$$\begin{aligned}\langle [\partial_n u_H^\gamma], \{v\}\rangle_e = &\sum_{K'\in\mathcal{T}_{h,\tilde{K}}} \Big((f+\Delta u_H^\gamma, v)_{K'} - (\nabla(u_h^\gamma - u_H^\gamma), \nabla v)_{K'}\Big) \\ &+ \sum_{e\in\mathcal{E}^I_{h,\tilde{K}}} \langle \{\partial_n v\}, [u_h^\gamma]\rangle_e - \sum_{e\in\mathcal{E}_h^D\cap\partial\tilde{K}} \langle \partial_n v, g_D - u_h^\gamma\rangle_e,\end{aligned} \tag{4.20}$$

where $\mathcal{T}_{h,\tilde{K}} = \{K' \in \mathcal{T}_h,\ K' \subseteq \tilde{K}\}$ and $\mathcal{E}^I_{h,\tilde{K}} = \{e \in \mathcal{E}_h^I,\ e \subseteq \tilde{K}\}$. Now note that

$$\langle [\partial_n u_H^\gamma], \{v\}\rangle_e = \int_e |\,[\partial_n u_H^\gamma]\,|^2 \ell(s) ds. \tag{4.21}$$

With ℓ acting as a weight function, we have

$$h_e \int_e |\,[\partial_n u_H^\gamma]\,|^2 \ell(s) ds \geq c h_e |\,[\partial_n u_H^\gamma]\,|_e^2, \tag{4.22}$$

where c is independent of h_e. Moreover, since $0 \leq \ell \leq 1$ and $\tilde{v}$ is constant along lines normal to e,

$$\|v\|^2_{\tilde{K}} \leq \|\tilde{v}\|^2_{\tilde{K}} = \int_e |\,[\partial_n u_H^\gamma]\,|^2 \nu(s) ds \leq c h_e |\,[\partial_n u_H^\gamma]\,|_e^2, \tag{4.23}$$

where ν is as in Figure 4.4(a). Now using the trace and inverse inequalities in (4.20), for any $\epsilon > 0$ we obtain

$$\begin{aligned}h_e |\,[\partial_n u_H^\gamma]\,|_e^2 \leq c\epsilon \|v\|^2_{\tilde{K}} + \frac{c}{\epsilon}\Bigg(&\sum_{K'\in\mathcal{T}_{h,\tilde{K}}} \Big(h^2_{K'}\|f+\Delta u_H^\gamma\|^2_{K'} + \|\nabla(u_h^\gamma - u_H^\gamma)\|^2_{K'}\Big) \\ &+ \sum_{e\in\mathcal{E}^I_{h,\tilde{K}}} h_e^{-1} |\,[u_h^\gamma]\,|_e^2 + \sum_{e\in\mathcal{E}_h^D\cap\partial\tilde{K}} h_e^{-1} |g_D - u_h^\gamma|_e^2\Bigg).\end{aligned} \tag{4.24}$$

Hence using (4.21)–(4.23) in (4.24), and choosing ϵ sufficiently small, we arrive at

$$\begin{aligned}h_e |\,[\partial_n u_H^\gamma]\,|_e^2 \leq c &\sum_{K'\in\mathcal{T}_{h,\tilde{K}}} \Big(h^2_{K'}\|f+\Delta u_H^\gamma\|^2_{K'} + \|\nabla(u_h^\gamma - u_H^\gamma)\|^2_{K'}\Big) \\ &+ c \sum_{e\in\mathcal{E}^I_{h,\tilde{K}}} h_e^{-1} |\,[u_h^\gamma]\,|_e^2 + c \sum_{e\in\mathcal{E}_h^D\cap\partial\tilde{K}} h_e^{-1} |g_D - u_h^\gamma|_e^2.\end{aligned} \tag{4.25}$$

Estimation of $h_e|g_N - \partial_n u_H^\gamma|_e^2$. We define a test function $v \in V_h^r \cap H^1_{0,\Gamma_D}$ as follows: Let $\tilde{v}$ be the extension of $g_N - \partial_n u_H^\gamma$ by constants along lines normal to e, and let ℓ be the continuous piecewise linear function that vanishes outside of K and that assumes the value 1 at the midpoint of e. We let $v = \tilde{v}\ell$ and note that since $g_N - \partial_n u_H^\gamma$ is a polynomial of degree less than or equal to $r-2$, $v \in V_h^r \cap H^1_{0,\Gamma_D}$. Using this v in (4.13), we obtain

$$\begin{aligned}\langle g_N - \partial_n u_H^\gamma, v\rangle_e = &-(f+\Delta u_H^\gamma, v)_K + \sum_{K'\in\mathcal{T}_{h,K}} (\nabla(u_h^\gamma - u_H^\gamma), \nabla v)_{K'} \\ &- \sum_{e\in\mathcal{E}^I_{h,K}} \langle \{\partial_n v\}, [u_h^\gamma]\rangle_e.\end{aligned} \tag{4.26}$$

Using the trace and inverse inequalities, we obtain

$$h_e \langle g_N - \partial_n u_H^\gamma, v\rangle_e \le c\epsilon \|v\|_K^2 + \frac{c}{\epsilon}\left(h_K^2 \|f + \Delta u_H^\gamma\|_K^2 + \sum_{K' \in \mathcal{T}_{h,K}} \|\nabla(u_h^\gamma - u_H^\gamma)\|_{K'}^2 + \sum_{e \in \mathcal{E}_{h,K}^I} h_e^{-1} |\,[u_h^\gamma]\,|_e^2 \right). \tag{4.27}$$

As in steps (4.21), (4.22), and (4.23), we have

$$h_e |g_N - \partial_n u_H^\gamma|_e^2 \le c h_e \langle g_N - \partial_n u_H^\gamma, v\rangle_e \quad \text{and} \quad \|v\|_K^2 \le c h_e |g_N - \partial_n u_H^\gamma|_e^2. \tag{4.28}$$

Thus, from (4.27) it follows that

$$h_e |g_N - \partial_n u_H^\gamma|_e^2 \le c h_K^2 \|f + \Delta u_H^\gamma\|_K^2 + c \sum_{K' \in \mathcal{T}_{h,K}} \|\nabla(u_h^\gamma - u_H^\gamma)\|_{K'}^2 + c \sum_{e \in \mathcal{E}_{h,K}^I} h_e^{-1} |\,[u_h^\gamma]\,|_e^2. \tag{4.29}$$

We are now ready to state and prove the main result of this paper.

THEOREM 4.1. *Let u_h^γ and u_H^γ denote the DG solutions in V_h^r and V_H^r, respectively, and e_H and e_h the corresponding errors. Assume that*

(i) *The data of the BVP (1.1)–(1.3) is such that $f \in P_{r-1}(\Omega)$, $g_D \in P_{r-1}(\Gamma_D)$, and $g_N \in P_{r-2}(\Gamma_N)$.*
(ii) *$\mathcal{T}_h$ is not too fine with respect to $\mathcal{T}_H$.*
(iii) *For some $\theta \in (0,1)$ the marking of triangles and edges of the mesh $\mathcal{T}_H$ and their refinement is done according to the rules specified above.*

Then, there exists γ_3 depending only on r, θ_0, and θ such that for all $\gamma \ge \gamma_3$, (4.1) holds with ρ given by (4.36).

Proof. First, using the trace and inverse inequalities, we have for $\gamma \ge \gamma_4(r, \theta_0)$

$$a_h^\gamma(u_h^\gamma - u_H^\gamma, u_h^\gamma - u_H^\gamma) \ge \frac{1}{2} \sum_{K \in \mathcal{T}_h} \|\nabla(u_h^\gamma - u_H^\gamma)\|_K^2 + \frac{1}{2} \sum_{e \in \mathcal{E}_h^I \cup \mathcal{E}_h^D} h_e^{-1} |\,[u_h^\gamma - u_H^\gamma]\,|_e^2. \tag{4.30}$$

On the other hand, from (4.19), (4.25), and (4.29), it follows that for some constant $C_3 > 0$ depending only on r and θ_0

$$E_{\mathcal{R}} \le C_3 \left(\sum_{K \in \mathcal{T}_h} \|\nabla(u_h^\gamma - u_H^\gamma)\|_K^2 + \sum_{e \in \mathcal{E}_h^I} h_e^{-1} |\,[u_h^\gamma]\,|_e^2 + \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2 \right). \tag{4.31}$$

Next, using (4.2), (4.3), (4.30), and (4.31), we obtain

$$\begin{aligned} a_H^\gamma(e_H, e_H) + c\gamma \sum_{e \in \mathcal{E}_H^I} h_e^{-1} |\,[u_H^\gamma]\,|_e^2 + c\gamma \sum_{e \in \mathcal{E}_H^D} h_e^{-1} |g_D - u_H^\gamma|_e^2 &\ge a_h^\gamma(e_H, e_H) \\ &= a_h^\gamma(e_h, e_h) + a_h^\gamma(u_h^\gamma - u_H^\gamma, u_h^\gamma - u_H^\gamma) \\ &\ge a_h^\gamma(e_h, e_h) + \frac{1}{2} \sum_{K \in \mathcal{T}_h} \|\nabla(u_h^\gamma - u_H^\gamma)\|_K^2 \\ &\ge a_h^\gamma(e_h, e_h) + \frac{E_{\mathcal{R}}}{2C_3} - \frac{1}{2} \left(\sum_{e \in \mathcal{E}_h^I} h_e^{-1} |\,[u_h^\gamma]\,|_e^2 + \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2 \right). \end{aligned} \tag{4.32}$$

Now from (3.20) it follows for $\gamma \geq \gamma_5(r, \theta_0, \theta)$ that

$$c\gamma \left(\sum_{e \in \mathcal{E}_H^I} h_e^{-1} |\, [u_H^\gamma]\, |_e^2 + \sum_{e \in \mathcal{E}_H^D} h_e^{-1} |g_D - u_H^\gamma|_e^2 \right) \leq \frac{cE}{\gamma} \leq \frac{\theta E}{4C_3}. \tag{4.33}$$

Also, from (4.5) we have

$$\sum_{e \in \mathcal{E}_h^I} h_e^{-1} |\, [u_h^\gamma]\, |_e^2 + \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2 \leq \frac{1}{C_1 \gamma^2} a_h^\gamma(e_h, e_h). \tag{4.34}$$

Thus, using (4.33) and (4.34) in (4.32), we obtain

$$a_H^\gamma(e_H, e_H) \geq \left(1 - \frac{1}{2C_1\gamma^2}\right) a_h^\gamma(e_h, e_h) + \frac{\theta E}{4c_3}. \tag{4.35}$$

We choose γ large so that $1 - \frac{1}{2C_1\gamma^2} > 0$. On the other hand, using (4.10) with H instead of h (recall that this result holds for a generic mesh), it follows from (3.20) and (3.3) that for some constant $C_4 > 0$ depending only on r and θ_0 one has

$$E \geq C_4 a_H^\gamma(e_H, e_H).$$

Using this in (4.35), it follows that

$$\left(1 - \frac{\theta C_4}{4C_3}\right) a_H^\gamma(e_H, e_H) \geq \left(1 - \frac{1}{2C_1\gamma^2}\right) a_h^\gamma(e_h, e_h).$$

If $\frac{\theta C_4}{4C_3} \geq 1$, then this means that $a_h^\gamma(e_h, e_h) = 0$. If, on the other hand, $0 < \frac{\theta C_4}{4C_3} < 1$, then we obtain (4.1) with ρ given by

$$\rho = \frac{1 - \frac{\theta C_4}{4C_3}}{1 - \frac{1}{2C_1\gamma^2}}. \tag{4.36}$$

The conclusion of the theorem now follows for γ sufficiently large. ∎

REMARK 4.3. *The conditions on the data of the BVP* (1.1)–(1.3) *are restrictive and are the price paid to simplify the proofs. We believe that they can be relaxed or dispensed with by introducing appropriate projections of the data functions. See, e.g.,* [15] *and* [20]. *The generalization of our results including an accounting for the effects of quadrature errors is being pursued.*

5. Numerical experiments. In this section we present the results of some numerical experiments to exhibit the performance of the adaptive strategy outlined in section 4. We used the Baker version of the method since the forms $\{\partial_n v\} = \nabla v^+ \cdot \mathbf{n}^+$ are easier to implement.

As a representative of a problem with a smooth solution we chose

$$-\Delta u = 2\pi^2 \sin \pi x \sin \pi y \quad \text{in } \Omega = [0,1]^2, \quad u = 0 \quad \text{on } \partial\Omega, \tag{P1}$$

with $u = \sin \pi x \sin \pi y$. The next problem has the smooth but oscillatory solution $u = \sin 8\pi x \sin 8\pi y$:

$$-\Delta u = 128\pi^2 \sin 8\pi x \sin 8\pi y \quad \text{in } \Omega = [0,1]^2, \quad u = 0 \quad \text{on } \partial\Omega. \tag{P2}$$

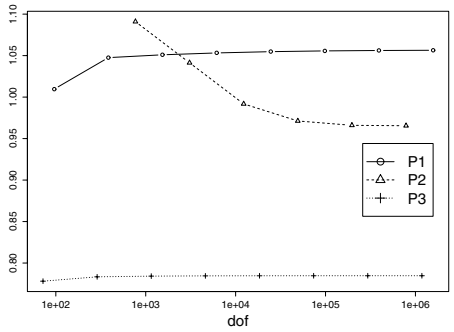

FIG. 5.1. *Effectivity indices;* $r = 3$, $\gamma = 6.3$.

Finally, as an example of a solution with a singularity we considered the problem

$$-\Delta u = 0 \quad \text{in } \Omega, \quad u = g_D \quad \text{on } \Gamma_D = \partial\Omega, \tag{P3}$$

where Ω is the polygon with vertices $(0,0)$, $(-1,-1)$, $(1,-1)$, $(1,1)$, $(-1,1)$, $(0,0)$ and has a reentrant corner at $(0,0)$. The datum g_D is adjusted so that the solution is $u = r^{2/3}\sin\frac{2\theta}{3}$ in polar coordinates.

We generated an adaptive code written in the C language and ran the experiments on a workstation with an Intel Pentium 4 chip rated at 3.06 GHz. The linear systems were solved by Multigrid with point Gauss–Seidel smoothing as a preconditioner for the conjugate gradient method. To assess the performance of the estimator and the adaptive algorithm, we monitored the following three quantities:

$$a_h^\gamma(e,e) = \sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 - 2\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle\{\partial_n e\},[e]\rangle_e + \gamma(r-1)^2 \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e^{-1}|[e]|_e^2,$$

$$\|e\|_{1,h} = \left(\sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 + \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \left(h_e\,|\{\partial_n e\}|_e^2 + \gamma(r-1)^2 h_e^{-1}|[e]|_e^2\right)\right)^{1/2},$$

$$\eta = \left(\sum_{K\in\mathcal{T}_h} h_K^2\|f+\Delta u_h^\gamma\|_K^2 + \sum_{e\in\mathcal{E}_h^I} h_e\left|\left[\partial_n u_h^\gamma\right]\right|_e^2 + \sum_{e\in\mathcal{E}_h^N} h_e\left|g_N - \partial_n u_h^\gamma\right|_e^2 \right.$$
$$\left. + \gamma^2(r-1)^4 \sum_{e\in\mathcal{E}_h^I} h_e^{-1}\left|[u_h^\gamma]\right|_e^2 + \gamma^2(r-1)^4 \sum_{e\in\mathcal{E}_h^D} h_e^{-1}\left|g_D - u_h^\gamma\right|_e^2\right)^{1/2}.$$

These quantities are modified versions of the bilinear form, the energy norm, and the residual error estimator. Since the coercivity threshold is known to increase quadratically as a function of the degree $r-1$, we replaced γ by $\gamma(r-1)^2$. This way, the calculations could be performed without the need for adjusting γ with r. Following the same reasoning, we attached $\gamma^2(r-1)^4$ to the jump terms of the residual estimator since γ^2 accompanied these terms both in the upper and lower bounds.

The first set of experiments concerned a study of the effectivity index $\eta/\|e\|_{1,h}$ as a function of the degrees of freedom (dof's). Figure 5.1 shows the effectivity indices for all three test problems. Starting with an initial mesh of 16 triangles (96 dof's), the mesh was refined uniformly until a maximum of about 10^6. In particular, the indices behaved rather well with values close to 1 (more so for (P1) and (P2) than

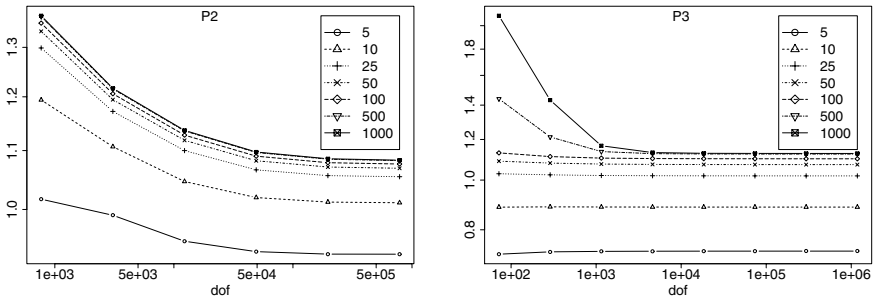

FIG. 5.2. *Dependence of effectivity indices on γ; $r = 3$.*

for (P3)), and the index for (P2) took longer to stabilize given the oscillatory nature of the solution. Similar behavior was observed for $r = 2, 4, 5$.

We also wanted to study the effect of γ on the effectivity indices. Figure 5.2 shows the results of experiments concerning test problems (P2) and (P3), $r = 3$, and values of γ from 5 to 1000. While such an effect does indeed exist, it is nevertheless quite mild, as evidenced by the narrow range of the changes in the effectivity indices. We also note that the effectivity indices seem to be convergent as γ increases. Similar results were obtained for (P1) and $r = 2, 4, 5$.

The remaining experiments were devoted to the validation of the convergence characteristics of the adaptive algorithm. We ran several experiments with $r = 2, 3, 4$, all three test problems, and several values of θ and γ. In all cases all three quantities $a_h^\gamma(e, e)$, $\|e\|_{1,h}$, and η decreased monotonically. We should also mention that in order to simplify the program, we cut the marked triangles into four triangles only, in variance with the patterns shown in Figure 4.1. The plots in Figure 5.3 show the excellent agreement between the error $\|e\|_{1,h}$ and the estimator η. On the other hand, the bilinear form $a_h^\gamma(e, e)$ seems to follow a very similar but parallel trajectory, evidence of its equivalence to the other two. The two plots of Figure 5.4 show the corresponding final meshes for (P2) and (P3), respectively.

Next, we wanted to study the effect of the choice of θ on the performance of the adaptive algorithm. Indeed, the experiments indicate that while convergence is not in doubt, the patterns of refinement are strongly influenced by this choice, as evidenced by the final triangle count and, more importantly, the CPU time. Postponing a detailed study of this important issue to a future work, we nevertheless maintain that if we accept the criterion that the most efficient algorithm is the one with the least execution time, then larger values of θ should be preferred. Tables 5.1–5.3 show, respectively, the CPU time, the number of iterations to convergence, and the triangle count in the final mesh for the three test problems and $\theta = 0.3, 0.5, 0.9$. While smaller values of θ lead to a smaller number of triangles, they are up to six times costlier in CPU time. This is due to the fact that at every cycle, relatively few triangles and

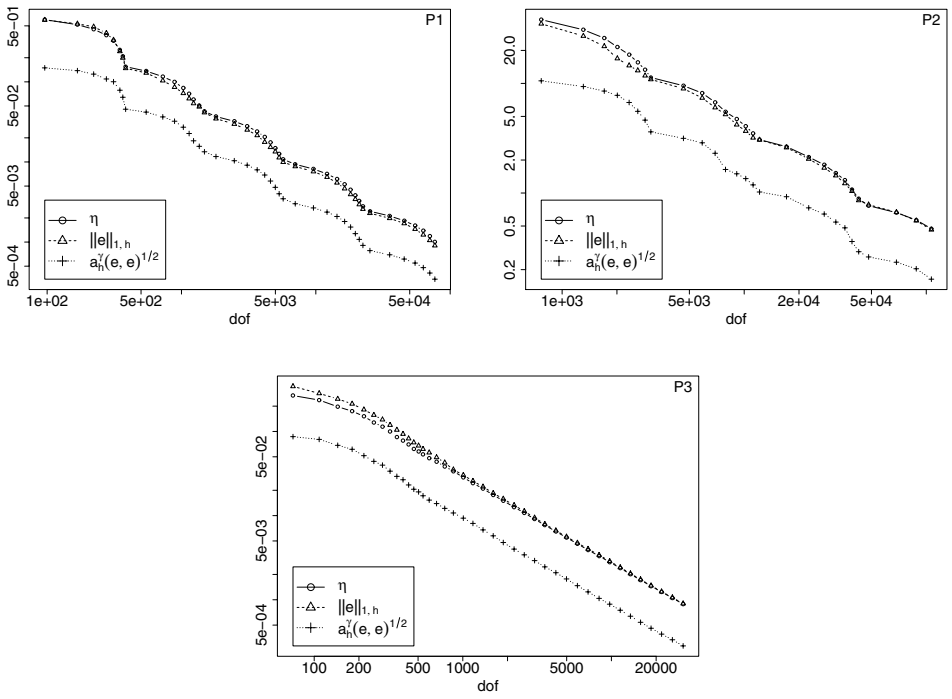

FIG. 5.3. $r = 3$, $\gamma = 6.3$, $\theta = 0.5$.

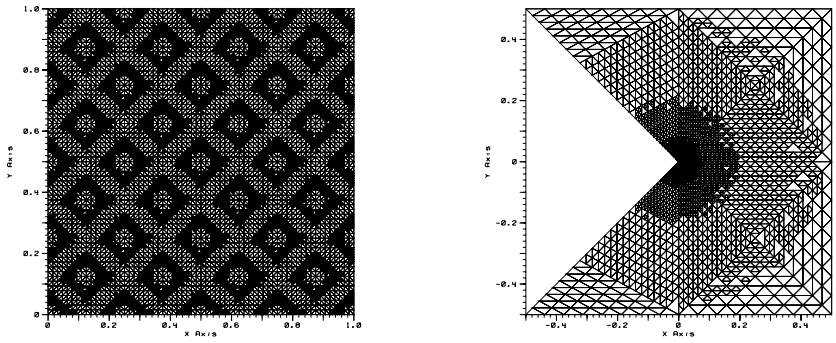

FIG. 5.4. *Final meshes for* (P2), (P3)*;* $r = 3$, $\gamma = 6.3$, $\theta = 0.5$.

edges are refined, resulting in a large, one could say unacceptable, number of cycles.

Tables 5.4, 5.5, and 5.6 encapsulate the results of an attempt to study the effect of θ on both the number of refinement levels and the distribution of triangles over the levels; in a sense they provide a spectral analysis of the mesh hierarchy. For test problem (P1), the value $\theta = 0.9$ caused a shift of the refinement to a higher level with a substantial number of triangles on level 6 (Table 5.4). On the other hand, Table 5.6 shows the opposite behavior for test problem (P3), whereby the smaller values of $\theta = 0.3, 0.5$ created five additional levels, albeit with a relatively small number of additional triangles.

These experiments, although limited in scope, provide a validation of the theo-

retical results of the paper. They also point to the importance of further exploration of the mechanisms of marking and refinement. In particular, a static choice of θ is far from being satisfactory and must be replaced by a more dynamic (adaptive!) mechanism.

Acknowledgments. The authors thank Mr. Mike Saum for help in the development of the code and the generation of tables and figures. The initial meshes were generated by the program "Triangle" developed by J. R. Shewchuk [22].

OPTIMIZED SCHWARZ WAVEFORM RELAXATION METHODS FOR ADVECTION REACTION DIFFUSION PROBLEMS*

M. J. GANDER† AND L. HALPERN‡

Abstract. We study in this paper a new class of waveform relaxation algorithms for large systems of ordinary differential equations arising from discretizations of partial differential equations of advection reaction diffusion type. We show that the transmission conditions between the subsystems have a tremendous influence on the convergence speed of the waveform relaxation algorithms, and we identify transmission conditions with optimal performance. Since these optimal transmission conditions are expensive to use, we introduce a class of local transmission conditions of Robin type, which approximate the optimal ones and can be used at the same cost as the classical transmission conditions. We determine the transmission conditions in this class with the best performance of the associated waveform relaxation algorithm. We show that the new algorithm is well posed and converges much faster than the classical one. We illustrate our analysis with numerical experiments.

1. Introduction.

Waveform relaxation algorithms have been invented to solve extremely large systems of ordinary differential equations arising in circuit simulation [26]. They use a partition of the original problem into subproblems, which are then solved separately, and an iteration with information exchange between subproblems leads to the solution of the original problem. Since the solution of the subproblems can be done in parallel, these algorithms are very well suited for implementations on parallel computers. The main drawback of waveform relaxation algorithms is in general their slow convergence, for a review, see [1].

There are two main classical approaches in the literature to solve parabolic problems in parallel. The first approach consists of discretizing the equations uniformly in time with an implicit scheme and then applying a domain decomposition technique to the elliptic problems obtained at each time step, see, for example, [2, 32, 3] and references therein. This approach has the disadvantage that a uniform time discretization needs to be enforced across different subdomains, and one thus loses one of the main features of domain decomposition algorithms, namely, to be able to treat different subdomains numerically differently with an adapted procedure for each subdomain. A second disadvantage is that small amounts of information need to be exchanged at every time level, which can be costly in a parallel environment where the startup cost to send information is significant. In addition, the iteration in time cannot proceed before all the subdomains have converged. An interesting variant, which avoids iterating by making explicit predictions at the interfaces, can be found in [36].

The second classical approach consists of discretizing the equations in space first and then applying a waveform relaxation algorithm to the large system of ordinary

differential equations obtained from the spatial discretization. A formulation using discretized subdomains can be found in [25]. The main disadvantage of this approach is that spatial information of the connectivity of the subsystems in the large system of ordinary differential equations is lost, and parameters like physical overlap and information exchange are difficult to interpret in this context. Using a different approach and abandoning the idea of subsystems, efficient waveform relaxation algorithms of multigrid type, see [29, 38, 21, 22], and also convolution waveform relaxation algorithms, see [20, 23], have been introduced and analyzed.

To avoid the inherent problems of the classical decomposition approaches, waveform relaxation algorithms for problems in space-time were formulated in [16, 14, 13] and independently in [18] directly at the continous level without discretization. The spatial domain is decomposed into subdomains, and time dependent problems are solved iteratively on subdomains, exchanging information at the interfaces between subdomains. This approach permits a different numerical treatment in both space and time of the subdomain problems, and information is exchanged less often between subdomains. The iteration is defined as in the classical Schwarz case, but as in waveform relaxation, time dependent subproblems are solved, which explains the names of these methods. Unfortunately these algorithms, although robust with respect to refinement, if the overlap is held constant, are still converging only slowly.

We show in this paper for a model problem of advection reaction diffusion type why the convergence of the Schwarz waveform relaxation algorithm is slow. By analyzing the convergence behavior of the classical overlapping Schwarz waveform relaxation algorithm applied to the model problem, we show that the classical algorithm is using ineffective transmission conditions. The classical transmission conditions inhibit the information exchange between subdomains and therefore slow down the convergence of the algorithm. Using ideas introduced in [10], we derive optimal transmission conditions for the Schwarz waveform relaxation algorithm. These transmission conditions coincide with the transparent boundary conditions used to truncate computational domains, which were first studied in [7] for hyperbolic problems and in [19] for advection diffusion problems. Transparent transmission conditions lead to Schwarz waveform relaxation algorithms which converge in a finite number of steps, equal to the number of subdomains, see [11] for the wave equation case. In general, however, the transparent boundary conditions are expensive to compute since they involve nonlocal operators. Similar to the approach for stationary problems in [34, 24, 8, 17], we approximate the transparent transmission conditions locally at the interfaces between subdomains, see [10, 12, 31]. This leads to algorithms which converge even without overlap and are well suited to couple different numerical methods, like finite element and finite differences methods, see [4]. We then optimize the convergence rate, including an overlap in the optimization if desired.

Since the algorithms are eventually discretized to be used on a parallel computer, we analyze the performance of the optimized algorithms asymptotically as the discretization parameter goes to zero. This analysis reveals an interesting relationship between the space-time discretization (implicit-explicit) and the convergence of the optimized algorithm. Numerical experiments show that the convergence rates are improved by orders of magnitude over the rate of the classical overlapping Schwarz waveform relaxation methods.

This paper is organized as follows: In section 2, we present the model problem for which we study the overlapping Schwarz waveform relaxation algorithm in what follows. We include fundamental existence results for the solution, which are later used to prove well posedness and convergence of the algorithm. In section 3, we intro-

duce the classical overlapping Schwarz waveform relaxation algorithm, show that it is well posed when applied to the advection reaction diffusion equation, and analyze its convergence. In section 4, we introduce the optimal Schwarz waveform relaxation algorithm, an algorithm that uses, instead of Dirichlet transmission conditions, transparent ones. Because such transmission conditions can be expensive to use, we also introduce local approximations of these transmission conditions. The core of this paper is contained in section 5, where we analyze the optimized Schwarz waveform relaxation algorithm with Robin transmission conditions. We show that the algorithm is well posed and convergent. We also derive the optimal parameters in the Robin transmission conditions and their dependence on the problem parameters, and we study the asymptotic dependence of the discretized algorithm on the mesh parameters. In section 6, we show numerical results for the classical and optimized Schwarz waveform relaxation algorithms, which show how drastically the convergence behavior is improved using optimized transmission conditions. We present our conclusions in section 7. All our analysis is performed for the simple case of a two subdomain decomposition, since we improve the algorithm locally between subdomains. We show, however, numerical experiments for more than two subdomains, which indicate that the results of our analysis are valid in that case as well.

2. Model problem and function spaces. Our guiding example is the one dimensional advection reaction diffusion equation

$$\mathcal{L}u := \partial_t u - \nu \partial_{xx} u + a\partial_x u + bu = f \quad \text{in } \Omega \times (0,T), \tag{2.1}$$

where $\Omega = \mathbb{R}$, $\nu > 0$, and a and b are constants which do not both vanish simultaneously. The case of the heat equation needs special treatment and can be found in [12]. Without loss of generality, we can assume that the advection coefficient a is nonnegative since $a < 0$ amounts to changing x into $-x$. We can also assume that the reaction coefficient b is nonnegative. If not, a change of variables $v = ue^{-\sigma t}$ with $\sigma + b > 0$ will lead to (2.1) with a positive reaction coefficient.

A weak solution of (2.1) for $\Omega = \mathbb{R}$ is defined to be a $u \in \mathcal{C}(0,T;L^2(\Omega)) \cap L^2(0,T;H^1(\Omega))$ such that for any v in $H^1(\Omega)$

$$\frac{d}{dt}(u,v) + \nu(\partial_x u, \partial_x v) + \frac{a}{2}((\partial_x u, v) - (\partial_x v, u)) + b(u,v) = (f,v) \text{ in } \mathcal{D}'(0,T), \tag{2.2}$$

where $(\cdot,\cdot)$ denotes the inner product in $L^2(\Omega)$. Problem (2.1) is completed by the initial condition

$$u(x,0) = u_0(x) \quad \text{in } \Omega. \tag{2.3}$$

We have a first existence and uniqueness result, proved in [27].

THEOREM 2.1. *For $\Omega = \mathbb{R}$, if the initial value u_0 is in $L^2(\Omega)$ and the right-hand side f is in $L^2(0,T;L^2(\Omega))$, then there exists a unique weak solution u of* (2.1), (2.3).

With the transmission conditions we will introduce later, we will need more regularity in our analysis, in the anisotropic Sobolev spaces $H^{r,s}(\Omega \times (0,T)) = L^2(0,T;H^r(\Omega)) \cap H^s(0,T;L^2(\Omega))$ defined in [27].

THEOREM 2.2. *For $\Omega = \mathbb{R}$, if the initial value u_0 is in $H^1(\Omega)$ and the right-hand side f is in $L^2(0,T;L^2(\Omega))$, then the weak solution u of* (2.1), (2.3) *is in $H^{2,1}(\Omega \times (0,T))$. If u_0 is in $H^2(\Omega)$ and f is in $H^{1,1/2}(\Omega \times (0,T))$, then u is in $H^{3,3/2}(\Omega \times (0,T))$.*

For the proof, and the trace theorems in $H^{r,s}$, we refer to [27].

3. Classical Schwarz waveform relaxation. We decompose the spatial domain $\Omega = \mathbb{R}$ into two overlapping subdomains $\Omega_1 = (-\infty, L)$ and $\Omega_2 = (0, \infty)$, $L > 0$. The overlapping Schwarz waveform relaxation algorithm consists then of solving iteratively subproblems on $\Omega_1 \times (0,T)$ and $\Omega_2 \times (0,T)$ using as a boundary condition at the interfaces $x = 0$ and $x = L$ the values obtained from the previous iteration. The algorithm is thus for iteration index $k = 1, 2, \ldots$, given by

$$
\begin{array}{llll}
\mathcal{L}u_1^k = f & \text{in } \Omega_1 \times (0,T), & \mathcal{L}u_2^k = f & \text{in } \Omega_2 \times (0,T), \\
u_1^k(\cdot,0) = u_0 & \text{in } \Omega_1, & u_2^k(\cdot,0) = u_0 & \text{in } \Omega_2, \\
u_1^k(L,\cdot) = u_2^{k-1}(L,\cdot) & \text{in } (0,T), & u_2^k(0,\cdot) = u_1^{k-1}(0,\cdot) & \text{in } (0,T),
\end{array} \tag{3.1}
$$

where an initial guess $u_1^0(0,t)$ and $u_2^0(L,t)$, $t \in (0,T)$, needs to be provided. We first study the well posedness of algorithm (3.1) and then analyze its convergence properties. While algorithm (3.1) is also well defined without overlap, $L = 0$, it is not convergent, since no information is exchanged in that case. This will be different for the optimized algorithms proposed in section 5.

3.1. Well posedness of the algorithm. We first need to show the well posedness of each subdomain problem. Without loss of generality, we consider the subdomain problem on Ω_1 only:

$$
\begin{array}{rcll}
\mathcal{L}v & = & f & \text{in } \Omega_1 \times (0,T), \\
v(\cdot,0) & = & u_0 & \text{in } \Omega_1, \\
v(L,\cdot) & = & g & \text{in } (0,T).
\end{array} \tag{3.2}
$$

THEOREM 3.1. *If $f \in L^2(0,T;L^2(\Omega_1))$, $u_0 \in H^1(\Omega_1)$, and $g \in H^{\frac{3}{4}}(0,T)$ and if the compatibility condition*

$$u_0(L) = g(0) \tag{3.3}$$

is satisfied, then problem (3.2) *has a unique solution v in $H^{2,1}(\Omega_1 \times (0,T))$. Moreover $v(0,\cdot)$ is in $H^{\frac{3}{4}}(0,T)$, and the following compatibility property holds:*

$$\lim_{t \to 0+} v(0,t) = u_0(0). \tag{3.4}$$

Proof. The proof of existence and uniqueness in $H^{2,1}(\Omega_1 \times 0,T))$ can be found in [27]. The compatibility relation follows from the trace theorem in [27]. ∎

By the Sobolev embedding theorem, u_0 is continuous on $\bar{\Omega}_1$ and g is continuous on $[0,T]$, which gives a classical meaning to the compatibility condition (3.3). The preceding result ensures that the subdomain problems are well posed in the classical algorithm, provided the initial and boundary conditions satisfy the compatibility condition (3.3) for each iteration step.

To show that this is indeed the case, let $u_2^0(L,\cdot)$ and $u_1^0(0,\cdot)$ be given in $H^{\frac{3}{4}}(0,T)$ such that $u_2^0(L,\cdot) = u_0(L)$ and $u_1^0(0,\cdot) = u_0(0)$. Then, by Theorem 3.1, the first iteration of the overlapping Schwarz waveform relaxation algorithm (3.1) defines a unique first iterate (u_1^1, u_2^1) in $H^{2,1}(\Omega_1 \times (0,T)) \times H^{2,1}(\Omega_2 \times (0,T))$. Furthermore, $u_1^1(0,\cdot)$ and $u_2^1(L,\cdot)$ are in $H^{\frac{3}{4}}(0,T)$, $\lim_{t\to 0+} u_1^1(0,t) = u_0(0)$, and $\lim_{t\to 0+} u_2^1(L,t) = u_0(L)$. Hence by induction, the algorithm is well posed.

3.2. Convergence of the algorithm. By linearity, the error between the solution u and the iterates u_j^k, $j = 1, 2$, of the overlapping Schwarz waveform relaxation algorithm (3.1) satisfies a homogeneous advection reaction diffusion equation with a

homogeneous initial condition. We therefore study in what follows the homogeneous problem with data on the interfaces only. Let h_L and h_0 be given in $H^{\frac{3}{4}}(0,T)$ with $h_L(0)=0$ and $h_0(0)=0$, to satisfy the compatibility conditions, and let (e_1,e_2) be the solution in $H^{2,1}(\Omega_1\times(0,T))\times H^{2,1}(\Omega_2\times(0,T))$ of the equations

$$\begin{array}{rclll} \mathcal{L}e_1 & = & 0 & \text{in } \Omega_1\times(0,T), & \mathcal{L}e_2 = 0 \quad \text{in } \Omega_2\times(0,T),\\ e_1(\cdot,0) & = & 0 & \text{in } \Omega_1, & e_2(\cdot,0) = 0 \quad \text{in } \Omega_2,\\ e_1(L,\cdot) & = & h_L & \text{in } (0,T), & e_2(0,\cdot) = h_0 \quad \text{in } (0,T). \end{array} \tag{3.5}$$

Our analysis is based on the Fourier transform, which we denote for any function $h\in L^2(\mathbb{R})$ by $\hat{h}:=\mathcal{F}h$. We define the one-sided space ${}_0H^{\frac{3}{4}}(0,T)=\{\varphi\in H^{\frac{3}{4}}(0,T),\varphi(0)=0\}$, equipped with the norm $\|\varphi\|_{{}_0H^{\frac{3}{4}}(0,T)}:=\inf\{\|\Phi\|_{H^{\frac{3}{4}}(\mathbb{R})},\Phi=\varphi \text{ a.e. in } (0,T),\Phi=0 \text{ a.e. in } (-\infty,0)\}$.

LEMMA 3.2. *Let $L>0$. If $a>0$ or $a=0$ and $b>0$, then the map $\mathcal{G}_D$ associated with equations* (3.5)*,*

$$\mathcal{G}_D:(h_L,h_0)\mapsto(e_2(L,\cdot),e_1(0,\cdot)), \tag{3.6}$$

is defined from $({}_0H^{\frac{3}{4}}(0,T))^2$ into itself, and $\mathcal{G}_D^2$ is a strict contraction on $({}_0H^{\frac{3}{4}}(0,T))^2$.

Proof. Since h_L and h_0 are in ${}_0H^{\frac{3}{4}}(0,T)$, we can extend them in $H^{\frac{3}{4}}(\mathbb{R})$ to obtain $\tilde{h}_L$ and $\tilde{h}_0$ vanishing on $(-\infty,0)$. We then extend equations (3.5) in time to $\mathbb{R}$, and their solution coincides with (e_1,e_2) on $(0,T)$. Therefore, we still call it (e_1,e_2). By Fourier transform in time, we find in each subdomain the same ordinary differential equation

$$i\omega\hat{e}_j-\nu\partial_{xx}\hat{e}_j+a\partial_x\hat{e}_j+b\hat{e}_j=0,\quad j=1,2, \tag{3.7}$$

with the characteristic roots

$$r^+=\frac{a+\sqrt{d}}{2\nu},\quad r^-=\frac{a-\sqrt{d}}{2\nu},\quad d=a^2+4\nu(b+i\omega), \tag{3.8}$$

where $\sqrt{d}$ is the complex square root with positive real part. Therefore, $\Re(r^+)>0$ and $\Re(r^-)<0$, and we find, using that e_j is in $L^2(\Omega_j)$,

$$\hat{e}_1(x,\omega)=\mathcal{F}\tilde{h}_L(\omega)e^{r^+(x-L)},\qquad \hat{e}_2(x,\omega)=\mathcal{F}\tilde{h}_0(\omega)e^{r^-x}. \tag{3.9}$$

On the interfaces of the subdomains, we therefore have

$$\mathcal{F}(\mathcal{G}_D(\tilde{h}_L,\tilde{h}_0))(\omega)=(\mathcal{F}\tilde{h}_0(\omega)e^{r^-L},\mathcal{F}\tilde{h}_L(\omega)e^{-r^+L}).$$

Since $\tilde{h}_0$ and $\tilde{h}_L$ vanish in $\mathbb{R}_-$, their Fourier transforms are analytic in the half-plane $\Im\tau<0$, and by (3.9) and the Paley–Wiener theorem [37], $e_1(0,\cdot)$ and $e_2(L,\cdot)$ vanish in $\mathbb{R}_-$. Since they are in $H^{\frac{3}{4}}(\mathbb{R})$, they are continuous, and therefore $e_2(L,0)=0$ and $e_1(0,0)=0$: the map $\mathcal{G}_D$ maps $({}_0H^{\frac{3}{4}}(0,T))^2$ into itself. We have furthermore

$$\mathcal{F}(\mathcal{G}_D^2(\tilde{h}_L,\tilde{h}_0))(\omega)=e^{(r^--r^+)L}(\mathcal{F}\tilde{h}_0(\omega),\mathcal{F}\tilde{h}_L(\omega)). \tag{3.10}$$

Denoting by

$$C_D:=\sup_{\omega\in\mathbb{R}}e^{(r^--r^+)L}=e^{-\frac{L}{\nu}(\sqrt{a^2+4\nu b})}, \tag{3.11}$$

we get for any extension $(\tilde{h}_0, \tilde{h}_L)$ of (h_0, h_L)

$$\|\mathcal{G}_D^2(h_L, h_0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2} \le \|\mathcal{G}_D^2(\tilde{h}_L, \tilde{h}_0)\|_{(H^{\frac{3}{4}}(\mathbb{R}))^2} \le C_D \|(\tilde{h}_L, \tilde{h}_0)\|_{(H^{\frac{3}{4}}(\mathbb{R}))^2}.$$

Taking the infimum on all the extensions on the right-hand side, we get

$$\|\mathcal{G}_D^2(h_L, h_0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2} \le C_D \|(h_L, h_0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2},$$

and since C_D is positive and strictly less than 1, we have proved that $\mathcal{G}_D^2$ is a contraction. ∎

We now prove convergence of the overlapping Schwarz waveform relaxation algorithm.

THEOREM 3.3. *Let $L > 0$. For $a > 0$ or $a = 0$ and $b > 0$, the iterates (u_1^k, u_2^k) of algorithm (3.1) converge to the solution of (2.1), (2.3) for any initial guess g_0 and g_L in $H^{\frac{3}{4}}(0,T)$ such that $g_0(0) = u_0(0)$ and $g_L(0) = u_0(L)$.*

Proof. The errors $e_j^k = u_j^k - u$, $j = 1, 2$, satisfy for $k \ge 1$ (3.1) with $f = 0$ and $u_0 = 0$. For positive k, we introduce the interface functions $h_L^k = e_2^k(L, \cdot)$ and $h_0^k = e_1^k(0, \cdot)$ and denote by $h_0^0 = h_0$ and $h_L^0 = h_L$. Using the map $\mathcal{G}_D$, we obtain by induction

$$(h_L^{2k}, h_0^{2k}) = \mathcal{G}_D^{2k}(h_L^0, h_0^0),$$

and thus by Lemma 3.2

$$\|(h_L^{2k}, h_0^{2k})\|_{({}_0H^{\frac{3}{4}}(0,T))^2} \le C_D^k \|(h_L^0, h_0^0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2},$$

with C_D given in (3.11). Solving (3.5) and using (3.9), we obtain for e_1

$$\|e_1\|^2_{L^2(0,T;H^2(\Omega_1))} \le \int_{-\infty}^{\infty} |r^+|^4 \int_{\Omega_1} e^{2\Re(r^+)(x-L)} |\mathcal{F}\tilde{h}_L|^2 dx\, d\omega = \int_{-\infty}^{\infty} \frac{|r^+|^4}{2\Re(r^+)} |\mathcal{F}\tilde{h}_L|^2 d\omega.$$

For $a > 0$ or $a = 0$ and $b > 0$, the denominator in the factor in front of $|\mathcal{F}\tilde{h}_L|^2$ is bounded from below, and for $|\omega|$ large, the factor behaves like $|\omega|^{3/2}$. Therefore

$$\|e_1\|_{L^2(0,T;H^2(\Omega_1))} \le C \|\tilde{h}_L\|_{H^{\frac{3}{4}}(\mathbb{R})},$$

and the same result also holds for $\|e_1\|_{H^1(0,T;L^2(\Omega_1))}$. Hence

$$\|e_1\|_{H^{2,1}((\Omega_1)\times(0,T))} \le M_D \|h_L\|_{{}_0H^{\frac{3}{4}}(0,T)}, \tag{3.12}$$

and similarly for e_2. Now we apply (3.12) to the errors e_1^{2k+1} and e_2^{2k+1} in the iteration and obtain

$$\begin{aligned}&\|(e_1^{2k+1}, e_2^{2k+1})\|_{H^{2,1}(\Omega_1\times(0,T))\times H^{2,1}(\Omega_2\times(0,T))} \\ &\quad \le M_D \|(h_L^{2k}, h_0^{2k})\|_{({}_0H^{\frac{3}{4}}(0,T))^2} \le M_D C_D^k \|(g_L - u(L,\cdot), g_0 - u(0,\cdot))\|_{({}_0H^{\frac{3}{4}}(0,T))^2},\end{aligned}$$

which together with Lemma 3.2 completes the proof. A similar argument also holds for even iteration numbers. ∎

Theorem 3.3 shows that the overlapping Schwarz waveform relaxation algorithm converges and that the convergence rate is at least linear and is independent of the length of the time interval. It does however depend on the problem parameters ν,

a, and b and the overlap L. Using also the preceding Lemma 3.2, the error in the overlapping Schwarz waveform relaxation algorithm satisfies on the interfaces over a double iteration step in Fourier space relation (3.10) or equivalently

$$\hat{e}_1^{k+1}(L,\omega) = \rho_D \hat{e}_1^{k-1}(L,\omega), \quad \hat{e}_2^{k+1}(0,\omega) = \rho_D \hat{e}_2^{k-1}(0,\omega), \tag{3.13}$$

where the convergence factor $\rho_D = \rho_D(\omega, L, \nu, a, b)$ is given by

$$\rho_D(\omega, L, \nu, a, b) := e^{(r^- - r^+)L} = e^{-\frac{\sqrt{a^2+4\nu(b+i\omega)}}{\nu}L}. \tag{3.14}$$

Note that the convergence factor ρ_D is uniformly bounded in modulus for all ω by a quantity strictly less than 1,

(3.15)

$$R_D(\omega, L, \nu, a, b) := |\rho_D(\omega, L, \nu, a, b)| \le \bar{R}_D(L, \nu, a, b) := R_D(0, L, \nu, a, b) = e^{-\frac{\sqrt{a^2+4\nu b}}{\nu}L},$$

and for L small, we have

$$\bar{R}_D = 1 - \frac{\sqrt{a^2+4\nu b}}{\nu}L + O(L^2). \tag{3.16}$$

Using the convergence factor ρ_D from Fourier analysis allows us to obtain a sharper convergence result for bounded time intervals.

THEOREM 3.4 (superlinear convergence). *For the advection reaction diffusion equation on a bounded time interval $(0,T)$, the asymptotic convergence rate of the overlapping Schwarz waveform relaxation algorithm* (3.1) *is superlinear:*

$$||e_j^{2k}(0,\cdot)||_{L^\infty(0,T)} \le \operatorname{erfc}\left(\frac{kL}{\sqrt{\nu T}}\right) ||e_j^0(0,\cdot)||_{L^\infty(0,T)}, \quad j = 1,2,$$

where the error function complement is defined by $\operatorname{erfc}(x) := \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-s^2} ds$.

Proof. By induction on the relations (3.13), we obtain

$$\hat{e}_1^{2k}(0,\omega) = \rho_D^k \hat{e}_1^0(0,\omega), \qquad \hat{e}_2^{2k}(L,\omega) = \rho_D^k \hat{e}_2^0(L,\omega). \tag{3.17}$$

Using the inverse Fourier transform and the convolution theorem, we find

$$e_1^{2k}(0,t) = (\mathcal{F}^{-1}\rho_D^k) * e_1^0(0,t), \qquad e_2^{2k}(L,t) = (\mathcal{F}^{-1}\rho_D^k) * e_2^0(L,t). \tag{3.18}$$

Now the inverse Fourier transform of ρ_D^k is

$$\mathcal{F}^{-1}\rho_D^k = \frac{kL}{\sqrt{\nu\pi}t^{3/2}} e^{-\frac{(kL)^2}{\nu t} - \left(\frac{a^2}{4\nu}+b\right)t},$$

and we can therefore estimate for $j = 1, 2$

$$\|e_j^{2k}(0,\cdot)\|_{L^\infty(0,T)} \le \|\mathcal{F}^{-1}\rho_D^k\|_{L^1(0,T)} \|e_j^0(0,\cdot)\|_{L^\infty(0,T)} \le \operatorname{erfc}\left(\frac{kL}{\sqrt{\nu T}}\right) \|e_j^0(0,\cdot)\|_{L^\infty(0,T)},$$

where the last inequality follows from estimating the term $e^{-(\frac{a^2}{4\nu}+b)t}$ by 1. By a similar argument for the second subdomain, the result follows. ∎

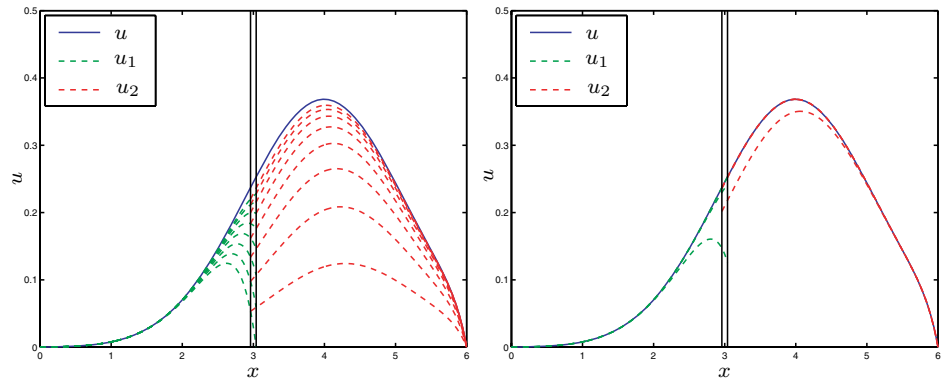

FIG. 3.1. *On the left, the first few iterates of the classical Schwarz waveform relaxation algorithm (dashed) at the end of the time interval $t = T$, together with the exact solution (solid), and on the right the first iterates of the new optimized Schwarz waveform relaxation algorithm.*

This result was first proved for bounded domains in [18], see also [15]. It also holds in higher dimensions and for general decompositions, for the heat equation, see [14], and for advection diffusion, see [5]. The result differs significantly from the classical linear convergence result of the overlapping Schwarz method for elliptic problems and also from the classical superlinear convergence results for waveform relaxation, which is slower, see [35]. Furthermore, one can show that the convergence rate depends only on the number of subdomains in higher order terms, see [15], and hence coarse grid preconditioners are not necessary for evolution problems of this type.

The Dirichlet transmission conditions at the interfaces are however responsible for slow convergence in the classical Schwarz waveform relaxation algorithm: in Figure 3.1 on the left, we show the first few iterations at the end of the time interval for a model problem. On the right, we show the first few iterations of the new, much faster algorithm we will develop in what follows.

4. Optimal Schwarz waveform relaxation. We now introduce transmission conditions which are more effective for the information exchange between subdomains. The new algorithm is

(4.1)
$$\begin{aligned} \mathcal{L}u_1^k &= f \quad \text{in } \Omega_1 \times (0,T), & \mathcal{L}u_2^k &= f \quad \text{in } \Omega_2 \times (0,T), \\ u_1^k(\cdot,0) &= u_0, & u_2^k(\cdot,0) &= u_0, \\ (\partial_x + \mathcal{S}_1)u_1^k(L,\cdot) &= (\partial_x + \mathcal{S}_1)u_2^{k-1}(L,\cdot), & (\partial_x + \mathcal{S}_2)u_2^k(0,\cdot) &= (\partial_x + \mathcal{S}_2)u_1^{k-1}(0,\cdot), \end{aligned}$$

where $\mathcal{S}_1$ and $\mathcal{S}_2$ are linear operators in time, possibly pseudodifferential.

4.1. Optimal transmission conditions. The following theorem gives the optimal choice for $\mathcal{S}_1$ and $\mathcal{S}_2$.

THEOREM 4.1. *For $a > 0$ or $a = 0$ and $b > 0$, algorithm (4.1) converges to the solution u of (2.1) in two iterations for all initial guesses $u_1^0 \in H^{2,1}(\Omega_1 \times (0,T))$ and $u_2^0 \in H^{2,1}(\Omega_2 \times (0,T))$, independently of the size of the overlap $L \geq 0$, if and only if the operators $\mathcal{S}_1$ and $\mathcal{S}_2$ have the corresponding symbols*

(4.2)
$$\sigma_1 = -r^-, \quad \sigma_2 = -r^+,$$

where $r^\pm$ are defined in (3.8).

Proof. Using the Fourier transform with parameter ω as in Lemma 3.2, we find for the error

$$\hat{e}_1^k(x,\omega) = \alpha^k(\omega)e^{r^+(x-L)}, \quad \hat{e}_2^k(x,\omega) = \beta^k(\omega)e^{r^-x}, \quad k \geq 1, \tag{4.3}$$

where α^k and β^k are constants, which, using the new transmission conditions, satisfy for $k \geq 1$ the recurrence relation

$$\begin{aligned} \alpha^{k+1}(r^+ + \sigma_1) &= \beta^k(r^- + \sigma_1)e^{r^-L}, \\ \beta^{k+1}(r^- + \sigma_2) &= \alpha^k(r^+ + \sigma_2)e^{-r^+L}. \end{aligned} \tag{4.4}$$

Now for an arbitrary initial guess u_1^0 and u_2^0, the coefficients α^1 and β^1 will in general not vanish. Since $r^- + \sigma_1 = r^+ + \sigma_2 = 0$ implies $r^+ + \sigma_1 \neq 0$ and $r^- + \sigma_2 \neq 0$, we obtain from (4.4) that α^2 and β^2 are identically zero if and only if $r^- + \sigma_1 = r^+ + \sigma_2 = 0$. ∎

Note that the symbols σ_1, σ_2 given in (4.2) are not polynomials in $i\omega$, and hence the optimal corresponding transmission operators $\mathcal{S}_1$, $\mathcal{S}_2$ are nonlocal operators in time; they correspond to integral transfer operators in time along the interfaces between subdomains. Even though such operators can be efficiently implemented, see, for example, [30], they are more costly than local transfer operators and the latter are in general preferred. It is therefore of interest to approximate the nonlocal operators by local ones, whose symbols are polynomials in $i\omega$. Using each equation in (4.4) at iteration k in the other one at iteration $k+1$, we find

$$\alpha^{k+1} = \rho\alpha^{k-1}, \quad \beta^{k+1} = \rho\beta^{k-1}$$

with the new convergence factor

$$\rho = \frac{r^- + \sigma_1}{r^+ + \sigma_1} \cdot \frac{r^+ + \sigma_2}{r^- + \sigma_2} e^{(r^- - r^+)L}. \tag{4.5}$$

4.2. Approximations of the optimal transmission conditions. We approximate the symbols σ_1 and σ_2 from (4.2) corresponding to the optimal transmission operators by constants, which leads to Robin transmission conditions in the Schwarz waveform relaxation algorithm (4.1), i.e.,

$$\mathcal{S}_1 := \frac{-a+p}{2\nu}, \qquad \mathcal{S}_2 := \frac{-a-p}{2\nu}. \tag{4.6}$$

The choice of the parameter p is restricted by the requirement that the subdomain problems need to be well posed, and a good choice should lead to a rapidly converging algorithm; both issues we will analyze in detail in the following section.

Notice that using the knowledge of the symbols (4.2) of the optimal transmission conditions, we have chosen a particular form for the low order approximation, leading to (4.6). In general one is not required to do so; in particular, we could have chosen, for example, two different parameters p in (4.6), which would have given more freedom in the optimization process we study later, or even chosen a different p at each iteration, as it was done for a steady problem in [9]. One could also choose higher order transmission conditions, i.e., approximations by polynomials in $i\omega$. Having one parameter only however greatly simplifies the optimization process, so we leave the more general cases for future studies.

5. Optimized Schwarz waveform relaxation. We now study the Schwarz waveform relaxation algorithm with Robin transmission conditions. We start with the overlapping case, $L > 0$. We first show under what conditions on the free parameter p the algorithm is well posed and then prove convergence of the algorithm for a general choice of p satisfying these conditions. We also study the influence of p on the performance of the algorithm and propose two choices for p: one choice motivated by a low frequency approximation and a second choice which optimizes the performance of the algorithm. We then prove that the algorithm converges also without overlap, and we again study the influence of p on the performance of the nonoverlapping algorithm.

5.1. Well posedness of the algorithm. As in the case of the classical Schwarz waveform relaxation algorithm studied in section 3, we first need to analyze under which conditions the subdomain problems of the algorithm with Robin transmission conditions is well posed. Without loss of generality, we study only the well posedness of the subdomain problem on Ω_1:

$$\begin{aligned} \mathcal{L}v &= f && \text{in } \Omega_1 \times (0,T), \\ v(\cdot,0) &= u_0 && \text{in } \Omega_1, \\ (\partial_x v + \mathcal{S}_1 v)(L,\cdot) &= g_L && \text{in } (0,T). \end{aligned} \tag{5.1}$$

We first show an extension result, which allows us to reduce the study of the well posedness to the case with homogeneous initial and boundary conditions.

LEMMA 5.1. *If u_0 is in $H^1(\Omega_1)$ and g_L is in $H^{\frac{1}{4}}(0,T)$, then there exists an extension w in $H^{2,1}(\Omega_1 \times (0,T))$ such that $w(\cdot,0) = u_0$ in Ω_1 and $(\partial_x w + \mathcal{S}_1 w)(L,\cdot) = g_L$ on $(0,T)$.*

Proof. Let $\tilde{g}_L$ be in $H^{\frac{3}{4}}(0,T)$ such that $\tilde{g}_L(0) = u_0(L)$. By the continuous extension theorem, there exists a w_1 in $H^{2,1}(\Omega \times (0,T))$ such that

$$w_1(\cdot,0) = u_0, \quad w_1(L,\cdot) = \tilde{g}_L, \quad \partial_x w_1(L,\cdot) = 0$$

and a w_2 in $H^{2,1}(\Omega \times (0,T))$ such that

$$w_2(\cdot,0) = 0, \quad w_2(L,\cdot) = 0, \quad \partial_x w_2(L,\cdot) = g_L - \mathcal{S}_1 \tilde{g}_L.$$

Now the sum $w := w_1 + w_2$ is the desired extension in $H^{2,1}(\Omega \times (0,T))$. ∎

Thus it suffices to analyze the well posedness of the problem with homogeneous initial and boundary conditions:

$$\begin{aligned} \mathcal{L}\tilde{v} &= F && \text{in } \Omega_1 \times (0,T), \\ \tilde{v}(\cdot,0) &= 0 && \text{in } \Omega_1, \\ (\partial_x \tilde{v} + \mathcal{S}_1 \tilde{v})(L,\cdot) &= 0 && \text{in } (0,T), \end{aligned} \tag{5.2}$$

where $\tilde{v} = v - w$ and the right-hand side function $F = f - \mathcal{L}w$ is in $L^2(0,T;L^2(\Omega_1))$ if f is in $L^2(0,T;L^2(\Omega_1))$. We start with the weak formulation: for any φ in $H^1(\Omega_1)$, we multiply the equation by φ, integrate, and use Green's formula and the boundary condition to obtain in $\mathcal{D}'(0,T)$

$$\frac{d}{dt}(\tilde{v},\varphi) + \nu(\partial_x \tilde{v}, \partial_x \varphi) + \frac{a}{2}((\partial_x \tilde{v},\varphi) - (\partial_x \varphi,\tilde{v})) + b(\tilde{v},\varphi) + \frac{p}{2}\tilde{v}(L)\varphi(L) = (F,\varphi). \tag{5.3}$$

The following Theorem gives existence, uniqueness, and regularity of the weak solution.

THEOREM 5.2. *Suppose F is in $L^2(0,T;L^2(\Omega_1))$. Then, for any p, problem* (5.2) *has a unique weak solution $\tilde{v}$ in $H^{2,1}(\Omega_1 \times (0,T))$.*

Proof. The proof is based on a priori estimates.

1. Multiplying equation (5.2) by $\tilde{v}$, integrating in space, and using the boundary condition, we obtain

$$\frac{1}{2}\frac{d}{dt}\|\tilde{v}\|^2 + \nu\|\partial_x\tilde{v}\|^2 + b\|\tilde{v}\|^2 + \frac{p}{2}\tilde{v}^2(L) = (F,\tilde{v}). \tag{5.4}$$

(a) Suppose first $p \geq 0$.

- If $b > 0$, by the Cauchy–Schwarz inequality, and using the inequality

$$\alpha\beta \leq \frac{\eta}{2}\,\alpha^2 + \frac{1}{2\eta}\,\beta^2 \quad \text{for all } \alpha,\beta \in \mathbb{R} \text{ and } \eta > 0 \tag{5.5}$$

in the form $||F||\,||\tilde{v}|| \leq \frac{1}{2b}||F||^2 + \frac{b}{2}||\tilde{v}||^2$, we obtain

$$\frac{1}{2}\frac{d}{dt}\|\tilde{v}\|^2 + \nu\|\partial_x\tilde{v}\|^2 + \frac{b}{2}\|\tilde{v}\|^2 \leq \frac{1}{2b}\|F\|^2,$$

which gives, after integration on any time interval $(0,t)$,

$$\frac{1}{2}||\tilde{v}||^2(t) + \nu\int_0^t ||\partial_x\tilde{v}||^2 + \frac{b}{2}\int_0^t ||\tilde{v}||^2 \leq \frac{1}{2b}\int_0^t ||F||^2. \tag{5.6}$$

- If $b = 0$, we use (5.5) with $\eta = 1$ and get through integration on $(0,t)$

$$\frac{1}{2}\|\tilde{v}\|^2(t) + \nu\int_0^t \|\partial_x\tilde{v}\|^2 \leq \frac{1}{2}\|F\|^2_{L^2(0,T;L^2(\Omega_1))} + \frac{1}{2}\int_0^t \|\tilde{v}\|^2.$$

We then apply the Gronwall lemma and obtain

$$\|\tilde{v}\|^2(t) + 2\nu\int_0^t \|\partial_x\tilde{v}\|^2 \leq e^T\|F\|^2_{L^2(0,T;L^2(\Omega_1)}.$$

(b) Suppose now $p < 0$. We move the boundary term in (5.4) to the right-hand side; using the Sobolev inequality in $H^1(\Omega_1)$,

$$\|\tilde{v}\|^2_{L^\infty(\overline{\Omega_1})} \leq 2\|\partial_x\tilde{v}\|\,\|\tilde{v}\|, \tag{5.7}$$

we bound the boundary term, applying again (5.5),

$$-\frac{p}{2}\tilde{v}^2(L) \leq \frac{\nu}{2}\|\partial_x\tilde{v}\|^2 + \frac{p^2}{2\nu}\|\tilde{v}\|^2;$$

and we conclude using the Gronwall lemma as before.

Thus, in both cases, we have a bound for $\tilde{v}$ in $L^\infty(0,T;L^2(\Omega_1)) \cap L^2(0,T;H^1(\Omega_1))$,

$$\|\tilde{v}\|_{L^\infty(0,T;L^2(\Omega_1))}, \|\tilde{v}\|_{L^2(0,T;H^1(\Omega_1))} \leq C(T)\|F\|_{L^2(0,T;L^2(\Omega_1))}. \tag{5.8}$$

2. To obtain the higher regularity result in the theorem, we need to show that $\partial_x^2\tilde{v}$ and $\partial_t\tilde{v}$ are also in $L^2(0,T;L^2(\Omega_1))$. Multiplying the equation by $-\partial_x^2\tilde{v}$ and integrating in space, we get

$$\frac{1}{2}\frac{d}{dt}||\partial_x\tilde{v}||^2+\nu||\partial_x^2\tilde{v}||^2+b||\partial_x\tilde{v}||^2 - \left((\partial_t\tilde{v})\partial_x\tilde{v}+\frac{a}{2}(\partial_x\tilde{v})^2+b(\partial_x\tilde{v})\tilde{v}\right)(L)=-\int_{-\infty}^{L}F\partial_x^2\tilde{v}.$$

Now using the boundary condition to replace $\partial_x\tilde{v}$, we obtain

$$\frac{d}{dt}\left(\frac{1}{2}\|\partial_x\tilde{v}\|^2+\frac{p-a}{4\nu}\tilde{v}^2(L)\right)+\nu\|\partial_x^2\tilde{v}\|^2+b\|\partial_x\tilde{v}\|^2 +\frac{p-a}{2\nu}\left(b-\frac{a}{2}\frac{p-a}{2\nu}\right)\tilde{v}^2(L)=-\int_{-\infty}^{L}F\partial_x^2\tilde{v}.$$

Again using the Cauchy–Schwarz inequality and (5.5) on the right, we find after integrating in time

$$\left(\frac{1}{2}\|\partial_x\tilde{v}\|^2+\frac{p-a}{4\nu}\tilde{v}^2(L)\right)(t)+\frac{\nu}{2}\int_0^t\|\partial_x^2\tilde{v}\|^2+b\int_0^t\|\partial_x\tilde{v}\|^2 +\frac{p-a}{2\nu}\left(b-\frac{a}{2}\frac{p-a}{2\nu}\right)\int_0^t\tilde{v}^2(L)\le\frac{1}{2\nu}\int_0^t||F||^2. \tag{5.9}$$

First the term $\frac{p-a}{2\nu}\left(b-\frac{a}{2}\frac{p-a}{2\nu}\right)\int_0^t\tilde{v}^2(L)$ is handled as in 1, using (5.7) and (5.8). Then, if $p\ge a$, we obtain

$$\|\partial_x\tilde{v}\|^2+\nu\|\partial_x^2\tilde{v}\|_{L^2(0,T;L^2(\Omega_1))}\le C(T)\|F\|_{L^2(0,T;L^2(\Omega_1))}.$$

If $p<a$, then we pass the term containing $\tilde{v}(L)$ to the right-hand side, and using (5.7), we obtain

$$\frac{1}{2}\|\partial_x\tilde{v}\|^2+\frac{\nu}{2}\int_0^t\|\partial_x^2\tilde{v}\|^2\le\frac{a-p}{4\nu}\left(\alpha||\partial_x\tilde{v}||^2+\frac{1}{\alpha}||\tilde{v}||^2\right)+C(T)\int_0^t||F||^2.$$

Now choosing $\alpha=\nu/(a-p)$ and using (5.8), we obtain

$$\|\partial_x\tilde{v}\|_{L^\infty(0,T;L^2(\Omega_1))},\|\partial_x^2\tilde{v}\|_{L^2(0,T;L^2(\Omega_1))}\le C(T)\|F\|_{L^2(0,T;L^2(\Omega_1))},$$

where we omit the dependence of the constant C on a, p, b, and ν.

Now using (5.2), we have

$$\partial_t\tilde{v}=\nu\partial_x^2\tilde{v}-a\partial_x\tilde{v}-b\tilde{v}+F,$$

and since all the terms on the right-hand side are in $L^2(0,T;L^2(\Omega_1))$ by the previous estimates, it follows that $\partial_t\tilde{v}$ is in $L^2(0,T;L^2(\Omega_1))$, which concludes the a priori estimates in $H^{2,1}(\Omega_1\times(0,T))$. Existence and uniqueness can now be shown using a Galerkin method [27]. □

Using Lemma 5.1 and Theorem 5.2, we obtain now the well posedness of the subdomain problems.

THEOREM 5.3. *If f is in $L^2(0,T;L^2(\Omega_1))$, u_0 is in $H^1(\Omega_1)$, and g_L is in $H^{\frac{1}{4}}(0,T)$, then, for any p, problem* (5.1) *has a unique solution v in $H^{2,1}(\Omega_1\times(0,T))$.*

The same result also holds on subdomain Ω_2, the only difference being that $-a$ becomes $+a$ in the estimate (5.9).

THEOREM 5.4. *Let g_L and g_0 be given in $H^{\frac{1}{4}}(0,T)$. If algorithm* (4.1) *with $\mathcal{S}_j$ defined in* (4.6) *is initialized by $(\partial_x u_1^1 + \mathcal{S}_1 u_1^1)(L,\cdot) = g_L$ and $(\partial_x u_2^1 + \mathcal{S}_2 u_2^1)(0,\cdot) = g_0$, then, for any p,* (4.1) and (4.6) *define a sequence of iterates (u_1^k, u_2^k) in $H^{2,1}(\Omega_1 \times (0,T)) \times H^{2,1}(\Omega_2 \times (0,T))$.*

Proof. The proof is done by induction: for $k = 1$, (4.1) defines a unique first iterate (u_1^1, u_2^1) in $H^{2,1}(\Omega_1 \times (0,T)) \times H^{2,1}(\Omega_2 \times (0,T))$ by Theorem 5.3. Assuming now that (u_1^k, u_2^k) is in $H^{2,1}(\Omega_1 \times (0,T)) \times H^{2,1}(\Omega_2 \times (0,T))$, by the trace theorem, we have that $(\partial_x u_2^k + \mathcal{S}_1 u_2^k)(L,\cdot)$ and $(\partial_x u_1^k + \mathcal{S}_2 u_1^k)(0,\cdot)$ are in $H^{\frac{1}{4}}(0,T)$, and thus by Theorem 5.3, (u_1^{k+1}, u_2^{k+1}) must be in $H^{2,1}(\Omega_1 \times (0,T)) \times H^{2,1}(\Omega_2 \times (0,T))$, which concludes the proof. ∎

For the proof of convergence in the overlapping case, we need however more regularity.

THEOREM 5.5. *For $a > 0$ or $a = 0$ and $b > 0$, let $p \geq 0$ and f be in $H^{1,\frac{1}{2}}(\Omega_1 \times (0,T))$, u_0 be in $H^2(\Omega)$, and g_L be in $H^{\frac{3}{4}}(0,T)$, with the compatibility conditions*

$$g_L(0) = \partial_x u_0(L) + \mathcal{S}_1 u_0(L). \tag{5.10}$$

Then the solution v of the subdomain problem (5.1) *is in $H^{3,\frac{3}{2}}(\Omega_1 \times (0,T))$. Furthermore the following compatibility property at $x = 0$ is satisfied:*

$$\lim_{t \to 0+} (\partial_x v + \mathcal{S}_2 v)(0,t) = \partial_x u_0(0) + \mathcal{S}_2 u_0(0). \tag{5.11}$$

Proof. In this more regular situation, the solution u of (2.1) is in $H^{3,\frac{3}{2}}(\Omega \times (0,T))$ by Theorem 2.2. Furthermore $\tilde{g}_L = (\partial_x u + \mathcal{S}_1 u)(L,\cdot)$ is in $H^{\frac{3}{4}}(0,T)$. Subtracting u from v, the difference e is in $H^{3,\frac{3}{2}}(\Omega_1 \times (0,T))$, the solution of (5.1) with data $(0,0,h_L = g_L - \tilde{g}_L)$. By Fourier transform, the same calculation as in Lemma 3.2 gives with $\tilde{h}_L$ being an extension of h_L on $\mathbb{R}$ vanishing in $\mathbb{R}_-$

$$\hat{e} = \frac{2\nu}{\sqrt{d} + p} \mathcal{F}\tilde{h}_L(\omega) e^{r^+(x-L)}. \tag{5.12}$$

The norm of $\partial_x^3 e$ is therefore given by

$$\|\partial_x^3 e\|^2_{L^2(\Omega_1 \times \mathbb{R})} = \int_{\mathbb{R}} \frac{4\nu^2 |r^+|^6}{2\Re r^+ |\sqrt{d} + p|^2} |\mathcal{F}\tilde{h}_L(\omega)|^2 d\omega,$$

and the norm of e in $H^{\frac{3}{2}}(\mathbb{R}, L^2(\Omega_1))$ is

$$\|e\|^2_{H^{3/2}(\mathbb{R}, L^2(\Omega_1))} = \int_{\mathbb{R}} \frac{4\nu^2 (1+\omega^2)^{3/2}}{2\Re r^+ |\sqrt{d} + p|^2} |\mathcal{F}\tilde{h}_L(\omega)|^2 d\omega.$$

In both cases, for $a > 0$ or $a = 0$ and $b > 0$, and $p \geq 0$, the denominator in the factor in front of $|\mathcal{F}\tilde{h}_L(\omega)|^2$ is bounded from below, and it is easy to see that for large $|\omega|$, it is equivalent to a constant times $|\omega|^{3/2}$. Therefore we have the bound

$$\|e\|_{H^{3,\frac{3}{2}}(\Omega_1 \times (0,T))} \leq C \|\tilde{h}_L\|_{H^{\frac{3}{4}}(\mathbb{R})}. \tag{5.13}$$

For the compatibility condition, since $\tilde{h}_L$ vanishes in $\mathbb{R}_-$, its Fourier transform is analytic in the half-plane $\Im\tau < 0$, and by (5.12) and the Paley–Wiener theorem [37],

$e(0,\cdot)$ and $\partial_x e(0,\cdot)$ vanish in $\mathbb{R}_-$. Since they are in $H^{\frac{5}{4}}(\mathbb{R})$ and $H^{\frac{3}{4}}(\mathbb{R})$, respectively, they are continuous, and therefore $\lim_{t\to 0+}(\partial_x e + \mathcal{S}_2 e)(0,t) = 0$, which gives the compatibility property for v. ∎

This regularity result shows the well posedness of the algorithm in $H^{3,\frac{3}{2}}(\Omega_1 \times (0,T))$.

THEOREM 5.6. *For $a > 0$ or $a = 0$ and $b > 0$, and $p \geq 0$, let f be in $H^{1,\frac{1}{2}}(\Omega_1 \times (0,T))$, u_0 be in $H^2(\Omega)$, and g_L and g_0 be in $H^{\frac{3}{4}}(0,T)$, with the compatibility conditions*

$$g_L(0) = \partial_x u_0(L) + \mathcal{S}_1 u_0(L), \qquad g_0(L) = \partial_x u_0(0) + \mathcal{S}_2 u_0(0). \tag{5.14}$$

Then, algorithm (4.1) *with transmission operators* (4.6) *defines a sequence of iterates (u_1^k, u_2^k) in $H^{3,\frac{3}{2}}(\Omega_1 \times (0,T)) \times H^{3,\frac{3}{2}}(\Omega_2 \times (0,T))$.*

5.2. Convergence of the overlapping algorithm. Let h_L and h_0 be given in ${}_0H^{\frac{3}{4}}(0,T)$. Let (e_1, e_2) be the solution in $H^{3,\frac{3}{2}}(\Omega_1 \times (0,T)) \times H^{3,\frac{3}{2}}(\Omega_2 \times (0,T))$ of the problem

$$\begin{aligned} \mathcal{L}e_1 &= 0 \quad \text{in } \Omega_1 \times (0,T), & \mathcal{L}e_2 &= 0 \quad \text{in } \Omega_2 \times (0,T), \\ e_1(\cdot,0) &= 0 \quad \text{in } \Omega_1, & e_2(\cdot,0) &= 0 \quad \text{in } \Omega_2, \\ (\partial_x e_1 + \mathcal{S}_1 e_1)(L,\cdot) &= h_L \text{ in } (0,T), & (\partial_x e_2 + \mathcal{S}_2 e_2)(0,\cdot) &= h_0 \text{ in } (0,T). \end{aligned} \tag{5.15}$$

LEMMA 5.7. *For $a > 0$ or $a = 0$ and $b > 0$, if $p \geq 0$ and $L > 0$, the map $\mathcal{G}_0$ associated with* (5.15),

$$\mathcal{G}_0 : (h_L, h_0) \mapsto ((\partial_x e_2 + \mathcal{S}_1 e_2)(L,\cdot), (\partial_x e_1 + \mathcal{S}_2 e_1)(0,\cdot)), \tag{5.16}$$

is defined from $({}_0H^{\frac{3}{4}}(0,T))^2$ into itself, and $\mathcal{G}_0^2$ is strictly contracting.

Proof. The proof is analogous to the proof of Lemma 3.2 using Fourier analysis. Defining $\tilde{h}_L$ and $\tilde{h}_0$ as any extensions of h_L and h_0 in $H^{\frac{3}{4}}(\mathbb{R})$, vanishing in $\mathbb{R}^-$, we obtain after a short calculation

$$\mathcal{F}(\mathcal{G}_0^2(\tilde{h}_L, \tilde{h}_0))(\omega) = \left(\frac{\sqrt{d} - p}{\sqrt{d} + p}\right)^2 (\mathcal{F}\tilde{h}_0(\omega) e^{(r^- - r^+)L}, \mathcal{F}\tilde{h}_L(\omega) e^{(r^- - r^+)L}),$$

where d and $r^\pm$ are defined in (3.8). Since $p \geq 0$, we have $\left|\frac{\sqrt{d}-p}{\sqrt{d}+p}\right| \leq 1$ and thus

$$\|\mathcal{G}_0^2(h_L, h_0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2} \leq C_D \|(h_L, h_0)\|_{({}_0H^{\frac{3}{4}}(0,T))^2},$$

and since C_D defined in (3.11) satisfies $C_D < 1$, the result follows. ∎

From the proof of this Lemma, we can see that the contraction of the overlapping Schwarz waveform relaxation map with Robin transmission conditions, $\mathcal{G}_0$ given in (5.16), is at least as good as the contraction of the classical map with Dirichlet transmission conditions, $\mathcal{G}_D$ given in (3.6), no matter what one chooses for the parameter $p \geq 0$ in the Robin transmission conditions. Before doing a more thorough comparison, we use the contraction property from Lemma 5.7 to prove convergence of the new algorithm.

THEOREM 5.8. *Let f be in $H^{1,\frac{1}{2}}(\Omega_1 \times (0,T))$ and u_0 be in $H^2(\Omega)$. For $a > 0$ or $a = 0$ and $b > 0$, if $p \geq 0$ and $L > 0$, then the solution (u_1^k, u_2^k) of algorithm* (4.1), (4.6) *converges to the solution u of* (2.1) *for any initial guess $(g_0, g_L) \in (H^{\frac{3}{4}}(0,T))^2$ with the compatibility conditions* (5.14).

Proof. The errors $e_j^k = u_j^k - u$, $j = 1, 2$, satisfy for $k \geq 1$ (4.1) with $f = 0$ and $u_0 = 0$. Introducing the interface functions $h_L^k = (\partial_x e_2^k + \mathcal{S}_1 e_2^k)(L, \cdot)$, $h_0^k = (\partial_x e_1^k + \mathcal{S}_2 e_1^k)(0, \cdot)$ and using the map $\mathcal{G}_0$, we obtain by induction $(h_L^{2k}, h_0^{2k}) = \mathcal{G}_0^{2k}(h_L^0, h_0^0)$, and thus by Lemma 5.7

$$\|(h_L^{2k}, h_0^{2k})\|_{(H^{\frac{3}{4}}(0,T))^2} \leq C_D^k \|(h_L^0, h_0^0)\|_{(H^{\frac{3}{4}}(0,T))^2}.$$

We have by (5.13)

$$\begin{aligned}\|(e_1^{2k+1}, e_2^{2k+1})\|_{H^{3,\frac{3}{2}}(\Omega_1\times(0,T))\times H^{3,\frac{3}{2}}(\Omega_2\times(0,T))} &\leq C\|(h_L^{2k}, h_0^{2k})\|_{(H^{\frac{3}{4}}(0,T))^2} \\ &\leq CC_D^k \|(h_L^0, h_0^0)\|_{(H^{\frac{3}{4}}(0,T))^2},\end{aligned}$$

which together with Lemma 5.7 completes the proof. ∎

Having proved convergence, we now compare the performance of the classical Schwarz waveform relaxation algorithm and the new one with Robin transmission conditions. We do this first at the continuous level, which motivates the optimization procedure we introduce in subsections 5.4 and 5.7 for the discretized case. Using Theorem 5.8 and Lemma 5.7, the error in the overlapping Schwarz waveform relaxation algorithm with Robin transmission conditions satisfies on the interfaces over a double iteration step in Fourier the relation

$$\mathcal{F}(\mathcal{G}_0^2(\tilde{h}_L, \tilde{h}_0))(\omega) = \left(\frac{\sqrt{d} - p}{\sqrt{d} + p}\right)^2 e^{(r^- - r^+)L}(\mathcal{F}\tilde{h}_L(\omega), \mathcal{F}\tilde{h}_0(\omega)),$$

where d, r^-, and r^+ are defined in (3.8). Equivalently, we have

$$\hat{e}_1^{k+1}(L, \omega) = \rho_0 \hat{e}_1^{k-1}(L, \omega), \quad \hat{e}_2^{k+1}(0, \omega) = \rho_0 \hat{e}_2^{k-1}(0, \omega), \tag{5.17}$$

where the convergence factor $\rho_0 = \rho_0(\omega, p, L, \nu, a, b)$ of the new algorithm with Robin transmission conditions is given by

$$\rho_0(\omega, p, L, \nu, a, b) := \left(\frac{\sqrt{a^2 + 4\nu(b + i\omega)} - p}{\sqrt{a^2 + 4\nu(b + i\omega)} + p}\right)^2 e^{-\frac{\sqrt{a^2+4\nu(b+i\omega)}}{\nu} L}. \tag{5.18}$$

For any frequency ω, we can therefore directly compare the performance of the classical Schwarz waveform relaxation algorithm with the new one with Robin transmission conditions: we have $\rho_0 = (\frac{\sqrt{d}-p}{\sqrt{d}+p})^2 \rho_D$, where ρ_D is the classical convergence factor defined in (3.14). This shows that for each ω we have $|\rho_0| < |\rho_D|$ for $p > 0$. Furthermore, for any $\epsilon > 0$ there exists an ω_ϵ such that

$$\int_{|\omega|>\omega_\epsilon} (1 + \omega^2)^{3/4} |\hat{e}_1^0(L, \omega)|^2 d\omega \leq \epsilon$$

because we assume that $e_1^0(L, \cdot)$ is in $H^{\frac{3}{4}}$. Since $|\rho_0| < 1$, we obtain

$$\|\hat{e}_1^{2k}(L, \cdot)\|^2_{H^{\frac{3}{4}}(0,T)} \leq \epsilon + \int_{|\omega|\leq\omega_\epsilon} (1 + \omega^2)^{\frac{3}{4}} |\rho_0(\omega, p, L, \nu, a, b)|^{2k} |\hat{e}_1^0(L, \omega)|^2 d\omega,$$

and taking the supremum of the convergence factor out of the integral, we have

$$\|\hat{e}_1^{2k}(L, \cdot)\|^2_{H^{\frac{3}{4}}(0,T)} \leq \epsilon + \sup_{|\omega|\leq\omega_\epsilon} |\rho_0(\omega, p, L, \nu, a, b)|^{2k} \|\hat{e}_1^0(L, \cdot)\|^2_{H^{\frac{3}{4}}(0,T)}.$$

A similar estimate for the classical algorithm gives

$$\|\hat{e}_1^{2k}(L,\cdot)\|^2_{H^{\frac{3}{4}}(0,T)} \leq \epsilon + \sup_{|\omega|\leq\omega_\epsilon} |\rho_D(\omega,L,\nu,a,b)|^{2k} \|\hat{e}_1^0(L,\cdot)\|^2_{H^{\frac{3}{4}}(0,T)},$$

which shows that improving the convergence factor on a sufficiently large bounded frequency range improves the overall convergence of the algorithm. The choice of a bounded frequency range is further motivated by the fact that computations are performed on a discretized problem, whose grid cannot carry arbitrarily high frequencies. We carefully analyze how to chose the free parameter p for optimal performance of the algorithm in the next subsections.

5.3. Low frequency approximation for the algorithm with overlap. We have seen that the convergence factor of the new algorithm with Robin transmission conditions is given by (5.18), and any choice of the free parameter $p \geq 0$ is admissible to obtain a well posed algorithm. But how should p be chosen, apart from $p \geq 0$? A simple choice is to use a low frequency approximation of the symbols σ_j, $j = 1, 2$, of the optimal transmission operators given in (4.2), based on a Taylor expansion about $\omega = 0$. This is motivated by the fact that with overlap, $L > 0$, the exponential term in the convergence factor (5.18) is exponentially small for ω large, and hence p should be used to make the transmission conditions effective for ω small. Using a Taylor expansion of the square root $\sqrt{a^2 + 4\nu(b + i\omega)}$ in (4.2) about $\omega = 0$, we find

$$\sqrt{a^2 + 4\nu(b + i\omega)} = \sqrt{a^2 + 4\nu b} + \frac{2\nu}{\sqrt{a^2 + 4\nu b}} i\omega + O(\omega^2), \tag{5.19}$$

and hence the low frequency approximation choice for p in the Robin transmission condition is

$$p = p_T := \sqrt{a^2 + 4\nu b}. \tag{5.20}$$

With this choice, the convergence factor vanishes for $\omega = 0$ and also when ω goes to infinity, since $L > 0$. To further analyze the convergence factor, we introduce a change of variables based on the real part of the square root in the convergence factor (5.18),

$$x := \Re(\sqrt{a^2 + 4\nu(b + i\omega)}). \tag{5.21}$$

In this new variable, the convergence factor (5.18) in modulus becomes

$$R_0(x, p, x_0, L) := |\rho_0| = \frac{(x-p)^2 + x^2 - x_0^2}{(x+p)^2 + x^2 - x_0^2} e^{-\frac{Lx}{\nu}}, \tag{5.22}$$

where $x_0^2 := a^2 + 4\nu b$. Note that $R_0 \geq 0$ by definition, which can also be seen from $x^2 \geq a^2 + 4\nu b = x_0^2$ from the change of variables (5.21). Using now the parameter p_T from the Taylor expansion, we find for the Taylor–Robin method (T0 for Taylor of order 0) the convergence factor in modulus to be

$$R_{T0}(x, x_0, L) := R_0(x, p_T, x_0, L) = \frac{x - x_0}{x + x_0} e^{-\frac{Lx}{\nu}} \geq 0, \qquad x \geq x_0. \tag{5.23}$$

THEOREM 5.9 (T0 performance with overlap). *Let $L > 0$ and $x_0 := \sqrt{a^2 + 4\nu b}$. The convergence factor R_{T0} in* (5.23) *of the overlapping Schwarz waveform relaxation*

algorithm with Robin transmission conditions (4.1),(4.6) *and* $p = p_T$ *from the Taylor low frequency approximation* (5.20) *is for* $x_0 \le x < \infty$ *uniformly bounded by*

(5.24)
$$R_{T0}(x, x_0, L) \le \bar{R}_{T0}(x_0, L) := R_{T0}(\bar{x}, x_0, L) = \frac{\bar{x} - x_0}{\bar{x} + x_0} e^{-\frac{L\bar{x}}{\nu}}, \quad \bar{x} = \sqrt{x_0^2 + \frac{2\nu x_0}{L}}.$$

For L *small, we have* $\bar{R}_{T0}(x_0, L) = 1 - 2\sqrt{\frac{2x_0}{\nu}}\sqrt{L} + O(L)$.

Proof. Taking a derivative of R_{T0} with respect to x shows that there is a unique maximum of R_{T0} for $x_0 \le x < \infty$ at $\bar{x}$, which leads to the bound given in (5.24). An expansion for L small leads then to the asymptotic result of the theorem. ∎

Now in a numerical calculation, two additional issues come into play: First the frequency parameter ω cannot be arbitrarily high, there is a maximum frequency that can be represented on a grid with spacing Δt, and an estimate for this maximum frequency is $\omega_{\max} = \frac{\pi}{\Delta t}$, the signal that oscillates between ± 1 from grid point to grid point. Second, the overlap L is in general not a fixed quantity, one can afford only a few grid cells overlap, and often $L = \Delta x$. The question therefore arises, if for a particular discretization, which might have to satisfy a stability constraint, the bound on the contraction factor in (5.24) is really relevant, or if the highest frequencies represented on the grid of the particular discretization stay below $\bar{\omega}$ where the maximum of R_{T0} is attained, which corresponds to $\bar{x}$ given in (5.24) in the transformed problem. To answer this question, we need to study for which cases the maximum numerical frequency $\omega_{\max}$ stays below $\bar{\omega}$ or, in the transformed problem, under which conditions

$$x_{\max} = \sqrt{\frac{\sqrt{x_0^4 + 16\nu^2\omega_{\max}^2} + x_0^2}{2}} \tag{5.25}$$

stays below $\bar{x}$ given in (5.24). A direct comparison shows that for

$$L > L_0 := \frac{4\nu x_0}{\sqrt{x_0^4 + 16\nu^2\omega_{\max}^2} - x_0^2} \tag{5.26}$$

the maximum numerical frequency $\omega_{\max} > \bar{\omega}$, and hence the bound given in Theorem 5.9 determines the convergence rate of the algorithm. If however $L \le L_0$, then the maximum on the numerically relevant convergence factor is attained at $\omega_{\max}$. Numerically, we therefore have

(5.27)
$$R_{T0}(x, x_0, L) \le \tilde{R}_{T0}(x_0, L) := \begin{cases} R_{T0}(\bar{x}, x_0, L) = \dfrac{\bar{x} - x_0}{\bar{x} + x_0} e^{-\frac{L\bar{x}}{\nu}} & \text{if } L > L_0, \\ R_{T0}(x_{\max}, x_0, L) = \dfrac{x_{\max} - x_0}{x_{\max} + x_0} e^{-\frac{Lx_{\max}}{\nu}} & \text{if } L \le L_0. \end{cases}$$

To obtain a concrete asymptotic result for the case where the overlap L is linked to the space discretization Δx, $L = C_1\Delta x$, and the space discretization Δx is linked to the time discretization Δt by a stability or accuracy constraint, $\Delta t = C_2\Delta x^\beta$, $\beta > 0$, we insert these relations into L_0 and expand to find

$$L_0 = \frac{x_0}{\pi}\Delta t + O(\Delta t^2), \tag{5.28}$$

which leads to the following asymptotic results.

THEOREM 5.10 (T0 discrete convergence estimate with overlap). *Let* $x_0 := \sqrt{a^2 + 4\nu b}$. *If* $L = C_1\Delta x$ *and* $\Delta t = C_2\Delta x^\beta$, *then the bound* $\tilde{R}_{T0}$ *in* (5.27) *on the convergence factor estimate of the discretized overlapping Schwarz waveform relaxation algorithm with Robin transmission conditions* (4.1),(4.6) *and* $p = p_T$ *from the Taylor low frequency approximation* (5.20) *is for* Δx *small given by*

(5.29)
$$\tilde{R}_{T0} = \begin{cases} 1 - 2\sqrt{\dfrac{2C_1x_0}{\nu}}\sqrt{\Delta x} + O(\Delta x) & \text{if } \beta > 1 \text{ or } \beta = 1 \text{ and } \frac{C_1}{C_2} > \frac{x_0}{\pi}, \\ 1 - \dfrac{\sqrt{2}(C_2x_0 + C_1\pi)}{\sqrt{C_2\pi\nu}}\sqrt{\Delta x} + O(\Delta x) & \text{if } \beta = 1 \text{ and } \frac{C_1}{C_2} \le \frac{x_0}{\pi}, \\ 1 - x_0\sqrt{\dfrac{2C_2}{\pi\nu}}\Delta x^{\frac{\beta}{2}} + o(\Delta x^{\frac{\beta}{2}}) & \text{if } \beta < 1. \end{cases}$$

Proof. Comparing $L = C_1\Delta x$ with the expansion of L_0 given in (5.28) and using that $\Delta t = C_2\Delta x^\beta$, we see that for Δx small the first case in (5.27) corresponds to the first case given in (5.29). The asymptotic bound on the convergence factor then follows by simply expanding for $L = C_1\Delta x$ and Δx small. For the second case, one can set $\beta = 1$ and directly expand the second case of (5.27) to find the result given. For the last case, we first notice that $x_{\max}$ satisfies

$$x_{\max} = \sqrt{2\pi\nu}\frac{1}{\sqrt{\Delta t}} + O(\sqrt{\Delta t}) = \sqrt{\frac{2\pi\nu}{C_2}}\Delta x^{-\frac{\beta}{2}} + O(\Delta x^{\frac{\beta}{2}}), \tag{5.30}$$

which together with $L = C_1\Delta x$ gives for the exponential the expansion

$$e^{-\frac{Lx_{\max}}{\nu}} = 1 - C_1\sqrt{\frac{2\pi}{C_2\nu}}\Delta x^{1-\frac{\beta}{2}} + O(\Delta x^{2-\beta}). \tag{5.31}$$

Multiplying this with the expansion for the coefficient in front of the exponential in (5.27), whose expansion is

$$\frac{x_{\max} - x_0}{x_{\max} + x_0} = 1 - x_0\sqrt{\frac{2C_2}{\pi\nu}}\Delta x^{\frac{\beta}{2}} + O(\Delta x^\beta), \tag{5.32}$$

the result follows. ∎

The preceding theorem shows that for explicit discretizations, which have a stability constraint of the type $\Delta t = C_2\Delta x^2$ for this problem and for which the present algorithm would still be of interest for nonmatching time grids, the optimized Schwarz waveform relaxation algorithm with Robin transmission conditions based on a low frequency approximation and an overlap of the order of the spatial discretization Δx will have an asymptotic convergence factor $1 - O(\sqrt{\Delta x})$, as one could expect from the continuous analysis in Theorem 5.9. This is still true for implicit discretizations, as long as Δt is of the same order as Δx. Once Δt becomes much larger than Δx, however, one can expect the algorithm to converge faster asymptotically because of the last relation in (5.29).

5.4. Optimization of the algorithm with overlap. We investigate now if there exists a better choice for p such that the overall convergence factor is smaller than with the parameter from the low frequency approximation. We will use the label O0 for these methods, which stands for optimized of order 0. We place ourselves first

again in the continuous context, where $\omega \in \mathbb{R}$, and thus $\omega_{\max} = \infty$. Later, we will also investigate the discretized case where $\omega_{\max} < \infty$. We introduce a change of variables, which will greatly simplify the analysis of the optimal parameter p. Setting $x := \frac{y\nu}{L}$, $p := \frac{\tilde{p}\nu}{L}$, and $x_0 := \frac{y_0\nu}{L}$ in the convergence factor (5.22), we obtain

$$R_0(y, \tilde{p}, y_0) = \frac{(y-\tilde{p})^2 + y^2 - y_0^2}{(y+\tilde{p})^2 + y^2 - y_0^2} e^{-y}, \tag{5.33}$$

which is now an expression independent of the overlap parameter L and the viscosity parameter ν. The best choice for the parameter $\tilde{p}$ is the one that makes R_0 as small as possible uniformly for all $y \geq y_0$ and is hence the solution of the min-max problem

$$\min_{\tilde{p}} \left(\max_{y \geq y_0} R_0(y, \tilde{p}, y_0) \right) = \min_{\tilde{p} \geq 0} \left(\max_{y \geq y_0} \frac{(y-\tilde{p})^2 + y^2 - y_0^2}{(y+\tilde{p})^2 + y^2 - y_0^2} e^{-y} \right), \tag{5.34}$$

where minimizing over nonnegative $\tilde{p}$ is equivalent to minimizing over all $\tilde{p}$, as one can see from (5.33). Note that $\tilde{p}$ nonnegative is also a requirement for the convergence proof of the algorithm in Theorem 5.8. To analyze the min-max problem (5.34), we need two lemmas.

LEMMA 5.11. *The function $y \mapsto R_0(y, \tilde{p}, y_0)$ defined in* (5.33) *has a unique local maximum at*

$$\bar{y}(y_0, \tilde{p}) = \sqrt{\frac{y_0^2 + 2\tilde{p} + \sqrt{d(y_0, \tilde{p})}}{2}}, \quad d(y_0, \tilde{p}) = \tilde{p}(-\tilde{p}^3 - 4\tilde{p}^2 + (4 + 2y_0^2)\tilde{p} + 8y_0^2), \tag{5.35}$$

if $0 \leq \tilde{p} < \tilde{p}_1(y_0)$, where $\tilde{p}_1(y_0)$ is the unique positive root of $d(y_0, \tilde{p})$ for $y_0 > 0$. If $\tilde{p} \geq \tilde{p}_1(y_0)$, then $R_0(y, \tilde{p}, y_0)$ is a monotonically decreasing function of y.

Proof. A partial derivative of $R_0(y, \tilde{p}, y_0)$ with respect to y gives

$$\frac{\partial R_0}{\partial y} = -\frac{e^{-y}(4y^4 - 4(2\tilde{p} + y_0^2)y^2 + (\tilde{p}^2 - y_0^2)(y_0^2 - 4\tilde{p} - \tilde{p}^2))}{((\tilde{p}+y)^2 + y^2 - y_0^2)^2},$$

and therefore $R_0(y, \tilde{p}, y_0)$ can have at most two extrema, $\bar{y} = \sqrt{(y_0^2 + 2\tilde{p} + \sqrt{d(y_0, \tilde{p})})/2}$ and $\underline{y} = \sqrt{(y_0^2 + 2\tilde{p} - \sqrt{d(y_0, \tilde{p})})/2}$, with the discriminant $d(y_0, \tilde{p})$ given in (5.35). The larger of the two, $\bar{y}$, must be a maximum, since $R_0 \geq 0$ and R_0 goes to 0 as y goes to ∞. Since the discriminant is positive for small positive $\tilde{p}$ and is negative for large positive $\tilde{p}$, it must have by continuity at least one real positive root $\tilde{p}_1(y_0) > 0$, $d(y_0, \tilde{p}_1) = 0$. To prove that this root is unique, we use the derivative of $d(y_0, \tilde{p})/\tilde{p}$ with respect to $\tilde{p}$, which shows that there are two extrema, one at $r_1 = -\frac{1}{3}(4 - \sqrt{28 + 6y_0^2})$ and one at $r_2 = -\frac{1}{3}(4 + \sqrt{28 + 6y_0^2})$. The larger one, r_1, must be a maximum, since the discriminant goes to $-\infty$ as $\tilde{p}$ goes to ∞, and thus r_2 is a minimum. Since r_2 is negative, $\tilde{p}_1$ is the only positive root of the discriminant, since this latter is still positive for arbitrary small $\tilde{p}$. For $\tilde{p} \geq \tilde{p}_1$, R_0 has no extrema in y and hence decreases monotonically to 0 as y goes to infinity. ∎

LEMMA 5.12. *For fixed $y > y_0$ and $\tilde{p} > 0$, we have $\frac{\partial R_0(y, \tilde{p}, y_0)}{\partial \tilde{p}}(\tilde{p} - \tilde{p}_2(y)) \geq 0$, where $\tilde{p}_2(y) := \sqrt{2y^2 - y_0^2}$.*

Proof. A partial derivative of $R_0(y, \tilde{p}, y_0)$ with respect to $\tilde{p}$ gives

$$\frac{\partial R_0}{\partial \tilde{p}} = -\frac{4e^{-y}y(-\tilde{p}^2 + 2y^2 - y_0^2)}{((\tilde{p}+y)^2 + y^2 - y_0^2)^2},$$

which has only one root in $\tilde{p}$, $\tilde{p}_2(y) = \sqrt{2y^2 - y_0^2}$, which is positive. For $\tilde{p} < \tilde{p}_2$, $\frac{\partial R_0}{\partial \tilde{p}}$ is negative and hence $R_0(y, \tilde{p}, y_0)$ decreases when $\tilde{p}$ increases, whereas for $\tilde{p} > \tilde{p}_2$, $R_0(y, \tilde{p}, y_0)$ increases when $\tilde{p}$ increases. ∎

THEOREM 5.13 (O0 performance with overlap). *Let $L > 0$ and $x_0 := \sqrt{a^2 + 4\nu b}$. The best performance of the optimized overlapping Schwarz waveform relaxation algorithm at the continuous level with Robin transmission conditions* (4.1),(4.6) *is obtained for $p = p^* := \frac{\tilde{p}^* \nu}{L}$, where $\tilde{p}^*$, the solution of the min-max problem* (5.34)*, is for $y_0 := \frac{x_0 L}{\nu} < y_c$ given by the unique solution $\tilde{p}^* \geq y_0$ of the nonlinear equation*

$$R_0(y_0, \tilde{p}^*, y_0) = R_0(\bar{y}(y_0, \tilde{p}^*), \tilde{p}^*, y_0), \tag{5.36}$$

where $R_0(y, \tilde{p}, y_0)$ is given in (5.33) *and $\bar{y}(y_0, \tilde{p})$ is given in* (5.35)*. For $y_0 \geq y_c$, $\tilde{p}^*$ is given by the unique solution of*

$$y_0 = \tilde{p}^* \sqrt{\frac{\tilde{p}^*}{(4 + \tilde{p}^*)}}. \tag{5.37}$$

The constant y_c is universal, $y_c = 1.618386576\ldots$, and the convergence factor with the optimal p^* is uniformly bounded by

$$R_0(y, \tilde{p}^*, y_0) \leq \bar{R}_{O0}(y_0, \tilde{p}^*) := R_0(\bar{y}(y_0, \tilde{p}^*), \tilde{p}^*, y_0). \tag{5.38}$$

For L small, we have the asymptotic result

$$p^* = \frac{\tilde{p}^* \nu}{L} \approx (2x_0^2 \nu)^{\frac{1}{3}} L^{-\frac{1}{3}}, \quad \bar{R}_{O0} \approx 1 - \left(\frac{2^5 x_0}{\nu}\right)^{\frac{1}{3}} L^{\frac{1}{3}}. \tag{5.39}$$

Proof. By Lemma 5.12, the optimal $\tilde{p}^* \geq y_0$ since for $\tilde{p} < \tilde{p}_2(y_0) = y_0$, increasing $\tilde{p}$ decreases $R_0(y, \tilde{p}, y_0)$ for all $y > y_0$. Now Lemma 5.11 implies that for $y_0 \leq \tilde{p} \leq \tilde{p}_1(y_0)$, the maximum of R_0 in the min-max problem can be attained at $y = y_0$ or at the interior maximum at $\bar{y}$ given in (5.35). For $\tilde{p} = y_0$, we have $R_0(y_0, \tilde{p}, y_0) = R_0(y_0, y_0, y_0) = 0$ and $d(y_0, \tilde{p}) = d(y_0, y_0) = y_0^2(2 + y_0)^2 \geq 0$, and hence $R_0(y, \tilde{p}, y_0)$ has for $y \geq y_0$ a unique maximum at $\bar{y}(y_0, y_0) = \sqrt{y_0(2 + y_0)} > y_0$. Increasing $\tilde{p}$ from y_0 increases $R_0(y_0, \tilde{p}, y_0)$ by Lemma 5.12 monotonically for all $\tilde{p} > \tilde{p}_2(y_0) = y_0$. Increasing $\tilde{p}$ from y_0 also decreases $R_0(\bar{y}(y_0, \tilde{p}), \tilde{p}, y_0)$ by Lemma 5.12, as long as it exists, $\tilde{p} < \tilde{p}_1(y_0)$ according to Lemma 5.11, and $\tilde{p} < \tilde{p}_2(\bar{y}(y_0, \tilde{p})) = \sqrt{2\bar{y}^2 - y_0^2}$, after which $R_0(\bar{y}, \tilde{p}, y_0)$ will increase again according to Lemma 5.12. By continuity, the maximum of R_0 is minimized either for $\tilde{p}_1^*$ satisfying

$$R_0(y_0, \tilde{p}_1^*, y_0) = R_0(\tilde{y}, \tilde{p}_1^*, y_0), \tag{5.40}$$

provided that $\tilde{p}_1^* \leq \tilde{p}_2(\bar{y}(y_0, \tilde{p}_1^*)) = \sqrt{2(\bar{y}(y_0, \tilde{p}_1^*))^2 - y_0^2}$, or for $\tilde{p}_2^*$ given by

$$\tilde{p}_2^* = \tilde{p}_2(\bar{y}(y_0, \tilde{p}_2^*)) = \sqrt{2(\bar{y}(y_0, \tilde{p}_2^*))^2 - y_0^2}. \tag{5.41}$$

It depends on the only parameter left, y_0, which of these two cases is the solution. Imposing $\tilde{p}_1^* = \tilde{p}_2^*$ and both (5.40) and (5.41), we can solve for the value of y_0 where both are equally optimal. We find

$$y_0 = y_c = 1.618386576\ldots, \quad \tilde{p}_1^* = \tilde{p}_2^* = 2.583490822\ldots.$$

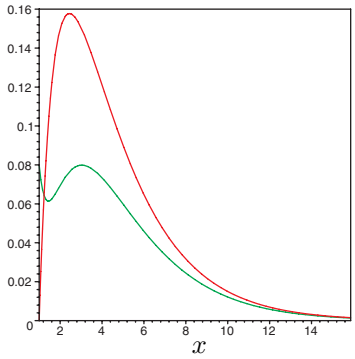

FIG. 5.1. *The top curve is the convergence factor R_{T0} from the Taylor low frequency approximation, and the curve below is the optimized convergence factor R_{O0}, for an example from the numerical section.*

TABLE 5.1
Comparison of the optimal $\tilde{p}^*$ from Theorem 5.13 *and its asymptotic approximation.*

y_0	0.1	0.01	0.001	0.0001	0.00001
$\tilde{p}^*$	0.2936	0.05952	0.01265	0.002717	0.0005849
Asymptotic $\tilde{p}^*$	0.2714	0.05848	0.01260	0.002714	0.0005848

Hence for $y_0 < y_c$ and for $y_0 \geq y_c$ (5.40) and (5.41), respectively, give the solution. (5.41) can be simplified by solving it for y_0, which gives (5.37) stated in the theorem, and a derivative with respect to $\tilde{p}^*$ shows that there is a unique positive root $\tilde{p}^*$ for $y_0 > 0$.

The uniform bound given in (5.38) is a direct consequence of (5.36) and (5.37), since in both cases the maximum is attained at $\bar{y}$.

To show the asymptotic result (5.39), we note that for L small and the other problem parameters a, b, and ν fixed, we have y_0 small, since from the variable transform we have $y_0 = \frac{x_0}{\nu} L = \frac{\sqrt{a^2+4\nu b}}{\nu} L$ and therefore the first result (5.36) applies asymptotically, $y_0 < y_c$. To solve (5.36) asymptotically, we insert the ansatz $\tilde{p}^* = C_p y_0^\alpha$ into (5.36) and expand both sides for y_0 small. Using that $\tilde{p}^* \geq y_0$, we find from its definition that asymptotically $\bar{y} \approx \sqrt{2C_p} y_0^{\frac{\alpha}{2}}$. Using this in equation (5.36), we find for the leading order terms

$$1 - 2^{\frac{5}{3}} y_0^{1-\alpha} - y_0 + 2^{\frac{5}{3}} y_0^{1-\alpha+1} y_0 + \cdots = 1 - 2^{\frac{3}{2}} \sqrt{C_p} y_0^{\frac{\alpha}{2}} + 4 C_p y_0^\alpha + \cdots ,$$

which implies $1 - \alpha = \frac{\alpha}{2}$ and thus $\alpha = \frac{2}{3}$ and $C_p = 2^{\frac{1}{3}}$, which leads to (5.39). ∎

In Figure 5.1 we show the convergence factors R_{T0} and R_{O0} for an example with $x_0 = 1$, $L = 0.08$, and $\nu = 0.2$ from the numerical section. One can see the better performance of the optimized Robin transmission conditions over the Taylor transmission conditions and also the equioscillation of the optimal choice.

Table 5.1 gives a comparison of the optimal $\tilde{p}^*$ from (5.36) with the asymptotic approximation (5.39). One can see that the asymptotic approximation is very close to the optimal $\tilde{p}^*$ already for moderately small values of y_0, which corresponds to a small overlap L. For larger values of y_0, the asymptotic approximation can be a valuable initial guess for the nonlinear equation solver to find the optimal $\tilde{p}^*$ from (5.36).

In Figure 3.1 on the right, we show the first few iterations, at the end of the time interval, of the optimized Schwarz waveform relaxation algorithm with Robin

transmission conditions for the same model problem for which the iterates of the classical Schwarz waveform relaxation algorithm are shown on the left. One can clearly see that the new algorithm with Robin transmission conditions converges much faster than the algorithm with Dirichlet transmission conditions.

Theorem 5.13 gives the optimal choice for the parameter in the Robin transmission conditions of the optimized Schwarz waveform relaxation algorithm at the continuous level. In a numerical setting, however, not all the frequencies are present, as we have seen, and we have to address the question again if the maximum of the convergence factor attained at $\bar{y}$ is relevant in a computation. Letting $L = C_1\Delta x$ and $\Delta t = C_2\Delta x^\beta$ as before, the maximum numerical frequency we can expect on the time discretization grid is $\omega_{\max} = \frac{\pi}{\Delta t} = \frac{\pi}{C_2\Delta x^\beta}$, which corresponds with the variable transform to

(5.42)
$$y_{\max} = \frac{Lx_{\max}}{\nu} = C_1\Delta x\sqrt{\frac{\sqrt{x_0^4 + \left(\frac{4\nu\pi}{C_2\Delta x^\beta}\right)^2} + 2x_0^2}{2}} = C_1\sqrt{\frac{2\pi}{\nu C_2}}\Delta x^{1-\frac{\beta}{2}} + O(\Delta x^{1+\frac{\beta}{2}}),$$

whereas $\bar{y}$ from the optimization in (5.36) has the expansion

$$\bar{y} = 2^{\frac{2}{3}}\left(\frac{x_0C_1}{\nu}\right)^{\frac{1}{3}}\Delta x^{\frac{1}{3}} + O(\Delta x). \tag{5.43}$$

Hence, if $1 - \frac{\beta}{2} = \frac{1}{3}$ or $\beta = \frac{4}{3}$ and $C_1 = \sqrt{x_0}\left(\frac{2\nu C_2^3}{\pi^3}\right)^{\frac{1}{4}} =: C_c$, the numerical $y_{\max}$ and $\bar{y}$ from the optimization are asymptotically at the same location, which represents the boundary between the usefulness of the continuous optimization result (5.36) and a different optimization for the discretized algorithm, which we show in the following theorem.

THEOREM 5.14 (O0 discrete convergence estimate with overlap). *Let* $x_0 := \sqrt{a^2 + 4\nu b}$. *If* $L = C_1\Delta x$ *and* $\Delta t = C_2\Delta x^\beta$, *then the convergence factor* $R_0(y, \tilde{p}, y_0)$ *of the discretized overlapping Schwarz waveform relaxation algorithm with Robin transmission conditions* (4.1),(4.6) *is for* Δx *small bounded for all* $y \in [y_0, y_{\max}]$ *by* $\tilde{R}_{O0}$, *where* $y_{\max}$ *is given in* (5.42), $\tilde{R}_{O0}$ *and* $\tilde{p}^*$ *satisfy*

(5.44)
$$\tilde{R}_{O0} \approx 1 - \left(\frac{2^5C_1x_0}{\nu}\right)^{\frac{1}{3}}\Delta x^{\frac{1}{3}},\ p^* \approx \left(\frac{2x_0^2\nu}{C_1}\right)^{\frac{1}{3}}\Delta x^{-\frac{1}{3}} \quad \text{if } \beta > \tfrac{4}{3} \text{ or } \beta = \tfrac{4}{3} \text{ and } C_1 > C_c,$$
$$\tilde{R}_{O0} \approx 1 - \tfrac{8C_1x_0}{C_p\nu}\Delta x^{\frac{1}{3}}, \qquad p^* \approx C_p\Delta x^{-\frac{1}{3}} \qquad \text{if } \beta = \tfrac{4}{3} \text{ and } C_1 \le C_c,$$
$$\tilde{R}_{O0} \approx 1 - 2\left(\frac{2C_2x_0^2}{\nu\pi}\right)^{\frac{1}{4}}\Delta x^{\frac{\beta}{4}},\ p^* \approx \left(\frac{2^3x_0^2\nu\pi}{C_2}\right)^{\frac{1}{4}}\Delta x^{-\frac{\beta}{4}} \text{ if } \beta < \tfrac{4}{3},$$

and the constants are given by $C_p = \frac{1}{2C_2}(\sqrt{\pi^2C_1^2 + 8\sqrt{2\nu\pi}C_2^{\frac{3}{2}}x_0} - \pi C_1)$, $C_c = \sqrt{x_0}(\frac{2\nu C_2^3}{\pi^3})^{\frac{1}{4}}$.

Proof. The first case is a direct consequence of Theorem 5.13, which applies in this case, since the maximum $\bar{y}$ is relevant for the numerical discretization if $\beta > \frac{4}{3}$ or $\beta = \frac{4}{3}$ and $C_1 > C_c$, as can be see from (5.42) and (5.43). For case two and three, the local maximum at $\bar{y}$ lies outside of the numerical frequencies, $\bar{y} > y_{\max}$, and hence the min-max problem needs to be adapted to this situation; the maximum needs now

be minimized only for $y \in [y_0, y_{\max}]$. For a small overlap, which corresponds to y_0 small, the solution is achieved according to Theorem 5.13 when

$$R_0(y_0, \tilde{p}^*, y_0) = R_0(y_{\max}, \tilde{p}^*, y_0). \tag{5.45}$$

Expanding both sides asymptotically for small Δx, we find, using the ansatz $\tilde{p}^* = \tilde{C}_p \Delta x^\alpha$, that the leading order terms of (5.45) are

$$1 - \frac{4x_0 C_1}{\tilde{C}_p \nu} \Delta x^{1-\alpha} + \cdots = 1 - \frac{2\tilde{C}_p}{C_1} \sqrt{\frac{\nu C_2}{2\pi}} \Delta x^{\alpha - 1 + \frac{\beta}{2}} - C_1 \sqrt{\frac{2\pi}{\nu C_2}} \Delta x^{1-\frac{\beta}{2}} + \cdots .$$

Hence in the limiting case, where $\beta = \frac{4}{3}$, we have $\alpha = \frac{2}{3}$, and both terms on the right have the same exponent. This leads to the constant C_p given in the theorem in case two, after having used the back transform $p^* = \frac{\tilde{p}^* \nu}{C_1 \Delta x}$. If however $\beta < \frac{4}{3}$, then the last term on the right-hand side is of lower order. Balancing the remaining two, we find for the exponents $1 - \alpha = \alpha - 1 + \frac{\beta}{2}$ or $\alpha = 1 - \frac{\beta}{4}$ and the constant $\tilde{C}_p = C_1 (\frac{2^3 x_0^2 \pi}{\nu^3 C_2})^{\frac{1}{4}}$, which leads after the back transform to the last case stated in the theorem. ∎

5.5. Convergence for the nonoverlapping algorithm. We now assume that the overlap is zero, $L = 0$. We first analyze convergence of the algorithm in the appropriate Sobolev spaces. The convergence analysis for the nonoverlapping case is based on energy estimates and follows an idea from [28], which has also been used in [6] and [33] for Schwarz algorithms applied to steady problems and in [11] for a nonoverlapping Schwarz waveform relaxation algorithm for hyperbolic evolution equations.

THEOREM 5.15. *Without overlap, $L = 0$, the Schwarz waveform relaxation algorithm* (4.1),(4.6) *converges for $p > 0$ in $(L^\infty(0,T;L^2(\Omega_1)) \cap L^2(0,T;H^1(\Omega_1))) \times (L^\infty(0,T;L^2(\Omega_2)) \cap L^2(0,T;H^1(\Omega_2)))$ to the solution u of* (2.1) *for any initial guess $g_0 \in H^{\frac{1}{4}}(0,T)$ and $g_L \in H^{\frac{1}{4}}(0,T)$.*

Proof. As in the proof of Theorem 5.2 we obtain the energy estimates

$$\frac{1}{2}\frac{d}{dt}\|e_1^k\|^2 + \nu\|\partial_x e_1^k\|^2 + b\|e_1^k\|^2 - \left(\nu\partial_x e_1^k - \frac{a}{2}e_1^k\right)(0)e_1^k(0) = 0, \tag{5.46}$$

$$\frac{1}{2}\frac{d}{dt}\|e_2^k\|^2 + \nu\|\partial_x e_2^k\|^2 + b\|e_2^k\|^2 + \left(\nu\partial_x e_2^k - \frac{a}{2}e_2^k\right)(0)e_2^k(0) = 0. \tag{5.47}$$

Introducing the boundary operators $\mathcal{B}^+ = \partial_x + \mathcal{S}_1$, $\mathcal{B}^- = \partial_x + \mathcal{S}_2$ and rewriting the terms on the interface in the form $(\nu\partial_x e - \frac{a}{2}e)e = \frac{\nu^2}{2p}((\mathcal{B}^+ e)^2 - (\mathcal{B}^- e)^2)$, we obtain the new energy estimates

$$\frac{1}{2}\frac{d}{dt}\|e_1^k\|^2 + \nu\|\partial_x e_1^k\|^2 + b\|e_1^k\|^2 + \frac{\nu^2}{2p}(\mathcal{B}^- e_1^k)^2(0) = \frac{\nu^2}{2p}(\mathcal{B}^+ e_1^k)^2(0), \tag{5.48}$$

$$\frac{1}{2}\frac{d}{dt}\|e_2^k\|^2 + \nu\|\partial_x e_2^k\|^2 + b\|e_2^k\|^2 + \frac{\nu^2}{2p}(\mathcal{B}^+ e_2^k)^2(0) = \frac{\nu^2}{2p}(\mathcal{B}^- e_2^k)^2(0). \tag{5.49}$$

Now note that the transmission conditions can be expressed with the operators $\mathcal{B}^\pm$,

$$\mathcal{B}^+ e_1^k = \mathcal{B}^+ e_2^{k-1}, \quad \mathcal{B}^- e_2^k = \mathcal{B}^- e_1^{k-1} \text{ on } \{0\} \times (0,T).$$

Replacing the corresponding terms in the two equations (5.48) and (5.49), adding the resulting equations, and summing in k, we get a telescopic sum on the interfaces and

therefore

$$\begin{aligned}\sum_{k=1}^{K}\left[\tfrac{1}{2}\tfrac{d}{dt}(\|e_1^k\|^2+\|e_2^k\|^2)+\nu(\|\partial_x e_1^k\|^2+\|\partial_x e_2^k\|^2)+b(\|e_1^k\|^2+\|e_2^k\|^2)\right]+\\ +\tfrac{\nu^2}{2p}((\mathcal{B}^- e_1^K)^2+(\mathcal{B}^+ e_2^K)^2)(0)=\tfrac{\nu^2}{2p}((\mathcal{B}^- e_1^1)^2+(\mathcal{B}^+ e_2^1)^2)(0).\end{aligned} \tag{5.50}$$

We can now integrate in time, and since the initial values of the error vanish, the sum of the energies over all the iterates remains bounded. Hence the energy in the iterates needs to go to zero and the algorithm converges. ∎

5.6. Low frequency approximation for the algorithm without overlap. One can choose the free parameter p in the Robin transmission conditions based on a low frequency Taylor approximation, as given in (5.20). But now there is no overlap to be effective on the high frequencies, the convergence factor (5.23) becomes

$$R_{T0}(x,x_0)=\frac{x-x_0}{x+x_0}, \tag{5.51}$$

where $x \geq x_0$ is given by the variable transform (5.21). Clearly R_{T0} is a monotonically increasing function of x for $x \geq x_0$ and tends to one as x tends to infinity. There is therefore no uniform bound on R_{T0} which is strictly less than one for all $x \geq x_0$ in the case without overlap. But we have already seen that in a numerical calculation the frequency parameter ω cannot be arbitrarily high. It suffices therefore for the numerical case to find a bound for R_{T0} for $x_0 \leq x \leq x_{\max}$, where $x_{\max}$ is given in (5.25).

THEOREM 5.16 (T0 discrete convergence estimate without overlap). *Let* $x_0 := \sqrt{a^2+4\nu b}$ *and* $L=0$. *Then the convergence factor estimate* R_{T0} *of the discretized nonoverlapping Schwarz waveform relaxation algorithm with Robin transmission conditions* (4.1),(4.6) *and* $p=p_T$ *from the Taylor low frequency approximation* (5.20) *is for* $x_0 \leq x \leq x_{\max}$, *where* $x_{\max}$ *is defined in* (5.25), *bounded by*

$$R_{T0}(x,x_0) \leq \tilde{R}_{T0}(x_0) := R_{T0}(x_{\max},x_0) = \frac{\sqrt{\sqrt{\Delta t^2 x_0^4+16\nu^2\pi^2}+x_0^2\Delta t}-\sqrt{2\Delta t}x_0}{\sqrt{\sqrt{\Delta t^2 x_0^4+16\nu^2\pi^2}+x_0^2\Delta t}+\sqrt{2\Delta t}x_0}. \tag{5.52}$$

For Δt *small, we have* $\tilde{R}_{T0}(x_0)=1-x_0\sqrt{\frac{2}{\nu\pi}}\sqrt{\Delta t}+O(\Delta t)$.

Proof. By the monotonicity of R_{T0} in x, the bound for $x_0 \leq x \leq x_{\max}$ on R_{T0} is attained at $x=x_{\max}$, which leads, using the variable transform (5.21) and $\omega_{\max}=\frac{\pi}{\Delta t}$, to the bound given in (5.52). ∎

Now we can compare the asymptotic performance of the algorithm without overlap to the performance of the algorithm with overlap. If in the discretization the time step Δt is linked to the spatial discretization step Δx by the relation $\Delta t = C_2 \Delta x^\beta$, then we see by comparing the results of Theorem 5.10 with the results of Theorem 5.16 that for $\beta \geq 1$ adding an overlap of size Δx does improve the asymptotic performance of the algorithm, whereas for $\beta < 1$ adding an overlap of the order of Δx does not improve the asymptotic performance. In particular this shows that with the Taylor transmission conditions and using an explicit time discretization with the stability constraint $\Delta t = C_1 \Delta x^2$, an overlap is helpful. Note that if an explicit scheme is used with the same time steps in both subdomains, there is no need to iterate, since one can explicitly advance the algorithm on the interface as well. A subdomain iteration would still be of interest if one uses nonmatching time grids, however, see, for example, [11].

5.7. Optimization of the algorithm without overlap. As in the case with overlap, there is a better choice for p than the low frequency approximation based on a Taylor expansion of the optimal symbol. We can again try to choose p such that the convergence factor

$$R_0(x,p,x_0) = \frac{(x-p)^2+x^2-x_0^2}{(x+p)^2+x^2-x_0^2} \tag{5.53}$$

is minimized over all $x_0 \le x \le x_{\max}$. Hence the optimal choice for p for the discretized algorithm is the solution of the min-max problem

$$\min_p \left(\max_{x_0 \le x \le x_{\max}} R_0(x,p,x_0) \right) = \min_{p \ge 0} \left(\max_{x_0 \le x \le x_{\max}} \frac{(x-p)^2+x^2-x_0^2}{(x+p)^2+x^2-x_0^2} \right), \tag{5.54}$$

where minimizing over nonnegative p is equivalent to minimizing over all p, as one can see from (5.53). The following theorem can be proved as in the case with overlap.

THEOREM 5.17 (O0 performance without overlap). *Let $L = 0$, $x_0 := \sqrt{a^2+4\nu b}$, and $x_{\max} < \infty$ be given. Then the best performance of the optimized nonoverlapping Schwarz waveform relaxation algorithm with Robin transmission conditions* (4.1),(4.6) *is obtained for $p = p^*$, where p^*, the solution of the min-max problem* (5.54)*, is for $x_{\max} \ge \frac{1+\sqrt{5}}{2} x_0$ given by*

(5.55)

$$p^* = \sqrt{x_0(2x_{\max}+x_0)}, \qquad R_0(x,p^*,x_0) \le \tilde{R}_{O0} = \frac{x_{\max}+x_0-\sqrt{2x_{\max}x_0+x_0^2}}{x_{\max}+x_0+\sqrt{2x_{\max}x_0+x_0^2}},$$

and for $x_{\max} < \frac{1+\sqrt{5}}{2} x_0$ we have

$$p^* = \sqrt{2x_{\max}^2 - x_0^2}, \qquad R_0(x,p^*,x_0) \le \tilde{R}_{O0} = \frac{\sqrt{2x_{\max}^2-x_0^2}-x_{\max}}{\sqrt{2x_{\max}^2-x_0^2}+x_{\max}}. \tag{5.56}$$

THEOREM 5.18 (O0 discrete convergence estimate without overlap). *Let $L = 0$ and $x_0 := \sqrt{a^2+4\nu b}$. If the nonoverlapping Schwarz waveform relaxation algorithm with optimized Robin transmission conditions is discretized in time with time step Δt, then for Δt small we have*

$$p^* = (2^3 x_0^2 \pi\nu)^{\frac{1}{4}} \Delta t^{-\frac{1}{4}} + O(\Delta t^{\frac{1}{4}}), \quad \tilde{R}_{O0} = 1 - 2\left(\frac{2x_0^2}{\pi\nu}\right)^{\frac{1}{4}} \Delta t^{\frac{1}{4}} + O(\sqrt{\Delta t}). \tag{5.57}$$

Proof. Using the variable transform (5.21), $x_{\max}$ behaves like

$$x_{\max} = \sqrt{2\pi\nu}\Delta t^{-\frac{1}{2}} + O(\sqrt{\Delta t}),$$

and thus the first result of (5.55) in Theorem 5.17 applies. Expanding p^* and $\tilde{R}_{O0}$ from (5.55) leads to (5.57). ∎

To summarize the results of this section, we show in Table 5.2 an overview of the performance one can obtain with the various choices of the parameter p in the transmission conditions. It is interesting to note that, for optimized Schwarz waveform relaxation methods, without overlap does not necessarily mean less performance than with overlap: in the T0 case, if $\beta \le 1$, the performance of the overlapping and nonoverapping algorithms is the same, and the same holds in the O0 case if $\beta \le \frac{4}{3}$.

TABLE 5.2
Summary of the asymptotic convergence factors for the various parameter choices in the Robin transmission conditions for $\Delta t = \Delta x^\beta$.

Method	Convergence factor	Parameter p
T0 overlap Δx	$\begin{cases} 1 - O(\sqrt{\Delta x}) & \text{if } \beta \geq 1 \\ 1 - O(\Delta x^{\frac{\beta}{2}}) & \text{if } \beta < 1 \end{cases}$	$\sqrt{a^2 + 4\nu b}$
O0 overlap Δx	$\begin{cases} 1 - O(\Delta x^{\frac{1}{3}}) & \text{if } \beta \geq \frac{4}{3} \\ 1 - O(\Delta x^{\frac{\beta}{4}}) & \text{if } \beta < \frac{4}{3} \end{cases}$	$(2\nu(a^2 + 4\nu b))^{\frac{1}{3}} \Delta x^{-\frac{1}{3}}$ $(8\nu\pi(a^2 + 4\nu b))^{\frac{1}{4}} \Delta x^{-\frac{\beta}{4}}$
T0 no overlap	$1 - O(\sqrt{\Delta t})$	$\sqrt{a^2 + 4\nu b}$
O0 no overlap	$1 - O(\Delta t^{\frac{1}{4}})$	$(8\nu\pi(a^2 + 4\nu b))^{\frac{1}{4}} \Delta t^{-\frac{1}{4}}$

6. Numerical results. We perform in this section numerical experiments to measure the convergence factors of the numerical implementation of the Schwarz waveform relaxation algorithms analyzed at the continuous level in this paper. We use the parabolic model problem (2.1) with $\Omega = (0, 6)$. We impose homogeneous boundary conditions, $u(0, t) = 0$ and $u(6, t) = 0$, and use various initial conditions $u(x, 0)$, $x \in \Omega$. We first use a decomposition of the domain Ω into the two subdomains $\Omega_1 = (0, L_2)$ and $\Omega_2 = (L_1, 6)$, $L_1 \leq L_2$, and hence $L = L_2 - L_1$. We refer with the term iteration to a double iteration of the respective algorithms, since for two subdomains one can perform all the iterations in an alternating fashion and thus obtain the even iterates on one subdomain and the odd ones on the other without having to compute the remaining ones. We show results of numerical experiments for only the algorithm with overlap since with overlap we can compare the results to the classical Schwarz waveform relaxation algorithm with Dirichlet transmission conditions, which does not converge without overlap.

6.1. Dirichlet transmission conditions. In this first set of experiments, we use the classical Schwarz waveform relaxation algorithm with Dirichlet transmission conditions analyzed in section 3. We chose for the problem parameters $\nu = 0.2$, $a = 1$, and $b = 0$. We discretize (2.1) using an upwind finite difference discretization in space with mesh parameter $\Delta x = 0.02$ and a backward Euler discretization in time, with time step $\Delta t = 0.005$. We chose $L_1 = 2.96$ and $L_2 = 3.04$, which means the overlap is $L = 0.08$, and we compute the numerical solution in the time interval $[0, T]$. Using as initial condition

$$u(x, 0) = e^{-3(1.2-x)^2},$$

we have already shown in Figure 3.1 for this example the first few iterations at the end of the time interval $T = 2.5$, where we started the algorithm with a zero initial guess. We show in Figure 6.1 the convergence behavior of the classical Schwarz waveform relaxation algorithm for this example for three different lengths of the time interval, $T = 1$, $T = 2.5$, and $T = 10$, together with the linear bound on the convergence rate from Theorem 3.3 and the superlinear convergence bound from Theorem 3.4. The dashed curve shows the error measured in the L_2 norm between the converged solution and the iterates at the interface L_2. One can clearly see that the behavior of the algorithm depends on the length of the time interval T, as predicted by Theorem 3.4. For short time intervals, the superlinear bound on the convergence rate is sharper, and hence the algorithm must converge superlinearly, as shown in Figure 6.1 on the left. If the time interval becomes longer, as in the middle graph of Figure 6.1, the linear bound of Theorem 3.3 is sharper than the superlinear one early in the iteration, and hence the algorithm converges linearly. But later the superlinear bound becomes

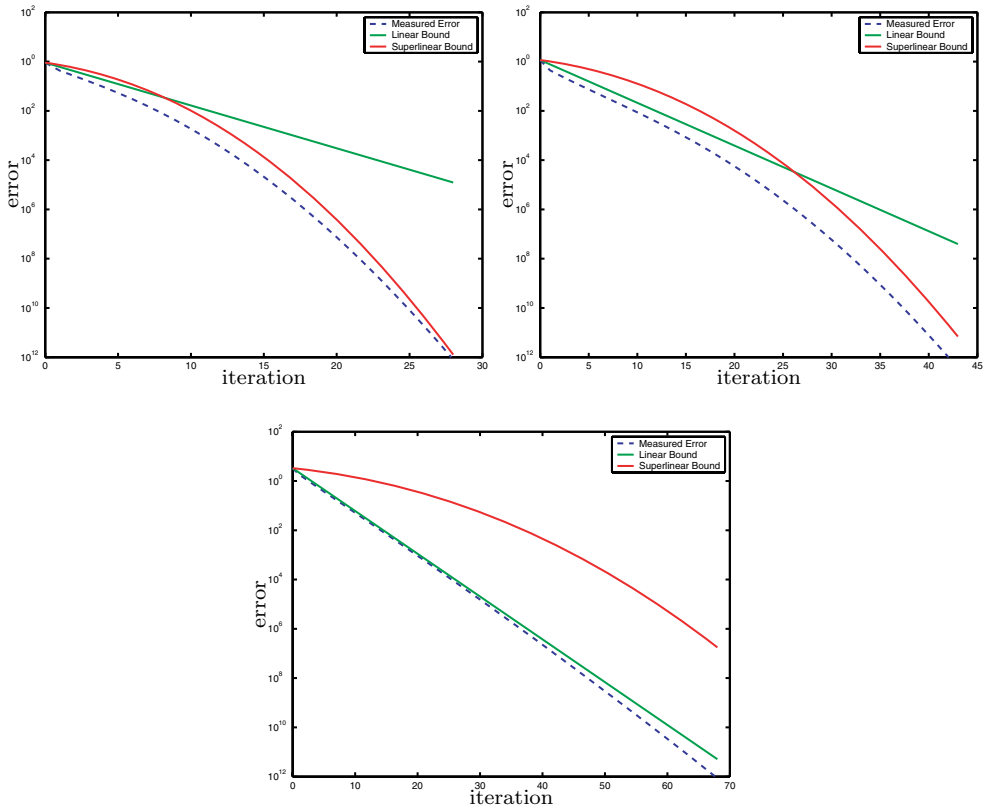

FIG. 6.1. *Convergence rate of the classical Schwarz waveform relaxation algorithm with Dirichlet transmission conditions together with the theoretical linear and superlinear bounds on the convergence rates: on the left for* $T = 1$*, in the middle for* $T = 2.5$*, and on the right for* $T = 10$*.*

sharper and hence a transition to the superlinear convergence regime occurs. For long time intervals, the initial linear convergence regime also prevails for more iterations, as one can see in Figure 6.1 on the right.

6.2. Robin transmission conditions. We now change the transmission conditions in the Schwarz waveform relaxation algorithm to Robin transmission conditions. Using the same numerical configuration as in the previous subsection, we obtain for the parameter p in the transmission conditions using a Taylor expansion $p = p_T = 1$, and using the optimization from Theorem 5.13, we obtain $p = p^* = 2.054275607$. In Figure 3.1 on the right, we have already seen the first few iterations at the end of the time interval $T = 2.5$ for this example with the optimal parameter p^*, starting the iteration with the zero initial guess. In Figure 6.2 one can see how much faster the algorithm converges with Robin transmission conditions compared to the classical algorithm. One can also see that the optimized parameter p^* leads to an even better performance than the parameter p_T from the Taylor transmission conditions. Note that for all the results comparing the performance of the algorithms, we started the iteration with a random initial guess. This is important to obtain a relevant comparison since, for smooth solutions starting with a smooth initial guess, high frequencies would not be present on the mesh and thus a much coarser mesh would have been sufficient for the computation. The random initial guess has the effect that the mesh resolution is indeed needed to resolve the iteration and thus corresponds to the

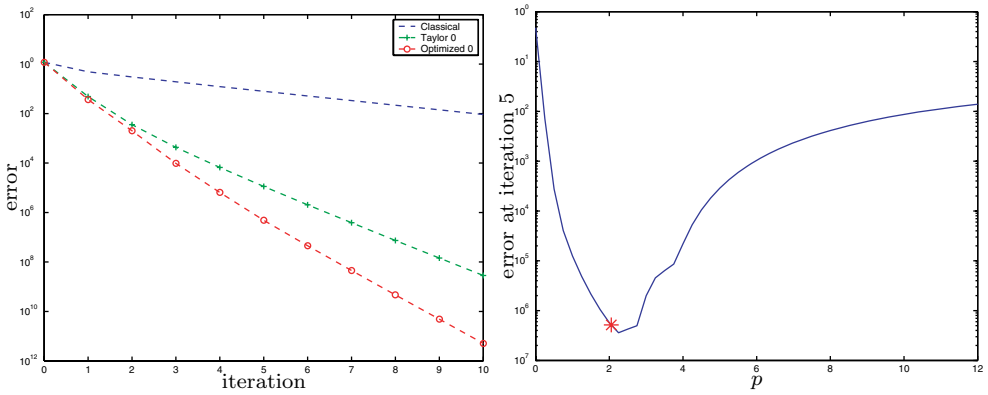

FIG. 6.2. *Left: Convergence rates of the classical Schwarz waveform relaxation algorithm with Dirichlet transmission conditions compared to the same algorithm with the new Robin transmission conditions, with the low frequency Taylor approximation or optimized. Right: The error obtained running the algorithm with Robin transmission conditions for* 5 *steps and various choices of the free parameter* p*, and indicated by a star the choice* p^* *predicted by the theory.*

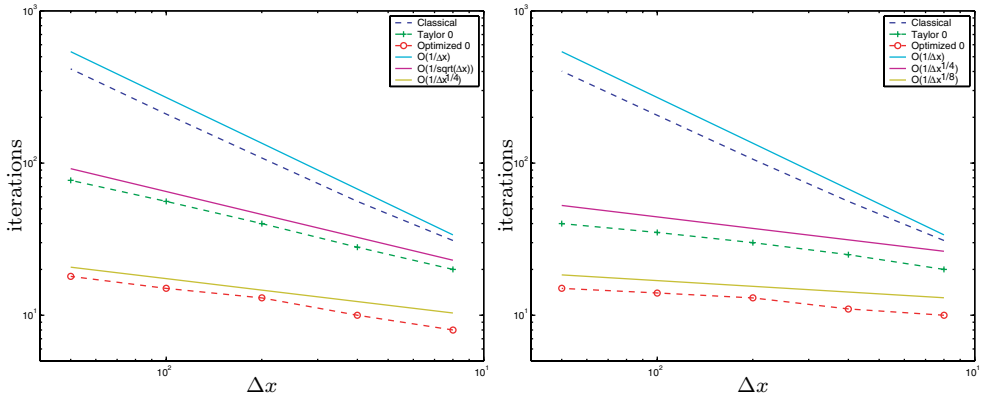

FIG. 6.3. *Asymptotic behavior as the mesh is refined with an overlap* $L = \Delta x$*: on the left the case where* $\Delta t = O(\Delta x)$ *and on the right the case where* $\Delta t = O(\sqrt{\Delta x})$*, together with the predicted rates from the analysis, both for the classical and the optimized Schwarz waveform relaxation algorithms with Taylor and optimized Robin transmission conditions.*

relevant case in practice.

Next, we verify if the optimal choice for the parameter $p = p^*$ derived using the continuous Fourier analysis in Theorem 5.13 really corresponds to the best choice one can make in the fully discretized algorithm. In Figure 6.2 on the right we show the error obtained after running the Schwarz waveform relaxation algorithm with Robin transmission conditions for five steps using various values for the free parameter p in the transmission conditions. The optimal choice p^* from Theorem 5.13 is indicated by a star. Clearly the continuous analysis predicts the optimal choice of the parameter p very well.

Finally, we illustrate the asymptotic analysis by performing two sets of experiments according to Theorems 5.10 and 5.14. We choose the same problem parameters as before but start now with a coarser mesh both in space and time, $\Delta x = 0.08$ and $\Delta t = 0.02$, and we fix the overlap to be $L = \Delta x$. We then run the classical and optimized Schwarz waveform relaxation algorithms with Taylor–Robin transmission

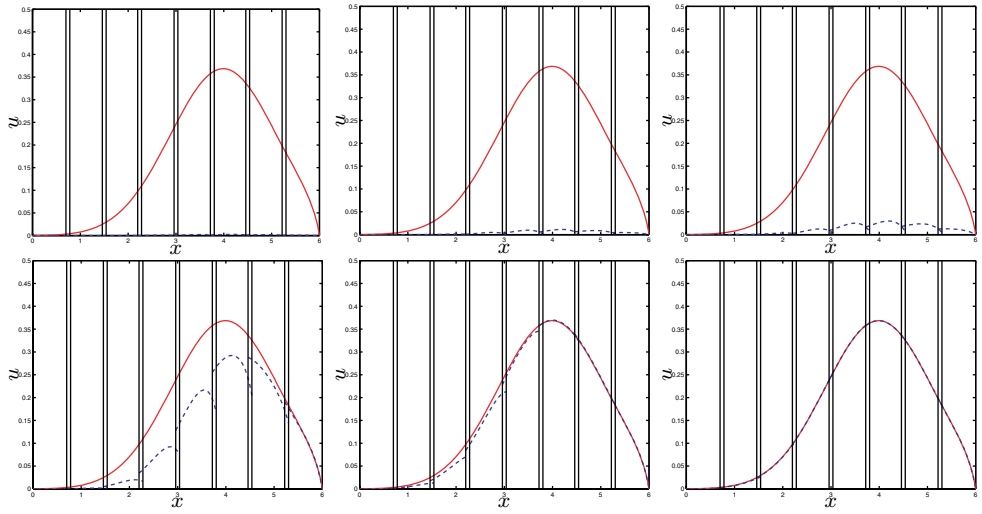

FIG. 6.4. *From left to right, the first iterates $u_j^k(x,T)$, $j=1,\ldots,8$, (dashed) at the end of the time interval $t=T$ together with the exact solution (solid) for the same model problem as before: top row the classical algorithm and bottom row the optimized algorithm.*

conditions until the error becomes smaller than 10^{-6} and count the number of iterations. We repeat this experiment dividing Δx and Δt by 2 several times, which implies $\Delta t = O(\Delta x)$. This corresponds to (3.16) for the classical algorithm, where the convergence factor should behave like $1 - O(\Delta x)$. For the algorithm with Taylor transmission conditions it corresponds to the case in Theorem 5.10, where the convergence factor should behave like $1 - O(\sqrt{\Delta x})$, and for the optimized algorithm it corresponds to the case in Theorem 5.14, where the convergence factor should behave like $1 - O(\Delta x^{\frac{1}{4}})$. Figure 6.3 shows on the left the results obtained from these experiments. One can see that the asymptotic analysis predicts very well the numerical behavior of the algorithms. Next, we perform a similar experiment, starting with the same values for Δx and Δt, but now we divide Δx by 2 each time and Δt only by $\sqrt{2}$ (such a refinement is admissible since our scheme is implicit), which implies

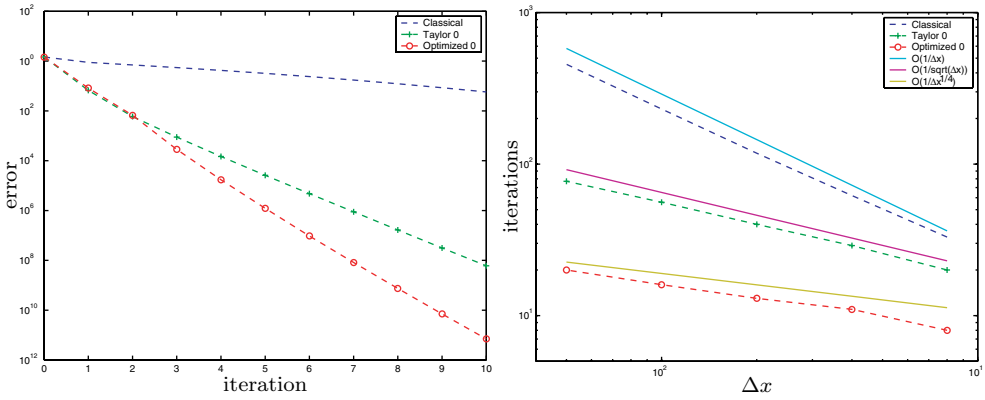

FIG. 6.5. *Left: convergence rate comparison for the eight subdomain case. Right: Asymptotic behavior as the mesh is refined with an overlap $L=\Delta x$ for the eight subdomain case, with $\Delta t = O(\Delta x)$, together with the predicted rates from the two subdomain analysis.*

$\Delta t = O(\sqrt{\Delta x})$. While this does not change anything for the classical algorithm, which still has the same bad convergence factor $1 - O(\Delta x)$, for the algorithm with Taylor–Robin transmission conditions now case 3 of Theorem 5.10 applies, and the algorithm should show the much better convergence factor $1 - O(\Delta x^{\frac{1}{4}})$. The optimized algorithm has according to Theorem 5.14 now the even better convergence factor $1 - O(\Delta x^{\frac{1}{8}})$, virtually independent of Δx. In Figure 6.3 on the right, one can clearly see that this is the case. The algorithm has different asymptotic convergence factors with the same overlap, depending on the discretization in time, as predicted.

6.3. Experiments with many subdomains. We now show experiments which indicate that the results we obtained for two subdomains are also relevant for many subdomains. Using the same model problem as before, we now decompose the domain into eight subdomains. In Figure 6.4, we show in the top row the first three iterations of the classical Schwarz waveform relaxation algorithm, and below we show the same iterations for the algorithm with optimized Robin transmission conditions. This clearly shows how important the transmission conditions are in the many subdomain case. We show the corresponding convergence rates in Figure 6.5 on the left, and on the right we perform the same asymptotic experiments as in Figure 6.3 on the left but now with eight subdomains, which indicates that the results of Theorems 5.10 and 5.14 also hold for more than two subdomains.

7. Conclusions. We have analyzed Schwarz waveform relaxation algorithms for advection reaction diffusion equations. We have shown that these methods, using the classical Dirichlet transmission conditions, are well defined and have a convergence rate which is bounded both by a linear and a superlinear rate. Both rates can be sharp, depending on the length of the time interval of the simulation. We then showed that there exist much better transmission conditions than the classical Dirichlet conditions. Optimal transmission conditions are transparent conditions, but they are in general nonlocal and thus less convenient to use. We introduced instead Robin transmission conditions in the Schwarz waveform relaxation algorithm, showed that the new algorithm is well posed and convergent, even if there is no overlap, and analyzed how to chose the free parameter in the new transmission conditions. We also gave asymptotic results when the overlap or the mesh parameters become small. We finally illustrated our findings with numerical experiments which document the relevance of our continuous analysis.

THE OPTIMAL CONVERGENCE OF THE *h-p* VERSION OF THE FINITE ELEMENT METHOD WITH QUASI-UNIFORM MESHES*

BENQI GUO† AND WEIWEI SUN‡

Dedicated to Professor R. S. Wong on the occasion of his sixtieth birthday

Abstract. In the framework of the Jacobi-weighted Besov spaces, we analyze the convergence of the *h-p* version of finite element solutions on quasi-uniform meshes and the lower and upper bounds of errors for elliptic problems on polygons. Both lower and upper bounds are proved to be optimal in h and p, which leads to the optimal convergence of the *h-p* version of the finite element method with quasi-uniform meshes for elliptic problems on polygons. The results proved for the *h-p* version include the *h*-version with quasi-uniform meshes and the *p*-version with quasi-uniform degrees as two special cases.

Key words. the *h-p* version, finite element method, quasi-uniform meshes, singularity, Jacobi-weighted Besov and Sobolev spaces, optimal rate of convergence

1. Introduction.

In this paper we investigate the convergence of the *h-p* version of the finite element method (FEM) with quasi-uniform meshes in two dimensions in the framework of the Jacobi-weighted Besov spaces. In particular, we prove asymptotically exact upper and lower bounds for the approximation error in finite element solutions of the *h-p* version for elliptic problems on polygonal domains whose solutions exhibit typical corner singularities. Our analysis is done within the framework of the Jacobi-weighted Besov spaces, which already has been proved an appropriate tool for obtaining optimal estimates for the *p*-version of the FEM for this type of problem; see [5, 6, 7]. Here we incorporate the mesh dependence into the analysis for the *p*-version and provide optimal estimates for any combination of mesh size and polynomial degree for the case of quasi-uniform meshes and uniform polynomial degrees.

The *p*-version of FEM uses a fixed mesh and improves the approximation of the solution by increasing degrees of piecewise polynomials. The *h*-version is based on mesh refinement and piecewise polynomials of low and fixed degrees. The *h-p* version combines mesh refinement with an increase of degrees. Let us recall the main theoretical achievements for the *h-p* version since its beginning. An analysis of the *h-p* version of the FEM in one dimension was given by Gui and Babuška [16]. They considered the approximation of typical singularities x^γ and proved optimal upper and lower bounds of error in the p and *h-p* finite element solutions in H^1 and L^2 norms. The approximation of singularities $x^\gamma \log^\nu x$ in one dimension was addressed, and

asymptotic analysis on the approximation error was given in [7]. The h-p version of the FEM with quasi-uniform meshes in two dimensions was analyzed by Babuška and Suri [10] after improving the approximation results of the p-version of the FEM [9]. They gave an upper bound of error in finite element approximation for elliptic problems with singularities $r^\gamma \log^\nu r$ ($r = |x|$ is the distance to the origin), which is actually of order $O(h^{-\gamma} p^{-2\gamma} \log^\nu (p/h))$. This upper bound is sharp for noninteger γ, and it can be sharper for integer γ and $\nu > 0$. Since then, the h-p FEM has been widely used for various scientific and engineering computations such as solid and fluid mechanics and electromagnetics [2, 3, 4, 13, 15, 29, 30]. The h-p FEM has been generalized to the h-p versions of the boundary element method (BEM) [19, 20, 28] and the discontinuous Galerkin method (DG FEM)[24, 25, 27, 26, 31] to solve linear and nonlinear elliptic, parabolic, and hyperbolic problems as well as multiscale problems. Commercial and research software packages based on the h-p FEM such as MSC/PROBE (MacNeal Schwendler, California), Poly FEM (IBM, Massachusetts), PHLEX (Computational Mechanics, Texas), STRESSCHECK (Engineering Software Research & Development, Missouri), and STRIPE (Aeronautical Research Institute of Sweden) are now widely used in engineering computation. While great progress in theory, algorithms, and applications of the h-p FEM were made in the last two decades, there has been no breakthrough in the optimal convergence of the h-p FEM for elliptic problems with singularities of $r^\gamma \log^\nu r$-type on polygonal domains. The lower bound and the sharpest estimation of the upper bound of the error in the h-p FEM solutions for elliptic problems with singular solutions of $r^\gamma \log^\nu r$-type have not been addressed until now. Therefore, the optimal convergence of the h-p version of FEM has not been well established yet.

The h-p version with quasi-uniform meshes is, from methodology and approximation theory, the p-version on scaled meshes. The approach of the p-version gives the p-dependence in the approximation errors, and a proper scaling argument will fully reveal the information of the h-dependence. Hence, the analysis for the best approximation of the h-p version with quasi-uniform meshes is not feasible unless the optimal convergence of the p-version is rigorously proved. Fortunately, the best a priori error estimation for the p-version has been recently established, and we are now ready to pursue the best a priori error estimation for the h-p version. In the last few years, with a series of papers by one of the authors and his collaborators [5, 6, 7, 19], a new analysis of the p-version has started in the framework of the Jacobi-weighted Besov and Sobolev spaces. The approximation theory of the FEM and BEM in two dimensions in this new mathematical framework is systematically developed in these papers, which demonstrates that Jacobi-weighted Besov and Sobolev spaces are the most appropriate tools for obtaining optimal upper and lower bounds of approximation errors when dealing with singular solutions on polygons. This framework has been generalized to the p-version of the FEM in three dimensions [17] and the h-p version of the BEM [20]. The Jacobi projection and interpolation have been developed recently in the spectral methods as well; see, e.g., [12, 21, 22, 23] and references therein. In this paper we will further develop the approximation theory of the h-p version of the FEM with quasi-uniform meshes. Based on the analysis of the upper and lower bounds of approximation error in the FEM solutions in terms of h and p, we will establish the optimal convergence of the h-p version of the FEM for elliptic problems on polygonal domains.

The rest of the paper is organized as follows. In section 2 we analyze approximation in the Jacobi-weighted Besov and Sobolev spaces on a standard domain

$Q = (-1,1)^2$. We introduce the Jacobi-weighted Besov and Sobolev spaces on a scaled domain $Q_h = (-h,h)^2$ in section 3 and analyze the approximation properties for smooth and singular functions of $r^\gamma \log^\nu r$-type in the framework of these spaces. These approximation results on scaled square domains are applied in section 4 to prove the convergence of the *h-p* version FEM with quasi-uniform meshes for elliptic problems with smooth solutions, and to derive the sharpest estimate of lower and upper bounds of error in FEM solutions of the *h-p* version for elliptic problems with singular solutions on polygonal domains, which leads to the optimal convergence of the *h-p* version of the FEM with quasi-uniform meshes. In the last section, we will make some concluding remarks.

2. Approximation in Jacobi-weighted spaces on a square domain.

2.1. Weighted Besov and Sobolev spaces.

Let $Q = I^2 = (-1,1)^2$, and let

$$w_{\alpha,\beta}(x) = \prod_{i=1}^{2} (1-x_i^2)^{\alpha_i+\beta_i} \tag{2.1}$$

be a weight function with integer $\alpha_i \geq 0$ and real number $\beta_i > -1$, which is referred to as the Jacobi weight. The weighted Sobolev space $H^{k,\beta}(Q)$ is defined as a closure of C^∞ functions in the norm with the Jacobi weight

$$\|u\|^2_{H^{k,\beta}(Q)} = \sum_{|\alpha|=0}^{k} \int_Q |D^\alpha u|^2 \, w_{\alpha,\beta}(x)\, dx, \tag{2.2}$$

where $D^\alpha u = u_{x_1^{\alpha_1},x_2^{\alpha_2}}$, $\alpha = (\alpha_1,\alpha_2), |\alpha| = \alpha_1+\alpha_2$, and $\beta = (\beta_1,\beta_2)$. By $|u|_{H^{k,\beta}(Q)}$ we denote the seminorm,

$$|u|_{H^{k,\beta}(Q)} = \sum_{|\alpha|=k} \int_Q |D^\alpha u|^2 \, w_{\alpha,\beta}(x)\, dx. \tag{2.3}$$

The Jacobi-weighted Sobolev space $H^{s,\beta}(Q)$ and Besov space $B^{s,\beta}(Q)$ are defined as interpolation spaces $\mathcal{B}^{s,\beta}_{2,q}(Q) = (H^{\ell,\beta}(Q), H^{k,\beta}(Q))_{\theta,q}$ with $q = 2$ and $q = \infty$, respectively, by the K-method, where $0 < \theta < 1$, $1 \leq q \leq \infty$, $s = (1-\theta)\ell + \theta k$, and ℓ and k are integers, $\ell < k$, furnished with norms

$$\|u\|_{\mathcal{B}^{s,\beta}_{2,2}(Q)} = \left(\int_0^\infty t^{-2\theta} \, |K(t,u)|^2 \frac{dt}{t} \right)^{1/q}, \quad \|u\|_{\mathcal{B}^{s,\beta}_{2,\infty}(Q)} = \sup_{t>0} t^{-\theta} \, K(t,u) \tag{2.4}$$

with

$$K(t,u) = \inf_{u=v+w} \Big(\|v\|_{H^{\ell,\beta}(Q)} + t\|w\|_{H^{k,\beta}(Q)} \Big).$$

The space $H^{s,\beta}(Q)$ is called the Jacobi-weighted Sobolev space with fractional order if s is not an integer, and the space $B^{s,\beta}(Q)$ is referred as to the Jacobi-weighted Besov space.

The modified weighted Besov space $B^{s,\beta}_\nu(Q)$ with $\nu \geq 0$ is defined as an interpolation space by a modified K-method,

$$B^{s,\beta}_\nu(Q) = \Big(H^{\ell,\beta}(Q), H^{k,\beta}(Q) \Big)_{\theta,\infty,\nu},$$

with a modified norm,

$$\|u\|_{B^{s,\beta}_{\nu}(Q)} = \sup_{t>0} K(t,u)\ \frac{t^{-\theta}}{(1+|\log t|)^{\nu}}. \tag{2.5}$$

Remark 2.1. The spaces $H^{s,\beta}(Q)$ and $B^{s,\beta}(Q) = B^{s,\beta}_0(Q)$ are exact of θ-exponent, but $B^{s,\beta}_{\nu}(Q)$ with $\nu > 0$ is not. It was proved in [5] that $B^{s,\beta}_{\nu}(Q)$ is weakly exact of θ-exponent. Suppose that E realizes a linear operator: $H_l \to H^{m_l,\beta}(Q)$, $l = 1, 2$, with norms denoted by $\|E\|_l$, where $H_l, l = 1, 2$, are Banach spaces. Then E is a linear operator: $(H_1, H_2)_{\theta,q} \to (H^{m_1,\beta}(Q), H^{m_2,\beta}(Q))_{\theta,q,\nu}$ such that for $\nu = 0$

$$\|E\|_{(H_1,H_2)_{\theta,q}\to(H^{m_1,\beta}(Q),H^{m_2,\beta}(Q))_{\theta,q,0}} \le \|E\|_1^{1-\theta}\|E\|_2^{\theta} \tag{2.6}$$

and for $\nu > 0$

$$\|E\|_{(H_1,H_2)_{\theta,q}\to(H^{m_1,\beta}(Q),H^{m_2,\beta}(Q))_{\theta,\infty,\nu}} \le \|E\|_1^{1-\theta}\|E\|_2^{\theta}\left(1+\log\frac{\|E\|_2}{\|E\|_1}\right)^{\nu}. \tag{2.7}$$

For the exact interpolation spaces of θ-exponent we refer to [11], and for the weak exactness of θ-exponent for the space $B^{s,\beta}_{\nu}(Q), \nu > 0$, we refer to [5].

We shall introduce the Jacobi projection and analyze its properties. Let $J^{\alpha,\beta}_n(x)$ be the Jacobi polynomial of degree n,

$$J^{\alpha,\beta}_n(x) = \frac{(1-x)^{-\alpha}(1+x)^{-\beta}}{2^n\, n!}\,\frac{d^n\,(1-x)^{\alpha+n}(1+x)^{\beta+n}}{dx^n} \tag{2.8}$$

with $\alpha, \beta > -1$. In particular, for $\alpha = \beta$, we write $J^{\beta,\beta}_n(x) = J^{\beta}_n(x)$. The Jacobi polynomials $J^{\beta}_n(x)$ are orthogonal with the Jacobi weight $w_\beta(x) = (1-x^2)^{\beta}$:

$$\int_I J^{\beta}_m(x)\, J^{\beta}_n(x)\, w_\beta(x)\, dx = \begin{cases} \gamma^{\beta}_n, & m = n, \\ 0, & m \ne n \end{cases}$$

with

$$\gamma^{\beta}_n = \frac{2^{2\beta+1}\Gamma^2(n+\beta+1)}{(2n+2\beta+1)\Gamma(n+1)\Gamma(n+2\beta+1)}. \tag{2.9}$$

Let $J^{\beta}_{n,k}(x) = \frac{d^k}{dx^k} J^{\beta}_n(x)$. Then for $0 \le k \le n$

$$J^{\beta}_{n,k}(x) = 2^{-k}\frac{\Gamma(n+2\beta+k+1)}{\Gamma(n+2\beta+1)} J^{\beta+k}_{n-k}(x),$$

which are orthogonal with the Jacobi weight $w_{\beta+k}(x) = (1-x^2)^{\beta+k}$:

$$\int_I J^{\beta}_{m,k}(x) J^{\beta}_{n,k}(x)\, w_{\beta+k}(x)\, dx = \begin{cases} \gamma^{\beta}_{n,k}, & m = n \ge k, \\ 0 & \text{otherwise} \end{cases}$$

with

$$\gamma^{\beta}_{n,k} = \frac{2^{2\beta+1}\,\Gamma(n+2\beta+k+1)\,\Gamma^2(n+\beta+1)}{(2n+2\beta+1)\,\Gamma(n+1-k)\,\Gamma^2(n+2\beta+1)}. \tag{2.10}$$

By the Stirling formula [14], there hold asymptotically

(2.11)
$$\gamma_n^\beta = \frac{2^{2\beta+1}}{(2n+2\beta+1)}(1+O((n+1)^{-1/5})),\ \ \gamma_{n,k}^\beta = \frac{2^{2\beta+1}n^{2k}}{(2n+2\beta+1)}(1+O((n+1)^{-1/5})).$$

It is known [1, 23] that for $x \in [-1,1]$ there holds

$$|J_n^\beta(x)| \le C(n+1)^{\max\{\beta,-1/2\}} \tag{2.12}$$

and for $x = \pm 1$, we have the more precise estimation

$$|J_n^\beta(1)| = |J_n^\beta(-1)| \le C(n+1)^\beta. \tag{2.13}$$

For $u \in H^{k,\beta}(Q), k \ge 0$, with $\beta = (\beta_1, \beta_2)$, there is the Jacobi–Fourier expansion

$$u = \sum_{i,j=0}^{\infty} c_{i,j} J_i^{\beta_1}(x_1) J_j^{\beta_2}(x_2)$$

with

$$c_{i,j} = \frac{1}{\gamma_i^{\beta_1}\gamma_j^{\beta_2}} \int_Q u(x)\, J_i^{\beta_1}(x_1) J_j^{\beta_2}(x_2)\, w_\beta(x) dx,$$

where $J_i^{\beta_1}(x_1)$ and $J_j^{\beta_2}(x_2)$ are the Jacobi polynomials and $w_\beta(x) = (1-x_1^2)^{\beta_1}(1-x_1^2)^{\beta_1}$. Then

$$\|u\|_{L_\beta^2}^2(Q) = \sum_{i,j=0}^{\infty} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} \tag{2.14}$$

and

(2.15)
$$|u|_{H^{k,\beta}(Q)}^2 = \sum_{|\alpha|=k} \sum_{i\ge\alpha_1, j\ge\alpha_2} |c_{i,j}|^2 \gamma_{i,\,\alpha_1}^{\beta_1}\gamma_{j,\,\alpha_2}^{\beta_2} \cong \sum_{|\alpha|=k} \sum_{i\ge\alpha_1, j\ge\alpha_2} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2\alpha_1} j^{2\alpha_2}.$$

Hereafter $A \cong B$ means $c_1 B \le A \le c_2 B$ with constants c_1 and c_2 independent of A and B.

Let $\mathcal{P}_p(Q)$ with $p \ge 0$ be the set of all polynomials of (separate) degree $\le p$ on Q. Then

$$u_p = \prod_p^\beta u = \sum_{i,j=0}^{p} c_{i,j} J_i^{\beta_1}(x_1) J_j^{\beta_2}(x_2)$$

is the Jacobi projection of $u \in H^{k,\beta}(Q), k \ge 0$, on $\mathcal{P}_p(Q)$.

2.2. Approximation properties of the Jacobi projection on $Q = (-1,1)^2$.

THEOREM 2.1. *Let $u \in H^{k,\beta}(Q)$ with integer $k \ge 0$, $\beta = (\beta_1, \beta_2)$, $\beta_i > -1$, $1 \le i \le 2$, and let $u_p = \Pi_p^\beta u$ be its Jacobi projection on $\mathcal{P}_p(Q)$ with $p \ge 0$. Then we have for integer $\ell \le k$*

$$\|u - u_p\|_{H^{\ell,\beta}(Q)} \le C\,(p+1)^{-(k-l)}\ \|u\|_{H^{k,\beta}(Q)}. \tag{2.16}$$

Furthermore, if $u \in H^{k,\beta}(Q)$ with $k > 1$, $\beta_i \le -1/2$, $1 \le i \le 2$, then for $x \in \bar{Q}$

$$\|u - u_p\|_{C^0(\bar{Q})} \le C(p+1)^{-(k-l)} \|u\|_{H^{k,\beta}(Q)}, \tag{2.17}$$

$$|(u - u_p)(\pm 1, x_2)| \le C(p+1)^{-(k-3/2-\beta_1)} \|u\|_{H^{k,\beta}(Q)}, \tag{2.18}$$

$$|(u - u_p)(x_1, \pm 1)| \le C(p+1)^{-(k-3/2-\beta_2)} \|u\|_{H^{k,\beta}(Q)}, \tag{2.19}$$

$$|(u - u_p)(\pm 1, \pm 1)| \le C(p+1)^{-(k-2-\beta_1-\beta_2)} \|u\|_{H^{k,\beta}(Q)}. \tag{2.20}$$

If $p \ge k-1$, $k \ge 1$, $l \le k$, we have estimations in seminorms

$$|u - u_p|_{H^{\ell,\beta}(Q)} \le C\,(p+1)^{-(k-\ell)}\, |u|_{H^{k,\beta}(Q)}, \tag{2.21}$$

and if, in addition, $k > 1$, $\beta_i \le -1/2$, $1 \le i \le 2$, there hold for $x \in \bar{Q}$

$$|(u - u_p)(x)| \le C(p+1)^{-(k-1)} |u|_{H^{k,\beta}(Q)}, \tag{2.22}$$

$$|(u - u_p)(\pm 1, x_2)| \le C(p+1)^{-(k-3/2-\beta_1)} |u|_{H^{k,\beta}(Q)}, \tag{2.23}$$

$$|(u - u_p)(x_1, \pm 1)| \le C(p+1)^{-(k-3/2-\beta_2)} |u|_{H^{k,\beta}(Q)}, \tag{2.24}$$

$$|(u - u_p)(\pm 1, \pm 1)| \le C(p+1)^{-(k-2-\beta_1-\beta_2)} |u|_{H^{k,\beta}(Q)}. \tag{2.25}$$

The constants C in the above inequalities are independent of p and u.

Proof. By (2.15) we have for $\alpha = (\alpha_1, \alpha_2)$ with $|\alpha| = l$

$$\begin{aligned} \int_Q |D^\alpha (u - u_p)|^2 w_{\alpha,\beta}(x)dx &= \sum_{i \ge \max\{p+1,\alpha_1\}, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i,\alpha_1} \gamma^{\beta_2}_{j,\alpha_2} \\ &+ \left(\sum_{\alpha_1 \le i \le p, j \ge \max\{p+1,\alpha_2\}} + \sum_{i \ge \max\{p+1,\alpha_1\}, \alpha_2 \le j \le p} \right) |c_{i,j}|^2 \gamma^{\beta_1}_{i,\alpha_1} \gamma^{\beta_2}_{j,\alpha_2}. \end{aligned} \tag{2.26}$$

Due to (2.11) there hold

$$\begin{aligned} &\sum_{i \ge \max\{p+1,\alpha_1\}, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i,\alpha_1} \gamma^{\beta_2}_{j,\alpha_2} \\ &\le C \sum_{i \ge \max\{p+1,\alpha_1\}, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i} \gamma^{\beta_2}_{j} i^{2\alpha_1} j^{2\alpha_2} \\ &\le C(p+1)^{-2(k-l)} \sum_{i \ge \max\{p+1,\alpha_1\}, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i} \gamma^{\beta_2}_{j} i^{2\alpha_1} j^{2(k-\alpha_1)}. \end{aligned} \tag{2.27}$$

Similarly, we have

$$\begin{aligned} &\sum_{\alpha_1 \le i \le p, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i,\alpha_1} \gamma^{\beta_2}_{j,\alpha_2} \\ &\le C(p+1)^{-2(k-l)} \sum_{\alpha_1 \le i \le p, j \ge \max\{p+1,\alpha_2\}} |c_{i,j}|^2 \gamma^{\beta_1}_{i} \gamma^{\beta_2}_{j} \gamma^{\beta_2}_{j} i^{2\alpha_1} j^{2(k-\alpha_1)} \end{aligned} \tag{2.28}$$

and

$$\begin{aligned} &\sum_{i \ge \max\{p+1,\alpha_1\}, \alpha_2 \le j \le p} |c_{i,j}|^2 \gamma^{\beta_3,\beta_1}_{i,\alpha_1} \gamma^{\beta_4,\beta_2}_{j,\alpha_2} \\ &\le C(p+1)^{-2(k-l)} \sum_{i \ge \max\{p+1,\alpha_1\}, \alpha_2 \le j \le p} |c_{i,j}|^2 \gamma^{\beta_1}_{i} \gamma^{\beta_2}_{j} \gamma^{\beta_2}_{j} i^{2(k-\alpha_2)} j^{2\alpha_2}. \end{aligned} \tag{2.29}$$

A combination of (2.26)–(2.29) leads to (2.17).

We shall next prove (2.17). Since $k > 1, \beta_1, \beta_2 \le -1/2$, $u \in C^0(\bar{Q})$ [18], and due to (2.11) and (2.12), there holds

$$|(u-u_p)(x)| \le \left(\sum_{i,j\ge p+1} + \sum_{i\ge p+1, 0\le j\le p} + \sum_{0\le i\le p, j\ge p+1} \right) |c_{i,j}| \sqrt{\gamma_i^{\beta_1}\gamma_j^{\beta_2}}. \tag{2.30}$$

By the Schwartz inequality there holds

(2.31)

$$\begin{aligned} \sum_{i\ge p+1,0\le j\le p} |c_{i,j}| \sqrt{\gamma_i^{\beta_1}\gamma_j^{\beta_2}} &\le \left(\sum_{i\ge p+1,0\le j<p} i^{-2k} \right)^{\frac{1}{2}} \left(\sum_{i\ge p+1,0\le j\le p} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2k} \right)^{\frac{1}{2}} \\ &\le C(p+1)^{-(k-1)} \left(\sum_{i\ge p+1,0\le j\le p} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2k} \right)^{\frac{1}{2}}. \end{aligned}$$

Similarly, we can prove that

$$\sum_{0\le i\le p, j\ge p+1} |c_{i,j}| \sqrt{\gamma_i^{\beta_1}\gamma_j^{\beta_2}} \le C(p+1)^{-(k-1)} \left(\sum_{0\le i\le p, j\ge p+1} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} j^{2k} \right)^{\frac{1}{2}} \tag{2.32}$$

and

$$\sum_{i,j\ge p+1} |c_{i,j}| \sqrt{\gamma_i^{\beta_1}\gamma_j^{\beta_2}} \le C(p+1)^{-(k-1)} \left(\sum_{p+1\le i,j<\infty} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2k} \right)^{1/2}. \tag{2.33}$$

Combining (2.30)–(2.33), we obtain (2.17). The above arguments can be carried out for (2.18)–(2.20) except that we use (2.13) instead of (2.12).

For $p \ge k-1 \ge 0$, there holds

$$\begin{aligned} &\int_Q |D^\alpha (u-u_p)|^2 w_{\alpha,\beta}(x)dx \\ &\qquad = \left(\sum_{i,j\ge p+1} + \sum_{\alpha_1\le i\le p, j\ge p+1} + \sum_{i\ge p+1,\alpha_2\le j\le p} \right) |c_{i,j}|^2 \gamma_{i,\alpha_1}^{\beta_3,\beta_1} \gamma_{j,\alpha_2}^{\beta_4,\beta_2}. \end{aligned}$$

Note that

$$\sum_{i,j\ge p+1} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2\alpha_1} j^{2(k-\alpha_1)} \le \sum_{i,j\ge k} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2\alpha_1} j^{2(k-\alpha_1)} \le |u|^2_{H^{k,\beta}(Q)},$$

$$\begin{aligned} \sum_{\alpha_1\le i\le p, j\ge p+1} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2\alpha_1} j^{2(k-\alpha_1)} &\le \sum_{\alpha_1\le i\le p, j\ge k} |c_{i,j}|^2 \gamma_i^{\beta_1}\gamma_j^{\beta_2} i^{2\alpha_1} j^{2(k-\alpha_1)} \\ &\le |u|^2_{H^{k,\beta}(Q)}, \end{aligned}$$

$$\sum_{i\ge p+1,\alpha_2\le j\le p}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2(k-\alpha_2)}j^{2\alpha_2}\le\sum_{i\ge k,\alpha_2\le j\le p}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2(k-\alpha_2)}j^{2\alpha_2}\le|u|^2_{H^{k,\beta}(Q)},$$

$$\sum_{i\ge p+1,0\le j\le p}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2k}\le\sum_{i\ge k,0\le j\le p}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2k}\le|u|^2_{H^{k,\beta}(Q)},$$

$$\sum_{0\le i\le p,j\ge p+1}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}j^{2k}\le\sum_{0\le i\le p,j\ge k}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}j^{2k}\le|u|^2_{H^{k,\beta}(Q)},$$

$$\sum_{i,j\ge p+1}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2k}\le\sum_{i,j\ge k}|c_{i,j}|^2\gamma_i^{\beta_1}\gamma_j^{\beta_2}i^{2k}\le|u|^2_{H^{k,\beta}(Q)},$$

which lead to (2.21)–(2.25) immediately. ∎

Remark 2.2. The estimates in seminorms are derived in [5] for $p\ge k-1$. The estimates in Jacobi-weighted Sobolev norms and C^0 norms for $p\ge 0$ are available in this paper for the first time.

The argument of interpolation spaces yields the approximation results in the spaces $H^{s,\beta}(Q)$ and $B^{s,\beta}_\nu(Q)$, $\nu\ge 0$. We refer to [11] for the details of the proof for the spaces $H^{s,\beta}(Q)$ and $B^{s,\beta}(Q)$, and to [5] for the spaces $B^{s,\beta}_\nu(Q)$, $\nu>0$.

THEOREM 2.2. *Let $u\in H^{s,\beta}(Q)$ (resp., $B^{s,\beta}_\nu(Q)$), $s>0$, $\beta_i=(\beta_1,\beta_2)$, $\beta_i>-1$, $1\le i\le 2$, integer $\nu\ge 0$, and let u_p be the Jacobi projection of u on $\mathcal{P}_p(Q)$ with $p\ge 1$. Then for any integer $\ell<s$ there holds*

(2.34)
$$\|u-u_p\|_{H^{\ell,\beta}(Q)}\le C\,(p+1)^{-(s-\ell)}\,\|u\|_{H^{s,\beta}(Q)}\left(resp.,\ \tfrac{(1+\log(p+1))^\nu}{(p+1)^{s-\ell}}\|u\|_{B^{s,\beta}_\nu(Q)}\right).$$

Furthermore, if $u\in H^{s,\beta}(Q)$ (resp., $B^{s,\beta}_\nu(Q)$) with $s>1,\beta_i\le -1/2, 1\le i\le 2$, then for $x\in\bar Q$

(2.35) $$\|u-u_p\|_{C^0(\bar Q)}\le C(p+1)^{-(s-1)}\,\|u\|_{H^{s,\beta}(Q)}\left(resp.,\ \tfrac{(1+\log(p+1))^\nu}{(p+1)^{s-1}}\|u\|_{B^{s,\beta}_\nu(Q)}\right),$$

(2.36)
$$|(u-u_p)(\pm1,x_2)|\le C(p+1)^{-(s-3/2-\beta_1)}\,\|u\|_{H^{s,\beta}(Q)}\left(resp.,\ \tfrac{(1+\log(p+1))^\nu}{(p+1)^{s-3/2-\beta_1}}\|u\|_{B^{s,\beta}_\nu(Q)}\right),$$

(2.37)
$$|(u-u_p)(x_1,\pm1)|\le C(p+1)^{-(s-3/2-\beta_2)}\,\|u\|_{H^{s,\beta}(Q)}\left(resp.,\ \tfrac{(1+\log(p+1))^\nu}{(p+1)^{s-3/2-\beta_2}}\|u\|_{B^{s,\beta}_\nu(Q)}\right),$$

(2.38)
$$|(u-u_p)(\pm1,\pm1)|\le C(p+1)^{-(s-2-\beta_1-\beta_2)}\,\|u\|_{H^{s,\beta}(Q)}\left(resp.,\ \tfrac{(1+\log(p+1))^\nu}{(p+1)^{s-2-\beta_1-\beta_2}}\|u\|_{B^{s,\beta}_\nu(Q)}\right).$$

The constants C in the above inequalities are independent of p and u.

Remark 2.3. By the usual argument of interpolation spaces defined by the real method, e.g., the K-method, Theorems 2.1–2.2 stand for noninteger ℓ.

2.3. Approximability of singular functions on $Q = (-1,1)^2$. Let (r,θ) be the polar coordinates with respect to the vertex $(-1,-1)$, where $r = \{(x_1+1)^2 + (x_2+1)^2\}^{1/2}$, $\theta = \arctan(\frac{x_2+1}{x_1+1})$. For $\gamma > 0$ and integer $\nu \geq 0$

$$u(x) = r^\gamma \log^\nu r\, \chi(r)\, \Phi(\theta) \tag{2.39}$$

is a singular function defined on $Q = (-1,1)^2$, where $\chi(r)$ and $\Phi(\theta)$ are C^∞ functions such that for $0 < r_0 < 2$

$$\chi(r) = \begin{cases} 1 & \text{for} \quad 0 < r \leq \frac{r_0}{2}, \\ 0 & \text{for} \quad r \geq r_0. \end{cases} \tag{2.40}$$

Let $R_0 = R_{r_0,\theta_0}$ be a subregion of Q with $\theta_0 \in (0, \pi/4)$ and $r_0 \in (0,2)$:

$$R_{r_0,\theta_0} = \left\{ x \in Q \;\middle|\; r < r_0, \quad \theta_0 < \theta < \pi/2 - \theta_0 \right\}, \tag{2.41}$$

which is shown in Figure 2.1. For $x \in R_0$ we have $0 < 2 - r_0 < (1 - x_i) < 2$, and

$$\kappa_0 = \tan\theta_0 \leq \frac{1+x_2}{1+x_1} \leq \frac{1}{\kappa_0}.$$

Now we characterize the singularity of $u(x)$ in terms of the weighted Besov spaces $B^{s,\beta}_\nu(Q)$.

THEOREM 2.3 (see [5, Theorem 3.10]). *Let $u = r^\gamma \log^\nu r\, \chi(r)\, \Phi(\theta)$ be as given in (2.39) with $\gamma > 0$ and integer $\nu \geq 0$. Then $u \in B^{s,\beta}_{\nu^*}(Q)$ with $s = 2 + 2\gamma + \beta_1 + \beta_2$, $\beta_i > -1$, $i = 1,2$, and*

$$\nu^* = \begin{cases} \nu & \text{if } \gamma \text{ is not an integer or } \nu = 0, \\ \nu - 1 & \text{if } \gamma \text{ is an integer and } \nu \geq 1. \end{cases} \tag{2.42}$$

A combination of Theorems 2.3 and 2.1–2.2 leads to the approximabilities of the singular functions of $r^\gamma \log^\nu r$-type with $\gamma > 0$ and integer $\nu \geq 0$.

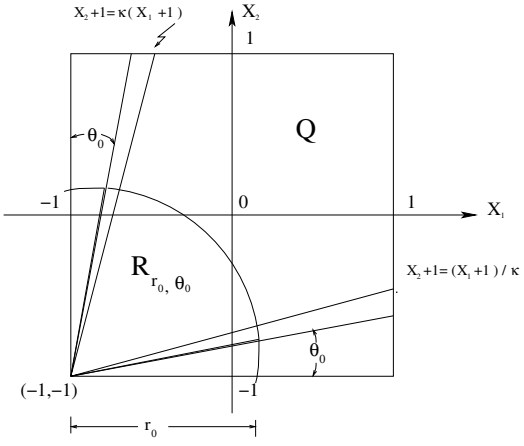

FIG. 2.1. *Square domain Q and subregion R_{ρ_0,θ_0}.*

THEOREM 2.4 (see [7, Theorem 3.8]). *Let $u(x)$ be as given in* (2.39) *with $\gamma > 0$ and integer $\nu \geq 0$, and let ψ and φ be the Jacobi projection of u on $\mathcal{P}_p(Q)$, $p \geq 1$, associated with $\beta = (0,0)$ and $\beta = (-1/2,-1/2)$, respectively. Then*

$$\|u-\psi\|_{L^2(Q)} \leq C\,(p+1)^{-2-2\gamma}(1+\log(1+p))^{\nu^*}\|v\|_{B^{2+2\gamma,\beta}_{\nu^*}(Q)} \tag{2.43}$$

with $\beta = (0,0)$, and

$$\|u-\phi\|_{H^1(R_0)} \leq C\,(p+1)^{-2\gamma}(1+\log(1+p))^{\nu^*}\|v\|_{B^{1+2\gamma,\beta}_{\nu^*}(Q)} \tag{2.44}$$

with $\beta = (-1/2,-1/2)$, where R_0 and ν^* are as given in (2.41) *and* (2.42).

THEOREM 2.5 (see [7, Theorems 2.9–2.11]). *Let $u(x)$ be as given in* (2.39) *with $\gamma > 0$ and $\nu \geq 1$.*

(i) *If $r^\gamma\,\Phi(\theta)$ is not a polynomial and $\nu = 0$, then*

$$\inf_{\varphi\in\mathcal{P}_p(Q)}\|u-\varphi\|_{H^1(R_0)} \geq C\,(p+1)^{-2\gamma}; \tag{2.45}$$

(ii) *If the integer $\nu \geq 1$, there holds*

$$\inf_{\varphi\in\mathcal{P}_p(Q)}\|v-\varphi\|_{H^1(R_0)} \geq C\,(p+1)^{-2\gamma}(1+\log(1+p))^{\nu^*}. \tag{2.46}$$

Here the constant C independent of p, R_0 and ν^* are as given in (2.41) *and* (2.42).

Remark 2.4. We exclude the trivial case that $\nu = 0$ and $r^\gamma\,\Phi(\theta)$ is a polynomial for which there is no approximation error. Throughout our paper, we assume that $r^\gamma\,\Phi(\theta)$ is not a polynomial while $\nu = 0$.

3. Approximation in Jacobi-weighted spaces on a scaled domain.

3.1. The Jacobi-weighted Besov and Sobolev spaces on $Q_h = (-h,h)^2$. For analyzing the approximation properties for smooth and singular functions on a scaled region we need to introduce the Jacobi-weighted Sobolev spaces $H^{k,\beta}(Q_h)$ and Besov spaces $B^{s,\beta}_\nu(Q_h)$ on a scaled square $Q_h = (-h,h)^2$.

Let $w^h_{\alpha,\beta}(x)$ be a weighted function on $Q_h = (-h,h)^2$:

$$w^h_{\alpha,\beta}(x) = \prod_{i=1}^{2}\left(\frac{h^2-x_i^2}{h^2}\right)^{\alpha_i+\beta_i} = \prod_{i=1}^{2}\left(1-\left(\frac{x_i}{h}\right)^2\right)^{\alpha_i+\beta_i},$$

where $\alpha = (\alpha_1,\alpha_2)$, $\alpha_i \geq 0$, integer, and $\beta = (\beta_1,\beta_2), \beta_i > -1$, real, $1 \leq i \leq 2$.

The Jacobi-weighted Sobolev space $H^{k,\beta}(Q_h)$, $k \geq 0$, is the closure of C^∞ functions furnished with the norm

$$\|u\|^2_{H^{k,\beta}(Q_h)} = \sum_{0\leq|\alpha|\leq k}\int_Q |D^\alpha u(x)|^2 w^h_{\alpha,\beta}(x)dx,$$

and $|u|_{H^{k,\beta}(Q_h)}$ denotes the seminorm involving only the kth derivatives.

The Jacobi-weighted Sobolev spaces $H^{s,\beta}(Q_h)$ and Besov spaces $B^{s,\beta}(Q_h)$ can be introduced as usual interpolation spaces by the K-method:

$$H^{s,\beta}(Q_h) = \Big(H^{\ell,\beta}(Q_h), H^{k,\beta}(Q_h)\Big)_{\theta,2}, \quad B^{s,\beta}(Q_h) = \Big(H^{\ell,\beta}(Q_h), H^{k,\beta}(Q)\Big)_{\theta,\infty}.$$

The space $B_\nu^{s,\beta}(Q_h)$ is an interpolation defined by the modified K-method:

$$B_\nu^{s,\beta}(Q_h) = \Big(H^{\ell,\beta}(Q_h), H^{k,\beta}(Q_h)\Big)_{\theta,\infty,\nu}.$$

Due to the definition of interpolation spaces and a simple scaling, the following proposition can be easily proved.

PROPOSITION 3.1. *Let $u(x)$ and $U(\xi) = u(h\xi)$ be functions defined on Q_h and Q, respectively.*

(i) *$u \in H^{k,\beta}(Q_h)$ with integer $k \geq 0$ if $U(\xi) = u(h\xi) \in H^{k,\beta}(Q)$, and vice versa. Furthermore, there holds for $l \leq k$*

$$|u|^2_{H^{\ell,\beta}(Q_h)} = h^{1-l}|U|_{H^{l,\beta}(Q)}. \tag{3.1}$$

(ii) *$u \in H^{s,\beta}(Q_h)$ with noninteger $s \geq 0$ if $U(\xi) \in H^{s,\beta}(Q)$, and vice versa.*

(iii) *$u \in B_\nu^{s,\beta}(Q_h)$ with real $s > 0$ and integer $\nu \geq 0$ if $U(\xi) \in B_\nu^{s,\beta}(Q)$, and vice versa.*

3.2. Approximation in Jacobi-weighted spaces on $Q_h = (-h, h)^2$. Let $\mathcal{P}_p(Q_h)$ be a set of polynomials of degree $\leq p$ on the scaled square Q_h, and let $\prod_{p,h}^\beta$ be the Jacobi projection operator on $\mathcal{P}_p(Q)$. Obviously, for $u \in H^{k,\beta}(Q_h)$ with $k \geq 0$, $u_{hp}(x) = \prod_{p,h}^\beta u$ is the Jacobi projection of $u \in H^{k,\beta}(Q_h)$ on $\mathcal{P}_p(Q_h)$ if and only if $U_p(\xi) = u_{hp}(h\xi)$ is the Jacobi projection of $U(\xi) = u(h\xi)$ on $\mathcal{P}_p(Q)$.

LEMMA 3.1. *Let $u \in H^{k,\beta}(Q_h), k \geq 0$. Then*

$$\|U - U_p\|_{H^{k,\beta}(Q)} \leq Ch^{\mu-1}\|u\|_{H^{k,\beta}(Q_h)}, \tag{3.2}$$

where $\mu = \min\{k, p+1\}$ and C is independent of p, h, k, and u.

Proof. For $k = 0$

$$\|U - U_p\|_{H^{0,\beta}(Q)} \leq \|U\|_{H^{0,\beta}(Q)} \leq h^{-1}\|u\|_{H^{0,\beta}(Q_h)}. \tag{3.3}$$

We now assume that the integer $k \geq 1$. Then we have by (2.21) of Theorem 2.1

$$\begin{aligned}\|U - U_p\|_{H^{k,\beta}(Q)} &\leq \|U - U_p\|_{H^{\mu,\beta}(Q)} + \sum_{m=\mu+1}^{k} (|U|_{H^{m,\beta}(Q)} + |U_p|_{H^{m,\beta}(Q)}) \\ &\leq C\left(|U|_{H^{\mu,\beta}(Q)} + \sum_{m=\mu+1}^{k} |U|_{H^{m,\beta}(Q)}\right).\end{aligned}$$

Here $\sum_{m=\mu+1}^{k} = 0$ if $\mu + 1 < k$. By the scaling argument (3.1), we obtain

$$\|U - U_p\|_{H^{k,\beta}(Q)} \leq C\sum_{m=\mu}^{k} h^{m-1}|u|_{H^{m,\beta}(Q_h)} \leq Ch^{\mu-1}\|u\|_{H^{k,\beta}(Q_h)},$$

which completes the proof. ∎

THEOREM 3.2. *Let $u \in H^{k,\beta}(Q_h)$ and let u_{ph} be its Jacobi projection on $\mathcal{P}_p(Q_h)$ with $p \geq 1$. Then, for $0 \leq l \leq k$,*

$$\|u - u_{hp}\|_{H^{l,\beta}(Q_h)} \leq C\frac{h^{\mu-l}}{(p+1)^{k-l}}\|u\|_{H^{k,\beta}(Q_h)} \tag{3.4}$$

with $\mu = \min\{k, p+1\}$. *Furthermore, if* $k > 1$, $\beta_\ell \le -1/2$, $1 \le \ell \le 2$, *then*

$$\|u - u_{hp}\|_{C^0(\bar{Q})} \le C \frac{h^{\mu-1}}{(p+1)^{k-1}} \|u\|_{H^{k,\beta}(Q_k)}. \tag{3.5}$$

The constants C *are independent of* $p, h, k,$ *and* u.

Proof. Let $\xi = \frac{x}{h}$ and $U(\xi) = u(h\xi)$. Then, due to Proposition 3.1, $U \in H^{k,\beta}(Q)$, and

$$\begin{aligned}\|U - U_p\|_{H^{l,\beta}(Q)} &= \|U - U_p - \textstyle\prod_p^\beta (U - U_p)\|_{H^{l,\beta}(Q)} \\ &\le C(p+1)^{-(k-l)} \|U - U_p\|_{H^{k,\beta}(Q)} \le C(p+1)^{-(k-l)} h^{\mu-1} \|u\|_{H^{k,\beta}(Q_h)},\end{aligned}$$

which together with the scaling argument (3.1) leads to

$$\|u - u_{hp}\|_{H^{l,\beta}(Q_h)} \le C h^{1-l} \|(U - U_p)\|_{H^{l,\beta}(Q)} \le C p^{-(k-l)} h^{\mu-l} \|u\|_{H^{k,\beta}(Q_h)}.$$

If $k > 1$ and $\beta_\ell \le -1/2, 1 \le \ell \le 2$, then there holds by Theorem 2.1 and Lemma 3.1

$$\begin{aligned}&|(u - u_{hp})(x)| = |U - U_p(\xi)| \le |(U - U_p - \textstyle\prod_p^\beta (U - U_p))(\xi)| \\ &\le C(p+1)^{-(k-1)} \|U - U_p\|_{H^{k,\beta}(Q)} \le C(p+1)^{-(k-1)} h^{\mu-1} \|u\|_{H^{k,\beta}(Q_h)}. \qquad \square\end{aligned}$$

By the argument of interpolation spaces, we have the approximation results in the spaces $H^{s,\beta}(Q_h)$ and $B_\nu^{s,\beta}(Q_h)$.

THEOREM 3.3. *Let* $u \in H^{s,\beta}(Q_h)$ $(resp., B_\nu^{s,\beta}(Q_h))$ *with* ≥ 0, *and let* u_{hp} *be the projection of* u *on* $\mathcal{P}_p(Q_h)$ *with* $p \ge 0$. *Then for* $0 \le l \le s$,

$$\begin{aligned}&\|u - u_{hp}\|_{H^{l,\beta}(Q_h)} \\ &\le C \frac{h^{\mu-l}}{(p+1)^{s-l}} \|u\|_{H^{s,\beta}(Q_h)} \left(resp., \frac{h^{\mu-1}}{(p+1)^{s-1}} \left(1 + \log \frac{p+1}{h}\right)^\nu B_\nu^{s,\beta}(Q_h) \right)\end{aligned} \tag{3.6}$$

with $\mu = \min\{s, p+1\}$. *Furthermore, if* $u \in H^{s,\beta}(Q_h)$ *with* $s > 1, \beta_\ell \le -1/2, 1 \le \ell \le 2$, *then for* $x \in \bar{Q}_h$

$$\begin{aligned}&|(u - u_{hp}(x)| \\ &\le C \frac{h^{\mu-l}}{(p+1)^{s-l}} \|u\|_{H^{s,\beta}(Q_k)} \left(resp., \frac{h^{\mu-1}}{(p+1)^{s-1}} \left(1 + \log \frac{p+1}{h}\right)^\nu B_\nu^{s,\beta}(Q_h) \right).\end{aligned} \tag{3.7}$$

The constants C *are independent of* $p, h,$ *and* u.

Proof. We will prove the theorem for $u \in B_\nu^{s,\beta}(Q_h)$. Let l and k be integers such that $0 \le l < s < k$ and $H^{s,\beta}(Q_h) = \left(H^{l,\beta}(Q_h), H^{k,\beta}(Q_h)\right)_{\theta,\infty,\nu}$ with $\theta = \frac{s-l}{k-l} \in (0,1)$. We have by Theorem 3.2

$$\|u - u_{hp}\|_{H^{l,\beta}(Q_h)} \le C h^{\mu_1 - l} \|u\|_{H^{l,\beta}(Q_h)} \tag{3.8}$$

with $\mu_1 = \min\{p+1, l\}$, and

$$\|u - u_{hp}\|_{H^{l,\beta}(Q_h)} \le C \frac{h^{\mu_2 - l}}{p^{k-l}} \|u\|_{H^{k,\beta}(Q_h)} \tag{3.9}$$

with $\mu_2 = \min\{p+1, k\}$. The weak exactness of θ-exponent (2.7) for the modified Jacobi-weighted Besov space $B^{s,\beta}_{\nu}(Q_h)$, together with (3.8) and (3.9), leads to

$$\begin{aligned}\|u-u_{hp}\|_{H^{l,\beta}(Q_h)} &\le C\frac{h^{(1-\theta)(\mu_1-l)+\theta(\mu_2-l)}}{(p+1)^{\theta(k-l)}}\left(1+\log\frac{(p+1)^{-(k-l)}h^{\mu_2-l}}{h^{\mu_1-l}}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}\\ &= C\frac{h^{\mu-l}}{(p+1)^{s-l}}\left(1+(k-l)\log(p+1)+(\mu_1-\mu_2)\log\frac{1}{h}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}\\ &\le C\frac{h^{\mu-l}}{(p+1)^{s-l}}\left(1+\log\frac{p+1}{h}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}.\end{aligned}$$

If $s>1, \beta_\ell \le -1/2, 1\le \ell\le 2$, select l and k such that $1<l<s<k$. Then by Theorem 3.2 there holds for $x\in\bar{Q}_h$

$$\|u-u_{hp}\|_{C^0(\bar{Q}_h)} \le Cp^{-(l-1)}h^{\mu_1-1}\|u\|_{H^{l,\beta}(Q_h)} \tag{3.10}$$

and

$$\|u-u_{hp}\|_{C^0(\bar{Q}_h)} \le Cp^{-(k-1)}h^{\mu_2-1}\|u\|_{H^{k,\beta}(Q_h)}. \tag{3.11}$$

The weak exactness of θ-exponent (2.7) together with (3.10)–(3.11) leads to

$$\begin{aligned}\|u-u_{hp}\|_{C^0(\bar{Q}_h)} &\le C\frac{h^{(1-\theta)(\mu_1-1)+\theta(\mu_2-1)}}{p^{\theta(k-1)+(1-\theta)(l-1)}}\left(1+\log\frac{(p+1)^{-(k-l)}h^{\mu_2-1}}{(p+1)^{-(l-1)}h^{\mu_1-1}}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}\\ &= C\frac{h^{\mu-l}}{(p+1)^{s-l}}\left(1+(k-l)\log(p+1)+(\mu_1-\mu_2)\log\frac{1}{h}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}\\ &\le C\frac{h^{\mu-l}}{(p+1)^{s-l}}\left(1+\log\frac{p+1}{h}\right)^{\nu}\|u\|_{B^{s,\beta}_{\nu}(Q_h)}.\end{aligned}$$

The proof for $u\in H^{s,\beta}(Q_h)$ is almost the same except that we apply (2.6) instead of (2.7). ∎

3.3. Approximation of singular functions on a scaled domain $Q_h = (-h,h)^2$. In this section we investigate the approximability of singular functions on a scaled square $Q_h=(-h,h)^2$:

$$u = r^{\gamma}\log^{\nu} r\chi_h(r)\,\Phi(\theta) \tag{3.12}$$

with $\gamma>0$ and integer $\nu\ge 0$, where $r=\sqrt{(x_1+h)^2+(x_2+h)^2}$, $\theta=\arctan\frac{h+x_2}{h+x_1}$, $\chi_h(r)=\chi(\frac{r}{h})$, and $\chi(\cdot)$ and $\Phi(\cdot)$ are C^∞ functions defined on the standard square as in the previous section.

Due to Proposition 3.1 and Theorem 2.3, a simple scaling leads us to the regularity of u in terms of the Jacobi-weighted Besov spaces.

THEOREM 3.4. *Let u be as given in* (3.12) *with $\gamma>0$ and $\nu\ge 0$. Then $u\in B^{s,\beta}_{\nu^*}(Q_h)$ with $s=2+2\gamma+\beta_1+\beta_2, \beta_l>-1, l=1,2$, and ν^* as given in* (2.42).

Proof. Let $\tilde{u}(\xi)=u(h\xi)$. Then for $\nu=0$

$$\tilde{u}(\xi)=u(h\xi)=h^{\gamma}\zeta^{\gamma}\chi(\zeta)\,\Phi(\theta)=h^{\gamma}w(\xi), \tag{3.13}$$

and for $\nu\ge 1$

$$\begin{aligned}\tilde{u}(\xi) &= h^{\gamma}\zeta^{\gamma}(\log h+\log\zeta)^{\nu}\chi(\zeta)\,\Phi(\theta)\\ &= h^{\gamma}\zeta^{\gamma}\,\chi(\zeta)\,\Phi(\theta)\sum_{m=0}^{\nu}\binom{\nu}{m}\log^{\nu-m}h\;\log^{m}\zeta = h^{\gamma}\sum_{m=0}^{\nu}\binom{\nu}{m}\tilde{v}_m(\xi)\log^{\nu-m}h,\end{aligned} \tag{3.14}$$

where $w(\xi) = \zeta^\gamma \chi(\zeta)\,\Phi(\theta), \tilde{v}_m(\xi) = \zeta^\gamma \chi(\zeta)\,\Phi(\theta)\log^m \zeta, \zeta = \sqrt{(\xi_1+1)^2+(\xi_2+1)^2}$. Due to Theorem 2.3, $w(\xi) \in B^{s,\beta}(Q)$ and $\tilde{v}_m(\xi) \in B^{s,\beta}_{m^*}(Q)$ with $s = 2+\gamma+\beta_1+\beta_2, \beta_\ell > -1, \ell = 1,2$, and

$$m^* = \begin{cases} m-1 & \text{if } \gamma \text{ is an integer and } m \geq 1, \\ m & \text{otherwise.} \end{cases} \tag{3.15}$$

The assertions of the theorem follow immediately from Theorem 2.3 and Proposition 3.1. ∎

By $R_0^h = R^h_{r_0,\theta_0}$ we denote a subregion of Q_h with $\theta_0 \in (0,\pi/4)$ and $r_0 \in (0,h)$,

$$R_0^h = R^h_{r_0,\theta_0} = \{x \in Q \mid r < r_0, \quad \theta_0 < \theta < \pi/2 - \theta_0\}. \tag{3.16}$$

A combination of Theorem 2.4 and a proper scaling gives a sharp estimation on the upper bound of approximation error in the Jacobi projections for the singular functions.

THEOREM 3.5. *Let $u(x)$ be as given in* (3.12). *Then there exist polynomials $\psi_{hp}(x)$ and $\varphi_{hp}(x)$ in $\mathcal{P}_p(Q)$, $p \geq 1$, such that*

$$\|u - \psi_{hp}\|_{L^2(Q_h)} \leq C\,\frac{h^{1+\gamma}}{(p+1)^{2(1+\gamma)}} F_\nu(p,h) \tag{3.17}$$

with $\beta = (0,0)$, and

$$\|u - \varphi_{hp}\|_{H^1(R_0^h)} \leq C\,\frac{h^{\gamma}}{(p+1)^{2\gamma}} F_\nu(p,h) \tag{3.18}$$

with $\beta = (-1/2,-1/2)$, where $F_\nu(p,h)$ is a log-polynomial,

$$F_\nu(p,h) = \begin{cases} (1+\log\frac{p+1}{h})^\nu & \text{for noninteger } \gamma, \\ (1+\log\frac{p+1}{h})^{\nu-1} & \text{for integer } \gamma \text{ and } r^\gamma\Phi(\theta) \in \mathcal{P}_\gamma(Q_h), \\ \max\Big\{ (1+\log\frac{p+1}{h})^{\nu-1},\ \log^\nu \frac{1}{h} \Big\} & \text{for integer } \gamma \text{ and } r^\gamma\Phi(\theta) \notin \mathcal{P}_\gamma(Q_h). \end{cases} \tag{3.19}$$

Furthermore, there holds

$$\|u - \varphi_{hp}\|_{C^0(\bar{Q}_h)} \leq C\,\frac{h^{\gamma}}{(p+1)^{2\gamma}} F_\nu(p,h). \tag{3.20}$$

The constants C in (3.17)–(3.20) *are independent of h and p.*

Proof. We shall concentrate on the proof of (3.18); the proofs for (3.17) and (3.20) are similar to what follows. By (3.13) for $\nu = 0$,

$$\tilde{u}(\xi) = u(h\xi) = h^\gamma \zeta^\gamma \chi(\zeta)\,\Phi(\theta) = h^\gamma w(\xi).$$

Then (3.17) and (3.18) with $\nu = 0$ follow from Theorem 2.4 immediately.

Due to (3.14) for $\nu \geq 1$,

$$\begin{aligned} \tilde{u}(\xi) &= h^\gamma \zeta^\gamma (\log h + \log\zeta)^\nu \chi(\zeta)\,\Phi(\theta) = h^\gamma \zeta^\gamma\,\chi(\zeta)\,\Phi(\theta) \sum_{m=0}^{\nu} \binom{\nu}{m} \log^{\nu-m} h\ \log^m \zeta \\ &= h^\gamma \sum_{m=0}^{\nu} \binom{\nu}{m} \tilde{v}_m(\xi) \log^{\nu-m} h. \end{aligned}$$

By Theorem 2.3, $\tilde{v}_m(\xi) \in B^{1+2\gamma,\beta}_{m^*}(Q)$ with $\beta = (-1/2,-1/2)$, and then due to Theorem 2.4, $\tilde{\varphi}_m(\xi) = \Pi^{\beta}_p \tilde{v}_m$ with $\beta = (-1/2,-1/2)$ satisfies

$$\|\tilde{v}_m(\xi) - \tilde{\varphi}_m(\xi)\|_{H^1(R_0)} \le C(p+1)^{-2\gamma}(1+\log(1+p))^{m^*}\|\tilde{v}_m\|_{B^{1+2\gamma,\beta}_{m^*}(Q)} \tag{3.21}$$

with m^* as given in (3.15).

If γ is not an integer, let $\tilde{\varphi}(\xi) = h^\gamma \sum_{m=0}^{\nu} \binom{\nu}{m} \tilde{\varphi}_m(\xi)\log^{\nu-m} h$, and let $\varphi(x) = \tilde{\varphi}(x/h) = \Pi^{\beta}_{p,h} u$ be associated with $\beta = (-1/2,-1/2)$. Then there hold

$$\begin{aligned}\|\tilde{u}(\xi) - \tilde{\varphi}(\xi)\|_{H^1(R_0)} &\le \frac{Ch^\gamma}{(p+1)^{2\gamma}} \sum_{m=0}^{\nu} \binom{\nu}{m} (1+\log(1+p))^m \log^{\nu-m}\frac{1}{h} \\ &\le C\frac{h^\gamma \left(1+\log\frac{p+1}{h}\right)^\nu}{(p+1)^{2\gamma}}\end{aligned}$$

and

$$\|u(x) - \varphi(x)\|_{H^1(R^h_0)} = \|\tilde{u}(\xi) - \tilde{\varphi}(\xi)\|_{H^1(R_0)} \le C\frac{h^\gamma}{(p+1)^{2\gamma}}\left(1+\log\frac{p+1}{h}\right)^\nu.$$

Thus (3.18) is proved for noninteger γ.

If γ is an integer, we have by (3.21)

$$\begin{aligned}\|\tilde{u}(\xi) - \tilde{\varphi}(\xi)\|_{H^1(R_0)} &\le \frac{Ch^\gamma}{(p+1)^{2\gamma}}\left(\log^\nu\frac{1}{h} + \sum_{m=1}^{\nu}\binom{\nu}{m}(1+\log(p+1))^{m-1}\log^{\nu-m}\frac{1}{h}\right) \\ &\le \frac{Ch^\gamma}{(p+1)^{2\gamma}}\max\left\{\left(1+\log\frac{p+1}{h}\right)^{\nu-1},\ \log^\nu\frac{1}{h}\right\},\end{aligned}$$

which implies (3.18) for integer γ.

If γ is an integer and $r^\gamma\Phi(\theta)$ is a polynomial of degree γ in Q_h, then $\zeta^\gamma\Phi(\theta)$ is a polynomial of degree γ in Q. We rewrite (3.14) as

$$\tilde{u}(\xi) = h^\gamma\left(\tilde{v}_0(\xi)\log^\nu h + \sum_{m=1}^{\nu}\binom{\nu}{m}\tilde{v}_m(\xi)\log^{\nu-m}h\right) = h^\gamma\Big(\tilde{v}_0(\xi)\log^\nu h + \tilde{w}(\xi)\Big).$$

By the arguments above, there exists polynomial $\tilde{\varphi}_w(\xi) \in \mathcal{P}_p(Q)$ such that

$$\begin{aligned}\|\tilde{w}(\xi) - \tilde{\varphi}_w(\xi)\|_{H^1(R_0)} &\le C\sum_{m=1}^{\nu}\binom{\nu}{m}\frac{(1+\log(p+1))^{(m-1)}}{(p+1)^{2\gamma}}\log^{\nu-m}\frac{1}{h} \\ &\le C\frac{\left(1+\log\frac{p+1}{h}\right)^{\nu-1}}{(p+1)^{2\gamma}}.\end{aligned}$$

Let $u_0(x) = \tilde{u}(\frac{x}{h}) = r^\gamma\chi_h(r)\Phi(\theta)\log^\nu h$ and $w(x) = h^\gamma\tilde{w}(\frac{x}{h})$. Then

$$u(x) = u_0(x) + w(x). \tag{3.22}$$

Since $u_0(x)$ is a C^∞ function, there exists a polynomial $\varphi_0(x) \in \mathcal{P}_p(Q_h)$ such that

$$\|u_0 - \varphi_0\|_{H^1(R^h_0)} \le C\left(\frac{h}{(p+1)^2}\right)^\gamma\left(1+\log\frac{p+1}{h}\right)^{\nu-1}. \tag{3.23}$$

Let $\varphi_{hp}(x) = \varphi_0(x) + \varphi_w(x)$ with $\varphi_w(x) = h^\gamma \tilde{\varphi}_w(\frac{x}{h})$. By (3.22)–(3.23), we have

$$\begin{aligned}\|v(x) - \varphi_{hp}(x)\|_{H^1(R_0^h)} &\le \|w(x) - \varphi_w(x)\|_{H^1(R_0^h)} + \|u_0 - \varphi_0\|_{H^1(R_0^h)} \\ &\le \frac{C\,h^\gamma}{p^{2\gamma}} \left(1 + \log\frac{p+1}{h}\right)^{\nu-1},\end{aligned}$$

which leads to the estimation (3.18) in the case that $r^\gamma \Phi(\theta)$ is a polynomial.

Arguments similar to the above can be carried out for (3.17) and (3.20), and we will not elaborate here. ∎

3.4. Asymptotic error analysis for Legendre projection for singular functions of $x^\gamma \log^\nu x$-type on a scaled interval. The estimation of the lower bounds of approximation error for the singular function v of $r^\gamma \log^\nu r$-type on Q_h is not trivial and has never been addressed in the literature because it is not a simple generalization of the approximation on standard square Q with a simple scaling. To this end we need asymptotic error analysis for singular functions of $x^\gamma \log^\nu x$-type on a scaled interval $(-h, h)$. The asymptotic error analysis of Legendre projection for singular functions of $x^\gamma \log^\nu x$-type on a standard interval $I = (-1, 1)$ was studied in [7]. We are here generalizing the result to a scaled interval $I_h = (-h, h)$ in terms of p and h.

Let

$$w_\nu(x) = (x + h)^\gamma \log^\nu(x + h), \quad x \in I_h = (-h, h), \tag{3.24}$$

with real $\gamma > 0$ and integer $\nu \ge 1$. Let $\mathcal{P}_p(I_h)$ be a set of polynomials of degree $\le p$ on I_h. We shall analyze the asymptotic of the approximation error of Legendre projection, which is essential to the sharpest estimates of the lower bounds of error in the finite element solutions of the h-p versions.

It was shown in [16] that on the standard interval $I = (-1, 1)$ the singular function $(1 + \xi)^\gamma$ has the Legendre expansion

$$(1 + \xi)^\gamma = \sum_{i=0}^{\infty} a_i(\gamma) L_i(\xi),$$

where $L_i(\xi)$ is the Legendre polynomial of degree i, and

$$a_i(\gamma) = (-1)^{i-1} \left(i + \frac{1}{2}\right) C_0(\gamma) \frac{\Gamma(i - \gamma)}{\Gamma(i + \gamma + 2)} \tag{3.25}$$

with

$$C_0(\gamma) = \frac{2^{1+\gamma}\Gamma^2(1 + \gamma) \sin \pi\gamma}{\pi}. \tag{3.26}$$

For the singular function $(1 + \xi)^\gamma \log^\nu(1 + \xi)$, it was proved in [7] that

$$(1 + \xi)^\gamma \log^\nu(1 + \xi) = \frac{d^\nu}{d\gamma^\nu}(1 + \xi)^\gamma = \sum_{i=0}^{\infty} b_i(\gamma) L_i(\xi),$$

where for $i > 0$

$$b_i(\gamma) = a_i^{(\nu)}(\gamma) = \frac{d^\nu}{d\gamma^\nu} a_i(\gamma) = \frac{(-1)^{i-1}}{i^{2\gamma+1}} \sum_{\ell=0}^{\nu} (-1)^{\nu-\ell} C_\ell(\gamma) \log^{\nu-\ell} i \ \left(1 + O\left(\frac{1}{i}\right)\right) \tag{3.27}$$

with $C_1(\gamma) = \nu C_0'(\gamma)$. By a scaling $x = h\xi$, we have

$$w_0(x) = (h+x)^\gamma = h^\gamma(1+\xi)^\gamma = \sum_{i=0}^{\infty} h^\gamma a_i(\gamma) L_i(\xi) = \tilde{w}_0(\xi)$$

and

$$w_\nu(x) = (h+x)^\gamma \log^\nu(h+x) = \frac{d^\nu}{d\gamma^\nu}(h+x)^\gamma = \sum_{i=0}^{\infty} b_i(\gamma,h) L_i(\xi) = \tilde{w}_\nu(\xi)$$

with

$$b_i(\gamma,h) = \frac{d^\nu}{d\gamma^\nu}\left(h^\gamma a_i(\gamma)\right) = h^\gamma \sum_{m=0}^{\nu} \left(\begin{array}{c} \nu \\ m \end{array} \right) a_i^{(m)}(\gamma)\, \log^{\nu-m} h. \tag{3.28}$$

Due to (3.27),

$$\begin{aligned} &a_i^{(m)}(\gamma) \\ &= (-1)^{i-1} \frac{(-1)^m C_0(\gamma) \ln^m i + (-1)^{m-1} C_1(\gamma) \ln^{m-1} i + \cdots + C_m(\gamma)}{i^{2\gamma+1}} \left(1 + O\left(\frac{1}{i}\right)\right) \end{aligned}$$

with $C_1(\gamma) = mC_0'(\gamma)$.

For noninteger $\gamma, C_0(\gamma) \neq 0$, and

$$\begin{aligned} b_i(\gamma,h) &= (-1)^{i-1+\nu} h^\gamma \sum_{m=0}^{\nu} \left(\begin{array}{c} \nu \\ m \end{array} \right) C_0(\gamma) \log^{\nu-m} \frac{1}{h}\ \log^m i \left(1 + O\left(\frac{1}{\log i}\right)\right) \\ &= \frac{(-1)^{i-1+\nu} h^\gamma C_0(\gamma)}{i^{2\gamma+1}} \log^\nu \frac{i}{h}. \end{aligned} \tag{3.29}$$

If γ is an integer, then $C_0(\gamma) = 0$ and $C_1(\gamma) = (-1)^\gamma(\gamma!)^2 \neq 0$. Hence

$$\begin{aligned} b_i(\gamma,h) &= \frac{(-1)^{i+\nu} h^\gamma}{i^{2\gamma+1}} \sum_{m=1}^{\nu} \left(\begin{array}{c} \nu \\ m \end{array} \right) (-1)^{\nu-m} C_1(\gamma) \log^{\nu-m} h \log^{m-1} i\ \left(1 + O\left(\frac{1}{\log i}\right)\right) \\ &= \frac{(-1)^{i+\nu} h^\gamma C_1(\gamma)}{i^{2\gamma+1}} \sum_{m'=0}^{\nu-1} \left(\begin{array}{c} \nu-1 \\ m' \end{array} \right) \frac{\nu}{m'+1} \log^{\nu-1-m'} \frac{1}{h} \log^{m'} i \left(1 + O\left(\frac{1}{\log i}\right)\right). \end{aligned}$$

Note that $1 \leq \frac{\nu}{m'+1} \leq \nu$ for $0 \leq m' \leq \nu - 1$; therefore there holds

$$\log^{\nu-1} \frac{i}{h} \leq \sum_{m'=0}^{\nu} \left(\begin{array}{c} \nu-1 \\ m' \end{array} \right) \frac{\nu}{m'+1} \log^{\nu-m} \frac{1}{h} \log^{m-1} i \leq \nu \log^{\nu-1} \frac{i}{h},$$

which implies that for integer γ

$$|C_1(\gamma)| \frac{h^\gamma}{i^{2\gamma+1}} \log^{\nu-1} \frac{i}{h} \leq |b_i(\gamma,h)| \leq \nu |C_1(\gamma)| \frac{h^\gamma}{i^{2\gamma+1}} \log^{\nu-1} \frac{i}{h}. \tag{3.30}$$

Let $\tilde{\varphi}_p^\nu(\xi) = \sum_{i=0}^p b_i(\gamma,h) L_i(\xi)$ and $\varphi_{hp}^\nu(x) = \sum_{i=0}^p b_i(\gamma,h) L_i(\frac{x}{h})$, which are the Legendre projection of $\tilde{w}_\nu(\xi)$ on $\mathcal{P}_p(I)$ and the Legendre projection of $w_\nu(x)$ on $\mathcal{P}_p(I_h)$, respectively. Then we have the following asymptotic error estimation.

THEOREM 3.6. *Let $w_\nu(x)$ be as given in* (3.24)*, and let $\varphi_{hp}^\nu(x)$ be its Legendre projection on $\mathcal{P}_p(I_h)$. There holds for noninteger $\gamma > 0$ and $\nu \geq 0$*

$$\|w_\nu(x) - \varphi_{hp}^\nu(x)\|_{L^2(I_h)} \cong \frac{h^{\gamma+1/2}}{(p+1)^{2\gamma+1}} \left(1 + \log \frac{p+1}{h}\right)^\nu, \tag{3.31}$$

and for integer $\gamma > 0$ and $\nu \geq 1$

$$\|w_\nu(x) - \varphi_{hp}^\nu(x)\|_{L^2(I_h)} \cong \frac{h^{\gamma+1/2}}{(p+1)^{2\gamma+1}} \left(1 + \log \frac{p+1}{h}\right)^{\nu-1}. \tag{3.32}$$

Proof. By a scaling argument we have

$$\|w_\nu(x) - \varphi_{hp}^\nu(x)\|_{L^2(I_h)} = h^{1/2} \|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)}.$$

It is sufficient to show that for noninteger γ

$$\|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)} \cong \frac{h^\gamma}{(p+1)^{2\gamma+1}} \log^\nu \frac{p+1}{h}, \tag{3.33}$$

and for integer $\gamma > 0$ and $\nu \geq 1$

$$\|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)} \cong \frac{h^\gamma}{(p+1)^{2\gamma+1}} \log^{\nu-1} \frac{p+1}{h}. \tag{3.34}$$

Because of the orthogonality of Legendre polynomials, there holds

$$\|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)}^2 = \sum_{i=p+1}^{\infty} |b_i(\gamma, h)|^2 \frac{2}{2i+1}.$$

Therefore it holds by (3.29) that for noninteger γ and integer $\nu \geq 1$,

$$\begin{aligned} \|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)}^2 &= |C_0(\gamma)|^2 h^{2\gamma} \sum_{i=p+1}^{\infty} i^{-(4\gamma+3)} \log^{2\nu} \frac{i}{h} \left(1 + O\left(\frac{1}{\log i}\right)\right) \\ &= \frac{|C_0(\gamma)|^2 h^{2\gamma}}{(4\gamma+2)p^{4\gamma+2}} \log^{2\nu} \frac{p+1}{h} \left(1 + O\left(\frac{1}{\log(p+1)}\right)\right). \end{aligned} \tag{3.35}$$

For noninteger γ and integer $\nu = 0$, $b_i(\gamma, h) = h^\gamma a_i(\gamma)$. By (3.25) we have

$$\begin{aligned} \|\tilde{w}_0(\xi) - \tilde{\varphi}_p^0(\xi)\|_{L^2(I)}^2 &= |C_0(\gamma)|^2 h^{2\gamma} \sum_{i=p+1}^{\infty} |a_i(\gamma)|^2 \frac{2}{2i+1} \\ &= \frac{|C_0(\gamma)|^2 h^{2\gamma}}{(4\gamma+2)(p+1)^{4\gamma+2}} \left(1 + O\left(\frac{1}{p+1}\right)\right), \end{aligned}$$

which together with (3.35) leads to (3.33) for noninteger γ and $\nu \geq 0$.

For integer γ and $\nu \geq 1$, (3.30) implies that

$$\begin{aligned} &\|\tilde{w}_\nu(\xi) - \tilde{\varphi}_p^\nu(\xi)\|_{L^2(I)}^2 \\ &\leq \nu |C_1(\gamma)|^2 h^{2\gamma} \sum_{i=p+1}^{\infty} i^{-(4\gamma+3)} \log^{2(\nu-1)} \frac{i}{h} \left(1 + O\left(\frac{1}{\log i}\right)\right) \\ &= \frac{\nu |C_1(\gamma)|^2 h^{2\gamma}}{(4\gamma+2)(p+1)^{4\gamma+2}} \log^{2(\nu-1)} \frac{p+1}{h} \left(1 + O\left(\frac{1}{\log(p+1)}\right)\right) \end{aligned} \tag{3.36}$$

and

(3.37)
$$\|\tilde{w}_\nu(\xi)-\tilde{\varphi}_p^\nu(\xi)\|^2_{L^2(I)}\geq\frac{|C_1(\gamma)|^2h^{2\gamma}}{(4\gamma+2)(p+1)^{4\gamma+2}}\log^{2(\nu-1)}\frac{p+1}{h}\ \left(1+O\left(\frac{1}{\log(p+1)}\right)\right).$$

Thus, (3.36)–(3.37) lead to (3.34) for integer γ and $\nu\geq 1$ and complete the proof of the theorem. ∎

3.5. Lower bound of approximation error for singular functions of $r^\gamma\log^\nu r$-type. We shall introduce the Jacobi-weighted Sobolev spaces $H^{k,\beta}(I_h)$ on scaled interval $I_h=(-h,h)$ and prove a lemma concerning error in the seminorm of $H^{k,\beta}(I_h)$, which will be used in deriving the lower bound of approximation error for singular functions of $r^\gamma\log^\nu r$-type.

The Jacobi-weighted Sobolev spaces $H^{k,\beta}(I_h), k\geq 0$, with $\beta>-1$ are furnished with weighted norm

$$\|u\|^2_{H^{k,\beta}(I_h)}=\sum_{\ell=0}^k\int_{I_h}|u^{(\ell)}(x)|^2\ w_{\ell,\beta}(x)\,dx,$$

where $w_{\ell,\beta}(x)=(1-\frac{x^2}{h^2})^{\ell+\beta}$. The seminorm $|u|_{H^{k,\beta}(I_h)}$ is involved in the kth derivative only. In the special case that $\beta=0$, the Jacobi weight $w_{\ell,0}(x)$ is called a Legendre weight, and the corresponding spaces are referred to as Legendre-weighted Sobolev spaces. For the Jacobi-weighted Sobolev spaces on standard interval $I=(-1,1)$ and the approximation theory in the framework of these spaces, including special cases $\beta=0$ (Legendre) and $\beta=-1/2$ (Chebyshev), we refer to [7, 19, 20].

LEMMA 3.7. *Let $w\in H^{1,\beta}(I_h)$ with $\beta=(0,0)$, and let w_p be its Legendre projection on $\mathcal{P}_p(I_h)$. Then there holds*

$$|w-w_p|_{H^{1,\beta}(I_h)}\geq\frac{p+1}{h}|w-w_p|_{L^2(I_h)}. \tag{3.38}$$

Proof. Let $x=h\xi$ for $\xi\in I=(-1,1)$, which introduces the functions $\tilde{w}(\xi)=w(h\xi)$ and $\tilde{w}_p(\xi)=w_p(h\xi)$ on I. By Lemma 2.1 of [7] and a scaling argument we have

$$\begin{aligned}\int_{I_h}|w'-w_p'|^2\left(1-\left(\frac{x}{h}\right)^2\right)dx&=\int_I|\tilde{w}'-\tilde{w}_p'|^2\frac{1-\xi^2}{h}d\xi\geq\frac{(p+1)^2}{h}\int_I|\tilde{w}-\tilde{w}_p|^2d\xi\\&=\frac{(p+1)^2}{h^2}\int_{I_h}|w-w_p|^2dx,\end{aligned}$$

which leads to (3.38). ∎

THEOREM 3.8. *Let $u(x)$ be as given in* (3.12) *with $\gamma>0$ and integer $\nu\geq 0$. Then*

$$\inf_{\phi\in\mathcal{P}_p(Q_h)}\|v-\phi\|_{H^1(R_0^h)}\geq C\frac{h^\gamma}{(p+1)^{2\gamma}}F_\nu(p,h) \tag{3.39}$$

with $F_\nu(p,h)$ as given in (3.19).

Proof. For $\nu=0$, $u(x)=h^\gamma w(\xi)$ with $w(\xi)=\zeta^\gamma\chi(\zeta)\,\Phi(\theta)$, where $\zeta=\{(\xi_1+1)^2+(\xi_2+1)^2\}^{1/2}$. Due to Theorem 2.5, there holds

$$\inf_{\phi\in\mathcal{P}_p(Q_h)}\|v-\phi\|_{H^1(R_0^h)}=h^\gamma\inf_{\tilde{\phi}\in\mathcal{P}_p(Q)}\|w-\tilde{\phi}\|_{H^1(R_0)}\geq Ch^\gamma(p+1)^{-2\gamma},$$

which proves (3.39) with $\nu = 0$. We assume that the integer $\nu \geq 1$ and further assume without loss of generality that $\Phi(\theta) \not\equiv 0$ and $\chi_h(r) \equiv 1$ for $0 \leq r \leq h$. There is an interval $[\theta_1, \theta_2]$ on which $|\Phi(\theta)| > \Phi_0 > 0$. For any $\varphi \in \mathcal{P}_p(Q_h)$

$$\begin{aligned}\int_{R_0^h} \left|\frac{\partial}{\partial r}(v-\varphi)\right|^2 dx &\geq \int_{\theta_1}^{\theta_2}\int_0^h \left|\frac{\partial}{\partial r}(r^\gamma \log^\nu r\Phi(\theta) - \varphi)\right|^2 r dr \\ &= \int_{\theta_1}^{\theta_2} |\Phi(\theta)|^2 \left(\int_0^h \left|\frac{\partial}{\partial r}(r^\gamma \log^\nu r - \Phi^{-1}(\theta)\varphi)\right|^2 r dr\right) d\theta.\end{aligned}$$

Since $\Phi^{-1}(\theta)\varphi(r,\theta)$ is a well-defined polynomial of degree p in variable r with θ as a parameter, by Lemma 3.7, we have that

$$\begin{aligned}&\int_0^h \left|\frac{\partial}{\partial r}(r^\gamma \log^\nu r - \Phi^{-1}(\theta)\varphi)\right|^2 r dr \geq h\int_0^h \left|\frac{\partial}{\partial r}(r^\gamma \log^\nu r - \Phi^{-1}(\theta)\varphi)\right|^2 \left(\frac{r}{h}\right)\left(\frac{h-r}{h}\right) dr \\ &\geq h\int_0^h \left|\frac{\partial}{\partial r}(r^\gamma \log^\nu r - \Phi^{-1}(\theta)\varphi))\right|^2 \left(\frac{r}{h}\right)\left(\frac{h-r}{h}\right) dr \geq \frac{(p+1)^2}{h}\|r^\gamma \log^\nu r - \psi_p^\nu\|^2_{L^2(I_h)},\end{aligned}$$

where ψ is the Legendre projection of $r^\gamma \log^\nu r$ on $\mathcal{P}_p(\tilde{I}_h), \tilde{I}_h = (0,h)$, which gives

$$\int_{Q_h} \left|\frac{\partial}{\partial r}(v-\varphi)\right|^2 dx \geq (\theta_2-\theta_1)\Phi_0\frac{(p+1)^2}{h}\|r^\gamma \log^\nu r - \psi\|^2_{L^2(\tilde{I}_h)}. \tag{3.40}$$

By Theorem 3.6, there holds

$$\|r^\gamma \log^\nu r - \psi\|^2_{L^2(\tilde{I}_h)} \geq C\frac{h^{\gamma+1/2}}{(p+1)^{2\gamma+1}}\left(1+\log\frac{p+1}{h}\right)^\nu \tag{3.41}$$

if γ is not an integer, and

$$\|r^\gamma \log^\nu r - \psi\|^2_{L^2(\tilde{I}_h)} \geq C\frac{h^{\gamma+1/2}}{(p+1)^{2\gamma+1}}\left(1+\log\frac{p+1}{h}\right)^{\nu-1} \tag{3.42}$$

if γ is an integer and $\nu \geq 1$. The combination of (3.40)–(3.42) leads to the third case of (3.39).

If $\log^\nu \frac{1}{h}$ is asymptotically larger than $\log^{\nu-1}\frac{p}{h}$, the lower bound is not sharp in the case that γ is an integer and $r^\gamma\Phi(\theta)$ is not a polynomial while comparing the upper bound. A sharper analysis is needed in that case. According to (3.22), $u(x)$ can be decomposed as

$$u(x) = u_0(x) + w(x),$$

where $u_0(x) = \tilde{v}_0(\frac{x}{h}) = r^\gamma\chi_h(r)\Phi(\theta)\log^\nu h$ and $w(x) = \tilde{w}(\frac{x}{h})$. It was shown that

$$\inf_{\varphi\in\mathcal{P}_p(Q_h)}\|w-\varphi\|_{H^1(R_0^h)} \geq C\left(\frac{h}{(p+1)^2}\right)^\gamma\left(1+\log\frac{p+1}{h}\right)^{\nu-1}.$$

Since we assume that $r^\gamma\Phi(\theta)$ is not a polynomial in variable x, it is a singular function. By Theorem 3.6,

$$\begin{aligned}\inf_{\varphi\in\mathcal{P}_p(Q_h)}\|u_0-\varphi\|_{H^1(R_0^h)} &= \log^\nu\frac{1}{h}\inf_{\varphi\in\mathcal{P}_p(Q_h)}\|r^\gamma\chi_h(r)\Phi(\theta)-\tilde{\varphi}\|_{H^1(R_0^h)} \\ &\geq C\frac{h^\gamma}{(p+1)^{2\gamma}}\log^\nu\frac{1}{h}.\end{aligned}$$

Therefore for any $\phi_1, \phi_2 \in \mathcal{P}_p(Q_h)$ and $\phi = \phi_1 + \phi_1$ there holds

$$\|u-\phi\|_{H^1(R_0^h)} \geq \|u_0-\phi_1\|_{H^1(R_0^h)} - \|w-\phi_2\|_{H^1(R_0^h)},$$

which implies

$$\begin{aligned}(3.43)\quad &\inf_{\varphi\in\mathcal{P}_p(Q_h)} \|u-\varphi\|_{H^1(R_0^h)} \\ &\geq \inf_{\varphi_1\in\mathcal{P}_p(Q_h)} \|u_0-\varphi_1\|_{H^1(R_0^h)} - \inf_{\varphi_2\in\mathcal{P}_p(Q_h)} \|w-\varphi_2\|_{H^1(R_0^h)} \\ &\geq C\frac{h^\gamma}{(p+1)^{2\gamma}}\log^\nu\frac{1}{h} - \tilde{C}\frac{h^\gamma}{(p+1)^{2\gamma}}\left(1+\log\frac{p+1}{h}\right)^{\nu-1} \geq C\frac{h^\gamma}{(p+1)^{2\gamma}}\log^\nu\frac{1}{h}.\end{aligned}$$

If $\log^{\nu-1}\frac{p}{h}$ is asymptotically larger than $\log^\nu\frac{1}{h}$, we can show similarly that

$$\begin{aligned}&\inf_{\varphi\in\mathcal{P}_p(Q_h)} \|u-\varphi\|_{H^1(R_0^h)} \geq \inf_{\varphi_2\in\mathcal{P}_p(Q_h)} \|w-\varphi_2\|_{H^1(R_0^h)} - \inf_{\varphi_1\in\mathcal{P}_p(Q_h)} \|u_0-\varphi_1\|_{H^1(R_0^h)} \\ &\geq C\frac{h^\gamma}{(p+1)^{2\gamma}}\left(1+\log\frac{p+1}{h}\right)^{\nu-1} - \tilde{C}\frac{h^\gamma}{(p+1)^{2\gamma}}\log^\nu\frac{1}{h} \\ &\geq C\frac{h^\gamma}{(p+1)^{2\gamma}}\left(1+\log\frac{p+1}{h}\right)^{\nu-1}.\end{aligned}$$

This with (3.43) gives the second case of (3.39) and completes the proof of the theorem. □

Remark 3.1. By the usual argument of interpolation spaces defined by the real method, e.g., the K-method, Theorems 3.2, 3.3, 3.5, and 3.8 stand for noninteger ℓ.

4. Optimal rate of convergence of the *h-p* version with quasi-uniform meshes. In this section we demonstrate how the optimal approximation results obtained in the previous section lead to optimal a priori upper and lower error estimates for the *h-p* version of the FEM with quasi-uniform meshes. We follow the notation and symbols introduced in [6] where we analyzed the performance of the *p*-version.

Let Ω be a polygon, shown in Figure 4.1, with vertices A_i, $1 \leq i \leq M$ ($A_{M+1} = A_1$), and (open) edges Γ_i connecting the vertices A_i and A_{i+1}. By ω_i we denote the internal angle between Γ_i and Γ_{i+1}. Let $\mathcal{D}$ be a subset of $\mathcal{B} = \{1, 2, \ldots, M\}$ and $\mathcal{N} = \mathcal{B} \setminus \mathcal{D}$. We refer to $\Gamma_{\mathrm{D}} = \cup_{i\in\mathcal{D}}\overline{\Gamma}_i$ as the Dirichlet boundary and to $\Gamma_{\mathrm{N}} = \cup_{i\in\mathcal{N}}\Gamma_i$ as the Neumann boundary. We also allow polygons with internal angle 2π, which is important in applications.

Consider the following boundary value problem:

$$\begin{aligned}&-\Delta u + u = f \qquad \text{in } \Omega, \\ &u|_{\Gamma_{\mathrm{D}}} = 0, \qquad \left.\frac{\partial u}{\partial n}\right|_{\Gamma_{\mathrm{N}}} = g.\end{aligned} \tag{4.1}$$

By this simple model problem we shall show how to derive the lower and upper bounds of the approximation error of the *h-p* version, which can be applied to general elliptic problems on nonsmooth domains. By $H^k(\Omega)$, $k \geq 0$, integer, we denote the usual Sobolev space and $H^1_{\mathrm{D}}(\Omega) = \{u \in H^1(\Omega) \mid u|_{\Gamma_{\mathrm{D}}} = 0\}$. The variational form of (4.1) is to seek $u(x) \in H^1_{\mathrm{D}}(\Omega)$ such that

$$B(u,v) = F(v) \qquad \forall\, v \in H^1_{\mathrm{D}}(\Omega), \tag{4.2}$$

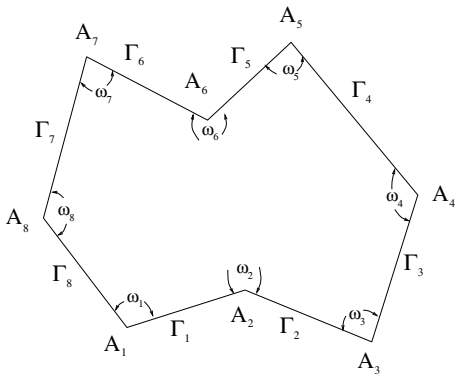

FIG. 4.1. *Polygonal domain* Ω.

where B is a bilinear form on $H^1_{\rm D}(\Omega)\times H^1_{\rm D}(\Omega)$ and F is a linear functional on $H^1_{\rm D}(\Omega)$, given by

$$B(u,v)=\int_\Omega (\nabla u\cdot\nabla v+u\,v)\,dx \tag{4.3}$$

and

$$F(v)=\int_\Omega f\,v\,dx+\int_{\Gamma_{\rm N}} g\,v\,ds. \tag{4.4}$$

4.1. The *h*-*p* version of the finite element method for problems with smooth solutions. Let $\Omega_h=\{\Omega_j,\ 1\le j\le J\}$ be a quasi-uniform mesh over the domain Ω. The elements Ω_i are shape-regular triangular and quadrilateral elements. We shall assume that $\overline{\Omega}_i\cap\overline{\Omega}_j$ is either the empty set, an entire side, or a vertex of Ω_i and Ω_j, and assume that all vertices of Ω are vertices of some Ω_i. By h_i we denote the size of element Ω_i; then there exists a constant C_q such that

$$1\le\frac{\max_i h_i}{\min_i h_i}\le C_q.$$

By $\mathcal{P}_p(\Omega)$ (or $\mathcal{P}_p(\Omega_i)$), we denote the space of all polynomials of degree $\le p$ defined on Ω (or Ω_i) and let $S^p(\Omega;\Delta_h)=\left\{u\mid u|_{\Omega_j}\in\mathcal{P}_p(\Omega_j),\ j=1,2,\ldots,J\right\}$ and $S^{p,1}_D(\Omega;\Delta_h)=S^p(\Omega;\Delta_h)\cap H^1_D(\Omega)$.

In practical applications, the finite element spaces $S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})$ are used in computations. Here $\mathcal{M}=\{M_j,1\le j\le J\}$ denotes a mapping vector and M_j is an affine mapping of standard triangle T or square S onto Ω_j. Let $S^p(\Omega;\Delta_h;\mathcal{M})=\left\{\phi(x)\ |\phi\ |_{\Omega_j}=\tilde{\phi}_j\circ M_j^{-1},\tilde{\phi}_j\in\mathcal{P}_p(T)\text{ or }\mathcal{P}_p(S),j=1,2,\ldots,J\right\}$, where $\mathcal{P}_p(T)$ or $\mathcal{P}_p(S)$ is a set of polynomials of total or separate degree p on T or S, and let $S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})=S^p(\Omega;\Delta_h;\mathcal{M})\cap H^1_D(\Omega)$ and $S^{p,1}(\Omega;\Delta_h;\mathcal{M})=S^p(\Omega;\Delta_h;\mathcal{M})\cap H^1(\Omega)$. The polynomials in the space $S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})$ are called piecewise pull-back polynomials, and $\mathcal{P}_p(\Omega_i)$ denotes a set of pull-back polynomials of degree $\le p$ on Ω_i.

Obviously, if all elements are triangles or parallelograms, then $S^{p,1}_D(\Omega;\Delta_h)=S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})$, and if all elements are triangles or quadrilaterals, then $S^{p,1}_D(\Omega;\Delta_h)\subset S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})$. We shall establish the results in a general setting, i.e., in $S^{p,1}_D(\Omega;\Delta_h;\mathcal{M})$.

The h-p version finite element solution $u_{hp} \in S_D^{p,1}(\Omega;\Delta_h;\mathcal{M})$ is such that

$$B(u_{hp},v) = F(v) \qquad \forall\, v \in S_D^{p,1}(\Omega;\Delta_h;\mathcal{M}). \tag{4.5}$$

Due to the coercivity and continuity of the bilinear form (4.3), one can show that

$$\|u-u_{hp}\|_{H^1(\Omega)} \le C \inf_{w\in S_D^{p,1}(\Omega;\Delta;\mathcal{M})} \|u-w\|_{H^1(\Omega)}. \tag{4.6}$$

LEMMA 4.1. *Let γ_h be an edge of T_h which is a triangle or a parallelogram, and let ψ be a polynomial of degree p on γ_h vanishing at the end points of γ_h. Then there exists an extension $\Psi(x) \in \mathcal{P}_p(T_h)$ such that $\Psi(x)\,|_{\gamma_h} = \psi$ and vanishes on other edges of T_h, and*

$$\|\Psi\|_{H^1(T_h)} \le C\|\psi\|_{H_{00}^{1/2}(\gamma_h)} \tag{4.7}$$

with the constant C independent of h.

If T_h is a quadrilateral and M is a bilinear mapping of standard square $S = (-1,1)^2$ onto T_h, then the extension is a pull-back polynomial $\Psi = \tilde{\Psi}\circ M^{-1}$ with $\tilde{\Psi} \in \mathcal{P}_p(S)$ such that $\Psi\,|_\gamma = \psi$ and vanishes on other edges of T_h, and (4.7) holds. If T_h is a curved triangle or quadrilateral and $\tilde{\psi} = \psi\circ M$ is a polynomial of degree p on $\tilde{\gamma}_h = \gamma_h \circ M$, where M is a mapping of a standard triangle or square T onto T_h, then there exists an extension $\Psi = \tilde{\Psi}\circ M^{-1}$ with $\tilde{\Psi} \in \mathcal{P}_p(T)$ such that $\Psi\,|_\gamma = \psi$ and vanishes on other edges of T_h, and (4.7) holds.

Proof. Let M be the mapping of T onto T_h and $\gamma = (-1,1)$ onto γ_h, and let $\tilde{\psi} = \psi\circ M \in$. Note that

$$\|\tilde{\psi}\|^2_{L^2(\gamma)} \le \int_{-1}^{0} \frac{|\tilde{\psi}(\tau)|^2}{1+\tau}d\tau + \int_0^1 \frac{|\tilde{\psi}(\tau)|^2}{1-\tau}d\tau,$$

which implies

$$\|\tilde{\psi}\|^2_{H_{00}^{1/2}(\gamma)} \le C|\tilde{\psi}|^2_{H_{00}^{1/2}(\gamma)} = C\left(|\tilde{\psi}|^2_{H^{1/2}(\gamma)} + \int_{-1}^{0} \frac{|\tilde{\psi}(\tau)|^2}{1+\tau}d\tau + \int_0^1 \frac{|\tilde{\psi}(\tau)|^2}{1-\tau}d\tau\right).$$

Due to Theorems 7.4–7.5 of [10], there exists an extension $\tilde{\Psi} \in \mathcal{P}_p(T)$ such that

$$\|\tilde{\Psi}\|_{H^1(T)} \le C\|\tilde{\psi}\|_{H_{00}^{1/2}(\gamma)} \le C|\tilde{\psi}|_{H_{00}^{1/2}(\gamma)}.$$

Let $\Psi = \tilde{\Psi}\circ M^{-1}$. Then $\Psi \in \mathcal{P}_p(T_h)$, and by a simple scaling there holds

$$\|\Psi\|_{H^1(T_h)} \le C\|\tilde{\Psi}\|_{H^1(T)} \le C|\tilde{\psi}|_{H_{00}^{1/2}(\gamma)} \le C|\psi|_{H_{00}^{1/2}(\gamma_h)},$$

which leads to (4.7). ∎

LEMMA 4.2. *Let $u \in H^k(\Omega_i)$, $k>1$, where Ω_i is a curved triangular or quadrilateral element of the mesh Δ_h with size h. Then there exists a polynomial $\phi \in \mathcal{P}_p(\Omega_i)$ such that*

$$\|u-\phi\|_{H^1(\Omega_i)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)} \tag{4.8}$$

with $\mu = \min\{p+1,k\}$, and $u(V_l) = \phi(V_l), 1 \le l \le 3$ or 4, are the vertices of Ω_i.

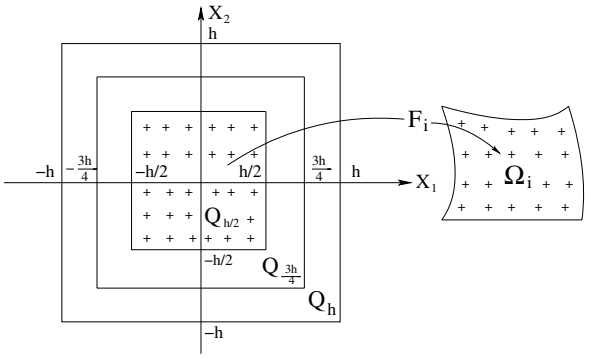

FIG. 4.2. *Mapping of quadrilateral.*

Proof. We assume first that Ω_i is a curved quadrilateral. Let F_i be a mapping of $Q_{h/2} = (-h/2, h/2)^2$ onto Ω_i. Then $\tilde{u} = u \circ F_i \in H^k(Q_{h/2})$, as shown in Figure 4.2, and it can be extended to Q_h such that the extended function has a support contained in $Q_{3h/4}$ and preserves the norm, i.e.,

$$\|\tilde{u}\|_{H^k(Q_h)} \le C\|\tilde{u}\|_{H^k(Q_{h/2})}\|u\|_{H^k(\Omega_i)}.$$

Since $\tilde{u}$ has a compact support in Q_h, $\tilde{u} \in H^{k,\beta}(Q_h)$ with the Jacobi weight $\beta = (-1/2, -1/2)$, and

$$\|\tilde{u}\|_{H^{k,\beta}(Q_h)} \le C\|\tilde{u}\|_{H^k(Q_h)} \le C\|u\|_{H^k(\Omega_i)}. \tag{4.9}$$

By Theorem 3.2, there exists a polynomial $\tilde{\phi} \in \mathcal{P}_p(Q_h)$, $p \ge 1$, such that

$$\|\tilde{u} - \tilde{\phi}\|_{H^{1,\beta}(Q_h)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|\tilde{u}\|_{H^{k,\beta}(Q_h)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)} \tag{4.10}$$

and for $1 \le l \le 4$

$$|\tilde{u}(\tilde{V}_l) - \tilde{\phi}(\tilde{V}_l)| \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)}, \tag{4.11}$$

where $\tilde{V}_l = \tilde{V}_l \circ M_i = (\pm h/2, \pm h/2)$. Let $g_1(x_1) = \frac{h-2x_1}{2h}$ and $g_2(x_1) = \frac{h+2x_1}{2h}$, and let

$$\begin{aligned}\bar{\phi} = \tilde{\phi} + g = \tilde{\phi} &+ (\tilde{u} - \tilde{\phi})(V_1)g_1(x_1)g_1(x_2) + (\tilde{u} - \tilde{\phi})(V_2)g_2(x_1)g_1(x_2)\\ &+ (\tilde{u} - \tilde{\phi})(V_3)g_2(x_1)g_2(x_2) + (\tilde{u} - \tilde{\phi})(V_4)g_1(x_1)g_2(x_2).\end{aligned} \tag{4.12}$$

It is trivial that

$$\|g_m\|_{H^t(\gamma_h)} \le Ch^{1/2-t},\ t = 0, 1, m = 1, 2, \quad \|g_l(x_1)g_m(x_2)\|_{H^1(\Omega)} \le C,\ l, m = 1, 2,$$

which together with (4.10) and (4.11) implies that $\tilde{u}(V_m) = \tilde{\phi}(V_m)$, $1 \le m \le 4$, and

$$\begin{aligned}\|\tilde{u} - \bar{\phi}\|_{H^1(Q_h)} &\le \|\tilde{u} - \tilde{\phi}\|_{H^1(Q_h)} + C\sum_{1\le m\le 4}|(\tilde{u} - \tilde{\phi})(V_m)|\\ &\le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)}.\end{aligned} \tag{4.13}$$

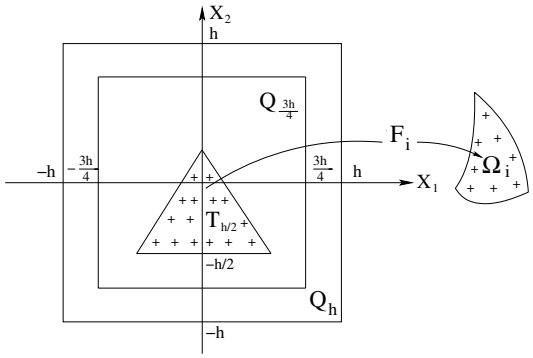

FIG. 4.3. *Mapping of triangle.*

Let $\phi = \bar{\phi} \circ M_i^{-1}$. Then $\phi \in \mathcal{P}_p(\Omega_i)$, $u(V_m) = \tilde{u}(V_m) = \bar{\phi}(V_m) = \phi(V_m)$, $1 \le m \le 4$, and

$$\|u - \phi\|_{H^1(\Omega_i)} \le C\|\tilde{u} - \bar{\phi}\|_{H^1(Q_h)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)}.$$

If Ω_i is a curved triangle, the mapping F_i maps $T_{h/2} = \{x = (x_1, x_2) \mid -\frac{h}{2} + \frac{x_2+h/2}{\sqrt{3}} \le x_1 \le \frac{h}{2} - \frac{x_2+h/2}{\sqrt{3}}, -\frac{h}{2} \le x_2 \le \frac{\sqrt{3}-1}{2}h\}$ onto Ω_i, and $(-h/2, -h/2), (h/2, -h/2)$, and $(0, \frac{\sqrt{3}-1}{2}h)$ are the vertices $\tilde{V}_m, 1 \le m \le 3$, of $T_{h/2}$, which are mapped to the vertices $V_m, 1 \le m \le 3$, of Ω_i, as shown in Figure 4.3. Then $\tilde{u} = u \circ F_i \in H^k(T_{h/2})$, and it can be extended to $H^k(Q_h)$ with a compact support contained in $H^k(Q_{3h/4})$. Then $\tilde{u} \in H^{k,\beta}(Q_h)$ with the Jacobi weight $\beta = (-1/2, -1/2)$, and (4.9) holds. By Theorem 3.2, there exists a polynomial $\tilde{\phi} \in \mathcal{P}_p(Q_h)$, $p \ge 1$, such that (4.10) and (4.11) hold.

Let

$$\bar{\phi} = \tilde{\phi} + g = \tilde{\phi} + \sum_{1 \le m \le 3} (u - \tilde{\phi})(\tilde{V}_m) g_m(x)$$

with

$$g_1(x) = \frac{1}{2} - \frac{x_1}{h} - \frac{x_2 + h/2}{\sqrt{3}}, \quad g_2(x) = \frac{1}{2} + \frac{x_1}{h} - \frac{x_2 + h/2}{\sqrt{3}}, \quad g_3(x) = \frac{2x_2}{\sqrt{3}h} + \frac{1}{\sqrt{3}}.$$

Obviously, $\bar{\phi}(\tilde{V}_m) = \tilde{u}(\tilde{V}_m), 1 \le m \le 3$, and (4.13) holds. Let $\phi = \bar{\phi} \circ M_i^{-1} \in \mathcal{P}_p(\Omega_i)$. Then $\phi(V_m) = u(V_m), 1 \le m \le 3$, and (4.8) holds. ∎

THEOREM 4.3. *Let $\Delta_h = \{\Omega_j,\ 1 \le j \le J\}$ be a quasi-uniform mesh with element size h over Ω containing triangular and quadrilateral elements, and let $S_D^{p,1}(\Omega; \Delta_h; \mathcal{M})$ be the finite element space defined as above. The data functions f and g are assumed such that the solution u of (4.1) is in $H^k(\Omega)$ with $k \ge 1$. Then the finite element solution $u_{hp} \in S_D^{p,1}(\Omega; \Delta_h; \mathcal{M})$ with $p \ge 0$ for the problem (4.1) satisfies*

$$\|u - u_{hp}\|_{H^1(\Omega)} \le C\,\frac{h^{\mu-1}}{(p+1)^{k-1}}\|u\|_{H^k(\Omega)}, \tag{4.14}$$

where $\mu = \min\{p+1, k\}$ and the constant C is independent of p and u.

Proof. We need to construct a polynomial $\varphi \in S_D^p(\Omega;\Delta_h;M)$ such that

$$\|u-\varphi\|_{H^1(\Omega)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega)}. \tag{4.15}$$

By Lemma 4.2, there exists a polynomial $\varphi^{[i]} \in \mathcal{P}_p(\Omega_i)$, $p \ge 1$, such that $\varphi^{[i]} = u$ at the vertices of Ω_i and

$$\|u-\varphi^{[i]}\|_{H^1(\Omega_i)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)}. \tag{4.16}$$

Let $\gamma = \bar\Omega_i \cap \bar\Omega_j$ be a common edge shared by the elements Ω_i and Ω_j, and let $\psi_{ij} = (\varphi^{[i]} - \varphi^{[j]})\,|_\gamma \in \mathcal{P}_p(\gamma)$. Note that $\varphi^{[i]}(V_m) = \varphi^{[j]}(V_m) = u(V_m), m = 1,2$, where V_m denote the end points of γ. Therefore ψ_{ij} vanishes at the end points of γ. By Lemma 4.1 there exists an extension $\Psi \in \mathcal{P}_p(\Omega_i)$ such that $\Psi_{ij}\,|_\gamma = \psi_{ij}$ and vanishes on $\partial\Omega_i\backslash\gamma$, and

$$\|\Psi_{ij}\|_{H^1(\Omega_i)} \le C\,\|\psi_{ij}\|_{H_{00}^{1/2}(\gamma)} \le C\Big(\|u-\varphi^{[i]}\|_{H_{00}^{1/2}(\gamma)} + \|u-\varphi^{[j]}\|_{H_{00}^{1/2}(\gamma)}\Big) \tag{4.17}$$

with the constant C independent of h. If $k \ge \frac{3}{2}$, by Theorem 3.2 and Remark 3.1, there holds for $t = 0, 1$

$$\|u-\varphi^{[i]}\|_{H^t(\gamma)} \le C\,\|u-\varphi^{[i]}\|_{H^{t+1/2}(\Omega_i)} \le C\,\frac{h^{\mu-t-1/2}}{p^{k-t-1/2}}\|u\|_{H^k(\Omega_i)}.$$

Note that $\psi_{ij} \in H_0^1(\gamma)$. Since $H_{00}^{1/2}(\gamma) = \big(L^2(\gamma),\, H_0^1(\gamma)\big)_{\frac{1}{2},2}$, by the standard argument of exact interpolation spaces of θ-exponent [11], it follows that

$$\|u-\varphi^{[i]}\|_{H_{00}^{1/2}(\gamma)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_i)}$$

and

$$\|u-\varphi^{[j]}\|_{H_{00}^{1/2}(\gamma)} \le C\,\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_j)},$$

which imply

$$\|\Psi_{ij}\|_{H^1(\Omega_i)} \le C\,\|\psi_{ij}\|_{H_{00}^{1/2}(\gamma)} \le C\frac{h^{\mu-1}}{p^{k-1}}\Big(\|u\|_{H^k(\Omega_i)} + \|u\|_{H^k(\Omega_j)}\Big). \tag{4.18}$$

Let $\tilde\varphi_p^{[i]} = \varphi_p^{[i]} - \Psi$ on Ω_i and $\tilde\varphi_p^{[j]} = \varphi_p^{[j]}$. Then $\tilde\varphi_p^{[i]}\,|_\gamma = \tilde\varphi_p^{[j]}\,|_\gamma = \varphi_p^{[j]}\,|_\gamma$, and there hold

$$\|u-\tilde\varphi_p^{[j]}\|_{H^1(\Omega_j)} = \|u-\varphi_p^{[j]}\|_{H^1(\Omega_j)} \le C\frac{h^{\mu-1}}{p^{k-1}}\|u\|_{H^k(\Omega_j)}$$

and

$$\begin{aligned}\|u-\tilde\varphi_p^{[i]}\|_{H^1(\Omega_i)} &\le C\,\Big(\|u-\varphi_p^{[i]}\|_{H^1(\Omega_i)} + \|\Psi\|_{H^1(\Omega_i)}\Big)\\ &\le C\frac{h^{\mu-1}}{p^{k-1}}\Big(\|u\|_{H^k(\Omega_i)} + \|u\|_{H^k(\Omega_j)}\Big).\end{aligned} \tag{4.19}$$

Adjusting $\varphi^{[i]}$ and $\varphi^{[j]}$ by Ψ_{ij} on each internal edge $\gamma = \bar{\Omega}_i \cap \bar{\Omega}_j$, we achieve the continuity across γ. $\varphi^{[i]}$ can be adjusted in the same way to satisfy the homogeneous Dirichlet boundary condition on each edge $\gamma \subset \Gamma^D$. Let $\varphi = \tilde{\varphi}^{[i]}$ in $\Omega_i, 1 \le i \le M$. Then $\varphi \in S_D^{p,1}(\Omega; \Delta_h; \mathcal{M})$ and satisfies (4.15).

So far we have proved the theorem for $k \ge \frac{3}{2}$. If $1 < k < \frac{3}{2}, k = (1-\theta) + 2\theta = 1 + \theta$ with $\theta = k - 1 \in (0, 1)$. Then $H_D^k(\Omega) = (H_D^1(\Omega), H^2(\Omega) \cap H_D^1(\Omega))_{\theta,2} = (H^1(\Omega), H^2(\Omega))_{\theta,2} \cap H_D^1(\Omega)$. It was shown in [8] that

$$H_D^k(\Omega) \subset \big(H^1(\Omega), H^2(\Omega)\big)_{\theta,\infty} \cap H_D^1(\Omega) = \mathcal{B}_{2,\infty}^k(\Omega) \cap H_D^1(\Omega) = B^k(\Omega) \cap H_D^1(\Omega).$$

Suppose that $v \in H_D^1(\Omega)$ and $w \in H^2(\Omega) \cap H_D^1(\Omega)$ form a decomposition of $u \in H_D^k(\Omega)$ such that $u = v + w$. Applying (4.18) for $k = 2$, we have a polynomial $\tilde{\varphi}_p^{[i]} \in S_D^{p,1}(\Omega; \Delta_h; \mathcal{M})$ with $p \ge 1$ such that

$$\|w - \varphi_p\|_{H^1(\Omega)} \le C\, \frac{h}{p} \|w\|_{H^2(\Omega)}.$$

Therefore, we have

$$\begin{aligned} \|u - \varphi\|_{H^1(\Omega)} &\le \|v\|_{H^1(\Omega)} + \|w - \varphi_p\|_{H^1(\Omega)} \le C \left(\|v\|_{H^1(\Omega)} + \frac{h}{p} \|w\|_{H^2(\Omega)} \right) \\ &= C \left(\|v\|_{H^1(\Omega)} + t \|w\|_{H^2(\Omega)} \right) \end{aligned}$$

with $t = \frac{h}{p}$. Due to the definition of the Besov spaces $B^k(\Omega) = \mathcal{B}_{2,\infty}^k(\Omega)$, we have

$$\|u - \tilde{\varphi}\|_{H^1(\Omega)} \le t^\theta \, \|u\|_{B^k(\Omega)} \le C \left(\frac{h}{p} \right)^{k-1} \|u\|_{H^k(\Omega)}, \tag{4.20}$$

which is (4.15) for $p \ge 1$, $1 < k < 3/2$, $\mu = \min\{k, p+1\} = k$. ∎

Remark 4.1. The theorem stands for $u \in B^s(\Omega)$ with $s > 1$ by a typical argument of interpolation spaces as we argued for $u \in H^k(\Omega)$ with $1 < k < 3/2$.

Remark 4.2. The convergence of the *h-p* version of FEM with quasi-uniform mesh containing triangular and parallel elements was proved in [10] for problems with smooth solutions. Lemma 4.1 and Theorem 4.3 generalize it to quadrilateral elements and curved elements, and the analysis is conducted in the framework of the Jacobi-weighted Sobolev spaces, which simplifies the proof and make it more robust. It proves that the Jacobi-weighted spaces not only work perfectly for the problems with singular solutions, but also work very well for problems with smooth solutions.

4.2. The *h-p* version finite element method for problems with singular solutions. Let $S_{\delta_i} = \big\{x \in \Omega \mid \operatorname{dist}(x, A_i) < \delta_i\big\}$ be a neighborhood of the vertices A_i, shown in Figure 4.4, with $\delta_i \in (0, 1)$. δ_i is selected such that $S_{\delta_i} \cap S_{\delta_j} = \emptyset$ for $i \ne j$. $\Omega_0 = \Omega \backslash \bigcup_{i \in \mathcal{M}} S_{\delta_i/2}$ contains no vertices of Ω, and $\Omega_0 \cap S_{\delta_i} \ne \emptyset$ for $i \in \mathcal{M}$. Ω_0 is called the regular part of Ω.

We assume that f and g are such that the solution u of (3.1) is in $H^k(\Omega_0), k \ge 1$, and in each neighborhood S_{δ_i}, u has an expansion in terms of singular functions of $r^\gamma \log^\nu r$-type:

$$u = \sum_{m \ge 1,\, 0 < \gamma_m^{[i]} \le k-1} \sum_{l=1}^{L_m^{[i]}} C_m^{[i]} \, r_i^{\gamma_m^{[i]}} \log^{\nu_{l,m}^{[i]}} r_i \Phi_m^{[i]}(\theta_i) \, \chi(r_i) + u_0^{[i]} = v + u_0^{[i]}, \tag{4.21}$$

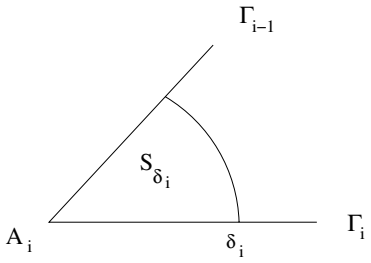

FIG. 4.4. *A neighborhood of the vertex A_i.*

where (r_i, θ_i) are polar coordinates with respect to the vertex A_i, $u_0^{[i]} \in H^k(S_{\delta_i})$ is the smooth part of u, $\gamma_m^{[i]} > 0$ are real, and $\nu_m^{[i]} \geq 0$ are integers. We assume that $\nu_{l,m}^{[i]} > \nu_{l+1,m}^{[i]}$ and $\gamma_m^{[i]} < \gamma_{m+1}^{[i]}$, $\chi(r_i)$ and $\Phi_m^{[i]}(\theta_i)$ are C^∞ functions, $\chi(r_i) = 1$ for $0 < r_i < \delta_i < \frac{1}{2}$, and $\chi(r_i) = 0$ for $r_i > \delta_i$. Let

$$\gamma = \min_i \gamma_1^{[i]}, \qquad \nu_\gamma = \max_{i, \gamma_1^{[i]} = \gamma} \nu_1^{[i]}. \tag{4.22}$$

There exists i_0 such that $\gamma_1^{[i_0]} = \gamma$ and $\nu_\gamma = \nu_1^{[i_0]}$. We will analyze the asymptotic rate of convergence of the h-p version of the FEM for problems with singularities on polygonal domains.

THEOREM 4.4. *Let $\Omega_h = \{\Omega_j,\ 1 \leq j \leq J\}$ be a quasi-uniform mesh over Ω containing triangular and parallelogram elements, and let $S_D^p(\Omega; \Delta_h; \mathcal{M})$ with $p > \gamma$ be the finite element space defined as above. The data functions f and g are assumed such that the solution u of* (4.1) *is in $H^k(\Omega_0)$ with $k > 1 + 2\gamma$, and u has the expansion* (4.21) *with $u_0^{[i]} \in H^k(S_{\delta_i})$ in each neighborhood S_{δ_i}. Then the finite element solution $u_{hp} \in S_D^{p,1}(\Omega; \Delta; \mathcal{M})$ for the problem* (4.1) *satisfies*

$$\|u - u_{hp}\|_{H^1(\Omega)} \leq C_1 \frac{h^\gamma}{p^{2\gamma}}\, F_{\nu_\gamma}(p, h) \tag{4.23}$$

with the constant C_1 depending on u, γ, and ν_γ, but not on p and h, where γ and ν_γ are as given in (4.22) *and $F_{\nu_\gamma}(p, h)$ is as given in* (3.19).

Proof. Due to (4.6), it suffices to construct a polynomial $\varphi \in S_D^p(\Omega; \Delta_h; \mathcal{M})$ with $p > \gamma$ such that

$$\|u - \varphi\|_{H^1(\Omega)} \leq C\, \frac{h^\gamma}{p^{2\gamma}}\, F_{\nu_\gamma}(p, h). \tag{4.24}$$

For elements Ω_i containing no vertices, by Lemma 4.2 there exists a polynomial $\varphi^{[i]} \in \mathcal{P}_p(\Omega_i)$ such that $\varphi^{[i]} = u$ at the vertices of Ω_i, and

$$\|u - \varphi^{[i]}\|_{H^1(\Omega_i)} \leq C\, \frac{h^{\tilde{\mu}-1}}{p^{k-1}} \leq C\, \frac{h^\gamma}{p^{2\gamma}} \|u\|_{H^k(\Omega_i)}$$

with $\tilde{\mu} = \min\{p+1, k\} \geq 1 + \gamma$.

Let the element Ω_j contain a vertex A_1 of Ω. Then (4.21) holds with $i = 1$ in S_{δ_1}. By Lemma 4.2, there exists a polynomial $\psi_0 \in \mathcal{P}_p(\Omega_j)$ such that $\psi_0 = u$ at the vertices of Ω_j, and

$$\|u_0 - \psi_0\|_{H^1(\Omega_j)} \leq C\, \frac{h^{\mu-1}}{p^{k-1}}$$

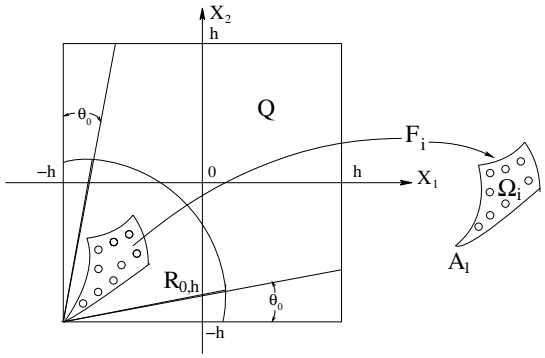

FIG. 4.5. *Mapping of element with a vertex of* Ω.

with $\mu = \min\{p+1, k\} \geq 1+\gamma$. For a sharp approximation to u_1, we map Ω_j into $R_0^h \subset Q_h$ by an affine mapping F_j such that $A_1 \circ F_j = (-h, -h)$ and Ω_j is contained in R_0^h, as shown in Figure 4.5. Without loss of generality we may assume that $A_1 = (-h, -h)$ and $\Omega_j \subseteq R_0^h$. Due to Theorem 3.5, there exists a polynomial $\psi_m \in \mathcal{P}_p(\Omega_j)$ such that $v_m = \psi_m$ at the vertices of Ω_j, and

$$\|v_m - \psi_m\|_{H^1(\Omega_j)} \leq C \, \frac{h^{\gamma^{[1]}}}{p^{2\gamma_m^{[1]}}} \, F_{\nu_{1,m}^{[1]}}(p,h),$$

where $v_m = \sum_{l=1}^{L_m^{[i]}} r_i^{\gamma_m^{[i]}} \log^{\nu_{l,m}^{[i]}} r_i \Phi_m^{[i]}(\theta_i)\, \chi(r_i)$. Let $\psi = \sum_{0<\gamma_m^{[1]} \leq k-1} C_m^{[1]} \psi_m$ and $\varphi_j = \psi + \psi_0$. Then $v = \psi$ at the vertices of Ω_j, and

$$\|v - \psi\|_{H^1(\Omega_j)} \leq C \sum_{0<\gamma_m^{[i]} \leq k-1} \frac{h^{\gamma^{[1]}}}{p^{2\gamma_m^{[1]}}} \, F_{\nu_{1,m}^{[1]}}(p,h) \leq C \frac{h^\gamma}{p^{2\gamma}} \, F_{\nu_\gamma}(p,h),$$

which implies that $u = \varphi^{[j]}$ at the vertices of Ω_j and that

$$\|u - \varphi^{[j]}\|_{H^1(\Omega_j)} \leq C \left(\frac{h^\gamma}{p^{2\gamma}} \, F_{\nu_\gamma}(p,h) + \frac{h^{\tilde{\mu}-1}}{p^{k-1}} \right) \leq C \frac{h^\gamma}{p^{2\gamma}} \, F_{\nu_\gamma}(p,h).$$

Noting that $u \in H^{1+\gamma-\epsilon}(\Omega)$ with $\epsilon > 0$ arbitrary, we can adjust these $\varphi^{[i]}$ as in the proof of Theorem 4.3 to achieve the continuity across internal edges γ of elements and the homogeneous Dirichlet boundary condition on the edges $\gamma \subset \Gamma_D$. Let $\varphi = \varphi^{[i]}$ on each $\Omega_i, 1 \leq i \leq J$; then $\varphi_p \in S_D^p(\Omega; \Delta; \mathcal{M})$ and satisfies (4.24). ∎

Remark 4.3. The convergence of the *h-p* version of the FEM for problems with singular solutions on polygonal domains was derived in [10], which is sharp for $\nu_\gamma = 0$. It is worth indicating that approximation properties of Chebyshev projection were utilized. Unfortunately, the Jacobi-weighted spaces were not introduced then to precisely describe the singularity and to fully explore approximability of singular solutions. Therefore, it was impossible to have the estimation (4.23) in the 1980s.

THEOREM 4.5. *Let* u *be the solution of the problem* (4.1) *such that* $u \in H^k(\Omega_0)$ *and* $u_0^{[i]} \in H^k(S_{\delta_i})$ *with* $k > 1 + 2\gamma$ *in each neighborhood* S_{δ_i}, *and let* u_{hp} *be its finite element solution in* $S_D^p(\Omega; \Delta_h; \mathcal{M})$ *with* $p > \gamma$. *Then*

$$\|u - u_{hp}\|_{H^1(\Omega)} \geq C_2 \left(\frac{h}{p^2} \right)^\gamma F_{\nu_\gamma}(p,h) \tag{4.25}$$

with constant C_2 depending on u, k, γ, and ν_γ, but not on p and h, where γ and ν_γ are as given in (4.22)*, and $F_{\nu_\gamma}(p,h)$ is as given in* (3.19)*.*

Proof. We may assume without loss of generality that the element Ω_1 contains the vertex $A_1 = (0,0)$ where the strongest singularity occurs, i.e., $\gamma = \gamma^{[1]}, \nu_\gamma = \nu_1^{[1]}$. According to (4.21),

$$u = u_1 + \sum_{m\geq 2, 0<\gamma_m\leq k-1} u_m + \sum_{l=2}^{L_m} v_l + u_0 \tag{4.26}$$

with

$$u_1 = c_{1,1}\, r^\gamma \log^{\nu_\gamma} r\Phi_1(\theta)\, \chi(r), \tag{4.27}$$

$$v_l = c_{l,1}\, r^\gamma \log^{\nu_{l,1}} r\Phi_1(\theta)\, \chi(r),\ l \geq 2, \tag{4.28}$$

$$u_m = \sum_{l=1}^{L_m} c_{l,m}\, r^{\gamma_m} \log^{\nu_{l,m}} r\, \Phi_m(\theta)\chi(r),\ m \geq 2. \tag{4.29}$$

Here we omit the index [1].

We now assume that the assertion of the theorem does not hold. Therefore, there exists a function $\delta(p,h)$ such that

$$\|u - u_{hp}\|_{H^1(\Omega_1)} \leq \|u - u_{hp}\|_{H^1(\Omega)} \leq C\left(\frac{h}{p^2}\right)^\gamma F_{\nu_\gamma}(p,h)\delta(p,h) \tag{4.30}$$

with $\delta(p,h) \to 0$ as $p \to \infty$ or $h \to 0$. By the argument of Theorem 4.3, there exist polynomials $w_m, z_l \in \mathcal{P}_p(\Omega_1)$ such that

$$\|u_m - w_m\|_{H^1(\Omega_1)} \leq C\left(\frac{h}{(p+1)^2}\right)^{\gamma_m} F_{\nu_{1,m}}(p,h)$$

and

$$\|v_l - z_l\|_{H^1(\Omega_1)} \leq C\left(\frac{h}{(p+1)^2}\right)^{\gamma} F_{\nu_{l,1}}(p,h).$$

Also, by Theorem 3.2, there exists a polynomial $w_0 \in \mathcal{P}_p(\Omega_1)$ such that

$$\|u_0 - w_0\|_{H^1(\Omega_1)} \leq Ch^{\mu-1}(p+1)^{-(k-1)},$$

where $\mu = \min\{k, p+1\}$. Therefore, combining the above estimates and the assumption (4.30) we obtain

$$\begin{aligned}
&\left\| u_1 - \left(u_{hp} - w_0 - \sum_{m\geq 2, 0<\gamma_m\leq k-1} w_m - \sum_{l=2}^{L_1} z_l \right) \right\|_{H^1(\Omega_1)} \\
&\leq \|u - u_{hp}\|_{H^1(\Omega_1)} + \|u_0 - w_0\|_{H^1(\Omega_1)} + \sum_{m\geq 2, 0<\gamma_m\leq k-1} \|u_m - w_m\|_{H^1(\Omega_1)} \\
&\quad + \sum_{l=2}^{L_1} \|v_l - z_l\|_{H^1(\Omega_1)} \leq C\left(\frac{h}{(p+1)^2}\right)^\gamma F_{\nu_\gamma}(p,h)\ \tilde{\delta}(p,h)
\end{aligned}$$

with

$$\tilde{\delta}(p,h) = \delta(p,h) + \frac{h^{\mu-1-\gamma}}{(p+1)^{k-1-2\gamma}} + \sum_{l=2}^{L_1} \frac{F_{\nu_{l,1}}(p,h)}{F_{\nu_\gamma}(p,h)} + \sum_{m\geq 2, 0<\gamma_m\leq k-1} \left(\frac{h}{(p+1)^2}\right)^{\gamma_m-\gamma} \frac{F_{\nu_{1,m}}(p,h)}{F_{\nu_\gamma}(p,h)}.$$

Note that $\gamma_m > \gamma$ for $m \geq 2$ and $\nu_{l,1} < \nu_\gamma$ for $l \geq 2$. Also note that $p > \gamma$ and $k > 1 + 2\gamma$, which implies $\mu > 1 + \gamma$. Hence $\tilde{\delta}(p,h) \to 0$ as $p \to \infty$ or $h \to 0$.

On the other hand, we have by Theorem 3.8

$$\left\| u_1 - \left(u_{hp} - w_0 - \sum_{m\geq 2, 0<\gamma_m\leq k-1} w_m - \sum_{l=2}^{L_1} z_l \right) \right\|_{H^1(\Omega_1)} \geq \inf_{\phi\in\mathcal{P}_p(\Omega_1)} \|u_1 - \phi\|_{H^1(\Omega_1)} \geq C \left(\frac{h}{(p+1)^2}\right)^\gamma F_{\nu_\gamma}(p,h),$$

which leads to a contradiction. Thus we complete the proof. □

As a corollary of Theorems 4.4 and 4.5, we have the optimal convergence of the finite element solutions of the h-p version with quasi-uniform meshes and quasi-uniform degree for elliptic problems on polygonal domains.

THEOREM 4.6. *Let u and u_{hp} be the solution of the problem* (4.1) *and its finite element solution in $S_D^p(\Omega;\Delta_h;\mathcal{M})$, respectively, as in the previous theorem. Then there exist two constants C_1 and C_2 depending on u, k, γ, and ν_γ but not on p and h such that*

$$C_2\left(\frac{h}{p^2}\right)^\gamma F_{\nu_\gamma}(p,h) \leq \|u - u_{hp}\|_{H^1(\Omega)} \leq C_1\left(\frac{h}{p^2}\right)^\gamma F_{\nu_\gamma}(p,h), \tag{4.31}$$

where γ and ν_γ are as given in (4.22) *and $F_{\nu_\gamma}(p,h)$ is as given in* (3.19).

5. Concluding remarks. Based on the approximabilities of smooth and singular functions in the Jacobi-weighted Besov and Sobolev spaces, we have proved the convergence of the h-p version of the FEM with quasi-uniform meshes for problems with smooth and singular solutions. The analysis is conducted in the framework of the Jacobi-weighted Besov and Sobolev spaces, which proves that the Jacobi-weighted spaces are not only appropriate for problems with singular solutions but also for problems with smooth solutions. Hence this framework is the most powerful tool for analyzing the p and h-p versions of the FEM.

For problems with singular solutions of $r^\gamma \log^\nu r$-type, the optimal convergence for the h-p version of the FEM is established after deriving the sharpest estimation of upper and lower bounds for the approximation errors in FEM solutions. Within the framework of the Jacobi-weighted Besov and Sobolev spaces and by incorporating properly the well-designed scaling arguments, we have proved the optimal rate of convergence of the h-p version of the FEM with quasi-uniform meshes for elliptic problems on polygonal domains where singularities of $r^\gamma \log r$-type occur. The results include the h- and p-versions of the FEM as two special cases. For fixed h, it coincides with the optimal convergence of the p-version of the FEM [6], and for fixed p, it gives the optimal convergence of the h-version. Also the results are parallel to those of the h-p version of the BEM with quasi-uniform meshes [20].

The concepts, methods, and techniques in this paper can be generalized to the *h-p* of the FEM in three-dimensional problems, but such a generalization will be substantial and is feasible only when the analysis for the convergence of the *p*-version of the FEM in three dimensions becomes available in the future.

FIRST-ORDER SYSTEM LEAST-SQUARES FOR DARCY–STOKES FLOW*

GARVIN DANISCH† AND GERHARD STARKE†

Abstract. The subject of this paper is a first-order system least-squares formulation for the Stokes equation which remains uniformly valid in the limit of vanishing viscosity. For this so-called Darcy–Stokes flow problem we establish continuity and coercivity of the corresponding least-squares functional in appropriate norms. Two types of finite element spaces for the approximation of the velocity field are investigated in detail: the well-known Raviart–Thomas elements and an element recently introduced by Mardal, Tai, and Winther specifically for mixed approaches to Darcy–Stokes flow. The computational results derived with next-to-lowest order Raviart–Thomas elements as well as the Mardal–Tai–Winther elements confirm our analysis.

Key words. least-squares finite element method, first-order system, Darcy–Stokes flow, small viscosity

1. Introduction.

Our purpose in this paper is to present a least-squares finite element method for Darcy–Stokes flow which remains valid for arbitrarily small viscosity. This type of singular perturbation problem was studied before in [11], where a successful mixed finite element approach was presented. The mixed variational formulation of [11] is of saddle point structure with its well-known limitation on the admissible combinations of finite element spaces. One of the motivations for the development of the least-squares approach presented in this paper is the greater flexibility in the choice of finite element spaces which is not restricted by a compatibility condition.

In the limit of vanishing viscosity, our least-squares formulation turns into the one proposed in [8]. The approach in [8] constructs approximations for the pressure and the velocity in $H^1(\Omega)$ and $H(\mathrm{div}, \Omega)$, respectively. In the viscous case, however, an approximation for the velocity is sought in $H^1(\Omega)^2$ instead. This is achieved by an augmentation with a least-squares functional along the edges of the triangulation over the jump of the tangential component and by introducing the velocity gradient as an additional variable. The case of small viscosity is handled by an appropriate weighting of the components in the least-squares functional.

Our main motivation for this work comes from the treatment of shallow water systems treated with the method of characteristics for time discretization. In this context, linearization of the boundary value problems at each time-step leads to flow problems of Darcy–Stokes type. Shallow water flow is described by the scalar water level and by the velocity field. These process variables are directly approximated by the first-order system least-squares formulation treated in this paper. The extension to shallow water systems including a viscosity term is therefore straightforward. For vanishing viscosity that approach reduces to the first-order system least-squares method investigated in [14].

Among the most popular methods for the case $\mu = 0$ is the Raviart–Thomas mixed finite element method which couples, for example, lowest-order Raviart–Thomas elements for the flux with piecewise constant functions for the scalar variable. This approach is well studied in the case of the linear first-order Darcy-type system (see, e.g., [4, section III.5]) as well as for the shallow water system without viscosity (see [10, 13]). For nonvanishing viscosity different pairs of finite element spaces are used. Among the most common approaches is the Taylor–Hood element pair which combines quadratic conforming elements for the velocity field with linear conforming ones on the same mesh for the scalar variable. Again, this approach is well known to be stable for the mixed variational formulation of the Stokes problem (see, e.g., [4, section III.7]). It is also widely used for the numerical treatment of the shallow water equations with viscosity (see, e.g., [12]).

A smooth transition between both of these situations was achieved only recently by Mardal, Tai, and Winther in [11]. Their element is nonconforming for the Stokes system (i.e., with respect to $H^1(\Omega)^2$), and it is conforming in the case of vanishing viscosity (i.e., with respect to $H(\mathrm{div}, \Omega)$). The finite element of the Mardal–Tai–Winther approach is represented by three basis functions per edge, two for the normal component and one for the tangential component of the velocity field. It is shown to be stable if combined with a piecewise constant pressure approximation (cf. [11]). Another nonconforming approach for the Darcy–Stokes problem was studied by Burman and Hansbo in [7] based on a stabilized Crouzeix–Raviart element.

Our approach proposed in this paper is based on a least-squares formulation of the Darcy–Stokes system, which is obtained by introducing the velocity flux as an auxiliary variable. For nonvanishing viscosity it is augmented with an edge functional involving the tangential velocity component. If next-to-lowest order (quadratic) Raviart–Thomas elements are used for the velocity field, then approximation order 2 is obtained for the case of zero viscosity. In the presence of positive viscosity, only approximation order 1 is achieved. More precisely, the behavior for small viscosity is such that the error reduction is of order 2 on coarse meshes and eventually reduces to order 1 on finer meshes where the viscous error components are no longer negligible. Of course, the finite elements of Mardal, Tai, and Winther can also be inserted into our least-squares formulation. This leads to approximation order 1 independently of the size of the viscosity which is also verified by our numerical computations.

The elementwise evaluation of the least-squares functional constitutes an a posteriori error estimator at no additional cost. This a posteriori error estimator gives rise to adaptive refinement strategies which dramatically increase the accuracy and efficiency of numerical methods in many practical situations. However, we do not report on adaptive computations in this paper and refer to the extension for the viscous shallow water equations in [9] instead.

For the above reasons, among others, least-squares finite element methods have become increasingly popular in recent years for a number of different application problems; see [2] for an overview. Several least-squares formulations for the Navier–Stokes equations have been studied in [1, 3], where the partial derivatives of the velocity field are also introduced as additional variables.

The structure of this paper is as follows. The first-order system formulation of Darcy–Stokes flow is presented in the next section. Section 3 investigates the nonconforming least-squares formulation, which is set in the space $H(\mathrm{div}, \Omega)$. It is shown that the least-squares functional satisfies continuity and coercivity estimates with respect to suitable norms. Finite element approximation estimates which are uniform in the limit of vanishing viscosity are derived in section 4. Finally, in section 5

the computational results for a test example with varying viscosity parameter μ are reported.

2. First-order system formulation of Darcy–Stokes flow. For a region $\Omega \subset \mathbb{R}^2$ with boundary $\Gamma = \partial\Omega$ we consider the boundary value problem

$$\begin{aligned} \delta\, p + \operatorname{div} \mathbf{u} &= 0 \quad \text{in } \Omega, \\ \mathbf{u} + \nabla p - \mu \boldsymbol{\Delta}\, \mathbf{u} &= \mathbf{0} \quad \text{in } \Omega, \\ \mathbf{n} \cdot \mathbf{u} &= g \quad \text{on } \Gamma, \\ \mu(\mathbf{t} \cdot \mathbf{u}) &= 0 \quad \text{on } \Gamma, \end{aligned} \tag{2.1}$$

with nonnegative parameters δ, μ. For $(\delta, \mu) = (0, 1)$ this constitutes a stationary Stokes system, while for $(\delta, \mu) = (0, 0)$, (2.1) is simply a first-order reformulation of the Laplace equation. Our aim in this work is the development of a discretization scheme which remains stable uniformly as $\mu \to 0$. This involves that the boundary condition for the tangential velocity component must be smoothly faded out for $\mu \to 0$.

For the solution of (2.1) we propose a least-squares finite element method which starts from the first-order system

$$\mathcal{R}(p, \mathbf{u}, \mathbf{U}) = \begin{pmatrix} \delta\, p + \operatorname{div} \mathbf{u} \\ \mathbf{u} + \nabla p + \mu^{1/2} \operatorname{div} \mathbf{U} \\ \mathbf{U} + \mu^{1/2} \nabla \mathbf{u} \end{pmatrix} = \mathbf{0} \tag{2.2}$$

resulting from the introduction of $\mathbf{U}$ as an additional variable. Our variational formulation will be based on the Sobolev spaces

$$\begin{aligned} H^1_\Gamma(\Omega) &= \{q \in H^1(\Omega) : q = 0 \text{ on } \Gamma\}, \\ H_\Gamma(\operatorname{div}, \Omega) &= \{\mathbf{v} \in H(\operatorname{div}, \Omega) : \mathbf{n} \cdot \mathbf{v} = 0 \text{ on } \Gamma\}. \end{aligned}$$

$H(\operatorname{div}, \Omega)$ denotes the Sobolev space corresponding to the norm

$$\|\mathbf{v}\|_{\operatorname{div},\Omega} = \left(\|\mathbf{v}\|^2_{0,\Omega} + \|\operatorname{div} \mathbf{v}\|^2_{0,\Omega}\right)^{1/2}.$$

If we construct a function $\mathbf{u}^N \in H^1(\Omega)$ which satisfies the boundary conditions in (2.1), then our aim is to solve (2.2) for $p \in H^1(\Omega)$, $\mathbf{u} = \mathbf{u}^N + \hat{\mathbf{u}}$ with $\hat{\mathbf{u}} \in H^1_\Gamma(\Omega)^2$, and $\mathbf{U} \in H(\operatorname{div}, \Omega)^2$. The associated least-squares variational formulation would consist in finding $(p, \hat{\mathbf{u}}, \mathbf{U}) \in H^1(\Omega) \times H^1_\Gamma(\Omega)^2 \times H(\operatorname{div}, \Omega)^2$ such that

$$\|\mathcal{R}(p, \mathbf{u}^N + \hat{\mathbf{u}}, \mathbf{U})\|^2_{0,\Omega} \le \|\mathcal{R}(q, \mathbf{u}^N + \mathbf{v}, \mathbf{V})\|^2_{0,\Omega} \tag{2.3}$$

holds for all $(q, \mathbf{v}, \mathbf{V}) \in H^1(\Omega) \times H^1_\Gamma(\Omega)^2 \times H(\operatorname{div}, \Omega)^2$.

Before we turn to the investigation of this least-squares formulation, we consider the special case $\mu = 0$ in more detail. Let us denote the first-order system (2.2) corresponding to $\mu = 0$ by

$$\mathcal{R}_0(p, \mathbf{u}, \mathbf{U}) = \begin{pmatrix} \delta\, p + \operatorname{div} \mathbf{u} \\ \mathbf{u} + \nabla p \\ \mathbf{U} \end{pmatrix}$$

and observe that

$$\mathcal{R}(p, \mathbf{u}, \mathbf{U}) = \mathcal{R}_0(p, \mathbf{u}, \mathbf{U}) + \mu^{1/2} \begin{pmatrix} 0 \\ \operatorname{div} \mathbf{U} \\ \nabla \mathbf{u} \end{pmatrix} \tag{2.4}$$

holds. For $\mu = 0$, (2.3) reduces to the least-squares minimization of $\|\mathcal{R}_0(p, \mathbf{u}, \mathbf{U})\|_{0,\Omega}$ for $p \in H^1(\Omega)$, $\mathbf{u} \in \mathbf{u}^N + H^1_\Gamma(\Omega)^2$, and $\mathbf{U} \in H(\mathrm{div}, \Omega)^2$. Unfortunately, this formulation is no longer well-posed and needs to be formulated in the larger product space $H^1(\Omega) \times (\mathbf{u}^N + H_\Gamma(\mathrm{div}, \Omega)) \times L^2(\Omega)^2$ instead. Moreover, only the normal component $\mathbf{n}\cdot\mathbf{u}^N$ may be prescribed at the boundary for $\mathbf{u}^N$, which only needs to be in $H(\mathrm{div}, \Omega)$. The well-posedness of this minimization problem may be deduced from coercivity and continuity of the associated variational formulation. In other words, it is required that there be positive constants α_0 and β_0 such that

$$\begin{aligned} \alpha_0 \left(\|q\|^2_{1,\Omega} + \|\mathbf{v}\|^2_{\mathrm{div},\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \right) &\leq \|\mathcal{R}_0(q, \mathbf{v}, \mathbf{V})\|^2_{0,\Omega} \\ &\leq \beta_0 \left(\|q\|^2_{1,\Omega} + \|\mathbf{v}\|^2_{\mathrm{div},\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \right) \end{aligned} \tag{2.5}$$

holds for all $(q, \mathbf{v}, \mathbf{V}) \in H^1(\Omega) \times H_\Gamma(\mathrm{div}, \Omega) \times L^2(\Omega)^2$. As a first step towards such an estimate we observe that

$$\|\mathcal{R}_0(q, \mathbf{v}, \mathbf{V})\|^2_{0,\Omega} \tag{2.6}$$
$$\begin{cases} \geq \min\{\delta, 1\} \left(\|\delta^{1/2} q + \delta^{-1/2} \,\mathrm{div}\, \mathbf{v}\|^2_{0,\Omega} + \|\mathbf{v} + \nabla q\|^2_{0,\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \right) \\ \leq \max\{\delta, 1\} \left(\|\delta^{1/2} q + \delta^{-1/2} \,\mathrm{div}\, \mathbf{v}\|^2_{0,\Omega} + \|\mathbf{v} + \nabla q\|^2_{0,\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \right) \end{cases}$$

holds. For $(q, \mathbf{v}, \mathbf{V}) \in H^1(\Omega) \times H_\Gamma(\mathrm{div}, \Omega) \times L^2(\Omega)^2$,

$$\begin{aligned} &\|\delta^{1/2} q + \delta^{-1/2} \,\mathrm{div}\, \mathbf{v}\|^2_{0,\Omega} + \|\mathbf{v} + \nabla q\|^2_{0,\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \\ &\quad = \delta \|q\|^2_{0,\Omega} + 2(q, \mathrm{div}\, \mathbf{v})_{0,\Omega} + \delta^{-1} \|\mathrm{div}\, \mathbf{v}\|^2_{0,\Omega} \\ &\qquad + \|\nabla q\|^2_{0,\Omega} + 2(\mathbf{v}, \nabla q)_{0,\Omega} + \|\mathbf{v}\|^2_{0,\Omega} + \|\mathbf{V}\|^2_{0,\Omega} \\ &\quad = \delta \|q\|^2_{0,\Omega} + \|\nabla q\|^2_{0,\Omega} + \|\mathbf{v}\|^2_{0,\Omega} + \delta^{-1} \|\mathrm{div}\, \mathbf{v}\|^2_{0,\Omega} + \|\mathbf{V}\|^2_{0,\Omega}, \end{aligned} \tag{2.7}$$

where the mixed terms vanish due to integration by parts. Combined with (2.6), this proves (2.5) with $\alpha_0 = \min\{\delta^2, \delta^{-1}\}$ and $\beta_0 = \max\{\delta^2, \delta^{-1}\}$. We have therefore established continuity and coercivity with respect to $H^1(\Omega) \times H_\Gamma(\mathrm{div}, \Omega) \times L^2(\Omega)^2$ in this case.

For simplicity, we have assumed $\delta > 0$ in our analysis above, and we will continue to do so throughout the rest of this paper. The case $\delta = 0$ in (2.2) may be considered by adding a constraint such as

$$\int_\Gamma p \, ds = 0,$$

which makes p unique. Of course, the boundary conditions must be compatible in this case, which implies that

$$\int_\Gamma g \, ds = 0$$

must hold. Such an example will also be included in our numerical results.

The formulation (2.3) based on the first-order system (2.2) is only meaningful under the assumption $\mu > 0$, while for $\mu \to 0$ the problem does not remain uniformly well-posed with respect to $H^1(\Omega) \times H^1_\Gamma(\Omega)^2 \times H(\mathrm{div}, \Omega)^2$. Our goal in this paper is to derive an approach which is valid for the entire parameter range of $\mu \geq 0$. To this end, a suitable transition from $\mathbf{u} \in H^1_\Gamma(\Omega)^2$ to the space $H_\Gamma(\mathrm{div}, \Omega)$ is required. In the next section, we present an approach which treats the velocity in the space $H_\Gamma(\mathrm{div}, \Omega)$ in all cases and enforces the condition $\mathbf{u} \in H^1_\Gamma(\Omega)^2$ weakly for $\mu > 0$.

3. A nonconforming least-squares formulation in $H(\mathrm{div},\Omega)$. For the nonconforming least-squares formulation we define a family of triangulations $\mathcal{T}_h$ with a parameter h measuring the mesh resolution. The set of edges associated with the triangulation $\mathcal{T}_h$ is denoted by $\mathcal{E}_h$. For a piecewise polynomial velocity field $\mathbf{u} \in L^2(\Omega)^2$ and an edge $E \in \mathcal{E}_h$, the jump term may be defined as

$$[\mathbf{u}]_E = \begin{cases} \mathbf{u}|_{K_{l,E}} - \mathbf{u}|_{K_{r,E}}, & E \in \mathcal{E}_h \cap \Omega, \\ \mathbf{u}|_{K_{l,E}}, & E \in \mathcal{E}_h \cap \Gamma. \end{cases}$$

Here, $K_{l,E}$ and $K_{r,E}$ denote the left and right triangles, respectively, adjacent to E. Similarly, the jump term for the tangential velocity component may be defined as

$$[\mathbf{t}\cdot\mathbf{u}]_E = \begin{cases} \mathbf{t}\cdot\mathbf{u}|_{K_{l,E}} - \mathbf{t}\cdot\mathbf{u}|_{K_{r,E}}, & E \in \mathcal{E}_h \cap \Omega, \\ \mathbf{t}\cdot\mathbf{u}|_{K_{l,E}}, & E \in \mathcal{E}_h \cap \Gamma. \end{cases}$$

For piecewise polynomial $\mathbf{u} \in H_\Gamma(\mathrm{div},\Omega)$, in fact, since the normal jump component vanishes on all edges,

$$[\mathbf{u}]_E = [\mathbf{n}\cdot\mathbf{u}]_E\,\mathbf{n} + [\mathbf{t}\cdot\mathbf{u}]_E\,\mathbf{t} = [\mathbf{t}\cdot\mathbf{u}]_E\,\mathbf{t} \tag{3.1}$$

holds for all $E \in \mathcal{E}_h$.

