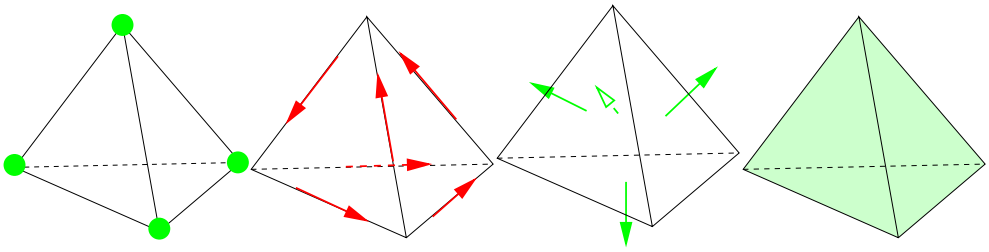

FIG. 4.1. *Symbolic notation for local degrees of freedom for* $V_h(\mathbf{grad}), V_h(\mathbf{curl}), V_h(\mathrm{div})$*, and* $V_h(0)$ *(left to right).*

These discrete potentials can even be chosen in a stable manner: with constants depending only on Ω, D, and the shape regularity of $\mathcal{T}_h$,

(4.2)
$$\forall \mathbf{v}_h \in V_h(\mathsf{D}0): \quad \exists p_h \in V_h(\mathsf{D}^-): \quad \mathbf{v}_h = \mathsf{D}^- p_h \quad \text{and} \quad \|p_h\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{L^2(\Omega)}.$$

For face elements this is a consequence of discrete Poincaré-type inequalities for $V_h(\mathbf{curl})$; see [21, Theorem 4.7]. For $\mathsf{D} = \mathbf{curl}$ and $\mathsf{D}^- = \mathbf{grad}$, (4.2) is just standard Poincaré–Friedrichs inequalities in $H^1(\Omega)/\mathbb{R}$ and $H^1_0(\Omega)$, respectively.

All the finite element spaces $V_h(\mathsf{D})$ are equipped with bases $\mathcal{B}(\mathsf{D})$ comprising locally supported functions; see [21, section 3.2]. These bases are L^2-stable in the sense that

(4.3)
$$\mathbf{v}_h = \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \mathbf{v}_\mathbf{b},\ \mathbf{v}_\mathbf{b} \in \mathrm{span}\{\mathbf{b}\}, \qquad \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v}_\mathbf{b}\|^2_{L^2(\Omega)} \approx \|\mathbf{v}_h\|^2_{L^2(\Omega)} \quad \forall \mathbf{v}_h \in V_h(\mathsf{D}),$$

with constants[1] depending only on the shape regularity of $\mathcal{T}_h$; see [24, section 2].

The spaces $V_h(\mathsf{D})$ also feature idempotent *nodal interpolation operators* Π^D_h whose range is $V_h(\mathsf{D})$. In the case $\mathsf{D} = \mathbf{grad}$ this is plain linear interpolation. For $\mathsf{D} = \mathbf{curl}$

[1] By the symbols $\approx$, $\lesssim$, and $\gtrsim$ we designate two- or one-sided inequalities, respectively, that hold up to multiplication of one side with a positive constant. In inequalities involving norms on function spaces this constant must not depend on the choice of functions. It may not depend on other problem and discretization parameters, and this will always be made clear.

the interpolation is based on path integrals along edges

$$\Pi_h^{\mathbf{curl}}\mathbf{v} = \sum_{e\in\mathcal{E}_h}\int_e \mathbf{v}\cdot \mathrm{d}\vec{s}\cdot \mathbf{b}_e, \tag{4.4}$$

where $\mathcal{E}_h$ is the set of (interior) edges of $\mathcal{T}_h$ and $\mathbf{b}_e$ is the edge element basis function associated with the edge e. For $\mathsf{D} = \mathrm{div}$, the interpolation relies on face fluxes:

$$\Pi_h^{\mathrm{div}}\mathbf{v} = \sum_{f\in\mathcal{F}_h}\int_f \mathbf{v}\cdot \mathrm{d}S\cdot \mathbf{b}_f, \tag{4.5}$$

with $\mathcal{F}_h$ designating the set of (interior) faces of $\mathcal{T}_h$. The relevant domains of integration for interpolation are depicted in Figure 4.1. Finally, the "interpolation" onto $V_h(0)$ agrees with $L^2(\Omega)$-projection. All these operators are well defined for continuous functions/vector fields, unbounded on $\mathcal{H}(\mathsf{D},\Omega)$ (except for $V_h(0)$), and possess the exceptional *commuting diagram property*

$$\mathsf{D}\circ\Pi_h^{\mathsf{D}} = \Pi_h^{+}\circ\mathsf{D} \quad \text{on domain of } \Pi_h^{\mathsf{D}}, \quad \Pi_h^{+} := \Pi_h^{\mathsf{D}^+}. \tag{4.6}$$

A concise way of writing (4.1) and (4.6) is through combined exact sequences and commuting diagrams:

$$\begin{array}{ccccccccccc}
0 & \longrightarrow & C^\infty(\Omega) & \xrightarrow{\mathbf{grad}} & (C^\infty(\Omega))^3 & \xrightarrow{\mathbf{curl}} & (C^\infty(\Omega))^3 & \xrightarrow{\mathrm{div}} & C^\infty(\Omega) & \longrightarrow & 0\\
 & & \downarrow{\scriptstyle \Pi_h^{\mathbf{grad}}} & & \downarrow{\scriptstyle \Pi_h^{\mathbf{curl}}} & & \downarrow{\scriptstyle \Pi_h^{\mathrm{div}}} & & \downarrow{\scriptstyle \Pi_h^{0}} & & \\
0 & \longrightarrow & V_h(\mathbf{grad}) & \xrightarrow{\mathbf{grad}} & V_h(\mathbf{curl}) & \xrightarrow{\mathbf{curl}} & V_h(\mathrm{div}) & \xrightarrow{\mathrm{div}} & V_h(0) & \longrightarrow & 0.
\end{array}$$

We write $h\in L^\infty(\Omega)$ for the piecewise constant meshwidth function, which assumes value $h_{|K} := \mathrm{diam}(K)$ in each cell K of $\mathcal{T}_h$. Using this function, we can state the following interpolation error estimate (see [21, section 3.6] and [21, Lemma 4.6]).

LEMMA 4.1. *The interpolation operators Π_h^{D} are bounded on $\{\mathbf{v}\in\boldsymbol{\mathcal{H}}^1,\ \mathsf{D}\mathbf{v}\in V_h(\mathsf{D}^+)\}\subset\boldsymbol{\mathcal{H}}^1$ and, with constants merely depending on D and the shape regularity of $\mathcal{T}_h$, they satisfy*

$$\left\|h^{-1}(Id-\Pi_h^{\mathsf{D}})\boldsymbol{\Psi}\right\|_{L^2(\Omega)} \lesssim \|\boldsymbol{\Psi}\|_{H^1(\Omega)} \quad \forall\boldsymbol{\Psi}\in\boldsymbol{\mathcal{H}}^1,\ \mathsf{D}\mathbf{v}\in V_h(\mathsf{D}^+). \tag{4.7}$$

Simple affine equivalence techniques also yield the inverse estimate

$$\|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)} \lesssim \left\|h^{-1}\mathbf{v}_h\right\|_{L^2(\Omega)} \quad \forall\mathbf{v}\in V_h(\mathsf{D}), \tag{4.8}$$

with a constant depending only on D and the shape regularity of the mesh.

The role of the discrete auxiliary space will be played by the finite element space $S_h\subset\boldsymbol{\mathcal{H}}^1$ of continuous functions or vector fields, whose Cartesian components are piecewise linear. We point out that

$$\mathsf{D}S_h\subset\mathsf{D}V_h(\mathsf{D}), \quad \mathsf{D}\in\{\mathbf{grad},\mathbf{curl},\mathrm{div}\}. \tag{4.9}$$

Thanks to the commuting diagram property, we immediately conclude

$$\mathsf{D}\Pi_h^{\mathsf{D}}\boldsymbol{\Psi}_h = \Pi_h^{+}\mathsf{D}\boldsymbol{\Psi}_h = \mathsf{D}\boldsymbol{\Psi}_h \quad \forall\boldsymbol{\Psi}_h\in S_h. \tag{4.10}$$

Moreover, straightforward scaling arguments bear out that, with constants depending only on the shape regularity of $\mathcal{T}_h$,

$$\left\|\mathsf{D}\Pi_h^{\mathsf{D}}\boldsymbol{\Psi}_h\right\|_{L^2(\Omega)} \lesssim |\boldsymbol{\Psi}_h|_{H^1(\Omega)}, \quad \left\|\Pi_h^{\mathsf{D}}\boldsymbol{\Psi}_h\right\|_{L^2(\Omega)} \lesssim \|\boldsymbol{\Psi}_h\|_{L^2(\Omega)} \quad \forall \boldsymbol{\Psi}_h \in S_h. \tag{4.11}$$

Finally, we recall the surjective and idempotent quasi-interpolation operators for Lagrangian finite element spaces introduced in [34]. We may apply them to the components of vector fields separately. In the generic case (see Table 3.1), this gives rise to the projectors $\widetilde{\mathsf{Q}}_h : \boldsymbol{\mathcal{H}}^1 \mapsto S_h$, which inherit the continuity

$$\left\|\widetilde{\mathsf{Q}}_h\boldsymbol{\Psi}\right\|_{H^1(\Omega)} \lesssim \|\boldsymbol{\Psi}\|_{H^1(\Omega)} \quad \forall \boldsymbol{\Psi} \in \boldsymbol{\mathcal{H}}^1, \tag{4.12}$$

respect possible boundary values in the sense that $\widetilde{\mathsf{Q}}_h(H_0^1(\Omega))^3 \subset (H_0^1(\Omega))^3$, and satisfy the local projection error estimate

$$\left\|h^{-1}(\widetilde{\mathsf{Q}}_h - Id)\boldsymbol{\Psi}\right\|_{L^2(\Omega)} \lesssim \|\boldsymbol{\Psi}\|_{H^1(\Omega)} \quad \forall \boldsymbol{\Psi} \in \boldsymbol{\mathcal{H}}^1. \tag{4.13}$$

In the 2-regular case (see the end of section 3 for a discussion and Table 3.2 for the slightly changed meanings of symbols), we will replace $\widetilde{\mathsf{Q}}_h$ with the $L^2(\Omega)$-orthogonal projections $\mathsf{Q}_h : (L^2(\Omega))^3 \mapsto S_h$. From interpolation arguments we readily infer the estimate

$$\left\|h^{-1}(\mathsf{Q}_h - Id)\boldsymbol{\Psi}\right\|_{L^2(\Omega)} \lesssim \|\boldsymbol{\Psi}\|_{H^1(\Omega)} \quad \forall \boldsymbol{\Psi} \in \boldsymbol{\mathcal{H}}^1, \tag{4.14}$$

but this time, in contrast to (4.13), the constants will *also* depend on the quasi-uniformity of the mesh. So, h in (4.14) should be read as the global meshwidth of $\mathcal{T}_h$. The approximation property also involves the continuity

$$\|\mathsf{Q}_h\boldsymbol{\Psi}\|_{H^1(\Omega)} \lesssim \|\boldsymbol{\Psi}\|_{H^1(\Omega)} \quad \forall \boldsymbol{\Psi} \in \boldsymbol{\mathcal{H}}^1, \tag{4.15}$$

again, with quasi-uniformity of the mesh also entering the constants.

Summing up, whenever we can take quasi-uniformity of the meshes for granted, Q_h can replace $\widetilde{\mathsf{Q}}_h$ with the extra benefit of $L^2(\Omega)$-continuity.

5. Discrete regular decompositions. Now, following [25], let us derive a discrete version of the above regular decomposition results of section 3. First, we focus on the generic case; see Table 3.1. We fix a $\mathbf{v}_h \in V_h(\mathsf{D})$ and use the stable regular decomposition of Lemma 3.10 to split it according to

$$\mathbf{v}_h = \boldsymbol{\Psi} + \mathsf{D}^- p, \quad \boldsymbol{\Psi} := \mathsf{R}\mathbf{v}_h \in \boldsymbol{\mathcal{H}}^1, \quad p := \mathsf{Z}\mathbf{v}_h \in \mathcal{H}(\mathsf{D}^-, \Omega). \tag{5.1}$$

We already know that the functions $\boldsymbol{\Psi}$ and p satisfy

$$\|\boldsymbol{\Psi}\|_{H^1(\Omega)} \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}, \qquad \left\|\mathsf{D}^- p\right\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{\mathcal{H}(\mathsf{D},\Omega)}, \tag{5.2}$$

with constants depending only on Ω.

So far, (5.1) is useless in the context of practical fictitious space preconditioning, because both $\boldsymbol{\Psi}$ and p fail to be finite element functions. The challenge is to convert (5.1) into a purely discrete decomposition without squandering the stability expressed by (5.2). This can be achieved only by incorporating another "high-frequency" contribution. Eventually, that forces us to incorporate a smoothing procedure into the algorithm.

LEMMA 5.1. *For any* $\mathbf{v}_h$ *there is* $\mathbf{\Psi}_h \in S_h$, $p_h \in V_h(\mathsf{D}^-)$, *and* $\widetilde{\mathbf{v}}_h \in V_h(\mathsf{D})$ *such that*

$$\mathbf{v}_h = \widetilde{\mathbf{v}}_h + \Pi_h^{\mathsf{D}} \mathbf{\Psi}_h + \mathsf{D}^- p_h, \tag{5.3}$$

and

$$\left\| h^{-1} \widetilde{\mathbf{v}}_h \right\|_{L^2(\Omega)}^2 + \|\mathbf{\Psi}_h\|_{H^1(\Omega)}^2 \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}^2, \qquad \|p_h\|_{\mathcal{H}(\mathsf{D}^-,\Omega)} \lesssim \|\mathbf{v}_h\|_{\mathcal{H}(\mathsf{D},\Omega)}. \tag{5.4}$$

The constants are allowed to depend on Ω *and the shape regularity of the mesh.*

Proof. First, note that in (5.1) $\mathsf{D}\mathbf{\Psi} = \mathsf{D}\mathbf{v}_h \in V_h(\mathsf{D}^+)$, and, owing to Lemma 4.1, $\Pi_h^{\mathsf{D}} \mathbf{\Psi}$ is well defined. Further, the commuting diagram property implies

$$\mathsf{D}\Pi_h^{\mathsf{D}} \mathbf{\Psi} = \Pi_h^+ \mathsf{D}\mathbf{\Psi} = \mathsf{D}\mathbf{\Psi} \quad \Rightarrow \quad \mathsf{D}(Id - \Pi_h^{\mathsf{D}})\mathbf{\Psi} = 0. \tag{5.5}$$

This confirms that the third term in the splitting

$$\mathbf{\Psi} = \Pi_h^{\mathsf{D}}(\mathbf{\Psi} - \widetilde{\mathsf{Q}}_h \mathbf{\Psi}) + \Pi_h^{\mathsf{D}} \widetilde{\mathsf{Q}}_h \mathbf{\Psi} + (Id - \Pi_h^{\mathsf{D}})\mathbf{\Psi} \tag{5.6}$$

actually belongs to the kernel of D. By (4.1), we conclude

$$\exists q \in \mathcal{H}(\mathsf{D}^-, \Omega): \quad (Id - \Pi_h^{\mathsf{D}})\mathbf{\Psi} = \mathsf{D}^- q, \tag{5.7}$$

and (4.7) together with (5.2) yields

$$\left\| h^{-1} \mathsf{D}^- q \right\|_{L^2(\Omega)} = \left\| h^{-1} (Id - \Pi_h^{\mathsf{D}})\mathbf{\Psi} \right\|_{L^2(\Omega)} \lesssim \|\mathbf{\Psi}\|_{H^1(\Omega)} \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}. \tag{5.8}$$

Thus, we can define the terms in the decomposition (5.3) as

$$\widetilde{\mathbf{v}}_h := \Pi_h^{\mathsf{D}}(\mathbf{\Psi} - \widetilde{\mathsf{Q}}_h \mathbf{\Psi}) \in V_h(\mathsf{D}), \tag{5.9}$$

$$\mathbf{\Psi}_h := \widetilde{\mathsf{Q}}_h \mathbf{\Psi} \in S_h, \tag{5.10}$$

$$\mathsf{D}^- p_h := \mathsf{D}^-(p + q), \quad p_h \in V_h(\mathsf{D}^-). \tag{5.11}$$

Indeed, $\mathsf{D}^-(p+q) \in V_h(\mathsf{D})$ such that we can add a contribution from $\mathcal{H}(\mathsf{D}^-, \Omega)$ to $p + q$ and obtain a discrete function. Thanks to (4.2) we can guarantee that $\|p_h\|_{L^2(\Omega)} \lesssim \|\mathsf{D}^- p_h\|_{L^2(\Omega)}$; this will not affect the decomposition. The stability of the decomposition (5.3) can be established as follows: first, make use of Lemma 4.1 and (4.13) to obtain

$$\begin{aligned}
\left\| h^{-1} \widetilde{\mathbf{v}}_h \right\|_{L^2(\Omega)} &\leq \left\| h^{-1} (Id - \Pi_h^{\mathsf{D}})(\mathbf{\Psi} - \widetilde{\mathsf{Q}}_h \mathbf{\Psi}) \right\|_{L^2(\Omega)} + \left\| h^{-1} (Id - \widetilde{\mathsf{Q}}_h)\mathbf{\Psi} \right\|_{L^2(\Omega)} \\
&\lesssim \left\| (Id - \widetilde{\mathsf{Q}}_h)\mathbf{\Psi} \right\|_{H^1(\Omega)} + \|\mathbf{\Psi}\|_{H^1(\Omega)} \\
&\lesssim \|\mathbf{\Psi}\|_{H^1(\Omega)} \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}.
\end{aligned}$$

Due to the definition (5.10), the next estimate is a simple consequence of (4.12) and Lemma 3.10:

$$\|\mathbf{\Psi}_h\|_{H^1(\Omega)} \lesssim \|\mathbf{\Psi}\|_{H^1(\Omega)} \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}. \tag{5.12}$$

Finally, the estimates established so far plus the triangle inequality yield

$$\left\| \mathsf{D}^- p_h \right\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{L^2(\Omega)} + \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}. \tag{5.13}$$

Owing to the discrete Poincaré–Friedrichs inequality (4.2), this implies (5.4). ∎

Remark 7. It is worth noting (see Table 3.1) that homogeneous boundary conditions imposed on $\mathcal{H}(\mathsf{D},\Omega)$ permit us to choose $S_h \subset (H_0^1(\Omega))^3$. This means that $\mathbf{\Psi}_h$ will completely vanish on $\partial\Omega$, though it is only the tangential or normal components of $\mathbf{v}_h$, respectively, that vanish on $\partial\Omega$.

LEMMA 5.2. *In the* 2*-regular case (see section* 3*, Table* 3.2*) the splitting* (5.3) *from Lemma* 5.1 *can be chosen such that, in addition to the estimates asserted in Lemma* 5.1*, we have*

$$\left\|\mathsf{D}^- p_h\right\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{L^2(\Omega)}\,, \qquad \|\mathbf{\Psi}_h\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{L^2(\Omega)}\,,$$

with constants additionally depending on the quasi-uniformity of the mesh $\mathcal{T}_h$*.*

Proof. We rely on the $L^2(\Omega)$-orthogonal Helmholtz decomposition (3.4) to define p and $\mathbf{\Psi}$ in (5.1). Consequently, we can expect

$$\|\mathbf{\Psi}\|_{L^2(\Omega)} \le \|\mathbf{v}_h\|_{L^2(\Omega)}\,, \qquad \left\|\mathsf{D}^- p\right\|_{L^2(\Omega)} \le \|\mathbf{v}_h\|_{L^2(\Omega)}\,. \tag{5.14}$$

Then follow the proof of Lemma 5.1 and replace the quasi-interpolation $\widetilde{\mathsf{Q}}_h$ with the $L^2(\Omega)$-orthogonal projection Q_h. Taking into account that h designates a global meshwidth when the constants are allowed to depend on quasi-uniformity, a glance at (4.14) and (4.15) confirms that all estimates of Lemma 5.1 remain true.

The replacement of $\widetilde{\mathsf{Q}}_h$ is necessary, because $\widetilde{\mathsf{Q}}_h$ fails to be continuous with respect to the $L^2(\Omega)$-norm. When using Q_h instead, we arrive at the trivial estimate

$$\mathbf{\Psi}_h := \mathsf{Q}_h\mathbf{\Psi} \quad \Rightarrow \quad \|\mathbf{\Psi}_h\|_{L^2(\Omega)} \le \|\mathbf{\Psi}\|_{L^2(\Omega)} \le \|\mathbf{v}_h\|_{L^2(\Omega)}\,. \tag{5.15}$$

In addition, use the interpolation estimate (5.8) and the inverse inequality (4.8):

$$\left\|\mathsf{D}^- q\right\|_{L^2(\Omega)} \lesssim h\,\|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)} \lesssim \|\mathbf{v}_h\|_{L^2(\Omega)}\,. \tag{5.16}$$

Again, h denotes the (global) meshwidth of $\mathcal{T}_h$. Owing to (5.11) and (5.14), this finishes the proof. ∎

6. Stable splittings. We first discuss the case $0 < \tau \le 1$; that is, the second order term in the bilinear form is dominant. The notation refers to the generic case of Table 3.1.

THEOREM 6.1. *Assume* $0 < \tau \le 1$*. For any* $\mathbf{v}_h \in V_h(\mathsf{D})$ *there is* $p_h \in V_h(\mathsf{D}^-)$*,* $\mathbf{\Psi}_h \in S_h$ *such that, when* $\mathbf{v}_\mathbf{b} \in \operatorname{span}\{\mathbf{b}\}$*,* $\mathbf{b} \in \mathcal{B}(\mathsf{D})$*, a locally supported basis function,*

$$\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \mathbf{v}_\mathbf{b} + \Pi_h^{\mathsf{D}}\mathbf{\Psi}_h + \mathsf{D}^- p_h = \mathbf{v}_h, \tag{6.1}$$

$$\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v}_\mathbf{b}\|_A^2 + \|\mathbf{\Psi}_h\|_{H^1(\Omega)}^2 + \left\|\mathsf{D}^- p_h\right\|_A^2 \lesssim \|\mathbf{v}_h\|_A^2\,, \tag{6.2}$$

with a constant depending only on Ω*,* D*, and the shape regularity of* $\mathcal{T}_h$*, but independent of* $\tau \in\,]0,1]$ *and quasi-uniformity.*

Proof. The contributions $\mathbf{\Psi}_h$ and p_h are chosen as in Lemma 5.1. Hence, reusing the notation of (5.3),

$$\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \mathbf{v}_\mathbf{b} = \widetilde{\mathbf{v}}_h. \tag{6.3}$$

By the inverse estimate (4.8), (4.3), and the bound for $\|h^{-1}\widetilde{\mathbf{v}}_h\|$ from Lemma 5.1

$$\begin{aligned}\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v_b}\|_A^2 &= \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathsf{D}\mathbf{v_b}\|_{L^2(\Omega)}^2 + \tau \|\mathbf{v_b}\|_{L^2(\Omega)}^2 \\ &\lesssim \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \left\|h^{-1}\mathbf{v_b}\right\|_{L^2(\Omega)}^2 + \tau \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v_b}\|_{L^2(\Omega)}^2 \\ &\lesssim \left\|h^{-1}\widetilde{\mathbf{v}}_h\right\|_{L^2(\Omega)}^2 + \tau \|\widetilde{\mathbf{v}}_h\|_{L^2(\Omega)}^2 \lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}^2 + \tau \|\mathbf{v}_h\|_{L^2(\Omega)}^2 .\end{aligned} \tag{6.4}$$

The remaining bounds are immediate from Lemma 5.1 because

$$\left\|\mathsf{D}^- p_h\right\|_A^2 = \left\|\mathsf{D}\mathsf{D}^- p_h\right\|_{L^2(\Omega)}^2 + \tau \left\|\mathsf{D}^- p_h\right\|_{L^2(\Omega)}^2 = \tau \left\|\mathsf{D}^- p_h\right\|_{L^2(\Omega)}^2 .$$

All the constants merely depend on Ω and the shape regularity of $\mathcal{T}_h$. ∎

The case $\mathsf{D} = \operatorname{div}$ deserves special attention, because the discrete potential belongs to $V_h(\mathbf{curl})$. This is not entirely desirable, because it entails solving an $\mathbf{H}(\mathbf{curl},\Omega)$-elliptic problem in $V_h(\mathbf{curl})$ when evaluating the preconditioner. Yet, as $\mathbf{curl}\circ\mathbf{grad} = 0$, we can apply the decomposition of Theorem 6.1 recursively and replace $p_h \in V_h(\mathbf{curl})$ by a $\mathbf{\Phi}_h \in S_h$ and some "high-frequency" edge element function.

Thus, for $\mathsf{D} = \operatorname{div}$ and $\mathbf{v}_h \in V_h(\operatorname{div})$, we examine the decomposition

$$\begin{aligned}\mathbf{v}_h &= \sum_{\mathbf{b}\in\mathcal{B}(\operatorname{div})} \mathbf{v_b} + \Pi_h^{\operatorname{div}} \mathbf{\Psi}_h + \mathbf{curl}\, p_h \\ &= \sum_{\mathbf{b}\in\mathcal{B}(\operatorname{div})} \mathbf{v_b} + \Pi_h^{\operatorname{div}} \mathbf{\Psi}_h + \sum_{\mathbf{q}\in\mathcal{B}(\mathbf{curl})} \mathbf{curl}\, p_{\mathbf{q}} + \mathbf{curl}\, \mathbf{\Phi}_h,\end{aligned} \tag{6.5}$$

where $\mathbf{\Psi}_h, \mathbf{\Phi}_h \in S_h$ and

$$\mathbf{v_b} \in \operatorname{span}\{\mathbf{b}\}, \quad \mathbf{b}\in\mathcal{B}(\operatorname{div}), \qquad p_{\mathbf{q}} \in \operatorname{span}\{\mathbf{q}\}, \quad \mathbf{q}\in\mathcal{B}(\mathbf{curl}).$$

From Theorem 6.1 we conclude that for $0 < \tau \le 1$

$$\sum_{\mathbf{b}\in\mathcal{B}(\operatorname{div})} \|\mathbf{v_b}\|_A^2 + \|\mathbf{\Psi}_h\|_{H^1(\Omega)}^2 + \tau \sum_{\mathbf{q}\in\mathcal{B}(\mathbf{curl})} \|\mathbf{curl}\, p_{\mathbf{q}}\|_{L^2(\Omega)}^2 + \tau \|\mathbf{\Phi}_h\|_{H^1(\Omega)}^2 \lesssim \|\mathbf{v}_h\|_A^2 . \tag{6.6}$$

From now on we permit dependence of the constants on the variation of h. In other words, the estimates below hinge on the assumption of quasi-uniformity of the mesh $\mathcal{T}_h$, which permits us to assume a global meshwidth $h > 0$. Then, we can establish stability *uniformly* for all $\tau > 0$.

THEOREM 6.2. *Assume the* 2-regular case. *Then, for all* $\mathbf{v}_h \in V_h(\mathsf{D})$, *we can find* $p_h \in V_h(\mathsf{D}^-)$, $\mathbf{\Psi}_h \in S_h$ *such that, when* $\mathbf{v_b} \in \operatorname{span}\{\mathbf{b}\}$, $\mathbf{b}\in\mathcal{B}(\mathsf{D})$,

$$\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \mathbf{v_b} + \Pi_h^{\mathsf{D}} \mathbf{\Psi}_h + \mathsf{D}^- p_h = \mathbf{v}_h, \tag{6.7}$$

$$\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v_b}\|_A^2 + \|\mathbf{\Psi}_h\|_{H^1(\Omega)}^2 + \tau \|\mathbf{\Psi}_h\|_{L^2(\Omega)}^2 + \left\|\mathsf{D}^- p_h\right\|_A^2 \lesssim \|\mathbf{v}_h\|_A^2 , \tag{6.8}$$

with a constant depending only on Ω, D, *and the shape regularity and quasi-uniformity of* $\mathcal{T}_h$, *but independent of* $\tau \ge 0$.

Proof. We rely on the decomposition established in Lemma 5.2,

$$\mathbf{v}_h = \widetilde{\mathbf{v}}_h + \Pi_h^{\mathsf{D}} \mathbf{\Psi}_h + \mathsf{D}^- p_h, \tag{6.9}$$

and find, using (4.8), (6.3), and (3.6),

$$\begin{aligned} \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v}_\mathbf{b}\|_A^2 &\lesssim \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} h^{-2} \|\mathbf{v}_\mathbf{b}\|_{L^2(\Omega)}^2 + \tau \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \|\mathbf{v}_\mathbf{b}\|_{L^2(\Omega)}^2 \\ &\lesssim (h^{-2}+\tau) \|\widetilde{\mathbf{v}}_h\|_{L^2(\Omega)}^2 \lesssim (h^{-2}+\tau) h^2 \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}^2 \\ &\lesssim \|\mathsf{D}\mathbf{v}_h\|_{L^2(\Omega)}^2 + \tau \|\mathbf{v}_h\|_{L^2(\Omega)}^2 . \end{aligned} \tag{6.10}$$

Bounds for the other terms are straightforward from the estimates of Lemmas 5.2 and 5.1. ∎

As regards $\mathsf{D} = \operatorname{div}$, in the 2-regular case we also get a τ-uniform estimate for the splitting (6.5):

$$\begin{aligned} \sum_{\mathbf{b}\in\mathcal{B}(\operatorname{div})} \|\mathbf{v}_\mathbf{b}\|_A^2 + \|\mathbf{\Psi}_h\|_{H^1(\Omega)}^2 + \tau \|\mathbf{\Psi}_h\|_{L^2(\Omega)}^2 \\ + \tau \sum_{\mathbf{b}\in\mathcal{B}(\mathbf{curl})} \|\mathbf{curl}\, p_\mathbf{b}\|_{L^2(\Omega)}^2 + \tau \|\mathbf{\Phi}_h\|_{H^1(\Omega)}^2 \lesssim \|\mathbf{v}_h\|_A^2 . \end{aligned} \tag{6.11}$$

Remark 8. The theory seems to indicate increased robustness of the preconditioner with respect to $\tau \to \infty$ in the 2-regular case. However, the numerical experiments of section 8 send the unequivocal message that the "generic case" version of the preconditioner does not deteriorate as τ becomes large. Here, theory obviously falls short of capturing the actual behavior of the method.

7. Auxiliary space preconditioners. We start from the stable decompositions of $V_h(\mathsf{D})$ introduced in Theorems 6.1 and 6.2 and (6.5) and apply the abstract theory of section 2 for $V = V_h(\mathsf{D})$ and the energy bilinear form $a(\cdot,\cdot)$ from (1.3).

Throughout, let $\mathbf{A}_\mathsf{D}$ denote the Galerkin matrix arising from (1.3) with respect to the standard basis $\mathcal{B}(\mathsf{D})$ of $V_h(\mathsf{D})$. We write $\mathbf{L}$ for the matrix related to the bilinear form

$$(\mathbf{\Psi}, \mathbf{\Phi}) \mapsto (\mathbf{grad}\, \mathbf{\Psi}, \mathbf{grad}\, \mathbf{\Phi})_0 , \quad \mathbf{\Phi}, \mathbf{\Psi} \in \boldsymbol{\mathcal{H}}^1,$$

on S_h, which is endowed with the usual nodal basis of hat functions (for the components of vector fields). The positive definite mass matrix on S_h, that is, the Galerkin matrix for the $L^2(\Omega)$-inner product, will be designated by $\mathbf{M}$. Further, we adopt the notation $\mathbf{P}_\mathsf{D}$ for the matrix describing the mapping $\Pi_h^{\mathsf{D}} : \boldsymbol{\mathcal{H}}^1 \mapsto V_h(\mathsf{D})$ with respect to the "hat function basis" of $\boldsymbol{\mathcal{H}}^1$ and the basis $\mathcal{B}(\mathsf{D})$ of $V_h(\mathsf{D})$.

We restrict ourselves to Jacobi smoothing; that is, the smoothing operator is characterized by the inner product

$$s(\mathbf{v}_h, \mathbf{v}_h) = \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} a(\mathbf{v}_\mathbf{b}, \mathbf{v}_\mathbf{b}), \quad \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})} \mathbf{v}_\mathbf{b} = \mathbf{v}_h, \quad \mathbf{v}_\mathbf{b} \in \operatorname{span}\{\mathbf{b}\}, \tag{7.1}$$

and its matrix representation coincides with the diagonal $\mathbf{D}_A$ of $\mathbf{A}_\mathsf{D}$. More generally, one could use any $s(\cdot,\cdot)$ that features the spectral equivalence $s(\mathbf{v}_h, \mathbf{v}_h) \approx \left\|h^{-1}\mathbf{v}_h\right\|_{L^2(\Omega)}^2 + \tau\|\mathbf{v}_h\|^2$.

Since the square of the energy norm can be computed by summing local contributions from the cells K of the mesh $\mathcal{T}_h$, we find

$$\begin{aligned}\|\mathbf{v}_h\|_A^2 &= \left\|\sum\nolimits_{\mathbf{b}\in\mathcal{B}(\mathsf{D})}\alpha_{\mathbf{b}}\mathbf{b}\right\|_A^2 = \sum\nolimits_{K\in\mathcal{T}_h}\left\|\sum\nolimits_{j=1}^{M}\alpha_{K_j}\mathbf{b}_{K,j}\right\|_A^2 \\ &\le M\sum_K\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})}|\alpha_{\mathbf{b}}|^2\,\|\mathbf{b}\|_A^2 = M\sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})}|\alpha_{\mathbf{b}}|^2\,\|\mathbf{b}\|_A^2 = Ms(\mathbf{v},\mathbf{v})\end{aligned} \tag{7.2}$$

if $\mathbf{v}_h = \sum_{\mathbf{b}\in\mathcal{B}(\mathsf{D})}\alpha_{\mathbf{b}}\mathbf{b} \in V_h(\mathsf{D})$. Here, M bounds the (small) number of basis functions whose support overlaps with a single element K. This implies that c_s in (2.12) can be chosen as a small universal constant.

For the sake of simplicity, we continue the discussion for the cases $\mathsf{D} = \mathbf{curl}$ (edge elements) and $\mathsf{D} = \mathrm{div}$ (face elements) separately.

7.1. A preconditioner for $\mathbf{H(curl,\Omega)}$-elliptic problems. We rely on the splitting (6.1) to define the preconditioner. This means that, in terms of the concepts developed in section 2, we have two auxiliary spaces:

1. The space $W_1 := S_h$ with inner product $\overline{a}_1(\mathbf{\Psi}_h,\mathbf{\Psi}_h) := \|\mathbf{\Psi}_h\|^2_{H^1(\Omega)} + \tau\,\|\mathbf{\Psi}_h\|^2_{L^2(\Omega)}$, which is suggested by (6.2) and (6.8). The corresponding transfer operator is $\Pi_1 := \Pi_h^{\mathbf{curl}}$, and, thanks to (4.11), (2.11) holds with constant c_1 depending only on the shape regularity of the mesh.
2. The discrete potential space $W_2 := V_h(\mathsf{D}^-)$ equipped with inner product $\overline{a}_2(p_h,p_h) := \tau\,|p_h|^2_{H^1(\Omega)}$ and transfer operator $\Pi_2 := \mathbf{grad} : V_h(\mathsf{D}^-) \mapsto V_h(\mathsf{D})$, whose norm is uniformly bounded by 1.

We write $\mathbf{G}$ for the matrix related to $\mathbf{grad} : V_h(\mathsf{D}^-) \mapsto V_h(\mathsf{D})$ and $\mathbf{\Delta}$ for the discrete Laplacian (matrix) on linear Lagrangian finite element space $V_h(\mathbf{grad})$. Then the matrix of the resulting auxiliary space preconditioner for the $\mathbf{H}(\mathbf{curl},\Omega)$-elliptic problem (1.1) reads

$$\mathbf{B}_{\mathbf{curl}} := \mathbf{D}_A^{-1} + \mathbf{P}_{\mathbf{curl}}(\mathbf{L}+\tau\mathbf{M})^{-1}\mathbf{P}_{\mathbf{curl}}^T + \tau^{-1}\mathbf{G}(-\mathbf{\Delta})^{-1}\mathbf{G}^T. \tag{7.3}$$

THEOREM 7.1. *For $0 < \tau \le 1$ the spectral condition number $\kappa(\mathbf{B}_{\mathbf{curl}}\mathbf{A}_{\mathbf{curl}})$ depends only on Ω and the shape regularity of the mesh.*

In the 2-regular case $\kappa(\mathbf{B}_{\mathbf{curl}}\mathbf{A}_{\mathbf{curl}})$ is bounded independently of τ, but the quasi-uniformity of the mesh may affect the bound.

Proof. Theorems 6.1 and 6.2 provide the bound for c_0 from (2.13). The constants c_s and c_1, c_2 have been discussed before. Thus, (2.14) leads to the assertion of the theorem. ∎

The impact of switching to spectrally equivalent bilinear forms on W_1, W_2 can be gauged as in Corollary 2.3.

We point out that the transfers can be realized by purely local operations; see [5, section 3] and [5, section 5]. In detail, assuming the standard bases, gradient-matrix $\mathbf{G}$ will agree with the edge-vertex incidence matrix of the mesh. The matrix $\mathbf{P}_{\mathbf{curl}}$ connected with the interpolation $\Pi_h^{\mathbf{curl}}$ describes a local distribution of vectorial degrees of freedom attached to the nodes of the mesh to adjacent edges: the edge connecting vertices with values $\mathbf{w}_1$ and $\mathbf{w}_2$ receives the value

$$\tfrac{1}{2}(\mathbf{w}_1+\mathbf{w}_2)\cdot\mathbf{e}, \tag{7.4}$$

where $\mathbf{e}$ is the direction vector of the edge.

7.2. A preconditioner for H(div, Ω)-elliptic problems. In this case the decomposition (6.5) provides the starting point. It suggests that we choose the following auxiliary spaces:

1. $W_1 := S_h$ with inner product $\overline{a}_1(\mathbf{\Psi}_h, \mathbf{\Psi}_h) := \|\mathbf{\Psi}_h\|^2_{H^1(\Omega)} + \tau \|\mathbf{\Psi}_h\|^2_{L^2(\Omega)}$, which is suggested by (6.6) and (6.11). The corresponding transfer operator is $\Pi_1 := \Pi_h^{\mathrm{div}}$ and, thanks to (4.11), (2.11) holds with constant c_1 depending only on the shape regularity of the mesh. The related interpolation matrix $\mathbf{P}_{\mathrm{div}}$ assigns to each face of the mesh with unit normal $\mathbf{n}$ and area $|F|$ the number
$$\tfrac{1}{3}|F|\,(\mathbf{w}_1 + \mathbf{w}_2 + \mathbf{w}_3)\cdot\mathbf{n}, \tag{7.5}$$
where $\mathbf{w}_i$ is the vectorial nodal value at vertex i of the face.
2. $W_2 := V_h(\mathbf{curl})$ endowed with the localized inner product
$$\overline{a}_2(\mathbf{w}_h, \mathbf{w}_h) := \tau \sum_{\mathbf{q}\in\mathcal{B}(\mathbf{curl})} \|\mathbf{curl}\,\mathbf{w}_{\mathbf{q}}\|^2_{L^2(\Omega)}\,, \qquad \sum_{\mathbf{q}\in\mathcal{B}(\mathbf{curl})} \mathbf{w}_{\mathbf{q}} = \mathbf{w}_h \tag{7.6}$$
for $\mathbf{w}_h \in V_h(\mathbf{curl})$. Evidently, the Galerkin discretization of $\overline{a}_2$ leads to a diagonal matrix denoted by $\mathbf{D}_{\mathbf{curl}}$. A closer inspection of $\mathcal{B}(\mathbf{curl})$ verifies that $\mathbf{D}_{\mathbf{curl}}$ can never be singular.
The transfer operator associated with W_2 is $\mathbf{curl} : V_h(\mathbf{curl}) \mapsto V_h(\mathrm{div})$ and $c_2 = 1$ is obvious. Its matrix representation $\mathbf{C}$ coincides with the incidence matrix of (interior) edges and faces of the mesh; see [21, section 3.1].
3. $W_3 := S_h$ with norm $\sqrt{\tau}\,\|\cdot\|_{H^1(\Omega)}$ (cf. (6.6) and (6.11)) and transfer operator $\mathbf{curl} : S_h \mapsto V_h(\mathsf{D})$. Again, we immediately get $c_3 = 1$ for the constant from (2.11). Owing to the commuting diagram property (4.6) and (4.9), the matrix associated with this transfer is given by $\mathbf{CP}_{\mathbf{curl}}$.

Summing up, the matrix representation of the auxiliary space preconditioner for the variational problem (1.2) discretized on $V_h(\mathrm{div})$ is given by

$$\begin{aligned}\mathbf{B}_{\mathrm{div}} := {}& \mathbf{D}_A^{-1} + \mathbf{P}_{\mathrm{div}}(\mathbf{L} + \tau\mathbf{M})^{-1}\mathbf{P}_{\mathrm{div}}^T + \mathbf{C}\mathbf{D}_{\mathbf{curl}}^{-1}\mathbf{C}^T \\ & + \tau^{-1}\mathbf{C}\mathbf{P}_{\mathbf{curl}}(\mathbf{L} + \tau\mathbf{M})^{-1}\mathbf{P}_{\mathbf{curl}}^T\mathbf{C}^T.\end{aligned} \tag{7.7}$$

All transfer operators are purely local.

THEOREM 7.2. *For $0 < \tau \le 1$ the spectral condition number $\kappa(\mathbf{B}_{\mathrm{div}}\mathbf{A}_{\mathrm{div}})$ depends only on Ω and the shape regularity of the mesh.*

In the 2-regular case $\kappa(\mathbf{B}_{\mathrm{div}}\mathbf{A}_{\mathrm{div}})$ is bounded independently of τ, but the quasi-uniformity of the mesh may affect the bound.

Proof. We merely need to appeal to (6.6), (6.11), and (2.14), because good bounds for c_1, c_2, c_3, and c_s follow from the above arguments. ∎

Remark 9. If boundary conditions are imposed on $\mathcal{H}(\mathsf{D}, \Omega)$, the auxiliary space S_h should be chosen differently in the 2-regular case: it should comprise piecewise linear continuous vector fields, for which merely the tangential or normal components, respectively, vanish on $\partial\Omega$. Of course, this choice can be made in any case, because enlarging the auxiliary space will not affect the estimates adversely unless the continuity of Π is destroyed. On the other hand, tangential boundary conditions are awkward in terms of implementation; cf. the discussion in [5, section 5]. Moreover, as stressed in Remark 8, there is absolutely no numerical evidence that total zero boundary conditions for S_h do any harm.

7.3. Applications to problems with variable coefficients. So far we have skirted the case of variable coefficients, for instance, when we encounter the bilinear form

$$a(\mathbf{u},\mathbf{v}) := (\alpha\,\mathbf{curl}\,\mathbf{u},\mathbf{curl}\,\mathbf{v})_0 + (\beta\mathbf{u},\mathbf{v})_0\,, \quad \mathbf{u},\mathbf{v}\in\mathbf{H}_0(\mathbf{curl},\Omega), \tag{7.8}$$

with coefficient functions $\alpha,\beta\in L^\infty(\Omega)$, because the current theory fails to give any useful information about how strong variations of α and β affect the quality of the nodal auxiliary space preconditioners.

We can give only a heuristic recipe for how the algorithms may be adapted to the general bilinear form from (7.8). The idea is that the coefficient α will be used to define the matrix $\mathbf{L}$ in (7.3). This means that $\mathbf{L}$ agrees with the Galerkin matrix of the bilinear form $(\mathbf{u},\mathbf{v})\mapsto(\alpha\,\mathbf{grad}\,\mathbf{u},\mathbf{grad}\,\mathbf{v})_0$ on $\boldsymbol{\mathcal{H}}^1$. The coefficient β enters the matrices $\mathbf{M}$ and $\boldsymbol{\Delta}$; that is, they represent $(\mathbf{u},\mathbf{v})\mapsto(\beta\mathbf{u},\mathbf{v})_0$ and $(\varphi,\psi)\mapsto(\beta\,\mathbf{grad}\,\varphi,\mathbf{grad}\,\psi)_0$ on $\boldsymbol{\mathcal{H}}^1$ and $V_h(\mathbf{grad})$, respectively. Note that τ is now incorporated into the coefficient β.

8. Numerical experiments. The theory makes a statement about the asymptotic behavior of the nodal auxiliary, but information about concrete condition numbers remains hidden in several elusive constants. In this section we wish to demonstrate that the preconditioner actually achieves reasonably small condition numbers for relevant model problems. Moreover, we monitor the impact of the relative scaling of both parts of the bilinear form $a(\cdot,\cdot)$ from (1.3). Reaching beyond the scope of the theory, we will also examine the impact of strongly varying coefficients in (7.8). Throughout, nodal auxiliary spaces with zero boundary values for all vector components will be used ("generic case").

The first series of experiments is conducted in two dimensions. Note that in two dimensions the operators div and curl acting on vector fields merely differ by a rotation of $\frac{\pi}{2}$. Therefore, both variational problems (1.1) and (1.2) are covered when we consider the bilinear form

$$a(\mathbf{u},\mathbf{v}) := (\operatorname{curl}\mathbf{u},\operatorname{curl}\mathbf{v})_0 + \tau\,(\mathbf{u},\mathbf{v})_0\,, \quad \mathbf{u},\mathbf{v}\in\mathbf{H}_0(\operatorname{curl},\Omega), \tag{8.1}$$

where curl is the scalar-valued two-dimensional rotation $\operatorname{curl}\mathbf{u}=\frac{\partial u_1}{\partial x_2}-\frac{\partial u_2}{\partial x_1}$.

In two dimensions we can study the asymptotics with manageable computational effort. We emphasize that all the considerations underlying the nodal auxiliary subspace approach in three dimensions carry over to (8.1): Galerkin discretization can be based on edge elements on triangular meshes, for which curl-free functions can represented as gradients of piecewise linear Lagrangian finite element functions.

In most experiments we used the preconditioner given by the two-dimensional counterpart of (7.3). A direct solver was employed to realize the multiplications with the inverse matrices. Extremal eigenvalues were computed by means of a Lanczos procedure up to an accuracy of at least two digits.

Experiment I. A sequence of meshes of two polygonal domains was created by the regular refinement of the coarse meshes depicted in Figure 8.1. One domain is convex, that is, it satisfies the assumptions of the 2-regular case, while the other fails to do so. Spectral condition numbers of $\mathbf{B}_{\mathrm{curl}}\mathbf{A}_{\mathrm{curl}}$, $\mathbf{A}_{\mathrm{curl}}$ the edge element Galerkin matrix related to (8.1), were computed for different choices of τ; see Tables 8.1 and 8.3. A variant of the preconditioner relying on two steps of Gauss–Seidel smoothing (see section 2) was tested in the same setting. The measured condition numbers are listed in Tables 8.5 and 8.6.

We also keep track of the number of PCG iterations required to solve the discrete variational problems with bilinear form $a(\cdot,\cdot)$ from (8.1) and constant vector field $\mathbf{f} = \binom{1}{1}$ as the right-hand side. A relative reduction of the Euclidean norm of the residual vector by a factor of 10^6 was used as termination criterion. The results are recorded in Tables 8.2 and 8.4.

The condition numbers hardly deteriorate on successively finer meshes. The slight dependence on the refinement level is a commonly observed preasymptotic phenomenon; cf. Remark 2 in [8]. A similar statement applies to the number of CG iterations. Robustness in τ is evident though not covered by theory when using a nodal auxiliary space with zero boundary conditions ("generic setting," Table 3.1). Using a Gauss–Seidel smoother instead of Jacobi improves the performance at increased costs for a single application of the preconditioner.

Experiment II. Starting from a coarse mesh on the "L-shaped domain" (Figure 8.1, right) we generate a sequence of meshes by strictly local refinement; see

Figure 8.2. As in the previous experiment we recorded spectral condition numbers $\kappa(\mathbf{B}_{\mathrm{curl}}\mathbf{A}_{\mathrm{curl}})$; see Figure 8.3. This time, we monitor their dependence on the smallest size $h_{\min}$ of mesh cells.

The conclusions drawn in Experiment I carry over verbatim.

Experiment III. To study the response of the preconditioner to nonconstant coefficients, we apply it to the bilinear form

$$a(\mathbf{u},\mathbf{v}) := (\alpha \operatorname{curl}\mathbf{u}, \operatorname{curl}\mathbf{v})_0 + \tau\,(\beta\mathbf{u},\mathbf{v})_0\,, \quad \mathbf{u},\mathbf{v}\mathbf{H}_0(\operatorname{curl},\Omega), \tag{8.2}$$

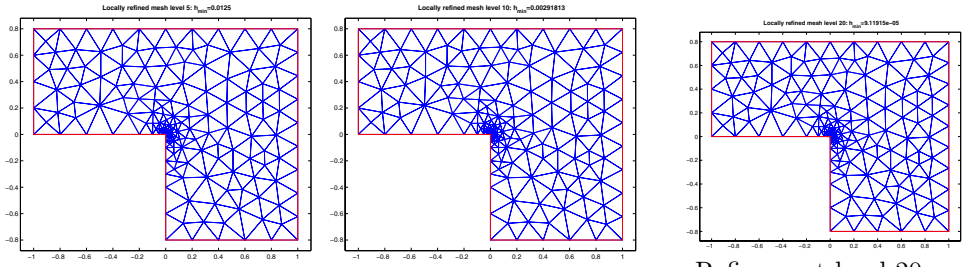

FIG. 8.2. *Sequence of locally refined meshes.*

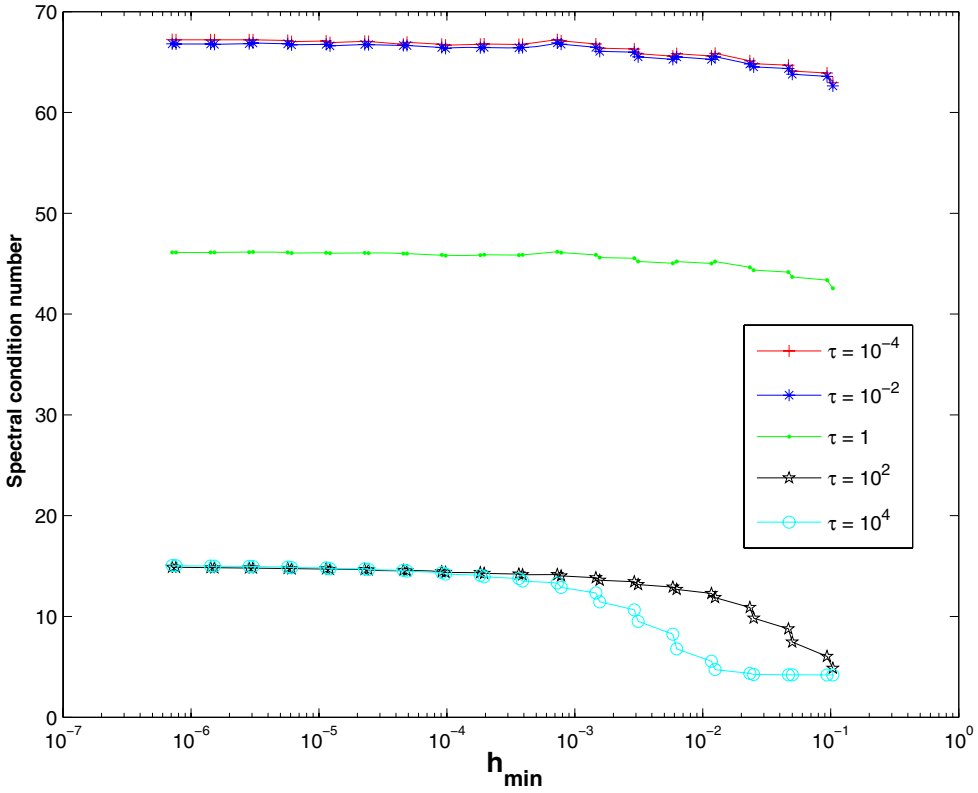

FIG. 8.3. *Behavior of auxiliary space preconditioner on locally refined meshes.*

with $\alpha, \beta \in L^\infty(\Omega)$. This is the two-dimensional analogue of (7.8). The implementation of the preconditioner $\mathbf{B}_{\mathrm{curl}}$ follows the policy outlined in section 7.3.

We consider $\Omega =]-1,1[^2$ with a triangular subdomain Ω_1 that is resolved by the mesh; see Figure 8.4. The coefficient functions behave like

$$\alpha(\mathbf{x}) := \begin{cases} \alpha_1 & \text{if } \mathbf{x} \in \Omega_1, \\ 1 & \text{elsewhere,} \end{cases} \qquad \beta(\mathbf{x}) := \begin{cases} \beta_1 & \text{if } \mathbf{x} \in \Omega_1, \\ 1 & \text{elsewhere.} \end{cases} \tag{8.3}$$

We recorded the condition numbers of the preconditioned stiffness matrices on sequences of meshes arising from successive regular refinement of the mesh depicted

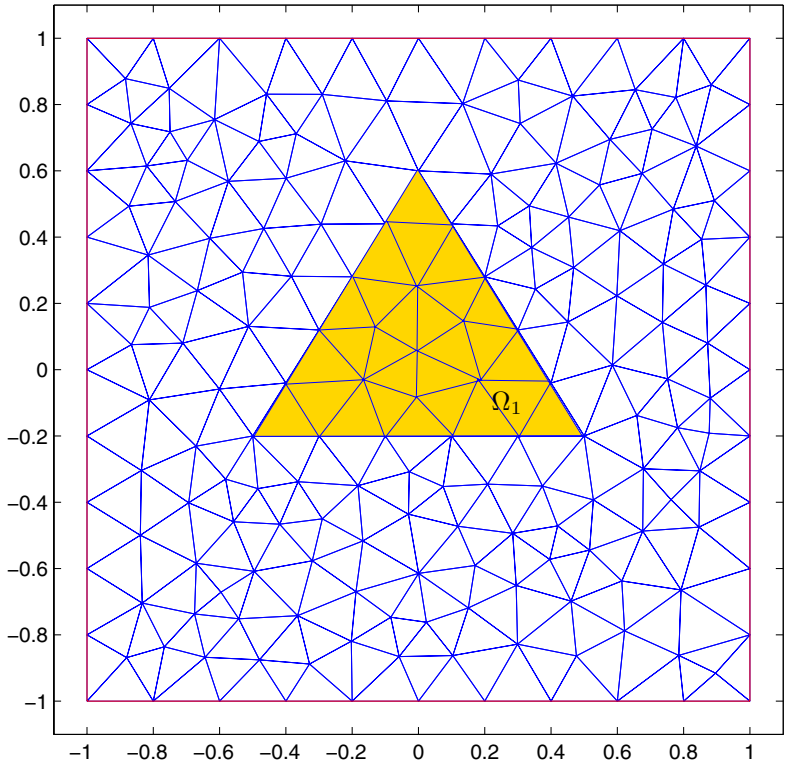

FIG. 8.4. *Subdomains with piecewise constant coefficients and associated coarsest triangular mesh.*

in Figure 8.4; see Tables 8.7 and 8.9. In addition, Tables 8.8 and 8.10 give the number of CG iterations required for a relative reduction of the Euclidean residual norm by a factor of 10^6. As before, zero was used as an initial guess and we chose the source field $\mathbf{f} = \binom{1}{1}$.

TABLE 8.7
Condition numbers *(two digits) recorded in Experiment* III: *Discontinuous coefficient* α, $\beta_1 = 1$.

		α_1										
Level	# cells	0.001	0.01	0.1	2	5	10	20	50	100	200	1000
0	332	19	18	16	18	21	24	28	31	33	34	35
1	1328	23	21	20	21	24	27	31	36	38	39	40
2	5312	28	27	22	23	25	29	33	37	40	41	42
3	21248	35	32	24	25	26	30	34	38	40	42	43
4	84992	41	36	26	26	27	30	34	38	41	42	43
5	339968	46	39	27	27	28	31	34	39	41	42	43

By and large, we observe that the condition number of the preconditioned system is not much affected by steep jumps in the coefficients α or β. A slight deterioration is caused by large values of β inside Ω_1. The same holds for the convergence of the preconditioned CG iterations. It seems that the behavior of the method surpasses the predictions of the theory.

Experiment IV. In this experiment we study the auxiliary space preconditioner for genuine three-dimensional boundary value problems of the form (1.1). Zero Dirich-

let boundary conditions are used throughout; that is, $\mathcal{H}(\mathbf{curl}, \Omega) = \mathbf{H}_0(\mathbf{curl}, \Omega)$.

We consider two different domains; one is the unit cube $\Omega = \Omega_\square := (0,1)^3$, and the other is the unit ball $\Omega = \Omega_\circ := \{x = (x_1, x_2, x_3) \in R^3 : x_1^2 + x_2^2 + x_3^2 < 1\}$. Lowest order edge elements (cf. section 4) are applied to discretize (1.1) on quasi-uniform simplicial triangulations of both domains. We apply the preconditioner $\mathbf{B}_{\mathbf{curl}}$ given in (7.3) to the discretized systems with

1. $\mathbf{D}_A^{-1}$ replaced with the approximate inverse corresponding to three iterations of the symmetric point Gauss–Seidel method for $\mathbf{A}_{\mathbf{curl}}$,
2. $(\mathbf{L} + \tau\mathbf{M})^{-1}$ replaced with one V-cycle of an AMG method [35] for $\mathbf{L} + \tau\mathbf{M}$, and
3. $(-\boldsymbol{\Delta})^{-1}$ replaced with one V-cycle AMG method for matrix $-\boldsymbol{\Delta}$ of the discrete vector Laplacian.

The matrices $\mathbf{L}$ and $\mathbf{M}$ correspond to the generic case; see Table 3.1.

We study the condition number of $\mathbf{B}_{\mathbf{curl}}\mathbf{A}_{\mathbf{curl}}$ on sequences of uniformly and regularly refined triangulations of both domains. On the unit cube the coarsest mesh is obtained by splitting each cell of a uniform tensor product grid into six tetrahedra. For the sphere, a mesh generator is employed to get a sequence of increasingly finer meshes, whose tetrahedra all have about the same size and little distortion. Condition number

estimates are computed by means of the Lanczos method and listed in Tables 8.11 and 8.12 for different values of the scaling parameter τ.

TABLE 8.11

8	242588	4.340	4.552	3.391

As before, we also record the the number of iterations required for the PCG method with the above preconditioner to reduce the $\mathbf{B_{curl}}$-norm of the residual by a factor of 10^6. The iteration counts for different values of τ are given in Tables 8.13 and 8.14. In both cases a zero initial guess was used and the right-hand side was such that the corresponding exact solutions of the boundary value problems are

$$\mathbf{u}(x,y,z) = \begin{pmatrix} xyz(x-1)(y-1)(z-1) \\ \sin(\pi x)\sin(\pi y)\sin(\pi z) \\ (1-e^x)(1-e^{x-1})(1-e^y)(1-e^{y-1})(1-e^z)(1-e^{z-1}) \end{pmatrix} \text{ on } \Omega_\square,$$

$$\mathbf{u}(x,y,z) = (x^2+y^2+z^2-1)\mathbf{1} \quad \text{on } \Omega_\circ.$$

TABLE 8.13
Number of PCG iterations on unit cube.

		τ								
Level	# cells	10^{-4}	10^{-3}	10^{-2}	10^{-1}	1	10	10^2	10^3	10^4
1	6×8^3	14	14	14	14	14	13	10	10	10
2	6×16^3	14	14	14	14	14	13	11	10	9
3	6×32^3	14	14	14	14	14	13	12	10	9
4	6×48^3	14	14	14	14	14	13	12	10	9

The observations perfectly match those made in two dimensions: the condition numbers and iteration counts are essentially independent of the meshwidth and τ. The number of PCG iterations decreases slightly when τ gets larger.

To illustrate the importance of the extra smoothings $\mathbf{D}_A^{-1}$ in our preconditioner (7.3), we recorded the number of iterations of the corresponding PCG method with the term $\mathbf{D}_A^{-1}$ removed from the preconditioner (7.3). The results are given in Table 8.15. We can see that the number of iterations doubles as the meshwidth gets halved.

Concluding remarks. Nodal auxiliary space preconditioning for discrete $\mathbf{H}(\mathbf{curl}, \Omega)$- and $\mathbf{H}(\mathrm{div}, \Omega)$-elliptic variational problems has a solid theoretical foundation and proves satisfactory in numerical tests. It can pave the way for applying standard AMG methods to boundary value problems discretized by means of edge or face finite elements. Numerous improvements of the method that can make use of better smoothers and refined auxiliary spaces are conceivable.

Acknowledgments. The authors wish to thank Wang Mengyu, Hangzhou University, and Patrick Meury, ETH Zürich, for writing parts of the MATLAB code for the two-dimensional experiments and also Tan Lin and Shu Shi, Xiangtan University, for their help with the three-dimensional experiments.

ERROR BOUNDS FOR APPROXIMATE EIGENVALUES OF PERIODIC-COEFFICIENT LINEAR DELAY DIFFERENTIAL EQUATIONS*

ED BUELER†

Abstract. We describe a new Chebyshev spectral collocation method for systems of variable-coefficient linear delay differential equations with a single fixed delay. Computable uniform a posteriori bounds are given for this method. When the coefficients are periodic, the system has a unique compact nonnormal monodromy operator whose spectrum determines the stability of the system. The spectral method approximates this operator by a dense matrix of modest size. In cases where the coefficients are smooth we observe spectral convergence of the eigenvalues of that matrix to those of the operator. Our main result is a computable a posteriori bound on the eigenvalue approximation error in the case that the coefficients are analytic.

Key words. Chebyshev, collocation, delay differential equations, eigenvalues, monodromy operator, a posteriori, spectral methods

1. Introduction.

Consider the linear delay differential equation (DDE)

$$\ddot{x} + \dot{x} + (\delta + 0.1\cos(\pi t))x = b\,x(t-2), \tag{1.1}$$

with $\delta, b \in \mathbb{R}$. This is a delayed, damped Mathieu equation [21].

> *Question*: For which values of δ, b is (1.1) asymptotically stable in the sense that all solutions go to zero as $t \to \infty$?

A practical and visual answer to this question, for $(\delta, b) \in [0, 20] \times [-10, 10]$ in (1.1), is the numerically produced *stability chart* in Figure 1.1.

Questions like this one arise in the stability analysis of many DDE models, including nonlinear models. Indeed, linear periodic DDEs frequently occur as the "variational equation" for perturbations of a periodic solution of a nonlinear DDE [18], and thus questions of this type are important in nonlinear dynamics as well. Stability charts like Figure 1.1 are useful in applications, including biology [25] and engineering [29] stability problems. In the context of machine tool vibrations, for instance, stability charts allow the choice of parameters which minimize regenerative vibrations and maximize throughput and quality [20, 37].

The stability chart in Figure 1.1 is produced pixel-by-pixel by numerically approximating the spectral radius of the compact monodromy operator associated to DDE (1.1). This operator is defined in section 2. Its eigenvalues are called *multipliers*. For each (δ, b) parameter pair there is a monodromy operator, and the pixel is marked as stable if the computed spectral radius is less than one. By "computed spectral radius" we mean this: Numerical methods applied to equations like (1.1) can usually be formulated as giving a square matrix which "approximates" the monodromy

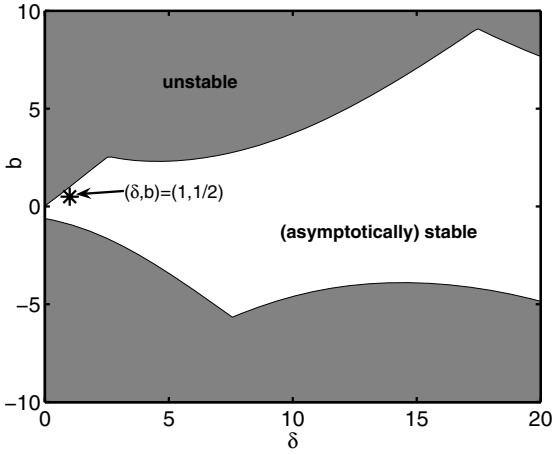

FIG. 1.1. *Stability chart for a delayed, damped Mathieu equation.*

operator, in the intended sense that the largest (magnitude) eigenvalues of the matrix approximate the largest multipliers of the operator [7, 10, 21, 24]. Standard numerical methods compute the eigenvalues of the matrix [17], and thus we get a computed spectral radius of the monodromy operator.

An example of the problem which motivates this paper is this: Based on Figure 1.1 we expect that the particular parameter pair $(\delta, b) = (1, 1/2)$ will be stable. In fact, for this parameter pair we get, from the spectral method introduced in this paper, the numerical value 0.612992319912 for the spectral radius of the monodromy operator. Based on many computations, by himself and others, of the eigenvalues of monodromy operators (the "multipliers") of periodic linear DDEs using spectral methods [8, 15, 21, 24], the author believes this value is trustworthy. In fact, the author believes that all twelve digits given are correct. But can one actually bound the difference between the actual multipliers and their approximations? Is the bound computable, and is it close to the actual error?

Figure 1.2 shows what we want, namely, to have the computed large eigenvalues of the matrix approximation within "error circles" in which the actual multipliers are known to reside. This figure results from applying our main result, which will be stated in Theorem I. It gives the desired kind of computable bounds for a class of DDEs which includes (1.1). We see, in particular, that the $(\delta, b) = (1, 1/2)$ case of (1.1) is stable because all error circles are within the unit disc.

This paper is concerned with linear periodic-coefficient DDEs with fixed delays. For such equations there is a Floquet theory [30] somewhat analogous to that for ordinary differential equations (ODEs). For constant-coefficient DDEs the multipliers can be determined, in theory or numerically, by finding the roots of a characteristic equation. For linear, periodic-coefficient DDEs with "integer" delays [19], if a Floquet transition matrix for certain linear ODEs associated to the DDE can be found exactly, then complex variable techniques can also in theory determine the multipliers [19, section 8.3]. (The Floquet transition matrix is the fundamental solution evaluated at one period of the coefficients of a periodic-coefficient linear ODE.) In general, however, ODE fundamental solutions must themselves be approximated. Furthermore, an approximation of the monodromy operator itself is of interest in many problems,

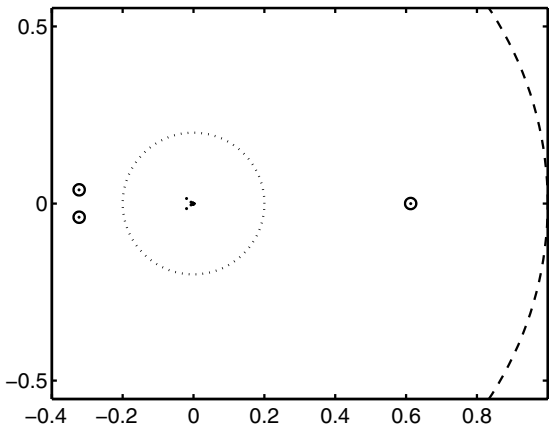

FIG. 1.2. *Computed multipliers (dots) of* (1.1) *with* $(\delta, b) = (1, 1/2)$. *Application of the technique of this paper (with* 76 *Chebyshev collocation points, in particular) gives an error radius of* 0.016 *around the computed multipliers (solid circles) for those actual multipliers* μ *such that* $|\mu| \geq 0.2$ *(dotted circle). The equation is seen to be stable because all eigenvalues are within the unit circle (dashed).*

including in cases where the eigenfunctions of the operator are important.

The DDEs addressed in this paper are d-dimensional systems of the form

$$\dot{y} = A(t)y + B(t)y(t-\tau), \tag{1.2}$$

where $\tau > 0$ is fixed and where $A(t), B(t)$ are $d \times d$ continuous matrix-valued coefficients. Higher-order scalar equations like (1.1) can, of course, be written as first-order systems of form (1.2). The Chebyshev collocation method for initial value problems (IVPs), described next and in section 3, makes no further restrictions on the form of the problem. To possess a unique monodromy operator, however, the coefficients A, B of the DDE must have common period T. We also assume $T = \tau$. The $T = \tau$ case is of importance in applications [20], and it is a technically easier first case in which to address the computation of error bounds on computed multipliers. To estimate the eigenvalue approximation error for our spectral method we will require the coefficients A, B to be analytic. Without some strong smoothness assumption we cannot, of course, expect spectral convergence of either solutions or eigenvalues.

This paper presents several new techniques for the numerical analysis of DDEs.

First we describe a new Chebyshev spectral collocation method for solving DDE IVPs of the form (1.2). The modest amount of notation necessary to describe the method in detail is given in section 3, but the essentials of the method can be communicated without it. Indeed, we choose N collocation points and then replace the DDE (1.2) by its collocation approximation

$$\hat{D}_N v = \hat{M}_A v + \hat{M}_B w, \tag{1.3}$$

where $\hat{D}_N$, $\hat{M}_A$, and $\hat{M}_B$ are square matrices of typically modest size—e.g., 30 to 300 rows—defined in section 3, and where v, w are vectors of collocation values of $y(t)$ and $y(t-\tau)$, respectively. The solution of the linear system (1.3) by Gauss elimination (or other dense matrix methods) completes the spectral method. We give computable a posteriori error bounds on the uniform error of this method (Theorem 3.4).

Second, we make an observation which is almost trivial, but which nonetheless gives a new spectral method for approximating the monodromy operator associated to DDE (1.2). We observe that the matrix which computes v from w, in (1.3), is a matrix approximation of the monodromy operator:

$$U_N = \left(\hat{D}_N - \hat{M}_A\right)^{-1} \hat{M}_B. \tag{1.4}$$

We have seen in many examples [9, 10] that the eigenvalues of U_N are excellent approximations of the multipliers.

In fact, spectral methods have been applied to DDEs many times in the past [5, 13, 23, 24]. Though the above specific spectral method is new to our knowledge, in that it uses collocation at the Chebyshev extreme points, the results just stated should not be surprising to many readers.

Our third new technique is very different from the existing literature, however. It says that one can compute bounds on the errors in the eigenvalues of U_N.

THEOREM I (Theorem 6.4 gives precise statement and proof). *If the coefficient functions $A(t)$, $B(t)$ in* (1.2) *are analytic on a closed interval of length T, and if the delay is equal to the period ($\tau = T$), then the distance from a large multiplier μ to the nearest of the computed eigenvalues λ_i of U_N is bounded*:

$$\min |\mu - \lambda_i| \leq \omega \ \mathrm{cond}(\tilde{V}).$$

Here "$\mathrm{cond}(\tilde{V})$*" is a computable condition number coming from a numerical diagonalization of U_N. The other factor ω comes from a combination of a priori bounds, derived from properties of the coefficients A, B in* (1.2), *and a posteriori estimates on IVPs for* (1.2) *with predetermined initial functions (namely, Chebyshev polynomials).*

We observe in many examples that ω decays exponentially, while $\mathrm{cond}(\tilde{V})$ grows slowly, as the number N of Chebyshev collocation points increases. Thus the estimate is usably small in these cases, and we give two examples here.

The a posteriori estimates on IVPs just mentioned come from an apparently new kind of result for spectral methods applied to ODEs (Theorem 3.4). A new "bootstrapping" method for achieving good a posteriori bounds on the growth of fundamental solutions to variable-coefficient ODEs is given in section 4. To prove Theorem I we also give an apparently new theorem on eigenvalue perturbation for diagonalizable operators on Hilbert spaces (Theorem 5.1 and Corollary 5.2). These are all technical results for our current purposes, but they may be of independent interest.

As noted, we address the case where the period of the coefficients T is equal to the (single, fixed) delay τ. A preprint by the author [8] sketches the generalization of the results to the situation in which $T \geq \tau$. Further generalization to multiple "integer" delays [19] presents only resolvable bookkeeping difficulties [9].

Regarding previous work in this area, spectral methods were first applied to DDE IVPs in [5] and [23]. More recently, collocation using the Gauss–Legendre points has been applied to the problem of finding periodic solutions to nonlinear DDEs in [13]. (Note that our problems have periodic coefficients but they do not, generally, have periodic solutions.) There is also a substantial engineering literature addressing stability—as opposed to solutions of IVPs—of ODEs and DDEs by spectral methods. For ODE problems, Sinha and Wu [28] use a Chebyshev Galerkin method, for example. Engineering applications led the author and colleagues to use spectral methods to address DDE stability questions [10]. Luzyanina and Engelborghs address the

application of spectral methods, among others, to the stability of linear DDEs and functional differential equations, and numerical evidence for spectral convergence of the multipliers is given [24, Table 2].

A recent paper by Breda, Maset, and Vermiglio [7] shows that for constant-coefficient DDEs with fixed discrete and distributed delays, a class of Runge–Kutta methods approximate the multipliers with a polynomial (in the mesh/step size) rate of convergence; spectral convergence does not, of course, occur. No computable error bounds are given.

The Chebyshev spectral method used here for DDEs first appeared in preprint form in [8]. Gilsinn and Potra [15] have recently sketched an a priori proof of the convergence of the numerical multipliers by this method. In [15] convergence is under mesh-refinement ("h-refinement"), based on the proof techniques of [5]. The regularity of the DDE to which the convergence argument applies is unspecified. No estimate of the rate of convergence is given.

Mesh-refinement has not been considered in the current paper, as one cannot achieve the spectral convergence necessary to have good eigenvalue estimation; in this paper we address only "p-refinement," where one increases the degree of polynomial approximation.

We believe that this paper represents the first quantitative technique for bounding the eigenvalue approximation error for a large class of continuous, infinite-dimensional systems whose dynamics are represented by *nonnormal* compact operators which are *not* already represented as integral operators with known kernels (compare [1]), or as Toeplitz operators (see [35] and the literature cited there), or which come from constant-coefficient equations (e.g., [7]). Note that the monodromy operators here are described by formula (2.4), so that they are operators of the form (finite rank operator) *plus* (integral operator). Finding the kernel of the integral operator part generally requires approximation of the fundamental solution of a variable-coefficient ODE, however. This is itself a nontrivial task in general [22].

2. The monodromy operator for a linear, periodic DDE. Consider the linear DDE system

$$\dot{y}(t) = A(t)\, y(t) + B(t)\, y(t-2) \tag{2.1}$$

for $y(t) \in \mathbb{C}^d$. Suppose A, B are continuous matrix-valued functions on $I = [-1, 1]$ which extend to not-necessarily-continuous periodic functions on the real line with period $T = 2$. The normalization of the period and the delay to 2, and the choice of interval $[-1, 1]$, are convenient for describing the Chebyshev collocation method (below). This normalization can be achieved by scaling and shifting the independent variable t in any linear periodic DDE with $T = \tau$, of course.

The *monodromy operator* U for (2.1) is defined as follows by considering the IVP [18]. Suppose $y(t)$ solves (2.1) with initial condition $y(t) = f(t)$ for $t \in I$; $y(t)$ is then defined for $t \in [-1, \infty)$. For $s \geq 1$, define $y_s(t) = y(t + s - 1)$ for $t \in I$; this is standard shift notation for DDEs [18]. Note that y_s is a $\mathbb{C}^d$-valued function defined on I and that $y_1 = f$. Define U to act on a soon-to-be-specified space of functions on I:

$$Uf = y_3. \tag{2.2}$$

Note U maps a function on I back to a function on I; such a form is essential if U is to have a spectrum.

Thus the monodromy operator acts by solving an ODE IVP

$$\dot{z}(t) = A(t)z(t) + B(t)f(t), \qquad z(-1) = f(1), \tag{2.3}$$

for $t \in I$, to give $Uf = z$. (Also, $z = y_3$, but we want to clearly show the ODE IVP.) This linear, nonhomogeneous ODE problem can be solved by integration *if* the solution to the corresponding homogeneous ODE problem is known. In fact,

$$(Uf)(t) = \Phi_A(t)f(1) + \int_{-1}^{t} \Phi_A(t)\Phi_A(s)^{-1}B(s)f(s)\,ds, \tag{2.4}$$

where $\Phi_A(t)$ is the fundamental solution of $\dot{z} = A(t)z$. (By definition $\Phi_A(t)$ solves $\dot{\Phi}_A = A\Phi_A$ on I and $\Phi_A(-1) = I_d$, where I_d is the identity on $\mathbb{C}^d$.) Note that the second summand in this formula for the monodromy operator is an integral operator of Volterra type. Knowledge of the kernel of this integral operator, namely, $k(t,s) = \Phi_A(t)\Phi_A(s)^{-1}B(s)$, generally requires the numerical solution of an ODE problem, however.

We emphasize that $y_{2n+1} = U^n f$ solves, by "the method of steps," the IVP consisting of (2.1) and $y(t) = f(t)$, $t \in I$. More precisely, if $2n - 1 \le t \le 2n + 1$, then $y(t) = (U^n f)(t - 2n)$, and so $y(t)$ is determined by steps for all of $[-1, \infty)$. The (asymptotic) stability of (2.1) is therefore given by the condition that the spectral radius of U be less than unity. (On the other hand, the degree of nonnormality of U will determine how much caution is required in extracting meaning from the multipliers of the linearization (variational equation) of a nonlinear DDE around a periodic solution; compare [35].)

Note that the solutions of linear DDEs with periodic coefficients are *not* themselves periodic. Also, the solutions are generally only regular in pieces. For instance, even if the initial function f is smooth on the interval I, and if A, B are smooth on all of $\mathbb{R}$, nonetheless some derivative of $y(t)$ is generally not continuous at $t = 1$.

An alternative form for the monodromy operator uses a fundamental solution to the DDE itself [18, 15]. In the periodic-coefficient case of the current paper, formula (2.4) is equivalent to, but easier to use than, this alternate form. Our reasons for the "easier to use" claim are necessarily complicated, but they relate to the piecewise regularity of the eigenfunctions of the DDE problem. See Lemma 4.3 below.

We still have not specified the space on which U acts, and it is vital to choose a usable space. Inspection of formula (2.4) shows that if f is continuous on I, then Uf is continuous on I. It is appropriate to fix notation.

DEFINITION 2.1. *Let $C(I)$ be the space of scalar continuous functions on I. Let $\mathcal{C} = C(I) \otimes \mathbb{C}^d$ be the space of $\mathbb{C}^d$-valued continuous functions.*

Certainly a monodromy operator $U : \mathcal{C} \to \mathcal{C}$ is well defined from formula (2.4). Its spectrum determines the stability of DDE (2.1). On the other hand, it will be desirable to work in a Hilbert space because we need tools for eigenvalue perturbation. In addition, the output of U is more regular than the input. We will suffer no loss of generality if we restrict our attention to a Hilbert space which is a subspace of $\mathcal{C}$ because, in particular, the eigenfunctions of $U : \mathcal{C} \to \mathcal{C}$ will in every case be in our chosen subspace.

The Hilbert space we choose is defined via a well-behaved orthogonal basis of nonperiodic, smooth functions which do a good job of approximating functions in $\mathcal{C}$, namely, Chebyshev polynomials with a well-chosen normalization. As is well known, these polynomials also do an excellent job of interpolating smooth functions on I; see section 3. In the next two definitions, and the two lemmas which follow, we confine

ourselves to the scalar case ($d = 1$) for notational convenience. There will be no actual loss of generality (as explained after Lemma 2.5).

DEFINITION 2.2. *Let L^2 be the Hilbert space of complex-valued (measurable) functions f on I such that $\int_{-1}^{1} |f(t)|^2(1-t^2)^{-1/2}\,dt < \infty$, and define the inner product $\langle f, g\rangle_{L^2} = \int_{-1}^{1} \overline{f(t)}\, g(t)\, \left(1-t^2\right)^{-1/2}\,dt$. (Note that "$L^2$" will always refer to a weighted L^2 space.) The (L^2-)*normalized Chebyshev polynomials *are defined as $\hat{T}_0(t) = (1/\sqrt{\pi})T_0(t)$, $\hat{T}_k(t) = (\sqrt{2/\pi})T_k(t)$, where $T_k(t) = \cos(k \arccos t)$ are the* standard Chebyshev polynomials. *The set $\{\hat{T}_k\}_{k=0}^{\infty}$ is an orthonormal (ON) basis of L^2. For $f \in L^2$ let $\hat{f}_k = \langle \hat{T}_k, f\rangle_{L^2}$ be the (L^2-)*Chebyshev expansion coefficients *of f. Thus $f(t) = \sum_{k=0}^{\infty} \hat{f}_k \hat{T}_k(t)$, with convergence in L^2, and $\|f\|_{L^2}^2 = \sum_{k=0}^{\infty} |\hat{f}_k|^2$.*

Unfortunately, the monodromy operator U is not bounded on L^2. In particular, (2.4) refers to the point values of the input function. Therefore, we turn to a Hilbert subspace of $L^2 \cap \mathcal{C}$ introduced by Tadmor [31].

DEFINITION 2.3. *$H^1 := \{f \in L^2 | \sum_{k=0}^{\infty}(1+k)^2|\hat{f}_k|^2 < \infty\}$. For $f, g \in H^1$ we define the inner product $\langle f, g\rangle_{H^1} = \sum_{k=0}^{\infty}(1+k)^2 \overline{\hat{f}_k}\, \hat{g}_k$. Let $\tilde{T}_k(t) = (1+k)^{-1}\hat{T}_k(t)$ be the H^1-*normalized Chebyshev polynomials. *The set $\{\tilde{T}_k\}_{k=0}^{\infty}$ is an ON basis of H^1.*

The space H^1 is a Sobolev space. It is not actually equivalent to $W_T^{1,2} = \left\{f \in L^2 \middle| \|f\|_{L^2} + \|\dot{f}\|_{L^2} < \infty\right\}$ [31], but we will have no need for such an equivalence. Next, we see that $H^1 \subset C(I)$ and pointwise evaluation is bounded.

LEMMA 2.4. *If $f \in H^1$, then f is continuous (it has a continuous representative) and $|f(t)| \le 0.9062\|f\|_{H^1}$. In particular,*

$$\delta_1 f \equiv \sum_{k=0}^{\infty} \hat{f}_k \hat{T}_k(1) = \sum_{k=0}^{\infty} \int_{-1}^{1} \hat{T}_k(1)\hat{T}_k(t)(1-t^2)^{-1/2} f(t)\,dt \tag{2.5}$$

is a bounded linear functional $f \mapsto f(1)$ on H^1.

Proof. The proof is a standard exercise for Sobolev spaces. See [8] for a complete proof. ∎

To use H^1 we also need to know that if f is sufficiently regular on I, then $f \in H^1$. We give a criterion via the Fourier series of $f(\cos\theta)$. In fact, if $f \in C^1(I)$, then the even function $\underline{f}(\theta) = f(\cos\theta)$ is in $C^1_{per}[-\pi, \pi]$; that is, $\underline{f}$ can be periodically extended with period 2π to be C^1 on $\mathbb{R}$. For $k \in \mathbb{Z}$ let $\hat{\underline{f}}(k)$ be the kth Fourier coefficient of $\underline{f}$; that is, $\hat{\underline{f}}(k) = (2\pi)^{-1/2}\int_{-\pi}^{\pi} e^{-ik\theta}\underline{f}(\theta)\,d\theta$. Then $\hat{f}_k = \hat{\underline{f}}(k) = \hat{\underline{f}}(-k)$ for $k > 0$ and $\hat{f}_0 = 2^{-1/2}\hat{\underline{f}}(0)$. For functions g on $[-\pi, \pi]$ define the norm $\|g\|_F^2 := \int_{-\pi}^{\pi} |g(\theta)|^2\,d\theta$.

LEMMA 2.5.

$$\|f\|_{L^2}^2 = \frac{1}{2}\sum_{k=-\infty}^{\infty} |\hat{\underline{f}}(k)|^2 = \frac{1}{2}\|\underline{f}\|_F^2, \text{ and} \tag{2.6}$$

$$\|f\|_{H^1}^2 = \frac{1}{2}\sum_{k=-\infty}^{\infty} (1+k)^2|\hat{\underline{f}}(k)|^2 \le \|\underline{f}\|_F^2 + \|\underline{f}'\|_F^2. \tag{2.7}$$

Thus $C^1(I) \subset H^1 \subset C(I)$ and

$$\|f\|_{H^1}^2 \le 2\pi\|f\|_{\infty}^2 + 2\pi\|\dot{f}\|_{\infty}^2 \tag{2.8}$$

if $f \in C^1(I)$.

Proof. Again the proof is standard and is found in [8]. ∎

Now we return to the general $\mathbb{C}^d$-valued (nonscalar) case. By mild abuse of notation, we let L^2 be the space of $\mathbb{C}^d$-valued measurable functions f for which $\int_{-1}^1 |f(t)|^2(1-t^2)^{-1/2}\,dt < \infty$; there is a corresponding inner product. Again by abuse of the notation we let H^1 be the subspace of L^2 for which $\sum_{k=0}^\infty (1+k)^2|\hat{f}_k|^2 < \infty$, where $\hat{f}_k = \langle \hat{T}_k, f\rangle_{L^2} \in \mathbb{C}^d$. We give H^1 the obvious inner product.

Since Uf solves IVP (2.3), U maps $\mathcal{C}$ to C^1 and indeed $U : H^1 \to H^1$. We can extract from (2.4) a useful estimate of $\|U\|_{H^1}$.

LEMMA 2.6. *Suppose* $\left|\Phi_A(t)\Phi_A(s)^{-1}\right| \le C_A$ *for all* $-1 \le s \le t \le 1$. *Let* $a^2 = 1 + \|A\|_\infty^2$ *and* $c = 0.9062$. *Then*

$$\|U\|_{H^1} \le \sqrt{2\pi d}\left(caC_A + \|B\|_\infty\left(c^2 + \pi a^2 C_A^2/2\right)^{1/2}\right). \tag{2.9}$$

Proof. Suppose $f \in H^1$ and let $g(t) = \int_{-1}^t \Phi_A(s)^{-1}B(s)f(s)\,ds$. Note that $\|Uf\|_{H^1} \le \|\Phi_A(t)f(-1)\|_{H^1} + \|\Phi_A(t)g(t)\|_{H^1}$. Letting $\varphi(t) = \Phi_A(t)f(-1)$, we have a bound from Lemma 2.5:

$$\|\varphi\|_{H^1}^2 \le 2\pi\sum_{k=1}^d \|\varphi_k\|_\infty^2 + \|(A\varphi)_k\|_\infty^2 \le 2\pi d\, C_A^2 a^2 |f(-1)|^2.$$

On the other hand, if $\omega(t) = \Phi_A(t)g(t)$, then $\dot\omega = A\omega + Bf$, and so by Lemma 2.5,

$$\|\omega\|_{H^1}^2 = 2\pi\sum_{k=1}^d \|\omega_k\|_\infty^2 + \left(\|(A\omega)_k\|_\infty + \|(Bf)_k\|_\infty\right)^2.$$

But

$$\begin{aligned}|\omega(t)_k| \le |\omega(t)| &\le \int_{-1}^1 \max_{-1\le s\le t\le 1}\left|\Phi_A(t)\Phi_A(s)^{-1}\right|\,|B(s)|\,|f(s)|\,ds\\ &\le C_A\|B\|_\infty\int_{-1}^1 |f(s)|\,ds \le \sqrt{\frac{\pi}{2}}C_A\|B\|_\infty\|f\|_{L^2} \le \sqrt{\frac{\pi}{2}}C_A\|B\|_\infty\|f\|_{H^1}\end{aligned}$$

by the Cauchy–Schwarz inequality with weight $(1-s^2)^{-1/2}\,ds$. Similarly, $|(A(t)\omega(t))_k| \le \sqrt{\frac{\pi}{2}}\|A\|_\infty C_A\|B\|_\infty\|f\|_{H^1}$. On the other hand, $|(B(t)f(t))_k| \le \|B\|_\infty|f(t)| \le c\|B\|_\infty\|f\|_{H^1}$. Thus

$$\|\omega(t)\|_{H^1}^2 \le 2\pi d\|B\|_\infty^2\left(\frac{\pi}{2}C_A^2 + \frac{\pi}{2}\|A\|_\infty^2 C_A^2 + c^2\right)\|f\|_{H^1}^2. \qquad \square$$

3. A Chebyshev collocation method for linear DDEs (and ODEs). First we consider IVPs for $(d \ge 1)$-dimensional ODE systems of the form

$$\dot y(t) = A(t)y(t) + u(t) \tag{3.1}$$

for $y(t), u(t) \in \mathbb{C}^d$, and $A(t)$ a $d \times d$ matrix.

Recall that $I = [-1, 1]$ and that $\mathcal{C}$ denotes $\mathbb{C}^d$-valued continuous functions on I. Denote $f \in \mathcal{C}$ by $f = (f_1, \ldots, f_d)^\top$. For $f \in \mathcal{C}$ let $\|f\|_\infty = \max_{t\in I}|f(t)|$, where "$|\cdot|$" is the Euclidean norm on $\mathbb{C}^d$. Note that $|\cdot|$ induces a norm on $d \times d$ matrices, also denoted "$|\cdot|$." For continuous matrix-valued functions $A(t) = (a_{ij}(t))$ define $\|A\|_\infty = \max_{t\in I}|A(t)|$.

To present our spectral method we need to recall the basics of, and give notation for, polynomial interpolation and collocation at the Chebyshev points.

DEFINITION 3.1. *Let $\mathcal{P}_N \subset \mathcal{C}$ be the space of $\mathbb{C}^d$-valued polynomials of degree at most N. Note that $\mathcal{P}_N$ has dimension $l = d(N+1)$. The* Chebyshev collocation (extreme) points *in I are $t_j = \{\cos(j\pi/N)\}$ for $j = 0, 1, \dots, N$* [33]. *Note that $t_0 = 1 > t_1 > \cdots > t_N = -1$.*

On the function (vector) spaces $\mathcal{C}$ and $\mathcal{P}_N$ we have collocation operators as follows. Evaluation at $N+1$ Chebyshev collocation points produces a vector in $\mathbb{C}^l$. We regard evaluation of continuous functions as a linear operator $G_N : \mathcal{C} \to \mathbb{C}^l$:

(3.2)
$$G_N f = (f_1(t_0), \dots, f_d(t_0), f_1(t_1), \dots, f_d(t_1), \dots, \dots, \dots, f_1(t_N), \dots, f_d(t_N))^\top.$$

We will always order the scalar components of an element of $\mathbb{C}^l$ consistently with the output of G_N (if the element refers to the collocation values of a $\mathbb{C}^d$-valued function). Restricting G_N to polynomials gives a *bijection* $E_N : \mathcal{P}_N \to \mathbb{C}^l$. The inverse of E_N, namely, $P_N : \mathbb{C}^l \to \mathcal{P}_N$, "creates" a $\mathbb{C}^d$-valued polynomial from collocation values; see (3.3) below for a method for computing P_N.

The composition of P_N and G_N is the interpolation operator $I_N = P_N \circ G_N : \mathcal{C} \to \mathcal{P}_N$. That is, if $p = I_N f$ for $f \in \mathcal{C}$, then p is a $\mathbb{C}^d$-valued polynomial of degree N such that $p(t_j) = f(t_j)$.

One may implement polynomial interpolation by "discrete Chebyshev series." Concretely, suppose $f \in C(I)$ is a scalar function. Recall that $T_k(t) = \cos(k \arccos t)$ are the standard Chebyshev polynomials. Then $p = I_N(f)$ is given by

$$p(t) = \sum_{k=0}^{N} \tilde{f}_k T_k(t), \qquad \tilde{f}_k = \sum_{j=0}^{N} C_{kj} f(t_j), \qquad C_{kj} = \frac{2}{N\gamma_j\gamma_k} \cos\left(\frac{\pi jk}{N}\right), \tag{3.3}$$

where $\gamma_j = 2$ if $j = 0$ or $j = N$ and $\gamma_j = 1$ otherwise [26]. These formulas can also be regarded as computing $p = P_N(\{f(t_j)\})$ if $\{f(t_j)\}$ is an arbitrary vector in $\mathbb{C}^l$. They may be implemented by a modification of the fast Fourier transform (FFT) [33].

A fundamental observation is that interpolation at the Chebyshev collocation points is spectrally accurate *for analytic functions*. Indeed, it converges exponentially with a known constant as follows. Note that an ellipse as described in the next lemma always exists because the region of analyticity is open and contains I by assumption.

LEMMA 3.2 (see [31]). *Suppose f is analytic on the closed set $I = [-1, 1]$. That is, suppose f is analytic in an open region $R \subset \mathbb{C}$ such that $I \subset R$. There exist constants $c > 0$ and $0 \le \rho < 1$ such that for all $N \ge 1$ the interpolant $p = I_N f$ satisfies $\|f - p\|_\infty \le c\rho^N$. Indeed, if E is an ellipse with foci ± 1, and if the interior of E is contained in R, and if the semimajor/-minor axes of E are of length S and s, respectively, then $\|f - p\|_\infty \le c'(S + s)^{-N}$ for some $c' > 0$.*

The "Chebyshev (spectral) differentiation matrix" is the map

$$D_N = E_N \circ \frac{d}{dt} \circ P_N : \mathbb{C}^l \to \mathbb{C}^l.$$

The entries of D_N are exactly known for all N [33]. In MATLAB, using `cheb.m` from [33], $D_N =$ `kron(cheb(N),eye(d))`. The action of D_N can also be computed efficiently by a modification of the FFT [33].

The matrix D_N is not invertible; it has kernel of dimension d. We do not quite seek its inverse, however, though solving the differential equation (3.1) by the Chebyshev spectral method we are about to describe is a closely related task. We need to

incorporate the initial condition from (3.1) before inverting, so we define $\hat{D}_N$ as the invertible $l \times l$ matrix which is equal to D_N in its first $dN = l - d$ rows but has

$$(\hat{D}_N)_{jk} = \begin{cases} 0, & 1 \le k \le dN, \\ \delta_{j-dN,k-dN}, & dN+1 \le k \le l, \end{cases}$$

for $dN+1 \le j \le l$. That is, the last d rows of $\hat{D}_N$ are zeroed, except that the identity I_d is inserted in the lower right $d \times d$ block.

Now, recalling ODE (3.1), define a block-diagonal matrix and a vector

$$\hat{M}_A = \begin{pmatrix} A(t_0) & & & \\ & \ddots & & \\ & & A(t_{N-1}) & \\ & & & 0_d \end{pmatrix}, \qquad \hat{u} = \begin{pmatrix} u(t_0) \\ \vdots \\ u(t_{N-1}) \\ y_0 \end{pmatrix}.$$

Here "0_d" denotes the $d \times d$ zero matrix. Both $\hat{D}_N, \hat{M}_A$ are $l \times l$, while $\hat{u}$ is $l \times 1$.

Our approximation of the IVP for (3.1) is described by the following lemma. The proof comes immediately from the definitions of $\hat{D}_N$, $\hat{M}_A$, and $\hat{u}$.

LEMMA 3.3 (our spectral method for ODE IVPs). *Fix $N \ge 1$. Suppose $A(t)$ is a continuous $d \times d$ matrix-valued function of $t \in I$, $u(t) \in \mathcal{C}$, and $y_0 \in \mathbb{C}^d$. The following are equivalent:*

- *$p \in \mathcal{P}_N$ satisfies*

$$\dot{p}(t_j) = A(t_j)p(t_j) + u(t_j) \quad \text{for } 0 \le j \le N-1 \qquad \text{and} \qquad p(-1) = y_0;$$

- *$v \in \mathbb{C}^l$ satisfies*

$$\hat{D}_N v = \hat{M}_A v + \hat{u}. \tag{3.4}$$

The equivalence is $p = P_N v$ and $v = E_N p$.

In practice one computes $v = (\hat{D}_N - \hat{M}_A)^{-1}\hat{u}$ by Gauss elimination to solve ODE (3.1). For this spectral method we have the a posteriori estimates given in the next theorem.

THEOREM 3.4. *Suppose $A(t)$ is a continuous $d \times d$ matrix-valued function of $t \in I$, $u(t) \in \mathcal{C}$, and $y_0 \in \mathbb{C}^d$. Suppose $y \in \mathcal{C}$ satisfies the IVP (3.1). Suppose the fundamental solution satisfies the bound*

$$\left|\Phi_A(t)\Phi_A(s)^{-1}\right| \le C_A \text{ for all } -1 \le s \le t \le 1. \tag{3.5}$$

Let $N \ge 1$, let $p \in \mathcal{P}_N$ be the $\mathbb{C}^d$-valued polynomial described by Lemma 3.3, and let $R_p = \dot{p}(-1) - A(-1)y_0 - u(-1)$. Then

$$\|y - p\|_\infty \le 2C_A\Big[\|Ap - I_N(Ap)\|_\infty + \|u - I_N(u)\|_\infty + |R_p|\Big] \tag{3.6}$$

and

$$\|\dot{y} - \dot{p}\|_\infty \le (2\|A\|_\infty C_A + 1)\,\Big[\|Ap - I_N(Ap)\|_\infty + \|u - I_N(u)\|_\infty + |R_p|\Big]. \tag{3.7}$$

The proof of Theorem 3.4 will be given momentarily, but some comments are in order. The estimates on the right sides of (3.6) and (3.7) have the structure

(stiffness) [(sum of uniform interpolation errors) + (initial residual)].

In fact, we interpret C_A as an estimate of the fastest possible exponential change in solving $\dot y = A(t)y$, and we interpret R_p as the amount by which (3.1) is not satisfied at the initial time -1. Section 8 gives practical methods for evaluating the uniform interpolation errors in (3.6) and (3.7).

To prove Theorem 3.4 we need a bound on the degree N monic polynomial with roots $t_0, \dots, t_{N-1}$. Such polynomials are uniformly exponentially small as $N \to \infty$. A proof of the following lemma, which seems not to appear in previous literature, is given in [8].

LEMMA 3.5. *For $N \geq 1$ let $Q_N(t) = (t-t_0)\dots(t-t_{N-1})$. For $t = \cos\theta \in I = [-1,1]$, $Q_N(t) = 2^{1-N}(\cos(\theta)-1)\sin(N\theta)/\sin(\theta)$. Thus $Q_N(-1) = (-1)^N N\, 2^{2-N}$ and $\|Q_N\|_\infty = N\, 2^{2-N}$ on I.*

Proof of Theorem 3.4. Let $q = I_N(Ap)$ and $w = I_N(u)$. Since $r = \dot p - q - w \in \mathcal{P}_N$ and $r(t_j) = 0$ for $j = 0, \dots, N-1$ by Lemma 3.3, it follows that there is $z \in \mathbb{C}^d$ such that $r = zQ_N$. Evaluating at $t = -1$, we find $R_p = z(-1)^N N 2^{2-N}$ so $|z| = |R_p|\, 2^{N-2}/N$. On the other hand,

$$\dot y - \dot p = A(y-p) + (Ap - q) + (u - w) - zQ_N, \tag{3.8}$$

so

$$y(t) - p(t) = \int_{-1}^{t} \Phi_A(t)\Phi_A(s)^{-1}\Big[(Ap(s) - q(s)) + (u(s) - w(s)) - zQ_N(s)\Big]\, ds.$$

Note that $y(-1) = p(-1)$. Taking norms, and using Lemma 3.5 to see that $\|zQ_N\|_\infty \leq |R_p|$,

$$|y(t) - p(t)| \leq 2C_A\Big[\|Ap - q\|_\infty + \|u - w\|_\infty + |R_p|\Big].$$

This inequality implies (3.6). Finally, using (3.8) and Lemma 3.5, we find that (3.6) implies (3.7). ∎

Example 1. We apply Theorem 3.4 to the ODE IVP

$$\dot y = (2t+1)y + (2t+1)\sin(3(t^2+t)), \quad y(-1) = 1. \tag{3.9}$$

The solution can be computed exactly by integration, and note that the solution $y(t)$ is entire because the coefficients are entire. The effectiveness of estimate (3.6) is seen in Figure 3.1 below. As N increases, spectral convergence starts to occur only when polynomial interpolation can "handle" the (complex) exponential rates present in the fundamental solution $\Phi_A(t)$ and the nonhomogeneity $u(t)$ on the interval I; this happens at $N \approx 10$ here. The error $\|y-p\|_\infty$ decreases to approximately 10^{-14}, and this is the level of rounding error because $\|y\|_\infty = 9.35$. The main point, however, is that the estimate from (3.6) nicely follows the error, though with a slowly growing overestimation factor of roughly 10^3 when $N = 40$. Both the combined interpolation error (the sum $\|Ap - I_N(Ap)\|_\infty + \|u - I_N(u)\|_\infty$) and the initial residual R_p contribute nontrivially to the estimate. Note that we use the optimal bound $C_A = e^{9/4}$ when applying Theorem 3.4 in this example.