With this, the least-squares functional may be defined as

$$\mathcal{F}(p,\mathbf{u},\mathbf{U}) = \sum_{K\in\mathcal{T}_h} \|\mathcal{R}(p,\mathbf{u},\mathbf{U})\|_{0,K}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{u}]_E\|_{0,E}^2. \tag{3.2}$$

The least-squares minimization problem consists of finding $(p,\hat{\mathbf{u}},\mathbf{U}) \in H^1(\Omega) \times H_\Gamma(\mathrm{div},\Omega) \times H(\mathrm{div},\Omega)^2$ such that

$$\mathcal{F}(p,\mathbf{u}^N+\hat{\mathbf{u}},\mathbf{U}) \le \mathcal{F}(q,\mathbf{u}^N+\mathbf{v},\mathbf{V}) \tag{3.3}$$

holds for all $(q,\mathbf{v},\mathbf{V}) \in H^1(\Omega)\times H_\Gamma(\mathrm{div},\Omega)\times H(\mathrm{div},\Omega)^2$. Similarly, the corresponding finite element approximation $(p_h,\hat{\mathbf{u}}_h,\mathbf{U}_h) \in Q_h \times \boldsymbol{\Sigma}_h \times \boldsymbol{\Theta}_h$ satisfies

$$\mathcal{F}(p_h,\mathbf{u}^N+\hat{\mathbf{u}}_h,\mathbf{U}_h) \le \mathcal{F}(q_h,\mathbf{u}^N+\mathbf{v}_h,\mathbf{V}_h) \tag{3.4}$$

for all $(q_h,\mathbf{v}_h,\mathbf{V}_h) \in Q_h \times \boldsymbol{\Sigma}_h \times \boldsymbol{\Theta}_h$. Here, $Q_h \times \boldsymbol{\Sigma}_h \times \boldsymbol{\Theta}_h \subset H^1(\Omega) \times H_\Gamma(\mathrm{div},\Omega) \times H(\mathrm{div},\Omega)^2$ denote appropriate finite-dimensional spaces to be specified in section 4. The bilinear form associated with the functional (3.2) is given by

$$\begin{aligned} &\mathcal{B}(p,\mathbf{u},\mathbf{U};q,\mathbf{v},\mathbf{V}) \\ &\quad= \sum_{K\in\mathcal{T}_h} (\mathcal{R}(p,\mathbf{u},\mathbf{U}),\mathcal{R}(q,\mathbf{v},\mathbf{V}))_{0,K} + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}([\mathbf{t}\cdot\mathbf{u}]_E,[\mathbf{t}\cdot\mathbf{v}]_E)_{0,E}. \end{aligned} \tag{3.5}$$

The solution of (3.3) also satisfies the variational formulation

$$\mathcal{B}(p,\mathbf{u}^N+\hat{\mathbf{u}},\mathbf{U};r,\mathbf{w},\mathbf{W}) = 0 \tag{3.6}$$

for all $(r,\mathbf{w},\mathbf{W}) \in H^1(\Omega) \times H_\Gamma(\mathrm{div},\Omega) \times H(\mathrm{div},\Omega)^2$. Similarly, the solution of (3.4) is characterized by

$$\mathcal{B}(p_h,\mathbf{u}^N+\hat{\mathbf{u}}_h,\mathbf{U}_h;r_h,\mathbf{w}_h,\mathbf{W}_h) = 0 \tag{3.7}$$

for all $(r_h, \mathbf{w}_h, \mathbf{W}_h) \in Q_h \times \mathbf{\Sigma}_h \times \mathbf{\Theta}_h$.

Our aim is to show that the least-squares functional associated with (3.3),

$$\sum_{K\in\mathcal{T}_h} \|\mathcal{R}(p,\mathbf{u},\mathbf{U})\|_{0,K}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{u}]_E\|_{0,E}^2, \tag{3.8}$$

is also continuous and coercive with respect to suitable norms. Clearly, as in (2.6), we have

$$\begin{aligned}\sum_{K\in\mathcal{T}_h} \|\mathcal{R}(q,\mathbf{v},\mathbf{V})\|_{0,K}^2 \le \max\{\delta,1\}\Bigg(&\|\delta^{1/2}q + \delta^{-1/2}\operatorname{div}\mathbf{v}\|_{0,\Omega}^2 \\ &+ \|\mathbf{v}+\nabla q+\mu^{1/2}\operatorname{div}\mathbf{V}\|_{0,\Omega}^2 + \sum_{K\in\mathcal{T}_h}\|\mathbf{V}+\mu^{1/2}\nabla\mathbf{v}\|_{0,K}^2\Bigg),\end{aligned}$$

and therefore

$$\begin{aligned}&\sum_{K\in\mathcal{T}_h} \|\mathcal{R}(q,\mathbf{v},\mathbf{V})\|_{0,K}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 \\ &\le 2\max\{\delta^2,\delta^{-1}\}\Bigg(\|\mathbf{v}\|_{0,\Omega}^2 + \|\operatorname{div}\mathbf{v}\|_{0,\Omega}^2 + \mu\sum_{K\in\mathcal{T}_h}\|\nabla\mathbf{v}\|_{0,\Omega}^2 + \mu\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 \\ &\qquad + \|q\|_{0,\Omega}^2 + \|\mathbf{V}\|_{0,\Omega}^2 + \|\nabla q+\mu^{1/2}\operatorname{div}\mathbf{V}\|_{0,\Omega}^2\Bigg)\end{aligned}$$

for all $(q,\mathbf{v},\mathbf{V}) \in H^1(\Omega)\times H_\Gamma(\operatorname{div},\Omega)\times H(\operatorname{div},\Omega)^2$. The term in brackets clearly defines a norm on $H^1(\Omega)\times H_\Gamma(\operatorname{div},\Omega)\times H(\operatorname{div},\Omega)^2$, which we may abbreviate as

$$\begin{aligned}|||(q,\mathbf{v},\mathbf{V})||| = \Bigg(&\|\mathbf{v}\|_{0,\Omega}^2 + \|\operatorname{div}\mathbf{v}\|_{0,\Omega}^2 + \mu\sum_{K\in\mathcal{T}_h}\|\nabla\mathbf{v}\|_{0,\Omega}^2 + \mu\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 \\ &+ \|q\|_{0,\Omega}^2 + \|\mathbf{V}\|_{0,\Omega}^2 + \|\nabla q+\mu^{1/2}\operatorname{div}\mathbf{V}\|_{0,\Omega}^2\Bigg)^{1/2}.\end{aligned}$$

From now on, we use the symbol $\lesssim$ to indicate that an inequality as above holds with constants which remain bounded as μ tends to 0. The above continuity estimate may therefore be rewritten as follows.

THEOREM 3.1. *For the least-squares functional defined in* (3.2),

$$\mathcal{F}(q,\mathbf{v},\mathbf{V}) \lesssim |||(q,\mathbf{v},\mathbf{V})|||^2 \tag{3.9}$$

holds for all $(q,\mathbf{v},\mathbf{V}) \in H^1(\Omega)\times H_\Gamma(\operatorname{div},\Omega)\times H(\operatorname{div},\Omega)^2$.

Naturally, the derivation of a coercivity estimate is more complicated. To this end, we define

$$\hat{\mathcal{R}}(q,\mathbf{v},\mathbf{V}) = \begin{pmatrix}\delta^{1/2}q + \delta^{-1/2}\operatorname{div}\mathbf{v}\\ \mathbf{v}+\nabla q+\mu^{1/2}\operatorname{div}\mathbf{V}\\ \mathbf{V}+\mu^{1/2}\nabla\mathbf{v}\end{pmatrix} \tag{3.10}$$

and observe that

$$\|\mathcal{R}(q,\mathbf{v},\mathbf{V})\|_{0,\Omega}^2 \geq \min\{\delta,1\}\|\hat{\mathcal{R}}(q,\mathbf{v},\mathbf{V})\|_{0,\Omega}^2$$

holds for all $(q,\mathbf{v},\mathbf{V}) \in H^1(\Omega)\times H_\Gamma(\mathrm{div},\Omega)\times H(\mathrm{div},\Omega)^2$ due to (2.6). This leaves us with the task of deriving a lower bound for $\hat{\mathcal{R}}(q,\mathbf{v},\mathbf{V})$. In fact, since our approximation results will be based on Strang's lemma (see, e.g., [4, section III.1] or [5, section 10.1]), it suffices to show coercivity of $\hat{\mathcal{R}}(q,\mathbf{v},\mathbf{V})$ with respect to the finite element spaces $Q_h\times\boldsymbol{\Sigma}_h\times\boldsymbol{\Theta}_h \subset H^1(\Omega)\times H_\Gamma(\mathrm{div},\Omega)\times H(\mathrm{div},\Omega)^2$.

We start with a technical lemma that will be used later in the analysis.

LEMMA 3.2. *Assume that $\boldsymbol{\Theta}_h \subset H(\mathrm{div},\Omega)^2$ and $\boldsymbol{\Sigma}_h \subset H_\Gamma(\mathrm{div},\Omega)$ are piecewise polynomial finite element spaces on $\mathcal{T}_h$. Then there is a constant $C>1$ such that the inequality*

$$2\left|\sum_{E\in\mathcal{E}_h}(\mathbf{V}_h\cdot\mathbf{n},[\mathbf{v}]_E)_{0,E}\right| \leq \frac{1}{2\mu^{1/2}}\|\mathbf{V}_h\|_{0,\Omega}^2 + 2C\mu^{1/2}\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E}^2 \tag{3.11}$$

holds for all $\mathbf{V}_h\in\boldsymbol{\Theta}_h$ and $\mathbf{v}\in\boldsymbol{\Sigma}_h$.

Proof. Using (3.1) and the Cauchy–Schwarz inequality, we are led to

$$\begin{aligned}\left|\sum_{E\in\mathcal{E}_h}(\mathbf{V}_h\cdot\mathbf{n},[\mathbf{v}]_E)_{0,E}\right| &= \left|\sum_{E\in\mathcal{E}_h}(\mathbf{t}(\mathbf{V}_h\cdot\mathbf{n}),[\mathbf{t}\cdot\mathbf{v}_h]_E)_{0,E}\right| \\ &\leq \sum_{E\in\mathcal{E}_h}\|\mathbf{t}\cdot(\mathbf{V}_h\cdot\mathbf{n})\|_{0,E}\,\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E} \qquad (3.12)\\ &\leq \frac{\rho}{2}\sum_{E\in\mathcal{E}_h}h_E\|\mathbf{t}\cdot(\mathbf{V}_h\cdot\mathbf{n})\|_{0,E}^2 + \frac{1}{2\rho}\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E}^2\end{aligned}$$

with $\rho\in(0,1)$ still to be chosen appropriately below. Moreover, for all $\mathbf{V}_h\in\boldsymbol{\Theta}_h$,

$$\begin{aligned}\sum_{E\in\mathcal{E}_h}h_E\|\mathbf{t}\cdot(\mathbf{V}_h\cdot\mathbf{n})\|_{0,E}^2 &\leq \sum_{E\in\mathcal{E}_h}h_E\|\mathbf{V}_h\|_{0,E}^2 \leq \sum_{K\in\mathcal{T}_h}\sum_{E\subset\partial K}h_E\|\mathbf{V}_h\|_{0,E}^2 \\ &\leq C\sum_{K\in\mathcal{T}_h}\|\mathbf{V}_h\|_{0,K}^2 = C\|\mathbf{V}_h\|_{0,\Omega}^2\end{aligned}$$

holds with a constant C ($h_E\|\mathbf{V}_h\|_{0,E}^2 \leq C\|\mathbf{V}_h\|_{0,K}^2$ is due to a scaling argument). Assuming, without loss of generality, $C>1/2$ and setting $\rho=1/(2C)$ in (3.12) finally implies

$$2\sum_{E\in\mathcal{E}_h}(\mathbf{V}_h\cdot\mathbf{n},[\mathbf{v}]_E)_{0,E} \leq \frac{1}{2\mu^{1/2}}\|\mathbf{V}_h\|_{0,\Omega}^2 + 2C\mu^{1/2}\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E}^2,$$

which also proves (3.11). ∎

We are now ready to establish our coercivity result.

THEOREM 3.3. *Assume that $Q_h\subset H^1(\Omega)$, $\boldsymbol{\Sigma}_h\subset H_\Gamma(\mathrm{div},\Omega)$, and $\boldsymbol{\Theta}_h\subset H(\mathrm{div},\Omega)^2$ are piecewise polynomial finite element spaces. Then, for the least-squares functional defined in* (3.2),

$$|||(q_h,\mathbf{v}_h,\mathbf{V}_h)|||^2 \lesssim \mathcal{F}(q_h,\mathbf{v}_h,\mathbf{V}_h) \tag{3.13}$$

holds for all $(q_h, \mathbf{v}_h, \mathbf{V}_h) \in Q_h \times \boldsymbol{\Sigma}_h \times \boldsymbol{\Theta}_h$.

Proof. The definition of the operator in (3.10) immediately leads to

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h} \|\hat{\mathcal{R}}(q,\mathbf{v},\mathbf{V})\|_{0,K}^2 \\
&\quad = \|\delta^{1/2} q + \delta^{-1/2}\operatorname{div}\mathbf{v}\|_{0,\Omega}^2 + \|\mathbf{v} + \nabla q + \mu^{1/2}\operatorname{div}\mathbf{V}\|_{0,\Omega}^2 + \sum_{K\in\mathcal{T}_h} \|\mathbf{V} + \mu^{1/2}\nabla\mathbf{v}\|_{0,K}^2 \\
&\quad = \delta\,\|q\|_{0,\Omega}^2 + \delta^{-1}\|\operatorname{div}\mathbf{v}\|_{0,\Omega}^2 + \|\mathbf{v}\|_{0,\Omega}^2 + \|\nabla q + \mu^{1/2}\operatorname{div}\mathbf{V}\|_{0,\Omega}^2 + \|\mathbf{V}\|_{0,\Omega}^2 \\
&\qquad + \mu \sum_{K\in\mathcal{T}_h} \|\nabla\mathbf{v}\|_{0,K}^2 + 2\mu^{1/2} \sum_{E\in\mathcal{E}_h} (\mathbf{V}\cdot\mathbf{n}, [\mathbf{v}]_E)_{0,E}
\end{aligned}$$

for all $(q,\mathbf{v},\mathbf{V}) \in H^1(\Omega)\times H_\Gamma(\operatorname{div},\Omega)\times H(\operatorname{div},\Omega)^2$, where integration by parts is used at appropriate places. With the constant C from Lemma 3.2, using (3.11) gives

(3.14)
$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h} \|\hat{\mathcal{R}}(q_h,\mathbf{v}_h,\mathbf{V}_h)\|_{0,K}^2 + (2C+1)\mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E}^2 \\
&\qquad \geq \|\mathbf{v}_h\|_{0,\Omega}^2 + \delta^{-1}\|\operatorname{div}\mathbf{v}_h\|_{0,\Omega}^2 + \mu \sum_{K\in\mathcal{T}_h} \|\nabla\mathbf{v}_h\|_{0,K}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 \\
&\qquad + \delta\,\|q_h\|_{0,\Omega}^2 + \frac{1}{2}\|\mathbf{V}_h\|_{0,\Omega}^2 + \|\nabla q_h + \mu^{1/2}\operatorname{div}\mathbf{V}_h\|_{0,\Omega}^2
\end{aligned}$$

for all $(q_h,\mathbf{v}_h,\mathbf{V}_h) \in Q_h \times \boldsymbol{\Sigma}_h \times \boldsymbol{\Theta}_h$, which completes the proof of (3.13). ∎

THEOREM 3.4. *Let* $(p,\mathbf{u},\mathbf{U}) \in H^1(\Omega)\times H_\Gamma(\operatorname{div},\Omega)\times H(\operatorname{div},\Omega)^2$ *be the exact solution of* (3.3)*, and let* $(p_h,\mathbf{u}_h,\mathbf{U}_h) \in Q_h\times\boldsymbol{\Sigma}_h\times\boldsymbol{\Theta}_h$ *be the nonconforming approximation* (3.4)*. Then,*

$$\begin{aligned}
&|||(p-p_h,\mathbf{u}-\mathbf{u}_h,\mathbf{U}-\mathbf{U}_h)||| \\
&\qquad \lesssim \inf_{(q_h,\mathbf{v}_h,\mathbf{V}_h)\in Q_h\times\boldsymbol{\Sigma}_h\times\boldsymbol{\Theta}_h} |||(p-q_h,\mathbf{u}-\mathbf{v}_h,\mathbf{U}-\mathbf{V}_h)|||.
\end{aligned} \tag{3.15}$$

Proof. Strang's lemma (cf. [5, Lemma 10.1.1]) gives

$$\begin{aligned}
|||(p-p_h,\mathbf{u}-\mathbf{u}_h,\mathbf{U}-\mathbf{U}_h)||| &\lesssim \inf_{(q_h,\mathbf{v}_h,\mathbf{V}_h)\in Q_h\times\boldsymbol{\Sigma}_h\times\boldsymbol{\Theta}_h} |||(p-q_h,\mathbf{u}-\mathbf{v}_h,\mathbf{U}-\mathbf{V}_h)||| \\
&+ \sup_{(r_h,\mathbf{w}_h,\mathbf{W}_h)\in Q_h\times\boldsymbol{\Sigma}_h\times\boldsymbol{\Theta}_h} \frac{\mathcal{B}(p-p_h,\mathbf{u}-\mathbf{u}_h,\mathbf{U}-\mathbf{U}_h;r_h,\mathbf{w}_h,\mathbf{W}_h)}{|||(r_h,\mathbf{w}_h,\mathbf{W}_h)|||}.
\end{aligned}$$

We investigate the second term on the right-hand side, the so-called consistency error, more closely. For its numerator, due to (3.7), we obtain

$$\begin{aligned}
&\mathcal{B}(p-p_h,\mathbf{u}-\mathbf{u}_h,\mathbf{U}-\mathbf{U}_h;r_h,\mathbf{w}_h,\mathbf{W}_h) = \mathcal{B}(p,\mathbf{u},\mathbf{U};r_h,\mathbf{w}_h,\mathbf{W}_h) \\
&\quad = \sum_{K\in\mathcal{T}_h} (\mathcal{R}(p,\mathbf{u},\mathbf{U}),\mathcal{R}(r_h,\mathbf{w}_h,\mathbf{W}_h))_{0,K} + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E}([\mathbf{t}\cdot\mathbf{u}]_E,[\mathbf{t}\cdot\mathbf{w}_h]_E)_{0,E}.
\end{aligned}$$

Since, for the exact solution $(p,\mathbf{u},\mathbf{U})$, $\mathcal{R}(p,\mathbf{u},\mathbf{U}) = 0$ and $\mu[\mathbf{t}\cdot\mathbf{u}]_E = 0$ for all $E\in\mathcal{E}_h$, the consistency error vanishes, which completes the proof. ∎

The norm $|||(\cdot,\cdot,\cdot)|||$ contains a term which, for $\mu > 0$, couples ∇q and $\operatorname{div} \mathbf{V}$. A bound without such a coupling can easily be obtained by noting that

$$\|\mathbf{v}\|_{0,\Omega}^2 + \|\operatorname{div} \mathbf{v}\|_{0,\Omega}^2 + \mu \sum_{K\in\mathcal{T}_h} \|\nabla \mathbf{v}\|_{0,\Omega}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E} \|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 + \|q\|_{0,\Omega}^2 + \|\mathbf{V}\|_{0,\Omega}^2 \le |||(q,\mathbf{v},\mathbf{V})|||^2$$

holds. Moreover, using

$$|||(q,\mathbf{v},\mathbf{V})|||^2 \le \|\mathbf{v}\|_{0,\Omega}^2 + \|\operatorname{div} \mathbf{v}\|_{0,\Omega}^2 + \mu \sum_{K\in\mathcal{T}_h} \|\nabla \mathbf{v}\|_{0,\Omega}^2 + \mu \sum_{E\in\mathcal{E}_h} \frac{1}{h_E} \|[\mathbf{t}\cdot\mathbf{v}]_E\|_{0,E}^2 + \|q\|_{0,\Omega}^2 + 2\|\nabla q\|_{0,\Omega}^2 + \|\mathbf{V}\|_{0,\Omega}^2 + 2\mu \|\operatorname{div} \mathbf{V}\|_{0,\Omega}^2$$

combined with the interpolation estimates presented in the following section, bounds for the approximation error may be deduced from Theorem 3.15.

4. Finite element approximation estimates. An appropriate choice of the combination of finite element spaces for the approximation of the variables in our least-squares formulation is motivated in the following discussion. To this end, let $m \ge 1$ be an integer. For the approximation p_h of $p \in H^1(\Omega)$, we use standard H^1-conforming finite elements of piecewise polynomials of degree $m+1$. We may denote the corresponding subspace as Q_h and get

$$\inf_{q_h\in Q_h} \|q - q_h\|_{1,\Omega} \lesssim h^{m+1} |q|_{m+2,\Omega} \tag{4.1}$$

from standard finite element interpolation results (cf. [4, section II.6]). For the finite element representation of the velocity field $\mathbf{u}$, $H(\operatorname{div},\Omega)$-conforming elements should be used. One possibility for the construction of an approximation $\mathbf{u}_h$ for the velocity field consists of the use of Raviart–Thomas spaces, which consist of piecewise polynomials of the form

$$\mathbf{u}_h|_K = \begin{pmatrix} p_m^{(I)} \\ p_m^{(II)} \end{pmatrix} + \mathbf{x} p_m^{(III)}$$

on each triangle $K \in \mathcal{T}_h$, where $p_m^{(I)}$, $p_m^{(II)}$, and $p_m^{(III)}$ denote polynomials of degree m. For $m = 1$, this implies

$$\mathbf{u}_h|_K = \begin{pmatrix} \alpha_K + \beta_K x_1 + \gamma_K x_2 \\ \delta_K + \rho_K x_1 + \sigma_K x_2 \end{pmatrix} + (\omega_K x_1 + \xi_K x_2) \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

with $\alpha_K, \beta_K, \gamma_K, \delta_K, \rho_K, \sigma_K, \omega_K, \xi_K \in \mathbb{R}$. If we denote the Raviart–Thomas space of degree m by $\mathbf{\Sigma}_h$, then [6, Proposition III.3.9] leads to

$$\inf_{\mathbf{v}_h\in\mathbf{\Sigma}_h} \|\mathbf{u} - \mathbf{v}_h\|_{\operatorname{div},\Omega} \lesssim h^{m+1} \left(|\mathbf{u}|_{m+1,\Omega} + |\operatorname{div} \mathbf{u}|_{m+1,\Omega} \right).$$

In addition, [6, Proposition III.3.6] generalizes this estimate to

$$\inf_{\mathbf{v}_h\in\mathbf{\Sigma}_h} \left(\|\mathbf{u} - \mathbf{v}_h\|_{\operatorname{div},\Omega}^2 + \mu \sum_{K\in\mathcal{T}_h} \|\nabla(\mathbf{u} - \mathbf{v}_h)\|_{0,K}^2 \right)^{1/2} \lesssim h^{m+1} \left(|\mathbf{u}|_{m+1,\Omega} + |\operatorname{div} \mathbf{u}|_{m+1,\Omega} \right) + h^m \mu^{1/2} |\mathbf{u}|_{m+1,\Omega}. \tag{4.2}$$

Let $\mathbf{\Pi}_h : H_\Gamma(\mathrm{div},\Omega) \to \mathbf{\Sigma}_h$ be the interpolation operator used in association with the Raviart–Thomas spaces (see [6, section III.3]). If, furthermore, $\mathbf{\Phi}_h : H^1_\Gamma(\Omega)^2 \to Q^2_h$ denotes the standard finite element interpolation operator, then we have

$$\begin{aligned}\|[\mathbf{t}\cdot(\mathbf{\Pi}_h\mathbf{u})]_E\|^2_{0,E} &= \|[\mathbf{\Pi}_h\mathbf{u}]_E\|^2_{0,E} = \|\,\mathbf{\Pi}_h\mathbf{u}|_{K_{l,E}} - \mathbf{\Pi}_h\mathbf{u}|_{K_{r,E}}\,\|^2_{0,E}\\ &\le 2\|\,\mathbf{\Pi}_h\mathbf{u}|_{K_{l,E}} - \mathbf{\Phi}_h\mathbf{u}\|^2_{0,E} + 2\|\,\mathbf{\Pi}_h\mathbf{u}|_{K_{r,E}} - \mathbf{\Phi}_h\mathbf{u}\|^2_{0,E},\end{aligned}$$

where the first identity follows from (3.1). This leads to

$$\begin{aligned}\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot(\mathbf{\Pi}_h\mathbf{u})]_E\|^2_{0,E} &\le 2\sum_{K\in\mathcal{T}_h}\sum_{E\subset\partial K}\frac{1}{h_E}\|\mathbf{\Pi}_h\mathbf{u}-\mathbf{\Phi}_h\mathbf{u}\|^2_{0,E}\\ &\lesssim \frac{1}{h}\sum_{K\in\mathcal{T}_h}\|\mathbf{\Pi}_h\mathbf{u}-\mathbf{\Phi}_h\mathbf{u}\|^2_{0,\partial K}\\ &\lesssim \frac{1}{h^2}\sum_{K\in\mathcal{T}_h}\|\mathbf{\Pi}_h\mathbf{u}-\mathbf{\Phi}_h\mathbf{u}\|^2_{0,K} = \frac{1}{h^2}\|\mathbf{\Pi}_h\mathbf{u}-\mathbf{\Phi}_h\mathbf{u}\|^2_{0,\Omega}\\ &\le \frac{2}{h^2}\|\mathbf{u}-\mathbf{\Pi}_h\mathbf{u}\|^2_{0,\Omega} + \|\mathbf{u}-\mathbf{\Phi}_h\mathbf{u}\|^2_{0,\Omega} \lesssim h^{2m}|\mathbf{u}|^2_{m+1,\Omega}.\end{aligned}$$

Thus, (4.2) can be augmented to

$$\begin{aligned}\inf_{\mathbf{v}_h\in\mathbf{\Sigma}_h}\left(\|\mathbf{u}-\mathbf{v}_h\|^2_{\mathrm{div},\Omega} + \mu\sum_{K\in\mathcal{T}_h}\|\nabla(\mathbf{u}-\mathbf{v}_h)\|^2_{0,K} + \mu\sum_{E\in\mathcal{E}_h}\frac{\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|^2_{0,E}}{h_E}\right)^{1/2}\\ \lesssim h^{m+1}\left(|\mathbf{u}|_{m+1,\Omega} + |\mathrm{div}\,\mathbf{u}|_{m+1,\Omega}\right) + h^m\mu^{1/2}|\mathbf{u}|_{m+1,\Omega}.\end{aligned} \tag{4.3}$$

The auxiliary variable $\mathbf{U}\in H(\mathrm{div},\Omega)^2$ may be approximated rowwise by Raviart–Thomas elements of order $m-1$, i.e.,

$$\mathbf{U}_h|_K = \begin{pmatrix}\alpha_{K,1}+\gamma_{K,1}x_1 & \beta_{K,1}+\gamma_{K,1}x_2\\ \alpha_{K,2}+\gamma_{K,2}x_1 & \beta_{K,2}+\gamma_{K,2}x_2\end{pmatrix}$$

with $\alpha_{K,i},\beta_{K,i},\gamma_{K,i}\in\mathbb{R}$, $i=1,2$. If $\mathbf{\Theta}_h\subset H(\mathrm{div},\Omega)^2$ denotes the corresponding finite element subspace, then we obtain, again from [6, Proposition III.3.9],

$$\begin{aligned}&\inf_{\mathbf{V}_h\in\mathbf{\Theta}_h}\left(\|\mathbf{U}-\mathbf{V}_h\|^2_{0,\Omega} + \mu\|\mathrm{div}(\mathbf{U}-\mathbf{V}_h)\|^2_{0,\Omega}\right)^{1/2}\\ &\quad\lesssim h^m\left(|\mathbf{U}|_{m,\Omega} + \mu^{1/2}|\mathrm{div}\,\mathbf{U}|_{m,\Omega}\right) = h^m\left(\mu^{1/2}|\nabla\mathbf{u}|_{m,\Omega} + \mu|\mathbf{\Delta}\mathbf{u}|_{m,\Omega}\right)\\ &\quad= h^m\mu^{1/2}\left(|\mathbf{u}|_{m+1,\Omega} + \mu^{1/2}|\mathbf{\Delta}\mathbf{u}|_{m,\Omega}\right).\end{aligned} \tag{4.4}$$

All this finally leads to

$$\begin{aligned}\left(\sum_{K\in\mathcal{T}_h}\|\mathcal{R}(p_h,\mathbf{u}_h,\mathbf{U}_h)\|^2_{0,K} + \mu\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{u}_h]_E\|^2_{0,E}\right)^{1/2}\\ \lesssim h^{m+1}\left(|\mathbf{u}|_{m+1,\Omega} + |\mathrm{div}\,\mathbf{u}|_{m+1,\Omega} + |p|_{m+2,\Omega}\right)\\ + h^m\left(\mu^{1/2}|\mathbf{u}|_{m+1,\Omega} + \mu|\mathbf{\Delta}\mathbf{u}|_{m,\Omega}\right).\end{aligned} \tag{4.5}$$

In particular, for $m = 1$, i.e., using quadratic conforming elements for Q_h, next-to-lowest order Raviart–Thomas elements for $\mathbf{\Sigma}_h$, and lowest-order Raviart–Thomas elements for $\mathbf{\Theta}_h$,

$$\left(\sum_{K \in \mathcal{T}_h} \|\mathcal{R}(p_h, \mathbf{u}_h, \mathbf{U}_h)\|_{0,K}^2 + \mu \sum_{E \in \mathcal{E}_h} \frac{1}{h_E} \|[\mathbf{t} \cdot \mathbf{u}_h]_E\|_{0,E}^2 \right)^{1/2} \lesssim h^2 \left(|\mathbf{u}|_{2,\Omega} + |\operatorname{div} \mathbf{u}|_{2,\Omega} + |p|_{3,\Omega} \right) + h \left(\mu^{1/2} |\mathbf{u}|_{2,\Omega} + \mu |\mathbf{\Delta u}|_{1,\Omega} \right) \tag{4.6}$$

is obtained for the finite element approximation.

As an alternative for the velocity approximation space $\mathbf{\Sigma}_h$, the finite element space by Mardal, Tai, and Winther [11] is considered. The Mardal–Tai–Winther element was introduced specifically for mixed approaches to Darcy–Stokes flow. In this case, each component of the velocity field is represented by a piecewise polynomial of degree 3,

$$\mathbf{u}_h|_K = \begin{pmatrix} p_3^{(I)} \\ p_3^{(II)} \end{pmatrix}$$

on each triangle $K \in \mathcal{T}_h$, with the restriction that $\operatorname{div} \mathbf{u}_h$ is constant on K and that $\mathbf{n} \cdot \mathbf{u}_h$ coincides with a polynomial of degree 1 on each edge. Continuity of $\mathbf{n} \cdot \mathbf{u}_h$ across edges makes this finite element space $H(\operatorname{div})$-conforming. In addition, the mean value of the tangential component is required to be continuous across edges; in other words,

$$\int_E [\mathbf{t} \cdot \mathbf{u}_h] \, ds = 0$$

for all $E \in \mathcal{E}_h$.

In order to analyze the approximation properties of the Mardal–Tai–Winther element in association with our least-squares formulation, let $\mathbf{\Pi}_h : H_\Gamma(\operatorname{div}, \Omega) \to \mathbf{\Sigma}_h$ be the corresponding interpolation operator (see [11, section 4]). Estimate (4.5) in [11] gives

$$\left(\|\mathbf{u} - \mathbf{\Pi}_h \mathbf{u}\|_{\operatorname{div},\Omega}^2 + \mu \sum_{K \in \mathcal{T}_h} \|\nabla(\mathbf{u} - \mathbf{\Pi}_h \mathbf{u})\|_{0,K}^2 \right)^{1/2} \lesssim h \, |\mathbf{u}|_{2,\Omega}. \tag{4.7}$$

Similarly as in the case of the Raviart–Thomas elements, (3.1) gives

$$\begin{aligned} \|[\mathbf{t} \cdot (\mathbf{\Pi}_h \mathbf{u})]_E\|_{0,E}^2 &= \|[\mathbf{\Pi}_h \mathbf{u}]_E\|_{0,E}^2 = \| \, \mathbf{\Pi}_h \mathbf{u}|_{K_{l,E}} - \mathbf{\Pi}_h \mathbf{u}|_{K_{r,E}} \, \|_{0,E}^2 \\ &\le 2 \| \, \mathbf{\Pi}_h \mathbf{u}|_{K_{l,E}} - \mathbf{\Phi}_h \mathbf{u}\|_{0,E}^2 + 2 \| \, \mathbf{\Pi}_h \mathbf{u}|_{K_{r,E}} - \mathbf{\Phi}_h \mathbf{u}\|_{0,E}^2, \end{aligned}$$

where $\mathbf{\Phi}_h$ again denotes the standard finite element interpolation operator. This leads to

$$\begin{aligned} &\sum_{E \in \mathcal{E}_h} \frac{1}{h_E} \|[\mathbf{t} \cdot (\mathbf{\Pi}_h \mathbf{u})]_E\|_{0,E}^2 \\ &\qquad \le 2 \sum_{E \in \mathcal{E}_h} \frac{1}{h_E} \left(\| \, \mathbf{\Pi}_h \mathbf{u}|_{K_{l,E}} - \mathbf{\Phi}_h \mathbf{u}\|_{0,E}^2 + \| \, \mathbf{\Pi}_h \mathbf{u}|_{K_{r,E}} - \mathbf{\Phi}_h \mathbf{u}\|_{0,E}^2 \right) \end{aligned}$$

$$\lesssim \sum_{E\in\mathcal{E}_h} \frac{1}{h_E^2}\left(\|\,\mathbf{\Pi}_h\mathbf{u}|_{K_{l,E}} - \mathbf{\Phi}_h\mathbf{u}\|_{0,K_{l,E}}^2 + \|\,\mathbf{\Pi}_h\mathbf{u}|_{K_{r,E}} - \mathbf{\Phi}_h\mathbf{u}\|_{0,K_{r,E}}^2\right)$$

$$\lesssim \sum_{K\in\mathcal{T}_h} \frac{1}{h_K^2}\|\mathbf{\Pi}_h\mathbf{u} - \mathbf{\Phi}_h\mathbf{u}\|_{0,K}^2$$

$$\lesssim \sum_{K\in\mathcal{T}_h} \frac{1}{h_K^2}\left(\|\mathbf{u} - \mathbf{\Pi}_h\mathbf{u}\|_{0,K}^2 + \|\mathbf{u} - \mathbf{\Phi}_h\mathbf{u}\|_{0,K}^2\right)$$

$$\lesssim \sum_{K\in\mathcal{T}_h} h_K^2|\mathbf{u}|_{2,K}^2 \lesssim h^2|\mathbf{u}|_{2,\Omega}^2,$$

where we used (4.5) in [11] once more for the interpolation estimate associated with $\mathbf{\Pi}_h$. Combined with (4.7), this implies

$$\inf_{\mathbf{v}_h\in\mathbf{\Sigma}_h}\left(\|\mathbf{u}-\mathbf{v}_h\|_{\mathrm{div},\Omega}^2 + \mu\sum_{K\in\mathcal{T}_h}\|\nabla(\mathbf{u}-\mathbf{v}_h)\|_{0,K}^2 + \mu\sum_{E\in\mathcal{E}_h}\frac{\|[\mathbf{t}\cdot\mathbf{v}_h]_E\|_{0,E}^2}{h_E}\right)^{1/2} \lesssim h\,|\mathbf{u}|_{2,\Omega}. \tag{4.8}$$

If the Mardal–Tai–Winther elements for the velocity approximation space $\mathbf{\Sigma}_h$ are combined with standard conforming linears for Q_h and with lowest-order Raviart–Thomas elements for $\mathbf{\Theta}_h$,

$$\left(\sum_{K\in\mathcal{T}_h}\|\mathcal{R}(p_h,\mathbf{u}_h,\mathbf{U}_h)\|_{0,K}^2 + \mu\sum_{E\in\mathcal{E}_h}\frac{1}{h_E}\|[\mathbf{t}\cdot\mathbf{u}_h]_E\|_{0,E}^2\right)^{1/2} \lesssim h\,(|\mathbf{u}|_{2,\Omega} + |p|_{2,\Omega} + \mu|\mathbf{\Delta}\mathbf{u}|_{1,\Omega}) \tag{4.9}$$

is obtained for the overall approximation of the least-squares finite element approach.

5. Computational results. The numerical tests for our least-squares finite element method are performed for the first-order system (2.2) on the square domain $\Omega = [-1,1]\times[-1,1]$ with

$$g(x_1,x_2) = \begin{cases} 1-x_1^2, & \text{if } x_2 = 1,\\ x_1^2 - 1, & \text{if } x_2 = -1,\\ 0, & \text{elsewhere on } \Gamma, \end{cases}$$

for the boundary conditions. Our interest is in the confirmation of the theoretical estimates for the finite element approximation properties derived in the previous sections of this paper. To this end, the computed values of the least-squares functional $\mathcal{F}(p_h,\mathbf{u}_h,\mathbf{U}_h)$ are shown in the following tables for variable sizes of μ and h. The coarsest triangulation ($l = 0$) consists of 12 triangles, 13 nodes, and 24 edges and is uniformly refined five times, resulting in a finest triangulation ($l = 5$) with 12288 triangles, 6337 nodes, and 18624 edges. The dimensions of the finite element spaces Q_h, $\mathbf{\Sigma}_h$, and $\mathbf{\Theta}_h$ are also given in the tables in order to allow a comparison to the computational effort.

The first two sets of results listed in Tables 5.1 and 5.2 are computed with (next-to-lowest order) Raviart–Thomas elements for the velocity approximation space $\mathbf{\Sigma}_h$. In order to achieve quadratic approximation order for $\mu = 0$, piecewise quadratic standard H^1-conforming elements are used for Q_h. On the other hand, lowest-order

Raviart–Thomas elements are sufficient for (each row of) the finite element space $\boldsymbol{\Theta}$ representing the velocity gradient.

Table 5.1 shows the results with this combination of finite element spaces for $\delta = 1$. For $\mu = 0$ quadratic convergence (i.e., the functional behaves like h^4 and, consequently, its square root like h^2) can clearly be observed in the last row of Table 5.1. For $\mu = 1$ it is also obvious that the square root of the functional decreases only proportional to h; i.e., only linear convergence is achieved. For intermediate values of μ it appears that there is an initial phase of almost quadratic convergence, which is then slowed down once the viscosity becomes dominant. Note that the functional even increases for certain values during a refinement step. The possibility that this may happen here is due to the nonconformity of the approach and the fact that the spaces are not nested. A closer inspection shows that the tangential jump term of the least-squares functional is actually responsible for this increase.

Table 5.2 shows the results with the same combination of finite element spaces as above for $\delta = 0$. The convergence behavior is quite similar to the case $\delta = 1$.

The next two sets of results listed in Tables 5.3 and 5.4 are obtained with the Mardal–Tai–Winther (MTW) elements for the approximation of the velocity field. Ta-

ble 5.3 shows that approximation order 2 is not achieved any longer for zero viscosity with this finite element space. The results for the MTW approximation of the velocity field clearly show a linear convergence behavior for all values of μ (i.e., the functional is proportional to h^2). In general, for $\mu > 0$, the computed values of the functional are always somewhat larger for the Mardal–Tai–Winther elements compared to the Raviart–Thomas elements. It seems that this does not compensate for the slight reduction of the size of the system resulting from the fewer degrees of freedom associated with $\mathbf{\Sigma}_h$. Since the overall approximation order is only 1 for the Mardal–Tai–Winther elements, we may as well use piecewise linears for p. This leads to a further reduction of the number of degrees of freedom and leads to almost the same results as in Table 5.3.

The computed results for the Mardal–Tai–Winther elements in the case $\delta = 0$ are shown in Table 5.4. Interestingly, the results indicate that for $\mu = 0$ the approximation order is significantly faster than linear.

Acknowledgment. We would like to thank Zhiqiang Cai for suggesting the ellipticity bound in the form (3.13), which is stronger than the one in an earlier version of this manuscript.

ON THE ASYMPTOTIC SPECTRUM OF FINITE ELEMENT MATRIX SEQUENCES*

BERNHARD BECKERMANN† AND STEFANO SERRA-CAPIZZANO‡

Abstract. We derive a new formula for the asymptotic eigenvalue distribution of stiffness matrices obtained by applying P_1 finite elements with standard mesh refinement to the semielliptic PDE of second order in divergence form $-\nabla(K\nabla^T u) = f$ on Ω, $u = g$ on $\partial\Omega$. Here $\Omega \subset \mathbb{R}^2$, and K is supposed to be piecewise continuous and pointwise symmetric semipositive definite. The symbol describing this asymptotic eigenvalue distribution depends on the PDE, but also both on the numerical scheme for approaching the underlying bilinear form and on the geometry of triangulation of the domain. Our work is motivated by recent results on the superlinear convergence behavior of the conjugate gradient method, which requires the knowledge of such asymptotic eigenvalue distributions for sequences of matrices depending on a discretization parameter h when $h \to 0$. We compare our findings with similar results for the finite difference method which were published in recent years. In particular we observe that our sequence of stiffness matrices is part of the class of generalized locally Toeplitz sequences for which many theoretical tools are available. This enables us to derive some results on the conditioning and preconditioning of such stiffness matrices.

1. Introduction and statement of the main results.

Consider the semielliptic PDE of second order in divergence form

$$-\nabla(K\nabla^T u) = f \quad \text{on } \Omega, \qquad u = g \quad \text{on } \partial\Omega, \tag{1}$$

where $\Omega \subset \mathbb{R}^2$ is a bounded open "smooth" set (say, with piecewise $\mathcal{C}^1$ boundary), and $K : \Omega \mapsto \mathbb{R}^{2\times 2}$ is piecewise continuous in Ω and symmetric semipositive definite at each point of Ω. In this paper we are interested in describing the asymptotic distribution of eigenvalues of the matrix of coefficients obtained by approximating the above elliptic PDE by P_1 finite elements in the case where the position of the vertices can be described by some mapping.

The task of finding the asymptotic eigenvalue distribution is motivated by some recent results on the (superlinear) convergence behavior for the method of conjugate gradients (CG) [4, 5, 6]: a discretization of (1) for some sequence of stepsizes h tending to zero leads to a sequence of systems of linear equations $A_n x_n = b_n$ with A_n some symmetric positive definite matrix of order n, where of course n depends on h and tends to ∞ for $h \to 0$. The CG method is a popular method for solving such systems, and its convergence properties have been analyzed by many authors (see, e.g., [3, 41]). For instance, one has a simple upper bound for the CG error in the energy norm in

terms of the spectral condition number of A_n, that is, the ratio of the largest divided by the smallest eigenvalue of A_n; see, e.g., [24, (6.106)]. Both for finite difference and finite element approximations, asymptotics for the smallest eigenvalue of A_n in terms of h and the smallest eigenvalue of the differential operator of (1) are known; see, for instance, [20]. By elementary means one also obtains upper bounds for the largest eigenvalue, and hence upper bounds for the CG error.

However, the (linear) upper bound based on the condition number is usually quite rough, especially in the range of superlinear convergence of CG. This superlinear convergence behavior is observed numerically to be quite pronounced in the context of discretized elliptic problems in ≥ 2 dimensions, in particular for small stepsizes h. Here CG convergence is known to be governed by the distribution of the spectrum $\Lambda(A_n)$ of A_n, which at least for very simple model problems can be computed explicitly. Roughly speaking, superlinear CG convergence occurs if the eigenvalue distribution of A_n is far from being a worst case eigenvalue distribution. This qualitative rule of thumb has been known already for some time, but has been quantified only recently in [4, 5, 6]: here the authors give asymptotic error estimates for CG in terms of the asymptotic eigenvalue distribution of $(A_n)_{n\geq 0}$, namely the so-called *asymptotic spectrum* defined as follows.

A sequence of matrices $(A_n)_{n\geq 0}$, A_n Hermitian of order n with spectrum $\Lambda(A_n) \subset \mathbb{R}$, is said to have an *asymptotic spectrum* given by some measure σ if for all functions $f \in \mathcal{C}_c(\mathbb{R})$ (i.e., continuous with compact support) there holds

$$\lim_{n\to\infty} \frac{1}{n} \sum_{\lambda\in\Lambda(A_n)} f(\lambda) = \int f(\lambda)\, d\sigma(\lambda), \tag{2}$$

where each eigenvalue is counted according to its multiplicity (and hence σ is a probability measure supported on the extended real line $\overline{\mathbb{R}} = \mathbb{R} \cup \{\pm\infty\}$). In the case where the limit (2) exists and takes the form

$$\lim_{n\to\infty} \frac{1}{n} \sum_{\lambda\in\Lambda(A_n)} f(\lambda) = \int_D f(\omega(t))\, \frac{dt}{m(D)} \tag{3}$$

with a domain $D \subset \mathbb{R}^d$ having finite Lebesgue measure $m(D) > 0$, the function ω will be referred to as the *symbol* of (A_n).

The probably most classical example of sequences of matrices having an asymptotic spectrum is given by Hermitian Toeplitz matrices $A_n = (t_{j-k})_{j,k=1,\ldots,n}$ obtained from the Fourier coefficients of the Lebesgue integrable generating function $\omega(s) = \sum_{j\in\mathbb{Z}} t_j e^{ijs}$, $i^2 = -1$; see, for instance, [8] and references therein. Here the symbol coincides with the generating function, and $D = (-\pi, \pi)$.

In the present paper, the matrices A_n will result from the same approximation process when using different (decreasing) stepsizes, and thus one might expect that the sequence of matrices (A_n) has an asymptotic spectrum. Indeed, in case of finite difference discretization for differential operators, explicit formulas for an asymptotic spectrum have been given in [23, 38, 33, 26] (one-dimensional setting) and [31, 32, 30, 28, 35] (two-dimensional and multidimensional setting). Each time, the underlying symbol includes information on the coefficients and the domain of the PDE and information on the discretization schemes for the derivatives. To our knowledge, results for finite element approximations are still lacking (except for some preliminary results in [26, 31]).

Before stating our results on stiffness matrices for finite elements in subsection 1.2, we first recall in subsection 1.1 some known examples of asymptotic spectra in the finite difference case.

1.1. The case of finite difference discretizations. Consider the discretization of the one-dimensional boundary value problem

$$\begin{cases} -\dfrac{d}{dx}\left(k(x)\dfrac{d}{dx}u(x)\right) = f(x), & x \in (0,1), \\ u(0), u(1) \ \text{ given numbers}, \end{cases}$$

on a uniformly spaced grid using centered finite differences of precision order 2 and minimal bandwidth. The resulting linear systems are of tridiagonal type with coefficient matrices (A_n) having entries which are weighted samples of k:

$$A_n = \begin{bmatrix} k_{\frac{1}{2}} + k_{\frac{3}{2}} & -k_{\frac{3}{2}} & & & & \\ -k_{\frac{3}{2}} & k_{\frac{3}{2}} + k_{\frac{5}{2}} & -k_{\frac{5}{2}} & & & \\ & -k_{\frac{5}{2}} & \ddots & \ddots & & \\ & & \ddots & \ddots & -k_{\frac{2n-1}{2}} & \\ & & & -k_{\frac{2n-1}{2}} & k_{\frac{2n-1}{2}} + k_{\frac{2n+1}{2}} & \end{bmatrix}, \tag{4}$$

with $k_t = k(t \cdot h)$, $h = (n+1)^{-1}$. When $k(x) \equiv 1$, the matrix A_n reduces to the Toeplitz matrix $T_n(a)$ of size n,

$$T_n(a) = \begin{bmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & -1 & \ddots & \ddots & \\ & & \ddots & \ddots & -1 \\ & & & -1 & 2 \end{bmatrix}, \tag{5}$$

generated by $a(s) = 2 - 2\cos(s)$: note that the numbers $-1, 2, -1$ are the (nonzero) Fourier coefficients c_1, c_0, c_{-1} of a and represent also the stencil of the finite difference formula. This latter statement is not a coincidence: if we change the stencil (for instance, in order to obtain more precise discretization schemes), then we obtain Toeplitz matrices generated by a new function a having Fourier coefficients given by the entries of this new stencil [33]. A well-known fact from the theory of Toeplitz matrices is that $(T_n(a))_n$ has an asymptotic spectrum given by $\omega(s) = a(s)$ with $D = [-\pi, \pi]$; see, for instance, the seminal work by Grenander and Szegö [17]. In the more general case of variable coefficients, it follows from the locally Toeplitz analysis of [38] that the matrices A_n of (4) have an asymptotic spectrum given by the symbol

$$\omega(x, s) = k(x)a(s)$$

with $D = (0,1) \times [-\pi, \pi]$ (see also [23]). We observe that the result is in some sense natural since the samplings of k move along the diagonals of A_n smoothly (if k is smooth), and therefore also the algebraic structure of A_n looks like a Toeplitz if we restrict our attention to a local portion of the matrix: this nice algebraic behavior has a natural counterpart in the global spectral behavior. As in the constant coefficient case, the change of the discretization scheme, i.e., of the stencil, will change only

the function a in the symbol (compare [33] and [38]). Finally, we observe that the matrices (A_n) are essentially of the same type as those which one encounters when dealing with sequences of orthogonal polynomials with varying coefficients. Here again locally Toeplitz tools have been used for finding the distribution of the zeros of the considered orthogonal polynomials under very weak assumptions (only measurability) on the regularity of the coefficients [22] (see also [40]).

A further variation which could be considered in the discretization of the above one-dimensional boundary value problem is the use of nonequispaced grids. Indeed, if the new grid of size n is obtained as the image under a map $\phi : [0,1] \mapsto [0,1]$ of a uniform grid of the same size n or if the new grid can be approximated in this way (see, e.g., [35, Definition 4.6]), then the corresponding matrix sequence (A_n) has an asymptotic spectrum described by the symbol

$$\omega(x,s) = \frac{k(\phi(x))}{[\phi'(x)]^2} a(s) \quad \text{with} \quad D = (0,1) \times [-\pi,\pi]. \tag{6}$$

For these results, motivated by the use of collocation techniques (see, e.g., [21]) for approximating the solution of one-dimensional and multidimensional boundary value problems, see [35].

In the case of a two-dimensional problem such as (1), the analysis is also quite complete concerning finite difference approximations. For instance, when $\Omega = (0,1)^2$ and $K = I_2$, using the classical 5 point stencil or the 7 point stencil (in this case there is no difference since $K_{1,2} = K_{2,1} = 0$), we obtain the two-level Toeplitz matrix

$$T_N(b) = T_{n_1}(a) \otimes I_{n_2} + I_{n_1} \otimes T_{n_2}(a), \tag{7}$$

where $N = (n_1, n_2)$ (n_1 is the number of internal points in the x_1 direction and n_2 is the number of internal points in the x_2 direction), $n = n_1 n_2$ is the size, and $b(s_1, s_2) = a(s_1) + a(s_2)$ with $a(s) = 2 - 2\cos(s)$. Also in this case the bivariate stencil represents the nonzero Fourier coefficients of the bivariate generating function b, and this property remains valid for other stencils. Moreover, according to relation (3), the asymptotic spectrum of $(T_N(b))_N$ is described by the symbol $\omega(s_1, s_2) = b(s_1, s_2)$ with $D = [-\pi, \pi]^2$ (see, e.g., [39]). We observe that the same matrix, with $n_1 = n_2 = \nu - 1$, is obtained when employing the P_1 finite element approximation with triangles having the vertices

$$\left(\frac{(j,k)}{\nu}, \frac{(j+\epsilon,k)}{\nu}, \frac{(j,k+\epsilon)}{\nu} \right), \qquad \epsilon = \pm 1. \tag{8}$$

More generally, as a consequence of the theory of generalized locally Toeplitz sequences presented in [31, 32], asymptotic spectra can be given for finite difference approximations of (1) for general functions K and a domain Ω, which guarantees the symmetry of the resulting matrix (e.g., a pluri-rectangle that is a connected finite union of rectangles with edges parallel to the main axes; see [36]). For instance, for a 7 point stencil (see the proof of Corollary 1.2(b) below) we know that the resulting matrix sequence has an asymptotic spectrum with symbol

$$\omega(x,s) = \begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix}^* \cdot K(x) \cdot \begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix}, \tag{9}$$

with $D = \Omega \times [-\pi, \pi]^2$. Notice that if $\Omega = (0,1)^2$ and $K(x) = I_2$, then the above symbol reduces to that of (7) since

$$\begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix}^* \begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix} = |1 - e^{is_1}|^2 + |1 - e^{is_2}|^2 = a(s_1) + a(s_2) = b(s).$$

Furthermore, for nonequispaced tensor grids obtained as the image under a bijective map $\phi(x) = (\phi_1(x_1), \phi_2(x_2))^T$ of an equispaced tensor grid, the general structure of the symbol (see [35, 31]) is the natural generalization of (6): denoting by $\nabla\phi$ the (diagonal) Jacobian of $\phi(x) = (\phi_1(x_1), \phi_2(x_2))^T$, we have

$$\omega(x,s) = \begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2} \end{bmatrix}^* \cdot \widetilde{K}(x) \cdot \begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2} \end{bmatrix}, \tag{10}$$

$$\widetilde{K}(x) = \nabla\phi(x)^{-1} K(\phi(x)) \nabla\phi(x)^{-T}$$

over $D = \widetilde{\Omega} \times [-\pi,\pi]^2$, $\widetilde{\Omega} := \phi^{-1}(\Omega)$. We notice that (10) is the natural two-dimensional generalization of (6) and that the symbol in (10) reduces to that in (9) if $\phi_1(x_1) = x_1$ and $\phi_2(x_2) = x_2$, i.e., in the case where the grids are uniform.

Finally, recently the above results have been extended to non-Hermitian matrices A_n occurring, e.g., in the finite difference discretization of PDEs containing lower order difference operators: it has been shown in [16, 18] that, provided that the spectral norm of A_n is uniformly bounded in n and that the trace norm of $S_n = (A_n - A_n^*)/(2i)$, the skew-Hermitian part of A_n, grows at most as $o(n)$, then the sequence (A_n) has the same asymptotic spectrum as the sequence $((A_n + A_n^*)/2)$ obtained from the Hermitian part of A_n. This result also implies [18, 19] that (9) remains true for more general domains Ω, even if one uses different approximation schemes for the boundary conditions.

1.2. The case of finite element approximations. Taking into account the results of the previous subsection, the natural question arises of whether similar results on the asymptotic spectrum hold for matrices obtained by applying finite elements to (1). We mentioned already the well-known fact that for the special case $K = I_2$, $\Omega = (0,1)^2$ and a uniform triangulation on the square such as (8), the stiffness matrix for P_1 elements is identical to that obtained by finite differences using a 5 point stencil. However, this connection is no longer true in the general case and is not sufficient for us to fully understand the asymptotic properties of stiffness matrices, since for finite elements, for instance, a triangulation does not need to be of tensor form.

Rather than developing a general theory, we will discuss in this paper only the example of an approximation of (1) using P_1 finite elements, together with triangulations $\mathcal{T}_\nu$ allowing for some a priori mesh refinement. More specifically, in the following we suppose that we have some $\nu \geq 1$, some open bounded set $\widetilde{\Omega}$, and a triangulation $\mathcal{T}_\nu$ of $\mathrm{Clos}(\Omega)$ with vertices described by a bijective mapping $\phi : \mathrm{Clos}(\widetilde{\Omega}) \mapsto \mathrm{Clos}(\Omega)$ of the form

$$(j/\nu, k/\nu)^T \in \mathrm{Clos}(\widetilde{\Omega}) : \qquad P_{j,k} = \phi((j/\nu, k/\nu)) \tag{11}$$

and triangles

$$(P_{j,k}, P_{j+\epsilon,k}, P_{j,k+\epsilon}), \qquad \epsilon = \pm 1. \tag{12}$$

Such a function ϕ allows us to include also graded triangulations which are suitable if our domain Ω has nonconvex vertices (e.g., for L-shaped domains); see Examples 1.3 and 1.4 below. The usual procedure for solving (the variational form of) (1) via P_1 finite elements (see, e.g., [10, 13]) is to consider for $P_{j,k} \in \Omega$ the hat function $\psi_{j,k}$ being linear on each of the triangles, taking the value 1 on the vertex $P_{j,k}$ and 0 on any other vertex (and thus having a support given by the set of the six triangles which

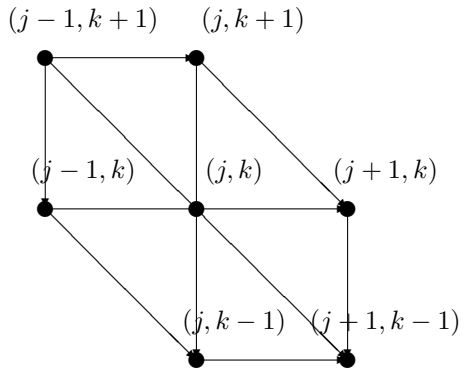

FIG. 1. *The vertex (j,k) and its adjacent vertices for P_1 finite elements.*

share the vertex $P_{j,k}$; see Figure 1), and to solve the system of linear equations

$$A_n x_n = b_n, \qquad A_n = \left(\int_\Omega \nabla \psi_{j,k}(x) K(x) \nabla \psi_{j',k'}(x)^T \, dx \right)_{P_{j,k}, P_{j',k'} \in \Omega} \tag{13}$$

with a suitable right-hand side b_n depending on f and g. The matrix A_n is usually referred to as the stiffness matrix. Notice that the same matrix of coefficients but a different right-hand side is obtained if the Dirichlet boundary conditions are partly replaced by Neumann boundary conditions. In what follows, the letter n will always denote the size of the matrix A_n, i.e., the number of vertices in Ω (which is proportional to ν^2; compare with (18) below).

THEOREM 1.1. *Consider the above triangulation $\mathcal{T}_\nu$ of* $\mathrm{Clos}(\Omega)$ *with vertices* (11) *and triangles* (12). *We suppose that $\phi : \mathrm{Clos}(\widetilde{\Omega}) \mapsto \mathrm{Clos}(\Omega)$ is bijective, $m(\widetilde{\Omega}) > 0$, and that there exists an "exceptional" compact set $\Gamma \subset \mathrm{Clos}(\widetilde{\Omega})$ with $\partial\widetilde{\Omega} \subset \Gamma$ and with Lebesgue measure $m(\Gamma) = 0$ such that $K \circ \phi$ is continuous in $\widetilde{\Omega} \setminus \Gamma$, and ϕ is of class $\mathcal{C}^1$ in $\widetilde{\Omega} \setminus \Gamma$, with nonsingular Jacobian $\nabla\phi$. Then an asymptotic spectrum of the stiffness matrices A_n of* (13) *for $\nu \to \infty$ exists and is given by the formula*

$$\int f \, d\sigma = \frac{1}{(2\pi)^2} \frac{1}{m(\widetilde{\Omega})} \int_{[-\pi,\pi]^2} ds \int_{\widetilde{\Omega}} dx \, f(\omega(x,s)),$$

where

$$\omega(x,s) = \begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix}^* \cdot \widetilde{K}(x) \cdot \begin{bmatrix} 1 - e^{is_1} \\ 1 - e^{is_2} \end{bmatrix},$$

$$\widetilde{K}(x) = |\det \nabla\phi(x)| \nabla\phi(x)^{-1} K(\phi(x)) \nabla\phi(x)^{-T}.$$

Moreover, this formula for the asymptotic spectrum remains valid if one uses numerical integration for evaluating the entries of A_n, as long as the quadrature formula has positive weights and integrates constants exactly.

Some consequences of Theorem 1.1 are summarized in the following result.

COROLLARY 1.2. *With the notations and assumptions of Theorem* 1.1, *the following hold:*

(a) *The sequence of matrices of coefficients (A_n) has the same asymptotic spectrum as the one obtained by applying P_1 elements on the uniform triangulation* (8) *to*

the PDE

$$-\nabla(\widetilde{K}\nabla^T u) = \widetilde{f} \quad \text{on } \widetilde{\Omega}, \qquad u = \widetilde{g} \quad \text{on } \partial\widetilde{\Omega}. \tag{14}$$

Moreover, the bilinear form in the weak formulation of problems (1) *and* (14) *are equivalent via variable transformation.*

(b) *One obtains for* (A_n) *the same asymptotic spectrum as that for matrices obtained by applying finite differences based on a* 7 *point stencil (see Figure* 1*) to* (14). *Moreover,* (A_n) *is a (reduced) generalized locally Toeplitz sequence in the sense of* [32, Definition 3.1], *with the symbol* $\omega(x,s)$ *of Theorem* 1.1.

It is quite instructive to compare the results of Theorem 1.1 and Corollary 1.2 with those of subsection 1.1 for finite difference discretizations. We observe that the symbol in formula (10) and the expression of ω in Theorem 1.1 have a similar structure; in particular, we have the same dependency on the domain Ω and on the matrix-valued coefficient function K. Also, the trigonometric polynomials in s_1, s_2 occurring in Theorem 1.1 are the same as those in (10). These polynomials translate the dependency of the asymptotic spectrum on the discretization scheme (5/7 point stencil or P_1 finite elements). The main difference between the two symbols is the dependency on the triangulation described by our function ϕ: in case of finite elements there is an additional factor $|\det \nabla\phi|$, leading to a smoother symbol in neighborhoods of points $x \in \Gamma$ with $|\det \nabla\phi(x)| = 0$ (corresponding, e.g., to nonconvex edges of Ω; compare with Example 1.3 below), and implying that the finite element matrix of coefficients has fewer eigenvalues of "large" magnitude than the corresponding finite difference matrix of coefficients.

We conclude this section by considering two examples for triangulations $\mathcal{T}_\nu$ induced by some mapping ϕ.

Example 1.3. Suppose that Ω is some nonconvex polygon Ω, with nonconvex vertices given by a_j, $j = 1, \ldots, p$, and corresponding inner angles $\beta_j\pi \in (\pi, 2\pi)$, and let $d > 0$ be sufficiently small. Consider the choice $\Omega = \widetilde{\Omega}$ and

$$\phi(x) = \begin{cases} a_j + (x - a_j) \cdot \left(\frac{||x-a_j||}{d}\right)^{\beta_j - 1} & \text{for } ||x - a_j|| < d, \\ x & \text{else,} \end{cases}$$

where $||\cdot||$ denotes the Euclidean norm. By construction, $\phi : \mathrm{Clos}(\Omega) \mapsto \mathrm{Clos}(\Omega)$ is bijective and of class $\mathcal{C}^1$ in $\widetilde{\Omega} \setminus \Gamma = \{z \in \Omega : ||z - a_j|| \neq d \text{ for } j = 1, 2, \ldots, p\}$. Its Jacobian for $||x - a_j|| < d$ is given by

$$\nabla\phi(x) = \frac{||x - a_j||^{\beta_j - 1}}{d^{\beta_j - 1}} \left[I_2 + (\beta_j - 1)\frac{(x - a_j)(x - a_j)^T}{||x - a_j||^2} \right],$$

and $|\det \nabla\phi(x)| = \beta_j(||x - a_j||/d)^{2\beta_j - 2}$ tends to 0 for $x \to a_j$. For the inverse of the normalized Jacobian occurring in the symbol of Theorem 1.1 we find

$$\sqrt{|\det(\nabla\phi(x))|}\nabla\phi(x)^{-1} = \sqrt{\beta_j}\left[I_2 - \left(1 - \frac{1}{\beta_j}\right)\frac{(x - a_j)(x - a_j)^T}{||x - a_j||^2} \right].$$

Notice also that $||\nabla\phi(x)||$ is bounded uniformly in $\widetilde{\Omega} \setminus \Gamma$, implying that the finesse parameter of the triangulation $\mathcal{T}_\nu$, i.e., the largest of the diameters of the triangles of this triangulation, is of order $\mathcal{O}(1/\nu)$. We finally observe that for triangles where the largest of the distances of the three vertices to a_j is given by $t^{\beta_j} \leq d$ have edges with

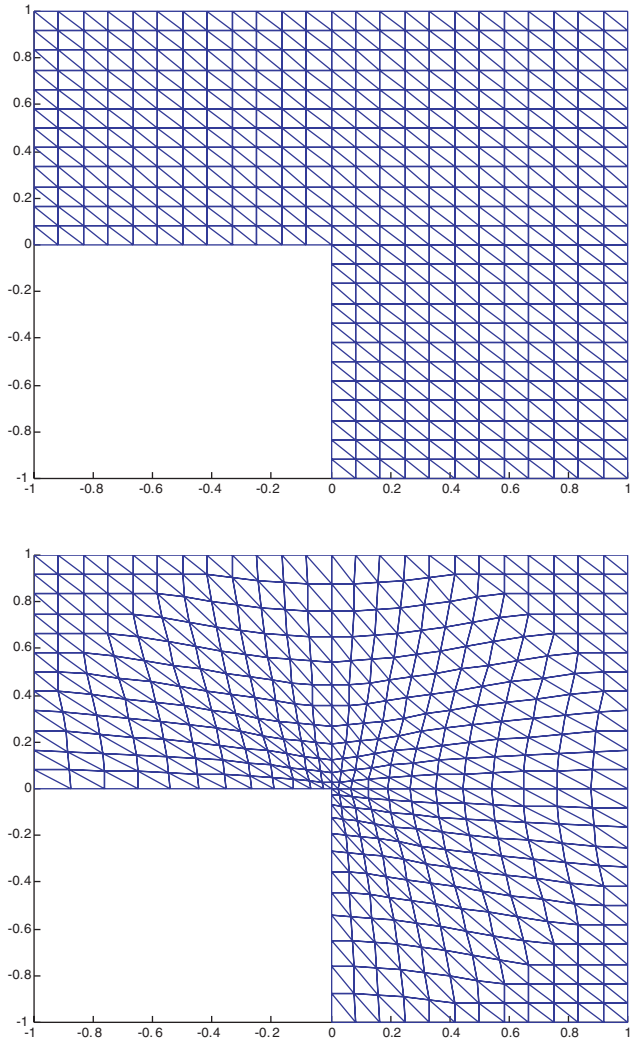

FIG. 2. *Triangulation of an L-shape for* $\nu = 12$. *On the top we find the uniform triangulation, and on the bottom its image under the map* $\phi(x) = x \cdot \min\{1, \sqrt{||x||}\}$ *leading to some grid refinement around the origin.*

size of order $t^{\beta_j - 1}/\nu$: such a mesh refinement based on the grading function $t \mapsto t^{\beta_j}$ is often used in order to keep the classical finite element error estimate also for singular solutions induced by nonconvex vertices.

Example 1.4. A typical example covered by Example 1.3 is a triangulation of an L-shape with vertices $(0,0), (-1,0), (-1,1), (1,1), (1,-1), (0,-1)$, the only nonconvex edge being at the origin $a_1 = 0$, with $\beta_1 := \beta = 3/2$. Here we can choose $d = 1$ in Example 1.3, leading to the function $\phi(x) = x \cdot \min\{1, ||x||^{\beta-1}\}$, with the inverse of the normalized Jacobian given by

$$\sqrt{|\det(\nabla\phi(x))|}\nabla\phi(x)^{-1} = \sqrt{\beta} I_2 - \left(\sqrt{\beta} - \frac{1}{\sqrt{\beta}}\right) \frac{xx^T}{||x||^2}, \qquad ||x|| < 1.$$

In Figure 2 we have drawn both the uniform triangulation and its image under ϕ, leading to some graduation around the origin.

We should notice that in the proof of Theorem 1.1 we do not need any properties of the triangles of $\mathcal{T}_\nu$ having a nonempty intersection with Γ. Thus Theorem 1.1 remains valid if one uses, for instance, curved elements in order to fit more complicated boundaries.

The remainder of the paper is organized as follows: in section 2 we give the proof of Theorem 1.1 and Corollary 1.2. In section 3 we discuss relations between stiffness matrices for different triangulations, in order to design efficient preconditioning strategies. Finally, in section 4 we draw some conclusions.

2. Proof. In what follows we write $\lambda_1(A_n) \leq \lambda_2(A_n) \leq \cdots \leq \lambda_n(A_n)$ for the eigenvalues of some symmetric matrix A_n of order n, and $\mu(A_n) = \frac{1}{n}\sum_{j=1}^{n} \delta_{\lambda_j(A_n)}$ for the corresponding counting measure. Moreover, we will write $\mu(A_n) \to \sigma$ for $n \to \infty$ if there is weak-star convergence in the sense of (2), i.e., the matrix sequence (A_n) has an asymptotic spectrum described by the measure σ.

For proving the above result we make use of the following result on (reduced) generalized locally Toeplitz matrix sequences (see [31, 32]), which we will not cite in its greatest generality: we will focus instead on a subclass of matrix sequences that are (reduced) generalized locally Toeplitz (see [32, Definition 3.1] for the precise definitions in full generality) and also banded and symmetric. Let (M_n) be a sequence of matrices of size n and of level $\gamma \in \mathbb{N}$ defined according to the multi-index rule

$$M_n = (M_{a,a'})_{a,a' \in \nu D \cap \mathbb{Z}^\gamma}, \tag{15}$$

$$M_{a,a'} = \frac{1}{(2\pi)^\gamma} \int_{[-\pi,\pi]^\gamma} ds e^{-s^T(a'-a)} \omega\left(\frac{a+a'}{2\nu}, s\right),$$

and corresponding to some open $D \subset \mathbb{R}^\gamma$, some integer $\nu \geq 1$, and some symbol $\omega : D \times [-\pi,\pi]^\gamma \to \mathbb{R}$ with $\omega(x,s) = \omega(x,-s)$ being a polynomial in e^{is}, e^{-is} with coefficients continuous in x. We observe that a matrix M_n of such a type and level 1 is just an ordinary banded matrix, where succeeding elements on any diagonal vary only slightly (for large ν and therefore a fortiori for large n) since they are values of some continuous function at arguments differing only by $1/\nu$ (which tends to zero as $n = n(\nu)$ tends to infinity). Also, a matrix M_n of level γ is block banded with blocks being themselves of the same structure as in (15) of level $\gamma - 1$. Finally, if the symbol $\omega(x,s)$ does not depend on x and $D = \bigotimes_{j=1}^{\gamma}(0,\alpha_j)$, we obtain the classical Toeplitz matrices of level γ and order $\prod_{j=1}^{\gamma}[\nu \cdot \alpha_j - 1]$. A basic result on such symmetric banded (reduced) generalized locally Toeplitz matrix sequences is that they have an asymptotic spectrum given by the following formula [31, 32]:

$$\lim_{n\to\infty} \mu(M_n) = \sigma, \qquad \int f\, d\sigma = \frac{1}{(2\pi)^\gamma} \frac{1}{m(D)} \int_{[-\pi,\pi]^\gamma} ds \int_D dx\, f(\omega(x,s)). \tag{16}$$

We will also apply the following statement on the behavior of an asymptotic spectrum under perturbations: the idea relies upon the use of some kind of (matrix) approximation theory for reducing the computation of the symbol of a complicated matrix sequence to the computation of the symbol of simpler matrix sequences (see [29, 31, 32]).

LEMMA 2.1. *Let $A_n \in \mathbb{C}^{n\times n}$ be symmetric, and suppose that there exist probability measures σ, σ' such that, for each $\epsilon > 0$, we may write $A_n = A'_n + A''_n + A'''_n$ with symmetric matrix sequences $A'_n := A'_n(\epsilon), A''_n := A''_n(\epsilon), A'''_n := A'''_n(\epsilon)$, where*

$$\limsup_{n\to\infty} ||A''_n|| \leq \epsilon, \qquad \limsup_{n\to\infty} \frac{\operatorname{rank}(A'''_n)}{n} < \epsilon,$$

and $(A'_n)_n$ *having an asymptotic spectrum* $\mu \le \epsilon\sigma' + \sigma$. *Then* (A_n) *has the asymptotic spectrum* σ.

Proof. Suppose that the assertion of the lemma is not true. Then by Helley's theorem [25, Theorem 0.1.3] there exists an infinite set of natural numbers $\mathcal{N}$ such that $(\mu(A_n))_{n\in\mathcal{N}}$ tends to some probability measure ν different from the probability measure σ. By possibly replacing A_n by $-A_n$ we may conclude that there exists a $b \in \mathbb{R}$ with

$$\nu([-\infty, b)) > \sigma([-\infty, b)) = \sigma([-\infty, b]). \tag{17}$$

Write $r_n = \operatorname{rank}(A'''_n)$. Any $V \subset \mathbb{C}^n$ can be written as direct sum $V' \oplus V''$, V' being a subset of the kernel of A'''_n, V'' being therefore a subset of the image of $(A'''_n)^* = A'''_n$, implying that $\dim(V') \ge \dim(V) - r_n$. Consequently, using the Courant min-max principle, we obtain for any $1 \le j \le n - r_n$

$$\begin{aligned}
\lambda_j(A'_n) &= \max_{V\subset\mathbb{C}^n, \dim(V)=n+1-j} \min_{y\in V} \frac{y^*A'_n y}{y^*y} \\
&\le \max_{V\subset\mathbb{C}^n, \dim(V)=n+1-j} \min_{y\in V} \frac{y^*(A'_n + A''_n)y}{y^*y} + ||A''_n|| \\
&\le \max_{V'\subset \operatorname{Ker}(A'''_n), \dim(V')\ge n+1-j-r_n} \min_{y\in V'} \frac{y^*(A'_n + A''_n)y}{y^*y} + ||A''_n|| \\
&\le \max_{V'\subset\mathbb{C}^n, \dim(V')\ge n+1-j-r_n} \min_{y\in V'} \frac{y^*A_n y}{y^*y} + ||A''_n|| = \lambda_{j+r_n}(A_n) + ||A''_n||.
\end{aligned}$$

Taking into account [25, Theorem 0.1.4], we conclude that

$$\begin{aligned}
\nu([-\infty, b)) &\le \limsup_{n\to\infty} \mu(A_n)([-\infty, b]) = \limsup_{n\to\infty} \frac{\#\{j : \lambda_j(A_n) \le b\}}{n} \\
&\le \limsup_{n\to\infty} \frac{r_n + \#\{j > r_n : \lambda_{j-r_n}(A'_n) \le b + ||A''_n||\}}{n} \\
&\le \epsilon + \limsup_{n\to\infty} \mu(A'_n)([-\infty, b + 2\epsilon]) \le \epsilon + \sigma([-\infty, b + 2\epsilon]).
\end{aligned}$$

For $\epsilon \to 0$, we are left with $\nu([-\infty, b)) \le \sigma([-\infty, b])$, in contradiction with (17). Hence the lemma is shown. ∎

The above lemma is essentially contained in original work by Tilli on (one-level) locally Toeplitz sequences [38] and can be considered an evolution of the low-rank, low-norm splittings used by Tyrtyshnikov [39]. A form which is closer to the present approach can be found in [31], where the main role is played by the symbols of the involved matrix sequences. However, in the present version the language and the tools of Lemma 2.1 are a bit different since the results are expressed in terms of measures (recall formulation (2)) rather than symbols (recall formulation (3)).

Proof of Theorem 1.1. We start by establishing the formula

$$\lim_{\nu\to\infty} \frac{n(\nu)}{\nu^2} = m(\widetilde{\Omega}), \qquad \text{where } n = n(\nu) = \#\left\{\frac{(j,k)}{\nu} \in \widetilde{\Omega}\right\} \tag{18}$$

is the size of the stiffness matrix (13) for the triangulation with parameter ν. For $d > 0$, denote by $\Gamma_d := \{y \in \mathbb{R}^2 : \operatorname{dist}(y, \Gamma) \le d\}$ the closed d-neighborhood of Γ,

where we recall that $\partial\widetilde{\Omega} \subset \Gamma$ by assumption on Γ. For any $\frac{(j,k)}{\nu} \in \widetilde{\Omega}$ we find an open square of Lebesgue measure $1/\nu^2$ being a subset of the $(2/\nu)$-neighborhood of $\widetilde{\Omega}$, any two of such squares having an empty intersection, and thus $n(\nu)/\nu^2 \leq m(\widetilde{\Omega} \cup \Gamma_{2/\nu})$. On the other hand, the set $\widetilde{\Omega} \setminus \Gamma_{2/\nu}$ is a subset of the union of closed squares of Lebesgue measure $1/\nu^2$ centered at $\frac{(j,k)}{\nu} \in \widetilde{\Omega}$, implying that $n(\nu)/\nu^2 \geq m(\widetilde{\Omega} \setminus \Gamma_{2/\nu})$. Taking into account that $m(\Gamma_d) \to m(\Gamma) = 0$ for $d \to 0$ by assumption of Theorem 1.1, we arrive at relation (18).

Let $\epsilon > 0$. We now choose suitable subsets of $\widetilde{\Omega}$. Let $d > 0$ with $m(\widetilde{\Omega} \setminus \Gamma_{3d}) > \left(1 - \frac{\epsilon}{3}\right) m(\widetilde{\Omega})$. By compactness of Γ, we may cover Γ with a finite number of open ∞-neighborhoods $U_d(x_j) = \{y \in \mathbb{R}^2 : ||y - x_j||_\infty < d\}$, $j = 1, \ldots, p$, with $x_j \in \Gamma$. Defining the pluri-rectangles

$$\widetilde{\Omega}' := \widetilde{\Omega} \setminus \bigcup_{j=1}^{p} \mathrm{Clos}(U_{2d}(x_j)), \quad \widetilde{\Omega}'' := \widetilde{\Omega} \setminus \bigcup_{j=1}^{p} U_d(x_j),$$

we find that $\widetilde{\Omega} \setminus \Gamma_{3d} \subset \widetilde{\Omega}' \subset \widetilde{\Omega}'' \subset \widetilde{\Omega} \setminus \Gamma$, with $\widetilde{\Omega}''$ being compact, $\widetilde{\Omega}'$ being open, and

(19)
$$\lim_{\nu\to\infty} \frac{n'(\nu)}{\nu^2} = m(\widetilde{\Omega}') \geq \left(1 - \frac{\epsilon}{3}\right) m(\widetilde{\Omega}), \qquad \text{where } \; n' = n'(\nu) = \#\left\{\frac{(j,k)}{\nu} \in \widetilde{\Omega}'\right\}.$$

Thus, for sufficiently large ν,

$$\frac{n'(\nu)}{n(\nu)} > 1 - \frac{\epsilon}{2}. \tag{20}$$

We are now prepared to introduce a suitable splitting of the stiffness matrix A_n of (13): we first apply a suitable simultaneous permutation of row and columns such that the first $n'(\nu)$ rows and columns of A_n correspond to indices with $(j,k)/\nu \in \widetilde{\Omega}'$. Then the matrix A_n''' defined by

$$A_n - A_n''' = \begin{bmatrix} \widetilde{A}_n & 0 \\ 0 & 0 \end{bmatrix}, \quad \widetilde{A}_n = \left(\int_\Omega \nabla\psi_{j,k}(x) K(x) \nabla\psi_{j',k'}(x)^T \, dx\right)_{(j,k)/\nu,(j',k')/\nu \in \widetilde{\Omega}'}$$

is symmetric and has a rank bounded above by twice the difference of the order $n = n(\nu)$ of A_n minus the order $n' = n'(\nu)$ of $\widetilde{A}_n$. A combination with (20) leads to the relations

$$(A_n''')^* = A_n''', \qquad \mathrm{rank}\,(A_n''') \leq \epsilon n. \tag{21}$$

We want to apply Lemma 2.1 via a splitting $\widetilde{A}_n = \widetilde{A}_n' + \widetilde{A}_n''$, and

$$A_n = A_n' + A_n'' + A_n''', \quad A_n' = \begin{bmatrix} \widetilde{A}_n' & 0 \\ 0 & 0 \end{bmatrix}, \quad A_n'' = \begin{bmatrix} \widetilde{A}_n'' & 0 \\ 0 & 0 \end{bmatrix}, \tag{22}$$

where $\widetilde{A}_n''$ will be a symmetric matrix of small norm, and $\widetilde{A}_n'$ symmetric and banded. Moreover, $(\widetilde{A}_n')$ will be (reduced) generalized locally Toeplitz of level 2 in the sense of (15), and thus we know the existence and the explicit form of the asymptotic spectrum of $(\widetilde{A}_n')$ for $\nu \to \infty$.

We make use of the classical assembling procedure of a P_1 finite element matrix A_n: starting from the zero matrix, the stiffness matrix A_n is obtained after applying for all triangles T of the form $(P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta})$, $\eta = \pm 1$, the updating formula

(23)

$$A_n \begin{pmatrix} (j,k),(j+\eta,k),(j,k+\eta) \\ (j,k),(j+\eta,k),(j,k+\eta) \end{pmatrix}$$
$$\leftarrow A_n \begin{pmatrix} (j,k),(j+\eta,k),(j,k+\eta) \\ (j,k),(j+\eta,k),(j,k+\eta) \end{pmatrix} + \frac{1}{2|\det(C^{-1})|} B^T C^{-1} \frac{\int_T K(x)\,dx}{\int_T dx} C^{-T} B,$$

where the affine mapping $x \mapsto P_{j,k} + Cx$ brings the points $(0,0),(1,0),(0,1)$ to $P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta}$, respectively, and

$$B = \begin{bmatrix} -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}.$$

An important observation in our proof is that the updating term in (23) behaves like $\frac{1}{2} B^T \widetilde{K}(\zeta) B$ for some $\zeta \in \phi^{-1}(T)$ for "most" triangles T. In order to make this claim more precise in (24) below, we notice that, by construction, $\widetilde{\Omega}''$ is a compact subset of $\widetilde{\Omega} \setminus \Gamma$, and hence the Jacobian $\nabla\phi$ of ϕ, its inverse $\nabla\phi(x)^{-1}$, and the function $K \circ \phi$ are uniformly continuous in $\widetilde{\Omega}''$. Let

$$M := \sup_{x \in \widetilde{\Omega}''} \max \left\{ ||\nabla\phi(x)||, ||\nabla\phi(x)^{-1}||, ||K(\phi(x))||, \sqrt{2\epsilon} \right\} \geq 1,$$

and choose ν sufficiently large such that a triangle having at least one vertex in $\widetilde{\Omega}'$ is a subset of $\widetilde{\Omega}''$, and that any of the above functions varies at most by $\epsilon/(4M^5)$ by choosing two arguments in any triangle that is a subset of $\widetilde{\Omega}''$. For the matrix $\widetilde{A}_n$ we need to consider only triangles T having at least one vertex with preimage in $\widetilde{\Omega}'$. Denoting by $\widetilde{T} \subset \widetilde{\Omega}''$ the corresponding triangle with vertices $\frac{(j,k)}{\nu}, \frac{(j+\eta,k)}{\nu}, \frac{(j,k+\eta)}{\nu}$, we may conclude with help of the mean value theorem that, for any $\zeta \in \widetilde{T}$,

$$\left\| \frac{\int_T K(x)\,dx}{\int_T dx} - K(\phi(\zeta)) \right\| \leq \frac{\epsilon}{4M^5} \leq M, \qquad \left\| \frac{\nu}{\eta} C - \nabla\phi(\zeta) \right\| \leq \frac{\epsilon}{M^5} \leq \frac{1}{2||\nabla\phi(\zeta)^{-1}||},$$

and hence

$$\left\| \left(\frac{\nu}{\eta} C \right)^{-1} - \nabla\phi(\zeta)^{-1} \right\| \leq \frac{2\epsilon}{M^3} \leq M, \qquad \left\| \det\left(\frac{\nu}{\eta} C \right) - \det(\nabla\phi(\zeta)) \right\| \leq \frac{4\epsilon}{M^4} \leq M.$$

Applying the triangular inequality several times, we obtain after some elementary computations the (quite rough) estimate

$$\max_{\zeta \in \widetilde{T}} \left\| \frac{1}{|\det(C^{-1})|} C^{-1} \frac{\int_T K(x)\,dx}{\int_T dx} C^{-T} - \widetilde{K}(\zeta) \right\| \leq 80\epsilon, \tag{24}$$

with $\widetilde{K}$ as in the statement of Theorem 1.1. We remark that the same conclusion holds if instead of exact integration one uses a quadrature formula with positive weights for

TABLE 1

The six adjacent vertices of $\frac{(j,k)}{\nu} \in \widetilde{\Omega}'$ and the corresponding off-diagonal entries of $\widetilde{A}'_n$: in the first column we find the index (j',k') of an adjacent vertex, in the second and third column the index of the third vertex of the two triangles giving a nontrivial contribution to the entry in row (j,k) and column (j',k') of A_n, and in the last column the entry of $\widetilde{A}'_n$ at the same position.

(j',k')	(j'',k'')	(j''',k''')	Corresponding entry of $\widetilde{A}'_n$
$(j-1,k)$	$(j,k-1)$	$(j-1,k+1)$	$B_1^T\,\widetilde{K}(\frac{(j+j',k+k')}{2\nu})\,B_2$

$(j+1,k-1)$	$(j+1,k)$	$(j,k-1)$	$B_2^T\,\widetilde{K}(\frac{(j+j',k+k')}{2\nu})\,B_3$
$(j+1,k)$	$(j,k+1)$	$(j+1,k-1)$	$B_1^T\,\widetilde{K}(\frac{(j+j',k+k')}{2\nu})\,B_2$
$(j,k+1)$	$(j-1,k+1)$	$(j+1,k)$	$B_1^T\,\widetilde{K}(\frac{(j+j',k+k')}{2\nu})\,B_3$
$(j-1,k+1)$	$(j-1,k)$	$(j,k+1)$	$B_2^T\,\widetilde{K}(\frac{(j+j',k+k')}{2\nu})\,B_3$

the entries of the stiffness matrix, provided that this quadrature formula integrates constants exactly.

Notice that, in the updating procedure (23), an off-diagonal entry of A_n is updated twice since a fixed edge of the triangulation is adjacent to two triangles, and a diagonal entry is updated six times since there are six triangles adjacent to a vertex; compare with Figure 1. More precisely, in row labeled (j,k), the matrix $\widetilde{A}_n$ has nonzero off-diagonal entries in columns labeled

$$(j',k') \in \{(j-1,k+1),(j,k+1),(j-1,k),(j+1,k),(j,k-1),(j+1,k-1)\},$$

i.e., the indices of adjacent vertices. For instance, for the entry in column $(j',k') = (j-1,k)$ we have to consider the two triangles T with third vertex labeled $(j'',k'') = (j,k-1)$, and $(j''',k''') = (j-1,k+1)$, respectively, and the corresponding updating quantities can be found at position $(1,2)$ and $(2,1)$, respectively, of the symmetric 3×3 updating matrix on the right-hand side of (23). Thus, defining the corresponding off-diagonal entry of $\widetilde{A}'_n$ by

$$\begin{aligned}\widetilde{A}'_n\begin{pmatrix}(j',k')\\(j,k)\end{pmatrix} &= B_1^T\widetilde{K}\left(\frac{1}{2}\left(\frac{(j,k)}{\nu}+\frac{(j',k')}{\nu}\right)\right)B_2\\ &= (-1,-1)\widetilde{K}\left(\frac{(j+j',k+k')}{2\nu}\right)(1,0)^T,\end{aligned}$$

B_ℓ denoting the ℓth column of B, we find according to (24) that

$$\left|\widetilde{A}'_n\begin{pmatrix}(j',k')\\(j,k)\end{pmatrix}-\widetilde{A}_n\begin{pmatrix}(j',k')\\(j,k)\end{pmatrix}\right| \le 80\epsilon\,||B||^2 = 240\epsilon.$$

The off-diagonal entries of $\widetilde{A}'_n$ for the other five adjacent vertices (j',k') of (j,k) are given in Table 1, and each time we obtain the same estimate for the off-diagonal entries of $\widetilde{A}'_n - \widetilde{A}_n$. We define the diagonal entries of $\widetilde{A}'_n$ by

$$\begin{aligned}\widetilde{A}'_n\begin{pmatrix}(j,k)\\(j,k)\end{pmatrix} &= \operatorname{trace}\Big(B^T\widetilde{K}\left(\frac{(j,k)}{\nu}\right)B\Big)\\ &= -2\left(B_1^T\widetilde{K}\left(\frac{(j,k)}{\nu}\right)B_2+B_1^T\widetilde{K}\left(\frac{(j,k)}{\nu}\right)B_3+B_2^T\widetilde{K}\left(\frac{(j,k)}{\nu}\right)B_3\right)\end{aligned}\qquad (25)$$

and find according to (24) that

$$\left|\widetilde{A}'_n\begin{pmatrix}(j,k)\\(j,k)\end{pmatrix}-\widetilde{A}_n\begin{pmatrix}(j,k)\\(j,k)\end{pmatrix}\right|\le 240\epsilon\,||B||^2=720\epsilon,$$

and thus, by (22),

$$||A''_n||=||\widetilde{A}_n-\widetilde{A}'_n||\le\sqrt{||\widetilde{A}_n-\widetilde{A}'_n||_1||\widetilde{A}_n-\widetilde{A}'_n||_\infty}\le(6\cdot 240+720)\epsilon=2160\,\epsilon.$$

It remains to analyze $\widetilde{A}'_n$. Comparing the definition (15) with the last column of Table 1 and with (25), we see that $(\widetilde{A}'_n)$ is a banded and symmetric generalized locally Toeplitz matrix sequence of level 2 corresponding to the domain $\widetilde{\Omega}'$ and the symbol

$$\begin{aligned}\omega(x,s)&=(2\cos(s_1)-2)\,B_1^T\widetilde{K}(x)B_2+(2\cos(s_2)-2)\,B_1^T\widetilde{K}(x)B_3\\&\quad+(2\cos(s_2-s_1)-2)\,B_2^T\widetilde{K}(x)B_3\\&=4\sin^2\left(\frac{s_1}{2}\right)\widetilde{K}_{1,1}(x)+4\sin^2\left(\frac{s_2}{2}\right)\widetilde{K}_{2,2}(x)\\&\quad+4\left[\sin^2\left(\frac{s_1}{2}\right)+\sin^2\left(\frac{s_2}{2}\right)-\sin^2\left(\frac{s_2-s_1}{2}\right)\right]\widetilde{K}_{1,2}(x),\end{aligned}$$

that is, the same symbol (but a different domain) as in the statement of Theorem 1.1. Using (16), we may conclude that $(\mu(\widetilde{A}'_n))$ has the limit $\widetilde{\sigma}$, with

$$\int f\,d\widetilde{\sigma}=\frac{1}{(2\pi)^2}\frac{1}{m(\widetilde{\Omega}')}\int_{[-\pi,\pi]^2}ds\int_{\widetilde{\Omega}'}dx\,f(\omega(x,s)).$$

According to (22), for the corresponding counting measures for $\nu\to\infty$, we get using (18), (19),

$$\mu(A'_n)=\frac{n(\nu)-n'(\nu)}{n(\nu)}\cdot\delta_0+\frac{n'(\nu)}{n(\nu)}\mu(\widetilde{A}'_n)\to\frac{m(\widetilde{\Omega})-m(\widetilde{\Omega}')}{m(\widetilde{\Omega})}\cdot\delta_0+\frac{m(\widetilde{\Omega}')}{m(\widetilde{\Omega})}\widetilde{\sigma}$$

and

$$\frac{m(\widetilde{\Omega})-m(\widetilde{\Omega}')}{m(\widetilde{\Omega})}\cdot\delta_0+\frac{m(\widetilde{\Omega}')}{m(\widetilde{\Omega})}\widetilde{\sigma}\le\epsilon\cdot\delta_0+\frac{m(\widetilde{\Omega}')}{m(\widetilde{\Omega})}\widetilde{\sigma}\le\epsilon\cdot\delta_0+\sigma,$$

since $\widetilde{\sigma}$ differs from σ by using a different normalization and a smaller set of integration $\widetilde{\Omega}'\subset\widetilde{\Omega}$. Thus we may apply Lemma 2.1, giving the asymptotic spectrum for (A_n) as claimed in Theorem 1.1. □

Proof of Corollary 1.2. The first sentence of part (a) follows immediately by applying the formulas of Theorem 1.1 twice. With respect to the second one, consider the variable transformation $x=\phi(\widetilde{x})$ in (1): with $\widetilde{f}(\widetilde{x})=f(\phi(\widetilde{x}))$, we have $\widetilde{\nabla}\widetilde{f}(\widetilde{x})=(\nabla f)(\phi(\widetilde{x}))\nabla\phi(\widetilde{x})$, and hence

$$\begin{aligned}&\int_\Omega(\nabla u)(x)K(x)(\nabla v)(x)^T\,dx\\&\quad=\int_{\widetilde{\Omega}}(\widetilde{\nabla}\widetilde{u})(\widetilde{x})\nabla\phi(\widetilde{x})^{-1}K(\phi(x))\nabla\phi(\widetilde{x})^{-T}(\widetilde{\nabla}\widetilde{v})(\widetilde{x})^T|\det\nabla\phi(\widetilde{x})|d\widetilde{x}\\&\quad=\int_{\widetilde{\Omega}}(\widetilde{\nabla}\widetilde{u})(\widetilde{x})\widetilde{K}(\widetilde{x})(\widetilde{\nabla}\widetilde{v})(\widetilde{x})^T\,d\widetilde{x}.\end{aligned}$$

For a proof of part (b), we consider

$$y_\nu = (u_{j,k})_{(j,k)/\nu\in\widetilde{\Omega}'}, \qquad \widetilde{u}_{j,k} \approx u\left(\frac{(j,k)}{\nu}\right)$$

and the second order central difference operators using the 7 point stencil of Figure 1,

$$\Delta_1 u_{j,k} = u_{j+1/2,k} - u_{j-1/2,k} \approx \frac{1}{\nu}\frac{\partial}{\partial\widetilde{x}_1}u\left(\frac{(j,k)}{\nu}\right),$$

$$\Delta_2 u_{j,k} = u_{j,k+1/2} - u_{j,k-1/2} \approx \frac{1}{\nu}\frac{\partial}{\partial\widetilde{x}_2}u\left(\frac{(j,k)}{\nu}\right),$$

$$\Delta_3 u_{j,k} = u_{j+1/2,k-1/2} - u_{j-1/2,k+1/2} \approx \frac{1}{\nu}\left(\frac{\partial}{\partial\widetilde{x}_1} - \frac{\partial}{\partial\widetilde{x}_2}\right)u\left(\frac{(j,k)}{\nu}\right).$$

Let $\widetilde{\Omega}'$ and $\widetilde{A}'_n$ be as in the preceding proof, and let C_n be obtained from the matrix $\widetilde{A}'_n$ by replacing the diagonal entries (25) by

$$\begin{aligned} C_n\begin{pmatrix}(j,k)\\(j,k)\end{pmatrix} = &-B_1^T\left(\widetilde{K}\left(\frac{(2j-1,2k)}{2\nu}\right) + \widetilde{K}\left(\frac{(2j+1,2k)}{2\nu}\right)\right)B_2 \\ &- B_1^T\left(\widetilde{K}\left(\frac{(2j,2k-1)}{2\nu}\right) + \widetilde{K}\left(\frac{(2j,2k+1)}{2\nu}\right)\right)B_3 \\ &-B_2^T\left(\widetilde{K}\left(\frac{(2j+1,2k-1)}{2\nu}\right) + \widetilde{K}\left(\frac{(2j-1,2k+1)}{2\nu}\right)\right)B_3, \end{aligned}$$

and hence $||\widetilde{A}'_n - C_n||$ is of order ϵ; compare with (24). For a grid point $\frac{(j,k)}{\nu} \in \widetilde{\Omega}'$ having all its adjacent vertices in $\widetilde{\Omega}'$, the component of $C_n y_\nu$ with index (j,k) can be written as

$$\begin{aligned} &[\widetilde{K}_{1,1} + \widetilde{K}_{1,2}]\left(\frac{(2j-1,2k)}{2\nu}\right)(u_{j,k} - u_{j-1,k}) \\ &\quad + [\widetilde{K}_{1,1} + \widetilde{K}_{1,2}]\left(\frac{(2j+1,2k)}{2\nu}\right)(u_{j,k} - u_{j+1,k}) \\ &\quad + [\widetilde{K}_{2,2} + \widetilde{K}_{1,2}]\left(\frac{(2j,2k-1)}{2\nu}\right)(u_{j,k} - u_{j,k-1}) \\ &\quad + [\widetilde{K}_{2,2} + \widetilde{K}_{2,1}]\left(\frac{(2j,2k+1)}{2\nu}\right)(u_{j,k} - u_{j,k+1}) \\ &\quad + \widetilde{K}_{1,2}\left(\frac{(2j+1,2k-1)}{2\nu}\right)(u_{j+1,k-1} - u_{j,k}) \\ &\quad + \widetilde{K}_{1,2}\left(\frac{(2j-1,2k+1)}{2\nu}\right)(u_{j-1,k+1} - u_{j,k}) \\ &= -\Delta_1[\widetilde{K}_{1,1} + \widetilde{K}_{1,2}]\Delta_1 u_{j,k} - \Delta_2[\widetilde{K}_{2,2} + \widetilde{K}_{1,2}]\Delta_2 u_{j,k} + \Delta_3\widetilde{K}_{1,2}\Delta_3 u_{j,k}. \end{aligned}$$

If some of the vertices $\frac{(j',k')}{\nu}$ adjacent to $\frac{(j,k)}{\nu}$ lie outside of $\widetilde{\Omega}'$, we get a similar expression, where the corresponding values $u_{j',k'}$ have to be dropped. Therefore the matrix C_n describes a finite difference discretization in $\widetilde{\Omega}'$ based on the 7 point stencil of Figure 1 for the differential expression

$$-\frac{\partial}{\partial\widetilde{x}_1}\left([\widetilde{K}_{1,1}+\widetilde{K}_{1,2}]\frac{\partial u}{\partial\widetilde{x}_1}\right)-\frac{\partial}{\partial\widetilde{x}_2}\left([\widetilde{K}_{2,2}+\widetilde{K}_{1,2}]\frac{\partial u}{\partial\widetilde{x}_2}\right)$$
$$+\left(\frac{\partial}{\partial\widetilde{x}_1}-\frac{\partial}{\partial\widetilde{x}_2}\right)\left(\widetilde{K}_{1,2}\left(\frac{\partial u}{\partial\widetilde{x}_1}-\frac{\partial u}{\partial\widetilde{x}_2}\right)\right),$$

coinciding with $-\nabla(\widetilde{K}\nabla u)$, the differential expression of the PDE of Corollary 1.2(a). Using the same limit considerations as in the proof of Theorem 1.1, the first assertion of Corollary 1.2(b) follows. The second assertion now is a simple consequence of the above relationship between A_n and the 7 point stencil finite difference matrix and of the fact that every finite difference discretization of second order PDEs leads to (reduced) generalized locally Toeplitz sequences (see [31, 32]). □

3. Uniform versus nonuniform triangulations and preconditioning. Let us briefly recall some classical terminology concerning finite element triangulations. The *finesse parameter* of a triangulation $\mathcal{T}_\nu$ is the largest among the diameters of the triangles of this triangulation. A family of triangulations $\mathcal{T}_\nu$ for varying ν is called quasi-uniform [2, 20] if the length of the shortest edge in $\mathcal{T}_\nu$ divided by the finesse parameter of $\mathcal{T}_\nu$ is bounded below by some constant uniformly in ν. The family of triangulations $\mathcal{T}_\nu$ is called *shape-regular* [9, Definition II.5.1] if the ratio of the diameter divided by the radius of the largest inscribed disk is bounded uniformly for each triangle $T\in\mathcal{T}_\nu$ and all ν (or, equivalently, if all angles are bounded away from zero uniformly in ν).

In the previous sections we have considered a triangulation $\mathcal{T}_\nu$ of Ω being the image under a bijective map ϕ of a uniform triangulation $\widetilde{\mathcal{T}}_\nu$ of $\widetilde{\Omega}$ with stepsize $1/\nu$. Denote by $A_n(K,\mathcal{T}_\nu)$ the corresponding stiffness matrix (13). Since in general the two triangulations $\mathcal{T}_\nu$ and $\widetilde{\mathcal{T}}_\nu$ lead to stiffness matrices of the same size, we want to discuss in this section in more detail some spectral properties of the matrix $A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}A_n(K,\mathcal{T}_\nu)$ and other related matrices. This analysis is motivated by the task of finding efficient preconditioning strategies for the method of conjugate gradients applied to the stiffness matrix $A_n(K,\mathcal{T}_\nu)$. Our uniform triangulation $(\widetilde{\mathcal{T}}_\nu)_\nu$ is trivially both quasi-uniform and shape-regular, while $(\mathcal{T}_\nu)_\nu$ is not necessarily so. For instance, for the graduated mesh of Example 1.3 we find a finesse parameter $\geq 1/\nu$, but the triangle with vertex a_j has edges of size $d(1/(d\nu))^{\beta_j}$, and hence $(\mathcal{T}_\nu)_\nu$ is not quasi-uniform. In this section we will be particularly interested in the case where $(\mathcal{T}_\nu)_\nu$ is only shape-regular.

The main results of this section are given in subsection 3.2: in Theorem 3.2 we first relate two stiffness matrices with respect to the partial ordering of Hermitian matrices ($M_1\leq M_2$ if M_1,M_2 are Hermitian and M_2-M_1 is semipositive definite). Subsequently, in Corollary 3.4 we deduce bounds for the smallest and the largest eigenvalue of such preconditioned stiffness matrices, and in Theorem 3.5 we give results on the asymptotic spectrum for such matrices. But first we provide in subsection 3.1 a basic proposition (based on the local analysis of finite element matrices), which is the keystone for proving the results of subsection 3.2.

3.1. Local domain analysis of the finite element matrices. In order to better understand the local properties of a stiffness matrix, let us go back to the classical assembling procedure of a P_1 finite element matrix A_n mentioned already in the proof of Theorem 1.1. Starting from the zero matrix, we have the following updating formulas: any triangle T of the form $(P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta})$, $\eta \in \{\pm 1\}$, gives the contribution

(26)

$$A_n \begin{pmatrix} (j,k),(j+\eta,k),(j,k+\eta) \\ (j,k),(j+\eta,k),(j,k+\eta) \end{pmatrix}$$
$$\leftarrow A_n \begin{pmatrix} (j,k),(j+\eta,k),(j,k+\eta) \\ (j,k),(j+\eta,k),(j,k+\eta) \end{pmatrix} + \frac{1}{2|\det(C^{-1})|} B^T C^{-1} \frac{\int_T K(x)\,dx}{\int_T dx} C^{-T} B,$$

where the affine mapping $x \mapsto P_{j,k} + Cx$ maps the points $(0,0),(1,0),(0,1)$ to $P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta}$, respectively, and

$$B = \begin{bmatrix} -1 & 1 & 0 \\ -1 & 0 & 1 \end{bmatrix}.$$

Suppose that the three points $(P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta})$ have positive orientation, and define by α, β, γ, respectively, the angles of the triangle T at these vertices. In addition, define Π to be a rotation matrix mapping the half line $(0, P_{j+\eta,k} - P_{j,k})$ to the half line $((0,0),(1,0))$; then

$$\Pi C = \frac{||P_{j+\eta,k} - P_{j,k+\eta}||}{\sin(\alpha)} \begin{bmatrix} \sin(\gamma) & \sin(\beta)\cos(\alpha) \\ 0 & \sin(\beta)\sin(\alpha) \end{bmatrix},$$

and, in addition,

$$\frac{C^{-1}}{\sqrt{|\det(C^{-1})|}} = \frac{1}{\sqrt{\sin(\alpha)\sin(\beta)\sin(\gamma)}} \begin{bmatrix} \sin(\alpha)\sin(\beta) & -\cos(\alpha)\sin(\beta) \\ 0 & \sin(\gamma) \end{bmatrix} \cdot \Pi.$$

Observe also that $C^{-1}/\sqrt{|\det(C^{-1})|}$ has the singular values $\sqrt{\delta_T}$ and $1/\sqrt{\delta_T}$ and thus a spectral condition number δ_T, which can be computed explicitly in terms of the angles of T:

(27)

$$\delta_T := \operatorname{cond}\left(\frac{C^{-1}}{\sqrt{|\det(C^{-1})|}}\right) = y_T + \sqrt{y_T^2 - 1}, \qquad y_T = \frac{\sin^2(\beta) + \sin^2(\gamma)}{2\sin(\alpha)\sin(\beta)\sin(\gamma)}.$$

Therefore

$$\frac{1}{\delta_T} I_2 \le \frac{1}{|\det(C^{-1})|} C^{-1} C^{-T} \le \delta_T I_2. \tag{28}$$

If the three points $(P_{j,k}, P_{j+\eta,k}, P_{j,k+\eta})$ have negative orientation, then we switch axes; that is, we exchange the role of β and γ, but the conclusions in (27) and (28) are the same. For instance, for a triangle $T \in \widetilde{\mathcal{T}}_\nu$ of a uniform triangulation we get $\alpha = \pi/2$ and $\beta = \gamma = \pi/4$, leading to $\delta_T = 1$, but in general $\delta_T \ge 1$.

The relation (28) enables us to compare the updating matrices in (26) for different meshes and $K = I_2$, and, by a similar argument, for different (pointwise symmetric positive definite) coefficient functions K.

PROPOSITION 3.1. *With*

$$\kappa_{\min} = \operatorname{essinf}_{x\in T}\lambda_{\min}(K(x)) \geq 0, \qquad \kappa_{\max} = \operatorname{esssup}_{x\in T}\lambda_{\max}(K(x)),$$

and B, C as in (26) *we have that*

$$\kappa_{\min}\frac{B^TC^{-1}\,C^{-T}B}{2|\det(C^{-1})|} \leq \frac{1}{2|\det(C^{-1})|}B^TC^{-1}\frac{\int_T K(x)\,dx}{\int_T dx}C^{-T}B \leq \kappa_{\max}\frac{B^TC^{-1}\,C^{-T}B}{2|\det(C^{-1})|},$$

and, with $\delta_T \geq 1$ as in (27),

$$\frac{1}{\delta_T}\frac{B^TB}{2} \leq \frac{B^TC^{-1}C^{-T}B}{2|\det(C^{-1})|} \leq \delta_T\frac{B^TB}{2}.$$

There are many ways of writing the constant δ_T of (27). For instance, if $\beta, \gamma \in (0, \pi/2)$, we find using the relation $\alpha + \beta + \gamma = \pi$ that

$$y_T = \frac{\sin^2(\beta) + \sin^2(\gamma)}{\sin^2(\beta)\sin(2\gamma) + \sin^2(\gamma)\sin(2\beta)} \leq \frac{1}{\min(\sin(2\beta), \sin(2\gamma))},$$

which is quite precise if β or γ is small compared to the other two angles. We also have that δ_T is uniformly bounded for $T \in \mathcal{T}_\nu$ for all ν if and only if all angles occurring in $\mathcal{T}_\nu$ are bounded away from zero uniformly in ν, i.e., $(\mathcal{T}_\nu)_\nu$ is shape-regular. Moreover, there holds

$$\delta_T \leq 2y_T = \frac{b^2 + c^2}{2m(T)} \leq \frac{a+b+c}{2m(T)}\,\max\{a, b, c\},$$

the expression on the right-hand side being bounded above by the ratio of the diameter of the triangle T to the radius of the largest disk contained in T.

For our triangulation $\mathcal{T}_\nu$ obtained as the image of the uniform triangulation, we also know from the proof of Theorem 1.1 that

$$\frac{C}{\sqrt{|\det(C)|}} \approx \eta\,\frac{\nabla\phi(\zeta)}{\sqrt{|\det(\nabla\phi(\zeta))|}}, \quad \zeta \in \phi^{-1}(T), \tag{29}$$

and hence

$$\delta := \sup_\nu \max_{T\in\mathcal{T}_\nu}\delta_T = \sup_\nu \max_{T\in\mathcal{T}_\nu} \operatorname{cond}\left(\frac{C}{\sqrt{|\det(C)|}}\right) \approx \sup_{\zeta\in\tilde{\Omega}\setminus\Gamma} \operatorname{cond}\left(\frac{\nabla\phi(\zeta)}{\sqrt{|\det(\nabla\phi(\zeta))|}}\right).$$

This latter quantity turns out to be very simple for the refined triangulations discussed in Examples 1.3 and 1.4, namely $\delta \approx \beta$, with $\beta\pi \in (\pi, 2\pi)$ being the largest inner angle of Ω. We should notice that these last arguments are not completely rigorous, since in general relation (29) can be shown to be true only for triangles T with $\phi^{-1}(T)$ having a certain distance to Γ. However, there exist similar mesh refinements where the resulting family $(\mathcal{T}_\nu)_\nu$ is shape-regular and where explicit lower bounds for the angles are known.

3.2. Extremal eigenvalues, condition numbers, and preconditioning. The four statements in this section will have a short proof since they are related to previously known results. For our first statement we have been strongly inspired by similar results for so-called matrix-valued linear and positive operators (LPOs) (see [27, 34]). Here we give a short direct proof.

THEOREM 3.2. *Assume that the matrix K is uniformly elliptic and bounded; i.e., there exist positive constant $\kappa_{\min}$ and $\kappa_{\max}$ such that $\kappa_{\min} I_2 \le K(x) \le \kappa_{\max} I_2$ almost everywhere with respect to x (for instance, $\kappa_{\min} = \operatorname{essinf}_x \lambda_{\min}(K(x))$, $\kappa_{\max} = \operatorname{esssup}_x \lambda_{\max}(K(x))$). Then*

$$(A_n(K, \mathcal{T}_\nu))_\nu \text{ and } (A_n(I_2, \mathcal{T}_\nu))_\nu \text{ are uniformly equivalent}$$

$$\text{and more precisely, } \kappa_{\min} A_n(I_2, \mathcal{T}_\nu) \le A_n(K, \mathcal{T}_\nu) \le \kappa_{\max} A_n(I_2, \mathcal{T}_\nu), \tag{30}$$

and the same result is true if one replaces $\mathcal{T}_\nu$ in (30) by $\widetilde{\mathcal{T}}_\nu$.

Assume that the family of triangulations $(\mathcal{T}_\nu)_\nu$ is shape-regular, and define

$$\delta := \sup_\nu \max_{T \in \mathcal{T}_\nu} \delta_T < \infty$$

with δ_T as in (27). Then

$$(A_n(I_2, \mathcal{T}_\nu))_\nu \text{ and } (A_n(I_2, \widetilde{\mathcal{T}}_\nu))_\nu \text{ are uniformly equivalent}$$

$$\text{and more precisely } \tfrac{1}{\delta} A_n(I_2, \widetilde{\mathcal{T}}_\nu) \le A_n(I_2, \mathcal{T}_\nu) \le \delta A_n(I_2, \widetilde{\mathcal{T}}_\nu). \tag{31}$$

Proof. The main work for proving statements (30) and (31) has been done already in subsection 3.1: according to (26), the claimed inequalities in (30) are obtained by summing over all triangles $T \in \mathcal{T}_\nu$ the first inequality of Proposition 3.1. Similarly, relating the triangulations $\mathcal{T}_\nu$ and $\widetilde{\mathcal{T}}_\nu$ for $K = I_2$ means that we have to study how the stiffness matrix changes if C in (26) is replaced by I_2: the answer is obtained by summing the last inequality of Proposition 3.1 for all triangles (after replacing δ_T by δ). ∎

The preceding result enables us to give more precise bounds for the smallest and largest eigenvalue of the different stiffness matrices occurring in Theorem 3.2.

COROLLARY 3.3. *Assume that the matrix K is uniformly elliptic and bounded, and that $(\mathcal{T}_\nu)_\nu$ is shape-regular. Then the largest eigenvalue of $A_n(K, \mathcal{T}_\nu)$ is uniformly bounded in ν, and the smallest behaves like $1/\nu^2$ for $\nu \to \infty$.*

In particular, the spectral condition number of $A_n(K, \mathcal{T}_\nu)$ behaves like n, the number of vertices of $\mathcal{T}_\nu$.

Proof. Since $\widetilde{\Omega}$ is bounded, it is contained in a square with sides of size d_{out} and contains a square of size d_{in}. Then $A_n(I_2, \widetilde{\mathcal{T}}_\nu)$ contains as submatrix the Toeplitz matrix generated by $4 - 2\cos(s_1) - 2\cos(s_2)$ of order $d_{\text{in}}(\nu - 1)^2$, and, in addition, $A_n(I_2, \widetilde{\mathcal{T}}_\nu)$ is a submatrix of a Toeplitz matrix generated by $4 - 2\cos(s_1) - 2\cos(s_2)$ of order $d_{\text{out}}^2 \nu^2$ (see [36]). Since the eigenvalues of Toeplitz matrices generated by linear cosine polynomials are explicitly known, it follows that the smallest eigenvalue of $A_n(I_2, \widetilde{\mathcal{T}}_\nu)$ is of order $1/\nu^2 \sim n^{-1}$, and its maximal eigenvalue is uniformly bounded by 8, which is also its limit for $\nu \to \infty$. Using, for instance, the well-known representation of extremal eigenvalues of Hermitian matrices in terms of Rayleigh quotients, it follows from Theorem 3.2, by combining (30) and (31), that all three matrices $A_n(K, \mathcal{T}_\nu)$, $A_n(I_2, \mathcal{T}_\nu)$, and $A_n(K, \widetilde{\mathcal{T}}_\nu)$ have a smallest eigenvalue of order $1/\nu^2 \sim n^{-1}$ and a maximal eigenvalue bounded uniformly in ν. ∎

Corollary 3.3 has been proved in [2, relation (5.102c), p. 235, and pp. 236–238], [9, Lemma V.2.6], [20, p. 61 and Lemma 2.6, p. 233], and [37, Theorem 5.1], under the additional assumption that $(\mathcal{T}_\nu)_\nu$ is also quasi-uniform. Notice that the proofs given in the above references consist of comparing suitable Sobolev norms, and here the quasi uniformity condition cannot be dropped. The idea contained in subsection 3.1 is to use the updating formulas, i.e., a kind of element-by-element local analysis which is more effective than a global analysis (see, e.g., [1] and the work by Fried [15], where a similar technique has been extensively used).

Let us finally turn to the problem of designing a preconditioner for the CG method applied to the system $A_n(K,\mathcal{T}_\nu)x_n = b_n$. We recall that the matrix $A_n(I_2,\widetilde{\mathcal{T}}_\nu)$ corresponding to the uniform triangulation $\widetilde{\mathcal{T}}_\nu$ coincides with that obtained by applying the classical finite difference 5 point stencil to the Poisson problem $-\Delta u = f$. Thus solving the system $A_n(I_2,\widetilde{\mathcal{T}}_\nu)y_n = c_n$ can be performed in $\mathcal{O}(n)$ operations using, e.g., the method of cyclic reductions [11, 12, 14], and thus such a matrix would be a practical preconditioner. Define also the matrix

$$D_n = \operatorname{diag}\left(\left\|\widetilde{K}\left(\frac{(j,k)}{\nu}\right)\right\|\right)_{\frac{(j,k)}{\nu}\in\widetilde{\Omega}_h},$$

which again is a practical preconditioner. Then, under the assumptions of Proposition 3.1, the condition number of $A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}A_n(K,\mathcal{T}_\nu)$ and of $A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}D_n^{-1/2}\cdot A_n(K,\mathcal{T}_\nu)D_n^{-1/2}$ can be bounded independently of the stepsize $1/\nu$ in terms of the smallest angle used in the triangulation of Ω, plus possibly the norm and the ellipicity constant of K. This means that the associated preconditioned CG (PCG) will achieve a fixed precision in $\mathcal{O}(n)$ operations also in the nonconstant coefficient case with a nonuniform triangulation.

In the following two results we give a complete picture (localization and distribution) of the spectral behavior of preconditioned matrix sequences arising from the use of the above-mentioned preconditioners.

COROLLARY 3.4. *Assume that the matrix K is uniformly elliptic and bounded, i.e., there exist positive constant $\kappa_{\min}$ and $\kappa_{\max}$ such that $\kappa_{\min}I_2 \le K(x) \le \kappa_{\max}I_2$ almost everywhere with respect to x (for instance, $\kappa_{\min} = \operatorname{essinf}_x\lambda_{\min}(K(x))$, $\kappa_{\max} = \operatorname{esssup}_x\lambda_{\max}(K(x))$). Then*

$$\text{(32)}\qquad \text{the eigenvalues of } A_n(I_2,\mathcal{T}_\nu)^{-1}A_n(K,\mathcal{T}_\nu) \text{ belong to } [\kappa_{\min},\kappa_{\max}],$$

and the same result is true if one replaces $\mathcal{T}_\nu$ in (32) by $\widetilde{\mathcal{T}}_\nu$.

Assume also that the family of triangulations $(\mathcal{T}_\nu)_\nu$ is shape-regular such that $\delta := \sup_\nu \max_{T\in\mathcal{T}_\nu}\delta_T < \infty$ with δ_T as in (27). Then

$$\text{(33)}\qquad \text{the eigenvalues of } A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}A_n(I_2,\mathcal{T}_\nu) \text{ belong to } [1/\delta,\delta];$$

$$\text{(34)}\qquad \text{the eigenvalues of } A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}A_n(K,\mathcal{T}_\nu) \text{ belong to } [\kappa_{\min}/\delta,\kappa_{\max}\delta].$$

Proof. Statements (32) and (33) follow from the corresponding statements (30) and (31) in Theorem 3.2 and the fact that, for Hermitian positive definite X, Y, we have for the spectrum $\Lambda(Y^{-1}X)$ the localization

$$\Lambda(Y^{-1}X) \subset \left\{\frac{u^*Xu}{u^*Yu} : u \neq 0\right\}.$$

The claim (34) follows from (30) and (31) by rewriting the Rayleigh quotient as

$$\frac{u^* A_n(K,\mathcal{T}_\nu)u}{u^* A_n(I_2,\widetilde{\mathcal{T}}_\nu)u} = \frac{u^* A_n(K,\mathcal{T}_\nu)u}{u^* A_n(I_2,\mathcal{T}_\nu)u}\frac{u^* A_n(I_2,\mathcal{T}_\nu)u}{u^* A_n(I_2,\widetilde{\mathcal{T}}_\nu)u}. \qquad \square$$

THEOREM 3.5. *Assume that the matrix K is uniformly elliptic in the sense of Corollary* 3.4. *Consider the preconditioned sequences $(Y_n^{-1}X_n)$ with*

$$[Y_n, X_n] \in \{[A_n(I_2,\widetilde{\mathcal{T}}_\nu), A_n(K,\widetilde{\mathcal{T}}_\nu)], [A_n(I_2,\mathcal{T}_\nu), A_n(K,\mathcal{T}_\nu)], \\ [A_n(I_2,\widetilde{\mathcal{T}}_\nu), A_n(I_2,\mathcal{T}_\nu)], [A_n(I_2,\widetilde{\mathcal{T}}_\nu), A_n(K,\mathcal{T}_\nu)]\}.$$

Then, calling ω_X the symbol of (X_n) and calling ω_Y the symbol of (Y_n), we have that the asymptotic spectrum of $(Y_n^{-1}X_n)$ is given by ω_X/ω_Y.

Proof. It is enough to observe that all the involved matrix sequences are such that both X_n and Y_n come from the same matrix-valued LPO for which the distribution is known (see Theorem 1.1) and is sparsely vanishing (i.e., the symbol vanishes in a set of zero Lebesgue measure). The conclusion follows from the general theory of LPOs as in Theorem 2.9 of [28] (compare also Theorem 4.6 in [33] and Theorem 3.7 in [26]). $\square$

With the notation of the above theorem, we remark that the same result could be proved for the matrices $[Y_n, X_n] = [D_n^{1/2} A_n(I_2,\widetilde{\mathcal{T}}_\nu) D_n^{1/2}, A_n(K,\mathcal{T}_\nu)]$. Indeed $D_n^{1/2}$, $A_n(I_2,\widetilde{\mathcal{T}}_\nu)$, and $A_n(K,\mathcal{T}_\nu)$ are all (reduced) generalized locally Toeplitz sequences with sparsely vanishing symbols (i.e., zero on at most a set of zero Lebesgue measure): for D_n the statement is trivial since the matrix is diagonal, while for the remaining two matrix sequences this has been proved in Corollary 1.2. Then our claims follow from the fact that, if the symbols are all sparsely vanishing and sparsely unbounded (the inverse of a sparsely vanishing), then the operation $X_n \odot Y_n$ also gives a sequence in the generalized locally Toeplitz class, with asymptotic spectrum described by the symbol $\omega_X \odot \omega_Y$; this has been shown in [31, Theorem 5.8] for $\odot$ being multiplication, in the same paper for $\odot$ being addition or subtraction, and is known to be true also for inversion, that is, for the sequence $(Y_n^{-1}X_n)$ (see [32, Theorems 2.2 and 3.2]).

In order to illustrate Theorem 3.5 and its link with Theorem 1.1, we mention more explicitly the example that the sequence of matrices $(A_n(I_2,\widetilde{\mathcal{T}}_\nu)^{-1}A_n(K,\mathcal{T}_\nu))$ for $\nu \to \infty$ has an asymptotic spectrum described by the measure σ, with

$$\int f\, d\sigma = \frac{1}{(2\pi)^2}\frac{1}{m(\widetilde{\Omega})}\int_{[-\pi,\pi]^2} ds \int_{\widetilde{\Omega}} dx\, f\left(\omega(x,s)\right),$$

$\widetilde{K}(x) = |\det \nabla\phi(x)| \nabla\phi(x)^{-1} K(\phi(x)) \nabla\phi(x)^{-T}$ as before,

$$\omega(x,s) = \frac{\omega_X(x,s)}{\omega_Y(x,s)} = \frac{\begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2}\end{bmatrix}^* \cdot \widetilde{K}(x) \cdot \begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2}\end{bmatrix}}{\begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2}\end{bmatrix}^* \cdot \begin{bmatrix} 1-e^{is_1} \\ 1-e^{is_2}\end{bmatrix}},$$

and with $\omega_X(x,s)$, $\omega_Y(x,s)$ according to the notation of Theorem 3.5.

In particular (compare with (34)), the most important part of its eigenvalues lies in the interval

$$[\kappa_{\min}, \kappa_{\max}] = \left[\operatorname{essinf}_{x\in\widetilde{\Omega}} \lambda_{\min}(\widetilde{K}(x)), \operatorname{esssup}_{x\in\widetilde{\Omega}} \lambda_{\max}(\widetilde{K}(x))\right].$$

4. Concluding remarks. We have shown the existence of an asymptotic spectrum for the sequence of stiffness matrices, which occur in the P_1 finite element approximation of the two-dimensional model problem (1) with an a priori mesh refinement and varying stepsizes. The underlying symbol ω of this asymptotic spectrum, given in Theorem 1.1, depends not only on the domain and the coefficient functions of the PDE, but also on the particular P_1 approximation scheme (via the dependency on the Fourier variable s) and the map ϕ which describes our mesh refinement. We expect, by analogy with the finite difference case (see [31]), that Theorem 1.1 holds also for other finite elements if one adapts the choice of the trigonometric polynomials in s. It is probably also possible to extend our results to higher dimensions and to other elliptic PDEs, and probably we need only quite weak regularity assumptions on the involved domain and the involved coefficient functions, as in the finite difference case (see [38, 31, 32]). On the other hand, the graded meshes used in modern solvers (especially those generated by a posteriori mesh refinements) in general are not topologically equivalent to the meshes considered in this paper. Notice that, for proving asymptotic spectral results of global type, it is sufficient that the graded meshes are equivalent to an approximation of our meshes (see [35]). These issues should be investigated in more detail in future works, in order to widen the practical impact of our findings.

In the second part of the paper we have analyzed the spectral behavior of some preconditioned finite element matrix sequences in terms of localization, extremal, and, especially, distributional spectral results. The analysis could be used for deducing more precise bounds on the (P)CG convergence, in view of the results in [4, 5, 6]: the related specific study and the related numerical experiments will be part of a subsequent work.

Beside the locally Toeplitz idea, we have used in section 3.1 another purely linear algebra tool, namely the local domain analysis: it consists of decomposing complicated matrix structures in linear combinations of nonnegative definite dyads or low-rank matrices for which the (spectral) analysis is very simple, and then combining these results to deduce properties of the original matrix. (For finite elements see [1] and the beautiful and rich paper by Fried [15, e.g., (47)]; for finite differences compare with [33, section 3.5], [7, Theorem 3.7]; and for general matrices see [26].) We mention that this simple tool is especially useful for preconditioning analysis and for the analysis of extremal eigenvalues asymptotics. As a byproduct we have deduced in Corollary 3.4 that the finite element matrix sequence with uniform triangulation and the nonuniform one (not necessarily verifying the quasi uniformity) are spectrally equivalent. Thus a simpler (projected) two-level Toeplitz structure associated with the uniform triangulation can be employed as preconditioner requiring a constant number of iterations independently of the size of the problem.

ULTRASPHERICAL STIELTJES POLYNOMIALS AND GAUSS–KRONROD QUADRATURE BEHAVE NICELY FOR $\lambda < 0$*

B. DE LA CALLE YSERN† AND F. PEHERSTORFER‡

Abstract. We show that the zeros of the Stieltjes polynomials associated with the ultraspherical weight function with parameter $\lambda < 0$ are real and simple and, except for two of them, belong to $(-1, 1)$. We also prove that they strictly interlace with the zeros of the corresponding ultraspherical polynomials. Consequently, a Gauss–Kronrod quadrature formula with two nodes outside the interval $[-1, 1]$ is obtained. We prove that the coefficients of such quadrature rules are positive. Finally, an asymptotic representation of Stieltjes polynomials which converges uniformly on the whole interval $[-1, 1]$ is provided.

Key words. Gauss–Kronrod quadrature, Stieltjes polynomials, ultraspherical polynomials, asymptotics

1. Introduction.

Let $p_n^\lambda(x) = \kappa_{\lambda,n} x^n + \ldots$, $\kappa_{\lambda,n} > 0$, be the orthonormal polynomial of degree n with respect to the ultraspherical weight function $w_\lambda(x) = (1-x^2)^{\lambda-1/2}$, $\lambda > -1/2$, i.e.,

$$\int_{-1}^{1} p_n^\lambda(x)\, p_m^\lambda(x)\, w_\lambda(x)\, dx = \delta_{n,m}, \tag{1.1}$$

where $\delta_{n,m}$ is the Kronecker symbol. Furthermore, let

$$q_n^\lambda(z) := \int_{-1}^{1} \frac{p_n^\lambda(x)}{z-x}\, w_\lambda(x)\, dx, \quad z \notin [-1, 1],$$

be the corresponding nth function of the second kind. Note that, by (1.1),

$$q_n^\lambda(z) = \mathcal{O}(1/z^{n+1}), \quad z \to \infty.$$

In 1894, in one of his letters to Hermite, Stieltjes [11] considered the polynomials $E_{n+1}^\lambda(z) = z^{n+1} + \ldots$, now called Stieltjes polynomials, which arise in the series expansion of $1/q_n^\lambda(z)$ at $z = \infty$, that is,

$$1/q_n^\lambda(z) = \kappa_{\lambda,n}\, E_{n+1}^\lambda(z) + \mathcal{O}(1/z), \quad z \to \infty, \tag{1.2}$$

and proved that these polynomials satisfy orthogonality conditions with respect to a sign-changing function, to be exact,

$$\int_{-1}^{1} x^j\, E_{n+1}^\lambda(x)\, p_n^\lambda(x)\, w_\lambda(x)\, dx = 0, \quad j = 0, \ldots, n. \tag{1.3}$$

In fact, Stieltjes considered only the Legendre weight $w_{1/2}(x) \equiv 1$ and conjectured that all the zeros of $E_{n+1}^{1/2}$ belong to the interval $(-1,1)$ and strictly interlace with the zeros of the Legendre polynomials $p_n^{1/2}$. Hermite [11] declared himself truly enchanted with the new polynomials, but no further progress seems to have been made either by him or Stieltjes.

Forty years later, Szegő [24] proved the conjecture of Stieltjes. Indeed, he proved that for $0 < \lambda \leq 2$ the Stieltjes polynomial E_{n+1}^{λ} has $n+1$ simple zeros in $(-1,1)$ and that the zeros of E_{n+1}^{λ} strictly interlace with the zeros of p_n^{λ}. The case $\lambda > 2$ has been recently studied by Petras and the second author in a series of papers [21, 22]. For $2 < \lambda < 3$ they show that on compact subsets $[-1+\epsilon, 1-\epsilon]$, $\epsilon > 0$ arbitrary but fixed, and for $n \geq n_0(\epsilon)$, the strictly interlacing property of the zeros of E_{n+1}^{λ} and p_n^{λ} still holds, whereas for $\lambda > 3$ they prove that the polynomials E_{n+1}^{λ} have only $o(n)$ real zeros. The case $-1/2 < \lambda < 0$ has remained open up to now.

An asymptotic representation of the Stieltjes polynomials for $\lambda \in (0,2)$ has been obtained by Ehrich [2, 3]. For $\lambda > 2$ asymptotic formulae are given in [21, 22].

The importance of the zeros of the Stieltjes polynomials in numerical integration arose in the sixties when Kronrod [14] suggested the so-called extended Gaussian quadrature formulae. In such quadrature rules, one looks for formulae of the form

$$\int_{-1}^{1} f(x)\, w_{\lambda}(x)\, dx = \sum_{i=1}^{n} A_{n,i}^{\lambda}\, f(x_{n,i}) + \sum_{j=1}^{n+1} B_{n,j}^{\lambda}\, f(y_{n,j}) + R_{2n+1}^{\lambda}(f), \tag{1.4}$$

where nodes $\{x_{n,i}\}_{i=1}^{n}$ are the zeros of p_n^{λ}, i.e., the Gaussian nodes, and the rest of nodes $\{y_{n,j}\}_{j=1}^{n+1}$ and all the quadrature weights $\{A_{n,i}\}_{i=1}^{n}, \{B_{n,j}\}_{j=1}^{n+1}$ are chosen so that

$$R_{2n+1}^{\lambda}(p) = 0 \quad \text{for all} \quad p \in \mathbb{P}_{3n+1} \tag{1.5}$$

(as usual $\mathbb{P}_m$ denotes the set of polynomials of degree less than or equal to m), where the degree of polynomial exactness is $3n+1$ when n is an even number and $3n+2$ if n is odd. Now, it is not difficult to show that condition (1.5) is equivalent to the fact that the nodal polynomial

$$\prod_{j=1}^{n+1} (x - y_{n,j})$$

satisfies the orthogonality relations (1.3) in the same way as E_{n+1}^{λ}. Hence, the nodes $\{y_{n,j}\}_{j=1}^{n+1}$ turn out to be the zeros of the Sieltjes polynomial E_{n+1}^{λ}.

This was the starting point for the renewed interest in Stieltjes polynomials, since the Gauss–Kronrod quadrature has been frequently used in automatic integration processes [7, 23]. For numerical stability reasons, positivity of the quadrature weights is an important and often required property. It may be easily proved that the positivity of the coefficients $\{B_{n,j}^{\lambda}\}_{j=1}^{n+1}$ is equivalent to the strict interlacing property of the zeros of E_{n+1}^{λ} and p_n^{λ}. Using this fact, and with the help of Szegő's results [24], Monegato [16] has proved the positivity of all of the quadrature weights appearing in (1.4) for $0 \leq \lambda \leq 1$. Recall that for $\lambda > 3$ the Gauss–Kronrod quadrature is not possible for sufficiently large n because only $o(n)$ nodes are real.

Surprisingly, except for the numerical work [9] of Gautschi and Notaris from which nice behavior of the zeros of E_{n+1}^{λ} is conjectured, nothing was known until now about the reality of the Kronrod nodes for $-1/2 < \lambda < 0$. In this paper we give a complete

description of the behavior of the nodes and the sign of the quadrature weights of the Gauss–Kronrod rule *for each* $n \in \mathbb{N}$. To be more precise, we show that E_{n+1}^{λ} has exactly two real zeros outside $[-1,1]$ and that, except for that feature, it has all the properties satisfied by the Stieltjes polynomial in the classical case $\lambda \in (0,1)$; that is, the zeros of E_{n+1}^{λ} strictly interlace with the zeros of p_n^{λ} and the quadrature weights are all positive. Furthermore, we provide an asymptotic representation of the Stieltjes polynomials that converges uniformly on the *whole* interval $[-1,1]$.

Finally, we mention that, in recent years, other wide classes of weight functions have been found for which Gauss–Kronrod quadrature with positive quadrature weights is possible for $n \geq n_0$, namely, weight functions of the form $\sqrt{1-x^2}\, v(x)$, where $v \in C^2[-1,1]$ and $v > 0$ on $[-1,1]$ (see [19, 20]). For Jacobi weights with parameters $0 \leq \alpha, \beta < 5/2$ asymptotic representations on $[-1+\epsilon, 1-\epsilon]$, $\epsilon > 0$, for the corresponding Stieltjes polynomials and quadrature weights have been given in [22]. For a more detailed discussion of weight functions admitting the Gauss–Kronrod quadrature rule as well as further references, see the surveys [17, 8, 18, 20, 5].

In the case of real measures $d\mu(x) = k(x)\, dx$, where $k \in L^1[-1,1]$, there exist results [4] concerning product integration based on the Gauss–Kronrod nodes which show that, from the practical point of view, Gauss–Kronrod nodes are as good as the Clenshaw–Curtis ones for constructing interpolatory (degree of polynomial exactness equal to $2n$) quadrature rules. For applications of the Stieltjes polynomials in interpolation theory, see, e.g., [6, 12].

2. Statement of the main results. Let T_n and U_n be the Chebyshev polynomials of degree n of the first and second kind, respectively.

THEOREM 2.1. *For $\lambda \in (-1/2, 0)$ and $n \in \mathbb{N}$, the zeros of $E_{n+1}^{\lambda}(x)$ are real and simple and, except for two of them, belong to the interval $(-1,1)$. Moreover, they strictly interlace with the zeros of the polynomial $(1-x^2)\, U_{n-2}(x)$ and also with the zeros of the orthonormal polynomial $p_n^{\lambda}(x)$.*

From results contained in [1] it follows that the two zeros outside $[-1,1]$ approach the ends of the interval as n tends to ∞. In this respect, it may be pertinent to recall that for $\lambda = 0$ the smallest zero and the largest zero of the Stieltjes polynomials coincide with the boundary points -1 and $+1$, respectively, and move inside the interval $(-1,1)$ as λ gets larger with n fixed.

As a consequence of the last assertion in Theorem 2.1, we can prove the following corollary.

COROLLARY 2.2. *For $\lambda \in (-1/2, 0)$ and $n \in \mathbb{N}$, the quadrature weights of* (1.4) *are all strictly positive.*

Regarding asymptotics of Stieltjes polynomials, we have the following theorem.

THEOREM 2.3. *For $\lambda \in (-1/2, 0)$ and $\theta \in [0, \pi]$, it holds that*

$$2^n E_{n+1}^{\lambda}(\cos\theta) = (2\sin\theta)^{1-\lambda}\, \cos\{(n+1)\theta + (\lambda-1)(\theta - \pi/2)\} + o(1), \tag{2.1}$$

uniformly on $[0,\pi]$.

For $\lambda \in [0,3)$ and $\theta \in [\epsilon, \pi - \epsilon]$, with $\epsilon > 0$ arbitrary but fixed, relation (2.1) has been proved in [2, 3, 22].

Remark 1. Taking a closer look at the right-hand side of (2.1), we obtain, for $\lambda \in (-1/2, 0)$ and $x \in [-1,1]$, the following asymptotic representation of Stieltjes polynomials in terms of Chebyshev polynomials:

$$2^n E_{n+1}^{\lambda}(x) = \sum_{k=0}^{[(n+1)/2]\dagger} \frac{\Gamma(k+\lambda-1)}{\Gamma(\lambda-1)\,\Gamma(k+1)}\, T_{n+1-2k}(x) + o(1), \tag{2.2}$$

uniformly on $[-1,1]$, where the symbol † indicates that the last term should be halved if n is odd. We note that (2.2) holds true for $\lambda \in [0,2)$ and $x \in [-1+\epsilon, 1-\epsilon]$, $\epsilon > 0$, taking into consideration what was mentioned immediately after Theorem 2.3. For more details, see section 4.4.

Remark 2. It is worth pointing out that, as a byproduct of the proof of Theorem 2.3 (cf. equalities (4.10) and (4.12) below), an asymptotic formula is obtained deserving of attention on its own. Namely, for $\lambda \in (-1/2, 0)$,

$$2^n E_{n+1}^{\lambda}(\cos\theta) = (2\sin\theta)^{1-\lambda}\,\cos\{(n+1)\theta + (\lambda-1)(\theta-\pi/2)\} + \mathcal{O}(1/n), \tag{2.3}$$

uniformly on $[\epsilon, \pi-\epsilon]$, with $\epsilon > 0$ arbitrary but fixed. It would be interesting to know whether the rate of convergence in (2.3) may be extended uniformly to the whole interval $[0,\pi]$. Numerical experiments support the possibility of such a result being true.

3. Preliminary results. Let $\lambda \neq 0$. In what follows, G_n^{λ} will denote the ultraspherical polynomial of degree n associated with w_λ (cf. [25, Chapter IV] for details of definitions and properties below) normalized so that

$$G_n^{\lambda}(1) = \frac{\Gamma(n+2\lambda)}{\Gamma(n+1)\Gamma(2\lambda)}.$$

A straightforward calculation shows that the leading coefficient of G_n^{λ}, which will be denoted by $d_{\lambda,n}$, is given by

$$d_{\lambda,n} = \frac{2^n\,\Gamma(n+\lambda)}{\Gamma(n+1)\,\Gamma(\lambda)}, \tag{3.1}$$

whereas $\kappa_{\lambda,n}$, the leading coefficient of the orthonormal polynomial p_n^{λ}, turns out to be

$$\kappa_{\lambda,n} = \frac{2^{n+\lambda}}{\sqrt{2\pi}}\,\Gamma(n+\lambda)\,\sqrt{\frac{n+\lambda}{\Gamma(n+1)\Gamma(n+2\lambda)}}. \tag{3.2}$$

Denote by Q_n^{λ} the ultraspherical function of the second kind normalized so that

$$Q_n^{\lambda}(z) = \frac{1}{2}\,\frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\int_{-1}^{1}\frac{G_n^{\lambda}(t)}{z-t}\,(1-t^2)^{\lambda-1/2}dt, \quad z \notin [-1,1].$$

It is known (see [25, Theorem 4.62.1]) that if $\lambda < 1/2$, then

$$\lim_{x\to 1^+} Q_n^{\lambda}(x)\,(x^2-1)^{1/2-\lambda} = K_{\lambda,n} > 0, \quad x \in \mathbb{R}. \tag{3.3}$$

The behavior of $Q_n^{\lambda}(x)$ at $x=-1$ is similar. As usual, Q_n^{λ} is defined on $[-1,1]$ as the Cauchy principal value, i.e.,

$$Q_n^{\lambda}(x) = \frac{(Q_n^{\lambda})^+(x) + (Q_n^{\lambda})^-(x)}{2} = \lim_{\epsilon\to 0^+}\frac{Q_n^{\lambda}(x+i\epsilon) + Q_n^{\lambda}(x-i\epsilon)}{2}, \tag{3.4}$$

whenever the above limit exists. It is known that (3.4) defines an analytic function on $(-1,1)$. Sometimes, it will be more convenient to consider, instead of Q_n^{λ}, the function

$$\widetilde{Q}_n^{\lambda}(x) = (1-x^2)^{1/2-\lambda}\,Q_n^{\lambda}(x), \quad x \in (-1,1).$$

Additionally, for $\theta \in (0,\pi)$, it holds that

$$(Q_n^\lambda)^+(\cos\theta) - (Q_n^\lambda)^-(\cos\theta) = -\pi i\, \frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\; G_n^\lambda(\cos\theta)\,(\sin\theta)^{2\lambda-1},$$

so

$$(Q_n^\lambda)^-(\cos\theta) = Q_n^\lambda(\cos\theta) + \frac{i\pi}{2}\, \frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\; G_n^\lambda(\cos\theta)\,(\sin\theta)^{2\lambda-1} \tag{3.5}$$

for $\theta \in (0,\pi)$.

Set

$$C_{\lambda,n} = \sqrt{\pi}\, \frac{\Gamma(n+2\lambda)}{\Gamma(n+\lambda+1)}.$$

Following the ideas of Szegő [24], from the representation of Q_n^λ as a hypergeometric function it follows that

$$Q_n^\lambda((z+1/z)/2) = C_{\lambda,n}\, z^{n+1} \sum_{k=0}^{\infty} a_{n,k}\, z^{2k}, \quad |z|<1, \tag{3.6}$$

where the sequence $\{a_{n,k}\}_{k=0}^{\infty}$ is defined by the relations

$$a_{n,0} = 1, \quad a_{n,k} = \left(1-\frac{\lambda}{k}\right)\left(1-\frac{\lambda}{n+k+\lambda}\right) a_{n,k-1}, \quad k\in\mathbb{N}. \tag{3.7}$$

It is clear that $a_{n,k}$ also depends on λ; yet this notation will not be misleading. From (3.5) and (3.6), we obtain

$$\lim_{r\to 1^-} C_{\lambda,n} \sum_{k=0}^{\infty} a_{n,k}\,(re^{i\theta})^{n+1+2k} = Q_n^\lambda(\cos\theta) + \frac{i\pi}{2}\, \frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\; G_n^\lambda(\cos\theta)\,(\sin\theta)^{2\lambda-1}, \tag{3.8}$$

where $\theta \in (0,\pi)$.

It is very easy to prove, using (1.2), that

$$\frac{C_{\lambda,n}\, z^{n+1}}{Q_n^\lambda((z+1/z)/2)} = (2z)^{n+1}\, E_{n+1}^\lambda((z+1/z)/2) + \mathcal{O}(z^{n+2}), \quad z\to 0.$$

Now, if real numbers $b_{n,k}$, $k\in\mathbb{N}\cup\{0\}$, are defined by the recurrence formula

$$b_{n,0} = 1, \qquad \sum_{j=0}^{k} a_{n,k-j}\, b_{n,j} = 0, \quad k\in\mathbb{N}, \tag{3.9}$$

which is equivalent to

$$\left(\sum_{k=0}^{\infty} a_{n,k}\, z^{2k}\right)\left(\sum_{k=0}^{\infty} b_{n,k}\, z^{2k}\right) = 1, \quad |z|<1, \tag{3.10}$$

then we can write

$$\sum_{k=0}^{\infty} b_{n,k}\, z^{2k} = (2z)^{n+1}\, E_{n+1}^\lambda((z+1/z)/2) + \mathcal{O}(z^{n+2}), \quad z\to 0.$$

Hence it may be proved (taking into account the symmetry of $E_{n+1}^{\lambda}((z+1/z)/2)$) that the numbers $b_{n,k}$ are precisely the coefficients of the Chebyshev polynomial representation of E_{n+1}^{λ}. Specifically, we have

$$2^n\, E_{n+1}^{\lambda}(x) = \sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, T_{n+1-2k}(x), \tag{3.11}$$

where, as we mentioned before, the symbol † indicates that the last term should be halved if n is odd.

Finally, we will need some asymptotic formulae for the proof of Theorem 2.3. Namely (cf. [25, Theorem 8.21.8]),

$$\frac{n^{1-\lambda}\,\pi}{2}\,\frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\,G_n^{\lambda}(\cos\theta) = \sqrt{\pi}\,2^{\lambda-1}\,(\sin\theta)^{-\lambda}\,\cos[n\theta+\lambda(\theta-\pi/2)] + \mathcal{O}(1/n), \tag{3.12}$$

where the convergence is uniform on $[\epsilon, \pi-\epsilon]$, with $\epsilon > 0$ arbitrary but fixed.

Also (cf., for instance, [2]), it holds that

$$n^{1-\lambda}\,\widetilde{Q}_n^{\lambda}(\cos\theta) = \sqrt{\pi}\,2^{\lambda-1}(\sin\theta)^{-\lambda}\,\cos[(n+1)\theta+(\lambda-1)\,(\theta-\pi/2)] + \mathcal{O}(1/n), \tag{3.13}$$

again uniformly on $[\epsilon, \pi-\epsilon]$, with ϵ as above.

4. Proofs. In the case that $\lambda \in (0,1)$, by using a theorem on reciprocal power series by Kaluza [13], all the coefficients $b_{n,k}$, $k \geq 1$, are proved to be negative, which turns out to be a key fact in proving the properties satisfied by E_{n+1}^{λ} (cf. [24]). To the best of our knowledge, there exist no general results concerning coefficients of reciprocal power series which can be applied when $\lambda < 0$. The following lemma supplies us with a result analogous to the Kaluza theorem for the specific coefficients (3.7). Due to its rather technical character and the fact that the arguments employed in its proof are not related to the rest, we prefer to delay its proof until the end of the paper; see section 4.5. For the rest of the proofs we have partly followed some ideas from [2, 3, 24].

LEMMA 4.1. *For all $\lambda \in (-1/2, 0)$ and $n \in \mathbb{N}$, the coefficients $b_{n,k}$ defined by relations* (3.9) *and* (3.7) *satisfy*

$$b_{n,1} < 0 \;\; \textit{and, for } k \geq 2, \;\; b_{n,k} > 0.$$

For proving the theorems mentioned above, we will need further knowledge of properties fulfilled by the coefficients $\{b_{n,k}\}_{k\in\mathbb{N}}$, $n \in \mathbb{N}$, which are stated in the following two lemmas.

LEMMA 4.2. *For all $\lambda \in (-1/2, 0)$ and $n \in \mathbb{N}$, it holds that*

$$\sum_{k=0}^{\infty} b_{n,k} = 0 \quad \textit{and} \quad \sum_{k=0}^{\infty} |b_{n,k}| < K,$$

where $K < +\infty$ is an absolute constant.

Proof. Use (3.6) to obtain

$$\lim_{r\to 1^-} \sum_{k=0}^{\infty} a_{n,k}\, r^{2k} = \lim_{r\to 1^-} \frac{Q_n^{\lambda}((r+1/r)/2)}{C_{\lambda,n}\, r^{n+1}} = \frac{1}{C_{\lambda,n}} \lim_{x\to 1^+} Q_n^{\lambda}(x) = +\infty, \tag{4.1}$$

according to (3.3). As we saw in Lemma 4.1, the coefficients $b_{n,k}$ are all positive whenever $k \geq 2$. Therefore,

$$\lim_{r\to 1^-} \sum_{k=0}^{\infty} b_{n,k}\, r^{2k} = \sum_{k=0}^{\infty} b_{n,k},$$

which, together with (3.10) and (4.1), proves the first part of our assertion. Regarding the second one, we have

$$\sum_{k=0}^{\infty} |b_{n,k}| = -b_{n,1} + \sum_{\substack{k=0\\ k\neq 1}}^{\infty} b_{n,k} = -2\, b_{n,1} = 2\, a_{n,1},$$

and the result follows from the fact that (see (3.7)) $\lim_{n\to\infty} a_{n,1} = 1 - \lambda$. □

LEMMA 4.3. *For all $\lambda \in (-1/2, 0)$ and $n \in \mathbb{N}$, it holds that*

$$\sum_{k=m+1}^{\infty} b_{n,k} = \mathcal{O}(1/m), \quad m \to \infty,$$

uniformly on $n \in \mathbb{N}$; i.e., the constants involved in the term $\mathcal{O}(1/m)$ are independent of $n \in \mathbb{N}$.

Proof. For convenience, we will prove the equivalent expression

$$\sum_{k=2m+1}^{\infty} b_{n,k} = \mathcal{O}(1/m), \quad m \to \infty.$$

Let us consider the product

$$\left(-\sum_{k=0}^{2m} b_{n,k}\right)\left(\sum_{k=0}^{2m} a_{n,k}\right) = (-b_{n,1})\,(a_{n,0} + a_{n,2m}) + \sum_{k=1}^{2m-1} (-b_{n,1}\, a_{n,k}) + t_m,$$

where we have included all of the negative terms of the product in t_m. Each of the terms $(-b_{n,1}\, a_{n,k})$, $k = 1, \ldots, 2m-1$, is to be canceled out by part of the negative terms contained in t_m, according to (3.9). Notice that we use each negative term at most once and that we have enough negative terms in t_m since $k = 1, \ldots, 2m-1$. Then, on account of Lemma 4.2, we obtain

$$\sum_{k=2m+1}^{\infty} b_{n,k} = -\sum_{k=0}^{2m} b_{n,k} < a_{n,1}\, \frac{a_{n,0} + a_{n,2m}}{\displaystyle\sum_{k=0}^{2m} a_{n,k}} < \frac{a_{n,1}(2a_{n,2m})}{\displaystyle\sum_{k=m+1}^{2m} a_{n,k}} < K\, \frac{a_{n,2m}}{m\, a_{n,m}}, \tag{4.2}$$

since $a_{n,0} = 1$ and the sequence $\{a_{n,k}\}_{k\in\mathbb{N}}$ is increasing. Let us estimate $a_{n,2m}$ and $a_{n,m}$. For this, we will need the limit (cf., for instance, [10, formula 8.328.2])

$$\lim_{n\to\infty} \frac{\Gamma(n+a)}{\Gamma(n+b)\, n^{a-b}} = 1, \quad a, b \in \mathbb{R}. \tag{4.3}$$

From (3.7), it is clear that

$$a_{n,k} = \frac{\Gamma(k-\lambda+1)}{\Gamma(k+1)}\, \frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\Gamma(1-\lambda)}\, \frac{\Gamma(n+k+1)}{\Gamma(n+k+\lambda+1)}. \tag{4.4}$$

When applied to the numbers (4.4), the limit (4.3) gives

$$(1/2)\,k^{-\lambda} < \frac{\Gamma(k-\lambda+1)}{\Gamma(k+1)} < (3/2)\,k^{-\lambda},$$

$$(1/2)\,(n+k)^{-\lambda} < \frac{\Gamma(n+k+1)}{\Gamma(n+k+\lambda+1)} < (3/2)\,(n+k)^{-\lambda}$$

for all $n \in \mathbb{N}$ and $k \geq k_0$. Then

$$\frac{1}{4}\{k\,(n+k)\}^{-\lambda}\,\frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\,\Gamma(1-\lambda)} < a_{n,k} < \frac{9}{4}\{k\,(n+k)\}^{-\lambda}\,\frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\,\Gamma(1-\lambda)}$$

again for all $n \in \mathbb{N}$ and $k \geq k_0$. So, by virtue of (4.2), we have

$$\sum_{k=2m+1}^{\infty} b_{n,k} < \frac{2^{-\lambda}\,9\,K}{m}\,\left(\frac{n+2m}{n+m}\right)^{-\lambda} < \frac{4^{-\lambda}\,9\,K}{m}$$

for $m \geq k_0$ and any $n \in \mathbb{N}$, which concludes the proof. □

4.1. Proof of Theorem 2.1. As the Stieltjes polynomial E_{n+1}^{λ} is either an even or an odd function depending on n, it is enough to prove that it has one zero greater than 1 to see that it has two zeros outside $[-1,1]$. So

$$2^n\,E_{n+1}^{\lambda}(1) = \sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\,T_{n+1-2k}(1) = \sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k} < \sum_{k=0}^{\infty} b_{n,k} = 0,$$

due to Lemmas 4.1 and 4.2 and (3.11). It is obvious that the leading coefficient of E_{n+1}^{λ} is positive since it is monic. Consequently, E_{n+1}^{λ} must have a zero in $(1,+\infty)$.

Now suppose that $n \geq 2$. It is very well known that the Chebyshev polynomial T_{n-1} has n points in $[-1,1]$ at which it attains its maximum value with alternate sign. Let x_0 be one such point with $T_{n-1}(x_0) = 1$. Then, using the same arguments as in the previous reasoning, we have

$$2^n\,E_{n+1}^{\lambda}(x_0) = b_{n,1} + \sum_{\substack{k=0\\k\neq 1}}^{[(n+1)/2]\dagger} b_{n,k}\,T_{n+1-2k}(x_0) < \sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k} < \sum_{k=0}^{\infty} b_{n,k} = 0.$$

On the other hand, if $T_{n-1}(y_0) = -1$, then

$$2^n\,E_{n+1}^{\lambda}(y_0) = -b_{n,1} + \sum_{\substack{k=0\\k\neq 1}}^{[(n+1)/2]\dagger} b_{n,k}\,T_{n+1-2k}(y_0) > -\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k} > 0.$$

Therefore, E_{n+1}^{λ} has $n-1$ simple zeros inside $(-1,1)$ and two simple zeros outside $[-1,1]$. As $T'_{n-1}(x) = (n-1)\,U_{n-2}(x)$, the zeros of E_{n+1}^{λ} strictly interlace with the zeros of $(1-x^2)\,U_{n-2}(x)$.

Next, we will prove the interlacing property with respect to the zeros of the ultraspherical polynomials. Notice that, due to Lemma 4.2, it holds that

$$\lim_{r\to 1^-} \sum_{k=0}^{\infty} b_{n,k}\,(re^{i\theta})^{2k} = \sum_{k=0}^{\infty} b_{n,k}\,e^{2ki\theta}, \quad \theta \in [0,2\pi]. \tag{4.5}$$

Let $\theta \in (0,\pi)$ and consider

$$\frac{\displaystyle\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta}}{\displaystyle\sum_{k=0}^{\infty} b_{n,k}\, e^{2ki\theta}} = \left(1 + \frac{\displaystyle\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}\, e^{2ki\theta}}{\displaystyle\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta}} \right)^{-1},$$

where the symbol ‡ means that the first term should be halved if n is odd. Then

$$\left| \frac{\displaystyle\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}\, e^{2ki\theta}}{\displaystyle\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta}} \right| < \frac{\displaystyle\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}}{|b_{n,1}| - \left| \displaystyle\sum_{\substack{k=0 \\ k\neq 1}}^{[(n+1)/2]\dagger} b_{n,k} \right|} = \frac{\displaystyle\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}}{\displaystyle\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}} = 1,$$

because of Lemma 4.2. An easy calculation shows that $\Re\,(1/(1+z)) > 1/2$ for $|z| < 1$. Therefore,

$$\Re\left[\left(\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta} \right) \left(\sum_{k=0}^{\infty} b_{n,k}\, e^{2ki\theta} \right)^{-1} \right] > \frac{1}{2}. \tag{4.6}$$

Taking (3.10), (4.5), and (3.8) into account, we obtain

$$\frac{C_{\lambda,n} \displaystyle\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta}}{\displaystyle\sum_{k=0}^{\infty} b_{n,k}\, e^{2ki\theta}} = \left(\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta} \right) \left(\lim_{r\to 1^-} C_{\lambda,n} \sum_{k=0}^{\infty} a_{n,k}\, (re^{i\theta})^{2k} \right)$$

$$= \left(\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{-(n+1-2k)i\theta} \right) \left(\lim_{r\to 1^-} C_{\lambda,n} \sum_{k=0}^{\infty} a_{n,k}\, (re^{i\theta})^{n+1+2k} \right)$$

$$= \left(2^n\, E_{n+1}^{\lambda}(\cos\theta) - i\widetilde{E}_n(\theta) \right) \left(Q_n^{\lambda}(\cos\theta) + \frac{\pi i}{2}\, \frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\, (\sin\theta)^{2\lambda-1} \right),$$

where $\widetilde{E}_n(\theta)$ is the imaginary part of

$$\sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{(n+1-2k)i\theta}.$$

Thus, the real part of

$$\left(C_{\lambda,n} \sum_{k=0}^{[(n+1)/2]\dagger} b_{n,k}\, e^{2ki\theta} \right) \left(\sum_{k=0}^{\infty} b_{n,k}\, e^{2ki\theta} \right)^{-1}$$

is

$$2^n\,E_{n+1}^\lambda(\cos\theta)\,Q_n^\lambda(\cos\theta)+\frac{\pi}{2}\,\widetilde{E}_n(\theta)\frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\;G_n^\lambda(\cos\theta)\,(\sin\theta)^{2\lambda-1},$$

which, together with (4.6), proves that

$$2^n\,E_{n+1}^\lambda(\cos\theta)\,Q_n^\lambda(\cos\theta)+\frac{\pi}{2}\,\widetilde{E}_n(\theta)\frac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\;G_n^\lambda(\cos\theta)\,(\sin\theta)^{2\lambda-1}>\frac{C_{\lambda,n}}{2}$$

for $\theta\in(0,\pi)$. In particular,

$$2^n\,E_{n+1}^\lambda(x_{n,i}^\lambda)\,Q_n^\lambda(x_{n,i}^\lambda)>\frac{C_{\lambda,n}}{2}>0,\quad i=1,\dots,n, \tag{4.7}$$

where the numbers $x_{n,i}^\lambda$, $i=1,\dots,n$, are the zeros of the ultraspherical polynomial G_n^λ. It is well known that the zeros of Q_n^λ and G_n^λ interlace since the functions $\widetilde{Q}_n^\lambda(x)=(1-x^2)^{1/2-\lambda}\,Q_n^\lambda(x)$ and $G_n^\lambda(x)$ satisfy the same differential equation (see [25, p. 78]). Thus, it follows from (4.7) that the zeros of E_{n+1}^λ and G_n^λ behave similarly.

4.2. Proof of Corollary 2.2. As we mentioned above, the interlacing property stated in Theorem 2.1 implies that the coefficients $B_{n,j}^\lambda$, $j=1,\dots,n+1$, are all positive. Regarding the coefficients $A_{n,i}^\lambda$, we have the representation (see [15, Theorem 2])

$$A_{n,i}^\lambda=\sigma_{n,i}^\lambda+\frac{d_{\lambda,n}}{\kappa_{\lambda,n}^2\,(G_n^\lambda)'(x_{n,i}^\lambda)\,E_{n+1}^\lambda(x_{n,i}^\lambda)},\quad i=1,\dots,n, \tag{4.8}$$

where $\sigma_{n,i}^\lambda$, $i=1,\dots,n$, are the Christoffel numbers corresponding to the weight function w_λ (recall that $d_{\lambda,n}<0$ is the leading coefficient of G_n^λ). Obviously

$$\sigma_{n,i}^\lambda=\frac{2\,\Gamma(\lambda+1/2)}{-\Gamma(2\lambda)}\left|\frac{Q_n^\lambda(x_{n,i}^\lambda)}{(G_n^\lambda)'(x_{n,i}^\lambda)}\right|,\quad i=1,\dots,n. \tag{4.9}$$

As the zeros of E_{n+1}^λ and G_n^λ interlace, it is clear that

$$(G_n^\lambda)'(x_{n,i}^\lambda)\,E_{n+1}^\lambda(x_{n,i}^\lambda)=|(G_n^\lambda)'(x_{n,i}^\lambda)\,E_{n+1}^\lambda(x_{n,i}^\lambda)|,\quad i=1,\dots,n.$$

On account of this equality and (4.7), (4.8), and (4.9) as well as the explicit formulae (3.1) and (3.2), we obtain

$$\begin{aligned}A_{n,i}^\lambda &> \left|\frac{Q_n^\lambda(x_{n,i}^\lambda)}{(G_n^\lambda)'(x_{n,i}^\lambda)}\right|\left(-\frac{2\,\Gamma(\lambda+1/2)}{\Gamma(2\lambda)}+\frac{2^{n+1}\,d_{\lambda,n}}{C_{\lambda,n}\,\kappa_{\lambda,n}^2}\right)\\ &= \left|\frac{Q_n^\lambda(x_{n,i}^\lambda)}{(G_n^\lambda)'(x_{n,i}^\lambda)}\right|\frac{2}{\Gamma(\lambda)}\left(-\frac{\Gamma(\lambda)\,\Gamma(\lambda+1/2)}{\Gamma(2\lambda)}+\frac{2\sqrt{\pi}}{4^\lambda}\right)=0,\end{aligned}$$

where we have used (cf. [25, formula (1.7.6)]) the functional equation

$$\Gamma(z)\,\Gamma(z+1/2)=\sqrt{\pi}\,2^{1-2z}\,\Gamma(2z),\quad z\neq 0,-1/2,-1,-3/2,-2,\dots,$$

in the last equality.

4.3. Proof of Theorem 2.3. For $\theta \in [0,\pi]$, we have

$$\begin{aligned} 2^n\, E_{n+1}^{\lambda}(\cos\theta) &= \Re\left(\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right) \\ &- \Re\left(\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right) \end{aligned}$$

because of (3.11). If $n \geq 2$, it is clear that

$$\left|\Re\left(\sum_{k=[n/2+1]\ddagger}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right)\right| \leq \sum_{k=[n/2+1]}^{\infty} b_{n,k} = \mathcal{O}(1/n)$$

due to Lemma 4.3. Thus, we have proved

$$2^n\, E_{n+1}^{\lambda}(\cos\theta) = \Re\left(\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right) + \mathcal{O}(1/n), \tag{4.10}$$

uniformly on $[0,\pi]$.

Additionally, if $\theta \in (0,\pi)$, reasoning as in the proof of Theorem 2.1, we have

$$\begin{aligned} \sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta} &= \left(\lim_{r\to 1^-} \sum_{k=0}^{\infty} a_{n,k}\,(re^{i\theta})^{n+1+2k}\right)^{-1} \\ &= \frac{C_{\lambda,n}}{Q_n^{\lambda}(\cos\theta) - \dfrac{\pi i}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\,(\sin\theta)^{2\lambda-1}} \\ &= \frac{C_{\lambda,n}\,(\sin\theta)^{1-2\lambda}}{\widetilde{Q}_n^{\lambda}(\cos\theta) - \dfrac{\pi i}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)} \\ &= (\sin\theta)^{1-2\lambda}\,\frac{C_{\lambda,n}\left(\widetilde{Q}_n^{\lambda}(\cos\theta) + \dfrac{\pi i}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\right)}{\left[\widetilde{Q}_n^{\lambda}(\cos\theta)\right]^2 + \left[\dfrac{\pi}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\right]^2}. \end{aligned}$$

Therefore, we obtain

$$\Re\left(\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right) = \frac{C_{\lambda,n}\,(\sin\theta)^{1-2\lambda}\,\widetilde{Q}_n^{\lambda}(\cos\theta)}{\left[\widetilde{Q}_n^{\lambda}(\cos\theta)\right]^2 + \left[\dfrac{\pi}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\right]^2} \tag{4.11}$$

for $\theta \in (0,\pi)$. Notice that the denominator in (4.11) cannot vanish since the zeros of $\widetilde{Q}_n^{\lambda}$ and G_n^{λ} interlace, as previously mentioned.

Fix $\epsilon > 0$. From (3.12) and (3.13), it readily follows that

$$\frac{1}{n^{2-2\lambda}}\,\frac{(\sin\theta)^{-2\lambda}}{\left[\widetilde{Q}_n^{\lambda}(\cos\theta)\right]^2 + \left[\dfrac{\pi}{2}\,\dfrac{\Gamma(2\lambda)}{\Gamma(\lambda+1/2)}\, G_n^{\lambda}(\cos\theta)\right]^2} = \frac{4^{1-\lambda}}{\pi} + \mathcal{O}(1/n),$$

uniformly on $[\epsilon, \pi - \epsilon]$. Additionally, $\lim_{n\to\infty} n^{1-\lambda} C_{\lambda,n} = \sqrt{\pi}$ is obtained with the help of (4.3). So, using (3.13) again and (4.11), we have

(4.12)
$$\Re\left(\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right) = (2\sin\theta)^{1-\lambda}\, \cos\{(n+1)\theta + (\lambda-1)(\theta-\pi/2)\} + \mathcal{O}(1/n),$$

uniformly on $[\epsilon, \pi - \epsilon]$.

For all $n \in \mathbb{N}$, let $f_n(\theta)$, $\theta \in [0, \pi]$, denote the continuous function

$$\Re\left(\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right),$$

whereas $g_n(\theta)$ stands for $(2\sin\theta)^{1-\lambda}\, \cos\{(n+1)\theta + (\lambda-1)(\theta-\pi/2)\}$, $\theta \in [0, \pi]$. We will reason by contradiction. Suppose that the sequence $\{f_n - g_n\}_{n\in\mathbb{N}}$ does not converge uniformly to 0 on $[0, \pi]$. So, there exist a sequence of points $\theta_n, n \in \Lambda \subset \mathbb{N}$, and a number $\epsilon_0 > 0$ such that

$$|f_n(\theta_n) - g_n(\theta_n)| \geq \epsilon_0 \tag{4.13}$$

for all $n \in \Lambda$. As the sequence $\{\theta_n\}_{n\in\Lambda}$ is included in $[0, \pi]$, we can assume that it is a convergent sequence. Moreover, as a result of (4.12), the limit point must be one of the two ends of the interval $[0, \pi]$. So, without loss of generality, we can also assume that

$$\lim_{n\in\Lambda} \theta_n = 0. \tag{4.14}$$

We will prove that given any $\epsilon > 0$ there exists $\delta > 0$ (depending only on ϵ) such that

$$|f_n(\theta) - g_n(\theta)| < \epsilon$$

for all $\theta \in [0, \delta)$ and any $n \in \mathbb{N}$. It is clear that this assertion contradicts (4.13) and (4.14).

Choose $\delta_1 > 0$ such that for all $\theta \in [0, \delta_1)$ it holds that

$$|g_n(\theta)| \leq |2\sin\theta|^{1-\lambda} < \epsilon/4, \quad n \in \mathbb{N}. \tag{4.15}$$

By the use of Lemma 4.3, fix $m \in \mathbb{N}$ such that

$$\sum_{k=m+1}^{\infty} b_{n,k} < \frac{\epsilon}{4}, \quad n \in \mathbb{N}. \tag{4.16}$$

Hence

$$-\frac{\epsilon}{4} < \sum_{k=0}^{m} b_{n,k} < 0, \quad n \in \mathbb{N}. \tag{4.17}$$

Next, choose $\delta_2 > 0$ such that for all $\theta \in [0, \delta_2)$ we have

$$|\sin(2k\theta)| < \epsilon/(8K), \quad k = 1, \ldots, m, \tag{4.18}$$

and

$$\cos(2k\theta) > 1 - \epsilon/(8K), \quad k = 1, \dots, m, \tag{4.19}$$

where K is the constant given by Lemma 4.2. Take $\delta = \min\{\delta_1, \delta_2\}$. Let $\theta \in [0, \delta)$. Then

$$\sum_{k=0}^{m} b_{n,k} \cos(2k\theta) < b_{n,1} \left(1 - \frac{\epsilon}{8K}\right) + \sum_{\substack{k=0 \\ k\neq 1}}^{m} b_{n,k} = \sum_{k=0}^{m} b_{n,k} - \frac{b_{n,1}\,\epsilon}{8K} < \frac{\epsilon}{16}, \tag{4.20}$$

where we have used (4.19) and (4.17) as well as the fact that $-b_{n,1} \leq K/2$ for all $n \in \mathbb{N}$. Analogously,

$$\sum_{k=0}^{m} b_{n,k} \cos(2k\theta) > b_{n,1} + \sum_{\substack{k=0 \\ k\neq 1}}^{m} b_{n,k} \left(1 - \frac{\epsilon}{8K}\right) = \sum_{k=0}^{m} b_{n,k} - \sum_{\substack{k=0 \\ k\neq 1}}^{m} b_{n,k} \frac{\epsilon}{8K} > -\frac{\epsilon}{4} - \frac{\epsilon}{16}. \tag{4.21}$$

Finally, for $\theta \in [0, \delta)$ and arbitrary $n \in \mathbb{N}$, we obtain

$$|f_n(\theta) - g_n(\theta)| \leq |f_n(\theta)| + |g_n(\theta)| < \left|\sum_{k=0}^{\infty} b_{n,k}\, e^{(n+1-2k)i\theta}\right| + \frac{\epsilon}{4}$$

$$\leq \left|\sum_{k=0}^{m} b_{n,k} \cos(2k\theta)\right| + \left|\sum_{k=0}^{m} b_{n,k} \sin(2k\theta)\right| + \sum_{k=m+1}^{\infty} b_{n,k} + \frac{\epsilon}{4} < \epsilon,$$

using (4.15) in the second step and (4.16), (4.18), (4.20), and (4.21) in the last one.

Once the contradiction has been established, we obtain $f_n(\theta) = g_n(\theta) + o(1)$, uniformly on $[0, \pi]$, which, together with (4.10), proves the theorem.

4.4. Proof of formula (2.2). It is well known that

$$\sum_{k=0}^{\infty} \frac{\Gamma(k+\lambda-1)}{\Gamma(k+1)\,\Gamma(\lambda-1)}\, z^k = (1-z)^{1-\lambda},$$

uniformly on $|z| \leq 1$ provided that $\lambda \leq 1$. Thus, if we put $z = e^{-2i\theta}$, we have

$$\sum_{k=0}^{[(n+1)/2]\dagger} \frac{\Gamma(k+\lambda-1)}{\Gamma(k+1)\,\Gamma(\lambda-1)}\, e^{i\theta(n+1-2k)} = \frac{e^{i\theta(n+1)}}{(1-e^{-2i\theta})^{\lambda-1}} + o(1),$$

uniformly on $[0, \pi]$. Now, the proof follows from taking real parts in the above expression and applying Theorem 2.3.

For $\lambda \in (1, 2)$ the proof is similar. In that case, by using Dirichlet's criterion on uniform convergence, we have

$$\sum_{k=0}^{\infty} \frac{\Gamma(k+\lambda-1)}{\Gamma(k+1)\,\Gamma(\lambda-1)}\, e^{-2ik\theta} = (1-e^{-2i\theta})^{1-\lambda},$$

uniformly on $[\epsilon, \pi - \epsilon]$. The rest is analogous.

4.5. Proof of Lemma 4.1. Obviously, $b_{n,0} = 1 > 0$ and $b_{n,1} = -a_{n,1} < -1$. Besides,

$$b_{n,2} = a_{n,1}^2 - a_{n,2} = a_{n,1}(a_{n,1}/a_{n,0} - a_{n,2}/a_{n,1}) > 0,$$

since the sequence $\{a_{n,k}/a_{n,k-1}\}_{k\in\mathbb{N}}$ is decreasing. Now, the idea is to obtain a formula similar to (3.9) without the term corresponding to $j = 1$ (which is negative) in order to carry out a proof by induction on the index $k \geq 2$. Thus, if we rewrite (3.9) using (4.4), we have

$$\sum_{\substack{j=0\\ j\neq 1}}^{k} b_{n,j}\, a_{n,k-j} + b_{n,1}\, \frac{\Gamma(k-\lambda)}{\Gamma(k)}\, \frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\Gamma(1-\lambda)}\, \frac{\Gamma(n+k)}{\Gamma(n+k+\lambda)} = 0. \tag{4.22}$$

Analogously, by replacing k with $k-1$, we obtain

$$\sum_{\substack{j=0\\ j\neq 1}}^{k-1} b_{n,j}\, a_{n,k-j-1} + b_{n,1}\, \frac{\Gamma(k-\lambda-1)}{\Gamma(k-1)}\, \frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\Gamma(1-\lambda)}\, \frac{\Gamma(n+k-1)}{\Gamma(n+k+\lambda-1)} = 0,$$

or, equivalently,

$$\begin{aligned}\sum_{\substack{j=0\\ j\neq 1}}^{k-1} b_{n,j}\, a_{n,k-j-1}\, \frac{(k-\lambda-1)(n+k-1)}{(k-1)(n+k+\lambda-1)} + b_{n,1} \left\{ \frac{\Gamma(k-\lambda-1)}{\Gamma(k-1)} \right.\\ \left. \times\, \frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\Gamma(1-\lambda)}\, \frac{\Gamma(n+k-1)}{\Gamma(n+k+\lambda-1)}\, \frac{(k-\lambda-1)(n+k-1)}{(k-1)(n+k+\lambda-1)} \right\} = 0.\end{aligned} \tag{4.23}$$

Subtracting (4.23) from (4.22), it follows that

$$\begin{aligned} b_{n,k} + \frac{\Gamma(n+\lambda+1)}{\Gamma(n+1)\Gamma(1-\lambda)} \sum_{\substack{j=0\\ j\neq 1}}^{k-1} \left[b_{n,j}\, \frac{\Gamma(k-j-\lambda)}{\Gamma(k-j)}\, \frac{\Gamma(n+k-j)}{\Gamma(n+k-j+\lambda)} \right.\\ \left. \times \left\{ \frac{(k-j-\lambda)(n+k-j)}{(k-j)(n+k-j+\lambda)} - \frac{(k-\lambda-1)(n+k-1)}{(k-1)(n+k+\lambda-1)} \right\} \right] = 0. \end{aligned}$$

The above expression may be written as

$$\begin{aligned} &\frac{\Gamma(-\lambda)(k-1)(n+k+\lambda-1)\Gamma(n+1)}{\Gamma(n+\lambda+1)}\, b_{n,k}\\ &+ \sum_{j=0}^{k-1} b_{n,j}\, (j-1)\, \frac{\Gamma(k-j-\lambda)}{\Gamma(k-j+1)}\, \frac{\Gamma(n+k-j)}{\Gamma(n+k-j+\lambda+1)}\, P_{n,\lambda}(k,j) = 0, \end{aligned}$$

where $P_{n,\lambda}(k,j) = n(n+k+\lambda-1) + (k-j)(n+2k-2)$. Therefore,

$$\sum_{j=0}^{k} b_{n,j}\, (j-1)\, \frac{\Gamma(k-j-\lambda)}{\Gamma(k-j+1)}\, \frac{\Gamma(n+k-j)}{\Gamma(n+k-j+\lambda+1)}\, P_{n,\lambda}(k,j) = 0. \tag{4.24}$$

As the term corresponding to $j = 0$ in (4.24) is now the only one which is negative, we then repeat the above argument in order to delete it. Replacing k with $k-1$ in (4.24), we obtain

$$\sum_{j=0}^{k-1} b_{n,j}\,(j-1)\,\frac{\Gamma(k-j-\lambda-1)}{\Gamma(k-j)}\,\frac{\Gamma(n+k-j-1)}{\Gamma(n+k-j+\lambda)}\,P_{n,\lambda}(k-1,j)=0.$$

Then

$$\begin{aligned}\sum_{j=0}^{k-1}\Bigg\{ & b_{n,j}\,(j-1)\,\frac{\Gamma(k-j-\lambda-1)}{\Gamma(k-j)}\,\frac{\Gamma(n+k-j-1)}{\Gamma(n+k-j+\lambda)}\\ & \times\frac{(k-\lambda-1)(n+k-1)}{k\,(n+k+\lambda)}\,P_{n,\lambda}(k-1,j)\,\frac{P_{n,\lambda}(k,0)}{P_{n,\lambda}(k-1,0)}\Bigg\}=0.\end{aligned}\tag{4.25}$$

Subtracting (4.25) from (4.24) gives

$$\begin{aligned}\frac{\Gamma(-\lambda)(k-1)(n+k+\lambda-1)\Gamma(n+1)}{\Gamma(n+\lambda+1)}\,b_{n,k} &= \sum_{j=2}^{k-1}\Bigg[\,b_{n,j}\,(j-1)\,\frac{\Gamma(k-j-\lambda-1)}{\Gamma(k-j)}\\ &\times\frac{\Gamma(n+k-j-1)}{\Gamma(n+k-j+\lambda)}\Bigg\{\frac{(k-\lambda-1)(n+k-1)}{k\,(n+k+\lambda)}\,\frac{P_{n,\lambda}(k-1,j)\,P_{n,\lambda}(k,0)}{P_{n,\lambda}(k-1,0)}\\ &-\frac{(k-j-\lambda-1)(n+k-j-1)}{(k-j)(n+k-j+\lambda)}P_{n,\lambda}(k,j)\Bigg\}\Bigg],\end{aligned}$$

which may be written as

$$\begin{aligned}&\frac{\Gamma(-\lambda)\,k\,(k-1)(n+k+\lambda)(n+k+\lambda-1)\Gamma(n+1)P_{n,\lambda}(k-1,0)}{\Gamma(n+\lambda+1)}\;b_{n,k}\\ &=\sum_{j=2}^{k-1}b_{n,j}\,(j-1)\,\frac{\Gamma(k-j-\lambda-1)}{\Gamma(k-j+1)}\,\frac{\Gamma(n+k-j-1)}{\Gamma(n+k-j+\lambda+1)}\,H_{n,\lambda}(k,j),\end{aligned}\tag{4.26}$$

where

$$\begin{aligned}H_{n,\lambda}(k,j) &= (k-j)(n+k-j+\lambda)(k-\lambda-1)(n+k-1)P_{n,\lambda}(k,0)P_{n,\lambda}(k-1,j)\\ &\quad -k\,(n+k+\lambda)(k-j-\lambda-1)(n+k-j-1)P_{n,\lambda}(k,j)P_{n,\lambda}(k-1,0).\end{aligned}$$

Therefore, a proof by induction may be carried out by the use of (4.26), provided that $H_{n,\lambda}(k,j) > 0$ for all $\lambda \in (-1/2, 0)$, $n \in \mathbb{N}$, and $k \geq 3$. The expression $H_{n,\lambda}(k,j)$ is a polynomial of degree 8 in the variables k, j, n, and λ which, apparently, cannot be factorized except for a factor j. It has 163 terms, about half of which are negative, and, additionally, it takes values arbitrarily close to zero. Despite these features, it is possible to show that $H_{n,\lambda}(k,j) > 0$ performing the following change of variables:

$$\left.\begin{array}{lcl} 1+2\lambda & = & \mu \\ n-1 & = & N \\ j-2 & = & i \\ k-j-1 & = & m \end{array}\right\} \quad\Leftrightarrow\quad \left\{\begin{array}{lcl} \lambda & = & (\mu-1)/2 \\ n & = & N+1 \\ j & = & i+2 \\ k & = & m+i+3 \end{array}\right.$$

$$(i+2)(144\,m^2N^4\mu+512\,m^2i\,\mu N^3+1296\,m^2N^3+384\,i^3m^2\mu\,N+32\,i\,N^5+48\,m\,N^5+960\,m^3N^2+640\,m^4i\,\mu\,N\;+\;768\,m^3i^2\mu\,N\;+\;56\,i^2N^4\;+\;256\,m^3N^3\mu\;+\;1305\,N\;+\;2880\,\mu\;+\;20032\,i\,m\,N\,\mu\;+15648\,m^2i\,\mu\,N+7984\,i^2m\,\mu\,N+2000\,\mu^2m\,i\,N+5248\,m^3i\,\mu\,N+4384\,i^2m^2\,\mu\,N+912\,\mu^2m^2i\,N+10208\,\mu\,N^2i\,m+2256\,i\,m\,N^3\mu+4944\,\mu\,m^2N^2i+2736\,\mu\,m\,N^2i^2+864\,\mu^2m\,N^2i+480\,\mu^2m\,N\,i^2+16\,\mu^3m\,i\,N+1280\,i^3m\,\mu\,N+9792\,\mu\,m+2244\,m^2N+2832\,m\,N+1752\,i\,N+13456\,\mu\,m^2+6768\,\mu\,N+4512\,\mu\,i+2712\,N^2+576\,\mu^2+1344\,\mu^2m+3396\,m^2N^2+768\,m^3N+5076\,m\,N^2+3148\,i\,N^2+872\,i^2N+2624\,i^2\mu+9600\,\mu\,m^3+1104\,\mu^2m^2+6050\,\mu\,N^2+1286\,\mu^2N+672\,\mu^2i+2816\,i\,m\,N+17632\,m\,N+13680\,\mu\,m\,i+4304\,i\,m\,N^2+11940\,\mu\,m\,N^2+2496\,\mu^2m\,N+1264\,\mu^2m\,i+17748\,m^2N\,\mu+1488\,m^2i\,N+15952\,m^2i\,\mu+912\,i^2m\,N+7024\,i^2m\,\mu+9252\,i\,N\,\mu+1872\,m^2N^2i+8484\,m^2N^2\mu\;+256\,m^3N\,i+240\,m^2N\,i^2+1152\,i^2m\,N^2+96\,i^3m\,N+6692\,i\,N^2\mu+4636\,i^2\mu\,N+1320\,\mu^2i\,N+1548\,\mu^2m\,N^2+1692\,\mu^2m^2N+48\,\mu^3m\,N+720\,\mu^2m^2i+368\,\mu^2m\,i^2+384\,m^2N^3i+1776\,m^2N^3\mu+256\,m^3N^2i+240\,m^2N^2i^2+2592\,m^3N^2\mu+1680\,m\,N^3i+3956\,m\,N^3\mu+2344\,i\,N^3\mu+2564\,i^2N^2\mu+1008\,i^3\mu\,N+440\,i^2\mu^2N+1568\,i^3\mu\,m+684\,\mu^2m^2N^2+480\,\mu^2m^3N+12\,\mu^3m^2N+128\,\mu^2m^3i+112\,\mu^2m^2i^2+892\,\mu^2N^2i+28\,\mu^3i\,N+1961\,N^3+96\,m^4N+2820\,m\,N^3+1756\,i\,N^3+1324\,i^2N^2+192\,i^3N+2820\,\mu\,N^3+1110\,\mu^2N^2+672\,\mu\,i^3+48\,\mu^3N+256\,\mu^2i^2+384\,\mu^2m^3+144\,m^2N^4+192\,m^3N^3+96\,m^4N^2+624\,m\,N^4+392\,i\,N^4+508\,i^2N^3+240\,i^3N^2+16\,i^4N+64\,i^4\mu+48\,\mu^2m^4+770\,\mu\,N^4+510\,\mu^2N^3+654\,N^4+78\,\mu^3N^2+32\,\mu^2i^3+3760\,m^4\mu+192\,i\,m\,N^4+240\,i^2m\,N^3+96\,i^3m\,N^2+672\,\mu\,m\,N^4+444\,\mu^2m\,N^3+60\,\mu^3m\,N^2+32\,\mu^2m\,i^3+2064\,m^4N\,\mu+2432\,m^4i\,\mu+2688\,m^3i^2\mu+1152\,m^2i^3\mu+128\,i^4m\,\mu+8672\,m^3N\,\mu+8960\,m^3i\,\mu+6704\,i^2m^2\mu+768\,m^3i\,\mu\,N^2+688\,m^2i^2\mu\,N^2+192\,m^2i\,\mu^2N^2+304\,i^2m\,\mu\,N^3+224\,i^3m\,\mu\,N^2+112\,i^2m\,\mu^2N^2+128\,\mu^2m\,i\,N^3+16\,\mu^3m\,i\,N^2+192\,\mu N^4i\,m+128\,\mu^2m^3i\,N+112\,\mu^2m^2i^2N+32\,\mu^2m\,i^3N+96\,m^2N^3\mu^2+424\,i\,N^4\mu+608\,i^2N^3\mu+276\,i\,N^3\mu^2+384\,i^3\mu\,N^2+220\,i^2\mu^2N^2+36\,\mu^3i\,N^2+48\,\mu^2m\,N^4+12\,\mu^3m\,N^3+96\,\mu^2m^3N^2+12\,\mu^3m^2N^2+288\,m^4N^2\mu+80\,\mu\,i^4N+48\,\mu^2i^3N+4\,\mu^3i^2N+64\,i^4m\,\mu\,N+768\,\mu\,m^5+48\,\mu^2m^4N+48\,m\,N^5\mu+32\,i\,N^5\mu+56\,i^2N^4\mu+32\,i\,N^4\mu^2+48\,i^3\mu\,N^3+16\,i^4\mu\,N^2+16\,i^3\mu^2N^2+36\,i^2\mu^2N^3+4\,i^2\mu^3N^2+8\,\mu^3N^3i+108\,N^5+8\,N^6+48\,i^3N^3+16\,i^4N^2+120\,\mu\,N^5+122\,\mu^2N^4+36\,\mu^3N^3+2\,\mu^4N^2+8\,\mu\,N^6+12\,\mu^2N^5+6\,\mu^3N^4+\mu^4N\;+\mu^4N^3+192\,m^5\mu\,N+256\,i^3\mu\,m^3+64\,i^4\mu\,m^2+256\,m^5i\,\mu+384\,m^4i^2\mu+64\,m^6\mu)/16$$

FIG. 4.1. $H_{n,\lambda}(k,j) = H_{N+1,(\mu-1)/2}(m+i+3, i+2)$.

Note that $\mu \in (0,1)$, $N \geq 0$, $i \geq 0$, $m \geq 0$. Thus

$$\begin{aligned}
H_{n,\lambda}(k,j) &= H_{N+1,(\mu-1)/2}(m+i+3, i+2)\\
&= (m+i+5/2-\mu/2)(N+m+i+3)(m+1)(N+m+3/2+\mu/2)\\
&\times\{(N+1)(N+m+i+5/2+\mu/2)+(m+i+3)(N+2m+2i+5)\}\\
&\times\{(N+1)(N+m+i+3/2+\mu/2)+m\,(N+2m+2i+3)\}\\
&-(m+1/2-\mu/2)\,(m+i+3)\,(N+m+1)\,(N+m+i+7/2+\mu/2)\\
&\times\{(N+1)(N+m+i+5/2+\mu/2)+(m+1)(N+2m+2i+5)\}\\
&\times\{(N+1)(N+m+i+3/2+\mu/2)+(m+i+2)\,(N+2m+2i+3)\}\,.
\end{aligned}$$

The resulting polynomial is of a similar complexity as the previous one. Nevertheless, a cumbersome calculation shows that all its coefficients are positive, which proves that $H_{n,\lambda}(k,j) \geq 0$. In order to help those readers interested in checking this last step of the proof, we include Figure 4.1 displaying the above-mentioned polynomial which has 197 terms as well as the factor $(i+2)/16$. The presence of the summand $2880\,\mu$ (second line in Fig. 4.1) guarantees that $H_{n,\lambda}(k,j) > 0$ for $\lambda \in (-1/2, 0)$, $n \in \mathbb{N}$, and $k \geq 3$.

Acknowledgment. The second author thanks Prof. Miodrag M. Spalević for providing numerical evidence of the results at an early stage of the work.

FOSLL* METHOD FOR THE EDDY CURRENT PROBLEM WITH THREE-DIMENSIONAL EDGE SINGULARITIES*

EUNJUNG LEE† AND THOMAS A. MANTEUFFEL†

Abstract. In the case that the domain has reentrant edges, the standard finite element method loses its global accuracy because of singularities on the boundary. To overcome this difficulty, FOSLL* is applied in this paper. FOSLL* is a methodology for solving PDEs using the dual operator. Here, a modified FOSLL* method is developed that employs a partially weighted functional and allows the use of a standard finite element scheme without losing global accuracy.

Key words. eddy current problem, singularities, least squares, finite element methods

AMS subject classification. 65N30

1. Introduction. The Maxwell equations are a set of fundamental equations governing all macroscopic electromagnetic phenomena. It is known that the numerical resolution of the full system of the Maxwell equations can be very expensive. However, it is possible to use a simplified model that approximates the Maxwell equations and explains particular problems encountered in electromagnetism. In many cases, one can use the so-called eddy current model, which is obtained by neglecting the displacement current in the Maxwell equations. Here, we consider the following two basic laws of electricity and magnetism, which form the eddy current model:

$$\text{Faraday's Law}: \quad \frac{\partial \mu \mathbf{H}}{\partial t} + \nabla \times \mathbf{E} = \mathbf{0},$$

$$\text{Ampère's Law}: \quad \nabla \times \mathbf{H} - \sigma \mathbf{E} = \mathbf{0},$$

where $\mathbf{E}$ is the electric field intensity, $\mathbf{H}$ is the magnetic field intensity, μ is the permeability, and σ is the conductivity. We consider two types of boundary conditions

$$\mathbf{n} \times \mathbf{E} = \mathbf{0}, \quad \mathbf{n} \cdot \mathbf{H} = 0, \qquad \text{and} \qquad \mathbf{n} \cdot \mathbf{E} = 0, \quad \mathbf{n} \times \mathbf{H} = \mathbf{0},$$

where $\mathbf{n}$ is the unit external normal vector. The electric and magnetic field intensities, $\mathbf{E}$ and $\mathbf{H}$, which follow Faraday's and Ampère's laws with homogeneous boundary conditions, satisfy

$$\mathbf{E} \in H_0(\nabla\times) \cap H(\nabla \cdot \sigma), \quad \mathbf{H} \in H(\nabla\times) \cap H_0(\nabla \cdot \mu)$$

or

$$\mathbf{E} \in H(\nabla\times) \cap H_0(\nabla \cdot \sigma), \quad \mathbf{H} \in H_0(\nabla\times) \cap H(\nabla \cdot \mu).$$

For a precise definition of the above Sobolev spaces, see section 2. In addition, if

- μ and σ are smooth,
- either the domain is a convex polyhedron or the boundary is $\mathcal{C}^{1,1}$, and
- different types of boundary conditions do not meet at an edge with the internal angle $> \pi/2$,

then $\mathbf{E} \in (H^1)^3$ and $\mathbf{H} \in (H^1)^3$. Standard numerical techniques can be used to approximately solve the equations under the above smoothness assumptions. For example, first-order system least squares (FOSLS) with H^1-finite element spaces and multigrid methods can be used to solve these equations efficiently (cf. [3], [4], [14]). The FOSLS method is based on minimization of the squared residual norm, $||L\mathbf{V} - \mathbf{F}||_0^2$, of the system $L\mathbf{U} = \mathbf{F}$, where L represents a system of linear first-order equations, $\mathbf{U}$ a vector of unknowns, and $\mathbf{F}$ a vector of known functions. The standard least squares method approximates unknown $\mathbf{U}$ in the given H^1-finite element space when the bilinear form corresponding to $||L\mathbf{V} - \mathbf{F}||_0^2$ is equivalent to the product H^1-norm, and this H^1-equivalence is provided under sufficient smoothness assumptions on the domain, coefficients, and data of the original problem.

In the presence of discontinuous coefficients, nonsmooth, nonconvex domain, or certain irregular boundary conditions, the solution may not be in H^1. This precludes the use of H^1-conforming finite element spaces in least squares and Galerkin formulations of the Maxwell equations.

A partial list of the remedies for this loss of H^1-regularity in FOSLS can be found in [1], [5], [18], and [24]. In [5], the first-order system LL* (FOSLL*) method was introduced to overcome the difficulty that arises from discontinuous coefficients. The basic idea of the FOSLL* method can be explained by looking at a linear system of equations, $A\mathbf{x} = \mathbf{b}$. The least squares method minimizes $||A\mathbf{x} - \mathbf{b}||_0^2$, which leads to the normal equations $A^tA\mathbf{x} = A^t\mathbf{b}$. The dual of this method involves the system, $AA^t\mathbf{y} = \mathbf{b}$, where $\mathbf{x} = A^t\mathbf{y}$. FOSLL* solves $AA^t\mathbf{y} = \mathbf{b}$ by minimizing the functional $\langle A^t\mathbf{y}, A^t\mathbf{y}\rangle - 2\langle \mathbf{y}, \mathbf{b}\rangle$ which is equivalent to minimizing $||A^t\mathbf{y} - \mathbf{x}||_0^2$. For a given first-order linear system of PDEs, $L\mathbf{U} = \mathbf{F}$, the FOSLL* method solves the system, $LL^*\mathbf{U}^* = \mathbf{F}$, by minimizing the functional, $||L^*\mathbf{U}^* - \mathbf{U}||_0^2$, with the dual variable, $\mathbf{U}^*$, and the L^2-adjoint operator, L^*, of L. Minimizing $||L^*\mathbf{U}^* - \mathbf{U}||_0^2$ over $\mathbf{U}^*$ in the domain of L^* is accomplished by solving the weak problem of finding $\mathbf{U}^*$ such that

$$\langle\, L^*\mathbf{U}^*, L^*\mathbf{V}\,\rangle \;=\; \langle\, \mathbf{U}, L^*\mathbf{V}\,\rangle \;=\; \langle\, L\mathbf{U}, \mathbf{V}\,\rangle \;=\; \langle\, \mathbf{F}, \mathbf{V}\,\rangle \tag{1.1}$$

for every $\mathbf{V}$ in the domain of L^*. Then, the solution we seek is $\mathbf{U} = L^*\mathbf{U}^*$. The equation in (1.1) shows that we can solve the dual problem with the given data (right-hand side) of the original problem without knowing the exact solution, $\mathbf{U}$.

In [18], a modified FOSLL* method was developed that allows an accurate approximation using H^1-conforming finite elements for the equations having singular boundary points in two dimension. The results in [24] established a modification of the FOSLS method for the problem in a two-dimensional nonconvex domain having irregular boundary conditions. A weighted norm was used in [24] in order to reduce the difficulties from dealing with the absence of the smoothness of the problem. As a different type of remedy, one of the most common approaches is to use Raviart–Thomas or Nédélec edge elements as a finite element space [20]. These Raviart–Thomas and Nédélec edge element spaces are in $H(\nabla\cdot)$ and $H(\nabla\times)$, respectively, but not in $(H^1)^3$. Another potential form to reduce the difficulties from low regularity of the solution was introduced in [2]. The analysis in [2] is based on a weak variational formulation; the authors employ an H^{-1}-norm least-squares approach in discrete space to avoid dealing with the inf-sup condition. In [10], weighted regularization of time

harmonic Maxwell equations in a polyhedral domain using a Galerkin formulation was investigated. Introducing special weights inside the divergence integral allows the approximation of nonsmooth solutions by an H^1-conforming finite element. Error estimates under the assumptions of special finite element spaces were established in [10].

As mentioned above, modifications to FOSLL* were developed that effectively handle discontinuous coefficients in two and three dimensions and irregular boundary points in two dimensions. However, there has not been any previous attempt to use FOSLL* to handle the difficulty from reentrant edges in three dimensions. First, we use standard FOSLL* to abate the difficulties from discontinuous coefficients, and then modify it to deal with the reentrant edges. We develop a modified FOSLL* using partially weighted norms in the functional to be minimized, so that we can use H^1-conforming finite elements. We do not consider the case that different types of boundary conditions meet at an edge with an internal angle greater than $\pi/2$ or the case in which the domain has conical points and vertices, where several reentrant edges meet. However, we believe that the approach developed here can be easily extended to those cases.

The approximate solution that the FOSLL* approach produces is of the form L^*U^h, where U^h is an H^1-conforming finite element. This approximation contains the curl-free Nédélec edge elements. Our approach involves a substantial decrease in computational cost over the curl-curl formulation because it is easy to implement and the resulting linear systems are easily solved by algebraic multigrid methods [23] even with higher order elements. We obtain the same error estimates as the Nédélec element approach in the L^2-norm and we can easily extend our approach to obtain the $H(\nabla\times)$-norm, while the approach in [2] provides only an L^2-error estimate. Moreover, we obtain error estimates in $H(\nabla\cdot\mu)$- and $H(\nabla\cdot\sigma)$-norms, too.

There are similarities between the FOSLL* approach developed here and the Galerkin formulation with the weighted regularization presented in [10]. While FOSLL* differs in many respects from a Galerkin formulation, under special circumstances we show that they are equivalent (see section 5). In [10], σ was assumed to be constant and E was approximated. It is easy to see that if μ were assumed constant, the same approach could be used to approximate for H. FOSLL* allows both σ and μ to be discontinuous in a natural way. We obtain the same error estimates as the approach in [10] while employing any standard H^1-conforming finite element spaces.

In this paper, we consider the Maxwell equations with discontinuous coefficients and irregular boundary. The error estimates established here hold for standard H^1-conforming finite element spaces and provide convergence rates that depend on the power of the weighting used. Numerical tests show surprising agreement with the theory. The model problem is given in section 2. In section 3, we introduce the FOSLS and FOSLL* methods briefly and explain the difficulties arising from singularities. In section 4, we modify standard FOSLL* and show that H^1-conforming elements can be used. A scaling is introduced and the connection to the Galerkin formulation in a special case is explored in section 5. In section 6, the discretization error estimates are obtained. The numerical results are given in section 7.

2. Model problem. Let Q be a polygon in $\mathbb{R}^2$ with a reentrant corner, that is, a corner that has inner angle bigger than π. Let $I \in \mathbb{R}$ be a bounded interval, and consider the prototype domain, $\Omega := Q \times I \subset \mathbb{R}^3$, which is a polyhedral cylinder. In this paper, we restrict ourselves to the case where the domain has one reentrant edge; however, the general case follows easily. By translation and rotation, we may suppose

that the reentrant edge on the boundary that induces the singularity is on the z-axis.

Throughout this paper, we use $\langle\cdot,\cdot\rangle$ and $||\cdot||$ to denote the L^2-inner product and norm, respectively. We use $||\cdot||_k$ to denote the standard Sobolev H^k-norm and $|\cdot|_k$ to denote the seminorm in $H^k(\Omega)$. Let $b \in L^\infty(\Omega)$ be a scalar function, and define

$$H_0(\nabla\times)\cap H(\nabla\cdot\, b) := \{\mathbf{u}\in L^2(\Omega)^3 \mid ||\nabla\times\mathbf{u}||^2+||\nabla\cdot b\mathbf{u}||^2<\infty,\ \mathbf{n}\times\mathbf{u}=\mathbf{0} \text{ on } \partial\Omega\},$$

$$H(\nabla\times)\cap H_0(\nabla\cdot\, b) := \{\mathbf{u}\in L^2(\Omega)^3 \mid ||\nabla\times\mathbf{u}||^2+||\nabla\cdot b\mathbf{u}||^2<\infty,\ \mathbf{n}\cdot\mathbf{u}=0 \text{ on } \partial\Omega\}.$$

Define $H^k_\beta(\Omega)$ as the weighted Sobolev space of functions u such that

$$||u||^2_{k,\beta} = \sum_{|m|=0}^{k}\int_\Omega r^{2(\beta+|m|-k)}\,|D^m u|^2\,d\Omega<\infty,$$

where $r := r(\mathbf{x})$ is the distance of $\mathbf{x}\in\Omega$ from the reentrant edge. We define partially weighted norms to use in our modification of the FOSLL* functional, for $\mathbf{u},\mathbf{v}\in L^2(\Omega)^3$ and $p,q\in H^0_\beta(\Omega)$, as

$$||(\mathbf{u}^t,p)^t||^2_\beta := ||\mathbf{u}||^2+||p||^2_{0,\beta}, \tag{2.1}$$

$$||(\mathbf{u}^t,p,\mathbf{v}^t,q)^t||^2_\beta := ||\mathbf{u}||^2+||p||^2_{0,\beta}+||\mathbf{v}||^2+||q||^2_{0,\beta}. \tag{2.2}$$

In the above, note that only the scalar terms, p and q, involve weighted norms.

Now, consider the following eddy current problem:

$$\begin{aligned}\frac{\partial\mu\mathbf{H}}{\partial t}+\nabla\times\mathbf{E}&=\mathbf{0}\quad\text{in}\quad\Omega,\\ \nabla\times\mathbf{H}-\sigma\mathbf{E}&=\mathbf{0}\quad\text{in}\quad\Omega,\end{aligned} \tag{2.3}$$

with $\mathbf{E}(\mathbf{x},t)$ the electric field intensity, $\mathbf{H}(\mathbf{x},t)$ the magnetic field intensity, $\mu(\mathbf{x})$ the permeability, and $\sigma(\mathbf{x})$ the conductivity. We assume that coefficients $\mu(\mathbf{x})$ and $\sigma(\mathbf{x})$ are piecewise smooth, positive real valued, and bounded; that is, they satisfy

$$\mu_0\le\mu(\mathbf{x})\le\mu_1,\quad \sigma_0\le\sigma(\mathbf{x})\le\sigma_1\quad\text{for all }\mathbf{x}\in\overline{\Omega}, \tag{2.4}$$

for positive constants μ_0, μ_1, σ_0, and σ_1. We consider two types of boundary conditions,

$$\begin{aligned}\text{type I}:&\quad \mathbf{n}\times\mathbf{E}=\mathbf{0},\quad \mathbf{n}\cdot\mathbf{H}=0,\\ \text{type II}:&\quad \mathbf{n}\cdot\mathbf{E}=0,\quad \mathbf{n}\times\mathbf{H}=\mathbf{0}.\end{aligned}$$

Type I corresponds to perfectly conducting walls, while type II corresponds to perfectly insulating walls. Using the backward Euler approximation in time gives

$$\frac{\mu}{\delta t}\mathbf{H}+\nabla\times\mathbf{E}=\frac{\mu}{\delta t}\mathbf{H}_{\text{old}},$$

where $\mathbf{H}_{\text{old}}$ is the solution at the previous time step. Equation (2.3) implies

$$\nabla\cdot\sigma\mathbf{E}=0,\qquad \nabla\cdot\mu\mathbf{H}=\nabla\cdot\mu\mathbf{H}_{\text{old}}. \tag{2.5}$$

Without loss of generality, we assume $\nabla \cdot \mu \mathbf{H}_{\text{old}} = 0$. The resulting system then is

$$\begin{aligned} -\sigma\mathbf{E} + \nabla \times \mathbf{H} &= \mathbf{0}, \quad \nabla \times \mathbf{E} + \tilde{\mu}\mathbf{H} = \tilde{\mu}\mathbf{H}_{\text{old}}, \\ \nabla \cdot \sigma\mathbf{E} &= 0, \quad \nabla \cdot \mu\mathbf{H} = 0, \end{aligned} \tag{2.6}$$

where $\tilde{\mu} = \mu/\delta t$. Since δt is a constant, $\nabla \cdot \tilde{\mu}\mathbf{H} = 0$. Let δt^{-1} be absorbed into μ and $\tilde{\mu}$ be replaced with μ. It is known that there exists a solution, $(\mathbf{E}, \mathbf{H})$, of the system (2.6) in $(H(\nabla\times) \cap H(\nabla \cdot \sigma)) \times (H(\nabla\times) \cap H(\nabla \cdot \mu))$ satisfying type I or II boundary conditions (cf. [14]). From now on, we consider only the case that the domain is surrounded by perfectly conducting walls, since the procedure is the same for perfectly insulating walls. Moreover, the case of mixed boundary conditions can be handled in a similar fashion.

In this paper, c is a generic term that is used to denote various constants. Its dependence on other quantities is indicated when necessary. For convenience of notation, superscript t for the vector transpose is omitted.

3. FOSLS and FOSLL*. In this section, we give a brief introduction to FOSLS and FOSLL* to explain the basic ideas and to show how they suffer in the presence of singularities. First, we introduce slack variables. Even though system (2.6) can be solved by itself, we extend the system since the extended system provides H^1-equivalence to the bilinear form of $||L^*\mathbf{U}^* - \mathbf{U}||$ in FOSLL* under sufficient smoothness assumptions. We extend system (2.6) by adding slack variables, s and k, to yield

$$\begin{array}{rcrcrcll} -\sigma\mathbf{E} & & + & \nabla \times \mathbf{H} & - & \nabla k & = \mathbf{0} & \text{in } \Omega, \\ & - a_1 s & + & \nabla \cdot \mu\mathbf{H} & & & = 0 & \text{in } \Omega, \\ \nabla \times \mathbf{E} & - \nabla s & + & \mu\mathbf{H} & & & = \mu\mathbf{H}_{\text{old}} & \text{in } \Omega, \\ \nabla \cdot \sigma\mathbf{E} & & & & + & a_2 k & = 0 & \text{in } \Omega, \end{array}$$

$$\mathbf{n} \times \mathbf{E} = \mathbf{0}, \quad \mathbf{n} \cdot \mathbf{H} = 0, \quad k = 0 \quad \text{on } \partial\Omega,$$

with nonnegative constants a_1 and a_2. The above system can be rewritten as

$$\mathcal{L}\mathbf{U} = \mathcal{L}(\mathbf{E}, s, \mathbf{H}, k) = \mathbf{F} \quad \text{in } \Omega,$$

where

$$\mathcal{L}\mathbf{U} = \begin{bmatrix} -\sigma I & 0 & \nabla\times & -\nabla \\ 0 & -a_1 & \nabla \cdot \mu & 0 \\ \nabla\times & -\nabla & \mu I & 0 \\ \nabla \cdot \sigma & 0 & 0 & a_2 \end{bmatrix} \begin{bmatrix} \mathbf{E} \\ s \\ \mathbf{H} \\ k \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ 0 \\ \mu\mathbf{H}_{\text{old}} \\ 0 \end{bmatrix} = \mathbf{F}. \tag{3.1}$$

The domain of $\mathcal{L}$ is

$$D(\mathcal{L}) = (H_0(\nabla\times) \cap H(\nabla \cdot \sigma)) \times H^1(\Omega)/\mathbb{R} \times (H(\nabla\times) \cap H_0(\nabla \cdot \mu)) \times H_0^1(\Omega),$$

which is a Hilbert space under the norm

$$\begin{aligned} ||(\mathbf{E}, s, \mathbf{H}, k)||_{\mathcal{L}}^2 &:= ||\mathbf{E}||^2 + ||\nabla \times \mathbf{E}||^2 + ||\nabla \cdot \sigma\mathbf{E}||^2 + ||s||_1^2 \\ &\quad + ||\mathbf{H}||^2 + ||\nabla \times \mathbf{H}||^2 + ||\nabla \cdot \mu\mathbf{H}||^2 + ||k||_1^2. \end{aligned} \tag{3.2}$$

The range of $\mathcal{L}$ is $L^2(\Omega)^8$. It is easily shown that $s = 0$ and $k = 0$ if $(\mathbf{E}, s, \mathbf{H}, k)$ is the solution of (3.1) in $D(\mathcal{L})$ as long as the constants a_1 and a_2 are nonnegative. The FOSLS method minimizes the least-squares functional

$$\mathcal{F}(\mathbf{U}; \mathbf{F}) = || \ \mathcal{L}\mathbf{U} - \mathbf{F} \ ||^2$$

in the weak sense, that is, we look for the solution of the corresponding weak form as follows: Find $\mathbf{U} \in D(\mathcal{L})$ satisfying

$$\langle \ \mathcal{L}\mathbf{U}, \mathcal{L}\mathbf{V} \ \rangle \ = \ \langle \ \mathbf{F}, \mathcal{L}\mathbf{V} \ \rangle \qquad \text{for all } \ \mathbf{V} \in D(\mathcal{L}). \tag{3.3}$$

The FOSLL* approach solves the corresponding dual problem

$$\mathcal{L}^*\mathbf{U}^* = \mathcal{L}^*(\mathcal{U}, p, \mathcal{V}, q) = \mathbf{U} \quad \text{in } \Omega, \tag{3.4}$$

where the L^2-adjoint operator $\mathcal{L}^*$ of $\mathcal{L}$ is defined by

$$\mathcal{L}^*\mathbf{U}^* = \begin{bmatrix} -\sigma I & 0 & \nabla\times & -\sigma\nabla \\ 0 & -a_1 & \nabla\cdot & 0 \\ \nabla\times & -\mu\nabla & \mu I & 0 \\ \nabla\cdot & 0 & 0 & a_2 \end{bmatrix} \begin{bmatrix} \mathcal{U} \\ p \\ \mathcal{V} \\ q \end{bmatrix} = \begin{bmatrix} \mathbf{E} \\ s \\ \mathbf{H} \\ k \end{bmatrix} = \mathbf{U}, \tag{3.5}$$

and $\mathcal{L}^* : D(\mathcal{L}^*) \to L^2(\Omega)^8$ with

$$D(\mathcal{L}^*) = (H_0(\nabla\times) \cap H(\nabla\cdot)) \times H^1(\Omega)/\mathbb{R} \times (H(\nabla\times) \cap H_0(\nabla\cdot)) \times H_0^1(\Omega).$$

To solve the dual problem we minimize the dual functional

$$\mathcal{F}^*(\mathbf{U}^*; \mathbf{U}) = || \ \mathcal{L}^*\mathbf{U}^* - \mathbf{U} \ ||^2 \tag{3.6}$$

on $D(\mathcal{L}^*)$. The corresponding weak form is the following: Find $\mathbf{U}^* \in D(\mathcal{L}^*)$ satisfying

$$\langle \ \mathcal{L}^*\mathbf{U}^*, \mathcal{L}^*\mathbf{V}^* \ \rangle = \langle \ \mathbf{U}, \mathcal{L}^*\mathbf{V}^* \ \rangle = \langle \ \mathbf{F}, \mathbf{V}^* \ \rangle \qquad \text{for all } \ \mathbf{V}^* \in D(\mathcal{L}^*), \tag{3.7}$$

where $\mathbf{U}$ is the solution of (3.1) for given $\mathbf{F}$. Equation (3.7) shows that we can solve the dual problem with the given data, $\mathbf{F}$, of the original problem without knowing the solution, $\mathbf{U}$. Then, we obtain the solution from (3.4), $\mathbf{U} = \mathcal{L}^*\mathbf{U}^*$.

LEMMA 3.1. *There exists a unique solution,* $\mathbf{U} \in D(\mathcal{L})$*, satisfying* (3.3).

Proof. Let $(E, e, H, h) \in D(\mathcal{L})$. Using the same manner which was used to prove Lemmas 3.4 and 3.6 in [12] for E, H and the Poincaré inequality for e, h, we have

$$||(E, e, H, h)||_{\mathcal{L}}^2 \le c \left(||\nabla \times E||^2 + ||\nabla\cdot \sigma E||^2 + |e|_1^2 + ||\nabla \times H||^2 + ||\nabla\cdot \mu H||^2 + |h|_1^2 \right).$$

Since $\mathbf{n} \times E = \mathbf{0}$ and $h = 0$ on the boundary, the conditions in (2.4) provide

$$\begin{aligned} \mu_1^{-1}||\nabla \times E||^2 \ &\le \ \left\langle \mu^{-1}\nabla \times E, \nabla \times E - \nabla e + \mu H \right\rangle - \langle \nabla \times E, H \rangle, \\ {\sigma_1}^{-1}||\nabla \times H||^2 \ &\le \ \left\langle \sigma^{-1}\nabla \times H, -\sigma E + \nabla \times H - \nabla h \right\rangle + \langle \nabla \times H, E \rangle. \end{aligned}$$

The above two inequalities, together with Hölder's inequality and the ϵ-inequality, give

$$||\nabla \times E||^2 + ||\nabla \times H||^2 \le c \left(||\nabla \times E - \nabla e + \mu H||^2 + || - \sigma E + \nabla \times H - \nabla h||^2 \right).$$

Consider the following several different cases for a_1 and a_2:

(*a*) If $a_1 \neq 0$ and $a_2 \neq 0$, then, by Green's formula,

$$||\nabla \cdot \sigma E||^2 = \langle \nabla \cdot \sigma E, \nabla \cdot \sigma E + a_2 h \rangle + a_2 \langle \sigma E, \nabla h \rangle , \tag{3.8}$$

$$||\nabla \cdot \mu H||^2 = \langle \nabla \cdot \mu H, \nabla \cdot \mu H - a_1 e \rangle - a_1 \langle \mu H, \nabla e \rangle , \tag{3.9}$$

$$||\nabla e||^2 = \langle \nabla e, -\nabla \times E + \nabla e - \mu H \rangle + \langle \nabla e, \mu H \rangle , \tag{3.10}$$

$$||\nabla h||^2 = \langle \nabla h, \sigma E - \nabla \times H + \nabla h \rangle - \langle \nabla h, \sigma E \rangle . \tag{3.11}$$

Multiply (3.10) by a_1 and (3.11) by a_2 and add to (3.9) and (3.8), respectively. Again use Hölder's inequality and the ϵ-inequality to obtain

$$||\nabla \cdot \sigma E||^2 + ||\nabla \cdot \mu H||^2 + ||\nabla e||^2 + ||\nabla h||^2 \leq c \, ||\mathcal{L}(E, e, H, h)||^2.$$

(*b*) If $a_1 = a_2 = 0$, taking Hölder's and Poincaré inequalities in (3.10) and (3.11) implies $||\nabla e||^2 + ||\nabla h||^2 \leq c \, ||\mathcal{L}(E, e, H, h)||^2$.

(*c*) If only one of a_1 and a_2 is 0, for example $a_1 = 0$ and $a_2 \neq 0$, then we use the same calculation in case (*a*) for ∇e. Multiply (3.11) by a_2 and add it to (3.8) to get $||\nabla \cdot \sigma E||^2 + ||\nabla h||^2 \leq c \, (||\nabla \cdot \sigma E + a_2 h||^2 + || - \sigma E + \nabla \times H - \nabla h||^2)$.

Thus, $||(E, e, H, h)||_{\mathcal{L}}^2 \leq c \, ||\mathcal{L}(E, e, H, h)||^2$, so that $\mathcal{L}$ is coercive. It is easy to prove the continuity of $\mathcal{L}$ by using the triangle inequality. Therefore, by the Lax–Milgram theorem, there exists the solution of (3.3). ∎

Now, we consider the dual weak problem (3.7). In a similar manner, we can show the existence and uniqueness of the solution for (3.7).

LEMMA 3.2. *There exists a unique solution,* $\mathbf{U}^* \in D(\mathcal{L}^*)$*, satisfying* (3.7).

COROLLARY 3.3. *The operator* $\mathcal{L} : D(\mathcal{L}) \to L^2(\Omega)^8$*, defined in* (3.1)*, is bijective.*

Proof. In Lemmas 3.1 and 3.2, it is proved that $\mathcal{L}$ and $\mathcal{L}^*$, defined in (3.1) and (3.5), respectively, are coercive. Therefore, $\mathcal{L}$ and $\mathcal{L}^*$ are injective. The coercivity and continuity of $\mathcal{L}$ provide that $\mathcal{L}$ is a closed operator. Then, by the closed range theorem (cf. [25]), the injectivity of $\mathcal{L}^*$ induces the surjectivity of $\mathcal{L}$. Thus, $\mathcal{L}$ is bijective. ∎

COROLLARY 3.4. *The operator* $\mathcal{L}^* \colon D(\mathcal{L}^*) \to L^2(\Omega)^8$*, defined in* (3.5)*, is bijective.*

Proof. Since $\mathcal{L}$ is a closed operator, by Lemma 2.1 in [5] and Corollary 3.3, $\mathcal{L}^*$ is bijective. ∎

Remark 3.5. Corollary 3.4 implies that, for given $\mathbf{F} \in L^2(\Omega)^8$, there exists a unique solution $\mathbf{U}^* \in D(\mathcal{L}^*)$ satisfying the weak form (3.7).

We consider several cases that incur difficulties in approximately solving the eddy current problem with H^1-conforming finite elements. Suppose that there are no boundary singularities but μ and σ are not smooth. Because the coefficients are not smooth, $D(\mathcal{L})$ is not imbedded into $H^1(\Omega)^8$. In fact, $H^1(\Omega)^8$ is a closed, proper subspace of $D(\mathcal{L})$. Therefore, H^1-conforming finite element spaces cannot be used to approximate the solution of system (3.1). The FOSLL* method may be used to overcome this difficulty. The efficiency of FOSLL* in this context can be seen by observing the dual operator $\mathcal{L}^*$ in (3.5). All of the discontinuous coefficients inside the derivatives in the $\mathcal{L}$ system are outside the differential operators in the $\mathcal{L}^*$ system. Accordingly, we have $D(\mathcal{L}^*)$ imbedded into $H^1(\Omega)^8$. Now, we suppose that μ and σ are not smooth and there is a boundary singularity. Although we can resolve the difficulty with the discontinuous coefficients by applying the standard FOSLL* method, the boundary singularity still leads to

$$H_0(\nabla\times) \cap H(\nabla\cdot) \not\subset H^1(\Omega)^3 \quad \text{and} \quad H(\nabla\times) \cap H_0(\nabla\cdot) \not\subset H^1(\Omega)^3.$$

In [18], a modification of the FOSLL* method was developed that overcomes this difficulty for the general scalar elliptic PDEs in the plane. In this paper, we introduce a different type of modification of FOSLL* to mitigate the difficulties with boundary singularities in three space dimensions.

4. The modified FOSLL* method. In this section, we present a modified FOSLL* functional in which the second and fourth equations in (3.5) involve weighted norms, that is, the functional is given by $\|\mathcal{L}^*\mathbf{U}^* - \mathbf{U}\|_\alpha^2$. Note that we have used the partially weighted norm that was introduced in (2.2). In subsection 4.2, we show how this modified FOSLL* functional works in the presence of singularities. Before getting into the details about the modified FOSLL* functional, we first show several Poincaré-type inequalities which are useful in many places. The first lemma appears in [15].

LEMMA 4.1. *Let* $\Omega = \Omega_1 \times (a,b)$ *with* $\Omega_1 = \{(r,\theta)|0 < r < R < 1, 0 < \theta < \omega, 0 < \omega \le 2\pi\}$. *If* $q \in H^1_{\beta+1}(\Omega)$ *vanishes on* $\partial\Omega$, *then, for any* β,

$$||q||_{0,\beta} \;\le\; c\,||\nabla q||_{0,\beta+1}. \tag{4.1}$$

Using the above lemma, we show the following.

LEMMA 4.2. *Assume that* Ω *is bounded, Lipschitz continuous, and simply connected. Let* $\phi \in H_0(\nabla\times) \cap H(\nabla\cdot)$; *then there exists a constant* c *such that, for any* $0 \le \alpha \le 1$,

$$||\phi|| \;\le\; c\;\left(||\nabla \times \phi|| + ||r^\alpha \nabla \cdot \phi||\right).$$

Proof. Let $\phi \in H_0(\nabla\times) \cap H(\nabla\cdot)$. By Lemma 3.4 in [12], ϕ can be written as

$$\phi = \varphi + \nabla\xi, \tag{4.2}$$

where $\varphi \in H_0(\nabla\times) \cap H(\nabla\cdot)$, $\nabla\cdot\varphi = 0$, and $\xi \in H^1_0(\Omega)$ satisfies $\Delta\xi = \nabla\cdot\phi$. Using the Cauchy–Schwarz inequality, Lemma 4.1, and the assumption on α yields

$$\begin{aligned} ||\nabla\xi||^2 = \langle\nabla\xi, \nabla\xi\rangle \;&=\; \langle -\nabla\cdot\phi, \xi\rangle \;\le\; ||r^\alpha\nabla\cdot\phi||\;||r^{-\alpha}\xi|| \\ &\le c||r^\alpha\nabla\cdot\phi||\;||r^{1-\alpha}\nabla\xi|| \;\le\; c||r^\alpha\nabla\cdot\phi||\;||\nabla\xi||. \end{aligned} \tag{4.3}$$

Now, (4.2), (4.3), and Lemma 3.4 in [12] imply

$$||\phi|| \le c(||\varphi|| + ||\nabla\xi||) \le c(||\nabla\times\varphi|| + ||r^\alpha\nabla\cdot\phi||) = c(||\nabla\times\phi|| + ||r^\alpha\nabla\cdot\phi||). \qquad \square$$

Lemmas 4.3 and 4.4 basically claim the same inequality in Lemma 4.1 without the zero boundary condition.

LEMMA 4.3. *Assume* Ω *is the same as in Lemma* 4.1 *and* $\beta > -1$. *For* $p \in H^1_{\beta+1}(\Omega)$, *there exists a constant* c *such that*

$$||p||_{0,\beta} \;\le\; c\;(||p||_{0,\beta+1} + ||\nabla p||_{0,\beta+1}).$$

Proof. Let $R_0 = \frac{R}{4}$, and let χ be a smooth function defined in Ω such that $\chi(r) = 1$ when $r < R_0$ and $\chi(r) = 0$ when $r > 2R_0$ and $|\chi'| \le cR_0^{-1}$ for some constant c. Since $1 = \chi + 1 - \chi$,

$$\int_0^R r^{2\beta}|p|^2 r dr = \int_0^R r^{2\beta}\left|\chi p + (1-\chi)p\right|^2 r dr \le 2\int_0^R r^{2\beta}\left(|\chi p|^2 + |(1-\chi)p|^2\right) r dr.$$

By the modified Hardy's inequality in [16], for $\beta > -1$,

$$\int_0^R r^{2\beta}|\chi p|^2 r\ dr \le c\int_0^R r^{2\beta+2}\left|\frac{\partial(\chi p)}{\partial r}\right|^2 r\ dr \le c\int_0^{2R_0} r^{2\beta+2}\left(\frac{1}{R_0^2}|p|^2+\left|\frac{\partial p}{\partial r}\right|^2\right) r\ dr.$$

Since $(1-\chi)p$ has nonzero values only on (R_0, R),

$$\int_0^R r^{2\beta}|(1-\chi)p|^2 r\ dr = \int_{R_0}^R r^{2\beta}|(1-\chi)p|^2 r\ dr = \int_{R_0}^R r^{-2}\ r^{2\beta+2}|(1-\chi)p|^2 r\ dr$$

$$\le {R_0}^{-2}\ \int_{R_0}^R r^{2\beta+2}|(1-\chi)p|^2 r\ dr \le {R_0}^{-2}\ \int_0^R r^{2\beta+2}|p|^2 r\ dr.$$

Hence

$$\int_\Omega r^{2\beta}|p|^2 d\Omega \le c\ R^{-2}\int_\Omega r^{2\beta+2}|p|^2 d\Omega + c\int_\Omega r^{2\beta+2}|\nabla p|^2 d\Omega. \qquad \square$$

To handle $||p||_{0,\beta+1}$ in Lemma 4.3, we prove the following lemma.

LEMMA 4.4. *Let $p \in H^1(\Omega)$ satisfying $||\nabla p||_{\beta+1-\epsilon} < \infty$; then there exist constants b and c such that, for any $\beta > -1$ and $\epsilon > 0$,*

$$||p-b||_{0,\beta}\ \le\ c\ ||\nabla p||_{0,\beta+1-\epsilon}.$$

Proof. Here, we show an outline of the proof. The details can be found in [17]. Let $p \in H^1(\Omega)$ satisfy the assumption and consider the following expression for P:

$$\begin{aligned} &p(r,\theta,z) - p(r_0,\theta_0,z_0)\\ &= p(r,\theta,z) - p(r,\theta_0,z) + p(r,\theta_0,z) - p(r_0,\theta_0,z) + p(r_0,\theta_0,z) - p(r_0,\theta_0,z_0)\\ &= \int_{\theta_0}^{\theta}\frac{\partial p}{\partial\tilde\theta}(r,\tilde\theta,z)\ d\tilde\theta + \int_{r_0}^{r}\frac{\partial p}{\partial\tilde r}(\tilde r,\theta_0,z)\ d\tilde r + \int_{z_0}^{z}\frac{\partial p}{\partial\tilde z}(r_0,\theta_0,\tilde z)\ d\tilde z. \end{aligned}$$

Multiply by $r_0^{\beta+\frac12}$ and perform the integration $\int_\Omega r_0 dr_0 d\theta_0 dz_0$ on both sides:

$$\begin{aligned} c_1 p(r,\theta,z) = &\int_\Omega r_0^{\beta+\frac12} p(r_0,\theta_0,z_0) r_0 dr_0 d\theta_0 dz_0 + \int_\Omega r_0^{\beta+\frac12}\left\{\int_{\theta_0}^{\theta}\frac{\partial p}{\partial\tilde\theta}(r,\tilde\theta,z)\ d\tilde\theta\right.\\ &\left. + \int_{r_0}^{r}\frac{\partial p}{\partial\tilde r}(\tilde r,\theta_0,z)\ d\tilde r + \int_{z_0}^{z}\frac{\partial p}{\partial\tilde z}(r_0,\theta_0,\tilde z)\ d\tilde z\right\} r_0 dr_0 d\theta_0 dz_0, \end{aligned} \tag{4.4}$$

where $c_1 = \int_\Omega r_0^{\beta+\frac12} r_0 dr_0 d\theta_0 dz_0$. Let

$$b = \frac{1}{c_1}\int_\Omega r_0^{\beta+\frac12} p(r_0,\theta_0,z_0)\ r_0 dr_0 d\theta_0 dz_0;$$

then $|b| \le c||p|| < \infty$. Subtracting b from both sides in (4.4), changing the order of integration, inserting $\tilde r^{\frac{-1+\epsilon}{2}}\cdot\tilde r^{\frac{1-\epsilon}{2}} = 1$ in order to group $\tilde r^{\frac{1-\epsilon}{2}}$ with the $\frac{\partial p}{\partial\tilde r}$ term, using the Cauchy–Schwarz inequality, and squaring both sides yield

$$\begin{aligned} |p(r,\theta,z)-b|^2 \le c\Bigg\{&\int_0^\omega\left|\frac{\partial p}{\partial\tilde\theta}(r,\tilde\theta,z)\right|^2 d\tilde\theta + \int_0^\omega\int_0^R \tilde r^{2\beta+3}\left|\frac{\partial p}{\partial\tilde r}(\tilde r,\theta_0,z)\right|^2 d\tilde r d\theta_0\\ &+\int_0^\omega\left\{\frac{R^\epsilon}{\epsilon}\int_r^R \tilde r^{1-\epsilon}\left|\frac{\partial p}{\partial\tilde r}(\tilde r,\theta_0,z)\right|^2 d\tilde r + \int_0^R r_0^{2\beta+3}\int_a^b\left|\frac{\partial p}{\partial\tilde z}(r_0,\theta_0,\tilde z)\right|^2 d\tilde z dr_0\right\} d\theta_0\Bigg\}. \end{aligned}$$

To establish the weighted L^2-norm of $|p-b|$, multiply by $r^{2\beta}$ and take an integration over Ω. Then, we have

$$\int_\Omega r^{2\beta}|p(r,\theta,z)-b|^2 d\Omega \le c\int_\Omega r^{2\beta+2}\left(\left|\frac{1}{r}\frac{\partial p}{\partial\theta}\right|^2+\left|\frac{\partial p}{\partial r}\right|^2+\left|\frac{\partial p}{\partial z}\right|^2\right)+r^{2\beta+2-\epsilon}\left|\frac{\partial p}{\partial r}\right|^2 d\Omega$$

$$\le c\int_\Omega r^{2\beta+2-\epsilon}|\nabla p\,|^2 d\Omega,$$

where $c=c(\Omega,\beta,\epsilon,(\beta+1)^{-1},\epsilon^{-1})\to\infty$ as $\epsilon\to 0$ and $\beta\to -1$. ∎

LEMMA 4.5. *Assume that Ω is bounded, Lipschitz continuous, and simply connected. Let $\psi\in H(\nabla\times)\cap H_0(\nabla\cdot)$; then there exists a constant c such that, for any $0\le\alpha<1$,*

$$||\psi|| \;\le\; c\,(||\nabla\times\psi||+||r^\alpha\nabla\cdot\psi||).$$

Proof. The proof follows similarly to Lemma 4.2 using Lemmas 4.3 and 4.4. ∎

If a vector function is in H^1 and satisfies certain boundary conditions, then the sum of norms of div and curl is equal to the semi-H^1-norm.

LEMMA 4.6. *Let Ω be a bounded polyhedral domain in $\mathbb{R}^3$. If $\mathbf{v}\in H^1(\Omega)^3$ and satisfies $\mathbf{n}\cdot\mathbf{v}=0$ or $\mathbf{n}\times\mathbf{v}=\mathbf{0}$ on the boundary $\partial\Omega$, then*

$$||\nabla\cdot\mathbf{v}||^2+||\nabla\times\mathbf{v}||^2=||\nabla\mathbf{v}||^2.$$

Proof. See [7] and [8]. ∎

The basic idea of the modification here is to use a weighted norm in certain terms of the least squares functional in (3.6). Using a weighted norm allows the existence of a sequence, $\{\mathbf{U}_n\}\subset D(\mathcal{L}^*)\cap H^1(\Omega)^8$, converging to the nonsmooth solution, $\mathbf{U}^*\in D(\mathcal{L}^*)$, in the functional norm. Consider the operator $\mathcal{L}^*$ blockwise. Let $D_A=H_0(\nabla\times)\cap H(\nabla\cdot)$ and $D_B=H(\nabla\times)\cap H_0(\nabla\cdot)$ and define

$$A=\begin{bmatrix}\nabla\times & -\mu\nabla\\ \nabla\cdot & 0\end{bmatrix}\quad\text{and}\quad B=\begin{bmatrix}\nabla\times & -\sigma\nabla\\ \nabla\cdot & 0\end{bmatrix}. \tag{4.5}$$

We first show that there exist sequences $\{\mathcal{X}_n\}$ and $\{\mathcal{Y}_n\}$ in $H^1(\Omega)^4$ such that

$$||A\mathcal{X}_n-F||_\alpha\longrightarrow 0\;\text{ and }\;||B\mathcal{Y}_n-G||_\alpha\longrightarrow 0\;\text{ as }\;n\longrightarrow\infty, \tag{4.6}$$

for given $F,G\in L^2(\Omega)^4$ and the norm $||\cdot||_\alpha$ defined in (2.1). We again emphasize that this notation implies that only the scalar term, the term involving $\nabla\cdot$, is weighted. Then, we discuss the density of H^1-functions in D_A and D_B under weighted norms.

4.1. The density arguments in D_A and D_B. As a first step to show the existence of H^1-sequences satisfying (4.6), we apply the well-known L^2-decomposition and show several lemmas. The next lemma provides the decomposition of $L^2(\Omega)^3$.

LEMMA 4.7. *Every function $\mathbf{w}\in L^2(\Omega)^3$ has the orthogonal decomposition*

$$\mathbf{w}=\nabla\times\mathbf{u}+\nabla\psi,$$

where $\psi\in H^1(\Omega)/\mathbb{R}$ is the only solution of $\langle\nabla\psi,\nabla\xi\rangle=\langle\mathbf{w},\nabla\xi\rangle$, for any $\xi\in H^1(\Omega)$, and $\mathbf{u}\in H^1(\Omega)^3$ satisfies $\nabla\cdot\mathbf{u}=0$.

Proof. See [12] for details. ∎

LEMMA 4.8. *For given $F \in L^2(\Omega)^4$, there exists a unique solution, $\mathcal{X} \in D_A \times H^1(\Omega)/\mathbb{R}$, of $A\mathcal{X} = F$.*

Proof. The result follows from a proof similar to the proofs of section 3. ∎

Analogously, we show the following lemma.

LEMMA 4.9. *For given $G \in L^2(\Omega)^4$, there exists a unique solution, $\mathcal{Y} \in D_B \times H_0^1(\Omega)$, of $B\mathcal{Y} = G$.*

Now, we provide some decompositions in D_A and D_B.

THEOREM 4.10. *Given $\tilde{\mathbf{u}} \in D_A$, there exists $\mathbf{u} \in H^1(\Omega)^3 \cap D_A$ and $\phi \in H_0^1(\Omega)$ such that*

$$\tilde{\mathbf{u}} = \mathbf{u} + \nabla\phi.$$

Proof. Use Lemma 4.7 to write $\nabla \times \tilde{\mathbf{u}} = \nabla \times \mathbf{u}_0 + \nabla\psi$ with $\mathbf{u}_0 \in H^1(\Omega)^3$ and $\psi \in H^1(\Omega)/\mathbb{R}$. Taking the divergence of the above equation leads to the conclusion that $\psi = 0$. Thus, $\nabla \times (\tilde{\mathbf{u}} - \mathbf{u}_0) = \mathbf{0}$, which implies that $\tilde{\mathbf{u}} = \mathbf{u}_0 + \nabla\phi_0$, for some $\phi_0 \in H^1(\Omega)/\mathbb{R}$. Now, $\mathbf{0} = \mathbf{n} \times \tilde{\mathbf{u}} = \mathbf{n} \times \mathbf{u}_0 + \mathbf{n} \times \nabla\phi_0$. Since $\mathbf{u}_0 \in H^1(\Omega)^3$, we have $\mathbf{n} \times \mathbf{u}_0 \in H^{\frac{1}{2}}(\partial\Omega)^3$. Thus, $\mathbf{n} \times \nabla\phi_0 = -\mathbf{n} \times \mathbf{u}_0$ on $\partial\Omega$, which implies $trace(\phi_0) \in H^{\frac{3}{2}}(\partial\Omega)$. Let $\phi_2 \in H^2(\Omega)$ satisfy $trace(\phi_0) = trace(\phi_2)$. Then, let

$$\mathbf{u} = \mathbf{u}_0 + \nabla\phi_2, \quad \phi = \phi_0 - \phi_2.$$

Since $\mathbf{n} \times \nabla\phi = \mathbf{0}$, the theorem is proved. ∎

THEOREM 4.11. *Given $\tilde{\mathbf{v}} \in D_B$, there exists $\mathbf{v} \in H^1(\Omega)^3 \cap D_B$ and $\psi \in H^1(\Omega)$ with $\mathbf{n} \cdot \nabla\psi = 0$ on $\partial\Omega$ such that*

$$\tilde{\mathbf{v}} = \mathbf{v} + \nabla\psi.$$

Proof. The proof is similar to the proof of Theorem 4.10. Here, we construct ψ satisfying $\mathbf{n} \cdot \nabla\psi = 0$ on the boundary. ∎

In the domain with a reentrant edge, the solution of the Poisson equation

$$-\Delta\phi = f$$

for $f \in L^2(\Omega)$, with a Dirichlet or Neumann boundary condition is, in general, not in $H^2(\Omega)$. It is in $H^2_{loc}(\Omega)$; that is, $\phi \in H^2(S)$ for any open subset S of Ω such that its closure $\overline{S}$ does not meet the reentrant edge (cf. [13]). The solution, ϕ, is also in $H^{1+\gamma}(\Omega)$ for some $\gamma \in (0, 1)$. A more precise measure is given by the weighted Sobolev space. This solution ϕ is in $H^2_\beta(\Omega)$ with β related to the angle of the reentrant edge (cf. [15], [21]). In the following theorems, we establish H^1-sequences satisfying (4.6).

From this point forward, if not mentioned explicitly, Ω is the prototype domain which was defined in section 2.

THEOREM 4.12. *For given $F \in L^2(\Omega)^4$ and an operator A defined in* (4.5), *there exists a sequence $\{\mathcal{X}_n\} \subset H^1(\Omega)^4 \cap \big(D_A \times H^1(\Omega)/\mathbb{R}\big)$ such that*

$$\|A\mathcal{X}_n - F\|_\alpha \longrightarrow 0 \quad \text{as} \quad n \to \infty,$$

where $\alpha > 1 - \lambda$, $\lambda = \pi/\omega$, and ω is the angle of the reentrant edge.

Proof. Let $F = (\mathbf{f}_1, f_2) \in L^2(\Omega)^4$. From Lemma 4.8, we have $\tilde{\mathbf{u}} \in D_A$ and $\tilde{p} \in H^1(\Omega)/\mathbb{R}$ satisfying $\nabla \times \tilde{\mathbf{u}} - \mu\nabla\tilde{p} = \mathbf{f}_1$ and $\nabla \cdot \tilde{\mathbf{u}} = f_2$. By Theorem 4.10, $\tilde{\mathbf{u}}$ is decomposed of $\tilde{\mathbf{u}} = \mathbf{u} + \nabla\phi$, where $\mathbf{u} \in H^1(\Omega)^3 \cap D_A$ and $\phi \in H_0^1(\Omega)$. Here, ϕ satisfies

$$\left\{ \begin{array}{rcll} \nabla \cdot \nabla\phi & = & -\nabla \cdot \mathbf{u} + f_2 & \text{in } \Omega, \\ \phi & = & 0 & \text{on } \partial\Omega. \end{array} \right. \tag{4.7}$$

Given $\alpha > 1-\lambda$, choose β such that $\beta < \alpha$ and $|\beta - 1| < \lambda$. It is known that the solution ϕ is in $H^1(\Omega) \cap H^2_\beta(\Omega)$. Define $\Omega_n = (\{(x,y)|\ 1/(2n) \le r \le 1/n\} \times \mathbb{R}) \cap \Omega$ with $r = \sqrt{x^2+y^2}$ and $\delta_n(r)$ a smooth function satisfying

$$\delta_n(r) = \begin{cases} 0 & \text{if } r < 1/(2n), \\ 1 & \text{if } r > 1/n, \end{cases} \tag{4.8}$$

where $|\ \delta_n'\ | \le c_1 n$ and $|\ \delta_n''\ | \le c_2 n^2$, for some positive constants c_1 and c_2. Define $\phi_n = \delta_n \phi$; then $\phi_n \in H^2(\Omega)$ (cf. [13]). Therefore, $\mathbf{u}_n := \mathbf{u} + \nabla\phi_n$ is in $H^1(\Omega)^3 \cap D_A$ and satisfies

$$\nabla \times \mathbf{u}_n - \mu\nabla\tilde{p} = \nabla \times \mathbf{u} - \mu\nabla\tilde{p} = \nabla \times \tilde{\mathbf{u}} - \mu\nabla\tilde{p} = \mathbf{f}_1.$$

Using the triangle inequality several times and the properties of δ_n yields

$$\|\nabla\cdot\mathbf{u}_n - f_2\|^2_{0,\alpha} = \|\nabla\cdot(\mathbf{u}+\nabla\phi_n) - \nabla\cdot(\mathbf{u}+\nabla\phi)\|^2_{0,\alpha} = \int_\Omega r^{2\alpha}|\Delta((\delta_n(r)-1)\phi)|^2\ d\Omega$$

$$= \int\int\left(\int_0^{\frac{1}{2n}} r^{2\alpha}|\Delta\phi|^2\ r dr + \int_{\frac{1}{2n}}^{\frac{1}{n}} r^{2\alpha}|\Delta((\delta_n(r)-1)\phi)|^2\ r dr\right) d\theta dz$$

$$\le\ c\left(\frac{1}{2n}\right)^{2(\alpha-\beta)} ||\Delta\phi||^2_{0,\beta} + c\int_{\Omega_n} r^{2\alpha}\left(|\Delta\phi|^2 + n^4|\phi|^2 + n^2\left(|\partial_x\phi|^2 + |\partial_y\phi|^2\right)\right) d\Omega$$

$$\le\ c\ n^{-2(\alpha-\beta)}|\phi|^2_{2,\beta} + c\ n^{-2(\alpha-\beta)}||\phi||^2_{2,\beta} = c\ n^{-2(\alpha-\beta)}||\phi||^2_{2,\beta}.$$

The right-hand side goes to 0 as n goes to infinity. By letting $\mathcal{X}_n := (\mathbf{u}_n, \tilde{p})$, the proof is completed. ∎

We can show the next theorem in the same manner.

THEOREM 4.13. *For given $G \in L^2(\Omega)^4$ and an operator B defined in* (4.5), *there exists a sequence $\{\mathcal{Y}_n\} \subset H^1(\Omega)^4 \cap \left(D_B \times H^1_0(\Omega)\right)$ such that*

$$\|B\mathcal{Y}_n - G\|_\alpha \longrightarrow 0 \quad \text{as} \quad n \to \infty,$$

where $\alpha > 1-\lambda$, $\lambda = \pi/\omega$, and ω is the angle of the reentrant edge.

Now, we state some density results. Define

$$D_{A_\alpha} := \{\mathbf{u} \in L^2(\Omega)^3 \mid ||\nabla\times\mathbf{u}|| + ||\nabla\cdot\mathbf{u}||_{0,\alpha} < \infty,\ \mathbf{n}\times\mathbf{u} = \mathbf{0} \text{ on } \partial\Omega\}, \tag{4.9}$$

$$D_{B_\alpha} := \{\mathbf{u} \in L^2(\Omega)^3 \mid ||\nabla\times\mathbf{u}|| + ||\nabla\cdot\mathbf{u}||_{0,\alpha} < \infty,\ \mathbf{n}\cdot\mathbf{u} = 0 \text{ on } \partial\Omega\}, \tag{4.10}$$

which are Hilbert spaces under the norm $||\mathbf{u}||_{D_{A_\alpha}} = ||\mathbf{u}||_{D_{B_\alpha}} := (||\mathbf{u}||^2 + ||\nabla\times\mathbf{u}||^2 + ||\nabla\cdot\mathbf{u}||^2_{0,\alpha})^{\frac{1}{2}}$. The density statement for D_{A_α} can be found in [8], [10], and [11] for $\alpha \in (1-\lambda, 1)$. Here, we extend the density results to $\alpha > 1-\lambda$.

THEOREM 4.14. *$D_{A_\alpha} \cap H^1(\Omega)^3$ is dense in D_{A_α} when $\alpha > 1-\lambda$, and $D_{B_\alpha} \cap H^1(\Omega)^3$ is dense in D_{B_α} when $\alpha > 1-\lambda$.*

Proof. We separate the proof into two cases. First, we consider $1-\lambda < \alpha < 1$. Let the operator A be defined as in (4.5) and let $(\mathbf{u}, p) \in D_{A_\alpha} \times H^1(\Omega)/\mathbb{R}$; then,

$$\|A(\mathbf{u},p)\|^2_\alpha = \|\nabla\times\mathbf{u} - \mu\nabla p\|^2 + ||\nabla\cdot\mathbf{u}||^2_{0,\alpha} \ge \mu_0||(1/\sqrt{\mu})\nabla\times\mathbf{u} - \sqrt{\mu}\nabla p||^2 + ||\nabla\cdot\mathbf{u}||^2_{0,\alpha}$$

$$\ge c(||\nabla\times\mathbf{u}||^2 + ||\nabla p||^2 + ||\nabla\cdot\mathbf{u}||^2_{0,\alpha}) \ge c(||\mathbf{u}||^2_{D_{A_\alpha}} + ||p||^2_1).$$

In the above, Lemma 4.2 and Theorem 4.12 imply the density in D_{A_α} for $1-\lambda < \alpha < 1$.

Now, we consider the case $\alpha \geq 1$. Let $\mathbf{u} \in D_{A_\alpha}$; then, similarly to Theorem 4.10, we can show that $\mathbf{u}$ is decomposed in the form of $\mathbf{u} = \mathbf{u}_0 + \nabla\phi$, where $\mathbf{u}_0 \in H^1(\Omega)^3 \cap D_{A_\alpha}$ and $\phi \in H_0^1(\Omega)$. Let Ω_n and the smooth cut-off function $\delta_n(r)$ be defined as in the proof of Theorem 4.12, and define $\Omega_{\tilde{n}} = (\{(x,y)|r \leq 1/n\} \times \mathbb{R}) \cap \Omega$. Define $\mathbf{u}_n = \mathbf{u}_0 + \nabla(\delta_n(r)\phi)$; then $\mathbf{u}_n$ is in $H^1(\Omega)^3 \cap D_{A_\alpha}$. Since $\phi \in H_0^1(\Omega)$ and $\|\nabla\cdot\nabla\phi\|_{0,\alpha} < \infty$, it is easy to see that

$$\|\Delta\phi\|_{0,\alpha,\Omega_{\tilde{n}}} \to 0 \quad \text{and} \quad \|\phi\|_{1,\Omega_{\tilde{n}}} \to 0 \tag{4.11}$$

as $n \to \infty$, where the subscript $\Omega_{\tilde{n}}$ means the integration over $\Omega_{\tilde{n}}$. Therefore, the triangle inequality and the property of $\delta_n(r)$ yield

$$\begin{aligned}
&\|\mathbf{u}-\mathbf{u}_n\|^2_{D_{A_\alpha}} = \|\mathbf{u}-\mathbf{u}_n\|^2 + \|\nabla\times(\mathbf{u}-\mathbf{u}_n)\|^2 + \|\nabla\cdot(\mathbf{u}-\mathbf{u}_n)\|^2_{0,\alpha}\\
&= \|\nabla((1-\delta_n(r))\phi)\|^2 + \|\nabla\cdot\nabla((1-\delta_n(r))\phi)\|^2_{0,\alpha}\\
&\leq c\left(\|\delta_n'\phi\|^2_{0,\Omega_n} + \|\nabla\phi\|^2_{0,\Omega_{\tilde{n}}} + \|\Delta\phi\|^2_{0,\alpha,\Omega_{\tilde{n}}} + \|\delta_n''\phi\|^2_{0,\alpha,\Omega_n} + \|r^{-1}\delta_n'\phi\|^2_{0,\alpha,\Omega_n} + \|\delta_n'\nabla\phi\|^2_{0,\alpha,\Omega_n}\right).
\end{aligned}$$

We have the second and third terms in the last line of the above go to 0 by (4.11) and we have $\|r^{-1}\delta_n'\phi\|_{0,\alpha,\Omega_n} \leq c\|\delta''\phi\|_{0,\alpha,\Omega_n}$ by the property of δ_n. Since $|\delta_n'(r)| \leq cn$, $1/(2n) \leq r \leq 1/n$ on Ω_n, and $\alpha \geq 1$, the sixth term in the above is

$$\|\delta_n'\nabla\phi\|^2_{0,\alpha,\Omega_n} \leq c\|r^\alpha n\nabla\phi\|^2_{0,\Omega_n} \leq c\|r^{\alpha-1}\nabla\phi\|^2_{0,\Omega_n} = c\|\nabla\phi\|^2_{0,\Omega_n} \to 0.$$

We now focus on the following two terms: By Lemma 4.3 and $\alpha \geq 1$, for $\epsilon > 0$,

$$\begin{aligned}
&\|\delta_n'\phi\|^2_{0,\Omega_n} + \|\delta_n''\phi\|^2_{0,\alpha,\Omega_n} \leq c\left(\|n\phi\|^2_{0,\Omega_n} + \|r^\alpha n^2\phi\|^2_{0,\Omega_n}\right) \leq c\left(\|r^{-1}\phi\|^2_{0,\Omega_n} + \|r^{\alpha-2}\phi\|^2_{0,\Omega_n}\right)\\
&\leq c(1/2n)^{-2\epsilon}\left(\|r^{-1+\epsilon}\phi\|^2_{0,\Omega_n} + \|r^{\alpha-2+\epsilon}\phi\|^2_{0,\Omega_n}\right) \leq cn^{2\epsilon}\left(\|r^{-1+\epsilon}\phi\|^2_{0,\Omega_{\tilde{n}}} + \|r^{\alpha-2+\epsilon}\phi\|^2_{0,\Omega_{\tilde{n}}}\right)\\
&\leq cn^{2\epsilon}\left(\|r^\epsilon\phi\|^2_{0,\Omega_{\tilde{n}}} + \|r^\epsilon\nabla\phi\|^2_{0,\Omega_{\tilde{n}}} + \|r^{\alpha-1+\epsilon}\phi\|^2_{0,\Omega_{\tilde{n}}} + \|r^{\alpha-1+\epsilon}\nabla\phi\|^2_{0,\Omega_{\tilde{n}}}\right)\\
&\leq cn^{2\epsilon}\left(n^{-2\epsilon}(\|\phi\|^2_{0,\Omega_{\tilde{n}}} + \|\nabla\phi\|^2_{0,\Omega_{\tilde{n}}}) + n^{-2(\alpha-1+\epsilon)}(\|\phi\|^2_{0,\Omega_{\tilde{n}}} + \|\nabla\phi\|^2_{0,\Omega_{\tilde{n}}})\right) \leq c\|\phi\|^2_{1,\Omega_{\tilde{n}}}.
\end{aligned}$$

Hence, we proved that $\|\mathbf{u}-\mathbf{u}_n\|^2_{D_{A_\alpha}} \to 0$ as long as $\alpha > 1-\lambda$. The density $D_{B_\alpha} \cap H^1(\Omega)^3$ in D_{B_α} follows the same process. ∎

4.2. The existence of H^1-sequences. So far, we have obtained H^1-sequences satisfying (4.6). For given $(\mathbf{E}, s, \mathbf{H}, k)$, we consider the minimization of the functional (3.6) in the partially weighted norm from (2.2),

$$\mathcal{F}^*_\alpha(\mathbf{U}^*; (\mathbf{E}, s, \mathbf{H}, k)) = ||\mathcal{L}^*\mathbf{U}^* - (\mathbf{E}, s, \mathbf{H}, k)||^2_\alpha \tag{4.12}$$

for all $(\mathcal{U}, p, \mathcal{V}, q) \in D(\mathcal{L}^*)$, where the weighted norms involve only the equations corresponding to slack variables s and k. Since s and k are slack variables of the original system, we may assume that $s = 0$ and $k = 0$. Then the corresponding weak form is as follows: Find $\mathbf{U}^* \in D(\mathcal{L}^*)$ satisfying

$$\langle\mathcal{L}^*\mathbf{U}^*, \mathcal{L}^*\mathbf{V}^*\rangle_\alpha = \langle(\mathbf{E}, 0, \mathbf{H}, 0), \mathcal{L}^*\mathbf{V}^*\rangle_\alpha = \langle\mathcal{L}(\mathbf{E}, 0, \mathbf{H}, 0), \mathbf{V}^*\rangle = \langle\mathbf{F}, \mathbf{V}^*\rangle$$

for all $\mathbf{V}^* \in D(\mathcal{L}^*)$, where $\langle\cdot,\cdot\rangle_\alpha = \langle J_\alpha\cdot, J_\alpha\cdot\rangle$ with J_α the diagonal matrix $J_\alpha = \text{diag}[\ 1,\ 1,\ 1,\ r^\alpha,\ 1,\ 1,\ 1,\ r^\alpha\ ]$. As an important step in achieving the goal of this paper, we show that there exists an H^1-sequence, $\{\mathbf{U}_n\}$, satisfying the following.

THEOREM 4.15. *Assume $\alpha > 1-\lambda$. For given $\mathbf{U} = (\mathbf{E}, s, \mathbf{H}, k) \in L^2(\Omega)^8$, there exists a sequence $\mathbf{U}_n \in D(\mathcal{L}^*) \cap H^1(\Omega)^8$ such that*

$$||\mathcal{L}^*\mathbf{U}_n - \mathbf{U}||_\alpha \longrightarrow 0 \tag{4.13}$$

as $n \longrightarrow \infty$.

Proof. By surjectivity of $\mathcal{L}^*$, there exists $\mathbf{U}^* = (\mathcal{U}, \tilde{p}, \mathcal{V}, \tilde{q}) \in D(\mathcal{L}^*)$ such that $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$. From Theorems 4.12 and 4.13, we have $\mathbf{U}_n \in D(\mathcal{L}^*) \cap H^1(\Omega)^8$ satisfying

(4.14)

$$\nabla \times \mathcal{V}_n - \sigma\nabla q = \mathbf{E} + \sigma\mathcal{U} = \nabla \times \mathcal{V} - \sigma\nabla\tilde{q}\ , \quad ||\nabla \cdot \mathcal{V}_n - a_1\tilde{p} - s||_{0,\alpha} \longrightarrow 0,$$

$$\nabla \times \mathcal{U}_n - \mu\nabla p = \mathbf{H} - \mu\mathcal{V} = \nabla \times \mathcal{U} - \mu\nabla\tilde{p}\ , \quad ||\nabla \cdot \mathcal{U}_n + a_2\tilde{q} - k||_{0,\alpha} \longrightarrow 0,$$

as n goes to infinity, where $\mathbf{U}_n = (\mathcal{U}_n, p, \mathcal{V}_n, q)$ and a_1, a_2 are nonnegative constants. First, consider the case $1-\lambda < \alpha < 1$. By substituting $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$ into (4.14) and using Lemmas 4.2 and 4.5, we have the first inequality in the following equation:

$$\begin{aligned} ||\mathcal{L}^*\mathbf{U}_n - \mathbf{U}||_\alpha^2 &\le c\,\big(\ ||\nabla \times (\mathcal{U}_n - \mathcal{U})||^2 + ||\nabla \cdot (\mathcal{U}_n - \mathcal{U})||_{0,\alpha}^2 \\ &\qquad + ||\nabla \times (\mathcal{V}_n - \mathcal{V})||^2 + ||\nabla \cdot (\mathcal{V}_n - \mathcal{V})||_{0,\alpha}^2\ \big) \\ &\le c\ (||\nabla \cdot (\mathcal{U}_n - \mathcal{U})||_{0,\alpha}^2 + ||\nabla \cdot (\mathcal{V}_n - \mathcal{V})||_{0,\alpha}^2), \end{aligned}$$

where $c = c(\Omega, \mu, \sigma, \alpha)$. Boundary conditions and orthogonality properties provide the second inequality in the above. By (4.14), the right-hand side converges to 0.

Now consider $\alpha \ge 1$. Since $|r| < 1$, it is easy to see that, when $\alpha_1 \ge \alpha_2$, $||\cdot||_{0,\alpha_1} \le ||\cdot||_{0,\alpha_2}$. Therefore, for $\alpha \ge 1$,

$$||\mathcal{L}^*\mathbf{U}_n - \mathbf{U}||_\alpha \ \le\ ||\mathcal{L}^*\mathbf{U}_n - \mathbf{U}||_{1-\epsilon}$$

for $\epsilon > 0$. Hence, the result holds. ∎

COROLLARY 4.16. *Let $\mathbf{U}^* = (\mathcal{U}, \tilde{p}, \mathcal{V}, \tilde{q}) \in D(\mathcal{L}^*)$ satisfying $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$ and let $\mathbf{U}_n = (\mathcal{U}_n, p, \mathcal{V}_n, q) \in D(\mathcal{L}^*) \cap H^1(\Omega)^8$ satisfying* (4.14)*, where $\mathcal{U}_n = \mathbf{u} + \nabla\delta_n\phi$ and $\mathcal{V}_n = \mathbf{v} + \nabla\delta_n\psi$ with δ_n defined as in* (4.8)*, $\mathbf{u} \in H^1(\Omega)^3 \cap D_A$, $\mathbf{v} \in H^1(\Omega)^3 \cap D_B$, $\phi \in H^1(\Omega)/\mathbb{R}$, and $\psi \in H_0^1(\Omega)$ from Theorems* 4.10 *and* 4.11*. Then*

$$\mathcal{U} = \mathbf{u} + \nabla\phi, \quad \mathcal{V} = \mathbf{v} + \nabla\psi, \quad \tilde{p} = p, \quad \textit{and} \quad \tilde{q} = q.$$

Proof. By taking divergence on the first and third equations in (4.14), we obtain $\tilde{p} = p$ and $\tilde{q} = q$. Then, we have

$$\mathbf{0} = \nabla \times (\mathcal{U} - \mathcal{U}_n) = \nabla \times (\mathcal{U} - (\mathbf{u} + \nabla\delta_n\phi)) = \nabla \times (\mathcal{U} - (\mathbf{u} + \nabla\phi)),$$

$$0 = \nabla \cdot \mathcal{U} + a_2 q - k = \nabla \cdot \mathcal{U} - (\nabla \cdot \mathbf{u} + \Delta\phi) = \nabla \cdot (\mathcal{U} - (\mathbf{u} + \nabla\phi)),$$

which imply $\mathcal{U} = \mathbf{u} + \nabla\phi$. Similarly, $\mathcal{V} = \mathbf{v} + \nabla\psi$. ∎

The singularity on the boundary implies that the solution, $\mathbf{U}^* \in D(\mathcal{L}^*)$, of $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$ is not in H^1. However, we have shown that there is an H^1-sequence, $\mathbf{U}_n$, satisfying (4.13). This allows us to use the standard H^1-conforming finite elements, as we demonstrate in section 7. In the next theorem we establish the coercivity and continuity of $\mathcal{F}^*$ in the partially weighted norm.

THEOREM 4.17. *If $(\mathcal{U}, p, \mathcal{V}, q) \in D(\mathcal{L}^*)$, then there exist c and C such that*

$$\begin{aligned} & c(||\mathcal{U}|| + ||\nabla \times \mathcal{U}|| + ||r^\alpha \nabla \cdot \mathcal{U}|| + ||p||_1 + ||\mathcal{V}|| + ||\nabla \times \mathcal{V}|| + ||r^\alpha \nabla \cdot \mathcal{V}|| + ||q||_1) \\ & \leq \ ||\mathcal{L}^*(\mathcal{U}, p, \mathcal{V}, q)||_\alpha \\ & \leq \ C(||\mathcal{U}|| + ||\nabla \times \mathcal{U}|| + ||r^\alpha \nabla \cdot \mathcal{U}|| + ||p||_1 + ||\mathcal{V}|| + ||\nabla \times \mathcal{V}|| + ||r^\alpha \nabla \cdot \mathcal{V}|| + ||q||_1), \end{aligned}$$

where $1 - \lambda < \alpha < 1$.

Proof. It is clear that $||r^\alpha \nabla \cdot \mathcal{U}|| + ||r^\alpha \nabla \cdot \mathcal{V}|| \leq ||\mathcal{L}^*(\mathcal{U}, p, \mathcal{V}, q)||_\alpha$. By Lemmas 4.2 and 4.5, and the Poincaré inequality, it is enough to show that

$$||\nabla \times \mathcal{U}|| + ||\nabla p|| + ||\nabla \times \mathcal{V}|| + ||\nabla q|| \leq c||\mathcal{L}^*(\mathcal{U}, p, \mathcal{V}, q)||_\alpha.$$

Using orthogonality and Hölder's inequality, we can easily show the lower inequality. The upper inequality follows by the triangle inequality. For more details, see [17]. ∎

5. Scaling in FOSLL*. In this section, we briefly introduce scaling in FOSLS and FOSLL*. From [18], it is known that using a scaling in FOSLS and FOSLL* sometimes has computational advantages. Here, we are particularly interested in scaling with $\sqrt{\mu}$ and $\sqrt{\sigma}$ since it gives orthogonality between $\nabla\times$ and ∇ in FOSLL*.

The eddy current equations (3.1) can be rewritten as

$$\mathcal{L}_s \mathbf{U} = \begin{bmatrix} -\sqrt{\sigma} I & 0 & \nabla \times \frac{1}{\sqrt{\mu}} & -\nabla \frac{1}{\sqrt{\mu}} \\ 0 & -\frac{1}{\sqrt{\sigma}} a_1 & \nabla \cdot \sqrt{\mu} & 0 \\ \nabla \times \frac{1}{\sqrt{\sigma}} & -\nabla \frac{1}{\sqrt{\sigma}} & \sqrt{\mu} I & 0 \\ \nabla \cdot \sqrt{\sigma} & 0 & 0 & \frac{1}{\sqrt{\mu}} a_2 \end{bmatrix} \begin{bmatrix} \sqrt{\sigma}\mathbf{E} \\ \sqrt{\sigma} s \\ \sqrt{\mu}\mathbf{H} \\ \sqrt{\mu} k \end{bmatrix} = \mathbf{F}. \tag{5.1}$$

Then, the corresponding dual problem has the form

$$\mathcal{L}_s^* \mathbf{U}^* = \begin{bmatrix} -\sqrt{\sigma} I & 0 & \frac{1}{\sqrt{\sigma}} \nabla \times & -\sqrt{\sigma} \nabla \\ 0 & -\frac{1}{\sqrt{\sigma}} a_1 & \frac{1}{\sqrt{\sigma}} \nabla \cdot & 0 \\ \frac{1}{\sqrt{\mu}} \nabla \times & -\sqrt{\mu} \nabla & \sqrt{\mu} I & 0 \\ \frac{1}{\sqrt{\mu}} \nabla \cdot & 0 & 0 & \frac{1}{\sqrt{\mu}} a_2 \end{bmatrix} \begin{bmatrix} \mathcal{U} \\ p \\ \mathcal{V} \\ q \end{bmatrix} = \begin{bmatrix} \sqrt{\sigma}\mathbf{E} \\ \sqrt{\sigma} s \\ \sqrt{\mu}\mathbf{H} \\ \sqrt{\mu} k \end{bmatrix}. \tag{5.2}$$

FOSLL* for the scaled system minimizes the dual functional $\mathcal{F}_s^*(\mathbf{U}^*; \mathbf{U}) = ||\mathcal{L}_s^* \mathbf{U}^* - \mathbf{U}||^2$ in the weak sense as follows: Find $\mathbf{U}^* \in D(\mathcal{L}^*)$ that satisfies

$$\langle \mathcal{L}_s^* \mathbf{U}^*, \mathcal{L}_s^* \mathbf{V}^* \rangle = \langle \mathbf{U}, \mathcal{L}_s^* \mathbf{V}^* \rangle = \langle \mathcal{L}_s \mathbf{U}, \mathbf{V}^* \rangle = \langle \mathbf{F}, \mathbf{V}^* \rangle \tag{5.3}$$

for all $\mathbf{V}^* \in D(\mathcal{L}^*)$. To gain insight into the effectiveness of the scaled approach in FOSLL*, we observe the formal normal, $\mathcal{L}_s \mathcal{L}_s^*$, of (5.3):

$$\begin{bmatrix} \sigma I + \nabla \times \frac{1}{\mu} \nabla \times - \nabla \frac{1}{\mu} \nabla \cdot & 0 & 0 & \sigma \nabla - \nabla \frac{a_2}{\mu} \\ 0 & \frac{a_1^2}{\sigma} - \nabla \cdot \mu \nabla & \nabla \cdot \mu - \frac{a_1}{\sigma} \nabla \cdot & 0 \\ 0 & \nabla \frac{a_1}{\sigma} - \mu \nabla & \nabla \times \frac{1}{\sigma} \nabla \times - \nabla \frac{1}{\sigma} \nabla \cdot + \mu I & 0 \\ \frac{a_2}{\mu} \nabla \cdot - \nabla \cdot \sigma & 0 & 0 & \frac{a_2^2}{\mu} - \nabla \cdot \sigma \nabla \end{bmatrix}.$$

Compare the above to the formal normal, $\mathcal{L}\mathcal{L}^*$, of the original system (3.1). The formal normal of the scaled system provides two small systems, each totally separated,

corresponding to the variables $(\mathcal{U}, q)$ and $(\mathcal{V}, p)$, respectively:

$$\begin{bmatrix} \sigma I + \nabla \times \frac{1}{\mu} \nabla \times - \nabla \frac{1}{\mu} \nabla \cdot & \sigma \nabla - \nabla \frac{a_2}{\mu} \\ \frac{a_2}{\mu} \nabla \cdot - \nabla \cdot \sigma & \frac{a_2^2}{\mu} - \nabla \cdot \sigma \nabla \end{bmatrix} \begin{bmatrix} \mathcal{U} \\ q \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ 0 \end{bmatrix} \tag{5.4}$$

and

$$\begin{bmatrix} \mu I + \nabla \times \frac{1}{\sigma} \nabla \times - \nabla \frac{1}{\sigma} \nabla \cdot & \nabla \frac{a_1}{\sigma} - \mu \nabla \\ \nabla \cdot \mu - \frac{a_1}{\sigma} \nabla \cdot & \frac{a_1^2}{\sigma} - \nabla \cdot \mu \nabla \end{bmatrix} \begin{bmatrix} \mathcal{V} \\ p \end{bmatrix} = \begin{bmatrix} \mu \mathbf{H}_{\text{old}} \\ 0 \end{bmatrix}. \tag{5.5}$$

The weak form also separates and we solve two smaller systems. For the eddy current problem, it is clear that $(\mathcal{U}, q) = (\mathbf{0}, 0)$. For more general formulations, both systems might have a nontrivial solution.

Remark 5.1. If σ, μ are constants and $a_1 = a_2 = \sigma \cdot \mu$, then (5.5) is reduced to

$$\begin{bmatrix} \mu I + \frac{1}{\sigma} (\nabla \times \nabla \times - \nabla \nabla \cdot) & 0 \\ 0 & \sigma \mu^2 - \mu \nabla \cdot \nabla \end{bmatrix} \begin{bmatrix} \mathcal{V} \\ p \end{bmatrix} = \begin{bmatrix} \mu \mathbf{H}_{\text{old}} \\ 0 \end{bmatrix}.$$

Clearly, $p = 0$ and $\mathcal{V}$ satisfies

$$\mu \mathcal{V} + \frac{1}{\sigma} \nabla \times \nabla \times \mathcal{V} - \frac{1}{\sigma} \nabla \nabla \cdot \mathcal{V} \;=\; \mu \mathbf{H}_{\text{old}}.$$

The above equation is the same as a modified Galerkin formulation for the magnetic field, $\mathbf{H}$. In the context of constant σ and μ, using FOSLL* with the square root scaling described in (5.1) and certain values for a_1, a_2 is equivalent to solving the original problem (2.6) by eliminating the electric field, $\mathbf{E}$, and using a modified Galerkin formulation on $\mathbf{H}$. However, it is the case of nonconstant σ and μ and the presence of reentrant edges that we consider in this paper.

Remark 5.2. In the modified FOSLL*, the formal normal of (5.3) is

$$\begin{bmatrix} \sigma I + \nabla \times \frac{1}{\mu} \nabla \times - \nabla \frac{r^{2\alpha}}{\mu} \nabla \cdot & 0 & 0 & \sigma \nabla - \nabla \frac{r^{2\alpha} a_2}{\mu} \\ 0 & \frac{r^{2\alpha} a_1^2}{\sigma} - \nabla \cdot \mu \nabla & \nabla \cdot \mu - \frac{r^{2\alpha} a_1}{\sigma} \nabla \cdot & 0 \\ 0 & \nabla \frac{r^{2\alpha} a_1}{\sigma} - \mu \nabla & \mu I + \nabla \times \frac{1}{\sigma} \nabla \times - \nabla \frac{r^{2\alpha}}{\sigma} \nabla \cdot & 0 \\ \frac{r^{2\alpha} a_2}{\mu} \nabla \cdot - \nabla \cdot \sigma & 0 & 0 & \frac{r^{2\alpha} a_2^2}{\mu} - \nabla \cdot \sigma \nabla \end{bmatrix}.$$

Because of the weighting terms, there is no simple way to further decouple the equations through a choice of a_1 and a_2. The term in the (3,3) position in the above is similar to the formal normal associated with the partially weighted modified Galerkin described in [10].

6. Discrete approximation. Let $\mathcal{T}_h$ be a partition of the domain $\overline{\Omega} = \cup_{K \in \mathcal{T}_h} K$, and each finite element $K \in \mathcal{T}_h$ be a closed subset of $\overline{\Omega}$ with $h := \max\{h_K := diam(K) : K \in \mathcal{T}_h\}$. Assume that the partition $\mathcal{T}_h$ is regular so that we can choose a finite element basis that is conforming and satisfies the approximation property (see [6]). We also assume that there exists a constant, ρ, satisfying $h \leq \rho h_K$. Define by P_k the space of all polynomials of degree $\leq k$ with respect to each variable. Let the standard polynomial interpolation operator, $I^h \in \mathcal{L}((H^1(\Omega))^8; (H^1(\Omega))^8)$, be such that $I^h p = p$ for all $p \in (P_1)^8$, and let the finite dimensional subspace, $\mathcal{W}^h \subset D(\mathcal{L}^*) \cap H^1(\Omega)^8$, have $I^h(D(\mathcal{L}^*) \cap H^1(\Omega)^8 \cap \mathcal{C}^0(\Omega)) \subset \mathcal{W}^h$.

From section 3, we know that, for given $\mathbf{U} \in L^2(\Omega)^8$, there exists the solution $\mathbf{U}^* \in D(\mathcal{L}^*)$ satisfying $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$, that is,

$$\mathbf{U}^* = \arg \min_{\mathcal{X} \in D(\mathcal{L}^*)} ||\mathcal{L}^*\mathcal{X} - \mathbf{U}||_\alpha. \tag{6.1}$$

Here, we minimize in (6.1) over a finite-dimensional subspace $\mathcal{W}^h$ which yields the corresponding weak form as follows: Find $\mathbf{U}^h \in \mathcal{W}^h$ satisfying

$$\left\langle \mathcal{L}^*\mathbf{U}^h, \mathcal{L}^*\mathbf{X}^h \right\rangle_\alpha = \left\langle \mathbf{U}, \mathcal{L}^*\mathbf{X}^h \right\rangle_\alpha = \left\langle (\mathbf{0}, 0, \mu\mathbf{H}_{\text{old}}, 0), \mathbf{X}^h \right\rangle \tag{6.2}$$

for all $\mathbf{X}^h \in \mathcal{W}^h$. By computing $\mathcal{L}^*\mathbf{U}^h$, we obtain the approximations for $\mathbf{E}$ and $\mathbf{H}$:

$$\mathbf{E}^h = -\sigma\mathcal{U}^h + \nabla \times \mathcal{V}^h - \sigma\nabla\tilde{q}^h, \quad \mathbf{H}^h = \nabla \times \mathcal{U}^h - \mu\nabla\tilde{p}^h + \mu\mathcal{V}^h, \tag{6.3}$$

where $\mathbf{U}^h = \left(\mathcal{U}^h, \tilde{p}^h, \mathcal{V}^h, \tilde{q}^h\right)$.

The following theorem provides the L^2-error estimates for the solution $\mathbf{E}$ and $\mathbf{H}$ of (2.6) with the approximation $\mathcal{L}^*\mathbf{U}^h$. Here, we use Theorem 4.15 to accomplish the L^2-error estimates by adopting the standard finite element approximation property. Vectors $(\mathbf{E}, s, \mathbf{H}, k)$, $(\mathcal{U}, p, \mathcal{V}, q)$, $(\mathcal{U}_n, p, \mathcal{V}_n, q)$, and $(\mathcal{U}_n^h, p^h, \mathcal{V}_n^h, q^h)$ are abbreviated to $\mathbf{U}$, $\mathbf{U}^*, \mathbf{U}_n$, and $\mathbf{U}_n^h$, respectively.

THEOREM 6.1. *Assume $\mathbf{U} \in D(\mathcal{L})$ and $\alpha > 1 - \lambda$. Let $\mathbf{U}^* = (\mathcal{U}, p, \mathcal{V}, q) \in D(\mathcal{L}^*)$ such that $\mathcal{L}^*\mathbf{U}^* = \mathbf{U}$. Then, Corollary* 4.16 *leads the decompositions $\mathcal{U} = \mathbf{u} + \nabla\phi$ and $\mathcal{V} = \mathbf{v} + \nabla\psi$. Assume $\mathbf{u}, \mathbf{v} \in H^{1+\eta_1}(\Omega)^3$ and $p, q \in H^{1+\eta_2}(\Omega)$ for some $\eta_1, \eta_2 > 0$. If $\mathbf{U}^h \in \mathcal{W}^h$ satisfies* (6.2), *then there exists a constant c such that*

$$||\mathbf{U} - \mathcal{L}^*\mathbf{U}^h||_\alpha^2 \le c\, h^{2\tau}\left(|\mathbf{u}|_{1+\eta_1}^2 + |\mathbf{v}|_{1+\eta_1}^2 + ||\phi||_{3,1+\beta}^2 + ||\psi||_{3,1+\beta}^2 + |p|_{1+\eta_2}^2 + |q|_{1+\eta_2}^2\right)$$

for any $\tau < \min\left\{\eta_1, \eta_2, \frac{\alpha-1+\lambda}{\alpha+1}\right\}$ and some $\beta \in (1-\lambda, 1)$, $\beta < \alpha$.

Proof. Let $\mathbf{U}_n \in D(\mathcal{L}^*) \cap H^1(\Omega)^8$ satisfying Theorem 4.15, and let

$$\mathbf{U}_n^h = (\mathcal{U}_n^h, p^h, \mathcal{V}_n^h, q^h) = \arg \min_{\mathcal{X}_n^h \in \mathcal{W}^h} ||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*\mathcal{X}_n^h||_\alpha. \tag{6.4}$$

By the triangle inequality,

$$||\mathbf{U} - \mathcal{L}^*\mathbf{U}^h||_\alpha^2 \le 3\left(||\mathcal{L}^*\mathbf{U}^* - \mathcal{L}^*\mathbf{U}_n||_\alpha^2 + ||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*\mathbf{U}_n^h||_\alpha^2 + ||\mathcal{L}^*\mathbf{U}_n^h - \mathcal{L}^*\mathbf{U}^h||_\alpha^2\right).$$

From Theorems 4.12, 4.13, and 4.15, we have

$$||\mathbf{U} - \mathcal{L}^*\mathbf{U}_n||_\alpha^2 \;<\; c\, n^{-2(\alpha-\beta)}\left(||\phi||_{2,\beta}^2 + ||\psi||_{2,\beta}^2\right). \tag{6.5}$$

The linearity of $\mathcal{L}^*$ and the optimality on the finite-dimensional space imply

$$\begin{aligned} ||\mathcal{L}^*\mathbf{U}_n^h - \mathcal{L}^*\mathbf{U}^h||_\alpha^2 &= \left\langle \mathcal{L}^*(\mathbf{U}_n^h - \mathbf{U}_n + \mathbf{U}_n - \mathbf{U}^* + \mathbf{U}^* - \mathbf{U}^h), \mathcal{L}^*(\mathbf{U}_n^h - \mathbf{U}^h)\right\rangle_\alpha \\ &\le ||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*\mathbf{U}^*||_\alpha \, ||\mathcal{L}^*\mathbf{U}_n^h - \mathcal{L}^*\mathbf{U}^h||_\alpha. \end{aligned} \tag{6.6}$$

Thus, (6.5) and (6.6) yield

$$||\mathbf{U} - \mathcal{L}^*\mathbf{U}^h||_\alpha^2 \le c\, n^{-2(\alpha-\beta)}\left(||\phi||_{2,\beta}^2 + ||\psi||_{2,\beta}^2\right) + c\, ||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*\mathbf{U}_n^h||_\alpha^2. \tag{6.7}$$

Since $\mathbf{U}_n^h$ satisfies (6.4), by Céa's lemma, $||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*\mathbf{U}_n^h||_\alpha^2 \leq c\,||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*I^h\mathbf{U}_n||_\alpha^2$. Using the triangle inequality, we have

$$\begin{aligned}||\mathcal{L}^*\mathbf{U}_n - \mathcal{L}^*I^h\mathbf{U}_n||_\alpha^2 \leq c\,\big(&||\mathcal{U}_n - I^h\mathcal{U}_n||^2 + ||\mathcal{V}_n - I^h\mathcal{V}_n||^2\\ &+ ||\nabla\times(\mathcal{U}_n - I^h\mathcal{U}_n)||^2 + ||\nabla\cdot(\mathcal{U}_n - I^h\mathcal{U}_n)||_{0,\alpha}^2 + ||\nabla(p - I^hp)||^2\\ &+||\nabla\times(\mathcal{V}_n - I^h\mathcal{V}_n)||^2 + ||\nabla\cdot(\mathcal{V}_n - I^h\mathcal{V}_n)||_{0,\alpha}^2 + ||\nabla(q - I^hq)||^2\big)\,.\end{aligned} \tag{6.8}$$

First, we consider $\mathcal{U}_n$-terms. By [12], we have

$$\begin{aligned}&||\mathcal{U}_n - I^h\mathcal{U}_n||^2 + ||\nabla\times(\mathcal{U}_n - I^h\mathcal{U}_n)||^2 + ||\nabla\cdot(\mathcal{U}_n - I^h\mathcal{U}_n)||_{0,\alpha}^2\\ &\qquad\leq c||\nabla(\mathcal{U}_n - I^h\mathcal{U}_n)||^2 = c\sum_{K\in\mathcal{T}_h}||\nabla(\mathcal{U}_n - I^h\mathcal{U}_n)||_K^2,\end{aligned}$$

where $||\cdot||_K$ means an integration over K. Since ϕ satisfies

$$\left\{\begin{array}{rcll}\nabla\cdot\nabla\phi &=& -\nabla\cdot\mathbf{u} - a_2\tilde{q} + k & \text{in } \Omega,\\ \phi &=& 0 & \text{on } \partial\Omega,\end{array}\right. \tag{6.9}$$

and $\nabla\cdot\mathbf{u} + a_2\tilde{q} - k \in H_\beta^1(\Omega) \subset H_{1+\beta}^1(\Omega)$, the solution, ϕ, of (6.9) is in $H_{1+\beta}^3(\Omega)$ (see [19]). From Theorems 4.12 and 4.15, $\mathcal{U}_n$ is decomposed of $\mathbf{u}+\nabla\delta_n\phi$, where δ_n is defined as in (4.8). The fact that $\phi \in H_{1+\beta}^3(\Omega)$ and the definition of δ_n yield $\delta_n\phi \in H^3(\Omega)$. On each element K, we use the triangle inequality and standard interpolation error estimates to obtain

$$\begin{aligned}||\nabla(\mathcal{U}_n - I^h\mathcal{U}_n)||_K^2 &\leq c\,\big(||\nabla(\mathbf{u} - I^h\mathbf{u})||_K^2 + ||\nabla(\nabla\phi_n - I^h\nabla\phi_n)||_K^2\big)\\ &\leq c\;h^{2\eta_1}|\mathbf{u}|_{1+\eta_1,K}^2 + c\;h^2|\phi_n|_{3,K}^2.\end{aligned}$$

Since $\delta_n = 0$ when $r \leq (1/2n)$ and $\delta_n' = 0$ when $r \notin (1/2n, 1/n)$,

$$\sum_K |\phi_n|_{3,K}^2 = |\phi_n|_3^2 \leq c\int |\delta_n'''\phi|^2 + |\delta_n''\nabla\phi|^2 + |\delta_n'\nabla^2\phi|^2 + |\delta_n\nabla^3\phi|^2 d\Omega$$

$$\leq c\iiint_{\frac{1}{2n}}^{\frac{1}{n}} |n^3\phi|^2 + |n^2\nabla\phi|^2 + |n\nabla^2\phi|^2 r dr d\theta dz + c\iiint_{\frac{1}{2n}}^{R(\theta)} |\nabla^3\phi|^2 r dr d\theta dz$$

$$\leq cn^{2(1+\beta)}\left(\iiint_{\frac{1}{2n}}^{\frac{1}{n}}\sum_{k=0}^{2}|r^{\beta-k}\nabla^{2-k}\phi|^2 d\Omega + \iiint_{\frac{1}{2n}}^{R(\theta)}|r^{1+\beta}\nabla^3\phi|^2 d\Omega\right) \leq cn^{2(1+\beta)}||\phi||_{3,1+\beta}^2.$$

Thus, we have $||\nabla(\mathcal{U}_n - I^h\mathcal{U}_n)||^2 \leq\; c\big(h^{2\eta_1}|\mathbf{u}|_{1+\eta_1}^2 + h^2n^{2(1+\beta)}||\phi||_{3,1+\beta}^2\big)$. Choose n such that $\frac{1}{2n} < \sqrt{2}h^{\frac{1}{\alpha+1}} < \frac{11}{20n}$ to balance with (6.7). Then, the optimal choice of β is $1-\lambda+\epsilon$ and this yields $hn^{1+\beta} = h^{\frac{\alpha-1+\lambda}{\alpha+1}-\epsilon}$. Then,

$$||\nabla(\mathcal{U}_n - I^h\mathcal{U}_n)||^2 \leq\; c\left(h^{2\eta_1}|\mathbf{u}|_{1+\eta_1}^2 + h^{2\frac{\alpha-1+\lambda}{\alpha+1}-\epsilon}||\phi||_{3,1+\beta}^2\right).$$

The above calculation can be applied to $\mathcal{V}_n$ analogously. For p and q, the standard error estimates yields $||\nabla(p-I^hp)||^2 + ||\nabla(q-I^hq)||^2 \leq ch^{2\eta_2}(|p|_{1+\eta_2}^2 + |q|_{1+\eta_2}^2)$. ∎

COROLLARY 6.2. *If μ, σ are constants, then η_1, η_2 are any real values $< \lambda$.*

Proof. If μ and σ are constants, then $\nabla \times \nabla \times (\mathbf{u} + \nabla\phi) \in L^2(\Omega)$, where $\mathbf{u}$ and ϕ are from the proof of Theorem 6.1. Also, $\nabla \cdot (\mathbf{u} + \nabla\phi) = 0$ and $\mathbf{n} \times (\mathbf{u} + \nabla\phi) = 0$ on $\partial\Omega$. Thus, by [9], we have $\mathbf{u} \in H^{1+\eta_1}(\Omega)^3$ for any $\eta_1 < \lambda$. The variable p is the solution of the Poisson equation with a Dirichlet boundary condition. Thus, $p \in H^{1+\eta_2}(\Omega)$, where $\eta_2 < \lambda$. Similarly, we have $\mathbf{v} \in H^{1+\eta_1}(\Omega)^3$ and $q \in H^{1+\eta_2}(\Omega)$ for any $\eta_1, \eta_2 < \lambda$. ∎

Remark 6.3. In [10], error estimates in the D_{A_α}-norm (see (4.9)) with higher regularity in $\mathbf{E}$ were developed. They used H^1-conforming finite element spaces which include $\nabla\Phi^h$, where Φ^h is an almost affine family of $\mathcal{C}^1$ elements and has good approximation properties in the H^2_β-norm. In this paper, we use H^1-conforming finite elements to approximately solve the problem and develop L^2-error estimates. Our approximation to the electric field is of the form $E^h = -\sigma\mathcal{U}^h + \nabla \times \mathcal{V}^h - \sigma\nabla\tilde{q}^h$, where $\mathcal{U}^h, \mathcal{V}^h$, and $\tilde{q}^h$ are chosen from H^1-conforming finite element spaces, which means we explicitly present the solution as a combination of such terms, and thus, do not need to construct special finite element spaces.

In the following section, we present several numerical examples. The results show clearly that the convergence rate is related to α values as well as to the regularity of the dual solution in agreement with the above theorem.

7. Numerical results. In this section, we report on numerical results of applying the modified FOSLL* method to problem (3.1). We choose the prototype domain described by

$$\Omega = (-0.5, 0.5)^3 \backslash \{(x, y, z) | 0 \le x \le 0.5, -0.5 \le y \le 0, -0.5 < z < 0.5\}.$$

The domain has a reentrant edge along the z-axis with interior angle $\frac{3\pi}{2}$. Thus, we expect the solution to have a singularity of the form $r^{-\frac{1}{3}}$, where r is the distance to the z-axis. The square root scaling described in section 5 was used for all three tests. This requires solving for only four dependent variables, denoted by $(\mathcal{V}, p)$, since the other four variables $(\mathcal{U}, q)$ are known to be zero. Trilinear finite elements were used for all variables. In this context, we minimize $||\mathcal{L}^*\mathcal{X}^h - (\mathbf{E}, 0, \mathbf{H}, 0)||_\alpha$ over $\mathcal{X}^h = (\mathcal{U}^h, p^h, \mathcal{V}^h, q^h)$ in the finite-dimensional subspace $\mathcal{W}^h$, holding $(\mathcal{U}^h, q^h) = (\mathbf{0}, 0)$, in order to get the approximation, $\mathbf{U}^h$, for the dual solution, $\mathbf{U}^*$, of (3.5). Then, we compute $\mathcal{L}^*\mathbf{U}^h$ as the approximation for $(\mathbf{E}, 0, \mathbf{H}, 0)$ and observe the L^2-errors $||\mathbf{E} - \mathbf{E}^h||$ and $||\mathbf{H} - \mathbf{H}^h||$.

The software package FOSPACK [22] was used to construct the discrete systems and to solve them by a conjugate gradient iteration preconditioned by algebraic multigrid (AMG) using W(1,1)-cycles. Problems with given exact solutions were constructed so that the error could be monitored. The constants a_1 and a_2 were fixed at 0. However, the results are similar to those achieved when they are fixed as positive constants. A residual reduction 10^{-10} was used as the AMG W-cycle stopping criterion. While this level of error is excessive in practice, we employ it here to remove algebraic error from the calculation of the convergence of the discrete solution.

Example 7.1. We choose the exact solutions $\mathbf{E}$ and $\mathbf{H}$ to be

$$\mathbf{E} = \frac{1}{\sigma}\nabla \times \mathbf{H} \quad \text{and} \quad \mathbf{H} = (\ \partial_y g,\ -\partial_x g,\ 0\ ),$$

where

$$g = \delta(r) r^{\frac{2}{3}} \sin\left(\frac{2}{3}\theta\right) \sin(2\pi z) \quad \text{and} \quad \delta(r) = \begin{cases} 1, & r \le 0.25, \\ 0, & r \ge 0.375 \end{cases}$$

with $r = \sqrt{x^2+y^2}$, $\theta = \arctan(\frac{y}{x})$, and $\delta(r) \in \mathcal{C}^3$ cut-off function. Then, the solution satisfies type II boundary conditions. We fix the $\mu = 1$ and $\sigma = 1$.

Table 7.1 displays the L^2-errors of $\mathbf{E}$ and $\mathbf{H}$. The rate, τ, represents the value of the observed convergent factor, h^τ, when the mesh decreases from h to $h/2$. As shown in Table 7.1, standard FOSLL* ($\alpha = 0$) gives poor convergence. The declines in convergence factors are dramatic in this case. This is to be expected because the exact dual solutions $\mathcal{U}$ and $\mathcal{V}$ are not in H^1, but rather in H^γ for any $\gamma < \frac{2}{3}$. The results in Table 7.1 for $\alpha > 1 - \lambda = \frac{1}{3}$ show that partial unweighting of the functional produces improved convergence in all terms of the functional. By Theorem 6.1, the L^2-errors of $\mathbf{E}$ and $\mathbf{H}$ are expected to exhibit $O(h^\tau)$, for any $\tau < \min\{\frac{2}{3}, \frac{\alpha-\frac{1}{3}}{\alpha+1}\}$ (dashed line in Figure 7.1) as long as $\alpha > \frac{1}{3}$, that is, the bound τ, on the convergence rate stays at $\frac{2}{3}$ for $\alpha > 3$. In fact, the results show better convergence than expected. In Figure 7.1, we compare convergence rates for the L^2-errors in $\mathbf{E}$ and $\mathbf{H}$ while the mesh moves from 1/32 to 1/64 with more α values than are showed in Table 7.1. We observe in Table 7.2 that increasing α results in an increasing convergence factor for

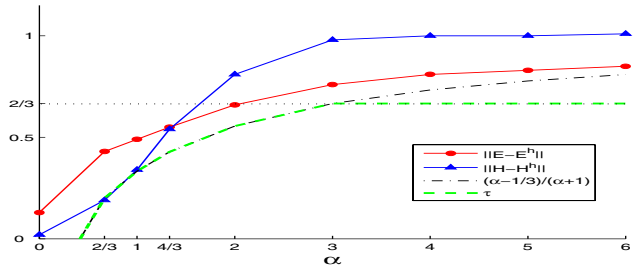

FIG. 7.2. *Finite element convergence rate, τ, as a function of α for Example* 7.2.

the AMG algorithm. This behavior is dependent on the particular AMG algorithm that was used in the test. An improved AMG would change the picture.

Example 7.2. In this example, we take a smooth function for the coefficient σ. Let $\mathbf{E}$ and $\mathbf{H}$ be the same as in Example 7.1 and let $\mu = 0.5$ and $\sigma = 100(x^2+y^2)+1$.

Table 7.3 shows the L^2-errors of $\mathbf{E}$ and $\mathbf{H}$ and the convergence rates. More convergence rates corresponding to α values when the mesh moves from 1/32 to 1/64 appear in Figure 7.2. Note that the observed convergence rates are slightly worse than the ones in Example 7.1. The AMG convergence factor behaves essentially the same as in the first example.

In the next example, we examine the case having discontinuous coefficients as well as a reentrant edge on the boundary.

Example 7.3. Let $\mathbf{E}$ and $\mathbf{H}$ be the same as in Example 7.1. Let $\mu = \sigma = 1$ if $r = \sqrt{x^2+y^2} \le 0.25$ and $\mu = 25$, $\sigma = 100$ otherwise.

In this example, we need to be careful about the regularity of $\mathbf{E}$ and $\mathbf{H}$. Since μ and σ have jumps at $r = 0.25$, $\mathbf{E}$ is not in $H(\nabla\times)$ but in $H(\nabla \times \sigma)$, and $\mathbf{H}$ is not in $H(\nabla \cdot \mu)$ but in $H(\nabla\cdot)$. $\mathbf{E}$ and $\mathbf{H}$ do not satisfy the eddy current equations, but are useful as a test to observe how modified FOSLL* would work for a problem with both discontinuous coefficients and a reentrant edge. Numerical results in Table 7.4 show great convergence with modified FOSLL* approximation even though the problem has both nongrid-aligned discontinuities in the coefficients and a boundary singularity. Convergence rates of the L^2-errors for $\mathbf{E}$ and $\mathbf{H}$ are greater than both of $\frac{2}{3}$ and $\frac{\alpha-\frac{1}{3}}{\alpha+1}$ for $\alpha > 3$. Figure 7.3 shows convergence rates for more values of α using grid size $h = 1/64$.

TABLE 7.4
The L^2-norm of the errors and observed convergence rates, τ, for Example 7.3, $\|\mathbf{E}\| \sim 8.1056$, $\|\mathbf{H}\| \sim 0.55727$.

TABLE 7.5
AMG convergence factors for Example 7.3.

	$\alpha=0$	$\alpha=2/3$	$\alpha=4/3$	$\alpha=2$	$\alpha=3$	$\alpha=4$	$\alpha=5$	$\alpha=6$
1/8	0.64	0.66	0.66	0.63	0.66	0.66	0.66	0.65
1/16	0.68	0.67	0.68	0.67	0.66	0.67	0.66	0.68
1/32	0.67	0.68	0.68	0.66	0.67	0.66	0.68	0.68
1/64	0.63	0.65	0.65	0.65	0.66	0.67	0.67	0.67

The AMG convergence factors are slightly worse, but still quite acceptable, for discontinuous coefficients, as indicated in Table 7.5. Again, we believe that an improved AMG algorithm may overcome this difficulty.

8. Conclusion. In this paper, we developed a FOSLL* method with a partially weighted norm for the eddy current approximation to Maxwell's equations on a three-dimensional domain with a reentrant edge. We have shown the existence of an H^1-sequence converging to the solution of the eddy current problem in the partially weighted functional norm. This allows accurate approximation using standard H^1-conforming finite element spaces. An L^2-error estimate was established that depends continuously on the weight parameter, α. Numerical tests support our theory. In the future, we will apply our theory to other problems, like full Maxwell's equations, elasticity equations, and Navier–Stokes equations. Also, the reentrant corners (e.g., the Fichera cube) will be considered. We don't anticipate the results, but we believe that our theory can be easily extended to these problems.

DETECTING INTERFACES IN A PARABOLIC-ELLIPTIC PROBLEM FROM SURFACE MEASUREMENTS*

FLORIAN FRÜHAUF†, BASTIAN GEBAUER‡, AND OTMAR SCHERZER†

Abstract. Assuming that the heat capacity of a body is negligible outside certain inclusions the heat equation degenerates to a parabolic-elliptic interface problem. In this work we aim to detect these interfaces from thermal measurements on the surface of the body. We deduce an equivalent variational formulation for the parabolic-elliptic problem and give a new proof of the unique solvability based on Lions's projection lemma. For the case that the heat conductivity is higher inside the inclusions, we develop an adaptation of the factorization method to this time-dependent problem. In particular this shows that the locations of the interfaces are uniquely determined by boundary measurements. The method also yields to a numerical algorithm to recover the inclusions and thus the interfaces. We demonstrate how measurement data can be simulated numerically by a coupling of a finite element method with a boundary element method, and finally we present some numerical results for the inverse problem.

Key words. parabolic-elliptic equation, inverse problems, factorization method

1. Introduction.

We consider the heat equation in a domain $B \subset \mathbb{R}^n$

$$\partial_t(c(x)u(x,t)) - \nabla \cdot (\kappa(x)\,\nabla u(x,t)) = 0 \quad \text{in } B\times]0,T[, \tag{1.1}$$

with (spatially dependent) heat capacity c and conductivity κ. The special case we are studying here is that the heat capacity $c(x)$ is bounded from below inside an inclusion $\overline{\Omega} \subset B$, and negligibly small on the outside $Q := B \setminus \overline{\Omega}$ (cf. Figure 1.1 for a sketch of the geometry). Throughout this work Ω is allowed to be disconnected; thus the case of multiple inclusions is covered as well.

If we assume for simplicity that $c(x) = \chi_\Omega(x)$ is the characteristic function of Ω, then the evolution equation (1.1) can be rewritten as a parabolic-elliptic equation,

$$\partial_t u(x,t) - \nabla \cdot (\kappa(x)\,\nabla u(x,t)) = 0 \text{ in } \Omega\times]0,T[, \tag{1.2}$$

$$\nabla \cdot (\kappa(x)\,\nabla u(x,t)) = 0 \text{ in } Q\times]0,T[, \tag{1.3}$$

together with appropriate interface conditions on $\partial\Omega$.

For the case $B = \mathbb{R}^2$ and $\kappa = 1$ this problem also arises in the study of two-dimensional eddy currents and was studied by MacCamy and Suri in [23] and by Costabel, Ervin, and Stephan in [9]. In both papers boundary integral operators are used to replace the Laplace equation in the exterior of Ω by a nonlocal boundary condition for the parabolic equation inside Ω. This problem is then solved by

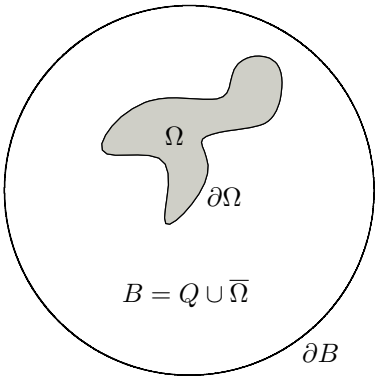

FIG. 1.1. *Sketch of geometry.*

a Galerkin method. In [8] Costabel uses boundary integral operators to solve the resulting interior problem also.