Now we return to DDE (2.1), which is our actual interest. Define

$$\hat M_B = \begin{pmatrix} B(t_0) & & & \\ & \ddots & & \\ & & B(t_{N-1}) & \\ I_d & & & 0_d \end{pmatrix},$$

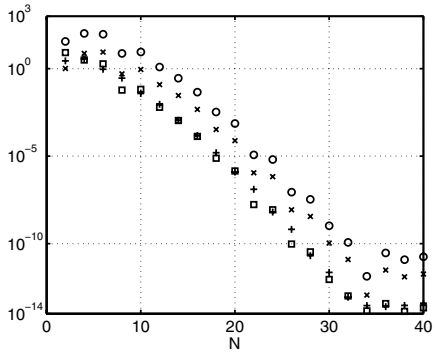

FIG. 3.1. *Theorem* 3.4 *applied to scalar ODE* (3.9) *reveals spectral convergence in uniform error* $\|y-p\|_\infty$ *on* I *(squares), where* y *is the solution and* p *is its polynomial approximation. The a posteriori estimates (circles) (the right side of* (3.6)*) closely track the actual error. The combined interpolation error ("+") and the initial residual ("×") are also shown; see the text.*

where I_d and 0_d are the $d \times d$ identity and zero matrices, respectively. The insertion of "I_d" in the lower left position represents the connection condition for the DDE method of steps. The Chebyshev collocation approximation of DDE (2.1), or, more particularly, of formula (2.3), is

$$\hat{D}_N v = \hat{M}_A v + \hat{M}_B w \tag{3.10}$$

if $v_j \approx z(t_j)$ and $w_j = f(t_j)$. Note the obvious fact that the IVP for DDE (2.1) is of the same form as ODE (3.1), but with $u = Bf$. Theorem 3.4 can therefore be applied to estimating errors in IVPs for (2.1).

The periodicity of the coefficients is not really relevant to solving a DDE of form (2.1) by the method of steps, when we use method (3.10). (Without periodicity there is no unique monodromy operator, however.) All that is required to use (3.10) to solve a nonperiodic DDE is that we must re-evaluate the collocated coefficient matrices $\hat{M}_A$ and $\hat{M}_B$ on each successive interval. The length of the interval would usually be equal to the delay if there is only one delay, in particular.

When the coefficients of (2.1) have period $T = \tau$, the matrix which approximates U is

$$U_N = \left(\hat{D}_N - \hat{M}_A\right)^{-1} \hat{M}_B \in \mathbb{C}^{l\times l}. \tag{3.11}$$

In practice we need to assume that the matrix inverse in (3.11) exists in order to find the entries of U_N, but we naturally observe the computed condition number for inversion. On the other hand, to compute the eigenvalues and eigenvectors of U_N we do not actually need the inverse. Vectors v such that $U_N v = \lambda v$ evidently solve the generalized eigenproblem

$$\hat{M}_B v = \lambda \left(\hat{D}_N - \hat{M}_A\right) v. \tag{3.12}$$

The eigenvalues can be approximated by the QZ algorithm [17], for instance.

4. Bounds on ODE fundamental solutions. Before we move on to the main goal of numerically approximating the monodromy operator and its eigenvalues, we

must find usable bounds on ODE fundamental solutions. In fact, we believe the results of this section are of independent interest for those needing computable bounds on the growth of solutions to variable-coefficient linear ODEs.

We recall existence and analytic continuation. The following result is proven by a straightforward Picard iteration argument [8].

LEMMA 4.1. *Suppose $A(z) \in \mathbb{C}^{d\times d}$ is (entrywise) analytic on a convex open set $E \supset I = [-1,1]$. Then there is a unique function $\Phi_A(z)$, analytic on E, satisfying*

$$\Phi_A(z) = I_d + \int_{-1}^{z} A(\zeta)\Phi_A(\zeta)\,d\zeta. \tag{4.1}$$

If $|A(z)| \le \alpha$ for $z \in E$, then $|\Phi_A(z)| \le e^{\alpha|z+1|}$ for $z \in E$. Furthermore, $\dot\Phi_A(t) = A(t)\Phi_A(t)$ for $t \in I$.

One can easily show, in addition, that the transition matrix $\Omega(t) = \Phi_A(t)\Phi_A(s)^{-1}$, for $-1 \le s \le t \le 1$, has an a priori estimate. (Note that Ω satisfies $\dot\Omega(t) = A(t)\Omega(t)$, $\Omega(s) = I_d$.) By Gronwall's inequality, in fact, $|\Omega(t)| \le e^{\tilde\alpha(t-s)}$ if $|A(\tau)| \le \tilde\alpha$ for $\tau \in [s,t]$. Unfortunately, this bound on $\Omega(t)$ is frequently not close to the actual maximum of $|\Omega(t)|$. We can, however, use the collocation algorithm to approximate the fundamental solution and then use a posteriori estimates from Theorem 3.4 to bound the fundamental solution. There is a "bootstrapping" aspect to such a technique: one must have some bound on the fundamental solution in order to apply Theorem 3.4, which leads to an improved bound. This is the content of the next lemma, for which one should recall that $\Psi_A(t) = (\Phi_A(t)^{-1})^\top$ satisfies the "adjoint equation" $\dot\Psi_A(t) = -A(t)^\top\Psi_A(t)$ with $\Psi_A(-1) = I_d$.

LEMMA 4.2. *Consider the following IVPs*:

$$\dot y_s(t) = A(t)y_s(t), \qquad y_s(-1) = e_s, \qquad s = 1,\dots,d, \tag{4.2}$$

where $\{e_s\}$ is the standard basis for $\mathbb{C}^d$.

Suppose that for each s we have a polynomial approximation p_s of y_s, and that we have estimates $\|y_s - p_s\|_\infty \le \mu_s$; see Theorem 3.4. Note that $\Phi_A(t) = \left[\, y_1(t) \;\middle|\; \dots \;\middle|\; y_d(t) \,\right]$ is the fundamental solution to $\dot y = A(t)y$. Let $\Phi_N(t) = \left[\, p_1(t) \;\middle|\; \dots \;\middle|\; p_d(t) \,\right]$, the approximation of $\Phi_A(t)$. If $\xi^2 = \sum_{s=1}^d \mu_s^2$, then $|\Phi_A(t) - \Phi_N(t)| \le \xi$ for all $t \in I$. Similarly, if $\Psi_A(t) = \left[\, z_1(t) \;\middle|\; \dots \;\middle|\; z_d(t) \,\right]$ is the fundamental solution to the adjoint equation $\dot z = -A(t)^\top z$, and if $\Psi_N(t) = \left[\, q_1(t) \;\middle|\; \dots \;\middle|\; q_d(t) \,\right]$, where $q_s(t)$ are polynomial approximations to $z_s(t)$ satisfying $\|z_s - q_s\|_\infty \le \nu_s$, so that $\Psi_N(t)$ is the collocation approximation of $\Psi_A(t)$, then $|\Psi_A(t) - \Psi_N(t)| \le \omega$ for $t \in I$, where $\omega^2 = \sum_{s=1}^d \nu_s^2$.

Also,

$$\left|\Phi_A(t)\Phi_A(s)^{-1}\right| \le \left(\xi + \|\Phi_N\|_\infty\right)\left(\omega + \|\Psi_N\|_\infty\right).$$

Proof. Note that

$$|\Phi_A(t)\Phi_A(s)^{-1}| \le \left(\|\Phi_A - \Phi_N\|_\infty + \|\Phi_N\|_\infty\right)\left(\|\Psi_A - \Psi_N\|_\infty + \|\Psi_N\|_\infty\right).$$

But

$$|\Phi_A(t) - \Phi_N(t)| = \max_{|u|=1}\left|\sum_{s=1}^d u_s\left(y_s(t) - p_s(t)\right)\right| \le \max_{|u|=1}|u|\left(\sum_{s=1}^d \mu_s^2\right)^{1/2} = \xi$$

using the Cauchy–Schwarz inequality, and similarly for $|\Psi_A(t) - \Psi_N(t)|$. ∎

Example 2. Consider the second-order ODE $\ddot{x} + \dot{x} + (10 + 9\cos(\pi t))x = 0$. It is a relatively stiff damped Mathieu equation corresponding to

$$A(t) = \begin{pmatrix} 0 & 1 \\ -10 - 9\cos(\pi t) & -1 \end{pmatrix}$$

in first-order form. A quick calculation gives $\|A\|_\infty \approx 19.026$. Thus $C_1 = e^{2\|A\|_\infty} \approx 3.5381 \times 10^{16}$ is the a priori bound on $|\Phi_A(t)\Phi_A(s)^{-1}|$ from Gronwall. We use the collocation algorithm with $N = 50$ to find $\Phi_N(t), \Psi_N(t)$ approximating $\Phi_A(t), \Psi_A(t)$. The a posteriori estimates from Theorem 3.4 are computed using $C_A = C_1$, and, as in Lemma 4.2, we find $|\Phi_A(t)\Phi_A(s)^{-1}| \le C_2 = 2.7117 \times 10^9$. This is a significant improvement, but also we can now iterate, using $C_A = C_2$ in the a posteriori estimates to generate C_3, and so on. The result is a sequence of bounds

$$|\Phi_A(t)\Phi_A(s)^{-1}| \le 3.5381 \times 10^{16},\ 2.7117 \times 10^9,\ 19.627,\ 19.587,\ 19.587, \ldots.$$

Each number on the right *is* a bound, with an a priori argument for the first and a posteriori arguments for the remainder. Evidently they converge superlinearly to about 19.6. By looking at the numerically approximated fundamental solution we see that this is a nearly optimal bound. In any case, such improvements by many orders of magnitude make further error estimation using Theorem 3.4 very practical.

In addition to the Lemma 2.6 estimate on the norm of U, we require, for the a posteriori estimation of eigenvalues, an a priori result on the polynomial approximation of eigenfunctions of U.

These eigenfunctions each solve a homogeneous ODE. In fact, if $Ux = \mu x$ for $\mu \in \mathbb{C}$, then $y = \mu x$ solves $\dot{y} = Ay + Bx$. Thus if $\mu \neq 0$, then $\dot{x} = \left(A + \mu^{-1}B\right)x$. Let $\Phi_\mu(t)$ be the fundamental solution to this ODE, so $\dot{\Phi}_\mu = (A + \mu^{-1}B)\Phi_\mu$ and $\Phi_\mu(-1) = I_d$. Note that $x(t) = \Phi_\mu(t)x(-1)$.

Suppose $A(z), B(z)$ are analytic on an ellipse E with foci ± 1. (If A, B are analytic on the compact set $I = [-1, 1]$, then they have such a common regularity ellipse.) Define $\|M\|_{\infty E} = \max_{z \in E} |M(z)|$ for continuous matrix-valued functions $M(z)$. From Lemma 4.1

$$|\Phi_\mu(z)| \le \exp\left(\|A + \mu^{-1}B\|_{\infty E}\,|z + 1|\right)$$

is an a priori bound on the analytic continuation of $\Phi_\mu(t)$ to $z \in E$. In fact, when we consider below those multipliers μ with magnitude greater than a chosen level $\sigma > 0$ we will use the bound

$$|\Phi_\mu(z)| \le C_\sigma := \exp\left(\left(\|A\|_{\infty E} + \sigma^{-1}\|B\|_{\infty E}\right)(S + 1)\right), \tag{4.3}$$

where S is the major semiaxis of a common regularity ellipse E for A and B. This a priori bound for $|\Phi_\mu(z)|$ turns out to be one of the two troublesome constants in the main Theorem 6.4 on multiplier estimation.

As announced, we now bound the interpolation error for eigenfunctions of U.

LEMMA 4.3. *Suppose A, B are analytic $d \times d$ matrix-valued functions with a common regularity ellipse $E \subset \mathbb{C}$ with foci ± 1 and sum of semiaxes $e^\eta = S + s > 1$. Suppose $Ux = \mu x$ for $\mu \neq 0$ and $\|x\|_{H^1} = 1$. Let $\Phi_\mu(z)$ be the unique analytic continuation of $\Phi_\mu(t)$ for $z \in E$ and suppose C_μ is a bound of $|\Phi_\mu(z)|$ for all $z \in E$. If $p = I_k x$, then*

$$\|x - p\|_{H^1} \le 8\sqrt{d}\,C_\mu(\sinh\eta)^{-1}k\,e^{-k\eta}. \tag{4.4}$$

Proof. First, $x(z) = \Phi_\mu(z)x(-1)$ is the analytic continuation of $x(t)$, $t \in I$, to $z \in E$. Furthermore, $|x(z)| \le C_\mu |x(-1)|$. It follows from (4.16) of [31] that

$$\|x - p\|_{H^1}^2 \le \sum_{j=1}^{d} \left(8C_\mu |x(-1)| (\sinh \eta)^{-1} k e^{-k\eta}\right)^2 = d \left(8C_\mu (\sinh \eta)^{-1} k e^{-k\eta}\right)^2 |x(-1)|^2.$$

Note that $|x(-1)| \le 0.9062 \|x\|_{H^1} = 0.9062$ by Lemma 2.4. ∎

Estimate (4.4), which bounds the polynomial approximation error for eigenfunctions of U, will be of great importance in controlling the *eigenvalue* approximation error from our spectral method (Theorem I).

DEFINITION 4.4. *Let $\sigma > 0$. The* a priori eigenfunction approximation error bound for large eigenvalues of U, *for $k+1$ point Chebyshev interpolation, is*

$$\epsilon_k = 8\sqrt{d} C_\sigma (\sinh \eta)^{-1} k\, e^{-k\eta}, \tag{4.5}$$

where $C_\sigma > 0$ is a bound on the analytic continuation of fundamental solutions:

$$|\Phi_\mu(z)| \le C_\sigma \quad \textit{for all } z \in E \textit{ and } |\mu| \le \sigma.$$

The crucial fact to note is that ϵ_k decays exponentially with increasing k and that the rate of decay is related to the size of the regularity ellipse E. Not surprisingly, in other words, if the coefficients of the DDE are more regular, then the spectral method is better at approximating the eigenfunctions. On the other hand, the constant C_σ generally increases rapidly as E is expanded.

5. Eigenvalue perturbation for operators on Hilbert spaces. The eigenvalue perturbation result in this section generalizes the well-known Bauer–Fike theorem for matrices [4]. It may not be new. It is fairly close to the definition of the eigenvalue condition number itself, introduced in [36]. It is also close to Proposition 1.15 in [11]. Nonetheless we need a precise statement, especially of Corollary 5.2, and we cannot find such in the literature.

Recall that a separable infinite-dimensional Hilbert space is isometrically isomorphic to the space of sequences $l^2 = \{a = (a_1, a_2, \dots) \,\big|\, a_j \in \mathbb{C}, \sum |a_j|^2 < \infty\}$. Denote the standard basis elements of l^2 by δ_j. By definition, a bounded operator $\Lambda \in \mathcal{L}(l^2)$ is *diagonal in the standard basis* if for each j, $\Lambda\delta_j = \lambda_j \delta_j$ for some $\lambda_j \in \mathbb{C}$.

THEOREM 5.1. *Let $\mathcal{X}$ be a separable infinite-dimensional complex Hilbert space. Suppose $A \in \mathcal{L}(\mathcal{X})$ is diagonalizable in the sense that there is a linear, bounded map $V : l^2 \to \mathcal{X}$ with bounded inverse and a diagonal (in the standard basis) operator $\Lambda \in \mathcal{L}(l^2)$ such that $A = V\Lambda V^{-1}$. Let $B \in \mathcal{L}(\mathcal{X})$. If $Bx = \mu x$ for $\mu \in \mathbb{C}$ and $\|x\| = 1$, then*

$$\min_{\lambda \in \sigma(A)} |\mu - \lambda| \le \|V\| \|V^{-1}\| \|(B - A)x\|. \tag{5.1}$$

Proof. If $\mu \in \sigma(A)$ there is nothing to prove. Otherwise, let $R_A = (A - \mu I)^{-1}$ and $R_\Lambda = (\Lambda - \mu I)^{-1}$. Note that $R_A = V R_\Lambda V^{-1}$ so that $\|R_\Lambda\|^{-1} \le \|V\|\, \|V^{-1}\| \,/\, \|R_A\|$. Also, R_Λ is diagonal and bounded with

$$\|R_\Lambda\| \le \sup_j |\lambda_j - \mu|^{-1} = \max_{\lambda \in \sigma(A)} |\lambda - \mu|^{-1} = \left(\min_{\lambda \in \sigma(A)} |\lambda - \mu|\right)^{-1},$$

where $\{\lambda_i\}$ are the diagonal entries of Λ. Thus

$$\min_{\lambda\in\sigma(A)} |\lambda-\mu| \le \|R_A\|^{-1}\|V\|\|V^{-1}\|. \tag{5.2}$$

On the other hand, if μ is an eigenvalue of B and $x \in H^1$ satisfies $Bx = \mu x$ and $\|x\| = 1$, then $(B-A)x = -(A-\mu I)x$, or $x = -(A-\mu I)^{-1}(B-A)x$. Taking norms, it follows that $1 \le \|R_A\|\|(B-A)x\|$. Combine this with inequality (5.2) to get estimate (5.1). ∎

An easy modification of Theorem 5.1 applies to $\mathcal{X} \cong \mathbb{C}^d$, and the result obviously implies the classical Bauer–Fike theorem. The hypotheses of Theorem 5.1 imply that $\sigma(A)$ is the closure of the set of diagonal entries of Λ. Because the spectrum $\sigma(A) \subset \mathbb{C}$ is compact for any bounded operator $A \in \mathcal{L}(\mathcal{X})$, the "min" in estimate (5.1) is appropriate.

Theorem 5.1 can be generalized to Banach spaces which are isomorphic to sequence spaces (i.e., l^p spaces). Specifically, we need to hypothesize an operator Λ, similar to A in the sense used in Theorem 5.1, for which $\|(\Lambda-\mu I)^{-1}\| \le \sup_{\lambda_i} |\lambda_i-\mu|^{-1}$, where $\{\lambda_i\}$ is a dense subset of $\sigma(A)$. Assuming A is similar to a diagonal operator on l^p suffices, for instance. (We will not use this generalization.)

Recall that if the coefficients A, B in DDE (2.1) are analytic, then there exist polynomials very close to the eigenfunctions of the monodromy operator U (see Lemma 4.3). This motivates the following corollary.

COROLLARY 5.2. *Suppose the hypotheses of Theorem* 5.1 *hold. Suppose also that* $p \in \mathcal{X}$ *satisfies* $\|x-p\| < \epsilon$. *Then*

$$\min_{\lambda\in\sigma(A)} |\mu-\lambda| \le \|V\|\|V^{-1}\|\Big[\epsilon(\|B\|+\|A\|) + \|(B-A)p\|\Big].$$

Proof. Note that $\|(B-A)x\| \le \|(B-A)(x-p)\| + \|(B-A)p\|$. ∎

Let us describe how this corollary will be used, and in so doing sketch the strategy for proving Theorem I. In section 3 we described a spectral method which produces an $l \times l$ matrix approximation U_N which approximates the monodromy operator U for DDE (2.1). We will numerically diagonalize U_N by standard methods for matrices of modest size, for instance, by the QR or QZ algorithms for eigenvalues and inverse iteration for eigenvectors [17]. Typically l is in the range 30 to 300 and U_N is dense. Thus it is a reasonable task to fully diagonalize U_N in practice. (Note that in stating our results we do not include errors made in these standard computations of finite-dimensional linear algebra.)

We want to know how close the unknown eigenvalues of U (the multipliers) are to the computed eigenvalues of U_N. The operators U and U_N act on different spaces, the former on a Hilbert–Sobolev space H^1 and the latter on $\mathbb{C}^l$. It turns out, however, that we can *extend* U_N to an operator $\tilde{U}_N$ which acts on H^1. Furthermore, it turns out (next section) that a diagonalization of U_N can be boosted to an operator diagonalization of $\tilde{U}_N$.

A numerical diagonalization of U_N is, of course, an invertible matrix $V \in \mathbb{C}^{l\times l}$ and a diagonal matrix $\Lambda \in \mathbb{C}^{l\times l}$ such that $U_N = V\Lambda V^{-1}$. We do not assert that U_N is diagonalizable in every case. Rather, we assert that diagonalizability is the generic case [34]. We necessarily incorporate the conditioning of the eigenvalue problem for U_N, and specifically the condition number $\|\tilde{V}\|\|\tilde{V}^{-1}\|$ where $\tilde{V}$ is the operator formed from the eigenfunctions of $\tilde{U}_N$. The above informal definitions, made precise in the next section, allow us to outline our strategy for estimating the error in the approximate multipliers:

(i) given a DDE of form (2.1), compute U_N as described in section 3;
(ii) numerically diagonalize $U_N = V\Lambda V^{-1}$; denote the polynomial described by the kth column of V by "p_k";
(iii) thereby diagonalize $\tilde{U}_N = \tilde{V}\tilde{\Lambda}\tilde{V}^{-1}$, where $\tilde{U}_N$ is an operator on the same space as U; compute bounds for $\|\tilde{V}\|, \|\tilde{V}^{-1}\|$ (Lemma 6.2);
(iv) consider only the eigenvalues μ of U which satisfy $|\mu| \geq \sigma$ for some $\sigma > 0$, and, for the finitely many normalized eigenfunctions of U with multipliers μ satisfying $|\mu| \geq \sigma$, note the a priori bound on degree k ($\leq N$) polynomial interpolation at the Chebyshev points (Lemma 4.3 and Definition 4.4);
(v) write each p_k as a linear combination of the H^1-normalized Chebyshev polynomials $\tilde{T}_0, \ldots, \tilde{T}_N$;
(vi) by simply applying U_N, approximately solve DDE IVPs with each initial function $\tilde{T}_0, \ldots, \tilde{T}_N$; record a posteriori estimates from Theorem 3.4;
(vii) use Corollary 5.2 with $\mathcal{X} = H^1$, $A = \tilde{U}_N$, and $B = U$; estimate norm $\|U\|$ from Lemma 2.6; bound $\|(B-A)p\| = \|(U-\tilde{U}_N)p\|$ by estimates in steps (iv) and (vi);
(viii) conclude with an upper bound on the distance $\min|\mu - \lambda_i|$ as λ_i ranges over the approximate multipliers (Theorem 6.4).

6. Complete statement and proof of Theorem I. The expression (3.11) for U_N, or of the corresponding generalized eigenproblem (3.12), is all that is needed to rapidly approximate the monodromy operator and compute approximate multipliers. This section is devoted to the additional task of producing computable error estimates for the approximate multipliers.

We start with some definitions and a technical lemma in which we make the diagonalized $l \times l$ matrix U_N into a diagonalized operator $\tilde{U}_N$ which acts on H^1 (as does the monodromy operator U). This will allow us to apply Corollary 5.2 with $A = \tilde{U}_N$ and $B = U$.

Recall that the polynomials $\mathcal{P}_N$ are a subspace of our Hilbert space H^1. Let $\Pi_N \in \mathcal{L}(H^1)$ be orthogonal projection onto $\mathcal{P}_N$. Using the operator notation of section 3, define the (finite rank) approximate monodromy operator

$$\tilde{U}_N = P_N U_N E_N \Pi_N \in \mathcal{L}(H^1). \tag{6.1}$$

We now have two operators on H^1 (U and $\tilde{U}_N$) and an $l \times l$ matrix (U_N). Lemma 6.2 below shows that a numerical diagonalization of U_N yields a diagonalization of $\tilde{U}_N$. To prove this we will need to consider how to expand a $\mathbb{C}^d$-valued polynomial $p(t)$ of degree N into the basis $\{\tilde{T}_j \otimes e_s\}$ for $j = 0, \ldots, N$ and $s = 1, \ldots, d$, where $\{e_s\}$ is the standard basis for $\mathbb{C}^d$. In fact, if

$$p(t) = \sum_{\substack{j=0,\ldots,N \\ s=1,\ldots,d}} \gamma_{j,s}\tilde{T}_j(t) \otimes e_s = \sum_{j,\,s} \gamma_{j,s} \frac{z_j}{\sqrt{\pi}(1+j)} T_j(t) \otimes e_s, \tag{6.2}$$

where $z_j = \sqrt{2}$ if $j \geq 1$ and $z_0 = 1$, and if $\{e_s^*\}$ is the dual basis to $\{e_s\}$, then

$$\gamma_{j,s} = \sqrt{\pi}(1+j) z_j^{-1} \sum_{r=0}^{N} C_{jr} e_s^*\left(p(t_r)\right), \tag{6.3}$$

where $C = \{C_{jr}\}$ is the matrix in (3.3). Thus we can find the expansion coefficients of $p(t)$ given the values of $p(t)$ at the collocation points. Formulas (6.2) and (6.3) are

perhaps memorable if we call them "H^1-normalized discrete Chebyshev series for $\mathbb{C}^d$-valued polynomials." The next definition gives notation for the expansion coefficients associated to the diagonalization of U_N.

DEFINITION 6.1. *Suppose $U_N = V\Lambda V^{-1}$ with $\Lambda = (\lambda_j)_{j=1}^l$ diagonal. Let v_k be the kth column of V $(1 \le k \le l)$. Define $p_k(t) = P_N v_k$, a $\mathbb{C}^d$-valued polynomial of degree N. Expand $p_k(t)$ in discrete Chebyshev series*

$$p_k(t) = \sum \Gamma^V_{jd+s,k} \tilde{T}_j(t) \otimes e_s,$$

where the matrix of coefficients is defined by

$$\Gamma^V_{jd+s,k} = \sqrt{\pi}(1+j) z_j^{-1} \sum_{r=0}^{N} C_{jr} e_s^* \left(p_k(t_r)\right) = \sqrt{\pi}(1+j) z_j^{-1} \sum_{r=0}^{N} C_{jr} (v_k)_{rd+s},$$

where $C = \{C_{jr}\}$ is given by (3.3). *Equivalently,*

$$\Gamma^V = \left(\tilde{C} \otimes I_d\right) V, \text{ where } \tilde{C} = \sqrt{\pi/2}\, \operatorname{diag}\left(2^{-1/2}, 2, 3, \ldots, N+1\right) C.$$

Note that Γ^V is an invertible $(l \times l)$ matrix because V and C are invertible.

In the next lemma we diagonalize the operator $\tilde{U}_N$. Recall that our meaning for such a diagonalization is given in the statement of Theorem 5.1. Denote a typical element of l^2 by $a = (a_j^s)$, $j = 0, 1, \ldots$, $1 \le s \le d$, with $a_j^s \in \mathbb{C}$. Informally, the next lemma describes an operator $\tilde{V} : l^2 \to H^1$ which has matrix form

$$\tilde{V} = \left(\begin{array}{c|c} \Gamma^V & 0 \\ \hline 0 & I \end{array}\right)$$

in the basis $\{\tilde{T}_j \otimes e_s\}$ for H^1 and the standard basis for l^2. Here "I" is the isometry on rows $l+1, l+2, \ldots, \infty$.

LEMMA 6.2. *Let $\tilde{V} : l^2 \to H^1$ be defined by*

$$\tilde{V}a = \sum_{\substack{j=0,\ldots,N \\ s=1,\ldots,d}} a_j^s\, p_{jd+s}(t) + \sum_{\substack{j>N \\ s=1,\ldots,d}} a_j^s\, \tilde{T}_j(t) \otimes e_s.$$

Then $\tilde{V}$ is bounded and boundedly invertible, and, recalling that "$|\cdot|$" is the matrix 2-norm,

$$\|\tilde{V}\| \le |\Gamma^V| + 1, \qquad \|\tilde{V}^{-1}\| \le |(\Gamma^V)^{-1}| + 1. \tag{6.4}$$

Define $\tilde{\Lambda} \in \mathcal{L}(l^2)$ by $(\tilde{\Lambda}a)_{jd+s} = \lambda_{jd+s} a_j^s$ if $j < N$ and $s = 1, \ldots, d$, while if $k > l$ then $(\tilde{\Lambda}a)_k = 0$. Then $\tilde{\Lambda}$ is a diagonal operator on l^2 of rank at most l, and we have the diagonalization $\tilde{U}_N = \tilde{V}\tilde{\Lambda}\tilde{V}^{-1}$.

Proof. First we compute $\tilde{V}^{-1} : H^1 \to l^2$ by its action on the basis $\{\tilde{T}_j \otimes e_s\}$:

$$\tilde{V}^{-1}\left(\tilde{T}_j \otimes e_s\right) = \begin{cases} \left((\Gamma^V)^{-1}_{1,jd+s}, \ldots, (\Gamma^V)^{-1}_{l,jd+s}, 0, \ldots\right), & 0 \le j \le N, \\ \delta_{jd+s}, & j > N, \end{cases}$$

if $\{\delta_k\}_{k=1}^\infty$ is the standard basis for l^2. It is routine to check $\tilde{V}^{-1}\tilde{V}a = a$ for all $a \in l^2$. Estimates (6.4) follow from the definition of Γ^V and the fact that $\tilde{V}$ and $\tilde{V}^{-1}$ act isometrically between $\mathcal{P}_N^\top \subset H^1$ and the corresponding subspace of l^2.

Now, $U_N V = V\Lambda$ if and only if $U_N E_N p_k = \lambda_k E_N p_k$ for $k = 1, \dots, l$. Note that $\tilde{V}\delta_k = p_k$ if $k \le l$ and $\tilde{V}\delta_k = \tilde{T}_j \otimes e_s$, where $k = jd + s$, if $k > l$. Note that $k = jd + s > l$ if and only if $j > N$. Thus if $k \le l$, then

$$\tilde{U}_N \tilde{V}\delta_k = P_N U_N E_N \Pi_N p_k = P_N U_N E_N p_k = \lambda_k p_k = \left(\tilde{V}\Lambda\right)\delta_k,$$

while if $k > l$, then $\tilde{U}_N \tilde{V}\delta_k = P_N U_N E_N \Pi_N (\tilde{T}_j \otimes e_s) = 0$. Thus $\tilde{U}_N = \tilde{V}\tilde{\Lambda}\tilde{V}^{-1}$. ∎

We will use the obvious bound $\|\tilde{U}_N\| \le (\max_{1\le j\le l} |\lambda_j|)\, \|\tilde{V}\|\|\tilde{V}^{-1}\|$.

To get a posteriori estimates on eigenvalues we need a posteriori estimates on specific IVPs for DDE (2.1). The following lemma summarizes the application of Theorem 3.4 for this purpose.

LEMMA 6.3. *Suppose $f \in H^1$ and let $u(t) = B(t)f(t)$. Let $p \in \mathcal{P}_N$ be the approximation of y found from the spectral method applied to $\dot{y} = Ay + u$, $y(-1) = f(1)$ (Lemma 3.3). Then*

$$\|Uf - \tilde{U}_N f\|_{H^1} \le \sqrt{2\pi d}\left((2C_A)^2 + (2\|A\|_\infty C_A + 1)^2\right)^{1/2} Z, \tag{6.5}$$

where C_A satisfies (3.5) *and where*

$$Z = \|Ap - I_N(Ap)\|_\infty + \|Bf - I_N(Bf)\|_\infty + |\dot{p}(-1) - A(-1)f(1) - B(-1)f(-1)|.$$

Proof. Note that $Uf = y$ and $\tilde{U}_N f = p$. Now combine the result of Theorem 3.4 with inequality (2.8) in Lemma 2.5. ∎

We now give our main theorem on the multipliers of DDE (2.1).

THEOREM 6.4 (precise form of Theorem I). *Suppose that A, B in* (2.1) *are analytic $d \times d$ matrix-valued functions with common regularity ellipse $E \supset I$. Let $N \ge 1$ and $l = d(N+1)$. Let $\sigma > 0$ and recall the definition of the a priori eigenfunction approximation error bounds for large eigenvalues, denoted ϵ_k (Definition 4.4). Assume that U_N, defined by formula* (3.11), *is diagonalized: $U_N = V\Lambda V^{-1}$ with V invertible and $\Lambda = (\lambda_i)_{i=1}^l$ diagonal. Order the eigenvalues $|\lambda_1| \ge |\lambda_2| \ge \cdots \ge 0$. Suppose we have a posteriori estimates for IVPs using the Chebyshev polynomials as initial functions:*

$$\|U(\tilde{T}_j \otimes e_s) - \tilde{U}_N(\tilde{T}_j \otimes e_s)\|_{H^1} \le \nu_j^s, \tag{6.6}$$

where $j = 0, \dots, N$ and $s = 1, \dots, d$ (Lemma 6.3; note that $\tilde{U}_N$ is defined by (6.1)*). Let $\xi_k^2 = \sum_{j=0}^k \sum_{s=1}^d (\nu_j^s)^2$.*

Consider a large eigenvalue $\mu \in \mathbb{C}$ of U: $Ux = \mu x$ for $x \in H^1$, $\|x\| = 1$, and $|\mu| \ge \sigma$. Let

$$\omega_k = \epsilon_k\left(\|U\| + |\lambda_1|\operatorname{cond}(\tilde{V})\right) + (1 + \epsilon_k)\xi_k$$

for $k = 1, \dots, N$. Then

$$\min_{i=1,\dots,l} |\mu - \lambda_i| \le \min\{\omega_1, \dots, \omega_N\}\operatorname{cond}(\tilde{V}). \tag{6.7}$$

Note that $\|U\|$ is estimated in Lemma 2.6 and $\operatorname{cond}(\tilde{V}) = \|\tilde{V}\|\|\tilde{V}^{-1}\|$ is estimated in Lemma 6.2.

Proof. By Lemma 4.3, for each $k = 1, \ldots, N$ we have $\|x - q_k\|_{H^1} < \epsilon_k$, where $q_k = I_k x$. Apply Corollary 5.2 with $\mathcal{X} = H^1$, $A = \tilde{U}_N$, $B = U$, $p = q_k$, and $\epsilon = \epsilon_k$:

$$\min |\mu - \lambda_i| \le \operatorname{cond}(\tilde{V}) \left(\epsilon_k (\|U\| + \|\tilde{U}_N\|) + \|(U - \tilde{U}_N) q_k\| \right). \tag{6.8}$$

On the other hand, $q_k = \sum_{j=0}^{k} \sum_{s=1}^{d} \alpha_k^{js} \tilde{T}_j \otimes e_s$ is a linear combination of Chebyshev polynomials, so from the a posteriori bounds ν_j^s,

$$\begin{aligned} \|(U - \tilde{U}_N) q_k\|_{H^1} &\le \sum_{j=0}^{k} \sum_{s=1}^{d} |\alpha_k^{js}| \nu_j^s \le \|q_k\|_{H^1} \xi_k \\ &\le \left(\|x\|_{H^1} + \|q_k - x_k\|_{H^1} \right) \xi_k \le (1 + \epsilon_k) \xi_k \end{aligned}$$

by Cauchy–Schwarz. From (6.8) and Lemma 6.2 we conclude with estimate (6.7). ∎

The idea in Theorem 6.4 is that all quantities on the right side of inequality (6.7) are known a priori, can be computed by a matrix eigenvalue package, or can be computed a posteriori (Theorem 3.4). Furthermore, the quantities ϵ_k and ξ_k are exponentially small, though for the latter this is in an a posteriori and fixed-precision-limited sense. Thus the computed eigenvalues of the matrix U_N can be shown to be exponentially close to those of the operator U as long as U_N is "well diagonalizable" in the sense that $\operatorname{cond}(\tilde{V})$ is small (which follows if $\operatorname{cond}(V)$ is small). Unfortunately, $\operatorname{cond}(\tilde{V})$, which depends on N, and C_σ, which does not, can be large. We observe below in two examples that $\operatorname{cond}(\tilde{V})$ grows slowly with N, however.

Bounds on fundamental solutions appear several times, at least implicitly, in the statement of Theorem 6.4. Recall that Lemma 2.6 estimates $\|U\|$ in terms of a bound C_A on $|\Phi_A(t)\Phi_A(s)^{-1}|$, $s, t \in I$, where $\Phi_A(t)$ is the fundamental solution to $\dot{x}(t) = A(t)x(t)$. Also, Theorem 3.4 uses C_A in the a posteriori bounds on IVPs. Fortunately, section 4 gives a technique for computing good bounds C_A. Thus the estimate for $\|U\|$ is reasonable and the a posteriori quantities ν_j^s are very small in practice (within a few orders of magnitude of machine precision). On the other hand, as noted, the bound C_σ on the analytic continuation $\Phi_\mu(z)$ of the fundamental solution $\Phi_\mu(t)$ to $\dot{x}(t) = (A(t) + B(t)/\mu)\, x(t)$, for the large multipliers with $|\mu| \ge \sigma$, which appears in Definition 4.4 of ϵ_k, is still a priori. Such a bound will inevitably be large. The result is that ϵ_k is large for small k but that ϵ_k decreases exponentially with k.

The a posteriori quantities ξ_k are, in practice, bounded below because precision is fixed. In Example 3 below using double precision, $\xi_k \approx 10^{-10}$ for $k << N$ and thus $\omega_k \ge 10^{-10}$. But $\operatorname{cond}(\tilde{V}) \approx 10^8$, so $\min\{\omega_k\} \operatorname{cond}(\tilde{V}) \approx 10^{-2}$, which gives only two digits of accuracy for the largest eigenvalue in that example. Application of Theorem 6.4 is a situation where 128-bit or 256-bit floating point representation would have substantial consequences.

7. An example of the application of Theorem I. Let us apply Theorem 6.4 to the damped delayed Mathieu equation (1.1).

Example 3. Consider the parameter values $(\delta, b) = (1, 1/2)$ in (1.1). Using the same method as in Example 2, we find an a priori bound $C_A^{(0)} = e^{2\sqrt{2+1.1^2}} \approx 35.99$ on the norm of $\Omega = \Phi_A(t)\Phi_A(s)^{-1}$. We improve this bound by a posteriori iterations as in section 4 to a new bound $C_A = 4.613$.

Recall that if x is an eigenfunction of U corresponding to eigenvalue μ, then $\dot{x} = (A + B/\mu)x$. Suppose we consider those eigenvalues $|\mu| \ge \sigma = 0.2$. Note that

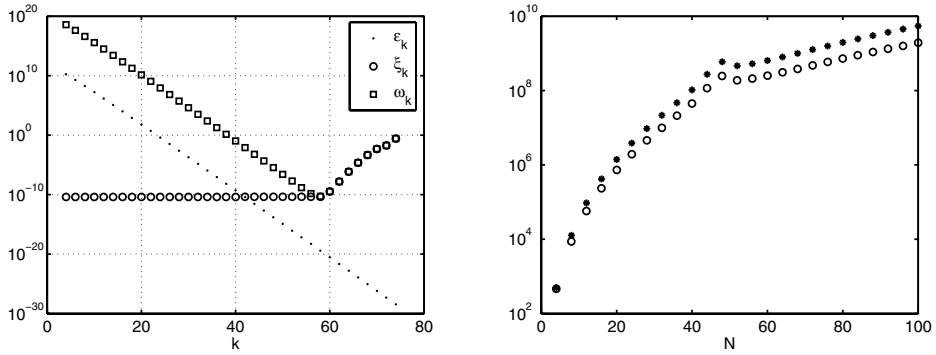

FIG. 7.1. *Behavior of constants (left figure) when Theorem* 6.4 *is applied to the delayed, damped Mathieu equation* (1.1) *with* $(\delta, b) = (1, 1/2)$ *and* $N = 75$. *The minimum of* ω_k *is about* 5×10^{-11}. *Right figure*: *The estimate on* $\operatorname{cond}(\tilde{V})$ *from Lemma* 6.2 *(circles) and the* 2*-norm condition number of* V *(dots), as functions of* N.

A, B are entire, so we are free to choose any common regularity ellipse $E \supset I$ with foci ± 1. The analytic continuation $\Phi_\mu(z)$ for $z \in E$ of the fundamental solution $\Phi_\mu(t)$ of $\dot{x} = (A + B/\mu)x$ is bounded by C_σ as in (4.3). Let $S = 1.996$ (a choice explained below) and $s = \sqrt{S^2 - 1}$ be semiaxes of E. Then from (4.3), $C_\sigma = 1.303 \times 10^{11}$; see below. Note that $e^\eta = S + s = 3.724$ determines the exponential rate of decrease of ϵ_k.

We now apply Theorem 6.4 with $N = 75$. The approximate multipliers are shown in Figure 1.2. The right side of (6.7) gives 0.01595, which is the radius of the small eigenvalue error bound circles in Figure 1.2.

The constants ϵ_k, ξ_k, and ω_k which appear in the statement of Theorem 6.4 are shown in Figure 7.1. For this value of N the condition number estimate for $\tilde{V}$ given in Lemma 6.2 is 3.5×10^8. The estimate of $\operatorname{cond}(\tilde{V})$ from Lemma 6.2 depends on N, as shown in Figure 7.1. We observe that it grows relatively slowly for large N. (The conditioning of the multipliers will be addressed in section 8.) In any case, the error bound (6.7) shows that the actual multipliers which exceed $\sigma = 0.2$ in magnitude lie within the error bound circles around the approximate multipliers in Figure 7.1. The DDE is, in particular, stable.

It is revealing to ask how to choose the regularity ellipse $E \supset I$ in the case when $A(z), B(z)$ are analytic in large neighborhoods of I or even when A, B are both entire. Such is the case if A, B are constant, for instance. The significance of the choice of E to Theorem 6.4 is that the sum of its semiaxes $e^\eta = S + s$ controls the rate of exponential decay of the a priori quantities ϵ_k, but also that the size of E affects the a priori bound C_σ which appears in Definition 4.4.

Fix $\sigma > 0$ and define C_σ as in Definition 4.4. Then, noting that the minor semiaxis $s = \sqrt{S^2 - 1}$ is a function of S, from (4.5) we find that ϵ_k is a function of S:

$$\epsilon_k(S) = 16\sqrt{d}\, k\, \frac{\exp\left([\|A\|_{\infty E} + \|B\|_{\infty E}/\sigma](S+1)\right)}{((S+s)^2 - 1)\ (S+s)^{k-1}}. \tag{7.1}$$

In general, $\|A\|_{\infty E}, \|B\|_{\infty E}$ depend on S.

Based on the evidence in examples like the one above, for sufficiently large N the a posteriori estimates ξ_k on IVPs first increase significantly at about $k = 3N/4$. We therefore choose S by seeking to minimize $\epsilon_{3N/4}(S)$.

Example 4 (continuation of Example 3). For (1.1) with $(\delta, b) = (1, 1/2)$ we have $|A(z)|_F^2 \le 2 + (1 + |\cos \pi z|)^2$. On E with foci ± 1 and semiaxes S, s, it follows that

$$\|A\|_{\infty E} \le \max_{z \in E} |A(z)|_F \le \left(2 + (1 + \sqrt{1 + e^{\pi s}})^2\right)^{1/2}.$$

The minor semiaxis s of E appears in this expression because the magnitude of $\cos(\pi z)$ grows exponentially in the imaginary direction. Note that $\|B\|_{\infty E} = 1/2$. To find the best S one must solve the problem

$$\min_{S>1} \quad \frac{\exp\left(\left[\left(2 + (1 + \sqrt{1 + e^{\pi s}})^2\right)^{1/2} + (2\sigma)^{-1}\right] (S+1)\right)}{((S+s)^2 - 1)\ (S+s)^{(3N/4)-1}}.$$

Upon inspection we see that this is a smooth and convex single-variable minimization problem. The minimum $S = 1.996$ is used above.

8. Discussion. We start with another example of the use of the spectral method to compute the multipliers of a DDE, and of Theorem 6.4 to estimate the errors in the multipliers.

Example 5. Consider the simple scalar DDE

$$\dot{x} = -x + x(t-2). \tag{8.1}$$

The multipliers are exactly known in the following sense [18, Theorem A.5]: The characteristic equation of (8.1) is $\lambda = -1 + e^{-2\lambda}$. The roots of this equation are the "exponents," and $\mu = e^{2\lambda}$ are the multipliers. Supposing $\lambda = \alpha + i\beta$, the characteristic equation can be written as a pair of real equations

$$\alpha = -1 + e^{-2\alpha} \cos 2\beta, \qquad \beta = -e^{-2\alpha} \sin 2\beta. \tag{8.2}$$

We find a single real exponent $\lambda_0 = 0$. All other exponents are complex and have imaginary parts β satisfying the transcendental equation $-\beta = \sin(2\beta) \exp(2 + 2\beta \cot 2\beta)$, which follows from (8.2). The solutions of this equation are easily seen to be simple roots β_k lying in the intervals $(k - 1/2)\pi < \beta_k < k\pi$ for $k = 1, 2, \ldots$. They can be found by the usual highly reliable numerical methods (e.g., bisection). The multipliers are then $\mu_0 = 1$ and $\mu_{\pm k} = \exp(\alpha_k \mp i\beta_k)$, where α_k is found from β_k by the first equation of (8.2). Note that these multipliers are already ordered by decreasing magnitude.

On the other hand, we can form U_N by the methods of this paper and find its $N+1$ eigenvalues $\mu_k^{(N)}$. The comparison of these numerical multipliers to the correct values for $N = 40$ ($N = 80$) is seen in Figure 8.1. We observe that the largest 10 (30, respectively) multipliers are accurate to full precision. The remaining smaller multipliers are quite inaccurate. This occurrence is no surprise as the eigenfunctions corresponding to the small multipliers are highly oscillatory and exponentially damped. (It is well known that Chebyshev interpolation requires somewhat more than 2 points per wavelength to achieve spectral accuracy [33, section 7].)

How does the impressive accuracy of the largest approximate eigenvalues compare to estimate (6.7) from Theorem 6.4? As also shown in Figure 8.1, if $\sigma = 0.1$, then estimate (6.7) decreases exponentially as a function of N to a minimum of 10^{-7} or so at $N \approx 55$. Thus the estimate remains roughly 8 orders of magnitude above the actual errors in the large multipliers. This difference has two sources. First, the a posteriori error estimates (6.6) coming from IVPs are too large by a few orders of

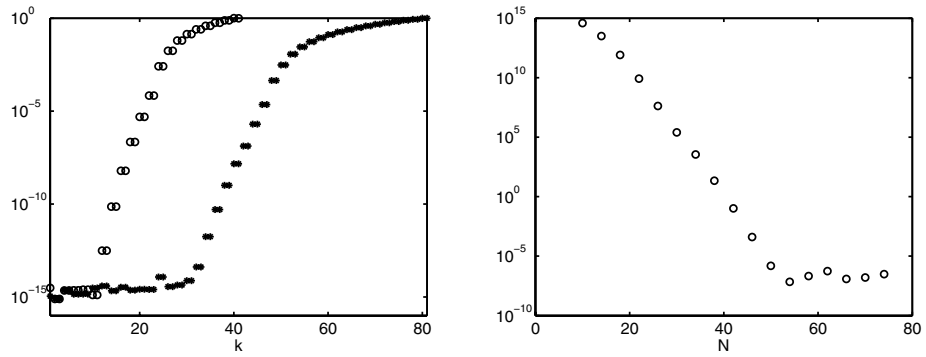

FIG. 8.1. *Left: Error in numerical multipliers for DDE* (8.1) *when* $N = 40$ *(circles) and* $N = 80$ *(dots). Right: Error bound* (6.7) *from Theorem* 6.4*, as a function of* N*, when* $\sigma = 0.1$.

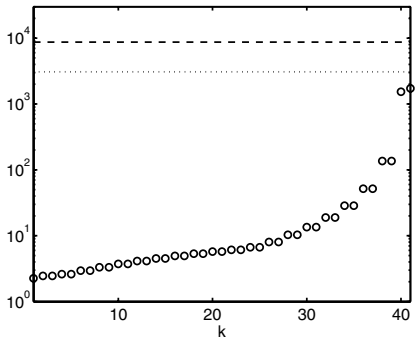

FIG. 8.2. *Condition numbers* $s_k^{(N)}$ *of the approximate multipliers* $\mu_k^{(N)}$ *for* $N = 40$; $\mathrm{cond}_2(V) = |V|\,|V^{-1}|$ *(dashed line) and estimate of* $\mathrm{cond}(\tilde{V})$ *(dotted line) from Lemma* 6.2 *are also shown.*

magnitude; compare Example 1 in section 3. Second, the estimate of $\mathrm{cond}(\tilde{V})$ is in the range 10^3–10^5 for $30 \le N \le 80$.

In fact, how badly conditioned are the computed multipliers in the above example? Recall that $s_k^{(N)} = |w_k^* v_k|^{-1}$ are the condition numbers of the eigenvalues $\mu_k^{(N)}$ of U_N if w_k and v_k are the associated normalized left and right eigenvectors, respectively [36, p. 68]. Figure 8.2 shows the computed $s_k^{(N)}$ for $N = 40$. We see that for $k \le N/2$ the condition numbers $s_k^{(N)}$ are small ($\approx 10^1$). For $k \approx N$, however, the condition numbers reach a maximum greater than 10^3. Recalling that these eigenvalues are ordered by decreasing size, we see that the difficult-to-approximate eigenvalues are the very small ones. These eigenvalues correspond to rapidly oscillating eigenfunctions for which we cannot expect our spectral method to do a good job anyway. Note that a priori estimates of these condition numbers, for the approximating matrix U_N or for the monodromy operator U, are not known.

A follow-up question is this: How does the conditioning of the individual eigenvalues relate to the matrix condition number used in Theorem 6.4? Figure 8.2 also shows $\mathrm{cond}_2(V) = |V|\,|V^{-1}|$ for the numerical diagonalization $U_N = V\Lambda V^{-1}$. We have an illustration of a quite general phenomenon: for any matrix, $\max s_k$ is always within a small factor of $\mathrm{cond}_2(V)$ [12]. Here the factor is about five.

The figure also shows our estimate of $\mathrm{cond}(\tilde{V}) = \|\tilde{V}\|\,\|\tilde{V}^{-1}\|$ from Lemma 6.2. We see that our estimate of $\mathrm{cond}(\tilde{V})$ is not problematic in this example. Indeed, $\max s_k \le$ (estimate of $\mathrm{cond}(\tilde{V})$ from Lemma 6.2) $\le \mathrm{cond}_2(V)$ in this and all other examples computed by the author. (A general proof of this fact is not known.)

We are led to a question which we can state somewhat imprecisely as follows: Let μ_k be the eigenvalues of a compact operator U, and let $\mu_k^{(N)}$ be the eigenvalues of a matrix U_N which approximates U. Is there a theorem which uses the computed condition numbers $s_k^{(N)}$ to bound the errors $|\mu_k - \mu_k^{(N)}|$? One might say that estimate (6.7) is uniform in k, because our analysis is based on a Bauer–Fike-type result (Corollary 5.2), while Figure 8.2 suggests $|\mu_k - \mu_k^{(N)}|$ should depend on k.

Let us address the practical computation of the bounds in this paper. First, a common task in computing the bound in Theorem 6.4 is the evaluation of a polynomial on the interval $I = [-1, 1]$ given its Chebyshev collocation values. This should be done by barycentric interpolation [27, 6]. A comparison of barycentric interpolation to more naive methods in computing the bounds here, which clearly shows the better performance of the barycentric method, is given in [8].

Also, in using Theorem 3.4 we need estimates of $\|\alpha\|_\infty$ where $\alpha(t)$ is a polynomial or an analytic function on I. For such norms a transform technique is useful. Consider the polynomial case first, as follows. Recall that $T_k(t) = \cos(k \arccos t)$ is the standard kth Chebyshev polynomial and that $|T_k(t)| \le 1$ for $t \in I$. If p is a polynomial and we want $\|p\|_\infty$, then we start by expanding $p(t) = \sum_{k=0}^{N} a_k T_k(t)$ by discrete Chebyshev series (3.3). It follows that

$$\|\alpha\|_\infty \le \sum_{k=0}^{N} |a_k|. \tag{8.3}$$

Estimate (8.3) uses the coefficients a_k in the Chebyshev expansion of p. These are easily calculated by the FFT [33]. Indeed, if `v` is a column vector of the collocation values of $p(t)$, then $\|p\|_\infty \le$ `sum(abs(coefft(v)))`, where "`coefft`" is the MATLAB function

```
function a = coefft(v)
   N = length(v)-1; if N==0, a=v; return, end
   U = fft([v; flipud(v(2:N))])/N;            % do t -> theta then FFT
   a = ([.5 ones(1,N-1) .5])'.*U(1:N+1);
```

If $\alpha(t)$ is analytic on I, then we estimate $\|\alpha\|_\infty$ by using (8.3) on a high degree polynomial interpolant of $\alpha(t)$. Concretely, we start with a modest value of M for Chebyshev interpolation and evaluate $\alpha(t)$ at collocation points $t_j^{(M)} = \cos(\pi j/M)$, $j = 0, \ldots, M$. Efficiency in the FFT suggests using M which is one less than a power of two, so perhaps $M = 15$. We use the FFT as above to calculate the coefficients a_k of the corresponding polynomial. We then determine whether the last few coefficients are small. For example, if $\max\{|a_{M-3}|, \ldots, |a_M|\} < 10\,\epsilon_m$, where ϵ_m is machine precision, then we accept the estimate $\|\alpha\|_\infty \approx \|p\|_\infty$ and use (8.3). If not, we double M—actually, $M_{\mathrm{new}} = 2(M_{\mathrm{old}} + 1) - 1$ for efficiency in the FFT—and try again. We might stop if $M = 2^{12} - 1$, for example. (A very similar issue to the one addressed in this paragraph appears in [3], and the technique here mimics the one there.)

Example 6. Consider estimating $\|u - I_5 u\|_\infty$ on I for $u(t) = \sin(2t)$. Our procedure with $\alpha = u - I_5 u$ stops at $N = 31$ with estimate $\|u - I_5 u\|_\infty \le 7.1 \times 10^{-4}$. By contrast, the use of 1000 equally spaced points in $[-1, 1]$ and barycentric interpolation of $p(t) = (I_5 u)(t)$ yields $\|u - I_5 u\|_\infty \approx 6.8 \times 10^{-4}$ at substantially greater cost.

A final technical concern is worth raising. It relates to the application of this paper to some of the periodic-coefficient linear DDEs which appear in practice. If DDE (2.1) came originally from an *approximate* periodic solution of a nonlinear DDE, as, for instance, when using the techniques of [13] or [14], then the period T is known only approximately (in general). The coefficients A, B are also known only approximately. Errors in the multipliers of the linear DDE in such cases may well be dominated by errors in computing the periodic solution to the original (nonlinear) DDE or by errors in computing the coefficients in (2.1).

9. Conclusion. We have introduced what we believe is a new spectral method for linear DDEs with a single fixed delay. The method uses collocation at the Chebyshev extreme points [33]. Extension of this method to multiple fixed delays is straightforward and has been implemented in MATLAB [9]. In the periodic-coefficient case, with period equal to the delay for technical convenience, we use the spectral method to compute a square matrix approximation to the monodromy operator associated to the DDE. The eigenvalues of this matrix approximation are seen in examples to be spectrally convergent to the eigenvalues of the monodromy operator (the multipliers).

Our main result uses new eigenvalue perturbation and a posteriori estimation techniques to give computable error bounds on the eigenvalue approximation error.

Now, one would obviously like an a priori proof of the spectral convergence of our collocation method when the coefficients of the DDE are analytic, but this is open. That is, one would want to show spectral convergence, as the degree of polynomial collocation increases, for the approximate solutions of ODEs and DDEs *and* for the approximate eigenvalues of the monodromy operator.

We can list some open questions related to the approximation of the multipliers by the technique of this paper:

- How can we get a better norm bound C_σ on $\Phi_\mu(z)$, the analytical continuation of the fundamental solution to $\dot{x} = (A + B/\mu)x$, for $|\mu| \geq \sigma > 0$ and z in a common regularity ellipse of A and B? (See Definition 4.4.)
- What is the best norm in which to compute $\operatorname{cond}(\tilde{V})$, the condition number of the infinite "matrix" of approximate eigenfunctions?

An additional question about the conditioning of the multipliers appears in section 8.

We have questions about the the monodromy operator U itself. For example, under what conditions does U actually diagonalize? Better yet, what a priori estimates can be computed for the conditioning of its eigenvalue problem? What can generally be said about the pseudospectra [32] of U? Do the eigenfunctions of U generically form a Riesz basis [2, 16] or some other strongly linearly independent basis for H^1? These latter questions do not affect our a posteriori methods, however.

Acknowledgments. This paper grows out of enjoyable work on engineering applications of DDEs initiated and sustained by Eric Butcher. Our ideas developed through work with Venkatesh Deshmukh and students Victoria Averina, Haitao Ma, Praveen Nindujarla, and Jacob Stroh. Correspondence with David Gilsinn on ideas and algorithms has been valuable and fun.

A LEAST-SQUARES FINITE ELEMENT METHOD FOR THE MAGNETOSTATIC PROBLEM IN A MULTIPLY CONNECTED LIPSCHITZ DOMAIN*

HUO-YUAN DUAN†, PING LIN†, P. SAIKRISHNAN†, AND ROGER C. E. TAN†

Abstract. A new least-squares finite element method is developed for the curl-div magnetostatic problem in Lipschitz and multiply connected domains filled with anisotropic nonhomogeneous materials. In order to deal with possibly low regularity of the solution, local L^2 projectors are introduced to standard least-squares formulation and applied to both curl and div operators. Coercivity is established by adding suitable mesh-dependent bilinear terms. As a result, any continuous finite elements (lower-order elements are enriched with suitable bubbles) can be employed. A desirable error bound is obtained: $||\mathbf{u}-\mathbf{u}_h||_0 \le C\,||\mathbf{u}-\tilde{\mathbf{u}}||_0$, where $\mathbf{u}_h$ and $\tilde{\mathbf{u}}$ are the finite element approximation and the finite element interpolant of the exact solution $\mathbf{u}$, respectively. Numerical tests confirm the theoretical results.

Key words. least-squares continuous finite element method, L^2 projector, curl-div magnetostatic problem

1. Introduction.

Recently, there has been increasing interest in seeking finite element solutions of Maxwell's equations; see [5, 7, 16, 21, 22, 23, 26] and references therein. As a typical model, the curl-div magnetostatic problem plays a central role in the study of finite element methods for Maxwell's equations and other mathematical subjects such as existence-uniqueness and regularity-singularity [1, 7, 15, 28]. Let us first recall this model. For a domain Ω of $\mathbb{R}^3$ filled with anisotropic nonhomogeneous materials described by a tensor ε, given two functions $\mathbf{g} \in (L^2(\Omega))^3$ and $f \in L^2(\Omega)$, with $\mathbf{u}$ the unknown field, the curl-div magnetostatic problem reads as follows [6, 7]:

$$\mathbf{curl}\,\mathbf{u} = \mathbf{g}, \quad \operatorname{div}(\varepsilon\,\mathbf{u}) = f \quad \text{in } \Omega. \tag{1.1}$$

In this paper we shall consider a least-squares C^0 finite element method to solve (1.1) numerically. Although (1.1) is simple in appearance, the C^0 finite element discretization is not straightforward generally. To illustrate this we consider a simple case below. Let Ω be a Lipschitz polyhedron of $\mathbb{R}^3$ with boundary $\partial\Omega$, $\varepsilon = 1$, and assuming a boundary condition $\mathbf{u}\cdot\mathbf{n} = 0$ on $\partial\Omega$. Let $X_T := \{\mathbf{v} \in (L^2(\Omega))^3; \mathbf{curl}\,\mathbf{v} \in (L^2(\Omega))^3, \operatorname{div}\mathbf{v} \in L^2(\Omega), \mathbf{v}\cdot\mathbf{n}|_{\partial\Omega} = 0\}$, equipped with the norm $||\mathbf{v}||^2_{X_T} = ||\mathbf{curl}\,\mathbf{v}||^2_0 + ||\operatorname{div}\mathbf{v}||^2_0 + ||\mathbf{v}||^2_0$, where $||\cdot||_0$ is the L^2 norm. Equation (1.1) can be formulated as a standard least-squares variational problem (see [22, 23]): Find $\mathbf{u} \in X_T$ such that, for all $\mathbf{v} \in X_T$,

$$\mathcal{L}(\mathbf{u},\mathbf{v}) := (\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v}) + (\operatorname{div}\mathbf{u}, \operatorname{div}\mathbf{v}) = (\mathbf{g}, \mathbf{curl}\,\mathbf{v}) + (f, \operatorname{div}\mathbf{v}), \tag{1.2}$$

where $(\cdot,\cdot)$ denotes the L^2 inner product. As is well known, $\mathcal{L}$ is coercive on X_T with respect to the norm $||\cdot||_{X_T}$ (cf. [2, 15, 20]). Then it seems to be natural to employ the C^0 finite element method for problem (1.2). This is indeed true for smooth domains or for convex polyhedra (see [12, 22, 23, 27]). However, when the domain is nonsmooth (Ω contains reentrant corners or edges), it turns out that the C^0 finite element method of problem (1.2) does not usually yield correct approximations (cf. [5, 15, 16]). Here we provide an intuitive interpretation. A more accurate interpretation may be found in [5, 15, 16, 24]. Let $\mathbf{u}_h$ be the C^0 finite element solution of (1.2), where $h > 0$ denotes the mesh-parameter of the simplex partition of Ω. The classical C^0 finite element and interpolation theory [8, 13] leads to an error estimate: $||\mathbf{u}-\mathbf{u}_h||_{X_T} \le C\,||\mathbf{u}-\tilde{\mathbf{u}}||_{X_T} \le C\,h^r\,||\mathbf{u}||_{1+r}$, for all $r \ge 0$, where $\tilde{\mathbf{u}}$ is an interpolant of $\mathbf{u}$ in a continuous piecewise $\mathcal{P}_r$ polynomial of order not greater than r. This error estimate indicates that $\mathbf{u}$ should be at least in H^1 in order to have a convergence. But, for nonsmooth domains, $\mathbf{u}$ may not be in H^1 (see [15]).

Nonetheless, this is not necessarily the problem of the use of C^0 finite elements. In fact, any function in L^2 (even in L^1) can be well approximated by C^0 elements, and we have

$$||\mathbf{u}-\tilde{\mathbf{u}}||_0 \le C\,h^s\,||\mathbf{u}||_s \tag{1.3}$$

when $\mathbf{u}$ is in H^s with $0 \le s < 1$ (see [3, 8, 13, 14, 29]). Since C^0 finite elements are good enough for H^s $(0 \le s < 1)$ functions, the use of the formulation (1.2) is the source of trouble when C^0 finite elements are used for the problem with singular (nonsmooth) solutions whose singularities generally result from nonsmoothness of domains or heterogeneities of materials filling the domain or both. This motivates the design of more suitable formulations to replace (1.2) so that C^0 finite elements may concurrently work for nonsmooth solutions (not in H^1) as well as smooth solutions (at least in H^1). Meanwhile, new formulations should still have the same merits as (1.2): (a) the resulting linear system is symmetric and positive definite; (b) a globally continuous solution can be produced. See a survey [4] on least-squares finite element methods.

There are a few modified formulations available. A weighted formulation, proposed in [16], may be employed. See also an earlier paper [17]. The weighted least-squares method is theoretically and numerically proven to be convergent correctly. A property of this method is that a positive weight function of nonpolynomials is applied to the div operator appearing in (1.2). In two dimensions the weight function may be taken in the form of r^γ, where r is the distance to the reentrant corner with opening angle greater than π, and γ is an index that characterizes the singularity of the exact solution. It becomes, however, rather complicated to determine the weight function in three dimensions, due to the more complex characterization of the singularity information for three-dimensional domains. Another property is that the C^0 finite element space is required to contain the gradient of some C^1 finite element space. This excludes the use of some simpler C^0 finite elements (e.g., the linear element). Several C^1 finite element spaces are available in two dimensions (cf. [13]), but, to our knowledge, few C^1 finite elements are known in three dimensions. So it is unclear how to choose a reasonable three-dimensional C^0 finite element space. There are other least-squares methods available—for example, the FOSLL* method [11, 25] and the *negative* norm method [9, 10]. Of a scaled version of (1.1) (setting $\mathbf{u}^* = \varepsilon^{1/2}\,\mathbf{u}$ and $\mathbf{g} = \mathbf{0}$) the FOSLL* method first seeks the solution of a dual problem associated with the dual operator of the differential operator of the scaled problem of (1.1), and

then the solution $\mathbf{u}^*$ is obtained by differentiating the dual solution. This FOSLL* method [25] is in essence a scalar potential method and the approximation of $\mathbf{u}^*$ is always discontinuous because of the differentiation. The negative norm method [9], to accommodate the case of nonsmooth solutions, formulates (1.1) in suitable dual norms (assuming that Ω is simply connected, $\partial\,\Omega$ has no disconnected components, $\varepsilon = 1$, and the boundary condition $\mathbf{u}\cdot\mathbf{n}|_{\partial\,\Omega} = 0$):

$$(\mathbf{curl}\,\mathbf{u}, \mathbf{curl}\,\mathbf{v})_{(H^{-1}(\Omega))^3} + (\operatorname{div}\mathbf{u}, \operatorname{div}\mathbf{v})_{(H^1(\Omega))^*}$$
$$= (\mathbf{g}, \mathbf{curl}\,\mathbf{v})_{(H^{-1}(\Omega))^3} + (f, \operatorname{div}\mathbf{v})_{(H^1(\Omega))^*},$$

where $(H^{-1}(\Omega))^3$ is the dual space of $(H_0^1(\Omega))^3$, with $H_0^1(\Omega) = \{v \in H^1(\Omega); v|_{\partial\,\Omega} = 0\}$, and $(H^1(\Omega))^*$ is the dual space of $H^1(\Omega)$, and $(\cdot,\cdot)_{(H^{-1}(\Omega))^3}$ and $(\cdot,\cdot)_{(H^1(\Omega))^*}$ denote the inner products of $(H^{-1}(\Omega))^3$ and $(H^1(\Omega))^*$, respectively. In the discrete level this method is something like adding the inverse of the discrete Laplace operator or its preconditioner in front of both curl and div operators in (1.2). The error estimate of the finite element approximation for nonsmooth solutions may be obtained from this method, but at the expense of multiple applications of the inverse of the discrete Laplacian or its preconditioner. The programming is rather tricky in practice as well.

In this paper, we develop new least-squares methods with the use of C^0 finite elements. The main idea is to apply local L^2 projectors to both curl and div operators appearing in (1.2), with a few extra mesh-dependent stabilization terms added. Specifically, let R_h and $\breve{R}_h$ be L^2 projectors defined relative to L^2 inner products $(\cdot,\cdot)_h$, and let $S_h(\cdot,\cdot)$ be a mesh-dependent bilinear form; we define a new least-squares bilinear form:

$$\mathcal{L}_h(\mathbf{u},\mathbf{v}) = (R_h(\mathbf{curl}\,\mathbf{u}), R_h(\mathbf{curl}\,\mathbf{v}))_h + (\breve{R}_h(\operatorname{div}(\varepsilon\,\mathbf{u})), \breve{R}_h(\operatorname{div}(\varepsilon\,\mathbf{v})))_h + S_h(\mathbf{u},\mathbf{v}). \tag{1.4}$$

These R_h and $\breve{R}_h$ are defined as local L^2 projectors or pseudolocal L^2 projectors. Local L^2 projectors are defined element-by-element onto the discontinuous piecewise constant finite element spaces and pseudolocal L^2 projectors are defined onto the continuous piecewise linear finite element spaces with respect to the trapezoidal quadrature scheme of the standard L^2 inner product (Note that the L^2 projectors defined in this way are essentially local. See Remark 3.1 of this paper.) We prove that both L^2 projected least-squares methods, labeled as the local L^2 projection method and the pseudolocal L^2 projection method, are coercive:

$$\mathcal{L}_h(\mathbf{v},\mathbf{v}) \geq C\,||\mathbf{v}||_0^2. \tag{1.5}$$

As a result, any C^0 finite elements can be employed. We also prove that the condition number of the resulting linear system is $\mathcal{O}(h^{-2})$. To show the idea, we focus on the error analysis of linear C^0 finite elements in three dimensions. We employ the linear element enriched face bubbles for the local L^2 projection method and the linear element enriched with element bubbles for the pseudolocal L^2 projection method. We can construct an interpolant $\tilde{\mathbf{u}}$ of the exact solution $\mathbf{u}$ that satisfies not only the usual interpolation error estimation (1.3) but also the exclusive interpolation property:

$$||R_h(\mathbf{curl}\,(\mathbf{u}-\tilde{\mathbf{u}}))||_h = ||\breve{R}_h(\operatorname{div}(\varepsilon\,(\mathbf{u}-\tilde{\mathbf{u}})))||_h = 0. \tag{1.6}$$

We thus obtain mainly from (1.5) and (1.6) the following desirable error estimates:

$$||\mathbf{u}-\mathbf{u}_h||_0 \leq C\,||\mathbf{u}-\tilde{\mathbf{u}}||_0, \tag{1.7}$$

where $\mathbf{u}_h$ is the finite element solution associated with (1.4). Equation (1.7) means that the finite element solution is almost the best approximation to the exact solution. In the case that $\mathbf{u} \in H^s$, an L^2 optimal error bound $\mathcal{O}(h^s)$ follows directly from (1.7) and (1.3). We point out that the role of the face bubbles and the element bubbles is to make (1.6) hold. For higher order C^0 finite elements (cubic elements and above), additional bubbles are not always needed, since they usually have face or/and element bubbles of their own.

Before closing this section, we would like to give several remarks. The implementation of the L^2 projected least-squares method of this paper is almost as easy as that of the standard least-squares method (1.2). But, the former allows less regular solution. In comparison with the weighted least-squares method, it does not need any a priori singularity information of the solution and allows the use of both lower-order (maybe enriched with suitable bubbles) and higher-order C^0 elements in both two and three dimensions. Also, it is not clear if there is an improved L^2 error bound for both the standard and the weighted methods in the case where the solution is smooth but the domain is nonsmooth, since to obtain an improved L^2 error bound one has to resort to the well-known Aubin–Nitsche duality argument [8, 13], but this argument usually requires the domain to be smooth enough in order that the associated auxiliary variational problem admits a solution with an appropriate regularity. Unlike the negative norm least-squares method which involves a preconditioner for second-order elliptic problems, the method here deals only with local L^2 projectors, so the practical implementation is simpler. Compared with the FOSLL* method, the method here avoids the differentiation of approximate solutions of potentials and obtains continuous approximate solutions.

The outline of this paper is as follows. In section 2, we review the curl-div magnetostatic problem and recall the L^2 orthogonal decomposition of vector fields. In section 3, two L^2 projected least-squares C^0 finite element methods are described. In section 4, coercivity is established and condition number is estimated. In section 5, the error estimate of the method is obtained. In the last section, some numerical tests are performed to demonstrate the theoretical results obtained.

2. The magnetostatic problem and L^2 decomposition. Let Ω of $\mathbb{R}^3$ be an open, bounded, and possible multiconnected Lipschitz polyhedron, with boundary $\Gamma = \partial\Omega$ and $\mathbf{n}$ the outward unit normal vector to Γ. Let $\varepsilon = (\varepsilon_{ij}) \in \mathbb{R}^{3\times 3}$ satisfy $\varepsilon_{ij} = \varepsilon_{ji}$, $1 \le i, j \le 3$, and

$$C \sum_{i=1}^{3} \xi_i^2 \le \sum_{i,j=1}^{3} \varepsilon_{ij}\xi_i\xi_j \le C^{-1} \sum_{i=1}^{3} \xi_i^2 \quad \text{a.e. in } \bar{\Omega} \quad \forall \xi = (\xi_i) \in \mathbb{R}^3.$$

For the sake of simplicity, we always assume that ε is Lipschitz continuous over $\bar{\Omega}$. With a few modifications, the method of this paper can deal with the case ε being piecewise Lipschitz continuous but not globally continuous (see Remark 5.4).

We now describe the curl-div system of magnetostatic problems.

Given $\mathbf{g} \in (L^2(\Omega))^3$ and $f \in L^2(\Omega)$, the curl-div magnetostatic problem is to find $\mathbf{u}$ such that

$$\mathbf{curl}\,\mathbf{u} = \mathbf{g}, \quad \operatorname{div}(\varepsilon\,\mathbf{u}) = f \quad \text{in } \Omega, \tag{2.1}$$

$$(\varepsilon\,\mathbf{u}) \cdot \mathbf{n} = 0 \quad \text{on } \Gamma, \tag{2.2}$$

where $\mathbf{curl}\,\mathbf{v} = \bigtriangledown \times \mathbf{v}$, $\operatorname{div}\mathbf{v} = \bigtriangledown \cdot \mathbf{v}$, and $\bigtriangledown$ is the gradient operator.

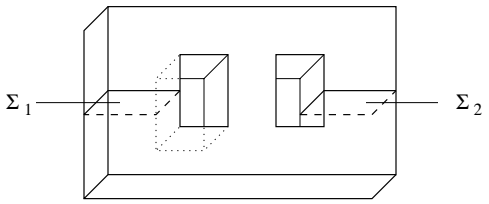

FIG. 1. *A multiply connected domain* Ω.

The solution of problem (2.1)–(2.2) may not be unique when Ω is multiconnected. In that case, to ensure the uniqueness of the solution we need to introduce additional constraints on the so-called *cuts*. (Roughly speaking, these cuts "cut" the multiconnected domain into a simply connected one.) Note that when Ω is simply connected, problem (2.1)–(2.2) has a unique solution. (Of course, $\mathbf{g}$ and f are required to satisfy necessary compatible conditions, e.g., $\operatorname{div}\mathbf{g} = 0$, $\int_\Omega f = 0$, etc.)

To that goal, as done in [2, 28], we assume that there is a set of N cuts Σ_j, $1 \le j \le N$, such that $\overset{\circ}{\Omega} = \Omega \setminus \Sigma$ (where $\Sigma = \bigcup_{j=1}^{N} \Sigma_j$) is pseudoLipschitz and simply connected, where $\bar{\Sigma}_j \subset \Omega$ is a compact and connected two-dimensional Lipschitz manifold with boundary $\partial\Sigma_j \subset \Gamma$, and $\bar{\Sigma}_i \cap \bar{\Sigma}_j = \emptyset$ if $i \ne j$, and Σ_j is globally two-sided, denoted by Σ_j^+ and Σ_j^-, and $\partial\overset{\circ}{\Omega} = \Gamma \cup \Sigma^+ \cup \Sigma^-$. As an illustrating example we consider a multiply connected domain shown in Figure 1. Cutting along Σ_1 and Σ_2 we get a simply connected domain $\overset{\circ}{\Omega}$ with boundary $\Gamma \cup \Sigma_1^+ \cup \Sigma_1^- \cup \Sigma_2^+ \cup \Sigma_2^-$, where $\Sigma_i^\pm$ are the upper and lower (relative to $\mathbf{n}_i$, the unit normals in Σ_i) sheets of Σ_i.

Additional constraints can be thus given by [2, 28]

$$\int_{\Sigma_j} (\varepsilon\,\mathbf{u}) \cdot \mathbf{n} = 0, \quad 1 \le j \le N. \tag{2.3}$$

Problem (2.1)–(2.3) then admits a unique solution, with compatible conditions satisfied by $\mathbf{g}$ and f. Readers may refer to [1, 6, 7, 28] for more details.

We next introduce some Hilbert spaces.

Let $D \subseteq \Omega$. Denote by $H^1(D)$, $H^1(D)/\mathbb{R}$, and $H_0^1(D)$ the usual Hilbert spaces. We also need $H(\operatorname{div};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^3, \operatorname{div}\mathbf{v} \in L^2(\Omega)\}$, $H(\operatorname{div}^0;\Omega) = \{\mathbf{v} \in H(\operatorname{div};\Omega); \operatorname{div}\mathbf{v} = 0\}$, $H_\Gamma(\operatorname{div};\Omega) = \{\mathbf{v} \in H(\operatorname{div};\Omega), \mathbf{v}\cdot\mathbf{n}|_\Gamma = 0\}$, $H_\Gamma(\operatorname{div}^0;\Omega) = H_\Gamma(\operatorname{div};\Omega) \cap H(\operatorname{div}^0;\Omega)$, $H(\mathbf{curl};\Omega) = \{\mathbf{v} \in (L^2(\Omega))^3, \mathbf{curl}\,\mathbf{v} \in (L^2(\Omega))^3\}$, $H_\Gamma(\mathbf{curl};\Omega) = \{\mathbf{v} \in H(\mathbf{curl};\Omega), \mathbf{v}\times\mathbf{n}|_\Gamma = \mathbf{0}\}$, and

$$U = \{\mathbf{v} \in (L^2(\Omega))^3; \operatorname{div}(\varepsilon\mathbf{v}) \in L^2(\Omega), \mathbf{curl}\mathbf{v} \in (L^2(\Omega))^3, (\varepsilon\mathbf{v})\cdot\mathbf{n}|_\Gamma \in L^2(\Gamma)\}, \tag{2.4}$$

$$H_{\text{flux},\Sigma}(\operatorname{div}^0;\Omega) = \left\{\mathbf{v} \in H(\operatorname{div}^0;\Omega); \int_{\Sigma_j} \mathbf{v}\cdot\mathbf{n} = 0, \quad 1 \le j \le N\right\}, \tag{2.5}$$

$$\mathbb{H} = \{\mathbf{v} \in U; \mathbf{curl}\,\mathbf{v} = 0, \operatorname{div}(\varepsilon\,\mathbf{v}) = 0, (\varepsilon\,\mathbf{v})\cdot\mathbf{n}|_\Gamma = 0\}. \tag{2.6}$$

The $\mathbb{H}$, referred to as "harmonic space," may not be trivial in the case of multiconnected domains and accounts for why the solution of problem (2.1)–(2.2) may not be unique. The $\mathbb{H}$ has a finite dimension and can be characterized as the space of gradients of a finite number of scalar functions (See Proposition 2.1 below).

PROPOSITION 2.1 (see [2, 28]). *For any $\Pi \in \mathbb{H}$, there is a $q \in H^1\big(\overset{\circ}{\Omega}\big)$ such that $\bigtriangledown q = \Pi$ in $\overset{\circ}{\Omega}$ and $||q||_{H^1\left(\overset{\circ}{\Omega}\right)} \leq C\,||\Pi||_0$, where q satisfies*

$$\operatorname{div}(\varepsilon \bigtriangledown q) = 0 \quad \text{in } \overset{\circ}{\Omega}, \quad (\varepsilon \bigtriangledown q)\cdot \mathbf{n}\Big|_{\Gamma\cap\partial\,\overset{\circ}{\Omega}} = 0,$$

$$[q]|_{\Sigma_j} = \text{constant}, \quad [(\varepsilon \bigtriangledown q)\cdot \mathbf{n}]\,\Big|_{\Sigma_j} = 0, \quad 1 \leq j \leq N,$$

where $[v]|_{\Sigma_j}$ denotes the jump in v across Σ_j.

Denote by $(\varepsilon\,\cdot,\cdot)$ the ε-weighted L^2 inner product, i.e.,

$$(\varepsilon\,\mathbf{u},\mathbf{v}) := \int_\Omega \varepsilon\,\mathbf{u}\,\mathbf{v}.$$

We now recall the L^2 orthogonal decomposition.

PROPOSITION 2.2 (see [2, 28]). *For any $\mathbf{v} \in (L^2(\Omega))^3$, it can be written as the following L^2 orthogonal decomposition, with respect to $(\varepsilon\,\cdot,\cdot)$:*

$$\mathbf{v} = \bigtriangledown p + \Pi + \varepsilon^{-1}\,\mathbf{curl}\,\psi,$$

where $p \in H^1(\Omega)/\mathbb{R}$, $\Pi \in \mathbb{H}$, $\psi \in H_\Gamma(\mathbf{curl};\Omega) \cap H_{\text{flux},\Sigma}(div^0;\Omega)$, and

$$||\psi||_0 \leq C\,||\mathbf{curl}\,\psi||_0, \quad ||\varepsilon^{\frac{1}{2}}\,\mathbf{v}||_0^2 = ||\varepsilon^{\frac{1}{2}}\bigtriangledown p||_0^2 + ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2 + ||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2.$$

Above and below, the letter C (with or without subscripts) stands for a generic constant which is independent of the mesh-parameter h and may take different values at different occurrences. Denote by $(\cdot,\cdot)_{0,D}$ and $||\cdot||_{0,D}$ the inner product and the norm of $L^2(D)$ or $(L^2(D))^3$, and $(\cdot,\cdot) := (\cdot,\cdot)_{0,\Omega}$, $||\cdot||_0 := ||\cdot||_{0,\Omega}$.

We finally recall Green's formula of integrating by parts:

$$(\operatorname{div}\mathbf{v}, q) = -(\mathbf{v}, \bigtriangledown q) + \int_\Gamma \mathbf{v}\cdot\mathbf{n}\,q \quad \forall \mathbf{v} \in H(\operatorname{div};\Omega), \forall q \in H^1(\Omega);$$

$$(\mathbf{curl}\,\mathbf{u},\mathbf{v}) = (\mathbf{u},\mathbf{curl}\,\mathbf{v}) + \int_\Gamma \mathbf{u}\times\mathbf{n}\cdot\mathbf{v} \quad \forall \mathbf{u} \in H(\mathbf{curl};\Omega), \forall \mathbf{v} \in (H^1(\Omega))^3.$$

3. The L^2 projected least-squares finite element methods. In this section, we shall describe two L^2 projected least-squares finite element methods: (1) the local L^2 projection method; (2) the pseudolocal L^2 projection method.

3.1. Bubbles and some finite dimensional spaces. Let $\mathcal{C}_h$ denote a regular triangulation of $\bar{\Omega}$ into tetrahedra, with diameters h_K for all $K \in \mathcal{C}_h$ bounded by h [8, 13]. We assume that the closure of each cut in $\{\Sigma_j; 1 \leq j \leq N\}$ is the union of the closure of some faces of tetrahedra in $\mathcal{C}_h$.

Let $\mathcal{E}_h^0$ be the set of all the interior faces in $\mathcal{C}_h$, $\mathcal{E}_h^\partial$ the set of all the faces on Γ, and $\mathcal{E}_h = \mathcal{E}_h^0 \bigcup \mathcal{E}_h^\partial$ the set of all faces in $\mathcal{C}_h$. We define $\mathcal{M}_h$ as the collection of macroelements in the following way. Each macroelement in $\mathcal{M}_h$ corresponds to a face $F \in \mathcal{E}_h$ one-by-one: (1) if $F \in \mathcal{E}_h^0$, then the macroelement in $\mathcal{M}_h$ is the union of the two tetrahedra sharing F; (2) if $F \in \mathcal{E}_h^\partial$, then the macroelement is the tetrahedron including F as a face. Note that some macroelements in $\mathcal{M}_h$, corresponding to different faces, are allowed to be identical and that the number of all macroelements is

the same as that of all faces. To emphasize the dependence on F, sometimes we write M as M_F.

We now introduce some bubbles. If K is a tetrahedron with vertices a_i, $1 \le i \le 4$, we denote by λ_i the barycoordinate of a_i, and by F_i the face opposite a_i, and then we introduce the face bubbles

$$b_{F_1} = \lambda_2\lambda_3\lambda_4, \quad b_{F_2} = \lambda_3\lambda_4\lambda_1, \quad b_{F_3} = \lambda_4\lambda_1\lambda_2, \quad b_{F_4} = \lambda_1\lambda_2\lambda_3 \tag{3.1}$$

and the usual element bubble on K,

$$b_K = \lambda_1\lambda_2\lambda_3\lambda_4 \in H_0^1(K). \tag{3.2}$$

We would have

$$b_{F_i} \in H_0^1(F_i), \quad b_{F_i}|_{F_j} = 0 \quad \forall j \neq i. \tag{3.3}$$

For any $M_F \in \mathcal{M}_h$, corresponding to $F \in \mathcal{E}_h$, we introduce the macroelement bubble b_{M_F} as follows.

(1) If $F \in \mathcal{E}_h^0$, i.e., $M_F = K_1 \cup K_2$ with $K_1, K_2 \in \mathcal{C}_h$ sharing F, we denote by $b_F^{K_1}$ and $b_F^{K_2}$ the face bubble of F in K_1 and K_2, respectively. We set

$$b_{M_F}(x), = \begin{cases} b_F^{K_1}(x), & x \in K_1, \\ b_F^{K_2}(x), & x \in K_2, \\ 0 \quad \text{elsewhere.} \end{cases} \tag{3.4}$$

It can be seen that $b_{M_F} \in H_0^1(M_F)$ and

$$b_{M_F}|_F \in H_0^1(F), \quad b_{M_F}|_{F'} = 0 \quad \forall F' (\neq F) \in \mathcal{E}_h. \tag{3.5}$$

(2) If $F \in \mathcal{E}_h^\partial$, i.e., $M_F = K$, with $K \in \mathcal{C}_h$ sharing F with Γ, we set

$$b_{M_F}(x) = \begin{cases} b_F(x), & x \in K, \\ 0 \quad \text{elsewhere.} \end{cases} \tag{3.6}$$

Also, we have (3.5), but $b_{M_F} \notin H_0^1(M_F)$.

Let $\mathcal{P}_r$ be the space of polynomials of order not greater than $r \ge 0$. We define

$$\mathbf{P}(M_F) := \operatorname{span}\{\varepsilon\,(\mathcal{P}_0(M_F))^3, (\mathcal{P}_0(M_F))^3\} = \operatorname{span}\{\mathbf{p}_{F,l}; 1 \le l \le m_F\}, \tag{3.7}$$

$$\mathbf{P}(K) := \operatorname{span}\{\varepsilon\,(\mathcal{P}_0(K))^3, (\mathcal{P}_0(K))^3\} = \operatorname{span}\{\mathbf{p}_l; 1 \le l \le m_K\}, \tag{3.8}$$

where m_F and m_K are positive integers standing for the dimensions of $\mathbf{P}(M_F)$ and $\mathbf{P}(K)$, respectively, and we define the following bubble spaces:

$$\Phi_h := \left\{ \mathbf{v} \in (H^1(\Omega))^3; \mathbf{v} = \sum_{F \in \mathcal{E}_h} \sum_{l=1}^{m_F} c_{F,l}\, \mathbf{p}_{F,l}\, b_{M_F} \ \forall c_{F,l} \in \mathbb{R} \right\}, \tag{3.9}$$

$$\Psi_h := \{\mathbf{v} \in (H_0^1(\Omega))^3; \mathbf{v}|_K \in \mathbf{P}(K)\, b_K \ \forall K \in \mathcal{C}_h\}. \tag{3.10}$$

We also need some additional finite dimensional spaces which will be used in the next section. First, let

$$P_h := \{q \in H^1(\Omega); q|_K \in \mathcal{P}_1(K) \ \forall K \in \mathcal{C}_h\}. \tag{3.11}$$

Second, let q_i^0, $1 \le i \le N$, be the piecewise linear polynomial function, taking value "1" at the nodes on one side of Σ_i, say, Σ_i^+, and "0" at all other nodes (including those on Σ_i^-, the other side of Σ_i). Let $A_h := \mathrm{span}\{q_i^0, i = 1, \ldots, N\}$; we define

$$V_h := P_h + A_h, \tag{3.12}$$

$$W_h := (P_h \cap H_0^1(\Omega))^3, \tag{3.13}$$

where V_h and W_h will be used only for the pseudolocal L^2 projection method below.

3.2. Finite element method. Let U_h be the finite element space. The L^2 projected least-squares finite element method is to find $\mathbf{u}_h \in U_h$ such that

$$\mathcal{L}_h(\mathbf{u}_h, \mathbf{v}) = \mathcal{F}_h(\mathbf{v}) \quad \forall \mathbf{v} \in U_h, \tag{3.14}$$

where

$$\begin{aligned} \mathcal{L}_h(\mathbf{u}, \mathbf{v}) := {} & (\breve{R}_h(\mathrm{div}(\varepsilon\mathbf{u})), \breve{R}_h(\mathrm{div}(\varepsilon\mathbf{v})))_h \\ & + (R_h(\mathbf{curl}\,\mathbf{u}), R_h(\mathbf{curl}\,\mathbf{v}))_h + S_h(\mathbf{u}, \mathbf{v}), \end{aligned} \tag{3.15}$$

$$\mathcal{F}_h(\mathbf{v}) := (f, \breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{v}))) + (\mathbf{g}, R_h(\mathbf{curl}\,\mathbf{v})) + Z_h(f, \mathbf{g}; \mathbf{v}), \tag{3.16}$$

$S_h(\mathbf{u}, \mathbf{v})$ is a mesh-dependent semipositive definite bilinear form on $U_h \times U_h$, $Z_h(f, \mathbf{g}; \mathbf{v})$ is a mesh-dependent linear form on U_h, $(\cdot, \cdot)_h$ is an approximation of L^2 inner product $(\cdot, \cdot)$, and $\breve{R}_h, R_h$ are L^2 projectors. These are to be defined below.

We first describe the *local L^2 projection method*.

We define $(\cdot, \cdot)_h := (\cdot, \cdot)$ and

$$U_h := (P_h)^3 + \Phi_h, \tag{3.17}$$

$$\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{u}))|_K := \frac{1}{|K|} \int_K \mathrm{div}\,(\varepsilon\,\mathbf{u}) \quad \forall K \in \mathcal{C}_h, \tag{3.18}$$

$$R_h(\mathbf{curl}\,\mathbf{u})|_K := \frac{1}{|K|} \int_K \mathbf{curl}\,\mathbf{u} \quad \forall K \in \mathcal{C}_h, \tag{3.19}$$

$$R_h^\Gamma((\varepsilon\,\mathbf{u}) \cdot \mathbf{n})|_F := \frac{1}{|F|} \int_F (\varepsilon\,\mathbf{u}) \cdot \mathbf{n} \quad \forall F \subset \Gamma, \tag{3.20}$$

where $\mathbf{u}$ is assumed to belong to U defined in (2.4), $|K|$ and $|F|$ respectively denote the volumes of K and F,

$$\begin{aligned} S_h(\mathbf{u}, \mathbf{v}) := {} & \int_\Gamma R_h^\Gamma((\varepsilon\,\mathbf{u}) \cdot \mathbf{n})\, R_h^\Gamma((\varepsilon\,\mathbf{v}) \cdot \mathbf{n}) + S_{h,\mathrm{div}}(\mathbf{u}, \mathbf{v}) \\ & + S_{h,\mathbf{curl}}(\mathbf{u}, \mathbf{v}) + S_{h,\Gamma}(\mathbf{u}, \mathbf{v}) + S_{\mathrm{flux},\Sigma}(\mathbf{u}, \mathbf{v}), \end{aligned} \tag{3.21}$$

$$Z_h(f, \mathbf{g}; \mathbf{v}) := Z_{h,\mathrm{div}}(f; \mathbf{v}) + Z_{h,\mathbf{curl}}(\mathbf{g}; \mathbf{v}) + Z_{h,\Gamma}(f; \mathbf{v}), \tag{3.22}$$

where the definitions of those mesh-dependent bilinear and linear forms of

$$S_{h,\mathrm{div}}(\mathbf{u}, \mathbf{v}), S_{h,\mathbf{curl}}(\mathbf{u}, \mathbf{v}), S_{h,\Gamma}(\mathbf{u}, \mathbf{v}), S_{\mathrm{flux},\Sigma}(\mathbf{u}, \mathbf{v}) \tag{3.23}$$

and

$$Z_{h,\mathrm{div}}(f;\mathbf{v}), Z_{h,\mathbf{curl}}(\mathbf{g};\mathbf{v}), Z_{h,\Gamma}(f;\mathbf{v}) \tag{3.24}$$

will be concretely given in section 3.3.

We next describe the *pseudolocal L^2 projection method.*

We define

$$(p,q)_h := \sum_{K\in\mathcal{C}_h} \frac{|K|}{4} \sum_{i=1}^{4} p(a_i)\, q(a_i) \quad \text{(trapezoidal quadrature)}, \tag{3.25}$$

$$U_h := (P_h)^3 + \Psi_h, \tag{3.26}$$

$$(\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{u})), q)_h = -\sum_{K\in\mathcal{C}_h} (\varepsilon\,\mathbf{u}, \bigtriangledown\, q)_{0,K} \quad \forall q \in V_h, \tag{3.27}$$

$$(R_h(\mathbf{curl}\,\mathbf{u}), \mathbf{v})_h = (\mathbf{u}, \mathbf{curl}\,\mathbf{v}) \quad \forall \mathbf{v} \in W_h, \tag{3.28}$$

where $\mathbf{u}$ is assumed to belong to $(L^2(\Omega))^3$, V_h and W_h are given by (3.12) and (3.13), and

$$S_h(\mathbf{u},\mathbf{v}) := S_{h,\mathrm{div}}(\mathbf{u},\mathbf{v}) + S_{h,\mathbf{curl}}(\mathbf{u},\mathbf{v}) + S_{h,\Gamma}(\mathbf{u},\mathbf{v}), \tag{3.29}$$

$$Z_h(f,\mathbf{g};\mathbf{v}) := Z_{h,\mathrm{div}}(f;\mathbf{v}) + Z_{h,\mathbf{curl}}(\mathbf{g};\mathbf{v}) + Z_{h,\Gamma}(f;\mathbf{v}). \tag{3.30}$$

Remark 3.1. Noting that the resulting matrix of the trapezoidal quadrature scheme defined by (3.25) is diagonal, for this reason we call R_h and $\breve{R}_h$, defined by (3.27) and (3.28), *pseudolocal L^2* projectors.

3.3. Mesh-dependent bilinear and linear forms. In this subsection we shall define those mesh-dependent bilinear and linear forms as in (3.23) and (3.24).

We need to introduce some local spaces of some suitable functions.

Let $\mathcal{F}_K : \hat{K} \to K$ denote the invertible mapping from the reference element $\hat{K}$ onto $K \in \mathcal{C}_h$, i.e., $K = \mathcal{F}_K(\hat{K})$, which associates the function q defined on K with the function $\hat{q}$ defined on $\hat{K}$ by $q = \hat{q} \circ \mathcal{F}_K^{-1}$. On $\hat{K}$ we introduce three spaces of some suitable functions as follows:

$$\begin{cases} S_{\mathrm{div}}(\hat{K}) := \mathrm{span}\{\hat{v}_l; 1 \le l \le m_{\mathrm{div}}\} \subset L^2(\hat{K}), \\ S_{\Gamma}(\hat{K}) := \mathrm{span}\{\hat{z}_l; 1 \le l \le m_{\Gamma}\} \subset L^2(\hat{K}), \\ S_{\mathbf{curl}}(\hat{K}) := \mathrm{span}\{\hat{\mathbf{w}}_l; 1 \le l \le m_{\mathbf{curl}}\} \subset (L^2(\hat{K}))^3, \end{cases} \tag{3.31}$$

where three integers $m_{\mathrm{div}}, m_{\Gamma}, m_{\mathbf{curl}}$ denoting the dimensions of corresponding spaces and these functions $\hat{v}, \hat{z}, \hat{\mathbf{w}}$ are determined according to Hypothesis H1 in section 4.1. Using $\mathcal{F}_K$ we obtain on $K \in \mathcal{C}_h$ three local spaces as follows:

$$\begin{cases} S_{\mathrm{div}}(K) := S_{\mathrm{div}}(\hat{K}) \circ \mathcal{F}_K^{-1} = \mathrm{span}\{v_{K,l} := \hat{v}_l \circ \mathcal{F}_K^{-1}; 1 \le l \le m_{\mathrm{div}}\}, \\ S_{\Gamma}(K) := S_{\Gamma}(\hat{K}) \circ \mathcal{F}_K^{-1} = \mathrm{span}\{z_{K,l} := \hat{z}_l \circ \mathcal{F}_K^{-1}; 1 \le l \le m_{\Gamma}\}, \\ S_{\mathbf{curl}}(K) := S_{\mathbf{curl}}(\hat{K}) \circ \mathcal{F}_K^{-1} = \mathrm{span}\{\mathbf{w}_{K,l} := \hat{\mathbf{w}}_l \circ \mathcal{F}_K^{-1}; 1 \le l \le m_{\mathbf{curl}}\}. \end{cases} \tag{3.32}$$

Remark 3.2. Consider $\varepsilon = 1$ on K. For the local L^2 projection method we may choose

$$S_{\mathrm{div}}(K) = \mathcal{P}_2(K), \quad S_{\Gamma}(K) = \mathcal{P}_3(K), \quad S_{\mathbf{curl}}(K) = (\mathcal{P}_2(K))^3.$$

For the pseudolocal L^2 projection method we can choose

$$S_{\mathrm{div}}(K) = \mathcal{P}_0(K) + \mathrm{span}\left\{\frac{\partial b_K}{\partial x}, \frac{\partial b_K}{\partial y}, \frac{\partial b_K}{\partial z}\right\}, \quad S_\Gamma(K) = \mathcal{P}_1(K),$$

$$S_{\mathbf{curl}}(K) = (\mathcal{P}_0(K))^3 + \mathrm{span}\left\{\left(c_3\frac{\partial b_K}{\partial y} - c_2\frac{\partial b_K}{\partial z}, c_1\frac{\partial b_K}{\partial z} - c_3\frac{\partial b_K}{\partial x}, c_2\frac{\partial b_K}{\partial x} - c_1\frac{\partial b_K}{\partial y}\right)^t \right.$$
$$\left. \forall (c_1, c_2, c_3) \in \mathbb{R}^3\right\}.$$

Note that, in general, $S_{\mathrm{div}}(K), S_\Gamma(K)$, and $S_{\mathbf{curl}}(K)$ are not spaces of polynomials. However, if ε is piecewise smooth, we may replace ε by its suitable piecewise polynomial approximation, say, ε_h. With this ε_h, then $S_{\mathrm{div}}(K), S_\Gamma(K)$, and $S_{\mathbf{curl}}(K)$ are of course chosen as piecewise polynomials. See also Remarks 5.4 and 5.5.

We are now in a position to define the mesh-dependent bilinear and linear forms:

$$S_{h,\mathrm{div}}(\mathbf{u},\mathbf{v}) := \sum_{K\in\mathcal{C}_h} \frac{\sum_{l=1}^{m_{\mathrm{div}}} (\varepsilon\,\mathbf{u}, \bigtriangledown\,(v_{K,l}\,b_K))_{0,K}\,(\varepsilon\,\mathbf{v}, \bigtriangledown\,(v_{K,l}\,b_K))_{0,K}}{\sum_{l=1}^{m_{\mathrm{div}}} ||\bigtriangledown\,(v_{K,l}\,b_K)||_{0,K}^2}, \tag{3.33}$$

$$Z_{h,\mathrm{div}}(f;\mathbf{v}) := -\sum_{K\in\mathcal{C}_h} \frac{\sum_{l=1}^{m_{\mathrm{div}}} (f, v_{K,l}\,b_K)_{0,K}\,(\varepsilon\,\mathbf{v}, \bigtriangledown\,(v_{K,l}\,b_K))_{0,K}}{\sum_{l=1}^{m_{\mathrm{div}}} ||\bigtriangledown\,(v_{K,l}\,b_K)||_{0,K}^2}, \tag{3.34}$$

$$S_{h,\mathbf{curl}}(\mathbf{u};\mathbf{v}) := \sum_{K\in\mathcal{C}_h} \frac{\sum_{l=1}^{m_{\mathbf{curl}}} (\mathbf{u}, \mathbf{curl}\,(\mathbf{w}_{K,l}\,b_K))_{0,K}\,(\mathbf{v}, \mathbf{curl}\,(\mathbf{w}_{K,l}\,b_K))_{0,K}}{\sum_{l=1}^{m_{\mathbf{curl}}} \|\mathbf{curl}\,(\mathbf{w}_{K,l}\,b_K)\|_{0,K}^2}, \tag{3.35}$$

$$Z_{h,\mathbf{curl}}(\mathbf{g};\mathbf{v}) := \sum_{K\in\mathcal{C}_h} \frac{\sum_{l=1}^{m_{\mathbf{curl}}} (\mathbf{g}, \mathbf{w}_{K,l}\,b_K)_{0,K}\,(\mathbf{v}, \mathbf{curl}\,(\mathbf{w}_{K,l}\,b_K))_{0,K}}{\sum_{l=1}^{m_{\mathbf{curl}}} ||\mathbf{curl}\,(\mathbf{w}_{K,l}\,b_K)||_{0,K}^2}, \tag{3.36}$$

$$S_{h,\Gamma}(\mathbf{u},\mathbf{v}) := \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} (\varepsilon\,\mathbf{u}, \bigtriangledown\,(z_{K,l}\,b_F))_{0,K}\,(\varepsilon\,\mathbf{v}, \bigtriangledown\,(z_{K,l}\,b_F))_{0,K}}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2}, \tag{3.37}$$

$$Z_{h,\Gamma}(f;\mathbf{v}) := -\sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} (f, z_{K,l}\,b_F)_{0,K}\,(\varepsilon\,\mathbf{v}, \bigtriangledown\,(z_{K,l}\,b_F))_{0,K}}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2}, \tag{3.38}$$

$$S_{\mathrm{flux},\Sigma}(\mathbf{u},\mathbf{v}) := \sum_{j=1}^{N} \frac{1}{|\Sigma_j|}\int_{\Sigma_j} (\varepsilon\,\mathbf{u})\cdot\mathbf{n} \int_{\Sigma_j} (\varepsilon\,\mathbf{v})\cdot\mathbf{n}. \tag{3.39}$$

Remark 3.3. Note that $b_K \in H_0^1(K)$ is the element bubble defined as in (3.2) and that $b_F \in H_0^1(F)$ is the face bubble defined as in (3.1); we have $v_{K,l}\,b_K \in H_0^1(K)$, $\mathbf{w}_{K,l}\,b_K \in (H_0^1(K))^3$ and $z_{K,l}\,b_F \in H_0^1(F)$, $z_{K,l}\,b_F|_{F'} = 0$ for $F'(\neq F) \subset \partial\,K$, so all the denominators above are not zero on any tetrahedron.

4. Coercivity and condition number. In this section we shall investigate the coercivity property and the condition number associated with the finite element problem described in the previous section.

4.1. Mesh-dependent norm. In this subsection we give some properties of the mesh-dependent bilinear forms in Propositions 4.1 and 4.2 below.

PROPOSITION 4.1. *We have*

$$|S_{h,\mathrm{div}}(\mathbf{u},\mathbf{v})| \le ||\varepsilon\,\mathbf{u}||_0\,||\varepsilon\,\mathbf{v}||_0,$$

$$|S_{h,\mathbf{curl}}(\mathbf{u},\mathbf{v})| \le ||\mathbf{u}||_0\,||\mathbf{v}||_0,$$

$$|S_{h,\Gamma}(\mathbf{u},\mathbf{v})| \le ||\varepsilon\,\mathbf{u}||_0\,||\varepsilon\,\mathbf{v}||_0,$$

$$0 \le S_{h,\mathrm{div}}(\mathbf{v},\mathbf{v}) \le C \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2,$$

$$0 \le S_{h,\mathbf{curl}}(\mathbf{v},\mathbf{v}) \le C \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathbf{curl}\,\mathbf{v}||_{0,K}^2,$$

$$0 \le S_{h,\Gamma}(\mathbf{v},\mathbf{v}) \le C \left(\sum_{K\in\mathcal{C}_h} h_K^2\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2 + \sum_{F\subset\Gamma} h_F \int_F |(\varepsilon\,\mathbf{v})\cdot\mathbf{n}|^2 \right).$$

Here h_F stands for the diameter of F.

Proof. The first three inequalities and the left-hand sides of the last three inequalities easily follow from the definitions given as in (3.33), (3.35), and (3.37). Here we show only the right-hand side of the last inequality as an example. Using Green's formula of integrating by parts, we have

$$\begin{aligned}
S_{h,\Gamma}(\mathbf{v},\mathbf{v}) &= \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left((\varepsilon\,\mathbf{v}, \bigtriangledown\,(z_{K,l}\,b_F))_{0,K}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2} \\
&= \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left(-(\mathrm{div}\,(\varepsilon\,\mathbf{v}), z_{K,l}\,b_F)_{0,K} + ((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{K,l}\,b_F)_{0,F}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2} \\
&\le C \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left(((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{K,l}\,b_F)_{0,F}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2} \\
&\quad + C \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left((\mathrm{div}\,(\varepsilon\,\mathbf{v}), z_{K,l}\,b_F)_{0,K}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2},
\end{aligned}$$

where, by a standard scaling argument [13, 8],

$$\begin{aligned}
\sum_{l=1}^{m_\Gamma} \left((\mathrm{div}\,(\varepsilon\,\mathbf{v}), z_{K,l}\,b_F)_{0,K}\right)^2 &\le ||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2 \sum_{l=1}^{m_\Gamma} ||z_{K,l}\,b_F||_{0,K}^2 \\
&\le C\,h_K^3\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2,
\end{aligned}$$

$$\sum_{l=1}^{m_\Gamma} \left(((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{K,l}\,b_F)_{0,F}\right)^2 \leq ||(\varepsilon\,\mathbf{v})\cdot\mathbf{n}||_{0,F}^2 \sum_{l=1}^{m_\Gamma} ||z_{K,l}\,b_F||_{0,F}^2$$

$$\leq C\,h_F^2\,||(\varepsilon\,\mathbf{v})\cdot\mathbf{n}||_{0,F}^2,$$

$$\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2 \geq C\,h_K,$$

where the last three constants C depend on the L^2 or H^1 norms of given functions $\hat{z}_l\,\hat{b}_{\hat{F}}$ on the reference element $\hat{K}$, $1 \leq l \leq m_\Gamma$, with $\hat{b}_{\hat{F}} = b_F \circ (\mathcal{F}_K|_F)$, but they are independent of h and K. It follows that the right-hand side of the last inequality in Proposition 4.1 holds. ∎

We define

$$||\mathbf{v}||_{\mathcal{C}_h}^2 := \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2 + \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathbf{curl}\,\mathbf{v}||_{0,K}^2 + \sum_{F\subset\Gamma} h_F \int_F |(\varepsilon\,\mathbf{v})\cdot\mathbf{n}|^2. \tag{4.1}$$

Hypothesis H1. We assume that, for any $\mathbf{u} \in U_h$, the following *local* inclusions hold:

$$\mathrm{div}\,((\varepsilon\,\mathbf{u})|_K) \in S_{\mathrm{div}}(K) = \mathrm{span}\{v_{K,l}; 1 \leq l \leq m_{\mathrm{div}}\} \quad \forall K \in \mathcal{C}_h, \tag{4.2}$$

$$(\varepsilon\,\mathbf{u})\cdot\mathbf{n}|_F \in S_\Gamma(K)|_F = \mathrm{span}\{z_{F,l} = z_{K,l}|_F; 1 \leq l \leq m_\Gamma\} \quad \forall F \subset \Gamma, \tag{4.3}$$

$$\mathbf{curl}\,(\mathbf{u}|_K) \in S_{\mathbf{curl}}(K) = \mathrm{span}\{\mathbf{w}_{K,l}; 1 \leq l \leq m_{\mathbf{curl}}\} \quad \forall K \in \mathcal{C}_h. \tag{4.4}$$

We additionally assume that $v_{K,l}$, $1 \leq l \leq m_{\mathrm{div}}$, constitutes a group of linearly independent basis and assume the same for $z_{F,l}, 1 \leq l \leq m_\Gamma$, and $\mathbf{w}_{K,l}, 1 \leq l \leq m_{\mathbf{curl}}$.

Remark 4.1. Considering the example in Remark 3.2, we see that Hypothesis H1 holds.

Proposition 4.2. *Assume Hypothesis* H1 holds. *We have on* U_h

$$S_{h,\mathrm{div}}(\mathbf{v},\mathbf{v}) \geq C \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2, \tag{4.5}$$

$$S_{h,\mathbf{curl}}(\mathbf{v},\mathbf{v}) \geq C \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathbf{curl}\,\mathbf{v}||_{0,K}^2, \tag{4.6}$$

$$S_{h,\Gamma}(\mathbf{v},\mathbf{v}) \geq C_1 \sum_{F\subset\Gamma} h_F \int_F |(\varepsilon\,\mathbf{v})\cdot\mathbf{n}|^2 - C_2 \sum_{K\in\mathcal{C}_h} h_K^2\,||\mathrm{div}\,(\varepsilon\,\mathbf{v})||_{0,K}^2. \tag{4.7}$$

Consequently, we have

$$S_{h,\mathrm{div}}(\mathbf{v},\mathbf{v}) + S_{h,\mathbf{curl}}(\mathbf{v},\mathbf{v}) + S_{h,\Gamma}(\mathbf{v},\mathbf{v}) \geq C\,||\mathbf{v}||_{\mathcal{C}_h}^2 \quad \forall \mathbf{v} \in U_h. \tag{4.8}$$

Proof. We first show (4.5). From (4.2) we write $\operatorname{div}(\varepsilon\,\mathbf{v})|_K = \sum_{l=1}^{m_{\rm div}} c_l\, v_{K,l}$. We have

$$\sum_{l=1}^{m_{\rm div}} \left((\varepsilon\,\mathbf{v}, \bigtriangledown(v_{K,l}\, b_K))_{0,K}\right)^2 = \sum_{l=1}^{m_{\rm div}} \left((\operatorname{div}(\varepsilon\,\mathbf{v}), v_{K,l}\, b_K)_{0,K}\right)^2$$

$$= \sum_{l=1}^{m_{\rm div}} (\mathbf{c}^t\, \mathbf{d}_l)^2 = \mathbf{c}^t\, A_K^2\, \mathbf{c},$$

where $\mathbf{c} = (c_1, \ldots, c_{m_{\rm div}})^t \in \mathbb{R}^{m_{\rm div}}$, $\mathbf{d}_l = (d_{1l}, \ldots, d_{m_{\rm div}l})^t \in \mathbb{R}^{m_{\rm div}}$, with $d_{il} = (v_{K,i}, v_{K,l}\, b_K)_{0,K}$, $i = 1, \ldots, m_{\rm div}$, and A_K is the mass matrix and $A_K = [\mathbf{d}_1, \ldots, \mathbf{d}_{m_{\rm div}}] \in \mathbb{R}^{m_{\rm div}\times m_{\rm div}}$. Clearly, A_K is symmetric and positive definite. Let $T \in \mathbb{R}^{m_{\rm div}\times m_{\rm div}}$ be the orthogonal matrix such that $A_K = T^t \operatorname{diag}(\lambda_1, \ldots, \lambda_{m_{\rm div}})\, T$, where $0 < \lambda_1 < \cdots < \lambda_{m_{\rm div}}$ are the eigenvalues of A_K. It can be easily seen that $\lambda_1 \geq C\,|K|$. Let $\bar{\mathbf{c}} := T\,\mathbf{c} = (\bar{c}_1, \ldots, \bar{c}_{m_{\rm div}})^t \in \mathbb{R}^{m_{\rm div}}$; we have $\sum_{l=1}^{m_{\rm div}} \left((\varepsilon\,\mathbf{v}, \bigtriangledown(v_{K,l}\, b_K))_{0,K}\right)^2 = \sum_{l=1}^{m_{\rm div}} (\bar{c}_l\, \lambda_l)^2$. By a similar argument we have $(\operatorname{div}(\varepsilon\,\mathbf{v}), \operatorname{div}(\varepsilon\,\mathbf{v})\, b_K)_{0,K} = \sum_{l=1}^{m_{\rm div}} (\bar{c}_l)^2\, \lambda_l$. We then obtain

$$\sum_{l=1}^{m_{\rm div}} \left((\varepsilon\,\mathbf{v}, \bigtriangledown(v_{K,l}\, b_K))_{0,K}\right)^2 = \sum_{l=1}^{m_{\rm div}} (\bar{c}_l\, \lambda_l)^2 \geq \lambda_1 \sum_{l=1}^{m_{\rm div}} (\bar{c}_l)^2\, \lambda_l$$

$$= \lambda_1\, (\operatorname{div}(\varepsilon\,\mathbf{v}), \operatorname{div}(\varepsilon\,\mathbf{v})\, b_K)_{0,K} \geq C\,|K|\, (\operatorname{div}(\varepsilon\,\mathbf{v}), \operatorname{div}(\varepsilon\,\mathbf{v}))_{0,K}.$$

Here we used the equivalence $C^{-1} \int_K |g| \leq \int_K |g|\, b_K \leq C \int_K |g|$ for any function g in deriving the last inequality. Noting that $\sum_{l=1}^{m_{\rm div}} ||\bigtriangledown\,(v_{K,l}\, b_K)||_{0,K}^2 \leq C\, h_K$ (where C depends on the H^1 norms of $\hat{v}_l\, \hat{b}$, with $\hat{b} = b_K \circ \mathcal{F}_K$ and $1 \leq l \leq m_{\rm div}$, but it is independent of h and K), over $\mathcal{C}_h$ we take the sum of $\frac{\sum_{l=1}^{m_{\rm div}} \left((\varepsilon\,\mathbf{v}, \bigtriangledown(v_{K,l}\, b_K))_{0,K}\right)^2}{\sum_{l=1}^{m_{\rm div}} ||\bigtriangledown\,(v_{K,l}\, b_K)||_{0,K}^2} \geq C\, h_K^2\, ||\operatorname{div}(\varepsilon\,\mathbf{v})||_{0,K}^2$ to get (4.5), with $S_{h,{\rm div}}(\cdot,\cdot)$ defined by (3.33).

The inequality (4.6) can be similarly established from the local inclusion condition (4.4). We next show (4.7). From the definition of $S_{h,\Gamma}(\cdot,\cdot)$ as in (3.37), using Green's formula of integrating by parts, we have

$$S_{h,\Gamma}(\mathbf{v},\mathbf{v}) = \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial\, K}} \frac{\sum_{l=1}^{m_\Gamma} \left((\varepsilon\,\mathbf{v}, \bigtriangledown(z_{K,l}\, b_F))_{0,K}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2}$$

$$= \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left(-(\operatorname{div}(\varepsilon\,\mathbf{v}), z_{K,l}\, b_F)_{0,K} + ((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{K,l}\, b_F)_{0,F}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2}$$

$$\geq C_3 \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left(((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{K,l}\, b_F)_{0,F}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2}$$

$$- C_4 \sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left((\operatorname{div}(\varepsilon\,\mathbf{v}), z_{K,l}\, b_F)_{0,K}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2},$$

where, using a similar argument for proving (4.5), we have from the local inclusion condition (4.3)

$$\sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left(((\varepsilon\,\mathbf{v})\cdot\mathbf{n}, z_{F,l}\, b_F)_{0,F}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2} \geq C \sum_{F\subset\Gamma} h_F\, ||(\varepsilon\,\mathbf{v})\cdot\mathbf{n}||_{0,F}^2,$$

and from Proposition 4.1 we have

$$\sum_{\substack{F\subset\Gamma \\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} \left((\operatorname{div}(\varepsilon\,\mathbf{v}), z_{K,l}\, b_F)_{0,K}\right)^2}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\, b_F)||_{0,K}^2} \le C \sum_{K\in\mathcal{C}_h} h_K^2\, ||\operatorname{div}(\varepsilon\,\mathbf{v})||_{0,K}^2.$$

The estimate (4.7) thus follows. ∎

Remark 4.2. Propositions 4.1 and 4.2 imply that, instead of using $S_{h,\mathrm{div}}(\mathbf{u},\mathbf{v})$, $S_{h,\mathbf{curl}}(\mathbf{u},\mathbf{v})$, and $S_{h,\Gamma}(\mathbf{u},\mathbf{v})$, one may equivalently use $(\mathbf{u},\mathbf{v})_{\mathcal{C}_h}$ which corresponds to the mesh-dependent norm (4.1). However, when deriving the error estimates of C^0 finite elements, one can bound only $||\mathbf{curl}\,\tilde{\mathbf{u}}||_0$ by $||\mathbf{u}||_1$; here $\tilde{\mathbf{u}}$ is the C^0 finite element interpolant of $\mathbf{u}$, but $\mathbf{u}$ is not generally in H^1 in the case of nonsmooth domains. The use of $S_{h,\mathrm{div}}(\mathbf{u},\mathbf{v})$, $S_{h,\mathbf{curl}}(\mathbf{u},\mathbf{v})$, and $S_{h,\Gamma}(\mathbf{u},\mathbf{v})$ allows the solution to be in H^s with $0\le s<1$. This can easily be seen from the first three inequalities in Proposition 4.1.

LEMMA 4.1. *Under the same hypotheses as in Proposition* 4.2, *for the local* L^2 *projection method we have*

$$S_h(\mathbf{v},\mathbf{v}) \ge C\,\left\{||R_h^\Gamma((\varepsilon\,\mathbf{v})\cdot\mathbf{n})||_{0,\Gamma}^2 + S_{\mathrm{flux},\Sigma}(\mathbf{v},\mathbf{v}) + ||\mathbf{v}||_{\mathcal{C}_h}^2\right\} \quad \forall \mathbf{v}\in U_h.$$

We can have a similar estimate for the pseudolocal L^2 *projection method.*

4.2. Coercivity. This subsection is devoted to the coercivity property of $\mathcal{L}_h$.

Hypothesis H2. We assume that for any $\psi\in H_\Gamma(\mathbf{curl};\Omega)\cap H_{\mathrm{flux},\Sigma}(\mathrm{div}^0;\Omega)$, it can be written as a regular-singular decomposition,

$$\psi=\psi^0+\psi^1, \qquad \psi^0\in H_\Gamma(\mathbf{curl};\Omega)\cap(H^1(\Omega))^3, \quad \mathbf{curl}\,\psi^1=\mathbf{0},$$

where ψ^0 is the regular part and ψ^1 the singular part, with

$$||\psi^0||_1 \le C\,\{||\psi||_0 + ||\mathbf{curl}\,\psi||_0\}.$$

Remark 4.3. From [5] any $\psi\in H_\Gamma(\mathbf{curl};\Omega)\cap H(\mathrm{div};\Omega)$ can be written as the following "regular-singular" decomposition:

$$\psi=\psi^*+\bigtriangledown\, p, \quad p\in H_0^1(\Omega),$$

with $\psi^*\in H_\Gamma(\mathbf{curl};\Omega)\cap(H^1(\Omega))^3$ and

$$||\psi^*||_1 \le C\,\{||\psi||_0 + ||\mathbf{curl}\,\psi||_0 + ||\mathrm{div}\,\psi||_0\}.$$

We may take $\psi^0:=\psi^*$ and $\psi^1:=\bigtriangledown\, p$, and then verify Hypothesis H2.

THEOREM 4.1. *Let Hypotheses* H1 *and* H2 *hold. We have*

$$\mathcal{L}_h(\mathbf{u},\mathbf{u}) \ge C\,||\mathbf{u}||_0^2 \quad \forall \mathbf{u}\in U_h. \tag{4.9}$$

Therefore, the finite element problem has a unique solution.

Proof. We consider only the local L^2 projection method. The following argument can easily be applied to the pseudolocal L^2 projection method, with minor modifications.

We first show

$$\begin{cases} ||\breve{R}_h(\operatorname{div}(\varepsilon\,\mathbf{u}))||_0^2 + ||R_h(\mathbf{curl}\,\mathbf{u})||_0^2 \\ \ge C_5\,||\mathbf{u}||_0^2 - C_6\,(||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}^2 + S_{\mathrm{flux},\Sigma}(\mathbf{u},\mathbf{u}) + ||\mathbf{u}||_{\mathcal{C}_h}^2), \end{cases} \tag{4.10}$$

and then use Lemma 4.1 to obtain (4.9).

To show (4.10), we need to use the L^2 orthogonal decomposition of $\mathbf{u}$. From Proposition 2.2 we write $\mathbf{u}$ as

$$\mathbf{u} = \bigtriangledown p + \Pi + \varepsilon^{-1}\,\mathbf{curl}\,\psi, \tag{4.11}$$

with $p \in H^1(\Omega)/\mathbb{R}$, $\Pi \in \mathbb{H}$, $\psi \in H_\Gamma(\mathbf{curl};\Omega) \cap H_{\text{flux},\Sigma}(\text{div}^0;\Omega)$, and

$$||\psi||_0 \le C\,||\mathbf{curl}\,\psi||_0, \quad ||\varepsilon^{\frac{1}{2}}\,\mathbf{u}||_0^2 = ||\varepsilon^{\frac{1}{2}}\bigtriangledown p||_0^2 + ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2 + ||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2. \tag{4.12}$$

From Hypothesis H2 we further write ψ as

$$\psi = \psi^0 + \psi^1, \tag{4.13}$$

where

$$\psi^0 \in H_\Gamma(\mathbf{curl};\Omega) \cap (H^1(\Omega))^3, \quad \mathbf{curl}\,\psi^1 = \mathbf{0}, \tag{4.14}$$

$$||\psi^0||_1 \le C\,\{||\psi||_0 + ||\mathbf{curl}\,\psi||_0\} \le C\,||\mathbf{curl}\,\psi||_0. \tag{4.15}$$

In what follows we divide the proof of (4.10) into three steps according to the three components (p, Π, ψ) from the decomposition (4.11).

Step 1. We consider Π.

From Proposition 2.1, let $q \in H^1\big(\overset{\circ}{\Omega}\big)$ such that $\bigtriangledown q = \Pi$ in $\overset{\circ}{\Omega}$ and $||q||_{H^1(\overset{\circ}{\Omega})} \le C\,||\Pi||_0$. Let $\tilde{q}$ and $\bar{q}$ be piecewise constants such that [18, 19, 20]

$$\tilde{q}|_K = \frac{1}{|K|}\int_K q, \quad ||\tilde{q}||_{0,K} \le ||q||_{0,K} \quad \forall K \in \mathcal{C}_h, \tag{4.16}$$

$$\left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,||\tilde{q}-q||_{0,K}^2\right)^{1/2} \le C\,||q||_{H^1\left(\overset{\circ}{\Omega}\right)}, \tag{4.17}$$

and

$$\bar{q}|_F = \frac{1}{|F|}\int_F q, \quad ||\bar{q}||_{0,F} \le ||q||_{0,F} \quad \forall F \subset \Gamma, \tag{4.18}$$

$$\left(\sum_{F\subset\Gamma} h_F^{-1}\,||\bar{q}-q||_{0,F}^2\right)^{1/2} \le C\,||q||_{H^1\left(\overset{\circ}{\Omega}\right)}. \tag{4.19}$$

Let $\epsilon_1 > 0$ be a constant to be determined. We have

$$||\breve{R}_h(\mathrm{div}(\varepsilon\mathbf{u}))||_0^2 = ||\breve{R}_h(\mathrm{div}(\varepsilon\mathbf{u})) + \epsilon_1\tilde{q}||_0^2 - \epsilon_1^2||\tilde{q}||_0^2 - 2\epsilon_1\,(\breve{R}_h(\mathrm{div}(\varepsilon\,\mathbf{u})),\tilde{q}), \tag{4.20}$$

$$||\tilde{q}||_0 \le C\,||q||_{L^2\left(\overset{\circ}{\Omega}\right)} \le C\,||q||_{H^1\left(\overset{\circ}{\Omega}\right)} \le C\,||\Pi||_0 \le C\,||\varepsilon^{\frac{1}{2}}\,\Pi||_0, \tag{4.21}$$

$$\begin{aligned} -2\,\epsilon_1\,(\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{u})),\tilde{q}) &= -2\,\epsilon_1\,\textstyle\sum_{K\in\mathcal{C}_h}(\mathrm{div}\,(\varepsilon\,\mathbf{u}),\tilde{q})_{0,K} \\ &= 2\,\epsilon_1\,\textstyle\sum_{K\in\mathcal{C}_h}(\mathrm{div}\,(\varepsilon\,\mathbf{u}),q-\tilde{q})_{0,K} \\ &\quad -2\,\epsilon_1\,\textstyle\sum_{K\in\mathcal{C}_h}(\mathrm{div}\,(\varepsilon\,\mathbf{u}),q)_{0,K}, \end{aligned} \tag{4.22}$$

$$\begin{aligned} -2\,\epsilon_1\,\textstyle\sum_{K\in\mathcal{C}_h}(\mathrm{div}\,(\varepsilon\,\mathbf{u}),q)_{0,K} &= 2\,\epsilon_1\,\textstyle\sum_{K\in\mathcal{C}_h}(\varepsilon\,\mathbf{u},\bigtriangledown q)_{0,K} \\ &\quad -2\,\epsilon_1\,\textstyle\sum_{F\subset\Gamma}\int_F(\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,q \\ &\quad -2\,\epsilon_1\,\textstyle\sum_{j=1}^{N}\int_{\Sigma_j}(\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,[q], \end{aligned} \tag{4.23}$$

$$2\,\epsilon_1\sum_{K\in\mathcal{C}_h}(\varepsilon\,\mathbf{u},\bigtriangledown q)_{0,K} = 2\,\epsilon_1\,(\varepsilon\,\mathbf{u},\Pi) = 2\,\epsilon_1\,(\varepsilon\,\Pi,\Pi) = 2\,\epsilon_1\,||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2, \tag{4.24}$$

$$-2\,\epsilon_1\sum_{F\subset\Gamma}\int_F(\varepsilon\,\mathbf{u})\cdot\mathbf{n}q = 2\epsilon_1\sum_{F\subset\Gamma}\int_F(\varepsilon\,\mathbf{u})\cdot\mathbf{n}(\bar{q}-q) - 2\epsilon_1\sum_{F\subset\Gamma}\int_F(\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,\bar{q}, \tag{4.25}$$

and

$$\begin{aligned} -2\,\epsilon_1\sum_{F\subset\Gamma}\int_F(\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,\bar{q} &= -2\,\epsilon_1\int_\Gamma R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})\,\bar{q} \\ &\ge -\epsilon_1\,C\,||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}\,||\bar{q}||_{0,\Gamma} \\ &\ge -\epsilon_1\,C\,||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}\,||q||_{0,\Gamma} \\ &\ge -\epsilon_1\,C\,||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}\,||q||_{H^1\left(\overset{\circ}{\Omega}\right)} \\ &\ge -\epsilon_2\,||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}^2 - \frac{C\,\epsilon_1^2}{\epsilon_2}\,||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2. \end{aligned} \tag{4.26}$$

Here we have used $||q||_{H^1(\overset{\circ}{\Omega})} \le C\,||\Pi||_0 \le C\,||\varepsilon^{\frac{1}{2}}\,\Pi||_0$ and the trace theorem,

$$||q||_{0,\Gamma} \le C\,||q||_{L^2\left(\partial\,\overset{\circ}{\Omega}\right)} \le C\,||q||_{H^1\left(\overset{\circ}{\Omega}\right)},$$

and Young's inequality,

$$|a|\,|b| \le \epsilon\,|a|^2 + \frac{1}{4\,\epsilon}\,|b|^2 \quad \forall a,b\in\mathbb{R},\forall\epsilon>0,$$

with $\epsilon = \epsilon_2$ a constant to be determined.

We also have

$$
\begin{aligned}
(4.27)\qquad & 2\,\epsilon_1 \sum_{K\in\mathcal{C}_h} (\operatorname{div}(\varepsilon\,\mathbf{u}), q-\tilde{q})_{0,K} + 2\,\epsilon_1 \sum_{F\subset\Gamma} \int_F (\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,(\bar{q}-q) \\
& \geq -\epsilon_1\, C \left(\sum_{K\in\mathcal{C}_h} h_K^2\, ||\operatorname{div}(\varepsilon\,\mathbf{u})||_{0,K}^2 + \sum_{F\subset\Gamma} h_F\, ||(\varepsilon\,\mathbf{u})\cdot\mathbf{n}||_{0,F}^2 \right)^{\frac{1}{2}} \\
& \quad \times \left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\, ||q-\tilde{q}||_{0,K}^2 + \sum_{F\subset\Gamma} h_F^{-1}\, ||\bar{q}-q||_{0,F}^2 \right)^{\frac{1}{2}} \\
& \geq -\epsilon_1\, C\, ||\mathbf{u}||_{\mathcal{C}_h}\, ||q||_{H^1\left(\overset{\circ}{\Omega}\right)} \geq -\epsilon_1\, C\, ||\mathbf{u}||_{\mathcal{C}_h}\, ||\varepsilon^{\frac{1}{2}}\,\Pi||_0 \\
& \geq -\epsilon_2\, ||\mathbf{u}||_{\mathcal{C}_h}^2 - \frac{C\,\epsilon_1^2}{\epsilon_2}\, ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2
\end{aligned}
$$

and

$$
\begin{aligned}
(4.28)\quad -2\,\epsilon_1 \sum_{j=1}^{N} \int_{\Sigma_j} (\varepsilon\,\mathbf{u})\cdot\mathbf{n}\,[q] & \geq -2\,\epsilon_1 \sum_{j=1}^{N} |\Sigma_j|^{-1/2} \left| \int_{\Sigma_j} (\varepsilon\,\mathbf{u})\cdot\mathbf{n} \right| |\Sigma_j|^{1/2}\, |[q]| \\
& \geq -2\,\epsilon_1 \left(\sum_{j=1}^{N} \frac{1}{|\Sigma_j|} \left(\int_{\Sigma_j} (\varepsilon\,\mathbf{u})\cdot\mathbf{n} \right)^2 \right)^{1/2} \\
& \quad \times \left(\sum_{j=1}^{N} \int_{\Sigma_j} |[q]|^2 \right)^{1/2} \\
& = -2\,\epsilon_1\, \left(S_{\text{flux},\Sigma}(\mathbf{u},\mathbf{u})\right)^{1/2} \left(\sum_{j=1}^{N} \int_{\Sigma_j} |[q]|^2 \right)^{1/2} \\
& \geq -2\,\epsilon_1\, C\, \left(S_{\text{flux},\Sigma}(\mathbf{u},\mathbf{u})\right)^{1/2}\, ||q||_{L^2\left(\partial\,\overset{\circ}{\Omega}\right)} \\
& \geq -2\,\epsilon_1\, C\, \left(S_{\text{flux},\Sigma}(\mathbf{u},\mathbf{u})\right)^{1/2}\, ||q||_{H^1\left(\overset{\circ}{\Omega}\right)} \\
& \geq -\epsilon_2\, S_{\text{flux},\Sigma}(\mathbf{u},\mathbf{u}) - \frac{C\,\epsilon_1^2}{\epsilon_2}\, ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2.
\end{aligned}
$$

Equations (4.20)–(4.28) yield

$$
\begin{aligned}
(4.29)\quad ||\breve{R}_h(\operatorname{div}(\varepsilon\,\mathbf{u}))||_0^2 & \geq \epsilon_1 \left(2 - C\,\epsilon_1 - \frac{C\,\epsilon_1}{\epsilon_2} \right) ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2 \\
& \quad - \epsilon_2 \left(||R_h^{\Gamma}((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}^2 + S_{\text{flux},\Sigma}(\mathbf{u},\mathbf{u}) + ||\mathbf{u}||_{\mathcal{C}_h}^2 \right).
\end{aligned}
$$

Step 2. We consider p.

By a similar argument as that used in proving (4.29) with Π replaced by $\bigtriangledown p$, we have

$$\begin{cases} ||\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{u}))||_0^2 & \geq \epsilon_1 \left(2 - C\,\epsilon_1 - \frac{C\,\epsilon_1}{\epsilon_2}\right) ||\varepsilon^{\frac{1}{2}} \bigtriangledown p||_0^2 \\ & \quad -\epsilon_2 \left(||R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}^2 + ||\mathbf{u}||_{\mathcal{C}_h}^2\right). \end{cases} \tag{4.30}$$

Step 3. We consider ψ.

Let $\tilde{\psi^0}$ be a piecewise constant vector such that

$$\tilde{\psi^0}|_K = \frac{1}{|K|}\int_K \psi^0, \quad ||\tilde{\psi^0}||_{0,K} \leq ||\psi^0||_{0,K} \quad \forall K \in \mathcal{C}_h, \tag{4.31}$$

$$\left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,||\psi^0 - \tilde{\psi^0}||_{0,K}^2\right)^{1/2} \leq C\,||\psi^0||_1. \tag{4.32}$$

We have

$$||R_h(\mathbf{curlu})||_0^2 = ||R_h(\mathbf{curlu}) - \epsilon_1\tilde{\psi^0}||_0^2 - \epsilon_1^2\,||\tilde{\psi^0}||_0^2 + 2\,\epsilon_1\,(R_h(\mathbf{curl}\,\mathbf{u}), \tilde{\psi^0}), \tag{4.33}$$

$$||\tilde{\psi^0}||_0 \leq ||\psi^0||_1 \leq C\,||\mathbf{curl}\,\psi||_0 \leq C\,||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0, \tag{4.34}$$

$$\begin{aligned} 2\,\epsilon_1\,(R_h(\mathbf{curl}\,\mathbf{u}), \tilde{\psi^0}) &= 2\,\epsilon_1 \textstyle\sum_{K\in\mathcal{C}_h} (\mathbf{curl}\,\mathbf{u}, \tilde{\psi^0})_{0,K} \\ &= 2\,\epsilon_1 \textstyle\sum_{K\in\mathcal{C}_h} (\mathbf{curl}\,\mathbf{u}, \tilde{\psi^0} - \psi^0)_{0,K} \\ &\quad + 2\,\epsilon_1 \textstyle\sum_{K\in\mathcal{C}_h} (\mathbf{curl}\,\mathbf{u}, \psi^0)_{0,K}, \end{aligned} \tag{4.35}$$

$$\begin{aligned} 2\,\epsilon_1 \textstyle\sum_{K\in\mathcal{C}_h} (\mathbf{curl}\,\mathbf{u}, \psi^0)_{0,K} &= 2\,\epsilon_1\,(\mathbf{u}, \mathbf{curl}\,\psi^0) = 2\,\epsilon_1\,(\mathbf{u}, \mathbf{curl}\,\psi) \\ &= 2\,\epsilon_1\,(\varepsilon^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi) \\ &= 2\,\epsilon_1\,||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2, \end{aligned} \tag{4.36}$$

and using Young's inequality,

$$\begin{aligned} 2\,\epsilon_1 \sum_{K\in\mathcal{C}_h} (\tilde{\psi^0} - \psi^0, \mathbf{curl}\,\mathbf{u}) &\geq -\epsilon_1\,C \left(\sum_{K\in\mathcal{C}_h} h_K^{-2}\,||\tilde{\psi^0} - \psi^0||_{0,K}^2\right)^{\frac{1}{2}} \\ &\quad \times \left(\sum_{K\in\mathcal{C}_h} h_K^2\,||\mathbf{curl}\,\mathbf{u}||_{0,K}^2\right)^{\frac{1}{2}} \\ &\geq -\epsilon_1\,C\,||\psi^0||_1\,||\mathbf{u}||_{\mathcal{C}_h} \\ &\geq -\epsilon_1\,C\,||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0\,||\mathbf{u}||_{\mathcal{C}_h} \\ &\geq -\epsilon_2\,||\mathbf{u}||_{\mathcal{C}_h}^2 - \frac{C\,\epsilon_1^2}{\epsilon_2}\,||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2. \end{aligned} \tag{4.37}$$

Summarizing (4.33)–(4.37), we have

$$||R_h(\mathbf{curl}\,\mathbf{u})||_0^2 \geq \epsilon_1 \left(2 - C\,\epsilon_1 - \frac{C\,\epsilon_1}{\epsilon_2}\right) ||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2 - \epsilon_2\,||\mathbf{u}||_{\mathcal{C}_h}^2. \tag{4.38}$$

Combining (4.29), (4.30), and (4.38), we obtain

$$2\,||\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{u}))||_0^2 + ||R_h(\mathbf{curl}\,\mathbf{u})||_0^2 \tag{4.39}$$

$$\geq \epsilon_1 \left(2 - C\,\epsilon_1 - \frac{C\,\epsilon_1}{\epsilon_2}\right) \times \left(||\varepsilon^{\frac{1}{2}} \bigtriangledown p||_0^2 + ||\varepsilon^{\frac{1}{2}}\,\Pi||_0^2 + ||\varepsilon^{-\frac{1}{2}}\,\mathbf{curl}\,\psi||_0^2\right)$$

$$-\epsilon_2\,C\,(||R_h^{\Gamma}((\varepsilon\,\mathbf{u})\cdot\mathbf{n})||_{0,\Gamma}^2 + S_{\mathrm{flux},\Sigma}(\mathbf{u},\mathbf{u}) + ||\mathbf{u}||_{\mathcal{C}_h}^2).$$

We therefore obtain (4.10), taking suitable values for ϵ_i, $i = 1, 2$. ∎

4.3. Condition number. We finally estimate the condition number of the resulting linear system. We here again consider only the local L^2 projection method.

THEOREM 4.2. *In addition to the same hypotheses as in Theorem* 4.1, *we assume uniform meshes. The condition number, associated with the resulting linear system, is* $\mathcal{O}(h^{-2})$.

Proof. Since, for all $\mathbf{v} \in U_h$,

$$(S_{h,\mathrm{div}}(\mathbf{v},\mathbf{v}))^{1/2} + (S_{h,\mathbf{curl}}(\mathbf{v},\mathbf{v}))^{1/2} + (S_{h,\Gamma}(\mathbf{v},\mathbf{v}))^{1/2} \leq C\,||\mathbf{v}||_0, \tag{4.40}$$

$$||R_h(\mathbf{curl}\,\mathbf{v})||_0 \leq ||\mathbf{curl}\,\mathbf{v}||_0 \leq C\,h^{-1}\,||\mathbf{v}||_0, \tag{4.41}$$

$$||\breve{R}_h(\mathrm{div}\,(\varepsilon\,\mathbf{v}))||_0 \leq C\,||\varepsilon||_\infty \left(\sum_{K\in\mathcal{C}_h} h_K^{-1}\,||\mathbf{v}||_{0,\partial\,K}^2\right)^{\frac{1}{2}} \leq C\,h^{-1}\,||\mathbf{v}||_0, \tag{4.42}$$

$$||R_h^{\Gamma}((\varepsilon\,\mathbf{v})\cdot\mathbf{n})||_{0,\Gamma} \leq \left(\sum_{F\subset\Gamma} ||(\varepsilon\,\mathbf{v})\cdot\mathbf{n}||_{0,F}^2\right)^{1/2} \leq C\,h^{-1}\,||\mathbf{v}||_0, \tag{4.43}$$

$$(S_{\mathrm{flux},\Sigma}(\mathbf{v},\mathbf{v}))^{1/2} \leq C\,h^{-1}\,||\mathbf{v}||_0, \tag{4.44}$$

we have

$$\mathcal{L}_h(\mathbf{v},\mathbf{v}) \leq C\,h^{-2}\,||\mathbf{v}||_0^2 \quad \forall \mathbf{v} \in U_h, \tag{4.45}$$

which, together with the coercivity property (4.9) and the symmetry property of $\mathcal{L}_h$, leads to the conclusion. ∎

5. Error bounds. In this section we shall establish the error bounds. We analyze only the local L^2 projection method. The analysis is similar for the pseudolocal L^2 projection method.

LEMMA 5.1. *Let* $\mathbf{u} \in U$ *and* $\mathbf{u}_h \in U_h$ *be the exact solution and the finite element solution to the local* L^2 *projection method. We have*

$$\mathcal{L}_h(\mathbf{u} - \mathbf{u}_h, \mathbf{v}_h) = 0 \quad \forall \mathbf{v}_h \in U_h. \tag{5.1}$$

Proof. Equation (5.1) holds, since

$$S_h(\mathbf{u},\mathbf{v}_h) = Z_h(f,\mathbf{g};\mathbf{v}_h), \tag{5.2}$$

$$(\breve{R}_h(\mathrm{div}(\varepsilon\mathbf{u})), \breve{R}_h(\mathrm{div}(\varepsilon\mathbf{v}_h))) = (\mathrm{div}(\varepsilon\,\mathbf{u}), \breve{R}_h(\mathrm{div}(\varepsilon\,\mathbf{v}_h))) = (f, \breve{R}_h(\mathrm{div}(\varepsilon\,\mathbf{v}_h))), \tag{5.3}$$

$$(R_h(\mathbf{curl}\,\mathbf{u}), R_h(\mathbf{curl}\,\mathbf{v}_h)) = (\mathbf{curl}\,\mathbf{u}, R_h(\mathbf{curl}\,\mathbf{v}_h)) = (\mathbf{g}, R_h(\mathbf{curl}\,\mathbf{v}_h)). \tag{5.4}$$

∎

LEMMA 5.2. *Assume that* $\mathbf{u} \in (H^s(\Omega))^3$ *with* $s > \frac{1}{2}$. *Then, there exists a* $\tilde{\mathbf{u}} \in U_h$ *such that*

$$||\breve{R}_h(\operatorname{div}(\varepsilon(\mathbf{u}-\tilde{\mathbf{u}})))||_0^2 = ||R_h(\mathbf{curl}(\mathbf{u}-\tilde{\mathbf{u}}))||_0^2 = 0, \tag{5.5}$$

$$||R_h^{\Gamma}((\varepsilon(\mathbf{u}-\tilde{\mathbf{u}}))\cdot\mathbf{n})||_{0,\Gamma}^2 = S_{\text{flux},\Sigma}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}}) = 0, \tag{5.6}$$

$$||\mathbf{u}-\tilde{\mathbf{u}}||_0 \le C\,h^s\,||\mathbf{u}||_s. \tag{5.7}$$

Proof. We first let $\mathbf{u}^0 \in (P_h)^3$ be such that [3, 14, 29]

$$||\mathbf{u}-\mathbf{u}^0||_0 + \left(\sum_{F\subset\mathcal{E}_h} h_F\,||\mathbf{u}-\mathbf{u}^0||_{0,F}^2\right)^{\frac{1}{2}} \le C\,h^s\,||\mathbf{u}||_s, \quad s>\frac{1}{2}. \tag{5.8}$$

We then define $\tilde{\mathbf{u}} \in U_h$ such that

$$\tilde{\mathbf{u}}(a) = \mathbf{u}^0(a) \qquad \text{for all vertices } a, \tag{5.9}$$

$$\int_F (\tilde{\mathbf{u}}-\mathbf{u})\cdot\mathbf{p} = \mathbf{0} \quad \forall \mathbf{p}\in\mathbf{P}(M_F), \forall F\in\mathcal{E}_h, \tag{5.10}$$

where $\mathbf{P}(M_F)$ is defined by (3.7). We write

$$\tilde{\mathbf{u}} = \mathbf{u}^0 + \sum_{F\in\mathcal{E}_h}\sum_{l=1}^{m_F} c_{F,l}\,\mathbf{p}_{F,l}\,b_{M_F}. \tag{5.11}$$

Noting that for any given $F\in\mathcal{E}_h$,

$$\sum_{F'\in\mathcal{E}_h, F'\neq F}\int_F \sum_{l=1}^{m_{F'}} c_{F',l}\,\mathbf{p}_{F',l}\,b_{M_{F'}} = 0, \tag{5.12}$$

from (5.10) we obtain

$$\sum_{l=1}^{m_F} c_{F,l}\int_F \mathbf{p}_{F,l}\cdot\mathbf{p}_{F,i}\,b_{M_F} = \int_F (\mathbf{u}-\mathbf{u}^0)\cdot\mathbf{p}_{F,i}, \quad 1\le i\le m_F\ \forall F\in\mathcal{E}_h, \tag{5.13}$$

which uniquely determines the coefficients $c_{F,l}$, $1\le l\le m_F$, $F\in\mathcal{E}_h$. Also, note that $\sum_{F\in\mathcal{E}_h}\sum_{l=1}^{m_F} c_{F,l}\,\mathbf{p}_{F,l}\,b_{M_F}$ is zero at all vertices, and (5.9) and (5.10) uniquely determine $\tilde{\mathbf{u}}$.

Let M be any given macroelement in $\mathcal{M}_h$ corresponding to a face $F\in\mathcal{E}_h$. We write M and F as M_{F_1} and F_1. We first consider the case $M_{F_1} = K_1\cup K_2$, with $K_1\cap K_2 = F_1\in\mathcal{E}_h^0$. For convenience we number all the faces in ∂M_{F_1} by F_i, one-to-one corresponding to M_{F_i}, $2\le i\le 7$. Denote $\mathbf{c}_i := (c_{F_i1},\dots,c_{F_im_{F_i}})^t \in \mathbb{R}^{m_{F_i}}$, and $\mathbf{L}_i := [\mathbf{p}_{F_i1},\dots,\mathbf{p}_{F_im_{F_i}}] \in \mathbb{R}^{m_{F_i}\times m_{F_i}}$; by a standard scaling argument we then have

from (5.12) and (5.13)

$$(5.14)\quad \int_{M_{F_1}} \left(\sum_{F\in\mathcal{E}_h} \sum_{l=1}^{m_F} c_{F,l}\, \mathbf{p}_{F,l}\, b_{M_F} \right)^2 = \int_{M_{F_1}} \left(\sum_{i=1}^{7} \sum_{l=1}^{m_{F_i}} c_{F_i,l}\, \mathbf{p}_{F_i,l}\, b_{M_{F_i}} \right)^2$$

$$= \int_{M_{F_1}} \left| \sum_{i=1}^{7} \mathbf{L}_i\, \mathbf{c}_i\, b_{M_{F_i}} \right|^2$$

$$\leq C \sum_{i=1}^{7} |\mathbf{c}_i|^2 \int_{M_{F_1}} \left(\sum_{i=1}^{7} \sum_{l=1}^{m_{F_i}} |\mathbf{p}_{F_i,l}\, b_{M_{F_i}}|^2 \right)$$

$$\leq C\, |M_{F_1}| \sum_{i=1}^{7} |\mathbf{c}_i|^2 \leq C \sum_{i=1}^{7} h_{F_i}\, ||\mathbf{u}-\mathbf{u}^0||^2_{0,F_i}.$$

We thus obtain

$$(5.15)\qquad ||\mathbf{u}-\tilde{\mathbf{u}}||_{0,M} \leq C\, ||\mathbf{u}-\mathbf{u}^0||_{0,M} + C \sum_{i=1}^{7} h_{F_i}^{\frac{1}{2}}\, ||\mathbf{u}-\mathbf{u}^0||_{0,F_i}.$$

Similarly, if M is the tetrahedron sharing an F with Γ, we have

$$(5.16)\qquad ||\mathbf{u}-\tilde{\mathbf{u}}||_{0,M} \leq C\, ||\mathbf{u}-\mathbf{u}^0||_{0,M} + C \sum_{F\subset\partial M} h_F^{\frac{1}{2}}\, ||\mathbf{u}-\mathbf{u}^0||_{0,F}.$$

Hence, from (5.15), (5.16), and (5.8), we obtain

$$(5.17)\qquad ||\mathbf{u}-\tilde{\mathbf{u}}||_0 \leq C\, ||\mathbf{u}-\mathbf{u}^0||_0 + C \left(\sum_{F\subset\mathcal{E}_h} h_F\, ||\mathbf{u}-\mathbf{u}^0||^2_{0,F} \right)^{\frac{1}{2}} \leq C\, h^s\, ||\mathbf{u}||_s.$$

Finally, noting that $\mathbf{n}$ is a constant vector and

$$(5.18)\qquad \mathcal{P}_0(M)\, \varepsilon\, \mathbf{n} \subset \mathbf{P}(M), \quad (\mathcal{P}_0(M))^3 \times \mathbf{n} \subset \mathbf{P}(M),$$

by virtue of (5.10) we can easily verify (5.5) and (5.6). □

THEOREM 5.1. *Assume that Hypotheses* H1 *and* H2 *hold and that* $\mathbf{u} \in (H^s(\Omega))^3$ *with* $s > \frac{1}{2}$. *Let* $\mathbf{u} \in U$ *and* $\mathbf{u}_h \in U_h$ *be the exact solution and the finite element solution to the local* L^2 *projection method. We have*

$$(5.19)\qquad ||\mathbf{u}-\mathbf{u}_h||_0 \leq C\, h^s\, ||\mathbf{u}||_s.$$

Proof. Let $\tilde{\mathbf{u}} \in U_h$ be constructed as in Lemma 5.2. We have from Lemma 5.1

$$(5.20)\qquad |||\mathbf{u}_h-\tilde{\mathbf{u}}|||^2 := \mathcal{L}_h(\mathbf{u}_h-\tilde{\mathbf{u}}, \mathbf{u}_h-\tilde{\mathbf{u}}) = \mathcal{L}_h(\mathbf{u}-\tilde{\mathbf{u}}, \mathbf{u}_h-\tilde{\mathbf{u}})$$

$$\leq |||\mathbf{u}-\tilde{\mathbf{u}}|||\, |||\mathbf{u}_h-\tilde{\mathbf{u}}|||;$$

that is,

$$(5.21)\qquad |||\mathbf{u}_h-\tilde{\mathbf{u}}||| \leq |||\mathbf{u}-\tilde{\mathbf{u}}|||.$$

On the other hand, from Lemma 5.2 and Proposition 4.1,

$$
\begin{aligned}
(5.22)\qquad |||\mathbf{u}-\tilde{\mathbf{u}}|||^2 &= \mathcal{L}_h(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&= ||\breve{R}_h(\operatorname{div}(\varepsilon(\mathbf{u}-\tilde{\mathbf{u}})))||_0^2 + ||R_h(\mathbf{curl}(\mathbf{u}-\tilde{\mathbf{u}}))||_0^2\\
&\quad + ||R_h^{\Gamma}((\varepsilon(\mathbf{u}-\tilde{\mathbf{u}}))\cdot\mathbf{n})||_{0,\Gamma}^2 + S_{h,\operatorname{div}}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&\quad + S_{h,\mathbf{curl}}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&\quad + S_{h,\Gamma}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}}) + S_{\text{flux},\Sigma}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&= S_{h,\operatorname{div}}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}}) + S_{h,\mathbf{curl}}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&\quad + S_{h,\Gamma}(\mathbf{u}-\tilde{\mathbf{u}},\mathbf{u}-\tilde{\mathbf{u}})\\
&\quad \le C\,||\mathbf{u}-\tilde{\mathbf{u}}||_0^2.
\end{aligned}
$$

Using the triangle inequality, Theorem 4.1, (5.21), (5.22), and Lemma 5.2, we obtain

$$
\begin{aligned}
(5.23)\qquad ||\mathbf{u}-\mathbf{u}_h||_0 &\le ||\mathbf{u}-\tilde{\mathbf{u}}||_0 + ||\mathbf{u}_h-\tilde{\mathbf{u}}||_0\\
&\le ||\mathbf{u}-\tilde{\mathbf{u}}||_0 + C\,|||\mathbf{u}_h-\tilde{\mathbf{u}}|||\\
&\le ||\mathbf{u}-\tilde{\mathbf{u}}||_0 + C\,|||\mathbf{u}-\tilde{\mathbf{u}}|||\\
&\le C\,||\mathbf{u}-\tilde{\mathbf{u}}||_0 \le C\,h^s\,||\mathbf{u}||_s. \qquad \square
\end{aligned}
$$

Remark 5.1. From [2] we know that, in the case of $\varepsilon = 1$, the solution of problem (2.1)–(2.3) is in $(H^s(\Omega))^3$ with $s > \frac{1}{2}$.

Remark 5.2. Regarding the pseudolocal L^2 projected method, following a similar argument in Lemma 5.2, we can find an interpolant $\tilde{\mathbf{u}} \in U_h$ of $\mathbf{u} \in (H^s(\Omega))^3$ with $s \ge 0$ such that $||\mathbf{u}-\tilde{\mathbf{u}}||_0 \le C\,h^s\,||\mathbf{u}||_s$, and $\tilde{\mathbf{u}}$ satisfies interpolation properties similar to (5.5) and (5.6). Let $\mathbf{u}$ and $\mathbf{u}_h$ be the exact solution and the finite element solution to the pseudolocal L^2 projection method. Following the same argument in Theorem 5.1, we can obtain

$$
(5.24)\qquad ||\mathbf{u}-\mathbf{u}_h||_0 \le C\,h^s\,||\mathbf{u}||_s \quad \forall s \ge 0.
$$

Remark 5.3. The pseudolocal L^2 projection method admits $\mathbf{u} \in (H^s(\Omega))^3$ for all $s \ge 0$. The local L^2 projection method requires a little more regularity of $\mathbf{u}$, i.e., $\mathbf{u} \in (H^s(\Omega))^3$ for all $s > \frac{1}{2}$. This is because the latter error estimates on element faces are involved with the trace theorem that requires $s > \frac{1}{2}$; see [12, 14]. However, it is allowed that $\mathbf{u}$ has weaker regularity; i.e., $\mathbf{u} \in (W^{s,r}(\Omega))^3$ with $s > \frac{1}{r}$ and $2 \le r \le \infty$. Then (5.19) would become

$$
(5.25)\qquad ||\mathbf{u}-\mathbf{u}_h||_0 \le C\,h^s\,||\mathbf{u}||_{s,r}, \quad s > \frac{1}{r}, \quad \text{and} \quad 2 \le r \le \infty.
$$

Remark 5.4. In the case when ε is not globally continuous, we assume that ε is a piecewise Lipschitz continuous function. This determines a partition $\mathscr{P}$ of Ω into a finite set of subdomains $\Omega_1, \ldots, \Omega_L$ (which are assumed to be polyhedra). In each Ω_l the restriction of ε is Lipschitz continuous. We denote by Γ_{ij} the faces of $\Omega_i \cap \Omega_j$ and assume that all Γ_{ij} are contained in Ω. As usual, the triangulation $\mathcal{C}_h$ should be

conformed with these material interfaces so that each material interface is the union of the element faces in $\mathcal{C}_h$. Let $\mathcal{E}_{\text{inter},\Gamma} \subset \mathcal{E}_h$ denote the set of all element faces on Γ and on interfaces Γ_{ij}, and let $\mathcal{M}_{\text{inter},\Gamma} \subset \mathcal{M}_h$ be the set of macroelements deduced from $\mathcal{E}_{\text{inter},\Gamma}$ in a similar way as that for $\mathcal{M}_h$ in subsection 3.1. The few modifications to our L^2 projected methods for the case of discontinuous materials are as follows. We need only modify (3.20) by

$$R_h^{\text{inter},\Gamma}([(\varepsilon\,\mathbf{u})\cdot\mathbf{n}])|_F := \frac{1}{|F|}\int_F [(\varepsilon\,\mathbf{u})\cdot\mathbf{n}] \quad \forall F \in \mathcal{E}_{\text{inter},\Gamma}, \tag{5.26}$$

modify the mesh-dependent terms $S_{h,\Gamma}(\cdot,\cdot)$, $Z_{h,\Gamma}(\cdot;\cdot)$ in (3.37) and (3.38) by $S_{h,\text{inter},\Gamma}(\cdot,\cdot)$, $Z_{h,\text{inter},\Gamma}(\cdot;\cdot)$:

$$S_{h,\text{inter},\Gamma}(\mathbf{u},\mathbf{v}) := \sum_{\substack{F\in\mathcal{E}_{\text{inter},\Gamma}\\ M\in\mathcal{M}_{\text{inter},\Gamma}, M=K_1\cup K_2,\\ \text{and } \partial K_1\cap\partial K_2=F\\ \text{or } M=K,\partial K\cap\Gamma=F}} \frac{\sum_{l=1}^{m_{\text{inter},\Gamma}} (\varepsilon\,\mathbf{u}, \bigtriangledown(z_{M,l}\,b_M))_{0,M}\,(\varepsilon\,\mathbf{v}, \bigtriangledown(z_{M,l}\,b_M))_{0,M}}{\sum_{l=1}^{m_{\text{inter},\Gamma}} ||\bigtriangledown\,(z_{M,l}\,b_M)||_{0,M}^2}, \tag{5.27}$$

$$Z_{h,\text{inter},\Gamma}(f;\mathbf{v}) := -\sum_{\substack{F\in\mathcal{E}_{\text{inter},\Gamma}\\ M\in\mathcal{M}_{\text{inter},\Gamma}, M=K_1\cup K_2,\\ \text{and } \partial K_1\cap\partial K_2=F\\ \text{or } M=K,\partial K\cap\Gamma=F}} \frac{\sum_{l=1}^{m_{\text{inter},\Gamma}} (f, z_{M,l}\,b_M)_{0,M}\,(\varepsilon\,\mathbf{v}, \bigtriangledown(z_{M,l}\,b_M))_{0,M}}{\sum_{l=1}^{m_{\text{inter},\Gamma}} ||\bigtriangledown\,(z_{M,l}\,b_M)||_{0,M}^2}, \tag{5.28}$$

modify the term $\int_\Gamma R_h^\Gamma((\varepsilon\,\mathbf{u})\cdot\mathbf{n})\,R_h^\Gamma((\varepsilon\,\mathbf{v})\cdot\mathbf{n})$ in (3.21) by

$$\sum_{F\in\mathcal{E}_{\text{inter},\Gamma}} (R_h^{\text{inter},\Gamma}([(\varepsilon\,\boldsymbol{u})\cdot\boldsymbol{n}]), R_h^{\text{inter},\Gamma}([(\varepsilon\,\boldsymbol{v})\cdot\boldsymbol{n}]))_{0,F}, \tag{5.29}$$

and finally modify the notation S_Γ in (3.31), (3.32), and (4.3) by $S_{\text{inter},\Gamma}$. With these modifications, one may follow the same routine in the previous sections to obtain similar stability results and error estimates.

Remark 5.5. In Remark 3.2, we mentioned that, to consider that $S_{\text{div}}(K), S_\Gamma(K)$, and $S_{\mathbf{curl}}(K)$ are simpler polynomial spaces, one may replace ε by a suitable piecewise polynomial approximation, say, ε_h. This replacement does not affect the theory of stability analysis and error estimates. Simply, one need only work with ε_h, but note that such replacement introduces inconsistent error terms in Lemma 5.1 as follows:

$$(\text{div}\,((\varepsilon-\varepsilon_h)\,\mathbf{u}), \breve{R}_h(\text{div}(\varepsilon_h\,\mathbf{v}_h))) \quad \text{for the local } L^2 \text{ projection method,} \tag{5.30}$$

$$\sum_{K\in\mathcal{C}_h} ((\varepsilon-\varepsilon_h)\,\mathbf{u}, \bigtriangledown \breve{R}_h(\text{div}(\varepsilon_h\,\mathbf{v}_h)))_{0,K} \text{ for the pseudolocal } L^2 \text{ projection method,} \tag{5.31}$$

$$\sum_{K\in\mathcal{C}_h} \frac{\sum_{l=1}^{m_{\text{div}}} ((\varepsilon-\varepsilon_h)\,\mathbf{u}, \bigtriangledown(v_{K,l}\,b_K))_{0,K}\,(\varepsilon_h\,\mathbf{v}_h, \bigtriangledown(v_{K,l}\,b_K))_{0,K}}{\sum_{l=1}^{m_{\text{div}}} ||\bigtriangledown\,(v_{K,l}\,b_K)||_{0,K}^2}, \tag{5.32}$$

$$\sum_{\substack{F\subset\Gamma\\ \text{with } F\subset\partial K}} \frac{\sum_{l=1}^{m_\Gamma} ((\varepsilon-\varepsilon_h)\,\mathbf{u}, \bigtriangledown(z_{K,l}\,b_F))_{0,K}\,(\varepsilon_h\,\mathbf{v}_h, \bigtriangledown(z_{K,l}\,b_F))_{0,K}}{\sum_{l=1}^{m_\Gamma} ||\bigtriangledown\,(z_{K,l}\,b_F)||_{0,K}^2}, \tag{5.33}$$

$$\sum_{j=1}^{N} \frac{1}{|\Sigma_j|}\int_{\Sigma_j} ((\varepsilon-\varepsilon_h)\,\mathbf{u})\cdot\mathbf{n} \int_{\Sigma_j} (\varepsilon_h\,\mathbf{v}_h)\cdot\mathbf{n} \quad \text{for the local } L^2 \text{ projection method.} \tag{5.34}$$

Assume that ε is smooth enough, say, $\varepsilon_{ij} \in H^{\frac{5}{2}}$, $1 \le i,\ j \le 3$. Let ε_h be taken as a C^0 finite element interpolant to ε: for the pseudolocal L^2 projection method, $\varepsilon_{ij,h}|_K \in \mathcal{P}_2^+(K)$ for all $K \in \mathcal{C}_h$, where $\mathcal{P}_2^+(K)$ denotes the quadratic element $\mathcal{P}_2(K)$ plus *one* element bubble, while for the local L^2 projection method, $\varepsilon_{ij,h}|_K \in \mathcal{P}_2^{\square}(K)$ for all $K \in \mathcal{C}_h$, where $\mathcal{P}_2^{\square}(K)$ denotes the quadratic element $\mathcal{P}_2(K)$ plus *four* face bubbles. Recall that $K \in \mathcal{C}_h$ is a tetrahedron. These bubbles ensure that $\varepsilon_{ij,h}$, $1 \le i,\ j \le 3$, satisfy the interpolation property

$$\int_K (\varepsilon_{ij} - \varepsilon_{ij,h}) = 0 \quad \forall K \in \mathcal{C}_h \quad \text{for the pseudolocal } L^2 \text{ projection method} \tag{5.35}$$

and

$$\int_F (\varepsilon_{ij} - \varepsilon_{ij,h}) = 0 \quad \forall F \in \partial K, \forall K \in \mathcal{C}_h, \quad \text{for the local } L^2 \text{ projection method.} \tag{5.36}$$

We have from [13, 20] that

$$||\varepsilon - \varepsilon_h||_{0,K} + h_K\, |\varepsilon - \varepsilon_h|_{1,K} \le C\, h_K^{\frac{5}{2}}\, |\varepsilon|_{\frac{5}{2},K} \quad \forall K \in \mathcal{C}_h, \tag{5.37}$$

where $|\cdot|_1$ denotes the seminorm of H^1. Note that ε_h satisfies the same uniform ellipticity property as ε for a suitably small h.

It suffices to explain how to estimate (5.30) for the local L^2 projection method and (5.31) for the pseudolocal L^2 projection method. Error terms (5.32)–(5.34) can be estimated similarly. We first consider (5.30). Since we have assumed that $\mathbf{u} \in (H^s(\Omega))^3$ with $s > \frac{1}{2}$, letting

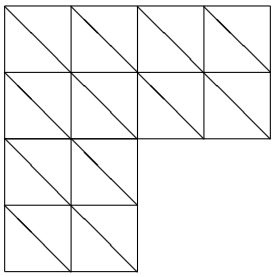
$$\bar{\mathbf{u}}|_K = \frac{1}{|K|} \int_K \mathbf{u} \quad \forall K \in \mathcal{C}_h, \tag{5.38}$$

we can obtain

$$\begin{aligned}
(\operatorname{div}((\varepsilon - \varepsilon_h)\,\mathbf{u}), \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h))) &= \sum_{K \in \mathcal{C}_h} \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h)) \sum_{F \subset \partial K} \int_F ((\varepsilon - \varepsilon_h)\,\mathbf{u}) \cdot \mathbf{n} \\
&= \sum_{K \in \mathcal{C}_h} \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h)) \sum_{F \subset \partial K} \int_F ((\varepsilon - \varepsilon_h)\,(\mathbf{u} - \bar{\mathbf{u}})) \cdot \mathbf{n} \\
&\le C\, h^s\, ||\mathbf{u}||_s\, ||\breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h))||_0.
\end{aligned} \tag{5.39}$$

We next consider (5.31). Since $\mathbf{u} \in (H^s(\Omega))^3$ with $s \ge 0$, we have

$$\begin{aligned}
\sum_{K \in \mathcal{C}_h} ((\varepsilon - \varepsilon_h)\,\mathbf{u}, \bigtriangledown \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h)))_{0,K} &= \sum_{K \in \mathcal{C}_h} \bigtriangledown \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h)) \cdot \int_K (\varepsilon - \varepsilon_h)\,\mathbf{u} \\
&= \sum_{K \in \mathcal{C}_h} \bigtriangledown \breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h)) \cdot \int_K (\varepsilon - \varepsilon_h)\,(\mathbf{u} - \bar{\mathbf{u}}) \\
&\le C\, h^s\, ||\mathbf{u}||_s\, ||\breve{R}_h(\operatorname{div}(\varepsilon_h\,\mathbf{v}_h))||_h,
\end{aligned} \tag{5.40}$$



$h = 1/2$

FIG. 2. *L-domain and uniform partition* $\mathcal{C}_h$.

where we have used the norm equivalence between $||\cdot||_0$ and $||\cdot||_h$ (since $||\cdot||_h$ is a norm induced from the trapezoidal quadrature scheme in (3.25)); see [13, 8].

If assuming $\varepsilon_{ij} \in W^{1,\infty}$, $1 \le i, j \le 3$, then for the pseudolocal L^2 projection method, we may choose ε_h as a piecewise linear (plus one element bubble) continuous approximation with $\varepsilon_{ij,h}|_K \in \mathcal{P}_1^+(K)$, where $\mathcal{P}_1^+(K)$ denotes the linear polynomial space plus one element bubble (so $\varepsilon_{ij,h}|_K$ can satisfy (5.35)). From [3, 19, 13] we have $||\varepsilon - \varepsilon_h||_{0,\infty,K} \le C\, h_K\, |\varepsilon|_{1,\infty,K}$ for all $K \in \mathcal{C}_h$, and we can obtain an estimate similar to (5.40); while for the local L^2 projection method, we may choose ε_h as a piecewise linear (plus four face bubbles) continuous approximation of ε with $\varepsilon_{ij,h}|_K \in \mathcal{P}_1^{\square}(K)$, where $\mathcal{P}_1^{\square}(K)$ denotes the linear polynomial space plus four face bubbles (so $\varepsilon_{ij,h}|_K$ can satisfy (5.36)). From [3, 19, 13] we have $||\varepsilon - \varepsilon_h||_{0,K} + h_K\, |\varepsilon - \varepsilon_h|_{1,K} \le C\, h_K^{5/2}\, |\varepsilon|_{1,\infty,K}$ for all $K \in \mathcal{C}_h$, and we can obtain an estimate similar to (5.39).

Note that we may also choose ε_h as a suitable discontinuous piecewise polynomial approximation to ε, provided that (5.35) (or (5.36)) and the corresponding interpolation error estimates are satisfied. For example, for the pseudolocal L^2 projection method, we may choose a discontinuous piecewise constant ε_h, with $\varepsilon_{ij,h}|_K \in \mathcal{P}_0(K)$ for all $K \in \mathcal{C}_h$. In that case, one should work with ε_h following a similar modifying routine for discontinuous materials as highlighted in Remark 5.4.

6. Numerical experiments. In this section we perform some numerical tests for the local L^2 projection method. We consider a two-dimensional problem, with an L domain $\Omega = [-1,1] \times [-1,1] \setminus [0,1] \times [-1,0]$ (see Figure 2).

The continuous problem reads: Find $\mathbf{u}$ such that

$$\operatorname{curl} \mathbf{u} = g, \quad \operatorname{div} \mathbf{u} = f \quad \text{in } \Omega, \quad \mathbf{u} \cdot \mathbf{n} = \chi \quad \text{on } \Gamma = \partial\,\Omega.$$

We first consider a case of nonsmooth solution and take

$$\mathbf{u} = \bigtriangledown \left(r^{\frac{2}{3}} \cos\left(\frac{2\,\theta}{3}\right)\right),$$

where $x = r\,\cos(\theta), y = r\,\sin(\theta)$, and r is the distance to the reentrant corner $(0,0)$ (at the origin) of opening angle $3\,\pi/2$. We determine $g := \operatorname{curl} \mathbf{u}$, $f := \operatorname{div} \mathbf{u}$, and $\chi := \mathbf{u} \cdot \mathbf{n}|_\Gamma$. We also consider a case of smooth solution and take

$$\mathbf{u} = (\sin(\pi x)\cos(\pi y)/2\pi, \cos(\pi x)\sin(\pi y)/2\pi)^t.$$

The regularity for the first $\mathbf{u}$ is $(H^{\frac{2}{3}-\epsilon})^2$ for any $\epsilon \in (0,1)$, and from the theoretical result obtained the error reduction ratio should be approximately $2^{2/3} \approx 1.586$. The

TABLE 1

$\frac{\|\mathbf{u}-\mathbf{u}_h\|_0}{\|\mathbf{u}\|_0}$	0.119837950	0.075507231	0.047692602	0.030055711

TABLE 2
Relative errors in L^2 norm for smooth solution.

	h=0.5	h=0.25	h=0.125	h=0.0625
$\frac{\|\mathbf{u}-\mathbf{u}_h\|_0}{\|\mathbf{u}\|_0}$	0.053623993	0.008008719	0.001067674	$1.361203187 \times 10^{-4}$

second $\mathbf{u}$ is infinitely smooth; the error reduction ratio should be around 8 since U_h corresponds to a quadratic element. (In two dimensions, the linear element enriched with edge bubbles is none other than the quadratic element.) The calculated results are listed in Tables 1 and 2 as follows. From Table 1 we see that the error reduction ratio is consistent with the predicted value 1.586, and from Table 2 we see that the error reduction ratio is approximately the predicted value 8 as h decreases. These computational results confirm our theoretical estimates.

Acknowledgment. The authors are very thankful to the anonymous referees for valuable comments which led to the improved presentation of this paper.

REDUCED CANCELLATION IN THE EVALUATION OF ENTIRE FUNCTIONS AND APPLICATIONS TO THE ERROR FUNCTION*

W. GAWRONSKI†, J. MÜLLER†, AND M. REINHARD†

Abstract. A general concept for the reduction of cancellation problems in the evaluation of Taylor sections of certain entire functions is proposed. The resulting method is applied to and tested in the case of the (complementary) error function.

Key words. cancellation, error function, entire functions

AMS subject classifications. Primary, 65D20; Secondary, 33F05, 33B20

1. Taylor sections of entire functions: Cancellation and how to reduce it.

Let f be an entire function given by its Taylor series

$$f(z) = \sum_{\nu=0}^{\infty} a_\nu z^\nu = \sum_{\nu=0}^{\infty} \frac{f^{(\nu)}(0)}{\nu!} z^\nu \qquad (z \in \mathbb{C})$$

with respect to the origin. Of course, one idea to numerically evaluate $f(z)$ is to truncate the series, that is, to take, for n sufficiently large,

$$s_n(f, z) := \sum_{\nu=0}^{n} a_\nu z^\nu$$

as an approximation to $f(z)$. However, it turns out that, in many interesting cases, serious cancellation problems arise (for a discussion of cancellation effects in general, see, e.g., [SW]), if z is not restricted to a more or less small neighborhood of the origin. The main reason is that the maximal term

$$\mu(r) := \mu_f(r) := \max_{\nu \in \mathbb{N}_0} |a_\nu|\, r^\nu \qquad (r \geq 0)$$

may happen to be much larger than the modulus of the function value $f(z)$ (where $|z| = r$) itself.

How can this phenomenon be quantified?

We write

$$s_{n,p}(f, z) := \sum_{\nu=0}^{n} a_\nu z^\nu$$

for the nth partial sum of the above Taylor series of f if the computations are performed in floating point arithmetic with a precision of p decimal digits and with input data a_ν and z given with an accuracy of p digits. In this situation, the loss of exact

*Received by the editors September 13, 2006; accepted for publication (in revised form) August 3, 2007; published electronically December 5, 2007.
http://www.siam.org/journals/sinum/45-6/66958.html
†Department of Mathematics, University of Trier, D-54286 Trier, Germany (gawron@uni-trier.de, jmueller@uni-trier.de, rein4501@uni-trier.de).

digits in the evaluation of at least one of the values $\operatorname{Re} s_{N(z),p}(f,z)$ and $\operatorname{Im} s_{N(z),p}(f,z)$ may be approximately measured by

$$d_f(z) := \log_{10} \mu_f(|z|) - \log_{10} |f(z)|$$

for $N(z)$ sufficiently large (actually, as is seen, e.g., from [He, p. 27], a more precise lower bound would be $[d_f(z) - \log_{10}(2\sqrt{2})]$ with $[x]$ denoting the greatest integer not exceeding a real number x, but for our considerations this difference can be ignored).

We always assume that the number of terms $N(z) = N_f(z)$ is taken so large that errors do not result from truncation of the series (so, increasing the number of terms does not improve the exactness).

This implies that the number of exact digits (here and in what follows always understood in the sense of the minimal number in both the real and the imaginary part) is approximately given by $\max(p - d_f(z), 0)$ in the case of computations with p exact figures. So one can run into serious problems, if $d_f(z)$ turns out to be large.

Our aim is to reduce such problems by modifying f in an appropriate way. Before we go into the details, we first describe d_f, for entire functions of finite order and type and of regular growth, approximately in terms of the indicator function of f. For that purpose we recall some definitions and facts concerning the growth of entire functions.

The order $\rho = \rho_f$ of a (transcendental) entire function f is given by

$$\rho_f := \limsup_{r\to\infty} \frac{\log\log M_f(r)}{\log r},$$

where

$$M_f(r) := \max_{|z|=r} |f(z)|.$$

We suppose that $0 < \rho < \infty$. Then the type $\tau = \tau_f$ of f is defined as

$$\tau_f := \limsup_{r\to\infty} \frac{\log M_f(r)}{r^\rho}.$$

Since

$$\log \mu_f(r) / \log M_f(r) \to 1 \qquad (r \to \infty)$$

(see, e.g., [Ru, Theorem 10.1]), we can replace $M_f(r)$ in the above definitions by $\mu_f(r)$. Moreover, the growth of f along rays emanating from the origin is asymptotically described by its indicator function $h = h_f$, given by

$$h_f(\vartheta) := \limsup_{r\to\infty} \frac{\log |f(re^{i\vartheta})|}{r^\rho} \qquad (\vartheta \in [-\pi, \pi]).$$

It is well known that h_f is continuous and that $\max_{[-\pi,\pi]} h_f(\vartheta) = \tau$.

Finally, if f has completely regular growth (for a definition, see, e.g., [Le]), the $\limsup_{r\to\infty}$ in the above definitions can be replaced by $\lim^{\substack{r\to\infty \\ r\notin E}}$, where E is a so-called C^0-set, that is, E is the union of circles $\{z : |z - z_j| < r_j\}$ with

$$\lim_{R\to\infty} \frac{1}{R} \sum_{|z_j|<R} r_j = 0.$$

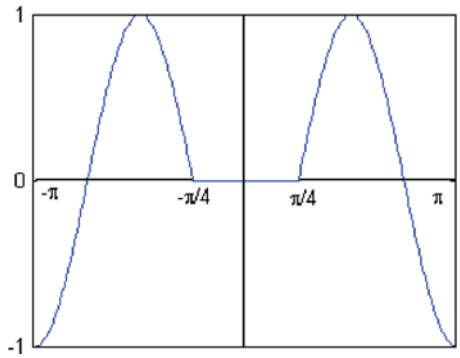

FIG. 1. *Indicator function of* $f(z) = \operatorname{erfc}(-z)$.

Hence

$$\lim_{\substack{r\to\infty \\ r\notin E}} \frac{\log(10)\cdot d_f(re^{i\vartheta})}{r^\rho} = \tau_f - h_f(\vartheta) =: \delta_f(\vartheta),$$

which means that the loss of exact decimal digits for $z = re^{i\vartheta}$ is (up to exceptional values, e.g., near the zeros of f) asymptotically described by $\delta_f(\vartheta)$ in the sense that

$$d_f(re^{i\vartheta}) \sim \delta_f(\vartheta) r^\rho / \log(10) \quad (r\to\infty,\ r\notin E).$$

Let us consider the following example.

Example. Suppose that $f(z) := 1 + \operatorname{erf}(z)$, where erf denotes the (complex) error function; that is,

$$\operatorname{erf}(z) := \frac{2}{\sqrt{\pi}} \int_0^z e^{-t^2}\, dt\ .$$

Then, by the definition of the complementary error function erfc, we have

$$f(z) = \operatorname{erfc}(-z)\ .$$

Moreover, from the asymptotic behavior of erfc near ∞ (see, e.g., [AS, Eq. 7.1.23]), we obtain that $\rho_f = 2$ and

$$h_f(\vartheta) = \begin{cases} 0, & |\vartheta| \le \pi/4, \\ -\cos(2\vartheta), & |\vartheta| > \pi/4. \end{cases}$$

See Figure 1. In Algorithm 680 of Poppe and Wijers (see [PW1], [PW2]), which is based on Gautschi's algorithm [Ga] and which may be viewed as a benchmark for algorithms concerning the evaluation of the complex error function (see, e.g., [Wei]), truncation of the Taylor series

$$f(z) = 1 + \operatorname{erf}(z) = 1 + \frac{2}{\sqrt{\pi}} \sum_{\nu=0}^{\infty} \frac{(-1)^\nu z^{2\nu+1}}{(2\nu+1)\nu!} \tag{1}$$

is performed in the second quadrant

$$S = \{z = re^{i\vartheta} : r \ge 0,\ \pi/2 \le \vartheta \le \pi\}$$

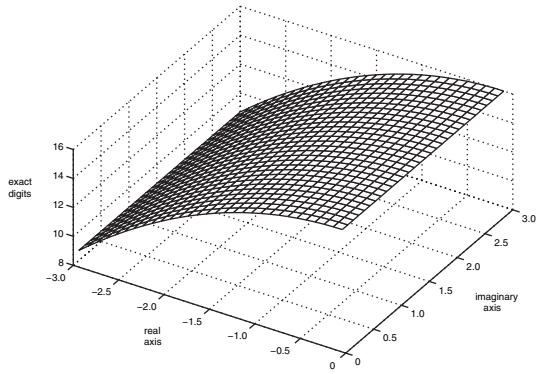

FIG. 2. $16 - \delta_f(\vartheta) r^2 / \log(10)$ *in the second quadrant* S.

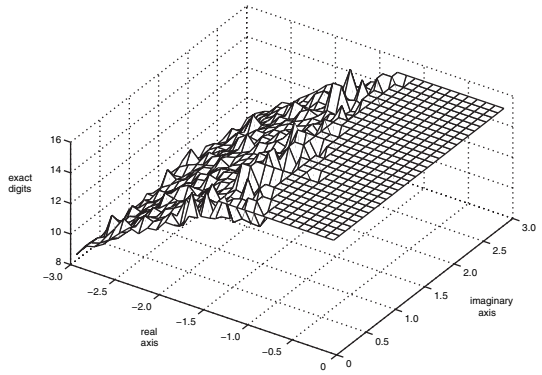

FIG. 3. $e_{f,s_{N(z),16}(f,\cdot)}(z)$ *in* S.

and for $|z| = r$ sufficiently small. Moreover, the calculation in the remaining quadrants is reduced to the second one by elementary operations.

According to the above considerations, we are faced with a loss of significant decimal digits of about

$$\delta_f(\vartheta) r^2 / \log(10) = \begin{cases} r^2 / \log(10), & |\vartheta| \le \pi/4, \\ (1 + \cos(2\vartheta)) r^2 / \log(10), & |\vartheta| > \pi/4, \end{cases}$$

for $z = re^{i\vartheta}$ and r large. So in S, the Taylor sections behave well on the imaginary axis, and the "worst case" appears in the neighborhood of the negative semiaxis (where $\operatorname{erfc}(-z)$ is very small).

Figure 2 shows the values of $16 - \delta_f(\vartheta) r^2 / \log(10)$ which, according to the above remarks, may be viewed as a theoretical measure for the exact digits if computations are performed in floating point arithmetic with a fixed precision of 16 decimal digits.

Moreover, Figure 3 shows $e_{f,s_{N(z),16}(f,\cdot)}(z)$, where

$$e_{f,g}(z) := -\log_{10}\left(\frac{|f(z) - g(z)|}{|f(z)|}\right), \tag{2}$$

that is, the decimal logarithm of the relative error when replacing $f(z)$ by $g(z)$. The value $e_{f,s_{N(z),16}(f,\cdot)}(z)$ measures approximately the smaller of the two numbers of

exact digits of the real part and the imaginary part of $f(z)$, if $f(z)$ is approximated by $s_{N(z),16}(f,z)$ and the computations are performed in double precision arithmetic, providing an accuracy of about 16 decimal digits.

The reference values for $f(z)$ were produced using exact arithmetic from IRRAM (see [Mue1]). Since the usual accuracy requirement of special function routines is 15 digits in double precision, we have cut off the error at a level of 15 digits. Therefore, all values on the 15-digit level represent approximations within the usual tolerance.

The numerical results shown in Figure 3 essentially fit to the theoretical values from Figure 2 and thus support the above considerations about the loss of exact decimal digits.

How can such cancellation problems be reduced? One idea is to modify the function f in such a way that, at least for certain parts of the complex plane, the order of magnitude of the modified $\tilde{f}$ and $\mu_{\tilde{f}}$ do not differ as much as for the function f. Then the Taylor sections $s_n(\tilde{f},z)$ can be computed with less cancellation, and an approximation of $f(z)$ may be obtained from $s_n(\tilde{f},z)$. Such a modification may consist in a multiplication of f by a certain elementary function. More precisely, the general idea is the following: Suppose that $S \subset \mathbb{C}$ is a given set (where f is to be numerically evaluated).

(i) Choose an elementary (entire) function $\varphi = \varphi_S$ so that

$$d_{f\varphi}(z) = \log_{10} \mu_{f\varphi}(|z|) - \log_{10} |f(z)\varphi(z)|$$

is "small" for $z \in S$ and $\varphi(z) \neq 0$ in S.

(ii) Take $\frac{1}{\varphi(z)} s_{N(z),p}(f\varphi,z)$ (for $N(z)$ sufficiently large) as an approximation of $f(z)$ for $z \in S$.

Of course, the question arises of how to choose φ appropriately. If f and φ are of the same order ρ (and of completely regular growth), then

$$h_{f\varphi} = h_f + h_\varphi,$$

and therefore

$$\delta_{f\varphi} = \tau_{f\varphi} - h_f - h_\varphi.$$

If $S = \{re^{i\vartheta} : r \geq 0, \vartheta \in \Theta\}$ is given, then $\varphi = \varphi_S$ should be chosen in such a way that

$$\max_{\vartheta\in\Theta} \delta_{f\varphi}(\vartheta) = \max_{\vartheta\in\Theta}\big(\max_{[-\pi,\pi]} (h_f + h_\varphi) - h_f(\vartheta) - h_\varphi(\vartheta)\big)$$

is small (compare also the considerations in [Mue2]).

If φ is taken from a parametrized family $\Phi = \{\varphi(a,\cdot) : a \in A\}$, we can try to solve the problem

$$\max_{\vartheta\in\Theta}\big(\max_{[-\pi,\pi]} (h_f + h_{\varphi(a,\cdot)}) - h_f(\vartheta) - h_{\varphi(a,\cdot)}(\vartheta)\big) \to \min_{a\in A}. \tag{3}$$

In the next section we study the case of f being the (complementary) error function in some detail.

2. The error function: Reducing errors. We again consider the complementary error function

$$f(z) = \operatorname{erfc}(-z) \qquad (z \in \mathbb{C}).$$

Since f is of order 2, an evident choice for Φ is

$$\Phi = \{\varphi(a,\cdot) : a \in A\}, \qquad \varphi(a,z) := e^{az^2} \qquad (z \in \mathbb{C}),$$

where $A \subset \mathbb{C}$. We (first) restrict our investigations to the case $A = \mathbb{R}$. Then

$$h_{\varphi(a,\cdot)}(\vartheta) = a\cos(2\vartheta) \qquad (\vartheta \in [-\pi,\pi]),$$

and thus, according to section 1,

$$(h_f + h_{\varphi(a,\cdot)})(\vartheta) = \begin{cases} a\cdot\cos(2\vartheta), & |\vartheta| \le \pi/4, \\ (a-1)\cos(2\vartheta), & |\vartheta| > \pi/4. \end{cases}$$

In particular, we obtain

$$\max_{[-\pi,\pi]}(h_f + h_{\varphi(a,\cdot)}) = \max(a, |a-1|) =: \tau(a),$$

and so the optimization problem (3) here reads as

$$\max_{\vartheta\in\Theta}\big(\tau(a) - (h_f + h_{\varphi(a,\cdot)})(\vartheta)\big) \to \min_{a\in\mathbb{R}}. \tag{4}$$

If Θ contains one of the points $\pm\pi/4$ or $\pm 3\pi/4$ (where $h_f - h_{\varphi(a,\cdot)}$ vanishes), then obviously the maximum in (4) is $\ge \tau(a)$, which is minimal exactly for $a = 1/2$. For $a = 1/2$ and $|\vartheta| \le 3\pi/4$ we find

$$\tau(a) - (h_f + h_{\varphi(a,\cdot)})(\vartheta) = \frac{1}{2}(1 - |\cos(2\vartheta)|) \le \frac{1}{2},$$

so $a = 1/2$ turns out to be the (unique) solution of (4) for all subsets Θ of the interval $[-3\pi/4, 3\pi/4]$, with $\{\pm\pi/4, \pm 3\pi/4\} \cap \Theta \ne \emptyset$.

As already mentioned above, in the algorithm of Poppe and Wijers, truncation of the Taylor series

$$f(z) = 1 + \frac{2}{\sqrt{\pi}}\sum_{\nu=0}^{\infty}\frac{(-1)^\nu z^{2\nu+1}}{(2\nu+1)\nu!}$$

is performed in the second quadrant $S = \{z = re^{i\vartheta} : r \ge 0,\ \pi/2 \le \vartheta \le \pi\}$ and for $|z| = r$ sufficiently small.

From the above considerations, the advice is to use Taylor sections of

$$(f\varphi)(z) := f(z)\varphi\left(\frac{1}{2}, z\right) = \operatorname{erfc}(-z)e^{z^2/2} \tag{5}$$

instead.

The following figures show the indicator function of $f\varphi$ and the corresponding approximation for the number of exact digits.

For the computation of the Taylor sections of (5) it is important to have a reasonable representation for the coefficients.

PROPOSITION 1. *For $z \in \mathbb{C}$ we have*

$$(f\varphi)(z) = f(z)\varphi\left(\frac{1}{2}, z\right) = \sum_{\nu=0}^{\infty} b_\nu z^\nu,$$

with

$$b_\nu = \begin{cases} \dfrac{1}{l!2^l} & \text{if} \quad \nu = 2l, \\ \dfrac{1}{\Gamma(l+3/2)\ 2^l} \displaystyle\sum_{k=0}^{l} \binom{k-1/2}{k} (-1)^k & \text{if} \quad \nu = 2l+1. \end{cases} \tag{6}$$

Proof. For $\alpha > 0$ the function

$$M_\alpha(z) := \sum_{k=0}^{\infty} \frac{z^k}{\Gamma(k/\alpha + 1)} \quad (z \in \mathbb{C})$$

is called the Mittag–Leffler function of order α. It is well known that for $\alpha = 2$ the Mittag–Leffler function is closely related to the complementary error function according to

$$\operatorname{erfc}(-z) = M_2(z) e^{-z^2} .$$

Hence, in terms of the Cauchy product we get

$$f(z)\varphi\left(\frac{1}{2}, z\right) = M_2(z) e^{-\frac{1}{2}z^2} = \sum_{\nu=0}^{\infty} b_\nu z^\nu,$$

with

$$b_\nu = \begin{cases} \dfrac{1}{l!2^l} & \text{if} \quad \nu = 2l, \\ \dfrac{1}{\Gamma(l+3/2)} \displaystyle\sum_{k=0}^{l} \binom{l+1/2}{k} \left(\frac{-1}{2}\right)^k & \text{if} \quad \nu = 2l+1. \end{cases} \tag{7}$$

So it remains to consider the case $\nu = 2l + 1$.

The binomial theorem and an index shift show that, for $x \in \mathbb{R}$, $z \in \mathbb{C}$, and $n \in \mathbb{N}_0$, we have

$$\sum_{k=0}^{n} \binom{x-n+k}{k} z^k (1+z)^{n-k} = \sum_{\mu=0}^{n} z^\mu \sum_{k=0}^{\mu} \binom{x-n+k}{k} \binom{n-k}{\mu-k}.$$

Furthermore, we obtain for $a,\ b \in \mathbb{C},\ \mu \in \mathbb{N}_0$

$$\sum_{k=0}^{\mu} \binom{a+k}{k} \binom{b+\mu-k}{\mu-k} = \binom{a+b+\mu+1}{\mu} .$$

Setting $a = x - n,\ b = n - \mu$ we have

$$\sum_{k=0}^{n} \binom{x+1}{k} z^k = \sum_{k=0}^{n} \binom{x-n+k}{k} z^k (1+z)^{n-k}. \tag{8}$$

Then applying (8) and setting $x = l - 1/2,\ n = l,\ z = -1/2$ in (7), we finally get the assertion. ∎

For

$$m_k := \binom{k-1/2}{k}$$

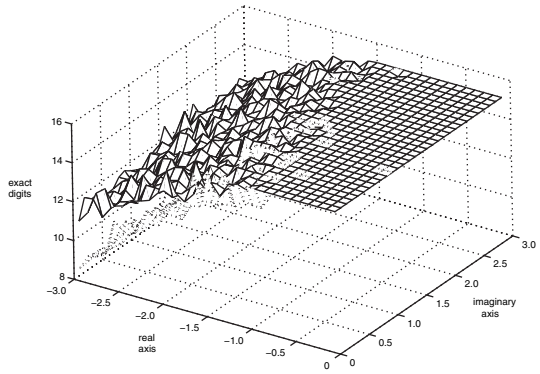

FIG. 4. $e_{f,s_{N(z),16}(f\varphi,\cdot)/\varphi}(z)$ *(solid line) and* $e_{f,s_{N(z),16}(f,\cdot)}(z)$ *(dotted line) in* S.

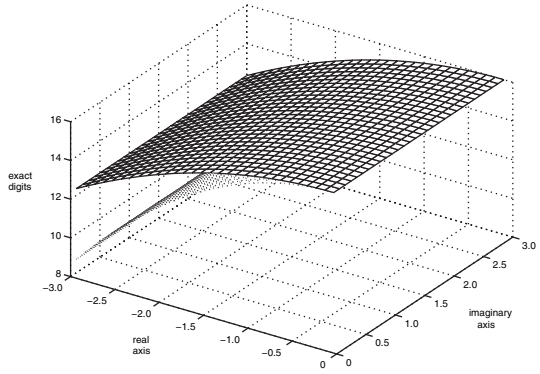

FIG. 5. $16-\delta_{f\varphi}(\vartheta)r^2/\log(10)$ *(solid line) and* $16-\delta_f(\vartheta)r^2/\log(10)$ *(dotted line) in the second quadrant* S.

we have $m_{k+1} = \frac{k+1/2}{k+1}\, m_k$, $k \in \mathbb{N}_0$. Thus, the sum $\sum_{k=0}^{l} \binom{k-1/2}{k}(-1)^k$ in (6) and therefore also the Taylor coefficients b_ν of (5) can be evaluated recursively (note that $\Gamma(l+\frac{3}{2}) = (l+\frac{1}{2})(l-\frac{1}{2})\ldots\frac{1}{2}\sqrt{\pi}$).

Even more suitable for numerical purposes is the two-term recursion

$$(\nu+1)(\nu+2)b_{\nu+2} = b_\nu + b_{\nu-2}, \quad b_{-2} := b_{-1} := 0,\ b_0 = 1,\ b_1 = \frac{2}{\sqrt{\pi}}$$

for the coefficients b_ν, which may be found by applying the above relations twice. More directly, this recursion follows from the fact that $F := f\varphi$ satisfies the differential equation $F'' = (1+z^2)F$ (which was pointed out by one of the referees).

We take $\frac{1}{\varphi(z)} s_{N(z),16}(f\varphi, z)$ (for $N(z)$ sufficiently large) as an approximation of $f(z)$ for $z \in S$ of small modulus and compare the results with the exact values of $f(z)$, which again were produced using exact arithmetic (IRRAM).

The numerical results shown in Figure 4 support our theoretical considerations which are illustrated in Figure 5 and demonstrate the advantages of this method compared to the computation of the Taylor sections of f (see Figures 2 and 3).

Although there is an improvement, the Taylor sections of $f\varphi$ also turn out to be numerically unstable with respect to cancellation near the negative axis, where $\delta_{f\varphi}$ is maximal (cf. Figure 6). So the question arises whether there is an appropriate entire function ψ such that $\delta_{f\psi}(\vartheta)$ is smaller than $\delta_{f\varphi}(\vartheta)$ for $\vartheta \approx \pi$.

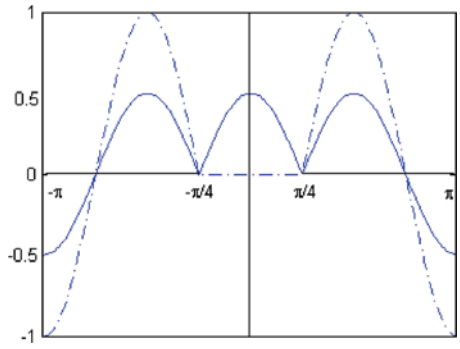

FIG. 6. *The indicator functions of $f\varphi$ (solid curve) and f (dotted curve).*

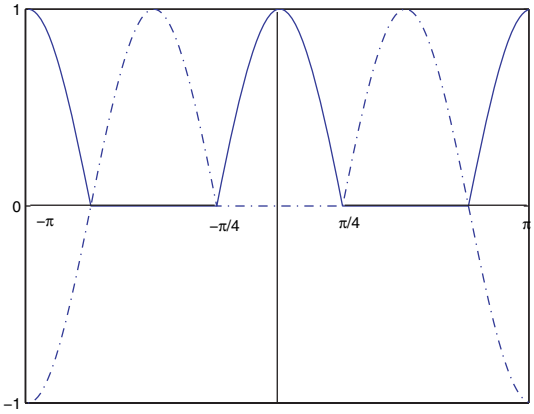

FIG. 7. *The indicator functions of $f\psi$ (solid curve) and f (dotted curve).*

If we take

$$\psi(z) = \operatorname{erfc}(z)\ e^{2z^2}\ ,$$

then we obtain for the indicator function

$$h_{f\psi}(\vartheta) = \begin{cases} 0, & \pi/4 \le |\vartheta| \le 3\pi/4, \\ \cos(2\vartheta), & \text{otherwise}, \end{cases}$$

and therefore $\delta_{f\psi}(\pi) = 0$. See Figure 7.

Thus it is reasonable to take $\frac{1}{\psi(z)} s_{N(z),16}(f\psi, z)$ as an approximation of $f(z)$ in particular close to the negative real axis (see Figure 8). The multiplication by $1/\psi(z)$ in the second quadrant S requires the evaluation of $\operatorname{erfc}(w)$ in the fourth (or the first) quadrant. In this part of the plane, the Taylor sections of $f\varphi$ from (5) turn out to be sufficiently well behaved. So we actually replace $\psi(z)$ by $\tilde{\psi}(z) := e^{2z^2} s_{N(-z),16}(f\varphi, -z)/\varphi(-z)$.

In order to find the Taylor coefficients of $f\psi$ with respect to the origin we just have to apply the Cauchy product again. This leads to

$$(f\psi)(z) = \operatorname{erfc}(-z)\psi(z) = M_2(z)\ M_2(-z) = \sum_{\nu=0}^{\infty} c_\nu z^\nu, \tag{9}$$

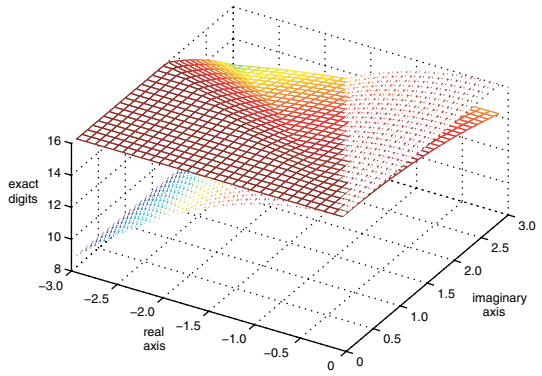

FIG. 8. $16 - \delta_{f\psi}(\vartheta)r^2/\log(10)$ *(solid line) and* $16 - \delta_f(\vartheta)r^2/\log(10)$ *(dotted line) in* S.

with

$$c_\nu = \begin{cases} 0 & \text{if } \nu \text{ is odd,} \\ \displaystyle\sum_{\mu=0}^{\nu} \frac{(-1)^\mu}{\Gamma(\frac{1}{2}\mu+1)\Gamma(\frac{1}{2}(\nu-\mu)+1)} & \text{if } \nu \text{ is even.} \end{cases}$$

As in the case of $f\varphi$ above, the coefficients c_ν, ν even, can be evaluated by recursion.

Setting $r := \nu/2$, we write

$$d_r := \sum_{\mu=0}^{2r} \frac{(-1)^\mu}{\Gamma(\frac{1}{2}\mu+1)\Gamma(r+1-\frac{1}{2}\mu)}, \quad r \in \mathbb{N}_0.$$

We get

$$d_r = \frac{2^r}{r!} - s_{r-1}, \tag{10}$$

with

$$s_n := \sum_{\nu=0}^{n} \frac{1}{\Gamma(\nu+\frac{3}{2})\Gamma(n-\nu+\frac{3}{2})}, \quad n \in \mathbb{N}_0, \text{ and } s_0 = \frac{4}{\pi}.$$

Then we can obtain that

$$s_{n+1} = \frac{2}{n+2}s_n + \frac{1}{(n+2)\Gamma(\frac{3}{2})\Gamma(n+\frac{5}{2})}, \; n \in \mathbb{N}_0, \; s_0 = \frac{4}{\pi}. \tag{11}$$

If we understand (11) as a difference equation, we get

$$s_n = \frac{2^n}{(n+1)!}\sum_{\nu=0}^{n} \frac{\nu!}{2^\nu\Gamma(\frac{3}{2})\Gamma(\nu+\frac{3}{2})}. \tag{12}$$

For the recursion to evaluate the coefficients d_r we obtain

$$d_{r+1} - \frac{2}{r+1}d_r = \frac{2^{r+1}}{(r+1)!} - s_r - \frac{2^{r+1}}{(r+1)!} + \frac{2}{r+1}s_{r-1} = -\frac{1}{(r+1)\Gamma(\frac{3}{2})\Gamma(r+\frac{3}{2})}$$

and therefore

$$d_{r+1} = \frac{2}{r+1} d_r - \frac{2}{(r+1)\pi} \prod_{\nu=0}^{r} \frac{2}{2\nu+1}, \ r \in \mathbb{N}_0, \ a_0 = 1.$$

It turns out, however, that this recursion tends to be unstable if performed upwards. Fortunately, this problem no longer occurs if we apply it in the *backward* direction, that is, we compute with an appropriate starting value $d_{R(z)}$ (or an approximation $\tilde{d}_{R(z)}$)

$$d_r = \frac{r+1}{2} d_{r+1} + \frac{1}{\pi} \prod_{\nu=0}^{r} \frac{2}{2\nu+1}$$

for $r = R(z) - 1, \ldots, 1, 0$. Of course, in this case the question arises of how to get the starting value. Since d_r tends to 0 very rapidly as r tends to ∞, it is possible to simply take $\tilde{d}_{R(z)} = 0$ for $R(z)$ sufficiently large.

In our case suitable values of $R(z)$ could be computed explicitly by using the representation

$$d_r = \frac{4}{\pi r!} \int_0^1 \frac{(1-\xi^2)^r}{1+\xi^2} d\xi, \quad r \in \mathbb{N}_0, \tag{13}$$

which follows from (10) and (12) after some routine calculations employing Euler's Beta integral. From (13) we also have the estimate

$$\sqrt{r}\ r!\ d_r \le \frac{2}{\sqrt{\pi}}$$

being asymptotically sharp as $r \to \infty$.

Similarly as in the case of $f\varphi$, a two-term recursion for the coefficients c_ν can be obtained from the fact that the function $G := f\psi$ satisfies the differential equation

$$G'' = 4(1-2z^2)G + 6zG' - \frac{8}{\pi}$$

(also pointed out by the referee), namely,

$$(\nu+1)(\nu+2)c_{\nu+2} = (4+6\nu)c_\nu - 8c_{\nu-2}.$$

This recursion is again stable (only) in the backward direction. Since now we have a second-order homogeneous equation, and since the exact value $c_0 = 1$ is known, the backward recurrence may be started with the (false) values $\hat{c}_K = 1$ and $\hat{c}_{K+2} = 0$ (for K large enough), and then the exact values are obtained by rescaling with factor $c_0/\hat{c}_0 = 1/\hat{c}_0$ (Miller's algorithm; cf. [Wi, section 4]).

The numerical results shown in Figure 9 demonstrate the efficiency of the proposed method for the evaluation $f(z)$ in particular near the negative real axis.

Obviously, the question arises of how the proposed method compares with the existing software for the computation of the error function. Algorithm 680 of Poppe and Wijers works with νth convergents of a certain continued fraction of $f(z)$ for z outside of a bounded region (and with ν depending on z). As already mentioned above, for z near the origin partial sums of the series (1) are used as an approximation.

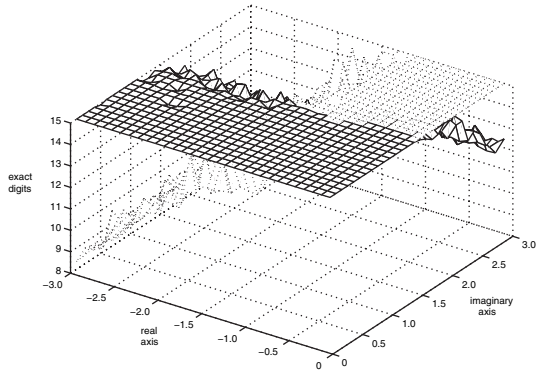

FIG. 9. $e_{f,s_{N(z),16}(f\psi,\cdot)/\tilde{\psi}}(z)$ *(solid line) and* $e_{f,s_{N(z),16}(f,\cdot)}(z)$ *(dotted line) in* S.

Moreover, there is an intermediate region in which Taylor sections not centered at the origin are applied. In this case, the computation of the coefficients is again based on continued fractions. Thus, the most challenging part is the intermediate region.

A combination of the continued fractions in the outer region as in Algorithm 680 and the approximations based on the Taylor expansions of $f\varphi$ and $f\psi$ as above yields an accuracy of at least 14 digits in the second quadrant near the axis but not in an intermediate part close to the line $\arg(z) = 3\pi/4$.