In this work we study the problem for general $\kappa \in L^\infty_+(B)$ in a bounded domain B with given Neumann boundary values on ∂B. By considering (1.1) in the sense of distributions we deduce (1.2), (1.3) together with natural interface conditions (that would otherwise have to be postulated). Moreover, we prove that the weak formulation in appropriate Sobolev spaces is equivalent to (1.1). We show existence of a unique solution using Lions's projection lemma; cf. section 2.

In section 3 we study the inverse problem of locating the interface $\partial\Omega$, resp., the inclusion Ω, from surface measurements on ∂B. If the conductivity is larger inside Ω than in the exterior Q, we show that the points belonging to Ω can be characterized using a variant of the so-called factorization method introduced by Kirsch in [16], generalized by Brühl and Hanke in [6, 5], and since then adapted to various stationary and time-harmonic problems; cf. [1, 2, 7, 15, 17, 18, 19] for more recent contributions. To our knowledge this is the first successful extension of this method to a time-dependent problem.

In section 4 we show how the direct problem can be solved numerically with a coupling of finite element methods and boundary element methods similar to [23]. Using simulated measurements we demonstrate the numerical realization of the factorization method following the ideas of Brühl and Hanke in [6, 5].

2. The direct problem.

2.1. A parabolic-elliptic problem. Let $T > 0$ and Ω, $B \subset \mathbb{R}^n$, $n \geq 2$, be bounded domains with smooth boundaries, $\overline{\Omega} \subset B$, and connected complement $Q := B \setminus \overline{\Omega}$.

In this section we study the parabolic-elliptic problem

$$\partial_t(\chi_\Omega(x)u(x,t)) - \nabla \cdot (\kappa(x)\,\nabla u(x,t)) = 0 \quad \text{in } B\times]0,T[, \tag{2.1}$$

with $\kappa \in L^\infty_+(B)$, where we denote by L^∞_+ the space of L^∞-functions with positive essential infima, and χ_Ω is the characteristic function of Ω.

A standard way to treat an equation like (2.1) is to multiply both sides with a test function followed by a formal partial integration. Assuming additional (also

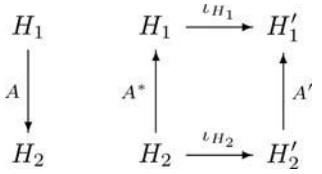

FIG. 2.1. *Relation between dual and adjoint operator.*

formal) boundary and initial conditions, this leads to a variational formulation, which is mathematically meaningful in some Sobolev spaces (and thus no longer formal). Instead of (2.1) one would then study this variational formulation, the so-called weak form of the equation.

In this work we proceed in a slightly different way. We start by noting that the left-hand side of (2.1) does have a mathematical meaning for every $u \in L^2(0,T,H^1(B))$ if the derivatives are interpreted in the sense of (scalar-valued) distributions.

We denote by $\mathcal{D}(B\times]0,T[)$ the space of infinitely often differentiable functions with support in $B\times]0,T[$ and by $\mathcal{D}'(B\times]0,T[)$ its dual space, i.e., the space of distributions on $B\times]0,T[$. By the definition of distributional derivatives, (2.1) is equivalent to

$$-\int_0^T \int_\Omega u(x,t)\partial_t\varphi(x,t)\,\mathrm{d}x\,\mathrm{d}t - \int_0^T \int_B \kappa(x)\,\nabla u(x,t)\cdot\nabla\varphi(x,t)\,\mathrm{d}x\,\mathrm{d}t = 0 \tag{2.2}$$

for all $\varphi \in \mathcal{D}(B\times]0,T[)$.

We will show in this section that (2.1) (together with appropriate boundary and initial conditions) has a unique solution in $L^2(0,T,H^1(B))$. In Theorem 2.6 we give an equivalent variational formulation in Sobolev spaces, using the time-derivative in the sense of vector-valued distributions (which we denote by u'). This variational formulation is the same that one would have obtained as the weak generalization of (2.1) using the above-mentioned formal arguments.

We denote by ν the exterior normal on ∂B, resp., the exterior normal on $\partial\Omega$, and by $\mathcal{D}(\overline{Q}\times]0,T[)$ the restrictions of functions from $\mathcal{D}(\mathbb{R}^n\times]0,T[)$ to $Q\times]0,T[$. Analogous notation is used for Ω and B, and $\mathcal{D}(\overline{B}\times[0,T[)$ is the space of restrictions of functions from $\mathcal{D}(\mathbb{R}^n\times]-\infty,T[)$ to $B\times]0,T[$.

We use the anisotropic Sobolev spaces from [22]. For $r,s\geq 0$ we write

$$H^{r,s}(\mathcal{X}) := L^2(0,T,H^r(\mathcal{X}))\cap H^s(0,T,L^2(\mathcal{X})) \text{ for } \mathcal{X}\in\{B,\Omega,Q,\partial B,\partial\Omega\},$$

and for $s<\frac{1}{2}$ and $\mathcal{X}\in\{\partial B,\partial\Omega\}$

$$H^{-r,-s}(\mathcal{X}) := \left(H^{r,s}(\mathcal{X})\right)'.$$

The inner product on a real Hilbert space H is denoted by $(\cdot,\cdot)$ and the dual pairing on $H'\times H$ by $\langle\cdot,\cdot\rangle$. They are related by the isometry $\iota_H : H\to H'$ that "identifies H with its dual"; i.e., $\langle\iota_H u,\cdot\rangle := (u,\cdot)$ for all $u\in H$. Throughout this work we rigorously distinguish between the dual operator (denoted by A') and the adjoint operator (denoted by A^*) of an operator $A\in\mathcal{L}(H_1,H_2)$ between real Hilbert spaces H_1, H_2. They satisfy the identity $A^* = \iota_{H_1}^{-1}A'\iota_{H_2}$; cf. Figure 2.1.

We summarize some known properties of the Dirichlet and Neumann traces for solutions of the Laplace, resp., heat equation. On the boundary $\partial\Omega$ we use the

superscript $^-$ when the trace is taken from inside the inclusion Ω and the superscript $^+$ when it is taken from the outside.

THEOREM 2.1. (a) *The trace mapping*

$$v \mapsto v|_{\partial B}, \text{ resp., } v \mapsto v^+|_{\partial\Omega}, \quad v \in \mathcal{D}(\overline{Q}\times]0,T[),$$

can be extended to a continuous mapping from $H^{1,0}(Q)$ *to* $H^{\frac{1}{2},0}(\partial B)$, *resp., to* $H^{\frac{1}{2},0}(\partial\Omega)$, *that has a continuous right inverse. The same holds for* $H^{1,0}(\Omega) \to H^{\frac{1}{2},0}(\partial\Omega)$, $v \mapsto v^-|_{\partial\Omega}$.

(b) *The Neumann traces* $\kappa\partial_\nu v|_{\partial B}$ *and* $\kappa\partial_\nu v^+|_{\partial\Omega}$ *are defined for every* $v \in H^{1,0}(Q)$ *that solves*

$$\nabla\cdot(\kappa\,\nabla v) = 0 \text{ in } Q\times]0,T[\tag{2.3}$$

by setting

$$\langle\kappa\partial_\nu v|_{\partial B}, f\rangle := \int_0^T\int_Q \kappa\,\nabla v\cdot\nabla v_f\,\mathrm{d}x\,\mathrm{d}t,$$
$$\langle\kappa\partial_\nu v^+|_{\partial\Omega}, \phi\rangle := -\int_0^T\int_Q \kappa\,\nabla v\cdot\nabla v_\phi\,\mathrm{d}x\,\mathrm{d}t$$

for every function f *on* ∂B *and every function* ϕ *on* $\partial\Omega$ *that have extensions* v_f, $v_\phi \in \mathcal{D}(\overline{Q}\times]0,T[)$ *with* $v_f|_{\partial B} = f$, $v_f|_{\partial\Omega} = 0$, *resp.,* $v_\phi|_{\partial B} = 0$, $v_\phi|_{\partial\Omega} = \phi$.

The Neumann traces can be extended to continuous mappings from the subspace of solutions of (2.3) *(equipped with the* $H^{1,0}(Q)$*-norm) to* $H^{-\frac{1}{2},0}(\partial B)$, *resp.,* $H^{-\frac{1}{2},0}(\partial\Omega)$.

(c) *The Neumann trace* $\kappa\partial_\nu v^-|_{\partial\Omega}$ *is defined for every* $v \in H^{1,0}(\Omega)$ *that solves*

$$\partial_t v - \nabla\cdot(\kappa\,\nabla v) = 0 \text{ in } \Omega\times]0,T[\tag{2.4}$$

by setting

$$\langle\kappa\partial_\nu v^-|_{\partial\Omega}, \phi\rangle := \int_0^T\int_\Omega \kappa\,\nabla v\cdot\nabla v_\phi\,\mathrm{d}x\,\mathrm{d}t - \int_0^T\int_\Omega v\,\partial_t v_\phi\,\mathrm{d}x\,\mathrm{d}t$$

for every function ϕ *on* $\partial\Omega$ *that has an extension* $v_\phi \in \mathcal{D}(\overline{\Omega}\times]0,T[)$ *with* $v_\phi|_{\partial\Omega} = \phi$.

The Neumann trace can be extended to a continuous mapping from the subspace of solutions of (2.4) *(equipped with the* $H^{1,0}(\Omega)$*-norm) to* $H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)$.

Proof. (a), (b) immediately follow from the classical trace theorems on H^1. For (c) we refer the reader to [8]. □

Denoting

$$[v]_{\partial\Omega} := v^+|_{\partial\Omega} - v^-|_{\partial\Omega} \text{ and } [\kappa\partial_\nu v]_{\partial\Omega} := \kappa\partial_\nu v^+|_{\partial\Omega} - \kappa\partial_\nu v^-|_{\partial\Omega}$$

we can write (2.1) as a diffraction problem.

LEMMA 2.2. $u \in H^{1,0}(B)$ *solves* (2.1) *if and only if* $u \in H^{1,0}(B\setminus\partial\Omega)$ *solves*

$$\partial_t u - \nabla\cdot(\kappa\,\nabla u) = 0 \text{ in } \Omega\times]0,T[, \tag{2.5}$$
$$\nabla\cdot(\kappa\,\nabla u) = 0 \text{ in } Q\times]0,T[, \tag{2.6}$$
$$[\kappa\partial_\nu u]_{\partial\Omega} = 0, \tag{2.7}$$
$$[u]_{\partial\Omega} = 0. \tag{2.8}$$

In particular, (2.6) *and* (2.7) *imply that* $\kappa\partial_\nu u^-|_{\partial\Omega}$ *can be extended by continuity to* $H^{-\frac{1}{2},0}(\partial\Omega)$.

Proof. Like in the stationary case we have $u \in H^{1,0}(B)$ if and only if $u \in H^{1,0}(B \setminus \partial\Omega)$ and u satisfies (2.8). The rest immediately follows from the definition of distributional derivatives and the Neumann traces. ∎

The next lemma shows uniqueness for the diffraction problem with a Neumann boundary condition and an initial condition on Ω. With respect to the Gelfand triple $H^1(\Omega) \hookrightarrow L^2(\Omega) \hookrightarrow H^1(\Omega)'$ we denote by

$$W := W(0, T, H^1(\Omega), H^1(\Omega)')$$

the space of functions $u \in L^2(0, T, H^1(\Omega))$ with vector-valued distributional time derivative $u' \in L^2(0, T, H^1(\Omega)')$. From [10, Chp. XVIII], it follows that

$$W \subset C^0([0, T], L^2(\Omega)).$$

LEMMA 2.3. *Let* $u \in H^{1,0}(B \setminus \partial\Omega)$ *solve* (2.5), (2.6), *and*

$$[\kappa\partial_\nu u]_{\partial\Omega} = \psi \in H^{-\frac{1}{2},0}(\partial\Omega), \tag{2.9}$$

$$[u]_{\partial\Omega} = f \in H^{\frac{1}{2},0}(\partial\Omega), \tag{2.10}$$

$$\kappa\partial_\nu u|_{\partial B} = g \in H^{-\frac{1}{2},0}(\partial B). \tag{2.11}$$

Then $u|_\Omega \in W$ *and* u *is uniquely determined by* ψ, f, g, *and the initial condition*

$$u(x, 0) = 0 \text{ on } \Omega. \tag{2.12}$$

Proof. Again (2.9) implies that the Neumann trace $\kappa\partial_\nu u^-|_{\partial\Omega}$ can be extended by continuity to $H^{-\frac{1}{2},0}(\partial\Omega)$.

Thus we can define $w \in L^2(0, T, H^1(\Omega)')$ by setting for every $t \in]0, T[$ and $v \in H^1(\Omega)$

$$\langle w(t), v\rangle := \left\langle \kappa\partial_\nu u^-(t)|_{\partial\Omega}, v^-|_{\partial\Omega}\right\rangle - \int_\Omega \kappa\nabla u(t) \cdot \nabla v \,\mathrm{d}x.$$

We have

$$\begin{aligned}
&\int_\Omega \left(-\int_0^T u\,\partial_t\varphi \,\mathrm{d}t\right) v \,\mathrm{d}x \\
&= \int_0^T \langle \kappa\partial_\nu u^-|_{\partial\Omega}, v^-|_{\partial\Omega}\rangle\varphi \,\mathrm{d}t - \int_0^T \int_\Omega \kappa\nabla u \cdot \nabla v \,\mathrm{d}x\,\varphi \,\mathrm{d}t \\
&= \left\langle \int_0^T w\varphi \,\mathrm{d}t, v \right\rangle
\end{aligned}$$

for all $v(x)\varphi(t) \in \mathcal{D}(\overline{\Omega}\times]0, T[)$ and thus by continuous extension for all $v\varphi \in H^1(\Omega) \otimes \mathcal{D}(]0, T[)$. Thus in the sense of vector-valued distributions

$$w = (u|_\Omega)' \text{ with respect to } H^1(\Omega) \hookrightarrow L^2(\Omega) \hookrightarrow H^1(\Omega)',$$

and hence $u|_\Omega \in W \subset C^0([0, T], L^2(\Omega))$.

To show uniqueness let $f = 0$, $\psi = 0$, $g = 0$, and (2.12) hold. Since Green's formula holds for functions in W we have

$$\begin{aligned}\frac{1}{2}\int_\Omega |u(T)|^2 \,\mathrm{d}x &= \int_0^T \langle u'(t), u(t)\rangle \,\mathrm{d}t \\ &= \int_0^T \langle \kappa \partial_\nu u^-|_{\partial\Omega}, u^-|_{\partial\Omega}\rangle \,\mathrm{d}t - \int_0^T \int_\Omega \kappa |\nabla u|^2 \,\mathrm{d}x\,\mathrm{d}t \\ &= -\int_0^T \int_B \kappa |\nabla u|^2 \,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

This implies that $u(x,t) = c(t)$, where $c \in C^0([0,T],\mathbb{R})$ solves $c' = 0$ and $c(0) = 0$. Thus $u = 0$. ∎

To show existence of a solution we proceed analogously to [8, Lemma 2.3] by using Lions's projection lemma.

LEMMA 2.4 (Lions's projection lemma). *Assume that H is a Hilbert space and Φ is a subspace of H. Moreover let $a : H \times \Phi \to \mathbb{R}$ be a bilinear form satisfying the following properties:*

(a) *For every $\varphi \in \Phi$, the linear form $u \mapsto a(u,\varphi)$ is continuous on H.*

(b) *There exists $\alpha > 0$ such that $a(\varphi,\varphi) \geq \alpha \|\varphi\|_H^2$ for all $\varphi \in \Phi$.*

Then for each continuous linear form $l \in H'$, there exists $u_0 \in H$ such that

$$a(u_0,\varphi) = \langle l, \varphi\rangle \text{ for all } \varphi \in \Phi \quad \text{and} \quad \|u_0\|_H \leq \frac{1}{\alpha}\|l\|_{H'}.$$

Proof. The lemma is proven in [20]. We repeat the proof for the sake of completeness.

From assumption (a) and the Riesz representation theorem it follows that for every $\varphi \in \Phi$ there exists $K\varphi \in H$ with

$$(u, K\varphi) = a(u,\varphi) \text{ for all } u \in H.$$

This defines a linear (possibly unbounded) operator $K : \Phi \to V := K(\Phi) \subseteq H$. From assumption (b) it follows that K is injective and thus possesses an inverse $R_0 : V \to \Phi$. Again using assumption (b) we have

$$\|R_0 v\|^2 \leq \frac{1}{\alpha} a(R_0 v, R_0 v) = \frac{1}{\alpha}(R_0 v, v) \leq \frac{1}{\alpha}\|R_0 v\|\,\|v\|,$$

which yields $\|R_0 v\| \leq \frac{1}{\alpha}\|v\|$. Thus R_0 can be extended by continuity to the closure $\overline{V}$ of V. If we denote this extension by $\overline{R}_0$ then we have $\overline{R}_0 : \overline{V} \to \overline{\Phi}$.

$\overline{\Phi}$ is a closed subspace of the Hilbert space H and thus also a Hilbert space. Using the Riesz representation theorem on $\overline{\Phi}$ we obtain a $\xi_l \in \overline{\Phi}$ with

$$l(\varphi) = (\xi_l, \varphi) \text{ for all } \varphi \in \overline{\Phi}.$$

Finally, let $P : H \to \overline{V}$ be the orthogonal projection onto $\overline{V}$; then $u_0 := P^* \overline{R}_0{}^* \xi_l$ has the desired properties. ∎

We prove existence of a solution of the parabolic-elliptic diffraction problem (2.5), (2.6), (2.9)–(2.12) under the additional assumption that g and ψ have vanishing integral mean. For $\mathcal{X} \in \{\partial B, \partial\Omega\}$ we define

$$H_\diamond^{-\frac{1}{2}}(\mathcal{X}) := \{g \in H^{-\frac{1}{2}}(\mathcal{X}) \,:\, \langle g, 1_{\mathcal{X}}\rangle = 0\} \quad \text{and} \quad H_\diamond^{-\frac{1}{2},0}(\mathcal{X}) := L^2(0,T,H_\diamond^{-\frac{1}{2}}(\mathcal{X})).$$

Again they are Hilbert spaces because they are closed subspaces of $H^{-\frac{1}{2}}(\mathcal{X})$, resp., $H^{-\frac{1}{2},0}(\mathcal{X})$.

LEMMA 2.5. *For every*

$$g \in H_{\diamond}^{-\frac{1}{2},0}(\partial B),\ f \in H^{\frac{1}{2},0}(\partial\Omega),\ \text{and } \psi \in H_{\diamond}^{-\frac{1}{2},0}(\partial\Omega),$$

there exists $u \in H^{1,0}(B \setminus \partial\Omega)$ *that solves* (2.5), (2.6), *and* (2.9)–(2.12).

u *depends continuously on* g, f, *and* ψ, *and it fulfills*

$$\int_{\Omega} u(x,t)\,\mathrm{d}x = 0 \quad \text{for } t \in [0,T] \text{ a.e.}$$

Proof. Let $\gamma^{-}_{\partial\Omega} : H^{\frac{1}{2}}(\partial\Omega) \to H^1(Q)$ be a lifting operator, i.e., a continuous right inverse of the trace operator $\cdot|_{\partial\Omega}$ with $(\gamma^{-}_{\partial\Omega}h)|_{\partial B} = 0$ for all $h \in H^{\frac{1}{2}}(\partial\Omega)$, and set $u_f = \gamma^{-}_{\partial\Omega} f \in H^{1,0}(Q)$.

We define the spaces

$$H^1_{\square}(B) := \left\{ v \in H^1(B) \ :\ \int_{\Omega} v\,\mathrm{d}x = 0 \right\}, \qquad H \ := \ L^2(0,T,H^1_{\square}(B)),$$
$$\Phi := \left\{ \varphi \in \mathcal{D}([0,T[\times\overline{B}) \ :\ \int_{\Omega} \varphi\,\mathrm{d}x = 0 \right\},$$

and we set for all $v \in H$ and $\varphi \in \Phi$

$$a(v,\varphi) := \int_0^T \int_B \kappa \nabla v \cdot \nabla\varphi\,\mathrm{d}x\,\mathrm{d}t - \int_0^T \int_{\Omega} v\,\partial_t\varphi\,\mathrm{d}x\,\mathrm{d}t,$$
$$\langle l, v\rangle := -\int_0^T \int_Q \kappa \nabla u_f \cdot \nabla v\,\mathrm{d}x\,\mathrm{d}t + \int_0^T \langle g, v|_{\partial B}\rangle\,\mathrm{d}t - \int_0^T \langle \psi, v|_{\partial\Omega}\rangle\,\mathrm{d}t.$$

Since H is a closed subspace of $H^{1,0}(B)$, it is a Hilbert space. $\Phi \subset H$ and for every $\varphi \in \Phi$, the linear form $v \to a(v,\varphi)$ is continuous on H.

Poincaré's inequality yields that $\left(\int_B |\nabla v|^2\,\mathrm{d}x\right)^{1/2}$ is an equivalent norm on $H^1_{\square}(B)$; thus there exists $\alpha > 0$ such that for all $\varphi \in \Phi$

$$\begin{aligned} a(\varphi,\varphi) &= \int_0^T \int_B \kappa |\nabla\varphi(x,t)|^2\,\mathrm{d}x\,\mathrm{d}t + \frac{1}{2}\int_{\Omega} |\varphi(0,x)|^2\,\mathrm{d}x \\ &\geq \int_0^T \int_B \kappa |\nabla\varphi|^2\,\mathrm{d}x\,\mathrm{d}t \geq \alpha \|\varphi\|_H^2 . \end{aligned}$$

Moreover, the continuity of the trace and lifting operators yields the existence of a constant C that does not depend on g, f, and ψ such that for all $v \in H$

$$\begin{aligned} \langle l, v\rangle &\leq C\left(\|g\|_{H^{-\frac{1}{2},0}(\partial B)} + \|f\|_{H^{\frac{1}{2},0}(\partial\Omega)} + \|\psi\|_{H^{-\frac{1}{2},0}(\partial\Omega)} \right) \|v\|_{H^{1,0}(B)} \\ &= C\left(\|g\|_{H_{\diamond}^{-\frac{1}{2},0}(\partial B)} + \|f\|_{H^{\frac{1}{2},0}(\partial\Omega)} + \|\psi\|_{H_{\diamond}^{-\frac{1}{2},0}(\partial\Omega)} \right) \|v\|_H , \end{aligned}$$

and thus $l \in H'$ with $\|l\|_{H'} \leq C\big(\|g\|_{H_{\diamond}^{-\frac{1}{2},0}(\partial B)} + \|f\|_{H^{\frac{1}{2},0}(\partial\Omega)} + \|\psi\|_{H_{\diamond}^{-\frac{1}{2},0}(\partial\Omega)} \big)$.

Now Lemma 2.4 gives existence of $\tilde{u} \in H$ that solves

$$\begin{aligned}(2.13)\quad &\int_0^T \int_B \kappa \nabla \tilde{u} \cdot \nabla \varphi \,\mathrm{d}x \,\mathrm{d}t - \int_0^T \int_\Omega \tilde{u}\, \partial_t \varphi \,\mathrm{d}x \,\mathrm{d}t \\ &\quad = -\int_0^T \int_Q \kappa \nabla u_f \cdot \nabla \varphi \,\mathrm{d}x \,\mathrm{d}t + \int_0^T \langle g, \varphi|_{\partial B} \rangle \,\mathrm{d}t - \int_0^T \langle \psi, \varphi|_{\partial\Omega} \rangle \,\mathrm{d}t\end{aligned}$$

for all $\varphi \in \Phi$ and $\tilde{u}$ depends continuously on l (and therefore on g, f, and ψ).

We define $u \in H^{1,0}(B \setminus \partial\Omega)$ by setting $u|_\Omega := \tilde{u}|_\Omega$ and $u|_Q := \tilde{u}|_Q + u_f$. Then u solves (2.10) and there exist constants $C', C'' > 0$ such that

$$\begin{aligned}\|u\|_{H^{1,0}(B\setminus\partial\Omega)} &\le C' \left(\|\tilde{u}|_\Omega\|_{H^{1,0}(\Omega)} + \|\tilde{u}|_Q\|_{H^{1,0}(Q)} + \|u_f\|_{H^{1,0}(Q)} \right) \\ &\le C'' \left(\|\tilde{u}\|_H + \|u_f\|_{H^{1,0}(Q)} \right),\end{aligned}$$

and thus u depends continuously on g, f, and ψ.

Since $\int_\Omega \tilde{u}(x,t) \,\mathrm{d}x = 0$ for $t \in [0,T]$ a.e., the left side of (2.13) vanishes for all $\varphi(x,t) = c(t) \in \mathcal{D}([0,T[\times\overline{B})$. Due to our additional assumptions on g and ψ, the right side of (2.13) also vanishes for those φ. Thus (2.13) holds for all $\varphi \in \Phi$ and for all $\varphi(x,t) = c(t)$, which shows that (2.13) holds for all $\varphi \in \mathcal{D}([0,T[\times\overline{B})$, and we immediately obtain that u solves (2.5), (2.6), (2.9), and (2.11).

From Lemma 2.3 it follows that $\tilde{u}|_\Omega = u|_\Omega \in W$ and thus Green's formula holds. We obtain that for every $\varphi \in \mathcal{D}([0,T[\times B)$ with support in $[0,T[\times\Omega$

$$\begin{aligned}&-\int_\Omega u(0)\varphi(0) \,\mathrm{d}x \\ &= \int_0^T \int_\Omega u\, \partial_t \varphi \,\mathrm{d}x \,\mathrm{d}t + \int_0^T \langle u', \varphi \rangle \,\mathrm{d}t \\ &= \int_0^T \int_\Omega \tilde{u}\, \partial_t \varphi \,\mathrm{d}x \,\mathrm{d}t + \int_0^T \langle \kappa \partial_\nu u^-|_{\partial\Omega}, \varphi|_{\partial\Omega} \rangle \,\mathrm{d}t - \int_0^T \int_\Omega \kappa \nabla u \cdot \nabla \varphi \,\mathrm{d}x \,\mathrm{d}t \\ &= \int_0^T \int_B \kappa \nabla \tilde{u} \cdot \nabla \varphi \,\mathrm{d}x \,\mathrm{d}t - \int_0^T \int_\Omega \kappa \nabla u \cdot \nabla \varphi \,\mathrm{d}x \,\mathrm{d}t \\ &= 0,\end{aligned}$$

where we used that the right side of (2.13) vanishes for $\operatorname{supp}\varphi \in [0,T[\times\Omega$. As $\mathcal{D}(\Omega)$ is dense in $L^2(\Omega)$ this yields that $u|_\Omega(0) = 0$. ∎

We summarize the results of this section and give a useful variational formulation in Sobolev spaces.

THEOREM 2.6. *Let $g \in H_\diamond^{-\frac{1}{2},0}(\partial B)$, $f \in H^{\frac{1}{2},0}(\partial\Omega)$, and $\psi \in H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$, and let $u_f \in H^{1,0}(B \setminus \partial\Omega)$ be such that $u_f|_{\partial B} = 0$, $u_f|_{\partial\Omega} = f$, and $u_f|_\Omega = 0$.*

For $u \in H^{1,0}(B \setminus \partial\Omega)$ the following three problems are equivalent and possess the same unique solution. The solution depends continuously on g, f, and ψ and it fulfills $\int_\Omega u(x,t) \,\mathrm{d}x = 0$ for $t \in [0,T]$ a.e.

(a) *u solves*

$$(2.14)\qquad \partial_t u - \nabla \cdot (\kappa \nabla u) = 0 \text{ in } \Omega\times]0,T[,$$

$$(2.15)\qquad \nabla \cdot (\kappa \nabla u) = 0 \text{ in } Q\times]0,T[,$$

$$(2.16)\qquad [\kappa \partial_\nu u]_{\partial\Omega} = \psi,$$

$$[u]_{\partial\Omega} = f, \tag{2.17}$$

$$\kappa\partial_\nu u|_{\partial B} = g, \tag{2.18}$$

$$u(x,0) = 0 \text{ in } \Omega. \tag{2.19}$$

(b) $u|_\Omega \in W$, $u(x,0) = 0$ *in* Ω, *and* $\tilde{u} := u - u_f$ *solves*

$$\begin{aligned}\int_0^T \langle (\tilde{u}|_\Omega)', v|_\Omega\rangle \,\mathrm{d}t + \int_0^T \int_B \kappa\nabla\tilde{u}\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t \\ = \int_0^T \langle g, v|_{\partial B}\rangle \,\mathrm{d}t - \int_0^T \langle \psi, v|_{\partial\Omega}\rangle \,\mathrm{d}t - \int_0^T \int_Q \kappa\nabla u_f\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t\end{aligned} \tag{2.20}$$

for all $v \in H^{1,0}(B)$.

(c) $\tilde{u} := u - u_f$ *solves*

$$\begin{aligned}&\int_0^T \int_B \kappa\nabla\tilde{u}\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t - \int_0^T \langle (v|_\Omega)', \tilde{u}|_\Omega\rangle \,\mathrm{d}t \\ &= \int_0^T \langle g, v|_{\partial B}\rangle \,\mathrm{d}t - \int_0^T \langle \psi, v|_{\partial\Omega}\rangle \,\mathrm{d}t - \int_0^T \int_Q \kappa\nabla u_f\nabla v \,\mathrm{d}x\,\mathrm{d}t\end{aligned}$$

for all $v \in H^{1,0}(B)$ *with* $v|_\Omega \in W$ *and* $v(x,T) = 0$ *on* Ω.

Proof. We showed the unique solvability of the equations in (a) and the properties of the solution in Lemmas 2.3 and 2.5. Thus it remains only to prove the equivalence of (a), (b), and (c).

(a) $\Rightarrow$ (b). Note that $\tilde{u} \in H^{1,0}(B)$, $\kappa\partial_\nu u^-|_{\partial\Omega} \in H^{-\frac{1}{2},0}(\partial\Omega)$, and, by Lemma 2.3, $\tilde{u}|_\Omega = u|_\Omega \in W$.

It suffices to show (2.20) for $v \in \mathcal{D}(]0,T[\times\overline{B})$. Equations (2.14) and (2.15) imply that

$$\begin{aligned}0 &= \int_0^T \langle (\tilde{u}|_\Omega)', v|_\Omega\rangle \,\mathrm{d}t - \int_0^T \langle \nabla\cdot(\kappa\,\nabla u|_\Omega), v|_\Omega\rangle \,\mathrm{d}t \\ &= \int_0^T \langle (\tilde{u}|_\Omega)', v|_\Omega\rangle \,\mathrm{d}t - \int_0^T \langle \kappa\,\partial_\nu u^-|_{\partial\Omega}, v|_{\partial\Omega}\rangle \,\mathrm{d}t + \int_0^T \int_\Omega \kappa\,\nabla u\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t\end{aligned}$$

and

$$\begin{aligned}0 &= \int_0^T \langle \nabla\cdot(\kappa\,\nabla u|_Q), v|_Q\rangle \,\mathrm{d}t \\ &= -\int_0^T \langle \kappa\,\partial_\nu u^+|_{\partial\Omega}, v|_{\partial\Omega}\rangle \,\mathrm{d}t + \int_0^T \langle \kappa\,\partial_\nu u|_{\partial B}, v|_{\partial B}\rangle \,\mathrm{d}t \\ &\quad - \int_0^T \int_Q \kappa\,\nabla u\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

Subtracting these two equations and using (2.16) and (2.18) give

$$\begin{aligned}0 = \int_0^T \langle (\tilde{u}|_\Omega)', v|_\Omega\rangle \,\mathrm{d}t + \int_0^T \langle \psi, v|_{\partial\Omega}\rangle \,\mathrm{d}t - \int_0^T \langle g, v|_{\partial B}\rangle \,\mathrm{d}t \\ + \int_0^T \int_\Omega \kappa\,\nabla u\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t + \int_0^T \int_Q \kappa\,\nabla u\cdot\nabla v \,\mathrm{d}x\,\mathrm{d}t.\end{aligned}$$

Now (2.20) follows from

$$\int_0^T \int_\Omega \kappa \nabla u \cdot \nabla v \,\mathrm{d}x \,\mathrm{d}t + \int_0^T \int_Q \kappa \nabla u \cdot \nabla v \,\mathrm{d}x \,\mathrm{d}t$$
$$= \int_0^T \int_B \kappa \nabla \tilde{u} \cdot \nabla v \,\mathrm{d}x \,\mathrm{d}t + \int_0^T \int_Q \kappa \nabla u_f \cdot \nabla v \,\mathrm{d}x \,\mathrm{d}t.$$

(b) $\Rightarrow$ (c). This part of the proof follows from Green's formula on W.
(c) $\Rightarrow$ (a). This part of the proof was shown in the proof of Lemma 2.5. ∎

2.2. Boundary measurements and a reference problem. We assume that the inclusion not only has a higher heat capacity but also has a higher conductivity κ than the background. For simplicity we fix $\kappa = 1$ on Q and therefore require that $\kappa|_\Omega - 1 \in L^\infty_+(\Omega)$.

We introduce the measurement operator

$$\Lambda_1 : \; g \mapsto u_1|_{\partial B}, \text{ where } u_1 \text{ solves (2.1) with } \partial_\nu u_1|_{\partial B} = g, \; u_1|_\Omega = 0 \text{ at } t = 0.$$

Using the results from section 2.1 we know that Λ_1 is a continuous linear operator from $H_\diamond^{-\frac{1}{2},0}(\partial B)$ to $H^{\frac{1}{2},0}(\partial B)$.

To locate the inclusion Ω we compare Λ_1 with boundary measurements of a domain without inclusions, i.e., with the measurement operator

$$\Lambda_0 : \; g \mapsto u_0|_{\partial B}, \text{ where } \Delta u_0 = 0 \text{ on } B\times]0,T[\text{ and } \partial_\nu u_0|_{\partial B} = g.$$

The Lax–Milgram theorem shows that u_0 is uniquely determined up to addition of a spatially constant function $u(x,t) = c(t) \in L^2(0,T,\mathbb{R})$ and that Λ_0 is a continuous linear operator from $H_\diamond^{-\frac{1}{2},0}(\partial B)$ to $H_\diamond^{\frac{1}{2},0}(\partial B) := L^2(0,T,H_\diamond^{\frac{1}{2}}(\partial B))$, where the quotient space $H_\diamond^{\frac{1}{2}}(\partial B) := H^{\frac{1}{2}}(\partial B)/\mathbb{R}$ can be identified with the dual space of $H_\diamond^{-\frac{1}{2}}(\partial B)$ and $H_\diamond^{\frac{1}{2},0}(\partial B)$ with the dual space of $H_\diamond^{-\frac{1}{2},0}(\partial B)$.

Analogously we define quotient spaces on B, Q, and $\partial\Omega$ and note that in the case that $\partial\Omega$ is disconnected the quotient space $H_\diamond^{\frac{1}{2}}(\partial\Omega)$ is still obtained by factoring out the one-dimensional space of functions that are constant on $\partial\Omega$, and not the multidimensional space of functions that are constant on each connected component.

Mathematically the elements of the quotient spaces $H_\diamond^{r,0}$, $r \geq 0$, are equivalence classes; i.e., all functions that differ only by a spatially constant function are called equivalent and combined into one class. For the sake of readability we write an equivalence class as a function and keep in mind that it is a representant of its class. We also note that the space $H_\diamond^{-\frac{1}{2},0}$, which we defined earlier, is not a quotient space.

Without changing notation we use the canonical epimorphism to restrict Λ_1 to the spaces of the reference problem. Thus we will investigate the inverse problem of locating the inclusion Ω from knowledge of

$$\Lambda_0, \Lambda_1 : \; H_\diamond^{-\frac{1}{2},0}(\partial B) \to H_\diamond^{\frac{1}{2},0}(\partial B).$$

3. The inverse problem. We use the factorization method to reconstruct Ω from the boundary measurements. To this end we show that the difference of the measurement operators $\Lambda_0 - \Lambda_1$ can be factorized into the product

$$\Lambda_0 - \Lambda_1 = L(F_0 - F_1)L' \tag{3.1}$$

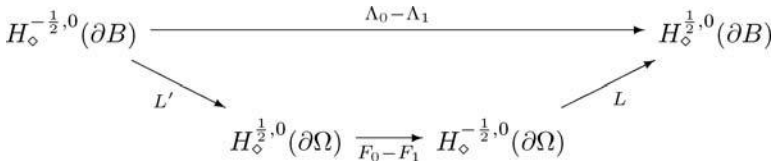

FIG. 3.1. *Factorization of* $\Lambda_0 - \Lambda_1$.

(cf. Figure 3.1), where the operator L corresponds to virtual measurements on the complement Q of the inclusion, and its range contains all information about Q and thus about the location of Ω.

Unlike previously known applications of the factorization method, the explicit time-dependence of the problem prevents us from calculating $\mathcal{R}(L)$ from the boundary measurements, but using a new approach we can show that the knowledge of $\Lambda_0 - \Lambda_1$ still suffices to determine Ω.

3.1. Factorization of the boundary measurements. We define a virtual measurement operator that corresponds to inducing a heat flux on the inclusion's boundary

$$L:\ H_\diamond^{-\frac{1}{2},0}(\partial\Omega) \to H_\diamond^{\frac{1}{2},0}(\partial B), \quad L\psi := v|_{\partial B},$$

where $v \in H_\diamond^{1,0}(Q)$ solves

$$\Delta v = 0 \text{ in } Q\times]0,T[, \quad \partial_\nu v = \begin{cases} -\psi & \text{on } \partial\Omega, \\ 0 & \text{on } \partial B. \end{cases} \tag{3.2}$$

We also need the two auxiliary operators

$$F_0:\ H^{\frac{1}{2},0}(\partial\Omega) \to H^{-\frac{1}{2},0}(\partial\Omega), \quad F_0\phi := \partial_\nu v_0^+|_{\partial\Omega},$$
$$F_1:\ H^{\frac{1}{2},0}(\partial\Omega) \to H^{-\frac{1}{2},0}(\partial\Omega), \quad F_1\phi := \partial_\nu v_1^+|_{\partial\Omega},$$

where $v_0, v_1 \in H^{1,0}(B \setminus \partial\Omega)$ solve

$$\begin{aligned} \Delta v_0 &= 0 \text{ in } (Q\cup\Omega)\times]0,T[, & [\partial_\nu v_0]_{\partial\Omega} &= 0, \\ \partial_\nu v_0|_{\partial B} &= 0, & [v_0]_{\partial\Omega} &= \phi, \end{aligned} \tag{3.3}$$

and

$$\begin{aligned} \Delta v_1 &= 0 \text{ in } Q\times]0,T[, & [\kappa\partial_\nu v_1]_{\partial\Omega} &= 0, \\ \partial_t v_1 - \nabla\cdot(\kappa\nabla v_1) &= 0 \text{ in } \Omega\times]0,T[, & [v_1]_{\partial\Omega} &= \phi, \\ v_1(x,0) &= 0 \text{ in } \Omega, & \partial_\nu v_1|_{\partial B} &= 0. \end{aligned} \tag{3.4}$$

Note that F_0 is well defined even though (3.3) determines v_0 only up to addition of a spatially constant function. Since the ranges of F_0 and F_1 are contained in $H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$ and their kernels contain $L^2(0,T,\mathbb{R})$, we will consider them as operators from

$$H_\diamond^{\frac{1}{2},0}(\partial\Omega) \text{ into } H_\diamond^{-\frac{1}{2},0}(\partial\Omega).$$

THEOREM 3.1. *The difference of the boundary measurements can be factorized into*

$$\Lambda_0 - \Lambda_1 = L(F_0 - F_1)L'.$$

The operators L *and* L' *are injective.*

Proof. For given $g \in H_\diamond^{-\frac{1}{2},0}(\partial B)$ let $w \in H_\diamond^{1,0}(Q)$ solve

$$\Delta w = 0 \text{ in } Q\times]0,T[, \text{ with } \partial_\nu w = \begin{cases} 0 & \text{on } \partial\Omega, \\ g & \text{on } \partial B. \end{cases}$$

Let $\psi \in H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$ and $v \in H_\diamond^{1,0}(Q)$ be the solution of (3.2) in the definition of $L\psi$. Then

$$\begin{aligned} \langle \psi, L'g\rangle = \langle g, L\psi\rangle = \langle \partial_\nu w|_{\partial B}, v|_{\partial B}\rangle = \int_0^T \int_Q \nabla w \cdot \nabla v \,\mathrm{d}x\,\mathrm{d}t \\ = \left\langle -\partial_\nu v^+|_{\partial\Omega}, w^+|_{\partial\Omega}\right\rangle = \left\langle \psi, w^+|_{\partial\Omega}\right\rangle, \end{aligned}$$

and thus $L'g = w^+|_{\partial\Omega}$.

Now let $v_0, v_1 \in H^{1,0}(B \setminus \partial\Omega)$ be the solutions of (3.3), resp., (3.4), from the definition of $F_0 w^+|_{\partial\Omega}$, resp., $F_1 w^+|_{\partial\Omega}$. We define $u_0, u_1 \in H^{1,0}(B \setminus \partial\Omega)$ by setting $u_i|_\Omega := -v_i|_\Omega$ and $u_i|_Q := w - v_i|_Q$, $i = 0, 1$. Then $u_0, u_1 \in H^{1,0}(B)$ and solve the equations in the definitions of $\Lambda_0 g$ and $\Lambda_1 g$. Thus

$$(\Lambda_0 - \Lambda_1)g = (u_0 - u_1)|_{\partial B} = -(v_0 - v_1)|_{\partial B}.$$

Since $\Delta(v_1 - v_0) = 0$ in $Q\times]0,T[$ and $\partial_\nu(v_1 - v_0)|_{\partial B} = 0$ we also have

$$L(\partial_\nu(v_0^+ - v_1^+)|_{\partial\Omega}) = -(v_0 - v_1)|_{\partial B},$$

and thus

$$(\Lambda_0 - \Lambda_1)g = L(\partial_\nu(v_0^+ - v_1^+)|_{\partial\Omega}) = L(F_0 - F_1)w^+|_{\partial\Omega} = L(F_0 - F_1)L'g.$$

To show injectivity of L' let $L'g = 0$ with some $g \in H_\diamond^{-\frac{1}{2},0}(\partial B)$. Then we obtain from the above characterization of L' a solution $w \in H^{1,0}(Q)$ of

$$\Delta w = 0 \quad \text{in } Q\times]0,T[, \qquad w^+|_{\partial\Omega} = 0, \quad \text{and} \quad \partial_\nu w = \begin{cases} 0 & \text{on } \partial\Omega, \\ g & \text{on } \partial B. \end{cases}$$

We set w to zero on $\Omega\times]0,T[$ and denote this continuation by $\tilde{w} \in H^{1,0}(B \setminus \partial\Omega)$. Then we have

$$\Delta\tilde{w} = 0 \quad \text{in } (B \setminus \partial\Omega)\times]0,T[, \qquad [\tilde{w}]_{\partial\Omega} = 0, \qquad [\kappa\partial_\nu\tilde{w}]_{\partial\Omega} = 0,$$

and thus $\tilde{w} \in H^{1,0}(B)$ and $\Delta\tilde{w} = 0$ in $B\times]0,T[$. Hence $\tilde{w}(\cdot,t)$ is analytic for $t \in]0,T[$ a.e. Since $\tilde{w}$ disappears on Ω and B is connected, we obtain that $w = \tilde{w} = 0$ in Q so that $g = 0$. Thus L' is injective.

The injectivity of L follows from the same arguments, when the function from the definition of L is set to zero in $(\mathbb{R}^n \setminus \overline{B})\times]0,T[$. Since Q is connected, $\mathbb{R}^n \setminus \overline{\Omega}$ is also connected. ∎

The injectivity of L and L' yields that they have dense ranges. The operator $F_0 - F_1$ satisfies a coerciveness condition; to show this we introduce the operators λ_1 and λ that correspond to measurements on the inclusion, resp., on its complement.

$$\begin{aligned} \lambda_1 :\ & H_\diamond^{-\frac{1}{2},0}(\partial\Omega) \to H^{\frac{1}{2},0}(\partial\Omega), \quad \lambda_1\psi := u_1^-|_{\partial\Omega}, \\ \lambda :\ & H_\diamond^{-\frac{1}{2},0}(\partial\Omega) \to H_\diamond^{\frac{1}{2},0}(\partial\Omega), \quad \lambda\psi := u^+|_{\partial\Omega}, \end{aligned}$$

where $u_1 \in W$ solves

$$\partial_t u_1 - \nabla \cdot (\kappa \nabla u_1) = 0 \text{ in } \Omega\times]0,T[, \quad \kappa \partial_\nu u_1^-|_{\partial\Omega} = \psi, \quad u_1(x,0) = 0 \text{ on } \Omega, \tag{3.5}$$

and $u \in H^{1,0}_\diamond(Q)$ solves

$$\Delta u = 0 \text{ in } Q\times]0,T[, \quad \partial_\nu u = \begin{cases} -\psi & \text{on } \partial\Omega, \\ 0 & \text{on } \partial B. \end{cases}$$

The unique solvability of (3.5) is shown in [8, Cor. 3.17] for general $\psi \in H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)$. In our case it can also be proven analogously to Lemmas 2.3 and 2.5.

Again we use the canonical epimorphism to restrict λ_1 to the same spaces as λ; i.e., from now on we consider it as an operator

$$\lambda_1 : \ H^{-\frac{1}{2},0}_\diamond(\partial\Omega) \to H^{\frac{1}{2},0}_\diamond(\partial\Omega).$$

LEMMA 3.2. (a) *For every $\psi \in H^{-\frac{1}{2},0}_\diamond(\partial\Omega)$ we have the identity*

$$\langle \psi, \lambda_1 \psi \rangle = \int_0^T \langle (u_1|_\Omega)', u_1|_\Omega \rangle \,\mathrm{d}t + \int_0^T \int_\Omega \kappa |\nabla u_1|^2 \,\mathrm{d}x\,\mathrm{d}t,$$

where $u_1 \in W$ is the solution of (3.5) *in the definition of λ_1.*

(b) *λ_1 is coercive with respect to $H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)$; i.e., there exists $c > 0$ such that*

$$\langle \psi, \lambda_1 \psi \rangle \geq c \, \|\psi\|^2_{H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)} \quad \textit{for all } \psi \in H^{-\frac{1}{2},0}_\diamond(\partial\Omega). \tag{3.6}$$

Proof. By setting it to zero on Q, every solution $u_1 \in W$ of (3.5) can be extended to a solution of (2.14), (2.15), and (2.19) in Theorem 2.6(a), with

$$[\kappa \partial_\nu u_1]_{\partial\Omega} = -\psi, \qquad [u_1]_{\partial\Omega} = -\lambda_1 \psi, \quad \text{and} \quad \kappa \partial_\nu u_1|_{\partial B} = 0.$$

It follows that

$$\int_\Omega u_1(x,t) \,\mathrm{d}x = 0 \quad \text{for } t \in [0,T] \text{ a.e.}, \tag{3.7}$$

and with $u_f \in H^{1,0}(B \setminus \partial\Omega)$ such that $u_f|_{\partial B} = 0$, $u_f|_{\partial\Omega} = -\lambda_1\psi$, and $u_f|_\Omega = 0$ we obtain from the variational formulation for $\tilde{u} := u_1 - u_f$ in Theorem 2.6(b)

$$\int_0^T \langle (\tilde{u}|_\Omega)', \tilde{u}|_\Omega \rangle \,\mathrm{d}t + \int_0^T \int_B \kappa |\nabla \tilde{u}|^2 \,\mathrm{d}x\,\mathrm{d}t = \int_0^T \langle \psi, \tilde{u}|_{\partial\Omega} \rangle \,\mathrm{d}t - \int_0^T \int_Q \kappa \nabla u_f \cdot \nabla \tilde{u} \,\mathrm{d}x\,\mathrm{d}t.$$

Using $\tilde{u}|_{\partial\Omega} = \lambda_1\psi$, $u_f|_\Omega = 0$, and $u_1|_Q = 0$ we conclude that

$$\langle \psi, \lambda_1 \psi \rangle = \int_0^T \langle (u_1|_\Omega)', u_1|_\Omega \rangle \,\mathrm{d}t + \int_0^T \int_\Omega \kappa |\nabla u_1|^2 \,\mathrm{d}x\,\mathrm{d}t,$$

and thus (a) holds.

Because of (3.7) Poincaré's inequality yields the existence of a $c' > 0$ such that

$$\langle \psi, \lambda_1 \psi \rangle \geq c' \, \|u_1\|^2_{H^{1,0}(\Omega)},$$

and so assertion (b) follows from the continuity of the Neumann trace in Theorem 2.1(c). □

LEMMA 3.3. *There exists $c' > 0$ such that*

$$\langle (F_0 - F_1)\phi, \phi \rangle \geq c' \, \|F_1 \phi\|^2_{H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)},$$

and F_1 is bijective with $F_1^{-1} = -\lambda - \lambda_1$.

Proof. For given $\phi \in H^{\frac{1}{2},0}(\partial\Omega)$ let $v_0, v_1 \in H^{1,0}(B \setminus \partial\Omega)$ be the solutions of (3.3) and (3.4) in the definition of F_0 and F_1, and let $v_\phi \in H^{1,0}(B \setminus \partial\Omega)$ be such that $v_\phi^+|_{\partial\Omega} = \phi$, $v_\phi|_{\partial B} = 0$, and $v_\phi|_\Omega = 0$.

Then $\tilde{v}_i := v_i - v_\phi$, $i = 0, 1$, solve

$$\int_0^T \int_B \nabla \tilde{v}_0 \cdot \nabla w \, \mathrm{d}x \, \mathrm{d}t = -\int_0^T \int_Q \nabla v_\phi \cdot \nabla w \, \mathrm{d}x \, \mathrm{d}t,$$

$$\int_0^T \langle (\tilde{v}_1|_\Omega)', w|_\Omega \rangle \, \mathrm{d}t + \int_0^T \int_B \kappa \nabla \tilde{v}_1 \cdot \nabla w \, \mathrm{d}x \, \mathrm{d}t = -\int_0^T \int_Q \nabla v_\phi \cdot \nabla w \, \mathrm{d}x \, \mathrm{d}t$$

for all $w \in H^{1,0}(B)$ (cf. Theorem 2.6 for the second equation). From the Lax–Milgram theorem it follows that for $t \in]0, T[$ a.e. $\tilde{v}_0(\cdot, t)$ minimizes the functional

$$w \mapsto \frac{1}{2} \int_B |\nabla w(x)|^2 \, \mathrm{d}x + \int_Q \nabla v_\phi(x,t) \cdot \nabla w(x) \, \mathrm{d}x$$

in $H^1(B)$ so that

$$\begin{aligned}
&\int_0^T \int_B |\nabla \tilde{v}_0|^2 \, \mathrm{d}x \, \mathrm{d}t \\
&= -2 \left(-\frac{1}{2} \int_0^T \int_B |\nabla \tilde{v}_0|^2 \, \mathrm{d}x \, \mathrm{d}t + \int_0^T \int_Q \nabla v_\phi \cdot \nabla \tilde{v}_0 \, \mathrm{d}x \, \mathrm{d}t \right) \\
&\geq -2 \left(\frac{1}{2} \int_0^T \int_B |\nabla \tilde{v}_1|^2 \, \mathrm{d}x \, \mathrm{d}t + \int_0^T \int_Q \nabla v_\phi \cdot \nabla \tilde{v}_1 \, \mathrm{d}x \, \mathrm{d}t \right) \\
&= -\int_0^T \int_B |\nabla \tilde{v}_1|^2 \, \mathrm{d}x \, \mathrm{d}t + 2 \int_0^T \int_B \kappa |\nabla \tilde{v}_1|^2 \, \mathrm{d}x \, \mathrm{d}t + 2 \int_0^T \langle (\tilde{v}_1|_\Omega)', \tilde{v}_1|_\Omega \rangle \, \mathrm{d}t
\end{aligned}$$

and thus

$$\begin{aligned}
&\langle (F_0 - F_1)\phi, \phi \rangle \\
&= \langle \partial_\nu v_0^+, \phi \rangle - \langle \partial_\nu v_1^+, \phi \rangle = \int_0^T \int_Q \nabla v_1 \cdot \nabla v_\phi \, \mathrm{d}x \, \mathrm{d}t - \int_0^T \int_Q \nabla v_0 \cdot \nabla v_\phi \, \mathrm{d}x \, \mathrm{d}t \\
&= \int_0^T \int_Q \nabla v_\phi \cdot \nabla \tilde{v}_1 \, \mathrm{d}x \, \mathrm{d}t - \int_0^T \int_Q \nabla v_\phi \cdot \nabla \tilde{v}_0 \, \mathrm{d}x \, \mathrm{d}t \\
&= \int_0^T \int_B |\nabla \tilde{v}_0|^2 \, \mathrm{d}x \, \mathrm{d}t - \int_0^T \int_B \kappa |\nabla \tilde{v}_1|^2 \, \mathrm{d}x \, \mathrm{d}t - \int_0^T \langle (\tilde{v}_1|_\Omega)', \tilde{v}_1|_\Omega \rangle \, \mathrm{d}t \\
&\geq \int_0^T \int_\Omega (\kappa - 1) |\nabla \tilde{v}_1|^2 \, \mathrm{d}x \, \mathrm{d}t + \int_0^T \langle (\tilde{v}_1|_\Omega)', \tilde{v}_1|_\Omega \rangle \, \mathrm{d}t.
\end{aligned}$$

Using $\kappa|_\Omega - 1 \in L^\infty_+(\Omega)$, $\int_0^T \langle (\tilde{v}_1|_\Omega)', \tilde{v}_1|_\Omega \rangle \, \mathrm{d}t \geq 0$, $\tilde{v}_1|_\Omega = v_1|_\Omega$, and Lemma 3.2(a) we conclude that there exists $c_\kappa > 0$ such that

$$\begin{aligned}\langle (F_0 - F_1)\phi, \phi \rangle &\geq c_\kappa \left(\int_0^T \int_\Omega \kappa |\nabla \tilde{v}_1|^2 + \int_0^T \langle (\tilde{v}_1|_\Omega)', \tilde{v}_1|_\Omega \rangle \, \mathrm{d}t \right) \\ &= c_\kappa \left\langle \left(\kappa \partial_\nu \tilde{v}_1^-|_{\partial\Omega}\right), \lambda_1 \left(\kappa \partial_\nu \tilde{v}_1^-|_{\partial\Omega}\right) \right\rangle = c_\kappa \left\langle \left(\partial_\nu v_1^+|_{\partial\Omega}\right), \lambda_1 \left(\partial_\nu v_1^+|_{\partial\Omega}\right) \right\rangle \\ &= c_\kappa \left\langle F_1\phi, \lambda_1 F_1 \phi \right\rangle,\end{aligned}$$

and so the first assertion follows from Lemma 3.2(b). To show surjectivity of F_1 let $\psi \in H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$ and denote by $u \in H^{1,0}(Q)$, $u_1 \in W$ the functions from the definition of $\lambda\psi$ and $\lambda_1\psi$.

Define $v_1 \in H^{1,0}(B \setminus \partial\Omega)$ by setting $v_1 := -u$ on Q and $v_1 := u_1$ on Ω. Then v_1 solves the equations in the definition of F_1 with $[v_1]_{\partial\Omega} = (-\lambda - \lambda_1)\psi$ (up to a spatially constant function) and thus $F_1(-\lambda - \lambda_1)\psi = \partial_\nu u_1^+|_{\partial\Omega} = \psi$.

It remains to show injectivity of F_1. To this end let $F_1\phi = 0$ and $v_1 \in H^{1,0}(B\setminus\partial\Omega)$ be the function from the definition of F_1. Then v_1 solves the Laplace equation on Q and the heat equation on Ω each with zero Neumann boundary values. Thus it vanishes on Ω and is spatially constant on Q, which implies that $\phi \in L^2(0,T,\mathbb{R})$. ∎

3.2. Range characterization. Lemma 3.3 implies that the symmetric part of $F_0 - F_1$ is positive and thus also the symmetric part of $\Lambda_0 - \Lambda_1$ is positive. Identifying Hilbert spaces with their duals, these operators have positive square roots, and their ranges can be related. The key to provide this relation is the following lemma that has been used by Brühl to extend the factorization method to the case of nonconstant conductivities in EIT [4, Satz 4.9]. We state it in the form in which it is called the "14th important property of Banach spaces" in [3] and give an elementary proof for the sake of completeness.

LEMMA 3.4. *Let X,Y be two Banach spaces, and let $A \in \mathcal{L}(X;Y)$ and $x' \in X'$. Then*

$$x' \in \mathcal{R}(A') \text{ if and only if } \exists C > 0 \,:\, |\langle x', x\rangle| \leq C \, \|Ax\| \text{ for all } x \in X.$$

Proof. If $x' \in \mathcal{R}(A')$ then there exists $y' \in Y'$ such that $x' = A'y'$. Thus

$$|\langle x', x\rangle| = |\langle y', Ax\rangle| \leq \|y'\| \, \|Ax\| \text{ for all } x \in X,$$

and the assertion holds with $C = \|y'\|$.

Now let $x' \in X'$ such that there exists $C > 0$ with $|\langle x', x\rangle| \leq C \, \|Ax\|$ for all $x \in X$. Define

$$f(z) := \langle x', x\rangle \text{ for every } z = Ax \in \mathcal{R}(A).$$

Then f is a well-defined, continuous, linear functional, with $\|f(z)\| \leq C \, \|z\|$. Using the Hahn–Banach theorem there exists $y' \in Y'$ with $y'|_{\mathcal{R}(A)} = f$. For all $x \in X$ we have

$$\langle A'y', x\rangle = \langle y', Ax\rangle = f(A(x)) = \langle x', x\rangle$$

and thus $x' = A'y' \in \mathcal{R}(A')$. ∎

We will make use of the following simple corollary.

COROLLARY 3.5. *Let H_i, $i = 1, 2$, be Hilbert spaces with norms $\|\cdot\|_i$, X be a third Hilbert space, and $A_i \in \mathcal{L}(X, H_i)$.*

If $\|A_1 x\|_1 \le \|A_2 x\|_2$ *for all* $x \in X$, *then* $\mathcal{R}(A_1^*) \subseteq \mathcal{R}(A_2^*)$.

Proof. Since $A_i' \iota_{H_1} = \iota_X A_i^*$, $i = 1, 2$, $y \in \mathcal{R}(A_1^*)$ implies $\iota_X y \in \mathcal{R}(A_1')$. Using Lemma 3.4 there exists $C > 0$ such that

$$|\langle \iota_X y, x\rangle| \le C \|A_1 x\|_1 \le C \|A_2 x\|_2 \text{ for all } x \in X,$$

and thus $\iota_X y \in \mathcal{R}(A_2')$, which implies $y \in \mathcal{R}(A_2^*)$. ∎

Note that in particular $A_1^* A_1 = A_2^* A_2$ implies $\mathcal{R}(A_1^*) = \mathcal{R}(A_2^*)$ (cf. [11]). Following the argument in [12] we can use Corollary 3.5 to characterize the range of the virtual measurement operator L by reformulating the symmetric part of (3.1) using adjoint operators.

We set

$$\begin{array}{rclcrcl} \Lambda & := & \Lambda_0 - \frac{1}{2}(\Lambda_1 + \Lambda_1'), & & \tilde{\Lambda} & = & \Lambda \iota_{H_\diamond^{1/2,0}(\partial B)}, \\ F & := & F_0 - \frac{1}{2}(F_1 + F_1'), & & \tilde{F} & = & \iota^{-1}_{H_\diamond^{1/2,0}(\partial\Omega)} F. \end{array}$$

LEMMA 3.6. *$\tilde{\Lambda}$ and $\tilde{F}$ are self-adjoint and positive operators and their square roots satisfy*

$$\mathcal{R}(\tilde{\Lambda}^{1/2}) = \mathcal{R}(L \iota_{H_\diamond^{1/2,0}(\partial\Omega)} \tilde{F}^{1/2}).$$

Proof. By construction $\tilde{\Lambda}$ and $\tilde{F}$ are self-adjoint and positive. From Theorem 3.1 it follows that

$$\begin{aligned} \tilde{\Lambda}^{1/2}\tilde{\Lambda}^{1/2} = \tilde{\Lambda} &= L \iota_{H_\diamond^{1/2,0}(\partial\Omega)} \tilde{F} L' \iota_{H_\diamond^{1/2,0}(\partial B)} \\ &= \left(L \iota_{H_\diamond^{1/2,0}(\partial\Omega)}\right) \tilde{F} \left(L \iota_{H_\diamond^{1/2,0}(\partial\Omega)}\right)^* \\ &= \left(L \iota_{H_\diamond^{1/2,0}(\partial\Omega)}\right) \tilde{F}^{1/2} \tilde{F}^{1/2} \left(L \iota_{H_\diamond^{1/2,0}(\partial\Omega)}\right)^*. \end{aligned}$$

The assertion now follows from Corollary 3.5. ∎

If F were coercive with respect to the space $H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$, we would obtain surjectivity of $\tilde{F}^{1/2}$ and thus the range characterization $\mathcal{R}(\tilde{\Lambda}^{1/2}) = \mathcal{R}(L)$ that was used in previous applications of the factorization method. In our situation we have only the weaker coercivity condition from Lemma 3.3. The next theorem shows that this weaker condition is still enough to guarantee that $\mathcal{R}(\tilde{F}^{1/2})$ contains all functions of a certain time regularity, which turns out to be sufficient for the method to work.

THEOREM 3.7.

$$\mathcal{R}(\tilde{\Lambda}^{1/2}) \subseteq \mathcal{R}(L) = L\left(H_\diamond^{-\frac{1}{2},0}(\partial\Omega)\right), \tag{3.8}$$

$$\mathcal{R}(\tilde{\Lambda}^{1/2}) \supseteq \qquad L\left(H^{\frac{1}{4}}(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega))\right). \tag{3.9}$$

Proof. Equation (3.8) immediately follows from Lemma 3.6.

Denote by $j\colon H_\diamond^{-\frac{1}{2},0}(\partial\Omega) \hookrightarrow H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)$ the imbedding operator. Using Lemma 3.3 we have for all $\phi \in H_\diamond^{\frac{1}{2},0}(\partial\Omega)$

$$\left\|\tilde{F}^{1/2}\phi\right\|^2_{H_\diamond^{\frac{1}{2},0}(\partial\Omega)} = \left(\tilde{F}\phi, \phi\right)_{H_\diamond^{\frac{1}{2},0}(\partial\Omega)} \ge c' \|jF_1\phi\|^2_{H^{-\frac{1}{2},-\frac{1}{4}}(\partial\Omega)}.$$

Since $F_1^* j^* = \iota^{-1}_{H^{1/2,0}_\diamond(\partial\Omega)} F_1' j' \iota_{H^{-1/2,-1/4}(\partial\Omega)}$ we obtain from Corollary 3.5

$$\mathcal{R}\left(\tilde{F}^{1/2}\right) \supseteq \mathcal{R}(F_1^* j^*) = \mathcal{R}\left(\iota^{-1}_{H^{1/2,0}_\diamond(\partial\Omega)} F_1' j'\right)$$

and from Lemma 3.6

$$\mathcal{R}(\tilde{\Lambda}^{1/2}) = \mathcal{R}(L\iota_{H^{1/2,0}_\diamond(\partial\Omega)}\tilde{F}^{1/2}) \supseteq \mathcal{R}(LF_1' j').$$

Using Lemma 3.4 it is easily seen that

$$\mathcal{R}(j') = H^{\frac{1}{2},\frac{1}{4}}_\diamond(\partial\Omega) := (H^{\frac{1}{2},\frac{1}{4}}(\partial\Omega) + L^2(0,T,\mathbb{R}))/L^2(0,T,\mathbb{R}) \subset H^{\frac{1}{2},0}_\diamond(\partial\Omega).$$

(Note that by this definition $H^{\frac{1}{2},\frac{1}{4}}_\diamond(\partial\Omega)$ is isomorphic to $H^{\frac{1}{2},\frac{1}{4}}(\partial\Omega)/H^{\frac{1}{4}}(0,T,\mathbb{R})$.)

Using Lemma 3.3 we have $(F_1')^{-1} = -\lambda' - \lambda_1'$. Since $\lambda = \lambda'$ and $\mathcal{R}(\lambda_1') \subseteq H^{\frac{1}{2},\frac{1}{4}}_\diamond(\partial\Omega)$ (cf. [8]) it remains only to show that

$$\lambda\left(H^{\frac{1}{4}}(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega))\right) \subseteq H^{\frac{1}{2},\frac{1}{4}}_\diamond(\partial\Omega). \tag{3.10}$$

To this end denote by $\overline{\lambda}:\ H_\diamond^{-\frac{1}{2}}(\partial\Omega) \to H^{\frac{1}{2}}_\diamond(\partial\Omega)$, $\overline{\psi} \mapsto \overline{u}^+|_{\partial\Omega}$, where $\overline{u} \in H^1_\diamond(Q)$ solves

$$\Delta\overline{u} = 0 \text{ in } Q, \quad \partial_\nu \overline{u} = \begin{cases} -\overline{\psi} & \text{on } \partial\Omega, \\ 0 & \text{on } \partial B. \end{cases}$$

Then for every $\psi \in H^1(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega))$ and $\varphi \in \mathcal{D}(]0,T[)$

$$\begin{aligned}\int_0^T (-1)(\lambda\psi)\varphi'\,\mathrm{d}t &= \overline{\lambda}\left(\int_0^T (-1)\psi\varphi'(t)\,\mathrm{d}t\right) = \overline{\lambda}\left(\int_0^T \psi'\varphi(t)\,\mathrm{d}t\right) \\ &= \int_0^T (\lambda\psi')\varphi\,\mathrm{d}t \in H^{\frac{1}{2}}_\diamond(\partial\Omega).\end{aligned}$$

Thus $\lambda\psi \in H^1(0,T,H^{\frac{1}{2}}_\diamond(\partial\Omega))$ with $(\lambda\psi)' = \lambda(\psi')$, which shows that λ is a continuous operator not only from $L^2(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega))$ to $L^2(0,T,H^{\frac{1}{2}}_\diamond(\partial\Omega))$ but also from $H^1(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega))$ to $H^1(0,T,H^{\frac{1}{2}}_\diamond(\partial\Omega))$.

By interpolation (cf. [21]) λ is a continuous operator from

$$H^{\frac{1}{4}}(0,T,H_\diamond^{-\frac{1}{2}}(\partial\Omega)) \to H^{\frac{1}{4}}(0,T,H^{\frac{1}{2}}_\diamond(\partial\Omega)) \subset H^{\frac{1}{2},\frac{1}{4}}_\diamond(\partial\Omega).$$

Thus (3.10) holds and the assertion follows. ∎

3.3. Characterization of the inclusion. The composition of time integration and the (compact) imbedding $H^{\frac{1}{2}}_\diamond(\partial B) \hookrightarrow L^2_\diamond(\partial B) := L^2(\partial B)/\mathbb{R}$ defines the operator

$$I:\ H^{\frac{1}{2},0}_\diamond(\partial B) \to L^2_\diamond(\partial B), \quad u \mapsto \int_0^T u(\cdot,t)\,\mathrm{d}t.$$

Identifying $L^2_\diamond(\partial B)$ with its dual we have

$$I\tilde{\Lambda}I^* = I\Lambda I', \tag{3.11}$$

where $I' : L^2_\diamond(\partial B) \to H^{-\frac{1}{2},0}_\diamond(\partial B)$ is given by

$$I'v = w, \text{ with } w(\cdot,t) = v(\cdot) \text{ for } t \in [0,T] \text{ a.e.}$$

The operator $I\Lambda I'$ corresponds to measurements of applying temporal constant (and spatially square integrable) heat fluxes to a body and measuring time integrals of the resulting temperature on the boundary.

We use the same dipole functions as Brühl and Hanke used in [13] for the implementation of the factorization method in EIT. For a direction $d \in \mathbb{R}^n$, $|d| = 1$, and a point $z \in B$ let

$$D_{z,d}(x) := \frac{(z-x)\cdot d}{|z-x|^n}.$$

Then $D_{z,d}(x)$ is analytic and $\Delta D_{z,d}(x) = 0$ in $\mathbb{R}^n \setminus \{z\}$. Moreover, using a ball $B_\epsilon(z)$ centered at z with such small radius $\epsilon > 0$ such that $\overline{B_\epsilon(z)} \subset B$,

$$\int_{\partial B} \partial_\nu D_{z,d}(x)\,\mathrm{d}x = \int_{\partial B_\epsilon(z)} \partial_\nu D_{z,d}(x)\,\mathrm{d}x = 0,$$

so in particular $\partial_\nu D_{z,d} \in H^{-\frac{1}{2}}_\diamond(\partial B)$ and there exists $v_{z,d} \in H^1(B)$ that solves

$$\Delta v_{z,d} = 0 \text{ in } B \quad \text{ and } \quad \partial_\nu v_{z,d} = -\partial_\nu D_{z,d} \text{ on } \partial B.$$

Now $H_{z,d} := D_{z,d} + v_{z,d}$ is harmonic (and thus analytic) in $B \setminus \{z\}$ with $\partial_\nu H_{z,d}|_{\partial B} = 0$ but $H_{z,d} \notin L^2(B \setminus \{z\})$. The inclusion can now be characterized by the traces $h_{z,d} := H_{z,d}|_{\partial B} \in H^{\frac{1}{2}}_\diamond(\partial B)$ (again we use the same notation for the equivalence class of functions that are identical up to addition of constant functions as we used for the original function).

THEOREM 3.8. *For every $d \in \mathbb{R}^n$, $|d| = 1$, and $z \in B$*

$$z \in \Omega \text{ if and only if } h_{z,d} \in \mathcal{R}\left((I\Lambda I')^{1/2}\right).$$

Proof. From Corollary 3.5 and (3.11) it follows that $\mathcal{R}\left((I\Lambda I')^{1/2}\right) = \mathcal{R}(I\tilde{\Lambda}^{1/2})$ and consequently from Theorem 3.7 we obtain

$$\begin{aligned}
\mathcal{R}\left((I\Lambda I')^{1/2}\right) &\subseteq IL\left(H^{-\frac{1}{2},0}_\diamond(\partial\Omega)\right),\\
\mathcal{R}\left((I\Lambda I')^{1/2}\right) &\supseteq IL\left(H^{\frac{1}{4}}(0,T,H^{-1/2}_\diamond(\partial\Omega))\right).
\end{aligned}$$

First let $z \in \Omega$; then we define $w \in H^{1,0}_\diamond(Q)$ by $w(x,t) := H_{z,d}(x)/T$ for $t \in [0,T]$ a.e. Then $-\partial_\nu w^+|_{\partial\Omega} \in H^{\frac{1}{4}}(0,T,H^{-1/2}_\diamond(\partial\Omega))$ and w solves (3.2) in the definition of L, so

$$\begin{aligned}
h_{z,d} = Iw|_{\partial B} &= IL(-\partial_\nu w^+|_{\partial\Omega})\\
&\in IL\left(H^{\frac{1}{4}}(0,T,H^{-1/2}_\diamond(\partial\Omega))\right) \subseteq \mathcal{R}\left((I\Lambda I')^{1/2}\right).
\end{aligned}$$

To show the converse let $h_{z,d} \in \mathcal{R}\left((I\Lambda I')^{1/2}\right) \subseteq IL(H^{-\frac{1}{2},0}_\diamond(\partial\Omega))$. Then $h_{z,d}$ coincides with the integral of the trace of a solution of the Laplace equation on Q with vanishing

Neumann boundary values. Taking the integral of that solution we have that $h_{z,d} = w|_{\partial B}$, with some

$$w \in H^1_\diamond(Q) \text{ that solves } \Delta w = 0 \text{ on } Q,\ \partial_\nu w = 0 \text{ on } \partial B.$$

As $H_{z,d}$ and w are both harmonic on $Q \setminus \{z\}$ with the same Cauchy data on ∂B, they coincide near ∂B and thus by analytic continuation on $Q \setminus \{z\}$. If $z \notin \Omega$ this leads to the contradiction that $w \in L^2_\diamond(Q \setminus \{z\})$ but $H_{z,d} \notin L^2_\diamond(Q \setminus \{z\})$. ∎

By construction $I\Lambda I'$ is a compact and self-adjoint operator and from the factorization and the positiveness of F it follows that it is positive. Since $I\Lambda I'g = 0$ implies that $\langle FL'I'g, L'I'g\rangle = 0$ and thus $L'I'g = 0$, we also obtain injectivity of $I\Lambda I'$ from the injectivity of L' and I'. Hence there exists an orthonormal basis $(v_k)_{k\in\mathbb{N}}$ of eigenfunctions with associated positive eigenvalues $(\lambda_k)_{k\in N}$. Following [13] we use this spectral decomposition to reformulate Theorem 3.8 with the Picard criterion.

COROLLARY 3.9. *For every $d \in \mathbb{R}^n$, $|d| = 1$, and $z \in B$*

$$z \in \Omega \text{ if and only if } \sum_{k\in\mathbb{N}} \frac{1}{\lambda_k} \left(\int_{\partial B} h_{z,d} v_k \,\mathrm{d}x \right)^2 < \infty.$$

We remark that the results of this subsection remain valid with identical proofs when I is replaced by

$$I_S :\ H^{\frac{1}{2},0}_\diamond(\partial B) \to L^2_\diamond(S), \quad u \mapsto \int_0^T u|_S(\cdot,t)\,\mathrm{d}t,$$

where S is a relatively open subset of the boundary ∂B. Thus Ω is uniquely determined by $I_S \Lambda I_S'$, i.e., by measurements of applying (temporal constant) heat fluxes on a part of the boundary and measuring (time integrals of) the resulting temperature on the same part; cf., e.g., [14, 24, 25] for corresponding results in impedance tomography and the effect of partial boundary data on numerical reconstructions.

4. Numerics.

4.1. The direct problem. In this section we show how the direct problem can be solved numerically with a coupling of a finite element method and a boundary element method similar to [9]. We start by reformulating the direct problem.

4.1.1. Reformulation of the direct problem. Recall that λ was defined by

$$\lambda :\ H^{-\frac{1}{2},0}_\diamond(\partial\Omega) \to H^{\frac{1}{2},0}_\diamond(\partial\Omega), \quad \lambda\psi := \eta^+|_{\partial\Omega}\,,$$

where $\eta \in H^{1,0}_\diamond(Q)$ solves

$$\Delta\eta = 0 \text{ in } Q, \quad \partial_\nu \eta = \begin{cases} -\psi & \text{on } \partial\Omega\,, \\ 0 & \text{on } \partial B\,. \end{cases}$$

We use the same notation for the time-independent Neumann–Dirichlet operator

$$\lambda :\ H^{-\frac{1}{2}}_\diamond(\partial\Omega) \to H^{\frac{1}{2}}_\diamond(\partial\Omega).$$

Note that λ is linear, continuous, and coercive, i.e., $\langle \psi, \lambda\psi\rangle \geq c\|\psi\|^2_{H^{-\frac{1}{2}}_\diamond(\partial\Omega)}$.

For the rest of this section we assume that $g \in H_\diamond^{-\frac{1}{2},0}(\partial B)$ and $\xi = \xi(g) \in H_\diamond^{1,0}(Q)$ solves

$$\Delta\xi = 0 \text{ in } Q, \quad \partial_\nu \xi = \begin{cases} 0 & \text{on } \partial\Omega\,, \\ g & \text{on } \partial B\,. \end{cases}$$

THEOREM 4.1. *If $u \in H^{1,0}(B)$ solves (2.5)–(2.8), (2.11), and (2.12), then $v := u|_\Omega$ and $\phi := -\kappa\partial_\nu u^-|_{\partial\Omega}$ satisfy*

$$\partial_t v - \nabla\cdot(\kappa\,\nabla v) = 0 \text{ in } \Omega\times]0,T[, \tag{4.1}$$

$$v^-|_{\partial\Omega} - \lambda\phi = \xi^+|_{\partial\Omega} \text{ in } H_\diamond^{\frac{1}{2},0}(\partial\Omega), \tag{4.2}$$

$$v(x,0) = 0 \text{ in } \Omega\,. \tag{4.3}$$

On the other hand, if $(v,\phi) \in H^{1,0}(\Omega)\times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$ solves (4.1)–(4.3) and

$$\kappa\partial_\nu v^-|_{\partial\Omega} = -\phi, \tag{4.4}$$

then there exists $u \in H^{1,0}(B)$ that solves (2.5)–(2.8), (2.11), (2.12), and $v = u|_\Omega$. Moreover $u|_Q \in H^{1,0}(Q)$ is the representant of $\xi+\eta \in H_\diamond^{1,0}(Q)$ with $\int_{\partial\Omega} u^+|_{\partial\Omega}\,\mathrm{d}s = \int_{\partial\Omega} u^-|_{\partial\Omega}\,\mathrm{d}s$, where η is as in the definition of $\lambda\phi$.

Proof. The proof immediately follows from the definitions of ξ and λ. □

THEOREM 4.2. *The following problems are equivalent:*

(a) *$(u,\phi) \in H^{1,0}(\Omega)\times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$ solves (4.1)–(4.4).*

(b) *$(u,\phi) \in W \times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$, $u(x,0) = 0$ in Ω, and (u,ϕ) solves*

$$\begin{aligned} &\int_0^T \langle u', v\rangle\,\mathrm{d}t + \int_0^T\int_\Omega \kappa\nabla u\cdot\nabla v\,\mathrm{d}x\,\mathrm{d}t + \int_0^T \langle \phi, v^-|_{\partial\Omega}\rangle\,\mathrm{d}t \\ &- \int_0^T \langle\tilde\psi, \lambda\phi\rangle\,\mathrm{d}t + \int_0^T \langle\tilde\psi, u^-|_{\partial\Omega}\rangle\,\mathrm{d}t = \int_0^T \langle\tilde\psi, \xi^+|_{\partial\Omega}\rangle\,\mathrm{d}t \end{aligned} \tag{4.5}$$

for all $v \in H^{1,0}(\Omega)$ and for all $\tilde\psi \in H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$.

(c) *$(u,\phi) \in W \times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$, $u(x,0) = 0$ in Ω, and (u,ϕ) solves*

$$\begin{aligned} &\langle u'(t), v\rangle + \int_\Omega \kappa\nabla u(t)\cdot\nabla v\,\mathrm{d}x + \langle\phi(t), v^-|_{\partial\Omega}\rangle - \langle\tilde\psi, \lambda\phi(t)\rangle + \langle\tilde\psi, u(t)^-|_{\partial\Omega}\rangle \\ &\qquad = \langle\tilde\psi, \xi(t)^+|_{\partial\Omega}\rangle \end{aligned} \tag{4.6}$$

for $t \in [0,T]$ a.e. and for all $v \in H^1(\Omega)$ and for all $\tilde\psi \in H_\diamond^{-\frac{1}{2}}(\partial\Omega)$.

Proof. (a)⇔(b) can be shown analogously to the proof of Theorem 2.6.

To show (b)⇔(c), note that (4.6) is fulfilled for $t \in [0,T]$ a.e. if and only if it is fulfilled in the sense of $L^2([0,T])$. The equivalence then follows from the fact that $L^2([0,T])\otimes H^1(\Omega)$, resp., $L^2([0,T])\otimes H_\diamond^{-\frac{1}{2}}(\partial\Omega)$, are dense in $H^{1,0}(\Omega)$, resp., $H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$. □

4.1.2. Implementation and convergence analysis of the reformulated problem. Let $\{H_h,\, h>0\}$ and $\{B_h,\, h>0\}$ be families of finite dimensional subspaces of $H^1(\Omega)$ and $H_\diamond^{-\frac{1}{2}}(\partial\Omega)$, respectively. Accordingly the family of L^2-projections $P_h : H^1(\Omega) \to H_h$ is defined by $\int_\Omega P_h v w_h\,\mathrm{d}x = \int_\Omega v w_h\,\mathrm{d}x$ for all $w_h \in H_h$. We assume

that P_h satisfies the following estimate: There exists a constant $\gamma > 0$, independent of h, such that

$$\sup_{v \in H^1(\Omega)} \frac{\|P_h v\|_{H^1(\Omega)}}{\|v\|_{H^1(\Omega)}} \leq \gamma \quad \text{for all } h > 0\,. \tag{4.7}$$

For example, let $\mathcal{T}$ be a regular triangulation of Ω with generic mesh spacing h and H_h be a space of piecewise linear polynomials on $\mathcal{T}$. Then following [23] the operator P_h fulfills (4.7).

We consider the following Galerkin scheme.

Find $u_h : [0,T] \to H_h$, $\phi_h : [0,T] \to B_h$ such that

$$\begin{aligned} \langle u_h', v_h \rangle + \int_\Omega \kappa \nabla u_h \cdot \nabla v_h \,\mathrm{d}x + \langle \phi_h, v_h^-|_{\partial\Omega} \rangle \\ - \langle \psi_h, \lambda \phi_h \rangle + \langle \psi_h, u_h^-|_{\partial\Omega} \rangle \quad = \quad \langle \psi_h, \xi^+|_{\partial\Omega} \rangle \end{aligned} \tag{4.8}$$

for all $(v_h, \psi_h) \in H_h \times B_h$, $t \in [0,T]$ a.e., and $u_h(0) = 0$.

LEMMA 4.3. *For every $h > 0$ the Galerkin scheme* (4.8) *has a unique solution in $H_h^T \times B_h^T$, where*

$$\begin{aligned} H_h^T &:= \left\{ u \in L^2(0,T,H_h) : u' \in L^2(0,T,H_h), u(x,0) = 0 \right\} \subset W, \\ B_h^T &:= L^2(0,T,B_h) \subset H_\diamond^{-\frac{1}{2},0}(\partial\Omega). \end{aligned}$$

Proof. Let $(w_k)_{k=1}^{n_h}$ be a basis of H_h which is orthonormal with respect to the $L^2(\Omega)$ scalar product and $(\psi_j)_{j=1}^{m_h}$ be a basis of B_h. Moreover, if we write $u_h(x,t) = \sum_{k=1}^{n_h} \alpha_k(t) w_k(x)$ and $\phi_h(x,t) = \sum_{j=1}^{m_h} \beta_j(t) \psi_j(x)$, then (4.8) is equivalent to

$$\partial_t \alpha(t) + K\alpha(t) + B\beta(t) = 0\,, \quad \alpha(0) = 0\,, \tag{4.9}$$

and

$$D\beta(t) - B^T \alpha(t) = d(t), \tag{4.10}$$

where $\alpha = (\alpha_1, \ldots, \alpha_{n_h})^T$ and $\beta = (\beta_1, \ldots, \beta_{m_h})^T$. Since λ is linear and coercive we can solve (4.10) for β in terms of α and substitute into (4.9) to obtain a system of ODEs for α. According to standard existence theory for ODEs, there exists a unique absolutely continuous solution α. ∎

LEMMA 4.4. *Assume that $(w_h, \zeta_h) \in H_h^T \times B_h^T$, $\zeta \in H_\diamond^{-\frac{1}{2},0}(\partial\Omega)$, $w \in W$ with $w(x,0) = 0$ in Ω. Moreover assume that the following equation is fulfilled:*

$$\begin{aligned} &\langle w_h', v_h \rangle + \int_\Omega \kappa \nabla w_h \cdot \nabla v_h \,\mathrm{d}x + \langle \zeta_h, v_h^-|_{\partial\Omega} \rangle - \langle \psi_h, \lambda \zeta_h \rangle + \langle \psi_h, w_h^-|_{\partial\Omega} \rangle \\ &= \langle w', v_h \rangle + \int_\Omega \kappa \nabla w \cdot \nabla v_h \,\mathrm{d}x + \langle \zeta, v_h^-|_{\partial\Omega} \rangle - \langle \psi_h, \lambda \zeta \rangle + \langle \psi_h, w^-|_{\partial\Omega} \rangle \end{aligned} \tag{4.11}$$

for $t \in [0,T]$ a.e. and for all $(v_h, \psi_h) \in H_h \times B_h$. Then there exists $c > 0$ independent of h such that

$$\|w_h\|_W + \|\zeta_h\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \leq c \left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \right).$$

Proof. 1. We use $(v_h, \psi_h) = (w_h, -\zeta_h)$ in (4.11) and obtain for $t \in [0,T]$ a.e.

$$\begin{aligned}
&\langle w_h', w_h\rangle + \int_\Omega \kappa|\nabla w_h|^2 \,\mathrm{d}x + \langle \zeta_h, \lambda\zeta_h\rangle \\
&= \langle w', w_h\rangle + \int_\Omega \kappa\nabla w\cdot\nabla w_h \,\mathrm{d}x + \langle \zeta, w_h^-|_{\partial\Omega}\rangle + \langle \zeta_h, \lambda\zeta\rangle - \langle \zeta_h, w^-|_{\partial\Omega}\rangle \\
&\le c_1\left(\|w'\|_{H^1(\Omega)'} + \|w\|_{H^1(\Omega)} + \|\zeta\|_{H_\diamond^{-\frac12}(\partial\Omega)}\right)\|w_h\|_{H^1(\Omega)} \\
&\quad + c_2\left(\|\zeta\|_{H_\diamond^{-\frac12}(\partial\Omega)} + \|w\|_{H^1(\Omega)}\right)\|\zeta_h\|_{H_\diamond^{-\frac12}(\partial\Omega)},
\end{aligned}$$

where c_i, $i = 1,\dots,8$, are not depending on h. Note that $\|\zeta\|_{H^{-\frac12}(\partial\Omega)} = \|\zeta\|_{H_\diamond^{-\frac12}(\partial\Omega)}$ and $\|\zeta_h\|_{H^{-\frac12}(\partial\Omega)} = \|\zeta_h\|_{H_\diamond^{-\frac12}(\partial\Omega)}$. Now we integrate the left- and the right-hand sides of this inequality from 0 to t and get for $t \in [0,T]$ a.e.

$$\begin{aligned}
&\frac12\|w_h(t)\|_{L^2(\Omega)}^2 + \int_0^t\int_\Omega \kappa|\nabla w_h|^2 \,\mathrm{d}x\,\mathrm{d}t + \int_0^t \langle \zeta_h, \lambda\zeta_h\rangle \,\mathrm{d}t \\
&\le c_3\left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right)\left(\|w_h\|_{H^{1,0}(\Omega)} + \|\zeta_h\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right). \qquad (4.12)
\end{aligned}$$

Again integrating both sides of this inequality from 0 to T yields

$$\begin{aligned}
&\|w_h\|_{L^2(0,T,L^2(\Omega))}^2 \\
&\le c_4\left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right)\left(\|w_h\|_{H^{1,0}(\Omega)} + \|\zeta_h\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right). \qquad (4.13)
\end{aligned}$$

2. Since λ is coercive, using (4.12) and (4.13) we get

$$\begin{aligned}
&\|w_h\|_{H^{1,0}(\Omega)}^2 + \|\zeta_h\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}^2 \\
&\le c_5\left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right)\left(\|w_h\|_{H^{1,0}(\Omega)} + \|\zeta_h\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right).
\end{aligned}$$

Therefore, we have

$$\|w_h\|_{H^{1,0}(\Omega)} + \|\zeta_h\|_{H_\diamond^{-\frac12,0}(\partial\Omega)} \le c_6\left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac12,0}(\partial\Omega)}\right). \qquad (4.14)$$

3. Since $w_h' \in H_h$ for $t \in [0,T]$ a.e., using the L^2-projection P_h we have for $t \in [0,T]$ a.e.

$$\|w_h'\|_{H^1(\Omega)'} = \sup_{w\in H^1(\Omega)} \frac{\langle w_h', w\rangle}{\|w\|_{H^1(\Omega)}} = \sup_{w\in H^1(\Omega)} \frac{\langle w_h', P_h w\rangle}{\|w\|_{H^1(\Omega)}}. \qquad (4.15)$$

Now we use $(v_h, \psi_h) = (P_h w, 0)$ in (4.11) and obtain for $t \in [0,T]$ a.e.

$$\begin{aligned}
\langle w_h', P_h w\rangle &= -\int_\Omega \kappa\nabla w_h\cdot\nabla P_h w \,\mathrm{d}x - \langle \zeta_h, P_h w^-|_{\partial\Omega}\rangle + \langle w', P_h w\rangle \\
&\quad + \int_\Omega \kappa\nabla w\cdot\nabla P_h w \,\mathrm{d}x + \langle \zeta, P_h w^-|_{\partial\Omega}\rangle \\
&\le c_7\|P_h w\|_{H^1(\Omega)}\left(\|w_h\|_{H^1(\Omega)} + \|\zeta_h\|_{H_\diamond^{-\frac12}(\partial\Omega)}\right. \\
&\quad \left. + \|w\|_W + \|\zeta\|_{H_\diamond^{-\frac12}(\partial\Omega)}\right).
\end{aligned}$$

Squaring and then integrating (4.15) from 0 to T and combining it with the inequality above, (4.7), and (4.14), we obtain

$$\|w_h'\|_{L^2(0,T,H^1(\Omega)')} \le c_8 \left(\|w\|_W + \|\zeta\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \right). \qquad \square$$

In particular, Lemma 4.4 holds for (u_h, ϕ_h) and (u, ϕ).

We proof a variant of Céa's lemma for this time-dependent problem.

THEOREM 4.5. *Assume that (u, ϕ) and (u_h, ϕ_h) are solutions of (4.5) with $u(x, 0) = 0$ and of the Galerkin scheme, respectively. Then there exists $c > 0$ such that*

$$\begin{aligned} &\|u - u_h\|_W + \|\phi - \phi_h\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \\ &\quad \le c \inf \left\{ \|u - z_h\|_W + \|\phi - \chi_h\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} : z_h \in H_h^T,\, \chi_h \in B_h^T \right\}. \end{aligned}$$

Proof. (u, ϕ) and (u_h, ϕ_h) obviously satisfy (4.11).

Let $(z_h, \chi_h) \in H_h^T \times B_h^T$. We set $(e_1, e_2) := (u_h, \phi_h) - (z_h, \chi_h)$ and $(\epsilon_1, \epsilon_2) := (u, \phi) - (z_h, \chi_h)$. Then (4.11) yields

$$\begin{aligned} &\langle e_1', v_h \rangle + \int_\Omega \kappa \nabla e_1 \cdot \nabla v_h \, dx + \langle e_2, v_h^- |_{\partial\Omega} \rangle - \langle \psi_h, \lambda e_2 \rangle + \langle \psi_h, e_1^- |_{\partial\Omega} \rangle \\ &= \langle \epsilon_1', v_h \rangle + \int_\Omega \kappa \nabla \epsilon_1 \cdot \nabla v_h \, dx + \langle \epsilon_2, v_h^- |_{\partial\Omega} \rangle - \langle \psi_h, \lambda \epsilon_2 \rangle + \langle \psi_h, \epsilon_1^- |_{\partial\Omega} \rangle \end{aligned}$$

for all $(v_h, \psi_h) \in H_h \times B_h$ and for $t \in [0, T]$ a.e. Lemma 4.4 shows that

$$\|e_1\|_W + \|e_2\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \le c_1 \left(\|\epsilon_1\|_W + \|\epsilon_2\|_{H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \right).$$

Hence

$$\begin{aligned} &\|(u_h, \phi_h) - (u, \phi)\|_{W \times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} \\ &\quad \le c_2 \inf \left\{ \|(u, \phi) - (z_h, \chi_h)\|_{W \times H_\diamond^{-\frac{1}{2},0}(\partial\Omega)} : z_h \in H_h^T,\, \chi_h \in B_h^T \right\}, \end{aligned}$$

which is the desired estimate. $\square$

For our numerical examples we choose the same subspaces as in [9] and [23]; i.e., H_h consists of continuous functions, which are piecewise linear on a finite element grid, and B_h consists of piecewise constant functions. Equations (4.9) and (4.10) are solved numerically by a Crank–Nicolson method; i.e., we solve in each time-step the linear system of equations

$$\begin{bmatrix} I + \frac{\Delta t}{2} K & \frac{\Delta t}{2} B \\ -\frac{1}{2} B^T & \frac{1}{2} D \end{bmatrix} \begin{bmatrix} \alpha(t + \Delta t) \\ \beta(t + \Delta t) \end{bmatrix} = \begin{bmatrix} I - \frac{\Delta t}{2} K & -\frac{\Delta t}{2} B \\ \frac{1}{2} B^T & -\frac{1}{2} D \end{bmatrix} \begin{bmatrix} \alpha(t) \\ \beta(t) \end{bmatrix} + \begin{bmatrix} 0 \\ d(t) \end{bmatrix},$$

with $\alpha(0) = 0$ and $\beta(0) = D^{-1} d(0)$.

For the calculation of ξ and λ we use a boundary element method.

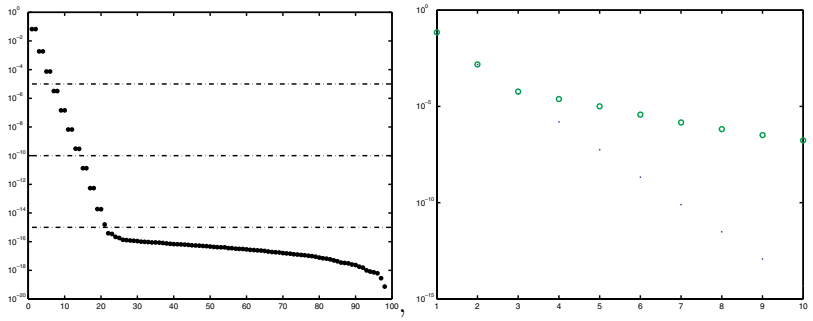

FIG. 4.1. *Left: The exact eigenvalues $\tilde{\lambda}_k$ from A. Right: Exact $(\cdot)$ and perturbed $(\circ)$ averaged eigenvalues.*

4.2. Implementation of the inverse problem. In this subsection we demonstrate how the factorization method can be used to solve the inverse problem, i.e., to locate the inclusion Ω from the knowledge of $I\Lambda I'$. We assume that we are given a finite dimensional approximation of $I\Lambda I'$ and thus a matrix $A \in \mathbb{R}^{m\times m}$. Let $(v_k)_{k\in\mathbb{N}}$, resp., $(\tilde{v}_k)_{k=1}^m$, be the eigenfunctions of $I\Lambda I'$, resp., A, with associated eigenvalues $(\lambda_k)_{k\in\mathbb{N}}$, resp., $(\tilde{\lambda}_k)_{k\in\mathbb{N}}$. Since $I\Lambda I'$ is self-adjoint and positive, the matrix A is symmetric and positive, too.

According to Corollary 3.9 a point $z \in B$ belongs to the inclusion Ω if and only if the infinite series

$$\sum_{k\in\mathbb{N}} \frac{(h_{z,d}, v_k)^2_{L^2(\partial B)}}{\lambda_k}$$

converges. For the numerical realization we have to decide about the convergence of this series from the knowledge of the finite sum

$$\sum_{k=1}^{m} \frac{(h_{z,d}, \tilde{v}_k)^2_{L^2(\partial B)}}{\tilde{\lambda}_k}\,.$$

For that we carry forward the ideas from [4]. Numerical examples show that the numerator and the denominator of the above series decay more or less exponentially and that every two eigenvalues have approximately the same value; cf. the left picture of Figure 4.1. Motivated by the examples and the method from [4], we compare the slopes of the least squares fitting straight lines of $h_1(k) = \log\left(\sqrt{\tilde{\lambda}_{2k-1}\tilde{\lambda}_{2k}}\right)$ and of

$$h_2(k) = \log\left(\frac{1}{2}\left((h_{z,d}, \tilde{v}_{2k-1})^2_{L^2(\partial B)} + (h_{z,d}, \tilde{v}_{2k})^2_{L^2(\partial B)}\right)\right)\,, \quad k = 1, \ldots, r\,.$$

We mark a sampling point z as inside the inclusion if h_1 decays slower than h_2. On the right side of Figure 4.2 the algorithm is demonstrated for two test points. If we apply this method to a large number of points, the black area on the left side of Figure 4.2 illustrates the reconstruction of the inclusion (dashed curve).

The number of the eigenvalues and Fourier coefficients which are used in the reconstruction procedure depends on the quality of the data. If A is known up to a perturbation of $\delta > 0$ (with respect to the spectral norm), then we trust in those

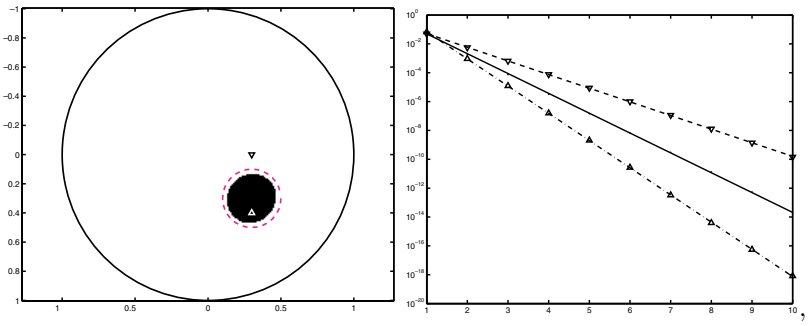

FIG. 4.2. *Least squares fitting straight lines of $h_2(k)$ for a point inside ($\triangle$) and outside ($\triangledown$) the inclusion compared with the least squares fitting straight line of $h_1(k)$ ($\cdot$).*

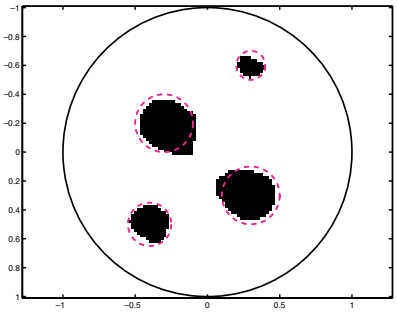

FIG. 4.3. *Reconstruction of four inclusions (dashed curves).*

eigenvalues which are larger than δ. On the left side of Figure 4.1, δ corresponds to the computational accuracy. The right side of Figure 4.1 shows the effect of a relative noise of 0.1% on the eigenvalues, and thus $\delta = 0.1\% \cdot \tilde{\lambda}_1$. The first three averaged pairs of the perturbed eigenvalues have nearly the exact values and they show the same exponential decay rates.

4.3. Numerical examples. To test this reconstruction algorithm we simulate the direct problem to produce the data. For this purpose we calculate the Dirichlet boundary data $f_k = I\Lambda I' g_k$, where $(g_k)_{k=1}^m$ are orthogonal input patterns. In the first examples this data was used for inversion. In the final example this data was perturbed with noise.

We restrict our attention to the case where $\kappa(x) = 2$ for $x \in \Omega$ and B is the unit disc in $\mathbb{R}^2$. For this case the function $h_{z,d}$ is known explicitly:

$$h_{z,d}(x) = \frac{1}{\pi} \frac{(z-x)\cdot d}{|z-x|^2}\,.$$

First we aim to reconstruct a single circle in the interior of B. The result is shown in the left picture of Figure 4.2. The location of Ω is detected but the size is underestimated.

In the second example four inclusions of different size should be located. In Figure 4.3 we demonstrate the possibility of the method to reconstruct nonconnected inclusions. The position and the different size of each are detected.

Our next example is to detect a nonconvex moon-like inclusion; cf. Figure 4.4. The top left picture shows the reconstruction with exact data. The shape of the moon

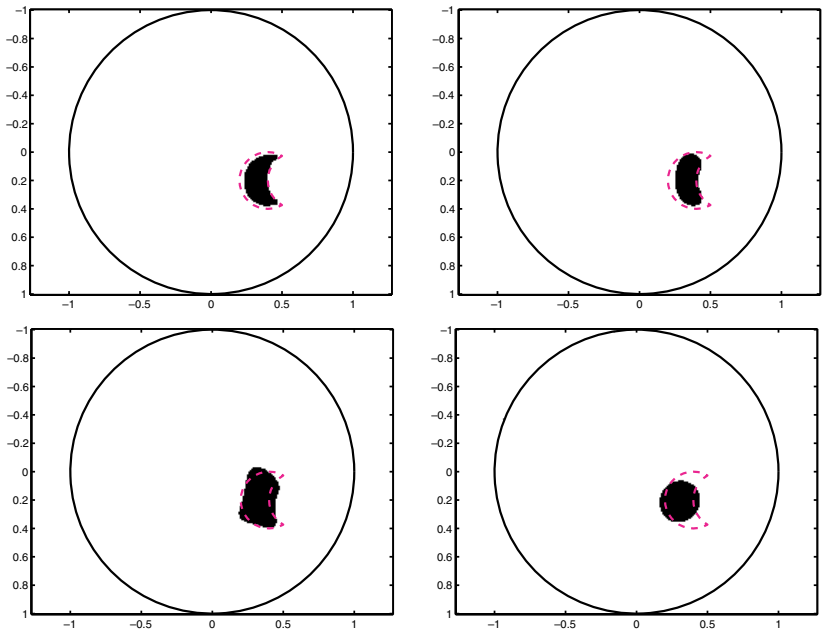

FIG. 4.4. *Reconstruction of a nonconvex inclusion (dashed curve). Top left: With exact data, and with perturbed data. Top right:* 0.05% *noise. Bottom left:* 0.1% *noise. Bottom right:* 1% *noise.*

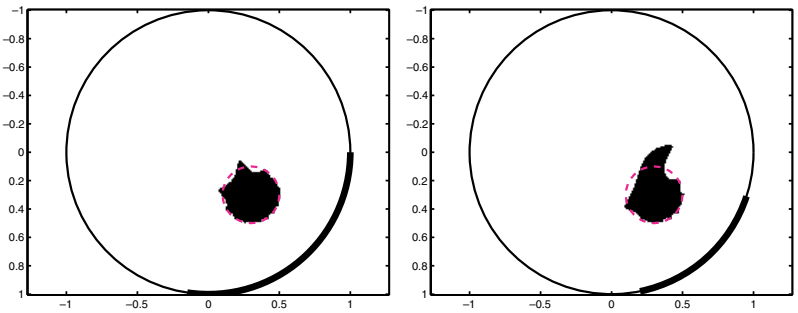

FIG. 4.5. *Reconstruction of an inclusion (dashed curve) by using partial boundary measurements (bold boundary).*

is recovered but the size is underestimated. Next we show the influence of noise on the reconstructions. By adding 0.05%, 0.1%, resp., 1%, noise the position of the inclusion is found, but the quality decreases with increasing noise level; cf. the top right and bottom pictures in Figure 4.4.

The last example shows the reconstruction of a single circle by partial boundary measurements (cf. our remark at the end of section 3). The location of the inclusion is detected and the shape next to the measuring boundary is recovered; see Figure 4.5.

Acknowledgments. We thank Prof. Martin Hanke-Bourgeois and Prof. Olaf Steinbach for stimulating discussion and constructive remarks.

STABILITY AND CONVERGENCE OF THE CRANK–NICOLSON/ADAMS–BASHFORTH SCHEME FOR THE TIME-DEPENDENT NAVIER–STOKES EQUATIONS*

YINNIAN HE† AND WEIWEI SUN‡

Abstract. In this paper, we study the stability and convergence of the Crank–Nicolson/Adams–Bashforth scheme for the two-dimensional nonstationary Navier–Stokes equations. A finite element method is applied for the spatial approximation of the velocity and pressure. The time discretization is based on the Crank–Nicolson scheme for the linear term and the explicit Adams–Bashforth scheme for the nonlinear term. Moreover, we present optimal error estimates and prove that the scheme is almost unconditionally stable and convergent, i.e., stable and convergent when the time step is less than or equal to a constant.

Key words. Navier–Stokes equations, mixed finite element, Adams–Bashforth scheme, Crank–Nicolson scheme

1. Introduction.

Let Ω be a bounded domain in R^2 assumed to have a Lipschitz continuous boundary $\partial\Omega$ and to satisfy a further condition stated in (A1) below. We consider the time-dependent Navier–Stokes problem

$$\begin{cases} u_t - \nu\Delta u + (u\cdot\nabla)u + \nabla p = f,\ \text{div } u = 0, \quad (x,t)\in\Omega\times(0,T], \\ u(x,0) = u_0(x), \quad x\in\Omega; \quad u(x,t)|_{\partial\Omega} = 0, \quad t\in[0,T], \end{cases} \tag{1.1}$$

where $u = u(x,t) = (u_1(x,t), u_2(x,t))$ represents the velocity vector, $p = p(x,t)$ represents the pressure, $f = f(x,t)$ represents the prescribed body force, $u_0(x)$ represents the initial velocity, $\nu > 0$ represents the viscosity, and $T > 0$ represents a finite time.

There are numerous works devoted to the development of efficient schemes for the Navier–Stokes equations [3, 4, 8, 9, 12, 13, 16, 20, 5, 23, 25, 24, 28, 30]: fully implicit, semi-implicit (semiexplicit), and explicit. Among them, high-order schemes are of more interest since first-order schemes are not sufficiently accurate for large time approximations. A key issue is the stability condition of schemes. Usually fully implicit schemes are (almost) unconditionally stable. However, at each time step, one has to solve a system of nonlinear equations. An explicit scheme is much easier in computation. But it suffers a severely restricted time step size from stability requirement. A popular approach is based on an implicit scheme for the linear term and a semi-implicit scheme or an explicit scheme for the nonlinear term. A semi-implicit scheme for the nonlinear term results in a linear system with a variable coefficient matrix of time, and an explicit treatment for the nonlinear term gives a constant matrix. Stability and convergence conditions of schemes have been studied

by many authors. The main results are summarized below, where we set $\Omega \subset R^d$ with $d = 2, 3$; $0 < h < 1$ denotes the mesh size in the spatial direction; and $0 < \tau = \frac{T}{N} < 1$ denotes the step size in the time direction.

- For the fully implicit Crank–Nicolson scheme (implicit for both linear and nonlinear terms), Heywood and Rannacher [16] proved that it is almost unconditionally stable and convergent, i.e., stable and convergent when

$$\tau \le C_0 \tag{1.2}$$

  for some positive constant C_0 depending on the data (ν, Ω, T, u_0, f) in the case of $d = 2, 3$.
- For a two-step scheme with a semi-implicit treatment for the nonlinear term, He and Li [12] gave the following convergence condition:

$$\tau h^{-1/2} \le C_0. \tag{1.3}$$

- For the Crank–Nicolson extrapolation scheme in which the discretization for the nonlinear term is semi-implicit, He [13] has proved that (1.2) is the stability and convergence condition of the scheme in the case of $d = 2$.
- For the Crank–Nicolson/Adams–Bashforth scheme in which the nonlinear term is treated explicitly, Marion and Temam provided in [25] the stability condition

$$\tau h^{-d} \le C_0, \quad d = 2, 3, \tag{1.4}$$

  and recently, Tone [30] proved the convergence under the condition

$$\tau h^{-2-d/2} \le C_0, \quad d = 2,\ 3. \tag{1.5}$$

- A modified Crank–Nicolson/Adams–Bashforth scheme was proposed by Johnston and Liu [19] in which the nonlinear term and pressure term are discretized explicitly. They claimed from their numerical simulations that the scheme is stable under the standard stability condition

$$\|u\|_{L^\infty} \tau h^{-1} \le 1, \quad d = 2, 3\,. \tag{1.6}$$

  No theoretical analysis has been given.
- For a three-step backward extrapolating scheme (explicit for the nonlinear term), Baker, Dougalis, and Karakashian [4] gave the convergence condition

$$\tau h^{-4/7} \le C_0 \tag{1.7}$$

  in the case of $d = 2, 3$.

Clearly, the time step condition

$$\tau h^{-\alpha} \le C_0 \tag{1.8}$$

for some $\alpha > 0$ was imposed in these previous works when a semi-implicit or an explicit scheme is applied for the nonlinear term, except for the Crank–Nicolson extrapolation scheme in [12] in which a semi-implicit scheme is used for the nonlinear term.

This paper focuses on the second-order Crank–Nicolson/Adams–Bashforth scheme with a finite element approximation in spatial direction for solving the time-dependent Navier–Stokes equations in the case of $d = 2$, which were studied by Marion and

Temam [25], Tone [30], Kim and Moin [20], and Issacson and Keller [18]. The scheme consists of using a finite element pair (X_h, M_h) for the spatial discretization of the Navier–Stokes equations, the Crank–Nicolson scheme for the linear term, and the Adams–Bashforth scheme for the nonlinear term. Under the assumption of $u_0 \in H^2(\Omega)^2 \cap H_0^1(\Omega)^2$ with $\mathrm{div} u_0 = 0$ and $f,\ f_t,\ f_{tt} \in L^\infty(0,T;L^2(\Omega)^2)$, we prove that the scheme is almost unconditionally stable, i.e.,

$$\|d_t u_h^m\|_{L^2}^2 + \nu \|A_h u_h^m\|_{L^2}^2 \le \kappa_2, \quad 1 \le m \le N, \tag{1.9}$$

when the condition (1.2) is satisfied. Moreover, we also provide the optimal error estimates

$$\|u(t_m) - u_h^m\|_{L^2} \le \kappa(\sigma^{-1}(t_m)\tau^2 + h^2), \quad 1 \le m \le N, \tag{1.10}$$

$$\|u(t_m) - u_h^m\|_{H^1} \le \kappa(\sigma^{-1/2}(t_m)\tau + h), \quad 1 \le m \le N, \tag{1.11}$$

$$\|p(t_m) - p_h^m\|_{L^2} \le \kappa(\sigma^{-1}(t_m)\tau + \sigma^{-1/2}(t_m)h), \quad 1 \le m \le N, \tag{1.12}$$

where the finite element space pair (X_h, M_h) satisfies the approximation assumption (A3); $\sigma(t) = \min\{1, t\}$; $\kappa_0,\ \kappa_1,\ \kappa_2$, and κ are some positive constants depending on the data (ν, Ω, T, u_0, f); and A_h is a discrete Stokes operator. The error bound (1.12) of the pressure is better than the error bound

$$\|p_h^m - p(t_m)\|_{L^2} \le \kappa(\sigma^{-3/2}(t_m)\tau + \sigma^{-1/2}(t_m)h), \quad 1 \le m \le N, \tag{1.13}$$

obtained by Heywood and Rannacher [16].

This paper is organized as follows. In section 2 an abstract functional setting of the Navier–Stokes problem is given together with some basic assumptions (A1) and (A2). In section 3 we set out our assumption (A3) concerning the finite element spaces X_h and M_h, finite element Galerkin approximation in space, and some properties on the trilinear form $b(\cdot,\cdot,\cdot)$. Section 3 contains the optimal error estimate and a priori estimate results of the finite element solution $(u_h(t), p_h(t))$. In section 4 we describe the Crank–Nicolson/Adams–Bashforth scheme and prove a stability result of this scheme. In section 5 we describe a second-order dual scheme and prove its stability result. In section 6 we provide optimal error estimates for the numerical solution (u_h^n, p_h^n) with $1 \le n \le N$.

2. Functional setting of the Navier–Stokes equations. For the mathematical setting of problem (1.1), we introduce the following Hilbert spaces:

$$X = H_0^1(\Omega)^2, \quad Y = L^2(\Omega)^2, \quad M = L_0^2(\Omega) = \left\{ q \in L^2(\Omega); \int_\Omega q dx = 0 \right\}.$$

The space $L^2(\Omega)^d$, $d = 1, 2, 4$, is equipped with the usual L^2-scalar product $(\cdot,\cdot)$ and L^2-norm $\|\cdot\|_{L^2}$ or $\|\cdot\|_0$. The spaces $H_0^1(\Omega)$ and X are equipped with their usual scalar product and equivalent norm

$$((u,v)) = (\nabla u, \nabla v), \quad \|u\|_{H_0^1} = \|\nabla u\|_{L^2}.$$

Next, let the closed subset V of X be given by

$$V = \{v \in X; \mathrm{div}\ v = 0\},$$

and denote by H the closed subset of Y, i.e.,

$$H = \{v \in Y; \mathrm{div}\ v = 0, v \cdot n|_{\partial\Omega} = 0\}.$$

We refer readers to [1, 9, 15, 29] for details on these spaces. We denote the Stokes operator by $A = -P\Delta$, where P is the L^2-orthogonal projection of Y onto H. As mentioned above, we need a further assumption on Ω provided in [16].

(A1). Assume that Ω is smooth so that the unique solution $(v, q) \in (X, M)$ of the steady Stokes problem

$$-\nu\Delta v + \nabla q = g, \quad \mathrm{div} v = 0 \quad \text{in } \Omega, \quad v|_{\partial\Omega} = 0,$$

for any prescribed $g \in Y$ exists and satisfies

$$\|v\|_{H^2} + \|q\|_{H^1} \le c\|g\|_{L^2},$$

where $c > 0$ is a generic constant depending on Ω and ν which may stand for different values at its different occurrences.

We remark that the validity of assumption (A1) is known (see [9, 15, 21, 29]) if $\partial\Omega$ is of C^2 or if Ω is a two-dimensional convex polygon. From the assumption (A1), it is well known [1, 15, 22] that

$$\|v\|_{H^2} \le c\|Av\|_{L^2}, \quad v \in D(A) = H^2(\Omega)^2 \cap V, \tag{2.1}$$

$$\|v\|_{L^2} \le \gamma_0\|v\|_{H_0^1}, \quad v \in X, \quad \|v\|_{H_0^1} \le \gamma_0\|Av\|_{L^2}, \quad v \in D(A), \tag{2.2}$$

where γ_0 is a positive constant depending only on Ω. We usually make the following assumption about the prescribed data for problem (1.1).

(A2). The initial velocity $u_0(x)$ and the force $f(x, t)$ satisfy that $u_0 \in D(A)$, $f \in L^\infty(0, T; H^1(\Omega)^2)$, f_t, and $f_{tt} \in L^\infty(0, T; Y)$ with

$$\|Au_0\|_{L^2} + \sup_{0\le t\le T}\{\|f(t)\|_{H^1} + \|f_t(t)\|_{L^2} + \|f_{tt}(t)\|_{L^2}\} \le C$$

for some positive constant C. We also introduce the following bilinear operator:

$$B(u, v) = (u \cdot \nabla)v + \frac{1}{2}(\mathrm{div} u)v, \quad u, \ v \in X.$$

Moreover, we define the continuous bilinear forms $a(\cdot, \cdot)$ and $d(\cdot, \cdot)$ on $X \times X$ and $X \times M$, respectively, by

$$a(u, v) = \nu((u, v)), \quad u, v \in X,$$

and

$$d(v, q) = (q, \mathrm{div} v), \quad v \in X, \quad q \in M,$$

and a trilinear form on $X \times X \times X$ by

$$b(u, v, w) = \langle B(u, v), w\rangle_{X',X} = ((u \cdot \nabla)v, w) + \frac{1}{2}((\mathrm{div} u)v, w)$$

$$= \frac{1}{2}((u \cdot \nabla)v, w) - \frac{1}{2}((u \cdot \nabla)w, v), \quad u, v, w \in X.$$

With the above notations, the variational formulation of problem (2.1) reads as follows: find $(u, p) \in (X, M)$ for all $t \in (0, T]$ such that, for all $(v, q) \in (X, M)$,

$$(u_t, v) + a(u, v) - d(v, p) + d(u, q) + b(u, u, v) = (f, v), \tag{2.3}$$

$$u(0) = u_0. \tag{2.4}$$

3. Finite element Galerkin approximation. Let $h > 0$ be a real positive parameter. The finite element subspace (X_h, M_h) of (X, M) is characterized by $J_h = J_h(\Omega)$, a partitioning of $\bar{\Omega}$ into triangles K or quadrilaterals K, assumed to be uniformly regular as $h \to 0$. For further details, readers can refer to Ciarlet [6] and Girault and Raviart [9].

We define the subspace V_h of X_h given by

$$V_h = \left\{ v_h \in X_h \,;\, d(v_h, q_h) = 0 \ \ \forall q_h \in M_h \right\}. \tag{3.1}$$

Let $P_h : Y \to V_h$ denote the L^2-orthogonal projection defined by

$$(P_h v,\ v_h) = (v, v_h), \quad v \in Y,\ v_h \in V_h.$$

We assume that the couple (X_h, M_h) satisfies the following approximation properties.

(A3) For each $v \in H^2(\Omega)^2 \cap X$ and $q \in H^1(\Omega) \cap M$, there exist approximations $\pi_h v \in X_h$ and $\rho_h q \in M_h$ such that

$$\|v - \pi_h v\|_{H_0^1} \le ch\|v\|_{H^2}, \qquad \|q - \rho_h q\|_{L^2} \le ch\|q\|_{H^1} \tag{3.2}$$

together with the inverse inequality

$$\|v_h\|_{H_0^1} \le \alpha h^{-1} \|v_h\|_{L^2}, \quad v_h \in X_h, \tag{3.3}$$

and we have the so-called inf-sup inequality: for each $q_h \in M_h$, there exists $v_h \in X_h, v_h \neq 0$, such that

$$d(v_h, q_h) \ge \beta \|q_h\|_{L^2} \|v_h\|_{H_0^1}, \tag{3.4}$$

where α and β are positive constants depending on Ω.

The following properties are classical (see [2, 9, 15, 17]):

$$\|P_h v\|_{H_0^1} \le \gamma \|v\|_{H_0^1}, \quad v \in X, \tag{3.5}$$

$$\|v - P_h v\|_{L^2} + h\|v - P_h v\|_{H_0^1} \le \gamma h^2 \|Av\|_{L^2}, \quad v \in D(A), \tag{3.6}$$

$$\|v - P_h v\|_{L^2} \le \gamma h \|v - P_h v\|_{H_0^1}, \quad v \in X \tag{3.7}$$

for some positive constant γ.

The standard finite element Galerkin approximation of (2.3)–(2.4) based on (X_h, M_h) reads as follows: find $(u_h, p_h) \in (X_h, M_h)$ such that, for all $0 < t \le T$ and $(v_h, q_h) \in (X_h, M_h)$,

$$(u_{ht}, v_h) + a(u_h, v_h) - d(v_h, p_h) + d(u_h, q_h) + b(u_h, u_h, v_h) = (f, v_h), \tag{3.8}$$

$$u_h(0) = u_{0h} = P_h u_0. \tag{3.9}$$

With the above statements, a discrete analogue $A_h = -P_h \Delta_h$ of the Stokes operator A is defined through the condition that $(-\Delta_h u_h, v_h) = ((u_h, v_h))$ for all $u_h, v_h \in X_h$. The restriction of A_h to V_h is invertible, with the inverse A_h^{-1}. Since A_h^{-1} is self-adjoint and positive definite, we may define "discrete" Sobolev norms on V_h, of any order $r \in R$, by setting

$$\|v_h\|_r = \|A_h^{r/2} v_h\|_{L^2}, \quad v_h \in V_h.$$

These norms will be assumed to have various properties similar to their continuous counterparts, an assumption that implicitly imposes conditions on the structure of the spaces X_h and M_h. In particular, there holds

$$\|v_h\|_0 = \|v_h\|_{L^2}, \quad \|v_h\|_1 = \|\nabla v_h\|_0, \quad \|v_h\|_2 = \|A_h v_h\|_0, \quad v_h \in V_h.$$

By the way, we derive from (2.2) that

$$\|v_h\|_0 \le \gamma_0 \|\nabla v_h\|_0, \quad \|\nabla v_h\|_0 \le \gamma_0 \|A_h v_h\|_0, \quad v_h \in V_h, \tag{3.10}$$

where $\gamma_0 > 0$ is a constant depending only on Ω.

Remark 3.1. The space V_h is introduced only for theoretical analysis. The practical computation should be based on the finite element space pair (X_h, M_h). For the details of the construction of (X_h, M_h), we refer readers to Heywood and Rannacher [15, 16] and to Hill and Süli [17]. Recently, Nochetto and Pyo [26] proposed a projection method for time-dependent Navier–Stokes equations, in which V_h is a discrete divergence free space which is discontinuous on the boundary of each element and $u \ne 0$ on $\partial\Omega$.

Under the conditions above, and with some further assumptions about the structure of the spaces X_h and M_h, it has been shown in Heywood and Rannacher [15] that

$$\|u(t) - u_h(t)\|_0 + h\|\nabla(u(t) - u_h(t))\|_0 + \sigma^{1/2}(t)h\|p(t) - p_h(t)\|_0 \le \kappa h^2 \tag{3.11}$$

for all $t \in (0, T]$.

This section considers preliminary estimates which are useful in the error estimates of finite element solution. Some estimates of the trilinear form b are given in the following lemma and in the proof can be found in [13, 14].

LEMMA 3.1. *The trilinear form b satisfies the following estimates:*

$$b(u_h, v_h, w_h) = -b(u_h, w_h, v_h), \tag{3.12}$$

$$\begin{aligned} |b(u_h, v_h, w_h)| &+ |b(v_h, u_h, w_h)| + |b(w_h, u_h, v_h)| \\ &\le \frac{c_0}{2}\|u_h\|_0^{1/2}\|u_h\|_1^{1/2}\|v_h\|_1\|w_h\|_0^{1/2}\|w_h\|_1^{1/2} \\ &+ \frac{c_0}{2}\|u_h\|_1\|v_h\|_0^{1/2}\|v_h\|_1^{1/2}\|w_h\|_0^{1/2}\|w_h\|_1^{1/2} \end{aligned} \tag{3.13}$$

for all u_h, v_h, and $w_h \in X_h$;

$$\begin{aligned} |b(u_h, v_h, w_h)| &+ |b(v_h, u_h, w_h)| + |b(w_h, u_h, v_h)| \\ &\le \frac{1}{2}c_0\|A_h v_h\|_0^{1/2}\|v_h\|_1^{1/2}\|u_h\|_0^{1/2}\|u_h\|_1^{1/2}\|w_h\|_0 \\ &+ \frac{1}{2}c_0\|A_h v_h\|_0^{1/2}\|v_h\|_0^{1/2}\|u_h\|_1\|w_h\|_0 \end{aligned} \tag{3.14}$$

for all $u_h,\ v_h \in V_h$, and $w_h \in X_h$; and

$$\begin{aligned} |b(u_h, v_h, w_h)| &+ |b(u_h, v_h, w_h)| + |b(w_h, u_h, v_h)| \\ &\le \frac{1}{3}c_0(\|u_h\|_0^{1/2}\|A_h u_h\|_0^{1/2}\|A_h v_h\|_0 + \|v_h\|_0^{1/2}\|A_h v_h\|_0^{1/2}\|A_h u_h\|_0)\|w_h\|_{-1} \\ &+ \frac{1}{3}c_0\|u_h\|_1^{1/2}\|A_h u_h\|_0^{1/2}\|A_h v_h\|_0^{1/2}\|v_h\|_1^{1/2}\|w_h\|_{-1} \end{aligned} \tag{3.15}$$

for all u_h, v_h, and $w_h \in V_h$, where $c_0 > 0$ is a constant depending only on Ω.

Proof. (3.12)–(3.14) can be found in [13, 14, 15, 17].

Before we proceed further with (3.15), we need some continuous and discrete Gadliardo-Nirenberg estimates (see Temam [29] and Hill and Süli [17]):

$$\|\nabla v\|_{L^4} \le c\|\nabla v\|_0^{1/2}\|Av\|_0^{1/2} \quad \forall v \in D(A), \tag{3.16}$$

$$\|v_h\|_{L^4} \le c\|v_h\|_0^{1/2}\|v_h\|_1^{1/2}, \quad \|v_h\|_{L^\infty} \le c\|v_h\|_0^{1/2}\|A_h v_h\|_0^{1/2},$$

$$\|\nabla v_h\|_{L^4} \le c\|\nabla v_h\|_0^{1/2}\|A_h v_h\|_0^{1/2} \quad \forall v_h \in V_h. \tag{3.17}$$

Moreover, let the map $A^{-1}PA_h : V_h \to D(A)$. Then Heywood and Rannacher [15] showed

$$\|A^{-1}PA_h v_h - v_h\|_0 + h\|\nabla(A^{-1}PA_h v_h - v_h)\|_0 \le ch^2\|A_h v_h\|_0. \tag{3.18}$$

Let $\phi_h = A_h^{-1} w_h$ for each $w_h \in V_h$; then (3.3) gives

$$\|w_h\|_0^2 = (w_h, A_h\phi_h) = (\nabla w_h, \nabla\phi_h) \le \|w_h\|_1\|w_h\|_{-1} \le ch^{-1}\|w_h\|_0\|w_h\|_{-1}. \tag{3.19}$$

Furthermore, we write the bilinear form b into the following:

$$\begin{aligned} b(u_h, v_h, w_h) \le{}& ((u_h\cdot\nabla)(v_h - PA_h v_h), w_h) + \frac{1}{2}(\mathrm{div}(u_h - A^{-1}PA_h u_h)v_h, w_h) \\ &+ \|\nabla P_h[(u_h\cdot\nabla)A^{-1}PA_h v_h]\|_0\|w_h\|_{-1}. \end{aligned} \tag{3.20}$$

Using (3.3), (3.5), and (3.16)–(3.19), we have

$$\begin{aligned} |((u_h\cdot\nabla)(v_h - PA_h v_h), w_h)| &\le ch\|u_h\|_{L^\infty}\|A_h v_h\|_0\|w_h\|_0 \\ &\le c\|u_h\|_{L^\infty}\|A_h v_h\|_0\|w_h\|_{-1}, \\ |(\mathrm{div}(u_h - A^{-1}PA_h u_h)v_h, w_h)| &\le ch\|A_h u_h\|_0\|v_h\|_{L^\infty}\|w_h\|_0 \\ &\le c\|A_h u_h\|_0\|v_h\|_{L^\infty}\|w_h\|_{-1}, \\ \|\nabla P_h[(u_h\cdot\nabla)A^{-1}PA_h v_h]\|_0 &\le c\|\nabla[(u_h\cdot\nabla)A^{-1}PA_h v_h]\|_0 \\ &\le c\|\nabla u_h\|_{L^4}\|\nabla A^{-1}PA_h v_h\|_{L^4} \\ &\quad + c\|u_h\|_{L^\infty}\|\nabla\nabla A^{-1}PA_h v_h\|_0 \\ &\le c\|u_h\|_1^{1/2}\|A_h u_h\|_0^{1/2}\|v_h\|_1^{1/2}\|A_h v_h\|_0^{1/2} \\ &\quad + c\|u_h\|_{L^\infty}\|A_h v_h\|_0. \end{aligned}$$

Combining these inequalities with (3.20), we have deduced

$$\begin{aligned} |b(u_h, v_h, w_h)| \le{}& c(\|u_h\|_{L^\infty}\|A_h v_h\|_0 + c\|A_h u_h\|_0\|v_h\|_{L^\infty})\|w_h\|_{-1} \\ &+ c\|u_h\|_1^{1/2}\|A_h u_h\|_0^{1/2}\|v_h\|_1^{1/2}\|A_h v_h\|_0^{1/2}\|w_h\|_{-1}. \end{aligned} \tag{3.21}$$

Also, we can obtain the above estimate for the trilinear terms $b(v_h, u_h, w_h)$ and $b(w_h, u_h, v_h)$. Hence, we deduce (3.15) by using the above estimates and (3.17). ∎

Remark 3.2. (3.13) and (3.14) are valid in two-dimensional space. One has to seek a different approach for problems in three-dimensional space, e.g., refer to E and Liu [7] and Nochetto and Pyo [26].

In order to obtain our error analysis for time discretization, we recall the following smooth properties of (u_h, p_h) given in [16].

THEOREM 3.2. *Assume that assumptions* (A1)–(A3) *are valid. Then the finite element solution* (u_h, p_h) *satisfies the following estimates:*

$$\|u_h(t)\|_2^2 + \|p_h(t)\|_0^2 \le \kappa, \quad \sigma^r(t)\|u_{ht}(t)\|_r^2 \le \kappa, \quad r = 0, 1, 2, \tag{3.22}$$

$$\sigma^{r+2}\|u_{htt}(t)\|_r^2 \le \kappa, \quad r = -1, 0, 1, \tag{3.23}$$

$$\int_0^t \sigma^r(s)\|u_{ht}(s)\|_{r+1}^2 ds \le \kappa, \quad r = 0, 1, \tag{3.24}$$

$$\int_0^t \sigma^{r+1}(s)\|u_{htt}(s)\|_r^2 ds \le \kappa, \quad r = -1, 0, 1, \tag{3.25}$$

$$\int_0^t \sigma^{r+2}(s)\|u_{http}(s)\|_{r-1}^2 ds \le \kappa, \quad r = -1, 0, 1 \tag{3.26}$$

for all $t \in (0, T]$.

THEOREM 3.3. *Under the assumptions of Theorem* 3.2*, there holds*

$$\int_0^t \sigma^3(s)\|A_h u_{htt}(s)\|_0^2 ds \le \kappa, \quad \sigma^2(t)\|p_{ht}(t)\|_0^2 \le \kappa \tag{3.27}$$

for all $t \in (0, T]$.

Proof. From (3.8), we have

$$\begin{aligned}(u_{http}, v_h) + a(u_{htt}, v_h) + b(u_{htt}, u_h, v_h) + b(u_h, u_{htt}, v_h) + 2b(u_{ht}, u_{ht}, v_h)\\ = (f_{tt}, v_h), \quad v_h \in V_h.\end{aligned} \tag{3.28}$$

Taking $v_h = 2A_h u_{htt} \in V_h$ in (3.28), we obtain

$$\begin{aligned}2(u_{http}, A_h u_{htt}) + 2\nu\|A_h u_{htt}\|_0^2 + 2b(u_{htt}, u_h, A_h u_{htt}) + 2b(u_h, u_{htt}, A_h u_{htt})\\ + 2b(u_{ht}, u_{ht}, A_h u_{htt}) = 2(f_{tt}, A_h u_{htt}).\end{aligned} \tag{3.29}$$

It follows from (3.10), (3.14), and the Young inequality that

$$\begin{aligned}2|b(u_{htt}, u_h, A_h u_{htt})| + 2|b(u_h, u_{htt}, A_h u_{htt})| &\le 2c_0\gamma_0\|A_h u_h\|_0\|u_{htt}\|_1\|A_h u_{htt}\|_0\\ &\le \frac{\nu}{4}\|A_h u_{htt}\|_0^2 + 4\nu^{-1}c_0^2\gamma_0^2\|A_h u_h\|_0^2\|u_{htt}\|_1^2,\\ 4|b(u_{ht}, u_{ht}, A_h u_{htt})| &\le 2c_0\|A_h u_{ht}\|_0^{1/2}\|u_{ht}\|_0^{1/2}\|u_{ht}\|_1\|A_h u_{htt}\|_0\\ &\le \frac{\nu}{4}\|A_h u_{htt}\|_0^2 + 4\nu^{-1}c_0^2\|A_h u_{ht}\|_0\|u_{ht}\|_0\|u_{ht}\|_1^2,\\ 2(u_{http}, A_h u_{htt}) &\le \frac{\nu}{4}\|A_h u_{htt}\|_0^2 + 4\nu^{-1}\|u_{http}\|_0^2,\\ 2|(f_{tt}, A_h u_{htt})| &\le \frac{\nu}{4}\|A_h u_{htt}\|_0^2 + 4\nu^{-1}\|f_{tt}\|_0^2.\end{aligned}$$

Combining these inequalities with (3.29) yields

$$\begin{aligned}\nu\|A_h u_{htt}\|_0^2 &\le 4\nu^{-1}c_0^2\gamma_0^2\|A_h u_h\|_0^2\|u_{htt}\|_0^2\\ &\quad + 4\nu^{-1}c_0^2\|A_h u_{ht}\|_0\|u_{ht}\|_0\|u_{ht}\|_1^2 + 4\nu^{-1}\|u_{http}\|_0^2 + 4\nu^{-1}\|f_{tt}\|_0^2.\end{aligned} \tag{3.30}$$

Multiplying (3.30) by $\sigma^3(t)$ and integrating from 0 to t, we have

$$\begin{aligned}\nu\int_0^t \sigma^3(s)\|A_h u_{htt}\|_0^2 ds &\le 4\nu^{-1}c_0^2\gamma_0^2\int_0^t \sigma^3(s)\|A_h u_h\|_0^2\|u_{htt}\|_1^2 ds\\ &\quad + 4\nu^{-1}c_0^2\int_0^t \sigma^3(s)\|A_h u_{ht}\|_0\|u_{ht}\|_0\|u_{ht}\|_1^2 ds\\ &\quad + \nu^{-1}\int_0^t \sigma^3(s)(\|u_{httt}\|_0^2 + \|f_{tt}\|_0^2) ds,\end{aligned}$$

which together with (3.22) and (3.24)–(3.26) leads to

$$\int_0^t \sigma^3(s)\|A_h u_{htt}\|_0^2 ds \le \kappa, \quad 0 < t \le T. \tag{3.31}$$

Moreover, by using (3.4), (3.10), Lemma 3.1, and (3.8), we have

$$\begin{aligned}\sigma^2(t)\|p_{ht}(t)\|_0^2 &\le c\sigma^2(t)\|u_{htt}(t)\|_0^2 + c\sigma^2(t)\|A_h u_{ht}(t)\|_0^2\\ &\quad + c\|A_h u_h(t)\|_0^2\|u_{ht}(t)\|_0^2,\end{aligned}$$

which with Theorem 3.2 results in

$$\sigma^2(t)\|p_{ht}(t)\|_0^2 \le \kappa, \quad 0 < t \le T.$$

Combining this inequality with (3.31) implies (3.27). ∎

We will frequently use a discrete version of the Gronwall lemmas used in [11] and [27].

LEMMA 3.4. *Let C, τ, a_n, b_n, c_n, and d_n for integers $n \ge 0$ be nonnegative numbers such that*

$$a_m + \tau\sum_{n=1}^{m} b_n \le \tau\sum_{n=0}^{m-1} a_n d_n + \tau\sum_{n=0}^{m-1} c_n + C, \quad m \ge 1. \tag{3.32}$$

Then

$$a_m + \tau\sum_{n=1}^{m} b_n \le \exp\left(\tau\sum_{n=0}^{m-1} d_n\right)\left(\tau\sum_{n=0}^{m-1} c_n + C\right), \quad m \ge 1. \tag{3.33}$$

4. Second-order fully discrete finite element method. In this section we consider the time discretization of the finite element Galerkin approximation (3.8)–(3.9). Let $t_n = n\tau (n = 0, 1, \ldots, N)$, $\tau = \frac{T}{N}$ be the time step size, and N be an integer. Due to the nature of the Adams–Bashforth scheme of three levels in time, we define $u_h^0 = u_{0h} = P_h u_0$ and $(u_h^1, p_h^1) \in (X_h, M_h)$ by the Euler-backward scheme:

$$(d_t u_h^1, v_h) + a(u_h^1, v_h) - d(v_h, p_h^1) + d(u_h^1, q_h) + b(u_h^0, u_h^0, v_h) = (f(t_1), v_h) \tag{4.1}$$

for all $(v_h, q_h) \in (X_h, M_h)$, while $d_t u_h^0 = \lim_{t\to 0} u_{ht}(t)$ is defined so that

$$(d_t u_h^0, v_h) + a(u_h^0, v_h) + b(u_h^0, u_h^0, v_h) = (f(t_0), v_h) \tag{4.2}$$

for all $v_h \in V_h$.

Now, we define recursively the finite element solutions $(u_h^n, p_h^n) \in (X_h, M_h)$, $n = 2, \ldots, N$, by setting

$$\begin{aligned}(d_t u_h^n, v_h) + a(\bar{u}_h^n, v_h) - d(v_h, p_h^n) + d(\bar{u}_h^n, q_h) \\ + \frac{3}{2} b(u_h^{n-1}, u_h^{n-1}, v_h) - \frac{1}{2} b(u_h^{n-2}, u_h^{n-2}, v_h) = (\bar{f}(t_n), v_h)\end{aligned} \tag{4.3}$$

or

$$\begin{aligned}&(d_t u_h^n, v_h) + a(\bar{u}_h^n, v_h) - d(v_h, p_h^n) + d(\bar{u}_h^n, q_h) + b(\bar{u}_h^{n-1}, \bar{u}_h^{n-1}, v_h) \\ &\quad + b(d_t u_h^{n-1}, \bar{u}_h^{n-1}, v_h)\tau + b(\bar{u}_h^{n-1}, d_t u_h^{n-1}, v_h)\tau + \frac{1}{4} b(d_t u_h^{n-1}, d_t u_h^{n-1}, v_h)\tau^2 \\ &\quad = (\bar{f}(t_n), v_h)\end{aligned} \tag{4.4}$$

for all $(v_h, q_h) \in (X_h, M_h)$.

Here and after, we often use the following notations:

$$\bar{u}_h^n = \frac{1}{2}(u_h^n + u_h^{n-1}), \quad \bar{u}_h(t_n) = \frac{1}{2}(u_h(t_n) + u_h(t_{n-1})), \quad d_t u_h^n = \frac{1}{\tau}(u_h^n - u_h^{n-1}).$$

We see from (3.3), (3.6), and the definition of A_h that

$$\begin{aligned}(A_h u_h^0, v_h) &= ((u_h^0 - u_0, v_h)) + ((u_0, v_h)) \le (\alpha h^{-1} \|\nabla(P_h u_0 - u_0)\|_0 + \|Au_0\|_0)\|v_h\|_0 \\ &\le (1 + \alpha\gamma)\|Au_0\|_0 \|v_h\|_0, \quad v_h \in V_h,\end{aligned}$$

which with (3.5) yields

$$\|u_h^0\|_0 \le \|u_0\|_0, \quad \|u_h^0\|_1 \le \gamma \|\nabla u_0\|_0, \quad \|A_h u_h^0\|_0 \le (1 + \alpha\gamma)\|Au_0\|_0. \tag{4.5}$$

We deduce from (4.2) and Lemma 3.1 that

$$\|d_t u_h^0\|_0 \le \nu \|A_h u_h^0\|_0 + c_0\gamma_0 \|A_h u_h^0\|_0 \|u_h^0\|_1 + \|f(t_0)\|_0$$

and by (4.5) that

$$\|d_t u_h^0\|_0 \le (1 + \alpha\gamma)(\nu + c_0\gamma_0\gamma\|\nabla u_0\|_0)\|Au_0\|_0 + \|f(t_0)\|_0. \tag{4.6}$$

LEMMA 4.1. *Suppose that the assumptions* (A1)–(A3) *are valid. Then* (u_h^1, p_h^1) *satisfies the following stabilities:*

$$\|u_h^1\|_0^2 + \nu \|\bar{u}_h^1\|_1^2 \tau \le \kappa_0', \tag{4.7}$$

$$\|u_h^1\|_1^2 + \nu \|A_h \bar{u}_h^1\|_0^2 \tau \le \kappa_1', \tag{4.8}$$

$$\|d_t u_h^1\|_0^2 + \nu \|A_h u_h^1\|_0^2 + \|p_h^1\|_0^2 + \nu \|d_t u_h^1\|_1^2 \tau \le \kappa_2' \tag{4.9}$$

for some positive constants κ_0', κ_1', *and* κ_2' *depending on the data* (ν, Ω, T, u_0, f).

Proof. Taking $v_h = 2A_h^r u_h^1 \tau \in V_h$ and $q_h = 0$ in (4.1) for $r = 0, 1$, we obtain

$$\begin{aligned}&\|u_h^1\|_r^2 - \|u_h^0\|_r^2 + \|d_t u_h^1\|_r^2 \tau^2 + 2\nu \|u_h^1\|_{r+1}^2 \tau + 2b(u_h^0, u_h^0, A_h^r u_h^1)\tau \\ &\quad = 2(f(t_1), A_h^r u_h^1)\tau.\end{aligned} \tag{4.10}$$

In view of Lemma 3.1 and (3.10), there hold

$$\begin{aligned}2|b(u_h^0, u_h^0, A_h^r u_h^1)|\tau &\le c_0\gamma_0 \|u_h^0\|_1 \|u_h^0\|_{r+1} \|u_h^1\|_{r+1}\tau \\ &\le \frac{\nu}{2}\|u_h^1\|_{r+1}^2 \tau + \nu^{-1} c_0^2 \gamma_0^2 \|u_h^0\|_1^2 \|u_h^0\|_{r+1}^2 \tau, \\ 2|(f(t_1), A_h^r u_h^1)|\tau &\le \frac{\nu}{2}\|u_h^1\|_{r+1}^2 + 2\nu^{-1}\gamma_0^{2(1-r)} \|f(t_1)\|_0^2 \tau.\end{aligned}$$

Combining these inequalities with (4.10) yields

$$\begin{aligned}&\|u_h^1\|_r^2 + \|d_t u_h^1\|_r^2\tau^2 + \nu\|u_h^1\|_{r+1}^2\tau\\ &\qquad \le \|u_h^0\|_r^2 + 2\nu^{-1}\gamma_0^{2(1-r)}\|f(t_1)\|_0^2\tau + \nu^{-1}c_0^2\gamma_0^2\|u_h^0\|_1^2\|u_h^0\|_{r+1}^2\tau,\end{aligned} \tag{4.11}$$

which with (4.5)–(4.6) and the triangle inequality implies (4.7)–(4.8).

Again, we deduce from (4.1)–(4.2) that

$$(d_{tt}u_h^1, v_h) + a(d_t u_h^1, v_h) - d(v_h, d_t p_h^1) + d(d_t u_h^1, q_h) = \frac{1}{\tau}\int_{t_0}^{t_1}(f_t(t), v_h)dt. \tag{4.12}$$

By taking $v_h = 2d_t u_h^1\tau$ and $q_h = 2d_t p_h^1\tau$ in (4.12), we have

$$\begin{aligned}&\|d_t u_h^1\|_0^2 + \|d_{tt}u_h^1\|_0^2\tau^2 + 2\nu\|d_t u_h^1\|_1^2\tau \le \|d_t u_h^0\|_0^2 + 2\gamma_0\int_{t_0}^{t_1}\|f_t(t)\|_0 dt\|d_t u_h^1\|_1\\ &\qquad \le \|d_t u_h^0\|_0^2 + \nu\|d_t u_h^1\|_1^2\tau + \nu^{-1}\gamma_0^2\int_{t_0}^{t_1}\|f_t(t)\|_0^2 dt.\end{aligned} \tag{4.13}$$

Moreover, it follows from (4.1) and Lemma 3.1 that

$$\nu\|A_h u_h^1\|_0 \le \|d_t u_h^1\|_0 + c_0\gamma_0\|u_h^0\|_1\|A_h u_h^0\|_0 + \|f(t_1)\|_0$$

and

$$\nu\|A_h u_h^1\|_0^2 \le 3\nu^{-1}(\|d_t u_h^1\|_0^2 + \|f(t_1)\|_0^2 + c_0^2\gamma_0^2\|u_h^0\|_1^2\|A_h u_h^0\|_0^2). \tag{4.14}$$

Finally, using (4.1), (3.4), (3.10), and Lemma 3.1, we arrive at

$$\begin{aligned}\|p_h^1\|_0 &\le \beta^{-1}\sup_{v_h\in X_h}\frac{d(v_h, p_h^1)}{\|v_h\|_1}\\ &\le \beta^{-1}(\|d_t u_h^1\|_0 + \nu\|A_h u_h^1\|_0 + c_0\gamma_0\|u_h^0\|_1^2 + \|f(t_1)\|_0)\end{aligned}$$

or equivalently

$$\|p_h^1\|_0^2 \le 4\beta^{-2}(\|d_t u_h^1\|_0^2 + \nu^2\|A_h u_h^1\|_0^2 + \|f(t_1)\|_0^2 + c_0^2\gamma_0^2\|u_h^0\|_1^2). \tag{4.15}$$

Combining (4.14)–(4.15) with (4.13) and using (4.5)–(4.6) yields (4.9). ∎

The following theorem provides the stability of the scheme in (4.1) and (4.3).

THEOREM 4.2. *Suppose that the assumptions* (A1)–(A3) *are valid and* $0 < \tau < 1$ *satisfies the following stability condition:*

$$160c_0^2\gamma_0^2\nu^{-2}\kappa_2\max\{1, \nu, \kappa_1^{1/2}\}\tau \le 1. \tag{4.16}$$

Then there hold

$$\|u_h^m\|_0^2 + \nu\tau\sum_{n=1}^{m}\|\bar{u}_h^n\|_1^2 \le \kappa_0, \tag{4.17}$$

$$\|u_h^m\|_1^2 + \nu\tau\sum_{n=1}^{m}\|A_h\bar{u}_h^n\|_0^2 \le \kappa_1, \tag{4.18}$$

$$\|d_t u_h^m\|_0^2 + \nu\|A_h u_h^m\|_0^2 + \|p_h^m\|_0^2 + \nu\|d_t u_h^m\|_1^2\tau \le \kappa_2 \tag{4.19}$$

for all $1 \le m \le N$, *where* $\kappa_0 \ge \kappa_0'$, $\kappa_1 \ge \kappa_1'$, *and* $\kappa_2 \ge \kappa_2'$ *are some positive constants depending on the data* (ν, Ω, T, u_0, f).

Proof. We prove (4.17)–(4.19) by the induction method. From Lemma 4.1, (4.17)–(4.19) are true for $m = 1$. We assume that (4.17)–(4.19) are true for $m = 1, \dots, J-1$ with $2 \le J \le N$. We need to prove that (4.17)–(4.19) are true for $m = J$.

First, taking $v_h = 2u_h^n\tau \in V_h$ and $q_h = 0$ in (4.3) and using (3.12) and the formulas

$$u_h^n = \bar{u}_h^n + \frac{1}{2}d_t u_h^n\tau, \quad u_h^n = 2\bar{u}^n - u_h^{n-1}, \quad u_h^n = \bar{u}_h^{n-1} + d_t u_h^n\tau + \frac{1}{2}d_t u_h^{n-1}\tau,$$
$$2(d_t u_h^n, u_h^n)\tau = \|u_h^n\|_0^2 - \|u_h^{n-1}\|_0^2 + \|d_t u_h^n\|_0^2\tau^2,$$
$$2a(\bar{u}_h^n, u_h^n)\tau = \frac{\nu}{2}(\|u_h^n\|_1^2 - \|u_h^{n-1}\|_1^2 + 4\|\bar{u}_h^n\|_1^2)\tau,$$

we obtain

$$\begin{aligned}
&\|u_h^n\|_0^2 - \|u_h^{n-1}\|_0^2 + \|d_t u_h^n\|_0^2\tau^2 + \frac{\nu}{2}(\|u_h^n\|_1^2 - \|u_h^{n-1}\|_1^2 + 4\|\bar{u}_h^n\|_1^2)\tau \\
&\quad + 2b\left(\bar{u}_h^{n-1}, \bar{u}_h^{n-1}, d_t u_h^n + \frac{1}{2}d_t u_h^{n-1}\right)\tau^2 + 2b\left(d_t u_h^{n-1}, \bar{u}_h^{n-1}, \bar{u}_h^n + \frac{1}{2}d_t u_h^n\tau\right)\tau^2 \\
&\quad + 2b\left(\bar{u}_h^{n-1}, d_t u_h^{n-1}, \bar{u}_h^n + \frac{1}{2}d_t u_h^n\tau\right)\tau^2 + b\left(d_t u_h^{n-1}, d_t u_h^{n-1}, \bar{u}_h^n - \frac{1}{2}u_h^{n-1}\right)\tau^3 \\
&= (\bar{f}(t_n), 2\bar{u}_h^n + d_t u_h^n\tau)\tau. \qquad (4.20)
\end{aligned}$$

In view of Lemma 3.1 and (3.10), there hold

$$\begin{aligned}
2\left|b\left(\bar{u}_h^{n-1}, \bar{u}_h^{n-1}, d_t u_h^n + \frac{1}{2}d_t u_h^{n-1}\right)\right|\tau^2 &\le 2c_0\gamma_0\|A_h\bar{u}_h^{n-1}\|_0\|\bar{u}_h^{n-1}\|_1\left\|d_t u_h^n + \frac{1}{2}d_t u_h^{n-1}\right\|_0\tau^2 \\
&\le \frac{1}{4}\|d_t u_h^n\|_0^2\tau^2 + \frac{1}{8}\|d_t u_h^{n-1}\|_0^2\tau^2 \\
&\quad + 6c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\|\bar{u}_h^{n-1}\|_1^2\tau^2, \\
2|b(d_t u_h^{n-1}, \bar{u}_h^{n-1}, \bar{u}_h^n)|\tau^2 + 2|b(\bar{u}_h^{n-1}, d_t u_h^{n-1}, \bar{u}_h^n)|\tau^2 &\le \frac{\nu}{4}\|\bar{u}_h^n\|_1^2\tau + 4\nu^{-1}c_0^2\gamma_0^2\|d_t u_h^{n-1}\|_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\tau^3, \\
|b(d_t u_h^{n-1}, \bar{u}_h^{n-1}, d_t u_h^n)|\tau^3 + |b(\bar{u}_h^{n-1}, d_t u_h^{n-1}, d_t u_h^n)|\tau^3 &\le \frac{1}{4}\|d_t u_h^n\|_0^2\tau^2 + c_0^2\gamma_0^2\|d_t u^{n-1}\|_1^2\|A_h\bar{u}_h^{n-1}\|_0^2\tau^4, \\
|b(d_t u_h^{n-1}, d_t u_h^{n-1}, \bar{u}_h^n)|\tau^3 &\le \frac{\nu}{4}\|\bar{u}_h^n\|_1^2\tau \\
&\quad + \nu^{-1}c_0^2\gamma_0^2\|d_t u_h^{n-1}\|_0^2\|A_h(u_h^{n-1} - u_h^{n-2})\|_0^2\tau^3, \\
\frac{1}{2}|b(d_t u_h^{n-1}, d_t u_h^{n-1}, u_h^{n-1})|\tau^3 &\le \frac{1}{8}\|d_t u_h^{n-1}\|_0^2\tau^2 + \frac{1}{2}c_0^2\gamma_0^2\|d_t u_h^{n-1}\|_1^2\|A_h u_h^{n-1}\|_0^2\tau^4, \\
|(\bar{f}(t_n), 2\bar{u}_h^n + d_t u_h^n\tau)|\tau &\le \frac{\nu}{4}\|\bar{u}_h^n\|_1^2\tau + \frac{1}{8}\|d_t u_h^n\|_0^2\tau^2 \\
&\quad + (4\nu^{-1}\gamma_0^2 + 2\tau)\|\bar{f}(t_n)\|_0^2\tau.
\end{aligned}$$

Combining these inequalities with (4.20) yields

$$\begin{aligned}
&\left(\|u_h^n\|_0^2+\frac{\nu}{2}\|u_h^n\|_1^2\tau\right)-\left(\|u_h^{n-1}\|_0^2+\frac{\nu}{2}\|u_h^{n-1}\|_1^2\tau\right)+\nu\|\bar u_h^n\|_1^2\tau\\
&\quad+\frac{\nu}{4}\|\bar u_h^n\|_1^2\tau-6c_0^2\gamma_0^2\|A_h\bar u_h^{n-1}\|_0^2\|\bar u_h^{n-1}\|_1^2\tau^2+\frac{3}{8}\|d_tu_h^n\|_0^2\tau^2-\frac{2}{8}\|d_tu_h^{n-1}\|_0^2\tau^2\\
&\quad-10\nu^{-1}c_0^2\gamma_0^2(\|A_hu_h^{n-1}\|_0^2+\|A_hu_h^{n-2}\|_0^2)\|d_tu_h^{n-1}\|_0^2\tau^3\\
&\quad\le 3\nu^{-1}c_0^2\gamma_0^2(\|A_hu_h^{n-1}\|_0^2+\|A_hu_h^{n-2}\|_0^2)\nu\|d_tu_h^{n-1}\|_1^2\tau^4\\
&\quad+(4\nu^{-1}\gamma_0^2+2\tau)\|\bar f(t_n)\|_0^2\tau. \qquad (4.21)
\end{aligned}$$

Using (4.16) and the induction assumption with $m=1,\dots,J-1$, we have

$$\begin{aligned}
6c_0^2\gamma_0^2\|A_h\bar u_h^{n-1}\|_0^2\tau&\le 6c_0^2\gamma_0^2\kappa_2\tau\le\frac{\nu}{4},\\
10\nu^{-1}c_0^2\gamma_0^2(\|A_hu_h^{n-1}\|_0^2+\|A_hu_h^{n-2}\|_0^2)\tau&\le 20\nu^{-2}c_0^2\gamma_0^2\kappa_2\tau\le\frac{1}{8},\\
3\nu^{-1}c_0^2\gamma_0^2(\|A_hu_h^{n-1}\|_0^2+\|A_hu_h^{n-2}\|_0^2)\nu\|d_tu_h^{n-1}\|_1^2\tau^4&\le 6\nu^{-2}c_0^2\gamma_0^2\kappa_2^2\tau^3
\end{aligned}$$

for all $n=2,\dots,J$. Summing (4.21) from 2 to J and using the above estimates, we have

$$\begin{aligned}
\|u_h^J\|_0^2+\nu\tau\sum_{n=1}^{J}\|\bar u_h^n\|_1^2&\le\|u_h^1\|_0^2+\frac{\nu}{2}\|u_h^1\|_1^2\tau+\frac{3}{8}\|d_tu_h^1\|_0^2\tau^2+\frac{\nu}{4}\|\bar u_h^1\|_1^2\tau\\
&\quad+6\nu^{-2}c_0^2\gamma_0^2T\kappa_2^2\tau^2+(4\nu^{-1}\gamma_0^2+2\tau)T\sup_{0\le t\le T}\|f(t)\|_0^2 \qquad (4.22)
\end{aligned}$$

for all $1\le J\le N$. Using Lemma 4.1 and (4.16) in (4.22) yields (4.17) with $m=J$.

Next, by taking $v_h=2A_h\bar u_h^n\tau\in V_h$ and $q_h=0$ in (4.4), we obtain

$$\begin{aligned}
&\|u_h^n\|_1^2-\|u_h^{n-1}\|_1^2+2\nu\|A_h\bar u_h^n\|_0^2\tau+2b(\bar u_h^{n-1},\bar u_h^{n-1},A_h\bar u_h^n)\tau\\
&\quad+2b(\bar u_h^{n-1},d_tu_h^{n-1},A_h\bar u_h^n)\tau^2+2b(d_tu_h^{n-1},\bar u_h^{n-1},A_h\bar u_h^n)\tau^2\\
&\quad+\frac{1}{2}b(d_tu_h^{n-1},d_tu_h^{n-1},A_h\bar u_h^n)\tau^3=2(\bar f(t_n),A_h\bar u_h^n)\tau. \qquad (4.23)
\end{aligned}$$

In view of Lemma 3.1 and (3.10), there hold

$$\begin{aligned}
2|b(\bar u_h^{n-1},\bar u_h^{n-1},A_h\bar u_h^n)|\tau&\le c_0\|A_h\bar u_h^{n-1}\|_0^{1/2}\|\bar u_h^{n-1}\|_0^{1/2}\|\bar u_h^{n-1}\|_1\|A_h\bar u_h^n\|_0\tau\\
&\le\frac{\nu}{8}\|A_h\bar u_h^n\|_0^2\tau+2\nu^{-1}c_0^2\|A_h\bar u_h^{n-1}\|_0\|\bar u_h^{n-1}\|_0\|\bar u_h^{n-1}\|_1^2\tau\\
&\le\frac{\nu}{8}(\|A_h\bar u_h^n\|_0^2+2\|A_h\bar u_h^{n-1}\|_0^2)\tau\\
&\quad+2\nu^{-3}c_0^4\|\bar u_h^{n-1}\|_1^4\|\bar u_h^{n-1}\|_0^2\tau,\\
2|b(\bar u_h^{n-1},d_tu_h^{n-1},A_h\bar u_h^n)|\tau^2&+2|b(d_tu_h^{n-1},\bar u_h^{n-1},A_h\bar u_h^n)|\tau^2\\
&\le 2c_0\gamma_0^{1/2}\|A_h\bar u_h^{n-1}\|_0^{1/2}\|\bar u_h^{n-1}\|_1^{1/2}\|d_tu_h^{n-1}\|_1\|A_h\bar u_h^n\|_0\tau^2\\
&\le\frac{\nu}{8}\|A_h\bar u_h^n\|_0^2\tau\\
&\quad+8\nu^{-1}c_0^2\gamma_0\|A_h\bar u_h^{n-1}\|_0\|\bar u_h^{n-1}\|_1\|d_tu_h^{n-1}\|_1^2\tau^3,
\end{aligned}$$

$$\begin{aligned}\frac{1}{2}|b(d_tu_h^{n-1},d_tu_h^{n-1},A_h\bar{u}_h^n)|\tau^3 &\le \frac{1}{2}c_0\|A_hd_tu_h^{n-1}\|_0^{1/2}\|d_tu_h^{n-1}\|_0^{1/2}\|d_tu_h^{n-1}\|_1\|A_h\bar{u}_h^n\|_0\tau^3\\ &\le \frac{\nu}{8}\|A_h\bar{u}_h^n\|_0^2\tau\\ &\quad+\nu^{-1}c_0^2\|A_h(u_h^{n-1}-u_h^{n-2})\|_0\|d_tu_h^{n-1}\|_0\|d_tu_h^{n-1}\|_1^2\tau^4,\\ 2|(\bar{f}(t_n),A_h\bar{u}_h^n)|\tau &\le \frac{\nu}{8}\|A_h\bar{u}_h^n\|_0^2\tau+8\nu^{-1}\|\bar{f}(t_n)\|_0^2\tau.\end{aligned}$$

Combining these inequalities with (4.23) gives

$$\begin{aligned}&(\|u_h^n\|_1^2-\|u_h^{n-1}\|_1^2+\frac{\nu}{2}(3\|A_h\bar{u}_h^n\|_0^2-\|A_h\bar{u}_h^{n-1}\|_0^2)\tau\\ &\quad\le 2\nu^{-3}c_0^4\|\bar{u}_h^{n-1}\|_1^4\|\bar{u}_h^{n-1}\|_0^2\tau+8\nu^{-1}\|\bar{f}(t_n)\|_0^2\tau\\ &\quad+8\nu^{-1}c_0^2\gamma_0\|A_h\bar{u}_h^{n-1}\|_0\|\bar{u}_h^{n-1}\|_1\|d_tu_h^{n-1}\|_1^2\tau^3\\ &\quad+\nu^{-1}c_0^2(\|A_hu_h^{n-1}\|_0+\|A_hu_h^{n-2}\|_0)\|d_tu_h^{n-1}\|_0\|d_tu_h^{n-1}\|_1^2\tau^4.\end{aligned}\tag{4.24}$$

Summing (4.24) from 2 to J and using (4.16) and the induction assumption with $m=0,1,\dots,J-1$, we obtain

$$\begin{aligned}\|u_h^J\|_1^2+\nu\tau\sum_{n=1}^{J}\|A_h\bar{u}_h^n\|_0^2 &\le \tau\sum_{n=1}^{J-1}d_n\|u_h^n\|_1^2+\frac{3}{2}\nu\|A_h\bar{u}_h^1\|_0^2\tau\\ &\quad+\|u_h^1\|_1^2+8\nu^{-1}T\sup_{0\le t\le T}\|f(t)\|_0^2\\ &\quad+\nu^{-1}\gamma_0^{-1}\kappa_0^{1/2}+\nu^{3/2}c_0^{-2}T\gamma_0^{-4}\end{aligned}\tag{4.25}$$

for all $1\le J\le N$, where

$$d_n=2\nu^{-3}c_0^4(\|\bar{u}_h^n\|_1^2\|\bar{u}_h^n\|_0^2+\|\bar{u}_h^{n+1}\|_1^2\|\bar{u}_h^{n+1}\|_0^2),\quad \bar{u}_h^0=u_h^0.$$

We set

$$\begin{aligned}a_n&=\|u_h^n\|_1^2,\quad b_n=\nu\|A_h\bar{u}_h^n\|_0^2,\\ C&=\|u_h^1\|_1^2+\frac{3}{2}\nu\|A_h\bar{u}_h^1\|_0^2\tau+8\nu^{-1}T\sup_{0\le t\le T}\|f(t)\|_0^2\\ &\quad+\nu^{-1}\gamma_0^{-1}\kappa_0^{1/2}+\nu^{3/2}c_0^{-2}T\gamma_0^{-4}.\end{aligned}$$

Applying Lemma 3.4 to (4.25) and using (4.16)–(4.17) and Lemma 4.1, we obtain (4.18) with $m=J$.

Now, we prove that (4.19) holds for $m=J$. For $n=2$, we deduce from (4.1) and (4.3) that

$$\begin{aligned}(d_{tt}u_h^2,v_h)+\frac{1}{2}a(d_tu_h^2,v_h)-d(v_h,d_tp_h^2)+(d_tu_h^2,q_h)\\ +\frac{3}{2}b(d_tu_h^1,\bar{u}_h^1,v_h)+\frac{3}{2}b(\bar{u}_h^1,d_tu_h^1,v_h)\\ =\frac{1}{2\tau}\int_{t_1}^{t_2}(f_t(t),v_h)dt\,.\end{aligned}\tag{4.26}$$

By taking $v_h=2d_tu_h^2\tau$ and $q_h=2d_tp_h^2\tau$ in (4.26) and using (3.10) and Lemma 3.1, we have

$$\begin{aligned}&\|d_tu_h^2\|_0^2-\|d_tu_h^1\|_0^2+\|d_{tt}u_h^2\|_0^2\tau^2+\frac{\nu}{2}\|d_tu_h^2\|_1^2\tau\\ &\quad\le\nu^{-1}\gamma_0^2\int_{t_1}^{t_2}\|f_t(t)\|_0^2dt+\frac{9}{4}\nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^1\|_0^2\|d_tu_h^1\|_0^2\tau.\end{aligned}\tag{4.27}$$

Moreover, it follows from (4.3) that for $3 \le n \le J$ there holds

$$\begin{aligned}
&(d_{tt}u_h^n, v_h) + a(d_t\bar{u}_h^n, v_h) - d(v_h, d_tp_h^n) + (d_t\bar{u}_h^n, q_h)\\
&\qquad + \frac{3}{2}b(d_tu_h^{n-1}, \bar{u}_h^{n-1}, v_h) + \frac{3}{2}b(\bar{u}_h^{n-1}, d_tu_h^{n-1}, v_h)\\
&\qquad - \frac{1}{2}b(d_tu_h^{n-2}, \bar{u}_h^{n-2}, v_h) - \frac{1}{2}b(\bar{u}_h^{n-2}, d_tu_h^{n-2}, v_h)\\
&\qquad = \frac{1}{2\tau}\int_{t_{n-2}}^{t_n}(f_t(t), v_h)dt. \qquad (4.28)
\end{aligned}$$

Taking $v_h = 2d_tu_h^n\tau$ in (4.28), using (3.12), and noting $d_tu_h^n = d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau$ yields

$$\begin{aligned}
&\|d_tu_h^n\|_0^2 - \|d_tu_h^{n-1}\|_0^2 + \|d_{tt}u_h^n\|_0^2\tau^2 + \frac{\nu}{2}(\|d_tu_h^n\|_1^2 - \|d_tu_h^{n-1}\|_1^2 + 4\|d_t\bar{u}_h^n\|_1^2)\tau\\
&\quad + 3b(\bar{u}_h^{n-1}, d_tu_h^{n-1}, d_{tt}u_h^n)\tau^2 + 3b\left(d_tu_h^{n-1}, \bar{u}_h^{n-1}, d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau\right)\tau\\
&\quad - b\left(d_tu_h^{n-2}, \bar{u}_h^{n-2}, d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau\right)\tau - b\left(\bar{u}_h^{n-2}, d_tu_h^{n-2}, d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau\right)\tau\\
&\quad = \left(\int_{t_{n-2}}^{t_n} f_t(t), d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau\right)dt. \qquad (4.29)
\end{aligned}$$

In view of Lemma 3.1 and (3.10), there hold

$$\begin{aligned}
3|b(d_tu_h^{n-1}, \bar{u}_h^{n-1}, d_t\bar{u}_h^n)|\tau &\le \frac{\nu}{4}\|d_t\bar{u}_h^n\|_1^2\tau + 9\nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\|d_tu_h^{n-1}\|_0^2\tau,\\
3|b(\bar{u}_h^{n-1}, d_tu_h^{n-1}, d_{tt}u_h^n)|\tau^2 &+ 3|b(d_tu_h^{n-1}, \bar{u}_h^{n-1}, d_{tt}u_h^n)|\tau^2\\
&\le \frac{1}{4}\|d_{tt}u_h^n\|_0^2\tau^2 + 9c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\|d_tu_h^{n-1}\|_1^2\tau^2,\\
|b(d_tu_h^{n-2}, \bar{u}_h^{n-2}, d_t\bar{u}_h^n)|\tau &+ |b(\bar{u}_h^{n-2}, d_tu_h^{n-2}, d_t\bar{u}_h^n)|\tau\\
&\le \frac{\nu}{4}\|d_tu_h^n\|_1^2\tau + \nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-2}\|_0^2\|d_tu_h^{n-2}\|_0^2\tau,\\
|b(d_tu_h^{n-2}, \bar{u}_h^{n-2}, d_{tt}u_h^n)|\tau^2 &+ |b(\bar{u}_h^{n-2}, d_tu_h^{n-2}, d_{tt}u_h^n)|\tau^2\\
&\le \frac{1}{4}\|d_{tt}u_h^n\|_0^2\tau^2 + c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-2}\|_0^2\|d_tu_h^{n-2}\|_1^2\tau^2,\\
\left|\int_{t_{n-2}}^{t_n}(f_t(t), d_t\bar{u}_h^n + \frac{1}{2}d_{tt}u_h^n\tau)dt\right| &\le \frac{\nu}{4}\|d_t\bar{u}_h^n\|_1^2\tau + \frac{1}{4}\|d_{tt}u_h^n\|_0^2\tau^2\\
&\quad + 2(\nu^{-1}\gamma_0^2 + \tau)\int_{t_{n-2}}^{t_n}\|f_t(t)\|_0^2dt.
\end{aligned}$$

Combining these inequalities with (4.29) and using Lemma 4.1 yields

$$\begin{aligned}
&\left(\|d_tu_h^n\|_0^2 + \frac{\nu}{2}\|d_tu_h^n\|_1^2\tau\right) - \left(\|d_tu_h^{n-1}\|_0^2 + \frac{\nu}{2}\|d_tu_h^{n-1}\|_1^2\tau\right)\\
&\quad \le 9\nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\|d_tu_h^{n-1}\|_0^2\tau + \nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-2}\|_0^2\|d_tu_h^{n-2}\|_0^2\tau\\
&\quad + 9c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-1}\|_0^2\|d_tu_h^{n-1}\|_1^2\tau^2 + c_0^2\gamma_0^2\|A_h\bar{u}_h^{n-2}\|_0^2\|d_tu_h^{n-2}\|_1^2\tau^2\\
&\quad + 2(\nu^{-1}\gamma_0^2 + \tau)\int_{t_{n-2}}^{t_n}\|f_t(t)\|_0^2dt. \qquad (4.30)
\end{aligned}$$

Summing this inequality from 3 to J, adding (4.27) in, and using the induction assumption with $m = 1, \ldots, J-1$ and (4.17)–(4.18), we arrive at

$$\begin{aligned}\|d_t u_h^J\|_0^2 + \frac{\nu}{2}\|d_t u_h^J\|_1^2\tau \le \tau\sum_{n=0}^{J-1} d_n\left(\|d_t u_h^n\|_0^2 + \frac{\nu}{2}\|d_t u_h^n\|_1^2\tau\right)\\ + \|d_t u_h^1\|_0^2 + \frac{\nu}{2}\|d_t u_h^1\|_1^2\tau + 2(\nu^{-1}\gamma_0^2+\tau)\int_0^T \|f_t(t)\|_0^2 dt \end{aligned} \tag{4.31}$$

for $1 \le J \le N$, where

$$d_n = 13\nu^{-1}c_0^2\gamma_0^2\|A_h\bar{u}_h^n\|_0^2, \quad 1 \le n \le J-1, \quad d_0 = 0.$$

We set

$$\begin{aligned} a_n &= \|d_t u_h^n\|_0^2 + \frac{\nu}{2}\|d_t u_h^n\|_1^2\tau, \quad b_n = 0, \quad c_n = 0,\\ C &= \|d_t u_h^1\|_0^2 + \frac{\nu}{2}\|d_t u_h^1\|_1^2\tau + 2(\nu^{-1}\gamma_0^2+\tau)\int_0^T \|f_t(t)\|_0^2 dt. \end{aligned}$$

Applying Lemma 3.4 to (4.31) and using (4.16)–(4.18) and Lemma 4.1, we obtain

$$\|d_t u_h^J\|_0^2 + \frac{\nu}{2}\|d_t u_h^J\|_1^2\tau \le \exp(13\nu^{-2}c_0^2\gamma_0^2\kappa_1)C. \tag{4.32}$$

Next, by taking $v_h = 2A_h d_t u_h^n\tau \in V_h$ and $q_h = 0$ in (4.4), we obtain

$$\begin{aligned}&2\|d_t u_h^n\|_1^2\tau + \nu\|A_h u_h^n\|_0^2 - \nu\|A_h u_h^{n-1}\|_0^2 + 2b(\bar{u}_h^{n-1}, \bar{u}_h^{n-1}, A_h d_t u_h^n)\tau\\ &\quad + 2b(\bar{u}_h^{n-1}, d_t u_h^{n-1}, A_h d_t u_h^n)\tau^2 + 2b(d_t u_h^{n-1}, \bar{u}_h^{n-1}, A_h d_t u_h^n)\tau^2\\ &\quad + \frac{1}{2}b(d_t u_h^{n-1}, d_t u_h^{n-1}, A_h d_t u_h^n)\tau^3 = 2(\bar{f}(t_n), A_h d_t u_h^n)\tau. \end{aligned} \tag{4.33}$$

In view of Lemma 3.1 and (3.10), there hold

$$\begin{aligned} 2|b(\bar{u}_h^{n-1}, \bar{u}_h^{n-1}, A_h d_t u_h^n)|\tau &\le c_0\gamma_0\|A_h\bar{u}_h^{n-1}\|_0^2\|d_t u_h^n\|_1\tau\\ &\le \frac{1}{8}\|d_t u_h^n\|_1^2\tau + c\|A_h\bar{u}_h^{n-1}\|_0^4\tau\\ 2|b(\bar{u}_h^{n-1}, d_t u_h^{n-1}, A_h d_t u_h^n)|\tau^2 &+ 2|b(d_t u_h^{n-1}, \bar{u}_h^{n-1}, A_h d_t u_h^n)|\tau^2\\ &\le 2c_0\gamma_0\|A_h\bar{u}_h^{n-1}\|_0\|A_h d_t u_h^{n-1}\|_0\|d_t u_h^n\|_1\tau^2\\ &\le \frac{1}{8}\|d_t u_h^n\|_1^2\tau + c\|A_h\bar{u}_h^{n-1}\|_0^2\|A_h u_h^{n-1} - A_h u_h^{n-2}\|_0^2\tau,\\ \frac{1}{2}|b(d_t u_h^{n-1}, d_t u_h^{n-1}, A_h d_t u_h^n)|\tau^3 &\le c\|d_t u_h^{n-1}\|_0^{1/2}\|A_h d_t u_h^{n-1}\|_0^{3/2}\|d_t u_h^n\|_1\tau^3\\ &\quad + c\|d_t u_h^{n-1}\|_1\|A_h d_t u_h^{n-1}\|_0\|d_t u_h^n\|_1\tau^3\\ &\le \frac{1}{8}\|d_t u_h^n\|_1^2\tau\\ &\quad + c(\|d_t u_h^{n-1}\|_1^2\tau^2 + \|d_t u_h^{n-1}\|_0\|A_h d_t u_h^{n-1}\|_0\tau^2)\\ &\quad \times \|A_h(u_h^{n-1} - u_h^{n-2})\|_0^2\tau,\\ 2|(\bar{f}(t_n), A_h d_t u_h^n)|\tau &\le \frac{1}{8}\|d_t u_h^n\|_1^2\tau + c\|\nabla\bar{f}(t_n)\|_0^2\tau. \end{aligned}$$

Combining these inequalities with (4.33) gives

$$\begin{aligned}&\nu\|A_h u_h^n\|_0^2 - \nu\|A_h u_h^{n-1}\|_0^2 + \|d_t u_h^n\|_1^2\tau\\ &\quad\le c(\|A_h\bar{u}_h^{n-1}\|_0^2 + c\|d_t u_h^{n-1}\|_1^2\tau^2 + \|d_t u_h^{n-1}\|_0\|A_h d_t u_h^{n-1}\|_0\tau^2)\\ &\quad\times(\|A_h u_h^{n-1}\|_0^2 + \|A_h u_h^{n-2}\|_0^2)\tau + c\|\nabla\bar{f}(t_n)\|_0^2\tau.\end{aligned}\tag{4.34}$$

Summing (4.34) from 2 to J and using (4.16)–(4.32) and the induction assumption with $m = 0, 1, \ldots, J-1$, we obtain

$$\begin{aligned}\nu\|A_h u_h^J\|_1^2 + \tau\sum_{n=1}^{J}\|d_t u_h^n\|_1^2 &\le \nu\tau\sum_{n=1}^{J-1} d_n\|A_h u_h^n\|_1^2\\ &\quad + \|A_h u_h^1\|_0^2 + c\sup_{0\le t\le T}\|\nabla f(t)\|_0^2\end{aligned}\tag{4.35}$$

for all $1 \le J \le N$, where

$$\begin{aligned}d_n &= c(\|A_h\bar{u}_h^{n+1}\|_0^2 + c\|d_t u_h^{n+1}\|_1^2\tau^2 + \|d_t u_h^{n+1}\|_0\|A_h d_t u_h^{n+1}\|_0\tau^2)\\ &\quad + c(\|A_h\bar{u}_h^{n}\|_0^2 + c\|d_t u_h^{n}\|_1^2\tau^2 + \|d_t u_h^{n}\|_0\|A_h d_t u_h^{n}\|_0\tau^2).\end{aligned}$$

Using (4.16)–(4.18), (4.32), and the induction assumption with $m = 0, 1, \ldots, J-1$, we obtain

$$\tau\sum^{J-1} d_n \le \kappa, \quad \kappa \text{ is independent of } \kappa_2.\tag{4.36}$$

We set

$$\begin{aligned}a_n &= \nu\|A_h u_h^n\|_0^2, \quad b_n = \|d_t u_h^n\|_1^2,\\ C &= \nu\|A_h u_h^1\|_1^2 + c\nu^{-1}T\sup_{0\le t\le T}\|\nabla f(t)\|_0^2.\end{aligned}$$

Applying the discrete Gronwall lemma to (4.35) and using (4.36), we obtain

$$\nu\|A_h u_h^J\|_1^2 + \tau\sum_{n=1}^{J}\|d_t u_h^n\|_1^2 \le \kappa, \quad \kappa \text{ is independent of } \kappa_2.\tag{4.37}$$

Finally, using (4.3), (3.4), (3.10), and Lemma 3.1, we arrive at

$$\begin{aligned}\|p_h^J\|_0 &= \beta^{-1}\sup_{v_h\in X_h}\frac{d(v_h, p_h^J)}{\|v_h\|_1}\\ &\le \beta^{-1}\left(\gamma_0\|d_t u_h^J\|_0 + \nu\|\bar{u}_h^J\|_1 + \gamma_0\|\bar{f}(t_n)\|_0 + \frac{3}{2}c_0\gamma_0\|u_h^{J-1}\|_1^2 + \frac{1}{2}c_0\gamma_0\|u_h^{J-2}\|_1^2\right),\end{aligned}$$

which yields

$$\begin{aligned}\|p_h^J\|_0^2 &\le 5\beta^{-2}\left(\gamma_0^2\|d_t u_h^J\|_0^2 + \nu^2\gamma_0^2\|A_h\bar{u}_h^J\|_0^2 + \gamma_0^2\sup_{0\le t\le T}\|f(t)\|_0^2\right)\\ &\quad + 5\beta^{-2}\left(\frac{9}{4}c_0^2\gamma_0^2\|u_h^{J-1}\|_1^4 + \frac{1}{4}c_0^2\gamma_0^2\|u_h^{J-2}\|_1^4\right).\end{aligned}\tag{4.38}$$

Combining (4.37) and (4.38) with (4.32), we get (4.19) with $m = J$. So, we have completed the proof of Theorem 4.2. □

LEMMA 4.3. *Suppose that the assumptions* (A1)–(A2) *are valid and the couple* (X_h, M_h) *satisfies the approximate properties* (3.2)–(3.4). *Then there hold*

$$\|e^1\|_\alpha^2 + \|d_t e^1\|_\alpha^2 \tau^2 + \nu \|e^1\|_{\alpha+1}^2 \tau \le \kappa \tau^{2-\alpha}, \quad \alpha = -2, \ -1, \ 0, \ 1, \tag{4.39}$$

$$\|\eta^1\|_0^2 \le \kappa, \tag{4.40}$$

where

$$e^0 = 0, \quad e^n = u_h(t_n) - u_h^n, \quad \eta^n = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} p_h(t)dt - p_h^n, \quad n = 1, \ldots, N.$$

Proof. By integrating (3.8) from t_0 to t_1,

$$\begin{aligned}(d_t u_h(t_1), v_h) + \frac{1}{\tau}\int_{t_0}^{t_1} a(u_h(t), v_h)dt - \frac{1}{\tau}\int_{t_0}^{t_1} d(v_h, p_h(t))dt \\ + \frac{1}{\tau}\int_{t_0}^{t_1} b(u_h(t), u_h(t), v_h)dt = \frac{1}{\tau}\int_{t_0}^{t_1} (f(t), v_h)dt.\end{aligned} \tag{4.41}$$

Subtracting (4.1) from (4.41) and using the integral formula by parts, we obtain

$$(d_t e^1, v_h) + a(e^1, v_h) - d(v_h, \eta^1) = (E_1, v_h), \tag{4.42}$$

where

$$\begin{aligned}(E_1, v_h) = -\frac{1}{\tau}\int_{t_0}^{t_1} (t - t_0)(f_t(t), v_h)dt + \frac{1}{\tau}\int_{t_0}^{t_1} (t - t_0) a(u_{ht}(t), v_h)dt \\ + \frac{1}{\tau}\int_{t_0}^{t_1} (t - t_1) b_t(u_h(t), u_h(t), v_h)dt\end{aligned} \tag{4.43}$$

and

$$b_t(u_h(t), u_h(t), v_h) = b(u_{ht}(t), u_h(t), v_h) + b(u_h(t), u_{ht}(t), v_h).$$

Hereafter, we need the L^2-orthogonal projection $R_h : Y \to X_h$ defined by

$$(R_h v, v_h) = (v, v_h) \ \ \forall v \in Y, \quad v_h \in X_h.$$

We see from (3.10), (4.43), Lemma 3.1, and Theorem 3.2 that

$$\begin{aligned}\|A_h^{\frac{\alpha-1}{2}} P_h E_1\|_0 &= \sup_{v_h \in V_h} \frac{(E_1, v_h)}{\|A_h^{\frac{1-\alpha}{2}} v_h\|_0} \\ &\le \left(\gamma_0^{1-\alpha}\tau \sup_{0\le t\le t_1} \|f_t(t)\|_0 + \nu\tau^{\frac{1-\alpha}{2}} \sup_{0\le t\le t_1} \sigma^{\frac{\alpha+1}{2}}(t)\|u_{ht}(t)\|_{\alpha+1}\right) \\ &+ c_0\gamma_0^{1-\alpha}\tau^{1-\frac{\alpha(\alpha+1)}{2}} \sup_{0\le t\le t_1} \sigma^{\frac{\alpha(\alpha+1)}{2}}(t)\|A_h u_h(t)\|_0\|u_{ht}(t)\|_0 \le \kappa\tau^{\frac{1-\alpha}{2}}\end{aligned} \tag{4.44}$$

for $\alpha = -1, \ 0, \ 1$ and

$$\begin{aligned}\|R_h E_1\|_0 = \sup_{v_h \in X_h} \frac{(E_1, v_h)}{\|v_h\|_0} \le \tau \sup_{0\le t\le t_1} \|f_t(t)\|_0 + \nu \sup_{0\le t\le t_1} \sigma(t)\|A_h u_{ht}(t)\|_0 \\ + c_0\gamma_0\|A_h u_h(t_0)\|_0\|u_h(t_0)\|_1 + c_0\gamma_0 \sup_{0\le t\le t_1} \|A_h u_h(t)\|_0\|u_h(t)\|_1 \le \kappa.\end{aligned} \tag{4.45}$$

Taking $v_h = 2A_h^{\alpha} e^1 \tau \in V_h$ in (4.42), we have

$$\|e^1\|_{\alpha}^2 + \|d_t e^1\|_{\alpha}^2 \tau^2 + \nu \|e^1\|_{\alpha+1}^2 \tau \le \nu^{-1} \|A_h^{\frac{\alpha-1}{2}} P_h E_1\|_0^2 \tau \le \kappa \tau^{2-\alpha}. \tag{4.46}$$

Then, we take $v_h = 2A_h^{-2} e^1 \tau \in V_h$ in (4.42) and use (4.44) with $\alpha = -1$ to obtain

$$\frac{1}{2}\|e^1\|_{-2}^2 + \|d_t e^1\|_{-2}^2 \tau^2 + \nu \|e^1\|_{-1}^2 \tau \le 2\|A_h^{-1} P_h E_1\|_0^2 \tau^2 \le \kappa \tau^4. \tag{4.47}$$

Finally, using (4.42), (3.4), (3.10), and Lemma 3.1, we arrive at

$$\begin{aligned} \|\eta^1\|_0 &\le \beta^{-1} \sup_{v_h \in X_h} \frac{d(v_h, \eta^1)}{\|v_h\|_1} \\ &\le \beta^{-1}(\gamma_0 \|d_t e^1\|_0 + \nu \|e^1\|_1 + \gamma_0 \|R_h E_1\|_0), \end{aligned}$$

which gives

$$\|\eta^1\|_0^2 \le 3\beta^{-2}(\|d_t e^1\|_0^2 + \nu^2 \|e^1\|_1^2 + \|P_h E_1\|_{-1}^2) \le \kappa. \tag{4.48}$$

Combining (4.48) with (4.46)–(4.47) has completed the proof of Lemma 4.3. ∎

5. Second-order dual scheme: Stability analysis. In order to derive the L^2-bound on the error $u_h(t_n) - u_h^n$, we employ a parabolic argument that has already been used in [16] for the Crank–Nicolson scheme of the time-dependent Navier–Stokes equation. Let $t_m \in (0, t]$ be given. We consider the linearized "backward" counterpart of the discrete Navier–Stokes equations (4.3): for $\xi^n \in V_h$, $2 \le n \le m$, find $\Phi_h^{n-1} \in V_h$ such that

$$\begin{aligned} &(v_h, d_t \Phi_h^n) - a(v_h, \bar{\Phi}_h^n) - b\left(\frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}, v_h, \Phi_h^n\right) \\ &\qquad - b\left(v_h, \frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}, \Phi_h^n\right) = (v_h, \bar{\xi}^n), \quad v_h \in V_h, \end{aligned} \tag{5.1}$$

with an initial value $\Phi_h^m \in V_h$.

Here, we need to introduce the following discrete dual Gronwall lemma provided in [10].

LEMMA 5.1. *Let C and a_n, b_n, d_n, h_n for integers $n_0 \le n \le m$ be nonnegative numbers such that*

$$a_k + \tau \sum_{n=k}^{m} b_n \le \tau \sum_{n=k}^{m} d_n a_n + C, \quad n_0 \le k \le m \tag{5.2}$$

and $d_n \tau < 1$ for all $n_0 \le n \le m$; then

$$a_k + \tau \sum_{n=k}^{m} b_n \le C \exp\left(\tau \sum_{n=k}^{m} (1 - d_n \tau)^{-1} d_n\right), \quad n_0 \le k \le m. \tag{5.3}$$

The following lemma provides the stability of the scheme (5.1).

LEMMA 5.2. *Under the assumptions of Theorem 4.2, the following a priori estimates hold:*

$$\|\Phi_h^k\|_0^2 + \tau \sum_{n=k+1}^{m} (\nu \|\bar{\Phi}_h^n\|_1^2 + \|d_t \Phi_h^n\|_{-1}^2) \le \kappa \left(\|\Phi_h^m\|_0^2 + \tau \sum_{n=2}^{m} \|\bar{\xi}^n\|_{-1}^2\right), \tag{5.4}$$

$$\|\Phi_h^k\|_1^2 + \nu\tau \sum_{n=k+1}^{m} \|A_h \bar{\Phi}_h^n\|_0^2 \le \kappa \left(\|\Phi_h^m\|_1^2 + \tau \sum_{n=2}^{m} \|\bar{\xi}^n\|_0^2\right) \tag{5.5}$$

for all $1 \le k \le m$.

Proof. The proof follows the line of argument used in the proofs of Theorem 4.2. First, taking $v_h = -2\bar{\Phi}_h^n\tau$ in (5.1) and using (3.12), we get

$$\begin{aligned}&\|\Phi_h^{n-1}\|_0^2 - \|\Phi_h^n\|_0^2 + 2\nu\|\bar{\Phi}_h^n\|_1^2\tau + b(\bar{\Phi}_h^n, 3u_h^{n-1} - u_h^{n-2}, \bar{\Phi}_h^n)\tau\\ &\qquad \le \frac{\nu}{4}\|\bar{\Phi}_h^n\|_1^2\tau + 4\nu^{-1}\|\bar{\xi}^n\|_{-1}^2\tau. \end{aligned}\tag{5.6}$$

It follows from Lemma 3.1 and (3.10) that

$$\begin{aligned}|b(\bar{\Phi}_h^n, 3u_h^{n-1} - u_h^{n-2}, \bar{\Phi}_h^n)|\tau &\le c_0\gamma_0\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0\|\bar{\Phi}_h^n\|_1\|\bar{\Phi}_h^n\|_0\\ &\le \frac{3}{4}\nu\|\bar{\Phi}_h^n\|_1^2\tau + \frac{2}{3}\nu^{-1}c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2(\|\Phi_h^n\|_0^2 + \|\Phi_h^{n-1}\|_0^2)\tau.\end{aligned}$$

Combining (5.6) with the above estimate gives

$$\begin{aligned}&\|\Phi_h^{n-1}\|_0^2 - \|\Phi_h^n\|_0^2 + \nu\|\bar{\Phi}_h^n\|_1^2\tau\\ &\qquad \le \frac{2}{3}\nu^{-1}c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2(\|\Phi_h^n\|_0^2 + \|\Phi_h^{n-1}\|_0^2)\tau + 4\nu^{-1}\|\xi^n\|_{-1}^2\tau\end{aligned}$$

for all $2 \le n \le m$. Summing the above inequality from $k+1$ to m, we obtain

$$\begin{aligned}&\|\Phi_h^k\|_0^2 + \nu\tau\sum_{n=k+1}^{m}\|\bar{\Phi}_h^n\|_1^2\\ &\qquad \le \tau\sum_{n=k}^{m} d_n\|\Phi_h^n\|_0^2 + \|\Phi_h^m\|_0^2 + 4\nu^{-1}\tau\sum_{n=2}^{m}\|\bar{\xi}^n\|_{-1}^2, \quad 1 \le k \le m.\end{aligned}\tag{5.7}$$

Let

$$\begin{aligned}a_n &= \|\Phi_h^n\|_0^2, \quad b_n = \nu\|\bar{\Phi}_h^n\|_1^2, \quad C = \|\Phi_h^m\|_0^2 + 4\nu^{-1}\tau\sum_{n=2}^{m}\|\bar{\xi}^n\|_{-1}^2,\\ d_n &= \frac{2}{3}\nu^{-1}c_0^2\gamma_0^2(\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2 + \|A_h(3u_h^n - u_h^{n-1})\|_0^2).\end{aligned}$$

Hence, by using Theorem 4.2 and (4.16), we find

$$d_n\tau \le 27\nu^{-2}c_0^2\gamma_0^2\kappa_2\tau \le \frac{7}{11}, \quad (1 - d_n\tau)^{-1} \le \frac{11}{4}, \quad 1 \le n \le m.\tag{5.8}$$

Then, applying Lemma 5.1 to (5.7) and using Theorem 4.2 to obtain

$$\|\Phi_h^k\|_0^2 + \nu\tau\sum_{n=k+1}^{m}\|\bar{\Phi}_h^n\|_1^2 \le C\exp\left(\frac{11}{4}\tau\sum_{n=k}^{m} d_n\right) \le \kappa\left(\|\Phi_h^m\|_0^2 + \tau\sum_{n=2}^{m}\|\bar{\xi}^n\|_{-1}^2\right)\tag{5.9}$$

for all $1 \le k \le m$.

Moreover, we obtain from (3.10), (5.1), and Lemma 3.1 that

$$\|d_t\Phi_h^n\|_{-1} \le \nu\|\bar{\Phi}_h^n\|_1 + \frac{1}{2}c_0\gamma_0\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0\|\bar{\Phi}_h^n\|_1 + \|\bar{\xi}^n\|_{-1}, \quad 2 \le n \le m,$$

and by Theorem 4.2 that

$$\begin{aligned}\tau\sum_{n=k+1}^{m}\|d_t\Phi_h^n\|_{-1}^2 &\le 3\tau\sum_{n=k+1}^{m}(\nu^2\|\bar{\Phi}_h^n\|_1^2 + c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2\|\bar{\Phi}_h^n\|_1^2 + \|\bar{\xi}^n\|_{-1}^2)\\ &\le \kappa\tau\sum_{n=k+1}^{m}(\|\bar{\Phi}_h^n\|_1^2 + \|\bar{\xi}^n\|_{-1}^2), \quad 1 \le k \le m.\end{aligned}\tag{5.10}$$

Combining this inequality with (5.9) yields (5.4).

Furthermore, by taking $v_h = -2A_h\bar{\Phi}_h^n\tau$ in (5.1), we obtain

$$\begin{aligned}&\|\Phi_h^{n-1}\|_1^2 - \|\Phi_h^n\|_1^2 + 2\nu\|A_h\bar{\Phi}_h^n\|_0^2\tau\\&\quad + b(A_h\bar{\Phi}_h^n, 3u_h^{n-1} - u_h^{n-2}, \bar{\Phi}_h^n)\tau + b(3u_h^{n-1} - u_h^{n-2}, A_h\bar{\Phi}_h^n, \bar{\Phi}_h^n)\tau\\&\quad \le \frac{\nu}{4}\|A_h\Phi_h^{n-1}\|_0^2\tau + \frac{4}{\nu}\|\bar{\xi}^n\|_0^2\tau.\end{aligned} \tag{5.11}$$

From Lemma 3.1 and (3.10), we have

$$\begin{aligned}&|b(A_h\bar{\Phi}_h^n, 3u_h^{n-1} - u_h^{n-2}, \bar{\Phi}_h^n)|\tau + |b(3u_h^{n-1} - u_h^{n-2}, A_h\bar{\Phi}_h^n, \bar{\Phi}_h^n)|\tau\\&\qquad \le c_0\gamma_0\|\bar{\Phi}_h^n\|_1\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0\|A_h\bar{\Phi}_h^n\|_0\tau\\&\qquad \le \frac{\nu}{4}\|A_h\bar{\Phi}_h^n\|_0^2\tau + \nu^{-1}c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2\|\bar{\Phi}_h^n\|_1^2\tau.\end{aligned}$$

Combining (5.11) with the above estimate gives

$$\begin{aligned}&\|\Phi_h^{n-1}\|_1^2 - \|\Phi_h^n\|_1^2 + \nu\|A_h\bar{\Phi}_h^n\|_0^2\tau\\&\qquad \le \nu^{-1}c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2\|\bar{\Phi}_h^n\|_1^2\tau + 4\nu^{-1}\|\xi^n\|_0^2\tau\end{aligned} \tag{5.12}$$

for all $2 \le n \le m$. Summing (5.12) from $k+1$ to m and using (3.10), (5.5), and Theorem 4.2, we obtain (5.5). ∎

LEMMA 5.3. *Under the assumptions of Theorem* 4.2*, the following a priori estimate holds:*

$$\nu\|A_h\Phi_h^1\|_0^2 + \tau\sum_{n=2}^{m}\|d_t\Phi_h^n\|_1^2 \le \kappa\left(\nu\|A_h\Phi_h^m\|_0^2 + \tau\sum_{n=2}^{m}\|\bar{\xi}^n\|_1^2\right). \tag{5.13}$$

Proof. To prove (5.13), we take $v_h = 2A_hd_t\Phi_h^n\tau$ in (5.1) and obtain

$$\begin{aligned}&\nu(\|A_h\Phi_h^{n-1}\|_2^2 - \|A_h\Phi_h^n\|_0^2) + 2\|d_t\Phi_h^n\|_1^2\tau\\&\quad - b(A_hd_t\Phi_h^n, 3u_h^{n-1} - u_h^{n-2}, \bar{\Phi}_h^n)\tau - b(3u_h^{n-1} - u_h^{n-2}, A_hd_t\Phi_h^n, \bar{\Phi}_h^n)\tau\\&\quad \le \frac{1}{4}\|d_t\Phi_h^n\|_1^2\tau + 4\|\bar{\xi}^n\|_1^2\tau.\end{aligned} \tag{5.14}$$

It follows from Lemma 3.1 and (3.10) that

$$\begin{aligned}&|b(3u_h^{n-1} - u_h^{n-2}, A_hd_t\Phi_h^n, \bar{\Phi}_h^n)|\tau + |b(d_t\Phi_h^n, 3u_h^{n-1} - u_h^{n-2}, A_h\bar{\Phi}_h^n)|\tau\\&\qquad \le c_0\gamma_0\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0\|A_h\bar{\Phi}_h^n\|_1\|d_t\Phi_h^n\|_1\\&\qquad \le \frac{1}{4}\|d_t\Phi_h^n\|_1^2\tau + c_0^2\gamma_0^2\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2\|A_h\bar{\Phi}_h^n\|_0^2\end{aligned}$$

and by (5.14) that

$$\begin{aligned}&\nu(\|A_h\Phi_h^{n-1}\|_2^2 - \|A_h\Phi_h^n\|_0^2) + \|d_t\Phi_h^n\|_1^2\tau\\&\qquad \le c_0\gamma_0\|A_h(3u_h^{n-1} - u_h^{n-2})\|_0^2\|A_h\bar{\Phi}_h^n\|_0^2\tau + 4\|\bar{\xi}^n\|_1^2\tau\end{aligned} \tag{5.15}$$

for all $2 \le n \le m$. Summing (5.15) from 2 to m and using Theorem 4.2, Lemma 5.2, and (3.10), we obtain (5.13). ∎

6. Error analysis. In this section, we establish the H^1- and L^2-bound of the error $e^n = u_h(t_n) - u_h^n$ and the L^2-bound of the error $\eta^n = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} p_h(t)dt - p_h^n$ for all $1 \le n \le N$. To do this, we integrate (3.8) from t_{n-1} to t_n. By noting that $u_h(t) \in V_h, \quad t \in [0,T]$, we obtain

$$\begin{aligned}(d_t u_h(t_n), v_h) + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} a(u_h(t), v_h)dt - \frac{1}{\tau}\int_{t_{n-1}}^{t_n} d(v_h, p_h(t))dt + d(\bar{u}_h(t_n), q_h)\\ + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} b(u_h(t), u_h(t), v_h)dt = \frac{1}{\tau}\int_{t_{n-1}}^{t_n} (f(t), v_h)dt.\end{aligned} \tag{6.1}$$

Subtracting (4.3) from (6.1) and using the integral formula

$$\bar{\phi}(t_n) - \frac{1}{\tau}\int_{t_{n-1}}^{t_n} \phi(t)dt = \frac{1}{2\tau}\int_{t_{n-1}}^{t_n} (t - t_{n-1})(t_n - t)\phi_{tt}(t)dt \tag{6.2}$$

for all $\phi \in L^2(t_{n-1}, t_n; H^2(t_{n-1}, t_n))$, we obtain

$$\begin{aligned}(d_t e^n, v_h) + a(\bar{e}^n, v_h) - d(v_h, \eta^n) + d(\bar{e}^n, q_h) + \frac{3}{2}b(e^{n-1}, u_h(t_{n-1}), v_h)\\ + \frac{3}{2}b(u_h^{n-1}, e^{n-1}, v_h) - \frac{1}{2}b(e^{n-2}, u_h(t_{n-2}), v_h) - \frac{1}{2}b(u_h^{n-2}, e^{n-2}, v_h)\\ = (E_n, v_h),\end{aligned} \tag{6.3}$$

with

$$\begin{aligned}(E_n, v_h) = \frac{1}{2\tau}\int_{t_{n-1}}^{t_n} (t - t_{n-1})(t_n - t)(f_{tt}(t), v_h)dt\\ + \frac{1}{\tau}\int_{t_{n-1}}^{t_n} (t - t_{n-1})(t_n - t)a(u_{htt}(t), v_h)dt\\ + \frac{1}{2\tau}\int_{t_{n-1}}^{t_n} (t - t_{n-1})(t_n - t)b_{tt}(u_h(t), u_h(t), v_h)dt\\ + \frac{1}{2}\int_{t_{n-1}}^{t_n} (t - t_n)b_{tt}(u_h(t), u_h(t), v_h)dt\\ - \frac{1}{2}\int_{t_{n-2}}^{t_{n-1}} (t - t_{n-2})b_{tt}(u_h(t), u_h(t), v_h)dt,\end{aligned} \tag{6.4}$$

where

$$b_{tt}(u_h(t), u_h(t), v_h) = b(u_{htt}(t), u_h(t), v_h) + b(u_h(t), u_{htt}(t), v_h) + 2b(u_{ht}, u_{ht}, v_h).$$

In order to derive a bound on the error e^n, we need to provide the following estimates on E_n.

LEMMA 6.1. *Under the assumptions of Theorem* 4.2, *the error* E_n *satisfies the following bounds:*

$$\tau\sum_{n=2}^{m} \sigma^i(t_n)\|A_h^{-1}P_h E_n\|_0^2 \le \kappa\ \tau^{3+i}, \quad i = 0, 1, \tag{6.5}$$

$$\tau\sum_{n=2}^{m} \sigma^i(t_n)\|A_h^{-1/2}P_h E_h\|_0^2 \le \kappa\tau^{2+i}, \quad i = 0, 1, 2, \tag{6.6}$$

$$\tau\sum_{n=2}^{m}\sigma^i(t_n)\|P_hE_n\|_0^2\le\kappa\tau^{1+i},\quad i=0,1,2,3, \tag{6.7}$$

$$\sigma^2(t_n)\|R_hE_n\|_0^2\le\kappa\tau^2, \tag{6.8}$$

for all $2\le m\le N$.

Proof. In view of (3.10) and Lemma 3.1, we deduce from (6.4) that

$$\begin{aligned}\|A_h^{(\alpha-1)/2}P_hE_n\|_0&=\sup_{v_h\in V_h}\frac{|(E_n,v_h)|}{\|A_h^{(1-\alpha)/2}v_h\|_0}\le\frac{1}{2}\gamma_0^{1-\alpha}\tau^{3/2}\left(\int_{t_{n-1}}^{t_n}\|f_{tt}(t)\|_0^2dt\right)^{1/2}\\&+\frac{\nu}{2}\tau^{-1/2}\left(\int_{t_{n-1}}^{t_n}(t_n-t)^2(t-t_{n-1})^2\|u_{htt}(t)\|_{\alpha+1}^2dt\right)^{1/2}\\&+c_0\gamma_0\tau^{1/2}\left(\int_{t_{n-1}}^{t_n}(t_n-t)^2(\|A_hu_h(t)\|_0^2\|u_{htt}(t)\|_\alpha^2+\|u_{ht}\|_1^2\|u_{ht}\|_{\alpha+1}^2)dt\right)^{1/2}\\&+c_0\gamma_0\tau^{1/2}\left(\int_{t_{n-2}}^{t_{n-1}}(t-t_{n-2})^2(\|A_hu_h(t)\|_0^2\|u_{htt}(t)\|_\alpha^2+\|u_{ht}\|_1^2\|u_{ht}\|_{\alpha+1}^2)dt\right)^{1/2},\end{aligned} \tag{6.9}$$

for $\alpha=-1,\ 0,\ 1$. In view of Theorems 3.2 and 3.3, (6.9), and the inequalities

$$t-t_{n-1}\le\sigma(t),\quad t\in[t_{n-1},t_n],\quad t-t_{n-2}\le\sigma(t),\quad t\in[t_{n-2},t_{n-1}], \tag{6.10}$$

$$\sigma(t_n)\le\sigma(t_{n-1})+\tau\le2\sigma(t),\quad t\in[t_{n-1},t_n], \tag{6.11}$$

$$\sigma(t_n)(t-t_{n-2})\le(\sigma(t_{n-2})+2\tau)(t-t_{n-2})\le3\sigma(t)\tau,\quad t\in[t_{n-2},t_{n-1}], \tag{6.12}$$

we have the estimates

$$\begin{aligned}\sigma^i(t_n)\|A_h^{-1}P_hE_n\|_0^2\tau&\le2\tau^{3+i}\int_{t_{n-1}}^{t_n}(\gamma_0^4\|f_{tt}\|_0^2+\nu^2\sigma(t)\|u_{htt}\|_0^2)dt\\&+4c_0^2\gamma_0^2\tau^{3+i}\int_{t_{n-2}}^{t_n}(\|A_hu_h(t)\|_0^2\|u_{htt}(t)\|_{-1}^2+\|u_{ht}\|_1^2\|u_{ht}\|_0^2)dt\end{aligned} \tag{6.13}$$

for $i=0,1$,

$$\begin{aligned}\sigma^i(t_n)\|A_h^{-1/2}P_hE_n\|_0^2\tau&\le4\tau^{2+i}\int_{t_{n-1}}^{t_n}(\gamma_0^2\|f_{tt}\|_0^2+\nu^2\sigma^2(t)\|u_{htt}\|_1^2)dt\\&+8c_0^2\gamma_0^2\tau^{2+i}\int_{t_{n-2}}^{t_n}(\sigma(t)\|u_{htt}(t)\|_0^2\|A_hu_h(t)\|_0^2+\sigma(t)\|u_{ht}\|_1^4)dt\end{aligned} \tag{6.14}$$

for $i=0,1,2$, and

$$\begin{aligned}\sigma^i(t_n)\|P_hE_n\|_0^2\tau&\le4\tau^{1+i}\int_{t_{n-1}}^{t_n}(\|f_{tt}\|_0^2+\nu^2\sigma^3(t)\|A_hu_{htt}\|_0^2)dt\\&+16c_0^2\gamma_0^2\tau^{1+i}\int_{t_{n-2}}^{t_n}(\sigma^2(t)\|u_{htt}(t)\|_1^2\|A_hu_h(t)\|_0^2+\sigma^2(t)\|A_hu_{ht}\|_0^2\|u_{ht}(t)\|_1^2)dt\end{aligned} \tag{6.15}$$

for $i = 0, 1, 2, 3$. Summing (6.13)–(6.15) from 2 to m, respectively, and using Theorem 3.2, we deduce (6.5)–(6.7). Similarly, we deduce from (6.4) and Lemma 3.1 that

$$\begin{aligned}
&\|R_h E_n\|_0 = \sup_{v_h \in X_h} \frac{|(E_n, v_h)|}{\|v_h\|_0} \\
&\le \frac{1}{2}\tau^{3/2}\left(\int_{t_{n-1}}^{t_n} \|f_{tt}(t)\|_0^2 dt\right)^{1/2} + \frac{\nu}{2}\left(\int_{t_{n-1}}^{t_n} (t_n - t)(t - t_{n-1})^2 \|\Delta_h u_{htt}(t)\|_0^2 dt\right)^{1/2} \\
&+ 2c_0\gamma_0\tau^{1/2}\left(\int_{t_{n-1}}^{t_n} (t - t_{n-1})^2 (\|u_{htt}(t)\|_1^2 \|A_h u_h(t)\|_0^2 + \|A_h u_{ht}\|_0^2 \|u_{ht}\|_1^2) dt\right)^{1/2} \\
&+ c_0\gamma_0\tau^{1/2}\left(\int_{t_{n-2}}^{t_{n-1}} (t - t_{n-2})^2 (\|u_{htt}(t)\|_1^2 \|A_h u_h(t)\|_0^2 + \|A_h u_{ht}\|_0^2 \|u_{ht}\|_1^2) dt\right)^{1/2}.
\end{aligned} \tag{6.16}$$

Because of the equivalent relation

$$\|A_h v_h\|_0 \le \|\Delta_h v_h\|_0 \le c_3 \|A_h v_h\|_0, \quad v_h \in V_h, \tag{6.17}$$

for some constant $c_3 > 0$, we deduce from (6.16) and (6.10)–(6.12) that

$$\begin{aligned}
\sigma^2(t_n)\|R_h E_n\|_0^2 \le{}& \tau^3 \int_{t_{n-1}}^{t_n} \|f_{tt}(t)\|_0^2 dt + \nu^2\tau^2 \int_{t_{n-1}}^{t_n} \sigma^3(t)\|A_h u_{htt}(t)\|_0^2 dt \\
&+ 4^2 c_0^2\gamma_0^2\tau^3 \int_{t_{n-1}}^{t_n} \sigma^2(t)(\|u_{htt}(t)\|_1^2 \|A_h u_h(t)\|_0^2 + \|A_h u_{ht}\|_0^2 \|u_{ht}\|_1^2) dt \\
&+ 4c_0^2\gamma_0^2\tau^3 \int_{t_{n-2}}^{t_{n-1}} \sigma^2(t)(\|u_{htt}(t)\|_1^2 \|A_h u_h(t)\|_0^2 + \|A_h u_{ht}\|_0^2 \|u_{ht}\|_1^2) dt.
\end{aligned} \tag{6.18}$$

Combining (6.18) with Theorem 3.2 yields (6.8). ∎

LEMMA 6.2. *Under the assumptions of Theorem 4.2, we have*

$$\|e^m\|_\alpha^2 + \nu\|e^m\|_{\alpha+1}^2\tau + \tau\sum_{n=1}^{m}\left(\frac{1}{2}\|d_t e^n\|_\alpha^2\tau + \nu\|\bar{e}^n\|_{\alpha+1}^2\right) \le \kappa\tau^{2-\alpha}, \quad \alpha = -1, 0, 1, \tag{6.19}$$

for all $1 \le m \le N$.

Proof. Taking $v_h = 2A_h^\alpha e^n\tau \in V_h$ and $q_h = 0$ in (6.3) and noting $e^n = \bar{e}^n + \frac{1}{2}d_t e^n$, we obtain

$$\begin{aligned}
&\|e^n\|_\alpha^2 - \|e^{n-1}\|_\alpha^2 + \|d_t e^n\|_\alpha^2\tau^2 + \frac{\nu}{2}(\|e^n\|_{\alpha+1}^2 - \|e^{n-1}\|_{\alpha+1}^2 + 4\|\bar{e}^n\|_{\alpha+1}^2)\tau \\
&\quad + 3b\left(e^{n-1}, u_h(t_{n-1}), A_h^\alpha\bar{e}^n + \frac{1}{2}A_h^\alpha d_t e^n\tau\right) + 3b\left(u_h^{n-1}, e^{n-1}, A_h^\alpha\bar{e}^n + \frac{1}{2}A_h^\alpha d_t e^n\tau\right)\tau \\
&\quad - b\left(e^{n-2}, u_h(t_{n-2}), A_h^\alpha\bar{e}^n + \frac{1}{2}A_h^\alpha d_t e^n\tau\right)\tau - b\left(u_h^{n-2}, e^{n-2}, A_h^\alpha\bar{e}^n + \frac{1}{2}A_h^\alpha d_t e^n\tau\right)\tau \\
&\quad = 2\left(E_n, A_h^\alpha\bar{e}^n + \frac{1}{2}A_h^\alpha d_t e^n\tau\right)\tau,
\end{aligned} \tag{6.20}$$

and by Lemma 3.1 and (3.10),

$$\begin{aligned}
&\frac{3}{2}|b(e^{n-1},u_h(t_{n-1}),A_h^\alpha d_t e^n)|\tau^2+\frac{3}{2}|b(u_h^{n-1},e^{n-1},A_h^\alpha d_t e^n)|\tau^2\\
&\le \frac{3}{2}c_0\gamma_0\|e^{n-1}\|_{\alpha+1}(\|A_h u_h(t_{n-1})\|_0+\|A_h u_h^{n-1}\|_0)\|d_t e^n\|_\alpha\tau^2\\
&\le \frac{1}{4}\|d_t e^n\|_\alpha^2\tau^2+\frac{9}{2}c_0^2\gamma_0^2(\|A_h u_h(t_{n-1})\|_0^2+\|A_h u_h^{n-1}\|_0^2)\|e^{n-1}\|_{\alpha+1}^2\tau^2,\\
&\frac{1}{2}|b(e^{n-2},u_h(t_{n-2}),A_h^\alpha d_t e^n)|\tau^2+\frac{1}{2}|b(u_h^{n-2},e^{n-2},A_h^\alpha d_t e^n)|\tau^2\\
&\le \frac{1}{8}\|d_t e^n\|_\alpha^2\tau^2+c_0^2\gamma_0^2(\|A_h u_h(t_{n-2})\|_0^2+\|A_h u_h^{n-2}\|_0^2)\|e^{n-2}\|_{\alpha+1}^2\tau^2,\\
&3|b(e^{n-1},u_h(t_{n-1}),A_h^\alpha\bar e^n)|\tau+3|b(u_h^{n-1},e^{n-1},A_h^\alpha\bar e^n)|\tau\\
&\le 3c_0\gamma_0\|e^{n-1}\|_\alpha(\|A_h u_h(t_{n-1})\|_0+\|A_h u_h^{n-1}\|_0)\|\bar e^n\|_{\alpha+1}\tau\\
&\le \frac{\nu}{4}\|\bar e^n\|_{\alpha+1}^2\tau+18\nu^{-1}c_0^2\gamma_0^2(\|A_h u_h(t_{n-1})\|_0^2+\|A_h u_h^{n-1}\|_0^2)\|e^{n-1}\|_\alpha^2\tau,\\
&|b(e^{n-2},u_h(t_{n-2}),A^\alpha\bar e^n)|\tau+|b(u_h^{n-2},e^{n-2},A^\alpha\bar e^n)|\tau\\
&\le \frac{\nu}{4}\|\bar e^n\|_{\alpha+1}^2\tau+18\nu^{-1}c_0^2\gamma_0^2(\|A_h u_h(t_{n-2})\|_0^2+\|A_h u_h^{n-2}\|_0^2)\|e^{n-2}\|_\alpha^2\\
&2\left(E_n,A^\alpha\bar e^n+\frac{1}{2}A^\alpha d_t e^n\tau\right)\tau\le\frac{\nu}{8}\|\bar e^n\|_{\alpha+1}^2\tau+\frac{1}{8}\|d_t e^n\|_\alpha^2\tau^2\\
&+8\nu^{-1}\|A_h^{\frac{\alpha-1}{2}}P_h E_n\|_0^2\tau+8\|A^{\frac{\alpha}{2}}P_h E_n\|_0^2\tau^2.
\end{aligned}$$

Hence, by combining the above inequalities with (6.20), we obtain

$$\begin{aligned}
&\left(\|e^n\|_\alpha^2+\frac{\nu}{2}\|e^n\|_{\alpha+1}^2\tau\right)-\left(\|e^{n-1}\|_\alpha^2+\frac{\nu}{2}\|e^{n-1}\|_{\alpha+1}^2\tau\right)+\frac{1}{2}\|d_t e^n\|_\alpha^2\tau^2+\nu\|\bar e^n\|_{\alpha+1}^2\tau\\
&\quad\le 18\nu^{-1}c_0^2\gamma_0^2(\|A_h u_h(t_{n-1})\|_0^2+\|A_h u_h^{n-1}\|_0^2)\left(\|e^{n-1}\|_\alpha^2+\frac{\nu}{2}\|e^{n-1}\|_{\alpha+1}^2\tau\right)\tau\\
&\quad+2\nu^{-1}c_0^2\gamma_0^2(\|A_h u_h(t_{n-2})\|_0^2+\|A_h u_h^{n-2}\|_0^2)\left(\|e^{n-2}\|_\alpha^2+\frac{\nu}{2}\|e^{n-2}\|_{\alpha+1}^2\tau\right)\tau\\
&\quad+8\nu^{-1}\|A_h^{\frac{\alpha-1}{2}}P_h E_n\|_0^2\tau+8\|A^{\frac{\alpha}{2}}P_h E_n\|_0^2\tau^2 \qquad (6.21)
\end{aligned}$$

for all $2\le n\le N$. Moreover, summing (6.21) from 2 to m and using Lemmas 4.3 and 6.1, we have

$$\begin{aligned}
&\|e^m\|_\alpha^2+\frac{\nu}{2}\|e^m\|_{\alpha+1}^2\tau+\tau\sum_{n=2}^m\left(\frac{1}{2}\|d_t e^n\|_\alpha^2\tau+\nu\|\bar e^n\|_{\alpha+1}^2\right)\\
&\quad\le\tau\sum_{n=1}^{m-1}d_n\left(\|e^n\|_\alpha^2+\frac{\nu}{2}\|e^n\|_{\alpha+1}^2\tau\right)+\|e^1\|_\alpha^2+\frac{\nu}{2}\|e^1\|_{\alpha+1}^2\tau\\
&\quad+8\nu^{-1}\tau\sum_{n=2}^m(\|A_h^{\frac{\alpha-1}{2}}P_h E_n\|_0^2+\nu\|A^{\frac{\alpha}{2}}P_h E_n\|_0^2\tau)\\
&\quad\le\tau\sum_{n=1}^m d_n\left(\|e^n\|_\alpha^2+\frac{\nu}{2}\|e^n\|_{\alpha+1}^2\tau\right)+\kappa\tau^{2-\alpha}, \qquad (6.22)
\end{aligned}$$

where

$$d_n=44\nu^{-1}c_0^2\gamma_0^2(\|A_h u_h(t_n)\|_0^2+\|A_h u_h^n\|_0^2).$$

We set

$$a_n = \|e^n\|_\alpha^2 + \frac{\nu}{2}\|e^n\|_{\alpha+1}^2\tau, \quad b_n = \frac{1}{2}\|d_t e^n\|_0^2\tau + \nu\|\bar{e}^n\|_1^2, \; C = \kappa\tau^{2-\alpha}$$

in (6.22), apply Lemma 3.4 to (6.22), and use Theorems 3.2 and 4.2 to deduce

$$\|e^m\|_\alpha^2 + \frac{\nu}{2}\|e^m\|_{\alpha+1}^2\tau + \tau\sum_{n=2}^{m}\left(\frac{1}{2}\|d_t e^n\|_\alpha^2\tau + \nu\|\bar{e}^n\|_{\alpha+1}^2\right) \le \kappa\tau^{2-\alpha} \tag{6.23}$$

for all $2 \le m \le N$. Combining (6.23) with Lemma 4.3 gives (6.19). ∎

With the aid of Lemma 6.2, we obtain the following preliminary lower-order smoothing error estimate.

LEMMA 6.3. *Under the assumptions of Theorem* 4.2*, we have*

$$\sigma(t_m)\|e^m\|_0^2 + \nu\sigma(t_m)\|e^m\|_1^2\tau + \tau\sum_{n=1}^{m}\sigma(t_n)\left(\frac{1}{2}\|d_t e^n\|_0^2\tau + \nu\|\bar{e}^n\|_1^2\right) \le \kappa\tau^3 \tag{6.24}$$

for all $1 \le m \le N$.

Proof. Multiplying (6.21) with $\alpha = 0$ by $\sigma(t_n)$ and using (6.11) gives

$$\begin{aligned}
&\sigma(t_n)\left(\|e^n\|_0^2 + \frac{\nu}{2}\|e^n\|_1^2\tau\right)\\
&\quad - \sigma(t_{n-1})\left(\|e^{n-1}\|_0^2 + \frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right)\\
&\quad + \frac{1}{2}\sigma(t_n)\|d_t e^n\|_0^2\tau^2 + \nu\sigma(t_n)\|\bar{e}^n\|_1^2\tau\\
&\quad \le \left(\|e^{n-1}\|_0^2 + \frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right)\tau\\
&\quad + 18\nu^{-1}c_0^2\gamma_0^2\sigma(t_n)(\|A_h u_h(t_{n-1})\|_0^2 + \|A_h u_h^{n-1}\|_0^2)\left(\|e^{n-1}\|_0^2 + \frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right)\tau\\
&\quad + 2\nu^{-1}c_0^2\gamma_0^2\sigma(t_n)(\|A_h u_h(t_{n-2})\|_0^2 + \|A_h u_h^{n-2}\|_0^2)\left(\|e^{n-2}\|_0^2 + \frac{\nu}{2}\|e^{n-2}\|_1^2\tau\right)\tau\\
&\quad + 8\nu^{-1}\sigma(t_n)\|A_h^{\frac{-1}{2}}P_h E_n\|_0^2\tau + 8\sigma(t_n)\|P_h E_n\|_0^2\tau^2
\end{aligned} \tag{6.25}$$

for all $2 \le n \le N$. Summing (6.25) from 2 to m and using (6.11), Lemmas 4.3, 6.1, and 6.2 and Theorems 3.2 and 4.2, we obtain

$$\begin{aligned}
&\sigma(t_m)\left(\|e^m\|_0^2 + \frac{\nu}{2}\|e^m\|_1^2\tau\right) + \tau\sum_{n=2}^{m}\sigma(t_n)\left(\frac{1}{2}\|d_t e^n\|_0^2\tau + \nu\|\bar{e}^n\|_1^2\right)\\
&\le \tau\sum_{n=2}^{m}\left(\|e^{n-1}\|_0^2 + \frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right) + \sigma(t_1)\left(\|e^1\|_0^2 + \frac{\nu}{2}\|e^1\|_1^2\tau\right)\\
&\quad + \tau\sum_{n=1}^{m-1} d_n\sigma(t_n)\left(\|e^n\|_0^2 + \frac{\nu}{2}\|e^n\|_1^2\tau\right)\\
&\quad + 8\tau\sum_{n=2}^{m}\sigma(t_n)(\nu^{-1}\|A_h^{-1/2}P_h E_n\|_0^2 + \|P_h E_n\|_0^2\tau)\\
&\quad + 18\nu^{-1}c_0^2\gamma_0^2\tau^2\sum_{n=2}^{m}(\|A_h u_h(t_{n-1})\|_0^2 + \|A_h u_h^{n-1}\|_0^2)\left(\|e^{n-1}\|_0^2 + \frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right)
\end{aligned}$$

$$
\begin{aligned}
&+ 4\nu^{-1}c_0^2\gamma_0^2\tau^2\sum_{n=2}^{m}(\|A_hu_h(t_{n-2})\|_0^2+\|A_hu_h^{n-2}\|_0^2)\left(\|e^{n-2}\|_0^2+\frac{\nu}{2}\|e^{n-2}\|_1^2\tau\right)\\
&\le \tau\sum_{n=2}^{m}\left(\|e^{n-1}\|_0^2+\frac{\nu}{2}\|e^{n-1}\|_1^2\tau\right)+\kappa\tau^3\\
&+ \tau\sum_{n=1}^{m-1}d_n\sigma(t_n)\left(\|e^{n}\|_0^2+\frac{\nu}{2}\|e^{n}\|_1^2\tau\right). \qquad (6.26)
\end{aligned}
$$

Because $e^{n-1}=\bar{e}^n-\frac{1}{2}d_te^n$, we deduce from Lemma 6.2 that

$$
\tau\sum_{n=2}^{m}\|e^{n-1}\|_0^2\le 2\tau\sum_{n=2}^{m}\|\bar{e}^n\|_0^2+\tau\sum_{n=2}^{m}\|d_te^n\|_0^2\tau^2\le\kappa\tau^3 \qquad (6.27)
$$

and

$$
\tau\sum_{n=2}^{m}\|e^{n-1}\|_1^2\le 2\tau\sum_{n=2}^{m}\|\bar{e}^n\|_1^2+\tau\sum_{n=2}^{m}\|d_te^n\|_1^2\tau^2\le\kappa\tau^2. \qquad (6.28)
$$

Combining (6.27)–(6.28) with (6.26) gives

$$
\begin{aligned}
&\sigma(t_m)\left(\|e^m\|_0^2+\frac{\nu}{2}\|e^m\|_1^2\tau\right)+\tau\sum_{n=2}^{m}\sigma(t_n)\left(\frac{1}{2}\|d_te^n\|_0^2\tau+\nu\|\bar{e}^n\|_1^2\right)\\
&\qquad\le\kappa\tau^3+\tau\sum_{n=1}^{m-1}d_n\sigma(t_n)\left(\|e^{n}\|_0^2+\frac{\nu}{2}\|e^{n}\|_1^2\tau\right). \qquad (6.29)
\end{aligned}
$$

Applying Lemma 3.4 to (6.29) yields (6.24). ∎

LEMMA 6.4. *Under the assumptions of Theorem* 4.2*, we have*

$$
\tau\sum_{n=1}^{m}\|\bar{e}^n\|_{-1}^2\le\kappa\tau^4 \qquad (6.30)
$$

for all $1\le m\le N$.

Proof. Let $\{\Phi_h^n\}$ be the solution of (5.1), corresponding to the initial value $\Phi_h^m=0$ and the right-hand side $\{\xi^n\}=\{A_h^{-1}e^n\}$. Then, by construction, there holds

$$
\begin{aligned}
\|\bar{e}^n\|_{-1}^2\tau&=(\bar{e}^n,d_t\Phi_h^n)\tau-a(\bar{e}^n,\bar{\Phi}_h^n)\tau-b\left(\frac{3}{2}u_h^{n-1}-\frac{1}{2}u_h^{n-2},\bar{e}^n,\bar{\Phi}_h^n\right)\tau\\
&\quad-b\left(\bar{e}^n,\frac{3}{2}u_h^{n-1}-\frac{1}{2}u_h^{n-2},\bar{\Phi}_h^n\right)\tau\\
&=d_t(e^n,\Phi_h^n)\tau-(d_te^n,\bar{\Phi}_h^n)\tau-a(\bar{e}^n,\bar{\Phi}_h^n)\tau-b\left(\frac{3}{2}u_h^{n-1}-\frac{1}{2}u_h^{n-2},\bar{e}^n,\bar{\Phi}_h^n\right)\tau\\
&\quad-b\left(\bar{e}^n,\frac{3}{2}u_h^{n-1}-\frac{1}{2}u_h^{n-2},\bar{\Phi}_h^n\right)\tau\\
&=(e^n,\Phi^n)-(e^{n-1},\Phi_h^{n-1})-(E_n,\bar{\Phi}_h^n)\tau+\frac{3}{2}b(e^{n-1},e^{n-1},\bar{\Phi}^n)\tau\\
&\quad-\frac{1}{2}b(e^{n-2},e^{n-2},\bar{\Phi}^n)\tau-\frac{3}{2}b\left(\frac{1}{2}d_te^n\tau,u_h^{n-1},\bar{\Phi}_h^n\right)\tau-\frac{3}{2}b\left(u_h^{n-1},\frac{1}{2}d_te^n\tau,\bar{\Phi}_h^n\right)\tau\\
&\quad+\frac{1}{2}b\left(\frac{1}{2}d_te^n\tau+d_te^{n-1}\tau,u_h^{n-2},\bar{\Phi}_h^n\right)\tau+\frac{1}{2}b\left(u_h^{n-2},\frac{1}{2}d_te^n\tau+d_te^{n-1}\tau,\bar{\Phi}_h^n\right)\tau. \qquad (6.31)
\end{aligned}
$$

Taking $v_h = u_{htt}$ in (5.1) and using (3.10) and Lemma 3.1, we see that

$$\begin{aligned}|a(u_{htt},\bar{\Phi}_h^n)| &\le |(u_{htt}, d_t\Phi_h^n - \bar{\xi}^n)| + \left|b\left(\frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}, u_{htt}, \bar{\Phi}_h^n\right)\right| \\ &\quad + \left|b\left(u_{htt}, \frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}, \bar{\Phi}_h^n\right)\right| \\ &\le \|u_{htt}\|_{-1}\left(\|d_t\Phi_h^n - \bar{\xi}^n\|_1 + c_0\gamma_0\left\|A_h\left(\frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}\right)\right\|_0 \|\bar{\Phi}_h^n\|_2\right). \end{aligned} \tag{6.32}$$

Using (6.4), (6.32), (3.10), and Lemma 3.1, we deduce that

$$\begin{aligned}&|(E_n,\bar{\Phi}_h^n)|\tau \le \tau^2\gamma_0^2\int_{t_{n-1}}^{t_n}\|f_{tt}\|_0 dt \|A_h\bar{\Phi}_h^n\|_0 \\ &+ c_0\gamma_0\tau^2\int_{t_{n-2}}^{t_n}(\|u_{htt}\|_{-1}\|A_hu_h\|_0 + 2\|u_{ht}\|_1\|u_{ht}\|_0)dt\|A_h\bar{\Phi}_h^n\|_0 \\ &+ \tau^2\int_{t_{n-1}}^{t_n}\|u_{htt}\|_{-1}dt\left(\|d_t\Phi_h^n - \bar{\xi}^n\|_1 + c_0\gamma_0\left\|A_h\left(\frac{3}{2}u_h^{n-1} - \frac{1}{2}u_h^{n-2}\right)\right\|_0\|A_h\bar{\Phi}_h^n\|_0\right). \end{aligned} \tag{6.33}$$

Summing (6.33) for $2 \le n \le m$ and using Theorem 3.2, we have

$$\begin{aligned}\tau\sum_{n=2}^{m}|(E_n,\bar{\Phi}_h^n)| &\le \tau^2\kappa\left(\int_{t_0}^{t_m}(\|f_{tt}\|_0^2 + \|u_{htt}\|_{-1}^2 + \|u_{ht}\|_1^2)dt\right)^{1/2} \\ &\quad\times\left(\tau\sum_{n=2}^{m}(\|A_h\bar{\Phi}_h^n\|^2 + \|d_t\Phi_h^n - \bar{\xi}^n\|_1^2)\right)^{1/2}. \end{aligned} \tag{6.34}$$

Moreover, by using (3.10) and Lemma 3.1, we have

$$\begin{aligned}\frac{3}{2}|b(e^{n-1},e^{n-1},\bar{\Phi}^n)|\tau + \frac{1}{2}|b(e^{n-2},e^{n-2},\bar{\Phi}_h^n)|\tau &\le \frac{3}{2}c_0\gamma_0(\|e^{n-1}\|_1\|e^{n-1}\|_0 \\ &\quad + \|e^{n-2}\|_1\|e^{n-2}\|_0)\|A_h\bar{\Phi}_h^n\|_0\tau, \\ \frac{3}{2}\left|b\left(\frac{1}{2}d_te^n\tau, u_h^{n-1},\bar{\Phi}_h^n\right)\right|\tau + \frac{3}{2}\left|b\left(u_h^{n-1},\frac{1}{2}d_te^n\tau,\bar{\Phi}_h^n\right)\right|\tau &\le c_0\gamma_0\|A_hu_h^{n-1}\|_0\|d_te^n\|_{-1}\|A_h\bar{\Phi}_h^n\|_0\tau^2, \\ \frac{1}{2}\left|b\left(\frac{1}{2}d_te^n\tau + d_te^{n-1}\tau, u_h^{n-2},\bar{\Phi}_h^n\right)\right|\tau + \frac{1}{2}\left|b\left(u_h^{n-2},\frac{1}{2}d_te^n\tau + d_te^{n-1}\tau,\bar{\Phi}_h^n\right)\right|\tau &\le c_0\gamma_0\|A_hu_h^{n-2}\|_0(\|d_te^n\|_{-1} \\ &\quad + \|d_te^{n-1}\|_{-1})\|A_h\bar{\Phi}_h^n\|_0\tau^2. \end{aligned}$$

Summing (6.31) from 2 to m and using the above estimates, (6.34), and Theorem 4.2, we arrive at

$$\begin{aligned}
&\tau\sum_{n=2}^{m}\|\bar{e}^n\|_{-1}^2 \le -(e^1,\Phi_h^1)+\tau\sum_{n=2}^{m}|(E_n,\bar{\Phi}_h^n)|\\
&+\frac{3}{2}c_0\gamma_0\tau\sum_{n=2}^{m}(\|e^{n-1}\|_1\|e^{n-1}\|_0+\|e^{n-2}\|_1\|e^{n-2}\|_0)\|A_h\bar{\Phi}_h^n\|_0\\
&+c_0\gamma_0\tau\sum_{n=2}^{m}(\|A_hu_h^{n-1}\|_0+\|A_hu_h^{n-2}\|_0)\|d_te^n\|_{-1}\|A_h\bar{\Phi}_h^n\|_0\tau^2\\
&+c_0\gamma_0\tau\sum_{n=2}^{m}\|A_hu_h^{n-2}\|_0\|d_te^{n-1}\|_{-1}\|A_h\bar{\Phi}_h^n\|_0\tau^2\\
&\le\|e^1\|_{-2}\|A_h\Phi_h^1\|_0+\kappa\tau^2\left(\tau\sum_{n=2}^{m}(\|A_h\bar{\Phi}_h^n\|^2+\|d_t\Phi_h^n-\bar{\xi}^n\|_1^2)\right)^{1/2}\\
&+\kappa\left(\tau\sum_{n=2}^{m}\|e^{n-1}\|_1^2\|e^{n-1}\|_0^2+\|e^{n-2}\|_1^2\|e^{n-2}\|_0^2\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|A_h\bar{\Phi}_h^n\|_0^2\right)^{1/2}\\
&+\kappa\left(\tau\sum_{n=1}^{m}\|d_te^n\|_{-1}^2\tau^2\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|A_h\bar{\Phi}_h^n\|_0^2\right)^{1/2}. \qquad (6.35)
\end{aligned}$$

Using Lemmas 5.2 and 5.3 in (6.35) yields

$$\begin{aligned}
&\tau\sum_{n=2}^{m}\|\bar{e}^n\|_{-1}^2\\
&\le\left(\|e^1\|_{-2}^2+\kappa\tau^4+\kappa\tau\sum_{n=2}^{m}(\|e^{n-1}\|_1^2\|e^{n-1}\|_0^2+\|e^{n-2}\|_1^2\|e^{n-2}\|_0^2)+\kappa\tau\sum_{n=1}^{m}\|d_te^n\|_{-1}^2\tau^2\right)^{1/2}\\
&\times\left(\|A_h\Phi_h^1\|_0^2+\tau\sum_{n=2}^{m}(\|A_h\bar{\Phi}_h^n\|_0^2+\|d_t\Phi_h^n-\bar{\xi}^n\|_1^2)\right)^{1/2}\\
&\le\kappa\left(\|e^1\|_{-2}^2+\tau^4+\tau\sum_{n=2}^{m}(\|e^{n-1}\|_1^2\|e^{n-1}\|_0^2+\|e^{n-2}\|_1^2\|e^{n-2}\|_0^2)+\tau\sum_{n=1}^{m}\|d_te^n\|_{-1}^2\tau^2\right)^{1/2}\\
&\times\left(\tau\sum_{n=2}^{m}\|\bar{\xi}^n\|_1^2\right)^{1/2},
\end{aligned}$$

which leads to

$$\begin{aligned}
&\tau\sum_{n=2}^{m}\|\bar{e}^n\|_{-1}^2\le\kappa(\|e^1\|_{-2}^2+\tau^4)\\
&+\kappa\tau\sum_{n=2}^{m}(\|e^{n-1}\|_1^2\|e^{n-1}\|_0^2+\|e^{n-2}\|_1^2\|e^{n-2}\|_0^2)+\kappa\tau\sum_{n=1}^{m}\|d_te^n\|_{-1}^2\tau^2 \qquad (6.36)
\end{aligned}$$

for all $2\le m\le N$. Using (6.28) and Lemmas 4.3, 6.2, and 6.3 in (6.36), we obtain (6.30). ∎

Next we prove (6.19) for the case $\alpha = -2$.

LEMMA 6.5. *Under the assumptions of Theorem* 4.2*, we have*

$$\sigma^2(t_m)\|e^m\|_0^2 \le \kappa\tau^4 \tag{6.37}$$

for all $1 \le m \le N$.

Proof. Let $\{\Phi_h^n\}$ be the solution of (5.1), corresponding to the initial value $\Phi_h^m = e^m$ and the right-hand side $\{\xi^n\} = \{0\}$. Then, by construction, there holds

$$\begin{aligned} d_t(e^n, \Phi_h^n) &= (d_t e^n, \bar{\Phi}^n) + (\bar{e}^n, d_t\Phi_h^n) \\ &= (E_n, \bar{\Phi}_h^n) - \frac{3}{2}b(e^{n-1}, e^{n-1}, \bar{\Phi}_h^n) + \frac{1}{2}b(e^{n-2}, e^{n-2}, \bar{\Phi}_h^n) \\ &\quad + \frac{3}{2}b\left(u_h^{n-1}, \frac{1}{2}d_t e^n\tau, \bar{\Phi}_h^n\right) - \frac{1}{2}b\left(u_h^{n-2}, d_t e^n\tau + \frac{1}{2}d_t e^{n-1}\tau, \bar{\Phi}_h^n\right)\tau \\ &\quad + \frac{3}{2}b\left(\frac{1}{2}d_t e^n\tau, u_h^{n-1}, \bar{\Phi}_h^n\right) - \frac{1}{2}b\left(d_t e^n\tau + \frac{1}{2}d_t e^{n-1}\tau, u_h^{n-2}, \bar{\Phi}_h^n\right). \end{aligned} \tag{6.38}$$

Using (3.10) and Lemma 3.1, we see that

$$\begin{aligned} &|(E_n, \bar{\Phi}_h^n)| \le \|A_h^{-1/2}P_h E_n\|_0\|\bar{\Phi}_h^n\|_1, \\ &\frac{3}{2}|b(e^{n-1}, e^{n-1}, \bar{\Phi}_h^n)| + \frac{1}{2}|b(e^{n-2}, e^{n-2}, \bar{\Phi}_h^n)| \\ &\le c_0(\|e^{n-1}\|_1\|e^{n-1}\|_0 + \|e^{n-2}\|_1\|e^{n-2}\|_0)\|\bar{\Phi}^n\|_1 + c_0(\|e^{n-1}\|_1^2 + \|e^{n-2}\|_1^2)\|\bar{\Phi}^n\|_0, \\ &\frac{3}{2}\left|b\left(u_h^{n-1}, \frac{1}{2}d_t e^n\tau, \bar{\Phi}_h^n\right)\right| + \frac{3}{2}\left|b\left(\frac{1}{2}d_t e^n\tau, u_h^{n-1}, \bar{\Phi}_h^n\right)\right| \\ &\le c_0\gamma_0\|A_h u_h^{n-1}\|_0\|d_t e^n\|_0\|\bar{\Phi}_h^n\|_1\tau, \\ &\frac{1}{2}\left|b\left(u_h^{n-2}, d_t e^n\tau + \frac{1}{2}d_t e^{n-1}\tau, \bar{\Phi}_h^n\right)\right|\tau + \frac{1}{2}\left|b\left(d_t e^n\tau + \frac{1}{2}d_t e^{n-1}\tau, u_h^{n-2}, \bar{\Phi}_h^n\right)\right| \\ &\le c_0\gamma_0\|A_h u_h^{n-2}\|_0\|d_t e^n + \frac{1}{2}d_t e^{n-1}\|_0\|\bar{\Phi}_h^n\|_1\tau. \end{aligned}$$

Multiplying (6.38) by $t_n\tau$, summing for $2 \le n \le m$, and using the above inequalities, we deduce that

$$\begin{aligned} t_m(e^m, \Phi_h^m) &= \tau(e^1, \Phi_h^1) + \tau\sum_{n=2}^{m}(e^{n-1}, \Phi_h^{n-1}) \\ &\quad + \left(\tau\sum_{n=2}^{m} t_n^2\|A_h^{-1/2}P_h E_n\|_0^2\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|\bar{\Phi}_h^n\|_1^2\right)^{1/2} \\ &\quad + 2c_0\left(\tau\sum_{n=2}^{m} t_n^2(\|e^{n-1}\|_1^2\|e^{n-1}\|_0^2 + \|e^{n-2}\|_1^2\|e^{n-2}\|_0^2)\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|\bar{\Phi}_h^n\|_1^2\right)^{1/2} \\ &\quad + 2c_0\tau\sum_{n=2}^{m} t_n^2(\|e^{n-1}\|_1^2 + \|e^{n-2}\|_1^2)\sup_{1\le n\le m}\|\Phi_h^n\|_0 \\ &\quad + 2c_0\left(\tau\sum_{n=2}^{m} t_n^2\|A_h u_h^{n-1}\|_0^2\|d_t e^n\|_0^2\tau^2\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|\bar{\Phi}_h^n\|_1^2\right)^{1/2} \\ &\quad + 2c_0\left(\tau\sum_{n=2}^{m} t_n^2\|A_h u_h^{n-2}\|_0^2\left\|d_t e^n + \frac{1}{2}d_t e^{n-1}\right\|_0^2\tau^2\right)^{1/2}\left(\tau\sum_{n=2}^{m}\|\bar{\Phi}_h^n\|_1^2\right)^{1/2}. \end{aligned} \tag{6.39}$$

Using Theorem 4.2, Lemmas 6.1, 6.2, and 6.3, (5.4) and (6.28) in (6.39) and noting

$$t_n \le \sigma(t_n)T, \quad t_n^2 \le 4t_{n-1}^2 \le 4\sigma^2(t_{n-1})T^2,$$

we arrive at

$$t_m(e^m, \Phi_h^m) = \tau(e^1, \Phi_h^1) + \tau \sum_{n=2}^{m} (e^{n-1}, \Phi_h^{n-1}) + \kappa\tau^2 \|\Phi_h^m\|_0^2. \tag{6.40}$$

Because

$$(e^{n-1}, \Phi_h^{n-1}) + (e^n, \Phi_h^n) = 2(\bar{e}^n, \bar{\Phi}_h^n) + \frac{1}{4}(d_t e^n, d_t \Phi_h^n)\tau^2,$$

there holds

$$\begin{aligned} \tau \sum_{n=2}^{m} (e^{n-1}, \Phi_h^{n-1}) &= \frac{\tau}{2} \sum_{n=2}^{m} [(e^{n-1}, \Phi_h^{n-1}) + (e^n, \Phi_h^n)] + \frac{\tau}{2}[(e^1, \Phi_h^1) - (e^m, \Phi_h^m)] \\ &= \tau \sum_{n=2}^{m} \left[(\bar{e}^n, \bar{\Phi}_h^n) + \frac{1}{4}(d_t e^n, d_t \Phi_h^n) \right] + \frac{\tau}{2}[(e^1, \Phi_h^1) - (e^m, \Phi_h^m)]. \end{aligned} \tag{6.41}$$

Furthermore, by using Lemmas 5.2, 6.2, and 6.4, we have

$$\begin{aligned} \tau \sum_{n=2}^{m} \left[(\bar{e}^n, \bar{\Phi}_h^n) + \frac{1}{4}(d_t e^n, d_t \Phi_h^n) \right] &\le \left(\tau \sum_{n=2}^{m} \|\bar{e}^n\|_{-1}^2 \right)^{1/2} \left(\tau \sum_{n=2}^{m} \|\bar{\Phi}_h^n\|_1^2 \right)^{1/2} \\ &\quad + \tau^2 \left(\tau \sum_{n=2}^{m} \|d_t e^n\|_1^2 \right)^{1/2} \left(\tau \sum_{n=2}^{m} \|d_t \Phi_h^n\|_{-1}^2 \right)^{1/2} \\ &\le \kappa\tau^2 \|\Phi_h^m\|_0. \end{aligned} \tag{6.42}$$

Combining (6.41)–(6.42) with (6.40) and using Lemmas 4.3 and 5.2 yields

$$\frac{\tau}{2}(e^m, \Phi_h^m) + t_m(e^m, \Phi_h^m) \le \frac{3}{2}\tau \|e^1\|_0 \|\Phi_h^1\|_0 + \kappa\tau^2 \|\Phi_h^m\|_0 \le \kappa\tau^2 \|\Phi_h^m\|_0. \tag{6.43}$$

The assertion follows $\Phi_h^m = e^m$ and $\sigma(t_m) \le t_m$. □

It remains to prove the error estimate for the approximate pressure p_h^m.

By (3.4), (3.10), (6.3), and Lemma 3.1,

$$\begin{aligned} \|\eta^m\|_0 \le \beta^{-1} &\left(\gamma_0 \|d_t e^m\|_0 + \nu \|\bar{e}^m\|_1 + \frac{3}{2} c_0 \gamma_0 \|e^{m-1}\|_0 (\|A_h u_h(t_{m-1})\|_0 + \|A_h u_h^{m-1}\|_0) \right) \\ &+ \frac{1}{2}\beta^{-1} c_0 \gamma_0 \|e^{m-2}\|_0 (\|A_h u_h(t_{m-2})\|_0 + \|A_h u_h^{m-2}\|_0) + \beta^{-1}\gamma_0 \|R_h E_m\|_0, \end{aligned}$$

which with Theorems 3.2 and 4.2 yields

$$\sigma(t_m)\|\eta^m\|_0 \le \kappa\sigma(t_m)(\|d_t e^m\|_0 + \|\bar{e}^m\|_1 + \|e^{m-1}\|_0 + \|e_h^{m-2}\|_0 + \|R_h E_m\|_0). \tag{6.44}$$

Using (6.11) and Lemmas 6.1, 6.3, and 6.5 in (6.44) yields

$$\sigma(t_m)\|\eta^m\|_0 \le \kappa\tau, \quad 2 \le m \le N. \tag{6.45}$$

Finally, by using Theorem 3.3 and the integral by part, we have

$$\begin{aligned}\sigma(t_m)\|p_h(t_m)-p_h^m\|_0 &\le \sigma(t_m)\|\eta^m\|_0+2\sigma(t_{m-1})\left\|p_h(t_m)-\frac{1}{\tau}\int_{t_{m-1}}^{t_m}p_h(t)dt\right\|_0\\ &\le \sigma(t_m)\|\eta^m\|_0+2\int_{t_{m-1}}^{t_m}\sigma(t)\|p_{ht}(t)\|_0dt\\ &\le \sigma(t_m)\|\eta^m\|_0+\kappa\tau,\quad 1\le m\le N.\end{aligned}$$

Combining this inequality with (6.45) and using Lemma 4.3 yields

$$\sigma(t_m)\|p_h(t_m)-p_h^m\|_0\le\kappa\tau,\quad 1\le m\le N. \tag{6.46}$$

THEOREM 6.6. *Under the assumptions of Theorem* 4.2*, the following error estimates hold:*

$$\sigma(t_m)\|u_h(t_m)-u_h^m\|_0+\sigma^{1/2}(t_m)\tau\|u_h(t_m)-u_h^m\|_1\le\kappa\tau^2,\quad t_m\in(0,T], \tag{6.47}$$

$$\sigma(t_m)\|p_h(t_m)-p_h^m\|_0\le\kappa\tau,\quad t_m\in(0,T]. \tag{6.48}$$

This proof is completed by combining (6.45) with Lemmas 6.3 and 6.5.

Remark 6.1. Combining Theorem 6.6 with (3.11) yields (1.10)–(1.12).

POSTPROCESSING FOR STOCHASTIC PARABOLIC PARTIAL DIFFERENTIAL EQUATIONS*

GABRIEL J. LORD† AND TONY SHARDLOW‡

Abstract. We investigate the strong approximation of stochastic parabolic partial differential equations with additive noise. We introduce postprocessing in the context of a standard Galerkin approximation, although other spatial discretizations are possible. In time, we follow [G. J. Lord and J. Rougemont, *IMA J. Numer. Anal.*, 24 (2004), pp. 587–604] and use an exponential integrator. We prove strong error estimates and discuss the best number of postprocessing terms to take. Numerically, we evaluate the efficiency of the methods and observe rates of convergence. Some experiments with the implicit Euler–Maruyama method are described.

Key words. stochastic exponential integrator, postprocessing, numerical solution of stochastic PDEs

1. Introduction.

We consider the numerical approximation of the stochastic evolution equation

$$du = \Big[\Delta u + F(u)\Big]\,dt + dW(t) \qquad \text{given} \quad u(0) = u_0, \tag{1.1}$$

with periodic boundary conditions on $[0, 2\pi)$, where $W(t)$ is a Q Wiener process [3] on $L^2(0, 2\pi)$ and F is nonlinear (precise assumptions are given in section 3.1).

Suppose that ϕ_n are eigenvectors of the Laplacian Δ with periodic boundary conditions so that $\Delta\phi_n = -n^2\phi_n$, $n \in \mathbb{Z}$. We assume that Q has eigenfunctions ϕ_n with corresponding eigenvalues $\lambda_n \geq 0$, in which case

$$W(t) = \sum_{n\in\mathbb{Z}} \lambda_n^{1/2}\phi_n\beta_n(t), \tag{1.2}$$

for independent Brownian motions β_n. We do not consider the existence of solutions to (1.1) here; instead we call on [3]. We will investigate the effect on numerics of the spatial regularity of the noise determined from the decay of λ_n.

There is a growing literature on numerical methods for stochastic PDEs, and the majority of these analyze convergence in the strong or root mean squared sense. Finite difference approximations have been examined by a number of authors (see, for example, [26, 11, 12, 4]) and finite element methods have also been considered, e.g., [29]. Galerkin approximations and strong Taylor schemes were considered in [10] with a scalar Wiener process. Strong convergence of the implicit Euler–Maruyama

method was investigated in [19]. A more general analysis is found in [14], which considers different types of spatial discretizations (Galerkin as well as collocation, finite differences, finite elements, and wavelet-based schemes) for similar forms of noise considered here. Mueller-Gronbach and Ritter [25] analyze convergence and complexity through the number of random samples of the Wiener process. Spatially smooth noise is considered in [21] and [27], and these papers also consider Fourier-based spatial discretizations. In [27], a Taylor-based discretization is taken, and efficient methods for approximating the Wiener process are considered. In [21] strong convergence of an exponential integrator (see also [24]) is examined, and we consider this scheme further in this paper; see section 3.

The purpose of this paper is to study Galerkin postprocessing methods for (1.1), prove their convergence in the strong sense, and evaluate their efficiency. We have restricted attention to reaction diffusion equations with homogeneous diffusion and additive noise, and plan to return to the general case in further work.

Section 2 is an introduction to postprocessing methods for deterministic PDEs. Section 3 describes our Galerkin postprocessing scheme, and section 3.1 a theorem on the convergence of the method. Section 4 investigates the numerical behavior of the method for the stochastic Allen–Cahn equation. We evaluate the efficiency of the methods, compare the rates of convergence to those predicted by the theorem, and illustrate numerically that postprocessing is efficient for other time stepping algorithms by experimenting with implicit Euler–Maruyama methods. We summarize our results and conclude in section 5. The proof of the theorem is given in section 6, with the proof of two lemmas left to the appendix.

2. A review of deterministic postprocessing. Postprocessing methods originate from analytical results on inertial manifolds for PDEs; see, for example, [6], where it can be shown that the dynamics of infinite dimensional PDEs converge to a finite dimensional system in large time. Typically, a graph Φ is obtained that "enslaves" the high Fourier modes (fine scale dynamics) to a finite number of low Fourier modes (large scale dynamics). For example, if P denotes the projection onto the first N Fourier modes and $u = p + q = Pu + (I - P)u$, we can write the deterministic PDE

$$u_t = \Delta u + F(u) \qquad \text{as} \qquad p_t = \Delta p + PF(p+q), \qquad q_t = \Delta q + (I-P)F(p+q).$$

The dynamics on the inertial manifold can be rewritten as

$$p_t = \Delta p + PF(p+q), \qquad q(t) = \Phi(p).$$

Numerically, the nonlinear Galerkin methods, also called approximate inertial manifolds (AIM) methods, make an approximation to the graph. In these methods, the evolution on a coarse mesh (i.e., low Fourier modes) uses information from the fine scale (i.e., high modes) at each time step, where a simpler form of equation is solved.

To deal with deterministic PDEs with nonsmooth initial data, long transients, or highly oscillatory time dependent forcing, Yinnian and Mattheij [15] introduced a dynamic form of postprocessing, where the following system is approximated:

$$p_t = \Delta p + PF(p), \qquad q_t = \Delta q + (1-P)F(p).$$

It extends the approach of [7], where a fine mesh solution is found at the end of the computations. For the dynamic postprocessing approach, both the coarse and fine mesh approximations are evolved in time and, unlike a traditional AIM approach, there is no communication from fine to coarse mesh until the end of the computation.

Indeed, this communication was one of the main reasons that the AIM approach was computationally less efficient than a standard Galerkin method; see [7, 8].

He and Mattheij [15] discretized the PDEs in space by a Galerkin method and in time by an implicit Euler method, examined stability and convergence of the scheme, and propose this as a computationally more efficient method. In [22] the postprocessing method is examined from a truncation analysis point of view. From a perturbation expansion for the high modes and by keeping terms to different orders, they obtain systems that correspond to the postprocessed Galerkin method and this yields convergence theory. Furthermore, from numerics based on Burgers' equation with highly oscillatory forcing, they show that postprocessing methods are more efficient and have an improved rate of convergence. These results suggest that postprocessing may be advantageous for a stochastically forced PDE.

Although inertial manifolds have been shown to exist for stochastic PDEs [2], we do not attempt to approximate this directly here. Instead we base our method on the postprocessing approaches of [15] and [22].

3. Numerical scheme. We will consider a Fourier-based Galerkin discretization, although other spatial discretizations are possible. The time discretization may be thought of as a stochastic version of an exponential integrator proposed by [20]; for a review of these methods in the deterministic case, see [23], and for an application using a finite difference spatial discretization, see [17]. In the stochastic context such schemes are considered in [21, 24] and related schemes by [28, 18] which are of the exponential time differencing type.

We describe our numerical scheme for (1.1). Represent $u(t)$ as a Fourier series $u(t) = \sum_n u_n(t)\phi_n$ and obtain the infinite system of coupled equations

$$u_n(t) = e^{-tn^2}u_n(0) + \int_0^t e^{-(t-s)n^2}F_n\big(u(s)\big)\,ds + \int_0^t e^{-(t-s)n^2}\lambda_n^{1/2}\,d\beta_n(s), \tag{3.1}$$

where F_n is the nth component of F, so that $F(u) = \sum_n F_n(u)\phi_n$. Let $\Delta t > 0$ denote the time step and N the size of the Galerkin truncation. Consider the discretization of (1.1) at times $t_k = k\Delta t$ given by

$$u_n^N\big(t_{k+1}\big) = e^{-\Delta t n^2}\left(u_n^N(t_k) + \Delta t F_n\big(u^N(t_k)\big) + \lambda_n^{1/2}\Delta B_{k,n}\right), \tag{3.2}$$

where $|n| \le N$, the noise terms $\Delta B_{k,n} = \beta_n(t_{k+1}) - \beta_n(t_k)$, and initial data $u_n^N(0) = u_n(0)$. The relationship between (3.2) and (3.1) is quite obvious when we iterate (3.2): for $t = k\Delta t$,

$$u_n^N(t) = e^{-tn^2}u_n^N(0) + \sum_{k=0}^{\lfloor t/\Delta t\rfloor - 1} e^{-(t-t_k)n^2}\left(\Delta t F_n(u^N(t_k)) + \lambda_n^{1/2}\Delta B_{k,n}\right) \tag{3.3}$$

(no terms in the sum for $0 \le t < \Delta t$). This approximation has been studied in detail in [21] for Gevrey (exponentially smooth) noise.

We study a generalization of this method, which incorporates postprocessing terms and flexibility in the approximation of $W(t)$. The generalized method has the following form: for $|n| \le N$,

$$u_n^N(t_{k+1}) = e^{-n^2\Delta t}\Big(u_n^N(t_k) + \Delta t F_n(u^N(t_k)) + \mathbf{1}_{\{|n|\le N_w\}}\lambda_n^{1/2}\Delta B_{k,n}\Big), \tag{3.4}$$

with initial data $u_n^N(0) = u_n(0) = u_{0,n}$, where $\mathbf{1}_X$ equals 1 if X holds, 0 otherwise. The constant N_w describes the number of modes used to approximate $W(t)$; this is the first generalization and we will show the advantages in taking $N_w < N$ in certain applications. As in [21], the analysis depends on an interpolant of $u_n^N(t_k)$ in time: let

$$u_n^N(t) = e^{-n^2 t} u_n^N(0) + \sum_{k=0}^{\lfloor t/\Delta t \rfloor - 1} e^{-(t-t_k)n^2} \Big(\Delta t F_n(u^N(t_k)) + \lambda_n^{1/2} \mathbf{1}_{\{|n| \le N_w\}} \Delta B_{k,n} \Big), \tag{3.5}$$

and note that the two definitions of $u_n^N(t_k)$ agree.

Now we introduce postprocessing. Given knowledge of u^N, the following are efficiently computed:

$$q_n^N(t_{k+1}) = e^{-n^2 \Delta t} \Big(q_n^N(t_k) + \Delta t \mathbf{1}_{\{|n| \le N_p\}} F_n(u^N(t_k)) + \lambda_n^{1/2} \mathbf{1}_{\{|n| \le N_w\}} \Delta B_{k,n} \Big), \tag{3.6}$$

with initial data $q_n^N(0) = u_n(0)$ for $N < |n| \le N_p$, where N_p describes the number of nonlinear terms. Again in the analysis in section 6, we use an interpolant

$$\begin{aligned} q_n^N(t) &= e^{-n^2 t} q_n^N(0) \\ &\quad + \sum_{k=0}^{\lfloor t/\Delta t \rfloor - 1} e^{-(t-t_k)n^2} \Big(\Delta t \mathbf{1}_{\{|n| \le N_p\}} F_n(u^N(t_k)) + \lambda_n^{1/2} \mathbf{1}_{\{|n| \le N_w\}} \Delta B_{k,n} \Big). \end{aligned} \tag{3.7}$$

We seek to estimate the error in approximating $u(t)$ by $u^N(t) + q^N(t)$, where $u^N = \sum_{|n| \le N} \phi_n u_n^N$ and $q^N = \sum_{N < |n| \le \max\{N_p, N_w\}} \phi_n q_n^N$, and, in particular, to understand the best choice of N_w and N_p.

3.1. Statement of main theorem. Let $\|\cdot\|$ denote the standard $L^2(0, 2\pi)$ norm. Denote the $H^m(0, 2\pi)$ Sobolev norm for $u = \sum_n u_n \phi_n$ by

$$\|u\|_m = \|(I - \Delta)^{m/2} u\| = \left(\sum_{n \in \mathbb{Z}} (1 + n^2)^m u_n^2 \right)^{1/2}.$$

We make the following assumption of f and Q.

ASSUMPTION 3.1. *For $u_1, u_2, u \in L^2(0, 2\pi)$, for some constant K_0 and some $m, r \ge 0$,*

$$\|F(u_1) - F(u_2)\|_r \le K_0 \|u_1 - u_2\|_r, \tag{3.8}$$

$$\|F(u)\|_r \le K_0 (1 + \|u\|_r) \tag{3.9}$$

and

$$\|F(u_1) - F(u_2)\|_m \le K_0 \|u_1 - u_2\|_m, \tag{3.10}$$

$$\|F(u)\|_m \le K_0 (1 + \|u\|_m). \tag{3.11}$$

There exists a constant K_1 such that for $u \in L^2(0, 2\pi)$ and $\delta, \delta_1, \delta_2 \in H^m(0, 2\pi)$,

$$\|dF(u)\delta\|_m \le K_1 \|\delta\|_m, \tag{3.12}$$

$$\|d^2 F(u)(\delta_1, \delta_2)\|_m \le K_1 \|\delta_1\|_m \|\delta_2\|_m. \tag{3.13}$$

The covariance Q of $W(t)$ satisfies $\mathrm{Tr}(I-\Delta)^\gamma Q<\infty$*; i.e.,*

$$\sum_{n\in\mathbb{Z}}(1+n^2)^\gamma\lambda_n<\infty. \tag{3.14}$$

We have introduced three regularity parameters: γ describes regularity of the noise, r gives the regularity of the solution $u(t)$, m indicates the norm for our error analysis.

THEOREM 3.2. *Let $u_0\in H^2(0,2\pi)$, $m<\min\{r,2\}$, $0\le r\le\gamma+1$, and $\gamma>-1$. For some $\nu>0$, consider $\Delta t\to 0$ and $N\to\infty$ with $\Delta t N^2\le\nu$. For each $T>0$, there exists $K>0$ such that*

$$\left(\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\right]\right)^{1/2}$$
$$\le K\Big(\Delta t+N^{-2}+\mathbf{1}_{N\le N_w}N^{-1-\gamma}+N_p^{-2-r+m}+\Delta t N_w^{1-\gamma+m}+N_w^{-1-\gamma+m}\Big),$$

where $u^N=\sum_{|n|\le N}\phi_n u_n^N$ and $q^N=\sum_{N<|n|\le\max\{N_p,N_w\}}\phi_n q_n^N$ with components defined by (3.5)–(3.7).

Proof. This is given in section 6. ∎

Note that we take limits in $\Delta t, N$ with $\Delta t N^2\le\nu$ but employ no restriction on ν. If an explicit Euler time integrator was used, we would require $\nu\le\frac{1}{2}$ [11], and the absence of this restriction is a clear advantage to the exponential time integrator.

The theorem is stated under the global Lipschitz assumption on the nonlinearity. This is the simplest setting in which to work and allows us to focus attention on postprocessing. The global Lipschitz assumption excludes many important cases, including the Allen–Cahn equation we discuss in section 4. The first approach to this problem is to change the nonlinearity without affecting the underlying model: for example, in the Allen–Cahn equation, the variable u describes the phase of some material and is only physically meaningful inside a bounded set. If we smooth out the nonlinear term at infinity, the essential features of the model remain. In section 4, we discover that our results are demonstrated without such a modification. The second approach is to develop the mathematics to include ever wider classes of nonlinearities. Approaches of this type include [16] for finite dimensional SDEs, which uses moment conditions to control the behavior of u at infinity and gain rates of convergence, and [11], which shows convergence in probability, without rates, for very general classes of f. The inclusion of these approaches in the present paper would obscure the main idea, which is postprocessing.

To understand postprocessing, we state two corollaries (using that $\Delta t N^2=\nu$). The first describes convergence for the method (3.2) for nonsmooth problems (extending work done in [21]). The second gives the values N_w, N_p that yield the best convergence rates.

COROLLARY 3.3 (no postprocessing). *Under the assumptions of Theorem* 3.2 *with $N=N_w=N_p$,*

$$\left(\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\right]\right)^{1/2}\le K\Big(N^{-2}+N^{-2-r+m}+N^{-1-\gamma+m}\Big).$$

For example, with $\gamma=-1/2$ (space-time white noise), the $L^2(0,2\pi)$ error (case $m=0$) converges like $N^{-1/2}$. This is consistent with related results in the literature

(e.g., [13, 19]). For Gevrey noise and a smooth nonlinearity, the parameters r and γ may be chosen arbitrarily large, and we recover the result of [21]: for any $z > 0$, there exists a constant K such that

$$\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)\|_1\right] \le K(N^{-z}+\Delta t). \tag{3.15}$$

This is faster convergence than any polynomial, although not the exponential rate found [5] for the deterministic case.

Now we turn to postprocessing.

COROLLARY 3.4 (postprocessing). *Let the assumptions of Theorem* 3.2 *hold.*

1. *If* $\gamma \ge 1$ *and* $m < \gamma - 1$, *then*

$$\left(\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\right]\right)^{1/2} \le KN^{-2}$$

   with $N_p = N$ *and* $N_w = \lceil N^{2/(1+\gamma-m)}\rceil$.
2. *If* $\gamma \ge 1$ *and* $m \ge \gamma - 1$, *then*

$$\left(\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\right]\right)^{1/2} \le KN^{-1-\gamma+m}$$

   with $N_p = N$ *and* $N_w = N$.
3. *If* $-1 < \gamma < 1$, *then*

$$\left(\mathbf{E}\left[\sup_{0<t_k\le T}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\right]\right)^{1/2} \le KN^{-1-\gamma}$$

   with $N_p = N$ *and* $N_w = \lceil N^{(1+\gamma)/(1+\gamma-m)}\rceil$.

These choices of N_p *and* N_w *provide the best convergence rate (up to scalar multiplication).*

Proof. We wish to choose N_p and N_w in terms of N to achieve the best convergence rate with N by balancing terms in the estimate provided in Theorem 3.2. We ignore multiplying constants which do not affect the rate.

1. We can achieve an N^{-2} convergence rate by balancing N_p^{-2-r+m}, $\Delta t N_w^{1-\gamma-m}$, and $N_w^{-1-\gamma+m}$ with N^{-2}. The condition $N_p^{-2-r+m} = N^{-2}$ yields $N_p = N^{2/(2+r-m)}$ and as $N^{2/(2+r-m)} \le N$ for $m \le r$, we choose $N_p = N$. Under assumption $m < \gamma - 1$, $\Delta t N_w^{1-\gamma-m} < N^{-2}$, and so the value N_w is found by solving $N^{-2} = N_w^{-1-\gamma+m}$.
2. In the case $m > \gamma - 1$, the accuracy is limited by the term $\Delta t N_w^{1-\gamma+m}$. The condition $\Delta t N_w^{1-\gamma+m} = N_w^{-1-\gamma+m}$ implies $N_w = N$. The condition $N_p^{-2-r+m} = N_w^{-1-\gamma+m}$ implies $N_p = N^{(2+r-m)/(1+\gamma-m)}$. Because we have $N^{(2+r-m)/(1+\gamma-m)} > N$ for $r > \gamma - 1$, the choice $N_p = N$ terms is optimal.
3. We achieve an $N^{-1-\gamma}$ rate by choosing $\Delta t N_w^{1-\gamma-m}$ and $N_w^{-1-\gamma+m}$ less than $N^{-1-\gamma}$. This is achieved by taking

$$N_w \ge \max\{N^{(1-\gamma)/(1-\gamma+m)}, N^{(1+\gamma)/(1+\gamma-m)}\}.$$

   As $m \ge 0$, we take $N_w = N^{(1+\gamma)/(1+\gamma-m)}$. Balancing the terms N_p^{-2-r+m} and $N^{-1-\gamma}$ provides $N_p = N^{(1+\gamma)/(2+r-m)}$. As $m < r$ and $\gamma < 1$, we have $N^{(1+\gamma)/(2+r-m)} < N$ and choose $N_p = N$. ∎

There are a number of issues to consider: the rate of convergence, the constant for this rate, and the efficiency of the scheme. We can improve the rate of convergence by choice of N_w and there are two cases to consider. For smooth noise $\gamma \geq 1+m$, the optimal value is $N_w < N$, which saves computing random numbers for many of the components u_n^N. This has been used with good effect in [27] for a Gevrey smooth noise. Note that $N_w \to 1$ as $\gamma \to \infty$. In practice, it is important for $N_w \to \infty$ as we ask for more accuracy and to take to enough modes to resolve the noise.

For nonsmooth noise ($\gamma < 1$), the optimal $N_w > N$, which implies that the postprocessing corrections q_n^N are Gaussian processes

$$q_n^N(t_{k+1}) = e^{-n^2\Delta t}\Big(q_n^N(t_k) + \lambda_n^{1/2}\mathbf{1}_{\{|n|\leq N_w\}}\Delta B_{k,n}\Big). \tag{3.16}$$

Thus, computing the postprocessing update is straightforward and cheap. To compare solutions for a single realization of $W(t)$, q_n^N must be found by time stepping. For weak approximation, it will be more efficient to compute and sample from the Gaussian distribution at the final time.

Our analysis predicts no improvement in the rate of convergence from postprocessing the nonlinear term. This contrasts with results on postprocessing in the deterministic case, where there is a gain in the rate of convergence [7, 8] (though this gain is often outweighed by extra computational cost).

4. Numerics. Consider the one-dimensional Allen–Cahn equation with noise:

$$du = \Big[\alpha u_{xx} + u - u^3\Big]\,dt + dW(t), \qquad u(0) = u_0, \tag{4.1}$$

with periodic boundary conditions on $[0, 2\pi)$. For numerical calculations, we take the diffusion coefficient $\alpha = 1/36$. We always take noise white in time and vary the spatial regularity γ; see (3.14).

To test the numerics, "true" solutions were computed by a standard Galerkin approximation with $N = 2^{11}$ modes and a time step $\Delta t = 5 \times 10^{-6}$. To avoid aliasing errors, the nonlinear term was computed with $2N$ terms (more than the optimal number of terms suggested by the 2/3 rule [1]). For a discussion of the role of aliasing in postprocessing (in the deterministic case), see [9].

Sample "true" solutions are plotted in Figure 4.1; this shows (left) the effect of different spatial regularity in real space and (right) the corresponding log-log plot in Fourier space. In real space, the solutions are smoother as the regularity of the noise increases. This is confirmed by the decay of the Fourier modes, and we see numerically that $r = \gamma + 1$, consistent with the results of Lemma A.1. Essentially, we gain a derivative on the regularity of the solution over the noise.

Let $\hat{N}$ denote a parameter for postprocessing (either $2N$, $4N$, $8N$, or N^2 in experiments). The "true" solutions were used to compute errors for the following approximations:

***Galerkin*:** A standard Galerkin approximation, from solving (3.4) with $N_w = N$.

***PP Full*:** A full postprocessed solution, from solving (3.4) and (3.6) with $N_w = N_p = \hat{N}$.

***PP Noise*:** A postprocessed solution on noise only, from solving (3.4) and (3.16) with $N_p = N$, $N_w = \hat{N}$.

We examine the rate of convergence and efficiency by a mean cpu time. From a practical point of view, plots of cpu time versus error can be interpreted in two ways: either fix a desired accuracy and see how long it would take to achieve, or fix a time

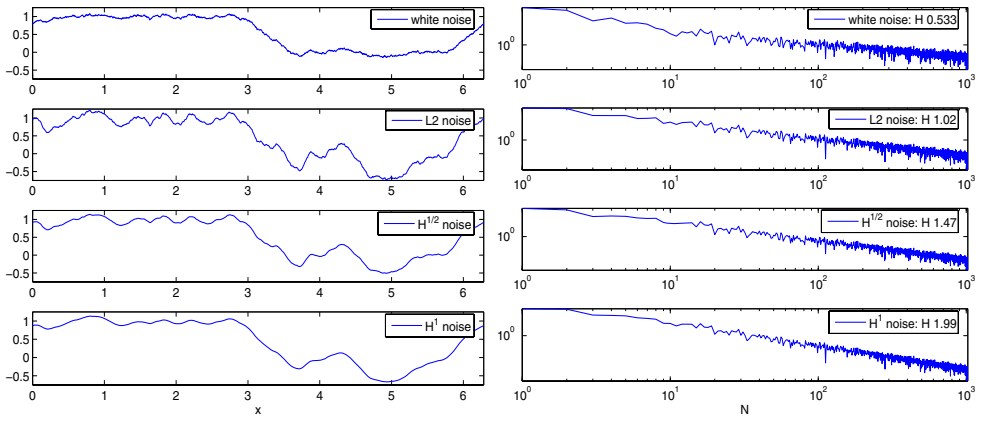

FIG. 4.1. *Plot (left) of "true" solutions at time $t = 1$ for $\gamma = -0.5, 0, 0.5, 1.0$ for one realization of the noise. Plot (right) is the corresponding log-log plot of the Fourier coefficients at time $t = 1$, which shows that for $\gamma > 0$ the solutions are in a Sobolev space H^r with $r = 0.5, 1, 1.5, 2$.*

and see how accurate a solution can be computed in that time. The expectation is computed from 10 samples, and we examine the root mean square of the error at time $t = 1$ in an appropriate norm. Normally we take the L^2 norm ($m = 0$) or H^1 norm ($m = 1$).

On the plots below we draw a line with slope equal to the predicted rate of convergence for *Galerkin*. We also report in the legend the observed slope from the data for the rate of convergence.

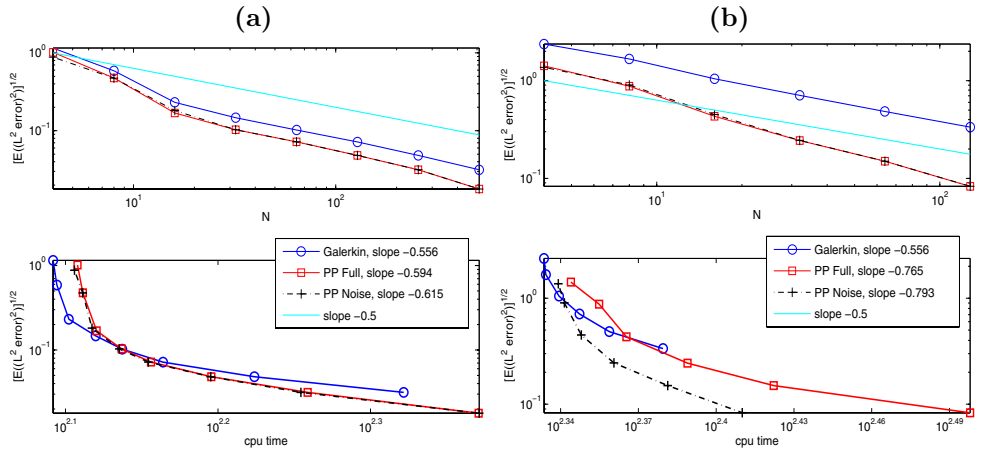

FIG. 4.2. *Space-time white noise* (a) *with $\hat{N} = 2N$ and* (b) *with $\hat{N} = 8N$. Plots show the L^2 error (top) rate of convergence and (below) plot of efficiency (cpu time).*

We examine the rates of convergence and computational efficiency for $W(t)$ defined by (1.2) with $\lambda_n = (1 + n^2)^{-\gamma}|n|^{-1}$, $n \neq 0$, and $\lambda_0 = 0$. We consider $\gamma = -1/2$ (*space-time white noise*), $\gamma = 0$ (L^2 *noise*), and $\gamma = 1/2, 1, 2$ (H^γ *noise*). Our predictions for the numerics are based on Theorem 3.2 where, motivated by Lemma A.1, we assume that $r = \gamma + 1$.

4.1. Space-time white noise: $\gamma = -\frac{1}{2}$. We observe in Figure 4.2 (top) the theoretically predicted rates of convergence for *Galerkin*: the L^2 error decays like $N^{-1/2}$. There is no convergence for H^1 error.

Postprocessing is not expected to improve the rate of convergence in the L^2 norm, as $N_w = N$ in Corollary 3.4. With $\hat{N} = 2N$, this is supported by computations; see Figure 4.2 (a) (top) where the postprocessing has no beneficial effect and the observed rate is the same as for *Galerkin*. However, there is an improvement in the error constant, and for $N > 32$ modes postprocessing is more efficient; see Figure 4.2 (a) (bottom). Taking this further and using more modes for the postprocessing, Figure 4.2 (b) shows *PP Full* and *PP Noise* with $\hat{N} = 8N$. The numerics suggest a rate of convergence faster than the theoretical one. This is encouraging, although the resolution is coarse and the theoretical rate may reappear for larger N.

We clearly see the computational advantage of *PP Noise* compared to *PP Full* and *Galerkin* in Figure 4.2 (a) and (b) bottom. Postprocessing on the noise terms only is far more efficient.

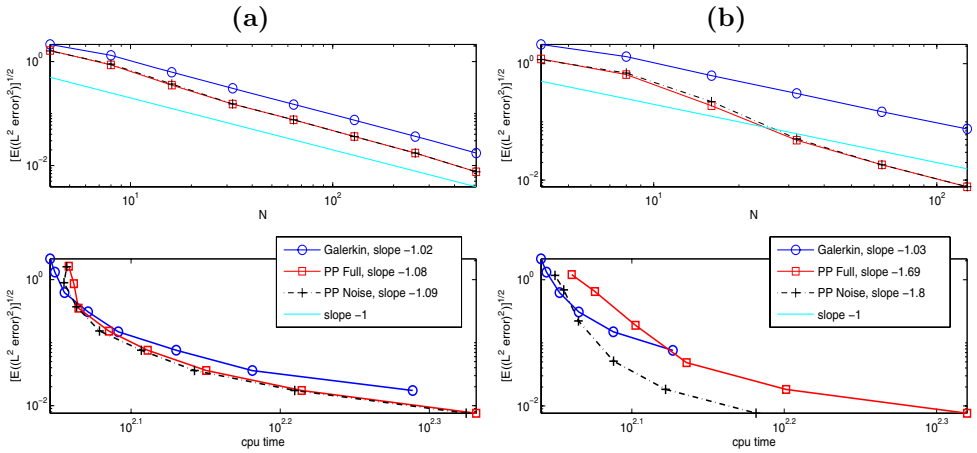

FIG. 4.3. *For L^2 noise, we plot* (a) *the L^2 error with $\hat{N} = 2N$ and* (b) *the L^2 error with $\hat{N} = 8N$. Top shows error against N, and bottom error against average cpu time.*

4.2. L^2 noise. This is similar to white noise: for *Galerkin*, the L^2 error decays like N^{-1}, which is observed in Figure 4.3 (a) and (b), and the H^1 error does not converge. In theory, postprocessing offers no improvement. In practice, there is an improvement in the error constant and an improvement in efficiency for $\hat{N} = 2N$ and further improvement for $\hat{N} = 8N$. See Figure 4.3 (a) and (b).

4.3. $H^{1/2}$ noise. Corollary 3.3 predicts convergence of the L^2 error like $N^{-3/2}$ and the H^1 error like $N^{-1/2}$ for *Galerkin*, and these rates are observed in Figure 4.4 (a) and (b). With postprocessing, the optimal rate for the L^2 error is not changed, and the H^1 error is like $N^{-3/2}$ if $N_w = N^3$. It is impractical to calculate with N^3 postprocessing terms for large N, and instead we look at $\hat{N} = 2N, 4N, 8N$. Figure 4.4 shows the effect of increasing $\hat{N}$ for L^2 error (left) and H^1 error (right) with $\hat{N}$ increasing top to bottom. For L^2 and H^1 errors, increasing $\hat{N}$ improves the error and seems to improve the rate of convergence—although this is not expected from the analysis for L^2 and we are a long way from taking the predicted N^3 modes for H^1. We clearly see that *PP Noise* is the most efficient method.

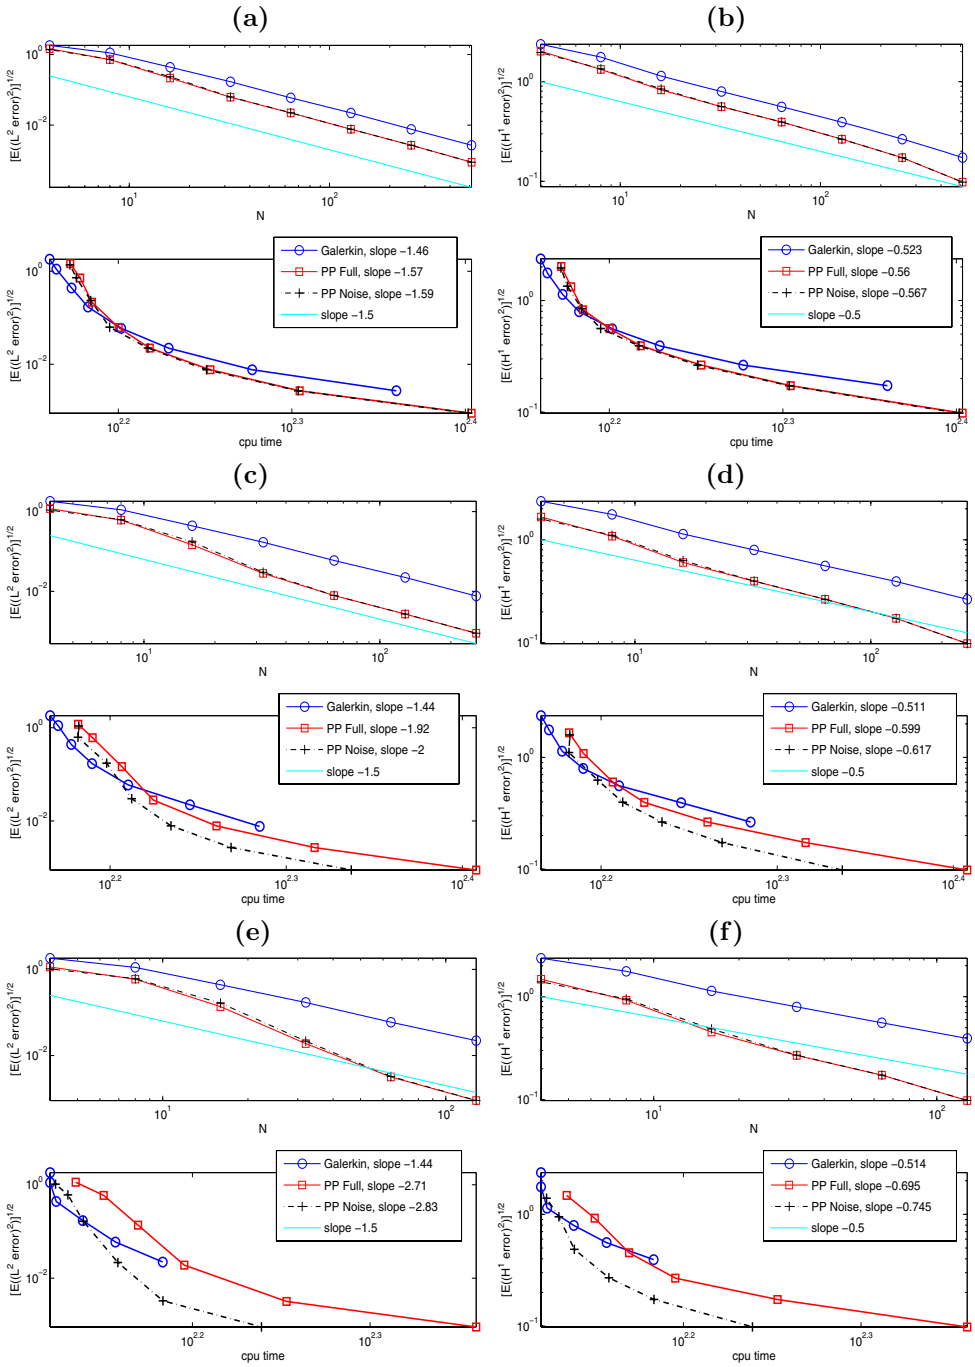

FIG. 4.4. *For $H^{1/2}$ noise, we examine the number of postprocessing terms $\hat{N}$. In* (a) *and* (b) *we take $\hat{N} = 2N$,* (c) *and* (d) *$\hat{N} = 4N$,* (e) *and* (f) *$\hat{N} = 8N$ with L_2 error (left) and H^1 error (right). For each case, we show plots of error against N (above) and error against cpu time (below).*

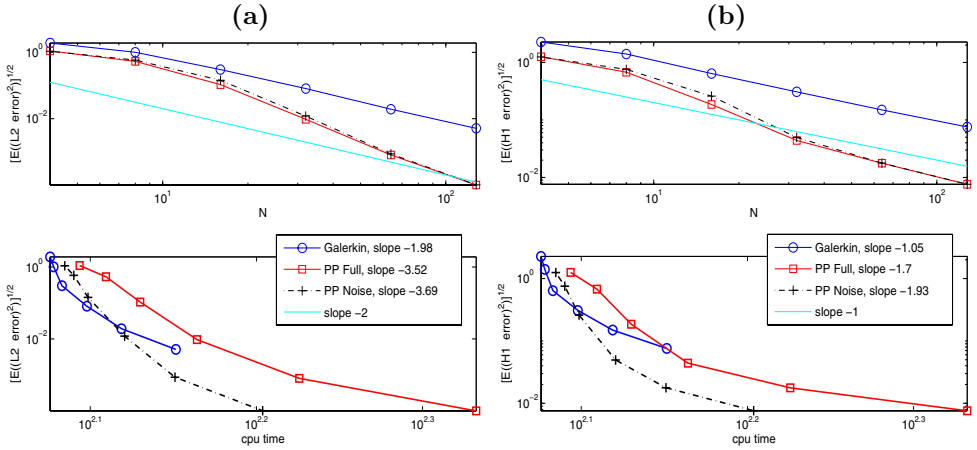

FIG. 4.5. *For H^1 noise with $\hat{N} = 8N$, we plot* (a) *L^2 error and* (b) *H^1 error. The top shows error against N, and the bottom shows error against cputime.*

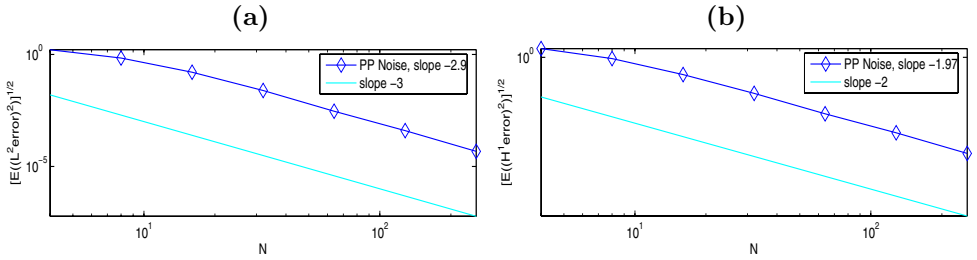

FIG. 4.6. *For H^2 noise, we see* (a) *faster than the predicted rate of convergence for the L^2 error with the optimal value $\hat{N} = N^{2/3}$ and* (b) *the N^{-2} convergence rate is achieved for the H^1 error, with $\hat{N} = N^{2/3}$ rather than the theoretical rate of $N_w = N$.*

4.4. H^1 noise. Corollary 3.3 predicts that the *Galerkin* L^2 error decays like N^{-2} and H^1 error decays like N^{-1}, as observed in Figure 4.5. This is the limiting case in Corollary 3.4, where we find N^{-2} convergence by taking $N_w = N$ for L^2 error and $N_w = N^2$ for H^1 error; the solution is smooth in space, and accuracy is now limited by time stepping. It is impractical to calculate with N^2 postprocessing terms for large N, and instead we look at $\hat{N} = 8N$; Figure 4.5 shows (a) the L^2 error and (b) the H^1 error. The postprocessing methods give smaller errors and are more efficient, in particular *PP Noise*.

4.5. H^2 noise. The optimal number of modes is $N_w = N^{2/3}$ for the L^2 error, giving N^{-2} convergence. We see in Figure 4.6 (a) that the L^2 error is converging faster than the theoretical rate, close to N^{-3}. Here we see a limitation of the analysis: the theoretical convergence rate is limited to an N^{-2} rate because of time stepping and regularity of the initial data. In this case, the error is dominated by the spatial approximation of smooth problems, which may decrease like N^{-3}, similar to rates described in (3.15).

The H^1 error in (b) shows N^{-2} convergence—although only $\hat{N} = N^{2/3}$ modes are used rather than the theoretical optimum value N. In this case, the accuracy is determined by approximation of the deterministic terms, and we are unable to

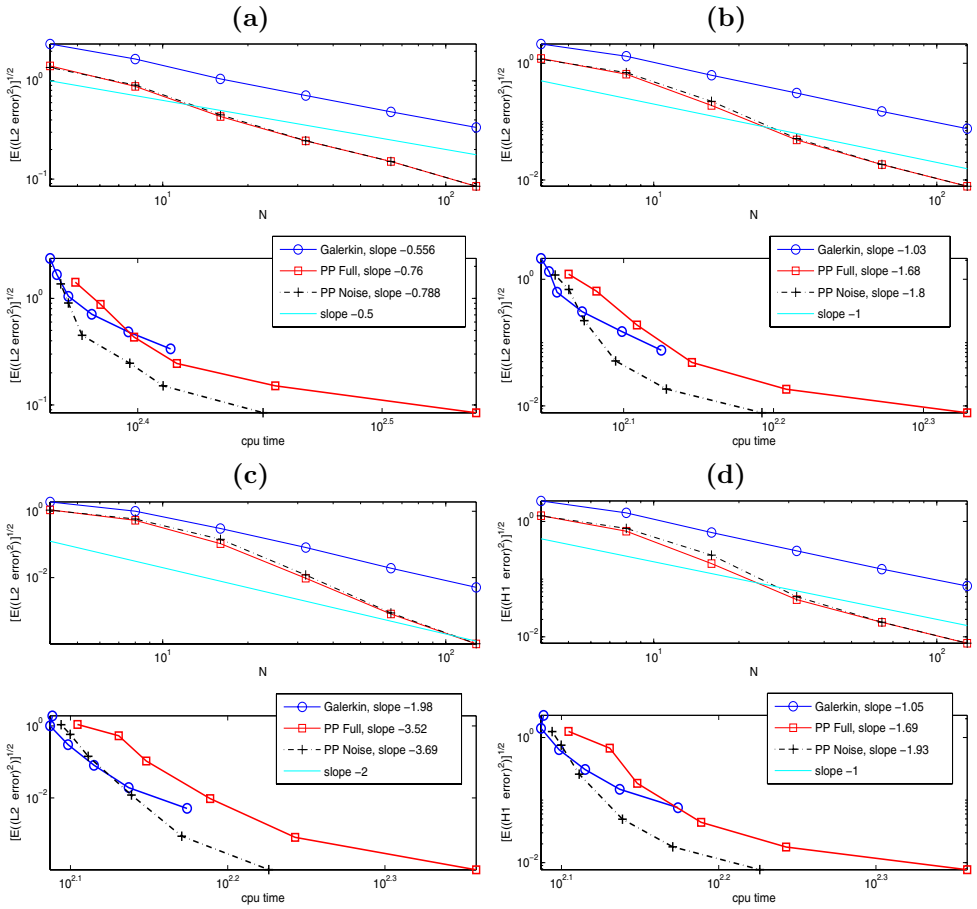

FIG. 4.7. *Postprocessing for the implicit Euler–Maruyama method. In* (a) *white noise and* L^2 *error,* (b) L^2 *noise and* L^2 *error,* (c) H^1 *noise and* L^2 *error,* (d) *again* H^1 *noise but with* H^1 *error.*

increase the number of modes to see the theoretical optimal number for N_w bite.

4.6. Postprocessing implicit Euler–Maruyama. Postprocessing is effective for other time stepping algorithms. In Figure 4.7, we plot results of experiments with the implicit Euler–Maruyama scheme. We take $\hat{N} = 8N$ and plot (a) the L^2 error for white noise, (b) the L^2 error with L^2 noise, (c) L^2 error with H^1 noise, and (d) H^1 error with H^1 noise. Again *PP Noise* is the most efficient of the methods, and there appears to be an improvement in the rate of convergence in addition to the constant. These trends are identical to those found in Theorem 3.2 and shown in Figures 4.2–4.6.

5. Conclusions. Theorem 3.2 shows that postprocessing can improve the rate of convergence over a standard Galerkin method for stochastic PDEs. For nonsmooth forcing, the best number of modes is greater than the standard Galerkin method. For smooth noise, as observed in [27], the optimal number of modes is smaller. With the smooth nonlinearity in (4.1), it is flexibility in the number of modes that approximate $W(t)$ that is key. This was confirmed in numerics. We found that postprocessing on the noise improves on the convergence and efficiency of the standard Galerkin

approximation and that the contribution from the (smooth) nonlinearity in the post-processing is negligible. This improvement in efficiency over the standard Galerkin method holds true for all spatial regularities of the noise that we tested.

It is often computationally prohibitive to use the number of modes suggested by the theorem. From a practical point of view, improvements were noted with $N_w = 2N$ even when the theoretical optimum number of nodes is $N_w = N^2$. For nonsmooth noise, we found numerically that taking $N_w = 8N$ gave a good compromise between the extra effort involved and accuracy. Indeed it seems we get a rate of convergence not predicted by the theory.

For smooth noise, our numerics suggest a convergence rate faster than that predicted by the theorem. From [21], it is known that for exponentially smooth noise a faster than polynomial convergence is available for smooth problems. Such techniques have not been used in the present paper, and the results we give are optimal for the H^2 initial data and time stepping method studied.

Finally, although our analysis is for the scheme (3.2), this approach works equally well for other time stepping methods, such as the implicit Euler–Maruyama time stepping scheme. Our presentation is for a Galerkin-based approximation; however, postprocessing can easily be extended to other spatial discretizations using, for example, two grids.

6. Proof of main theorem. We prove Theorem 3.2 by estimating

$$\mathbf{E}\left[\sup_{0\le t_j\le t'}\|u(t_j)-u^N(t_j)-q^N(t_j)\|_m^2\right]$$

for $0 \le t' \le T$ and applying Gronwall's lemma. To estimate terms, we use a generic constant K which varies between instances but is independent of Δt and N (it may depend on (1.1) and the length of time integration T and constant ν). Consider the difference of the variation of constants formulae (3.1), (3.5), and (3.7). Split into Fourier modes with $|n| \le N_p$ and $|n| > N_p$ and by nonlinear and noise terms.

Nonlinear terms: Modes $|n| \le N_p$.

$$\begin{aligned}
&\mathbf{E}\sup_{0\le t_j\le t'}\sum_{|n|\le N_p}(1+n^2)^m\left|\sum_{k=0}^{j-1}\times\int_{t_k}^{t_{k+1}}e^{-(t_j-t_k)n^2}(e^{(s-t_k)n^2}F_n(u(s))-F_n(u^N(t_k)))\,ds\right|^2\\
&\qquad=\sum_{|n|\le N_p}\mathbf{E}\Bigg[\sup_{0\le t_j\le t'}\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}}e^{-(t_j-t_k)n^2}(1+n^2)^{m/2}\\
&\qquad\Big(\Big(F_n(u(s))-F_n(u(t_k))\Big)+\Big(F_n(u(t_k))-F_n(u^N(t_k)+q^N(t_k))\Big)\\
&\qquad+\Big(F_n(u^N(t_k)+q^N(t_k))-F_n(u^N(t_k))\Big)+\Big((e^{(s-t_k)n^2}-1)F_n(u(s))\Big)\Big)\,ds\Bigg]^2\\
&\qquad\le K(\mathbf{NL}_1+\cdots+\mathbf{NL}_4),
\end{aligned}$$

where the four terms $\mathbf{NL}_i$ are analyzed below.