It turns out that a further improvement concerning the accuracy is possible. Multiplication of $f\psi$ with $\varphi(-1/2, z) = e^{-z^2/2}$ results in the indicator function

$$h_{f\psi\varphi(-1/2,\cdot)}(\vartheta) = \frac{1}{2}|\cos(2\vartheta)| \; .$$

The above theory shows that $f\psi\varphi(-1/2, \cdot)$ shares the advantages of $f\varphi$ and $f\psi$ concerning the reduction of cancellation. We were, however, not able to find a reasonable recursion relation for the coefficients, and, unfortunately, the computation from the coefficients of $f\psi$ and $\varphi(-1/2, \cdot)$ by convolution leads again to cancellation. So it seems necessary to evaluate the coefficients using exact arithmetic and then to implement them as data.

If we agree with the same disadvantage, then we can do even better in the area in which we are interested, namely, near the line $\arg(z) = 3\pi/4$.

With

$$a := e^{3\pi i/4} - 1/2$$

and $\varphi(a, z) = e^{az^2}$, we obtain for $f\psi\varphi(a, \cdot)$ the indicator function

$$h_{f\psi\varphi(a,\cdot)}(\vartheta) = h_{f\psi\varphi(-1/2,\cdot)}(\vartheta) + \cos(2\vartheta - 3\pi/2)$$

(see Figure 10), which is comparably "large" for $\vartheta \approx 3\pi/4$.

Numerical experiments confirm that a combination of the four types of approximants based on the continued fractions and the Taylor series of $f\varphi$, $f\psi$, and $f\psi\varphi(a, \cdot)$ provide a reasonable method in the sense that at least 14 exact figures are reached in the second quandrant (and thus in all of the complex plane; cf. [PW1]).

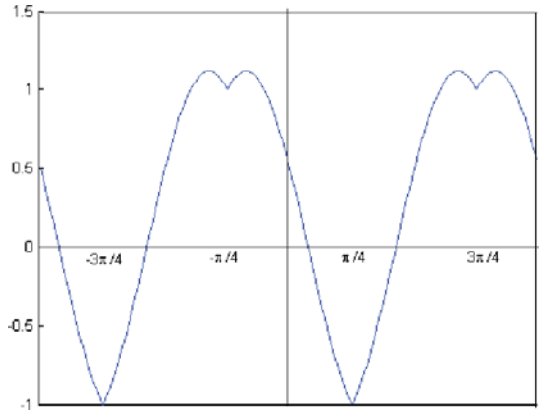

FIG. 10. *Indicator function of* $f\psi\varphi(a,\cdot)$.

Conclusion. The above numerical results have shown that an essential improvement with respect to cancellation is possible in the case of the error function if the growth of the function (measured in terms of the indicator function) is taken into account. Of course, similar ideas apply to other entire functions as, for example, confluent hypergeometric functions or Mittag–Leffler functions. In these cases, the corresponding indicator functions are also easily derived from the asymptotic behavior.

Acknowledgment. The authors express their gratitude to two referees whose expertise led to an improvement of the paper.

CONVERGENCE OF A VARIANT OF THE ZIPPER ALGORITHM FOR CONFORMAL MAPPING*

DONALD E. MARSHALL† AND STEFFEN ROHDE†

Abstract. In the early 1980s an elementary algorithm for computing conformal maps was discovered by R. Kühnau and the first author. The algorithm is fast and accurate, but convergence was not known. Given points $z_0, \ldots, z_n$ in the plane, the algorithm computes an explicit conformal map of the unit disk onto a region bounded by a Jordan curve γ with $z_0, \ldots, z_n \in \gamma$. We prove convergence for Jordan regions in the sense of uniformly close boundaries and give corresponding uniform estimates on the closed region and the closed disc for the mapping functions and their inverses. Improved estimates are obtained if the data points lie on a C^1 curve or a K-quasicircle. The algorithm was discovered as an approximate method for conformal welding; however, it can also be viewed as a discretization of the Loewner differential equation.

DOI. 10.1137/060659119

Introduction. Conformal maps have applications to problems in physics, engineering, and mathematics, but how do you find a conformal map, say, of the upper-half plane $\mathbb{H}$ to a complicated region? Rather few maps can be given explicitly by hand, so that a computer must be used to find the map approximately. One reasonable way to describe a region numerically is to give a large number of points on the boundary (see Figure 1). One way to say that a computed map defined on $\mathbb{H}$ is "close" to a map to the region is to require that the boundary of the image be uniformly close to the polygonal curve through the data points. Indeed, the only information we may have about the boundary of a region is this collection of data points.

In the early 1980s an elementary algorithm was discovered independently by Kühnau [K] and the first author. The algorithm is fast and accurate, but convergence was not known. The purpose of this paper is to prove convergence in the sense of uniformly close boundaries and discuss related numerical issues. In many applications both the conformal map and its inverse are required. One important aspect of the algorithm that sets it apart from others is that this algorithm finds both maps simultaneously.

The algorithm can be viewed as an approximate solution to a conformal welding problem or as a discretization of the Loewner differential equation. The approximation to the conformal map is obtained as a composition of conformal maps onto slit half planes. Osculation methods also approximate a conformal map by repeated composition of simple maps. See Henrici [H] for a discussion of osculation methods and uniform convergence on compact sets. The algorithms of the present article follow the boundary of a given region much more closely than, for instance, the Koebe algorithm and give uniform convergence on all of $\mathbb{H}$ rather than just on compact subsets. Uniform convergence on the closure of the region is particularly important in applications

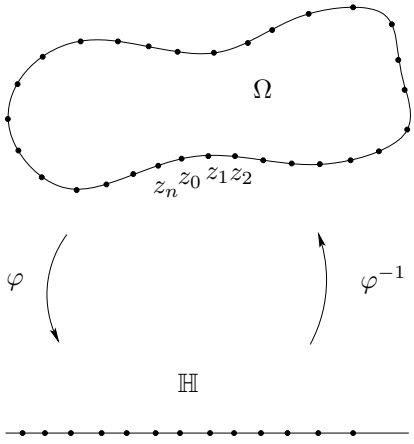

FIG. 1.

that involve boundary values of functions defined on the region. It is possible to use the techniques of this paper to prove that a version of the algorithm is an osculation method for smooth curves, and therefore by the results in [H] repeated applications converge, in the weaker sense, uniformly on compact subsets. However, prior to this article, even a proof that these methods satisfied the osculation family conditions was not known.

Depending on the type of slit (hyperbolic geodesic, straight line segment, or circular arc) we actually obtain different versions of this algorithm. These are described in section 1. We then focus our attention on the "geodesic algorithm" and study its behavior in different situations. The easiest case is discussed in section 2: If the data points $z_0, z_1, \ldots$ are the consecutive contact points of a chain of disjoint discs (see Figures 7 and 8 below), then a simple but very useful reinterpretation of the algorithm, together with the hyperbolic convexity of discs in simply connected domains (Jørgensen's theorem), implies that the curve produced by the algorithm is confined to the chain of discs (Theorem 2.2). One consequence is that for any bounded simply connected domain Ω, the geodesic algorithm can be used to compute a conformal map to a Jordan region Ω_c ("c" is for "computed") so that the Hausdorff distance between $\partial\Omega$ and $\partial\Omega_c$ is as small as desired (Theorem 2.4).

In section 3, we describe an extension of the ideas of section 2 that applies to a variety of domains such as smooth domains or quasiconformal discs with small constants, with better estimates. For instance, if $\partial\Omega$ is a C^1 curve, then the geodesic algorithm can be used to compute a conformal map to a Jordan region Ω_c with $\partial\Omega_c \in C^1$ so that the boundaries are uniformly close and so that the unit tangent vectors are uniformly close (Theorem 3.10). The heart of the convergence proof in these cases comprises the technical "self-improvement" in Lemmas 3.5 and 3.6. In fact, this approach constituted our first convergence proof.

In sections 4 and 5, we show how estimates on the distance between boundaries of Jordan regions give estimates for the uniform distance between the corresponding conformal maps to $\mathbb{D}$, and we apply these estimates to obtain bounds for the convergence of the conformal maps produced by the algorithm. We summarize some of our results as follows: If $\partial\Omega$ is contained in a chain of discs of radius $\leq \epsilon$ with the data points being the contact points of the discs, or if $\partial\Omega$ is a K-quasicircle with K close to one and the data points are consecutive points on $\partial\Omega$ of distance comparable to ϵ,

then the Hausdorff distance between $\partial\Omega$ and the boundary of the domain computed by the geodesic algorithm, $\partial\Omega_c$, is at most ε. Moreover, the conformal maps φ, φ_c onto $\mathbb{D}$ satisfy

$$\sup_{\Omega\cap\Omega_c} |\varphi - \varphi_c| \le C\epsilon^p,$$

where any $p < 1/2$ works in the disc-chain case, and p is close to one if K is close to one. In the case of quasicircles, we also have

$$\sup_{\mathbb{D}} |\varphi^{-1} - \varphi_c^{-1}| \le C\epsilon^p$$

with p close to one. Better estimates are obtained for regions bounded by smoother Jordan curves.

Section 6 contains a brief discussion of numerical results. The appendix has a simple self-contained proof of Jørgensen's theorem.

In a forthcoming paper we plan to address the convergence of the slit and zipper variants of the algorithm. The basic conformal maps and their inverses used in the geodesic algorithm are given in terms of linear fractional transformations, squares, and square roots. The slit and zipper algorithms use elementary maps whose inverses cannot be written in terms of elementary maps. In that paper we will discuss how to divide the plane into four regions so that Newton's method applied to variants of the inverses will converge quadratically in each region. Newton's method converges so rapidly that it virtually provides a formula for the inverses.

1. Conformal mapping algorithms. The geodesic algorithm. The most elementary version of the conformal mapping algorithm is based on the simple map $f_a : \mathbb{H} \setminus \gamma \longrightarrow \mathbb{H}$, where γ is an arc of a circle from 0 to $a \in \mathbb{H}$ which is orthogonal to $\mathbb{R}$ at 0.

This map can be realized by a composition of a linear fractional transformation, the square, and the square root map, as illustrated in Figure 2. The orthogonal circle

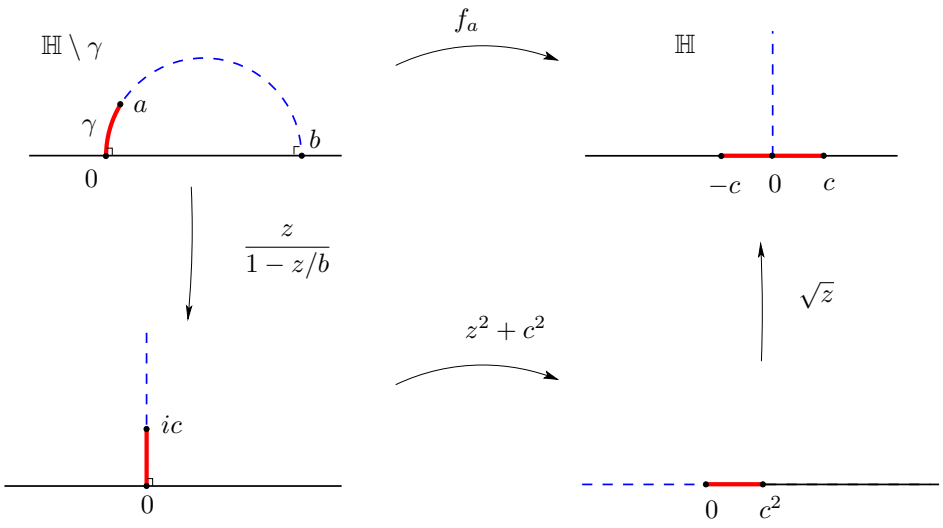

FIG. 2. *The basic map f_a.*

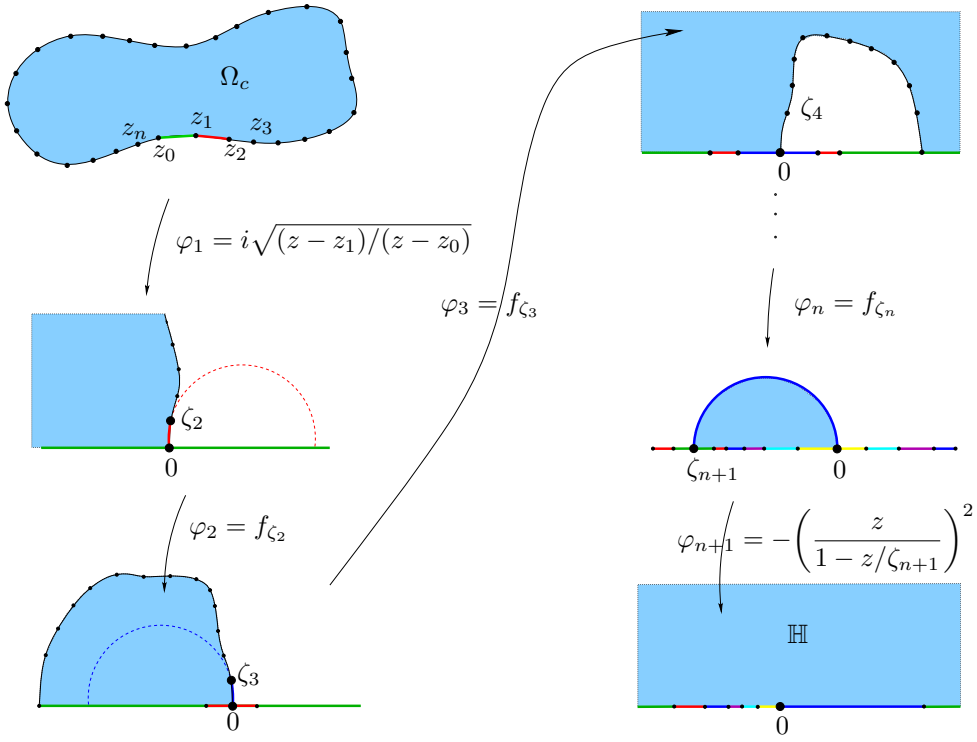

FIG. 3. *The geodesic algorithm.*

also meets $\mathbb{R}$ orthogonally at a point $b = |a|^2/\operatorname{Re} a$ and is illustrated by a dashed curve in Figure 2. In Figure 2, $c = |a|^2/\operatorname{Im} a$. Observe that the arc γ is opened to two adjacent intervals at 0 with a, the tip of γ, mapped to 0. The inverse f_a^{-1} can be easily found by composing the inverses of these elementary maps in the reverse order.

Now suppose that $z_0, z_1, \ldots, z_n$ are points in the plane. The basic maps f_a can be used to compute a conformal map of $\mathbb{H}$ onto a region Ω_c bounded by a Jordan curve which passes through the data points, as illustrated in Figure 3.

The complement in the extended plane of the line segment from z_0 to z_1 can be mapped onto $\mathbb{H}$ with the map

$$\varphi_1(z) = i\sqrt{\frac{z-z_1}{z-z_0}},$$

$\varphi_1(z_1) = 0$, and $\varphi_1(z_0) = \infty$. Set $\zeta_2 = \varphi_1(z_2)$ and $\varphi_2 = f_{\zeta_2}$. Repeating this process, define

$$\zeta_k = \varphi_{k-1} \circ \varphi_{k-2} \circ \cdots \circ \varphi_1(z_k)$$

and

$$\varphi_k = f_{\zeta_k}$$

for $k = 2, \ldots, n$. Finally, map a half disc to $\mathbb{H}$ by letting

$$\zeta_{n+1} = \varphi_n \circ \cdots \circ \varphi_1(z_0) \in \mathbb{R}$$

be the image of z_0, and set

$$\varphi_{n+1} = \pm\left(\frac{z}{1 - z/\zeta_{n+1}}\right)^2.$$

The + sign is chosen in the definition of φ_{n+1} if the data points have a negative winding number (clockwise) around an interior point of $\partial\Omega$, and otherwise the $-$ sign is chosen. Set

$$\varphi = \varphi_{n+1} \circ \varphi_n \circ \cdots \circ \varphi_2 \circ \varphi_1$$

and

$$\varphi^{-1} = \varphi_1^{-1} \circ \varphi_2^{-1} \circ \cdots \circ \varphi_{n+1}^{-1}.$$

Then φ^{-1} is a conformal map of $\mathbb{H}$ onto a region Ω_c such that $z_j \in \partial\Omega_c$, $j = 0, \ldots, n$. The portion γ_j of $\partial\Omega_c$ between z_j and z_{j+1} is the image of the arc of a circle in the upper-half plane by the analytic map $\varphi_1^{-1} \circ \cdots \circ \varphi_j^{-1}$. In more picturesque language, after applying φ_1, we grab the ends of the displayed horizontal line segment and pull, splitting apart or unzipping the curve at 0. The remaining data points move down until they hit 0, and then each splits into two points, one on each side of 0, moving further apart as we continue to pull.

As an aside, we make a few comments. As mentioned, $\partial\Omega_c$ is piecewise analytic. A curve is called C^1 if the arc length parameterization has a continuous first derivative. In other words, the direction of the unit tangent vector is continuous. It is easy to see that $\partial\Omega_c$ is also C^1 since the inverse of the basic map f_a in Figure 2 doubles angles at 0 and halves angles at $\pm c$. In fact, it is also $C^{\frac{3}{2}}$ (see Proposition 3.12). If the data points $\{z_j\}$ lie on the boundary of a given region $\partial\Omega$, the analyticity of $\partial\Omega_c$ also allows us in many situations (see Proposition 2.5 and Corollary 3.9) to extend φ_c analytically across $\partial\Omega_c$ so that the extended map is a conformal map of Ω onto a region with boundary very close to $\partial\mathbb{D}$. Note also that φ is a conformal map of the complement of Ω_c, $\mathbb{C}^* \setminus \overline{\Omega_c}$, onto the lower-half plane, $\mathbb{C} \setminus \overline{\mathbb{H}}$, where $\mathbb{C}^*$ denotes the extended plane. Simply follow the unshaded region in $\mathbb{H}$ in Figure 3. Finally, we remark that it is easier to use geodesic arcs in the right-half plane instead of in the upper-half plane when coding the algorithm because of the usual convention that $-\frac{\pi}{2} < \arg\sqrt{z} \leq \frac{\pi}{2}$.

The slit algorithm. Given a region Ω, we can select boundary points $z_0, \ldots, z_n$ on $\partial\Omega$ and apply the geodesic algorithm. We can view the circular arcs γ for the basic maps f_a as approximating the image of the boundary of Ω between 0 and a with a circular arc at each stage. We can improve the approximation by using straight lines instead of orthogonal arcs. So in the slit algorithm we replace the inverse of the maps f_a by conformal maps $g_a : \mathbb{H} \longrightarrow \mathbb{H} \setminus \mathrm{L}$, where L is a line segment from 0 to a. Explicitly

$$g_a(z) = C(z - p)^p (z + 1 - p)^{1-p},$$

where $p = \arg a/\pi$ and $C = |a|/p^p(1-p)^{1-p}$.

One way to see that g_a is a conformal map is to note that as x traces the real line from $-\infty$ to $+\infty$, $g_a(x)$ traces the boundary of $\mathbb{H} \setminus \mathrm{L}$ and $g_a(z) \sim Cz$ for large z, and then apply the argument principle. Another method would be to construct $\mathrm{Re}\log g_a$ using harmonic measure, as in the first two pages of [GM]. As in the basic maps of the

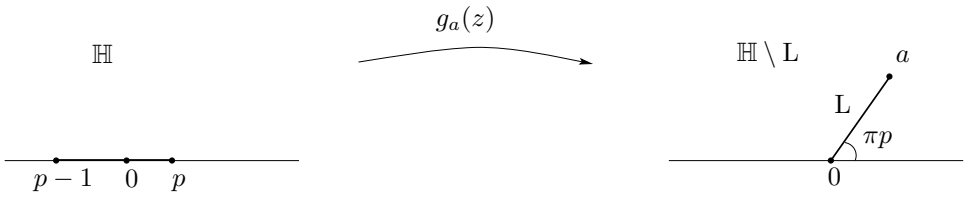

FIG. 4. *The slit maps.*

geodesic algorithm, the line segment from 0 to a is opened to two adjacent intervals on $\mathbb{R}$ by $f_a = g_a^{-1}$ with $f_a(a) = 0$ and $f_a(\infty) = \infty$. The map f_a cannot be written in terms of elementary functions, but an effective and rapid numerical inverse will be described in a subsequent paper.

We note that, as in the geodesic algorithm, the boundary of the region Ω_c computed with the slit algorithm will be piecewise analytic. However, it will not be C^1. Indeed, if g_a is the map illustrated by Figure 4, and if g_b is another such map, then $g_b \circ g_a$ forms a curve with angles $2\pi p$ and $2\pi(1-p)$ on either side of the curve at $b = g_b(0)$. Since analytic maps preserve angles, the boundary of the computed region consists of analytic arcs with endpoints at the data points, and angles determined by the basic maps. This will allow us to accurately compute conformal maps to regions with (a finite number of) "corners" or "bends."

The zipper algorithm. We can further improve the approximation by replacing the linear slits with arcs of (nonorthogonal) circles. In this version we assume there is an even number of boundary points, $z_0, z_1, \ldots, z_{2n+1}$. The first map is replaced by

$$\varphi_1(z) = \sqrt{\frac{(z-z_2)(z_1-z_0)}{(z-z_0)(z_1-z_2)}},$$

which maps the complement in the extended plane of the circular arc through z_0, z_1, z_2 onto $\mathbb{H}$. At each subsequent stage, instead of pulling down one point ζ_k, we can find a unique circular arc through 0 and the (images of) the next two data points ζ_{2k-1} and ζ_{2k}. By a linear fractional transformation ℓ_a which preserves $\mathbb{H}$, this arc is mapped to a line segment (assuming the arc is not tangent to $\mathbb{R}$ at 0). See Figure 5.

The complement of this segment in $\mathbb{H}$ can then be mapped to $\mathbb{H}$ as described in the slit algorithm, using g_d^{-1}, where $d = a/(1-a/b)$. The composition $h_{a,c} = g_d^{-1} \circ \ell_a$ then maps the complement of the circular arc in $\mathbb{H}$ onto $\mathbb{H}$. Thus at each stage we are giving a "quadratic approximation" instead of a linear approximation to the (image of) the boundary. The last map φ_{n+1} is a conformal map of the intersection of a disc with $\mathbb{H}$ where the boundary circular arc passes through 0, the image of z_{2n+1}, and the image of z_0 by the composition $\varphi_n \circ \cdots \circ \varphi_1$. See Figure 6.

If the zipper algorithm is used to approximate the boundary of a region with bends or angles at some boundary points, then better accuracy is obtained if the bends occur only at even numbered vertices $\{z_{2n}\}$, $n \neq 0$.

Conformal welding. The discovery of the slit algorithm by the first author came from considering conformal weldings. (The simpler geodesic algorithm was discovered later.) A decreasing continuous function $h : [0, +\infty) \to (-\infty, 0]$ with $h(0) = 0$ is called a *conformal welding* if there is a conformal map f of $\mathbb{H}$ onto $\mathbb{C} \setminus \gamma$, where γ is a Jordan arc from 0 to ∞ such that $f(x) = f(h(x))$ for $x \in [0, +\infty)$. In other words, the map f pastes the negative and positive real half lines together according to the

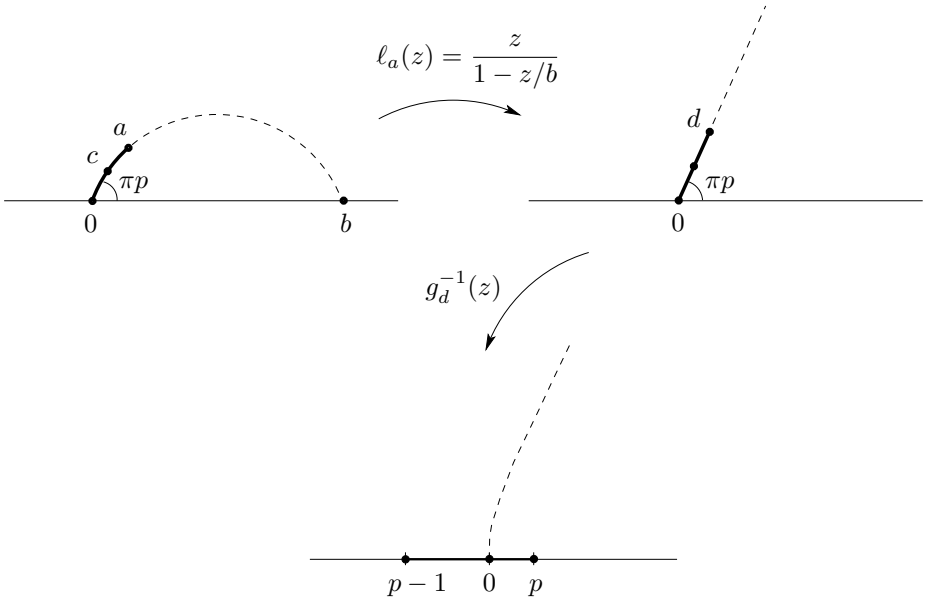

FIG. 5. *The circular slit maps.*

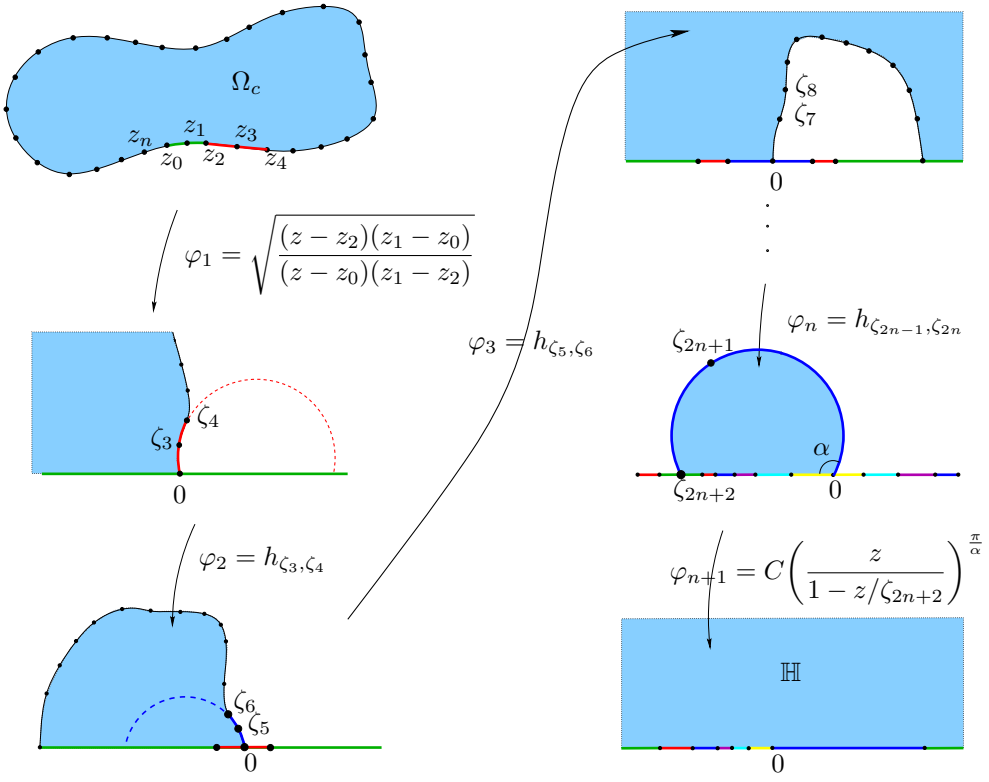

FIG. 6. *The zipper algorithm.*

prescription h to form a curve. One way to approximate a conformal welding is to prescribe the map h at finitely many points and then construct a conformal mapping of $\mathbb{H}$ which identifies the associated intervals.

A related problem, which the first author considered in joint work with L. Carleson, is as follows: Given angles $\alpha_1, \alpha_2, \ldots, \alpha_n$ and $0 < x_1 < x_2 < \cdots < x_n$, find points $y_n < \cdots < y_1 < 0$ so that there is a Schwarz–Christoffel map f of $\mathbb{H}$ onto a region bounded by a polygonal arc tending to ∞ with angles $\alpha_j, 2\pi - \alpha_j$ at the jth vertex $f(x_j) = f(y_j)$. This map welds the intervals $[x_j, x_{j+1}]$ and $[y_{j+1}, y_j]$, $j = 1, \ldots, n$. Unfortunately, at the time the best Schwarz–Christoffel method was only fast enough to do this problem with polygonal curves with up to 20 bends.

The basic maps g_a can be used to compute the conformal maps of weldings. Indeed, suppose $y_1 < 0 < x_1$, let $a = x_1/(x_1 - y_1)$, and apply the map $g_a(z/(x_1 - y_1))$. This map identifies the intervals $[y_1, 0]$ and $[0, x_1]$ by mapping them to the two "sides" of a line segment $L \subset \mathbb{H}$. Composing maps of this form will give a conformal map $\varphi : \mathbb{H} \to \mathbb{C} \setminus \gamma$ such that $\varphi([x_j, x_{j+1}]) = \varphi([y_{j+1}, y_j])$. The final intervals are welded together using the map z^2. The numerical computation of these maps is easily fast enough to compose 10^5 basic maps, thereby giving an approximation to almost any conformal welding. Conversely, given a Jordan arc γ connecting 0 to ∞, the associated welding can be found approximately by using the slit algorithm to approximate the conformal map from $\mathbb{H}$ to the complement of γ.

From this point of view, the slit or the geodesic algorithms find the conformal welding of a curve (approximately). From the point of view of increasing the boundary via a small curve γ_j from z_j to z_{j+1}, the algorithms are discrete solutions of Loewner's differential equation.

The idea of closing up such a region using a map of the form φ_{n+1} was suggested by L. Carleson, for which we thank him.

2. Disc-chains. The geodesic algorithm can be applied to any sequence of data points $z_0, z_1, \ldots, z_n$, unless the points are out of order in the sense that a data point z_j belongs to the geodesic from z_{k-1} to z_k for some $k < j$. In this section we will give a simple condition on the data points $z_0, z_1, \ldots, z_n$ which is sufficient to guarantee that the curve computed by the geodesic algorithm is close to the polygon with vertices $\{z_j\}$.

DEFINITION 2.1. *A* disc-chain $D_0, D_1, \ldots, D_n$ *is a sequence of pairwise disjoint open discs such that* ∂D_j *is tangent to* ∂D_{j+1} *for* $j = 0, \ldots, n-1$. *A* closed disc-chain *is a disc-chain such that* ∂D_n *is tangent to* ∂D_0.

Any closed Jordan polygon P, for example, can be covered by (the closure of) a closed disc-chain with arbitrarily small radii and centers on P (see Figure 7). There are several ways to accomplish this, but one straightforward method is the following: Given $\varepsilon > 0$, find pairwise disjoint discs $\{B_j\}$ centered at each vertex and of radius less than ε so that $B_j \cap P$ is connected for each j. Then

$$P \setminus \bigcup_j B_j = \bigcup L_k,$$

where $\{L_k\}$ are pairwise disjoint closed line segments. Cover each L_k with a disc-chain centered on L_k tangent to the corresponding B_j at the ends, and radius less than half the distance to any other L_i, and less than ε.

Another method for constructing a disc-chain is to draw a Jordan curve using only line segments of length 2^{-n} parallel to the coordinate axes. The circles with radius 2^{-n-1} centered at the endpoints of these segments form a disc-chain. The points of

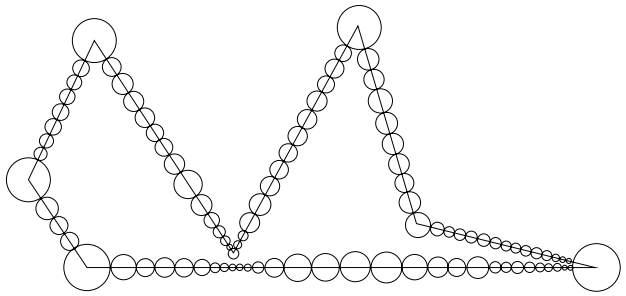

FIG. 7. *Disc-chain covering a polygon.*

tangency are the midpoints of the line segments. Such curves arise from the Whitney decomposition of a simply connected domain, which can be described as follows (see also [GM, p. 21]). If Q is a square, let $2Q$ denote the square with the same center and twice the diameter. Suppose Ω is a simply connected domain contained in the unit square. Divide the unit square into four equal squares.

(a) Discard any square which does not intersect Ω.
(b) If Q is one of the remaining squares for which $2Q \not\subset \Omega$, then divide Q into four equal squares.
(c) Repeat (a), (b), and (c) for the squares obtained in (b).

If this process is repeated ad infinitum, we obtain a decomposition of Ω into squares with the property that for each such square, the distance of the square to the boundary of Ω is comparable to the side length of the square: $2Q \subset \Omega$ and $5Q \cap \partial\Omega \neq \emptyset$. Fix n and $z_0 \in \Omega$ with $\operatorname{dist}(z_0, \partial\Omega) > 2^{-n}$. Let U_n be the union of all squares Q in the Whitney decomposition with side length at least 2^{-n} and let Ω_n be the component of the interior of U_n containing z_0. Then $\partial\Omega_n$ is a polygonal Jordan curve consisting of segments of length 2^{-n}. The discs of radius 2^{-n-1} centered at the endpoints of these segments form a disc-chain and the points of tangency are the midpoints of these segments.

Yet another method for constructing a disc-chain would be to start with a hexagonal grid of tangent discs, all of the same size, and then select a sequence of these discs which form a disc-chain. The boundary circles of a circle packing of a simply connected domain can also be used to form a disc-chain. See, for example, any of the pictures in Stephenson [SK].

If $D_0, D_1, \ldots, D_n$ is a closed disc-chain, set

$$z_j = \partial D_j \cap \partial D_{j+1}$$

for $j = 0, \ldots, n$, where $D_{n+1} \equiv D_0$.

THEOREM 2.2. *If $D_0, D_1, \ldots, D_n$ is a closed disc-chain, then the geodesic algorithm applied to the data $z_0, z_1, \ldots, z_n$ produces a conformal map φ_c^{-1} from the upper-half plane $\mathbb{H}$ to a region bounded by a C^1 and piecewise analytic Jordan curve γ with*

$$\gamma \subset \bigcup_0^n (D_j \cup z_j).$$

Proof. An arc of a circle which is orthogonal to $\mathbb{R}$ is a hyperbolic geodesic in the upper-half plane $\mathbb{H}$. Let γ_j denote the portion of the computed boundary, $\partial\Omega_c$,

between z_j and z_{j+1}. Since hyperbolic geodesics are preserved by conformal maps, γ_j is a hyperbolic geodesic in

$$\mathbb{C}^* \setminus \bigcup_{k=0}^{j-1} \gamma_k.$$

For this reason, we call the algorithm the "geodesic" algorithm.

Using the notation of Figure 2, each map f_a^{-1} is analytic across $\mathbb{R} \setminus \{\pm c\}$, where $f_a^{-1}(\pm c) = 0$, and f_a^{-1} is approximated by a square root near $\pm c$. If f_b^{-1} is another basic map, then f_b^{-1} is analytic and asymptotic to a multiple of z^2 near 0. Thus $f_b^{-1} \circ f_a^{-1}$ preserves angles at $\pm c$. The geodesic γ_j then is an analytic arc which meets γ_{j-1} at z_j with angle π. Thus the computed boundary $\partial\Omega$ is C^1 and piecewise analytic. The first arc γ_0 is a chord of D_0 and hence not tangent to ∂D_0. Since the angle at z_1 between γ_0 and γ_1 is π, γ_1 must enter D_1, and so by Jørgensen's theorem (see Theorem A.1 in the appendix)

$$\gamma_1 \subset D_1,$$

and γ_1 is not tangent to ∂D_1. By induction

$$\gamma_j \subset D_j,$$

$j = 0, 1, \ldots, n$. □

Disc-chains can be used to approximate the boundary of an arbitrary simply connected domain.

LEMMA 2.3. *Suppose that Ω is a bounded simply connected domain. If $\varepsilon > 0$, then there is a disc-chain $D_0, \ldots, D_n$ so that the radius of each D_j is at most ε and $\partial\Omega$ is contained in an ε-neighborhood of $\bigcup D_j$.*

Proof. We may suppose that Ω is contained in the unit square. Then for n sufficiently large, the disc-chain constructed using the Whitney squares with side length at least 2^{-n}, as described above, satisfies the conclusions of Lemma 2.3. □

The *Hausdorff distance* d_H in a metric ρ between two sets A and B is the smallest number d such that every point of A is within ρ-distance d of B, and every point of B is within ρ-distance d of A. The ρ-metrics we will consider in this article are the Euclidean and spherical metrics.

A consequence is the following theorem.

THEOREM 2.4. *If Ω is a bounded simply connected domain, then, for any $\varepsilon > 0$, the geodesic algorithm can be used to find a conformal map f_c of $\mathbb{D}$ onto a Jordan region Ω_c so that*

$$d_H(\partial\Omega, \partial\Omega_c) < \varepsilon, \tag{2.1}$$

where d_H is the Hausdorff distance in the Euclidean metric. If $\partial\Omega$ is a Jordan curve, then we can find f_c so that

$$\sup_{z \in \overline{\mathbb{D}}} |f(z) - f_c(z)| < \varepsilon,$$

where f is a conformal map of $\mathbb{D}$ onto Ω.

Proof. The first statement follows immediately from Theorem 2.2 and Lemma 2.3. To prove the second statement, note that the boundary of the regions constructed with

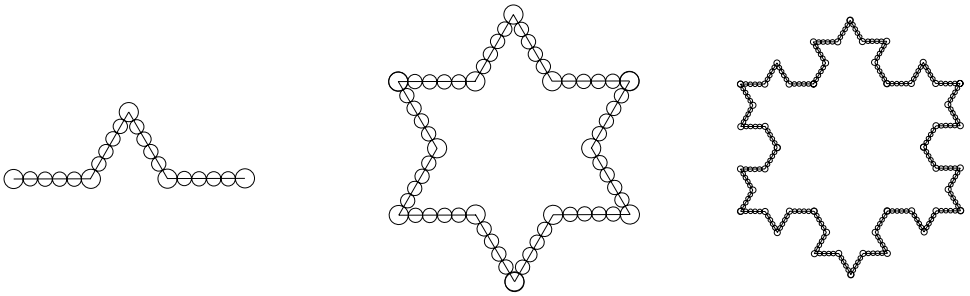

FIG. 8. *Approximating the von Koch snowflake.*

the Whitney decomposition converges to $\partial\Omega$ in the Fréchet sense. By a theorem of Courant [T, p. 383], the mapping functions can be chosen to be uniformly close. □

We note that if Ω is unbounded, Lemma 2.3 and Theorem 2.4 remain true if we use the spherical metric instead of the Euclidean metric to measure the radii of the discs and the distance to $\partial\Omega$.

There are other ways besides using the Whitney decomposition to approximate the boundary of a region by a disc-chain and hence to approximate the mapping function. However, Theorem 2.4 does not give an explicit estimate of the distance between mapping functions in terms of the geometry of the regions. This issue will be explored in greater detail in sections 4 and 5.

The von Koch snowflake is an example of a simply connected Jordan-domain whose boundary has Hausdorff dimension > 1. The standard construction of the von Koch snowflake provides a sequence of polygons which approximate it (see Figure 8). By Theorem 2.4 the mapping functions constructed from these disc-chains converge uniformly to the conformal map to the snowflake.

It is somewhat amusing and perhaps known that a constructive proof of the Riemann mapping theorem (without the use of normal families) then follows. Using linear fractional transformations and a square root map, we may suppose Ω is a bounded simply connected domain. Using the disc-chains associated with increasing levels of the Whitney decomposition, for instance, Ω can be exhausted by an increasing sequence of domains Ω_n for which the geodesic algorithm can be used to compute the conformal map φ_n of Ω_n onto $\mathbb{D}$ with $\varphi_n(z_0) = 0$ and $\varphi_n'(z_0) > 0$. Then by Schwarz's lemma

$$u_n(w) = \log \left| \frac{\varphi_m(w)}{\varphi_n(w)} \right|$$

for $n = m+1, m+2, \ldots$ is an increasing sequence of positive harmonic functions on Ω_m which is bounded above at z_0 by Schwarz's lemma applied to φ_n^{-1}, since Ω is bounded. By Harnack's estimate u_n is bounded on compact subsets of Ω, and by the Herglotz integral formula, $\log \frac{\varphi_m(w)}{\varphi_n(w)}$ converges uniformly on closed discs contained in Ω_m. Thus φ_n converges uniformly on compact subsets of Ω to an analytic function φ. By Hurwitz's theorem φ is one-to-one. Similarly, $\log|\varphi \circ \varphi_m^{-1}(z)/z|$ is an increasing sequence of negative harmonic functions on $\mathbb{D}$ which tend to 0 at $z = 0$. By Harnack again, $|\varphi \circ \varphi_m^{-1}(z)|$ converges to $|z|$ uniformly on compact subsets of $\mathbb{D}$. If $s < 1$, then $|\varphi \circ \varphi_m^{-1}(z)| > s$ for $|z|$ sufficiently close to 1, so by the argument principle, $\{w : |w| < s\} \subset \varphi(\Omega)$, and since s is arbitrary, $\varphi(\Omega) = \mathbb{D}$.

In the geodesic algorithm, we have viewed the maps φ_c and φ_c^{-1} as conformal maps

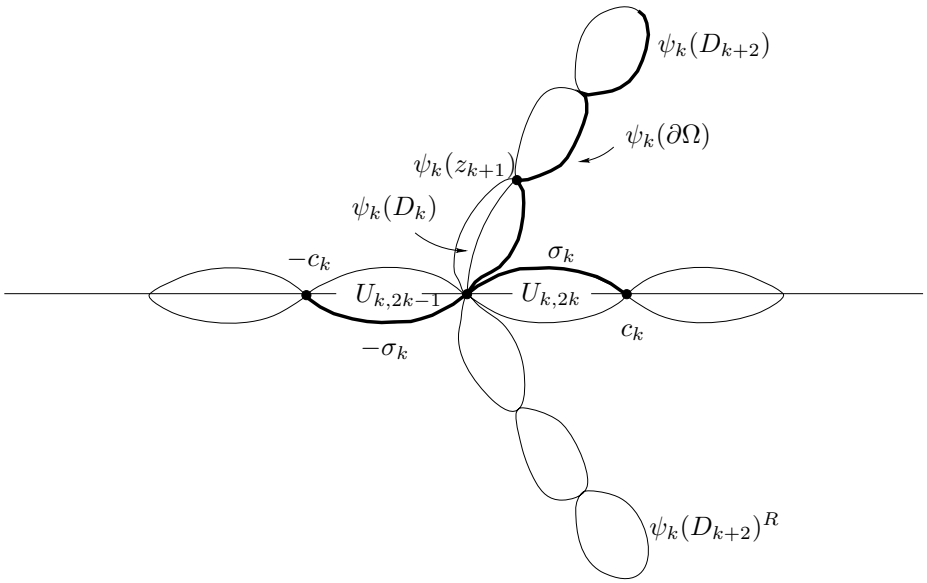

FIG. 9. *Proof of Proposition* 2.5.

between $\mathbb{H}$ and a region Ω_c whose boundary contains the data points. If we are given a region Ω and choose data points $\{z_k\} \in \partial\Omega$ properly, then the next proposition says that the computed maps φ_c and φ_c^{-1} are also conformal maps between the original region Ω and a region "close" to $\mathbb{H}$.

PROPOSITION 2.5. *If $D_0, \ldots, D_n$ is a closed disc-chain with points of tangency $\{z_k\}$, and if Ω is a simply connected domain such that*

$$\partial\Omega \subset \bigcup_{k=0}^{n} \overline{D_k},$$

then the computed map φ_c for the data points $\{z_k\}_0^n$ extends to be conformal on Ω.

We remark that changing the sign of the last map φ_{n+1} in the construction of φ_c gives a conformal map of the complement of the computed region onto $\mathbb{H}$. We choose the sign so that the computed boundary winds once around a given interior point of Ω.

Proof (see Figure 9). Without loss of generality $\Omega \supset \bigcup_{k=0}^{n} D_k$, and hence $\partial\Omega \subset \bigcup \partial D_k$. The basic map f_a in Figure 2 extends by reflection to be a conformal map of $\mathbb{C}^* \setminus (\gamma \cup \gamma^R)$ onto $\mathbb{C}^* \setminus [-c, c]$, where γ^R is the reflection of γ about $\mathbb{R}$. We will first describe the image of $\mathbb{C}^* \setminus \{D_0 \cup \cdots \cup D_n\}$ using these reflected maps. Set

$$\psi_k \equiv \varphi_k \circ \cdots \circ \varphi_1$$

and

$$W_k = \psi_k(\mathbb{C}^* \setminus \{D_0 \cup \cdots \cup D_n\}).$$

Then we claim $\mathbb{C}^* \setminus \{W_k \cup W_k^R\}$ consists of $2(n+1)$ pairwise disjoint simply connected regions:

$$\mathbb{C}^* \setminus \{W_k \cup W_k^R\} = \bigcup_{j=k}^{n} \psi_k(D_j) \cup \psi_k(D_j)^R \cup \bigcup_{j=1}^{2k} U_{k,j},$$

where each region $U_{k,j}$ is symmetric about $\mathbb{R}$ and $\mathbb{R} \subset \bigcup_{j=1}^{2k} \overline{U_{k,j}}$. The case $k = 1$ follows since $\psi_1(\mathbb{C}^* \setminus D_0)$ is bounded by two lines from 0 to ∞. The region $\psi_k(D_k)$ is a subset of $\mathbb{H}$ with 0 and $\psi_k(z_{k+1})$ on its boundary and containing the circular arc from 0 to $\psi_k(z_{k+1})$ which is orthogonal to $\mathbb{R}$. Then

$$\varphi_k\Big(\mathbb{C}^* \setminus (\psi_{k-1}(D_{k-1}) \cup \psi_{k-1}(D_{k-1})^R)\Big)$$

consists of two regions V and $-V = \{-z : z \in V\}$ with 0 and $c_k \in \partial V \cap \mathbb{R}$ and $-c_k \in \partial(-V) \cap \mathbb{R}$. Set $U_{k,2k} = V$, $U_{k,2k-1} = -V$, and $U_{k,p} = \varphi_k(U_{k-1,p})$ for $p \le 2k-2$. The claim now follows by induction.

Finally, we describe the extension of our maps to $\Omega \supset \bigcup_j D_j$. The map φ_k is the composition of a linear fractional transformation τ_k and the map $\sqrt{z^2 + c_k^2}$ (see Figure 2). Note that $\delta_k = \tau_k \circ \psi_{k-1}(\partial\Omega \cap \partial D_{k-1})$ is a curve in $\mathbb{H}$ connecting 0 to ic_k. The map $\sqrt{z^2 + c_k^2}$ is one-to-one and analytic on $\mathbb{C}^* \setminus (\delta_k \cup -\delta_k)$ with image $\mathbb{C}^* \setminus (\sigma_k \cup -\sigma_k)$, where σ_k is a curve connecting 0 to $c_k \in \mathbb{R}$. Thus φ_k extends to be one-to-one and analytic on Ω with image contained in $\mathbb{H} \cup \bigcup_{j=1}^{2k} U_{k,j}$. By induction, ψ_n is one-to-one and analytic on Ω. By direct inspection, the final map φ_{n+1} extends to be one-to-one and analytic, completing the proof of Proposition 2.5. □

As one might surmise from the proof of Proposition 2.5, care must be taken in any numerical implementation to ensure that the proper branch of $\sqrt{z^2 + c^2}$ is chosen at each stage in order to find the analytic extension of the computed map to all of Ω. For this reason, in the numerical implementation of the geodesic algorithm we define our maps using the right-half plane $\mathbb{H}^+ = \{z : \operatorname{Re} z > 0\}$ instead of $\mathbb{H}$.

3. Diamond-chains and pacmen. If we have more control than the disc-chain condition on the behavior of the boundary of a region, then we show in this section that the geodesic algorithm approximates the boundary with better estimates. The computed curve always has a continuously turning tangent direction. The goal in this section is to show that if enough data points are taken on a C^1 Jordan curve, then not only is the computed curve uniformly close, but also the tangent directions are uniformly close to the tangent directions of the given curve. If a subcollection $z_k, z_{k+1}, \ldots, z_p$ of the data points all lie along a line segment, then it is conceivable that the computed curve passing through the data points is oscillating alternately up and down between the data points, and then if z_{p+1} is off the line, it could conceivably cause subsequent oscillations to worsen. Over the long run, the oscillations might then become so large that the curve is no longer a C^1 approximation to the given curve. The key lemma, Lemma 3.5 below, shows that the tangent direction at the end of the geodesic arc actually improves if z_{p+1} is not too far from the line. It is this fixed fractional improvement which does not depend on the number of data points that allows us to iterate the argument.

We will first restrict our attention to domains of the form $\mathbb{C} \setminus \gamma$, where γ is a Jordan arc tending to ∞.

DEFINITION 3.1. *An* ε-diamond $D(a, b)$ *is an open rhombus with opposite vertices* a *and* b *and interior angle* 2ε *at* a *and at* b. *If* $a = \infty$, *then an* ε-diamond $D(\infty, b)$ *is a sector* $\{z : |\arg(z-b) - \theta| < \varepsilon\}$. *An* ε-diamond-chain *is a pairwise disjoint sequence of* ε*-diamonds* $D(z_0, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$. *A* closed ε-diamond-chain *is an* ε*-diamond-chain with* $z_n = z_0$.

See Figure 10. Let $B(z, R)$ denote the disc centered at z with radius R.

DEFINITION 3.2. *A* pacman *is a region of the form*

$$P = B(z_0, R) \setminus \{z : |\arg(\overline{\lambda}(z - z_0))| \le \varepsilon\}$$

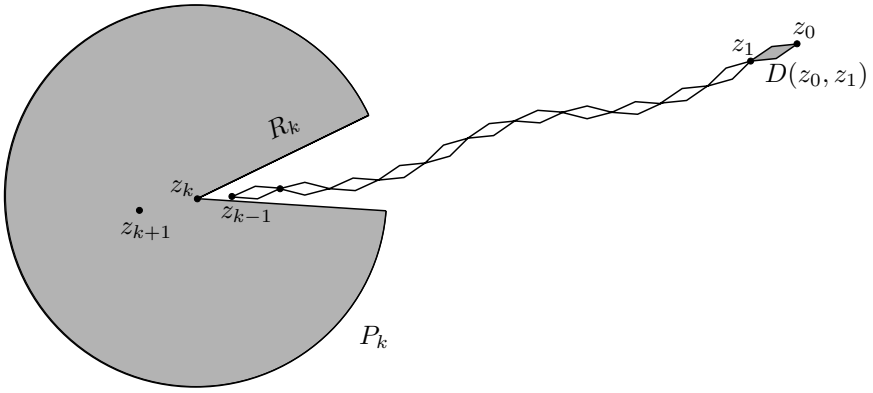

FIG. 10. *A diamond-chain and a pacman.*

for some radius $R < \infty$, center z_0, opening $2\varepsilon > 0$, *and* rotation λ, $|\lambda| = 1$.

Let C_1 be a constant to be chosen later (see Lemma 3.7), and let $z_0 = \infty$.

DEFINITION 3.3. *An ε-diamond-chain $D(\infty, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$ satisfies the* ε-pacman condition *if for each $1 \le k \le n-1$ the pacman*

$$P_k = B(z_k, R_k) \setminus \left\{ z : \left| \arg\left(\frac{z - z_k}{z_k - z_{k+1}} \right) \right| \le \varepsilon \right\}$$

with radius $R_k = C_1 |z_{k+1} - z_k| / \varepsilon^2$ satisfies

$$\left(\bigcup_{j=0}^{k-2} D(z_j, z_{j+1}) \right) \cap P_k = \emptyset.$$

The pacman P_k in Definition 3.3 is chosen to be symmetric about the segment between z_k and z_{k+1} with opening 2ε equal to the interior angle 2ε in the diamond-chain. Note that the ε-diamond $D(z_{k-1}, z_k)$ may intersect P_k.

The pacman condition is a quantitative method of estimating how "flat" the polygonal curve through the data points is and prevents the data point z_k from being too close to z_p for larger p (relative to $|z_k - z_{k+1}|$), as might happen if the polygon almost folded back onto itself as in Figure 7. The requirement is more stringent than the disc-chain condition, and it will allow us to control the smoothness of the unit tangent vector on the boundary of the computed region. If we start with a C^1 curve, then we can select data points that satisfy the pacman condition by making the spacing between successive data points smaller in places where the tangent vector is changing rapidly and where the curve almost folds back on itself.

When $z_0 = \infty$, the first map in the geodesic algorithm is replaced by $\varphi_1(z) = \lambda\sqrt{z - z_1}$. The argument of λ can be chosen so that $\varphi_1(z_2)$ is purely imaginary, in which case the boundary of the constructed region contains the half line from z_2 through z_1 and ∞. We will henceforth assume that

$$D(\infty, z_1) = \left\{ z : \left| \arg\left(\frac{z - z_1}{z_1 - z_2} \right) \right| < \varepsilon \right\}.$$

THEOREM 3.4. *There exist universal constants $\varepsilon_0 > 0$ and C_1 such that if an ε-diamond-chain*

$$D(\infty, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$$

satisfies the ε-pacman condition with $\varepsilon < \varepsilon_0$, and if

$$\left|\arg\left(\frac{z_{k+1}-z_k}{z_k-z_{k-1}}\right)\right| < \frac{\varepsilon}{10} \tag{3.1}$$

for $k = 2, \dots, n-1$, then the boundary curve γ_c computed by the geodesic algorithm with the data $z_0 = \infty, z_1, \dots, z_n$ satisfies

$$\gamma_c \subset \bigcup_{k=1}^{n} \Big(D(z_{k-1}, z_k) \cup \{z_k\} \Big).$$

Moreover, the argument θ of the tangent to γ_c between z_k and z_{k+1} satisfies

$$|\theta - \arg(z_{k+1} - z_k)| < 3\epsilon.$$

To prove Theorem 3.4, we first give several lemmas. To understand the motivation for the lemmas, perhaps it is helpful to point out that the computed boundary $\partial\Omega$ has a smoothly turning tangent, so that if $\gamma_j \subset D(z_j, z_{j+1})$ were tangent to $\partial D(z_j, z_{j+1})$ at z_{j+1}, then, if z_{j+2} were even slightly off the continuation of the straight line from z_j to z_{j+1} (on one side), γ_{j+1} would not be contained in $D(z_{j+1}, z_{j+2})$. This is why we need the improvement provided by the lemmas.

LEMMA 3.5. *There exists $\varepsilon_0 > 0$ such that if $\varepsilon < \varepsilon_0$, and if Ω is a simply connected region bounded by a Jordan arc $\partial\Omega$ from 0 to ∞ with*

$$\{z : |\arg z| < \pi - \varepsilon\} \subset \Omega,$$

then the conformal map f of $\mathbb{H}^+ = \{z : \operatorname{Re} z > 0\}$ onto Ω normalized so that $f(0) = 0$ and $f(\infty) = \infty$ satisfies

$$|\arg z_0^2 f'(z_0)| < \frac{5\varepsilon}{6}, \tag{3.2}$$

where $z_0 = f^{-1}(1)$.

The circle C_{z_0}, which is orthogonal to the imaginary axis at 0 and passes through z_0, has a tangent vector at z_0 with argument equal to $2 \arg z_0$. The quantity $\arg z_0^2 f'(z_0)$ in (3.2) is the argument of the tangent vector to $f(C_{z_0})$ at $f(z_0)$.

Proof. We may suppose that $|z_0| = 1$. Set

$$g(z) = \log \frac{f(z)}{z^2}.$$

Then $|\operatorname{Im} g(z)| \le \varepsilon$ on $\partial\mathbb{H}^+$ and hence also on $\mathbb{H}^+$, and $|\arg z_0| \le \frac{\varepsilon}{2}$, since $f(z_0) = 1$. Set $\alpha = \frac{\pi}{2\varepsilon}$ and

$$A = e^{\alpha g(z_0)} = z_0^{-2\alpha},$$

$$\varphi(z) = \frac{e^{\alpha z} - A}{e^{\alpha z} + \overline{A}},$$

and

$$\tau(z) = \frac{1+z}{1-z} \operatorname{Re} z_0 + i \operatorname{Im} z_0.$$

Then τ is a conformal map of $\mathbb{D}$ onto $\mathbb{H}^+$ such that $\tau(0) = z_0$ and φ is a conformal map of the strip $\{|\operatorname{Im} z| < \varepsilon\}$ onto $\mathbb{D}$ so that $\varphi(g(z_0)) = 0$. Thus $h = \varphi \circ g \circ \tau$ is analytic on $\mathbb{D}$ and bounded by 1 and $h(0) = 0$, so that by Schwarz's lemma

$$|\varphi'(g(z_0))|\,|g'(z_0)|\,|\tau'(0)| = |h'(0)| \le 1.$$

Consequently

$$\left|\frac{f'(z_0)}{f(z_0)} - \frac{2}{z_0}\right| = |g'(z_0)| \le \frac{2\varepsilon|\operatorname{Re} A|}{\pi \operatorname{Re} z_0} \le \frac{2\varepsilon}{\pi \cos\frac{\varepsilon}{2}},$$

and hence

$$\begin{aligned}|\arg z_0^2 f'(z_0)| &= \left|\arg z_0 + \arg \frac{z_0 f'(z_0)}{f(z_0)}\right| \\ &\le \frac{\varepsilon}{2} + \sin^{-1}\left(\frac{\varepsilon}{\pi \cos\frac{\varepsilon}{2}}\right) \\ &= \left(\frac{1}{2} + \frac{1}{\pi}\right)\varepsilon + \mathrm{O}(\varepsilon^2).\end{aligned}$$

This proves Lemma 3.5 if ε is sufficiently small. □

LEMMA 3.6. *Let Ω satisfy the hypotheses of Lemma 3.5. If $\varepsilon < \varepsilon_0/2$, then the hyperbolic geodesic γ from 0 to 1 for the region Ω lies in the kite*

$$P = \{z : |\arg z| < \varepsilon\} \cap \left\{z : |\arg(1-z)| < \frac{5\varepsilon}{6}\right\},$$

and the tangent vectors to γ have argument less than $\frac{8}{3}\varepsilon$.

Proof. By Jørgensen's theorem, γ is contained in the closed disc through 1 and 0 which has slope $\tan\varepsilon$ at 0. Likewise γ is contained in the reflection of this disc about $\mathbb{R}$, and hence $|\arg z| < \varepsilon$ on γ. This also shows that γ is contained in a kite like P but with angles ε at both 0 and 1. In the proof of Theorem 3.4, however, we need the improvement to $\frac{5\varepsilon}{6}$ of the angle at 1.

By Lemma 3.5, a portion of γ near 1 lies in P. Suppose $w_1 \in \gamma$ with $|\arg w_1| = \delta < \varepsilon$ and then apply Lemma 3.5 to the region $\frac{1}{w_1}\Omega$ with ε replaced by $\varepsilon + \delta$. Then the tangent vector to γ at w_1 has argument θ, where

$$|\theta - \arg w_1| < \frac{5}{6}(\varepsilon + |\arg w_1|). \tag{3.3}$$

Since $|\arg w_1| < \varepsilon$, we have $|\theta| \le \frac{8}{3}\varepsilon$. Moreover, (3.3) also implies $\theta < \frac{5}{6}\varepsilon$ when $\arg w_1 \le 0$ and $\theta > -\frac{5}{6}\varepsilon$ when $\arg w_1 \ge 0$. But if w_1 is the last point on $\gamma \cap \partial P$ before reaching 1, this is impossible. Thus $\gamma \subset P$, proving the lemma. □

The next lemma improves Lemma 3.5 by requiring only that the portion of $\partial\Omega$ in a large disc lies inside a small sector.

LEMMA 3.7. *There is a constant C_1 so that if $\varepsilon < \varepsilon_0/2$ and if $\partial\Omega$ is a Jordan arc such that $0 \in \partial\Omega$, $\partial\Omega \cap \{|z| > C_1/\varepsilon^2\} \ne \emptyset$, and*

$$P_\varepsilon = \left\{z : |\arg z| < \pi - \varepsilon \text{ and } |z| \le \frac{C_1}{\varepsilon^2}\right\} \subset \Omega,$$

then the conformal map $f : \mathbb{H}^+ \longrightarrow \Omega$ with $f(0) = 0$ and $|f(\infty)| > \frac{C_1}{\varepsilon^2}$ satisfies

$$|\arg z_0^2 f'(z_0)| < \frac{9\varepsilon}{10}, \tag{3.4}$$

where $z_0 = f^{-1}(1)$.

Proof. Set $R = \frac{C_1}{\varepsilon^2}$ and $B_R = B(0,R) = \{|z| < R\}$. Let U_R be the component of $\Omega \cap B_R$ containing the point 1. Then $f^{-1}(U_R) \subset \mathbb{H}^+$ is bounded by a set $F \subset i\mathbb{R}$ and curves $\sigma_j \subset \mathbb{H}^+$ on which $|f| = R$. Since $0 \in \partial f^{-1}(U_R)$ and $f(\infty) \notin B_R$, exactly one of the curves (call it σ_1) will connect the positive imaginary axis to the negative imaginary axis. The function $u(z) = \arg f(z) - \arg z^2$ is harmonic on the simply connected region $f^{-1}(U_R)$ with $|u| \le 2\pi + \varepsilon$. Then $\partial\Omega \cap B_R$ contains a subarc δ connecting 0 to ∂B_R and $|u| < \varepsilon$ on $f^{-1}(\delta)$. It is possible that B_R contains other subarcs of $\partial\Omega$, none of which intersect P_ε. We may suppose that $P_\varepsilon \cap \partial B_R \subset f(\sigma_1)$, for if $P_\varepsilon \cap \partial B_R \subset f(\sigma_j)$, $j \neq 1$, then σ_j separates a point $z_1 \in i\mathbb{R}$ from $f^{-1}(U_R)$. Then

$$g(\zeta) = f\left(\frac{\zeta}{1 + \zeta/z_1}\right)$$

satisfies the hypotheses of the lemma and $P_\varepsilon \cap \partial B_R$ is a subset of the image of the corresponding curve in $\mathbb{H}^+$ connecting the positive and negative imaginary axes. Moreover, a direct computation shows that

$$\zeta_0^2 g'(\zeta_0) = z_0^2 f'(z_0),$$

where $\zeta_0 = z_0/(1 - z_0/z_1)$.

We conclude $|u(z)| < \varepsilon$ at the endpoints of each σ_j because $P_\varepsilon \subset U_R$. Since u is continuous on the closure of $f^{-1}(U_R)$, and $|\arg f| > \pi - \varepsilon$ on $\partial f^{-1}(U_R) \cap i\mathbb{R}$, and $\arg z^2$ is the same at each endpoint of σ_j, $j > 1$, we conclude that $|u| < \varepsilon$ on $\partial f^{-1}(U_R) \cap i\mathbb{R}$. By the maximum principle

$$|u(z)| \le \varepsilon + (2\pi + \varepsilon)\omega(f(z), \partial B_r, U_R)$$

for $z \in f^{-1}(U_R)$, where $\omega(z, E, V)$ is the harmonic measure at z for $E \cap \overline{V}$ in $V \setminus E$. By Beurling's projection theorem [GM, p. 105] and a direct computation (see [GM, Corollary III.9.3])

$$\omega(1, \partial B_R, \Omega) \le \omega(1, \partial B_R, B_R \setminus [-R, 0]) = \frac{4}{\pi}\tan^{-1}\left(\frac{1}{R^{\frac{1}{2}}}\right). \tag{3.5}$$

Evaluating at $z_0 = f^{-1}(1)$, we obtain

$$|u(z_0)| = |-\arg z_0^2| \le \varepsilon + (2\pi + \varepsilon)\frac{4}{\pi}\tan^{-1}\left(\frac{\varepsilon}{C_1^{\frac{1}{2}}}\right) < \frac{11\varepsilon}{10}$$

for C_1 sufficiently large. Thus

$$|\arg z_0| \le \frac{11\varepsilon}{20}. \tag{3.6}$$

Next we show that there is a large half disc contained in $f^{-1}(\Omega \cap B_R)$. We may suppose that $|z_0| = 1$. Set

$$S = \inf\{|w - i\operatorname{Im} z_0| : w \in \mathbb{H}^+ \text{ and } f(w) \in \partial B_R\}.$$

Using the map

$$\frac{z - i\operatorname{Im} z_0 - S}{z - i\operatorname{Im} z_0 + S}$$

of $\mathbb{H}^+$ onto $\mathbb{D}$ and Beurling's projection theorem again,

$$\omega(z_0, f^{-1}(\partial B_R), \mathbb{H}^+) \geq \omega(z_0, [S, \infty) + i \operatorname{Im} z_0, \mathbb{H}^+).$$

Then by (3.5), (3.6), and an explicit computation

$$\frac{4}{\pi} \tan^{-1}\left(\frac{\varepsilon}{C_1^{\frac{1}{2}}}\right) \geq \frac{2}{\pi} \tan^{-1}\left(\frac{\operatorname{Re} z_0}{\sqrt{S^2 - \operatorname{Re} z_0^2}}\right).$$

For ε sufficiently small, this implies

$$B\left(0, \frac{C_1^{\frac{1}{2}}}{2\varepsilon}\right) \cap \mathbb{H}^+ \subset f^{-1}\left(\Omega \cap B\left(0, \frac{C_1}{\varepsilon^2}\right)\right).$$

Now follow the proof of Lemma 3.5 replacing τ with a conformal map of $\mathbb{D}$ onto $\mathbb{H}^+ \cap \{|z| < \frac{C_1^{1/2}}{2\varepsilon}\}$ such that $\tau(0) = z_0$. Then $\tau'(0) = 2 \operatorname{Re} z_0 + O(\frac{\varepsilon}{C_1^{1/2}})$, and for C_1 sufficiently large, (3.4) holds. □

Following the proof of Lemma 3.6 (replacing 5/6 by 9/10), the next corollary is obtained.

COROLLARY 3.8. *Suppose $\partial\Omega$ is a Jordan arc such that $0 \in \partial\Omega$, $\partial\Omega \cap \{|z| > C_1/\varepsilon^2\} \neq \emptyset$, and*

$$\left\{z : |\arg z| < \pi - \varepsilon \text{ and } |z| \leq \frac{C_1}{\varepsilon^2}\right\} \subset \Omega.$$

If $\varepsilon < \varepsilon_0/2$, then the hyperbolic geodesic γ from 0 to 1 for the region Ω lies in the kite

$$P = \{z : |\arg z| \leq \varepsilon\} \cap \left\{z : |\arg(1 - z)| \leq \frac{9\varepsilon}{10}\right\}. \tag{3.7}$$

Moreover, the tangent vectors to this geodesic have argument at most 3ε.

Proof of Theorem 3.4. Use the constant C_1 from Lemma 3.7 in Definition 3.3. As in Theorem 2.2, let γ_j denote the portion of the computed boundary $\partial\Omega_c$ between z_j and z_{j+1}. By construction $\gamma_0 \cup \gamma_1$ is a half line through $z_0 = \infty$, z_1, and z_2. Make the inductive hypotheses that

$$\bigcup_{j=0}^{k-1} \gamma_j \subset \bigcup_{j=0}^{k-1} D(z_j, z_{j+1}) \tag{3.8}$$

and

$$\gamma_{k-1} \cap P_k = \emptyset. \tag{3.9}$$

Since the ε-diamond-chain $D(\infty, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$ satisfies the ε-pacman condition, (3.8) and (3.9) show that the hypotheses of Corollary 3.8 hold for the curve $\gamma = \bigcup_0^{k-1} \gamma_j$ and hence $\gamma_k \subset D(z_k, z_{k+1})$. Also, by Corollary 3.8 and (3.1),

$$\gamma_k \cap P_{k+1} = \emptyset.$$

By induction, the theorem follows. □

If the hypotheses of Theorem 3.4 hold, then the proof of Proposition 2.5 gives the following corollary.

COROLLARY 3.9. *If Ω and the diamond-chain $D(z_k, z_{k+1})$ satisfy the hypotheses of Theorem 3.4, then the conformal map φ_c computed in the geodesic algorithm extends to be conformal on $\Omega \cup \bigcup_{k=0}^{n} D(z_k, z_{k+1})$.*

The next theorem says that for a region Ω bounded by a C^1 curve, the geodesic algorithm with data points $z_0, z_1, \ldots, z_n$ produces a region Ω_c whose boundary is a C^1 approximation to $\partial\Omega$.

THEOREM 3.10. *Suppose Ω is a Jordan region bounded by a C^1 curve $\partial\Omega$. Then there exists $\delta_0 > 0$ depending on $\partial\Omega$ so that for $\delta < \delta_0$,*

$$\partial\Omega \subset \bigcup_k \big(D(z_k, z_{k+1}) \cup \{z_k\}\big),$$

where $D = \bigcup D(z_k, z_{k+1})$ is a δ-diamond-chain, and so that $\partial\Omega_c$, the boundary of the region computed by the geodesic algorithm, is contained in $D \cup (\bigcup_k \{z_k\})$. Moreover, if $\zeta \in \partial\Omega_c$ and if $\alpha \in \partial\Omega$ with $|\zeta - \alpha| < \delta$, then

$$|\eta_\zeta - \eta_\alpha| < 6\delta, \tag{3.10}$$

where η_ζ and η_α are the unit tangent vectors to $\partial\Omega$ and $\partial\Omega_c$ at ζ and α, respectively.

Proof. There were two reasons for requiring that $z_0 = \infty$ in Theorem 3.4. The first reason was to ensure that

$$\left(\bigcup_0^{k-1} \gamma_j \right) \cap (\mathbb{C} \setminus B(z_k, R_k)) \neq \emptyset, \tag{3.11}$$

as needed for Lemma 3.7. The second reason is the difficulty in closing the curve, since Lemma 3.7 does not apply. The difficulty is that a pacman centered at z_n will contain z_0 if z_0 is too close to z_n. Since $\partial\Omega \in C^1$, we may suppose that the δ-diamond-chain $D(z_0, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$ satisfies the pacman condition. Note that this requires z_n to be much closer to z_{n-1} than to z_0. Since $\partial\Omega \in C^1$, if $|z_n - z_0|$ is sufficiently small, we can find two discs

$$\Delta_p \subset \mathbb{C} \setminus \bigcup_0^{n-1} D(z_k, z_{k+1})$$

for $p = 1, 2$ with

$$\{z_0, z_n\} = \partial\Delta_1 \cap \partial\Delta_2 \quad \text{and} \quad \Delta_1 \cap \Delta_2 \subset D(z_n, z_0),$$

where $D(z_n, z_0)$ is a δ-diamond. By Jørgensen's theorem, as in the proof of Theorem 2.2, the geodesic γ_n between z_n and z_0 is contained in $\Delta_1 \cap \Delta_2$. Then by the proof of Theorem 3.4, $\partial\Omega_c$ is contained in the δ-diamond-chain. The statement about tangent vectors now follows from Corollary 3.8. ∎

We say that $\{z_k\}$ are *locally evenly spaced* if

$$\frac{1}{D} \leq \left| \frac{z_k - z_{k-1}}{z_k - z_{k+1}} \right| \leq D \tag{3.12}$$

for some constant $D < \infty$. Note that the spacing between points can still grow or decay geometrically. We define the *mesh size* μ of the data points $\{z_j\}$ to be

$$\mu(\{z_j\}) = \sup_k |z_k - z_{k+1}|.$$

We say that a Jordan curve Γ in the extended plane $\mathbb{C}^*$ is a *K-quasicircle* if for some linear fractional transformation τ

$$\frac{|w_1 - w| + |w - w_2|}{|w_1 - w_2|} \le K \tag{3.13}$$

for all $w_1, w_2 \in \tau(\Gamma)$ and for all w on the subarc of $\tau(\Gamma)$ with smaller diameter. Thus circles and lines are 1-quasicircles. Quasicircles look very flat on all scales if K is close to 1, but for any $K > 1$ they can contain a dense set of spirals. See, for example, Figure 8.

If Γ satisfies (3.13) with $K = 1+\delta$ and small δ and if $\{z_k\} \subset \tau(\Gamma)$ is locally evenly spaced, then

$$\left|\arg\left(\frac{z_k - z_{k-1}}{z_{k+1} - z_k}\right)\right| \le C\delta^{\frac{1}{2}} \tag{3.14}$$

for some constant C, depending on D. The referee suggested that a proof of this fact might help the reader. Note that (3.12), (3.13), and (3.14) are invariant under translations and dilations, so that we may assume $z_{k-1} = -1$ and $z_k = 0$ and write $z_{k+1} = \zeta$. Then (3.13), with $w_1 = -1$, $w = 0$, and $w_2 = \zeta$, shows that

$$1 + |\zeta| \le (1 + \delta)|1 + \zeta|.$$

Writing $\zeta = re^{i\theta}$ and squaring yield

$$1 - \cos\theta \le (2\delta + \delta^2)\frac{(1 + r)^2}{2r}.$$

By (3.12) $D^{-1} \le |\zeta| = r \le D$ so that

$$\frac{\theta^2}{2} \le (2\delta + \delta^2)\frac{(1 + D)^2}{2D},$$

and

$$\left|\arg\left(\frac{z_k - z_{k-1}}{z_{k+1} - z_k}\right)\right| = |\theta| \le C\delta^{\frac{1}{2}}.$$

THEOREM 3.11. *There is a constant $K_0 > 1$ so that if Γ is a K-quasicircle with $K = 1 + \delta < K_0$ and if $\{z_k\}$ are locally evenly spaced on Γ, then the geodesic algorithm finds a conformal map of $\mathbb{H}$ onto a region Ω_c bounded by a $C(K)$-quasicircle containing the data points $\{z_k\}$, where $C(K)$ is a constant depending only on K.*

We can choose $C(K)$ so that $C(K) \to 1$ as $K \to 1$. Moreover, given $\eta > 0$, if the mesh size $\mu(\{z_k\})$ is sufficiently small, then

$$d_H(\Gamma, \partial\Omega_c) < \eta,$$

where d_H is the Hausdorff distance in the spherical metric.

Proof. We may suppose that Γ satisfies (3.13) with $K = 1 + \delta$ and δ small. Note that $\infty \in \Gamma$. If $\{z_k\}_1^n$ are locally evenly spaced points on $\partial\Omega$, with $\mu = \max|z_k - z_{k-1}|$ sufficiently small, then (3.14) holds and $D(\infty, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n), D(z_n, \infty)$ is a $C\delta^{\frac{1}{2}}$-diamond-chain, where the main axis of the cone $D(\infty, z_1)$ is in the direction $z_1 - z_2$ and the main axis of $D(z_n, \infty)$ is in the direction $z_n - z_{n-1}$. Moreover, $D(\infty, z_1), D(z_1, z_2), \ldots, D(z_{n-1}, z_n)$ satisfies the ε-pacman condition if

$$\varepsilon \ge C\delta^{\frac{1}{4}}$$

for some universal constant C. Now apply Theorem 3.4 to obtain $\gamma_j \subset D(z_{j-1}, z_j)$, $j = 1, \ldots, n-1$. By an argument similar to the proof of Theorem 3.10, we can also find a geodesic arc for $\mathbb{C} \setminus (\bigcup_0^{n-1} \gamma_j)$ from z_n to ∞ contained in $D(z_n, \infty)$. Then the computed curve will be a $C(K)$-quasicircle.

Note that if w_1, w, and w_2 are data points, then by assumption (3.13) holds with $K = 1 + \delta$. By Corollary 3.8, the tangent directions to the computed curve change by no more than $C\delta^{\frac{1}{4}}$ between the data points, and hence the computed curve is a $(1 + C'\delta^{\frac{1}{4}})$-quasicircle. □

As noted before, the boundary of the region computed with the geodesic algorithm, $\partial\Omega_c$, is a C^1 curve. We end this section by proving that $\partial\Omega_c$ is slightly better than C^1. If $0 < \alpha < 1$, we say that a curve Γ *belongs to* $C^{1+\alpha}$ if arc length parameterization $\gamma(s)$ of Γ satisfies

$$|\gamma'(s_1) - \gamma'(s_2)| \leq C|s_1 - s_2|^\alpha$$

for some constant $C < \infty$.

We say that a conformal map f defined on a region Ω *belongs to* $C^{1+\alpha}(\overline{\Omega})$, $0 < \alpha < 1$, provided f and f' extend to be continuous on $\overline{\Omega}$ and there is a constant C so that

$$|f'(z_1) - f'(z_2)| \leq C|z_1 - z_2|^\alpha$$

for all z_1, z_2 in $\overline{\Omega}$.

PROPOSITION 3.12. *If the bounded Jordan region Ω_c is the image of the unit disc by the geodesic algorithm, then*

$$\partial\Omega_c \in C^{3/2},$$

and $\partial\Omega_c \notin C^{1+\alpha}$ for $\alpha > 1/2$, unless Ω_c is a circle or a line. Moreover, $\varphi \in C^{3/2}(\overline{\Omega_c})$ and $\varphi^{-1} \in C^{3/2}(\overline{\mathbb{D}})$.

Proof. To prove the first statement, it is enough to show that if γ is an arc of a circle in $\mathbb{H}$ which meets $\mathbb{R}$ orthogonally at 0 (constructed by application of one of the maps f_a^{-1} as in Figure 2), then the curve σ which is the image of $[-1, 1] \cup \gamma$ by the map $S(z) = \sqrt{z^2 - d^2}$ is $C^{\frac{3}{2}}$ (and no better class) in a neighborhood of $S(0) = id$. Indeed, subsequent maps in the composition φ^{-1} are conformal in $\mathbb{H}$ and hence preserve smoothness. For $d > 0$, the function

$$\psi(z) = \sqrt{\left(\frac{\sqrt{z^2 - c^2}}{1 + \sqrt{z^2 - c^2}/b}\right)^2 - d^2} = id + \frac{i}{2d}(z^2 - c^2) - \frac{i}{bd}(z^2 - c^2)^{\frac{3}{2}} + \mathrm{O}((z^2 - c^2)^2)$$

for some choice of $b \in \mathbb{R}$ and $c > 0$ is a conformal map of the upper-half plane onto a region whose complement contains the curve σ. Clearly $\psi \in C^{\frac{3}{2}}$ near $z = \pm c$, and so by a theorem of Kellogg (see [GM, p. 62]), $\sigma \in C^{\frac{3}{2}}$. The same theorem implies σ is not in C^α for $\alpha > \frac{3}{2}$ unless $1/b = 0$. This argument also shows that $\varphi_c \in C^{3/2}(\overline{\Omega})$. To prove $\varphi_c^{-1} \in C^{\frac{3}{2}}(\overline{\mathbb{D}})$, apply the same ideas above to the inverse maps. Alternatively, this last fact can be proved by following the proof of Lemma II.4.4 in [GM]. □

4. Estimates for conformal maps onto nearby domains. We begin this section with a discussion of the following question. Consider two simply connected planar domains Ω_j with $0 \in \Omega_j$ and conformal maps $\varphi_j : \Omega_j \to \mathbb{D}$ fixing 0, suitably normalized (for instance, positive derivative at 0). If Ω_1 and Ω_2 are "close," what can

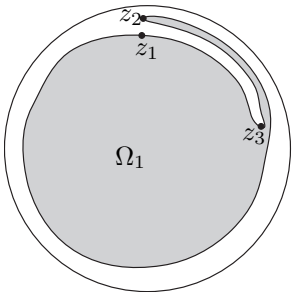

FIG. 11. *Small Hausdorff distance.*

be said about $|\varphi_1 - \varphi_2|$ on $\Omega_1 \cap \Omega_2$, or about $|\varphi_1^{-1} - \varphi_2^{-1}|$ on $\mathbb{D}$? The article [W] gives an overview and numerous results in this direction. How should "closeness" of the two domains be measured? Simple examples show that the Hausdorff distance in the Euclidean or spherical metric between the boundaries does not give uniform estimates for either $||\varphi_1 - \varphi_2||_\infty$ or $||\varphi_1^{-1} - \varphi_2^{-1}||_\infty$. For example, in Figure 11, Ω_1 contains a disc of radius $1 - \delta$, where δ is small, and hence for $\Omega_2 = \mathbb{D}$, $d_H(\Omega_1, \Omega_2) \leq \delta$, but $|\varphi_1(z_1) - \varphi_1(z_2)|$ is large and $|\varphi_1(z_2) - \varphi_1(z_3)|$ is small so that neither $||\varphi_1(z) - z||_\infty$ nor $||\varphi_1^{-1}(z) - z||_\infty$ is small.

Mainly for ease of notation, we will assume throughout this section that the Ω_j are Jordan-domains, and denote by $\gamma_j : \partial\mathbb{D} \to \partial\Omega_j$ an orientation preserving parameterization. Even the more refined distance

$$\inf_\alpha ||\gamma_1 - \gamma_2 \circ \alpha||_\infty,$$

where the infimum is over all homeomorphisms α of $\partial\mathbb{D}$, does not control $||\varphi_1^{-1} - \varphi_2^{-1}||_\infty$ or $||\varphi_1 - \varphi_2||_\infty$. For example, let Ω_2 be a small rotation of the region Ω_1 in Figure 11. What is needed is some control on the "roughness" of the boundary. Following [W], for a simply connected domain Ω we define

$$\eta(\delta) = \eta_\Omega(\delta) = \sup_C \operatorname{diam} T(C),$$

where the supremum is over all crosscuts of Ω with $\operatorname{diam} C \leq \delta$, and where $T(C)$ is the component of $\Omega \setminus C$ that does not contain 0. Notice that $\eta(\delta) \to 0$ as $\delta \to 0$ is equivalent to saying that $\partial\Omega$ is locally connected, and the condition $\eta(\delta) \leq K\delta$ for some constant K is equivalent to saying that Ω is a John-domain (see, e.g., [P, Chapter 5]). It is not difficult to control the modulus of continuity of $\varphi^{-1} : \mathbb{D} \to \Omega$ in terms of η; see [W, Theorem I]. This can be used to estimate $||\varphi_1^{-1} - \varphi_2^{-1}||_\infty$ in terms of the Hausdorff distance between the boundaries, for example.

THEOREM 4.1 (Warschawski [W, Theorem VI]). *If Ω_1 and Ω_2 are John-domains, $\eta_j(\delta) \leq \kappa\delta$ for $j = 1, 2$, and if $d_H(\partial\Omega_1, \partial\Omega_2) \leq \epsilon$, then*

$$||\varphi_1^{-1} - \varphi_2^{-1}||_\infty \leq C\epsilon^\alpha$$

with $\alpha = \alpha(\kappa)$ and $C = C(\kappa, \operatorname{dist}(0, \partial\Omega_1 \cup \partial\Omega_2))$.

In fact, Warschawski proves that every $\alpha < 2/(\pi^2\kappa^2)$ will work (with $C = C(\alpha)$). Using the Hölder continuity of quasiconformal maps, his proof can easily be modified to give the following better estimate if Ω_1 and Ω_2 are K-quasidiscs with K near 1. A K-quasidisc is a Jordan region bounded by a K-quasicircle.

COROLLARY 4.2. *If Ω_1 and Ω_2 are K-quasidiscs, and if $d_H(\partial\Omega_1, \partial\Omega_2) \le \epsilon$, then*

$$||\varphi_1^{-1} - \varphi_2^{-1}||_\infty \le C\epsilon^\alpha$$

with $\alpha = \alpha(K) \to 1$ as $K \to 1$.

As for estimates of $||\varphi_1 - \varphi_2||_\infty$, Warschawski shows [W, Theorem VII] that

$$\sup_{\Omega_1} |\varphi_1 - \varphi_2| \le C\epsilon^{1/2} \log \frac{2}{\epsilon}$$

if $\Omega_1 \subset \Omega_2$ and if Ω_1 is a John-domain, with C depending on κ and on dist$(0, \partial\Omega_1 \cup \partial\Omega_2)$. However, his result does not apply without the assumption of inclusion $\Omega_1 \subset \Omega_2$. To treat the general case the trick of controlling $|\varphi_1 - \varphi_2|$ by passing to the conformal map φ of the component Ω of $\Omega_1 \cap \Omega_2$ containing 0 (which now is included in Ω_j) does not seem to work, as the geometry of Ω cannot be controlled. Nevertheless, for the case of disc-chain domains, the above estimate can be proved, even without any further assumption on the geometry on the disk-chain.

THEOREM 4.3. *Let $D_1, D_2, \dots, D_n$ be a closed ε-disc-chain surrounding 0. Suppose $\partial\Omega_j \subset \bigcup_k \overline{D_k}$ for $j = 1, 2$, and let $\varphi_j : \Omega_j \to \mathbb{D}$ be conformal maps with $\varphi_1(0) = \varphi_2(0) = 0$ and $\varphi_1(p) = \varphi_2(p)$ for a point $p \in \partial\Omega_1 \cap \partial\Omega_2$. Then*

$$\sup_{w \in \Omega_1 \cap \Omega_2} |\varphi_1(w) - \varphi_2(w)| \le C\epsilon^{1/2} \log \frac{1}{\epsilon},$$

where C depends on dist$(0, \bigcup_k D_k)$ *only.*

In case we have control on the geometry of the domains, we have the following counterpart to Corollary 4.2.

THEOREM 4.4. *If Ω_1 and Ω_2 are K-quasidiscs, if $d_H(\partial\Omega_1, \partial\Omega_2) \le \epsilon$, and if $\varphi_1(p_1) = \varphi_2(p_2)$ for a pair of points $p_j \in \partial\Omega_j$ with $|p_1 - p_2| \le \epsilon$, then*

$$\sup_{w \in \Omega} |\varphi_1(w) - \varphi_2(w)| \le C\epsilon^\alpha$$

with $\alpha = \alpha(K) \to 1$ as $K \to 1$, where Ω is the component of $\Omega_1 \cap \Omega_2$ containing 0.

The proofs of both theorems rely on the following harmonic measure estimate, which is an immediate consequence of a theorem of Marchenko [M] (see [W, section 3] for the statement and a proof). To keep this paper self-contained, we include a simple proof, shown to us by John Garnett, for which we thank him.

LEMMA 4.5. *Let $0 < \theta < \pi$, $0 < \epsilon < 1/2$, and set $D = \mathbb{D} \setminus \{re^{it} : -\theta \le t \le \theta, 1 - \epsilon \le r < 1\}$, $A = \partial D \setminus \partial\mathbb{D}$. Then*

$$\omega(0, A, D) \le \frac{\theta}{\pi} + C\epsilon \log \frac{1}{\epsilon}$$

for some universal constant C.

Proof. Set $\omega(z) = \omega(z, A, D)$ for $z \in D$. By the mean value property, it is enough to show that

$$\omega(z) \le C\frac{\epsilon}{t - \theta}$$

for $z = (1 - \epsilon)e^{it}$ and $\theta + \epsilon \le t \le \pi$. To this end, set $I = \{e^{i\tau} : -\theta \le \tau \le \theta\}$ and consider the circular arc $\{\zeta : \omega(\zeta, I, \mathbb{D}) = \frac{1}{3}\}$. If $\epsilon < \epsilon_0$ for some universal ϵ_0 (for $\epsilon \ge \epsilon_0$ there is nothing to prove), then A is disjoint from this arc and it follows that

$\omega(\zeta, I, \mathbb{D}) \geq \frac{1}{3}$ on A. The maximum principle implies $\omega(\zeta) \leq 3\omega(\zeta, I, \mathbb{D})$ on D. Now the desired inequality follows from

$$\omega((1-\epsilon)e^{it}, I, \mathbb{D}) = \frac{1}{2\pi}\int_{-\theta}^{\theta} \frac{1-(1-\epsilon)^2}{|(1-\epsilon)e^{it}-e^{i\tau}|^2} d\tau \leq C\epsilon \int_{-\theta}^{\theta} \frac{1}{(t-\tau)^2} d\tau < C\frac{\epsilon}{t-\theta}. \qquad \square$$

Proof of Theorem 4.3. We may assume that $\varphi_j(p) = 1$. We will first assume that p is one of the points $D_k \cap D_{k+1}$. Denote by Ω the largest simply connected domain $\subset \mathbb{C}$ containing 0 whose boundary is contained in $\bigcup_k D_k$ (thus $\overline{\Omega}$ is the union of $\bigcup_k D_k$ and the bounded component of $\mathbb{C} \setminus \bigcup_k D_k$), and φ is the conformal map from Ω to $\mathbb{D}$ with $\varphi(0) = 0$ and $\varphi(p) = 1$. First, let $z \in \partial\Omega_1 \cap \partial\Omega$. Denote by B, respectively, B_1, the arc of $\partial\Omega$ ($\partial\Omega_1$) from p to z. By the Beurling projection theorem (or the distortion theorem), every $\varphi(D_j)$ has diameter $\leq C\sqrt{\epsilon}$. Therefore, $\varphi(B_1)$ is an arc in $\overline{\mathbb{D}}$, with the same endpoints as $\varphi(B)$, that is contained in $S = \{re^{it} : 1 - C\sqrt{\epsilon} \leq r < 1, -C\sqrt{\epsilon} < t < \arg\varphi(z) + C\sqrt{\epsilon}\}$. Denote $A = \partial S$. By Lemma 4.5,

$$\omega(0, B_1, \Omega_1) \leq \omega(0, B_1, \Omega \setminus B_1) \leq \omega(0, A, \mathbb{D} \setminus A) \leq \frac{1}{2\pi}\arg\varphi(z) + 2C\sqrt{\epsilon} + C\sqrt{\epsilon}\log\frac{1}{\sqrt{\epsilon}}$$

and we obtain

$$\arg\varphi_1(z) = 2\pi\omega(0, B_1, \Omega_1) \leq \arg\varphi(z) + C\epsilon^{1/2}\log\frac{1}{\epsilon}.$$

The same argument, applied to the other arc from p to z, gives the opposite inequality, and together it follows that

$$|\varphi(z) - \varphi_1(z)| \leq C\epsilon^{1/2}\log\frac{1}{\epsilon}.$$

Now let $z \in \partial\Omega_1$ be arbitrary. If z' is a point of $\partial\Omega_1 \cap \partial\Omega$ in the same disc D_j as z, then we have

$$|\varphi(z)-\varphi_1(z)| \leq |\varphi(z)-\varphi(z')|+|\varphi(z')-\varphi_1(z')|+|\varphi_1(z)-\varphi_1(z')| \leq 2C\sqrt{\epsilon}+C\epsilon^{1/2}\log\frac{1}{\epsilon}.$$

The maximum principle yields $|\varphi - \varphi_1| \leq C\epsilon^{1/2}\log\frac{1}{\epsilon}$ on Ω_1. The same argument applies to $|\varphi - \varphi_2|$, and the theorem follows from the triangle inequality.

If $p \in \partial\Omega_1 \cap \partial\Omega_2$ is arbitrary, let p' be one of the points $D_k \cap D_{k+1}$ in the same disc D_j as p. Then the above estimate, applied to a rotation of φ_1, φ_2, and p', gives $|\varphi_2(p')/\varphi_1(p')\varphi_1 - \varphi_2| \leq C\epsilon^{1/2}\log\frac{2}{\epsilon}$, and the theorem follows from $|\varphi_j(p) - \varphi_j(p')| \leq C\sqrt{\epsilon}$. $\square$

The following lemma is another easy consequence of the aforementioned theorem of Marchenko [M] (see [W, section 3]).

LEMMA 4.6. *Let $H \subset \mathbb{D}$ be a K-quasidisc with $0 \in H$ such that $\partial H \subset \{1 - \epsilon < |z| < 1\}$, and let h be a conformal map from $\mathbb{D}$ to H with $h(0) = 0$ and $|h(p) - p| < \epsilon$ for some $p \in \partial\mathbb{D}$. Then*

$$|h(z) - z| \leq C\epsilon\log\frac{1}{\epsilon},$$

where C depends on K only.

Proof. We may assume that $p = 1$. Let $z = e^{i\tau}$ and consider the arc $A = \{h(e^{it}) : 0 \leq t \leq \tau\} \subset \partial H$ of harmonic measure $\tau/2\pi$. For a suitable constant C, depending

on K, we have that $D = \mathbb{D} \setminus \{re^{it} : -C\epsilon \le t \le \arg h(z) + C\epsilon,\ 1-\epsilon \le r < 1\}$ contains A. By the maximum principle and Lemma 4.5,

$$\tau/2\pi = \omega(0, A, H) \le \omega(0, \partial D \cap \mathbb{D}, D) \le \arg h(z)/2\pi + C\epsilon \log \frac{1}{\epsilon}.$$

Applying the same reasoning to $\partial H \setminus A$, the lemma follows for all $z \in \partial\mathbb{D}$ and thus for all $z \in \mathbb{D}$. □

Note that the conclusion of Lemma 4.6 is true if, instead of assuming that H is a K-quasidisc, we assume only that $\arg z$ is increasing on ∂H.

Proof of Theorem 4.4. Because Ω_1 and Ω_2 are K-quasidiscs, φ_1 and φ_2 have K^2-quasiconformal extensions to $\mathbb{C}$ (see [L, Chapter I.6]). In particular, they are Hölder continuous with exponent $1/K^2$ (see [A]), and it follows that with $\alpha = 1/K^2$ and $r = 1 - C\epsilon^\alpha$, we have $\varphi_1^{-1}(\{|z| \le r\}) \subset \Omega_2$. In particular, $h(z) = \varphi_2(\varphi_1^{-1}(rz))$ is a conformal map from $\mathbb{D}$ onto a K^4-quasidisc $H \subset \mathbb{D}$, and by the Hölder continuity of φ_2 and φ_1^{-1} we have $\partial H \subset \{1 - C\epsilon^{\alpha^3} < |z| < 1\}$. Now Lemma 4.6 yields $|h(z) - z| \le C\epsilon^\beta$ for any $\beta < \alpha^3$ and $C = C(\beta)$. For $w \in \Omega \subset \Omega_1 \cap \Omega_2$, let $z = \varphi_1(w)$; then

$$\begin{aligned} |\varphi_1(w) - \varphi_2(w)| &= |z - \varphi_2(\varphi_1^{-1}(z))| \\ &\le |z - \varphi_2(\varphi_1^{-1}(rz))| + |\varphi_2(\varphi_1^{-1}(rz)) - \varphi_2(\varphi_1^{-1}(z))| \le C\epsilon^\beta, \end{aligned}$$

where again we have used the Hölder continuity of φ_2 and φ_1^{-1}. The theorem follows. □

5. Convergence of the mapping functions. We will now combine the results of sections 2 and 3 with the estimates of the previous section to obtain quantitative estimates on the convergence of the geodesic algorithm. Throughout this section, Ω will denote a given simply connected domain containing 0, bounded by a Jordan curve $\partial\Omega$, $z_0, \dots, z_n$ are consecutive points on $\partial\Omega$, Ω_c is the domain and $\varphi_c : \Omega_c \to \mathbb{D}$ is the map computed by the geodesic algorithm, and $\varphi : \Omega \to \mathbb{D}$ is a conformal map, normalized so that $\varphi_c(0) = \varphi(0) = 0$ and $\varphi_c(p_0) = \varphi(p_0)$ for some $p_0 \in \partial\Omega \cap \partial\Omega_c$.

Combining Theorems 2.2 and 4.3 and Propositions 2.5 and 3.12 we immediately obtain the following theorem.

THEOREM 5.1. *If $\partial\Omega$ is contained in a closed ϵ-disc-chain $\bigcup_{j=0}^n \overline{D_j}$ and if $z_j = \partial D_j \cap \partial D_{j+1}$, then $\partial\Omega_c$ is a smooth ($C^{\frac{3}{2}}$) piecewise analytic Jordan curve contained in $\bigcup_{j=0}^n D_j \cup z_j$, the map φ_c extends to be conformal on $\Omega \cup \Omega_c$, and*

$$\sup_{w\in\Omega} |\varphi(w) - \varphi_c(w)| \le C\epsilon^{1/2} \log \frac{1}{\epsilon}.$$

Now assume that $\partial\Omega$ is a K-quasicircle with $K < K_0$, and assume approximate equal spacing of the z_j, say, $\frac{1}{2}\epsilon < |z_{j+1} - z_j| < 2\epsilon$. Then

$$\frac{C}{\epsilon} \le n \le \frac{C}{\epsilon^d}, \tag{5.1}$$

where d (essentially the Minkowski dimension) is close to 1 when K is close to 1. Combining Theorem 3.11 with Corollary 4.2 and Theorem 4.4, we have the following theorem.

THEOREM 5.2. *Suppose $\partial\Omega$ is a K-quasicircle with $K < K_0$. The Hausdorff distance between $\partial\Omega$ and $\partial\Omega_c$ is bounded by $C'(K)\epsilon$, where $C'(K)$ is a constant depending upon K that tends to 0 as K tends to 1 and n to infinity. Furthermore,*

$$||\varphi^{-1} - \varphi_c^{-1}||_\infty \le C\epsilon^\alpha$$

and

$$\sup_{w\in\Omega_0} |\varphi(w) - \varphi_c(w)| \le C\epsilon^\alpha$$

with $\alpha = \alpha(K) \to 1$ *as* $K \to 1$, *where* Ω_0 *is the component of* $\Omega \cap \Omega_c$ *containing* 0.

The best possible exponent in (5.1) in terms of the standard definition of $K(\partial\Omega)$, which slightly differs from our geometric definition, is given by Smirnov's (unpublished) proof of Astala's conjecture,

$$d \le 1 + \left(\frac{K-1}{K+1}\right)^2.$$

This allows us to easily convert estimates given in terms of ε, as in Theorem 5.2, into estimates involving n.

Finally, assume that $\partial\Omega$ is a smooth closed Jordan curve. Then Ω is a K-quasicircle and a John-domain by the uniform continuity of the derivative of the arc length parameterization of $\partial\Omega$. The quasiconformal norm $K(\partial\Omega)$ and the John constant depend on the global geometry, as does the ε-pacman condition when there are not very many data points. As the example in Figure 11 shows, even an infinitely differentiable boundary can have a large quasiconformal constant and a large John constant. However, the ε-pacman condition becomes a local condition if the mesh size $\mu(\{z_k\}) = \max_k |z_{k+1} - z_k|$ of the data points is sufficiently small. The radii of the balls in the definition of the ε-pacman condition

$$R_k = C_1 \frac{|z_{k+1} - z_k|}{\varepsilon^2} \tag{5.2}$$

increase as ε decreases but can be chosen small for a fixed ε if the mesh size μ is small. To apply the geodesic algorithm we suppose that the data points have small mesh size and, as in the proof of Theorem 3.10, $|(z_0 - z_n)/(z_{n-1} - z_n)|$ is sufficiently large so that the ε-diamond-chain $D(z_0, z_1), \dots, D(z_{n-1}, z_n)$ satisfies the ε-pacman condition and

$$\partial\Omega \subset \bigcup_{k=0}^{n} D(z_k, z_{k+1}),$$

where $D(z_n, z_{n+1}) = D(z_n, z_0)$ is an ε-diamond. This can be accomplished for smooth curves by taking data points $z_0, \dots, z_n, z_0$ with small mesh size and discarding the last few $z_{n-n_1}, \dots, z_n$, where n_1 is an integer depending on ε and on $\partial\Omega$. The remaining subset still has small mesh size (albeit larger). This process of removing the last few data points is necessary to apply the proof of Theorem 3.10, but in practice it is omitted. We view it only as a defect in the method of proof.

If $\partial\Omega \in C^1$ and if φ is a conformal map of Ω onto $\mathbb{D}$, then $\arg(\varphi^{-1})'$ is continuous. Indeed, it gives the direction of the unit tangent vector. However, there are examples of C^1 boundaries where φ' and $(\varphi^{-1})'$ are not continuous. In fact, it is possible for both to be unbounded. If we make the slightly stronger assumption that $\partial\Omega \in C^{1+\alpha}$ for some $0 < \alpha < 1$, then $\varphi \in C^{1+\alpha}$ and $\varphi^{-1} \in C^{1+\alpha}$ by Kellogg's theorem (see [GM, p. 62]). In particular, the derivatives are bounded above and below on $\overline{\Omega}$ and $\overline{\mathbb{D}}$, respectively. Because of Proposition 3.12, we will consider the case $1 + \alpha = 3/2$. Similar results are true for $1 + \alpha < 3/2$.

THEOREM 5.3. *Suppose $\partial\Omega$ is a closed Jordan curve in $C^{3/2}$ and φ is a conformal map of Ω onto $\mathbb{D}$. Suppose $z_0, z_1, \ldots, z_n, z_0$ are data points on $\partial\Omega$ with mesh size $\mu = \max |z_j - z_{j+1}|$. Then there is a constant C_1 depending on the geometry of $\partial\Omega$, so that the Hausdorff distance between $\partial\Omega$ and $\partial\Omega_c$ satisfies*

$$d_H(\partial\Omega, \partial\Omega_c) \le C_1 \mu^{3/2} \tag{5.3}$$

and the conformal map φ_c satisfies

$$||\varphi^{-1} - \varphi_c^{-1}||_\infty \le C\mu^p \tag{5.4}$$

and

$$\sup_{z \in \Omega \cap \Omega_c} |\varphi(z) - \varphi_c(z)| \le C\mu^p \tag{5.5}$$

for every $p < 3/2$.