The first term. Fix t_j and consider $k \le j-1$. Define

$$L_{k,n}=\int_{t_k}^{t_{k+1}}e^{-(t_j-t_k)n^2}(1+n^2)^{m/2}\Big(F_n(u(s))-F_n(u(t_k))\Big)\,ds,$$

and let

$$\mathbf{NL}'_1 = \sum_{|n|\le N_p} \mathbf{E}\left[\sum_{k=0}^{j-1} L_{k,n}\right]^2. \tag{6.1}$$

Write $U_k = u(t_k)$ and $u(s) = u(t_k) + \delta_s$ for $t_k \le s < t_{k+1}$; then

$$F_n(u(s)) - F_n(u(t_k)) = dF_n(U_k)\delta_s + \int_0^1 \int_0^\eta d^2F_n(U_k + \xi\delta_s)(\delta_s, \delta_s)\, d\xi\, d\eta.$$

In the following argument we neglect the remainder term, which can be dealt with easily under (3.13). Denote by $\mathcal{F}_t$ the filtration for the Wiener process $W(t)$. For $k > i$, under (3.12), the cross terms in (6.1)

$$\begin{aligned}\sum_{|n|\le N_p} \mathbf{E}L_{k,n}L_{i,n} = &\sum_{|n|\le N_p} (1+n^2)^m \mathbf{E}\bigg[\int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}\mathbf{E}\Big[dF_n(U_k)\delta_s|\mathcal{F}_{t_k}\Big]\, ds \\ &\times \int_{t_i}^{t_{i+1}} e^{-(t_j-t_i)n^2} dF_n(U_i)\delta_s\, ds\bigg] + \text{higher order terms (h.o.t.)} \\ \le\ & K\Delta t^4,\end{aligned}$$

because $dF_n(U_i)\delta_s$ is $\mathcal{F}_{t_k}$ measurable and $\|\mathbf{E}\big[dF(U_k)\delta_s|\mathcal{F}_{t_k}\big]\|_m \le K\Delta t$. As

$$\left[\int_{t_k}^{t_{k+1}} \phi(s)\, ds\right]^2 \le (t_{k+1}-t_k)\int_{t_k}^{t_{k+1}} \phi(s)^2\, ds, \text{ for } \phi \in L^2(0,T),$$

$$\sum_{|n|\le N_p} \mathbf{E}L_{k,n}^2 \le \Delta t \sum_{|n|\le N_p} \int_{t_k}^{t_{k+1}} \mathbf{E}\big[e^{-(t_j-t_k)n^2}(1+n^2)^{m/2} dF_n(U_k)\delta_s\big]^2\, ds + \text{h.o.t.}$$

Here

$$\begin{aligned}&\sum_{|n|\le N_p} \int_{t_k}^{t_{k+1}} \mathbf{E}\big[e^{-(t_j-t_k)n^2}(1+n^2)^{m/2} dF_n(U_k)\delta_s\big]^2\, ds \\ &\qquad \le \int_{t_k}^{t_{k+1}} \mathbf{E}\big[\|dF_n(U_k)\|_m^2 \cdot \|\delta_s\|_m^2\big]\, ds.\end{aligned}$$

Because $\mathbf{E}\|u^N(t) - u^N(s)\|_m^2 \le K|t-s|\|u_0\|_m^2$ and (3.12) holds, we conclude that

$$\sum_{|n|\le N_p} \int_{t_k}^{t_{k+1}} \mathbf{E}\big[e^{-(t_j-t_k)n^2}(1+n^2)^{m/2} dF_n(U_k)\delta_s\big]^2\, ds \le K\Delta t^2.$$

Thus, we may estimate

$$\mathbf{NL}'_1 \le \sup_{0\le t_j\le t'} \sum_{|n|\le N_p} \left\{\sum_{k=0}^{j-1} \mathbf{E}\big[L_{k,n}\big]^2 + \sum_{k,i=0,\, k\ne i}^{j-1} \mathbf{E}L_{k,n}L_{i,n}\right\} \le K\Delta t^2.$$

Apply the Doob martingale inequality to get

$$\mathbf{E}\Big[\sup_{0\le t_j\le t'} NL_1'\Big] \le 4K\Delta t^2.$$

The second term.

$$\begin{aligned}\mathbf{NL}_2 &= \sum_{|n|\le N_p}(1+n^2)^m\mathbf{E}\Big[\sup_{0\le t_j\le t'}\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}\\ &\qquad\qquad\times\Big(|F_n(u(t_k))-F_n(u^N(t_k)+q^N(t_k))|\Big)\,ds\Big]^2\\ &\le \int_0^{t'}\sum_{|n|\le N_p}\mathbf{E}\Big[\sup_{0\le t_k\le t}(1+n^2)^m|F_n(u(t_k))-F_n(u^N(t_k)+q^N(t_k))|^2\Big]\,dt.\end{aligned}$$

Using (3.10),

$$\mathbf{NL}_2 \le K\int_0^{t'}\mathbf{E}\Big[\sup_{0\le t_k\le t}\|u(t_k)-u^N(t_k)-q^N(t_k)\|_m^2\Big]\,dt.$$

The third nonlinear term.

$$\begin{aligned}\mathbf{NL}_3 &= \sum_{|n|\le N_p}(1+n^2)^m\mathbf{E}\Big[\sup_{0\le t_j\le t'}\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}\\ &\qquad\qquad\times\Big(|F_n(u^N(t_k)+q^N(t_k))-F_n(u^N(t_k))|\Big)\,ds\Big]^2\\ &\le \sum_{|n|\le N_p}(1+n^2)^m\mathbf{E}\Big[\sup_{0\le t_j\le t'}|F_n(u^N(t_j)+q^N(t_j))-F_n(u^N(t_j))|\\ &\qquad\qquad\times\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}\,ds\Big]^2\\ &\le \sum_{0<|n|\le N_p}(1+n^2)^m\mathbf{E}\Big[\sup_{0\le t_k\le t'}|F_n(u^N(t_k)+q^N(t_k))-F_n(u^N(t_k))|\frac{1}{n^2}\Big]^2\\ &+\ \mathbf{E}\Big[\sup_{0\le t_k\le t'}|F_0(u^N(t_k)+q^N(t_k))-F_0(u^N(t_k))|\Big].\end{aligned}$$

Choose $m\le 2$, then using (3.8),

$$\begin{aligned}\mathbf{NL}_3 &\le \sum_{|n|\le N_p}\mathbf{E}\Big[\sup_{0\le t_k\le t'}(1+n^2)^m|F_n(u^N(t_k)+q^N(t_k))-F_n(u^N(t_k))|^2\Big]\\ &\le\ K\int_0^{t'}\mathbf{E}\Big[\sup_{0<t_k\le t}\|q^N(t_k)\|^2\Big]\,dt.\end{aligned}$$

Finally, from Lemma A.2,

$$\mathbf{NL}_3 \le K(N^{2(-2)}+\mathbf{1}_{N\le N_w}N^{2(-1-\gamma)}+N^{2(-2-r)}).$$

The fourth nonlinear term.

$$\mathbf{NL}_4 = \sum_{|n|\le N_p} (1+n^2)^m \mathbf{E}\Big[\sup_{0\le t_j\le t'} \sum_{k=0}^{j-1} \int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}\Big(|(e^{(s-t_k)n^2}-1)F_n(u(s))|\Big)\,ds\Big]^2$$
$$\le \sum_{|n|\le N_p} (1+n^2)^m \mathbf{E}\Big[\sup_{0\le t_j\le t'} |F_n(u(t_j))|^2 \sum_{k=0}^{\lfloor t/\Delta t\rfloor -1} e^{-(t_j-t_k)n^2} K\Delta t^2 n^2\Big]^2.$$

Note that for $0 \le \Delta t n^2 \le \nu$

$$\int_{t_k}^{t_{k+1}} |e^{(s-t_k)n^2}-1|\,ds \le \Big(\frac{e^{\Delta t n^2}-1}{n^2} - \Delta t\Big) \le n^{-2}(K\Delta t^2 n^4 e^{n^2\Delta t}) \le K\Delta t^2 n^2 e^{\nu}$$

and

$$\sum_{k=1}^{\infty} e^{-kn^2\Delta t} \le \frac{1}{1-e^{-n^2\Delta t}} \le \frac{K}{n^2\Delta t}.$$

Thus, using (3.11),

$$\mathbf{NL}_4 \le K \sum_{|n|\le N_p} (1+n^2)^m \mathbf{E}\Big[\sup_{0\le s\le t'} |F_n(u(s))|^2 \Delta t\Big]^2$$
$$\le K\Delta t^2 \Big(1 + \mathbf{E}\Big[\sup_{0\le s\le t'} \|u(s)\|_m\Big]^2\Big).$$

By (3.10) and Lemma A.1,

$$\mathbf{NL}_4 \le K\,\Delta t^2.$$

Nonlinear terms: Modes $|n| > N_p$. Consider now the tail of the expansion of $u(t)$; i.e., the modes not included in either u^N or q^N. If $r > m$,

$$\mathbf{TAIL} = \mathbf{E}\Big[\sup_{0\le t_j\le t'} \sum_{|n|>N_p} (1+n^2)^m \Big| \int_0^{t_j} e^{-(t_j-s)n^2} F_n(u(s))\,ds\Big|^2\Big]$$
$$\le K\Big(\int_0^{t'} (1+N_p^2)^{-(r-m)/2} e^{-(t_j-s)N_p^2}\,ds\Big)^2 \mathbf{E}\Big[\sup_{0\le s\le t'} \|F(u(s))\|_r^2\Big].$$

By (3.9) and Lemma A.1,

$$\mathbf{TAIL} \le K\,N_p^{2(m-2-r)}.$$

Noise with modes $|n| \le N_w$.

$$\mathbf{NOISE}_1 = \mathbf{E}\Big[\sup_{0<t_j\le t'} \sum_{|n|\le N_w} (1+n^2)^m$$
$$\times \Big|\sum_{k=0}^{j-1}\Big(\int_{t_k}^{t_{k+1}} e^{-(t_j-s)n^2}\lambda_n^{1/2} d\beta_n(s) - e^{-(t-t_k)n^2}\lambda_n^{1/2}\Delta B_{k,n}\Big)\Big|^2\Big]$$
$$\le \sum_{|n|\le N_w} (1+n^2)^m |\lambda_n| \mathbf{E}\Big[\sup_{0<t_j\le t'} \int_0^{t_j} (e^{-(t_j-s)n^2} - e^{-(t_j-\lfloor s/\Delta t\rfloor \Delta t)n^2}) d\beta_n(s)\Big]^2.$$

By Doob's martingale inequality

$$\begin{aligned}\mathbf{NOISE}_1 \leq\ & 4\sum_{|n|\leq N_w}(1+n^2)^m|\lambda_n|\int_0^{t'}(e^{-(t_j-s)n^2}-e^{-(t_j-\lfloor s/\Delta t\rfloor\Delta t)n^2})^2\,ds\\ =\ & 4\sum_{|n|\leq N_w}(1+n^2)^m|\lambda_n|\int_0^{t'}e^{-2(t_j-s)n^2}(1-e^{-(s-\lfloor s/\Delta t\rfloor\Delta t)n^2})^2\,ds.\end{aligned}$$

Note that $1-e^{-tn^2}\leq tn^2$ for $0\leq t\leq\Delta t$ and

$$\int_0^{t'}e^{-2(t_j-s)n^2}(1-e^{-(s-\lfloor s/\Delta t\rfloor\Delta t)n^2})^2\,ds\leq(\Delta tn^2)^2\int_0^{t'}e^{-2(t_j-s)n^2}\,ds\leq K\Delta t^2n^2.$$

Hence

$$\begin{aligned}\mathbf{NOISE}_1 \leq\ & 4\sum_{|n|\leq N_w}(1+n^2)^m|\lambda_n|\Delta t^2n^2\\ \leq\ & K\Delta t^2(1+N_w^2)^{(1+m-\gamma)}\sum_{|n|\leq N_w}(1+n^2)^\gamma|\lambda_n|\\ \leq\ & K\Delta t^2(1+N_w^2)^{(1+m-\gamma)},\end{aligned}$$

under (3.14).

Noise with modes $|n|>N_w$.

$$\begin{aligned}\mathbf{NOISE}_2 =\ & \mathbf{E}\left[\sup_{0\leq t_j\leq t'}\sum_{|n|>N_w}(1+n^2)^m\left|\int_0^{t_j}e^{-(t_j-s)n^2}\lambda_n^{1/2}d\beta_n(s)\right|^2\right]\\ \leq\ & 4(1+N_w^2)^{m-\gamma}\frac{1-e^{-t'N_w^2}}{N_w^2}\sum_{|n|\geq N_w}\lambda_n(1+n^2)^\gamma\leq K\,N_w^{2(m-1-\gamma)},\end{aligned}$$

using (3.14).

Conclusion. We have achieved the following inequality:

$$\begin{aligned}&\mathbf{E}\left[\sup_{0\leq t_j\leq t'}\|u(t_j)-u^N(t_j)-q^N(t_j)\|_m^2\right],\\ &\leq K\Bigg(\Delta t^2+(N^{2(-2)}+\mathbf{1}_{N\leq N_w}N^{2(-1-\gamma)}+N^{2(-2-r)})+N_p^{2(-2-r+m)}+\Delta t^2N_w^{2(-\gamma+1+m)}\\ &+N_w^{2(-1-\gamma+m)}+\int_0^T\mathbf{E}\left[\sup_{0<t_k\leq t}\|u(t_k)-u^N(t_k)-q^N(t_k)\|^2\right]dt\Bigg).\end{aligned}$$

Note $N^{2(-2-r)}\leq N^{2(-2)}$, and then Gronwall's lemma provides

$$\begin{aligned}\mathbf{E}\left[\sup_{0\leq t\leq t'}\|u(t)-u^N(t)-q^N(t)\|_m^2\right]\leq\ & K\Big(\Delta t^2+N^{2(-2)}+\mathbf{1}_{N\leq N_w}N^{2(-1-\gamma)}\\ &+N_p^{2(-2-r+m)}+\Delta t^2N_w^{2(-\gamma+1+m)}+N_w^{2(-\gamma-1+m)}\Big).\end{aligned}$$

This completes the proof of Theorem 3.2. □

Appendix (lemmas). We collect two elementary lemmas used in the proof of the main theorem.

LEMMA A.1. *For $r \le \gamma + 1$,*

$$\mathbf{E} \sup_{0\le t\le T} \|u(t)\|_r^2 \le K(1 + \|u_0\|_r^2).$$

Proof. Examine the nonlinear term in (3.1) under (3.9):

$$\mathbf{E}\left[\sup_{0\le t\le t'} \sum_n \left|(1+n^2)^{r/2} \int_0^t e^{-(t-s)n^2} F_n\big(u(s)\big)\, ds\right|^2\right] \le K \int_0^{t'} \left(1 + \mathbf{E}\left[\sup_{0\le s\le t} \|u(s)\|_r^2\right]\right) dt$$

and the noise term (modes with $n \ne 0$)

$$\begin{aligned}\mathbf{E}&\left[\sup_{0\le t\le t'} \sum_{n\ne 0} (1+n^2)^{r/2} \left| \int_0^t e^{-(t-s)n^2} \lambda_n^{1/2} d\beta(s)\right|^2\right] \\ &\le 4\mathbf{E}\left[\sum_{n\ne 0} (1+n^2)^{(r-\gamma)} \left| \int_0^{t'} e^{-2(t-s)n^2} (1+n^2)^{\gamma} \lambda_n ds\right|\right] \\ &\le \sum_{n\ne 0} \frac{(1+n^2)^{(r-\gamma)}}{n^2} (1+n^2)^{\gamma} \lambda_n\end{aligned}$$

using (3.14). This is finite if $r - \gamma \le 1$, so that the Gronwall lemma completes the proof. □

LEMMA A.2. *Under the assumptions of Lemma* A.1,

$$\mathbf{E} \sup_{0\le t\le T} \|q^N(t)\|^2 \le K(N^{2(-2)} + \mathbf{1}_{N\le N_w} N^{2(-1-\gamma)} + N^{2(-2-r)}).$$

Proof. We seek upper estimates on

$$\mathbf{E}\left[\sup_{0\le t\le T} \|q^N(t)\|^2\right].$$

To do this, estimate the influence of the initial data

$$\begin{aligned}\sum_{N<|n|\le \max N_p, N_w} \mathbf{E}\left[\sup_{0\le t_k\le T} |e^{-t_k n^2} u_n(0)|^2\right] &= \sum_{N<|n|\le \max N_p, N_w} u_{0,n}^2 \\ &\le KN^{-4} \sum_{N<|n|\le \max N_p, N_w} (1+n^2)^2 u_{0,n}^2.\end{aligned}$$

If $u_0 \in H^2(0, 2\pi)$, this term is bounded by $KN^{2(-2)}$.

Now the nonlinear terms

$$\mathbf{E}\left[\sup_{0\le t_j\le T}\sum_{N<|n|\le N_p}\left|\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}} e^{-(t_j-t_k)n^2}F_n(u^N(t_k))\,ds\right|^2\right]$$

$$\le \mathbf{E}\left[\sup_{0\le t_j\le T}\sum_{N<|n|\le N_p}(1+n^2)^r|F_n(u^N(t_k))|^2\left|\sum_{k=0}^{j-1}\int_{t_k}^{t_{k+1}}(1+n^2)^{-r/2}e^{-(t_j-t_k)n^2}\,ds\right|^2\right]$$

$$\le \mathbf{E}\left[\sup_{0\le t\le T}\|u^N(t)\|_r^2\right].\left|\sum_{k=0}^{\lfloor t/\Delta t\rfloor-1}\int_{t_k}^{t_{k+1}}(1+n^2)^{-r/2}e^{-(t_j-t_k)n^2}\,ds\right|^2$$

$$\le \mathbf{E}\left[\sup_{0\le t\le T}\|u^N(t)\|_r^2\right]\frac{(1+N^2)^{-r}}{N^4}.$$

This term is bounded by $K\,N^{2(-r-2)}$ by applying Lemma A.1. The noise term is

$$\mathbf{E}\left[\sup_{0\le t_j\le T}\sum_{N<|n|\le N_w}\left|\sum_{k=0}^{j-1}\left(\int_{t_k}^{t_{k+1}} e^{-(t-t_k)n^2}\lambda_n^{1/2}\Delta B_{k,n}\right)\right|^2\right]$$

$$= 4\sum_{N<|n|\le N_w}(1+n^2)^{\gamma}\lambda_n\int_0^T(1+n^2)^{-\gamma}e^{-2(t_j-t_k)n^2}\,ds$$

$$\le 4\,\mathbf{1}_{N\le N_w}\,N^{2(-1-\gamma)}\sum_{N<|n|\le N_w}(1+n^2)^{\gamma}\lambda_n.$$

This completes the proof. □

MONTE CARLO METHODS IN PAGERANK COMPUTATION: WHEN ONE ITERATION IS SUFFICIENT*

K. AVRACHENKOV†, N. LITVAK‡, D. NEMIROVSKY§, AND N. OSIPOVA†

Abstract. PageRank is one of the principle criteria according to which Google ranks Web pages. PageRank can be interpreted as a frequency of visiting a Web page by a random surfer, and thus it reflects the popularity of a Web page. Google computes the PageRank using the power iteration method, which requires about one week of intensive computations. In the present work we propose and analyze Monte Carlo-type methods for the PageRank computation. There are several advantages of the probabilistic Monte Carlo methods over the deterministic power iteration method: Monte Carlo methods already provide good estimation of the PageRank for relatively important pages after one iteration; Monte Carlo methods have natural parallel implementation; and finally, Monte Carlo methods allow one to perform continuous update of the PageRank as the structure of the Web changes.

Key words. Google, PageRank, Monte Carlo methods, absorbing Markov chains

1. Introduction.

Surfers on the Internet frequently use search engines to find pages satisfying their query. However, there are typically hundreds or thousands of relevant pages available on the Web. Thus, listing them in a proper order is a crucial and nontrivial task. The original idea of Google presented in [5] is to list pages according to their PageRank, which reflects the popularity of a page. The PageRank is defined in the following way. Denote by n the total number of pages on the Web, and define the $n \times n$ hyperlink matrix P as follows. Suppose that page i has $k > 0$ outgoing links. Then $p_{ij} = 1/k$ if j is one of the outgoing links, and $p_{ij} = 0$ otherwise. If a page does not have outgoing links, the probability is spread among all pages of the Web, namely, $p_{ij} = 1/n$. In order to make the hyperlink graph connected, it is assumed that a random surfer goes with some probability to an arbitrary Web page with uniform distribution. Thus, the PageRank is defined as a stationary distribution of a Markov chain whose state space is the set of all Web pages, and the transition matrix is

$$\tilde{P} = cP + (1-c)(1/n)E, \tag{1.1}$$

where E is a matrix whose all entries are equal to one and $c \in (0,1)$ is the probability of not jumping to a random page (it is chosen by Google to be 0.85). The Google matrix $\tilde{P}$ is stochastic, aperiodic, and irreducible, so there exists a unique row vector

π such that

$$\pi \tilde{P} = \pi, \quad \pi \underline{1} = 1, \tag{1.2}$$

where $\underline{1}$ is a column vector of ones. The row vector π satisfying (1.2) is called a PageRank vector, or simply PageRank. If a surfer follows a hyperlink with probability c and jumps to a random page with probability $1-c$, then π_i can be interpreted as a stationary probability that the surfer is at page i. The PageRank also allows several different interpretations through expectations. For instance, in [2], the PageRank is seen as the average number of surfers navigating a given page at a given time instant, provided that at each time instant $t \geq 0$ a surfer can cease from navigating with probability $(1-c)$ and on average $(1-c)$ surfers start navigating from each page. This interpretation is helpful for deeper understanding of the PageRank, but it is hard to use in practice because it involves the time component. The interpretation via absorbing Markov chains that we explore in the present paper is easier and leads naturally to simple simulation algorithms for the computation of PageRank. The endpoint of a random walk that starts from a random page and can be terminated at each step with probability $1-c$ appears to be a sample from the distribution π [4, 8, 10]. Thus, after repeating the process many times, the estimate of π_j for $j = 1, \ldots, n$ is determined as the number of times when a run terminated at j, divided by the total number of runs.

In order to keep up with constant modifications of the Web structure, Google updates its PageRank at least once per month. According to publicly available information Google still uses a simple power iteration (PI) method to compute the PageRank. Starting from the initial approximation as the uniform distribution vector $\pi^{(0)} = (1/n)\underline{1}^T$, the kth approximation vector is calculated by

$$\pi^{(k)} = \pi^{(k-1)} \tilde{P}, \quad k \geq 1. \tag{1.3}$$

The method stops when the required precision ε is achieved. The number of flops needed for the method to converge is of the order $\frac{\log \varepsilon}{\log c}\, nnz(P)$, where $nnz(P)$ is the number of nonzero elements of the matrix P [15]. We note that the relative error decreases uniformly for all pages. Several proposals [9, 12, 13, 16] (see also an extensive survey paper [15]) have recently been put forward to accelerate the PI algorithm.

In contrast, here we study Monte Carlo (MC)-type methods for the PageRank computation. To the best far knowledge, in only two works [3, 8] are the MC methods applied to the PageRank computation. The principle advantages of the probabilistic MC-type methods over the deterministic methods are that the PageRank of important pages is determined with high accuracy already after the first iteration; MC methods have natural parallel implementation; and MC methods allow continuous update of the PageRank as the structure of the Web changes.

The structure and the contributions of the paper are as follows. In section 2, we describe different MC algorithms. In particular, we propose an algorithm that takes into account the information not only about the last visited page (as in [3, 8]), but also about all pages visited during the simulation run. In section 3, we analyze and compare the convergence of MC algorithms in terms of confidence intervals. We show that the PageRank of relatively important pages can be determined with high accuracy even after the first iteration. In section 4, we show that experiments with real data from the Web confirm our theoretical analysis. Finally, we summarize the results of the present work in section 5.

2. Monte Carlo algorithms. MC algorithms are motivated by the following convenient formula, which follows directly from the definition of the PageRank:

$$\pi = \frac{1-c}{n}\underline{1}^T[I-cP]^{-1} = \frac{1-c}{n}\underline{1}^T\sum_{k=0}^{\infty}c^kP^k. \tag{2.1}$$

This formula suggests a simple way of sampling from the PageRank distribution [4, 8, 10]. Consider a random walk $\{X_t\}_{t\geq 0}$ that starts from a randomly chosen page. Assume that at each step the random walk terminates with probability $(1-c)$ and makes a transition according to the matrix P with probability c. It follows from (2.1) that the end-point of such a random walk has a distribution π. Hence, one can suggest the following algorithm employed in [3].

ALGORITHM 1. MC END-POINT WITH RANDOM START. *Simulate N runs of the random walk $\{X_t\}_{t\geq 0}$ initiated at a randomly chosen page. Evaluate π_j as a fraction of N random walks which end at page $j=1,\dots,n$.*

Let $\hat{\pi}_{j,N}$ be the estimator of π_j obtained by Algorithm 1. It is straightforward that $\mathbb{E}(\hat{\pi}_{j,N})=\pi_j$ and $Var(\hat{\pi}_{j,N})=N^{-1}\pi_j(1-\pi_j)$. A rough estimate $Var(\hat{\pi}_{j,N})<1/(4N)$ given in [3] results in a conclusion that the number of samples (random walks) needed to achieve a good relative accuracy with high probability, is of the order $O(n^2)$. In the ensuing sections 3 and 4 we will show that this complexity evaluation is quite pessimistic. The number of required samples turns out to be linear in n. Moreover, a reasonable evaluation of the PageRank for popular pages can be obtained even with $N=n$; that is, one needs only as little as one run per page!

In order to improve the estimator $\hat{\pi}$, one can think of various methods of variance reduction. For instance, denoting $Z=[I-cP]^{-1}$ and writing π_j in (2.1) as $\pi_j=\frac{1-c}{n}\sum_{i=1}^n z_{ij}$ for $j=1,\dots,n$, we can view π_j as a given number $(1/n)$ multiplied by a sum of conditional probabilities $p_{ij}=(1-c)z_{ij}$ that the random walk ends at j given that it started at i. Since n is known, an unnecessary randomness in experiments can be avoided by taking $N=mn$ and initiating the random walk exactly m times from each page in a cyclic fashion, rather than jumping N times to a random page. This results in the following algorithm, whose version was used in [8] for computing personalized PageRank.

ALGORITHM 2. MC END-POINT WITH CYCLIC START. *Simulate $N=mn$ runs of the random walk $\{X_t\}_{t\geq 0}$ initiated at each page exactly m times. Evaluate π_j as a fraction of N random walks which end at page $j=1,\dots,n$.*

Let $\hat{p}_{ij}$ be a fraction of m random walks initiated at i that ended at j. Then the estimator for π_j suggested by Algorithm 2 can be expressed as $\hat{\hat{\pi}}_j=\frac{1}{n}\sum_{i=1}\hat{p}_{ij}$. For this estimator, we have $\mathbb{E}(\hat{\hat{\pi}}_j)=\pi_j$ and $Var(\hat{\hat{\pi}}_j)=(N)^{-1}[\pi_j-n^{-1}\sum_{i=1}^n p_{ij}^2]<Var(\hat{\pi}_j)$. Besides the variance reduction, the estimator $\hat{\hat{\pi}}_i$ has important advantages in implementation, because picking a page at random from a huge database is not a trivial problem [11]. This difficulty is completely avoided if the pages are visited in a cyclic fashion.[1] As the only advantage of the MC with random start, note that it does not require the number of samples N to be a multiple of n.

Another and probably more promising way of reducing the variance is to look at formula (2.1) from yet another angle. Note that for all $i,j=1,\dots,n$, the element z_{ij}

[1] When referring to MC algorithms with cyclic start, we shall use the words "cycle" and "iteration" interchangeably.

of the matrix

$$Z = [I - cP]^{-1} = \sum_{k=0}^{\infty} c^k P^k \tag{2.2}$$

can be regarded as the average number of times that the random walk $\{X_t\}_{t\geq 0}$ visits a page j, given that this random walk started at page i. Thus, we can propose an estimator based on a complete path of the random walk $\{X_t\}_{t\geq 0}$ instead of taking into account only its end-point. The complete path version of the MC method can be described as follows.

ALGORITHM 3. MC COMPLETE PATH. *Simulate the random walk $\{X_t\}_{t\geq 0}$ exactly m times from each page. For any page i, evaluate π_j as the total number of visits to page j multiplied by $(1-c)/(n\cdot m)$.*

Algorithm 3 can be further improved by getting rid of artifacts in the matrix P related to pages without outgoing links (so-called dangling nodes). When a random walk reaches a dangling node, it jumps with uniform probability to an arbitrary page. Clearly, it is more efficient just to terminate the random walk once it reaches a dangling node. Thus, we aim to rewrite (2.1) in terms of the original hyperlink matrix Q with elements defined as $Q_{ij} = 1/k$ if page i has $k > 0$ outgoing links and a link points to page j, and 0 otherwise. The artificial links from dangling pages are not taken into account in hyperlink matrix Q. Denote by $\mathcal{I}_0$ a set of dangling pages and by $\mathcal{I}_1 = \{1,\dots,n\}\backslash\mathcal{I}_0$ a set of pages which have at least one outgoing link. For all $j = 1,\dots,n$, it follows from (1.1) and (1.2) that

$$\pi_j = c\sum_{i=1}^{n} P_{ij}\pi_i + \frac{(1-c)}{n}\sum_{i=1}^{n}\pi_i = c\sum_{i=1}^{n} Q_{ij}\pi_i + \gamma, \tag{2.3}$$

where γ is the same for each j:

$$\gamma = \frac{c}{n}\sum_{i\in\mathcal{I}_0}\pi_i + \frac{(1-c)}{n} < \frac{1}{n}. \tag{2.4}$$

Now, we rewrite (2.3) in the matrix form $\pi = \pi cQ + \gamma \underline{1}^T$, which leads to the new expression for π:

$$\pi = \gamma \underline{1}^T [I - cQ]^{-1}. \tag{2.5}$$

Note that the above equation is in accordance with the original definition of PageRank presented by Brin et al. [5]. The definition via the matrix P appeared later in order to develop the Markov chain formulation of the PageRank problem. The one-to-one correspondence between (2.1) and (2.5) was noticed and proved in [2], but we find the proof presented above more insightful in our context.

Consider now a random walk $\{Y_t\}_{t\geq 0}$ which follows hyperlinks exactly as $\{X_t\}_{t\geq 0}$ except that the transitions are governed by the matrix Q instead of the matrix P. Thus, the random walk $\{Y_t\}_{t\geq 0}$ can be terminated at each step either with probability $(1-c)$ or when it reaches a dangling node. For all $i,j = 1,\dots,n$, the element w_{ij} of the matrix $W = [I - cQ]^{-1}$ is the average number of visits of $\{Y_t\}_{t\geq 0}$ to page j, given that the random walk started at page i. Denote $w_{\cdot j} = \sum_{i=1}^{n} w_{ij}$. Since the coordinates of π in (2.5) sum up to one, we have

$$\gamma = \left[\sum_{i,j=1}^{n} w_{ij}\right]^{-1} = \left[\sum_{j=1}^{n} w_{\cdot j}\right]^{-1} \tag{2.6}$$

and

$$\pi_j = w_{\cdot j} \left[\sum_{j=1}^{n} w_{\cdot j} \right]^{-1}. \tag{2.7}$$

This calls for another version of the complete path method.

ALGORITHM 4. MC COMPLETE PATH STOPPING AT DANGLING NODES. *Simulate the random walk $\{Y_t\}_{t\geq 0}$ starting exactly m times from each page. For any page j, evaluate π_j as the total number of visits to page j divided by the total number of visited pages.*

Let W_{ij} be a random variable distributed as a number of visits to page $j = 1, \ldots, n$ by the random walk $\{Y_t\}_{t\geq 0}$ given that the random walk initiated at state $i = 1, \ldots, n$. Formally, $\mathbb{P}(W_{ij} = x) = \mathbb{P}\left(\left[\sum_{t=0}^{\infty} \mathbf{1}_{\{Y_t = j\}}\right] = x | Y_0 = i\right)$ for $x = 0, 1, \ldots$, where $\mathbf{1}_{\{\cdot\}}$ is the indicator function. Let $W_{ij}^{(l)}$, $l \geq 1$, be independent random variables distributed as W_{ij}. Then the estimator produced by Algorithm 4 can be written as

$$\bar{\pi}_j = \left[\sum_{l=1}^{m} \sum_{i=1}^{n} W_{ij}^{(l)} \right] \left[\sum_{l=1}^{m} \sum_{i,j=1}^{n} W_{ij}^{(l)} \right]^{-1}. \tag{2.8}$$

In the next section we present the analysis of this estimator.

We note that the complete path versions of the MC methods also admit a random start. The corresponding algorithm is as follows.

ALGORITHM 5. MC COMPLETE PATH WITH RANDOM START. *Simulate N samples of the random walk $\{Y_t\}_{t\geq 0}$ started at a random page. For any page j, evaluate π_j as the total number of visits to page i divided by the total number of visited pages.*

One can show, however, that Algorithm 4 provides an estimator with a smaller variance than Algorithm 5. Indeed, let W_{Uj} be the number of visits to page j from a randomly chosen page $U \in \{1, \ldots, n\}$. Then, we have

$$Var(W_{Uj}) = \frac{1}{n} \sum_{i=1}^{n} Var(W_{ij}) + \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}^2(W_{ij}) - \left[\frac{1}{n} \sum_{i=1}^{n} \mathbb{E}(W_{ij}) \right]^2 > \frac{1}{n} \sum_{i=1}^{n} Var(W_{ij}).$$

Now note that in n simulation runs, Algorithm 4 generates one sample of the sum $\sum_{i=1}^{n} W_{ij}$, whereas Algorithm 5 generates n samples of W_{Uj}. Hence, Algorithm 4 provides random variables with smaller variance in both numerator and denominator of (2.8).

3. Convergence analysis. From the preliminary analysis of the previous section, we can already conclude that MC algorithms with cyclic start are preferable to the analogous MC algorithms with random start. In the present section we thoroughly analyze and compare MC complete path stopping at dangling nodes with MC end-point. We show that under natural conditions MC complete path stopping at dangling nodes outperforms MC end-point.

We start by studying the properties of W_{ij}'s. Denote by q_{ij} the probability that starting from page i, the random walk $\{Y_t\}_{t\geq 0}$ reaches page j:

$$q_{ij} = \mathbb{P}\left(\bigcup_{t\geq 1} \{Y_t = j\} | Y_0 = i \right), \quad i, j = 1, \ldots, n.$$

Note that in this definition, $q_{jj} < 1$ is the probability of returning to state j if the process started at j. It follows from the strong Markov property that W_{jj} has a geometric distribution with parameter $1-q_{jj} \geq 1-c$: $\mathbb{P}(W_{jj} = x) = q_{jj}^{x-1}(1-q_{jj})$, $x = 1, 2, \ldots$, which implies $\mathbb{E}(W_{jj}) = 1/(1-q_{jj}), Var(W_{jj}) = q_{jj}/(1-q_{jj})^2$. Further, applying again the strong Markov property, one can show that for all $i, j = 1, \ldots, n$, W_{ij} has a shifted geometric distribution:

$$\mathbb{P}(W_{ij} = x) = \begin{cases} 1 - q_{ij}, & x = 0, \\ q_{ij}\mathbb{P}(W_{jj} = x), & x = 1, 2, \ldots . \end{cases}$$

Consequently,

$$\mathbb{E}(W_{ij}) = w_{ij} = q_{ij}\mathbb{E}(W_{jj}) = \frac{q_{ij}}{1 - q_{jj}} \tag{3.1}$$

and

$$Var(W_{ij}) = \frac{1 + q_{jj}}{1 - q_{jj}}\, w_{ij} - w_{ij}^2. \tag{3.2}$$

Now, define $W_{\cdot j} = \sum_{i=1}^n W_{ij}$ for $j = 1, \ldots, n$, and $W = \sum_{j=1}^n W_{\cdot j}$. Assuming that all W_{ij}'s are independent, we immediately obtain

$$\mathbb{E}(W_{\cdot j}) = \sum_{i=1}^n w_{ij} = w_{\cdot j},$$

$$Var(W_{\cdot j}) = \frac{1 + q_{jj}}{1 - q_{jj}}\, w_{\cdot j} - \sum_{i=1}^n w_{ij}^2 < \frac{1 + q_{jj}}{1 - q_{jj}}\, w_{\cdot j},$$

$$\mathbb{E}(W) = \sum_{j=1}^n w_{\cdot j} = \gamma^{-1}.$$

For $i, j = 1, \ldots, n$, let the empirical mean $\bar{W}_{ij} = \frac{1}{m}\sum_{l=1}^m W_{ij}^{(l)}$ be the estimator of w_{ij}, and view $\bar{W}_{\cdot j} = \sum_{i=1}^n \bar{W}_{ij}$, $j = 1, \ldots, n$, and $\bar{W} = \sum_{j=1}^n \bar{W}_{\cdot j}$ as estimators of $w_{\cdot j}$ and γ^{-1}, respectively. The estimator (2.8) can be then written as

$$\bar{\pi}_j = \bar{W}_{\cdot j}\bar{W}^{-1}. \tag{3.3}$$

Since the second multiplier in (3.3) is the same for all $j = 1, \ldots, n$, the estimator $\bar{\pi}_j$ is completely determined by $\bar{W}_{\cdot j}$. The following theorem states that the relative errors of $\bar{\pi}$ and $\bar{W}_{\cdot j}$ are similar.

THEOREM 3.1. *Given the event that the estimator $\bar{W}_{\cdot j}$ satisfies*

$$|\bar{W}_{\cdot j} - w_{\cdot j}| \leq \varepsilon w_{\cdot j}, \tag{3.4}$$

the event

$$|\bar{\pi}_j - \pi_j| \leq \varepsilon_{n,\beta}\pi_j$$

occurs with probability at least $1-\beta$ *for any* $\beta > 0$ *and* $\varepsilon_{n,\beta}$ *satisfying*

$$|\varepsilon - \varepsilon_{n,\beta}| < \frac{C(\beta)(1+\varepsilon)}{\sqrt{nm}}.$$

The factor $C(\beta)$ *can be approximated as*

$$C(\beta) \approx x_{1-\beta/2}\sqrt{\frac{n-n_0}{n}\,(1+c^3)}\frac{c}{1-c},$$

where $x_{1-\beta/2}$ *is a* $(1-\beta/2)$*-quantile of the standard normal distribution and* n_0 *is the number of dangling nodes.*

Proof. See the appendix.

Theorem 3.1 has two important consequences. First, it states that the estimator $\bar{\pi}_j$ converges to π_j in probability when m goes to infinity. Thus, the estimator $\bar{\pi}_j$ is consistent. Second, Theorem 3.1 states that the error in the estimate of π_j originates mainly from estimating $w_{\cdot j}$. The additional relative error caused by estimating γ as $\left[\sum \bar{W}_{\cdot j}\right]^{-1}$ is of the order $1/\sqrt{mn}$ with arbitrarily high probability, and thus this error can essentially be neglected.

It follows from the above analysis that the quality of the estimator $\bar{\pi}_j$ as well as the complexity of the algorithm can be evaluated by the estimator $\bar{W}_{\cdot j}$. We proceed by analyzing the confidence intervals. Consider the confidence interval for $\bar{W}_{\cdot j}$ defined as

$$\mathbb{P}(|\bar{W}_{\cdot j} - w_{\cdot j}| < \varepsilon w_{\cdot j}) \geq 1-\alpha. \tag{3.5}$$

From (3.1) and (3.2), we have $\mathbb{E}(\bar{W}_{\cdot j}) = w_{\cdot j}$ and $Var(\bar{W}_{\cdot j}) \leq \frac{1}{m}\frac{1+q_{jj}}{1-q_{jj}} w_{\cdot j}$. Since $\bar{W}_{\cdot j}$ is the sum of a large number of terms, the random variable $[\bar{W}_{\cdot j} - w_{\cdot j}]/\sqrt{Var(\bar{W}_{\cdot j})}$ has approximately a standard normal distribution. Thus, from (3.5) we deduce that $\varepsilon w_{\cdot j}/\sqrt{Var(\bar{W}_{\cdot j})} \geq x_{1-\alpha/2}$, which results in

$$m \geq \frac{1+q_{jj}}{1-q_{jj}}\frac{x^2_{1-\alpha/2}}{\varepsilon^2 w_{\cdot j}}.$$

Now applying $w_{\cdot j} = \gamma^{-1}\pi_j$, we get

$$m \approx \frac{1+q_{jj}}{1-q_{jj}}\frac{\gamma x^2_{1-\alpha/2}}{\varepsilon^2 \pi_j}. \tag{3.6}$$

Note that $\pi_j \geq \gamma$ for all $j = 1, \ldots, n$. Thus, with a high probability, a couple of hundred iterations allow us to evaluate the PageRank of all pages with relative error at most 0.1. In practice, however, it is essential to evaluate well the PageRank of important pages in a short time. We argue that a typical user of a search engine does not check more than a dozen of the first answers to his/her query. Therefore, let us evaluate the relative error ε for a given value of π_j. Using (2.4), from (3.6) we derive

$$\varepsilon \approx x_{1-\alpha/2}\sqrt{\frac{1+q_{jj}}{1-q_{jj}}}\frac{\sqrt{1-c+c\sum_{i\in\mathcal{I}_0}\pi_i}}{\sqrt{\pi_j}\sqrt{mn}}. \tag{3.7}$$

Strikingly, it follows from (3.7) that the MC method gives good results for important pages in one iteration only, that is, when $m = 1$. From the examples of PageRank

values presented in [5], it follows that the PageRank of popular pages is at least 10^4 times greater than the PageRank of an average page. Since the PageRank value is bounded from below by $(1-c)/n$, the formula (3.7) implies that if the important pages have PageRank 10^4 times larger than the PageRank of the pages with the minimal PageRank value, the MC method achieves an error of about 1% for the important pages already after the first iteration. In contrast, the power iteration method takes into account only the weighted sum of the number of incoming links after the first iteration.

Let us now compare the precision of the end-point version and the complete path version of the MC method. According to Algorithm 1, the end-point version estimates π_j simply as a fraction of $N = mn$ random walks that end at page j. Using standard techniques for such an estimate, we construct a confidence interval $\mathbb{P}(|\hat{\pi}_{j,N} - \pi_{j,N}| < \varepsilon\pi_{j,N}) = 1 - \alpha$. Using again the standard normal distribution, we get

$$\varepsilon = x_{1-\alpha/2}\frac{\sqrt{1-\pi_j}}{\sqrt{\pi_j}\sqrt{mn}}. \tag{3.8}$$

Forgetting for a moment about slight corrections caused by the trade-off between random and cyclic start, we see that the choice between the end-point version and the complete-path version essentially depends on two factors: the total PageRank of dangling nodes and the probability of a cycle when a random walk started from j returns back to j. If the Web graph has many short cycles, then the extra information from registering visits to every page is obtained at cost of a high extra variability, which leads to a worse precision. If the total rank of dangling nodes is high, the random walk will often reach dangling nodes and stop. This can have a negative impact on the complete path algorithm. The above mentioned two phenomena, if present, can make the difference between the end-point and the complete-path versions negligible. The experiments of the next section on the real data, however, indicate that the real Web structure is such that the complete path version is more efficient than the end-point version.

We remark that if the results of the first iteration are not satisfactory, it is hard to improve them by increasing m. After m iterations, the relative error of the MC method will reduce on average only by the factor $1/\sqrt{m}$, whereas the error of the power iteration method decreases exponentially with m. However, because of simplicity in implementation (in particular, simplicity in parallel implementation), the MC algorithms can still be advantageous even if a high precision is required.

Let us also evaluate a magnitude of π_j's for which a desired relative error ε is achieved. Rewriting (3.7), we get

$$\pi_j \approx x^2_{1-\alpha/2}\frac{1+q_{jj}}{1-q_{jj}}\frac{(1-c+c\sum_{i\in\mathcal{I}_0}\pi_i)}{\varepsilon^2 mn}. \tag{3.9}$$

Finally, we would like to discuss the implementation issues of the MC algorithms and to compare MC and PI methods. Each available processor can run an independent MC simulation. At the end of computations one central normalization procedure is needed. In contrast, any parallel implementation of the PI method requires the exchange of information at every iteration. Thus, if the Web graph does not fit into the main memory, there is a trade-off between the frequent request of MC to the database and the exchange of information in the parallel implementation of the PI

method. The problem of frequent requests of MC to the database can be partially mitigated by using hashing mechanisms. It is hard to say in advance which method (MC or PI) will work faster in the case of parallel implementation. However, it is possible to compare the performance of PI and MC methods in the case when the Web graph fits into the main memory. In such a case, one iteration of MC will be faster than one iteration of PI, if the expected length of the MC run is smaller than the ratio between the number of links and number of pages. If there were no dangling nodes, the expected length of the MC run would be $1/(1-c) \approx 6.7$. When dangling nodes are present, this value is smaller. According to [6, 14], the ratio between the number of links and number of pages of the Web is between 7.2 and 7.5. If one computes the PageRank for a Web graph with the latter property and the Web graph fits into the main memory, the MC method should outperform the PI method.

Moreover, the MC algorithms allow one to perform a continuous update of the PageRank vector. Since the PageRank vector changes significantly during one month, Google prefers to recompute the PageRank vector starting from the uniform distribution rather than to use the PageRank vector of the previous month as the initial approximation [15]. Then, it takes about a week to compute a new PageRank vector. It is possible to update the PageRank vector using linear algebra methods [16]. However, one needs first to separate new nodes and links from the old ones. This is not necessary if one uses MC algorithms. Specifically, we suggest running MC algorithms continuously while the database is updated with new data, and hence having an up-to-date estimation of the PageRank for relatively important pages with high accuracy. Then, once in a while one can run the power iteration method to have a good PageRank estimation for all pages. In particular, the continuous update should eliminate the negative reaction of users to the so-called "Google dance" [17].

4. Experiments. For our numerical experiments we have used the Web site of INRIA Sophia Antipolis (http://www-sop.inria.fr). It is a typical Web site with about 50000 Web pages and 200000 hyperlinks. Since the Web has a fractal structure [7], we expect that our dataset is sufficiently representative. Accordingly, datasets of similar sizes have been extensively used in experimental studies of novel algorithms for PageRank computation [1, 15, 16]. To collect the Web graph data, we construct our own Web crawler which works with the Oracle database. The crawler consists of two parts: the first part is realized based on Java and is responsible for downloading pages from the Internet, parsing the pages, and inserting their hyperlinks into the database; the second part is realized with the help of stored procedures written in PL/SQL language and is responsible for the data management. The program allows one to run several crawlers in parallel to efficiently use the network and computer resources. Since multi user access is already realized in the Oracle database management system, it is relatively easy to organize the information collection by several crawlers and parallel implementation of MC algorithms. We have also implemented the power iteration method and the following three MC algorithms in PL/SQL language:

- MC complete path stopping in dangling nodes,
  MC comp path dangl nodes, for short;
- MC end-point with cyclic start,
  MC end-point cycl start, for short;
- MC complete path with random start,
  MC comp path rand start, for short.

First, we performed a sufficient number of power iterations to obtain the value of PageRank with 20 digits accuracy. We sorted the PageRank vector in the decreasing order and plotted it in the log-log scale (see Figure 4.1). It is interesting to observe

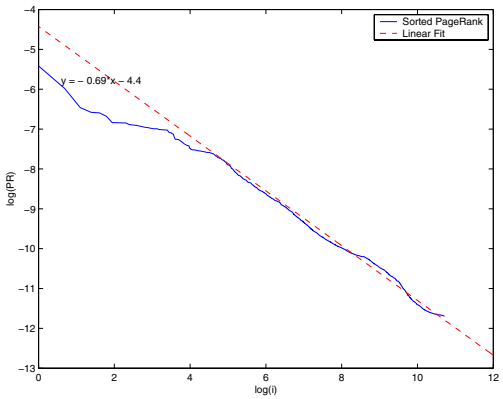

FIG. 4.1. *Sorted PageRank in log-log scale.*

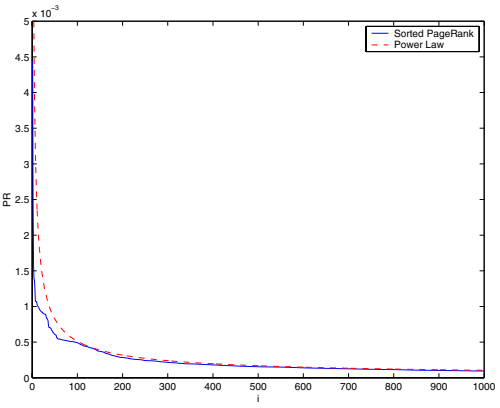

FIG. 4.2. *Sorted PageRank in linear scale.*

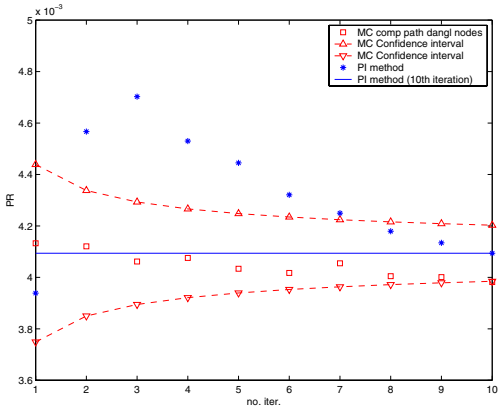

FIG. 4.3. *PI versus MC:* π_1.

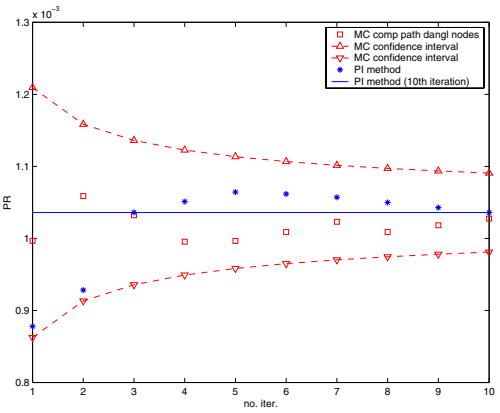

FIG. 4.4. *PI versus MC:* π_{10}.

that the PageRank vector very closely follows a power law. One can also see in Figure 4.2 how well the power law approximates the PageRank vector in linear scale starting from approximately the 100th largest element. Then, we have chosen four elements from the sorted PageRank vector:

$$\begin{aligned} \pi_1 &= 0.004093834, \\ \pi_{10} &= 0.001035867, \\ \pi_{100} &= 0.000546446, \\ \pi_{1000} &= 0.000097785. \end{aligned} \tag{4.1}$$

We have performed ten iterations of the PI method and ten iterations of the three implemented MC algorithms. In Figures 4.3–4.6, we compare the results of ten iterations of PI method and MC complete path stopping in dangling nodes method for the four chosen pages (4.1). Indeed, as predicted by formula (3.7), already the first iteration of the MC complete path stopping in dangling nodes algorithm gives a small error for important Web pages. In fact, from Figures 4.3–4.6 one can see that MC complete path stopping in dangling nodes algorithm outperforms the PI method

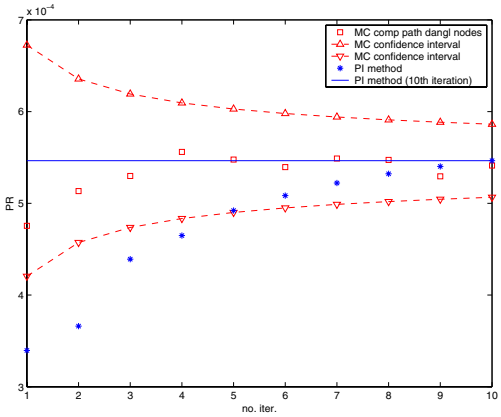

FIG. 4.5. *PI versus MC:* π_{100}.

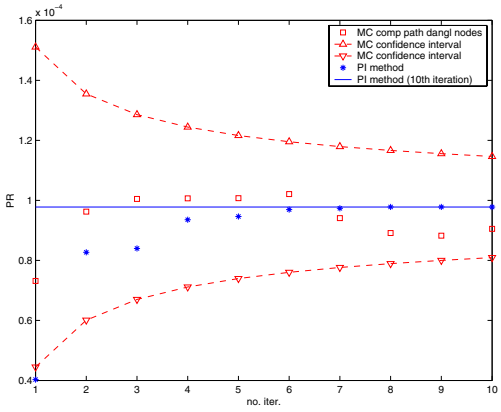

FIG. 4.6. *PI versus MC:* π_{1000}.

even for the first 1000 most important pages. In Figures 4.3–4.6, we also plotted 95% confidence intervals for the MC method. As expected, there is some randomness in the convergence pattern of the MC method, and some points might fall outside of confidence intervals. However, as one can see from Figures 4.3–4.4, the PI method does not converge in a monotone fashion for the first few iterations either.

At first sight, it looks surprising that one iteration gives a relative error of only 7% with 95% confidence for pages with high PageRank. On the other hand, such a result is to be expected. Roughly speaking, we use $5 \cdot 10^4$ independent samples in order to estimate the probability $\pi = 0.004$. A binomial random variable B with parameters $n = 5 \cdot 10^4$, $p = 0.004$ has mean 200 and standard deviation 14.1, and thus, with a high probability, a relative error of a standard estimator $\tilde{\pi} = B/n$ will be less than 11%. The additional gain that we get in (3.7) is due to regular visits to every page and the usage of the complete path information.

Next, in Figures 4.7–4.10 we compare three versions of the MC method: MC complete path stopping in dangling nodes, MC end-point with cyclic start, and MC complete path with random start. We plotted actual relative error and the estimated 95% confidence intervals. It turns out that on our dataset MC complete path stopping in dangling nodes performs the best, followed by MC complete path with random start. MC end-point with cyclic start has the worst performance. The better performance of MC with cyclic start in respect to MC with random start was expected from the preliminary analysis of section 2. MC is not trapped in cycles in our instance of the Web graph and the total PageRank of dangling nodes is relatively small

$$\sum_{i \in \mathcal{I}_0} \pi_i = 0.23;$$

hence, we have

$$\varepsilon_{comp.path} \approx \sqrt{1 - c + c \sum_{i \in \mathcal{I}_0} \pi_i}\, \varepsilon_{end-point} \approx 0.59 \varepsilon_{end-point}.$$

To check whether the presence of cycles hinders the convergence of the MC methods, we took into account the intra-page hyperlinks. On the modified graph the MC

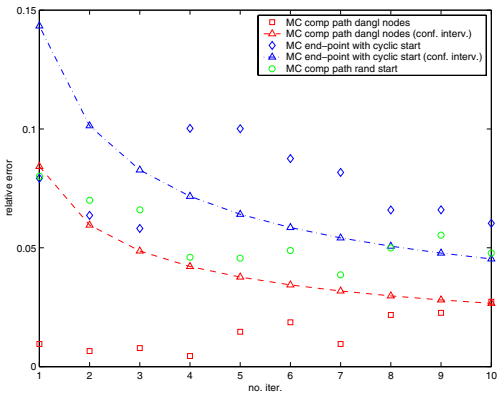

FIG. 4.7. *Comparison of MC algorithms:* π_1.

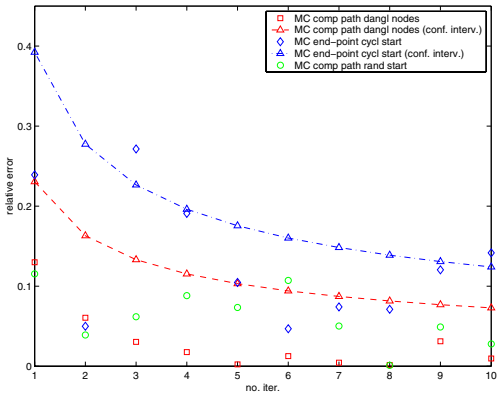

FIG. 4.9. *Comparison of MC algorithms:* π_{100}.

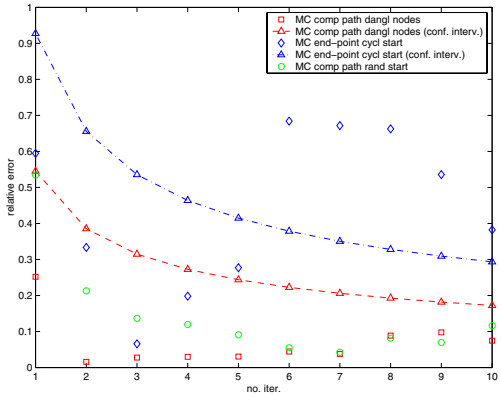

FIG. 4.10. *Comparison of MC algorithms:* π_{1000}.

methods have shown a very slow convergence. It is thus fortunate for MC methods that the original definition of the PageRank excludes the intra-page hyperlinks.

We may conclude that on the web data, MC algorithms with cyclic start outperform MC algorithms with random start. Besides, our theoretical and experimental results have demonstrated that the MC algorithms determine the PageRank of relatively important pages already after the first iteration. Here is a sharp contrast with the PI method, which approximates the PageRank vector with the uniform relative error and takes into account only the weighted sum of the number of incoming links after the first iteration. The other advantages of MC algorithms are natural parallel implementation and the possibility of continuous PageRank update while the crawler brings new data from the Web.

5. Conclusions. We have considered several MC algorithms for PageRank computation. In particular, we have proposed a new MC algorithm that takes into account not only the information about the last visited page, but about all visited pages during the simulation run. We have shown that MC algorithms with cyclic start outperform MC algorithms with random start. Our theoretical and experimental results have demonstrated that the MC algorithms determine the PageRank of relatively impor-

tant pages already after the first iteration. Here is a sharp contrast with the PI method that approximates the PageRank vector with the uniform relative error and takes into account only the weighted sum of the number of incoming links after the first iteration. The other advantages of MC algorithms are natural parallel implementation and the possibility of continuous PageRank update while the crawler brings new data from the Web. As a future research direction, it is necessary to address the question of how fast the continuous update version of the MC method can adapt to the perpetual changes in Web structure. One more promising future research direction is the development of MC methods for the other link-based ranking criteria such as HITS and SALSA.

Appendix: The proof of Theorem 3.1. To prove Theorem 3.1 we need the following lemma.

LEMMA A.1. *Let* $W_{i\cdot} = \sum_{j=1}^{n} W_{ij}$ *be the length of the random walk* $\{Y_t\}_{t\geq 0}$ *initiated at page* $i = 1, \ldots, n$. *Then for all dangling nodes* $i \in \mathcal{I}_0$, $W_{i\cdot} \equiv 1$ *holds, and for nondangling nodes* $i \in \mathcal{I}_1$,

$$\mathbb{E}(W_{i\cdot}) \leq \frac{1}{1-c}, \qquad Var(W_{i\cdot}) \leq \frac{c(1+c^3)}{(1-c)^2}. \tag{A.1}$$

Proof. The statement for dangling nodes is obvious. For nondangling nodes, (A.1) essentially follows from the distributional identity

$$W_{i\cdot} \stackrel{d}{=} \min\{X, N_i\}, \quad i = 1, \ldots, n, \tag{A.2}$$

where N_i is a number of transitions needed to reach a dangling node from page i, and X has a geometric distribution with parameter $1-c$. The mean and variance of X are given by

$$\mathbb{E}(X) = \frac{1}{1-c}, \quad Var(X) = \frac{c}{(1-c)^2}.$$

The upper bound for the expectation of $W_{i\cdot}$ now follows directly from (A.2). For the variance, we write

$$Var(W_{i\cdot}) = \mathbb{E}[Var(W_{i\cdot}|N_i)] + Var[\mathbb{E}(W_{i\cdot}|N_i)].$$

Conditioning on events $[N_i = k]$ and computing $Var(W_i|k)$ for $k = 1, 2, \ldots$, one can show that

$$\mathbb{E}[Var(W_{i\cdot}|N_i)] < Var(X).$$

Furthermore, we derive

$$\mathbb{E}(W_{i\cdot}|N_i) = \sum_{k=1}^{N_i} \mathbb{P}(X \geq k) = \sum_{k=1}^{N_i} c^k = \frac{c(1-c^{N_i})}{1-c},$$

and thus the variance of $\mathbb{E}(W_{i\cdot}|N_i)$ satisfies

$$Var(\mathbb{E}(W_{i\cdot}|N_i)) = \frac{c^2 Var(c^{N_i})}{(1-c)^2} \leq \frac{c^4}{(1-c)^2},$$

because for nondangling nodes, the random variable c^{N_i} takes values only in the interval $[0, c]$. This completes the proof of the lemma. ∎

We are now ready to prove Theorem 3.1.

Proof of Theorem 3.1. Using (2.6) and (2.7), we derive

$$\begin{aligned}\bar{\pi}_j - \pi_j &= \bar{W}_{\cdot j}\bar{W}^{-1} - \pi_j \\ &= \gamma(\bar{W}_{\cdot j} - w_{\cdot j})(\gamma\bar{W})^{-1} + \left((\gamma\bar{W})^{-1} - 1\right)\pi_j.\end{aligned}$$

Given the event (3.4), the last equation together with (2.6) and (2.7) yields

$$|\bar{\pi}_j - \pi_j| \le \varepsilon\pi_j + \left|(\gamma\bar{W})^{-1} - 1\right|(1+\varepsilon)\pi_j. \tag{A.3}$$

Let us now investigate the magnitude of the term $(\gamma\bar{W})^{-1}$. First, note that the random variables

$$\bar{W}_{i\cdot} = \sum_{j=1}^{n} \bar{W}_{ij}, \quad i \in \mathcal{I}_1,$$

are independent because they are determined by simulation runs initiated at different pages. Further, for a nondangling node i, using Lemma A.1, we find

$$\begin{aligned}\mathbb{E}(\bar{W}_{i\cdot}) &= \sum_{j=1}^{n} w_{ij}, \\ Var(\bar{W}_{i\cdot}) &= \frac{1}{m} Var(W_{i\cdot}) \le \frac{1}{m}\,\frac{c(1+c^3)}{(1-c)^2}.\end{aligned}$$

Thus, $\bar{W}$ equals the number of dangling nodes n_0 plus the sum of $n-n_0$ independent random variables $\bar{W}_{i\cdot}$, $i \in \mathcal{I}_1$. Since the number $n-n_0$ is obviously very large, $\bar{W}$ is approximately normally distributed with mean γ^{-1} and variance

$$Var(\bar{W}) = \sum_{i\in\mathcal{I}_1} Var(\bar{W}_{i\cdot}) \le (n-n_0)\frac{c(1+c^3)}{m(1-c)^2}.$$

Hence, $\gamma\bar{W}$ is approximately normally distributed with mean 1 and variance

$$Var(\gamma\bar{W}) \le \gamma^2(n-n_0)\frac{c(1+c^3)}{m(1-c)^2} < \frac{n-n_0}{n^2}\,\frac{c(1+c^3)}{m(1-c)^2}, \tag{A.4}$$

which is a value of the order $(nm)^{-1}$. Now, let us consider a $(1-\beta)$-confidence interval defined as

$$\mathbb{P}\left(\left|(\gamma\bar{W})^{-1} - 1\right| < \epsilon\right) > 1-\beta \tag{A.5}$$

for some small positive β and ϵ. If ϵ is small enough so that $1/(1-\epsilon) \approx 1+\epsilon$ and $1/(1+\epsilon) \approx 1-\epsilon$, then the above probability approximately equals $\mathbb{P}\left(\left|\gamma\bar{W} - 1\right| < \epsilon\right)$, and because of (A.4), the inequality (A.5) holds for all ϵ satisfying

$$\epsilon \ge x_{1-\beta/2}\frac{c}{1-c}\sqrt{\frac{n-n_0}{n}\,(1+c^3)}\,\frac{1}{\sqrt{nm}}. \tag{A.6}$$

The right-hand side of (A.6) constitutes the additional relative error in estimating π_j. For any $\beta > 0$, this additional error can be exceeded with probability at most β. This completes the proof of the theorem. □

A CONVERGENT AND CONSTRAINT-PRESERVING FINITE ELEMENT METHOD FOR THE P-HARMONIC FLOW INTO SPHERES*

JOHN W. BARRETT†, SÖREN BARTELS‡, XIAOBING FENG§, AND ANDREAS PROHL¶

Abstract. An explicit fully discrete finite element method, which satisfies the nonconvex side constraint at every node, is developed for approximating the p-harmonic flow for $p \in (1, \infty)$. Convergence of the method is established under certain conditions on the domain and mesh. Computational examples are presented to demonstrate finite-time blow-ups and qualitative geometric changes of weak solutions of the p-harmonic flow.

Key words. p-harmonic map, singular and degenerate PDE, finite element method, convergence analysis

1. Introduction and summary.

Minimizing the energy

$$E_p(\mathbf{u}) := \frac{1}{p} \int_\Omega |\nabla \mathbf{u}|^p \, d\mathbf{x}, \quad 1 \le p < \infty, \tag{1.1}$$

for maps $\mathbf{u} : \Omega \to S^{m-1}$ ($m \ge 2$), where $\Omega \subset \mathbb{R}^n$ ($n \ge 1$) is bounded and $S^{m-1} \subset \mathbb{R}^m$ is the unit sphere, gives rise to p-harmonic maps. Such maps have natural applications such as micromagnetics [12, 28], liquid crystal theory [1, 24, 29, 7] ($p = 2$), or color image denoising [33, 34, 36, 11, 22] ($p = 1$). At present, there are not many schemes available to reliably approximate such maps. The main numerical difficulties are the nonconvexity of the constraint, $|\mathbf{u}| = 1$ a.e. in Ω, and the limited regularity and nonuniqueness of minimizers.

The first numerical schemes to approximate (1.1) in the case $p = 2$ were proposed in [17, 18, 23, 29]. The idea is in each search direction, first to reduce the energy functional ignoring the sphere constraint; then renormalize this solution $\mathbf{V}^j$ to obtain $\mathbf{U}^j = \frac{\mathbf{V}^j}{|\mathbf{V}^j|}$. However, the question is then whether the energy is still decreased during the renormalization step. This problem has been elegantly solved in [1], where an interesting convergent algorithm is proposed. Given an admissible $\mathbf{U}^j$, the strategy there is to decrease the energy $E_2(\mathbf{U}^j - \mathbf{V}^j)$ for $\mathbf{V}^j$ belonging to the tangential plane $\{\mathbf{w} \in H^1(\Omega, \mathbb{R}^m) : \langle \mathbf{w}, \mathbf{U}^j \rangle_{\mathbb{R}^m} = 0 \text{ a.e. in } \Omega\}$; then perform the renormalization $\mathbf{U}^{j+1} = \frac{\mathbf{U}^j - \mathbf{V}^j}{|\mathbf{U}^j - \mathbf{V}^j|} \in H^1(\Omega, S^{m-1})$. By construction, it follows that $E_2(\mathbf{U}^j - \mathbf{V}^j) = \min_{\mathbf{w}} E_2(\mathbf{U}^j - \mathbf{w}) \le E_2(\mathbf{U}^j)$, since $\mathbf{w} = \mathbf{0}$ is admissible. Moreover, $|\mathbf{U}^j - \mathbf{V}^j| \ge 1$

a.e. in Ω, which is sufficient to guarantee decrease of the energy in the renormalization step. Recently, convergence of a finite element realization of this algorithm has been verified for restricted (acute) mesh partitions [6]. A generalization of this (Alouges') strategy to the degenerate regime $p \neq 2$ is easily possible, but convergence behavior seems unclear to the authors for the singular cases $p < 2$.

Another discretization approach is based on the convergent penalization strategy; see [30]. Here the nonconvex constraint is approximated by adding the penalty term $\varepsilon^{-1} \int_\Omega (|\mathbf{u}|^2 - 1)^2 \, \mathrm{d}\mathbf{x}$ to $E_p(\mathbf{u})$, leading to the unconstrained Ginzburg–Landau energy $E_{p,\varepsilon}(\mathbf{u})$ for an $\varepsilon > 0$. However, a numerical approximation of $E_{p,\varepsilon}(\mathbf{u})$ requires that the penalization parameter ε and the mesh parameter h be tuned. In [36] a different approach is proposed. This is based on the unconstrained minimization of

$$F_p(\mathbf{v}) := \int_\Omega \left| \nabla \left(\frac{\mathbf{v}}{|\,\mathbf{v}\,|} \right) \right|^p \mathrm{d}\mathbf{x}, \quad 1 \leq p < \infty, \tag{1.2}$$

for maps $\mathbf{v} : \Omega \to \mathbb{R}^m \backslash \{0\}$. A parametrization of the sphere then yields an efficient unconstrained numerical scheme, which is consistent with the nonconvex side-constraint and leads to energy decay. However, this approach restricts possible minimizers of (1.1) and leaves convergence properties of (1.2) unclear.

An alternative strategy to study minimizers of (1.1) is to consider the long-time behavior of the p-harmonic flow into spheres:

$$\mathbf{u}_t - \Delta_p \mathbf{u} = |\,\nabla \mathbf{u}\,|^p \mathbf{u} \quad \text{on } \Omega_T, \qquad \frac{\partial \mathbf{u}}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega_T, \tag{1.3}$$

$$|\,\mathbf{u}(\cdot,\cdot)\,| = 1 \quad \text{a.e. in } \Omega_T, \qquad \mathbf{u}(0,\cdot) = \mathbf{u}_0 \quad \text{on } \Omega, \tag{1.4}$$

for any $T > 0$. Here $\Omega_T := (0,T) \times \Omega$, $\partial\Omega_T := (0,T) \times \partial\Omega$ with $\partial\Omega$ being the boundary of Ω with normal $\mathbf{n}$. The system (1.3)–(1.4) characterizes the L^2-gradient flow of (1.1) with $\Delta_p \mathbf{u} \equiv \nabla \cdot (|\nabla \mathbf{u}|^{p-2} \nabla \mathbf{u})$. Solutions to this problem have been studied intensively over the last fifteen years, starting with the case $p = 2$ [14], and followed by $p > 2$ (existence [15, 27], nonuniqueness [25]), and $1 < p < 2$ (existence and nonuniqueness [19, 31]). Weak solutions to (1.3)–(1.4) satisfy (1.3) in a distributional sense and the initial condition in (1.4) in the sense of traces for $\mathbf{u}_0 \in W^{1,p}(\Omega, S^{m-1})$. Weak solutions that also satisfy the energy inequality

$$\int_0^t \| \, \mathbf{u}_t(s) \, \|_{L^2}^2 \, \mathrm{d}s + E_p\big(\mathbf{u}(t)\big) \leq E_p(\mathbf{u}_0) \quad \text{for a.e. } t \in (0,T) \tag{1.5}$$

are sometimes referred to as Struwe weak solutions (cf. [32]). This energy decay motivates the conjecture that there exists a subsequence $\{t_{k'}\} \subset \{t_k\}$, for $t_k \to \infty$, such that $\mathbf{u}^* = \lim_{k' \to \infty} \mathbf{u}(t_{k'}, \cdot)$ is a p-harmonic map, which is known for the case $p = 2$, and for any $p > 1$ in the case of small initial data [20]. We remark that there exist weak solutions to (1.3)–(1.4), which do not satisfy (1.5); cf. [8, 9, 35] for the case $p = 2$.

In order to verify existence of a weak solution to (1.3)–(1.4), the problem is modified to first finding a solution $\mathbf{u}^\varepsilon : \Omega_T \to \mathbb{R}^m$ to the following unconstrained penalized formulation [14, 16]: for $\varepsilon > 0$ and $T > 0$,

$$\mathbf{u}^\varepsilon_t - \Delta_p \mathbf{u}^\varepsilon + \frac{1}{2\varepsilon} \big(|\,\mathbf{u}^\varepsilon\,|^2 - 1 \big) \mathbf{u}^\varepsilon = 0 \quad \text{on } \Omega_T, \qquad \frac{\partial \mathbf{u}^\varepsilon}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega_T, \tag{1.6}$$

$$\mathbf{u}^\varepsilon(0,\cdot) = \mathbf{u}_0 \quad \text{on } \Omega. \tag{1.7}$$

Tracing the limit as $\varepsilon \to 0$ for solutions to (1.6)–(1.7) then leads to weak solutions of (1.3)–(1.4) satisfying (1.5) for the cases $1 < p < \infty$. When $p = 1$, local strong solutions are proved by Giga, Kashima, and Yamazaki in [22]. Apart from its use as an analytical tool, problem (1.6)–(1.7) is often the starting point to construct convergent discretizations for which the computed (discrete) solutions $\mathbf{U}_{k,h}^{\varepsilon}$ converge to solutions of (1.3)–(1.4) as the time step k, the mesh parameter h, and the penalization parameter ε tend to zero. Popularization of this approach is partially due to the fact that the direct construction of a convergent discretization of (1.3)–(1.4) is a nontrivial task.

The goal of this paper is to propose a convergent fully discrete finite element approximation of (1.3)–(1.4). Its construction is inspired by the recent work [2] for the Landau–Lifshitz equations. Our numerical scheme is based on the following equivalent reformulation of (1.3)–(1.4): find $\mathbf{u}$ satisfying the constraint and the initial condition such that

$$\int_0^T (\mathbf{u}_t(t), \mathbf{w})\,\mathrm{d}t + \int_0^T (|\nabla \mathbf{u}(t)|^{p-2}\nabla \mathbf{u}(t), \nabla \mathbf{w})\,\mathrm{d}t = 0 \quad \forall\, T > 0, \tag{1.8}$$

for all $\mathbf{w} \in L^2\big((0,T); W^{1,p}(\Omega, \mathbb{R}^m)\big) \cap L^\infty(\Omega_T, \mathbb{R}^m)$, such that $\langle \mathbf{w}, \mathbf{u}\rangle_{\mathbb{R}^m} = 0$ a.e. in Ω_T, where $(\boldsymbol{\eta}_1, \boldsymbol{\eta}_2) := \int_\Omega \langle \boldsymbol{\eta}_1, \boldsymbol{\eta}_2\rangle_{\mathbb{R}^{\ell_1\times\ell_2}}\,\mathrm{d}\mathbf{x}$ for $\boldsymbol{\eta}_i(t,\cdot) \in \mathbb{R}^{\ell_1\times\ell_2}$ and $\langle\cdot,\cdot\rangle_{\mathbb{R}^{\ell_1\times\ell_2}}$ is the standard inner product on $\mathbb{R}^{\ell_1\times\ell_2}$.

To introduce our finite element scheme and state the main convergence result, we need to make the following assumptions on the finite element partitioning:

(A1) Assuming that Ω is either polygonal ($n = 2$) or polyhedral ($n = 3$), let $\mathcal{T}_h$ be a quasi-uniform partitioning of Ω into disjoint open simplices K with $h_K := \mathrm{diam}(K)$ and $h := \max_{K\in\mathcal{T}_h} h_K$, so that $\overline{\Omega} = \cup_{K\in\mathcal{T}_h} \overline{K}$.

We require the quasi-uniformity constraint on the partitioning, as many of the proofs in this paper use the inverse inequalities on functions in $\boldsymbol{\mathcal{V}}_h$. The convergence proof of our finite element approximation for $p > n$ or $p = 2$ is fairly straightforward. In order to prove convergence if $p \le n$ and $p \ne 2$, our proof requires the denseness of $C^\infty(\overline{\Omega}, S^{m-1})$ in $W^{1,p}(\Omega, S^{m-1})$, which imposes the restrictions of either $p = n$ or $p < m - 1$; see [10]. Moreover, in this case we have to place a further restriction on the partitioning for a monotonicity argument to hold.

(A2) In addition to the assumption (A1) above, we assume that all simplices $K \in \mathcal{T}_h$ are right-angled. (For $n = 3$ this means that all tetrahedrons have one vertex with exactly one right angle, one vertex with exactly two right angles, and all other angles are strictly acute; see section 4 for more details. We note that a cube is easily partitioned into such tetrahedrons. Sufficient for our analysis is to assume that each element has n mutually perpendicular edges; the case that a tetrahedron has a vertex with three right angles is unrealistic in practice and therefore, for ease of exposition, excluded.)

Let $\mathcal{P}_1$ be the space of linear polynomials. We then introduce the following sets of functions:

$$\begin{aligned}
\boldsymbol{\mathcal{V}}_h &:= \big\{\mathbf{W} \in C(\overline{\Omega}, \mathbb{R}^m);\ \mathbf{W}\big|_K \in \boldsymbol{\mathcal{P}}_1(K, \mathbb{R}^m)\ \forall\ K \in \mathcal{T}_h\big\},\\
\boldsymbol{\mathcal{M}}_h &:= \big\{\mathbf{W} \in \boldsymbol{\mathcal{V}}_h;\ |\,\mathbf{W}(\mathbf{q}_i)\,| = 1\ \forall \text{ nodes } \mathbf{q}_i \text{ of } \mathcal{T}_h\big\},\\
\boldsymbol{\mathcal{F}}_h(\boldsymbol{\chi}) &:= \big\{\mathbf{W} \in \boldsymbol{\mathcal{V}}_h;\ \big\langle \mathbf{W}(\mathbf{q}_i), \boldsymbol{\chi}(\mathbf{q}_i)\big\rangle_{\mathbb{R}^m} = 0 \quad \forall \text{ nodes } \mathbf{q}_i \text{ of } \mathcal{T}_h\big\}, \quad \text{where } \boldsymbol{\chi} \in \boldsymbol{\mathcal{M}}_h.
\end{aligned}$$

Let $I_h : C(\overline{\Omega}, \mathbb{R}) \to V_h$ be the linear interpolation operator, where $V_h \equiv \boldsymbol{\mathcal{V}}_h$ with $m = 1$, such that $(I_h\, v)(\mathbf{q}_i) = v(\mathbf{q}_i)$ for all nodes $\mathbf{q}_i$ of $\mathcal{T}_h$. We then set $(\cdot,\cdot)_h$:

$C(\overline{\Omega},\mathbb{R}^m)\times C(\overline{\Omega},\mathbb{R}^m)\to\mathbb{R}$ to be

$$(\boldsymbol{\chi},\boldsymbol{\mathfrak{Z}})_h := \int_\Omega I_h\big(\langle\boldsymbol{\chi},\boldsymbol{\mathfrak{Z}}\rangle_{\mathbb{R}^m}\big)\,\mathrm{d}\mathbf{x} \equiv \sum_{K\in\mathcal{T}_h}\frac{|K|}{n+1}\sum_{\mathbf{q}_i\in K}\langle\boldsymbol{\chi}(\mathbf{q}_i),\boldsymbol{\mathfrak{Z}}(\mathbf{q}_i)\rangle_{\mathbb{R}^m}, \tag{1.9}$$

where $|K|$ is the area/volume of K.

Let k be the time step such that $Jk=T$ and $d_tv^j=k^{-1}\,(v^j-v^{j-1})$. Then a fully discrete implicit approximation of (1.8) reads: For $j=0\to J-1$, given $\widehat{\mathbf{U}}^j\in\boldsymbol{\mathcal{M}}_h$, find $\widehat{\mathbf{U}}^{j+1}\in\boldsymbol{\mathcal{M}}_h$ such that

$$(d_t\widehat{\mathbf{U}}^{j+1},\mathbf{W})+(\,|\,\nabla\widehat{\mathbf{U}}^{j+1}\,|^{p-2}\nabla\widehat{\mathbf{U}}^{j+1},\nabla\mathbf{W})=0\quad\forall\,\mathbf{W}\in\boldsymbol{\mathcal{F}}_h(\widehat{\mathbf{U}}^j), \tag{1.10}$$

where $\widehat{\mathbf{U}}^0$ is an approximation of $\mathbf{u}_0\in W^{1,p}(\Omega,S^{m-1})$. This problem is clearly too difficult to solve because of the imposed nonconvex constraint on $\boldsymbol{\mathcal{M}}_h$. However, since $\langle\mathbf{u}_t,\mathbf{u}\rangle_{\mathbb{R}^m}=0$, we may assume that $d_t\widehat{\mathbf{U}}^{j+1}$ is almost an element of $\boldsymbol{\mathcal{F}}_h(\widehat{\mathbf{U}}^j)$. This motivates our explicit scheme, which adapts the algorithm in [2] for the Landau–Lifshitz equations to the p-harmonic flow with $p\in(1,\infty)$.

SCHEME.

Step 1: Start with an initial vector field $\mathbf{U}^0\in\boldsymbol{\mathcal{M}}_h$.

Step 2: For $j=0\to J-1$, given $\mathbf{U}^j\in\boldsymbol{\mathcal{M}}_h$, find $\mathbf{V}^j\in\boldsymbol{\mathcal{F}}_h(\mathbf{U}^j)$ which solves

$$(\mathbf{V}^j,\mathbf{W})_h=-(\,|\,\nabla\mathbf{U}^j\,|^{p-2}\nabla\mathbf{U}^j,\nabla\mathbf{W})\qquad\forall\,\mathbf{W}\in\boldsymbol{\mathcal{F}}_h(\mathbf{U}^j).$$

Step 3: Define $\mathbf{U}^{j+1}\in\boldsymbol{\mathcal{M}}_h$ via

$$\mathbf{U}^{j+1}(\mathbf{q}_i)=\frac{\mathbf{U}^j(\mathbf{q}_i)+k\mathbf{V}^j(\mathbf{q}_i)}{|\,\mathbf{U}^j(\mathbf{q}_i)+k\mathbf{V}^j(\mathbf{q}_i)\,|}\qquad\forall\text{ nodes }\mathbf{q}_i\text{ of }\mathcal{T}_h.$$

We note that Step 2 is explicit, due to the use of numerical integration on the left-hand side, but remark that our analysis also holds if exact integration is used. For the fully discrete finite element solution $\{\mathbf{U}^j\}_{j\ge1}$ we define its constant and linear interpolations in time as follows:

$$\begin{aligned}&\underline{\mathbf{U}}(t,\cdot):=\mathbf{U}^{j-1}(\cdot)&&\forall\,t\in[t_{j-1},t_j),\quad 1\le j\le J,\\ &\mathbf{U}(t,\cdot):=\frac{t-t_{j-1}}{k}\mathbf{U}^j(\cdot)+\frac{t_j-t}{k}\mathbf{U}^{j-1}(\cdot)&&\forall\,t\in[t_{j-1},t_j],\quad 1\le j\le J.\end{aligned} \tag{1.11}$$

In this paper we will prove the following theorem.

THEOREM 1.1. *If $p=2$ or $p\in(n,\infty)$, let the assumption* (A1) *hold. If $p=n$ or $p\in(1,m-1)$, let the assumption* (A2) *hold. In addition, we assume that $\mathbf{u}_0\in W^{1,p}(\Omega,S^{m-1})$ and $\mathbf{U}^0\in\boldsymbol{\mathcal{M}}_h$ satisfies $\mathbf{U}^0\to\mathbf{u}_0$ strongly in $W^{1,p}(\Omega,\mathbb{R}^m)$ as $h\to0$, and*

$$k\le\begin{cases}o\big(\min\{h^{\frac{p}{p-1}},h^{p+\frac{n}{2}}\}\big) & \text{for } 1<p<2,\\ o\big(\min\{h^p,h^{1+n\,(1-\frac{1}{p})}\}\big) & \text{for } 2\le p<\infty.\end{cases} \tag{1.12}$$

Then there exists a subsequence of $\{\mathbf{U}\}_h$ such that as $h\to0$

$$\mathbf{U}\rightharpoonup\mathbf{u}\quad\text{weakly* in } L^\infty\big(0,T;W^{1,p}(\Omega,\mathbb{R}^m)\big),\quad \mathbf{U}_t\rightharpoonup\mathbf{u}_t\quad\text{weakly in } L^2(\Omega_T,\mathbb{R}^m),$$

where $\mathbf{u}\in H^1\big((0,T);L^2(\Omega,\mathbb{R}^m)\big)\cap L^\infty\big((0,T);W^{1,p}(\Omega,\mathbb{R}^m)\big)$ is a weak solution to (1.3)–(1.4).

To summarize: we prove convergence of our finite element approximation when

$$\begin{aligned} &n = 2, \text{ if either (i) } m = 2 \text{ and } p \in [2, \infty) \text{ or (ii) } m \geq 3 \text{ and } p \in (1, \infty); \\ &n = 3, \text{ if either (i) } m = 2 \text{ and } p \in \{2\} \cup [3, \infty) \text{ or (ii) } m = 3 \\ &\qquad \text{and } p \in (1, 2] \cup [3, \infty) \text{ or (iii) } m \geq 4 \text{ and } p \in (1, \infty). \end{aligned} \tag{1.13}$$

We also remark that the above theorem does not hold for $p = 1$, in which case the weak solutions are only BV-functions, instead of Sobolev functions. Moreover, computational experiments suggest that the constraint on the time step k is sharp as $p \to 1$.

The remainder of this paper is organized as follows. In section 2, we give a precise weak formulation of problem (1.3)–(1.4). In section 3, we establish the stability of the numerical solution and the mesh conditions on k described in Theorem 1.1. In section 4, we prove the convergence result of Theorem 1.1. Finally, in section 5, we present some numerical experiments, which show discrete finite-time blow-up and other qualitative behaviors of solutions of the p-harmonic flow for various values of p.

2. Preliminaries. With $\Omega \subset \mathbb{R}^n$ bounded, we define the nonlinear Sobolev space

$$W^{1,p}(\Omega, S^{m-1}) = \left\{ \mathbf{v} \in W^{1,p}(\Omega, \mathbb{R}^m) \,\middle|\, \mathbf{v} \in S^{m-1} \text{ a.e. in } \Omega \right\}, \quad 1 < p < \infty.$$

Critical points $\mathbf{u} \in W^{1,p}(\Omega, S^{m-1})$ of $E_p(\mathbf{u})$ for $p \in (1, \infty)$ can be characterized as solutions to the Euler–Lagrange equation

$$-\Delta_p \mathbf{u} = |\nabla \mathbf{u}|^p \mathbf{u} \quad \text{on } \Omega, \qquad \frac{\partial \mathbf{u}}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega. \tag{2.1}$$

If a map $\mathbf{u} \in W^{1,p}(\Omega, S^{m-1})$ satisfies (2.1) in the sense of distributions, $\mathbf{u}$ is called a weakly p-harmonic map. The p-harmonic flow (1.3)–(1.4) was first studied in [15, 26]. We now make precise what we mean by a weak solution to (1.3)–(1.4).

DEFINITION 2.1. *Let $\mathbf{u}_0 \in W^{1,p}(\Omega, \mathbb{R}^m)$, $p > 1$; then $\mathbf{u}$ is a weak solution to* (1.3)–(1.4) *if $\mathbf{u}$ is a function defined a.e. on $\Omega \times \mathbb{R}^+$ such that*

1. $\mathbf{u} \in L^\infty\big((0,T); W^{1,p}(\Omega, \mathbb{R}^m)\big) \cap H^1\big((0,T); L^2(\Omega, \mathbb{R}^m)\big)$ *for all $T > 0$,*
2. $\mathbf{u}$ *is weakly continuous for $t > 0$ with values in $W^{1,p}(\Omega, \mathbb{R}^m)$, i.e., for any test function $\mathbf{g} \in C^\infty(\Omega, \mathbb{R}^m)$,*

$$f_1(t) = \int_\Omega \langle \mathbf{u}, \mathbf{g} \rangle_{\mathbb{R}^m} \, \mathrm{d}\mathbf{x}, \quad f_2(t) = \int_\Omega \langle \nabla \mathbf{u}, \nabla \mathbf{g} \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}$$

   are continuous for $t > 0$, with possible modification on a set of measure zero on $(0, \infty)$,
3. $|\mathbf{u}| = 1$ *a.e. on $\Omega \times \mathbb{R}^+$,*
4. (1.3) *holds in the sense of distributions,*
5. *the initial condition holds in the sense of traces.*

Verification of the existence of a weak solution to (1.3)–(1.4) uses monotonicity arguments for a penalization approach to approximate the p-harmonic flow on the space $W^{1,p}(\Omega, \mathbb{R}^m)$. A parabolic version of Murat's lemma then gives enough compactness to identify limits of terms of a wedged version of the penalized problem as a wedged version of (1.3), which holds in distributional sense. This weak solution is known to satisfy the energy law (1.5), and we refer to [32, 24] for further details in this direction. Also, weak solutions to (1.3)–(1.4) are not unique; see, e.g., [31] and [25].

Of course, the subsequent proof of Theorem 1.1 can be considered as an alternative way to construct weak solutions to (1.3)–(1.4).

REMARK 2.1. *In* [31] (*see also* [27], *for* $p > 2$), *Misawa demonstrates existence of weak solutions to* (1.3)–(1.4) *by the Rothe method: set* $\mathbf{u}^0 = \mathbf{u}_0$; *then for* $j \geq 1$ *minimizers* $\mathbf{u}^j = \operatorname{argmin}_{W^{1,p}(\Omega,S^{m-1})} E_p(\mathbf{v})$, *of* $E_p(\mathbf{v}) := E_p(\mathbf{v}) + \frac{1}{2k}\int_\Omega |\,\mathbf{v}-\mathbf{u}^{j-1}\,|^2\,\mathrm{d}\mathbf{x}$, *exist, and solve*

$$d_t\mathbf{u}^j - \Delta_p\mathbf{u}^j = \left(|\,\nabla\mathbf{u}^j\,|^p + \frac{k}{2}\,|\,d_t\mathbf{u}^j\,|^2\right)\mathbf{u}^j \quad \text{on } \Omega, \qquad \frac{\partial \mathbf{u}^j}{\partial \mathbf{n}} = 0 \quad \text{on } \partial\Omega. \tag{2.2}$$

In addition, they satisfy a semidiscrete version of energy inequality (1.5) *on the equidistant time mesh* $\{t_j\}_{j\geq 0}$. *Then a compactness argument as in* [15] *together with a parabolic version of Murat's lemma* (*cf.* [27]) *proves subsequence convergence to a weak solution of* (1.3)–(1.4) *as* $k \to 0$. *Unfortunately, the scheme* (2.2) *is not practically useful, due to the nonconvex constraint.*

We end this section by introducing some notation and stating a few useful results. Let $1 < p < \infty$. For all $\mathbf{P}, \mathbf{Q} \in \mathbb{R}^{m\times n}$, $m, n \geq 1$, and $\delta \geq 0$ there exist positive constants $C_i(p, m, n)$ such that

$$\text{(i)}\ \big||\,\mathbf{P}\,|^{p-2}\mathbf{P} - |\,\mathbf{Q}\,|^{p-2}\mathbf{Q}\big| \leq C_1\big(|\,\mathbf{P}\,| + |\,\mathbf{Q}\,|\big)^{p-2+\delta}|\,\mathbf{P}-\mathbf{Q}\,|^{1-\delta},$$
$$\text{(ii)}\ \big\langle |\,\mathbf{P}\,|^{p-2}\mathbf{P} - |\,\mathbf{Q}\,|^{p-2}\mathbf{Q}, \mathbf{P}-\mathbf{Q}\big\rangle_{\mathbb{R}^{m\times n}} \geq C_2\big(|\,\mathbf{P}\,| + |\,\mathbf{Q}\,|\big)^{p-2-\delta}|\,\mathbf{P}-\mathbf{Q}\,|^{2+\delta}. \tag{2.3}$$

For example, these results were proved in [5] for the case $\mathbb{R}^{n\times n}$, and that proof easily transfers to the present case. We recall the following results concerning $(\cdot,\cdot)_h$:

$$\|\boldsymbol{\chi}\|_{L^2}^2 \leq |\boldsymbol{\chi}|_h^2 := (\boldsymbol{\chi},\boldsymbol{\chi})_h \leq (n+2)\|\boldsymbol{\chi}\|_{L^2}^2 \qquad \forall \boldsymbol{\chi} \in \boldsymbol{\mathcal{V}}_h\,; \tag{2.4}$$

$$|(\boldsymbol{\chi},\boldsymbol{\mathfrak{Z}}) - (\boldsymbol{\chi},\boldsymbol{\mathfrak{Z}})_h| \leq Ch\|\boldsymbol{\chi}\|_{L^2}\|\nabla\boldsymbol{\mathfrak{Z}}\|_{L^2} \leq C\|\boldsymbol{\chi}\|_{L^2}\|\boldsymbol{\mathfrak{Z}}\|_{L^2} \qquad \forall \boldsymbol{\chi}, \boldsymbol{\mathfrak{Z}} \in \boldsymbol{\mathcal{V}}_h. \tag{2.5}$$

For later purposes, we also introduce the linear interpolation operator $\mathcal{I}_h : C(\overline{\Omega},\mathbb{R}^m) \to \boldsymbol{\mathcal{V}}_h$ such that $(\mathcal{I}_h\mathbf{v})(\mathbf{q}_i) = \mathbf{v}(\mathbf{q}_i)$ for all nodes $\mathbf{q}_i$ of $\mathcal{T}_h$. Finally, throughout the paper we adopt the standard notation for Sobolev spaces and their associated norms. For notational convenience, we drop the domain from the norm subscript if the domain is Ω, that is, $\|\cdot\|_{L^2} \equiv \|\cdot\|_{L^2(\Omega)}$.

3. Stability. As a first step toward showing the convergence of our numerical scheme to a weak solution of problem (1.3)–(1.4), we shall establish a discrete version of the energy inequality (1.5).

LEMMA 3.1. *Let the assumption* (A1) *hold. Let* $\mathbf{u}_0 \in W^{1,p}(\Omega, S^{m-1})$ *and* $\mathbf{U}^0 \in \boldsymbol{\mathcal{M}}_h$ *satisfy* $\mathbf{U}^0 \to \mathbf{u}_0$ *strongly in* $W^{1,p}(\Omega,\mathbb{R}^m)$ *as* $h \to 0$, *and let* k *satisfy* (1.12). *Then the iterates* $\{\mathbf{V}^{j-1}, \mathbf{U}^j\}_{j=1}^J$ *computed from our scheme satisfy for* $j = 1 \to J$

$$\begin{aligned}(1-c_0)k\sum_{\ell=1}^{j}\|\,d_t\mathbf{U}^\ell\,\|_{L^2}^2 + \frac{1}{p}\|\,\nabla\mathbf{U}^j\,\|_{L^p}^p &\leq (1-c_1)k\sum_{\ell=0}^{j-1}\|\,\mathbf{V}^\ell\,\|_{L^2}^2 + \frac{1}{p}\|\,\nabla\mathbf{U}^j\,\|_{L^p}^p \\ &\leq \frac{1}{p}\|\,\nabla\mathbf{U}^0\,\|_{L^p}^p + c_2,\end{aligned} \tag{3.1}$$

where c_i *are* $o(1)$.

Proof. First, we choose $\mathbf{W} = \mathbf{V}^j$ in Step 2 of the scheme. As $\mathbf{U}^j \in \boldsymbol{\mathcal{M}}_h$, on noting (2.4) and on applying an inverse inequality, we conclude that

$$\begin{aligned}\|\,\mathbf{V}^j\,\|_{L^2}^2 \leq |\mathbf{V}^j|_h^2 &= -\big(|\,\nabla\mathbf{U}^j\,|^{p-2}\nabla\mathbf{U}^j, \nabla\mathbf{V}^j\big) \leq \int_\Omega |\,\nabla\mathbf{U}^j\,|^{p-1}|\,\nabla\mathbf{V}^j\,|\,\mathrm{d}\mathbf{x} \\ &\leq \|\,\nabla\mathbf{U}^j\,\|_{L^{2(p-1)}}^{p-1}\|\,\nabla\mathbf{V}^j\,\|_{L^2} \leq Ch^{-p}\,\|\,\mathbf{U}^j\,\|_{L^{2(p-1)}}^{p-1}\|\,\mathbf{V}^j\,\|_{L^2} \leq Ch^{-2p}.\end{aligned} \tag{3.2}$$

We note that if $\|\nabla \mathbf{U}^j\|_{L^p} \le C$, then we have, via (2.4) and inverse inequalities, the improved bound

$$\begin{aligned} \| \mathbf{V}^j \|_{L^2}^2 \le |\mathbf{V}^j|_h^2 &= -\big(|\nabla \mathbf{U}^j|^{p-2}\nabla \mathbf{U}^j, \nabla \mathbf{V}^j\big) \le \| \nabla \mathbf{U}^j \|_{L^p}^{p-1} \| \nabla \mathbf{V}^j \|_{L^p} \\ &\le Ch^{-1} \| \mathbf{V}^j \|_{L^p} \le \begin{cases} Ch^{-2} & \text{for } 1 \le p \le 2, \\ Ch^{-2-n(1-\frac{2}{p})} & \text{for } 2 \le p < \infty. \end{cases} \end{aligned} \tag{3.3}$$

The following argument is adapted from [2]. On defining $\mathbf{R}^j := \mathbf{U}^{j+1} - \mathbf{U}^j - k\mathbf{V}^j \in \boldsymbol{\mathcal{V}}_h$, then Step 3 of the scheme yields for all nodes $\mathbf{q}_i$ of $\mathcal{T}_h$ that

$$|\,\mathbf{R}^j(\mathbf{q}_i)\,| = \left| \frac{\mathbf{U}^j(\mathbf{q}_i) + k\mathbf{V}^j(\mathbf{q}_i)}{|\,\mathbf{U}^j(\mathbf{q}_i) + k\mathbf{V}^j(\mathbf{q}_i)\,|} - \mathbf{U}^j(\mathbf{q}_i) - k\mathbf{V}^j(\mathbf{q}_i) \right| = \Big| 1 - \big|\mathbf{U}^j(\mathbf{q}_i) + k\mathbf{V}^j(\mathbf{q}_i)\big| \Big|,$$

and since $1 \le |\,\mathbf{U}^j(\mathbf{q}_i) + k\mathbf{V}^j(\mathbf{q}_i)\,| = \sqrt{1 + k^2|\,\mathbf{V}^j(\mathbf{q}_i)\,|^2} \le 1 + \frac{k^2}{2}|\,\mathbf{V}^j(\mathbf{q}_i)\,|^2$, we conclude that

$$|\,\mathbf{R}^j(\mathbf{q}_i)\,| \le \frac{k^2}{2}|\,\mathbf{V}^j(\mathbf{q}_i)\,|^2. \tag{3.4}$$

Therefore, on recalling (2.4), we have that

$$\int_\Omega |\mathbf{R}^j|\,\mathrm{d}\mathbf{x} \le \int_\Omega I_h[\,|\mathbf{R}^j|\,]\,\mathrm{d}\mathbf{x} \le \frac{k^2}{2}\int_\Omega I_h[\,|\mathbf{V}^j|^2\,]\,\mathrm{d}\mathbf{x} \le \frac{k^2(n+2)}{2}\int_\Omega |\mathbf{V}^j|^2\,\mathrm{d}\mathbf{x}. \tag{3.5}$$

Similarly, it follows from (2.4) and an inverse inequality that

$$\|\mathbf{R}^j\|_{L^2}^2 \le |\mathbf{R}^j|_h^2 \le \frac{k^4}{4}\|\mathbf{V}^j\|_{L^\infty}^2 |\mathbf{V}^j|_h^2 \le Ck^4h^{-n}\|\mathbf{V}^j\|_{L^2}^4; \tag{3.6}$$

and hence we have that

$$\|d_t\mathbf{U}^{j+1}\|_{L^2}^2 \le [\|\mathbf{V}^j\|_{L^2} + k^{-1}\|\mathbf{R}^j\|_{L^2}]^2 \le [1 + Ckh^{-\frac{n}{2}}\|\mathbf{V}^j\|_{L^2}]^2\|\mathbf{V}^j\|_{L^2}^2. \tag{3.7}$$

Now, choosing $\mathbf{W} = \mathbf{V}^j = d_t\mathbf{U}^{j+1} - k^{-1}\mathbf{R}^j$ in Step 2 of our scheme, noting the convexity of $|\nabla \cdot|^p$, that $\mathbf{U}^j$, $\mathbf{U}^{j+1} \in \boldsymbol{\mathcal{M}}_h$ and applying (2.3)(i) with $\delta = 2 - p$ if $p \in (1, 2]$ and $\delta = 0$ if $p \in [2, \infty)$, together with inverse estimates and (3.5), we arrive at

$$\begin{aligned} \| \mathbf{V}^j \|_{L^2}^2 + \frac{1}{p}d_t\| \nabla \mathbf{U}^{j+1} \|_{L^p}^p &\le |\mathbf{V}^j|_h^2 + (|\nabla \mathbf{U}^{j+1}|^{p-2}\nabla \mathbf{U}^{j+1}, \nabla(d_t\mathbf{U}^{j+1})) \\ &= k^{-1}\big(|\,\nabla \mathbf{U}^j\,|^{p-2}\nabla \mathbf{U}^j, \nabla \mathbf{R}^j\big) + \big(|\,\nabla \mathbf{U}^{j+1}\,|^{p-2}\nabla \mathbf{U}^{j+1} \\ &\qquad - |\,\nabla \mathbf{U}^j\,|^{p-2}\nabla \mathbf{U}^j, \nabla(d_t\mathbf{U}^{j+1})\big) \\ &\le k^{-1}\| \nabla \mathbf{U}^j \|_{L^\infty}^{p-1}\| \nabla \mathbf{R}^j \|_{L^1} + Ck^{1-\delta}[\,\|\nabla \mathbf{U}^{j+1}\|_{L^\infty} \\ &\quad + \|\nabla \mathbf{U}^j\|_{L^\infty}\,]^{p-2+\delta}\|\nabla(d_t\mathbf{U}^{j+1})\|_{L^2}^{2-\delta} \\ &\le Ck^{-1}h^{-p}\| \mathbf{R}^j \|_{L^1} + Ck^{1-\delta}h^{-p}\|d_t\mathbf{U}^{j+1}\|_{L^2}^{2-\delta} \\ &\le Ckh^{-p}\| \mathbf{V}^j \|_{L^2}^2 + Ck^{1-\delta}h^{-p}\|d_t\mathbf{U}^{j+1}\|_{L^2}^{2-\delta}. \end{aligned} \tag{3.8}$$

We first consider the simpler case, $p \in [2, \infty)$. It follows from our assumptions on $\mathbf{U}^\mathbf{0}$ that there exists a constant $C_1 > 0$ such that $\| \nabla \mathbf{U}^0 \|_{L^p} \le C_1$ for all $h > 0$. Assuming that $\| \nabla \mathbf{U}^j \|_{L^p} \le C_1$ and $k = O(h^{1+n(1-\frac{1}{p})})$, it then follows from (3.3) that

there exists a constant $C_2 > 0$ such that $kh^{-\frac{n}{2}}\|\mathbf{V}^j\|_{L^2} \leq C_2$. Therefore, combining (3.7) and (3.8) yields in the case $p \in [2,\infty)$ that there exists a constant $C_3 > 0$ such that

$$\left(1 - C_3\frac{k}{h^p}\right) k\| \mathbf{V}^j \|_{L^2}^2 + \frac{1}{p}\| \nabla\mathbf{U}^{j+1} \|_{L^p}^p \leq \frac{1}{p}\| \nabla\mathbf{U}^j \|_{L^p}^p. \tag{3.9}$$

If the time step k satisfies $C_3 k \leq h^p$, it follows from the above inequality that $\| \nabla\mathbf{U}^{j+1} \|_{L^p} \leq C_1$. Hence, by induction, (3.9) holds for $j = 0 \to J-1$ under the above two restrictions on k. On recalling our assumptions on k, (1.12), the desired stability result (3.1) for $p \in [2,\infty)$, with no c_2 term on the right-hand side, follows from summing (3.9) and noting from (3.7) that $\|d_t\mathbf{U}^{j+1}\|_{L^2}^2 \leq (1 + o(1))\|\mathbf{V}^j\|_{L^2}^2$.

We now consider the case $p \in (1,2)$. First, there exists a constant $C_4(p) > 0$ such that

$$\|d_t\mathbf{U}^{j+1}\|_{L^2}^p \leq \|d_t\mathbf{U}^{j+1}\|_{L^2}^2 + C_4. \tag{3.10}$$

Assuming $k = O(h^{p+\frac{n}{2}})$, it then follows from (3.2) that there exists a constant $C_5 > 0$ such that $kh^{-\frac{n}{2}}\|\mathbf{V}^j\|_{L^2} \leq C_5$. Therefore combining (3.7), (3.8), and (3.10) yields in the case $p \in (1,2)$ that there exists a constant $C_6 > 0$ such that

$$\left(1 - C_6\frac{k^{p-1}}{h^p}\right) k\| \mathbf{V}^j \|_{L^2}^2 + \frac{1}{p}\| \nabla\mathbf{U}^{j+1} \|_{L^p}^p \leq \frac{1}{p}\| \nabla\mathbf{U}^j \|_{L^p}^p + C_5\frac{k^p}{h^p}. \tag{3.11}$$

On recalling our assumptions on k, (1.12), the desired stability result (3.1) for $p \in (1,2)$ then follows from summing (3.11) and noting (3.7). ∎

4. Convergence. The following lemma, where we adopt the notation (1.11), will be needed for showing the convergence of our scheme.

LEMMA 4.1. *Let the assumptions of Lemma* 3.1 *hold. Then for all* $\mathbf{W} \in L^2\big((0,T);\boldsymbol{\mathcal{F}}_h(\underline{\mathbf{U}})\big)$ *it follows that*

$$\begin{aligned}\left|\int_0^T \left[(\mathbf{U}_t,\mathbf{W}) + (|\nabla\underline{\mathbf{U}}|^{p-2}\nabla\underline{\mathbf{U}},\nabla\mathbf{W})\right]\mathrm{d}t\right| \\ \leq C\left[kh^{-(\frac{n}{2}+1+\sigma)}\|\mathbf{W}\|_{L^2(\Omega_T)} + h\|\nabla\mathbf{W}\|_{L^2(\Omega_T)}\right],\end{aligned} \tag{4.1}$$

where $\sigma = 0$ *if* $p \in (1,2)$ *and* $\sigma = n(\frac{1}{2} - \frac{1}{p})$ *if* $p \in [2,\infty)$.

Proof. Write $\underline{\mathbf{V}} = \mathbf{U}_t - k^{-1}\underline{\mathbf{R}}$ in Step 2 of our scheme to obtain for any $\mathbf{W} \in L^2\big((0,T);\boldsymbol{\mathcal{F}}_h(\underline{\mathbf{U}})\big)$ that

$$\begin{aligned}\int_0^T \left[(\mathbf{U}_t,\mathbf{W}) + (|\nabla\underline{\mathbf{U}}|^{p-2}\nabla\underline{\mathbf{U}},\nabla\mathbf{W})\right]\mathrm{d}t \\ = k^{-1}\int_0^T (\underline{\mathbf{R}},\mathbf{W})\,\mathrm{d}t + \int_0^T \left[(\mathbf{U}_t,\mathbf{W}) - (\mathbf{U}_t,\mathbf{W})_h\right]\mathrm{d}t.\end{aligned} \tag{4.2}$$

From (3.6), (3.3), and (3.1) we have that

$$\begin{aligned}\int_0^T \| \underline{\mathbf{R}} \|_{L^2}^2\,\mathrm{d}t &\leq Ck^4h^{-n}\int_0^T \| \underline{\mathbf{V}} \|_{L^2}^4\,\mathrm{d}t \\ &\leq Ck^4h^{-(n+2+2\sigma)}\int_0^T \| \underline{\mathbf{V}} \|_{L^2}^2\,\mathrm{d}t \leq Ck^4h^{-(n+2+2\sigma)}.\end{aligned} \tag{4.3}$$

Hence the desired result (4.1) follows from (4.2), (4.3), (2.5), and (3.1). ∎

It follows from (3.1), our assumptions on $\mathbf{U}^0$, and as $\mathbf{U} \in \boldsymbol{\mathcal{M}}_h$ that there exists a function $\mathbf{u} \in H^1((0,T);\, L^2(\Omega,\mathbb{R}^m)) \cap L^\infty((0,T);W^{1,p}(\Omega,\mathbb{R}^m))$ and a subsequence of $\{\mathbf{U}\}_h$ such that as $h \to 0$

$$\begin{aligned} &\mathbf{U},\, \underline{\mathbf{U}} \rightharpoonup \mathbf{u} \text{ weakly* in } L^\infty\big(0,T;W^{1,p}(\Omega,\mathbb{R}^m)\big), \\ &\mathbf{U},\, \underline{\mathbf{U}} \to \mathbf{u} \text{ strongly in } L^q\big(\Omega_T,\mathbb{R}^m\big), \quad \mathbf{U}_t \rightharpoonup \mathbf{u}_t \text{ weakly in } L^2(\Omega_T,\mathbb{R}^m), \end{aligned} \tag{4.4}$$

where $q < \infty$ if $p \le n$ and $q = \infty$ if $p > n$. Furthermore, we have that (1.5) holds.

As $\mathbf{U} \in \boldsymbol{\mathcal{M}}_h$, it follows that $I_h[|\mathbf{U}|] \equiv 1$, and hence for every $K \in \mathcal{T}_h$ that

$$\begin{aligned} \big\| |\,\mathbf{U}\,|^2 - 1\big\|_{L^p(K)} &\le Ch^2 \|D^2(|\,\mathbf{U}\,|^2)\|_{L^p(K)} \\ &\le Ch^2 \big\|\nabla \mathbf{U}\big\|^2_{L^{2p}(K)} \le Ch \|\nabla \mathbf{U}\big\|_{L^p(K)}. \end{aligned} \tag{4.5}$$

Therefore, we deduce that

$$|\,\mathbf{u}\,| = 1 \text{ a.e. in } \Omega_T. \tag{4.6}$$

Next, in order to identify the limit of the p-Laplacian term in (4.1), we need to establish that

$$|\,\nabla \underline{\mathbf{U}}\,|^{p-2} \nabla \underline{\mathbf{U}} \rightharpoonup |\,\nabla \mathbf{u}\,|^{p-2} \nabla \mathbf{u} \quad \text{weakly in } L^{\frac{p}{p-1}}(\Omega_T,\mathbb{R}^{m\times n}) \quad \text{as } h \to 0. \tag{4.7}$$

The standard employment of Minty's lemma for monotone operators (see [37], "the decisive monotonicity trick") is not so straightforward, as (4.1) is only valid for $\mathbf{W} \in L^2((0,T);\boldsymbol{\mathcal{F}}_h(\underline{\mathbf{U}}))$ and not for all $\mathbf{W} \in L^2((0,T);\boldsymbol{\mathcal{V}}_h)$. Obviously, if $p = 2$, then (4.7) follows immediately from (4.4). The lemma below establishes a stronger version of (4.7) in the easier case when $p \in (n,\infty)$.

LEMMA 4.2. *In addition to the assumptions of Lemma* 3.1 *holding, let* $p \in (n,\infty)$. *Then we have for the subsequence* $\{\mathbf{U}\}_\mathbf{h}$ *of* (4.4) *that*

$$|\,\nabla \underline{\mathbf{U}}\,|^{p-2} \nabla \underline{\mathbf{U}} \to |\,\nabla \mathbf{u}\,|^{p-2} \nabla \mathbf{u} \quad \textit{strongly in } L^{\frac{p}{p-1}}(\Omega_T,\mathbb{R}^{m\times n}) \qquad \textit{as } h \to 0. \tag{4.8}$$

Proof. As $p \in (n,\infty)$, it follows that $\mathcal{I}_h \mathbf{u}$ is well-defined and

$$\mathcal{I}_h \mathbf{u} \to \mathbf{u} \quad \text{strongly in } L^\infty\big((0,T);W^{1,p}(\Omega,\mathbb{R}^m)\big) \text{ and hence in } L^\infty\big(\Omega_T,\mathbb{R}^m\big). \tag{4.9}$$

We deduce from (2.3)(ii) with $\delta = p-2$ that

$$\begin{aligned} \int_{\Omega_T} |\nabla(\mathbf{u} - \underline{\mathbf{U}})|^p \,\mathrm{d}\mathbf{x}\mathrm{d}t \le{}& \int_{\Omega_T} |\nabla \mathbf{u}|^{p-2} \langle \nabla \mathbf{u}, \nabla(\mathbf{u} - \underline{\mathbf{U}})\rangle_{\mathbb{R}^{m\times n}} \,\mathrm{d}\mathbf{x}\mathrm{d}t \\ &- \int_{\Omega_T} |\nabla \underline{\mathbf{U}}|^{p-2} \langle \nabla \underline{\mathbf{U}}, \nabla(\mathbf{u} - \mathcal{I}_h \mathbf{u})\rangle_{\mathbb{R}^{m\times n}} \,\mathrm{d}\mathbf{x}\mathrm{d}t \\ &- \int_{\Omega_T} |\nabla \underline{\mathbf{U}}|^{p-2} \langle \nabla \underline{\mathbf{U}}, \nabla(\mathcal{I}_h \mathbf{u} - \underline{\mathbf{U}})\rangle_{\mathbb{R}^{m\times n}} \,\mathrm{d}\mathbf{x}\mathrm{d}t \\ =:{}& T_1 + T_2 + T_3. \end{aligned}$$

It follows from (4.4), (3.1), and (4.9) that $T_1, T_2 \to 0$ as $h \to 0$. As $\mathcal{I}_h \underline{\mathbf{U}} \equiv \underline{\mathbf{U}}$ and $\underline{\mathbf{U}}, \mathcal{I}_h \mathbf{u} \in \boldsymbol{\mathcal{M}}_h$ (recall (4.6)), we have that $\mathcal{I}_h \mathbf{u} - \underline{\mathbf{U}} \equiv \mathbf{W} + \mathbf{Z}$, where

$$\begin{aligned} &\mathbf{W} = \mathcal{I}_h[\mathbf{u} - \langle \mathbf{u}, \underline{\mathbf{U}}\rangle_{\mathbb{R}^m} \underline{\mathbf{U}}] \in \boldsymbol{\mathcal{F}}_h(\underline{\mathbf{U}}), \\ &\mathbf{Z} = \mathcal{I}_h[(\langle \mathbf{u}, \underline{\mathbf{U}}\rangle_{\mathbb{R}^m} - 1)\underline{\mathbf{U}}] = -\frac{1}{2}\mathcal{I}_h[|\mathbf{u} - \underline{\mathbf{U}}|^2 \underline{\mathbf{U}}]. \end{aligned} \tag{4.10}$$

It follows from (4.10), (4.1), (1.12), an inverse inequality, and (3.1) that

$$
\begin{aligned}
|T_3| &\le C\,\big[1+\|\mathbf{U}_t\|_{L^2(\Omega_T)}\big]\,\|\mathcal{I}_h[\mathbf{u}-\langle\mathbf{u},\underline{\mathbf{U}}\rangle_{\mathbb{R}^m}\underline{\mathbf{U}}]\|_{L^2(\Omega_T)}\\
&\quad + C\|\underline{\mathbf{U}}\|^{p-1}_{L^\infty(0,T;W^{1,p}(\Omega))}\,\|\mathcal{I}_h[(\langle\mathbf{u},\underline{\mathbf{U}}\rangle_{\mathbb{R}^m}-1)\underline{\mathbf{U}}]\|_{L^1(0,T;W^{1,p}(\Omega))}\\
&\le C\,\big[\|\mathbf{u}-\langle\mathbf{u},\underline{\mathbf{U}}\rangle_{\mathbb{R}^m}\underline{\mathbf{U}}\|_{L^\infty(\Omega_T)}+\|\mathcal{I}_h[|\mathbf{u}-\underline{\mathbf{U}}|^2\,\underline{\mathbf{U}}]\|_{L^1(0,T;W^{1,p}(\Omega))}\big]\\
&\le C\,\big[\|\mathbf{u}-\underline{\mathbf{U}}\|_{L^\infty(\Omega_T)}+\||\mathbf{u}-\underline{\mathbf{U}}|^2\,\underline{\mathbf{U}}\|_{L^1(0,T;W^{1,p}(\Omega))}\big]\\
&\le C\|\mathbf{u}-\underline{\mathbf{U}}\|_{L^\infty(\Omega_T)}.
\end{aligned}
\tag{4.11}
$$

On noting (4.4), as $p>n$, we have that $T_3\to 0$ as $h\to 0$; and hence we have that the subsequence of $\{\mathbf{U}\}_h$ in (4.4) is such that

$$
\underline{\mathbf{U}}\to\mathbf{u}\quad\text{strongly in } L^p\big(0,T;W^{1,p}(\Omega,\mathbb{R}^m)\big)\qquad\text{as } h\to 0.
\tag{4.12}
$$

The above and (2.3)(i) with $\delta=0$ immediately yields the desired result (4.8). ∎

Unfortunately, if $p\in(1,n]$ and $p\neq 2$, the proof of the desired result (4.7) is far more complicated. One difficulty occurs as $\mathcal{I}_h$ is not well-defined on $\mathbf{u}$. If one replaces $\mathcal{I}_h$ by a generalized interpolation operator, $\mathcal{I}^g_h$, then $\mathcal{I}^g_h\underline{\mathbf{U}}\not\equiv\underline{\mathbf{U}}$, $\mathcal{I}^g_h\mathbf{u}\notin\boldsymbol{\mathcal{M}}_{\mathbf{h}}$, and, moreover, a generalization of (4.10) with the second crucial identity for $\mathbf{Z}$, exploited in (4.11) above, does not hold. To overcome this difficulty, we employ a density argument by smoothing $\mathbf{u}$ and continue to work with $\mathcal{I}_h$. However, to obtain a generalization of the second identity for $\mathbf{Z}$ in (4.10) we require this smoothed $\mathbf{u}(\cdot,t)$ to belong to S^{m-1} and not just $\mathbb{R}^m$. This requires the denseness of $C^\infty(\overline{\Omega},S^{m-1})$ in $W^{1,p}(\Omega,S^{m-1})$, which imposes the restrictions of either $p=n$ or $p<m-1$; see [10]. Another difficulty occurs if $p\in(1,n]$ and $p\neq 2$ as $\underline{\mathbf{U}}\to\mathbf{u}$ in $L^q(\Omega_T,\mathbb{R}^m)$ only for $q<\infty$ and not for $q=\infty$; recall (4.4). To overcome this we require a discrete version of Theorem 2.1 in [15], which exploits a monotonicity argument to deduce that the term II' in the proof there is nonpositive. To obtain a discrete analogue of this, we require the right angle constraint, (A2), on our partitioning, which we now discuss in more detail.

Let $\{\mathbf{e}_i\}_{i=1}^n$ be the standard orthonormal vectors in $\mathbb{R}^n$, such that the jth component of $\mathbf{e}_i$ is δ_{ij}, $i,j=1\to n$. Given nonzero constants ρ_i, $i=1\to n$, let $\widehat{K}(\{\rho_i\}_{i=1}^n)$ be a reference simplex in $\mathbb{R}^n$ with vertices $\{\widehat{\mathbf{q}}_i\}_{i=0}^n$, where $\widehat{\mathbf{q}}_0$ is the origin and $\widehat{\mathbf{q}}_i=\widehat{\mathbf{q}}_{i-1}+\rho_i\mathbf{e}_i$, $i=1\to n$. Then under assumption (A2), given a $K\in\mathcal{T}_h$ with vertices $\{\mathbf{q}_{j_i}\}_{i=0}^n$ such that $\mathbf{q}_{i_0}$ is not a right-angled vertex, there exists a rotation/reflection matrix $B_K\in\mathbb{R}^{n\times n}$ such that the mapping $\mathcal{F}_K:\widehat{\mathbf{x}}\in\mathbb{R}^n\to\mathbf{q}_{j_0}+B_K\widehat{\mathbf{x}}\in\mathbb{R}^n$ maps the vertex $\widehat{\mathbf{q}}_i$ to $\mathbf{q}_{j_i}$, $i=0\to n$, and hence $\widehat{K}(\{\rho_i\}_{i=1}^n)$ to K. Then for all $K\in\mathcal{T}_h$, $\phi\in C(\overline{K},\mathbb{R})$, and $\boldsymbol{\phi}\in C(\overline{K},\mathbb{R}^m)$, we set for all $\widehat{\mathbf{x}}\in\widehat{K}(\{\rho_i\}_{i=1}^n)$

$$
\begin{aligned}
&\widehat{\phi}(\widehat{\mathbf{x}})\equiv\phi(\mathcal{F}_K\widehat{\mathbf{x}}), && (\widehat{I\phi})(\widehat{\mathbf{x}})\equiv(I_h\phi)(\mathcal{F}_K\widehat{\mathbf{x}});\\
&\widehat{\boldsymbol{\phi}}(\widehat{\mathbf{x}})\equiv\boldsymbol{\phi}(\mathcal{F}_K\widehat{\mathbf{x}}), && (\widehat{\mathcal{I}\boldsymbol{\phi}})(\widehat{\mathbf{x}})\equiv(\mathcal{I}_h\boldsymbol{\phi})(\mathcal{F}_K\widehat{\mathbf{x}}).
\end{aligned}
\tag{4.13}
$$

We have for any $\mathbf{Z}\in\boldsymbol{\mathcal{V}}_h$ and $K\in\mathcal{T}_h$ that

$$
\nabla\mathbf{Z}\equiv(\widehat{\nabla}\widehat{\mathbf{Z}})\,B_K^{-1}\qquad\text{on } K;
\tag{4.14}
$$

here $\mathbf{x}\equiv(x_1,\ldots,x_n)^T$, $\nabla\equiv(\frac{\partial}{\partial x_1},\ldots,\frac{\partial}{\partial x_n})$, $\widehat{\mathbf{x}}\equiv(\widehat{x}_1,\ldots,\widehat{x}_n)^T$, and $\widehat{\nabla}\equiv(\frac{\partial}{\partial\widehat{x}_1},\ldots,\frac{\partial}{\partial\widehat{x}_n})$. It is easily deduced (see, e.g., [4] for details) that for any z_1, $z_2\in C(\overline{\Omega},\mathbb{R})$

$$
\nabla(I_h[z_1z_2])=\nabla(I_hz_2)D(I_hz_1)+\nabla(I_hz_1)D(I_hz_2),
\tag{4.15}
$$

where for any $Z \in V^h$,

$$D(Z)\,|_K := B_K\,\widehat{D}(\widehat{Z})B_K^{-1} \qquad \forall\ K \in \mathcal{T}_h, \tag{4.16}$$

and $\widehat{D}(\widehat{Z})$ is the $n \times n$ diagonal matrix with diagonal entries

$$[\widehat{D}(\widehat{Z})]_{ii} := \frac{1}{2}\left[\widehat{Z}(\widehat{\mathbf{q}}_i) + \widehat{Z}(\widehat{\mathbf{q}}_{i-1})\right], \qquad i = 1 \to n. \tag{4.17}$$

LEMMA 4.3. *In addition to the assumptions of Lemma* 3.1 *holding, let either* $p = n$ *or* $p < m-1$, *and let the assumption* (A2) *hold. Then we have for the subsequence* $\{\mathbf{U}\}_{\mathbf{h}}$ *of* (4.4) *and for any* $s \in [1, p)$ *that*

$$\nabla \underline{\mathbf{U}} \to \nabla \mathbf{u} \qquad \textit{strongly in } L^s(\Omega_T, \mathbb{R}^{m\times n}) \textit{ as } h \to 0. \tag{4.18}$$

Hence the desired result (4.7) *holds.*

Proof. As either $p = n$ or $p < m-1$, it follows that $C^\infty(\overline{\Omega}, S^{m-1})$ is a dense subset of $W^{1,p}(\Omega, S^{m-1})$; see [10]. Hence for any fixed $\alpha \in (0,1)$ there exists $\mathbf{u}_\alpha \in L^\infty(0,T; C^\infty(\overline{\Omega}, S^{m-1}))$ such that

$$\|\mathbf{u} - \mathbf{u}_\alpha\|_{L^\infty(0,T;W^{1,p}(\Omega))} \le \alpha^2. \tag{4.19}$$

Therefore $\mathcal{I}_h\mathbf{u}_\alpha$ is well-defined and

$$\mathcal{I}_h\mathbf{u}_\alpha \to \mathbf{u}_\alpha \quad \text{strongly in } L^\infty\big(0,T; W^{1,p}(\Omega, \mathbb{R}^m\big). \tag{4.20}$$

In addition, we introduce $\boldsymbol{\eta}_\alpha : \mathbb{R}^m \to \mathbb{R}^m$ and $\eta_\alpha : \mathbb{R} \to \mathbb{R}$ such that

$$\boldsymbol{\eta}_\alpha(\mathbf{y}) := \eta_\alpha(|\mathbf{y}|)\mathbf{y} := \begin{cases} \mathbf{y} & \text{if } |\mathbf{y}| \le \alpha, \\ \frac{\alpha}{|\mathbf{y}|}\mathbf{y} & \text{if } |\mathbf{y}| \ge \alpha. \end{cases} \tag{4.21}$$

On adopting the notation in (4.13) and (4.14), we have for all $\mathbf{Z} \in \boldsymbol{\mathcal{V}}_h$ and $K \in \mathcal{T}_h$ that

$$\frac{\partial}{\partial \widehat{x}_k}\widehat{\mathcal{I}}[\boldsymbol{\eta}_\alpha(\widehat{\mathbf{Z}})] \equiv A_\alpha^{(k)}(\widehat{\mathbf{Z}})\frac{\partial \widehat{\mathbf{Z}}}{\partial \widehat{x}_k} \qquad \text{on } \widehat{K}, \qquad k = 1 \to n, \tag{4.22}$$

where $A_\alpha^{(k)}(\widehat{\mathbf{Z}}) \in \mathbb{R}^{m\times m}$ is such that for $i,\, j = 1 \to m$

$$\begin{aligned}[A_\alpha^{(k)}(\widehat{\mathbf{Z}})]_{ij} &= \frac{1}{2}[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) + \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)]\delta_{ij} \\ &+ \frac{1}{2}\frac{[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) - \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)]}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| - |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|}\frac{([\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)]_i + [\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})]_i)([\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)]_j + [\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})]_j)}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| + |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|}. \end{aligned}$$

For any $\mathbf{y} \in \mathbb{R}^m$, we deduce from the monotonicity of η_α that

$$\begin{aligned}\mathbf{y}^T A_\alpha^{(k)}(\widehat{\mathbf{Z}})\mathbf{y} &\ge \frac{1}{2}[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) + \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)]|\mathbf{y}|^2 \\ &\quad + \frac{1}{2}\frac{[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) - \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)]}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| - |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|}\frac{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k) + \widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|^2}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| + |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|}|\mathbf{y}|^2 \\ &\ge \frac{1}{2}\Bigg([\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) + \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)] + \frac{[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|) - \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)]}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| - |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|} \\ &\qquad \times (|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| + |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)\Bigg)|\mathbf{y}|^2 \\ &\ge \frac{[\eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)|)|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| - \eta_\alpha(|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|)|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|]}{|\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_k)| - |\widehat{\mathbf{Z}}(\widehat{\mathbf{q}}_{k-1})|}|\mathbf{y}|^2 \ge 0. \end{aligned} \tag{4.23}$$

Therefore $A_\alpha^{(k)}(\widehat{\mathbf{Z}})$ is symmetric positive semidefinite for any $\mathbf{Z} \in \boldsymbol{\mathcal{V}}_h$. Similar to (4.23), we have for all $\mathbf{Z} \in \boldsymbol{\mathcal{V}}_h$ and on any $K \in \mathcal{T}^h$ that

$$\begin{aligned}\mathbf{y}^T A_\alpha^{(k)}(\widehat{\mathbf{Z}})\mathbf{y} &\leq \frac{\eta_\alpha(|\widehat{\mathbf{Z}}(\mathbf{q}_{k-1})|)|\widehat{\mathbf{Z}}(\mathbf{q}_k)| - \eta_\alpha(|\widehat{\mathbf{Z}}(\mathbf{q}_k)|)|\widehat{\mathbf{Z}}(\mathbf{q}_{k-1})|}{|\widehat{\mathbf{Z}}(\mathbf{q}_k)| - |\widehat{\mathbf{Z}}(\mathbf{q}_{k-1})|}|\mathbf{y}|^2 \\ &\leq [\eta_\alpha(|\widehat{\mathbf{Z}}(\mathbf{q}_k)|) + \eta_\alpha(|\widehat{\mathbf{Z}}(\mathbf{q}_{k-1})|)]|\mathbf{y}|^2 \leq 2|\mathbf{y}|^2 \qquad \forall \mathbf{y} \in \mathbb{R}^m. \end{aligned} \tag{4.24}$$

It follows from (4.14), $B_K^{-1} \equiv B_K^T$, (4.22), (4.23), and (4.24) that for all $\mathbf{Z}$, $\mathbf{Y} \in \boldsymbol{\mathcal{V}}_h$, and on any $K \in \mathcal{T}_h$

$$\begin{aligned}\langle \nabla \mathbf{Z}, \nabla(\mathcal{I}_{\mathbf{h}}[\eta_\alpha(\mathbf{Y}-\mathbf{Z})])\rangle_{\mathbb{R}^{\mathrm{m}\times\mathrm{n}}} &= \langle (\widehat{\nabla}\widehat{\mathbf{Z}})B_K^{-1}, (\widehat{\nabla}(\widehat{\mathcal{I}}[\eta_\alpha(\widehat{\mathbf{Y}}-\widehat{\mathbf{Z}})]))B_K^{-1}\rangle_{\mathbb{R}^{m\times n}} \\ &= \langle \widehat{\nabla}\widehat{\mathbf{Z}}, \widehat{\nabla}(\widehat{\mathcal{I}}[\eta_\alpha(\widehat{\mathbf{Y}}-\widehat{\mathbf{Z}})])\rangle_{\mathbb{R}^{m\times n}} \\ &= \sum_{k=1}^n \left\langle \frac{\partial \widehat{\mathbf{Z}}}{\partial \widehat{x}_k}, A_\alpha^{(k)}(\widehat{\mathbf{Y}}-\widehat{\mathbf{Z}})\frac{\partial(\widehat{\mathbf{Y}}-\widehat{\mathbf{Z}})}{\partial \widehat{x}_k}\right\rangle_{\mathbb{R}^m} \\ &\leq C|\widehat{\nabla}\widehat{\mathbf{Z}}||\widehat{\nabla}\widehat{\mathbf{Y}}| \leq C|\nabla \mathbf{Z}||\nabla \mathbf{Y}|. \end{aligned} \tag{4.25}$$

Hence we deduce from (4.25) that for all $\mathbf{Z}, \mathbf{Y} \in \boldsymbol{\mathcal{V}}_h$, and $K \in \mathcal{T}_h$

$$\int_K |\nabla \mathbf{Z}|^{p-2}\langle \nabla \mathbf{Z}, \nabla(\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{Y}-\mathbf{Z})])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x} \leq C\|\nabla \mathbf{Z}\|_{L^p(K)}^{p-1}\|\nabla \mathbf{Y}\|_{L^p(K)}. \tag{4.26}$$

It is this bound, which we use in bounding T_3 below (containing the analogue of the term II' in the proof of Theorem 2.1 in [15]), that exploits the right-angle constraint, (A2), on the partitioning.

As $|\mathbf{u}_\alpha| = |\underline{\mathbf{U}}| = 1$ in Ω_T, we have from (4.21) that

$$\langle \boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha - \underline{\mathbf{U}}), \underline{\mathbf{U}}\rangle_{\mathbb{R}^m} = -\frac{1}{2}\langle \boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha - \underline{\mathbf{U}}), \mathbf{u}_\alpha - \underline{\mathbf{U}}\rangle_{\mathbb{R}^m}. \tag{4.27}$$

It follows from (4.27) and (4.21) that

$$\|I_h[\langle \boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha - \underline{\mathbf{U}}), \underline{\mathbf{U}}\rangle_{\mathbb{R}^m}]\|_{L^\infty(\Omega_T)} \leq \frac{1}{2}\alpha\|\mathbf{u}_\alpha - \underline{\mathbf{U}}\|_{L^\infty(\Omega_T)} \leq \alpha. \tag{4.28}$$

It follows from (4.14), (4.13), (4.27), and (4.21) that for all $K \in \mathcal{T}_h$

$$\begin{aligned}\|\nabla(I_h[\langle \boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha - \underline{\mathbf{U}}), \underline{\mathbf{U}}\rangle_{\mathbb{R}^m}])\|_{L^p(K)} &\leq C\|\widehat{\nabla}(\widehat{I}[\langle \boldsymbol{\eta}_\alpha(\widehat{\mathbf{u}}_\alpha - \widehat{\underline{\mathbf{U}}}), \widehat{\underline{\mathbf{U}}}\rangle_{\mathbb{R}^m}])\|_{L^p(\widehat{K})} \\ &\leq C\alpha\|\widehat{\nabla}|\widehat{I}(\widehat{\mathbf{u}}_\alpha) - \widehat{\underline{\mathbf{U}}}|\|_{L^p(\widehat{K})} \\ &\leq C\alpha\|\widehat{\nabla}[\widehat{I}(\widehat{\mathbf{u}}_\alpha) - \widehat{\underline{\mathbf{U}}}]\|_{L^p(\widehat{K})} \\ &\leq C\alpha\|\nabla[I_h(\mathbf{u}_\alpha) - \underline{\mathbf{U}}]\|_{L^p(K)}. \end{aligned} \tag{4.29}$$

For a.e. $t \in (0,T)$ let

$$\begin{aligned}\mathcal{J}_{h,\alpha}(t) &:= \{\text{nodes } \mathbf{q}_i \text{ of } \mathcal{T}_h : |(\mathcal{I}_h\mathbf{u}_\alpha)(t,\mathbf{q}_i) - \underline{\mathbf{U}}(t,\mathbf{q}_i)| \geq \alpha\}, \\ \mathcal{T}_{h,\alpha}(t) &:= \{K \in \mathcal{T}_h : K \text{ has a vertex } \mathbf{q}_i \in \mathcal{J}^{h,\alpha}(t)\}, \\ \mathcal{R}_{h,\alpha}(t) &:= \bigcup_{K \in \mathcal{T}_{h,\alpha}(t)} \overline{K}. \end{aligned} \tag{4.30}$$

It follows from (2.4), (1.9), and (4.30) that

$$\begin{aligned}\frac{\alpha^2}{n+1}\int_0^T |\mathcal{R}_{h,\alpha}(t)|\,\mathrm{d}t &\le \int_0^T |\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}}|_h^2\,\mathrm{d}t \le (n+2)\|\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}}\|^2_{L^2(\Omega_T)}\\ &\le 2(n+2)\left[\|\mathbf{u}_\alpha - \mathcal{I}_h\mathbf{u}_\alpha\|^2_{L^2(\Omega_T)} + \|\mathbf{u}_\alpha - \underline{\mathbf{U}}\|^2_{L^2(\Omega_T)}\right].\end{aligned} \tag{4.31}$$

Hence we deduce from (4.31), (4.20), (4.4), and (4.19) that

$$\lim_{h\to 0}\int_0^T |\mathcal{R}_{h,\alpha}(t)|\,\mathrm{d}t \le C\alpha^2. \tag{4.32}$$

In addition, it follows from (4.20) and (4.19) that

$$\lim_{h\to 0}\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t \le \lim_{h\to 0}\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)} |\nabla\mathbf{u}|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t + C\alpha^2. \tag{4.33}$$

For any $s\in[1,p)$, we have that

$$\begin{aligned}&\int_0^T\left(\int_{\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})|^s\mathrm{d}\mathbf{x}\right)\mathrm{d}t\\ &\quad\le \left(\int_0^T |\mathcal{R}_{h,\alpha}(t)|\,\mathrm{d}t\right)^{\frac{p-s}{p}}\left(\int_0^T\left(\int_{\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})|^p\mathrm{d}\mathbf{x}\right)\mathrm{d}t\right)^{\frac{s}{p}}.\end{aligned} \tag{4.34}$$

Let $p^\star := \max\{2,p\}$. Then on applying a Hölder inequality, noting (4.19), (4.20), (4.4), and (2.3)(ii) with $\delta = p^\star - 2$, we have that

$$\begin{aligned}&\left(\int_0^T\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})|^p\mathrm{d}\mathbf{x}\mathrm{d}t\right)^{\frac{p^\star}{p}}\\ &\quad\le C\int_0^T\left(\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} [\,|\nabla(\mathcal{I}_h\mathbf{u}_\alpha)| + |\nabla\underline{\mathbf{U}}|\,]^p\,\mathrm{d}\mathbf{x}\right)^{-\frac{(p^\star-p)}{p}}\\ &\qquad\times\left(\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})|^p\mathrm{d}\mathbf{x}\right)^{\frac{p^\star}{p}}\mathrm{d}t\\ &\quad\le C\int_0^T\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} [\,|\nabla(\mathcal{I}_h\mathbf{u}_\alpha)| + |\nabla\underline{\mathbf{U}}|\,]^{p-p^\star}\,|\nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})|^{p^\star}\mathrm{d}\mathbf{x}\mathrm{d}t\\ &\quad\le C\int_0^T\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^{p-2}\langle\nabla(\mathcal{I}_h\mathbf{u}_\alpha), \nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t\\ &\qquad - C\int_0^T\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)} |\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}}, \nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t =: T_1 + T_2.\end{aligned} \tag{4.35}$$

It follows from (3.1), (4.20), and (4.19) that

$$\begin{aligned}|T_1| \le &\left|\int_{\Omega_T} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^{p-2}\langle\nabla(\mathcal{I}_h\mathbf{u}_\alpha), \nabla(\mathcal{I}_h\mathbf{u}_\alpha - \underline{\mathbf{U}})\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t\right|\\ &+ C\left(\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)} |\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t\right)^{\frac{p-1}{p}}.\end{aligned} \tag{4.36}$$

Hence we deduce from (4.36), (4.20), (4.4), and (4.19) that

$$\lim_{h\to 0}|T_1| \le C\,\alpha^2 + C\lim_{h\to 0}\left(\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)}|\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t\right)^{\frac{p-1}{p}}. \tag{4.37}$$

Next we note from (4.30) and (4.21) that

$$\begin{aligned} T_2 &= -\int_0^T\int_{\Omega\setminus\mathcal{R}_{h,\alpha}(t)}|\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}},\nabla(\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t\\ &= \int_0^T\int_{\mathcal{R}_{h,\alpha}(t)}|\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}},\nabla(\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t\\ &\quad-\int_{\Omega_T}|\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}},\nabla(\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t =: T_3 - T_4. \end{aligned} \tag{4.38}$$

It follows from (4.26) and (3.1) that

$$\begin{aligned} T_3 &\le C\|\nabla\underline{\mathbf{U}}\|^{p-1}_{L^p(\Omega_T)}\left(\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)}|\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t\right)^{\frac{1}{p}}\\ &\le C\left(\int_0^T\int_{\mathcal{R}_{h,\alpha}(t)}|\nabla(\mathcal{I}_h\mathbf{u}_\alpha)|^p\,\mathrm{d}\mathbf{x}\mathrm{d}t\right)^{\frac{1}{p}}. \end{aligned} \tag{4.39}$$

Noting that $\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})-\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}]\in\boldsymbol{\mathcal{F}}_h(\underline{\mathbf{U}})$, we have that

$$\begin{aligned} T_4 &= \int_{\Omega_T}|\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}},\nabla(\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})-\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t\\ &\quad-\int_{\Omega_T}|\nabla\underline{\mathbf{U}}|^{p-2}\langle\nabla\underline{\mathbf{U}},\nabla(\mathcal{I}_h[\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}])\rangle_{\mathbb{R}^{m\times n}}\,\mathrm{d}\mathbf{x}\mathrm{d}t =: T_5 + T_6. \end{aligned} \tag{4.40}$$

It then follows from (4.1), (1.12), an inverse inequality, (3.1), (2.4), (4.21), and (4.19) that

$$\begin{aligned} |T_5| &\le C\left[1+\|\mathbf{U}_t\|_{L^2(\Omega_T)}\right]\left[\int_0^T\|\mathcal{I}_h[\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}})-\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}]\|^2_{L^2}\,\mathrm{d}t\right]^{\frac{1}{2}}\\ &\le C\|\mathcal{I}_h[\mathbf{u}_\alpha-\underline{\mathbf{U}}]\|_{L^2(\Omega_T)} \le C\,[\,\|\mathbf{u}-\underline{\mathbf{U}}\|_{L^2(\Omega_T)}+\|\mathbf{u}_\alpha-\mathcal{I}_h\mathbf{u}_\alpha\|_{L^2(\Omega_T)}+\alpha^2\,]. \end{aligned} \tag{4.41}$$

We note from (3.1), (4.15), (4.16), (4.17), (4.28), and (4.29) that

$$\begin{aligned} |T_6| &\le \|\nabla\underline{\mathbf{U}}\|^{p-1}_{L^p(\Omega_T)}\,\|\nabla(\mathcal{I}_h[\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}])\|_{L^p(\Omega_T)}\\ &\le C\,\|\nabla(\mathcal{I}_h[\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}\underline{\mathbf{U}}])\|_{L^p(\Omega_T)}\\ &\le \|\underline{\mathbf{U}}\|_{L^\infty(\Omega_T)}\|\nabla(\mathcal{I}_h[\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}])\|_{L^p(\Omega_T)}\\ &\quad+\|\mathcal{I}_h[\langle\boldsymbol{\eta}_\alpha(\mathbf{u}_\alpha-\underline{\mathbf{U}}),\underline{\mathbf{U}}\rangle_{\mathbf{R}^m}]\|_{L^\infty(\Omega_T)}\|\nabla\underline{\mathbf{U}}\|_{L^p(\Omega_T)}\\ &\le C\alpha\left[\|\nabla\mathbf{u}_\alpha\|_{L^p(\Omega_T)}+\|\nabla\underline{\mathbf{U}}\|_{L^p(\Omega_T)}\right]. \end{aligned} \tag{4.42}$$

On combining (4.34)–(4.42), (3.1), (4.19), (4.20), (4.32), (4.33), and (4.4) we have that given any $\epsilon > 0$, there exist an $\alpha(\epsilon)$ and an $h_0(\alpha)$ such that for the subsequence $\{\mathbf{U}\}_{\mathbf{h}}$ of (4.4)

$$\|\nabla(\mathbf{u}_\alpha - \underline{\mathbf{U}})\|_{L^s(\Omega_T)} \le \epsilon \qquad \forall h \le h_0. \tag{4.43}$$

The desired result (4.18) then follows immediately from (4.43), (4.19), and (4.20). Finally, the desired result (4.7) follows immediately from (4.18) and (3.1); cf. [31, Lemma 6]. ∎

We now are ready to give a proof for Theorem 1.1.

Proof of Theorem 1.1. Given any $\boldsymbol{\phi} \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m)$, let $\mathbf{w} = \mathbf{u} \wedge \boldsymbol{\phi}$ and $\mathbf{W} = \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})$. Here $\wedge$ is the wedge (exterior) product, which is the extension of the cross (vector) product on vectors in $\mathbb{R}^3$ to $\mathbb{R}^n$. Interpolation theory yields that

$$\begin{aligned} \| \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi}) - \underline{\mathbf{U}} \wedge \boldsymbol{\phi} \|_{L^2}^2 &\le Ch^4 \sum_{K \in \mathcal{T}_h} \| D^2\big(\underline{\mathbf{U}} \wedge \boldsymbol{\phi}\big) \|_{L^2(K)}^2 \\ &\le Ch^4 \left[\| \, |\underline{\mathbf{U}}| \, |D^2 \boldsymbol{\phi}| \, \|_{L^2}^2 + \| \, |\nabla \underline{\mathbf{U}}| \, |\nabla \boldsymbol{\phi}| \, \|_{L^2}^2 \right] \\ &\le Ch^4 \| \boldsymbol{\phi} \|_{H^2}^2 + Ch^{4-\gamma} \|\nabla \boldsymbol{\phi}\|_{L^\infty}^2 \| \nabla \underline{\mathbf{U}} \|_{L^p}^2, \end{aligned} \tag{4.44}$$

where $\gamma = n(2-p)/p$ if $p \in (1,2]$ and $\gamma = 0$ if $p \in (2, \infty)$. Therefore (4.44) and (4.4) yield that $\mathbf{W} \to \mathbf{w}$ strongly in $L^2(\Omega_T, \mathbb{R}^m)$, which in turn implies that

$$\int_{\Omega_T} \langle \mathbf{U}_t, \mathbf{W} \rangle_{\mathbb{R}^m} \, \mathrm{d}\mathbf{x}\mathrm{d}t \to \int_{\Omega_T} \langle \mathbf{u}_t, \mathbf{w} \rangle_{\mathbb{R}^m} \, \mathrm{d}\mathbf{x}\mathrm{d}t \qquad \text{as } h \to 0. \tag{4.45}$$

We now consider the p-Laplacian term. Similarly to (4.44), we have that

$$\| \nabla(\mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi}) - \underline{\mathbf{U}} \wedge \boldsymbol{\phi}) \|_{L^p}^2 \le Ch^2 \left[\| \boldsymbol{\phi} \|_{W^{2,p}}^2 + \|\nabla \boldsymbol{\phi}\|_{L^\infty}^2 \| \nabla \underline{\mathbf{U}} \|_{L^p}^2 \right]. \tag{4.46}$$

On noting the vector identity $\langle \nabla \mathbf{z}, \nabla(\mathbf{z} \wedge \boldsymbol{\phi}) \rangle_{\mathbb{R}^{m \times n}} = \langle \nabla \mathbf{z}, \mathbf{z} \wedge \nabla \boldsymbol{\phi} \rangle_{\mathbb{R}^{m \times n}}$, (4.4), and (4.7), it follows that as $h \to 0$

$$\begin{aligned} &\int_{\Omega_T} |\nabla \underline{\mathbf{U}}|^{p-2} \langle \nabla \underline{\mathbf{U}}, \nabla(\underline{\mathbf{U}} \wedge \boldsymbol{\phi}) \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t = \int_{\Omega_T} |\nabla \underline{\mathbf{U}}|^{p-2} \langle \nabla \underline{\mathbf{U}}, \underline{\mathbf{U}} \wedge \nabla \boldsymbol{\phi} \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t \\ &\to \int_{\Omega_T} |\nabla \mathbf{u}|^{p-2} \langle \nabla \mathbf{u}, \mathbf{u} \wedge \nabla \boldsymbol{\phi} \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t = \int_{\Omega_T} |\nabla \mathbf{u}|^{p-2} \langle \nabla \mathbf{u}, \nabla(\mathbf{u} \wedge \boldsymbol{\phi}) \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t. \end{aligned} \tag{4.47}$$

Noting (4.46), (4.47), and (4.7), we have that

$$\int_{\Omega_T} |\nabla \underline{\mathbf{U}}|^{p-2} \langle \nabla \underline{\mathbf{U}}, \nabla \mathbf{W} \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t \longrightarrow \int_{\Omega_T} |\nabla \mathbf{u}|^{p-2} \langle \nabla \mathbf{u}, \nabla \mathbf{w} \rangle_{\mathbb{R}^{m \times n}} \, \mathrm{d}\mathbf{x}\mathrm{d}t \tag{4.48}$$

as $h \to 0$. Finally if $p \in (1,2]$, we deduce from an inverse inequality that

$$\begin{aligned} h^2 \|\nabla \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^2}^2 &\le h^2 \|\nabla \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^\infty}^{2-p} \|\nabla \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^p}^p \\ &\le Ch^p \|\mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^\infty}^{2-p} \|\nabla \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^p}^p \\ &\le Ch^p \|\nabla \mathcal{I}_h(\underline{\mathbf{U}} \wedge \boldsymbol{\phi})\|_{L^p}^p. \end{aligned} \tag{4.49}$$

It follows from (4.45), (4.48), (4.1), (4.44), (4.4), our constraints on the time step k, (1.12), (4.49), (4.46), and (3.1) that we now can pass to the limit $h \to 0$ in (4.1) to obtain that for all $\boldsymbol{\phi} \in C^\infty(\overline{\Omega_T}, \mathbb{R}^m)$

$$\int_0^T \left[(\mathbf{u}_t, \mathbf{u} \wedge \boldsymbol{\phi}) + (|\nabla \mathbf{u}|^{\mathrm{p}-2} \nabla \mathbf{u}, \nabla(\mathbf{u} \wedge \boldsymbol{\phi})) \right] \, \mathrm{dt} = 0. \tag{4.50}$$

However, as (4.6) holds, the above equation implies that $\mathbf{u} : \Omega_T \to S^{m-1}$ satisfies (1.3)–(1.4) in the weak sense; see Lemma 1.8 in [32] or the proof of Theorem 2.2 in [15]. Hence, we have proved Theorem 1.1. ∎

5. Numerical experiments: Finite-time blow-up and geometric changes. The global existence and the nonuniqueness of weak solutions to (1.3)–(1.4) for $p > 1$, and the local existence of smooth solutions motivate finite-time blow-up studies. We say that the numerical solution $\mathbf{U}$, for fixed mesh parameters, blows up at $t^\star$ if

$$\|\nabla \mathbf{U}(t^\star, \cdot)\|_{L^\infty} = \max_{\mathbf{V} \in \boldsymbol{\mathcal{M}}_h} \|\nabla \mathbf{V}\|_{L^\infty}.$$

We remark that this discrete blow-up behavior may disappear as the mesh is refined, and may be different if we changed from Neumann to Dirichlet-type boundary conditions. We employ our convergent numerical scheme to compute such phenomena. Throughout these numerical experiments, we set $\Omega := (-1, 1)^2 \subset \mathbb{R}^2$, i.e., $n = 2$, and $m = 3$; recall (1.13). We choose a uniform right-angled triangulation of Ω with $h = \sqrt{2}/2^3$ and set $\mathbf{U}^0 \equiv \mathcal{I}_h \mathbf{u_0}$. Unless otherwise stated, we choose $k = h^{s+1/2}/10$ for $s = \max\{p/(p-1), p\}$. In all of the experiments reported below we observed that $E_p(\mathbf{U}^{j+1}) \leq E_p(\mathbf{U}^j)$ for all $j \geq 0$ for this choice of k; recall the stability requirements of Theorem 1.1 and that for $p \in (1, 2)$ we computed with $p = 3/2$ and $5/4 \Rightarrow p/(p-1) \geq p + 1 \equiv p + \frac{n}{2}$. Finally, as $m = 3$, below we plot at each node $\mathbf{q}_i$ of $\mathcal{T}_h$ a vector based on the first two components of $\mathbf{U}^j(\mathbf{x}_i)$.

EXAMPLE 5.1. *Let $b > 0$, and define $\mathbf{u}_0 : \overline{\Omega} \to S^2$ by*

$$\mathbf{u}_0(\mathbf{x}) := \left(\frac{\mathbf{x}}{|\mathbf{x}|} \sin \phi(|\mathbf{x}|), \cos \phi(|\mathbf{x}|) \right), \quad \textit{where} \quad \phi(r) := \begin{cases} br^2 & \textit{for } r \leq 1, \\ b & \textit{for } r \geq 1. \end{cases}$$

According to the results in [13, 32] *we expect finite-time blow-up for $p = 2$ if $b > \pi$. We choose*
(ai) *$p = 2$ and $b = \pi/2$ and* (aii) *$p = 2$ and $b = 3\pi/2$,*
(bi) *$p = 3/2$ and $b = \pi/2$ and* (bii) *$p = 3/2$ and $b = 3\pi/2$,*
(ci) *$p = 5/2$ and $b = \pi/2$ and* (cii) *$p = 5/2$ and $b = 3\pi/2$.*

Figure 5.1 displays the numerical solution in Example 5.1(ai) at various times. As expected, we do not observe finite-time blow-up; at $t = 0.9090$ all vectors point in the same direction. We observe a similar behavior in (bi) and (ci).

In Figure 5.2 we plot the numerical solution in Example 5.1(aii) at various times. Blow-up occurs at $t \approx 0.4$ when the vector at the origin changes its direction from $(0, 0, 1)$ to $-(0, 0, 1)$. A zoom at the values of the nodes in a neighborhood of the origin at some times is displayed in Figure 5.5 and magnifies the change of direction at the origin.

The blow-up happens differently for (bii). Some snapshots of its dynamics are displayed in Figure 5.3. In the time interval $0.5 \leq t \leq 0.8$ all vectors apart from the one at $\mathbf{x} = \mathbf{0}$ approximately point out of the plane. Then, at time $t \approx 0.93$ the vector at the origin changes direction so that a uniform state is achieved.

The behavior in (cii) is different from that in (aii) and (bii). No blow-up occurs; cf. Figure 5.6. The vector field $\mathbf{U}$ obtained in (cii) is shown for various times in Figure 5.4.

The lower right plot in Figure 5.6 displays the energy $E_2\big(\mathbf{U}(t, \cdot)\big)$ in Example 5.1 (ai) obtained with $k = \frac{1}{2}h^2$ using the numerical integration rule (1.9) as stated in Step 2 of our scheme, and for comparison exact integration. The results clearly indicate

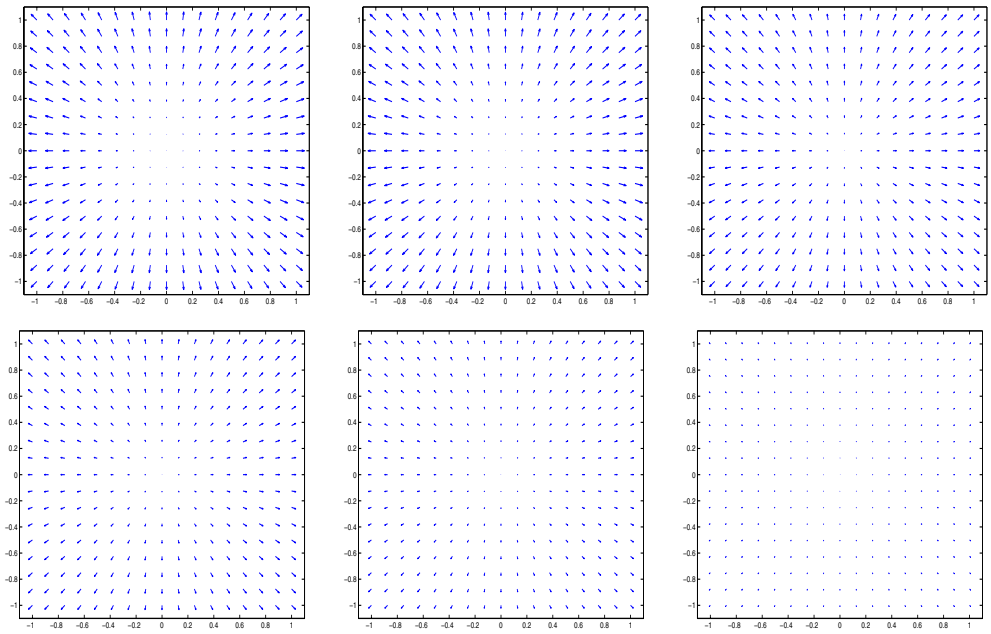

FIG. 5.1. $\mathbf{U}(t,\cdot)$ *in Example* 5.1(ai) *for* $t = 0$, 0.0102, 0.1625, 0.3301, 0.5078, 0.9090.

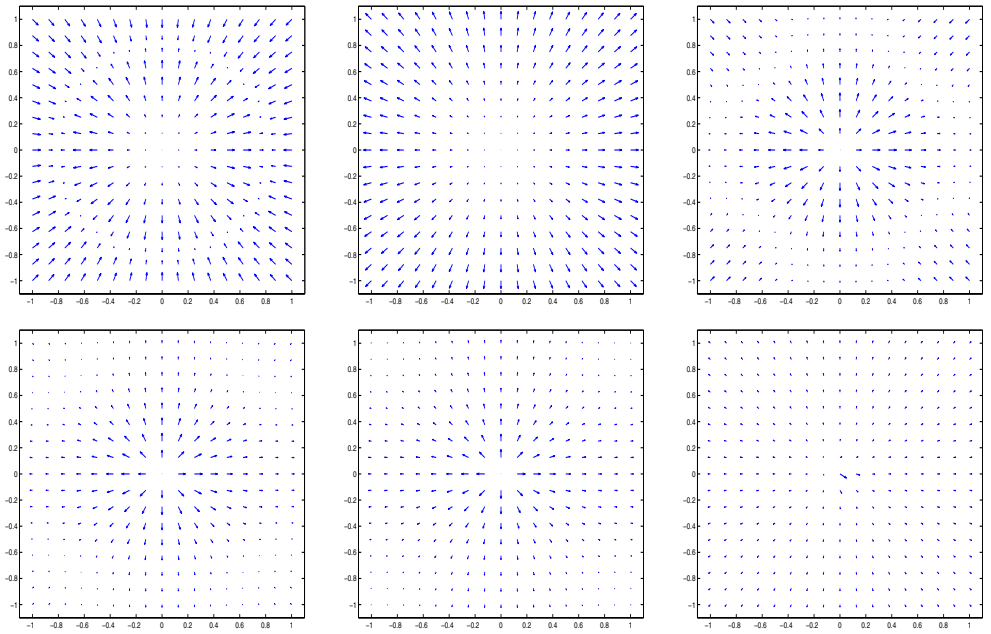

FIG. 5.2. $\mathbf{U}(t,\cdot)$ *in Example* 5.1(aii) *for* $t = 0$, 0.0102, 0.1016, 0.1828, 0.2539, 0.4467.

that $k = \frac{1}{2}h^2$ is not small enough for $p = 2$ and $n = 2$ in this experiment with exact integration, and reveal a stabilizing effect of numerical integration.

Analytical studies [3] of the scalar-valued total variation (TV) flow ($p = 1$) $-u_t \in \partial J(u)$, $u(0) = u_0 \in L^2(\Omega)$, for $J(u) = |Du|(\Omega)$ show interesting characterizations

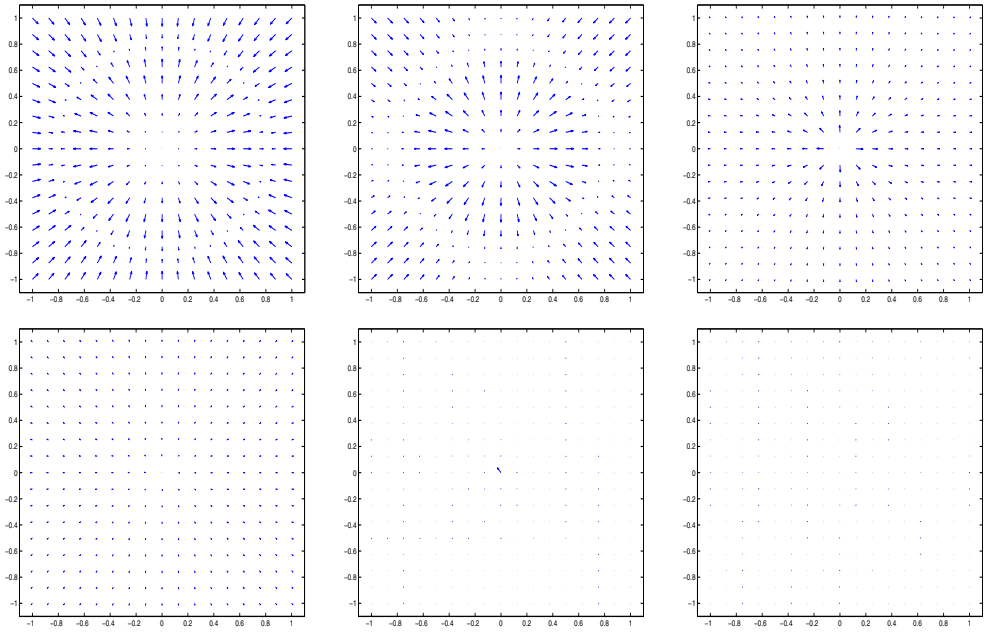

FIG. 5.3. $\mathbf{U}(t,\cdot)$ *in Example* 5.1(bii) *for* $t = 0$, 0.1051, 0.4054, 0.5105, 0.9259, 0.9910.

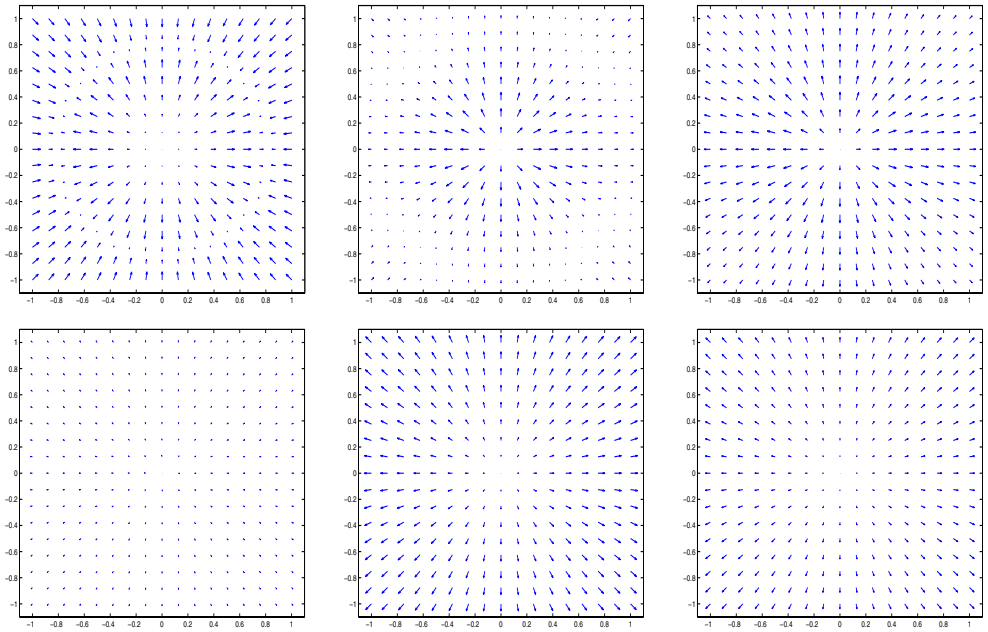

FIG. 5.4. $\mathbf{U}(t,\cdot)$ *in Example* 5.1(cii) *for* $t = 0$, 0.1001, 0.3053, 0.5105, 0.7157, 0.9209.

of the strong solution in the sense of semigroup theory: (i) finite extinction time ($n = 2$), (ii) $u(t,\cdot) \in L^\infty(\Omega)$, $t > 0$, if $u_0 \in L^n(\Omega)$, and no $L^1 - L^2$-regularizing effect for $L^1(\Omega)$-initial data, in general, (iii) $C^{1,\alpha}$-regularity of level sets $\partial^*\big[u(t) > \lambda\big]$ for $u_0 \in L^n(\Omega)$ of decreasing size, i.e., $\frac{d}{dt}\mathcal{H}^{n-1}\big(\partial^*\big[u(t) > \lambda\big]\big) \le 0$, and (iv) invariance

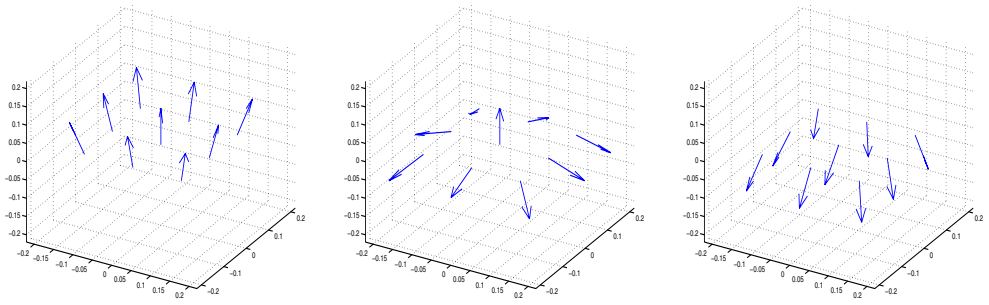

FIG. 5.5. *Nodal values* $\mathbf{U}(t, \mathbf{q}_i)$ *for nodes* $\mathbf{q}_i$ *close to the origin in Example* 5.1(aii) *for* $t = 0.0195, 0.2539, 0.3516$.

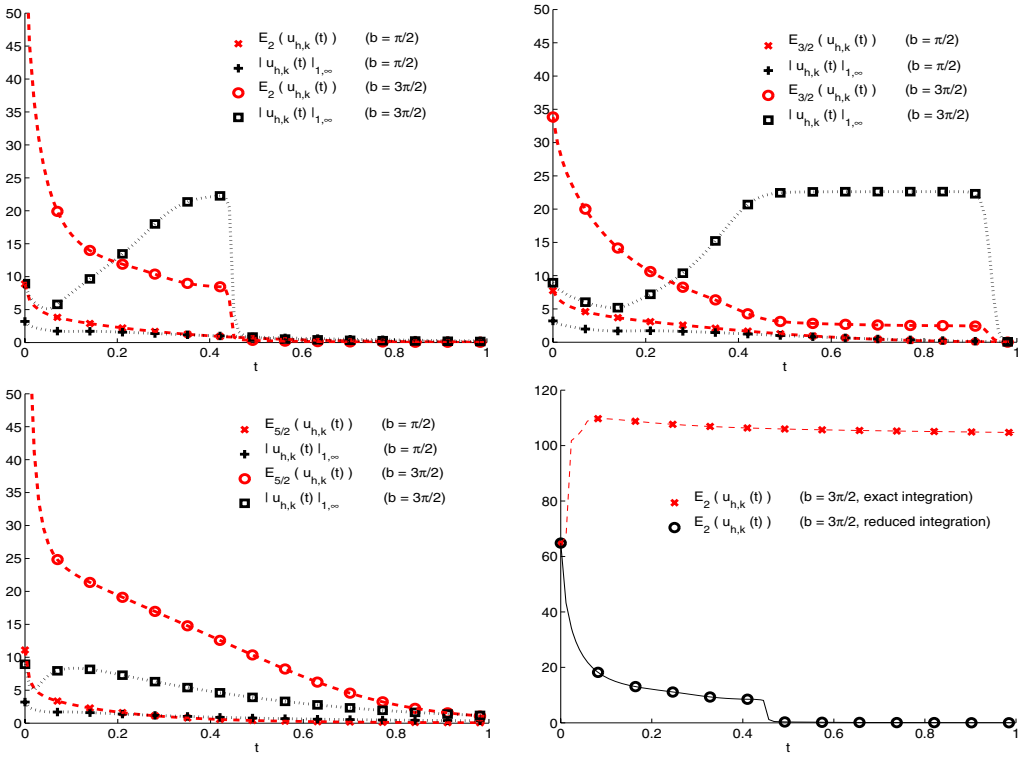

FIG. 5.6. *Energy decay and* $W^{1,\infty}$ *seminorm in Example* 5.1(a), (b), *and* (c) *and instability in Example* 5.1(ai) *for* $k = \frac{1}{2}h^2$.

of supports, provided, e.g., that the curvature of the smooth boundary of the simply connected convex staring support is not too large; cf. [21] for a convergence analysis of a regularized, fully discrete scheme and corresponding computational studies. We next discuss the latter issue in the present vectorial case.

EXAMPLE 5.2. *We define* $\mathbf{u}_0 : \overline{\Omega} \to S^2$ *by*

$$\mathbf{u}_0(\mathbf{x}) := \begin{cases} (1,0,0) & \text{for } |\mathbf{x}| < 0.5, \\ (0,1,0) & \text{for } |\mathbf{x}| \geq 0.5, \end{cases}$$

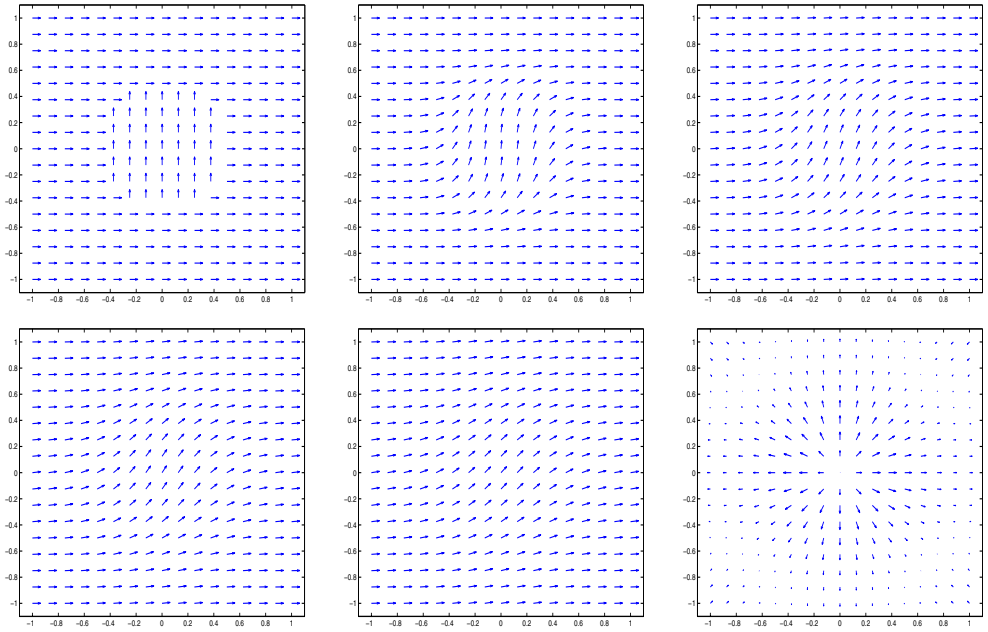

FIG. 5.7. $\mathbf{U}(t,\cdot)$ *in Example* 5.2(i) *for* $t = 0$, 0.02, 0.04, 0.06, 0.08, 0.10.

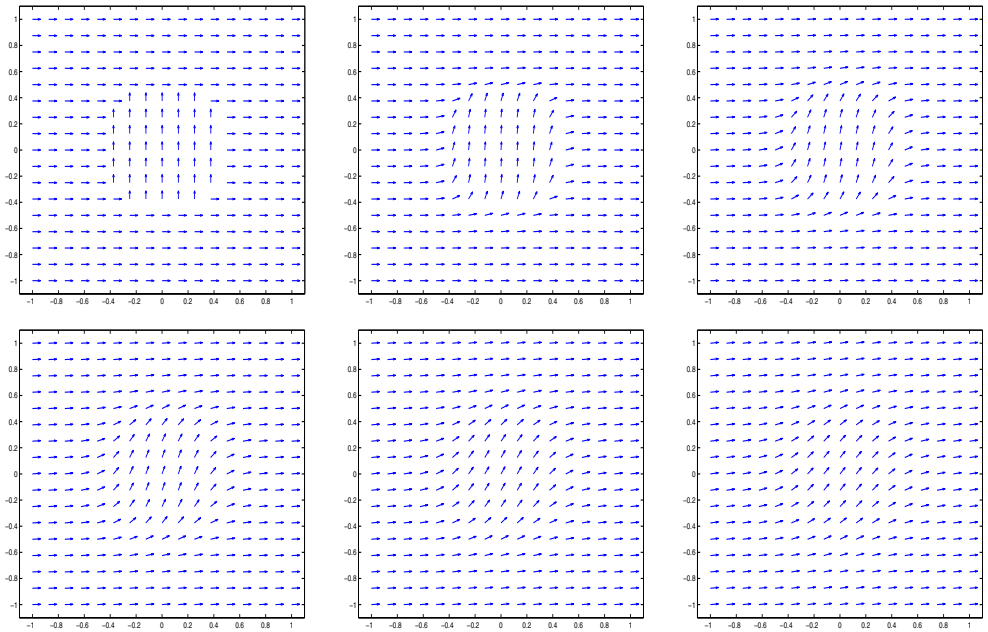

FIG. 5.8. $\mathbf{U}(t,\cdot)$ *in Example* 5.2(ii) *for* $t = 0$, 0.02, 0.04, 0.06, 0.08, 0.10.

and set (i) $p = 2$, (ii) $p = 3/2$, *and* (iii) $p = 5/4$.

Figures 5.7, 5.8, and 5.9 display snapshots of the numerical solutions in Example 5.2(i), (ii), and (iii), respectively. For $p = 2$ in (i) we observe that the solution is rather smooth for positive times and that at $t \approx 0.1$ an almost uniform (constant)

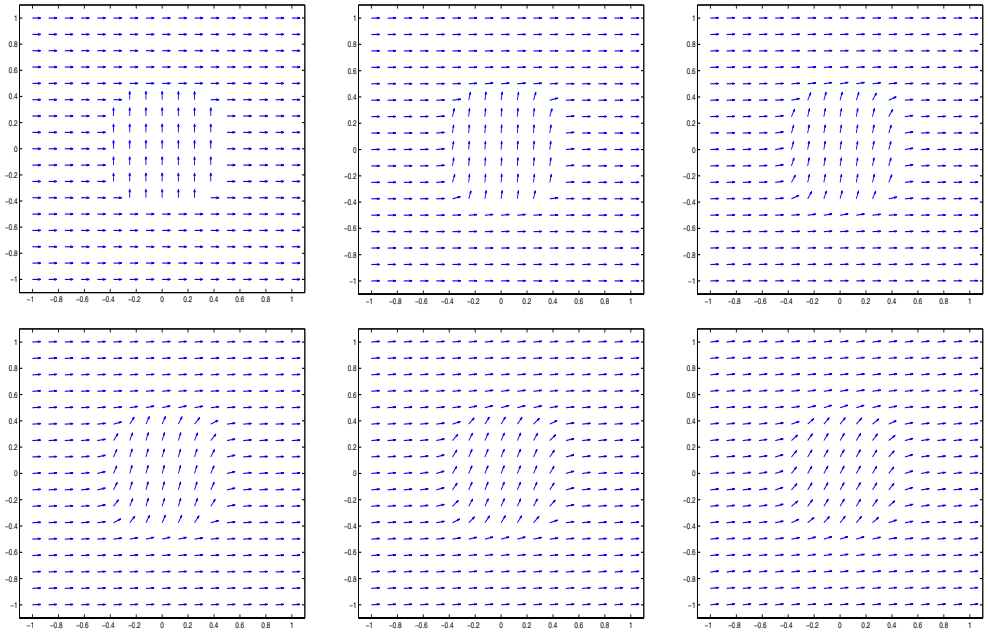

FIG. 5.9. $\mathbf{U}(t,\cdot)$ *in Example* 5.2(iii) *for* $t = 0,\ 0.02,\ 0.04,\ 0.06,\ 0.08,\ 0.10$.

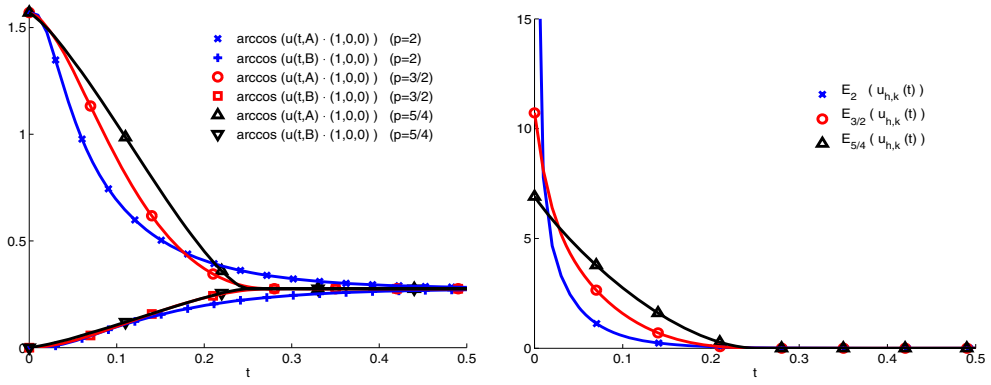

FIG. 5.10. *Angles and energy decay in Example* 5.2.

state is obtained. As opposed to the results in (i) for $p = 2$, the discontinuity along the circle $|\mathbf{x}| = 0.5$ is preserved for $p = 3/2$ in (ii) until $t \approx 0.04$. For $p = 5/4$ the discontinuity is preserved for a significantly longer time; cf. Figure 5.9. In the left plot of Figure 5.10 we display the angle between the vectors $\mathbf{U}(t,\mathbf{x})$ and $(1,0,0)$ for $t \in (0,1)$ and $\mathbf{x} \in \{\mathbf{A},\mathbf{B}\}$, where $\mathbf{A} = (0,0)$ and $\mathbf{B} = (3/4,3/4)$, and for $p = 2$, $p = 3/2$, and $p = 5/4$. We observe that the angle at the origin changes almost linearly in case $p = 3/2$. In the right plot of Figure 5.10 we display the energies $E_2(\mathbf{U}(t,\cdot))$, $E_{3/2}(\mathbf{U}(t,\cdot))$, and $E_{5/4}(\mathbf{U}(t,\cdot))$ as a function of t for the solutions in Example 5.2(i), (ii), and (iii), respectively. Of course, even though $\mathbf{u}_0$ is discontinuous, $\mathbf{U}^0 \equiv \mathcal{I}_h\mathbf{u}_0 \in W^{1,p}(\Omega,\mathbb{R}^3)$ with a mesh dependent norm, and so we still expect energy decay. We observe that this energy decay is slower for smaller exponents p.

Acknowledgment. J. W. Barrett, X. Feng, and A. Prohl would like to thank the Mathematisches Forschungsinstitut Oberwolfach for their kind hospitality and the opportunity of its "Research in Pairs" program in May, 2004.

TWO-SIDED A POSTERIORI ERROR ESTIMATES FOR MIXED FORMULATIONS OF ELLIPTIC PROBLEMS*

SERGEY REPIN†, STEFAN SAUTER‡, AND ANTON SMOLIANSKI‡

Abstract. The present work is devoted to the a posteriori error estimation for mixed approximations of linear self-adjoint elliptic problems. New guaranteed upper and lower bounds for the error measured in the natural product norm are derived, and individual sharp upper bounds are obtained for approximation errors in each of the physical variables. All estimates are reliable and valid for any approximate solution from the class of admissible functions. The estimates contain only global constants depending solely on the domain geometry and the given operators. Moreover, it is shown that, after an appropriate scaling of the coordinates and the equation, the ratio of the upper and lower bounds for the error in the product norm never exceeds 3. The possible methods of finding the approximate mixed solution in the class of admissible functions are discussed. The estimates are computationally very cheap and can also be used for the indication of the local error distribution. As applications, the diffusion problem as well as the problem of linear elasticity are considered.

Key words. a posteriori estimate, two-sided bounds, mixed approximation, elliptic problem

DOI. 10.1137/050641533

1. Introduction.

Most of the existing elliptic problems of continuum mechanics are originally derived in the mixed form; i.e., they contain *two* physical variables that are often equally important in the applications. For example, the stationary heat conduction (resp., diffusion) equation

$$-\Delta u + f = 0$$

comes from the energy (resp., mass) balance equation

$$-\operatorname{div} \mathbf{p} + f = 0 \tag{1}$$

and the empirical Fourier (resp., Fick) law for the heat (resp., mass) flux

$$\mathbf{p} = \nabla u. \tag{2}$$

Here we have set, for simplicity, the conduction (diffusion) coefficient equal to 1 and changed the sign in the flux relation (2). Both the temperature (molecular concentration) u and the flux $\mathbf{p}$ may be needed for understanding the real physical process, and this requirement becomes of utmost importance in the problems of the flows in porous media and in the elasticity problems, where the *complete* solution of the problem is the *pair* of the pressure and velocity for flows, or respectively the displacement and stress in elasticity.

These considerations served as a motivation for the extensive research in the field of so-called mixed methods, that is, the methods allowing one to obtain the

approximations to both physical variables of the problem. As general references on the subject, the books [9], [30], and [17] can be recommended. Although the computing methods are very important, reliable modeling also requires an explicit error control for the obtained approximations. This issue, namely, the a posteriori error estimation for the mixed formulations of elliptic problems, constitutes the primary goal of the present work.

There have been quite a few papers on the a posteriori error estimation for the mixed finite element methods (FEM). The residual-based estimates were developed in [2], [6], [12], [1], [16] for the diffusion-type equation and extended in [14] and [20] to equations of linear elasticity. The superconvergence-based (averaging-type) error estimators were proposed in [7] and [13] to control the L_2-error of the flux variable. Further, the estimators based on the solution of local problems were presented in [2], [16], and [20], and the hierarchical estimator can be found in [32]. Finally, a comparison of these four types of error estimators for mixed finite element discretizations by Raviart–Thomas elements (cf. [24]) was presented in [32]. We also refer to a recent paper [21], where further references on the subject can be found.

In this paper, we derive a posteriori error estimates of another type, the so-called *functional-type estimates* (see also [25], [26], [27], [28]). For the example of problem (1)–(2) equipped with the zero Dirichlet boundary condition for u and under the assumption that $f \in L_2(\Omega)$ (where Ω is the physical domain), the main estimates look as follows:

$$\begin{aligned} \|(u-v, \mathbf{p}-\mathbf{y})\|_{1\times\mathrm{div}} &\le \|\nabla v - \mathbf{y}\| + (1+2C_\Omega^2)^{1/2}\|\mathrm{div}\,\mathbf{y} - f\|, \\ \|(u-v, \mathbf{p}-\mathbf{y})\|_{1\times\mathrm{div}} &\ge \frac{1}{\sqrt{3}}\left(\|\nabla v - \mathbf{y}\| + \|\mathrm{div}\,\mathbf{y} - f\|\right). \end{aligned}$$

Here $\|\cdot\|$ is the norm in $L_2(\Omega)$, the *full* norm $\|(\cdot,\cdot)\|_{1\times\mathrm{div}}$ is defined as

$$\|(u-v, \mathbf{p}-\mathbf{y})\|_{1\times\mathrm{div}} := (\|\nabla(u-v)\|^2 + \|\mathbf{p}-\mathbf{y}\|^2 + \|\mathrm{div}(\mathbf{p}-\mathbf{y})\|^2)^{1/2},$$

and the pair $(v, \mathbf{y})$ from the product space $H_0^1(\Omega) \times H(\Omega;\mathrm{div})$ is *any* approximate solution to the mixed problem. The constant C_Ω is the global constant from the Friedrichs inequality and depends only on the domain geometry.

We see that, while these estimates provide *guaranteed* upper and lower bounds for the error of the mixed solution in the *full* norm, the estimates are also very flexible in the sense that they can be applied to a variety of different approximations, not being restricted to a particular discretization method. This fact makes the functional-type estimates especially attractive for the control of the modelling errors, like those arising in dimension reduction methods of continuum mechanics (see [29]). The sharpness of the estimates and the ability to indicate the local error distribution required for the mesh adaptation will also be shown. Last but not least, we remark that, once the approximate solution has been found in the product space, the estimates cost very little: their computation amounts to the calculation of the corresponding norms.

It is worth noting that, if the given data $f \in L_2(\Omega)$, the exact mixed solution $(u, \mathbf{p})$ belongs to the product space $H^1(\Omega) \times H(\Omega;\mathrm{div})$; thus, in this case, i.e., if the right-hand side f belongs to $L_2(\Omega)$, the latter product space seems to be a natural space for the approximation of the mixed solution. While the standard primal and dual mixed FEM approximate the mixed pair in $H^1(\Omega) \times L_2(\Omega;\mathbb{R}^n)$, resp., $L_2(\Omega) \times H(\Omega;\mathrm{div})$ (hence, not using the full regularity of the exact solution), there are alternative methods that allow us to construct the approximate solution directly

in $H^1(\Omega) \times H(\Omega;\mathrm{div})$. Some of these methods seem to be very promising and competitive, also in the case when one wants to find an approximation of the flux (stress) variable only. Although the comparative analysis of these methods is a subject of the next paper, we briefly review here four of them, since it is important for the application of our error estimates.

The rest of the paper is organized as follows. In section 2, we introduce the notation for the mixed formulation of a general linear self-adjoint elliptic problem. In section 3, the two-sided sharp a posteriori error estimate is derived for an arbitrary approximate solution from the natural class of admissible functions. Next, the individual a posteriori estimates for each of the two variables are derived and shown to be sharp as well. Section 4 is devoted to the applications of the developed theory. First, we consider the diffusion problem and obtain the explicit error bounds for its approximate mixed solution; then, we discuss possible methods of constructing the solution in the natural product space. Finally, the a posteriori error estimates are derived for both displacement and stress approximations in the problem of linear elasticity.

2. Preliminaries. Let V be a reflexive Banach space with the norm $\|\cdot\|_V$, Y a Hilbert space equipped with the inner product $(\cdot,\cdot)_Y$ and the norm $\|\cdot\|_Y$, and V_0 a linear subspace of V. By $\mathcal{B}$ we denote a linear bounded operator acting from V into Y, and by $\mathcal{B}^* : Y \to V_0^*$ the dual operator to $\mathcal{B}\big|_{V_0}$ (the restriction of $\mathcal{B}$ to V_0) in the sense that, for any $y \in Y$,

$$(y, \mathcal{B}w)_Y = \langle \mathcal{B}^* y, w\rangle \quad \forall w \in V_0.$$

Here $\langle w^*, w\rangle$ denotes the value of the functional $w^* \in V_0^*$ on the element $w \in V_0$.

Next, let us introduce a self-adjoint operator $\mathcal{A} \in \mathcal{L}(Y, Y)$ such that

$$\lambda_A \|y\|_Y^2 \le (\mathcal{A}y, y)_Y \le \Lambda_A \|y\|_Y^2 \quad \forall y \in Y, \tag{3}$$

where λ_A and Λ_A are positive constants independent of y. Such an operator defines the equivalent norm on Y:

$$|\!|\!| y |\!|\!| := (\mathcal{A}y, y)_Y^{1/2}.$$

The inverse operator $\mathcal{A}^{-1}$ satisfies an inequality of type (3) with constants Λ_A^{-1} and λ_A^{-1} and defines another equivalent norm on Y:

$$|\!|\!| y |\!|\!|_* := (\mathcal{A}^{-1} y, y)_Y^{1/2}.$$

Assume also that the operator $\mathcal{B}$ satisfies the coercivity inequality on V_0,

$$\|w\|_V \le C_{\mathcal{B}} \|\mathcal{B}w\|_Y \quad \forall w \in V_0, \tag{4}$$

where $C_{\mathcal{B}}$ is some positive constant independent of w. Using (3) and (4), one can define an equivalent norm $|\!|\!| \mathcal{B}\cdot |\!|\!|$ on V_0 as well as the following norm on the dual space V_0^*:

$$[\![w^*]\!] := \sup_{w \in V_0 \setminus \{0\}} \frac{\langle w^*, w\rangle}{|\!|\!| \mathcal{B}w |\!|\!|}.$$

Now let u_0 be some given function from V and

$$V_0 + u_0 := \{v \in V \mid v = w + u_0,\ w \in V_0\}.$$

Let, in addition, l be some given functional from V_0^*. Then, the problem

($\underline{\mathcal{P}}$): Find $u \in V_0 + u_0$ such that

$$(\mathcal{A}\mathcal{B}u, \mathcal{B}w)_Y + \langle l, w\rangle = 0 \quad \forall w \in V_0$$

has the unique solution (this follows from (3) and (4)).

The problem can be rewritten in the operator form as follows:

$$\mathcal{B}^*\mathcal{A}\mathcal{B}u + l = 0 \quad \text{in } V_0^*.$$

The mixed formulation of the problem can be immediately obtained by the introduction of the new unknown function

$$p = \mathcal{A}\mathcal{B}u,$$

which leads to the problem

($\underline{\mathcal{M}}$): Find $(u, p) \in (V_0 + u_0) \times Y$ such that

$$\begin{aligned} p &= \mathcal{A}\mathcal{B}u \quad \text{in } Y,\\ \mathcal{B}^*p + l &= 0 \quad \text{in } V_0^*. \end{aligned}$$

It is clear that problem $(\mathcal{M})$ has the well-known saddle-point structure; its unique solvability is a direct consequence of conditions (3) and (4) (see, e.g., [9]).

In what follows, we will adopt the terminology used in the duality theory of convex analysis (see, e.g., [15]) and call the solution of problem $(\mathcal{P})$ the *primal variable* (*primal solution*) and the new unknown p the *dual variable* (*dual solution*). Accordingly, the letters u, v, w will be reserved for the functions related to the primal variable, i.e., belonging to the space V, and the letters p, q, y for those related to the dual variable, i.e., in the space Y.

In view of the second equation of problem $(\mathcal{M})$, the dual variable p belongs to the set

$$Q_l := \{q \in Y \mid \mathcal{B}^*q = -l \text{ in } V_0^*\}.$$

Thus, for the full control of the dual variable one needs an extended norm on Y, which we define as

$$\|y\|_{\mathcal{B}^*} := \left(\| y \|_*^2 + [\![\mathcal{B}^*y]\!]^2\right)^{1/2} \quad \forall y \in Y. \tag{5}$$

Although this is an equivalent norm on Y (since $[\![\mathcal{B}^*y]\!] = \sup_{w\in V_0} \frac{\langle \mathcal{B}^*y, w\rangle}{\| \mathcal{B}w \|} = \sup_{w\in V_0} \frac{(y, \mathcal{B}w)_Y}{\| \mathcal{B}w \|} \le \sqrt{\frac{\Lambda_A}{\lambda_A}}\, \| y \|_*$), we need it to explicitly control the error in the "equilibrium equation," i.e., in the second equation of $(\mathcal{M})$.

Finally, we define the *full norm* on the product space $V_0 \times Y$:

$$\|(w, y)\|_{V_0\times Y} := \left(\| \mathcal{B}w \|^2 + \|y\|_{\mathcal{B}^*}^2\right)^{1/2} \quad \forall (w, y) \in V_0 \times Y. \tag{6}$$

3. General estimates.

3.1. Estimate in the full norm. Let $(v, q) \in (V_0 + u_0) \times Q_l$ be an arbitrary approximation to the exact solution (u, p) of problem $(\mathcal{M})$. Then, with the help of the relation $p = \mathcal{A}\mathcal{B}u$ and the fact that $\mathcal{A}$ is a self-adjoint linear operator, it is easy to show (see also [26]) that

$$\begin{aligned} \| \mathcal{B}(u - v) \|^2 + \| p - q \|_*^2 &= (\mathcal{A}\mathcal{B}(u - v), \mathcal{B}(u - v))_Y + (\mathcal{A}^{-1}(p - q), p - q)_Y\\ &= (\mathcal{A}\mathcal{B}v - q, \mathcal{B}v - \mathcal{A}^{-1}q)_Y + 2(p - q, \mathcal{B}(u - v))_Y. \end{aligned}$$

Since both p and q belong to the set Q_l, $\mathcal{B}^*(p-q) = -l + l = 0$ in V_0^* and $(p-q, \mathcal{B}(u-v))_Y = \langle \mathcal{B}^*(p-q), u-v\rangle = 0$; this implies

$$\| \mathcal{B}(u-v) \|^2 + \| p-q \|_*^2 = (\mathcal{A}\mathcal{B}v - q, \mathcal{B}v - \mathcal{A}^{-1}q)_Y = \| \mathcal{A}\mathcal{B}v - q \|_*^2. \tag{7}$$

This equality can be referred to as the generalized Prager–Synge hypercircle identity (see [23]).

Relation (7) may already be viewed as an a posteriori error estimate, since the right-hand side does not depend on the exact solution (u,p). However, the estimate holds only for $q \in Q_l$, which seriously restricts the field of its practical application. In fact, the constraint of the set Q_l is virtually impossible to satisfy exactly (this would be nearly equivalent to finding the exact dual solution p), and that is why it is desirable to obtain an estimate allowing the approximate dual solution to be in some large *unconstrained* space.

If we waive the constraint $\mathcal{B}^*q = -l$ in V_0^* for the approximate dual variable, the latter remains to be considered in the whole space Y. Let $y \in Y$ be an arbitrary approximation to p, and $v \in V_0 + u_0$ as before. Then, using (7), one can derive

$$\begin{aligned} &\| \mathcal{B}(u-v) \|^2 + \| p-y \|_*^2 \\ &\qquad = \| \mathcal{B}(u-v) \|^2 + \| p-q \|_*^2 + 2(\mathcal{A}^{-1}(p-q), q-y)_Y + \| q-y \|_*^2 \\ &\qquad = \| \mathcal{A}\mathcal{B}v - q \|_*^2 + 2(\mathcal{A}^{-1}(p-q), q-y)_Y + \| q-y \|_*^2 \quad \forall q \in Q_l. \end{aligned} \tag{8}$$

Now we would like to estimate the right-hand side of (8) from above, so as to eliminate $q \in Q_l$. It is clear that, in order to obtain an explicitly computable and efficient upper bound, one has to carefully choose some special q in Q_l.

First, define the auxiliary function $w_y \in V_0$ such that

$$\mathcal{B}^*\mathcal{A}\mathcal{B}w_y = l + \mathcal{B}^*y \quad \text{in } V_0^*.$$

Due to assumptions (3) and (4), this problem has a unique solution.

Now set $q := y - \mathcal{A}\mathcal{B}w_y$. It is evident that such a function q belongs to Y and $\mathcal{B}^*q = \mathcal{B}^*y - \mathcal{B}^*\mathcal{A}\mathcal{B}w_y = \mathcal{B}^*y - l - \mathcal{B}^*y = -l$ in V_0^*, that is, $q \in Q_l$. It may be noticed that, with this specific choice of q, the sum $q + \mathcal{A}\mathcal{B}w_y$ obviously becomes a nonorthogonal variant of the Helmholtz decomposition for the function $y \in Y$.

Now we can plug the constructed q into the right-hand side of (8). For the first term we have

$$\| \mathcal{A}\mathcal{B}v - q \|_* \le \| \mathcal{A}\mathcal{B}v - y \|_* + \| \mathcal{A}\mathcal{B}w_y \|_*. \tag{9}$$

Here $\| \mathcal{A}\mathcal{B}w_y \|_* = \big(\mathcal{A}^{-1}\mathcal{A}\mathcal{B}w_y, \mathcal{A}\mathcal{B}w_y\big)_Y^{1/2} = \| \mathcal{B}w_y \|$. The latter norm can be estimated by

$$\| \mathcal{B}w_y \|^2 = \langle \mathcal{B}^*\mathcal{A}\mathcal{B}w_y, w_y\rangle \le [\![\mathcal{B}^*\mathcal{A}\mathcal{B}w_y]\!] \, \| \mathcal{B}w_y \|,$$

which implies $\| \mathcal{B}w_y \| \le [\![\mathcal{B}^*\mathcal{A}\mathcal{B}w_y]\!]$. We notice now that, by the definition of w_y, $\mathcal{B}^*\mathcal{A}\mathcal{B}w_y = l + \mathcal{B}^*y$ in V_0^*, which ultimately leads to the estimate

$$\| \mathcal{A}\mathcal{B}w_y \|_* \le [\![l + \mathcal{B}^*y]\!]. \tag{10}$$

Inserting this into (9), one obtains

$$\| \mathcal{A}\mathcal{B}v - q \|_* \le \| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^*y]\!]. \tag{11}$$

The second term on the right-hand side of (8) can be rewritten as

$$2(\mathcal{A}^{-1}(p-q),q-y)_Y = 2(\mathcal{A}^{-1}(p-q),-\mathcal{A}\mathcal{B}w_y)_Y = -2(p-q,\mathcal{B}w_y)_Y \\ = -2\langle \mathcal{B}^*(p-q),w_y\rangle = 0, \tag{12}$$

since $\mathcal{B}^*(p-q) = -l + l = 0$ in V_0^*.

The third term on the right-hand side of (8) equals $\| \mathcal{A}\mathcal{B}w_y \|_*^2$, which has been estimated from above by $[\![l + \mathcal{B}^*y]\!]^2$ (see (10)). Hence, combining this result with (11) and (12), we obtain from (8)

$$\| \mathcal{B}(u-v) \|^2 + \| p-y \|_*^2 \le (\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^*y]\!])^2 + [\![l + \mathcal{B}^*y]\!]^2, \tag{13}$$

where v is an arbitrary function from $V_0 + u_0$ and y is any function from Y.

From (13) one immediately derives the estimate

$$\left(\| \mathcal{B}(u-v) \|^2 + \| p-y \|_*^2\right)^{1/2} \le \| \mathcal{A}\mathcal{B}v - y \|_* + \sqrt{2}\, [\![l + \mathcal{B}^*y]\!] \tag{14}$$

and the following theorem.

THEOREM 3.1. *Let $(u,p) \in (V_0+u_0)\times Y$ be the solution of problem $(\mathcal{M})$, and let $v \in V_0+u_0$ and $y \in Y$ be arbitrary approximations to u and p.*

Then, the following estimates hold true:

$$\|(u-v,p-y)\|_{V_0\times Y} \le \| \mathcal{A}\mathcal{B}v - y \|_* + \sqrt{3}\, [\![l + \mathcal{B}^*y]\!], \tag{15}$$

$$\|(u-v,p-y)\|_{V_0\times Y} \ge \frac{1}{\sqrt{3}} \left(\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^*y]\!]\right). \tag{16}$$

Proof. The upper bound (15) immediately follows from estimate (13) and the definition of the full norm $\|(\cdot,\cdot)\|_{V_0\times Y}$, since $[\![\mathcal{B}^*(p-y)]\!] = [\![l + \mathcal{B}^*y]\!]$.

To obtain the lower bound (16) we use first the triangle inequality to derive

$$\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^*y]\!] \le \| \mathcal{A}\mathcal{B}v - \mathcal{A}\mathcal{B}u \|_* + \| p-y \|_* + [\![l + \mathcal{B}^*y]\!] \\ = \| \mathcal{B}(u-v) \| + \| p-y \|_* + [\![\mathcal{B}^*(p-y)]\!],$$

and then the inequality $a+b+c \le \sqrt{3}\sqrt{a^2+b^2+c^2}\ \ \forall a,b,c \ge 0$ to obtain the estimate

$$\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^*y]\!] \le \sqrt{3}\, \|(u-v,p-y)\|_{V_0\times Y}.$$

This implies the lower bound (16). ∎

Let

$$M_\oplus := \| \mathcal{A}\mathcal{B}v - y \|_* + \sqrt{3}\, [\![l + \mathcal{B}^*y]\!] \tag{17}$$

denote the upper bound (15) for the error in the full norm.

Remarks. 1. If $y \to p$ in Y and $v \to u$ in V, the estimates (15) and (16) tend to zero, precisely as the exact error in the full norm $\|(u-v,p-y)\|_{V_0\times Y}$ does.

2. The error majorant $M_\oplus$ is *sharp*. Indeed, if one takes $y = p$ (i.e., $l + \mathcal{B}^*y \equiv 0$ in V_0^*), estimate (15) becomes

$$\| \mathcal{B}(u-v) \| \le \| \mathcal{A}\mathcal{B}v - p \|_* = \| \mathcal{B}(u-v) \|,$$

which shows that the constant "1" in front of the first term of $M_\oplus$ cannot be improved in general. On the other hand, if, in the case $u_0 = 0$, we set $v = 0$ and $y = 0$, then estimate (15) takes the form

$$\left(2 \| \mathcal{B}u \|^2 + [\![l]\!]^2\right)^{1/2} \le \sqrt{3}[\![l]\!],$$

which is a sharp estimate since $\| \mathcal{B}u \| \le [\![l]\!]$ (set $w = u$ in problem $(\mathcal{P})$), and this estimate, evidently, cannot be improved. Thus, the factor "$\sqrt{3}$" multiplying the second term in $M_\oplus$ cannot be taken smaller in a general case.

The sharpness of the lower bound (16) in a general case is obvious from the estimate's derivation.

3. The efficiency of the estimator $M_\oplus$ can be easily evaluated using the lower bound (16). Namely, for the effectivity index of $M_\oplus$ we have

$$\mathrm{i}_{\mathrm{eff}} := \frac{M_\oplus}{\|(u-v, p-y)\|_{V_0 \times Y}} \le \sqrt{3} \frac{\| \mathcal{A}\mathcal{B}v - y \|_* + \sqrt{3}\, [\![l + \mathcal{B}^* y]\!]}{\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^* y]\!]} \le 3. \tag{18}$$

Estimate (18) provides a rough upper bound for the effectivity index that in most of the cases will be strictly less than 3. Indeed, if the second term $[\![l + \mathcal{B}^* y]\!]$ is essentially smaller than the first one, then $\mathrm{i}_{\mathrm{eff}}$ is close to $\sqrt{3}$. On the other hand, since (15) is a guaranteed upper bound of the error, we always have $\mathrm{i}_{\mathrm{eff}} \ge 1$.

The two-sided estimate (15)–(16) is important, because it provides a control over the error in the full norm, i.e., with respect to both primal and dual variables. However, the individual errors in primal and dual variables may also be of interest; in the next two sections we derive sharp upper bounds for the corresponding norms of these errors. It is worth noticing that the individual estimates which immediately follow from (15) are not sharp and hence may lead to a certain overestimation.

3.2. Estimate for error in the primal variable.

THEOREM 3.2. *Let $u \in V_0 + u_0$ be the solution of problem $(\mathcal{P})$, and $v \in V_0 + u_0$ an arbitrary approximate solution to $(\mathcal{P})$. Then*

$$\| \mathcal{B}(u-v) \| \le \| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^* y]\!] \quad \forall y \in Y. \tag{19}$$

Proof. It immediately follows from (7) that $\| \mathcal{B}(u-v) \|^2 = \inf_{q \in Q_l} \| \mathcal{A}\mathcal{B}v - q \|_*^2$; i.e.,

$$\| \mathcal{B}(u-v) \| \le \| \mathcal{A}\mathcal{B}v - q \|_* \quad \forall q \in Q_l. \tag{20}$$

The right-hand side of (20) has been already estimated for the proof of Theorem 3.1, where the function $q \in Q_l$ was constructed such that $q = y - \mathcal{A}\mathcal{B}w_y$ with y being any function from Y and w_y being the solution to the problem $\mathcal{B}^* \mathcal{A}\mathcal{B} w_y = l + \mathcal{B}^* y$ in V_0^*. Then, estimate (19) follows directly from (11). ∎

Remarks. 1. Estimate (19) is *sharp*. Indeed, if we set $y = p = \mathcal{A}\mathcal{B}u$, the estimate will be

$$\| \mathcal{B}(u-v) \| \le \| \mathcal{A}\mathcal{B}v - \mathcal{A}\mathcal{B}u \|_* = \| \mathcal{B}(u-v) \|.$$

On the other hand, in the case $u_0 = 0$, setting $v = 0$ and $y = 0$, we obtain from (19)

$$\| \mathcal{B}u \| \le [\![l]\!],$$

which is the sharp energy estimate for the solution u of problem $(\mathcal{P})$. Thus, the weights equal to 1 on the right-hand side of estimate (19) are optimal, in a general case.

2. Estimate (19) is *asymptotically exact* in the sense that, if $y \to p$ in Y, then the upper bound (19) tends to the norm $\| \mathcal{A}\mathcal{B}v - \mathcal{A}\mathcal{B}u \|_* = \| \mathcal{B}(u-v) \|$ of the error in primal variable.

3. The estimate remains *efficient* if y is close to p in Y, since

$$\begin{aligned}\| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^* y]\!] &\le \| \mathcal{A}\mathcal{B}v - \mathcal{A}\mathcal{B}u \|_* + \| p - y \|_* + [\![\mathcal{B}^*(p-y)]\!] \\ &\le \| \mathcal{B}(u-v) \| + \sqrt{2}\|p-y\|_{\mathcal{B}^*}.\end{aligned}$$

Here the last, presumably small, term measures the level of the overestimation due to estimate (19).

4. If one considers only $y \in Q_l$ in (19), one arrives at estimate (20), which is the "constitutive relation-based" estimate (see [19]). On the other hand, if one takes $y = \mathcal{A}\mathcal{B}v$ in (19), one obtains the estimate $\| \mathcal{B}(u-v) \| \le [\![l + \mathcal{B}^* \mathcal{A}\mathcal{B}v]\!]$, which is the "residual-based" estimate for problem $(\mathcal{P})$ (see [4]). Thus, estimate (19) includes these two estimates as particular cases, combining their advantages and providing a greater flexibility. More on the links between the error majorant and other estimates can be found in [25].

3.3. Estimate for error in the dual variable.

THEOREM 3.3. *Let $(u,p) \in (V_0 + u_0) \times Y$ be the solution to problem $(\mathcal{M})$, and let $y \in Y$ be any approximation of p. Then*

$$\| p - y \|_* \le \| \mathcal{A}\mathcal{B}v - y \|_* + [\![l + \mathcal{B}^* y]\!] \quad \forall v \in V_0 + u_0, \tag{21}$$

$$\|p - y\|_{\mathcal{B}^*} \le \| \mathcal{A}\mathcal{B}v - y \|_* + \sqrt{2}[\![l + \mathcal{B}^* y]\!] \quad \forall v \in V_0 + u_0. \tag{22}$$

Proof. We have for any $v \in V_0 + u_0$

$$\begin{aligned}\| \mathcal{B}(u-v) \|^2 + \| p - y \|_*^2 &= (\mathcal{A}\mathcal{B}(u-v), \mathcal{B}(u-v))_Y + (\mathcal{A}^{-1}(p-y), p-y)_Y \\ &= (\mathcal{A}\mathcal{B}v - y, \mathcal{B}v - \mathcal{A}^{-1}y)_Y + 2(p-y, \mathcal{B}(u-v))_Y,\end{aligned} \tag{23}$$

where the self-adjointness of $\mathcal{A}$ and $\mathcal{A}^{-1}$ as well as the relation $p = \mathcal{A}\mathcal{B}u$ have been used. For the second term on the right-hand side of (23) we have

$$(p-y, \mathcal{B}(u-v))_Y = \langle \mathcal{B}^*(p-y), u-v \rangle = \langle -l - \mathcal{B}^* y, u - v \rangle \quad \forall v \in V_0 + u_0,$$

which implies the estimate

$$| (p-y, \mathcal{B}(u-v))_Y | \le [\![l + \mathcal{B}^* y]\!] \| \mathcal{B}(u-v) \| \le \frac{1}{2} \left([\![l + \mathcal{B}^* y]\!]^2 + \| \mathcal{B}(u-v) \|^2 \right).$$

Using this estimate and noticing that the first term on the right-hand side of (23) equals $\| \mathcal{A}\mathcal{B}v - y \|_*^2$, we derive from (23)

$$\| \mathcal{B}(u-v) \|^2 + \| p - y \|_*^2 \le \| \mathcal{A}\mathcal{B}v - y \|_*^2 + [\![l + \mathcal{B}^* y]\!]^2 + \| \mathcal{B}(u-v) \|^2,$$

that is,

$$\| p - y \|_*^2 \le \| \mathcal{A}\mathcal{B}v - y \|_*^2 + [\![l + \mathcal{B}^* y]\!]^2 \quad \forall v \in V_0 + u_0.$$

This immediately yields estimate (21). Then, (22) is obvious. □

Remark. Estimate (21) is *sharp* (hence, estimate (22) is sharp too). Indeed, if our approximation y belongs to Q_l and we set $v = u$, we obtain from (21)

$$\| p - y \|_* \le \| \mathcal{A}\mathcal{B}u - y \|_* = \| p - y \|_*.$$

On the other hand, if, in the case $u_0 = 0$, we set $v = 0$ and $y = 0$, we have from (21)

$$\| p \|_* \le [\![l]\!], \quad \text{i.e.,} \quad \| \mathcal{B}u \| \le [\![l]\!],$$

which is the sharp energy estimate for the solution of problem $(\mathcal{P})$. Thus, the weights of both terms on the right-hand side of (21) are, in general, optimal.

3.4. Important special case. The estimates obtained above provide reliable measures of the errors in a very general situation when the exact solution to problem $(\mathcal{P})$ is sought in an arbitrary reflexive Banach space V and the given functional l belongs to V_0^*. As a result, the norm in V_0^* enters the estimates, making them less convenient for computational purposes. However, in most practically interesting cases one can significantly simplify the estimates. Indeed, usually one has

$$\text{the } \textit{continuous embedding } V \subset U \tag{24}$$

for some Hilbert space U with the inner product $(\cdot,\cdot)_U$ and the norm $\|\cdot\|_U$. This means that $\|\cdot\|_U \le C\|\cdot\|_V$ with some constant C; however, in what follows we mostly deal with cases like $U = L_2(\Omega)$, $V = H^1(\Omega)$ and hence make a stronger assumption,

$$\|\cdot\|_U \le \|\cdot\|_V. \tag{25}$$

One may notice that $U \subset V_0^*$. (It immediately follows from (24).) We also assume the given data

$$l \in U. \tag{26}$$

First, one can notice that, if assumption (26) holds true, the exact dual solution p satisfies the equation $\mathcal{B}^*p + l = 0$ in U and hence belongs to the space

$$Y_{\mathcal{B}^*} := \{y \in Y \mid \mathcal{B}^*y \in U\},$$

which is the Banach space with respect to the norm

$$|\!|\!| y |\!|\!|_{\mathcal{B}^*} := \big(\|\!|\!| y |\!|\!|_*^2 + \|\mathcal{B}^*y\|_U^2\big)^{1/2} \quad \forall y \in Y_{\mathcal{B}^*}. \tag{27}$$

As compared to the definition of the norm $\|\cdot\|_{\mathcal{B}^*}$ (see (5)), the newly defined norm is stronger, which reflects the fact that $Y_{\mathcal{B}^*}$ is a subspace of Y.

It is natural now to consider the approximation y of the exact dual solution in $Y_{\mathcal{B}^*}$ rather than in Y; this is still much less restrictive than an approximation in the set Q_l, whose definition contains the complicated constraint $\mathcal{B}^*y = -l$.

Then, we can estimate the term $[\![\, l + \mathcal{B}^*y \,]\!]$ as follows:

$$\begin{aligned}
[\![\, l + \mathcal{B}^*y \,]\!] &= \sup_{w\in V_0\setminus\{0\}} \frac{\langle l + \mathcal{B}^*y, w\rangle}{|\!|\!| \mathcal{B}w |\!|\!|} = \sup_{w\in V_0\setminus\{0\}} \frac{(l + \mathcal{B}^*y, w)_U}{|\!|\!| \mathcal{B}w |\!|\!|} \\
&\le \sup_{w\in V_0\setminus\{0\}} \frac{\|l + \mathcal{B}^*y\|_U \, \|w\|_U}{|\!|\!| \mathcal{B}w |\!|\!|} \le \sup_{w\in V_0\setminus\{0\}} \frac{\|l + \mathcal{B}^*y\|_U \, \|w\|_V}{|\!|\!| \mathcal{B}w |\!|\!|} \\
&\le \frac{C_{\mathcal{B}}}{\lambda_A^{1/2}} \, \|l + \mathcal{B}^*y\|_U \quad \forall y \in Y_{\mathcal{B}^*},
\end{aligned} \tag{28}$$

where inequalities (3), (4), and (25) have been used. It is important to notice that one often has the inequality

$$\|w\|_U \le \widetilde{C}_{\mathcal{B}} \, \|\mathcal{B}w\|_Y \quad \forall w \in V_0 \tag{29}$$

in addition to (4); in such a case, the constant $C_{\mathcal{B}}$ in (28) is to be replaced by $\widetilde{C}_{\mathcal{B}}$ from (29).

With the definition of the $Y_{\mathcal{B}^*}$-norm (see (27)), the *full norm* (6) should be understood on the product space $V_0 \times Y_{\mathcal{B}^*}$ in the following sense:

$$\|(v,y)\|_{V_0\times Y_{\mathcal{B}^*}} := \left(\| \mathcal{B}v \|^2 + \| y \|_*^2 + \|\mathcal{B}^* y\|_U^2\right)^{1/2} \quad \forall (v,y) \in V_0 \times Y_{\mathcal{B}^*}. \tag{30}$$

THEOREM 3.4. *Let V be continuously embedded into some Hilbert space U and $l \in U$. Suppose in addition that $\|\cdot\|_U \le \|\cdot\|_V$. Let $(u,p) \in (V_0+u_0)\times Y_{\mathcal{B}^*}$ be the solution to problem $(\mathcal{M})$, and let $(v,y) \in (V_0+u_0)\times Y_{\mathcal{B}^*}$ be any approximate solution to $(\mathcal{M})$.*

Then, the following a posteriori error estimates hold true:

$$\|(u-v,p-y)\|_{V_0\times Y_{\mathcal{B}^*}} \le \| \mathcal{A}\mathcal{B}v - y \|_* + \left(1 + 2\frac{C_{\mathcal{B}}^2}{\lambda_A}\right)^{1/2} \|l + \mathcal{B}^* y\|_U, \tag{31}$$

$$\|(u-v,p-y)\|_{V_0\times Y_{\mathcal{B}^*}} \ge \frac{1}{\sqrt{3}} \left(\| \mathcal{A}\mathcal{B}v - y \|_* + \|l + \mathcal{B}^* y\|_U\right), \tag{32}$$

$$\| \mathcal{B}(u-v) \| \le \| \mathcal{A}\mathcal{B}v - y \|_* + \frac{C_{\mathcal{B}}}{\lambda_A^{1/2}} \|l + \mathcal{B}^* y\|_U, \tag{33}$$

$$\| p - y \|_* \le \| \mathcal{A}\mathcal{B}v - y \|_* + \frac{C_{\mathcal{B}}}{\lambda_A^{1/2}} \|l + \mathcal{B}^* y\|_U, \tag{34}$$

$$\|p-y\|_{\mathcal{B}^*} \le \| \mathcal{A}\mathcal{B}v - y \|_* + \left(1 + \frac{C_{\mathcal{B}}^2}{\lambda_A}\right)^{1/2} \|l + \mathcal{B}^* y\|_U. \tag{35}$$

Proof. The upper bound (31) immediately follows from estimates (13) and (28); the lower bound (32) is a simple consequence of the triangle inequality, like the lower bound (16) in Theorem 3.1.

Estimate (33) can easily be derived from (19) and (28), while estimates (34) and (35) follow from (21) and (28). ∎

Remarks. 1. Estimates (31)–(35) are *sharp*, which follows from the sharpness of the estimates of Theorems 3.1–3.3 and of inequality (28).

2. Estimates (31) and (32) imply that the effectivity index of the error majorant (31) is always between 1 and $\sqrt{3}\left(1+2\frac{C_{\mathcal{B}}^2}{\lambda_A}\right)^{1/2}$. It is worth noting that the constant λ_A can be made equal to 1 if one performs the corresponding rescaling of the operator $\mathcal{A}$ and of the functional l (i.e., multiplication of the linear problem $(\mathcal{P})$ by $1/\lambda_A$). The constant $C_{\mathcal{B}}$ depends only on the operator $\mathcal{B}$ and can easily be evaluated a priori. (We discuss this issue in the next section.) We will also show that, after an appropriate scaling of the geometric coordinates, one can make the constant $C_{\mathcal{B}} \le 1$, which means that the effectivity index of the upper bound (31) for the new "rescaled" problem will always be between 1 and 3.

3. It is worthwhile to notice a remarkable symmetry of estimates (33) and (34) for the primal and dual variables.

4. Applications.

4.1. Diffusion problem.

4.1.1. Error estimates. Let $V = H^1(\Omega)$, where Ω is a bounded domain in $\mathbb{R}^n$ with Lipschitz boundary $\partial\Omega$, $V_0 = H_0^1(\Omega)$, $Y = L_2(\Omega;\mathbb{R}^n)$. Consider the case

$$\mathcal{B} = \nabla := \left(\frac{\partial}{\partial x_1}, \dots, \frac{\partial}{\partial x_n}\right).$$

Then, $\mathcal{B}^*\mathbf{y} = -\operatorname{div}\mathbf{y} \in H^{-1}(\Omega) = V_0^*$ for any $\mathbf{y} \in Y$, and

$$\langle \mathcal{B}^*\mathbf{y}, w\rangle = \int_\Omega \mathbf{y}\cdot\nabla w\,dx \quad \forall w \in V_0,$$

where the dot denotes the scalar product of vectors in $\mathbb{R}^n$. The operator $\mathcal{A}$ is defined by a symmetric uniformly positive definite matrix $\mathbf{A} = \{a_{ij}(x)\}_{i,j=\overline{1,n}}$ with coefficients from $L_\infty(\Omega)$. Then, the norms $\|\!|\cdot|\!\|$ and $\|\!|\cdot|\!\|_*$ are defined as

$$\|\!|\mathbf{y}|\!\|^2 = \int_\Omega \mathbf{A}\mathbf{y}\cdot\mathbf{y}\,dx, \qquad \|\!|\mathbf{y}|\!\|_*^2 = \int_\Omega \mathbf{A}^{-1}\mathbf{y}\cdot\mathbf{y}\,dx.$$

Inequality (3) is obviously satisfied, and (4) follows from the Friedrichs inequality.

Assume now that u_0 is some given function from $H^1(\Omega)$ and that l is some given functional from $H^{-1}(\Omega)$. Then, problem $(\mathcal{P})$ defines the weak solution of the boundary-value problem

$$-\operatorname{div}(\mathbf{A}\nabla u) + l = 0 \quad \text{in } \Omega, \tag{36}$$

$$u = u_0 \quad \text{on } \partial\Omega. \tag{37}$$

We can also write all the estimates of Theorems 3.1–3.3, where $[\![\cdot]\!]$ is equivalent to the $H^{-1}(\Omega)$-norm.

We see, however, that V is continuously embedded into the Hilbert space $U = L_2(\Omega)$ and that inequality (25) is valid; hence, if we suppose that the data $l \in L_2(\Omega)$, we can use the results of Theorem 3.4.

First, we note that the space $Y_{\mathcal{B}^*}$ is, in fact, the space $H(\Omega;\operatorname{div}) := \{\mathbf{y} \in L_2(\Omega;\mathbb{R}^n) \mid \operatorname{div}\mathbf{y} \in L_2(\Omega)\}$ with the norm

$$\|\mathbf{y}\|_{\operatorname{div}} := \left(\|\!|\mathbf{y}|\!\|_*^2 + \|\operatorname{div}\mathbf{y}\|^2\right)^{1/2},$$

where $\|\cdot\|$ denotes the norm in $L_2(\Omega)$.

The *full norm* then takes the form

$$\|(v,\mathbf{y})\|_{1\times\operatorname{div}} := \left(\|\!|\nabla v|\!\|^2 + \|\!|\mathbf{y}|\!\|_*^2 + \|\operatorname{div}\mathbf{y}\|^2\right)^{1/2} \quad \forall (v,\mathbf{y}) \in H_0^1(\Omega)\times H(\Omega;\operatorname{div}).$$

It is important to notice that, in the considered case, we have an inequality of type (29) that is exactly the Friedrichs inequality

$$\|w\| \le C_\Omega \|\!|\nabla w|\!\| \quad \forall w \in H_0^1(\Omega).$$

Thus, the constant $C_{\mathcal{B}}$ in (28) and in Theorem 3.4 is, in fact, the constant C_Ω from the Friedrichs inequality.

Hence, if $(u,\mathbf{p}) \in (H_0^1(\Omega)+u_0)\times H(\Omega;\operatorname{div})$ is the exact solution to the mixed problem

$$\mathbf{p} = \mathbf{A}\nabla u \quad \text{in } \Omega, \tag{38}$$

$$-\operatorname{div}\mathbf{p} + l = 0 \quad \text{in } \Omega, \tag{39}$$

and $(v,\mathbf{y}) \in (H_0^1(\Omega)+u_0)\times H(\Omega;\operatorname{div})$ is any approximate solution to the problem,

then the following a posteriori error estimates follow directly from Theorem 3.4:

$$\|(u-v,\mathbf{p}-\mathbf{y})\|_{1\times\mathrm{div}} \le \| \mathbf{A}\nabla v-\mathbf{y} \|_{*} + \left(1+2\frac{C_\Omega^2}{\lambda_A}\right)^{1/2} \|\mathrm{div}\,\mathbf{y}-l\|, \tag{40}$$

$$\|(u-v,\mathbf{p}-\mathbf{y})\|_{1\times\mathrm{div}} \ge \frac{1}{\sqrt{3}} \left(\| \mathbf{A}\nabla v-\mathbf{y} \|_{*} + \|\mathrm{div}\,\mathbf{y}-l\|\right), \tag{41}$$

$$\| \nabla(u-v) \| \le \| \mathbf{A}\nabla v-\mathbf{y} \|_{*} + \frac{C_\Omega}{\lambda_A^{1/2}}\|\mathrm{div}\,\mathbf{y}-l\|, \tag{42}$$

$$\| \mathbf{p}-\mathbf{y} \|_{*} \le \| \mathbf{A}\nabla v-\mathbf{y} \|_{*} + \frac{C_\Omega}{\lambda_A^{1/2}}\|\mathrm{div}\,\mathbf{y}-l\|, \tag{43}$$

$$\|\mathbf{p}-\mathbf{y}\|_{\mathrm{div}} \le \| \mathbf{A}\nabla v-\mathbf{y} \|_{*} + \left(1+\frac{C_\Omega^2}{\lambda_A}\right)^{1/2} \|\mathrm{div}\,\mathbf{y}-l\|. \tag{44}$$

Estimates (40)–(44) provide sharp error bounds that are explicitly computable, if one has the approximate solution to (38)–(39) in the product space $H^1(\Omega)\times H(\Omega;\mathrm{div})$. It is, of course, clear that, having found the approximate mixed solution $(v,\mathbf{y})$ by primal or dual mixed FEM, one can use some local averaging (projection) to recover the needed $H^1(\Omega)$ (respectively, $H(\Omega;\mathrm{div})$) regularity for the approximate primal (respectively, dual) variable. There exist, however, several methods allowing one to approximate the mixed solution $(u,\mathbf{p})$ in the space $H^1(\Omega)\times H(\Omega;\mathrm{div})$ directly. Below, we briefly review four of them.

4.1.2. Approximation of the mixed solution in $H^1(\Omega)\times H(\Omega;\mathrm{div})$.

(a) *Least-squares mixed method.* This method was analyzed in [22] and, under the name first-order-system least-squares (FOSLS), in [10], [11] (see also the references therein). In this method, the saddle-point (min-max) problem (38)–(39) is reformulated as a quadratic minimization (min-min) problem

$$\inf_{v\in H_0^1(\Omega)+u_0}\ \inf_{\mathbf{y}\in H(\Omega;\mathrm{div})} \left(\| \mathbf{A}\nabla v-\mathbf{y} \|_{*}^2 + \|\mathrm{div}\,\mathbf{y}-l\|^2\right), \tag{45}$$

which leads to the solution of the "stabilized" saddle-point problem, given next.

Find $(u,\mathbf{p})\in (H_0^1(\Omega)+u_0)\times H(\Omega;\mathrm{div})$ such that

$$\begin{aligned}\int_\Omega \mathbf{A}^{-1}\mathbf{p}\cdot\mathbf{q}\,dx + \int_\Omega (\mathrm{div}\,\mathbf{p})(\mathrm{div}\,\mathbf{q})\,dx - \int_\Omega \nabla u\cdot\mathbf{q}\,dx \\ = \int_\Omega l\,(\mathrm{div}\,\mathbf{q})\,dx \quad \forall \mathbf{q}\in H(\Omega;\mathrm{div}),\end{aligned} \tag{46}$$

$$\int_\Omega (\mathrm{div}\,\mathbf{p})\,v\,dx + \int_\Omega \mathbf{A}\nabla u\cdot\nabla v\,dx = 0 \quad \forall v\in H_0^1(\Omega). \tag{47}$$

We have to note that, in the original version of the method, the squared L_2-norm was used in the first term of the functional (45) instead of the squared $\| \cdot \|_*$-norm, which somehow changes the system of the functional's optimality conditions (46)–(47).

System (46)–(47), unlike (38)–(39), leads to a symmetric *positive definite* discrete problem, and the discrete *inf-sup* condition is always satisfied owing to the least-squares stabilization. The latter fact allows one to choose the approximation spaces for u and $\mathbf{p}$ independently of each other.

However, in (46)–(47) the primal and the dual variables are *strongly coupled*. The following method yields only a weak coupling of the variables.

(b) *Method of minimizing the squared majorant.* From estimate (42) for the error in the primal variable one can easily derive the estimate for the squared energy norm of the error:

$$\| \nabla(u-v) \|^2 \le (1+\beta) \| \mathbf{A}\nabla v - \mathbf{y} \|_*^2 + \left(1+\frac{1}{\beta}\right) \frac{C_\Omega^2}{\lambda_A} \|\operatorname{div} \mathbf{y} - l\|^2, \tag{48}$$

where $\beta > 0$ is an arbitrary number and $\mathbf{y}$ is any function from $H(\Omega;\operatorname{div})$. Denote the right-hand side of (48) by $M^2(v;\mathbf{y},\beta)$ ("the squared error majorant"). It is evident that $M^2(v;\mathbf{y},\beta)$ is, in fact, the least-squares functional (45) with differently weighted terms. However, instead of minimizing the functional with respect to both v and $\mathbf{y}$ simultaneously as in the least-squares mixed method, the following simple algorithm was proposed in [27]:

1. Find the approximate solution $v \in V_0 + u_0$ to the problem (36)–(37).
2. Set $\beta = 1$, and find $\mathbf{y}$ by minimizing $M^2(v;\mathbf{y},\beta)$ with respect to $\mathbf{y}$.

The algorithm was initially motivated by the goal of finding a best possible upper bound for the energy error in the primal variable; however, it also provides a computationally efficient way of computing approximate primal and dual solutions in $H^1(\Omega) \times H(\Omega;\operatorname{div})$ in a *weakly coupled* manner. Indeed, the problems for v and $\mathbf{y}$ now have to be solved successively.

While the problem of finding an approximate solution to (36)–(37) in step 1 is quite standard, the computation of $\mathbf{y}$ in step 2 also does not present serious difficulty. Since $M^2(v;\mathbf{y},\beta)$ is a quadratic functional with respect to the dual variable $\mathbf{y}$ for any fixed v and β, the minimization of the functional on any finite-dimensional subspace Y_h of $H(\Omega;\operatorname{div})$ leads to the solution of a linear system with symmetric positive definite matrix.

This algorithm was independently proposed in [8] as an alternative to the least-squares mixed method and considered as a single Picard–Uzawa-type iteration for the solution of the coupled system (46)–(47). (In [8], the least-squares functional (45) was used, not $M^2(v;\mathbf{y},\beta)$.) It has been shown in [8] that, with v found by a conforming FEM for the problem (36)–(37), the minimizer $\mathbf{y}_h$ of the functional on the subspace Y_h has the optimal order of the $H(\Omega;\operatorname{div})$-error with respect to the mesh size (i.e., the order of the interpolation error for Y_h), provided that the $H^1(\Omega)$-error of the approximation v is not of lower order. The advantage over the dual mixed FEM as well as the least-squares mixed method is obvious: the computation of the primal variable is completely independent of the calculation of the dual one (this reduces the total computational cost), and the discrete problem for each of the variables is moderately sized, symmetric, and positive definite (i.e., one does not have to deal with an indefinite saddle-point problem as in the case of the dual mixed FEM).

As follows from the numerical studies of [27], using the parameter β, one can gain a further improvement in the approximation of the dual solution. Namely, for the unique minimizer $\mathbf{y}_\beta \in H(\Omega;\operatorname{div})$ of $M^2(v;\mathbf{y},\beta)$ for any fixed $v \in V_0 + u_0$ and $\beta > 0$, it was proved in [27] that $\mathbf{y}_\beta$ converges to the exact dual solution p in $H(\Omega;\operatorname{div})$ as $\beta \to 0$, and, moreover,

$$\begin{aligned} \| \mathbf{p} - \mathbf{y} \|_* &\le C\,\beta^{1/2}, \\ \|\operatorname{div}(\mathbf{p} - \mathbf{y})\| &\le C\,\beta, \end{aligned}$$

with some constant C independent of $\mathbf{y}$ and β. Thus, the one-stroke minimization of the functional $M^2(v;\mathbf{y},\beta)$ with respect to $\mathbf{y}$ and with some moderately small β may yield even better accuracy of the dual-solution approximation than the minimization

with $\beta = 1$. Numerical experiments (see [27]) show that, for example, if one uses linear finite elements for both primal and dual variables, the value $\beta = 1/10$ is a good choice. Taking β moderately small allows one to circumvent the difficulties with the condition number of the resulting discrete system and with the locking phenomenon, typical for penalty methods.

A possible way of finding the concrete value of β is to minimize the functional $M^2(v; \mathbf{y}, \beta)$ with respect to β having fixed v and $\mathbf{y}$. This immediately implies the explicit formula

$$\beta = \frac{C_\Omega \|\operatorname{div} \mathbf{y} - l\|}{\lambda_A^{1/2} \, \| \mathbf{A}\nabla v - \mathbf{y} \|_*}, \tag{49}$$

and the modified algorithm for the approximation of the primal and dual solutions reads as follows:

1. Find the approximate solution $v \in V_0 + u_0$ to the problem (36)–(37).
2. Set $\beta^{(1)} = 1$ and find $\mathbf{y}^{(1)}$ by minimizing $M^2(v; \mathbf{y}, \beta^{(1)})$ with respect to $\mathbf{y}$.
3. Compute $\beta^{(2)}$ using $\mathbf{y}^{(1)}$ in formula (49); find $\mathbf{y}^{(2)}$ by minimizing $M^2(v; \mathbf{y}, \beta^{(2)})$ with respect to $\mathbf{y}$.

A further iteration of the process of minimizing the squared majorant with respect to $\mathbf{y}$ and β does not bring any essential benefits, as shown in the detailed study of [27].

To summarize, the minimization of the squared majorant either at a one-stroke (only steps 1 and 2 in the algorithm above) or by two iterations provides a competitive approach to the approximation of the dual solution. The whole method of finding the primal variable in $H^1(\Omega)$ and the dual variable in $H(\Omega; \operatorname{div})$ amounts to the successive solution of two elliptic problems. It is worth noting that the approximation spaces for v and $\mathbf{y}$ can be chosen independently of each other, as in the least-squares mixed method.

(c) *Dual penalty method.* This method can be viewed as a limiting case of the previous method, i.e., the case when the parameter β in the squared majorant is considered as a very small penalty parameter. The classical dual penalty method has, however, a slightly different formulation. Namely, after finding $v \in V_0 + u_0$ as an approximate solution to (36)–(37), one has to minimize the quadratic "penalized functional"

$$I(\mathbf{y}) := \| \mathbf{y} \|_*^2 + \frac{1}{\varepsilon} \|\operatorname{div} \mathbf{y} - l\|^2$$

over $H(\Omega; \operatorname{div})$ for some small $\varepsilon > 0$. The main difference with the method of minimizing the squared majorant is that the approximation of $\mathbf{y}$ is now *fully decoupled* from the approximation of v. As immediate drawbacks, one has the deterioration of the condition number of the resulting discrete problem and a possible locking phenomenon.

(d) *Method of local projections.* In this method, the dual variable is found by some local projections of the approximate flux $\mathbf{A}\nabla v$ into the space $H(\Omega; \operatorname{div})$. The approximate flux is derived from the approximate primal solution $v \in V_0 + u_0$ previously found by solving (36)–(37). Thus, we have here again a *weakly coupled* approach. The method is usually referred to as the "gradient recovery" or "gradient averaging," and its diverse variants have been considered by many researchers (see, e.g., [18], [34], [35], [33] and the references therein). In particular, the so-called "equilibrium-enhanced" gradient recovery methods (see [5], [31]) seem to be especially advantageous for computing an accurate approximation to the dual variable in the $H(\Omega; \operatorname{div})$-norm.

Remarks. 1. It is clear that each of the four methods addressed above has both advantages and drawbacks. A thorough comparison of the methods still remains to be done.

2. If the approximation to $(u, \mathbf{p})$ has been found in $(H^1_0(\Omega) + u_0) \times H(\Omega; \mathrm{div})$ by one of the above considered methods, it can be inserted into estimates (40)–(44) to yield the explicit a posteriori control of the errors in both variables. Since the norms in the estimates can be computed by summation of the local contributions from subdomains of Ω (given some finite subdivision of Ω), they may be used also for an *adaptive* improvement of the approximation. In particular, it is obvious that, if $\mathbf{y}$ is close to $\mathbf{p}$ in $H(\Omega; \mathrm{div})$, the term $\| \mathbf{A}\nabla v - \mathbf{y} \|_*$ computed over any subdomain $\omega \subset \Omega$ is close to $\| \nabla(u - v) \|$ considered on ω. More on the use of the error majorants for the indication of the local error distribution can be found in [27], [28].

3. The constant C_Ω stemming from Friedrichs' inequality is equal to $1/\sqrt{\lambda_\Omega}$, where λ_Ω is the minimal eigenvalue of the Laplace operator equipped with the homogeneous Dirichlet boundary condition on $\partial\Omega$. It is, however, clear that C_Ω can always be estimated from above by $C_\mathcal{D}$, where $\mathcal{D} \supset \Omega$ is some domain of a simple shape (e.g., a rectangle in two dimensions). Then, $C_\mathcal{D}$ can be computed analytically.

4. Since the evaluation of C_Ω is fairly easy, the total computational cost of estimates (40)–(44) is very small (only the computation of norms), provided that the pair $(v, \mathbf{y})$ is found in $(H^1_0(\Omega) + u_0) \times H(\Omega; \mathrm{div})$, for instance, by one of the methods discussed above.

5. Using translation and rescaling of the geometric coordinates (which amounts to a linear coordinate transformation), one can make it so that the rescaled physical domain $\widetilde{\Omega}$ would be completely inside of a unit cube (square in two dimensions). After having rewritten the original elliptic problem in the new coordinates and subsequently rescaling the equation so that $\lambda_A = 1$ (see Remark 2 at the end of section 3.4), we can write down all the estimates (40)–(44) for the approximation error of the solution to the rescaled problem on the new domain $\widetilde{\Omega}$. The most important fact here is that all the estimates for the new problem will contain only numerical constants (like $\sqrt{3}$, $\sqrt{2}$), since $\lambda_A = 1$ and the Friedrichs constant $C_{\widetilde{\Omega}}$ may be estimated from above by 1 (see Remark 3 above). As an immediate consequence, one infers that the effectivity index of the upper bound (40) for the error in the full norm will be between 1 and 3.

4.2. Linear elasticity. Although the application of the theory to the problem of linear elasticity is similar to the case of the diffusion problem, it is, however, interesting to consider the elasticity problem in detail.

Let $V = H^1(\Omega; \mathbb{R}^n)$, where Ω is a bounded domain in $\mathbb{R}^n$ with Lipschitz boundary $\partial\Omega$, $V_0 = \{\mathbf{v} \in V \mid \mathbf{v} = 0 \text{ on } \partial\Omega\}$, and $\mathbf{Y} = L_2(\Omega; \mathbb{M}^{n\times n}_s)$, where $\mathbb{M}^{n\times n}_s$ is the space of symmetric $n \times n$-matrices. Now define the operator $\mathcal{B}$ as follows:

$$\mathcal{B}\mathbf{v} := \underline{\underline{\mathbf{e}}}(\mathbf{v}) = \frac{1}{2}\left(\nabla\mathbf{v} + (\nabla\mathbf{v})^T\right).$$

Here $\nabla\mathbf{v} = \{v_{i,j}\}$ is a tensor (the gradient of the vector $\mathbf{v}$), and the symbol ^{T} means the transposition. Then, $\mathcal{B}^*\underline{\underline{\mathbf{y}}} = -\mathrm{div}\,\underline{\underline{\mathbf{y}}} \in H^{-1}(\Omega; \mathbb{R}^n) = V_0^*$ for any $\underline{\underline{\mathbf{y}}} \in \mathbf{Y}$, and

$$\langle \mathcal{B}^*\underline{\underline{\mathbf{y}}}, \mathbf{w} \rangle = \int_\Omega \underline{\underline{\mathbf{y}}} : \underline{\underline{\mathbf{e}}}(\mathbf{w})\, dx \quad \forall \mathbf{w} \in V_0,$$

where the colon denotes the inner product in $\mathbb{M}^{n\times n}_s$ ($a : b = \sum a_{ij}b_{ij}$ $\forall a, b \in \mathbb{M}^{n\times n}_s$).

The operator $\mathcal{A}$ is defined by the so-called tensor of elastic moduli $\mathbb{L} = \{\mathbb{L}_{ijkl}\}$, which satisfies the double inequality

$$\lambda_{\mathbb{L}} \,|\, \underline{\underline{\mathbf{e}}} \,|^2 \,\le\, \mathbb{L}\underline{\underline{\mathbf{e}}} \colon \underline{\underline{\mathbf{e}}} \,\le\, \Lambda_{\mathbb{L}} \,|\, \underline{\underline{\mathbf{e}}} \,|^2 \quad \forall \underline{\underline{\mathbf{e}}} \in \mathbb{M}^{n\times n}_s \tag{50}$$

and the symmetry and boundedness conditions

$$\mathbb{L}_{ijkl} = \mathbb{L}_{jikl} = \mathbb{L}_{klij}, \quad \mathbb{L}_{ijkl} \in L_\infty(\Omega). \tag{51}$$

Then, the norms $\|\!|\!| \cdot |\!|\!|$ and $\|\!|\!| \cdot |\!|\!|_*$ are defined as

$$\|\!|\!| \,\underline{\underline{\mathbf{y}}} \,|\!|\!|^2 = \int_\Omega \mathbb{L}\underline{\underline{\mathbf{y}}} \colon \underline{\underline{\mathbf{y}}}\, dx, \quad \|\!|\!| \,\underline{\underline{\mathbf{y}}} \,|\!|\!|^2_* = \int_\Omega \mathbb{L}^{-1}\underline{\underline{\mathbf{y}}} \colon \underline{\underline{\mathbf{y}}}\, dx \quad \forall \underline{\underline{\mathbf{y}}} \in \mathbf{Y}.$$

Inequality (3) is obviously satisfied, and (4) follows from the Korn inequality.

Assume now that $\mathbf{u}_0$ is some given function from $H^1(\Omega;\mathbb{R}^n)$ and that $\mathbf{f}$ is some given functional from $H^{-1}(\Omega;\mathbb{R}^n)$. Then, problem $(\mathcal{P})$ can be formulated as follows.

Find $\mathbf{u} \in V_0 + \mathbf{u}_0$ such that

$$\int_\Omega \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{u}) \colon \underline{\underline{\mathbf{e}}}(\mathbf{w})\, dx + \langle \mathbf{f}, \mathbf{w}\rangle = 0 \quad \forall \mathbf{w} \in V_0, \tag{52}$$

where $\langle \mathbf{f}, \mathbf{w}\rangle = \int_\Omega \mathbf{f}\cdot\mathbf{w}\, dx$. The corresponding mixed formulation of (52) defines the weak solution of the boundary-value problem of linear elasticity:

$$\underline{\underline{\mathbf{p}}} = \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{u}) \quad \text{in } \Omega, \tag{53}$$

$$\operatorname{div} \underline{\underline{\mathbf{p}}} = \mathbf{f} \quad \text{in } \Omega, \tag{54}$$

$$\mathbf{u} = \mathbf{u}_0 \quad \text{on } \partial\Omega. \tag{55}$$

We see that V is continuously embedded into the Hilbert space $U = L_2(\Omega;\mathbb{R}^n)$ and that inequality (25) holds true; hence, if we suppose the given body force $\mathbf{f} \in L_2(\Omega;\mathbb{R}^n)$, we can use the results of Theorem 3.4.

First, we note that the space $Y_{\mathcal{B}^*}$ is, in fact, the space $\mathbf{H}(\Omega;\operatorname{div}) := \{\underline{\underline{\mathbf{y}}} \in \mathbf{Y} \mid \operatorname{div} \underline{\underline{\mathbf{y}}} \in L_2(\Omega;\mathbb{R}^n)\}$ with the norm

$$\|\underline{\underline{\mathbf{y}}}\|_{\operatorname{div}} := \left(\|\!|\!| \,\underline{\underline{\mathbf{y}}} \,|\!|\!|^2_* + \|\operatorname{div} \underline{\underline{\mathbf{y}}}\|^2\right)^{1/2},$$

where $\|\cdot\|$ denotes the norm in $L_2(\Omega;\mathbb{R}^n)$.

The *full norm* then takes the form

$$\|(\mathbf{v}, \underline{\underline{\mathbf{y}}})\|_{1\times\operatorname{div}} := \left(\|\!|\!| \,\underline{\underline{\mathbf{e}}}(\mathbf{v}) \,|\!|\!|^2 + \|\!|\!| \,\underline{\underline{\mathbf{y}}} \,|\!|\!|^2_* + \|\operatorname{div} \underline{\underline{\mathbf{y}}}\|^2\right)^{1/2} \quad \forall (\mathbf{v}, \underline{\underline{\mathbf{y}}}) \in V_0 \times \mathbf{H}(\Omega;\operatorname{div}).$$

It is important to notice that, in the considered case, we have the inequality of type (29) that is a vector variant of the Friedrichs inequality, namely,

$$\|\mathbf{w}\| \,\le\, C_\Omega \,\|\underline{\underline{\mathbf{e}}}(\mathbf{w})\| \quad \forall \mathbf{w} \in V_0. \tag{56}$$

Thus, the constant $C_{\mathcal{B}}$ in (28) and in Theorem 3.4 is, in fact, the constant C_Ω from (56).

Remark. The constant C_Ω from (56) equals $1/\sqrt{\lambda_\Omega}$, where λ_Ω is the minimal eigenvalue of the vector-valued elliptic operator $\mathcal{L} : V_0 \to H^{-1}(\Omega;\mathbb{R}^n)$, $\mathcal{L}\mathbf{w} =$

$-\frac{1}{2}\left(\operatorname{div}(\nabla \mathbf{w}) + \nabla(\operatorname{div} \mathbf{w})\right)$ for any $\mathbf{w} \in V_0$, equipped with the zero Dirichlet boundary condition on $\partial\Omega$. The minimal eigenvalue λ_Ω can be estimated from below by one half of the sum of the minimal eigenvalues of the operators $\mathcal{L}_1 : V_0 \to H^{-1}(\Omega;\mathbb{R}^n)$, $\mathcal{L}_1\mathbf{w} = -\operatorname{div}(\nabla\mathbf{w}) = -\Delta\mathbf{w}$, and $\mathcal{L}_2 : V_0 \to H^{-1}(\Omega;\mathbb{R}^n)$, $\mathcal{L}_2\mathbf{w} = -\nabla(\operatorname{div}\mathbf{w})$. It is clear that the smallest eigenvalue of the second operator is zero, while the minimal eigenvalue of the first one equals the minimal eigenvalue of the scalar Laplace operator in Ω; the latter depends only on the geometry of the domain Ω and can be estimated from below by embedding Ω into a larger domain of a simpler shape, as discussed in Remark 3 at the end of section 4.1. This ultimately leads to an easily computable upper bound for the constant C_Ω from (56).

Hence, if $(\mathbf{u}, \underline{\underline{\mathbf{p}}}) \in (V_0 + \mathbf{u}_0) \times \mathbf{H}(\Omega;\operatorname{div})$ is the exact solution to the mixed problem (53)–(55) and $(\mathbf{v}, \underline{\underline{\mathbf{y}}}) \in (V_0 + \mathbf{u}_0) \times \mathbf{H}(\Omega;\operatorname{div})$ is any approximate solution to the problem, then the following a posteriori error estimates follow directly from Theorem 3.4:

$$\|(\mathbf{u}-\mathbf{v}, \underline{\underline{\mathbf{p}}} - \underline{\underline{\mathbf{y}}})\|_{1\times\operatorname{div}} \le \| \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{v}) - \underline{\underline{\mathbf{y}}} \|_* + \left(1 + 2\frac{C_\Omega^2}{\lambda_{\mathbb{L}}}\right)^{1/2} \|\operatorname{div}\underline{\underline{\mathbf{y}}} - \mathbf{f}\|, \tag{57}$$

$$\|(\mathbf{u}-\mathbf{v}, \underline{\underline{\mathbf{p}}} - \underline{\underline{\mathbf{y}}})\|_{1\times\operatorname{div}} \ge \frac{1}{\sqrt{3}}\left(\| \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{v}) - \underline{\underline{\mathbf{y}}} \|_* + \|\operatorname{div}\underline{\underline{\mathbf{y}}} - \mathbf{f}\|\right), \tag{58}$$

$$\| \underline{\underline{\mathbf{e}}}(\mathbf{u}-\mathbf{v}) \| \le \| \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{v}) - \underline{\underline{\mathbf{y}}} \|_* + \frac{C_\Omega}{\lambda_{\mathbb{L}}^{1/2}} \|\operatorname{div}\underline{\underline{\mathbf{y}}} - \mathbf{f}\|, \tag{59}$$

$$\| \underline{\underline{\mathbf{p}}} - \underline{\underline{\mathbf{y}}} \|_* \le \| \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{v}) - \underline{\underline{\mathbf{y}}} \|_* + \frac{C_\Omega}{\lambda_{\mathbb{L}}^{1/2}} \|\operatorname{div}\underline{\underline{\mathbf{y}}} - \mathbf{f}\|, \tag{60}$$

$$\|\underline{\underline{\mathbf{p}}} - \underline{\underline{\mathbf{y}}}\|_{\operatorname{div}} \le \| \mathbb{L}\underline{\underline{\mathbf{e}}}(\mathbf{v}) - \underline{\underline{\mathbf{y}}} \|_* + \left(1 + \frac{C_\Omega^2}{\lambda_{\mathbb{L}}}\right)^{1/2} \|\operatorname{div}\underline{\underline{\mathbf{y}}} - \mathbf{f}\|. \tag{61}$$

Estimates (57)–(61) provide sharp error bounds that are explicitly computable, if one has the approximate solution to problem (53)–(55) in the product space $(V_0 + \mathbf{u}_0) \times \mathbf{H}(\Omega;\operatorname{div})$. The construction of the approximation in this space can be done along the lines presented in the previous section for the case of a scalar elliptic problem.

NONCONFORMING BOX-SCHEMES FOR ELLIPTIC PROBLEMS ON RECTANGULAR GRIDS*

ISABELLE GREFF†

Abstract. Recently, Courbet and Croisille [*RAIRO Modél. Math. Anal. Numér.*, 32 (1998), pp. 631–649] introduced the finite volume box-scheme for the two-dimensional (2D) Poisson problem in the case of triangular meshes. Generalizations to higher degree box-schemes have been published by Croisille and Greff [*Numer. Methods Partial Differential Equations*, 18 (2002), pp. 355–373]. These box-schemes are based on the principle of the finite volume method in that they take the average of the equations on each cell of the grid. This gives rise to a natural choice of unknowns located at the interface of the mesh. These box-schemes are conservative and use only one mesh. They can be interpreted as a discrete mixed Petrov–Galerkin formulation of the Poisson problem. In this paper we focus our interest on box-schemes for the Poisson problem in two dimensions on rectangular grids. We discuss the basic finite volume box-scheme and analyze and interpret it as three different box-schemes. The method is demonstrated by numerical examples.

Key words. Petrov–Galerkin method, finite volume, mixed finite elements, elliptic problems, nonconforming spaces

1. Introduction.

The aim of this paper is to introduce several box-schemes for elliptic problems on rectangular grids based on the model of [6, 7, 8, 13]. The principle of the box-scheme we intend to discuss here in the case of rectangular grids goes back to H. B. Keller [17], where a box-scheme for the one-dimensional (1D) heat equation is introduced. In the case of an elliptic system, the principle of the box-schemes consists of discretizing the mixed form of the equation, by taking the average of the conservation and the constitutive laws on the same grid, without any integration by part. In a sense, it is the most natural way to discretize a system in mixed form, very close to the physical setting of the equation. The finite element counterpart of that point of view is a Petrov–Galerkin formulation with two trial spaces and two test spaces. A comprehensive understanding of this kind of scheme has been introduced in [6, 7, 8] in the case of a triangular mesh. We also refer the reader to [21] for finite volume methods and their relations with Petrov–Galerkin formulation. It is the main purpose of this paper to understand the nature of the coupling between all the spaces involved, with a particular emphasis on the identification of the spurious modes typical of rectangular grids. It is hoped that this can be useful also for more standard schemes.

Here, we consider a rectangular domain $\Omega \subset \mathbb{R}^2$ covered by a regular grid $\mathcal{T}_h$ of rectangles with edges parallel to those of the domain. For the simplicity of the presentation and since we focus on the design principles of different box-schemes, we restrict ourselves to the Poisson problem $-\Delta u = f$ for $f \in L^2(\Omega)$ with homogeneous boundary conditions. The mixed form we consider is as follows: Find $(u, p) \in H_0^1(\Omega) \times$

$H_{\mathrm{div}}(\Omega)$ such that

$$\begin{cases} (\operatorname{div} p + f, v)_{0,\Omega} = 0 \quad \text{for all } v \in L^2(\Omega), \\ (p - \nabla u, q)_{0,\Omega} = 0 \quad \text{for all } q \in (L^2(\Omega))^2, \end{cases} \tag{1}$$

where $H_{\mathrm{div}}(\Omega) = \{p \in (L^2(\Omega))^2 \,;\, \operatorname{div} p \in L^2(\Omega)\}$. As in [6, 8], the discretization of (1) is performed by a mixed Petrov–Galerkin scheme called a box-scheme. It involves four discrete spaces: $M_{1,h}, X_{1,h}$ as trial spaces and $M_{2,h}, X_{2,h}$ as test spaces. The box-scheme reads as follows: Find $(u_h, p_h) \in M_{1,h} \times X_{1,h}$ such that

$$\begin{cases} \displaystyle\sum_{K \in \mathcal{T}_h} (\operatorname{div} p_h + f, v_h)_{0,K} = 0 \quad \text{for all } v_h \in M_{2,h}, \\ \displaystyle\sum_{K \in \mathcal{T}_h} (p_h - \nabla u_h, q_h)_{0,K} = 0 \quad \text{for all } q_h \in X_{2,h}. \end{cases} \tag{2}$$

The uniqueness of the solution of (2) implies in particular the identity of the dimensions

$$\dim M_{1,h} + \dim X_{1,h} = \dim M_{2,h} + \dim X_{2,h}. \tag{3}$$

The starting point of this article is the paper [5] by Courbet, where an original algebraic box-scheme on quadrangles is introduced for the time dependent diffusive problem. We give a finite element interpretation of that scheme with three different box-schemes; this allows us to state its stability and accuracy properties. As is the case on a triangular mesh, a natural choice for the approximation of the flux p_h is the lowest order Raviart–Thomas space. For the unknown u_h three possible choices are the standard Q^1-Lagrange space, its nonconforming analogue, Q^1_{nc}, or the so-called P^1-nonconforming quadrilateral finite element, introduced by Park and Sheen [19]. Due to the properties of the different trial spaces, we can make the link between these three box-schemes explicit. An important characteristic of these box-schemes is their equivalence with a decoupled formulation in the unknowns u_h and p_h. This allows the computation of the discrete flux p_h in an inexpensive way, since it is given as a function of ∇u_h and the right-hand side f. This local reconstruction of the flux p_h in each cell is of particular interest for porous media problems, e.g., contaminant transport, where the velocity is computed by the Darcy law and introduced in a convection-diffusion equation for the computation of the concentration. This decoupled feature of the box-scheme extends the observation by Marini [18], that the flux in the mixed finite element method can be recovered in an inexpensive way. Concerning the a posteriori error estimates of the box-scheme, we refer the reader to the recent works by El Alaoui and Ern [10, 11]. Finally, let us mention that an increasing interest in box-schemes has recently appeared [3, 4]. Note that a different possibility for extending the box-scheme of [6] on rectangles, using the Rannacher–Turek nonconforming finite element space, has been studied in [3, 14, 15].

Let us give now some standard notation. We introduce the mesh dependent norms defined, respectively, on the mesh dependent spaces $H^1_0(\Omega)+M_{1,h}$ and $H_{\mathrm{div}}(\Omega)+X_{1,h}$:

$$|u|_{1,h} = \left(\sum_K |\nabla u|^2_{0,K} \right)^{1/2},$$

$$\|u\|_{1,h} = (|u|^2_{0,\Omega} + |u|^2_{1,h})^{1/2} \quad \text{for all } u \in H^1_0(\Omega) + M_{1,h},$$

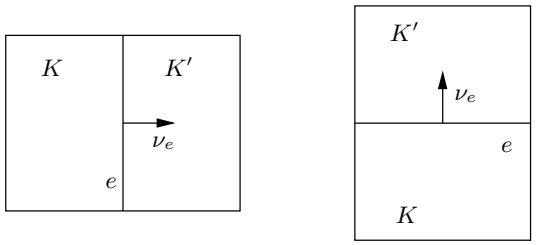

FIG. 1. *Vertical and horizontal edges.*

$$|p|_{\mathrm{div},h} = \left(\sum_K |\mathrm{div}\, p|^2_{0,K} \right)^{1/2},$$
$$\|p\|_{\mathrm{div},h} = (|p|^2_{0,\Omega} + |p|^2_{\mathrm{div},h})^{1/2} \quad \text{for all } p \in H_{\mathrm{div}}(\Omega) + X_{1,h}.$$

The geometrical notation is as follows. The rectangles are denoted by K with center $G_K(x_K, y_K)$, area $|K|$, and diameter h_K. We denote by h the maximum of the diameters of the elements of the mesh. The sizes of the sides of the rectangle K are $|e_{x,K}|$ and $|e_{y,K}|$. We will write ∂K for the set of edges of K. Let ν be the unit outward normal vector along the boundary $\partial\Omega$ and ν_K the one along the boundary ∂K of the rectangle K. The unitary normal vector to an edge e on the boundary $\partial\Omega$ is simply $\nu_e = \nu$. To each interior edge $e = \partial K \cap \partial K'$, we also associate a unit normal vector ν_e, which is arbitrarily defined as $\nu_e = \nu_K$ and $\nu_e = -\nu_{K'}$ in accordance with Figure 1. For an interior edge $e = \partial K \cap \partial K'$, $[u]_e = u_{|K',e} - u_{|K,e}$ denotes the jump of u along e with respect to the normal along the edge e. The midpoint of an edge e is x_e. The sets $\mathcal{A}_i$ and $\mathcal{A}_b$ denote the internal and boundary edges, respectively. We define $\mathcal{A} = \mathcal{A}_i \cup \mathcal{A}_b$ to be the set of all edges with global numbering. The number of rectangles is *NE*. The number of edges (respectively, internal, boundary edges) is *NA* (respectively, NA_i, NA_b). The number of vertices (respectively, internal, boundary vertices) is *NV* (respectively, NV_i, NV_b). The Euler relations are

$$4NE = NA_i + NA \quad \text{and} \quad NE - NA + NV = 1. \tag{4}$$

The gradient of f is $\nabla f = (\partial_x f, \partial_y f)^T$ and the two-dimensional (2D) rotational is $\mathrm{curl}\, f = (\partial_y f, -\partial_x f)^T$. Let P^0 be the space of piecewise constant functions, P^1 be the space of piecewise affine functions, and Q^1 be the space of bilinear functions. We define Π^0 to be the L^2-projection operator on the piecewise constant functions. Let us recall the definition of RT^0, the lowest order space of Raviart and Thomas [20], useful to discretize the flux $p = \nabla u$:

$$RT^0 = \{q_h \in H_{\mathrm{div}}(\Omega)\,;\, q_h \in RT^0(K) \quad \text{for all } K \in \mathcal{T}_h\},$$

where the local space $RT^0(K)$ is

$$RT^0(K) = P^0(K)^2 + P^0(K) \begin{pmatrix} x \\ 0 \end{pmatrix} + P^0(K) \begin{pmatrix} 0 \\ y \end{pmatrix}.$$

The space RT^0 is of dimension *NA*, the degrees of freedom being given by the linear forms

$$L_a(q_h) = \frac{1}{|a|} \int_a q_h \cdot \nu_a \, d\sigma \quad \text{for all } a \in \mathcal{A}.$$

Note that the normal component $p_h \cdot \nu_a$ of p along each interior edge is constant.

The outline of the paper is as follows. In section 2, we recall briefly the design principles of Courbet's scheme. To interpret it as a finite element method, we introduce in section 3 a finite element box-scheme based on the space used by Courbet to approximate the unknown u and the standard Q^1-Lagrange finite element space. The approximation of the flux $p = \nabla u$ is done using the Raviart–Thomas space. However, this box-scheme seems to be unstable. In section 4 we build a new box-scheme generalizing the previous one and based on the inclusion of the space Q^1-Lagrange into the nonconforming Q^1 space, Q^1_{nc}. Both unknowns u and p are discretized in nonconforming spaces with respect to $H^1_0(\Omega)$ and $H^1_{\mathrm{div}}(\Omega)$. We perform the numerical analysis of the scheme and its equivalence to a decoupled problem in u_h and p_h: a nonconforming scheme in u_h and a local reconstruction formula of p_h. Consequently, we can make explicit the link to the box-scheme of section 3. It turns out that the solution u_h of the box-scheme is only affine (and not bilinear) per rectangle. Section 5 is devoted to the development and the analysis of a reduced box-scheme. We conclude this work with numerical results in section 6. Note that this paper has been presented partly in [13, 14].

2. Courbet's box-scheme.

2.1. Introduction. In [5], Courbet introduced a box-scheme for the time dependent mixed formulation of the compressible Navier–Stokes equations. The scheme intended to extend to a rectangular grid the well-known box-scheme of H. B. Keller for the heat equation [17]. In the case of the Poisson problem, the box-scheme of Courbet is a derivation of the mixed form of the problem taken as mean value on each rectangle K:

$$\begin{cases} \displaystyle\int_K \operatorname{div} p \, dx + \int_K f \, dx = 0, \\ \displaystyle\int_K p \, dx - \int_K \nabla u \, dx = 0, \\ u = 0 \text{ on } \partial\Omega. \end{cases} \tag{5}$$

We refer to the Courbet box-scheme later as (BS1): Find $u = (u_a)_{a\in\mathcal{A}}$ and $p = (p_a)_{a\in\mathcal{A}}$ such that for all rectangles K of the grid,

$$\text{(BS1)} \quad \begin{cases} \displaystyle\sum_{a\in\partial K} |a|\, p_{a,K} + \int_K f \, dx = 0, \\ \displaystyle\frac{(p_{a_{1,K}} - p_{a_{3,K}})}{2} - \frac{(|a_{1,K}| u_{a_{1,K}} - |a_{3,K}| u_{a_{3,K}})}{|K|} = 0, \\ \displaystyle\frac{(p_{a_{2,K}} - p_{a_{4,K}})}{2} - \frac{(|a_{2,K}| u_{a_{2,K}} - |a_{4,K}| u_{a_{4,K}})}{|K|} = 0, \\ u_a = 0 \quad \text{for all } a \in \mathcal{A}_b, \end{cases} \tag{6}$$

where the subscripts $a_{1,K}$, $a_{2,K}$, $a_{3,K}$, and $a_{4,K}$ are related to the edges $a_{1,K}$, $a_{2,K}$, $a_{3,K}$, and $a_{4,K}$ of each rectangle K (see Figure 2). The unknowns u_a and p_a denote, respectively, the average of u and the normal component of the flux $p = \nabla u$ along an edge a and are located at the interface of the mesh. This gives $4NE$ unknowns and $3NE$ equations. In contrast to the analogous scheme on triangles introduced in [6], here is a lack of NE equations. Courbet suggests adding the constraint on each

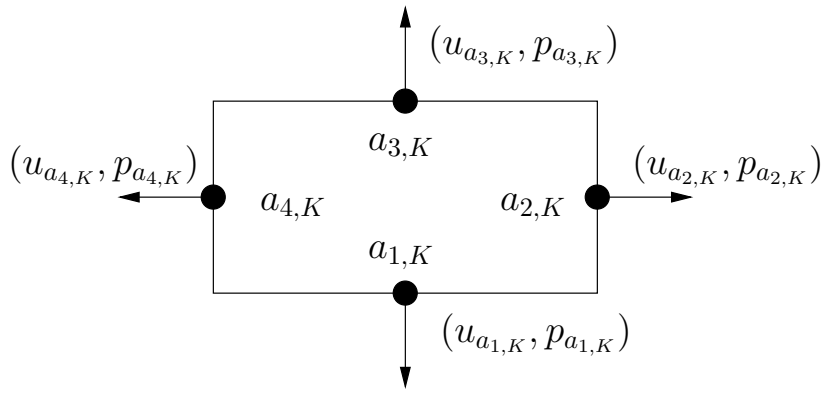

FIG. 2. *Rectangle K, with edges $a_{i,K}$ and unknowns $(u_{a_{i,K}}, p_{a_{i,K}})$ for $i = 1, \ldots, 4$.*

rectangle K as a discrete equation:

$$u_{a_{1,K}} + u_{a_{3,K}} = u_{a_{2,K}} + u_{a_{4,K}}. \tag{7}$$

In particular, the mean value of the solution u in each box coincides with its horizontal and vertical averages. Let us denote by C_0 the space introduced by Courbet to discretize the unknown u. It is generated by vectors of size NA, vanishing at the boundary, and satisfying the additional condition (7) on each rectangle of the grid. The space C_0 is defined by

$$\begin{aligned} C_0 = \big\{ (u_a)_{a\in\mathcal{A}} \in \mathbb{R}^{NA} \text{ such that } u_a = 0 \text{ for all } a \in \mathcal{A}_b \text{ and} \\ u_{a_{1,K}} + u_{a_{3,K}} = u_{a_{2,K}} + u_{a_{4,K}} \text{ on each rectangle } K \big\} \\ = \big\{ (u_a)_{a\in\mathcal{A}_i} \in \mathbb{R}^{NA_i},\ u_{a_{1,K}} + u_{a_{3,K}} = u_{a_{2,K}} + u_{a_{4,K}} \text{ on each rectangle } K \big\}. \end{aligned}$$

However, the dimension of the space C_0 is $\dim C_0 = NV_i = NA_i - NE + 1 > NA_i - NE$. Indeed, the boundary degrees of freedom of the space C_0 are not independent. In fact, if $u_a = 0$ for $NA_b - 1$ boundary edges, then $u_a = 0$ holds on the last one. This implies that the box-scheme (BS1) does not define a well-posed problem in the sense that the number of unknowns is larger than the number of equations. Actually, due to the dimension of the space C_0, the number of unknowns is: Number of unknowns $(u_a, p_a) = NV_i + NA = 3NE + 1$, whereas there are only $3NE$ equations. Despite this dimension inconsistency, very good numerical results are reported in [5] for the time dependent heat equation.

The observation that $\dim C_0 = NV_i$ suggests that the space C_0 is identical to the Q^1-Lagrange space with homogeneous boundary conditions.

LEMMA 2.1. *The mapping L defines a bijection between $Q^1_{c,0}$ and the Courbet space*

$$\begin{aligned} L :\ Q^1_{c,0} &\longrightarrow C_0, \\ u &\longmapsto \big(u(x_a)\big)_{a\in\mathcal{A}}, \end{aligned}$$

where x_a denotes the midedge of a and Q^1_c is the standard Q^1-Lagrange finite element space

$$Q^1_c = \{u \in \mathcal{C}^0(\Omega)\,;\, u \in Q^1(K) \text{ for all } K \in \mathcal{T}_h\}, \quad Q^1(K) = \mathrm{Span}\{1, x, y, xy\},$$

and $Q^1_{c,0}$ is its restriction to functions vanishing on $\partial\Omega$.

The proof of the lemma follows from the linearity, injectivity (see Proposition 2.1 hereafter) of the mapping L, and the equality of the dimensions of the spaces C_0 and $Q^1_{c,0}$. Before going further with the stabilization of the box-scheme (BS1), we recall some useful properties of the nonconforming Q^1 finite element space and its relation to Q^1_c.

2.2. Some properties of the Q^1 nonconforming space. The nonconforming Q^1 finite element space denoted by Q^1_{nc} is defined by

$$Q^1_{nc} = \Big\{ u_h \in L^2(\Omega)\,;\, u_h \in Q^1(K) \text{ for all } K \in \mathcal{T}_h; \\ \int_a u_{h|K_1}\, d\sigma = \int_a u_{h|K_2}\, d\sigma \text{ for all } a = \partial K_1 \cap \partial K_2 \in \mathcal{A}_i \Big\}.$$

The space $Q^1_{nc,0}$ is the zero boundary space:

$$Q^1_{nc,0} = \Big\{ u_h \in Q^1_{nc}\,;\, \int_a u_h\, d\sigma = 0 \text{ for all } a \in \mathcal{A}_b \Big\}.$$

Since the edges of the grid are parallel to the axis of the domain, the mean value of a function in Q^1 along an edge is the value at the midpoint of the edge. We recall that for all $v_h \in Q^1_{nc}$, the set of values

$$p_a(v_h) = v_h(x_a) \text{ for all } a \in \mathcal{A} \text{ with the associated midpoint } x_a$$

does not form a unisolvent set of degrees of freedom [1, 2, 12]. Indeed, let η be the function defined on $Q^1(K)$ by

$$\eta :\, Q^1(K) \longrightarrow \mathbb{R}^4, \\ p \longmapsto \big(p(x_a)\big)_{a\in\partial K}.$$

It is well known that the kernel of η is of dimension 1, generated by the nonconforming bubble b_K,

$$\operatorname{Ker}\eta = \operatorname{Span}\{b_K\}, \quad b_K(x,y) = \frac{4}{|K|}(x - x_K)(y - y_K),$$

where (x_K, y_K) is the center of the rectangle K. It is easy to check that for any $K \in \mathcal{T}_h$ and any $v \in Q^1(K)$, the function b_K has the following properties:

$$\int_{\partial K} b_K\, d\sigma = 0, \qquad \int_K \operatorname{curl} b_K \cdot \nabla v\, dx = 0, \\ \int_{\partial K} (\operatorname{curl} b_K \cdot \nu_K)\, v\, d\sigma = 0. \tag{8}$$

Let Ψ be the vector space generated by the local bubbles:

$$\Psi = \{\psi\,;\, \psi_{|K} = \alpha_K b_K,\, \alpha_K \in \mathbb{R} \text{ for all } K \in \mathcal{T}_h\}.$$

Then, $\dim \Psi = NE$ and $\Psi \subseteq Q^1_{nc,0}$.

DEFINITION 2.1. *We define $\mathcal{B} \in Q^1_c$ by $\mathcal{B} = \sum_{K\in\mathcal{T}_h} \operatorname{sgn}(K) b_K$, where $\operatorname{sgn}(K)$ takes alternately the values -1, $+1$ as displayed in Figure 3.*

−	+	−	+	−
+	−	K	−	+
−	+	−	+	−

FIG. 3. *Sign of K.*

The function $\mathcal{B}$ is the so-called *hourglass mode* introduced by Hansbo in [16], which gives rise to some instability. By using this definition and the properties of the previous spaces, we prove the following proposition.

PROPOSITION 2.1. *The spaces Q_c^1, Q_{nc}^1, and Ψ satisfy*

$$\text{(i)}\quad Q_c^1 \cap \Psi = \mathrm{Span}\{\mathcal{B}\}, \quad \text{(ii)}\quad Q_{nc}^1 = Q_c^1 + \Psi, \quad \text{(iii)}\quad Q_{nc,0}^1 = Q_{c,0}^1 \oplus \Psi.$$

In particular, $\dim Q_{nc}^1 = NA$ *and* $\dim Q_{nc,0}^1 = NA_i + 1$.

Proof. (i) Let $\psi = \sum_{K\in\mathcal{T}_h} \alpha_K b_K \in Q_c^1 \cap \Psi$. For an internal edge $a = \partial K_1 \cap \partial K_2$ the bubble satisfies $b_{K_1}|_a = -b_{K_2}|_a$. Then, the continuity of ψ along each internal edge implies $\alpha_K = \mathrm{sgn}(K)\,\alpha$ for all $K \in \mathcal{T}_h$, $\alpha \in \mathbb{R}$. So, $\mathrm{Span}\{\mathcal{B}\} \subset Q_c^1 \cap \Psi$. The reverse inclusion is clear.

(ii) Let us define the space $M = Q_c^1 + \Psi$. Then, $M \subseteq Q_{nc}^1$. To prove $M = Q_{nc}^1$, we will prove that $\dim M = \dim Q_{nc}^1$. Let i be the linear map

$$\begin{aligned} i :\, Q_{nc}^1 &\longrightarrow \mathbb{R}^{NA}, \\ u &\longmapsto \big(u(x_a)\big)_{a\in\mathcal{A}}, \end{aligned}$$

where x_a is the midpoint of the edge $a \in \mathcal{A}$. Using the definitions of Ψ and b_K, we prove that

$$\mathrm{Ker}\, i = \Big\{ u \in Q_{nc}^1 ;\, u(x_a) = 0 \text{ for all } a \in \mathcal{A} \Big\} \subseteq \Psi,$$

and according to the notation of Figure 2, where $x_{a_{i,K}}$ is the midpoint of the edge $a_{i,K} \in \partial K$, $i = 1, \ldots, 4$,

$$\mathrm{Im}\, i = \Big\{ \big(u(x_a)\big)_{a\in\mathcal{A}} \in \mathbb{R}^{NA} ;\, u(x_{a_{1,K}}) + u(x_{a_{3,K}}) = u(x_{a_{2,K}}) + u(x_{a_{4,K}}) \text{ for all } K \in \mathcal{T}_h \Big\}.$$

This in turn gives that $\dim Q_{nc}^1 = \dim(\mathrm{Ker}\, i) + \dim(\mathrm{Im}\, i) \le NA$. Moreover, $\dim M = \dim Q_c^1 + \dim \Psi - \dim(Q_c^1 \cap \Psi) = NV + NE - 1$. The Euler relation gives $\dim M = NA$. $M \subseteq Q_{nc}^1$, so $\dim M \le \dim Q_{nc}^1$. We deduce that $\dim Q_{nc}^1 = NA$, which concludes the proof of (ii).

The statement (iii) is directly implied by (i) and (ii). ∎

Using the property of $\mathcal{B}$ and the continuity of the normal component of the element in RT^0, we deduce the following lemma.

LEMMA 2.2. *Let Φ be the vector space generated by the curl of the nonconforming bubble*

$$\Phi = \mathrm{curl}\, \Psi = \left\{ \phi = \sum_{K\in\mathcal{T}_h} \beta_K\, \mathrm{curl}\, b_K, \quad \beta_K \in \mathbb{R} \right\}.$$

Then, $\Phi \cap RT^0 = \mathrm{Span}\{\mathrm{curl}(\mathcal{B})\}$.

Note that the box-scheme (BS1) is a derivation of the mixed formulation of the Laplace equation on each rectangle K given by the system (5). Since $\int_K \mathrm{curl}\, b_K\, dx = 0$ and $\mathrm{div}(\mathrm{curl}\, b_K) = 0$ we get from the mixed formulation (5) that for any β_K, we can superpose to p_h any function $\sum_K \beta_K \,\mathrm{curl}\, b_K$, which is a parasitic mode. Therefore a stabilization of the scheme has to eliminate that mode.

3. A first stabilization of Courbet's box-scheme. We will now give a first stabilization of the box-scheme (BS1) using the finite element interpretation of the space C_0 coupled with the Raviart–Thomas space RT^0 in order to discretize the unknowns (u, p). We also need to add one additional test function in order to have the right number of equations. The element $\mathcal{B}$ is the simplest choice according to results of the previous section.

PROPOSITION 3.1. *Let us call* (BS2) *the box-scheme: Find the solution* $(u_h, p_h) \in Q^1_{c,0} \times RT^0$ *of*

$$\text{(BS2)} \quad \begin{cases} (\mathrm{div}\, p_h + f, v_h)_{0,\Omega} = 0 & \text{for all } v_h \in P^0, \\ (p_h - \nabla u_h, q_h)_{0,\Omega} = 0 & \text{for all } q_h \in X_{2,h} = (P^0)^2 + \mathrm{Span}\{\mathrm{curl}(\mathcal{B})\}. \end{cases} \tag{9}$$

(i) *The box-scheme* (BS2) *has* $3NE + 1$ *unknowns.*

(ii) *The box-scheme* (BS2) *has a unique solution given by*

(a) $u_h \in Q^1_{c,0}$ *is the solution of*

$$\sum_{K \in \mathcal{T}_h} (\Pi^0 \nabla u_h, \Pi^0 \nabla v_h)_{0,K} = (\Pi^0 f, v_h)_{0,\Omega} \quad \text{for all } v_h \in Q^1_{c,0}. \tag{10}$$

(b) p_h *is given by*

$$p_{h|K} = (\Pi^0 \nabla u_h)_K - \frac{\Pi^0 f_{|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix} + \gamma_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}, \tag{11}$$

where γ_K *is the solution of a certain sparse linear system.*

Proof. (i) Using the Euler relation, we get the following identity between the number of unknowns and the number of equations:

$$\dim Q^1_{c,0} + \dim RT^0 = NV_i + NA = 3NE + 1 = \dim P^0 + \dim (X_{2,h}).$$

(ii) Let $(u_h, p_h) \in Q^1_{c,0} \times RT^0$ be a solution of (BS2). We prove that (u_h, p_h) satisfies the system ((a), (b)).

(a) Suppose we are given $v_h \in Q^1_{c,0}$; then $q_h = \Pi^0(\nabla v_h) \in X_{2,h}$. Introducing this value of q_h in the second equation of (9) and afterward using the decomposition $\nabla v_{h|K} = \Pi^0 \nabla v_{h|K} + \delta_K \nabla b_K$ for any $\delta_K \in \mathbb{R}$ and Green's formula, we get

$$\begin{aligned} \sum_K (\nabla u_h, \Pi^0 \nabla v_h)_{0,K} &= \sum_K (p_h, \Pi^0 \nabla v_h)_{0,K} \\ &= \sum_K (p_h, \nabla v_h - \delta_K \nabla b_K)_{0,K} \\ &= -\sum_K \int_K \mathrm{div}\, p_h\, v_h\, dx + \sum_K \int_{\partial K} v_h\, p_h \cdot \nu_K\, d\sigma \\ &\quad + \sum_K \int_K \delta_K \,\mathrm{div}\, p_h\, b_K\, dx - \sum_K \int_{\partial K} p_h \cdot \nu_K\, \delta_K\, b_K\, d\sigma. \end{aligned} \tag{12}$$

Since the mean value of the bubble function b_K vanishes and $p_h \in RT^0$, we have that $\int_K \delta_K \operatorname{div} p_h \, b_K \, dx = 0$ and $\int_{\partial K} p_h \cdot \nu_K \, \delta_K \, b_K \, d\sigma = 0$. On the other hand, the first equation of (9) gives $\operatorname{div} p_{h|K} = -\Pi^0 f_{|K}$ for all $K \in \mathcal{T}_h$. Therefore, the equality (12) becomes

$$\begin{aligned}\sum_K (\nabla u_h, \Pi^0 \nabla v_h)_{0,K} = \sum_K \int_K \Pi^0 f v_h \, dx - \sum_{a \in \mathcal{A}_i} \int_a p_h \cdot \nu_a \, [v_h]_a \, d\sigma \\ + \sum_{a \in \mathcal{A}_b} \int_a p_h \cdot \nu_a \, v_h \, d\sigma.\end{aligned} \tag{13}$$

Since $v_h \in Q^1_{c,0}$, $[v_h]_a = 0$ for all $a \in \mathcal{A}_i$ and $v_{h|a} = 0$ for all $a \in \mathcal{A}_b$, the relation (13) becomes

$$\sum_K (\nabla u_h, \Pi^0 \nabla v_h)_{0,K} = \sum_K (\Pi^0 f, v_h)_{0,K},$$

which concludes (a).

(b) Any function p_h in $RT^0(K)$ can be decomposed as

$$p_{h|K} = (\Pi^0 p_h)_{|K} + \frac{\operatorname{div} p_{h|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix} + \gamma_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}, \quad \gamma_K \in \mathbb{R}.$$

Using, respectively, the first and second equations of (9), we get $\operatorname{div} p_{h|K} = -\Pi^0 f_{|K}$ and $(\Pi^0 p_h)_{|K} = (\Pi^0 \nabla u_h)_{|K}$. Then

$$p_{h|K} = (\Pi^0 \nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix} + \gamma_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}. \tag{14}$$

The computation of the coefficient γ_K is done using (a), the second equation of (9) with $q_h = \sum_K \operatorname{sgn}(K) \operatorname{curl} b_K$, and the continuity of the normal component of p_h. More details can be found at the end of this paper in the appendix.

This implies that any solution of the box-scheme (BS2) is a solution of the system ((a), (b)), which is unique. Indeed, $f = 0$ in (a) implies $\Pi^0 \nabla u_h = 0$. Lemma A.3 (see the appendix) and the zero values of u_h on $\partial\Omega$ permit us to conclude that $u_h = 0$. Replacing $f = 0$ and $u_h = 0$ in (11) implies $p_{h|K} = \gamma_K$. Proposition A.1 gives $\big(\gamma_K\big)_K$ as the solution of a linear system with a vanishing right-hand side. This means that $\gamma_K = 0$ for all K, and therefore $p_h = 0$. This concludes that $f = 0$ implies $u_h = 0$, $p_h = 0$. The existence of solutions of (BS2) is deduced from the uniqueness of the solution, the linearity of the problem, and the equality between the number of unknowns and equations. □

Remarks. (i) As proved by Hansbo [16], the one-point integration of the gradient of u_h (Proposition 3.1(ii)) is not sufficient to obtain the stability of the scheme.

(ii) The parasitic perturbation $\sum_K \beta_K \operatorname{curl} b_K \in \Phi$ seems to be controlled globally by the box-scheme but not locally. As a consequence, we do not get a local reconstruction of the flux p_h in each rectangle K.

4. A second stabilization of Courbet's box-scheme. Due to its possible instability, the box-scheme (BS2) is not totally satisfying. So, we want to build a box-scheme using larger spaces for both unknowns u and p. The basic idea is to use the nonconforming space $Q^1_{nc,0}$ containing the Q^1-Lagrange space $Q^1_{c,0}$ (used in (BS2)) for the approximation of u. For the flux, we consider the space RT^0 of Raviart

and Thomas, supplemented with the space Φ of the rotational of the bubble. Note that those spaces are both nonconforming, respectively, in $H_0^1(\Omega)$ and $H_{\mathrm{div}}(\Omega)$. Also this choice of spaces gives the advantage of getting the number of unknowns to be proportional to the number of rectangles; i.e., the trial spaces in (2) can be piecewise polynomial spaces.

4.1. Definition of the box-scheme.

PROPOSITION 4.1. *Let (BS_{nc}) be the following box-scheme: Find $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$, being the solution of*

(15)
$$(BS_{nc}) \quad \begin{cases} \displaystyle\sum_{K\in\mathcal{T}_h} (\operatorname{div} p_h + f, v_h)_{0,K} = 0 \text{ for all } v_h \in M_{2,h} = P^0, \\ \displaystyle\sum_{K\in\mathcal{T}_h} (p_h - \nabla u_h, q_h)_{0,K} = 0 \text{ for all } q_h \in X_{2,h} = (P^0)^2 + P^0 \begin{pmatrix} y \\ x \end{pmatrix} + P^0 \begin{pmatrix} x \\ -y \end{pmatrix}. \end{cases}$$

(i) *The box-scheme (BS_{nc}) has $5NE$ degrees of freedom.*

(ii) *The box-scheme (BS_{nc}) has a unique solution $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$ given by the following:*

(a) *u_h is the solution of the following variational problem: Find $u_h \in Q^1_{nc,0}$ such that*
$$\sum_{K\in\mathcal{T}_h} (\nabla u_h, \nabla v_h)_{0,K} = (\Pi^0 f, v_h)_{0,\Omega} \quad \text{for all } v_h \in Q^1_{nc,0}.$$

(b) *p_h is locally given by*
$$p_{h|K} = (\nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{|e_{x,K}|^2 + |e_{y,K}|^2} \begin{pmatrix} |e_{y,K}|^2 (x - x_K) \\ |e_{x,K}|^2 (y - y_K) \end{pmatrix}.$$

Note that this box-scheme is nonconforming for both unknowns u_h and p_h. The test spaces $M_{2,h}$ and $X_{2,h}$ (in the system (2)) are piecewise polynomial functions. We remark that $X_{2,h}$ is also $X_{2,h} = (P^0)^2 + P^0(\nabla b_K) + P^0(\operatorname{curl} b_K)$; in particular, $\nabla(M_{1,h}) \subseteq X_{2,h}$.

Proof. (i) By the Euler relations, we prove that $\dim Q^1_{nc,0} + \dim (RT^0 + \Phi) = (NA_i + 1) + (NA + NE - 1) = 5\,NE = \dim X_{2,h} + \dim P^0$.

(ii) Let us prove that any $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$ satisfying the equations (BS_{nc}) fulfills the system ((a), (b)).

(a) Let $v_h \in Q^1_{nc,0}$. Let $q_h = \nabla v_h \in X_{2,h}$ in the second equation of (15). By integration by parts,
$$\sum_K (\nabla u_h, \nabla v_h)_{0,K} = -\sum_K \int_K \operatorname{div} p_h \, v_h \, dx + \sum_K \int_{\partial K} (p_h \cdot \nu_K) \, v_h \, d\sigma.$$
Moreover, since $\operatorname{div} p_{h|K} \in P^0(K)$, the first equation of (15) gives $\operatorname{div} p_{h|K} = -\Pi^0 f_{|K}$. Hence, $p_h \in RT^0 + \Phi$ can be written as $p_h = \bar{p}_h + \sum_K \beta_K \operatorname{curl} b_K$, with $\bar{p}_h \in RT^0$. This implies that
$$\begin{aligned} \sum_K (\nabla u_h, \nabla v_h)_{0,K} &= \sum_K (\Pi^0 f, v_h)_{0,K} + \sum_K \int_{\partial K} (\bar{p}_h + \beta_K \operatorname{curl} b_K) \cdot \nu_K \, v_h \, d\sigma \\ &= (\Pi^0 f, v_h)_{0,\Omega} + \sum_K \int_{\partial K} \bar{p}_h \cdot \nu_K \, v_h \, d\sigma \\ &\quad + \sum_K \int_{\partial K} \beta_K \operatorname{curl} b_K \cdot \nu_K \, v_h \, d\sigma. \end{aligned}$$

Using the properties (8) of the bubble b_K and the continuity of the normal component of elements $p_h \in RT^0 \subset H_{\mathrm{div}}(\Omega)$, we obtain

$$\sum_K (\nabla u_h, \nabla v_h)_{0,K} = (\Pi^0 f, v_h)_{0,\Omega} + \sum_{a\in\mathcal{A}_b} \int_a \bar{p}_h \cdot \nu_a \, v_h \, d\sigma - \sum_{a\in\mathcal{A}_i} \int_a \bar{p}_h \cdot \nu_a \, [v_h]_a \, d\sigma.$$

Since $v_h \in Q^1_{nc,0}$ and $p_h \cdot \nu_a \in P^0(a)$,

$$\int_a \bar{p}_h \cdot \nu_a \, v_h \, d\sigma = 0 \quad \text{for all } a \in \mathcal{A}_b \quad \text{and} \quad \int_a \bar{p}_h \cdot \nu_a \, [v_h]_a \, d\sigma = 0 \quad \text{for all } a \in \mathcal{A}_i,$$

which concludes (a). In particular, for $v_h = b_K \in Q^1_{nc,0}$,

$$(\nabla u_h, \nabla b_K)_{0,K} = (\Pi^0 f, b_K)_{0,K}.$$

The mean value of b_K equals zero on each rectangle; hence $(\Pi^0 f, b_K)_{0,K} = 0$. Also, ∇u_h is locally written as $(\nabla u_h)_{|K} = (\Pi^0 \nabla u_h)_{|K} + d_K \nabla b_K$, where d_K is given by u_h. We deduce that

$$\begin{aligned} 0 = (\nabla u_h, \nabla b_K)_{0,K} &= \big((\Pi^0 \nabla u_h)_{|K} + d_K \nabla b_K, \nabla b_K\big)_{0,K} \\ &= \underbrace{\big((\Pi^0 \nabla u_h)_{|K}, \nabla b_K\big)_{0,K}}_{=0} + d_K |\nabla b_K|^2_{0,K}. \end{aligned}$$

This means that $d_K = 0$ or, equivalently, that the bubble component of the solution u_h vanishes. In particular, $(\nabla u_h)_{|K} = (\Pi^0 \nabla u_h)_{|K}$.

(b) Since $p_h \in RT^0 + \Phi$, we have $p_h = \bar{p}_h + \sum_K \beta_K \operatorname{curl} b_K$ with $\bar{p}_h \in H_{\mathrm{div}}(\Omega)$. Again for each rectangle K, $\operatorname{div} p_{h|K} = -\Pi^0 f_{|K}$ and $\operatorname{div}(\operatorname{curl} b_K) = 0$, so that

$$\operatorname{div} p_h = \operatorname{div} \bar{p}_h = -\Pi^0 f.$$

The second equation of (15) implies that $(\Pi^0 p_h)_{|K} = (\Pi^0 \nabla u_h)_{|K} = (\nabla u_h)_{|K}$. On the other hand,

$$p_{h|K} = (\Pi^0 p_h)_{|K} + \frac{\operatorname{div} p_{h|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix} + \tilde{\beta}_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}, \quad \tilde{\beta}_K \in \mathbb{R}.$$

This is equivalent to

$$p_{h|K} = \underbrace{(\nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix}}_{p_{h,1}} + \underbrace{\tilde{\beta}_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}}_{p_{h,2}}.$$

For evaluating the coefficient $\tilde{\beta}_K$, we use the second equation of (15) with $q_h = \operatorname{curl} b_K$:

$$\int_K (p_{h,1} + p_{h,2} - \nabla u_h) \cdot \operatorname{curl} b_K \, dx = 0. \tag{16}$$

We know by (8) that $\int_K \nabla u_h \cdot \operatorname{curl} b_K \, dx = 0$. Inserting the value of $p_{h,1}$, (16) becomes

$$\int_K p_{h,2} \cdot \operatorname{curl} b_K \, dx = \frac{2\Pi^0 f_{|K}}{|K|} \int_K \Big((x - x_K)^2 - (y - y_K)^2 \Big) \, dx.$$

Using the identities

$$\int_K (x-x_K)^2 = \tfrac{|K|}{12}|e_{x,K}|^2, \quad \int_K (y-y_K)^2 = \tfrac{|K|}{12}|e_{y,K}|^2 \tag{17}$$

and the definition of $p_{h,2}$ gives

$$\tilde{\beta}_K = \frac{\Pi^0 f_{|K}}{2}\frac{|e_{x,K}|^2 - |e_{y,K}|^2}{|e_{x,K}|^2 + |e_{y,K}|^2}.$$

We have proved that a solution (u_h, p_h) of the box-scheme (BS_{nc}) is also a solution of the problem ((a), (b)), which is unique. This proves the uniqueness of the solution of the box-scheme (BS_{nc}). The linearity and the equality between the number of unknowns and the number of equations permit us to conclude existence and uniqueness of the solution of the box-scheme (BS_{nc}) and its equivalence with the formulation ((a), (b)). This concludes (ii). ∎

The previous result states that the box-scheme (BS_{nc}) is well-posed and equivalent to a single scheme in u_h alone and an explicit reconstruction formula for p_h. More precisely, u_h is the solution of the nonconforming variational formulation for the problem $-\Delta u = \Pi^0 f$. It also generalizes the previous box-scheme (BS2) and addresses the above instability problem. This box-scheme seems to be a generalization on rectangles of the box-scheme $((u_h, p_h) \in P^1_{nc,0} \times RT^0)$ of Courbet and Croisille [6]. Contrary to the triangles case, here the unknowns are not located at the interface of the mesh. Nevertheless, in the particular case of a uniform grid consisting of squares, $\tilde{\beta}_K = 0$ on each K, p_h can be written in the square K as

$$p_{h|K} = (\nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{2}\begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix},$$

which is the formulation of p_h in the box-scheme of Courbet and Croisille on triangles.

4.2. Numerical analysis. In this section, we provide the stability and the optimal a priori error estimates for the box-scheme (BS_{nc}). In the rest of the paper, C stands for a constant independent of the mesh.

LEMMA 4.1 (discrete Poincaré lemma). *There exists a constant $C > 0$ dependent only on Ω such that for all $u \in Q^1_{nc,0} + H^1_0(\Omega)$,*

$$|u|_{0,\Omega} \le C|u|_{1,h}.$$

Proof (see [13]). Let $u \in Q^1_{nc,0} + H^1_0(\Omega)$. Then

$$|u|_{0,\Omega} = \sup_{g \in L^2(\Omega)} \frac{|(u,g)_{0,\Omega}|}{|g|_{0,\Omega}}. \tag{18}$$

For $g \in L^2(\Omega)$, there exists $p \in H^1(\Omega)^2$ such that $\operatorname{div} p = g$ and $\|p\|_{1,\Omega} \le C|g|_{0,\Omega}$ [2]. By replacing g by this value in (18) and using Green's formula, we get

$$(u,g)_{0,\Omega} = (u, \operatorname{div} p)_{0,\Omega} = \underbrace{-\sum_K \int_K \nabla u \cdot p \, dx}_{(A)} + \underbrace{\sum_K \int_{\partial K} p \cdot \nu_K \, u \, d\sigma}_{(B)}. \tag{19}$$

First, we obtain $|(A)| = |\sum_K \int_K \nabla u \cdot p \, dx| \le |u|_{1,h} \, |p|_{1,\Omega}$. Let us estimate $|(B)|$. Since $p \in (H^1(\Omega))^2 \cap H_{\mathrm{div}}(\Omega)$,

$$(B) = \sum_K \int_{\partial K} p \cdot \nu_K \, u \, d\sigma = \sum_{a \in \mathcal{A}_b} \int_a p \cdot \nu_a \, u \, d\sigma - \sum_{a \in A_i} \int_a p \cdot \nu_a \, [u]_a \, d\sigma. \tag{20}$$

Let $\overline{p\cdot\nu_a} = \frac{1}{|a|}\int_a p\cdot\nu_a\,d\sigma$ be the mean value of $p\cdot\nu_a$ along the edge a. Since $u\in H_0^1(\Omega)+Q_{nc,0}^1$, by the property of $Q_{nc,0}^1$ to satisfy the *patch-test*, we have

$$\int_a \overline{p\cdot\nu_a}\,u\,d\sigma = 0 \quad \text{for all } a\in\mathcal{A}_b \quad \text{and} \quad \int_a \overline{p\cdot\nu_a}\,[u]_a\,d\sigma = 0 \quad \text{for all } a\in\mathcal{A}_i.$$

Therefore, equality (20) becomes

$$\begin{aligned}\sum_K \int_{\partial K} p\cdot\nu_K\,u\,d\sigma &= \sum_{a\in\mathcal{A}_b}\int_a (p\cdot\nu_a - \overline{p\cdot\nu_a})\,u\,d\sigma - \sum_{a\in\mathcal{A}_i}\int_a (p\cdot\nu_a - \overline{p\cdot\nu_a})\,[u]_a\,d\sigma\\ &= \sum_K\sum_{e\in\partial K}\int_e (p\cdot\nu_e - \overline{p\cdot\nu_e})\,u\,d\sigma.\end{aligned}$$

The lemma of Crouzeix and Raviart [9] gives

$$\left|\int_e (p\cdot\nu_e - \overline{p\cdot\nu_e})\,u\,d\sigma\right| \le C\,h_K|u|_{1,K}\,|p|_{1,K}.$$

Then,

$$|(B)| = \left|\sum_K \int_{\partial K} p\cdot\nu_K\,u\,d\sigma\right| \le 4\,Ch|u|_{1,h}\,|p|_{1,\Omega}.$$

Finally,

$$|(u,g)_{0,\Omega}| \le (4Ch+1)|u|_{1,h}\,|p|_{1,\Omega} \le (4\,Ch+1)|u|_{1,h}\underbrace{\|p\|_{1,\Omega}}_{\le C(\Omega)|g|_{0,\Omega}}. \qquad \square$$

PROPOSITION 4.2 (stability). *The solution $(u_h,p_h)\in Q_{nc,0}^1\times(RT^0+\Phi)$ of the problem (BS_{nc}) satisfies the stability estimate*

$$\|u_h\|_{1,h} + \|p_h\|_{\mathrm{div},h} \le C|f|_{0,\Omega}.$$

Proof. Using the formulation of Proposition 4.1 with $v_h = u_h$ and applying the Cauchy–Schwarz inequality and the Poincaré inequality give

$$\|u_h\|_{1,h} \le C(\Omega)\,|f|_{0,\Omega}.$$

On the other hand, the local formula (b) from Proposition 4.1 for p_h and the identity $\operatorname{div} p_h = -\Pi^0 f$ imply $\|p_h\|_{\mathrm{div},h}\le C|f|_{0,\Omega}$. This concludes the proof. $\square$

PROPOSITION 4.3 (a priori error estimates). *Let $(u,p)\in H_0^1(\Omega)\times H_{\mathrm{div}}(\Omega)$ be the solution of the continuous problem* (1) *and $(u_h,p_h)\in Q_{nc,0}^1\times(RT^0+\Phi)$ be the solution of the box-scheme (BS_{nc}). If $f\in H^1(\Omega)$, we have*

$$\begin{array}{ll}\text{(i)}\quad |u-u_h|_{1,h}\le Ch|f|_{0,\Omega}, & \text{(ii)}\quad |u-u_h|_{0,\Omega}\le Ch^2(|f|_{0,\Omega}+|f|_{1,\Omega}),\\ \text{(iii)}\quad |p-p_h|_{0,\Omega}\le Ch|f|_{0,\Omega}, & \text{(iv)}\quad |p-p_h|_{\mathrm{div},h}\le Ch|f|_{1,\Omega}.\end{array} \tag{21}$$

Proof. (i) Let us introduce the bilinear form a_h defined for all $u,v\in H_0^1(\Omega)+Q_{nc,0}^1$ by

$$a_h(u,v) = \sum_{K\in\mathcal{T}_h}(\nabla u,\nabla v)_{0,K}.$$

Then we obtain the classical inequality

$$|u-u_h|_{1,h} \le 2 \inf_{w_h \in Q^1_{nc,0}} |u-w_h|_{1,h} + \sup_{w_h \in Q^1_{nc,0}} \frac{|a_h(u_h-u,w_h)|}{|w_h|_{1,h}}.$$

The estimation of the consistency error is deduced from the variational formulation from Proposition 4.1:

$$\sup_{w_h \in Q^1_{nc,0}} \frac{|a_h(u_h-u,w_h)|}{|w_h|_{1,h}} \le C\, h\, |f|_{0,\Omega}. \tag{22}$$

By using the Q^1-Lagrange interpolation, we get

$$\inf_{w_h \in Q^1_{nc,0}} |u-w_h|_{1,h} \le Ch|u|_{2,\Omega}.$$

This concludes (i).