For example, if n data points are approximately evenly spaced on $\partial\Omega$, so that $\mu = C/n$, then the error estimates are of the form $C/n^{3/2}$ in (5.3) and C/n^p for $p < 3/2$ in (5.4) and (5.5). While Theorem 5.3 gives simple estimates in terms of the mesh size or the number of data points, smaller error estimates can be obtained with fewer data points if the data points are distributed so that there are fewer on subarcs where $\partial\Omega$ is flat and more where the boundary bends or where it folds back on itself. In other words, construct diamond-chains with angles ε_k satisfying the ε_k-pacman condition centered at z_k for each k. The errors will then be given by

$$\max_k \big(\varepsilon_k |z_k - z_{k+1}|\big)^p.$$

Proof. It is not hard to see from (5.2) that $\partial\Omega$ satisfies the ϵ-pacman condition with

$$\epsilon = C\mu^{1/2}$$

for C sufficiently large. By the proof of Theorem 3.10, $\partial\Omega_c$ is contained in the union of the diamonds. The diamonds $D(z_k, z_{k+1})$ have angle $C\mu^{1/2}$ and width bounded by $C\mu$, and therefore (5.3) holds.

Let ψ be a conformal map of $\mathbb{D}$ onto the complement of $\overline{\Omega}$, $\mathbb{C}^* \setminus \overline{\Omega}$. Then by Kellogg's theorem, as mentioned above, $\psi \in C^{3/2}$. In particular, $|\psi'|$ is bounded above and below on $1/2 < |z| < 1$. By the Koebe distortion theorem there are constants C_1, C_2 so that

$$C_1(1 - |z|) \le \operatorname{dist}(\psi(z), \partial\Omega) \le C_2(1 - |z|)$$

for all z with $1/2 < |z| < 1$. Thus we can choose $r = 1 - C_3\mu^{3/2}$ so that the image of the circle of radius r, $I_r = \psi(\{|z| = r\})$, does not intersect the diamond-chain and $d_H(I_r, \partial\Omega) \sim \mu^{3/2}$. Then the bounded component of the complement of I_r is a Jordan region U_r containing Ω and bounded by $I_r \in C^{3/2}$, with $C^{3/2}$ norm dependent only on $\partial\Omega$, and the bounds on $|\psi'|$.

Let σ be a conformal map of U_r onto $\mathbb{D}$. Inequality (5.4) now follows from [W, Theorem VIII] by comparing the conformal maps φ^{-1} and φ_c^{-1} to the conformal map σ^{-1}, where $\sigma : U_r \to \mathbb{D}$ and where all three (inverse) conformal maps are normalized to have positive derivative at 0 and map 0 to the same point in Ω.

To see (5.5), note that

$$\sigma(\partial\Omega \cup \partial\Omega_c) \subset \{z : 1 - |z| < c\mu^{3/2}\}.$$

Moreover, because $\partial\Omega \cup \partial\Omega_c$ is contained in the diamond-chain, and because both $\sigma \in C^{3/2}$ and $\sigma^{-1} \in C^{3/2}$, $\arg \sigma(\zeta)$ is increasing along $\partial\Omega$ for μ sufficiently small. By the remark after the proof of Lemma 4.6,

$$|\omega(0, \gamma, \sigma(\Omega)) - \omega(0, \gamma^*, \mathbb{D})| \le C\mu^{3/2} \log \mu$$

for every subarc γ of $\sigma(\partial\Omega)$, where γ^* denotes the radial projection of γ onto $\partial\mathbb{D}$. The same statements are true for $\partial\Omega_c$. Then (5.5) follows because the harmonic measure of the subarc γ_p of $\partial\Omega$ from p_0 to p is given by

$$\omega(0, \gamma_p, \Omega) = \frac{1}{2\pi} \arg\left(\frac{\varphi(p)}{\varphi(p_0)}\right),$$

and a similar statement is true for φ_c. □

The constant C in Theorem 5.3 depends on the quasiconformality constant $K = K(\partial\Omega)$, p, $\operatorname{diam}(\Omega)$, $\operatorname{dist}(0, \partial\Omega)$, and

$$M = \sup_{1/2<|z|<1} \big(|\psi'|, 1/|\psi'|\big),$$

where ψ is a conformal map of the complement of Ω to $\mathbb{D}$. If $I_r = \psi(\{|z| = r\})$ is replaced by a $C^{3/2}$ curve which is constructed geometrically instead of using the conformal map ψ, then the constant C can be taken to depend only on the geometry of the region Ω.

Similar results, albeit more complicated, for uniform convergence of the derivatives of the computed maps and the derivatives of their inverses could also be obtained from the results in [W2, Theorems III and V].

6. Some numerical results. An in-depth comparision of the algorithms in this article with other methods of conformal mapping and convergence rates will be written separately. To give the reader a sense of the speed and accuracy of computations, if 10,000 data points are given, it takes about 25 seconds with the geodesic algorithm to compute the conformal maps to the interior, the exterior, and their inverses on a 3.2 GHz Pentium IV computer. Since all of the basic maps are given explicitly in terms of elementary maps, the speed depends only on the number of points and not the shape of the region or the distribution of the data points. The accuracy can be measured if the true conformal map is known. For example,

$$f(z) = \frac{rz}{1 - (rz)^2},$$

where $r < 1$ maps the unit disc into an inverted ellipse. See Figure 12.

The region was chosen because it almost pinches off at 0, and because the stretching/compression given by $\max|f'| / \min|f'|$ is big for r near 1. This is sometimes called the "crowding phenomenon." We chose $r = .95$ and used as data points the image by f of 10,000 equally spaced points on the unit circle, and we compared the corresponding points on the unit circle computed by the geodesic algorithm with 10,000 equally spaced points. The errors were less than $1.8 \cdot 10^{-6}$. The same procedure using the zipper algorithm took 84 seconds and had errors less than $9.2 \cdot 10^{-8}$. When

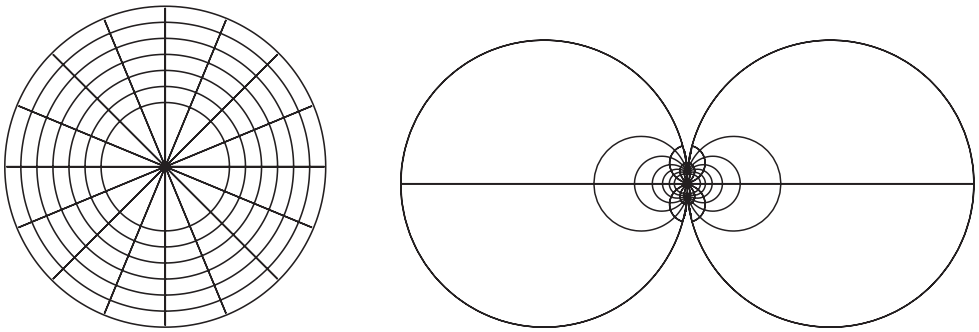

FIG. 12. *Inverted ellipse with* $r = .95$.

the number of data points was increased to 100,000, the time to run the geodesic algorithm increased to 25 minutes with errors less than $2 \cdot 10^{-8}$. In this example, the difference between successive (given) boundary data points on the inverted ellipse ranged from .025 to $3 \cdot 10^{-6}$ so that perhaps a better distribution of data points would have given even smaller errors.

In practice, the choice of data points corresponding to equally spaced points on the circle is not available. An alternative approach to this example is to select data points on the inverted ellipse which are approximately equally spaced in arc length. However, if we choose 10,000 points in this manner, then three consecutive points at the inward pointing "tips" of the region form a "turning angle" of more than 100° because the curvature is so large. This leads to relatively large errors in the map since the tip has large harmonic measure. Another method is to select data points so that the "turning angle"

$$\left|\arg\left(\frac{z_{k+1}-z_k}{z_k-z_{k-1}}\right)\right|$$

is not too big. This results in inaccuracies for this region because the curvature rapidly decreases to zero near the tips, and hence the data points are not very "evenly spaced."

A better method is to use a combination of these ideas. We generated a list of 10^6 points on the boundary of the inverted ellipse and then selected a subset using the following criteria: Having selected $z_1, \ldots, z_k$, choose z_{k+1} to be the first data point in the list after z_k satisfying

$$\left|\arg\left(\frac{z_{k+1}-z_k}{z_k-z_{k-1}}\right)\right| > \delta$$

or

$$\log\left|\frac{z_{k+1}-z_k}{z_k-z_{k-1}}\right| > \delta.$$

To compare with our previous results, we selected $\delta = .0025$ and thereby obtained 9,890 data points with the property that the "turning angle" is small and the ratio of lengths of successive arcs is close to 1. We compared the points on the unit circle obtained from the geodesic algorithm with the true inverse images. The maximal error was less than 5.3×10^{-6}. It is interesting to note that the maximal distance between successive points on the unit circle is 4.2×10^{-2} so that the errors are much

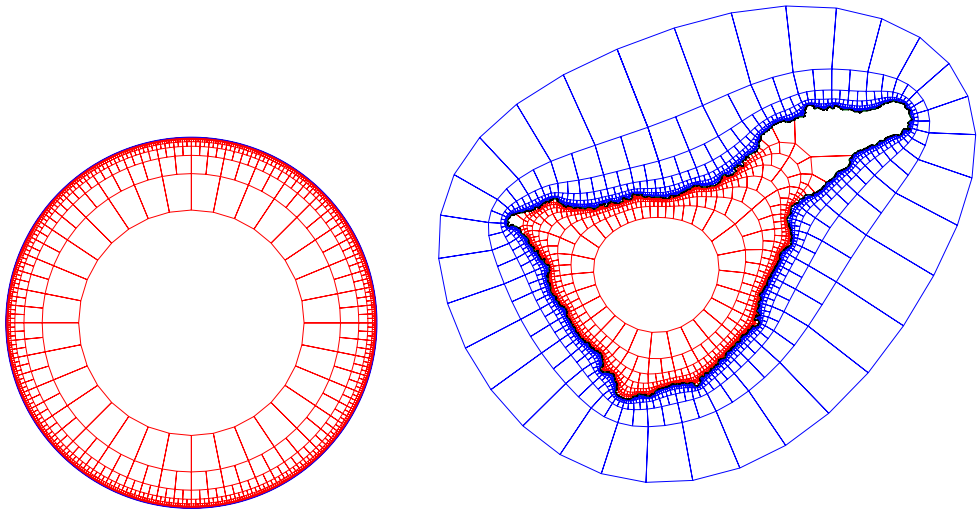

FIG. 13. *Tenerife.*

smaller than the harmonic measure of the corresponding arcs. This technique can be applied to any region where the boundary is known at a very large number of points.

Figure 13 shows the conformal map of a Carleson grid on the disc to both the interior and exterior of the island Tenerife (Canary Islands). We chose this region to illustrate the method on a nonsmooth region where no symmetry is involved. The center of the interior is the volcano Teide. It also shows both the original data for the coastline, connected with straight line segments, and the boundary curve connecting the data points using the zipper algorithm. At this resolution, it is not possible to see the difference between these curves. The zipper algorithm was applied to 6,168 data points and took 36 seconds. The image of 24,673 points on the unit circle took 48 seconds, and all of these points were within $9 \cdot 10^{-5}$ of the polygon formed by connecting the 6,168 data points. The points on the circle corresponding to the 6,168 vertices were mapped to points within 10^{-10} of the vertices. This error is due to the tolerance set for Newton's method, round-off error, and the compression/expansion of harmonic measure. The image of 8,160 vertices in the Carleson grid took 25 seconds to be mapped to the interior and 25 seconds to the exterior.

The first objection one might have in applying these algorithms with a large number of data points is that compositions of even very simple analytic maps can be quite chaotic. Indeed, this is the subject of the field of complex dynamics. We could redefine the basic maps f_a by composing with a linear fractional transformation of the upper-half plane so that the composed map is asymptotic to z as $z \to \infty$. This will not affect the computed curve in these algorithms since the next basic map begins with a linear fractional transformation (albeit altered). However, if we formulate the basic maps in this way, then because the maps are nearly linear near ∞, the numerical errors will accumulate only linearly.

Banjai and Trefethen [BT] adapted fast multipole techniques to the Schwarz–Christoffel algorithm and successfully computed the conformal map to a region which is bounded by a polygon with about 10^5 edges. They used a 12-fold symmetry in the region to immediately reduce the parameter problem to size 10^4. Any other

conformal mapping technique can also use symmetry and obtain a 12-fold reduction in the number of data points required; however, their work does show at least that Schwarz–Christoffel is possible with 10^4 vertices, though convergence of the algorithm to solve the parameter problem is not always ensured. The time it takes to run the zipper algorithm and the resulting accuracy for these snowflake regions is very close to the timing and accuracy for the fast multipole improvements in the Schwarz–Christoffel method. The geodesic algorithm is almost as good and has the advantage that it is very easy to code and convergence can be proved. For a region bounded by a polygon with a small number of vertices, where high accuracy is desired (for instance, errors on the order of 10^{-14}), the Schwarz–Christoffel method is preferable. It would be interesting to try to prove convergence of the technique used in [BT] to find the prevertices in the Schwarz–Christoffel representation for polygons which are K-quasicircles in terms of K. It would be interesting as well to apply multipole techniques to the zipper algorithm. A first step in this direction can be found in Kennedy [KT].

One additional observation worth repeating in this context is that the geodesic and zipper algorithms *always* compute a conformal map of $\mathbb{H}$ to a region bounded by a Jordan curve passing through the data points, even if the disc-chain or pacman conditions are not met. The image region can be found by evaluating the function at a large number of points on the real line. By Proposition 2.5 and Corollary 3.9, if the data points $\{z_j\}$ satisfy the hypotheses of Theorem 2.2 or 3.4, then φ can be analytically extended to be a conformal map of the original region Ω to a region very close to $\mathbb{D}$. To do so requires careful consideration of the appropriate branch of $\sqrt{z}$ at each stage of the composition.

Theorems 2.2 and 3.4 and their proofs suggest how to select points on the boundary of a region to give good accuracy for the mapping functions. Roughly speaking, points need to be chosen closer together where the region comes close to folding back on itself. See Figure 12, for example. Greater accuracy can be obtained by placing more points on the boundary near the center and fewer on the big lobes. See also the remarks after Theorem 5.3 in this regard. In practice, the zipper map works well if points are distributed so that

$$B(z_k, 5|z_{k+1} - z_k|) \cap \partial\Omega \tag{6.1}$$

is connected.

When the boundary of the given region is not smooth, then one of the processes described in section 2 should be used to generate the boundary data, if the geodesic algorithm is to be used. For example, if nothing is known about the boundary except for a list of data points, then we preprocess the data by taking data points along the line segments between the original data points, so that these new points correspond to points of tangency of disjoint circles centered on the line segments, including circles centered at the original data points. Note that the original boundary points are not among these new data points. The geodesic algorithm then finds a conformal map to a region with the new data points on the boundary. The boundary of the new region will be close to the polygonal curve through the original data points but will not pass through the original data points. This boundary is "rounded" near the original data points. Indeed, it is a smooth curve.

When the boundary of the desired region is less smooth, for example, with "corners," then the zipper or slit algorithms should be used. In this case additional points are placed along the line segments between the data points, with at least five points

per edge and satisfying (6.1). In practice, at least 500 points are chosen on the boundary so that the image of the circle will be close to the polygonal line through the data points. Since two data points are pulled down to the real line with each basic map in the zipper algorithm, the original data points should occur at even numbered indices in the resulting data set (the first data point is called z_0). Then the computed boundary Ω_c will have corners at each of the original data points, with angles very close to the angles of the polygon through the original data points.

Fortran programs for a version of the zipper algorithm can be obtained from [MD]. Also included is a graphics program, written in C with X-11 graphics by Mike Stark, for the display of the conformal maps. There are also several demo programs applying the algorithm to problems in elementary fluid flow, extremal length, and hyperbolic geometry. Extensive testing of the geodesic algorithm [MM] and an early version of the zipper algorithm was done in the 1980s with Morrow. In particular, that experimentation suggested the initial function φ_0 in the zipper algorithm which maps the complement of a circular arc through z_0, z_1, and z_2 onto $\mathbb{H}$.

Appendix. Jørgensen's theorem. Since Jørgensen's theorem is a key component of the proof of the convergence of the geodesic algorithm, we include a short self-contained proof. It says that discs are strictly convex in the hyperbolic geometry of a simply connected domain Ω (unless $\partial\Omega$ is contained in the boundary of the disk).

THEOREM A.1 (Jørgensen [J]). *Suppose Ω is a simply connected domain. If Δ is an open disc contained in Ω and if γ is a hyperbolic geodesic in Ω, then $\gamma \cap \Delta$ is connected, and if it is nonempty, it is not tangent to $\partial\Delta$ in Ω.*

Proof (see [P, pp. 91–93]). Applying a linear fractional transformation to Ω, we replace the disc Δ by the upper-half plane $\mathbb{H}$. Suppose $x \in \mathbb{R}$ and suppose that f is a conformal map of $\mathbb{D}$ onto Ω such that $f(0) = x$ and $f'(0) > 0$. We will use the auxiliary function $z + 1/z$, which is real-valued on $\partial\mathbb{D} \cup (-1, 1)$. Then

$$\operatorname{Im}\left(\frac{f'(0)}{f(z) - x} - \left(\frac{1}{z} + z \right) \right)$$

is a bounded harmonic function on $\mathbb{D}$ which is greater than or equal to 0 by the maximum principle. Thus $\operatorname{Im} \frac{f'(0)}{f(z)-x} \geq 0$ on $(-1, 1)$, and hence $\operatorname{Im} f(z) \leq 0$ on the diameter $(-1, 1)$. The condition $f'(0) > 0$ means that the geodesic $f\big((-1, 1)\big)$ is tangent to $\mathbb{R}$ at x. Two circles which are orthogonal to $\partial\mathbb{D}$ can meet in $\mathbb{D}$ in at most one point, and hence hyperbolic geodesics in simply connected domains (images of orthogonal circles) meet in at most one point and are not tangent. Thus if γ is a geodesic in Ω which intersects $\mathbb{H}$ and contains the point x, then it cannot be tangent to $\mathbb{R}$ at x and cannot re-enter $\mathbb{H}$ after leaving it at x because it is separated from $\mathbb{H}$ by the geodesic $f\big((-1, 1)\big)$. The theorem follows. □

In section 2, we commented that a constructive proof of the Riemann mapping theorem followed from the proof of Theorem 2.2. The application of Jørgensen's theorem in the proof of Theorem 2.2 is only to domains for which the Riemann map has been explicitly constructed.

Acknowledgments. The first author would like to express his deep gratitude to L. Carleson for our exciting investigations at The Mittag-Leffler Institute (1982–1983) which led to the discovery of the zipper algorithms. We would like to thank the referees for careful reading and useful comments.

CONVERGENCE RATES OF GENERAL REGULARIZATION METHODS FOR STATISTICAL INVERSE PROBLEMS AND APPLICATIONS*

N. BISSANTZ†, T. HOHAGE‡, A. MUNK‡, AND F. RUYMGAART§

Abstract. Previously, the convergence analysis for linear statistical inverse problems has mainly focused on spectral cut-off and Tikhonov-type estimators. Spectral cut-off estimators achieve minimax rates for a broad range of smoothness classes and operators, but their practical usefulness is limited by the fact that they require a complete spectral decomposition of the operator. Tikhonov estimators are simpler to compute but still involve the inversion of an operator and achieve minimax rates only in restricted smoothness classes. In this paper we introduce a unifying technique to study the mean square error of a large class of regularization methods (spectral methods) including the aforementioned estimators as well as many iterative methods, such as ν-methods and the Landweber iteration. The latter estimators converge at the same rate as spectral cut-off but require only matrix-vector products. Our results are applied to various problems; in particular we obtain precise convergence rates for satellite gradiometry, L^2-boosting, and errors in variable problems.

Key words. statistical inverse problems, iterative regularization methods, Tikhonov regularization, nonparametric regression, minimax convergence rates, satellite gradiometry, Hilbert scales, boosting, errors in variable

1. Introduction.

This paper is concerned with estimating an element f of a Hilbert space $\mathbb{H}_1$ from indirect noisy measurements

$$Y = Kf + \text{“noise”} \tag{1.1}$$

related to f by a (known) operator $K : \mathbb{H}_1 \to \mathbb{H}_2$ mapping $\mathbb{H}_1$ to another Hilbert space $\mathbb{H}_2$. The operator K is assumed to be linear, bounded, and injective, but *not* necessarily compact. We are interested in the case that the operator equation (1.1) is ill-posed in the sense that the Moore–Penrose inverse of K is unbounded. The analysis of regularization methods for the stable solution of (1.1) depends on the mathematical model for the noise term on the right-hand side of (1.1): If the noise is considered as a deterministic quantity, it is natural to study the worst-case error. In the literature a number of efficient methods for the solution of (1.1) have been developed, and it has been shown under certain conditions that the worst-case error converges at optimal order as the noise level tends to 0 (see Engl, Hanke, and Neubauer [14]). If the noise is modeled as a random quantity, the convergence of estimators $\hat{f}$ of f should be studied in statistical terms. Here we consider the expected square error $\mathbf{E}\,\|\hat{f} - f\|^2$, also

called the *mean integrated square error* (MISE). This problem has also been studied extensively in the statistical literature, but the numerical efficiency has not been a major issue so far. It is the purpose of this paper to provide an analysis of a class of computationally efficient regularization methods including Landweber iteration, ν-methods, and iterated Tikhonov regularization, which is applicable to linear inverse problems with random noise as they occur, for example, in parameter identification problems in partial differential equations (PDEs), deconvolution, or errors in variable models.

There exists a considerable amount of literature on regularization methods for linear inverse problems with random noise. For surveys we refer to O'Sullivan [37], Nychka and Cox [36], Evans and Stark [16], and Kaipio and Somersalo [26]. A large part of the literature focuses on methods which require the explicit knowledge of a spectral decomposition of the operator K^*K. The simplest of these methods is spectral cut-off (or truncated singular value decomposition (SVD) for compact operators) where an estimator is constructed by a truncated expansion of f with respect to (w.r.t.) the eigenfunctions of K^*K (see, e.g., Diggle and Hall [10] and Healy, Hendriks, and Kim [21]). It has been shown in a number of papers that spectral cut-off estimators are order optimal in a minimax sense under certain conditions (see, e.g., Mair and Ruymgaart [30], Efromovich [13], and Kim and Koo [27]). Based on an SVD of K it is also possible to construct exact minimax estimators for given smoothness classes (see Johnstone and Silverman [25]).

Another major approach is wavelet-vaguelette (and vaguelette-wavelet)-based methods which lead to estimators of a functional form similar to that of SVD methods. In general these estimators are based on expansions of f and Kf w.r.t. different bases of the respective function spaces than those provided by the SVD of K (see, e.g., Donoho [12], Abramovich and Silverman [1], and Johnstone et al. [24]).

A well-known method both in the statistical and the deterministic inverse problems literature is Tikhonov regularization. This has been studied for certain classes of linear statistical inverse problems by Cox [9], Nychka and Cox [36], and Mathé and Pereverzev [31, 33].

The main restriction of the usefulness of spectral cut-off and related estimators is the need of the spectral data of the operator (i.e., an SVD if K is compact) to implement these estimators. This is known explicitly only in a limited number of special cases, and numerical computation of the spectral data is prohibitively expensive for many situations. Although Tikhonov regularization does not require the spectral data of the operator, there is still the requirement of setting up and inverting a matrix representing the operator. For iterative regularization methods such as Landweber iteration or ν-methods (see Nemirovskii and Polyak [35], Brakhage [6], and Engl, Hanke, and Neubauer [14]) only matrix-vector multiplications are required. Furthermore, it is known that Tikhonov regularization achieves minimax rates of convergence only in a restricted number of smoothness classes, which is highlighted by the fact that its qualification number is 1, whereas Landweber iteration has infinitely large qualification, and ν-methods with qualification ν are available for every $\nu > 0$ (see [14]).

Iterative regularization methods are particularly attractive for inverse problems in PDEs. Here the operator K maps an unknown parameter f in a PDE to (part of) the solution to this PDE. Hence, applying K to a vector f simply means solving the PDE with the parameter f, whereas inverting or even setting up the matrix for K is often not feasible. We will discuss two linear inverse problem for PDEs (the backwards

heat equation and satellite gradiometry) in section 5. However, most inverse problems for PDEs are nonlinear even if the PDE is linear. Such problems are often solved by regularized Newton methods. In this case the methods and the analysis of this paper can be applied to the linearized operator equations in each Newton step as discussed in the forthcoming paper [2].

In this paper we will show that general spectral regularization methods as defined in section 2 achieve the same rates of convergence of the MISE as spectral cut-off, which is known to be optimal in most cases (see above). Whereas the bias or approximation error is exactly the same in a deterministic and a statistical framework, the analysis significantly differs in the estimation of the noise term. In spectral cut-off for compact operators, the noise (or variance) part of the estimators $\hat{f}_\alpha$ belongs to a finite-dimensional space of "low-frequencies." The main difficulty in the analysis of general spectral regularization methods is the estimation of the "high frequency" components of the noise. Unlike in a deterministic framework, the bound on the noise term depends not only on the regularization parameter, but also on the distribution of the singular values of K (if K is compact). Therefore, a statistical analysis has to impose additional conditions on the operator. We will verify these conditions for several important problems, including inverse problems in PDEs and errors in variable models. As an example of particular interest in the machine learning context we obtain optimal rates of convergence of L^2-boosting by interpreting L^2-boosting as a Landweber iteration (see also Bühlmann and Yu [7] and Yao, Rosasco, and Caponnetto [42]).

The plan of this paper is as follows: Section 2 gives a brief overview of regularization methods and source conditions and introduces an abstract noise model. Section 3 contains the main results of this paper on the rates of convergence of general spectral regularization methods. In section 4 we demonstrate how a number of commonly used statistical noise models fit into our general framework. Finally, in section 5 we discuss the application of our results to the backwards heat equation, satellite gradiometry, errors in variable models with dependent random variables, L^2-boosting, and operators in Hilbert scales. Proofs of section 3 are collected in section 6.

2. Framework.

We first review some basic notions of regularization theory.

2.1. Spectral theorem.

Halmos's version of the spectral theorem (see, for instance, Halmos [20] and Taylor [40]) turns out to be particularly convenient for the construction and statistical analysis of regularized inverses of a self-adjoint operator. This has been demonstrated by Mair and Ruymgaart [30] for the spectral cut-off estimator. The theorem claims that for a (not necessarily bounded) self-adjoint operator $A : D(A) \to \mathbb{H}$ defined on a dense subset $D(A)$ of a separable Hilbert space $\mathbb{H}$ there exists a σ-compact space $\mathbb{S}$, a Borel measure Σ on $\mathbb{S}$, a unitary operator $U : \mathbb{H} \to L^2(\Sigma)$, and a measurable function $\rho : \mathbb{S} \to \mathbb{R}$ such that

$$UAf = \rho \cdot Uf, \qquad \Sigma\text{-a.e.}, \tag{2.1}$$

for all $f \in D(A)$. Introducing the multiplication operator $M_\rho : D(M_\rho) \to L^2(\Sigma)$, $M_\rho\varphi := \rho \cdot \varphi$ defined on $D(M_\rho) := \{\varphi \in L^2(\Sigma) : \rho\varphi \in L^2(\Sigma)\}$, we can rewrite (2.1) as $A = U^* M_\rho U$, i.e., A is unitarily equivalent to a multiplication operator. The essential range of ρ is the spectrum $\sigma(A)$ of A. If A is bounded and positive definite as below, then $0 < \rho \le \|A\|$, Σ-a.e.

Remark 1. In the special case that A is compact, a well-known version of the spectral theorem states that A has a complete orthonormal system of eigenvectors

u_i with corresponding eigenvalues ρ_i, and $Af = \sum_{j=0}^{\infty} \rho_j \langle u_j, f\rangle u_j$. This can be rewritten in the multiplicative form (2.1) by choosing Σ as the counting measure on $\mathbb{S} = \mathbb{N}$, i.e., $L^2(\Sigma) = l^2(\mathbb{N})$, the multiplicator function as $\rho(i) = \rho_i$, $i \in \mathbb{N}$, and defining the unitary operator $U : \mathbb{H} \to l^2(\mathbb{N})$ by $(Uf)(i) := \langle f, u_i\rangle$, $i \in \mathbb{N}$.

2.2. Regularized estimators. Recall Halmos's spectral theorem from section 2.1. For a self-adjoint operator $A : D(A) \to \mathbb{H}$ and a bounded, measurable function $\Phi : \sigma(A) \to \mathbb{R}$ one defines an operator $\Phi(A) \in L(\mathbb{H})$ by

$$\Phi(A) = U^* M_{\Phi(\rho)} U \tag{2.2}$$

(see, e.g., Taylor [40]). The mapping $\Phi \mapsto \Phi(A)$, called the *functional calculus* at A, is an algebra homomorphism from the algebra of bounded measurable functions on $\sigma(A)$ to the algebra $L(\mathbb{H})$ of bounded linear operators on $\mathbb{H}$, and

$$\|\Phi(A)\| \le \sup_{\lambda \in \sigma(A)} |\Phi(\lambda)|, \tag{2.3}$$

with equality if Φ is continuous. We will construct estimators of the input function by regularization methods of the form

$$\hat{f}_{\alpha,\sigma} = \Phi_\alpha(K^*K)K^*Y. \tag{2.4}$$

Here $\Phi_\alpha : \sigma(K^*K) \to \mathbb{R}$ is a collection of bounded filter functions approximating the unbounded function $t \mapsto \frac{1}{t}$ on $\sigma(K^*K)$, which are parametrized by a *regularization parameter* $\alpha > 0$.

A particular example of a regularization method of the form (2.4) is the *spectral cut-off* estimator (also known as *truncated SVD*) described by the functions

$$\Phi_\alpha^{\mathrm{SC}}(t) := \begin{cases} t^{-1}, & t \ge \alpha, \\ 0, & t < \alpha. \end{cases}$$

As explained in the introduction, we will focus on regularization methods which can be implemented without explicit knowledge of the spectral decomposition of the operator K^*K. This includes both *implicit methods* such as Tikhonov regularization ($\Phi_\alpha(t) = (\alpha + t)^{-1}$), iterated Tikhonov regularization, and Lardy's method, which involve the inversion of an operator, and *explicit methods* such as Landweber iteration ($\Phi_{1/(k+1)}(t) = \sum_{j=0}^{k-1}(1 - \beta t)^j$, where $\beta \in (0, \|K^*K\|^{-2})$ is a step-length parameter, and ν-methods, which require only matrix-vector products in a discrete setting. For a derivation and discussion of these methods we refer to the monograph [14].

2.3. Smoothness classes. We will measure the smoothness of the input function f relative to the smoothing properties of K in terms of *source conditions*: Let $\Lambda : [0, \infty) \to [0, \infty)$ be a continuous, strictly increasing function with $\Lambda(0) = 0$, and assume that there exists a "source" $w \in \mathbb{H}_1$ such that

$$f = \Lambda(K^*K)w \tag{2.5}$$

(see [14, 15, 32]). The set of all f satisfying this condition with $\|w\|_{\mathbb{H}_1} \le \overline{w}$, $\overline{w} > 0$ will be denoted by $F_{\Lambda,\overline{w},K^*K} := \{\Lambda(K^*K)w : w \in \mathbb{H}_1, \|w\| \le \overline{w}\}$. We will shorten this to $F_{\Lambda,\overline{w}} := F_{\Lambda,\overline{w},K^*K}$ if there is no ambiguity. The most common choice, which is usually appropriate for finitely smoothing operators K, is

$$\Lambda(t) = t^\nu, \qquad \nu > 0. \tag{2.6}$$

In particular, (2.5) with $\Lambda(t) = \sqrt{t}$ is equivalent to $f = K^*v$, $\|v\|_{\mathbb{H}_2} \leq 1$ (see Engl, Hanke, and Neubauer [14, Prop. 2.18]). For exponentially ill-posed problems such as the backwards heat equation, (2.6) is usually too restrictive, and *logarithmic source conditions* corresponding to the choice

$$\Lambda(t) = (-\ln t)^{-p}, \qquad p > 0, \tag{2.7}$$

are more appropriate (see Hohage [23] and Mair [29]). Since Λ is singular at $t = 1$, we assume that the norms in $\mathbb{H}_1$ and $\mathbb{H}_2$ are scaled such that $\|K^*K\| < 1$ in this case. For a further discussion of source conditions and interpretations as smoothness conditions in Sobolev spaces we refer to the applications in section 5.

If f belongs to the smoothness class $F_{\Lambda,\overline{w}}$ and we are given exact data $Y = g$, then the error is bounded by

$$\begin{aligned} \|\Phi_\alpha(K^*K)K^*g - f\| &= \|(\Phi_\alpha(K^*K)K^*K - I)\Lambda(K^*K)w\| \\ &\leq \sup_{t\in\sigma(K^*K)} |(\Phi_\alpha(t)t - 1)\Lambda(t)|\overline{w}, \end{aligned} \tag{2.8}$$

where we have used (2.3).

2.4. Assumptions on smoothness and the regularization method. In the following we discuss a number of standard assumptions on the filter functions Φ_α satisfied for all commonly used regularization methods, in particular those discussed in section 2.2 (see [14]). First, we assume that there exists a constant $C_2 > 0$ such that

$$\sup_{t\in\sigma(K^*K)} |t\Phi_\alpha(t)| \leq C_2, \qquad \text{uniformly in } \alpha > 0. \tag{2.9a}$$

To bound the so-called propagated deterministic noise error $\tau\|\Phi_\alpha(K^*K)K^*\xi\|$, we impose the following condition:

$$\text{there exists } C_3 > 0 : \sup_{\alpha>0} \sup_{t\in\sigma(K^*K)} |\alpha\Phi_\alpha(t)| \leq C_3. \tag{2.9b}$$

In view of the bound (2.8) on the approximation error, we also assume that there exists a number $\nu_0 > 0$ called *qualification* of the method and constants $\gamma_\nu > 0$ such that

$$\sup_{t\in\sigma(K^*K)} |t^\nu(1 - t\Phi_\alpha(t))| \leq \gamma_\nu\alpha^\nu \qquad \text{for all } \alpha \text{ and all } 0 \leq \nu \leq \nu_0. \tag{2.9c}$$

The qualification of a method is a measure of the maximal degree of smoothness in terms of the Hölder-type conditions (2.5), (2.6) under which the approximation error (2.8) converges at optimal order. The following are qualifications of some commonly used methods: Tikhonov regularization: 1; K-times iterated Tikhonov regularization: K; Landweber iteration: ∞ (in the sense that it is greater than any real number); ν-methods: ν (where $\nu > 0$ is a parameter in the method); see references in the introduction.

Note that the condition (2.9c) with $\nu_0 > 0$ implies that $\lim_{\alpha\searrow 0} \Phi_\alpha(t) = \frac{1}{t}$ for all $t \in \sigma(K^*K)$. For $\nu = 0$ the condition (2.9c) implies (2.9a) with $C_2 = 1+\gamma_0$. However, this value of C_2 is usually not optimal since for most regularization methods (2.9a) holds true with $C_2 = 1$.

For general source conditions we assume that there exists a constant γ_Λ such that

$$\sup_{t\in\sigma(K^*K)} |\Lambda(t)(1-t\Phi_\alpha(t))| \le \gamma_\Lambda \Lambda(\alpha), \qquad \alpha \searrow 0. \tag{2.10}$$

Under Hölder-type source conditions (2.6) this holds true for $\nu \le \nu_0$ by assumption (2.9c). For the choice $\Lambda(t) = (-\ln t)^{-p}$, it has been shown in Hohage [23] that (2.9c) with $\nu_0 > 0$ implies (2.10). For more general functions Λ we refer to Mathé and Pereverzev [32] for similar implications.

2.5. Noise model. In this subsection we introduce an abstract noise model which will be used in the proof of our main result. In section 4 we will demonstrate that several noise models commonly encountered in statistical modeling fit into this general framework.

Following Mathé and Pereverzev [31], we assume that our given data can be written as

$$Y = g + \sigma\varepsilon + \tau\xi, \qquad g := Kf, \tag{2.11}$$

where $\xi \in \mathbb{H}_2$, $\|\xi\| \le 1$ is a deterministic error, ε is a stochastic error, and $\tau, \sigma > 0$ are the corresponding noise levels. Note that model (2.11) allows for stochastic and deterministic noise, simultaneously.

Often, the stochastic error is modeled as a Hilbert space–valued random variable Ξ, i.e., a measurable function $\Xi : \Omega \to \mathbb{H}_2$, where $(\Omega, \mathcal{P}, P)$ is the underlying probability space. However, we will assume more generally that it is a Hilbert-space process, i.e., a continuous linear operator

$$\varepsilon : \mathbb{H}_2 \to L^2(\Omega, \mathcal{P}, P).$$

Every Hilbert space–valued random variable Ξ with finite second moments, $\mathbf{E}\,\|\Xi\|^2 < \infty$, can be identified with a Hilbert-space process $\varphi \mapsto \langle \Xi, \varphi\rangle$, $\varphi \in \mathbb{H}_2$, but not vice versa. We will use the notation $\langle \varepsilon, \varphi\rangle := \varepsilon\varphi$, $\varphi \in \mathbb{H}_2$. The covariance $\mathbf{Cov}_\varepsilon : \mathbb{H}_2 \to \mathbb{H}_2$ of a Hilbert-space process $\varepsilon : \mathbb{H}_2 \to L^2(\Omega, \mathcal{P}, P)$ is the bounded linear operator defined implicitly by $\langle \mathbf{Cov}_\varepsilon \varphi_1, \varphi_2\rangle = \mathbf{Cov}\left(\langle \varepsilon, \varphi_1\rangle, \langle \varepsilon, \varphi_2\rangle\right)$, $\varphi_1, \varphi_2 \in \mathbb{H}_2$. We call ε a *white noise process* if $\mathbf{Cov}_\varepsilon = I$ and $\mathbf{E}\,\langle \varepsilon, \varphi\rangle = 0$ for all $\varphi \in \mathbb{H}_2$. Note that a Gaussian white noise process in an infinite-dimensional Hilbert space cannot be identified with a Hilbert space–valued random variable.

If $\varepsilon : \mathbb{H}_2 \to L^2(\Omega, \mathcal{P}, P)$ is a Hilbert-space process and $A : \mathbb{H}_2 \to \mathbb{H}_1$ is a bounded linear operator, we define the Hilbert-space process $A\varepsilon : \mathbb{H}_1 \to L^2(\Omega, \mathcal{P}, P)$ by $\langle A\varepsilon, \varphi\rangle := \langle \varepsilon, A^*\varphi\rangle$, $\varphi \in \mathbb{H}_1$. Its covariance operator is given by $\mathbf{Cov}_{A\varepsilon} = A\mathbf{Cov}_\varepsilon A^*$.

Assumption 1. In the noise model (2.11) $\xi \in \mathbb{H}_2$ is a deterministic vector with $\|\xi\| = 1$, and ε is a Hilbert-space process such that

$$\mathbf{E}\,\langle \varepsilon, \varphi\rangle = 0, \qquad \|\mathbf{Cov}_\varepsilon\| \le 1 \tag{2.12}$$

for all $\varphi \in \mathbb{H}_2$. Moreover, $K^*\varepsilon$ is a Hilbert space–valued random variable satisfying

$$\mathbf{E}\,\|K^*\varepsilon\|^2 < \infty, \tag{2.13}$$

and there exists a spectral decomposition (2.1) of K^*K such that for almost all $s \in \mathbb{S}$

$$\mathbf{Var}\,(UK^*\varepsilon(s)) \le \rho(s). \tag{2.14}$$

The first condition in (2.12) is not a restriction since an expected value different from zero can be included in $\tau\xi$, and the second condition is a scaling condition analogous to $\|\xi\| \le 1$. Assumption (2.13) ensures that the estimators defined in (2.4) are Hilbert space–valued random variables with finite second moments. Inequality (2.13) is usually a mild assumption, but it excludes, e.g., very mildly ill-posed problems in combination with white noise. The following lemma implies that (2.14) is a condition on the choice of U in the Halmos representation (2.1) rather than a condition on the noise model. Moreover, we can arrange that $\rho \in L^1(\Sigma)$, as required in section 3 below. Noise models with a finite number of observations satisfying Assumption 1 are discussed in section 4 below.

LEMMA 2. *If ε is a Hilbert-space process satisfying* (2.12), *$K^*\varepsilon$ is a Hilbert space–valued random variable satisfying* (2.13), *and K is injective, then there exists a spectral decomposition* (2.1) *of K^*K such that* (2.14) *holds true, and $\rho \in L^1(\Sigma)$.*

Proof. According to Halmos's spectral theorem there exists a Borel measure $\tilde\Sigma$ on a σ-compact space $\mathbb{S}$, and a unitary operator $\tilde U : L^2(\mathbb{R}^d) \to L^2(\tilde\Sigma)$ such that $K^*K = \tilde U^* M_\rho \tilde U$. For any $\tilde\Sigma$-measurable function $\chi > 0$ on $\mathbb{S}$ we can construct another Halmos representation of K^*K by introducing the Borel measure $\Sigma := \chi\tilde\Sigma$ on $\mathbb{S}$ and the mapping $U : L^2(\mathbb{R}^d) \to L^2(\Sigma)$, $Uf := \chi^{-1/2} \cdot \tilde U f$ since U is unitary and $UK^*Kf = \rho \cdot Uf$, Σ-a.e., for all $f \in \mathbb{H}_1$. In particular, we may define

(2.15)
$$\chi(s) := \frac{\mathbf{Var}\,(\tilde U K^*\varepsilon)(s)}{\rho(s)} \qquad \text{for } s \in M, \quad M := \{s \in \mathbb{S} : \mathbf{Var}\,(\tilde U K^*\varepsilon)(s) > 0\}.$$

Here we use that $\rho > 0$, $\tilde\Sigma$-a.e., since K and hence K^*K is injective by assumption. We first consider the case $\tilde\Sigma(M^c) = 0$, where $M^c := \mathbb{S} \setminus M$. Then (2.14) holds true for $s \in M$ as $\mathbf{Var}\,(UK^*\varepsilon)(s) = \chi(s)^{-1}\mathbf{Var}\,(\tilde U K^*\varepsilon)(s) = \rho(s)$. Moreover,

$$\int \rho \,\mathrm{d}\Sigma = \int \mathbf{Var}\,(UK^*\varepsilon)\,\mathrm{d}\Sigma = \mathbf{E}\int |UK^*\varepsilon|^2\,\mathrm{d}\Sigma = \mathbf{E}\,\|K^*\varepsilon\|^2 < \infty, \tag{2.16}$$

which is the assertion. Now assume that $\tilde\Sigma(M^c) > 0$. Let ψ be an arbitrary strictly positive function in $L^1(\tilde\Sigma)$, e.g., $\psi(s) := \big(j(s)^2\tilde\Sigma(A_{j(s)})\big)^{-1}$, where $j(s) := \min\{j : s \in A_j\}$ for a sequence $A_1 \subset A_2 \subset \cdots \subset \Omega$ with $\tilde\Sigma(A_j) < \infty$ and $\tilde\Sigma(\mathbb{S} \setminus \bigcup_j A_j) = 0$. Such a sequence exists because $\tilde\Sigma$ is σ-finite. We define $\chi(s)$ by (2.15) for $s \in M$ and $\chi(s) := \frac{\psi(s)}{\rho(s)}$ for $s \in M^c$. Then (2.14) is trivially satisfied for $s \in M^c$, and $\rho \in L^1(\Sigma)$ since $\int_M \rho\,\mathrm{d}\Sigma < \infty$ as in (2.16) and $\int_{M^c} \rho\,\mathrm{d}\Sigma \le \int \psi\,\mathrm{d}\tilde\Sigma < \infty$. This finishes the proof. ∎

3. MISE estimates. In this section the main results of this paper are presented. Recall the definition of the estimator $\hat f_{\alpha,\sigma}$ of the input function f in (2.4). Since $\mathbf{E}\,\Phi_\alpha(K^*K)K^*\varepsilon = 0$, the MISE satisfies the bias-variance decomposition

$$\mathbf{E}\,\|\hat f_{\alpha,\sigma} - f\|^2 = \mathbf{B}\,(\hat f_{\alpha,\sigma})^2 + \mathbf{E}\,\|\hat f_{\alpha,\sigma} - \mathbf{E}\,\hat f_{\alpha,\sigma}\|^2, \tag{3.1}$$

with the bias term $\mathbf{B}\,(\hat f_{\alpha,\sigma}) := \|\mathbf{E}\,\hat f_{\alpha,\sigma} - f\|$. As discussed in the introduction, the bias term can be bounded by standard estimates, whereas the variance term requires a special treatment involving a splitting in the frequency domain.

3.1. Estimation of the bias. The bias in our model coincides with the error in a deterministic setting and can be estimated by standard techniques (see [14]).

Using the triangle inequality, the noise model (2.11), (2.12), and the definition (2.4) of $\hat{f}_{\alpha,\sigma}$, we get

$$\mathbf{B}\,(\hat{f}_{\alpha,\sigma}) \le \|\Phi_\alpha(K^*K)K^*Kf - f\| + \tau\|\Phi_\alpha(K^*K)K^*\xi\|.$$

The first term (called the approximation error) is bounded by $\gamma_\Lambda\Lambda(\alpha)\overline{w}$ due to (2.8) and (2.10). For the second term (called the propagated deterministic noise error) we obtain the bound

$$\|\Phi_\alpha(K^*K)K^*\xi\|^2 = \langle\Phi_\alpha(KK^*)\xi, KK^*\Phi_\alpha(KK^*)\xi\rangle \le \frac{C_2C_3}{\alpha} \tag{3.2}$$

using the identity $\Phi_\alpha(K^*K)K^* = K^*\Phi_\alpha(KK^*)$ (see [14, eq. (2.43)]) and (2.9). Hence,

$$\mathbf{B}\,(\hat{f}_{\alpha,\sigma}) \le \gamma_\Lambda\Lambda(\alpha)\overline{w} + \sqrt{\frac{C_2C_3}{\alpha}}\tau. \tag{3.3}$$

Since we aim to show optimality of general regularization methods by comparison to spectral cut-off (see the introduction and section 3.3), we now compare the approximation errors of general regularization methods and spectral cut-off. To this end, we introduce the following notation.

Notation. For two real-valued functions f, g defined on an interval $(0, \bar{\alpha}]$ we write

$$f(\alpha) \sim g(\alpha) \qquad (\text{or } f(\alpha) \lesssim g(\alpha)), \qquad \text{as } \alpha \searrow 0,$$

if $g(\alpha) \neq 0$ for α in some neighborhood of 0 and $\lim_{\alpha\searrow 0}\frac{f(\alpha)}{g(\alpha)} = 1$ or $\limsup_{\alpha\searrow 0}\frac{f(\alpha)}{g(\alpha)} \le 1$. Furthermore, we write

$$f(\alpha) \asymp g(\alpha), \qquad \text{as } \alpha \searrow 0,$$

if there exist constants $\bar{\alpha} > 0$ and $C_{\bar{\alpha}} \ge 1$ such that $(1/C_{\bar{\alpha}})f(\alpha) \le g(\alpha) \le C_{\bar{\alpha}}f(\alpha)$ for $0 < \alpha \le \bar{\alpha}$.

Recall that $\Lambda : [0,\infty) \to [0,\infty)$ is assumed to be a strictly increasing, continuous function with $\Lambda(0) = 0$ and that $1 - t\Phi_\alpha^{\mathrm{SC}}(t) = \chi_{[0,\alpha]}(t)$, i.e., $(I - K^*K\Phi_\alpha^{\mathrm{SC}}(K^*K))$ is an orthogonal projection operator. Therefore,

$$\sup_{f\in F_{\Lambda,\overline{w}}}\|(I - K^*K\Phi_\alpha^{\mathrm{SC}}(K^*K))f\| = \sup_{t\in\sigma(K^*K)}(1 - t\Phi_\alpha^{\mathrm{SC}}(t))\Lambda(t)\overline{w} \sim \Lambda(\alpha)\overline{w}, \quad \alpha \searrow 0.$$

The last relation holds since 0 is not an isolated point of the spectrum $\sigma(K^*K)$ for ill-posed operator equations. Using (2.8) and (2.10) we obtain the estimate

$$\begin{aligned}\sup_{f\in F_{\Lambda,\overline{w}}}&\|(I - K^*K\Phi_\alpha(K^*K))f\| \\ &\le \gamma_\Lambda\Lambda(\alpha)\overline{w} \sim \gamma_\Lambda \sup_{f\in F_{\Lambda,\overline{w}}}\|(I - K^*K\Phi_\alpha^{\mathrm{SC}}(K^*K))f\|\end{aligned} \tag{3.4}$$

as $\alpha \searrow 0$. For many regularization methods and smoothness classes we have $\gamma_\Lambda \le 1$.

3.2. Estimation of the integrated variance and rate of convergence of the MISE. The more difficult part is the estimation of the integrated variance of the error $\hat{f}_{\alpha,\sigma} - f$. Under Assumption 1 we have

$$\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - \mathbf{E}\,\hat{f}_{\alpha,\sigma}\|^2 = \sigma^2\mathbf{E}\,\|\Phi_\alpha(\rho)UK^*\varepsilon\|^2 \le \sigma^2\int_{\mathbb{S}}\Phi_\alpha^2(\rho)\rho\,\mathrm{d}\Sigma. \tag{3.5}$$

A crucial point in the following analysis is the estimation of the tails of the spectral function ρ. To this end, we bound the variance in terms of the function

$$R(\alpha) := \Sigma(\{\rho \geq \alpha\}) \qquad \text{for } \alpha > 0. \tag{3.6}$$

In order to control the MISE of $\hat{f}_{\alpha,\sigma}$ as $\alpha \searrow 0$ it is tempting to assume that R is smooth in a neighborhood around 0. However, this is not true in general. Therefore, we will pose instead that R can be approximated suitably by a smooth function S with properties similar to those of R as $\alpha \searrow 0$. Obviously, R is monotonically decreasing (see (3.8a) below). If $\rho \geq 0$ belongs to $L^1(\Sigma)$, then $-\int_0^\infty \alpha \, \mathrm{d}R(\alpha) = \int_{\mathbb{S}} \rho \, \mathrm{d}\Sigma < \infty$ (see (3.8b)), and it follows from Lebesgue's dominated convergence theorem that $\lim_{\alpha\searrow 0} \alpha R(\alpha) = \lim_{\alpha\searrow 0} \int_{\mathbb{S}} \alpha \, 1_{\{\rho\geq\alpha\}} \, \mathrm{d}\Sigma = 0$ (see (3.8c)).

Assumption 2. There exists a constant $\bar{\alpha} \in (0, \|\rho\|_\infty]$ and a function $S \in C^2((0,\bar{\alpha}])$ such that

$$R(\alpha) \sim S(\alpha), \qquad \text{as } \alpha \searrow 0, \tag{3.7}$$

with R defined by (3.6) in terms of the spectral decomposition (2.1), and S satisfies

$$S' < 0, \tag{3.8a}$$

$$-\alpha S'(\alpha) \text{ is integrable on } (0,\bar{\alpha}], \tag{3.8b}$$

$$\lim_{\alpha\searrow 0} \alpha S(\alpha) = 0, \tag{3.8c}$$

$$\exists \gamma_{\mathrm{S}} \in (0,2) \text{ for all } \alpha \in (0,\bar{\alpha}] : \frac{S''(\alpha)}{-S'(\alpha)} \leq \frac{\gamma_{\mathrm{S}}}{\alpha}. \tag{3.8d}$$

We will show in section 5 for a number of examples that this assumption is satisfied. Now we are in a position to give an estimate of the MISE. The estimate of the MISE in the image space $\mathbb{H}_2$ in (3.10) is needed in the analysis of L^2-boosting (section 5.4) and for nonlinear inverse problems.

THEOREM 3. *Consider the model* (2.11), *and let Assumptions* 1 *and* 2 *hold true. We define a general spectral estimator* $\hat{f}_{\alpha,\sigma}$ *by* (2.4) *and assume that* Φ_α *satisfies* (2.9).

1. *If condition* (2.10) *is satisfied for the function* Λ *defining the smoothness class* $F_{\Lambda,\overline{w},K^*K}$, *then for all* $f \in F_{\Lambda,\overline{w},K^*K}$ *the MISE can be asymptotically bounded by*

$$\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - f\|_{\mathbb{H}_1}^2 \lesssim \left(\gamma_\Lambda \Lambda(\alpha)\overline{w} + \sqrt{\frac{C_2 C_3}{\alpha}}\tau\right)^2 + \frac{(C_2^2 + C_3^2)\sigma^2}{\alpha^2} \int_0^\alpha S(\beta)\,\mathrm{d}\beta, \qquad \text{as } \alpha \searrow 0. \tag{3.9}$$

2. *Assume that* $g \in F_{\tilde{\Lambda},\overline{w},KK^*} \subset \mathbb{H}_2$ *and that* $\tilde{\Lambda}$ *satisfies* (2.10). *(If* $g = Kf$ *with* $f \in F_{\Lambda,\overline{w},K^*K}$, *then* $\tilde{\Lambda}(t) := \sqrt{t}\Lambda(t)$, *but we do* not *assume* $g \in R(K)$ *here!) Then*

$$\mathbf{E}\,\|K\hat{f}_{\alpha,\sigma} - g\|_{\mathbb{H}_2}^2 \lesssim \left(\gamma_{\tilde{\Lambda}} \tilde{\Lambda}(\alpha)\overline{w} + C_2\tau\right)^2 + \frac{(C_2^2 + C_3^2)\sigma^2}{\alpha^2} \int_0^\alpha \beta S(\beta)\,\mathrm{d}\beta, \qquad \text{as } \alpha \searrow 0. \tag{3.10}$$

Note that for statistical inverse problems, as opposed to deterministic inverse problems, the estimates of the noise term and hence the rates of convergence of the MISE do not depend only on the relative smoothness of the solution (i.e., on Λ), but also on the operator (i.e., on S).

Remark 4. We comment on the choice of the regularization parameter $\alpha > 0$. If the noise levels σ and τ, the spectral properties of K^*K (i.e., S), and the smoothness of f (i.e., Λ) are known, one can choose α by minimizing the right-hand side of (3.9). Since typically the smoothness of the solution is not known a priori, so-called *adaptive* methods must be employed for the selection of α. We do not intend to review the considerable amount of literature on this topic here but want to mention that the explicit bounds on the variance given in Theorem 3 allow the application of the Lepskij balancing principle as proposed for inverse problems by Mathé and Pereverzev [32, 33] and Bauer and Pereverzev [3]. We will discuss this in more detail elsewhere. With this method one typically loses a log factor in the asymptotic rates of convergence. In most cases this can be avoided by using Akaike's method as studied for spectral cut-off and related methods by Cavalier et al. [8]. Unfortunately, Assumption 2 in this paper is not satisfied for the methods discussed here.

3.3. Comparison with spectral cut-off. To show that with an optimal choice of α our estimators can achieve the best possible order of convergence among all estimators as $\sigma \searrow 0$, we compare them to the spectral cut-off estimator for which minimax results are known in many situations (see references in the introduction). Since we are mainly interested in the case that the statistical noise is asymptotically dominant, we will assume that $\tau = 0$ for simplicity. Moreover, we assume in addition to (2.14) that the lower bound

$$\mathbf{Var}\left(UK^*\varepsilon(s)\right) \geq \gamma_{\mathbf{var}}\rho(s) \tag{3.11}$$

holds true for some constant $\gamma_{\mathbf{var}} > 0$. For the white noise model this is satisfied with $\gamma_{\mathbf{var}} = 1$ and for the inverse regression model with $\gamma_{\mathbf{var}} = C_{v,l}/C_1$ (see (4.13)). Moreover, we need the following assumption to prove optimal rates in many mildly ill-posed problems.

Assumption 3. There exists a constant $C_4 > 0$ such that for all $\alpha \in (0, \bar{\alpha}]$

$$\frac{C_4}{\alpha} \leq \frac{-S'(\alpha)}{S(\alpha)}. \tag{3.12}$$

THEOREM 5. *Let Assumptions* 1 *and* 2 *and the lower bound* (3.11) *hold true and assume that the family of functions* $\{\Phi_\alpha\}$ *satisfies* (2.9). *Moreover, assume that either* $S = R$ *or Assumption* 3 *holds true. Then the integrated variance of the estimator* $\hat{f}_{\alpha,\sigma}$ *is bounded by the integrated variance of the spectral cut-off estimator* $\hat{f}^{\mathrm{SC}}_{\alpha,\sigma}$,

$$\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - \mathbf{E}\,\hat{f}_{\alpha,\sigma}\|^2 \lesssim \frac{C_2^2 + \kappa C_3^2}{\gamma_{\mathbf{var}}}\,\mathbf{E}\,\|\hat{f}^{\mathrm{SC}}_{\alpha,\sigma} - \mathbf{E}\,\hat{f}^{\mathrm{SC}}_{\alpha,\sigma}\|^2, \qquad \text{as } \alpha \searrow 0, \tag{3.13}$$

with C_2 *and* C_3 *as in Theorem* 3 *and* $\kappa := \gamma_{\mathrm{S}}/(2-\gamma_{\mathrm{S}})$, γ_{S} *defined in* (3.8d). *Moreover, if condition* (2.10) *is satisfied for the function* Λ *defining the smoothness class* $F_{\Lambda,\overline{w}}$ *and if* $\tau = 0$, *then there exists a constant* $C > 0$ *such that*

$$\sup_{f\in F_{\Lambda,\overline{w}}} \mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - f\|^2 \leq C \sup_{f\in F_{\Lambda,\overline{w}}} \mathbf{E}\,\|\hat{f}^{\mathrm{SC}}_{\alpha,\sigma} - f\|^2 \tag{3.14}$$

for all $\sigma > 0$ *and all* $\alpha > 0$ *sufficiently small.*

Whereas condition (3.12) is usually satisfied for mildly ill-posed problems, it is not satisfied for exponentially ill-posed problems where $S(\alpha) \sim c(-\ln\alpha)^q$ for constants $c, q > 0$. Nevertheless, the error bounds in Theorem 3 yield optimal rates of convergence in the limit $\sigma \searrow 0$ for logarithmic source conditions after taking the infimum over all α. This is made precise in the following result, which relies on a comparison of the rates for general regularization methods and bounds on the spectral cut-off rates, which are known to be optimal in many situations (see, e.g., Mair and Ruymgaart [30]).

THEOREM 6. *Under the assumptions of Theorem* 3, *Part* 1 *with* $\tau = 0$, *define the increasing functions* $\gamma_1(\alpha) := -\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}R(\beta)$ *and* $\gamma_2(\alpha) := \frac{1}{\alpha^2}\int_0^\alpha S(\beta)\,\mathrm{d}\beta$ *and assume that*

$$\Lambda\left(\overline{\gamma_2}(\gamma_1(\alpha))\right) \lesssim C\Lambda(\alpha), \qquad \text{as } \alpha \searrow 0, \tag{3.15}$$

with the inverse function $\overline{\gamma_2}$ *of* γ_2 *and a constant* $C > 0$. *Then*

$$\inf_{\alpha>0} \mathbf{E}\,\|\hat f_{\alpha,\sigma} - f\|^2 \lesssim \inf_{\alpha>0}\left((C\gamma_\Lambda\Lambda(\alpha)\overline{w})^2 + (C_3^2 + C_2^2)\sigma^2\gamma_1(\alpha)\right), \qquad \text{as } \sigma \searrow 0;$$

i.e., if we choose the optimal value of α *for every noise level* σ, *all spectral regularization methods achieve the same rate of convergence of the MISE as spectral cut-off.*

Assumption (3.15) is satisfied if $\Lambda(t) = (-\ln t)^{-p}$ and $\gamma_1(\alpha) \le \gamma_2(\alpha^2)$ since

$$\Lambda(\overline{\gamma_2}(\gamma_1(\alpha))) \le \Lambda(\alpha^2) = (-2\ln\alpha)^{-p} = 2^{-p}\Lambda(\alpha).$$

4. Noise models satisfying Assumption 1. In this section we show that several commonly used noise models fit into the general framework described in Assumption 1. We start with an (infinite-dimensional) white noise model, and then continue with several models based on finitely many observations.

4.1. White noise. A frequently used model is to assume that ε in (2.11) is a white noise process in $\mathbb{H}_2$ (see, e.g., Donoho [11, 12] and Mathé and Pereverzev [31]). Moreover, we assume that K^*K is a trace-class operator; i.e., it is compact and the eigenvalues ρ_j of K^*K satisfy $\operatorname{tr}(K^*K) := \sum_{j=0}^\infty \rho_j < \infty$. Then $\mathbf{Cov}_{K^*\varepsilon} = K^*K$, so

$$\mathbf{E}\,\|K^*\varepsilon\|^2 = \operatorname{tr}(\mathbf{Cov}_{K^*\varepsilon}) = \operatorname{tr}(K^*K) < \infty.$$

Therefore, $K^*\varepsilon$ can be identified with a Hilbert space–valued random variable. Using the notation introduced in Remark 1 and defining $e_j : \mathbb{N} \to \mathbb{R}$ by $e_j(k) := \delta_{jk}$, $u_j = U^*e_j \in \mathbb{H}_1$ is a unit-length eigenvector of K^*K to the eigenvalue ρ_j, and

$$\mathbf{Var}\,(UK^*\varepsilon(j)) = \mathbf{Var}\,\langle UK^*\varepsilon, e_j\rangle = \mathbf{Var}\,\langle\varepsilon, Ku_j\rangle = \|Ku_j\|^2 = \rho_j$$

for $j = 0, 1, 2, \ldots$. Therefore, (2.14) is satisfied with equality.

4.2. Quasi deconvolution, errors in variable, noncompact operators. Suppose we want to estimate the density f of a random variable Z with values in $\mathbb{R}^d$, but we can observe only a random variable $X = Z + W$ perturbed by a random variable W. Hence, our data are

$$X_1, \ldots, X_n \overset{\text{i.i.d.}}{\sim} X = Z + W. \tag{4.1}$$

The density g of X is given by

$$g = \int_{\mathbb{R}^d} h(\cdot - z|z) f(z)\,\mathrm{d}z =: Kf, \tag{4.2}$$

where $h(\cdot|z)$ is the conditional density of W given $Z = z$. If Z and W are stochastically independent, K is a convolution operator. The recovering of f is known as the *deconvolution problem* and has been studied extensively (see, e.g., Stefanski and Carroll [38], Fan [17], and Diggle and Hall [10]). Dependent Z and W in (4.1) occur in many scientific applications, e.g., brightness determination of extragalactic star clusters in astrophysics, where the variance σ^2 of the noise W increases monotonically with decreasing brightness of the object Z. Here, a reasonable model is described by $h(y|z) = (2\pi\sigma^2(z))^{-1/2}\exp(-y^2/\sigma^2(z))$ (see Bissantz [4]).

We assume that $f \in L^2(\mathbb{R}^d)$ and that K is a bounded, injective operator in $L^2(\mathbb{R}^d)$. As opposed to the previous section, in general, K is not compact here. Obviously, an unbiased estimator of $q := K^*g$ is given by

$$\hat{q}_n(y) := \frac{1}{n}\sum_{j=1}^{n} h(X_j - y|y). \tag{4.3}$$

To fit this into our general framework, we show that $\hat{q}_n = q + K^*\tilde{\varepsilon}$ for a Hilbert-space process $\tilde{\varepsilon}: L^2(\mathbb{R}^d) \to L^2(\Omega, \mathcal{P}, P)$ defined by

$$\langle \tilde{\varepsilon}, \varphi\rangle := \frac{1}{n}\sum_{j=1}^{n}\varphi(X_j) - \langle g, \varphi\rangle . \tag{4.4}$$

In fact, for $\psi \in L^2(\mathbb{R}^d)$,

$$\langle K^*\tilde{\varepsilon}, \psi\rangle = \langle \tilde{\varepsilon}, K\psi\rangle = \frac{1}{n}\sum_{j=1}^{n}\int_{\mathbb{R}^d} h(X_j - z|z)\psi(z)\,\mathrm{d}z - \langle K^*g, \psi\rangle = \langle \hat{q}_n - q, \psi\rangle .$$

The next result states that Assumption 1 is satisfied.

PROPOSITION 7. *Assume that the operator K defined by* (4.2) *is injective and satisfies $\|K\|_{2,2} < \infty$ and $\|K\|_{2,\infty} < \infty$, where $\|K\|_{r,s}$ is defined as the operator norm of $K: L^r(\mathbb{R}^d) \to L^s(\mathbb{R}^d)$. Moreover, let $\hat{q}_n$ and $\tilde{\varepsilon}$ be defined by* (4.3) *and* (4.4), *and let*

$$\sigma := \frac{1}{\sqrt{n}}\left(\|g\|_{L^\infty} + \|g\|_{L^2}^2\right)^{1/2} \quad \text{and} \quad \varepsilon := \tilde{\varepsilon}/\sigma. \tag{4.5}$$

Then ε satisfies Assumption 1, *and $\hat{q}_n = q + \sigma K^*\varepsilon$.*

Proof. We have to show that (2.12)–(2.14) hold true. Since the X_j are assumed to be independent, it suffices to consider the case $n = 1$. The first part of (2.12), i.e., $\langle \varepsilon, \varphi\rangle = 0$ for $\varphi \in L^2(\mathbb{R}^d)$, follows from $E\varphi(X) = \int \varphi g\,\mathrm{d}x$. Since

$$\mathbf{Cov}(\langle\tilde{\varepsilon}, \varphi_1\rangle, \langle\tilde{\varepsilon}, \varphi_2\rangle) = \int_{\mathbb{R}^d}\varphi_1\varphi_2 g\,\mathrm{d}x - \langle g, \varphi_1\rangle\langle g, \varphi_2\rangle \quad \text{for all } \varphi_1, \varphi_2 \in \mathbb{H}_2,$$

the covariance operator of $\tilde{\varepsilon}$ is given by $\mathbf{Cov}_{\tilde{\varepsilon}} = M_g - g \otimes g$, where M_g means multiplication by g, and $g \otimes g: L^2(\mathbb{R}^d) \to L^2(\mathbb{R}^d)$ is the rank-1 operator defined by $(g \otimes g)\varphi := g\langle\varphi, g\rangle$. Now $\|\mathbf{Cov}_\varepsilon\| \le 1$ follows from the estimate $\|\mathbf{Cov}_{\tilde{\varepsilon}}\| \le \|g\|_{L^\infty} + \|g\|_{L^2}^2$, which completes the proof of (2.12).

To show (2.13), i.e., $\mathbf{E}\,\|\hat{q}_n - q\|^2 < \infty$, note that

$$\mathbf{Cov}_{\hat{q}_1} = K^*\mathbf{Cov}_{\tilde{\varepsilon}}K = K^*M_gK - (K^*g)\otimes(K^*g).$$

We have to show that this is a trace-class operator. Obviously $(K^*g)\otimes(K^*g)$ is trace class as a rank-1 operator. It is not obvious, however, that K^*M_gK is trace class since neither K nor M_g are even compact in general. To show this, we rewrite the kernel of K as $k(x,z) := h(x-z|z)$ and note that $\operatorname{ess\,sup}\|k(x,\cdot)\|_{L^2} = \|K\|_{2,\infty} < \infty$. Since $g \geq 0$, the operator K^*M_gK is self-adjoint and positive semidefinite. Let $\{\varphi_j : j \in \mathbb{N}\}$ be a complete orthonormal system in the separable Hilbert space $L^2(\mathbb{R}^d)$. The B. Levi theorem yields

$$\sum_{j\in\mathbb{N}} \langle \varphi_j, K^*M_gK\varphi_j\rangle = \sum_{j\in\mathbb{N}} \int g(x)|(K\varphi_j)(x)|^2 dx$$

$$= \sum_{j\in\mathbb{N}} \int g(x)|\,\langle k(x,\cdot),\varphi_j\rangle\,|^2 dx \leq \|g\|_{L^1} \operatorname*{ess\,sup}_{x\in\mathbb{X}_2} \|k(x,\cdot)\|_{L^2}^2 < \infty,$$

which implies that K^*M_gK is trace class with $\operatorname{tr}(K^*M_gK) \leq \|K\|_{2,\infty}^2$. Finally, (2.14) follows from Lemma 2. □

If K is a convolution operator with convolution kernel $w(x-z)$, then the canonical choice of the unitary operator U in the Halmos decomposition is the Fourier transform

$$(U\varphi)(\xi) = (\mathcal{F}\varphi)(\xi) = \int_{\mathbb{R}^d} \varphi(x) e^{-2\pi i \xi\cdot x} dx, \tag{4.6}$$

and the multiplier function is then $\rho = |\mathcal{F}w|^2$. In this case the condition (2.14) in Assumption 1 can be verified explicitly; see Mair and Ruymgaart [30].

4.3. Inverse regression. We now review another commonly used noise model (see Wabha [41], O'Sullivan [37], Nychka and Cox [36], and Bissantz, Hohage, and Munk [5]) and show how it is related to the model (2.11). Suppose that $\mathbb{H}_i = L^2(\mu_i)$ are L^2-spaces w.r.t. measure spaces $(\mathbb{X}_i, \mathcal{X}_i, \mu_i)$, $i = 1, 2$, $\mathbb{H}_1$ is separable, and $K : L^2(\mu_1) \to L^2(\mu_2)$ is an integral operator

$$(Kf)(x) := \int_{\mathbb{X}_1} k(x,y) f(y)\,\mathrm{d}\mu_1(y), \qquad x \in \mathbb{X}_2, \tag{4.7}$$

with kernel k. Recall that K^*K is trace class if and only if K is Hilbert–Schmidt and that K is a Hilbert–Schmidt operator if and only if $k \in L^2(\mu_2 \times \mu_1)$ (see Taylor [39]). The latter condition is easy to verify in most applications.

We will assume in the following that the measure space $\mathbb{H}_2$ is finite. Then we can arrange that $\mu_2(\mathbb{X}_2) = 1$. We consider the regression model

$$Y_i = (Kf)(X_i) + \varepsilon_i, \qquad f \in \mathbb{H}_1, \quad i = 1, \dots, n, \tag{4.8}$$

where we assume for simplicity that the random variables $X_i \in \mathbb{X}_2$ have uniform distribution on $\mathbb{X}_2$ (see also Remark 9). Moreover, we assume that $(Y_i, X_i) \sim (Y, X)$, $i = 1, \dots, n$, are independent and identically distributed random variables with values in $\mathbb{R} \times \mathbb{X}_2$ such that

$$\mathbf{E}\,[Y|X] = (Kf)(X), \tag{4.9}$$

and hence $\mathbf{E}\,[\varepsilon|X] = 0$ for $\varepsilon := Y - (Kf)(X)$. Finally we assume that that $v(X) := \sqrt{\mathbf{E}\,[\varepsilon^2|X]}$ satisfies

$$0 < C_{v,l} \leq v(X) \leq C_{v,u} < \infty \qquad \text{a.s.} \tag{4.10}$$

for some constants $C_{v,l}, C_{v,u} > 0$. A straightforward computation shows that

$$\hat{q}_n = \frac{1}{n}\sum_{i=1}^{n} Y_i k(X_i, \cdot) \tag{4.11}$$

is an unbiased estimator of the vector $q := K^*Kf$. To fit the inverse regression model with random design in our general framework, we introduce the Hilbert-space (noise) process $\tilde{\varepsilon} : \mathbb{H}_2 \to L^2(\Omega, \mathcal{P}, P)$ by

$$\langle \tilde{\varepsilon}, \varphi \rangle := \frac{1}{n}\sum_{j=1}^{n} Y_j \varphi(X_j) - \langle g, \varphi \rangle, \qquad \varphi \in \mathbb{H}_2, \tag{4.12}$$

and show that

$$\langle K^*\tilde{\varepsilon}, \psi \rangle = \langle \tilde{\varepsilon}, K\psi \rangle = \frac{1}{n}\sum_{j=1}^{n} Y_j \int_{\mathbb{X}_j} k(X_j, y)\psi(y)\,\mathrm{d}\mu_1(y) - \langle K^*g, \psi \rangle = \langle \hat{q}_n - q, \psi \rangle$$

for all $\psi \in \mathbb{H}_1$, i.e., $\hat{q}_n = q + K^*\tilde{\varepsilon}$.

PROPOSITION 8. *Assume the inverse regression model* (4.7)–(4.10), *and let* $\hat{q}_n$ *and* $\tilde{\varepsilon}$ *be defined by* (4.11) *and* (4.12). *Moreover, let* $K : L^2(\mu_1) \to L^2(\mu_2)$ *be Hilbert–Schmidt, and* $\mu_2 - \operatorname{ess\,sup} \|k(x, \cdot)\|_{L^2(\mu_1)} < \infty$. *Define*

$$\sigma := \sqrt{\frac{C_1}{n}} \qquad \textit{and} \qquad \varepsilon := \tilde{\varepsilon}/\sigma,$$

with $C_1 := C_{v,u} + \|g\|^2_{L^\infty(\mu_2)} + \|g\|^2_{L^2(\mu_2)}$. *Then* ε *satisfies Assumption* 1 *for the unitary transform* U *defined in Remark* 1, *and* $\hat{q}_n = q + \sigma K^*\varepsilon$. *Moreover,*

$$\frac{C_{v,l}}{n}\rho(j) \le \mathbf{Var}\left((U\hat{q}_n)(j)\right), \qquad j = 0, 1, 2, \ldots. \tag{4.13}$$

Proof. It suffices to prove this for $n = 1$. Since X is uniformly distributed and (4.9) holds true, we have

$$\mathbf{E}\left(Y\varphi(X)\right) = \mathbf{E}\left(\mathbf{E}\left[\varepsilon|X\right]\varphi(X)\right) + \mathbf{E}\left(g(X)\varphi(X)\right) = \int g\varphi\,\mathrm{d}\mu_2 = \langle g, \varphi \rangle$$

for all $\varphi \in \mathbb{H}_2$, and hence the first part of (2.12) holds true. Using once more the same properties of X and Y we find that

$$\begin{aligned}
\mathbf{Cov}(\langle \tilde{\varepsilon}, \varphi_1 \rangle, \langle \tilde{\varepsilon}, \varphi_2 \rangle) &= \mathbf{E}\left\{Y^2\varphi_1(X)\varphi_2(X)\right\} - \langle g, \varphi_1 \rangle \langle g, \varphi_2 \rangle \\
&= \mathbf{E}\left\{(\varepsilon^2 + 2\varepsilon g(X) + g(X)^2)\varphi_1(X)\varphi_2(X)\right\} - \langle g, \varphi_1 \rangle \langle g, \varphi_2 \rangle \\
&= \int \varphi_1 \left(v^2 + g^2\right)\varphi_2\,\mathrm{d}\mu_2 - \langle g, \varphi_1 \rangle \langle g, \varphi_2 \rangle
\end{aligned}$$

for all $\varphi_1, \varphi_2 \in \mathbb{H}_2$. Hence, $\mathbf{Cov}_{\tilde{\varepsilon}} = M_{v^2+g^2} - g \otimes g$, where $M_{v^2+g^2}\varphi := (v^2 + g^2) \cdot \varphi$ and $(g \otimes g)\varphi := \langle g, \varphi \rangle\, g$. This implies $\|\mathbf{Cov}_{\tilde{\varepsilon}}\| \le C_1$ and finishes the proof of (2.12). Using the notation of Remark 1, condition (2.13) can be seen as follows:

$$\begin{aligned}
\mathbf{E}\,\|\hat{q}_1 - q\|^2 = \operatorname{tr}\left(\mathbf{Cov}_{\hat{q}_1 - q}\right) &= \sum_{j=0}^{\infty} \langle Ku_j, \mathbf{Cov}_{\tilde{\varepsilon}} Ku_j \rangle \\
&\le C_1 \sum_{j=0}^{\infty} \|Ku_j\|^2 = C_1 \operatorname{tr}(K^*K) < \infty.
\end{aligned}$$

Since

$$\mathbf{Var}\,(U\hat{q}_1)(j) = \langle u_j, \mathbf{Cov}_{\hat{q}_1} u_j\rangle = \langle Ku_j, \mathbf{Cov}_{\tilde{\varepsilon}} Ku_j\rangle \le C_1\|Ku_j\|^2 = C_1\rho_j,$$

we obtain the bound (2.14). The lower bound in (4.13) holds true since the operator $M_g^2 - g\otimes g$ is positive definite as covariance operator of $\tilde{\varepsilon}$ for the case $\varepsilon \equiv 0$. □

In contrast to [30] we do not need the assumption that the singular vectors $u_j \in \mathbb{H}_1$ and $v_j \in \mathbb{H}_2$ in the SVD $Kf = \sum_{j=0}^{\infty} \sqrt{\rho_j}\,\langle f, u_j\rangle_{\mathbb{H}_1} v_j$ are uniformly bounded sequences in $L^\infty(\mu_1)$ and $L^\infty(\mu_2)$, respectively. We require only that $\mu_2 - \operatorname{ess\,sup} \|k(x,\cdot)\|_{L^2(\mu_1)} < \infty$. This condition is often less restrictive and easier to verify.

Remark 9. Generalizations:

1. We can replace $L^2(\mu_1)$ by an arbitrary Hilbert space $\mathbb{H}_1$ (e.g., a Sobolev space) by replacing $k(x,\cdot)$ by $\tilde{k}(x) := \sum_{j=0}^{\infty} \sqrt{\rho}_j v(x) u_j$, $x \in \mathbb{X}_2$. Then (4.7) and (4.11) read $(Kf)(x) = \langle \tilde{k}(x), f\rangle_{\mathbb{H}_1}$ and $\hat{q}_n = \frac{1}{n}\sum_{i=1}^n Y_i \tilde{k}(X_i)$, respectively. Proposition 8 remains valid with literally the same proof if $L^2(\mathbb{X}_1)$ is replaced by $\mathbb{H}_1$.
2. (Deterministic and nonuniform design.) The noise model (2.11) also allows us to treat models of the form (4.8) where the measurement points are either nonuniformly distributed on $\mathbb{X}_2$ or $x_i = x_i^{(n)}$ are deterministic quantities (see, for instance, Nychka and Cox [36] and O'Sullivan [37]). For conditions on the design density see Munk [34].

5. Applications. In this section we discuss how Assumption 2 of our main result (Theorem 5) can be verified for some specific operators A of practical interest.

A remarkable number of interesting inverse problem can be expressed in the form

$$K^*K = \Theta(-\Delta) \tag{5.1}$$

in terms of the Laplace operator Δ on some compact, smooth d-dimensional Riemannian manifold M with a (possibly empty) boundary ∂M. Our first three examples are of this form. Here $\Theta : [0,\infty) \to (0,\infty)$ is a function satisfying $\lim_{\lambda\to\infty}\Theta(\lambda) = 0$. Under the given assumptions the Laplace operator $-\Delta$ defined on $D(-\Delta) := H_0^1(M) \cap H^2(M) \subset L^2(M)$ (i.e., with Dirichlet condition on ∂M) is a positive, self-adjoint operator, which has a complete orthonormal system of eigenvectors u_i in $L^2(M)$ with corresponding eigenvalues λ_i (see, e.g., Taylor [40, Chap. 8.2]). Hence the operator on the right-hand side of (5.1) defined in (2.2) can be written as $\Theta(-\Delta)f = \sum_i \Theta(\lambda_i)\,\langle f, u_i\rangle\, u_i$ for $f \in L^2(M)$. Due to a famous result of Weyl (see Taylor [40, Chap. 8, Thm. 3.1., and Cor. 3.5]), the distribution of the eigenvalues

$$N(\lambda) := \#\{\lambda_i : \lambda_i \le \lambda\}, \qquad \lambda \ge 0,$$

has the asymptotic behavior

$$N(\lambda) \sim c_M \lambda^{d/2}, \qquad c_M := \frac{\operatorname{vol} M}{\Gamma\left(\frac{d}{2}+1\right)(4\pi)^{d/2}} \tag{5.2}$$

as $\lambda \to \infty$, where $\operatorname{vol} M = \int_M 1\,dx$ denotes the volume of M. Under the given assumptions the operator A is compact as operator norm limit of the finite rank operators $\sum_{i=1}^k \Theta(\lambda_i)\,\langle u_i, \cdot\rangle\, u_i$ as $k \to \infty$. Assume that $\Theta(\lambda)$ is monotonically decreasing for $\lambda \ge \lambda_0$ and that $\Theta(\lambda) > \alpha_0 := \Theta(\lambda_0)$ for $\lambda < \lambda_0$. As $\lim_{\lambda\to\infty}\Theta(\lambda) = 0$, the inverse function $\overline{\Theta} : (0,\alpha_0] \to [\lambda_0,\infty)$ satisfies $\lim_{\alpha\searrow 0}\overline{\Theta}(\alpha) = \infty$. If the spectral decomposition of A is chosen as in Remark 1, then the function R defined in (3.6) satisfies

$$R(\alpha) = \#\{\lambda_i : \Theta(\lambda_i) \ge \alpha\} = N\left(\overline{\Theta}(\alpha)\right) \sim c_M\left(\overline{\Theta}(\alpha)\right)^{d/2}, \qquad \text{as } \alpha \searrow 0. \tag{5.3}$$

5.1. Backwards heat equation. We consider the inverse problem of reconstructing the temperature at time $t = 0$ on M from measurements of the temperature at time $t = T$. The forward problem is described by the parabolic equation

$$\begin{aligned} &\partial_t u(x,t) = \Delta u(x,t), && x \in M,\ t \in (0,T), \\ &u(x,t) = 0, && x \in \partial M,\ t \in (0,T], \\ &u(x,0) = f(x), && x \in M, \end{aligned} \tag{5.4}$$

with an initial temperature $f \in L^2(M)$ and the final temperature in $g(x) := u(x,T)$, $x \in M$. We have $g = \exp(-T\Delta)f$, i.e., $K = \exp(-T\Delta) \in L(L^2(M))$ and $K^*K = \exp(-2T\Delta)$. Hence,

$$\Theta(\lambda) = \exp(-2T\lambda)$$

in (5.1). By virtue of (5.3) the condition $R \sim S$ is satisfied for

$$S(\alpha) := c_M \left(-\frac{1}{2T}\ln\alpha\right)^{d/2}.$$

It is easy to check that this function satisfies the conditions (3.8). In particular

$$\frac{S''(\alpha)}{-S'(\alpha)} = \frac{1}{\alpha}\left(1 - \frac{d-2}{2}\frac{1}{\ln\alpha}\right), \tag{5.5}$$

so (3.8d) holds with any $\gamma_S \in (1,2)$ for sufficiently small $\bar\alpha$ if $d \geq 3$ and with $\gamma_S = 1$ for all $\bar\alpha < 1$ for $d \leq 2$.

If M is a compact Riemannian manifold without boundary, then the smoothness class $F_{\Lambda,1}$ for a logarithmic source condition (2.7) is the unit ball in the Sobolev space $H^{2p}(M)$ w.r.t. some equivalent norm (see Hohage [23]). Similar results hold true if M has a boundary with a Dirichlet or Neumann condition. In this case we additionally need to impose boundary conditions. Hence, if the initial temperature is bounded in some Sobolev norm, $\|f\|_{H^s} \leq C$, $s = 2p > 0$, if the regularization parameter is chosen such that $\alpha \asymp \sigma$, and if $\tau = O(\sigma^\mu)$ with $\mu > \frac{1}{2}$ as $\sigma \searrow 0$, then it follows from Theorem 3 after some elementary computations that the MISE decays like

$$\mathbf{E}\,\|\hat f_{\alpha,\sigma} - f\|_{L^2}^2 = \mathrm{O}\left((-\ln\sigma)^{-s}\right), \qquad \text{as } \sigma \searrow 0,$$

for all regularization methods satisfying (2.9).

5.2. Satellite gradiometry. In satellite gradiometry measurements of the gravitational force of the earth at a distance a from the center are used to reconstruct the gravitational potential u at the surface of the earth (see Hohage [23], Bauer and Pereverzev [3], and the references therein). Let the earth be described by $E := \{x : |x| < 1\}$, and let $M := \partial E$ denote the surface of the earth. Then u satisfies the Laplace equation

$$\Delta u(x) = 0, \qquad x \in \mathbb{R}^3 \setminus \overline{E},$$

and decays like $|u(x)| = O\left(|x|^{-1}\right)$ as $|x| \to \infty$. The available data consist of noisy measurements of the rate of change of the gravitational force $-\nabla u$ in radial direction $r = |x|$, i.e.,

$$g(x) := \frac{\partial^2 u}{\partial r^2}(x) \qquad \text{for } |x| = a.$$

A discussion of the measurement errors shows that they are mainly random in nature (see [3]). The problem is to determine the potential $f = u\big|_M$ at the surface M of the earth. Introducing the operator $K : L^2(M) \to L^2(aM)$ mapping the solution f to the data g, we can write K^*K in the form (5.1) with $\Theta(\lambda) = \Phi(\Lambda(\lambda))$ and

$$\Phi(t) := c\left(\frac{1}{2}+t\right)^2\left(\frac{3}{2}+t\right)^2 a^{-2t}, \qquad \Lambda(\lambda) := \sqrt{\lambda+\frac{1}{2}}$$

(see Hohage [23]). It is easy to show that $\Phi(t)$ is decreasing for sufficiently large t and that $\Lambda(\lambda)$ is monotonic increasing for all $\lambda > 0$. Obviously, $\overline{\Theta}(\alpha) = \overline{\Lambda}\left(\overline{\Phi}(\alpha)\right) = \overline{\Phi}(\alpha)^2 - \frac{1}{2}$. The function $\overline{\Phi}(\alpha)$ cannot be computed explicitly, but we can estimate its asymptotic behavior as $\alpha \searrow 0$. Writing $t = \overline{\Phi}(\alpha)$ for α sufficiently small and $p(t) := c\left(\frac{1}{2}+t\right)^2\left(\frac{3}{2}+t\right)^2$, we obtain

$$\begin{aligned}\overline{\Phi}(\alpha) &= -\log_a \alpha \frac{t}{-\log_a \alpha} = -\log_a \alpha \frac{t}{-\log_a\left(p(t)a^{-2t}\right)} \\ &= -\log_a \alpha \left(\frac{t}{-\log_a(p(t)) + 2t}\right) \sim -\frac{\ln \alpha}{2\ln a},\end{aligned}$$

as $\alpha \searrow 0$. Therefore, using (5.3), we get

$$R(\alpha) = c_M \overline{\Theta}(\alpha) \sim \left(-\frac{\ln \alpha}{2\ln a}\right)^2, \qquad \text{as } \alpha \searrow 0.$$

The function $S(\alpha) := \left(-\frac{\ln \alpha}{2\ln a}\right)^2$ satisfies the conditions (3.8) (see (5.5)). Moreover, the smoothness classes $F_{\Lambda,1}$ for logarithmic source conditions (2.7) are unit balls in the Sobolev spaces $H^p(M)$ w.r.t. equivalent norms (see Hohage [23]). Since the gravitational potential satisfies the Poisson equation $\Delta u = -\phi$ in $\mathbb{R}^3$ and since the mass density ϕ of the earth E belongs to $L^2(E)$, it follows from elliptic regularity results that $u \in H^2(E)$, so $f = u|_M \in H^{3/2}(M)$ in the sense of the trace operator (see, e.g., Taylor [39]). Therefore,

$$\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - f\|_{L^2}^2 = \mathrm{O}\left((-\ln \sigma)^{-3}\right), \qquad \text{as } \sigma \searrow 0,$$

if $\tau = O(\sigma)$ and if we choose $\alpha \asymp \sigma$.

5.3. Operators in Hilbert scales. In the following we show that our assumptions are satisfied for operators acting in Hilbert scales (see Mair and Ruymgaart [30] and Mathé and Pereverzev [31]). Hence, spectral regularization methods yield optimal rates of convergence for this class of operators.

Let $L : D(L) \subset H \to H$ be an unbounded, positive, self-adjoint operator defined on a dense domain $D(L) \subset H$, and assume the inverse $L^{-1} : H \to H$ is bounded. Then L generates a scale of Hilbert spaces H_μ, $\mu \in \mathbb{R}$, defined as completion of $\bigcap_{n\in\mathbb{N}} D(L^n)$ under the norm generated by the inner product $\langle f, g\rangle_\mu := \langle L^\mu f, L^\mu g\rangle$. We have $H_\mu \subset H_\lambda$ for $\mu, \lambda \in \mathbb{R}$ with $\mu > \lambda$. A prototype is $L = \sqrt{I - \Delta}$ with the Laplace operator Δ on a closed manifold M, which leads to the usual Sobolev spaces on M.

We assume that K is a-times smoothing ($a > 0$) in (part of) the Hilbert scale (H_μ), i.e., $K : H_{\mu-a} \to H_\mu$ is a bounded operator for all $\mu \in [\underline{\mu}, \overline{\mu}]$ which has a bounded inverse $K^{-1} : H_\mu \to H_{\mu-a}$. This is equivalent to $\frac{1}{C_\mu}\|f\|_{\mu-a} \le \|Kf\|_\mu \le$

$C_\mu \|f\|_{\mu-a}$ for all $f \in H_{\mu-a}$ and some constants $C_\mu \geq 1$. Such conditions are satisfied for many boundary integral operators, multiplication operators, convolution operators, and compositions of such operators (see also the discussion after (5.10)). We do not assume here that K is self-adjoint or that K^*K and L commute, i.e., that they can be diagonalized by the same unitary operator U.

Usually the nature of the noise dictates the choice $\mathbb{H}_2 = H_0$, and one is interested in error bounds for the estimator in the positive norm, i.e., $\mathbb{H}_1 = H_{\mu-a}$ for $\mu \geq a$. Then the operator equation $Kf = g$ is ill-posed with $K = K_{0\leftarrow\mu-a}$ considered as an operator from $H_{\mu-a}$ to H_0.

To verify Assumptions 2 and 3 with $R \sim S$ in (3.7) replaced by $R \asymp S$ (see Remark 14), we assume that L has a complete orthonormal system of eigenvectors with eigenvalues $0 < \lambda_0 \leq \lambda_1 \leq \lambda_2 \leq \cdots$ tending to infinity. Then the embedding operator $J : H_\mu \hookrightarrow H_0$ is compact, and its singular values are given by $\sigma_j(J) = \lambda_j^{-\mu}$. It follows from the decomposition $K_{0\leftarrow\mu-a} = JK_{\mu\leftarrow\mu-a}$ and the Courant minimax characterization of the singular values $\sigma_j = \sigma_j(K_{0\leftarrow\mu-a})$ (see, e.g., Kress [28]) that

$$\frac{1}{\|K^{-1}\|_{\mu-a\leftarrow\mu}} \lambda_j^{-\mu} \leq \sigma_j(K_{0\leftarrow\mu-a}) \leq \|K\|_{\mu\leftarrow\mu-a} \lambda_j^{-\mu}, \qquad j = 0, 1, \ldots.$$

Hence if $N(\lambda) := \#\{\lambda_j : \lambda_j \leq \lambda\}$ and $C := \max(\|K\|_{\mu\leftarrow\mu-a}, \|K^{-1}\|_{\mu-a\leftarrow\mu})$, then $R(\alpha) := \{\sigma_j : \sigma_j^2 \geq \alpha\}$ satisfies

$$N\left((\alpha/C^2)^{-1/2\mu}\right) \leq R(\alpha) \leq N\left((C^2\alpha)^{-1/2\mu}\right).$$

If the counting function has the asymptotic behavior $N(\lambda) \asymp \lambda^d$ for some $d > 0$, then $R(\alpha) \asymp \alpha^{-d/2\mu}$. For the case $L = \sqrt{I - \Delta}$, d is the space dimension (see (5.2)). A straightforward computation shows that $S(\alpha) := \alpha^{-d/2\mu}$ satisfies (3.8) and (3.12) in Assumptions 2 and 3 if and only if $d/(2\mu) \in (0, 1)$. Under this condition, it follows from Remark 14 that Theorems 3 and 5 hold true with different constants.

It remains to discuss the Hölder-type source conditions (2.6) in this setting. To do this we assume for simplicity that $\mathbb{H}_1 = \mathbb{H}_2 = H_0$. Let K^* denote the adjoint of K w.r.t. the inner product in H_0. It is easy to show that $K^* : H_{-\mu} \to H_{-\mu+a}$ is bounded and boundedly invertible for all $\mu \in [\underline{\mu}, \overline{\mu}]$. Let $l \in \mathbb{N}$ such that $[-2al + 1, 2al - 1] \subset [\underline{\mu}, \overline{\mu}]$. Then there exists a constant $\gamma \geq 1$ such that

$$\gamma^{-1} \|L^{2al} f\|_{H_0} \leq \|(K^*K)^{-l} f\|_{H_0} \leq \gamma \|L^{2al} f\|_{H_0}$$

for all $f \in H_{2al}$. It follows from the Heinz inequality (see Engl, Hanke, and Neubauer [14] and Heinz [22]) that

$$\gamma^{-\sigma} \|L^{2a\sigma l} f\|_{H_0} \leq \|(K^*K)^{-\sigma l} f\|_{H_0} \leq \gamma^\sigma \|L^{2a\sigma l} f\|_{H_0}$$

for all $\sigma \in [0, 1]$ and $f \in H_{2a\sigma l}$. Therefore, the source condition $f = (K^*K)^\nu w$, $w \in H_0$, is equivalent to $f \in H_{2a\nu}$. Let $u := 2a\nu$ and $f \in H_u$. Then

$$\mathbf{E}\, \|\hat{f}_{\alpha,\sigma} - f\|_{H_0}^2 = \mathrm{O}\left(\sigma^{\frac{2u}{u+a+d/2}}\right), \qquad \text{as } \sigma \searrow 0,$$

for the choice $\alpha \asymp \sigma^{\frac{2a}{u+a+d/2}}$ if $\tau = \mathrm{O}\left(\sigma^{\frac{u+a}{u+a+d/2}}\right)$ and $\mu_0 \geq u/2a$.

5.4. L^2-boosting. Boosting algorithms include a large class of iterative procedures which improve stagewise the performance of estimators. They have attracted significant interest in the context of machine learning and more recently in statistics (see Freund and Schapire [18] or Friedman [19], among many others). One of the main challenges is to provide a proper convergence analysis and proper stopping rules for the iteration depth (see Zhang and Yu [43]). L^2-boosting has been introduced in the context of regression analysis by Bühlmann and Yu [7] for classification and more general learning problems. We consider the inverse regression problem described in section 4.3 if K is an embedding operator and $\mathbb{X}_2$ is a d-dimensional smooth, compact Riemannian manifold (e.g., a smooth compact subset of $\mathbb{R}^d$). Consider a *weak learner* of the form

$$\hat{f}_{0,n} = \frac{1}{n}\sum_{j=1}^{n} Y_i k(y, X_j), \tag{5.6}$$

with a continuous, symmetric kernel $k : \mathbb{X}_2 \times \mathbb{X}_2 \to \mathbb{R}$ such that the integral operator $\tilde{K} : L^2(\mathbb{X}_2) \to L^2(\mathbb{X}_2)$ with kernel k is compact and strictly positive definite with eigenvalues $\kappa_0 \geq \kappa_1 \geq \cdots$ and satisfies

$$\operatorname{ess\,sup}_{x\in\mathbb{X}_2} k(x,x) < \infty \qquad \text{and} \qquad \#\{\kappa_j \geq \alpha\} \asymp \alpha^{-d/(2\mu_0)}, \quad \text{as } \alpha \to 0, \tag{5.7}$$

for some $\mu_0 > 0$. Further, let H_μ, $\mu \in \mathbb{R}$ be the Hilbert scale generated by the operator $L := \tilde{K}^{-1/(2\mu_0)}$ as described in section 5.3. If we set $\mathbb{H}_1 := H_{\mu_0}$ and $\mathbb{H}_2 = H_0 = L^2(\mathbb{X}_2)$, then $\mathbb{H}_1 \subset \mathbb{H}_2$, and the adjoint of the embedding operator $K : \mathbb{H}_1 \hookrightarrow \mathbb{H}_2$ is given by $K^*\varphi = \tilde{K}\varphi$ since $\langle \varphi, \tilde{K}\psi\rangle_{\mathbb{H}_1} = \langle L^{\mu_0}\varphi, L^{\mu_0}\tilde{K}\psi\rangle_{L^2} = \langle \varphi, \psi\rangle_{L^2}$ for all $\psi \in L^2(\mathbb{X}_2)$ and all $\varphi \in \mathbb{H}_1$. By a similar reasoning one can show that $\mathbb{H}_1$ is a reproducing kernel Hilbert space (RKHS) with reproducing kernel $k(\cdot, x)$. A typical example of a weak learner is a spline smoother which leads to Sobolev spaces H_μ (see [7]).

Note that the weak learner (5.6) can be abbreviated as $\hat{f}_{0,n} = K^*Y$. Boosting this learner results in a recursive iteration,

$$\hat{f}_{j+1,n} = \hat{f}_{j,n} - \beta K^*(Y - K\hat{f}_{j,n}), \qquad j = 0, 1, 2, \ldots, \tag{5.8}$$

which is in fact a Landweber iteration (see section 2.2). Hence, Theorem 3 gives the following bound.

COROLLARY 10. *Assume that k satisfies* (5.7) *with $\mu_0 > \frac{d}{2}$, let $g \in H_\mu$ with $\mu > 0$, and let $\beta \in (0, \|KK^*\|^2]$. Then the MISE is bounded by*

$$\mathbf{E}\,\|\hat{f}_{j,n} - g\|^2_{L^2(\mathbb{X}_2)} \leq C\left((j+1)^{-\mu/\mu_0} + n^{-1}(j+1)^{d/(2\mu_0)}\right). \tag{5.9}$$

For the optimal stopping index $j_*(n) \asymp n^{2\mu_0/(2\mu+d)}$ we obtain the rate $\mathbf{E}\,\|\hat{f}_{j_*(n),n} - f\|^2_{L^2(\mathbb{X}_2)} \leq Cn^{-2\mu/(2\mu+d)}$, which is the well-known minimax rate in the case of Sobolev spaces.

Proof. It follows easily from the definitions that $g \in H_\mu$ is equivalent to $g \in F_{\tilde{\Lambda},\overline{w}}$ with $\tilde{\Lambda}(t) = t^{\mu/2\mu_0}$ for some $\overline{w} > 0$. Since Landweber iteration has infinite qualification (see [14]), $\tilde{\Lambda}$ satisfies (2.10). Moreover, as the singular values of K are $\sigma_j(K) = \sqrt{\kappa_j}$, (5.7) implies that $R(\alpha) = \#\{\sigma_j(K)^2 \geq \alpha\} \asymp S(\alpha)$ with $S(\alpha) := \alpha^{-d/2\mu_0}$, and S satisfies (3.8) in Assumption 2 for $\mu_0 > \frac{d}{2}$. To verify the assumptions of Proposition 8, we note that $\operatorname{tr}(K^*K) = -\int_0^\infty \alpha\,\mathrm{d}R(\alpha) < \infty$ for $\mu_0 > \frac{d}{2}$ (i.e., K is Hilbert–Schmidt) and that $\operatorname{ess\,sup}_{x\in\mathbb{X}_2}\|k(x,\cdot)\|_{\mathbb{H}_1} = \operatorname{ess\,sup}_{x\in\mathbb{X}_2}\sqrt{\langle k(x,\cdot), k(x,\cdot)\rangle_{\mathbb{H}_1}} =$

$\operatorname{ess\,sup}_{x\in\mathbb{X}_2}\sqrt{k(x,x)} < \infty$. Therefore, Proposition 8 and Remark 9, Part 1 imply that Assumption 1 is satisfied with $\sigma \asymp n^{-1/2}$. Hence (5.9) follows from (3.10) in Theorem 3 with $\alpha = (j+1)^{-1}$ and Remark 14. □

Corollary 10 immediately applies to all other regularization methods covered by Theorem 3. In particular, ν-methods require only the square root of the number of Landweber iterations to achieve the optimal rate, but they seem to be unknown in statistics and machine learning.

Often a discretized sample variant of the iteration (5.8) is considered. Convergence of this algorithm has been analyzed by Yao, Rosasco, and Caponnetto [42], but without optimal rates. It is still an open problem whether this discretized version achieves the minimax rates of Corollary 10 in the general context of RKHS, as was shown in [7] for the particular case of spline learning.

5.5. Errors in variable problems. We now further discuss the errors in variable problems introduced in section 4.2. Our aim is to establish rates of convergence of estimators of the density f of $Z \in \mathbb{R}^d$ as the sample size n tends to infinity. Therefore, with a slight abuse of notation, we will write $\hat{f}_{\alpha,n} = \hat{f}_{\alpha,\sigma(n,g)}$ in this context. It follows from the definition (4.5) of σ and the boundedness of $\|\Lambda(K^*K)\|_{2,2}$ that

$$\begin{aligned}\sup_{f\in F_{\Lambda,\overline{w}}} \sigma(n,Kf) &= \sup_{\|w\|=\overline{w}} \sigma(n,K\Lambda(K^*K)w)\\ &\le \frac{\overline{w}}{\sqrt{n}}\left(\|K\Lambda(K^*K)\|_{2,\infty}^2 + \|K\Lambda(K^*K)\|_{2,2}^2\right),\end{aligned}$$

where the expression in parenthesis is finite under the assumptions of Proposition 7.

We first consider two important special cases

$$h_1(y|z) = w_1(y) := \exp(-\pi\|y\|_2^2), \qquad h_2(y|z) = w_2(y) := c_d\exp(-\|y\|_2), \quad y,z\in\mathbb{R}^d,$$

with normalization constant $c_d := \pi^{-d/2}\Gamma(d/2+1)/\Gamma(d+1)$ corresponding to an error variable W independent of Z. Here K is a convolution operator, the canonical unitary transformation U in the spectral decomposition is the Fourier transform $\mathcal{F}$ defined in (4.6), and the multiplier function is $\rho_j = |\mathcal{F}w_j|^2$, i.e., $\rho_1(\xi) = \exp(-2\pi\|\xi\|_2^2)$, and $\rho_2(\xi) = (1+4\pi^2\|\xi\|^2)^{-d-1}$. Hence, the corresponding functions R are given by

$$R_1(\alpha) = V_d\left(-\frac{1}{2\pi}\ln\alpha\right)^{d/2}, \quad R_2(\alpha) = V_d(2\pi)^{-d}\left(\alpha^{-1/(d+1)}-1\right)^{d/2}, \quad 0<\alpha<1,$$

where V_d denotes the volume of the unit ball in $\mathbb{R}^d$. Hence, Assumption 2 is satisfied for R_1 with $S = R_1$ (see (5.5)) and for R_2 with $S(\alpha) = V_d(2\pi)^{-d}\alpha^{-d/(2d+2)}$. Since the norm of the Sobolev space $H^s(\mathbb{R}^d)$ is defined by $\|f\|_{H^s(\mathbb{R}^d)} = (\int(1+|\xi|^2)^s|\mathcal{F}f(\xi)|^2\,\mathrm{d}\xi)^{1/2}$, a simple computation shows that in the first case a logarithmic source condition (2.7) is equivalent to $f\in H^{2p}(\mathbb{R}^d)$, and in the second case a Hölder-type source condition (2.6) is equivalent to $f\in H^{2(d+1)\nu}(\mathbb{R}^d)$. Suppose that $f\in H^s(\mathbb{R}^d)$. Then we find in the first case for the choice $\alpha\asymp n^{-1/2}$ the asymptotic rates

$$\mathbf{E}\,\|\hat{f}_{\alpha,n}-f\|_{L^2}^2 = \mathrm{O}\left((\ln n)^{-s}\right), \qquad \text{as } n\to\infty,$$

and in the second case the rate

$$\mathbf{E}\,\|\hat{f}_{\alpha,n}-f\|_{L^2}^2 = \mathrm{O}\left(n^{-\frac{s}{s+3d/2+1}}\right), \qquad \text{as } n\to\infty,$$

for the choice $\alpha \asymp n^{-\frac{d+1}{s+3d/2+1}}$. This generalizes results in Mair and Ruymgaart [30] for spectral cut-off to arbitrary regularization methods and to the multivariate setting.

We now consider the case that the random variables Z and W are not stochastically independent. We assume that the conditional density h is of the form

$$h(x-z|z) = w(x-z) + p(x,z), \tag{5.10}$$

where $\underline{c}(1+\|\xi\|_2^2)^{-a} \le |\mathcal{F}w(\xi)|^2 \le \overline{c}(1+\|\xi\|_2^2)^{-a}$ for some constants $a, \underline{c}, \overline{c} > 0$, and p is C^∞-smooth and decays exponentially as $\|x\|, \|z\| \to \infty$. Then the convolution operator $\tilde{K}$ with kernel w is bounded and boundedly invertible from $H^{\mu-a}(\mathbb{R}^d)$ to $H^\mu(\mathbb{R}^d)$ for all $\mu \in \mathbb{R}$, and the integral operator P with kernel p is compact from $H^{\mu-a}(\mathbb{R}^d)$ to $H^\mu(\mathbb{R}^d)$ for all $\mu \in \mathbb{R}$. Under our general assumption that $K = \tilde{K} + P$ is injective, it follows from Riesz theory that $K : H^{\mu-a}(\mathbb{R}^d) \to H^\mu(\mathbb{R}^d)$ has a bounded inverse. Hence, it follows from the arguments of the previous paragraph that Hölder source condition (2.6) for K is equivalent to $f \in H^{2a\nu}(\mathbb{R}^d)$. If we additionally assume periodicity of w and p with arbitrary size of the periodicity interval, then it follows from our results on operators in Hilbert scales that also Assumptions 1 and 2 are satisfied.

6. Appendix: Proofs and auxiliary results. This section contains the proofs of our main results on the MISE. First, we require some technical lemmas.

LEMMA 11. *If Assumption* 1 *holds true and the family of functions* $\{\Phi_\alpha\}$ *satisfies* (2.9), *then*

$$\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - \mathbf{E}\,\hat{f}_{\alpha,\sigma}\|^2 \le -\frac{(\sigma C_3)^2}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}R(\beta) - (\sigma C_2)^2\int_\alpha^\infty \frac{1}{\beta}\,\mathrm{d}R(\beta), \tag{6.1a}$$

$$\mathbf{E}\,\|K\hat{f}_{\alpha,\sigma} - \mathbf{E}\,K\hat{f}_{\alpha,\sigma}\|^2 \le (\sigma C_2)^2 R(\alpha) - \frac{(\sigma C_3)^2}{\alpha^2}\int_0^\alpha \beta^2\,\mathrm{d}R(\beta). \tag{6.1b}$$

(Recall that R is decreasing, i.e., the right-hand sides of the inequalities above are nonnegative.)

Proof. Recall the bound (3.5) on $\mathbf{E}\,\|\hat{f}_{\alpha,\sigma} - \mathbf{E}\,\hat{f}_{\alpha,\sigma}\|^2$. We split the integral on the right-hand side of (3.5) of the variance over the "frequency domain" $\mathbb{S}$ into low frequency components $\{\rho \ge \alpha\}$ and high frequency components $\{\rho < \alpha\}$. The low frequency components are bounded by

$$\int_{\{\rho\ge\alpha\}} \Phi_\alpha(\rho)^2\rho\,\mathrm{d}\Sigma \le C_2^2\int_{\{\rho\ge\alpha\}}\frac{1}{\rho}\,\mathrm{d}\Sigma = -C_2^2\int_\alpha^\infty \frac{1}{\beta}\,\mathrm{d}R(\beta),$$

where the latter equality holds by a transformation of the integral on the left-hand side to an integral w.r.t. the image measure Σ^ρ, and subsequent reformulation as the Lebesgue–Stieltjes integral given on the right-hand side of the equation. Similarly, the high frequency components of the variance can be estimated by

$$\int_{\{\rho<\alpha\}} \Phi_\alpha(\rho)^2\rho\,\mathrm{d}\Sigma \le \frac{C_3^2}{\alpha^2}\int_{\{\rho<\alpha\}}\rho\,\mathrm{d}\Sigma = -\frac{C_3^2}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}R(\beta)$$

using (2.9b). This completes the proof of (6.1a).

In analogy to (3.5) we have $\mathbf{E}\,\|K\hat{f}_{\alpha,\sigma} - \mathbf{E}\,K\hat{f}_{\alpha,\sigma}\|^2 \le \sigma^2\int_{\mathbb{S}}\Phi_\alpha(\rho)^2\rho^2\,\mathrm{d}\Sigma$, and the right-hand side of this inequality can be estimated as above to establish the bound (6.1b). ∎

The next lemma shows that for $R = S$ the high frequency components of the variance are asymptotically bounded by low frequency components and that the relative magnitude of these components is determined by the constant γ_S in (3.8d).

LEMMA 12. *Assume that* $S \in C^2((0,\bar\alpha])$ *satisfies* (3.8), *and define* $\kappa := \frac{\gamma_S}{2-\gamma_S}$, *i.e.*, $\frac{2\kappa}{\kappa+1} = \gamma_S$. *Then*

$$-\frac{1}{\alpha^2}\int_0^\alpha \beta \,\mathrm{d}S(\beta) \le -\kappa \int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}S(\beta) - \frac{\kappa+1}{2}S'(\bar\alpha), \qquad \alpha \in (0,\bar\alpha]. \tag{6.2}$$

Proof. We rewrite (3.8d) as $(\kappa+1)S''(\alpha) \le 2\kappa\frac{-S'(\alpha)}{\alpha}$. Integrating this inequality from α to $\bar\alpha$ yields $(\kappa+1)(S'(\bar\alpha) - S'(\alpha)) \le 2\kappa\int_\alpha^{\bar\alpha} \frac{-S'(\beta)}{\beta}\,\mathrm{d}\beta$, or equivalently

$$0 \le \alpha S'(\alpha) + \kappa\alpha S'(\alpha) + 2\kappa\alpha \int_\alpha^{\bar\alpha} \frac{-S'(\beta)}{\beta}\,\mathrm{d}\beta - \alpha(\kappa+1)S'(\bar\alpha). \tag{6.3}$$

It follows that

$$0 \le \int_0^\alpha \beta\,\mathrm{d}S(\beta) - \kappa\alpha^2 \int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}S(\beta) - \frac{\alpha^2}{2}(\kappa+1)S'(\bar\alpha), \qquad \alpha \in (0,\bar\alpha]. \tag{6.4}$$

To verify this we check that the derivative of the right-hand side of (6.4) is the right-hand side of (6.3) and that the limit of the right-hand side of (6.4) as $\alpha \searrow 0$ is nonnegative by assumptions (3.8a) and (3.8b). Inequality (6.4) is equivalent to (6.2). ∎

Next we show under an additional assumption that the asymptotic balance between high and low frequency components of the variance also holds true if R is not smooth.

LEMMA 13. *If Assumption* 2 *holds true, then for* $j \in \{1,2\}$

$$-\frac{1}{\alpha^2}\int_0^\alpha \beta^j\,\mathrm{d}S(\beta) \le \frac{1}{\alpha^2}\int_0^\alpha j\beta^{j-1}S(\beta)\,\mathrm{d}\beta, \tag{6.5a}$$

$$\left|\frac{1}{\alpha^2}\int_0^\alpha \beta^j\,\mathrm{d}(R-S)(\beta)\right| = \mathrm{o}\left(\frac{1}{\alpha^2}\int_0^\alpha j\beta^{j-1}S(\beta)\,\mathrm{d}\beta\right), \tag{6.5b}$$

$$-\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}S(\beta) \le \frac{1}{\alpha}S(\alpha), \tag{6.5c}$$

$$\left|\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}(R-S)(\beta)\right| = \mathrm{o}\left(\frac{1}{\alpha}S(\alpha)\right), \tag{6.5d}$$

as $\alpha \searrow 0$. *If additionally Assumption* 3 *is satisfied, then*

$$-\frac{1}{\alpha^2}\int_0^\alpha \beta^j\,\mathrm{d}R(\beta) \sim -\frac{1}{\alpha^2}\int_0^\alpha \beta^j\,\mathrm{d}S(\beta), \tag{6.6a}$$

$$-\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}R(\beta) \sim -\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}S(\beta). \tag{6.6b}$$

Proof. Using (3.8c), a partial integration yields

$$-\int_0^\alpha \beta^j\,\mathrm{d}T(\beta) = -\alpha^j T(\alpha) + \int_0^\alpha j\beta^{j-1}T(\beta)\,\mathrm{d}\beta \qquad \text{for } T = S \text{ and } T = R-S. \tag{6.7}$$

Due to assumption (3.7) and (3.8b), the left-hand side of (6.7), and hence $\int_0^\alpha j\beta^{j-1} T(\beta)\,\mathrm{d}\beta$, is finite. Inequality (6.5a) follows from (6.7) with $T = S$ since $R(\alpha)$, and hence $S(\alpha)$, are positive for small α. By assumption (3.7), there exists for all $\epsilon > 0$ a $\delta = \delta(\epsilon) > 0$ such that

$$|R(\alpha) - S(\alpha)| \le \epsilon S(\alpha) \qquad \text{for } \alpha < \delta. \tag{6.8}$$

Therefore, using (6.7) with $T = S - R$,

$$\left| \int_0^\alpha \beta^j \,\mathrm{d}(S(\beta) - R(\beta)) \right| \le \epsilon \alpha^j S(\alpha) + \epsilon \int_0^\alpha j\beta^{j-1} S(\beta)\,\mathrm{d}\beta$$

for $\alpha < \delta$. As $\alpha^j S(\alpha) = \int_0^\alpha j\beta^{j-1} S(\alpha)\,\mathrm{d}\beta \le \int_0^\alpha j\beta^{j-1} S(\beta)\,\mathrm{d}\beta$ due to (3.8a), we obtain (6.5b).

To prove (6.5c) and (6.5d), again partial integration yields for $T = S$ or $T = R - S$

$$-\int_\alpha^{\bar\alpha} \frac{1}{\beta}\,\mathrm{d}T(\beta) = \frac{1}{\alpha} T(\alpha) - \frac{1}{\bar\alpha} T(\bar\alpha) - \int_\alpha^{\bar\alpha} \frac{1}{\beta^2} T(\beta)\,\mathrm{d}\beta. \tag{6.9}$$

For $T = S$ this yields (6.5c). Let $\epsilon > 0$ and choose $\delta_1 := \delta(\epsilon)$ according to (6.8) and $\delta_2 := \delta_1 \epsilon$. Then

$$\left| \int_\alpha^{\bar\alpha} \frac{R(\beta) - S(\beta)}{\beta^2}\,\mathrm{d}\beta \right| \le \epsilon \int_\alpha^{\delta_1} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta + \int_{\delta_1}^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta + \int_{\delta_1}^{\bar\alpha} \frac{R(\beta)}{\beta^2}\,\mathrm{d}\beta$$

for $\alpha \le \delta_2$. Due to the monotonicity of S we have

$$\int_\alpha^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta \ge \int_{\delta_2}^{\delta_1} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta \ge S(\delta_1) \int_{\delta_2}^{\delta_1} \frac{\mathrm{d}\beta}{\beta^2} = S(\delta_1) \left(\frac{1}{\delta_2} - \frac{1}{\delta_1} \right) = \frac{1-\epsilon}{\epsilon} \frac{S(\delta_1)}{\delta_1},$$

so

$$\int_{\delta_1}^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta \le S(\delta_1) \int_{\delta_1}^{\infty} \frac{\mathrm{d}\beta}{\beta^2} = \frac{S(\delta_1)}{\delta_1} \le \frac{\epsilon}{1-\epsilon} \int_\alpha^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta,$$

$$\int_{\delta_1}^{\bar\alpha} \frac{R(\beta)}{\beta^2}\,\mathrm{d}\beta \le \frac{1}{\delta_1} R(\delta_1) \le (1+\epsilon) \frac{S(\delta_1)}{\delta_1} \le \epsilon \frac{1+\epsilon}{1-\epsilon} \int_\alpha^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta.$$

Since $S(\alpha) > 0$ for all $\alpha \in (0, \bar\alpha]$ due to (3.12) we can extend the integrals over $[\delta_2, \delta_1]$ and $[\alpha, \delta_1]$ to $[\alpha, \bar\alpha]$ and obtain

$$\left| \int_\alpha^{\bar\alpha} \frac{R(\beta) - S(\beta)}{\beta^2}\,\mathrm{d}\beta \right| \le \epsilon \left(1 + \frac{1}{1-\epsilon} + \frac{1+\epsilon}{1-\epsilon} \right) \int_\alpha^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta$$

for $\epsilon < 1$ and $\alpha \le \delta_2$. Since $\int_\alpha^{\bar\alpha} \frac{S(\beta)}{\beta^2}\,\mathrm{d}\beta \le S(\alpha)/\alpha - S(\bar\alpha)/\bar\alpha \lesssim S(\alpha)/\alpha$ due to (6.9) and (3.8a), we obtain (6.5d).

Assume now that Assumption 3 holds true. Written as $-\alpha^j S'(\alpha) \ge C_4 \alpha^{j-1} S(\alpha)$ and integrated from 0 to α, (3.12) yields

$$-\int_0^\alpha \beta^j \,\mathrm{d}S(\beta) \ge C_4 \int_0^\alpha \beta^{j-1} S(\beta)\,\mathrm{d}\beta \qquad \text{for } \alpha \in (0, \bar\alpha].$$

Together with (6.5b) this implies (6.6a). Writing (3.12) as $-S'(\alpha)/\alpha \geq C_4(S(\alpha)/\alpha^2)$ and adding $C_4(-S'(\alpha)/\alpha)$ on both sides, we obtain

$$(C_4+1)\frac{-S'(\alpha)}{\alpha} \geq C_4\left(\frac{-S'(\alpha)}{\alpha}+\frac{S(\alpha)}{\alpha^2}\right) = C_4\frac{d}{d\alpha}\left\{-\frac{1}{\alpha}S(\alpha)\right\}.$$

Integrating this inequality from α to $\bar{\alpha}$ and multiplying by $(C_4+1)^{-1}$ yields

$$-\int_\alpha^{\bar{\alpha}} \frac{1}{\beta}\,\mathrm{d}S(\beta) \geq \frac{C_4}{C_4+1}\left(\frac{1}{\alpha}S(\alpha)-\frac{1}{\bar{\alpha}}S(\bar{\alpha})\right) \gtrsim \frac{C_4}{C_4+1}\frac{S(\alpha)}{\alpha}, \qquad \text{as } \alpha \searrow 0.$$

This together with (6.5d) implies (6.6b). □

Remark 14. Assume

$$R(\alpha) \asymp S(\alpha), \qquad \text{as } \alpha \searrow 0; \tag{6.10}$$

i.e., there exist constants $C \geq 1$ and $\bar{\alpha} > 0$ such that $(1/C)R(\alpha) \leq S(\alpha) \leq CR(\alpha)$ for $0 < \alpha \leq \bar{\alpha}$. In this case (6.8) holds true with $\delta = \bar{\alpha}$ and $\epsilon = \max(C-1, 1-1/C)$. Proceeding as in the proof of Lemma 13 and choosing $\delta_1 = \delta_2 = \bar{\alpha}$, we find that (6.5) holds true with $\mathrm{o}(\ldots)$ replaced by $\mathrm{O}(\ldots)$ if S satisfies (3.8). If additionally (3.12) holds true, then

$$-\frac{1}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}R(\beta) \asymp \frac{1}{\alpha^2}\int_0^\alpha S(\beta)\,\mathrm{d}\beta \asymp -\frac{1}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}S(\beta),$$

$$-\int_\alpha^{\bar{\alpha}} \frac{1}{\beta}\,\mathrm{d}R(\beta) \asymp \frac{1}{\alpha}S(\alpha) \asymp -\int_\alpha^{\bar{\alpha}} \frac{1}{\beta}\,\mathrm{d}S(\beta).$$

Therefore similar convergence rate results with different constants can be shown if condition (3.7) in Assumption 2 is replaced by (6.10).

Proof of Theorem 3. To prove (3.9), we use the bias-variance decomposition (3.1) and the bound (3.3) of the bias. To bound the variance we start from (6.1a) in Lemma 11. From (6.5a) and (6.5b) we obtain $-\alpha^{-2}\int_0^\alpha \beta\,\mathrm{d}R(\beta) \lesssim \alpha^{-2}\int_0^\alpha S(\beta)\,\mathrm{d}\beta$. For the second term in (6.1a) the partial integration (6.9) with $T = R$ and $\bar{\alpha} > \|K^*K\|$ and (3.7) yield

$$-\int_\alpha^\infty \frac{1}{\beta}\,\mathrm{d}R(\beta) \leq \frac{1}{\alpha}R(\alpha) \sim \frac{1}{\alpha}S(\alpha), \quad \text{as } \alpha \searrow 0.$$

Using the partial integration (6.7) with $T = S$ and (3.8a) we obtain

$$\frac{1}{\alpha}S(\alpha) = \frac{1}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}S(\beta) + \frac{1}{\alpha^2}\int_0^\alpha S(\beta)\,\mathrm{d}\beta \leq \frac{1}{\alpha^2}\int_0^\alpha S(\beta)\,\mathrm{d}\beta.$$

This completes the proof of (3.9). The proof of (3.10) also relies on the bias-variance decomposition $\mathbf{E}\,\|K\hat{f}_{\alpha,\sigma} - g\|^2 = B^2 + V$, where the bias term satisfies

$$\begin{aligned} B &= \|\mathbf{E}\,K\hat{f}_{\alpha,\sigma} - g\| \leq \|K\Phi_\alpha(K^*K)K^*g - g\| + \tau\|K\Phi_\alpha(K^*K)K\xi\| \\ &\leq \|(\Phi_\alpha(KK^*)KK^* - I)\tilde{\Lambda}(KK^*)w\| + \tau\|\Phi_\alpha(KK^*)KK^*\| \leq \gamma_{\tilde{\Lambda}}\tilde{\Lambda}(\alpha)\overline{w} + \tau C_2. \end{aligned}$$

The bound on the variance term $V = \mathbf{E}\,\|K\hat{f}_{\alpha,\sigma} - \mathbf{E}\,K\hat{f}_{\alpha,\sigma}\|^2$ we start from (6.1b) in Lemma 11. By (6.5a) and (6.5b), the first term on the right-hand side satisfies

$\int_0^\alpha \beta^2 \,\mathrm{d}R(\beta) \lesssim \frac{1}{\alpha^2}\int_0^\alpha j\beta^{j-1}S(\beta)\,\mathrm{d}\beta$, and for the second term we obtain $R(\alpha) \sim S(\alpha) = \alpha^{-2}\int_0^\alpha 2\beta S(\alpha)\,\mathrm{d}\beta \le \alpha^{-2}\int_0^\alpha 2\beta S(\beta)\,\mathrm{d}\beta$ due to (3.8a). This shows that $V \le (\sigma/\alpha)^2(C_2^2+C_3^2)\int_0^\alpha 2\beta S(\beta)\,\mathrm{d}\beta$ and finishes the proof of (3.10). ∎

Proof of Theorem 5. Using (3.11) we can bound the variance of the spectral cut-off estimator as follows:

$$\sigma^{-2}\mathbf{E}\,\|\hat f_{\alpha,\sigma}^{\mathrm{SC}} - \mathbf{E}\,\hat f_{\alpha,\sigma}^{\mathrm{SC}}\|^2 = \int_{\mathbb{S}} \Phi_\alpha^{\mathrm{SC}}(\rho)^2 \mathbf{Var}\,(UK^*\varepsilon)\,\mathrm{d}\Sigma$$

$$\ge \gamma_{\mathbf{var}} \int_{\{\rho\ge\alpha\}} \frac{1}{\rho}\,\mathrm{d}\Sigma = -\gamma_{\mathbf{var}}\int_\alpha^\infty \frac{1}{\beta}\,\mathrm{d}R(\beta).$$

On the other hand, using Lemmas 12 and 13 we can bound the first term on the right-hand side of (6.1a) as follows:

$$-\frac{1}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}R(\beta) \sim -\frac{1}{\alpha^2}\int_0^\alpha \beta\,\mathrm{d}S(\beta) \lesssim -\kappa\int_\alpha^{\bar\alpha}\frac{1}{\beta}\,\mathrm{d}S(\beta) \lesssim -\kappa\int_\alpha^\infty \frac{1}{\beta}\,\mathrm{d}R(\beta).$$

This yields (3.13). Inequality (3.14) follows from (3.1), (3.4), and (3.13). ∎

Proof of Theorem 6. Using the substitution $\alpha = \overline{\gamma_2}(\gamma_1(\beta))$ and Theorem 3, this follows from

$$\inf_{\alpha>0}\mathbf{E}\,\|\hat f_{\alpha,\sigma} - f\|^2 \lesssim \inf_{\alpha>0}\left(\gamma_\Lambda^2\Lambda(\alpha)^2\overline{w}^2 + (C_3^2+C_2^2)\sigma^2\gamma_2(\alpha)\right)$$

$$= \inf_{\beta>0}\left(\gamma_\Lambda^2\Lambda(\overline{\gamma_2}(\gamma_1(\beta)))^2\overline{w}^2 + (C_3^2+C_2^2)\sigma^2\gamma_1(\beta)\right)$$

$$\le \inf_{\beta>0}\left(C\gamma_\Lambda^2\Lambda(\beta)^2\overline{w}^2 + (C_3^2+C_2^2)\sigma^2\gamma_1(\beta)\right). \qquad ∎$$

Acknowledgments. We would like to thank P. Bühlmann and L. Rosasco for helpful discussions on L^2-boosting. Moreover, we are grateful to the anonymous referees for their valuable comments, which helped to improve the presentation of the material.

NUMERICAL ANALYSIS OF A UNILATERAL PROBLEM IN PLANAR THERMOELASTICITY*

M. I. M. COPETTI†

Abstract. We consider in this paper the numerical approximation of a quasi-static contact problem in linear thermoelasticity that models the evolution of the temperature and displacement of an elastic, homogeneous, and isotropic body that may come in contact with an elastic obstacle. We propose a finite element method to numerically approximate the continuous solution. Convergence without any regularity assumptions is proved and error estimates are obtained if the continuous solution is sufficiently regular.

Key words. planar thermoelasticity, contact problem, finite element approximation

1. Introduction.

Let $\Omega \subset \mathbf{R}^2$ be a convex polygonal bounded domain which represents the reference configuration of a thermoelastic, homogeneous, and isotropic body, and assume that the boundary $\partial\Omega$ is divided into three mutually disjoint parts Γ_0, Γ_t, Γ_c such that $\partial\Omega = \overline{\Gamma}_0 \cup \overline{\Gamma}_t \cup \overline{\Gamma}_c$, $\Gamma_0 \neq \emptyset$, and $\Gamma_c \neq \emptyset$.

The equations that describe the evolution of the system under consideration are (see [15], [17])

$$\theta_t - \triangle\, \theta = -m\, \mathrm{div}\, \boldsymbol{u}_t \qquad \text{in } \Omega,\ t > 0, \tag{1.1}$$

$$\mathrm{div}\, \boldsymbol{\sigma}(\boldsymbol{u}) = \mathbf{0} \qquad \text{in } \Omega,\ t > 0, \tag{1.2}$$

where $\theta = \theta(\mathbf{x}, t)$ is the body temperature, $\boldsymbol{u} = \boldsymbol{u}(\mathbf{x}, t) = (u_1(\mathbf{x}, t),\, u_2(\mathbf{x}, t))^t$ is the displacement from the reference configuration, and $\boldsymbol{\sigma}(\boldsymbol{u}) = \lambda\, \mathrm{div}\, \boldsymbol{u}\mathbf{I} + 2\,\mu\, \boldsymbol{\epsilon}(\boldsymbol{u}) - m\,\theta\,\mathbf{I}$ is the stress. Here $\lambda,\ \mu > 0$ are the Lamé constants, $m > 0$ is the coefficient of thermal expansion, $\mathbf{I}$ is the 2×2 identity matrix, $\boldsymbol{\epsilon} = \boldsymbol{\epsilon}(\boldsymbol{u}) = 0.5(\nabla \boldsymbol{u} + (\nabla \boldsymbol{u})^t)$ is the linearized 2×2 strain function, and $\mathrm{div}\, \boldsymbol{\sigma}$ is the 2-vector with ith component $\{\mathrm{div}\, \boldsymbol{\sigma}\}_i = \sum_{j=1}^{2} \boldsymbol{\sigma}_{ij,j}$. The index j that follows the comma indicates a partial derivative with respect to $\mathbf{x}_j$.

The body is held fixed on Γ_0 and tractions are zero on Γ_t so that

$$\boldsymbol{u} = \mathbf{0} \quad \text{on } \Gamma_0, \qquad \boldsymbol{\sigma\nu} = \mathbf{0} \quad \text{on } \Gamma_t,\ t > 0, \tag{1.3}$$

with $\boldsymbol{\nu} = (\nu_1, \nu_2)^t$ the normal unit vector pointing out of Ω. At Γ_c the body may come in contact with an elastic obstacle with rigidity $\frac{1}{\epsilon} > 0$ located initially at distance $g(\mathbf{x}) \geq 0$ from Γ_c. At the region of contact the normal stress is compressive, the contact is frictionless, and the body can penetrate the obstacle:

$$\left.\begin{array}{l} \boldsymbol{\sigma}_T = \boldsymbol{\sigma\nu} - \sigma_\nu \boldsymbol{\nu} = \mathbf{0}, \\ \sigma_\nu = -\frac{1}{\epsilon}[u_\nu - g]_+ \end{array}\right\} \quad \text{on } \Gamma_c,\ \ t > 0, \tag{1.4}$$

†Laboratório de Análise Numérica e Astrofísica, Departamento de Matemática, Universidade Federal de Santa Maria, 97105-900 Santa Maria, RS, Brazil (mimc@lana.ccne.ufsm.br).

where $\sigma_\nu = (\boldsymbol{\sigma\nu})\cdot\boldsymbol{\nu}$, $u_\nu = \boldsymbol{u}\cdot\boldsymbol{\nu}$, and $[\chi]_+ \equiv \max\{\chi, 0\}$. For simplicity, we assume that the temperature is equal to zero at the boundary of Ω and it is initially prescribed:

$$\theta = 0 \quad \text{on } \partial\Omega, \qquad \theta(\mathbf{x}, 0) = \theta_0(\mathbf{x}), \qquad \mathbf{x} \in \Omega. \tag{1.5}$$

This problem, for a nonisotropic, nonhomogeneous elastic body was used by Rivera and Racke [15] as a penalization to the contact problem with a rigid obstacle where (1.4) is replaced by the so-called Signorini contact condition

$$\left.\begin{array}{ll} u_\nu \le g, & \sigma_\nu = (\boldsymbol{\sigma\nu})\cdot\boldsymbol{\nu} \le 0, \\ \sigma_\nu(u_\nu - g) = 0, & \boldsymbol{\sigma}_T = \boldsymbol{\sigma\nu} - \sigma_\nu\boldsymbol{\nu} = \mathbf{0} \end{array}\right\} \quad \text{on } \Gamma_c, \quad t > 0. \tag{1.6}$$

One dimensional quasi-static contact problems with various boundary conditions for the temperature have been extensively studied by mathematicians and engineers both theoretically and numerically. In particular, existence and uniqueness results were obtained by Gilbert, Shi, and Shillor [12] and Shi and Shillor [16]. Finite element approximations were analyzed by Copetti and Elliott [10] and Copetti [8], [9]. Error estimates were given and numerical experiments performed. In [14], the stability of steady-state solutions was considered.

Multidimensional contact problems are more complex due to the presence of the elasticity equations. An existence result for the Signorini contact problem, with either a Dirichlet or a heat exchange condition for the temperature, was proved by Shi and Shillor [17] using truncation and compactness arguments, while uniqueness was established by Ames and Payne [1]. Quasi-static and dynamic problems with Barber's heat exchange condition were studied by Xu [19] and Bien [3], respectively. The papers [2], [5], and [6] provide error analysis for some contact problems in elasticity. A static problem in thermoelasticity with many bodies in contact is numerically approximated by the finite element method in [13]. To our knowledge, the present paper is the first work dealing with the numerical approximation of problem (1.1)–(1.5).

Let us introduce the spaces $\mathbf{L}^2(\Omega) = \{L^2(\Omega)\}^2$, $\mathbf{H}^s(\Omega) = \{H^s(\Omega)\}^2$, and $\mathbf{H}^1_E(\Omega) = \{\boldsymbol{v} \in \mathbf{H}^1(\Omega) \mid \boldsymbol{v} = \mathbf{0} \text{ on } \Gamma_0\}$. We indicate the inner product in $\{L^2(\Omega)\}^n$, $n = 1, 2$, by $(\cdot,\cdot)$ and the norms of $\{L^2(\Omega)\}^n$ and $\{H^s(\Omega)\}^n$ by $\|\cdot\|$ and $\|\cdot\|_s$, respectively.

Throughout the paper, the letter C is used to denote a positive constant which depends on the data and is independent of mesh sizes.

If $\boldsymbol{\sigma}$ and $\boldsymbol{\tau}$ are 2×2 matrix-valued functions, we define

$$\boldsymbol{\sigma} : \boldsymbol{\tau} = \sum_{i,j=1}^{2} \sigma_{ij}\tau_{ij},$$

and we consider on $\mathbf{H}^1_E(\Omega)$ the inner product

$$b(\boldsymbol{u}, \boldsymbol{v}) = \int_\Omega \boldsymbol{\epsilon}(\boldsymbol{u}) : \boldsymbol{\epsilon}(\boldsymbol{v}) d\mathbf{x}$$

and let $\|v\|_b = (b(\boldsymbol{v}, \boldsymbol{v}))^{\frac{1}{2}}$ be the associated norm. Since $\Gamma_0 \neq \emptyset$, the Korn inequality [4]

$$\|\boldsymbol{v}\|_b \ge C\|\boldsymbol{v}\|_1 \quad \forall\, \boldsymbol{v} \in \mathbf{H}^1_E(\Omega) \tag{1.7}$$

implies that the bounded bilinear form $a(\boldsymbol{v}, \mathbf{w}) \equiv \lambda(\operatorname{div}\boldsymbol{v}, \operatorname{div}\mathbf{w}) + 2\mu\, b(\boldsymbol{v}, \mathbf{w})$ is coercive.

The following result holds [1], [15].

THEOREM 1.1. *If $\theta_0 \in H_0^1(\Omega)$, $g \in H^{\frac{1}{2}}(\Gamma_c)$, and m is sufficiently small, there exists a unique solution to* (1.1)–(1.5) *such that*

$$\begin{aligned} \theta \in L^2(0,T;H^2(\Omega)\cap H_0^1(\Omega)), \quad \theta_t \in L^2(0,T;L^2(\Omega)),\\ \boldsymbol{u} \in L^2(0,T;\mathbf{H}_E^1(\Omega)), \quad \boldsymbol{u}_t \in L^2(0,T;\mathbf{H}^1(\Omega)),\\ \{\operatorname{div}\boldsymbol{\sigma}(\boldsymbol{u})\}_i \in L^2(0,T;L^2(\Omega)), \quad i=1,2. \end{aligned}$$

Given any $w \in H_0^1(\Omega)$ and $\boldsymbol{v} \in \mathbf{H}_E^1(\Omega)$, the weak form

$$(\theta_t, w) + (\nabla\theta, \nabla w) = -m(\operatorname{div}\boldsymbol{u}_t, w), \tag{1.8}$$

$$\lambda(\operatorname{div}\boldsymbol{u}, \operatorname{div}\boldsymbol{v}) + 2\mu\, b(\boldsymbol{u},\boldsymbol{v}) - m(\theta, \operatorname{div}\boldsymbol{v}) + \frac{1}{\epsilon}([u_\nu - g]_+, v_\nu)_{\Gamma_c} = 0 \tag{1.9}$$

will be the base of our numerical method. We define $\boldsymbol{u}(\mathbf{x},0) \equiv \boldsymbol{u}_0(\mathbf{x})$ as the unique solution in $\mathbf{H}_E^1(\Omega)$ of (1.2)–(1.4) when $\theta = \theta_0$.

2. Numerical approximation. Let T^h be a regular family of triangulations of Ω, $\overline{\Omega} = \bigcup_{\tau\in T^h}\tau$ with mesh size h such that any point where the boundary condition changes is a vertex of the triangulations. Let $S^h \subset H^1(\Omega)$ and $\mathbf{S}^h \subset \mathbf{H}^1(\Omega)$ be finite element spaces of continuous functions on $\overline{\Omega}$ which are linear on each $\tau \in T^h$. We introduce the spaces

$$S_0^h = \{v \in S^h \mid v = 0 \text{ on } \partial\Omega\} \text{ and } \mathbf{S}_E^h = \{\boldsymbol{v} \in \mathbf{S}^h \mid \boldsymbol{v} = \mathbf{0} \text{ on } \Gamma_0\}$$

and the projection $P_E^h : \mathbf{H}_E^1 \to \mathbf{S}_E^h$ defined by $a(\boldsymbol{v} - P_E^h\boldsymbol{v}, \mathbf{w}) = 0\ \forall\, \mathbf{w} \in \mathbf{S}_E^h$. As a consequence of Korn's inequality (1.7) we have

$$\|\boldsymbol{v} - P_E^h\boldsymbol{v}\|_1 \le C \inf_{\mathbf{w}\in\mathbf{S}_E^h} \|\boldsymbol{v} - \mathbf{w}\|_1. \tag{2.1}$$

We will also use the elliptic projection $P_0^h : H_0^1 \to S_0^h$, $(\nabla(\eta - P_0^h\eta), \nabla\chi) = 0$ $\forall\,\chi \in S_0^h$, and the L^2-projection $P^h : \mathbf{L}^2 \to \mathbf{S}_E^h$, $(\boldsymbol{\zeta} - P^h\boldsymbol{\zeta}, \boldsymbol{\phi}) = 0\ \forall\boldsymbol{\phi} \in \mathbf{S}_E^h$, which satisfy [18]

$$\|\eta - P_0^h\eta\| + h\|\nabla(\eta - P_0^h\eta)\| \le Ch^s\|\eta\|_s, \quad 1 \le s \le 2, \tag{2.2}$$

$$\|\boldsymbol{\zeta} - P^h\boldsymbol{\zeta}\| \le Ch^s\|\boldsymbol{\zeta}\|_s, \quad 1 \le s \le 2. \tag{2.3}$$

For continuous functions $\boldsymbol{v}$, we denote by $I^h\boldsymbol{v}$ the interpolant of $\boldsymbol{v}$ in $\mathbf{S}_E^h$ with respect to the triangulation T^h. The following approximation property holds [18]:

$$\|\boldsymbol{v} - I^h\boldsymbol{v}\| + h\|\nabla(\boldsymbol{v} - I^h\boldsymbol{v})\| \le Ch^s\|\boldsymbol{v}\|_s, \quad 1 \le s \le 2. \tag{2.4}$$

The finite element approximation to (1.1)–(1.5) is to find $\Theta^n \in S_0^h$, $\boldsymbol{U}^n \in \mathbf{S}_E^h$, $n = 1, 2, \ldots, N$, such that $\forall\, W \in S_0^h$ and $\forall\,\boldsymbol{V} \in \mathbf{S}_E^h$

$$\frac{1}{\Delta t}(\Theta^n - \Theta^{n-1}, W) + (\nabla\Theta^n, \nabla W) = -\frac{m}{\Delta t}(\operatorname{div}(\boldsymbol{U}^n - \boldsymbol{U}^{n-1}), W), \tag{2.5}$$

$$\lambda(\operatorname{div}\boldsymbol{U}^n, \operatorname{div}\boldsymbol{V}) + 2\mu\, b(\boldsymbol{U}^n, \boldsymbol{V}) - m(\Theta^n, \operatorname{div}\boldsymbol{V}) + \frac{1}{\epsilon}([U_\nu^n - g]_+, V_\nu)_{\Gamma_c} = 0. \tag{2.6}$$

Here $\Delta t = T/N$ and Θ^0, $\boldsymbol{U}^0$ are approximations to θ_0 and $\boldsymbol{u}_0$, respectively.

Suppose that $\{\Theta^n, \boldsymbol{U}^n\}$ and $\{\tilde{\Theta}^n, \tilde{\boldsymbol{U}}^n\}$ are two solutions of (2.5)–(2.6), and define $\psi = \Theta^n - \tilde{\Theta}^n, \boldsymbol{\eta} = \boldsymbol{U}^n - \tilde{\boldsymbol{U}}^n$. Thus, $\forall\, W \in S_0^h$ and $\forall\, \boldsymbol{V} \in \mathbf{S}_E^h$,

$$(\psi, W) + \Delta t(\nabla\psi, \nabla W) = -m(\operatorname{div}\boldsymbol{\eta}, W),$$
$$\lambda(\operatorname{div}\boldsymbol{\eta}, \operatorname{div}\boldsymbol{V}) + 2\mu\, b(\boldsymbol{\eta}, \boldsymbol{V}) - m(\psi, \operatorname{div}\boldsymbol{V}) + \frac{1}{\epsilon}([U_\nu^n - g]_+ - [\tilde{U}_\nu^n - g]_+, V_\nu)_{\Gamma_c} = 0,$$

and

$$\|\psi\|^2 + \Delta t\|\nabla\psi\|^2 + \lambda\|\operatorname{div}\boldsymbol{\eta}\|^2 + 2\mu\,\|\boldsymbol{\eta}\|_b^2 = -\frac{1}{\epsilon}([U_\nu^n - g]_+ - [\tilde{U}_\nu^n - g]_+, U_\nu^n - \tilde{U}_\nu^n)_{\Gamma_c} \le 0$$

since the functional $[\cdot]_+$ is monotone. It follows that (2.5)–(2.6) has a unique solution.

2.1. Implementation. To compute the numerical solution we used the iterative procedure

$$\frac{1}{\Delta t}(\Theta^{n,l} - \Theta^{n-1}, W) + (\nabla\Theta^{n,l}, \nabla W) = -\frac{m}{\Delta t}(\operatorname{div}(\boldsymbol{U}^{n,l-1} - \boldsymbol{U}^{n-1}), W),$$
$$\lambda(\operatorname{div}\boldsymbol{U}^{n,l}, \operatorname{div}\boldsymbol{V}) + 2\mu\, b(\boldsymbol{U}^{n,l}, \boldsymbol{V}) - m(\Theta^{n,l}, \operatorname{div}\boldsymbol{V}) + \frac{1}{\epsilon}([U_\nu^{n,l-1} - g]_+, V_\nu)_{\Gamma_c} = 0,$$

where $\boldsymbol{U}^{n,0} = \boldsymbol{U}^{n-1}$. At each iteration l, two systems of linear equations need to be solved. Since the coefficient matrices are symmetric positive definite, these systems have unique solutions and the Gauss–Seidel method can be used to solve them.

THEOREM 2.1. *If μ is sufficiently large and m is sufficiently small, the sequences $\{\Theta^{n,l}\}$ and $\{\boldsymbol{U}^{n,l}\}$ converge to the unique solution of* (2.5)–(2.6).

Proof. Let $p^l = \Theta^{n,l} - \Theta^{n,l-1}$ and $\boldsymbol{q}^l = \boldsymbol{U}^{n,l} - \boldsymbol{U}^{n,l-1}$. We have

$$\|p^l\|^2 + \Delta t\|\nabla p^l\|^2 + \lambda\|\operatorname{div}\boldsymbol{q}^l\|^2 + 2\mu\,\|\boldsymbol{q}^l\|_b^2 = m(\operatorname{div}(\boldsymbol{q}^l - \boldsymbol{q}^{l-1}), p^l)$$
$$- \frac{1}{\epsilon}([U_\nu^{n,l-1} - g]_+ - [U_\nu^{n,l-2} - g]_+, q_\nu^l)_{\Gamma_c}.$$

Using Sobolev's trace theorem and (1.7) we find that, for $\alpha > 0$,

$$\frac{1}{\epsilon}([U_\nu^{n,l-1} - g]_+ - [U_\nu^{n,l-2} - g]_+, q_\nu^l)_{\Gamma_c} \le \frac{1}{\epsilon}\|q_\nu^{l-1}\|_{L^2(\Gamma_c)}\,\|q_\nu^l\|_{L^2(\Gamma_c)}$$
$$\le \frac{C}{\epsilon}\|\boldsymbol{q}^{l-1}\|_b\,\|\boldsymbol{q}^l\|_b \le \frac{\alpha C}{2\epsilon}\|\boldsymbol{q}^{l-1}\|_b^2 + \frac{C}{2\alpha\epsilon}\,\|\boldsymbol{q}^l\|_b^2.$$

Therefore, for $\delta > 0$,

$$\|\ p^l\|^2 + \Delta t\|\nabla p^l\|^2 + \lambda\|\operatorname{div}\boldsymbol{q}^l\|^2 + 2\mu\,\|\boldsymbol{q}^l\|_b^2 \le \frac{\delta m^2}{2}\|\operatorname{div}(\boldsymbol{q}^l - \boldsymbol{q}^{l-1})\|^2$$
$$+\ \frac{1}{2\delta}\|p^l\|^2 + \frac{\alpha C}{2\epsilon}\|\boldsymbol{q}^{l-1}\|_b^2 + \frac{C}{2\alpha\epsilon}\|\boldsymbol{q}^l\|_b^2$$
$$\le \delta m^2 C\left(\|\boldsymbol{q}^l\|_b^2 + \|\boldsymbol{q}^{l-1}\|_b^2\right) + \frac{1}{2\delta}\|p^l\|^2 + \frac{\alpha C}{2\epsilon}\|\boldsymbol{q}^{l-1}\|_b^2 + \frac{C}{2\alpha\epsilon}\,\|\boldsymbol{q}^l\|_b^2.$$

It follows that

$$\left(1 - \frac{1}{2\delta}\right)\|p^l\|^2 + \Delta t\|\nabla p^l\|^2 + \lambda\|\operatorname{div}\boldsymbol{q}^l\|^2 + \left(2\mu - \delta m^2 C - \frac{C}{2\alpha\epsilon}\right)\|\boldsymbol{q}^l\|_b^2$$
$$\le \left(\delta m^2 C + \frac{\alpha C}{2\epsilon}\right)\|\boldsymbol{q}^{l-1}\|_b^2.$$

Taking $\delta = \alpha = 1$ results in

$$\left(2\mu - m^2C - \frac{C}{2\epsilon}\right)\|\boldsymbol{q}^l\|_b^2 \le \left(m^2C + \frac{C}{2\epsilon}\right)\|\boldsymbol{q}^{l-1}\|_b^2.$$

Thus, for sufficiently large μ and sufficiently small m, $2\mu - m^2C - C/(2\epsilon) > 0$ and there exists M, $0 < M < 1$, such that

$$\|\boldsymbol{q}^l\|_b^2 \le M\|\boldsymbol{q}^{l-1}\|_b^2,$$

which proves the result. □

We choose the initial displacement $\boldsymbol{U}^0$ as the unique solution of (2.6) when $\Theta^n = \Theta^0$. To find $\boldsymbol{U}^0$ we iterate in the nonlinear term. Convergence follows as in the previous theorem.

3. Convergence. In this section, a convergence analysis and an error estimate are presented. We follow the work of Copetti and French [11].

Let us define $t_n = n\Delta t$, $\theta^n = \theta(\cdot, t_n)$, $\boldsymbol{u}^n = \boldsymbol{u}(\cdot, t_n)$, and

$$\hat{\theta}^n = \int_0^{t_n} \theta(\cdot,t)dt, \quad \bar{\boldsymbol{u}}^n = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \boldsymbol{u}(\cdot,t)dt, \quad \bar{\theta}^n = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \theta(\cdot,t)dt,$$

$$\beta_\epsilon(\chi) = \frac{1}{\epsilon}[\chi]_+, \quad \bar{\beta}_\epsilon^n(\chi) = \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \beta_\epsilon(\chi)dt,$$

$$\varepsilon^j = \Delta t\sum_{i=1}^{j}\Theta^i - P_0^h\hat{\theta}^j, \ j = 1,\dots,n, \quad \varepsilon^0 = 0,$$

and note that

$$\varepsilon^n - \varepsilon^{n-1} = \Delta t(\Theta^n - P_0^h\bar{\theta}^n). \tag{3.1}$$

THEOREM 3.1. *Let $E(\theta, \boldsymbol{u})$ be defined by*

$$E(\theta,\boldsymbol{u}) = \left\|\int_0^T \nabla\theta(\cdot,t)dt - \Delta t\sum_{i=1}^{N}\nabla\Theta^i\right\|^2 + \Delta t\sum_{i=1}^{N}\|\Theta^i - \theta(\cdot,t_i)\|^2$$
$$+ \lambda\Delta t\sum_{i=1}^{N}\|\mathrm{div}\,(\boldsymbol{U}^i - \boldsymbol{u}(\cdot,t_i))\|^2 + \mu\Delta t\sum_{i=1}^{N}\|\boldsymbol{U}^i - \boldsymbol{u}(\cdot,t_i)\|_b^2.$$

Then,

$$E(\theta,\boldsymbol{u}) \le C(\lambda,\mu,\epsilon)\bigg(\|\Theta^0 - \theta_0\|^2 + \frac{1}{\Delta t}\|\boldsymbol{U}^0 - \boldsymbol{u}_0\|^2 + (\Delta t)^2 + h^4$$
$$+ \left(\frac{1}{\Delta t} + 1\right)\Delta t\sum_{i=1}^{N}\|\boldsymbol{u}^i - P_E^h\boldsymbol{u}^i\|_1^2\bigg).$$

Proof. Integrating (1.8) from 0 to t_n and adding (2.5) from 1 to n ($1 \le n \le N$), we find, $\forall\, W \in S_0^h$,

$$(\Theta^n - \theta^n, W) + \left(\Delta t\sum_{i=1}^{n}\nabla\Theta^i - \nabla\hat{\theta}^n, \nabla W\right) = -m(\mathrm{div}\,(\boldsymbol{U}^n - \boldsymbol{u}^n), W)$$
$$+ \ (\Theta^0 - \theta_0, W) + m(\mathrm{div}\,(\boldsymbol{U}^0 - \boldsymbol{u}_0), W),$$

which can be written as

$$\frac{1}{\Delta t}(\varepsilon^n-\varepsilon^{n-1},W)+(\nabla\varepsilon^n,\nabla W)=-m(\operatorname{div}(\boldsymbol{U}^n-\boldsymbol{u}^n),W)$$
$$+(\Theta^0-\theta_0,W)+m(\operatorname{div}(\boldsymbol{U}^0-\boldsymbol{u}_0),W)+(\theta^n-P_0^h\bar\theta^n,W).$$

Taking $W=\frac{\varepsilon^n-\varepsilon^{n-1}}{\Delta t}$ results in

$$\frac{1}{(\Delta t)^2}\|\varepsilon^n-\varepsilon^{n-1}\|^2+\frac{1}{2\Delta t}\left(\|\nabla\varepsilon^n-\nabla\varepsilon^{n-1}\|^2+\|\nabla\varepsilon^n\|^2-\|\nabla\varepsilon^{n-1}\|^2\right)$$
$$=-\frac{m}{\Delta t}(\operatorname{div}(\boldsymbol{U}^n-\boldsymbol{u}^n),\varepsilon^n-\varepsilon^{n-1})+\frac{1}{\Delta t}(\Theta^0-\theta_0,\varepsilon^n-\varepsilon^{n-1})$$
$$+\frac{m}{\Delta t}(\operatorname{div}(\boldsymbol{U}^0-\boldsymbol{u}_0),\varepsilon^n-\varepsilon^{n-1})+\frac{1}{\Delta t}(\theta^n-P_0^h\bar\theta^n,\varepsilon^n-\varepsilon^{n-1}). \tag{3.2}$$

Integrating (1.9) from t_{n-1} to t_n and subtracting the result from (2.6), we get

$$\lambda(\operatorname{div}(\boldsymbol{U}^n-\bar{\boldsymbol{u}}^n),\operatorname{div}\boldsymbol{V})+2\mu\,b(\boldsymbol{U}^n-\bar{\boldsymbol{u}}^n,\boldsymbol{V})-m(\Theta^n-\bar\theta^n,\operatorname{div}\boldsymbol{V})$$
$$+\left(\beta_\epsilon(U_\nu^n-g)-\bar\beta_\epsilon^n(u_\nu-g),V_\nu\right)_{\Gamma_c}=0,$$

and the definition of P_E^h yields

$$\lambda(\operatorname{div}\boldsymbol{e}^n,\operatorname{div}\boldsymbol{V})+2\mu\,b(\boldsymbol{e}^n,\boldsymbol{V})-m(\Theta^n-\bar\theta^n,\operatorname{div}\boldsymbol{V})$$
$$+\left(\beta_\epsilon(U_\nu^n-g)-\bar\beta_\epsilon^n(u_\nu-g),V_\nu\right)_{\Gamma_c}$$
$$=\lambda(\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n),\operatorname{div}\boldsymbol{V})+2\mu\,b(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n,\boldsymbol{V}), \tag{3.3}$$

where $\boldsymbol{e}^n=\boldsymbol{U}^n-P_E^h\boldsymbol{u}^n$. Let us observe that

$$\beta_\epsilon(U_\nu^n-g)-\bar\beta_\epsilon^n(u_\nu-g)=\beta_\epsilon(U_\nu^n-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g)+\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g)-\bar\beta_\epsilon^n(u_\nu-g)$$

and that

$$(\beta_\epsilon(\chi)-\beta_\epsilon(\eta),\chi-\eta)\geq 0.$$

Taking $\boldsymbol{V}=\boldsymbol{e}^n$ in (3.3), we can write

$$\lambda\|\operatorname{div}\boldsymbol{e}^n\|^2+2\mu\|\boldsymbol{e}^n\|_b^2+\left(\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g)-\bar\beta_\epsilon^n(u_\nu-g),e_\nu^n\right)_{\Gamma_c}$$
$$\leq\lambda(\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n),\operatorname{div}\boldsymbol{e}^n)+2\mu\,b(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n,\boldsymbol{e}^n)+m(\Theta^n-\bar\theta^n,\operatorname{div}\boldsymbol{e}^n)$$
$$\leq\lambda(\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n),\operatorname{div}\boldsymbol{e}^n)+2\mu\,b(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n,\boldsymbol{e}^n)$$
$$+\ m(\Theta^n-P_0^h\bar\theta^n,\operatorname{div}(\boldsymbol{U}^n-\boldsymbol{u}^n))+m(\bar\theta^n-P_0^h\bar\theta^n,\operatorname{div}(\boldsymbol{u}^n-\boldsymbol{U}^n))$$
$$+\ m(\Theta^n-P_0^h\bar\theta^n+P_0^h\bar\theta^n-\bar\theta^n,\operatorname{div}(\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n)). \tag{3.4}$$

Adding (3.2) and (3.4) and recalling (3.1) result in

$$\frac{1}{(\Delta t)^2}\|\varepsilon^n-\varepsilon^{n-1}\|^2+\frac{1}{2\Delta t}\left(\|\nabla\varepsilon^n-\nabla\varepsilon^{n-1}\|^2+\|\nabla\varepsilon^n\|^2-\|\nabla\varepsilon^{n-1}\|^2\right)+\lambda\|\operatorname{div}\boldsymbol{e}^n\|^2$$
$$+\ 2\mu\|\boldsymbol{e}^n\|_b^2\leq\frac{1}{\Delta t}(\Theta^0-\theta_0,\varepsilon^n-\varepsilon^{n-1})+\frac{m}{\Delta t}(\operatorname{div}(\boldsymbol{U}^0-\boldsymbol{u}_0),\varepsilon^n-\varepsilon^{n-1})$$
$$+\ \frac{1}{\Delta t}(\theta^n-P_0^h\bar\theta^n,\varepsilon^n-\varepsilon^{n-1})+\lambda(\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n),\operatorname{div}\boldsymbol{e}^n)$$
$$+\ 2\mu\,b(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n,\boldsymbol{e}^n)+m(\bar\theta^n-P_0^h\bar\theta^n,\operatorname{div}(P_E^h\boldsymbol{u}^n-\boldsymbol{U}^n))$$
$$+\ \frac{m}{\Delta t}(\varepsilon^n-\varepsilon^{n-1},\operatorname{div}(\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n))+\left(\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g),e_\nu^n\right)_{\Gamma_c}.$$

Thus

$$\frac{1}{2(\Delta t)^2}\|\varepsilon^n-\varepsilon^{n-1}\|^2+\frac{1}{4\Delta t}\left(\|\nabla\varepsilon^n-\nabla\varepsilon^{n-1}\|^2\right)+\frac{1}{2\Delta t}\left(\|\nabla\varepsilon^n\|^2-\|\nabla\varepsilon^{n-1}\|^2\right)$$
$$+\ \frac{\lambda}{2}\|\operatorname{div}\boldsymbol{e}^n\|^2+\mu\|\boldsymbol{e}^n\|_b^2\le\|\Theta^0-\theta_0\|^2+\frac{2m^2}{\Delta t}\|\boldsymbol{U}^0-\boldsymbol{u}_0\|^2+\|\theta^n-P_0^h\bar\theta^n\|^2$$
$$+\ \lambda\|\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n)\|^2+\mu\|\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n\|_b^2+\frac{2m^2}{\Delta t}\|\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n\|^2+\frac{m^2}{\lambda}\|\bar\theta^n-P_0^h\bar\theta^n\|^2$$
$$+\ \frac{1}{2}\|\operatorname{div}(\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n)\|^2+\left(\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g),e_\nu^n\right)_{\Gamma_c}, \tag{3.5}$$

where we used that $(\operatorname{div}\boldsymbol{v},w)=-(\boldsymbol{v},\nabla w),\ w\in H_0^1(\Omega)$.

Let us estimate the last seven terms in the latter inequality. Thus

$$I_1\equiv\|\theta^n-P_0^h\bar\theta^n\|^2=\|\theta^n-\bar\theta^n+\bar\theta^n-P_0^h\bar\theta^n\|^2$$
$$\le 2\left\|\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}\int_t^{t_n}\theta_t(\cdot,s)dsdt\right\|^2+2\left\|\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}(\theta-P_0^h\theta)(\cdot,t)dt\right\|^2$$
$$\le C\left(\Delta t\int_{t_{n-1}}^{t_n}\|\theta_t\|^2dt+\frac{h^4}{\Delta t}\int_{t_{n-1}}^{t_n}\|\theta\|_2^2dt\right),$$
$$I_2\equiv\lambda\|\operatorname{div}(\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n)\|^2\le C\Delta t\int_{t_{n-1}}^{t_n}\|\operatorname{div}\boldsymbol{u}_t\|^2dt,$$
$$I_3\equiv\mu\|\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n\|_b^2\le C\mu\|\bar{\boldsymbol{u}}^n-\boldsymbol{u}^n\|_1^2\le C\mu\Delta t\int_{t_{n-1}}^{t_n}\|\boldsymbol{u}_t\|_1^2dt,$$
$$I_4\equiv\frac{2m^2}{\Delta t}\|\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n\|^2\le\frac{C}{\Delta t}\|\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n\|_1^2,$$
$$I_5\equiv\frac{m^2}{\lambda}\|\bar\theta^n-P_0^h\bar\theta^n\|^2\le\frac{Ch^4}{\lambda\Delta t}\int_{t_{n-1}}^{t_n}\|\theta\|_2^2dt,$$
$$I_6\equiv\frac{1}{2}\|\operatorname{div}(\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n)\|^2\le C\|\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n\|_1^2,$$
$$I_7\equiv\left(\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g),e_\nu^n\right)_{\Gamma_c}$$
$$=\left(\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)+\beta_\epsilon(u_\nu^n-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g),e_\nu^n\right)_{\Gamma_c}.$$

We have, using Sobolev's trace theorem and (1.7),

$$\left(\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g),e_\nu^n\right)_{\Gamma_c}\le\|\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\|_{L^2(\Gamma_c)}\|e_\nu^n\|_{L^2(\Gamma_c)}$$
$$\le\|\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\|_{L^2(\Gamma_c)}\|\boldsymbol{e}^n\|_{\mathbf{L}^2(\Gamma_c)}\le C\|\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\|_{L^2(\Gamma_c)}\|\boldsymbol{e}^n\|_1$$
$$\le\frac{C}{\mu}\|\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\|_{L^2(\Gamma_c)}^2+\frac{\mu}{4}\|\boldsymbol{e}^n\|_b^2$$

and

$$\|\bar\beta_\epsilon^n(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\|_{L^2(\Gamma_c)}^2=\left\|\frac{1}{\Delta t}\int_{t_{n-1}}^{t_n}\left(\beta_\epsilon(u_\nu-g)-\beta_\epsilon(u_\nu^n-g)\right)dt\right\|_{L^2(\Gamma_c)}^2$$
$$\le\left\|\frac{1}{\epsilon\Delta t}\int_{t_{n-1}}^{t_n}|u_\nu-u_\nu^n|dt\right\|_{L^2(\Gamma_c)}^2\le\left\|\frac{1}{\epsilon\Delta t}\int_{t_{n-1}}^{t_n}\left|\int_{t_n}^t u_{\nu t}(\cdot,s)ds\right|dt\right\|_{L^2(\Gamma_c)}^2$$

$$\leq \frac{C\Delta t}{\epsilon^2}\int_{t_{n-1}}^{t_n}\|\boldsymbol{u}_t\|_1^2 dt.$$

On the other hand,

$$\begin{aligned}&\left(\beta_\epsilon(u_\nu^n-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g),e_\nu^n\right)_{\Gamma_c}\\ &\leq\frac{1}{\mu}\left\|\beta_\epsilon(u_\nu^n-g)-\beta_\epsilon((P_E^h\boldsymbol{u}^n)_\nu-g)\right\|_{L^2(\Gamma_c)}^2+\frac{\mu}{4}\|e_\nu^n\|_{L^2(\Gamma_c)}^2\\ \leq\frac{1}{\epsilon^2\mu}\left\|u_\nu^n-(P_E^h\boldsymbol{u}^n)_\nu\right\|_{L^2(\Gamma_c)}^2+\frac{\mu}{4}\|e_\nu^n\|_{L^2(\Gamma_c)}^2&\leq\frac{C}{\epsilon^2\mu}\left\|\boldsymbol{u}^n-P_E^h\boldsymbol{u}^n\right\|_1^2+\frac{\mu}{4}\|\boldsymbol{e}^n\|_b^2.\end{aligned}$$

Collecting all the bounds and summing (3.5) over n result in

$$\begin{aligned}&\Delta t\sum_{i=1}^n\left\|\frac{\varepsilon^i-\varepsilon^{i-1}}{\Delta t}\right\|^2+\sum_{i=1}^n\|\nabla(\varepsilon^i-\varepsilon^{i-1})\|^2+\|\nabla\varepsilon^n\|^2+\lambda\Delta t\sum_{i=1}^n\|\operatorname{div}\boldsymbol{e}^i\|^2\\ &+\mu\Delta t\sum_{i=1}^n\|\boldsymbol{e}^i\|_b^2\leq C(\lambda,\mu,\epsilon)\bigg(\|\nabla\varepsilon^0\|^2+\|\Theta^0-\theta_0\|^2+\frac{1}{\Delta t}\|\boldsymbol{U}^0-\boldsymbol{u}_0\|^2\\ &+(\Delta t)^2\int_0^{t_n}\|\theta_t\|^2dt+h^4\int_0^{t_n}\|\theta\|_2^2dt+(\Delta t)^2\int_0^{t_n}\|\operatorname{div}\boldsymbol{u}_t\|^2dt\\ &+(\Delta t)^2\int_0^{t_n}\|\boldsymbol{u}_t\|_1^2dt+\left(\frac{1}{\Delta t}+1\right)\Delta t\sum_{i=1}^n\|\boldsymbol{u}^i-P_E^h\boldsymbol{u}^i\|_1^2\bigg).\end{aligned}$$

The definition of ε^0 and the regularity of θ and $\boldsymbol{u}$ yield

$$\begin{aligned}&\Delta t\sum_{i=1}^n\left\|\frac{\varepsilon^i-\varepsilon^{i-1}}{\Delta t}\right\|^2+\|\nabla\varepsilon^n\|^2+\lambda\Delta t\sum_{i=1}^n\|\operatorname{div}\boldsymbol{e}^i\|^2+\mu\Delta t\sum_{i=1}^n\|\boldsymbol{e}^i\|_b^2\\ &\leq C(\lambda,\mu,\epsilon)\bigg(\|\Theta^0-\theta_0\|^2+\frac{1}{\Delta t}\|\boldsymbol{U}^0-\boldsymbol{u}_0\|^2+(\Delta t)^2+h^4\\ &+\left(\frac{1}{\Delta t}+1\right)\Delta t\sum_{i=1}^n\|\boldsymbol{u}^i-P_E^h\boldsymbol{u}^i\|_1^2\bigg),\end{aligned}$$

and the result follows observing that

$$\begin{aligned}\left\|\int_0^{t_n}\nabla\theta(\cdot,t)dt-\Delta t\sum_{i=1}^n\nabla\Theta^i\right\|^2&=\left\|\nabla(\hat\theta^n-P_0^h\hat\theta^n)-\nabla\varepsilon^n\right\|^2,\\ \Delta t\sum_{i=1}^n\|\Theta^i-\theta(\cdot,t_i)\|^2=\Delta t\sum_{i=1}^n\left\|\frac{\varepsilon^i-\varepsilon^{i-1}}{\Delta t}+P_0^h\bar\theta^i-\theta^i\right\|^2,&\\ \lambda\Delta t\sum_{i=1}^n\|\operatorname{div}(\boldsymbol{U}^i-\boldsymbol{u}(\cdot,t_i))\|^2\leq\lambda\Delta t\sum_{i=1}^n\|\operatorname{div}(\boldsymbol{e}^i+P_E^h\boldsymbol{u}^i-\boldsymbol{u}^i)\|^2&\end{aligned}$$

and

$$\mu\Delta t\sum_{i=1}^n\|\boldsymbol{U}^i-\boldsymbol{u}(\cdot,t_i)\|_b^2\leq C\mu\Delta t\sum_{i=1}^n\|\boldsymbol{e}^i+P_E^h\boldsymbol{u}^i-\boldsymbol{u}^i\|_b^2.\qquad\square$$

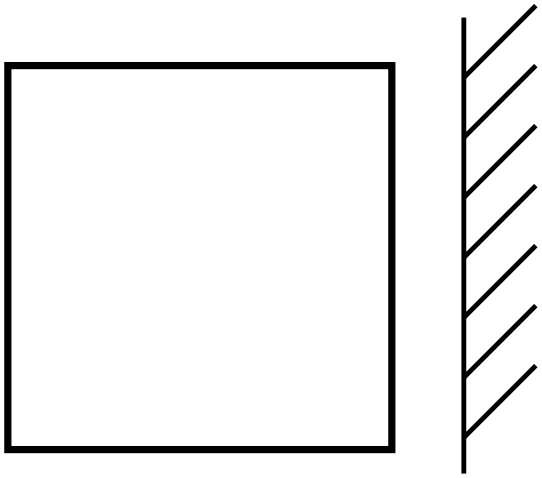

FIG. 1. *The contact problem setting.*

COROLLARY 3.2. *Let* $\Theta^0 = P_0^h\theta_0$, $\boldsymbol{U}^0 = P^h\boldsymbol{u}_0$, *and* $\Delta t = O(h)$. *Under the assumptions of Theorem* 3.1,

$$E(\theta, \boldsymbol{u}) \to 0 \quad as \quad h \to 0.$$

Proof. We follow Ciarlet [7]. Given $\varepsilon^{'} > 0$, since $\mathbf{H}^2(\Omega) \cap \mathbf{H}_E^1(\Omega)$ is dense in $\mathbf{H}_E^1(\Omega)$, there exists $\tilde{\boldsymbol{u}} \in \mathbf{H}^2(\Omega) \cap \mathbf{H}_E^1(\Omega)$ such that

$$\|\boldsymbol{u}^n - \tilde{\boldsymbol{u}}\|_1^2 \leq \varepsilon^{'}.$$

Thus, using (2.1) and (2.4),

$$\|\boldsymbol{u}^n - P_E^h\boldsymbol{u}^n\|_1^2 \leq C\|\boldsymbol{u}^n - \tilde{\boldsymbol{u}} + \tilde{\boldsymbol{u}} - I^h\tilde{\boldsymbol{u}}\|_1^2 \leq C(\varepsilon^{'} + h^2\|\tilde{\boldsymbol{u}}\|_2^2).$$

Recalling (2.2) and (2.3), the convergence result is obtained taking $\varepsilon^{'} = O(h^2)$. ∎

COROLLARY 3.3. *Suppose that* $\boldsymbol{u} \in L^\infty(0, T; \mathbf{H}^2(\Omega))$, $\theta_0 \in H^2(\Omega)$, *and* $\boldsymbol{u}_0 \in \mathbf{H}^2(\Omega)$. *Let* $\Theta^0 = P_0^h\theta_0$ *and* $\boldsymbol{U}^0 = P^h\boldsymbol{u}_0$. *Then the error estimate*

$$E(\theta, \boldsymbol{u}) \leq C(\lambda, \mu, \epsilon)\left(\frac{h^4}{\Delta t} + (\Delta t)^2 + h^4 + \frac{h^2}{\Delta t} + h^2\right)$$

holds and the error bound is $O(h)$ *if* $\Delta t = h$.

Proof. The estimate is a consequence of the additional assumed regularity. ∎

4. Numerical experiments. In our experiments, the reference configuration is the square $\Omega = (0,1) \times (0,1)$ with $\Gamma_C = \{(1, x_2) \,|\, 0 < x_2 < 1\}$ and Γ_0 the remaining boundary of Ω. The elastic obstacle is located at distance $g(\mathbf{x}) = 0.02$ from Γ_C (see Figure 1) and the initial temperature Θ^0 is the linear interpolant of $\theta_0(\mathbf{x}) = 20000\, x_1 x_2 (x_1 - 1)(x_2 - 1)$. We let $\lambda = 1$, $\mu = 30$, and $m = 0.008$, and tolerance of 1×10^{-7} was used to stop the iterative procedures. A uniform triangulation of Ω was obtained by dividing the square into $M \times M$ squares with side $h = 1/M$ and connecting the north-west vertex to the south-east vertex of each square.

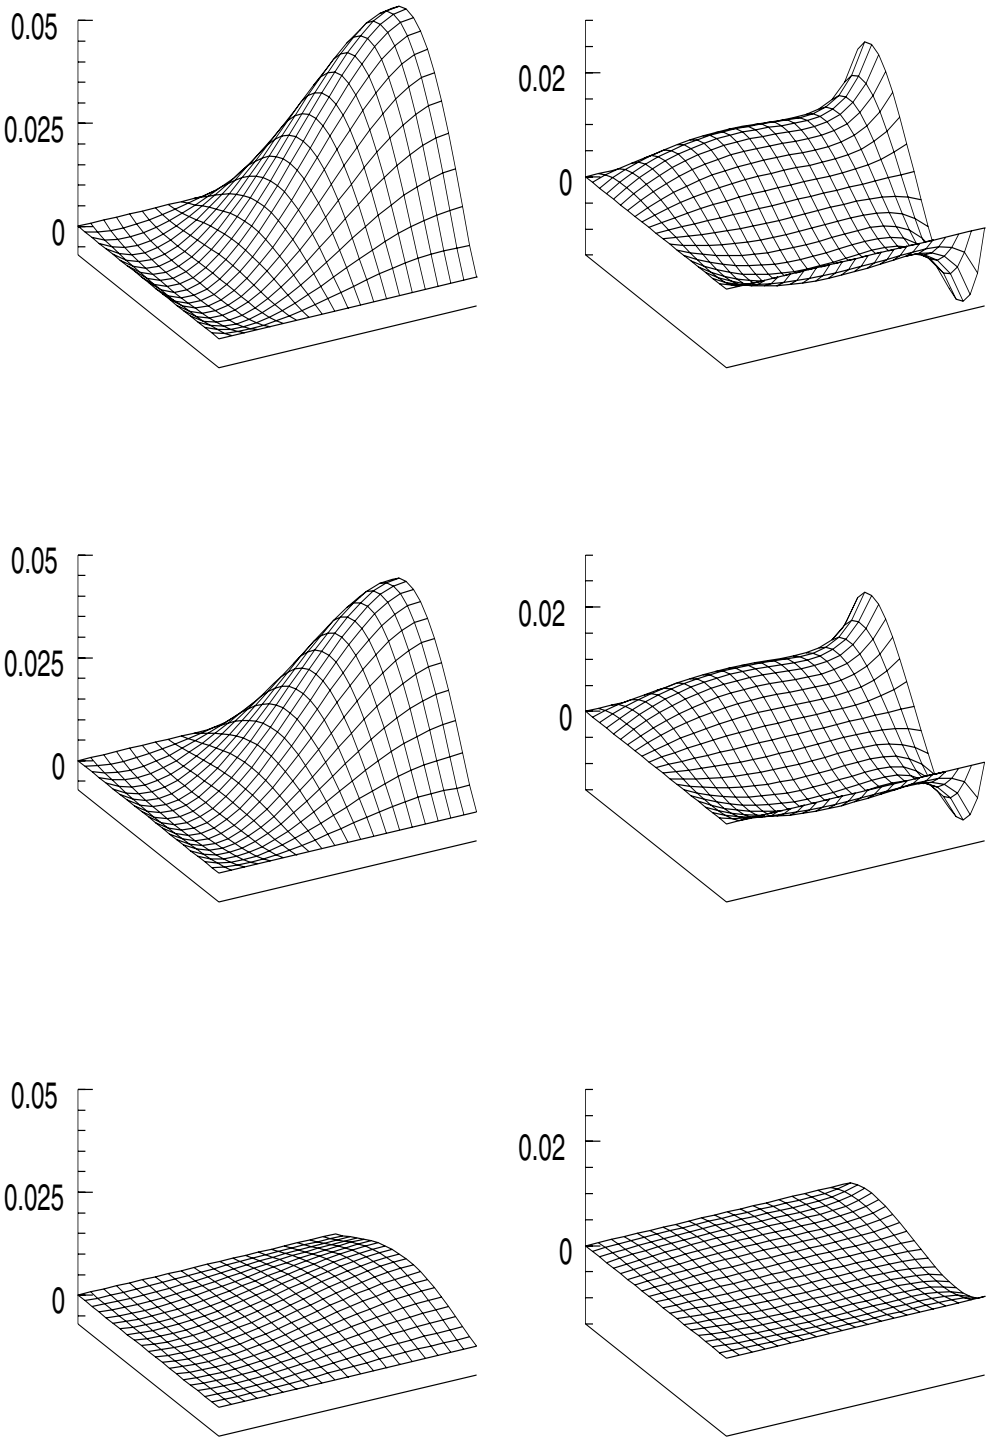

FIG. 2. *The evolution of the displacement components when* $\epsilon = 0.1$. *The left and right columns show* u_1 *and* u_2, *respectively, at* $t = 0,\ 0.01$, *and* 0.1.

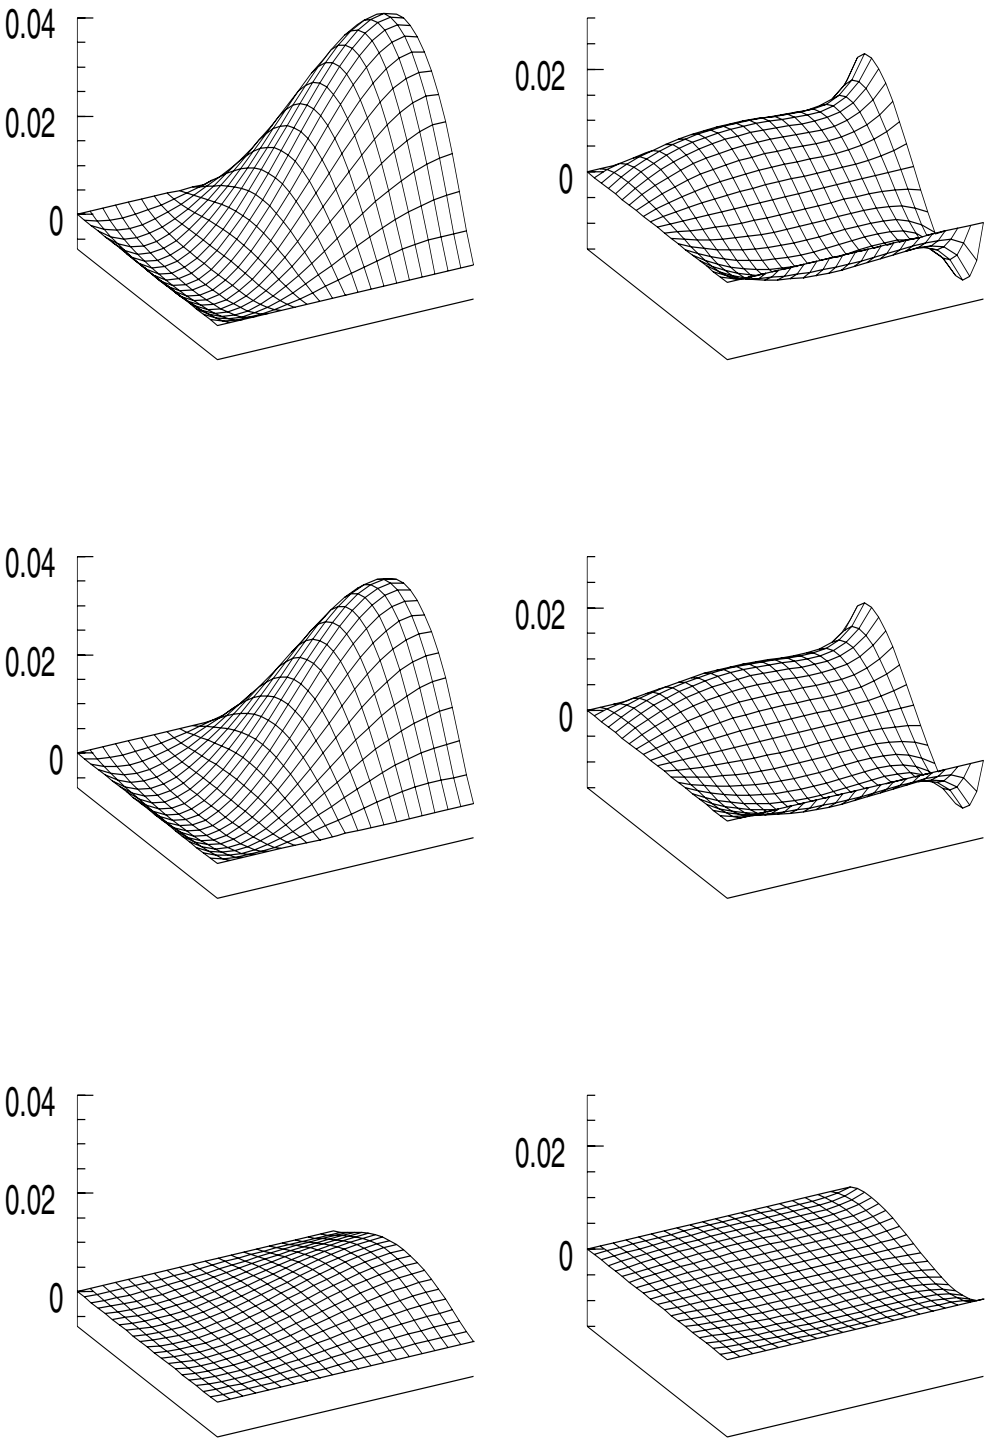

FIG. 3. *The evolution of the displacement components when* $\epsilon = 0.01$. *The left and right columns show* u_1 *and* u_2, *respectively, at* $t = 0,\ 0.01,$ *and* 0.1.

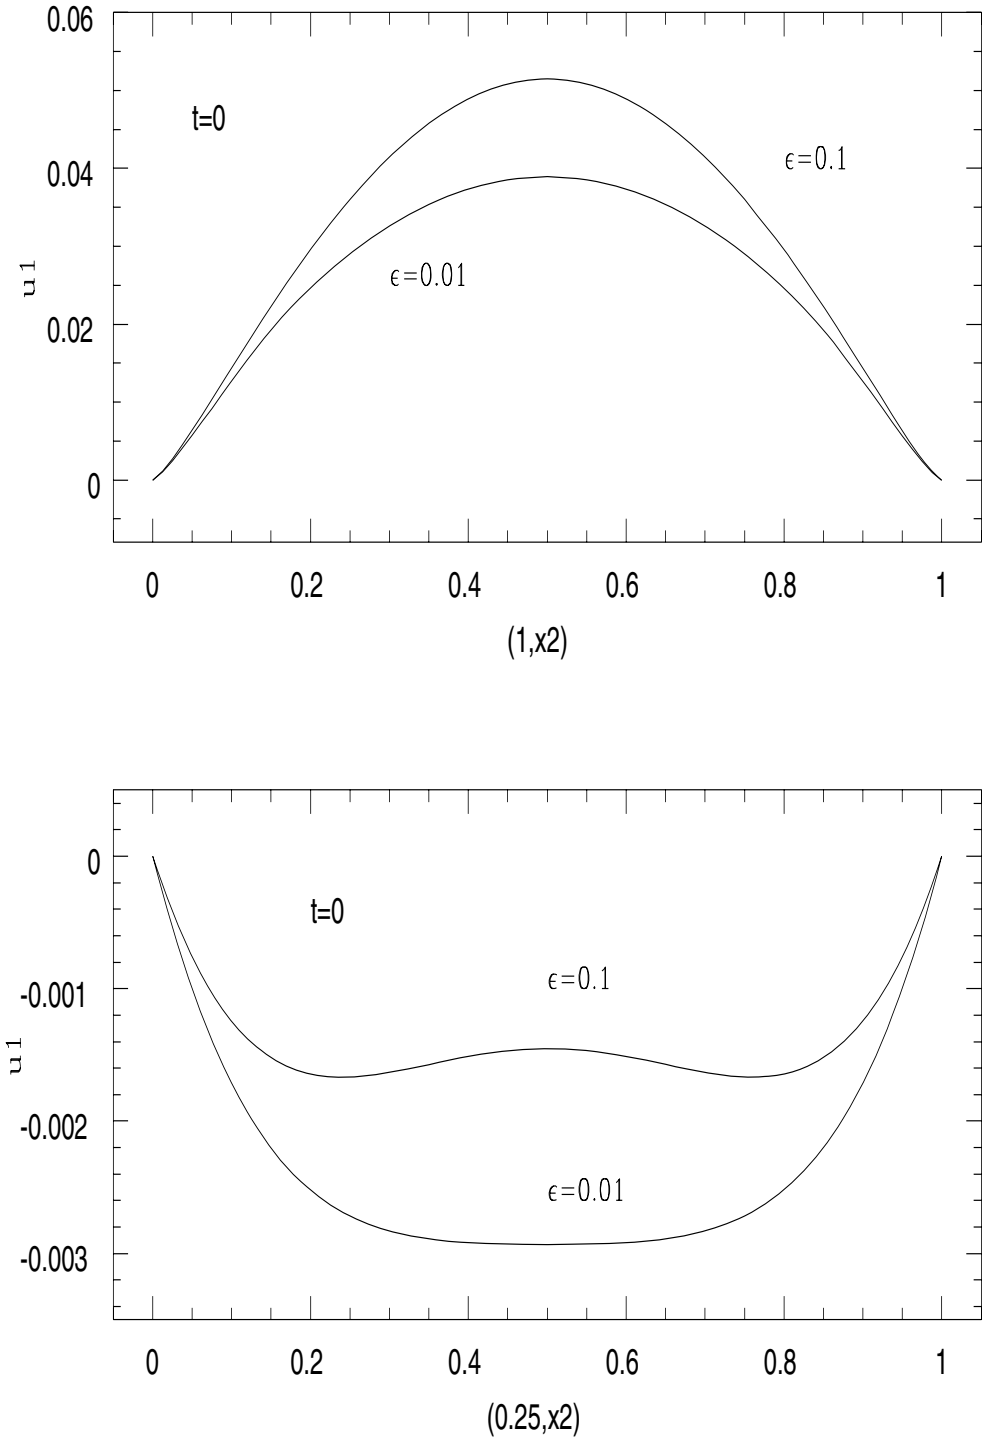

FIG. 4. *The displacement component* u_1 *at* $t = 0$ *for* $\mathbf{x} = (1, x_2)$ *and* $\mathbf{x} = (0.25, x_2)$.

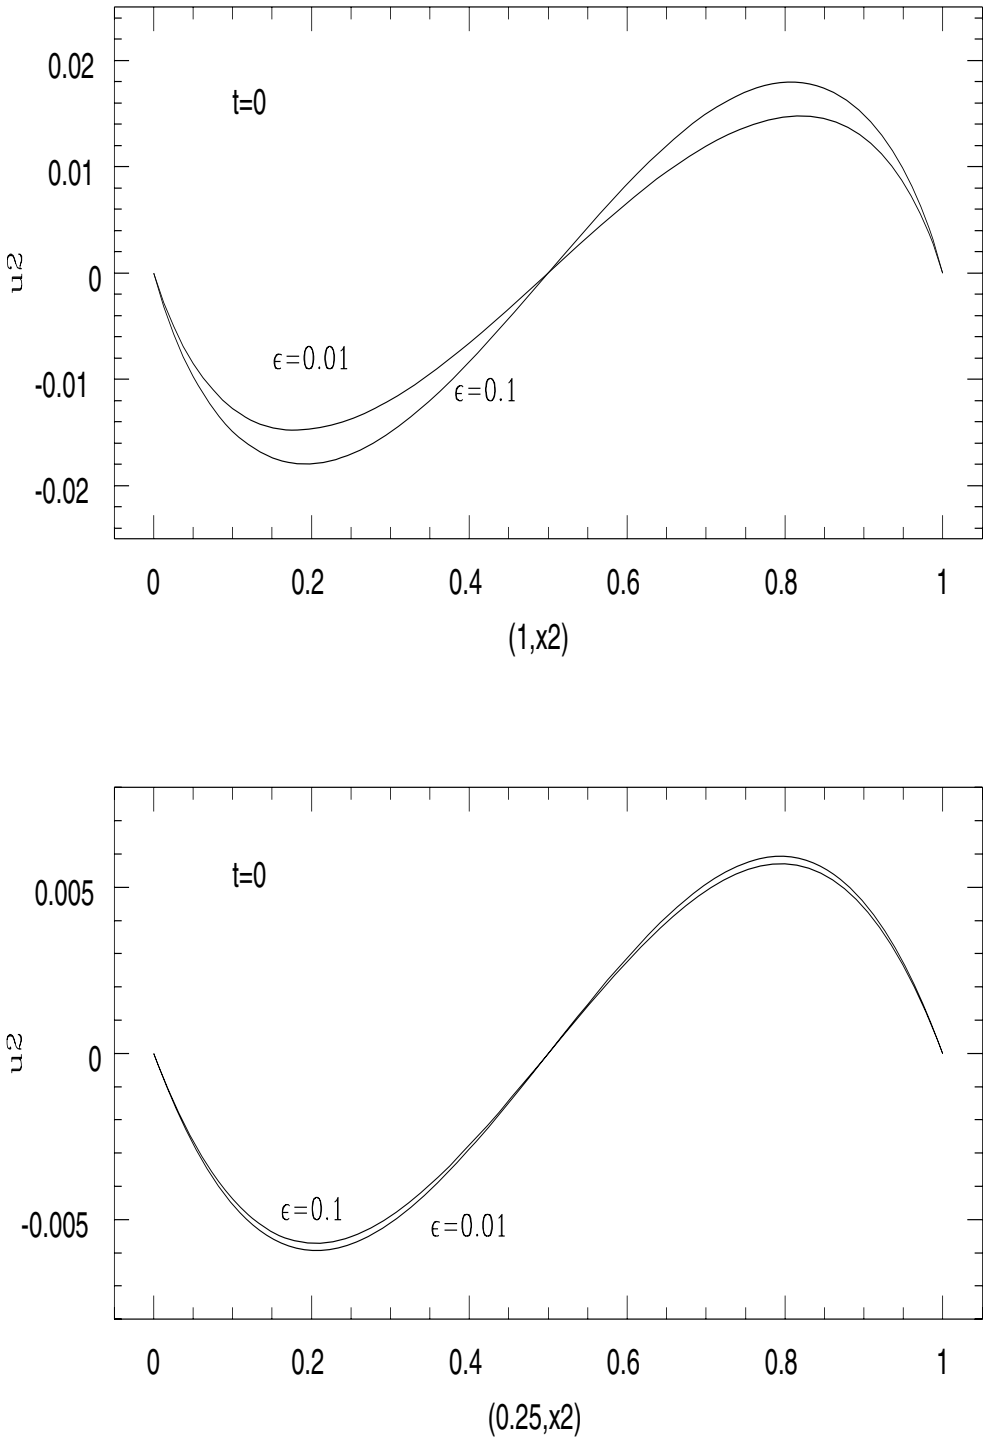

FIG. 5. *The displacement component* u_2 *at* $t = 0$ *for* $\mathbf{x} = (1, x_2)$ *and* $\mathbf{x} = (0.25, x_2)$.

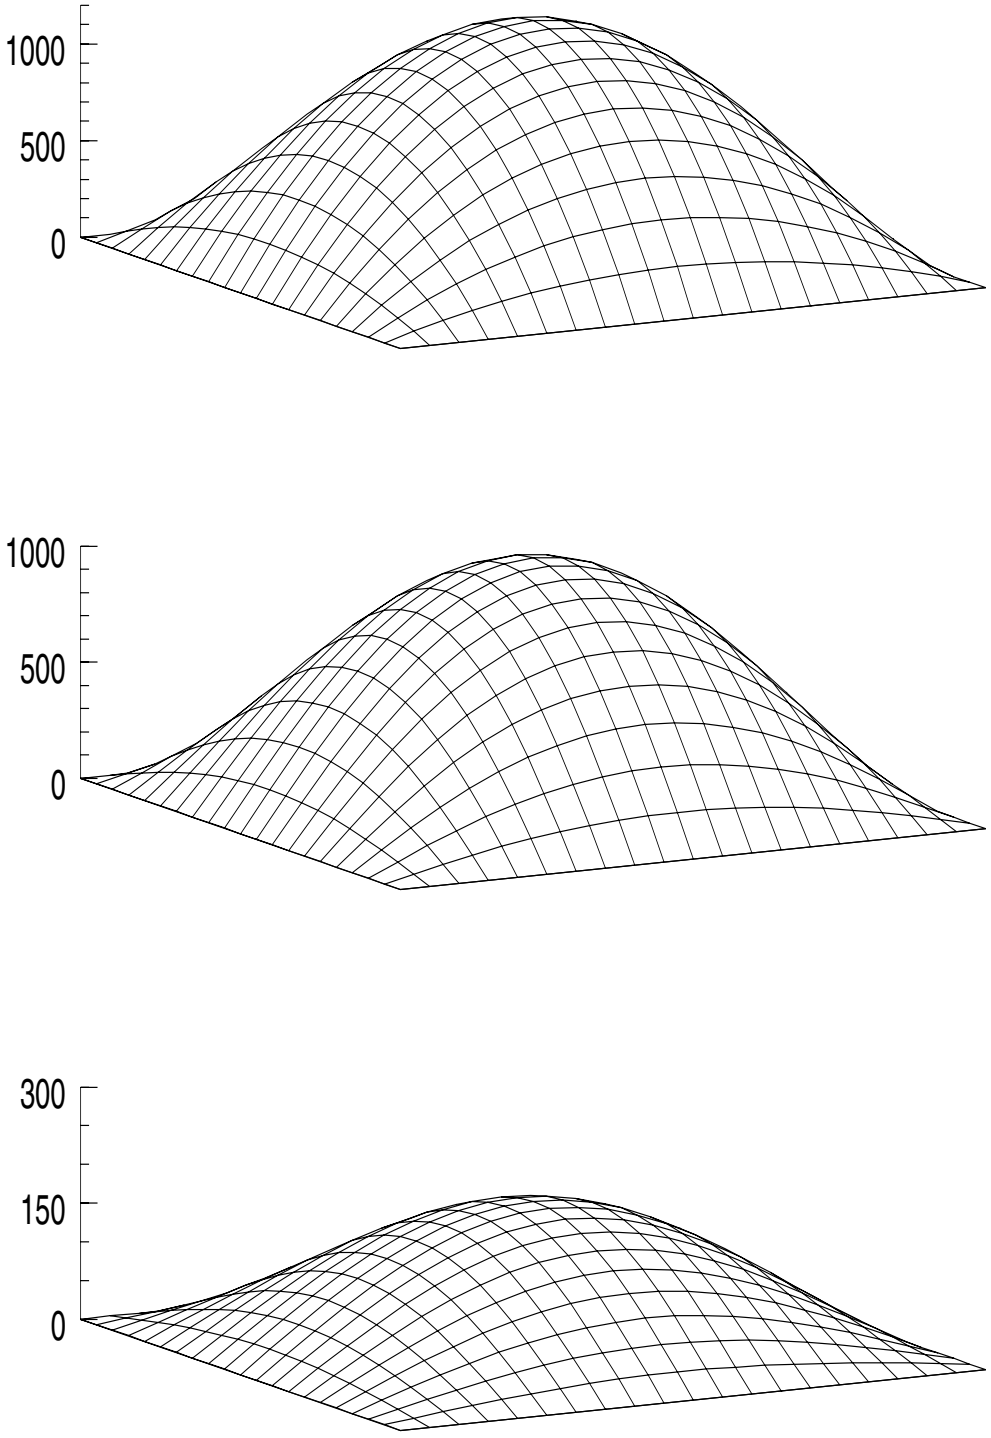

FIG. 6. *The temperature at* $t = 0,\ 0.01,$ *and* 0.1.

TABLE 1
The computed errors for $T = 0.2$ and $\epsilon = 0.1$.

$h = \Delta t$	$\Delta t \sum_{i=1}^{N} \|\Theta^i - \theta(\cdot, t_i)\|^2$	Rate	$\Delta t \sum_{i=1}^{N} \|U^i - u(\cdot, t_i)\|_b^2$	Rate
1/10	2.05×10^3		1.68×10^{-5}	
1/20	8.29×10^2	1.30	6.21×10^{-6}	1.44
1/40	2.61×10^2	1.67	1.64×10^{-6}	1.92
1/80	7.39×10	1.82	5.25×10^{-7}	1.64
1/160	1.98×10	1.90	2.51×10^{-7}	1.07

In the first experiment, $M = 80$, $\Delta t = 1 \times 10^{-5}$, and we took two values for the parameter ϵ, $\epsilon = 0.1$ and $\epsilon = 0.01$. The results are shown in Figures 2–6. At $t = 0$ the body is in contact with the obstacle and the evolution is toward the state $\theta = 0$, $\boldsymbol{u} = \mathbf{0}$. As expected, when ϵ decreases the obstacle becomes more rigid and penetration is more difficult. Note that there is a region where the body has contracted. The temperature profiles were virtually the same in both cases.

In order to test the error estimates, we compared the numerical solutions on coarse meshes with the solution obtained with the finer mesh ($M = 320$ and $\Delta t = 1 \times 10^{-5}$). The computed errors for $T = 0.2$ and $\epsilon = 0.1$ are reported in Table 1, where we observe convergence rates larger than those given by Corollary 3.3.

5. Remark on the Signorini problem. In [11], Copetti and French considered the numerical approximation of the one dimensional Signorini problem with viscosity effects and proved error estimates using the decomposition

$$\theta - \Theta^n = \theta - \theta^\epsilon + \theta^\epsilon - \Theta^n,$$
$$u - U^n = u - u^\epsilon + u^\epsilon - U^n,$$

where $\{\theta, u\}$ represents the solution to the Signorini problem, $\{\theta^\epsilon, u^\epsilon\}$ the solution to the penalized problem, and $\{\Theta^n, U^n\}$ the numerical solution based on the penalization.

In the two dimensional case, similar results can be obtained if the solutions to the continuous problems are sufficiently smooth. We can show that

$$\int_0^T \|\theta - \theta^\epsilon\|^2 dt + \frac{1}{2} \left\| \int_0^T \nabla(\theta - \theta^\epsilon) dt \right\|^2 + \lambda \int_0^T \|\mathrm{div}\,(\boldsymbol{u} - \boldsymbol{u}^\epsilon)\|^2 dt$$
$$+ 2\mu \int_0^T \|\boldsymbol{u} - \boldsymbol{u}^\epsilon\|_b^2 dt + \frac{1}{\epsilon} \int_0^T \|u_\nu - u_\nu^\epsilon\|_{L^2(\Gamma_c)}^2 dt \le \frac{\epsilon}{2} \int_0^T \|\sigma_\nu\|_{L^2(\Gamma_c)}^2 dt,$$

which together with Corollary 3.3 yields error bounds for the numerical approximation of (1.1)–(1.3) and (1.5)–(1.6) by the discrete solution $\{\Theta^n, \boldsymbol{U}^n\}$.

Acknowledgment. The author wishes to thank the referees for their valuable comments which improved the manuscript.

SPECTRAL DISCRETIZATION OF A NAGHDI SHELL MODEL*

CHRISTINE BERNARDI† AND ADEL BLOUZA‡

Abstract. We consider the Naghdi equations which model a thin three-dimensional shell. We propose a spectral discretization of this problem in the case where the midsurface of the shell is weakly regular. We perform the numerical analysis of the discrete problem and prove optimal error estimates.

Key words. spectral methods, Naghdi shell model

1. Introduction.

We consider a formulation of Naghdi's shell model in Cartesian coordinates which is appropriate for linearly elastic shells that present curvature discontinuities. The aim of this paper is to propose a spectral discretization of the mixed formulation of this problem and to perform its numerical analysis.

The formulation of Naghdi's model which is used here was introduced in [7], [11]. This formulation relies on the idea of using a local basis-free formulation in which the unknowns are described in Cartesian coordinates instead of covariant or contravariant components as is usually done in shell theory; see, for example, [2]. Such a formulation is able to handle shells with a $W^{2,\infty}$-midsurface, thus allowing for curvature discontinuities, as opposed to $\mathscr{C}^3$ in the classical formalism (see [15, Chap. 7] and the references therein), and leads to much simpler expressions. Even though it is proved in [11] to be well-posed and to be the natural limit of the classical formulation when a sequence of regular midsurfaces converges to a $W^{2,\infty}$-midsurface, the new formulation has not been used in a numerical spectral setting to the best of our knowledge. For simplicity, we only consider the case of a shell with a $W^{2,\infty}$-midsurface.

The literature on finite element approximation of two-dimensional shell models is large. Let us mention a few approaches. Concerning conforming methods, the Ganev and Argyris triangles provide interpolation by polynomials of degree 4 and 5, with high order convergence in $c\,h^4$ when the solution is smooth enough. These elements are used, for example, to study the linear Koiter model for $\mathscr{C}^3$-shells in the classical covariant formulation; see [1, Part II, Chap. 1]. This method is applied to approximate geometrically exact shell models in [13]. The Argyris elements are also used in [18] for numerical analysis of Koiter's model with little regularity in the Cartesian formulation proposed in [10]. We also mention the three-dimensional shell element approach; see [14]. Still in the context of shells with little regularity, i.e., when the midsurface is of $W^{2,\infty}$-regularity, a nonconforming discrete Kirchhoff triangle (DKT) element is used in [21] to approximate a Koiter equation similar to the model introduced in [10]. Other works [19], [20] concern the finite element discretization of shell problems with domain decomposition. The main difficulty of all these discretizations is that, in

most situations, a locking phenomenon appears when the choice of the discretization parameter is not sufficient to handle the thickness of the shell.

In this paper, we propose a spectral discretization of Naghdi's model. It relies on a mixed variational formulation of the corresponding equation proposed in [9]: A Lagrange multiplier is introduced to enforce the tangency requirement on one of the unknowns. A further penalization term is also added in order to stabilize the system. We first describe the discrete problem which is constructed from the variational formulation of the model by the Galerkin method with numerical integration (see [4, sect. 15] or [6, Chap. V] for a detailed presentation of this procedure). Under some further but likely regularity assumptions on the midsurface of the shell, we prove that it is well-posed. Finally, relying on standard polynomial approximation and interpolation results, we prove error estimates which are fully optimal from a numerical point of view for a fixed thickness of the shell.

The extension of this study to the case of a piecewise regular shell discretized by the spectral element method is under consideration. Numerical experiments should confirm the interest of this discretization.

An outline of the paper is as follows.

- In section 2, we recall the geometry of the midsurface and Naghdi's shell formulation. We introduce a mixed version of Naghdi's model intended to approximate the above mentioned tangency. We prove the existence and uniqueness of the solution.
- Section 3 is devoted to the description of the spectral discrete problem. We also prove its well-posedness.
- Error estimates are derived in section 4.

2. Presentation of the model. Greek indices and exponents take their values in the set $\{1,2\}$, and Latin indices and exponents take their values in the set $\{1,2,3\}$. Unless otherwise specified, the summation convention for repeated indices and exponents according to this set of values is assumed. Let $\{\boldsymbol{e}_1,\boldsymbol{e}_2,\boldsymbol{e}_3\}$ be the canonical orthonormal basis of the Euclidean space $\mathbb{R}^3$. We denote by $\boldsymbol{u}\cdot\boldsymbol{v}$ the inner product of $\mathbb{R}^3$, $|\boldsymbol{u}|=\sqrt{\boldsymbol{u}\cdot\boldsymbol{u}}$ the associated Euclidean norm, and $\boldsymbol{u}\wedge\boldsymbol{v}$ the vector product of $\boldsymbol{u}$ and $\boldsymbol{v}$.