(ii) Part (ii) is proved by using the Aubin–Nitsche argument and the result (i).

(iii) Part (iii) is a deduction of the local formula p_h given by Proposition 4.1(ii).

(iv) Part (iv) results from $\operatorname{div} p = -f$ and $\operatorname{div} p_h = -\Pi^0 f$. ∎

4.3. Link to the box-scheme (BS2). We already mentioned that the one-point integration of the gradient of u_h is not sufficient to obtain the stability of the scheme (see section 2.1). Nevertheless, the addition of the local bubble in both trial and test spaces permits us to overcome the previous difficulty, as we have just observed. In this sense, the nonconforming bubble is a stabilization parameter. Moreover, from the decomposition of the space $Q^1_{nc,0}$ given in Proposition 2.1, we deduce the following result.

LEMMA 4.2 (link to the box-scheme (BS2)). *The solution* $(u_h,p_h) \in Q^1_{nc,0} \times (RT^0+\Phi)$ *of the box-scheme* (BS_{nc}) *is given as a function of the solution* $(\bar u_h,\bar p_h) \in Q^1_{c,0} \times RT^0$ *of the box-scheme* (BS2) *by*

$$u_h = \bar u_h + \sum_{K\in\mathcal{T}_h} \alpha_K\, b_K \quad \textit{and} \quad p_h = \bar p_h + \sum_{K\in\mathcal{T}_h} \beta_K \operatorname{curl} b_K,$$

where

$$\alpha_K = \frac{3|K|}{4} \frac{1}{|e_{x,K}|^2+|e_{y,K}|^2} (\bar p_h - \nabla \bar u_h, \nabla b_K)_{0,K},$$
$$\beta_K = -\frac{3|K|}{4} \frac{1}{|e_{x,K}|^2+|e_{y,K}|^2} (\bar p_h - \nabla \bar u_h, \operatorname{curl} b_K)_{0,K}.$$

Proof. Let $(\bar u_h,\bar p_h) \in Q^1_{c,0} \times RT^0$ be the solution of the box-scheme (BS2). We are looking for $(\alpha_K,\beta_K)_{K\in\mathcal{T}_h}$ such that

$$u_h = \bar u_h + \sum_K \alpha_K\, b_K, \qquad p_h = \bar p_h + \sum_K \beta_K \operatorname{curl} b_K$$

define the solution $(u_h,p_h) \in Q^1_{nc,0} \times (RT^0+\Phi)$ of the box-scheme (BS_{nc}). Due to $\operatorname{div} p_h = \operatorname{div} \bar p_h$, the first equation of (BS_{nc}) is valid for p_h. Let us suppose that (u_h,p_h) satisfies the second equation of (BS_{nc}). By the definition of (u_h,p_h) and since $(\bar u_h,\bar p_h)$ satisfies the second equation of (BS2),

$$\sum_{K\in\mathcal{T}_h} (p_h - \nabla u_h, q_h)_{0,K} = 0 \quad \text{for all } q_h \in P^0(\nabla b_K) + P^0(\operatorname{curl} b_K). \tag{23}$$

By taking $q_h = \nabla b_K$ in (23), we get

$$\begin{aligned} 0 &= (p_h - \nabla u_h, q_h)_{0,K} \\ &= (\bar{p}_h - \nabla \bar{u}_h, \nabla b_K)_{0,K} + (\beta_K \operatorname{curl} b_K, \nabla b_K)_{0,K} - (\alpha_K \nabla b_K, \nabla b_K)_{0,K}. \end{aligned}$$

Since $(\operatorname{curl} b_K, \nabla b_K)_{0,K} = 0$, we deduce the formula of α_K on each rectangle K. Then for each K, α_K is uniquely determined by the unique solution $(\bar{u}_h, \bar{p}_h)$ of the box-scheme (BS2). In the same way, by taking $q_h = \operatorname{curl} b_K$ in (23), we get

$$0 = (p_h - \nabla u_h, \operatorname{curl} b_K)_{0,K} = (\bar{p}_h - \nabla \bar{u}_h, \operatorname{curl} b_K)_{0,K} + (\beta_K \operatorname{curl} b_K, \operatorname{curl} b_K)_{0,K}$$

and deduce the formula for β_K. Then with this definition of the coefficients α_K, β_K, we prove that $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$ is the unique solution of the box-scheme (BS_{nc}). □

5. A simplified stabilized box-scheme. In this section, we investigate a new way to stabilize the box-scheme (BS1). In fact it seems that the solution of the previous box-scheme is locally in $P^1(K) \times (RT^0(K) + \Phi)$ (see the proof of Proposition 4.1). We are looking for a space locally in $P^1(K)$ instead of $Q^1(K)$ with the same continuity properties as $Q^1_{nc,0}$. The space $\widetilde{M}_{1,h}$ recently introduced by Park and Sheen [19] fulfills those conditions:

$$\widetilde{M}_{1,h} = \left\{ v \in L^2(\Omega);\ v_{|K} \in P^1(K) \text{ for all } K \in \mathcal{T}_h; \right.$$
$$\left. \int_a v_{|K_1}\, dx = \int_a v_{|K_2} dx \text{ for all } a = \partial K_1 \cap \partial K_2 \in \mathcal{A}_i \right\}.$$

Its dimension is $\dim \widetilde{M}_{1,h} = 3NE - NA_i = NV - 1$, since there are three unknowns for each rectangle subject to NA_i independent continuity relations. The corresponding space with homogeneous boundary is

$$\widetilde{M}_{1,h,0} = \left\{ v \in \widetilde{M}_{1,h};\ \int_a v\, dx = 0 \text{ for all } a \in \mathcal{A}_b \right\}.$$

Its dimension is also $\dim \widetilde{M}_{1,h,0} = NA - NE - (NA_b - 1) = NV_i$. Note that this space satisfies the additional condition (7) of Courbet. However, in contrast to the space Q^1_c, it does not contain the nonconforming bubble. The space $\widetilde{M}_{1,h,0}$ is by definition included in $Q^1_{nc,0}$. Similarly to Lemma 2.1, we deduce from the linearity and the injectivity of L and the equality $\dim \widetilde{M}_{1,h,0} = \dim C_0$ the following lemma.

LEMMA 5.1. *The mapping L defines a bijection between $\widetilde{M}_{1,h,0}$ and the Courbet space C_0:*

$$\begin{aligned} L :\ \widetilde{M}_{1,h,0} &\longrightarrow C_0, \\ u &\longmapsto \big(u(x_a)\big)_{a \in \mathcal{A}}. \end{aligned}$$

DEFINITION 5.1. *Let* (BS3) *be the box-scheme: Find $(u_h, p_h) \in \widetilde{M}_{1,h,0} \times (RT^0 + \Phi)$ such that*

$$\text{(BS3)} \quad \begin{cases} \displaystyle\sum_{K \in \mathcal{T}_h} (\operatorname{div} p_h + f, v_h)_{0,K} = 0 & \text{for all } v_h \in P^0, \\ \displaystyle\sum_{K \in \mathcal{T}_h} (p_h - \nabla u_h, q_h)_{0,K} = 0 & \text{for all } q_h \in X_{2,h} = (P^0)^2 + \Phi. \end{cases} \tag{24}$$

The box-scheme has $4NE$ *unknowns.*

Indeed $\dim \widetilde{M}_{1,h,0} + \dim(RT^0 + \Phi) = NV_i + NA + NE - 1 = 4NE = \dim P^0 + \dim X_{2,h}$.

LEMMA 5.2 (link to the box-scheme (BS_{nc})). *The solution* $(\tilde{u}_h, \tilde{p}_h) \in \widetilde{M}_{1,h,0} \times (RT^0 + \Phi)$ *of the box-scheme* (BS3) *is unique and is given as a function of the solution* $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$ *of the box-scheme* (BS_{nc}) *by*

$$\tilde{u}_h = u_h \quad \textit{and} \quad \tilde{p}_h = p_h.$$

Proof. Any solution $(\tilde{u}_h, \tilde{p}_h) \in \widetilde{M}_{1,h,0} \times (RT^0 + \Phi)$ of the box-scheme (BS3) is included in $Q^1_{nc,0} \times (RT^0 + \Phi)$ and satisfies (15). By uniqueness of the solution of the box-scheme (BS_{nc}) and the linearity of the scheme (BS3), we deduce the result. ∎

Note that we rediscover that $u_h \in Q^1_{nc,0}$ in the scheme (BS_{nc}) is locally in $P^1(K)$ (see the proof of Proposition 4.1). In particular, this means that the bilinear term "$x\,y$" is not needed. In fact the solution of the box-scheme (BS_{nc}) is already the solution of the box-scheme (BS3).

COROLLARY 5.1. *The box-scheme* (BS3) *has a unique solution* $(u_h, p_h) \in \widetilde{M}_{1,h,0} \times (RT^0 + \Phi)$ *such that*

(a) $u_h \in \widetilde{M}_{1,h,0}$ *is the solution of*

$$\sum_{K \in \mathcal{T}_h} (\nabla u_h, \nabla v_h)_{0,K} = (\Pi^0 f, v_h)_{0,\Omega} \quad \textit{for all } v_h \in \widetilde{M}_{1,h,0};$$

(b) p_h *is locally given by*

$$p_{h|K} = (\nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{|e_{x,K}|^2 + |e_{y,K}|^2} \begin{pmatrix} |e_{y,K}|^2 (x - x_K) \\ |e_{x,K}|^2 (y - y_K) \end{pmatrix}.$$

Proof. This result is deduced from Lemma 5.2 and Proposition 4.1, since $\widetilde{M}_{1,h,0} \subset Q^1_{nc,0}$. ∎

COROLLARY 5.2 (a priori error estimates). *Let* $(u, p) \in H^1_0(\Omega) \times H_{\mathrm{div}}(\Omega)$ *be the solution of the continuous problem* (1) *and* $(u_h, p_h) \in \widetilde{M}_{1,h,0} \times (RT^0 + \Phi)$ *be the solution of the box-scheme* (BS3). *If* $f \in H^1(\Omega)$, *we have*

(i) $|u - u_h|_{1,h} \le Ch|f|_{0,\Omega}$, (ii) $|u - u_h|_{0,\Omega} \le Ch^2(|f|_{0,\Omega} + |f|_{1,\Omega})$,

(iii) $|p - p_h|_{0,\Omega} \le Ch|f|_{0,\Omega}$, (iv) $|p - p_h|_{\mathrm{div},h} \le Ch|f|_{1,\Omega}$.

6. Numerical results. In this section we present several numerical results which demonstrate the theoretical convergence rates obtained for the box-scheme of section 4. We compute the error estimates for the unknown u and the flux p of the box-scheme (BS_{nc}) on two different domains Ω meshed by rectangles. The solution of the box-scheme (BS_{nc}) is computed according to the decoupled formulation given in Proposition 4.1. The unknown u is the solution of the variational formulation, whereas p is deduced from the local reconstruction on each rectangle. From the computed error, we deduce the numerical convergence rate for each solution of each test. The results for each test case are reported in Tables 1–4.

Test cases 1 and 2 of section 6.1 are given on the unit square domain $\Omega = [0,1]^2$ meshed by squares, whereas section 6.2 is devoted to the computation of the error estimates of the box-scheme (BS_{nc}) on $\Omega = [0,1]^2$ meshed by rectangles. Finally, in section 6.3, we present one test case on the L-shaped domain $\Omega = [0,2] \times [0,1] \cup [1,2] \times [1,2]$, meshed by squares. All the computed convergence rates are in agreement with the theoretical ones given in Proposition 4.3.

6.1. Square domain meshed by squares. The domain Ω is meshed by four different regular grids made of 100, 225, 400, and 900 squares.

1. *Test case* 1: In this first example, the source term f and the Dirichlet data g are chosen such that $u(x, y) = x\,(1 - x)\sin(\pi\, y)$ is the exact solution of the Poisson problem

$$\begin{cases} -\Delta u = f \quad \text{on} \quad \Omega, \\ u = g \quad \text{on} \quad \partial\Omega. \end{cases} \tag{25}$$

   The results for the box-scheme $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$ defined by (BS_{nc}) are given in Table 1. The error for the unknown u is of order 1 in the seminorm $|\cdot|_{1,h}$ and of order 2 for the L^2-norm. For p we get also order 1 in the L^2-norm. The numerical results are of order of those computed theoretically in Proposition 4.3.
2. *Test case* 2: Our second example is a test case proposed by Arnold, Boffi, and Falk [1]. The source term and the boundary conditions are chosen such that $u(x, y) = \exp\big(-100\,((x - 1/4)^2 + (y - 1/3)^2)\big)$ is the exact solution of problem (25). It concerns a Gaussian pulse centered at the point $(x_0, y_0) = (\frac{1}{4}, \frac{1}{3})$. The error estimates for both unknowns u and $p = \nabla u$ are given in Table 2 for the box-scheme $(u_h, p_h) \in Q^1_{nc,0} \times (RT^0 + \Phi)$. The convergence rates are a little lower than expected (1.8 instead of 2 for u in the L^2-norm and 0.97 instead of 1 for p in the L^2-norm) but still close to the a priori error estimates of Proposition 4.3. This is due to the high gradient of the exact solution at the point (x_0, y_0).

6.2. Test case 3: Square domain meshed by rectangles. In this example, we consider the domain $\Omega = [0, 1]^2$ meshed by rectangles and the solution $u(x, y) = x\,(1 - x)\,y\,(1 - y)\exp(5\,x)$ of the problem (25), where the right-hand side and the Dirichlet conditions are computed using the exact solution u. The grid is made of $n_x \times n_y$ rectangles, where n_x and n_y are the numbers of subdivisions of the segment $[0, 1]$ in each direction (O_x) and (O_y). We compute the solution (u_h, p_h) for (n_x, n_y)

TABLE 3

taking the values $(20, 5)$, $(40, 10)$, $(80, 20)$, and $(100, 25)$, i.e., 100, 400, 1600, and 2500 rectangles. The exact solution presents a boundary layer at $x = 1$. Nevertheless, the computed solution u_h and the discrete flux p_h of (BS_{nc}) seem to take it into account. The convergence rates between the exact and the discrete solutions for both unknowns u and $p = \nabla u$ are assembled in Table 3. The numerical results really satisfy the theoretical estimates of Proposition 4.3.

6.3. Test case 4: Test case on an L-shaped domain. In this case we consider a different domain Ω_L, given by the square $[0, 2] \times [0, 2]$ without the part $[0, 1] \times [1, 2]$. We obtain an L-shaped domain. We compute the solution (u_h, p_h) of the box-scheme (BS_{nc}) associated with the Poisson problem (25). The data f and g are chosen such that $u(x, y) = x\,(2 - x)\,y^2\,(2 - y)\sin(x + 2y)$ is the exact solution of (25). The convergence rate and error for both unknowns u and $p = \nabla u$ are given in Table 4. The computed results conform to the theoretical ones.

7. Conclusion. We have presented three different box-schemes which are in fact strongly connected to each other through the initial box-scheme introduced by Courbet. The box-scheme (BS3) presents the advantage of giving a completely local formulation of the flux, which is not the case of the box-scheme (BS2). The box-scheme (BS_{nc}) gives the same solution as the box-scheme (BS3) but seems to be the most stable of all the schemes of the paper. The choice of the trial and test spaces erases the effect of the hourglass mode of the initial box-scheme. In particular, the box-scheme (BS_{nc}) is probably the one to implement for generalized quadrangles in two and three dimensions. The box-schemes can be generalized to the Poisson problem with a diffusion tensor $\mathcal{K}$. In this case, we would consider for the flux $p = \mathcal{K} \cdot \nabla u$. Particularly, the box-scheme method is adapted to the direct computation of the speed of the flow in the Darcy law.

Appendix. In this section, we are going to complete the proof of Proposition 3.1. Actually, we determine the coefficient γ_K of formula (11). For this purpose, we consider the H_{div}-property of elements of RT^0 to have their normal component continuous along the internal edges of the mesh. Indeed, for any internal edge $a = \partial K \cap \partial K'$,

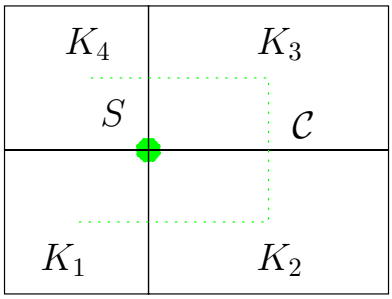

FIG. 4. *Path* $\mathcal{C}$.

$p_h \in RT^0$ satisfies

$$p_{h_{|K}} \cdot \nu_a + p_{h_{|K'}} \cdot \nu'_a = 0 \qquad \text{along the edge } a.$$

At first, we consider a grid made of four elements K_1, K_2, K_3, and K_4 and a path $\mathcal{C}$ crossing each element K_i for $i = 1, \ldots, 4$ once and only once as pictured in Figure 4.

Let a_1, a_2, a_3, and a_4 be the four internal edges $a_1 = \partial K_1 \cap \partial K_2$, $a_2 = \partial K_2 \cap \partial K_3$, $a_3 = \partial K_3 \cap \partial K_4$, and $a_4 = \partial K_1 \cap \partial K_4$. Let S be the common vertex of K_1, K_2, K_3, and K_4.

LEMMA A.1. *Let* u_h *be the solution of* (10) *and* p_h *be given on each rectangle* K *by the relation* (14), *where* γ_K *has to be defined. The continuity of* $p_h \cdot \nu_a$ *along the edges* $a = a_1, a_2, a_3$ *crossing the path* $\mathcal{C}$ *implies the continuity of* $p_h \cdot \nu_{a_4}$ *along the edge* a_4.

Proof. Considering the edges a_1, a_2, a_3 and the continuity of $p_h \cdot \nu_a$ along these edges, we get the following system:

$$\begin{cases} |K_2|\gamma_{K_2} = -|K_1|\gamma_{K_1} + F(u_h, f, a, K_1, K_2), \\ -|K_3|\gamma_{K_3} = -|K_1|\gamma_{K_1} + F(u_h, f, a_1, K_1, K_2) - G(u_h, f, a_2, K_2, K_3), \\ |K_4|\gamma_{K_4} = -|K_1|\gamma_{K_1} + F(u_h, f, a_3, K_4, K_3) \\ \qquad + F(u_h, f, a_1, K_1, K_2) - G(u_h, f, a_2, K_2, K_3), \end{cases} \tag{26}$$

where F is defined for the rectangles K_1 and K_2 by

$$F(u_h, f, a_1, K_1, K_2) = -2|a_1|\Big(\Pi^0(\nabla u_h)_{|K_1} - \Pi^0(\nabla u_h)_{|K_2}\Big) \cdot \begin{pmatrix} 1 \\ 0 \end{pmatrix} + \frac{|K_1|}{2}\Pi^0 f_{|K_1} + \frac{|K_2|}{2}\Pi^0 f_{|K_2}.$$

The same formula holds for the rectangles K_4 and K_3. The function G is defined by

$$G(u_h, f, a_2, K_2, K_3) = 2|a_2|\Big((\Pi^0\nabla u_h)_{|K_2} - (\Pi^0\nabla u_h)_{|K_3}\Big) \cdot \begin{pmatrix} 0 \\ 1 \end{pmatrix} - \frac{|K_2|}{2}\Pi^0 f_{|K_2} - \frac{|K_3|}{2}\Pi^0 f_{|K_3}.$$

The system (26) leads to the following relation between the rectangles K_1 and K_4:

$$
\begin{aligned}
|K_4|\gamma_{K_4} = &-|K_1|\gamma_{K_1} - 2\Big[|a_3|\Big(\Pi^0(\nabla u_h)_{|K_4} - \Pi^0(\nabla u_h)_{|K_3}\Big) \\
&+ |a_1|\Big(\Pi^0(\nabla u_h)_{|K_1} - \Pi^0(\nabla u_h)_{|K_2}\Big)\Big] \cdot \begin{pmatrix}1\\0\end{pmatrix} \\
&- 2|a_2|\Big((\Pi^0\nabla u_h)_{|K_2} - (\Pi^0\nabla u_h)_{|K_3}\Big) \cdot \begin{pmatrix}0\\1\end{pmatrix} \\
&+ \sum_K \frac{|K|}{2}\Pi^0 f_{|K} - \frac{|K_4|}{2}\Pi^0 f_{|K_4} - \frac{|K_1|}{2}\Pi^0 f_{|K_1}.
\end{aligned} \tag{27}
$$

Using the variational form (10) whose solution is u_h and taking v_h to be the basis function from $Q^1_{c,0}$ associated to the vertex S (Figure 4), we get

(28)

$$
\begin{aligned}
&\Big[|a_1|\Big(\Pi^0(\nabla u_h)_{K_1} - \Pi^0(\nabla u_h)_{K_2}\Big) + |a_3|\Big(\Pi^0(\nabla u_h)_{K_4} - \Pi^0(\nabla u_h)_{K_3}\Big)\Big] \cdot \begin{pmatrix}1\\0\end{pmatrix} \\
&\quad + \Big[|a_2|\Big(\Pi^0(\nabla u_h)_{K_2} - \Pi^0(\nabla u_h)_{K_3}\Big) + |a_4|\Big(\Pi^0(\nabla u_h)_{K_1} - \Pi^0(\nabla u_h)_{K_4}\Big)\Big] \cdot \begin{pmatrix}0\\1\end{pmatrix} \\
&= \sum_{i=1}^{4} \frac{|K_i|}{2}(\Pi^0 f)_{K_i}.
\end{aligned}
$$

After substituting equality (28) into (27), we get

$$
\begin{aligned}
|K_4|\gamma_{K_4} = &-|K_1|\gamma_{K_1} + 2|a_4|\Big(\Pi^0(\nabla u_h)_{K_1} - \Pi^0(\nabla u_h)_{K_4}\Big) \cdot \begin{pmatrix}0\\1\end{pmatrix} \\
&- \frac{|K_4|}{2}\Pi^0 f_{|K_4} - \frac{|K_1|}{2}\Pi^0 f_{|K_1},
\end{aligned}
$$

which is exactly the continuity of $p_h \cdot \nu_{a_4}$ along the edge a_4. This concludes the proof of the lemma. □

The result for four rectangles is extended recursively to a rectangle domain Ω with a grid of rectangles (see Figure 5) as follows.

LEMMA A.2. *Let u_h be the solution of* (10) *and p_h be given on each rectangle K by the relation* (14)*, where γ_K has to be defined. Let $\mathcal{C}$ be a path covering all the rectangles of the domain Ω. The continuity of $p_h \cdot \nu_a$ along each edge a crossing the path $\mathcal{C}$ (Figure* 5*) is equivalent to the continuity of $p_h \cdot \nu_a$ along each internal edge of the domain Ω.*

On the other hand, we consider the choice $q_h = \sum_K \operatorname{sgn}(K) \operatorname{curl} b_K$ in (9). Since the scalar product between ∇u_h and $\operatorname{curl} b_K$ (from (8)) is null on each rectangle K, we get

$$
0 = \sum_K (p_h, q_h)_{0,K} = \sum_K \int_K p_h \cdot \operatorname{sgn}(K) \operatorname{curl} b_K \, dx.
$$

Using the formula (14) for p_h,

$$
\sum_K \int_K \left[(\Pi^0\nabla u_h)_{|K} - \frac{\Pi^0 f_{|K}}{2}\begin{pmatrix}x - x_K\\ y - y_K\end{pmatrix} + \gamma_K \begin{pmatrix}x - x_K\\ -(y - y_K)\end{pmatrix}\right] \cdot \operatorname{sgn}(K) \operatorname{curl} b_K \, dx = 0,
$$

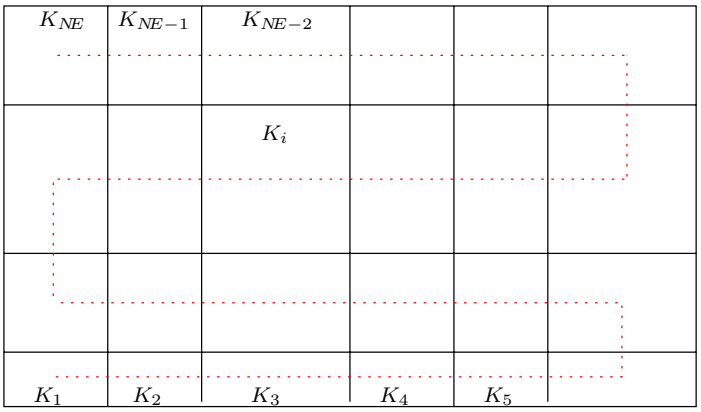

FIG. 5. *Path $\mathcal{C}$ for the whole grid $\mathcal{T}_h$ of the domain Ω.*

and $\int_K \Pi^0(\nabla u_h)\cdot \operatorname{curl} b_K\, dx = 0$ (property of the bubble), and the identities (17), we deduce

$$\sum_K \gamma_K \operatorname{sgn}(K)(|e_{x,K}|^2 + |e_{y,K}|^2) = \sum_K \operatorname{sgn}(K)\frac{\Pi^0 f_{|K}}{2}(|e_{x,K}|^2 - |e_{y,K}|^2). \tag{29}$$

Finally, we can deduce a linear system with NE equations and NE unknowns $(\gamma_1, \gamma_2, \ldots, \gamma_{NE})$. It is given by the $(NE-1)$ continuity conditions of $p_h\cdot\nu_a$ along each internal edge a, crossing the path $\mathcal{C}$ and (29).

PROPOSITION A.1. *Let u_h be the solution of* (10) *and p_h be given on each rectangle K by the relation* (14)*, where γ_K has to be defined on each rectangle. The vector $\gamma = (\gamma_1, \gamma_2, \ldots, \gamma_{NE})$ is a solution of the system $A\gamma = b$, where N denotes NE and*

$$A = \begin{pmatrix} |K_1| & |K_2| & 0 & \cdots & 0 \\ 0 & |K_2| & 0 & \cdots & 0 \\ \vdots & & \ddots & \ddots & \\ & 0 & & & 0 \\ & & \ddots & \ddots & \\ 0 & \cdots & & & 0 \\ 0 & \cdots & 0 & |K_{N-1}| & |K_N| \\ |e_{x,K_1}|^2 + |e_{y,K_1}|^2 & -(|e_{x,K_2}|^2 + |e_{y,K_2}|^2) & \cdots & \cdots & \operatorname{sgn}(K_N)(|e_{x,K_N}|^2 + |e_{y,K_N}|^2) \end{pmatrix},$$

$$b = \begin{pmatrix} H(u_h, f, |a_1|, K_1, K_2) \\ H(u_h, f, |a_2|K_2, K_3) \\ \vdots \\ \vdots \\ H(u_h, f, |a_{N-1}|, K_{N-2}, K_{N-1}) \\ \sum_K \operatorname{sgn}(K)\frac{\Pi^0 f_{|K}}{2}(|e_{x,K}|^2 - |e_{y,K}|^2) \end{pmatrix},$$

H is either F or G according to the cases, and a_i is the common edge to the rectangles K_i and K_{i+1} (see Figure 5*).*

Proof. We prove this result in the case of a uniform grid, i.e., where the rectangles have the same size, $e_x := e_{x,K}$, and $e_y := e_{y,K}$ for all rectangles K. Then, the determinant of the matrix A is

$$\det A = |K_2|\cdots|K_{NE-1}|\Big(|e_x|^2 + |e_y|^2\Big)\Big(\operatorname{sgn}(K_{NE})|K_1| + (-1)^{NE+1}\operatorname{sgn}(K_1)|K_{NE}|\Big).$$

Also the sign of the last rectangle seen by the path $\mathcal{C}$ is $\operatorname{sgn}(K_{NE}) = (-1)^{NE+1}$ and $\operatorname{sgn}(K_1) = 1$. Therefore, $|\det A| = |K_2| \cdots |K_{NE-1}| \big(|e_x|^2 + |e_y|^2\big)\big(|K_1| + |K_{NE}|\big)$ is different from zero.

Then, γ_K is given in each rectangle by the resolution of the system $A\gamma = b$ and p_h can be written in each rectangle as a function of γ_K (which depends on the neighboring rectangles):

$$p_{h|K} = \Pi^0(\nabla u_h) - \frac{\Pi^0 f_{|K}}{2} \begin{pmatrix} x - x_K \\ y - y_K \end{pmatrix} + \gamma_K \begin{pmatrix} x - x_K \\ -(y - y_K) \end{pmatrix}. \qquad \square$$

Resulting from this work on the path we can deduce the following characterization of the space Q_c^1.

LEMMA A.3 (characterization of Q_c^1). *Let u_h be such that $u_{h|K} \in Q^1(K)$ for all rectangles K of the grid $\mathcal{T}_h$. Then $u_h \in Q_c^1$ if and only if u_h is continuous at the midpoint of the internal edges and $\nabla u_h \cdot \tau$ is continuous along the path $\mathcal{C}$, where the path is crossing once and only once all the rectangles of the grid. This means*

$$Q_c^1 = \Big\{ u_h / u_{h|K} \in Q^1(K) \text{ for all } K \in \mathcal{T}_h,\ \int_a [u_h]\, d\sigma = 0 \text{ for all } a \in \mathcal{A}_i, \\ \nabla u_h \cdot \tau_a \text{ is continuous along the path } \mathcal{C} \Big\}.$$

Its dimension is $\dim Q_c^1 = 4NE - NA_i - (NE - 1) = NP$.

Proof. Let Q be defined by

$$Q = \Big\{ u_h \in Q^1(K) \text{ for all } K \in \mathcal{T}_h,\ \int_a [u_h]\, d\sigma = 0 \text{ for all } a \in \mathcal{A}_i, \\ \nabla u_h \cdot \tau_a \text{ is continuous along the path } \mathcal{C} \Big\}.$$

The inclusion $Q_c^1 \subseteq Q$ is clear. Let us prove that $Q \subseteq Q_c^1$. Again, we can restrict the proof to the case of four rectangles (see Figure 4). Let us suppose that u_h is continuous at the midpoint of the four edges a_1, a_2, a_3, and a_4 and that $\nabla u_h \cdot \tau_{a_i}$ is continuous along the edges a_i for $i = 1, 2, 3$. We deduce algebraically that $\nabla u_h \cdot \tau_{a_4}$ is continuous along the edge a_4. On the other hand, the continuity of u_h at the midpoint of the internal edges and the continuity of $\nabla u_h \cdot \tau_a$ at the internal edges imply the continuity of u_h at the interfaces of the mesh, which means the continuity of u_h on the whole domain. Then we get $Q \subseteq Q_c^1$, which concludes the lemma. $\square$

Acknowledgments. I am grateful to Professor J.-P. Croisille for fruitful discussions and suggestions concerning this work. I would like to thank the Max Planck Institute for Mathematics in the Sciences in Leipzig for providing the opportunity of finishing the present work.

ON THE CONTRACTIVITY AND CONVERGENCE OF GENERAL LINEAR METHODS ON SEMI-INFINITE INTERVALS*

S. GONZÁLEZ-PINTO† AND D. HERNÁNDEZ-ABREU†

Abstract. The strict-contractivity and the convergence of General Linear Methods on the classes of strictly dissipative and dissipative differential systems regarding some inner product are analyzed. New convergence and contractivity results of the methods on semi-infinite intervals are provided for the case of strictly dissipative problems. Some applications of the main results to the class of Runge–Kutta multistep methods are supplied.

Key words. General Linear Methods, contractivity, convergence, dissipative differential systems

1. Introduction.

Let us consider initial value problems

$$y' = f(t,y), \quad y(0) = y_0, \qquad f : [0,\infty) \times \mathbb{C}^m \to \mathbb{C}^m, \tag{1.1}$$

where the function f is supposed to be continuously differentiable on an appropriate domain and it is also assumed to satisfy the one-sided Lipschitz condition

$$\mathrm{Re}\langle f(t,y) - f(t,z), y - z\rangle_X \le \nu \, \|y - z\|_X^2 \quad \forall t \ge 0 \; \forall y, z, \tag{1.2}$$

regarding some inner product in $\mathbb{C}^m$, where ν is some constant. It would suffice that (1.2) were satisfied in some cylinder around the exact solution $y(t)$ which will be assumed to exist for $t \ge 0$. The inner product is defined by

$$\langle u, v\rangle_X := \sum_{i,j=1}^{m} x_{ij} \overline{v}_j u_i; \quad u = (u_j)_{j=1}^m, \; v = (v_j)_{j=1}^m, \tag{1.3}$$

where the matrix $X = (x_{ij})_{i,j=1}^m \in \mathbb{R}^{m,m}$ is symmetric and positive definite, and $\bar{z}$ denotes the conjugate of a complex number z. The notation $\|\cdot\|_X$ will be used throughout this paper for the norm associated to that inner product. It is well known that under the previous assumptions, the difference between two solutions with initial values y_0 and z_0, respectively, satisfies [8, Ch. I]

$$\|y(t;0,y_0) - y(t;0,z_0)\|_X \le \exp(\nu t) \, \|y_0 - z_0\|_X \quad \forall t \ge 0.$$

Thus, when the constant ν is negative (strictly dissipative case), besides strict-contractivity for neighboring solutions, we have asymptotic stability (in the Lyapunov sense) for any solution defined on the interval $[0, +\infty)$. It would be desirable that in such a situation, the numerical methods applied to (1.1) also preserve the asymptotic stability in the Lyapunov sense for their numerical solutions.

The goal of this paper is to study the strict-contractivity and the convergence (and B-convergence) of General Linear Methods on semi-infinite intervals for strictly dissipative differential systems, i.e., $\nu < 0$ in (1.2). Some of the B-convergence results presented here are similar to those by Huang, Chang, and Xiao [12] for the case of finite intervals and dissipative problems ($\nu = 0$ in (1.2)). However, our results also apply to semi-infinite intervals, whereas those results given in [12] do not. The strict-contractivity analysis extends the ideas given by Hairer and Zennaro [11] for implicit Runge–Kutta methods, and the superexponential character of the linear stability function associated to a General Linear Method is exploited in the same way as in [11]. The convergence results, which make use of the previous contractivity analysis and are partly inspired by the work of Hundsdorfer [14], are postponed to the last part of the paper. Applications of our results to some classes of General Linear Methods appearing in the literature are also given.

The paper is organized as follows. In section 2, some preliminaries about General Linear Methods and the norms to be used are given, and some tools to prove the main results are provided. In section 3, the strict-contractivity analysis is carried out. Section 4 is devoted to the existence and uniqueness of the stage solutions. The convergence studies are developed in section 5, and some applications of the main results are postponed to section 6.

2. Preliminary results. A k-step s-stage General Linear Method (see, e.g., [3], [10, p. 356]) applied to (1.1) is given by

$$\begin{array}{rcl} Y^{(n+1)} & = & h(A \otimes I_m)F(t_n, h, V^{(n)}) + (B \otimes I_m)Y^{(n)}, \quad n \geq 0, \\ V^{(n)} & = & h(\tilde{A} \otimes I_m)F(t_n, h, V^{(n)}) + (\tilde{B} \otimes I_m)Y^{(n)}, \end{array} \tag{2.1}$$

where $h > 0$ denotes the step-size, $V^{(n)} := ({v_1^{(n)}}^T, {v_2^{(n)}}^T, \ldots, {v_s^{(n)}}^T)^T \in \mathbb{C}^{ms}$ stands for the stages of the method, $Y^{(n+1)} := ({y_1^{(n+1)}}^T, {y_2^{(n+1)}}^T, \ldots, {y_k^{(n+1)}}^T)^T \in \mathbb{C}^{mk}$ is the advancing solution, $F(t_n, h, V^{(n)}) := (f(t_n + c_1 h, v_1^{(n)})^T, f(t_n + c_2 h, v_2^{(n)})^T, \ldots, f(t_n + c_s h, v_s^{(n)})^T)^T$, and $Y^{(n)}$ denotes a piece of information about the true solution known from the previous step. The method possesses as free parameters the matrices $\tilde{A} \in \mathbb{R}^{s,s}$, $\tilde{B} \in \mathbb{R}^{s,k}$, $A \in \mathbb{R}^{k,s}$, and $B \in \mathbb{R}^{k,k}$ and the vector $c := (c_1, \ldots, c_s)^T \in \mathbb{R}^s$, and they can be chosen in order to gain both stability and global stage order. Above $\otimes$ stands for the usual Kronecker product of matrices, $A \otimes B = (a_{ij}B)$, and I_m for the identity matrix of dimension m.

The difference $\Delta Y^{(n+1)} := \hat{Y}^{(n+1)} - Y^{(n+1)}$ between two numerical solutions provided by the method (2.1) when applied to (1.1) in a fixed step-size setting fulfills the recurrent relation

$$\Delta Y^{(n+1)} = M(Z^{(n)})\Delta Y^{(n)}, \quad n \geq 0, \quad Z^{(n)} = hJ^{(n)}, \tag{2.2}$$

with

$$J^{(n)} := \text{BlockDiag}(J_1^{(n)}, \ldots, J_s^{(n)}) \in \mathbb{C}^{ms,ms}, \tag{2.3}$$

and where $J_i^{(n)} \in \mathbb{C}^{m,m}$, $1 \leq i \leq s$, are matrices given by

$$J_i^{(n)} := \int_0^1 \frac{\partial f}{\partial y}(t_n + c_i h, v_i^{(n)} + \theta(\hat{v}_i^{(n)} - v_i^{(n)}))d\theta. \tag{2.4}$$

Besides, $M(Z) \in \mathbb{C}^{mk,mk}$ is the supermatrix given by

$$M(Z) = B \otimes I_m + (A \otimes I_m)Z(I_{sm} - (\tilde{A} \otimes I_m)Z)^{-1}(\tilde{B} \otimes I_m). \tag{2.5}$$

The linear stability analysis of General Linear Methods is carried out by considering the basic linear complex test problem $y' = \lambda y$, with $\lambda \in \mathbb{C}$. In such a case, the advancing solution satisfies $Y^{(n+1)} = R(z)Y^{(n)}$, $z = \lambda h$, $n \geq 0$, where $R(z)$ is the so-called *stability matrix*

$$R(z) := B + zA(I - z\tilde{A})^{-1}\tilde{B}. \tag{2.6}$$

Then, (2.1) is said to be A-stable if the eigenvalues of $R(z)$ satisfy the *root condition*, i.e., they have either modulus smaller than one or modulus one and they are simple, provided that $z \in \mathbb{C}^- := \{z \in \mathbb{C}, \operatorname{Re} z \leq 0\}$.

On the other hand, the nonlinear stability properties of the methods are studied on dissipative nonlinear systems ($\nu = 0$ in (1.2)). Thus, a General Linear Method is said to be G-stable if there exists a symmetric and positive definite matrix $G = (g_{ij})_{i,j=1}^k \in \mathbb{R}^{k,k}$ such that for two arbitrary advancing solutions we have that

$$\left\|\hat{Y}^{(n+1)} - Y^{(n+1)}\right\|_{G\otimes X} \leq \left\|\hat{Y}^{(n)} - Y^{(n)}\right\|_{G\otimes X},$$

where $\|Y^{(n)}\|_{G\otimes X} := \sum_{i,j=1}^k g_{ij}\langle Y_i^{(n)}, Y_j^{(n)}\rangle_X$. Burrage and Butcher proved in [3] that *algebraic stability* is enough for G-stability. We recall that a General Linear Method is said to be *algebraically stable* if there exist a nonnegative definite matrix $D = \operatorname{Diag}(d_1, \ldots, d_s)$ and a positive definite matrix $G \in \mathbb{R}^{k,k}$ such that

$$N = \begin{pmatrix} G - B^T G B & \tilde{B}^T D - B^T G A \\ D\tilde{B} - A^T G B & D\tilde{A} + \tilde{A}^T D - A^T G A \end{pmatrix} \in \mathbb{R}^{k+s,k+s} \tag{2.7}$$

is nonnegative definite. Moreover, both concepts G-stability and algebraic stability turn out to be equivalent for most of the General Linear Methods of interest. Thus, for a nonconfluent General Linear Method ($c_i \neq c_j \ \forall i \neq j$) which is preconsistent, i.e., there exists a vector $\xi_0 \in \mathbb{R}^k$ such that

$$B\xi_0 = \xi_0, \qquad \tilde{B}\xi_0 = e := (1, \ldots, 1)^T \in \mathbb{R}^s, \tag{2.8}$$

G-stability turns out to be equivalent to algebraic stability [4, 5] (see also [10, Ch. V.9]).

Next, we give some basic general results which exploit the superexponential character of certain complex valued matrix mappings. This will be used to prove new contractivity results in the forthcoming section. Concerning the matrix norms to be used, we recall that for a given vector norm $\|\cdot\|$ in $\mathbb{C}^m$, the operator norm will be $\|J\| := \max_{\|v\|=1} \|Jv\|$, $J \in \mathbb{C}^{m,m}$, and its associated logarithmic norm is defined by (see, e.g., [8, p. 27]) $\mu[J] := \lim_{\epsilon\to 0^+}(\|I_m + \epsilon J\| - 1)/\epsilon$. It must be noted that for the matrices $J_i^{(n)}$ given in (2.4), $\mu_X[J_i^{(n)}] \leq \nu$, $1 \leq i \leq s$, holds by virtue of (1.2). We will often consider norms associated to the inner product in (1.3). For this case, by splitting $X = Y^T Y$, where $Y \in \mathbb{R}^{m,m}$ is a nonsingular matrix (the decomposition is not unique), we have that

$$\|J\|_X := \left\|YJY^{-1}\right\|_2, \quad \mu_X[J] = \mu_2[YJY^{-1}] \quad \forall J \in \mathbb{C}^{m,m}. \tag{2.9}$$

We will also make use of an operator norm in the superspace $\mathbb{C}^{mk}$ for some $k \in \mathbb{N}$. Thus, for a given symmetric positive definite matrix $G = (g_{ij})_{i,j=1}^{k} \in \mathbb{R}^{k,k}$, the inner product in (1.3) can be extended to $\mathbb{C}^{mk}$ in the usual way:

$$\langle u, v\rangle_{G\otimes X} := \sum_{i,j=1}^{k} g_{ij}\langle u_i, v_j\rangle_X, \tag{2.10}$$
$$u = (u_j)_{j=1}^{k},\ v = (v_j)_{j=1}^{k},\ u_j, v_j \in \mathbb{C}^m,\ 1 \le j \le k.$$

By splitting the matrix $G = L^T L$, with $L \in \mathbb{R}^{k,k}$ nonsingular (the decomposition is not unique), it is not difficult to show that

$$\langle u, v\rangle_{G\otimes X} = \langle (L \otimes Y)u, (L \otimes Y)v\rangle_2. \tag{2.11}$$

Then, the operator norm associated to the inner product (2.10) satisfies for any $K \in \mathbb{C}^{mk,mk}$ that

$$\|K\|_{G\otimes X} := \max_{\|v\|_{G\otimes X}=1} \|Kv\|_{G\otimes X} = \max_{\substack{\|u\|_{G\otimes X}=1\\ \|v\|_{G\otimes X}=1}} |u^*(G \otimes X)Kv|. \tag{2.12}$$

It must be taken into account that for every l_p-norm with $p \ge 1$ and $q^{-1} + p^{-1} = 1$, it holds that

$$\|v\|_p = \max_{\|u\|_q=1} |u^* v|\ \ \forall v \in \mathbb{C}^n, \quad \|J\|_p = \max_{\substack{\|u\|_q=1\\ \|v\|_p=1}} |u^* J v|\ \ \forall J \in \mathbb{C}^{n,n},\ n \in \mathbb{N}. \tag{2.13}$$

This latter property (2.13) follows from the duality between the spaces l_p and l_q, with $p \ge 1$ and $q^{-1} + p^{-1} = 1$; see, e.g., [15, sect. 19]. Thus, by taking $p = 2$ in (2.13), the second equality in (2.12) is deduced from (2.11). Here, u^* stands for the transpose conjugate of the vector u. With these preliminaries and denoting by $\mu_X[\cdot]$ and $\mu_p[\cdot]$ the logarithmic norms associated to the norms $\|\cdot\|_X$ and $\|\cdot\|_p$, respectively, we have the following theorem.

THEOREM 1. *Let $M(Z_1, \dots, Z_s) := (m_{ij}(Z_1, \dots, Z_s))_{i,j=1}^{k} \in \mathbb{C}^{mk,mk}$ be a matrix mapping acting on the matrix-set $\{(Z_1, \dots, Z_s),\ Z_j \in \mathbb{C}^{m,m},\ j = 1, \dots, s\}$. Assume that $m_{ij}(Z_1 + zI_m, \dots, Z_s + zI_m)$, $1 \le i, j \le k$, is an (m, m)-matrix having analytic components on* $\operatorname{Re} z \le 0$ *whenever the matrices Z_j satisfy either*

(a) $\mu_X[Z_j] \le 0$ $(j = 1, \dots, s)$ *or*

(b) $\mu_p[Z_j] \le 0$ $(j = 1, \dots, s)$ *(for some l_p-norm, $p \ge 1$).*

Then, respectively, for each case we have that (a) *the real function*

$$\varphi_{G,M}(x) := \sup_{\substack{\mu_X[Z_j]\le x\\ 1\le j\le s}} \|M(Z_1, \dots, Z_s)\|_{G\otimes X} \tag{2.14}$$

is nondecreasing for $x \le 0$ and fulfills the superexponential property

$$\varphi(x)\varphi(y) \le \varphi(0)\varphi(x + y) \quad \forall\, x, y \le 0, \tag{2.15}$$

provided that $G \in \mathbb{R}^{k,k}$ is symmetric and positive definite; and (b) *the real function*

$$\varphi_{p,M}(x) := \sup_{\substack{\mu_p[Z_j]\le x\\ 1\le j\le s}} \|M(Z_1, \dots, Z_s)\|_p$$

is nondecreasing for $x \le 0$ and satisfies (2.15).

Proof. The proof closely follows the ideas of the proof in [11, Theorem 4.3]. However, we point out some minor modifications related to the matrix case.

(a) Take $x < 0$ and $y < 0$ and assume $\varphi_{G,M}(0) < \infty$. Let us consider vectors $u_i, v_i \in \mathbb{C}^{mk}$, with $\|u_i\|_{G\otimes X} = \|v_i\|_{G\otimes X} = 1$ $(i = 1, 2)$, and matrices $A_1, \ldots, A_s$, $B_1, \ldots, B_s \in \mathbb{C}^{m,m}$ satisfying $\mu_X[A_i] \le x + y$, $\mu_X[B_i] \le 0$, $1 \le i \le s$. Let us define, for $z \in \mathbb{C}$,

$$S(z) = (u_1^*(G \otimes X)M(A_1 - zI_m, \ldots, A_s - zI_m)v_1) \cdot (u_2^*(G \otimes X)M(B_1 + zI_m, \ldots, B_s + zI_m)v_2).$$

Thus, taking into account that in general the logarithmic norms satisfy [8, p. 31] $\mu[J + zI_m] = \mu[J] + \operatorname{Re} z$ for any $J \in \mathbb{C}^{m,m}$, we deduce that $S(z)$ is an analytic function on the strip $\mathcal{S}(0, x + y) := \{z \in \mathbb{C} : \ x + y \le \operatorname{Re} z \le 0\}$. Then from the maximum modulus principle and from (2.12), it follows that

$$|S(z)| \le \sup_{\substack{Re\ z=0,\\ Re\ z=x+y}} |S(z)| \le \varphi_{G,M}(0)\varphi_{G,M}(x + y) \quad \forall z \in \mathcal{S}(0, x + y). \tag{2.16}$$

Now, by taking $z = y$ and considering the maximum over $\|u_2\|_{G\otimes X} = \|v_2\|_{G\otimes X} = 1$ and the supremum over $\mu_X[B_j] \le 0$ $(j = 1, \ldots, s)$, it follows from (2.16) that

$$|u_1^*(G \otimes X)M(A_1 - yI_m, \ldots, A_s - yI_m)v_1|\, \varphi_{G,M}(y) \le \varphi_{G,M}(0)\varphi_{G,M}(x + y).$$

The proof is concluded by taking the maximum over $\|u_1\|_{G\otimes X} = \|v_1\|_{G\otimes X} = 1$ and the supremum over $\mu_X[A_i] \le x + y$ $(i = 1, \ldots, s)$.

(b) This part of the proof is along the lines of that of part (a) but this time defines

$$S(z) = \left(u_1^* M(A_1 - zI_m, \ldots, A_s - zI_m)v_1\right)\left(u_2^* M(B_1 + zI_m, \ldots, B_s + zI_m)v_2\right)$$

and takes $\|u_i\|_q = \|v_i\|_p = 1$ $(i = 1, 2)$, with $q^{-1} + p^{-1} = 1$. ∎

COROLLARY 1. *Let $M(z_1, \ldots, z_s) := (m_{ij}(z_1, \ldots, z_s))_{i,j=1}^k \in \mathbb{C}^{k,k}$, where $m_{ij}(\cdot)$ are analytic functions on each complex variable z_j for* $\operatorname{Re} z_j \le 0$ $(j = 1, \ldots, s)$. *Then the increasing functions*

$$\varphi_{G,M}(x) = \sup_{\substack{Re\ z_j \le x\\ 1\le j\le s}} \|M(z_1, \ldots, z_s)\|_G \quad \textit{and} \quad \varphi_{p,M}(x) = \sup_{\substack{Re\ z_j \le x\\ 1\le j\le s}} \|M(z_1, \ldots, z_s)\|_p$$

fulfill (2.15) *for any symmetric positive definite matrix $G \in \mathbb{R}^{k,k}$ and any l_p-norm $(p \ge 1)$.*

Remark 1. The statements in Corollary 1 remain true when x and y have the same sign and satisfy $x + y \le x_0$ for some $x_0 \ge 0$, and the functions $m_{ij}(z_1, \ldots, z_s)$, $1 \le i, j \le s$, are analytic on $\operatorname{Re} z_j \le x_0$ $(j = 1, \ldots, s)$. The statements in Theorem 1 also hold under similar assumptions.

Although the results presented in this section are related to both Euclidean and l_p-norms, the main applications for General Linear Methods arise when considering Euclidean norms.

3. Strict-contractivity analysis for General Linear Methods. We start with a simple lemma that will be used to prove the main results of strict-contractivity in this section.

LEMMA 1. *Let $\varphi : (-\infty, 0] \to [0, +\infty)$ be a function such that*

$$\text{(i)} \lim_{x\to-\infty} \varphi(x) = \zeta < 1, \quad \text{(ii)} \ \varphi(x)\varphi(y) \le \varphi(0)\varphi(x+y) \quad \forall x, y \in (-\infty, 0].$$

Then, there exists a constant $\sigma > 0$ such that $\varphi(x) \le \max\{\frac{1+\zeta}{2}, Ke^{\sigma x}\}$ $\forall x \le 0$, where $K = \max\{1, \varphi(0)\}$.

Proof. By virtue of (i), there exists $x_0 < 0$ such that $\varphi(x) \le \delta := \frac{1+\zeta}{2}$ $\forall x \le x_0$. Let us take $\sigma := \frac{\ln \delta}{2x_0} > 0$. Thus, if $x \in [2x_0, x_0]$, it follows that $\varphi(x) \le \delta = e^{\sigma(2x_0)} \le e^{\sigma x}$. By virtue of (ii), this implies $\varphi(\frac{x}{l}) \le Ke^{\sigma(\frac{x}{l})}$, $K = \max\{1, \varphi(0)\}$ $\forall x \in [2x_0, x_0]$ and $l \in \mathbb{N}$. On the other hand, for each $x \in (x_0, 0)$ there exists $n \in \mathbb{N}$ such that $x \in [\frac{x_0}{n}, \frac{x_0}{n+1})$. Therefore, $y := (n+1)x \in [2x_0, x_0)$, and $\varphi(x) = \varphi(\frac{y}{n+1}) \le Ke^{\sigma(\frac{y}{n+1})} = Ke^{\sigma x}$. This concludes the proof. ∎

The following theorem gives an estimate about the behavior at infinity of the function $\varphi_{G,M}(x)$ in (2.14).

THEOREM 2. *Let $M(Z)$, with $Z = \text{BlockDiag}(Z_1, \ldots, Z_s)$, be given by* (2.5). *Assume that $\tilde{A}$ is nonsingular. Then, for any symmetric positive definite matrix $G = L^T L \in \mathbb{R}^{k,k}$, we have for $\varphi_{G,M}$, given by* (2.14), *that*

$$\varphi_{G,M}(x) \le \left\|B - A\tilde{A}^{-1}\tilde{B}\right\|_G + \left\|LA\tilde{A}^{-1}\right\|_2 \left\|\tilde{B}L^{-1}\right\|_2 \frac{\left\|\tilde{A}^{-1}\right\|_2}{|x| - \left\|\tilde{A}^{-1}\right\|_2} \quad \forall x < -\left\|\tilde{A}^{-1}\right\|_2.$$

It must be observed that the upper bound in the theorem does not depend on the factorization of G.

Proof. Since $\tilde{A}$ is a nonsingular matrix, from (2.5) we can write

$$M(Z) = (B - A\tilde{A}^{-1}\tilde{B}) \otimes I_m + (A\tilde{A}^{-1} \otimes I_m)(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}(\tilde{B} \otimes I_m).$$

By taking into account that $X = Y^T Y$, $Y \in \mathbb{R}^{m,m}$, from (2.9) and (2.11) it follows that

$$\|M(Z)\|_{G\otimes X} \le \left\|B - A\tilde{A}^{-1}\tilde{B}\right\|_G + \left\|LA\tilde{A}^{-1}\right\|_2 \left\|\tilde{B}L^{-1}\right\|_2 \left\|(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}\right\|_{I_s\otimes X}. \tag{3.1}$$

Take $u \in \mathbb{C}^{ms}$, $\|u\|_2 = 1$, and define $v = (I_s \otimes Y)(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}(I_s \otimes Y^{-1})u$. We are addressed to provide an upper bound for $\|v\|_2$. From the definition of v

$$(\tilde{A}^{-1} \otimes I_m)u = (\tilde{A}^{-1} \otimes I_m)v - (I_s \otimes Y)Z(I_s \otimes Y^{-1})v, \tag{3.2}$$

and from here

$$\text{Re}\langle v, (\tilde{A}^{-1} \otimes I_m)u\rangle_2 = \text{Re}\langle v, (\tilde{A}^{-1} \otimes I_m)v\rangle_2 - \text{Re}\langle v, (I_s \otimes Y)Z(I_s \otimes Y^{-1})v\rangle_2. \tag{3.3}$$

Then, by denoting $v = (v_1^T, \ldots, v_s^T)^T$, with $v_i \in \mathbb{C}^m$, $1 \le i \le s$, we deduce that

$$\text{Re}\langle v, (I_s \otimes Y)Z(I_s \otimes Y^{-1})v\rangle_2 = \sum_{i=1}^{s} \text{Re}\langle v_i, YZ_iY^{-1}v_i\rangle_2 \le \sum_{i=1}^{s} \mu_X[Z_i]\,\|v_i\|_2^2 \le x\,\|v\|_2^2,$$

with $x = \max_{1\le i\le s} \mu_X[Z_i]$. Moreover, from elementary properties of the inner products we deduce that $\mathrm{Re}\langle v, (\tilde{A}^{-1}\otimes I_m)v\rangle_2 \ge -\|\tilde{A}^{-1}\|_2 \|v\|_2^2$, and $\mathrm{Re}\langle v, (\tilde{A}^{-1}\otimes I_m)u\rangle_2 \le \|\tilde{A}^{-1}\|_2 \|v\|_2$. From (3.3) we then conclude that

$$\left(-x - \left\|\tilde{A}^{-1}\right\|_2\right) \|v\|_2^2 \le \left\|\tilde{A}^{-1}\right\|_2 \|v\|_2 .$$

The proof is completed taking (3.1) into account. □

Next, we deduce, as a consequence of those previous results, the following contractivity result for General Linear Methods. Observe that $R(\infty) = B - A\tilde{A}^{-1}\tilde{B}$ holds for the stability function $R(z)$ in (2.6) associated to a General Linear Method with nonsingular $\tilde{A}$.

THEOREM 3. *Consider a G-stable General Linear Method* (2.1) *with a nonsingular matrix* $\tilde{A}$. *Assume that its linear stability matrix* (2.6) *satisfies* $\|R(\infty)\|_G < 1$. *Then, the method is strictly contractive on the class of strictly dissipative differential systems* ($\nu < 0$ *in* (1.2)); *i.e., there exist two positive constants* σ *and* $\gamma < 1$ (σ *and* γ *depending only on the coefficients of the method) such that*

$$\left\|\Delta Y^{(n+1)}\right\|_{G\otimes X} \le \max\{\gamma, e^{h\sigma\nu}\} \left\|\Delta Y^{(n)}\right\|_{G\otimes X} \qquad \forall h > 0,\ n \ge 0.$$

Proof. By virtue of Theorem 1 and the G-stability of the method, we have that the function $\varphi_{G,M}(x)$ in (2.14) fulfills (2.15) with $\varphi_{G,M}(0) \le 1$. On the other hand, since $\|R(\infty)\|_G < 1$ we deduce from Theorem 2 and Lemma 1 that there exist two positive constants σ and $\gamma < 1$ such that $\varphi_{G,M}(h\nu) \le \max\{\gamma, e^{h\sigma\nu}\}$. This concludes the proof by taking (2.2) into account. □

Remark 2. In general, a G-stable General Linear Method (2.1) does not necessarily satisfy $\varphi_{G,M}(0) \le 1$. However, that statement is true when the linear system associated to the stages of the method

$$\begin{aligned} V &= (\widetilde{B}\otimes I_m)Y + (\widetilde{A}\otimes I_m)ZV, \\ Z &= \mathrm{BlockDiag}(Z_1, \ldots, Z_s) \in \mathbb{C}^{ms,ms} \end{aligned}$$

admits a solution $V \in \mathbb{C}^{ms}$ for every $Y \in \mathbb{C}^{mk,mk}$, provided that $\mu_X[Z_j] \le 0$, $j = 1, \ldots, s$ (see the proof of [10, Theorem 12.23, p. 193]). Some results on the existence of solution for G-stable General Linear Methods are presented in section 4.

The main drawback when applying the previous theorem to Runge–Kutta multistep methods comes from the fact that many of these methods fulfill $\|R(\infty)\|_G = 1$, where G denotes the G-stability matrix. For instance, this is the case of the two-step backward differentiation formula (BDF) method and of the multistep Runge–Kutta Gauss methods introduced by Burrage [1, 2], as it will be shown later in section 6. Thus, to reach strict-contractivity for some G-stable methods it seems necessary to compose the method on several consecutive steps, namely, l. For multistep Runge–Kutta methods l will sometimes coincide with the number of steps (k) on which the multistep method is based; see (2.1). This motivates the study of the *l-step composed method* related to a given General Linear Method. □

A straightforward calculation shows that the numerical solution provided by (2.1) after l consecutive steps, with fixed step-size $h > 0$, satisfies

$$Y^{(n+l)} = h\sum_{i=0}^{l-1} (B^{l-1-i}A\otimes I_m)F(t_{n+i}, h, V^{(n+i)}) + (B^l\otimes I_m)Y^{(n)}, \quad l \ge 1,$$

where the stages $V^{(n+j)}$ are computed from

$$\begin{aligned} V^{(n+j)} &= h\sum_{i=0}^{j-1}(\tilde{B}B^{j-1-i}A\otimes I_m)F(t_{n+i},h,V^{(n+i)}) \\ &\quad + h(\tilde{A}\otimes I_m)F(t_{n+j},h,V^{(n+j)}) + (\tilde{B}B^j\otimes I_m)Y^{(n)}, \quad 0\le j\le l-1. \end{aligned}$$

Thus, the l-step composed method can be seen as a new k-step ls-stage General Linear Method having the form

$$\begin{aligned} Y^{(n+l)} &= h(\alpha\otimes I_m)\overline{F}(t_n,h,\overline{V}^{(n+l-1)}) + (\beta\otimes I_m)Y^{(n)}, \\ \overline{V}^{(n+l-1)} &= h(\tilde{\alpha}\otimes I_m)\overline{F}(t_n,h,\overline{V}^{(n+l-1)}) + (\tilde{\beta}\otimes I_m)Y^{(n)}, \end{aligned} \tag{3.4}$$

where

$$\begin{aligned} \overline{V}^{(n+l-1)} &:= ({V^{(n)}}^T,{V^{(n+1)}}^T,\dots,{V^{(n+l-1)}}^T)^T\in\mathbb{C}^{mls}, \\ \overline{F}(t_n,h,\overline{V}^{(n+l-1)}) &:= (F(t_{n+j},h,{V^{(n+j)}}^T)^T)_{0\le j\le l-1}^T\in\mathbb{C}^{mls} \end{aligned}$$

and

$$\tilde{c}=\begin{pmatrix} c \\ c+e \\ \vdots \\ c+(l-1)e \end{pmatrix}\in\mathbb{R}^{ls},\quad \alpha=[B^{l-1}A,\ B^{l-2}A,\ \dots\ BA,\ A]\in\mathbb{R}^{k,ls},\quad \beta=B^l\in\mathbb{R}^{k,k},$$

$$\tilde{\alpha}=\begin{pmatrix} \tilde{A} & O & O & \dots & O & O \\ \tilde{B}A & \tilde{A} & O & \dots & O & O \\ \tilde{B}BA & \tilde{B}A & \tilde{A} & \dots & O & O \\ \vdots & \vdots & \vdots & \ddots & \vdots & \vdots \\ \tilde{B}B^{l-2}A, & \tilde{B}B^{l-3}A, & \dots & \dots, & \tilde{B}A, & \tilde{A} \end{pmatrix}\in\mathbb{R}^{ls,ls},\quad \tilde{\beta}=\begin{pmatrix} \tilde{B} \\ \tilde{B}B \\ \vdots \\ \tilde{B}B^{l-1} \end{pmatrix}\in\mathbb{R}^{ls,k}.$$

To study the A-stability of the method (3.4), one has to consider the matrix $R_l(z)=\beta+z\alpha(I-z\tilde{\alpha})^{-1}\tilde{\beta}$. Since, for linear problems $y'=\lambda y$, $z=\lambda h$, the l-step composed method gives $Y^{(n+l)}=R_l(z)Y^{(n)}$ and also $Y^{(n+l)}=R(z)^lY^{(n)}$, where $R(z)$ is the stability matrix (2.6) of the original method (2.1), then it follows that $R_l(z)=R(z)^l$ $\forall z\in\mathbb{C}$. It also becomes evident that if $\tilde{A}$ is nonsingular, then so is $\tilde{\alpha}$. To study the strict-contractivity of the l-step composed method on nonlinear problems in general, proceeding the same way as in (2.2), one has that $\Delta Y^{(n+l)}=M_l(h\overline{J})\Delta Y^{(n)}$, $n\ge 0$, where $\overline{J}=\text{BlockDiag}(J^{(n+1)},\dots,J^{(n+l)})\in\mathbb{C}^{mls,mls}$, with the matrices $J^{(n+j)}$, $1\le j\le l$, given as in (2.3), and the supermatrix $M_l(\cdot)$ given by

$$M_l(\overline{Z}):=\beta\otimes I_m+(\alpha\otimes I_m)\overline{Z}(I_{mls}-(\tilde{\alpha}\otimes I_m)\overline{Z})^{-1}(\tilde{\beta}\otimes I_m)\in\mathbb{C}^{mk,mk}.$$

Of course, if the original method (2.1) is G-stable, then so is the l-step composed method (3.4). Thus, we can apply Theorem 3 to the resulting l-step composed method to get the following theorem.

THEOREM 4. *Assume that the coefficient matrix $\tilde{A}$ of a G-stable General Linear Method* (2.1) *is nonsingular and that $\rho(R(\infty))<1$. Then, there exist a first positive integer l and two positive constants σ and $\gamma<1$, depending only on the coefficients of the method, such that*

$$\left\|\Delta Y^{(n+l)}\right\|_{G\otimes X}\le\max\{\gamma,e^{h\sigma\nu}\}\left\|\Delta Y^{(n)}\right\|_{G\otimes X}\quad\forall h>0,\quad n\ge 0,$$

holds on the class of strictly dissipative differential systems ($\nu < 0$ in (1.2)). Hence, the l-step composed method (3.4) is strictly contractive.

Proof. The proof is an immediate consequence of Theorem 3, just by taking into account that $\rho(R(\infty)) = \lim_{l\to\infty} \|R(\infty)^l\|_G^{1/l} < 1$. ∎

Remark 3. It is still possible to deduce contractivity results when the matrix $\tilde{A}$ of the original General Linear Method is singular and the method is *algebraically stable*, preconsistent (see (2.8)), and irreducible (there are nonredundant stages; see, e.g., [12, p. 24] for a precise definition of irreducibility). On the other hand, it must be recalled that the matrix $D = \mathrm{Diag}(d_1, \ldots, d_s)$, appearing in the algebraic stability matrix N (2.7), has positive diagonal entries ($D > 0$) due to the algebraic stability; see [14, Lemma 4.1] or [12, Lemma 3.2].

THEOREM 5. *For a preconsistent, algebraically stable General Linear Method with $D > 0$ (see (2.7)), the difference $\Delta Y^{(n)} = \hat{Y}^{(n)} - Y^{(n)}$ between two numerical solutions for dissipative differential systems ($\nu \le 0$ in (1.2)) satisfies*

$$\left\|\Delta Y^{(n+1)}\right\|_{G\otimes X} \le \eta(h\nu) \left\|\Delta Y^{(n)}\right\|_{G\otimes X}, \ n \ge 0,$$

where

$$\eta(x) := \frac{\sqrt{1 - 2x\gamma(1-\zeta^2)} - 2x\gamma\zeta}{1 - 2x\gamma}, \tag{3.5}$$

$$\zeta = \|R(\infty)\|_G, \qquad R(\infty) := \lim_{\varepsilon\to 0}(B - A(\tilde{A} + \varepsilon I)^{-1}\tilde{B}),$$

and

$$\gamma = \left(\lim_{\varepsilon\to 0} \left\|LA(\tilde{A} + \varepsilon I)^{-1}D^{-1/2}\right\|_2\right)^{-2}, \quad \text{with } G = L^T L. \tag{3.6}$$

Remark 4. This result can be seen as a generalization of [11, Theorem 3.1] to General Linear Methods. For the sake of brevity, we do not reproduce its proof, which closely follows the ideas in the proof of the above-mentioned theorem.

The existence of $\lim_{\varepsilon\to 0} A(\tilde{A} + \varepsilon I)^{-1}$ can be ensured by virtue of [13, Lemma 3.8, p. 388].

According to [11, p. 214], the function $\eta(x)$ in (3.5) turns out to be superexponential ($\eta(0) = 1$ and $\eta(x)\eta(y) \le \eta(x + y)$, $x \le 0$, $y \le 0$). Moreover, it can be easily shown that $\zeta < \eta(x) < 1$ $\forall x < 0$ whenever $\zeta < 1$; whereas $\eta(x) = 1$ $\forall x \le 0$ in case $\zeta = 1$.

Analogous qualitative results of strict-contractivity for General Linear Methods on the class of strictly dissipative problems are deduced from Theorems 3 and 5. However, in order to simplify the presentation, our convergence results appearing in section 5 will be obtained from Theorems 2, 3, and 4.

4. Existence and uniqueness of solution for the stage equations. The existence of solution for the stage equations of General Linear Methods is derived along the same lines as in the case of implicit Runge–Kutta methods; see, e.g., [6], [8, Ch. 5], and [10, Ch. IV.14]. Below, we collect a few results whose proofs can be carried out by closely following the ideas in the above-mentioned works.

DEFINITION 1. *For any matrix $C \in \mathbb{R}^{s,s}$ and for any positive definite diagonal matrix $\tilde{D} \in \mathbb{R}^{s,s}$*

$$\alpha_{\tilde{D}}(C) := \inf_{u\neq 0} \frac{\langle Cu, u\rangle_{\tilde{D}}}{\langle u, u\rangle_{\tilde{D}}} = \frac{1}{2}\lambda_{min}(\tilde{D}^{1/2}C\tilde{D}^{-1/2} + \tilde{D}^{-1/2}C^T\tilde{D}^{1/2}),$$

and $\alpha_0(C) := \sup_{\tilde{D}>0} \alpha_{\tilde{D}}(C)$*, where* $\langle u, v\rangle_{\tilde{D}} := v^T \tilde{D} u$.

By following, for instance, the proofs of Theorems 14.2 and 14.3 in [10, Ch. IV.14] we have the following theorem.

THEOREM 6. *For the class of problems* (1.1)–(1.2)*, a General Linear Method having a nonsingular matrix* $\tilde{A}$ *has a unique solution for its stage equations whenever* $\nu h < \alpha_0(\tilde{A}^{-1})$ *is fulfilled.*

The condition $\nu h < \alpha_0(\tilde{A}^{-1})$ is *essentially optimal* as has been remarked by Kraaijevanger and Schneid [16, Theorem 2.12] for the more particular case of implicit Runge–Kutta methods. For the case of dissipative differential systems we also have the following theorem.

THEOREM 7. *An irreducible, preconsistent, and algebraically stable General Linear Method having a nonsingular matrix* $\tilde{A}$ *has a unique solution for its stage equations on the class of strictly dissipative problems* ($\nu < 0$ *in* (1.2))*.*

Proof. Due to the algebraic stability, the matrix N in (2.7) is nonnegative definite ($N \geq 0$). Moreover, the diagonal matrix D appearing in N is positive definite [14, Lemma 4.1]. Then, the matrix $D\tilde{A} + \tilde{A}^T D \geq 0$, and this implies $D\tilde{A}^{-1} + \tilde{A}^{-T} D \geq 0$. Consequently $\alpha_D(\tilde{A}^{-1}) \geq 0$. The proof is completed from Theorem 6. ∎

In case the matrix $\tilde{A}$ is singular, a more careful and particular study must be carried out. Thus, in situations where some stages are explicit, the above results can still be applied after deleting the corresponding rows (and columns) of the matrix $\tilde{A}$. This is, e.g., the case of the Runge–Kutta Lobatto IIIA methods.

5. Convergence results. We start by recalling that the discretization local errors associated to a General Linear Method (2.1) are given by the pair of vectors $(\xi(t_n), \eta(t_n))$ by means of [14, p. 366]

$$\begin{array}{rcl} \xi(t_n) & := & Y(t_n + h) - (B \otimes I_m) Y(t_n) - h(A \otimes I_m) V'(t_n), \\ \eta(t_n) & := & V(t_n) - (\tilde{B} \otimes I_m) Y(t_n) - h(\tilde{A} \otimes I_m) V'(t_n), \end{array} \tag{5.1}$$

where $V(t_n) = (y(t_n + c_j h))_{j=1}^s$, $V'(t_n) = (y'(t_n + c_j h))_{j=1}^s \in \mathbb{C}^{ms}$, and $Y(t_n) = (Y_j(t_n))_{j=1}^k \in \mathbb{C}^{mk}$. Here, $Y(t_n)$ denotes the exact advancing solution to be approximated for the method, and $y(t)$ stands for the exact solution of the initial value problem (1.1). It is straightforward to see that if the method has stage order q, then

$$\begin{array}{l} \xi(t_n) = h^{q+1}(d_1^{(q+1)} \otimes I_m) y^{(q+1)}(t_n) + \mathcal{O}(h^{q+2}), \\ \eta(t_n) = h^{q+1}(d_2^{(q+1)} \otimes I_m) y^{(q+1)}(t_n) + \mathcal{O}(h^{q+2}), \end{array} \tag{5.2}$$

where the vectors $d_1^{(q+1)} \in \mathbb{R}^k$ and $d_2^{(q+1)} \in \mathbb{R}^s$ depend only on the coefficients of the method; see, e.g., [14, p. 366]. From a straightforward calculation we deduce the next two upper bounds for the discretization local errors (5.1)

$$\begin{array}{rcl} \|\xi(t_n)\|_{I_k \otimes X} & \leq & h^q C_1 \int_{t_n}^{t_{n+1}} \left\| y^{(q+1)}(t) \right\|_X dt, \\ \|\eta(t_n)\|_{I_s \otimes X} & \leq & h^q C_2 \int_{t_n}^{t_{n+1}} \left\| y^{(q+1)}(t) \right\|_X dt, \end{array} \tag{5.3}$$

(5.4)

$$\begin{array}{rcl} \left\| \xi(t_n) - h^{q+1}(d_1^{(q+1)} \otimes I_m) y^{(q+1)}(t_n) \right\|_{I_k \otimes X} & \leq & h^{q+1} C_1' \int_{t_n}^{t_{n+1}} \left\| y^{(q+2)}(t) \right\|_X dt, \\ \left\| \eta(t_n) - h^{q+1}(d_2^{(q+1)} \otimes I_m) y^{(q+1)}(t_n) \right\|_{I_s \otimes X} & \leq & h^{q+1} C_2' \int_{t_n}^{t_{n+1}} \left\| y^{(q+2)}(t) \right\|_X dt, \end{array}$$

where the constants C_j, C_j', $j = 1, 2$, depend only on the coefficients of the method.

The study of the global errors $\epsilon_n := Y(t_n) - Y^{(n)}$ $(n = 1, 2, \dots)$, can be carried out, for instance, as it is done in [14, sect. 2]. Thus, it is immediate to show that they satisfy the recurrence

$$\begin{array}{c} \epsilon_{n+1} = M(Z^{(n)})\epsilon_n + \tau_n, \quad n = 0, 1, \dots, \\ \tau_n := \xi(t_n) + \omega(Z^{(n)})\eta(t_n), \\ \omega(Z) := (A \otimes I_m)Z(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}, \end{array} \tag{5.5}$$

where $M(Z)$ is the stability function given in (2.5), with $Z^{(n)} = hJ^{(n)}$ and $J^{(n)}$ given by (2.3) and (2.4). Thus, we are involved with getting upper bounds for $\|\prod_{j=0}^{q} M(Z^{(n-j)})\|_{G\otimes X}$ (for arbitrary $q \le n$) and for $\max_{\|u\|_{I_s\otimes X}=1} \|\omega(Z^{(n)})u\|_{G\otimes X}$. In order to bound the latter norm we have the following theorem.

THEOREM 8. *Assume that $\tilde{A}$ is nonsingular and that there exists a positive definite diagonal matrix $\tilde{D} = \mathrm{Diag}(\tilde{d}_1, \dots, \tilde{d}_s)$ such that $\tilde{\alpha} := \frac{1}{2}\lambda_{min}(\tilde{D}\tilde{A}^{-1} + \tilde{A}^{-T}\tilde{D}) \ge 0$. Then, for any symmetric positive definite matrix G and for any $Z = \mathrm{BlockDiag}(Z_1, \dots, Z_s)$, with $Z_j \in \mathbb{C}^m$, $1 \le j \le s$, it holds that*

$$\sup_{\substack{\|u\|_{I_s\otimes X}=1 \\ \mu_X[Z_j]\le x,\ 1\le j\le s}} \|\omega(Z)u\|_{G\otimes X} \le \kappa \left(1 + \frac{\left\|\tilde{D}\tilde{A}^{-1}\right\|_2}{\tilde{\alpha} - x\delta}\right) \quad \forall x < 0,$$

where

$$\kappa = \sqrt{\lambda_{max}((A\tilde{A}^{-1})^T G A\tilde{A}^{-1})} \quad \textit{and} \quad \delta = \min_{1\le j\le s} \tilde{d}_j. \tag{5.6}$$

Moreover, if $\tilde{\alpha} > 0$ the statement also holds for $x = 0$.

Proof. Let us consider $G = L^T L$ and $X = Y^T Y$ and take an arbitrary $u \in \mathbb{C}^{ms}$ satisfying $\|u\|_{I_s\otimes X} = \|(I_s \otimes Y)u\|_2 = 1$. By defining $y = \omega(Z)u$, it follows that

$$\begin{aligned} \|y\|_{G\otimes X} &= \left\|((A\tilde{A}^{-1}) \otimes I_m)((I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}u - u)\right\|_{G\otimes X} \\ &\le \left\|LA\tilde{A}^{-1}\right\|_2 \left(\left\|(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}\right\|_{I_s\otimes X} + 1\right). \end{aligned}$$

In order to bound $\|(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}\|_{I_s\otimes X}$, take an arbitrary $w \in \mathbb{C}^{ms}$, with $\|w\|_2 = 1$, and set $v = (I_s \otimes Y)(I_{ms} - (\tilde{A} \otimes I_m)Z)^{-1}(I_s \otimes Y^{-1})w$. Now, proceeding as in the proof of Theorem 2 and premultiplying by $v^*(\tilde{D} \otimes I_m)$ in both sides of the formula (3.2), we get that

$$v^*(\tilde{D}\tilde{A}^{-1} \otimes I_m)w = v^*(\tilde{D}\tilde{A}^{-1} \otimes I_m)v - v^*(I_s \otimes Y)(\tilde{D} \otimes I_m)Z(I_s \otimes Y^{-1})v. \tag{5.7}$$

By taking real part in the above equation and making use of the inequalities

$$\mathrm{Re}(v^*(I_s \otimes Y)(\tilde{D} \otimes I_m)Z(I_s \otimes Y^{-1})v) \le \delta x \|v\|_2^2 \quad \forall x < 0,$$

and

$$\mathrm{Re}(v^*((\tilde{D}\tilde{A}^{-1}) \otimes I_m)v) = 2^{-1}v^*((\tilde{D}\tilde{A}^{-1} + \tilde{A}^{-T}\tilde{D}) \otimes I_m)v \ge \tilde{\alpha}\|v\|_2^2,$$

it follows from (5.7) that

$$(\tilde{\alpha} - \delta x)\|v\|_2^2 \le \mathrm{Re}(v^*(\tilde{D}\tilde{A}^{-1} \otimes I_m)w) \le \left\|\tilde{D}\tilde{A}^{-1}\right\|_2 \|v\|_2.$$

Then, it yields that $\|(I_{ms}-(\tilde{A}\otimes I_m)Z)^{-1}\|_{I_s\otimes X}\leq \frac{\|\tilde{D}\tilde{A}^{-1}\|_2}{\tilde{\alpha}-\delta x}$. This completes the proof. ∎

Next, we give the main convergence results.

THEOREM 9. *Consider an irreducible and algebraically stable (for the matrices G and D) General Linear Method* (2.1)*, with stage order q and a nonsingular matrix $\tilde{A}$. Assume that $\rho(R(\infty))<1$. Then, by taking any positive definite diagonal matrix $\tilde{D}$ such that $\tilde{\alpha}=\alpha_{\tilde{D}}(\tilde{A}^{-1})\geq 0$, we have that the global errors $\epsilon_n=Y(t_n)-Y^{(n)}$ on strictly dissipative problems ($\nu<0$) satisfy for $n\geq 1$ and $h>0$ that*

$$\|\epsilon_n\|_{G\otimes X}\leq \varrho^{[l^{-1}n]}\,\|\epsilon_0\|_{G\otimes X}+h^{q+1}C_3 l\frac{1-\varrho^{1+l^{-1}h^{-1}t_{n-1}}}{1-\varrho}\mathcal{M}_{q+1}(t_n),$$

where $[x]$ denotes the integer part of the real number x and

$$C_3=C_1\sqrt{\rho(G)}+\kappa C_2\left(1+\frac{\left\|\tilde{D}\tilde{A}^{-1}\right\|_2}{\tilde{\alpha}+|\nu|\delta h}\right). \tag{5.8}$$

Here, l is the first positive integer verifying $\left\|R^l(\infty)\right\|_G<1$, $\varrho=\max\{\gamma,e^{h\sigma\nu}\}$, ($0<\gamma<1$ and $\sigma>0$ are those two constants given in Theorem 4), C_1 and C_2 are those two constants given in (5.3)*, κ and δ are both given in* (5.6)*, and*

$$\mathcal{M}_j(t_n):=\max_{t\in[0,t_n]}\left\|y^{(j)}(t)\right\|_X. \tag{5.9}$$

All the constants (with the exception of ϱ) depend only on the coefficients of the method. Recall that the matrix $\tilde{D}$ also depends exclusively on the matrix $\widetilde{A}$.

Proof. Let us take $\varrho=\max\{\gamma,e^{h\sigma\nu}\}<1$, where $0<\gamma<1$ and $\sigma>0$ are the constants given in Theorem 4. Then, by virtue of Theorem 4 it follows that (below $\|\cdot\|\equiv\|\cdot\|_{G\otimes X}$)

$$\left\|\prod_{k=1}^{j}M(Z^{(n-k)})\right\|\leq\varrho^{[j/l]}\quad\forall\, j\leq n. \tag{5.10}$$

From (5.5) we get for the global errors that

$$\|\epsilon_n\|\leq\|\tau_{n-1}\|+\sum_{j=1}^{n-1}\left\|\prod_{k=1}^{j}M(Z^{(n-k)})\right\|\|\tau_{n-j-1}\|+\left\|\prod_{k=1}^{n}M(Z^{(n-k)})\right\|\|\epsilon_0\|. \tag{5.11}$$

In order to bound $\|\tau_j\|$, from (5.3) and from Theorem 8 we deduce that

$$\|\tau_j\|\leq C_3h^{q+1}\mathcal{M}_{q+1}(t_{j+1}),\quad h>0,\ j\geq 0, \tag{5.12}$$

where C_3 is defined by (5.8). By inserting (5.10) and (5.12) into (5.11), it follows that

$$\|\epsilon_n\|\leq h^{q+1}C_3\mathcal{M}_{q+1}(t_n)\sum_{j=0}^{n-1}\varrho^{[j/l]}+\varrho^{[n/l]}\,\|\epsilon_0\|,\quad h>0,\ n\geq 1.$$

By setting $n-1=pl+q$, with p and q integers, $0\leq q<l$, we have that

$$\sum_{j=0}^{n-1}\varrho^{[j/l]}=l\sum_{k=0}^{p-1}\varrho^k+(q+1)\varrho^p\leq l\sum_{k=0}^{p}\varrho^k=l\frac{1-\varrho^{p+1}}{1-\varrho}=l\frac{1-\varrho^{1+[l^{-1}(n-1)]}}{1-\varrho}.$$

This concludes the proof since $\varrho^{1+[l^{-1}(n-1)]} \geq \varrho^{1+l^{-1}(n-1)}$. ∎

As a consequence of the previous theorem, we deduce the orders of convergence on semi-infinite intervals (and B-convergence on finite intervals) of algebraically stable General Linear Methods. It will be seen that the convergence results extend the pioneer results of B-convergence given by Frank, Schneid, and Ueberhuber [9] (see also [10, Theorem 15.3]) to the case of General Linear Methods. Our results for finite intervals are similar to those presented in [12]. However, the results on semi-infinite intervals, as far as we are aware, are completely new.

THEOREM 10. *Under the assumptions made in Theorem* 9 *for a General Linear Method, we have for dissipative problems* ($\nu \leq 0$) *that its global errors* $\epsilon_n := Y(t_n) - Y^{(n)}$ *satisfy for* $h > 0$, $n \geq 1$

1. *if* $\tilde{\alpha} > 0$ *and* $\nu < 0$, *then* $\|\epsilon_n\|_{G\otimes X} \leq h^q \frac{K}{|\nu|} \mathcal{M}_{q+1}(t_n) + \varrho^{[l^{-1}n]} \|\epsilon_0\|_{G\otimes X}$,
2. *if* $\tilde{\alpha} > 0$ *and* $\nu \leq 0$, *then* $\|\epsilon_n\|_{G\otimes X} \leq h^q K t_n \mathcal{M}_{q+1}(t_n) + \varrho^{[l^{-1}n]} \|\epsilon_0\|_{G\otimes X}$, *and*
3. *if* $\tilde{\alpha} = 0$ *and* $\nu < 0$, *then* $\|\epsilon_n\|_{G\otimes X} \leq h^{q-1} \frac{K}{|\nu|} \min\{\frac{1}{|\nu|}, t_n\} \mathcal{M}_{q+1}(t_n) + \varrho^{[l^{-1}n]} \|\epsilon_0\|_{G\otimes X}$,

where $\mathcal{M}_{q+1}(t_n)$ *is given in* (5.9), ϱ *and* l *are supplied by Theorem* 9, *and the constant* K *depends only on the coefficients of the method.*

Proof. The proof follows in a straightforward way from Theorem 9. It must be taken into account that if $\nu < 0$ then

$$\chi(\nu, h) := l \frac{1 - e^{\sigma\nu h(1+\frac{n-1}{l})}}{1 - e^{\sigma\nu h}} \leq \frac{l}{1 - e^{\sigma\nu h}} = \frac{l}{\sigma|\nu|h} + \mathcal{O}(1),\ h \to 0.$$

Moreover, for $\nu < 0$, $\chi(\nu, h) \leq \lim_{\nu\to 0^-} \chi(\nu, h) = h^{-1}t_n + l - 1$, since the function $(1 - e^x)^{-1}(1 - e^{ax})$ is increasing on x whenever the constant $a > 1$. ∎

It is still possible to gain one more order of convergence for a General Linear Method when

$$d_1^{(q+1)} = (I_k - B)x, \quad d_2^{(q+1)} = -\tilde{B}x \tag{5.13}$$

hold for some vector $x \in \mathbb{R}^k$. Here, $d_1^{(q+1)}$ and $d_2^{(q+1)}$ are given by (5.2).

THEOREM 11. *If a General Linear Method satisfies* (5.13) *and the assumptions in Theorem* 9, *then, for dissipative problems* ($\nu \leq 0$), *its global errors fulfill the statements in Theorem* 10 *with* q *replaced by* $q + 1$.

Proof. The proof is along the lines of that of Theorem 9, but with the following minor modifications, which are inspired by the proof of Theorem 4.2 in [14]. We define the modified global errors

$$\bar{\epsilon}_n := \epsilon_n - (x \otimes I_m) h^{q+1} y^{(q+1)}(t_n),$$

which, by virtue of (5.4) and (5.13), fulfill the recurrent relation

$$\bar{\epsilon}_n = M(Z^{(n)})\bar{\epsilon}_{n-1} + \bar{\tau}_{n-1},\ n \geq 1,\ \text{with}\ \|\bar{\tau}_{n-1}\|_{G\otimes X} \leq h^{q+2} C_3' \mathcal{M}_{q+2}(t_n).$$

Here C_3' has the same expression as C_3 in (5.8) but just replacing the constants C_i by C_i' ($i = 1, 2$), with C_i' given in (5.4). ∎

From the previous theorem it seems that one more order than the stage order can be achieved, but as it has been remarked by Hundsdorfer [14, p. 378], very few interesting methods satisfy (5.13), and this assumption seems necessary also to gain one order with regard to the stage order [14, Theorem 4.2]. We discuss this possibility more in the next section.

6. Some applications of the main results. Below, we consider a few methods in the Runge–Kutta multistep family which take the form of a General Linear Method (2.1) with

$$A = \begin{pmatrix} \gamma_1 & \cdots & \gamma_s \\ O & \dots & O \end{pmatrix}, \qquad B = \left(\begin{array}{ccc|c} \alpha_1 & \dots & \alpha_{k-1} & \alpha_k \\ \hline & I_{k-1} & & O \end{array}\right),$$

where $\gamma_1, \dots, \gamma_s, \alpha_1, \dots, \alpha_k \in \mathbb{R}$, I_{k-1} denotes the identity matrix of dimension $k-1$ and $O \in \mathbb{R}^{k-1}$ stands for the null vector. Moreover, due to preconsistency, they always satisfy $\alpha_1 + \cdots + \alpha_k = 1$.

In the case of $k = 1$, we get the classical Runge–Kutta methods. Thus, for the s-stage Runge–Kutta Radau IA, Radau IIA, and Lobatto IIIC methods (see, e.g., [10, Ch. IV.5]), we have that $(\gamma_k)_{k=1,s}$ is the weight vector and $B = (1)$. Then, since $R(\infty) = 0$, $G = (1)$, and $D = \mathrm{Diag}(\gamma_k)_{k=1,s} > 0$, by virtue of Theorem 4 these methods turn out to be strictly contractive for the strictly dissipative class ($\nu < 0$). Moreover, from Theorem 10 (see also [10, p. 220]) we deduce that for semi-infinite intervals, the Radau IIA methods have order of convergence $q = s$, whereas Radau IA methods reach order of convergence $q = s-1$. In the same way, the two-stage Lobatto IIIC methods reach order $q = 1$. However, for Lobatto IIIC methods with $s \geq 3$, only order of convergence $q = s - 2$ can be derived from Theorem 10.

It should be mentioned that one more order than the stage order cannot be guaranteed since these families do not fulfill the condition (5.13).

Next, we consider the classical two-step backward differentiation formula $BDF2$, given by $\frac{3}{2}y_{n+1} - 2y_n + \frac{1}{2}y_{n-1} = hf(t_{n+1}, y_{n+1})$, $n \geq 1$. This method is a two-step one-stage G-stable General Linear Method for the symmetric positive definite matrix $G := \begin{pmatrix} \frac{5}{4} & -\frac{1}{2} \\ -\frac{1}{2} & \frac{1}{4} \end{pmatrix}$ (see, e.g., [7], [10, Example 6.5, pp. 308–309]). Its stability matrix satisfies $\|R(\infty)\|_G = 1$ and $\left\|R(\infty)^2\right\|_G = 0$. Then, according to Theorem 4, the composed method defined by two consecutive steps of the $BDF2$ formula defines a strictly contractive method on the class of strictly dissipative differential systems. By taking $D = \tilde{A} = (2/3)$, it is readily seen that $\alpha_D(\tilde{A}^{-1}) = 3/2$. Then, from Theorem 10, this method achieves order of convergence two on semi-infinite intervals. It can be easily checked that this method does not fulfill the condition (5.13), and hence Theorem 11 cannot be applied. It is well known that this method has exactly order of convergence 2 on the class $\nu < 0$.

On the other hand, Burrage [1, 2] introduced the following set of simplifying conditions in order to construct high order algebraically stable multistep Runge–Kutta methods:

$$\begin{aligned}
B(p): \quad \bar{b}_p &:= q\sum_{j=1}^{s} \gamma_j c_j^{q-1} + \sum_{j=1}^{k} \alpha_j (1-j)^q - 1 = 0, && 1 \leq q \leq p, \\
C(p): \quad \bar{c}_p &:= q\sum_{j=1}^{s} \tilde{a}_{ij} c_j^{q-1} + \sum_{j=1}^{k} \tilde{b}_{ij} (1-j)^q - c_i^q = 0, && 1 \leq q \leq p,\ \forall i, \\
D(p): \quad \bar{d}_p &:= q\sum_{i=1}^{s} \gamma_i c_i^{q-1} \tilde{b}_{ij} - \alpha_j (1-(1-j)^q) = 0, && 1 \leq q \leq p,\ \forall j, \\
E(p): \quad \bar{e}_p &:= q\sum_{i=1}^{s} \gamma_i c_i^{q-1} \tilde{a}_{ij} - \gamma_j (1 - c_j^q) = 0, && 1 \leq q \leq p,\ \forall j.
\end{aligned}$$

Thus, the family of k-step s-stage Runge–Kutta Gauss methods with stage order $q = s$ and order of consistency $2s$ has been derived by Burrage [1, 2] by imposing

$B(s)$, $C(s)$, $D(s)$, and $E(s)$. This family of methods, with parameters $\alpha_j \geq 0$ ($j = 1, \ldots, k-1$), $\alpha_k > 0$, and $\alpha_1 + \ldots \alpha_k = 1$ provides G-stable methods, where $G = \mathrm{Diag}(1, \alpha_2 + \ldots \alpha_k, \ldots, \alpha_{k-1} + \alpha_k, \alpha_k)$; see Theorem 9.15 in [10, p. 367]. The nodes $c_1, \ldots, c_s$ depend on $k-1$ parameters α_j ($j = 2, \ldots, k$), they are placed on the real interval $(1-k, 1)$, and they are uniquely determined in terms of the $k-1$ parameters by the condition $B(2s)$ (see, e.g., [10, Lemma 9.11]); that is,

$$\sum_{j=1}^{k} \alpha_j \int_{1-j}^{1} \pi(x) x^{q-1} dx = 0, \quad 1 \leq q \leq s, \tag{6.1}$$

where $\pi(x) = (x - c_1) \cdot \cdots \cdot (x - c_s)$ stands for the nodal polynomial. In particular, for the uniparametric family of two-step two-stage Runge–Kutta Gauss methods, which will be here denoted by $Gauss(\alpha)$, with free parameter $\alpha \equiv \alpha_2 \in (0, 1]$ ($\alpha_1 = 1 - \alpha$), the nodes c_1 and c_2 can be computed in terms of α from (6.1). The weights γ_1, γ_2 and the coefficient matrices $\widetilde{B}$ and $\widetilde{A}$ are uniquely determined in terms of α by the conditions $B(2)$, $D(2)$, and $C(2)$, respectively. For every $\alpha \in (0, 1]$, such methods are G-stable and algebraically stable with matrix $G = \mathrm{Diag}(1, \alpha)$ and diagonal matrix $D = \mathrm{Diag}(\gamma_1, \gamma_2)$. For $\alpha \to 0^+$ we get the classical one-step Gauss method with step-size $h > 0$ to advance from t_n to t_{n+1}; whereas for $\alpha \to 1^-$ the classical one-step Gauss method with step-size $2h$ to advance from t_{n-1} to t_{n+1} is deduced. In Table 1 the main features of this family of methods are displayed. In particular, from

TABLE 1

Some features of the 2-step 2-stage algebraically stable Runge–Kutta multistep methods, denoted by $Gauss(\alpha)$, $RadauIIA(\alpha)$, $RadauIA(\alpha)$, and $LobattoIIIC(\alpha)$, $0 < \alpha \leq 1$.

	$Gauss(\alpha)$
$\|R(\infty)\|_G < 1$	Never
$\left\|R(\infty)^2\right\|_G < 1$	$0 < \alpha < 1$
$\alpha_D(\widetilde{A}^{-1}) > 0$	$0 < \alpha < 1$
$\rho(R(\infty)) = 1,\ \alpha_D(\widetilde{A}^{-1}) = 0$	$\alpha = 1$
Simplifying conditions	$B(2),\ C(2),\ D(2),\ E(2)$
Convergence on $[0, \infty)$	$q = 2$ (only for $0 < \alpha < 1$)
	$RadauIIA(\alpha)$
$\|R(\infty)\|_G < 1$	$0 < \alpha < 1$
$\left\|R(\infty)^2\right\|_G < 1$	$0 < \alpha \leq 1$
$\alpha_D(\widetilde{A}^{-1}) > 0$	$0 < \alpha \leq 1$
Simplifying conditions	$B(2),\ C(2),\ D(2),\ E(1),\ c_2 = 1$
Convergence on $[0, \infty)$	$q = 2$ ($0 < \alpha \leq 1$)
	$RadauIA(\alpha)$
$\|R(\infty)\|_G < 1$	$0 < \alpha < 1$
$\left\|R(\infty)^2\right\|_G < 1$	$0 < \alpha \leq 1$
$\alpha_D(\widetilde{A}^{-1}) > 0$	$0 < \alpha \leq 1$
Simplifying conditions	$B(2),\ C(1),\ D(2),\ E(2),\ c_1 = -1$
Convergence on $[0, \infty)$	$q = 1$ ($0 < \alpha \leq 1$)
	$LobattoIIIC(\alpha)$
$\|R(\infty)\|_G < 1$	$0 < \alpha < 1$
$\left\|R(\infty)^2\right\|_G < 1$	$0 < \alpha \leq 1$
$\alpha_D(\widetilde{A}^{-1}) > 0$	$0 < \alpha \leq 1$
Simplifying conditions	$B(2),\ C(1),\ D(2),\ E(1),\ c_{1,2} = -1, 1,\ \tilde{a}_{22} = 1$
Convergence on $[0, \infty)$	$q = 1$ ($0 < \alpha \leq 1$)

Theorems 4 and 10 it can be deduced that they are strictly contractive and convergent of order two on semi-infinite intervals whenever $0 < \alpha < 1$.

Under the same simplifying conditions above, Li [17] derived six classes of high order algebraically stable and B-convergent Runge–Kutta multistep methods. In particular, those methods belonging to the classes 2–4 (see [17, p. 1491]) can be respectively regarded as generalizations of the one-step Runge–Kutta RadauIIA, RadauIA, and LobattoIIIC methods. Here, we have studied in detail the cases in [17, p. 1491] for which $k = s = 2$. In Table 1, we have considered particular uniparametric families belonging to the classes 2, 3, and 4 in [17], denoted, respectively, by $RadauIIA(\alpha)$, $RadauIA(\alpha)$, and $LobattoIIIC(\alpha)$, where $0 < \alpha_2 = \alpha \leq 1$, $\alpha_1 = 1 - \alpha$, with α as a free parameter. The main features concerning the derivation of the methods, the strict-contractivity and its convergence order on semi-infinite intervals, are displayed in Table 1. All these methods are algebraically stable whenever $0 < \alpha \leq 1$, with matrices $G = (1, \alpha)$ and $D = (\gamma_1, \gamma_2)$. The weights $\{\gamma_j,\, j = 1, 2\}$ are readily obtained from the simplifying conditions in Table 1. The order of convergence is deduced from Theorem 10. It should be mentioned that one more order than the stage order cannot be guaranteed since the condition (5.13) is never satisfied.

7. Concluding remarks. New results related to the strict-contractivity and the convergence of General Linear Methods on the class of strictly dissipative problems have been derived. A previous result of strict-contractivity on Runge–Kutta methods by Hairer and Zennaro [11] has been generalized to the class of General Linear Methods. On the other hand, the convergence results on Runge–Kutta methods by Frank, Schneid, and Ueberhuber [9] and on General Linear Methods by Huang, Chang, and Xiao [12] are extended to semi-infinite intervals. The new convergence results meet applications on interesting methods appearing in the literature.

OPTIMAL SUPERCONVERGENCE RESULTS FOR DELAY INTEGRO-DIFFERENTIAL EQUATIONS OF PANTOGRAPH TYPE*

HERMANN BRUNNER† AND QIYA HU‡

Abstract. We analyze the optimal (global and local) orders of superconvergence of collocation solutions u_h on uniform meshes I_h for delay Volterra integro-differential equations with proportional delay functions given by $\theta(t) = qt$ $(0 < q < 1,\ t \in [0,T])$. In particular, we show that if u_h is a continuous piecewise polynomial of degree $m \geq 2$, and if collocation is at the Gauss (–Legendre) points, then the (optimal) order of local superconvergence on I_h is $p^* = m+2$. It turns out that the same order p^* holds for nonlinear (strictly increasing) delay functions vanishing at $t = 0$. However, on judiciously chosen geometric meshes, collocation at the Gauss points yields the order $2m - \varepsilon_N$, where $\varepsilon_N \to 0$ as the number N of mesh points tends to infinity. Optimal local superconvergence results for the pantograph delay differential equation are obtained as special cases of our general analysis.

Key words. Volterra integro-differential equation, vanishing delays, proportional delays, pantograph equation, collocation solutions, optimal order of superconvergence

AMS subject classifications. 65R20, 34K06, 34K28

DOI. 10.1137/060660357

1. Introduction.

It is well known that collocation in the space of continuous piecewise polynomials of degree $m \geq 1$ for first-order delay differential and integro-differential equations with *nonvanishing delays* leads to (optimal) $\mathcal{O}(h^{2m})$-superconvergence at the mesh points of a suitably chosen (constrained) mesh I_h if the collocation points are the Gauss (–Legendre) points (see, e.g., Bellen [3], Bellen and Zennaro [7], Brunner [8, 11], and Chapter 4 of the monograph [12]). For the prototype of a functional differential equation with *vanishing delay*, the pantograph equation,

$$y'(t) = a(t)y(t) + b(t)y(qt), \quad t \in I := [0,T] \quad (0 < q < 1) \tag{1.1}$$

(first analyzed by Fox et al. [18] and Kato and McLeod [29]; see also the survey paper [23] by Iserles); this high order of local superconvergence can be attained on special *geometric meshes* (Bellen [4]). The same is true for its generalization, the pantograph Volterra integro-differential equation

$$y'(t) = a(t)y(t) + b(t)y(qt) + g(t) + \int_0^t K_0(t,s)y(s)ds + \int_0^{qt} K_1(t,s)y(s)ds, \quad t \in I \tag{1.2}$$

(Bellen et al. [5]).

On *uniform meshes* the problem regarding optimal (local) superconvergence of collocation solutions for pantograph-type functional differential equations, and in particular for the pantograph equation itself, has remained open (compare the survey paper [10]). An indication that the "classical" superconvergence results might not remain valid for pantograph-type differential (and integral) equations was given in Brunner [9], Takama, Muroya, and Ishiwata [33], Ishiwata [28], and Muroya, Ishiwata, and Brunner [32]: it was shown in these papers that the collocation solution corresponding to the m Gauss points does not exhibit the (local) order $2m+1$ at $t = t_1 = h$, in contrast to ordinary differential equations or delay differential equations with constant delay.

It is the aim of the present paper to show, employing techniques rather different from those in [13], that for $m > 2$ the attainable order of superconvergence at the points of a uniform mesh $I_h = \{t_n = nh : \ 0 \le n \le N \ (t_N = T)\}$ (with $N \ge 2$) cannot exceed $p^* := m+2$, and that this optimal value p^* can be attained for *any* $q \in (0,1)$ and all $m \ge 2$. This is in sharp contrast to the optimal local superconvergence result in (iterated) collocation solutions for pantograph-type Volterra *integral* equations: Brunner and Hu [13] have shown that the optimal local order $p^* = m+2$ can be attained *only* when $q = 1/2$ and m is even.

2. Volterra integro-differential equations of pantograph type.

2.1. Regularity and representation of solutions. Consider the general linear pantograph Volterra integro-differential equation

$$y'(t) = a(t)y(t) + b(t)y(\theta(t)) + g(t) + (\mathcal{V}y)(t) + (\mathcal{V}_\theta y)(t), \quad t \in I := [0,T], \tag{2.1}$$

with initial condition $y(0) = y_0$ and delay function $\theta(t) := t - \tau(t)$ satisfying $\theta(0) = 0$ and $\theta(t) < t$ when $t \in (0,T]$ (see also (D1)–(D3) below). The Volterra integral operators $\mathcal{V}$ and $\mathcal{V}_\theta$ are defined by

$$(\mathcal{V}y)(t) := \int_0^t K_0(t,s)y(s)ds, \quad K_0 \in C(D), \tag{2.2}$$

$$(\mathcal{V}_\theta y)(t) := \int_0^{\theta(t)} K_1(t,s)y(s)ds, \quad K_1 \in C(D_\theta), \tag{2.3}$$

where $D := \{(t,s) : \ 0 \le s \le t \le T\}$. We set

$$D_\theta^{(k)} := \{(t,s) : \ 0 \le s \le \theta^k(t), \ t \in I\} \quad (k \ge 1) \quad \text{and} \quad D_\theta := D_\theta^{(1)}.$$

$\theta(t) = qt$ $(0 < q < 1)$, and we will usually write $D_\theta^{(k)} = D_q^{(k)}$.

The delay function $\theta(t) = t - \tau(t)$ is subject to the following conditions:

(D1) $\theta \in C^d(I)$, with $d \ge 1$, and $\theta(0) = 0$;
(D2) $\theta(t) \le q_1 t$ $(t \in I)$, with $q_1 < 1$; and
(D3) $\min_{t\in I} \theta'(t) =: q_0 > 0$, with $q_0 \le q_1$.

Equation (2.1) includes two important special cases: the *pantograph equation* with variable coefficients, (1.1) (which corresponds to $\theta(t) = qt = t - (1-q)t$), and the delay Volterra integro-differential equation with "pure delay,"

$$y'(t) = b(t)y(\theta(t)) + g(t) + (\mathcal{V}_\theta y)(t), \quad t \in I, \tag{2.4}$$

which exhibits all the essential (quantitative) properties of (2.1) on which the subsequent analysis will focus.

It is readily verified that the initial-value problem for (2.1) is equivalent to the delay integral equation

$$y(t) = g_0(t) + \int_0^t H_0(t,s)y(s)ds + \int_0^{\theta(t)} H_1(t,s)y(s)ds, \quad t \in I, \tag{2.5}$$

where we have set

$$g_0(t) := y_0 + \int_0^t g(s)ds, \tag{2.6}$$

$$H_0(t,s) := a(s) + \int_s^t K_0(v,s)dv, \tag{2.7}$$

$$H_1(t,s) := b(\theta^{-1}(s))\theta'(\theta^{-1}(s)) + \int_{\theta^{-1}(s)}^t K_1(v,s)dv. \tag{2.8}$$

In complete analogy with the pantograph equation (1.1), smooth data in (2.1) lead to smooth solutions on I. This is made precise in the following theorem.

THEOREM 2.1. *Assume that, for some $d \geq 0$, the given functions in* (2.1) *satisfy*
(i) $a,\ b,\ g \in C^d(I)$;
(ii) $K_0 \in C^d(D),\ K_1 \in C^d(D_\theta)$; *and*
(iii) (D1)–(D3), *with* $\theta \in C^{d+1}(I)$.
Then for each $y_0 \in \mathbb{R}$ the initial-value problem for (2.1) *has a unique solution $y \in C^{d+1}(I)$.*

The proof of this existence and regularity result (which generalizes Theorems 5.16 and 5.18 in Brunner [12]) follows readily from the Picard iteration process applied to the delay integral equation (2.5). For the delay Volterra integro-differential equation (2.4)—on which our subsequent analysis will focus—we obtain the following theorem on the representation of solutions. This result is an obvious generalization of the one for $\theta(t) = qt$ $(0 < q < 1)$ derived by Chambers [17]; in fact, this result is already implicitly contained in the 1914 paper [1] by Andreoli.

THEOREM 2.2. *Under the assumptions of Theorem* 2.1, *the unique solution of the initial-value problem for the delay Volterra integro-differential equation* (2.4) *can be represented in the form*

$$y(t) = g_0(t) + \sum_{k=1}^{\infty} \int_0^{\theta^k(t)} H_k(t,s)g_0(s)ds, \quad t \in I, \tag{2.9}$$

where $\theta^k := \underbrace{\theta \circ \cdots \circ \theta}_{k}$. The iterated kernels $H_k(t,s)$ of the kernel $H_1(t,s)$ defined in (2.8) *are determined recursively by*

$$H_{k+1}(t,s) := \int_{\theta^{-k}(s)}^{\theta(t)} H_1(t,v)H_k(v,s)dv \tag{2.10}$$

$$= \int_{\theta^{-1}(s)}^{\theta^k(t)} H_k(t,v)H_1(v,s)dv, \quad (t,s) \in D_\theta^{(k+1)}\ (k \geq 1). \tag{2.11}$$

An alternative form of the solution representation (2.9) *is*

$$y(t) = \left(1 + \sum_{k=1}^{\infty} \tilde{H}_k(t,0)\right) y_0 + \int_0^t g(s)ds + \sum_{k=1}^{\infty} \int_0^{\theta^k(t)} \tilde{H}_k(t,s)g(s)ds, \tag{2.12}$$

with

$$\tilde{H}_k(t,s) := \int_s^{\theta^k(t)} H_k(t,v)dv, \quad (t,s) \in D_\theta^{(k)}. \tag{2.13}$$

Proof. The only new ingredient in Theorem 2.2 is the alternative expression (2.11) for the iterated kernel $H_{k+1}(t,s)$. It is readily verified by induction, using an obvious change in the order of integration (which is based on assumption (D3) for θ). We will illustrate this by considering $k = 2$. By (2.10),

$$H_3(t,s) = \int_{\theta^{-2}(s)}^{\theta(t)} H_1(t,v)H_2(v,s)dv,$$

and hence,

$$\begin{aligned} H_3(t,s) &= \int_{\theta^{-2}(s)}^{\theta(t)} H_1(t,v)\left(\int_{\theta^{-1}(s)}^{\theta(v)} H_1(v,z)H_1(z,s)dz\right)dv \\ &= \int_{\theta^{-1}(s)}^{\theta^2(t)} \left(\int_{\theta^{-1}(z)}^{\theta(t)} H_1(t,v)H_1(v,z)dv\right) H_1(z,s)dz \\ &= \int_{\theta^{-1}(s)}^{\theta^2(t)} H_2(t,z)H_1(z,s)dz, \quad (t,s) \in D_\theta^{(3)}. \end{aligned}$$

The completion of the induction argument is now clear. The representation (2.12) follows from (2.9) and the definition (2.6) of $g_0(t)$. □

COROLLARY 2.3. *Let* $\theta(t) = qt,\ 0 < q < 1$, *and define*

$$\beta := q^{-1}\max\{|b(t)| :\ t \in I\}, \quad \bar{K}_1 := \max\{|K_1(t,s)| :\ (t,s) \in D_q\}.$$

Then the iterated kernels $\{H_k(t,s)\}$ *corresponding to the kernel* $K_1(t,s)$ *in* (2.4), (2.8) *are bounded by*

$$|H_k(t,s)| \le \frac{(\beta + \bar{K}_1 T)^k}{(k-1)!} q^{(k-1)(k-2)/2}[qt - q^{-(k-1)}s]^{k-1}, \tag{2.14}$$
$$(t,s) \in D_q^{(k)} \quad (k \ge 1).$$

Moreover, the kernels $\{\tilde{H}_k(t,s)\}$ *defined in* (2.13) *satisfy*

$$|\tilde{H}_k(t,s)| \le \frac{(\beta + \bar{K}_1 T)^k}{k!} q^{k(k-1)/2}[qt - q^{-(k-1)}s]^k, \quad (t,s) \in D_q^{(k)} \quad (k \ge 1). \tag{2.15}$$

The estimates (2.14) follow directly from the expression (2.11) for the iterated kernels, using an inductive argument and integration by parts. Hence, the estimates for the integrated kernels $\tilde{H}_k(t,s)$ are an obvious consequence of (2.13).

COROLLARY 2.4. *If* $K_1(t,s) \equiv 0$, *then the iterated kernels associated with the delay integral equation* (2.5) *corresponding to the pantograph equation* (1.1) *satisfy*

$$|H_k(t,s)| \le \frac{\beta^k q^{(k-1)(k-2)/2}}{(k-1)!}[qt - q^{-(k-1)}s]^{k-1}, \quad (t,s) \in D_q^{(k)} \quad (k \ge 1). \tag{2.16}$$

For the sake of completeness we conclude this section by observing that the results of Theorem 2.2 on the representation of the solution to (2.4) are easily extended to

the general pantograph equation (2.1), by applying Picard iteration to its equivalent delay integral equation (2.5). The precise result is given in the following theorem.

THEOREM 2.5. *If the given functions in the general pantograph Volterra integro-differential equation* (2.1) *are continuous on their respective domains, and if the delay function* θ *is subject to* (D1)–(D3)*, then its unique solution* $y \in C^1(I)$ *has the representation*

$$\begin{aligned} y(t) &= g_0(t) + \int_0^t \sum_{k=1}^{\infty} H_{0,k}(t,s) g_0(s) ds \\ &\quad + \sum_{k=1}^{\infty} \int_0^{\theta^k(t)} H_{1,k}(t,s) g_0(s) ds + \mathcal{M}(t), \quad t \in I, \end{aligned} \tag{2.17}$$

where

$$\mathcal{M}(t) := \sum_{k=1}^{\infty} \int_0^{\theta^k(t)} H_k^{(0,1)}(t,s) g_0(s) ds, \tag{2.18}$$

and $\theta^0(t) := t$*. The kernels* $H_{0,k}(t,s)$ *and* $H_{1,k}(t,s)$ *are the iterated kernels associated with the kernels* $H_0(t,s)$ *and* $H_1(t,s)$ *defined in* (2.7) *and* (2.8)*, and* g_0 *is given by* (2.6)*. The infinite series in* (2.17) *and* (2.18) *converge absolutely and uniformly on* I*, and we have* $H_k^{(0,1)}(t,s) \equiv 0$ $(k \geq 1)$ *when* $H_0(t,s) \equiv 0$ *or* $H_1(t,s) \equiv 0$*.*

Proof. As indicated before, the representation (2.17) follows readily from Picard iteration applied to the integral equation (2.5); here, the following lemma (an obvious extension of Dirichlet's formula regarding the change in the order of integration in integrals with variable limits of integration) plays a key role. ∎

LEMMA 2.6. *Let* k *and* ℓ *be given nonnegative integers, and assume that the delay function* θ *is subject to the hypotheses* (D1)–(D3)*. Then for any function* $\phi \in C(D_\theta^{(k+\ell)})$*,*

$$\int_0^{\theta^k(t)} \left(\int_0^{\theta^\ell(s)} \phi(s,v) dv \right) ds = \int_0^{\theta^{k+\ell}(t)} \left(\int_{\theta^{-\ell}(v)}^{\theta^k(t)} \phi(s,v) ds \right) dv, \quad (t,s) \in D_\theta^{(k+\ell)}. \tag{2.19}$$

We leave the details of the proof of Theorem 2.5 to the reader but illustrate the basic result underlying its induction argument, thus revealing the structure of the kernels $H_k^{(0,1)}(t,s)$ in (2.18). Setting $y_0(t) := g_0(t)$ and $H_{0,1}(t,s) := H_0(t,s)$, $H_{1,1}(t,s) := H_1(t,s)$, the first two iterates obtained by Picard iteration for (2.5) are, respectively,

$$y_1(t) = g_0(t) + \int_0^t H_{0,1}(t,s) g_0(s) ds + \int_0^{\theta(t)} H_{1,1}(t,s) g_0(s) ds,$$

and hence, by Lemma 2.6,

$$\begin{aligned} y_2(t) &= g_0(t) + \int_0^t H_{0,1}(t,s) y_1(s) ds + \int_0^{\theta(t)} H_{1,1}(t,s) y_1(s) ds \\ &= g_0(t) + \int_0^t H_{0,1}(t,s) \Bigg(g_0(s) + \int_0^s H_{0,1}(s,v) g_0(v) dv \\ &\quad + \int_0^{\theta(s)} H_{1,1}(s,v) g_0(v) dv \Bigg) ds \end{aligned}$$

$$+\int_0^{\theta(t)} H_{1,1}(t,s)\left(g_0(s)+\int_0^s H_{0,1}(s,v)g_0(v)dv+\int_0^{\theta(s)} H_{1,1}(s,v)g_0(v)dv\right)ds$$
$$=g_0(t)+\int_0^t H_{0,1}(t,s)g_0(s)ds+\int_0^t H_{0,2}(t,s)g_0(s)ds$$
$$+\int_0^{\theta(t)} H_{1,1}(t,s)g_0(s)ds+\int_0^{\theta^2(t)} H_{1,2}(t,s)g_0(s)ds+\int_0^{\theta(t)} H_2^{(0,1)}(t,s)g_0(s)ds.$$

Here, $H_{0,2}(t,s)$ and $H_{1,2}(t,s)$ are the first nontrivial iterated kernels for the given kernels $H_0(t,s)$ and $H_1(t,s)$:

$$H_{0,2}(t,s):=\int_s^t H_{0,1}(t,v)H_{0,k-1}(v,s)dv,$$
$$H_{1,2}(t,s):=\int_{\theta^{-(k-1)}(s)}^{\theta(t)} H_{1,1}(t,v)H_{1,k-1}(v,s)dv$$

(cf. (2.10)), and the "mixed" kernel $H_2^{(0,1)}(t,s)$ has the form

$$H_2^{(0,1)}(t,s):=\int_{\theta^{-1}(s)}^t H_{0,1}(t,v)H_{1,1}(v,s)dv+\int_v^{\theta(t)} H_{1,1}(t,v)H_{0,1}(v,s)dv.$$

2.2. Collocation methods in piecewise polynomial spaces. As we have seen in section 2.1 (Theorem 2.1), the analytical solution to the pantograph integro-differential equation (2.1) with smooth data is smooth on the entire interval $I:=[0,T]$, in contrast to solutions to such functional equations with nonvanishing delays. Thus, the mesh underlying the piecewise polynomial space in which the approximation u_h to the exact solution will be sought will be chosen as

$$I_h:=\{t_n:\ 0=t_0<t_1<\cdots<t_N=T\}\quad(\text{with }\ t_n=t_n^{(N)}),\tag{2.20}$$

and we set $h_n:=t_{n+1}-t_n,\ h:=\max\{h_n:\ 0\le n\le N-1\}$. For given I_h and $m\ge 1$, the collocation solution u_h to (2.1) will be an element of the space

$$S_m^{(0)}(I_h):=\{v\in C^0(I):\ v|_{[t_n,t_{n+1}]}\in\pi_m\ (0\le n\le N-1)\}\tag{2.21}$$

of continuous (real) piecewise polynomials of degree not exceeding m; u_h is determined by the collocation equation

$$u_h'(t)=a(t)u_h(t)+b(t)u_h(\theta(t))+g(t)+(\mathcal{V}u_h)(t)+(\mathcal{V}_\theta u_h)(t),\quad t\in X_h,\ \ u_h(0)=y_0.\tag{2.22}$$

Here,

$$X_h:=\{t_n+c_ih_n:\ 0<c_1<\cdots<c_m\le 1\ (0\le n\le N-1)\}\tag{2.23}$$

is the set of collocation points corresponding to given collocation parameters $\{c_i\}$. For continuous data there exists $\bar h>0$ so that (2.19) has a unique solution $u_h\in S_m^{(0)}(I_h)$ for all meshes I_h with $h\in(0,\bar h)$ (see, e.g., [12, section 5.5.1]).

It is also known [12, section 5.5.2] that, for arbitrarily chosen collocation parameters $\{c_i\}$, the collocation error tends to zero uniformly, as $h\to 0$. More precisely, we

have the following global convergence result (which we state for further reference); its proof can be found in [12, Ch. 5].

THEOREM 2.7. *Assume that* a, b, g, K_0, K_1 *are in* C^m *on their respective domains, and let* θ *be subject to the conditions* (D1)–(D3), *with* $d \geq m+1$ *(cf. section* 2.1*). Then for* $h \in (0, \bar{h})$ *the collocation solution* $u_h \in S_m^{(0)}(I_h)$ *for* (2.1) *satisfies*

$$\|y^{(\nu)} - u_h^{(\nu)}\|_\infty \leq C_\nu h^m \quad (\nu = 0, 1), \tag{2.24}$$

where the constants C_ν *depend on* $\{c_i\}$ *and on* q *but not on* h.

The collocation solution $u_h \in S_m^{(0)}(I_h)$ for (2.1) induces the *defect* (or residual) δ_h defined by

$$\delta_h(t) := -u_h'(t) + a(t)u_h(t) + b(t)u_h(\theta(t)) + g(t) + (\mathcal{V}u_h)(t) + (\mathcal{V}_\theta u_h)(t), \quad t \in I, \tag{2.25}$$

with $\delta_h(t) = 0$ for all $t \in X_h$. It inherits (piecewise, on the subintervals $[t_n, t_{n+1}]$) the regularity of the given functions in (2.1). Since $\delta_h(t)$ can also be written as

$$\delta_h(t) = e_h'(t) - a(t)e_h(t) - b(t)e_h(\theta(t)) - (\mathcal{V}e_h)(t) - (\mathcal{V}_\theta e_h)(t), \quad t \in I, \tag{2.26}$$

where $e_h := y - u_h$, the following result is an immediate consequence of Theorem 2.7.

COROLLARY 2.8. *Under the assumptions of Theorem* 2.7 *we have*

$$\|\delta_h\|_\infty \leq D_0 h^m$$

for all $h \in (0, \bar{h})$, *where the constant* D_0 *does not depend on* h.

3. Optimal global superconvergence on I.

THEOREM 3.1. *Assume the following:*

(i) *The given functions in the pantograph Volterra integro-differential equation* (2.1) *satisfy, for* κ *specified in* (3.1), a, b, $g \in C^{m+\kappa}(I)$, $K_0 \in C^{m+\kappa}(D)$, $K_1 \in C^{m+\kappa}(D_\theta)$, *and* $\theta(t) = qt$ $(0 < q < 1)$.

(ii) $u_h \in S_m^{(0)}(I_h)$ *is the collocation solution, with respect to the uniform mesh* I_h *and collocation parameters* $\{c_i\}$, *to* (2.1).

(iii) *The collocation parameters are such that, for some* κ *with* $1 \leq \kappa \leq m$,

$$J_\nu := \int_0^1 s^\nu \prod_{i=1}^m (s - c_i)ds = 0, \quad \nu = 0, \ldots, \kappa - 1; \tag{3.1}$$

that is, the interpolatory m*-point quadrature based on the abscissas given by the collocation parameters* $\{c_i\}$ *has degree of precision* $m + \kappa - 1$.

Then u_h *is globally superconvergent:*

$$\|y - u_h\|_\infty \leq Ch^{m+1},$$

where in general the order $m+1$ *cannot be replaced by* $m+2$. *The constant* C *depends on* q *and on* $\{c_i\}$ *but not on* h.

Proof. For ease of exposition we will give the proof for (2.4); it is readily adapted (using the representation (2.17) in Theorem 2.5) to the general pantograph integro-differential equation (2.1). It follows from (2.4) and (2.25) (with $a = 0$, $\mathcal{V} = 0$) that the collocation error $e_h := y - u_h$ solves the initial-value problem

$$e_h'(t) = b(t)e_h(qt) + \delta_h(t) + (\mathcal{V}_\theta e_h)(t), \quad t \in I, \quad e_h(0) = 0. \tag{3.2}$$

Hence, by (2.12) of Theorem 2.2 (where the roles of y and g are now assumed by e_h and δ_h, respectively),

$$e_h(t) = \int_0^t \delta_h(s)ds + \sum_{k=1}^{\infty} \int_0^{q^k t} \tilde{H}_k(t,s)\delta_h(s)ds, \quad t \in I. \tag{3.3}$$

Let now $t = t_n + vh$ ($v \in [0,1]$), and define

$$\begin{aligned} q_{k,n}(v) &:= \lfloor q^k(n+v) \rfloor, \quad \gamma_{k,n} = \gamma_{k,n}(v) := q^k n - q_{k,n}, \\ k_n^*(q) &:= \max\{k : \ q_{k,n}(v) \geq 1\}. \end{aligned} \tag{3.4}$$

Thus, (3.3) can be written in the form

$$e_h(t) = h\sum_{\ell=0}^{n-1} \int_0^1 \delta_h(t_\ell + sh)ds + h\int_0^v \delta_h(t_n + sh)ds + S_n^I(v) + S_n^{II}(v), \tag{3.5}$$

where we have set

$$S_n^I(v) := \sum_{k=1}^{k_n^*(q)} \int_0^{t_{q_{k,n}}} \tilde{H}_k(t,s)\delta_h(s)ds = h\sum_{k=1}^{k_n^*(q)} \left(\sum_{\ell=0}^{q_{k,n}-1} \int_0^1 \tilde{H}_k(t, t_\ell + sh)\delta_h(t_\ell + sh)ds \right) \tag{3.6}$$

and

$$S_n^{II}(v) := h\sum_{k=1}^{\infty} \int_0^{\gamma_{n,k}} \tilde{H}_k(t, t_{q_{k,n}} + sh)\delta_h(t_{q_{k,n}} + sh)ds. \tag{3.7}$$

In order to derive the (optimal) order estimate for $S_n^I(v)$, we first observe that, using m-point interpolatory quadrature formulas, with abscissas based on the m collocation parameters $\{c_i\}$ and with $E_{n,\ell}(v)$ and $\tilde{E}_{n,\ell}^{(k)}(v)$ denoting, respectively, the resulting quadrature errors for the integrals with integrands $\delta_h(t_\ell + sh)$ and those with integrands $\tilde{H}_k(t, t_\ell + sh)\delta_h(t_\ell + sh)$, and observing that on each subinterval $[t_n, t_{n+1}]$ the defect δ_h is in $C^{m+\kappa}$, we may write

$$|S_n^I(v)| \leq h\sum_{k=1}^{k_n^*(q)} \left(\sum_{\ell=0}^{q_{k,n}-1} |\tilde{E}_{n,\ell}^{(k)}(v)| \right). \tag{3.8}$$

By assumption (3.1) on the collocation parameters $\{c_i\}$, these quadrature formulas have degree of precision $m + \kappa - 1$, and hence, by the regularity of the integrands on the subintervals $[t_n, t_{n+1}]$,

$$|E_{n,\ell}(v)| \leq Q_m h^{m+\kappa}, \quad |\tilde{E}_{n,\ell}^{(k)}(v)| \leq \tilde{Q}_m h^{m+\kappa}.$$

We therefore obtain

$$|S_n^I(v)| \leq h \cdot \tilde{Q}_m h^{m+\kappa} \sum_{k=1}^{k_n^*(q)} q_{k,n}(v) \leq Nh \cdot \tilde{Q}_m h^{m+\kappa} \frac{q}{1-q} = T\tilde{Q}_m h^{m+\kappa} \frac{q}{1-q} \tag{3.9}$$

($0 \leq n \leq N-1$), since, by (3.4), $q_{k,n} \leq q^k n \leq q^k N$. ∎

Consider now $S_n^{II}(v)$: it follows from (3.7), Corollary 2.8, and (2.15) that

$$|S_n^{II}(v)| \le h\|\delta_h\|_\infty \sum_{k=1}^{\infty} \frac{(\beta + \bar{K}_1 T)^k}{k!} q^{k(k-1)/2} \int_0^{\gamma_{k,n}} [qt - q^{-(k-1)}s]^k ds$$

$$\le h\|\delta_h\|_\infty \sum_{k=1}^{\infty} \frac{(\beta + \bar{K}_1 T)^k T^{k+1}}{(k+1)!} q^{k(k+3)/2} =: D_0 \tilde{B}(q) h^{m+1}, \quad v \in [0,1] \tag{3.10}$$

$(0 \le n \le N-1)$. Thus, (3.5) together with (3.9) and (3.10) lead to the (optimal) global superconvergence estimate

$$|e_h(t)| \le Ch^{m+1}, \quad \text{with} \quad C := (TQ_m + D_0) + (T\tilde{Q}_m q/(1-q) + D_0\tilde{B}(q)),$$

which holds uniformly for $t \in I$, and for any κ between 1 and m in (3.1).

Owing to the smoothness of the exact solution of the pantograph integro-differential equation (2.1), the optimal global convergence estimate in Theorem 3.1 is not surprising: it agrees with the one for classical and constant-delay Volterra integral equations. However, the picture changes completely for the optimal order of the collocation solution for (2.1) at the mesh points of a uniform mesh, as shown in the following section.

4. Optimal local superconvergence on uniform meshes. It was shown in Brunner and Hu [13] that for Volterra *integral* equations of pantograph type, the optimal order of local superconvergence at the points of a uniform mesh cannot exceed $p^* = m+2$, and that the optimal value is attained only when $q = 1/2$ and m is even. For Volterra *integro-differential* equations of pantograph type, we obtain the same value of p^* but it is now attained for all $q \in (0,1)$ and all $m \ge 2$. This result, stated in the following theorem, provides the (affirmative) answer to a conjecture in [11, section 4] and [12, section 5.5.2]. We will comment on the reason for this difference in the optimal local superconvergence orders following the proof of Theorem 4.1.

THEOREM 4.1. *Assume the following:*

(i) *The given functions in* (2.1) *satisfy* a, b, $g \in C^{m+\kappa}(I)$, $K_0 \in C^{m+\kappa}(D)$, *and* $K_1 \in C^{m+\kappa}(D_\theta)$ *for some* κ *with* $1 \le \kappa \le m$.

(ii) $\theta(t) = qt$ $(0 < q < 1)$.

(iii) $u_h \in S_m^{(0)}(I_h)$ *is the collocation solution to* (2.1) *on a uniform mesh* I_h *and corresponding to collocation parameters* $\{c_i\}$ *satisfying the orthogonality conditions* (3.1) *with* $1 \le \kappa \le m$.

Then for any $q \in (0,1)$ *and any* $m \ge 2$,

$$\max\{|y(t) - u_h(t)| : \ t \in I_h\} \le C^* h^{m+2}, \tag{4.1}$$

and the exponent $m+2$ *cannot, in general, be replaced by* $m+3$.

Proof. The starting point is again the error equation (3.2): for the representation of its solution we now use (2.9), where the roles of g in (2.6) and those of y are assumed by δ_h and e_h, respectively. For a given mesh point $t = t_n$ $(n = 1, \ldots, N)$ we set, in analogy to (3.4),

$$q_{k,n} := \lfloor q^k n \rfloor, \quad \gamma_{k,n} := q^k n - q_{k,n}, \quad k_n^*(q) := \max\{k : \ q_{k,n} \ge 1\}. \tag{4.2}$$

Thus, the counterpart of (3.5) is given by

$$e_h(t_n) = \int_0^{t_n} \delta_h(s) ds + S_n^I + S_n^{II}, \tag{4.3}$$

where

$$S_n^I := \sum_{k=1}^{k_n^*(q)} \int_0^{t_{q_{k,n}}} H_k(t_n, s) \left(\int_0^s \delta_h(v)dv \right) ds \tag{4.4}$$
$$= h \sum_{k=1}^{k_n^*(q)} \sum_{\ell=0}^{q_{k,n}-1} H_k(t_n, t_\ell + sh) \left(h \sum_{\nu=0}^{\ell-1} \int_0^1 \delta_h(t_\nu + vh)dv + h \int_0^s \delta_h(t_\ell + vh)dv \right) ds$$

and

$$S_n^{II} := h \sum_{k=1}^{\infty} \int_0^{\gamma_{k,n}} H_k(t_n, t_{q_{k,n}} + sh) \left(\int_0^{t_{q_{k,n}}+sh} \delta_h(v)dv \right) ds \tag{4.5}$$
$$= h \sum_{k=1}^{\infty} \int_0^{\gamma_{k,n}} H_k(t_n, t_{q_{k,n}} + sh) \left(h \sum_{\ell=0}^{q_{k,n}-1} \int_0^1 \delta_h(t_\ell + vh)dv + h \int_0^s \delta_h(t_{q_{k,n}} + vh)dv \right) ds.$$

The techniques for estimating $|S_n^I|$ and $|S_n^{II}|$ closely parallel the ones used in section 3 (cf. (3.8) and (3.9)). Observe first that in the upper bound for $|S_n^I|$ we have

$$h \sum_{\nu=0}^{\ell-1} \left| \int_0^1 \delta_h(t_\nu + vh)dv \right| + h \left| \int_0^s \delta_h(t_\ell + vh)dv \right| \le TQ_m h^{m+\kappa} + h \cdot D_0 h^m =: \tilde{D}_0 h^{m+1}.$$

Hence, by (2.14) of Corollary 2.3 and by observing the factor h in front of the first summation sign in the second line of (4.4) we are led to

$$|S_n^I| \le h \cdot \tilde{D}_0 h^{m+1} \cdot \sum_{k=1}^{k_n^*(q)} \sum_{\ell=0}^{q_{k,n}-1} \int_0^1 |H_k(t_n, t_\ell + sh)|ds$$
$$\le \tilde{D}_0 h^{m+2} \sum_{k=1}^{k_n^*(q)} \frac{(\beta + \bar{K}_1 T)^k T^{k-1}}{(k-1)!} q^{(k-1)(3k-4)/2} =: C_0 h^{m+2}. \tag{4.6}$$

Similarly, (4.5) together with (2.14) and Corollary 2.8 allow us to obtain the estimate

$$|S_n^{II}| \le C_1 h^{m+2} \quad (1 \le n \le N). \tag{4.7}$$

Hence, (4.3) and the two estimates (4.6) and (4.7) yield the desired optimal superconvergence result on I_h,

$$|e_h(t_n)| \le (C_0 + C_1) h^{m+2} =: C^* h^{m+2}, \quad n = 1, \ldots, N;$$

as the above analysis shows, the power h^{m+2} cannot be replaced by h^{m+3}, except in trivial cases. □

The above result answers the question regarding the optimal order of local superconvergence for the pantograph delay differential equation (1.1).

COROLLARY 4.2. *The collocation solution* $u_h \in S_m^{(0)}(I_h)$ $(m \geq 2)$ *for the pantograph delay differential equation* (1.1)*, with uniform mesh* I_h *and collocation points based on the Gauss points* $\{c_i\}$*, has the optimal local superconvergence order* $p^* = m+2$ *on* I_h*:*

$$\max\{|y(t) - u_h(t)| : \ t \in I_h\} \leq Ch^{m+2}.$$

Remark. As we have indicated before, the above optimal local superconvergence result differs sharply from the one corresponding to the collocation solution $u_h \in S_{m-1}^{(-1)}(I_h)$ (the space of piecewise polynomials of degree $m-1 \geq 0$ that are allowed to possess finite jumps at the mesh points) and its iterate $u_h^{it|}$ for the pantograph integral equation

$$u(t) = g(t) + \int_0^{qt} K_1(t,s)u(s)ds, \quad t \in [0,T]. \tag{4.8}$$

Here, the iterated collocation error e_h^{it} $(= e_h - \delta_h)$ at $t = t_n$ has the representation

$$e_h^{it}(t_n) = \sum_{k=1}^{\infty} \int_0^{q^k t_n} H_k(t_n, s)\delta_h(s)ds, \quad n = 1, \ldots, N,$$

which, recalling (4.2), can be written in a form analogous to (4.3), namely, $e_h^{it}(t_n) = \hat{S}_n^I + \hat{S}_n^{II}$. However, the terms $\hat{S}_n^I$ and $\hat{S}_n^{II}$ corresponding to S_n^I and S_n^{II} (cf. (4.4) and (4.5)) no longer contain integrals of the defect function δ_h. In particular, we now have

$$\hat{S}_n^{II} = h\sum_{k=1}^{\infty} \int_0^{\gamma_{k,n}} H_k(t_n, t_{q_{k,n}} + sh)\delta_h(s)ds,$$

where, as before, $\|\delta_h\|_\infty = \mathcal{O}(h^m)$. This implies that if collocation is at the Gauss points, then $\hat{S}_n^{II} = \mathcal{O}(h^{m+2})$ $(n = 1, \ldots, N)$ can now be attained only for special values of q and m, namely, when $q = 1/2$ and m is even. Details can be found in Brunner and Hu [13, p. 1940].

5. Equations with nonlinear vanishing delays vanishing at $t = 0$. We now turn to the superconvergence analysis of collocation solutions for pantograph-type Volterra integro-differential equations (2.1) where delay function given by $\theta(t) = t - \tau(t)$ is nonlinear and satisfies the hypotheses (D1)–(D3). Since (D2) implies the inequalities

$$\theta^k(t) \leq q_1^k t \quad (k \geq 1) \quad \text{and} \quad \theta^{-1}(s) \geq q_1^{-1} s \tag{5.1}$$

(cf. (2.11)), they suggest that our global and local superconvergence results of Theorems 3.1 and 4.1 will remain valid for such nonlinear vanishing delays. The basis for the proofs is given by the following generalization of Corollary 2.3.

LEMMA 5.1. *Let* θ *be subject to the hypotheses* (D1)–(D3) *of section* 2*, and define*

$$\beta := \max\{|b(\theta^{-1}(t))|\theta'(\theta^{-1}(t)) : \ t \in I\}, \quad \bar{K}_1 := \max\{|K_1(t,s)| : \ (t,s) \in D_\theta\}.$$

The iterated kernels associated with the delay integral equation (2.5) *corresponding to the pantograph integro-differential equation* (2.4) *satisfy*

$$|H_k(t,s)| \leq \frac{(\beta + \bar{K}_1 T)^k}{(k-1)!} q_1^{(k-1)(k-2)/2}[q_1 t - q_1^{-(k-1)}s]^{k-1}, \tag{5.2}$$
$$(t,s) \in D_\theta^{(k)} \ \ (k \geq 1).$$

Moreover, the kernels $\{\tilde{H}_k(t,s)\}$ *defined in* (2.13) *satisfy*

$$|\tilde{H}_k(t,s)| \le \frac{(\beta+\bar{K}_1T)^k}{k!} q_1^{k(k-1)/2}[q_1t - q_1^{-(k-1)}s]^k, \quad (t,s)\in D_\theta^{(k)} \ \ (k\ge 1). \tag{5.3}$$

The proof is an immediate consequence of (5.1) (which is based on the condition (D2) for the delay function θ)) and the result of Corollary 2.3, where the role of q is now assumed by q_1.

THEOREM 5.2. *Assume the following:*

(i) *The given functions* a, b, g, K_0, *and* K_1 *in the general Volterra pantograph integro-differential equation* (2.1) *possess continuous derivatives of order* $m+\kappa$ *for some* κ *with* $1\le\kappa\le m$ *on their respective domains.*

(ii) *The delay function* θ *is subject to the hypotheses* (D1)–(D3) *of section* 2, *with* $d\ge m+\kappa+1$.

(iii) $u_h\in S_m^{(0)}(I_h)$ *is the collocation solution, with respect to a uniform mesh* I_h *with sufficiently small mesh diameter* $h>0$, *to the initial-value problem for* (2.1).

(iv) *The collocation parameters* $\{c_i\}$ *in* (2.21) *satisfy* (3.1) *for some* κ *with* $1\le\kappa\le m$.

Then the following hold:

(a) u_h *is globally superconvergent on* I, *with optimal order described by*

$$\|y-u_h\|_\infty \le Ch^{m+1}. \tag{5.4}$$

(b) *For any* $q_1\in(0,1)$ *(cf. hypothesis* (D3)*) and any* $m\ge 2$, u_h *is locally superconvergent at the mesh points*

$$\max\{|y(t)-u_h(t)|:\ t\in I_h\}\le C^*h^{m+2}, \tag{5.5}$$

where in general the order $p^*:=m+2$ *cannot be replaced by* $m+3$.

Proof. We will prove the local superconvergence estimate (5.5); the global estimate (5.4) can be established along very similar lines, as is already suggested by the proof of Theorem 3.1.

By (2.1) and (2.20) the collocation error satisfies the initial-value problem

$$\begin{aligned} &e_h'(t) = a(t)e_h(t)+b(t)e_h(\theta(t))+\delta_h(t)+(\mathcal{V}e_h)(t)+(\mathcal{V}_\theta e_h)(t), \quad t\in I,\\ &e_h(0)=0, \end{aligned}$$

where $\delta_h(t)=0$ on the set X_h of collocation points. Hence, it follows from the solution representation (2.9) in Theorem 2.5 (with e_h and δ_h replacing y and g, respectively) that, at $t=t_n$ $(n=1,\dots,N)$,

$$\begin{aligned} e_h(t_n) &= \int_0^{t_n}\delta_h(s)ds+\sum_{k=0}^{\infty}\int_0^{\theta^k(t_n)}H_k(t_n,s)\left(\int_0^s\delta_h(v)dv\right)ds\\ &= \int_0^{t_n}\delta_h(s)ds+\int_0^{t_n}H_0(t,s)(t_n,s)\left(\int_0^s\delta_h(v)dv\right)ds \qquad (5.6)\\ &\quad +\sum_{k=1}^{\infty}\int_0^{\theta^k(t_n)}H_k(t_n,s)\left(\int_0^s\delta_h(v)dv\right)ds. \qquad (5.7) \end{aligned}$$

For given n and $k\ge 1$ let, in analogy to (4.2), the (unique) $q_{k,n}\in\mathbb{N}$ be such that

$$\theta^k(t_n)\in[t_{q_{k,n}},t_{q_{k,n}+1}), \tag{5.8}$$

and define

$$\gamma_{k,n} := (\theta^k(t_n) - t_{q_{k,n}})/h, \quad k_n^* := \max\{k : \ q_{k,n} \geq 1\}. \tag{5.9}$$

We thus may write, in analogy to (4.3)–(4.5),

$$e_h(t_n) = h\sum_{\ell=0}^{n-1}\int_0^1 \delta_h(t_\ell + sh)ds + h\sum_{\ell=0}^{n-1}\int_0^1 H_0(t_n, t_\ell + sh)\left(\int_0^{t_\ell+sh}\delta_h(v)dv\right)ds$$
$$+ S_n^I + S_n^{II} \quad (n = 1, \ldots, N), \tag{5.10}$$

where

$$S_n^I := \sum_{k=1}^{k_n^*}\int_0^{t_{q_{k,n}}} H_k(t_n, s)\left(\int_0^s \delta_h(v)dv\right)ds \tag{5.11}$$

and

$$S_n^{II} := h\sum_{k=1}^{\infty}\int_0^{\gamma_{k,n}} H_k(t_n, t_{q_{k,n}} + sh)\left(\int_0^{t_{q_{k,n}}+sh}\delta_h(v)dv\right)ds. \tag{5.12}$$

(Recall that by Lemma 5.1 the above infinite series converge uniformly for all $n = 1, \ldots, N$.)

A glimpse at (4.4) and (4.5) now reveals that the estimates (4.6) and (4.7) carry over to S_n^I and S_n^{II} defined in (5.11) and (5.12), except that now, by (5.2) in Lemma 5.1, q has to be replaced by $q_1 \in (0,1)$, corresponding to the hypothesis (D2) for the nonlinear delay function θ. Thus, employing the arguments used in the proof of Theorem 4.1 allows us to derive the optimal estimate (5.5) of Theorem 5.2.

COROLLARY 5.3. *Assume that the delay function θ satisfies the conditions* (D1)–(D3) *of section 2, with $d \geq 2m+1$, and let I_h be a uniform mesh with sufficiently small $h > 0$. If a, b, $g \in C^{2m}(I)$, then the collocation solution $u_h \in S_m^{(0)}(I_h)$ $(m \geq 2)$ for the generalized pantograph delay differential equation*

$$y'(t) = a(t)y(t) + b(t)y(\theta(t)) + g(t), \quad t \in I, \quad y(0) = y_0, \tag{5.13}$$

with collocation points (2.21) *based on the Gauss points $\{c_i\}$, has the optimal local superconvergence order $p^* = m+2$ for all $q \in (0,1)$:*

$$\max\{|y(t) - u_h(t)| : \ t \in I_h\} \leq C^* h^{m+2}.$$

Here, the constant C^* depends on the $\{c_i\}$ and on q_1 but not on h.

Remarks. 1. Recall that the hypothesis (D2) (section 2) requires that $\theta(t) \leq q_1 t$, $t \in I$, for some $q_1 \in (0,1)$. Do the optimal superconvergence estimates (5.4) and (5.5) remain true if the nonlinear delay function θ satisfies only (D1) and (D3) and is such that $\theta'(0) = 1$? Examples of such delay functions are $\theta(t) = q_1\log(1+t)$, $0 < q_1 \leq 1$, for which we have $\theta'(t) = q_1\frac{1}{1+t}$, $t \in [0,T]$, and thus $\theta'(0) = 1$ when $q_1 = 1$; and $\theta(t) = t - t^r$, $r \in \mathbb{N}$ $(r \geq 2)$. In this case, $\theta'(0) = 1$, $\theta^{(\nu)}(0) = 0$ $(\nu = 2, \ldots, r-1)$ (see also [5, section 4]).

The analysis of optimal superconvergence of collocation solutions for (2.1) with delay functions of the above type is yet to be carried out. It appears that the approach in Brunner and Maset [15] will yield the tools to extend the analysis in the present

paper to functional differential and integro-differential equations (2.1) containing these more general θ.

2. A related question concerns delay functions θ that satisfy (D1) and (D3) on $[0,T]$ but have the properties that (i) $\theta(0) = 0$ and $\theta(t) < t$ for $t \in (0, t^*)$, (ii) $\theta(t^*) = t^*$ (i.e., $\tau(t^*) = 0$), and (iii) e.g., (D1)–(D3) hold on $[t^*, T]$. The optimal convergence analysis of (2.1) with such "doubly vanishing" delay functions is studied in [15].

6. Optimal local superconvergence on geometric meshes. We shall now show that, in analogy to pantograph-type Volterra integral equations (Brunner and Hu [13]), $\mathcal{O}(h^{2m})$-superconvergence at the mesh points can (almost) be restored if we replace the uniform mesh I_h by a judiciously chosen *geometric mesh* (see also [21] and [14]). To be precise, we shall seek the collocation solution u_h to (2.1) in $S_m^{(0)}(I_h)$, where the underlying mesh I_h is defined by the mesh points

$$t_0 = 0, \;\; t_n = t_n^{(N)} = d^{N-n}T \quad (n = 1, \ldots, N) \tag{6.1}$$

for some $d = d(q; N) \in (0, 1)$.

THEOREM 6.1. *Let the assumptions of Theorem* 3.1 *hold with* $\kappa = m$ *(implying, by* (3.1)*, that the* $\{c_i\}$ *are the* m *Gauss points). If the mesh* I_h *corresponds to the points defined by* (6.1)*, with*

$$d = q^{1/r}, \quad r := \left\lfloor \frac{\ln(q)}{\ln[1 - \frac{2m\ln(N)}{(m+2)N}]} \right\rfloor, \tag{6.2}$$

then the estimate

$$\max\{|y(t) - u_h(t)| : \; t \in I_h\} \le CN^{-(2m-\varepsilon_N)} \quad \text{as} \;\; N \to \infty \tag{6.3}$$

for the collocation solution $u_h \in S_m^{(0)}(I_h)$ $(m \ge 2)$ *to* (2.1) *holds for any* $q \in (0, 1)$. *Here,* $C = C(q)$*, and* ε_N *is defined by*

$$\varepsilon_N := \log_N \left(\frac{(2m \cdot \ln N)^{2m}}{(2m+1)(m+2)^{2m}} \right) \tag{6.4}$$

and has the property $\varepsilon_N \to 0^+$ *as* $N \to \infty$.

Proof. For ease of exposition we describe the proof of (2.4); the analysis is readily extended to the general pantograph integro-differential equation (2.1) by employing the error representation based on the result (2.17) in Theorem 2.5. By (2.9) of Theorem 2.2 we obtain the error representation

$$e_h(t_n) = \int_0^{t_n} \delta_h(s)ds + \sum_{k=1}^{\infty} \int_0^{\theta^k(t_n)} H_k(t_n, s) \left(\int_0^s \delta_h(\tau)d\tau \right) ds, \quad n = 1, \ldots, N$$

(recall also (3.3)). Using integration by parts, this expression can be rewritten as

$$e_h(t_n) = \int_0^{t_n} \delta_h(s)ds + \sum_{k=1}^{\infty} \int_0^{\theta^k(t_n)} \tilde{H}_k(t_n, \tau)\delta_h(\tau)d\tau, \quad n = 1, \ldots, N, \tag{6.5}$$

with

$$\tilde{H}_k(t_n, \tau) := \int_\tau^{\theta^k(t_n)} H_k(t_n, s)ds.$$

Resorting to the quadrature argument used in the proof of Theorem 4.1, we find that

$$\left|\int_0^{t_n} \delta_h(s)ds\right| \le CN^{-2m} \quad (n=1,\dots,N). \tag{6.6}$$

Thus, the proof reduces to estimating the infinite series in (6.5). It is easy to see that

$$\theta^k(t_n) = q^k t_n = d^{kr}\cdot t_n = d^{N-n+kr}T,$$

with r as defined in (6.2). This, together with the definition (6.1) of t_n, leads to the following results:

(i) For $kr-n \ge -1$, we have $\theta^k(t_n) \le t_1 \le CN^{-\frac{2m}{m+2}}$ (as $N\to+\infty$).

(ii) For $kr-n \le -1$, there holds $\theta^k(t_n) = t_{n-kr} \in I_h$.

Note that (i) follows from Lemma 3.1(i) of [14].

We now assume, without loss of generality, that $n \ge r+1$. Otherwise, the case (i) always occurs for each k, and the corresponding analysis is obvious. We decompose the infinite series in (6.5) into two parts:

$$\begin{aligned}\sum_{k=1}^{\infty}\int_0^{\theta^k(t_n)} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau &= \sum_{k=[\frac{n-1}{r}]+1}^{\infty}\int_0^{\theta^k(t_n)} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau \\ &\quad + \sum_{k=1}^{[\frac{n-1}{r}]}\int_0^{t_{n-kr}} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau =: I_1 + I_2.\end{aligned} \tag{6.7}$$

Since

$$|\tilde{H}_k(t_n,\tau)| \le C\theta^k(t_n), \quad \tau\in[0,\ \theta^k(t_n)],$$

a standard argument leads to

$$\left|\int_0^{\theta^k(t_n)} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau\right| \le C(\theta^k(t_n))^{m+2} \le C(d^{N-n+kr})^{m+2}.$$

Furthermore, it is easy to verify that

$$|I_1| \le Cd^{(m+2)(N-1)} \le Ct_1^{m+2} \le CN^{-2m}. \tag{6.8}$$

Since the term I_2 in (6.7) can be written in the form

$$I_2 = \sum_{k=1}^{[\frac{n-1}{r}]}\sum_{i=1}^{n-kr}\int_{t_{i-1}}^{t_i} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau,$$

we obtain, observing Corollary 2.3,

$$\left|\int_{t_{i-1}}^{t_i} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau\right| \le C(t_i-t_{i-1})^{2m+1}.$$

It then follows from part (ii) of Lemma 3.1 in [14] that

$$|I_2| \le C(1-d)^{2m+1}\sum_{k=1}^{[\frac{n-1}{r}]}\sum_{i=1}^{n-kr} d^{(N-i)(2m+1)}$$

$$\leq C(1-d)^{2m} \sum_{k=1}^{[\frac{n-1}{r}]} d^{(2m+1)(N-n+kr)}$$
$$\leq C\frac{q^{2m+1}(1-d)^{2m}}{1-q^{2m+1}} \leq CN^{-(2m-\varepsilon_N)},$$

with ε_N given by (6.4). We now substitute (6.8) and the above inequality into (6.7); this yields

$$\left|\sum_{k=1}^{\infty} \int_0^{\theta^k(t_n)} \tilde{H}_k(t_n,\tau)\delta_h(\tau)d\tau\right| \leq CN^{-(2m-\varepsilon_N)}.$$

The result (6.3) in Theorem 6.1 now follows from (6.5), (6.6), and the above estimate. ∎

COROLLARY 6.2. *Let $a, b, g \in C^{2m}(I)$. If the solution y of the pantograph delay differential equation* (5.13) *is approximated by the collocation solution $u_h \in S_m^{(0)}(I_h)$ $(m \geq 2)$, with geometric mesh I_h given by* (6.1), (6.2)*, and with collocation points corresponding to the Gauss points $\{c_i\}$, then*

$$\max\{|y(t)-u_h(t)| : t \in I_h\} \leq CN^{-(2m-\varepsilon_N)} \quad \text{as } N \to \infty,$$

with ε_N defined in (6.4).

Remark. It was shown in Bellen [4] (see also [7] and [5]) that the optimal local superconvergence order $p^* = 2m$ can be restored if a different type of (quasi-) geometric mesh is employed (see also [31] and [6], where such meshes were introduced for the stability analysis of one-point collocation methods for the pantograph equation). This approach relies, however, on the assumption that a sufficiently accurate initial approximation is known on a "small" initial interval $[0, t_0]$; the quasi-geometric mesh is then generated on $[t_0, T]$. This contrasts the quasi-optimal local superconvergence results of Theorem 6.1 and Corollary 6.2 which do not require such an initial approximation.

7. Concluding remarks. We conclude our presentation by pointing to a number of open problems in the numerical analysis of pantograph-type functional differential equations.

(i) *Higher-order pantograph-type integro-differential equations.* Special cases of the initial-value problem

$$y''(t) = a(t)y(t) + b(t)y(\theta) + (\mathcal{V}y)(t) + (\mathcal{V}_\theta y)(t), \quad t \in I := [0,T], \tag{7.1}$$

with $\theta(t) = qt$ $(0 < q < 1)$, were studied, both theoretically and numerically, by Bélair [2] and by Zhang and Brunner [34]. If (7.1) is rewritten as a system of first-order integro-differential equations and solved by collocation in the piecewise polynomial space $S_m^{(0)}(I_h)$, then the superconvergence analysis of the previous sections can be readily extended to this system. However, if the initial-value problem (7.1) is solved directly, by using the collocation space $S_{m+1}^{(1)}(I_h)$, then the analysis of the optimal order of superconvergence on uniform meshes remains to be carried out.

(ii) *Pantograph equations of neutral type.* The convergence analysis in $S_m^{(0)}(I_h)$ for the neutral-type analogue of (2.4),

$$u'(t) = b(t)u(\theta(t)) + c(t)u'(\theta(t)) + g(t) + \int_0^{\theta(t)} (K_1(t,s)u(s) + K_2(t,s)u'(s))\,ds, \quad t \in [0,T], \tag{7.2}$$

with $\theta(t) = qt$ $(0 < q < 1)$, is much more complex than the one for (2.4) and is the subject of ongoing work. The key difficulty lies in the fact that (7.2) is in essence equivalent to a nonstandard pantograph-type Volterra integral equation of the form

$$u(t) = g_0(t) + \hat{b}(t)u(qt) + \int_0^{qt} \hat{K}(t,s)u(s)ds, \quad t \in I.$$

We note that even for the initial-value problem for the neutral pantograph equation

$$u'(t) = a(t)u(t) + b(t)u(qt) + c(t)u'(qt) + g(t), \quad t \in [0,T],$$

the existence of a unique (exact or collocation) solution is a nontrivial problem (it depends on the "size" of $c(t)$); compare, e.g., [27, 26, 16].

(iii) *Pantograph equations with multiple delays.* The paper [35] by Zhao, Xu, and Qiao contains an analysis of the optimal order of piecewise polynomial collocation solutions at $t = t_1 = h$ for the double pantograph equation (that is, for (1.1) with two proportional delays). Their result generalizes the analogous ones in [9, 33, 28, 32] for (1.1) with constant a and b. It is not yet known if the optimal superconvergence results of Corollaries 4.2 and 5.3 remain valid for delay differential equations with several proportional delays.

(iv) *Asymptotic stability of collocation solutions.* The problem of the asymptotic behavior (asymptotic stability; contractivity) of collocation solutions on *uniform meshes* to pantograph-type (integro-) differential equations remains essentially open. While there is such a result for the special case $u_h \in S_1^{(0)}(I_h)$ $(m = 1)$ and $q = 1/2$ (see Buhmann, Iserles, and Nørsett [16]; compare also Iserles [23, 24], Iserles and Liu [25]), there has been extensive work on asymptotic stability for (1.1) when I_h is a *geometric mesh*. We refer the reader to the papers by Liu [30, 31], Bellen, Guglielmi, and Torelli [6], Guglielmi and Zennaro [20], Huang and Vandewalle [22], and Guglielmi [19] and to the monograph [7] by Bellen and Zennaro.

Acknowledgments. Part of the work by the first author was carried out while he was a University Fellow at Hong Kong Baptist University (January–May 2006). He gratefully acknowledges the financial support and the hospitality extended to him by HKBU's Department of Mathematics.

The authors wish to thank Wei Gong (Academy of Mathematics and Systems Science, Chinese Academy of Sciences) and the anonymous referee for their careful reading of a previous version of this paper and for suggestions that led to a better presentation of the material.

A STOCHASTIC COLLOCATION METHOD FOR ELLIPTIC PARTIAL DIFFERENTIAL EQUATIONS WITH RANDOM INPUT DATA*

IVO BABUŠKA†, FABIO NOBILE‡, AND RAÚL TEMPONE§

Abstract. In this paper we propose and analyze a stochastic collocation method to solve elliptic partial differential equations with random coefficients and forcing terms (input data of the model). The input data are assumed to depend on a finite number of random variables. The method consists in a Galerkin approximation in space and a collocation in the zeros of suitable tensor product orthogonal polynomials (Gauss points) in the probability space and naturally leads to the solution of uncoupled deterministic problems as in the Monte Carlo approach. It can be seen as a generalization of the stochastic Galerkin method proposed in [I. Babuška, R. Tempone, and G. E. Zouraris, *SIAM J. Numer. Anal.,* 42 (2004), pp. 800–825] and allows one to treat easily a wider range of situations, such as input data that depend nonlinearly on the random variables, diffusivity coefficients with unbounded second moments, and random variables that are correlated or even unbounded. We provide a rigorous convergence analysis and demonstrate exponential convergence of the "probability error" with respect to the number of Gauss points in each direction in the probability space, under some regularity assumptions on the random input data. Numerical examples show the effectiveness of the method.

Key words. collocation method, stochastic partial differential equations, finite elements, uncertainty quantification, exponential convergence

Introduction. Thanks to the fast growing power of computers, numerical simulations are increasingly used to produce predictions of the behavior of complex physical or engineering systems. Some sources of errors arising in computer simulations now can be controlled and reduced by using sophisticated techniques such as a posteriori error estimation [1, 3, 37], mesh adaptivity, and the more recent *modeling error* analysis [31, 32, 10]. All this has increased the accuracy of numerical predictions as well as our confidence in them.

Yet, many engineering applications are affected by a relatively large amount of uncertainty in the input data such as model coefficients, forcing terms, boundary conditions, and geometry. In this case, to obtain a reliable numerical prediction, one has to include uncertainty quantification due to the uncertainty in the input data.

Uncertainty can be described in several ways, depending on the amount of information available; among others we mention the worst case scenario analysis and fuzzy set theory, evidence theory, probabilistic setting, etc. (see [6, 24] and the references therein). In this paper we focus on elliptic partial differential equations with a probabilistic description of the uncertainty in the input data. The model problem has the form

$$\mathcal{L}(a)u = f \quad \text{in } D, \tag{0.1}$$

where $\mathcal{L}$ is an elliptic operator in a domain $D \subset \mathbb{R}^d$, which depends on some coefficients $a(x, \omega)$, with $x \in D$, $\omega \in \Omega$, and Ω indicating the set of possible outcomes. Similarly, the forcing term $f = f(x, \omega)$ can be assumed to be random as well.

We will focus on the case where the probability space has a low dimensionality, which means that the stochastic problem depends only on a relatively small number of random variables.

This can be the case if, for instance, the mathematical model depends on few parameters, which can be taken as random variables with a given joint probability distribution. For example, we might think of the deformation of an elastic homogeneous material in which Young's modulus and Poisson's ratio (parameters that characterize the material properties) are random variables, either independent or not.

In other situations, the input data may vary randomly from one point of the physical domain D to another, and their uncertainty should rather be described in terms of random fields with a given covariance structure (i.e., each point of the domain is a random variable, and the correlation between two distinct points in the domain is known and nonzero, in general; this case is sometimes referred to as *colored noise*).

Examples of this situation are the deformation of inhomogeneous materials such as wood, foams, or biomaterials such as arteries and bones; groundwater flow problems where the permeability in each layer of sediments (rocks, sand, etc.) should not be assumed constant; and the action of wind (direction and point intensity) on structures.

A possible way to describe such random fields consists in using a Karhunen–Loève [27, 28] or a polynomial chaos (PC) expansion [38, 42]. The former represents the random field as a linear combination of an infinite number of uncorrelated random variables, while the latter uses polynomial expansions in terms of independent random variables. Both expansions exist provided that the random field $a : \Omega \to V$, as a mapping from the probability space into a functional space V, has bounded second moments. Other nonlinear expansions can be considered as well (see, e.g., [22] for a technique to express a stationary random field with given covariance structure and marginal distribution as a function of (infinite) independent random variables; nonlinear transformations also have been used in [30, 39]). The use of nonpolynomial expansions may be advantageous in some situations: for instance, in groundwater flow problems, the permeability coefficient within each layer of sediments can feature huge variability, which is often expressed in a logarithm scale. In this case, one might want to use a Karhunen–Loève (or PC) expansion for the logarithm of the permeability, instead of the permeability field itself. This leads to an exponential dependence of the permeability on the random variables, and the resulting random field might even have unbounded second moments. An advantage of such a nonlinear expansion is that it guarantees a positive permeability almost surely (a condition which is difficult to enforce with a standard truncated Karhunen–Loève or PC expansion).

Although such random fields are properly described only by means of an infinite number of random variables, whenever the input data vary slowly in space, with a correlation length comparable to the size of the domain, only a few terms in the above

mentioned expansions are typically enough to describe the random field with sufficient accuracy. Therefore, for this type of application it is reasonable to limit the analysis to just a few random variables in the expansion (see, e.g., [2]).

This argument is also strengthened by the fact that the amount of measured data one has at hand to identify the input data as random fields is in general very limited and barely sufficient to identify the first few random variables in the expansion.

Conversely, situations in which the random fields are highly oscillatory with a short correlation length, as in the case of materials with a random microstructure, do not fall into this category and will not be considered in the present work. The interested reader should refer, instead, to the wide literature in homogenization and multiscale analysis (see, e.g., [16] and references therein).

To solve numerically the stochastic PDE (0.1), a relatively new numerical technique, which has gained much attention in the last few years, is the so-called *spectral Galerkin* approximation (see, e.g., [21]). It employs standard approximations in space (finite elements, finite volumes, spectral or h-p finite elements, etc.) and polynomial approximation in the probability domain, either by full polynomial spaces [41, 30, 20, 34], tensor product polynomial spaces [4, 18], or piecewise polynomial spaces [4, 26].

The use of tensor product spaces is particularly attractive in the case of a small number of random variables, since it allows naturally the use of anisotropic spaces where the polynomial degree is chosen differently with respect to each random variable. Moreover, whenever the random fields are expanded in a truncated Karhunen–Loève expansion and the underlying random variables are assumed independent, a particular choice of the basis for the tensor product space (as proposed in [4, 5]), leads to the solution of uncoupled deterministic problems as in a Monte Carlo simulation. In this case, exponential convergence of the "probability error" has been proved in [4].

On the other hand, tensor product spaces suffer from the so-called *curse of dimensionality* since the dimension of the approximating space grows exponentially fast in the number of random variables. If the number of random variables is moderate or large, one should rather consider full polynomial spaces or sparse tensor product spaces [7, 18, 40]. We will not address this issue in this paper.

The extension of the spectral Galerkin method to cases in which the input data depend nonlinearly on the random variables and possibly have unbounded second moments is not straightforward and, in any case, would lead to fully coupled systems of equations, which call for highly efficient parallel solvers.

In this work we propose a collocation method which consists in collocating problem (0.1) in the zeros of tensor product orthogonal polynomials with respect to the joint probability density ρ of the random variables, should they be independent, or any other auxiliary density $\hat{\rho}$ corresponding to independent random variables, as long as the ratio $\rho/\hat{\rho}$ is bounded. Stochastic collocation has already been applied in a variety of problems and is the subject of ongoing research; see among others [35, 29] and the recent work [40], which the authors became aware of upon completion of this work.

As will be pointed out in the paper, this method offers several advantages:

- It naturally leads to uncoupled deterministic problems also in the case of input data which depend nonlinearly on the random variables.
- It treats efficiently the case of nonindependent random variables with the introduction of the auxiliary density $\hat{\rho}$.
- It can easily deal with unbounded random variables, such as Gaussian or exponential ones.

- It deals without difficulty with a diffusivity coefficient a with unbounded second moment.

The main result of the paper is given in Theorem 4.1 in section 4, where we prove that the collocation method preserves the same accuracy as the spectral Galerkin approach and achieves exponential convergence in all the above mentioned cases, provided that the input data are infinitely differentiable with respect to the random variables, under very mild assumptions on the growth of such derivatives, as is the case for standard expansions of random fields.

The collocation method can also be seen as a pseudospectral method (see, e.g., [33] and [19] for unbounded domains), i.e., a spectral Galerkin approximation with the use of suitable Gaussian quadrature formulas. We will also show that in some particular cases, where such Gaussian quadratures are exact, it actually coincides with the spectral Galerkin method based on tensor product spaces.

The outline of the paper is as follows: in section 1 we introduce the mathematical problem and the main notation used throughout. In section 2 we describe the collocation method. In section 3 we provide some regularity results on the solution of the stochastic PDE. In particular, we show that the solution is analytic with respect to the random variables, provided that the input data, as functions of the random variables, have infinite derivatives which do not grow too fast. In section 4 we give a complete convergence result for the collocation method and prove exponential convergence. Finally, in section 5 we present some numerical results showing the effectiveness of the proposed method.

1. Problem setting. Let D be a convex bounded polygonal domain in $\mathbb{R}^d$ and let $(\Omega, \mathcal{F}, P)$ be a complete probability space. Here Ω is the set of outcomes, $\mathcal{F} \subset 2^\Omega$ is the σ-algebra of events, and $P : \mathcal{F} \to [0,1]$ is a probability measure. Consider the stochastic linear elliptic boundary value problem: find a random function, $u : \Omega \times \overline{D} \to \mathbb{R}$, such that P-almost everywhere (a.e.) in Ω, or in other words, almost surely (a.s.) the following equation holds:

$$\begin{aligned} -\nabla \cdot (a(\omega,\cdot)\nabla u(\omega,\cdot)) &= f(\omega,\cdot) \quad \text{on} \quad D, \\ u(\omega,\cdot) &= 0 \quad \text{on} \quad \partial D. \end{aligned} \tag{1.1}$$

We will make the following assumptions:

(A_1) $a(\omega,\cdot)$ is uniformly bounded from below; i.e.,

$$\text{there exist } a_{min} > 0 \text{ such that} \quad P\big(\, \omega \in \Omega : \; a(\omega,x) > a_{min} \; \forall x \in \overline{D} \,\big) = 1.$$

(A_2) $f(\omega,\cdot)$ is square integrable with respect to P; i.e., $\int_D E[f^2]\,dx < \infty$.

Moreover, we introduce the following Hilbert spaces:

- $V_P = L^2_P(\Omega) \otimes H^1_0(D)$, equipped with the norm $\|v\|_P^2 = \int_D E\big[|\nabla v|^2\big]\,dx$.
- $V_{P,a} \equiv \{v \in V_P : \; \int_D E\big[a|\nabla v|^2\big]\,dx < \infty\}$, equipped with the norm $\|v\|_{P,a} = \sqrt{\int_D E\big[a|\nabla v|^2\big]\,dx}$.

Observe that under the above assumptions, the space $V_{P,a}$ is continuously embedded in V_P and

$$\|v\|_P \le \frac{1}{\sqrt{a_{min}}} \|v\|_{P,a}.$$

Problem (1.1) can be written in a weak form as

$$\text{find } u \in V_{P,a} \text{ such that} \quad \int_D E[a\nabla u \cdot \nabla v]\,dx = \int_D E[fv]\,dx \quad \forall\, v \in V_{P,a}. \tag{1.2}$$

A straightforward application of the Lax–Milgram theorem allows one to state the well posedness of problem (1.2) in the following lemma.

LEMMA 1.1. *Under assumptions* (A_1) *and* (A_2), *problem* (1.2) *admits a unique solution* $u \in V_{P,a}$, *which satisfies the estimate*

$$\|u\|_P \le \frac{C_P}{a_{min}} \left(\int_D E[f^2]\, dx \right)^{\frac{1}{2}}. \tag{1.3}$$

In the previous lemma we have used the Poincaré inequality

$$\|w\|_{L^2(D)} \le C_P \|\nabla w\|_{L^2(D)} \qquad \forall w \in H_0^1(D).$$

Weaker assumptions on the random coefficients. It is possible to relax the assumptions (A_1) and (A_2) substantially and still guarantee the existence and uniqueness of the solution u to problem (1.2). In particular, if the lower bound for the coefficient a is no longer a constant but a random variable, i.e., $a(x,\omega) \ge a_{min}(\omega) > 0$ a.s. a.e. on D, we have the following estimate for the moments of the solution.

LEMMA 1.2 (moments estimates). *Let* $p, q \ge 0$ *with* $1/p + 1/q = 1$. *Take a positive integer* k. *Then if* $f \in L_P^{kp}(\Omega; L^2(D))$ *and* $1/a_{min} \in L_P^{kq}(\Omega)$, *we have that* $u \in L_P^k(\Omega; H_0^1(D))$.

Proof. Since

$$\|u(\cdot,\omega)\|_{H_0^1(D)} \le C_P \frac{\|f(\cdot,\omega)\|_{L^2(D)}}{a_{min}(\omega)} \quad a.s.,$$

the result is a direct application of Hölder's inequality:

$$\begin{aligned}\int_\Omega \|u(\cdot,\omega)\|_{H_0^1(D)}^k dP(\omega) &\le C_P^k \int_\Omega \left(\frac{\|f(\cdot,\omega)\|_{L^2(D)}}{a_{min}(\omega)} \right)^k dP(\omega) \\ &\le C_P^k \left(\int_\Omega \|f(\cdot,\omega)\|_{L^2(D)}^{kp} dP(\omega) \right)^{1/p} \left(\int_\Omega \left(\frac{1}{a_{min}(\omega)} \right)^{qk} dP(\omega) \right)^{1/q}. \qquad \square\end{aligned}$$

Example 1 (lognormal diffusion coefficient). As an application of the previous lemma, we can conclude the well posedness of (1.2) with a lognormal diffusion coefficient. For instance, let

$$a(x,\omega) = \exp\left(\sum_{n=1}^N b_n(x) Y_n(\omega) \right), \quad Y_n \sim N(0,1) \quad \text{independent and identically distributed.}$$

Use the lower bound

$$a_{min}(\omega) = \exp\left(-\sum_{n=1}^N \|b_n\|_{L^\infty(D)} |Y_n(\omega)| \right)$$

and then for $k, q < \infty$

$$\begin{aligned}\|1/a_{min}\|_{L_P^{kq}(\Omega)}^{kq} &= \int_\Omega \left(\frac{1}{a_{min}(\omega)} \right)^{qk} dP(\omega) \\ &= \int_{\mathbb{R}^N} \exp\left(kq \sum_{n=1}^N \|b_n\|_{L^\infty(D)} |z_n| \right) \exp\left(-\frac{1}{2} \sum_{n=1}^N z_n^2 \right) dz_1 \cdots dz_N < \infty.\end{aligned} \tag{1.4}$$

Now let $\epsilon > 0$. Then by Lemma 1.2 the assumption $f \in L_P^{k(1+\epsilon)}(\Omega; L^2(D))$ together with (1.4) implies $u \in L_P^k(\Omega; H_0^1(D))$.

1.1. Finite dimensional noise assumption. In many problems the source of randomness can be approximated using just a small number of uncorrelated, sometimes independent, random variables; take, for example, the case of a truncated Karhunen–Loève expansion [4]. This motivates us to make the following assumption.

ASSUMPTION 1 (finite dimensional noise). *The coefficients used in the computations have the form*

$$a(\omega,x)=a(Y_1(\omega),\dots,Y_N(\omega),x) \quad \text{and} \quad f(\omega,x)=f(Y_1(\omega),\dots,Y_N(\omega),x) \quad \text{on} \quad \Omega\times\overline{D},$$

where $N\in\mathbb{N}_+$ and $\{Y_n\}_{n=1}^N$ are real valued random variables with mean value zero and unit variance.

We will denote with $\Gamma_n\equiv Y_n(\Omega)$ the image of Y_n, $\Gamma=\prod_{n=1}^N\Gamma_n$ and we will assume that the random variables $[Y_1,Y_2,\dots,Y_N]$ have a joint probability *density function* $\rho:\Gamma\to\mathbb{R}_+$, with $\rho\in L^\infty(\Gamma)$.

Example 2. The following standard transformation guarantees that the diffusivity coefficient is bounded away from zero a.s.:

$$\log(a-a_{min})(\omega,x)=b_0(x)+\sum_{1\le n\le N}\sqrt{\lambda_n}b_n(x)Y_n(\omega); \tag{1.5}$$

i.e., one performs a Karhunen–Loève expansion for $\log(a-a_{min})$, assuming that $a>a_{min}$ a.s. On the other hand, the right-hand side of (1.1) can be represented as a truncated Karhunen–Loève expansion:

$$f(\omega,x)=c_0(x)+\sum_{1\le n\le N}\sqrt{\mu_n}c_n(x)Y_n(\omega).$$

Remark 1. It is usual to have f and a independent, because the loads and the material properties are seldom related. In such a situation we have $a(Y(\omega),x)=a(Y_a(\omega),x)$ and $f(Y(\omega),x)=f(Y_f(\omega),x)$, with $Y=[Y_a,Y_f]$ and the vectors Y_a, Y_f independent.

After making Assumption 1, the solution u of the stochastic elliptic boundary value problem (1.2) can be described by just a finite number of random variables, i.e., $u(\omega,x)=u(Y_1(\omega),\dots,Y_N(\omega),x)$. Thus, the goal is to approximate the function $u=u(y,x)$, where $y\in\Gamma$ and $x\in\overline{D}$. Observe that the stochastic variational formulation (1.2) has a "deterministic" equivalent which is the following: find $u\in V_{\rho,a}$ such that

$$\int_\Gamma \rho\,(a\nabla u,\nabla v)_{L^2(D)}\,dy=\int_\Gamma\rho\,(f,v)_{L^2(D)}\,dy\quad\forall\,v\in V_{\rho,a}, \tag{1.6}$$

noting that here and later in this work the gradient notation, ∇, always means differentiation with respect to $x\in D$ only, unless otherwise stated. The space $V_{\rho,a}$ is the analogue of $V_{P,a}$ with $(\Omega,\mathcal{F},P)$ replaced by $(\Gamma,\mathcal{B}^N,\rho\,dy)$.

Since the solution to (1.6) is unique and is also a solution to (1.2), it follows that the solution has necessarily the form $u(\omega,x)=u(Y_1(\omega),\dots,Y_N(\omega),x)$. The stochastic boundary value problem (1.1) now becomes a deterministic Dirichlet boundary value problem for an elliptic PDE with an N-dimensional parameter. For convenience, we consider the solution u as a function $u:\Gamma\to H_0^1(D)$ and we use the notation $u(y)$ whenever we want to highlight the dependence on the parameter y. We use similar notation for the coefficient a and the forcing term f. Then it can be shown that problem (1.1) is equivalent to

$$\int_D a(y)\nabla u(y)\cdot\nabla\phi\,dx=\int_D f(y)\phi\,dx\quad\forall\phi\in H_0^1(D),\ \ \rho\text{-a.e. in }\Gamma. \tag{1.7}$$

For our convenience, we will suppose that the coefficient a and the forcing term f admit a smooth extension on the $\rho\,dy$-zero measure sets. Then (1.7) can be extended a.e. in Γ with respect to the Lebesgue measure (instead of the measure $\rho\,dy$).

Remark 2. Strictly speaking, (1.7) will hold only for those values of $y \in \Gamma$ for which the coefficient $a(y)$ is finite. In this paper we will assume that $a(y)$ may go to infinity only at the boundary of the parameter domain Γ.

Making Assumption 1 is a crucial step, turning the original stochastic elliptic equation into a deterministic parametric elliptic equation and allowing the use of finite element and finite difference techniques to approximate the solution of the resulting deterministic problem (cf. [25, 13]).

Observe that the knowledge of $u = u(y, x)$ fully determines the law of the random field $u(\omega, x)$. Yet, the computation of some quantities of interest such as failure probabilities might pose extra challenges from the numerical point of view. On the other hand, computation of moments of the solution or functionals of the solution is direct (see sections 2 and 4.1).

2. Collocation method. We seek a numerical approximation to the exact solution of (1.6) in a finite dimensional subspace $V_{p,h}$ based on a tensor product, $V_{p,h} = \mathcal{P}_p(\Gamma) \otimes H_h(D)$, where the following hold.

- $H_h(D) \subset H_0^1(D)$ is a standard finite element space of dimension N_h, which contains continuous piecewise polynomials defined on regular triangulations $\mathcal{T}_h$ that have a maximum mesh spacing parameter $h > 0$.
- $\mathcal{P}_p(\Gamma) \subset L^2_\rho(\Gamma)$ is the span of tensor product polynomials with degree at most $p = (p_1, \dots, p_N)$; i.e., $\mathcal{P}_p(\Gamma) = \bigotimes_{n=1}^N \mathcal{P}_{p_n}(\Gamma_n)$, with

$$\mathcal{P}_{p_n}(\Gamma_n) = \operatorname{span}(y_n^m,\ m = 0, \dots, p_n), \quad n = 1, \dots, N.$$

  Hence the dimension of $\mathcal{P}_p$ is $N_p = \prod_{n=1}^N (p_n + 1)$.

We first introduce the semidiscrete approximation $u_h : \Gamma \to H_h(D)$, obtained by projecting (1.7) onto the subspace $H_h(D)$, for each $y \in \Gamma$, i.e.,

$$\int_D a(y)\nabla u_h(y) \cdot \nabla \phi_h \, dx = \int_D f(y)\phi_h \, dx \quad \forall \phi_h \in H_h(D), \ \text{ for a.e. } y \in \Gamma. \tag{2.1}$$

The next step consists in collocating (2.1) on the zeros of orthogonal polynomials and building the discrete solution $u_{h,p} \in \mathcal{P}_p(\Gamma) \otimes H_h(D)$ by interpolating in y the collocated solutions.

To this end, we first introduce an auxiliary probability density function $\hat\rho : \Gamma \to \mathbb{R}^+$ that can be seen as the joint probability of N independent random variables; i.e., it factorizes as

$$\hat\rho(y) = \prod_{n=1}^N \hat\rho_n(y_n) \ \ \forall y \in \Gamma, \qquad \text{and is such that} \quad \left\| \frac{\rho}{\hat\rho} \right\|_{L^\infty(\Gamma)} < \infty. \tag{2.2}$$

For each dimension $n = 1, \dots, N$, let y_{n,k_n}, $1 \le k_n \le p_n + 1$, be the $p_n + 1$ roots of the orthogonal polynomial q_{p_n+1} with respect to the weight $\hat\rho_n$, which then satisfies $\int_{\Gamma_n} q_{p_n+1}(y) v(y) \hat\rho_n(y) dy = 0$ for all $v \in \mathcal{P}_{p_n}(\Gamma_n)$.

Standard choices for $\hat\rho$, such as constant, Gaussian, etc., lead to well-known roots of the polynomial q_{p_n+1}, which are tabulated to full accuracy and do not need to be computed.

To any vector of indexes $[k_1, \dots, k_N]$ we associate the global index

$$k = k_1 + p_1(k_2 - 1) + p_1 p_2 (k_3 - 1) + \cdots$$

and we denote by y_k the point $y_k = [y_{1,k_1}, y_{2,k_2}, \ldots, y_{N,k_N}] \in \Gamma$. We also introduce, for each $n = 1, 2, \ldots, N$, the Lagrange basis $\{l_{n,j}\}_{j=1}^{p_n+1}$ of the space $\mathcal{P}_{p_n}$,

$$l_{n,j} \in \mathcal{P}_{p_n}(\Gamma_n), \qquad l_{n,j}(y_{n,k}) = \delta_{jk}, \quad j,k = 1, \ldots, p_n + 1,$$

where δ_{jk} is the Kronecker symbol, and we set $l_k(y) = \prod_{n=1}^{N} l_{n,k_n}(y_n)$. Hence, the final approximation is given by

$$u_{h,p}(y,x) = \sum_{k=1}^{N_p} u_h(y_k, x) l_k(y),$$

where $u_h(y_k, x)$ is the solution of problem (2.1) for $y = y_k$.

Equivalently, if we introduce the Lagrange interpolant operator $\mathcal{I}_p : C^0(\Gamma; H_0^1(D)) \to \mathcal{P}_p(\Gamma) \otimes H_0^1(D)$, such that

$$\mathcal{I}_p v(y) = \sum_{n=1}^{N} v(y_k) l_k(y) \qquad \forall v \in C^0(\Gamma; H_0^1(D)),$$

then we have simply $u_{h,p} = \mathcal{I}_p u_h$.

Finally, for any continuous function $g : \Gamma \to \mathbb{R}$ we introduce the Gauss quadrature formula $E_{\hat\rho}^p[g]$ approximating the integral $\int_\Gamma g(y)\hat\rho(y)\,dy$ as

$$E_{\hat\rho}^p[g] = \sum_{k=1}^{N_p} \omega_k g(y_k), \quad \omega_k = \prod_{n=1}^{N} \omega_{k_n}, \quad \omega_{k_n} = \int_{\Gamma_n} l_{k_n}^2(y)\hat\rho_n(y)\,dy. \tag{2.3}$$

This can be used to approximate the mean value or the variance of u as

$$\bar u_h \in H_h(D), \qquad \bar u_h(x) = E_{\hat\rho}^p\left[\frac{\rho}{\hat\rho} u_h(x)\right],$$
$$\mathrm{var}_h(u_h) \in L^1(D), \qquad \mathrm{var}_h(u_h)(x) = E_{\hat\rho}^p\left[\frac{\rho}{\hat\rho}\left(u_h(x) - \bar u_h(x)\right)^2\right]$$

as long as $\rho/\hat\rho$ is a smooth function. Otherwise, $\bar u_h$ and $\mathrm{var}_h(u_h)$ should be computed with a suitable quadrature formula which takes into account eventual discontinuities or singularities of $\rho/\hat\rho$.

2.1. Collocation versus spectral Galerkin approximation. An alternative approach to the collocation method introduced thus far consists in approximating problem (1.6) with a spectral Galerkin method: find $u_{h,p}^G \in \mathcal{P}_p(\Gamma) \otimes H_h(D)$ such that

$$\int_\Gamma \rho\,(a\nabla u_{h,p}^G, \nabla v)_{L^2(D)}\,dy = \int_\Gamma \rho\,(f, v)_{L^2(D)}\,dy \quad \forall\, v \in \mathcal{P}_p(\Gamma) \otimes H_h(D). \tag{2.4}$$

This approach has been considered by several authors [4, 13, 18, 41, 21, 30]. Observe that, in general, problem (2.4) leads to a fully coupled system of linear equations, whose dimension is $N_h \times N_p$ and that demands highly efficient strategies and parallel computations for its numerical solution [15]. Conversely, the collocation method requires only the solutions of N_p uncoupled linear systems of dimension N_h and is fully parallelizable.

In [4, 5] a particular choice of basis functions (named *double orthogonal polynomials*) for the space $P_p(\Gamma)$ is proposed. This choice allows us to decouple the system in

the special case where the diffusivity coefficient and the forcing term are multilinear combinations of the random variables $Y_n(\omega)$ (as is the case if one performs a truncated linear Karhunen–Loève expansion) and the random variables are independent, i.e., $\rho(y) = \prod_{n=1}^{N} \rho_n(y_n)$. The proposed basis is then obtained by solving the following eigenvalue problems, for each $n = 1, \dots, N$:

$$\int_{\Gamma_n} z\psi_{kn}(z)v(z)\rho_n(z)\,dz = c_{kn}\int_{\Gamma_n} \psi_{kn}(z)v(z)\rho_n(z)\,dz, \qquad k = 1, \dots, p_n + 1.$$

The eigenvectors ψ_{kn} are normalized so as to satisfy the property

$$\int_{\Gamma_n} \psi_{kn}(z)\psi_{jn}(z)\rho_n(z)\,dz = \delta_{kj}, \qquad \int_{\Gamma_n} z\psi_{kn}(z)\psi_{jn}(z)\rho_n(z)\,dz = c_{kn}\delta_{kj}.$$

See [4, 5] for further details on the double orthogonal basis.

We aim at analyzing, now, the analogies between the collocation and the spectral Galerkin methods. The collocation method can be seen as a *pseudospectral* Galerkin method (see, e.g., [33]), where the integrals over Γ in (2.4) are replaced by the quadrature formula (2.3): *find* $u_{h,p} \in \mathcal{P}_p(\Gamma) \otimes H_h(D)$ *such that*

$$E_{\hat{\rho}}^p\left[\frac{\rho}{\hat{\rho}}\,(a\nabla u_{h,p}, \nabla v)_{L^2(D)}\right] = E_{\hat{\rho}}^p\left[\frac{\rho}{\hat{\rho}}\,(f, v)_{L^2(D)}\right] \quad \forall\, v \in \mathcal{P}_p(\Gamma) \otimes H_h(D). \tag{2.5}$$

Indeed, by choosing in (2.5) the test functions of the form $v(y, x) = l_k(y)\phi(x)$, where $\phi(x) \in H_h(D)$ and $l_k(y)$ is the Lagrange basis function associated to the knot y_k, $k = 1, \dots, N_p$, one is led to solve a sequence of uncoupled problems of the form (2.1) collocated in the points y_k, which, ultimately, gives the same solution as the collocation method.

In the particular case where the diffusivity coefficient and the forcing term are multilinear combinations of the random variables $Y_n(\omega)$ and the random variables are independent, it turns out that the quadrature formula is exact if one chooses $\hat{\rho} = \rho$. In this case, the solution obtained by the collocation method actually coincides with the spectral Galerkin one. This can be seen easily by observing that, with the above assumptions, the integrand in (2.4), i.e., $(a\nabla u_{h,p} \cdot \nabla v)$, is a polynomial at most of degree $2p_n + 1$ in the variable y_n and the Gauss quadrature formula is exact for polynomials up to degree $2p_n + 1$ integrated against the weight ρ.

The collocation method is a natural generalization of the spectral Galerkin approach and has the following advantages:

- It decouples the system of linear equations in Y also in the case where the diffusivity coefficient a and the forcing term f are nonlinear functions of the random variables Y_n.
- It treats efficiently the case of nonindependent random variables with the introduction of the auxiliary measure $\hat{\rho}$.
- It can easily deal with unbounded random variables (see Theorem 4.1 in section 4).

As will be shown in section 4, the collocation method preserves the same accuracy as the spectral Galerkin approach and achieves exponential convergence if the coefficient a and forcing term f are infinitely differentiable with respect to the random variables Y_n, under very mild requirements on the growth of their derivatives in Y.

As a final remark, we show that the double orthogonal polynomials proposed in [4] coincide with the Lagrange basis $l_k(y)$ and the eigenvalues c_{kn} are nothing but the Gauss knots of integration.

LEMMA 2.1. *Let $\Gamma \subset \mathbb{R}$, $\rho : \Gamma \to \mathbb{R}$ be a positive weight, and $\{\psi_k\}_{k=1}^{p+1}$ be the set of double orthogonal polynomials of degree p satisfying*

$$\int_\Gamma \psi_k(y)\psi_j(y)\rho(y)\,dy = \delta_{kj}, \qquad \int_\Gamma y\psi_k(y)\psi_j(y)\rho(y)\,dy = c_k\delta_{kj}.$$

Then the eigenvalues c_k are the nodes of the Gaussian quadrature formula associated to the weight ρ, and the eigenfunctions ψ_k are, up to multiplicative factors, the corresponding Lagrange polynomials built on the nodes c_k.

Proof. We have, for $k = 1, \dots, p+1$,

$$\int_\Gamma (y - c_k)\psi_k(y)v(y)\rho(y)dy = 0 \quad \forall v \in P_p(\Gamma).$$

Take $v = \prod_{\substack{j=1\\ j\neq k}}^{p+1}(y - c_j) \in P_p(\Gamma)$ in the above and let $w = \prod_{j=1}^{p+1}(y - c_j)$. Then

$$\int_\Gamma w(y)\psi_k(y)\rho(y)dy = 0 \quad \forall k = 1, \dots, p+1.$$

Since $\{\psi_k\}_{k=1}^{p+1}$ defines a basis of the space $\mathcal{P}_p(\Gamma)$, the previous relation implies that w is ρ-orthogonal to $P_p(\Gamma)$. Besides, the functions $(y - c_k)\psi_k$ are also orthogonal to the same subspace: this yields, due to the one-dimensional nature of the orthogonal complement of $P_p(\Gamma)$ over $P_{p+1}(\Gamma)$,

$$(y - c_k)\psi_k = \alpha_k w = \alpha_k \prod_{j=1}^{p+1}(y - c_j), \quad k = 1, \dots, p+1,$$

which gives

$$\psi_k = \alpha_k \prod_{\substack{j=1\\ j\neq k}}^{p+1}(y - c_j), \quad k = 1, \dots, p+1;$$

i.e., the double orthogonal polynomials ψ_k are collinear to Lagrange interpolants at the nodes c_j. Moreover, the eigenvalues c_j are the roots of the polynomial $w \in P_{p+1}(\Gamma)$, which is ρ-orthogonal to $P_p(\Gamma)$, and therefore they coincide with the nodes of the Gaussian quadrature formula associated with the weight ρ. ∎

3. Regularity results. Before going through the convergence analysis of the method, we need to state some regularity assumptions on the data of the problem and consequent regularity results for the exact solution u and the semidiscrete solution u_h.

In what follows we will need some restrictive assumptions on f and ρ. In particular, we will assume f to be a continuous function in y, whose growth at infinity, whenever the domain Γ is unbounded, is at most exponential. At the same time we will assume that ρ behaves as a Gaussian weight at infinity, as does the auxiliary density $\hat{\rho}$, in light of assumption (2.2).

Other types of growth of f at infinity and corresponding decay of the probability density ρ, for instance, of exponential type, could be considered as well. Yet we will limit the analysis to the aforementioned case.

To make these assumptions precise, we introduce a weight $\sigma(y) = \prod_{n=1}^{N} \sigma_n(y_n) \leq 1$, where

$$\sigma_n(y_n) = \begin{cases} 1 & \text{if } \Gamma_n \text{ is bounded,} \\ e^{-\alpha_n |y_n|} \text{ for some } \alpha_n > 0 & \text{if } \Gamma_n \text{ is unbounded,} \end{cases} \tag{3.1}$$

and the functional space

$$C^0_\sigma(\Gamma; V) \equiv \left\{ v : \Gamma \to V, \;\; v \text{ continuous in } y, \;\; \max_{y \in \Gamma} \|\sigma(y) v(y)\|_V < +\infty \right\},$$

where V is a Banach space of functions defined in D.

ASSUMPTION 2 (growth at infinity). *In what follows we will assume that*

(a) $f \in C^0_\sigma(\Gamma; L^2(D))$, *and*

(b) *the joint probability density* ρ *satisfies*

$$\rho(y) \leq C_\rho \, e^{-\sum_{n=1}^{N} (\delta_n y_n)^2} \qquad \forall y \in \Gamma, \tag{3.2}$$

for some constant $C_\rho > 0$ *and* δ_n *strictly positive if* Γ_n *is unbounded and zero otherwise.*

The parameter δ_n in (3.2) gives a scale for the decay of ρ at infinity and provides an estimate of the dispersion of the random variable Y_n. On the other hand, the parameter α_n in (3.1) controls the growth of the forcing term f at infinity.

Remark 3 (growth of f). The convergence result given in Theorem 4.1 in section 4 extends to a wider class of functions f. For instance, we could take $f \in C^0_\sigma(\Gamma; L^2(D))$ with $\sigma = e^{-\sum_{n=1}^{N} (\delta_n y_n)^2/8}$. Yet the class given in (3.1) is already large enough for most practical applications (see Example 2).

We can now choose any suitable auxiliary density $\hat{\rho}(y) = \prod_{n=1}^{N} \hat{\rho}_n(y_n)$ that satisfies, for each $n = 1, \ldots, N$,

$$C^n_{min} e^{-(\delta_n y_n)^2} \leq \hat{\rho}_n(y_n) < C^n_{max} e^{-(\delta_n y_n)^2} \qquad \forall y_n \in \Gamma_n \tag{3.3}$$

for some positive constants C^n_{min} and C^n_{max} that do not depend on y_n.

Observe that this choice satisfies the requirement given in (2.2), i.e., $\|\rho/\hat{\rho}\|_{L^\infty(\Gamma)} \leq C_\rho / C_{min}$ with $C_{min} = \prod_{n=1}^{N} C^n_{min}$.

Under the above assumptions, the following inclusions hold true:

$$C^0_\sigma(\Gamma; V) \subset L^2_{\hat{\rho}}(\Gamma; V) \subset L^2_\rho(\Gamma; V)$$

with continuous embedding. Indeed, on one hand we have

$$\|v\|_{L^2_\rho(\Gamma;V)} \leq \left\| \frac{\rho}{\hat{\rho}} \right\|^{\frac{1}{2}}_{L^\infty(\Gamma)} \|v\|_{L^2_{\hat{\rho}}(\Gamma;V)} \leq \sqrt{\frac{C_\rho}{C_{min}}} \|v\|_{L^2_{\hat{\rho}}(\Gamma;V)}.$$

On the other hand,

$$\|v\|^2_{L^2_{\hat{\rho}}(\Gamma;V)} = \int_\Gamma \hat{\rho}(y) \|v(y)\|^2_V \, dy \leq \|v\|^2_{C^0_\sigma(\Gamma;V)} \int_\Gamma \frac{\hat{\rho}(y)}{\sigma^2(y)} \, dy \leq \prod_{n=1}^{N} M_n \|v\|^2_{C^0_\sigma(\Gamma;V)}$$

with $M_n = \int_{\Gamma_n} \hat{\rho}_n / \sigma_n^2$. Now, for Γ_n bounded, $M_n \leq C^n_{max} |\Gamma_n|$, whereas if Γ_n is unbounded,

$$M_n = \int_{\Gamma_n} \left(e^{-\frac{(\delta_n y)^2}{2} + 2\alpha_n |y|} \right) e^{\frac{(\delta_n y)^2}{2}} \hat{\rho}_n(y) \, dy \leq C^n_{max} \sqrt{\frac{2\pi}{\delta_n}} e^{2(\alpha_n/\delta_n)^2}.$$

The first result we need is the following lemma.

LEMMA 3.1. *If $f \in C^0_\sigma(\Gamma; L^2(D))$ and $a \in C^0_{loc}(\Gamma; L^\infty(D))$, uniformly bounded away from zero, then the solution to problem* (1.7) *satisfies $u \in C^0_\sigma(\Gamma; H^1_0(D))$.*

The proof of this lemma is immediate. The next result concerns the analyticity of the solution u whenever the diffusivity coefficient a and the forcing term f are infinitely differentiable with respect to y, under mild assumptions on the growth of their derivatives in y. We will perform a one-dimensional analysis in each direction y_n, $n = 1, \dots, N$. For this, we introduce the following notation:

$$\Gamma_n^* = \prod_{\substack{j=1 \\ j\neq n}}^{N} \Gamma_j,$$

with y_n^* denoting an arbitrary element of Γ_n^*. Similarly, we set

$$\hat{\rho}_n^* = \prod_{\substack{j=1 \\ j\neq n}}^{N} \hat{\rho}_j$$

and

$$\sigma_n^* = \prod_{\substack{j=1 \\ j\neq n}}^{N} \sigma_j.$$

LEMMA 3.2. *Under the assumption that, for every $y = (y_n, y_n^*) \in \Gamma$, there exists $\gamma_n < +\infty$ such that*

$$\left\| \frac{\partial_{y_n}^k a(y)}{a(y)} \right\|_{L^\infty(D)} \leq \gamma_n^k k! \qquad \text{and} \qquad \frac{\|\partial_{y_n}^k f(y)\|_{L^2(D)}}{1 + \|f(y)\|_{L^2(D)}} \leq \gamma_n^k k!, \tag{3.4}$$

the solution $u(y_n, y_n^*, x)$ as a function of y_n, $u : \Gamma_n \to C^0_{\sigma_n^*}(\Gamma_n^*; H^1_0(D))$ admits an analytic extension $u(z, y_n^*, x)$, $z \in \mathbb{C}$, in the region of the complex plane

$$\Sigma(\Gamma_n; \tau_n) \equiv \{z \in \mathbb{C}, \ \operatorname{dist}(z, \Gamma_n) \leq \tau_n\} \tag{3.5}$$

with $0 < \tau_n < 1/(2\gamma_n)$. Moreover, for all $z \in \Sigma(\Gamma_n; \tau_n)$,

$$\|\sigma_n(\operatorname{Re} z)\, u(z)\|_{C^0_{\sigma_n^*}(\Gamma_n^*; H^1_0(D))} \leq \frac{C_P e^{\alpha_n \tau_n}}{a_{min}(1 - 2\tau_n\gamma_n)} (2\|f\|_{C^0_\sigma(\Gamma; H^1_0(D))} + 1) \tag{3.6}$$

with the constant C_p as in (1.3).

Proof. In every point $y \in \Gamma$, the kth derivative of u with respect to y_n satisfies the problem

$$B(y; \partial_{y_n}^k u, v) = -\sum_{l=1}^{k} \binom{k}{l} \partial_{y_n}^l B(y; \partial_{y_n}^{k-l} u, v) + (\partial_{y_n}^k f, v) \quad \forall v \in H^1_0(D),$$

where B is the parametric bilinear form $B(y; u, v) = \int_D a(y) \nabla u \cdot \nabla v \, dx$. Hence

$$\begin{aligned} \|\sqrt{a(y)} \nabla \partial_{y_n}^k u\|_{L^2(D)} \leq & \sum_{l=1}^{k} \binom{k}{l} \left\| \frac{\partial_{y_n}^l a(y)}{a(y)} \right\|_{L^\infty(D)} \|\sqrt{a(y)} \nabla \partial_{y_n}^{k-l} u\|_{L^2(D)} \\ & + \frac{C_p}{\sqrt{a_{min}}} \|\partial_{y_n}^k f\|_{L^2(D)}. \end{aligned}$$

Setting $R_k = \|\sqrt{a(y)}\nabla\partial_{y_n}^k u\|_{L^2(D)}/k!$ and using the bounds on the derivatives of a and f, we obtain the recursive inequality

$$R_k \le \sum_{l=1}^{k} \gamma_n^l R_{k-l} + \frac{C_p}{\sqrt{a_{min}}}\gamma_n^k(1+\|f\|_{L^2(D)}).$$

The generic term R_k admits the bound

$$R_k \le (2\gamma_n)^k R_0 + \frac{C_p}{\sqrt{a_{min}}}(1+\|f\|_{L^2(D)})\gamma_n^k \sum_{l=0}^{k-1} 2^l.$$

Observing that $R_0 = \|\sqrt{a(y)}\nabla u(y)\|_{L^2(D)} \le \frac{C_p}{\sqrt{a_{min}}}\|f(y)\|_{L^2(D)}$ and

$$\frac{\|\nabla\partial_{y_n}^k u\|_{L^2(D)}}{k!} \le \frac{R_k}{\sqrt{a_{min}}},$$

we get the final estimate on the growth of the derivatives of u,

$$\frac{\|\nabla\partial_{y_n}^k u(y)\|_{L^2(D)}}{k!} \le \frac{C_p}{a_{min}}(2\|f(y)\|_{L^2(D)}+1)(2\gamma_n)^k.$$

We now define for every $y_n \in \Gamma_n$ the power series $u : \mathbb{C} \to C^0_{\sigma_n^*}(\Gamma_n^*, H_0^1(D))$ as

$$u(z, y_n^*, x) = \sum_{k=0}^{\infty} \frac{(z-y_n)^k}{k!}\partial_{y_n}^k u(y_n, y_n^*, x).$$

Hence,

$$\begin{aligned}
\sigma_n(y_n)\|u(z)\|_{C^0_{\sigma_n^*}(\Gamma_n^*,H_0^1(D))} &\le \sum_{k=0}^{\infty} \frac{|z-y_n|^k}{k!}\sigma_n(y_n)\|\partial_{y_n}^k u(y_n)\|_{C^0_{\sigma_n^*}(\Gamma_n^*;H_0^1(D))} \\
&\le \frac{C_P}{a_{min}} \max_{y_n\in\Gamma_n}\left\{\sigma_n(y_n)\left(2\|f(y_n)\|_{C^0_{\sigma_n^*}(\Gamma_n^*;L^2(D))}+1\right)\right\}\sum_{k=0}^{\infty}\left(|z-y_n|2\gamma_n\right)^k \\
&\le \frac{C_P}{a_{min}}(2\|f\|_{C^0_\sigma(\Gamma;L^2(D))}+1)\sum_{k=0}^{\infty}\left(|z-y_n|2\gamma_n\right)^k,
\end{aligned}$$

where we have exploited the fact that $\sigma_n(y_n) \le 1$ for all $y_n \in \Gamma_n$; the series converges for all $z \in \mathbb{C}$ such that $|z-y_n| \le \tau_n < 1/(2\gamma_n)$. Moreover, in the ball $|z-y_n| \le \tau_n$, we have, by virtue of (3.1), $\sigma_n(\mathrm{Re}\, z) \le e^{\alpha_n\tau_n}\sigma_n(y_n)$, and then

$$\sigma_n(\mathrm{Re}\, z)\|u(z)\|_{C^0_{\sigma_n^*}(\Gamma_n^*,H_0^1(D))} \le \frac{C_P e^{\alpha_n\tau_n}}{a_{min}(1-2\tau_n\gamma_n)}(2\|f\|_{C^0_\sigma(\Gamma;L^2(D))}+1).$$

The power series converges for every $y_n \in \Gamma_n$; hence, by a continuation argument, the function u can be extended analytically on the whole region $\Sigma(\Gamma_n;\tau_n)$ and estimate (3.6) follows. □

Example 3. Let us consider the case where the diffusivity coefficient a is expanded in a linear truncated Karhunen–Loève expansion

$$a(\omega, x) = b_0(x) + \sum_{n=1}^{N}\sqrt{\lambda_n}b_n(x)Y_n(\omega),$$

provided that such expansion guarantees $a(\omega, x) \geq a_{min}$ for almost every $\omega \in \Omega$ and $x \in D$ [18]. In this case we have

$$\left\| \frac{\partial_{y_n}^k a}{a} \right\|_{L^\infty(\Gamma \times D)} \leq \begin{cases} \sqrt{\lambda_n} \|b_n\|_{L^\infty(D)} / a_{min} & \text{for } k = 1, \\ 0 & \text{for } k > 1 \end{cases}$$

and we can safely take $\gamma_n = \sqrt{\lambda_n} \|b_n\|_{L^\infty(D)} / a_{min}$ in (3.4).

If we consider, instead, a truncated *exponential* expansion

$$a(\omega, x) = a_{min} + e^{b_0(x) + \sum_{n=1}^N \sqrt{\lambda_n} b_n(x) Y_n(\omega)},$$

we have

$$\left\| \frac{\partial_{y_n}^k a}{a} \right\|_{L^\infty(\Gamma \times D)} \leq \left(\sqrt{\lambda_n} \|b_n\|_{L^\infty(D)} \right)^k$$

and we can take $\gamma_n = \sqrt{\lambda_n} \|b_n\|_{L^\infty(D)}$. Hence, both choices fulfill the assumption in Lemma 3.2.

Example 4. Similarly to the previous case, let us consider a forcing term f of the form

$$f(\omega, x) = c_0(x) + \sum_{n=1}^N c_n(x) Y_n(\omega),$$

where the random variables Y_n are Gaussian (either independent or not) and the functions $c_n(x)$ are square integrable for any $n = 1, \ldots, N$. Then, the function f belongs to the space $C^0_\sigma(\Gamma; L^2(D))$, with weight σ defined in (3.1), for any choice of the exponent coefficients $\alpha_n > 0$.

Moreover,

$$\frac{\|\partial_{y_n}^k f(y)\|_{L^2(D)}}{1 + \|f(y)\|_{L^2(D)}} \leq \begin{cases} \|c_n\|_{L^2(D)} & \text{for } k = 1, \\ 0 & \text{for } k > 1, \end{cases}$$

and we can safely take $\gamma_n = \|c_n\|_{L^2(D)}$ in (3.4). Hence, such a forcing term satisfies the assumptions of Lemma 3.2. In this case, though, the solution u is linear with respect to the random variables Y_n (hence, clearly analytic), and our theory is not needed.

Observe that the regularity results are valid also for the semidiscrete solution u_h.

4. Convergence analysis. Our aim is to give a priori estimates for the total error $\epsilon = u - u_{h,p}$ in the natural norm $L^2_\rho(\Gamma) \otimes H^1_0(D)$. The next theorem states the convergence result we are seeking, and the rest of the section will be devoted to its proof. In particular, we will prove that the error decays (sub)exponentially fast with respect to p under the regularity assumptions made in section 3. The convergence with respect to h will be dictated by standard approximability properties of the finite element space $H_h(D)$ and the regularity in space of the solution u (see, e.g., [12, 11]).

THEOREM 4.1. *Under the assumptions of Lemmas* 3.1 *and* 3.2*, there exist positive constants r_n, $n = 1, \ldots, N$, and C, independent of h and p, such that*

$$\begin{aligned} \|u - u_{h,p}\|_{L^2_\rho \otimes H^1_0} \leq & \frac{1}{\sqrt{a_{min}}} \inf_{v \in L^2_\rho \otimes H_h} \left(\int_{\Gamma \times D} \rho a |\nabla(u - v)|^2 \right)^{\frac{1}{2}} \\ & + C \sum_{n=1}^N \beta_n(p_n) \exp\{-r_n p_n^{\theta_n}\}, \end{aligned} \tag{4.1}$$

where

- *if* Γ_n *is bounded,* $\begin{cases}\theta_n = \beta_n = 1,\\ r_n = \log\left[\frac{2\tau_n}{|\Gamma_n|}\left(1+\sqrt{1+\frac{|\Gamma_n|^2}{4\tau_n^2}}\right)\right],\end{cases}$
- *if* Γ_n *is unbounded,* $\begin{cases}\theta_n = 1/2, \quad \beta_n = O(\sqrt{p_n}),\\ r_n = \tau_n\delta_n,\end{cases}$

τ_n *is smaller than the distance between* Γ_n *and the nearest singularity in the complex plane, as defined in Lemma* 3.2*, and* δ_n *is defined as in* (3.2).

The first term on the right-hand side of (4.1) concerns the space approximability of u in the subspace $H_h(D)$ and is controlled by the mesh size h. The actual rate of convergence will depend on the regularity in space of $a(y)$ and $f(y)$ for each $y \in \Gamma$ as well as on the smoothness on the domain D. Observe that an h or $h-p$ adaptive strategy to reduce the error in space is not precluded by this approach.

The exponential rate of convergence in the Y direction depends on the constants r_n, which in turn are related to the distances from the sets Γ_n to their nearest singularities in the complex plane. In Examples 3 and 4 we have estimated these constants in the case where the random fields a and f are represented by either a linear or exponential truncated Karhunen–Loève expansion. Hence, a full characterization of the convergence rate is available in these cases.

Observe that in Theorem 4.1 it is not necessary to assume the finiteness of the second moment of the coefficient a.

Before proving the theorem, we recall some known results of approximation theory for a function f defined on a one-dimensional domain (bounded or unbounded) with values in a Banach space V, $f : \Gamma \subset \mathbb{R} \to V$. As in section 2, let $\rho : \Gamma \to \mathbb{R}^+$ be a positive weight which satisfies, for all $y \in \Gamma$, $\rho(y) \le C_M e^{-(\delta y)^2}$ for some $C_M > 0$ and δ strictly positive if Γ is unbounded and zero otherwise; let $y_k \in \Gamma$, $k = 1, \dots, p+1$ be the set of zeros of the polynomial of degree p orthogonal to the space $\mathcal{P}_{p-1}$ with respect to the weight ρ; and let σ be an extra positive weight such that $\sigma(y) \ge C_m e^{-(\delta y)^2/4}$ for some $C_m > 0$. With this choice, the embedding $C^0_\sigma(\Gamma; V) \subset L^2_\rho(\Gamma; V)$ is continuous. Observe that the condition on σ is satisfied both by a Gaussian weight $\sigma = e^{-(\mu y)^2}$ with $\mu \le \delta/2$ and by an exponential weight $\sigma = e^{-\alpha|y|}$ for any $\alpha \ge 0$. Finally, we denote by $\mathcal{I}_p$ the Lagrange interpolant operator, $\mathcal{I}_p v(y) = \sum_{k=1}^{p+1} v(y_k) l_k(y)$ for every continuous function v, and by $\omega_k = \int_\Gamma l_k^2(y)\rho(y)\,dy$ the weights of the Gaussian quadrature formula built upon $\mathcal{I}_p$.

The following two lemmas are a slight generalization of a classical result by Erdös and Turán [17].

LEMMA 4.2. *The operator* $\mathcal{I}_p : C^0_\sigma(\Gamma; V) \to L^2_\rho(\Gamma; V)$ *is continuous.*

Proof. We have, indeed, that for any $v \in C^0_\sigma(\Gamma; V)$

$$\|\mathcal{I}_p v\|^2_{L^2_\rho(\Gamma;V)} = \int_\Gamma \left\| \sum_{k=1}^{p+1} v(y_k) l_k(y) \right\|^2_V \rho(y)\,dy \le \int_\Gamma \left(\sum_{k=1}^{p+1} \|v(y_k)\|_V l_k(y) \right)^2 \rho(y)\,dy.$$

Thanks to the orthogonality property $\int_\Gamma l_j(y) l_k(y) \rho(y)\, dy = \delta_{jk}$, we have

$$\begin{aligned}
\|\mathcal{I}_p v\|^2_{L^2_\rho(\Gamma;V)} &\le \int_\Gamma \sum_{k=1}^{p+1} \|v(y_k)\|^2_V \, l_k^2(y) \rho(y)\, dy \\
&\le \max_{k=1,\dots,p+1} \|v(y_k)\|^2_V \sigma^2(y_k) \sum_{k=1}^{p+1} \int_\Gamma \frac{l_k^2(y)\rho(y)}{\sigma^2(y_k)}\, dy \\
&\le \|v\|^2_{C^0_\sigma(\Gamma;V)} \sum_{k=1}^{p+1} \frac{\omega_k}{\sigma^2(y_k)}.
\end{aligned}$$

In the case of Γ bounded, we have $\sigma \ge C_m$ and $\sum_{k=1}^{p+1} \omega_k = 1$ for any p, and the result follows immediately. For Γ unbounded, since $\rho(y) \le C_M e^{-(\delta y)^2}$, all the even moments $c_{2m} = \int_\Gamma y^{2m} \rho(y)\, dy$ are bounded, up to a constant, by the moments of the Gaussian density $e^{-(\delta y)^2}$. Therefore, using a result from Uspensky in 1928 [36], it follows that

$$\sum_{k=1}^{p+1} \frac{\omega_k}{\sigma^2(y_k)} \overset{p\to\infty}{\longrightarrow} \int_\Gamma \frac{\rho(y)}{\sigma^2(y)}\, dy \le \frac{C_M}{C_m^2} \sqrt{\frac{2\pi}{\delta}},$$

and we conclude that

$$\|\mathcal{I}_p v\|_{L^2_\rho(\Gamma;V)} \le C_1 \|v\|_{C^0_\sigma(\Gamma;V)}. \qquad \square$$

LEMMA 4.3. *For every function $v \in C^0_\sigma(\Gamma;V)$ the interpolation error satisfies*

$$\|v - \mathcal{I}_p v\|_{L^2_\rho(\Gamma;V)} \le C_2 \inf_{w \in \mathcal{P}_p(\Gamma)\otimes V} \|v - w\|_{C^0_\sigma(\Gamma;V)}$$

with a constant C_2 independent of p.

Proof. Let us observe that for all $w \in \mathcal{P}_p(\Gamma) \otimes V$, it holds that $\mathcal{I}_p w = w$. Then,

$$\begin{aligned}
\|v - \mathcal{I}_p v\|_{L^2_\rho(\Gamma;V)} &\le \|v - w\|_{L^2_\rho(\Gamma;V)} + \|\mathcal{I}_p(w - v)\|_{L^2_\rho(\Gamma;V)} \\
&\le C_2 \|v - w\|_{C^0_\sigma(\Gamma;V)}.
\end{aligned}$$

Since w is arbitrary in the right-hand side, the result follows. $\square$

Lemma 4.3 relates the approximation error $(v - \mathcal{I}_p v)$ in the L^2_ρ-norm with the *best approximation* error in the weighted C^0_σ-norm for any weight $\sigma(y) \ge C_m e^{-(\delta y)^2/4}$. We now analyze the best approximation error for a function $v : \Gamma \to V$ which admits an analytic extension in the complex plane, in the region $\Sigma(\Gamma;\tau) = \{z \in \mathbb{C},\ \operatorname{dist}(z,\Gamma) < \tau\}$ for some $\tau > 0$. We will still denote the extension by v; in this case, τ represents the distance between $\Gamma \subset \mathbb{R}$ and the nearest singularity of $v(z)$ in the complex plane.

We study separately the two cases of Γ bounded and unbounded. We start with the bounded case, in which the extra weight σ is set equal to 1. The following result is an immediate extension of the result given in [14, Chapter 7, section 8]

LEMMA 4.4. *Given a function $v \in C^0(\Gamma;V)$ which admits an analytic extension in the region of the complex plane $\Sigma(\Gamma;\tau) = \{z \in \mathbb{C},\ \operatorname{dist}(z,\Gamma) \le \tau\}$ for some $\tau > 0$, it holds that*

$$\min_{w \in \mathcal{P}_p \otimes V} \|v - w\|_{C^0(\Gamma;V)} \le \frac{2}{\varrho - 1} e^{-p \log(\varrho)} \max_{z \in \Sigma(\Gamma;\tau)} \|v(z)\|_V,$$

where

$$1 < \varrho = \frac{2\tau}{|\Gamma|} + \sqrt{1 + \frac{4\tau^2}{|\Gamma|^2}}.$$

Proof. We sketch the proof for completeness. We first make a change of variables, $y(t) = y_0 + \frac{|\Gamma|}{2}t$, where y_0 is the midpoint of Γ. Hence, $y([-1,1]) = \Gamma$. We set $\tilde{v}(t) = v(y(t))$. Clearly, $\tilde{v}$ can be extended analytically in the region of the complex plane $\Sigma([-1,1]; 2\tau/|\Gamma|) \equiv \{z \in \mathbb{C}, \mathrm{dist}(z,[-1,1]) \le 2\tau/|\Gamma|\}$.

We then introduce the Chebyshev polynomials $C_k(t)$ on $[-1,1]$ and the expansion of $\tilde{v} : [-1,1] \to V$ as

$$\tilde{v}(t) = \frac{a_0}{2} + \sum_{k=1}^{\infty} a_k C_k(t), \tag{4.2}$$

where the Fourier coefficients $a_k \in V$, $k = 0, 1, \ldots$, are defined as

$$a_k = \frac{1}{\pi}\int_{-\pi}^{\pi} \tilde{v}(\cos(t))\,\cos(kt)\,dt.$$

It is well known (see, e.g., [14, 9]) that the series (4.2) converges in any elliptic disc $D_\varrho \subset \mathbb{C}$, with $\varrho > 1$, delimited by the ellipse

$$E_\varrho = \left\{ z = t + is \in \mathbb{C},\ \ t = \frac{\varrho + \varrho^{-1}}{2}\cos\phi,\ \ s = \frac{\varrho - \varrho^{-1}}{2}\sin(\phi),\ \ \phi \in [0, 2\pi) \right\}$$

in which the function $\tilde{v}$ is analytic. Moreover (see [14] for details), we have

$$\|a_k\|_V \le 2\varrho^{-k} \max_{z \in D_\varrho} \|\tilde{v}(z)\|_V.$$

If we denote by $\Pi_p v \in \mathcal{P}_p(\Gamma) \otimes V$ the truncated Chebyshev expansion up to the polynomial degree p and observe that $|C_k(t)| \le 1$ for all $t \in [-1,1]$, we have

$$\begin{aligned}\min_{w \in \mathcal{P}_p \otimes V} \|v - w\|_{C^0(\Gamma;V)} &\le \|\tilde{v} - \Pi_p \tilde{v}\|_{C^0([-1,1];V)} \\ &\le \sum_{k=p+1}^{\infty} \|a_k\|_V \le \frac{2}{\varrho - 1}\varrho^{-p} \max_{z \in D_\varrho} \|\tilde{v}(z)\|_V.\end{aligned}$$

Finally, we have to link ϱ to the size of the analyticity region of $\tilde{v}$. It is easy to verify that the ellipse given by

$$\varrho = \frac{2\tau}{|\Gamma|}\left(1 + \sqrt{1 + \frac{|\Gamma|^2}{4\tau^2}}\right)$$

is the largest ellipse that can be drawn inside $\Sigma([-1,1]; 2\tau/|\Gamma|)$, and this proves the stated result. ∎

For the case of unbounded Γ we first recall a result given in [23] and then we state in Lemma 4.6 a result tuned to our situation.

We denote by $H_n(y) \in P_n(\mathbb{R})$ the normalized Hermite polynomials

$$H_n(y) = \sqrt{\pi^{\frac{1}{2}} 2^n n!}\,(-1)^n e^{y^2}\frac{\partial^n}{\partial y^n}\left(e^{-y^2}\right)$$

and by $h_n(y) = e^{-y^2/2}H_n(y)$ the Hermite functions. We recall that the Hermite polynomials form a complete orthonormal basis of the $L^2(\mathbb{R})$ space with respect to the weight e^{-y^2}, i.e.,

$$\int_{\mathbb{R}} H_k(y)H_l(y)e^{-y^2}\,dy = \delta_{kl}.$$

LEMMA 4.5 (Hille [23]). *Let $f(z)$ be an analytic function in the strip of the complex plane $\Sigma(\mathbb{R};\tau) \equiv \{z = (y+iw) \in \mathbb{C}, -\tau \le w \le \tau\}$. A necessary and sufficient condition in order that the Fourier–Hermite series*

$$\sum_{k=0}^{\infty} f_k h_k(z), \qquad f_k = \int_{\mathbb{R}} f(y)h_k(y)\,dy, \tag{4.3}$$

shall exist and converge to the sum $f(z)$ in $\Sigma(\mathbb{R};\tau)$ is that for every β, $0 \le \beta < \tau$, there exists a finite positive $C(\beta)$ such that

$$|f(y+iw)| \le C(\beta)e^{-|y|\sqrt{\beta^2-w^2}}, \quad -\infty < y < \infty, \ -\beta \le w \le \beta. \tag{4.4}$$

Moreover, the following bound for the Fourier coefficients holds:

$$|f_n| \le Ce^{-\tau\sqrt{2n+1}}. \tag{4.5}$$

In particular, the previous result tells us that, in order to have exponential decay of the Fourier coefficients f_n, we not only need $f(z)$ to be analytic in $\Sigma(\mathbb{R};\tau)$ but also must require that it decays on the real line, for $y \to \infty$, at least as $e^{-\tau|y|}$.

We now introduce two weights: the exponential $\sigma = e^{-\alpha|y|}$, for some $\alpha > 0$, and the Gaussian $G = e^{-(\delta y)^2/4}$. We recall that Lemma 4.3 holds for both. We will assume that the function v is in the space $C^0_\sigma(\Gamma;V)$, but we will measure the best approximation error in the weaker norm $C^0_G(\Gamma;V)$, with Gaussian weight, so that we can use the result from Hille given in Lemma 4.5. The following lemma holds.

LEMMA 4.6. *Let v be a function in $C^0_\sigma(\mathbb{R};V)$. We suppose that v admits an analytic extension in the strip of the complex plane $\Sigma(\mathbb{R};\tau) = \{z \in \mathbb{C}, \ \operatorname{dist}(z,\mathbb{R}) \le \tau\}$ for some $\tau > 0$, and that*

$$\forall z = (y+iw) \in \Sigma(\mathbb{R};\tau), \quad \sigma(y)\|v(z)\|_V \le C_v(\tau).$$

Then, for any $\delta > 0$, there exist a constant C, independent of p, and a function $\Theta(p) = O(\sqrt{p})$ such that

$$\min_{w\in\mathcal{P}_p\otimes V} \max_{y\in\mathbb{R}} \left| \|v(y) - w(y)\|_V e^{-\frac{(\delta y)^2}{4}} \right| \le C\Theta(p)e^{-\tau\delta\sqrt{p}}.$$

Proof. We introduce the change of variable $t = \delta\, y/\sqrt{2}$ and we denote $\tilde{v}(t) = v(y(t))$. Observe that $\tilde{v} \in C^0_{\tilde{\sigma}}(\mathbb{R};V)$ with weight $\tilde{\sigma} = e^{-\sqrt{2}\frac{\alpha}{\delta}|t|}$. We consider the expansion of $\tilde{v}$ in Hermite polynomials

$$\tilde{v}(t) = \sum_{k=0}^{\infty} v_k H_k(t), \quad \text{where } v_k \in V, \quad v_k = \int_{\mathbb{R}} \tilde{v}(t)H_k(t)e^{-t^2}\,dt. \tag{4.6}$$

We now set $f(z) = \tilde{v}(z)e^{-\frac{z^2}{2}}$. Observe that the Hermite expansion of f as defined in (4.3) has the same Fourier coefficients as the expansion of $\tilde{v}$ defined in (4.6). Indeed

$$f_k = \int_{\mathbb{R}} f(t)h_k(t)\,dt = \int_{\mathbb{R}} \tilde{v}(t)H_k(t)e^{-t^2}\,dt = v_k.$$

Clearly, $f(z)$ is analytic in the strip $\Sigma(\mathbb{R}; \frac{\tau\delta}{\sqrt{2}})$, being the product of analytic functions. Moreover,

$$\|f(y+iw)\|_V = |e^{-\frac{(y+iw)^2}{2}}| \|\tilde{v}(z)\|_V \leq e^{-\frac{y^2-w^2}{2}} e^{\sqrt{2}\frac{\alpha}{\delta}|y|} C_v(\tau).$$

Setting

$$C(\beta) = \max_{\substack{-\infty<y<\infty \\ -\beta\leq w\leq\beta}} \exp\left\{-\frac{y^2-w^2}{2} + \sqrt{2}\frac{\alpha}{\delta}|y| + |y|\sqrt{\beta^2-w^2}\right\},$$

which is bounded for all $-\frac{\tau\delta}{\sqrt{2}} \leq \beta \leq \frac{\tau\delta}{\sqrt{2}}$, the function $f(z)$ satisfies the hypotheses of Lemma 4.5. Hence the Hermite series converges in $\Sigma(\mathbb{R}; \frac{\tau\delta}{\sqrt{2}})$ and the Fourier coefficients v_k behave as in (4.5). We chose $w \in \mathcal{P}_p \otimes V$ as the truncated Hermite expansion of v, up to degree p: $\tilde{w}(t) = \Pi_p \tilde{v}(t) = \sum_{k=0}^{p} v_k H_k(t)$. We have

$$\begin{aligned} E_p(v) &= \min_{w\in\mathcal{P}_p\otimes V} \max_{y\in\mathbb{R}} \left| \|v(y) - w(y)\|_V e^{-\frac{(\delta y)^2}{4}} \right| \\ &\leq \max_{t\in\mathbb{R}} \left| \|\tilde{v}(t) - \Pi_p\tilde{v}(t)\|_V e^{-\frac{t^2}{2}} \right| \leq \max_{t\in\mathbb{R}} \| \sum_{k=p+1}^{\infty} v_k h_k(t) \|_V. \end{aligned}$$

It is well known (see, e.g., [8]) that the Hermite functions $h_k(t)$ satisfy $|h_k(t)| < 1$ for all $t \in \mathbb{R}$ and all $k = 0, 1, \ldots$. Hence, the previous series can be bound as

$$E_p(v) \leq \sum_{k=p+1}^{\infty} \|v_k\|_V \leq C \sum_{k=p+1}^{\infty} e^{-\frac{\tau\delta}{\sqrt{2}}\sqrt{2k+1}}.$$

Lemma A.2 in the appendix provides a bound for such a series, and this concludes the proof. ∎

We are now ready to prove Theorem 4.1.

Proof of Theorem 4.1. The error naturally splits into $\epsilon = (u-u_h)+(u_h-u_{h,p})$. The first term depends on the space discretization only and can be estimated easily; indeed, the function u_h is the orthogonal projection of u onto the subspace $L^2_\rho(\Gamma) \otimes H^1_0(D)$ with respect to the inner product $\int_{\Gamma\times D} \rho a |\nabla \cdot|^2$. Hence

$$\begin{aligned} \|u - u_h\|_{L^2_\rho(\Gamma)\otimes H^1_0(D)} &\leq \frac{1}{\sqrt{a_{min}}} \left(\int_{\Gamma\times D} \rho a |\nabla(u-u_h)|^2 \right)^{\frac{1}{2}} \\ &\leq \frac{1}{\sqrt{a_{min}}} \inf_{v\in L^2_\rho(\Gamma)\otimes H_h(D)} \left(\int_{\Gamma\times D} \rho a |\nabla(u-v)|^2 \right)^{\frac{1}{2}}. \end{aligned}$$

The second term $u_h - u_{h,p}$ is an interpolation error. We recall, indeed, that $u_{h,p} = \mathcal{I}_p u_h$. To lighten the notation, we will drop the subscript h, being understood that we work on the semidiscrete solution. We recall, moreover, that u_h has the same regularity as the exact solution u with respect to y.

To analyze this term we employ a one-dimensional argument. We first pass from the norm L^2_ρ to $L^2_{\hat{\rho}}$:

$$\|u - \mathcal{I}_p u\|_{L^2_\rho\otimes H^1_0} \leq \left\| \frac{\rho}{\hat{\rho}} \right\|^{\frac{1}{2}}_{L^\infty(\Gamma)} \|u - \mathcal{I}_p u\|_{L^2_{\hat{\rho}}\otimes H^1_0}.$$

Here we adopt the same notation as in section 3; namely, we indicate with $\bullet_n$ a quantity relative to the direction y_n and with $\bullet_n^*$ the analogous quantity relative to all other directions y_j, $j \neq n$. We focus on the first direction y_1 and define an interpolation operator $\mathcal{I}_1 : C^0_{\sigma_1}(\Gamma_1; L^2_{\hat{\rho}_1^*} \otimes H^1_0) \to L^2_{\hat{\rho}_1}(\Gamma_1; L^2_{\hat{\rho}_1^*} \otimes H^1_0)$,

$$\mathcal{I}_{p_1} v(y_1, y_1^*, x) = \sum_{k=1}^{p_1+1} v(y_{1,k}, y_1^*, x) l_{1,k}(y_1).$$

Then, the global interpolant $\mathcal{I}_p$ can be written as the composition of two interpolation operators $\mathcal{I}_p = \mathcal{I}_1 \circ \mathcal{I}_p^{(1)}$, where $\mathcal{I}_p^{(1)}$ is the interpolation operator in all directions $y_2, y_3, \ldots, y_N$ except y_1: $\mathcal{I}_p^{(1)} : C^0_{\sigma_1^*}(\Gamma_1^*; H^1_0) \to L^2_{\hat{\rho}_1^*}(\Gamma_1^*; H^1_0)$. We then have

$$\|u - \mathcal{I}_p u\|_{L^2_{\hat{\rho}} \times H^1_0} \leq \underbrace{\|u - \mathcal{I}_1 u\|_{L^2_{\hat{\rho}} \times H^1_0}}_{\mathrm{I}} + \underbrace{\|\mathcal{I}_1(u - \mathcal{I}_p^{(1)} u)\|_{L^2_{\hat{\rho}} \times H^1_0}}_{\mathrm{II}}.$$

Let us bound the first term. We think of u as a function of y_1 with values in a Banach space V, $u \in L^2_{\hat{\rho}_1}(\Gamma_1; V)$, where $V = L^2_{\hat{\rho}_1^*}(\Gamma_1^*) \otimes H^1_0(D)$. Under Assumption 2 in section 3 and the choice of $\hat{\rho}$ given in (3.3), the following inclusions hold true:

$$C^0_{\sigma_1}(\Gamma_1; V) \subset C^0_{G_1}(\Gamma_1; V) \subset L^2_{\hat{\rho}_1}(\Gamma_1; V)$$

with $\sigma_1 = G_1 = 1$ if Γ_1 is bounded and $\sigma_1 = e^{-\alpha_1 |y_1|}$, $G_1 = e^{-\frac{(\delta_1 y_1)^2}{4}}$ if Γ_1 is unbounded. We know also from Lemma 4.2 that the interpolation operator $\mathcal{I}_1$ is continuous both as an operator from $C^0_{\sigma_1}(\Gamma_1; V)$ with values in $L^2_{\hat{\rho}_1}(\Gamma_1; V)$ and from $C^0_{G_1}(\Gamma_1; V)$ in $L^2_{\hat{\rho}_1}(\Gamma_1; V)$. In particular, we can estimate

$$\mathrm{I} = \|u - \mathcal{I}_1 u\|_{L^2_{\hat{\rho}_1}(\Gamma_1; V)} \leq C_2 \inf_{w \in \mathcal{P}_{p_1} \otimes V} \|u - w\|_{C^0_{G_1}(\Gamma; V)}.$$

To bound the best approximation error in $C^0_{G_1}(\Gamma; V)$, in the case of Γ_1 bounded we use Lemma 4.4, whereas if Γ_1 is unbounded, we employ Lemma 4.6 and the fact that $u \in C^0_{\sigma_1}(\Gamma_1; V)$ (see Lemma 3.1). In both cases, we need the analyticity result, for the solution u, stated in Lemma 3.2. Putting everything together, we can say that

$$\mathrm{I} \leq \begin{cases} C e^{-r_1 p_1}, & \Gamma_1 \text{ bounded}, \\ C \Theta(p_1) e^{-r_1 \sqrt{p_1}}, & \Gamma_1 \text{ unbounded}, \end{cases}$$

the value of r_1 being specified in Lemmas 4.4 and 4.6. To bound the term II, we use Lemma 4.2:

$$\mathrm{II} \leq C_1 \|u - \mathcal{I}_p^{(1)} u\|_{C^0_{\sigma_1}(\Gamma_1; V)}.$$

The term on the right-hand side is again an interpolation error. Thus we have to bound the interpolation error in all the other $N-1$ directions, uniformly with respect to y_1 (in the weighted norm $C^0_{\sigma_1}$). We can proceed iteratively, defining an interpolation $\mathcal{I}_2$, bounding the resulting error in the direction y_2, and so on. ∎

4.1. Convergence of moments. In some cases one might be interested only in computing the first few moments of the solution, namely $E[u^m]$, $m = 1, 2, \ldots$. We show in the next two lemmas that the error in the first two moments, measured in a

suitable spatial norm, is bounded by the *mean square error* $\|u - u_{h,p}\|_{L^2_\rho \otimes H^1_0}$, which, due to Theorem 4.1, is exponentially convergent with respect to the polynomial degree p employed in the y directions. In particular, without extra regularity assumptions on the solution u of the problem, we have optimal convergence for the error in the mean value (first moment) measured in $L^2(D)$ or $H^1(D)$ and for the error in the second moment measured in $L^1(D)$.

LEMMA 4.7 (approximation of mean value).

$$\|E[u - u_{h,p}]\|_{V(D)} \le \|u - u_{h,p}\|_{L^2_\rho(\Gamma)\otimes V(D)}, \text{ with } V(D) = L^2(D) \text{ or } H^1(D).$$

The proof is immediate and omitted. Although the previous estimate implies exponential convergence with respect to p, under the assumptions of Theorem 4.1, the above estimate is suboptimal and can be improved by a duality argument (see [4] and Remark 5.2 in [5]).

LEMMA 4.8 (approximation of the second moment).

$$\|E[u^2 - u^2_{h,p}]\|_{L^1(D)} \le C\|u - u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)}$$

with C independent of the discretization parameters h and p.

Proof. We have

$$\begin{aligned}\|E[u^2 - u^2_{h,p}]\|_{L^1(D)} &\le \|E[(u - u_{h,p})(u + u_{h,p})]\|_{L^1(D)} \\ &\le \|u - u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)}\|u + u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)} \\ &\le \|u - u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)} \left(\|u\|_{L^2_\rho(\Gamma)\otimes L^2(D)} + \|u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)}\right).\end{aligned}$$

The term $\|u_{h,p}\|_{L^2_\rho \otimes L^2}$ can be bounded as

$$\|u_{h,p}\|_{L^2_\rho(\Gamma)\otimes L^2(D)} = \|\mathcal{I}_p u_h\|_{L^2_\rho(\Gamma)\otimes L^2(D)} \le C_1\|u_h\|_{C^0_\sigma(\Gamma;L^2(D))} \le C(f, a_{\min}),$$

where we have used the boundedness of the interpolation operator $\mathcal{I}_p$ stated in Lemma 4.2. The last inequality follows from the fact that the semidiscrete solution u_h is the orthogonal projection of the exact solution u onto the subspace H_h with respect to the *energy* inner product; hence

$$\|\sqrt{a(y)}\nabla u_h(y)\|_{L^2(D)} \le \|\sqrt{a(y)}\nabla u(y)\|_{L^2(D)} \quad \forall y \in \Gamma,$$

and the last term can be controlled in terms of $a_{\min}$ and the forcing term, f. ∎

Similarly, it is possible to estimate the approximation error in the covariance function of the solution u.

On the other hand, to estimate the convergence rate of the error in higher order moments, or of the second moment in higher norms, we need extra regularity assumptions on the solution to ensure proper integrability and then be able to use analyticity.

5. Numerical examples. This section illustrates the convergence of the collocation method for a stochastic elliptic problem in two dimensions. The computational results are in accordance with the convergence rate predicted by the theory.

The problem to solve is

$$\begin{aligned} -\nabla\cdot(a\nabla u) &= 0 \quad \text{on } \Omega \times D, \\ u &= 0 \quad \text{on } \Omega \times \partial D_D, \\ -a\partial_n u &= 1 \quad \text{on } \Omega \times \partial D_N, \\ \partial_n u &= 0 \quad \text{on } \Omega \times (\partial D - (\partial D_D \cup \partial D_N)), \end{aligned}$$

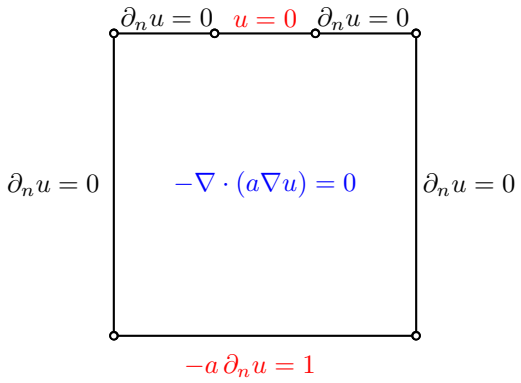

FIG. 1. *Geometry and boundary conditions for the numerical example.*

with

$$D = \{(x,z) \in \mathbb{R}^2 : -1.5 \le x \le 0,\ -0.4 \le z \le 0.8\},$$
$$\partial D_D = \{(x,z) \in \mathbb{R}^2 : -1 \le x \le -0.5,\ z = 0.8\},$$
$$\partial D_N = \{(x,z) \in \mathbb{R}^2 :\ -1.5 \le x \le 0,\ z = -0.4\};$$

cf. Figure 1.

The random diffusivity coefficient is a nonlinear function of the random vector Y, namely,

$$a(\omega, x) = a_{min} + \exp\Big\{ [Y_1(\omega)\cos(\pi z) + Y_3(\omega)\sin(\pi z)]\, e^{-\frac{1}{8}} + [Y_2(\omega)\cos(\pi x) + Y_4(\omega)\sin(\pi x)]\, e^{-\frac{1}{8}} \Big\}. \tag{5.1}$$

Here $a_{min} = 1/100$, and the real random variables Y_n, $n = 1, \ldots, 4$, are independent and identically distributed with mean value zero and unit variance. To illustrate the behavior of the collocation method with either unbounded or bounded random variables Y_n, this section presents two different cases, corresponding to either Gaussian or uniform densities. The corresponding collocation points are then Cartesian products determined by the roots of either Hermite or Legendre polynomials.

Observe that the collocation method requires only the solution of uncoupled deterministic problems in the collocation points, even in the presence of a diffusivity coefficient which depends nonlinearly on the random variables as in (5.1). This is a great advantage with respect to the classical stochastic Galerkin finite element method as considered in [4] or [30] (see also the considerations given in section 2.1). Observe, moreover, how easily the collocation method can deal with unbounded random variables.

Figure 2 shows some realizations of the logarithm of the diffusivity coefficient, while Figures 3 and 4 show the mean and variance of the corresponding solutions. The finite element space for spatial discretization is the span of continuous functions that are piecewise polynomials with degree five over a triangulation with 1178 triangles and 642 vertices; see Figure 5. This triangulation has been adaptively graded to control

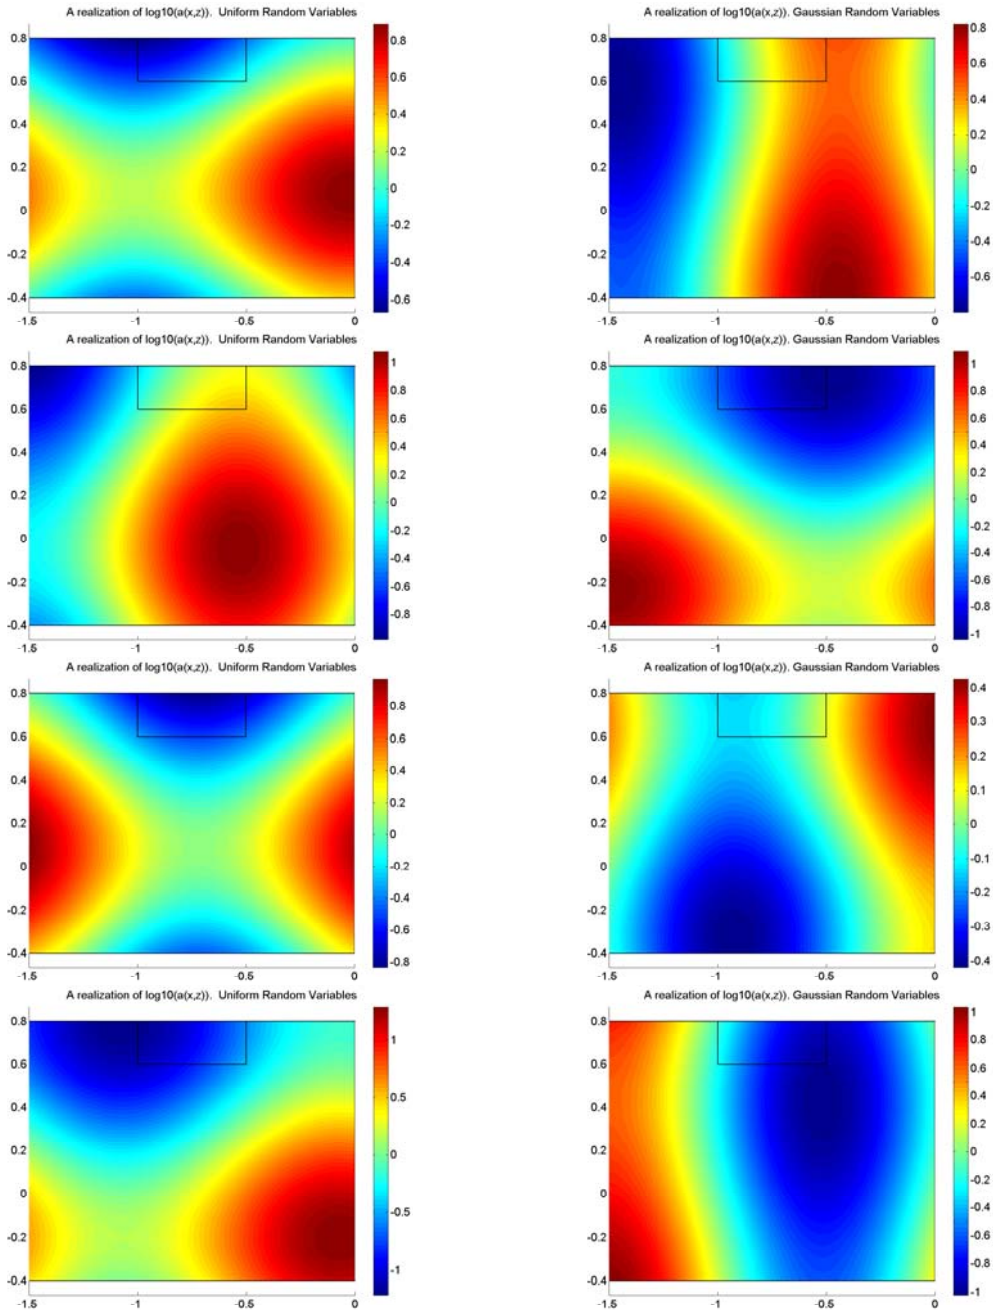

FIG. 2. *Some realizations of* $\log(a)$.

the singularities at the boundary points $(-1, 0.8)$ and $(-0.5, 0.8)$. These singularities occur where the Dirichlet and Neumann boundaries meet, and they essentially behave like $\sqrt{r}$, with r being the distance to the closest singularity point.

To study the convergence of the tensor product collocation method, we increase the order p for the approximating polynomial spaces, $\mathcal{P}_p(\Gamma)$, following the adaptive

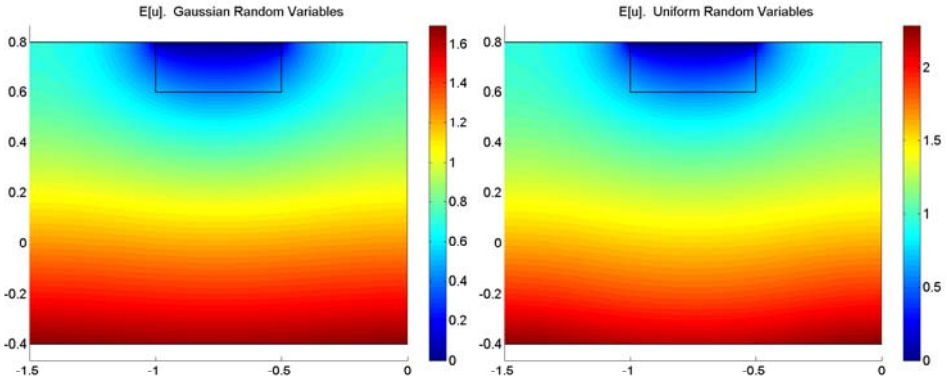

FIG. 3. *Results for the computation of the expected value for the solution, $E[u]$.*

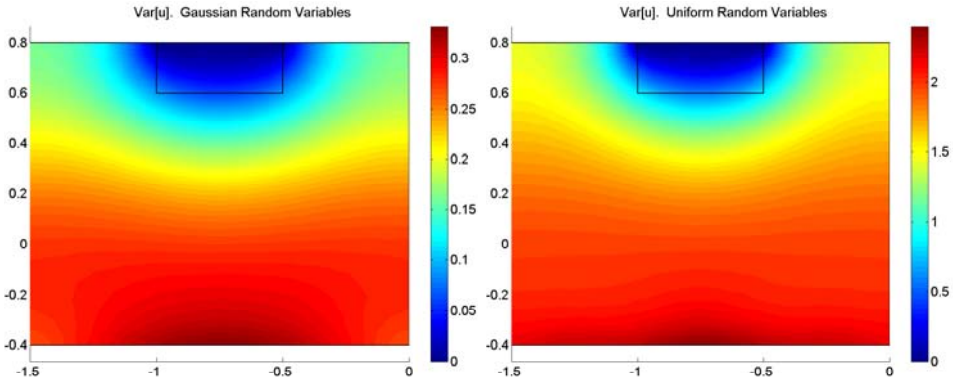

FIG. 4. *Results for the computation of the variance of the solution, $Var[u]$.*

algorithm described on page 1287 of [5]. This adaptive algorithm increases the tensor polynomial degree with an anisotropic strategy: it increases the order of approximation in one direction as much as possible before considering the next direction.

The computational results for the $H_0^1(D)$ approximation error in the expected value, $E[u]$, are shown on Figure 6, while those corresponding to the approximation of the second moment, $E[u^2]$, are shown on Figure 7. To estimate the computational error in the ith direction, corresponding to a multi-index $p = (p_1, \ldots, p_i, \ldots, p_N)$, we approximate it by $E[e] \approx E[u_{h,p} - u_{h,\tilde{p}}]$, with $\tilde{p} = (p_1, \ldots, p_i + 1, \ldots, p_N)$. We proceed similarly for the error in the approximation of the second moment.

As expected, the estimated approximation error decreases exponentially fast as the polynomial order increases, for both the computation of $E[u]$ and $E[u^2]$, with either Gaussian or uniform probability densities.

6. Conclusions. In this work we have proposed a collocation method for the solution of elliptic partial differential equations with random coefficients and forcing terms. This method has the advantages of leading to uncoupled deterministic problems also in the case of input data which depend nonlinearly on the random variables; treating efficiently the case of nonindependent random variables with the introduction of an auxiliary density $\hat{\rho}$; dealing easily with unbounded random variables, such as Gaussian or exponential ones; and dealing with no difficulty with a diffusivity

coefficient a with unbounded second moment.

We have provided a full convergence analysis and proved exponential convergence "in probability" for a broad range of situations. The theoretical result is given in Theorem 4.1 and confirmed numerically by the tests presented in section 5.

The method is very versatile and very accurate for the class of problems considered (as accurate as the stochastic Galerkin approach). It leads to the solution of uncoupled deterministic problems and, as such, is fully parallelizable like a Monte Carlo method. The extension of the analysis to other classes of linear and nonlinear problems is the subject of ongoing research.

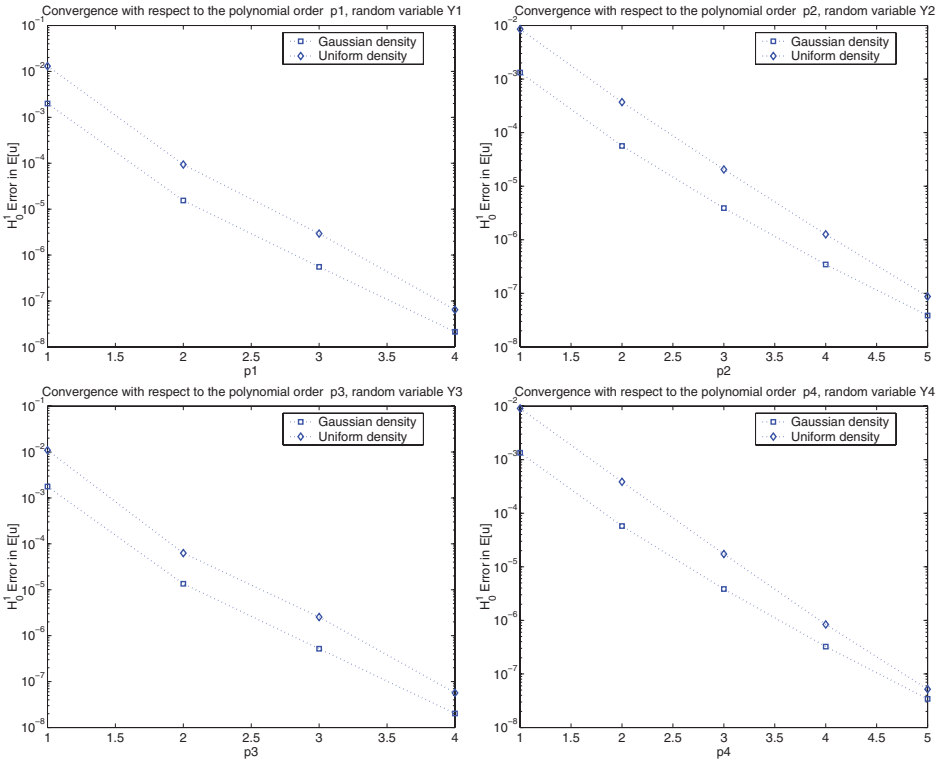

FIG. 6. *Convergence results for the approximation of the expected value, $E[u]$.*

The use of tensor product polynomials suffers from the *curse of dimensionality*. Hence, this method is efficient only for a small number of random variables. For a moderate or large dimensionality of the probability space, one should rather turn to *sparse tensor product spaces*. This aspect will be investigated in a future work.

Appendix.

LEMMA A.1. *Let $r \in \mathbb{R}^+$, $r < 1$. Then*

- $$\sum_{k=0}^{n}(2k+1)r^k = \frac{1}{(1-r)^2}\left\{1 + r - r^{n+1}\left[(2n+1)(1-r)+2\right]\right\}.$$
- $$\sum_{k=n+1}^{\infty}(2k+1)r^k = r^{n+1}\frac{(2n+1)(1-r)+2}{(1-r)^2}.$$

Proof. We use the summation-by-parts formula

$$\sum_{k=0}^{n} f_k g_k = f_n G_n - \sum_{k=0}^{n-1} G_k(f_{k+1} - f_k), \qquad G_k = \sum_{j=0}^{k} g_j$$

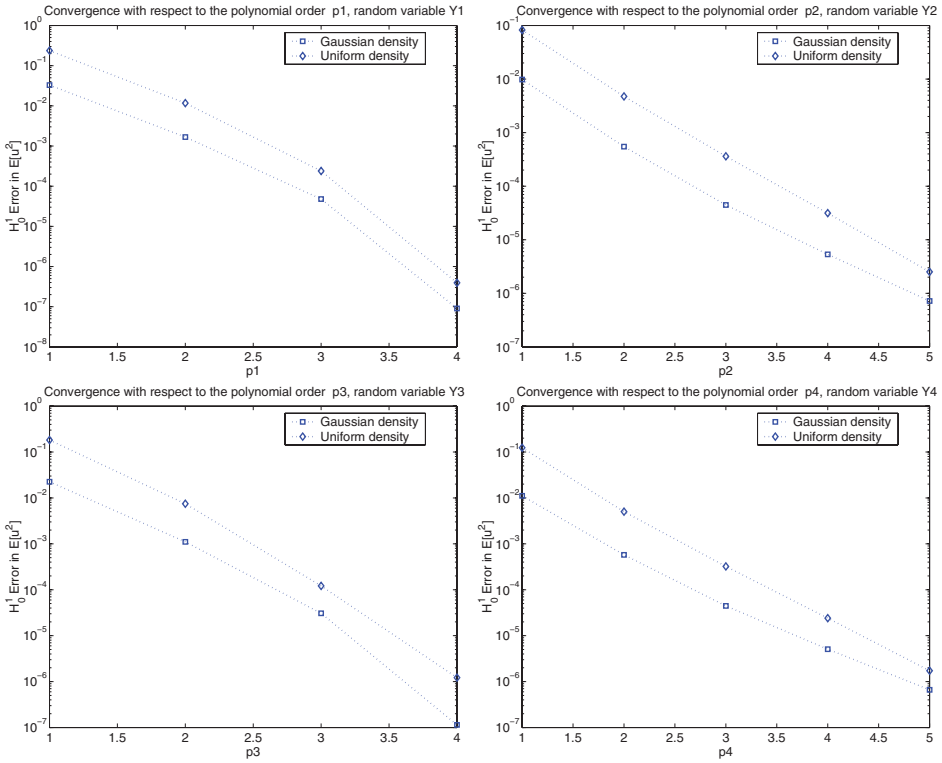

FIG. 7. *Convergence results for the approximation of the second moment,* $E[u^2]$.

with $f_k = (2k+1)$, $g_k = r^k$, and $G_k = (1-r^{k+1})/(1-r)$. Then

$$\begin{aligned}\sum_{k=0}^{n}(2k+1)r^k &= (2n+1)\frac{1-r^{n+1}}{1-r} - \sum_{k=0}^{n-1} 2\frac{1-r^{k+1}}{1-r} \\ &= (2n+1)\frac{1-r^{n+1}}{1-r} - \frac{2}{1-r}\left[n - r\frac{1-r^n}{1-r}\right] \\ &= \frac{1}{1-r}\left[(2n+1) - (2n+1)r^{n+1} - 2n + 2r\frac{1-r^n}{1-r}\right] \\ &= \frac{1}{1-r}\left\{1 + \frac{2r}{1-r} - r^{n+1}\left[(2n+1) + \frac{2}{1-r}\right]\right\},\end{aligned}$$

which gives the first result. Clearly,

$$\sum_{k=0}^{\infty}(2k+1)r^k = \frac{1+r}{(1-r)^2}.$$

Then, computing the tail series as

$$\sum_{k=n+1}^{\infty}(2k+1)r^k = \sum_{k=0}^{\infty}(2k+1)r^k - \sum_{k=0}^{n}(2k+1)r^k,$$

we easily obtain the second result as well. □

LEMMA A.2. *Let $r \in \mathbb{R}^+$, $r < 1$. Then*

$$\sum_{k=n+1}^{\infty} r^{\sqrt{2k+1}} \leq \left[\frac{2\sqrt{n+1}}{a(1-a)} + O(1)\right] a^{\sqrt{n}}, \qquad a = r^{\sqrt{2}}.$$

Proof. We start bounding

$$\sum_{k=n+1}^{\infty} r^{\sqrt{2k+1}} \leq \sum_{k=n+1}^{\infty} r^{\sqrt{2k}} = \sum_{k=n+1}^{\infty} a^{\sqrt{k}}.$$

Let us observe, now, that

$$\sum_{k=n+1}^{\infty} a^{\sqrt{k}} \leq \sum_{k=[\sqrt{n+1}]}^{\infty} (2k+1)a^k,$$

where we have denoted by $[v]$ the integer part of a real number v. Then, using the result from Lemma A.1, we have

$$\sum_{k=[\sqrt{n+1}]}^{\infty} (2k+1)a^k \leq a^{[\sqrt{n+1}]} \frac{(2[\sqrt{n+1}]-1)(1-a)+2}{(1-a)^2}.$$

Observing now that $\sqrt{n+1} - 1 \leq [\sqrt{n+1}] \leq \sqrt{n+1} + 1$, we obtain

$$\sum_{k=n+1}^{\infty} a^{\sqrt{k}} \leq a^{\sqrt{n+1}} \frac{(2\sqrt{n+1}+1)(1-a)+2}{a(1-a)^2},$$

which leads immediately to the final result. ∎

CONVERGENCE ANALYSIS OF PERTURBED TWO-GRID AND MULTIGRID METHODS*

YVAN NOTAY†

Abstract. We consider multigrid methods for symmetric positive definite linear systems. We present a new algebraic convergence analysis of two-grid schemes with inexact solution of the coarse grid system. This analysis allows us to bound the convergence factor of such perturbed two-grid schemes, assuming only a certain bound on the convergence factor for the unperturbed scheme (with exact solution of the coarse grid system). Applied to multigrid methods with the standard W-cycle, this analysis shows that if the convergence factor of the (unperturbed) two-grid method is uniformly bounded by $\sigma < 1/2$, then the convergence factor of the multigrid method is uniformly bounded by $\sigma/(1-\sigma)$. The analysis is purely algebraic and requires only that pre- and postsmoothing are applied in a symmetric way. It covers both geometric and algebraic multigrid methods, and the coarse grid matrix may be of any type (not necessarily Galerkin).

1. Introduction.

We consider multigrid methods for solving symmetric positive definite (SPD) $n \times n$ linear systems

$$A\,\mathbf{u} \;=\; \mathbf{b}. \tag{1.1}$$

We focus on symmetric multigrid schemes, more precisely on methods for which the basic two-grid cycle is defined as follows:

- Relax ν times on $A\,\mathbf{u} = \mathbf{b}$ using a smoother R;
  we assume that R is an $n \times n$ matrix such that $\rho(I - R\,A) < 1$,
  where $\rho(\cdot)$ stands for the spectral radius;
  ν (the number of pre- and postsmoothing steps) is a given positive integer.
- Perform the coarse grid correction: $\mathbf{u} \leftarrow \mathbf{u} + p\,A_C^{-1} p^T(\mathbf{b} - A\,\mathbf{u})$;
  we assume that A_C (the coarse grid matrix) is an $n_c \times n_c$ SPD matrix,
  where $n_c \le n$ is the number of coarse variables;
  p (the prolongation) is an $n \times n_c$ matrix.
- Relax ν times on $A\,\mathbf{u} = \mathbf{b}$ using R^T.

Note that we do not assume any specific form for the coarse grid matrix.

In this paper, we analyze the influence of the perturbations that arise when the coarse grid systems are solved approximately. More precisely, we consider schemes as above in which A_C^{-1} is exchanged for some $n_c \times n_c$ SPD matrix K_C that approximates it. Our main result relates the convergence of this perturbed two-grid method with that of the "ideal" two-grid method that requires the inversion of A_C.

To express this relation, consider the iteration matrices that govern the convergence of the schemes described above:

$$T_{\mathrm{TG}} \;=\; (I - R^T A)^\nu\,(I - p\,A_C^{-1}\,p^T\,A)\,(I - R\,A)^\nu \tag{1.2}$$

*Received by the editors February 17, 2006; accepted for publication (in revised form) December 19, 2006; published electronically May 7, 2007. This work was supported by the Belgian FNRS (Maître de Recherches).

†Service de Métrologie Nucléaire (C.P. 165/84), Université Libre de Bruxelles, 50 Av. F.D. Roosevelt, B-1050 Brussels, Belgium (ynotay@ulb.ac.be).

for the unperturbed two-grid cycle and

$$T_{\mathrm{PTG}} \;=\; (I - R^T A)^\nu \,(I - p\, K_C\, p^T\, A)\,(I - R\, A)^\nu \tag{1.3}$$

for the perturbed one; see, e.g., [19, p. 40]. As is well known, performing m iterations implies that

$$\hat{\mathbf{u}} - \mathbf{u}_{\mathrm{TG}}^{(m)} = \big(T_{\mathrm{TG}}\big)^m \big(\hat{\mathbf{u}} - \mathbf{u}_{\mathrm{TG}}^{(0)}\big) \qquad \text{or} \qquad \hat{\mathbf{u}} - \mathbf{u}_{\mathrm{PTG}}^{(m)} = \big(T_{\mathrm{PTG}}\big)^m \big(\hat{\mathbf{u}} - \mathbf{u}_{\mathrm{PTG}}^{(0)}\big)$$

(respectively), where $\hat{\mathbf{u}} = A^{-1}\mathbf{b}$ is the exact solution to (1.1). Hence, the asymptotic convergence rate is equal to the spectral radius of the iteration matrix, which is referred to as the *convergence factor*. On the other hand, both the perturbed and the unperturbed two-grid cycle implicitly define a preconditioner, which we denote B_{TG} and B_{PTG}, respectively. They are related to the iteration matrices by

$$I - B_{\mathrm{TG}}^{-1}\, A \;=\; T_{\mathrm{TG}} \qquad \text{and} \qquad I - B_{\mathrm{PTG}}^{-1}\, A \;=\; T_{\mathrm{PTG}}. \tag{1.4}$$

Note that because A, B_{TG}, and B_{PTG} are SPD (see below), the eigenvalues of $B_{\mathrm{TG}}^{-1}A$ and $B_{\mathrm{PTG}}^{-1}A$ are real and the convergence factors satisfy

$$\begin{aligned}
\rho\,(T_{\mathrm{TG}}) &= \max\big(\lambda_{\max}(B_{\mathrm{TG}}^{-1}A) - 1,\; 1 - \lambda_{\min}(B_{\mathrm{TG}}^{-1}A)\big),\\
\rho\,(T_{\mathrm{PTG}}) &= \max\big(\lambda_{\max}(B_{\mathrm{PTG}}^{-1}A) - 1,\; 1 - \lambda_{\min}(B_{\mathrm{PTG}}^{-1}A)\big),
\end{aligned}$$

where $\lambda_{\max}(\cdot)$ and $\lambda_{\min}(\cdot)$ stand for the largest and the smallest eigenvalue, respectively. In section 2, we prove

$$\lambda_{\max}(B_{\mathrm{PTG}}^{-1}\, A) \le \lambda_{\max}(B_{\mathrm{TG}}^{-1}\, A) \;\cdot\; \max(\lambda_{\max}(K_C\, A_C),\, 1), \tag{1.5}$$

$$\lambda_{\min}(B_{\mathrm{PTG}}^{-1}\, A) \ge \lambda_{\min}(B_{\mathrm{TG}}^{-1}\, A) \;\cdot\; \min(\lambda_{\min}(K_C\, A_C),\, 1). \tag{1.6}$$

Multigrid cycles are obtained when a two-grid method is used recursively, exchanging the solution of the coarse grid system for a given number γ of two-grid cycles on the coarser level, and so on, until the coarsest level on which an exact solve is performed. Multigrid cycles are thus particular cases of perturbed two-grid cycles, and the above results enable us to analyze them. For the so-called W-cycle (which corresponds to $\gamma = 2$), we show in section 3 that if $\sigma < 1/2$ is a uniform (i.e., holding at every level) bound on the convergence factor of the unperturbed two-grid method, then the convergence factor of the multigrid method is bounded by $\sigma/(1-\sigma)$.

This improves the state of the art in multigrid convergence theory. Analyzing the two-grid convergence factor is often sufficient to assess the convergence of a multigrid scheme; see, e.g., [19, p. 77]. However, this is not yet completely supported by theoretical results. The standard algebraic analysis considers the multigrid iteration matrix as a two-grid iteration matrix plus some perturbation term; see [11, sect. 4.2] or [19, Thm. 3.2.1]. It allows us to obtain a useful bound on the convergence factor of the multigrid method with the W-cycle if σ satisfies

$$\sigma \;\le\; \frac{1}{4\,C}, \tag{1.7}$$

where C is a constant whose exact value is difficult to predict, except that it is in general not smaller than 1 (see section 3 below for details). Because of this condition, this result on multigrid convergence is sometimes stated as follows: "if the two-grid method converges *sufficiently well*, then the multigrid method with W-cycle will have

similar convergence properties" [19, p. 77]. However, condition (1.7) may be violated when textbook multigrid efficiency is difficult to achieve. It may also be difficult to check when using an algebraic multigrid (AMG) method. Below we also show that, when both our new analysis and the standard algebraic analysis apply, our bound on the convergence factor is generally sharper.

For the case of Galerkin coarse grid matrices (i.e., assuming $A_C = p^T A\, p$), an interesting analysis of the W-cycle multigrid has been developed by Braess in [6, pp. 226–228]. This analysis is based on two-grid schemes without postsmoothing, which also gives a worst case estimate for the general case. As will be seen in section 3, our bound on the convergence factor for the W-cycle is always equal to the square of Braess's bound. This suggests that, as proved for the two-grid case in [15, eq. (41)], the W-cycle multigrid scheme with symmetrized pre- and postsmoothing can converge twice as fast as the corresponding scheme without postsmoothing.

On the other hand, in the SPD case, it is also possible to prove optimal convergence properties (with respect to the number of levels) of multigrid methods via so-called smoothing and approximation properties or via the theory of subspace correction methods (using the multilevel splitting of finite element spaces); see, e.g., [5, 7, 11, 12, 13, 14, 16, 17, 22, 23]. However, bounds derived in this way do not, in general, give satisfactorily sharp predictions of actual multigrid convergence [19, p. 96]. Moreover, they require assumptions that are more restrictive than just the convergence of the two-grid method. To our knowledge, for instance, these assumptions have not yet been checked for AMG methods. These analyses, nevertheless, play an important role in the multigrid convergence theory, complementary to the algebraic approach developed here. Indeed, they cover the V-cycle, for which both the standard analysis mentioned above and our new analysis fail to deliver bounds independent of the number of levels.

Eventually, it should be noted that our bounds (1.5), (1.6) have a wider scope than just the analysis of standard multigrid cycles. First, these relations are similar to the ones holding for AMLI-type methods [2, 3]. Hence, when the two-grid method does not converge fast enough for the standard W-cycle, it is possible to use polynomially accelerated cycles based on Chebyshev polynomials, as considered in these references [21]. Another potential application lies in the simplification of coarse grid matrices: (1.5), (1.6) indeed show that one may replace a given coarse grid matrix by a spectrally equivalent approximation. For instance, the theory of algebraic two-grid methods heavily relies on the use of Galerkin coarse grid matrices, that is, on the assumption that $A_C = p^T A\, p$ [8, 9, 10, 15, 18]. However, in practice, such matrices may be costly to compute, and so it could be interesting to develop cheaper alternatives.

The remainder of this paper is organized as follows. In section 2, we prove the main inequalities (1.5), (1.6). Their application to multigrid cycles is discussed in section 3.

2. Perturbed two-grid methods. We first show that B_{TG} is the Schur complement of an extended matrix $\widehat{B}_{\mathrm{TG}}$ given in factored form. Note that this holds for any SPD coarse grid matrix A_C; hence, similarly, B_{PTG} is the Schur complement of an extended matrix $\widehat{B}_{\mathrm{PTG}}$. This factored form has been inspired by the factored form existing for the preconditioner defined by the so-called hierarchical basis multigrid method[1] [4]. Our derivation is also related to equation (15) in [10].

[1] This latter method does not fit into our framework because only fine grid unknowns are relaxed during smoothing steps, and hence R is singular.

Let us introduce some notation. Let M be the matrix such that

$$I - M^{-1}A \;=\; (I - R\,A)^{\nu}; \tag{2.1}$$

from the assumption, $\rho(I - R\,A) < 1$, and M exists, is invertible, and is such that $\rho(I - M^{-1}A) < 1$. This latter relation implies that

$$Q \;= M^{-1} + M^{-T} - M^{-T}\,A\,M^{-1} \;=\; M^{-T}\left(M + M^T - A\right)\,M^{-1} \tag{2.2}$$

is positive definite; see [9, 15].

Define

$$\widehat{B}_{\mathrm{TG}} \;=\; \begin{pmatrix} I_{n\times n} & 0 \\ -p^T(I - A\,M^{-1}) & I_{n_c\times n_c}\end{pmatrix}\begin{pmatrix} Q^{-1} & 0 \\ 0 & A_C\end{pmatrix}\begin{pmatrix} I_{n\times n} & -(I - M^{-T}A)p \\ 0 & I_{n_c\times n_c}\end{pmatrix}. \tag{2.3}$$

Straightforward calculation shows that

$$\begin{aligned}\widehat{B}_{\mathrm{TG}}{}^{-1} &= \begin{pmatrix} I_{n\times n} & (I - M^{-T}A)p \\ 0 & I_{n_c\times n_c}\end{pmatrix}\begin{pmatrix} Q & 0 \\ 0 & A_C^{-1}\end{pmatrix}\begin{pmatrix} I_{n\times n} & 0 \\ p^T(I - A\,M^{-1}) & I_{n_c\times n_c}\end{pmatrix} \\ &= \begin{pmatrix} Q + (I - M^{-T}A)p\,A_C^{-1}\,p^T(I - A\,M^{-1}) & (I - M^{-T}A)p\,A_C^{-1} \\ A_C^{-1}\,p^T(I - A\,M^{-1}) & A_C^{-1}\end{pmatrix} \\ &= \begin{pmatrix} B_{\mathrm{TG}}^{-1} & (I - M^{-T}A)p\,A_C^{-1} \\ A_C^{-1}\,p^T(I - A\,M^{-1}) & A_C^{-1}\end{pmatrix}.\end{aligned}$$

Because $\widehat{B}_{\mathrm{TG}}$ is SPD, this first shows that B_{TG} is SPD too. Further, the inverse of B_{TG} is a principal submatrix of the inverse of $\widehat{B}_{\mathrm{TG}}$ if and only if B_{TG} is equal to the corresponding Schur complement in $\widehat{B}_{\mathrm{TG}}$; see, e.g., [1, eq. (3.4), p. 93]. That is, considering the 2×2 block form

$$\widehat{B}_{\mathrm{TG}} \;=\; \begin{pmatrix} (\widehat{B}_{\mathrm{TG}})_{FF} & (\widehat{B}_{\mathrm{TG}})_{FC} \\ (\widehat{B}_{\mathrm{TG}})_{CF} & (\widehat{B}_{\mathrm{TG}})_{CC}\end{pmatrix}$$

(where $(\widehat{B}_{\mathrm{TG}})_{FF}$ is $n\times n$ and $(\widehat{B}_{\mathrm{TG}})_{CC}$ is $n_c\times n_c$), B_{TG} is the Schur complement of $\widehat{B}_{\mathrm{TG}}$ with respect to the bottom right block:

$$B_{\mathrm{TG}} \;=\; (\widehat{B}_{\mathrm{TG}})_{FF} - (\widehat{B}_{\mathrm{TG}})_{FC}\,(\widehat{B}_{\mathrm{TG}})_{CC}^{-1}\,(\widehat{B}_{\mathrm{TG}})_{CF}.$$

This, together with Theorem 3.8 in [1], proves the following lemma.

LEMMA 2.1. *Let B_{TG} be defined by* (1.2), (1.4) *with A, R, p, A_C satisfying the assumptions stated in section* 1. *Let $\widehat{B}_{TG}$ be defined by* (2.3) *with M defined by* (2.1) *and Q defined by* (2.2). *B_{TG} is SPD, and one has, for all $\mathbf{z}\in\Re^n$,*

$$\mathbf{z}^T\,B_{TG}\,\mathbf{z} \;=\; \min_{\mathbf{w}_C\in\Re^{n_c}}\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{TG}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}. \tag{2.4}$$

Moreover,

$$\lambda_{\max}(B_{TG}^{-1}A) = \max_{\mathbf{z}\in\Re^n\setminus\{0\}}\;\max_{\mathbf{w}_C\in\Re^{n_c}}\;\frac{\mathbf{z}^T\,A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{TG}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}}, \tag{2.5}$$

$$\lambda_{\min}(B_{TG}^{-1}A) = \min_{\mathbf{z}\in\Re^n\setminus\{0\}}\;\max_{\mathbf{w}_C\in\Re^{n_c}}\;\frac{\mathbf{z}^T\,A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{TG}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}}. \tag{2.6}$$

We now prove (1.5), (1.6). Note that these inequalities may also be proved from the factored form of two-grid preconditioners as obtained by Vassilevski in [20, 21]. Their use is also implicit in the building of AMLI-cycle multigrid developed independently by the same author [21].

THEOREM 2.2. *Let B_{TG}, B_{PTG} be defined by* (1.2), (1.3), (1.4) *with A, R, p, A_C, K_C satisfying the assumptions stated in section* 1. *Inequalities* (1.5) *and* (1.6) *hold.*

Proof. Let M, Q, $\widehat{B}_{\mathrm{TG}}$ be defined by (2.1), (2.2), (2.3), and define $\widehat{B}_{\mathrm{PTG}}$ similarly to $\widehat{B}_{\mathrm{TG}}$, exchanging A_C for K_C^{-1} in (2.3). Lemma 2.1 yields

$$\begin{aligned}
\lambda_{\max}(B_{\mathrm{PTG}}^{-1}A) &= \max_{\mathbf{z}\in\Re^n\setminus\{0\}} \max_{\mathbf{w}_C\in\Re^{n_c}} \frac{\mathbf{z}^T A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{\mathrm{PTG}}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}} \\
&\le \max_{\mathbf{z}\in\Re^n\setminus\{0\}} \max_{\mathbf{w}_C\in\Re^{n_c}} \frac{\mathbf{z}^T A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{\mathrm{TG}}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}} \cdot \max_{\widehat{\mathbf{z}}\in\Re^{n+n_c}\setminus\{0\}} \frac{\widehat{\mathbf{z}}^T\widehat{B}_{\mathrm{TG}}\,\widehat{\mathbf{z}}}{\widehat{\mathbf{z}}^T\widehat{B}_{\mathrm{PTG}}\,\widehat{\mathbf{z}}} \\
&= \lambda_{\max}(B_{\mathrm{TG}}^{-1}A) \cdot \max_{\widehat{\mathbf{w}}\in\Re^{n+n_c}\setminus\{0\}} \frac{\widehat{\mathbf{w}}^T\begin{pmatrix}Q^{-1} & 0\\ 0 & A_C\end{pmatrix}\widehat{\mathbf{w}}}{\widehat{\mathbf{w}}^T\begin{pmatrix}Q^{-1} & 0\\ 0 & K_C^{-1}\end{pmatrix}\widehat{\mathbf{w}}} \\
&= \lambda_{\max}(B_{\mathrm{TG}}^{-1}A) \cdot \max(\lambda_{\max}(K_C\,A_C),\,1).
\end{aligned}$$

Similarly, one finds

$$\begin{aligned}
\lambda_{\min}(B_{\mathrm{PTG}}^{-1}A) &= \min_{\mathbf{z}\in\Re^n\setminus\{0\}} \max_{\mathbf{w}_C\in\Re^{n_c}} \frac{\mathbf{z}^T A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{\mathrm{PTG}}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}} \\
&\ge \min_{\mathbf{z}\in\Re^n\setminus\{0\}} \max_{\mathbf{w}_C\in\Re^{n_c}} \frac{\mathbf{z}^T A\,\mathbf{z}}{\begin{pmatrix}\mathbf{z}^T & \mathbf{w}_C^T\end{pmatrix}\widehat{B}_{\mathrm{TG}}\begin{pmatrix}\mathbf{z}\\ \mathbf{w}_C\end{pmatrix}} \cdot \min_{\widehat{\mathbf{z}}\in\Re^{n+n_c}\setminus\{0\}} \frac{\widehat{\mathbf{z}}^T\widehat{B}_{\mathrm{TG}}\,\widehat{\mathbf{z}}}{\widehat{\mathbf{z}}^T\widehat{B}_{\mathrm{PTG}}\,\widehat{\mathbf{z}}} \\
&= \lambda_{\min}(B_{\mathrm{TG}}^{-1}A) \cdot \min_{\widehat{\mathbf{w}}\in\Re^{n+n_c}\setminus\{0\}} \frac{\widehat{\mathbf{w}}^T\begin{pmatrix}Q^{-1} & 0\\ 0 & A_C\end{pmatrix}\widehat{\mathbf{w}}}{\widehat{\mathbf{w}}^T\begin{pmatrix}Q^{-1} & 0\\ 0 & K_C^{-1}\end{pmatrix}\widehat{\mathbf{w}}} \\
&= \lambda_{\min}(B_{\mathrm{TG}}^{-1}A) \cdot \min(\lambda_{\min}(K_C\,A_C),\,1). \qquad \square
\end{aligned}$$

3. Multigrid cycles. Multigrid methods are recursively defined. In the SPD case considered here, the iteration matrix $T_{\mathrm{MG}}^{(\ell)}$ at level ℓ depends on the iteration matrix $T_{\mathrm{MG}}^{(\ell-1)}$ at level $\ell-1$ (the next coarser level) according to

$$T_{\mathrm{MG}}^{(\ell)} = \left(I - R_\ell^T A_\ell\right)^{\nu_\ell}\left(I - p_\ell\left(I - \left(T_{\mathrm{MG}}^{(\ell-1)}\right)^\gamma\right)A_{\ell-1}^{-1}\,p_\ell^T A_\ell\right)\left(I - R_\ell\,A_\ell\right)^{\nu_\ell} \tag{3.1}$$

(see, e.g., [19, pp. 48–49]). In this equation, γ is the *cycle index*; $\gamma = 1$ corresponds to the V-cycle and $\gamma = 2$ to the W-cycle; larger values of γ are seldom considered in practice.

Now $T_{\rm MG}^{(\ell)}$ is a perturbed two-grid iteration matrix (1.3) with $A = A_\ell$, $R = R_\ell$, $\nu = \nu_\ell$, $p = p_\ell$ and K_C given by

$$K_C \;=\; \left(I - \left(T_{\rm MG}^{(\ell-1)}\right)^\gamma\right) A_{\ell-1}^{-1}.$$

Defining the iteration matrix $T_{\rm TG}^{(\ell)}$ of the (unperturbed) two-grid method by (1.2) with $A_C = A_{\ell-1}$ and letting $B_{\rm TG}^{(\ell)}$, $B_{\rm MG}^{(\ell)}$ be such that

$$I - {B_{\rm TG}^{(\ell)}}^{-1} A_\ell \;=\; T_{\rm TG}^{(\ell)}, \qquad I - {B_{\rm MG}^{(\ell)}}^{-1} A_\ell \;=\; T_{\rm MG}^{(\ell)},$$

inequalities (1.5), (1.6) imply

$$\begin{aligned}
\lambda_{\max}\left({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\right) &\le \lambda_{\max}\left({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\right) \;\cdot\; \max\left(\lambda_{\max}\big(I - \left(T_{\rm MG}^{(\ell-1)}\right)^\gamma\big),\, 1\right),\\
\lambda_{\min}\left({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\right) &\ge \lambda_{\min}\left({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\right) \;\cdot\; \min\left(\lambda_{\min}\big(I - \left(T_{\rm MG}^{(\ell-1)}\right)^\gamma\big),\, 1\right).
\end{aligned}$$

Let

$$\sigma_{\rm MG}^{(\ell)} \;=\; \rho\left(T_{\rm MG}^{(\ell)}\right) \;=\; \max\left(\lambda_{\max}\big({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\big) - 1,\; 1 - \lambda_{\min}\big({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\big)\right)$$

be the convergence factor of the multigrid method at level ℓ. One has, assuming $\sigma_{\rm MG}^{(\ell-1)} \le 1$,

$$\lambda_{\max}\left({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\right) - 1 \;\le\; \begin{cases} \lambda_{\max}\left({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\right)\left(1 + \left(\sigma_{\rm MG}^{(\ell-1)}\right)^\gamma\right) - 1 & \text{if } \gamma \text{ is odd and } T_{\rm MG}^{(\ell-1)} \text{ has some negative eig.,} \\ \lambda_{\max}\left({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\right) - 1 & \text{otherwise,} \end{cases}$$

whereas

$$1 - \lambda_{\min}\left({B_{\rm MG}^{(\ell)}}^{-1} A_\ell\right) \;\le\; 1 - \lambda_{\min}\left({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\right)\left(1 - \left(\sigma_{\rm MG}^{(\ell-1)}\right)^\gamma\right).$$

Then let

$$\sigma_{\rm TG}^{(\ell)} \;=\; \rho\left(T_{\rm TG}^{(\ell)}\right) \;=\; \max\left(\lambda_{\max}\big({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\big) - 1,\; 1 - \lambda_{\min}\big({B_{\rm TG}^{(\ell)}}^{-1} A_\ell\big)\right)$$

be the convergence factor of the (unperturbed) two-grid method at level ℓ. If $\sigma_{\rm TG}^{(\ell)} \le 1$ and if either $\lambda_{\max}({B_{\rm TG}^{(\ell)}}^{-1} A_\ell) \le 1$ for all ℓ (as occurs when using Galerkin coarse grid matrices) or γ is even (or both), there holds

$$\sigma_{\rm MG}^{(\ell)} \;\le\; 1 - \left(1 - \sigma_{\rm TG}^{(\ell)}\right)\left(1 - \left(\sigma_{\rm MG}^{(\ell-1)}\right)^\gamma\right) \;\le\; 1. \tag{3.2}$$

If the matrix A_0 on the coarsest level is inverted exactly, one has $\sigma_{\rm MG}^{(1)} = \sigma_{\rm TG}^{(1)}$, and (3.2) defines a recursion which may be followed from $\ell = 2, 3, \ldots$ until the finest level.

For $\gamma = 1$ (the V-cycle), this does not yield bounds independent of the number of levels, although the estimates may be practically relevant for few levels if the $\sigma_{\rm TG}^{(\ell)}$ are small. For instance, $\sigma_{\rm TG}^{(\ell)} \le 0.1$ yields $\sigma_{\rm MG}^{(\ell)} \le 0.41$ for $\ell = 5$, which is not that bad.

The most interesting application is $\gamma = 2$ (the W-cycle). No additional assumption on $\lambda_{\max}(B_{\mathrm{TG}}^{(\ell)\,-1} A)$ is needed (γ is even), and one may check that if

$$\sigma_{\mathrm{TG}}^{(\ell)} \;\leq\; \sigma$$

and

$$\sigma_{\mathrm{MG}}^{(\ell-1)} \;\leq\; \frac{\sigma}{1-\sigma}$$

hold for some $\sigma < 1/2$, then

$$\sigma_{\mathrm{MG}}^{(\ell)} \;\leq\; \frac{\sigma}{1-\sigma}.$$

This proves the following theorem.

THEOREM 3.1. *Consider a multigrid method recursively defined by the iteration matrix* (3.1) *with* $\gamma = 2$ *for* $\ell = 1, 2, \ldots$ *and* $T_{MG}^{(0)} = 0$ *(exact inversion on the coarsest level). Assume that* A_ℓ, $\ell = 0, 1, \ldots$, *is SPD and that* R_ℓ, $\ell = 1, 2, \ldots$, *is such that* $\rho(I - R_\ell A_\ell) < 1$. *If the spectral radius of the two-grid iteration matrix* (1.2) *with* $A = A_\ell$, $R = R_\ell$, $\nu = \nu_\ell$, $p = p_\ell$, *and* $A_C = A_{\ell-l}$ *is bounded by some* $\sigma < 1/2$ *independently of* ℓ, *then the spectral radius of the multigrid iteration matrix* (3.1) *is bounded by* $\sigma/(1-\sigma)$, *independently of* ℓ.

Comparison with the standard algebraic analysis. This analysis, see, e.g., [11, 19], is based on matrix norms, instead of spectral radii, and applies to the nonsymmetric case as well. In the framework considered here, this analysis proves that if

$$\|T_{\mathrm{TG}}^{(\ell)}\| \;\leq\; \sigma^*$$

and

$$\left\| \left(I - R_\ell^T A_\ell\right)^{\nu_\ell} p_\ell \right\| \;\cdot\; \left\| A_{\ell-1}^{-1} p_\ell^T A_\ell \left(I - R_\ell A_\ell\right)^{\nu_\ell} \right\| \;\leq\; C$$

hold for some σ^*, C such that

$$4\, C\, \sigma^* \;\leq\; 1, \tag{3.3}$$

then the iteration matrix for the W-cycle ($\gamma = 2$) satisfies

$$\|T_{\mathrm{TG}}^{(\ell)}\| \;\leq\; \frac{1 - \sqrt{1 - 4\, C\, \sigma^*}}{2\, C} \;\leq\; 2\, \sigma^*. \tag{3.4}$$

Note that this result holds for any matrix norm $\|\cdot\|$.

To comment on it, first observe that

$$\begin{aligned}
&\left\| \left(I - R_\ell^T A_\ell\right)^{\nu_\ell} p_\ell \right\| \;\cdot\; \left\| A_{\ell-1}^{-1} p_\ell^T A_\ell \left(I - R_\ell A_\ell\right)^{\nu_\ell} \right\| \\
&\qquad \geq \left\| \left(I - R_\ell^T A_\ell\right)^{\nu_\ell} p_\ell A_{\ell-1}^{-1} p_\ell^T A_\ell \left(I - R_\ell A_\ell\right)^{\nu_\ell} \right\| \qquad (3.5) \\
&\qquad = \left\| \left(I - R_\ell^T A_\ell\right)^{\nu_\ell} \left(I - R_\ell A_\ell\right)^{\nu_\ell} - T_{\mathrm{TG}}^{(\ell)} \right\| \\
&\qquad \geq \left\| \left(I - R_\ell^T A_\ell\right)^{\nu_\ell} \left(I - R_\ell A_\ell\right)^{\nu_\ell} \right\| - \left\| T_{\mathrm{TG}}^{(\ell)} \right\| \\
&\qquad \geq \left(\rho\left(I - R_\ell A_\ell\right)\right)^{2\,\nu_\ell} - \sigma^*. \qquad (3.6)
\end{aligned}$$

In practical situations, $\rho\,(I - R_\ell\, A_\ell) \approx 1$ (otherwise, the coarse grid correction would be unnecessary for fast convergence). Hence, $C \gtrsim 1-\sigma^*$. Moreover, if $A_{\ell-1} = p_\ell^T A_\ell\, p_\ell$ (i.e., with a Galerkin coarse grid matrix), the middle term in the right-hand side of (3.5) is a projector that leaves the vectors in the range of p_ℓ unchanged, leading to expect $C \gtrsim 1$ in such cases. Since $\sigma^* \geq \sigma$ (the spectral radius is a lower bound on the matrix norm for any norm), the condition (3.3) is thus generally more restrictive than our condition $\sigma < 1/2$, even if one uses the energy norm for which $\sigma^* = \sigma$. For instance, $C \gtrsim 1$ then means that (3.3) requires $\sigma \leq \sigma^* \lesssim 1/4$.

When both bounds apply, if, in addition,

$$C \;\geq\; 1 - \sigma^*$$

(as one expects according to (3.6) and the discussion above), then our bound $\sigma/(1-\sigma)$ is always better than the bound (3.4). Indeed, taking $\sigma^* = \sigma$ (which is the most favorable for (3.4)), one has (since $\sigma(1+2\,C) = \sigma + \frac{1}{2} 4\,C\,\sigma < 1$)

$$\begin{aligned}
\frac{\sigma}{1-\sigma} \;\leq\; \frac{1-\sqrt{1-4\,C\,\sigma}}{2\,C} \;&\Longleftrightarrow\; \sqrt{1-4\,C\,\sigma^*} \;\leq\; \frac{1-\sigma(1+2\,C)}{1-\sigma} \\
&\Longleftrightarrow\; (1-\sigma)^2(1-4\,C\,\sigma) - (1-\sigma(1+2\,C))^2 \;\leq\; 0 \\
&\Longleftrightarrow\; -4\,C\,\sigma^3 + (4\,C - 4\,C^2)\sigma^2 \;\leq\; 0 \\
&\Longleftrightarrow\; -\sigma + 1 - C \;\leq\; 0.
\end{aligned}$$

By way of illustration, consider the case $\sigma = \sigma^* = 1/4$ and $C = 1$. Then our bound for the W-cycle is $1/3$, whereas (3.4) gives $1/2$. Note, however, that, for σ going to 0, both bounds converge to σ.

Comparison with Braess's analysis. Braess's analysis [6, pp. 226–228] assumes Galerkin coarse grid matrices and is based on two-grid and multigrid schemes without postsmoothing. To make things clear, let

$$\begin{aligned}
\widetilde{T}_{\rm TG}^{(\ell)} &= \left(I - p_\ell\, A_{\ell-1}^{-1}\, p_\ell^T\, A_\ell\right)\, (I - R_\ell\, A_\ell)^{\nu_\ell}\,, \\
\widetilde{T}_{\rm MG}^{(\ell)} &= \left(I - p_\ell \left(I - \left(\widetilde{T}_{\rm MG}^{(\ell-1)}\right)^{\gamma}\right) A_{\ell-1}^{-1}\, p_\ell^T\, A_\ell\right)\, (I - R_\ell\, A_\ell)^{\nu_\ell}
\end{aligned}$$

be the corresponding iteration matrices, and denote by $\widetilde{\rho}_{\rm TG}^{(\ell)}$, $\widetilde{\rho}_{\rm MG}^{(\ell)}$ their energy norm:

$$\widetilde{\rho}_{\rm TG}^{(\ell)} \;=\; \|\widetilde{T}_{\rm TG}^{(\ell)}\|_{A_\ell}, \qquad \widetilde{\rho}_{\rm MG}^{(\ell)} \;=\; \|\widetilde{T}_{\rm MG}^{(\ell)}\|_{A_\ell}.$$

The main convergence result for multigrid cycles in [6] is inequality (3.9) from Chapter V. With the above notation, this inequality amounts to

$$\left(\widetilde{\rho}_{\rm MG}^{(\ell)}\right)^2 \;\leq\; 1 \;-\; \left(1 - \left(\widetilde{\rho}_{\rm TG}^{(\ell)}\right)^2\right) \left(1 - \left(\widetilde{\rho}_{\rm MG}^{(\ell-1)}\right)^{2\gamma}\right). \tag{3.7}$$

Comparing with (3.2), the requirement on $\widetilde{\rho}_{\rm TG}^{(\ell)}$ to have an optimal method is less restrictive than the requirement we have on $\sigma_{\rm TG}^{(\ell)}$. However, as seen in [15, eq. (41)], when $A_{\ell-1} = p_\ell^T A_\ell\, p_\ell$ (as needed to prove (3.7)), there holds

$$A_\ell\, T_{\rm TG}^{(\ell)} \;=\; \left(\widetilde{T}_{\rm TG}^{(\ell)}\right)^T\, A_\ell\, \widetilde{T}_{\rm TG}^{(\ell)}$$

entailing

$$\sigma_{\mathrm{TG}}^{(\ell)} \;=\; \left(\widetilde{\rho}_{\mathrm{TG}}^{(\ell)}\right)^2. \tag{3.8}$$

That is, if one uses the same smoother and prolongation, the two-grid method with symmetrized pre- and postsmoothing converges twice as fast as the method without postsmoothing.

Acknowledging this fact, one sees that (3.7) defines recursively a bound on $\widetilde{\rho}_{\mathrm{MG}}^{(\ell)}$ which is equal to the square root of the bound on $\sigma_{\mathrm{MG}}^{(\ell)}$ obtained from our result (3.2). This suggests that, as shown by (3.8) in the two-grid case, the W-cycle multigrid with symmetrized smoothing can converge twice as fast as the corresponding algorithm without postsmoothing.

Sometimes the bound for the scheme without postsmoothing is used as worst case estimate for the general case. From that point of view, our analysis gives sharper bounds. For instance, Theorem 3.4 in [6, Chapter V] states that the convergence factor for the W-cycle is not larger that $3/5$ when $\widetilde{\rho}_{\mathrm{TG}}^{(\ell)} \leq 1/2$ for all ℓ, whereas, with $\sigma_{\mathrm{TG}}^{(\ell)} \leq 1/4$, our theorem, Theorem 3.1, then proves that the convergence factor for the W-cycle does not exceed $1/3$.

Acknowledgments. I thank M. Hochstenbach for a careful reading of the manuscript. An anonymous referee suggested numerous improvements which are deeply appreciated. Another referee drew our attention to [6].

THE STABILITY OF FRONT-TRACKING SCHEME FOR TWO SPATIAL DIMENSIONAL MISCIBLE TWO PHASE FLOW*

KOU-KUNG ALEX CHANG†

Abstract. The front-tracking method of Glimm et al. is designed for physical applications which are governed by a hyperbolic system of equations in which codimension one (cd-1) jump discontinuities in the solution are important. The core of this method is the curve propagation algorithm. A theoretical analysis is presented here to show that this curve propagation algorithm is stable. Chang and Lindquist developed a new curve propagation algorithm which conserves mass for any grid of finite spacing. We also present a proof to show the new curve propagation algorithm is stable under some conditions.

Key words. front tracking, discontinuity propagation, two phase flow

1. Introduction.

In 1981, Glimm et al. presented a computational method called front tracking [5], [8], [9], which is designed for physical applications which are governed by a hyperbolic system of equations in which codimension one (cd-1) jump discontinuities in the solution are important. The front-tracking scheme has been developed into a computational code, FronTier, for dealing with two or three spatial dimensional problems [4], [11] and has been used in various applications [3], [6], [7], [12].