Let ω be a bounded connected domain of $\mathbb{R}^2$ with a Lipschitz-continuous boundary $\partial\omega$. We consider a shell whose midsurface is given by $S=\varphi(\bar\omega)$, where φ is a one-to-one mapping in $W^{2,\infty}(\omega)^3$ such that the two vectors $\boldsymbol{a}_\alpha(\boldsymbol{x})=(\partial_\alpha\varphi)(\boldsymbol{x})$ are linearly independent at each point $\boldsymbol{x}$ of $\bar\omega$. Thus,

$$\boldsymbol{a}_3(\boldsymbol{x})=\frac{\boldsymbol{a}_1(\boldsymbol{x})\wedge\boldsymbol{a}_2(\boldsymbol{x})}{|\boldsymbol{a}_1(\boldsymbol{x})\wedge\boldsymbol{a}_2(\boldsymbol{x})|}$$

is the unit normal vector on the midsurface at point $\varphi(\boldsymbol{x})$. The vectors $\boldsymbol{a}_i(\boldsymbol{x})$ define the local covariant basis at point $\varphi(\boldsymbol{x})$. The contravariant basis $\boldsymbol{a}^i(\boldsymbol{x})$ is defined by the relations $\boldsymbol{a}_i\cdot\boldsymbol{a}^j=\delta_i^j$, where δ_i^j is the Kronecker symbol. In particular $\boldsymbol{a}^3(\boldsymbol{x})$ coincides with $\boldsymbol{a}_3(\boldsymbol{x})$. Note that all of these vectors belong to $W^{1,\infty}(\omega)^3$. We set $a(\boldsymbol{x})=|\boldsymbol{a}_1(\boldsymbol{x})\wedge\boldsymbol{a}_2(\boldsymbol{x})|^2$ so that $\sqrt{a(\boldsymbol{x})}$ is the area element of the midsurface in the chart φ. Finally, the first fundamental form of the surface is given in covariant components by $a_{\alpha\beta}=\boldsymbol{a}_\alpha\cdot\boldsymbol{a}_\beta$.

Let $\boldsymbol{u}$ be a midsurface displacement in $H^1(\omega)^3$ and $\boldsymbol{r}$ be a rotation vector in $H^1(\omega)^3$ such that $\boldsymbol{r}$ is tangential to the midsurface. These functions are given in covariant and Cartesian components by

$$\boldsymbol{u}(\boldsymbol{x})=u_i(\boldsymbol{x})\boldsymbol{a}^i(\boldsymbol{x})=u_i^c(\boldsymbol{x})\boldsymbol{e}_i,\qquad\text{with}\quad u_i=\boldsymbol{u}\cdot\boldsymbol{a}_i\quad\text{and}\quad u_i^c=\boldsymbol{u}\cdot\boldsymbol{e}_i,$$

and

$$\boldsymbol{r}(\boldsymbol{x}) = r_\alpha(\boldsymbol{x})\boldsymbol{a}^\alpha(\boldsymbol{x}) = r_i^c(\boldsymbol{x})\boldsymbol{e}_i, \qquad \text{with} \quad r_\alpha = \boldsymbol{r}\cdot\boldsymbol{a}_\alpha \quad \text{and} \quad r_i^c = \boldsymbol{r}\cdot\boldsymbol{e}_i.$$

Note that the tangency requirement is easily expressed in covariant coordinates, as it simply reads $r_3 = 0$, whereas it becomes $r_i^c(\boldsymbol{x})a_{3,i}^c(\boldsymbol{x}) = 0$ in ω in Cartesian coordinates.

Let $a^{\alpha\beta\rho\sigma}$ denote the coefficients of the elasticity tensor. In the case of homogeneous, isotropic material with Young modulus $E > 0$ and Poisson coefficient ν, $0 \le \nu < \frac{1}{2}$, these coefficients are given by

$$a^{\alpha\beta\rho\sigma} = \frac{E}{2(1+\nu)}(a^{\alpha\rho}a^{\beta\sigma} + a^{\alpha\sigma}a^{\beta\rho}) + \frac{E\nu}{1-\nu^2}a^{\alpha\beta}a^{\rho\sigma}, \tag{2.1}$$

where $a^{\alpha\beta} = \boldsymbol{a}^\alpha\cdot\boldsymbol{a}^\beta$ are the contravariant components of the first fundamental form. We note that each coefficient of this tensor belongs to $L^\infty(\omega)$. Moreover, it satisfies the usual symmetry properties

$$a^{\alpha\beta\rho\sigma}(\boldsymbol{x}) = a^{\rho\sigma\alpha\beta}(\boldsymbol{x}) = a^{\beta\alpha\rho\sigma}(\boldsymbol{x}) \qquad \text{for a.e. } \boldsymbol{x}\in\omega \tag{2.2}$$

and is uniformly strictly positive: There exists a positive constant c_0 such that, for all symmetric tensors $\boldsymbol{\tau} = (\tau_{\alpha\beta})$ in $\mathbb{R}^{2\times 2}$,

$$a^{\alpha\beta\rho\sigma}(\boldsymbol{x})\tau_{\alpha\beta}\tau_{\rho\sigma} \ge c_0\,|\boldsymbol{\tau}|^2 \qquad \text{for a.e. } \boldsymbol{x}\in\omega. \tag{2.3}$$

In this context, the covariant components of the change of metric tensor read

$$\gamma_{\alpha\beta}(\boldsymbol{u}) = \frac{1}{2}(\partial_\alpha\boldsymbol{u}\cdot\boldsymbol{a}_\beta + \partial_\beta\boldsymbol{u}\cdot\boldsymbol{a}_\alpha), \tag{2.4}$$

the covariant components of the change of transverse shear tensor read

$$\delta_{\alpha 3}(\boldsymbol{u},\boldsymbol{r}) = \frac{1}{2}(\partial_\alpha\boldsymbol{u}\cdot\boldsymbol{a}_3 + \boldsymbol{r}\cdot\boldsymbol{a}_\alpha), \tag{2.5}$$

and the covariant components of the change of curvature tensor read

$$\chi_{\alpha\beta}(\boldsymbol{u},\boldsymbol{r}) = \frac{1}{2}(\partial_\alpha\boldsymbol{u}\cdot\partial_\beta\boldsymbol{a}_3 + \partial_\beta\boldsymbol{u}\cdot\partial_\alpha\boldsymbol{a}_3 + \partial_\alpha\boldsymbol{r}\cdot\boldsymbol{a}_\beta + \partial_\beta\boldsymbol{r}\cdot\boldsymbol{a}_\alpha); \tag{2.6}$$

see [7], [11]. Note that all these quantities make sense for shells with little regularity and are easily expressed with the Cartesian coordinates of the unknowns and geometrical data. For instance, we have

$$\partial_\alpha\boldsymbol{u}\cdot\boldsymbol{a}_\beta = (\partial_\alpha u_i^c)\,a_{\beta,i}^c,$$

and so on.

We assume that the boundary $\partial\omega$ of the chart domain is divided into two parts: γ_0, which has a finite number of connected components and a strictly positive one-dimensional measure and on which the shell is clamped, and the complementary part $\gamma_1 = \partial\omega\setminus\gamma_0$, on which the shell is subjected to applied tractions and moments.

To take into account the boundary conditions, we define the space

$$H^1_{\gamma_0}(\omega) = \big\{\mu\in H^1(\omega);\ \mu = 0 \text{ on } \gamma_0\big\}. \tag{2.7}$$

We also denote by $H^{\frac{1}{2}}_{00}(\gamma_1)$ the space of functions in $H^{\frac{1}{2}}(\gamma_1)$ such that their extension by zero to $\partial\omega$ belongs to $H^{\frac{1}{2}}(\partial\omega)$; see [22, Chap. 1, sect. 11]. Let us now consider the function space, introduced in [7], [11], which is appropriate in the context of

shells with little regularity

$$\mathbb{V}(\omega) = \big\{(\boldsymbol{v},\boldsymbol{s}) \in H^1_{\gamma_0}(\omega)^3 \times H^1_{\gamma_0}(\omega)^3;\ \boldsymbol{s}\cdot\boldsymbol{a}_3 = 0 \text{ in } \omega\big\}. \tag{2.8}$$

This space is endowed with the natural Hilbert norm

$$\|(\boldsymbol{v},\boldsymbol{s})\|_{\mathbb{V}(\omega)} = \big(\|\boldsymbol{v}\|^2_{H^1(\omega)^3} + \|\boldsymbol{s}\|^2_{H^1(\omega)^3}\big)^{1/2}. \tag{2.9}$$

We now recall the variational formulation of the problem corresponding to the linear Naghdi model for shells with little regularity. It reads:

Find $(\boldsymbol{u},\boldsymbol{r})$ *in* $\mathbb{V}(\omega)$ *such that*

$$\forall (\boldsymbol{v},\boldsymbol{s}) \in \mathbb{V}(\omega), \quad a\big((\boldsymbol{u},\boldsymbol{r});(\boldsymbol{v},\boldsymbol{s})\big) = \mathcal{L}((\boldsymbol{v},\boldsymbol{s})), \tag{2.10}$$

where the bilinear form $a(\cdot;\cdot)$ is defined by

$$\begin{aligned} a\big((\boldsymbol{u},\boldsymbol{r});(\boldsymbol{v},\boldsymbol{s})\big) = \int_\omega \Big\{ e a^{\alpha\beta\rho\sigma}\Big[\gamma_{\rho\sigma}(\boldsymbol{v}) + \frac{e^2}{12}\chi_{\alpha\beta}(\boldsymbol{u},\boldsymbol{r})\chi_{\rho\sigma}(\boldsymbol{v},\boldsymbol{s})\Big] \\ + 2e\frac{E}{1+\nu} a^{\alpha\beta}\delta_{\alpha 3}(\boldsymbol{u},\boldsymbol{r})\delta_{\beta 3}(\boldsymbol{v},\boldsymbol{s})\Big\}\sqrt{a}\, d\boldsymbol{x}, \end{aligned} \tag{2.11}$$

and the linear form $\mathcal{L}(\cdot)$ is given by

$$\mathcal{L}((\boldsymbol{v},\boldsymbol{s})) = \int_\omega \boldsymbol{f}\cdot\boldsymbol{v}\,\sqrt{a}\, d\boldsymbol{x} + \int_{\gamma_1} (\boldsymbol{M}\cdot\boldsymbol{v} + \boldsymbol{N}\cdot\boldsymbol{s})\, d\tau. \tag{2.12}$$

The three terms in $a(\cdot,\cdot)$ represent the membrane, bending, and shear deformations, respectively. The data $\boldsymbol{f}$, $\boldsymbol{M}$, and $\boldsymbol{N}$ represent a given resultant force density, an applied moment density, and an applied traction density (so that usually $\boldsymbol{N}\cdot\boldsymbol{a}_3 = 0$), respectively. Finally the thickness of the shell which is assumed to be constant is denoted by e, $0 < e < 1$.

We refer to [7], [11] for the proof of the well-posedness of this problem which is stated in the next theorem. Since $\boldsymbol{a}_3$ belongs to $W^{1,\infty}(\omega)^3$, the form $a(\cdot;\cdot)$ is obviously continuous on $\mathbb{V}(\omega)\times\mathbb{V}(\omega)$, with the norm smaller than $c\,e$. Similarly, the form $\mathcal{L}$ is continuous on $\mathbb{V}(\omega)$, and its norm satisfies, with obvious notation,

$$\|\mathcal{L}\| \le c\,\big(\|\boldsymbol{f}\|_{H^1_{\gamma_0}(\omega)^{3\prime}} + \|\boldsymbol{M}\|_{H^{\frac12}_{00}(s\gamma_1)^{3\prime}} + \|\boldsymbol{N}\|_{H^{\frac12}_{00}(\gamma_1)^{3\prime}}\big). \tag{2.13}$$

So the well-posedness mainly relies on the following ellipticity property which is proved in [11, Lem. 3.6]: There exists a constant $c_* > 0$ such that

$$\forall (\boldsymbol{v},\boldsymbol{s}) \in \mathbb{V}(\omega), \quad a\big((\boldsymbol{v},\boldsymbol{s});(\boldsymbol{v},\boldsymbol{s})\big) \ge c_*\, e^3\, \|(\boldsymbol{v},\boldsymbol{s})\|^2_{\mathbb{V}(\omega)}. \tag{2.14}$$

THEOREM 2.1. *For any data* $(\boldsymbol{f},\boldsymbol{M},\boldsymbol{N})$ *in* $H^1_{\gamma_0}(\omega)^{3\prime} \times H^{\frac12}_{00}(\gamma_1)^{3\prime} \times H^{\frac12}_{00}(\gamma_1)^{3\prime}$, *problem* (2.10) *admits a unique solution* $(\boldsymbol{u},\boldsymbol{r})$ *in* $\mathbb{V}(\omega)$. *Moreover this solution satisfies*

$$\|(\boldsymbol{u},\boldsymbol{r})\|_{\mathbb{V}(\omega)} \le c\, e^{-3}\, \|\mathcal{L}\|. \tag{2.15}$$

However, since the purpose of the present work is to approximate the solution of problem (2.10) with a spectral method and to proceed in the simplest possible way, we immediately encounter a problem: The tangency constraint $\boldsymbol{s}\cdot\boldsymbol{a}_3 = 0$ which appears in the definition of $\mathbb{V}(\omega)$ clearly cannot be implemented in a standard way for a general shell. So the idea, already proposed in [9], consists in handling this constraint via the introduction of a Lagrange multiplier. We thus consider a mixed Naghdi problem in which the unknowns are the displacement $\boldsymbol{u}$ and the rotation $\boldsymbol{r}$, which belong to $H^1_{\gamma_0}(\omega)^3$ without any orthogonality constraint on $\boldsymbol{r}$, and the Lagrange

multiplier λ, which belongs to the space $H^1_{\gamma_0}(\omega)$ and is aimed to enforce the tangency constraint $\boldsymbol{r}\cdot\boldsymbol{a}_3=0$. In view of the discretization, we also possibly add a stabilizing term. Its usefulness appears in the next section.

Let us introduce the relaxed function space

$$\mathbb{X}(\omega)=H^1_{\gamma_0}(\omega)^3\times H^1_{\gamma_0}(\omega)^3, \tag{2.16}$$

still equipped with the norm defined in (2.9) which is now denoted by $\|\cdot\|_{\mathbb{X}(\omega)}$. We also set $\mathbb{M}(\omega)=H^1_{\gamma_0}(\omega)$. For simplicity, we use an extension of the forms $a(\cdot;\cdot)$ and $\mathcal{L}(\cdot)$ defined in (2.11) and (2.12), respectively, to $\mathbb{X}(\omega)\times\mathbb{X}(\omega)$ and $\mathbb{X}(\omega)$.

For a nonnegative parameter η, we consider the variational problem:

Find (U^η,ψ^η) *in* $\mathbb{X}(\omega)\times\mathbb{M}(\omega)$ *such that*

$$\begin{array}{ll}\forall V\in\mathbb{X}(\omega), & a(U^\eta;V)+\eta\,\tilde a(U^\eta;V)+b(V;\psi^\eta)=\mathcal{L}(V),\\ \forall\chi\in\mathbb{M}(\omega), & b(U^\eta;\chi)=0,\end{array} \tag{2.17}$$

where the bilinear forms $\tilde a(\cdot;\cdot)$ and $b(\cdot;\cdot)$ are defined by, with the notation $U=(\boldsymbol{u},\boldsymbol{r})$ and $V=(\boldsymbol{v},\boldsymbol{s})$,

$$\tilde a(U;V)=\int_\omega \partial_\alpha(\boldsymbol{r}\cdot\boldsymbol{a}_3)\partial_\alpha(\boldsymbol{s}\cdot\boldsymbol{a}_3)\,d\boldsymbol{x},\quad b(V;\chi)=\int_\omega\partial_\alpha(\boldsymbol{s}\cdot\boldsymbol{a}_3)\partial_\alpha\chi\,d\boldsymbol{x}. \tag{2.18}$$

Remark. Since we are aiming for simplicity of implementation, we have made no attempt to make the duality term intrinsic. In fact, it does depend on the chart, whereas the other terms do not. This could arguably be considered to be a poor choice, especially if a chart was used that gave much more weight to one part of the shell compared to the rest. An intrinsic choice that obviously works is

$$\tilde b(V;\chi)=\int_\omega a^{\alpha\beta}\partial_\alpha(\boldsymbol{s}\cdot\boldsymbol{a}_3)\partial_\beta\chi\,\sqrt{a}\,d\boldsymbol{x}.$$

Remark. In the case $\eta=0$, it can be checked that $\psi=\psi^0$ is the solution of the Laplace equation

$$-\sum_{\alpha=1}^{2}\partial^2_\alpha\psi=\frac{e^3}{12}a^{\alpha\beta\rho\sigma}\,\chi_{\alpha\beta}(\boldsymbol{u},\boldsymbol{r})\,b_{\rho\sigma}\,\sqrt{a}\quad\text{in }\omega,$$

with mixed Dirichlet boundary conditions on γ_0 and Neumann conditions on γ_1 and the $b_{\rho\sigma}$ are the components of the second fundamental form of the surface. Thus the function ψ seems to have no physical meaning and is only useful to handle the tangency condition.

It must be observed that, since $\boldsymbol{a}_3$ belongs to $W^{1,\infty}(\omega)^3$, the forms $\tilde a(\cdot;\cdot)$ and $b(\cdot;\cdot)$ are continuous on $\mathbb{X}(\omega)\times\mathbb{X}(\omega)$ and $\mathbb{X}(\omega)\times\mathbb{M}(\omega)$, respectively. Moreover, the following identity is readily checked:

$$\mathbb{V}(\omega)=\big\{V=(\boldsymbol{v},\boldsymbol{s})\in\mathbb{X}(\omega);\ \forall\chi\in\mathbb{M}(\omega),\ b(V;\chi)=0\big\}. \tag{2.19}$$

The next ellipticity property

$$\forall V\in\mathbb{V}(\omega),\quad a(V;V)+\eta\,\tilde a(V;V)\ge c_*\,e^3\,\|V\|^2_{\mathbb{X}(\omega)}, \tag{2.20}$$

is an obvious consequence of (2.14), and it can be checked thanks to exactly the same argument as in [9] that an analogous property still holds for all V in $\mathbb{X}(\omega)$ whenever η is positive. We now investigate the inf-sup condition on the form $b(\cdot;\cdot)$.

PROPOSITION 2.2. *There exists a positive constant $c_\sharp$ such that the following inf-sup condition holds:*

$$\forall \chi \in \mathbb{M}(\omega), \quad \sup_{V \in \mathbb{X}(\omega)} \frac{b(V;\chi)}{\|V\|_{\mathbb{X}(\omega)}} \geq c_\sharp \, \|\chi\|_{H^1(\omega)}. \tag{2.21}$$

Proof. Let χ be an arbitrary element of $\mathbb{M}(\omega)$. Since χ vanishes on γ_0 and $\boldsymbol{a}_3$ belongs to $W^{1,\infty}(\omega)^3$, it is readily checked that $V = (\mathbf{0}, \chi \mathbf{a}_3)$ belongs to $\mathbb{X}(\omega)$. Using the fact that $\chi \, \mathbf{a}_3 \cdot \mathbf{a}_3$ is equal to χ, we have with this choice of V

$$b(V;\chi) \geq |\chi|^2_{H^1(\omega)},$$

so that, thanks to a generalized Poincaré–Friedrichs inequality,

$$b(V;\chi) \geq c \, \|\chi\|^2_{H^1(\omega)}.$$

On the other hand, we observe that, owing to the regularity of $\mathbf{a}_3$,

$$\|V\|_{\mathbb{X}(\omega)} \leq \|\chi \mathbf{a}_3\|_{H^1(\omega)^3} \leq c \, \|\chi\|_{H^1(\omega)}.$$

Combining the last two inequalities gives the desired inf-sup condition. ∎

We are now in a position to prove the main result of this section.

THEOREM 2.3. *For any data $(\mathbf{f}, \mathbf{M}, \mathbf{N})$ in $H^1_{\gamma_0}(\omega)^{3\prime} \times H^{\frac{1}{2}}_{00}(\gamma_1)^{3\prime} \times H^{\frac{1}{2}}_{00}(\gamma_1)^{3\prime}$, problem (2.17) admits a unique solution (U^η, ψ^η) in $\mathbb{X}(\omega) \times \mathbb{M}(\omega)$. Moreover this solution satisfies*

$$\|U^\eta\|_{\mathbb{X}(\omega)} + \|\psi^\eta\|_{H^1(\omega)} \leq c \, e^{-3} \, \|\mathcal{L}\|. \tag{2.22}$$

Moreover, the part U^η of this solution is equal to the solution U of problem (2.10).

Proof. The existence and uniqueness of the solution (U^η, ψ^η), together with estimate (2.22), are a direct consequence of properties (2.20) and (2.21); see [12, Chap. II, Thm. 1.1] and [16, Chap. I, Cor. 4.1], for instance. Moreover, U^η belongs to $\mathbb{V}(\omega)$, and it is readily checked that, for any V in $\mathbb{V}(\omega)$, $\tilde{a}(U^\eta; V)$ is zero, so that U^η satisfies (2.10). ∎

3. The spectral discrete problem and its well-posedness. To describe the discrete problem, we now assume that ω is the square $]-1,1[^2$ (this can induce a further diffeomorphism; however, for simplicity we keep the notation φ for the chart). We assume that γ_0 is the union of one, two, three, or four whole edges of ω.

For each nonnegative integer n, we denote by $\mathbb{P}_n(\omega)$ the space of restrictions to ω of polynomials with two variables and degree $\leq n$ with respect to each variable. In order to take into account the boundary conditions of the problem, we introduce the space $\mathbb{P}^{\gamma_0}_n(\omega) = \mathbb{P}_n(\omega) \cap H^1_{\gamma_0}(\omega)$. Next, for a fixed integer $N \geq 2$ and another integer L, $2 \leq L \leq N$, we define the discrete spaces

$$\mathbb{X}_N = \mathbb{P}^{\gamma_0}_N(\omega)^3 \times \mathbb{P}^{\gamma_0}_N(\omega)^3, \qquad \mathbb{M}_N = \mathbb{P}^{\gamma_0}_L(\omega). \tag{3.1}$$

The reason for using two different parameters L and N is explained later.

We also make use of the Gauss–Lobatto formula on the interval $]-1,1[$. Let $\mathbb{P}_n(-1,1)$ denote the space of restrictions to $]-1,1[$ of polynomials with degree $\leq n$. For a third integer $M \geq N$, we set: $\xi_0 = -1$ and $\xi_M = 1$. We recall that there exist

$M-1$ nodes ξ_j, $1 \le j \le M-1$, in $]-1,1[$, with $\xi_0 < \xi_1 < \cdots < \xi_M$, and $M+1$ positive weights ρ_j, $0 \le j \le M$, such that

$$\forall \Phi \in \mathbb{P}_{2M-1}(-1,1), \quad \int_{-1}^{1} \Phi(\zeta)\, d\zeta = \sum_{j=0}^{M} \Phi(\xi_j)\, \rho_j. \tag{3.2}$$

Moreover the following property holds [4, Form. (13.20)]:

$$\forall \varphi \in \mathbb{P}_M(-1,1), \quad \|\varphi\|^2_{L^2(-1,1)} \le \sum_{j=0}^{M} \varphi^2(\xi_j)\, \rho_j \le 3\, \|\varphi\|^2_{L^2(-1,1)}. \tag{3.3}$$

The interest of using "overintegration," i.e., taking $M > N$, in the case of nonconstant coefficients has been fully brought to light in [23].

This leads to define a discrete product on ω: For any continuous functions u and v on $\bar{\omega}$,

$$(u,v)_M = \sum_{i=0}^{M} \sum_{j=0}^{M} u(\xi_i,\xi_j) v(\xi_i,\xi_j)\, \rho_i \rho_j. \tag{3.4}$$

It follows from (3.3) that this product is a scalar product on $\mathbb{P}_M(\omega)$. We also introduce the Lagrange interpolation operator $\mathcal{I}_M$ at the nodes (ξ_i,ξ_j), $0 \le i,j \le M$, with values in $\mathbb{P}_M(\omega)$. Finally, the discrete product $(\cdot,\cdot)^{\gamma_1}_M$ is defined according to the geometry of γ_1: For any continuous functions u and v on $\bar{\gamma}_1$, if γ_1 is the edge $\{-1\}\times]-1,1[$,

$$(u,v)^{\gamma_1}_M = \sum_{j=0}^{M} u(-1,\xi_j) v(-1,\xi_j)\, \rho_j, \tag{3.5}$$

while, if γ_1 is the union of the two edges $\{-1\}\times]-1,1]$ and $[-1,1[\times\{1\}$,

$$(u,v)^{\gamma_1}_M = \sum_{j=0}^{M} u(-1,\xi_j) v(-1,\xi_j)\, \rho_j + \sum_{j=0}^{M} u(\xi_j,1) v(\xi_j,1)\, \rho_j, \tag{3.6}$$

and so on. The Lagrange interpolation operator $i^{\gamma_1}_M$ is simply defined as the trace of $\mathcal{I}_M$ on γ_1.

From now on, we make the further nonrestrictive hypothesis.

Assumption 3.1. The $\mathbf{a}_\alpha$, $\alpha = 1$ and 2, belong to $H^{s_0}(\omega)^3$ and $\mathbf{a}_3$ belongs to $H^{s_0+1}(\omega)^3$ for a real number $s_0 > 1$.

In order to take into account this rather weak regularity, we introduce the $H^1(\omega)$-projection $\mathbf{a}_{kN}$ of each $\mathbf{a}_k$ onto $\mathbb{P}_N(\omega)^3$, which satisfies

$$\begin{aligned} &\forall \mathbf{v}_N \in \mathbb{P}_N(\omega)^3, \qquad (\partial_\alpha \mathbf{a}_{kN}, \partial_\alpha \mathbf{v}_N)_M = \int_\omega (\partial_\alpha \mathbf{a}_k)(\partial_\alpha \mathbf{v}_N)\, d\mathbf{x}, \\ &(\mathbf{a}_{kN}, 1)_M = \int_\omega \mathbf{a}_k(\mathbf{x})\, d\mathbf{x}. \end{aligned} \tag{3.7}$$

In a similar way, we define the $\mathbf{c}_{\beta N}$ as the solution of the same problem with $\mathbf{a}_k$ replaced by $\partial_\beta \mathbf{a}_3$. It follows from (3.3) that the $\mathbf{a}_{kN}$ and $\mathbf{c}_{\beta N}$ are uniquely defined from these equations. This leads to the following discrete forms of the tensors:

$$\gamma^N_{\alpha\beta}(\mathbf{u}) = \frac{1}{2}(\partial_\alpha \mathbf{u} \cdot \mathbf{a}_{\beta N} + \partial_\beta \mathbf{u} \cdot \mathbf{a}_{\alpha N}), \tag{3.8}$$

$$\delta^N_{\alpha 3}(U) = \frac{1}{2}(\partial_\alpha \mathbf{u}\cdot\mathbf{a}_{3N} + \mathbf{r}\cdot\mathbf{a}_{\alpha N}), \tag{3.9}$$

$$\chi^N_{\alpha\beta}(U) = \frac{1}{2}(\partial_\alpha \mathbf{u}\cdot\mathbf{c}_{\beta N} + \partial_\beta \mathbf{u}\cdot\mathbf{c}_{\alpha N} + \partial_\alpha \mathbf{r}\cdot\mathbf{a}_{\beta N} + \partial_\beta \mathbf{r}\cdot\mathbf{a}_{\alpha N}). \tag{3.10}$$

Up to the replacement of the $\mathbf{a}_k$ by $\mathbf{a}_{kN}$ and also of the $\partial_\beta \mathbf{a}_3$ by $\mathbf{c}_{\beta N}$, the discrete problem is now constructed from (2.17) by the Galerkin method with numerical integration. It reads:

Find (U_N, ψ_N) *in* $\mathbb{X}_N \times \mathbb{M}_N$ *such that*

$$\begin{array}{ll} \forall V_N \in \mathbb{X}_N, & a_M(U_N;V_N) + \eta\, \tilde{a}_M(U_N;V_N) + b_M(V_N;\psi_N) = \mathcal{L}_M(V_N), \\ \forall \chi_N \in \mathbb{M}_N, & b_M(U_N;\chi_N) = 0, \end{array} \tag{3.11}$$

where the bilinear forms $a_M(\cdot;\cdot)$, $\tilde{a}_M(\cdot;\cdot)$, and $b_M(\cdot;\cdot)$ are defined, with the notation $U_N = (\mathbf{u}_N, \mathbf{r}_N)$ and $V_N = (\mathbf{v}_N, \mathbf{s}_N)$, by

$$\begin{aligned} a_M(U_N;V_N) &= e\left(a^{\alpha\beta\rho\sigma}\,\gamma^N_{\alpha\beta}(\mathbf{u}_N), \gamma^N_{\rho\sigma}(\mathbf{v}_N)\sqrt{a}\right)_M \\ &\quad + \frac{e^3}{12}\left(a^{\alpha\beta\rho\sigma}\,\chi^N_{\alpha\beta}(U_N), \chi^N_{\rho\sigma}(V_N)\sqrt{a}\right)_M \\ &\quad + 2e\frac{E}{1+\nu}\left(a^{\alpha\beta}\delta^N_{\alpha 3}(U_N), \delta^N_{\beta 3}(V_N)\sqrt{a}\right)_M, \\ \tilde{a}_M(U_N;V_N) &= \left(\partial_\alpha \mathcal{I}_M(\mathbf{r}_N\cdot\mathbf{a}_{3N}), \partial_\alpha \mathcal{I}_M(\mathbf{s}_N\cdot\mathbf{a}_{3N})\right)_M, \\ b_M(V_N;\chi_N) &= \left(\partial_\alpha \mathcal{I}_M(\mathbf{s}_N\cdot\mathbf{a}_{3N}), \partial_\alpha \chi_N\right)_M. \end{aligned} \tag{3.12}$$

The linear form $\mathcal{L}_M(\cdot)$ is given by

$$\mathcal{L}_M(V_N) = (\mathbf{f}, \mathbf{v}_N\sqrt{a})_M + (\mathbf{M}, \mathbf{v}_N)^{\gamma_1}_M + (\mathbf{N}, \mathbf{s}_N)^{\gamma_1}_M. \tag{3.13}$$

Remark. The discrete problem (3.11) differs from the standard spectral discretization of elliptic problems in two ways.

- The idea for the replacement of the $\mathbf{a}_k$ by $\mathbf{a}_{kN}$ and of the $\partial_\beta \mathbf{a}_3$ by $\mathbf{c}_{\beta N}$ in the definition of the forms $a_M(\cdot,\cdot)$ and $b_M(\cdot,\cdot)$ comes from the lack of regularity of the $\mathbf{a}_k$. Indeed, if one of the $\mathbf{a}_\alpha$ is not replaced by $\mathbf{a}_{\alpha N}$, the continuity of these forms would require the boundedness of $\mathcal{I}_M\mathbf{a}_\alpha$ at least in $H^1(\omega)^3$, which would require that $\mathbf{a}_\alpha$ belongs to $H^s(\omega)^3$ for some $s > \frac{3}{2}$. We prefer to avoid this restriction.
- It is usual in spectral methods to take M equal to N, in order that the mass matrix is diagonal. The choice of an M possibly larger than N here is due to the fact that the coefficients involved in the previous forms depend on the space variable and are not very smooth (see [23] for more details). However, if ξ^*_j denote the nodes ξ_j for M equal to N and φ^*_j are the associated Lagrange polynomials, the unknown U_N admits the expansion

$$U_N(x,y) = \sum_{i=0}^{N}\sum_{j=0}^{N} U_N(\xi^*_i, \xi^*_j)\,\varphi^*_i(x)\varphi^*_j(y). \tag{3.14}$$

  So computing the values of U_N and $\partial_\alpha U_N$ at the nodes (ξ_j, ξ_j) only requires the knowledge of the two matrices made of the $\varphi^*_i(\xi_k)$ and of the $\varphi^{*\prime}_i(\xi_k)$, respectively.

The analysis of problem (3.11) relies on a number of properties of the previous forms. We begin with their continuity. In a preliminary step, we establish some results concerning the new coefficients $\mathbf{a}_{kN}$ and $\mathbf{c}_{\beta N}$.

LEMMA 3.2. *There exists a constant c independent of N such that, for any real number p, $2 \le p \le \frac{2}{2-s_0}$,*

$$\|\mathbf{a}_\alpha - \mathbf{a}_{\alpha N}\|_{L^\infty(\omega)^3} \le c\, N^{1-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|\mathbf{a}_\alpha\|_{H^{s_0}(\omega)^3}, \tag{3.15}$$

$$\|\mathbf{a}_3 - \mathbf{a}_{3N}\|_{L^\infty(\omega)^3} \le c\, N^{-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|\mathbf{a}_3\|_{H^{s_0+1}(\omega)^3}, \tag{3.16}$$

$$\|\mathbf{a}_3 - \mathbf{a}_{3N}\|_{W^{1,p}(\omega)^3} \le c\, N^{4(\frac{1}{2}-\frac{1}{p})-s_0}\, \|\mathbf{a}_3\|_{H^{s_0+1}(\omega)^3}, \tag{3.17}$$

$$\|\partial_\beta \mathbf{a}_3 - \mathbf{c}_{\beta N}\|_{L^\infty(\omega)^3} \le c\, N^{1-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|\mathbf{a}_3\|_{H^{s_0+1}(\omega)^3}. \tag{3.18}$$

Proof. There exists [4, Thm. 7.4] a polynomial $\tilde{\mathbf{a}}_{kN}$ in $\mathbb{P}_N(\omega)^3$ such that, for all real numbers s, $0 \le s \le s_0$,

$$\|\mathbf{a}_\alpha - \tilde{\mathbf{a}}_{\alpha N}\|_{H^s(\omega)^3} \le c\, N^{s-s_0}\, \|\mathbf{a}_\alpha\|_{H^{s_0}(\omega)^3}. \tag{3.19}$$

To prove the first estimate, we use the triangle inequality

$$\|\mathbf{a}_\alpha - \mathbf{a}_{\alpha N}\|_{L^\infty(\omega)^3} \le \|\mathbf{a}_\alpha - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3} + \|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3}.$$

To bound the first quantity, we recall from [17] that, for all ε, $0 < \varepsilon < s_0 - 1$, the norm of the Sobolev embedding of $H^{1+\varepsilon}(\omega)$ into $L^\infty(\omega)$ is bounded by $c\,\varepsilon^{-\frac{1}{2}}$ for a constant c independent of ε. Combining this result with (3.20) with $s = 1 + \varepsilon$ gives

$$\|\mathbf{a}_\alpha - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3} \le c\,\varepsilon^{-\frac{1}{2}}\, \|\mathbf{a}_\alpha - \tilde{\mathbf{a}}_{\alpha N}\|_{H^{1+\varepsilon}(\omega)^3} \le c'\,\varepsilon^{-\frac{1}{2}}\, N^{\varepsilon+1-s_0}\, \|\mathbf{a}_\alpha\|_{H^{s_0}(\omega)^3}.$$

Evaluating the second one relies on the inverse inequality (see [3, Chap. III, Prop. 3.1]), valid for any $p < +\infty$,

$$\|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3} \le c\, N^{\frac{4}{p}}\, \|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{L^p(\omega)^3}.$$

We recall from [25] that the norm of the embedding of $H^1(\omega)$ into $L^p(\omega)$ behaves like $c\,p^{\frac{1}{2}}$ for a constant c independent of p. This yields

$$\begin{aligned}\|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3} &\le c\,p^{\frac{1}{2}}\, N^{\frac{4}{p}}\, \|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{H^1(\omega)^3} \\ &\le c\,p^{\frac{1}{2}}\, N^{\frac{4}{p}}\, \big(\|\mathbf{a}_\alpha - \mathbf{a}_{\alpha N}\|_{H^1(\omega)^3} + \|\mathbf{a}_\alpha - \tilde{\mathbf{a}}_{\alpha N}\|_{H^1(\omega)^3}\big).\end{aligned}$$

It follows from the definition of $\mathbf{a}_{\alpha N}$ that

$$\|\mathbf{a}_\alpha - \mathbf{a}_{\alpha N}\|_{H^1(\omega)^3} \le c\, N^{1-s_0}\, \|\mathbf{a}_\alpha\|_{H^{s_0}(\omega)^3}. \tag{3.20}$$

Combining this with (3.19) for $s = 1$ thus leads to

$$\|\mathbf{a}_{\alpha N} - \tilde{\mathbf{a}}_{\alpha N}\|_{L^\infty(\omega)^3} \le c\,p^{\frac{1}{2}}\, N^{\frac{4}{p}+1-s_0}\ \|\mathbf{a}_\alpha\|_{H^{s_0}(\omega)^3}.$$

Thus estimate (3.15) follows from the previous lines by taking $\varepsilon = \frac{4}{p} = \frac{1}{\log\, N}$. Estimates (3.16) and (3.18) rely on exactly the same arguments with s_0 replaced or not by $s_0 + 1$. To prove (3.17), we first take s such that $\frac{1}{p} = \frac{2-s}{2}$, so that $H^s(\omega)$ is embedded in $W^{1,p}(\omega)$ and use an analogous inverse inequality as previously (see again [3, Chap. III, Prop. 3.1]), which gives

$$\|\mathbf{a}_3 - \mathbf{a}_{3N}\|_{W^{1,p}(\omega)^3} \le c\,\|\mathbf{a}_3 - \tilde{\mathbf{a}}_{3N}\|_{H^s(\omega)^3} + c'\, N^{4(\frac{1}{2}-\frac{1}{p})}\, \|\mathbf{a}_{3N} - \tilde{\mathbf{a}}_{3N}\|_{H^1(\omega)^3}.$$

Thus, we deduce from the analogues of (3.19) and (3.20), with s_0 replaced by s_0+1, that

$$\|\mathbf{a}_3-\mathbf{a}_{3N}\|_{W^{1,p}(\omega)^3}\le c\,(N^{s-s_0-1}+N^{4(\frac12-\frac1p)-s_0})\|\mathbf{a}_3\|_{H^{s_0+1}(\omega)^3}.$$

Noting that $s-s_0-1$ is equal to $2(\frac12-\frac1p)-s_0$, hence smaller than $4(\frac12-\frac1p)-s_0$, gives the desired result. ∎

As a consequence of the previous lemma, the norms of the coefficients $\mathbf{a}_{kN}$ and $\mathbf{c}_{\beta N}$ in $L^\infty(\omega)^3$ and also of $\mathbf{a}_{3N}$ in $W^{1,p}(\omega)^3$ are bounded independently of N. This leads to the following continuity results.

LEMMA 3.3. *There exists a constant c independent of N and $M\ge N$ such that the following continuity property holds:*

$$\forall U_N\in\mathbb{X}_N,\forall V_N\in\mathbb{X}_N,\quad |a_M(U_N;V_N)|\le c\,e\,\|U_N\|_{\mathbb{X}(\omega)}\|V_N\|_{\mathbb{X}(\omega)}. \tag{3.21}$$

Proof. Since the coefficients $a^{\alpha\beta\rho\sigma}$ and also $\sqrt{a}$ are bounded, we derive by a Cauchy–Schwarz inequality

$$e\,\big|\big(a^{\alpha\beta\rho\sigma}\,\gamma^N_{\alpha\beta}(\mathbf{u}_N),\gamma^N_{\rho\sigma}(\mathbf{v}_N)\,\sqrt{a}\big)_M\big|\le c\,e\,(\gamma^N_{\alpha\beta}(\mathbf{u}_N),\gamma^N_{\alpha\beta}(\mathbf{u}_N))^{\frac12}_M(\gamma^N_{\rho\sigma}(\mathbf{v}_N),\gamma^N_{\rho\sigma}(\mathbf{v}_N))^{\frac12}_M.$$

Thanks to Lemma 3.2, we observe that, at each node (ξ_i,ξ_j), $0\le i,j\le M$,

$$\gamma^N_{\alpha\beta}(\mathbf{u}_N)(\xi_i,\xi_j)\le c\,\big(|(\partial_\alpha\mathbf{u}_N)(\xi_i,\xi_j)|+|(\partial_\beta\mathbf{u}_N)(\xi_i,\xi_j)|\big),$$

so that

$$(\gamma^N_{\alpha\beta}(\mathbf{u}_N),\gamma^N_{\alpha\beta}(\mathbf{u}_N))_M\le c'\,\big((\partial_\alpha\mathbf{u}_N,\partial_\alpha\mathbf{u}_N)_M+(\partial_\beta\mathbf{u}_N,\partial_\beta\mathbf{u}_N)_M\big).$$

Using (3.3) and a similar estimate for $(\gamma^N_{\rho\sigma}(\mathbf{v}_N),\gamma^N_{\rho\sigma}(\mathbf{v}_N))_M$ leads to

$$e\,\big|\big(a^{\alpha\beta\rho\sigma}\,\gamma^N_{\alpha\beta}(\mathbf{u}_N),\gamma^N_{\rho\sigma}(\mathbf{v}_N)\,\sqrt{a}\big)_M\big|\le c\,e\,\|\mathbf{u}_N\|_{H^1(\omega)^3}\|\mathbf{v}_N\|_{H^1(\omega)^3}.$$

Similar arguments also yield the desired estimates for the second and third terms in $a_M(U_N,V_N)$. ∎

LEMMA 3.4. *There exists a constant c independent of N and $M\ge N$ such that the following continuity property holds:*

$$\forall U_N\in\mathbb{X}_N,\forall V_N\in\mathbb{X}_N,\quad |\tilde a_M(U_N;V_N)|\le c\,\|U_N\|_{\mathbb{X}(\omega)}\|V_N\|_{\mathbb{X}(\omega)}. \tag{3.22}$$

Proof. We derive from (3.3) that

$$|\tilde a_M(U_N;V_N)|\le 3\,|\mathcal{I}_M(\mathbf{r}_N\cdot\mathbf{a}_{3N})|_{H^1(\omega)}|\mathcal{I}_M(\mathbf{s}_N\cdot\mathbf{a}_{3N})|_{H^1(\omega)}.$$

We recall from [4, Forms. (13.27) and (13.28)] the following property, valid for all integers K:

$$\forall w_K\in\mathbb{P}_K(\omega),\quad |\mathcal{I}_M w_K|_{H^1(\omega)}\le c\,\left(1+\frac{K}{M}\right)|w_K|_{H^1(\omega)}. \tag{3.23}$$

Since both $\mathbf{r}_N\cdot\mathbf{a}_{3N}$ and $\mathbf{s}_N\cdot\mathbf{a}_{3N}$ are polynomials with degree smaller than $2N$, this implies

$$|\tilde a_M(U_N;V_N)|\le c\,|\mathbf{r}_N\cdot\mathbf{a}_{3N}|_{H^1(\omega)}|\mathbf{s}_N\cdot\mathbf{a}_{3N}|_{H^1(\omega)}.$$

Then we observe that

$$\partial_\alpha(\mathbf{r}_N \cdot \mathbf{a}_{3N}) = \partial_\alpha \mathbf{r}_N \cdot \mathbf{a}_{3N} + \mathbf{r}_N \cdot \partial_\alpha \mathbf{a}_{3N}.$$

This yields, for the p such that $4(\frac{1}{2} - \frac{1}{p}) < s_0$ and q given by $\frac{1}{p} + \frac{1}{q} = \frac{1}{2}$,

$$|\mathbf{r}_N \cdot \mathbf{a}_{3N}|_{H^1(\omega)} \le |\mathbf{r}_N|_{H^1(\omega)^3} \|\mathbf{a}_{3N}\|_{L^\infty(\omega)^3} + \|\mathbf{r}_N\|_{L^q(\omega)^3} \|\mathbf{a}_{3N}\|_{W^{1,p}(\omega)^3}.$$

By combining Lemma 3.2 with the embedding of $H^1(\omega)$ into $L^q(\omega)$, we obtain

$$|\mathbf{r}_N \cdot \mathbf{a}_{3N}|_{H^1(\omega)} \le c \, \|\mathbf{r}_N\|_{H^1(\omega)^3} \|\mathbf{a}_3\|_{H^{s_0+1}(\omega)^3}.$$

A similar estimate holds for $|\mathbf{s}_N \cdot \mathbf{a}_{3N}|_{H^1(\omega)}$, which yields the desired continuity property. ∎

The continuity of $b_M(\cdot;\cdot)$ relies on the same arguments, so we omit the proof of the next lemma.

LEMMA 3.5. *There exists a constant c independent of N and $M \ge N$ such that the following continuity property holds:*

$$\forall V_N \in \mathbb{X}_N, \forall \chi_N \in \mathbb{M}_N, \quad |b_M(V_N;\chi_N)| \le c \, \|V_N\|_{\mathbb{X}(\omega)} \|\chi_N\|_{H^1(\omega)}. \tag{3.24}$$

Finally we derive from (3.3) that, if $\|\mathcal{L}_M\|_N$ denotes the norm of $\mathcal{L}_M$ in the space of linear forms on $\mathbb{X}_N$,

$$\|\mathcal{L}_M\|_N \le c \left(\|\mathcal{I}_M \mathbf{f}\|_{L^2(\omega)^3} + \|i_M^{\gamma_1} \mathbf{M}\|_{L^2(\gamma_1)^3} + \|i_M^{\gamma_1} \mathbf{N}\|_{L^2(\gamma_1)^3} \right). \tag{3.25}$$

To go further, we introduce the kernel

$$\mathbb{V}_N = \left\{ V_N = (\mathbf{v}_N, \mathbf{s}_N) \in \mathbb{X}_N; \ \forall \chi_N \in \mathbb{M}_N, \ b_M(V_N;\chi_N) = 0 \right\}. \tag{3.26}$$

It is readily checked that $\mathbb{V}_N$ is not contained in $\mathbb{V}(\omega)$ in the general case. So the proof of the next ellipticity property relies on the following result, due to [9, Lem. 3.3]: For a constant $c_\flat > 0$,

$$\forall V \in \mathbb{X}(\omega), \quad [V]^2 + \tilde{a}(V;V) \ge c_\flat \, \|V\|^2_{\mathbb{X}(\omega)}, \tag{3.27}$$

where the seminorm $[\cdot]$ is defined by

$$[V] = \left(\sum_{\alpha=1}^{2} \sum_{\beta=1}^{2} \|\gamma_{\alpha\beta}(\mathbf{v})\|^2_{L^2(\omega)} + \sum_{\alpha=1}^{2} \sum_{\beta=1}^{2} \|\chi_{\alpha\beta}(\mathbf{v},\mathbf{s})\|^2_{L^2(\omega)} + \sum_{\alpha=1}^{2} \|\delta_{\alpha 3}(\mathbf{v},\mathbf{s})\|^2_{L^2(\omega)} \right)^{\frac{1}{2}}.$$

Let us also consider its discrete analogue on $\mathbb{X}_N$:

$$\begin{aligned} [V_N]_M = \Big(&\left(\gamma^N_{\alpha\beta}(\mathbf{v}_N), \gamma^N_{\alpha\beta}(\mathbf{v}_N)\right)_M + \left(\chi^N_{\alpha\beta}(\mathbf{v}_N,\mathbf{s}_N), \chi^N_{\alpha\beta}(\mathbf{v}_N,\mathbf{s}_N)\right)_M \\ &+ \left(\delta^N_{\alpha 3}(\mathbf{v}_N,\mathbf{s}_N), \delta^N_{\alpha 3}(\mathbf{v}_N,\mathbf{s}_N)\right)_M \Big)^{\frac{1}{2}}. \end{aligned} \tag{3.28}$$

From now on, denoting by $\lfloor \cdot \rfloor$ the integer part, we choose L and M such that, for fixed real numbers λ and μ, $0 < \lambda < 1$ and $0 < \mu \le 1$,

$$L = \lfloor (1-\lambda) N \rfloor \qquad \text{and} \qquad M = \lfloor (1+\mu) N \rfloor. \tag{3.29}$$

PROPOSITION 3.6. *There exist a positive integer N_* and a positive constant $\tilde{c}_*$ such that, for all $N \geq N_*$, the following ellipticity property holds:*

$$\forall V_N \in \mathbb{X}_N, \quad a_M(V_N;V_N) + \eta\, \tilde{a}_M(V_N;V_N) \geq \tilde{c}_*\, \min\{e^3,\eta\}\, \|V_N\|^2_{\mathbb{X}(\omega)}. \tag{3.30}$$

Proof. It is readily checked from (2.3) that, for all V_N in $\mathbb{X}_N$,

$$a_M(V_N;V_N) + \eta\, \tilde{a}_M(V_N;V_N) \geq \tilde{c}_*\, \min\{e^3,\eta\} \Big([V_N]^2_M + \tilde{a}_M(V_N;V_N) \Big). \tag{3.31}$$

On the other hand, since $\mathbb{X}_N$ is contained in $\mathbb{X}(\omega)$, it follows from (3.27) that

$$[V_N]^2 + \tilde{a}(V_N;V_N) \geq c_\flat\, \|V_N\|^2_{\mathbb{X}(\omega)}. \tag{3.32}$$

So it remains to compare $[V_N]$ and $[V_N]_M$ and also $\tilde{a}(V_N;V_N)$ and $\tilde{a}_M(V_N;V_N)$. Let K denote the integer part of $\mu\, N - 1$ (we assume N large enough for K to be positive).

(1) Let $\mathbf{a}_{\alpha K}$ denote an approximation of $\mathbf{a}_\alpha$ in $\mathbb{P}_K(\omega)^3$ which still satisfies (3.15), and let $\gamma^K_{\alpha\beta}(\mathbf{v}_N)$ be defined as in (3.8) with $\mathbf{a}_{\alpha N}$ replaced by $\mathbf{a}_{\alpha K}$. It follows from the exactness property (3.2) that

$$\big(\gamma^K_{\alpha\beta}(\mathbf{v}_N), \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)_M = \|\gamma^K_{\alpha\beta}(\mathbf{v}_N)\|^2_{L^2(\omega)^{2\times 2}}.$$

Then we use the inequalities

$$\big(\gamma^N_{\alpha\beta}(\mathbf{v}_N), \gamma^N_{\alpha\beta}(\mathbf{v}_N)\big)_M \geq \big(\gamma^K_{\alpha\beta}(\mathbf{v}_N), \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)_M + 2\big((\gamma^N_{\alpha\beta} - \gamma^K_{\alpha\beta})(\mathbf{v}_N), \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)_M,$$

and

$$\|\gamma^K_{\alpha\beta}(\mathbf{v}_N)\|^2_{L^2(\omega)^{2\times 2}} \geq \|\gamma_{\alpha\beta}(\mathbf{v}_N)\|^2_{L^2(\omega)^{2\times 2}} - 2\int_\Omega \big(\gamma_{\alpha\beta}(\mathbf{v}_N) - \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)\gamma_{\alpha\beta}(\mathbf{v}_N)\, d\mathbf{x}.$$

On the other hand, the same arguments as for Lemma 3.3 yield that

$$\big|\big((\gamma^N_{\alpha\beta} - \gamma^K_{\alpha\beta})(\mathbf{v}_N), \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)_M\big| \leq c \sum_{\alpha=1}^2 \|\mathbf{a}_{\alpha N} - \mathbf{a}_{\alpha K}\|_{L^\infty(\omega)^3}\, \|\mathbf{v}_N\|^2_{H^1(\omega)^3},$$

while it is readily checked that

$$\left|\int_\Omega \big(\gamma_{\alpha\beta}(\mathbf{v}_N) - \gamma^K_{\alpha\beta}(\mathbf{v}_N)\big)\gamma_{\alpha\beta}(\mathbf{v}_N)\, d\mathbf{x}\right| \leq c \sum_{\alpha=1}^2 \|\mathbf{a}_\alpha - \mathbf{a}_{\alpha K}\|_{L^\infty(\omega)^3}\, \|\mathbf{v}_N\|^2_{H^1(\omega)^3}.$$

All of this yields

$$\begin{aligned}\big(\gamma^N_{\alpha\beta}(\mathbf{v}_N), \gamma^N_{\alpha\beta}(\mathbf{v}_N)\big)_M \geq\ & \|\gamma_{\alpha\beta}(\mathbf{v}_N)\|^2_{L^2(\omega)^{2\times 2}} \\ & - c\sum_{\alpha=1}^2 \big(\|\mathbf{a}_\alpha - \mathbf{a}_{\alpha N}\|_{L^\infty(\omega)^3} + \|\mathbf{a}_\alpha - \mathbf{a}_{\alpha K}\|_{L^\infty(\omega)^3}\big)\|\mathbf{v}_N\|^2_{H^1(\omega)^3}.\end{aligned}$$

Using the same arguments for estimating the two other terms together with Lemma 3.2 leads to

$$[V_N]^2_M \geq [V_N]^2 - c\, N^{1-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|V_N\|^2_{\mathbb{X}(\omega)}. \tag{3.33}$$

(2) Similarly, let $\mathbf{a}_{3K}$ denote an approximation of $\mathbf{a}_3$ in $\mathbb{P}_K(\omega)^3$ which still satisfies (3.17). Since $\mathbf{s}_N \cdot \mathbf{a}_{3K}$ now belongs to $\mathbb{P}_M(\omega)$, it is equal to $\mathcal{I}_M(\mathbf{s}_N \cdot \mathbf{a}_{3K})$ and, moreover,

$$\big(\partial_\alpha \mathcal{I}_M(\mathbf{s}_N \cdot \mathbf{a}_{3K}), \partial_\alpha \mathcal{I}_M(\mathbf{s}_N \cdot \mathbf{a}_{3K})\big)_M = \int_\omega \partial_\alpha(\mathbf{s}_N \cdot \mathbf{a}_{3K}) \partial_\alpha(\mathbf{s}_N \cdot \mathbf{a}_{3K})\, d\mathbf{x}.$$

Thus, the same arguments as for Lemma 3.4 (see (3.23)) yield that

$$\tilde{a}_M(V_N;V_N) \geq \tilde{a}(V_N,V_N) - c\sum_{\alpha=1}^{2}\big(\|\partial_\alpha(\mathbf{s}_N\cdot(\mathbf{a}_3-\mathbf{a}_{3N}))\|_{L^2(\omega)^3}+\|\partial_\alpha(\mathbf{s}_N\cdot(\mathbf{a}_3-\mathbf{a}_{3K}))\|_{L^2(\omega)^3}\big)\,\|\mathbf{s}_N\|_{H^1(\omega)^3}.$$

Using once more Lemma 3.2 (with p such that $4(\frac{1}{2}-\frac{1}{p})\leq 1$) leads to

$$\tilde{a}_M(V_N;V_N) \geq \tilde{a}(V_N,V_N) - c\,N^{1-s_0}\,(\log\,N)^{\frac{1}{2}}\,\|\mathbf{s}_N\|^2_{H^1(\omega)^3}. \tag{3.34}$$

Combining (3.32) to (3.34) gives

$$[V_N]^2_M + \tilde{a}_M(V_N;V_N) \geq \big(c_\flat - c\,N^{1-s_0}\,(\log\,N)^{\frac{1}{2}}\big)\,\|V_N\|^2_{\mathbb{X}(\omega)}.$$

We choose N_* such that $c\,N_*^{1-s_0}\,(\log\,N_*)^{\frac{1}{2}} \leq \frac{c_\flat}{2}$. Thus, the desired property follows from (3.31). ∎

Proving the inf-sup condition on $b_M(\cdot,\cdot)$ is performed in two steps. Note that it requires the choice of L made in (3.30) (we refer to [5, sect. 3] for proving an inf-sup condition with such a choice in a completely different context).

LEMMA 3.7. *There exist a positive integer $N_\sharp$ and a positive constant $\tilde{c}_\sharp$ such that, for all $N \geq N_\sharp$, the following inf-sup condition holds:*

$$\forall \chi_N \in \mathbb{M}_N, \quad \sup_{V\in\mathbb{X}_N}\frac{b(V_N;\chi_N)}{\|V_N\|_{\mathbb{X}(\omega)}} \geq \tilde{c}_\sharp\,\|\chi_N\|_{H^1(\omega)}. \tag{3.35}$$

Proof. Let χ_N be any element of $\mathbb{M}_N$. Let now K' stand for the integer part of $\lambda N - 1$. We introduce an approximation $\mathbf{a}_{3K'}$ of $\mathbf{a}_3$ in $\mathbb{P}_{K'}(\omega)^3$ which satisfies (3.16) and (3.17). It follows from the definition (3.1) of $\mathbb{M}_N$ and the choice (3.29) of L that, for any χ_N in $\mathbb{M}_N$, the function $\mathbf{s}_N = \chi_N\,\mathbf{a}_{3K'}$ belongs to $\mathbb{P}_N(\omega)^3$. Since χ_N vanishes on γ_0, the function $V_N = (\mathbf{0},\mathbf{s}_N)$ belongs to $\mathbb{X}_N$ and satisfies

$$b(V_N;\chi_N) = \int_\omega \partial_\alpha(\chi_N\,\mathbf{a}_{3K'}\cdot\mathbf{a}_3)\partial_\alpha\chi_N\,d\mathbf{x}.$$

Since $\mathbf{a}_3\cdot\mathbf{a}_3$ is equal to 1, this gives

$$b(V_N;\chi_N) = |\chi_N|^2_{H^1(\omega)} - \int_\omega \partial_\alpha(\chi_N\,(\mathbf{a}_3-\mathbf{a}_{3K'})\cdot\mathbf{a}_3)\partial_\alpha\chi_N\,d\mathbf{x}.$$

Combining the Poincaré–Friedrichs inequality with the continuity of $b(\cdot;\cdot)$ yields

$$b(V_N;\chi_N) \geq c\,\|\chi_N\|^2_{H^1(\omega)} - |\chi_N\,(\mathbf{a}_3-\mathbf{a}_{3K'})\cdot\mathbf{a}_3)|_{H^1(\omega)}|\chi_N|_{H^1(\omega)}.$$

We have, for an appropriate value of p and with $\frac{1}{p}+\frac{1}{q}=\frac{1}{2}$,

$$\begin{aligned}\|\partial_\alpha(\chi_N\,(\mathbf{a}_3-\mathbf{a}_{3K'})\cdot\mathbf{a}_3)\|_{L^2(\omega)} \leq\ & |\chi_N|_{H^1(\omega)}\|\mathbf{a}_3\|_{L^\infty(\omega)^3}\|\mathbf{a}_3-\mathbf{a}_{3K'}\|_{L^\infty(\omega)^3}\\ &+\|\chi_N\|_{L^2(\omega)}\|\mathbf{a}_3\|_{W^{1,\infty}(\omega)^3}\|\mathbf{a}_3-\mathbf{a}_{3K'}\|_{L^\infty(\omega)^3}\\ &+\|\chi_N\|_{L^q(\Omega)}\|\mathbf{a}_3\|_{L^\infty(\omega)^3}\|\mathbf{a}_3-\mathbf{a}_{3K'}\|_{W^{1,p}(\omega)^3}.\end{aligned}$$

Using the fact [25] that the norm of the embedding of $H^1(\omega)$ into $L^q(\omega)$ behaves like $c\,q^{\frac{1}{2}}$, combined with (3.16) and (3.17), and taking q equal to $\log N$ lead to

$$b(V_N;\chi_N) \geq \big(c - c'\,N^{-s_0}\,(\log\,N)^{\frac{1}{2}}\big)\,\|\chi_N\|^2_{H^1(\omega)},$$

whence, for N large enough,

$$b(V_N;\chi_N) \geq \frac{c}{2}\,\|\chi_N\|^2_{H^1(\omega)}.$$

On the other hand, the usual arguments combined with (3.16) and (3.17) give $\|\mathbf{s}_N\|_{H^1(\omega)^3} \leq c\,\|\chi_N\|_{H^1(\omega)}$, which yields the desired inf-sup condition. ∎

Thanks to Lemma 3.7, the proof of the next proposition relies on the same arguments as for Proposition 3.6.

PROPOSITION 3.8. *There exist a positive integer $N_{\sharp\sharp}$ and a positive constant $\tilde{c}_{\sharp\sharp}$ such that, for all $N \geq N_{\sharp\sharp}$, the following inf-sup condition holds:*

$$\forall \chi_N \in \mathbb{M}_N, \quad \sup_{V\in\mathbb{X}_N} \frac{b_M(V_N;\chi_N)}{\|V_N\|_{\mathbb{X}(\omega)}} \geq \tilde{c}_{\sharp\sharp}\,\|\chi_N\|_{H^1(\omega)}. \tag{3.36}$$

The well-posedness result is now a direct consequence of Propositions 3.6 and 3.8. The stability estimate also requires (3.25).

THEOREM 3.9. *There exists a positive integer N_0 such that, for any data $(\mathbf{f},\mathbf{M},\mathbf{N})$ in $\mathscr{C}^0(\overline{\omega})^3 \times \mathscr{C}^0(\overline{\gamma}_1)^3 \times \mathscr{C}^0(\overline{\gamma}_1)^3$ and for $N \geq N_0$, problem (3.11) admits a unique solution (U_N,ψ_N) in $\mathbb{X}_N \times \mathbb{M}_N$. Moreover this solution satisfies*

$$\|U_N\|_{\mathbb{X}(\omega)} + \|\psi_N\|_{H^1(\omega)} \leq c\,\max\{e^{-3},\eta^{-1}\}\,\|\mathcal{L}_M\|_N. \tag{3.37}$$

4. Error estimates. The error estimate that we now prove is derived from Proposition 3.6 and requires the integer N_* introduced there. Indeed we are not interested in the evaluation of the error concerning the Lagrange multiplier ψ. We first prove the following version of the second Strang's lemma.

PROPOSITION 4.1. *For any integer $N \geq N_*$, the following error estimate holds between the solution (U^η,ψ^η) of problem (2.17) and the solution (U_N,ψ_N) of problem (3.11):*

$$\begin{aligned}\|U^\eta - U_N\|_{\mathbb{X}(\omega)} \leq c\,\max\{e^{-3},\eta^{-1}\}\\ \Big(\inf_{W_N\in\mathbb{V}_N}\Big(\max\{e,\eta\}\,\|U^\eta - W_N\|_{\mathbb{X}(\omega)} + \sup_{V_N\in\mathbb{X}_N}\frac{E^a_M(W_N;V_N)+\eta\,\tilde{E}^a_M(W_N;V_N)}{\|V_N\|_{\mathbb{X}(\omega)}}\Big)\\ + \inf_{\chi_N\in\mathbb{M}_N}\Big(\|\psi^\eta-\chi_N\|_{H^1(\omega)} + \sup_{V_N\in\mathbb{X}_N}\frac{E^b_M(V_N;\chi_N)}{\|V_N\|_{\mathbb{X}(\omega)}}\Big)\\ + \sup_{V_N\in\mathbb{X}_N}\frac{E^{\mathcal{L}}_M(V_N)}{\|V_N\|_{\mathbb{X}(\omega)}}\Big),\end{aligned} \tag{4.1}$$

where the four quantities E^a_M, $\tilde{E}^a_M$, E^b_M, and $E^{\mathcal{L}}_M$ are defined by

$$\begin{aligned} E^a_M(W_N;V_N) &= (a-a_M)(W_N;V_N), \quad & \tilde{E}^a_M(W_N;V_N) &= (\tilde{a}-\tilde{a}_M)(W_N;V_N),\\ E^b_M(V_N;\chi_N) &= (b-b_M)(V_N;\chi_N), & E^{\mathcal{L}}_M(V_N) &= (\mathcal{L}-\mathcal{L}_M)(V_N).\end{aligned} \tag{4.2}$$

Proof. Let V_N and W_N be any functions in $\mathbb{V}_N$. We derive from problem (3.11) that

$$a_M(U_N-W_N;V_N)+\eta\,\tilde{a}_M(U_N-W_N;V_N) = \mathcal{L}_M(V_N)-a_M(W_N;V_N)-\eta\,\tilde{a}_M(W_N;V_N).$$

Then, using problem (2.17) yields for any χ_N in $\mathbb{M}_N$ (note that $b_M(V_N;\chi_N)$ is equal to zero)

$$\begin{aligned} a_M(U_N-W_N;V_N)+\eta\,\tilde{a}_M(U_N-W_N;V_N)\\ = -E^{\mathcal{L}}_M(V_N) + a(U^\eta-W_N;V_N) + E^a_M(W_N;V_N)\\ + \eta\,\tilde{a}(U^\eta-W_N;V_N) + \eta\,\tilde{E}^a_M(W_N;V_N) + b(V_N;\psi^\eta-\chi_N) + E^b_M(V_N;\chi_N).\end{aligned}$$

Next, we take V_N equal to $U_N - W_N$ (which belongs to $\mathbb{V}_N$) and use the ellipticity property (3.30). Since the norm of $a(\cdot;\cdot)$ is smaller than $c\,e$, this gives the desired estimate for the term $\|U_N - W_N\|_{\mathbb{X}(\omega)}$. We conclude thanks to a triangle inequality by noting that $e\,\max\{e^{-3}, \eta^{-1}\}$ is larger than 1. ∎

The two terms $\inf_{W_N\in\mathbb{V}_N} \|U^\eta - W_N\|_{\mathbb{X}(\omega)}$ and $\inf_{\chi_N\in\mathbb{M}_N} \|\psi^\eta - \chi_N\|_{H^1(\omega)}$ represent the approximation errors, while the four other terms are issued from numerical integration and the replacement of the coefficients of the initial problem by discrete ones. We begin with the first approximation error.

LEMMA 4.2. *For any integer $N \geq N_{\sharp\sharp}$, there exists a constant c independent of N such that, for all U in $\mathbb{V}(\omega)$,*

$$\inf_{W_N\in\mathbb{V}_N} \|U - W_N\|_{\mathbb{X}(\omega)} \leq c \inf_{Z_N\in\mathbb{X}_N} \left(\|U - Z_N\|_{\mathbb{X}(\omega)} + \sup_{\omega_N\in\mathbb{M}_N} \frac{E_M^b(Z_N;\omega_N)}{\|\omega_N\|_{H^1(\omega)}} \right). \tag{4.3}$$

Proof. Let Z_N be any element of $\mathbb{X}_N$. It follows from the inf-sup condition (3.36) (see [16, Chap. I, Lem. 4.1]) that there exists a $\tilde{Z}_N$ in $\mathbb{X}_N$ such that

$$\begin{aligned} &\forall \omega_N \in \mathbb{M}_N, \quad b_M(\tilde{Z}_N;\omega_N) = b_M(Z_N;\omega_N) \\ &\text{and} \quad \|\tilde{Z}_N\|_{\mathbb{X}(\omega)} \leq \tilde{c}_{\sharp\sharp}^{-1} \sup_{\omega_N\in\mathbb{M}_N} \frac{b_M(Z_N;\omega_N)}{\|\omega_N\|_{H^1(\omega)}}. \end{aligned} \tag{4.4}$$

Then the function $W_N = Z_N - \tilde{Z}_N$ belongs to $\mathbb{V}_N$. Moreover, we obtain the desired estimate by using the triangle inequality

$$\|U - W_N\|_{\mathbb{X}(\omega)} \leq \|U - Z_N\|_{\mathbb{X}(\omega)} + \|\tilde{Z}_N\|_{\mathbb{X}(\omega)},$$

combined with (4.4), the identity

$$b_M(Z_N;\omega_N) = -b(U - Z_N;\omega_N) - E_M^b(Z_N;\omega_N),$$

and the continuity of $b(\cdot;\cdot)$.

Since γ_0 is the union of whole edges of ω, the following estimates are standard; see [4, sect. 7], for instance: If the solution (U^η, ψ^η) belongs to $H^S(\omega)^{3\times3} \times H^S(\omega)$ for a real number $S \geq 1$,

$$\begin{aligned} \inf_{Z_N\in\mathbb{X}_N} \|U^\eta - Z_N\|_{\mathbb{X}(\omega)} &\leq c\,N^{1-S}\,\|U^\eta\|_{H^S(\omega)^{3\times3}}, \\ \inf_{\chi_N\in\mathbb{M}_N} \|\psi^\eta - \chi_N\|_{H^1(\omega)} &\leq c\,N^{1-S}\,\|\psi^\eta\|_{H^S(\omega)}. \end{aligned} \tag{4.5}$$

So it remains to investigate the four terms defined in (4.2). This involves the real number s_0 introduced in Assumption 3.1. ∎

LEMMA 4.3. *There exists a constant c only depending on the norms of the $\mathbf{a}_\alpha$ in $H^{s_0}(\omega)^3$ and of $\mathbf{a}_3$ in $H^{s_0+1}(\omega)^3$ such that*

$$\forall W_N \in \mathbb{X}_N, \quad \sup_{V_N\in\mathbb{X}_N} \frac{E_M^a(W_N;V_N)}{\|V_N\|_{\mathbb{X}(\omega)}} \leq c\,e\,N^{1-s_0}\,(\log\,N)^{\frac{1}{2}}\,\|W_N\|_{\mathbb{X}(\omega)}. \tag{4.6}$$

Proof. Let K'' now denote the integral part of $\frac{\mu\,N-1}{2}$. It follows from the definition of the $a^{\alpha\beta\rho\sigma}$ and also of a that all of these coefficients and also $\sqrt{a}$ belong to $H^{s_0}(\omega)$. We denote by $\mathbf{a}_{\alpha K''}$, $a_{K''}^{\alpha\beta\rho\sigma}$ and $(\sqrt{a})_{K''}$ some approximations of the $\mathbf{a}_\alpha$, $a^{\alpha\beta\rho\sigma}$, and $\sqrt{a}$ in $\mathbb{P}_{K''}(\omega)^3$ or in $\mathbb{P}_{K''}(\omega)$ which still satisfy (3.15). We then derive from the exactness

property (3.2) and with obvious notation

$$\big(a_{K''}^{\alpha\beta\rho\sigma}\,\gamma_{\alpha\beta}^{K''}(\mathbf{w}_N),\gamma_{\rho\sigma}^{K''}(\mathbf{v}_N)\,(\sqrt{a})_{K''}\big)_M=\int_\omega a_{K''}^{\alpha\beta\rho\sigma}\gamma_{a\beta}^{K''}(\mathbf{w}_N)\gamma_{\rho\sigma}^{K''}(\mathbf{v}_N)\,(\sqrt{a})_{K''}\,d\mathbf{x}.$$

Inserting this equality in the definition of $a^M(\cdot;\cdot)$ and similar ones for the other terms of $a(\cdot;\cdot)$ and $a_M(\cdot;\cdot)$ leads to the following bound:

$$E_M^a(W_N;V_N)\le c\,\kappa_N\,\|W_N\|_{\mathbb{X}(\omega)}\|V_N\|_{\mathbb{X}(\omega)},$$

where the quantity κ_N is equal to

$$\begin{aligned}\kappa_N=\max\Big\{&\|\mathbf{a}_k-\mathbf{a}_{kK''}\|_{L^\infty(\omega)^3},\|\mathbf{a}_k-\mathbf{a}_{kN}\|_{L^\infty(\omega)^3},\\&\|\partial_\alpha\mathbf{a}_3-\mathbf{c}_{\alpha K''}\|_{L^\infty(\omega)^3},\|\partial_\alpha\mathbf{a}_3-\mathbf{c}_{\alpha N}\|_{L^\infty(\omega)^3},\\&\|a^{\alpha\beta\rho\sigma}-a_{K''}^{\alpha\beta\rho\sigma}\|_{L^\infty(\omega)},\|\sqrt{a}-(\sqrt{a})_{K''}\|_{L^\infty(\omega)}\Big\}.\end{aligned}$$

So the desired estimate is obviously derived from (3.15), (3.16), and (3.18). ∎

LEMMA 4.4. *There exists a constant c only depending on the norms of $\mathbf{a}_3$ in $H^{s_0+1}(\omega)^3$ such that*

$$\forall W_N\in\mathbb{X}_N,\quad\sup_{V_N\in\mathbb{X}_N}\frac{\tilde E_M^a(W_N;V_N)}{\|V_N\|_{\mathbb{X}(\omega)}}\le c\,N^{-s_0}\,(\log\,N)^{\frac12}\,\|W_N\|_{\mathbb{X}(\omega)}.\tag{4.7}$$

Proof. We set $W_N=(\mathbf{w}_N,\mathbf{t}_N)$ and $V_N=(\mathbf{v}_N,\mathbf{s}_N)$. As in the proof of Proposition 3.6, we take K equal to the integer part of $\mu\,N-1$ and consider an approximation $\mathbf{a}_{3K}$ of $\mathbf{a}_3$ in $\mathbb{P}_K(\omega)^3$ which still satisfies (3.16) and (3.17). Thus, $\mathcal{I}_M(\mathbf{t}_N\cdot\mathbf{a}_{3K})$ and $\mathcal{I}_M(\mathbf{s}_N\cdot\mathbf{a}_{3K})$ are equal to $\mathbf{t}_N\cdot\mathbf{a}_{3K}$ and $\mathbf{s}_N\cdot\mathbf{a}_{3K}$, respectively, whence

$$\big(\partial_\alpha\mathcal{I}_M(\mathbf{t}_N\cdot\mathbf{a}_{3K}),\partial_\alpha\mathcal{I}_M(\mathbf{s}_N\cdot\mathbf{a}_{3K})\big)_M=\int_\omega\partial_\alpha(\mathbf{t}_N\cdot\mathbf{a}_{3K})\partial_\alpha(\mathbf{s}_N\cdot\mathbf{a}_{3K})\,d\mathbf{x}.$$

Adding and subtracting this equality and using the continuity of $\tilde a_M(\cdot;\cdot)$ proved in Lemma 3.4, we derive

$$\begin{aligned}\frac{\tilde E_M^a(W_N;V_N)}{\|V_N\|_{\mathbb{X}(\omega)}}\le c\,\Big(&\|W_N\|_{\mathbb{X}(\omega)}\big(\|\mathbf{s}_N\cdot(\mathbf{a}_{3N}-\mathbf{a}_{3K})\|_{H^1(\omega)}+\|\mathbf{s}_N\cdot(\mathbf{a}_3-\mathbf{a}_{3K})\|_{H^1(\omega)}\big)\\&+\|V_N\|_{\mathbb{X}(\omega)}\big(\|\mathbf{t}_N\cdot(\mathbf{a}_{3N}-\mathbf{a}_{3K})\|_{H^1(\omega)}+\|\mathbf{t}_N\cdot(\mathbf{a}_3-\mathbf{a}_{3K})\|_{H^1(\omega)}\big)\Big).\end{aligned}$$

Then we use the inequality, with $\frac1p+\frac1q=\frac12$,

$$\|\mathbf{s}_N\cdot(\mathbf{a}_3-\mathbf{a}_{3K})\|_{H^1(\omega)}\le\|\mathbf{s}_N\|_{H^1(\omega)^3}\|\mathbf{a}_3-\mathbf{a}_{3K}\|_{L^\infty(\omega)^3}+\|\mathbf{s}_N\|_{L^q(\omega)^3}\|\mathbf{a}_3-\mathbf{a}_{3K}\|_{W^{1,p}(\omega)^3}$$

and similar ones for the other terms. Combining this with (3.16) and (3.17), using once more the fact that the norm of the embedding of $H^1(\omega)$ into $L^q(\omega)$ is smaller than $c\,q^{\frac12}$ and taking q equal to $\log N$, gives the desired result. ∎

The proof of the next lemma relies on exactly the same arguments as for Proposition 3.6. So we omit it.

LEMMA 4.5. *There exists a constant c only depending on the norms of $\mathbf{a}_3$ in $H^{s_0+1}(\omega)^3$ such that*

$$\forall \chi_N \in \mathbb{M}_N, \quad \sup_{V_N \in \mathbb{X}_N} \frac{E_M^b(V_N;\chi_N)}{\|V_N\|_{\mathbb{X}(\omega)}} \leq c\, N^{-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|\chi_N\|_{H^1(\omega)}, \tag{4.8}$$

and

$$\forall Z_N \in \mathbb{X}_N, \quad \sup_{\omega_N \in \mathbb{M}_N} \frac{E_M^b(Z_N;\omega_N)}{\|\omega_N\|_{H^1(\omega)}} \leq c\, N^{-s_0}\, (\log\, N)^{\frac{1}{2}}\, \|Z_N\|_{\mathbb{X}(\omega)}. \tag{4.9}$$

LEMMA 4.6. *Assume that the data $(\mathbf{f},\mathbf{M},\mathbf{N})$ belong to $H^{s_1}(\omega)^3 \times H^{s_1}(\gamma_1)^3 \times H^{s_1}(\gamma_1)^3$ for a real number $s_1 > 1$. There exists a constant $\tilde{c}$ only depending on the norms of the $\mathbf{a}_\alpha$ in $H^{s_0}(\omega)^3$ such that*

$$\sup_{V_N \in \mathbb{X}_N} \frac{E_M^L(V_N)}{\|V_N\|_{\mathbb{X}(\omega)}} \leq c\left(\tilde{c}\, N^{1-s_0}\, (\log\, N)^{\frac{1}{2}} + c(\mathbf{f},\mathbf{M},\mathbf{N})\, N^{-s_1}\right), \tag{4.10}$$

with the quantity $c(\mathbf{f},\mathbf{M},\mathbf{N})$ equal to $\|\mathbf{f}\|_{H^{s_1}(\omega)^3} + \|\mathbf{M}\|_{H^{s_1}(\gamma_1)^3} + \|\mathbf{N}\|_{H^{s_1}(\gamma_1)^3}$.

Proof. If K denotes the integer part of $\mu\, N - 1$ and $(\sqrt{a})_K$ an approximation of $\sqrt{a}$ in $\mathbb{P}_K(\omega)$ which satisfies (3.15) (we recall that $\sqrt{a}$ belongs to $H^{s_0}(\omega)$), we derive from (3.2) the identity, for all $V_N = (\mathbf{v}_N, \mathbf{s}_N)$ in $\mathbb{X}_N$,

$$\left(\mathbf{f}, \mathbf{v}_N\, (\sqrt{a})_K\, \right)_M = \int_\omega \mathcal{I}_M \mathbf{f} \cdot \mathbf{v}_N (\sqrt{a}\,)_K\, d\mathbf{x},$$

whence

$$\left| \int_\omega \mathbf{f} \cdot \mathbf{v}_N \sqrt{a}\, d\mathbf{x} - \left(\mathbf{f}, \mathbf{v}_N\, \sqrt{a}\right)_M \right|$$
$$\leq \left(\|\sqrt{a} - (\sqrt{a})_K\|_{L^\infty(\omega)} \|\mathbf{f}\|_{L^2(\omega)^3} + \|(\sqrt{a})_K\|_{L^\infty(\omega)} \|\mathbf{f} - \mathcal{I}_M \mathbf{f}\|_{L^2(\omega)^3} \right) \|\mathbf{v}_N\|_{L^2(\omega)^3}.$$

Similar but simpler arguments also yield analogous estimates for the terms involving $\mathbf{M}$ and $\mathbf{N}$. So estimate (4.10) is a direct consequence of (3.15) and the approximation properties of the operators $\mathcal{I}_M$ and $i_M^{\gamma_1}$; see [4, Thms. 13.4 and 14.2].

To conclude, we insert (4.3) into (4.1). Next, we use (4.5) and Lemmas 4.3–4.6 to bound all of the terms on the right-hand side. ∎

THEOREM 4.7. *Assume that:*

(i) *the solution (U^η, ψ^η) of problem (2.17) belongs to $H^S(\omega)^{3\times 3} \times H^S(\omega)$ for a real number $S \geq 1$, and*

(ii) *the data $(\mathbf{f},\mathbf{M},\mathbf{N})$ belongs to $H^{s_1}(\omega)^3 \times H^{s_1}(\gamma_1)^3 \times H^{s_1}(\gamma_1)^3$ for a real number $s_1 > 1$.*

Then, for any integer $N \geq N_0$, the following error estimate holds between this solution (U^η, ψ^η) and the solution (U_N, ψ_N) of problem (3.11):

$$\begin{aligned} \|U^\eta - U_N\|_{\mathbb{X}(\omega)} &\leq c\, \max\{e^{-3}, \eta^{-1}\} \\ &\left(c(U^\eta, \psi^\eta)\, \max\{e, \eta\}\, N^{1-S} + \tilde{c}\, N^{1-s_0}\, (\log\, N)^{\frac{1}{2}} + c(\mathbf{f},\mathbf{M},\mathbf{N})\, N^{-s_1}\right), \end{aligned} \tag{4.11}$$

where s_0 is introduced in Assumption 3.1, the quantity $c(U^\eta, \psi^\eta)$ is equal to $\|U^\eta\|_{H^S(\omega)^{3\times 3}} + \|\psi^\eta\|_{H^S(\omega)}$, the constant $\tilde{c}$ only depends on the coefficients involved in problem (2.10), and the quantity $c(\mathbf{f},\mathbf{M},\mathbf{N})$ is introduced in Lemma 4.6.

Estimate (4.11) is optimal and proves the convergence of the method without any restriction, for a fixed value of e. So taking N large enough gives an error smaller than any fixed tolerance.

ADJOINT CONSISTENCY ANALYSIS OF DISCONTINUOUS GALERKIN DISCRETIZATIONS*

RALF HARTMANN†

Abstract. This paper is concerned with the adjoint consistency of discontinuous Galerkin (DG) discretizations. Adjoint consistency—in addition to consistency—is the key requirement for DG discretizations to be of optimal order in L^2 as well as measured in terms of target functionals. We provide a general framework for analyzing the adjoint consistency of DG discretizations which is also useful for the derivation of adjoint consistent methods. This analysis will be performed for the DG discretizations of the linear advection equation, the interior penalty DG method for elliptic problems, and the DG discretization of the compressible Euler equations. This framework is then used to derive an adjoint consistent DG discretization of the compressible Navier–Stokes equations. Numerical experiments demonstrate the link of adjoint consistency to the accuracy of numerical flow solutions and the smoothness of discrete adjoint solutions.

Key words. discontinuous Galerkin discretization, adjoint consistency, compressible Navier–Stokes equations, continuous adjoint problem, discrete adjoint problem

1. Introduction.

The past few years have seen considerable progress in the development and analysis of discontinuous Galerkin (DG) methods. In addition to consistency in numerical analysis the so-called adjoint consistency property of discretizations has experienced increasing interest [1, 11, 12, 24]. Adjoint consistency is the key property of discretizations that ensures optimal order of convergence of the error measured in L^2 as well as in terms of specific target functionals $J(\cdot)$. A typical situation is given by the interior penalty discontinuous Galerkin methods. While both the symmetric version (SIPG) and the nonsymmetric version (NIPG) are of optimal order $\mathcal{O}(h^p)$ measured in H^1, only the symmetric version is adjoint consistent which allows employment of a duality argument resulting in an optimal $\mathcal{O}(h^{p+1})$ order of convergence in L^2. In contrast to that, the nonsymmetric interior penalty method is suboptimal, $\mathcal{O}(h^p)$ in L^2. Similarly, adjoint consistency in conjunction with a duality argument leads to the so-called order doubling in the error measured in target functionals $J(\cdot)$. Whereas the adjoint consistency of the SIPG method results in $\mathcal{O}(h^{2p})$ of the error in $J(\cdot)$, the nonsymmetric version (NIPG) lacks adjoint consistency and target functionals behave like $\mathcal{O}(h^p)$. Adjoint consistency is closely linked to the smoothness of the discrete adjoint solutions. For adjoint consistent discretizations the discrete adjoint problem represents a consistent discretization of the continuous adjoint problem. Consequently, discrete adjoint solutions inherit the smoothness properties of the continuous adjoint solutions. Conversely, it has been seen that adjoint inconsistent discretizations exhibit some nonsmoothness. In particular, in [12] it has been shown that the discrete adjoint solutions arising from the SIPG method are essentially continuous. In contrast to that, the adjoint solutions arising from the

NIPG method are discontinuous between element interfaces where the jumps in the adjoint solutions persist even as the mesh is refined. The lack of regularity of the adjoint solution leads to the suboptimal rate of convergence of the NIPG method.

Adjoint consistency has been considered (cf. [1]) for linear elliptic problems with homogeneous boundary conditions which results in a characterization of element and interior face terms while ignoring the discretization of boundary terms. However, adjoint consistency is equally important for the discretization of boundary terms and for the discretization of target functionals $J(\cdot)$. In [11] it has been shown that the interior penalty method for Poisson's equation with nonhomogeneous Dirichlet in combination with a specific target functional $J(\cdot)$ results in an adjoint inconsistent discretization of boundary conditions and a nonsmooth adjoint solution even for the SIPG discretization, which is known to be adjoint consistent in the interior of the domain. Only after an appropriate modification of the target functional have adjoint consistency, smoothness of the adjoint solution, and optimal convergence rates in $J(\cdot)$ been recovered; see also [23] for elliptic problems discretized by the BR2 scheme [5]. First results for the compressible Euler equations in [23, 24] indicate that adjoint consistency is of similar importance for nonlinear problems. Whereas adjoint inconsistent discretizations of boundary terms [4, 15] lead to irregular adjoint solutions near a reflective boundary, it has been shown in [23, 24, 14] that a specific discretization of boundary conditions and target functionals is required for recovering the adjoint consistency property and a smooth discrete adjoint solution.

We note that adjoint consistency is of importance also in continuous finite element methods. In [18] it was shown that, for the streamline diffusion (SD) discretization of the linear advection equation, the discrete adjoint problem is not a consistent discretization of the continuous adjoint problem; i.e., the SD discretization is not adjoint consistent. It is, however, asymptotically adjoint consistent.

As outlined so far, adjoint consistency is a desirable property which, however, involves several issues. In addition to the adjoint consistency of element and interior face terms, it involves the discretization of boundary conditions and target functionals. The purpose of this paper is to give a general framework for analyzing the adjoint consistency property of DG discretizations for linear as well as nonlinear problems. This framework includes the derivation of the continuous adjoint problems and boundary conditions provided the primal problems and the target functionals satisfy a compatibility condition. Furthermore, it includes the derivation of the discrete adjoint problems and of primal and adjoint residuals and a discussion of under which conditions the residuals vanish for the exact primal and adjoint solutions, respectively. Additionally, a so-called consistent modification of target functionals is introduced. The analysis is performed for various model problems, recovering properties and conclusions drawn in [1, 11, 24]. In addition, this framework is used to derive an adjoint consistent DG discretization of the compressible Navier–Stokes equations. Altogether, this publication provides a general framework of an adjoint consistency analysis which can be applied to a wide range of (more complex) linear and nonlinear problems.

The paper is structured as follows: We begin by outlining the main ingredients of the framework in section 2, including the definition of adjoint consistency for linear and nonlinear problems. Then in sections 3, 4, and 5 the DG discretization of the linear advection equation, the interior penalty DG method for Poisson's equation, and the DG discretization of the compressible Euler equations are analyzed. Then in section 6 it is shown that the interior penalty DG discretization of the compressible Navier–Stokes equations in [16] is not adjoint consistent. Within the framework appropriate modifications are derived for recovering adjoint consistency. These mod-

ifications include a specific treatment of convective and diffusive fluxes at boundaries and a consistent modification of total force coefficients. Then in section 7 we show some numerical results demonstrating the effect of adjoint consistency on the accuracy of the flow solution and on the smoothness of the discrete adjoint solution.

2. General framework. We begin by defining the adjoint consistency for linear and nonlinear problems. Let Ω be a bounded open domain in $\mathbb{R}^d$ with boundary Γ.

2.1. Linear problems. For $f \in L^2(\Omega)$ and $g \in L^2(\Gamma)$ consider the following linear problem:

$$Lu = f \quad \text{in } \Omega, \qquad\qquad Bu = g \quad \text{on } \Gamma, \tag{2.1}$$

where L denotes a linear differential operator on Ω and B denotes a linear differential (boundary) operator on Γ. Let J be a linear target functional given by

$$J(u) = \int_\Omega j_\Omega \, u \, \mathrm{d}\mathbf{x} + \int_\Gamma j_\Gamma \, Cu \, \mathrm{d}s, \tag{2.2}$$

where $j_\Omega \in L^2(\Omega)$, $j_\Gamma \in L^2(\Gamma)$, and C is a differential (boundary) operator on Γ. We say that the target functional (2.2) is *compatible* with (2.1), provided the following compatibility condition based on Green's formula holds (see, e.g., [2, 22] for elliptic problems):

$$(Lu, z)_\Omega + (Bu, C^* z)_\Gamma = (u, L^* z)_\Omega + (Cu, B^* z)_\Gamma, \tag{2.3}$$

where L^*, B^*, and C^* denote the adjoint operators to L, B, and C, respectively, and $(\cdot,\cdot)_\Omega$ and $(\cdot,\cdot)_\Gamma$ denote the $L^2(\Omega)$ and $L^2(\Gamma)$ scalar products, respectively. We note that, for given operators L and B associated with the primal problem (2.1), only some target functionals (2.2) with operators C are compatible, whereas others are not. However, assuming that (2.3) holds the adjoint problem associated to (2.1), (2.2) is given by

$$L^* z = j_\Omega \quad \text{in } \Omega, \qquad\qquad B^* z = j_\Gamma \quad \text{on } \Gamma. \tag{2.4}$$

In an adjoint-based optimization framework (see, e.g., [10]) this ensures that

$$\begin{aligned} J(u) &= (u, j_\Omega)_\Omega + (Cu, j_\Gamma)_\Gamma = (u, L^* z)_\Omega + (Cu, B^* z)_\Gamma \\ &= (Lu, z)_\Omega + (Bu, C^* z)_\Gamma = (f, z)_\Omega + (g, C^* z)_\Gamma. \end{aligned} \tag{2.5}$$

Let Ω be subdivided into shape-regular meshes $\mathcal{T}_h = \{\kappa\}$ consisting of elements κ, and let V_h be a discrete function space on $\mathcal{T}_h$. Furthermore, let V be a broken Sobolev space on $\mathcal{T}_h$ appropriately chosen such that $V_h \subset V$ and $u, z \in V$, where u and z are the solutions to (2.1) and (2.4), respectively. A typical situation is $V = H^2(\mathcal{T}_h)$, with $V_h \subset V$ and $u, z \in H^2(\Omega) \subset V$; see, e.g., [1, 6]. Finally, let $\mathcal{B} : V \times V \to \mathbb{R}$ be a bilinear form such that problem (2.1) is discretized as follows: Find $u_h \in V_h$ such that

$$\mathcal{B}(u_h, v) = \mathcal{F}(v) \quad \forall v \in V_h, \tag{2.6}$$

where $\mathcal{F} : V \to \mathbb{R}$ is a linear form including the prescribed force and boundary data functions f and g. Then the discretization (2.6) is said to be *consistent* if the exact solution $u \in V$ to the primal problem (2.1) satisfies:

$$\mathcal{B}(u, v) = \mathcal{F}(v) \quad \forall v \in V, \tag{2.7}$$

which can then be viewed as a (broken) weak formulation of (2.1); see [6]. We note that defining $\mathcal{B}$ via the discretization scheme (2.6) instead of the weak formulation (2.7) allows us to represent also inconsistent DG discretizations; see, e.g., [1].

Similarly, the discretization (2.6) is said to be *adjoint consistent* if the exact solution $z \in V$ to the adjoint problem (2.4) satisfies:

$$\mathcal{B}(w, z) = J(w) \quad \forall w \in V. \tag{2.8}$$

In the following we generalize this definition to nonlinear problems.

2.2. Nonlinear problems. We now consider the nonlinear problem

$$Nu = 0 \quad \text{in } \Omega, \qquad\qquad Bu = 0 \quad \text{on } \Gamma, \tag{2.9}$$

where N is a nonlinear differential (and Fréchet-differentiable) operator and B is a (possibly nonlinear) boundary operator. Let $J(\cdot)$ be a nonlinear target functional

$$J(u) = \int_\Omega j_\Omega(u)\,\mathrm{d}\mathbf{x} + \int_\Gamma j_\Gamma(Cu)\,\mathrm{d}s, \tag{2.10}$$

with Fréchet derivative

$$J'[u](w) = \int_\Omega j'_\Omega[u]\,w\,\mathrm{d}\mathbf{x} + \int_\Gamma j'_\Gamma[Cu]\,C'[u]w\,\mathrm{d}s, \tag{2.11}$$

where $j_\Omega(\cdot)$ and $j_\Gamma(\cdot)$ may be nonlinear with derivatives j'_Ω and j'_Γ, respectively, and C is a differential boundary operator on Γ and may be nonlinear with derivative C'. Here $'$ denotes the (total) Fréchet derivative, and the square bracket $[\cdot]$ denotes the state about which linearization is performed. Again, we say that the target functional (2.10) is *compatible* with (2.9) provided the following compatibility condition holds:

$$(N'[u]w, z)_\Omega + (B'[u]w, (C'[u])^* z)_\Gamma = (w, (N'[u])^* z)_\Omega + (C'[u]w, (B'[u])^* z)_\Gamma, \tag{2.12}$$

where $(N'[u])^*$, $(B'[u])^*$, and $(C'[u])^*$ denote the adjoint operators to $N'[u]$, $B'[u]$, and $C'[u]$, respectively. This condition is analogous to (2.3), with L, B, and C replaced by $N'[u]$, $B'[u]$, and $C'[u]$, respectively. Assuming that (2.12) holds, the continuous adjoint problem associated to (2.9) and (2.11) is given by

$$(N'[u])^* z = j'_\Omega[u] \quad \text{in } \Omega, \qquad\qquad (B'[u])^* z = j'_\Gamma[Cu] \quad \text{on } \Gamma. \tag{2.13}$$

We note that, in an optimization framework [10], this ensures, analogous to (2.5), that

$$\begin{aligned} J'[u](w) &= (w, j'_\Omega[u])_\Omega + (C'[u]w, j'_\Gamma[Cu])_\Gamma = (w, (N'[u])^* z)_\Omega + (C'[u]w, (B'[u])^* z)_\Gamma \\ &= (N'[u]w, z)_\Omega + (B'[u]w, (C'[u])^* z)_\Gamma. \end{aligned} \tag{2.14}$$

Let $\mathcal{N} : V \times V \to \mathbb{R}$ be a semilinear form, nonlinear in its first and linear in its second argument, such that the nonlinear problem (2.9) is discretized as follows: Find $u_h \in V_h$ such that

$$\mathcal{N}(u_h, v) = 0 \quad \forall v \in V_h. \tag{2.15}$$

Then the discretization (2.15) is said to be consistent if the exact solution $u \in V$ to the primal problem (2.9) satisfies the following equation:

$$\mathcal{N}(u, v) = 0 \quad \forall v \in V. \tag{2.16}$$

Furthermore, the discretization (2.15) is said to be adjoint consistent if the exact solutions $u, z \in V$ to the primal and adjoint problems (2.9) and (2.13), respectively, satisfy the following equation:

$$\mathcal{N}'[u](w,z) = J'[u](w) \quad \forall w \in V, \tag{2.17}$$

where $\mathcal{N}'[u]$ denotes the Fréchet derivatives of $\mathcal{N}(u,v)$ with respect to u.

In other words, a discretization is adjoint consistent if the discrete adjoint problem is a consistent discretization of the continuous adjoint problem. Finally, we note that, in the case of a linear problem and target functional, the definition of adjoint consistency in (2.17) reduces to the definition of linear adjoint consistency given in section 2.1.

2.3. The adjoint consistency analysis. Based on the definition of adjoint consistency in the previous two sections, we outline a framework of analyzing the adjoint consistency of discontinuous Galerkin discretizations. This framework can also be used to derive adjoint consistent DG discretizations.

2.3.1. Derivation of the continuous adjoint problem. Let the primal problem be given by (2.1) or by (2.9) in the nonlinear case. Furthermore, assume that $J(\cdot)$ is a linear (2.2) or linearized (2.11) compatible target functional. Then we derive the continuous adjoint problem (2.4) or (2.13) including adjoint boundary conditions.

We note that the derivation of the adjoint operator $(N'[u])^*$ for nonlinear systems is a considerably more complicated task than deriving L^* for scalar linear problems. Still more involved is the derivation of the adjoint boundary operators $(B'[u])^*$. In the framework of optimal design, [10] gives a general approach of deriving $(B'[u])^*$ and $(C'[u])^*$ assumed to be connected to B, C, N, and $(N'[u])^*$ through (2.12). This approach is based on a matrix representation of boundary operators which for systems of equations leads to lengthy and error prone derivations. In contrast to optimization where both $(B'[u])^*$ and C^* are required, in the following analysis we require only the adjoint operator $(B'[u])^*$. Due to this we can circumvent the approach described in [10] and use a simpler way of deriving the adjoint boundary operators $(B'[u])^*$.

2.3.2. Consistency analysis of the discrete primal problem. We rewrite the discontinuous Galerkin discretization (2.15) of problem (2.9) in the following element-based primal residual form: Find $u_h \in V_h$ such that

$$\sum_{\kappa\in\mathcal{T}_h} \int_\kappa R(u_h) v \,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa\setminus\Gamma} r(u_h) v \,\mathrm{d}s + \int_\Gamma r_\Gamma(u_h) v \,\mathrm{d}s = 0 \quad \forall v \in V_h, \tag{2.18}$$

where $R(u_h)$, $r(u_h)$, and $r_\Gamma(u_h)$ denote the element, interior face, and boundary residuals, respectively. According to (2.16), the discretization (2.15) is consistent if the exact solution u to (2.9) satisfies

$$\sum_{\kappa\in\mathcal{T}_h} \int_\kappa R(u) v \,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa\setminus\Gamma} r(u) v \,\mathrm{d}s + \int_\Gamma r_\Gamma(u) v \,\mathrm{d}s = 0 \quad \forall v \in V, \tag{2.19}$$

which holds, provided u satisfies

$$R(u) = 0 \ \text{ in } \kappa, \kappa \in \mathcal{T}_h, \quad r(u) = 0 \ \text{ on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \quad r_\Gamma(u) = 0 \ \text{ on } \Gamma. \tag{2.20}$$

2.3.3. Derivation of the discrete adjoint problem. Given the discretization (2.15), the target functional (2.10), and its linearization (2.11), we derive the discrete

adjoint problem: Find $z_h \in V_h$ such that

$$\mathcal{N}'[u_h](w, z_h) = J'[u_h](w) \quad \forall w \in V_h. \tag{2.21}$$

$\mathcal{N}'[u_h]$ is called the Jacobian of the numerical scheme and is required also for implicit and adjoint methods, e.g., Newton iteration, a posteriori error estimation, adjoint-based adaptation (see [13]), and for optimization.

2.3.4. Adjoint consistency of element, interior face, and boundary terms. We rewrite the discrete adjoint problem (2.21) in element-based adjoint residual form: Find $z_h \in V_h$ such that

$$\sum_{\kappa \in \mathcal{T}_h} \int_\kappa w\, R^*[u_h](z_h)\, \mathrm{d}\mathbf{x} + \sum_{\kappa \in \mathcal{T}_h} \int_{\partial\kappa \setminus \Gamma} w\, r^*[u_h](z_h)\, \mathrm{d}s + \int_\Gamma w\, r^*_\Gamma[u_h](z_h)\, \mathrm{d}s = 0 \tag{2.22}$$

for all $w \in V_h$, where $R^*[u_h](z_h)$, $r^*[u_h](z_h)$, and $r^*_\Gamma[u_h](z_h)$ denote the element, interior face, and boundary adjoint residuals, respectively. According to (2.17), the discretization (2.15) is adjoint consistent if the exact solutions u and z satisfy

$$\sum_{\kappa \in \mathcal{T}_h} \int_\kappa w\, R^*[u](z)\, \mathrm{d}\mathbf{x} + \sum_{\kappa \in \mathcal{T}_h} \int_{\partial\kappa \setminus \Gamma} w\, r^*[u](z)\, \mathrm{d}s + \int_\Gamma w\, r^*_\Gamma[u](z)\, \mathrm{d}s = 0 \quad \forall w \in V, \tag{2.23}$$

which holds, provided u and z satisfy

$$R^*[u](z) = 0 \ \text{ in } \kappa, \quad r^*[u](z) = 0 \ \text{ on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \quad r^*_\Gamma[u](z) = 0 \ \text{ on } \Gamma. \tag{2.24}$$

We note that the adjoint problem and consequently the adjoint consistency of a discretization depend on the specific target functional $J(\cdot)$ under consideration. Given a target functional of the form (2.10), we see that $R^*[u](z)$ depends on $j_\Omega(\cdot)$ and $r^*_\Gamma[u](z)$ depends on $j_\Gamma(\cdot)$. For obtaining an adjoint consistent discretization it is, in some cases (see following sections) necessary to modify the target functional as follows:

$$\tilde{J}(u_h) = J(i(u_h)) + \int_\Gamma r_J(u_h)\, \mathrm{d}s, \tag{2.25}$$

where $i(\cdot)$ and $r_J(\cdot)$ are functions to be specified. A modification of a target functional is called consistent if $\tilde{J}(u) = J(u)$ holds for the exact solution u. Thereby, the modification in (2.25) is consistent if the exact solution u satisfies $i(u) = u$ and $r_J(u) = 0$. Although the true value of the target functional is unchanged, $\tilde{J}(u) = J(u)$, the computed value $J(u_h)$ of the target functional is modified, and, more importantly, $\tilde{J}'[u_h]$ differs from $J'[u_h]$. This modification can be used to recover an adjoint consistent discretization. We note that (2.25) is not a unique choice of a consistent modification of $J(\cdot)$; other examples are $\tilde{J}(u_h) = J(u_h) + \int_\Omega R_J(u_h)\, \mathrm{d}\mathbf{x}$, with $R_J(u) = 0$, or $\tilde{J}(u_h) = m(J(u_h), J(i(u_h)))$, with $i(u) = u$ and $m(j, j) = j$. However, the consistent modification as given in (2.25) will be sufficient for the purposes of this work.