In this computational method, two important problems are of concern; one is if the mass balance is conserved when it is applied in practice; the other is if this numerical method is stable.

For the first problem, Glimm, Lindquist, and Zhang address five algorithmic areas that need to be corrected for maintaining mass conservation when applying this method to two phase flow in porous media [7]. In the same paper, Glimm et al. present algorithms to resolve four of them. The fifth algorithmic area of problem is the explicit movement of the fluid discontinuity curves (the curve propagation algorithm). Errors produced by the curve propagation algorithm for a nonlinear case can be absorbed by the numerical approximations. For the linear case, errors are not dissipated and increase with time. Chang and Lindquist analyzed the mass balance error produced by the curve propagation algorithm for miscible flow case (linear case) and showed that up to a finite time T, the mass balance error vanishes as the length of the line segments of the continuous piecewise linear discontinuity curve goes to zero when the numerical velocity field is piecewise constant or the numerical velocity field is Lipschitz continuous [1], [2]. Meanwhile, Chang and Lindquist developed a new curve propagation algorithm which is assured to conserve mass for any grid of finite spacing [1].

In this paper, we study the other problem: the stability property of the front-tracking scheme applied to miscible two phase incompressible flow in porous media.

Our analysis focuses on the stability of the curve propagation (both original and new) algorithms, which are the core of the front-tracking scheme.

The behavior of two phase incompressible flow in porous media is governed by a specific system of equations,

$$\phi(X)\frac{\partial s}{\partial t} + \nabla \cdot \overrightarrow{v}(X) f(s) = 0, \tag{1}$$

$$\nabla \cdot \overrightarrow{v}(X) = 0, \tag{2}$$

$$\overrightarrow{v}(X) = -\lambda(s)\kappa(X) \bigtriangledown P(X), \tag{3}$$

where (1) is a hyperbolic subsystem, and (2) and (3) are elliptic subsystems. In this system of equations, X is the space variable in R^2, and ϕ is the medium porosity (volume fraction of pore space); s and $1-s$ are the respective saturations (fractions of available pore volume) of the two flowing fluid phases; $\overrightarrow{v}$ is the total fluid velocity; $f\overrightarrow{v}$ and $(1-f)\overrightarrow{v}$ are the respective fractions of the total fluid velocity carried by each phase; P is the pressure field in the medium; κ is the medium permeability; and λ is the saturation-dependent total relative transmissibility. We shall also refer to the mobility ratio, $\mathrm{M} \equiv \lambda(1)/\lambda(0)$, which governs the linearized analysis for fingering instability in two phase flows; $\mathrm{M} \leq 1$ corresponds to stable flows and $\mathrm{M} > 1$ to unstable flows. We specify our problem on miscible two phase flow for more fundamental reasons, and (1) becomes

$$\phi(X)\frac{\partial s}{\partial t} + \overrightarrow{v}(X) \cdot \nabla s = 0. \tag{1'}$$

We outline the rest of this paper as follows: section 2 will describe the front-tracking method, curve propagation algorithms, and some relative assumptions and definitions. Section 3 contains our proof of the stability of the original curve propagation algorithm. Section 4 shows the stability of the mass conserved curve propagation algorithm.

2. The front-tracking method. The front-tracking method approach to solving (1)–(3) utilizes an implicit pressure explicit saturation scheme of sequential solution of the coupled hyperbolic-elliptic system (1)–(3). The elliptic subsystem is solved by mixed finite elements yielding simultaneous solutions of P and $\overrightarrow{v}$. Because our analysis focuses on the stability of the front tracking for solving the hyperbolic subsystem, we do not discuss this mixed finite element algorithm further. Besides, without loss of generality, we may assume that the velocity field is Lipschitz continuous.

The hyperbolic subsystem is solved by the front-tracking algorithms which employ a fixed, volume filling grid to resolve the smooth part of the solution and moving cd-1 grids to resolve jump discontinuities and their motion. The fixed grid is regular rectangular and of discretization spacing Δx and Δy; we shall refer to it as the hyperbolic grid. The moving cd-1 discontinuity grids in two dimensional space are unions of *curves*. For our specific miscible flow problem, the curves separate the domain geometrically to several disconnected subdomains. Each curve has an orientation and is replaced by its continuous piecewise linear approximant. We denote a linear segment from this approximant by $\overline{ab}$, where a is the start point and b is the end point of this segment. The start and end points of all segments in the piecewise linear approximant are called *points of the curve* or simply *interior points* or *points*. The first point on the piecewise linear approximant is called the *start node*, and the last is the *end node*. The points on a curve carry physical data in the left and right sides of the curve, which are the saturations in our case. For details, we refer the reader to [10].

The algorithmic procedure for updating the numerical solution to subsystem (1) consists of two major tasks: (I) achieve curve propagation, which generates the discontinuity curves, transmits waves across the front, and updates flow tangentially to the front; (II) update the solution on the fixed grid. We describe them as follows:

(I) Basically, curve propagation is achieved by changing the coordinates locally at each curve point in normal and tangential directions to the discontinuity curve. Therefore (1) becomes

$$\phi(X)s_t + (\hat{n}\cdot\nabla)\overrightarrow{v}f(s) + (\hat{t}\cdot\nabla)\overrightarrow{v}f(s) = 0 \tag{4}$$

at each point p, $\hat{n}$ is the normal vector to the discontinuity curve, and $\hat{t}$ is the tangent vector. The algorithm for solving (4) can be described in terms of series of splittings of hyperbolic operators:

(a) Solve the local Riemann problem at curve point p for equation

$$\phi(X)s_t + (\hat{n}\cdot\nabla)\overrightarrow{v}f(s) = 0, \tag{5}$$

with state values

$$s(p+\hat{n}) \equiv s_{left}, \qquad s(p-\hat{n}) \equiv s_{right},$$

to find propagation speed. This solution provides a new propagated position p' for the point. In the miscible case (i.e., the linear case), the propagation speed is $\overrightarrow{v}(x)\cdot\hat{n}|_p$.

(b) At each point on the propagated discontinuity grid, solve equation

$$\phi(X)s_t + (\hat{t}\cdot\nabla)\overrightarrow{v}f(s) = 0 \tag{6}$$

by using a one dimensional finite difference scheme to update the state value on both sides of the discontinuity curve. For the miscible flow case, the state value on each side should be constant.

(c) It may happen that an unphysical crossing of the discontinuity curve occurred during movement. We need to untangle this unphysical crossing to ensure physical correctness of the discontinuity grids. This untangling step is required between steps (a) and (b).

(d) Points on the discontinuity curve may become too far apart or too close together, and so a redistribution step is necessary to redistribute points on the propagated grids for ensuring adequate sampling of the discontinuity grid along its arc length. For more detail on these actions, we refer the reader to [1] and [13].

(II) Updating the solution on the fixed grid is done by solving an initial-boundary value problem on both sides of the front (discontinuity curve). We treat the front as a moving boundary and never use states (phase saturations s here) on the opposite side of the front. This can be done by using any stable, two spatial dimensional, numerical algorithm. For the miscible flow case studied here, the phase saturations remain piecewise constant in space, and implementation of (II) is trivial and stable. Therefore we concentrate on the curve propagation algorithms. We recall some fundamental definitions, underlying algorithmic procedures, and theorems in [1] and [2].

DEFINITION NBC. *The normal direction to the linear segment $\overline{p_1p_2}$ is the direction perpendicular to $\overline{p_1p_2}$, oriented from the right side to the left side.*

DEFINITION NC. *Let $\overline{p_1p_2}$ and $\overline{p_2p_3}$ be two consecutive segments from the piecewise linear approximant. Then the normal to the curve at p_2 is the direction perpendicular to the segment $\overline{p_1p_3}$, oriented from the right side to the left side of the curve.*

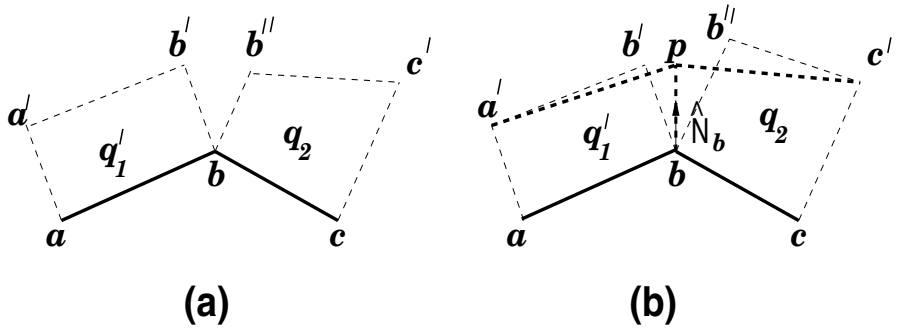

FIG. 2.1. (a) q_1' *(area* $aa'b'b$*) and* q_2 *(area* $bb''c'c$*) are the conserved mass changes by the movement of linear segments* $\overline{ab}$ *and* $\overline{bc}$*.* (b) $\hat{N}_b$ *is the curve normal at point* b*. Along* $\hat{N}_b$*, find a position* p *such that the mass change in the area* $aa'pc'cb$ *is equal to* $q_1' + q_2$*.*

ALGORITHM BP. *Given* p *of* $\overline{p_1 p}$ *(or* $\overline{pp_1}$*), then its propagated image,* p'*, is obtained by solving a one dimensional Riemann problem along the* normal to the linear segment $\overline{p_1 p}$ *(*$\overline{pp_1}$*).*

ALGORITHM PC. *Given* p_2 *of* $\overline{p_1 p_2}$ *and* $\overline{p_2 p_3}$*, then its propagated image,* p_2''*, is obtained by the solution of a one dimensional Riemann problem along the* normal to the curve *at* p_2*.*

ALGORITHM CP. *The movement of a tracked curve is achieved by propagating each interior point by Algorithm PC over a time step* Δt*.*

THEOREM 2.1. *Let* $E(T, \Delta t)$ *be the total mass error at time* T *produced by moving the interior of discontinuity curve under Algorithm PC. Assume the curvature of the curve is bounded by* $K(T) < \infty$*. Then* $E(T, \Delta t) = O(\Delta t)$ *as* $\Delta t \to 0$*.*

ALGORITHM NPC. *Consider the propagation of point* b*, where* $\overline{ab}$ *and* $\overline{bc}$ *are two consecutive segments from the piecewise linear approximant to the discontinuity curve. Assume point "a" has been previously propagated to* a' *in a mass conserving manner. With reference to Figure* 2.1(a)*, propagate* b *to* b' *by Algorithm BP (*b *is considered as a point from* $\overline{ab}$*); propagate* b *and* c*, respectively, to* b'' *and* c' *by Algorithm BP (*b *and* c *are considered as points from* $\overline{bc}$*). Consider the respective conservative mass changes* q_1' *and* q_2 *produced by the movements* $\overline{ab} \to a'b'$ *and* $\overline{bc} \to b''c'$*. Find a point* p *(illustrated in Figure* 2.1(b)*) lying along the curve normal direction at* b *such that the mass change in the area* $abpa' + bcc'p$ *is equal to* $q_1' + q_2$*.*

Remark 1. For the miscible flow case, the phase saturations are piecewise constant in space (we assume the saturations are 0 and 1 here). Therefore the mass change q_1' in the quadrilateral $abb'a'$ is equal to the area of $abb'a'$, i.e., $q_1' = \frac{1}{2}[\overrightarrow{ab} \times (\overrightarrow{aa'} + \overrightarrow{bb'}) + \overrightarrow{bb'} \times \overrightarrow{aa'}]$. Similarly, $q_2 = \frac{1}{2}[\overrightarrow{bc} \times (\overrightarrow{bb''} + \overrightarrow{cc'}) + \overrightarrow{bb''} \times \overrightarrow{cc'}]$. Since $\overrightarrow{bb''}$ is parallel to $\overrightarrow{cc'}$, q_2 becomes $\frac{1}{2}\overrightarrow{bc} \times (\overrightarrow{bb''} + \overrightarrow{cc'})$.

THEOREM 2.2. *In Algorithm NPC, there exists a unique point* p *lying along the curve normal direction at* b *such that the mass change in the area* $abpa' + bcc'p$ *is equal to* $q_1' + q_2$ *iff* $\hat{N}_b \times \overrightarrow{c'a'} \neq 0$*, where* $\hat{N}_b$ *is the unit curve normal vector at* b*.*

Proof. In order to find a unique point p lying along the curve normal direction at b such that the mass change in the area $abpa' + bcc'p$ is equal to $q_1' + q_2$, we need to

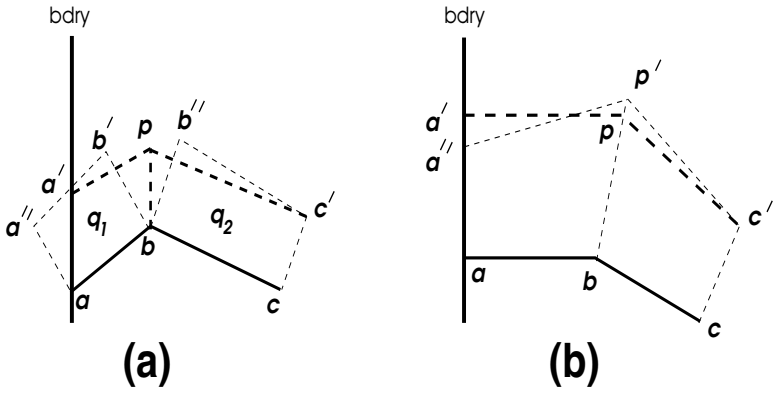

FIG. 2.2. (a) *Propagation of a point adjacent to a start node.* (b) *Propagation of a point adjacent to a start node with the first linear segment perpendicular to the boundary.*

find a scalar λ such that

$$[\lambda\hat{N}_b \times \overrightarrow{aa'} + \overrightarrow{ab} \times (\lambda\hat{N}_b + \overrightarrow{aa'})] + [\overrightarrow{cc'} \times \lambda\hat{N}_b + \overrightarrow{bc} \times (\overrightarrow{cc'} + \lambda\hat{N}_b)] = 2(q_1' + q_2). \tag{7}$$

After an easy calculation, we have

$$\lambda[\hat{N}_b \times \overrightarrow{c'a'}] = 2(q_1' + q_2) + \overrightarrow{aa'} \times \overrightarrow{ab} + \overrightarrow{cc'} \times \overrightarrow{bc}. \tag{8}$$

This equation has a unique solution λ iff $\hat{N}_b \times \overrightarrow{c'a'} \neq 0$. □

Remark 2. Equation (8) has no solution for λ when $\hat{N}_b \times \overrightarrow{c'a'} = 0$. For resolving this problem, we reduce the time step size to produce new propagated positions c' and a' for c and a. After reducing the time step, $\hat{N}_b \times \overrightarrow{c'a'}$ will still vanish only if the linear segments $\overline{ab}$ and $\overline{bc}$ are colinear. In this case, we propagate point b by Algorithm PC, which will be mass conserving.

Remark 3. In general, Algorithm NPC requires a minor modification when applied to the first interior point of a curve. Assume point a of Figure 2.2(a) is the start node of a curve and is propagated to point a' by an appropriate node propagation algorithm. Consider the point a'' obtained by propagating a by Algorithm BP. In propagating the first interior point, b, the mass change q_1 in the area $abb'a''$ (rather than $q_1{}'$ of $abb'a'$) should be used in applying Algorithm NPC. Analogous modification is required when NPC is applied to the last interior point of a curve.

Remark 4. In practice, for many fluid calculation cases, the contact discontinuity curve should be perpendicular to the boundary. Algorithm NPC propagates the first interior point of a curve in the following way: After every point of a curve has been propagated by Algorithm NPC (general case), adjust point a'' to a' as well as p' to p such that the mass change of the area $abcc'pa'$ equals that of the area $abcc'p'a''$ (see Figure 2.2(b)), and the linear approximation $\overline{ap}$ must be perpendicular to the boundary. Similar modification is required when NPC is applied to the last interior point of a curve.

3. Stability of front tracking. In this section, we will discuss the stability of the original curve propagation algorithm. Before continuing our discussion, we will present the definition of stability and some assumptions.

DEFINITION 3.1. *Let U be a numerical method and $U_{\Delta t}$ be the numerical solution with the length of time step Δt. Then U is stable if there are R, M, and N depending*

on the initial U_0 and the velocity field $\overrightarrow{v}(x,y)$ such that all approximations $U_{\Delta t}$ satisfy the following conditions:

(a) *Supp*$(U_{\Delta t}(\cdot, n\Delta t)) \subset [-M,M]\times[-N,N]$, *where* $n\Delta t \in [0,T]$.

(b) $\sum_{n=0}^{T/\Delta t}\sum_{i=-\infty}^{\infty}\sum_{j=-\infty}^{\infty}(\Delta t\Delta x|U^n_{i,j+1}-U^n_{i,j}|+\Delta t\Delta y|U^n_{i+1,j}-U^n_{i,j}|+\Delta x\Delta y|U^{n+1}_{i,j}-U^n_{i,j}|) \le R$ *for all* $\Delta t < \Delta t_0$ *for some* Δt_0. *Here* Δx, Δy *are the block lengths in the direction of* x *and* y, *and* $U^n_{i,j}$ *is the value of* $U_{\Delta t}$ *at* $t = n\Delta t$, $x = i\Delta x$, *and* $y = j\Delta y$.

Our discussions require two assumptions: one is that the velocity field $\overrightarrow{v}(x)$ satisfies the Lipschitz condition; the other is the discontinuity curves at all time steps are C^2 curves, and the curvature on every point of the curve is bounded by κ. These two assumptions are explained as follows.

Assumption L1. Let $\{\Delta_i\}$ denote the set of the mesh elements of the velocity field. We assume the velocity $\overrightarrow{v_i}$ in a mesh element Δ_i is assigned by $\overrightarrow{v}(X)$ for some $X \in \Delta_i$. Furthermore, we assume the velocity field $\overrightarrow{v}(X)$ is Lipschitz continuous; i.e., $|\overrightarrow{v}(X)-\overrightarrow{v}(Y)| \le K||X-Y||$ for some constant K, where $||\cdot||$ is the space norm and X and Y are two dimensional space variables.

Assumption C1. Let σ^n be the discontinuity curve at time step n; we assume σ^n is a C^2 curve for all n, and the curvature $|\kappa(p)| \le \kappa < \infty$ for all points p of σ^n.

A curve is represented by its continuous piecewise linear approximant. If the length of any of the segments from this approximant is too big, then this is a poor approximation to the curve. If it is too small, it leads to numerical induced tangling during propagation. Therefore we need an assumption (Assumption R1) that restricts a piecewise linear approximation. In practice, The FronTier package uses algorithms described in section 2 to achieve this restriction.

Assumption R1. Let σ^n be the discontinuity curve at time step n and h be the hyperbolic grid size. We restrict the length b^n_i of a linear segment from the piecewise linear approximant to $c_1 h < |b^n_i| < c_2 h$ for all i, n, where c_1 and c_2 are constants.

Assumption R2. We assume the algorithm satisfies the CFL condition $\Delta t \le \alpha c_1 h/V$, where α is some constant $\alpha < 1$, c_1 is the same as in Assumption R1, and V is the largest magnitude velocity of discontinuity motion in the computational region during the entire flow process. Furthermore, we assume there is a positive integer N such that $T = \Delta t N$.

LEMMA 3.2. *Let b^n_i be a linear segment from the continuous piecewise linear approximation to the discontinuity curve σ^n at time step n and b^{n+1}_i be the line segment propagated from b^n_i. Then under Assumptions L1 and C1, the length* $|b^{n+1}_i| \le |b^n_i|(1+\Delta t(2V\kappa + K))$.

Proof. Let $\overrightarrow{pq} = b^n_i$, $\hat{n}_1$ be the normal to the curve at q and $\hat{n}_2$ be the normal to the curve at p (see Figure 3.1). Then

$$b^{n+1}_i = \overrightarrow{p'q'} = (\Delta t\,\overrightarrow{v}_1\cdot\hat{n}_1)\hat{n}_1 + b^n_i - (\Delta t\,\overrightarrow{v}_2\cdot\hat{n}_2)\hat{n}_2. \tag{9}$$

By triangle inequality,

$$|b^{n+1}_i| \le |b^n_i| + |(\Delta t\overrightarrow{v_1}\cdot\hat{n}_1)\cdot\hat{n}_1 - (\Delta t\overrightarrow{v_2}\cdot\hat{n}_2)\cdot\hat{n}_2|, \tag{10}$$

and by an intermediate calculation, we have

$$\begin{aligned}|b^{n+1}_i| \le |b^n_i| &+ \Delta t|(\overrightarrow{v_1}\cdot(\hat{n}_1-\hat{n}_2))\hat{n}_1| + \Delta t|(\overrightarrow{v_1}\cdot\hat{n}_2)(\hat{n}_1-\hat{n}_2)| \\ &+ \Delta t|((\overrightarrow{v_1}-\overrightarrow{v_2})\cdot\hat{n}_2)\hat{n}_2|.\end{aligned} \tag{11}$$

Since $\overrightarrow{v}(X)$ is continuous on a closed and bounded region, $[-M,M]\times[-N,N]$, there is a maximum velocity, V, such that $|\overrightarrow{v}(X)| \le V$ for all $X \in [-M,M]\times[-N,N]$.

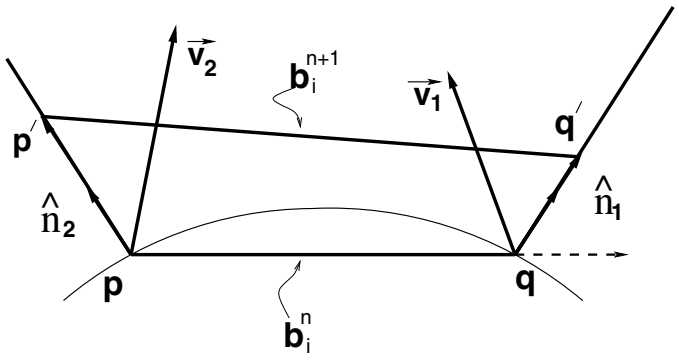

FIG. 3.1. *Piecewise linear approximation $\overline{pq}$ of discontinuity curve σ^n.*

And, because σ^n is a C^2 curve, if $|b_i^n|$ is small enough, then

$$|\hat{n}_1 - \hat{n}_2| \approx |\kappa(p)||b_i^n| \le \kappa|b_i^n|, \tag{12}$$

where $\kappa(p)$ is the curvature at p on σ^n. By Assumption L1, $\overrightarrow{v}(X)$ is Lipschitz continuous; then

$$|(\overrightarrow{v_1} - \overrightarrow{v_2})| \le K|b_i^n|. \tag{13}$$

Hence, from (11), we have

$$\begin{aligned} |b_i^{n+1}| &\le |b_i^n| + \Delta t V\kappa|b_i^n| + \Delta t V\kappa|b_i^n| + \Delta t K|b_i^n| \\ &\le |b_i^n|(1 + \Delta t(2V\kappa + K)). \end{aligned} \tag{14}$$

This completes our proof. ∎

LEMMA 3.3. *Let σ^n be the discontinuity curve at the nth time step. Then under Assumptions L1 and C1, $|\sigma^n| \le |\sigma^0|(1 + \Delta t(2V\kappa + K))^n$.*

Proof. Assume σ^n consists of m linear pieces b_i^n, $i = 1, 2, \cdot, m$. From Lemma 3.2,

$$|\sigma^{n+1}| = \sum_{i=1}^{m} |b_i^{n+1}| \le \sum_{i=1}^{m} |b_i^n|(1 + \Delta t(2V\kappa + K)) \le |\sigma^n|(1 + \Delta t(2V\kappa + K)). \tag{15}$$

By induction, we have

$$|\sigma^n| \le |\sigma^0|(1 + \Delta t(2V\kappa + K))^n. \quad \blacksquare \tag{16}$$

LEMMA 3.4. *Let $U_{i,j}^n$ be the numerical approximation solution of $s(x, y; t)$ of* (1), (2), and (3) *at $t = n\Delta t$, $x = i\Delta x$, and $y = j\Delta y$. Without loss of generality, we assume $\Delta x = \Delta y = h$; then under Assumptions L1, C1, R1, and R2,*

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta t h|U_{i,j+1}^n - U_{i,j}^n| \le R_1 \tag{17}$$

and

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta t h|U_{i+1,j}^n - U_{i,j}^n| \le R_2 \tag{18}$$

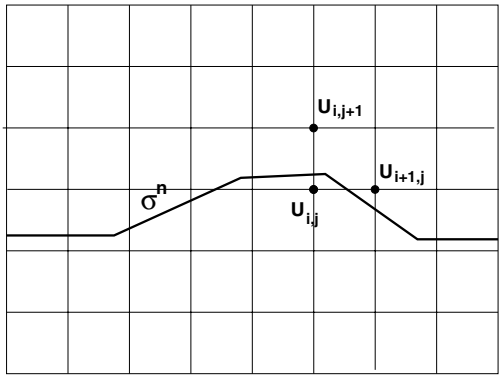

FIG. 3.2. *The discontinuity curve σ^n crosses the grid line between $(i, j+1)$ and (i, j).*

for some constants R_1 and R_2 and for all $\Delta t < \Delta t_0$.

Proof. We want to prove

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta t h |U_{i,j+1}^n - U_{i,j}^n| \le R_1$$

for some constant R_1. First, we see

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta t h |U_{i,j+1}^n - U_{i,j}^n| = \sum_{n=0}^{T/\Delta t} \Delta t \left(\sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} h |U_{i,j+1}^n - U_{i,j}^n| \right). \tag{19}$$

Since $U_{i,j}^n$ only has two values, say 1 or 0, then

$$|U_{i,j+1}^n - U_{i,j}^n| = \begin{cases} 1 & \text{if } \sigma^n \text{ crosses the grid line between } (i,\, j+1) \text{ and } (i,\, j), \\ 0 & \text{otherwise,} \end{cases} \tag{20}$$

where σ^n is the discontinuity curve at time step $n\Delta t$ (see Figure 3.2). Then the computation of

$$\sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} h |U_{i,j+1}^n - U_{i,j}^n|$$

is equivalent to counting how many vertical grid lines σ^n intersects. Note that we restricted that the length of each piece of the piecewise linear approximant is bounded by $c_1 h \le |b_i^n| \le c_2 h$. Then each piece may cross $r = [c_2 h/h] + 1 = [c_2] + 1$ vertical grid lines, where $[c_2]$ means the largest integer that is no greater than c_2. A discontinuity curve σ^n may have at most $|\sigma^n|/(c_1 h)$ linear pieces. Therefore $\sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} h |U_{i,j+1}^n - U_{i,j}^n| \le hr|\sigma^n|/(c_1 h)$. Hence

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta t h |U_{i,j+1}^n - U_{i,j}^n| \le \sum_{n=0}^{T/\Delta t} \Delta t h r \frac{|\sigma^n|}{c_1 h} = \frac{r}{c_1} \sum_{n=0}^{T/\Delta t} \Delta t |\sigma^n|. \tag{21}$$

By Lemma 3.3, $|\sigma^n| \le |\sigma^0|(1+\Delta t(2V\kappa+K))^n$; then

$$\begin{aligned}\frac{r}{c_1}\sum_{n=0}^{T/\Delta t}\Delta t|\sigma^n| &\le \frac{r}{c_1}\sum_{n=0}^{T/\Delta t}\Delta t|\sigma^0|(1+\Delta t(2V\kappa+K))^n \\ &\le \frac{r|\sigma^0|}{c_1}\sum_{n=0}^{T/\Delta t}\Delta t(1+\Delta t(2V\kappa+K))^n. \qquad (22)\end{aligned}$$

From our assumption, $T=\Delta tN$ implies $\Delta t=\frac{T}{N}$. Therefore

$$\begin{aligned}&\frac{r|\sigma^0|}{c_1}\sum_{n=0}^{T/\Delta t}\Delta t(1+\Delta t(2V\kappa+K))^n \\ &= \Delta t\frac{r|\sigma^0|}{c_1}+\frac{r|\sigma^0|}{c_1}\sum_{n=1}^{T/\Delta t}\Delta t\left(1+\frac{T(2V\kappa+K)}{N}\right)^n. \qquad (23)\end{aligned}$$

Since $1\le n\le N$,

$$1+\frac{T(2V\kappa+K)}{N} \le 1+\frac{T(2V\kappa+K)}{n}. \qquad (24)$$

Furthermore, $(1+T(2V\kappa+K)/n)^n$ is increasing to $e^{T(2V\kappa+K)}$ as n goes to ∞; then

$$\left(1+\frac{T(2V\kappa+K)}{n}\right)^n \le e^{T(2V\kappa+K)} \qquad (25)$$

for all n. Then

$$\begin{aligned}&\Delta t\frac{r|\sigma^0|}{c_1}+\frac{r|\sigma^0|}{c_1}\sum_{n=1}^{T/\Delta t}\Delta t\left(1+\frac{T(2V\kappa+K)}{N}\right)^n \\ &\le \Delta t\frac{r|\sigma^0|}{c_1}+\frac{r|\sigma^0|}{c_1}\sum_{n=1}^{T/\Delta t}\Delta t\left(1+\frac{T(2V\kappa+K)}{n}\right)^n \\ &\le \Delta t\frac{r|\sigma^0|}{c_1}+\frac{r|\sigma^0|}{c_1}\sum_{n=1}^{T/\Delta t}\Delta te^{T(2V\kappa+K)} = \frac{r|\sigma^0|}{c_1}Te^{T(2V\kappa+K)}. \qquad (26)\end{aligned}$$

Define $R_1=(r|\sigma^0|/c_1)Te^{T(2V\kappa+K)}$; then we have

$$\sum_{n=0}^{T/\Delta t}\sum_{i=-\infty}^{\infty}\sum_{j=-\infty}^{\infty}\Delta th|U^n_{i,j+1}-U^n_{i,j}| \le R_1. \qquad (27)$$

Similarly, we may have

$$\sum_{n=0}^{T/\Delta t}\sum_{i=-\infty}^{\infty}\sum_{j=-\infty}^{\infty}\Delta th|U^n_{i+1,j}-U^n_{i,j}| \le R_2 \qquad (28)$$

for all $\Delta t<\Delta t_0$. □

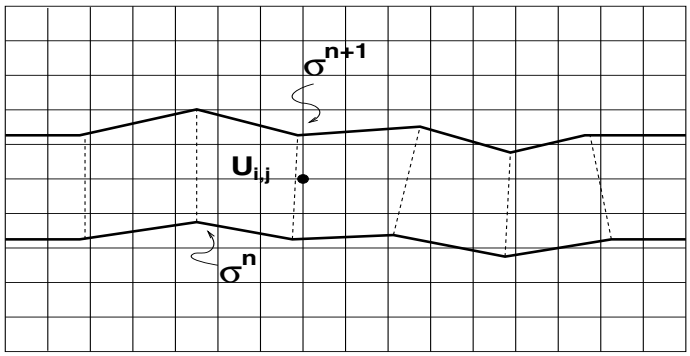

FIG. 3.3. $|U_{i,j}^{n+1} - U_{i,j}^n| \neq 0$ *only when* (i,j) *is in the region of* σ *swept from time step* $n\Delta t$ *to time step* $(n+1)\Delta t$.

LEMMA 3.5. *Let* $U_{i,j}^n$ *be the numerical approximation solution of* $s(x,y;t)$ *of* (1), (2), and (3) *at* $t = n\Delta t$, $x = i\Delta x$, *and* $y = j\Delta y$. *Then under Assumptions* $L1$, $C1$, $R1$, *and* $R2$,

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} \Delta x \Delta y |U_{i,j}^{n+1} - U_{i,j}^n| \leq R_3 \tag{29}$$

for some constant R_3 *and for all* $\Delta t < \Delta t_0$.

Proof. Without loss of generality, one may assume $\Delta x = \Delta y = h$. Because we are considering miscible two phase flow, calculating

$$\sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} h^2 |U_{i,j}^{n+1} - U_{i,j}^n|$$

is equivalent to calculating the area that the discontinuity curve sweeps from time step $n\Delta t$ to time step $(n+1)\Delta t$ (see Figure 3.3). Therefore evaluating

$$\sum_{n=0}^{T/\Delta t} \sum_{i=-\infty}^{\infty} \sum_{j=-\infty}^{\infty} h^2 |U_{i,j}^{n+1} - U_{i,j}^n|$$

is equivalent to evaluating

$$\sum_{n=0}^{T/\Delta t} A(\sigma^n),$$

where $\mathrm{A}(\sigma^n)$ is the area that the discontinuity curve σ^n sweeps from time $n\Delta t$ to time $(n+1)\Delta t$. Since a discontinuity curve consists of linear pieces, we first need to compute the area swept by a linear piece $\overline{ab}$ from time $n\Delta t$ to time $(n+1)\Delta t$. Let us denote by $\overline{cd}$ the image of $\overline{ab}$ at time $(n+1)\Delta t$. Then the swept area is the area of the quadrilateral $abcd$, denoted by $A(abcd)$. Let $q_{\overline{ab}}$ be the conserved mass movement across the linear piece $\overline{ab}$ from time $n\Delta t$ to time $(n+1)\Delta t$. Then

$$q_{\overline{ab}} = \Delta t \left| \int_0^{l_{ab}} \overrightarrow{v_\perp}(x,y) d\sigma \right|, \tag{30}$$

where $\overrightarrow{v_\perp}$ is the normal component of the velocity field at the linear piece $\overline{ab}$ with length l_{ab}, and σ is the arc length along $\overline{ab}$. Because we are considering miscible flow, $\overrightarrow{v_\perp}$ becomes $\overrightarrow{v}(x,y)\cdot\hat{n}$, where $\overrightarrow{v}(x,y)$ is the velocity of the linear piece $\overline{ab}$ and $\hat{n}$ is its normal. If the numerical velocity field $\overrightarrow{v}(x,y)$ is bounded by a velocity V, i.e., $|\overrightarrow{v}(x,y)|\le V$ for all x and y, then

$$q_{\overline{ab}} = \int_0^{l_{ab}} \Delta t(\overrightarrow{v}\cdot\hat{n})d\sigma \le \Delta t V l_{ab}. \tag{31}$$

If we define $err(\overline{ab})$ to be $|A(abdc) - q_{\overline{ab}}|$, then

$$|A(abdc)| = |A(abdc) - q_{\overline{ab}} + q_{\overline{ab}}| \le \Delta t V|\overline{ab}| + err(\overline{ab}). \tag{32}$$

Now assume σ^n has m pieces b_i^n, $i=1,\dots,m$, at time $t=n\Delta t$. The area swept by σ^n from time $n\Delta t$ to $(n+1)\Delta t$ is

$$|A(\sigma^n)| \le \sum_{i=1}^m |A(b_i^n)| \le \sum_{i=1}^m (\Delta t V|b_i^n| + err(b_i^n)) \le \Delta t V|\sigma^n| + E(\sigma^n), \tag{33}$$

where $E(\sigma^n) = \sum_{i=1}^m err(b_i^n)$. Similarly to the proof of Lemma 3.4,

$$\sum_{n=0}^{T/\Delta t} \Delta t V|\sigma^n| \le V|\sigma^0|Te^{T(2V\kappa+K)}. \tag{34}$$

By Theorem 2.1,

$$\sum_{n=0}^{T/\Delta t} E(\sigma^n) \to 0$$

as $\Delta t\to 0$. Therefore, given any constant, say 1, there is Δt_0 such that $\sum_{n=0}^{T/\Delta t} E(\sigma^n) < 1$ whenever $\Delta t \le \Delta t_0$. Let $R_3 = TV|\sigma^0|\exp(T(2V\kappa+K))+1$. Then

$$\sum_{n=0}^{T/\Delta t} |A(\sigma^n)| \le \sum_{n=0}^{T/\Delta t} (\Delta t V|\sigma^n| + E(\sigma^n)) = \sum_{n=0}^{T/\Delta t} \Delta t V|\sigma^n| + \sum_{n=0}^{T/\Delta t} E(\sigma^n) \le R_3. \qquad \square \tag{35}$$

Now we have the following theorem.

THEOREM 3.6. *Under Assumptions L1, R1, R2, and C1, the curve propagation algorithm, Algorithm PC, of the front-tracking scheme for incompressible miscible two phase flow on porous media is stable.*

Proof. By Lemmas 3.4 and 3.5, the result holds. $\square$

4. Stability of mass conserved curve propagation algorithm. By Theorem 2.2, the new point propagation algorithm, Algorithm NPC, determines unique point p' iff $\hat{N}_b \times \overrightarrow{c'a'} \ne 0$. The only problem is that if $\hat{N}_b \times \overrightarrow{c'a'} = \epsilon \ne 0$ is very small, the new point p' will be far away from the old point p. This will change the shape of the discontinuity curve and make this algorithm unstable. Therefore we need to analyze in which condition this algorithm will be stable.

In Assumption C1, we assume that the curvature of the discontinuity curve is bounded by a constant κ. A natural consequential assumption is as follows.

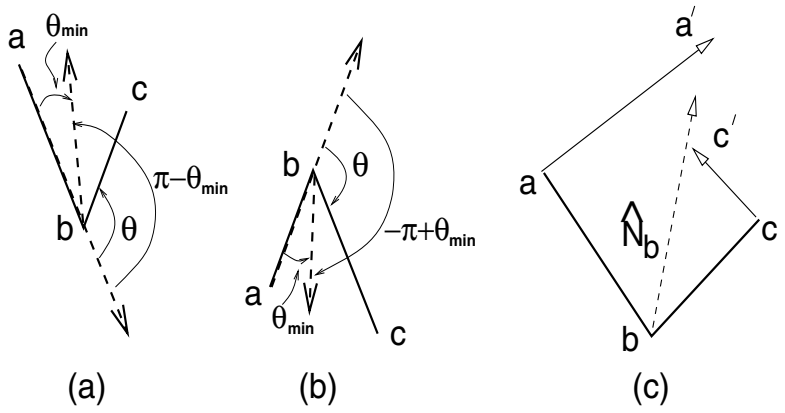

FIG. 4.1. (a) and (b) *the angle* θ *between* $\overrightarrow{ab}$ *and* $\overrightarrow{bc}$ *is bounded by* $-\pi + \theta_{min} \le \theta \le \pi - \theta_{min}$. (c) $\overrightarrow{c'a'}$ *is almost parallel to* $\hat{N}_b$.

Assumption C2. Let $\overline{ab}$ and $\overline{bc}$ be two adjoint linear segments. We assume there is a θ_{min} such that the angle θ between $\overrightarrow{ab}$ and $\overrightarrow{bc}$ is bounded by $-\pi+\theta_{min} \le \theta \le \pi-\theta_{min}$ (see Figure 4.1(a)–(b)).

Remark 5. After several propagation time steps, Assumptions R1, C1, or C2 may be violated; i.e., a linear segment may become excessively lengthened or shortened, or the angle between two adjacent linear segments may become smaller than θ_{min}. These problems can be resolved by redistributing points on the propagated grids for ensuring adequate sampling of the discontinuity grid along its arc length and eliminating any small angle. In practice, a redistribution routine [1], [13] is used to maintain these restrictions.

We want to investigate when $\hat{N}_b \times \overrightarrow{c'a'} = \epsilon$ small will happen. The case happened when the propagation time step Δt is large enough so that $\overrightarrow{c'a'}$ is almost parallel to the normal vector $\hat{N}_b$ (see Figure 4.1(c)). Therefore we need to give a restriction for Δt such that $\hat{N}_b \times \overrightarrow{c'a'}$ is larger than some constant. Lemmas 4.1 and 4.2 give the condition

$$\Delta t V \left(\frac{1}{2} + \frac{4c_2}{c_1 \theta_{min}} \right) \le \frac{1}{4} c_1 h \theta_{min}, \tag{36}$$

where c_1 and c_2 are the same as those in Assumption R1, so that the length between point b and propagation image p is less than $|\overrightarrow{ac}|/4$.

LEMMA 4.1. *Let* $\overline{ab}$ *and* $\overline{bc}$ *be two adjoint linear segments. Let* a' *be the point propagated from* a *by algorithm NPC and* c' *be the point propagated from* c *along normal to the linear segment* $\overline{bc}$ *by algorithm PB. If* $|\overline{aa'}| \le |\overline{ac}|/4$ *and* $|\overline{cc'}| \le |\overline{ac}|/4$, *then* $|\hat{N}_b \times \overrightarrow{a'c'}| \ge |\overline{ac}|/2$.

Proof. Let s_1 be the length of $|\overline{aa'}|$, s_2 the length of $|\overline{cc'}|$, θ_1 the angle between $\overrightarrow{ac}$ and $\overrightarrow{aa'}$, and θ_2 the angle between $\overrightarrow{ac}$ and $\overrightarrow{cc'}$. Since s_1, s_2 are less than or equal to $|\overline{ac}|/4$ and θ_1, θ_2 are arbitrary, this problem is equivalent to calculating that the minimum of $|\hat{N}_b \times \overrightarrow{a'c'}|$ restricted by a' is in the disk with center a and radius $|\overline{ac}|/4$ and c' is in the disk with center c and radius $|\overline{ac}|/4$.

Without loss of generality, we may assume that $a = (0, 0)$, $c = (\ell, 0)$, $\hat{N}_b = (0, 1)$, $\overrightarrow{aa'} = (s_1 \cos\theta_1, s_1 \sin\theta_1)$, and $\overrightarrow{cc'} = (s_2 \cos\theta_2 + \ell, s_2 \sin\theta_2)$. Then

$$|\hat{N}_b \times \overrightarrow{a'c'}| = |(s_2 \cos\theta_2 - s_1 \cos\theta_1 + \ell)|. \tag{37}$$

By the method of Lagrange multiplier, it is easy to find the minimum of $|\hat{N}_b \times \overrightarrow{a'c'}|$ is $\ell/2 = |\overrightarrow{ac}|/2$ when $\theta_2 = \pi$, $\theta_1 = 0$, and s_1 and s_2 are $|\overline{ac}|/4$. ∎

LEMMA 4.2. *Let $\overline{ab}$ and $\overline{bc}$ be two adjoint linear segments and p be the image of b by Algorithm NPC. If we choose Δt such that*

$$\Delta t V \left(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}\right) \le \frac{1}{4} c_1 h \theta_{min}, \tag{38}$$

then under Assumptions L1, R1, R2, C1, and C2, $|\overline{bp}| \le |\overline{ac}|/4$, where V is the maximum of the velocity field and c_1, c_2 are the same as those in Assumption R1.

Proof. Let a' be the previously propagated image of a by algorithm NPC and c' be the image of c (if c is considered as point from $\overline{bc}$; see Figure 2.1) by Algorithm BP. Let q_1' and q_2 be the mass changes produced by the movements $\overline{ab} \rightarrow a'b'$ and $\overline{bc} \rightarrow b''c'$. Then, by Remark 1,

$$q_1' = \frac{1}{2}[\overrightarrow{ab} \times (\overrightarrow{aa'} + \overrightarrow{bb'}) + \overrightarrow{bb'} \times \overrightarrow{aa'}], \quad q_2 = \frac{1}{2}[\overrightarrow{bc} \times (\overrightarrow{bb''} + \overrightarrow{cc'})]. \tag{39}$$

Similar to the proof of Theorem 2.2, λ is the unique scalar such that

$$\lambda[\hat{N}_b \times \overrightarrow{c'a'}] = 2(q_1' + q_2) + \overrightarrow{aa'} \times \overrightarrow{ab} + \overrightarrow{cc'} \times \overrightarrow{bc} = \overrightarrow{ab} \times \overrightarrow{bb'} + \overrightarrow{bb'} \times \overrightarrow{aa'} + \overrightarrow{bc} \times \overrightarrow{bb''}. \tag{40}$$

By Lemma 4.1, $|\hat{N}_b \times \overrightarrow{c'a'}| \ge |\overrightarrow{ac}|/2$; then

$$|\lambda| = \frac{|\overrightarrow{ab} \times \overrightarrow{bb'} + \overrightarrow{bb'} \times \overrightarrow{aa'} + \overrightarrow{bc} \times \overrightarrow{bb''}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \le \frac{2}{|\overrightarrow{ac}|}(|\overrightarrow{ab}||\overrightarrow{bb'}| + |\overrightarrow{bb'}||\overrightarrow{aa'}| + |\overrightarrow{bc}||\overrightarrow{bb''}|). \tag{41}$$

Since $|\overrightarrow{bb'}| \le \Delta t V$, $|\overrightarrow{bb''}| \le \Delta t V$, and by induction we may assume $|\overrightarrow{aa'}| \le |\overrightarrow{ac}|/4$, then

$$|\lambda| \le \frac{2}{|\overrightarrow{ac}|}\Delta t V(|\overrightarrow{ab}| + |\overrightarrow{aa'}| + |\overrightarrow{bc}|) \le \frac{1}{2}\Delta t V + \frac{2}{|\overrightarrow{ac}|}\Delta t V(|\overrightarrow{ab}| + |\overrightarrow{bc}|). \tag{42}$$

Since by Assumption R1, both $|\overrightarrow{ab}|$ and $|\overrightarrow{bc}|$ are greater than or equal to $c_1 h$, and by Assumption C2, the angle between $\overrightarrow{ba}$ and $\overrightarrow{bc}$ is greater than θ_{min} (see Figure 4.1(a)–(b)), we have $|\overrightarrow{ac}| \ge c_1 h \theta_{min}$. By our assumptions, $|\overrightarrow{ab}| \le c_2 h$, $|\overrightarrow{bc}| \le c_2 h$, and

$$|\lambda| \le \Delta t V \left(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}\right). \tag{43}$$

If we choose Δt such that

$$\Delta t V \left(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}\right) \le \frac{1}{4} c_1 h \theta_{min}, \tag{44}$$

we have

$$|\overrightarrow{bp}| = |\lambda \hat{N}_b| \le \Delta t V \left(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}\right) \le \frac{1}{4} c_1 h \theta_{min} \le \frac{1}{4}|\overrightarrow{ac}|. \tag{45}$$

∎

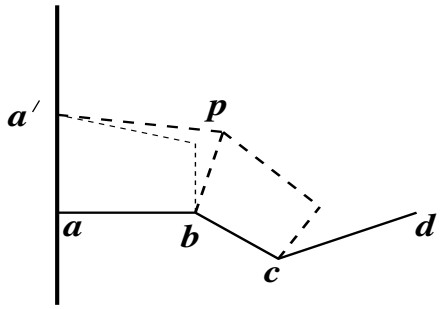

FIG. 4.2. *The propagation of the first interior point of a curve.*

Remark 6. In propagating the first interior point of a curve, we first propagate start node a to a' by a nonmass conserving propagating algorithm (see Figure 4.2). Because $|\overrightarrow{aa'}| \le \Delta tV$ and $(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}) > 1$, $|\overrightarrow{aa'}| \le \Delta tV(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}) \le \frac{1}{4}c_1h\theta_{min}$, and this implies $|\overrightarrow{bp}| \le \frac{1}{4}c_1h\theta_{min}$ (the proof of Lemma 4.2). Next, in propagating point c, we need $|\overrightarrow{bp}| \le \frac{1}{4}|\overrightarrow{bd}|$. But because $|\overrightarrow{bp}| \le \frac{1}{4}c_1h\theta_{min}$ and the angle between $\overrightarrow{cb}$ and $\overrightarrow{cd}$ is greater than θ_{min} as well as both $|\overrightarrow{bc}|$ and $|\overrightarrow{cd}|$ are greater than or equal to c_1h, we have $|\overrightarrow{bp}| \le \frac{1}{4}|\overrightarrow{bd}|$. Thus by induction it can be assumed $|\overrightarrow{aa'}| \le \frac{1}{4}c_1h\theta_{min} \le \frac{1}{4}|\overrightarrow{ac}|$ for each interior point propagation.

Next, we want to use a method similar to that in section 3 to analyze the stability of Algorithm NPC. Therefore we have to show that the length of the discontinuity curve σ^n is bounded by $|\sigma^0|(1 + \Delta t\widetilde{C})^n$ for Δt small and some constant $\widetilde{C}$ while using Algorithm NPC. Before doing this, we need to show that the difference between two propagation images by Algorithms PC and NPC is less than ΔthK for some constant K. This is done by Lemma 4.3.

LEMMA 4.3. *Let $\overline{ab}$ and $\overline{bc}$ be two adjoint linear pieces, p' be the image of b by algorithm PC, and p be the image of b by Algorithm NPC. Then under assumptions L1, R1, R2, C1, C2, and*

$$\Delta tV\left(\frac{1}{2} + \frac{4c_2}{c_1\theta_{min}}\right) \le \frac{1}{4}c_1h\theta_{min}, \tag{46}$$

$|\overline{bp} - \overline{bp'}| \le \Delta thK$ *for some constant* K.

Proof. Because propagating point b by Algorithm NPC is related to previous propagated point a', two cases for a' need to be considered. The first case is to consider a as a start node; line segment $\overline{ab}$ is always perpendicular to the boundary (see Figure 4.3(a)). This implies a can be propagated to a' by Algorithm BP and $\overrightarrow{aa'}$ is always perpendicular to $\overline{ab}$. The second case considers a as an interior point. In this case, a' is the image of a by Algorithm NPC, and $\overrightarrow{aa'}$ may not be perpendicular to $\overline{ab}$ (see Figure 4.3(b)).

Let a' be the previously propagated image of a by Algorithm NPC or Algorithm BP, let c' be the image of c by Algorithm BP, where c is considered as a point from $\overline{bc}$, and let b' and b'' be the images of b by Algorithm BP if b is considered as a point from $\overline{ab}$ and $\overline{bc}$, respectively. From (7), there exists a scalar λ such that $\overrightarrow{bp} = \lambda\hat{N}_b$

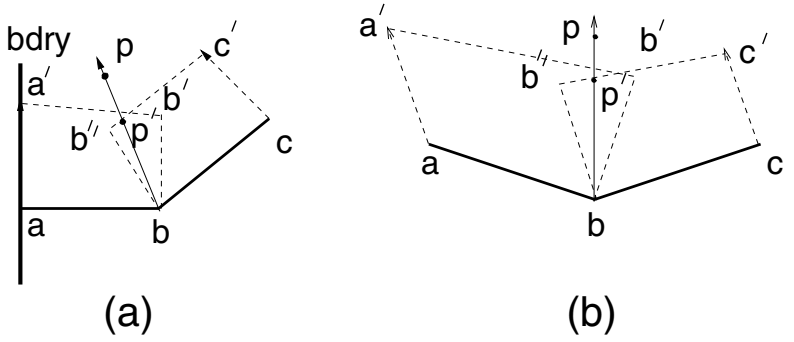

FIG. 4.3. (a) *a propagated to a' by Algorithm PC.* (b) *a propagated to a' by Algorithm NPC.*

and

$$\lambda[\hat{N}_b \times (\overrightarrow{aa'} - \overrightarrow{ab} - \overrightarrow{cc'} - \overrightarrow{bc})] = 2(q_1' + q_2) + \overrightarrow{aa'} \times \overrightarrow{ab} + \overrightarrow{cc'} \times \overrightarrow{bc}, \tag{47}$$

where q_1' and q_2 are as in Remark 1. Let $\gamma = (\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)$ and $\overrightarrow{p'p} = \beta \hat{N}_b$, where β is a scalar. Since $\overrightarrow{bp} = \overrightarrow{bp'} + \overrightarrow{p'p}$ as well as $\overrightarrow{bp'} = \gamma \hat{N}_b$, $\overrightarrow{bp} = \gamma \hat{N}_b + \beta \hat{N}_b = (\gamma + \beta)\hat{N}_b$. Then (47) implies

$$(\gamma + \beta)[\hat{N}_b \times (\overrightarrow{aa'} - \overrightarrow{ab} - \overrightarrow{cc'} - \overrightarrow{bc})] = -\overrightarrow{bb'} \times \overrightarrow{ab} - \overrightarrow{bb''} \times \overrightarrow{bc}. \tag{48}$$

Case I. In this case, a' is the image of a by Algorithm BP; then $\overrightarrow{aa'} = (\Delta t \overrightarrow{v_a} \cdot \hat{N}_a)\hat{N}_a$. From (48),

$$\beta = \frac{1}{\hat{N}_b \times \overrightarrow{c'a'}}[\gamma \hat{N}_b \times \overrightarrow{cc'} - \gamma \hat{N}_b \times \overrightarrow{aa'} + (\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab} + (\gamma \hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}]. \tag{49}$$

Hence

$$|\beta| \le \frac{|\gamma \hat{N}_b \times \overrightarrow{cc'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|\gamma \hat{N}_b \times \overrightarrow{aa'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|(\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|(\gamma \hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|}{|\hat{N}_b \times \overrightarrow{c'a'}|}. \tag{50}$$

We want to estimate the values $|\gamma \hat{N}_b \times \overrightarrow{cc'}|$, $|\gamma \hat{N}_b \times \overrightarrow{cc'}|$, $|(\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}|$, and $|(\gamma \hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|$ separately. Now

$$|\gamma \hat{N}_b \times \overrightarrow{cc'}| = |\gamma||\overrightarrow{cc'}||\hat{N}_b \times \hat{n}_{bc}| = (\Delta t \overrightarrow{v_a} \cdot \hat{N}_a)(\Delta t \overrightarrow{v_a} \cdot \hat{N}_a) \sin\theta, \tag{51}$$

where θ is the angle between $\hat{N}_a$ and $\hat{n}_{bc}$. By Assumption R1, κ is the maximum curvature of all σ^n; therefore

$$\sin\theta \approx \theta \le \kappa |\overrightarrow{ac}|. \tag{52}$$

Then

$$|\gamma \hat{N}_b \times \overrightarrow{cc'}| \le (\Delta t \overrightarrow{v}_a)(\Delta t \overrightarrow{v}_c) \sin\theta \le (\Delta t V)^2 \kappa |\overrightarrow{ac}|, \tag{53}$$

where V is the maximum velocity on velocity field. By Assumption R2, $\Delta t \leq \alpha h$, and let $\alpha V^2 \kappa = K_1$. Then

$$|\gamma \hat{N}_b \times \overrightarrow{cc'}| \leq (\Delta t V)^2 \kappa |\overrightarrow{ac}| \leq \Delta t h K_1 |\overrightarrow{ac}|. \tag{54}$$

From Lemma 4.1, we have $|\hat{N}_b \times \overrightarrow{c'a'}| \geq \frac{1}{2}|\overrightarrow{ac}|$. Therefore

$$\frac{|\gamma \hat{N}_b \times \overrightarrow{cc'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \Delta t h K_1. \tag{55}$$

Similarly,

$$\frac{|\gamma \hat{N}_b \times \overrightarrow{aa'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \Delta t h K_2 \tag{56}$$

for some constant K_2. Next,

$$|(\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}| = |\gamma \hat{N}_b - \overrightarrow{bb'}||\overrightarrow{ab}||\sin\phi|, \tag{57}$$

where ϕ is the angle between $\gamma \hat{N}_b - \overrightarrow{bb'}$ and $\overrightarrow{ab}$. Since $|\sin\phi| \leq 1$ and $|\overrightarrow{ab}| \leq c_2 h$ by Assumption R1, we also have

$$\begin{aligned} |\gamma \hat{N}_b - \overrightarrow{bb'}| &= |(\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)\hat{N}_b - (\Delta t \overrightarrow{v_b} \cdot \hat{n}_{ab})\hat{n}_{ab}| \\ &\leq |(\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)\hat{N}_b - (\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)\hat{n}_{ab}| + |(\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)\hat{n}_{ab} - (\Delta t \overrightarrow{v_b} \cdot \hat{n}_{ab})\hat{n}_{ab}| \\ &\leq ||(\Delta t \overrightarrow{v_b} \cdot \hat{N}_b)||\hat{N}_b - \hat{n}_{ab}| + |(\Delta t \overrightarrow{v_b})||\hat{N}_b - \hat{n}_{ab}| \leq 2\Delta t V |\hat{N}_b - \hat{n}_{ab}|. \end{aligned} \tag{58}$$

Since $|\hat{N}_b - \hat{n}_{ab}| \approx \theta \leq \kappa c_2 h$, then we have

$$|\gamma \hat{N}_b - \overrightarrow{bb'}| \leq 2\Delta t V |\hat{N}_b - \hat{n}_{ab}| \leq 2\Delta t V \kappa c_2 h. \tag{59}$$

Because $|\hat{N}_b \times \overrightarrow{c'a'}| \geq \frac{1}{2}|\overrightarrow{ac}|$ and $|\overrightarrow{ac}| \geq c_1 h \theta_{min}$,

$$\frac{|(\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \frac{|\gamma \hat{N}_b - \overrightarrow{bb'}||\overrightarrow{ab}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \frac{4\Delta t V \kappa c_2 h c_2 h}{c_1 h \theta_{min}} \leq \frac{4\Delta t V \kappa c_2 h c_2}{c_1 \theta_{min}}. \tag{60}$$

Let

$$K_3 = \frac{4V\kappa c_2 c_2}{c_1 \theta_{min}};$$

then

$$\frac{|(\gamma \hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \Delta t h K_3. \tag{61}$$

With a similar method, we have

$$\frac{|(\gamma \hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} \leq \Delta t h K_4. \tag{62}$$

Therefore

(63)
$$|\overline{bp}-\overline{bp'}| = |\beta| \le \frac{|\gamma\hat{N}_b \times \overrightarrow{cc'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|\gamma\hat{N}_b \times \overrightarrow{aa'}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|(\gamma\hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab}|}{|\hat{N}_b \times \overrightarrow{c'a'}|} + \frac{|(\gamma\hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|}{|\hat{N}_b \times \overrightarrow{c'a'}|}$$
$$\le \Delta thK_1 + \Delta thK_2 + \Delta thK_3 + \Delta thK_4 = \Delta thK.$$

Case II. Consider a' to be the image of a by Algorithm NPC. Then $\overrightarrow{aa'} = (\gamma' + \beta')\hat{N}_a$, where $\gamma' = \Delta t\overrightarrow{v_a}\cdot\hat{N}_a$ and $|\beta'| \le \Delta thK$ for some constant K. Let $\xi = \Delta t\overrightarrow{v_c}\cdot\hat{N}_c$. Similarly, we have

$$\lambda[\hat{N}_b \times (\overrightarrow{aa'} - \overrightarrow{ab} - \overrightarrow{cc'} - \overrightarrow{bc})] = 2(q_1' + q_2) + \overrightarrow{aa'} \times \overrightarrow{ab} + \overrightarrow{cc'} \times \overrightarrow{bc}, \tag{64}$$

which leads to

$$\beta(\hat{N}_b \times \overrightarrow{c'a'}) = -\gamma(\gamma' + \beta')(\hat{N}_b \times \hat{N}_a) + \gamma\xi(\hat{N}_b \times \hat{n_{bc}}) + (\gamma\hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab} + (\gamma\hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}. \tag{65}$$

Therefore

(66)
$$|\beta| \le \frac{1}{|(\hat{N}_b \times \overrightarrow{c'a'})|}|\gamma\gamma'(\hat{N}_b \times \hat{N}_a) + \gamma\xi(\hat{N}_b \times \hat{n_{bc}}) + (\gamma\hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab} + (\gamma\hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|$$
$$+ \frac{1}{|(\hat{N}_b \times \overrightarrow{c'a'})|}|\gamma\beta'(\hat{N}_b \times \hat{N}_a)|.$$

By Case I of this proof, we have

(67)
$$\frac{1}{|(\hat{N}_b \times \overrightarrow{c'a'})|}|\gamma\gamma'(\hat{N}_b \times \hat{N}_a) + \gamma\xi(\hat{N}_b \times \hat{n_{bc}}) + (\gamma\hat{N}_b - \overrightarrow{bb'}) \times \overrightarrow{ab} + (\gamma\hat{N}_b - \overrightarrow{bb''}) \times \overrightarrow{bc}|$$
$$\le \Delta thK$$

for some constant K. Since $\hat{N}_b \times \hat{N}_a = \sin\theta$, where θ is the angle between $\hat{N}_b$ and $\hat{N}_a$, then

$$\sin\theta \approx \theta \le \kappa c_2 h. \tag{68}$$

Hence

$$\frac{1}{|(\hat{N}_b \times \overrightarrow{c'a'})|}|\gamma\beta'(\hat{N}_b \times \hat{N}_a)| \le \Delta t^2 hK. \tag{69}$$

Choose $\Delta t \le 1$; then

$$\frac{1}{|(\hat{N}_b \times \overrightarrow{c'a'})|}|\gamma\beta'(\hat{N}_b \times \hat{N}_a)| \le \Delta t^2 hK \le \Delta thK. \tag{70}$$

Therefore

$$|\beta| \le \Delta thK. \qquad \square \tag{71}$$

LEMMA 4.4. *Let σ^n be the discontinuity curve at the nth time step by Algorithm NPC. Then under Assumptions L1, R1, R2, C1, C2, and condition*

$$\Delta t V\left(\frac{1}{2}+\frac{4c_2}{c_1\theta_{min}}\right)\le\frac{1}{4}c_1h\theta_{min},$$

$|\sigma^n|\le|\sigma^0|(1+\Delta t\widetilde{C})^n$ *for some constant* $\widetilde{C}$.

Proof. From Lemma 4.2, we choose Δt small such that

$$\Delta t V\left(\frac{1}{2}+\frac{4c_2}{c_1\theta_{min}}\right)\le\frac{1}{4}c_1h\theta_{min}$$

for every propagation time step, where c_1, c_2 are the same as in Assumption R1 and θ_{min} is the same as in Assumption C2.

Let $\overrightarrow{ab}=b_i^n$, $\hat{N}_a$ be the normal to the curve at a and $\widehat{N}_b$ be the normal to the curve at b. Then

$$b_i^{n+1}=-(\gamma_a'+\beta_a')\hat{N}_a+b_i^n+(\gamma_b'+\beta_b')\hat{N}_b, \tag{72}$$

where $\gamma_a'=(\Delta t\overrightarrow{v_a}\hat{N}_a)$, $\gamma_b'=(\Delta t\overrightarrow{v_b}\hat{N}_b)$, $|\beta_a'|\le\Delta thK$, and $|\beta_b'|\le\Delta thK$. By triangle inequality,

$$|b_i^{n+1}|\le|-\gamma_a'\hat{N}_a+\overrightarrow{b_i^n}+\gamma_b'\hat{N}_b|+|\beta_a'\hat{N}_a+\beta_b'\hat{N}_b|, \tag{73}$$

and by Lemma 3.2,

$$|-\gamma_a'\hat{N}_a+b_i^n+\gamma_b'\hat{N}_b|\le|b_i^n|(1+\Delta t(2V\kappa+C)), \tag{74}$$

where V is the maximum of the velocity field, κ is the maximum curvature of all discontinuity curves, and C is a constant. Hence

$$|b_i^{n+1}|\le|b_i^n|(1+\Delta t(2V\kappa+C))+2\Delta thK. \tag{75}$$

Now

$$\begin{aligned}|\sigma^{n+1}|=\sum_{i=1}^{m}|b_i^{n+1}|&\le\sum_{i=1}^{m}|b_i^n|(1+\Delta t(2V\kappa+C))+\sum_{i=1}^{m}2\Delta thK\\&\le|\sigma^n|(1+\Delta t(2V\kappa+C))+m2\Delta thK,\end{aligned} \tag{76}$$

where m is the number of pieces in σ^n. Since the length of every linear piece is no less than c_1h, then $m\le|\sigma^n|/c_1h$. Therefore

$$\begin{aligned}|\sigma^{n+1}|&\le|\sigma^n|(1+\Delta t(2V\kappa+C))+\frac{|\sigma^n|}{c_1h}2\Delta thK\le|\sigma^n|(1+\Delta t(2V\kappa+C))+|\sigma^n|\frac{2}{c_1}\Delta tK\\&=|\sigma^n|\left(1+\Delta t\left(2V\kappa+C+\frac{2}{c_1}K\right)\right).\end{aligned} \tag{77}$$

Let $\widetilde{C}=2V\kappa+C+\frac{2}{c_1}K$; then

$$|\sigma^{n+1}|\le|\sigma^n|(1+\Delta t\widetilde{C}). \tag{78}$$

By induction,

$$|\sigma^{n+1}| \le |\sigma^0|(1+\Delta t\widetilde{C})^n. \qquad \square \tag{79}$$

THEOREM 4.5. *Under Assumptions L1, R1, R2, C1, C2, and condition*

$$\Delta t V\left(\frac{1}{2}+\frac{4c_2}{c_1\theta_{min}}\right) \le \frac{1}{4}c_1 h\theta_{min},$$

the curve propagation algorithm, Algorithm NPC, of the front-tracking scheme for incompressible miscible two phase flow on porous media is stable.

Proof. The proof is similar to those of Lemmas 3.4 and 3.5 and Theorem 3.6. We omit it here. $\square$

Remark 7. A condition is required in Theorem 4.5 that $\Delta t V(\frac{1}{2}+\frac{4c_2}{c_1\theta_{min}}) \le \frac{1}{4}c_1 h\theta_{min}$. Because V, c_1, c_2, h, and θ_{min} are constants, $\Delta t V(\frac{1}{2}+\frac{4c_2}{c_1\theta_{min}}) \le \frac{1}{4}c_1 h\theta_{min}$ will be satisfied if the time step Δt is chosen to be small enough.

Acknowledgment. I wish to thank the anonymous referee for his/her due diligence in editing this paper. This resulted in a new understanding and clarified my thinking about this topic.

FUNCTION, GRADIENT, AND HESSIAN RECOVERY USING QUADRATIC EDGE-BUMP FUNCTIONS*

JEFFREY S. OVALL†

Abstract. An approximate error function for the discretization error on a given mesh is obtained by projecting (via the energy inner product) the functional residual onto the space of continuous, piecewise quadratic functions which vanish on the vertices of the mesh. Conditions are given under which one can expect this hierarchical basis error estimator to give efficient and reliable function recovery, asymptotically exact gradient recovery, and convergent Hessian recovery in the square norms. One does not find similar function recovery results in the literature. The analysis given here is based on a certain superconvergence result which has been used elsewhere in the analysis of gradient recovery methods. Numerical experiments are provided which demonstrate the effectivity of the approximate error function in practice.

Key words. finite elements, a posteriori estimates, hierarchical bases, superconvergence, gradient recovery

1. Introduction.

Hierarchical basis a posteriori error estimators were introduced in the early 1980s [22], and a general framework for the analysis of their effectivity and computational cost has been given by Bank [5] and Bank and Smith [1]. The basic idea behind such methods is that the base space of functions V_h, in which we wish to find our finite element approximation u_h, is augmented by a complementary space $\tilde{V}_h$ such that the composite space $V_h \oplus \tilde{V}_h$ provides an improved finite element approximation $\bar{u}_h$. In symbols, we show this as $|||u - \bar{u}_h||| \leq \beta |||u - u_h|||$ for some $\beta \in [0, 1)$, where $|||\cdot|||$ is the energy norm associated with the underlying bilinear form. This improved approximation assumption is referred to as a saturation assumption. An approximate error function $\varepsilon_h \approx u - u_h$ is computed in the space $\tilde{V}_h$. Using the saturation assumption and strengthened Cauchy inequalities between the spaces V_h and $\tilde{V}_h$, effectivity estimates of the form

$$c_1 \leq \frac{|||\varepsilon_h|||}{|||u - u_h|||} \leq c_2 \tag{1}$$

are proved.

In this paper a different sort of analysis, which yields stronger assertions, is given for the case where V_h is the space of continuous, piecewise linear functions on a given mesh and $\bar{V}_h$ is the space of continuous, piecewise quadratic functions on that same mesh. The augmenting space $\tilde{V}_h$ consists of quadratic "bump" functions which vanish on the vertices of the mesh. In particular, we show that the approximate error function, $\varepsilon_h \approx u - u_h$, provides efficient and reliable function recovery, asymptotically exact gradient recovery, and convergent Hessian recovery:

$$c_1 \leq \frac{\|\varepsilon_h\|_{0,\Omega}}{\|u - u_h\|_{0,\Omega}} \leq c_2, \qquad \frac{\|\varepsilon_h\|_{1,\Omega}}{\|u - u_h\|_{1,\Omega}} \to 1, \qquad \sum_{\tau \in \mathcal{T}_h} |\varepsilon_h|^2_{2,\tau} \to |u|^2_{2,\Omega}. \tag{2}$$

Our analysis is based on a superconvergence result of Bank and Xu [3, 4], which also appears in a slightly more general form in [20]. This result was used in these papers to explain the success of a number of popular gradient recovery methods, but we use it here in the context of hierarchical basis error estimation to establish our key approximation results (2).

The rest of this paper is organized as follows. In section 2 we lay out the basic notation and assumptions for this paper. Section 3 contains a statement of the superconvergence result of Bank and Xu, which we then use to prove the above mentioned gradient and Hessian recovery results. In section 4 we prove the function recovery result and show why we cannot generally hope for asymptotic exactness in this case. Section 5 comprises almost half of the paper and consists of four examples, which are used to verify the effectivity of our estimator in practice, and a brief subsection on computational cost.

2. Notation and basic assumptions. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with Lipschitz boundary $\partial\Omega = \partial\Omega_D \cup \partial\Omega_N$, and define

$$\mathcal{H} \equiv \left\{ v \in H^1(\Omega) : v|_{\partial\Omega_D} = 0 \text{ in the trace sense} \right\}. \tag{3}$$

The usual spaces $W_p^k(\Omega)$ and $H^k(\Omega) \equiv W_2^k(\Omega)$ are equipped with their standard norms $\|\cdot\|_{k,p,\Omega}$ and $\|\cdot\|_{k,\Omega} \equiv \|\cdot\|_{k,2,\Omega}$, and seminorms $|\cdot|_{k,p,\Omega}$ and $|\cdot|_{k,\Omega}$, respectively. For simplicity in exposition, we will assume that $\partial\Omega$ is a polygon. Let data functions $a : \bar{\Omega} \to \mathbb{R}^{2\times 2}$, $\mathbf{b} : \bar{\Omega} \to \mathbb{R}^2$, $c, f : \bar{\Omega} \to \mathbb{R}$, and $g : \partial\Omega_N \to \mathbb{R}$ be given. The problem is to find $u \in \mathcal{H}$ such that

$$B(u, v) = F(v) \text{ for all } v \in \mathcal{H}, \tag{4}$$

$$B(u, v) \equiv \int_\Omega a\nabla u \cdot \nabla v + (\mathbf{b} \cdot \nabla u + cu)v \, dx, \tag{5}$$

$$F(v) \equiv \int_\Omega fv \, dx + \int_{\partial\Omega_N} gv \, ds. \tag{6}$$

We will assume that the data functions are sufficiently smooth, and that the matrix a is positive definite, with the smallest eigenvalue bounded below on Ω by some constant $\gamma > 0$. We make the following standard assumptions concerning the bilinear form B and linear functional F: There exist constants $\alpha, \nu, \mu > 0$, such that, for all $v, w \in \mathcal{H}$,

$$\begin{aligned} |F(v)| &\le \alpha \|v\|_{1,\Omega}, \\ |B(v, w)| &\le \nu \|v\|_{1,\Omega} \|w\|_{1,\Omega}, \\ B(v, v) &\ge \mu \|v\|_{1,\Omega}^2. \end{aligned}$$

Let $\mathcal{T}_h$ denote a shape-regular triangulation of Ω with mesh size $h \in (0, 1)$. Let $V_h \subset \mathcal{H}$ denote the space of continuous, piecewise-linear polynomials defined on $\mathcal{T}_h$, and let $\bar{V}_h \subset \mathcal{H}$ denote the continuous, piecewise-quadratic polynomials. We will think of $\bar{V}_h$ hierarchically as

$$\bar{V}_h = V_h \oplus \tilde{V}_h, \tag{7}$$

where $\tilde{V}_h$ is the space of quadratic "bump" functions, i.e., continuous piecewise-quadratic polynomials which vanish at all of the vertices of the triangulation. In what follows, $u_h \in V_h$ and $\bar{u}_h \in \bar{V}_h$ denote, respectively, the piecewise-linear and

piecewise-quadratic approximate solutions of (4):

$$B(u_h, v) = F(v) \text{ for all } v \in V_h, \tag{8}$$

$$B(\bar{u}_h, v) = F(v) \text{ for all } v \in \bar{V}_h. \tag{9}$$

Let $u_\ell \in V_h$ and $u_q \in \bar{V}_h$ denote piecewise-linear and piecewise-quadratic interpolants of u on $\mathcal{T}_h$. We make the following standard assumptions about their asymptotic approximation quality:

$$\|u - u_\ell\|_{k,\Omega} \lesssim h^{2-k}\|u\|_{2,\Omega}, \tag{10}$$

$$\|u - u_q\|_{k,\Omega} \lesssim h^{3-k}\|u\|_{3,\Omega}, \tag{11}$$

for $0 \le k \le 1$.

3. Gradient and Hessian recovery. In this section we prove asymptotically exact gradient recovery and convergent Hessian recovery results,

$$\frac{\|\varepsilon_h\|_{1,\Omega}}{\|u - u_h\|_{1,\Omega}} \to 1, \qquad \sum_{\tau \in \mathcal{T}_h} |\varepsilon_h|^2_{2,\tau} \to |u|^2_{2,\Omega} \tag{12}$$

for the approximate error function $\varepsilon_h \approx u - u_h$ described below. We first describe the key assumption on the mesh that will play a role in these results. This mesh condition and a slight generalization of it can be found in [3, 20].

Let e denote an interior edge in $\mathcal{T}_h$ with adjacent triangles τ and τ'. We say that the quadrilateral formed by τ and τ' satisfies the *approximate $O(h^2)$-parallelogram property* provided that the lengths of opposite edges differ by only $O(h^2)$. The equivalent property at the boundary is as follows: Let e and e' denote adjacent boundary edges sharing the vertex x, and let τ and τ' be the triangles having the edges e and e', respectively. Let $\mathbf{t}$ and $\mathbf{t}'$ be the unit tangent vectors, corresponding to a counterclockwise orientation on τ and τ'. Starting with e for τ and e' for τ' we identify corresponding edges of τ and τ' by traversing their edges counterclockwise. We say that the triangles τ and τ' associated with the boundary vertex x satisfy the approximate $O(h^2)$-parallelogram property, provided that the lengths of corresponding edges in τ and τ' differ by only $O(h^2)$, and $|\mathbf{t} - \mathbf{t}'| = O(h)$. The key assumption on the triangulation follows.

ASSUMPTION 3.1 (an $O(h^{2\sigma})$-irregular triangulation).

1. *Let $\mathcal{E} = \mathcal{E}_1 \oplus \mathcal{E}_2$ denote the set of interior edges in $\mathcal{T}_h$. For each $e \in \mathcal{E}_1$, τ and τ' satisfy the approximate $\mathcal{O}(h^2)$-parallelogram property, while*

$$\sum_{e \in \mathcal{E}_2} |\tau| + |\tau'| = \mathcal{O}(h^{2\sigma}).$$

2. *Let $\mathcal{P} = \mathcal{P}_1 \oplus \mathcal{P}_2$ denote the set of boundary vertices. The elements associated with $x \in \mathcal{P}_1$ satisfy the approximate $\mathcal{O}(h^2)$-parallelogram property, and $|\mathcal{P}_2| = \kappa$, where κ is fixed independent of h.*

The second condition is necessary only in the case of Neumann boundary conditions, $\partial\Omega_N \neq \emptyset$. The following result, due to Bank and Xu [3], is the key lemma for the results in this paper.

LEMMA 3.2. *Under Assumption* 3.1*, we have*

$$\|u_h - u_\ell\|_{1,\Omega} \lesssim h^{1+\min(\sigma,1)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{13}$$

We now present a new result based on Lemma 3.2 for computing a superconvergent approximation of the gradient. Suppose that we first solve for the linear finite element approximation, $u_h \in V_h$, and then augment this approximation by solving the residual equation on $\tilde{V}_h$, the space of quadratic bumps. In other words,

$$B(u_h, v) = F(v) \text{ for all } v \in V_h, \tag{14}$$

$$B(\varepsilon_h, v) = F(v) - B(u_h, v) \text{ for all } v \in \tilde{V}_h. \tag{15}$$

One can think of this as a projection of the residual error onto the space $\tilde{V}_h$. We have the following result.

THEOREM 3.3. *Under Assumption* 3.1*, we have*

$$\|u - (u_h + \varepsilon_h)\|_{1,\Omega} \lesssim h^{1+\min(\sigma,1)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}. \tag{16}$$

Proof. Using Galerkin orthogonality to replace $\varepsilon_h \in \tilde{V}_h$ with $u_b \in \tilde{V}_h$, the "bump" portion of the quadratic interpolant $u_q = u_\ell + u_b$, we get the following estimate:

$$\|u - (u_h + \varepsilon_h)\|_{1,\Omega}^2 \lesssim B(u - (u_h + \varepsilon_h), u - (u_h + \varepsilon_h)) \tag{17}$$

$$= B(u - (u_h + \varepsilon_h), u - (u_h + u_b)) \tag{18}$$

$$\lesssim \|u - (u_h + \varepsilon_h)\|_{1,\Omega} \|u - (u_h + u_b)\|_{1,\Omega}. \tag{19}$$

We bound the term $\|u - (u_h + u_b)\|_{1,\Omega}$ as follows:

$$\|u - (u_h + u_b)\|_{1,\Omega} \le \|u - u_q\|_{1,\Omega} + \|u_q - (u_h + u_b)\|_{1,\Omega} \tag{20}$$

$$= \|u - u_q\|_{1,\Omega} + \|u_\ell - u_h\|_{1,\Omega} \tag{21}$$

$$\lesssim h^2 \|u\|_{3,\Omega} + h^{1+\min(\sigma,1)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}. \tag{22}$$

This completes the proof. ∎

As an immediate corollary, we see conditions under which we can expect $\|\varepsilon_h\|_{1,\Omega}$ to be an asymptotically exact estimator of the true gradient error $\|u - u_h\|_{1,\Omega}$.

COROLLARY 3.4. *Suppose that there is some constant $c > 0$ such that $\|u - u_h\|_{1,\Omega} \ge ch$. Then under Assumption* 3.1*, we have*

$$\frac{\|\varepsilon_h\|_{1,\Omega}}{\|u - u_h\|_{1,\Omega}} \to 1. \tag{23}$$

Proof. It holds that

$$\left| \frac{\|\varepsilon_h\|_{1,\Omega}}{\|u - u_h\|_{1,\Omega}} - 1 \right| \le \frac{\|u - (u_h + \varepsilon_h)\|_{1,\Omega}}{\|u - u_h\|_{1,\Omega}}. \tag{24}$$

Combining this with the estimate from Theorem 3.3 completes the proof. ∎

Theorem 3.3 and Corollary 3.4 and their proofs have also appeared in [17, 18].

Recall that the quadratic interpolant $u_q \in \bar{V}_h$ of u is decomposed as the sum $u_q = u_\ell + u_b$ with $u_\ell \in V_h$ and $u_b \in \tilde{V}_h$. In the following lemma we compare the first and second derivatives of ε_h and u_b. The second of these results is used in the proof of Theorem 3.6 to establish the Hessian recovery result, and the first will play an important role in the next section, where we prove the function recovery result.

LEMMA 3.5. *Under Assumption* 3.1*, we have*

$$\|\varepsilon_h - u_b\|_{1,\Omega} \lesssim h^{1+\min(\sigma,1)} |\log h|^{1/2} \|u\|_{3,\infty,\Omega}, \tag{25}$$

$$\sum_{\tau \in \mathcal{T}_h} |\varepsilon_h - u_b|_{2,\tau}^2 \lesssim h^{2\min(\sigma,1)} |\log h| \|u\|_{3,\infty,\Omega}^2. \tag{26}$$

Proof. In the proof of Theorem 3.3, we saw that

$$\|u-(u_h+\varepsilon_h)\|_{1,\Omega},\ \|u-(u_h+u_b)\|_{1,\Omega} \lesssim h^{1+\min(\sigma,1)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{27}$$

This gives us

$$\|\varepsilon_h-u_b\|_{1,\Omega} \le \|u-(u_h+\varepsilon_h)\|_{1,\Omega}+\|u-(u_h+u_b)\|_{1,\Omega} \tag{28}$$

$$\lesssim h^{1+\min(\sigma,1)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{29}$$

Using a standard inverse estimate, we see that

$$\sum_{\tau\in\mathcal{T}_h}|\varepsilon_h-u_b|_{2,\tau}^2 \lesssim h^{-2}\|\varepsilon_h-u_b\|_{1,\Omega}^2 \lesssim h^{2\min(1,\sigma)}\,|\log h|\,\|u\|_{3,\infty,\Omega}^2, \tag{30}$$

so we have proven both results. ∎

The convergent Hessian recovery result follows.

THEOREM 3.6. *Under Assumption* 3.1*, we have*

$$\sum_{\tau\in\mathcal{T}_h}|u-\varepsilon_h|_{2,\tau}^2 \lesssim h^{2\min(\sigma,1)}|\log h|\|u\|_{3,\infty,\Omega}^2. \tag{31}$$

Proof. We have $|u-\varepsilon_h|_{2,\tau} \le |u-u_b|_{2,\tau}+|u_b-\varepsilon_h|_{2,\tau}$, so

$$\sum_{\tau\in\mathcal{T}_h}|u-\varepsilon_h|_{2,\tau}^2 \le 2\left(\sum_{\tau\in\mathcal{T}_h}|u-u_b|_{2,\tau}^2+\sum_{\tau\in\mathcal{T}_h}|u_b-\varepsilon_h|_{2,\tau}^2\right) \tag{32}$$

$$\lesssim h^2\|u\|_{3,\infty,\Omega}^2+\sum_{\tau\in\mathcal{T}_h}|u_b-\varepsilon_h|_{2,\tau}^2. \tag{33}$$

Combining this with the second estimate in Lemma 3.5 completes the proof. ∎

Provided that $\|u\|_{3,\infty,\Omega}<\infty$, the estimate in Theorem 3.5 is equivalent to

$$\sum_{\tau\in\mathcal{T}_h}|\varepsilon_h|_{2,\tau}^2 \to |u|_{2,\Omega}^2. \tag{34}$$

4. Function recovery. In this section we prove that the approximate error function ε_h provides efficient and reliable approximation of the true error $u-u_h$ in the L_2-norm,

$$c_1 \le \frac{\|\varepsilon_h\|_{0,\Omega}}{\|u-u_h\|_{0,\Omega}} \le c_2. \tag{35}$$

We also explain why we cannot generally expect the same sort of asymptotic exactness result which we saw for the gradient error. In other words, we *cannot* generally expect that

$$\frac{\|\varepsilon_h\|_{0,\Omega}}{\|u-u_h\|_{0,\Omega}} \to 1, \tag{36}$$

although the constants c_1, c_2 may be near 1 in practice.

This first lemma will allow us to convert the gradient approximation result from Lemma 3.5 into the function (L_2) approximation results that follow.

LEMMA 4.1. *Let $\mathcal{T}_h$ be a shape-regular quasi-uniform mesh. For any $b \in \tilde{V}_h$, we have*

$$\|b\|_{0,\Omega} \lesssim h\|\nabla b\|_{0,\Omega}. \tag{37}$$

Proof. Let $\tau \in \mathcal{T}_h$ be given, and write b in terms of its three bump basis functions on τ, $b = c_1 b_1 + c_2 b_2 + c_3 b_3$. We denote the length of the edge on which b_k does *not* vanish by L_k, and without loss of generality take $L_1 \le L_2 \le L_3$. It holds that

$$\|b\|_{0,\tau}^2 = \frac{8|\tau|}{45}(c_1^2 + c_2^2 + c_3^2 + c_1c_2 + c_1c_3 + c_2c_3), \tag{38}$$

$$\|\nabla b\|_{0,\tau}^2 = \frac{1}{3|\tau|}\left((c_1 - c_2 - c_3)^2 L_1^2 + (c_2 - c_1 - c_3)^2 L_2^2 + (c_3 - c_1 - c_2)^2 L_3^2\right). \tag{39}$$

We bound $\|\nabla b\|_{0,\tau}^2$ from below as follows:

$$\|\nabla b\|_{0,\tau}^2 \ge \frac{L_1^2}{3|\tau|}\left((c_1 - c_2 - c_3)^2 + (c_2 - c_1 - c_3)^2 + (c_3 - c_1 - c_2)^2\right) \tag{40}$$

$$= \frac{L_1^2}{3|\tau|}(3c_1^2 + 3c_2^2 + 3c_3^2 - 2c_1c_2 - 2c_1c_3 - 2c_2c_3) \tag{41}$$

$$\ge \frac{L_1^2}{3|\tau|}\frac{1}{2}(c_1^2 + c_2^2 + c_3^2 + c_1c_2 + c_1c_3 + c_2c_3). \tag{42}$$

This gives us

$$\|b\|_{0,\tau}^2 \le \frac{48}{45}\frac{|\tau|^2}{L_1^2}\|\nabla b\|_{0,\tau}^2 \lesssim h^2\|\nabla b\|_{0,\tau}^2. \tag{43}$$

Summing over triangles completes the proof. ∎

LEMMA 4.2. *Under Assumption* 3.1*, we have*

$$\|\varepsilon_h - u_b\|_{0,\Omega} \lesssim h^{2+\min(\sigma,1)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}, \tag{44}$$

$$\|u - (u_\ell + \varepsilon_h)\|_{0,\Omega} \lesssim h^{2+\min(\sigma,1)}|\log h|^{1/2}\|u\|_{3,\infty,\Omega}. \tag{45}$$

Proof. Combining the first estimate from Lemma 3.5 with the result of Lemma 4.1 proves the first of these two estimates. We also have

$$\|u - (u_\ell + \varepsilon_h)\|_{0,\Omega} \le \|u - u_q\|_{0,\Omega} + \|\varepsilon_h - u_b\|_{0,\Omega} \lesssim h^3\|u\|_{3,\Omega} + \|\varepsilon_h - u_b\|_{0,\Omega}. \tag{46}$$

Combining this second estimate with the first completes the proof. ∎

We see from the estimate $\|u-(u_\ell+\varepsilon_h)\|_{0,\Omega} = o(h^2)$ that $\|\varepsilon_h\|_{0,\Omega}$ is an asymptotically exact estimator of the interpolation error $\|u-u_\ell\|_{0,\Omega}$, provided that $\|u-u_\ell\|_{0,\Omega} > m_1h^2$ for some positive constant m_1. We are now ready to prove the main result of this section.

THEOREM 4.3. *Suppose that there are constants $m_1, m_2 > 0$, such that $\|u - u_\ell\|_{0,\Omega} \ge m_1h^2$ and $\|u - u_h\|_{0,\Omega} \ge m_2h^2$. Then, under Assumption* 3.1*, there are constants $c_1, c_2 > 0$, such that*

$$c_1 \le \frac{\|\varepsilon_h\|_{0,\Omega}}{\|u - u_h\|_{0,\Omega}} \le c_2. \tag{47}$$

Proof. It is certainly the case that there are constants $M_1, M_2 > 0$, such that $\|u - u_\ell\|_{0,\Omega} \leq M_1 h^2$ and $\|u - u_h\|_{0,\Omega} \leq M_2 h^2$. So we have

$$\frac{m_1}{M_2} \leq \frac{\|u - u_\ell\|_{0,\Omega}}{\|u - u_h\|_{0,\Omega}} \leq \frac{M_1}{m_2}. \tag{48}$$

The proof is completed by using the fact that $\|\varepsilon_h\|_{0,\Omega}$ is an asymptotically exact estimator of $\|u - u_\ell\|_{0,\Omega}$. ∎

Recall that the proof of the asymptotic exactness of $\|\varepsilon_h\|_{1,\Omega}$ as an estimator of $\|u-u_h\|_{1,\Omega}$ relied on the fact that $\|u_\ell-u_h\|_{1,\Omega} = o(h)$. We see in Lemma 4.4 below that we need $\|u_\ell - u_h\|_{0,\Omega} = o(h^2)$ to get asymptotic exactness of $\|\varepsilon_h\|_{0,\Omega}$ as an estimator of $\|u - u_h\|_{0,\Omega}$.

LEMMA 4.4. *Under Assumption* 3.1*, we have*

$$\|u - (u_h + \varepsilon_h)\|_{0,\Omega} = o(h^2) \iff \|u_h - u_\ell\|_{0,\Omega} = o(h^2). \tag{49}$$

Proof. We have the inequalities

$$\|u - (u_h + \varepsilon_h)\|_{0,\Omega} \leq \|u - (u_\ell + \varepsilon_h)\|_{0,\Omega} + \|u_h - u_\ell\|_{0,\Omega}, \tag{50}$$

$$\|u_h - u_\ell\|_{0,\Omega} \leq \|u - (u_\ell + \varepsilon_h)\|_{0,\Omega} + \|u - (u_h + \varepsilon_h)\|_{0,\Omega}. \tag{51}$$

Lemma 4.2 completes the proof. ∎

The rest of this section is devoted to demonstrating by example that we *cannot* generally expect $\|u_\ell - u_h\|_{0,\Omega} = o(h^2)$ even in an ideal situation for which we can prove $\|u_\ell - u_h\|_{1,\Omega} \lesssim h^2 |\log h|^{1/2} \|u\|_{3,\infty,\Omega}$. Thus, we cannot generally expect asymptotic exactness in the L_2-norm.

Consider the following simple problem on the unit square $\Omega = (0,1) \times (0,1)$:

$$\begin{aligned} -\Delta u &= 2x(1-x) + 2y(1-y) \text{ in } \Omega, \\ u &= 0 \text{ on } \partial\Omega. \end{aligned}$$

The exact solution is $u = x(1-x)y(1-y)$. We take the family of uniform meshes having mesh size $h = \frac{1}{n+1}$ and n^2 degrees of freedom located at $(x_i, y_j) = (ih, jh)$; see Figure 1. We will show that $h^2 \lesssim \|u_\ell - u_h\|_{0,\Omega}$.

Let $T \in \mathbb{R}^{n \times n}$ be the tridiagonal matrix with stencil $(-1,\ 2,\ -1)$. Under the standard ordering of unknowns (left to right, bottom to top) the stiffness matrix for this problem is given by

$$A = T \otimes I + I \otimes T = (V \otimes V)(D \otimes I + I \otimes D)(V \otimes V), \tag{52}$$

$$V_{ij} = \sqrt{\frac{2}{n+1}} \sin \frac{ij\pi}{n+1}\ ,\ D_{ij} = \delta_{ij} \left(2 - 2\cos\frac{i\pi}{n+1}\right) = \delta_{ij} 4 \sin^2 \frac{i\pi}{2(n+1)}. \tag{53}$$

We note that $V = V^T = V^{-1}$. As a notational convenience, for $\mathbf{x} \in \mathbb{R}^{n^2}$ we use $\mathbf{x}_{(i,j)} \equiv \mathbf{x}_{(i-1)n+j}$. Similarly, we take $\phi_{(i,j)}$ to be the Lagrange nodal basis function associated with the grid point (x_i, y_j). We define $\mathbf{d}$ and $\mathbf{r}$ to be the error and residual, respectively, at the grid points

$$\mathbf{d}_{(i,j)} = u(x_i, y_j) - u_h(x_i, y_j) = u_\ell(x_i, y_j) - u_h(x_i, y_j), \tag{54}$$

$$\mathbf{r}_{(i,j)} = h^2 f(x_i, y_j) - \int_\Omega f \phi_{(i,j)}\, dxdy = \frac{2}{3} h^4. \tag{55}$$

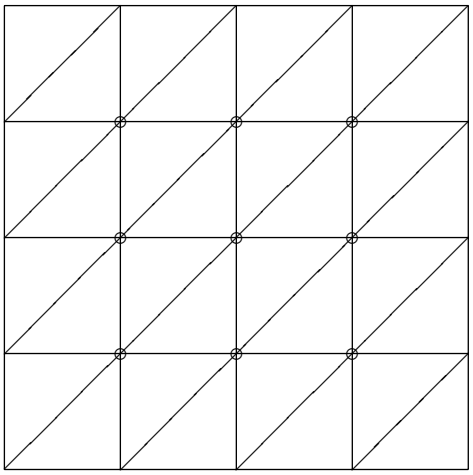

FIG. 1. *Uniform mesh with* $n = 3$.

We have $A\mathbf{d} = \mathbf{r}$. We first argue that $\|u_\ell - u_h\|_{0,\Omega} \geq \frac{h}{2}\|\mathbf{d}\|$, and then establish that $\|\mathbf{d}\| \geq Ch$, thereby proving that $h^2 \lesssim \|u_\ell - u_h\|_{0,\Omega}$. We begin by noting that for any linear function g on a triangle τ, given in terms of its three nodal basis functions, $g = c_1\ell_1 + c_2\ell_2 + c_3\ell_3$, we have

$$\|g\|_{0,\tau}^2 = \frac{|\tau|}{6}(c_1^2 + c_2^2 + c_3^2 + c_1c_2 + c_1c_3 + c_2c_3) \geq \frac{|\tau|}{12}(c_1^2 + c_2^2 + c_3^2). \tag{56}$$

Therefore, if g is continuous and piecewise-linear on $\mathcal{T}$, we have

$$\|g\|_{0,\Omega}^2 = \sum_{\tau\in\mathcal{T}_h} \|g\|_{0,\tau}^2 \geq \frac{|\tau|}{2}\|\mathbf{c}\|^2 = \frac{h^2}{4}\|\mathbf{c}\|^2, \tag{57}$$

where $\mathbf{c}$ is the vector of coefficients. The factor of 6 comes from the fact that each coefficient appears in 6 of the summands $\|g\|_{0,\tau}^2$. This proves that

$$\|u_\ell - u_h\|_{0,\Omega} \geq \frac{h}{2}\|\mathbf{d}\|. \tag{58}$$

We now consider $\|\mathbf{d}\| = \|A^{-1}\mathbf{r}\| = \frac{2}{3}h^4\|A^{-1}(\mathbf{e}\otimes\mathbf{e})\|$, where $\mathbf{e} \in \mathbb{R}^n$ is the vector of ones. It holds that $\|A^{-1}(\mathbf{e}\otimes\mathbf{e})\| = \|(D\otimes I + I\otimes D)^{-1}(V\mathbf{e}\otimes V\mathbf{e})\|$, and

$$(V\mathbf{e})_i = \sqrt{\frac{2}{n+1}}\sum_{j=1}^{n}\sin\frac{ij\pi}{n+1} = \sqrt{\frac{2}{n+1}}\cot\frac{i\pi}{2(n+1)}\left|\sin\frac{i\pi}{2}\right|. \tag{59}$$

This gives us

$$\|A^{-1}(\mathbf{e}\otimes\mathbf{e})\|^2 = \frac{h^2}{4}\sum_{i=1}^{n}\sum_{j=1}^{n}\left|\sin\frac{i\pi}{2}\sin\frac{j\pi}{2}\right|\left(\frac{\cot\frac{i\pi}{2(n+1)}\cot\frac{j\pi}{2(n+1)}}{\sin^2\frac{i\pi}{2(n+1)} + \sin^2\frac{j\pi}{2(n+1)}}\right)^2 \tag{60}$$

$$> \frac{h^2}{4}\left(\frac{\cot\frac{\pi}{2(n+1)}\cot\frac{\pi}{2(n+1)}}{\sin^2\frac{\pi}{2(n+1)} + \sin^2\frac{\pi}{2(n+1)}}\right)^2 \tag{61}$$

$$= \frac{h^2}{16}\frac{\cos^4\frac{\pi}{2(n+1)}}{\sin^8\frac{\pi}{2(n+1)}} > \frac{h^2}{16}\frac{(\frac{1}{\sqrt{2}})^4}{(\frac{\pi}{2(n+1)})^8} = \frac{4}{\pi^8}\,h^{-6}. \tag{62}$$

Combining these results we have $\|u_\ell - u_h\|_{0,\Omega} > \frac{h}{2}\frac{2h^4}{3}\frac{2h^{-3}}{\pi^4} = \frac{2h^2}{3\pi^4}$, which completes the argument.

5. Experiments. In this section we offer four examples which illustrate the effectivity of our estimator and provide some comments on its computational cost. In particular, we wish to verify (2), the key results of this paper, in practice. The exact error for each of the examples solution is known, so we can judge the quality of our estimator directly. Throughout this section we use $e_h \equiv u - u_h$ for the exact error and the abbreviation EFF for each of the effectivity ratios

$$\frac{\|\varepsilon_h\|_{0,\Omega}}{\|e_h\|_{0,\Omega}}, \qquad \frac{|\varepsilon_h|_{1,\Omega}}{|e_h|_{1,\Omega}}, \qquad \frac{|\varepsilon_h|_{2,\Omega}}{|u|_{2,\Omega}}. \tag{63}$$

For the sake of convenience we abuse notation slightly by taking

$$|\varepsilon_h|_{2,\Omega} \equiv \sqrt{\sum_{\tau\in\mathcal{T}} |\varepsilon_h|^2_{2,\tau}}. \tag{64}$$

This is an abuse because $|v|_{2,\Omega}$ is infinite by its standard definition for functions such as ε_h, which have a gradient jump between elements in a mesh. Additionally, we abbreviate the standard scientific notation by placing the base 10 exponent as a subscript, for example, $3.54_{-2} \equiv 3.54 \times 10^{-2}$.

The quantity N appearing in the tables is the number of triangles in the mesh. For the larger values of N, this is roughly twice the number of vertices in the mesh. In the first four examples, for which the exact error is known, we use the error model $E = CN^{-p}$, derived from standard a priori estimates and $Nh^2 \sim 1$, to give a sense of the rate of convergence of error. In particular, we give the least-squares best fit for each of the normed errors. We note that $p = 1$ (resp., $p = 1/2$) corresponds to what is generally called *quadratic* (resp., *linear*) convergence—in terms of the mesh parameter h—and we use this language in the explanations below. The code used for the numerical experiments is PLTMG [6], with modifications necessary to implement our error estimation technique.

5.1. The simple problem. For our first experiment, we revisit the example from section 4 which was used to demonstrate that one cannot generally expect asymptotic exactness from our estimator in L_2. We will see, however, that the function recovery is very nearly exact in this case. Recall that the problem is to find u such that

$$\begin{aligned} -\Delta u &= 2x(1-x) + 2y(1-y) \text{ in } \Omega, \\ u &= 0 \text{ on } \partial\Omega. \end{aligned}$$

Here Ω is the unit square, and the exact solution is $u = x(1-x)y(1-y)$. We provide the values of the various norms of u so that the relative errors can be readily assessed if desired:

$$\|u\|_{0,\Omega} = \sqrt{\frac{1}{900}} = 0.0\bar{3}, \qquad |u|_{1,\Omega} = \sqrt{\frac{1}{45}} \approx 0.149, \qquad |u|_{2,\Omega} = \sqrt{\frac{22}{45}} \approx 0.699.$$

This example is also used in the numerical experiments in [21, 23].

In Table 1 we see the predicted performance of the estimator in each of the square norms, with the L_2 error estimate having effectivity very near 1 on each mesh. Below, we give the approximate error models for the function and gradient errors:

$$\|e_h\|_{0,\Omega} \approx 0.159N^{-1.02}, \qquad |e_h|_{1,\Omega} \approx 0.307N^{-0.502}.$$

We point out that we observe the predicted a priori quadratic convergence of $\|e_h\|_{0,\Omega}$ and linear convergence of $|e_h|_{1,\Omega}$.

5.2. The oscillatory problem. In this second example we consider the situation where the exact solution still possesses no singularities, but oscillates strongly. The problem is to find u such that

$$-\Delta u = 128\pi^2 \sin(8\pi x)\sin(8\pi y) \text{ in } \Omega,$$
$$u = 0 \text{ on } \partial\Omega.$$

Here Ω is again the unit square, and the exact solution is $u = \sin(8\pi x)\sin(8\pi y)$. The pertinent norms of u are given below:

$$\|u\|_{0,\Omega} = \sqrt{\frac{1}{4}} = 0.5, \qquad |u|_{1,\Omega} = \sqrt{32\pi^2} \approx 17.8, \qquad |u|_{2,\Omega} = \sqrt{4096\pi^4} \approx 632.$$

In Table 2 we again see effectivity approaching 1 for the gradient error and the Hessian in both norms. The effectivity of the function error estimate tends to stay in the 80–85% range. We see in the approximate error models below that the adaptive refinement seems to be producing suboptimal reduction of function and gradient error:

$$\|e_h\|_{0,\Omega} \approx 36.5N^{-0.873}, \qquad |e_h|_{1,\Omega} \approx 149N^{-0.443}.$$

This is due to the fact that the two coarsest meshes are just beginning to resolve the oscillatory behavior. When the error data from these two initial meshes is removed, we see the expected quadratic and linear convergence for the function and gradient errors, respectively. More precisely, the exponents for the L_2 and H^1 error models are $p = 1.09$ and 0.536, respectively.

5.3. The slit domain problem. For our third example we consider a problem for which the boundary conditions force a singularity at the origin. Because of the infinite gradient at the origin, it is interesting to investigate the effectivity of the estimators. The problem is to find u such that

$$-\Delta u = 0 \text{ in } \Omega, \qquad u(r,0^+) = 0, \qquad \nabla u \cdot \mathbf{n}\,(r,2\pi^-) = 0, \qquad u(1,\theta) = \sin(\theta/4).$$

Here Ω is the unit disk with the positive x-axis removed, and the exact solution is $u = r^{1/4}\sin(\theta/4)$. Though the gradient of u is infinite at the origin, $|u|_{1,\Omega}$ is finite. However, this is not the case for $|u|_{2,\Omega}$—here we must avoid the origin to get a finite H^2 seminorm. Let Ω_s denote Ω with the disk of radius s about the origin removed. In the experiments, we take $s = 1/100$. The pertinent norms are given below:

$$\|u\|_{0,\Omega} = \sqrt{\frac{2\pi}{5}} \approx 1.12,\ |u|_{1,\Omega} = \sqrt{\frac{\pi}{4}} \approx 0.886,\ |u|_{2,\Omega_s} = \sqrt{\frac{3\pi}{32}(s^{-3/2}-1)} \approx 17.2.$$

We note that the global smoothness condition $u \in W^3_\infty(\Omega)$ is certainly not satisfied here.

In Table 3 we see the clear effects of this singularity on the performance of the function error estimates and the gradient error. Here the function error estimates underestimate the true function error by roughly a factor of 26.5 at worst and a factor of 5 at best, and the gradient error estimate underestimates the true gradient error by 28% at best, though it is slowly improving. We also point out that the second derivatives are recovered quite well. Concerning Table 3, we mention finally that the performance of the gradient error estimate improves markedly if we restrict our attention to the error on the subdomain Ω_s, as is seen at the bottom of that table, but the performance of the function error estimate does not improve appreciably. The approximate error models given below, though showing subquadratic convergence of the function error and sublinear convergence of the gradient error, are actually quite encouraging for a problem with this sort of singularity, where we would expect $p \approx 1/8$ asymptotically for the gradient error $|e_h|_{1,\Omega}$ under uniform refinement:

$$\|e_h\|_{0,\Omega} \approx 9.31N^{-0.894}, \qquad |e_h|_{1,\Omega} \approx 5.11N^{-0.447}.$$

TABLE 4

EFF	0.504	1.07	1.07	1.03	1.01	1.00

5.4. The jumping coefficient problem. The problem is to find u such that

$$-a_k \Delta u = 0 \text{ in } \Omega, u(r,0) = 0,$$
$$\nabla u \cdot \mathbf{n}\,(r,\pi) = 0, u(1,\theta) = b_k \sin(\alpha\theta) + c_k \cos(\alpha\theta).$$

Here Ω is the upper half of the unit disk, which is divided into two regions having differing coefficients of diffusion. In the first region, $0 < \theta < \frac{\pi}{4}$, we have $a_1 = 10^3$. In the second region, $\frac{\pi}{4} < \theta < \pi$, we have $a_2 = 1$. The exact solution is $u = r^\alpha(b_k \sin(\alpha\theta) + c_k \cos(\alpha\theta))$, where the values α, b_k, c_k are determined by the boundary conditions at $\theta = 0, \pi$ and the continuity of u and $a_k \nabla u \cdot \mathbf{n}$ along the interface $\theta = \frac{\pi}{4}$ between the two regions. The boundary condition at $r = 1$ is chosen to match the solution in the interior. The boundary conditions on the positive and negative x-axes and the continuity conditions at the interface provide four equations which are linear in b_1, c_1, b_2, c_2 (and trigonometric in α). It is clear that $b_1 = c_1 = b_2 = c_2 = 0$ trivially satisfies all of the specified conditions, so we must select α so that the resulting linear system is singular—therefore admitting nontrivial solutions. If there are any such choices of α, then there are infinitely many. We selected the following solution, with $\alpha \approx 0.666422$:

$$b_1 = 1, \qquad c_1 = 0, \qquad b_2 \approx 750.416, \qquad c_2 \approx -432.484,$$
$$\|u\|_{0,\Omega} \approx 515, \qquad |u|_{1,\Omega} \approx 767, \qquad |u|_{2,\Omega_s} \approx 2.32_3.$$

Again we take Ω_s to be Ω with the disk of radius $s = 1/100$ removed. Although $u \notin H^2(\Omega_s)$ because of the jump discontinuity of ∇u at the interface between the two regions, we abuse notation by taking

$$|u|^2_{2,\Omega_s} \equiv \sum_{\tau \in \mathcal{T}_s} |u|^2_{2,\tau} \tag{65}$$

for Table 4. This sum is finite because the interface between the two regions does not pass through the interior of any of the triangles.

In Table 4, we see the data for this experiment. We point out that the performance of the various error estimates based on the approximate error function seem to be unaffected by the jump in the coefficient. In particular, we see effectivity ratios near or approaching 1 for the gradient error and the Hessian, and slightly better than 80% for the function values in each norm. The approximate error models given below show error convergence which is better than one would expect, with superquadratic convergence in function error and superlinear convergence in gradient error:

$$\|e_h\|_{0,\Omega} \approx 1.12_3 N^{-1.20}, \qquad |e_h|_{1,\Omega} \approx 1.58_3 N^{-0.589}.$$

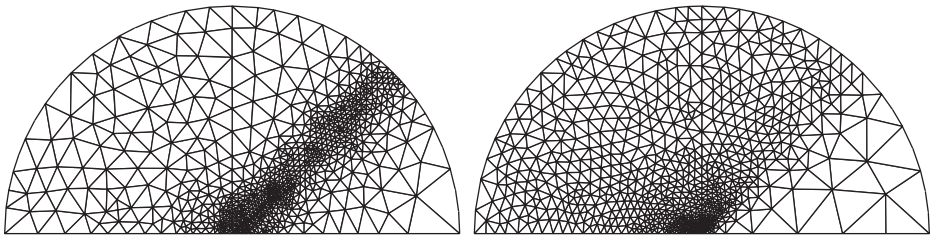

FIG. 2. *The meshes for the jumping coefficient problem after three stages of adaptive refinement, using Bank–Xu gradient recovery estimates (left) and bump function error estimates (right). The mesh on the left has* 804 *vertices and* 1534 *triangles, and the mesh on the right has* 808 *vertices and 1530 triangles.*

These convergence rates are elevated in the models because of the significant error reduction in the early stages of refinement. When we remove the error data from the first two meshes, the convergence rates drop to the more normal quadratic and linear levels.

In addition to having an r^α, $\alpha < 1$ singularity at the origin, the solution also has a jump discontinuity in its gradient at $\theta = \pi/4$. It is relevant at this point to consider which of these two types of singularities has the stronger (negative) effect on the performance of the estimator for problems of this sort. Considering that the slit domain problem possesses only an r^α singularity and that the α for that problem is smaller than the one for this problem, comparing the performance of the estimator in both cases suggests that r^α singularities are more influential than jump discontinuities in the gradient. In fact, a careful reading of either the Bank–Xu paper [3] or the Xu–Zhang paper [20] reveals that the key superconvergence result for this paper,

$$\|u_h - u_\ell\|_{1,\Omega} = o(h),$$

holds for u having a finite number of gradient jump discontinuities provided that u is sufficiently smooth in each of corresponding subdomains. So we see that, asymptotically, the effectivity of the estimator is affected by jumping coefficients only if they lead to singularities which are worse than gradient jump discontinuities.

We also mention that, for problems of the sort for which we can expect gradient jumps, a naive application of gradient recovery error estimators will lead to suboptimal and sometimes terrible performance. This is because of the fact that gradient recovery schemes involve some sort of local or global averaging. If care is not taken to avoid averaging across an interface where ∇u jumps, then the local error estimates near the interface will tend to overestimate the actual error there—particularly when u_h approximates u well. To illustrate this explicitly we give a brief summary of the result using the Bank–Xu recovery technique, which is a global recovery technique. In Figure 2, we see a clear qualitative difference between the sort of refinement produced by the bump estimator and the naive use of the Bank–Xu estimator—the sort of difference we might have guessed due to the overestimation of error near the interface for the latter. The error model for this refinement is $|e_h|_{1,\Omega} \approx 845\, N^{-0.487}$, with effectivity $EFF \approx 3$ as the mesh is refined. We are not trying to make the point that this sort of bad behavior is unavoidable for gradient recovery schemes—in practice it can be avoided by taking care to not average out a gradient jump where there should be one. Bank and Xu noted this in an example in [4], and performing their gradient recovery scheme for our problem on each subdomain separately restores the optimal performance. The point that we are trying to make with this discussion is that with

TABLE 5

Timing comparison: the ratio of the costs to compute ε_h and $\mathcal{R}\nabla u_h$. Ratios in the first three rows correspond to using SGS-CG to compute ε_h, and the bottom three rows correspond to using unpreconditioned CG.

Simple	3.17	3.37	3.53	3.25	2.66	2.24
Oscillatory	3.15	4.07	3.61	3.40	2.05	2.38

Simple	2.50	2.56	2.63	2.38	1.98	1.49
Oscillatory	2.45	2.53	2.74	2.59	1.44	1.53
Slit domain	2.55	2.09	2.15	2.12	1.94	1.40

the bump error estimator it is not necessary to treat subdomains differently. We think that this is an attractive feature of the estimator, particularly in cases where the number of jumps in the coefficient on the diffusion term (and hence the number of jumps in the gradient of the solution) is large, or where there are small or narrow regions in which the number of elements needed to get a good approximation of the true solution there is smaller than the number of elements needed to perform any of the standard gradient recovery techniques.

5.5. Computational cost. Although the linear system involved in the computation of ε_h can be expected to have roughly three times the number of unknowns as that for computing u_h, the system itself is readily solved because it is well-conditioned (see [5, p. 11], for example). But how does the cost compare with that of various gradient recovery schemes? We content ourselves with a direct comparison to the recovery scheme of Bank and Xu as it is currently implemented in PLTMG. In Table 5, we have the ratios of the times needed to compute ε_h and the recovered gradient $\mathcal{R}\nabla u_h$ for three of the four problems considered here—the jumping coefficient problem was omitted because it would have required a modification of the gradient recovery subroutines in PLTMG. We have used the symmetric Gauß–Seidel method as a preconditioner for CG in the computation of ε_h, as in all of the experiments above, and these data correspond to those experiments. For example, the ratio 3.17 for the simple problem corresponds to the coarsest mesh (88 triangles for both ε_h and $\mathcal{R}\nabla u_h$), and 2.24 corresponds to the finest mesh (126919 triangles for ε_h and 127020 for $\mathcal{R}\nabla u_h$).

For these three problems, unpreconditioned CG can be used instead with no loss in effectivity. When this is done, the timing ratios improve, as is shown in the bottom three rows of Table 5. We generally advocate using some sort of preconditioner for problems such as the jumping coefficient problem because otherwise one notices a drop in effectivity. We suggest that the greater computational cost, still quite small with respect to the total computational cost of the adaptive algorithm, may be worthwhile for this very robust and flexible error estimator. The robustness of the estimator is seen theoretically in that, even in situations where the assumptions taken here do not apply, we can fall back on the "old" analysis based on the milder saturation assumption and on the strengthened Cauchy inequality, which hold under quite general conditions (see [9] and [10, pp. 436–445]). The flexibility of the approximate error function $\varepsilon_h \approx u - u_h$ is clear in that it can be used to measure error in other norms or to approximate error in certain functionals of interest (see [18]), as well as for mesh smoothing procedures such as that proposed by Bank and Smith [2].

6. Final remarks. We have given proof and numerical evidence of the effectiveness of the hierarchical basis type bump function estimator $\varepsilon_h \approx u - u_h$ in recovering function values and first and second derivatives. The proofs offered here are based on

the superconvergence result $\|u_h - u_\ell\|_{1,\Omega} = o(h)$, which is usually used in the proofs of the effectiveness of gradient recovery methods. In our proofs, we replace the standard saturation assumption and strengthened Cauchy inequality used in the analysis commonly given for hierarchical basis methods with relatively mild mesh symmetry conditions and relatively strong smoothness assumptions, which are sufficient but often not seen to be necessary in practice. We thereby obtain stronger theoretical results than are generally given for such estimators, and these results are borne out in practice. The approximation $\varepsilon_h \approx u - u_h$ is provably quite robust and can be used for error estimation and adaptivity in a variety of norms and other measures.

In terms of the asymptotically exact recovery of gradient error, our estimator $\|\nabla\varepsilon_h\|_{0,\Omega}$ has a lot of very good competition in the many gradient recovery procedures proposed in the literature. In addition to the recovery procedure of Bank and Xu, which is mentioned several times above, we also cite the local least-squares fitting of Zienkiewicz and Zhu [23, 24] (perhaps the most popular), the polynomial preserving method of Zhang and Naga [16, 21], and the method proposed by Wiberg and Li [15, 19], which has the most in common with our own in that it can be used directly to produce a locally quadratic (though not globally continuous) approximation of the error $u-u_h$. These methods should also be suitable for recovering second derivatives—Bank and Xu argue as much for their estimator—but not much has been written in the gradient recovery literature about estimating the function error. The notable exception in this regard is in the aforementioned works of Wiberg and Li, where numerical evidence of efficiency and reliability of their estimator are given, but no analysis is provided.

We now briefly consider a few straightforward generalizations of what has been presented here. The $\mathcal{O}(h^{2\sigma})$-irregular triangulation assumption is generalized in [20], where Xu and Zhang call it *Condition*(α,σ). We note that the σ in the Xu–Zhang paper plays the role of the 2σ used in both the Bank–Xu paper and our own, and an $\mathcal{O}(h^{1+\alpha})$-parallelogram property is used instead of an $\mathcal{O}(h^2)$-parallelogram property. In their paper, Xu and Zhang also use the less stringent regularity condition $u \in H^3(\Omega) \cap W^2_\infty(\Omega)$. Under these assumptions and a few natural assumptions on the bilinear form for the problem, they prove that

$$\|u_h - u_\ell\|_{1,\Omega} \lesssim h^{1+\min(\alpha,1/2,\sigma/2)}(\|u\|_{3,\Omega} + |u|_{2,\infty,\Omega}). \tag{66}$$

The results in this paper can be modified in the obvious way to incorporate the Xu–Zhang version of the mesh symmetry conditions and the weaker regularity assumption, with no change in the proofs.

We will mention two other ways in which the arguments given here can be readily generalized. The first is to consider linear simplicial elements in $\mathbb{R}^n$, $n > 2$. Recall that the key result from which all of the other estimates were proved was of the form

$$\|u_h - u_\ell\|_{1,\Omega} = o(h), \tag{67}$$

where u_h is the linear finite element approximation and u_ℓ is the linear Lagrange interpolant. Brandts and Křížek [7, 12] show that

$$\|u_h - u_\ell\|_{1,\Omega} \lesssim h^2\|u\|_{3,\Omega} \tag{68}$$

on very regular meshes for $u \in H^1_0(\Omega) \cap H^s(\Omega)$ and $s = 3$ for $n \le 5$ and $s > n/2$ for $n \ge 6$. Any s greater than 3 is needed only to ensure that the nodal interpolant u_ℓ can be well-defined. Chen [8] generalizes the argument of [3] to mildly structured

tetrahedral meshes in $\mathbb{R}^3$ to obtain

$$\|u_h - u_\ell\|_{1,\Omega} \lesssim h^{1+\min(1,\sigma)}\|u\|_{3,\infty,\Omega}, \tag{69}$$

where $u \in H_0^1(\Omega) \cap W_\infty^3(\Omega)$ and σ measures the violation of an $\mathcal{O}(h^2)$-parallelepiped property. With such superconvergence results, the extension of our results proceeds in the obvious fashion.

Another generalization would be to consider hierarchical error estimators for higher order elements. For example, let $\hat{V}_h = \bar{V}_h \oplus (\hat{V}_h \setminus \bar{V}_h)$ be the piecewise cubic finite element space, which we think of hierarchically. If $\bar{u}_h \in \bar{V}_h$ is the finite element solution, we might want to estimate the error $u - \bar{u}_h$ using a function in $\hat{V}_h \setminus \bar{V}_h$; call it $\bar{\varepsilon}_h$. Li [13, 14] has shown that Lagrange interpolation does not generally give the analogous superconvergence results for elements of degree 3 or higher in $\mathbb{R}^2$, but we are free to use some other appropriate interpolation scheme. Let $\Pi_q : C(\bar{\Omega}) \to \bar{V}_h$ and $\Pi_c : C(\bar{\Omega}) \to \hat{V}_h$ be defined by

$$\begin{aligned}
&\Pi_q u(v_i) = \Pi_c u(v_i) = u(v_i) \text{ for vertices } v_i,\\
&\int_{e_j} u - \Pi_q u \, ds = \int_{e_j} (u - \Pi_c u) v \, ds = 0 \text{ for edges } e_j \text{ and linear functions } v,\\
&\int_\tau u - \Pi_c u \, dx = 0 \text{ for triangles } \tau.
\end{aligned}$$

Huang and Xu [11] argue that

$$\|\bar{u}_h - \Pi_q u\|_{1,\Omega} \lesssim h^{2+\min(1,\sigma)/2}(\|u\|_{4,\Omega} + |u|_{3,\infty,\Omega}),\ \Pi_c u - \Pi_q u \in \hat{V}_h \setminus \bar{V}_h. \tag{70}$$

One might correctly infer from the statement of the result that a similar argument to those found in [3, 20] is used. With an estimate like this, the analogue of Theorem 3.3 can be proved in the obvious way. Using arguments like those given in Lemma 3.5 and Theorem 3.6, we see that our approximate error function $\bar{\varepsilon}_h \approx u - \bar{u}_h$ provides superconvergent approximation of $\|u - \bar{u}_h\|_{2,\Omega}$ and convergent approximation of $\|u\|_{3,\Omega}$. Finally, arguing along the same lines as in section 4 we get even better results than in the case of piecewise linears, because it actually does hold that $\|\bar{u}_h - \Pi_q u\|_{0,\Omega} = o(h^3)$. Huang and Xu have plans to extend their results to higher order elements as well, and the analogous results should be able to be plugged into our framework with little difficulty.

Acknowledgments. The author thanks Wolfgang Hackbusch and other colleagues in the scientific computation group at the Max Planck Institute in Leipzig for many helpful discussions, as well as Randy Bank at University of California, San Diego for assistance with PLTMG, and for useful comments concerning this manuscript. Additionally I thank the referees for their helpful input.

NUMERICAL METHODS FOR QUASI-LINEAR ELLIPTIC EQUATIONS WITH NONLINEAR BOUNDARY CONDITIONS*

C. V. PAO†

Abstract. The purpose of this paper is to give a numerical treatment for a class of quasi-linear elliptic equations under nonlinear boundary conditions, including the three basic types of linear boundary conditions. The quasi-linear equation is discretized by the finite difference method, and the method of upper-lower solutions and its associated monotone iteration are used to compute the solutions of the finite difference system. This method leads to monotone iterative schemes for the computation of numerical solutions as well as some comparison results among the monotone iterative schemes. It also leads to the existence of a maximal and a minimal finite difference solution, including the uniqueness of the solution, and the convergence of the finite difference solution to the corresponding continuous solution. Applications are given to two physical problems in heat conduction and combustion theory, and numerical results for the heat-conduction problem are given, and are compared with the known true continuous solution.

Key words. density-dependent reaction diffusion, nonlinear boundary condition, monotone iterative schemes, upper and lower solutions, convergence of finite difference solution, heat conduction

1. Introduction.

Nonlinear elliptic boundary value problems arise from many fields of applied sciences and have been investigated extensively in the literature both analytically and numerically. The analytical consideration is mostly for the existence, uniqueness, multiplicity, and bifurcation of solutions, while the numerical investigation is often devoted to accurate and efficient computational algorithms, error estimates, and convergence of the discrete solution to the corresponding continuous solution of the original problem. In this paper, we investigate some of the numerical aspects for a class of quasi-linear elliptic equations under nonlinear boundary conditions, including the three basic types of linear boundary conditions: Dirichlet, Neumann, and Robin. The class of quasi-linear boundary problems under consideration is given in the form

$$\begin{aligned} -\nabla\cdot(D(u)\nabla u) \;+\; \boldsymbol{c}(x)\cdot(D(u)\nabla u) \;&=\; f(x,u) \quad (x\in\Omega), \\ D(u)\partial u/\partial\nu \;&=\; g(x,u) \qquad\qquad\quad (x\in\partial\Omega), \end{aligned} \tag{1.1}$$

where Ω is a bounded domain in $\mathbb{R}^p$ with boundary $\partial\Omega (p = 1, 2, \ldots)$, ∇ is the gradient operator in Ω, and $\partial u/\partial\nu$ denotes the outward normal derivative of u on $\partial\Omega$. The vector $\boldsymbol{c}(x) = (c^{(1)}(x), \ldots, c^{(p)}(x))$ and the functions $D(u)$, $f(x,u)$, and $g(x,u)$ (which, in general, are nonlinear in u) are prescribed continuous functions of their respective arguments. In terms of reaction diffusion problems, the three terms in the quasi-linear equation of (1.1) are referred to as diffusion, convection, and reaction, respectively. It is assumed that $D(u) > 0$ for u in a subset $\mathcal{S}_0$ of $\mathbb{R}^1$(see (2.12)), but we allow $D(u) = 0$ at $u = 0$ for homogeneous Dirichlet boundary condition in (1.1a) below. This assumption implies that problem (1.1a) may be degenerate at the boundary points when the boundary condition is of Dirichlet type. The consideration

†Department of Mathematics, North Carolina State University, Raleigh, NC 27695-8205 (cvpao@math.ncsu.edu).

of the boundary condition in (1.1) includes the Neumann or Robin type

$$\partial u/\partial \nu + \beta(x)u = g^*(x,u) \quad (x \in \partial\Omega),$$

where $\beta(x) \geq 0$ on $\partial\Omega$. In fact, the above boundary condition, including the linear case $g^*(x,u) = g^*(x)$, can be written in the form of (1.1) with $g(x,u) = D(u)(g^*(x,u) - \beta(x)u)$. The above nonlinear boundary condition has been given considerable attention in the literature, and various special forms of the nonlinear functions were treated (cf. [13, 17, 21, 23, 25, 31]). In order to include all three basic types of linear boundary conditions, we also consider the Dirichlet boundary condition

$$u(x) = \xi(x) \qquad (x \in \partial\Omega) \tag{1.1a}$$

and refer to this problem as problem (1.1a). It is to be noted that if the diffusion coefficient $D(u)$ is replaced by the more general function $b(x)D(u)$ for a smooth function $b(x)$ in Ω, then problem (1.1) can be reduced to the same form except with the convection coefficient $\boldsymbol{c}$ replaced by $(\boldsymbol{c} + \nabla b)$. Hence our investigation in the following discussions is directly applicable to the above more general equation without any complication.

Numerical treatment of the quasi-linear boundary problem (1.1) is extensive, and various aspects of the problem, such as method of computation, error estimate, and convergence of discrete solution, have been discussed (cf. [2, 8, 11, 15, 16, 18, 19, 32, 35]). There is also extensive numerical treatment for the corresponding time-dependent problem (cf. [1, 6, 9, 26, 34]). However, most of the treatments in these works are devoted either to semilinear equations where the diffusion coefficient is density independent or to quasi-linear equations with linear boundary conditions. The papers in [23, 26, 29] are for semilinear equations with linear boundary conditions where monotone iterative methods are used to develop computational algorithms. The same method is used in [25] for semilinear equations with nonlinear boundary conditions and in [26, 34] for time-dependent problems. On the other hand, the treatment in [2, 8, 11, 15, 16, 18, 19, 20, 35] is for linear Dirichlet or Neumann boundary condition, and most of the discussions are concerned with error estimates of solutions using the finite element method. In the above works, a unique solution to the problem is often assumed to exist, although the existence of more than one solution for nonlinear elliptic boundary problems occurs often in many physical problems (cf. [23]).

In this paper, we use the method of upper and lower solutions and its associated monotone iteration for the computation of numerical solutions of problems (1.1) and (1.1a). Our approach to the problem is to formulate it as a coupled system of a semilinear elliptic equation and an algebraic equation and then to develop monotone iterative schemes for the corresponding discrete system by the finite difference method (see also Remark 3.1). This approach makes it possible to apply the ideas and techniques for semilinear equations to the present quasi-linear boundary problems. The purpose of this paper is (i) to present three monotone iterative schemes (called Picard, Gauss–Seidel, and Jacobi iterations, respectively) for the computation of solutions of the finite difference system, including the existence of maximal and minimal solutions, and some comparison theorems among the three monotone iterations, and (ii) to show the convergence of the finite difference solution to the corresponding continuous solution as the mesh size tends to zero. Applications are given to some physical problems in heat transfer and combustion theory, and numerical results are given to some heat-conduction problems.

The plan of the paper is as follows: In section 2, we formulate the quasi-linear boundary problem (1.1) (or (1.1a)) as a coupled system of semilinear boundary problem and an algebraic equation and then develop a Picard type of monotone iteration for the finite difference system of the coupled equations. The Gauss–Seidel and Jacobi iterations are given in section 3, and some comparison theorems among these monotone iterations are given in section 4. Section 5 is devoted to the convergence of the maximal and minimal solutions to the corresponding maximal and minimal solutions of the continuous system. In section 6, we give some applications of the monotone iterations to some heat-conduction problems. Some numerical results with (and without) a known continuous solution are given in section 7 to demonstrate the monotone property of the iterative schemes and the reliability of the numerical computations.

2. A Picard-type monotone iteration. In order to develop computational schemes for numerical solutions of (1.1) or (1.1a), we form the problem as a coupled system of a semilinear elliptic boundary value problem and an algebraic equation. Define

$$w(x) \quad = \quad \int_0^{u(x)} D(s)ds \quad (x \in \overline{\Omega}). \tag{2.1}$$

Then $\nabla w = D(u)\nabla u$ and $\partial w/\partial \nu = D(u)\partial u/\partial \nu$. Since $dw/du = D(u)$, we see that if $D(u) > 0$ for $u \in \mathcal{S}_0$, then the inverse function of (2.1), denoted by $u = q(w)$, exists and $dq/dw = 1/D(u)$. Hence problem (1.1) may be written in the equivalent form

$$\begin{aligned} &-\nabla^2 w + \boldsymbol{c}\cdot\nabla w = f(x,u), \quad u = q(w) \quad (x \in \Omega), \\ &\partial w/\partial \nu = g(x,u) \qquad\qquad\qquad\quad (x \in \partial\Omega). \end{aligned} \tag{2.2}$$

Let $\gamma^{(l)}(x)$, $l = 1, 2$, be some nonnegative functions to be chosen, and define

$$\begin{aligned} F(x,u) \quad &= \quad f(x,u) + \gamma^{(1)}(x)\int_0^u D(s)ds \quad (x \in \Omega), \\ G(x,u) \quad &= \quad g(x,u) + \gamma^{(2)}(x)\int_0^u D(s)ds \quad (x \in \partial\Omega). \end{aligned} \tag{2.3}$$

Then, by adding $\gamma^{(1)}w$ and $\gamma^{(2)}w$ on both sides of the respective equations in (2.2) and using the relation (2.1), we obtain the equivalent system

$$\begin{aligned} &-\nabla^2 w + \boldsymbol{c}\cdot\nabla w + \gamma^{(1)}w = F(x,u), \quad u = q(w) \quad (x \in \Omega), \\ &\partial w/\partial \nu + \gamma^{(2)}w = G(x,u) \qquad\qquad\qquad\quad (x \in \partial\Omega). \end{aligned} \tag{2.4}$$

For the Dirichlet problem (1.1a), we replace the boundary condition in (2.4) (or (2.2)) by

$$w(x) \quad = \quad \int_0^{\xi(x)} D(s)ds \equiv \xi^*(x) \quad (x \in \partial\Omega) \tag{2.4a}$$

and refer to this system as problem (2.4a). It is obvious that u is a solution of (1.1) (resp., (1.1a)) if and only if (u, w) is a solution of (2.4) (resp., (2.4a)). Although the above system can be written as an uncoupled boundary value problem in w, we find it more convenient to treat it as a coupled system. In fact, our discretized system for numerical solutions is based on the form (2.4) or (2.4a).

Let $i = (i_1, \dots, i_p)$ be a multiple index with $i_\nu = 1, \dots, M_\nu$, and let $x_i = (x_{i_1}, \dots, x_{i_p})$ be a mesh point on $\overline{\Omega} \equiv \Omega \cup \partial\Omega$, where $\nu = 1, \dots, p$ and M_ν is the total number of intervals in the x_ν-direction. Denote by Λ, $\partial\Lambda$, and $\overline{\Lambda}$ the sets of mesh points of Ω, $\partial\Omega$, and $\overline{\Omega}$, respectively, and when no confusion arises we write $i \in \Lambda'$ when $x_i \in \Lambda'$, where Λ' stands for Λ, $\partial\Lambda$, or $\overline{\Lambda}$. Let h_ν be the spatial increment in the x_ν-direction, and let $u_i = u(x_i)$, $w_i = w(x_i)$, and $\boldsymbol{c}_i = (c^{(1)}(x_i), \dots, c^{(p)}(x_i))$. Define

$$\begin{aligned} &D(u_i) = D(u(x_i)), && q(w_i) = q(w(x_i)), \\ &F_i(u_i) = F(x_i, u(x_i)), && G_i(u_i) = G(x_i, u(x_i)). \end{aligned} \tag{2.5}$$

Then, by the central difference approximations

$$\begin{aligned} \Delta_p[w_i] &\equiv \sum_{\nu=1}^{p} \Delta^{(\nu)} w_i \equiv \sum_{\nu=1}^{p} h_\nu^{-2}[w(x_i + h_\nu e_\nu) - 2w(x_i) + w(x_i - h_\nu e_\nu], \\ \boldsymbol{c}_i \cdot \delta_p[w_i] &= \sum_{\nu=1}^{p} (c^{(\nu)}(x_i)/2h_\nu)[w(x_i + h_\nu e_\nu) - w(x_i - h_\nu e_\nu)] \end{aligned} \tag{2.6}$$

and the boundary approximation

$$\hat{B}[w_0] \quad = \quad [w(x_0) - w(\hat{x})]/|x_0 - \hat{x}| \quad (x_0 \in \overline{\Lambda}), \tag{2.7}$$

where e_ν is the unit vector in $\mathbb{R}^p$ with the νth component one and zero elsewhere and $\hat{x}$ is a suitable neighboring point of x_0 in Λ, we approximate (2.4) by the finite difference system

$$\begin{aligned} &-\Delta_p[w_i] + \boldsymbol{c}_i \cdot \delta_p[w_i] + \gamma_i^{(1)} w_i = F_i(u_i), \quad u_i = q(w_i) \quad (i \in \Lambda), \\ &\hat{B}[w_i] + \gamma_i^{(2)} w_i = G_i(u_i) \qquad\qquad\qquad\qquad (i \in \partial\Lambda). \end{aligned} \tag{2.8}$$

For the Dirichlet problem (2.4a), the boundary condition in (2.8) is replaced by

$$w_i = \xi_i^* \qquad (i \in \partial\Lambda), \tag{2.8a}$$

and the corresponding finite difference system is referred to as problem (2.8a). Although the boundary approximation in (2.7) can be approximated by a suitable central differencing scheme, the present formulation is more convenient in the discussion for the general multidimensional domain Ω (cf. [3, 12, 27, 29]).

To develop monotone iterative schemes for the solution of (2.8) or (2.8a), we impose the following basic hypothesis:

(H_1) (i) $D(u) > 0$ for $u \in \mathcal{S}_0$ and $h_\nu < |c^{(\nu)}(x_i)|^{-1}$ for $x_i \in \Lambda$ and $\nu = 1, \dots, p$.

(ii) $f(\cdot, u)$ and $g(\cdot, u)$ are C^1-functions of u, and there exist nonnegative functions $\gamma^{(1)}(x)$, $\gamma^{(2)}(x)$, not both identically zero, such that

$$\begin{aligned} \gamma^{(1)}(x) D(u) + f_u(x, u) \quad &\geq \quad 0, \\ &\text{for} \quad u \in \mathcal{S}_0 \quad (x \in \Omega, x' \in \partial\Omega), \\ \gamma^{(2)}(x') D(u) + g_u(x', u) \quad &\geq \quad 0, \end{aligned} \tag{2.9}$$

where $\mathcal{S}_0$ is a sector in $\mathbb{R}^1$ given by (2.12) below. It is clear that condition (2.9) is trivially satisfied (with $\gamma^{(1)}(x) = \gamma^{(2)}(x) = 0$) if $f(\cdot, u)$ and $g(\cdot, u)$ are either independent of u or nondecreasing in u for $u \in \mathcal{S}_0$. It is also satisfied by any functions $\gamma^{(1)}(x)$, $\gamma^{(2)}(x)$ satisfying

$$\gamma^{(1)}(x) \geq -f_u(x, u)/d_0, \quad \gamma^{(2)}(x') \geq -g_u(x', u)/d_0 \quad (u \in \mathcal{S}_0)$$

if $D(u) \geq d_0 > 0$ for $u \in \mathcal{S}_0$. Hence condition (2.9) is needed only for the degenerate case $D(0) = 0$, and $f(\cdot, u)$ and $g(\cdot, u)$ are not nondecreasing in u. Since, by (2.3),

$$\begin{aligned} F_u(x,u) &= f_u(x,u) + \gamma^{(1)}(x)D(u), \\ G_u(x,u) &= g_u(x,u) + \gamma^{(2)}(x)D(u), \end{aligned} \tag{2.10}$$

condition (2.9) implies that $F(\cdot, u)$ and $G(\cdot, u)$ are nondecreasing in u for $u \in \mathcal{S}_0$. The subset $\mathcal{S}_0$ is the sector between a pair of upper and lower solutions which are defined by the following.

DEFINITION 2.1. *A function $(\tilde{u}_i, \tilde{w}_i)$ is called an upper solution of* (2.8) *if*

$$\begin{aligned} &-\Delta_p[\tilde{w}_i] + \boldsymbol{c}_i \cdot \delta_p[\tilde{w}_i] + \gamma_i^{(1)}\tilde{w}_i \geq F_i(\tilde{u}_i), \quad \tilde{u}_i \geq q(\tilde{w}_i) \quad (i \in A), \\ &\hat{B}[\tilde{w}_i] + \gamma_i^{(2)}\tilde{w}_i \geq G_i(\tilde{u}_i) \qquad\qquad\qquad\qquad\quad (i \in \partial\Lambda). \end{aligned} \tag{2.11}$$

Similarly, $(\hat{u}_i, \hat{w}_i)$ is called a lower solution if it satisfies (2.11) *with the inequalities reversed. The pair $(\tilde{u}_i, \tilde{w}_i)$, $(\hat{u}_i, \hat{w}_i)$ is said to be ordered if $(\tilde{u}_i, \tilde{w}_i) \geq (\hat{u}_i, \hat{w}_i)$ for every $i \in \overline{\Lambda}$.*

For the Dirichlet problem (2.8a), the inequalities for $\tilde{w}_i$ and $\hat{w}_i$ on the boundary in (2.11) are replaced by

$$\tilde{w}_i \geq \xi_i^* \geq \hat{w}_i \qquad (i \in \partial\Lambda). \tag{2.11a}$$

It is obvious from the above definition that a solution (u_i, w_i) of (2.8) (or (2.8a)) is an upper solution as well as a lower solution of the corresponding problem. For a given pair of ordered upper and lower solutions, we set

$$\begin{aligned} \mathcal{S}_0 &= \{u_i \in \mathbb{R}^1; \hat{u}_i \leq u_i \leq \tilde{u}_i\}, \\ \mathcal{S} &= \{(u_i, w_i) \in \mathbb{R}^2; (\hat{u}_i, \hat{w}_i) \leq (u_i, w_i) \leq (\tilde{u}_i, \tilde{w}_i)\}. \end{aligned} \tag{2.12}$$

Also, for notational convenience, we define the linear operators

$$\begin{aligned} &L[w_i] = -\Delta_p[w_i] + \boldsymbol{c}_i \cdot \delta_p[w_i] + \gamma_i^{(1)}w_i \quad (i \in \Lambda), \\ &B[w_i] = \hat{B}[w_i] + \gamma_i^{(2)}w_i \qquad\qquad\qquad\quad (i \in \partial\Lambda). \end{aligned} \tag{2.13}$$

Using $\tilde{u}_i$ or $\hat{u}_i$ as an initial iteration, we can construct a sequence $\{u_i^{(m)}, w_i^{(m)}\}$ from the Picard type of iteration process

$$\begin{aligned} &L[w_i^{(m)}] = F_i(u_i^{(m-1)}) \quad (i \in \Lambda), \\ &B[w_i^{(m)}] = G_i(u_i^{(m-1)}) \quad (i \in \partial\Lambda), \\ &u_i^{(m)} = q(w_i^{(m)}) \qquad\quad (i \in \overline{\Lambda}), \qquad m = 1, 2, \ldots. \end{aligned} \tag{2.14}$$

For the Dirichlet problem (2.8a), the boundary condition in (2.14) is replaced by

$$w_i^{(m)} = \xi_i^* \qquad (i \in \partial\Lambda), \qquad m = 1, 2, \ldots. \tag{2.14a}$$

It is clear from (2.14) (with $m = 1$) that starting from any $u^{(0)}$ we can compute $w_i^{(1)}$ from the first two equations in (2.14) because $F_i(u^{(0)})$ and $G_i(u^{(0)})$ are known. Using the value of $w^{(1)}$ in the third equation of (2.14) gives $u_i^{(1)}$. Continuation of this process shows that the sequence $\{u^{(m)}, w^{(m)}\}$ is well defined and can be computed

from (2.14) for every $m = 1, 2, \ldots$. The same is true for the Dirichlet problem (2.14a). Denote the sequence by $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$ if $u_i^{(0)} = \tilde{u}_i$ and by $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ if $u_i^{(0)} = \hat{u}_i$, and refer to them as maximal and minimal sequences, respectively. Our aim is to show that each of these sequences converges monotonically to a solution of (2.8) or (2.8a), respectively. For this purpose, we state the following well-known positivity lemma (e.g., see [24]).

LEMMA 2.1. *Let hypothesis* (H_1) *hold, and let* $\gamma_i^{(l)} \geq 0$, $l = 1, 2$. *If* z_i *satisfies*

$$L[z_i] \geq 0 \quad \text{in} \quad \Lambda, \quad B[z_i] \geq 0 \quad \text{on} \quad \partial\Lambda, \tag{2.15}$$

and $\gamma_i^{(1)} + \gamma_i^{(2)} > 0$ *for at least one* $i \in \overline{\Lambda}$, *then either* $z_i > 0$ *in* Λ *or* $z_i \equiv 0$ *on* $\overline{\Lambda}$. *The same conclusion holds if*

$$L[z_i] \geq 0 \quad \text{in} \quad \Lambda, \quad z_i \geq 0 \quad \text{on} \quad \partial\Lambda \tag{2.16}$$

without the requirement of $\gamma_i^{(1)} + \gamma_i^{(2)} > 0$ *for some* i.

Lemma 2.1 is a discrete version of the maximum principle and is useful for proving the following monotone property of the maximal and minimal sequences.

LEMMA 2.2. *Under the hypothesis* (H_1), *the sequences* $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ *governed by* (2.14) *or* (2.14a) *possess the monotone property*

$$(\underline{u}_i^{(m)}, \underline{w}_i^{(m)}) \leq (\underline{u}_i^{(m+1)}, \underline{w}_i^{(m+1)}) \leq (\overline{u}_i^{(m+1)}, \overline{w}_i^{(m+1)}) \leq (\overline{u}_i^{(m)}, \overline{w}_i^{(m)}) (i \in \overline{\Lambda}) \tag{2.17}$$

for every $m = 0, 1, 2, \ldots$.

Proof. Let $\overline{z}_i^{(0)} = \overline{w}_i^{(0)} - \overline{w}_i^{(1)} \equiv \tilde{w}_i - \overline{w}_i^{(1)}$. By (2.11), (2.13), and (2.14),

$$\begin{aligned} L[\overline{z}_i^{(0)}] &= (-\Delta_p[\tilde{w}_i] + \boldsymbol{c}_i \cdot \delta_p[\tilde{w}_i] + \gamma_i^{(1)}\tilde{w}_i) - F_i(\tilde{u}_i) \geq 0, \\ B[\overline{z}_i^{(0)}] &= (\hat{B}[\tilde{w}_i] + \gamma_i^{(2)}\tilde{w}_i) - G_i(\tilde{u}_i) \geq 0. \end{aligned}$$

In view of Lemma 2.1, we have $\overline{z}_i^{(0)} \geq 0$, which gives $\overline{w}_i^{(0)} \geq \overline{w}_i^{(1)}$. Since $q(w_i)$ is nondecreasing in w_i, the above result and (2.11) imply that

$$\overline{u}_i^{(0)} - \overline{u}_i^{(1)} = \tilde{u}_i - q(\overline{w}^{(1)}) \geq \tilde{u}_i - q(\tilde{w}_i) \geq 0.$$

This proves $(\overline{u}_i^{(0)}, \overline{w}_i^{(0)}) \geq (\overline{u}_i^{(1)}, \overline{w}_i^{(1)})$. A similar argument gives $(\underline{u}_i^{(1)}, \underline{w}_i^{(1)}) \geq (\underline{u}_i^{(0)}, \underline{w}_i^{(0)})$. Moreover, by (2.14) and the nondecreasing property of $F_i(u_i)$ and $G_i(u_i)$,

$$\begin{aligned} L[\overline{w}_i^{(1)} - \underline{w}_i^{(1)}] &= F_i(\overline{u}_i^{(0)}) - F_i(\underline{u}_i^{(0)}) \geq 0, \\ B[\overline{w}_i^{(1)} - \underline{w}_i^{(1)}] &= G_i(\overline{u}_i^{(0)}) - G_i(\underline{u}_i^{(0)}) \geq 0. \end{aligned}$$

This leads to $\overline{w}_i^{(1)} \geq \underline{w}_i^{(1)}$. Again the nondecreasing property of $q(w_i)$ gives $\overline{u}_i^{(1)} - \underline{u}_i^{(1)} = q(\overline{w}_i^{(1)}) - q(\underline{w}_i^{(1)}) \geq 0$, which proves $(\overline{u}_i^{(1)}, \overline{w}_i^{(1)}) \geq (\underline{u}_i^{(1)}, \underline{w}_i^{(1)})$. The above conclusions show that (2.17) holds for $m = 0$. Assume, by induction, that (2.17) holds when m is replaced by $(m-1)$. Then, by (2.14),

$$\begin{aligned} L[\overline{w}_i^{(m)} - \overline{w}_i^{(m+1)}] &= F_i(\overline{u}_i^{(m-1)}) - F_i(\overline{u}_i^{(m)}) \geq 0, \\ B[\overline{w}_i^{(m)} - \overline{w}_i^{(m+1)}] &= G_i(\overline{u}_i^{(m-1)}) - G_i(\overline{u}_i^{(m)}) \geq 0. \end{aligned}$$

It follows from Lemma 2.1 that $\overline{w}_i^{(m)} \geq \overline{w}_i^{(m+1)}$. This implies that

$$\overline{u}_i^{(m)} - \overline{u}_i^{(m+1)} = q(\overline{w}_i^{(m)}) - q(\overline{w}_i^{(m+1)}) \geq 0,$$

which proves $(\overline{u}_i^{(m+1)}, \overline{w}_i^{(m+1)}) \leq (\overline{u}_i^{(m)}, \overline{w}_i^{(m)})$. A similar argument yields $(\underline{u}_i^{(m+1)}, \underline{w}_i^{(m+1)}) \geq (\underline{u}_i^{(m)}, \underline{w}_i^{(m)})$ and $(\overline{u}_i^{(m+1)}, \overline{w}_i^{(m+1)}) \geq (\underline{u}_i^{(m+1)}, \underline{w}_i^{(m+1)})$. The conclusion of the lemma follows from the principle of induction. The proof for the Dirichlet problem (2.14a) is similar and is omitted. □

Based on the monotone property (2.17), we have the following conclusion for the nonlinear boundary problem (2.8).

THEOREM 2.1. *Let $(\tilde{u}_i, \tilde{w}_i)$, $(\hat{u}_i, \hat{w}_i)$ be ordered upper and lower solutions of* (2.8)*, and let hypothesis* (H_1) *hold. Then $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$ converges monotonically to a maximal solution $(\overline{u}_i, \overline{w}_i)$ of* (2.8) *in $\mathcal{S}$, while $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ converges monotonically to a minimal solution $(\underline{u}_i, \underline{w}_i)$. Moreover,*

$$\begin{aligned}(\hat{u}_i, \hat{w}_i) \leq (\underline{u}_i^{(m)}, \underline{w}_i^{(m)}) \quad &\leq (\underline{u}_i^{(m+1)}, \underline{w}_i^{(m+1)}) \leq (\underline{u}_i, \underline{w}_i) \leq (\overline{u}_i, \overline{w}_i) \\ \leq (\overline{u}_i^{(m+1)}, \overline{w}_i^{(m+1)}) &\leq (\overline{u}_i^{(m)}, \overline{w}_i^{(m)}) \quad \leq (\tilde{u}_i, \tilde{w}_i), \quad m = 1, 2, \ldots,\end{aligned} \tag{2.18}$$

and if $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$ $(\equiv (u_i^*, w_i^*))$, then (u_i^*, w_i^*) is the unique solution of (2.8) *in $\mathcal{S}$.*

Proof. By the monotone property (2.17), the limits

$$\lim_{m\to\infty} (\overline{u}_i^{(m)}, \overline{w}_i^{(m)}) = (\overline{u}_i, \overline{w}_i), \quad \lim_{m\to\infty} (\underline{u}_i^{(m)}, \underline{w}_i^{(m)}) = (\underline{u}_i, \underline{w}_i) \tag{2.19}$$

exist and satisfy relation (2.18). Letting $m \to \infty$ in (2.14) shows that both $(\overline{u}_i, \overline{w}_i)$ and $(\underline{u}_i, \underline{w}_i)$ are solutions of (2.8). We show that these solutions are the respective maximal and minimal solutions in the sense that if (u_i, w_i) is any other solution of (2.8) in $\mathcal{S}$, then $(\underline{u}_i, \underline{w}_i) \leq (u_i, w_i) \leq (\overline{u}_i, \overline{w}_i)$ on $\overline{\Lambda}$.

Let $\overline{z}_i^{(m)} = \overline{w}_i^{(m)} - w_i$. By (2.8) and (2.14),

$$\begin{aligned}L[\overline{z}_i^{(m)}] &= F_i(\overline{u}_i^{(m-1)}) - F_i(u_i), \\ B[\overline{z}_i^{(m)}] &= G_i(\overline{u}_i^{(m-1)}) - G_i(u_i), \quad m = 1, 2, \ldots.\end{aligned}$$

Since $\hat{u}_i \leq u_i \leq \tilde{u}_i$ and $F_i(u_i)$ and $G_i(u_i)$ are nondecreasing functions of u_i, the above relation for $m = 1$ gives

$$\begin{aligned}L[\overline{z}_i^{(1)}] &= F_i(\tilde{u}_i) - F_i(u_i) \geq 0, \\ B[\overline{z}_i^{(1)}] &= G_i(\tilde{u}_i) - G_i(u_i) \geq 0.\end{aligned}$$

This yields $\overline{w}_i^{(1)} \geq w_i$. Hence $\overline{u}_i^{(1)} - u_i = q(\overline{w}_i^{(1)}) - q(w_i) \geq 0$, which proves $(\overline{u}_i^{(1)}, \overline{w}_i^{(1)}) \geq (u_i, w_i)$. As in the proof of Lemma 2.2, an induction argument shows that $(\overline{u}_i^{(m)}, \overline{w}_i^{(m)}) \geq (u_i, w_i)$ for every m. Letting $m \to \infty$ and using the relation in (2.19) lead to $(\overline{u}_i, \overline{w}_i) \geq (u_i, w_i)$. A similar argument gives $(\overline{u}_i, \overline{w}_i) \leq (u_i, w_i)$, which proves the maximal and minimal property of $(\overline{u}_i, \overline{w}_i)$ and $(\underline{u}_i, \underline{w}_i)$. It is obvious from this property that (u_i^*, w_i^*) is the unique solution of (2.8) in $\mathcal{S}$ if $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$. This proves the theorem. □

To ensure that $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$, it is necessary to impose some additional conditions on $f(\cdot, u)$ and $g(\cdot, u)$. A sufficient condition is given in the following.

(H_2) $f_u(x,u) \le 0$, $g_u(x',u) \le 0$ for $x \in \Omega$, $x' \in \partial\Omega$, $u \in \mathcal{S}_0$, and either $f_u(x,u) < 0$ for some $x \in \Omega$ or $g_u(x',u) < 0$ for some $x' \in \partial\Omega$.

THEOREM 2.2. *Let $(\tilde{u}_i, \tilde{w}_i)$, $(\hat{u}_i, \hat{w}_i)$ be ordered upper and lower solutions of* (2.8)*, and let hypotheses* (H_1)*,* (H_2) *hold. Then* $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$ $(\equiv (u_i^*, w_i^*))$ *and* (u_i^*, w_i^*) *is the unique solution of* (2.8) *in* $\mathcal{S}$.

Proof. Since, by (2.1) and (2.3),

$$F_i(u_i) = f_i(u_i) + \gamma_i^{(1)} w_i, \quad G_i(u_i) = g_i(u_i) + \gamma_i^{(2)} w_i,$$

the maximal and minimal solutions $(\overline{u}_i, \overline{w}_i)$, $(\underline{u}_i, \underline{w}_i)$ of (2.8) satisfy the equations

$$\begin{aligned} -\Delta_p[\overline{w}_i] + \boldsymbol{c}_i \cdot \delta_p[\overline{w}_i] &= f_i(\overline{u}_i), \quad \hat{B}[\overline{w}_i] = g_i(\overline{u}_i), \quad \overline{u}_i = q(\overline{w}_i), \\ -\Delta_p[\underline{w}_i] + \boldsymbol{c}_i \cdot \delta_p[\underline{w}_i] &= f_i(\underline{u}_i), \quad \hat{B}[\underline{w}_i] = g_i(\underline{u}_i), \quad \underline{u}_i = q(\underline{w}_i). \end{aligned}$$

A subtraction of the corresponding equations in the above relation and using the nonincreasing property of $f_i(u_i)$, $g_i(u_i)$ in (H_2) lead to

$$\begin{aligned} &-\Delta_p[\underline{w}_i - \overline{w}_i] + \boldsymbol{c}_i \cdot \delta_p[\underline{w}_i - \overline{w}_i] = f_i(\underline{u}_i) - f_i(\overline{u}_i) \ge 0, \\ &\hat{B}[\underline{w}_i - \overline{w}_i] = g_i(\underline{u}_i) - g_i(\overline{u}_i) \ge 0, \\ &\underline{u}_i - \overline{u}_i = q(\underline{w}_i) - q(\overline{w}_i). \end{aligned}$$

Applying Lemma 2.1 to the first two of the above relations gives $\underline{w}_i - \overline{w}_i \ge 0$. By Theorem 2.1, we obtain $\underline{w}_i = \overline{w}_i$, which ensures that $\underline{u}_i = \overline{u}_i$. This proves $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$ and thus the uniqueness of the solution. □

When the nonlinear boundary condition in (2.8) is replaced by the Dirichlet boundary condition (2.8a), the equation for $w_i^{(m)}$ on $\partial\Lambda$ in the iteration process (2.14) is replaced by (2.14a). By using the same argument as that in the proof of Theorems 2.1 and 2.2, we have the following analogous conclusions.

THEOREM 2.3. *Let $(\tilde{u}_i, \tilde{w}_i)$, $(\hat{u}_i, \hat{w}_i)$ be ordered upper and lower solutions of the Dirichlet problem* (2.8a)*, and let hypothesis* (H_1) *hold. Then all the conclusions in Theorem* 2.1 *hold true for the corresponding sequences* $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ *from* (2.14), (2.14a)*. Moreover, the uniqueness result in Theorem* 2.1 *holds if* $f_u(x,u) \le 0$ *for* $x \in \Omega$, $u \in \mathcal{S}_0$.

Proof. The proof follows from the same argument as that in the proof for problem (2.8) and is omitted. □

Remark 2.1. (a) If $D(u) = d_0$ is a positive constant, then all the conclusions in Theorems 2.1–2.3 hold true for the semilinear system (2.8) with $w_i = d_0 u_i$ and $q(w_i) = w_i/d_0$. In this situation, the iteration process (2.14) (or (2.14a)) is reduced to that in [25, 27]. On the other hand, Theorems 2.1 and 2.3 hold true for any $D(u) > 0$ if either $f_i(u_i) = f_i$ or $g_i(u) = g_i$ is independent of u since the requirement in (H_1) is trivially satisfied.

(b) For the uniqueness result in Theorem 2.2, the strict inequality $f_u(x,u) < 0$ for some $x \in \Omega$ or $g_u(x',u) < 0$ for some $x' \in \partial\Omega$ in hypothesis (H_2) is needed. For example, if $f(x,u) = f(x)$, $g(x',u) = g(x')$, and $D(u) = d_0$ are all independent of u, then problem (2.2) has no solution or infinite number of solutions depending on whether $\int_\Omega f(x)dx + d_0 \int_{\partial\Omega} g(x')dx'$ is nonzero or zero. However, for the Dirichlet problem (2.8a), this requirement is not needed.

(c) For each m, $(\overline{u}_i^{(m)}, \overline{w}_i^{(m)})$ is an upper bound of the maximal solution $(\overline{u}_i, \overline{w}_i)$, while $(\underline{u}_i^{(m)}, \underline{w}_i^{(m)})$ is a lower bound of the minimal solution $(\underline{u}_i, \underline{w}_i)$, and if $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$ $(\equiv (u_i^*, w_i^*))$, then they become upper and lower bounds of (u_i^*, w_i^*). In the latter situation, the difference $(\overline{u}_i^{(m)} - \underline{u}_i^{(m)}, \overline{w}_i^{(m)} - \underline{w}_i^{(m)})$ gives a maximum possible error of the solution and is often used as a stopping criterion in practical computation.

(d) In the hypothesis $(H_1) - (i)$, it is assumed that $h_\nu < |c^{(\nu)}(x_i)|^{-1}$ for $\nu = 1, \ldots, p$. If the convection coefficient $|\boldsymbol{c}|$ is extremely large (that is, convection dominate diffusion), then the conclusions in Theorems 2.1–2.3 remain true, provided that an upwind differencing scheme is used for the convection term $\boldsymbol{c} \cdot \nabla w$ (cf. [3, 12]).

3. Gauss–Seidel and Jacobi monotone iterations. In the Picard-type iteration (2.14), it is necessary to solve a linear algebraic system for each iteration. Since the number of equations in this system may be very large when the spatial domain Ω is of multiple dimension, it may require another iterative scheme for the computation of the iteration $(u_i^{(m)}, w_i^{(m)})$. To avoid additional iterations while maintaining the monotone convergence of the sequence, we consider two additional iteration processes, called Gauss–Seidel and Jacobi iterations. To describe these iterations, it is more convenient to write the finite difference system (2.8) (or (2.8a)) in vector form.

Let $M = (M_1 - 1) \cdots (M_p - 1)$ be the total number of interior mesh points in Λ. Define (column) vectors

$$\begin{aligned} &U = (u_1, \ldots, u_M)^T, \quad W = (w_1, \ldots, w_M)^T, \quad Q(W) = (q(w_1), \ldots, q(w_M))^T, \\ &F(U) = (F_1(u_1), \ldots, F_M(u_M))^T, \quad G(U) = (G_1(u_1), \ldots, G_M(u_M))^T, \end{aligned} \tag{3.1}$$

where $(\cdot)^T$ denotes the transpose of a row vector. Then the finite difference system (2.8) may be written in the vector form

$$\mathcal{A}W = F(U) + G(U), \quad U = Q(W), \tag{3.2}$$

where $\mathcal{A} = A + \Gamma$. The matrix A is, in general, an M by M block matrix which is associated with the diffusion-convection operator in (2.6) and the boundary approximation in (2.7), and Γ is a nonnegative diagonal matrix with its diagonal elements determined by $\gamma_i^{(1)}$ and $\gamma_i^{(2)}$ (cf. [25, 26, 27]) for some details). For the Dirichlet problem (2.8a), the vector form is given by

$$\mathcal{A}W = F(U) + \boldsymbol{\xi}^*, \quad U = Q(W), \tag{3.2a}$$

where $\boldsymbol{\xi}^*$ is associated with $(\xi_1^*, \ldots, \xi_M^*)^T$. Since our concern here is the mathematical structure of the finite difference system, detailed formulation of the above vector form will not be given here. However, we make the following hypothesis on the matrix A.

(H_3) The matrix $A = (a_{jk})$ is irreducible, and $a_{jj} > 0$, $a_{jk} \le 0$ for $k \ne j$ and

$$\sum_{k=1}^{M} a_{jk} \ge 0 \quad \text{for} \quad \text{all} \quad j = 1, \ldots, M. \tag{3.3}$$

It is easy to show from (2.6) and $h_\nu < |c^{(\nu)}(x_i)|^{-1}$ that for both the Neumann boundary problem (2.8) and the Dirichlet problem (2.8a) the conditions in (H_3) are all satisfied. In fact, for the Dirichlet problem (2.8a), A is symmetric, and strict inequality in (3.3) holds for at least one j, while for the Neumann problem (2.8)

condition (3.3) becomes

$$\sum_{k=1}^{M} a_{jk} = 0 \quad \text{for} \quad \text{all} \quad j = 1, \ldots, M. \tag{3.4}$$

The connectedness of Ω ensures that A is irreducible. The condition in (H_3) implies that A is an M-matrix, and for any nontrivial nonnegative diagonal matrix Γ the inverse $\mathcal{A}^{-1} = (A + \Gamma)^{-1}$ exists and is a positive matrix (cf. [33, 36]). Moreover, the smallest eigenvalue μ_0 of A is nonnegative, and its corresponding eigenvector may be chosen positive. For the boundary problem (2.8a), $\mu_0 > 0$, and A^{-1} exists and is a positive matrix (cf. [33]). In the following discussion, we consider the Dirichlet problem (3.2a) as a special case of (3.2) with $G(U) = \boldsymbol{\xi}^*$ and $\Gamma \equiv \text{diag}(\gamma_1^{(1)}, \ldots, \gamma_M^{(1)})$.

In terms of the above vector form, the definition of upper and lower solutions in Definition 2.1 is reduced to the following.

DEFINITION 3.1. *A vector* $(\tilde{U}, \tilde{W}) \in \mathbb{R}^M \times \mathbb{R}^M$ *is called an upper solution of* (3.2) *if*

$$\mathcal{A}\tilde{W} \geq F(\tilde{U}) + G(\tilde{U}), \quad \tilde{U} \geq Q(\tilde{W}). \tag{3.5}$$

Similarly, $(\hat{U}, \hat{W})$ *is called a lower solution if it satisfies* (3.5) *with the inequalities reversed.*

In the above definition, inequalities between vectors are always in the componentwise sense. It is easy to check that if the components $(\tilde{u}_i, \tilde{w}_i)$, $(\hat{u}_i, \hat{w}_i)$ of $(\tilde{U}, \tilde{W})$ and $(\hat{U}, \hat{W})$ satisfy the requirements in Definition 2.1, then $(\tilde{U}, \tilde{W})$ and $(\hat{U}, \hat{W})$ satisfy the requirements in Definition 3.1. For a given pair of ordered upper and lower solutions $(\tilde{U}, \tilde{W})$, $(\hat{U}, \hat{W})$ (that is, $(\tilde{U}, \tilde{W}) \geq (\hat{U}, \hat{W})$), we again set

$$\begin{aligned} \mathcal{S}_0 &= \{U \in \mathbb{R}^M; \hat{U} \leq U \leq \tilde{U}\}, \\ S &= \{(U, W) \in \mathbb{R}^M \times \mathbb{R}^M; (\hat{U}, \hat{W}) \leq (U, W) \leq (\tilde{U}, \tilde{W})\}. \end{aligned} \tag{3.6}$$

To describe the Gauss–Seidel and Jacobi iterations, we write the matrix $\mathcal{A}$ in the split form $\mathcal{A} = \mathcal{D} - \mathcal{L} - \mathcal{U}$, where $\mathcal{D}$, $-\mathcal{L}$, and $-\mathcal{U}$ are the diagonal, lower-off-diagonal, and upper-off-diagonal submatrices of $\mathcal{A}$, respectively. It is clear from hypothesis (H_3) that all the diagonal elements of $\mathcal{D}$ are positive and all the elements of $\mathcal{L}$ and $\mathcal{U}$ are nonnegative. Define a triangular matrix $\mathcal{G}$ and a diagonal matrix $\mathcal{J}$ by

$$\mathcal{G} = \mathcal{D} + \Gamma - \mathcal{L}, \quad \mathcal{J} = \mathcal{D} + \Gamma. \tag{3.7}$$

Then we have the following three types of iterations:

Picard iteration

$$\mathcal{A}W^{(m)} = F(U^{(m-1)}) + G(U^{(m-1)}), \quad U^{(m)} = Q(W^{(m)}). \tag{3.8}$$

Gauss–Seidel iteration

$$\mathcal{G}W^{(m)} = \mathcal{U}W^{(m-1)} + F(U^{(m-1)}) + G(U^{(m-1)}), \quad U^{(m)} = Q(W^{(m)}). \tag{3.9}$$

Jacobi iteration

$$\mathcal{J}W^{(m)} = (\mathcal{U} + \mathcal{L})W^{(m-1)} + F(U^{(m-1)}) + G(U^{(m-1)}), \quad U^{(m)} = Q(W^{(m)}). \tag{3.10}$$

For the Dirichlet problem (3.2a), we replace $G(U^{(m-1)})$ in (3.8)–(3.10) by $\boldsymbol{\xi}^*$ for every m. It is clear that the Picard iteration (3.8) is simply a vector representation of the iteration process (2.14).

To obtain monotone convergent sequences, we observe from hypothesis (H_3) that the inverse matrices $\mathcal{A}^{-1}$, $\mathcal{G}^{-1}$, and $\mathcal{J}^{-1}$ all exist and are positive matrices (cf. [33, 36]). This implies that given any initial iteration $U^{(0)}$ the sequence $\{U^{(m)}, W^{(m)}\}$ governed by any one of the iteration processes in (3.8), (3.9), and (3.10) is well defined. In each case, we denote the sequences by $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$ if $U^{(0)} = \tilde{U}$, and by $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ if $U^{(0)} = \hat{U}$, and refer to them as maximal and minimal sequences, respectively. The following theorem gives the monotone convergence of these sequences.

THEOREM 3.1. *Let $(\tilde{U}, \tilde{W})$, $(\hat{U}, \hat{W})$ be ordered upper and lower solutions of* (3.2)*, and let $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$, $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ be the maximal and minimal sequences governed by any one of the iteration processes in* (3.8)*,* (3.9)*, and* (3.10)*. Assume that hypotheses (H_1) and (H_3) hold. Then $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$ converges monotonically to a maximal solution $(\overline{U}, \overline{W})$ of* (3.2)*, and $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ converges monotonically to a minimal solution $(\underline{U}, \underline{W})$. Moreover,*

$$
\begin{aligned}
(\hat{U}, \hat{W}) \le (\underline{U}^{(m)}, \underline{W}^{(m)}) \quad &\le (\underline{U}^{(m+1)}, \underline{W}^{(m-1)}) \le (\underline{U}, \underline{W}) \le (\overline{U}, \overline{W}) \\
&\le (\overline{U}^{(m+1)}, \overline{W}^{(m+1)}) \le (\overline{U}^{(m)}, \overline{W}^{(m)}) \quad \le (\tilde{U}, \tilde{W}), \quad m = 1, 2, \ldots,
\end{aligned} \tag{3.11}
$$

and if hypothesis (H_2) holds, then $(\overline{U}, \overline{W}) = (\underline{U}, \underline{W})$ $(\equiv (U^*, W^*))$ and (U^*, W^*) is the unique solution of (3.2) *in $\mathcal{S}$.*

Proof. Since the Picard iteration (3.8) is a vector representation of the iteration process (2.14), the conclusion of the theorem for the Picard iteration follows from Theorems 2.1 and 2.2. We show the monotone property

$$
\begin{aligned}
(\underline{U}^{(m)}, \underline{W}^{(m)}) &\le (\underline{U}^{(m+1)}, \underline{W}^{(m+1)}) \\
&\le (\overline{U}^{(m+1)}, \overline{W}^{(m+1)}) \le (\overline{U}^{(m)}, \overline{W}^{(m)}), \quad m = 0, 1, 2, \ldots,
\end{aligned} \tag{3.12}
$$

for the Gauss–Seidel iteration (3.9). It is obvious from (3.5), (3.9) (with $m = 1$), and $\mathcal{A} = \mathcal{G} - \mathcal{U}$ that

$$
\begin{aligned}
\mathcal{G}(\overline{W}^{(0)} - \overline{W}^{(1)}) &= \mathcal{G}\overline{W}^{(0)} - [\mathcal{U}\overline{W}^{(0)} + F(\overline{U}^{(0)}) + G(\overline{U}^{(0)})] \\
&= A\tilde{W} - F(\tilde{U}) - G(\tilde{U}) \ge 0.
\end{aligned}
$$

The positivity of $\mathcal{G}^{-1}$ implies that $\overline{W}^{(0)} \ge \overline{W}^{(1)}$. Using this relation in the second equation of (3.9) and applying the nondecreasing property of $Q(W)$ yield

$$
\overline{U}^{(0)} - \overline{U}^{(1)} = \tilde{U} - Q(\overline{W}^{(1)}) \ge \tilde{U} - Q(\tilde{W}) \ge 0.
$$

This proves $(\overline{U}^{(1)}, \overline{W}^{(1)}) \le (\overline{U}^{(0)}, \overline{W}^{(0)})$. A similar argument gives $(\underline{U}^{(0)}, \underline{W}^{(0)}) \le (\underline{U}^{(1)}, \underline{W}^{(1)})$. Moreover, by the nonnegative property of $\mathcal{U}$ and the nondecreasing property of $F(U)$ and $G(U)$, we have

$$
\mathcal{G}(\overline{W}^{(1)} - \underline{W}^{(1)}) = \mathcal{U}(\overline{U}^{(0)} - \underline{U}^{(0)}) + F(\overline{U}^{(0)}) - F(\underline{U}^{(0)}) + G(\overline{U}^{(0)}) - G(\underline{U}^{(0)}) \ge 0.
$$

This leads to $\overline{W}^{(1)} \ge \underline{W}^{(1)}$, and therefore $\overline{U}^{(1)} - \underline{U}^{(1)} = Q(\overline{W}^{(1)}) - Q(\underline{W}^{(1)}) \ge 0$. The above conclusions show that (3.12) holds for $m = 0$. Assume, by induction, that

(3.12) is satisfied when m is replaced by $m-1$ for some $m > 1$. Then, again by $\mathcal{U} \geq 0$ and the nondecreasing property of $F(U)$ and $G(U)$,

$$\mathcal{G}(\overline{W}^{(m)} - \overline{W}^{(m+1)}) = \mathcal{U}(\overline{W}^{(m-1)} - \overline{W}^{(m)}) + F(\overline{U}^{(m-1)}) - F(\overline{U}^{(m)}) + G(\overline{U}^{(m-1)}) - G(\overline{U}^{(m)}) \geq 0.$$

This gives $\overline{W}^{(m)} \geq \overline{W}^{(m+1)}$, and hence $\overline{U}^{(m)} - \overline{U}^{(m+1)} = Q(\overline{W}^{(m)}) - Q(\overline{W}^{(m+1)}) \geq 0$, which proves $(\overline{U}^{(m+1)}, \overline{W}^{(m+1)}) \leq (\overline{U}^{(m)}, \overline{W}^{(m)})$. The same reasoning shows that $(\underline{U}^{(m)}, \underline{W}^{(m)}) \leq (\underline{U}^{(m+1)}, \underline{W}^{(m+1)}) \leq (\overline{U}^{(m+1)}, \overline{W}^{(m+1)})$. The monotone property (3.12) follows from the principle of induction.

In view of (3.12), the limits

$$\lim_{m\to\infty} (\overline{U}^{(m)}, \overline{W}^{(m)}) = (\overline{U}, \overline{W}), \quad \lim_{m\to\infty} (\underline{U}^{(m)}, \underline{W}^{(m)}) = (\underline{U}, \underline{W}) \tag{3.13}$$

exist and satisfy relation (3.11). Letting $m \to \infty$ in (3.9) and using the relation $\mathcal{A} = \mathcal{G} - \mathcal{U}$ show that both $(\overline{U}, \overline{W})$ and $(\underline{U}, \underline{W})$ are solutions of (3.2). The maximal property of $(\overline{U}, \overline{W})$ and the minimal property of $(\underline{U}, \underline{W})$ follow from the argument in the proof of Theorem 2.1. Finally, if (H_2) holds, then, by (3.2),

$$\mathcal{A}(\underline{W} - \overline{W}) = [F(\underline{U}) + G(\underline{U})] - [F(\overline{U}) + G(\overline{U})] \geq 0.$$

The positivity of $\mathcal{A}^{-1}$ ensures $\underline{W} \geq \overline{W}$. In view of (3.11), we have $\underline{W} = \overline{W}$. This implies that $\underline{U} - \overline{U} = Q(\underline{W}) - Q(\overline{W}) = 0$, which shows that $(\overline{U}, \overline{W}) = (\underline{U}, \underline{W})$. The uniqueness of the solution in $\mathcal{S}^*$ follows from the maximal and minimal property of $(\overline{U}, \overline{W})$ and $(\underline{U}, \underline{W})$. This proves the theorem for the Gauss–Seidel iteration. The proof for the Jacobi iteration is similar and is omitted. □

For the Dirichlet problem (3.2a), we have the following analogous results.

THEOREM 3.2. *Let $(\tilde{U}, \tilde{W})$, $(\hat{U}, \hat{W})$ be ordered upper and lower solutions of* (3.2a), *and let hypotheses (H_1) and (H_3) hold. Then the maximal and minimal sequences obtained from any one of the iterations in* (3.8), (3.9), *and* (3.10), *where $\mathcal{G}(U^{(m-1)})$ is replaced by $\boldsymbol{\xi}^*$, possess the convergence property in Theorem* 3.1. *Moreover, the solution is unique in $\mathcal{S}$ if $f_u(x,u) \leq 0$ for $x \in \Omega$, $u \in \mathcal{S}_0$.*

Proof. Since the proof of the theorem is similar to that for Theorem 3.1, we omit the details. □

Remark 3.1. Although the discrete system (3.2a) for the Dirichlet boundary problem is formulated by the finite difference method, the same vector form can also be obtained by the finite element method. It can be shown by a suitable choice of the basis in the finite element method that the matrix A and the function $F(U)$ possess the same property as that given in hypotheses (H_1) and (H_3). Hence all the conclusions in Theorems 2.3 and 3.2 are directly applicable to the corresponding finite element system of the Dirichlet problem (2.8a).

4. Comparison of monotone sequences. In this section, we present some comparison results for the maximal and minimal sequences of the three iterative schemes (3.8), (3.9), and (3.10). The following comparison results among the three monotone iterations are for both the nonlinear boundary condition and Dirichlet boundary condition.

THEOREM 4.1. *Let the conditions in Theorem* 3.1 *be satisfied, and let* $(\{\overline{U}_P^{(m)}, \overline{W}_P^{(m)}\}, \{\underline{U}_P^{(m)}, \underline{W}_P^{(m)}\})$, $(\{\overline{U}_G^{(m)}, \overline{W}_G^{(m)}\}, \{\underline{U}_G^{(m)}, \underline{W}_G^{(m)}\})$, $(\{\overline{U}_J^{(m)}, \overline{W}_J^{(m)}\}, \{\underline{U}_J^{(m)}, \underline{W}_J^{(m)}\})$ *be the maximal-minimal sequences given by* (3.8), (3.9), *and* (3.10), *respectively, where* $(\overline{U}_P^{(0)}, \overline{W}_P^{(0)}) = (\overline{U}_G^{(0)}, \overline{W}_G^{(0)}) = (\overline{U}_J^{(0)}, \overline{W}_J^{(0)}) = (\tilde{U}, \tilde{W})$ *and* $(\underline{U}_P^{(0)}, \underline{W}_P^{(0)}) = (\underline{U}_G^{(0)}, \underline{W}_G^{(0)}) = (\underline{U}_J^{(0)}, \underline{W}_J^{(0)}) = (\hat{U}, \hat{W})$. *Then*

$$\begin{aligned} (\overline{U}_P^{(m)}, \overline{W}_P^{(m)}) &\le (\overline{U}_G^{(m)}, \overline{W}_G^{(m)}) \le (\overline{U}_J^{(m)}, \overline{W}_J^{(m)}), \\ (\underline{U}_P^{(m)}, \underline{W}_P^{(m)}) &\ge (\underline{U}_G^{(m)}, \underline{W}_G^{(m)}) \ge (\underline{U}_J^{(m)}, \underline{W}_J^{(m)}), \quad m = 1, 2, \ldots. \end{aligned} \tag{4.1}$$

Proof. We first prove the theorem for the maximal sequences between Picard and Gauss–Seidel iterations. Let $Z^{(m)} = \overline{W}_G^{(m)} - \overline{W}_P^{(m)}$ for $m = 1, 2, \ldots$. By a subtraction of (3.8) from (3.9) and using the relation $\mathcal{A} = \mathcal{G} - \mathcal{U}$ and $\mathcal{U}(\overline{U}_G^{(m-1)} - \overline{U}_G^{(m)}) \ge 0$, we have

$$\begin{aligned} \mathcal{A}Z^{(m)} &= (\mathcal{G} - \mathcal{U})\overline{W}_G^{(m)} - \mathcal{A}\overline{W}_P^{(m)} \\ &= \mathcal{U}(\overline{W}_G^{(m-1)} - \overline{W}_G^{(m)}) + [F(\overline{U}_G^{(m-1)}) + G(\overline{U}_G^{(m-1)})] \\ &\qquad - [F(\overline{U}_P^{(m-1)}) + G(\overline{U}_P^{(m-1)})] \\ &\ge F(\overline{U}_G^{(m-1)}) - F(\overline{U}_P^{(m-1)}) + G(\overline{U}_G^{(m-1)}) - G(\overline{U}_P^{(m-1)}), \\ \overline{U}_G^{(m)} - \overline{U}_P^{(m)} &= Q(\overline{W}_G^{(m)}) - Q(\overline{W}_P^{(m)}), \quad m = 1, 2, \ldots. \end{aligned} \tag{4.2}$$

Since $\overline{U}_G^{(0)} = \overline{U}_P^{(0)}$, the above relation for $m = 1$ yields $\mathcal{A}Z^{(1)} \ge 0$. This gives $Z^{(1)} \ge 0$ or, equivalently, $\overline{W}_P^{(1)} \le \overline{W}_G^{(1)}$. Using this result in the last equation in (4.2) (with $m = 1$) gives $\overline{U}_G^{(1)} - \overline{U}_P^{(1)} = Q(W_G^{(1)}) - Q(W_P^{(1)}) \ge 0$. This proves $(\overline{U}_P^{(1)}, \overline{W}_P^{(1)}) \le (\overline{U}_G^{(1)}, \overline{W}_G^{(1)})$. Assume $(\overline{U}_P^{(m-1)}, \overline{W}_P^{(m-1)}) \le (\overline{U}_G^{(m-1)}, \overline{W}_G^{(m-1)})$ for some $m > 1$. Then, by (4.2) and the nondecreasing property of $F(U)$ and $G(U)$, we obtain $\mathcal{A}Z^{(m)} \ge 0$, which yields $\overline{W}_P^{(m)} \le \overline{W}_G^{(m)}$. This implies that $\overline{U}_G^{(m)} - \overline{U}_P^{(m)} = Q(\overline{W}_G^{(m)}) - Q(\overline{W}_P^{(m)}) \ge 0$, and therefore $(\underline{U}_P^{(m)}, \underline{W}_P^{(m)}) \le (\overline{U}_G^{(m)}, W_G^{(m)})$. The first inequality in (4.1) for the maximal sequences follows from the principle of induction.

To show the second inequality for the maximal sequences between Gauss–Seidel and Jacobi iterations, we consider $\overline{Z}^{(m)} = \overline{W}_J^{(m)} - \overline{W}_G^{(m)}$ for $m = 1, 2, \ldots$. By a subtraction of (3.9) from (3.10) and using the relation $\mathcal{G} = \mathcal{J} - \mathcal{L}$ and $\mathcal{L}(\overline{W}_J^{(m-1)} - \overline{W}_J^{(m)}) \ge 0$, we obtain

$$\begin{aligned} \mathcal{G}\overline{Z}^{(m)} &= (\mathcal{J} - \mathcal{L})\overline{W}_J^{(m)} - \mathcal{G}\overline{W}_G^{(m)} \\ &= [\mathcal{U}\overline{W}_J^{(m-1)} + \mathcal{L}(\overline{W}_J^{(m-1)} - \overline{W}_J^{(m)}) + F(\overline{U}_J^{(m-1)}) + G(\overline{U}_J^{(m-1)})] \\ &\quad - [\mathcal{U}\overline{W}_G^{(m-1)} + F(\overline{U}_G^{(m-1)}) + G(\overline{U}_G^{(m-1)})] \\ &\ge \mathcal{U}\overline{Z}^{(m-1)} + F(\overline{U}_J^{(m-1)}) - F(\overline{U}_G^{(m-1)}) \\ &\quad + G(\overline{U}_J^{(m-1)}) - G(\overline{U}_G^{(m-1)}), \quad m = 1, 2, \ldots. \end{aligned} \tag{4.3}$$

Since $\overline{U}_J^{(0)} = \overline{U}_G^{(0)}$ and $\overline{W}_J^{(0)} = \overline{W}_G^{(0)}$, the above relation for $m = 1$ gives $\mathcal{G}\overline{Z}^{(1)} \geq 0$. The positivity of $\mathcal{G}^{-1}$ yields $\overline{Z}^{(1)} \geq 0$, that is, $\overline{W}_G^{(1)} \leq \overline{W}_J^{(1)}$. It follows from $\overline{U}_J^{(1)} - \overline{U}_G^{(1)} = Q(\overline{W}_J^{(1)}) - Q(\overline{W}_G^{(1)}) \geq 0$ that $(\overline{U}_G^{(1)}, \overline{W}_G^{(1)}) \leq (\overline{U}_J^{(1)}, \overline{W}_J^{(1)})$. Using the relation (4.3), an induction argument shows that $(\overline{U}_G^{(m)}, \overline{W}_G^{(m)}) \leq (\overline{U}_J^{(m)}, \overline{W}_J^{(m)})$ for every m. This proves the theorem for the maximal sequences. The proof for the minimal sequences is similar and is omitted. □

Remark 4.1. The comparison result in Theorem 4.1 implies that with the same initial iteration, which is either an upper solution or a lower solution, the sequence given by the Picard iteration converges faster than the one given by the Gauss–Seidel iteration, which in turn converges faster than the one by Jacobi iteration. This is true for both the maximal sequence and the minimal sequence. However, the Jacobi iteration is the simplest to use in practical computation, while the Picard iteration may require additional iterations when the size of the system is large.

5. Convergence of finite difference solutions. To investigate the convergence of a finite difference solution of (2.8) to its corresponding continuous solution of (2.4), we make use of a similar monotone iteration process for the continuous problem by the method of upper and lower solutions. To ensure the existence of a classical solution of (2.4), we assume that $f(x,\cdot)$, $g(x,\cdot)$, $\boldsymbol{c}(x)$, and $\gamma^{(l)}(x)$, $l = 1, 2$, are all Hölder continuous in x and hypothesis (H_1) is satisfied. For the Dirichlet problem (2.4a), it is assumed that $\xi^* \in C^{2+\alpha}(\Omega)$, where $C^{m+\alpha}(\Omega)$ $(m = 0, 1, 2, \ldots)$ is the set of functions $C^{(m)}(\Omega)$ that are Hölder continuous in Ω with exponents $\alpha \in (0, 1)$. The product space $C^{(m)}(\Omega') \times C^{(m)}(\Omega')$ is denoted by $\mathcal{C}^{(m)}(\Omega')$, where Ω' stands for Ω, $\partial\Omega$, or $\overline{\Omega}$. Set $|h| = h_1 + \cdots + h_p$, and define

$$\mathcal{L}[w] = -\nabla^2 w + \boldsymbol{c} \cdot \nabla w + \gamma^{(1)} w.$$

Then we have the following similar definition of upper and lower solutions for the continuous problem.

DEFINITION 5.1. *A function* $(\tilde{u}, \tilde{w}) \in \mathcal{C}^{(2)}(\Omega) \cap \mathcal{C}^{(0)}(\overline{\Omega})$ *is called an upper solution of* (2.4) *if*

$$\begin{aligned} &\mathcal{L}[\tilde{w}] \geq F(x, \tilde{u}), \quad \tilde{u} \geq q(\tilde{w}) \quad \textit{in} \quad \Omega, \\ &\partial\tilde{w}/\partial\nu + \gamma^{(2)}\tilde{w} \geq G(x, \tilde{u}) \qquad \textit{on} \quad \partial\Omega. \end{aligned} \tag{5.1}$$

Similarly, $(\hat{u}, \hat{w})$ *is called a lower solution if it satisfies* (5.1) *with the inequalities reversed.*

For the Dirichlet boundary problem (2.4a), the boundary requirement in (5.1) is replaced by

$$\tilde{w}(x) \geq \xi^*(x) \geq \hat{w}(x) \qquad (x \in \partial\Omega). \tag{5.1a}$$

The pair $(\tilde{u}, \tilde{w})$, $(\hat{u}, \hat{w})$ is said to be ordered if $(\tilde{u}, \tilde{w}) \geq (\hat{u}, \hat{w})$. For a given pair of ordered upper and lower solutions, we set

$$\begin{aligned} \mathcal{S}_0^* &\equiv \{u \in C(\overline{\Omega}); \quad \hat{u} \leq u \leq \tilde{u}\}, \\ \mathcal{S}^* &\equiv \{(u, w) \in \mathcal{C}(\overline{\Omega}); \quad (\hat{u}, \hat{w}) \leq (u, w) \leq (\tilde{u}, \tilde{w})\}. \end{aligned} \tag{5.2}$$

Using either $\tilde{u}$ or $\hat{u}$ as an initial iteration, we construct a sequence from the linear iteration process

$$\begin{aligned} &\mathcal{L}[w^{(m)}] = F(x, u^{(m-1)}) && (x \in \Omega), \\ &\partial w^{(m)}/\partial \nu + \gamma^{(2)} w^{(m)} = G(x, u^{(m-1)}) && (x \in \partial\Omega), \\ &u^{(m)} = q(w^{(m)}) && (x \in \overline{\Omega}), \quad m = 1, 2, \ldots . \end{aligned} \tag{5.3}$$

For the Dirichlet problem (2.4a), we replace the boundary condition in (5.3) by

$$w^{(m)}(x) = \xi^*(x) \quad (x \in \partial\Omega), \quad m = 1, 2, \ldots . \tag{5.3a}$$

Denote the sequence by $\{\overline{u}^{(m)}, \overline{w}^{(m)}\}$ if $u^{(0)} = \tilde{u}$ and by $\{\underline{u}^{(m)}, \underline{w}^{(m)}\}$ if $u^{(0)} = \hat{u}$, and refer to them as maximal and minimal sequences, respectively. The following theorem from [28] is analogous to Theorem 2.1.

THEOREM 5.1. *Let $(\tilde{u}, \tilde{w})$, $(\hat{u}, \hat{w})$ be ordered upper and lower solutions of* (2.4) *(or* (2.4a)*, and let hypothesis (H_1) hold. Then $\{\overline{u}^{(m)}, \overline{w}^{(m)}\}$ converges monotonically to a maximal solution $(\overline{u}, \overline{w})$ of* (2.4) *in $\mathcal{S}^*$, while $\{\underline{u}^{(m)}, \underline{w}^{(m)}\}$ converges monotonically to a minimal solution $(\underline{u}, \underline{w})$. Moreover,*

$$\begin{aligned} (\hat{u}, \hat{w}) &\leq (\underline{u}^{(m)}, \underline{w}^{(m)}) \leq (\underline{u}^{(m+1)}, \underline{w}^{(m+1)}) \leq (\underline{u}, \underline{w}) \leq (\overline{u}, \overline{w}) \\ &\leq (\overline{u}^{(m+1)}, \overline{w}^{(m+1)}) \leq (\overline{u}^{(m)}, \overline{w}^{(m)}) \leq (\tilde{u}, \tilde{w}), \quad m = 1, 2, \ldots , \end{aligned} \tag{5.4}$$

and if either hypothesis (H_2) is satisfied or $(\overline{u}, \overline{w}) = (\underline{u}, \underline{w})$ $(\equiv (u^*, w^*))$, then (u^*, w^*) is the unique solution of (2.4)*. The same conclusions hold true for the Dirichlet boundary problem* (2.4a)*.*

Based on Theorems 2.1 and 5.1, we show the convergence of the maximal and minimal finite difference solutions to their respective maximal and minimal solutions of the continuous problem for $x_i \in \overline{\Lambda}^*$, where $\overline{\Lambda}^*$ is a fixed partition of $\overline{\Omega}$. It is assumed that every refinement of $\overline{\Lambda}^*$ contains $\overline{\Lambda}^*$ and there exist ordered upper and lower solutions $((\tilde{u}_i, \tilde{w}_i), (\hat{u}_i, \hat{w}_i))$ and $((\tilde{u}(x), \tilde{w}(x)), (\hat{u}(x), \hat{w}(x)))$ of (2.4) and (2.8), respectively (or (2.4a) and (2.8a), respectively). We also assume that given any $\epsilon > 0$ there exists $\delta > 0$ such that

$$|\tilde{u}(x_i) - \tilde{u}_i| + |\tilde{w}(x_i) - \hat{w}_i| < \epsilon, \ |\hat{u}(x_i) - \hat{u}_i| + |\hat{w}(x_i) - \hat{w}_i| < \epsilon \text{ whenever } |h| < \delta. \tag{5.5}$$

THEOREM 5.2. *Let hypothesis (H_1) and condition* (5.5) *be satisfied, and let $((\overline{u}_i, \overline{w}_i), (\underline{u}_i, \underline{w}_i))$ and $((\overline{u}(x), \overline{w}(x)), (\underline{u}(x), \underline{w}(x)))$ be the respective maximal-minimal solutions of* (2.4) *and* (2.8) *(or* (2.4a) *and* (2.8a)*). Then, as $|h| \to 0$,*

$$(\overline{u}_i, \overline{w}_i) \to (\overline{u}(x_i), \overline{w}(x_i)) \quad \text{and} \quad (\underline{u}_i, \underline{w}_i) \to (\underline{u}(x_i), \underline{w}(x_i)) \tag{5.6}$$

at every point $x_i \in \overline{\Lambda}^*$. The same convergence result holds true for the Dirichlet boundary problem (2.4a) *and* (2.8a)*.*

Proof. It suffices to show that given any $\epsilon' > 0$ there exists $\delta' > 0$ such that for every $x_i \in \overline{\Lambda}^*$

$$|\overline{u}(x_i) - \overline{u}_i| + |\overline{w}(x_i) - \overline{w}_i| < \epsilon', \ |\underline{u}(x_i) - \underline{u}_i| + |\underline{w}(x_i) - \underline{w}_i| < \epsilon' \text{ when } |h| < \delta'. \tag{5.7}$$

We prove (5.7) for the maximal solutions $(\overline{u}(x_i), \overline{w}(x_i))$ and $(\overline{u}_i, \overline{w}_i)$ because the proof for the minimal solutions is similar. Let $\{\overline{u}^{(m)}(x_i), \overline{w}^{(m)}(x_i)\}$, $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$ be the

respective maximal sequences of (2.4) and (2.8). By Theorems 2.1 and 5.1, there exists $m^* \geq 1$ such that for all $m \geq m^*$ and $i \in \overline{\Lambda}^*$

$$|\overline{u}^{(m)}(x_i) - \overline{u}(x_i)| + |\overline{u}_i^{(m)} - \overline{u}_i| < \epsilon'/3, \quad |\overline{w}^{(m)}(x_i) - \overline{w}(x_i)| + |\overline{w}_i^{(m)} - \overline{w}_i| < \epsilon'/3.$$

Since

$$|\overline{u}(x_i) - \overline{u}_i| \leq |\overline{u}(x_i) - \overline{u}^{(m)}(x_i)| + |\overline{u}^{(m)}(x_i) - \overline{u}_i^{(m)}| + |\overline{u}_i^{(m)} - \overline{u}_i|,$$
$$|\overline{w}(x_i) - \overline{w}_i| \leq |\overline{w}(x_i) - \overline{w}^{(m)}(x_i)| + |\overline{w}^{(m)}(x_i) - \overline{w}_i^{(m)}| + |\overline{w}_i^{(m)} - \overline{w}_i|,$$

condition (5.7) is fulfilled if, for some $m \geq m^*$,

$$|\overline{u}^{(m)}(x_i) - \overline{u}_i^{(m)}| + |\overline{w}^{(m)}(x_i) - \overline{w}_i^{(m)}| < \epsilon'/3 \quad \text{when} \quad |h| < \delta'. \tag{5.8}$$

It is easily seen from (5.3) and the central difference and boundary approximations in (2.6) and (2.7) that

$$\begin{aligned} -L[\overline{w}^{(m)}(x_i)] &= F_i(\overline{u}^{(m-1)}(x_i)) + o^{(m)}(|h|) \quad (x_i \in \Lambda^*), \\ B[\overline{w}^{(m)}(x_i')] &= G_i(\overline{u}^{(m-1)}(x_i')) + o^{(m)}(|h|) \quad (x_i' \in \partial\overline{\Lambda}^*), \\ \overline{u}^{(m)}(x_i) &= q(\overline{w}^{(m)}(x_i)) + o^{(m)}(|h|) \quad (x_i \in \Lambda^*), \end{aligned} \tag{5.9}$$

where $o^{(m)}(|h|) \to 0$ as $|h| \to 0$. Let $(v_i^{(m)}, z_i^{(m)}) = (\overline{u}^{(m)}(x_i) - \overline{u}_i^{(m)}, \overline{w}^{(m)}(x_i) - \overline{w}_i^{(m)})$. Then a subtraction of (2.14) from (5.9) gives

$$\begin{aligned} L[z_i^{(m)}] &= F_i(\overline{u}^{(m-1)}(x_i)) - F_i(\overline{u}_i^{(m-1)}) + o^{(m)}(|h|), \\ B[z_i^{(m)}] &= G_i(\overline{u}^{(m-1)}(x_i')) - G_i(\overline{u}_i^{(m-1)}) + o^{(m)}(|h|), \\ v_i^{(m)} &= q(\overline{w}^{(m)}(x_i)) - q(\overline{w}_i^{(m)}) + o^{(m)}(|h|). \end{aligned}$$

In vector form, the above system is equivalent to

$$\begin{aligned} \mathcal{A}Z^{(m)} &= [F(\overline{U}^{(m-1)}(x)) + G(\overline{U}^{(m-1)}(x))] - [F(\overline{U}^{(m-1)}) + G(\overline{U}^{(m-1)})] + O^{(m)}(|h|) \\ V^{(m)} &= Q(\overline{W}^{(m)}(x)) - Q(\overline{W}^{(m)}) + O^{(m)}(|h|), \end{aligned} \tag{5.10}$$

where $Z^{(m)} = (z_1^{(m)}, \ldots, z_M^{(m)})^T$, $\overline{U}^{(m)}(x) = (\overline{u}^{(m)}(x_1), \ldots, \overline{u}^{(m)}(x_M))^T$, etc., and for any convenient norm in $\mathbb{R}^M$, $||O^{(m)}(|h|)|| \to 0$ as $|h| \to 0$. By the positivity of $\mathcal{A}^{-1}$, the above relation implies that

$$\begin{aligned} |Z^{(m)}| &\leq \mathcal{A}^{-1}[(k_f + k_g)|V^{(m-1)}| + |O^{(m)}(|h|)|], \\ |V^{(m)}| &\leq k_q|Z^{(m)}| + |O^{(m)}(|h|)|, \end{aligned} \tag{5.11}$$

where k_f, k_g, and k_q are the Lipschitz constants of $F(U)$, $G(U)$, and $Q(W)$, respectively, and $|Y| = |y_1| + \cdots + |y_M|$ for any vector $Y = (y_1, \ldots, y_M)^T$.

It is well known that given any $\epsilon_1 > 0$ there exist a matrix norm and a vector norm in $\mathbb{R}^M$ such that

$$||\mathcal{A}^{-1}|| \leq (\mu_0 + \overline{\gamma} - \epsilon_1)^{-1} \equiv \sigma, \quad ||\mathcal{A}^{-1}Y|| \leq \sigma||Y||$$

for every $Y \in \mathbb{R}^M$, where μ_0 is the smallest eigenvalue of A and $\overline{\gamma} \equiv \max\{\gamma_i^{(l)}; i = 1, \ldots, M, l = 1, 2\}$ (cf. [36]). Since $\mu_0 \geq 0$, it suffices to choose $\sigma = (\overline{\gamma} - \epsilon)^{-1}$, which

is independent of A and therefore is independent of $|h|$. Using this relation in (5.11) leads to

$$||Z^{(m)}|| \le \sigma(k_f + k_g)||V^{(m-1)}|| + ||O^{(m)}(|h|)||,$$
$$||V^{(m)}|| \le k_q||Z^{(m)}|| + ||O^{(m)}(|h|)||,$$

where $||O^{(m)}(|h|)|| \to 0$ as $|h| \to 0$. For notational convenience, we define

$$r^{(m)} = ||V^{(m)}||, \quad s^{(m)} = ||Z^{(m)}||, \quad c = \max\{k_q, \sigma(k_f + k_g)\}.$$

Then the above inequalities yield

$$\begin{aligned} &s^{(m)} \le cr^{(m-1)} + o(|h|), \\ &r^{(m)} \le cs^{(m)} + o(|h|), \qquad m = 1, 2, \dots, \end{aligned} \tag{5.12}$$

where $o(|h|) = \sup\{||O^{(m)}(|h|)||; m \ge 1\}$.

Consider the case $m = 1$. Since $r^{(0)} = ||V^{(0)}|| = ||\overline{U}^{(0)}(x) - \overline{U}^{(0)}||$ and $\overline{U}^{(0)}(x) = (\tilde{u}(x_1), \dots, \tilde{u}(x_M))^T$, $\overline{U}^{(0)} = (\tilde{u}_1, \dots, \tilde{u}_M)^T$, we see from (5.5) that for any $\epsilon_0 > 0$ there exists $\delta_0 > 0$ such that $O(|h|) < \epsilon_0$ when $|h| < \delta_0$. In view of (5.12), we have

$$s^{(1)} \le cr^{(0)} + o(|h|) \le c\epsilon_0 + \epsilon_0 = (1 + c)\epsilon_0,$$
$$r^{(1)} \le cs^{(1)} + o(|h|) \le c(1 + c)\epsilon_0 + \epsilon_0 = (c^2 + c + 1)\epsilon_0.$$

An induction argument gives

$$s^{(2)} = (c^3 + c^2 + c + 1)\epsilon_0, \qquad r^{(2)} \le (c^4 + c^3 + c^2 + 1)\epsilon_0,$$
$$\vdots$$
$$s^{(m)} = (c^{2m-1} + c^{2m-2} + \cdots + 1)\epsilon_0, \quad r^{(m)} \le (c^{2m} + c^{2m-1} + \cdots + 1)\epsilon_0.$$

Let $m \ge m^*$ be fixed. Then by choosing ϵ_0 sufficiently small there exists $\delta' > 0$ such that $s^{(m)} + r^{(m)} < \epsilon'/3$ when $|h| < \delta'$. This is equivalent to

$$||V^{(m)}|| + ||Z^{(m)}|| < \epsilon'/3 \quad \text{when} \quad |h| < \delta'.$$

The above relation implies that (5.8) holds because the components of $V^{(m)}$ and $Z^{(m)}$ are $(\overline{u}^{(m)}(x_i) - \overline{u}_i^{(m)})$ and $(\overline{w}^{(m)}(x_i) - \overline{w}_i^{(m)})$, respectively. This proves (5.7) for the maximal solutions. Proofs for the minimal solutions and for the Dirichlet problem are similar and are omitted. □

An immediate consequence of Theorem 5.2 is the following result.

THEOREM 5.3. *Let the conditions in Theorem* 5.2 *be satisfied. If hypothesis* (H_2) *holds, then each of the problems* (2.4) *and* (2.8) *has a unique solution* $(u^*(x), w^*(x))$ *and* (u_i^*, w_i^*)*, and at every mesh point* $x_i \in \overline{\Lambda}^*$*,*

$$(u_i^*, w_i^*) \to (u^*(x_i), w^*(x_i)) \quad \textit{as} \quad |h| \to 0. \tag{5.13}$$

The same is true for the Dirichlet problems (2.4a) *and* (2.8a) *if* $f_u(x, u) \le 0$.

6. Application to model problems. In this section, we apply the results of the previous sections to some model problems in heat transfer and chemical engineering as illustrations. In the application of the iterative scheme (2.14) (or (2.14a), we make use of the relation

$$
\begin{aligned}
F_i(u_i^{(m-1)}) &= \gamma_i^{(1)} \int_0^{u_i^{(m-1)}} D(s)ds + f_i(u_i^{(m-1)}) = \gamma_i^{(1)} w_i^{(m-1)} + f_i(u_i^{(m-1)}), \\
G_i(u_i^{(m-1)}) &= \gamma_i^{(2)} \int_0^{u_i^{(m-1)}} D(s)ds + g_i(u_i^{(m-1)}), \\
&= \gamma_i^{(2)} w_i^{(m-1)} + g_i(u_i^{(m-1)}), \quad m = 1, 2, \ldots,
\end{aligned} \tag{6.1}
$$

to obtain an equivalent iterative scheme in the form

$$
\begin{aligned}
L[w_i^{(m)}] &= \gamma_i^{(1)} w_i^{(m-1)} + f_i(u_i^{(m-1)}), \\
B[w_i^{(m)}] &= \gamma_i^{(2)} w_i^{(m-1)} + g_i(u_i^{(m-1)}), \\
u_i^{(m)} &= q(w_i^{(m)}), m = 1, 2, \ldots.
\end{aligned} \tag{6.2}
$$

This form of iteration avoids the computation of the integral term $\int_0^u D(s)ds$ in each iteration, especially when it cannot be given in explicit form. The value of $u_i^{(m)}$ in (6.2) can be solved from the algebraic equation $w_i^{(m)} = D(u_i^{(m)})$ if the inverse function $q(w)$ cannot be explicitly given. For Dirichlet boundary problems, the boundary condition in (6.2) is replaced by

$$
w_i^{(m)} = \xi_i^*, \qquad m = 1, 2, \ldots, \tag{6.2a}
$$

where ξ_i^* is assumed nonnegative.

Some heat-conduction problems. In the heat-conduction problem, the thermal conductivity is often considered temperature dependent, and the boundary or internal source may also be temperature dependent. A frequently assumed form of the source function is based on the so-called Boltzmann fourth-power law, which is given in the form $\sigma(a^4 - u^4)$, where $u \equiv u(x)$ denotes the steady-state temperature distribution, $a \equiv a(x)$ is the surrounding temperature, and σ is a positive constant. This leads to the boundary value problem (1.1) with

$$
f(x, u) = 0, \quad g(x, u) = \sigma(a^4 - u^4) \tag{6.3}
$$

if the fourth-power law applies to the boundary surface and

$$
f(x, u) = \sigma(a^4 - u^4), \quad g(x, u) = 0 \tag{6.4}
$$

if the law applies to the conducting medium (cf. [2, 10, 13, 22, 23]), The above heat-conduction problem, including some numerical aspect and the corresponding time-dependent system, has been investigated by many workers (e.g., see [13, 14, 21, 22, 23, 24, 25]). Although various forms of the thermal conductivity $D(u)$ have been assumed, including the special cases of $D(u) = d_0 + d_1 u$ and $D(u) = e^{\alpha u}$, we need only the positivity of $D(u) \geq d_0 > 0$ in the construction of upper and lower solutions.

It is easy to verify that the functions $f(x, u)$, $g(x, u)$ in either (6.3) or (6.4) satisfy hypotheses (H_1) and (H_2) for $u \geq 0$ (that is, $\mathcal{S}_0 = R^+$). Hence, by Theorems 2.1

and 2.2, the finite difference system (2.8), (6.3) (that is, problem (2.8) with $f(x,u)$, $g(x,u)$ given by (6.3)) has a unique nonnegative solution (u_i, w_i) if there exists a pair of ordered nonnegative upper and lower solutions. The same is true for the system (2.8), (6.4) (or (2.8a), (6.4)). Moreover, by the positivity lemma, Lemma 2.1, for discrete boundary problems, the solution (u_i, w_i) is positive in Λ. Consider the case where $f(x,u)$ and $g(x,u)$ are given by (6.3). It is easy to verify from $f_i(u_i) = 0$, $g_i(0) = \sigma a_i^4 > 0$ and $g_i(\overline{a}) \le 0$ for any constant $\overline{a} \ge \max\{a_i, i \in \overline{\Lambda}\}$ that the pair

$$(\tilde{u}_i, \tilde{w}_i) = (\overline{a}, \overline{a}^*), \quad (\hat{u}_i, \hat{w}_i) = (0,0), \tag{6.5}$$

where $\overline{a}^* = \int_0^{\overline{a}} D(s)ds$, are ordered upper and lower solutions of (2.8), (6.3). By Theorems 2.1 and 2.2, problem (2.8), (6.3) has a unique positive solution (u_i^*, w_i^*) and $(u_i^*, w_i^*) \le (\overline{a}, \overline{a}^*)$.

In order to compute the solution (u_i^*, w_i^*) by any one of the iterative schemes in (3.8), (3.9), and (3.10), we need to find the functions $\gamma^{(1)}(x)$, $\gamma^{(2)}(x)$ that satisfy the condition (2.9) in (H_1). Since $f_u(x,u) = 0$, $g_u(x,u) = -4\sigma u^3$ and $\mathcal{S}_0 = [0, \overline{a}]$, it suffices to choose $\gamma^{(1)} = 0$, $\gamma^{(2)} = 4\sigma\overline{a}^3/d_0$ (or any $\gamma^{(2)} \ge 4\sigma\overline{a}^3/d_0$). Using the above values of $(\gamma^{(1)}, \gamma^{(2)})$ and the functions

$$f_i(u_i^{(m-1)}) = 0, \quad g_i(u_i^{(m-1)}) = \sigma\left[a_i^4 - (u_i^{(m-1)})^4\right] \tag{6.6}$$

in the iteration process (6.2), we can compute the maximal and minimal sequences $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$, where $(\overline{u}_i^{(0)}, \overline{w}_i^{(0)}) = (\overline{a}, \overline{a}^*)$ and $(\underline{u}_i^{(0)}, \underline{w}_i^{(0)}) = (0,0)$. The function $q(w_i)$ in (6.2) is determined from (2.1) and can sometimes be obtained explicitly. For example, if $D(u) = d_0 e^{\alpha u}$ or $D(u) = d_0 + d_1 u$, where d_0 and d_1 are positive constants and $\alpha \ne 0$, then

$$q(w) = \alpha^{-1}\ln[1 + (\alpha/d_0)w] \quad \text{and} \quad q(w) = d_1^{-1}[d_0^2 + 2d_1 w)^{1/2} - d_0], \tag{6.7}$$

respectively. In the special case of the linear function $D(u)$, which will be used in our numerical computations, the equation $u_i^{(m)} = q(w_i^{(m)})$ in (6.2) is given explicitly by

$$u_i^{(m)} \quad = \quad d_1^{-1}[(d_0^2 + 2d_1 w^{(m)})^{1/2} - d_0]. \tag{6.8}$$

By writing the finite difference problem (2.8), (6.3) in the vector form (3.2), we can also compute the maximal and minimal sequences $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$, $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ from either the Gauss–Seidel iteration (3.9) or the Jacobi iteration (3.10), where $(\overline{U}^{(0)}, \overline{W}^{(0)}) = (\overline{a}E, \overline{a}^*E)$, $(\underline{U}^{(0)}, \underline{W}^{(0)}) = (0,0)$, and $E = (1, \ldots, 1)^T \in \mathbb{R}^M$. By Theorem 3.1, these sequences converge monotonically to the unique solution (U^*, W^*), where $U^* = (u_1^*, \ldots, u_M^*)^T$, and $W^* = (w_1^*, \ldots, w_M^*)^T$.

To guarantee the convergence of the finite difference solution of this model, we observe that the pair in (6.5) are also ordered upper and lower solutions of the continuous problem (2.4), (6.3). By Theorem 5.1, the continuous problem (2.4), (6.3) has a unique solution $(u^*(x), w^*(x))$. Since condition (5.5) is trivially satisfied, Theorem 5.2 implies that $(u_i^*, w_i^*) \to (u^*(x_i), w^*(x_i))$ as $|h| \to 0$. To summarize the above conclusions, we have the following.

THEOREM 6.1. *Let $f(x,u)$, $g(x,u)$ be given by* (6.3) *and $D(u) \ge d_0 > 0$, and let $(\overline{u}_i^{(0)}, \overline{w}^{(0)}) = (\overline{a}, \overline{a}^*)$, $(\underline{u}_i^{(0)}, \underline{w}_i^{(0)}) = (0,0)$, and $(\gamma_i^{(1)}, \gamma_i^{(2)}) = (0, 4\sigma\overline{a}^3/d_0)$, where $\overline{a} \ge a(x)$ on $\overline{\Omega}$. Then the following statements hold true for the problem* (2.8), (6.3)*:*

(i) *A unique positive solution (u_i^*, w_i^*) exists and is bounded by $(\overline{a}, \overline{a}^*)$.*

(ii) *The maximal sequence* $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$ *from* (6.2) *converges monotonically from above to* (u_i^*, w_i^*), *while the minimal sequence* $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ *converges monotonically from below to* (u_i^*, w_i^*).

(iii) *In vector form, the sequences* $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$, $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ *given either by* (3.9) *or by* (3.10) *converge monotonically to the unique solution* (U^*, W^*).

(iv) *As* $|h| \to 0$, *the finite difference solution* (u^*, w^*) *converges to the continuous solution* $(u^*(x_i), w^*(x_i))$ *at every mesh point* $x_i \in \Lambda^*$.

We next consider the case where $f(x,u)$ and $g(x,u)$ are given by (6.4). It is easy to verify that the pair in (6.5) are also ordered upper and lower solutions of (2.8), (6.4). This leads to the choice of $(\gamma_i^{(1)}, \gamma_i^{(2)}) = (4\sigma\overline{a}^3/d_0, 0)$, which ensures that condition (2.9) is satisfied. With this value of $(\gamma_i^{(1)}, \gamma_i^{(2)})$ and the functions

$$f_i(u_i^{(m-1)}) = \sigma[a_i^4 - (u_i^{(m-1)})^4], \quad g_i(u_i^{(m-1)}) = 0 \tag{6.9}$$

in the iteration process (6.2), we compute the maximal and minimal sequences $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ as in the previous problem. In the special case of $D(u) = d_0 + d_1 u$, the equation $u_i^{(m)} = q(w_i^{(m)})$ is given by (6.8). As a consequence of the theorems in the previous sections, we have the following conclusion.

THEOREM 6.2. *Let* $f(x,u)$, $g(x,u)$ *be given by* (6.4) *and* $D(u) \geq d_0 > 0$, *and let* $(\overline{u}_i^{(0)}, \overline{w}_i^{(0)}) = (\overline{a}, \overline{a}^*)$, $(\underline{u}_i, \underline{w}_i) = (0,0)$, *and* $(\gamma_i^{(1)}, \gamma_i^{(2)}) = (4\sigma\overline{a}^3/d_0, 0)$. *Then all the conclusions in* (i)–(iv) *of Theorem* 6.1 *hold true for problem* (2.8), (6.4).

If the boundary condition in (2.8), is replaced by (2.8a), where $0 \leq \xi_i^* \leq \overline{a}^*$ (that is, $0 \leq \xi_i \leq \overline{a}$), then the pair in (6.4) are ordered upper and lower solutions of problem (2.8a), (6.4), and therefore the choice of $(\gamma_i^{(1)}, \gamma_i^{(2)})$ remains the same. The only difference in the iteration process (6.2) is that the boundary condition should be replaced by (6.2a). In vector form, the function $G(U^{(m-1)})$ in (3.9) and (3.10) should be replaced by $\boldsymbol{\xi}^* \equiv (\xi_1^*, \ldots, \xi_M^*)^T$. This observation leads to the following.

THEOREM 6.3. *Let the conditions in Theorem* 6.2 *be satisfied for the problem* (2.8a), (6.4), *where* $0 \leq \xi_i^* \leq \overline{a}^*$, *and let the boundary condition in* (6.2) *be replaced by* (6.2a). *In vector form, let* $G(U^{(m-1)})$ *in* (3.9) *and* (3.10) *be replaced by* $\boldsymbol{\xi}^*$. *Then all the conclusions in* (i)–(iv) *of Theorem* 6.1 *hold true for the Dirichlet problem* (2.8a), (6.4).

A chemical reactor problem. In a nonisothermal chemical reactor with first-order reaction, if the diffusion coefficient is density dependent, then the equation governing the steady-state chemical concentration $u(x)$ is given by (1.1) with

$$f(x,u) = \sigma(1-u)\exp[\gamma u/(1+u)], \quad g(x,u) = -\beta(x)u, \tag{6.10}$$

where σ and γ are positive constants and $\beta(x) \geq 0$ on $\partial\Omega$ (cf. [4, 5, 7, 10, 23, 27, 30]). This implies that the boundary condition of this model problem is given by the Robin type

$$\mathcal{D}(u)\partial u/\partial\nu + \beta(x)u = 0 \quad (x \in \partial\Omega).$$

Problem (1.1), (6.10) also describes the temperature distribution in a combustible material and has been investigated by many workers in combustion theory (see [10] and the references therein). It is obvious that for any $D(u) \geq d_0 > 0$, condition (2.9) in (H_1) is satisfied by some $(\gamma^{(1)}, \gamma^{(2)})$. Unlike the heat-conduction problem, this model may have multiple positive solutions depending on the parameters of σ and γ.

In fact, it is known that in the case of constant diffusion coefficient $D(u) = d_0$ this problem has a unique solution if σ and γ are either small or large, and it has two or more positive solutions if σ and γ have certain intermediate values (see [23, p. 124] and [27] for some numerical results). Since, by (6.10),

$$f(x,0) = \sigma > 0, \quad g(x,0) = 0 \quad \text{and} \quad f(x,1) = 0, \quad g(x,1) \le 0,$$

Definition 2.1 implies that for any constant $\overline{a} \ge 1$ the pair in (6.5) are ordered upper and lower solutions of problem (2.8), (6.10). To find $(\gamma_i^{(1)}, \gamma_i^{(2)})$, we observe from (6.10) that

$$\begin{aligned} f_u(x,u) &= -\sigma(1+u)^{-2}\exp[(\gamma u/(1+u))][u^2 + (2+\gamma)u + (u-\gamma)], \\ g_u(x,u) &= -\beta(x). \end{aligned} \tag{6.11}$$

This implies that $-f_u(x,u) \le 4\sigma e^{\gamma}$ for $0 \le u \le 1$. Hence, by choosing $\overline{a} = 1$, we see that condition (2.9) holds for any $\gamma_i^{(1)} \ge 4\sigma e^{\gamma}/d_0$, $\gamma_i^{(2)} \ge \beta_i/d_0$. Using this value of $(\gamma_i^{(1)}, \gamma_i^{(2)})$, we compute the maximal and minimal sequences from (6.2) with

$$\begin{aligned} f_i(u_i^{(m-1)}) &= \sigma(1 - u_i^{(m-1)})\exp[\gamma u_i^{(m-1)}/(1 + u_i^{(m-1)})], \\ g_i(u_i^{(m-1)}) &= -\beta_i u_i^{(m-1)}, \quad m = 1, 2, \ldots. \end{aligned} \tag{6.12}$$

It is easy to verify that the pair in (6.5) (with $\overline{a} = 1$) are also ordered upper and lower solutions of the continuous problem (2.4), (6.10). This implies that condition (5.5) is trivially satisfied, and, by Theorem 5.1, problem (2.4), (6.10) has a positive maximal solution $(\overline{u}(x), \overline{w}(x))$ and a positive minimal solution $(\underline{u}(x), \underline{w}(x))$. It follows from Theorems 2.1, 3.1, and 5.2 that we have the following conclusion.

THEOREM 6.4. *Let $D(u) \ge d_0 > 0$ and $f(x,u)$, $g(x,u)$ be given by* (6.10)*, and let $(\overline{u}_i^{(0)}, \overline{w}_i^{(0)}) = (\overline{a}, \overline{a}^*)$, $(\underline{u}_i^{(0)}, \underline{w}_i^{(0)}) = (0,0)$, and $(\gamma_i^{(1)}, \gamma_i^{(2)}) = (4\sigma e^{\gamma}/d_0, \beta_i/d_0)$, where $\overline{a} = 1$. Then the following statements hold true:*

(i) *$\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$ converges monotonically from above to a maximal solution $(\overline{u}_i, \overline{w}_i)$ of problem* (2.8)*,* (6.10)*, and $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ converges monotonically from below to a minimal solution $(\underline{u}_i, \underline{w}_i)$.*

(ii) *Every solution (u_i, w_i) of problem* (2.8)*,* (6.10) *in $\mathcal{S}$ satisfies $(\underline{u}_i, \underline{w}_i) \le (u_i, w_i) \le (\overline{u}_i, \overline{w}_i)$, and problem* (2.8)*,* (6.10) *has a unique solution in $\mathcal{S}$ if $(\overline{u}_i, \overline{w}_i) = (\underline{u}_i, \underline{w}_i)$.*

(iii) *In vector form, the sequences $\{\overline{U}^{(m)}, \overline{W}^{(m)}\}$, $\{\underline{U}^{(m)}, \underline{W}^{(m)}\}$ obtained from either* (3.9) *or* (3.10) *converge monotonically to $(\overline{U}, \overline{W})$ and $(\underline{U}, \underline{W})$, respectively.*

(iv) *As $|h| \to 0$, the finite difference solution $(\overline{u}_i, \overline{w}_i)$ converges to $(\overline{u}(x_i), \overline{w}(x_i))$, and $(\underline{u}_i, \underline{w}_i)$ converges to $(\underline{u}(x_i), \underline{w}(x_i))$ at every mesh point $x_i \in \overline{\Lambda}^*$.*

7. Numerical results. To compute numerical solutions of (2.8) or (2.8a) by the monotone iterative schemes, we consider some model problems from heat transfer, where the true continuous solution is explicitly given. This continuous solution is then used to compare with the computed solution to check the accuracy of the monotone iterative scheme. Numerical results for the model where the true solution is not known explicitly is also obtained.

Example 1. In the first example, we consider a heat-conduction problem in a one-dimensional domain $\Omega = (0,1)$, which is given by

$$\begin{aligned} &-[(1+u)u_x]_x + 2(1+u)u_x = a^4(x) - u^4 \quad (0 < x < 1), \\ &u(0) = 0, \quad u(1) = 1 - e^{-1}, \end{aligned} \tag{7.1}$$

where

$$a(x) = \left[6e^{-x} - 4e^{-2x} + (1 - e^{-x})^4\right]^{1/4}. \tag{7.2}$$

The above model is a special case of (1.1a), (6.4) with $D(u) = 1+u$, $c = 2$, $\sigma = 1$, and $\xi(0) = 0$, $\xi(1) = 1 - e^{-1}$. It is easy to check that $u = 1 - e^{-x}$ is the unique solution of (7.1). To compute numerical values of the solution by the monotone iterative scheme (6.2), (6.2a), we observe that

$$w_i = u_i + u_i^2/2, \quad L[w_i] = -\Delta_1[w_i] + 2\delta_i[w_i], \quad q(w_i) = (1 + 2w_i)^{1/2} - 1.$$

Since $a_i^4 \le 7$ and $0 \le \xi_i^* \le 3/2$, it suffices to choose $(\tilde{u}_i, \tilde{w}_i) = (7, 32)$, $(\hat{u}_i, \hat{w}_i) = (0, 0)$, and $(\gamma_i^{(1)}, \gamma_i^{(2)}) = (28, 0)$. With the above data in the iteration process (6.2)–(6.2a), we compute the maximal and minimal sequences $\{\overline{u}_i^{(m)}, \overline{w}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}, \underline{w}_i^{(m)}\}$ for various values of $h \equiv \Delta x$. The stopping criterion in the iteration process is $||\overline{u}^{(m)} - \underline{u}^{(m)}|| + ||\overline{w}^{(m)} - \underline{w}^{(m)}|| < \epsilon$ for various $\epsilon > 0$, where $||u||$ is the maximal norm of u_i over $i = 1, \ldots, M$. Numerical values of the sequences $\{\overline{u}_i^{(m)}\}$, $\{\underline{u}_i^{(m)}\}$ together with the values of the true analytical solution u_i^* at various mesh points in $(0, 1)$ for the case $h = 1/80, \epsilon = 10^{-4}$ are given in Table 1. It is seen from this table that the monotone property of both the maximal sequence and minimal sequence are observed at every mesh point, and after about 14 iterations the values of $\overline{u}_i^{(m)}$ and $\underline{u}_i^{(m)}$ differ from u_i^* by less than 0.01 percent. We also compute the solution for various values of $a(x)$ where the true solution is not explicitly known. Numerical values of $\{\overline{u}_i^{(m)}\}$ and $\{\underline{u}_i^{(m)}\}$ corresponding to the case $a(x) = 1$ are given in Table 2 and are sketched in Figure 1.

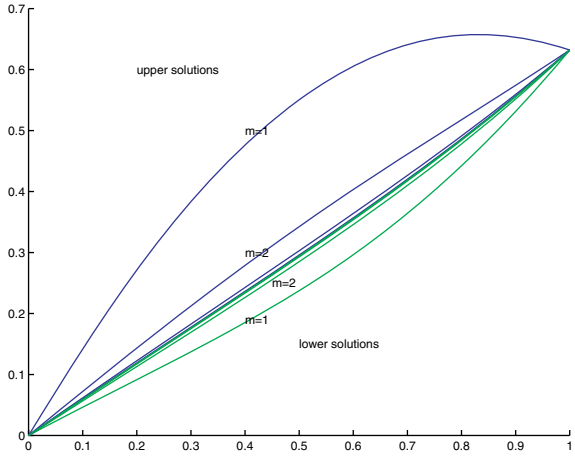

FIG. 1. *Upper and lower sequences for Example* 1(b).

Example 2. We next consider a quasi-linear equation with a nonlinear boundary condition in the form

$$\begin{aligned} &-[(1+u)u_x]_x + 2(1+u)u_x = 0 \quad (0 \le x < 1), \\ &u(0) = 0, \quad (1+u(1))u_x(1) = a^4 - u^4(1), \end{aligned} \tag{7.3}$$

where a is a constant given by

$$a^4 = 2e^2 + [(2e^2-1)^{1/2} - 1]^4. \tag{7.4}$$

This problem is a special case of (1.1a), (6.3) with $D(u) = 1 + u$, $c = 2$, and $\sigma = 1$, and the analytical solution is

$$u(x) = (2e^{2x} - 1)^{1/2} - 1. \tag{7.5}$$

STRICT DIAGONAL DOMINANCE AND OPTIMAL BOUNDS FOR THE SKEEL CONDITION NUMBER*

J.M. PEÑA†

Abstract. An optimal bound for the Skeel condition number of a triangular matrix strictly diagonally dominant by rows is obtained.

Key words. Skeel condition number, diagonal dominance, Gaussian elimination

AMS subject classifications. 65F05, 65G05, 65G99

DOI. 10.1137/060677562

We say that matrix $A = (a_{ij})_{1\le i,j\le n}$ is *strictly diagonally dominant by rows* if $|a_{ii}| > \sum_{j\neq i} |a_{ij}|$ for all $i = 1, \dots, n$. The *Skeel condition number* of a matrix A is defined as $\mathrm{Cond}(A) = \| \, |A^{-1}| \, |A| \, \|_\infty$, where $|M|$ denotes the matrix whose entries are the absolute values of the entries of the matrix M. Given a real matrix $A = (a_{ij})_{1\le i,j\le n}$ whose rows are not null, the *minimal scaled diagonal element* of A is the number p defined as: $p := \min_{i=1,\dots,n} |a_{ii}|/(\sum_{j=1}^n |a_{ij}|)$. Observe that, if U is the upper triangular matrix obtained after Gauss elimination of a matrix A, then the minimal scaled diagonal element of U coincides with the concept (introduced in [1]) of the minimal scaled pivot of A. The minimal scaled diagonal element p of matrix which is strictly diagonally dominant by rows satisfies $1/2 < p \le 1$. The following result uses p to obtain an optimal bound for the Skeel condition number of a triangular matrix strictly diagonally dominant by rows. Besides, it provides a proof for Theorem 3.1 of [1] when $p > 1/2$ and shows the optimality of the corresponding bound. The proof of Theorem 3.1 of [1] is correct only when $p < 1/2$ because only in this case $(1-p)/p > 1$ and the proof that $|(V^{-1})_{ij}| < ((1-p)/p)^{(j-i)}$ is correct.

THEOREM 0.1. *Let $U = (u_{ij})_{1\le i,j\le n}$ be an upper triangular matrix which is strictly diagonally dominant by rows, and let $p(> 1/2)$ be its minimal scaled diagonal element. Then*

$$\mathrm{Cond}(U) \le \frac{1 - \left(\frac{1-p}{p}\right)^{n-1}(2-2p)}{2p-1}. \tag{0.1}$$

Moreover, for any $p > 1/2$ and $n \ge 1$ there exist matrices U for which the previous inequality (0.1) *is an equality.*

Proof. Let $V := D^{-1}U$, where D is the diagonal matrix whose (i,i)-entry is u_{ii} for all i. Then $\mathrm{Cond}(U) = \mathrm{Cond}(V)$ and $V = (V_{ij})_{1\le i,j\le n}$ is upper triangular with $V_{ii} = 1$. Let $r := \max_{1\le i\le n}\{\sum_{j=i+1}^n |V_{ij}|\} (< 1)$. Then

$$r = \max_{1\le i\le n}\left\{\sum_{j=i+1}^{n} \frac{|u_{ij}|}{|u_{ii}|}\right\} = \max_{1\le i\le n}\left\{\frac{\sum_{j=i}^n |u_{ij}| - |u_{ii}|}{|u_{ii}|}\right\} = \frac{1}{p} - 1 = \frac{1-p}{p}. \tag{0.2}$$

Let us now prove by induction on n that, if V is an $n \times n$ upper triangular matrix with a unit diagonal which is strictly diagonally dominant by rows with a minimal

scaled diagonal element not less than p, then

$$\|V^{-1}\|_\infty \leq \frac{1-r^{n-1}(2-2p)}{(2p-1)(r+1)}. \tag{0.3}$$

The result is trivial for $n=1$. Let us assume that it holds for $n-1$, and let us prove it for n.

If we compute V^{-1} by Gauss–Jordan, starting from the last column, we can easily obtain the following bound for the absolute value of $(V^{-1})_{ij}$ for any $i \in \{1,\dots,n\}$ and $j > i$:

$$|(V^{-1})_{ij}| \leq |V_{ij}| + |V_{i,j-1}|\,|(V^{-1})_{j-1,j}| + |V_{i,j-2}|\,|(V^{-1})_{j-2,j}| + \cdots + |V_{i,i+1}|\,|(V^{-1})_{i+1,j}|.$$

Then, taking into account that $(V^{-1})_{ii} = 1$, we can derive

$$\sum_{j=i}^{n} |(V^{-1})_{ij}| \leq 1 + |V_{i,i+1}| \left(\sum_{j=i+1}^{n} |(V^{-1})_{i+1,j}| \right) + \cdots + |V_{i,n}|.$$

Let Z^{-1} be the submatrix of V^{-1} formed by rows and columns $2,\dots,n$. From the previous formula, we can deduce that

$$\sum_{j=i}^{n} |(V^{-1})_{ij}| \leq 1 + \|Z^{-1}\|_\infty \left(\sum_{j=i+1}^{n} |V_{ij}| \right). \tag{0.4}$$

Since Z is an $(n-1)\times(n-1)$ matrix satisfying the induction hypothesis, $\|Z^{-1}\|_\infty \leq (1-r^{n-2}(2-2p))/((2p-1)(r+1))$. Then, using the definition of r and taking the maximum in (0.4) among $i=1,\dots,n$, we can deduce from the previous formula that

$$\|V^{-1}\|_\infty \leq 1 + \|Z^{-1}\|_\infty r \leq \frac{2p(1+r)-1-r^{n-1}(2-2p)}{(2p-1)(r+1)}. \tag{0.5}$$

By (0.2), $2p(1+r)-1=1$, and so we deduce from (0.5) that (0.3) (and so, the induction) holds. Since $\|V\|_\infty \leq 1+r$, the bound (0.1) follows from (0.3) and (0.2).

Now let $0 \leq r < 1$, and let us consider the following matrix U and its inverse U^{-1}:

$$U = \begin{pmatrix} 1 & -r & 0 & \cdots & 0 \\ 0 & 1 & -r & \ddots & \vdots \\ \vdots & \ddots & \ddots & \ddots & 0 \\ \vdots & & \ddots & 1 & -r \\ 0 & \cdots & \cdots & 0 & 1 \end{pmatrix}, \quad U^{-1} = \begin{pmatrix} 1 & r & r^2 & \cdots & r^{n-1} \\ 0 & 1 & r & \cdots & r^{n-2} \\ \vdots & \ddots & \ddots & \ddots & \vdots \\ \vdots & & \ddots & 1 & r \\ 0 & \cdots & \cdots & 0 & 1 \end{pmatrix}.$$

Then the minimal scaled diagonal element of U is $p = 1/(1+r)$ and then

$$\mathrm{Cond}(U) = \frac{2r^n - r - 1}{r-1}. \tag{0.6}$$

Substituting $p = 1/(1+r)$ in (0.1), we deduce that $\mathrm{Cond}(U)$ is bounded above by the right-hand side of (0.6), and so this bound can be achieved for any $p > 1/2$ and positive integer $n \geq 1$. ∎

ON CORNER AVOIDANCE PROPERTIES OF RANDOM-START HALTON SEQUENCES*

JÜRGEN HARTINGER† AND VOLKER ZIEGLER‡

Abstract. Recently, the analysis of quasi-Monte Carlo (QMC) sampling of integrands with singularities has gained considerable interest. In this setting error bounds for QMC integration, in addition to discrepancy, include a measure of how well the singularities are avoided by the utilized sequences. The article aims to generalize results for the corner avoidance of the classical Halton sequence to Halton sequences that start in an arbitrary point of the unit cube. In particular, it is shown that almost all (in Lebesgue sense) random-start Halton sequences exhibit the same corner avoidance property as the original Halton sequence.

Key words. quasi-Monte Carlo integration for singular integrands, random-start Halton sequence, corner avoidance

DOI. 10.1137/050645361

1. Introduction.

Quasi-Monte Carlo (QMC) methods are deterministic alternatives to classical Monte Carlo methods with asymptotically superior error bounds for integration problems when the integrand belongs to a suitable class of functions.

Let $\bar{U}^s = [0,1]^s$ be the s-dimensional unit cube, and consider functions $f : \bar{U}^s \to \mathbb{R}$ such that $I = \int_{\bar{U}^s} f(\mathbf{x})d\mathbf{x}$ exists. Furthermore, let $(\mathbf{x}_n)_{n>0}$ be a sequence with $\mathbf{x}_n = (x_n^{(1)}, \ldots, x_n^{(s)}) \in [0,1)^s$. For a subset $B \subseteq \bar{U}^s$, denote by $\lambda(B)$ its Lebesgue measure and by χ_B its characteristic function, i.e., $\chi_B(\mathbf{x})$ equals 1 for $\mathbf{x} \in B$ and 0 otherwise. The star discrepancy of the set $(\mathbf{x}_n)_{1\le n\le N}$, measuring its uniformness, is given by

$$D_N^* (\mathbf{x}_1, \ldots, \mathbf{x}_N) = \sup_{J\in\mathcal{J}^*} \left| \frac{1}{N} \sum_{n=1}^{N} \chi_J (\mathbf{x}_n) - \lambda(J) \right|,$$

where $\mathcal{J}^*$ is the set of all subintervals of $\bar{U}^s$ of the form $\prod_{i=1}^s [0, u_i)$. Sequences with best known order of discrepancy ($\mathcal{O}(N^{-1}(\log N)^s)$) are called low-discrepancy sequences (LDS). Different LDS constructions were proposed by Halton [3], Sobol' [15], Faure [2], and Niederreiter [7, 8]. Tezuka and Tokuyama [17] show that the last three approaches can be unified by a generalization of Niederreiter's principles.

We define the QMC estimator of I as $\hat{I}_N = \frac{1}{N} \sum_{n=1}^{N} f(\mathbf{x}_n)$. Hlawka's theorem [6] bounds the QMC integration error as follows:

$$\left| I - \hat{I}_N \right| \le V_{HK}(f) D_N^* (\mathbf{x}_1, \ldots, \mathbf{x}_N),$$

where $V_{HK}(f)$ denotes the variation in the sense of Hardy and Krause (for a definition and a survey on concepts of multidimensional variation, see [11]). A thorough introduction to the field of QMC integration may be found in the monograph [9].

Mainly inspired by financial applications, the theory of QMC quadrature formulae for singular integrands (those that do not have bounded Hardy–Krause variation) was intensively studied recently. In a setting where the singularities lie in the boundary, Owen [12] shows that the QMC convergence order under suitable growth conditions on the integrand in addition to the discrepancy depends on the speed with which the utilized sequence approaches the boundary of the unit cube.

The quantity of main interest within this setting is the hyperbolic distance from a point $\mathbf{z} = (z_1, \dots, z_s) \in [0,1)^s$ to a corner of the unit cube $\mathbf{h} = (h_1, \dots, h_s) \in \{0,1\}^s$, which is defined by $\|\mathbf{z}\|_{\mathbf{h}} = \prod_{i=1}^{s} |z_i - h_i|$. In order to get (asymptotically) efficient QMC rules for these integrands one has to find point sequences satisfying the condition

$$\exists n_0 \in \mathbb{Z}^+ : \forall n \geq n_0 : \ \|\mathbf{x}_n\|_{\mathbf{h}} \geq c\, n^{-r}, \tag{1}$$

with a constant $c = c(r) > 0$ and small r. A sequence is said to avoid the corner $\mathbf{h}$ if (1) is fulfilled with $r \leq 1 + \varepsilon$ for all $\varepsilon > 0$.

Let us state Owen's result [12] in order to shed some light on the role of r. Let $f : (0,1]^s \to \mathbb{R}$ be a real-valued Lebesgue measurable function which is singular in the origin. Moreover, we assume some growth conditions. For a set $u \subset \{1, \dots, s\}$ of indices, the symbol $\partial^u f(\mathbf{x})$ represents $(\prod_{j \in u} \partial/\partial x_j) f(\mathbf{x})$, with the convention that $\partial^{\emptyset} f(\mathbf{x}) = f(\mathbf{x})$. Our growth condition is that

$$|\partial^u f(\mathbf{x})| \leq B \prod_{j=1}^{s} (x_j)^{-A_j - \mathbf{1}_{j \in u}} \tag{2}$$

holds for some $A_j > 0$, some $B < \infty$, and all $u \subseteq \{1, \dots, s\}$, where $\mathbf{1}_{j \in u} = 1$ if $j \in u$ and $\mathbf{1}_{j \in u} = 0$ otherwise. Now we can state Owen's result [12, Theorem 5.5].

THEOREM 1. *Let $f(\mathbf{x})$ be as above and suppose $\mathbf{x}_1, \dots, \mathbf{x}_N$ satisfy (1). Then for any $\eta > 0$,*

$$|\hat{I}_N - I| \leq C_1 D_N^*(\mathbf{x}_1, \dots \mathbf{x}_N) N^{\eta + r \max_j A_j} + C_2 N^{r(\max_j A_j - 1)}$$

holds for finite C_1 and C_2 that may depend on η.

A similar result also holds for other corners than $\mathbf{0}$.

As Owen [12] remarks, the QMC integration is superior to Monte Carlo integration, if $\max_j A_j < 1/(2r)$, provided $D_N^*(\mathbf{x}_1, \dots \mathbf{x}_N) = O(N^{-1+\epsilon})$. In view of applications of QMC integration of singular functions, we have to use LDS which avoid corners with small r.

In the case $\mathbf{h} = 0$, the lower bound $r \geq 1$ is obvious for (t,s)-sequences (for a definition, see, e.g., [9]) and for Halton sequences. Sobol' [16] shows that $r = 1$ holds for Sobol' sequences, and Owen [12] establishes $r = 1$ for Halton sequences. Hartinger, Kainhofer, and Ziegler [4] show $r = 1$ for generalized Niederreiter sequences. For all $\mathbf{h}$, i.e., $\min_{\mathbf{h} \in \{0,1\}^s} \|x_N\|_{\mathbf{h}}$, much less is known: Hartinger, Kainhofer, and Ziegler [4] establish that $r \leq 1 + \varepsilon$ for Halton sequences and $r \geq 3/2$ for the Faure sequence. In a randomized setting Owen [10] shows that the expected error of randomized QMC (under mild conditions on the moments of the integrand) is superior to Monte Carlo even if there exist point singularities with unknown locations. In this paper we show that $r \leq 1 + \epsilon$ holds also for almost all random-start Halton sequences.

Section 2 reviews the definition of random-start Halton sequences, that might be considered as Halton sequences started at an arbitrary point in the unit cube (the classical Halton sequence starts in $\mathbf{0}$). In view of an application of Schmidt's subspace theorem we formulate and discuss this theorem in section 3. The subspace theorem will be an essential part of the proof of the results in section 4, which establishes corner avoidance results for Halton sequences started in special points of the unit cube. In section 5 we show that the set of start points inducing Halton sequences that do not avoid all corners has Lebesgue measure zero.

2. Random-start Halton sequences. For a base $p \in \mathbb{Z}^+$ ($\mathbb{Z}^+$ denotes the set of positive integers) and an integer n with p-adic expansion $n = \sum_{r=1}^{l} a_r(n)p^{r-1}$, define the radical inverse function by $\Phi_p(n) = \sum_{r=1}^{l} a_r(n)p^{-r}$. The nth element of the s-dimensional Halton sequence [3] in relatively coprime bases $p_1, \ldots, p_s$ (typically the first s primes) is given by $\mathbf{x}_n = (\Phi_{p_1}(n), \ldots, \Phi_{p_s}(n))$.

Wang and Hickernell [18] propose to generalize the Halton sequence in the following way: Let $z \in [0, 1)$ be written as

$$z = \sum_{r=1}^{\infty} \frac{a_r(z)}{p^r}, \tag{3}$$

where for all $r_0 \in \mathbb{Z}^+$ there exists an $r \geq r_0$ such that $a_r(z) < p-1$ and $1 = \sum_{r=1}^{\infty} \frac{p-1}{p^r}$. The p-adic von Neumann–Kakutani transform is given by rightward-carry addition in base p, i.e., $T_p(z) = z \oplus \frac{1}{p} = \frac{1+a_m(z)}{p^m} + \sum_{r>m} \frac{a_r(z)}{p^r}$, where $m = \min\{r \in \mathbb{Z}^+ \mid u_r \neq p-1\}$. For relatively coprime bases $p_1, \ldots, p_s$, the s-dimensional $\mathbf{z}$-start Halton sequence is recursively defined by $\mathbf{z} = \mathbf{x}_0 = (x_0^{(1)}, \ldots, x_0^{(s)}) \in [0, 1]^s$ and $\mathbf{x}_{n+1} = (T_{p_1}(x_n^{(1)}), \ldots, T_{p_s}(x_n^{(s)}))$ for $n \in \mathbb{Z}_0^+$. Wang and Hickernell [18] show that for all $\mathbf{z} \in [0, 1]^s$ the induced Halton sequence is an LDS and propose a randomization of the Halton sequence by choosing $\mathbf{z}$ through a realization of a uniformly distributed random variable on $[0, 1]^s$ (therefore this construction is known as a random-start Halton sequence).

For later convenience, we give an equivalent p-adic definition of the $\mathbf{z}$-start Halton sequence: For a prime p, let $\mathbb{Z}_p$ denote the set of all p-adic integers. Supposing $z = \sum_{r=1}^{\infty} a_r(z)p^{r-1} \in \mathbb{Z}_p$, we define the extended radical inverse function $\Phi_p : \mathbb{Z}_p \to [0, 1]$, with $z \mapsto \sum_{r=1}^{\infty} a_r(z)p^{-r}$. Since $a_r(z) \in \{0, 1, \ldots, p-1\}$, the sum converges and Φ_p is a well-defined function. The z-start van der Corput sequence $(\phi_p(n; z))_{n\geq 1}$ for a starting point $z \in \mathbb{Z}_p$ is defined by $\phi_p(n; z) = \Phi_p(n + z)$. Finally, for distinct primes $p_1, \ldots, p_s$ and fixed p_i-adic integers z_i ($1 \leq i \leq s$), the $\mathbf{z}$-start Halton sequence $(\mathbf{x}_n)_{n\geq 1}$ is given by

$$\mathbf{x}_n = (\phi_{p_1}(n; z_1), \ldots, \phi_{p_s}(n; z_s)).$$

For $k \in \mathbb{Z}^+$, the sequence $(\phi_p(n; k))_{n\geq 1} = (\Phi_p(n+k))_{n\geq 1}$ is a shift of the van der Corput sequence by k elements. Therefore a $\mathbf{z}$-start Halton sequence with $\mathbf{z} \in \mathbb{Z}^s$ is called a finitely shifted Halton sequence. If there exists a coordinate in $\mathbf{z}$ such that $z_i \in \mathbb{Z}_p \setminus \mathbb{Z}$, the corresponding Halton sequence is said to be infinitely shifted.

Let us define the map $\tilde{\Phi}_p(z) : [0, 1] \to \mathbb{Z}_p$ with $z \mapsto \sum_{r=1}^{\infty} a_r(z)p^{r-1}$, where the coefficients are obtained by (3). Thus, we have $\Phi_p \circ \tilde{\Phi}_p = \mathrm{id}$. For $\mathbf{z} = (z_1, \ldots, z_s) \in [0, 1)^s$ and $n \in \mathbb{Z}^+$, the corresponding $\mathbf{z}$-start Halton sequence may now be written in the following form:

$$\mathbf{x}_n := \mathbf{x}_n^{(z_1,\ldots,z_s)} = \left(\phi_{p_1}(n; \tilde{\Phi}(z_1)), \ldots, \phi_{p_s}(n; \tilde{\Phi}(z_s))\right).$$

Remark. Note that we have defined the Halton sequence only for prime basis. A similar construction may be obtained for relative prime basis. Observe that for a prime p, $\mathbb{Z}_p$ may be defined by $\mathbb{Z}_p = \varprojlim \mathbb{Z}/p^k\mathbb{Z}$, the inverse limit of the rings $\mathbb{Z}/p^k\mathbb{Z}$. This inverse limit exists even if p is not a prime. Considered as a limit of rings, it does not give a suitable structure, i.e., in general $\mathbb{Z}_p$ is not a domain. Nevertheless, viewed as a limit of additive groups one gets a similar structure as in the prime case. Since in the definition above only the additive structure is needed, the definition is suitable to any relatively coprime basis.

3. The subspace theorem. Akin to the classical Halton sequence (cf. [4]) the backbone in the proof for finitely shifted Halton sequences (see section 4) is the p-adic subspace theorem due to Schlickewei [13] (see also [14, Chapter V, Theorem 1D]). In the literature there exist many versions of the subspace theorem. The most general form was established by Evertse and Schlickewei [1]. Because of technical reasons we only state a nonquantitative version of this theorem, which can be found in Schmidt's book [14, Chapter V]. Before we state the subspace theorem, we introduce some notations.

Let $\mathbb{Q}$ be the field of rationals; then there exist several absolute values on $\mathbb{Q}$. One of them is the so-called Archimedian absolute value $|\cdot|_\infty$, which is the usual absolute value. For any prime p we obtain an absolute value $|\cdot|_p$, with $|x|_p = p^{-\alpha}$, where $x = p^\alpha u/v$ with $p \nmid uv$; these absolute values are called non-Archimedian. The Archimedian and non-Archimedian absolute values form the set $M(\mathbb{Q})$, the canonical absolute value. Let K be some number field; then every absolute value can be extended to an absolute value on K, possibly in several ways. Absolute values obtained in this way are called Archimedian again, if they are extensions of the usual absolute value and are called non-Archimedian if they are induced by an absolute value of the form $|\cdot|_p$ with p a prime. The union of these absolute values is denoted by $M(K)$ and is called the set of canonical absolute values. Let $p \in \{\infty, 2, 3, 5, \dots\} = M(\mathbb{Q})$ (we identify p with $|\cdot|_p$) and let $\nu \in M(K)$; then we write $\nu|p$ if ν is induced by p. Again let $\nu \in M(K)$ with $\nu|p$. Then we denote by K_ν the (topological) closure of K with respect to ν. The index $n_\nu := [K_\nu : \mathbb{Q}_p]$ is called the local degree. Note that if $p = \infty$, then $n_\nu = 1, 2$ depending on whether the K_ν is real or complex. We also use the following notation. Let $\mathbf{x} \in K^s$; then we use the notation

$$\overline{|\mathbf{x}|} = \max_{\substack{1 \le i \le s \\ \nu \in M(K),\, \nu|\infty}} |x_i|_\nu.$$

Note that by linear forms we mean homogeneous polynomials of degree 1 over some number field K. We say that linear forms are linearly independent if they are linearly independent over their (fixed) field of coefficients. Now we can state a nonquantitative form of the subspace theorem (see [14, Chapter V, Theorem 1D]—note the misprint non-Archimedian instead of Archimedian).

THEOREM 2. *Let K be an algebraic number field, and let $S \subset M(K)$ be a finite set of absolute values containing all of the Archimedian ones. For each $\nu \in S$ let $L_{\nu,1}, \dots, L_{\nu,s}$ be s linearly independent (over K) linear forms in s variables with coefficients in K. Then for a given $\delta > 0$, the solutions of the inequality*

$$\prod_{\nu \in S} \prod_{i=1}^{s} |L_{\nu,i}(\mathbf{x})|_\nu^{n_\nu} < \overline{|\mathbf{x}|}^{-\delta}$$

with $\mathbf{x} \in \mathfrak{o}_K^s$ and $\mathbf{x} \neq \mathbf{0}$, where $\mathfrak{o}_K$ is the ring of integers of K, lie in finitely many proper subspaces of K^s.

In view of the next section we only need Theorem 2 in the case of $K = \mathbb{Q}$. Therefore we state also following version of the subspace theorem.

THEOREM 3. *Let $\{\infty\} \subset S \subset M(\mathbb{Q})$ be a finite set of absolute values. For each $\nu \in S$ let $L_{\nu,1}, \ldots, L_{\nu,s}$ be s rational, linearly independent linear forms in s variables. Then for a given $\delta > 0$, the solutions of the inequality*

$$\prod_{\nu \in S} \prod_{i=1}^{s} |L_{\nu,i}(\mathbf{x})|_\nu < \left(\max_{1 \le i \le s} |x_i| \right)^{-\delta}$$

with $\mathbf{x} \in \mathbb{Z}^s$ and $\mathbf{x} \neq \mathbf{0}$ lie in finitely many proper subspaces of $\mathbb{Q}^s$.

4. Finite shifts. In this section we show that almost all finite shifts preserve the corner avoidance properties of the Halton sequence in basis $p_1, \ldots, p_s$. The first step is to establish a relation between the hyperbolic distance and exact powers of basis elements dividing certain p-adic integers. For a p-adic integer z, we say α is the exact power of p dividing z (in symbols $p^\alpha \| z$), if $\alpha = \min\{r \ge 0 : a_{r+1}(z) \neq 0\}$.

LEMMA 1. *Let $\mathbf{h}$ be a corner of the unit cube and let $\mathbf{z} \in [0,1]^s$ such that $p_i^{\alpha_i} \| (\tilde{\Phi}_{p_i}(z_i) + h_i)$ for $i = 1, \ldots, s$. Then*

$$\prod_{i=1}^{s} p_i^{-\alpha_i - 1} \le \|\mathbf{z}\|_{\mathbf{h}} \le \prod_{i=1}^{s} p_i^{-\alpha_i}.$$

Proof. Obviously, it suffices to prove

$$p_i^{-\alpha_i - 1} \le |z_i - h_i| \le p_i^{-\alpha_i},$$

for $i = 1, \ldots, s$.

First, consider the case $h_i = 0$. For notational convenience omit the index i. Due to $p^\alpha \| \tilde{\Phi}(z)$, we have $\tilde{\Phi}(z) = \sum_{r=\alpha+1}^{\infty} a_r(z) p^{r-1}$ $(a_{\alpha+1}(z) \neq 0)$. Since Φ is the left inverse of $\tilde{\Phi}$, we obtain

$$z = \Phi \circ \tilde{\Phi}(z) = \sum_{r=\alpha+1}^{\infty} \frac{a_r(z)}{p^r}, \qquad a_{\alpha+1}(z) \neq 0.$$

Now, $p^{-\alpha-1} \le z \le p^{-\alpha}$ follows immediately by $0 \le a_r(z) \le p - 1$ for $r \ge 1$.

Consider the case $h_i = 1$. Omitting indices again, we have $p^\alpha \| (\tilde{\Phi}(z) + 1)$. Hence, $\tilde{\Phi}(z) + 1 = \sum_{r=\alpha+1}^{\infty} a_r(z) p^{r-1}$ $(a_{\alpha+1}(z) \neq 0)$, and

$$\tilde{\Phi}(z) = \sum_{r=1}^{\alpha} (p-1) p^{r-1} + (a_{\alpha+1}(z) - 1) p^\alpha + \sum_{r=\alpha+2}^{\infty} a_r(z) p^{r-1}.$$

Again, an application of Φ to $\tilde{\Phi}(z)$ yields

$$z = \Phi \circ \tilde{\Phi}(z) = \sum_{r=1}^{\alpha} \frac{p-1}{p^r} + \frac{a_{\alpha+1}(z) - 1}{p^{\alpha+1}} + \sum_{r=\alpha+2}^{\infty} \frac{a_r(z)}{p^r}$$

and furthermore

$$\begin{aligned} 1 - z &= \sum_{r=1}^{\infty} \frac{p-1}{p^r} - \sum_{r=1}^{\alpha} \frac{p-1}{p^r} - \frac{a_{\alpha+1}(z) - 1}{p^{\alpha+1}} - \sum_{r=\alpha+2}^{\infty} \frac{a_r(z)}{p^r} \\ &= \frac{p - a_{\alpha+1}(z)}{p^{\alpha+1}} + \sum_{r=\alpha+2}^{\infty} \frac{p - 1 - a_r(z)}{p^r}. \end{aligned}$$

Thus, $p^{-\alpha-1} \leq 1 - z \leq p^{-\alpha}$. □

THEOREM 4. *For* $\mathbf{k} = (k_1, \ldots, k_s) \in \mathbb{Z}^s$, *let*

$$\mathbf{x}_n = (x_n^{(1)}, \ldots, x_n^{(s)}) = (\phi_{p_1}(n; k_1), \ldots, \phi_{p_s}(n; k_s))$$

be the $\mathbf{k}$*-start Halton sequence in relatively coprime basis* $p_1, \ldots, p_s$. *Denote by* $K(L)$ *the set of all shift-vectors* $\mathbf{k}$ *with* $\|\mathbf{k}\|_\infty < L$ *such that the* $\mathbf{k}$*-start Halton sequence does not avoid all corners, i.e.,*

$$K(L) = \{\mathbf{k} \in ([0, L] \cap \mathbb{Z})^s \ : \ \exists \varepsilon > 0 \ \exists h \in \{0,1\}^s \ \forall n_0 \in \mathbb{Z}^+ \ \exists n \geq n_0 \\ : \ \|\mathbf{x}_n\|_{\mathbf{h}} < n^{-1-\epsilon}\}.$$

Then

$$\lim_{L \to \infty} \frac{\#K(L)}{L^s} = 0.$$

Proof. Let $1 \leq i \leq s$. Let us first assume that all quantities $k_i + h_i$ are the same, say equal to β. By the virtue of Lemma 1, it suffices to show that for every $\epsilon > 0$ there are only finitely many $n \in \mathbb{Z}^+$, such that

$$p_i^{\alpha_i} \| (n + k_i + h_i) = n + \beta \qquad \text{and} \qquad \prod_{i=1}^{s} p_i^{\alpha_i} \geq n^{1+\epsilon}. \tag{4}$$

Since our assumption we have $\prod_{i=1}^s p_i^{\alpha_i} | (n + \beta)$, and therefore (4) can hold only for finitely many n.

Now let us assume not all $k_i + h_i$ are the same. Let us write $x_i = n + k_i + h_i = C_i p_i^{\alpha_i}$. Note that C_i and p_i are relative prime. We may assume that the quantities $k_i + h_i$ are pairwise distinct. (If $k_i + h_i = k_j + h_j$ for two indices $i \neq j$, set $x_i = x_j = \tilde{C}_i p_i^{\alpha_i} p_j^{\alpha_j}$.) Fix some index j and assume that $\frac{C_1 \cdots C_s}{\prod_{i \neq j} x_i} \geq n^{-\epsilon/2}$. For n large, such that $n^{1+\epsilon/2} \geq n + k_j + h_j = x_j$, we obtain

$$n^{1+\epsilon} \geq x_j n^{\epsilon/2} \geq x_j \frac{\prod_{i \neq j} x_i}{\prod_{i=1}^s C_i} = \prod_{i=1}^{s} p_i^{\alpha_i}.$$

Now, assume that $\frac{C_1 \cdots C_s}{\prod_{i \neq j} x_i} \leq n^{-\epsilon/2}$. We now come to the key point of the proof, the application of the subspace theorem (Theorem 3). Let S be the set of absolute values corresponding to a prime that divides a basis together with the usual Archimedian absolute value. For every non-Archimedian absolute values ν we choose $L_{\nu,i}(x_1, \ldots, x_s) = x_i$. The linear forms corresponding to the Archimedian absolute value are $L_{\infty,j}(x_1, \ldots, x_s) = x_j$ and $L_{\infty,i}(x_1, \ldots, x_s) = x_j - x_i$ for $i \neq j$. For n large, such that $n^2 \geq \max\{n + k_i + h_i, (k_i + h_i)^{8s/\varepsilon}\}$ for all i, we obtain the following inequality:

$$\begin{aligned} \overline{|\mathbf{x}|}^{-\epsilon/8} &= \left(\max_{i=1,\ldots,s} |n + k_i + h_i| \right)^{-\epsilon/8} \\ &\geq n^{-\epsilon/4} \geq n^{-\epsilon/2} \max_{1 \leq i \leq s} (k_i + h_i)^s \\ &\geq \frac{C_1 \cdots C_s}{\prod_{i \neq j} x_i} \prod_{i \neq j} |k_j + h_j - k_i - h_i| \end{aligned}$$

$$= \frac{x_j}{p_j^{\alpha_j}} \prod_{i \neq j} \frac{|k_j + h_j - k_i - h_i|}{p_i^{\alpha_i}}$$

$$\geq \prod_{\nu \in S} \prod_{i=1}^{s} |L_{\nu,i}(\mathbf{x})|_\nu.$$

The last inequality holds since $|L_{\infty,i}(\mathbf{x})| = |x_j - x_i| = |k_j + h_j - k_i - h_i|$ in case of $j \neq i$ and $|L_{\infty,j}(\mathbf{x})| = |x_j|$. Furthermore, $|L_{p,i}(\mathbf{x})|_p = |C_i p_i^{\alpha_i}|_p = p^{-\alpha_i}$ if $p|p_i$, and $|L_{p,i}(\mathbf{x})|_p \leq 1$ otherwise.

By Theorem 2 the solutions of this inequality lie only in finitely many subspaces. Therefore the vector $\mathbf{x}$ satisfies the linear system (let T be an adequate subspace)

$$\begin{aligned} x_1 t_1 + \cdots + x_s t_s &= 0 \qquad && (\text{subspace } T), \\ x_j - x_i &= k_j + h_j - k_i - h_i \qquad && (i \neq j). \end{aligned} \tag{5}$$

System (5) may be written in the following form:

$$\begin{pmatrix} t_1 & t_2 & \cdots & t_{j-1} & t_j & t_{j+1} & \cdots & t_s \\ -1 & 0 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ 0 & -1 & \cdots & 0 & 1 & 0 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & -1 & 1 & 0 & \cdots & 0 \\ 0 & 0 & \cdots & 0 & 1 & -1 & \cdots & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & \cdots & 0 & 1 & 0 & \cdots & -1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ \vdots \\ x_j \\ x_{j+1} \\ \vdots \\ x_s \end{pmatrix}$$

$$= \begin{pmatrix} 0 \\ k_j + h_j - k_1 - h_1 \\ k_j + h_j - k_2 - h_2 \\ \vdots \\ k_j + h_j - k_{j-1} - h_{j-1} \\ k_j + h_j - k_{j+1} - h_{j+1} \\ \vdots \\ k_j + h_j - k_s - h_s \end{pmatrix}.$$

Note that the $\mathbf{k}$-start Halton sequence avoids the corner $\mathbf{h}$ if and only if system (5) has infinitely many solutions. But the system has infinitely many solutions if and only if

$$\sum_{i=1}^{s} t_i = 0 \quad \text{and} \quad \sum_{i \neq j} t_i (k_i + h_i) = -t_j (k_j + h_j). \tag{6}$$

But (6) yields at most L^{s-1} possibilities for $(k_1 + h_1, \ldots, k_s + h_s)$ such that $\max_{1 \leq i \leq s}(k_i + h_i) \leq L$. Moreover, the subspace theorem yields only a finite number of t subspaces. Thus, we have at most tL^{s-1} different vectors $\mathbf{k}$ that do not admit corner avoidance. Hence, $K(L) \leq tL^{s-1}$ and $\lim_{L \to \infty} \frac{\#K(L)}{L^s} = 0$. □

5. Metric results. This section aims to provide metric results on corner properties of random-start Halton sequences. It is shown that (Lebesgue) almost all $\mathbf{z}$-start Halton sequences avoid corners. In the spirit of Lemma 1 we use the following notion to characterize points that are near the corners.

DEFINITION 1. *Let $f : \mathbb{Z}^+ \to \mathbb{R}^+$ be a fixed arithmetic function such that $f(n) \geq 1$ and*

$$\sum_{n=1}^{\infty} \frac{(\log(nf(n)))^{s-1}}{nf(n)} < \infty.$$

For $\mathbf{z} = (z_1, \ldots, z_s) \in \mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$ and $n \geq 1$, let $\mathbf{x}_n = (\phi_{p_1}(n; z_1), \ldots, \phi_{p_s}(n; z_s))$ be the $\mathbf{z}$-start Halton sequence in relatively coprime basis $p_1, \ldots, p_s$. The point $\mathbf{x}_n$ is said to be close to the corner $\mathbf{h}$ if there exist $\alpha_1, \ldots, \alpha_s$ such that for $i = 1, \ldots, s$,

$$p_i^{\alpha_i} \| (z_i + h_i + n) \quad \text{and} \quad \prod_{i=1}^{s} p_i^{\alpha_i} > nf(n). \tag{7}$$

If (7) is fulfilled for infinitely many n, the $\mathbf{z}$-start Halton sequence $(\mathbf{x}_n)_{n\geq 1}$ is said to approach $\mathbf{h}$.

For the rest of this section we fix an arithmetic function f, which is assumed to fulfill the properties of Definition 1.

THEOREM 5. *For $\mathbf{z} = (z_1, \ldots, z_s) \in [0, 1)^s$ and $n \geq 1$, let*

$$(\mathbf{x}_n)_{n\geq 1} = (\mathbf{x}_n^{\mathbf{z}})_{n\geq 1} = \left(\phi_{p_1}(n; \tilde{\Phi}(z_1)), \ldots, \phi_{p_s}(n; \tilde{\Phi}(z_s))\right)_{n\geq 1}$$

be the $\mathbf{z}$-start Halton sequence in relatively coprime basis $p_1, \ldots, p_s$. Then the set

$$\mathcal{A} = \{\mathbf{z} \in [0, 1)^s \,:\, (\mathbf{x}_n^{\mathbf{z}})_{n\geq 1} \text{ approaches a corner } \mathbf{h}\}$$

has Lebesgue measure zero, i.e., $\lambda(\mathcal{A}) = 0$.

Proof. The proof will be done in several steps.

- *A tiling for $\mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$.*
  For $l_1, \ldots, l_s \in \mathbb{Z}^+$, let us define the fundamental tile by

  $$X_{l_1,\ldots,l_s} := \{\mathbf{y} \in \mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s} \,:\, p^{\alpha_i} | y_i,\ i = 1, \ldots, s\}.$$

  A tiling of $\mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$ is obtained by the tiles

  $$X_{l_1,\ldots,l_s} + (k_1, \ldots, k_s) := \{\mathbf{y} \in \mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s} \,:\, p^{\alpha_i} | (y_i - k_i),\ i = 1, \ldots, s\},$$

  for all integers k_i with at most α_i p_i-adic digits, i.e., $k_i < p_i^{l_i} \in \mathbb{Z}^+$ $(i = 1, \ldots, s)$.
  Since Φ_p is surjective we also have a tiling of $[0, 1]^s$. In most cases we will need a tiling induced by the fundamental tile $X_l := X_{l,\ldots,l}$, for a fixed $l \in \mathbb{Z}^+$.
  Remark. The tiles $X_{l_1,\ldots,l_s} + (k_1, \ldots, k_s)$ generate the σ-algebra of the Borel sets of the topological group $\mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$. The Haar measure μ such that $\mu(\mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}) = 1$ is obtained if we allocate to each tile $X_{l_1,\ldots,l_s} + (k_1, \ldots, k_s)$ the measure $p_1^{-l_1} \cdots p_s^{-l_s}$ (see [5, pp. 202–203]). Moreover, the functions Φ and $\tilde{\Phi}$ are measurable and the Haar measure μ is induced by the Lebesgue measure λ and vice versa, i.e., $\mu(A) = \lambda(\tilde{\Phi}^{-1}(A))$ and $\lambda(B) = \mu(\Phi^{-1}(B))$ for all measurable (Borel) sets $A \subseteq \mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$ and $B \subseteq [0, 1)^s$.

To prove that Φ is measurable we only need to show that every element of a generating system of the Borel sets of $[0,1)^s$ has as preimage a Borel set of $\mathbb{Z}_{p_1} \times \cdots \times \mathbb{Z}_{p_s}$. In fact, we have

$$\Phi^{-1}\left(\left[\frac{k_1}{p_1^{l_1}}, \frac{k_1+1}{p_1^{l_1}}\right) \times \cdots \times \left[\frac{k_s}{p_s^{l_s}}, \frac{k_s+1}{p_s^{l_s}}\right)\right) = X^-_{l_1,\ldots,l_s} + (k_1,\ldots,k_s),$$

where $X^-_{l_1,\ldots,l_s}$ is $X_{l_1,\ldots,l_s}$ without elements which have a component $y_i \in \mathbb{Z}_{p_i}$ of the form $y_i = \sum_{r=l_i+1}^{\infty}(p_i-1)p_i^r$. Loosely speaking, $X^-_{l_1,\ldots,l_s}$ is $X_{l_1,\ldots,l_s}$ without right upper border. It is easily seen that this right upper border is a Borel set, which shows that Φ is measurable, since $X_{l_1,\ldots,l_s}$ is also a Borel set.

Similarly we have

$$\tilde{\Phi}^{-1}\left(X_{l_1,\ldots,l_s} + (k_1,\ldots,k_s)\right) = \left[\frac{k_1}{p_1^{l_1}}, \frac{k_1+1}{p_1^{l_1}}\right] \times \cdots \times \left[\frac{k_s}{p_s^{l_s}}, \frac{k_s+1}{p_s^{l_s}}\right].$$

Since the right side is a Borel set, $\tilde{\Phi}$ is measurable.

- *Let $N \in \mathbb{Z}^+$ be fixed and $l \in \mathbb{Z}^+$ be large. Consider the tiling induced by X_l; if $\mathbf{x}_N^{\mathbf{z}}$ is close to the corner $\mathbf{0}$, then the whole tile corresponding to $\mathbf{z}$ is close to the corner $\mathbf{0}$.*

  Define $\Phi(\mathbf{z}) := (\Phi_{p_1}(z_1), \ldots \Phi_{p_s}(z_s))$. First, observe that for $i = 1,\ldots,s$ and $a_i \in \mathbb{Z}_{p_i}$, we have

$$\left(p_i^{\alpha_i} | (\tilde{\Phi}_{p_i}(z_i) + N)\right) \quad \Longrightarrow \quad \left(p_i^{\alpha_i} | (\tilde{\Phi}_{p_i}(z_i) + a_i p_i^{\alpha_i} + N)\right). \tag{8}$$

  For $i = 1,\ldots,s$, let $\bar{k}_i = \sum_{r=0}^{\alpha_i} a_{r+1}(z_i)p_i^r$. From (8), we conclude that if $\mathbf{x}_N^{\mathbf{z}}$ is close to $\mathbf{0}$, then $\mathbf{x}_N^{\Phi(\bar{\mathbf{k}})}$ is close to $\mathbf{0}$. Thus, all points of the form $\mathbf{x}_N^{\Phi(\bar{\mathbf{k}}+\mathbf{y})}$ with $y \in X_{\alpha_1,\ldots,\alpha_s}$ are close to $\mathbf{0}$.

  The same holds for all points of the form $\mathbf{x}_N^{\Phi(\bar{\mathbf{k}}+\mathbf{y})}$ with $y \in X_{\beta_1,\ldots,\beta_s}$, where $\beta_i \geq \alpha_i$ $(i = 1,\ldots,s)$, in particular for $y \in X_l$ with $l \geq \max\{\alpha_1,\ldots,\alpha_s\}$.

- *Reduction of the problem to a counting problem.*

  Let us define the set

$$\mathcal{A}_N := \{\mathbf{z} \in [0,1)^s \ : \ \mathbf{x}_N^{\mathbf{z}} \text{ is close to } \mathbf{0}\}.$$

  The idea is to find a Borel measureable set $\mathcal{A}'_N \supset \mathcal{A}_N$, such that we are able to estimate the measure of $\mathcal{A}'_N$ by solving a counting problem. We denote the set of s-tuples of integers that possess p_i-adic expansions with at most l digits by $\mathcal{F}_{(l)}$, i.e.,

$$\mathcal{F}_{(l)} = \mathbb{Z}^s \cap \left([0,p_1^l) \times \cdots \times [0,p_s^l)\right),$$

  and consider the set

$$\mathcal{C}_{N,l} = \{(k_1,\ldots,k_s) \in \mathcal{F}_{(l)} \ : \ \mathbf{x}_N^{\Phi(k_1,\ldots,k_s)} \text{ is close to } \mathbf{0}\}.$$

  Let $l > \frac{\log(Nf(N))}{\log 2}$; thus $l \geq \max\{\alpha_1,\ldots,\alpha_s\}$. We know that with $\mathbf{k} \in \mathcal{C}_{N,l}$ all $\mathbf{x}_N^{\Phi(\mathbf{k}+y)}$ are close to $\mathbf{0}$ provided $y \in X_l$. Therefore we define

$$\mathcal{A}'_N = \bigcap_{l=\lfloor \frac{\log(Nf(N))}{\log 2} \rfloor + 1}^{\infty} \mathcal{A}'_{N,l} \quad \text{and} \quad \mathcal{A}'_{N,l} = \Phi\left(\bigcup_{\mathbf{k} \in \mathcal{C}_{N,l}} \mathbf{k} + X_l\right).$$

Since the sets $\Phi(\mathbf{k}+X_l)$ are disjunct intervals with side lengths p_i^{-l}, we have

$$\lambda(\mathcal{A}'_{N,l}) = \frac{\sharp\mathcal{C}_{N,l}}{(p_1\cdots p_s)^l}.$$

- *Reduction to compute a volume.*
We define the set $\mathcal{H}_{N,l} = \{\mathbf{x}_N^{\Phi(\mathbf{k})} : \mathbf{k} \in \mathcal{F}_{(l)}\}$ and the following tiling of $[0,1)^s$:

$$T_{\mathbf{k},l} = \left[\frac{k_1}{p_1^l}, \frac{k_1+1}{p_1^l}\right) \times \cdots \times \left[\frac{k_s}{p_s^l}, \frac{k_s+1}{p_s^l}\right), \qquad \mathbf{k} \in \mathcal{F}_{(l)}.$$

We know that distinct elements of $\mathcal{H}_{N,l}$ lie in distinct sets $T_{\mathbf{k},l}$. Suppose $\mathbf{u}, \mathbf{v} \in \mathcal{F}_{(l)}$ and $\mathbf{x}_N^{\Phi(\mathbf{u})}, \mathbf{x}_N^{\Phi(\mathbf{v})} \in T_{\mathbf{k},l}$. Then for $i = 1, \ldots, s$, $p_i^l | ((u_i + N) - (v_i + N))$; thus $u_i - v_i \geq p_i^l$ or $u_i - v_i = 0$. By $0 \leq u_i, v_i < p_i^l$, we have $\mathbf{u} = \mathbf{v}$.
In order to compute $\sharp\mathcal{C}_{N,l}$ we have to compute the number of elements of $\mathcal{H}_{N,l}$, which have hyperbolic distance less than $\frac{1}{Nf(N)}$. As each element of $\mathcal{H}_{N,l}$ lies in one and only one tile $T_{\mathbf{k},l}$, we get an upper bound on $\sharp\mathcal{C}_{N,l}$ by computing the number of tiles $T_{\mathbf{k},l}$ possessing a left lower corner with hyperbolic distance less than $\frac{1}{Nf(N)}$, i.e.,

$$\sharp\mathcal{C}_{N,l} \leq \sharp\left\{\mathbf{k} \in \mathcal{F}_{(l)} : ||\Phi(\mathbf{k})||_{\mathbf{0}} \leq \frac{1}{Nf(N)}\right\}.$$

Thus, we have reduced the problem to count lattice points contained in some body. The number of lattice points contained in a body is about the volume of the body divided by the volume of the fundamental parallelotope plus the number of lattice points that lie near the border. Here, to each lattice point there is a parallelotope with side lengths p_i^{-l} $(i = 1, \ldots, s)$ attached. Let R denote the number of points lying on one of the hyperplanes characterized by $\{\mathbf{z} \in [0,1]^s : x_i = 0\}$ for some $i = 1, \ldots, s$. Furthermore, define the sets

$$\mathcal{C}_{Nf(N)} = \left\{\mathbf{z} \in [0,1)^s \ : \ z_1 \cdots z_s < \frac{1}{Nf(N)}\right\}$$

and

$$\delta\mathcal{C}_{Nf(N)} = \left\{\mathbf{z} \in [0,1)^s \ : \ z_1 \cdots z_s = \frac{1}{Nf(N)}\right\}.$$

Set $\varepsilon := \sqrt{p_1^{-2l} + \cdots + p_s^{-2l}}$. The area near the border is given by

$$\Delta\mathcal{C}_{Nf(N)} = \{\mathbf{z} \in (\mathbb{R}^+)^s \ : \ |\delta\mathcal{C}_{Nf(N)} - \mathbf{z}| < \varepsilon\} \setminus \mathcal{C}_{Nf(N)},$$

where $|\delta\mathcal{C}_{Nf(N)} - \mathbf{z}|$ denotes the minimal Euclidean distance from $\delta\mathcal{C}_{Nf(N)}$ to $\mathbf{z}$.
Thus, a bound for $\sharp\mathcal{C}_{N,l}$ is given by

$$\sharp\mathcal{C}_{N,l} \leq \left(\lambda(\mathcal{C}_{Nf(N)}) + \lambda(\Delta\mathcal{C}_{Nf(N)})\right)(p_1\cdots p_s)^l + R,$$

where R is the number of lattice points lying in $\mathcal{C}_{Nf(N)} \cap \{\mathbf{z} \in [0,1)^s : z_i = 1\}$ for some $i \in \{1, \ldots, s\}$, i.e., the number of lattice points which lie on the remaining borders. By the definition of R we find that

$$R \leq (p_1\cdots p_s)^l \sum_{j=1}^{s} p_j^{-l} \leq (p_1\cdots p_s)^l \sqrt{s}\varepsilon.$$

Since $\delta\mathcal{C}_{Nf(N)}$ is convex, we may project it on each hyperplane $x_i = 0$ to get a bound for the volume of $\Delta C_{Nf(N)}$ of the form $s\epsilon$. This yields

$$\sharp\mathcal{C}_{N,l} \leq \left(\lambda(\mathcal{C}_{Nf(N)}) + (s+\sqrt{s})\varepsilon\right)(p_1 \cdots p_s)^l.$$

- *Computation of the volume.*
We claim that

$$\lambda(\mathcal{C}_k) = \frac{1}{k}\sum_{j=0}^{s-1}\frac{(\log k)^j}{j!} < \frac{(\log k)^{s-1}}{k}e.$$

Let us denote by $C_k^{(j)}$ the cylinder $\{(z_1, \dots z_s) \in [0,1)^s : z_1 \cdots z_j \leq 1/k\}$. Once we have proved $\lambda\left(C_k^{(j+1)} \setminus C_k^{(j)}\right) = \frac{(\log k)^j}{k(j!)}$, the claim follows by induction,

$$\begin{aligned}
&\lambda\left(C_k^{(j+1)} \setminus C_k^{(j)}\right) \\
&\quad= \int_{z_1=\frac{1}{k}}^1 \int_{z_2=\frac{1}{kz_1}}^1 \cdots \int_{z_j=\frac{1}{kz_1\cdots z_{j-1}}}^1 \int_{z_{j+1}=0}^{\frac{1}{kz_1\cdots z_j}} \int_{z_{j+2}=0}^1 \cdots \int_{z_s=0}^1 1 \; dz_s \cdots dz_1 \\
&\quad= \int_{z_1=\frac{1}{k}}^1 \int_{z_2=\frac{1}{kz_1}}^1 \cdots \int_{z_j=\frac{1}{kz_1\cdots z_{j-1}}}^1 \frac{1}{kz_1\cdots z_j}\; dz_j \cdots z_1 \\
&\quad= \int_{z_1=\frac{1}{k}}^1 \int_{z_2=\frac{1}{kz_1}}^1 \cdots \int_{z_{j-1}=\frac{1}{kz_1\cdots z_{j-2}}}^1 \frac{\log(kz_1\cdots z_{j-1})}{kz_1\cdots z_{j-1}}\; dz_{j-1}\cdots dz_1 \\
&\quad= \int_{z_1=\frac{1}{k}}^1 \int_{z_2=\frac{1}{kz_1}}^1 \cdots \int_{z_{j-2}=\frac{1}{kz_1\cdots z_{j-3}}}^1 \frac{(\log(kz_1\cdots z_{j-2}))^2}{2kz_1\cdots z_{j-2}}\; dz_{j-2}\cdots dz_1 \\
&\quad= \cdots = \frac{(\log k)^j}{k(j!)}.
\end{aligned}$$

- *The probability that the Nth point of a Halton sequence is close to* $\mathbf{0}$.
Remember that $\mathcal{A}'_N := \bigcap_{l=l_0}^{\infty}\mathcal{A}'_{N,l}$, where $l_0 = \left\lfloor\frac{\log(Nf(N))}{\log 2}\right\rfloor + 1$. Since $\mathcal{A}'_{N,l+1} \subset \mathcal{A}'_{N,l}$, the set A'_N is measurable.
The volume of $A'_{N,l}$ may now be estimated by

$$\lambda(\mathcal{A}'_{N,l}) \leq e\frac{(\log(Nf(N)))^{s-1}}{Nf(N)} + (s+\sqrt{s})\varepsilon.$$

Since $\varepsilon \to 0$ as $l \to \infty$, we conclude that

$$\lambda(\mathcal{A}'_N) \leq e\frac{(\log(Nf(N)))^{s-1}}{Nf(N)}.$$

- *The probability that the random-start Halton sequence is approaching* $\mathbf{0}$.
Let us define the sets

$$\mathcal{B}_0 := \{\mathbf{z} : (\mathbf{x}_n^{\mathbf{z}})_{n\geq 1} \text{ is approaching } \mathbf{0}\} \quad \text{and}$$

$$\mathcal{B}_0^{(k)} := \{\mathbf{z} : (\mathbf{x}_n^{\mathbf{z}})_{n\geq 1} \text{ has at least } k \text{ points that are close to } \mathbf{0}\}.$$

Hence, $\mathcal{B}_0^{(k+1)} \subset \mathcal{B}_0^{(k)}$ and

$$\bigcap_{k=1}^{\infty} \mathcal{B}_0^{(k)} = \mathcal{B}_0.$$

If in a sequence $(\mathbf{x}_n)$ there are k points close to $\mathbf{0}$, then the index N_k of the kth point $\mathbf{x}_{N_k}$ that is close to $\mathbf{0}$ is in the set $\{N \in \mathbb{Z}^+ : N \geq k\}$. Therefore

$$\mathcal{B}_0^{(k)} \subset \bigcup_{N=k}^{\infty} \mathcal{A}'_N.$$

If we take into account the definition of $\mathcal{B}_0$, then

$$\mathcal{B}_0 \subset \mathcal{B}'_0 := \bigcap_{k=1}^{\infty} \bigcup_{N=k}^{\infty} \mathcal{A}'_N.$$

Since the Lebesgue measure is continuous, we find

$$\mathcal{B}'_0 = \lim_{k\to\infty} \sum_{N=k}^{\infty} \lambda(\mathcal{A}'_N) \leq \lim_{k\to\infty} \sum_{N=k}^{\infty} e\frac{(\log(Nf(N)))^{s-1}}{Nf(N)} = 0,$$

by the assumption $\sum_{N=1}^{\infty} \frac{(\log(Nf(N)))^{s-1}}{Nf(N)} < \infty$. Finally, $\lambda(\mathcal{B}'_0) = 0$ includes $\lambda(\mathcal{B}_0) = 0$ by the completeness of the Lebesgue measure.

- *Deduction from one corner to all corners.*
  If a sequence $(\mathbf{x}_n^{\mathbf{z}})_{n\geq 1}$ approaches a corner $\mathbf{h} \in \{0,1\}^s$, then the sequence $\left(\mathbf{x}_n^{\mathbf{z}'}\right)_{n\geq 1}$ with $z'_i = \Phi_{p_i}(\tilde{\Phi}_{p_i}(x_i) - h_i)$ approaches the corner $\mathbf{0}$. Thus, the probability for a random-start Halton sequence to approach any corner is 2^s times the probability for approaching $\mathbf{0}$. Hence, $\lambda(\mathcal{A}) = 0$. ∎

Finally, let us give the following corollary.

COROLLARY 1. *Almost all random-start Halton sequences avoid all corners, i.e., for any fixed $\epsilon > 0$ there exists a constant $c = c(\epsilon, p_1, \ldots, p_s) > 0$ such that for any corner $\mathbf{h} \in \{0,1\}^s$ and all $n \geq 1$ the condition*

$$\|\mathbf{x}_n\|_{\mathbf{h}} > cn^{-1-\epsilon}$$

is fulfilled.

Proof. The result is a direct consequence of Theorem 5 and Lemma 1 combined with the fact that

$$\sum_{n=1}^{\infty} \frac{\log(n^{1+\epsilon})^{s-1}}{n^{1+\epsilon}} = \sum_{n=1}^{\infty} \frac{(1+\epsilon)^{s-1}\log(n)^{s-1}}{n^{1+\epsilon}} < \infty. \qquad ∎$$

Remark. Theorem 4 could also be proved by similar methods (counting lattice points in hyperbolic areas) as used in the proof of Theorem 5. However, we gave a "Diophantine proof" of Theorem 4, because it is completely different and, moreover, it provides more information on the structure whose points avoid corners. For example, it is possible to show that the (nonrandomized) Halton sequence avoids all corners with the "Diophantine approach" (cf. [4]).

On the other hand we could also use Theorem 4 in the proof of Theorem 5. Indeed instead of counting lattice points one could apply Theorem 4 directly to estimate the

number of starting points that come close to a corner. But in this case we had to restrict the proof to the case $f(n) = n^{\epsilon}$.

Lastly, note that in Corollary 1 the factor $\frac{c}{n^{1+\epsilon}}$ could be replaced by $\frac{c}{n(\log n)^s \log_2 n \cdots \log_{l-1} n(\log_l n)^{1+\epsilon}}$, where $\log_k n$ is the k times iterated logarithm of n.

ANALYSIS OF PROFILE FUNCTIONS FOR GENERAL LINEAR REGULARIZATION METHODS*

BERND HOFMANN† AND PETER MATHÉ‡

Abstract. The stable approximate solution of ill-posed linear operator equations in Hilbert spaces requires regularization. Tight bounds for the noise-free part of the regularization error are constitutive for bounding the overall error. Norm bounds of the noise-free part which decrease to zero along with the regularization parameter are called profile functions and are the subject of our analysis. The interplay between properties of the regularization and certain smoothness properties of solution sets, which we shall describe in terms of sourcewise representations, is crucial for the decay of associated profile functions. On the one hand, we show that a given decay rate is possible only if the underlying true solution has appropriate smoothness. On the other hand, if smoothness fits the regularization, then decay rates are easily obtained. If smoothness does not fit, then we will measure this in terms of some distance function. Tight bounds for these allow us to obtain profile functions. Finally we study the most realistic case when smoothness is measured with respect to some operator which is related to the one governing the original equation only through a link condition. In many parts the analysis is done on geometric basis, extending classical concepts of linear regularization theory in Hilbert spaces. We emphasize intrinsic features of linear ill-posed problems which are frequently hidden in the classical analysis of such problems.

Key words. linear ill-posed problems, regularization, distance function, convergence rates, index function, source condition, qualification, range inclusion

1. Introduction.

We study noisy linear operator equations

$$y^\delta = Ax^\dagger + \delta\xi \qquad (\|\xi\| \le 1)\,, \tag{1.1}$$

where $A : X \to Y$ is some bounded linear operator mapping between infinite-dimensional separable Hilbert spaces X and Y and $\delta > 0$ denotes the noise level. The spaces X and Y are equipped with norms $\|\cdot\|$. The same norm symbol is also used for associated operator norms.

We assume that A is *injective* and that the range $\mathcal{R}(A)$ is *not closed* in Y. Then the *linear operator equation* $Ax = y$ has a unique solution $x = x^\dagger \in X$, for every $y \in \mathcal{R}(A)$, but the equation is *ill-posed* since A^{-1} is an unbounded operator. Thus regularization is required in order to find stable approximate solutions of the operator equation based on noisy data $y^\delta \in Y$. We consider general linear regularization schemes based on a family of piecewise continuous functions $g_\alpha(t)$ $(0 < t \le a := \|A^*A\|)$ for regularization parameters $0 < \alpha \le \overline{\alpha}$. The family g_α determines the *regularization method*. Once a regularization g_α is chosen, the approximate solution to (1.1) is given by

$$x_\alpha^\delta = g_\alpha(A^*A)A^*y^\delta.$$

‡Weierstraß Institute for Applied Analysis and Stochastics, Mohrenstraße 39, 10117 Berlin, Germany (mathe@wias-berlin.de).

For such approximate solution x_α^δ we obtain an obvious error bound, using the intermediate quantity $x_\alpha = g_\alpha(A^*A)A^*y = g_\alpha(A^*A)A^*Ax^\dagger$, as

$$(1.2)\quad e(x^\dagger,\alpha,\delta) := \|x_\alpha^\delta - x^\dagger\| \le \|x^\dagger - x_\alpha\| + \delta\|g_\alpha(A^*A)A^*\| \qquad \text{for all} \quad 0<\alpha\le\overline{\alpha}.$$

The second summand on the right is independent of the underlying true solution. Let us denote by $r_\alpha(t) := 1 - t\,g_\alpha(t)$ $(0 < t \le a)$ the residual or bias functions related to the regularization method g_α, thus $\|x^\dagger - x_\alpha\| = \|r_\alpha(A^*A)x^\dagger\|$. In these terms, tight bounds on the norm of the residual are constitutive for the accuracy of the regularized solution. Bounds which are increasing functions in $\alpha > 0$ will give rise to what we call profile functions.

The outline is as follows. In section 2 we recall the basic underlying quantities, namely general linear regularization methods for operator equations in Hilbert space and the concept of solution smoothness in terms of general source conditions. Then, in section 3 we associate profile functions to any given regularization and to any set of smooth solutions and discuss their existence. The rate at which profile functions decay to zero turns out to be crucial and is the objective of our analysis. It will become clear that this rate depends on the underlying regularization as well as on the solution smoothness. In section 4 we indicate situations when maximal rates of decay occur, regardless of the underlying solution smoothness, namely due to the limited qualification of the regularization method. We close this part by showing that decay rates imply solution smoothness.

The constructive part of obtaining explicit descriptions of profile functions, as dependent on the qualification of the regularization and smoothness properties of the solution with respect to the operator A, is carried out in sections 5 and 6 for several degrees of generality. We start in section 5 with the easiest case, when solution smoothness is measured in terms of general source conditions given through functions of A^*A. This is then extended to the situation where a source condition is satisfied only approximately, measured in terms of a specific concept of distance functions. Tight upper bounds for such distance functions imply profile functions.

We close the analysis with section 6 discussing the situation when solution smoothness is measured with respect to a self-adjoint operator $G : X \to X$ with nonclosed range which is different from A^*A. In this case an assumption, linking A^*A and G, will allow us to draw conclusions on the decay rate of the associated profile functions.

In many parts the analysis is done on a geometric basis, extending classical concepts as those used in the theory of linear ill-posed equations in Hilbert space. By doing so we not only extend previous results to a more general situation, but we aim at emphasizing intrinsic features of the problems under consideration. Such features are often hidden in the classical analysis of linear ill-posed problems.

2. General linear regularization methods and general smoothness. As mentioned in the introduction, profile functions will be assigned to regularization methods and solution sets of (1.1). We start with the notion of a general linear regularization scheme. Then we turn to the description of solution smoothness in terms of general source conditions.

The basic underlying objects are index functions, and we recall the following definition, as known in the literature (e.g., [7, 14, 3]).

DEFINITION 2.1. *A real function $\varphi(t)$ $(0 < t \le \bar{t})$ is called an* index function *if it is continuous, strictly increasing, and satisfies the limit condition* $\lim_{t\to 0+}\varphi(t) = 0$.

2.1. General regularization methods.

DEFINITION 2.2. *A family of functions $g_\alpha(t)$ $(0 < t \le a)$, defined for parameters $0 < \alpha \le \overline{\alpha}$, is called a* regularization *if they are piecewise continuous in α and the following three properties are satisfied:*

(i) *For each $0 < t \le a$ there is convergence $|r_\alpha(t)| \to 0$ as $\alpha \to 0$.*

(ii) *There is a constant γ_1 such that $|r_\alpha(t)| \le \gamma_1$ for all $0 < \alpha \le \overline{\alpha}$.*

(iii) *There is a constant γ_* such that $\sqrt{t}\,|g_\alpha(t)| \le \gamma_*/\sqrt{\alpha}$ for all $0 < \alpha \le \overline{\alpha}$.*

Example 2.3. The most famous method of regularization is the *Tikhonov method* with $g_\alpha(t) = 1/(t+\alpha)$, which satisfies the properties of Definition 2.2 for the constants $\gamma_1 = 1$ and $\gamma_* = 1/2$ and arbitrarily large $\overline{\alpha} > 0$.

Example 2.4. Another common regularization method is *spectral cut-off*, which is given as

$$g_\alpha(t) = \begin{cases} 0 & (0 < t < \alpha) \\ 1/t & (\alpha \le t \le a) \end{cases} \quad \text{with respective residual } r_\alpha(t) = \begin{cases} 1 & (0 < t < \alpha) \\ 0 & (\alpha \le t \le a). \end{cases}$$

Obviously this obeys the properties from Definition 2.2 with $\gamma_1 = \gamma_* = 1$. Also for that method, the upper bound $\overline{\alpha}$ for the regularization parameter can be selected arbitrarily.

Example 2.5. Iterative regularization methods, as, for instance, *Landweber iteration*, where for some $0 < \mu < 1/\|A^*A\|$ we let

$$x_n^\delta := \mu \sum_{j=0}^{n-1} (I - \mu A^*A)^j A^* y^\delta, \quad n = 1, 2, \dots,$$

are conform to this approach when assigning $n := \lfloor 1/\alpha \rfloor$ $(0 < \alpha < 1)$. Thus with this identification we obtain $g_\alpha(t) := 1/t\left(1 - (1-\mu t)^{\lfloor 1/\alpha \rfloor}\right)$ and the corresponding residual $r_\alpha(t) := (1-\mu t)^{\lfloor 1/\alpha \rfloor}$ $(0 < \alpha < 1)$, hence obviously $\gamma_1 = 1$. It remains to bound γ_*. Bernoulli's inequality yields $1 - n\mu t \le (1-\mu t)^n$, which can be used to bound

$$\sqrt{t} g_\alpha(t) = 1/\sqrt{t}\,(1 - (1-\mu t)^n) \le (1/t\,(1 - (1-\mu t)^n))^{1/2} \le \sqrt{\mu n}\,.$$

By the definition of n this yields $\gamma_* = \sqrt{\mu}$.

The above requirements (i)–(iii) are made to ensure convergence of regularization methods for any given element $x^\dagger \in X$. However, these are not enough to describe rates of convergence.

As introduced in the papers [13, 14, 15, 16], we measure the *qualification* of any regularization method in terms of index functions ψ.

DEFINITION 2.6. *Let $\psi(t)$ $(0 < t \le a)$ be an index function. A regularization g_α for the operator equation* (1.1) *is said to have qualification ψ with constant $\gamma \in (0, \infty)$ if*

$$\sup_{0<t\le a} |r_\alpha(t)|\,\psi(t) \le \gamma\,\psi(\alpha) \qquad \text{for all} \quad 0 < \alpha \le a\,. \tag{2.1}$$

This definition generalizes the concept of qualification of a regularization method as a finite number or infinity, as, for example, used in [5]. We remark that a first systematic discussion of the interrelations between solution smoothness and the traditional concept of qualification was given in [25, 26].

For Tikhonov regularization (see Example 2.3) we can give sufficient conditions for ψ being a qualification in different ways, as this is formulated in the following proposition. For more details and proofs we refer to [15, 16, 3].

PROPOSITION 2.7. *The index function $\psi(t)$ $(0 < t \le a)$ is a qualification of Tikhonov regularization with constant $\gamma = 1$ if either* (a) *$\psi(t)/t$ is nonincreasing on $(0, a]$ or* (b) *$\psi(t)$ is concave on $(0, a]$.*

If there exists an argument $\hat{t} \in (0, a)$ such that (c) *$\psi(t)/t$ is nonincreasing on $(0, \hat{t}\,]$ or* (d) *$\psi(t)$ is concave on $(0, \hat{t}\,]$, then ψ is a qualification with constant $\gamma = \psi(a)/\psi(\hat{t}\,)$.*

2.2. Measuring solution smoothness. In a wide sense the smoothness of expected solutions $x^\dagger$ to (1.1) can be written as a property of the form $x^\dagger \in M$ with $M \subseteq \mathcal{R}(G)$ for some "smoothing" linear operator $G : X \to X$, where G is assumed to be positive self-adjoint with nonclosed range $\mathcal{R}(G)$ (see also [3, 18]). Specifically, here we shall assume that the solution $x^\dagger$ belongs to a set

$$G_\tau(R) := \{x \in X : \ x = \tau(G)w, \quad \|w\| \le R\} \tag{2.2}$$

with some index function $\tau(t)$ $(0 < t \le \|G\|)$.

As the following lemma asserts, such a set is closed in X and even compact whenever G is compact.

LEMMA 2.8. *For a positive self-adjoint bounded linear operator $G : X \to X$ and an index function $\tau(t)$ $(0 < t \le \|G\|)$ the set $G_\tau(R)$ from* (2.2) *is closed in X. Moreover, $G_\tau(R)$ is a compact subset of X whenever G is a compact operator.*

Proof. First we show that $G_\tau(R)$ is a closed subset in X. We show that the image $\{x \in X : x = Gw, \ w \in X, \ \|w\| \le R\}$ of the centered ball with radius R in X with respect to any bounded positive self-adjoint linear operator $G : X \to X$ is a closed subset of X. Since $\tau(G)$ has the same properties as a consequence of the boundedness of any index function τ, this shows the closedness of $G_\tau(R)$. Consider a convergent sequence of images $Gx_n \to y_0 \in X$ with $\|x_n\| \le R$. Since any closed ball in X is weakly precompact and weakly closed, there is a weakly convergent subsequence $x_{n_k} \rightharpoonup x_0$ with $\|x_0\| \le R$. Since every continuous operator G is also weakly continuous and hence weakly closed, this implies the weak convergence $Gx_{n_k} \rightharpoonup Gx_0$, thus $y_0 = Gx_0$ which shows the required closedness. Moreover, for compact G it is evident that $\tau(G) : X \to X$ is a compact operator and then $G_\tau(R)$ is a precompact subset of X. Since $G_\tau(R)$ is closed in X, this implies the compactness and proves the lemma. ∎

In our analysis below for index functions τ we shall assign pairs (G, τ) Hilbert spaces X_τ^G having $G_\tau(1)$ as their unit balls. In particular, we use the shortcut $H := A^*A$ and consider Hilbert spaces X_φ^H for index functions φ with the set $H_\varphi(1)$ as unit ball, where we define

$$H_\varphi(R) := \{x \in X : \ x = \varphi(A^*A)w, \quad \|w\| \le R\}\,. \tag{2.3}$$

Corresponding norms will be denoted by $\|\cdot\|_{X_\tau^G}$ and $\|\cdot\|_{X_\varphi^H}$, respectively. This construction is basically due to [6].