3. The linear advection equation. We consider the linear advection equation

$$\nabla \cdot (\mathbf{b}u) + cu = f \quad \text{in } \Omega, \qquad u = g \quad \text{on } \Gamma_-, \tag{3.1}$$

where $f \in L^2(\Omega)$ and $c \in L^\infty(\Omega)$ are real-valued and $\mathbf{b} = \{\beta_i\}_{i=1}^d$ is a vector function whose entries β_i are Lipschitz continuous real-valued functions on Ω. By $\Gamma_- = \{x \in \Gamma, \mathbf{b}\cdot\mathbf{n} < 0\}$ we denote the inflow part of the boundary $\Gamma = \partial\Omega$. Furthermore, we adopt the following hypothesis: There exists a $c_0 \in L^\infty(\Omega)$ and a number $\gamma_0 > 0$ such that $c(\mathbf{x}) + \frac{1}{2}\nabla\cdot\mathbf{b}(\mathbf{x}) = c_0^2(\mathbf{x}) \geq \gamma_0 > 0$. To demonstrate the similarities with the compressible Euler equations in section 5, we consider the linear advection equation in conservative form which is equivalent to the nonconservative form $\mathbf{b}\cdot\nabla u + \tilde{c}u = f$ (see, e.g., [19]), with $\tilde{c} - \frac{1}{2}\nabla\cdot\mathbf{b} = c_0^2$ and $\tilde{c} = c + \nabla\cdot\mathbf{b}$.

In order to derive the continuous adjoint problem, we multiply the left-hand side of (3.1) by z and integrate by parts over the domain Ω. Thereby, we obtain

$$(\nabla\cdot(\mathbf{b}u) + cu, z)_\Omega + (u, -\mathbf{b}\cdot\mathbf{n}z)_{\Gamma_-} = (u, -\mathbf{b}\cdot\nabla z + cz)_\Omega + (u, \mathbf{b}\cdot\mathbf{n}z)_{\Gamma_+}. \tag{3.2}$$

From (2.3) we see that, for $Lu = \nabla\cdot(\mathbf{b}u) + cu$ in Ω, and $Bu = u$ and $Cu = 0$ on Γ_-, and $Bu = 0$ and $Cu = u$ on Γ_+, we have $L^*z = -\mathbf{b}\cdot\nabla z + cz$ in Ω, $B^*z = 0$ and $C^*z = -\mathbf{b}\cdot\mathbf{n}z$ on Γ_-, and $B^*z = \mathbf{b}\cdot\mathbf{n}z$ and $C^*z = 0$ on Γ_+. In particular, the target functional $J(u) = \int_\Omega j_\Omega\, u\,\mathrm{d}\mathbf{x} + \int_{\Gamma_+} j_\Gamma\, u\,\mathrm{d}s$ is compatible, and the adjoint problem is given by

$$-\mathbf{b}\cdot\nabla z + cz = j_\Omega \quad \text{in } \Omega, \qquad\qquad \mathbf{b}\cdot\mathbf{n}\, z = j_\Gamma \quad \text{on } \Gamma_+. \tag{3.3}$$

Let Ω be subdivided into shape-regular meshes $\mathcal{T}_h = \{\kappa\}$ consisting of elements κ, and let V_h^p be the discrete function space consisting of discontinuous piecewise polynomial functions of degree $p \geq 0$. Suppose that $v|_\kappa \in H^1(\kappa)$ for each $\kappa \in \mathcal{T}_h$. Let κ^+ and κ^- be two adjacent elements of $\mathcal{T}_h$ and $\mathbf{x}$ be an arbitrary point on the interior edge $e = \partial\kappa^+ \cap \partial\kappa^- \subset \Gamma_\mathcal{I}$, where $\Gamma_\mathcal{I}$ denotes the union of all interior edges of $\mathcal{T}_h$. Moreover, let v and $\boldsymbol{\phi}$ be a scalar and a d-vector-valued function, respectively, that are smooth inside each element $\kappa^\pm$. By $u^\pm := u|_{\partial\kappa^\pm}$ and $\boldsymbol{\phi}^\pm := \boldsymbol{\phi}|_{\partial\kappa^\pm}$ we denote the traces of u and $\boldsymbol{\phi}$, respectively, on e taken from within the interior of $\kappa^\pm$. Then we define the averages at $\mathbf{x} \in e$ by $\{v\} = (v^+ + v^-)/2$ and $\{\boldsymbol{\phi}\} = (\boldsymbol{\phi}^+ + \boldsymbol{\phi}^-)/2$. Similarly, the jump at $\mathbf{x} \in e$ is given by $[\![v]\!] = v^+\mathbf{n}^+ + v^-\mathbf{n}^-$ and by $[\![\boldsymbol{\phi}]\!] = \boldsymbol{\phi}^+\cdot\mathbf{n}^+ + \boldsymbol{\phi}^-\cdot\mathbf{n}^-$. On a boundary edge $e \subset \Gamma$ the average and jump operators are defined by $\{v\} = v^+$, $\{\boldsymbol{\phi}\} = \boldsymbol{\phi}^+$, $[\![v]\!] = v^+\mathbf{n}^+$, and $[\![\boldsymbol{\phi}]\!] = \boldsymbol{\phi}^+\cdot\mathbf{n}^+$.

The DG discretization of (3.1) (e.g., [12, 7]) is given by: Find $u_h \in V_h^p$ such that

$$\begin{aligned}\mathcal{B}(u_h, v) \equiv &-\int_\Omega u_h\mathbf{b}\cdot\nabla_h v\,\mathrm{d}\mathbf{x} + \int_\Omega cu_h v\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa_-\setminus\Gamma} \mathbf{b}\cdot\mathbf{n}\, u_h^- v^+\,\mathrm{d}s \\ &+ \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa_+} \mathbf{b}\cdot\mathbf{n}\, u_h^+ v^+\,\mathrm{d}s = \int_\Omega fv\,\mathrm{d}\mathbf{x} - \int_{\Gamma_-}\mathbf{b}\cdot\mathbf{n}\, gv^+\,\mathrm{d}s\end{aligned} \tag{3.4}$$

for all $v \in V_h^p$. Then integration by parts on each $\kappa \in \mathcal{T}_h$ yields: Find $u_h \in V_h^p$:

$$\int_\Omega (\nabla_h\cdot(\mathbf{b}u_h) + cu_h)\, v\,\mathrm{d}\mathbf{x} - \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa_-}\mathbf{b}\cdot[\![u_h]\!]v^+\,\mathrm{d}s = \int_\Omega fv\,\mathrm{d}\mathbf{x} - \int_{\Gamma_-}\mathbf{b}\cdot\mathbf{n}\, gv^+\,\mathrm{d}s$$

for all $v \in V_h^p$. Hence we have the primal residual form (2.18) with

$$\begin{aligned} R(u_h) &= f - \nabla_h\cdot(\mathbf{b}u_h) - cu_h && \text{in } \kappa, \kappa \in \mathcal{T}_h, \\ r(u_h) &= \mathbf{b}\cdot[\![u_h]\!] && \text{on } \partial\kappa\setminus\Gamma, \kappa \in \mathcal{T}_h, \\ r_\Gamma(u_h) &= \mathbf{b}\cdot\mathbf{n}\,(u_h - g) && \text{on } \Gamma_-, \end{aligned}$$

and $r_\Gamma(u_h) \equiv 0$ on Γ_+. As (2.19) holds for the exact solution u to (3.1), we conclude that (3.4) is a consistent discretization of (3.1). Substituting

$$\sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa_-\setminus\Gamma} \mathbf{b}\cdot\mathbf{n}\, u_h^- v^+ \,\mathrm{d}s = -\sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa_+\setminus\Gamma} \mathbf{b}\cdot\mathbf{n}\, u_h^+ v^- \,\mathrm{d}s$$

in (3.4), we find that the discrete adjoint problem to the discretization (3.4) is given by: Find $z_h \in V_h$ such that

$$\mathcal{B}(w, z_h) \equiv \int_\Omega w\,(-\mathbf{b}\cdot\nabla_h z_h + c z_h)\,\mathrm{d}\mathbf{x} + \sum_\kappa \int_{\partial\kappa_+\setminus\Gamma} w^+\,\mathbf{b}\cdot[\![z_h]\!]\,\mathrm{d}s = J(w)$$

for all $w \in V_h$. Hence we have the adjoint residual form (2.22) with

$$\begin{aligned}
R^*(z_h) &= j_\Omega + \mathbf{b}\cdot\nabla_h z_h - c z_h && \text{in } \kappa, \kappa\in\mathcal{T}_h,\\
r^*(z_h) &= -\mathbf{b}\cdot[\![z_h]\!] && \text{on } \partial\kappa\setminus\Gamma, \kappa\in\mathcal{T}_h, \qquad (3.5)\\
r_\Gamma^*(z_h) &= j_\Gamma - \mathbf{b}\cdot\mathbf{n}\, z_h && \text{on } \Gamma_+, \qquad (3.6)
\end{aligned}$$

and $r_\Gamma^*(z_h) \equiv 0$ on Γ_-. As the adjoint residuals vanish for the exact solution z to (3.3), we conclude that (3.4) is an adjoint consistent discretization of (3.1).

4. Poisson's equation. We now consider the elliptic model problem

$$-\Delta u = f \quad \text{in } \Omega, \qquad u = g_D \quad \text{on } \Gamma_D, \qquad \mathbf{n}\cdot\nabla u = g_N \quad \text{on } \Gamma_N, \tag{4.1}$$

where $f \in L^2(\Omega)$, $g_D \in L^2(\Gamma_D)$, and $g_N \in L^2(\Gamma_N)$ are given functions. We assume that Γ_D and Γ_N are disjoint subsets with union Γ. We also assume that Γ_D is nonempty.

In order to derive the continuous adjoint problem we multiply the left-hand side of (4.1) by z and integrate twice by parts over the domain Ω. Thereby, we obtain

$$(-\Delta u, z)_\Omega + (u, -\mathbf{n}\cdot\nabla z)_{\Gamma_D} + (\mathbf{n}\cdot\nabla u, z)_{\Gamma_N} = (u, -\Delta z)_\Omega + (\mathbf{n}\cdot\nabla u, -z)_{\Gamma_D} + (u, \mathbf{n}\cdot\nabla z)_{\Gamma_N}.$$

From (2.3) we see that, for $Lu = -\Delta u$ in Ω, $Bu = u$ and $Cu = \mathbf{n}\cdot\nabla u$ on Γ_D, and $Bu = \mathbf{n}\cdot\nabla u$ and $Cu = u$ on Γ_N, we have $L^*z = -\Delta z$ in Ω, $B^*z = -z$ and $C^*z = -\mathbf{n}\cdot\nabla z$ on Γ_D, and $B^*z = \mathbf{n}\cdot\nabla z$ and $C^*z = z$ on Γ_N. Then (2.2) reduces to

$$J(u) = \int_\Omega j_\Omega\, u\,\mathrm{d}\mathbf{x} + \int_{\Gamma_D} j_D\,\mathbf{n}\cdot\nabla u\,\mathrm{d}s + \int_{\Gamma_N} j_N\, u\,\mathrm{d}s. \tag{4.2}$$

This target functional is compatible, and the continuous adjoint problem is given by

$$-\Delta z = j_\Omega \quad \text{in } \Omega, \qquad z = j_D \quad \text{on } \Gamma_D, \qquad \mathbf{n}\cdot\nabla z = j_N \quad \text{on } \Gamma_N. \tag{4.3}$$

The method by Baumann–Oden and the symmetric and nonsymmetric interior penalty methods can be expressed as follows (see, e.g., [25]): Find $u_h \in V_h^p$ such that

$$\begin{aligned}
\mathcal{B}(u_h, v) \equiv{}& \int_\Omega \nabla_h u_h\cdot\nabla_h v\,\mathrm{d}\mathbf{x}\\
&+ \int_{\Gamma_\mathcal{I}\cup\Gamma_D} \left(\theta[\![u_h]\!]\cdot\{\nabla_h v\} - \{\nabla_h u_h\}\cdot[\![v]\!]\right)\mathrm{d}s + \int_{\Gamma_\mathcal{I}\cup\Gamma_D} \delta[\![u_h]\!]\cdot[\![v]\!]\,\mathrm{d}s\\
={}& \int_\Omega f v\,\mathrm{d}\mathbf{x} + \int_{\Gamma_D} \theta g_D \mathbf{n}\cdot\nabla v\,\mathrm{d}s + \int_{\Gamma_D} \delta g_D v\,\mathrm{d}s + \int_{\Gamma_N} g_N v\,\mathrm{d}s \qquad (4.4)
\end{aligned}$$

for all $v \in V_h^p$, where the constants θ and δ are given by $\theta = 1, \delta = 0$ for Baumann–Oden, by $\theta = 1, \delta > 0$ for NIPG, and by $\theta = -1, \delta > \delta_0 > 0$ for SIPG.

The scheme in (4.4) is given in face-based form including integrals over all interior faces $\Gamma_{\mathcal{I}}$. Rewriting the interior face terms in element-based form, we obtain

$$\begin{aligned}\mathcal{B}(u_h, v) = &\int_\Omega \nabla_h u_h \cdot \nabla_h v \,\mathrm{d}\mathbf{x} + \sum_\kappa \int_{\partial\kappa\setminus\Gamma} \frac{1}{2}\theta[\![u_h]\!] \cdot \nabla_h v \,\mathrm{d}s \\ &- \sum_\kappa \int_{\partial\kappa\setminus\Gamma_N} \{\nabla_h u_h\} \cdot \mathbf{n}\, v \,\mathrm{d}s + \sum_\kappa \int_{\partial\kappa} \delta[\![u_h]\!] \cdot \mathbf{n} v \,\mathrm{d}s + \int_{\Gamma_D} \theta u_h \mathbf{n} \cdot \nabla_h v \,\mathrm{d}s. \end{aligned} \tag{4.5}$$

Using integration by parts and the relation

$$\nabla_h u^+ \cdot \mathbf{n}^+ v^+ = \{\nabla_h u\} \cdot \mathbf{n}^+ v^+ + \frac{1}{2}[\![\nabla_h u]\!] v^+, \tag{4.6}$$

we can rewrite (4.4) as follows: Find $u_h \in V_h^p$ such that

$$\begin{aligned}\mathcal{B}(u_h, v) \equiv &-\int_\Omega \Delta_h u_h v \,\mathrm{d}\mathbf{x} + \int_{\Gamma_N} \nabla_h u_h \cdot \mathbf{n}\, v \,\mathrm{d}s + \sum_\kappa \int_{\partial\kappa\setminus\Gamma} \frac{1}{2}\theta[\![u_h]\!] \cdot \nabla_h v \,\mathrm{d}s \\ &+ \sum_\kappa \int_{\partial\kappa\setminus\Gamma} \left(\frac{1}{2}[\![\nabla_h u_h]\!] + \delta[\![u_h]\!] \cdot \mathbf{n}\right) v \,\mathrm{d}s + \int_{\Gamma_D} \theta u_h \mathbf{n} \cdot \nabla_h v \,\mathrm{d}s + \int_{\Gamma_D} \delta u_h v \,\mathrm{d}s \\ = &\int_\Omega f v \,\mathrm{d}\mathbf{x} + \int_{\Gamma_D} \theta g_D \mathbf{n} \cdot \nabla v \,\mathrm{d}s + \int_{\Gamma_D} \delta g_D v \,\mathrm{d}s + \int_{\Gamma_N} g_N v \,\mathrm{d}s \end{aligned} \tag{4.7}$$

for all $v \in V_h^p$. Hence we have the element-based primal residual form

$$\begin{aligned}&\int_\Omega R(u_h) v \,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa\setminus\Gamma} r(u_h) v + \boldsymbol{\rho}(u_h) \cdot \nabla v \,\mathrm{d}s \\ &\qquad + \int_\Gamma r_\Gamma(u_h) v + \boldsymbol{\rho}_\Gamma(u_h) \cdot \nabla v \,\mathrm{d}s = 0 \quad \forall v \in V_h, \end{aligned} \tag{4.8}$$

where the residuals are given by $R(u_h) = f + \Delta_h u_h$ in Ω, and

$$\begin{aligned} &r(u_h) = -\tfrac{1}{2}[\![\nabla_h u_h]\!] - \delta[\![u_h]\!] \cdot \mathbf{n}, && \boldsymbol{\rho}(u) = -\tfrac{1}{2}\theta[\![u_h]\!] && \text{on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \\ &r_\Gamma(u_h) = \delta(g_D - u_h), && \boldsymbol{\rho}_\Gamma(u_h) = \theta(g_D - u_h)\mathbf{n} && \text{on } \Gamma_D, \\ &r_\Gamma(u_h) = g_N - \mathbf{n} \cdot \nabla_h u_h, && \boldsymbol{\rho}_\Gamma(u_h) = 0 && \text{on } \Gamma_N. \end{aligned} \tag{4.9}$$

We note that (4.8) is a generalization to (2.18) to include ∇v terms. Furthermore, we note that the discretization is consistent as the residuals in (4.9) vanish for the exact solution u to (4.1). Given the target functional defined in (4.2), the discrete adjoint problem (2.8) to the discretization (4.4) is given by: Find $z_h \in V_h$ such that

$$\int_\Omega \nabla_h w \cdot \nabla_h z_h \,\mathrm{d}\mathbf{x} + \int_{\Gamma_{\mathcal{I}}\cup\Gamma_D} \left(\theta[\![w]\!] \cdot \{\nabla_h z_h\} - \{\nabla_h w\} \cdot [\![z_h]\!] + \delta[\![w]\!] \cdot [\![z_h]\!]\right) \mathrm{d}s = J(w)$$

for all $w \in V_h$. Then in element-based form we have: Find $z_h \in V_h$ such that

$$\begin{aligned}&\int_\Omega \nabla_h w \cdot \nabla_h z_h \,\mathrm{d}\mathbf{x} + \sum_\kappa \int_{\partial\kappa\setminus\Gamma_N} w \left(\theta \mathbf{n} \cdot \{\nabla_h z_h\} + \delta[\![z_h]\!] \cdot \mathbf{n}\right) \mathrm{d}s \\ &\qquad - \frac{1}{2}\sum_\kappa \int_{\partial\kappa\setminus\Gamma} \nabla_h w \cdot [\![z_h]\!] \,\mathrm{d}s - \int_{\Gamma_D} \nabla_h w \cdot \mathbf{n} z_h \,\mathrm{d}s = J(w) \quad \forall w \in V_h. \end{aligned}$$

Using integration by parts and (4.6) with u_h and v replaced by z_h and w yields

$$
\begin{aligned}
-\int_\Omega w\Delta_h z_h \,\mathrm{d}x + \sum_\kappa \int_{\partial\kappa\setminus\Gamma} w\left(\frac{1}{2}[\![\nabla_h z_h]\!] + (1+\theta)\mathbf{n}\cdot\{\nabla_h z_h\} + \delta[\![z_h]\!]\cdot\mathbf{n}\right)\mathrm{d}s \\
- \sum_\kappa \int_{\partial\kappa\setminus\Gamma} \frac{1}{2}\nabla_h w\cdot[\![z_h]\!]\,\mathrm{d}s + \int_{\Gamma_N} w\mathbf{n}\cdot\nabla_h z_h\,\mathrm{d}s \\
+ \int_{\Gamma_D} w\left((1+\theta)\mathbf{n}\cdot\nabla_h z_h + \delta z_h\right)\mathrm{d}s - \int_{\Gamma_D}\nabla_h w\cdot\mathbf{n} z_h\,\mathrm{d}s \\
= \int_\Omega w\, j_\Omega\,\mathrm{d}\mathbf{x} + \int_{\Gamma_D}\nabla w\cdot\mathbf{n}\, j_D\,\mathrm{d}s + \int_{\Gamma_N} w\, j_N\,\mathrm{d}s,
\end{aligned}
$$

and we obtain the element-based adjoint residual form: Find $z_h \in V_h$ such that

$$
\begin{aligned}
&\int_\Omega w\, R^*(z_h)\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} w\, r^*(z_h) + \nabla w\cdot\boldsymbol{\rho}^*(z_h)\,\mathrm{d}s \\
&\qquad + \int_\Gamma w\, r_\Gamma^*(z_h) + \nabla w\cdot\boldsymbol{\rho}_\Gamma^*(z_h)\,\mathrm{d}s = 0 \quad \forall w\in V_h,
\end{aligned} \tag{4.10}
$$

where the adjoint residuals are given by $R^*(z_h) = j_\Omega + \Delta_h z_h$ in Ω, by

$$
r^*(z_h) = -\tfrac{1}{2}[\![\nabla_h z_h]\!] - (1+\theta)\mathbf{n}\cdot\{\nabla_h z\} - \delta[\![z_h]\!]\cdot\mathbf{n}, \qquad \boldsymbol{\rho}^*(z_h) = \tfrac{1}{2}[\![z_h]\!], \tag{4.11}
$$

on interior faces $\partial\kappa\setminus\Gamma, \kappa\in\mathcal{T}_h$, and by

$$
\begin{aligned}
&r_\Gamma^*(z_h) = -(1+\theta)\mathbf{n}\cdot\nabla_h z_h - \delta z_h, && \boldsymbol{\rho}_\Gamma^*(z_h) = (j_D + z_h)\mathbf{n} && \text{on } \Gamma_D, \\
&r_\Gamma^*(z_h) = j_N - \mathbf{n}\cdot\nabla_h z_h, && \boldsymbol{\rho}_\Gamma^*(z_h) = 0 && \text{on } \Gamma_N.
\end{aligned} \tag{4.12}
$$

From (4.11) we see that the exact solution z to the adjoint problem (4.3) satisfies $r^*(z) = 0$, provided $\theta = -1$. Furthermore, we have $R^*(z) = 0$. This shows the well-known result (see, e.g., [1]) that the method by Baumann–Oden and NIPG are not adjoint consistent whereas the interior face terms of SIPG are adjoint consistent. In fact, in [12] it has been demonstrated that the lack of adjoint consistency of the NIPG method leads to nonsmooth adjoint solutions and a suboptimal convergence of the method for the primal problem. In contrast to that, the adjoint consistent SIPG method shows an optimal order of convergence.

As $r_\Gamma^*(z) = 0$ and $\boldsymbol{\rho}_\Gamma^*(z) = 0$ on Γ_N the SIPG method is also adjoint consistent on Γ_N. However, on Γ_D the requirements $r_\Gamma^*(z) = 0$ and $\boldsymbol{\rho}_\Gamma^*(z) = 0$ reduce to the conditions $z = 0$ (note that $\theta = -1$) and $z = -j_D$, respectively, which are compatible for $j_D = 0$ but conflict for $j_D \neq 0$. This incompatibility can be resolved by modifying the target functional according to (2.25), with $i(u_h) = u_h$ and

$$
r_J(u_h) = -\delta(u_h - g_D)j_D, \tag{4.13}
$$

which in the following will be denoted by the *IP modification* of the target functional. This modification is consistent, as $i(u) = u$ and $r_J(u) = 0$ hold for the exact solution u to (4.1). As the modified functional is not linear in u_h (it is affine), the discrete adjoint problem includes its linearization as follows: Find $z_h \in V_h$ such that

$$
\mathcal{B}(w, z_h) = \tilde{J}'[u](w) \quad \forall w\in V_h, \tag{4.14}
$$

where

$$\tilde{J}'[u](w) = J'[u](w) + \int_{\Gamma_D} r'_J[u](w)\,\mathrm{d}s = J(w) - \int_{\Gamma_D} w\,\delta j_D\,\mathrm{d}s. \tag{4.15}$$

Then the adjoint residuals on Γ_D are given by

$$r^*_\Gamma(z_h) = -\delta j_D - (1+\theta)\mathbf{n}\cdot\nabla_h z_h - \delta z_h, \quad \boldsymbol{\rho}^*_\Gamma(z_h) = (j_D + z_h)\mathbf{n} \quad \text{on } \Gamma_D, \tag{4.16}$$

which vanish for $z = -j_D$. Hence the SIPG method is adjoint consistent also on Γ_D.

In contrast to the presentation in [11, 12], where the $\frac{1}{2}[\![\nabla_h z]\!]$ term in the interelement conditions analogous to (4.11) has been omitted, we see that for $\theta = -1$ there is a clear correspondence of the adjoint residuals to the primal residuals (4.9). In fact, the discrete adjoint equations correspond to the discrete primal equations with u, f, g_D, and g_N replaced by z, j_Ω, $-j_D$, and j_N, respectively; i.e., the discrete adjoint equation to the SIPG discretization represents an SIPG discretization of the continuous adjoint equation.

Furthermore, we note that [11] considers the target functional $J(u) = \int_{\Gamma_0} \mathbf{n}\cdot\nabla u j_D\,\mathrm{d}s$, $\Gamma_0 \subset \Gamma_D$, which is a special case of (4.2) with $j_\Omega \equiv 0$ in Ω, $j_N \equiv 0$ on Γ_N, and $j_D \equiv 0$ on $\Gamma_D \setminus \Gamma_0$. Numerical experiments in [11] have shown that the discrete adjoint solution associated with this target functional is nonsmooth near Γ_0. Furthermore, it has been demonstrated that, either by setting $\delta = 0$ on Γ_0 or by modifying the target functional appropriately, this effect vanishes, and the adjoint solution becomes smooth. We note that the modification of the target functional proposed in [11] is connected to (4.15). However, here we derive (4.15) in the more general framework of consistent modifications of target functionals; see (2.25).

5. The compressible Euler equations. In this section we consider the two-dimensional stationary compressible Euler equations

$$\nabla\cdot\mathcal{F}^c(\mathbf{u}) = 0 \quad \text{in } \Omega, \tag{5.1}$$

subject to various boundary conditions, e.g., slip-wall boundary conditions at solid wall boundaries $\Gamma_W \subset \Gamma$, with vanishing normal velocity $\mathbf{n}\cdot\mathbf{v} = n_1 v_1 + n_2 v_2 = 0$; i.e.,

$$B\mathbf{u} = n_1 u_2 + n_2 u_3 = 0 \quad \text{on } \Gamma_W \tag{5.2}$$

is imposed, where the vector of conservative variables $\mathbf{u} = (u_1, u_2, u_3, u_4)^\top$ and the convective fluxes $\mathcal{F}^c(\mathbf{u}) = (\mathbf{f}^c_1(\mathbf{u}), \mathbf{f}^c_2(\mathbf{u}))$ are defined by

$$\mathbf{u} = \begin{bmatrix} \rho \\ \rho v_1 \\ \rho v_2 \\ \rho E \end{bmatrix}, \quad \mathbf{f}^c_1(\mathbf{u}) = \begin{bmatrix} \rho v_1 \\ \rho v_1^2 + p \\ \rho v_1 v_2 \\ \rho H v_1 \end{bmatrix}, \quad \text{and} \quad \mathbf{f}^c_2(\mathbf{u}) = \begin{bmatrix} \rho v_2 \\ \rho v_1 v_2 \\ \rho v_2^2 + p \\ \rho H v_2 \end{bmatrix}, \tag{5.3}$$

and ρ, $\mathbf{v} = (v_1, v_2)^\top$, p, and E denote the density, velocity vector, pressure, and specific total energy, respectively. Additionally, H is the total enthalpy given by $H = E + \frac{p}{\rho} = e + \frac{1}{2}\mathbf{v}^2 + \frac{p}{\rho}$, where e is the specific static internal energy, and the pressure is determined by the equation of state of an ideal gas $p = (\gamma - 1)\rho e$, where $\gamma = c_p/c_v$ is the ratio of specific heat capacities at constant pressure c_p and constant volume c_v; for dry air $\gamma = 1.4$. Let us consider the target functional

$$J(\mathbf{u}) = \int_\Gamma j(C\mathbf{u})\,\mathrm{d}s = \int_{\Gamma_W} p(\mathbf{u})\,\mathbf{n}\cdot\boldsymbol{\psi}_{\Gamma_W}\,\mathrm{d}s, \tag{5.4}$$

with $C\mathbf{u} = p(\mathbf{u})$, $j(p) = p\,\mathbf{n}\cdot\boldsymbol{\psi}_{\Gamma_W}$ on Γ_W and $j(p) \equiv 0$ elsewhere, and $\boldsymbol{\psi}_{\Gamma_W} \in [L^2(\Gamma_W)]^2$. As we will see later, this target functional is compatible with (5.1) and (5.2). The most important target quantities of type (5.4) in inviscid compressible flows are the pressure-induced drag and lift coefficients c_{dp} and c_{lp}, where $\boldsymbol{\psi}_{\Gamma_W} = \frac{1}{C_\infty}\boldsymbol{\psi}$. Here $\boldsymbol{\psi}$ is given by $\boldsymbol{\psi}_d = (\cos(\alpha), \sin(\alpha))^\top$ and $\boldsymbol{\psi}_l = (-\sin(\alpha), \cos(\alpha))^\top$ for the drag and lift coefficients, respectively. Furthermore, $C_\infty = \frac{1}{2}\gamma p_\infty M_\infty^2 \bar{l} = \frac{1}{2}\gamma\frac{|\mathbf{v}_\infty|^2}{c_\infty^2} p_\infty \bar{l} = \frac{1}{2}\rho_\infty |\mathbf{v}_\infty|^2 \bar{l}$, where M_∞ denotes the Mach number at free-stream conditions, c_∞ is the speed of sound defined by $c_\infty^2 = \gamma p_\infty/\rho_\infty$, and $\bar{l}$ denotes a reference length.

In order to derive the continuous adjoint problem, we multiply the left-hand side of (5.1) by $\mathbf{z}$, integrate by parts, and linearize about $\mathbf{u}$ to obtain

$$(\nabla\cdot(\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}](\mathbf{w}))\,,\mathbf{z})_\Omega = -\,(\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}](\mathbf{w}), \nabla\mathbf{z})_\Omega + (\mathbf{n}\cdot\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}](\mathbf{w}), \mathbf{z})_\Gamma\,, \tag{5.5}$$

where $\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}] := (\mathcal{F}^c)'[\mathbf{u}]$ denotes the Fréchet derivative of $\mathcal{F}^c$ with respect to $\mathbf{u}$. Here we already use the subscript $_{\mathbf{u}}$ notation which we require in section 6 to distinguish from subscript $_{\nabla\mathbf{u}}$ denoting the derivative with respect to $\nabla\mathbf{u}$. Thereby, the variational formulation of the continuous adjoint problem is given by: Find $\mathbf{z}$ such that

$$-\left(\mathbf{w}, (\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}])^\top\nabla\mathbf{z}\right)_\Omega + \left(\mathbf{w}, (\mathbf{n}\cdot\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}])^\top\mathbf{z}\right)_\Gamma = J'[\mathbf{u}](\mathbf{w}) \quad \forall\mathbf{w}\in V, \tag{5.6}$$

and the continuous adjoint problem is given by

$$-(\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}])^\top\nabla\mathbf{z} = 0 \quad \text{in } \Omega, \qquad\qquad (\mathbf{n}\cdot\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}])^\top\mathbf{z} = j'[\mathbf{u}] \quad \text{on } \Gamma. \tag{5.7}$$

Using $\mathcal{F}^c(\mathbf{u})\cdot\mathbf{n} = p(0, n_1, n_2, 0)^\top$ on Γ_W and the definition of j in (5.4), we obtain

$$p'[\mathbf{u}](0, n_1, n_2, 0)\cdot\mathbf{z} = \frac{1}{C_\infty}p'[\mathbf{u}]\mathbf{n}\cdot\boldsymbol{\psi} \quad \text{on } \Gamma_W,$$

which reduces to the boundary condition of the adjoint compressible Euler equations

$$(B'[\mathbf{u}])^*\mathbf{z} = n_1 z_2 + n_2 z_3 = \frac{1}{C_\infty}\mathbf{n}\cdot\boldsymbol{\psi} \quad \text{on } \Gamma_W. \tag{5.8}$$

Comparing (5.5) with (2.12) we see that the target functional (5.4) is compatible. Furthermore, we note that the adjoint boundary condition (5.8) has first been derived in [20]. In the framework of matrix representations of adjoint boundary operators related to (2.3), they have been derived in [10]; see also [9] for a more detailed derivation.

Let $\mathbf{V}_h^p$ be a discrete function space consisting of discontinuous piecewise vector-valued polynomial functions of degree $p \geq 0$. Then the discontinuous Galerkin discretization in element-based form of (5.1) is given by: Find $\mathbf{u}_h \in \mathbf{V}_h^p$ such that

$$\begin{aligned}\mathcal{N}(\mathbf{u}_h, \mathbf{v}) \equiv -\int_\Omega \mathcal{F}^c(\mathbf{u}_h) : \nabla_h\mathbf{v}\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \mathcal{H}(\mathbf{u}_h^+, \mathbf{u}_h^-, \mathbf{n}^+)\,\mathbf{v}^+\,\mathrm{d}s \\ + \int_\Gamma \tilde{\mathcal{H}}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}^+)\,\mathbf{v}^+\,\mathrm{d}s = 0 \quad \forall\mathbf{v}\in\mathbf{V}_h^p,\end{aligned} \tag{5.9}$$

where $\mathcal{H}$ and $\tilde{\mathcal{H}}$ may be any Lipschitz continuous, consistent, and conservative numerical flux functions approximating the normal flux $\mathbf{n}\cdot\mathcal{F}^c(\mathbf{u}_h)$. On interior faces, $\mathcal{H}$ takes into account the possible discontinuities of $\mathbf{u}_h$ at element interfaces. On the boundary Γ, $\tilde{\mathcal{H}}$ may depend on the interior trace $\mathbf{u}_h^+$ and a consistent boundary function $\mathbf{u}_\Gamma(\mathbf{u}_h^+)$. We note that $\tilde{\mathcal{H}}$ may be different from $\mathcal{H}$. In fact, we will see below

that, depending on the specific choice of $\tilde{\mathcal{H}}$, the discontinuous Galerkin discretization (5.9) may be adjoint consistent or not.

Using integration by parts we obtain the residual form: Find $\mathbf{u}_h \in \mathbf{V}_h^p$ such that

$$\int_\Omega \mathbf{R}(\mathbf{u}_h)\cdot\mathbf{v}\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma}\mathbf{r}(\mathbf{u}_h)\cdot\mathbf{v}^+\,\mathrm{d}s + \int_\Gamma \mathbf{r}_\Gamma(\mathbf{u}_h)\cdot\mathbf{v}^+\,\mathrm{d}s = 0 \quad \forall\mathbf{v}\in\mathbf{V}_h^p, \tag{5.10}$$

where the primal residuals are given by

$$\begin{aligned} \mathbf{R}(\mathbf{u}_h) &= -\nabla\cdot\mathcal{F}^c(\mathbf{u}_h) && \text{in } \kappa,\kappa\in\mathcal{T}_h,\\ \mathbf{r}(\mathbf{u}_h) &= \mathbf{n}\cdot\mathcal{F}^c(\mathbf{u}_h^+) - \mathcal{H}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+) && \text{on } \partial\kappa\setminus\Gamma,\kappa\in\mathcal{T}_h,\\ \mathbf{r}_\Gamma(\mathbf{u}_h) &= \mathbf{n}\cdot\mathcal{F}^c(\mathbf{u}_h^+) - \tilde{\mathcal{H}}(\mathbf{u}_h^+,\mathbf{u}_\Gamma(\mathbf{u}_h^+),\mathbf{n}^+) && \text{on } \Gamma. \end{aligned} \tag{5.11}$$

Given the consistency of the numerical flux $\mathcal{H}(\mathbf{w},\mathbf{w},\mathbf{n}) = \mathbf{n}\cdot\mathcal{F}^c(\mathbf{w})$ and the consistency of the boundary function, i.e., $\mathbf{u}_\Gamma(\mathbf{u}) = \mathbf{u}$ for the exact solution $\mathbf{u}$ to (5.1), we find that $\mathbf{u}$ satisfies the following equations:

$$\mathbf{R}(\mathbf{u}) = 0 \ \text{ in } \kappa,\kappa\in\mathcal{T}_h, \quad \mathbf{r}(\mathbf{u}) = 0 \ \text{ on } \partial\kappa\setminus\Gamma,\kappa\in\mathcal{T}_h, \quad \mathbf{r}_\Gamma(\mathbf{u}) = 0 \ \text{ on } \Gamma. \tag{5.12}$$

We conclude that (5.9) is a consistent discretization of (5.1).

For the target functional $J(\cdot)$ defined in (5.4) with Fréchet derivative $J'[\mathbf{u}](\cdot)$, the discrete adjoint problem is given by: Find $\mathbf{z}_h \in \mathbf{V}_h^p$ such that

$$\mathcal{N}'[\mathbf{u}_h](\mathbf{w},\mathbf{z}_h) = J'[\mathbf{u}_h](\mathbf{w}) \quad \forall\mathbf{w}\in\mathbf{V}_h^p, \tag{5.13}$$

where

$$\begin{aligned} \mathcal{N}'[\mathbf{u}_h](\mathbf{w},\mathbf{z}_h) \equiv& -\int_\Omega (\mathcal{F}^c_{\mathbf{u}}[\mathbf{u}_h]\mathbf{w}) : \nabla_h\mathbf{z}_h\,\mathrm{d}\mathbf{x}\\ &+ \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma}\left(\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+)\mathbf{w}^+ + \mathcal{H}'_{\mathbf{u}^-}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+)\mathbf{w}^-\right)\mathbf{z}_h^+\,\mathrm{d}s\\ &+ \int_\Gamma\left(\tilde{\mathcal{H}}'_{\mathbf{u}^+}\left(\mathbf{u}_h^+,\mathbf{u}_\Gamma(\mathbf{u}_h^+),\mathbf{n}^+\right) + \tilde{\mathcal{H}}'_{\mathbf{u}^-}\left(\mathbf{u}_h^+,\mathbf{u}_\Gamma(\mathbf{u}_h^+),\mathbf{n}^+\right)\mathbf{u}'_\Gamma[\mathbf{u}_h^+]\right)\mathbf{w}^+\mathbf{z}_h^+\,\mathrm{d}s. \end{aligned} \tag{5.14}$$

Here $\mathbf{v}\to\mathcal{H}'_{\mathbf{u}^+}(\mathbf{v}^+,\mathbf{v}^-,\mathbf{n})$ and $\mathbf{v}\to\mathcal{H}'_{\mathbf{u}^-}(\mathbf{v}^+,\mathbf{v}^-,\mathbf{n})$ denote the derivatives of the flux function $\mathcal{H}(\cdot,\cdot,\cdot)$ with respect to its first and second arguments, respectively. As the numerical flux is conservative $\mathcal{H}(\mathbf{v},\mathbf{w},\mathbf{n}) = -\mathcal{H}(\mathbf{w},\mathbf{v},-\mathbf{n})$, we obtain $\mathcal{H}'_{\mathbf{u}^-}(\mathbf{v},\mathbf{w},\mathbf{n}) = \partial_{\mathbf{w}}\mathcal{H}(\mathbf{v},\mathbf{w},\mathbf{n}) = -\partial_{\mathbf{w}}\mathcal{H}(\mathbf{w},\mathbf{v},-\mathbf{n}) = -\mathcal{H}'_{\mathbf{u}^+}(\mathbf{w},\mathbf{v},-\mathbf{n})$, and

$$\begin{aligned} \int_{\Gamma_{\mathcal{I}}}\mathcal{H}'_{\mathbf{u}^-}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+)\mathbf{w}^-\mathbf{z}^+\,\mathrm{d}s &= -\int_{\Gamma_{\mathcal{I}}}\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^-,\mathbf{u}_h^+,\mathbf{n}^-)\mathbf{w}^-\mathbf{z}^+\,\mathrm{d}s\\ &= -\int_{\Gamma_{\mathcal{I}}}\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+)\mathbf{w}^+\mathbf{z}^-\,\mathrm{d}s, \end{aligned} \tag{5.15}$$

where we exchanged notations $^+$ and $^-$ on $\Gamma_{\mathcal{I}}$. Then the discrete adjoint problem (5.13) with (5.14) is given in adjoint residual form as follows: Find $\mathbf{z}_h \in \mathbf{V}_h^p$ such that

$$\int_\Omega \mathbf{w}\cdot\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma}\mathbf{w}^+\cdot\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}s + \int_\Gamma \mathbf{w}^+\cdot\mathbf{r}^*_\Gamma[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}s = 0 \tag{5.16}$$

for all $\mathbf{w} \in \mathbf{V}_h^p$, where the adjoint residuals are given by

$$\begin{aligned}
\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h) =& (\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}_h])^\top \nabla \mathbf{z}_h && \text{in } \kappa, \kappa \in \mathcal{T}_h, \\
\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h) =& -\left(\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^+, \mathbf{u}_h^-, \mathbf{n}^+)\right)^\top [\![\mathbf{z}_h]\!] \cdot \mathbf{n} && \text{on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \\
\mathbf{r}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h) =& j'[\mathbf{u}_h] - \left(\tilde{\mathcal{H}}'_{\mathbf{u}^+} + \tilde{\mathcal{H}}'_{\mathbf{u}^-} \mathbf{u}'_\Gamma[\mathbf{u}_h]\right)^\top \mathbf{z}_h^+ && \text{on } \Gamma,
\end{aligned} \tag{5.17}$$

where $\tilde{\mathcal{H}}'_{\mathbf{u}^+} := \tilde{\mathcal{H}}'_{\mathbf{u}^+}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}^+)$ and $\tilde{\mathcal{H}}'_{\mathbf{u}^-} := \tilde{\mathcal{H}}'_{\mathbf{u}^-}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}^+)$.

Comparing the discrete adjoint boundary condition

$$\left(\tilde{\mathcal{H}}'_{\mathbf{u}^+} + \tilde{\mathcal{H}}'_{\mathbf{u}^-} \mathbf{u}'_\Gamma[\mathbf{u}_h]\right)^\top \mathbf{z}_h^+ = j'[\mathbf{u}_h] \quad \text{on } \Gamma \tag{5.18}$$

and the continuous adjoint boundary condition in (5.7), we notice that not all choices of $\tilde{\mathcal{H}}$ give rise to an adjoint consistent discretization. In fact, we require $\tilde{\mathcal{H}}$ to have the following properties: In order to incorporate boundary conditions in the primal discretization (5.9), $\tilde{\mathcal{H}}$ must depend on $\mathbf{u}_\Gamma(\mathbf{u}_h^+)$; hence, $\tilde{\mathcal{H}}'_{\mathbf{u}^-} \neq 0$. Furthermore, we require $\tilde{\mathcal{H}}'_{\mathbf{u}^+} = 0$ as otherwise the left-hand side in (5.17) involves two summands which is in contrast to the continuous adjoint boundary condition in (5.7). Finally, we recall that $\tilde{\mathcal{H}}$ is consistent $\tilde{\mathcal{H}}(\mathbf{v}, \mathbf{v}, \mathbf{n}) = \mathbf{n} \cdot \mathcal{F}^c(\mathbf{v})$ and conclude that $\tilde{\mathcal{H}}$ is given by $\tilde{\mathcal{H}}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}) = \mathbf{n} \cdot \mathcal{F}^c(\mathbf{u}_\Gamma(\mathbf{u}_h^+))$. Employing a modified target functional $\tilde{J}(\mathbf{u}_h) = J(\mathbf{i}(\mathbf{u}_h))$, i.e., (2.25) with $r_j(\mathbf{u}_h) \equiv 0$, (5.18) yields

$$\left(\mathbf{n} \cdot \left(\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}_\Gamma(\mathbf{u}_h^+)]\right) \mathbf{u}'_\Gamma[\mathbf{u}_h^+]\right)^\top \mathbf{z} = j'[\mathbf{i}(\mathbf{u}_h^+)]\mathbf{i}'[\mathbf{u}_h^+]. \tag{5.19}$$

We find the modification $\mathbf{i}(\mathbf{u}_h) = \mathbf{u}_\Gamma(\mathbf{u}_h)$, which is consistent as $\mathbf{i}(\mathbf{u}) = \mathbf{u}_\Gamma(\mathbf{u}) = \mathbf{u}$ holds for the exact solution $\mathbf{u}$. Thereby (5.19) reduces to

$$\left(\mathbf{n} \cdot \mathcal{F}_{\mathbf{u}}^c[\mathbf{u}_\Gamma(\mathbf{u}_h^+)]\right)^\top \mathbf{z} = j'[\mathbf{u}_\Gamma(\mathbf{u}_h^+)], \tag{5.20}$$

which represents a discretization of the continuous adjoint boundary condition in (5.7). In order to obtain a discretization of the adjoint boundary condition at solid wall boundaries (5.8), we require $B\mathbf{u}_\Gamma(\mathbf{u}_h^+) = 0$ on Γ_W. This condition is satisfied by

$$\mathbf{u}_\Gamma(\mathbf{u}) = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 1-n_1^2 & -n_1 n_2 & 0 \\ 0 & -n_1 n_2 & 1-n_2^2 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \mathbf{u} \quad \text{on} \quad \Gamma_W, \tag{5.21}$$

which originates from $\mathbf{u}$ by subtracting the normal velocity component of $\mathbf{u}$; i.e., $\mathbf{v} = (v_1, v_2)$ is replaced by $\mathbf{v}_\Gamma = \mathbf{v} - (\mathbf{v} \cdot \mathbf{n})\mathbf{n}$ which ensures that the normal velocity component vanishes: $\mathbf{v}_\Gamma \cdot \mathbf{n} = 0$.

In summary, let $\mathbf{u}_\Gamma$ be given by (5.21) and $\tilde{\mathcal{H}}$ and $\tilde{J}$ be defined by

$$\tilde{\mathcal{H}}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}) = \mathbf{n} \cdot \mathcal{F}_\Gamma^c(\mathbf{u}_h^+), \qquad \tilde{J}(\mathbf{u}_h) = J_\Gamma(\mathbf{u}_h), \tag{5.22}$$

respectively, where $\mathcal{F}_\Gamma^c(\mathbf{u}_h^+) := \mathcal{F}^c(\mathbf{u}_\Gamma(\mathbf{u}_h^+))$, $J_\Gamma(\mathbf{u}_h) := J(\mathbf{u}_\Gamma(\mathbf{u}_h))$, and $j_\Gamma(\mathbf{u}_h) := j(\mathbf{u}_\Gamma(\mathbf{u}_h))$; then the adjoint residuals (5.17) are given by

$$\begin{aligned}
\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h) =& (\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}_h])^\top \nabla \mathbf{z}_h && \text{in } \kappa, \kappa \in \mathcal{T}_h, \\
\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h) =& -\left(\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^+, \mathbf{u}_h^-, \mathbf{n}^+)\right)^\top [\![\mathbf{z}_h]\!] \cdot \mathbf{n} && \text{on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \\
\mathbf{r}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h) =& j'_\Gamma[\mathbf{u}_h^+] - \left(\mathbf{n} \cdot \mathcal{F}_{\Gamma,\mathbf{u}}^c[\mathbf{u}_h^+]\right)^\top \mathbf{z}_h^+ && \text{on } \Gamma.
\end{aligned} \tag{5.23}$$

In particular, the discretization (5.9) together with (5.22) is adjoint consistent as the exact solutions u and $\mathbf{z}$ to (5.1) and (5.7), respectively, satisfy

$$\mathbf{R}^*[\mathbf{u}](\mathbf{z}) = 0 \ \text{ in } \kappa, \kappa \in \mathcal{T}_h, \quad \mathbf{r}^*[\mathbf{u}](\mathbf{z}) = 0 \ \text{ on } \partial\kappa \setminus \Gamma, \kappa \in \mathcal{T}_h, \quad \mathbf{r}^*_\Gamma[\mathbf{u}](\mathbf{z}) = 0 \ \text{ on } \Gamma.$$

Note that the adjoint residuals in (5.23) reduce to the adjoint residuals (3.5) of the linear advection equation with $b = 0$, when setting $\mathcal{F}^c(u) = \mathbf{b}u$ and $\mathcal{H}'_{u^+} = \mathbf{b} \cdot \mathbf{n}$.

Also note that the standard discontinuous Galerkin discretizations for the compressible Euler equations (see, e.g., [4, 15, 16] among several others) take the same numerical flux function on the boundary Γ as in the interior of the domain, and simply replace $\mathbf{u}_h^-$ in $\mathcal{H}(\mathbf{u}_h^+, \mathbf{u}_h^-, \mathbf{n})$ by the boundary function $\mathbf{u}_\Gamma(\mathbf{u}_h^+)$, resulting in $\tilde{\mathcal{H}}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n})$. Furthermore, the definition of $\mathbf{u}_\Gamma$ in [4, 15] based on $\mathbf{v}_\Gamma = \mathbf{v} - 2(\mathbf{v} \cdot \mathbf{n})\mathbf{n}$ ensures a vanishing average normal velocity $\bar{\mathbf{v}} \cdot \mathbf{n} = \frac{1}{2}(\mathbf{v} + \mathbf{v}_\Gamma) \cdot \mathbf{n} = 0$. However, $\mathbf{v}_\Gamma \cdot \mathbf{n} = 0$ and $B\mathbf{u}_\Gamma(\mathbf{u}_h^+) = 0$, as required in (5.20), are not satisfied. Thereby, the discontinuous Galerkin discretization based on the standard choice of $\tilde{\mathcal{H}}$ and $\mathbf{u}_\Gamma$ is not adjoint consistent. In fact, already the numerical experiments in [15] indicated large gradients, i.e., an irregular adjoint solution near solid wall boundaries. The lack of adjoint consistency of this standard approach was first analyzed by Lu [23, 24], who also proposed the adjoint consistent approach (5.22) and demonstrated that this approach gives rise to smooth adjoint solutions for an inviscid compressible flow over a Gaussian bump. The smoothness of the discrete adjoint has been confirmed in [14] for an inviscid compressible flow around a NACA0012 airfoil. Furthermore, [14] studies the effect of adjoint consistency on the accuracy of the flow solution and on error cancellation in an a posteriori error estimation approach.

6. The compressible Navier–Stokes equations. In this section we consider the two-dimensional stationary compressible Navier–Stokes equations

$$\nabla \cdot (\mathcal{F}^c(\mathbf{u}) - \mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u})) = 0 \quad \text{in } \Omega, \tag{6.1}$$

subject to various boundary conditions, e.g., no-slip wall boundary conditions with vanishing velocity $\mathbf{v} = (v_1, v_2)^\top = 0$ at isothermal walls Γ_{iso} where $T = T_{wall}$ or at adiabatic walls Γ_{adia} where $\mathbf{n} \cdot \nabla T = 0$. The vector of conservative variables $\mathbf{u}$ and the convective fluxes $\mathcal{F}^c(\mathbf{u})$ are as defined in (5.3). Furthermore, the viscous fluxes $\mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u}) = (\mathbf{f}_1^v(\mathbf{u}, \nabla\mathbf{u}), \mathbf{f}_2^v(\mathbf{u}, \nabla\mathbf{u}))$ are defined by

$$\mathbf{f}_1^v(\mathbf{u}, \nabla\mathbf{u}) = \begin{bmatrix} 0 \\ \tau_{11} \\ \tau_{21} \\ \tau_{1j}v_j + \mathcal{K}T_{x_1} \end{bmatrix} \quad \text{and} \quad \mathbf{f}_2^v(\mathbf{u}, \nabla\mathbf{u}) = \begin{bmatrix} 0 \\ \tau_{12} \\ \tau_{22} \\ \tau_{2j}v_j + \mathcal{K}T_{x_2} \end{bmatrix}. \tag{6.2}$$

Here T denotes the temperature given by $e = c_v T$, $\mathcal{K}$ is the thermal conductivity coefficient, and $\underline{\tau}$ is the viscous stress tensor defined by $\underline{\tau} = \mu(\nabla\mathbf{v} + (\nabla\mathbf{v})^\top - \frac{2}{3}(\nabla \cdot \mathbf{v})I)$, where μ is the dynamic viscosity coefficient. Using the homogeneity tensor G (e.g., [16]) with $G_{ij}(\mathbf{u}) = \partial\mathbf{f}_i^v(\mathbf{u}, \nabla\mathbf{u})/\partial u_{x_j}$, for $i, j = 1, 2$, the viscous fluxes are $\mathbf{f}_i^v(\mathbf{u}, \nabla\mathbf{u}) = G_{ij}(\mathbf{u})\partial\mathbf{u}/\partial x_j$, $i = 1, 2$, and $\mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u}) = G(\mathbf{u})\nabla\mathbf{u}$. Consider the target functional

$$J(\mathbf{u}) = \int_\Gamma j(C\mathbf{u})\,\mathrm{d}s = \int_{\Gamma_W} (p\,\mathbf{n} - \underline{\tau}\,\mathbf{n}) \cdot \boldsymbol{\psi}_{\Gamma_W}\,\mathrm{d}s, \tag{6.3}$$

where $(C\mathbf{u})_{ij} = p(\mathbf{u})\delta_{ij} - \tau_{ij}(\mathbf{u}, \nabla\mathbf{u})$, $j(C\mathbf{u}) = (C\mathbf{u})_{ij} n_j (\psi_{\Gamma_W})_i$ on Γ_W, and $j(C\mathbf{u}) \equiv 0$ elsewhere, with $\boldsymbol{\psi}_{\Gamma_W} \in [L^2(\Gamma_W)]^2$. Important target quantities of type (6.3) in viscous compressible flows are the (total) drag and lift coefficients c_d and c_l, which include both pressure-induced and viscous forces. Then $\boldsymbol{\psi}_{\Gamma_W} = \frac{1}{C_\infty}\boldsymbol{\psi}$, and C_∞ and $\boldsymbol{\psi}$ are as in (5.4).

In order to derive the adjoint problem, we multiply the left-hand side of (6.1) by $\mathbf{z}$, integrate by parts, and linearize about $\mathbf{u}$ to obtain

$$\begin{aligned}&\left(\nabla\cdot\left(\mathcal{F}^c_{\mathbf{u}}\mathbf{w} - \mathcal{F}^v_{\mathbf{u}}\mathbf{w} - \mathcal{F}^v_{\nabla\mathbf{u}}\nabla\mathbf{w}\right), \mathbf{z}\right)_\Omega \\ &\qquad = -\left(\left(\mathcal{F}^c_{\mathbf{u}} - \mathcal{F}^v_{\mathbf{u}}\right)\mathbf{w} - \mathcal{F}^v_{\nabla\mathbf{u}}\nabla\mathbf{w}, \nabla\mathbf{z}\right)_\Omega + \left(\mathbf{n}\cdot\left(\mathcal{F}^c_{\mathbf{u}}\mathbf{w} - \mathcal{F}^v_{\mathbf{u}}\mathbf{w} - \mathcal{F}^v_{\nabla\mathbf{u}}\nabla\mathbf{w}\right), \mathbf{z}\right)_\Gamma,\end{aligned}$$

where $\mathcal{F}^v_{\mathbf{u}} := \partial_{\mathbf{u}}\mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u}) = G'[\mathbf{u}]\nabla\mathbf{u}$ and $\mathcal{F}^v_{\nabla\mathbf{u}} := \partial_{\nabla\mathbf{u}}\mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u}) = G(\mathbf{u})$ denote the derivatives of $\mathcal{F}^v$ with respect to $\mathbf{u}$ and $\nabla\mathbf{u}$, respectively. Using integration by parts once more we obtain the following variational formulation of the continuous adjoint problem: Find $\mathbf{z}$ such that

$$\begin{aligned}&-\left(\mathbf{w}, \left(\mathcal{F}^c_{\mathbf{u}} - \mathcal{F}^v_{\mathbf{u}}\right)^\top \nabla\mathbf{z}\right)_\Omega - \left(\mathbf{w}, \nabla\cdot\left(\left(\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \nabla\mathbf{z}\right)\right)_\Omega + \left(\mathbf{w}, \mathbf{n}\cdot\left(\left(\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \nabla\mathbf{z}\right)\right)_\Gamma \\ &\qquad + \left(\mathbf{w}, \left(\mathbf{n}\cdot\left(\mathcal{F}^c_{\mathbf{u}} - \mathcal{F}^v_{\mathbf{u}}\right)\right)^\top \mathbf{z}\right)_\Gamma - \left(\nabla\mathbf{w}, \left(\mathbf{n}\cdot\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \mathbf{z}\right)_\Gamma = J'[\mathbf{u}](\mathbf{w}) \quad \forall\mathbf{w}\in\mathbf{V}.\end{aligned}$$

Given that

$$\begin{aligned}J'[\mathbf{u}](\mathbf{w}) &= \frac{1}{C_\infty}\int_{\Gamma_W} \left(p_{\mathbf{u}}[\mathbf{u}]\,\mathbf{n} - \underline{\tau}_{\mathbf{u}}[\mathbf{u}]\,\mathbf{n}\right)\cdot\boldsymbol{\psi}\,\mathbf{w} - \left(\underline{\tau}_{\nabla\mathbf{u}}[\mathbf{u}]\,\mathbf{n}\right)\cdot\boldsymbol{\psi}\,\nabla\mathbf{w}\,\mathrm{d}s \\ &= \left(\mathbf{w}, \frac{1}{C_\infty}\left(p_{\mathbf{u}}\,\mathbf{n} - \underline{\tau}_{\mathbf{u}}\,\mathbf{n}\right)\cdot\boldsymbol{\psi}\right)_{\Gamma_W} - \left(\nabla\mathbf{w}, \frac{1}{C_\infty}\left(\underline{\tau}_{\nabla\mathbf{u}}\,\mathbf{n}\right)\cdot\boldsymbol{\psi}\right)_{\Gamma_W},\end{aligned} \tag{6.4}$$

we see that the adjoint solution $\mathbf{z}$ satisfies the following equation:

$$-\left(\mathcal{F}^c_{\mathbf{u}} - \mathcal{F}^v_{\mathbf{u}}\right)^\top \nabla\mathbf{z} - \nabla\cdot\left(\left(\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \nabla\mathbf{z}\right) = 0, \tag{6.5}$$

subject to the boundary conditions on $\Gamma_W = \Gamma_{iso}\cup\Gamma_{adia}$,

$$\left(\mathbf{n}\cdot\left(\mathcal{F}^c_{\mathbf{u}} - \mathcal{F}^v_{\mathbf{u}}\right)\right)^\top \mathbf{z} + \mathbf{n}\cdot\left(\left(\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \nabla\mathbf{z}\right) = \frac{1}{C_\infty}\left(p_{\mathbf{u}}\,\mathbf{n} - \underline{\tau}_{\mathbf{u}}\,\mathbf{n}\right)\cdot\boldsymbol{\psi}, \tag{6.6}$$

$$\left(\mathbf{n}\cdot\mathcal{F}^v_{\nabla\mathbf{u}}\right)^\top \mathbf{z} = \frac{1}{C_\infty}\left(\underline{\tau}_{\nabla\mathbf{u}}\,\mathbf{n}\right)\cdot\boldsymbol{\psi}. \tag{6.7}$$

At wall boundaries Γ_W where $\mathbf{v} = (v_1, v_2)^\top = 0$, the normal viscous flux reduces to $\mathbf{n}\cdot\mathcal{F}^v(\mathbf{u}, \nabla\mathbf{u}) = (0, (\tau\mathbf{n})_1, (\tau\mathbf{n})_2, \mathbf{n}\cdot\nabla T)^\top$. Hence (6.7) is fulfilled, provided $\mathbf{z}$ satisfies

$$\begin{pmatrix} 0 \\ (\tau_{\nabla\mathbf{u}}\mathbf{n})_1\, z_2 \\ (\tau_{\nabla\mathbf{u}}\mathbf{n})_2\, z_3 \\ (\mathbf{n}\cdot\nabla T_{\nabla\mathbf{u}})\, z_4 \end{pmatrix} = \frac{1}{C_\infty}\begin{pmatrix} 0 \\ (\tau_{\nabla\mathbf{u}}\mathbf{n})_1\,\psi_1 \\ (\tau_{\nabla\mathbf{u}}\mathbf{n})_2\,\psi_2 \\ 0 \end{pmatrix}, \tag{6.8}$$

which reduces to the conditions $z_2 = \frac{1}{C_\infty}\psi_1$ on Γ_W, $z_3 = \frac{1}{C_\infty}\psi_2$ on Γ_W, and $z_4 = 0$ on Γ_{iso}. At adiabatic boundaries we have $\mathbf{n}\cdot\nabla T = 0$, and the last condition in (6.8) vanishes. Substituted into (6.6) we obtain $\mathbf{n}\cdot((\mathcal{F}^v_{\nabla\mathbf{u}})^\top\nabla\mathbf{z}) = 0$ on Γ_W, which at adiabatic boundaries reduces to $\mathbf{n}\cdot\nabla z_4 = 0$. On isothermal boundaries no additional

boundary condition is obtained. In summary, the boundary conditions of the adjoint problem (6.5) to the compressible Navier–Stokes equations are given by

$$z_2 = \frac{1}{C_\infty}\psi_1,\ z_3 = \frac{1}{C_\infty}\psi_2 \ \text{ on } \Gamma_W, \quad z_4 = 0 \ \text{ on } \Gamma_{iso}, \quad \mathbf{n}\cdot\nabla z_4 = 0 \ \text{ on } \Gamma_{adia}. \tag{6.9}$$

These boundary conditions have been derived by computing the adjoint equations of each of the four primal equations separately in [21] and [8].

In addition to the notation introduced in section 3, we use the standard notation $\underline{\sigma} : \underline{\tau} = \sum_{k=1}^{m}\sum_{l=1}^{n}\sigma_{kl}\tau_{kl}$ for matrices $\underline{\sigma}, \underline{\tau} \in \mathbb{R}^{m\times n}$, $m, n \geq 1$; additionally, for vectors $\mathbf{v} \in \mathbb{R}^m, \mathbf{w} \in \mathbb{R}^n$, the matrix $\mathbf{v}\otimes\mathbf{w} \in \mathbb{R}^{m\times n}$ is defined by $(\mathbf{v}\otimes\mathbf{w})_{kl} = v_k\, w_l$.

According to [16, 17] the interior penalty discontinuous Galerkin discretization of the compressible Navier–Stokes equations (6.1) is given by: Find $\mathbf{u}_h \in \mathbf{V}_h^p$ such that

$$\begin{aligned}\mathcal{N}(\mathbf{u}_h, \mathbf{v}) \equiv &- \int_\Omega \mathcal{F}^c(\mathbf{u}_h) : \nabla_h \mathbf{v}\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \mathcal{H}(\mathbf{u}_h^+, \mathbf{u}_h^-, \mathbf{n}^+)\cdot\mathbf{v}^+\,\mathrm{d}s \\ &+ \int_\Omega \mathcal{F}^v(\mathbf{u}_h, \nabla_h\mathbf{u}_h) : \nabla_h\mathbf{v}\,\mathrm{d}\mathbf{x} - \int_{\Gamma_\mathcal{I}} \{\mathcal{F}^v(\mathbf{u}_h, \nabla_h\mathbf{u}_h)\} : \underline{[\![\mathbf{v}]\!]}\,\mathrm{d}s \\ &+ \int_{\Gamma_\mathcal{I}} \theta\{G^\top(\mathbf{u}_h)\nabla_h\mathbf{v}\} : \underline{[\![\mathbf{u}_h]\!]}\,\mathrm{d}s + \int_{\Gamma_\mathcal{I}} \delta\underline{[\![\mathbf{u}_h]\!]} : \underline{[\![\mathbf{v}]\!]}\,\mathrm{d}s + \mathcal{N}_\Gamma(\mathbf{u}_h, \mathbf{v}) = 0\end{aligned} \tag{6.10}$$

for all $\mathbf{v}$ in $\mathbf{V}_h^p$. Here $\mathcal{N}_\Gamma(\mathbf{u}_h, \mathbf{v})$ includes all boundary terms which will be specified in the following. Recalling the discussion at the end of section 5, we know that the discretization of boundary terms in [16] is not adjoint consistent. In fact, [16] uses the standard discretization of convective boundary fluxes as opposed to the adjoint consistent discretization given in (5.22). Thereby, in the following we consider the boundary terms like in [16] but with an adjoint consistent treatment of convective fluxes like in (5.22). Furthermore, we treat the viscous fluxes analogous to the convective fluxes; i.e., we replace the viscous boundary flux $\mathcal{F}^v$ by $\mathcal{F}_\Gamma^v$, where

$$\mathcal{F}_\Gamma^v(\mathbf{u}_h, \nabla\mathbf{u}_h) = \mathcal{F}^v(\mathbf{u}_\Gamma(\mathbf{u}_h), \nabla\mathbf{u}_h) = G_\Gamma(\mathbf{u}_h)\nabla\mathbf{u}_h = G(\mathbf{u}_\Gamma(\mathbf{u}_h))\nabla\mathbf{u}_h. \tag{6.11}$$

Thereby, the discretization of boundary terms is given by

$$\begin{aligned}\mathcal{N}_\Gamma(\mathbf{u}_h, \mathbf{v}) = &\int_\Gamma \mathbf{n}\cdot\mathcal{F}_\Gamma^c(\mathbf{u}_h^+)\mathbf{v}^+\,\mathrm{d}s + \int_\Gamma \delta\left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)\cdot\mathbf{v}^+\,\mathrm{d}s \\ &- \int_\Gamma \mathbf{n}\cdot\mathcal{F}_\Gamma^v(\mathbf{u}_h^+, \nabla\mathbf{u}_h^+)\,\mathbf{v}^+\,\mathrm{d}s \\ &+ \theta\int_\Gamma \left(G_\Gamma^\top(\mathbf{u}_h^+)\nabla\mathbf{v}_h^+\right) : \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)\otimes\mathbf{n}\,\mathrm{d}s,\end{aligned} \tag{6.12}$$

where on adiabatic boundaries $\Gamma_{adia} \subset \Gamma_W$ the viscous flux $\mathcal{F}_\Gamma^v$ and the corresponding homogeneity tensor G_Γ are modified such that $\mathbf{n}\cdot\nabla T = 0$. Using integration by parts in (6.10), we obtain the primal residual form as follows: Find $\mathbf{u}_h \in \mathbf{V}_h^p$ such that

$$\begin{aligned}\int_\Omega \mathbf{R}(\mathbf{u}_h)\cdot\mathbf{v}\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \mathbf{r}(\mathbf{u}_h)\cdot\mathbf{v}^+ + \boldsymbol{\rho}(\mathbf{u}_h) : \nabla\mathbf{v}^+\,\mathrm{d}s \\ + \int_\Gamma \mathbf{r}_\Gamma(\mathbf{u}_h)\cdot\mathbf{v}^+ + \boldsymbol{\rho}_\Gamma(\mathbf{u}_h) : \nabla\mathbf{v}^+\,\mathrm{d}s = 0 \quad \forall\mathbf{v}\in\mathbf{V}_h^p,\end{aligned} \tag{6.13}$$

where the primal residuals are given by

$$
\begin{aligned}
\mathbf{R}(\mathbf{u}_h) &= -\nabla\cdot\mathcal{F}^c(\mathbf{u}_h) + \nabla\cdot\mathcal{F}^v(\mathbf{u}_h,\nabla_h\mathbf{u}_h) && \text{in } \kappa,\kappa\in\mathcal{T}_h,\\
\mathbf{r}(\mathbf{u}_h) &= \mathbf{n}\cdot\mathcal{F}^c(\mathbf{u}_h^+) - \mathcal{H}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+) - \frac{1}{2}[\![\mathcal{F}^v(\mathbf{u}_h,\nabla_h\mathbf{u}_h)]\!] - \delta[\![\mathbf{u}_h]\!]\cdot\mathbf{n},\\
\boldsymbol{\rho}(\mathbf{u}_h) &= -\frac{\theta}{2}\left(G(\mathbf{u}_h)\underline{[\![\mathbf{u}_h]\!]}\right)^\top && \text{on } \partial\kappa\setminus\Gamma,\kappa\in\mathcal{T}_h,\\
\mathbf{r}_\Gamma(\mathbf{u}_h) &= \mathbf{n}\cdot(\mathcal{F}^c(\mathbf{u}_h^+) - \mathcal{F}_\Gamma^c(\mathbf{u}_h^+) - \mathcal{F}^v(\mathbf{u}_h^+,\nabla\mathbf{u}_h^+) + \mathcal{F}_\Gamma^v(\mathbf{u}_h^+,\nabla\mathbf{u}_h^+)) - \delta(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)),\\
\boldsymbol{\rho}_\Gamma(\mathbf{u}_h) &= -\theta\left(G_\Gamma^\top(\mathbf{u}_h^+) : \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)\otimes\mathbf{n}\right)^\top && \text{on } \Gamma.
\end{aligned}
$$

We see that the exact solution $\mathbf{u}$ to (6.1) satisfies

$$
\mathbf{R}(\mathbf{u}) = 0, \qquad \mathbf{r}(\mathbf{u}) = 0, \qquad \boldsymbol{\rho}(\mathbf{u}) = 0, \qquad \mathbf{r}_\Gamma(\mathbf{u}) = 0, \qquad \boldsymbol{\rho}_\Gamma(\mathbf{u}) = 0,
$$

where we used consistency of the numerical flux $\mathcal{H}(\mathbf{w},\mathbf{w},\mathbf{n}) = \mathbf{n}\cdot\mathcal{F}^c(\mathbf{w})$, continuity of $\mathbf{u}$, and the consistency of the boundary function, i.e., $\mathbf{u}$ satisfies $\mathbf{u}_\Gamma(\mathbf{u}) = \mathbf{u}$ on Γ. We conclude that the discretization given in (6.10) and (6.12) is consistent.

Given the target quantity $J(\cdot)$ defined in (6.3) with Fréchet derivative (6.4), we consider the following modification of $J(\cdot)$:

$$
\tilde{J}(\mathbf{u}_h) = J(\mathbf{i}(\mathbf{u}_h)) + \int_\Gamma r_J(\mathbf{u}_h)\,\mathrm{d}s = J_\Gamma(\mathbf{u}_h) + \int_\Gamma r_J(\mathbf{u}_h)\,\mathrm{d}s. \tag{6.14}
$$

As in section 5, here we set $\mathbf{i}(\mathbf{u}_h) = \mathbf{u}_\Gamma(\mathbf{u}_h)$ and $J_\Gamma(\mathbf{u}_h) = J(\mathbf{u}_\Gamma(\mathbf{u}_h))$; $r_J(\mathbf{u}_h)$ will be specified later. Noting that $\mathbf{u}_\Gamma(\mathbf{u}) = \mathbf{u}$ holds for the exact solution $\mathbf{u}$, $\tilde{J}(\cdot)$ in (6.14) is a consistent modification of $J(\cdot)$, provided that $\mathbf{u}$ satisfies $r_J(\mathbf{u}) = 0$; see also (2.25).

Rewriting $\mathcal{N}(\mathbf{u}_h,\mathbf{v})$ in (6.10) in terms of the homogeneity tensor G and recalling (5.15), we see that the discrete adjoint problem is given by: Find $\mathbf{z}_h\in\mathbf{V}_h$ such that

$$
\mathcal{N}'[\mathbf{u}_h](\mathbf{w},\mathbf{z}_h) = \tilde{J}'[\mathbf{u}_h](\mathbf{w}) \quad \forall\mathbf{w}\in\mathbf{V}, \tag{6.15}
$$

where $\mathcal{N}'[\mathbf{u}](\mathbf{w},\mathbf{z})$ is given by

$$
\begin{aligned}
\mathcal{N}'[\mathbf{u}](\mathbf{w},\mathbf{z}) = &-\int_\Omega (\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}]\mathbf{w}) : \nabla_h\mathbf{z}\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma}\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}^+,\mathbf{u}^-,\mathbf{n}^+)\mathbf{w}^+[\![\mathbf{z}]\!]\cdot\mathbf{n}\,\mathrm{d}\mathbf{s}\\
&+\int_\Omega (G'[\mathbf{u}]\mathbf{w}\nabla_h\mathbf{u}) : \nabla_h\mathbf{z}\,\mathrm{d}\mathbf{x} + \int_\Omega (G(\mathbf{u})\nabla_h\mathbf{w}) : \nabla_h\mathbf{z}\,\mathrm{d}\mathbf{x}\\
&-\int_{\Gamma_{\mathcal{I}}}\{G'[\mathbf{u}]\mathbf{w}\nabla_h\mathbf{u}\} : \underline{[\![\mathbf{z}]\!]}\,\mathrm{d}s - \int_{\Gamma_{\mathcal{I}}}\{G(\mathbf{u})\nabla_h\mathbf{w}\} : \underline{[\![\mathbf{z}]\!]}\,\mathrm{d}s\\
&+\int_{\Gamma_{\mathcal{I}}}\theta\{\left(G^\top\right)'[\mathbf{u}]\mathbf{w}\nabla_h\mathbf{z}\} : \underline{[\![\mathbf{u}]\!]}\,\mathrm{d}s + \int_{\Gamma_{\mathcal{I}}}\theta\{G^\top(\mathbf{u})\nabla_h\mathbf{z}\} : \underline{[\![\mathbf{w}]\!]}\,\mathrm{d}s\\
&+\int_{\Gamma_{\mathcal{I}}}\delta\underline{[\![\mathbf{w}]\!]} : \underline{[\![\mathbf{z}]\!]}\,\mathrm{d}s + \mathcal{N}'_\Gamma[\mathbf{u}](\mathbf{w},\mathbf{z}).
\end{aligned} \tag{6.16}
$$

Using integration by parts, this can be rewritten as follows:

$$
\begin{aligned}
&- \int_\Omega \mathbf{w} \left(\mathcal{F}_{\mathbf{u}}^c[\mathbf{u}]\right)^\top \nabla_h \mathbf{z} \,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h} \int_{\partial\kappa\setminus\Gamma} \mathbf{w}^+ \left(\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}^+,\mathbf{u}^-,\mathbf{n}^+)\right)^\top [\![\mathbf{z}]\!]\cdot\mathbf{n}\,\mathrm{d}\mathbf{s} \\
&+ \int_\Omega \mathbf{w} \left(G'[\mathbf{u}]\nabla_h\mathbf{u}\right)^\top \nabla_h\mathbf{z}\,\mathrm{d}\mathbf{x} - \int_\Omega \mathbf{w}\nabla_h\cdot\left(G^\top(\mathbf{u})\nabla_h\mathbf{z}\right)\,\mathrm{d}\mathbf{x} \\
&- \frac{1}{2}\sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} (G'[\mathbf{u}]\mathbf{w}\nabla_h\mathbf{u}) : \underline{[\![\mathbf{z}]\!]}\,\mathrm{d}s - \frac{1}{2}\sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} (G(\mathbf{u})\nabla_h\mathbf{w}) : \underline{[\![\mathbf{z}]\!]}\,\mathrm{d}s \\
&+ \frac{1}{2}\theta\sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \left(\left(G^\top\right)'[\mathbf{u}]\mathbf{w}\nabla_h\mathbf{z}\right) : \underline{[\![\mathbf{u}]\!]}\,\mathrm{d}s + \frac{1}{2}\sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \mathbf{w}[\![G^\top(\mathbf{u})\nabla_h\mathbf{z}]\!]\,\mathrm{d}s \\
&+ (1+\theta)\sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} (\mathbf{w}\otimes\mathbf{n}) : \{G^\top(\mathbf{u})\nabla_h\mathbf{z}\}\,\mathrm{d}s + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \delta\mathbf{w}[\![\mathbf{z}]\!]\cdot\mathbf{n}\,\mathrm{d}\mathbf{s} \\
&+ \int_\Gamma (\mathbf{w}\otimes\mathbf{n}) : \left(G^\top(\mathbf{u})\nabla_h\mathbf{z}\right)\,\mathrm{d}s + \mathcal{N}'_\Gamma[\mathbf{u}](\mathbf{w},\mathbf{z}).
\end{aligned}
\tag{6.17}
$$

Hence the discrete adjoint problem (6.15) in adjoint residual form is given as follows: Find $\mathbf{z}_h \in \mathbf{V}_h$ such that

$$
\begin{aligned}
&\int_\Omega \mathbf{w}\cdot\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}\mathbf{x} + \sum_{\kappa\in\mathcal{T}_h}\int_{\partial\kappa\setminus\Gamma} \mathbf{w}\cdot\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h) + \nabla\mathbf{w} : \boldsymbol{\rho}^*[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}s \\
&\qquad + \int_\Gamma \mathbf{w}\cdot\mathbf{r}^*_\Gamma[\mathbf{u}_h](\mathbf{z}_h) + \nabla\mathbf{w} : \boldsymbol{\rho}^*_\Gamma[\mathbf{u}_h](\mathbf{z}_h)\,\mathrm{d}s = 0 \quad \forall \mathbf{w}\in\mathbf{V}_h,
\end{aligned}
\tag{6.18}
$$

where the adjoint residuals are given by

$$
\begin{aligned}
\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h) &= \left(\mathcal{F}_{\mathbf{u}}^c(\mathbf{u}_h) - G'[\mathbf{u}_h]\nabla\mathbf{u}_h\right)^\top \nabla_h\mathbf{z}_h + \nabla_h\cdot\left(G^\top(\mathbf{u}_h)\nabla_h\mathbf{z}_h\right) \quad \text{in } \kappa,\kappa\in\mathcal{T}_h, \\
\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h) &= -\left(\mathcal{H}'_{\mathbf{u}^+}(\mathbf{u}_h^+,\mathbf{u}_h^-,\mathbf{n}^+)\right)^\top [\![\mathbf{z}_h]\!]\cdot\mathbf{n} \\
&\quad - \frac{1}{2}[\![G^\top(\mathbf{u}_h)\nabla\mathbf{z}_h]\!] - (1+\theta)\mathbf{n}\cdot\{G^\top(\mathbf{u}_h)\nabla_h\mathbf{z}_h\} - \delta[\![\mathbf{z}_h]\!]\cdot\mathbf{n} \\
&\quad + \frac{1}{2}\left(G'[\mathbf{u}_h]\nabla\mathbf{u}_h\right)^\top \underline{[\![\mathbf{z}_h]\!]} - \frac{1}{2}\theta\left(G'[\mathbf{u}_h]\underline{[\![\mathbf{u}_h]\!]}\right)^\top \nabla_h\mathbf{z}_h \quad \text{on } \partial\kappa\setminus\Gamma,\kappa\in\mathcal{T}_h, \\
\boldsymbol{\rho}^*[\mathbf{u}_h](\mathbf{z}_h) &= \frac{1}{2}G^\top[\mathbf{u}_h]\underline{[\![\mathbf{z}_h]\!]} \qquad \text{on } \partial\kappa\setminus\Gamma,\kappa\in\mathcal{T}_h.
\end{aligned}
\tag{6.19}
$$

The adjoint boundary residuals $\mathbf{r}^*_\Gamma$ and $\boldsymbol{\rho}^*_\Gamma$ will be specified below. Recalling that $\mathcal{F}^v_{\mathbf{u}} = G'[\mathbf{u}]\nabla\mathbf{u}$ and $\mathcal{F}^v_{\nabla\mathbf{u}} = G(\mathbf{u})$, we see that the exact solution $\mathbf{z}$ to the continuous adjoint problem (6.5) satisfies $\mathbf{R}^*[\mathbf{u}](\mathbf{z}) = 0$. In the three lines in (6.19) representing the face residual term $\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h)$, we recognize the jump $-(\mathcal{H}'_{\mathbf{u}^+})^\top[\![\mathbf{z}_h]\!]\cdot\mathbf{n}$ due to the convective part of the equations (cf. (5.23)); furthermore, the terms in the second line correspond to the adjoint face residuals of Poisson's equation (cf. (4.11)); and finally the two terms in the third line are due to the nonlinearity of the compressible Navier–Stokes equations. Whereas the last term in the third line vanishes for a smooth exact primal solution $\mathbf{u}$, all other terms vanish for the exact solution $\mathbf{z}$ to the adjoint problem (6.5), provided $\theta = -1$. Thereby, the adjoint solution $\mathbf{z}$ satisfies $\mathbf{r}^*[\mathbf{u}](\mathbf{z}) = 0$, provided that $\theta = -1$. Furthermore, $\mathbf{z}$ satisfies $\boldsymbol{\rho}^*[\mathbf{u}](\mathbf{z}) = 0$. In summary, we see that, like for Poisson's equation, the element and interior face terms of the IP discretization of the compressible Navier–Stokes equation are adjoint consistent for the symmetric ($\theta = -1$) but not for the nonsymmetric ($\theta = 1$) version.

The boundary terms of the discrete adjoint problem are given by

$$\begin{aligned}\mathcal{N}_\Gamma'[\mathbf{u}_h](\mathbf{w},\mathbf{z}_h)+&\int_\Gamma (\mathbf{w}\otimes\mathbf{n}) : \left(G_\Gamma^\top(\mathbf{u}_h)\nabla_h\mathbf{z}_h\right)\,\mathrm{d}s \equiv\\ &+\int_\Gamma \mathbf{n}\cdot\left(\mathcal{F}^c_{\Gamma,\mathbf{u}}[\mathbf{u}_h](\mathbf{w})\right)\mathbf{z}_h\,\mathrm{d}s+\int_\Gamma \delta\left(\mathbf{w}-\mathbf{u}_\Gamma'[\mathbf{u}_h]\mathbf{w}\right)\cdot\mathbf{z}\,\mathrm{d}s,\\ &-\int_\Gamma \mathbf{n}\cdot\left(\mathcal{F}^v_{\Gamma,\mathbf{u}}[\mathbf{u}_h,\nabla_h\mathbf{u}_h](\mathbf{w})+\mathcal{F}^v_{\Gamma,\nabla\mathbf{u}}[\mathbf{u}_h,\nabla_h\mathbf{u}_h](\nabla_h\mathbf{w})\right)\mathbf{z}_h\,\mathrm{d}s\\ &+\theta\int_\Gamma\left(\left(\left(G_\Gamma^\top\right)'[\mathbf{u}_h]\mathbf{w}\right)\nabla_h\mathbf{z}_h\right) : (\mathbf{u}_h-\mathbf{u}_\Gamma(\mathbf{u}_h))\otimes\mathbf{n}\,\mathrm{d}s\\ &+\theta\int_\Gamma\left(G_\Gamma^\top(\mathbf{u}_h)\nabla_h\mathbf{z}_h\right) : (\mathbf{w}-\mathbf{u}_\Gamma'[\mathbf{u}_h]\mathbf{w})\otimes\mathbf{n}\,\mathrm{d}s\\ &+\int_\Gamma(\mathbf{w}\otimes\mathbf{n}) : \left(G_\Gamma^\top(\mathbf{u}_h)\nabla_h\mathbf{z}_h\right)\,\mathrm{d}s=\tilde{J}'[\mathbf{u}_h](\mathbf{w}).\end{aligned}$$

Thus the adjoint boundary residuals in (6.18) on Γ_W are given by

$$\begin{aligned}\mathbf{r}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h)=&\frac{1}{C_\infty}\left(p_\mathbf{u}\,\mathbf{n}-\underline{\tau}_\mathbf{u}\,\mathbf{n}\right)\cdot\psi-\left(\mathbf{n}\cdot\left(\mathcal{F}^c_{\Gamma,\mathbf{u}}-\mathcal{F}^v_{\Gamma,\mathbf{u}}\right)\right)^\top\mathbf{z}_h-\mathbf{n}\cdot\left(G_\Gamma^\top\nabla\mathbf{z}_h\right)\\ &+r_J'[\mathbf{u}_h]-\delta\left(I-\mathbf{u}_\Gamma'[\mathbf{u}_h]\right)^\top\mathbf{z}_h-\theta\left(G_\Gamma'[\mathbf{u}_h] : (\mathbf{u}_h-\mathbf{u}_\Gamma(\mathbf{u}_h))\otimes\mathbf{n}\right)^\top\nabla_h\mathbf{z}_h\\ &-\theta\left(G_\Gamma(\mathbf{u}_h) : (I-\mathbf{u}_\Gamma'[\mathbf{u}_h])\otimes\mathbf{n}\right)^\top\nabla_h\mathbf{z}_h,\end{aligned}\tag{6.20}$$

$$\boldsymbol{\rho}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h)=-\frac{1}{C_\infty}\left(\underline{\tau}_{\nabla\mathbf{u}}\mathbf{n}\right)\cdot\psi+\left(\mathbf{n}\cdot\mathcal{F}^v_{\Gamma,\nabla\mathbf{u}}\right)^\top\mathbf{z}_h.\tag{6.21}$$

We recall (6.7), $\mathcal{F}^v_{\Gamma,\nabla\mathbf{u}}=G_\Gamma(\mathbf{u})$, and see that the exact solutions $\mathbf{u}$ and $\mathbf{z}$ to the primal problem (6.1) and the continuous adjoint problem (6.5)–(6.9) satisfy $\boldsymbol{\rho}_\Gamma^*[\mathbf{u}](\mathbf{z})=0$.

We now choose the modification $r_J(\mathbf{u}_h)$ of the target functional in (6.14) as follows:

$$r_J(\mathbf{u}_h)=\delta\left(\mathbf{u}_h^+-\mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)\cdot\mathbf{z}_\Gamma+\theta\left(G_\Gamma^\top(\mathbf{u}_h^+)\nabla_h\mathbf{z}_\Gamma\right) : \left(\mathbf{u}_h^+-\mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)\otimes\mathbf{n},\tag{6.22}$$

with Fréchet derivative

$$\begin{aligned}r_J'[\mathbf{u}_h](\mathbf{w})=&\,\delta\left(I-\mathbf{u}_\Gamma'[\mathbf{u}_h]\right)\mathbf{w}\cdot\mathbf{z}_\Gamma+\theta\left(G_\Gamma'[\mathbf{u}_h] : (\mathbf{u}-\mathbf{u}_\Gamma(\mathbf{u}_h))\otimes\mathbf{n}\right)^\top\nabla_h\mathbf{z}_\Gamma\\ &+\theta\left(G_\Gamma(\mathbf{u}_h) : (I-\mathbf{u}_\Gamma'[\mathbf{u}_h])\otimes\mathbf{n}\right)^\top\nabla_h\mathbf{z}_\Gamma.\end{aligned}$$

As the exact solution $\mathbf{u}$ to the primal problem satisfies $\mathbf{u}_\Gamma(\mathbf{u})=\mathbf{u}$, we have $r_J(\mathbf{u})=0$. Hence (6.22) is a consistent modification of the target functional. Recalling (6.6) we see that the exact solutions $\mathbf{u}$ and $\mathbf{z}$ satisfy

$$\begin{aligned}\mathbf{r}_\Gamma^*[\mathbf{u}](\mathbf{z})=&\,\delta\left(I-\mathbf{u}_\Gamma'[\mathbf{u}]\right)^\top(\mathbf{z}_\Gamma-\mathbf{z})+\theta\left(G'[\mathbf{u}] : (\mathbf{u}-\mathbf{u}_\Gamma(\mathbf{u}))\otimes\mathbf{n}\right)^\top(\nabla\mathbf{z}_\Gamma-\nabla\mathbf{z})\\ &+\theta\left(G(\mathbf{u}) : (I-\mathbf{u}_\Gamma'[\mathbf{u}])\otimes\mathbf{n}\right)^\top(\nabla\mathbf{z}_\Gamma-\nabla\mathbf{z}).\end{aligned}\tag{6.23}$$

Furthermore, setting $\mathbf{z}_\Gamma=\mathbf{z}$ on Γ_W we obtain $\mathbf{r}_\Gamma^*[\mathbf{u}](\mathbf{z})=0$ and conclude that the discretization of boundary terms is adjoint consistent.

Due to $\mathbf{n}\cdot(G_\Gamma^\top(\mathbf{u}_h^+)\nabla\mathbf{z})=\mathbf{n}\cdot((\mathcal{F}^v_{\nabla\mathbf{u}})^\top\nabla\mathbf{z})=0$ on Γ_W the second term in (6.22) vanishes. Furthermore, on adiabatic boundaries Γ_{adia} we have $(\mathbf{u}_h^+-\mathbf{u}_\Gamma(\mathbf{u}_h^+))_i=0$,

$i = 1, 4$, and on isothermal boundaries Γ_{iso} we have $(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+))_1 = 0$. Together with (6.9) the consistent modification (6.22) reduces to

$$\begin{aligned} r_J(\mathbf{u}_h) &= \delta \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right) \cdot \mathbf{z}_\Gamma \\ &= \delta \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)_2 \frac{1}{C_\infty}\psi_1 + \delta \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right)_3 \frac{1}{C_\infty}\psi_2, \end{aligned} \tag{6.24}$$

which completes the adjoint consistency analysis of the interior penalty discontinuous Galerkin discretization of the compressible Navier–Stokes equations. Finally, we note that the consistent modification $r_J(\mathbf{u}_h)$ given in (6.24) corresponds to the IP modification of target functionals for Poisson's equation where $r_J(u_h) = \delta(u_h - g_D)z_\Gamma$ with $z_\Gamma = -j_D$; see (4.13).

In summary, we have shown that the adjoint element and interior residuals $\mathbf{R}^*[\mathbf{u}_h](\mathbf{z}_h)$, $\mathbf{r}^*[\mathbf{u}_h](\mathbf{z}_h)$, and $\boldsymbol{\rho}^*[\mathbf{u}_h](\mathbf{z}_h)$ (see (6.19)) vanish for the exact solutions $\mathbf{u}$ and $\mathbf{z}$ to (6.1) and (6.5), respectively, provided $\theta = -1$. Additionally, using an adjoint consistent treatment of convective and diffusive boundary fluxes,

$$\mathbf{n} \cdot \mathcal{F}_\Gamma^c(\mathbf{u}_h^+) = \mathbf{n} \cdot \mathcal{F}^c(\mathbf{u}_\Gamma(\mathbf{u}_h^+)), \qquad \mathbf{n} \cdot \mathcal{F}_\Gamma^v(\mathbf{u}_h^+) = \mathbf{n} \cdot \mathcal{F}^v(\mathbf{u}_\Gamma(\mathbf{u}_h^+), \nabla_h \mathbf{u}_h^+), \tag{6.25}$$

and using the following consistent modification of the target functional:

$$\tilde{J}(\mathbf{u}_h) = J(\mathbf{u}_\Gamma(\mathbf{u}_h)) + \int_{\Gamma_W} \delta \left(\mathbf{u}_h^+ - \mathbf{u}_\Gamma(\mathbf{u}_h^+)\right) \cdot \mathbf{z}_\Gamma \, \mathrm{d}s, \tag{6.26}$$

with $\mathbf{z}_\Gamma = \frac{1}{C_\infty}(0, \psi_1, \psi_2, 0)^\top$, for $J(\cdot)$ representing a total force coefficient defined in (6.3), the adjoint boundary residuals $\mathbf{r}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h)$ and $\boldsymbol{\rho}_\Gamma^*[\mathbf{u}_h](\mathbf{z}_h)$ (see (6.20) and (6.21)) vanish for the exact solutions $\mathbf{u}$ and $\mathbf{z}$. Thereby, using the modifications given in (6.25) and (6.26) we recover an adjoint consistent symmetric interior penalty discontinuous Galerkin discretization of the compressible Navier–Stokes equations in conjunction with total force coefficients. Finally, we note that arguments given in [23] en route to obtaining an adjoint consistent discretization based on the BR2 scheme [5] can also be covered within the presented framework and lead to analogous modifications.

7. Numerical experiments for the compressible Navier–Stokes equations. In this section we will demonstrate the effect on the smoothness of the discrete adjoint solution when employing the adjoint consistent SIPG discretization based on (6.25) and (6.26) in comparison to the original SIPG discretization of the compressible Navier–Stokes equations [16], which instead uses

$$\mathcal{H}(\mathbf{u}_h^+, \mathbf{u}_\Gamma(\mathbf{u}_h^+), \mathbf{n}), \qquad \mathbf{n} \cdot \mathcal{F}^v(\mathbf{u}_h^+, \nabla_h \mathbf{u}_h^+) \quad \text{on } \Gamma, \qquad \text{and} \qquad J(\mathbf{u}_h). \tag{7.1}$$

Furthermore, we compare the accuracy of the original formulation and the adjoint consistent discretization on a sequence of globally refined meshes.

To this end, we revisit the standard test case [3, 16, 17] of a $M = 0.5$ viscous flow at $\mathrm{Re} = 5000$ and at zero angle of attack around the NACA0012 airfoil with adiabatic no-slip boundary conditions imposed on the profile. Figure 7.1 shows the primal flow solution based on the adjoint consistent discretization on a (locally) refined mesh created by repeated refinement of the coarse C-type mesh depicted in Figure 7.2. Then, in Figure 7.3 we show the components z_1–z_4 of the corresponding discrete adjoint solution $\mathbf{z}_h$. In particular, we find that the second and third components $z_2 \approx 1/C_\infty = 40/7$ and $z_3 \approx 0$ are constant on the profile. Furthermore, we see that $\mathbf{n} \cdot \nabla z_4 \approx 0$ as required by the continuous adjoint boundary conditions (6.9).

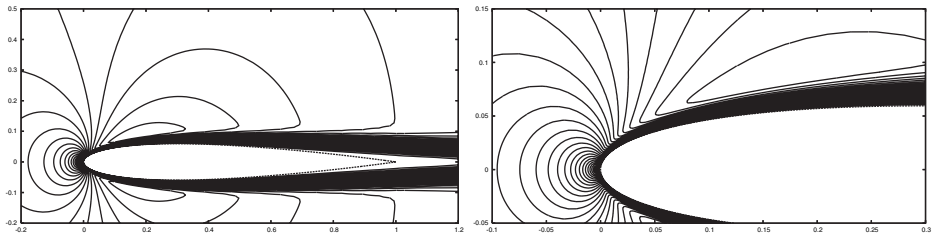

FIG. 7.1. *Adjoint consistent DG discretization of the* $M = 0.5, \alpha = 0°, \mathrm{Re} = 5000$ *flow around the NACA*0012 *airfoil: Mach isolines* $(0.02i, i \in \mathbb{N})$ *of the (primal) flow solution.*

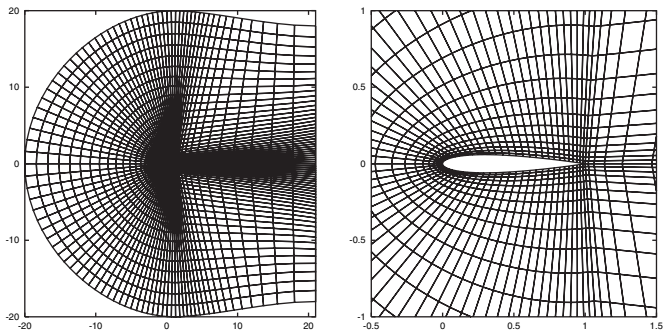

FIG. 7.2. *Computational mesh with* 3072 *element: (left) full and (right) detailed view.*

For comparison, Figure 7.4 shows the z_4 component of the discrete adjoint to the original DG discretization [16]. We clearly see an irregular adjoint solution at the profile boundary. In contrast, the discrete adjoint solution (see Figure 7.3) based on the adjoint consistent discretization is entirely smooth. The components z_i, $i = 1, 2, 3$, show a similar behavior.

For a quantitative comparison of the original and the adjoint consistent discretization, we collect the errors of the computed solutions on a sequence of globally refined meshes in Table 7.1. Here we show the number of elements, the number of degrees of freedom, and the error $J(\mathbf{u}) - J(\mathbf{u}_h)$ of the flow solution for three different discretizations. The error of $\mathbf{u}_h \in \mathbf{V}_h^1$ is measured in terms of the total drag coefficient c_d where the reference value $J(\mathbf{u}) \approx 0.05482$ is based on very fine grid computations. In columns (a) and (b) we collect the errors and rates of convergence of the original SIPG formulation (7.1) (cf. [16]) and for the adjoint consistent discretization based on (6.25) and (6.26), respectively. We see that the adjoint consistent discretization is by a factor of about 2–400 more accurate than the original discretization on the same mesh and with the same numerical complexity. Furthermore the adjoint consistent discretization shows an $\mathcal{O}(h^5)$ order of convergence which is significantly higher than that of the original discretization. In order to demonstrate the relevance of the IP modification (6.24) of the target functional, in column (c) of Table 7.1 we collect the respective errors based on the same discretization as in column (b) while omitting the IP modification; i.e., column (c) is based on (6.25) and $\tilde{J}(\mathbf{u}_h) = J(\mathbf{u}_\Gamma(\mathbf{u}_h))$. The accuracy is significantly reduced, partly even below the accuracy of the original discretization. From this, we see that the IP modification is essential for the adjoint consistency of the discretization and the accuracy of the numerical flow solution. A similar behavior is seen for $\mathbf{u}_h \in \mathbf{V}_h^2$ in Table 7.2. Here the original discretization

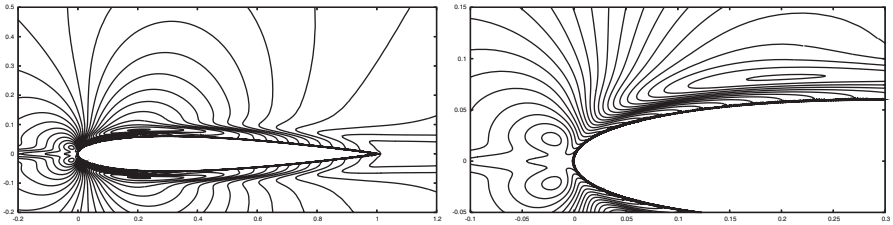

FIG. 7.4. *Original DG discretization* [16] *of the* $M = 0.5, \alpha = 0^\circ, \mathrm{Re} = 5000$ *flow around the NACA*0012 *airfoil: Isolines of component* z_4 *of the adjoint solution* $\mathbf{z}$ *for* c_d.

shows an $\mathcal{O}(h^3)$ convergence on average, whereas the convergence of the adjoint consistent discretization is $\mathcal{O}(h^6)$.

We note that independently Lu [23] demonstrated, for a $M = 0.5$ viscous compressible flow around the NACA0012 airfoil at $\mathrm{Re} = 5000$ and $\alpha = 2^\circ$ angle of attack, that the discrete adjoint solution to the adjoint consistent discretization based on the BR2 scheme [5] is smooth whereas that to the standard discretization is not. Fur-

thermore, [23] showed optimal order of convergence results for the adjoint consistent discretization in comparison to reduced ones for the standard discretization which lacks adjoint consistency.

8. Conclusion. A discretization is adjoint consistent if the discrete adjoint problem is a consistent discretization of the continuous adjoint problem. In fact, adjoint consistency is the link between the so-called continuous adjoint approach (which discretizes the adjoint equations) and the discrete adjoint approach (which takes the adjoint of the discrete equations) in that the solutions to both approaches coincide. In particular, adjoint consistency is the key requirement for optimal order duality-based error estimates in L^2 as well as measured in terms of target functionals. Furthermore, adjoint consistency is closely related to the smoothness of the discrete adjoint solutions. However, in addition to the adjoint consistency of element and interior face terms, an adjoint consistent treatment of boundary terms as well as of target functionals is required for an adjoint consistent discontinuous Galerkin discretization.

In this article we have introduced a framework for analyzing consistency and adjoint consistency of discontinuous Galerkin discretizations of linear and nonlinear problems. This framework includes the derivation of the continuous adjoint problems and adjoint boundary conditions, provided the primal problem and the target functional satisfy a compatibility condition. It includes the derivation of the discrete adjoint problems and primal and adjoint residuals and a discussion of under which conditions the residuals vanish for the exact primal and adjoint solutions. In addition, we have introduced so-called consistent modifications of target functionals which allow us to modify (and possibly improve) computed target quantities without changing their exact values. We then analyzed the DG discretization of the linear advection equation, the interior penalty (IP)DG discretization of Poisson's equation, and the DG discretization of the compressible Euler equations. While recovering properties and conclusions drawn in [1, 11, 24], the outlined framework gives a unified analysis of these discretizations, including the definition of consistent modification of a target functional such as the so-called IP modification as well as a consistent modification of the force coefficients for inviscid compressible flows.

This framework has then been used to analyze the adjoint consistency property of the symmetric interior penalty discontinuous Galerkin discretization of the compressible Navier–Stokes equations. While the original formulation of the SIPG discretization [16] has been shown to be adjoint inconsistent, the analysis revealed that a special treatment of boundary terms as well as an IP modification of viscous force coefficients is required for recovering an adjoint consistent DG discretization of the compressible Navier–Stokes equations. Numerical experiments have confirmed that, in contrast to the original formulation in [16], the discrete adjoint solution to the adjoint consistent discretization is entirely smooth. Furthermore, numerical tests on globally refined meshes have shown that the adjoint consistent discretization is by a factor of 2–400 more accurate measured in terms of viscous force coefficients than the original formulation. Also, a significantly improved order of convergence has been observed.