3. Profile functions. In this section we shall introduce the notion of a profile function, discuss the problem of existence, and show that their decay is related to smoothness of the underlying solution $x^\dagger$ of (1.1).

3.1. Definition and existence. Having chosen a linear regularization g_α, and having fixed a set $M \subset X$ of possible solutions to (1.1) we assign profile functions as follows.

DEFINITION 3.1. *An index function* $f\colon (0,\overline{\alpha}] \to (0,\infty)$ *is called* profile function for (M, g_α) *whenever*

$$\sup_{x\in M} \|r_\alpha(A^*A)x\| \le f(\alpha) \qquad \textit{for all} \quad 0<\alpha\le\overline{\alpha}\,. \tag{3.1}$$

In the definition we suppress the dependence of profile functions f on the operator A, governing (1.1). If $M := \{x\} \in X$ is a singleton, then we shall write (x, g_α) instead of $(\{x\}, g_\alpha)$. Note that the bound (3.1) is required only for $\alpha \le \overline{\alpha}$, which is useful for asymptotic considerations as $\delta \to 0$ in (1.1).

The character of possible profile functions f for (M, g_α) is closely connected with three ingredients and their interplay. In this context, properties of the regularization g_α as first component and of the set $M \subset X$ expressing the solution smoothness as second components meet as third component the smoothing behavior of the operator A in (1.1), which leads to the nonclosedness of the range $\mathcal{R}(A)$.

Remark 3.2. Once a profile function $f(\alpha)$ as above is found, together with property (iii) of Definition 2.2, we may then continue the estimate (1.2) to derive

$$e(x^\dagger,\alpha,\delta) \le f(\alpha) + \frac{\gamma_*\,\delta}{\sqrt{\alpha}} \qquad \text{for all} \quad 0<\alpha\le\overline{\alpha}\,, \tag{3.2}$$

uniformly for $x^\dagger \in M$. The bound on the right in (3.2) can be balanced with respect to the choice of α depending on δ. To this end we consider the index function

$$\Theta(\alpha) := \sqrt{\alpha}\, f(\alpha) \qquad (0<\alpha\le\overline{\alpha}).$$

Let $\alpha_* = \alpha_*(\delta) = \Theta^{-1}(\delta)$ $(0 < \delta \le \Theta(\bar\alpha))$. Then we obtain uniformly for $x^\dagger \in M$ that

$$e(x^\dagger,\alpha_*,\delta) \le (1+\gamma_*) f(\alpha_*). \tag{3.3}$$

Thus the function $f(\Theta^{-1}(\delta))$ yields a *convergence rate* of the regularization g_α for $x^\dagger$ as $\delta \to 0$. This rate is achieved by an a priori parameter choice $\alpha_* = \alpha_*(\delta)$.

First we shall establish that profile functions exist for any regularization g_α and compact subsets $M \subset X$.

PROPOSITION 3.3. *Let* g_α *be any regularization and* $M \subset X$ *be compact. Then there is a profile function for* (M, g_α).

Proof. From the properties (i) and (ii) of Definition 2.2, we deduce for $\alpha \to 0$ pointwise convergence $r_\alpha(A^*A)x \to 0$ for all $x \in X$ (see, e.g., [5, Theorem 4.1]). This convergence is uniform on compact sets $M \subset X$. Hence we have

$$h(\alpha) := \sup_{x\in M} \|r_\alpha(A^*A)x\| \to 0 \quad \text{as } \alpha\to 0.$$

Its increasing majorant $\bar h(\alpha) := \sup_{0<s\le\alpha} h(s)$, which is well-defined for sufficiently small positive α, satisfies $\lim_{\alpha\to 0} \bar h(\alpha) = 0$. If $\bar h(\alpha)$ is continuous and nonvanishing, then it is a profile function. Otherwise, suppose $\bar h(s) = 0$ for some $s > 0$. We fix some $t > 0$ with $\bar h(t) > 0$ and let

$$\hat h(x) := \begin{cases} \bar h(x), & x > t,\\ \bar h(t), & s < x \le t,\\ x/s\ \bar h(t), & 0 < x \le s, \end{cases}$$

which, when continuous, defines an index function. ∎

Thus if G is compact and τ is an index function, then for any regularization g_α there are profile functions for $(G_\tau(R), g_\alpha)$, where the sets $G_\tau(R)$ were defined in (2.2).

On the other hand, there cannot exist profile functions for (M, g_α), where $M := \{x \in X : \|x\| \le 1\}$ is the unit ball in X. Their existence would imply that $\|r_\alpha(A^*A)\|$ tends to zero as $\alpha \to 0$ and hence that the range $\mathcal{R}(A)$ were closed, which would be contrary to the ill-posedness of the problem under consideration (see, e.g., [23] and [5, Chapter 3.1]). More generally, extending this argument, profile functions cannot exist for (M, g_α), whenever M possesses an interior point.

However, there are profile functions for noncompact sets. In Proposition 5.1, profile functions for $(H_\varphi(R), g_\alpha)$ will be obtained, where the operator A may be compact (ill-posedness of type II in the sense of Nashed [19]) or noncompact (ill-posedness of type I). In the latter case this yields noncompact sets $M = H_\varphi(R)$. Another specific example of profile functions for the noncompact set $M = \{x \in L^\infty(0,1) : \|x\|_{L^\infty(0,1)} \le R\} \subset X = L^2(0,1)$ for the Tikhonov regularization and multiplication operators A mapping in $L^2(0,1)$ can be taken from [10]. This is not by chance and some explanation will be given in Remark 5.2. Roughly speaking, if smoothness properties of M are appropriate for the underlying operator A from (1.1), then profile functions exist for (M, g_α), regardless of their compactness. In this respect, compactness of M may be viewed as universal (problem independent) smoothness.

3.2. Decay rates yield solution smoothness. To exhibit the fact that a decay rate of a profile function implies solution smoothness in the sense of section 2.2, we start with the following result, which extends analysis in [21], and we also refer to the recent monograph [1]. We recall that the operator $H = A^*A$ admits a spectral resolution with a family $(E_\lambda)_{0<\lambda\le a}$ of projections, which is assumed to be such that $\lambda \mapsto \|E_\lambda x^\dagger\|^2$ is left continuous, thus representing a (spectral) measure. We start with the following technical result from [21, Lemma 2.1]; see also [5, Proof of Proposition 4.13].

LEMMA 3.4. *Let $g_\alpha(t)$ $(0 < t \le a,\ 0 < \alpha \le \bar\alpha)$ be a regularization with constant γ_*. If $0 < t \le \min\{\alpha, a\}$, then $\left|r_{(4\gamma_*^2\alpha)}(t)\right| \ge 1/2$.*

The above lemma yields the following estimate.

LEMMA 3.5. *Let g_α be a regularization with constant γ_* as in property* (iii) *of Definition* 2.2. *The following estimate holds true:*

$$\|r_{(4\gamma_*^2\alpha)}x^\dagger\| \ge \frac{1}{2}\left(\int_0^\alpha d\|E_\lambda x^\dagger\|^2\right)^{1/2} \qquad \text{for all} \quad 0 < \alpha \le \min\left\{a, \bar\alpha/4\gamma_*^2\right\}. \tag{3.4}$$

Before turning to the main result of this section we state the following lemma.

LEMMA 3.6. *Suppose $\varphi(t)$ $(0 < t \le \bar t)$ is an index function. There is a sequence $f_n(t)$ $(0 < t \le \bar t)$ of step functions of the form $\sum_{j=1}^m c_j \chi_{(0,\alpha_j)}(t)$ converging to $1/\varphi(t)$ pointwise and $f_n(t) \le 1/\varphi(t)$.*

Proof. Given any such φ and $n \in \mathbb{N}$ large enough $n \ge n_0$, we let $f(t) = 1/\varphi(t)$ and truncate at $t_n = f^{-1}(n) < \bar t$ to obtain $g^n(t)$ $(0 \le t \le \bar t)$, which is a nonincreasing bounded continuous function on the closed interval $[0, \bar t]$. Thus there is a step function $f_n(t)$ of the required form, satisfying $|f_n(t) - g^n(t)| \le 1/n$. The sequence $f_n(t)$ $(0 < t \le \bar t)$, $n = n_0, n_0+1, \ldots$, converges pointwise to f. ∎

Given a regularization g_α with constant γ_* and any index function $h(t)$ $(0 < t \le$

a), we can assign a nonnegative measure Φ_h on $(0,a]$ by letting

$$\Phi_h[0,\alpha) := h(4\gamma_*^2\alpha) \quad (0 < 4\gamma_*^2\alpha \le a).$$

With this notation we can formulate the following result.

THEOREM 3.7. *Let $g_\alpha(t)$ $(0 < t \le a)$ for the parameters $0 < \alpha \le \bar\alpha$ be a regularization with constant γ_*. We assume that the index function $f(\alpha)$ $(0 < \alpha \le \bar\alpha)$ is a profile function for $(x^\dagger, g_\alpha)$ with associated measure $\Phi = \Phi_{f^2}$, restricted to the interval $J_* := (0, \min\{a, \bar\alpha/4\gamma_*^2\}]$. Then the following assertions are true:*

(a) *If ψ is any index function such that $1/\psi \in L^2(J_*, d\Phi)$, then necessarily $x^\dagger \in X_\psi^H$.*

(b) *Let ψ be an index function for which $t \mapsto 1/(\psi^2((f^2)^{-1}(t))) \in L^1_{\rm loc}(J_*, dt)$, i.e., it is locally integrable. Then $x^\dagger \in X_\psi^H$.*

Proof. Using Lemma 3.5 and the fact that $f(\alpha)$ $(0 < \alpha \le \bar\alpha)$ is assumed to be a profile function for $(x^\dagger, g_\alpha)$ we conclude that the estimate

$$\frac{1}{4}\int_0^\alpha d\|E_\lambda x^\dagger\|^2 \le \|r_{(4\gamma_*\alpha)}x^\dagger\|^2 \le f^2(4\gamma_*^2\alpha) = \int_0^\alpha d\Phi(\lambda) \quad (\alpha \in J_*) \tag{3.5}$$

is valid.

Now let ψ be any index function such that $1/\psi(t) \in L^2(J_*, d\Phi)$. By Lemma 3.6 we can find a sequence $f_n(t)$ of step functions on J_*, converging to $1/\psi^2(t)$ pointwise. Using (3.5) and the particular form of f_n we deduce that

$$\frac{1}{4}\int_{J_*} f_n(\lambda) d\|E_\lambda x^\dagger\|^2 \le \int_{J_*} f_n(\lambda) d\Phi(\lambda) \le \int_{J_*} \frac{1}{\psi^2(\lambda)} d\Phi(\lambda).$$

By Fatou's lemma we conclude that also $1/\psi(t) \in L^2(J_*, d\|E_\lambda x^\dagger\|^2)$ and

$$\|1/\psi\|_{L^2(J_*, d\|E_\lambda x^\dagger\|^2)} \le 2\|1/\psi\|_{L^2(J_*, d\Phi)}.$$

Consequently,

$$\begin{aligned}
\|x^\dagger\|_{X_\psi^H}^2 &= \int_0^a \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 \\
&= \int_{J_*} \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 + \int_{(0,a]\setminus J_*} \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 \\
&\le 4\|1/\psi\|^2_{L^2(J_*, d\Phi)} + \frac{1}{\min_{\lambda\in(0,a]\setminus J_*}\psi^2(\lambda)}\|x^\dagger\|^2 < \infty,
\end{aligned} \tag{3.6}$$

because the second summand on the right is finite, which proves assertion (a).

We use a change of measure to establish assertion (b). The proof is complete. ∎

Remark 3.8. If the interval J_* coincides with $(0,a]$, then the second summand on the right in (3.6) does not appear and we get a bound $\|x^\dagger\|_{X_\psi^H} \le 2\|1/\psi\|_{L^2((0,a], d\Phi)}$. The following elementary observation is useful.

LEMMA 3.9. *Suppose ψ, ψ_1 and f, f_1 are pairs of index functions which are related by some common strictly increasing function g as $f(t) = f_1(g(t))$ and $\psi(t) = \psi_1(g(t))$ on the respective domains of the definition. Then it holds true that $f(\psi^{-1}(t)) = f_1(\psi_1^{-1}(t))$.*

Theorem 3.7 also covers cases which were known before, like the ones discussed in the following examples.

Example 3.10 (see [21]). If the profile function f for $(x^\dagger, g_\alpha)$ is a monomial $f(\alpha) = \alpha^\nu$ for some $\nu > 0$, then we can draw the following conclusion. For every monomial $\psi(t) = t^\mu$ we obtain $1/\psi^2((f^2)^{-1}(t)) = t^{-\mu/\nu}$, which is integrable on every finite interval for $\mu < \nu$. Hence we deduce that necessarily $x^\dagger \in X_\psi^H$ for all $0 < \mu < \nu$.

Example 3.11 (see [12, Theorem 8]). If the profile function f for $(x^\dagger, g_\alpha)$ is of logarithmic type, say $f(\alpha) = \log^{-\nu}(1/\alpha)$ $(0 < \alpha < 1)$ for some $\nu > 0$, then by using Lemma 3.9 we also deduce that necessarily $x^\dagger \in X_\psi^H$ for all functions $\psi(t) = \log^{-\mu}(1/t)$ $(0 < t < 1)$ with $\mu < \nu$, because both are related to the respective functions from Example 3.10 through $g(t) := \log^{-1}(1/t)$ $(0 < t < 1)$.

4. Lower bounds for profile functions. In general profile functions $f(\alpha)$ can decrease to zero arbitrarily fast as α tends to zero. This is, for instance, the case when g_α is chosen as spectral cut-off in Example 2.4 and $x^\dagger$ is an eigenelement of A^*A, in which case $\|r_\alpha(A^*A)x^\dagger\| \equiv 0$ for α small enough.

However, for many regularization methods there is a maximal speed of convergence $\|r_\alpha(A^*A)x^\dagger\| \to 0$ as $\alpha \to 0$, for any $x^\dagger \neq 0$, regardless of its smoothness. This phenomenon is related to *saturation*, as was studied, e.g., in [21, 22], and in more generality in [13], from which the present approach is taken. The impact of limited qualification on profile functions can be seen under an additional convexity assumption.

THEOREM 4.1. *Let g_α be any regularization with residual r_α. Suppose that for all $0 < t \le a$ the functions*

$$\alpha \mapsto |r_\alpha(t)| \qquad (0 < \alpha \le \overline{\alpha}) \tag{4.1}$$

are increasing, and for all $0 < \alpha \le \overline{\alpha}$ the functions

$$t \mapsto |r_\alpha(t)|^2 \quad (0 < t \le a) \tag{4.2}$$

are convex. Let $\bar\psi$ be given as

$$\bar\psi(\alpha) := \inf_{0<t\le a} |r_\alpha(t)| \quad (0 < \alpha \le \overline{\alpha}). \tag{4.3}$$

Then for each $0 \neq x \in X$ we have

$$\bar\psi(\alpha) \le \frac{1}{\|x\|}\|r_\alpha(A^*A)x\| \qquad \textit{for all} \quad 0 < \alpha \le \overline{\alpha}. \tag{4.4}$$

Hence $\bar\psi$ is a nondecreasing lower bound to any profile function for (x_0, g_α) uniformly for all elements $x_0 \in X$ of the unit sphere, i.e., with $\|x_0\| = 1$.

Sketch of a proof. To prove that $\bar\psi$ is a lower bound to any profile function for (x_0, g_α) we use a Jensen-type inequality (see, e.g., [13]), which yields that under (4.2) we have

$$\bar\psi(\alpha) \le \left|r_\alpha(\|Ax\|^2/\|x\|^2)\right| \le \frac{\|r_\alpha(A^*A)x\|}{\|x\|} \qquad \text{for all} \quad 0 < \alpha \le \overline{\alpha}.$$

Moreover, under (4.1) the function $\bar\psi$ is nondecreasing. This completes the proof. ∎

Remark 4.2. In many cases, the above function $\bar\psi(\alpha)$ turns out to be a qualification of the regularization g_α. In such a case it is maximal qualification.

We shall exhibit the above result in the following examples.

Example 4.3. For Tikhonov regularization as in Example 2.3 we easily verify that the assumptions are satisfied. We conclude that $\bar\psi(\alpha) = \alpha/(\alpha + a)$ with $\bar\psi(\alpha) \ge \alpha/(2a)$ $(0 < \alpha < a)$. In this case this corresponds to the maximal qualification which is $\psi(\alpha) = \alpha$.

Example 4.4. The n-fold iterated Tikhonov regularization, which has $r_\alpha(t) = (\alpha/(\alpha+t))^n$ as its residual function, also satisfies the assumptions from Theorem 4.1 and $\bar\psi(\alpha) = (\alpha/(\alpha + a))^n \ge (\alpha/(2a))^n$. This method corresponds to the maximal known qualification $\psi(\alpha) = \alpha^n$.

As in [13] we close with the following example, which is interesting as it shows that regularization, which has arbitrary classical qualification in the form $\psi(t) = t^q$ for any $0 < q < \infty$, still has a limited rate of decay for the profile functions, although these can decay exponentially fast.

Example 4.5. Landweber iteration from Example 2.5 also satisfies all the assumptions. The function $\bar\psi$, letting $0 < b := 1/(1 - \mu a) < \infty$, turns out to be $\bar\psi(\alpha) = (1 - \mu a)^{\lfloor 1/\alpha \rfloor} \ge \exp(-b/\alpha)$ $(0 < \alpha < 1)$.

Finally we stress that spectral cut-off, as in Example 2.4, does not fulfill the above assumptions. Moreover, formally we would obtain the lower bound $\bar\psi(\alpha) \equiv 0$, which is trivial.

Remark 4.6. Lower bounds for profile functions are related to the saturation phenomenon as we shall briefly sketch. The following estimate is shown in the cause of the proof of the theorem in [13]:

$$\sup_{\|\xi\| \le 1} e(x^\dagger, g_\alpha, \delta) \ge \max\left\{\|r_\alpha(A^*A)x^\dagger\|, \delta/\sqrt{\alpha}\right\} \quad (0 < \alpha \le \bar\alpha). \tag{4.5}$$

Thus, if $\bar\psi(\alpha)$ is a lower bound as in (4.4), then for any $x^\dagger$ with $\|x^\dagger\| = 1$ we derive that

$$\sup_{\|\xi\| \le 1} e(x^\dagger, g_\alpha, \delta) \ge \max\left\{\bar\psi(\alpha), \delta/\sqrt{\alpha}\right\} \ge \bar\psi(\Theta^{-1}(\delta)) \quad (0 < \alpha \le \bar\alpha)$$

with $\Theta(t) := \sqrt{t}\,\bar\psi(t)$ $(0 < t \le \overline{\alpha})$. Hence, the function $\bar\psi(\Theta^{-1}(\delta))$ is a lower bound for the error at $x^\dagger$, no matter how smooth the true solution $x^\dagger \in X$ was.

The functions $\bar\psi$ derived in Examples 4.3–4.5 can be seen to be the saturation rates caused by the limited qualifications of the underlying regularization methods.

5. Impact of solution smoothness.

As stressed earlier, the behavior of profile functions is determined by both the chosen regularization g_α and the underlying solution smoothness. As introduced in section 2.2, we measure this in terms of smoothness conditions of the form $x^\dagger \in G_\tau(R)$, see (2.2), determined by an operator G and an index function τ. The impact of such a smoothness assumption on the decay rate of profile functions is best seen if G is a function of A^*A.

5.1. G as a function of A^*A.

To obtain profile functions f for the regularization method g_α, the concept of *general source conditions*, as expressed in

$$x^\dagger = \psi(A^*A)\, w \qquad (w \in X,\ \|w\| \le R), \tag{5.1}$$

for some index functions $\psi(t)$ $(0 < t \le a)$ was used recently (see, e.g., [12, 14, 15, 24]). We note that (5.1) is a specific smoothing condition (2.2) with $\tau(G) = \psi(A^*A)$ (cf. [3] for further discussion of such conditions).

We are going to find profile functions f uniformly for sets $H_\psi(R)$, as defined by formula (2.3), provided the corresponding function ψ is a qualification of the chosen regularization g_α.

PROPOSITION 5.1. *Let the index function ψ be a qualification of the regularization method g_α with constant $0 < \gamma < \infty$. Then uniformly for each $x^\dagger \in H_\psi(R)$ the inequality*

$$\|x_\alpha - x^\dagger\| \le \gamma\, R\, \psi(\alpha) \qquad \text{for all} \quad 0 < \alpha \le a \tag{5.2}$$

is valid. Hence $f(\alpha) := \gamma\, R\, \psi(\alpha)$ is a profile function for $(H_\psi(R), g_\alpha)$.

Proof. From spectral theory (see, e.g., [5, formula (2.47)]) we have with (5.1) that

$$\|x_\alpha - x^\dagger\| = \|r_\alpha(A^*A)\, x^\dagger\| = \|r_\alpha(A^*A)\, \psi(A^*A)\, w\| \le R \sup_{0<t\le a} |r_\alpha(t)|\, \psi(t)\,.$$

Taking into account inequality (2.1), this yields (5.2) and proves the proposition. ∎

Remark 5.2. This proposition can be reformulated as follows. Suppose that we are given a pair (M, g_α) of a solution set M and a regularization g_α. If we can find an index function ψ on $(0, a]$ that is *both* a qualification for g_α and a smoothness for M, i.e., $M \subseteq H_\psi(R)$ for some R, then there is a profile function for (M, g_α). In addition the index function ψ provides a decay rate. Although this is a simple observation it explains the existence of profile functions for noncompact sets M, as discussed at the end of section 3.1.

5.2. Approximate source conditions. An important extension of the above concept is obtained by relaxing requirement (5.1). In this context, we restrict ourselves to a fixed index function $\varphi(t)$ $(0 < t \le a)$ as *benchmark function*. We suppose that the solution $x^\dagger \in X$ of (1.1) is not smooth enough to satisfy a condition (5.1) with φ instead of ψ even if $R \ge 0$ is arbitrary large. The injectivity of A implies the injectivity of $\varphi(A^*A)$ for any index function φ. Hence the range $\mathcal{R}(\varphi(A^*A))$ is dense in X. Consequently, for all $0 \le R < \infty$ the element $x^\dagger$ satisfies such a general source condition in an approximate manner as $x^\dagger = \varphi(A^*A)\, w + \xi \quad (\|w\| \le R,\ \xi \in X)$, where the norm of the perturbation $\|\xi\|$ tends to zero as R tends to infinity.

In the following we shall confine to this situation, when

$$x^\dagger \notin \mathcal{R}(\varphi(A^*A)). \tag{5.3}$$

The quality of the approximation of $x^\dagger$ by elements from $H_\varphi(1)$ can be expressed by favor of the *distance function*

(5.4)
$$\rho_{x^\dagger}(t) = \rho_{x^\dagger}^{(H,\varphi)} := \operatorname{dist}(tx^\dagger, H_\varphi(1)) = \inf\left\{\|tx^\dagger - \varphi(H)v\| : v \in X, \|v\| \le 1\right\} \quad (t > 0).$$

If the reference to the benchmark (H, φ) is clear, as in the following lemma, then we shall omit the superscript.

LEMMA 5.3. *Under the assumption* (5.3) *the functions $\rho_{x^\dagger}(t)$ and $\rho_{x^\dagger}(t)/t$ $(t > 0)$ are both index functions. Moreover, we have $\lim_{t\to\infty} \rho_{x^\dagger}(t) = \infty$.*

Proof. The idea of the proof is standard in regularization theory. For each $t > 0$ the value $\rho_{x^\dagger}(t)/t = \operatorname{dist}(x^\dagger, H_\varphi(1/t))$ is obtained from constrained minimization, and Lagrange multipliers can be used to determine this value. Hence, given $x^\dagger \in X$ let

$$F_{x^\dagger}(\lambda) := \|x^\dagger - \varphi(A^*A)v\|^2 + \lambda\|v\|^2.$$

At given λ its minimizer with respect to $v \in X$ is

$$v_\lambda := \left[\varphi^2(A^*A) + \lambda I\right]^{-1} \varphi(A^*A)x^\dagger,$$

which has to obey the side constraint $\chi(\lambda) = 1/t$, where setting

$$\chi(\lambda) := \| \left[\varphi^2(A^*A) + \lambda I\right]^{-1} \varphi(A^*A)x^\dagger \|. \tag{5.5}$$

Based on the injectivity of $\varphi(A^*A)$, spectral calculus yields that the function $\chi(\lambda)$ ($\lambda > 0$) is positive, continuous, and strictly decreasing to zero as $\lambda \to \infty$. Moreover, under (5.3) we have $\lim_{\lambda \to 0+} \chi(\lambda) = \infty$. Therefore for all $t > 0$ the function $\lambda(t) := \chi^{-1}(1/t)$ exists and is an index function. Hence we obtain

$$\rho_{x^\dagger}(t)/t = \|x^\dagger - \varphi(A^*A)v_{\lambda(t)}\| = \lambda(t) \, \| \left[\varphi^2(A^*A) + \lambda(t) I\right]^{-1} x^\dagger \| \quad (t > 0), \tag{5.6}$$

which is the composition of two index functions in t. As a consequence, both functions $\rho_{x^\dagger}(t)/t$ and $\rho_{x^\dagger}(t)$ have that property. On the other hand, we have

$$\lim_{t \to \infty} \rho_{x^\dagger}(t) = \lim_{t \to \infty} t \left(\frac{\rho_{x^\dagger}(t)}{t} \right) = \infty \,,$$

since $\rho_{x^\dagger}(t)/t$ as an index function cannot tend to zero as $t \to \infty$. This completes the proof. ∎

Remark 5.4. By using distance functions of the form

$$d(R) := \operatorname{dist}(x^\dagger, H_\varphi(R)) \, = \, R\rho_{x^\dagger}(1/R) \quad (0 < R < \infty), \tag{5.7}$$

error estimates for the Tikhonov regularization were obtained in [9] and [4]; see also [2, 8, 11] for variants thereof. The fundamental estimate for profile functions under approximate source conditions is as follows.

THEOREM 5.5. *Let g_α be a regularization method with qualification φ and constant γ. If the solution $x^\dagger$ to* (1.1) *obeys* (5.3)*, then*

$$\|x_\alpha - x^\dagger\| \le \max\{\gamma, \gamma_1\} \, \frac{1}{t} \, (\rho_{x^\dagger}(t) + \varphi(\alpha)) \quad \textit{for all} \quad t > 0 \quad \textit{and} \quad 0 < \alpha \le a. \tag{5.8}$$

Thus the function

$$f(\alpha) := 2 \max\{\gamma, \gamma_1\} \, \frac{\varphi(\alpha)}{\rho_{x^\dagger}^{-1}(\varphi(\alpha))} \quad (0 < \alpha \le a) \tag{5.9}$$

is a profile function for $(x^\dagger, g_\alpha)$.

Proof. First we establish (5.8). For any $v \in X$ with $\|v\| \le 1$ we can estimate

$$\begin{aligned}
\|x_\alpha - x^\dagger\| &= \frac{1}{t} \|r_\alpha(A^*A)tx^\dagger\| \\
&= \frac{1}{t} \|r_\alpha(A^*A)\, tx^\dagger - r_\alpha(A^*A)\, \varphi(A^*A)v + r_\alpha(A^*A)\, \varphi(A^*A)v\| \\
&\le \frac{1}{t} \left(\|r_\alpha(A^*A)(tx^\dagger - \varphi(A^*A)v)\| \, + \, \|r_\alpha(A^*A)\, \varphi(A^*A)v\| \right) \\
&\le \frac{1}{t} \left(\gamma_1 \|tx^\dagger - \varphi(A^*A)v\| \, + \, \|r_\alpha(A^*A)\, \varphi(A^*A)\| \right) \\
&\le \frac{1}{t} \left(\gamma_1 \, \|tx^\dagger - \varphi(A^*A)v\| + \gamma \, \varphi(\alpha) \right).
\end{aligned}$$

Since this estimate remains true if we substitute $\|tx^\dagger - \varphi(A^*A)v\|$ by its infimum over all v from the unit ball of X and since φ is a qualification of the used regularization method, we obtain

$$\|x^\dagger - x_\alpha\| \le \max\{\gamma, \gamma_1\} \, \frac{1}{t} \, (\rho_{x^\dagger}(t) + \varphi(\alpha)) \quad \text{for all} \quad t > 0 \quad \text{and} \quad 0 < \alpha \le a,$$

which proves estimate (5.8). Since this estimate is valid for all $t > 0$ and we have by Lemma 5.3 for the index function $\rho_{x^\dagger}$ the limit condition $\lim_{t\to\infty} \rho_{x^\dagger}(t) = \infty$, we can equate the two terms in brackets of the right-hand side of (5.8). Taking into account the strict monotonicity of function $\rho_{x^\dagger}(t)$ $(t > 0)$, (5.9) is yielded. ∎

Remark 5.6. We notice that the upper bound in (5.8) cannot be improved by other values of t, because it is the balance of a strictly increasing function $\rho_{x^\dagger}(t)/t$ and a decreasing, with respect to t, function $\varphi(\alpha)/t$.

We also mention that the same arguments yield a slightly different bound

$$\|x^\dagger - x_\alpha\| \le \frac{(\gamma + \gamma_1)}{t} \max\{\rho_{x^\dagger}(t), \varphi(\alpha)\} \quad \text{for all} \quad t > 0 \quad \text{and} \quad 0 < \alpha \le a,$$

which is better if the constants γ and γ_1 differ. This implies that in all estimates below the expression $2\max\{\gamma, \gamma_1\}$ can be replaced by $(\gamma + \gamma_1)$.

Remark 5.7. Since the denominator $\rho^{-1}_{x^\dagger}(\varphi(\alpha))$ in (5.9) expresses an index function tending to zero as α tends to zero, the decay rate of $f(\alpha) \to 0$ as $\alpha \to 0$ is always *lower* than the corresponding rate of the benchmark function φ, i.e., $\varphi(\alpha) = o(f(\alpha))$ as $\alpha \to 0$. In particular, one has to choose a sufficiently good benchmark function and a regularization with high enough qualification to achieve by that way the best possible rate for given $x^\dagger$.

5.3. Approximate source conditions for solutions in sourcewise representation. It is worthwhile to discuss the situation when $x^\dagger$ has a sourcewise representation (5.1), but the benchmark function φ is chosen in such a way that $x^\dagger \notin \mathcal{R}(\varphi(A^*A))$. This can happen in the following case only.

LEMMA 5.8. *Suppose $x^\dagger$ obeys* (5.1). *If $x^\dagger \notin \mathcal{R}(\varphi(A^*A))$, then necessarily $(\varphi/\psi)(t) \to 0$ as $t \to 0$.*

Proof. Suppose $\varphi(t) \ne o(\psi(t))$. Then there is $C < \infty$ such that $\psi(t) \le C\varphi(t)$ for small $0 < t \le \bar{t}$. Given $0 < \varepsilon \le \bar{t}$ we can bound

$$\begin{aligned}
\int_\varepsilon^a \frac{1}{\varphi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 &= \int_\varepsilon^{\bar{t}} \frac{1}{\varphi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 + \int_{\bar{t}}^a \frac{1}{\varphi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 \\
&\le C^2 \int_\varepsilon^{\bar{t}} \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 + \sup_{\lambda \ge \bar{t}} \frac{\psi^2(\lambda)}{\varphi^2(\lambda)} \int_{\bar{t}}^a \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 \\
&\le \max\left\{C^2, \sup_{\lambda \ge \bar{t}} \frac{\psi^2(\lambda)}{\varphi^2(\lambda)}\right\} \int_\varepsilon^a \frac{1}{\psi^2(\lambda)} d\|E_\lambda x^\dagger\|^2 \\
&\le \max\left\{C^2, \sup_{\lambda \ge \bar{t}} \frac{\psi^2(\lambda)}{\varphi^2(\lambda)}\right\} \|x^\dagger\|^2_{X^H_\psi}.
\end{aligned}$$

Letting $\varepsilon \to 0$ we obtain $\|x^\dagger\|_{X^H_\varphi} < \infty$, thus $x^\dagger \in \mathcal{R}(\varphi(A^*A))$, which completes the proof. ∎

If, slightly stronger but geometrically intuitive, we assume that the quotient $(\varphi/\psi)(t)$ is strictly increasing, then we can give a clear picture of the resulting function $\rho_{x^\dagger}(t)$ for $t > 0$ sufficiently small.

THEOREM 5.9. *We suppose that $x^\dagger$ obeys* (5.1) *and that the quotient $(\varphi/\psi)(t)$ is an index function for $0 < t \le a$. Then we can estimate the distance function as*

$$\rho_{x^\dagger}(t) \le \varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1}(Rt)\right) \qquad \text{for all} \quad 0 < t \le \frac{1}{R}\frac{\varphi(a)}{\psi(a)}. \tag{5.10}$$

Proof. The proof is carried out using the analysis from the proof of Lemma 5.3, and we shall make use of the notation introduced there. According to the proof of Lemma 5.3, let $\lambda(t) := \chi^{-1}(1/t)$ $(t > 0)$ with function χ from (5.5). Then for $x^\dagger = \psi(A^*A)v$ with $\|v\| \le R$, representation (5.6) allows for the following bound:

$$\begin{aligned}\rho_{x^\dagger}(t) &= t\lambda(t)\| \left[\varphi^2(A^*A) + \lambda(t)I\right]^{-1} x^\dagger\| \le (Rt)\lambda(t)\| \left[\varphi^2(A^*A) + \lambda(t)I\right]^{-1} \psi(A^*A)\| \\ &= (Rt) \sup_{0<s\le a} \frac{\lambda(t)\psi(s)}{\varphi^2(s) + \lambda(t)} = (Rt) \sup_{0<u\le\varphi^2(a)} \frac{\lambda(t)}{u + \lambda(t)} \psi((\varphi^2)^{-1}(u))\,,\end{aligned}$$

where we make the crucial observation that $u \mapsto \lambda(t)/(u + \lambda(t))$ is the residual of Tikhonov regularization. To continue we introduce the auxiliary function

$$\kappa(s) := \frac{\psi((\varphi^2)^{-1}(s))}{\sqrt{s}} = \left(\frac{\psi}{\varphi}\right)\left((\varphi^2)^{-1}(s)\right) \qquad (0 < s \le \varphi^2(a)). \tag{5.11}$$

It is clear that $1/\kappa(s)$ is an index function, hence $\lim_{s\to 0+} \kappa(s) = \infty$. Also, the function $\kappa(u)/\sqrt{u}$ is decreasing whenever κ is. Hence Proposition 2.7(a) applies and allows us to conclude the estimate

$$\rho_{x^\dagger}(t) \le (Rt)\psi((\varphi^2)^{-1}(\lambda(t))) \qquad (t > 0)\,, \tag{5.12}$$

noting that $\psi((\varphi^2)^{-1}(s))$ for sufficiently small $s > 0$ is an index function.

Next we shall establish for sufficiently small $t > 0$ an upper bound $\tilde\lambda(t)$ for $\lambda(t)$ which then will yield estimate (5.10). Indeed, let $\tilde\lambda(t)$ be obtained as inverse

$$\tilde\lambda(t) = \kappa^{-1}(1/(Rt)). \tag{5.13}$$

It is enough to show that $\lambda(t) \le \tilde\lambda(t)$. To this end notice that κ was decreasing, hence $u \mapsto (\psi((\varphi^2)^{-1}(u))\sqrt{u})/u$ is so, and we derive, again using arguments as above, that for $0 < t \le \frac{1}{R}\frac{\varphi(a)}{\psi(a)}$ the estimate

$$\begin{aligned}\kappa(\tilde\lambda(t)) \le \frac{1}{Rt} = \frac{\chi(\lambda(t))}{R} &\le \| \left[\varphi^2(A^*A) + \lambda(t)I\right]^{-1} \varphi(A^*A)\psi(A^*A)\| \\ &\le \frac{1}{\lambda(t)} \sup_{0<u\le\varphi^2(a)} \frac{\lambda(t)}{u + \lambda(t)} \psi((\varphi^2)^{-1}(u))\sqrt{u} \le \frac{1}{\lambda(t)} \psi((\varphi^2)^{-1}(\lambda(t)))\sqrt{\lambda(t)} \\ &= \kappa(\lambda(t))\,.\end{aligned}$$

Consequently, $\lambda(t) \le \tilde\lambda(t)$ and we arrive at

$$\rho_{x^\dagger}(t) \le (Rt)\psi((\varphi^2)^{-1}(\lambda(t))) \le (Rt)\psi((\varphi^2)^{-1}(\tilde\lambda(t))) = \sqrt{\kappa^{-1}\left(\frac{1}{Rt}\right)}. \tag{5.14}$$

It is a routine matter to check that both versions in the right-hand side of (5.14) are equal. Indeed, starting from the identity $\psi(u)/\varphi(u) = \psi(u)/\varphi(u)$, a variable substitution $u := (\varphi/\psi)^{-1}(Rt)$ yields

$$\frac{1}{Rt} = \frac{\psi\left((\varphi/\psi)^{-1}(Rt)\right)}{\varphi\left((\varphi/\psi)^{-1}(Rt)\right)} = \kappa\left(\varphi^2\left(\left(\frac{\varphi}{\psi}\right)^{-1}(Rt)\right)\right),$$

completing the proof. ∎

COROLLARY 5.10. *Suppose that φ is a qualification for g_α with constant γ. Under the assumptions of Theorem 5.9 there is some $\overline{\alpha} > 0$ such that*

$$f(\alpha) := 2\max\{\gamma, \gamma_1\}\, R\,\psi(\alpha) \qquad (0 < \alpha \le \overline{\alpha}) \tag{5.15}$$

is a profile function for $(H_\psi(R), g_\alpha)$.

Proof. For proving that (5.15) is a profile function for $(H_\psi(R), g_\alpha)$ we use the estimate (5.8) of Theorem 5.5 and the bound (5.10) which together yield for some sufficiently small $\bar{t} > 0$ the error bound

$$\|x_\alpha - x^\dagger\| \le \max\{\gamma, \gamma_1\}\, \frac{1}{t}\left(\varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1}(Rt)\right) + \varphi(\alpha)\right) \quad (0 < t \le \bar{t},\ 0 < \alpha \le a).$$

Then for sufficiently small $\alpha > 0$ there is some $t_* = t_*(\alpha) \in (0, \bar{t}\,]$ satisfying the equation

$\varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1}(Rt_*)\right) = \varphi(\alpha)$, namely $t_* = \varphi(\alpha)/(R\,\psi(\alpha))$ implying

$$\|x_\alpha - x^\dagger\| \le 2\,\max\{\gamma, \gamma_1\}\,\frac{\varphi(\alpha)}{t_*} = 2\,\max\{\gamma, \gamma_1\}\; R\,\psi(\alpha).$$

This, however, completes the proof. ∎

Example 5.11. For monomials $\varphi(t) = t^\nu$ and $\psi(t) = t^\eta$ with $\nu, \eta > 0$, everything can be made explicit. Lemma 5.8 states that (5.3) is valid if and only if $0 < \eta < \nu$, which in the case of monomials is equivalent to saying that $(\varphi/\psi)(t)$ is an index function. We obtain the bound $\rho_{x^\dagger}(t) \le (Rt)^{\nu/(\nu-\eta)}$.

The global properties required for the quotient function φ/ψ on $(0, a]$ are rather strong assumptions in Theorem 5.9 used for obtaining the estimate (5.15) in Corollary 5.10. On the other hand, in [11] and [4] by a completely different technique there have been developed error estimates of type (5.15) with some other constant which only need local properties of φ/ψ on an arbitrarily small interval $(0, \varepsilon]$. In order to show that our approach is powerful enough to work with such weaker assumptions, we conclude this section with a local variant of Theorem 5.9 yielding the results of Corollary 5.10 with different constant under the local assumption on the quotient function.

THEOREM 5.12. *We suppose that $x^\dagger$ obeys (5.1) and that φ, ψ are index functions on $(0, a]$. Moreover, it is assumed that there exists some $0 < \varepsilon \le a$ such that the quotient function φ/ψ is an index function on the interval $(0, \varepsilon]$. Then with the constants $C_\varepsilon = \frac{\psi(a)}{\psi(\varepsilon)} \ge 1$ and $K_\varepsilon = \frac{\psi(a)}{\psi(\varepsilon)}\,\frac{\varphi(a)}{\varphi(\varepsilon)} \ge 1$ we can estimate the distance function as*

$$\rho_{x^\dagger}(t) \le \frac{C_\varepsilon}{K_\varepsilon}\,\varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1}(R\,K_\varepsilon\,t)\right) \qquad \text{for all} \quad 0 < t \le \bar{t} \tag{5.16}$$

and sufficiently small $\bar{t} > 0$. If, moreover, φ is a qualification for g_α with constant γ, then there is $\bar{\alpha} > 0$ such that the function

$$f(\alpha) := 2\max\{\gamma, \gamma_1\}\, K_\varepsilon\, R\,\psi(\alpha) \quad (0 < \alpha \le \bar{\alpha}) \tag{5.17}$$

is a profile function for $(H_\psi(R), g_\alpha)$.

Sketch of a proof. We follow the proof of Theorem 5.9, but the local version of the estimate (5.12) is obtained using Proposition 2.7(c) with $\hat{t} = \varphi^2(\varepsilon)$ as

$$\rho_{x^\dagger}(t) \le (Rt)\, C_\varepsilon\, \psi((\varphi^2)^{-1}(\lambda(t)))$$

for sufficiently small $t > 0$. Moreover, instead of (5.13) in the local variant we have to set

$$\tilde{\lambda}(t) \colon = \kappa^{-1}(1/(R\,K_\varepsilon\, t))\,,$$

which is well-defined for $t \in (0, \bar{t}\,]$ with $\bar{t} > 0$ sufficiently small. Then as in the original proof it can be shown that $\lambda(t) \le \tilde{\lambda}(t)$ for $0 < t \le \bar{t}$ again based on Proposition 2.7(c). Precisely, we have the estimate

$$\begin{aligned}
\kappa(\tilde{\lambda}(t)) &= \frac{1}{RK_\varepsilon t} = \frac{\chi(\lambda(t))}{RK_\varepsilon} \le \frac{1}{K_\varepsilon} \left\| \left[\varphi^2(A^*A) + \lambda(t) I\right]^{-1} \varphi(A^*A)\psi(A^*A) \right\| \\
&= \frac{1}{K_\varepsilon \lambda(t)} \sup_{0<u\le\varphi^2(a)} \frac{\lambda(t)}{u+\lambda(t)} \psi((\varphi^2)^{-1}(u))\sqrt{u} \le \frac{1}{\lambda(t)} \psi((\varphi^2)^{-1}(\lambda(t)))\sqrt{\lambda(t)} \\
&= \kappa(\lambda(t))\,.
\end{aligned}$$

Finally we arrive at

$$\rho_{x^\dagger}(t) \le (Rt)\, C_\varepsilon\, \psi((\varphi^2)^{-1}(\lambda(t))) \le (Rt)\, C_\varepsilon\, \psi((\varphi^2)^{-1}(\tilde{\lambda}(t))) = \frac{C_\varepsilon}{K_\epsilon} \sqrt{\kappa^{-1}\left(\frac{1}{RK_\varepsilon t}\right)}$$

which proves (5.16). For proving (5.17) we use the estimate (5.8) of Theorem 5.5 yielding here for sufficiently small $t > 0$ and $\alpha > 0$, and since $\frac{C_\varepsilon}{K_\varepsilon} \le 1$,

$$\|x_\alpha - x^\dagger\| \le \max\{\gamma, \gamma_1\}\, \frac{1}{t} \left(\varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1} (R\,K_\varepsilon\, t) \right) + \varphi(\alpha) \right).$$

Now we choose $t_* = t_*(\alpha)$ such that the equation

$$\varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1} (R\,K_\varepsilon\, t_*) \right) = \varphi(\alpha)$$

holds. This is possible for sufficiently small $\alpha > 0$ and yields $t_* = \frac{\varphi(\alpha)}{\psi(\alpha)}\, \frac{1}{R\,K_\varepsilon}$. Hence we obtain the profile function (5.17) as required. ∎

6. Linking scales by range inclusions. Since the initial study of linear inverse problems in Hilbert scales (see [20]), it is well known that the operator G measuring smoothness of the solution $x^\dagger$ must be linked to the operator A governing (1.1) in order to obtain error bounds. There are various ways to establish such a link and we will investigate its impact on profile functions next.

Again we start with the benchmark function φ and assume in addition that

$$x^\dagger \in G_\tau(R) \tag{6.1}$$

with $G_\tau(R)$ defined by (2.2). Moreover, we impose the following *link condition*; precisely, that there is an index function $\sigma(t)$ $(0 < t \le \|G\|)$ and a constant $C < \infty$ such that

$$\|\sigma(G)v\| \le C\|\varphi(A^*A)v\| \qquad \text{for all} \quad v \in X. \tag{6.2}$$

Remark 6.1. There is an extensive analysis in [3] of linking conditions in various ways. In particular, it is shown as Proposition 2.1 in [3] that the validity of condition (6.2) with some positive C is equivalent to the *range inclusion*

$$\mathcal{R}(\sigma(G)) \subseteq \mathcal{R}(\varphi(A^*A))\,. \tag{6.3}$$

We mention the following consequence of (6.2) (see, e.g., [17]). Given Hilbert spaces X and Z with $Z \subset X$ let $J\colon Z \to X$ be the canonical embedding, leaving elements from Z invariant.

LEMMA 6.2. *Under* (6.2) *the canonical embedding* $J_{G,\sigma}^{H,\varphi}\colon X_\sigma^G \to X_\varphi^H$ *is norm bounded by* C *and we have*

$$G_\sigma(R) \subseteq H_\varphi(C\,R). \tag{6.4}$$

Proof. It is well known that for any pair S, T of operators a relation $\|Sv\| \le \|Tv\|$ implies $\|T^{-1}v\| \le \|S^{-1}v\|$, whenever the right-hand sides are finite. Thus (6.2) implies for any $x \in X_\sigma^G$ with $\|x\|_{X_\sigma^G} \le 1$ that $\|x\|_{X_\varphi^H} \le C$ and hence (6.4). ∎

We will distinguish two scenarios and start with the easier one.

PROPOSITION 6.3. *Let* g_α *be a regularization which has qualification* φ *with constant* γ *and assume that* $x^\dagger$ *obeys* (6.1). *If condition* (6.2) *is valid for an index function* σ, *and if there is* $K < \infty$ *such that* $\tau(t)/\sigma(t) \le K$ $(0 < t \le \|G\|)$, *then the function*

$$f(\alpha) := \gamma\,C\,K\,R\,\varphi(\alpha) \qquad (0 < \alpha \le a) \tag{6.5}$$

is a profile function for $(G_\tau(R), g_\alpha)$.

Proof. From $\tau(t)/\sigma(t) \le K$ $(0 < t \le a)$ we deduce from Lemma 6.2 that $G_\tau(R) \subseteq G_\sigma(KR)$, which is equivalent to $\|\tau(G)x\| \le K\,\|\sigma(G)x\|$ for all $x \in X$. Furthermore, in the light of Lemma 6.2, the link condition (6.2) implies $G_\sigma(KR) \subseteq H_\varphi(CKR)$, and any profile function for $H_\varphi(CKR)$ provides us with a profile function for $G_\tau(R)$, such that the proof can be completed using Proposition 5.1. ∎

Thus we are left with the case when

$$(\sigma/\tau)(t) \to 0 \quad \text{as} \quad t \to 0. \tag{6.6}$$

Then we have $X_\sigma^G \subset X_\tau^G$ and the canonical embedding $J_{G,\sigma}^{G,\tau}\colon X_\sigma^G \to X_\tau^G$ is norm bounded. The question is whether one can use condition (6.2) to draw conclusions for the behavior of profile functions in this case.

Suppose we assume a linking condition (6.3), but smoothness is measured as $x^\dagger \in G_\tau(R)$ with respect to a different index function τ. Can we establish an index function ψ, assigned to a triplet (σ, τ, φ), such that the following range implication holds true:

$$\mathcal{R}(\sigma(G)) \subseteq \mathcal{R}(\varphi(H)) \quad \Longrightarrow \quad \mathcal{R}(\tau(G)) \subseteq \mathcal{R}(\psi(H))? \tag{6.7}$$

In specific situations this problem was already posed (cf. [11, formula (5.10), p. 815]) and partially answered previously (cf. [3, Corollary 2.3]). Most prominently, the Heinz–Kato inequality (see [5, Proposition 8.21]) yields

$$\mathcal{R}(G) \subseteq \mathcal{R}(H) \quad \Longrightarrow \quad \mathcal{R}(G^\mu) \subseteq \mathcal{R}(H^\mu)$$

for $0 < \mu \le 1$ as a consequence of operator monotonicity. In fact this can be extended to more general situations in which operator monotone functions occur. It is convenient to draw the following diagram.

$$\begin{array}{ccccc} G{:}X_\sigma^G & \xrightarrow{J_{G,\sigma}^{G,\tau}} & X_\tau^G & \xrightarrow{J_{G,\tau}^{I}} & X \\ \Big\downarrow J_{G,\sigma}^{H,\varphi} & & \Big\downarrow J_{G,\tau}^{H,\psi} & & \Big\downarrow I \\ H{:}X_\varphi^H & \xrightarrow{J_{H,\varphi}^{H,\psi}} & X_{\psi?}^H & \xrightarrow{J_{H,\psi}^{I}} & X \end{array} \tag{6.8}$$

Under (6.6) the upper row shows embeddings which are bounded. Using Lemma 6.2 the embedding $J_{G,\sigma}^{H,\varphi}$ is norm bounded by C, provided the link condition (6.2) holds true. Plainly the identity $I\colon X \to X$ has norm equal to one. The question addressed in this diagram is whether we can describe an index function ψ such that the corresponding embedding $J_{G,\tau}^{H,\psi}$ is norm bounded, say by some constant $L < \infty$. Diagram (6.8) also suggests that the resulting function ψ will describe smoothness not covered by φ, and approximate source conditions must be used to obtain results.

Remark 6.4. If the embedding $J_{G,\tau}^{H,\psi}$ were norm bounded, say by some constant $L < \infty$, then $G_\tau(R) \subseteq H_\psi(LR)$, and any profile function for $(H_\psi(LR), g_\alpha)$ would also be a profile function for $(G_\tau(R), g_\alpha)$.

As the diagram (6.8) clearly indicates, interpolation properties may help to find suitable index function ψ. The implication (6.7) of range inclusions is indeed true if operator monotonicity occurs and we shall mention the following result from [17].

THEOREM 6.5. *Let $x^\dagger$ obey* (6.1). *We assume that G and A^*A are linked by* (6.2), *where we suppose that σ is such that there is an extension $\sigma(t)$ $(0 < t \le b)$ with $\sigma(b) \ge \varphi(a)$ and this extension is an index function. Moreover, given an index function $\tau(t)$ $(0 < t \le \|G\|)$ we assign the index function*

$$\psi(t) := \tau(\sigma^{-1}(\varphi(t))) \quad (0 < t \le a). \tag{6.9}$$

Then the implication (6.7) *is satisfied whenever the function $\tau^2((\sigma^2)^{-1}(t))$ $(0 < t \le \varphi^2(a))$ is operator monotone and $(\sigma/\tau)(t)$ $(0 < t \le \|G\|)$ is an index function.*

Precisely, the norm bound

$$\|J_{G,\tau}^{H,\psi}\colon X_\tau^G \to X_\psi^H\| \le \max\{1, C\} \tag{6.10}$$

with C from (6.2) *is valid.*

Now we return to the analysis of profile functions. To establish these functions the full strength of the implication (6.7) is not necessary. But we shall also indicate its strength in Theorem 6.11. However, the function ψ from (6.9) will occur, nonetheless.

There are in principle two ways to use the link conditions (6.2) or (6.3), respectively, to obtain profile functions. One can either transfer all information to the scale generated by the operator G or to the scale generated by $H := A^*A$. Both ways finally provide the same asymptotic results but under assumptions of different strength. We start with the first approach which requires weaker assumptions.

LEMMA 6.6. *The link condition* (6.2) *implies*

$$\rho_{x^\dagger}^{(H,\varphi)}(t) \le \frac{1}{C}\rho_{x^\dagger}^{(G,\sigma)}(Ct) \qquad \textit{for all} \quad 0 < t < \infty. \tag{6.11}$$

Proof. Plainly, condition (6.2) yields $G_\sigma(1/C) \subseteq H_\varphi(1)$ and we obtain

$$\begin{aligned}\rho_{x^\dagger}^{(H,\varphi)}(t) &= \operatorname{dist}(tx^\dagger, H_\varphi(1)) \le \operatorname{dist}(tx^\dagger, G_\sigma(1/C)) \\ &= \frac{1}{C}\operatorname{dist}(Ctx^\dagger, G_\sigma(1)) = \frac{1}{C}\rho_{x^\dagger}^{(G,\sigma)}(Ct). \qquad \square\end{aligned}$$

With this preparation we can state the main result of this section.

THEOREM 6.7. *Let g_α be a regularization method with qualification φ and constant γ for the operator equation* (1.1) *with solution $x^\dagger$ the smoothness of which is characterized by the conditions* (5.3) *and* (6.1) *with some index functions φ and τ. We suppose the link condition* (6.2) *with some index function σ for connecting A^*A and G. If the function*

$$(\sigma/\tau)(t) \ \ (0 < t \le \|G\|) \quad \text{is an index function}, \tag{6.12}$$

then there is some $\bar\alpha > 0$ for which the function $\psi(t)$ $(0 < t \le \bar\alpha)$ from (6.9) *is an index function and*

$$f(\alpha) := 2\,\max\{\gamma, \gamma_1\}\,\max\{1, C\}R\,\psi(\alpha) \quad (0 < \alpha \le \bar\alpha) \tag{6.13}$$

is a profile function for $(G_\tau(R), g_\alpha)$.

Remark 6.8. Assume (6.3) instead of (6.2). Let $C := \|(\varphi(A^*A))^{-1}\tau(G)\| < \infty$. Then the function f from (6.13) is a profile function with the constant C.

Proof of Theorem 6.7. For an arbitrary $x^\dagger \in G_\tau(R)$ using the bound (5.8) and Lemma 6.6 we obtain for all $0 < \alpha \le a$ that

$$\|x_\alpha - x^\dagger\| \le \frac{\max\{\gamma, \gamma_1\}}{t}\left(\rho_{x^\dagger}^{(H,\varphi)}(t) + \varphi(\alpha)\right) \le \max\{\gamma, \gamma_1\}\frac{1}{t}\left(\frac{1}{C}\rho_{x^\dagger}^{(G,\sigma)}(Ct) + \varphi(\alpha)\right).$$

By exploiting Theorem 5.9 in the scale generated by G we can continue and bound

$$\|x_\alpha - x^\dagger\| \le \frac{\max\{\gamma, \gamma_1\}}{t}\left(\frac{1}{C}\sigma\left(\left(\frac{\sigma}{\tau}\right)^{-1}(RCt)\right) + \varphi(\alpha)\right) \tag{6.14}$$

for $0 < \alpha \le \frac{1}{RC}\left(\frac{\sigma}{\tau}\right)(\|G\|)$. There is some $0 < \bar\alpha \le \|G\|/C$ for which we can equate both summands on the right of formula (6.14) whenever $0 < \alpha \le \bar\alpha$. This leads to

$$t_* = t_*(\alpha) := \frac{1}{R}\frac{\varphi(\alpha)}{\tau(\sigma^{-1}(C\varphi(\alpha)))} \quad (0 < \alpha \le \bar\alpha).$$

Moreover, by (6.12) we have that $\tau(\sigma^{-1}(Ct)) \le \max\{1, C\}\,\tau(\sigma^{-1}(t))$ for $0 < t \le \overline{\alpha}$. Thus we can estimate for $0 < \alpha \le \bar\alpha$

$$\|x_\alpha - x^\dagger\| \le 2\,\max\{\gamma, \gamma_1\}\,\frac{\varphi(\alpha)}{t_*} \le 2\,\max\{\gamma, \gamma_1\}\,R\,\tau(\sigma^{-1}(C\varphi(\alpha)))\,.$$

Consequently, we obtain

$$\|x_\alpha - x^\dagger\| \le 2\,\max\{\gamma, \gamma_1\}\,\max\{1, C\}\;R\,\psi(\alpha) \qquad (0 < \alpha \le \bar\alpha),$$

completing the proof. $\square$

Remark 6.9. The results of Theorem 6.7 with an appropriately modified constant in (6.13) can also be obtained under the weaker assumption that

$$(\sigma/\tau)(t) \ \ (0 < t \le \varepsilon) \quad \text{is an index function}$$

for arbitrarily small $\varepsilon > 0$ instead of the global assumption (6.12). This is an immediate result of the opportunity of localization as outlined in Theorem 5.12 and its proof.

As mentioned above, we can also try to transfer the information from the link conditions (6.2) and (6.3) to the scale generated by $H = A^*A$.

We recall the definition of the function ψ in formula (6.9) in the context of Theorem 6.5. The following observation is useful.

LEMMA 6.10. *Let the functions τ, σ and φ, ψ be as in Theorem* 6.5. *If the quotient σ/τ is an index function on $(0, \|G\|]$, then φ/ψ is an index function on $(0, a]$.*

Proof. We assign $s = s(t) := \sigma^{-1}(\varphi(t))$ $(0 < t \le a)$, thus $s \in (0, b]$. With this identification we obtain

$$\frac{\varphi(t)}{\psi(t)} = \frac{\sigma(s)}{\psi(\varphi^{-1}(\sigma(s)))} = \frac{\sigma(s)}{\tau(\sigma^{-1}(\sigma(s)))} = \frac{\sigma(s)}{\tau(s)}. \qquad \square$$

Keeping this lemma in mind we can prove the following counterpart of Theorem 6.7.

THEOREM 6.11. *Assume that the regularization g_α has qualification φ with constant γ and that σ/τ is an index function on $(0, \|G\|]$. Under the assumptions of Theorem* 6.5*, in particular the operator monotonicity of the function $\tau^2((\sigma^2)^{-1}(t))$ $(0 < t \le \varphi^2(a))$, the function*

$$f(\alpha) = 2 \max\{\gamma, \gamma_1\} \max\{1, C\}\ R\psi(\alpha) \qquad (0 < \alpha \le a) \tag{6.15}$$

is a profile function for $(G_\tau(R), g_\alpha)$.

Proof. Let $L := \max\{1, C\}$. The estimate (6.10) of Theorem 6.5 yields the inclusion $G_\tau(R) \subset H_\psi(LR)$. Thus profile functions for $(H_\psi(LR), g_\alpha)$ are also profile functions for $(G_\tau(R), g_\alpha)$. By Lemma 6.10 the function $\varphi(t)/\psi(t)$ $(0 < t \le a)$ is an index function and we can apply Theorem 5.9 to bound the distance function $\rho_{x^\dagger}^{(H,\psi)}$ as

$$\rho_{x^\dagger}^{(H,\psi)}(t) \le \varphi\left(\left(\frac{\varphi}{\psi}\right)^{-1}(LRt)\right) \qquad \left(0 < t \le \frac{\varphi(a)}{LR\psi(a)}\right).$$

Corollary 5.10 provides us with the profile function as given in (6.15). $\square$

Example 6.12. Again, let us discuss the situation when the index functions are in the form of monomials; more precisely, we assume that $\sigma(t) = t^\mu,\ \tau(t) = t$. Then the operator monotonicity as required in Theorem 6.11 is fulfilled whenever $\mu \ge 1$, which can be deduced from the Heinz–Kato inequality. If the link condition (6.2) is assumed to hold for $\varphi(t) = t^\nu$, and if the regularization has qualification φ, then we arrive at a profile function $f(\alpha) = C\alpha^{\nu/\mu}$, uniformly for $x^\dagger$ satisfying (5.3) and (6.1).

A DISCRETE DUALITY FINITE VOLUME APPROACH TO HODGE DECOMPOSITION AND DIV-CURL PROBLEMS ON ALMOST ARBITRARY TWO-DIMENSIONAL MESHES*

SARAH DELCOURTE†, KOMLA DOMELEVO‡, AND PASCAL OMNES†

Abstract. We define discrete differential operators such as gradient, divergence, and curl, on general two-dimensional nonorthogonal meshes. These discrete operators verify discrete analogues of usual continuous theorems: discrete Green formulae, discrete Hodge decomposition of vector fields, and vector curls have a vanishing divergence and gradients have a vanishing curl. We apply these ideas to discretize div-curl systems. We give error estimates based on the reformulation of these systems into equivalent equations for the potentials. Numerical results illustrate the use of the method on several types of meshes, some of which are degenerating triangular meshes and nonconforming locally refined meshes.

Key words. discrete duality finite volume method, discrete Green formula, discrete Hodge decomposition, discrete differential operators, div-curl equations, arbitrary meshes, nonconforming meshes, degenerating meshes, convergence, error estimates

1. Introduction.

Discretization schemes which are based on a discrete vector analysis satisfying discrete analogues of the usual continuous theorems lead to robust and efficient approximations of various physical models. Based on finite volume-like formulations, they provide discrete approximations of differential operators such as gradient, divergence, and curl.

Such schemes were, for example, constructed by Hyman, Shashkov, and co-workers, initially on logically rectangular grids. We refer to [13, 14] for the construction of the discrete operators and to [15] for the proof of a discrete Hodge decomposition. These schemes were then applied in several different circumstances (see, e.g., [16, 17]) and extended to unstructured [5] or even nonconforming grids [19], although on those types of meshes, to our knowledge, no discrete Hodge decomposition has been proved.

Our interests in this paper are related to other schemes based on a discrete vector analysis. These schemes were proposed by Nicolaides and co-workers to solve fluid mechanics problems [7], div-curl problems [20, 12], or Maxwell equations [21]. In these works, these so-called covolume schemes are restricted to locally equiangular triangular meshes in the two-dimensional case. Given such a primal triangular mesh, a dual mesh is constructed by joining the circumcenters of adjacent triangles. Thus the edges of the primal and dual meshes are orthogonal. In what follows, this property will be called "the orthogonality property." The necessity for the mesh to verify this property might in certain cases be a severe restriction, particularly with respect to mesh adaptivity.

In [20], discrete field components are defined as normal to the edges of the primal mesh and, therefore, thanks to the orthogonality property, along the edges of the dual mesh. This single component is enough to permit the definition of a discrete divergence operator on the primal mesh and of a discrete curl operator on the dual mesh. Reciprocally, discrete analogues of the normal (with respect to the edges of the primal mesh) components of the gradients (resp., vector curls) are obtained over the edges with the help of scalar quantities defined at the circumcenters (resp., at the vertices) of the primal cells.

Due to the anisotropy of the media considered in [12], the authors are led to introduce both components of vector fields on the edges of the mesh, which allows them to define discrete divergence and curl operators on both the primal and dual meshes. Nevertheless, they keep on considering only the normal components of the discrete gradient and curl vectors, thus leaving the generalization of [20] incomplete.

In the present work, we extend the covolume ideas of Nicolaides to almost arbitrary two-dimensional meshes, including, in particular, nonconforming meshes. The only requirement on the mesh is that the dual cells (which are obtained in a different way) form a partition of the domain of computation. These meshes do not necessarily verify the orthogonality property, and we therefore discretize vector fields by their two components over so-called diamond-cells which are quadrilaterals whose vertices are the extremities of primal and associated dual edges. Like in [12], these two field components enable us to define discrete divergence and curl operators both on the primal and dual meshes. Reciprocally, and in contrast to [12], both components of discrete gradient and vector curl operators are defined over the diamond-cells with the help of scalar quantities given on both the primal and dual cells. Together with the definition of appropriate discrete scalar products, we establish that these discrete operators verify discrete properties which are analogous to those verified by their continuous counterparts: discrete Green formulae, discrete Hodge decomposition of vector fields, the divergence of vector curls, and the curl of gradients vanish. These results thus generalize those obtained in [12, 20], with the major novelty that they hold on a much wider class of meshes. Because of the discrete Green formulae, finite volume schemes based on these ideas have been named discrete duality finite volume (DDFV) schemes in [9] and their use has started with the construction and analysis of a finite volume method for the Laplace equation on almost arbitrary two-dimensional meshes [10]. Then, these ideas have been applied to the discretization of nonlinear elliptic equations [2], drift-diffusion and energy-transport models [6], and electro-cardiology problems [22].

In this article, we apply these ideas to the numerical solution of div-curl problems which occur, for example, in fluid dynamics and electro- and magnetostatics. Using the discrete Hodge decomposition of the discrete unknown vector field, this problem is recast into two discrete Laplace equations for the discrete potentials, just like in the continuous problem. Using results obtained in [10], we prove the convergence of the scheme provided the continuous potentials are smooth enough and under geometrical hypotheses related to the nondegeneracy of the diamond-cells.

This paper is organized as follows: in section 2, we explain the construction of the primal, dual, and diamond meshes and define our notations. In section 3 we construct the discrete differential operators, while section 4 is devoted to the proof of the properties of the discrete operators. Then, we apply these ideas in section 5 to discretize the div-curl problem and obtain error estimates. Several numerical experiments are reported in section 6 and conclusions are drawn in section 7.

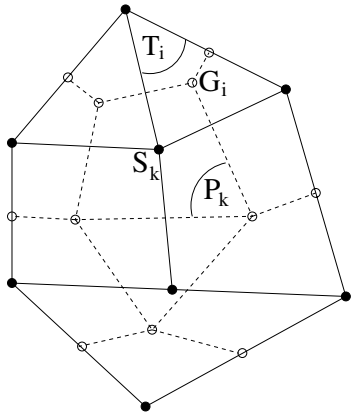

FIG. 2.1. *An example of a primal mesh and its associated dual mesh.*

2. Definitions and notations. Let Ω be a bounded polygon of $\mathbb{R}^2$, not necessarily simply connected, whose boundary is denoted by Γ. We suppose, in addition, that the domain has Q holes. Throughout the paper, we shall assume that $Q > 0$, but the results also hold for the case $Q = 0$.

Let Γ_0 denote the exterior boundary of Ω and let Γ_q, with $q \in [1, Q]$, be the interior polygonal boundaries of Ω, so that $\Gamma = \Gamma_0 \bigcup_{q\in[1,Q]} \Gamma_q$.

The domain Ω will be covered by three different meshes whose constructions are similar to those given in [10].

2.1. Construction of the primal mesh. We consider a first partition of Ω (named primal mesh) composed of elements T_i, with $i \in [1, I]$, which are supposed to be convex polygons. For each element T_i of the mesh, we associate a node G_i located inside T_i. This point may be the barycenter of T_i, but is not necessarily. The area of T_i is denoted by $|T_i|$. We shall denote by J the total number of edges of this mesh. Note that in the case of a nonconforming mesh, an edge is any segment whose extremities are nodes of the mesh. We also denote by J^Γ the number of edges which are located on the boundary Γ and we associate with each of these boundary edges its midpoint, also denoted by G_i with $i \in [I + 1, I + J^\Gamma]$. By a slight abuse of notations, we shall write $i \in \Gamma_q$ iff $G_i \in \Gamma_q$.

2.2. Construction of the dual mesh. We denote by S_k, with $k \in [1, K]$, the nodes of the polygons of the primal mesh. For each of these points, we associate a polygon denoted by P_k, obtained by joining the points G_i associated with the elements of the primal mesh (and possibly to the boundary edges) of which S_k is a node. The area of P_k is denoted by $|P_k|$. In what follows, we shall only consider the cases where the P_ks constitute a second partition of Ω, which we name dual mesh.[1] Figure 2.1 displays an example of a nonconforming primal mesh and its associated dual mesh.

Moreover, we suppose that the set $[1, K]$ is ordered so that when S_k is not on Γ, then $k \in [1, K - J^\Gamma]$, and when S_k is on Γ, then $k \in [K - J^\Gamma + 1, K]$. We shall also write $k \in \Gamma_q$ iff $S_k \in \Gamma_q$.

2.3. Construction of the diamond mesh. With each edge of the primal mesh, denoted by A_j (whose length is $|A_j|$), with $j \in [1, J]$, we associate a quadrilateral

[1] It may happen that the P_ks overlap, as seen on Figure 2 of [10].

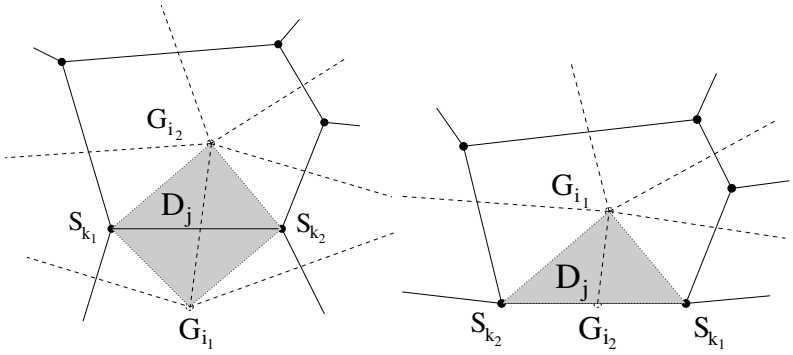

FIG. 2.2. *Examples of diamond-cells.*

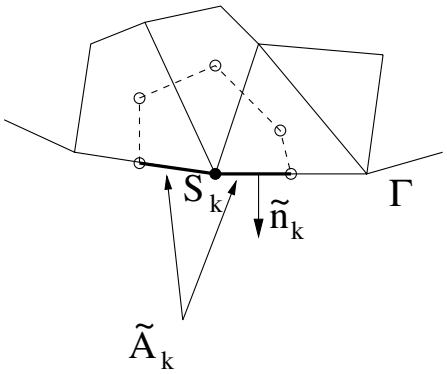

FIG. 2.3. *Definition of $\tilde{A}_k$ and $\tilde{\mathbf{n}}_k$ for the boundary nodes.*

named "diamond-cell" denoted by D_j. When A_j is not on the boundary, this cell is obtained by joining the points $S_{k_1(j)}$ and $S_{k_2(j)}$, which are the two nodes of A_j, with the points $G_{i_1(j)}$ and $G_{i_2(j)}$ associated with the elements of the primal mesh which share this edge. When A_j is on the boundary Γ, the cell D_j is obtained by joining the two nodes of A_j with the point $G_{i_1(j)}$ associated with the only element of the primal mesh of which A_j is an edge and to the point $G_{i_2(j)}$ associated with A_j (i.e., by convention, $i_2(j)$ is an element of $[I+1, I+J^\Gamma]$ when A_j is located on Γ). The cells D_j constitute a third partition of Ω, which we name "diamond mesh." The area of the cell D_j is denoted by $|D_j|$. Such cells are displayed on Figure 2.2.

Moreover, we suppose that the set $[1, J]$ is ordered so that when A_j is not on Γ, then $j \in [1, J-J^\Gamma]$, and when A_j is on Γ, then $j \in [J-J^\Gamma+1, J]$. We shall also write $j \in \Gamma_q$ iff $A_j \subset \Gamma_q$.

2.4. Definitions of geometrical elements. The unit vector normal to A_j is denoted by $\mathbf{n}_j$ and is oriented so that $\mathbf{G_{i_1(j)}G_{i_2(j)}} \cdot \mathbf{n}_j \geq 0$. We further denote by A'_j the segment $[G_{i_1(j)}G_{i_2(j)}]$ (whose length is $|A'_j|$) and by $\mathbf{n}'_j$ the unit vector normal to A'_j oriented so that $\mathbf{S_{k_1(j)}S_{k_2(j)}} \cdot \mathbf{n}'_j \geq 0$.

When $S_k \in \Gamma$ ($k \in [K-J^\Gamma+1, K]$), we define $\tilde{A}_k$ as the part of the boundary Γ which consists of the union of the halves of the two segments A_j located on Γ, of which S_k is a node and by $\tilde{\mathbf{n}}_k$ the exterior unit normal vector to $\tilde{A}_k$ (see Figure 2.3). We denote by $M_{i_\alpha(j)\,k_\beta(j)}$ the midpoint of the segment $[G_{i_\alpha(j)}S_{k_\beta(j)}]$, for each pair of

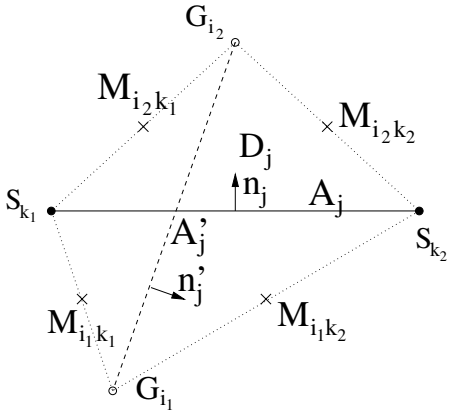

FIG. 2.4. *Notations for the diamond-cell.*

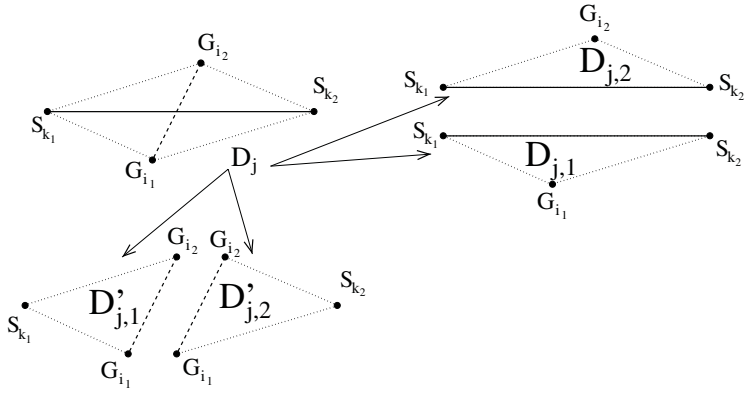

FIG. 2.5. *A diamond-cell may be split into two triangles in two distinct ways.*

integers (α, β) in $\{1;2\}^2$ (see Figure 2.4). We define for each $i \in [1, I]$ the set $\mathcal{V}(i)$ of integers $j \in [1, J]$ such that A_j is an edge of T_i and for each $k \in [1, K]$ the set $\mathcal{E}(k)$ of integers $j \in [1, J]$ such that S_k is a node of A_j.

We define for each $j \in [1, J]$ and each k such that $j \in \mathcal{E}(k)$ (resp., each i such that $j \in \mathcal{V}(i)$) the real-valued number s'_{jk} (resp., s_{ji}) whose value is $+1$ or -1 whether $\mathbf{n}'_j$ (resp., $\mathbf{n}_j$) points outwards or inwards P_k (resp., T_i). We define $\mathbf{n}'_{jk} := s'_{jk}\mathbf{n}'_j$ (resp., $\mathbf{n}_{ji} := s_{ji}\mathbf{n}_j$) and remark that $\mathbf{n}'_{jk}$ (resp., $\mathbf{n}_{ji}$) always points outwards P_k (resp., T_i).

For $j \in [1, J - J^\Gamma]$, as indicated on Figure 2.5, we also denote by $D_{j,1}$ and $D_{j,2}$, the triangles $S_{k_1(j)}G_{i_1(j)}S_{k_2(j)}$ and $S_{k_2(j)}G_{i_2(j)}S_{k_1(j)}$). In the same way, we denote by $D'_{j,1}$ and $D'_{j,2}$, the triangles $G_{i_2(j)}S_{k_1(j)}G_{i_1(j)}$ and $G_{i_1(j)}S_{k_2(j)}G_{i_2(j)}$.

The characteristic functions of the cells T_i and P_k will be denoted by θ_i^T and θ_k^P.

2.5. Definitions of discrete and continuous scalar products and norms. As will be seen in what follows, we shall associate with each point G_i ($i \in [1, I + J^\Gamma]$) and each vertex S_k ($k \in [1, K]$) discrete values. This leads us to the definition of the

following discrete scalar product for all $(\phi,\psi)=\big((\phi_i^T,\phi_k^P),(\psi_i^T,\psi_k^P)\big)\in\big(\mathbb{R}^I\times\mathbb{R}^K\big)^2$:

$$(\phi,\psi)_{T,P}:=\frac{1}{2}\left(\sum_{i\in[1,I]}|T_i|\,\phi_i^T\,\psi_i^T+\sum_{k\in[1,K]}|P_k|\,\phi_k^P\,\psi_k^P\right). \tag{2.1}$$

In the same way, we define a discrete scalar product on the diamond mesh for all $(\mathbf{u},\mathbf{v})=((\mathbf{u}_j),(\mathbf{v}_j))\in\big(\mathbb{R}^2\big)^J\times\big(\mathbb{R}^2\big)^J$

$$(\mathbf{u},\mathbf{v})_D:=\sum_{j\in[1,J]}|D_j|\,\mathbf{u}_j\cdot\mathbf{v}_j \tag{2.2}$$

and a discrete scalar product for the traces of $u\in\mathbb{R}^J$ and $\phi\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$ on the boundaries Γ_q

$$(u,\phi)_{\Gamma_q,h}:=\sum_{j\in\Gamma_q}|A_j|\,u_j\times\frac{1}{4}\left(\phi^P_{k_1(j)}+2\phi^T_{i_2(j)}+\phi^P_{k_2(j)}\right)$$

and on Γ

$$(u,\phi)_{\Gamma,h}:=\sum_{q\in[0,Q]}(u,\phi)_{\Gamma_q,h}. \tag{2.3}$$

Further, for any $\phi\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$, we define a discrete H^1 seminorm on the diamond mesh with the help of the discrete gradient operator (see (3.2)):

$$|\phi|_{1,D}:=\left(\boldsymbol{\nabla}_h^D\phi,\boldsymbol{\nabla}_h^D\phi\right)_D^{1/2}.$$

Finally, H^m is the space of functions v of $\mathrm{L}^2(\Omega)$ whose partial derivatives (in the distributional sense) $\partial^\alpha v$, with $|\alpha|\le m$, all belong to $\mathrm{L}^2(\Omega)$, while $||\cdot||_{m,\Omega}$ is the associated norm. The standard $\mathrm{L}^2(\Omega)$ inner product will be denoted by $(\cdot,\cdot)_\Omega$.

3. Construction of the discrete operators. In this section, we approach the gradient, divergence, and curl operators by discrete counterparts. We would like to stress that in two dimensions a distinction is usually made between the vector curl operator from $\mathbb{R}$ to $\mathbb{R}^2$, defined by $\boldsymbol{\nabla}\times\phi=(\frac{\partial\phi}{\partial y},-\frac{\partial\phi}{\partial x})^T$ and the scalar curl operator from $\mathbb{R}^2$ to $\mathbb{R}$, defined by $\nabla\times\mathbf{u}=\frac{\partial\mathbf{u}_y}{\partial x}-\frac{\partial\mathbf{u}_x}{\partial y}$.

Figure 3.1 shows the stencils of the different operators and their combinations: The stencil for the discrete gradient and vector curl operators simply consists of the four corners of the diamond-cell D_j. The stencil for the discrete divergence and scalar curl operators consists of the diamonds associated with the edges of the primal and dual cells. Arrows are displayed on Figure 3.1 to represent the normal and tangential components of the vector fields associated with the diamonds. The stencils for the discrete Laplacian on the primal and dual cells, respectively, consist of the black and white circles on the left and right part of the figure.

3.1. Construction of the discrete gradient and vector curl operators on the diamond-cells. We define the discrete gradient of a function ϕ by its values on the diamond-cells of the mesh. We follow [8, 10] and compute the mean-value of the

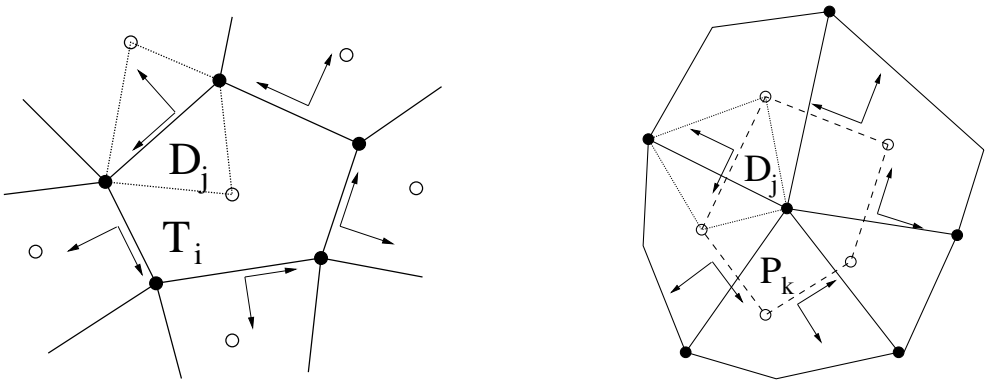

FIG. 3.1. *Stencils for the discrete operators. Left part: primal cell. Right part: dual cell.*

gradient of any function ϕ on such a cell D_j by the following formula:

$$
\begin{aligned}
|D_j| \left\langle \boldsymbol{\nabla}\phi_{|D_j} \right\rangle &= \int_{D_j} \boldsymbol{\nabla}\phi(\mathbf{x})\, d\mathbf{x} = \int_{\partial D_j} \phi(\xi)\mathbf{n}(\xi)\, d\xi \\
&= \sum_{(\alpha,\beta)} \int_{[G_{i_\alpha} S_{k_\beta}]} \phi(\xi)\, \mathbf{n}\, d\xi,
\end{aligned}
\tag{3.1}
$$

where $\mathbf{n}(\xi)$ stands for the outward unit normal vector to D_j at point ξ. The integrals in (3.1) can be approximated by the following formula:

$$
\int_{[GS]} \phi(\xi)\, d\xi \approx \ell_{GS}\, \frac{[\phi(G) + \phi(S)]}{2},
$$

where ℓ_{GS} denotes the length of the segment $[GS]$. Summing the contributions of the different vertices of D_j and using elementary geometrical equalities allows us to give *the definition* of the discrete gradient $\boldsymbol{\nabla}_h^D$ on D_j.

DEFINITION 3.1. *The discrete gradient $\boldsymbol{\nabla}_h^D$ is defined by its values over the diamond-cells D_j:*

$$
(\boldsymbol{\nabla}_h^D \phi)_j := \frac{1}{2\,|D_j|} \left\{ \left[\phi_{k_2}^P - \phi_{k_1}^P\right] |A_j'| \mathbf{n}_j' + \left[\phi_{i_2}^T - \phi_{i_1}^T\right] |A_j| \mathbf{n}_j \right\},
\tag{3.2}
$$

where we set $\phi_{k_\alpha}^P := \phi(S_{k_\alpha})$ and $\phi_{i_\alpha}^T := \phi(G_{i_\alpha})$, for $\alpha \in \{1;2\}$.

Note that formula (3.2) is exact for polynomials of degree one. Computing the discrete gradient only requires the values of ϕ at the nodes of the primal and dual meshes. The operator $\boldsymbol{\nabla}_h^D$ thus acts from $\mathbb{R}^{I+J^\Gamma} \times \mathbb{R}^K$ into $\left(\mathbb{R}^2\right)^J$.

In the same way, we may approach the vector curl operator $\boldsymbol{\nabla} \times \bullet = (\frac{\partial \bullet}{\partial y}, -\frac{\partial \bullet}{\partial x})^T$ by a discrete vector curl operator.

DEFINITION 3.2. *The discrete vector curl operator $\boldsymbol{\nabla}_h^D \times$ is defined by its values over the diamond-cells D_j:*

$$
(\boldsymbol{\nabla}_h^D \times \phi)_j := -\frac{1}{2\,|D_j|} \left\{ \left[\phi_{k_2}^P - \phi_{k_1}^P\right] |A_j'| \boldsymbol{\tau}_j' + \left[\phi_{i_2}^T - \phi_{i_1}^T\right] |A_j| \boldsymbol{\tau}_j \right\},
\tag{3.3}
$$

where the unit vectors $\boldsymbol{\tau}_j$ and $\boldsymbol{\tau}_j'$ are such that $(\mathbf{n}_j, \boldsymbol{\tau}_j)$ and $(\mathbf{n}_j', \boldsymbol{\tau}_j')$ are orthonormal positively oriented bases of $\mathbb{R}^2$.

Remark 3.3. In a connected domain, the discrete gradient and vector curl of a given $\phi = ((\phi_i^T), (\phi_k^P))$ vanish iff there exist two constants c^T and c^P, such that $\phi_i^T = c^T \ \forall\ i$ and $\phi_k^P = c^P \ \forall\ k$. The fact that c^T and c^P may differ from each other means that such a ϕ may, in general, present oscillations. However, in the applications studied in the present work, such oscillations never appear due to information on the mean-value of ϕ (see (4.16) and (5.7d)), or due to boundary conditions (4.17) and (5.8e).

3.2. Construction of the discrete divergence and scalar curl operators on the primal and dual meshes. Next, we choose to define the discrete divergence of a vector field $\mathbf{u}$ by its values both on the primal and dual cells of the mesh. A very natural way to do so on the primal cell T_i is to write

$$|T_i| \left\langle \nabla \cdot \mathbf{u}_{|T_i} \right\rangle = \int_{T_i} \nabla \cdot \mathbf{u}(\mathbf{x})\, d\mathbf{x} = \int_{\partial T_i} \mathbf{u}(\xi) \cdot \mathbf{n}(\xi) = \sum_{j \in \mathcal{V}(i)} \int_{A_j} \mathbf{u}(\xi) \cdot \mathbf{n}_{ji}\,,$$

where we recall that $\mathcal{V}(i)$ is the set of integers $j \in [1, J]$ such that A_j is an edge of T_i and that $\mathbf{n}_{ji}$ is the unit vector orthogonal to A_j pointing outward T_i. Supposing that the vector field $\mathbf{u}$ is given by both of the Cartesian components of its discrete values $\mathbf{u}_j$ on the diamond-cells D_j, and performing a similar computation over the cells P_k, we obtain *the definition* of the discrete divergence $\nabla_h^T \cdot$ on each T_i and the discrete divergence $\nabla_h^P \cdot$ on each P_k.

DEFINITION 3.4. *The discrete divergence* $\nabla_h^{T,P} \cdot := (\nabla_h^T \cdot, \nabla_h^P \cdot)$ *is defined by its values over the primal cells* T_i *and the dual cells* P_k*:*

$$\begin{aligned} (\nabla_h^T \cdot \mathbf{u})_i &:= \frac{1}{|T_i|} \sum_{j \in \mathcal{V}(i)} |A_j| \mathbf{u}_j \cdot \mathbf{n}_{ji}, \\ (\nabla_h^P \cdot \mathbf{u})_k &:= \frac{1}{|P_k|} \left(\sum_{j \in \mathcal{E}(k)} |A'_j| \mathbf{u}_j \cdot \mathbf{n}'_{jk} + \sum_{j \in \mathcal{E}(k) \cap [J - J^\Gamma + 1, J]} \frac{1}{2}\, |A_j| \mathbf{u}_j \cdot \mathbf{n}_j \right). \end{aligned} \tag{3.4}$$

Remark that if the node S_k is not on the boundary Γ (i.e., if $k \in [1, K - J^\Gamma]$), then the set $\mathcal{E}(k) \cap [J - J^\Gamma + 1, J]$ is empty. On the contrary, if P_k is a boundary dual cell, then the set $\mathcal{E}(k) \cap [J - J^\Gamma + 1, J]$ is composed of the two boundary edges which have S_k as a vertex. In this case, the quantity $\sum_{j \in \mathcal{E}(k) \cap [J - J^\Gamma + 1, J]} \frac{1}{2}\, |A_j| \mathbf{u}_j \cdot \mathbf{n}_j$ is an approximation of $\int_{\tilde{A}_k} \mathbf{u} \cdot \tilde{\mathbf{n}}_k(\xi)\, d\xi$ (see Figure 2.3).

For a given vector field $\mathbf{u}$, it is easily checked that these formulae are the exact mean-values of $\nabla \cdot \mathbf{u}$ over the primal and inner dual cells if $\mathbf{u}_j \cdot \mathbf{n}_{ji}$ and $\mathbf{u}_j \cdot \mathbf{n}'_{jk}$ represent the mean-values of $\mathbf{u} \cdot \mathbf{n}_{ji}$ over A_j and of $\mathbf{u} \cdot \mathbf{n}'_{jk}$ over A'_j. The operator $\nabla_h \cdot$ acts from $\left(\mathbb{R}^2\right)^J$ into $\mathbb{R}^I \times \mathbb{R}^K$.

In the same way, we may approach the scalar curl operator $\nabla \times \bullet = (\frac{\partial \bullet_y}{\partial x} - \frac{\partial \bullet_x}{\partial y})$ by a discrete scalar curl operator in the following definition.

DEFINITION 3.5. *The discrete scalar curl operator* $\nabla_h^{T,P} \times := (\nabla_h^T \times, \nabla_h^P \times)$ *is*

defined by its values over the primal cells T_i and the dual cells P_k:

$$(\nabla_h^T \times \mathbf{u})_i := \frac{1}{|T_i|} \sum_{j \in \mathcal{V}(i)} |A_j| \mathbf{u}_j \cdot \boldsymbol{\tau}_{ji},$$

$$(\nabla_h^P \times \mathbf{u})_k := \frac{1}{|P_k|} \left(\sum_{j \in \mathcal{E}(k)} |A_j^{'}| \mathbf{u}_j \cdot \boldsymbol{\tau}_{jk}^{'} + \sum_{j \in \mathcal{E}(k) \cap [J - J^\Gamma + 1, J]} \frac{1}{2} |A_j| \mathbf{u}_j \cdot \boldsymbol{\tau}_j \right). \tag{3.5}$$

4. Properties of the operators.

4.1. Discrete Green formulae. Here, we check that the discrete operators verify some discrete duality principles.

PROPOSITION 4.1. *The following discrete analogues of the Green formulae hold:*

$$(\nabla_h^{T,P} \cdot \mathbf{u}, \phi)_{T,P} = -(\mathbf{u}, \boldsymbol{\nabla}_h^D \phi)_D + (\mathbf{u} \cdot \mathbf{n}, \phi)_{\Gamma,h}, \tag{4.1}$$

$$(\nabla_h^{T,P} \times \mathbf{u}, \phi)_{T,P} = (\mathbf{u}, \boldsymbol{\nabla}_h^D \times \phi)_D + (\mathbf{u} \cdot \boldsymbol{\tau}, \phi)_{\Gamma,h} \tag{4.2}$$

for all $\mathbf{u} \in \left(\mathbb{R}^2\right)^J$ and all $\phi = (\phi^T, \phi^P) \in \mathbb{R}^{I+J^\Gamma} \times \mathbb{R}^K$, where the definitions (2.1), (2.2), *and* (2.3) *have been used.*

Proof. The proof of (4.1) may be found in [10] and is based on a discrete summation by parts. The proof of (4.2) follows exactly the same lines. ∎

4.2. Compositions of the discrete operators. The aim of this section is to verify a discrete analogue of the following continuous identities: $\nabla \cdot (\boldsymbol{\nabla} \times) = 0$, $\nabla \times \boldsymbol{\nabla} = 0$, and $\nabla \times \boldsymbol{\nabla} \times = -\nabla \cdot \boldsymbol{\nabla}$. For this, we start with a useful lemma.

LEMMA 4.2. *Recall that s_{ji} and s'_{jk} are defined in section* 2.4. *Then,*

$$\sum_{j \in \mathcal{V}(i)} s_{ji} \left(\phi^P_{k_2(j)} - \phi^P_{k_1(j)} \right) = 0 \quad \forall i \in [1, I], \tag{4.3}$$

$$\sum_{j \in \mathcal{E}(k)} s'_{jk} \left(\phi^T_{i_2(j)} - \phi^T_{i_1(j)} \right) = 0 \quad \forall\, k \in [1, K - J^\Gamma]. \tag{4.4}$$

Proof. Let us consider a given primal cell T_i. For each edge A_j of T_i, with $j \in \mathcal{V}(i)$, there are two possibilities for the orientation of $\mathbf{n}_j$ (see Figure 4.1): If $\mathbf{n}_j$ is the inward unit normal vector to T_i (case 1), then $s_{ji} = -1$ and $s_{ji}\,(\phi^P_{k_2(j)} - \phi^P_{k_1(j)}) = \phi^P_{k_1(j)} - \phi^P_{k_2(j)}$. If $\mathbf{n}_j$ is the outward unit normal vector to T_i (case 2), then $s_{ji} = 1$ and $s_{ji}\,(\phi^P_{k_2(j)} - \phi^P_{k_1(j)}) = \phi^P_{k_2(j)} - \phi^P_{k_1(j)}$; moreover, $S_{k_1}(j)$ and $S_{k_2}(j)$ are swapped. What appears finally is that, whatever the case, the value ϕ^P_k associated with the "left" vertex of the considered edge A_j appears in the sum (4.3) with a positive sign and the value ϕ^P_k associated with the "right" vertex of the considered edge A_j appears in the sum (4.3) with a negative sign. But each ϕ^P_k appears twice in that sum, once as the value associated with the "right" vertex of a given edge, and once as the value associated with the "left" vertex of the following edge, so that these two contributions cancel. This ends the proof of (4.3). The proof of (4.4) follows the same lines. ∎

Next, the following properties are direct consequences of the computation of the area $|D_j|$.

LEMMA 4.3.

$$\frac{|A_j|\,|A'_j|}{2\,|D_j|}\ \mathbf{n}_j\cdot\boldsymbol{\tau}'_j=1\quad\forall j\in[1,J], \tag{4.5}$$

$$\frac{|A_j|\,|A'_j|}{2\,|D_j|}\ \mathbf{n}'_j\cdot\boldsymbol{\tau}_j=-1\quad\forall j\in[1,J]. \tag{4.6}$$

We may now state the following results.

PROPOSITION 4.4. *Given any* $\phi=(\phi_i^T,\phi_k^P)\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$, *there holds*

$$\left(\nabla_h^T\cdot(\boldsymbol{\nabla}_h^D\times\phi)\right)_i=0\quad\forall i\in[1,I], \tag{4.7}$$

$$\left(\nabla_h^P\cdot(\boldsymbol{\nabla}_h^D\times\phi)\right)_k=0\quad\forall k\in[1,K-J^\Gamma], \tag{4.8}$$

$$\left(\nabla_h^T\times(\boldsymbol{\nabla}_h^D\phi)\right)_i=0\quad\forall i\in[1,I], \tag{4.9}$$

$$\left(\nabla_h^P\times(\boldsymbol{\nabla}_h^D\phi)\right)_k=0\quad\forall k\in[1,K-J^\Gamma]. \tag{4.10}$$

Moreover, on each boundary dual cell P_k *(*$k\in[K-J^\Gamma+1,K]$*),* (4.8) *and* (4.10) *still hold if there exist for each boundary* Γ_q, *with* $q\in[0,Q]$, *two real numbers* (c_q^T,c_q^P) *such that* $\phi_i^T=c_q^T$ *and* $\phi_k^P=c_q^P$ *uniformly over* Γ_q.

Proof. Let us first prove (4.7); combining (3.4), (3.3), and the fact that $\mathbf{n}_{ji}\cdot\boldsymbol{\tau}_j=0$, we get

$$\begin{aligned}(\nabla_h^T\cdot(\boldsymbol{\nabla}_h^D\times\phi))_i&=\frac{1}{|T_i|}\sum_{j\in\mathcal{V}(i)}|A_j|(\boldsymbol{\nabla}_h^D\times\phi)_j\cdot\mathbf{n}_{ji}\\&=-\frac{1}{|T_i|}\sum_{j\in\mathcal{V}(i)}\frac{|A_j|\,|A'_j|}{2\,|D_j|}\,\mathbf{n}_j\cdot\boldsymbol{\tau}'_j\,s_{ji}\left(\phi^P_{k_2(j)}-\phi^P_{k_1(j)}\right)\quad\forall i\in[1,I].\end{aligned}$$

Applying (4.5) and (4.3) successively, we obtain

$$(\nabla_h^T\cdot(\boldsymbol{\nabla}_h^D\times\phi))_i=0\quad\forall i\in[1,I].$$

Equation (4.9) can be proved in a similar way.

Next, for each interior dual cell P_k, with $k\in[1,K-J^\Gamma]$, the set $\mathcal{E}(k)\cap[J-J^\Gamma+1,J]$ is empty, so that (4.8) and (4.10) can be proved like (4.7) and (4.9), using (4.6), (4.4) and the fact that $\mathbf{n}'_{jk}\cdot\boldsymbol{\tau}'_j=0$.

As far as the boundary dual cells P_k are concerned ($k\in[K-J^\Gamma+1,K]$), similar computations show that (see Figure 4.2 for the notations)

$$(\nabla_h^P\cdot(\boldsymbol{\nabla}_h^D\times\phi))_k=\frac{1}{|P_k|}\left(\phi^T_{I_2}-\phi^T_{I_1}\right)+\frac{1}{2\,|P_k|}\left(\phi^P_{K_1}-\phi^P_{K_2}\right). \tag{4.11}$$

If all ϕ_i^T are equal to the same constant c_q^T over Γ_q and if all ϕ_k^P are equal to the same constant c_q^P over Γ_q, then $\phi^T_{I_2}=\phi^T_{I_1}$ and $\phi^P_{K_1}=\phi^P_{K_2}$ so that

$$(\nabla_h^P\cdot(\boldsymbol{\nabla}_h^D\times\phi))_k=0,$$

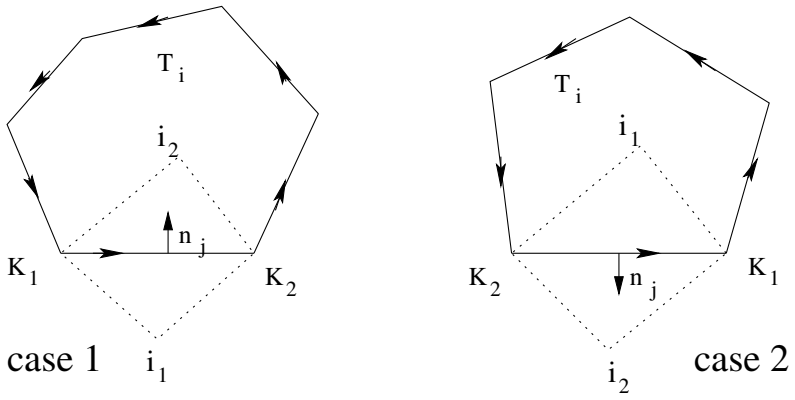

FIG. 4.1. *Two possibilities of orientation for each edge.*

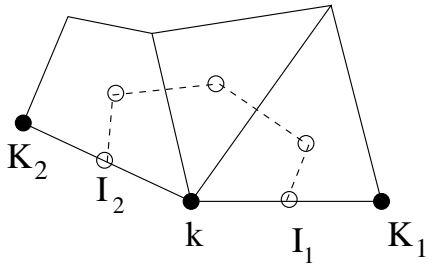

FIG. 4.2. *Notations for the boundary dual cells.*

for the boundary dual cells, and (4.10) for the boundary dual cells is proved in a similar way. ∎

PROPOSITION 4.5. *The following equalities hold:*

$$
\begin{aligned}
(\nabla_h^T \times \boldsymbol{\nabla}_h^D \times \phi)_i &= -(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \phi)_i \quad \forall i \in [1, I], \\
(\nabla_h^P \times \boldsymbol{\nabla}_h^D \times \phi)_k &= -(\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \phi)_k \quad \forall k \in [1, K].
\end{aligned} \tag{4.12}
$$

Proof. These formulae follow immediately from the definitions (3.2), (3.3), (3.4), and (3.5) and from the equality $\boldsymbol{\tau}_j \cdot \boldsymbol{\tau}'_j = \mathbf{n}_j \cdot \mathbf{n}'_j \quad \forall j \in [1, J]$. ∎

4.3. Hodge's decomposition. In the continuous case, the Hodge decomposition for nonsimply connected domains reads

$$
(L^2)^2 = \boldsymbol{\nabla} V \overset{\perp}{\oplus} \boldsymbol{\nabla} \times W, \tag{4.13}
$$

with $V = \{\phi \in H^1 : \int_\Omega \phi = 0\}$ and $W = \{\psi \in H^1 : \psi_{|\Gamma_0} = 0, \quad \psi_{|\Gamma_q} = c_q \ \forall q \in [1, Q]\}$. To prove an analogous property in the discrete case, we rely on the following result.

LEMMA 4.6 (Euler's formula). *For a nonsimply connected bidimensional domain covered by a mesh with I elements, K vertices, J edges, and Q holes, there holds*

$$
I + K = J + 1 - Q. \tag{4.14}
$$

We may now state the following discrete Hodge decomposition.

THEOREM 4.7. *Let $(\mathbf{u}_j)_{j\in[1,J]}$ be a discrete vector field defined by its values on the diamond-cells D_j. There exist unique $\phi = (\phi_i^T, \phi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, $\psi = (\psi_i^T, \psi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, and $(c_q^T, c_q^P)_{q\in[1,Q]}$ such that*

$$\mathbf{u}_j = (\boldsymbol{\nabla}_h^D \phi)_j + (\boldsymbol{\nabla}_h^D \times \psi)_j \quad \forall j \in [1, J], \tag{4.15}$$

$$\sum_{i\in[1,I]} |T_i|\phi_i^T = \sum_{k\in[1,K]} |P_k|\phi_k^P = 0, \tag{4.16}$$

$$\psi_i^T = 0 \ \ \forall i \in \Gamma_0, \quad \psi_k^P = 0 \ \ \forall k \in \Gamma_0, \tag{4.17}$$

and

$$\forall q \in [1, Q], \qquad \psi_i^T = c_q^T \ \ \forall i \in \Gamma_q, \quad \psi_k^P = c_q^P \ \ \forall k \in \Gamma_q. \tag{4.18}$$

Moreover, the decomposition (4.15) *is orthogonal.*

Proof. There are $2(I + K + J^\Gamma) + 2Q$ unknowns corresponding to (ϕ_i^T, ϕ_k^P) and (ψ_i^T, ψ_k^P) and to the constants (c_q^T, c_q^P). On the other hand, $2J$ equations are given by (4.15), while (4.17) and (4.18) provide $2J^\Gamma$ constraints. Finally, (4.16) gives two supplementary equalities, so that the total number of equations is $2J + 2 + 2J^\Gamma$. Consequently, according to (4.14), there are as many equations as unknowns. Therefore, existence and uniqueness of the decomposition are equivalent, and we shall prove uniqueness through injectivity.

Proving the orthogonality of $(\boldsymbol{\nabla}_h^D \phi)$ and $(\boldsymbol{\nabla}_h^D \times \psi)$ for any (ϕ, ψ) verifying (4.17) and (4.18) amounts to showing $(\boldsymbol{\nabla}_h^D \times \psi, \boldsymbol{\nabla}_h^D \phi)_D = 0$. Thanks to (4.1), there holds

$$(\boldsymbol{\nabla}_h^D \times \psi, \boldsymbol{\nabla}_h^D \phi)_D = -(\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D \times \psi, \phi)_{T,P} + (\boldsymbol{\nabla}_h^D \times \psi \cdot \mathbf{n}, \phi)_{\Gamma,h}.$$

Next, thanks to Proposition 4.4, $\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D \times \psi$ vanishes on all primal and inner dual cells. Because ψ verifies (4.17) and (4.18), we infer from Proposition 4.4 that $\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D \times \psi$ also vanishes on the boundary dual cells. Finally, according to (3.3), we have

$$(\boldsymbol{\nabla}_h^D \times \psi)_j \cdot \mathbf{n}_j = -\frac{1}{2\,|D_j|} \left(\psi_{k_2}^P - \psi_{k_1}^P\right) |A_j'| \boldsymbol{\tau}_j' \cdot \mathbf{n}_j,$$

which also vanishes on the boundary because of (4.17) and (4.18). Thus, orthogonality is proved. In order to prove injectivity, we suppose $\mathbf{u}_j = 0 \ \forall j \in [1, J]$:

$$0 = (\boldsymbol{\nabla}_h^D \phi)_j + (\boldsymbol{\nabla}_h^D \times \psi)_j \quad \forall j \in [1, J]. \tag{4.19}$$

We carry out the scalar product of (4.19) with $|D_j|\ (\boldsymbol{\nabla}_h^D \phi)_j$ and sum over $j \in [1, J]$:

$$0 = (\boldsymbol{\nabla}_h^D \phi, \boldsymbol{\nabla}_h^D \phi)_D + (\boldsymbol{\nabla}_h^D \times \psi, \boldsymbol{\nabla}_h^D \phi)_D. \tag{4.20}$$

Thanks to the orthogonality proved above, (4.20) implies that $(\boldsymbol{\nabla}_h^D \phi, \boldsymbol{\nabla}_h^D \phi)_D = \sum_{j\in[1,J]} |D_j| |(\boldsymbol{\nabla}_h^D \phi)_j|^2 = 0$, so that $(\boldsymbol{\nabla}_h^D \phi)_j = 0 \ \forall$ j. Since the domain is connected, there exist two real constants α and β such that $\phi_k^P = \alpha \ \forall k \in [1, K]$ and $\phi_i^T = \beta \ \forall i \in [1, I + J^\Gamma]$. Equation (4.16) implies that these two constants vanish, so that

$$\phi_i^T = 0 \quad \forall i \in [1, I + J^\Gamma] \ \text{ and } \ \phi_k^P = 0 \quad \forall k \in [1, K].$$

Consequently, (4.19) is equivalent to $(\boldsymbol{\nabla}_h^D \times \psi)_j = 0 \; \forall j \in [1, J]$. Since the domain is connected, there exist two real constants α and β such as $\psi_k^P = \alpha \; \forall k \in [1, K]$ and $\psi_i^T = \beta \; \forall i \in [1, I + J^\Gamma]$. As $\psi = 0$ over Γ_0 these two constants vanish and

$$\psi_i^T = 0 \quad \forall i \in [1, I + J^\Gamma] \;\text{ and }\; \psi_k^P = 0 \quad \forall k \in [1, K] \,. \qquad \square$$

Remark 4.8. The two equalities in (4.16) are discrete analogues, respectively stated on the primal mesh and dual mesh, of the condition $\int_\Omega \phi = 0$ that appears in the definition of the space V in (4.13), while formulae (4.17) and (4.18) are discrete analogues of the boundary conditions that appear in the definition of W.

5. Numerical solution of the div-curl problem for nonsimply connected domains.

5.1. Discretization of the div-curl problem with normal boundary conditions. We are interested in the approximation of the following continuous problem: given f, g, σ, $(k_q)_{q\in[1,Q]}$, find $\mathbf{u}$ such that

$$\begin{cases} \nabla \cdot \mathbf{u} = f \;\text{ in }\; \Omega, \\ \nabla \times \mathbf{u} = g \;\text{ in }\; \Omega, \\ \mathbf{u} \cdot \mathbf{n} = \sigma \;\text{ on }\; \Gamma, \\ \int_{\Gamma_q} \mathbf{u} \cdot \boldsymbol{\tau} = k_q \quad \forall q \in [1, Q]. \end{cases} \tag{5.1}$$

A necessary condition for the existence of a solution to (5.1) is given by the formula

$$\int_\Omega f(\mathbf{x}) d\mathbf{x} = \int_\Gamma \sigma(\xi) \, d\xi. \tag{5.2}$$

We discretize the solution of this problem by a vector field $(\mathbf{u}_j)_{j\in[1,J]}$ defined by its values over the diamond-cells of the mesh. Using the discrete differential operators defined in section 3, and following [12], we write the following discrete equations:

$$\left(\nabla_h^T \cdot \mathbf{u}\right)_i = f_i^T \quad \forall i \in [1, I], \tag{5.3a}$$

$$\left(\nabla_h^P \cdot \mathbf{u}\right)_k = f_k^P \quad \forall k \in [1, K], \tag{5.3b}$$

$$\left(\nabla_h^T \times \mathbf{u}\right)_i = g_i^T \quad \forall i \in [1, I], \tag{5.3c}$$

$$\left(\nabla_h^P \times \mathbf{u}\right)_k = g_k^P \quad \forall k \in [1, K - J^\Gamma], \tag{5.3d}$$

$$\mathbf{u}_j \cdot \mathbf{n}_j = \sigma_j \quad \forall j \in [J - J^\Gamma + 1, J], \tag{5.3e}$$

$$(\mathbf{u} \cdot \boldsymbol{\tau}, 1)_{\Gamma_q, h} = k_q \quad \forall q \in [1, Q], \tag{5.3f}$$

$$\sum_{k\in\Gamma_q} |P_k| \;\; (\nabla_h^P \times \mathbf{u})_k = \sum_{k\in\Gamma_q} |P_k| \;\; g_k^P \quad \forall q \in [1, Q], \tag{5.3g}$$

where the following definitions have been used:

$$f_i^T = \frac{1}{|T_i|} \int_{T_i} f(\mathbf{x}) \, d\mathbf{x} \quad \forall i \in [1, I], \;\; f_k^P = \frac{1}{|P_k|} \int_{P_k} f(\mathbf{x}) \, d\mathbf{x} \quad \forall k \in [1, K], \tag{5.4}$$

$$g_i^T = \frac{1}{|T_i|} \int_{T_i} g(\mathbf{x}) \, d\mathbf{x} \quad \forall i \in [1, I], \;\; g_k^P = \frac{1}{|P_k|} \int_{P_k} g(\mathbf{x}) \, d\mathbf{x} \quad \forall k \in [1, K], \tag{5.5}$$

$$\sigma_j = \frac{1}{|A_j|} \int_{A_j} \sigma(\xi) \, d\xi \quad \forall j \in [J - J^\Gamma + 1, J]. \tag{5.6}$$

Using the discrete Hodge decomposition of $(\mathbf{u}_j)_{j\in[1,J]}$, problem (5.3) may be split into two independent problems involving the following potentials.

PROPOSITION 5.1. *Problem* (5.3) *can be split into two independent problems: Find* $(\phi_i^T, \phi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$ *such that*

$$(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \phi)_i = f_i^T \quad \forall i \in [1, I], \tag{5.7a}$$

$$(\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \phi)_k = f_k^P \quad \forall k \in [1, K], \tag{5.7b}$$

$$(\boldsymbol{\nabla}_h^D \phi)_j \cdot \mathbf{n}_j = \sigma_j \quad \forall j \in [J - J^\Gamma + 1, J], \tag{5.7c}$$

$$\sum_{i\in[1,I]} |T_i| \phi_i^T = \sum_{k\in[1,K]} |P_k| \phi_k^P = 0. \tag{5.7d}$$

Find $(\psi_i^T, \psi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$ *and* $(c_q^T, c_q^P)_{q\in[1,Q]}$ *such that*

$$-(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \psi)_i = g_i^T \quad \forall i \in [1, I], \tag{5.8a}$$

$$-(\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k = g_k^P \quad \forall k \in [1, K - J^\Gamma], \tag{5.8b}$$

$$(\boldsymbol{\nabla}_h^D \psi \cdot \mathbf{n}, 1)_{\Gamma_q,h} = -k_q \quad \forall q \in [1, Q], \tag{5.8c}$$

$$-\sum_{k\in\Gamma_q} |P_k| \ (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k = \sum_{k\in\Gamma_q} |P_k| \ g_k^P \quad \forall q \in [1, Q], \tag{5.8d}$$

$$\psi_i^T = \psi_k^P = 0 \quad \forall i \in \Gamma_0 \quad \forall k \in \Gamma_0, \tag{5.8e}$$

$$\forall q \in [1, Q] \ \ \psi_i^T = c_q^T \ \ \forall i \in \Gamma_q, \tag{5.8f}$$

$$\forall q \in [1, Q] \ \ \psi_k^P = c_q^P \ \ \forall k \in \Gamma_q. \tag{5.8g}$$

The vector $\mathbf{u}$ *is then reconstructed by*

$$\mathbf{u}_j = (\boldsymbol{\nabla}_h^D \phi)_j + (\boldsymbol{\nabla}_h^D \times \psi)_j \quad \forall j \in [1, J]. \tag{5.9}$$

Proof. First, the discrete Hodge decomposition of $(\mathbf{u}_j)_{j\in[1,J]}$ shows the existence of $(\phi_i^T, \phi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, $(\psi_i^T, \psi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, and $(c_q^T, c_q^P)_{q\in[1,Q]}$ such that (5.9), (5.7d), and (5.8e)–(5.8g) are verified. Next, (5.7a) is proved using (4.7):

$$f_i^T = (\nabla_h^T \cdot \mathbf{u})_i = (\nabla_h^T \cdot (\boldsymbol{\nabla}_h^D \phi + \boldsymbol{\nabla}_h^D \times \psi))_i = (\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \phi)_i \quad \forall i \in [1, I].$$

Similarly, using (4.8) and $\psi_i^T = c_q^T$ and $\psi_k^P = c_q^P \ \ \forall q \in [0, Q]$, we obtain (5.7b). As far as the boundary conditions are concerned, using (3.3) shows that

$$(\boldsymbol{\nabla}_h^D \times \psi)_j \cdot \mathbf{n}_j = -\frac{1}{2\,|D_j|} \left(\psi_{k_2} - \psi_{k_1}\right) |A_j'| \boldsymbol{\tau}_j' \cdot \mathbf{n}_j \quad \forall j \in [J - J^\Gamma + 1, J]. \tag{5.10}$$

Since $\psi_k^P = c_q^P \ \ \forall q \in [0, Q]$, we infer from (5.10)

$$(\boldsymbol{\nabla}_h^D \times \psi)_j \cdot \mathbf{n}_j = 0 \quad \forall j \in [J - J^\Gamma + 1, J],$$

so that (5.3e) and (5.9) imply (5.7c). Further, using (5.9), (5.3c)–(5.3d), (4.9), (4.10), and (4.12), we may prove (5.8a)–(5.8b). Moreover, there holds

$$(\boldsymbol{\nabla}_h^D \phi)_j \cdot \boldsymbol{\tau}_j = \frac{1}{2|D_j|} \left(\phi_{k_2(j)}^T - \phi_{k_1(j)}^T\right) |A_j'| \mathbf{n}_j' \cdot \boldsymbol{\tau}_j,$$

so that, using (4.6),

$$(\boldsymbol{\nabla}_h^D \phi \cdot \boldsymbol{\tau}, 1)_{\Gamma_q,h} = \sum_{j\in\Gamma_q} \frac{|A_j|\,|A_j'|}{2\,|D_j|}\mathbf{n}_j' \cdot \boldsymbol{\tau}_j \left(\phi_{k_2(j)}^T - \phi_{k_1(j)}^T\right) = -\sum_{j\in\Gamma_q} \left(\phi_{k_2(j)}^T - \phi_{k_1(j)}^T\right),$$

which vanishes because Γ_q is a closed contour. Thus, (5.3f) implies (5.8c) because $(\boldsymbol{\nabla}_h^D \times \psi)\cdot\boldsymbol{\tau}_j = -\boldsymbol{\nabla}_h^D\psi\cdot\mathbf{n}_j$. Finally, a computation similar to that which led to (4.11) shows that

$$(\nabla_h^P \times (\boldsymbol{\nabla}_h^D\phi))_k = \frac{1}{|P_k|}\left(\phi_{I_2}^T - \phi_{I_1}^T\right) + \frac{1}{2\,|P_k|}\left(\phi_{K_1}^P - \phi_{K_2}^P\right)$$

for boundary cells $k \in [K - J^\Gamma + 1, K]$ (see Figure 4.2 for the notations). Thus, when summing these contributions over a closed contour Γ_q, we obtain

$$\sum_{k\in\Gamma_q} |P_k|(\nabla_h^P \times (\boldsymbol{\nabla}_h^D\phi))_k = 0,$$

so that (5.3g) implies (5.8d). ∎

PROPOSITION 5.2. *Problems* (5.7) *and* (5.8) *both have a unique solution.*

Proof. As far as problem (5.7) is concerned, the existence and uniqueness of its solution have been proved in [10] if the following discrete equivalent of (5.2) is verified:

$$\sum_{i\in[1,I]} |T_i|\, f_i^T = \sum_{k\in[1,K]} |P_k|\, f_k^P = \sum_{j\in[J-J^\Gamma+1,J]} |A_j|\,\sigma_j,$$

which is the case here because, thanks to the definitions (5.4) and (5.6), we have

$$\sum_{i\in[1,I]} |T_i|\, f_i^T = \sum_{k\in[1,K]} |P_k|\, f_k^P = \int_\Omega f(\mathbf{x})\,d\mathbf{x} \text{ and } \sum_{j\in[J-J^\Gamma+1,J]} |A_j|\,\sigma_j = \int_\Gamma \sigma(\xi)\,d\xi.$$

As far as problem (5.8) is concerned, there are $I+K+J^\Gamma+2Q$ unknowns, while (5.8a) and (5.8b), respectively, provide I and $K-J^\Gamma$ equations. Equations (5.8c) and (5.8d) provide $2Q$ additional relations. Finally, boundary conditions (5.8e)–(5.8g) provide the last $2J^\Gamma$ equations. Since there are as many equations as unknowns, it suffices to check the injectivity of the system. Let us set $g_i^T = g_k^P = k_q = 0$ in system (5.8) and compute the following discrete scalar product $(\nabla_h^{T,P}\cdot\boldsymbol{\nabla}_h^D\psi,\psi)_{T,P}$ (see (2.1) for the definition). In this scalar product, the sum over the indices $i\in[1,I]$ and the sum over the indices $k\in[1,K-J^\Gamma]$ vanish, respectively, because of (5.8a) and (5.8b). Further, due to (5.8e), the contributions of the indices $k\in\Gamma_0$ also vanish, so that

$$(\nabla_h^{T,P}\cdot\boldsymbol{\nabla}_h^D\psi,\psi)_{T,P} = \frac{1}{2}\sum_{q\in[1,Q]}\sum_{k\in\Gamma_q} |P_k|\,(\nabla_h^P\cdot\boldsymbol{\nabla}_h^D\psi)_k\,\psi_k^P.$$

Further, (5.8g) implies that

$$(\nabla_h^{T,P}\cdot\boldsymbol{\nabla}_h^D\psi,\psi)_{T,P} = \frac{1}{2}\sum_{q\in[1,Q]} c_q^P \sum_{k\in\Gamma_q} |P_k|\,(\nabla_h^P\cdot\boldsymbol{\nabla}_h^D\psi)_k,$$

which vanishes due to (5.8d). Thanks to the discrete Green formula (4.2), there holds

$$(\nabla_h^{T,P}\cdot\boldsymbol{\nabla}_h^D\psi,\psi)_{T,P} = -(\boldsymbol{\nabla}_h^D\psi,\boldsymbol{\nabla}_h^D\psi)_D + (\boldsymbol{\nabla}_h^D\psi\cdot\mathbf{n},\psi)_{\Gamma,h} = 0. \tag{5.11}$$

Now, due to boundary conditions (5.8e)–(5.8g), we may write

$$(\boldsymbol{\nabla}_h^D\psi\cdot\mathbf{n},\psi)_{\Gamma,h}=\sum_{q\in[1,Q]}\frac{c_q^T+c_q^P}{2}\ (\boldsymbol{\nabla}_h^D\psi\cdot\mathbf{n},1)_{\Gamma_q,h}, \tag{5.12}$$

which vanishes thanks to (5.8c). Thus, (5.11), (5.12), and definition (2.2) imply that

$$(\boldsymbol{\nabla}_h^D\psi,\boldsymbol{\nabla}_h^D\psi)_D=\sum_{j\in[1,J]}|D_j||\boldsymbol{\nabla}_h^D\psi|^2=0.$$

Consequently, just like at the end of the proof of Theorem 4.7, we infer that

$$\psi_i^T=0\quad\forall i\in[1,I+J^\Gamma]\ \text{ and }\ \psi_k^P=0\quad\forall k\in[1,K],$$

which proves uniqueness and thus existence. ∎

5.2. The div-curl problem with tangential boundary conditions. We consider the following continuous problem: given f, g, σ, $(k_q)_{q\in[1,Q]}$, find $\mathbf{u}$ such that

$$\begin{cases}\nabla\cdot\mathbf{u}=f\ \text{ in }\ \Omega,\\ \nabla\times\mathbf{u}=g\ \text{ in }\ \Omega,\\ \mathbf{u}\cdot\boldsymbol{\tau}=\sigma\ \text{ on }\ \Gamma,\\ \int_{\Gamma_q}\mathbf{u}\cdot\mathbf{n}=k_q\ \ \forall q\in[1,Q].\end{cases}$$

A necessary condition for the existence of a solution to this system is given by Green's formula: $\int_\Omega g(\mathbf{x})d\mathbf{x}=\int_\Gamma\sigma(\xi)\,d\xi$. This problem is discretized like in section 5.1 by a vector field $(\mathbf{u}_j)_{j\in[1,J]}$ defined by its values over the diamond-cells. Using the discrete differential operators defined in section 3, we write the following discrete equations:

$$\begin{cases}\big(\nabla_h^T\cdot\mathbf{u}\big)_i=f_i^T\quad\forall i\in[1,I],\\ \big(\nabla_h^P\cdot\mathbf{u}\big)_k=f_k^P\quad\forall k\in[1,K-J^\Gamma],\\ \big(\nabla_h^T\times\mathbf{u}\big)_i=g_i^T\quad\forall i\in[1,I],\\ \big(\nabla_h^P\times\mathbf{u}\big)_k=g_k^P\quad\forall k\in[1,K],\\ \mathbf{u}_j\cdot\boldsymbol{\tau}_j=\sigma_j\quad\forall j\in[J-J^\Gamma+1,J],\\ (\mathbf{u}\cdot\mathbf{n},1)_{\Gamma_q,h}=k_q\quad\forall q\in[1,Q],\\ \sum_{k\in\Gamma_q}|P_k|\ (\nabla_h^P\cdot\mathbf{u})_k=\sum_{k\in\Gamma_q}|P_k|\ f_k^P\quad\forall q\in[1,Q].\end{cases} \tag{5.13}$$

Existence and uniqueness of the solution of (5.13) are proved similarly to section 5.1; the main difference is that the Hodge decomposition is modified in the following way.

THEOREM 5.3. *Let $(\mathbf{u}_j)_{j\in[1,J]}$ be a discrete vector field defined by its values on the diamond-cells D_j. There exist unique $\phi=(\phi_i^T,\phi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, $\psi=(\psi_i^T,\psi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$, and $(c_q^T,c_q^P)_{q\in[1,Q]}$ such that*

$$\begin{gathered}\mathbf{u}_j=(\boldsymbol{\nabla}_h^D\psi)_j+(\boldsymbol{\nabla}_h^D\times\phi)_j\quad\forall j\in[1,J],\\ \sum_{i\in[1,I]}|T_i|\phi_i^T=\sum_{k\in[1,K]}|P_k|\phi_k^P=0,\\ \psi_i^T=0\quad\forall i\in\Gamma_0,\quad\psi_k^P=0\quad\forall k\in\Gamma_0,\end{gathered} \tag{5.14}$$

and

$$\forall q \in [1,Q], \quad \psi_i^T = c_q^T \quad \forall i \in \Gamma_q, \quad \psi_k^P = c_q^P \quad \forall k \in \Gamma_q.$$

Moreover, the decomposition (5.14) *is orthogonal.*

Further, problem (5.13) decouples into two independent subproblems involving the following potentials.

PROPOSITION 5.4. *Problem* (5.13) *can be split into two independent problems. Find* $(\phi_i^T, \phi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$ *such that*

$$\begin{cases} -(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \phi)_i = g_i^T \quad \forall i \in [1,I], \\ -(\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \phi)_k = g_k^P \quad \forall k \in [1,K], \\ -(\boldsymbol{\nabla}_h^D \phi)_j \cdot \mathbf{n}_j = \sigma_j \quad \forall j \in [J - J^\Gamma + 1, J], \\ \sum_{i\in[1,I]} |T_i| \phi_i^T = \sum_{k\in[1,K]} |P_k| \phi_k^P = 0. \end{cases}$$

Find $(\psi_i^T, \psi_k^P)_{i\in[1,I+J^\Gamma],k\in[1,K]}$ *and* $(c_q^T, c_q^P)_{q\in[1,Q]}$

$$\begin{cases} (\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \psi)_i = f_i^T \quad \forall i \in [1,I], \\ (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k = f_k^P \quad \forall k \in [1, K - J^\Gamma], \\ (\boldsymbol{\nabla}_h^D \psi \cdot \mathbf{n}, 1)_{\Gamma_q} = k_q \quad \forall q \in [1,Q], \\ \sum_{k\in\Gamma_q} |P_k| \ (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k = \sum_{k\in\Gamma_q} |P_k| \ f_k^P \quad \forall q \in [1,Q], \\ \psi_i^T = \psi_k^P = 0 \quad \forall i \in \Gamma_0, \quad \forall k \in \Gamma_0, \\ \forall q \in [1,Q], \ \ \psi_i^T = c_q^T \quad \forall i \in \Gamma_q, \\ \forall q \in [1,Q], \ \ \psi_k^P = c_q^P \quad \forall k \in \Gamma_q. \end{cases}$$

The vector $\mathbf{u}$ *is then reconstructed by*

$$\mathbf{u}_j = (\boldsymbol{\nabla}_h^D \psi)_j + (\boldsymbol{\nabla}_h^D \times \phi)_j \quad \forall j \in [1,J].$$

5.3. Error estimate for the div-curl problem. Unlike in [20], we shall derive estimates for the potentials involved in the Hodge decomposition of $\mathbf{u}$; indeed we shall rely on similar estimates which have been obtained in [10]. For the sake of simplicity, we shall restrict ourselves to the case where all diamond-cells are convex; the case of nonconvex diamond-cells requires additional hypotheses similar to those given in [10]. We shall obtain error estimates under the following hypothesis (see Figures 2.5 and 5.1 for the notations).

Hypothesis 5.5. There exists an angle τ^*, strictly lower than π and independent of the mesh, such that the following hold:

1. For any *interior* diamond-cell D_j, the smallest in the maximum angle of the couple of triangles $(D_{j,1}, D_{j,2})$ *or* in the maximum angle of the couple of triangles $(D'_{j,1}, D'_{j,2})$ is bounded by τ^*:

$$\min\left(\max(\alpha_1, \beta_1, \mu_1 + \mu_2, \alpha_2, \beta_2, \nu_1 + \nu_2), \max(\mu_1, \nu_1, \alpha_1 + \alpha_2, \mu_2, \nu_2, \beta_1 + \beta_2)\right) \leq \tau^*.$$

2. The greatest angle of any boundary cell D_j is bounded by the angle τ^*.

Obtaining error estimates usually relies on regularity assumptions on the solution of the problem. In order to apply results given in [10], we shall assume regularity of

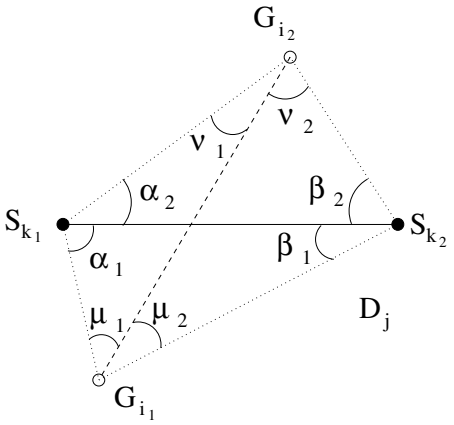

FIG. 5.1. *Notations for section* 5.3.

the potentials given by the following proposition.

PROPOSITION 5.6. *Let* (f, g, σ) *belong to* $\mathrm{L}^2(\Omega)^2 \times \mathrm{H}^{1/2}(\Gamma)$*, and let* $(k_q)_{q\in[1,Q]}$ *be a set of given real numbers; let* $\hat{\mathbf{u}}$ *be the exact solution of problem* (5.1)*. Then, there exist* $\hat{\phi}$ *and* $\hat{\psi}$ *both in* $\mathrm{H}^1(\Omega)$ *and a set of real numbers* $(C_q)_{q\in[1,Q]}$ *such that*

$$\hat{\mathbf{u}} = \boldsymbol{\nabla}\hat{\phi} + \boldsymbol{\nabla} \times \hat{\psi},$$

where $\hat{\phi}$ *is the solution of*

$$\begin{cases} \Delta\hat{\phi} = \nabla \cdot \hat{\mathbf{u}} = f \ \ in \ \ \Omega, \\ \boldsymbol{\nabla}\hat{\phi} \cdot \mathbf{n} = \hat{\mathbf{u}} \cdot \mathbf{n} = \sigma \ \ on \ \ \Gamma, \\ \int_\Omega \hat{\phi} = 0, \end{cases} \tag{5.15}$$

and $\hat{\psi}$ *is the solution of*

$$\begin{cases} -\Delta\hat{\psi} = \nabla \times \hat{\mathbf{u}} = g \ \ in \ \ \Omega, \\ \hat{\psi}_{|\Gamma_0} = 0; \ \ \hat{\psi}_{|\Gamma_q} = C_q \ \ \forall\, q \in [1, Q], \\ \int_{\Gamma_q} \boldsymbol{\nabla}\hat{\psi} \cdot n = -k_q. \end{cases} \tag{5.16}$$

Proof. The Hodge decomposition of $\hat{\mathbf{u}}$ and the determination of $\hat{\phi}$ and $\hat{\psi}$ through (5.15) and (5.16) are direct consequences of [11, Theorem 3.2 and Corollary 3.1]. ∎

Hypothesis 5.7. We suppose that the potentials $\hat{\phi}$ and $\hat{\psi}$ given by Proposition 5.6 belong to $\mathrm{H}^2(\Omega)$.

We remark that due to reentrant corners related to the internal polygonal boundaries Γ_q, the H^2 regularity of the potentials is not a consequence of the regularity of the data (f, g, σ).

Obviously, we may relate the L^2 error between the solution $\hat{\mathbf{u}}$ of (5.1) and the discrete solution $(\mathbf{u}_j)_{j\in[1,J]}$ of (5.3) to the errors between the solutions $\hat{\phi}$ and $\hat{\psi}$ of (5.15) and (5.16) and the discrete solutions (ϕ_i^T, ϕ_k^P) and (ψ_i^T, ψ_k^P) defined in Proposition 5.1,

respectively, by (5.7) and (5.8). Indeed we see that

$$\sum_{j\in[1,J]}\int_{D_j}|\mathbf{u}_j-\hat{\mathbf{u}}(\mathbf{x})|^2\,d\mathbf{x}\le 2\Bigg(\sum_{j\in[1,J]}\int_{D_j}\left|(\boldsymbol{\nabla}_h^D\phi)_j-\boldsymbol{\nabla}\hat{\phi}(\mathbf{x})\right|^2 d\mathbf{x} + \sum_{j\in[1,J]}\int_{D_j}\left|(\boldsymbol{\nabla}_h^D\psi)_j-\boldsymbol{\nabla}\hat{\psi}(\mathbf{x})\right|^2 d\mathbf{x}\Bigg). \tag{5.17}$$

5.3.1. Equivalent finite element formulations for the potentials. In order to evaluate the errors on the potentials, we follow [10] and rewrite (5.7) and (5.8) in terms of equivalent (nonconforming) finite element formulations. Recalling that the points $M_{i_\alpha(j)\,k_\beta(j)}$ are illustrated on Figure 2.4, we construct the following functions.

PROPOSITION 5.8. *Let $(\phi_i^T,\phi_k^P)\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$ be given; there exists a function ϕ_h defined by*

$$(\phi_h)_{|D_j}\in P^1(D_j)\quad\forall j\in[1,J],$$

$$\phi_h(M_{i_\alpha(j)\,k_\beta(j)})=\frac{1}{2}(\phi^T_{i_\alpha(j)}+\phi^P_{k_\beta(j)})\quad\forall j\in[1,J],\quad\forall(\alpha\,,\,\beta)\in\{1;2\}^2\,. \tag{5.18}$$

Moreover, we have the following essential property:

$$(\boldsymbol{\nabla}\phi_h)_{|D_j}=(\boldsymbol{\nabla}_h^D\phi)_j\quad\forall j\in[1,J]. \tag{5.19}$$

Proof. The proof is given in [10]. We recall that the definition of ϕ_h through the four equalities contained in (5.18) is possible because $(M_{i_1k_1}M_{i_1k_2}M_{i_2k_2}M_{i_2k_1})$ is a parallelogram and $\phi_h(M_{i_1k_1})+\phi_h(M_{i_2k_2})=\phi_h(M_{i_1k_2})+\phi_h(M_{i_2k_1})$. ∎

DEFINITION 5.9. *We shall denote by L the linear operator which associates ϕ_h, defined by Proposition* 5.8, *with a given $(\phi_i^T,\phi_k^P)\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$. Further, the solution of* (5.7) *is in the following space:*

$$V_N:=\left\{(\phi_i^T,\phi_k^P)\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K\ /\ \sum_{i\in[1,I]}|T_i|\phi_i^T=\sum_{k\in[1,K]}|P_k|\phi_k^P=0\right\}.$$

The solution of (5.8) *is in the following space:*

$$V_D:=\Big\{(\phi_i^T,\phi_k^P)\in\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K\ /\ \phi_i^T=\phi_k^P=0\ \forall\, i\in\Gamma_0\ \ \forall\, k\in\Gamma_0\ \ \textit{and}$$

$$\exists\,(c^T_{q,\phi},c^P_{q,\phi})\in(\mathbb{R}^2)^Q\ \ \textit{s.t.}\ \ \phi_i^T=c^T_{q,\phi}\ \forall\, i\in\Gamma_q,\ \textit{and}\ \phi_k^P=c^P_{q,\phi}\ \forall\, k\in\Gamma_q\ \ \forall\, q\in[1,Q]\Big\}.$$

Remark 5.10. It is easily proved that the linear operator L introduced in Definition 5.9 is injective over V_N and over V_D. Thus, for any Φ_h in $L(V_N)$ or in $L(V_D)$, there exists a unique $\Phi=(\Phi_i^T,\Phi_k^P)$ in $\mathbb{R}^{I+J^\Gamma}\times\mathbb{R}^K$, either in V_N or in V_D such that $\Phi_h=L(\Phi)$. The values (Φ_i^T,Φ_k^P) are used in the definitions of Φ_h^* and $\tilde{\Phi}_h$ associated with Φ_h, respectively, by (5.22) and (5.23).

With these definitions, we may state the following result.

PROPOSITION 5.11. *Problem* (5.7) *amounts to finding $\phi_h\in L(V_N)$, such that*

$$a_h(\phi_h,\Phi_h)=\ell_N(\Phi_h)\quad\forall\ \Phi_h\in L(V_N) \tag{5.20}$$

with

$$
\begin{aligned}
a_h(\phi_h, \Phi_h) &:= \sum_{j\in[1,J]} \int_{D_j} \boldsymbol{\nabla}\phi_h \cdot \boldsymbol{\nabla}\Phi_h\,(\mathbf{x})d\mathbf{x},\\
\ell_N(\Phi_h) &:= -\int_\Omega f\Phi_h^*(\mathbf{x})d\mathbf{x} \;+ \int_\Gamma \sigma\,\tilde{\Phi}_h(\xi)\,d\xi,
\end{aligned}
\tag{5.21}
$$

where Φ_h^* *is defined over* Ω *by*

$$
\Phi_h^*(\mathbf{x}) := \frac{1}{2}\left(\sum_{i\in[1,I]} \Phi_i^T\theta_i^T(\mathbf{x}) + \sum_{k\in[1,K]} \Phi_k^P\theta_k^P(\mathbf{x})\right)
\tag{5.22}
$$

and $\tilde{\Phi}_h$ *is defined over* Γ *by*

$$
\tilde{\Phi}_h(\xi) = \sum_{j\in[1,J]} \frac{1}{4}\left(\Phi^P_{k_1(j)} + 2\Phi^T_{i_2(j)} + \Phi^P_{k_2(j)}\right)\theta_j^\Gamma(\xi),
\tag{5.23}
$$

where we recall that θ_i^T, θ_k^P, *and* θ_j^Γ *are, respectively, the characteristic functions of the cells* T_i, P_k *and of the boundary edge* A_j.

Proof. Let us suppose that $\phi \in V_N$ is the solution of (5.7); then multiplying the first equation by $\frac{1}{2}|T_i|\Phi_i^T$, the second equation by $\frac{1}{2}|P_k|\Phi_k^P$, and summing over all $i \in [1, I]$ and all $k \in [1, K]$ yields

$$
(\nabla_h^{T,P}\cdot\boldsymbol{\nabla}_h^D\phi, \Phi)_{T,P} = (f, \Phi)_{T,P}.
\tag{5.24}
$$

Thanks to the discrete Green formula (4.1), we may write the left-hand side of (5.24) in the following way:

$$
\begin{aligned}
-(\boldsymbol{\nabla}_h^D\phi, \boldsymbol{\nabla}_h^D\Phi)_D + (\boldsymbol{\nabla}_h^D\phi\cdot\mathbf{n}, \Phi)_{\Gamma,h} \;&= -\sum_{j\in[1,J]} |D_j|\,(\boldsymbol{\nabla}_h^D\phi)_j\cdot(\boldsymbol{\nabla}_h^D\Phi)_j\\
&\quad + \sum_{j\in[J-J^\Gamma+1,J]} |A_j|\,(\boldsymbol{\nabla}_h^D\phi)_j\cdot\mathbf{n}_j \times \frac{1}{4}\left(\Phi^P_{k_1(j)} + 2\Phi^T_{i_2(j)} + \Phi^P_{k_2(j)}\right).
\end{aligned}
$$

Next, thanks to (5.19), and because $(\boldsymbol{\nabla}_h^D\phi)_j\cdot(\boldsymbol{\nabla}_h^D\Phi)_j$ is a constant over D_j, we may write

$$
-\sum_{j\in[1,J]} |D_j|\,(\boldsymbol{\nabla}_h^D\phi)_j\cdot(\boldsymbol{\nabla}_h^D\Phi)_j = -\sum_{j\in[1,J]}\int_{D_j}\boldsymbol{\nabla}\phi_h\cdot\boldsymbol{\nabla}\Phi_h\,(\mathbf{x})d\mathbf{x}.
$$

Moreover, according to the boundary conditions given by (5.7c),

$$
|A_j|\,(\boldsymbol{\nabla}_h^D\phi)_j\cdot\mathbf{n}_j = |A_j|\,\sigma_j = \int_{A_j}\sigma(\xi)d\xi,
$$

so that

$$
|A_j|\,(\boldsymbol{\nabla}_h^D\phi)_j\cdot\mathbf{n}_j \times \frac{1}{4}\left(\Phi^P_{k_1} + 2\Phi^T_{i_2} + \Phi^P_{k_2}\right) = \int_{A_j}\sigma\,\left(\tilde{\Phi}_h\right)_{|A_j}(\xi)\,d\xi.
$$

Finally, the left-hand side of (5.24) is equal to

$$-a_h(\phi_h, \Phi_h) + \int_\Gamma \sigma\, \tilde{\Phi}_h(\xi)\, d\xi.$$

By (5.4), and because $\Phi_i^T \theta_i^T(\mathbf{x})_{|T_i} = \Phi_i^T$ and $\Phi_k^P \theta_k^P(\mathbf{x})_{|P_k} = \Phi_k^P$, the right-hand side of (5.24) is equal to

$$\int_\Omega f(\mathbf{x})\, \frac{1}{2} \left(\sum_{i\in[1,I]} \Phi_i^T \theta_i^T(\mathbf{x}) + \sum_{k\in[1,K]} \Phi_k^P \theta_k^P(\mathbf{x}) \right) d\mathbf{x},$$

which ends this part of the proof.

Conversely, let $\phi_h \in L(V_N)$ satisfy (5.20) for all $\Phi_h \in L(V_N)$; then $\phi = L^{-1}(\phi_h)$ satisfies (5.7d) by definition of V_N. Further, we prove that the boundary condition (5.7c) is verified along each boundary edge $j_0 \in [J - J^\Gamma + 1, J]$ by considering its corresponding basis element $\Phi_0 \in V_N$ defined by (recall that the index $i_2(j_0)$ is associated with the unknown located at the center of the segment A_{j_0})

$$\forall i \in [1, I + J^\Gamma],\ (\Phi_0)_i^T = \delta_i^{i_2(j_0)} \ \text{ and } \ \forall k \in [1, K],\ (\Phi_0)_k^P = 0.$$

Then, defining $(\Phi_0)_h = L(\Phi_0)$, we obviously have the following properties:

$$(\boldsymbol{\nabla}(\Phi_0)_h)_{|D_j} = 0 \ \text{ if } \ j \neq j_0 \quad \text{and} \quad (\boldsymbol{\nabla}(\Phi_0)_h)_{|D_{j_0}} = \frac{1}{2\,|D_{j_0}|}\, |A_{j_0}|\, \mathbf{n}_{j_0}$$

and

$$(\Phi_0)_h^*(\mathbf{x}) = 0 \ \ \forall \mathbf{x} \in \Omega \quad \text{and} \quad (\tilde{\Phi}_0)_h(\xi) = \frac{1}{2} \theta_{j_0}^\Gamma(\xi) \ \ \forall \xi \in \Gamma.$$

We thus have

$$\sum_{j\in[1,J]} \int_{D_j} \boldsymbol{\nabla}\phi_h \cdot \boldsymbol{\nabla}(\Phi_0)_h\, (\mathbf{x}) d\mathbf{x} = \frac{1}{2}\, |A_{j_0}|\, (\boldsymbol{\nabla}\phi_h)_{|D_{j_0}} \cdot \mathbf{n}_{j_0} = \frac{1}{2}\, |A_{j_0}|\, (\boldsymbol{\nabla}_h^D \phi)_{j_0} \cdot \mathbf{n}_{j_0}$$

and

$$-\int_\Omega f(\Phi_0)_h^*(\mathbf{x}) d\mathbf{x} \ + \int_\Gamma \sigma\, (\tilde{\Phi}_0)_h(\xi)\, d\xi \ = \int_{A_{j_0}} \frac{1}{2} \sigma(\xi)\, d\xi \ = \frac{1}{2}\, |A_{j_0}|\, \sigma_{j_0}.$$

Finally, writing (5.20) for $(\Phi_0)_h$ proves that ϕ satisfies the boundary condition

$$(\boldsymbol{\nabla}_h^D \phi)_{j_0} \cdot \mathbf{n}_{j_0} = \sigma_{j_0} \quad \forall\, j_0 \in [J - J^\Gamma + 1, J].$$

Next, in order to prove (5.7a) for any primal cell $i_0 \in [1, I]$, we consider its corresponding basis element $\Phi_1 \in V_N$ defined by

$$\forall i \in [1, I + J^\Gamma],\ (\Phi_1)_i^T = \delta_i^{i_0} - \frac{|T_{i_0}|}{|\Omega|}, \ \text{ and } \ \forall k \in [1, K],\ (\Phi_1)_k^P = 0.$$

Then, defining $(\Phi_1)_h = L(\Phi_1)$ and according to (5.20), we may write

$$\sum_{j\in[1,J]} \int_{D_j} \boldsymbol{\nabla}\phi_h \cdot \boldsymbol{\nabla}(\Phi_1)_h\, (\mathbf{x}) d\mathbf{x} = -\int_\Omega f(\Phi_1)_h^*(\mathbf{x}) d\mathbf{x} \ + \int_\Gamma \sigma\, (\tilde{\Phi}_1)_h(\xi)\, d\xi. \tag{5.25}$$

To evaluate the left-hand side of (5.25), we consider $\Phi \in \mathbb{R}^{I+J^\Gamma} \times \mathbb{R}^K$ such that

$$\forall i \in [1, I + J^\Gamma],\ \Phi_i^T = \delta_i^{i_0} \ \text{ and } \ \forall k \in [1, K],\ \Phi_k^P = 0.$$

Note that $\Phi \notin V_N$ but that its discrete gradient (see (3.2)) obviously equals that of Φ_1. Thanks to this equality and to (5.19), we have

$$\sum_{j\in[1,J]} \int_{D_j} \boldsymbol{\nabla}\phi_h \cdot \boldsymbol{\nabla}(\Phi_1)_h\,(\mathbf{x})d\mathbf{x} = (\boldsymbol{\nabla}_h^D\phi, \boldsymbol{\nabla}_h^D\Phi_1)_D = (\boldsymbol{\nabla}_h^D\phi, \boldsymbol{\nabla}_h^D\Phi)_D,$$

which, in turn, can be transformed, thanks to (4.1), into

$$-(\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D\phi, \Phi)_{T,P} + (\boldsymbol{\nabla}_h^D\phi \cdot \mathbf{n}, \Phi)_{\Gamma,h}.$$

Thanks to the definition of Φ, this quantity reduces to the contribution of i_0, which proves that the left-hand side of (5.25) may be written

$$\sum_{j\in[1,J]} \int_{D_j} \boldsymbol{\nabla}\phi_h \cdot \boldsymbol{\nabla}(\Phi_1)_h\,(\mathbf{x})d\mathbf{x} = -\frac{1}{2}\,|T_{i_0}|\,(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D\phi)_{i_0}. \tag{5.26}$$

Next, we compute the right-hand side of (5.25)

$$\begin{aligned}
-\int_\Omega f(\Phi_1)_h^*(\mathbf{x})d\mathbf{x} &= -\frac{1}{2}\sum_{i\in[1,I]} \int_{T_i} \left(\delta_i^{i_0} - \frac{|T_{i_0}|}{|\Omega|}\right) f(\mathbf{x})\,d\mathbf{x} \\
&= -\frac{1}{2}\int_{T_{i_0}} f(\mathbf{x})\,d\mathbf{x} + \frac{1}{2}\frac{|T_{i_0}|}{|\Omega|}\int_\Omega f(\mathbf{x})\,d\mathbf{x};
\end{aligned}$$

$$\int_\Gamma \sigma\,(\tilde{\Phi}_1)_h(\xi)\,d\xi = \sum_{j\in[J-J^\Gamma+1,J]} \int_{A_j} \sigma(\xi)\,\frac{1}{4}\left(-2\frac{|T_{i_0}|}{|\Omega|}\right)\,d\xi = -\frac{1}{2}\frac{|T_{i_0}|}{|\Omega|}\int_\Gamma \sigma(\xi)d\xi,$$

so that the right-hand side of (5.25) equals

$$-\frac{1}{2}\int_{T_{i_0}} f(\mathbf{x})\,d\mathbf{x} + \frac{1}{2}\frac{|T_{i_0}|}{|\Omega|}\int_\Omega f(\mathbf{x})\,d\mathbf{x} - \frac{1}{2}\frac{|T_{i_0}|}{|\Omega|}\int_\Gamma \sigma(\xi)d\xi.$$

Because of (5.2), the last two terms in the previous sum cancel and we get

$$-\int_\Omega f(\Phi_1)_h^*(\mathbf{x})d\mathbf{x} + \int_\Gamma \sigma\,(\tilde{\Phi}_1)_h(\xi)\,d\xi = -\frac{1}{2}\int_{T_{i_0}} f(\mathbf{x})\,d\mathbf{x} = -\frac{1}{2}\,|T_{i_0}|\,f_{i_0}^T. \tag{5.27}$$

Comparing (5.25), (5.26), and (5.27), we infer that

$$(\nabla_h^T \cdot \boldsymbol{\nabla}_h^D\phi)_{i_0} = f_{i_0}^T.$$

In a similar way, we can prove (5.7b) for any dual cell $k_0 \in [1, K]$ by considering its corresponding basis element $\Phi_2 \in V_N$, defined by

$$\forall i \in [1, I + J^\Gamma],\ (\Phi_2)_i^T = 0 \ \text{ and } \ \forall k \in [1, K],\ (\Phi_2)_k^P = \delta_k^{k_0} - \frac{|P_{k_0}|}{|\Omega|},$$

which ends the proof of the equivalence. ∎

PROPOSITION 5.12. *Problem* (5.8) *is equivalent to finding* $\psi_h \in L(V_D)$*, such that* $\forall \Psi_h \in L(V_D)$*,*

$$a_h(\psi_h, \Psi_h) = \ell_D(\Psi_h) \tag{5.28}$$

with

$$\ell_D(\Psi_h) := \int_\Omega g \Psi_h^*(\mathbf{x}) d\mathbf{x} \; - \sum_{q \in [1,Q]} k_q \left(\frac{c_{q,\Psi}^T + c_{q,\Psi}^P}{2} \right).$$

Proof. Let us suppose that $\psi \in V_D$ is the solution of (5.8); then we may compute the following discrete scalar product:

$$\begin{aligned} -(\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D \psi, \Psi)_{T,P} = & -\frac{1}{2} \sum_{i \in [1,I]} |T_i| (\nabla_h^T \cdot \boldsymbol{\nabla}_h^D \psi)_i \Psi_i^T \\ & -\frac{1}{2} \sum_{k \in [1, K - J^\Gamma]} |P_k| (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k \Psi_k^P \\ & -\frac{1}{2} \sum_{k \in [K - J^\Gamma + 1, K]} |P_k| (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k \Psi_k^P. \end{aligned} \tag{5.29}$$

Due to (5.8a)–(5.8b), the sum of the first two terms on the right-hand side of (5.29) equals

$$\frac{1}{2} \sum_{i \in [1,I]} |T_i| g_i^T \Psi_i^T + \frac{1}{2} \sum_{k \in [1, K - J^\Gamma]} |P_k| g_k^P \Psi_k^P.$$

Next, using the fact that Ψ^P is equal to a constant $c_{q,\Psi}^P$ over each Γ_q and vanishes over Γ_0, we may write, according to (5.8d),

$$\begin{aligned} -\sum_{k \in [K - J^\Gamma + 1, K]} |P_k| (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k \Psi_k^P &= -\sum_{q \in [1,Q]} c_{q,\Psi}^P \sum_{k \in \Gamma_q} |P_k| (\nabla_h^P \cdot \boldsymbol{\nabla}_h^D \psi)_k \\ &= \sum_{q \in [1,Q]} c_{q,\Psi}^P \sum_{k \in \Gamma_q} |P_k| g_k^P = \sum_{k \in [K - J^\Gamma + 1, K]} |P_k| g_k^P \Psi_k^P. \end{aligned}$$

Finally, (5.29) may be rewritten in the following way:

$$-(\nabla_h^{T,P} \cdot \boldsymbol{\nabla}_h^D \psi, \Psi)_{T,P} = (g, \Psi)_{T,P}. \tag{5.30}$$

Using the discrete Green formula (4.1), the left-hand side of (5.30) is equal to

$$(\boldsymbol{\nabla}_h^D \psi, \boldsymbol{\nabla}_h^D \Psi)_D - (\boldsymbol{\nabla}_h^D \psi \cdot \mathbf{n}, \Psi)_{\Gamma,h}.$$

Like previously, the first of these terms equals $a_h(\psi_h, \Psi_h)$. Next, using the fact that Ψ^P (resp., Ψ^T) is equal to a constant $c_{q,\Psi}^P$ (resp., $c_{q,\Psi}^T$) over each Γ_q and vanishes over Γ_0, and using (5.8c), there holds

$$(\boldsymbol{\nabla}_h^D \psi \cdot \mathbf{n}, \Psi)_{\Gamma,h} = \sum_{q \in [1,Q]} \left(\frac{c_{q,\Psi}^T + c_{q,\Psi}^P}{2} \right) \sum_{\Gamma_q} (\boldsymbol{\nabla}_h^D \psi)_j \cdot \mathbf{n}_j = -\sum_{q \in [1,Q]} k_q \left(\frac{c_{q,\Psi}^T + c_{q,\Psi}^P}{2} \right),$$

which shows that the left-hand side of (5.30) is equal to

$$a_h(\psi_h, \Psi_h) + \sum_{q\in[1,Q]} k_q \left(\frac{c^T_{q,\Psi} + c^P_{q,\Psi}}{2} \right).$$

This ends the first part of the proof.

Conversely, if $\psi_h \in L(V_D)$ satisfies (5.28) for all $\Psi_h \in L(V_D)$, then $\psi = L^{-1}(\psi_h)$ verifies (5.8e), (5.8f), and (5.8g) by definition of V_D. Next, in order to prove (5.8a) for any primal cell $i_0 \in [1, I]$, let us consider its associated basis element $\Psi_1 \in V_D$ defined through

$$(\Psi_1)^T_i = \delta^{i_0}_i \quad \forall\, i \in [1, I + J^\Gamma] \text{ and } (\Psi_1)^P_k = 0 \quad \forall\, k \in [1, K].$$

Applying (5.28) for $\Psi_h = L(\Psi_1)$ and using (5.19), (4.1), and (5.5) shows that (5.8a) is verified for the considered $i_0 \in [1, I]$. Equality (5.8b) can be proved in the same way for any dual cell $k_0 \in [1, K - J^\Gamma]$ by considering its associated basis element $\Psi_2 \in V_D$ defined through

$$(\Psi_2)^T_i = 0 \quad \forall\, i \in [1, I + J^\Gamma] \text{ and } (\Psi_2)^P_k = \delta^{k_0}_k \quad \forall\, k \in [1, K].$$

Next, let us consider an internal boundary Γ_{q_0} with $q_0 \in [1, Q]$ and let us consider $\Psi_3 \in V_D$ which vanishes everywhere but on Γ_{q_0}, where it has a constant value:

$$(\Psi_3)^T_i = (\Psi_3)^P_k = 0\, \forall\, i \in [1, I],\ \forall\, k \in [1, K] \text{ and } (\Psi_3)^T_i = \delta^{q_0}_q\ \forall\, i \in \Gamma_q,\ \forall\, q \in [0, Q].$$

Applying (5.28) for $\Psi_h = L(\Psi_3)$ and using (5.19) and (4.1) shows that (5.8c) is verified for the considered $q_0 \in [1, Q]$. In the same way, we prove (5.8d) for a given $q_0 \in [1, Q]$ by choosing $\Psi_4 \in V_D$ defined through

$$(\Psi_4)^T_i = 0 \quad \forall\, i \in [1, I],\ (\Psi_4)^P_k = 0 \quad \forall\, k \in [1, K - J^\Gamma],$$

$$(\Psi_4)^T_i = \delta^{q_0}_q \quad \forall\, i \in \Gamma_q \text{ and } (\Psi_4)^P_k = -\delta^{q_0}_q \quad \forall\, k \in \Gamma_q,\ \forall\, q \in [0, Q].$$

This ends the proof of Proposition 5.12. ∎

5.3.2. Error estimates for the potentials. We may now turn to error estimates for the potentials $\hat{\phi}$ and $\hat{\psi}$. First, given the equivalent finite element formulation stated by Proposition 5.11 (resp., Proposition 5.12), we may study the numerical error concerning $\hat{\phi}$ (resp., $\hat{\psi}$) in a traditional way by noting that a_h acts on $\mathrm{H}^1 + L(V_N)$ (resp., $\mathrm{H}^1 + L(V_D)$), on which we define $|x|_{1,h} := \sqrt{a_h(x,x)}$, and by using the so-called "Strang second lemma" [24]:

$$|\hat{\phi} - \phi_h|_{1,h} \le 2 \inf_{\omega_h \in L(V_N)} |\hat{\phi} - \omega_h|_{1,h} + \sup_{\omega_h \in L(V_N)} \frac{|a_h(\hat{\phi}, \omega_h) - \ell_N(\omega_h)|}{|\omega_h|_{1,h}} \tag{5.31}$$

and

$$|\hat{\psi} - \psi_h|_{1,h} \le 2 \inf_{\omega_h \in L(V_D)} |\hat{\psi} - \omega_h|_{1,h} + \sup_{\omega_h \in L(V_D)} \frac{|a_h(\hat{\psi}, \omega_h) - \ell_D(\omega_h)|}{|\omega_h|_{1,h}}\,. \tag{5.32}$$

The first term in (5.31) and (5.32) is named the "interpolation error," while the second is called the "consistency error."

Interpolation error for $\hat{\phi}$. We start with the following proposition.

PROPOSITION 5.13. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *there exists a constant $C(\tau^*)$ depending only on τ^* such that*

$$\inf_{\omega_h \in L(V_N)} |\hat{\phi} - \omega_h|_{1,h} \leq C(\tau^*)\, h\, ||\hat{\phi}||_{2,\Omega}\,. \tag{5.33}$$

Proof. Consider the pointwise projection of the exact solution onto $\mathbb{R}^{I+J^\Gamma} \times \mathbb{R}^K$:

$$\forall i \in [1, I + J^\Gamma]\,,\ \ (\Pi\hat{\phi})_i^T = \hat{\phi}(G_i) \quad \text{and} \quad \forall k \in [1, K]\,,\ \ (\Pi\hat{\phi})_k^P = \hat{\phi}(S_k)\,.$$

Then, this element is itself projected onto V_N in the following way:

$$\forall i \in [1, I + J^\Gamma],\ \ (\tilde{\Pi}\hat{\phi})_i^T = (\Pi\hat{\phi})_i^T - \frac{\displaystyle\sum_{i\in[1,I]} |T_i|(\Pi\hat{\phi})_i^T}{|\Omega|}$$

$$\forall k \in [1, K],\ \ (\tilde{\Pi}\hat{\phi})_k^P = (\Pi\hat{\phi})_k^P - \frac{\displaystyle\sum_{k\in[1,K]} |P_k|(\Pi\hat{\phi})_k^P}{|\Omega|}.$$

Obviously, $\tilde{\Pi}\hat{\phi}$ and $\Pi\hat{\phi}$ have the same discrete gradient so that the interpolation error in (5.33) is bounded in the following way:

$$\inf_{\omega_h \in L(V_N)} |\hat{\phi} - \omega_h|_{1,h} \leq |\hat{\phi} - L(\tilde{\Pi}\hat{\phi})|_{1,h} = |\hat{\phi} - L(\Pi\hat{\phi})|_{1,h}.$$

Finally, an upper bound for $|\hat{\phi} - L(\Pi\hat{\phi})|_{1,h}$ has been given in [10] and is based on the relation between $L(\Pi\hat{\phi})$ and the standard Lagrange P^1 interpolants on the pairs $(D_{j,1}, D_{j,2})$ and $(D'_{j,1}, D'_{j,2})$. It leads to the estimation (5.33). Hypothesis 5.5 is here to ensure that the so-called maximum angle condition [3, 18] is verified for at least one of the pairs of triangles $(D_{j,1}, D_{j,2})$ or $(D'_{j,1}, D'_{j,2})$. ∎

Consistency error for $\hat{\phi}$. Let $\omega_h = L(\omega)$. Thanks to (5.21), we start by writing

$$a_h(\hat{\phi}, \omega_h) - \ell_N(\omega_h) = \left[a_h(\hat{\phi}, \omega_h) + (f, \omega_h)_\Omega - \int_\Gamma \sigma\, \tilde{\omega}_h(\xi)\, d\xi\right] - (f, \omega_h - \omega_h^*)_\Omega. \tag{5.34}$$

The last term in (5.34) can be bounded by the following lemma.

LEMMA 5.14. *If all diamond-cells are convex, there exists a constant C independent of the grid such that*

$$|(f, \omega_h - \omega_h^*)_\Omega| \leq Ch||f||_{0,\Omega}|\omega_h|_{1,h}. \tag{5.35}$$

Proof. The proof is identical to that given in [10] for homogeneous Dirichlet conditions. ∎

Then, we follow [10] with a slight modification due to nonhomogeneous Neumann boundary conditions. We divide each *interior* diamond-cell D_j (with $j \in [1, J - J^\Gamma]$) either into $D_{j,1} \cup D_{j,2}$, or into $D'_{j,1} \cup D'_{j,2}$ (see Figure 2.5). Note that this choice is local to D_j and does not influence the choice which can be made for the division of $D_{j'}$, for $j' \neq j$. Boundary diamond-cells are such that $D_{j,1} = D_j$ and $D_{j,2} = \emptyset$ and will never be split into $D'_{j,1} \cup D'_{j,2}$. To simplify notations, we shall write $\mathcal{T}_{j,\alpha}$

to represent either $D_{j,\alpha}$ or $D'_{j,\alpha}$. Further, we define $RT(\boldsymbol{\nabla}\hat{\phi})$, the Raviart–Thomas interpolation of $\boldsymbol{\nabla}\hat{\phi}$ on each $\mathcal{T}_{j,\alpha}$ (see [23]), by

$$RT(\boldsymbol{\nabla}\hat{\phi})_{|\mathcal{T}_{j,\alpha}} \in (P_0(\mathcal{T}_{j,\alpha}))^2 \oplus \begin{pmatrix} x \\ y \end{pmatrix} P_0(\mathcal{T}_{j,\alpha}) \quad \text{and} \quad \int_s RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}\, d\xi = \int_s \boldsymbol{\nabla}\hat{\phi}.\mathbf{n}\, d\xi$$

for any edge s of $\mathcal{T}_{j,\alpha}$ whose normal exterior unit vector is denoted by $\mathbf{n}$. We can state the following lemma.

LEMMA 5.15. *Let $\hat{\phi}$ be the solution of* (5.15) *and let $\omega_h \in L(V_N)$. Denote by $\langle \omega_h \rangle_{j,\alpha}$ the average value of ω_h over $\mathcal{T}_{j,\alpha}$. Then, if all diamond-cells are convex, we have*

$$a_h(\hat{\phi}, \omega_h) + (f, \omega_h)_\Omega - \int_\Gamma \sigma\, \tilde{\omega}_h(\xi)\, d\xi = \sum_{j\in[1,J]} \sum_{\alpha=1}^{2} \int_{\mathcal{T}_{j,\alpha}} \left[(\boldsymbol{\nabla}\hat{\phi} - RT(\boldsymbol{\nabla}\hat{\phi})) \cdot \boldsymbol{\nabla}\omega_h - f \left(\langle \omega_h \rangle_{j,\alpha} - \omega_h \right) \right] d\mathbf{x}. \tag{5.36}$$

Proof. By definition, $RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}$ is a constant on each edge of $\mathcal{T}_{j,\alpha}$. In addition, on two neighboring triangles $\mathcal{T}_{j,\alpha}$, the values of $RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}$ on both sides of their common edge are opposite of each other, because of the orientation of the normal vector $\mathbf{n}$. By noting $\mathcal{S}$ the set of all the edges of all the $\mathcal{T}_{j,\alpha}$, $\mathbf{n}$ the normal unit vector to an edge s in $\mathcal{S}$, and $[\omega_h]_s$ the jump of ω_h through s, then

$$\begin{aligned} \sum_{j\in[1,J]} \sum_{\alpha=1}^{2} \int_{\partial\mathcal{T}_{j,\alpha}} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}\, \omega_h\, d\xi &= \sum_{s\in\mathcal{S},\ s\not\subset\Gamma} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n} \int_s [\omega_h]_s\, d\xi \\ &\quad + \sum_{s\in\mathcal{S},\ s\subset\Gamma} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n} \int_s \omega_h\, d\xi. \end{aligned} \tag{5.37}$$

Since ω_h is in $L(V_N)$, then $[\omega_h]_s$ is a polynomial of degree one, which vanishes at the midpoint of s (by construction of the functions of $L(V_N)$). Its integral on s is thus null. Further, there is an obvious one-to-one correspondence between a given $s \in \mathcal{S},\ s \subset \Gamma$, and some boundary edge A_j, with $j \in [J - J^\Gamma + 1, J]$ because boundary diamond-cells are such that $D_j = D_{j,1} = \mathcal{T}_{j,\alpha}$, with $\alpha = 1$. Therefore, for such $s \in \mathcal{S},\ s \subset \Gamma$, there exists a unique $j \in [J - J^\Gamma + 1, J]$ such that

$$RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n} = \frac{1}{|A_j|} \int_{A_j} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}_j = \frac{1}{|A_j|} \int_{A_j} \boldsymbol{\nabla}\hat{\phi} \cdot \mathbf{n}_j = \frac{1}{|A_j|} \int_{A_j} \sigma(\xi)\, d\xi.$$

Further, on this A_j, the function ω_h is a polynomial of degree one, whose integral is easy to compute:

$$\int_s \omega_h\, d\xi = \frac{|A_j|}{4} \left(\omega_{k_1}^P + 2\omega_{i_2}^T + \omega_{k_2}^P \right).$$

Recalling the definition (5.23) of the piecewise constant function $\tilde{\omega}_h$, we may write

$$\sum_{j\in[1,J]} \sum_{\alpha=1}^{2} \int_{\partial\mathcal{T}_{j,\alpha}} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n}\, \omega_h\, d\xi = \sum_{s\in\mathcal{S},\ s\subset\Gamma} RT(\boldsymbol{\nabla}\hat{\phi}) \cdot \mathbf{n} \int_s \omega_h\, d\xi = \int_\Gamma \sigma\tilde{\omega}_h(\xi) d\xi.$$

But we may also write the previous equality in the following way:

$$\sum_{j\in[1,J]}\sum_{\alpha=1}^{2}\left(\int_{\mathcal{T}_{j,\alpha}}\nabla\cdot(RT(\boldsymbol{\nabla}\hat{\phi}))\,\omega_h\,d\mathbf{x}+\int_{\mathcal{T}_{j,\alpha}}RT(\boldsymbol{\nabla}\hat{\phi})\cdot\boldsymbol{\nabla}\omega_h\,d\mathbf{x}\right)=\int_\Gamma\sigma\tilde{\omega}_h(\xi)d\xi.$$

By subtracting this equality from $a_h(\hat{\phi},\omega_h)$, we obtain

$$\begin{aligned}a_h(\hat{\phi},\omega_h)-\int_\Gamma\sigma\tilde{\omega}_h(\xi)d\xi=&\sum_{j\in[1,J]}\sum_{\alpha=1}^{2}\int_{\mathcal{T}_{j,\alpha}}(\boldsymbol{\nabla}\hat{\phi}-RT(\boldsymbol{\nabla}\hat{\phi}))\cdot\boldsymbol{\nabla}\omega_h\,d\mathbf{x}\\&-\sum_{j\in[1,J]}\sum_{\alpha=1}^{2}\int_{\mathcal{T}_{j,\alpha}}\nabla\cdot(RT(\boldsymbol{\nabla}\hat{\phi}))\,\omega_h\,d\mathbf{x}.\end{aligned}\tag{5.38}$$

Let us note $\langle\omega_h\rangle_{j,\alpha}$ the mean value of ω_h on $\mathcal{T}_{j,\alpha}$. Since $\nabla\cdot(RT(\boldsymbol{\nabla}\hat{\phi}))$ is by construction a constant on $\mathcal{T}_{j,\alpha}$, we may write the following series of equalities:

$$\begin{aligned}\int_{\mathcal{T}_{j,\alpha}}\nabla\cdot(RT(\boldsymbol{\nabla}\hat{\phi}))\,\omega_h\,d\mathbf{x}&=\langle\omega_h\rangle_{j,\alpha}\int_{\mathcal{T}_{j,\alpha}}\nabla\cdot(RT(\boldsymbol{\nabla}\hat{\phi}))\,d\mathbf{x}\\&=\langle\omega_h\rangle_{j,\alpha}\int_{\partial\mathcal{T}_{j,\alpha}}RT(\boldsymbol{\nabla}\hat{\phi})\cdot\mathbf{n}\,d\xi=\langle\omega_h\rangle_{j,\alpha}\int_{\partial\mathcal{T}_{j,\alpha}}\boldsymbol{\nabla}\hat{\phi}\cdot\mathbf{n}\,d\xi\\&=\langle\omega_h\rangle_{j,\alpha}\int_{\mathcal{T}_{j,\alpha}}\Delta\hat{\phi}\,d\mathbf{x}=\langle\omega_h\rangle_{j,\alpha}\int_{\mathcal{T}_{j,\alpha}}f\,d\mathbf{x}.\end{aligned}\tag{5.39}$$

Equality (5.36) follows from (5.38) and (5.39). ∎

The first term in the right-hand side of (5.34) can be bounded by the following lemma.

LEMMA 5.16. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *there exists a constant C independent of the grid such that*

$$\left|a_h(\hat{\phi},\omega_h)+(f,\omega_h)_\Omega-\int_\Gamma\sigma\tilde{\omega}_h(\xi)\,d\xi\right|\leq C\frac{h}{\sin\tau^*}|\omega_h|_{1,h}\left(||f||_{0,\Omega}+||\hat{\phi}||_{2,\Omega}\right).\tag{5.40}$$

Proof. By virtue of Lemma 5.15, bounding the left-hand side of (5.40) amounts to bounding the right-hand side of (5.36). This was performed in [10]. Again, Hypothesis 5.5 is here to ensure the maximum angle condition needed by the Raviart–Thomas interpolation of $\boldsymbol{\nabla}\hat{\phi}$; see [1]. ∎

We end the consistency error estimation with the following proposition.

PROPOSITION 5.17. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *then there exists a constant C independent of the grid such that*

$$\sup_{\omega_h\in L(V_N)}\frac{|a_h(\hat{\phi},\omega_h)-\ell_N(\omega_h)|}{|\omega_h|_{1,h}}\leq C\frac{h}{\sin\tau^*}\left(||f||_{0,\Omega}+||\hat{\phi}||_{2,\Omega}\right).\tag{5.41}$$

Proof. The result follows from (5.34), (5.35), and (5.40). ∎

Interpolation error for $\hat{\psi}$. Next, given the equivalent finite element formulation stated by Proposition 5.12, we may study the numerical error concerning ψ in a very analogous way: The interpolation error is bounded by choosing $\omega_h = L(\Pi\hat{\psi})$ with $\Pi\hat{\psi} \in V_D$ defined by

$$\forall i \in [1, I + J^\Gamma]\,, \;\; (\Pi\hat{\psi})_i^T = \hat{\psi}(G_i) \quad \text{and} \quad \forall k \in [1, K]\,, \;\; (\Pi\hat{\psi})_k^P = \hat{\psi}(S_k)$$

and we obtain a result analogous to (5.33).

PROPOSITION 5.18. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *then there exists a constant $C(\tau^*)$ depending only on τ^* such that*

$$\inf_{\omega_h \in L(V_D)} |\hat{\psi} - \omega_h|_{1,h} \leq C(\tau^*)\, h\, ||\hat{\psi}||_{2,\Omega}. \tag{5.42}$$

Consistency error for $\hat{\psi}$. Concerning the consistency error, we may prove a result analogous to (5.36).

LEMMA 5.19. *Let $\hat{\psi}$ be the solution of* (5.16) *and let $\omega_h \in L(V_D)$. Then, if all diamond-cells are convex, we have*

$$\begin{aligned} &a_h(\hat{\psi}, \omega_h) - (g, \omega_h)_\Omega + \sum_{q \in [1,Q]} k_q \left(\frac{c_{q,\omega}^T + c_{q,\omega}^P}{2} \right) \\ &\qquad = \sum_{j \in [1,J]} \sum_{\alpha=1}^{2} \int_{\mathcal{T}_{j,\alpha}} \left[(\boldsymbol{\nabla}\hat{\psi} - RT(\boldsymbol{\nabla}\hat{\psi})) \cdot \boldsymbol{\nabla}\omega_h + g \left(\langle \omega_h \rangle_{j,\alpha} - \omega_h \right) \right] d\mathbf{x}. \end{aligned} \tag{5.43}$$

Proof. We first write for $\hat{\psi}$ an equality analogous to (5.37). For the same reasons as in the proof of Lemma 5.15, this amounts to evaluating the boundary part:

$$\sum_{j \in [1,J]} \sum_{\alpha=1}^{2} \int_{\partial \mathcal{T}_{j,\alpha}} RT(\boldsymbol{\nabla}\hat{\psi}) \cdot \mathbf{n}\, \omega_h \, d\xi = \sum_{q \in [1,Q]} \sum_{j \in \Gamma_q} RT(\boldsymbol{\nabla}\hat{\psi}) \cdot \mathbf{n}_j \int_{A_j} \omega_h \, d\xi$$

$$= \sum_{q \in [1,Q]} \left(\frac{c_{q,\omega}^T + c_{q,\omega}^P}{2} \right) \sum_{j \in \Gamma_q} |A_j| RT(\boldsymbol{\nabla}\hat{\psi}) \cdot \mathbf{n}_j = \sum_{q \in [1,Q]} \left(\frac{c_{q,\omega}^T + c_{q,\omega}^P}{2} \right) \sum_{j \in \Gamma_q} \int_{A_j} \boldsymbol{\nabla}\hat{\psi} \cdot \mathbf{n}_j$$

$$= \sum_{q \in [1,Q]} \left(\frac{c_{q,\omega}^T + c_{q,\omega}^P}{2} \right) \int_{\Gamma_q} \boldsymbol{\nabla}\hat{\psi} \cdot \mathbf{n}_j = - \sum_{q \in [1,Q]} k_q \left(\frac{c_{q,\omega}^T + c_{q,\omega}^P}{2} \right).$$

The end of the proof of (5.43) follows exactly the same lines as that of (5.36) and is thus skipped. ∎

Next, bounding the right-hand side of (5.43) is performed like in [10], and we obtain a result analogous to (5.41)

PROPOSITION 5.20. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *then there exists a constant C independent of the grid such that*

$$\sup_{\omega_h \in L(V_D)} \frac{|a_h(\hat{\psi}, \omega_h) - \ell_D(\omega_h)|}{|\omega_h|_{1,h}} \leq C \frac{h}{\sin \tau^*} \left(||g||_{0,\Omega} + ||\hat{\psi}||_{2,\Omega} \right). \tag{5.44}$$

To conclude subsection 5.3.2, estimates (5.31), (5.33), and (5.41) on the one hand and (5.32), (5.42), and (5.44) on the other hand allow us to state the following theorem.

THEOREM 5.21. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *then there exists a constant* $C(\tau^*)$ *independent of the grid such that*

$$|\hat{\phi} - \phi_h|_{1,h} \leq C(\tau^*)h \left(||f||_{0,\Omega} + ||\hat{\phi}||_{2,\Omega} \right) \tag{5.45}$$

and

$$|\hat{\psi} - \psi_h|_{1,h} \leq C(\tau^*)h \left(||g||_{0,\Omega} + ||\hat{\psi}||_{2,\Omega} \right). \tag{5.46}$$

To conclude section 5.3, Theorem 5.21, along with (5.17) and (5.19), leads to the following theorem.

THEOREM 5.22. *If all diamond-cells are convex and under Hypotheses* 5.5 *and* 5.7, *then there exists a constant* $C(\tau^*)$ *independent of the grid such that*

$$\left(\sum_{j \in [1,J]} \int_{D_j} |\mathbf{u}_j - \hat{\mathbf{u}}(\mathbf{x})|^2 \, d\mathbf{x} \right)^{1/2} \leq C(\tau^*)h \left(||f||_{0,\Omega} + ||g||_{0,\Omega} + ||\hat{\phi}||_{2,\Omega} + ||\hat{\psi}||_{2,\Omega} \right).$$

6. Numerical results. We test the finite volume method over different types of meshes and define the discrete relative L^2 error by

$$e^2(h) := \frac{\sum_j |D_j| \, |\mathbf{u} - \Pi\hat{\mathbf{u}}|_j^2}{\sum_j |D_j| \, |\Pi\hat{\mathbf{u}}|_j^2},$$

where $(\Pi\hat{\mathbf{u}})_j$ is the value of the exact solution at the barycenter of D_j (noted B_j):

$$\forall \, j \in [1, J], (\Pi\hat{\mathbf{u}})_j = \hat{\mathbf{u}}(B_j).$$

For the first three families of meshes (triangular unstructured, nonconforming, and degenerating triangular), the domain of computation is the unit square $\Omega = [0;1] \times [0;1]$. We choose the data f, g and the boundary conditions so that the analytical solution is given by

$$\hat{\mathbf{u}}(x, y) = \begin{pmatrix} \exp(x) \, \cos(\pi y) + \pi \, \sin(\pi x) \, \cos(\pi y) \\ -\pi \, \exp(x) \, \sin(\pi y) - \pi \, \cos(\pi x) \, \sin(\pi y) \end{pmatrix}.$$

This means that the exact potentials are given by

$$\hat{\phi}(x, y) = \exp(x) \, \cos(\pi y) \quad \text{and} \quad \hat{\psi}(x, y) = \sin(\pi x) \, \sin(\pi y).$$

In addition, we always choose the points G_i associated with the control volumes of the primal mesh to be the barycenters of the cell T_i.

6.1. Unstructured meshes. First of all, we consider a family of six unstructured grids made up of increasingly small triangles. The first two of these grids are represented on the left and central parts of Figure 6.1. The numerical errors in the discrete L^2 norm are presented in logarithmic scale on the right part of Figure 6.1, on which we also plotted a straight line of slope 1. We remark, as proved previously, a first order convergence of the presented scheme.

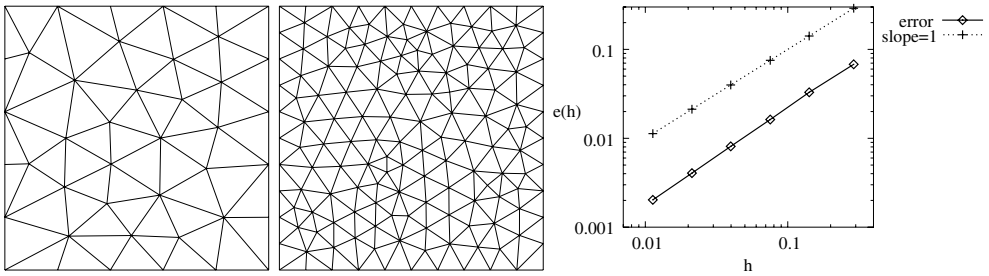

FIG. 6.1. *Unstructured triangular meshes.*

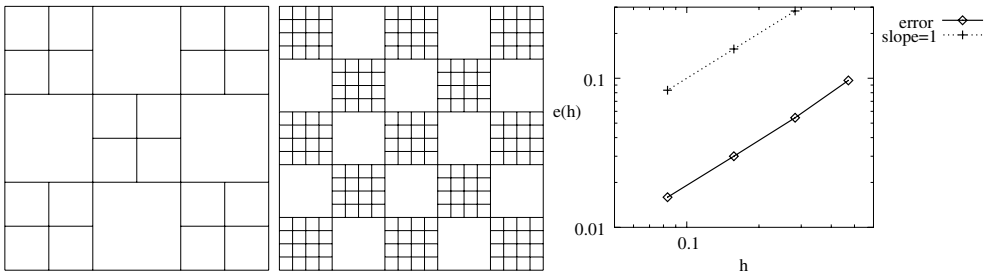

FIG. 6.2. *Nonconforming square meshes.*

6.2. Nonconforming meshes. Next, we consider the nonconforming family of meshes constructed in the following way. Let n be a nonzero integer. We split Ω into $(2^n+1)\times(2^n+1)$ identical squares. Then, every other square is itself divided into $2^n\times 2^n$ identical subsquares. We choose $n\in[1;4]_N$. The left and central parts of Figure 6.2 display the first two of these meshes. Of course, this family of meshes is not of practical use, but constitutes, in our opinion, a good choice in order to test the applicability of the presented method on arbitrarily locally refined nonconforming meshes. A zoom on the most distorted diamond-cell for this type of mesh (with $n=2$) is displayed on Figure 6.3. Comparing this figure with Figure 5.1, we infer that

$$\max(\alpha_1,\beta_1,\mu_1+\mu_2,\alpha_2,\beta_2,\nu_1+\nu_2)=\beta_2,$$

which is always lower than $\frac{3\pi}{4}$ for all values of n. Moreover, it is easily checked that the maximum angle of every boundary diamond-cell equals $\frac{\pi}{2}$, so that this family of meshes satisfies Hypothesis 5.5 with an angle $\tau^*=\frac{3\pi}{4}$. The discrete L^2 error is displayed in logarithmic scale on the right part of Figure 6.2, together with a reference straight line with a slope equal to one. We observe, on this family of nonconforming, locally refined meshes, a first order convergence in the discrete L^2 norm.

6.3. Degenerating meshes. The third family is made up of grids of increasingly flat triangles built in the following way. Let n be a nonzero integer. We divide Ω into 4^n horizontal stripes of the same height and divide each of these stripes into similar triangles (except those at both ends) so that there are 2^n bases of triangles in the width of a stripe and choose $n\in[1;6]_N$. The left and central parts of Figure 6.4 represent the first two of these grids. The numerical errors in the L^2 norm are presented in logarithmic scale on the right part of Figure 6.4, as well as a straight line of slope 1.5. Although such a family of meshes does not verify Hypothesis 5.5 (due to boundary diamond-cells), we observe a superconvergence of the method in this case,

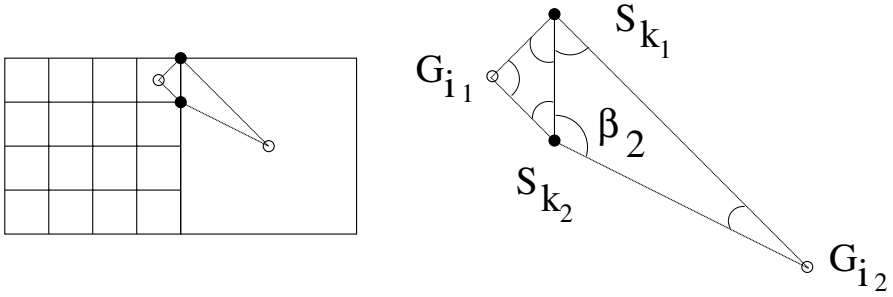

FIG. 6.3. *Zoom on a diamond-cell for the locally refined meshes with* $n = 2$.

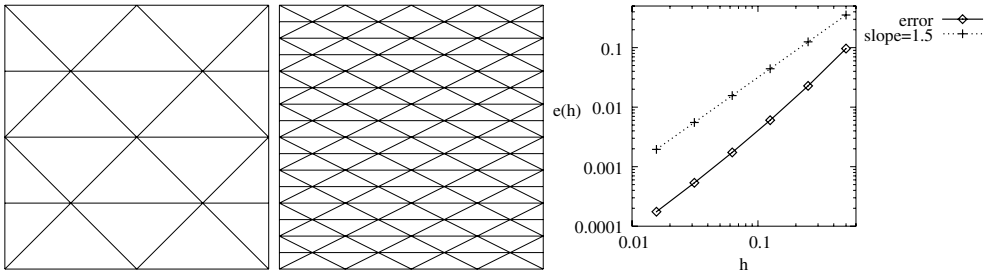

FIG. 6.4. *Degenerating triangular meshes.*

which is due to the fact, as shown in [10], that almost all diamond-cells (except those at the boundary) are parallelograms.

6.4. Nonsimply connected domains. Here, the domain of computation is $\Omega = [0,1]^2 \setminus [1/3, 2/3]^2$ and the data and boundary conditions are chosen so that the analytic solution is given by

$$\hat{\mathbf{u}}(x,y) = \begin{pmatrix} \exp(x)\,\cos(\pi y) + 3\pi\,\sin(3\pi x)\,\cos(3\pi y) \\ -\pi\,\exp(x)\,\sin(\pi y) - 3\pi\,\cos(3\pi x)\,\sin(3\pi y) \end{pmatrix}.$$

This means that the exact potentials are given by

$$\hat{\phi}(x,y) = \exp(x)\,\cos(\pi y) \quad \text{and} \quad \hat{\psi}(x,y) = \sin(3\pi x)\,\sin(3\pi y).$$

We compute the numerical solution on a family of five increasingly fine triangular meshes. The first two of the meshes are displayed on the left and central parts of Figure 6.5. The numerical errors in the L^2 norm are presented in logarithmic scale on the right part of Figure 6.5, as well as a straight line of slope 1. We observe the first order convergence of the scheme on this type of nonconvex meshes when the solution is regular enough, which is not the case of the last example.

6.5. Nonconvex domains and less regular solutions. Here, the domain of computation is $\Omega =]-1/2; 1/2[^2 \backslash]0; 1/2[^2$ and the data and boundary conditions are chosen so that the analytic solution, expressed in polar coordinates centered on $(0,0)$, is given by

$$\hat{\mathbf{u}}(r,\theta) = \boldsymbol{\nabla}\left(r^{2/3}\cos\left(\frac{2}{3}\theta\right)\right),$$

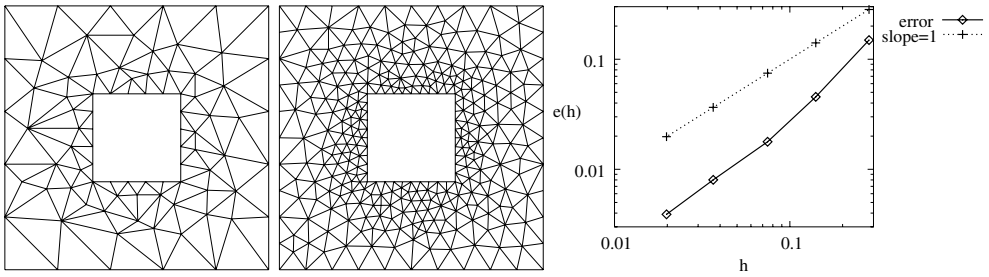

FIG. 6.5. *Nonsimply connected meshes.*

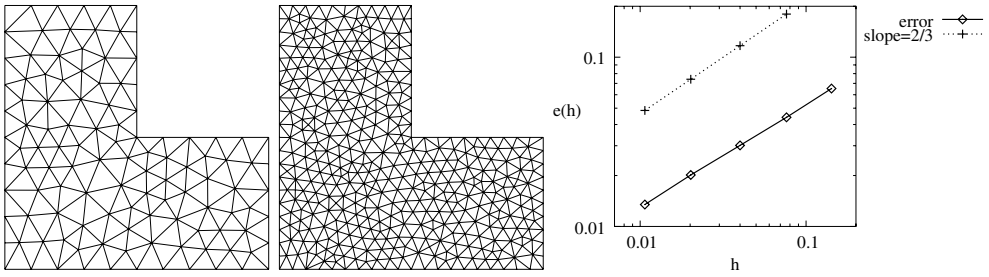

FIG. 6.6. *Nonconvex meshes.*

that is to say $\hat{\phi}(r,\theta) = r^{2/3}\cos(\frac{2}{3}\theta)$ and $\hat{\psi} = 0$. Note that $\hat{\phi}$ is still in H^1 but not in H^2, so that the error estimate derived in section 5.3 is not valid. More precisely, $\hat{\phi} \in (H^{1+s}(\Omega))^2$ with $s < 2/3$. We use a family of five unstructured triangular grids. The first two meshes of this family are displayed on the left and central parts of Figure 6.6, while the error curve in the discrete L^2 norm is shown on the right part of Figure 6.6, together with a reference line of slope 2/3. The order of convergence of the scheme seems to be 2/3 in this case, like that obtained in [4].

7. Conclusion. We have proposed new discretizations of differential operators such as divergence, gradient, and curl on almost arbitrary two-dimensional meshes. These discrete operators verify discrete properties analogous to their continuous counterparts. We have applied these ideas to approximate the solution of two-dimensional div-curl problems and have given error estimations for the resulting scheme. Finally, we have demonstrated the possibilities of the method by providing a series of numerical tests. Extensions of these ideas to problems with inhomogeneous and/or anisotropic and/or discontinuous coefficients and to the discretization of Stokes-like problems are currently being investigated.

B-SPLINE-BASED MONOTONE MULTIGRID METHODS*

MARKUS HOLTZ† AND ANGELA KUNOTH†

Abstract. For the efficient numerical solution of elliptic variational inequalities on closed convex sets, multigrid methods based on piecewise linear finite elements have been investigated over the past decades. Essential to their success is the appropriate approximation of the constraint set on coarser grids which is based on function values for piecewise linear finite elements. On the other hand, there are a number of problems which profit from higher order approximations. Among these are the problem of pricing American options, formulated as a parabolic boundary value problem involving Black–Scholes' equation with a free boundary. In addition to computing the free boundary (the optimal exercise price of the option) of particular importance are accurate pointwise derivatives of the value of the stock option up to order two, the so-called Greek letters. In this paper, we propose a monotone multigrid method for discretizations in terms of B-splines of arbitrary order to solve elliptic variational inequalities on a closed convex set. In order to maintain monotonicity (upper bound) and quasi optimality (lower bound) of the coarse grid corrections, we propose an optimized coarse grid correction (OCGC) algorithm which is based on B-spline expansion coefficients. We prove that the OCGC algorithm is of optimal complexity of the degrees of freedom of the coarse grid and, therefore, the resulting monotone multigrid method is of asymptotically optimal multigrid complexity. Finally, the method is applied to a standard model for the valuation of American options. In particular, it is shown that a discretization based on B-splines of order four enables us to compute the second derivative of the value of the stock option to high precision.

Key words. variational inequality, linear complementary problem, monotone multigrid method, cardinal higher order B-spline, system of linear inequalities, optimized coarse grid correction algorithm, optimal complexity, convergence rates, American option, Greek letters, high precision

1. Introduction.

The motivation for this paper stems from an application in Mathematical Finance, the fair pricing of American options. In a standard model, this problem can be formulated as a parabolic boundary value problem involving Black–Scholes' equation [BS] with a free boundary. In addition to computing the free boundary (the optimal exercise price of the option), pointwise higher order derivatives of the solution (the value of the stock option) are particularly important. These so-called Greek letters are needed with high precision as they play a crucial role as hedge parameters in the analysis of market risks. Thus, a discretization in terms of higher order basis functions is preferable.

On the other hand, for the fast numerical solution of the resulting (semidiscrete) elliptic variational inequality, the method of choice is the monotone multigrid method developed in [Ko1, Ko2]. Multigrid methods have been proposed previously for such problems using second order discretizations (i.e., standard finite difference stencils or piecewise linear finite elements) in different variants [BC, HM, Ho, Ma] where, however, not all of them have assured, consequently, that the obstacle criterion is met. Using piecewise linear finite element ansatz functions, geometric considerations

based on point values are used in [Ko1] to represent the problem-inherent obstacles on coarser grids in such a way that a violation of the obstacle is excluded. The difficulty to correctly identifying coarse grid approximations has also been the motivation for a cascadic multigrid algorithm for variational inequalities in [BBS] for which, however, no convergence theory is yet available.

In this paper, we generalize the monotone multigrid (MMG) method from [Ko1, Ko2] to discretizations involving higher order B-splines. One of the key ingredients of an MMG method are restrictions of the obstacle to coarser grids which satisfy the (upper) bound imposed by the obstacle (monotonicity) as well as a lower one which corresponds to the condition of quasi optimality in [Ko1]. We formulate the construction of coarse grid approximations as a linear constrained optimization problem with respect to the B-spline expansion coefficients. Our construction heavily profits from properties of B-splines [Bo, Sb]. In particular, we present with our optimized coarse grid correction (OCGC) algorithm a method to construct monotone and quasi-optimal coarse grid approximations to the obstacle function in optimal complexity of the coarse grid for B-spline basis functions of any degree.

Building the OCGC scheme into the MMG method, our higher order MMG method is shown to be of optimal multigrid complexity. Moreover, following the arguments in [Ko1], we can prove that our method is globally convergent and reduces asymptotically to a linear subspace correction method once the contact set has been identified [HzK]. Hence, we can expect particular robustness of the scheme and full multigrid efficiency in the asymptotic range in the numerical experiments. This is confirmed by computations for an American option pricing problem in terms of cubic B-splines. Details about the derivation of the problem of fair pricing American options and its formulation as a free boundary value problem and corresponding results can be found in [WHD, Hz]. Of course, once higher order MMG methods are available, they may be applied to other obstacle problems like Signorini's problem which has been solved using piecewise linear hat functions in [Kr].

This paper is structured as follows. In section 2 we introduce monotone multigrid methods, recollect the main features of B-splines, and specify a B-spline-based projected Gauss–Seidel relaxation as a smoothing component of the scheme. In section 3 the crucial ingredients of the higher order MMG schemes, suitable restriction operators for the obstacle function, are presented for B-spline functions of arbitrary degree in the univariate case. Their construction for higher spatial dimensions is presented in section 4 using tensor products. In section 5 some short remarks concerning the convergence theory for B-spline-based MMG schemes are made. Finally, in section 6 we present a numerical example of pricing American options. The convergence behavior of the projected Gauss–Seidel and the multigrid schemes is compared for basis functions of different orders. We conclude with an estimation of asymptotic multigrid convergence rates which exhibit full multigrid efficiency for the truncated version.

2. MMG methods.

2.1. Elliptic variational inequalities and linear complementary problems. Let Ω be a domain in $\mathbb{R}^d$ and $\mathcal{J}(v) := \frac{1}{2}a(v,v) - f(v)$ a quadratic functional induced by a continuous, symmetric, and H_0^1– elliptic bilinear form $a(\cdot,\cdot) : H_0^1(\Omega) \times H_0^1(\Omega) \to \mathbb{R}$ and a linear functional $f : H_0^1(\Omega) \to \mathbb{R}$. As usual, $H_0^1(\Omega)$ is the subspace of functions belonging to the Sobolev space $H^1(\Omega)$ with zero trace on the boundary. We consider the constrained minimization problem

$$\text{find } u \in \mathcal{K} : \quad \mathcal{J}(u) \le \mathcal{J}(v) \quad \text{for all } v \in \mathcal{K} \tag{2.1}$$

on the closed and convex set

$$\mathcal{K} := \{v \in H_0^1(\Omega) : \ v(x) \le g(x) \ \text{ for all } x \in \Omega\} \subset H_0^1(\Omega).$$

The function $g \in H_0^1(\Omega)$ represents an upper obstacle for the solution $u \in H_0^1(\Omega)$. Lower obstacles can be treated in the obvious analogous way. If g satisfies $g(x) \ge 0$ for all $x \in \partial\Omega$, then problem (2.1) admits a unique solution $u \in \mathcal{K}$ by the Lax–Milgram theorem. It is well-known that (2.1) can be rewritten as a variational inequality; see, e.g., [EO, KS]: find $u \in \mathcal{K}$: $a(u, v-u) \ge f(v-u)$ for all $v \in \mathcal{K}$ or, equivalently, as a *linear complementary problem*

$$\begin{aligned} \mathcal{L}u &\ge f, \\ u &\le g, \\ (u-g)(\mathcal{L}u - f) &= 0 \end{aligned} \tag{2.2}$$

almost everywhere in Ω. Here $\mathcal{L} : H_0^1(\Omega) \to H^{-1}(= (H_0^1(\Omega))')$ is the Riesz operator defined by $\langle \mathcal{L}u, v\rangle := a(u, v)$ for all $v \in H_0^1(\Omega)$.

Discretizing in a finite dimensional spline space S_L of piecewise polynomials on a grid Δ_L with uniform grid spacing h_L leads to the discrete formulation of (2.1),

$$\text{find } u_L \in \mathcal{K}_L : \quad \mathcal{J}(u_L) \le \mathcal{J}(v_L) \quad \text{ for all } v_L \in \mathcal{K}_L \tag{2.3}$$

on the closed and convex set $\mathcal{K}_L := \{v_L \in S_L : \ v_L(x) \le g_L(x) \ \text{ for all } x \in \Omega\} \subset S_L$, or, equivalently,

$$\begin{aligned} \mathcal{L}_L u_L &\ge f_L, \\ u_L &\le g_L, \\ (u_L - g_L)(\mathcal{L}_L u_L - f_L) &= 0. \end{aligned} \tag{2.4}$$

In [BHR] regularity $u \in H^{5/2-\epsilon}(\Omega)$ of the solution u to (2.2) is shown for arbitrary $\epsilon > 0$. Moreover, error estimates $\|u - u_L\|_{H^1(\Omega)} = O(h_L)$ and $\|u - u_L\|_{H^1(\Omega)} = O(h_L^{3/2-\epsilon})$ are proved in the case of piecewise linear (respectively, piecewise quadratic) functions, provided the functions f, g are sufficiently regular.

2.2. The MMG-algorithm. For solving (2.3) numerically, a now-popular method is the MMG method [Ko1]. By adding a projection step and employing specific restriction operators, it can be implemented as a variant of a standard multigrid scheme. Let $S_1 \subset S_2 \subset \cdots \subset S_L \subset H_0^1(\Omega)$ be a nested sequence of finite dimensional spaces, and let $u_L^\nu \in S_L$ be the approximation in the νth iteration of the MMG method. The basic multigrid idea is that the error $v_L := u_L - u_L^{\nu,1}$ between the smoothed iterate $u_L^{\nu,1} := \mathcal{S}(u_L^\nu)$ ($\mathcal{S}$ always being the standard Gauss–Seidel iteration) and the exact solution u_L can be approximated without essential loss of information on a coarser grid Δ_{L-1}. We explain how this is realized in the case of a linear complementary problem for two grids Δ_L and Δ_{L-1}. Introducing the defect $d_L := f_L - \mathcal{L}_L u_L^{\nu,1}$, (2.4) can be written as

$$\begin{aligned} \mathcal{L}_L v_L &\ge d_L, \\ v_L &\le g_L - u_L^{\nu,1}, \\ (v_L - g_L + u_L^{\nu,1})(\mathcal{L}_L v_L - d_L) &= 0. \end{aligned} \tag{2.5}$$

On a coarser grid Δ_{L-1}, the defect problem can now be approximated by

$$\begin{aligned} \mathcal{L}_{L-1} v_{L-1} &\geq d_{L-1}, \\ v_{L-1} &\leq g_{L-1}, \\ (v_{L-1} - g_{L-1})(\mathcal{L}_{L-1} v_{L-1} - d_{L-1}) &= 0, \end{aligned}$$

where $d_{L-1} := r\, d_L$ and $g_{L-1} := \tilde{r}(g_L - u_L^{\nu,1})$ with (different) restriction operators $r, \tilde{r} : S_L \to S_{L-1}$. The solution v_{L-1} of the coarse grid problem is then used as an approximation to the error v_L. It is first transported back to the fine grid by a prolongation operator p and is then added to the approximation $u_L^{\nu,1}$. It is important that the restriction $\tilde{r}$ is chosen such that the new iterate satisfies the constraint

$$u_L^{\nu,2} := u_L^{\nu,1} + p v_{L-1} \leq g_L \tag{2.6}$$

on the fine grid. Applying this idea recursively on several different grids, one obtains the MMG method for linear complementary problems.

ALGORITHM 2.1. **MMG**$_\ell$ *(νth cycle on level $\ell \geq 1$).*
Let $u_\ell^\nu \in S_\ell$ be a given approximation.

1. *A priori smoothing and projection:* $u_\ell^{\nu,1} := (\mathcal{P} \circ \mathcal{S}(u_\ell^\nu))^{\eta_1}$.
2. *Coarse grid correction:*
$$\begin{aligned} d_{\ell-1} &:= r(f_\ell - \mathcal{L}_\ell u_\ell^{\nu,1}), \\ g_{\ell-1} &:= \tilde{r}(g_\ell - u_\ell^{\nu,1}), \\ \mathcal{L}_{\ell-1} &:= r \mathcal{L}_\ell p. \end{aligned}$$
If $\ell = 1$, solve exactly the linear complementary problem
$$\begin{aligned} \mathcal{L}_{\ell-1} v &\geq d_{\ell-1}, \\ v &\leq g_{\ell-1}, \\ (v - g_{\ell-1})(\mathcal{L}_{\ell-1} v - d_{\ell-1}) &= 0, \end{aligned}$$
and set $v_{\ell-1} := v$.
If $\ell > 1$, do γ steps of **MMG**$_{\ell-1}$ *with initial value $u_{\ell-1}^0 := 0$ and solution $v_{\ell-1}$.*
Set $u_\ell^{\nu,2} := u_\ell^{\nu,1} + p v_{\ell-1}$.
3. *A posteriori smoothing and projection:* $u_\ell^{\nu,3} := (\mathcal{P} \circ \mathcal{S}(u_\ell^{\nu,2}))^{\eta_2}$.
Set $u_\ell^{\nu+1} := u_\ell^{\nu,3}$.

The number of a priori and a posteriori smoothing steps is denoted by η_1 and η_2, respectively. For $\gamma = 1$ one obtains a V-cycle, for $\gamma = 2$ a W-cycle. $\mathcal{P}$ denotes a projection operator defined in (2.7) and (2.11).

Condition (2.6) leads to an inner approximation of the solution set $\mathcal{K}_L$ and ensures that the multigrid scheme is robust [Ko1]. Striving for optimal multigrid efficiency, satisfaction of the constraint should *not* be checked by interpolating v_ℓ back to the finest grid. Instead, special restriction operators $\tilde{r}$ are needed for the obstacle function. A corresponding construction for B-splines of general order k will be introduced in sections 3 and 4. Next we discuss the projection step for general order B-splines.

2.3. A B-spline-based projected Gauss–Seidel scheme. Since the operator $\mathcal{L}$ is symmetric positive definite and continuous piecewise linear functions are used for discretization, the discrete form (2.4) can be solved by the projected Gauss–Seidel scheme; see, e.g., [Cr]. Given an iterate u_L^ν, a standard Gauss–Seidel sweep $\bar{u}_L^\nu := \mathcal{S}(u_L^\nu)$ is supplemented by a projection $u_L^{\nu+1} = \mathcal{P}\, \bar{u}_L^\nu$ into the convex set $\mathcal{K}_L$. If

S_L consists of hat functions, the projection can be defined for given grid points $\{\theta_i\}_i$ by

$$\mathcal{P}\, v_L(\theta_i) := \min\{v_L(\theta_i),\, g_L(\theta_i)\}. \tag{2.7}$$

For higher order functions v_L, the difficulty arises already in the univariate case that for given $x \in [\theta_i, \theta_{i+1}]$ the estimate

$$\min\{v_L(\theta_i), v_L(\theta_{i+1})\} \le v_L(x) \le \max\{v_L(\theta_i), v_L(\theta_{i+1})\} \tag{2.8}$$

is no longer valid. Thus, controlling function values on grid points is not a sufficient criterion in this case. Instead, we propose here a construction using higher order B-splines, which compares B-spline expansion coefficients instead of function values and heavily profits from the fact that B-splines are nonnegative. We begin with the univariate case. For readers' convenience, we recall the relevant facts about B-spline bases from [Bo].

DEFINITION 2.2 (B-spline basis functions). *For $k \in \mathbb{N}$ and $n \in \mathbb{N}$ let $T := \{\theta_i\}_{i=1,\dots,n+k}$ be an* expanded knot sequence *with uniform grid spacing h_L in the interior of the interval $I := [a, b]$ of the form*

$$\theta_1 = \cdots = \theta_k = a < \theta_{k+1} < \cdots < \theta_n < b = \theta_{n+1} = \cdots = \theta_{n+k}. \tag{2.9}$$

Then the B-spline basis functions $N_{i,k}$ of order k are recursively defined for $i = 1, \dots, n$ by

$$\begin{aligned} N_{i,1}(x) &= \begin{cases} 1 & \text{if } x \in [\theta_i, \theta_{i+1}) \\ 0 & \text{else,} \end{cases} \\ N_{i,k}(x) &= \frac{x - \theta_i}{\theta_{i+k-1} - \theta_i}\, N_{i,k-1}(x) + \frac{\theta_{i+k} - x}{\theta_{i+k} - \theta_{i+1}}\, N_{i+1,k-1}(x) \end{aligned} \tag{2.10}$$

for $x \in I$.

It is known that $\operatorname{supp} N_{i,k} \subseteq [\theta_i,\, \theta_{i+k}]$ (local support), $N_{i,k}(x) \ge 0$ for all $x \in I$ (nonnegativity), and $N_{i,k} \in C^{k-2}(I)$ (differentiability) holds. Moreover, the set $\Sigma_L := \{N_{1,k}, \dots, N_{n,k}\}$ constitutes a locally independent and unconditionally stable basis with respect to $\|\cdot\|_{L_p}$, $1 \le p \le \infty$ for the finite dimensional space $S_L = \mathcal{N}_{k,T} := \operatorname{span} \Sigma_L$ of the splines of order k.

LEMMA 2.3. *If the B-spline coefficients of $v_L, g_L \in \mathcal{N}_{k,T} = S_L$ satisfy $v_i \le g_i$ for all $i = 1, \dots, n$, then $v_L(x) \le g_L(x)$ holds for all $x \in I$.*

Proof. Using the representation $v_L = \sum_{i=1}^n v_i\, N_{i,k}$ and $g_L = \sum_{i=1}^n g_i\, N_{i,k}$ and the nonnegativity $N_{i,k}(x) \ge 0$ for all $x \in I$, we deduce that $g_L(x) - v_L(x) = \sum_{i=1}^n (g_i - v_i)\, N_{i,k}(x) \ge 0$ for all $x \in I$. ∎

Here and in section 5, we use the subscript i in $v_i = (v_L)_i$ to denote B-spline expansion coefficients.

The projection can now be defined for B-spline functions of general order k similar to (2.7), but now involving expansion coefficients by setting

$$\mathcal{P}\, v_i := \min\{v_i,\, g_i\}. \tag{2.11}$$

Using the same arguments as in [Cr], the resulting projected Gauss–Seidel scheme still converges since the discrete solution set $\{\mathbf{v} \in \mathbb{R}^n : v_i \le g_i \text{ for } i = 1, \dots, n\}$ describes a cuboid in $\mathbb{R}^n$. Moreover, if the problem is nondegenerate, the contact set,

defined by all coefficients for which equality holds, is identified after a finite number of iterations [Cr, EO].

We treat the multivariate case by taking tensor products. Specifying the domain Ω as $\Omega := \prod_{\ell=1}^{d}[a_\ell, b_\ell] \subset \mathbb{R}^d$, the ith d-dimensional tensor product B-spline of order k on a tensorized extended knot sequence $T^{(d)}$ is defined by

$$N_{i,k}^{(d)}(x) := \prod_{\ell=1}^{d} N_{i_\ell,k}(x_\ell), \qquad x \in \Omega, \tag{2.12}$$

where $i := (i_1, \ldots, i_d)$ denotes a multi-index. Defining S_L in analogy to the univariate case, the result of Lemma 2.3 immediately carries over to the d-dimensional setting.

3. Construction of monotone and quasi-optimal obstacle approximations. In this section, the second essential ingredient for our B-spline-based MMG methods is provided, the construction of so-called *monotone* and *quasi-optimal coarse grid approximations* of the obstacle function, which lead to suitable restriction operators $\tilde{r}$. We begin with the univariate case; the extension to d dimensions follows in section 4. We consider in what follows only two grids, as the generalization to several grids is obvious. Given an obstacle function $\tilde{S}$ which is defined on a fine grid $\Delta \subset I$, we provide an approximation S with respect to a coarser grid T which satisfies

1. $S(x) \le \tilde{S}(x)$ for all $x \in I$;
2. $S(x) \ge L_k(x)$ for all $x \in I$ and a still-to-be-specified lower barrier $L_k(x)$ provided in section 3.2;
3. $S \approx \tilde{S}$ with respect to a target functional F_k defined below in (3.10).

The first condition ensures the monotonicity and robustness of the multigrid scheme, the second an asymptotical reduction of the method to a linear relaxation, and the third an efficient coarse grid correction. As the construction is used as a component of the monotone multigrid scheme striving for optimal computational multigrid complexity, it also has to satisfy

4. the number of arithmetic operations must be of order $O(n)$, where n denotes the number of degrees of freedom on the coarse grid.

Specifically, let T be an extended knot sequence with grid spacing H as in (2.9) and let $\Delta := \{\tilde{\theta}_i\}_{i=1,\ldots,\tilde{n}+k}$ be a *finer* knot sequence

$$\tilde{\theta}_1 = \cdots = \tilde{\theta}_k = a < \tilde{\theta}_{k+1} < \cdots < \tilde{\theta}_{\tilde{n}} < b = \tilde{\theta}_{\tilde{n}+1} = \cdots = \tilde{\theta}_{\tilde{n}+k} \tag{3.1}$$

with grid spacing $h = \frac{1}{2}H$. It is defined such that $\theta_i = \tilde{\theta}_{2i-k}$ for $i = k, \ldots, n+1$ and $\frac{1}{2}(\theta_{i-1} + \theta_i) = \tilde{\theta}_{2i-k-1}$ for $i = k+1, \ldots, n+1$. Then it holds that

$$\tilde{n} = 2n + 1 - k. \tag{3.2}$$

The corresponding spline spaces are $\mathcal{N}_{k,\Delta}$ and $\mathcal{N}_{k,T}$ with member functions $N_{i,k,\Delta}$ and $N_{i,k,T}$, respectively. Now let the obstacle function on the fine grid $\tilde{S} \in \mathcal{N}_{k,\Delta}$ and its approximation $S \in \mathcal{N}_{k,T}$ be expanded as

$$\tilde{S} = \sum_{i=1}^{\tilde{n}} \tilde{c}_i\, N_{i,k,\Delta} =: \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}, \qquad S = \sum_{i=1}^{n} c_i\, N_{i,k,T} =: \mathbf{c}^T \mathbf{N}_{k,T}. \tag{3.3}$$

There is a natural *prolongation operator* p from $\mathcal{N}_{k,T}$ to $\mathcal{N}_{k,\Delta}$ for B-splines $N_{i,k,T}$ in terms of their refinement or mask coefficients [Bo, Sb]. In the special case $H = 2\,h$

considered here the refinement relation is given by

$$N_{i,k,T} = \sum_{j=0}^{k} a_j \, N_{2i-k+j,k,\Delta} \tag{3.4}$$

with the *subdivision* or *mask* coefficients

$$a_j := 2^{1-k} \binom{k}{j} \quad \text{for } j = 0, \ldots, k. \tag{3.5}$$

In step 2 of Algorithm 2.1, we choose the restriction r as the adjoint of p, following [Ha]. However, for the obstacle function the restriction operator r cannot be used since it does not satisfy condition (2.6).

3.1. Monotone coarse grid approximations. There is a vast amount of literature, see, e.g., [DV, Mv, Pi] especially from approximation theory, dealing with monotone approximations to a given function g. The function $\hat{g}$ is a *monotone* (or *one-sided*) *lower approximation* to g if $\hat{g}(x) \le g(x)$ for all $x \in I$. There the number n of degrees of freedom of the function $\hat{g}$ is chosen such that a given approximation accuracy can be reached. In contrast to these studies, the question here is different, since the number n of degrees of freedom is given by the mesh size H.

DEFINITION 3.1 (monotone coarse grid approximation). *For knot sequences T and Δ from* (2.9) *and* (3.1), *respectively, we call $S \in \mathcal{N}_{k,T}$ a* monotone lower coarse grid approximation *to $\tilde{S} \in \mathcal{N}_{k,\Delta}$ if $S(x) \le \tilde{S}(x)$ holds for all $x \in I$.*

For hat functions such approximations are constructed in [Ma, Ko1]. A corresponding construction for higher order functions has, to our knowledge, not been provided so far. In view of Lemma 2.3 we propose here to control B-spline expansion coefficients.

THEOREM 3.2 (monotone coarse grid approximation). *Let $\tilde{S} \in \mathcal{N}_{k,\Delta}$ be an upper obstacle with $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}$ for a given order k and the knot sequence Δ from* (3.1). *Then $S \in \mathcal{N}_{k,T}$ with $S = \mathbf{c}^T \mathbf{N}_{k,T}$ defined on the knot sequence T from* (2.9) *is a monotone lower coarse grid approximation to $\tilde{S}$ if the inequality system*

$$A_k \, \mathbf{c} \le \tilde{\mathbf{c}} \tag{3.6}$$

is satisfied. The two-slanted *matrix A_k is defined by*

$$A_k := \begin{pmatrix}
a_{k-1} & a_{k-3} & \ddots & & & & \\
a_k & a_{k-2} & & & & & \\
 & a_{k-1} & & a_0 & & & \\
 & a_k & & a_1 & & & \\
 & & \ddots & a_2 & & & \\
 & & & \vdots & & & \\
 & & & a_{k-1} & \ddots & & \\
 & & & a_k & & & \\
 & & & & \ddots & a_0 & \\
 & & & & & a_1 &
\end{pmatrix} \in \mathbb{R}^{\tilde{n} \times n}$$

with the subdivision coefficients a_j from (3.5) *and has maximal rank.*

Proof. The proof relies on the subdivision property (3.4) and on the nonnegativity of B-splines. We only consider the case k even as the other case is analogous. Substituting (3.4) into (3.3) and sorting according to the basis functions $N_{i,k,\Delta}$ leads to

$$S(x) = \sum_{\substack{i=1\\ i \text{ odd}}}^{\tilde{n}} \left(a_{k-1}\, c_{(i+1)/2} + a_{k-3}\, c_{(i+3)/2} + \cdots + a_1\, c_{(i+k-1)/2}\right) N_{i,k,\Delta}(x) + \sum_{\substack{i=2\\ i \text{ even}}}^{\tilde{n}-1} \left(a_k\, c_{i/2} + a_{k-2}\, c_{(i+2)/2} + \cdots + a_0\, c_{(i+k)/2}\right) N_{i,k,\Delta}(x),$$

where all c_j with $j < 1$ or $j > n$ are treated as zero. Defining the coefficients

$$d_i := \begin{cases} \tilde{c}_i - \left(a_{k-1}\, c_{(i+1)/2} + a_{k-3}\, c_{(i+3)/2} + \cdots + a_1\, c_{(i+k-1)/2}\right) & \text{if } i \text{ is odd,} \\ \tilde{c}_i - \left(a_k\, c_{i/2} + a_{k-2}\, c_{(i+2)/2} + \cdots + a_0\, c_{(i+k)/2}\right) & \text{if } i \text{ is even,} \end{cases}$$

which can be written in compact matrix/vector form as

$$d_i = \tilde{c}_i - (A_k\, \mathbf{c})_i \tag{3.7}$$

(involving the ith component of the vector $A_k\, \mathbf{c}$), we obtain

$$\tilde{S}(x) - S(x) = \sum_{i=1}^{\tilde{n}} d_i\, N_{i,k,\Delta}(x). \tag{3.8}$$

By Lemma 2.3 we have $\tilde{S}(x) - S(x) \geq 0$ for all $x \in I$, provided $d_i \geq 0$ holds for all $i = 1, \ldots, \tilde{n}$. By (3.7), we obtain the inequality system (3.6). Since the B-splines form bases for $\mathcal{N}_{k,T}$ and $\mathcal{N}_{k,\Delta}$, the matrix A_k has full rank for each k. ∎

Example 3.3. In the special case of continuous, piecewise linear functions ($k = 2$), C^1-smooth; piecewise quadratic ($k = 3$); and C^2-smooth, piecewise cubic ($k = 4$) splines, one has

$$A_2 = \begin{pmatrix} 1 & & & & & \\ \frac{1}{2} & \frac{1}{2} & & & & \\ & 1 & & & & \\ & \frac{1}{2} & \frac{1}{2} & & & \\ & \ddots & & & & \\ & & & \frac{1}{2} & & \\ & & & 1 & & \\ & & & \frac{1}{2} & \frac{1}{2} & \\ & & & & 1 \end{pmatrix} \in \mathbb{R}^{(2n-1)\times n}, \quad A_3 = \frac{1}{4} \begin{pmatrix} 3 & 1 & & & & \\ 1 & 3 & & & & \\ & 3 & 1 & & & \\ & 1 & 3 & & & \\ & \ddots & & \ddots & & \\ & & & 3 & 1 & \\ & & & 1 & 3 & \\ & & & & 3 & 1 \\ & & & & 1 & 3 \end{pmatrix} \in \mathbb{R}^{(2n-2)\times n},$$

$$A_4 = \frac{1}{8} \begin{pmatrix} 4 & 4 & & & & \\ 1 & 6 & 1 & & & \\ & 4 & 4 & & & \\ & 1 & 6 & 1 & & \\ & \ddots & & \ddots & & \\ & & 1 & 6 & 1 & \\ & & & 4 & 4 & \\ & & & 1 & 6 & 1 \\ & & & & 4 & 4 \end{pmatrix} \in \mathbb{R}^{(2n-3)\times n}.$$

TABLE 3.1
The values β_k and γ_k for orders $k = 2, 4, 6, 8$.

k	2	4	6	8
β_k	1	$\frac{2}{3}$	$\frac{17}{30}$	$\frac{166}{315}$
γ_k	0	$\frac{1}{3}$	$\frac{13}{30}$	$\frac{149}{315}$

3.2. Quasi-optimal coarse grid approximations. Now we can immediately derive a monotone lower coarse approximation.

PROPOSITION 3.4. *The spline $L_k := \mathbf{q}^T \mathbf{N}_{k,T} \in \mathcal{N}_{k,T}$ with coefficients*

$$q_i := \min\{\tilde{c}_{2i-k}, \ldots, \tilde{c}_{2i}\} \quad \text{for } i = 1, \ldots, n \tag{3.9}$$

(leaving out $\tilde{c}_j$ in the right-hand side if $j < 1$ or $j > \tilde{n}$) is a monotone lower coarse grid approximation to $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta} \in \mathcal{N}_{k,\Delta}$.

Proof. As all row sums of A_k are equal to one, the vector $\mathbf{q} := (q_1, \ldots, q_n)^T$ defined in (3.9) obviously satisfies the inequality system $A_k\,\mathbf{q} \le \tilde{\mathbf{c}}$ so that the assertion directly follows from Theorem 3.2. ∎

Remark 3.5. In the special case $k = 2$, the restriction operator $\hat{r} : \mathcal{N}_{2,\Delta} \to \mathcal{N}_{2,T}$, $\tilde{S} \mapsto L_2$ induced by Proposition 3.4 coincides with the restriction operator from [Ma].

As is illustrated in Figures 3.1 and 3.2 for the cases $k = 2$ and $k = 3$, the approximation L_k can be further improved in many cases. This will be the subject of the next subsections: there $\mathbf{q}$ is interpreted as a componentwise lower barrier for the B-spline coefficients $\mathbf{c}$ of the desired coarse grid approximation.

DEFINITION 3.6 (quasi-optimal coarse grid approximation). *We call a monotone lower coarse grid approximation $S = \mathbf{c}^T \mathbf{N}_{k,T}$ to the spline $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}$* quasi-optimal *if it is an improvement over L_k in the sense that $\mathbf{c} \ge \mathbf{q}$ holds with $\mathbf{q}$ defined in* (3.9).

3.3. A linear optimization problem. Aiming at improving the coarse grid approximation L_k from Proposition 3.4, we define an *optimal* monotone and quasi-optimal coarse grid approximation $S = \mathbf{c}^T \mathbf{N}_{k,T}$ to a given $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}$ by formulating a linear optimization problem. We choose a target functional F_k which estimates the sum of the distances from approximation to obstacle on all coarse grid points, i.e.,

$$F_k(\mathbf{c}) := \sum_{\theta \in T} |\tilde{S}(\theta) - S(\theta)|. \tag{3.10}$$

LEMMA 3.7. *The function F_k defined in* (3.10) *is a linear function $\mathbb{R}^n \to \mathbb{R}$ of the form*

$$F_k(\mathbf{c}) = \boldsymbol{\xi}^T \mathbf{c} + \eta, \tag{3.11}$$

where

$$\boldsymbol{\xi} := -A_k^T \mathbf{s}_k \in \mathbb{R}^n, \quad \mathbf{s}_k := (\beta_k, \gamma_k, \beta_k, \ldots)^T \in \mathbb{R}^{\tilde{n}}, \text{ and } \eta := \mathbf{s}_k^T \tilde{\mathbf{c}} \in \mathbb{R}. \tag{3.12}$$

The values β_k and γ_k can be computed explicitly: for odd k we have $\beta_k = \gamma_k = \frac{1}{2}$, and for even $k = 2, 4, 6, 8$ the values are displayed in Table 3.1.

Proof. By Theorem 3.2 we have $|\tilde{S}(x) - S(x)| = \tilde{S}(x) - S(x)$ for all $x \in I$. Using (3.8) we obtain

$$F_k(\mathbf{c}) = \sum_{\theta \in T} \Big(\tilde{S}(\theta) - S(\theta)\Big) = \sum_{\theta \in T} \sum_{i=1}^{\tilde{n}} d_i\, N_{i,k,\Delta}(\theta) = \sum_{i=1}^{\tilde{n}} d_i \sum_{\theta \in T} N_{i,k,\Delta}(\theta). \tag{3.13}$$

Abbreviating $(\tilde{\mathbf{s}}_k)_i := \sum_{\theta\in T} N_{i,k,\Delta}(\theta)$, we next show that $\tilde{\mathbf{s}}_k$ coincides with $\mathbf{s}_k$ defined in (3.12). In fact, $\sum_{\theta\in\Delta} N_{i,k,\Delta}(\theta) = 1$ is easily shown by induction for $k \in \mathbb{N}$. For odd k we can use a simple symmetry argument to conclude $(\tilde{\mathbf{s}}_k)_i = \frac{1}{2}$. For even k two cases must be distinguished according to the position of $N_{i,k,\Delta}$. Evaluating the B-spline on coarse grid points leads to $(\tilde{\mathbf{s}}_k)_i = \beta_k$ if $\theta_{i+k/2} \in T$ and $(\tilde{\mathbf{s}}_k)_i = \gamma_k$ in the other case. For orders $k = 2, 4, 6, 8$, the concrete values β_k and γ_k are displayed in Table 3.1. Thus, we have $(\mathbf{s}_k)_i = (\tilde{\mathbf{s}}_k)_i$ and employing (3.7) in (3.13) leads to (3.11), i.e., $F_k(\mathbf{c}) = \sum_{i=1}^{\tilde{n}} (\mathbf{s}_k)_i\,(\tilde{c}_i - (A_k\,\mathbf{c})_i) = \mathbf{s}_k^T\tilde{\mathbf{c}} - \mathbf{s}_k^T\,A_k\,\mathbf{c} = \boldsymbol{\xi}^T\mathbf{c} + \eta$. ∎

We can now define an optimal monotone and quasi-optimal coarse grid approximation as the solution of the linear optimization problem

$$\begin{aligned} &\text{Minimize the target functional} && F_k(\mathbf{c}) = \boldsymbol{\xi}^T\mathbf{c} + \eta \\ &\text{with respect to the constraints} && A_k\,\mathbf{c} \le \tilde{\mathbf{c}} \quad\text{and}\quad \mathbf{c} \ge \mathbf{q}. \end{aligned} \tag{3.14}$$

Here $A_k \in \mathbb{R}^{\tilde{n}\times n}$, $\tilde{\mathbf{c}} \in \mathbb{R}^{\tilde{n}}$, and $\mathbf{q} \in \mathbb{R}^n$ are defined as before with $\tilde{n} = 2n - k + 1$ and $\boldsymbol{\xi} \in \mathbb{R}^n$ and $\eta \in \mathbb{R}$ are given as in (3.12). The upper inequality guarantees the monotonicity of the approximation by Theorem 3.2, while the second one ensures quasi optimality by Proposition 3.4.

3.4. Solution of the linear optimization problem. Via the linear optimization formulation (3.14) a (with respect to the target functional F_k) optimal monotone and quasi-optimal coarse grid approximation may now be obtained, in principle, by the *simplex algorithm*; see, e.g., [Sj]. Here the point $\mathbf{q} \in \mathbb{R}^n$ could be used as a starting corner by Proposition 3.4. In a multigrid scheme, however, the simplex algorithm should not be used because the optimal complexity $O(n)$ would be destroyed. As shown next, a direct solution for $k = 2$ can be obtained by the *Fourier–Motzkin elimination*; see, e.g., [Sj]. For the general case $k > 2$ we present afterwards an approximate solution algorithm which can be applied in optimal complexity.

LEMMA 3.8 (direct solution for hat functions). *For $k = 2$ and given $\tilde{\mathbf{c}} \in \mathbb{R}^{\tilde{n}}$, the solution of the linear optimization problem* (3.14) *is recursively given by*

$$\begin{aligned} c_1 &:= \min\{\tilde{c}_1,\, 2\tilde{c}_2 - q_2\} \\ c_i &:= \min\{2\,\tilde{c}_{2i-2} - c_{i-1},\, \tilde{c}_{2i-1},\, 2\,\tilde{c}_{2i} - q_{i+1}\} \quad \textit{for } i = 2, \dots, n-1, \\ c_n &:= \min\{2\,\tilde{c}_{2n-2} - c_{n-1},\, \tilde{c}_{2n-1}\} \end{aligned} \tag{3.15}$$

with $q_i = \min\{\tilde{c}_{2i-2},\, \tilde{c}_{2i-1},\, \tilde{c}_{2i}\}$ for $i = 1, \dots, n$ defined in (3.9). *In particular, $S = \mathbf{c}^T\,\mathbf{N}_{k,T}$ is a monotone and quasi-optimal coarse grid approximation to the obstacle $\tilde{S} = \tilde{\mathbf{c}}^T\,\mathbf{N}_{2,\Delta}$.*

Proof. First, the n conditions $-\mathbf{c} \le -\mathbf{q}$ are integrated into the inequality system $A_2\,\mathbf{c} \le \tilde{\mathbf{c}}$ from Theorem 3.2. Then, Fourier–Motzkin elimination is applied to the resulting $(3n-1) \times n$ inequality system so that we obtain the solution range

$$\begin{aligned} q_1 &\le c_1 \le \min\{\tilde{c}_1,\, 2\tilde{c}_2 - q_2\}, \\ q_i &\le c_i \le \min\{2\tilde{c}_{2i-2} - c_{i-1},\, \tilde{c}_{2i-1},\, 2\tilde{c}_{2i} - q_{i+1}\} \quad \text{for } i = 2, \dots, n-1, \\ q_n &\le c_n \le \min\{2\tilde{c}_{2n-2} - c_{n-1},\, \tilde{c}_{2n-1}\}. \end{aligned}$$

Because of (3.9), $q_1 \le \min\{\tilde{c}_1, 2\tilde{c}_2 - q_2\}$ holds. To minimize the target function F_2 given by Lemma 3.7, all coefficients c_i must be chosen as large as possible which leads to (3.15). ∎

Remark 3.9. The restriction operator $\tilde{r} : \mathcal{N}_{2,\Delta} \to \mathcal{N}_{2,T}$, $\tilde{S} \mapsto S$, implied by Lemma 3.8, corresponds to the restriction operator from [Ko1] which is derived by

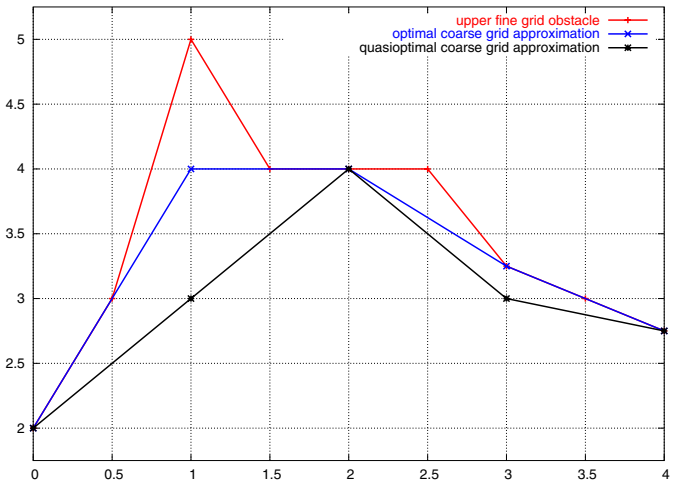

FIG. 3.1. *Continuous piecewise linear upper obstacle function on the fine grid* $[0,4] \cap \mathbb{Z}/2$ *and coarse grid approximations according to Lemma* 3.8 *and Proposition* 3.4, *respectively, on the coarse grid* $[0,4] \cap \mathbb{Z}$.

geometric considerations. It is an improvement of the restriction operator $\hat{r}$ from Remark 3.5 or [Ma] since $\tilde{r}(\tilde{S}) \geq \hat{r}(\tilde{S})$ holds for all $\tilde{S} \in \mathcal{N}_{2,\Delta}$.

In Figure 3.1 a continuous, piecewise linear, upper obstacle function, the optimal coarse grid approximation according to Lemma 3.8 and the coarse grid approximation according to Proposition 3.4 are displayed. The improvement of the simple approximation L_2 is clearly visible. Since the band width of A_k increases with increasing order k, and since the Fourier–Motzkin elimination is only suited for small matrices or for matrices with mainly zero entries [Sj], a different approach must be found to solve the linear optimization problem in the higher order case $k > 2$.

To simplify the notation we define in addition to (3.5) that $a_j := 0$ for $j > k$ and $j < 0$.

THEOREM 3.10 (optimized coarse grid correction (OCGC) scheme). *Let* $\tilde{S} \in \mathcal{N}_{k,\Delta}$ *be given with* $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}$. *Let* $L_k \in \mathcal{N}_{k,T}$ *with* $L_k = \mathbf{q}^T \mathbf{N}_{k,T}$ *be as in* (3.9) *and define*

$$\tilde{b}_j = \tilde{b}_j(c_1, \ldots, c_{\lfloor (j+k)/2 \rfloor - 1}) := \tilde{c}_j - \sum_{\nu=1}^{\lfloor (j+k)/2 \rfloor - 1} a_{j+k-2\nu}\, c_\nu \tag{3.16}$$

for $j = 1, \ldots, \tilde{n}$ *and* $\tilde{b}_j := \infty$ *for* $j < 1$. *Let* $\hat{b}_{m,i} := \infty$ *for* $m > \tilde{n}$ *or* $m < 1$ *and*

$$\hat{b}_{m,i} = \hat{b}_{m,i}(c_1, \ldots, c_{i-1}) := \tilde{c}_m - \sum_{\nu=1}^{i-1} a_{m+k-2\nu}\, c_\nu - \sum_{\nu=i+1}^{\lfloor (m+k)/2 \rfloor} a_{m+k-2\nu}\, q_\nu \tag{3.17}$$

for $i = 1, \ldots, n$ *and* $m = 2i - k + 2, \ldots, 2i$, *where* $q_j := 0$ *for* $j > n$. *Further, let the*

vector $\mathbf{c}$ *be recursively defined by*

$$c_i := \min\left\{ \frac{\tilde{b}_{2i-k}}{a_0}, \frac{\tilde{b}_{2i-k+1}}{a_1}, \frac{\hat{b}_{2i-k+2,i}}{a_2}, \ldots, \frac{\hat{b}_{2i,i}}{a_k} \right\} \quad \textit{for } i = 1, \ldots, n. \tag{3.18}$$

Then $S = \mathbf{c}^T \mathbf{N}_{k,T} \in \mathcal{N}_{k,T}$ *is a monotone and quasi-optimal coarse grid approximation to* $\tilde{S}$*, i.e.,*

$$L_k(x) \le S(x) \le \tilde{S}(x) \quad \textit{for all } x \in I.$$

Proof. We only consider the case k odd as the other case is analogous.

We first derive conditions which guarantee monotonicity (3.6) of the approximation. Moving all entries $a_{i+k-2j}c_j$ of the inequality system (3.6) except for the rightmost nonzero ones in each row to the right-hand side leads to

$$\begin{pmatrix} a_0 & 0 & & \\ a_1 & 0 & & \\ 0 & a_0 & 0 & \\ 0 & a_1 & 0 & \\ & & \ddots & \\ & & 0 & a_0 \\ 0 & \cdots & 0 & a_1 \end{pmatrix} \begin{pmatrix} c_{\ell+1} \\ c_{\ell+2} \\ \vdots \\ c_n \end{pmatrix} \le \begin{pmatrix} \tilde{b}_1 \\ \tilde{b}_2 \\ \tilde{b}_3 \\ \tilde{b}_4 \\ \vdots \\ \tilde{b}_{\tilde{n}-1} \\ \tilde{b}_{\tilde{n}} \end{pmatrix} \tag{3.19}$$

with $\ell := \lfloor (k-1)/2 \rfloor$ and the new right-hand side coefficients $\tilde{b}_i$ defined in (3.16). From (3.19) we immediately obtain that the inequality system $A_k\mathbf{c} \le \tilde{\mathbf{c}}$ is satisfied for arbitrary $c_1, \ldots, c_\ell$ if

$$c_i \le \min\left\{ \frac{\tilde{b}_{2i-k}}{a_0}, \frac{\tilde{b}_{2i-k+1}}{a_1} \right\} \quad \text{for } i = \ell+1, \ldots, n \tag{3.20}$$

holds.

Second, we derive conditions which ensure quasi-optimality $\mathbf{c} \ge \mathbf{q}$ of the approximation. For an arbitrary $j \in \{\ell+1, \ldots, n\}$ the first inequality of (3.20) and definition (3.16) imply

$$a_0 c_j \le \tilde{b}_{2j-k} = \tilde{c}_{2j-k} - \sum_{\nu=1}^{j-1} a_{2j-2\nu}\, c_\nu.$$

For every $i \in \{1, \ldots, j-1\}$, we therefore obtain the condition

$$a_{2j-2i} c_i \le \tilde{c}_{2j-k} - \sum_{\substack{\nu=1 \\ \nu \ne i}}^{j} a_{2j-2\nu}\, c_\nu.$$

When we determine c_i, we can assume that the c_ν's for $\nu = 1, \ldots, i-1$ are already computed. For the c_ν, $\nu = i+1, \ldots, j$, which are yet to be determined, demanding quasi-optimality $c_\nu \ge q_\nu$ leads to

$$a_{2j-2i} c_i \le \tilde{c}_{2j-k} - \sum_{\nu=1}^{i-1} a_{2j-2\nu}\, c_\nu - \sum_{\nu=i+1}^{j} a_{2j-2\nu}\, q_\nu = \hat{b}_{2j-k,i} \tag{3.21}$$

with $\hat{b}_{j,i}$ defined in (3.17). Analogously we get

$$a_{2j-2i+1}c_i \le \hat{b}_{2j-k+1,i} \tag{3.22}$$

for $i < j$ using the second inequality of (3.20). Because of $a_m = 0$ for $m > k$, the inequalities (3.21) and (3.22) only apply for $i+1 \le j \le i+\ell$ so that we obtain the conditions

$$c_i \le \min\left\{ \frac{\hat{b}_{2i-k+2,i}}{a_2}, \ldots, \frac{\hat{b}_{2i,i}}{a_k} \right\} \tag{3.23}$$

for $i = 1, \ldots, n$. Then both (3.20) and (3.23) are satisfied by defining c_i, $i = 1, \ldots, n$, as in (3.18) which completes the proof. ∎

Remark 3.11. If one only aims at a coarse grid approximation S which is monotone by construction, one could use the relation (3.20) and replace the inequality by an equality sign. However, in many cases the as-large-as-possible choice of the components c_i according to (3.20) then has to be balanced to preserve monotonicity by very small, maybe even negative components c_j, $j > i$, which leads to undesirable oscillations in the solution. This is avoided by taking in addition the lower bounds into consideration.

Example 3.12. In the case $k = 2$ the recursion (3.18) recovers the direct solution

$$c_i = \min\{2\,\tilde{c}_{2i-2} - c_{i-1},\ \tilde{c}_{2i-1},\ 2\,\tilde{c}_{2i} - q_{i+1}\} \tag{3.24}$$

from Lemma 3.8. For $k = 3$ the recursion (3.18) simplifies to

$$c_i = \min\left\{4\,\tilde{c}_{2i-3} - 3\,c_{i-1},\ \tfrac{4}{3}\tilde{c}_{2i-2} - \tfrac{1}{3}c_{i-1},\ \tfrac{4}{3}\tilde{c}_{2i-1} - \tfrac{1}{3}q_{i+1},\ 4\,\tilde{c}_{2i} - 3\,q_{i+1}\right\}. \tag{3.25}$$

In the case $k = 4$, one obtains

$$\begin{aligned} c_i := \min\big\{&8\tilde{c}_{2i-4} - c_{i-2} - 6c_{i-1},\ 2\tilde{c}_{2i-3} - c_{i-1},\ \tfrac{4}{3}\tilde{c}_{2i-2} - \tfrac{1}{6}(c_{i-1} + q_{i+1}),\\ &2\tilde{c}_{2i-1} - q_{i+1},\ 8\tilde{c}_{2i} - 6q_{i+1} - q_{i+2}\big\}, \end{aligned} \tag{3.26}$$

where we use the notation that all terms in (3.24)–(3.26) which involve c_j with $j < 1$ or q_j with $j > n$ have to be omitted.

Using (3.2) and exploiting the fact that the number of nonzero terms in each of the sums in the definitions (3.16) and (3.17) is bounded by k, the above algorithm works in optimal complexity.

THEOREM 3.13. *For fixed $k \in \mathbb{N}$, the costs of the OCGC algorithm is restricted by $O(n)$ operations.*

Next, we visualize the effect of our algorithm. In Figure 3.2, one can see a C^1-smooth, piecewise quadratic upper obstacle, the coarse grid approximation obtained by the OCGC algorithm, the coarse grid approximation $L_3 \in \mathcal{N}_{3,T}$ according to Proposition 3.4, and the optimal coarse grid approximation obtained by the simplex algorithm. (Recall, however, that the simplex algorithm does not yield the solution in optimal complexity.) The improvement of the OCGC approximation over the spline L_3 is clearly visible. There is no difference of our OCGC approximation to the optimal coarse grid approximation obtained by the simplex method, except for a slight variation in the interval [0,2]. This difference seems to be caused by boundary effects which has been confirmed in further numerical experiments. As expected, smooth parts of the obstacle are very well approximated, while variations of the obstacle

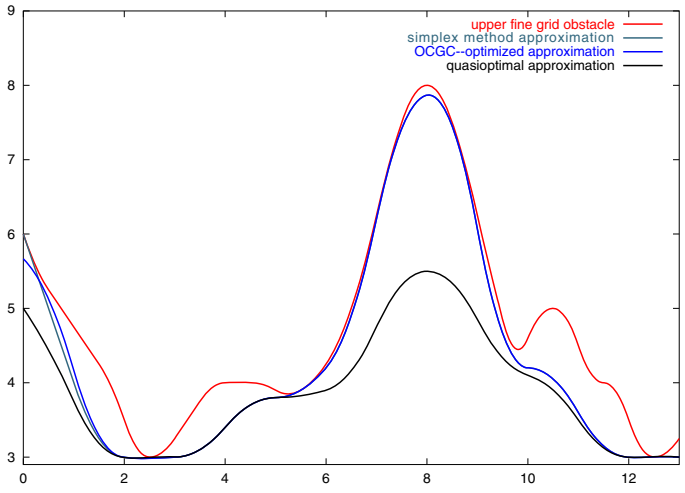

FIG. 3.2. *Right: C^1-smooth, quadratic upper obstacle function on the fine grid $\Delta := [0,13] \cap \mathbb{Z}/2$ with OCGC-optimized quadratic restriction, the optimal coarse grid approximation obtained by the simplex method and lower quasi–optimal barrier L_3, all three of which are defined on the coarse grid $T := [0,13] \cap \mathbb{Z}$.*

of higher frequency can only be partly approximated as it is visible in the interval $[10,12]$. In this example, the control polygon of the B-spline coefficients of the OCGC approximation (which is not displayed here) is partly above the control polygon of the obstacle function, although by construction the OCGC approximation always lies below the obstacle. This indicates that the result of our OCGC algorithm is superior to alternative methods in which monotone approximations are obtained via monotone restrictions of control polygons.

4. Higher spatial dimensions. In the multivariate case $\Omega \subset \mathbb{R}^d$, using (2.12), a d-dimensional spline $S : \Omega \to \mathbb{R}$ of order k can be represented by

$$S(x) = \sum_{i \in \mathbb{I}_c} c_i \, N^{(d)}_{i,k,T}(x) =: \mathbf{c}^T \, \mathbf{N}^{(d)}_{k,T}(x), \quad x \in \Omega, \tag{4.1}$$

with coefficients $\mathbf{c} \in \mathbb{R}^{n^d}$ and indices from $\mathbb{I}_c := \{i \in \mathbb{N}^d : 1 \le i_m \le n,\ m = 1, \dots, d\}$. The two-scale relation (3.4) attains the multivariate refinement relation

$$N^{(d)}_{i,k,T} = \sum_{j \in J} a^{(d)}_j \, N^{(d)}_{2i-k+j,k,\Delta} \tag{4.2}$$

with the index set $J := \{j \in \mathbb{N}^d : 0 \le j_m \le k \text{ for } m = 1, \dots, d\}$ and the subdivision coefficients

$$a^{(d)}_j := 2^{(1-k)d} \prod_{\nu=1}^{d} \binom{k}{j_\nu} \quad \text{for } j \in J. \tag{4.3}$$

The extension of Theorem 3.2 then reads as follows.

THEOREM 4.1 (monotone coarse grid approximation). *The spline* $S = \mathbf{c}^T \mathbf{N}_{k,T}^{(d)}$ *is a monotone coarse grid approximation to the upper obstacle* $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}^{(d)}$ *if their B-spline expansion coefficients satisfy the linear inequality system*

$$A_k^{(d)}\, \mathbf{c} \;\le\; \tilde{\mathbf{c}} \tag{4.4}$$

with the tensor product matrix $A_k^{(d)} := A_k \otimes \ldots \otimes A_k \in \mathbb{R}^{(\tilde{n}\times n)^d}$ *and* A_k *as in* (3.6).

Proof. The proof follows by the same arguments as in the univariate case, by using the refinement relation (4.2) and applying the multivariate version of Lemma 2.3 to

$$\tilde{S}(x) - S(x) = \sum_{i\in\mathbb{I}_f} (A_k^{(d)}\, \mathbf{c} \,-\, \tilde{\mathbf{c}})_i \, N_{i,k,\Delta}^{(d)}(x),$$

where $\mathbb{I}_f := \{i \in \mathbb{N}^d : \, 1 \le i_m \le \tilde{n},\ m = 1, \ldots, d\}$ using the nonnegativity of (tensor product) B-splines. ∎

Example 4.2. In the special case of C^2-smooth, piecewise cubic ($k = 4$) splines on a two-dimensional domain, the system (4.4) reads

$$\begin{pmatrix}
\frac{4}{8}A_4 & \frac{4}{8}A_4 & & & & & & \\
\frac{1}{8}A_4 & \frac{6}{8}A_4 & \frac{1}{8}A_4 & & & & & \\
 & \frac{4}{8}A_4 & \frac{4}{8}A_4 & & & & & \\
 & \frac{1}{8}A_4 & \frac{6}{8}A_4 & & & & & \\
 & & & \ddots & \ddots & & & \\
 & & & & & \frac{6}{8}A_4 & \frac{1}{8}A_4 & \\
 & & & & & \frac{4}{8}A_4 & \frac{4}{8}A_4 &
\end{pmatrix}
\begin{pmatrix} c_{1,1} \\ \vdots \\ c_{1,n} \\ \vdots \\ \vdots \\ c_{n,1} \\ \vdots \\ c_{n,n} \end{pmatrix}
\le
\begin{pmatrix} \tilde{c}_{1,1} \\ \vdots \\ \tilde{c}_{1,\tilde{n}} \\ \tilde{c}_{2,1} \\ \vdots \\ \tilde{c}_{2,\tilde{n}} \\ \vdots \\ \tilde{c}_{\tilde{n},1} \\ \vdots \\ \tilde{c}_{\tilde{n},\tilde{n}} \end{pmatrix}.$$

As all rows in the system (4.4) sum to one we immediately obtain from Theorem 4.1 the following generalization of Proposition 3.4.

PROPOSITION 4.3. *The spline* $L_k := \mathbf{q}^T\, \mathbf{N}_{k,T}^{(d)}$ *with expansion coefficients*

$$q_i := \min\{\tilde{c}_j : \; 2i_m - k \le j_m \le 2i_m,\ m = 1, \ldots, d\} \quad \text{for } i \in \mathbb{I}_c \tag{4.5}$$

(leaving out $\tilde{c}_j$ *in the right-hand side if* $j_m < 1$ *or* $j_m > \tilde{n}$*) is a monotone coarse grid approximation to the obstacle function* $\tilde{S} = \tilde{\mathbf{c}}^T \mathbf{N}_{k,\Delta}^{(d)}$.

In the special case $k = 2$ Fourier–Motzkin elimination can be applied to the inequality system (4.4) with the constraint $\mathbf{c} \ge \mathbf{q}$ as in the univariate case to obtain Lemma 3.8 for arbitrary d.

LEMMA 4.4 (direct solution for hat functions). *Define the sum* $s_{\ell,i}$ *of all neighboring coarse grid coefficients* c_j *to a given fine grid coefficient* $\tilde{c}_\ell$ *except* c_i *by*

$$s_{\ell,i} := \sum_{\{j\in\mathbb{I}_c:\, j\ne i,\, |\theta_{j+1} - \tilde{\theta}_{\ell+1}| < H\}} c_j \quad \text{for } \ell \in \mathbb{I}_f,\ i \in \mathbb{I}_c,$$

with the Euclidean distance $|\cdot|$ *and the mesh size* H *of the coarse grid. Define* $\bar{s}_{\ell,i}$ *as* $s_{\ell,i}$ *with the modification that all coefficients* c_j *in the sum which are not yet known*

are replaced by q_j given from (4.5). *Then, for $k = 2$, a monotone and quasi-optimal coarse grid approximation is recursively given by*

$$c_i := \min\{2^{\sum_{m=1}^d |\ell_m-(2i_m-1)|}\,\tilde{c}_\ell - \bar{s}_{\ell,i} :\ 2i_m - 2 \le \ell_m \le 2i_m \ \ \textit{for}\ \ m = 1,\dots,d\}$$

for $i \in \mathbb{I}_c$, leaving out $\tilde{c}_j$ in the right-hand side if $j_m < 1$ or $j_m > \tilde{n}$.

To improve the approximation from Proposition 4.3 in the case $k > 2$, the OCGC algorithm can be applied recursively with respect to the dimension d as follows.

THEOREM 4.5 (optimized coarse grid correction (OCGC) scheme for $d > 1$). *The OCGC algorithm applied dimension-recursively to the multivariate inequality system* (4.4) *provides in optimal complexity of $O(n^d)$ arithmetic operations a coarse grid approximation S which satisfies the monotonicity and quasi-optimality condition*

$$L_k(x) \le S(x) \le \tilde{S}(x) \quad \textit{for all } x \in \Omega.$$

Proof. We provide the proof for the case $k = 3$; the other cases follow immediately by exchanging the system matrix $A_3^{(d)}$ by $A_k^{(d)}$. The $(n \times \tilde{n})^d$ tensor product matrix $A_3^{(d)}$ can be written as a $n \times \tilde{n}$ matrix of $(n \times \tilde{n})^{(d-1)}$ tensor product matrices

$$A_3^{(d)} := \begin{pmatrix}
\frac{3}{4}A_3^{(d-1)} & \frac{1}{4}A_3^{(d-1)} & & & & & \\
\frac{1}{4}A_3^{(d-1)} & \frac{3}{4}A_3^{(d-1)} & & & & & \\
 & \frac{3}{4}A_3^{(d-1)} & \frac{1}{4}A_3^{(d-1)} & & & & \\
 & \frac{1}{4}A_3^{(d-1)} & \frac{3}{4}A_3^{(d-1)} & & & & \\
 & & & \ddots & \ddots & & \\
 & & & & \frac{3}{4}A_3^{(d-1)} & \frac{1}{4}A_3^{(d-1)} & \\
 & & & & \frac{1}{4}A_3^{(d-1)} & \frac{3}{4}A_3^{(d-1)} &
\end{pmatrix}.$$

Accordingly, we define $\mathbf{c}_{i\bullet} := (c_{ij})_{i=1,\dots,n,j\in\mathbb{N}^{(d-1)}:\,1\le j_l\le n} \in \mathbb{R}^{n^{(d-1)}}$. Applying the OCGC algorithm for $d = 1$ (3.25) to this formulation, we obtain for $i = 1,\dots n$ the conditions

$$\begin{aligned} A_3^{(d-1)}\mathbf{c}_{i\bullet} \le \min\{&4\,\tilde{c}_{2i-3\bullet} - 3A_3^{(d-1)}\,c_{i-1\bullet}, \tfrac{4}{3}\tilde{c}_{2i-2\bullet} - \tfrac{1}{3}A_3^{(d-1)}c_{i-1\bullet}, \\ &\tfrac{4}{3}\tilde{c}_{2i-1\bullet} - \tfrac{1}{3}A_3^{(d-1)}q_{i+1\bullet}, 4\,\tilde{c}_{2i\bullet} - 3A_3^{(d-1)}\,q_{i+1\bullet}\} \end{aligned}$$

for $\mathbf{c}_{i\bullet} \in \mathbb{R}^{n^{(d-1)}}$. Each of these conditions can again be reduced by one dimension by a further application of the OCGC algorithm until the whole system is solved. As the complexity of the OCGC algorithm is $O(n)$, the overall complexity is given by $O(n^d)$ arithmetic operations. ∎

Example 4.6. In the case $k = 3$ and $d = 2$ the multivariate OCGC algorithm is defined as follows:

(1) For given $\tilde{\mathbf{c}} \in \mathbb{R}^{\tilde{n}^2}$ determine $\mathbf{q} \in \mathbb{R}^{n^2}$ by (4.5).

(2) For $i = 1,\dots,n$

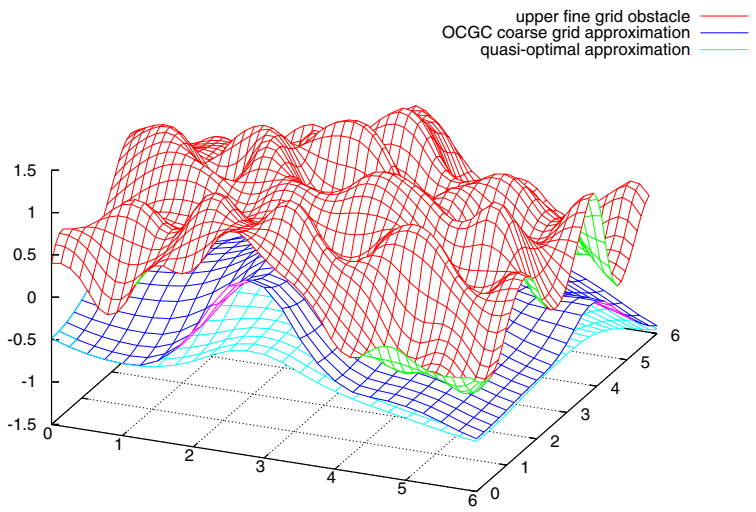

FIG. 4.1. *Two-dimensional C^1-smooth, quadratic, upper obstacle function defined on fine grid $[0,6]^2 \cap (\mathbb{Z}/2)^2$ and coarse grid approximations from Proposition* 4.3 *(quasi-optimal) and Theorem* 4.5 *(OCGC) on the coarse grid $[0,6]^2 \cap \mathbb{Z}^2$.*

define $\mathbf{g} \in \mathbb{R}^n$ by $g_j := q_{i,j}$ and $\mathbf{f} \in \mathbb{R}^{\tilde{n}}$ by $f_j := \min\{4\,\tilde{c}_{2i-3,j} - 3(A_3\, c_{i-1}\bullet)_j,$
$\frac{4}{3}\tilde{c}_{2i-2,j} - \frac{1}{3}(A_3 c_{i-1}\bullet)_j, \frac{4}{3}\tilde{c}_{2i-1,j} - \frac{1}{3}(A_3 q_{i+1}\bullet)_j, 4\,\tilde{c}_{2i,j} - 3(A_3\, q_{i+1}\bullet)_j\}$,
solve the univariate problem $A_3\mathbf{e} \le \mathbf{f}, \quad \mathbf{e} \ge \mathbf{g}$ by the 1d-OCGC Algorithm,
set $c_{i,j} := e_j$.

The splines which correspond to the coefficient vector $\mathbf{q}$ and $\mathbf{c}$ from Proposition 4.3 and Theorem 4.5, respectively, are displayed in Figure 4.1 for a given upper obstacle function defined on the fine grid $[0,6]^2 \cap (\mathbb{Z}/2)^2$.

The resulting MMG method in the multivariate case can now be implemented by adding the projection operator (2.11) and the obstacle approximation from Theorem 4.5 to a standard multigrid method. The standard multigrid method for tensor products of higher order B-splines is described, e.g., in [Hö, HRW] for the case $d > 1$.

5. Convergence theory for B-spline-based MMG methods. It is shown in [Ko1] that MMG methods are globally convergent and asymptotically reducing to a linear subspace correction method, provided nodal basis functions and monotone and quasi-optimal restriction operators $\tilde{r}$ are used. Because of the lack of such restriction operators for smooth functions, the MMG method has so far been restricted to hat functions. Using B-splines as basis functions, we have already transferred the scheme to functions of general smoothness in section 2. Suitable restriction operators have been constructed in sections 3 and 4. We have established in the extended version of this paper [HzK] that all convergence results from [Ko1] can be transferred to B-spline basis functions, using their expansion coefficients instead of function values.

6. Numerical example. To present a numerical example from the area of Mathematical Finance, we choose the domain $\Omega_{\mathcal{L}} := \mathbb{R}^+ \times [0,T)$, the differential

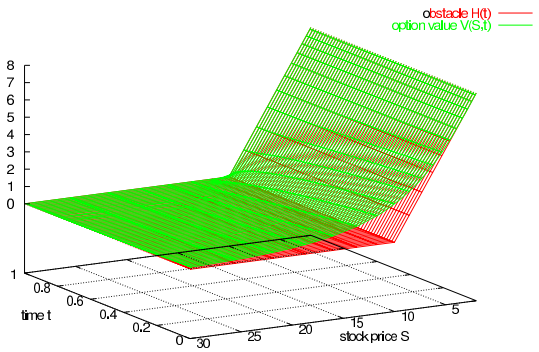

FIG. 6.1. *Solution $V(S,t)$ of the linear complementary problem* (6.2).

operator

$$\mathcal{L} := \frac{\partial}{\partial t} + \frac{1}{2}\sigma^2 S^2 \frac{\partial^2}{\partial S^2} + rS\frac{\partial}{\partial S} - r, \tag{6.1}$$

and the function $\mathcal{H}(S) := (K-S)^+$. We consider the linear complementary problem to find $V = V(S,t) \in H^1(\Omega_{\mathcal{L}})$, such that

$$\begin{aligned} [(\mathcal{L}\,V)(S,t)]\,(V(S,t) - \mathcal{H}(S)) &= 0, \\ (\mathcal{L}\,V)(S,t) &\le 0, \\ V(S,t) &\ge \mathcal{H}(S) \end{aligned} \tag{6.2}$$

holds for all $(S,t) \in \Omega_{\mathcal{L}}$, with boundary data $V(S,t) = 0$ for $S \to \infty$, $V(S,t) = \mathcal{H}(S)$ for $S \to 0$ and final data $V(S,T) = \mathcal{H}(S)$ for $S \in \mathbb{R}^+$.

As it is shown in [WHD], the solution V describes the fair value of an *American put option* with strike price K and maturity T which depends on an underlying stock with value S and volatility σ. No analytical solution is known for the problem (6.2) so that one has to resort to numerical solution schemes. In the numerical experiments we used for the linear complementary problem (6.2), the parameters $K = 10$ for the strike price, $T = 1$ for maturity, $\sigma = 0.6$ for volatility, and $r = 2.5\%$ for the interest rate. The numerical solution V and the obstacle function $\mathcal{H}$ are displayed in Figure 6.1 in the case of $M = N = 64$ grid points in space and time.

If the obstacle function is set to minus infinity, the solution V describes the fair value of a *European put option* (see [WHD]). In that case an analytical solution is known and given by the famous Black–Scholes formula; see [BS].

Using a Crank–Nicolson finite difference scheme for the time discretization and at least continuous piecewise finite elements for the space discretization, the method converges quadratically. Employing higher order finite element functions, the derivatives of the solution V which provide important hedge parameters in the option pricing context can be determined by direct differentiation of the basis functions. Using B-spline

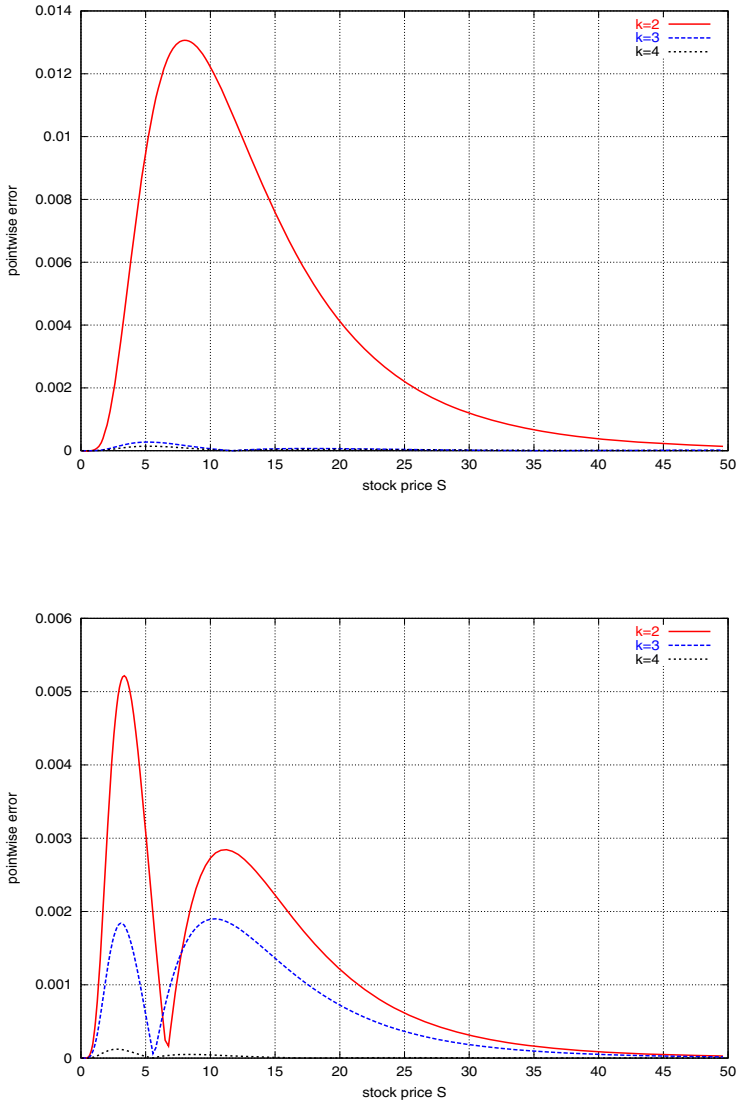

FIG. 6.2. *Comparison of pointwise error for* Delta *and* Gamma *at time* $t = 0$ *for orders* $k = 2, 3, 4$ *and* $N = M = 275$.

bases of order k we obtain all derivatives up to the $(k-2)$th derivative in quadratic convergence. In particular, pointwise derivatives, the so-called Greek letters, can be computed up to high accuracy. These results, as well as extensive discussion, can be found in [Hz]. As an illustration of the impressible difference a variable order k may offer, we display in Figure 6.2 only the pointwise errors of $Delta := \frac{\partial V}{\partial S}$ and $Gamma := \frac{\partial^2 V}{\partial S^2}$.

In view of this application, we would like to point out that our higher order MMG method could also be applied to the valuation of basket options, at least for small

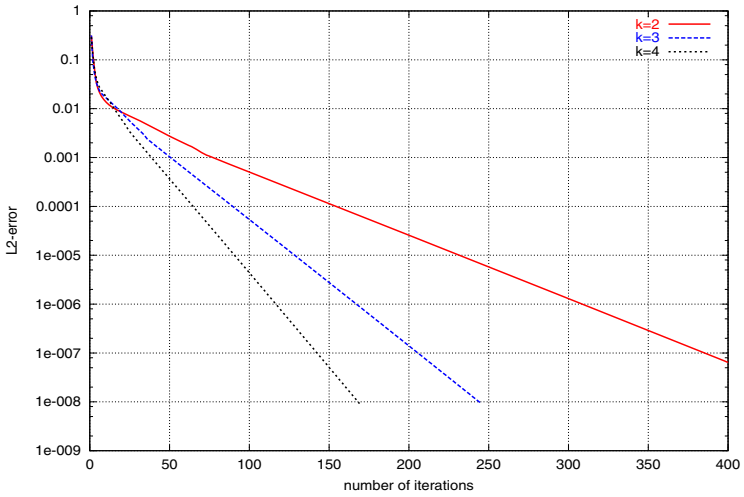

FIG. 6.3. *PSOR–iteration history of one time step with* $M = 256$.

baskets with $d = 2$ or $d = 3$. Similar to the univariate case, the multivariate Black–Scholes equation can be transformed into a multivariate heat diffusion problem, as shown in [RW].

6.1. Convergence behavior of Gauss–Seidel and MMG schemes. In the following, only one time step of problem (6.2) is considered to analyze the performance of the multigrid scheme. In Figure 6.3, the iteration errors of the projected Gauss–Seidel scheme are displayed for different orders k. The impact of the order k is clearly visible. Next we compare the convergence behavior of the following methods:

PSOR	Projected Gauss–Seidel scheme,
MMG	Monotone multigrid method with optimized approximation of the obstacle according to Lemma 3.8 and Theorem 3.10,
TrMMG	Truncated version of the monotone multigrid method [Ko1] with optimized approximation of the obstacle according to Lemma 3.8 and Theorem 3.10,
MMG (q-opt)	Monotone multigrid method with simple approximation of the obstacle according to Proposition 3.4,
TrMMG (q-opt)	Truncated version of the monotone multigrid method with simple approximation of the obstacle according to Proposition 3.4,
MG	Linear multigrid method applied to the unrestricted problem.

To analyze the influence of the order k on the convergence behavior, the case $k = 2$ is systematically compared to the case $k = 3$. For $k > 3$ similar results are expected. In the experiments of the finance parameters used in the previous section, the finest level $L = 7$ and a random initial guess have been chosen. To make sure that the iteration does not terminate too early, we have selected independently of the discretization error the stopping criterion

$$\|u_L^{\nu+1} - u_L^{\nu}\|_\infty \leq 10^{-12},$$

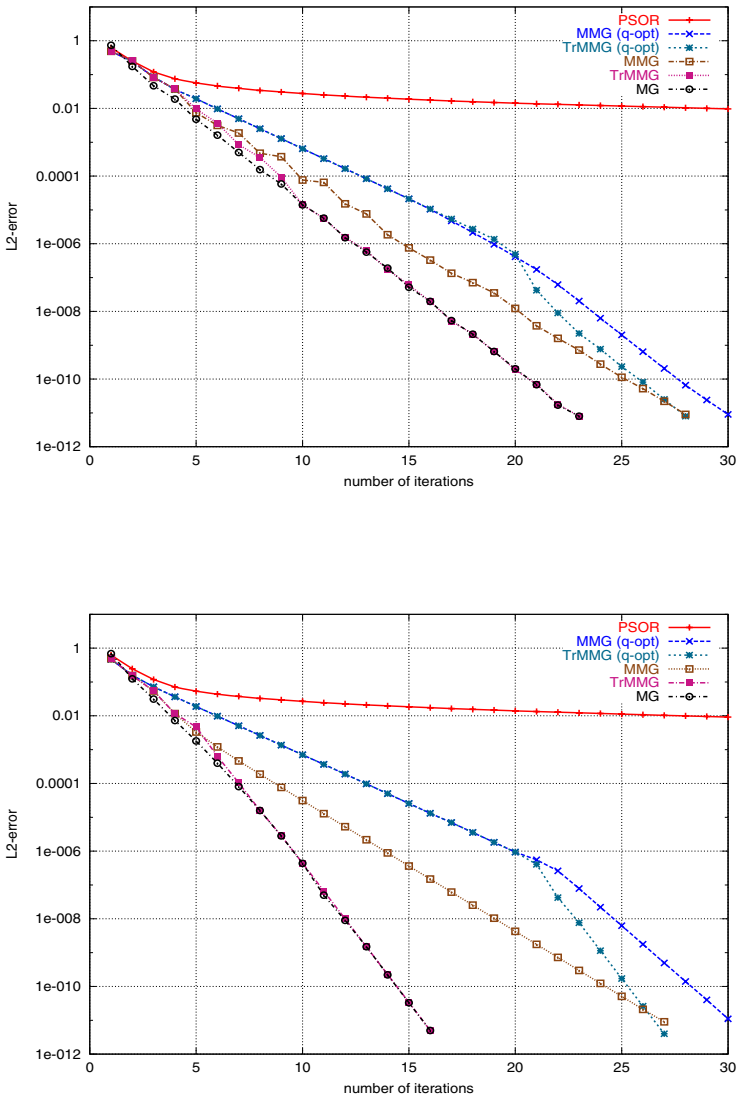

FIG. 6.4. *Iteration history for hat functions ($k = 2$) (top) and for C^1-smooth basis functions ($k = 3$) (bottom).*

where u_L^ν denotes the νth iterate on the finest grid L.

The numerical results are summarized in Figure 6.4 and Table 6.1. In the third column in Table 6.1, the number ν_0 of iterations needed to identify the contact set $K^\bullet(u_L)$ is displayed. In the next column $\sharp$`It.`, we list the number of iterations which are needed to solve the problem up to machine accuracy. To compare the costs of the schemes, we employ the definition of a work unit (`WU`) from [BC]. A work unit $\texttt{WU} = \texttt{WU}_L$ denotes the costs of one iteration step of the projected Gauss–Seidel scheme on the finest grid L. The costs $\texttt{WU}_\ell$ of one iteration step on level $\ell \leq L$ is then given

	Scheme	1 smoothing step			2 smoothing steps		
		ν_0	♯ It.	♯WU	ν_0	♯ It.	♯ WU
$k=2$	PSOR	134	403	403	—	—	—
	MMG (q-opt)	6	30	59.06	5	21	82.69
	TrMMG (q-opt)	7	28	55.13	5	17	66.94
	MMG	7	28	55.13	5	14	55.13
	TrMMG	7	23	45.28	5	13	51.19
$k=3$	PSOR	103	447	447	—	—	—
	MMG (q-opt)	5	31	61.03	4	20	78.75
	TrMMG (q-opt)	6	27	53.16	4	17	66.94
	MMG	5	27	53.16	4	14	55.13
	TrMMG	5	16	31.5	4	11	43.31

TABLE 6.1

Number of iterations needed to identify the contact set and to compute the solution up to machine accuracy and the cost in work units.

by

$$\mathtt{WU}_\ell = 2^{L-\ell}\,\mathtt{WU}_L.$$

The number of work units which is needed to reach the stop criteria is displayed in the last column ♯WU in Table 6.1.

The numerical results show that already one or two smoothing steps are sufficient with regard to cost and accuracy. In comparison to the Gauss–Seidel relaxation, the cost is substantially reduced in the multigrid schemes. The truncated versions TrMMG and TrMMG (q-opt) converge in all cases faster than the standard versions MMG or MMG (q-opt). Moreover, multigrid methods with an optimized approximation of the obstacle according to Lemma 3.8 or Theorem 3.10 converge faster than the simple approximations according to Proposition 3.4. For hat functions, this corresponds to the results in [Ko1]. For the higher order case, this indicates the quality of the OCGC approximations from section 3.4. The contact set is identified correctly by all methods within only a few iterations.

Considering the above results within the time discretization when solving the instationary problem, we wish to point out that the average number of iterations per time step is much smaller. This is due to the fact that the solution of the previous time step serves as a good initial guess. Therefore, we can expect that the asymptotic phase dominates the convergence behavior of the multigrid scheme. The asymptotic multigrid rates are discussed in the following section.

6.2. Multigrid convergence rates. The convergence rate ρ_ℓ of a multigrid scheme with $\ell+1$ levels is given by

$$\|u_\ell^{\nu+1} - u_\ell\|_{\ell_2} \le \rho_\ell \|u_\ell^{\nu} - u_\ell\|_{\ell_2}.$$

Here $u_\ell \in S_\ell$ denotes the exact solution and $u_\ell^\nu \in S_\ell$ the approximate solution in the νth iteration step. A scheme is said to have multigrid convergence if ρ_ℓ is bounded independently of the grid size by a constant $\rho_\infty < 1$.

The asymptotic convergence rates are estimated for the V-cycle of the truncated version TrMMG with $\ell+1$ levels according to

$$\rho_\ell \approx \frac{\|u_\ell^{\nu^*+1} - u_\ell^{\nu^*}\|_{\ell_2}}{\|u_\ell^{\nu^*} - u_\ell^{\nu^*-1}\|_{\ell_2}}.$$

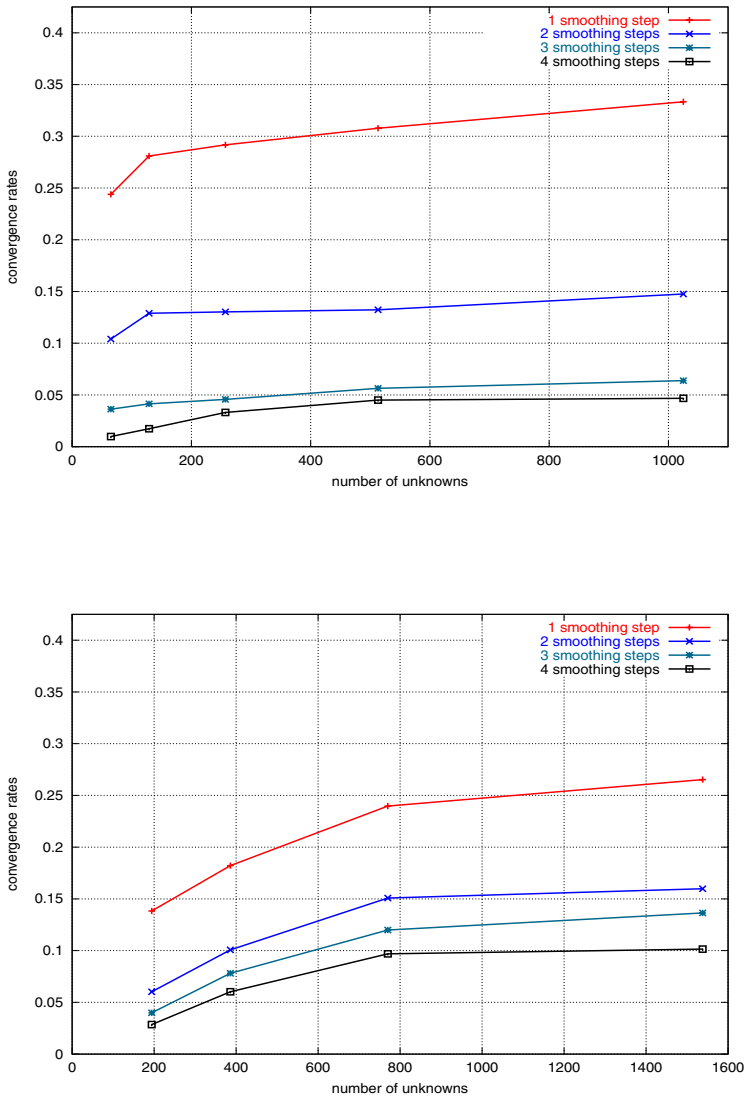

FIG. 6.5. *Asymptotic convergence rates for the case $k = 2$ (left) and $k = 3$ (right) depending on the number M of unknowns.*

Here ν^* is chosen such that $\|u_\ell^{\nu^*+1} - u_\ell^{\nu^*}\|_{\ell_2} \leq 10^{-12}$. In Figure 6.5 the results are displayed on the left-hand side for continuous, piecewise linear basis functions and on the right-hand side for C^1-smooth, piecewise quadratic basis functions. We recover the favorable convergence rates of standard multigrid schemes which are bounded in our case by $\rho_\infty \approx 0.31$ $(k = 2)$ and $\rho_\infty \approx 0.27$ $(k = 3)$ in the case of only one smoothing step on each refinement level.

Acknowledgments. We would like to thank Michael Griebel for pointing out the problem of deriving MMG methods based on higher order basis functions and their possible application to the computation of American options. We also want to thank Rolf Krause for helpful discussions on MMG methods.

SMOOTHNESS EQUIVALENCE PROPERTIES OF MANIFOLD-VALUED DATA SUBDIVISION SCHEMES BASED ON THE PROJECTION APPROACH*

GANG XIE† AND THOMAS P.-Y. YU†

Abstract. Interpolation of manifold-valued data is a fundamental problem which has applications in many fields. The linear subdivision method is an efficient and well-studied method for interpolating or approximating real-valued data in a multiresolution fashion. A natural way to apply a linear subdivision scheme $\overline{S}$ to interpolate manifold-valued data is to first embed the manifold at hand into an Euclidean space and construct a projection operator P that maps points from the ambient space to a closest point on the embedded surface, and then consider the *nonlinear* subdivision operator $S := P \circ \overline{S}$. When applied to symmetric spaces such as S^{n-1}, $SO(n)$, $SL(n)$, $SE(n)$, $G(n,k)$ the projection method can also be carried out in such a way that the resulting schemes enjoy natural coordinate invariance properties and robust numerical implementations. Despite such nice features, the mathematical analysis of such nonlinear subdivision schemes is in its infancy. In this article, we attack the so-called smoothness equivalence conjecture, which asserts that the smoothness property of S is exactly the same as that of $\overline{S}$. We show that in the cases of S^{n-1}, $SO(n)$, and related manifolds, we have a proximity condition of the form $|(S-\overline{S})y|_\infty \cdot \sum_{i=1}^{p-1} |\Delta^i y|_\infty |\Delta^{p-i} y|_\infty$, where p is the accuracy order of $\overline{S}$. Armed with this proximity condition and other known approximation theoretic results, we can establish the result that the Hölder smoothness exponent of S is always as high as that of $\overline{S}$—no matter how high the latter is.

Key words. linear subdivision schemes, nonlinear subdivision schemes, Riemannian manifold, Lie groups, sphere, $SO(n)$, smoothness, approximation order, closest point projection, interpolation, singular value decomposition

1. Introduction.

Given a smooth manifold $\mathcal{M}$ and a sequence of points $p_i \in \mathcal{M}$ on the manifold (called a control polygon), a fundamental problem is to find a smooth curve that either interpolates or approximates the control polygon. A typical application in robotics and computer vision is rigid body motion interpolation, in which the manifold is the Lie group $\mathcal{M} = SE(3)$ [2]. In the curve design problem on the sphere described in [27], we have $\mathcal{M} = \mathbb{S}^2$. In the "grand tour" method for visualizing p-dimensional data points based on ortho-projection of the points to two-dimensional subspaces [1], we have the Grassmannian manifold $\mathcal{M} = G(p,2)$. Time series that take values on a Grassmannian manifold $G(n,k)$ also arise in array signal processing. There is also a lot of interest in numerical analysis for interpolation in Lie groups, especially in the geometric methods for numerical solution of ODEs; see, e.g., [20, 18, 17].

Some, if not many, of the existing methods for the manifold interpolation problem appear to be quite specific to the manifold at hand. On the other hand, in certain applications it is quite desirable that the curve be given in various levels of detail; in this case subdivision-based methods would be very attractive.

In recent papers [30, 24, 31], various general subdivision methods have been proposed which can be used to subdivide data that takes values on a manifold (or data that obeys some other forms of nonlinear constraints). A common feature of these methods is that they are all based on adapting a linear subdivision scheme to a manifold, resulting in nonlinear algorithms that are easy to implement but difficult to analyze. Since in each case the method is based on taking a *linear* subdivision scheme and applying it to subdivision of data obeying *nonlinear* constraints, we refer to such a method as a *linearization* method. Here, we discuss the following three classes of linearization methods:

- *Tangent plane approach*: In this approach, the basic operation is that for any given $p \in \mathcal{M}$ there is a map f_p with inverse f_p^{-1} such that the map points in a neighborhood of p back and forth between the manifold and the tangent plane $T_p\mathcal{M}$. Then a subdivided point is obtained from a group of points in the coarser scale by first mapping these points to the tangent plane based at one of these points using the corresponding map f_p, then applying the linear subdivision rule in $T_p\mathcal{M}$ (a linear space) and mapping the subdivided point in the tangent plane back to the manifold using f_p^{-1}. The specific f_p and f_p^{-1} proposed in [24] are the logarithmic and exponential maps (in either the setting of a Riemannian manifold or Lie group; see, e.g., [3, 11]); we refer to this linearization method as the *Log-Exp scheme*.
- *Factorization-geodesic scheme*: The mask of any linear subdivision scheme can be factorized (in a nonunique way) into a number of two point weighted averages [30, Theorem 1]. On any Riemannian manifold, the notion of geodesic is well defined, and so one can perform subdivision based on replacing the weighted averages by "weighted geodesic averages." See [30] for details.
- *Projection approach*: In this approach $\mathcal{M}$ is supposed to be immersed or embedded in an Euclidean space $\mathbb{R}^n$; as such, we view $\mathcal{M}$ as a subset of $\mathbb{R}^n$. Also a projection operator that maps points in a neighborhood of $\mathcal{M}$ onto $\mathcal{M}$ is chosen. A natural example of such an operator would be the one that maps a $p \in \mathbb{R}^n$ to a point in $\mathcal{M}$ *closest* to p. We refer to this as the *closest point projection scheme*. A subdivision step is based on first applying the linear subdivision rule in $\mathbb{R}^n$, resulting in points that are typically not in $\mathcal{M}$, then followed by applying the projection operator to force these subdivided points back to $\mathcal{M}$.

Any of the above linearization methods can be used in conjunction with an arbitrary linear subdivision scheme.

The Log-Exp scheme and the factorization-geodesic schemes are both based on geodesics and are *intrinsic* in nature, whereas the projection approach is *extrinsic* in nature: in the projection approach, one may have two isometric embeddings of a given Riemannian manifold $(\mathcal{M}, g)$ into two Euclidean spaces, and the (closest point, say) projection scheme may result in two different curves on $\mathcal{M}$ for the same set of initial points on $\mathcal{M}$. From a practical point of view, the projection method is probably the most natural to use for manifolds with a "natural" embedding[1] into an Euclidean space, e.g., $\mathbb{S}^n \hookrightarrow \mathbb{R}^{n+1}$, $SO(n) \hookrightarrow SL(n) \hookrightarrow GL(n) \hookrightarrow \mathbb{R}^{n\times n}$, or $SE(n) \hookrightarrow GL(n+1) \hookrightarrow \mathbb{R}^{(n+1)\times(n+1)}$.

[1] If G is a group that acts transitively on $\mathcal{M}$, some authors call an embedding $\Phi : \mathcal{M} \to \mathbb{R}^n$ *natural* if there is a smooth group homomorphism $\rho : G \to SE(n)$ such that $\phi(g \cdot x) = \rho(g) \cdot \Phi(x)$ for all $x \in \mathcal{M}$ and $g \in G$.

1.1. Linear subdivision schemes. We recall in this section some of the basic definitions, notions, and notation related to linear subdivision schemes. We keep the exposition to the minimum, as there are plenty of references on this topic; see, for example, [4, 14, 25, 6, 7] and the references therein.

In the simplest setting, a linear stationary subdivision scheme is defined by a linear operator S on $\ell(\mathbb{Z}) := \{x \mid x : \mathbb{Z} \to \mathbb{R}\}$ of the form

$$(Sx)(2k) = \sum_{i\in\mathbb{Z}} x(i)\, a_e(k-i), \quad (Sx)(2k+1) = \sum_{i\in\mathbb{Z}} x(i)\, a_o(k-i), \tag{1.1}$$

where a_e and a_o are two finitely supported real-valued sequences such that $\sum_i a_e(i) = \sum_i a_o(i) = 1$. This operator is usually written by analysts in the following more compact form: $(Sx)(k) = \sum_{i\in\mathbb{Z}} x(i)\, \mathbf{a}(k-2i)$. Here, $\mathbf{a}$ is called the *mask* of the subdivision scheme and can be easily assembled from the a_o and a_e above.

If $a_e = \delta_0$ (the Kronecker sequence), then we say S is *interpolatory*. Interpolatory subdivision schemes were first studied in [12, 9].

A subdivision operator S is meant to be *iterated*. Moreover, for any initial sequence $v : \mathbb{Z} \to \mathbb{R}$, one is supposed to visualize $S^j v$ as a function on the grid $2^{-j}\mathbb{Z}$, as opposed to a function on $\mathbb{Z}$ as our mathematical notation may unduly suggest. We say S is *convergent* if for any $v \in \ell(\mathbb{Z})$ the sequence $f_j := \sum_{k\in\mathbb{Z}} v_{j,k} 1_{[2^{-j}k,\, 2^{-j}(k+1))}$, $j = 0, 1, 2, \ldots$, $v_j := S^j v$, converges uniformly on compact sets to a limit function; we denote this (necessarily unique) limit function by $S^\infty v$. For a convergent subdivision operator S, we define its critical Hölder smoothness (a.k.a. L^∞-Lipschitz smoothness) by

$$s_\infty(S) := \inf_{v\in\ell^\infty} \sup\{\alpha : S^\infty v \in \operatorname{Lip}\alpha\}. \tag{1.2}$$

While a subdivision scheme S as defined above operates on scalars, one can apply it in a componentwise fashion to m-vectors; this, in particular, gives a practical curve drawing algorithm with input being a coarse control polygon in $\mathbb{R}^m$ ($m = 2$ or 3). When we later write Sy, where y is a sequence of m-vectors, this is to be interpreted as the componentwise application of S to y.

For any (finite or infinite) sequence of m-vectors $y = (y_i)_{i\in\mathcal{I}}$, $y_i \in \mathbb{R}^m$, $\mathcal{I} = \mathbb{Z}$ or $\{1, \ldots, n\}$, we write

$$|y|_\infty := \sup_{i\in\mathcal{I}} \|y_i\|_2$$

and define its difference sequences by $(\Delta y)_i := y_i - y_{i-1}$, $(\Delta^k y)_i := (\Delta^{k-1}y)_i - (\Delta^{k-1}y)_{i-1}$, $k > 1$, where i ranges through the appropriate set of indices when $\mathcal{I}$ is finite. We denote by $\ell^\infty(\mathbb{Z} \to \mathbb{R}^m)$, or simply ℓ^∞ when there is no source of confusion, the space of all sequences $y : \mathbb{Z} \to \mathbb{R}^m$ such that $|y|_\infty$ is finite.

An interpolatory subdivision scheme S is said to have approximation order p ($\in \mathbb{Z}_+$) if for any bounded C^p function $f : \mathbb{R} \to \mathbb{R}$ the interpolant of f on the grid $h\mathbb{Z}$ defined by

$$f_h := (S^\infty v)(\cdot/h), \quad v_k = f(kh), \tag{1.3}$$

satisfies

$$\|f - f_h\|_\infty = O(h^p), \quad h \to 0.$$

For an interpolatory scheme S, it is not hard to show that, based on simple twists of the arguments already presented by Dubuc [12], S has approximation order p if and only if S reproduces the polynomial space Π_{p-1}, i.e., $S(p\,|_{\mathbb{Z}}) = p\,|_{\frac{1}{2}\mathbb{Z}}$ for all $p \in \Pi_{p-1}$. This condition imposes a set of linear conditions on the mask of S.

If $s_\infty(S) > p$, then S must have approximation order $p+1$; the converse is far from the truth: an interpolatory scheme can have an arbitrarily high approximation order but an arbitrarily low smoothness.

1.2. Smoothness equivalence. Intuitively, both the Log-Exp scheme and the factorization-geodesic scheme try to use geodesics to mimic weighted averages (1.1) on a manifold locally. Hence, one may expect that the nonlinearities presented in the resulting schemes are rather weak *at fine subdivision levels*. This seems to be true in the sense that the nonlinearity at fine scales is too weak to affect either the smoothness or the approximation order. We discuss smoothness in this paper and approximation order in a companion paper [35].

From many computational experiments both the Log-Exp scheme and the factorization-geodesic scheme are observed empirically to produce limit paths on the manifold with Hölder regularity exactly the same as that produced by the underlying linear scheme [24, 36]. This is the so-called *smoothness equivalence* property and is conjectured to hold for both the Log-Exp scheme and the factorization-geodesic scheme when applied in conjunction with any linear subdivision scheme on any C^∞ Riemannian manifold.

The smoothness equivalence conjecture is true for both Log-Exp and factorization-geodesic schemes if $\mathcal{M}$ is an Abelian Lie group (e.g., the n-torus $\mathbb{T}^n$) viewed as a Riemannian manifold with a bi-invariant metric. (Caution: For $\mathbb{T}^n$, we are referring to the so-called flat torus; when $n = 2$, it is diffeomorphic, but not isometric, to the bagel-like torus as drawn in $\mathbb{R}^3$ with the induced Riemannian metric from $\mathbb{R}^3$. We still believe that the conjecture is true for the "bagel-like torus," just that the proof is not going to be as trivial.)

The goal of this paper is to study the smoothness equivalence properties of the closest point projection scheme, which is *not* based on geodesics. Our empirical experiments suggest that the corresponding smoothness equivalence conjecture for closest point projection schemes also holds true. We note that, even in the case of the circle $\mathbb{S}^1$ ($\cong \mathbb{T}^1$), the proof is, unlike that for Log-Exp or factorization-geodesic, already not trivial.

1.3. Warming up on the circle. As a warmup, we consider here the case when $\mathcal{M} = \mathbb{S}^1 = \{x \in \mathbb{R}^2 : \|x\|_2 = 1\}$ and the linear subdivision schemes are Deslauriers–Dubuc $2L$-point interpolatory subdivision schemes. Here the metric on $\mathbb{S}^1$ is induced by the standard Euclidean metric of $\mathbb{R}^2$. In this case the geodesic distance is just the arc length on the circle, and the Log-Exp and factorization-geodesic schemes are essentially the same. If $p_{0,k} = [\cos(\theta_{0,k}), \sin(\theta_{0,k})]^T \in \mathbb{S}^1$, and we assume for simplicity that all $\theta_{0,k} \in (-\delta, \delta)$ for a not so big δ, then either scheme generates the subdivided points $p_{j,k} = [\cos(\theta_{j,k}), \sin(\theta_{j,k})]^T$ based on *linearly* subdividing the *angles* $\theta_{j,k}$ using the linear rule:

$$\theta_{j+1,2k} = \theta_{j,k}, \quad \theta_{j+1,2k+1} = \sum_{i=-L+1}^{L} w_i \theta_{j,k+i}. \tag{1.4}$$

Here the w_i's are the mask entries of the $2L$-point Deslauriers–Dubuc scheme; e.g., $w_0 = w_1 = 9/16$, $w_{-1} = w_2 = -1/16$ if $L = 2$. In this case, the Log-Exp scheme

produces a limit function $f : \mathbb{R} \to \mathbb{S}^1$ of the form $f(t) = [\cos(\theta(t)), \sin(\theta(t))]^T$, where $\theta(t)$ is the scalar-valued limit function obtained by applying the Deslauriers–Dubuc scheme to the initial *scalar* data $(\theta_{0,k})_{k\in\mathbb{Z}}$. Thus smoothness equivalence between the linear subdivision scheme and the associated "nonlinear" scheme is readily clear.

On the other hand, the nonlinear subdivision scheme based on closest point projection gives: $p_{j+1,2k} = p_{j,k}$, $p_{j+1,2k+1} = \sum_{i=-L+1}^{L} w_i p_{j,k+i} / \| \sum_{i=-L+1}^{L} w_i p_{j,k+i} \|_2$, or

$$\theta_{j+1,2k} = \theta_{j,k}, \quad \theta_{j+1,2k+1} = \arctan \frac{\sum_{i=-L+1}^{L} w_i \sin(\theta_{j,k+i})}{\sum_{i=-L+1}^{L} w_i \cos(\theta_{j,k+i})}.$$

The smoothness equivalence property is far less obvious in this case. Using Taylor's theorem, one can show that

$$\arctan \frac{\sum_{i=-L+1}^{L} w_i \sin(\theta_{j,k+i})}{\sum_{i=-L+1}^{L} w_i \cos(\theta_{j,k+i})} = \sum_{i=-L+1}^{L} w_i \theta_{j,k+i} + O\left(|\Delta\theta_j|_\infty^3\right). \tag{1.5}$$

Using the proximity and perturbation arguments detailed in this article, the above estimate allows us to conclude that the closest point projection scheme on $\mathbb{S}^1$ shares the same Hölder regularity of the underlying linear subdivision scheme *if the linear scheme has a critical Hölder regularity* $\leqslant 3$. However, when $L \geqslant 4$, the Deslauriers–Dubuc schemes have critical Hölder regularity > 3, and the above estimate is insufficient for proving smoothness equivalence. We can still use (1.5) to conclude that the nonlinear scheme has critical Hölder smoothness no less than 3, but we can no longer conclude that the nonlinear scheme is as smooth as the linear scheme.

We note that (1.5) is a kind of proximity condition between a linear and a nonlinear scheme, similar to, but not the same as, the proximity results in [30]. Using either a general result in [30] or the first part of Theorem 3.7, we have

$$\frac{\sum_{i=-L+1}^{L} w_i p_{j,k+i}}{\| \sum_{i=-L+1}^{L} w_i p_{j,k+i} \|} = \sum_{i=-L+1}^{L} w_i p_{j,k+i} + O\left(|\Delta p_j|_\infty^2\right). \tag{1.6}$$

This is yet another proximity condition. While (1.6) may seem more natural than (1.5), the former is not as powerful as the latter: (1.6) allows us to conclude smoothness equivalence only when the linear scheme has smoothness $\leqslant 2$.

Regardless, neither (1.6) nor (1.5) is nearly good enough to prove the smoothness equivalence conjecture of the $\mathbb{S}^1$-closest point projection scheme based on Deslauriers–Dubuc schemes for an *arbitrary* L, as it is well known that the smoothness of Deslauriers-Dubuc schemes grows unboundedly as $L \to \infty$.

1.4. Contributions and organization of this paper. This paper aims to attack the *arbitrary degree* smoothness equivalence conjectures as described in previous sections. We prove that smoothness equivalence holds when the closest point projection scheme is applied in conjunction with an *arbitrary* linear interpolatory subdivision scheme to data that takes values on $\mathbb{S}^n$, $SO(n)$, and their direct products.

These results stand in contrast to the recent low degree smoothness equivalence results in [30, 29, 36]. Related low degree smoothness equivalence results of nonlinear subdivision schemes arising from other applications can be found in [33, 32, 8].

The idea—and limitation—of [30, 36] are that by bounding the nonlinearity using a quadratic term, one can show smoothness equivalence when—and only when—the

linear scheme has smoothness $\leqslant 2$. Wallner's preprint [29] shows how one may go from "$\leqslant 2$" to "$\leqslant 3$" for certain linear schemes used in conjunction with the factorization-geodesic and the projection schemes.

The key discovery reported in this paper is that the polynomial reproducibility property of a linear interpolatory subdivision scheme $\overline{S}$ can lend itself to a useful "factorization" of the nonlinearity (section 3.1): by bounding the nonlinearity of the $\mathbb{S}^n$-closest point projection scheme expressed in *specific* quadratic terms that involve the interpolatory subdivision mask (see (3.7)-(3.9)), we can somehow lift the quadratic proximity bound $|(S-\overline{S})y|_\infty = O(|\Delta y|_\infty^2)$ into a higher order proximity bound

$$(*) \qquad |(S-\overline{S})y|_\infty \leqslant B_p \sum_{i=1}^{p-1} |\Delta^i y|_\infty |\Delta^{p-i} y|_\infty$$

when $\overline{S}$ *reproduces* Π_{p-1}.

Once $(*)$ is proved, we have a strong enough proximity condition that allows us, when it is combined with the perturbation theorem [8, Theorem 3.3] and a "bootstrapping" argument that relies on the interpolatory property of the subdivision scheme, to prove the desired arbitrary degree smoothness equivalence result. See section 3.2.

In section 3.3, we show how to relax the closest point projection operator to a near-closest projection operation without jeopardizing the arbitrary degree smoothness equivalence property.

In section 4, we show how to extend the main smoothness equivalence result to $SO(n)$, $SE(n)$, and related manifolds.

We discuss in section 5 possible extensions of our results.

In section 2, we streamline some of the general proximity results in [30, 29]. The proofs of a number of lemmas and theorems are recorded in the appendix.

2. General proximity results. The following theorem is a restatement of [29, Theorem 2]. It is an extension of [30, Theorem 2].

THEOREM 2.1. *Let* $T_1, T_2 : \ell^\infty \to \ell^\infty$. *Suppose that there exist* $\delta, A > 0, \mu \in (0,1)$, *and* $\alpha > 1$ *such that for any* $p \in \ell^\infty$ *with* $|\Delta p|_\infty < \delta$ *we have*

$$|\Delta T_1^j p|_\infty \leqslant \mu^j |\Delta p|_\infty \quad \forall j \in \mathbb{N}, \tag{2.1}$$

$$|T_1 p - T_2 p|_\infty \leqslant A |\Delta p|_\infty^\alpha.$$

Then for any $\epsilon > 0$ *there exists* $\delta' > 0$ *such that when* $|\Delta p|_\infty < \delta'$,

$$|\Delta T_2^j p|_\infty \leqslant (\mu + \epsilon)^j |\Delta p|_\infty \quad \forall j \in \mathbb{N}.$$

Our goal is to extend the above theorem to Theorem 2.4. For this purpose, we need the next two lemmas.

LEMMA 2.2. *Let* $T_1, T_2 : \ell^\infty \to \ell^\infty$. *Suppose that there exist* $C, \delta, A > 0$ *and* $\alpha > 1$ *such that for all* $p \in \ell^\infty$ *with* $|\Delta p|_\infty < \delta$ *we have*

$$|\Delta T_1 p|_\infty \leqslant C |\Delta p|_\infty, \tag{2.2}$$

$$|T_1 p - T_2 p|_\infty \leqslant A |\Delta p|_\infty^\alpha. \tag{2.3}$$

Then there exist $C' > 0$ *and* $\delta' > 0$ *such that when* $|\Delta p|_\infty < \delta'$,

$$|\Delta T_2 p|_\infty \leqslant C' |\Delta p|_\infty. \tag{2.4}$$

Proof. See Appendix A.1 for the proof.

The following lemma is an extension of [29, Lemma 2].

LEMMA 2.3. *Let $T_1, T_2 : \ell^\infty \to \ell^\infty$. Suppose that there exist $C, A, \delta > 0$ and $\alpha > 1$ such that for all $p \in \ell^\infty$ with $|\Delta p|_\infty < \delta$ we have*

$$|\Delta T_1 p|_\infty \leqslant C|\Delta p|_\infty, \tag{2.5}$$

$$|T_1 p - T_2 p|_\infty \leqslant A|\Delta p|_\infty^\alpha. \tag{2.6}$$

If T_1 is bounded and linear, then for any $j \in \mathbb{N}$ there exist $\delta_j, C_j > 0$ such that when $|\Delta p|_\infty < \delta_j$,

$$|T_1^j p - T_2^j p|_\infty \leqslant C_j|\Delta p|_\infty^\alpha. \tag{2.7}$$

Proof. See Appendix A.2 for the proof.

THEOREM 2.4. *Let $T_1, T_2 : \ell^\infty \to \ell^\infty$. Suppose that there exist $C, A, \delta > 0$, $\mu \in (0, 1)$, and $\alpha > 1$ such that for all $p \in \ell^\infty$ with $|\Delta p|_\infty < \delta$ we have*

$$|\Delta T_1^j p|_\infty \leqslant C\mu^j|\Delta p|_\infty \quad \forall j \in \mathbb{N}, \tag{2.8}$$

$$|T_1 p - T_2 p|_\infty \leqslant A|\Delta p|_\infty^\alpha. \tag{2.9}$$

If at least one of T_1 and T_2 is bounded and linear, then for any $\epsilon > 0$ there exist $\delta', C' > 0$ such that when $|\Delta p|_\infty < \delta'$,

$$|\Delta T_2^j p|_\infty \leqslant C'(\mu + \epsilon)^j|\Delta p|_\infty \quad \forall j \in \mathbb{N}.$$

Proof. See Appendix A.3 for the proof.

Remark 2.5. In Theorem 2.4, we make the assumption that one of T_1 and T_2 is bounded and linear to accommodate the assumption (2.8) on T_1, which is weaker than (2.1) in Theorem 2.1.

3. Closest point projection scheme for $\mathbb{S}^{m-1}$-valued data. Let $\overline{S}$ be a linear interpolatory subdivision operator defined by

$$(\overline{S}y)_{2k} = y_k, \quad (\overline{S}y)_{2k+1} = \sum_{i=1}^{n} w_i\, y_{k+i+\ell}, \tag{3.1}$$

where $\ell \in \mathbb{Z}$ is fixed. We also assume that $\overline{S}$ reproduces Π_{p-1}. By linearity and the well-posedness of Lagrange interpolation, it is necessary that $p \leqslant n$, and there is a unique mask with $p = n$. Since we are in the business of proving smoothness equivalence, we assume that $\overline{S}$ has at least some smoothness: $s_\infty(\overline{S}) > 0$. This, in turn, implies that (i) $p \geqslant 1$, (ii)

$$\sum_{i=1}^{n} w_i = 1, \tag{3.2}$$

and (iii) there exists a subdivision operator $\overline{S}^{[1]}$ such that $\overline{S}^{[1]} \circ \Delta = \Delta \circ \overline{S}$. The special cases of Deslauriers–Dubuc schemes [12, 9] correspond to $n = 2L$ (i.e., n is even), $\ell = -L$, and $p = n$.

In the z-transform domain, the polynomial reproduction property is equivalent to the existence of a polynomial $b(z)$ such that

$$\sum_{i=1}^{n} w_i' z^{2i} + z^{2n'+1} = (1+z)^p\, b(z), \tag{3.3}$$

where $w_i' = w_{n+1-i}$ and $n' = n + \ell$. By taking derivatives of both sides of (3.3) and evaluating at $z = -1$, we get the sum rules

$$\sum_{i=1}^{n} \binom{2i}{\gamma} w_i' = \binom{2n'+1}{\gamma}, \quad \gamma = 0, \ldots, p-1, \tag{3.4}$$

where $\binom{u}{v}$ is the standard binomial coefficient, i.e.,

$$\binom{u}{v} = \begin{cases} \frac{u!}{v!(u-v)!} & \text{if } u \geqslant v \geqslant 0, \\ 0 & \text{otherwise.} \end{cases}$$

Let $\mathbb{S}^{m-1}$ be the unit sphere in $\mathbb{R}^m$, i.e., $\mathbb{S}^{m-1} = \{x \in \mathbb{R}^m : \|x\| = 1\}$. Let $P : \mathbb{R}^m \backslash \{0\} \to \mathbb{S}^{m-1}$ be the closest point projection operator onto the sphere, i.e., $P(x) = x/\|x\|$.

Consider the nonlinear subdivision operator S for $\mathbb{S}^{m-1}$-valued data defined by

$$(Sy)_{2k} = y_k, \quad (Sy)_{2k+1} = P\left(\sum_{i=1}^{n} w_i y_{k+i+\ell}\right). \tag{3.5}$$

Remark 3.1. The subdivision operation (3.5) is well defined as long as $y : \mathbb{Z} \to \mathbb{S}^{m-1}$ is such that $\sum_{i=1}^{n} w_i\, y_{k+i+\ell} \neq 0$ for all $k \in \mathbb{Z}$. We show in Lemma 3.3 that as long as $|\Delta y|_\infty$ is small enough, $S^j y$ is well defined for all j.

Let $x_1, \ldots, x_n \in \mathbb{S}^{m-1}$ with $\sum_{i=1}^{n} w_i\, x_i \neq 0$. For any $y \in \mathbb{R}^m \backslash \{0\}$,

$$\left\| y - P(y) \right\| = \left\| y - \frac{y}{\|y\|} \right\| = \left| 1 - \|y\| \right| \leqslant \left| 1 - \|y\|^2 \right|. \tag{3.6}$$

Combined with the facts that $x_i \in \mathbb{S}^{m-1}$ and $\sum_i w_i = 1$, we have

$$\left\| \sum_{i=1}^{n} w_i x_i - P\left(\sum_{i=1}^{n} w_i x_i\right) \right\| = \left| 1 - \left\| \sum_{i=1}^{n} w_i x_i \right\| \right| \leqslant \left| 1 - \left\| \sum_{i=1}^{n} w_i x_i \right\|^2 \right| \tag{3.7}$$

$$= \left| \sum_{i=1}^{n} w_i \langle x_i, x_i \rangle - \sum_{i=1}^{n} \sum_{j=1}^{n} w_i w_j \langle x_i, x_j \rangle \right| \tag{3.8}$$

$$= \left| \sum_{i=1}^{n} \sum_{j=1}^{n} c_{i,j}^0 \langle x_i, x_j \rangle \right|,$$

where the $n \times n$ matrix $C_0 = (c_{i,j}^0)$ is given by

$$c_{i,j}^0 := \begin{cases} w_i - w_i^2, & i = j, \\ -w_i w_j, & i \neq j. \end{cases} \tag{3.9}$$

We shall come back to this matrix after a few remarks.

Remark 3.2. Using the identity $\langle x_i, x_j\rangle = 1 - \|x_i - x_j\|^2/2$, we can also rewrite the upper bound (3.7) as

(3.10)
$$\left\|\sum_{i=1}^n w_i x_i - P\left(\sum_{i=1}^n w_i x_i\right)\right\| \leqslant \left|1 - \left\|\sum_{i=1}^n w_i x_i\right\|^2\right| = \left|\frac{1}{2}\sum_{i=1}^n\sum_{j=1}^n w_i w_j \|x_i - x_j\|^2\right|.$$

LEMMA 3.3 (well-definedness of $S^j y$). *There exist $\delta^* > 0$ and $K > 0$ such that for any $y : \mathbb{Z} \to \mathbb{S}^{m-1}$ with $\|\Delta y\|_\infty \leqslant \delta^*$, $|\Delta S^j y|_\infty \leqslant K\delta^*$ and $S^j y$ is well defined for all $j = 1, 2, \ldots$.*

Proof. The proof is easy, and we just give the main idea: (3.10) says that as long as $|\Delta y|_\infty$ is small enough, $(Sy)_k$ stays away from the origin for every k. Since we assume $s_\infty(\overline{S}) > 0$, $|\Delta \overline{S}^j y|_\infty = O(2^{-j\nu})$ for any $0 < \nu < \min(1, s_\infty(\overline{S}))$, with (hidden constant) $\propto |\Delta y|_\infty$. Again by (3.10), S and $\overline{S}$ satisfy the proximity condition (2.9) in Theorem 2.4 (with $\alpha = 2$); hence by the theorem, $|\Delta S^j y|_\infty = O(2^{-j\nu^-})$ for any $\nu^- < \nu$, again with (hidden constant) $\propto |\Delta y|_\infty$. This means that if $|\Delta y|_\infty$ is small enough to begin with, then all $|\Delta S^j y|_\infty$ are small (in fact, decay that exponentially fast as j increases) and all $S^j y$ are well defined. ∎

Remark 3.4. We define convergence of $S^j y$ and the limit function $S^\infty y$ analogous to the linear case. Similar to (1.2), we define

$$s_\infty(S) := \inf_y \sup\{\alpha : S^\infty y \in \operatorname{Lip}\alpha\},$$

where the infimum is taken over all sequences y for which $S^\infty y$ is well defined. Since, for any such y, $|\Delta S^j y|_\infty$ decays and the smoothness of $S^\infty y$ does not depend on the behavior of $S^j y$ at coarse scales, there is no difference if we take the infimum over all y such that $|\Delta y|_\infty \leqslant \delta$, for any $0 < \delta \leqslant \delta^*$, where δ^* is given by Lemma 3.3.

3.1. Main proximity theorem. In this section, we show that the difference between Sy and $\overline{S}y$ can be bounded by the magnitudes of high order differences of y.

LEMMA 3.5. *Let $y_1, \ldots, y_n, z_1, \ldots, z_n \in \mathbb{R}^m$. Suppose*

$$y_i = \sum_{j=1}^n f_{i,j} z_j, \quad i = 1, \ldots, n.$$

Let $F = (f_{i,j})$ and $A_0 = (a^0_{i,j})$ be $n \times n$ real matrices. Then

$$\sum_{i=1}^n\sum_{k=1}^n a^0_{i,k}\langle y_i, y_k\rangle = \sum_{i=1}^n\sum_{k=1}^n a^1_{i,k}\langle z_i, z_k\rangle,$$

where matrix $A_1 = (a^1_{i,k})$ is given by

$$A_1 = F^T A_0 F.$$

The proof is straightforward and we omit it.

Define $d^0_i = x_i$, $i = 1, \ldots, n$, and for $k = 1, \ldots, n$,

$$d^k_i = \begin{cases} d^{k-1}_i, & i = 1, \ldots, k \\ d^{k-1}_i - d^{k-1}_{i-1}, & i = k+1, \ldots, n. \end{cases} \tag{3.11}$$

It follows from Lemma 3.5 and (3.11) that we can further rewrite (3.8) as follows:

$$\sum_{i=1}^{n}\sum_{j=1}^{n} c_{i,j}^{0}\langle x_i, x_j\rangle = \sum_{i=1}^{n}\sum_{j=1}^{n} c_{i,j}^{k}\langle d_i^k, d_j^k\rangle, \quad k = 1,\dots,n-1, \tag{3.12}$$

where $C_k = (c_{i,j}^k)$ is given by

$$C_k = F_{k-1}^T C_{k-1} F_{k-1}, \quad k = 1,\dots,n-1,$$

and

$$F_{k-1} = \begin{pmatrix} I_{k-1} & & & \\ & 1 & & \\ & \vdots & \ddots & \\ & 1 & \cdots & 1 \end{pmatrix}. \quad (I_{k-1} \text{ is the } (k-1)\times(k-1) \text{ identity matrix.}) \tag{3.13}$$

The next result says that the matrix C_k has many vanishing entries when the interpolatory subdivision mask reproduces polynomials; in particular, if $n = p$, i.e., the interpolatory mask has the highest possible order of polynomial reproducibility, then C_{n-1} has the following form:

$$C_{n-1} = \begin{bmatrix} 0 & 0 & \cdots & \cdots & 0 \\ 0 & \cdots & \cdots & 0 & * \\ \vdots & \vdots & \ddots & * & \vdots \\ \vdots & 0 & * & \cdots & \vdots \\ 0 & * & \cdots & \cdots & * \end{bmatrix}.$$

LEMMA 3.6 (vanishing property of C_k). *If the interpolatory subdivision mask that defines the matrices C_k reproduces Π_{p-1}, then $c_{i,j}^k = 0$ if $i = 1$ or $j = 1$ or $i, j \leqslant k$, $i + j \leqslant p + 1$.*

Proof. See Appendix A.4 for the proof.

Lemma 3.6 leads to our main proximity result, as follows.

THEOREM 3.7. *Let $\overline{S}$ be a linear interpolatory subdivision scheme which reproduces Π_{p-1}. There are constants $B_2,\dots,B_p$ such that for any $y : \mathbb{Z} \to \mathbb{S}^{m-1}$ such that* (3.5) *is well defined, we have*

$$\text{if } p \geqslant 1, \quad |\overline{S}y - Sy|_\infty \leqslant B_2 |\Delta y|_\infty^2; \tag{3.14}$$

$$\text{if } p \geqslant 3, \quad |\overline{S}y - Sy|_\infty \leqslant B_k \sum_{i=1}^{k-1} |\Delta^i y|_\infty |\Delta^{k-i} y|_\infty, \quad k = 3,\dots,p. \tag{3.15}$$

Proof. Let $1 \leqslant k \leqslant p$. By Lemma 3.6, $c_{i,j}^k = 0$ when $i = 1$ or $j = 1$ or $i+j \leqslant k+1$. When $k = 1$, we have

$$\left|\sum_{i=1}^{n}\sum_{j=1}^{n} c_{i,j}^1\langle d_i^1, d_j^1\rangle\right| = \left|\sum_{i=2}^{n}\sum_{j=2}^{n} c_{i,j}^1\langle d_i^1, d_j^1\rangle\right| \leqslant \sum_{i=2}^{n}\sum_{j=2}^{n} |c_{i,j}^1| \left\|d_i^1\right\| \left\|d_j^1\right\| \leqslant B_2 |\Delta x|_\infty^2,$$

where B_2 is a constant that depends on $w_1,\dots,w_n$.

If $p \geqslant 3$, then for $3 \leqslant k \leqslant p$,

$$\left|\sum_{i=1}^{n}\sum_{j=1}^{n} c_{i,j}^{k}\,\langle d_i^k, d_j^k\rangle\right| = \left|\sum_{\substack{i+j>k+1\\ i>1,j>1}} c_{i,j}^{k}\,\langle d_i^k, d_j^k\rangle\right| \leqslant \sum_{\substack{i+j>k+1\\ i>1,j>1}} |c_{i,j}^{k}|\,\|d_i^k\|\,\|d_j^k\|$$

$$\leqslant B_k \sum_{i=1}^{k-1} |\Delta^i x|_\infty |\Delta^{k-i} x|_\infty,$$

where B_k is a constant that depends on $w_1, \ldots, w_n$.

Combined with (3.8) and (3.12), the above two estimates yield

$$\text{if } p \geqslant 1, \quad \left\|\sum_{i=1}^{n} w_i x_i - P\left(\sum_{i=1}^{n} w_i x_i\right)\right\|_\infty \leqslant B_2 |\Delta x|_\infty^2;$$

$$\text{if } p \geqslant 3, \quad \left\|\sum_{i=1}^{n} w_i x_i - P\left(\sum_{i=1}^{n} w_i x_i\right)\right\|_\infty \leqslant B_k \sum_{i=1}^{k-1} |\Delta^i x|_\infty |\Delta^{k-i} x|_\infty, \quad k = 3, \ldots, p\,.$$

The above can be applied to any n consecutive entries of an infinite sequence y, so we have proved the theorem. □

3.2. Smoothness equivalence. We now prove the main smoothness equivalence result, as follows.

THEOREM 3.8. *If $\overline{S}$ is a linear interpolatory subdivision scheme with $s_\infty(\overline{S}) > 0$, then*

$$s_\infty(S) \geqslant s_\infty(\overline{S}).$$

To prove this theorem, we need to first recall two results.

The first one is well known; see, e.g., [5, 10], which basically says that one can characterize the Hölder smoothness of a continuous function based on its samples at dyadic points. If $f : \mathbb{R} \to \mathbb{R}$ is bounded and continuous, then for any $\alpha > 0$,

$$\begin{aligned} f \in \text{Lip}\,\alpha \quad &\Longleftrightarrow \quad \exists\, r \in \mathbb{Z}_+,\, r > \alpha, \text{ s.t. } |(\Delta^r f_j)_k|_\infty = O(2^{-j\alpha}) \\ &\Longleftrightarrow \quad \forall\, r \in \mathbb{Z}_+,\, r > \alpha,\, |(\Delta^r f_j)_k|_\infty = O(2^{-j\alpha}), \end{aligned} \tag{3.16}$$

where $f_j := f|_{2^{-j}\mathbb{Z}}$, i.e., $(f_j)_k := f(2^{-j}k)$. These equivalences also imply that the critical Hölder regularity exponent of f can be determined from the exact asymptotic decay rate of $|(\Delta^r f_j)_k|_\infty$ for a large enough differencing order r, i.e.,

$$\sup\{\alpha : f \in \text{Lip}\,\alpha\} = \sup\left\{\alpha : |(\Delta^r f_j)_k|_\infty = O(2^{-j\alpha})\right\}. \tag{3.17}$$

The second result is the perturbation theorem [8, Theorem 3.3]. Originally derived to meet the needs of the analysis of a specific nonlinear subdivision algorithm, the theorem has been proved to be useful in the analysis of other nonlinear subdivision algorithms as well; see [33, 32, 23, 22, 36]. We restate this result in a form convenient to us, as follows.

THEOREM 3.9 (see [8, Theorem 3.3]). *Let $\overline{S}$ be a linear subdivision operator with $s_\infty(\overline{S}) > 0$. Let S be a (linear or nonlinear) subdivision operator that maps $\mathcal{D}(S) \subseteq \ell^\infty$ into itself. Let $y \in \mathcal{D}(S)$. If there exists $\nu > 0$ such that*

$$\left|(S - \overline{S}\,)S^j y\right|_\infty = O(2^{-j\nu}),$$

then S is convergent and $s_\infty(S, y) := \sup\{\alpha : S^\infty y \in \operatorname{Lip}\alpha\} \geqslant \min(\nu, s_\infty(\overline{S}))$.

Proof of Theorem 3.8. By Remark 3.4, it suffices to prove $s_\infty(S, y) := \sup\{\alpha : S^\infty y \in \operatorname{Lip}\alpha\} \geqslant s_\infty(\overline{S})$ for those y such that $|\Delta y|_\infty$ is small.

1° For any $0 < \gamma < \min(1, s_\infty(\overline{S}))$, there exists a constant $C > 0$ such that

$$|\Delta \overline{S}^j y|_\infty \leqslant C\, 2^{-\gamma j} |\Delta y|_\infty \quad \forall\, y \in \ell^\infty.$$

For any $\gamma' \in (0, \gamma)$, let $\epsilon := 2^{-\gamma'} - 2^{-\gamma} > 0$. Then it follows from (3.14) and Theorem 2.4 that there exist $\delta_{\gamma'} > 0$ and $C' > 0$ such that

(3.18)
$$|\Delta S^j y|_\infty \leqslant C'\,(2^{-\gamma} + \epsilon)^j |\Delta y|_\infty = C'\, 2^{-\gamma' j} |\Delta y|_\infty \quad \forall\, y : \mathbb{Z} \to \mathbb{S}^{m-1} \text{ s.t. } |\Delta y|_\infty < \delta_{\gamma'}.$$

2° It suffices to consider a fixed y with $|\Delta y|_\infty$ small enough so that (3.18) can be applied and all $S^j y$ are well defined. Recall Lemma 3.3 and Remark 3.4.

By (3.14) in Theorem 3.7, we have

$$|S(S^j y) - \overline{S}(S^j y)|_\infty \leqslant B_2 |\Delta S^j y|_\infty^2 \overset{(3.18)}{=} O(2^{-2\gamma' j}).$$

Then, by Theorem 3.9, we have $s_\infty(S, y) \geqslant \min(2\gamma', s_\infty(\overline{S}))$. Since γ' can be arbitrarily close to $\min(1, s_\infty(\overline{S}))$, we get

$$s_\infty(S, y) \geqslant \min(2, s_\infty(\overline{S})). \tag{3.19}$$

Thus the theorem is proved if $s_\infty(\overline{S}) \leqslant 2$. From now on we assume $s_\infty(\overline{S}) > 2$.

3° Let q be the unique integer such that

$$p \geqslant q + 1 \geqslant s_\infty(\overline{S}) > q \geqslant 2. \tag{3.20}$$

(Recall that $\overline{S}$ reproduces Π_{p-1} with $p \geqslant s_\infty(\overline{S})$ according to the theory of linear subdivision.)

We use induction to prove

$$s_\infty(S, y) \geqslant q. \tag{3.21}$$

Let $2 \leqslant k < q$. Assume that we have proved $s_\infty(S, y) \geqslant k$. By (3.16),

$$\begin{aligned} &|\Delta^\ell S^j y|_\infty = O(2^{-\ell j}), \quad \ell = 1, \dots, k-1, \\ &|\Delta^k S^j y|_\infty = O(2^{-(k-\epsilon)j}). \end{aligned} \tag{3.22}$$

Since $p > k + 1$, Theorem 3.7 applies, and we have

$$|\overline{S} S^j y - S^{j+1} y|_\infty \leqslant B_{k+1} \sum_{\ell=1}^{k} |\Delta^\ell S^j y|_\infty |\Delta^{k+1-\ell} S^j y|_\infty \overset{(3.22)}{=} O(2^{-(k+1-\epsilon)j}). \tag{3.23}$$

So by Theorem 3.9,

$$s_\infty(S, y) \geqslant \min(k + 1 - \epsilon, s_\infty(\overline{S})) \overset{(3.20)}{=} k + 1 - \epsilon$$

for any $\epsilon > 0$, which implies $s_\infty(S, y) \geqslant k + 1$. This completes the induction.

Since we have now proved (3.21), both (3.22) and (3.23) hold for $k = q$. Using Theorem 3.9 one more time gives

$$s_\infty(S, y) \geqslant \min(q + 1, s_\infty(\overline{S})) \overset{(3.20)}{=} s_\infty(\overline{S}).$$

This completes the proof. ∎

3.3. Near-closest projections onto the sphere. In this section, we show that for projections that are close to the closest point projection onto the sphere, the associated nonlinear schemes are also at least as smooth as the underlying interpolatory linear scheme. Such a result is to be expected: recall that the starting point of our proximity result is the simple inequality in (3.6); it is clear that we can relax P a little to achieve essentially the same upper bound on the right-hand side of (3.6). It is also clear that for any such projection operator, all the arguments for our smoothness equivalence result pertaining to the nonlinear subdivision operator $S = P \circ \overline{S}$ go through verbatim.[2]

In order for $S = P \circ \overline{S}$ to have a chance of being convergent, for any sequence y such that all $S^j y$ are well defined, $|\Delta S^j y|_\infty$ must converge to zero as $j \to \infty$. Also, by (3.10), as long as consecutive points in a sequence $z : \mathbb{Z} \to \mathbb{S}^{m-1}$ are sufficiently close to each other, the points in $\overline{S}z$ can be made as close to the sphere as we want. Therefore, we need to study only the property of P in a neighborhood of the sphere as far as the smoothness analysis of S is concerned.

LEMMA 3.10. *Let $P : \mathbb{R}^m \to \mathbb{S}^{m-1}$. If there exist $\delta, C > 0$ such that when $\big|\|x\| - 1\big| < \delta$,*

$$\cos(\angle(x, P(x))) \geqslant \frac{1 + \|x\|^2 - C(1 - \|x\|^2)^2}{2\|x\|}, \tag{3.24}$$

then $\|P(x) - x\| \leqslant \sqrt{C}\,\big|1 - \|x\|^2\big|$ when $\big|\|x\| - 1\big| < \delta$.

Proof. Since $\langle x, P(x)\rangle = \|x\|\,\|P(x)\|\cos(\angle(x, P(x))) = \|x\|\cos(\angle(x, P(x)))$, it follows from (3.24) that

$$\langle x, P(x)\rangle \geqslant \frac{1 + \|x\|^2 - C(1 - \|x\|^2)^2}{2}.$$

Hence

$$\begin{aligned}
\|P(x) - x\|^2 &= \langle P(x) - x, P(x) - x\rangle \\
&= 1 - 2\langle x, P(x)\rangle + \|x\|^2 \\
&\leqslant 1 - (1 + \|x\|^2 - C(1 - \|x\|^2)^2) + \|x\|^2 \\
&= C(1 - \|x\|^2)^2.
\end{aligned}$$

Thus $\|P(x) - x\| \leqslant \sqrt{C}\,\big|1 - \|x\|^2\big|$. ∎

When P is the closest point projection, we always have $\angle(x, P(x)) = 0$. The above lemma shows that as long as P satisfies (3.24), the same bound (3.8) applies

[2] We abuse notation and extend the definition of P to a map that maps sequences of m-vectors to sequences of points on the sphere; i.e. if y is a sequence of non-zero m-vectors, $P(y)$ is the sequence $P(y)_i = y_i/\|y_i\|$. We will abuse notation in a similar manner later without mention.

with an adjustment of the hidden constant. Consequently, we have the following result.

THEOREM 3.11. *For any projection operator P satisfying* (3.24) *and any interpolatory linear subdivision scheme $\overline{S}$, the corresponding nonlinear subdivision S_P satisfies $s_\infty(S_P) \geqslant s_\infty(\overline{S})$.*

4. Projection scheme for $SO(m)$-valued data and extensions. In this section, we first extend our smoothness equivalence result to the Lie group of special orthogonal matrices:

$$SO(m) = \{Y \in \mathbb{R}^{m\times m} : YY^T = I,\ \det(Y) = 1\}.$$

In order to use the projection approach for data taking values in $SO(m)$, we need to (i) embed $SO(m)$ into an Euclidean space and (ii) define a projection operator P from the Euclidean space to the embedded surface. From a practical point of view, we would also like such a P to be efficiently computable.

There is a natural way to embed $SO(m)$ in $\mathbb{R}^{m^2}$: simply treat every matrix in $SO(m)$ as a point in $\mathbb{R}^{m^2}$. It is not hard to prove that such a procedure indeed defines a smooth embedding; so $SO(m)$ now "looks like" a $m(m-1)/2$-dimensional curved surface in $\mathbb{R}^{m^2}$, and we shall decide how to project a given point outside of this surface onto the surface.

For $X_1, X_2 \in \mathbb{R}^{m\times m}$, define $\langle , \rangle$ by

$$\langle X_1, X_2\rangle := \operatorname{trace}(X_1 X_2^T), \tag{4.1}$$

where $\operatorname{trace}(X) = \sum_{i=1}^m x_{i,i}$ is the trace of a matrix $X = (x_{i,j})$. This inner product induces the so-called Frobenius norm:

$$\|X\|_F := \left(\sum_{i=1}^m \sum_{j=1}^m x_{i,j}^2\right)^{1/2}. \tag{4.2}$$

Recall that for any orthogonal matrices U, V,

$$\|UXV\|_F^2 = \|X\|_F^2. \tag{4.3}$$

If we identify $\mathbb{R}^{m\times m}$ with $\mathbb{R}^{m^2}$, then (4.1) and (4.2) are just the most standard inner product and Euclidean norm (respectively) in $\mathbb{R}^{m^2}$.

We can also extend the definitions of Δ and $|\cdot|_\infty$ to sequences with entries in $\mathbb{R}^{m\times m}$. For example, $|Y|_\infty := \sup_i \|Y_i\|_F$.

The closest point projection onto $SO(m)$ of a matrix with positive determinant can be computed efficiently using its singular value decomposition (SVD); a now-classical reference for (especially the computational aspect of) SVD is [15].

PROPOSITION 4.1. *Let $A \in \mathbb{R}^{m\times m}$ with $\det(A) > 0$. Then*

$$P(A) := \operatorname*{argmin}_{X\in SO(m)} \|A - X\|_F = UV^T = (AA^T)^{-1/2}A, \tag{4.4}$$

where $A = U\Sigma V^T$ is an SVD of A.

Proof. Let $A = U\Sigma V^T$ be an SVD of A, where U, V are orthogonal matrices and D is a diagonal matrix with positive diagonal entries $\sigma_1 \geqslant \cdots \geqslant \sigma_m > 0$. Then

$$\begin{aligned}\operatorname*{argmin}_{X\in SO(m)} \|A - X\|_F &= \operatorname*{argmin}_{X\in SO(m)} \|U\Sigma V^T - X\|_F \\ &= U\left(\operatorname*{argmin}_{X\in SO(m)} \|\Sigma - U^T X V\|_F\right) V^T \\ &= U\left(\operatorname*{argmin}_{R\in SO(m)} \|\Sigma - R\|_F\right) V^T.\end{aligned}$$

It is easy to show that $\operatorname{argmin}_{R\in SO(m)} \|\Sigma - R\|_F = I$:

$$\begin{aligned}\|\Sigma - R\|_F^2 &= \sum_{i=1}^m \left[(\sigma_i - R_{ii})^2 + \sum_{j\neq i} R_{ij}^2\right] = \sum_{i=1}^m \left[(\sigma_i - R_{ii})^2 + (1 - R_{ii}^2)\right] \\ &= \sum_{i=1}^m (\sigma_i^2 + 1 - 2\sigma_i R_{ii}).\end{aligned}$$

Since $R_{ii} \leqslant 1$, the right-hand side is minimized when $R_{ii} = 1$ which, since $R \in SO(m)$, also implies $R = I$. Notice also that $(AA^T)^{-1/2}A = (U\Sigma^2 U^T)^{-1/2}U\Sigma V^T = (U\Sigma^{-1}U^T)U\Sigma V^T = UV^T$. ∎

Remark 4.2. Proposition 4.1 is essentially a result published in [2, 28] and seems to be known to others as well. We present our proof anyway not only because it is short and elementary but also because we want to address a subtle point. First of all, we note that the projection operator defined by (4.4) has the invariance property: $P(R_1 A R_2) = R_1 P(A) R_2$ for any $R_1, R_2 \in SO(m)$. It implies that our resulting subdivision algorithm has the desirable property that it does not depend on the artificial choice of orthogonal coordinate system for representing m-dimensional rotations. Our presentation above is more elementary than that in [2] because we are unconcerned with invariance at the beginning, simply think of $SO(m)$ as a regular surface in $\mathbb{R}^{m^2}$, and use the plain Euclidean metric in $\mathbb{R}^{m^2}$. The approach in [2], instead, considers $SO(m)$ as a subgroup $GL(m)$ and uses a (left-)invariant Riemannian metric of $GL(m)$ in defining "closest." While the two different points of view yield the same projector $P(A) = (AA^T)^{-1/2}A$, the coincidence is due to (4.3) and is specific to $SO(m)$. We will revisit this issue in section 4.2.

Let $X = (X_1, \ldots, X_n)$ with $X_i \in SO(m)$ and $w_1, \ldots, w_n$ be as in (3.1). Then it follows from $\sum_{i=1}^n w_i = 1$ that

$$\left\|\sum_{i=1}^n w_i X_i - X_1\right\|_F = \left\|\sum_{i=1}^n w_i (X_i - X_1)\right\|_F \leqslant \left(\sum_{j=1}^n |w_j|\right) \max_i \|X_i - X_1\|_F. \tag{4.5}$$

Since $\det(X)$ is a continuous function of $X \in \mathbb{R}^{m\times m}$ and $\det(X_1) = 1 > 0$, it follows from (4.5) that there exists $\delta > 0$ such that when $\max_i \|X_i - X_1\|_F < \delta$,

$$\det\left(\sum_{i=1}^n w_i X_i\right) > 0,$$

and consequently Proposition 4.1 can be applied to define $P(\sum_{i=1}^n w_i X_i)$.

Let $\sum_{i=1}^n w_i X_i = U\Sigma V^T$ be the SVD of $\sum_{i=1}^n w_i X_i$, where U, V are orthogonal matrices and Σ is a diagonal matrix with positive diagonal entries $\sigma_1 \geqslant \sigma_2 \geqslant \cdots \geqslant \sigma_m > 0$. Then it follows from Proposition 4.1 that

(4.6)
$$\left\|\sum_{i=1}^n w_i X_i - P\left(\sum_{i=1}^n w_i X_i\right)\right\|_F = \|U\Sigma V^T - UV^T\|_F = \|\Sigma - I\|_F = \left(\sum_{\ell=1}^m (\sigma_\ell - 1)^2\right)^{1/2}$$
$$\leqslant \sqrt{m}\max_\ell |\sigma_\ell - 1| \leqslant \sqrt{m}\max_\ell |\sigma_\ell^2 - 1|.$$

Since $(\sum_{i=1}^n w_i X_i)V = U\Sigma$, it follows that $(\sum_{i=1}^n w_i X_i)v_\ell = \sigma_\ell u_\ell$, where $u_\ell, v_\ell \in \mathbb{S}^{m-1}$ are the columns of U, V respectively. So

$$\sigma_\ell^2 = \|\sigma_\ell u_\ell\|^2 = \left\|\left(\sum_{i=1}^n w_i X_i\right) v_\ell\right\|^2 = \left\langle \left(\sum_{i=1}^n w_i X_i\right) v_\ell, \left(\sum_{i=1}^n w_i X_i\right) v_\ell \right\rangle$$
$$= \sum_{i=1}^n \sum_{j=1}^n w_i w_j v_\ell^T X_j^T X_i v_\ell.$$

Note that $\|(X_i - X_j)v_\ell\|^2 = \langle X_i v_\ell - X_j v_\ell, X_i v_\ell - X_j v_\ell\rangle = 2 - 2v_\ell^T X_j^T X_i v_\ell$; hence

$$\sigma_\ell^2 = \sum_{i=1}^n \sum_{j=1}^n w_i w_j \left(1 - \frac{1}{2}\|(X_i - X_j)v_\ell\|^2\right)$$
$$= 1 - \frac{1}{2}\sum_{i=1}^n \sum_{j=1}^n w_i w_j \|(X_i - X_j)v_\ell\|^2.$$

Thus

$$|\sigma_\ell^2 - 1| = \left|\frac{1}{2}\sum_{i=1}^n \sum_{j=1}^n w_i w_j \|(X_i - X_j)v_\ell\|^2\right|.$$

Now fix ℓ and let $x_i := X_i v_\ell$, $i = 1, \ldots, n$. Then

$$|\sigma_\ell^2 - 1| = \left|\frac{1}{2}\sum_{i=1}^n \sum_{j=1}^n w_i w_j \|x_i - x_j\|^2\right|. \tag{4.7}$$

Note that the right-hand side of (4.7) looks exactly the same as the right-hand side of (3.10). Following exactly the same arguments there, we can show the following: If $p \geqslant 1$,

$$\left|\frac{1}{2}\sum_{i=1}^n \sum_{j=1}^n w_i w_j \|x_i - x_j\|^2\right| \leqslant \sum_{i=2}^n \sum_{j=2}^n |c_{i,j}^1| \left\|d_i^1\right\| \left\|d_j^1\right\|. \tag{4.8}$$

If $p \geqslant 3$, then for $3 \leqslant k \leqslant p$,

$$\left|\frac{1}{2}\sum_{i=1}^n \sum_{j=1}^n w_i w_j \|x_i - x_j\|^2\right| \leqslant \sum_{\substack{i+j>k+1 \\ i>1, j>1}} |c_{i,j}^k| \left\|d_i^k\right\| \left\|d_j^k\right\|, \tag{4.9}$$

where $c_{i,j}^k$ and d_i^k are as defined in section 3.

Parallel to the definition of d_i^k, we define $D_i^0 = D_i$, $i = 1, \ldots, n$, and for $k = 1, \ldots, n$,

$$D_i^k = \begin{cases} D_i^{k-1}, & i = 1, \ldots, k, \\ D_i^{k-1} - D_{i-1}^{k-1}, & i = k+1, \ldots, n. \end{cases}$$

Then for any k and i,

$$d_i^k = D_i^k v_\ell.$$

So

$$\|d_i^k\| = \|D_i^k v_\ell\| \leqslant \|D_i^k\|_2 \|v_\ell\| = \|D_i^k\|_2 \leqslant \|D_i^k\|_F, \tag{4.10}$$

where $\|.\|_2$ denotes the 2-norm of a matrix and we used the fact that $\|Y\|_2 \leqslant \|Y\|_F$ for any matrix Y.

Combining (4.10) with (4.7), (4.8), and (4.9), we get

$$(p \geqslant 1) \qquad |\sigma_\ell^2 - 1| \leqslant \sum_{i=2}^{n} \sum_{j=2}^{n} |c_{i,j}^1| \left\|D_i^1\right\|_F \left\|D_j^1\right\|_F \leqslant B_2 |\Delta X|_\infty^2$$

and for $3 \leqslant k \leqslant p$,

$$(p \geqslant 3) \qquad |\sigma_\ell^2 - 1| \leqslant \sum_{\substack{i+j>k+1 \\ i>1, j>1}} |c_{i,j}^k| \|D_i^k\|_F \|D_j^k\|_F \leqslant B_k \sum_{i=1}^{k-1} |\Delta^i X|_\infty |\Delta^{k-i} X|_\infty,$$

where $B_2, B_3, \ldots, B_p$ are constants that depend only on $w_1, \ldots, w_n$. Combining this with (4.6), we get

$$\left\| \sum_{i=1}^{n} w_i X_i - P\left(\sum_{i=1}^{n} w_i X_i \right) \right\|_F \tag{4.11}$$

$$\leqslant \begin{cases} \sqrt{m}\, B_2 |\Delta X|_\infty^2 & \text{if } p \geqslant 1 \\ \sqrt{m}\, B_k \sum_{i=1}^{k-1} |\Delta^i X|_\infty |\Delta^{k-i} X|_\infty, & k = 3, \ldots, p, \quad \text{if } p \geqslant 3. \end{cases} \tag{4.12}$$

This is essentially the same as (3.14) and (3.15) in Theorem 3.7, on which the proof of Theorem 3.8 is based; this also means that we have proved the following claim.

THEOREM 4.3. *For any interpolating linear subdivision $\overline{S}$, the corresponding closest point projection scheme S for $SO(m)$-valued data satisfies $s_\infty(S) \geqslant s_\infty(\overline{S})$.*

4.1. Extensions to related Lie groups. We consider rigid body displacements:

$$SE(m) = \{T_{A,b} : \mathbb{R}^m \to \mathbb{R}^m \mid T_{A,b}(x) = Ax + b,\ A \in SO(m),\ b \in \mathbb{R}^m\}.$$

There is a standard way to smoothly embed this matrix Lie group into $\mathbb{R}^{(m+1)\times(m+1)}$:

$$T_{A,b} \mapsto \begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix}.$$

This embedding is also a group homomorphism from $SE(m)$ to the general linear group $GL(m+1)$, as $T_{A',b'} \circ T_{A,b} = T_{A'A,A'b+b}$ and

$$\begin{bmatrix} A' & b' \\ 0 & 1 \end{bmatrix} \begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} A'A & A'b+b' \\ 0 & 1 \end{bmatrix}.$$

So, once again, we are in the situation as discussed in Remark 4.2: for the purpose of constructing a subdivision scheme for $SE(m)$-valued data based on a *linear* subdivision scheme $\overline{S}$, we take the point of view that $SE(m)$ is a regular surface in the *linear space* $\mathbb{R}^{(m+1)\times(m+1)}$; however, for the purpose of constructing a projection operator P with a sensible invariance property, we should take the point of view that $SE(m)$ is embedded in the Lie group $GL(m)$ and define a projection operator based on a (left-) invariant metric with respect to the group operation. In this case, the projection operator is given by

$$P\left(\begin{bmatrix} A & b \\ 0 & 1 \end{bmatrix}\right) = \begin{bmatrix} UV^T & b \\ 0 & 1 \end{bmatrix}, \tag{4.13}$$

where $A = U\Sigma V^T$ is an SVD of A. However, again as in the case of $SO(m)$, it does not quite matter whether we think of "closest point projection" in terms of the standard Euclidean metric in $\mathbb{R}^{m^2}$ or an invariant metric in $GL(m+1)$.

After all, the most important fact is that the nonlinear subdivision operator $S = P \circ \overline{S}$ with P given by (4.13) and $\overline{S}$ a linear interpolatory subdivision scheme acting componentwise is well defined when applied to any sequence $Y : \mathbb{Z} \to SE(m)$ with a small enough $|\Delta Y|_\infty$; moreover, S has the desirable property that it is invariant under any change of orthogonal reference frame for representing rigid motions in an m-dimensional space.

Motivated by motion design, we are also interested in direct products of $SO(m)$; e.g., one can model the combined motion of 17 major human joints as an element in

$$\underbrace{SO(3)}_{\text{neck}} \times \underbrace{SO(3)\times SO(3)}_{\text{shoulders}} \times \underbrace{SO(2)\times SO(2)}_{\text{elbows}} \times \underbrace{SO(3)\times SO(3)}_{\text{wrists}}$$
$$\times \underbrace{SO(3)\times SO(3)}_{\text{hips}} \times \underbrace{SO(2)\times SO(2)}_{\text{knees}} \times \underbrace{SO(3)\times SO(3)}_{\text{ankles}}$$
$$\times \underbrace{SO(3)\times SO(3)\times SO(3)\times SO(3)}_{\text{spine}}.$$

See [19, Figure 3.2] for a graphical illustration.

It is obvious that we can extend the projection approach to subdivide data taking values on such a direct product. It is also obvious that we can extend Theorem 4.3 to $SE(m)$ and such direct products. For the record, let us state it formally, as follows.

THEOREM 4.4. *Let $\mathcal{M} = SE(m)$ or $\prod_{i=1}^{k} SO(m_i) \times \prod_{j=1}^{k'} SE(n_j)$. For any interpolating linear subdivision $\overline{S}$, the corresponding closest point projection scheme $S = P \circ \overline{S}$ for $\mathcal{M}$-valued data satisfies $s_\infty(S) \geqslant s_\infty(\overline{S})$.*

4.2. $SL(m)$. We recall once again the dual view first discussed in Remark 4.2. This time we consider the matrix Lie group of all measure- and orientation-preserving linear transformations:

$$SL(m) := \{Y \in \mathbb{R}^{m\times m} : \det(Y) = 1\}.$$

$SL(m)$ has a natural embedding as a regular hypersurface in $\mathbb{R}^{m^2}$, but is also a subgroup of $GL(m)$. Unlike the cases of $SO(m)$ and $SE(m)$, the two points of view give different projectors. Using the latter setup which offers invariance, the resulting projector P is given by (see [13])

$$A \mapsto A/\det A^{1/m}. \tag{4.14}$$

Note that $P(UAV) = UP(A)V$ for all $U, V \in SL(m)$. On the other hand, solving $\min_{X \in SL(m)} \|A - X\|_F$ is in principle a straightforward application of the method of Lagrange multipliers but gives a very complicated projector—which also lacks invariance—even in dimension $m = 2$.

Our computational experiment (akin to those "smoothness equivalence experiments" found in [33, 23, 24]) clearly indicates that the nonlinear subdivision scheme $S = P \circ \overline{S}$ enjoys the same smoothness equivalence property as in the case of Theorems 3.8, 4.3, 4.4. A proof is yet to be found.

5. Conclusions and discussions. Interpolation of manifold-valued data is a fundamental problem that has applications in many fields. The linear subdivision method is an efficient and very well-studied method for interpolating or approximating real-valued data in a multiresolution fashion. We described in section 1 three sets of approaches for adapting a linear subdivision scheme to subdivide manifold-valued data. The mathematical analysis of such nonlinear subdivision schemes is at its infancy. We mentioned a number of articles which offer some low degree smoothness equivalence results for certain nonlinear subdivision schemes. To the best of our knowledge, this is the first article that attacks the arbitrary degree smoothness equivalence conjectures.

We suspect that Theorems 3.8, 4.3, and 4.4 can be extended to any C^∞ k-dimensional regular surface in $\mathbb{R}^n$ with any near-closest projection operator.

We mention a recent smoothness *non*-equivalence result in the nonlinear subdivision literature: in [37], a seemingly nonadaptive nonlinear subdivision scheme is shown to have a fairly strong data-dependent property, *unlike* any linear subdivision scheme or weakly nonlinear subdivision schemes such as the ones studied in this article. Specifically, it is shown in [37] that a nonlinear convexity-preserving subdivision scheme produces limit curves with critical Hölder regularity depending on the initial data, and the regularity can be anywhere between 1 and 2.

We discuss potential applications of our results in the following two seemingly unrelated problems:

- *Conics-reproducing subdivision scheme.* A standard complaint of standard B-splines and standard linear subdivision schemes is that they can reproduce only polynomials and not conic sections. The industrial standard NURBS uses rational B-splines because rational polynomials can reproduce conics while polynomials cannot. But it is widely argued that NURBS methods lack some of the key advantages of subdivision methods.[3] A linear but *non-stationary* 4-point interpolatory scheme is derived in [14, 26], which reproduces $\mathrm{span}(1, x, \cos(x), \sin(x))$ instead of the usual $\Pi_3 = \mathrm{span}(1, x, x^2, x^3)$, and hence can reproduce circles when the initial control polygon is sampled uniformly from a circle. Given the result in this paper, it seems as though a better way to solve this problem is to use the projection approach. When one demands that a subdivision scheme exactly reproduce a circle, or any

[3]The debate, however, is mostly on surface modeling, not curve modeling.

conic section, or any other prespecified shape $\mathcal{C}$, our proposed method is to use a nonlinear but stationary scheme of the form $S = P_{\mathcal{C}} \circ \overline{S}$, as opposed to the linear but nonstationary scheme proposed in [14, 26]. The projection approach seems more general and flexible: it does not require uniform sampling, it can be used in conjunction with any interpolatory subdivision scheme (not just 4-point), and, for the circle at least, Theorem 3.8 says that the nonlinear scheme is as smooth as the underlying linear scheme. (The exact Hölder regularity of the specific non-stationary 4-point scheme in [14, 26] is not known, but the scheme is shown to be at least C^1.)

- *Normal multiresolution of curves.* Underlying the method of normal multiresolution of curves in [8] is a nonlinear subdivision scheme of almost exactly the same form as those studied in this paper, i.e., $S = P \circ \overline{S}$. The key difference is that the P's in this article are such that $P(y)_i$ is dependent only on y_i, whereas the P in [8] is more data-adaptive: $P(y)_{2i} = y_{2i}$ and $P(y)_{2i+1} =$ an intersection point of $\mathcal{C}$ with the line passing through y_{2i+1} and normal to the line $\overline{y_{2i}\, y_{2i+2}}$. See [8, Figure 2] for a graphical illustration. (Here $\mathcal{C}$ is a planar curve subject to a normal multiresolution analysis.) It is conjectured that the parametrization induced by a normal multisolution has exactly the same smoothness as that of the underlying interpolatory subdivision scheme. Similar to the other low degree smoothness equivalence results in [29, 30, 36], Daubechies et al. prove the smoothness equivalence only when (in the notation of this paper) $s_\infty(\overline{S}) \leqslant 2$. It seems possible to adapt the ideas and results in this paper to solve the full smoothness equivalence conjecture pertaining to normal multiresolution.

Yet another extension is to consider Hermite subdivision schemes on manifolds. See, e.g., [20] for the interests of Hermite interpolation in Lie groups arising from geometric integration of ODEs. Hermite subdivision schemes in the linear setting are quite well studied; see [21, 34, 16] and the references therein. It is not hard to construct Hermite subdivision schemes on Lie groups, but the analysis of such schemes is likely to be difficult.

Finally, it is needless to say that similar smoothness equivalence results for the more intrinsic linearization methods described in section 1 are waiting to be developed.

Appendix.

A.1. Proof of Lemma 2.2. Since $|\Delta x - \Delta y|_\infty \leqslant 2|x-y|_\infty$ for any $x, y \in \ell^\infty$, it follows that

$$|\Delta T_2 p - \Delta T_1 p|_\infty \leqslant 2|T_2 p - T_1 p|_\infty.$$

Combining this with (2.3), we get

$$|\Delta T_2 p - \Delta T_1 p|_\infty \leqslant 2A|\Delta p|_\infty^\alpha \quad \forall\, p \in \ell^\infty,\ |\Delta p|_\infty < \delta.$$

Thus

$$|\Delta T_2 p|_\infty \leqslant |\Delta T_1 p|_\infty + 2A|\Delta p|_\infty^\alpha \quad \forall\, p \in \ell^\infty,\ |\Delta p|_\infty < \delta.$$

Since we have (2.2), it follows that for all $p \in \ell^\infty$ with $|\Delta p|_\infty < \min(\delta, 1)$, we have

$$|\Delta T_2 p|_\infty \leqslant C|\Delta p|_\infty + 2A|\Delta p|_\infty^\alpha = (C + 2A|\Delta p|_\infty^{\alpha-1})|\Delta p|_\infty < (C+2A)|\Delta p|_\infty. \tag{A.1}$$

Therefore (2.4) holds for $C' = C + 2A$ and $\delta' = \min(\delta, 1)$. ∎

A.2. Proof of Lemma 2.3. We use induction. For $j = 1$, (2.7) follows immediately from (2.6) by choosing $\delta_1 = \delta$ and $C_1 = A$. Now suppose that (2.7) holds for some $j \geqslant 1$.

It follows from Lemma 2.2 that there exist $C' > 1$ and $\delta' > 0$ such that when $|\Delta p|_\infty < \delta'$,

$$|\Delta T_2 p|_\infty \leqslant C' |\Delta p|_\infty.$$

Thus for any $j \in \mathbb{N}$,

$$|\Delta T_2^j p|_\infty \leqslant C'^j |\Delta p|_\infty < \delta \quad \text{if } |\Delta p|_\infty < \min(\delta, \delta') C'^{-j}.$$

Since T_1 is bounded and linear, it follows from (2.6) that for $q \in \ell^\infty$ satisfying $|\Delta q|_\infty < \delta$ we have

$$|T_1 p - T_2 q|_\infty \leqslant |T_1 p - T_1 q|_\infty + |T_1 q - T_2 q|_\infty \leqslant |T_1|_\infty |p - q|_\infty + A|\Delta q|^\alpha.$$

Hence if $|\Delta p|_\infty < \min(\min(\delta, \delta') C'^{-j}, \delta_j)$, then

$$\begin{aligned} |T_1^{j+1} p - T_2^{j+1} p|_\infty &\leqslant |T_1|_\infty |T_1^j p - T_2^j p|_\infty + A|\Delta T_2^j p|_\infty^\alpha \\ &\leqslant |T_1|_\infty |T_1^j p - T_2^j p|_\infty + AC'^{j\alpha} |\Delta p|_\infty^\alpha \\ &\leqslant (|T_1|_\infty C_j + AC'^{j\alpha}) |\Delta p|_\infty^\alpha. \end{aligned}$$

This means that (2.7) holds for $j + 1$. By induction, (2.7) holds for any $j \in \mathbb{N}$. ∎

A.3. Proof of Theorem 2.4. Theorem 2.1 already covers the case of $C \leqslant 1$, so we can assume $C > 1$.

For any $\epsilon \in (0, 1 - \mu)$, we can find $N \in \mathbb{N}$ such that $C^{1/N} < 1 + \epsilon/\mu$. So $C\mu^N < (\mu + \epsilon)^N < 1$. Hence when $|\Delta p|_\infty < \delta$,

$$|\Delta T_1^{jN} p|_\infty \leqslant C\mu^{jN} |\Delta p|_\infty \leqslant (C\mu^N)^j |\Delta p|_\infty \quad \forall j \in \mathbb{N}.$$

It follows from (2.8), (2.9), and Lemma 2.2 that there exist $\tilde{C}, \tilde{\delta} > 0$ such that when $|\Delta p|_\infty < \tilde{\delta}$,

$$|\Delta T_2 p|_\infty \leqslant \tilde{C} |\Delta p|_\infty. \tag{A.2}$$

Since one of T_1 and T_2 is bounded and linear, it follows from (2.8), (A.2), (2.9), and Lemma 2.3 that there exist $C_N > 0$ and $\delta_N > 0$ such that when $|\Delta p|_\infty < \delta_N$,

$$|T_1^N p - T_2^N p|_\infty \leqslant C_N |\Delta p|_\infty^\alpha.$$

Now we can apply Theorem 2.1 to operators T_1^N and T_2^N. We have that for any $0 < \epsilon_0 < (\mu + \epsilon)^N - C\mu^N$ there exists $0 < \delta_0 < \delta$ such that

$$|\Delta T_2^N p|_\infty \leqslant (C\mu^N + \epsilon_0) |\Delta p|_\infty \leqslant (\mu + \epsilon)^N |\Delta p|_\infty \quad \text{if } |\Delta p|_\infty < \delta_0.$$

Therefore for $k = 0, 1, \ldots,$ and $r = 0, 1, \ldots, N - 1$

$$|\Delta T_2^{kN+r} p|_\infty \leqslant (\mu + \epsilon)^{kN} |\Delta T_2^r p|_\infty \quad \text{if } |\Delta T_2^r p|_\infty < \delta_0. \tag{A.3}$$

It follows from (A.2) that

$$|\Delta T_2^r p|_\infty \leqslant \tilde{C}^r |\Delta p|_\infty < \delta_0 \quad \text{if } |\Delta p|_\infty < \min(\delta_0, \tilde{\delta}) \tilde{C}^{-r}. \tag{A.4}$$

Combining (A.3) and (A.4), we have

$$|\Delta T_2^{kN+r}p|_\infty \leqslant (\mu+\epsilon)^{kN}\tilde{C}^r|\Delta p|_\infty \leqslant (\mu+\epsilon)^{kN+r}(\mu+\epsilon)^{-N}\tilde{C}^N|\Delta p|_\infty$$

if $|\Delta p| < \delta' := \min(\delta_0, \tilde{\delta})\tilde{C}^{-r}$. Let $C' = (\mu+\epsilon)^{-N}\tilde{C}^N$. Then when $|\Delta p|_\infty < \delta'$,

$$|\Delta T_2^j p|_\infty \leqslant C'(\mu+\epsilon)^j|\Delta p|_\infty$$

for any $j \in \mathbb{N}$ and $|\Delta p|_\infty < \delta'$. ∎

A.4. Proof of Lemma 3.6. By (3.9), $c^0_{i,j} = c^0_{j,i}$ and for $j = 1, \dots, n$,

$$\sum_{i=1}^n c^0_{i,j} = c^0_{j,j} + \sum_{\substack{i=1\\ i\neq j}}^n c^0_{i,j} = w_j - w_j^2 - \sum_{\substack{i=1\\ i\neq j}}^n w_i w_j = w_j - w_j^2 - w_j(1-w_j) = 0. \tag{A.5}$$

Thus the first row and first column of C_0 both sum to zero.

LEMMA A.1. *Let $A_0 = (a^0_{i,j})$ be an $n \times n$ real matrix. For $k = 0, \dots, n-2$, define*

$$A_{k+1} = F_k^T A_k F_k,$$

where F_k is defined by (3.13). *Then for $k = 0, \dots, n-2$, $A_{k+1} = (a^{k+1}_{\alpha,\beta})$ is given by*

$$a^{k+1}_{\alpha,\beta} = \begin{cases} \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} a^0_{i,j}, & \alpha,\beta \leqslant k+1, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+k}{k}\binom{j-1}{\beta-1} a^0_{i,j}, & \alpha > k+1, \beta \leqslant k+1, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-\beta+k}{k} a^0_{i,j}, & \alpha \leqslant k+1, \beta > k+1, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+k}{k}\binom{j-\beta+k}{k} a^0_{i,j}, & \alpha,\beta > k+1. \end{cases} \tag{A.6}$$

Proof. We prove (A.6) by induction. It follows from $A_1 = F_0^T A_0 F_0$ that

$$a^1_{\alpha,\beta} = \sum_{i=\alpha}^n \sum_{j=\beta}^n a^0_{i,j} = \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha}{0}\binom{j-\beta}{0} a^0_{i,j}.$$

This shows that (A.6) is true for $k = 0$.

Suppose that (A.6) is true for $k = q-1$; i.e.,

$$a^q_{\alpha,\beta} = \begin{cases} \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} a^0_{i,j}, & \alpha,\beta \leqslant q, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+q-1}{q-1}\binom{j-1}{\beta-1} a^0_{i,j}, & \alpha > q, \beta \leqslant q, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-\beta+q-1}{q-1} a^0_{i,j}, & \alpha \leqslant q, \beta > q, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+q-1}{q-1}\binom{j-\beta+q-1}{q-1} a^0_{i,j}, & \alpha,\beta > q. \end{cases} \tag{A.7}$$

It follows from $A_{q+1} = F_q^T A_q F_q$ that

$$a_{\alpha,\beta}^{q+1} = \begin{cases} a_{\alpha,\beta}^q, & \alpha,\beta \leqslant q, \\ \sum_{s=\alpha}^{n} a_{s,\beta}^q, & \alpha > q, \beta \leqslant q, \\ \sum_{t=\beta}^{n} a_{\alpha,t}^q, & \alpha \leqslant q, \beta > q, \\ \sum_{s=\alpha}^{n}\sum_{t=\beta}^{n} a_{s,t}^q, & \alpha,\beta > q. \end{cases} \tag{A.8}$$

Substituting (A.7) into (A.8), we get

$$a_{\alpha,\beta}^{q+1} = \begin{cases} \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} a_{i,j}^0, & \alpha,\beta \leqslant q, \\ \sum_{s=\alpha}^{n}\sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-s+q-1}{q-1}\binom{j-1}{\beta-1} a_{i,j}^0, & \alpha > q, \beta \leqslant q, \\ \sum_{t=\beta}^{n}\sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-t+q-1}{q-1} a_{i,j}^0, & \alpha \leqslant q, \beta > q, \\ \sum_{s=\alpha}^{n}\sum_{t=\beta}^{n}\sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-s+q-1}{q-1}\binom{j-t+q-1}{q-1} a_{i,j}^0, & \alpha,\beta > q. \end{cases}$$

Using the following identities on combinatorial numbers,

$$\sum_{s=\alpha}^{n} \binom{i-s+q-1}{q-1} = \binom{i-\alpha+q}{q}, \quad \sum_{t=\beta}^{n} \binom{j-t+q-1}{q-1} = \binom{j-\beta+q}{q},$$

we get

$$a_{\alpha,\beta}^{q+1} = \begin{cases} \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} a_{i,j}^0, & \alpha,\beta \leqslant q, \\ \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-\alpha+q}{q}\binom{j-1}{\beta-1} a_{i,j}^0, & \alpha > q, \beta \leqslant q, \\ \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-\beta+q}{q} a_{i,j}^0, & \alpha \leqslant q, \beta > q, \\ \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-\alpha+q}{q}\binom{j-\beta+q}{q} a_{i,j}^0, & \alpha,\beta > q. \end{cases} \tag{A.9}$$

It can be easily verified that (A.9) agrees with (A.6) when $k = q$. This concludes the proof. □

It follows from Lemma A.1 that for $k = 1, \dots, n-1$,

$$c^k_{\alpha,\beta} = \begin{cases} \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} c^0_{i,j}, & \alpha, \beta \leqslant k, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+k-1}{k-1}\binom{j-1}{\beta-1} c^0_{i,j}, & \alpha > k, \beta \leqslant k, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-1}{\alpha-1}\binom{j-\beta+k-1}{k-1} c^0_{i,j}, & \alpha \leqslant k, \beta > k, \\ \sum_{i=1}^n \sum_{j=1}^n \binom{i-\alpha+k-1}{k-1}\binom{j-\beta+k-1}{k-1} c^0_{i,j}, & \alpha, \beta > k. \end{cases} \tag{A.10}$$

Combining this with (A.5), we get for $k = 1, \dots, n-1$ and $\ell = 1, \dots, n$ that

$$c^k_{\ell,1} = c^k_{1,\ell} = \left\{ \begin{array}{ll} \sum_{i=1}^n \sum_{j=1}^n \binom{j-1}{\ell-1} c^0_{i,j}, & \ell \leqslant k \\ \sum_{i=1}^n \sum_{j=1}^n \binom{j-\ell+k-1}{k-1} c^0_{i,j}, & \ell > k \end{array} \right\} = 0. \tag{A.11}$$

For any $z \in \mathbb{R}$ and $\ell \in \mathbb{N} \cup \{0\}$, the generalized binomial coefficient $\binom{z}{\ell}$ is defined as

$$\binom{z}{\ell} = \frac{z(z-1)\cdots(z-\ell+1)}{\ell!}.$$

For each fixed ℓ, let $q_\ell(z) = \binom{z}{\ell}$. Then $q_\ell(z)$ is the unique polynomial in z of degree ℓ satisfying

$$q_\ell(0) = q_\ell(1) = \cdots = q_\ell(\ell-1) = 0, \quad q_\ell(\ell) = 1.$$

Furthermore, $q_0(z), q_1(z), \dots, q_\ell(z)$ form a basis of the polynomial space Π_ℓ. So for each $\gamma \in \mathbb{N} \cup \{0\}$, there exist constants $\tau^\gamma_0, \dots, \tau^\gamma_\gamma$ satisfying

$$\binom{n - \frac{z}{2}}{\gamma} = \sum_{j=0}^{\gamma} \tau^\gamma_j \binom{z}{j}.$$

Combining this with (3.4), we get for $\gamma = 0, \dots, p-1$

$$\sum_{i=1}^n \binom{n-i}{\gamma} w'_i = \sum_{i=1}^n \sum_{j=0}^{\gamma} \tau^\gamma_j \binom{2i}{j} w'_i = \sum_{j=0}^{\gamma} \tau^\gamma_j \binom{2n'+1}{j} = \binom{n-n'-\frac{1}{2}}{\gamma}. \tag{A.12}$$

More generally, for each $\gamma_1, \gamma_2 \in \mathbb{N} \cup \{0\}$, there exist constants $\tau^{\gamma_1,\gamma_2}_0, \dots, \tau^{\gamma_1,\gamma_2}_{\gamma_1+\gamma_2}$ satisfying

$$\binom{n - \frac{z}{2}}{\gamma_1}\binom{n - \frac{z}{2}}{\gamma_2} = \sum_{j=0}^{\gamma_1+\gamma_2} \tau^{\gamma_1,\gamma_2}_j \binom{z}{j} \qquad \forall z \in \mathbb{R}.$$

Together with (3.4), we get for $\gamma_1 + \gamma_2 \leqslant p-1$

$$\begin{aligned} \sum_{i=1}^n \binom{n-i}{\gamma_1}\binom{n-i}{\gamma_2} w'_i &= \sum_{i=1}^n \sum_{j=0}^{\gamma_1+\gamma_2} \tau^{\gamma_1,\gamma_2}_j \binom{2i}{j} w'_i = \sum_{j=0}^{\gamma_1+\gamma_2} \tau^{\gamma_1,\gamma_2}_j \binom{2n'+1}{j} \\ &= \binom{n-n'-\frac{1}{2}}{\gamma_1}\binom{n-n'-\frac{1}{2}}{\gamma_2}. \end{aligned} \tag{A.13}$$

Therefore it follows from (A.10), (3.9), (A.12), and (A.13) that for $\alpha, \beta \leqslant k$ and $\alpha + \beta \leqslant p + 1$ we have

$$\begin{aligned}
c^k_{\alpha,\beta} &= \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} c^0_{i,j} \\
&= \sum_{i=1}^{n} \binom{i-1}{\alpha-1}\binom{i-1}{\beta-1} w_i - \sum_{i=1}^{n}\sum_{j=1}^{n} \binom{i-1}{\alpha-1}\binom{j-1}{\beta-1} w_i w_j \\
&= \sum_{i=1}^{n} \binom{n-i}{\alpha-1}\binom{n-i}{\beta-1} w'_i - \left(\sum_{i=1}^{n} \binom{n-i}{\alpha-1} w'_i\right)\left(\sum_{j=1}^{n} \binom{n-j}{\beta-1} w'_j\right) \\
&= \binom{n-n'-\frac{1}{2}}{\alpha-1}\binom{n-n'-\frac{1}{2}}{\beta-1} - \binom{n-n'-\frac{1}{2}}{\alpha-1}\binom{n-n'-\frac{1}{2}}{\beta-1} \\
&= 0.
\end{aligned}$$

We have completed the proof of Lemma 3.6. □

Acknowledgment. We thank Tom Duchamp for many stimulating discussions.

STEPSIZE CONDITIONS FOR GENERAL MONOTONICITY IN NUMERICAL INITIAL VALUE PROBLEMS*

M. N. SPIJKER†

Abstract. For Runge–Kutta methods and linear multistep methods, much attention has been paid, in the literature, to special nonlinear stability properties indicated by the terms total-variation-diminishing (TVD), strong-stability-preserving (SSP), and monotonicity. Stepsize conditions, guaranteeing these properties, were studied, e.g., by Shu and Osher [*J. Comput. Phys.*, 77 (1988), pp. 439–471], Gottlieb, Shu, and Tadmor [*SIAM Rev.*, 43 (2001), pp. 89–112], Hundsdorfer and Ruuth [*Monotonicity for Time Discretizations*, Dundee Conference Report NA/217 2003, University of Dundee, Dundee, UK, 2003, pp. 85–94], Higueras [*J. Sci. Comput.*, 21 (2004), pp. 193–223] and [*SIAM J. Numer. Anal.*, 43 (2005), pp. 924–948], Spiteri and Ruuth [*SIAM J. Numer. Anal.*, 40 (2002), pp. 469–491], Gottlieb [*J. Sci. Comput.*, 25 (2005), pp. 105–128], and Ferracina and Spijker [*SIAM J. Numer. Anal.*, 42 (2004), pp. 1073–1093] and [*Math. Comp.*, 74 (2005), pp. 201–219]. In the present paper, we obtain a special stepsize condition guaranteeing the above properties, for a generic numerical process. This condition is best possible in a well defined and natural sense. It is applicable to the important class of general linear methods, and it can also be used to answer some open questions, for methods of which the above stability properties were studied earlier.

Key words. initial value problem, method of lines, ordinary differential equation, general linear method, total-variation-diminishing, strong-stability-preserving, monotonicity

1. Introduction.

1.1. Maximal stepsize-coefficients for monotonicity.

Consider an initial value problem for a system of ordinary differential equations of type

$$\frac{d}{dt}U(t) = f(t, U(t)) \quad (t \geq 0), \quad U(0) = u_0. \tag{1.1}$$

We shall deal with step-by-step-methods for finding numerical approximations u_n to the true solution values $U(n\Delta t)$, where Δt denotes a positive stepsize and $n = 1, 2, 3, \ldots$.

The general Runge–Kutta method (RKM) for computing u_n can be written in the form

$$y_i = u_{n-1} \; + \; \Delta t \cdot \sum_{j=1}^{s} a_{ij}\, f((n-1+c_j)\Delta t, y_j) \quad (1 \leq i \leq s+1), \tag{1.2.a}$$

$$u_n = y_{s+1}. \tag{1.2.b}$$

Here $a_{i,j}$ and c_j are parameters defining the method, whereas y_i $(1 \leq i \leq s)$ are intermediate approximations used for computing $u_n = y_{s+1}$ from u_{n-1}. If $a_{ij} = 0$ (for $j \geq i$), the method is called *explicit*.

In the following, $\mathbb{V}$ stands for the vector space on which the differential equation is defined, and $\|\cdot\|$ denotes a convex function on $\mathbb{V}$ (i.e., $\|\lambda v + (1-\lambda)w\| \leq \lambda\|v\| + (1-$

*Received by the editors June 1, 2006; accepted for publication (in revised form) November 17, 2006; published electronically May 22, 2007.

$\lambda)\|w\|$ for $0 \le \lambda \le 1$ and $v, w \in \mathbb{V}$). Much attention has been paid in the literature to the property

$$\|y_i\| \le \|u_{n-1}\| \quad (\text{for } 1 \le i \le s+1). \tag{1.3}$$

Clearly, (1.3) implies $\|u_n\| \le \|u_{n-1}\|$. The latter property, as well as property (1.3), is often referred to by the term *monotonicity* or *strong stability*; it is of particular importance in situations where (1.1) results from (method of lines) semidiscretizations of time-dependent partial differential equations. Choices for $\|\cdot\|$, which occur in that context, include, e.g., the *supremum norm* $\|x\| = \|x\|_\infty = \sup_i |\xi_i|$ and the *total variation seminorm* $\|x\| = \|x\|_{TV} = \sum_i |\xi_{i+1} - \xi_i|$ (for vectors x with components ξ_i). Numerical processes satisfying $\|u_n\|_{TV} \le \|u_{n-1}\|_{TV}$ play a special role in the solution of hyperbolic conservation laws and are called *total variation diminishing*; cf., e.g., Harten [13], Shu [28], Shu and Osher [30], LeVeque [26], and Hundsdorfer and Verwer [21]. We note that, for practical calculations, special importance has been attached to the inequality $\|y_i\| \le \|u_{n-1}\|$ being fulfilled for *all* i with $1 \le i \le s+1$ (rather than just for $i = s+1$); see, e.g., Shu [29] and Gottlieb [8].

Conditions on Δt which guarantee (1.3) were given in the literature, mainly for autonomous differential equations (i.e., f is independent of t). These conditions apply, however, equally well to general f and we discuss them below for that case. In many papers one starts from an assumption about f which, for given $\tau_0 > 0$, essentially amounts to

$$\|v + \tau_0 f(t, v)\| \le \|v\| \quad (\text{for } t \in \mathbb{R},\, v \in \mathbb{V}). \tag{1.4}$$

Assumption (1.4) means that the forward Euler method is monotonic with stepsize τ_0. It can be interpreted as a condition on the manner in which the semidiscretization is performed, in case $\frac{d}{dt}U(t) = f(t, U(t))$ stands for a semidiscrete version of a partial differential equation.

In the literature, *stepsize-coefficients* c were determined such that monotonicity, in the sense of (1.3), is present for all Δt with

$$0 < \Delta t \le c \cdot \tau_0. \tag{1.5}$$

For explicit RKMs, this was done by rewriting the right-hand members of (1.2.a) as convex combinations of forward Euler steps; see, e.g., Shu and Osher [30], Spiteri and Ruuth [31], and Ruuth [27]. For more general RKMs, stepsize-coefficients were obtained, e.g., in Gottlieb, Shu, and Tadmor [10], Higueras [14, 16], and Ferracina and Spijker [6, 7]. We note that, in the context of discretizations for hyperbolic problems, the above coefficients c are sometimes called *CFL coefficients*; see, e.g., Gottlieb and Shu [9] and Shu [29].

The linear multistep method (LMM) for computing u_n can be written in the form

$$u_n = \sum_{j=1}^{k} \alpha_j\, u_{n-j} \;+\; \Delta t \cdot \sum_{j=0}^{k} \beta_j\, f((n-j)\Delta t, u_{n-j}). \tag{1.6}$$

Here α_j, β_j are parameters defining the method and u_n is computed from $u_{n-k}, \ldots, u_{n-1}$. If $\beta_0 = 0$, the method is called *explicit*.

Monotonicity has been studied for (1.6) in the sense of the inequality

$$\|u_n\| \le \max_{1 \le j \le k} \|u_{n-j}\|. \tag{1.7}$$

For explicit LMMs, stepsize-coefficients c, with the property that (1.4), (1.5) guarantee (1.7), were determined by rewriting the right-hand member of (1.6) as a convex combination of forward Euler steps; see, e.g., Shu [28]. Stepsize-coefficients, relevant to more general LMMs, were given, e.g., in Gottlieb, Shu, and Tadmor [10], Hundsdorfer and Ruuth [19], and Hundsdorfer, Ruuth, and Spiteri [20].

Clearly, the larger c is, the less restrictive is condition (1.5). For any given method, the *maximal stepsize-coefficient* c, with the property that (1.4), (1.5) imply monotonicity, is thus an important and characteristic quantity. When comparing the computational efficiency of different methods, it is natural to take these characteristic quantities into account.

Special attention was paid to the problem of determining, for any given RKM, the corresponding maximal stepsize-coefficient; in Higueras [14] and Ferracina and Spijker [6, 7] conditions were given under which this coefficient equals the famous coefficient $R(A, b)$, which was introduced by Kraaijevanger [24]. For completeness, we note also that much attention was paid to the related, but different, problem of optimizing, over given *classes* of RKMs or LMMs, the *special* stepsize-coefficients obtainable via convex combinations of Euler steps; see, e.g., Shu [28], Shu and Osher [30], Gottlieb and Shu [9], Gottlieb [8], Spiteri and Ruuth [31], and Ruuth [27].

Both RKMs and LMMs are examples of methods belonging to the important and very large class of *general linear methods* (GLMs), introduced by Butcher [3], and studied extensively in the literature; see, e.g., Butcher [4, 5], Hairer, Nørsett, and Wanner [12], Hairer and Wanner [11], and the references therein. No theory seems to be available in the literature for determining maximal stepsize-coefficients for arbitrary GLMs.

In this paper, we determine the maximal stepsize-coefficient for a generic numerical process. This result enables us to obtain maximal stepsize-coefficients for arbitrary GLMs and to gain new insights for numerical methods of which the monotonicity properties were studied earlier.

For completeness we note that, already in Burrage and Butcher [2], monotonicity of GLMs was studied, but, for seminorms $\|\cdot\|$ generated by (pseudo) inner products, excluding, e.g., the seminorm $\|\cdot\|_{TV}$. This paper deals with arbitrary convex functions $\|\cdot\|$; as a result, our analysis is largely different from the one in the paper just mentioned.

1.2. Scope of the paper. Section 2 contains our theory for the generic numerical process mentioned above. In section 2.1, we specify GLMs as well as the generic numerical process and characterize them by a pair of matrices S, T. We also give a formal definition of monotonicity.

In section 2.2, we introduce in an algebraic way a coefficient $c(S, T)$, which can be viewed as a generalization of Kraaijevanger's coefficient $R(A, b)$. We state typical properties of $c(S, T)$ in Theorem 2.2. This theorem extends earlier results about $R(A, b)$.

In section 2.3 we state, without proof, the basic results of the paper, Theorems 2.4 and 2.7. These theorems specify situations in which the maximal stepsize-coefficient, for monotonicity of the generic numerical process, is equal to $c(S, T)$. Theorem 2.7 has a wider scope than Theorem 2.4, but the latter theorem has a more simple structure and is of independent interest.

Section 3 contains examples and applications of the theory given in section 2. In section 3.1, we focus on arbitrary GLMs. Theorem 3.1 tells us that the maximal stepsize-coefficient for these methods equals $c(S, T)$. Corollaries 3.3 and 3.4, respec-

tively, show that $c(S,T)$ is not only relevant to monotonicity, but also to a *discrete maximum principle* and *numerical contractivity* of GLMs.

In section 3.2, we apply the preceding theory to RKMs, LMMs, and a class of multistep-multistage methods (MMMs). We arrive at conclusions supplementing earlier results about these methods. In particular, we find (optimal) second order and third order MMMs which we have not seen elsewhere.

In section 3.3, we apply material from section 2 to the interesting class of *additive Runge–Kutta methods*. In this way we obtain Theorem 3.6, which answers an open and fundamental question about these methods.

Section 4 contains the proof of Theorems 2.4 and 2.7. In section 4.1, we prove $c(S,T)$ to be a stepsize-coefficient for the generic numerical process, and in section 4.2 we prove it to be maximal.

2. A theory for monotonicity.

2.1. Monotonicity in a general setting.

2.1.1. General linear methods. The GLM for solving (1.1) depends on parameters c_j $(1 \le j \le m)$ and parameter matrices $S = (s_{i,j}) \in \mathbb{R}^{m\times l}$, $T = (t_{i,j}) \in \mathbb{R}^{m\times m}$, where $1 \le l \le m$. The method can be written in the following form:

$$\text{(2.1.a)} \quad y_i = \sum_{j=1}^{l} s_{ij}\, u_j^{(n-1)} \;+\; \Delta t \cdot \sum_{j=1}^{m} t_{ij}\, f((n-1+c_j)\Delta t,\, y_j) \quad (1 \le i \le m),$$

$$\text{(2.1.b)} \quad u_i^{(n)} = y_{m-l+i} \quad (1 \le i \le l).$$

Here $u_i^{(n-1)}$ are input vectors available at the nth step of the method, whereas y_i are (intermediate) approximations used for computing the input vectors $u_i^{(n)}$ for the next step; cf., e.g., Butcher [4, pp. 336–338] and [5, p. 358] and Hairer, Nørsett, and Wanner [12, p. 390] for related representations of GLMs.

Obviously, the RKM (1.2) is an example of (2.1), with $l = 1,\ m = s+1$, $u_i^{(n)} = u_n \simeq U(n\cdot\Delta t)$, and $s_{i1} = 1,\ t_{ij} = a_{ij}$ (for $1 \le j \le s$), $t_{ij} = 0$ (for $j = s+1$).

The LMM (1.6) is another example of (2.1), with $l = k,\ m = k+1$, and $u_i^{(n)} = u_{n-l+i}$ $(1 \le i \le l)$, $y_i = u_{n-m+i}$ $(1 \le i \le m)$. Method (1.6) can be written in the form (2.1) with $c_j = j-k$, $S = \binom{I}{A}$, $T = \binom{O}{B}$, where I denotes the $k\times k$ identity matrix, O the $k\times(k+1)$ zero matrix and $A = (\alpha_k, \dots, \alpha_1)$, $B = (\beta_k, \dots, \beta_0)$.

We denote the vector space on which the differential equation is defined again by $\mathbb{V}$, and assume $\|\cdot\|$ to be a convex function on $\mathbb{V}$. We will say that method (2.1) is *monotonic* (for the stepsize Δt, function f, and convex function $\|.\|$) if

$$\|y_i\| \;\le\; \max_{1\le j\le l} \|u_j^{(n-1)}\| \quad (\text{for } 1 \le i \le m), \tag{2.2}$$

whenever $u_i^{(n-1)}$ and y_i satisfy (2.1.a). Note that the inequalities (2.2) reduce to (1.3) or (1.7), respectively, if method (2.1) stands for (1.2) or (1.6) in the way just indicated.

In the following, we shall assume that the parameters $s_{i,j}$ satisfy

$$s_{i\,1} + s_{i\,2} + \cdots + s_{i\,l} = 1 \quad (1 \le i \le m). \tag{2.3}$$

This condition is fulfilled if (2.1) stands, in the above way, for (1.2) or (1.6) (provided

$\sum_j \alpha_j = 1$). Moreover, the condition can be seen to be no essential restriction for the general process (2.1): any (preconsistent) GLM can be transformed into an equivalent method satisfying (2.3); see Butcher [5, pp. 358–360] for transformations of GLMs.

2.1.2. A generic numerical process with a simple form. The relations (2.1.a) can be rewritten a bit more compactly. Defining

(2.4)
$$x_i = u_i^{(n-1)} \text{ (for } 1 \le i \le l), \quad f_i(v) = f((n-1+c_i)\Delta t, v) \text{ (for } 1 \le i \le m,\ v \in \mathbb{V}),$$

the relations (2.1.a) reduce to

$$y_i = \sum_{j=1}^{l} s_{ij}\, x_j \ + \ \Delta t \cdot \sum_{j=1}^{m} t_{ij}\, f_j(y_j) \quad (1 \le i \le m). \tag{2.5}$$

Furthermore, when $f : \mathbb{R} \times \mathbb{V} \to \mathbb{V}$ satisfies (1.4), then definition (2.4) implies

$$\|v + \tau_0\, f_i(v)\| \ \le \ \|v\| \quad (\text{for } 1 \le \ i \le \ m \text{ and } v \in \mathbb{V}). \tag{2.6}$$

In the rest of section 2 we shall deal with (2.5) rather than (2.1.a), not only because (2.5) has a more simple form, but also because this widens, in a natural way, the range of applications: in section 3.3 we shall apply our results, to be obtained for the generic process (2.5), to numerical methods which, strictly speaking, are *not* of the form (2.1).

We shall interpret $x_i \in V$ and $y_i \in V$ as *input* and *output vectors*, respectively, of the process (2.5). In the general situation (2.3), (2.5), (2.6), we shall focus on the bound

$$\|y_i\| \ \le \ \max_{1 \le j \le l} \|x_j\| \quad (\text{for } 1 \le i \le m), \tag{2.7}$$

and we will say that process (2.5) is *monotonic* (for the stepsize Δt, functions f_i, and convex function $\|.\|$) if (2.7) holds whenever x_i and y_i satisfy (2.5). Clearly, when (2.5) stands for (2.1.a) via the relations (2.4), then monotonicity of (2.5) corresponds to monotonicity as defined above for the GLM.

In section 2.3 we shall present the basic results of the paper, the best possible stepsize conditions which guarantee monotonicity of process (2.5). In formulating these results we need a coefficient which we first introduce in section 2.2.

2.2. The coefficient $c(S,T)$. Throughout this section we denote by $S \in \mathbb{R}^{m \times l}$ and $T \in \mathbb{R}^{m \times m}$ arbitrary matrices, with property (2.3). In section 2.3 we shall use a coefficient $c(S,T)$ which can be adjoined to S and T. The definition of this coefficient involves the following condition, in which γ denotes a real variable:

$$I + \gamma\, T \text{ is invertible and } (I + \gamma\, T)^{-1} \big[\ S \ \ \gamma\, T\ \big] \ge 0. \tag{2.8}$$

Here I denotes the $m \times m$ identity matrix, and $\big[\ S \ \ \gamma\, T\ \big]$ stands for the $m \times (l+m)$ matrix whose first l columns equal to those of S and whose last m columns equal those of $\gamma\, T$. The inequality in (2.8) should be interpreted entrywise; all inequalities for matrices occurring below are to be interpreted in the same way.

Definition 2.1 (the coefficient $c(S,T)$). *We define $c(S,T) = 0$ if there is no $\gamma > 0$ satisfying* (2.8)*; otherwise*

$$c(S,T) = \sup\{\gamma \ : \ \gamma \text{ satisfies (2.8)}\}.$$

The previous definition may seem to appear out of the blue. The author was led to it, however, by important earlier work of Kraaijevanger [24] and Higueras [16]. In case (2.1) stands for the RKM (1.2) in the way indicated in section 2.1.1, then $c(S,T)$ can be seen to reduce to the coefficient introduced and denoted by $R(A,b)$ in Kraaijevanger [24]; see also section 3.2.1 of this paper. In Higueras [16] the original conditions used by Kraaijevanger for defining his coefficient were simplified to an elegant form which has a resemblance to condition (2.8).

By Definition 2.1 we have $c(S,T) \geq 0$. Part (i) of Theorem 2.2 makes it relatively easy to see whether $c(S,T)$ is zero or not. If $c(S,T) > 0$, part (ii) of Theorem 2.2 is useful for simplifying the (numerical) computation of $c(S,T)$; e.g., by using a bisection-type algorithm as in Ferracina and Spijker [6, section 4.3] and Kraaijevanger [24, p. 498].

In part (i) of Theorem 2.2 we use, for any given matrix $M = (m_{ij})$, the notation $\mathrm{Inc}(M)$ to denote the *incidence matrix* of M (which has the same dimensions as M), given by

$$\mathrm{Inc}(M) = (\widetilde{m}_{ij}), \quad \text{with } \widetilde{m}_{ij} = 1 \text{ (if } m_{ij} \neq 0) \text{ and } \widetilde{m}_{ij} = 0 \text{ (if } m_{ij} = 0).$$

THEOREM 2.2 (properties of $c(S,T)$).

(i) $c(S,T) > 0$ *if and only if* $S \geq 0,\ T \geq 0,\ Inc(T\,S) \leq Inc(S)$, *and* $Inc(T^2) \leq Inc(T)$.

(ii) *Suppose* $0 < \gamma < \infty$ *with* $\gamma \leq c(S,T)$. *Let* $D = \mathrm{diag}(\delta_1, \ldots, \delta_m)$, *where* $0 \leq \delta_i \leq 1$. *Then* (2.8) *holds, with* T *replaced by* TD.

We note that part (ii) of the theorem is already nontrivial and useful in the simple case where D equals the identity matrix I. The theorem can be viewed as an extension (and improvement) of earlier results in the literature; for related results concerning $R(A,b)$, see Kraaijevanger [24, Theorem 4.2, Lemma 4.4], Higueras [15, Proposition 2.11], and Horváth [18, Theorem 4].

Below we shall prove Theorem 2.2 using Lemma 2.3. We think the lemma is of independent interest: it gives an interesting interpretation of (2.8). We shall use for $x \in \mathbb{R}^n$ (with components ξ_i) and arbitrary $A = (a_{i,j}) \in \mathbb{R}^{m\times n}$ the notations $\|x\|_\infty = \max_i |\xi_i|$, $\|A\|_\infty = \max_{x\neq 0} \frac{\|Ax\|_\infty}{\|x\|_\infty}$, and the well known formula $\|A\|_\infty = \max_i \sum_j |a_{i,j}|$.

LEMMA 2.3 (interpretation of (2.8)). *Let* $0 < \gamma < \infty$. *Then* (2.8) *holds if and only if* $(I + \gamma\,T)$ *is invertible and* $\|(I + \gamma\,T)^{-1}\big[\ S\ \ \gamma\,T\ \big]\|_\infty \leq 1$.

Proof of Lemma 2.3. For any integer $q \geq 1$ we denote by e_q the vector in $\mathbb{R}^q$ with all components equal to 1. We assume that $0 < \gamma < \infty$ and $I + \gamma\,T$ is invertible.

In view of (2.3) we have $Se_l = e_m$. Introducing the matrices

$$P = (p_{i,j}) = (I + \gamma\,T)^{-1}(\gamma T),\ \ Q = (q_{i,j}) = (I + \gamma\,T)^{-1},\ \ R = (r_{i,j}) = Q\,S, \tag{2.9}$$

we thus have $R = (I - P)S$ and $\big[\ R\ \ P\ \big]e_{l+m} = R\,e_l + P\,e_m = e_m$. Consequently,

$$\sum_{j=1}^{l} r_{i,j} + \sum_{j=1}^{m} p_{i,j} = 1 \quad (\text{for } 1 \leq i \leq m). \tag{2.10}$$

If (2.8) holds, then all $r_{i,j},\ p_{i,j}$ are nonnegative, so that (2.10) implies $\|\big[\ R\ \ P\ \big]\|_\infty \leq 1$. Conversely, if $\|\big[\ R\ \ P\ \big]\|_\infty \leq 1$, then $\sum_{j=1}^{l} |r_{i,j}| + \sum_{j=1}^{m} |p_{i,j}| \leq \sum_{j=1}^{l} r_{i,j} + \sum_{j=1}^{m} p_{i,j}$. The last inequality proves that all $r_{i,j},\ p_{i,j}$ are nonnegative, so that (2.8) holds. □

We now turn to the proof of Theorem 2.2.

Proof of Theorem 2.2(i). In view of part (ii) of Theorem 2.2 (to be proved below), we have $c(S,T) > 0$ if and only if there is a $\gamma_0 > 0$ such that the matrix $M(\gamma) = (I+\gamma T)^{-1}\left[\begin{array}{cc} S & \gamma T \end{array}\right]$ is nonnegative for all $\gamma \in [0,\gamma_0]$. Therefore, we can assume with no loss of generality that $S \geq 0,\ T \geq 0$.

We have, for $\gamma > 0$ sufficiently small, $M(\gamma) = \{\sum_{k=0}^{\infty}(\gamma T)^{2k}\}\left[\begin{array}{cc} (I-\gamma T)S & (I-\gamma T)\gamma T \end{array}\right]$. It follows that $M(\gamma) \geq 0$ for $\gamma \downarrow 0$ if and only if $\mathrm{Inc}(TS) \leq \mathrm{Inc}(S)$ and $\mathrm{Inc}(TT) \leq \mathrm{Inc}(T)$, which proves (i).

Proof of Theorem 2.2(ii). Let γ_i be any finite values with $0 \leq \gamma_i \leq c(S,T)$ and put $\Gamma = \mathrm{diag}(\gamma_1 \ldots \gamma_m)$. In order to prove statement (ii), it is enough to assume $c(S,T) > 0$ and to show that (2.8) holds with matrix γT replaced throughout by the product $T\Gamma$.

Choose any finite γ satisfying (2.8) with $0 < \gamma \leq c(S,T)$ and put $E = \mathrm{diag}(\varepsilon_1 \ldots \varepsilon_m)$, where $\varepsilon_i = (\gamma - \gamma_i)\gamma^{-1}$. In order to prove the invertibility of $I + T\Gamma$, we write

$$I + T\Gamma = (I+\gamma T)(I-X), \text{ with } X = PE \text{ and } P \text{ as in (2.9)}.$$

In view of Lemma 2.3, we have $\|P\|_\infty \leq 1$, so that $\|X\|_\infty \leq \|E\|_\infty$.

First, consider the special case where $c(S,T) < \infty$ and $\gamma_i = c(S,T)$ (for $1 \leq i \leq m$). Choosing the above γ sufficiently close to $c(S,T)$, we can arrange that $\|E\|_\infty < 1$, which implies that in this special case $I + T\Gamma = I + c(S,T)\,T$ is invertible. Using a continuity argument it follows that (2.8) holds with $\gamma = c(S,T)$.

Next, consider again the general case of arbitrary finite γ_i with $0 \leq \gamma_i \leq c(S,T) \leq \infty$. In view of the above, we can choose a positive γ satisfying (2.8), with $\gamma \geq \max_i \gamma_i$. With this γ we have $0 \leq X = PE \leq P$, which implies that the spectral radii of X and P satisfy $\mathrm{spr}(X) \leq \mathrm{spr}(P) \leq \|P\|_\infty \leq 1$. In view of (2.9), the matrix $Q = I - P$ is invertible, so that P has no eigenvalue equal to 1. Applying the Perron–Frobenius theory (see, e.g., Horn and Johnson [17, p. 503]), it follows that $\mathrm{spr}(P) < 1$. Hence $\mathrm{spr}(X) < 1$, so that $I + T\Gamma = (I+\gamma T)(I-X)$ has an inverse equal to $(I-X)^{-1}(I+\gamma T)^{-1}$. Using $(I+T\Gamma)^{-1} = \left(\sum_0^\infty X^k\right)(I+\gamma T)^{-1}$, it follows that (2.8) is valid with γT replaced by $T\Gamma$. □

2.3. Stepsize-coefficients for monotonicity. In this section we give, without proof, the basic results of the paper, Theorems 2.4 and 2.7. Throughout the section, $S \in \mathbb{R}^{m\times l}$ and $T \in \mathbb{R}^{m\times m}$ are again arbitrary matrices satisfying (2.3). We study stepsize conditions $0 < \Delta t \leq c \cdot \tau_0$, guaranteeing monotonicity of process (2.5) when f_i satisfies (2.6). The following inequality will be of crucial importance:

$$c \ \leq \ c(S,T). \tag{2.11}$$

Our first result is as follows.

THEOREM 2.4 (monotonicity for arbitrary f_i satisfying (2.6)). *Consider numerical process* (2.5). *Let* τ_0, c *be given with* $0 < \tau_0 < \infty$, $0 < c \leq \infty$. *Then each of the following statements* (2.12), (2.13) *is equivalent to* (2.11)*:*

(2.12) *Condition* $0 < \Delta t \leq c \cdot \tau_0$ *implies monotonicity whenever* $\mathbb{V}$ *is a vector space,* $\|\cdot\|$ *a convex function on* $\mathbb{V}$, *and arbitrary* $f_i : \mathbb{V} \to \mathbb{V}$ *satisfy* (2.6)*;*

(2.13) *Condition* $0 < \Delta t \leq c \cdot \tau_0$ *implies monotonicity when* $\mathbb{V} = \mathbb{R}^m$, $\|\cdot\| = \|\cdot\|_\infty$, *and arbitrary* $f_i : \mathbb{V} \to \mathbb{V}$ *satisfy* (2.6).

Clearly, (2.12) is a priori a stronger statement than (2.13). Accordingly, the essence of Theorem 2.4 is that the (algebraic) property (2.11) implies the (strong) statement (2.12), whereas already the (weaker) statement (2.13) implies (2.11).

The theorem highlights the importance of the quantity $c(S,T)$: Theorem 2.4 shows that, with respect to the situations specified in (2.12), (2.13), *the maximal stepsize-coefficient* c, with the property that condition $0 < \Delta t \leq c \cdot \tau_0$ guarantees monotonicity, is equal to $c(S,T)$.

Our second result, Theorem 2.7, deals with important situations not adequately covered by Theorem 2.4: it is often *not* natural to allow, as in Theorem 2.4, that all functions f_i are different from each other. For instance, if in method (2.1) we have $c_i = c_j$ for some $i \neq j$, or if the differential equation is autonomous, then (2.1) is represented by a process (2.5) with $f_i = f_j$ for some, or all, indices $i \neq j$. In section 3.3 we will come across another situation where the functions f_i in (2.5) are not independent of each other. In order to cover all of such cases, we consider index sets I_q with $I_q \subset \{1, \ldots, m\}$ (for $1 \leq q \leq r$) and functions $f_i : \mathbb{V} \to \mathbb{V}$ (for $1 \leq i \leq m$), such that

(2.14)
$I_1, \ldots, I_r$ are nonempty and mutually disjoint, with $I_1 \cup \cdots \cup I_r = \{1, \ldots, m\}$,

(2.15) $f_i = f_j$ whenever i and j belong to the same index set I_q.

According to Theorem 2.4, also when (2.14), (2.15) hold, inequality (2.11) is *sufficient* in order that condition $0 < \Delta t \leq c \cdot \tau_0$ implies monotonicity of numerical process (2.5); but the following counterexample shows that, under the assumptions (2.14), (2.15), the *maximal stepsize-coefficient* $c = c_{max}$ can be larger than $c(S,T)$.

EXAMPLE 2.5. *Consider process* (2.5) *with* $l = 1$, $m = 2$, *and* $s_{i,1} = 1$, $t_{i,1} = 2$, $t_{i,2} = -1$ *(for* $i = 1, 2$*). Suppose* (2.14), (2.15) *with* $r = 1$, $I_1 = \{1, 2\}$. *Since condition* $T \geq 0$ *in Theorem* 2.2(i) *is violated, we have* $c(S,T) = 0$. *But, with* $f_1 = f_2 = f$, *the process reduces to the (backward Euler) method* $y_1 = x_1 + \Delta t\, f(y_1)$, *which is again of the form* (2.5), *with* $\tilde{l} = \tilde{m} = 1$ *and* $c(\tilde{S}, \tilde{T}) = \infty$. *In line with Theorem* 2.4, *the maximal stepsize-coefficient* $c = c_{max}$ *such that condition* $0 < \Delta t \leq c \cdot \tau_0$ *implies monotonicity (for the original process with* $m = 2$ *and* (2.6), (2.14), (2.15) *in force), is equal to* $c_{max} = \infty > c(S,T) = 0$.

Theorem 2.7 will make clear that the inequality $c_{max} > c(S,T)$, in Example 2.5, is an anomaly related to reducibility of the method. We shall use the following formal definition of reducibility and irreducibility, with regard to index sets $I_1, \ldots, I_r$ satisfying (2.14).

DEFINITION 2.6 (reducibility and irreducibility). *Process* (2.5) *is called reducible with respect to* $I_1, \ldots, I_r$, *if indices* i, j, q *exist with the following properties:* $i \in I_q$, $j \in I_q$, *and* $i \neq j$, *whereas the* i*th and the* j*th row of the matrix* $\begin{bmatrix} S & T \end{bmatrix}$ *are equal to each other. Process* (2.5) *is called irreducible with respect to* $I_1, \ldots, I_r$, *if such indices* i, j, q *do not exist.*

Clearly, if $r < m$ and there is reducibility with respect to $I_1, \ldots, I_r$, then process (2.5), with f_i satisfying (2.15), is equivalent to a process (2.5) with a smaller value of m.

THEOREM 2.7 (monotonicity when f_i satisfy (2.6), (2.15)). *Assume* (2.14) *and irreducibility of process* (2.5) *with respect to* $I_1, \ldots, I_r$. *Let* τ_0, c *be given with* $0 < \tau_0 < \infty$, $0 < c \leq \infty$. *Then each of the following statements* (2.16), (2.17) *is equivalent*

to (2.11)*:*

(2.16) *Condition* $0 < \Delta t \le c \cdot \tau_0$ *implies monotonicity whenever* $\mathbb{V}$ *is a vector space,* $\|\cdot\|$ *a convex function on* $\mathbb{V}$*, and functions* $f_i : \mathbb{V} \to \mathbb{V}$ *satisfy* (2.6), (2.15);

(2.17) *Condition* $0 < \Delta t \le c \cdot \tau_0$ *implies monotonicity whenever* $\mathbb{V} = \mathbb{R}^m$, $\|\cdot\| = \|\cdot\|_\infty$*, and functions* $f_i : \mathbb{V} \to \mathbb{V}$ *satisfy* (2.6), (2.15).

Theorem 2.7 implies that, in the situations specified by (2.16) and (2.17), the *maximal stepsize-coefficient* c, such that condition $0 < \Delta t \le c \cdot \tau_0$ implies monotonicity, is still equal to $c(S,T)$, provided there is irreducibility with respect to the relevant index sets.

The following counterexample shows that the dimension of the space $\mathbb{V}$ in statements (2.13) and (2.17) cannot be replaced, in general, by an integer smaller than m.

EXAMPLE 2.8. *Consider numerical process* (2.5) *with* $l = 1$, $m = 2$*, and* $s_{1,1} = s_{2,1} = 1$, $t_{1,1} = 1/3$, $t_{1,2} = 8/3$, $t_{2,1} = 0$, $t_{2,2} = 1$*. A straightforward calculation yields* $c(S,T) = 3/5$*. On the other hand, it can be proved that propositions* (2.13) *and* (2.17) *would be valid with* $c = 3/2 > c(S,T)$*, if the space* $\mathbb{V} = \mathbb{R}^m = \mathbb{R}^2$ *would be replaced by* $\mathbb{V} = \mathbb{R}^1$*.*

Theorem 2.4 can formally be viewed as a special case of Theorem 2.7; the latter theorem with $r = m$ reduces to the former. We have formulated Theorem 2.4 separately in view of its importance and simplicity: it does not need (2.14), (2.15) or Definition 2.6. Furthermore, in section 4, where the theorems are proved, we will see that it is convenient to focus first on Theorem 2.4 and to use (arguments used in the proof of) that theorem for proving Theorem 2.7.

3. Examples and applications.

3.1. Applications to arbitrary GLMs. In this section we consider method (2.1). We assume (2.3) and give some results which follow readily from the above theory. We focus on stepsize-coefficients c such that

(3.1) Condition $0 < \Delta t \le c \cdot \tau_0$ implies monotonicity whenever $\mathbb{V}$ is a vector space, $\|\cdot\|$ a convex function on $\mathbb{V}$, and functions $f : \mathbb{R} \times \mathbb{V} \to \mathbb{V}$ satisfy (1.4).

In the following theorem, the columns of the matrix $T = (t_{ij})$ are denoted by T_i $(1 \le i \le m)$ and the rows of the $m \times (l+m)$ matrix $[\,S \;\; T\,]$ by R_i $(1 \le i \le m)$.

THEOREM 3.1 (monotonicity of GLMs). *Consider method* (2.1)*, and given* $\tau_o > 0$.

(i) *Let* $c \le c(S,T)$*. Then statement* (3.1) *is valid.*

(ii) *Assume the method is irreducible in the sense that* $R_i \ne R_j$ *for all* i, j *with* $i \ne j$, $T_i \ne 0$, $T_j \ne 0$, $c_i = c_j$*. Then, conversely, statement* (3.1) *implies that* $c \le c(S,T)$.

Note that the irreducibility assumption in (ii) is trivially fulfilled if the method is *nonconfluent*, i.e., if $c_i \ne c_j$ (for all $i \ne j$). Moreover, in case $c_i = c_j$ (for some $i \ne j$), the assumption of irreducibility is *no* strong restriction, because any given method, violating the assumption, is equivalent to a method (with a smaller number of stages) which is irreducible. The theorem highlights the importance of $c(S,T)$ for (irreducible) GLMs: it implies that the *maximal stepsize-coefficient* c, with property (3.1), is equal to $c(S,T)$.

Proof of Theorem 3.1. In order to prove (i), it is enough to apply Theorem 2.4 to process (2.5), where x_i and f_i are defined via (2.4).

For proving (ii), note that, when $T_k = 0$, the value of the parameter c_k is *irrelevant* to monotonicity of method (2.1). We can thus arrange, without loss of generality, that $c_k \neq c_i$ (for $T_k = 0$ and $i \neq k$). Under the irreducibility assumption in (ii), we thus have

$$R_i \neq R_j \quad \text{whenever} \quad i \neq j,\ c_i = c_j.$$

In order to apply Theorem 2.7, we specify index sets I_q by the following requirement: indices i, j belong to the same index set, if and only if $c_i = c_j$. Since process (2.5) is now irreducible in the sense of Definition 2.6, we can apply Theorem 2.7. For proving (ii) it is thus enough to show that (3.1) (for the GLM) implies (2.16) (for process (2.5)).

In order to prove the last implication, we assume (3.1) and suppose x_i, y_i satisfy (2.5) with $0 < \Delta t \leq c \cdot \tau_0$ and functions $f_i : \mathbb{V} \to \mathbb{V}$ satisfying (2.6), (2.15).

We shall show that (2.1) holds with $u_i^{(n-1)} = x_i$ and some function f satisfying (1.4). In defining f we use the notations $t_i = (n-1+c_i)\Delta t$, $\alpha = \min t_i$, $\beta = \max t_i$. We put $f(t_i, v) = f_i(v)$, and extend this function to a function $f : \mathbb{R} \times \mathbb{V} \to \mathbb{V}$ by linear interpolation for $\alpha \leq t \leq \beta$, and by setting $f(t, v) = f(\alpha, v)$ (for $t < \alpha$) and $f(t, v) = f(\beta, v)$ (for $t > \beta$). This function f satisfies (1.4); and (2.1) holds with $u_i^{(n-1)} = x_i$.

Applying (3.1), it follows that (2.2)—and therefore also (2.7)—is fulfilled. This implies (2.16) and concludes the proof. □

Remark 3.2. Theorems 2.4 and 2.7, used in the above proof, can also be applied to prove a variant of Theorem 3.1 tuned to *autonomous* differential equations. In such a variant, property (3.1) is modified by including that f is independent of t, and the irreducibility condition in (ii) becomes: $R_i \neq R_j$ whenever $i \neq j$, $T_i \neq 0$, $T_j \neq 0$.

The subsequent corollaries to Theorem 3.1 involve two properties different in appearance from (2.2).

Property 1 (discrete maximum principle). Let $\mathbb{V} = \mathbb{R}^N$, $N \geq 1$. Suppose vectors y_i, $u_i^{(n-1)} \in \mathbb{R}^N$ satisfy (2.1.a). We denote the components of these vectors by y_{pi} and $u_{pi}^{(n-1)}$, respectively ($1 \leq p \leq N$). The property

(3.2)
$$\min_{1\leq j\leq l} \min_{1\leq q\leq N} u_{qj}^{(n-1)} \ \leq\ y_{pi} \ \leq\ \max_{1\leq j\leq l} \max_{1\leq q\leq N} u_{qj}^{(n-1)} \quad (\text{for } 1 \leq i \leq m,\ 1 \leq p \leq N)$$

can be interpreted as a *discrete maximum principle*. It is of importance in the solution of partial differential equations (via the method of lines) and can be associated with the absence of undesirable overshoots and undershoots; see, e.g., Hundsdorfer and Verwer [21, pp. 9 and 118]. Below we denote the components of $f(t, x) \in \mathbb{R}^N$ by $f_p(t, x)$ ($1 \leq p \leq N$).

Corollary 3.3 (discrete maximum principle for GLMs). *Let $f : \mathbb{R} \times \mathbb{R}^N \to \mathbb{R}^N$ and $\tau_0 > 0$ be such that, for $x \in \mathbb{R}^N$ with components ξ_p,*

$$\min_{1\leq q\leq N} \xi_q \ \leq\ \xi_p + \tau_0 \cdot f_p(t, x) \ \leq\ \max_{1\leq q\leq N} \xi_q \quad (\textit{for } 1 \leq p \leq N).$$

Then (3.2) *holds, whenever $u_i^{(n-1)}$ and y_i satisfy* (2.1.a) *with $0 < \Delta t \leq c(S, T) \cdot \tau_0$.*

Proof of Corollary 3.3. Define the convex functions $\|x\|_+ = \max_p \xi_p$ and $\|x\|_- = -\min_p \xi_p$ for $x \in \mathbb{V}$. The assumption in the corollary, about f and τ_0, can be

rewritten as

$$\|x+\tau_0 f(t,x)\|_- \le \|x\|_- , \quad \|x+\tau_0 f(t,x)\|_+ \le \|x\|_+,$$

so that (1.4) holds with $\|\cdot\|$ equal to $\|\cdot\|_-$ and $\|\cdot\|_+$, respectively.

Assume (2.1.a) with $0 < \Delta t \le c(S,T)\cdot\tau_0$. Choosing $c = c(S,T)$ and applying Theorem 3.1(i), we get from (3.1) the inequalities $\|y_i\|_+ \le \max_{1\le j\le l}\|u_i^{(n-1)}\|_+$ and $\|y_i\|_- \le \max_{1\le j\le l}\|u_i^{(n-1)}\|_-$, which imply (3.2). □

Property 2 (contractivity). Let $\|.\|$ be a convex function on the vector space $\mathbb{V}$. We consider the *contractivity* property

$$\|\tilde y_i - y_i\| \le \max_{1\le j\le l}\|\tilde u_j^{(n-1)} - u_j^{(n-1)}\| \quad (\text{for } 1\le i\le m), \tag{3.3}$$

where $u_i^{(n-1)}$, y_i and $\tilde u_i^{(n-1)}$, $\tilde y_i$ satisfy (2.1.a) with the same stepsize $\Delta t > 0$. Contractivity of numerical processes were studied earlier in various frameworks; cf., e.g., Kraaijevanger [24] Hairer and Wanner [11].

COROLLARY 3.4 (contractivity for GLMs). *Let $f : \mathbb{R}\times\mathbb{V}\to\mathbb{V}$ and $\tau_0 > 0$ be such that $\|\tilde v - v + \tau_0\cdot(f(t,\tilde v) - f(t,v))\| \le \|\tilde v - v\|$ (for $t\in\mathbb{R}$ and v, $\tilde v\in\mathbb{V}$). Then* (3.3) *holds, whenever $u_i^{(n-1)}$, y_i and $\tilde u_i^{(n-1)}$, $\tilde y_i$ satisfy* (2.1.a) *with $0 < \Delta t \le c(S,T)\cdot\tau_0$.*

Proof of Corollary 3.4. The corollary follows from Theorem 3.1, using arguments similar to those in Burrage and Butcher [2, p. 190]: We introduce the auxiliary space $\mathbb{W} = \mathbb{V}\times\mathbb{V}$ and put $\|w\| = \|\tilde v - v\|$, $g(t,w) = (f(t,\tilde v), f(t,v))$ (for $w = (\tilde v, v)$ with $\tilde v, v\in\mathbb{V}$). The above assumption, about f and τ_0, implies that $\|w+\tau_0\cdot g(t,w)\| \le \|w\|$ (for $w\in\mathbb{W}$).

Let $u_i^{(n-1)}$, y_i and $\tilde u_i^{(n-1)}$, $\tilde y_i$ satisfy (2.1.a). Defining $U_i = (\tilde u_i^{(n-1)}, u_i^{(n-1)})$, $Y_i = (\tilde y_i, y_i)$, we have $Y_i = \sum_j s_{ij} U_j + \Delta t\cdot\sum_j t_{ij} g((n-1+c_j)\Delta t,\ Y_j)$ and $\|Y_i\| = \|\tilde y_i - y_i\|$, $\|U_i\| = \|\tilde u_i^{(n-1)} - u_i^{(n-1)}\|$. An application of Theorem 3.1(i) (to the space $\mathbb{W}$ and the function g) proves the proposition. □

3.2. Applications to RKMs, LMMs, and a MMM. We illustrate the preceding theory by applying it to some concrete numerical methods.

3.2.1. Runge–Kutta methods. Consider method (1.2). We denote by A_{s+1} the $(s+1)\times s$ matrix with entries a_{ij} and by A_s the matrix of order s obtained from A_{s+1} by omitting its last row. By E_{s+1} and E_s, respectively, we denote the $(s+1)\times 1$ and the $s\times 1$ matrix with all entries equal to 1. In section 2.1.1, method (1.2) was already represented as a GLM of form (2.1), with $l = 1$, $m = s+1$ and

$$S = E_{s+1},\ T = [\,A_{s+1}\ O\,].$$

Monotonicity of this GLM amounts to (1.3). Hence, according to Theorem 3.1, the largest stepsize-coefficient c, such that (3.1) holds for the RKM, is essentially equal to $c(S,T)$. Below we reformulate this result in a more explicit form.

For S, T just defined, it follows easily, similarly as in Higueras [16], that (2.8) is equivalent to the following condition:

(3.4)
$I+\gamma A_s$ is invertible and $A_{s+1}(I+\gamma A_s)^{-1} \ge O$, $E_{s+1} \ge \gamma A_{s+1}(I+\gamma A_s)^{-1}E_s$.

In view of Definition 2.1, it thus follows, after a simple application of Theorem 2.2(i), that $c(S,T) = \Gamma$, where

$$\Gamma = \sup\{\gamma :\ \gamma \text{ satisfies (3.4)}\}\ (\text{if } A_{s+1}\ge O) \quad \text{and}\ \ \Gamma = 0\ \ (\text{otherwise}). \tag{3.5}$$

We denote the rows of the $s \times s$ matrix A_s by $r_1, \ldots, r_s$. Applying Theorem 3.1, we immediately arrive at the following two conclusions:

(i) *For method* (1.2)*, statement* (3.1) *is valid with* $c = \Gamma$*, where* Γ *is given by* (3.5).

(ii) *Assume the RKM is irreducible in the sense that* $r_i \neq r_j$ *for all* i, j *with* $i \neq j$, $c_i = c_j$. *Then the value* $c = \Gamma$ *in conclusion* (i) *is optimal, in that* (3.1) *is not valid with* $c > \Gamma$.

These results imply that for (irreducible) RKMs the *maximal stepsize-coefficient* c with property (3.1) equals Γ. Statements (i) and (ii) supplement related material in Higueras [14, 16] and Ferracina and Spijker [6, 7]. The irreducibility condition in (ii) is essentially weaker than in these papers, whereas the monotonicity property (3.1) in (i) and (ii) is stronger than in (most of) the papers.

Definition (3.5) can be viewed as a smooth variant of similar definitions in the papers just mentioned. For many RKMs, the corresponding value of Γ is explicitly known, because it equals the coefficient introduced, and denoted by $R(A, b)$, in Kraaijevanger [24]; the equality $\Gamma = R(A, b)$ is an easy consequence of Theorem 2.2(ii). For various interesting RKMs, the actual value of $R(A, b)$ was studied and computed in the last mentioned paper; see also Higueras [14] and Ferracina and Spijker [6].

Versions of (i) and (ii) tuned to *autonomous* differential equations can easily be obtained by applying the variant of Theorem 3.1 mentioned in Remark 3.2. In these versions, the assumption on f in (3.1) includes that f is independent of t, and the irreducibility condition on the RKM becomes: $r_i \neq r_j$ (whenever $i \neq j$).

3.2.2. Linear multistep methods. Consider method (1.6), with $\sum_1^k \alpha_i = 1$. In section 2.1.1, the method was represented as a GLM of form (2.1), with $l = k,\ m = k + 1,\ c_j = j - k,\ S = \binom{I}{A},\ T = \binom{O}{B}$, where $A = (\alpha_k, \ldots, \alpha_1),\ B = (\beta_k, \ldots, \beta_0)$. This GLM is irreducible in the sense of Theorem 3.1, because $c_i \neq c_j$ (for $i \neq j$). Its monotonicity amounts to (1.7). Theorem 3.1 thus implies that the largest c, for which the LMM has property (3.1), is equal to $c = c(S, T)$.

In order to find a convenient expression for $c(S, T)$, we consider, for $\gamma > 0$, condition (2.8) with S, T as defined above. One easily sees (using $\sum_1^k \alpha_i = 1$) that (2.8) is equivalent to the requirement that $\beta_0 \geq 0$ and $\alpha_i \geq 0,\ \beta_i \geq 0,\ \alpha_i - \gamma\,\beta_i \geq 0\ \ (1 \leq i \leq k)$. By Definition 2.1, we obtain $c(S, T) = \Gamma$, where

$$\Gamma = \min_{1 \leq i \leq k} \alpha_i/\beta_i \ \text{ (if all } \alpha_i, \beta_i \text{ are nonnegative)} \quad \text{and} \quad \Gamma = 0 \ \text{ (otherwise).} \tag{3.6}$$

Here we use the convention that $a/0 = \infty$ for all $a \geq 0$. In view of the above, we have the following conclusions:

(i) *For method* (1.6)*, statement* (3.1) *is valid with* $c = \Gamma$*, where* Γ *is given by* (3.6).

(ii) *The value* $c = \Gamma$ *in conclusion* (i) *is optimal, in that* (3.1) *is not valid with* $c > \Gamma$.

Statements (i) and (ii) imply that the *maximal stepsize-coefficient* c with property (3.1) equals Γ. Results similar to (i) were given earlier; see, e.g., Shu [28], Gottlieb, Shu, and Tadmor [10], Hundsdorfer and Ruuth [19], and Hundsdorfer, Ruuth, and Spiteri [20].

As an illustration we consider the following LMM, taken from Shu [28]:

$$u_n = \tfrac{3}{4}\, u_{n-1} + \tfrac{1}{4}\, u_{n-3} + \tfrac{3}{2}\, \Delta t\, f((n-1)\Delta t, u_{n-1}). \tag{3.7}$$

For this second order method, we have $\Gamma = 1/2$, so that (3.1) holds with $c = 1/2$. In Gottlieb, Shu, and Tadmor [10], the method was proved to be optimal, in that there exists no explicit second order method (1.6), with $k = 3$ and $\Gamma > 1/2$. In view of statement (ii), it follows that (3.7) is even *optimal in a wider and more fundamental sense* than stated in the last paper: there exists no explicit second order method (1.6), with $k = 3$, satisfying (3.1) with $c > 1/2$.

Versions of (i) and (ii) for *autonomous* differential equations follow again from the variant of Theorem 3.1 mentioned in Remark 3.2. No explicit irreducibility assumption, about the LMM, is needed in these versions.

3.2.3. A multistep-multistage method. We illustrate Theorems 2.2 and 3.1 with the method

$$v_n = \gamma_1\, u_{n-1} + \gamma_2\, u_{n-2} \;+\; \Delta t \cdot [\delta_0\, f_n + \delta_1\, f_{n-1} + \delta_2\, f_{n-2} + \delta_3\, g_n], \tag{3.8.a}$$

$$u_n = \alpha_1\, u_{n-1} + \alpha_2\, u_{n-2} \;+\; \Delta t \cdot [\beta_0\, f_n + \beta_1\, f_{n-1} + \beta_2\, f_{n-2} + \beta_3\, g_n]. \tag{3.8.b}$$

Here v_n is an intermediate approximation used for computing u_n from u_{n-1}, u_{n-2}, and $f_n = f(n\Delta t,\, u_n)$, $g_n = f((n-\sigma)\Delta t,\, v_n)$. We assume $\alpha_1 + \alpha_2 = \gamma_1 + \gamma_2 = 1$ and, in order to prevent reducibility, that the coefficient vectors $(\alpha_1, \alpha_2, \beta_0, \beta_1, \beta_2, \beta_3)$ and $(\gamma_1, \gamma_2, \delta_0, \delta_1, \delta_2, \delta_3)$ are different. Method (3.8) can be viewed as a modified LMM or a two-step RKM; cf., e.g., Butcher [5] and Jackiewicz and Tracogna [22]. In Gottlieb, Shu, and Tadmor [10, pp. 102 and 103], methods of type (3.8) were explored which are *explicit*, i.e., $\beta_0 = \delta_0 = \delta_3 = 0$.

The general method (3.8) can be written as a GLM (2.1), with $l = 2$, $m = 4$ and with matrices S, T, determined by α_i, β_i, γ_i, δ_i, such that $y_1 = v_n$, $y_2 = u_{n-2}$, $y_3 = u_{n-1}$, $y_4 = u_n$. The monotonicity relation (2.2) reduces to $\max\{\|v_n\|, \|u_n\|\} \le \max\{\|u_{n-1}\|, \|u_{n-2}\|\}$. Applying Theorem 3.1, we conclude that the largest c, for which method (3.8) satisfies (3.1), is equal to $c(S,T)$. By combining this conclusion with Theorem 2.2(i), we arrive after a short calculation at the following proposition.

PROPOSITION 3.1. *For method* (3.8)*, a positive c exists with property* (3.1)*, if and only if all coefficients α_i, β_i, γ_i, δ_i are nonnegative, with $\frac{\alpha_i}{\beta_i + \beta_3\,\gamma_i} > 0$, $\frac{\gamma_i}{\delta_i + \delta_0\,\alpha_i} > 0$ $(i = 1, 2)$ and $\frac{\beta_{i-1}}{\beta_3\,\delta_{i-1}} > 0$, $\frac{\delta_i}{\delta_0\,\beta_i} > 0$ $(i = 1, 2, 3)$.*

Here we use again the convention that $a/0 = \infty > 0$ for $a \ge 0$.

With E_2 we denote the class of all *explicit* methods (3.8) with *order of accuracy* 2. We consider the problem of determining a method in the class which is *optimal*, in that it has property (3.1) with a value c which is maximal in E_2. In view of Theorem 3.1, this problem amounts to finding the maximum of $c(S,T)$ over the class E_2. According to Definition 2.1, this maximum can be computed by performing an optimization, with objective function γ and search variables α_i, β_i, γ_i, δ_i, σ, γ, under the constraints (2.8), supplemented by the order conditions. We performed a numerical search along these lines (using MATLAB) and obtained an (optimal) method of form (3.8), for which we found that the nonzero parameters can be represented (up to 13 decimal digits) as follows:

$$\alpha_1 = 2(\sqrt{2}-1),\;\; \alpha_2 = 3-2\sqrt{2},\;\; \beta_1 = \beta_3 = 2-\sqrt{2},\;\; \gamma_1 = 1,\;\; \delta_1 = \sqrt{2}/2,\;\; \sigma = 1-\sqrt{2}/2.$$

This method is of order 2 and it satisfies (3.1) with stepsize-coefficient $c = \sqrt{2}$.

Second order methods with a larger stepsize-coefficient can be found in the class G_2 of *general second order* methods (3.8). By a numerical search in G_2, similar to the above, we arrived at an (optimal) method with the following nonzero parameters:

$$\alpha_1 = \gamma_1 = 1,\;\; \beta_0 = \beta_1 = \delta_1 = \delta_3 = 1/4,\;\; \beta_3 = 1/2,\;\; \sigma = 1/2.$$

This method is of order 2 and it satisfies (3.1) with stepsize-coefficient $c = 4$. Note that the method is equivalent to two applications of the trapezoidal rule (TR) starting from u_{n-1} and using stepsize $\Delta t/2$; we refer to Lenferink [25, p. 180] for a related interesting optimality property of the TR.

We also performed a similar numerical search in the class E_3 of all *explicit third order* methods (3.8). Our search resulted in an (optimal) method for which the nonzero parameters can be represented (up to 13 decimal digits) as follows:

$$\alpha_1 = 6\sqrt{3} - 10, \;\; \alpha_2 = 11 - 6\sqrt{3}, \;\; \beta_1 = 4 - 2\sqrt{3}, \;\; \beta_2 = 2 - \sqrt{3}, \;\; \beta_3 = 6 - 3\sqrt{3},$$

$$\gamma_1 = 2/3, \;\; \gamma_2 = 1/3, \;\; \delta_1 = (1 + \sqrt{3})/3, \;\; \sigma = 1 - \sqrt{3}/3.$$

The method is of order 3 and satisfies (3.1) with stepsize-coefficient $c = \sqrt{3} - 1 \approx 0.732$. This result extends an earlier numerical search in Gottlieb, Shu, and Tadmor [10, pp. 102 and 103], where a special method of class E_3 was found which can be implemented, at the cost of an additional function evaluation $\tilde{f}_{n-1}$, such that (3.1) holds with $c \approx 0.473$.

We also did a numerical search in the class G_3 of *general third order* methods (3.8). The best method we could find has a coefficient $\delta_0 = 0$ and it satisfies (3.1) with stepsize-coefficient $c \approx 3.233$, but we did not succeed in finding simple closed-form expressions, similarly as above, for the parameters specifying the method.

We do not go into details here of higher order methods. We just refer to Gottlieb, Shu, and Tadmor [10, p. 103] for an interesting proposition about explicit fourth order methods, and note that fifth order methods with $\delta_0 = 0$ exist satisfying (3.1) with positive c.

3.3. Applications to additive RKMs. Numerical methods of the form

$$\text{(3.9.a)} \;\; y_i = u_{n-1} \;+\; \Delta t \cdot \sum_{j=1}^{s} a_{ij}\, f(y_j) \;+\; \Delta t \cdot \sum_{j=1}^{s} \widehat{a}_{ij}\, \widehat{f}(y_j) \quad (1 \le i \le s+1),$$

$$\text{(3.9.b)} \; u_n = y_{s+1}$$

have been considered for the efficient solution of equations $\frac{d}{dt}U(t) = f(U(t)) + \widehat{f}(U(t))$, where f and $\widehat{f}$ have different stiffness properties; cf., e.g., Ascher, Ruuth, and Spiteri [1] and Kennedy and Carpenter [23]. The methods are known as *additive Runge–Kutta methods*; and also as *implicit-explicit (IMEX) methods* in case the RKM with coefficients a_{ij} is implicit and the one with $\widehat{a}_{ij}$ explicit. Furthermore, methods of the form (3.9) have been studied under the name of *perturbed Runge–Kutta methods*, in the context of solving semidiscrete versions of hyperbolic problems. In that situation, (3.9) is equivalent to a *Shu–Osher implementation* of a standard RKM where some a_{ij} are negative; cf. Higueras [15, 16].

In the last mentioned papers, monotonicity, in the sense of (1.3), was studied for (3.9), under the assumption

$$\text{(3.10)} \qquad \|v + \tau_0 f(v)\| \le \|v\|, \quad \|v + \widehat{\tau}_0 \widehat{f}(v)\| \le \|v\| \qquad (\text{for all } v \in \mathbb{V});$$

a stepsize $(\Delta t)^*$ was presented with the following crucial property:

(3.11) Condition $0 < \Delta t \le (\Delta t)^*$ implies monotonicity of (3.9) whenever $\mathbb{V}$ is a vector space, $\|.\|$ a convex function on $\mathbb{V}$, and functions f, $\widehat{f} : \mathbb{V} \to \mathbb{V}$ satisfy (3.10).

In order to specify $(\Delta t)^*$, we introduce the $(s+1) \times s$ matrices $A = (a_{ij})$, $\widehat{A} = (\widehat{a}_{ij})$, and the $(s+1) \times (s+1)$ matrices $K = [A\ O]$, $\widehat{K} = [\widehat{A}\ O]$. We define $\mathcal{R}$ to be the set of all pairs $(\gamma, \widehat{\gamma}) \in \mathbb{R}^2$ such that

$$I + \gamma K + \widehat{\gamma}\,\widehat{K} \text{ is invertible and } (I + \gamma K + \widehat{\gamma}\,\widehat{K})^{-1}\big[\, E \ \ \gamma K \ \ \widehat{\gamma}\,\widehat{K} \,\big] \geq 0. \tag{3.12}$$

Here E stands for the $(s+1) \times 1$ matrix with all entries equal to 1 and the inequality in (3.12) is to be interpreted entrywise. For a given $\tau_0 > 0$, $\widehat{\tau}_0 > 0$, we put

$$\begin{aligned} &(\Delta t)^* = 0 \quad \text{if there is no pair } (\gamma, \widehat{\gamma}) \text{ in } \mathcal{R} \text{ with } \gamma\,\tau_0 = \widehat{\gamma}\,\widehat{\tau}_0 > 0; \text{ otherwise} \\ &(\Delta t)^* = \sup\{\tau :\ \tau = \gamma\,\tau_0 = \widehat{\gamma}\,\widehat{\tau}_0 > 0 \text{ with } (\gamma, \widehat{\gamma}) \text{ in } \mathcal{R}\}. \end{aligned} \tag{3.13}$$

The following theorem follows immediately from the material in Higueras [15].

THEOREM 3.5 (Higueras, 2006). *Consider method* (3.9) *and let* $\tau_0 > 0$, $\widehat{\tau}_0 > 0$ *be given. Then statement* (3.11) *is valid, with* $(\Delta t)^*$ *defined by* (3.13).

In Higueras [15], sets $\mathcal{R}$ were computed for a series of important additive RKMs. For any given τ_0, $\widehat{\tau}_0$, these sets allow the immediate calculation of $(\Delta t)^*$ defined by (3.13). One may be tempted to view these sets as important characteristics of the underlying methods, and to compare the efficiency of different methods by taking (the magnitude of) the corresponding sets $\mathcal{R}$ into account. However, if (3.11) would also be valid for some $(\Delta t)^*$ which is *greater* than the one given by (3.13), such a use of these sets might be misleading. The natural question arises of whether the value $(\Delta t)^*$, given in the above theorem, is best possible. We think this fundamental question has not yet been answered in the literature.

By applying the theorems of section 2, one can recover the above theorem and essentially answer the question just raised (in the positive); we have the following theorem.

THEOREM 3.6 (upper bound for $(\Delta t)^*$ in (3.11)). *Let* (3.9) *be irreducible, in the sense that the first* s *rows of the* $(s+1) \times 2\,s$ *matrix* $\big[\, A \ \ \widehat{A} \,\big]$ *are different from each other. Let* $\tau_0 > 0$, $\widehat{\tau}_0 > 0$ *be given. If* $(\Delta t)^*$ *is such that statement* (3.11) *holds, then* $(\Delta t)^*$ *cannot exceed the value given in* (3.13).

Proof of Theorems 3.5 *and* 3.6 *using the theory of section* 2. (i) Let $\tau_0 > 0$, $\widehat{\tau}_0 > 0$ be given. We shall relate (3.9) to a numerical process of the form (2.5): we put $l = 1$, $m = 2(s+1)$, and $S = (s_{ij}) = \binom{E}{E}$, $T = (t_{ij}) = \binom{K\ \delta\widehat{K}}{K\ \delta\widehat{K}}$, where $\delta = \tau_0/\widehat{\tau}_0$. We define index sets $I_1 = \{1, \ldots, s\}$, $I_2 = \{s+1\}$, $I_3 = \{s+2, \ldots, 2s+1\}$, and $I_4 = \{2(s+1)\}$.

Let y_i, u_{n-1} satisfy (3.9.a) with f, $\widehat{f}$ as in (3.10). Then $x_1 = u_{n-1}$ and y_i, with

$$y_{s+1+i} = y_i \ \ (\text{for } 1 \leq i \leq s+1), \tag{3.14}$$

can be seen to fulfill (2.5), with some functions f_i satisfying (2.6).

Conversely, let x_i, y_i fulfill (2.5) with f_i satisfying (2.6), (2.15). Then (3.14) holds, so that y_i and $u_{n-1} = x_1$ satisfy (3.9.a) with some f, $\widehat{f}$ as in (3.10).

(ii) In view of the above, it follows that (3.11) holds, with $(\Delta t)^* = c \cdot \tau_0$, as soon as (2.12) is in force for process (2.5). According to Theorem 2.4, we can choose $c = c(S,T)$. Hence (3.11) is valid with $(\Delta t)^* = c(S,T) \cdot \tau_0$. A straightforward calculation shows that $c(S,T) \cdot \tau_0$ is equal to the value $(\Delta t)^*$ defined by (3.13). This proves Theorem 3.5.

(iii) Assume (3.11) holds for some $(\Delta t)^*$. We see now that property (2.16) must be valid for process (2.5), with $c = (\Delta t)^*/\tau_0$. The irreducibility assumption in Theorem

3.6 implies that process (2.5) is irreducible with respect to $I_1, \dots, I_4$, so that Theorem 2.7 can be applied. It follows that the largest value c in (2.16) equals $c(S,T)$, which implies $(\Delta t)^*/\tau_0 \le c(S,T)$. Using again that $c(S,T)\cdot\tau_0$ equals the value defined by (3.13), we arrive at Theorem 3.6. □

Remark 3.7. The set $\mathcal{R}$ has the following interesting property:

$$\text{If } (\gamma, \widehat{\gamma}) \in \mathcal{R}, \text{ then } (\beta, \widehat{\beta}) \in \mathcal{R} \text{ whenever } 0 \le \beta \le \gamma,\ 0 \le \widehat{\beta} \le \widehat{\gamma}. \tag{3.15}$$

This can be proved by defining S, T similarly as in the above proof and applying Theorem 2.2(ii).

For related material, see Higueras [15].

4. Proof of Theorems 2.4 and 2.7.

4.1. Sufficiency of the inequality (2.11). In order to write (2.5) and similar relations more concisely, we introduce some notations relevant to the vector space $\mathbb{V}$. For any integer $n \ge 1$ and vectors $x_1, \dots, x_n \in \mathbb{V}$, we denote the vector in $\mathbb{V}^n$ with components x_i by

$$x = [x_i] = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \in \mathbb{V}^n.$$

Furthermore, we denote with a boldface letter the linear operators from $\mathbb{V}^n$ to $\mathbb{V}^m$ determined in a natural way by $m \times n$ matrices: for any matrix $A = (a_{i,j}) \in \mathbb{R}^{m\times n}$ and $x = [x_i] \in \mathbb{V}^n$ we define $\boldsymbol{A}(x) = y$, where $y = [y_i] \in \mathbb{V}^m$ is given by $y_i = \sum_{j=1}^n a_{ij}\, x_j$ $(1 \le i \le m)$.

We combine the vectors x_i and y_i, occurring in (2.5), into the vectors $x = [x_i] \in \mathbb{V}^l$ and $y = [y_i] \in \mathbb{V}^m$, respectively. Furthermore, for given functions $f_i : \mathbb{V} \to \mathbb{V}$ $(1 \le i \le m)$, we define a function F, from $\mathbb{V}^m$ to $\mathbb{V}^m$, by $F(y) = [f_i(y_i)] \in \mathbb{V}^m$ for $y = [y_i] \in \mathbb{V}^m$. With these notations, the relations (2.5) can be written as an equality in $\mathbb{V}^m$:

$$y \;=\; \boldsymbol{S}x \;+\; \Delta t\cdot\; \boldsymbol{T}\, F(y). \tag{4.1}$$

The simple Lemma 4.1 will be quite useful, in the present section for proving that (2.11) implies (2.12) and (2.16), and in the next section for proving that (2.13) and (2.17) imply (2.11). In the lemma we use the notations (2.9) and we relate (4.1), with f_i satisfying (2.6), (2.15), to the conditions

$$y \;=\; \boldsymbol{R}x \;+\; \boldsymbol{P}\, z, \quad \text{with } \|z_i\| \le \|y_i\| \ (1 \le i \le m), \tag{4.2.a}$$

$$z_i = z_j, \quad \text{whenever } y_i = y_j \text{ and } i, j \text{ belong to the same index set } I_q. \tag{4.2.b}$$

LEMMA 4.1 (reformulation of (4.1) with f_i satisfying (2.6), (2.15)). *Let* $\tau_0 > 0$, $\Delta t > 0$, $\gamma = \Delta t/\tau_0$, *and* $I + \gamma T$ *be invertible. Assume* (2.14), *and let* $x = [x_i] \in \mathbb{V}^l$ *and* $y = [y_i] \in \mathbb{V}^m$ *be given. Then* (4.1) *holds for some* $f_i : \mathbb{V} \to \mathbb{V}$ *satisfying* (2.6), (2.15), *if and only if there exists a vector* $z = [z_i] \in \mathbb{V}^m$ *such that* (4.2) *holds.*

Proof of Lemma 4.1. Assume (4.1), (2.6), (2.15), and define $z_i = y_i + \tau_0\, f_i(y_i)$, $z = [z_i] \in \mathbb{V}^m$. Applying (2.6), (2.9), and the equality $y = \mathbf{S}\, x + \gamma\, \mathbf{T}\, (-y + z)$, we arrive at (4.2.a); and by applying (2.15) we obtain (4.2.b).

Conversely, suppose (4.2.a) and (4.2.b) hold. For $i \in I_q$ we define $f_i : \mathbb{V} \to \mathbb{V}$ by

$$f_i(v) = (1/\tau_0)(-y_j + z_j) \ \text{ (if } v = y_j,\ j \in I_q), \ \text{ and } \ f_i(v) = 0 \ \text{ (otherwise) .}$$

Using again (2.9), it follows easily that (4.1) holds with f_i satisfying (2.6), (2.15). ∎

Proof that inequality (2.11) *implies* (2.12) *and* (2.16). Assume $0 < \tau_0 < \infty$, $0 < c \le c(S,T)$. We shall prove (2.12), which is enough because (2.16) follows from (2.12).

Let $\mathbb{V}$, $\|.\|$, f_i be as assumed in (2.12), and suppose x_i, y_i satisfy (2.5) with $0 < \Delta t \le c \cdot \tau_0$. We put $\gamma = \Delta t/\tau_0$ so that $0 < \gamma \le c(S,T)$. Applying Theorem 2.2(ii), it thus follows that γ satisfies (2.8), so that $I + \gamma T$ is invertible.

Since (4.1) holds with f_i satisfying (2.6), we can apply Lemma 4.1, with the trivial index sets $I_q = \{q\}$ for $1 \le q \le m$. It follows that (4.2.a) holds, so that, with the notations (2.9),

$$y_i \;=\; \sum_{j=1}^{l} r_{ij}\, x_j \;+\; \sum_{j=1}^{m} p_{ij}\, z_j, \quad \|z_i\| \le \|y_i\| \quad (1 \le i \le m).$$

In view of (2.8), (2.9), we have $r_{ij} \ge 0$, $p_{ij} \ge 0$; similarly, as in the proof of Lemma 2.3 we have (2.10), i.e., $\sum_j r_{ij} + \sum_j p_{ij} = 1$.

We denote the column vector in $\mathbb{R}^l$ with components $\|x_i\|$ by $[\|x_i\|]$, and we use a similar notation with regard to y_i and z_i. Using the convexity of the function $\|\cdot\|$, it thus follows that $[\|y_i\|] \le R\,[\|x_i\|] + P\,[\|z_i\|] \le Q\,S\,[\|x_i\|] + (I - Q)\,[\|y_i\|]$, i.e., $Q\,[\|y_i\|] \le Q\,S\,[\|x_i\|]$. Multiplying the last inequality by the matrix $Q^{-1} = I + \gamma T$ (which is nonnegative, in view of Theorem 2.2(i)), we get

$$\|y_i\| \;\le\; \sum_{j=1}^{l} s_{ij}\, \|x_j\| \quad (1 \le i \le m). \tag{4.3}$$

Using (2.3) and the nonnegativity of s_{ij} (cf. Theorem 2.2(i)), we obtain (2.7). ∎

4.2. Necessity of the inequality (2.11). In proving that (2.13) and (2.17) imply (2.11), we shall use the following lemma.

LEMMA 4.2 (invertibility of $I + \gamma T$). *Let $\tau_0 > 0$, $\Delta t > 0$ be given and $\gamma = \Delta t/\tau_0$. Assume $\mathbb{V} = \mathbb{R}^m$, $\|\cdot\| = \|\cdot\|_\infty$, and let $I_1, \ldots, I_r$ be index sets as in* (2.14). *Suppose process* (2.5) *is monotonic for all functions f_i satisfying* (2.6), (2.15). *Then $I + \gamma T$ is invertible.*

Proof of Lemma 4.2. Suppose $(I + \gamma T)\,\eta = 0$ for some vector $\eta = [\eta_i] \in \mathbb{R}^m$. Define $f_i(v) = -(1/\tau_0)\,v$ (for all $v \in \mathbb{V}$). Then (2.5) is satisfied by the vectors $x_i = 0$ $(1 \le i \le l)$ and $y_i = \eta_i\, e_m$ $(1 \le i \le m)$, where e_m is the vector in $\mathbb{R}^m$ with all components equal to 1. Since the functions f_i satisfy (2.6), (2.15), it follows that $|\eta_i| = \|y_i\| \le \max_j \|x_j\| = 0$, so that $\eta = 0$. ∎

Proof that (2.13) *implies* (2.11). Let τ_0, c be given with $0 < \tau_0 < \infty$, $0 < c \le \infty$, and assume (2.3), (2.13). We choose $\Delta t = \gamma\,\tau_0$, where γ is an arbitrary finite value with $0 < \gamma \le c$; and we define $\mathbb{V} = \mathbb{R}^m$.

An application of Lemma 4.2, with the trivial index sets $I_q = \{q\}$ (for $1 \le q \le m$), shows that the matrix $I + \gamma T$ is invertible. We thus can use the notations (2.9) and apply Lemma 4.1 (again with the trivial index sets), so as to conclude that, for any $x \in \mathbb{V}^l$ and $y,\, z \in \mathbb{V}^m$, the relations

$$y \;=\; \boldsymbol{R}\,x \;+\; \boldsymbol{P}\,z, \;\; \text{with} \;\; \|z_j\|_\infty \le \|y_j\|_\infty \;(1 \le j \le m), \tag{4.4}$$

imply that

$$\|y_j\|_\infty \;\le\; \max_{1 \le k \le l} \|x_k\|_\infty \quad (\text{for } 1 \le j \le m). \tag{4.5}$$

Below we shall use this implication for proving that

$$\| [\, R \;\; P \,] \|_\infty \le 1. \tag{4.6}$$

By Lemma 2.3, inequality (4.6) implies that $\gamma \le c(S,T)$. Since γ was chosen arbitrarily in $(0,c]$, the last inequality implies (2.11).

In proving (4.6), we shall use the notation $\mathrm{sgn}(\alpha) = 1$ (for $\alpha \ge 0$), $\mathrm{sgn}(\alpha) = -1$ (for $\alpha < 0$). We put $x_{ij} = \mathrm{sgn}(r_{ij})$, $z_{ij} = \mathrm{sgn}(p_{ij})$, where r_{ij}, p_{ij} are the entries of R and P, and we consider the special vectors x_j, $z_j \in \mathbb{V} = \mathbb{R}^m$ with components x_{ij} and z_{ij}, respectively $(1 \le i \le m)$. We define $x \in \mathbb{V}^l$ and y, $z \in \mathbb{V}^m$ by $x = [x_j]$, $z = [z_j]$, $y = [y_j] = \boldsymbol{R}x + \boldsymbol{P}z$, and denote the components of the vectors y_j by y_{ij} $(1 \le i \le m)$.

The relations (4.4) hold, with these special vectors, because

$$\|y_j\|_\infty \ge y_{jj} = \sum_k r_{jk}\, x_{jk} \;+\; \sum_k p_{jk}\, z_{jk} \;=\; \sum_k |r_{jk}| \;+\; \sum_k |p_{jk}|,$$

and, in view of (2.10),

$$\|z_j\|_\infty = 1 \;=\; \sum_k r_{jk} \;+\; \sum_k p_{jk} \;\le\; \sum_k |r_{jk}| \;+\; \sum_k |p_{jk}|.$$

Since (4.4) implies (4.5), we obtain $\sum_k |r_{jk}| \;+\; \sum_k |p_{jk}| \;\le\; 1$, i.e., (4.6). □

Proof that (2.17) *implies* (2.11). (i) Assume (2.3), (2.14) and irreducibility with respect to the index sets under consideration. Let τ_0, c be given with $0 < \tau_0 < \infty$, $0 < c \le \infty$, and assume (2.17). We choose $\Delta t = \gamma\, \tau_0$, where γ is an arbitrary finite value with $0 < \gamma \le c$ and we define $\mathbb{V} = \mathbb{R}^m$.

Similar to the proof above, $I + \gamma\, T$ is invertible, and for any $x \in \mathbb{V}^l$ and $y,\ z \in \mathbb{V}^m$, the implication

$$(4.4) \;\text{ and }\; (4.2.\mathrm{b}) \;\;\Rightarrow\;\; (4.5)$$

is valid. For completing the present proof, it is again enough to deduce (from the last implication) that (4.6) holds.

Below we shall denote by x_j, y_j, z_j the special vectors in $\mathbb{V} = \mathbb{R}^m$, with components x_{ij}, y_{ij}, z_{ij}, used in the previous proof that (2.13) implies (2.11).

(ii) First, assume that $y_i \ne y_j$ whenever indices $i \ne j$ belong to the same index set. Clearly, under this assumption (4.2.b) holds. Furthermore, just as in the previous proof, we have (4.4) so that (4.5) is valid. This again implies (4.6).

(iii) Next, assume the last assumption is violated, i.e., there are indices s, q belonging to the same index set, with $s \ne q$ and $y_s = y_q$. In this situation, we modify (only) the qth component of our special vectors x_j, y_j, z_j into $\tilde{x}_{qj} = \xi_j$, $\tilde{y}_{qj} = \eta_j$, and $\tilde{z}_{qj} = \zeta_j$, respectively. Here $\xi = [\xi_j] \in \mathbb{R}^l$, $\eta = [\eta_j] \in \mathbb{R}^m$, and $\zeta = [\zeta_j] \in \mathbb{R}^m$ are vectors such that

$$\eta \;=\; R\,\xi \;+\; P\,\zeta, \;\; \text{with } \|\xi\|_\infty \le 1,\; \|\zeta\|_\infty \le 1, \tag{4.7.a}$$

$$\eta_i \ne \eta_j \text{ whenever } i \ne j \text{ belong to the same index set.} \tag{4.7.b}$$

We will show that such vectors exist in part (iv) of the proof. In order to distinguish the original vectors x_j, y_j, z_j from the modified ones, we denote the latter by $\tilde{x}_j$, $\tilde{y}_j$, $\tilde{z}_j$, respectively.

Clearly, for $\tilde{x} = [\tilde{x}_j]$, $\tilde{y} = [\tilde{y}_j]$, $\tilde{z} = [\tilde{z}_j]$, the equality $\tilde{y} = \boldsymbol{R}\tilde{x} + \boldsymbol{P}\tilde{z}$ holds. Furthermore, $\tilde{y}_i \neq \tilde{y}_j$, whenever $i \neq j$ belong to the same index set. Finally (using $|y_{ss}| = |y_{sq}| \leq \|\tilde{y}_q\|_\infty$), we see that $\|\tilde{z}_j\|_\infty \leq 1 \leq \|\tilde{y}_j\|_\infty$ $(1 \leq j \leq m)$. The modified vectors thus satisfy (4.4), (4.2.b). Consequently, they satisfy (4.5), which implies $\sum_k |r_{jk}| + \sum_k |p_{jk}| \leq 1$ (for all $j \neq q$). By interchanging the role of s and q, we see that the last inequality is also valid for all $j \neq s$. Hence, (4.6) holds.

(iv) In view of the irreducibility assumption, the polynomials $f_i(\lambda) = \sum_{k=1}^{l} s_{ik}\,\lambda^k + \gamma \cdot \sum_{k=1}^{m} t_{ik}\,\lambda^{l+k}$ satisfy $f_i \neq f_j$, if $i \neq j$ belong to the same index set. It follows that, for sufficiently small $\lambda > 0$, the vectors $\xi = [\xi_j]$, $\eta = [\eta_j]$, $\zeta = [\zeta_j]$, with $\xi_k = \lambda^k$ $(1 \leq k \leq l)$, $\eta_k = f_k(\lambda)$ $(1 \leq k \leq m)$, $\zeta_k = \lambda^{l+k} + f_k(\lambda)$ $(1 \leq k \leq m)$, satisfy (4.7). □

ROBIN–ROBIN DOMAIN DECOMPOSITION METHODS FOR THE STOKES–DARCY COUPLING*

MARCO DISCACCIATI†, ALFIO QUARTERONI‡, AND ALBERTO VALLI§

Abstract. In this paper we consider a coupled system made of the Stokes and Darcy equations, and we propose some iteration-by-subdomain methods based on Robin conditions on the interface. We prove the convergence of these algorithms, and for suitable finite element approximations we show that the rate of convergence is independent of the mesh size h. Special attention is paid to the optimization of the performance of the methods when both the kinematic viscosity ν of the fluid and the hydraulic conductivity tensor K of the porous medium are very small.

Key words. Stokes and Darcy equations, domain decomposition, Robin interface condition, finite element approximation

1. Introduction and problem setting.

Let $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ be a bounded domain, decomposed in two nonintersecting subdomains Ω_f and Ω_p separated by an interface Γ, i.e., $\overline{\Omega} = \overline{\Omega_f} \cup \overline{\Omega_p}$, $\Omega_f \cap \Omega_p = \emptyset$, and $\overline{\Omega_f} \cap \overline{\Omega_p} = \Gamma$.

We are interested in the case in which Γ is a surface separating an upper domain Ω_f filled by a fluid, from a lower domain Ω_p formed by a porous medium. We assume that the fluid contained in Ω_f has an upper fixed surface (i.e., we do not consider the free surface fluid case) and can filtrate through the porous medium beneath.

The motion of the fluid in Ω_f is modeled by the Stokes equations:

$$-\boldsymbol{\nabla} \cdot \mathsf{T}(\mathbf{u}_f, p_f) = \mathbf{f}, \quad \nabla \cdot \mathbf{u}_f = 0 \qquad \text{in } \Omega_f, \tag{1}$$

where $\mathsf{T}(\mathbf{u}_f, p_f) = 2\,\nu\,\mathsf{D}(\mathbf{u}_f) - p_f \mathsf{I}$ is the stress tensor, and $\mathsf{D}(\mathbf{u}_f) = \frac{1}{2}(\nabla \mathbf{u}_f + \nabla^T \mathbf{u}_f)$ is the deformation tensor; as usual, ∇ and $\nabla\cdot$ denote the gradient operator and the divergence operator, respectively, with respect to the space coordinates. The parameter $\nu > 0$ is the kinematic viscosity of the fluid, while $\mathbf{u}_f$ and p_f denote the fluid velocity and pressure, respectively. We suppose ν to be constant in the whole domain Ω_f.

In the lower domain Ω_p we define the piezometric head $\varphi = z + p_p/(\rho g)$, where z is the elevation from a reference level, p_p the pressure of the fluid in Ω_p, $\rho > 0$ the density of the fluid (assumed to be constant in the whole domain Ω), and $g > 0$ the gravity acceleration.

The flow in Ω_p is modeled by the equations:

$$\mathbf{u}_p = -\frac{K}{n} \nabla \varphi, \quad \nabla \cdot \mathbf{u}_p = 0 \qquad \text{in } \Omega_p, \tag{2}$$

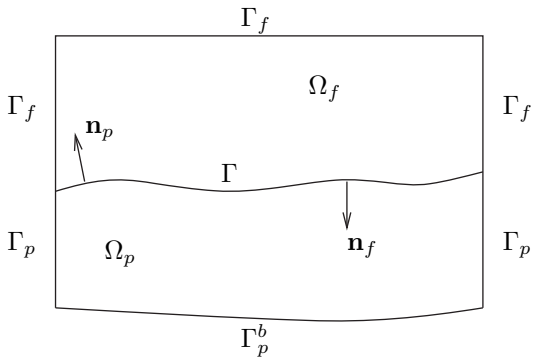

FIG. 1. *Schematic representation of a* 2D *vertical section of the computational domain.*

where $\mathbf{u}_p$ is the fluid velocity, and $n > 0$ is the volumetric porosity. The tensor K is the hydraulic conductivity $K = \mathrm{diag}\,(K_1, \ldots, K_d)$, and we suppose that $K_i \in L^\infty(\Omega_p)$ and $\inf_{\Omega_p} K_i > 0$, $i = 1, \ldots, d$. In the following we shall denote $\mathsf{K} = K/n = \mathrm{diag}\,(K_i/n)$ $(i = 1, \ldots, d)$. The first equation in (2) is Darcy's law.

For the sake of simplicity, we adopt homogenous boundary conditions. We impose the no-slip condition $\mathbf{u}_f = \mathbf{0}$ on $\Gamma_f = \partial\Omega_f \setminus \Gamma$ for the Stokes problem (1), while, for the Darcy problem (2), we set the piezometric head $\varphi = 0$ on the lateral surface Γ_p, and we require a slip condition on Γ_p^b: $\mathbf{u}_p \cdot \mathbf{n}_p = 0$ on Γ_p, where $\partial\Omega_p = \Gamma \cup \Gamma_p^b \cup \Gamma_p$ (see Figure 1). The vectors $\mathbf{n}_p$ and $\mathbf{n}_f$ denote the unit outward normal vectors to the surfaces $\partial\Omega_p$ and $\partial\Omega_f$, respectively; in particular, we have $\mathbf{n}_f = -\mathbf{n}_p$ on Γ. In the following we shall indicate $\mathbf{n} = \mathbf{n}_f$ for simplicity of notation. We also assume that the boundary $\partial\Omega$ and the interface Γ are piecewise smooth manifolds.

Other boundary conditions (see, e.g., [6, 7, 13, 10, 11]) could also be considered, and all of the results in this paper would remain true without essential changes in the proofs.

We supplement the Stokes and Darcy problems with the following matching conditions on Γ (see [12]):

$$\mathbf{u}_p \cdot \mathbf{n} = \mathbf{u}_f \cdot \mathbf{n}, \tag{3}$$

$$-\varepsilon \boldsymbol{\tau}_j \cdot (\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n}) = \nu \mathbf{u}_f \cdot \boldsymbol{\tau}_j, \qquad j = 1, \ldots, d-1, \tag{4}$$

$$-\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n}) = g\varphi_{|\Gamma}, \tag{5}$$

where $\boldsymbol{\tau}_j$ $(j = 1, \ldots, d-1)$ are linear independent unit tangential vectors to the interface Γ, and ε represents the characteristic length of the pores of the porous medium.

Conditions (3)–(5) impose the continuity of the normal velocity on Γ, as well as that of the normal component of the normal stress, but they allow the pressure to be discontinuous across the interface.

This problem has been studied in several works. In [8, 6, 7] the mathematical and numerical analysis of the coupled problem was carried out, in the case in which the Darcy equation is replaced by a scalar elliptic problem for the sole piezometric head φ. The analysis of the coupled problem in its original form (1)–(2) has been considered in [13, 10], and the recent works [18, 11] address the analysis and preconditioning of mortar discretizations of the Stokes–Darcy problem.

A domain decomposition method of the Dirichlet–Neumann type based on the choice of the fluid normal velocity across Γ as an interface variable was proposed and analyzed in [6, 7]. A similar approach, using the trace of φ on Γ as an interface

variable, has been studied in [8]. After proving that this method is equivalent to a preconditioned Richardson algorithm for the Steklov–Poincaré interface equation associated to the Stokes–Darcy problem, it was proved that the convergence rate of the algorithm is independent of the mesh parameter h, for suitable conforming finite element approximations of the coupled problem. An extension to the time-dependent case has been presented in [9].

The previous results indicate that, in the steady case, preconditioners of the Dirichlet–Neumann type may be sensitive to the variation of the viscosity ν and of the entries of the hydraulic conductivity K, downgrading the convergence rate of the algorithm.

In this work we extend some preliminary results contained in [8], by presenting improved domain decomposition methods based on Robin interface conditions. The aim is twofold: first, to propose an algorithm whose rate of convergence does not deteriorate as ν and the entries of K become smaller and smaller, and second, to devise an algorithm that is more "symmetric" with respect to the treatment of either Ω_f and Ω_p, namely, being based on solvers that treat simultaneously (i.e., in parallel) the two subdomains.

After having presented in section 2 the weak formulation of the coupled problem, in section 3 we introduce two methods, based on a multiplicative and on an additive paradigm, respectively. Then, in section 4 the convergence analysis of the algorithms is developed. Finally, some numerical results are presented in section 5.

The first algorithm has optimal convergence properties with respect to ν and K. On the other hand, the second algorithm, which indeed for small values of ν and K does not outperform the Dirichlet–Neumann scheme, is interesting for its parallel nature. Moreover, its convergence analysis is rather simple and is based on the fact that the so-called Robin-to-Dirichlet and Robin-to-Neumann maps are symmetric and positive, uniformly with respect to the mesh size h. These important properties seem to be yet overlooked in the literature and could be revealed to be very useful also in different contexts.

2. Weak form of the coupled problem. From now on, instead of (2), we will take the following scalar formulation of the Darcy problem:

$$-\nabla \cdot (\mathsf{K}\nabla\varphi) = 0 \quad \text{in } \Omega_p. \tag{6}$$

Accordingly, (3) becomes

$$-\mathsf{K}\nabla\varphi \cdot \mathbf{n} = \mathbf{u}_f \cdot \mathbf{n} \quad \text{on } \Gamma. \tag{7}$$

We define the following functional spaces:

$$H_f = \{\mathbf{v} \in (H^1(\Omega_f))^d |\ \mathbf{v} = \mathbf{0} \text{ on } \Gamma_f\}, \quad Q = L^2(\Omega_f), \tag{8}$$

$$H_p = \{\psi \in H^1(\Omega_p) |\ \psi = 0 \text{ on } \Gamma_p^b\} \tag{9}$$

and the bilinear forms

$$a_f(\mathbf{v}, \mathbf{w}) = 2\nu \int_{\Omega_f} \mathsf{D}(\mathbf{v}) : \mathsf{D}(\mathbf{w}) \qquad \forall \mathbf{v}, \mathbf{w} \in (H^1(\Omega_f))^d, \tag{10}$$

$$b_f(\mathbf{v}, q) = -\int_{\Omega_f} q\, \nabla \cdot \mathbf{v} \qquad \forall \mathbf{v} \in (H^1(\Omega_f))^d, \quad \forall q \in Q, \tag{11}$$

$$a_p(\varphi, \psi) = \int_{\Omega_p} \nabla\psi \cdot \mathsf{K}\nabla\varphi \qquad \forall \varphi, \psi \in H^1(\Omega_p). \tag{12}$$

The coupling conditions (4), (5), and (7) can be incorporated in the weak formulation of the global problem as natural conditions on Γ. In particular, we can write the following weak saddle-point formulation of the coupled Stokes–Darcy problem:

Find $(\mathbf{u}_f, p_f) \in H_f \times Q$, $\varphi \in H_p$ such that

$$a_f(\mathbf{u}_f, \mathbf{v}) + b_f(\mathbf{v}, p_f) + g\, a_p(\varphi, \psi) + \int_\Gamma g\, \varphi(\mathbf{v}\cdot\mathbf{n}) - \int_\Gamma g\, \psi(\mathbf{u}_f\cdot\mathbf{n}) + \int_\Gamma \sum_{j=1}^{d-1} \frac{\nu}{\varepsilon}(\mathbf{u}_f\cdot\boldsymbol{\tau}_j)(\mathbf{v}\cdot\boldsymbol{\tau}_j) = \int_{\Omega_f} \mathbf{f}\cdot\mathbf{v} \qquad \forall \mathbf{v} \in H_f,\ \psi \in H_p, \tag{13}$$

$$b_f(\mathbf{u}_f, q) = 0 \qquad \forall q \in Q. \tag{14}$$

Using Brezzi's theory of saddle-point problems [2], we can guarantee that the coupled problem (13)–(14) has a unique solution (see [8, 6, 13]).

In the rest of the paper, instead of (4) we shall adopt the following simplified condition on the interface:

$$\mathbf{u}_f\cdot\boldsymbol{\tau}_j = 0 \quad \text{on } \Gamma \qquad (j = 1, \ldots, d-1), \tag{15}$$

and, consequently, we will use the functional space:

$$H_f^\tau = \{\mathbf{v} \in H_f |\ \mathbf{v}\cdot\boldsymbol{\tau}_j = 0 \text{ on } \Gamma,\ j = 1, \ldots, d-1\}. \tag{16}$$

This simplification is acceptable from the physical viewpoint, since the term in (4) involving the normal derivative of $\mathbf{u}_f$ is multiplied by ε and the velocity itself can be supposed at least of order $O(\varepsilon)$ in the neighborhood of Γ, so that the left-hand side can be approximated by zero. We point out that this simplification does not dramatically influence the coupling of the two subproblems, since (4) is not strictly speaking a coupling condition but only a boundary condition for the fluid problem in Ω_f. In any case, all of the results in the paper are still true for the more general interface condition (4), provided H_f^τ is replaced by H_f and the bilinear form $a_f(\mathbf{w}, \mathbf{v})$ by $a_f(\mathbf{w}, \mathbf{v}) + \int_\Gamma \sum_{j=1}^{d-1} \frac{\nu}{\varepsilon}(\mathbf{w}\cdot\boldsymbol{\tau}_j)(\mathbf{v}\cdot\boldsymbol{\tau}_j)$.

Remark 2.1. In [6, 7] we considered another simplified form of (4), i.e., $\boldsymbol{\tau}_j \cdot (\mathsf{T}(\mathbf{u}_f, p_f)\cdot\mathbf{n}) = 0$ on Γ. Although not completely precise from the physical point of view, this simplified condition is perfectly acceptable from the mathematical viewpoint for the setup and analysis of solution methods for the coupled problem.

3. Iterative domain decomposition methods for solving the coupled problem. In this section we propose new iterative methods to compute the solution of the coupled problem which exploit the decoupled structure of the problem, thus requiring one at each step to solve independently the fluid and the groundwater subproblems, i.e., using as building blocks a Stokes solver and an elliptic solver.

As we have already remarked, the numerical performances of the domain decomposition methods of the Dirichlet–Neumann type presented in [6, 7] strongly depend on the fluid viscosity ν and on the entries of the hydraulic conductivity K. More precisely, the convergence rate of the algorithm deteriorates as ν and the entries of K decrease. The following numerical example illustrates the situation.

Example 3.1. We consider the computational domain $\Omega \subset \mathbb{R}^2$, with $\Omega_f = (0,1)\times(1,2)$, $\Omega_p = (0,1)\times(0,1)$, and $\Gamma = (0,1)\times\{1\}$, and choose the parameter $g = 1$; moreover, we assume that the hydraulic conductivity tensor K is a multiple of the identity tensor, namely, a scalar function. Boundary conditions and the right-hand

TABLE 1
Iterations using PCG with the Dirichlet–Neumann preconditioner with respect to several values of ν and K and of the grid parameter h ($h_1 \approx 0.14$ and $h_i = h_1/2^{i-1}$, $i = 2, 3, 4$).

ν	K	h_1	h_2	h_3	h_4
1	1	5	5	5	5
10^{-1}	10^{-1}	10	10	8	8
10^{-2}	10^{-1}	13	15	14	14
10^{-3}	10^{-2}	19	49	60	55
10^{-4}	10^{-3}	20	58	143	167
10^{-6}	10^{-4}	20	56	138	202

side $\mathbf{f}$ are chosen in such a way that the exact solution of the coupled Stokes–Darcy problem is $\mathbf{u}_f = (y^2 - 2y + 1, x^2 - x)^T$, $p_f = 2\nu(x + y - 1) + 1/(3\mathsf{K})$, $\varphi = (x(1 - x)(y-1) + y^3/3 - y^2 + y)/\mathsf{K} + 2x\nu$, with ν and K constant in Ω_f and Ω_p, respectively. Table 1 reports the number of iterations obtained for several choices of ν and K and four different grid sizes, using the preconditioned conjugate gradient (PCG) method on the interface equation, with the preconditioner characterized by the Dirichlet–Neumann method. A tolerance of 10^{-9} has been imposed on the relative increment. Taylor–Hood finite elements have been used to approximate the Stokes problem and quadratic Lagrangian elements for the Darcy equation (6).

Such small values of ν and K are quite realistic for real-life physical flows. This fact motivates our interest to set up new algorithms that are more robust to parameter variations.

3.1. Iterative methods based on Robin interface conditions. We present two possible domain decomposition methods based on the adoption of Robin interface conditions, i.e., proper linear combinations of the coupling conditions (5) and (7).

3.1.1. A sequential Robin–Robin method. We consider a sequential Robin–Robin (sRR) method, which at each iteration requires one to solve a Darcy problem in Ω_p followed by a Stokes problem in Ω_f, both with Robin conditions on Γ. Precisely, the algorithm reads as follows.

Having assigned a trace function $\eta^0 \in L^2(\Gamma)$ and two acceleration parameters $\gamma_f \geq 0$ and $\gamma_p > 0$, for each $k \geq 0$:

(i) find $\varphi^{k+1} \in H_p$ such that

$$\gamma_p a_p(\varphi^{k+1}, \psi) + \int_\Gamma g\varphi^{k+1}_{|\Gamma}\psi_{|\Gamma} = \int_\Gamma \eta^k \psi_{|\Gamma} \qquad \forall\ \psi \in H_p. \tag{17}$$

This corresponds to imposing the following interface condition (in weak, or natural, form) for the Darcy problem:

$$-\gamma_p \mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n} + g\varphi^{k+1}_{|\Gamma} = \eta^k \qquad \text{on } \Gamma. \tag{18}$$

(ii) Then find $(\mathbf{u}_f^{k+1}, p_f^{k+1}) \in H_f^\tau \times Q$ such that

$$\begin{aligned} &a_f(\mathbf{u}_f^{k+1}, \mathbf{v}) + b_f(\mathbf{v}, p_f^{k+1}) + \gamma_f \int_\Gamma (\mathbf{u}_f^{k+1} \cdot \mathbf{n})(\mathbf{v} \cdot \mathbf{n}) \\ &\quad = \int_\Gamma \Big(\frac{\gamma_f}{\gamma_p}\eta^k - \frac{\gamma_f + \gamma_p}{\gamma_p} g\varphi^{k+1}_{|\Gamma}\Big)(\mathbf{v} \cdot \mathbf{n}) + \int_{\Omega_f} \mathbf{f} \cdot \mathbf{v} \quad \forall\ \mathbf{v} \in H_f^\tau, \\ &b_f(\mathbf{u}_f^{k+1}, q) = 0 \qquad \forall\ q \in Q. \end{aligned} \tag{19}$$

This corresponds to imposing on the Stokes problem the following matching conditions on Γ (still in natural form):

$$\begin{aligned}
&\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_f^{k+1},p_f^{k+1})\cdot\mathbf{n})+\gamma_f\mathbf{u}_f^{k+1}\cdot\mathbf{n}=\frac{\gamma_f}{\gamma_p}\eta^k-\frac{\gamma_f+\gamma_p}{\gamma_p}g\varphi_{|\Gamma}^{k+1}\\
&\qquad=-g\varphi_{|\Gamma}^{k+1}-\gamma_f\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n},\\
&\mathbf{u}_f^{k+1}\cdot\boldsymbol{\tau}_j=0,\qquad j=1,\dots,d-1.
\end{aligned}\tag{20}$$

(iii) Finally, set

$$\begin{aligned}
\eta^{k+1}&=-\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_f^{k+1},p_f^{k+1})\cdot\mathbf{n})+\gamma_p\mathbf{u}_f^{k+1}\cdot\mathbf{n}\\
&=(\gamma_f+\gamma_p)(\mathbf{u}_f^{k+1}\cdot\mathbf{n})+\frac{\gamma_f+\gamma_p}{\gamma_p}g\varphi_{|\Gamma}^{k+1}-\frac{\gamma_f}{\gamma_p}\eta^k\in L^2(\Gamma).
\end{aligned}\tag{21}$$

Concerning the solvability of problem (19), we note first that using the trace theorem and the Korn inequality (see, e.g., [3, p. 416]), there exist two constants $\kappa_1,\kappa_2>0$ such that

$$\int_\Gamma|\mathbf{u}_f\cdot\mathbf{n}|^2\le\kappa_1\left(\int_{\Omega_f}(|\mathbf{u}_f|^2+|\nabla\mathbf{u}_f|^2)\right)\le\kappa_2\int_{\Omega_f}|\mathsf{D}(\mathbf{u}_f)|^2.\tag{22}$$

Therefore, the bilinear form

$$a_f(\mathbf{u}_f,\mathbf{v})+\gamma_f\int_\Gamma(\mathbf{u}_f\cdot\mathbf{n})(\mathbf{v}\cdot\mathbf{n})$$

is continuous and coercive in $H_f^\tau\times H_f^\tau$. Moreover, the bilinear form $b_f(\mathbf{v},p)$ satisfies an inf–sup condition on the space $H_f^\tau\times Q$ (see, e.g., [17, pp. 157–158]). Then, for every $\mathbf{f}\in(L^2(\Omega_f))^d$, $\eta^k\in L^2(\Gamma)$, and $\varphi_{|\Gamma}^{k+1}\in L^2(\Gamma)$, there exists a unique solution of problem (19).

If the sRR method converges, in the limit we recover the solution $(\mathbf{u}_f,p_f)\in H_f^\tau\times Q$ and $\varphi\in H_p$ of the coupled Stokes–Darcy problem. Indeed, denoting by φ^* the limit of the sequence φ^k in $H^1(\Omega_p)$ and by $(\mathbf{u}_f^*,p_f^*)$ that of $(\mathbf{u}_f^k,p_f^k)$ in $(H^1(\Omega_f))^d\times Q$, we obtain

$$-\gamma_p\mathsf{K}\nabla\varphi^*\cdot\mathbf{n}+g\varphi_{|\Gamma}^*=-\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_f^*,p_f^*)\cdot\mathbf{n})+\gamma_p\mathbf{u}_f^*\cdot\mathbf{n}\quad\text{on }\Gamma,\tag{23}$$

so that, as a consequence of (20), we have

$$(\gamma_f+\gamma_p)\mathbf{u}_f^*\cdot\mathbf{n}=-(\gamma_f+\gamma_p)\mathsf{K}\nabla\varphi^*\cdot\mathbf{n}\quad\text{on }\Gamma,$$

yielding, since $\gamma_f+\gamma_p\neq0$, $\mathbf{u}_f^*\cdot\mathbf{n}=-\mathsf{K}\nabla\varphi^*\cdot\mathbf{n}$ on Γ and also, from (23), that $\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_f^*,p_f^*)\cdot\mathbf{n})=-g\varphi_{|\Gamma}^*$ on Γ. Thus, the two interface conditions (5) and (7) are satisfied, and we can conclude that the limit functions $\varphi^*\in H_p$ and $(\mathbf{u}_f^*,p_f^*)\in H_f^\tau\times Q$ are the solutions of the coupled Stokes–Darcy problem.

The proof of convergence will be given in section 4.1.

3.1.2. A parallel Robin–Robin method. We consider now a parallel Robin–Robin (pRR) algorithm. The idea behind this new method resembles that for a Neumann–Neumann scheme. However, the latter cannot be considered straightforwardly in our case, since we would not be able to guarantee the correct regularity of the data for each subproblem, as we shall point out more precisely in Remark 3.1.

The pRR algorithm that we propose reads as follows: Let $\mu^k \in L^2(\Gamma)$ be an assigned trace function on Γ, and let γ_1, γ_2 be two positive parameters; then, for $k \geq 0$,

(i) find $(\mathbf{u}_f^{k+1}, p_f^{k+1}) \in H_f^\tau \times Q$ such that

$$\begin{aligned} &a_f(\mathbf{u}_f^{k+1}, \mathbf{v}) + b_f(\mathbf{v}, p_f^{k+1}) - \gamma_1 \int_\Gamma (\mathbf{u}_f^{k+1} \cdot \mathbf{n})(\mathbf{v} \cdot \mathbf{n}) \\ &\qquad = \int_\Gamma \mu^k (\mathbf{v} \cdot \mathbf{n}) + \int_{\Omega_f} \mathbf{f} \cdot \mathbf{v} \qquad \forall\, \mathbf{v} \in H_f^\tau, \\ &b_f(\mathbf{u}_f^{k+1}, q) = 0 \qquad \forall\, q \in Q, \end{aligned} \tag{24}$$

and, at the same time, find $\varphi^{k+1} \in H_p$ such that

$$a_p(\varphi^{k+1}, \psi) + \frac{1}{\gamma_1} \int_\Gamma g \varphi_{|\Gamma}^{k+1} \psi_{|\Gamma} = -\frac{1}{\gamma_1} \int_\Gamma \mu^k \psi_{|\Gamma} \qquad \forall\, \psi \in H_p. \tag{25}$$

Remark that on the interface Γ we are imposing the matching conditions

$$\begin{aligned} &\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f^{k+1}, p^{k+1}) \cdot \mathbf{n}) - \gamma_1 \mathbf{u}_f^{k+1} \cdot \mathbf{n} = \mu^k \\ &\qquad = -g \varphi_{|\Gamma}^{k+1} + \gamma_1 \mathsf{K} \nabla \varphi^{k+1} \cdot \mathbf{n}, \\ &\mathbf{u}_f^{k+1} \cdot \boldsymbol{\tau}_j = 0, \quad j = 1, \ldots, d-1. \end{aligned} \tag{26}$$

(ii) As a second step, find $(\widehat{\boldsymbol{\omega}}^{k+1}, \widehat{\pi}^{k+1}) \in H_f^\tau \times Q$ such that

$$\begin{aligned} &a_f(\widehat{\boldsymbol{\omega}}^{k+1}, \mathbf{v}) + b_f(\mathbf{v}, \widehat{\pi}^{k+1}) + \gamma_2 \int_\Gamma (\widehat{\boldsymbol{\omega}}^{k+1} \cdot \mathbf{n})(\mathbf{v} \cdot \mathbf{n}) \\ &\qquad = \gamma_2 \int_\Gamma \widehat{\sigma}^{k+1} (\mathbf{v} \cdot \mathbf{n}) \qquad \forall\, \mathbf{v} \in H_f^\tau, \\ &b_f(\widehat{\boldsymbol{\omega}}^{k+1}, q) = 0 \qquad \forall\, q \in Q, \end{aligned} \tag{27}$$

and find $\widehat{\chi}^{k+1} \in H_p$ such that

$$a_p(\widehat{\chi}^{k+1}, \psi) + \frac{1}{\gamma_2} \int_\Gamma g \widehat{\chi}_{|\Gamma}^{k+1} \psi_{|\Gamma} = \int_\Gamma \widehat{\sigma}^{k+1} \psi_{|\Gamma} \qquad \forall\, \psi \in H_p, \tag{28}$$

where

$$\widehat{\sigma}^{k+1} = \mathbf{u}_f^{k+1} \cdot \mathbf{n} + \mathsf{K} \nabla \varphi^{k+1} \cdot \mathbf{n} = \mathbf{u}_f^{k+1} \cdot \mathbf{n} + \frac{1}{\gamma_1} (g \varphi_{|\Gamma}^{k+1} + \mu^k) \in L^2(\Gamma). \tag{29}$$

Note that on the interface Γ we are now imposing the matching conditions

$$\begin{aligned} &\mathbf{n} \cdot (\mathsf{T}(\widehat{\boldsymbol{\omega}}^{k+1}, \widehat{\pi}^{k+1}) \cdot \mathbf{n}) + \gamma_2 \widehat{\boldsymbol{\omega}}^{k+1} \cdot \mathbf{n} = \gamma_2 \widehat{\sigma}^{k+1} \\ &\qquad = g \widehat{\chi}_{|\Gamma}^{k+1} - \gamma_2 \mathsf{K} \nabla \widehat{\chi}^{k+1} \cdot \mathbf{n}, \\ &\widehat{\boldsymbol{\omega}}^{k+1} \cdot \boldsymbol{\tau}_j = 0, \quad j = 1, \ldots, d-1. \end{aligned} \tag{30}$$

(iii) Finally, set

$$\begin{aligned} \mu^{k+1} &= \mu^k - \theta [\mathbf{n} \cdot (\mathsf{T}(\widehat{\boldsymbol{\omega}}^{k+1}, \widehat{\pi}^{k+1}) \cdot \mathbf{n}) + g \widehat{\chi}_{|\Gamma}^{k+1}] \\ &= \mu^k - \theta [\gamma_2 (\widehat{\sigma}^{k+1} - \widehat{\boldsymbol{\omega}}^{k+1} \cdot \mathbf{n}) + g \widehat{\chi}_{|\Gamma}^{k+1}] \in L^2(\Gamma), \end{aligned} \tag{31}$$

where $\theta > 0$ is a further acceleration parameter.

Before moving to the convergence analysis of the pRR method (24)–(31), a few remarks are in order.

Concerning the well-posedness of problem (24), since the inf–sup condition is satisfied (see [17, pp. 157–158]), and thanks to (22), the bilinear form

$$a_f(\mathbf{u}_f, \mathbf{v}) - \gamma_1 \int_\Gamma (\mathbf{u}_f \cdot \mathbf{n})(\mathbf{v} \cdot \mathbf{n})$$

is coercive in $H_f^\tau \times H_f^\tau$ provided

$$\gamma_1 < \frac{2\nu}{\kappa_2}. \tag{32}$$

As regards the consistency of the algorithm, note that if we find a fixed point μ^*, from (31) we have (again denoting the limit functions by an upper $*$)

$$\gamma_2(\widehat{\boldsymbol{\omega}}^* \cdot \mathbf{n} - \widehat{\sigma}^*) = g\widehat{\chi}^*_{|\Gamma} \qquad \text{on } \Gamma \tag{33}$$

and also, equivalently,

$$\frac{1}{\gamma_2} g\widehat{\chi}^*_{|\Gamma} - \widehat{\sigma}^* = \frac{2}{\gamma_2} g\widehat{\chi}^*_{|\Gamma} - \widehat{\boldsymbol{\omega}}^* \cdot \mathbf{n} \qquad \text{on } \Gamma. \tag{34}$$

Therefore, if we multiply (28) by g, sum the resulting equation to (27), and use relations (33) and (34), we obtain

$$\begin{aligned} a_f(\widehat{\boldsymbol{\omega}}^*, \mathbf{v}) + b_f(\mathbf{v}, \widehat{\pi}^*) + \int_\Gamma g\widehat{\chi}^*_{|\Gamma}(\mathbf{v} \cdot \mathbf{n}) + g a_p(\widehat{\chi}^*, \psi) \\ - \int_\Gamma g(\widehat{\boldsymbol{\omega}}^* \cdot \mathbf{n})\psi_{|\Gamma} + \int_\Gamma \frac{2g^2}{\gamma_2} \widehat{\chi}^*_{|\Gamma} \psi_{|\Gamma} = 0 \qquad \forall (\mathbf{v}, \psi) \in H_f^\tau \times H_p. \end{aligned}$$

Taking $\mathbf{v} = \widehat{\boldsymbol{\omega}}^*$ and $\psi = \widehat{\chi}^*$, we find

$$a_f(\widehat{\boldsymbol{\omega}}^*, \widehat{\boldsymbol{\omega}}^*) + g a_p(\widehat{\chi}^*, \widehat{\chi}^*) + \int_\Gamma \frac{2g^2}{\gamma_2} (\widehat{\chi}^*_{|\Gamma})^2 = 0\,;$$

hence, $\widehat{\chi}^* = 0$ in Ω_p, and $\widehat{\boldsymbol{\omega}}^* = \mathbf{0}$ in Ω_f thanks to the Korn inequality.

The interface equation (30) gives $\widehat{\sigma}^* = 0$ on Γ; hence, $\mathbf{u}_f^* \cdot \mathbf{n} = -\mathsf{K}\nabla\varphi^* \cdot \mathbf{n}$ on Γ. Moreover, using (26), we obtain $\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f^*, p_f^*) \cdot \mathbf{n}) = -g\varphi^*_{|\Gamma}$ on Γ. Thus, the two interface conditions (5) and (7) are fulfilled, so that the solutions $(\mathbf{u}_f^*, p_f^*) \in H_f^\tau \times Q$ and $\varphi^* \in H_p$ (corresponding to the fixed point μ^*) satisfy the coupled Stokes–Darcy problem.

Our aim is now to prove that the map generating the sequence μ^k is a contraction in $L^2(\Gamma)$. We shall address this point in section 4.2.

Remark 3.1. A Neumann–Neumann method corresponding to the choice of the normal velocity $\mathbf{u}_f \cdot \mathbf{n}$ as an interface variable would involve the following steps. For an assigned function $\lambda^k \in H_{00}^{1/2}(\Gamma)$, with $\int_\Gamma \lambda^k = 0$ (we refer to [14] for a definition of the trace space $H_{00}^{1/2}(\Gamma)$), first solve a Stokes problem in Ω_f with boundary conditions $\mathbf{u}_f^{k+1} \cdot \mathbf{n} = \lambda^k$, $\mathbf{u}_f^{k+1} \cdot \boldsymbol{\tau}_j = 0$ on Γ, and a Darcy problem in Ω_p imposing $-\mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n} = \lambda^k$ on Γ. Then, similarly to (29), we have to compute $\widehat{\sigma}^{k+1} = -\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f^{k+1}, p_f^{k+1}) \cdot \mathbf{n}) - g\varphi^{k+1}_{|\Gamma}$ on Γ. Here we would have $\widehat{\sigma}^{k+1} \in H^{-1/2}(\Gamma)$. Therefore, this regularity of $\widehat{\sigma}^{k+1}$ would not be enough to guarantee the solvability of the subsequent Darcy problem, which would demand one to impose $g\widehat{\chi}^{k+1}_{|\Gamma} = \widehat{\sigma}^{k+1}$ as a boundary condition

on Γ. Thus, a Neumann–Neumann method does not guarantee that the regularity of the interface data is preserved at each iteration and that the sequence λ^k generated by the algorithm is in $H_{00}^{1/2}(\Gamma)$.

Of course one may speculate that this issue of lack of regularity is not relevant at the finite dimensional level, for instance, for finite element approximation. However, the difficulty is only hidden, and we should expect that it will show up as the mesh parameter h goes to 0.

4. Convergence analysis. In what follows, for either an open set or a manifold D, we denote the norm in the Sobolev space $H^s(D)$, $s \geq -1$, by $\|\cdot\|_{s,D}$.

4.1. Convergence of the sRR method. We prove that the sequences φ^k and $(\mathbf{u}_f^k, p_f^k)$ generated by the sRR method (17)–(21) converge in $H^1(\Omega_p)$ and $(H^1(\Omega_f))^d \times Q$, respectively. As a consequence, the sequence η^k is convergent in the dual space $H^{-1/2}(\Gamma)$ and weakly convergent in $L^2(\Gamma)$.

The proof of convergence that we are presenting follows the guidelines of the theory by Lions [15] for the Robin–Robin method (see also [17, section 4.5]).

We denote by $\mathbf{e}_u^k = \mathbf{u}_f^k - \mathbf{u}_f$, $e_p^k = p_f^k - p_f$, and $e_\varphi^k = \varphi^k - \varphi$ the errors at the kth step. Remark that, thanks to the linearity, the functions $(\mathbf{e}_u^k, e_p^k)$ satisfy problem (19) with $\mathbf{f} = \mathbf{0}$, while e_φ^k is a solution to (17). Moreover, we assume that $\gamma_p = \gamma_f$, and we denote by γ their common value.

Finally, let us point out that the solutions $(\mathbf{u}_f, p_f) \in H_f^\tau \times Q$ and $\varphi \in H_p$ of the coupled Stokes–Darcy problem satisfy $\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n}) \in H^{1/2}(\Gamma)$ (as it is equal to $-g\varphi_{|\Gamma}$ on Γ), and $\nabla\varphi \cdot \mathbf{n} \in L^2(\Gamma)$ (as it is equal to $-\mathsf{K}^{-1}\mathbf{u}_f \cdot \mathbf{n}$ on Γ); i.e., these functions enjoy a better regularity than one might usually expect. Therefore, the interface conditions (18) and (20) for the error functions hold in $L^2(\Gamma)$.

Let us come to the proof of convergence. Choosing $\psi = e_\varphi^{k+1}$ in (17), and using the identity

$$AB = \frac{1}{4}[(A+B)^2 - (A-B)^2],$$

we have

$$\begin{aligned} g\, a_p(e_\varphi^{k+1}, e_\varphi^{k+1}) &= \frac{1}{\gamma}\int_\Gamma (\eta^k - g e_{\varphi|\Gamma}^{k+1}) g e_{\varphi|\Gamma}^{k+1} \\ &= \frac{1}{4\gamma}\int_\Gamma (\eta^k)^2 - \frac{1}{4\gamma}\int_\Gamma (\eta^k - 2g e_{\varphi|\Gamma}^{k+1})^2. \end{aligned} \tag{35}$$

Similarly, taking $\mathbf{v} = \mathbf{e}_u^{k+1}$ in (19) and using (21), we have

$$\begin{aligned} a_f(\mathbf{e}_u^{k+1}, \mathbf{e}_u^{k+1}) &= \frac{1}{\gamma}\int_\Gamma (\eta^k - 2g e_{\varphi|\Gamma}^{k+1} - \gamma \mathbf{e}_u^{k+1}\cdot\mathbf{n})(\gamma \mathbf{e}_u^{k+1}\cdot\mathbf{n}) \\ &= \frac{1}{4\gamma}\int_\Gamma (\eta^k - 2g e_{\varphi|\Gamma}^{k+1})^2 - \frac{1}{4\gamma}\int_\Gamma (\eta^k - 2g e_{\varphi|\Gamma}^{k+1} - 2\gamma \mathbf{e}_u^{k+1}\cdot\mathbf{n})^2 \\ &= \frac{1}{4\gamma}\int_\Gamma (\eta^k - 2g e_{\varphi|\Gamma}^{k+1})^2 - \frac{1}{4\gamma}\int_\Gamma (\eta^{k+1})^2. \end{aligned} \tag{36}$$

Adding (35) and (36), we find

$$g\, a_p(e_\varphi^{k+1}, e_\varphi^{k+1}) + a_f(\mathbf{e}_u^{k+1}, \mathbf{e}_u^{k+1}) + \frac{1}{4\gamma}\int_\Gamma (\eta^{k+1})^2 = \frac{1}{4\gamma}\int_\Gamma (\eta^k)^2.$$

Summing over k from $k=0$ to $k=N$, with $N \geq 1$, we finally obtain

$$\sum_{k=0}^{N} \left(g\, a_p(e_\varphi^{k+1}, e_\varphi^{k+1}) + a_f(\mathbf{e}_u^{k+1}, \mathbf{e}_u^{k+1}) \right) + \frac{1}{4\gamma} \int_\Gamma (\eta^{N+1})^2 = \frac{1}{4\gamma} \int_\Gamma (\eta^0)^2.$$

Thus, the series

$$\sum_{k=0}^{\infty} \left(g\, a_p(e_\varphi^{k+1}, e_\varphi^{k+1}) + a_f(\mathbf{e}_u^{k+1}, \mathbf{e}_u^{k+1}) \right)$$

is convergent, and the errors e_φ^k and $\mathbf{e}_u^k$ tend to zero in $H^1(\Omega_p)$ and $(H^1(\Omega_f))^d$, respectively. The convergence of the pressure error e_p^k to 0 in Q is then a well-known consequence of the convergence of the velocity.

4.1.1. Interpretation of the sRR method as an alternating direction scheme. The sRR method can be interpreted as an alternating direction scheme (see [1]; see also [8]). For technical reasons, to make precise this statement let us assume that a flux boundary condition $\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n} = \mathbf{g}$ is imposed on the top of the fluid domain Ω_f, $\mathbf{g}$ being a given vector function. Moreover, we assume that the interface Γ is smooth, say, a $\mathcal{C}^2$-manifold with a boundary.

Then introduce the spaces

$$\begin{aligned}
&\widehat{H}_f = \{\mathbf{v} \in (H^1(\Omega_f))^d |\ \mathbf{v} = \mathbf{0} \text{ on the lateral boundary of } \Omega_f\},\\
&\widehat{H}_f^\tau = \{\mathbf{v} \in \widehat{H}_f |\ \mathbf{v} \cdot \boldsymbol{\tau}_j = 0 \text{ on } \Gamma,\ j = 1, \ldots, d-1\},\\
&\widehat{H}_f^{\tau,n} = \{\mathbf{v} \in \widehat{H}_f^\tau |\ \mathbf{v} \cdot \mathbf{n} = 0 \ \text{ on } \Gamma\}, \quad H_p^0 = \{\psi \in H_p |\ \psi = 0 \ \text{ on } \Gamma_p\},
\end{aligned}$$

and define the operator S_f as

$$S_f : H_{00}^{1/2}(\Gamma) \to (H_{00}^{1/2}(\Gamma))', \quad \chi \to S_f\chi = \mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_\chi, p_\chi) \cdot \mathbf{n}),$$

where $(\mathbf{u}_\chi, p_\chi) \in \widehat{H}_f^\tau \times Q$ satisfies

$$\begin{aligned}
&a_f(\mathbf{u}_\chi, \mathbf{v}) + b_f(\mathbf{v}, p_\chi) = 0 \qquad \forall\ \mathbf{v} \in \widehat{H}_f^{\tau,n}(\Omega_f),\\
&b_f(\mathbf{u}_\chi, q) = 0 \qquad \forall\ q \in Q,
\end{aligned}$$

with $\mathbf{u}_\chi \cdot \mathbf{n} = \chi$ on Γ.

In a similar way, for each $\eta \in (H_{00}^{1/2}(\Gamma))'$ define the operator S_p as

$$S_p : (H_{00}^{1/2}(\Gamma))' \to H_{00}^{1/2}(\Gamma), \quad \eta \to S_p\eta = g\varphi_{\eta|\Gamma},$$

where $\varphi_\eta \in H_p^0$ is the solution to

$$a_p(\varphi_\eta, \psi) = \langle \eta, \psi_{|\Gamma} \rangle_\Gamma \qquad \forall\ \psi \in H_p^0,$$

where $\langle \cdot, \cdot \rangle_\Gamma$ denotes the duality pairing between $(H_{00}^{1/2}(\Gamma))'$ and $H_{00}^{1/2}(\Gamma)$. As a consequence, we have $-\mathsf{K}\nabla\varphi_\eta \cdot \mathbf{n} = \eta$ on Γ.

Since for each $\varphi \in H_p^0$ we have $S_p(-\mathsf{K}\nabla\varphi \cdot \mathbf{n}) = g\varphi_{|\Gamma}$, the first step (19) of our procedure corresponds to imposing on Γ

$$\begin{aligned}
-\gamma_p \mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n} + g\varphi_{|\Gamma}^{k+1} &= -\gamma_p \mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n} + S_p(-\mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n})\\
&= (\gamma_p I + S_p)(-\mathsf{K}\nabla\varphi^{k+1} \cdot \mathbf{n}) = \eta^k\ ;
\end{aligned}$$

hence

$$-\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n} = (\gamma_p I + S_p)^{-1}\eta^k. \tag{37}$$

On the other hand, the right-hand side in (20) can be written as

$$\begin{aligned} -g\varphi_{|\Gamma}^{k+1} - \gamma_f\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n} &= S_p(\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n}) - \gamma_f\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n} \\ &= -(\gamma_f I - S_p)\mathsf{K}\nabla\varphi^{k+1}\cdot\mathbf{n} \\ &= (\gamma_f I - S_p)(\gamma_p I + S_p)^{-1}\eta^k. \end{aligned} \tag{38}$$

In an analogous way, still denoting by $(\mathbf{u}_f^{k+1}, p_f^{k+1})$ the solution to (19) with $\mathbf{f} = \mathbf{0}$ and H_f^τ replaced by $\widehat{H}_f^\tau$, one has $S_f(\mathbf{u}_f^{k+1}\cdot\mathbf{n}) = \mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_f^{k+1}, p_f^{k+1})\cdot\mathbf{n})$. Then, the left-hand side in (20) can be written as

$$\begin{aligned} \mathbf{n}\cdot(\mathsf{T}(\mathbf{u}^{k+1}, p^{k+1})\cdot\mathbf{n}) + \gamma_f\mathbf{u}^{k+1}\cdot\mathbf{n} &= S_f(\mathbf{u}^{k+1}\cdot\mathbf{n}) + \gamma_f\mathbf{u}^{k+1}\cdot\mathbf{n} \\ &= (\gamma_f I + S_f)(\mathbf{u}^{k+1}\cdot\mathbf{n}). \end{aligned} \tag{39}$$

Using (38) and (39), the interface condition (20) becomes

$$\mathbf{u}^{k+1}\cdot\mathbf{n} = (\gamma_f I + S_f)^{-1}(\gamma_f I - S_p)(\gamma_p I + S_p)^{-1}\eta^k. \tag{40}$$

In conclusion, our iterative procedure (with homogeneous data $\mathbf{f}$ and $\mathbf{g}$) can be written as

$$\begin{aligned} \eta^{k+1} &= -\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}^{k+1}, p^{k+1})\cdot\mathbf{n}) + \gamma_p\mathbf{u}^{k+1}\cdot\mathbf{n} \\ &= -S_f(\mathbf{u}^{k+1}\cdot\mathbf{n}) + \gamma_p\mathbf{u}^{k+1}\cdot\mathbf{n} \\ &= (\gamma_p I - S_f)\mathbf{u}^{k+1}\cdot\mathbf{n} \\ &= (\gamma_p I - S_f)(\gamma_f I + S_f)^{-1}(\gamma_f I - S_p)(\gamma_p I + S_p)^{-1}\eta^k. \end{aligned} \tag{41}$$

This is an alternating direction scheme, à la Peaceman and Rachford (see [16]), that has been deeply analyzed. Sufficient conditions for convergence are that $\gamma_f = \gamma_p$ and that the operators S_f and S_p are bounded and strictly positive in a given Hilbert space. These do not apply in the present situation, as the operators S_f and S_p act from a space into its dual. In fact, we can prove only that the iteration operator is nonexpansive but not a contraction in $(H_{00}^{1/2}(\Gamma))'$.

On the other hand, it is worthy to note that the convergence of this alternating direction scheme can be easily proved in the discrete case, as the matrices that correspond to the finite dimensional Steklov–Poincaré operators S_f and S_p are in fact symmetric and positive definite.

To illustrate how the proof of convergence works, we consider a suitable modification of the iteration scheme. Let us introduce the operators $J_- : H_{00}^{1/2}(\Gamma) \to (H_{00}^{1/2}(\Gamma))'$ and $J_+ : (H_{00}^{1/2}(\Gamma))' \to H_{00}^{1/2}(\Gamma)$ defined as follows:

$$\begin{aligned} (J_-\chi, \mu)_{-1/2,00,\Gamma} &= \langle\mu, \chi\rangle_\Gamma \qquad \forall\ \chi \in H_{00}^{1/2}(\Gamma),\ \mu \in (H_{00}^{1/2}(\Gamma))', \\ (J_+\eta, \xi)_{1/2,00,\Gamma} &= \langle\eta, \xi\rangle_\Gamma \qquad \forall\ \eta \in (H_{00}^{1/2}(\Gamma))',\ \xi \in H_{00}^{1/2}(\Gamma). \end{aligned}$$

(Here and in what follows we are denoting by $(\cdot,\cdot)_{1/2,00,\Gamma}$ and $(\cdot,\cdot)_{-1/2,00,\Gamma}$ the scalar products in $H^{1/2}(\Gamma)$ and $(H_{00}^{1/2}(\Gamma))'$, respectively, and by $\|\cdot\|_{1/2,00,\Gamma}$ and $\|\cdot\|_{-1/2,00,\Gamma}$ the associated norms.)

The existence of these operators is guaranteed by the Riesz representation theorem. Moreover, it is easily verified that $\|J_-\chi\|_{-1/2,00,\Gamma} = \|\chi\|_{1/2,00,\Gamma}$, $\|J_+\eta\|_{1/2,00,\Gamma} = \|\eta\|_{-1/2,00,\Gamma}$ (and consequently the operator norms are $\|J_-\| = \|J_+\| = 1$), and $(J_-\chi,\eta)_{-1/2,00,\Gamma} = (\chi, J_+\eta)_{1/2,00,\Gamma}$.

We consider the following iterative scheme:

$$\eta^{k+1} = (\gamma J_- - S_f)(\gamma J_- + S_f)^{-1} J_-(\gamma J_+ - S_p)(\gamma J_+ + S_p)^{-1} J_+ \eta^k. \tag{42}$$

This represents a slight modification of (41), in which we have inserted the operators J_- and J_+ instead of the identity I, and we have taken $\gamma_p = \gamma_f = \gamma$. The convergence of (42) is a consequence of the contraction mapping theorem (see the appendix).

Remark 4.1. One could argue that the iterative scheme (42) is not relevant with the problem at hand, since it is not equivalent to (41). Indeed, (42) converges to our original problem with slightly modified interface conditions, which read

$$\begin{aligned} &\gamma\, J_-(\mathbf{u}_f \cdot \mathbf{n}) + \mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n}) = -\gamma\, J_- J_+(\mathsf{K}\nabla\varphi \cdot \mathbf{n}) - J_-(g\varphi_{|\Gamma}) \quad \text{on } \Gamma, \\ &\gamma\, J_+ J_-(\mathbf{u}_f \cdot \mathbf{n}) - J_+(\mathbf{n} \cdot (\mathsf{T}(\mathbf{u}_f, p_f) \cdot \mathbf{n})) = -\gamma\, J_+(\mathsf{K}\nabla\varphi \cdot \mathbf{n}) + g\varphi_{|\Gamma} \quad \text{on } \Gamma. \end{aligned}$$

The operators J_- and J_+ have the role of assuring that the functions on either side are in the same trace space.

The problem of equalization of trace spaces can be encountered in other domain decompositions of heterogeneous problems as well. For these cases, the procedure that we have advocated here (and the associated convergence proof) might be useful.

4.2. Convergence of the pRR method. We turn now to the proof of convergence of the parallel method (24)–(31). Our aim is to prove that the map $\mu^k \to \mu^{k+1}$ defined through (24)–(31) is a contraction in $L^2(\Gamma)$. As a consequence of linearity, in the whole section we can assume without restriction that $\mathbf{f} = \mathbf{0}$. In order to introduce a suitable representation of this map, we define several interface operators.

Let $\mathcal{H}_S$ be the *Robin-to-Dirichlet* map for the *Stokes problem*,

$$\mathcal{H}_S : L^2(\Gamma) \to L^2(\Gamma), \qquad \mu \to \mathcal{H}_S\mu = \mathbf{u}_\mu \cdot \mathbf{n}, \tag{43}$$

where $(\mathbf{u}_\mu, p_\mu) \in H_f^\tau \times Q$ is the solution to (24) with $\mathbf{f} = \mathbf{0}$ and the Robin boundary datum μ.

Define $\mathcal{H}_D$ as the *Robin-to-Neumann* operator for the *Darcy scalar problem*,

$$\mathcal{H}_D : L^2(\Gamma) \to L^2(\Gamma), \qquad \mu \to \mathcal{H}_D\mu = \frac{1}{\gamma_1}(g\varphi_{\mu|\Gamma} + \mu), \tag{44}$$

where $\varphi_\mu \in H_p$ is the solution to (25) corresponding to the Robin boundary datum μ.

Moreover, let $\mathcal{K}_S$ be the *Robin-to-Neumann* operator for the *Stokes problem*,

$$\mathcal{K}_S : L^2(\Gamma) \to L^2(\Gamma), \qquad \sigma \to \mathcal{K}_S\sigma = \gamma_2(\sigma - \boldsymbol{\omega}_\sigma \cdot \mathbf{n}), \tag{45}$$

where $(\boldsymbol{\omega}_\sigma, \pi_\sigma) \in H_f^\tau \times Q$ is the solution to (27) with the Robin boundary datum σ.

Finally, $\mathcal{K}_D$ denotes the *Robin-to-Dirichlet* operator for the *Darcy scalar problem*,

$$\mathcal{K}_D : L^2(\Gamma) \to L^2(\Gamma), \qquad \sigma \to \mathcal{K}_D\sigma = g\chi_{\sigma|\Gamma}, \tag{46}$$

$\chi_\sigma \in H_p$ being the solution to (28) with the Robin boundary datum σ.

By means of these operators, we reformulate (29) as

$$\widehat{\sigma}^{k+1} = \mathcal{H}_S\mu^k + \mathcal{H}_D\mu^k = (\mathcal{H}_S + \mathcal{H}_D)\mu^k$$

and the relaxation step (31) as

$$\begin{aligned}\mu^{k+1} &= \mu^k - \theta(\mathcal{K}_S\widehat{\sigma}^{k+1} + \mathcal{K}_D\widehat{\sigma}^{k+1}) = \mu^k - \theta(\mathcal{K}_S + \mathcal{K}_D)(\mathcal{H}_S + \mathcal{H}_D)\mu^k \\ &= [I - \theta(\mathcal{K}_S + \mathcal{K}_D)(\mathcal{H}_S + \mathcal{H}_D)]\mu^k.\end{aligned}$$

PROPOSITION 4.1. *The operators defined in* (43)–(46) *enjoy the following properties:*

1. *$\mathcal{H}_S$ and $\mathcal{K}_D$ are symmetric, continuous, and nonnegative in $L^2(\Gamma)$;*
2. *$\mathcal{H}_D$ and $\mathcal{K}_S$ are symmetric, continuous, and coercive in $L^2(\Gamma)$.*

Proof. 1. We consider first the operator $\mathcal{H}_S$. For every η and μ, letting $\mathbf{u}_\eta \cdot \mathbf{n} = \mathcal{H}_S\eta$ and $\mathbf{u}_\mu \cdot \mathbf{n} = \mathcal{H}_S\mu$, we have

$$\begin{aligned}\int_\Gamma (\mathcal{H}_S\mu)\eta &= \int_\Gamma \mathbf{u}_\mu \cdot \mathbf{n}\,\eta = a_f(\mathbf{u}_\eta, \mathbf{u}_\mu) - \gamma_1 \int_\Gamma (\mathbf{u}_\eta \cdot \mathbf{n})(\mathbf{u}_\mu \cdot \mathbf{n}) \\ &= \int_\Gamma \mu\, \mathbf{u}_\eta \cdot \mathbf{n} = \int_\Gamma \mu\, (\mathcal{H}_S\eta);\end{aligned}$$

therefore, $\mathcal{H}_S$ is symmetric.

Now, taking $\mathbf{v} = \mathbf{u}_\mu$ in (24) (with $\mathbf{f} = \mathbf{0}$), thanks to (22) we have

$$\begin{aligned}2\nu \int_{\Omega_f} |\mathsf{D}(\mathbf{u}_\mu)|^2 = a_f(\mathbf{u}_\mu, \mathbf{u}_\mu) &= \gamma_1 \int_\Gamma |\mathbf{u}_\mu \cdot \mathbf{n}|^2 + \int_\Gamma \mu\, \mathbf{u}_\mu \cdot \mathbf{n} \\ &\le \gamma_1\kappa_2 \int_{\Omega_f} |\mathsf{D}(\mathbf{u}_\mu)|^2 + \kappa_2^{1/2}\|\mu\|_{0,\Gamma}\|\mathsf{D}(\mathbf{u}_\mu)\|_{0,\Omega_f}.\end{aligned}$$

Therefore, for $\gamma_1 < (2\nu)/\kappa_2$, one has $\|\mathsf{D}(\mathbf{u}_\mu)\|_{0,\Omega_f} \le \kappa_3\|\mu\|_{0,\Gamma}$, with $\kappa_3 = \kappa_2^{1/2}/(2\nu - \gamma_1\kappa_2)$. Hence, from (22), $\mathcal{H}_S$ is a continuous operator.

Finally, for $\gamma_1 < (2\nu)/\kappa_2$ we have

$$\int_\Gamma (\mathcal{H}_S\mu)\,\mu = 2\nu \int_{\Omega_f} |\mathsf{D}(\mathbf{u}_\mu)|^2 - \gamma_1 \int_\Gamma |\mathbf{u}_\mu \cdot \mathbf{n}|^2 \ge (2\nu - \gamma_1\kappa_2) \int_{\Omega_f} |\mathsf{D}(\mathbf{u}_\mu)|^2 \ge 0;$$

hence, $\mathcal{H}_S$ is a nonnegative operator.

We consider now the operator $\mathcal{K}_D$. We denote by χ_σ and χ_ξ the solutions to (28) with data σ and ξ, respectively. Thus, $\mathcal{K}_D\sigma = g\chi_{\sigma|\Gamma}$ and $\mathcal{K}_D\xi = g\chi_{\xi|\Gamma}$. Then using (28) we have

$$\begin{aligned}\int_\Gamma (\mathcal{K}_D\sigma)\xi = \int_\Gamma g\chi_{\sigma|\Gamma}\xi &= g\, a_p(\chi_\xi, \chi_\sigma) + \frac{g^2}{\gamma_2}\int_\Gamma \chi_{\xi|\Gamma}\,\chi_{\sigma|\Gamma} \\ &= \int_\Gamma g\sigma\chi_{\xi|\Gamma} = \int_\Gamma \sigma(\mathcal{K}_D\xi),\end{aligned}$$

which proves the symmetry of $\mathcal{K}_D$.

Now if we take in (28) the test function $\psi = \chi_\sigma$, we find

$$a_p(\chi_\sigma, \chi_\sigma) + \frac{1}{\gamma_2}\int_\Gamma g\chi_{\sigma|\Gamma}^2 = \int_\Gamma \sigma\chi_{\sigma|\Gamma} \le \left(\int_\Gamma \sigma^2\right)^{1/2}\left(\int_\Gamma \chi_{\sigma|\Gamma}^2\right)^{1/2};$$

consequently, since $a_p(\chi_\sigma, \chi_\sigma) \ge 0$, we have $g\|\chi_{\sigma|\Gamma}\|_{0,\Gamma} \le \gamma_2\|\sigma\|_{0,\Gamma}$; i.e., $\mathcal{K}_D$ is a continuous operator.

Finally, $\mathcal{K}_D$ is nonnegative, since

$$\int_\Gamma (\mathcal{K}_D\sigma)\,\sigma = \int_\Gamma g\chi_{\sigma|\Gamma}\,\sigma = g\,a_p(\chi_\sigma,\chi_\sigma) + \frac{g^2}{\gamma_2}\int_\Gamma \chi^2_{\sigma|\Gamma} \geq 0 \quad \forall\sigma\in L^2(\Gamma).$$

2. Consider now the operator $\mathcal{H}_D$. For all μ and η we denote by φ_μ and φ_η the solutions of (25) corresponding to the data μ and η, respectively, so that $\mathcal{H}_D\mu = (g\varphi_{\mu|\Gamma}+\mu)/\gamma_1$ and $\mathcal{H}_D\eta = (g\varphi_{\eta|\Gamma}+\eta)/\gamma_1$. Then, proceeding as we did for the operator $\mathcal{K}_D$, we have

$$\begin{aligned}\int_\Gamma (\mathcal{H}_D\mu)\,\eta &= \frac{1}{\gamma_1}\int_\Gamma (\mu\,\eta + g\varphi_{\mu|\Gamma}\,\eta)\\ &= \frac{1}{\gamma_1}\int_\Gamma \mu\,\eta - \frac{g^2}{\gamma_1}\int_\Gamma \varphi_{\eta|\Gamma}\varphi_{\mu|\Gamma} - g\,a_p(\varphi_\eta,\varphi_\mu)\\ &= \frac{1}{\gamma_1}\int_\Gamma \mu\,\eta + \frac{g}{\gamma_1}\int_\Gamma \mu\,\varphi_{\eta|\Gamma} = \int_\Gamma \mu\,(\mathcal{H}_D\eta);\end{aligned}$$

thus, $\mathcal{H}_D$ is symmetric.

Moreover, taking $\psi = \varphi_\mu$ in (25), the continuity of $\mathcal{H}_D$ easily follows from the estimate:

$$a_p(\varphi_\mu,\varphi_\mu) + \frac{g}{\gamma_1}\int_\Gamma \varphi^2_{\mu|\Gamma} = -\frac{1}{\gamma_1}\int_\Gamma \mu\varphi_{\mu|\Gamma} \leq \frac{1}{\gamma_1}\left(\int_\Gamma \mu^2\right)^{1/2}\left(\int_\Gamma \varphi^2_{\mu|\Gamma}\right)^{1/2},$$

which yields $\|\varphi_{\mu|\Gamma}\|_{0,\Gamma} \leq g^{-1}\|\mu\|_{0,\Gamma}$, as $a_p(\varphi_\mu,\varphi_\mu)\geq 0$.

Finally, let us show that $\mathcal{H}_D$ is a coercive operator. Recalling its definition, we have

$$\begin{aligned}a_p(\varphi_\mu,\varphi_\mu) &= -\frac{1}{\gamma_1}\int_\Gamma g\varphi^2_{\mu|\Gamma} - \frac{1}{\gamma_1}\int_\Gamma \mu\varphi_{\sigma|\Gamma} = -\int_\Gamma (\mathcal{H}_D\mu)\,\varphi_{\mu|\Gamma}\\ &= -\frac{1}{g}\int_\Gamma (\mathcal{H}_D\mu)(\gamma_1\mathcal{H}_D\mu - \mu) = \frac{1}{g}\int_\Gamma (\mathcal{H}_D\mu)\,\mu - \frac{\gamma_1}{g}\int_\Gamma (\mathcal{H}_D\mu)^2.\end{aligned}$$

Consequently, since $a_p(\varphi_\mu,\varphi_\mu)\geq \kappa_3\int_{\Omega_p}|\nabla\varphi_\mu|^2$ for a suitable constant $\kappa_3>0$, there exists a constant $q_1>0$ such that

$$\int_\Gamma (\mathcal{H}_D\mu)\,\mu \geq q_1\left(\int_\Gamma (\mathcal{H}_D\mu)^2 + \int_{\Omega_p}|\nabla\varphi_\mu|^2\right).$$

On the other hand, using the trace inequality and the Poincaré inequality,

$$\begin{aligned}\int_\Gamma \mu^2 &= \int_\Gamma (\gamma_1\mathcal{H}_D\mu - g\varphi_{\mu|\Gamma})^2 \leq 2\gamma_1^2\int_\Gamma (\mathcal{H}_D\mu)^2 + 2g^2\int_\Gamma \varphi^2_{\mu|\Gamma}\\ &\leq Q_1\left(\int_\Gamma (\mathcal{H}_D\mu)^2 + \int_{\Omega_p}|\nabla\varphi_\mu|^2\right)\end{aligned}$$

where $Q_1>0$ is a suitable constant. The coerciveness of $\mathcal{H}_D$ now follows.

Turning now to the operator $\mathcal{K}_S$, its symmetry can be proved as we did for $\mathcal{H}_S$. Moreover, taking $\mathbf{v} = \boldsymbol{\omega}_\sigma$ in (27) (where $\boldsymbol{\omega}_\sigma$ is the solution with datum σ), one has

$$a_f(\boldsymbol{\omega}_\sigma,\boldsymbol{\omega}_\sigma) + \gamma_2\int_\Gamma (\boldsymbol{\omega}_\sigma\cdot\mathbf{n})^2 = \gamma_2\int_\Gamma \sigma\,\boldsymbol{\omega}_\sigma\cdot\mathbf{n}.$$

Since $a_f(\boldsymbol{\omega}_\sigma, \boldsymbol{\omega}_\sigma) \geq 0$, this yields

$$\int_\Gamma (\boldsymbol{\omega}_\sigma \cdot \mathbf{n})^2 \leq \int_\Gamma \sigma\, \boldsymbol{\omega}_\sigma \cdot \mathbf{n} \leq \left(\int_\Gamma \sigma^2 \right)^{1/2} \left(\int_\Gamma (\boldsymbol{\omega}_\sigma \cdot \mathbf{n})^2 \right)^{1/2},$$

and this proves that the operator $\mathcal{K}_S$ is continuous.

Finally, using the definition (45) of $\mathcal{K}_S$, we have

$$\begin{aligned} a_f(\boldsymbol{\omega}_\sigma, \boldsymbol{\omega}_\sigma) &= -\gamma_2 \int_\Gamma (\boldsymbol{\omega}_\sigma \cdot \mathbf{n})^2 + \gamma_2 \int_\Gamma \sigma\, \boldsymbol{\omega}_\sigma \cdot \mathbf{n} = \int_\Gamma (\mathcal{K}_S \sigma)\, \boldsymbol{\omega}_\sigma \cdot \mathbf{n} \\ &= \int_\Gamma (\mathcal{K}_S \sigma)\, (\sigma - \gamma_2^{-1} \mathcal{K}_S \sigma) = \int_\Gamma (\mathcal{K}_S \sigma)\, \sigma - \gamma_2^{-1} \int_\Gamma (\mathcal{K}_S \sigma)^2. \end{aligned}$$

Therefore, since $a_f(\boldsymbol{\omega}_\sigma, \boldsymbol{\omega}_\sigma) = 2\nu \int_{\Omega_f} |\mathsf{D}(\boldsymbol{\omega}_\sigma)|^2$, there exists a constant $q_2 > 0$ such that

$$\int_\Gamma (\mathcal{K}_S \sigma)\, \sigma \geq q_2 \left(\int_{\Omega_f} |\mathsf{D}(\boldsymbol{\omega}_\sigma)|^2 + \int_\Gamma (\mathcal{K}_S \sigma)^2 \right).$$

On the other hand, by the trace and the Korn inequalities, we have

$$\begin{aligned} \int_\Gamma \sigma^2 &= \int_\Gamma (\boldsymbol{\omega}_\sigma \cdot \mathbf{n} + \gamma_2^{-1} \mathcal{K}_S \sigma)^2 \leq 2 \int_\Gamma (\boldsymbol{\omega}_\sigma \cdot \mathbf{n})^2 + 2\gamma_2^{-2} \int_\Gamma (\mathcal{K}_S \sigma)^2 \\ &\leq Q_2 \left(\int_{\Omega_f} |\mathsf{D}(\boldsymbol{\omega}_\sigma)|^2 + \int_\Gamma (\mathcal{K}_S \sigma)^2 \right) \end{aligned}$$

for a suitable constant $Q_2 > 0$. Thus, the operator $\mathcal{K}_S$ is coercive. ∎

It follows from Proposition 4.1 that the operators $\mathcal{H} = \mathcal{H}_S + \mathcal{H}_D$ and $\mathcal{K} = \mathcal{K}_S + \mathcal{K}_D$ are both *symmetric, continuous, and coercive* on $L^2(\Gamma)$.

To prove the convergence of the pRR iterative scheme, we shall apply the following abstract result whose proof is similar to that of Theorem 4.2.5 in [17].

THEOREM 4.1. *Let X be a (real) Hilbert space and X' its dual. We consider a linear invertible continuous operator $\mathcal{Q}\colon X \to X'$, which can be split as $\mathcal{Q} = \mathcal{Q}_1 + \mathcal{Q}_2$, where both $\mathcal{Q}_1$ and $\mathcal{Q}_2$ are linear operators. Take $\mathcal{Z} \in X'$, let $x \in X$ be the unknown solution to the equation $\mathcal{Q}x = \mathcal{Z}$, and consider for its solution the preconditioned Richardson method*

$$x^{k+1} = x^k + \theta \mathcal{N}(\mathcal{Z} - \mathcal{Q}x^k), \quad k \geq 0, \tag{47}$$

θ being a positive relaxation parameter and $\mathcal{N} : X' \to X$ a suitable scaling operator. Suppose that the following conditions are satisfied:

1. *$\mathcal{Q}_i$ $(i = 1, 2)$ are continuous and coercive;*
2. *$\mathcal{N}$ is symmetric, continuous, and coercive.*

Then there exists $\theta_{max} > 0$ such that for each $\theta \in (0, \theta_{max})$ and for any given $x^0 \in X$ the sequence (47) converges in X to the solution of problem $\mathcal{Q}x = \mathcal{Z}$.

We can now prove the main result of this section.

COROLLARY 4.1. *Under the constraint (32), the pRR iterative method (24), (25), (27), (28), (31) converges to the solution $(\mathbf{u}_f, p_f) \in H_f^\tau \times Q$, $\varphi \in H_p$ of the coupled Stokes–Darcy problem for any choice of the initial guess $\mu^0 \in L^2(\Gamma)$ and for suitable values of the relaxation parameter θ.*

Proof. It follows from Theorem 4.1, whose hypotheses are satisfied thanks to Proposition 4.1. ∎

5. Finite element approximation and numerical results. We consider a regular family of triangulations $\mathcal{T}_h$ of the domain $\overline{\Omega_f} \cup \overline{\Omega_p}$ depending on a positive parameter $h > 0$, made up of triangles if $d = 2$ or of tetrahedra in the 3-dimensional case. We assume that the triangulations $\mathcal{T}_{fh}$ and $\mathcal{T}_{ph}$ induced on the subdomains Ω_f and Ω_p are compatible on Γ; i.e., they share the same edges (if $d = 2$) or faces (if $d = 3$) therein. The family of triangulations induced on Γ will be denoted by $\mathcal{B}_h$.

Several choices of finite element spaces can be made to approximate the coupled problem (13)–(14). For the sake of exposition, we will consider the following conforming spaces ($d = 2, 3$):

$$H_{fh} = \{\mathbf{v}_h \in (X_{fh})^d |\, \mathbf{v}_h = \mathbf{0} \text{ on } \Gamma_f\},$$

with

$$X_{fh} = \{v_h \in \mathcal{C}^0(\overline{\Omega_f}) |\, v_{h|T} \in \mathbb{P}_2(T)\ \forall T \in \mathcal{T}_{fh}\},$$

and

$$Q_h = \{q_h \in \mathcal{C}^0(\overline{\Omega_f}) |\, q_{h|T} \in \mathbb{P}_1(T),\ \forall T \in \mathcal{T}_{fh}\};$$

moreover, H^τ_{fh} will be an internal approximation of H^τ_f.

On the other hand, we set

$$H_{ph} = \{\psi_h \in X_{ph} |\, \psi_h = 0 \text{ on } \Gamma^b_p\},$$

with

$$X_{ph} = \{\psi_h \in \mathcal{C}^0(\overline{\Omega_p}) |\, \psi_{h|T} \in \mathbb{P}_2(T)\ \forall T \in \mathcal{T}_{ph}\}.$$

Finally, we define

$$\Lambda_h = \{\eta_h \in L^2(\Gamma) \,|\, \eta_{h|\tau} \in \mathbb{P}_2(\tau)\ \forall \tau \in \mathcal{B}_h\};$$

in particular, we have that $\mathbf{v}_h \cdot \mathbf{n} \in \Lambda_h$ for each $\mathbf{v}_h \in H_{fh}$ and $\psi_{h|\Gamma} \in \Lambda_h$ for each $\psi_h \in H_{ph}$.

We will now present the discrete counterpart of the sRR and pRR algorithms.

5.1. The discrete sRR method. The finite element discretization of the coupled Stokes–Darcy problem (13)–(16) reads as follows:

Find $(\mathbf{u}_{fh}, p_{fh}) \in H^\tau_{fh} \times Q_h$, $\varphi_h \in H_{ph}$ such that

$$\begin{aligned} &a_f(\mathbf{u}_{fh}, \mathbf{v}_h) + b_f(\mathbf{v}_h, p_{fh}) + g\, a_p(\varphi_h, \psi_h) + \int_\Gamma g\, \varphi_h(\mathbf{v}_h \cdot \mathbf{n}) \\ &\qquad - \int_\Gamma g\, \psi_h(\mathbf{u}_{fh} \cdot \mathbf{n}) = \int_{\Omega_f} \mathbf{f} \cdot \mathbf{v}_h \qquad \forall \mathbf{v}_h \in H^\tau_{fh},\ \psi_h \in H_{ph}, \end{aligned} \tag{48}$$

$$b_f(\mathbf{u}_{fh}, q_h) = 0 \qquad \forall q_h \in Q_h. \tag{49}$$

The sRR algorithm on the discrete problem (48)–(49) becomes, taking a trace function $\eta^0_h \in \Lambda_h$ and considering two acceleration parameters $\gamma_f \geq 0$ and $\gamma_p > 0$, for each $k \geq 0$,

(i) find $\varphi^{k+1}_h \in H_{ph}$ such that

$$\gamma_p a_p(\varphi^{k+1}_h, \psi_h) + \int_\Gamma g \varphi^{k+1}_{h|\Gamma} \psi_{h|\Gamma} = \int_\Gamma \eta^k_h \psi_{h|\Gamma} \qquad \forall\ \psi_h \in H_{ph}. \tag{50}$$

(ii) Then find $(\mathbf{u}_{fh}^{k+1}, p_{fh}^{k+1}) \in H_{fh}^{\tau} \times Q_h$ such that

$$
\begin{aligned}
&a_f(\mathbf{u}_{fh}^{k+1}, \mathbf{v}_h) + b_f(\mathbf{v}_h, p_{fh}^{k+1}) + \gamma_f \int_\Gamma (\mathbf{u}_{fh}^{k+1} \cdot \mathbf{n})(\mathbf{v}_h \cdot \mathbf{n}) \\
&\quad = \int_\Gamma \Big(\frac{\gamma_f}{\gamma_p} \eta_h^k - \frac{\gamma_f + \gamma_p}{\gamma_p} g \varphi_{h|\Gamma}^{k+1} \Big) (\mathbf{v}_h \cdot \mathbf{n}) + \int_{\Omega_f} \mathbf{f} \cdot \mathbf{v}_h \quad \forall\, \mathbf{v}_h \in H_{fh}^{\tau}, \\
&b_f(\mathbf{u}_{fh}^{k+1}, q_h) = 0 \qquad \forall\, q_h \in Q_h.
\end{aligned} \tag{51}
$$

(iii) Finally, set

$$
\eta_h^{k+1} = (\gamma_f + \gamma_p)(\mathbf{u}_{fh}^{k+1} \cdot \mathbf{n}) + \frac{\gamma_f + \gamma_p}{\gamma_p} g \varphi_{h|\Gamma}^{k+1} - \frac{\gamma_f}{\gamma_p} \eta_h^k \in \Lambda_h. \tag{52}
$$

For $\gamma_p = \gamma_f$, the convergence of this algorithm to the solution of (48)–(49) can be proved as we did in section 4.1 to show the convergence of (17)–(20) to the solution of problems (13)–(16). Moreover, it is also possible to prove the convergence of the alternating direction scheme (see section 4.1.1), as the discrete Steklov–Poincaré operators are positive definite (however, in principle the proof of convergence cannot assure that the rate of convergence is independent of the mesh size h).

For the numerical tests we have exploited the interpretation of the method in terms of ADI iterations (section 4.1.1) in order to obtain some guidelines for the choice of the relaxation parameters, at least for the case of our interest, that is, when ν and the entries of K are very small (we recall that in this case the convergence rate of the Dirichlet–Neumann method deteriorates).

In particular, considering (41), we are led to investigate the behavior of the eigenvalues, say δ_f^j and δ_p^j, of the operators S_f and S_p, respectively; in fact, if we can estimate

$$
\max_j \left| \frac{\gamma_p - \delta_f^j}{\gamma_f + \delta_f^j} \right| \cdot \max_j \left| \frac{\gamma_f - \delta_p^j}{\gamma_p + \delta_p^j} \right|, \tag{53}
$$

this could be taken as a rough estimate of the convergence rate of the algorithm.

Assuming that K is a constant multiple of the identity, we proved that in the limit $\nu \to 0$ and $\mathsf{K} \to 0$ (for a fixed mesh size h) $\delta_f^j \to 0$ while $\delta_p^j \to \infty$ [8]. Thus, for small values of ν and K the ratio (53) behaves like γ_p/γ_f. This provides a first indication for the choice of the relaxation parameters; i.e., one should take $\gamma_f > \gamma_p > 0$. Moreover, γ_f and γ_p should not be taken too large to avoid possible increases of the condition numbers of the Stokes and Darcy stiffness matrices in (50) and (51), respectively. A reasonable trade-off is to choose both parameters approximately equal to 10^{-1}.

For the numerical tests, we take the same setting as in Example 3.1. In Table 2 we report the number of iterations obtained using the sRR method for some small values of ν and K and for four different computational grids. A convergence test based on the relative increment of the trace of the discrete normal velocity on the interface

TABLE 2

Number of iterations using the sRR method with respect to ν, K, and four different grid sizes h ($h_1 \approx 0.14$ and $h_i = h_1/2^{i-1}$, $i = 2, 3, 4$); the acceleration parameters are $\gamma_f = 0.3$ and $\gamma_p = 0.1$.

ν	K	h_1	h_2	h_3	h_4
10^{-4}	10^{-3}	19	19	19	19
10^{-6}	10^{-4}	20	20	20	20
10^{-6}	10^{-7}	20	20	20	20

$\mathbf{u}_{fh}^k \cdot \mathbf{n}_{|\Gamma}$ has been considered with tolerance 10^{-9}. In all computations we have taken $\gamma_f = 0.3$ and $\gamma_p = 0.1$.

5.2. The discrete pRR method. The pRR algorithm designed on (48)–(49) reads as follows: Let $\mu_h^0 \in \Lambda_h$ be a discrete trace function on Γ, and let $\gamma_1, \gamma_2 > 0$ be two positive relaxation parameters; then for $k \geq 0$

(i) find $(\mathbf{u}_{fh}^{k+1}, p_{fh}^{k+1}) \in H_{fh}^\tau \times Q_h$ such that

$$\begin{aligned} &a_f(\mathbf{u}_{fh}^{k+1}, \mathbf{v}_h) + b_f(\mathbf{v}_h, p_{fh}^{k+1}) - \gamma_1 \int_\Gamma (\mathbf{u}_{fh}^{k+1} \cdot \mathbf{n})(\mathbf{v}_h \cdot \mathbf{n}) \\ &\qquad = \int_\Gamma \mu_h^k (\mathbf{v}_h \cdot \mathbf{n}) + \int_{\Omega_f} \mathbf{f} \cdot \mathbf{v}_h \qquad \forall\, \mathbf{v}_h \in H_{fh}^\tau, \\ &b_f(\mathbf{u}_{fh}^{k+1}, q_h) = 0 \qquad \forall\, q_h \in Q_h, \end{aligned} \tag{54}$$

and find $\varphi_h^{k+1} \in H_{ph}$ such that

$$a_p(\varphi_h^{k+1}, \psi_h) + \frac{1}{\gamma_1} \int_\Gamma g \varphi_{h|\Gamma}^{k+1} \psi_{h|\Gamma} = -\frac{1}{\gamma_1} \int_\Gamma \mu_h^k \psi_{h|\Gamma} \qquad \forall\, \psi_h \in H_{ph}. \tag{55}$$

(ii) Then find $(\widehat{\boldsymbol{\omega}}_h^{k+1}, \widehat{\pi}_h^{k+1}) \in H_{fh}^\tau \times Q_h$ such that

$$\begin{aligned} &a_f(\widehat{\boldsymbol{\omega}}_h^{k+1}, \mathbf{v}_h) + b_f(\mathbf{v}_h, \widehat{\pi}_h^{k+1}) + \gamma_2 \int_\Gamma (\widehat{\boldsymbol{\omega}}_h^{k+1} \cdot \mathbf{n})(\mathbf{v}_h \cdot \mathbf{n}) \\ &\qquad = \gamma_2 \int_\Gamma \widehat{\sigma}_h^{k+1} (\mathbf{v}_h \cdot \mathbf{n}) \qquad \forall\, \mathbf{v}_h \in H_{fh}^\tau, \\ &b_f(\widehat{\boldsymbol{\omega}}_h^{k+1} q_h) = 0 \qquad \forall\, q_h \in Q_h, \end{aligned} \tag{56}$$

and find $\widehat{\chi}_h^{k+1} \in H_{ph}$ such that

$$a_p(\widehat{\chi}_h^{k+1}, \psi_h) + \frac{1}{\gamma_2} \int_\Gamma g \widehat{\chi}_{h|\Gamma}^{k+1} \psi_{h|\Gamma} = \int_\Gamma \widehat{\sigma}_h^{k+1} \psi_{h|\Gamma} \qquad \forall\, \psi_h \in H_{ph}, \tag{57}$$

where

$$\widehat{\sigma}_h^{k+1} = \mathbf{u}_{fh}^{k+1} \cdot \mathbf{n} + \frac{1}{\gamma_1}(g \varphi_{h|\Gamma}^{k+1} + \mu_h^k) \in \Lambda_h. \tag{58}$$

(iii) Finally, update μ_h^k as follows:

$$\mu_h^{k+1} = \mu_h^k - \theta[\gamma_2(\widehat{\sigma}_h^{k+1} - \widehat{\boldsymbol{\omega}}_h^{k+1} \cdot \mathbf{n}) + g \widehat{\chi}_{h|\Gamma}^{k+1}] \in \Lambda_h, \tag{59}$$

where $\theta > 0$ is an acceleration parameter.

As for the continuous case, this iterative scheme can be reformulated in terms of suitable interface operators on Λ_h. Precisely, let $\mathcal{H}_{Sh}$ and $\mathcal{K}_{Dh}$ be the discrete Robin-to-Dirichlet maps:

$$\begin{aligned} &\mathcal{H}_{Sh} : \Lambda_h \to \Lambda_h, \qquad \mu_h \to \mathcal{H}_{Sh}\mu_h = \mathbf{u}_{\mu_h} \cdot \mathbf{n}, \\ &\mathcal{K}_{Dh} : \Lambda_h \to \Lambda_h, \qquad \sigma_h \to \mathcal{K}_{Dh}\sigma_h = g\chi_{\sigma_h|\Gamma}, \end{aligned}$$

where $(\mathbf{u}_{\mu_h}, p_{\mu_h}) \in H_{fh}^\tau \times Q_h$ is the solution to (54) with $\mathbf{f} = \mathbf{0}$ and Robin boundary datum μ_h, while $\chi_{\sigma_h} \in H_{ph}$ is the solution of (57) with boundary datum σ_h on Γ.

Then consider the discrete Robin-to-Neumann operators

$$\mathcal{H}_{Dh} : \Lambda_h \to \Lambda_h, \qquad \mu_h \to \mathcal{H}_{Dh}\mu_h = \frac{1}{\gamma_1}(g\varphi_{\mu_h|\Gamma} + \mu_h),$$
$$\mathcal{K}_{Sh} : \Lambda_h \to \Lambda_h, \qquad \sigma_h \to \mathcal{K}_{Sh}\sigma_h = \gamma_2(\sigma_h - \boldsymbol{\omega}_{\sigma_h} \cdot \mathbf{n}),$$

where $\varphi_{\mu_h} \in H_{ph}$ is the solution of (55) with boundary datum μ_h, and $(\boldsymbol{\omega}_{\sigma_h}, \pi_{\sigma_h})$ is the solution of (56) with boundary datum σ_h.

Finally, we denote by $(\widetilde{\mathbf{u}}_h, \widetilde{p}_h) \in H^{\tau}_{fh} \times Q_h$ the solution of (54) with null boundary conditions, so that $\mathbf{u}^{k+1}_{fh} \cdot \mathbf{n} = \mathcal{H}_{Sh}\mu^k_h + \widetilde{\mathbf{u}}_h \cdot \mathbf{n}$ for all $k \geq 0$.

Then (58) becomes

$$\widehat{\sigma}^{k+1}_h = \mathcal{H}_{Sh}\mu^k_h + \mathcal{H}_{Dh}\mu^k_h + \widetilde{\mathbf{u}}_h \cdot \mathbf{n}.$$

Problem (48)–(49) can be associated with the discrete interface problem

$$\text{Find } \mu_h \in \Lambda_h : \quad (\mathcal{H}_{Sh} + \mathcal{H}_{Dh})\mu_h = -\widetilde{\mathbf{u}}_h \cdot \mathbf{n} \qquad \text{on } \Gamma. \tag{60}$$

Thus the discrete pRR method can be interpreted as the following preconditioned Richardson scheme to solve (60):

$$\mu^{k+1}_h = \mu^k_h - \theta(\mathcal{K}_{Sh} + \mathcal{K}_{Dh})[\widetilde{\mathbf{u}}_h \cdot \mathbf{n} + (\mathcal{H}_{Sh} + \mathcal{H}_{Dh})\mu^k_h], \qquad k \geq 0, \tag{61}$$

the preconditioner being

$$P = (\mathcal{K}_{Sh} + \mathcal{K}_{Dh})^{-1}. \tag{62}$$

The convergence of (61) is proved as done in section 4.2 for the infinite dimensional case; besides, its rate of convergence is independent of the mesh size h, as it depends only on the continuity and coerciveness constants of the operators $\mathcal{H}_{Sh}$, $\mathcal{H}_{Dh}$, $\mathcal{K}_{Sh}$, and $\mathcal{K}_{Dh}$, which are all independent of h.

Moreover, since the operators $\mathcal{H}_{Sh}$ and $\mathcal{H}_{Dh}$ are symmetric, we can use the PCG method to compute the solution of (60) using the same preconditioner (62).

More generally, we consider the following (variable) preconditioner:

$$P_k = (\sigma^k_1\mathcal{K}_{Sh} + \sigma^k_2\mathcal{K}_{Dh})^{-1}, \tag{63}$$

where σ^k_1 and σ^k_2 are two suitable acceleration coefficients (possibly depending on the iteration k).

The choice of the coefficients γ_1, γ_2, σ^k_1, and σ^k_2 to accelerate convergence is not straightforward. In our numerical experiments we have adopted two different strategies. First, we have used the PCG method with $P^{-1} = \sigma_1\mathcal{K}_{Sh} + \sigma_2\mathcal{K}_{Dh}$ with a suitable choice of the acceleration coefficients. Second, we have considered the preconditioner P^{-1}_k as in (63) in the framework of a Richardson method, and we have computed σ^k_1 and σ^k_2 according to an Aitken acceleration procedure (see, e.g., [5, 4]).

More precisely, the algorithm reads: Let r^0_h be the residual of (60) computed with respect to an initial datum $\mu^0_h \in \Lambda_h$, and let $z^0_h = P^{-1}_0 r^0_h$. Then for $k \geq 0$

1. compute the local preconditioned residuals $z^k_{Dh} = \mathcal{K}_{Dh}r^k_h$, $z^k_{Sh} = \mathcal{K}_{Sh}r^k_h$;
2. solve the linear system

$$A^T_k A_k \begin{pmatrix} \sigma^k_1 \\ \sigma^k_2 \end{pmatrix} = -A^T_k(\mu^k_h - \mu^{k-1}_h),$$

where A_k is the two column matrix $A_k = (z^k_{Sh} - z^{k-1}_{Sh};\ z^k_{Dh} - z^{k-1}_{Dh})$.

TABLE 3

Number of iterations using the PCG method with the pRR preconditioner P as in (62)*, with respect to ν and the grid size h ($h_1 \approx 0.14$ and $h_i = h_1/2^{i-1}$, $i = 2, 3, 4$).*

ν	K	γ_1	γ_2	σ_1	σ_2	h_1	h_2	h_3	h_4
1	1	0.5	0.5	1	1	11	12	11	12
10^{-1}	1	10^{-1}	1	1	1	27	28	29	28
10^{-2}	1	10^{-2}	1	1	1	68	76	72	64

TABLE 4

Number of iterations using the Aitken-accelerated Richardson method with the pRR preconditioner P_k as in (63)*; in the last two columns we indicate the mean value of the absolute values of the parameters σ_1^k and σ_2^k generated by the method. The h_i are as in Table* 3*.*

ν	K	γ_1	γ_2	Grid size	Iter.	$\lvert\bar{\sigma}_1\rvert$	$\lvert\bar{\sigma}_2\rvert$
1	1	0.5	0.5	h_1	10	2.68	0.64
				h_2	10	2.67	0.66
				h_3	10	2.66	0.67
				h_4	10	2.66	0.68
10^{-1}	1	10^{-1}	1	h_1	12	1.53	0.13
				h_2	11	1.50	0.13
				h_3	11	1.54	0.13
				h_4	12	1.50	0.12
10^{-2}	1	10^{-2}	1	h_1	23	0.90	0.06
				h_2	23	0.95	0.04
				h_3	23	0.96	0.06
				h_4	23	0.94	0.06
10^{-3}	1	10^{-3}	1	h_1	47	0.33	0.07
				h_2	47	0.38	0.04
				h_3	50	0.37	0.03
				h_4	52	0.38	0.03
10^{-1}	10^{-1}	10^{-1}	10	h_1	23	0.90	0.06
				h_2	23	0.95	0.04
				h_3	23	0.96	0.06
				h_4	23	0.94	0.06
10^{-2}	10^{-1}	10^{-2}	10^2	h_1	40	0.25	0.02
				h_2	39	0.26	0.01
				h_3	40	0.30	0.01
				h_4	44	0.27	0.01

This corresponds to minimizing

$$\|(\mu_h^k - \mu_h^{k-1}) + \sigma_1(z_{Sh}^k - z_{Sh}^{k-1}) + \sigma_2(z_{Dh}^k - z_{Dh}^{k-1})\|$$

over all possible values of σ_1 and σ_2.

3. Finally, update $z_h^{k+1} = \sigma_1^k z_{Sh}^k + \sigma_2^k z_{Dh}^k$, $r_h^{k+1} = r_h^k - (\mathcal{H}_{Sh} + \mathcal{H}_{Dh}) z_h^{k+1}$, and $\mu_h^{k+1} = \mu_h^k + z_h^{k+1}$.

For the numerical tests, we have considered the same settings as in Example 3.1. A tolerance of 10^{-9} has been imposed on the relative increment, and a maximal number of iterations `maxit = 300` has been required.

Table 3 reports the number of iterations obtained using the PCG method for three values of ν and four different grids. It is apparent that the rate of convergence deteriorates as ν goes to 0. We have noticed a similar behavior for small values of K as well.

The Richardson–Aitken strategy gives better results, as shown in Table 4. However, the Dirichlet–Neumann algorithm still turns out to be more efficient in this respect (see Table 1).

6. Appendix. We present here the proof of the convergence of the (modified) sRR scheme (42).

THEOREM 6.1. *Let us assume that the interface* Γ *is smooth, say, a* $\mathcal{C}^2$*-manifold with a boundary. Then for each* $\gamma > 0$ *the operator* $(\gamma J_- - S_f)(\gamma J_- + S_f)^{-1}$ *is a contraction in* $(H_{00}^{1/2}(\Gamma))'$*, and the operator* $(\gamma J_+ - S_p)(\gamma J_+ + S_p)^{-1}$ *is a contraction in* $H_{00}^{1/2}(\Gamma)$*.*

Proof. We have

$$\begin{aligned}
\|(\gamma J_- - S_f)(\gamma J_- + S_f)^{-1}\|^2 &= \sup_{\mu\neq 0} \frac{\|(\gamma J_- - S_f)(\gamma J_- + S_f)^{-1}\mu\|^2_{-1/2,00,\Gamma}}{\|\mu\|^2_{-1/2,00,\Gamma}} \\
&= \sup_{\chi\neq 0} \frac{\|(\gamma J_- - S_f)\chi\|^2_{-1/2,00,\Gamma}}{\|(\gamma J_- + S_f)\chi\|^2_{-1/2,00,\Gamma}} \\
&= \sup_{\chi\neq 0} \frac{\gamma^2\|J_-\chi\|^2_{-1/2,00,\Gamma} - 2\gamma(S_f\chi, J_-\chi)_{-1/2,00,\Gamma} + \|S_f\chi\|^2_{-1/2,00,\Gamma}}{\gamma^2\|J_-\chi\|^2_{-1/2,00,\Gamma} + 2\gamma(S_f\chi, J_-\chi)_{-1/2,00,\Gamma} + \|S_f\chi\|^2_{-1/2,00,\Gamma}} \\
&= \sup_{\chi\neq 0} \frac{\gamma^2\|\chi\|^2_{1/2,00,\Gamma} - 2\gamma\langle S_f\chi,\chi\rangle_\Gamma + \|S_f\chi\|^2_{-1/2,00,\Gamma}}{\gamma^2\|\chi\|^2_{1/2,00,\Gamma} + 2\gamma\langle S_f\chi,\chi\rangle_\Gamma + \|S_f\chi\|^2_{-1/2,00,\Gamma}}.
\end{aligned}$$

We prove now that S_f is positive and bounded; that is, there exist two positive constants C_1 and C_2 such that

$$\langle S_f\chi,\chi\rangle_\Gamma \geq C_1\|\chi\|^2_{1/2,00,\Gamma}, \qquad \|S_f\chi\|^2_{-1/2,00,\Gamma} \leq C_2\|\chi\|^2_{1/2,00,\Gamma}. \tag{64}$$

In fact, using the Korn and the trace inequality in $H_{00}^{1/2}(\Gamma)$ we have

$$\begin{aligned}
\langle S_f\chi,\chi\rangle_\Gamma &= \langle \mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{n}), \mathbf{u}_\chi\cdot\mathbf{n}\rangle_\Gamma \\
&= \left\langle \mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{n}, \mathbf{n}(\mathbf{u}_\chi\cdot\mathbf{n}) + \sum_{j=1}^{d-1}\boldsymbol{\tau}_j(\mathbf{u}_\chi\cdot\boldsymbol{\tau}_j)\right\rangle_\Gamma \\
&\quad (\text{as } \mathbf{u}_\chi\cdot\boldsymbol{\tau}_j = 0 \text{ on } \Gamma) \\
&= \int_{\Omega_f} \boldsymbol{\nabla}\cdot[\mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{u}_\chi] = 2\nu\int_{\Omega_f}|\mathsf{D}(\mathbf{u}_\chi)|^2 \\
&\geq c_1\|\mathbf{u}_\chi\|^2_{1,\Omega_f} \geq c_2\|\mathbf{u}_{\chi|\Gamma}\|^2_{1/2,00,\Gamma}.
\end{aligned}$$

The regularity assumption on Γ yields $\|\mathbf{u}_\chi\cdot\mathbf{n}\|_{1/2,00,\Gamma} \leq c_3\|\mathbf{u}_{\chi|\Gamma}\|_{1/2,00,\Gamma}$; hence,

$$\langle S_f\chi,\chi\rangle_\Gamma \geq C_1\|\mathbf{u}_\chi\cdot\mathbf{n}\|^2_{1/2,00,\Gamma} = C_1\|\chi\|^2_{1/2,00,\Gamma}.$$

Moreover, the regularity assumption on Γ also yields

$$\|\mathbf{n}\cdot(\mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{n})\|_{-1/2,00,\Gamma} \leq c_4\|\mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{n}\|_{-1/2,00,\Gamma};$$

therefore, the trace inequality in $(H_{00}^{1/2}(\Gamma))'$ and the a priori estimate for the solution of the Stokes problem give

$$\begin{aligned}
\|S_f\chi\|^2_{-1/2,00,\Gamma} &\leq c_4^2\|\mathsf{T}(\mathbf{u}_\chi,p_\chi)\cdot\mathbf{n}\|^2_{-1/2,00,\Gamma} \\
&\leq c_5\|\mathsf{T}(\mathbf{u}_\chi,p_\chi)\|^2_{0,\Omega_f} \leq C_2\|\chi\|^2_{1/2,00,\Gamma},
\end{aligned}$$

so that both inequalities in (64) are proved.

Consequently, setting $q_0 = (C_2 - 2\gamma C_1 + \gamma^2)/(C_2 + 2\gamma C_1 + \gamma^2)$, we can easily prove that

$$\sup_{\chi \neq 0} \frac{\gamma^2 \|\chi\|^2_{1/2,00,\Gamma} - 2\gamma \langle S_f \chi, \chi \rangle_\Gamma + \|S_f \chi\|^2_{-1/2,00,\Gamma}}{\gamma^2 \|\chi\|^2_{1/2,00,\Gamma} + 2\gamma \langle S_f \chi, \chi \rangle_\Gamma + \|S_f \chi\|^2_{-1/2,00,\Gamma}} \leq q_0 < 1.$$

The proof that $\|(\gamma J_+ - S_p)(\gamma J_+ + S_p)^{-1}\| < 1$ can be done in a similar way. In fact, using the trace inequality in $(H^{1/2}_{00}(\Gamma))'$ we have

$$\begin{aligned}
\langle \eta, S_p \eta \rangle_\Gamma &= -g \langle \mathsf{K} \nabla \varphi_\eta \cdot \mathbf{n}, \varphi_{\eta|\Gamma} \rangle_\Gamma \\
&= g \int_{\Omega_p} \nabla \cdot [\varphi_\eta \mathsf{K} \nabla \varphi_\eta] = g \int_{\Omega_p} \nabla \varphi_\eta \cdot \mathsf{K} \nabla \varphi_\eta \\
&= g \int_{\Omega_p} \mathsf{K}^{-1} \mathsf{K} \nabla \varphi_\eta \cdot \mathsf{K} \nabla \varphi_\eta \geq c_6 \int_{\Omega_p} |\mathsf{K} \nabla \varphi_\eta|^2 \\
&\geq C_3 \|\mathsf{K} \nabla \varphi_\eta \cdot \mathbf{n}\|^2_{-1/2,00,\Gamma} = C_3 \|\eta\|^2_{-1/2,00,\Gamma}.
\end{aligned}$$

Moreover, by the trace inequality in $H^{1/2}_{00}(\Gamma)$ and the a priori estimate for the solution of the Laplace equation, we obtain

$$\|S_p \eta\|^2_{1/2,00,\Gamma} = \|g \varphi_{\eta|\Gamma}\|^2_{1/2,00,\Gamma} \leq c_7 \|\varphi_\eta\|^2_{1,\Omega_p} \leq C_4 \|\eta\|^2_{-1/2,00,\Gamma}.$$

These two inequalities permit one to repeat for the operator S_p the same procedure used for the operator S_f. ∎

NEW FINITE ELEMENT METHODS IN COMPUTATIONAL FLUID DYNAMICS BY $H(\mathrm{DIV})$ ELEMENTS*

JUNPING WANG† AND XIU YE‡

Abstract. In this paper, the authors present two formulations for the Stokes problem which make use of the existing $H(\mathrm{div})$ elements of the Raviart–Thomas type originally developed for the second-order elliptic problems. In addition, two new $H(\mathrm{div})$ elements are constructed and analyzed particularly for the new formulations. Optimal-order error estimates are established for the corresponding finite element solutions in various Sobolev norms. The finite element solutions feature a full satisfaction of the continuity equation when existing Raviart–Thomas-type elements are employed in the numerical scheme.

1. Introduction.

This paper is concerned with numerical solutions of incompressible fluid flow problems by finite element methods. Our objective is to introduce a finite element scheme with attention paid to the discretization of the mass continuity equation. For illustrative purposes, we show how the method works for the Stokes problem, which seeks a pair of unknown functions $(\mathbf{u}; p)$ satisfying

$$-\nu\Delta\mathbf{u} + \nabla p = \mathbf{f} \quad \text{in } \Omega, \tag{1.1}$$

$$\nabla \cdot \mathbf{u} = 0 \quad \text{in } \Omega, \tag{1.2}$$

$$\mathbf{u} = 0 \quad \text{on } \partial\Omega, \tag{1.3}$$

where ν denotes the fluid viscosity; Δ, ∇, and $\nabla\cdot$ denote the Laplacian, gradient, and divergence operators, respectively; $\Omega \subset \mathbb{R}^d$ is the region occupied by the fluid; $\mathbf{f} = \mathbf{f}(\mathbf{x}) \in (L^2(\Omega))^d$ is the unit external volumetric force acting on the fluid at $\mathbf{x} \in \Omega$.

The commonly used finite element methods for the Stokes problem (1.1)–(1.3) are based on a variational equation which is obtained by testing the momentum equation (1.1) by functions in $(H_0^1(\Omega))^d$ and the continuity equation (1.2) by functions in $L^2(\Omega)$ (see section 2 for their definition). The corresponding finite element method requires a pair of finite element spaces which are conforming in $(H_0^1(\Omega))^d \times L^2(\Omega)$ and satisfy the inf-sup condition of Babuška [2] and Brezzi [3]. These constraints result in finite element approximations, denoted by $(\mathbf{u}_h; p_h)$, which hardly satisfy the continuity equation

$$\nabla \cdot \mathbf{u}_h(\mathbf{x}) = 0 \quad \forall\, \mathbf{x} \in \Omega. \tag{1.4}$$

Readers are referred to [8, 19, 21] for more details regarding the approximation methods and their properties.

The recent development in discontinuous Galerkin methods [1, 4, 5, 6, 10, 11, 13] provides new means of solving the Stokes equations numerically. However, the corresponding finite element solutions are usually totally discontinuous and fail to satisfy the continuity equation (1.4) in the classical sense [12, 22, 24, 27].

The continuity equation (1.4) requires the numerical solution $\mathbf{u}_h$ to be a member of the Sobolev space $H(\mathrm{div};\Omega)$. Therefore, the discontinuous Galerkin methods [12, 22, 24, 27] appear to be noncompetitive when (1.4) needs to be satisfied. On the other hand, the $(H_0^1)^d \times L^2$ conforming finite element methods require the total continuity of $\mathbf{u}_h$, which is too much to satisfy for (1.4). Therefore, it seems that the $H(\mathrm{div})$ elements of Raviart–Thomas type [25, 7, 8, 17] might be good candidates for producing new numerical schemes that satisfy (1.4).

The goal of this paper is to present a method that demonstrates the use of $H(\mathrm{div})$ elements in solving the Stokes problem. Our main contribution is on the development of a new formulation for the Stokes problem which makes use of the existing $H(\mathrm{div})$ elements in numerical schemes. Optimal-order error estimates are derived for the resulting $H(\mathrm{div})$ finite element approximations. In addition, two new families of $H(\mathrm{div})$ elements are proposed and analyzed in this article.

This paper is organized as follows. In section 2, we introduce some preliminaries and notations for Sobolev spaces. A new variational formula is presented in section 3 for the Stokes problem. In section 4, we present a $H(\mathrm{div})$ finite element method by using the variational formula developed in section 3. In section 5, we establish some optimal-order error estimates for the new finite element approximations in H^1 and L^2 norms. Finally, in section 6, we review some representatives of $H(\mathrm{div})$ elements, followed with a detailed description of two new $H(\mathrm{div})$ elements.

2. Preliminaries and notations. Let D be any domain in $\mathbb{R}^d, d = 2, 3$. For simplicity, the method will be presented for two-dimensional problems only. An extension to higher-dimensional problems can be made formally for general polyhedral domains.

We use standard definitions for the Sobolev spaces $H^s(D)$ and their associated inner products $(\cdot,\cdot)_{s,D}$, norms $\|\cdot\|_{s,D}$, and seminorms $|\cdot|_{s,D}$ for $s \geq 0$. For example, for any integer $s \geq 0$, the seminorm $|\cdot|_{s,D}$ is given by

$$|v|_{s,D} = \left(\sum_{|\alpha|=s} \int_D |\partial^\alpha v|^2 dD \right)^{\frac{1}{2}},$$

with the usual notation

$$\alpha = (\alpha_1, \alpha_2), \quad |\alpha| = \alpha_1 + \alpha_2, \quad \partial^\alpha = \partial_{x_1}^{\alpha_1} \partial_{x_2}^{\alpha_2}.$$

The Sobolev norm $\|\cdot\|_{m,D}$ is given by

$$\|v\|_{m,D} = \left(\sum_{j=0}^{m} |v|_{j,D}^2 \right)^{\frac{1}{2}}.$$

The space $H^0(D)$ coincides with $L^2(D)$, for which the norm and the inner product are denoted by $\|\cdot\|_D$ and $(\cdot,\cdot)_D$, respectively. When $D = \Omega$, we shall drop the subscript D in the norm and inner product notation. We also use $L_0^2(\Omega)$ to denote the subspace of $L^2(\Omega)$ consisting of functions with mean value zero.

The space $H(\mathrm{div};\Omega)$ is defined as the set of vector-valued functions on Ω which, together with their divergence, are square integrable; i.e.,

$$H(\mathrm{div};\Omega) = \left\{\mathbf{v} :\ \mathbf{v} \in (L^2(\Omega))^2, \nabla\cdot\mathbf{v} \in L^2(\Omega)\right\}.$$

The norm in $H(\mathrm{div};\Omega)$ is defined by

$$\|\mathbf{v}\|_{H(\mathrm{div};\Omega)} = \left(\|\mathbf{v}\|^2 + \|\nabla\cdot\mathbf{v}\|^2\right)^{\frac{1}{2}}.$$

Let $K \subset \Omega$ be a triangle or quadrilateral. For any smooth vector-valued functions $\mathbf{w}$ and $\mathbf{v}$, it follows from the divergence theorem that

$$\int_K (-\Delta\mathbf{w})\cdot\mathbf{v}dK = (\nabla\mathbf{w},\nabla\mathbf{v})_K - \int_{\partial K}\frac{\partial\mathbf{w}}{\partial\mathbf{n}_K}\cdot\mathbf{v}\ ds, \tag{2.1}$$

where ds represents the boundary element, $\mathbf{n}_K$ is the outward normal direction on ∂K, and

$$(\nabla\mathbf{w},\nabla\mathbf{v})_K = \sum_{i,j=1}^{2}\int_K \frac{\partial w_i}{\partial x_j}\frac{\partial v_i}{\partial x_j}dK.$$

Let τ_K be the tangential direction to ∂K so that $\mathbf{n}_K$ and τ_K form a right-hand coordinate system. It follows from the representation

$$\mathbf{v} = (\mathbf{v}\cdot\mathbf{n}_K)\mathbf{n}_K + (\mathbf{v}\cdot\tau_K)\tau_K$$

that

$$\frac{\partial\mathbf{w}}{\partial\mathbf{n}_K}\cdot\mathbf{v} = \frac{\partial(\mathbf{w}\cdot\mathbf{n}_K)}{\partial\mathbf{n}_K}(\mathbf{v}\cdot\mathbf{n}_K) + \frac{\partial(\mathbf{w}\cdot\tau_K)}{\partial\mathbf{n}_K}(\mathbf{v}\cdot\tau_K). \tag{2.2}$$

3. A variational formula. For simplicity, we let $\nu = 1$ for the fluid viscosity in the Stokes equation (1.1). Furthermore, we assume that Ω is a plane polygonal domain without cracks.

Let $\mathcal{T}_h$ be a finite element partition of the domain Ω with mesh size h. Assume that the partition $\mathcal{T}_h$ is shape regular so that the routine inverse inequality in finite elements holds true (see [9]). Define the finite element spaces V_h and W_h for the velocity and pressure variables, respectively, by

$$V_h = \{\mathbf{v} \in H(\mathrm{div};\Omega) :\ \mathbf{v}|_K \in V_r(K) \quad \forall K \in \mathcal{T}_h;\ \mathbf{v}\cdot\mathbf{n}|_{\partial\Omega} = 0\}$$

$$W_h = \{q \in L_0^2(\Omega) :\ q|_K \in W_m(K) \quad \forall K \in \mathcal{T}_h\},$$

where $\mathbf{n}$ is the outward normal direction on the boundary of Ω, $V_r(K)$ is a space of vector-valued polynomials on the element K with index $r \geq 1$, and $W_m(K)$ is a set of polynomials on the element K with index $m \geq 0$. Examples of $V_r(K)$ and $W_m(K)$ will be given in section 6.

To derive a weak formulation, we multiply the equation (1.1) by any $\mathbf{v} \in V_h$ and use (2.1) to obtain

$$\sum_{K\in\mathcal{T}_h}\left((\nabla\mathbf{u},\nabla\mathbf{v})_K - \int_{\partial K}\frac{\partial\mathbf{u}}{\partial\mathbf{n}_K}\cdot\mathbf{v}\ ds\right) - (p,\nabla\cdot\mathbf{v}) = (\mathbf{f},\mathbf{v}), \tag{3.1}$$

where we have also used the integration by parts to deduce

$$\int_\Omega \nabla p \cdot \mathbf{v} d\Omega = -(p, \nabla \cdot \mathbf{v}).$$

The fact that $\mathbf{v} \in V_h$ implies that $\mathbf{v} \cdot \mathbf{n}_K$ is continuous across each interior boundary. Thus, it follows from (2.2) that

$$\sum_{K\in\mathcal{T}_h} \int_{\partial K} \frac{\partial \mathbf{u}}{\partial \mathbf{n}_K} \cdot \mathbf{v}\ ds = \sum_{K\in\mathcal{T}_h} \int_{\partial K} \frac{\partial (\mathbf{u}\cdot\tau_K)}{\partial \mathbf{n}_K}\ \mathbf{v}\cdot\tau_K\ ds. \tag{3.2}$$

Introduce the following notation:

$$(\nabla_h \mathbf{u}, \nabla_h \mathbf{v}) = \sum_{K\in\mathcal{T}_h} (\nabla \mathbf{u}, \nabla \mathbf{v})_K.$$

By substituting (3.2) into (3.1) we obtain

$$(\nabla_h \mathbf{u}, \nabla_h \mathbf{v}) - (p, \nabla\cdot\mathbf{v}) - \sum_{K\in\mathcal{T}_h} \int_{\partial K} \frac{\partial (\mathbf{u}\cdot\tau_K)}{\partial \mathbf{n}_K}\ \mathbf{v}\cdot\tau_K ds = (\mathbf{f}, \mathbf{v}), \tag{3.3}$$

which is the basis of our first equation in the new variational form. Our second equation can be derived from testing (1.2) against any $q \in W_h$, yielding

$$(\nabla\cdot\mathbf{u}, q) = 0. \tag{3.4}$$

We now reformulate the boundary integrals in (3.3). Let e be an interior edge shared by two elements K_1 and K_2, and let $\mathbf{n}_1$ and $\mathbf{n}_2$ be unit normal vectors on e pointing exterior to K_1 and K_2, respectively. Denote by τ_1 and τ_2 the two tangential directions which make the right-hand coordinate systems with $\mathbf{n}_1$ and $\mathbf{n}_2$, respectively. We define the average $\{\!\{\cdot\}\!\}$ and jump $[\![\cdot]\!]$ on e for vector-valued functions $\mathbf{w}$ as follows:

$$\begin{aligned} \{\!\{\varepsilon(\mathbf{w})\}\!\} &= \frac{1}{2}\left(\mathbf{n}_1\cdot\nabla(\mathbf{w}\cdot\tau_1)|_{\partial K_1} + \mathbf{n}_2\cdot\nabla(\mathbf{w}\cdot\tau_2)|_{\partial K_2}\right), \\ [\![\mathbf{w}]\!] &= \mathbf{w}|_{\partial K_1}\cdot\tau_1 + \mathbf{w}|_{\partial K_2}\cdot\tau_2. \end{aligned}$$

For boundary edge $e = \partial K_1 \cap \partial\Omega$, the above two operations must be modified by

$$\{\!\{\varepsilon(\mathbf{w})\}\!\} = \mathbf{n}_1\cdot\nabla(\mathbf{w}\cdot\tau_1)|_{\partial K_1}, \quad [\![\mathbf{w}]\!] = \mathbf{w}|_{\partial K_1}\cdot\tau_1.$$

Let $\mathcal{E}_h$ denote the union of the boundaries of all elements K in $\mathcal{T}_h$. For sufficiently smooth $\mathbf{u}$ (e.g., $\mathbf{u} \in H^{\frac{3}{2}+\epsilon}(\Omega)$ for some $\epsilon > 0$), it is not hard to see that

$$\sum_{K\in\mathcal{T}_h} \int_{\partial K} \frac{\partial (\mathbf{u}\cdot\tau_K)}{\partial \mathbf{n}_K}\ \mathbf{v}\cdot\tau_K ds = \sum_{e\in\mathcal{E}_h} \int_e \{\!\{\varepsilon(\mathbf{u})\}\!\}[\![\mathbf{v}]\!] ds.$$

Substituting the above into (3.3) we obtain

$$(\nabla_h \mathbf{u}, \nabla_h \mathbf{v}) - (\nabla\cdot\mathbf{v}, p) - \sum_{e\in\mathcal{E}_h} \int_e \{\!\{\varepsilon(\mathbf{u})\}\!\}[\![\mathbf{v}]\!] ds = (\mathbf{f}, \mathbf{v}). \tag{3.5}$$

Let $V(h) = V_h + (H^s(\Omega)\cap H_0^1(\Omega))^2$, with $s > \frac{3}{2}$. Denote by

$$a_o(\mathbf{u}, \mathbf{v}) = (\nabla_h \mathbf{u}, \nabla_h \mathbf{v}) - \sum_{e\in\mathcal{E}_h} \int_e \{\!\{\varepsilon(\mathbf{u})\}\!\}[\![\mathbf{v}]\!] ds$$

and

$$b(\mathbf{v}, q) = (\nabla \cdot \mathbf{v}, q)$$

two bilinear forms on $V(h) \times V(h)$ and $V(h) \times L_0^2(\Omega)$. With the conditions specified in this paper, it can be proved that the exact solution $(\mathbf{u}; p)$ of the Stokes problem in 2D belongs to $V(h)$ for some $s > \frac{3}{2}$. Readers are referred to [20, 15, 14, 23] for details. As a result, it follows from (3.5) and (3.4) that the exact solution of the 2D Stokes problem satisfies the following variational equations:

$$a_o(\mathbf{u}, \mathbf{v}) - b(\mathbf{v}, p) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in V_h, \tag{3.6}$$

$$b(\mathbf{u}, q) = 0 \qquad \forall q \in W_h. \tag{3.7}$$

However, it is not clear if the same statement can be made for the Stokes problem in three-dimensional space without assuming a smooth boundary $\partial\Omega$ or a convex polyhedral domain Ω [16, 18].

4. Finite element schemes. Our goal of this section is to propose two finite element schemes based on two modifications of the weak formulation (3.6)–(3.7) for the Stokes problem (1.1)–(1.3). To this end, let us introduce a symmetric bilinear form on $V(h) \times V(h)$ as follows:

$$a_s(\mathbf{w}, \mathbf{v}) = a_o(\mathbf{w}, \mathbf{v}) + \sum_{e \in \mathcal{E}_h} \int_e \left(\alpha h_e^{-1} [\![\mathbf{w}]\!][\![\mathbf{v}]\!] - \{\!\{\varepsilon(\mathbf{v})\}\!\}[\![\mathbf{w}]\!] \right) ds,$$

where $\alpha > 0$ is a parameter to be determined later, and h_e is the length of the edge e. For the exact solution $(\mathbf{u}; p)$ of the Stokes problem, we clearly have

$$a_s(\mathbf{u}, \mathbf{v}) = a_o(\mathbf{u}, \mathbf{v}) \qquad \forall \mathbf{v} \in V_h.$$

Therefore, it follows from (3.6) and (3.7) that

$$a_s(\mathbf{u}, \mathbf{v}) - b(\mathbf{v}, p) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in V_h, \tag{4.1}$$

$$b(\mathbf{u}, q) = 0 \qquad \forall q \in W_h. \tag{4.2}$$

The corresponding finite element scheme for (1.1)–(1.3) seeks $(\mathbf{u}_h; p_h) \in V_h \times W_h$ such that

$$a_s(\mathbf{u}_h, \mathbf{v}) - b(\mathbf{v}, p_h) = (\mathbf{f}, \mathbf{v}) \quad \forall \mathbf{v} \in V_h, \tag{4.3}$$

$$b(\mathbf{u}_h, q) = 0 \qquad \forall q \in W_h. \tag{4.4}$$

To investigate the properties of the above numerical scheme, we introduce two norms $|\!|\!| \cdot |\!|\!|_1$ and $|\!|\!| \cdot |\!|\!|$ for the set $V(h)$ as follows:

$$|\!|\!|\mathbf{v}|\!|\!|_1^2 = |\mathbf{v}|_{1,h}^2 + \sum_{e \in \mathcal{E}_h} h_e^{-1} \|[\![\mathbf{v}]\!]\|_e^2, \tag{4.5}$$

$$|\!|\!|\mathbf{v}|\!|\!|^2 = |\!|\!|\mathbf{v}|\!|\!|_1^2 + \sum_{e \in \mathcal{E}_h} h_e \|\{\!\{\varepsilon(\mathbf{v})\}\!\}\|_e^2, \tag{4.6}$$

where $|\mathbf{v}|_{1,h}^2 = \sum_{K \in \mathcal{T}_h} |\mathbf{v}|_{1,K}^2$ and $\|\mathbf{v}\|_e^2 = \displaystyle\int_e \mathbf{v} \cdot \mathbf{v} ds$.

Let K be an element with e as an edge. It is well known that there exists a constant C such that for any function $g \in H^1(K)$

$$\|g\|_e^2 \leq C\left(h_K^{-1}\|g\|_K^2 + h_K\|\nabla g\|_K^2\right). \tag{4.7}$$

In particular, for any $\mathbf{v} \in V_h$, we have

$$h_e\|\{\!\{\varepsilon(\mathbf{v})\}\!\}\|_e^2 \leq C\left(\|\nabla \mathbf{v}\|_K^2 + h_K^2\|\nabla^2\mathbf{v}\|_K^2\right). \tag{4.8}$$

The standard inverse inequality can be employed to the last term of the above inequality, yielding

$$h_e\|\{\!\{\varepsilon(\mathbf{v})\}\!\}\|_e^2 \leq C\|\nabla \mathbf{v}\|_K^2 \tag{4.9}$$

for some constant C independent of the mesh size h. Consequently, there is a constant C such that

$$|\!|\!|\mathbf{v}|\!|\!| \leq C_0|\!|\!|\mathbf{v}|\!|\!|_1 \qquad \forall \mathbf{v} \in V_h. \tag{4.10}$$

The following result is concerned with the ellipticity of the bilinear form $a_s(\cdot,\cdot)$ in $V_h \times V_h$.

LEMMA 4.1. *There exists a constant α_0 independent of h such that for any $\mathbf{v} \in V_h$ we have*

$$a_s(\mathbf{v},\mathbf{v}) \geq \alpha_0|\!|\!|\mathbf{v}|\!|\!|^2, \tag{4.11}$$

provided that α is sufficiently large.

Proof. It follows from the Cauchy–Schwarz inequality that there is a constant C such that

$$\begin{aligned}
\left|\sum_{e\in\mathcal{E}_h}\int_e \{\!\{\varepsilon(\mathbf{w})\}\!\}[\![\mathbf{v}]\!]ds\right| &\leq C\left(\sum_{e\in\mathcal{E}_h} h_e\|\{\!\{\varepsilon(\mathbf{w})\}\!\}\|_e^2\right)^{\frac{1}{2}}\left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2\right)^{\frac{1}{2}}\\
&\leq C|\mathbf{w}|_{1,h}\left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2\right)^{\frac{1}{2}}\\
&\leq \frac{1}{2}|\mathbf{w}|_{1,h}^2 + C\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2,
\end{aligned}$$

where we have used the estimate (4.9) in the second line. Using the above inequality and (4.10), we obtain

$$\begin{aligned}
a_s(\mathbf{v},\mathbf{v}) &= (\nabla_h\mathbf{v},\nabla_h\mathbf{v}) + \alpha\sum_{e\in\mathcal{E}_h} h_e^{-1}\int_e [\![\mathbf{v}]\!]^2 ds - 2\sum_{e\in\mathcal{E}_h}\int_e \{\!\{\varepsilon(\mathbf{v})\}\!\}[\![\mathbf{v}]\!]ds\\
&\geq |\mathbf{v}|_{1,h}^2 + \alpha\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2 - \frac{1}{2}|\mathbf{v}|_{1,h}^2 - C\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2\\
&= \frac{1}{2}|\mathbf{v}|_{1,h}^2 + (\alpha - C)\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2 \geq \alpha_1|\!|\!|\mathbf{v}|\!|\!|_1^2 \geq \alpha_0|\!|\!|\mathbf{v}|\!|\!|^2,
\end{aligned}$$

with $\alpha_1 = \min(\frac{1}{2}, \alpha - C)$ and $\alpha_0 = \alpha_1/C_0$. For example, one may have $\alpha_0 = 1/(2C_0)$ if the parameter α is chosen so that $\alpha \geq C + \frac{1}{2}$. ∎

In the rest of the paper, we assume that the parameter α is chosen so that (4.11) holds true for the symmetric bilinear from $a_s(\cdot,\cdot)$. The proof of Lemma 4.1 indicates that the value of α depends upon the constant in the inverse inequality for finite element functions. Therefore, the value of α for which $a_s(\cdot,\cdot)$ is coercive is mesh-dependent. Existing results for saddle-point problems indicate that it is theoretically and computationally important to have the coercivity (4.11). Therefore, the mesh dependence of the parameter α makes the finite element scheme (4.3)–(4.4) conditionally interesting in practical computation.

To overcome the difficulty on the parameter selection, we introduce a second finite element scheme which is parameter-insensitive. To this end, we define a nonsymmetric bilinear form on $V(h)\times V(h)$ as follows:

$$a_{ns}(\mathbf{w},\mathbf{v}) = a_o(\mathbf{w},\mathbf{v}) + \sum_{e\in\mathcal{E}_h}\int_e \left(\alpha h_e^{-1}[\![\mathbf{w}]\!][\![\mathbf{v}]\!] + \{\!\{\varepsilon(\mathbf{v})\}\!\}[\![\mathbf{w}]\!]\right) ds.$$

Similar to the bilinear form $a_s(\cdot,\cdot)$, for the exact solution $(\mathbf{u};p)$ of the Stokes problem we have

$$a_{ns}(\mathbf{u},\mathbf{v}) = a_o(\mathbf{u},\mathbf{v}) \qquad \forall \mathbf{v}\in V_h.$$

Consequently, the solution of the Stokes problem satisfies the following variational equations:

$$a_{ns}(\mathbf{u},\mathbf{v}) - b(\mathbf{v},p) = (\mathbf{f},\mathbf{v}) \quad \forall \mathbf{v}\in V_h, \tag{4.12}$$

$$b(\mathbf{u},q) = 0 \qquad \forall q\in W_h. \tag{4.13}$$

Our second finite element scheme for (1.1)–(1.3) seeks $(\mathbf{u}_h;p_h)\in V_h\times W_h$ such that

$$a_{ns}(\mathbf{u}_h,\mathbf{v}) - b(\mathbf{v},p_h) = (\mathbf{f},\mathbf{v}) \quad \forall \mathbf{v}\in V_h, \tag{4.14}$$

$$b(\mathbf{u}_h,q) = 0 \qquad \forall q\in W_h. \tag{4.15}$$

To see the coercivity of the bilinear form $a_{ns}(\cdot,\cdot)$, we use its definition and (4.10) to obtain

$$\begin{aligned} a_{ns}(\mathbf{v},\mathbf{v}) &= (\nabla_h\mathbf{v},\nabla_h\mathbf{v}) + \alpha\sum_{e\in\mathcal{E}_h} h_e^{-1}\int_e [\![\mathbf{v}]\!]^2 ds \\ &\geq \min(1,\alpha)|\!|\!|\mathbf{v}|\!|\!|_1^2 \geq \min(1,\alpha)C_0^{-1}|\!|\!|\mathbf{v}|\!|\!|^2, \end{aligned}$$

where $\mathbf{v}\in V_h$. Thus, the coercivity (4.11) holds true for the bilinear form $a_{ns}(\cdot,\cdot)$ with any value of $\alpha>0$.

The following is a result on the boundedness of the bilinear forms $a_s(\cdot,\cdot)$ and $a_{ns}(\cdot,\cdot)$.

LEMMA 4.2. *There exists a constant C independent of h such that*

$$|a_i(\mathbf{w},\mathbf{v})| \leq C|\!|\!|\mathbf{w}|\!|\!||\!|\!|\mathbf{v}|\!|\!| \quad \forall \mathbf{w},\mathbf{v}\in V(h), \tag{4.16}$$

where $i=s,ns$.

Proof. For simplicity, we shall present the analysis for $a_s(\cdot,\cdot)$ only. By the definition of $a_s(\mathbf{w},\mathbf{v})$ and the Schwarz inequality, there exists a constant C such that

$$\begin{aligned}|a_s(\mathbf{w},\mathbf{v})| \le C \Bigg\{ & |\mathbf{w}|_{1,h}|\mathbf{v}|_{1,h} + \left(\sum_{e\in\mathcal{E}_h} h_e \|\{\!\{\varepsilon(\mathbf{w})\}\!\}\|_e^2\right)^{\frac12} \left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2\right)^{\frac12} \\ & + \left(\sum_{e\in\mathcal{E}_h} h_e \|\{\!\{\varepsilon(\mathbf{v})\}\!\}\|_e^2\right)^{\frac12} \left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{w}]\!]\|_e^2\right)^{\frac12} \\ & + \alpha \left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{w}]\!]\|_e^2\right)^{\frac12} \left(\sum_{e\in\mathcal{E}_h} h_e^{-1}\|[\![\mathbf{v}]\!]\|_e^2\right)^{\frac12} \Bigg\} \\ & \le C|||\mathbf{w}|||\,|||\mathbf{v}|||,\end{aligned}$$

which proves the desired boundedness. ∎

5. Error estimates. The first goal of this section is to derive an optimal-order error estimate for the pressure in $L^2(\Omega)$ and the velocity in the norm given by (4.6). The second goal is to derive an optimal-order error estimate for the velocity approximation in the L^2-norm for the symmetric scheme (4.3)–(4.4).

Assumption 1. *There exists an operator* $\Pi_h : (H_0^1(\Omega))^2 \to V_h$ *such that*

$$b(\mathbf{v}-\Pi_h\mathbf{v}, q) = 0 \qquad \forall q \in W_h. \tag{5.1}$$

In addition, the operator Π_h *is assumed to satisfy the following:*

$$|\mathbf{v}-\Pi_h\mathbf{v}|_{s,K} \le Ch^{t-s}|\mathbf{v}|_{t,K} \quad \forall K\in\mathcal{T}_h,\ \ s=0,1, \tag{5.2}$$

where the constant C *depends only on the shape of* K *and* $1\le t\le r+1$.

From (5.2) and the inequality (4.7) it is not hard to see that

$$|||\mathbf{v}-\Pi_h\mathbf{v}|||_1 \le C\|\mathbf{v}\|_1 \quad \forall \mathbf{v}\in(H_0^1(\Omega))^2.$$

Thus, it follows from $|||\mathbf{v}|||_1 = |\mathbf{v}|_1 \le \|\mathbf{v}\|_1$ and the triangle inequality that

$$|||\Pi_h\mathbf{v}|||_1 \le C\|\mathbf{v}\|_1. \tag{5.3}$$

For our finite element formulations, the inf-sup condition given in Brezzi's framework would read as follows: There exists a positive constant β, independent of h, such that

$$\sup_{\mathbf{v}\in V_h} \frac{b(\mathbf{v},q)}{|||\mathbf{v}|||} \ge \beta\|q\| \quad \forall q\in W_h. \tag{5.4}$$

To verify (5.4), we first use the operator Π_h to obtain

$$\sup_{\mathbf{v}\in V_h} \frac{b(\mathbf{v},q)}{|||\mathbf{v}|||} \ge \sup_{\mathbf{v}\in(H_0^1(\Omega))^2} \frac{b(\Pi_h\mathbf{v},q)}{|||\Pi_h\mathbf{v}|||} = \sup_{\mathbf{v}\in(H_0^1(\Omega))^2} \frac{b(\mathbf{v},q)}{|||\Pi_h\mathbf{v}|||}. \tag{5.5}$$

Observe that by using (5.3), and (4.10), we have for all $\mathbf{v}\in(H_0^1(\Omega))^2$

$$|||\Pi_h\mathbf{v}||| \le C|||\Pi_h\mathbf{v}|||_1 \le C\|\mathbf{v}\|_1. \tag{5.6}$$

Thus, substituting (5.6) into the inequality (5.5) gives

$$\sup_{\mathbf{v}\in V_h} \frac{b(\mathbf{v},q)}{|||\mathbf{v}|||} \ge C^{-1} \sup_{\mathbf{v}\in(H_0^1(\Omega))^2} \frac{b(\mathbf{v},q)}{\|\mathbf{v}\|_1} \ge \beta\|q\|,$$

where we have used the inf-sup condition for the continuous case [19, 8].

5.1. Error estimates in $H^1 \times L^2$. The error analysis requires the L^2 projection from $L_0^2(\Omega)$ to the finite element space W_h, which is denoted by Q_h. In addition, the following error equations turn out to be useful:

$$a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) - b(\mathbf{v}, p - p_h) = 0 \qquad \forall \mathbf{v} \in V_h, \tag{5.7}$$

$$b(\mathbf{u} - \mathbf{u}_h, q) = 0 \qquad \forall q \in W_h. \tag{5.8}$$

These error equations can be obtained by subtracting (4.3)–(4.4) from (4.1)–(4.2). Similar error equations hold true for the nonsymmetric scheme (4.14)–(4.15) with $a_s(\cdot,\cdot)$ being replaced by $a_{ns}(\cdot,\cdot)$. Now we are in a position to present an error estimate for the new finite element approximations.

THEOREM 5.1. *Let* $(\mathbf{u}; p)$ *be the solution of* (1.1)–(1.3) *and* $(\mathbf{u}_h; p_h) \in V_h \times W_h$ *be obtained from either* (4.3)–(4.4) *or* (4.14)–(4.15). *Assume that Assumption* 1 *holds true. Then, there exists a constant* C *independent of* h *such that*

$$|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\| \le C \left(|||\mathbf{u} - \Pi_h \mathbf{u}||| + \|p - Q_h p\| \right). \tag{5.9}$$

Proof. Let

$$\xi_h = \mathbf{u}_h - \Pi_h \mathbf{u}, \qquad \eta_h = p_h - Q_h p$$

be the error between the finite element solution $(\mathbf{u}_h; p_h)$ and the projection $(\Pi_h \mathbf{u}; Q_h p)$ of the exact solution. Denote by

$$\xi = \mathbf{u} - \Pi_h \mathbf{u}, \qquad \eta = p - Q_h p$$

the error between the exact solution $(\mathbf{u}; p)$ and its projection. It follows from the error equations (5.7) and (5.8) that

$$a(\xi_h, \mathbf{v}) - b(\mathbf{v}, \eta_h) = a(\xi, \mathbf{v}) - b(\mathbf{v}, \eta), \tag{5.10}$$

$$b(\xi_h, q) = b(\xi, q) = 0 \tag{5.11}$$

for any $\mathbf{v} \in V_h$ and $q \in W_h$. Here and in what follows of this section, $a(\cdot,\cdot)$ denotes either $a_s(\cdot,\cdot)$ or $a_{ns}(\cdot,\cdot)$.

By letting $\mathbf{v} = \xi_h$ in (5.10) and $q = \eta_h$ in (5.11), the sum of (5.10) and (5.11) gives

$$a(\xi_h, \xi_h) = a(\xi, \xi_h) - b(\xi_h, \eta).$$

Thus, it follows from the coercivity (4.11) and the boundedness (4.16) that

$$\alpha_0 |||\xi_h|||^2 \le C(|||\xi||| |||\xi_h||| + \|\eta\| |||\xi_h|||),$$

which implies the following:

$$|||\xi_h||| \le C \left(|||\xi||| + \|\eta\| \right).$$

The above estimate can be rewritten as

$$|||\mathbf{u}_h - \Pi_h \mathbf{u}||| \le C \left(|||\mathbf{u} - \Pi_h \mathbf{u}||| + \|p - Q_h p\| \right). \tag{5.12}$$

Now using the triangle inequality and the error estimate (5.12) we get

$$|||\mathbf{u} - \mathbf{u}_h||| \le C \left(|||\mathbf{u} - \Pi_h \mathbf{u}||| + \|p - Q_h p\| \right), \tag{5.13}$$

which completes the estimate for the velocity approximation.

It remains to estimate the pressure approximation p_h. To this end, we use the discrete inf-sup condition (5.4) to obtain

$$\begin{aligned}
\|p_h - Q_h p\| &\le \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{b(\mathbf{v}, p_h - Q_h p)}{|||\mathbf{v}|||} \\
&= \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{b(\mathbf{v}, p_h - p) + b(\mathbf{v}, p - Q_h p)}{|||\mathbf{v}|||} \\
&= \frac{1}{\beta} \sup_{\mathbf{v}\in V_h} \frac{a(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) + b(\mathbf{v}, p - Q_h p)}{|||\mathbf{v}|||} \\
&\le C \sup_{\mathbf{v}\in V_h} \frac{1}{|||\mathbf{v}|||} |||\mathbf{v}|||(|||\mathbf{u} - \mathbf{u}_h||| + \|p - Q_h p\|) \\
&\le C(|||\mathbf{u} - \mathbf{u}_h||| + \|p - Q_h p\|),
\end{aligned}$$

which, together with (5.13), implies that

$$\|p_h - Q_h p\| \le C\left(|||\mathbf{u} - \Pi_h \mathbf{u}||| + \|p - Q_h p\|\right).$$

The error estimate for the pressure approximation is then completed by combining the above inequality with the standard triangle inequality. ∎

5.2. An L^2-error estimate for the velocity approximation. Consider only the finite element approximate solutions arising from the symmetric finite element scheme. To derive an L^2-error estimate for the velocity approximation, we seek $(\mathbf{w}; \lambda) \in (H_0^1(\Omega))^2 \times L_0^2(\Omega)$ satisfying

$$\begin{aligned}
-\Delta \mathbf{w} + \nabla \lambda &= \mathbf{u} - \mathbf{u}_h \qquad \text{in } \Omega, \\
\nabla \cdot \mathbf{w} &= 0 \qquad \text{in } \Omega, \\
\mathbf{w} &= 0 \qquad \text{on } \partial\Omega.
\end{aligned}$$

Note that for any $(\mathbf{v}; q) \in V(h) \times L_0^2(\Omega)$ the solution $(\mathbf{w}; \lambda)$ satisfies

$$a_s(\mathbf{w}, \mathbf{v}) - b(\mathbf{v}, \lambda) = (\mathbf{u} - \mathbf{u}_h, \mathbf{v}), \tag{5.14}$$

$$b(\mathbf{w}, q) = 0. \tag{5.15}$$

Assume that the Stokes problem has the $H^2(\Omega) \times H^1(\Omega)$-regularity property in the sense that the solution $(\mathbf{w}; \lambda) \in (H^2(\Omega))^2 \times H^1(\Omega)$ and the following a priori estimate holds true:

$$\|\mathbf{w}\|_2 + \|\lambda\|_1 \le C\|\mathbf{u} - \mathbf{u}_h\|. \tag{5.16}$$

In addition, we assume that the finite element space V_h and the projection operator Π_h have the following property:

$$|||\mathbf{w} - \Pi_h \mathbf{w}||| \le Ch\|\mathbf{w}\|_2. \tag{5.17}$$

With these assumptions, it is not hard to see that there exists a constant C independent of h such that

$$|||\mathbf{w} - \Pi_h \mathbf{w}||| + \|\lambda - Q_h \lambda\| \le Ch\|\mathbf{u} - \mathbf{u}_h\|. \tag{5.18}$$

It must be pointed out that the $H^2 \times H^1$-regularity property assumption stated as above requires that the polygonal domain Ω be convex. For nonconvex but smooth

domains, the regularity (5.16) can be proved to be valid. However, isoparametric elements would need to be employed in the finite element scheme in order to maintain optimal-order error estimates in either H^1- or L^2-norms.

THEOREM 5.2. *Let* $(\mathbf{u}_h; p_h) \in V_h \times W_h$ *and* $(\mathbf{u}; p)$ *be the solutions of* (4.3)–(4.4) *and* (1.1)–(1.3)*, respectively. Assume that Assumption* 1 *and the estimate* (5.17) *hold true and that the Stokes problem* (1.1)–(1.3) *has the* $H^2(\Omega) \times H^1(\Omega)$*-regularity property. Then there exists a constant* C *independent of* h *such that*

$$\|\mathbf{u} - \mathbf{u}_h\| \le Ch(|||\mathbf{u} - \Pi_h\mathbf{u}||| + \|p - Q_h p\|). \tag{5.19}$$

Proof. By letting $\mathbf{v} = \mathbf{u} - \mathbf{u}_h$ in (5.14) we arrive at

$$a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w}) - b(\mathbf{u} - \mathbf{u}_h, \lambda) = \|\mathbf{u} - \mathbf{u}_h\|^2. \tag{5.20}$$

Notice that

$$b(\mathbf{u} - \mathbf{u}_h, \lambda) = b(\mathbf{u} - \mathbf{u}_h, \lambda - Q_h\lambda) \tag{5.21}$$

and

$$\begin{aligned} a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w}) &= a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w} - \Pi_h\mathbf{w}) + a_s(\mathbf{u} - \mathbf{u}_h, \Pi_h\mathbf{w}) \\ &= a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w} - \Pi_h\mathbf{w}) + b(\Pi_h\mathbf{w}, p - p_h) \\ &= a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w} - \Pi_h\mathbf{w}) + b(\Pi_h\mathbf{w} - \mathbf{w}, p - p_h). \end{aligned} \tag{5.22}$$

Substituting (5.21) and (5.22) into (5.20) we obtain

$$\|\mathbf{u} - \mathbf{u}_h\|^2 = a_s(\mathbf{u} - \mathbf{u}_h, \mathbf{w} - \Pi_h\mathbf{w}) + b(\Pi_h\mathbf{w} - \mathbf{w}, p - p_h) - b(\mathbf{u} - \mathbf{u}_h, \lambda - Q_h\lambda).$$

Thus,

$$\|\mathbf{u} - \mathbf{u}_h\|^2 \le C\left(|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\|\right)\ \left(|||\mathbf{w} - \Pi_h\mathbf{w}||| + \|\lambda - Q_h\lambda\|\right).$$

Substituting (5.18) into the above estimate we obtain

$$\|\mathbf{u} - \mathbf{u}_h\|^2 \le Ch\left(|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\|\right)\|\mathbf{u} - \mathbf{u}_h\|,$$

which implies that

$$\|\mathbf{u} - \mathbf{u}_h\| \le Ch\left(|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\|\right).$$

The above inequality and the error estimate (5.9) imply

$$\|\mathbf{u} - \mathbf{u}_h\| \le Ch(|||\mathbf{u} - \Pi_h\mathbf{u}||| + \|p - Q_h p\|).$$

This completes the proof of the theorem. ∎

6. Examples of $H(\mathrm{div})$ elements. Let us recall that the error estimates established in section 5 are based on the following three properties:

B1. $V_h \subset H(\mathrm{div}; \Omega)$,

B2. Assumption 1 and the estimate (5.17) as described in section 5, and

B3. the $H^2 \times H^1$-regularity property assumption for the Stokes problem.

The last property (B3) is required only for the L^2-error estimate for the velocity approximation. This means that any finite element pair $V_h \times W_h$ satisfying properties B1–B2 is applicable for the formulations presented earlier in this manuscript.

Denote by $P_k(K)$ the space of polynomials of degree $\leq k$ and

$$P_{k_1,k_2}(K) = \left\{ p(x_1,x_2) : \quad p(x_1,x_2) = \sum_{0\leq i\leq k_1, 0\leq j\leq k_2} a_{ij} x_1^i x_2^j \right\}.$$

$P_{k_1,k_2,k_3}(K)$ is defined similarly in three-dimensional spaces. Define $Q_k(K)$ as follows:

$$Q_k(K) = \begin{cases} P_{k,k}(K) & \text{for } d = 2, \\ P_{k,k,k}(K) & \text{for } d = 3. \end{cases}$$

Observe that the finite element pair $V_h \times W_h$ is constructed from local elements $V_r(K)$ and $W_m(K)$ as described in section 3. Therefore, it suffices to specify the local pair $V_r(K) \times W_m(K)$ for each example to be presented.

6.1. Existing elements. All of the existing $H(\mathrm{div})$ elements designed for the second-order elliptic problems (e.g., see [25, 8, 7, 17, 19]) satisfy properties B1–B2, except the estimate (5.17) for the lowest-order Raviart–Thomas element on triangles and quadrilaterals. Therefore, there are plenty of finite element spaces applicable to the new formulation of the Stokes problem. For illustrative purposes, we mention three examples. Readers are referred to the book by Brezzi and Fortin [8] for more examples of the $H(\mathrm{div})$ element.

6.1.1. Raviart–Thomas elements on triangles or tetrahedra: $RT_k(K)$. Let $k \geq 1$ be any integer. For any triangular or tetrahedral element K, the local element $V_r(K) \times W_m(K)$ is defined by

$$V_k(K) = (P_k(K))^d \oplus \mathbf{x}P_k(K), \qquad W_k(K) = P_k(K),$$

where $d = 2$ if K is a triangle and $d = 3$ if K is a tetrahedron. The projection operator Π_h satisfying all of the required properties is given locally on each element K. For example, the restriction of Π_h on the element K, denoted by Π_K, is defined as follows:

$$\int_{\partial K} (\mathbf{v} - \Pi_K \mathbf{v}) \cdot \mathbf{n} q ds = 0 \quad \forall q \in P_k(\partial K),$$
$$\int_K (\mathbf{v} - \Pi_K \mathbf{v}) \cdot q dK = 0 \quad \forall q \in (P_{k-1}(K))^d, k \geq 1.$$

6.1.2. BDM elements on triangles or tetrahedra: $BDM_k(K)$ [8]. Let $k \geq 1$ be any integer. For any triangular or tetrahedral element K, the local element $V_r(K) \times W_m(K)$ is defined by setting $r = m + 1 = k$ and

$$V_k(K) = (P_k(K))^d, \quad W_{k-1}(K) = P_{k-1}(K).$$

On a triangular element K, the local projection operator $\Pi_K : (H^1(K))^2 \to V_k(K)$ is defined by

$$\int_{\partial K} (\mathbf{v} - \Pi_K \mathbf{v}) \cdot \mathbf{n} q ds = 0 \quad \forall q \in P_k(\partial K),$$
$$\int_K (\mathbf{v} - \Pi_K \mathbf{v}) \cdot \nabla q dK = 0 \quad \forall q \in P_{k-1}(K),$$
$$\int_K (\mathbf{v} - \Pi_K \mathbf{v}) \cdot \mathrm{curl}(b_K q) dK = 0 \quad \forall q \in P_{k-2}(K), k \geq 2,$$

where b_K is the bubble function defined on K. On a tetrahedral element K, the corresponding local projection Π_K is given by

$$\begin{aligned}\int_{\partial K}(\mathbf{v}-\Pi_K\mathbf{v})\cdot\mathbf{n}qds=0 \quad \forall q\in P_k(\partial K),\\ \int_K(\mathbf{v}-\Pi_K\mathbf{v})\cdot\nabla qdK=0 \quad \forall q\in P_{k-1}(K),\\ \int_K(\mathbf{v}-\Pi_K\mathbf{v})\cdot qdK=0 \quad \forall q\in \Phi_k(K),\end{aligned}$$

where

$$\Phi(K)=\{\phi\in(P_k(K))^3:\quad \nabla\cdot\phi=0,\ \phi\cdot\mathbf{n}=0 \text{ on } \partial K\}.$$

6.1.3. BDM elements on quadrilaterals: $BDM_{[k]}(K)$. It is sufficient to describe the element on the unit square. Let $k\geq 1$ be any integer. The local element $V_r(K)\times W_m(K)$ is defined by

$$\begin{aligned}V_k(K)&=(P_k(K))^2\oplus \operatorname{curl}(x_1^{k+1}x_2)\oplus\operatorname{curl}(x_1x_2^{k+1}),\\ W_{k-1}(K)&=P_{k-1}(K).\end{aligned}$$

On the unit square element K, the local projection operator $\Pi_K:(H^1(K))^2\to V_k(K)$ is defined by

$$\begin{aligned}\int_{\partial K}(\mathbf{v}-\Pi_K\mathbf{v})\cdot\mathbf{n}qds=0 \quad \forall q\in P_k(\partial K),\\ \int_K(\mathbf{v}-\Pi_K\mathbf{v})\cdot\mathbf{w}dK=0 \quad \forall\mathbf{w}\in(P_{k-2}(K))^2, k\geq 2.\end{aligned}$$

6.1.4. Error estimates for the existing elements. Recall that the velocity V_h and the pressure space W_h are defined, respectively, by

$$V_h=\{\mathbf{v}\in H(\operatorname{div};\Omega):\quad \mathbf{v}|_K\in V_r(K)\quad \forall K\in\mathcal{T}_h;\ \mathbf{v}\cdot\mathbf{n}|_{\partial\Omega}=0\} \tag{6.1}$$

and

$$W_h=\{q\in L_0^2(\Omega):\ q|_K\in W_m(K)\quad \forall K\in\mathcal{T}_h\}. \tag{6.2}$$

For the existing $H(\operatorname{div})$ elements listed above, we have $V_r(K)=RT_k(K)$, $BDM_k(K)$, or $BDM_{[k]}(K)$ and $W_m(K)=P_k(K)$, $P_{k-1}(K)$, or $P_{k-1}(K)$, respectively. The projection operator Π_h is given by

$$(\Pi_h\mathbf{v})\big|_K=\Pi_K(\mathbf{v}\big|_K). \tag{6.3}$$

The definition of Π_h implies that

$$b(\mathbf{v}-\Pi_h\mathbf{v},q)=0\quad \forall q\in W_h. \tag{6.4}$$

Furthermore, it has been proved in [8] that (5.2) and (5.17) hold true for Π_h defined in (6.3). Therefore, properties B1–B2 are well justified.

Let Q_h be the L^2 projection from $L_0^2(\Omega)$ to W_h. It is not hard to see that W_h has the following local approximation properties: For $BDM_k(K)$ and $BDM_{[k]}(K)$

$$|p-Q_hp|_{s,K}\leq Ch^{k-s}|p|_{k,K}\quad \forall K\in\mathcal{T}_h,\ \ s=0,1, \tag{6.5}$$

and for $RT_k(K)$

$$|p - Q_h p|_{s,K} \le Ch^{k+1-s}|p|_{k+1,K} \quad \forall K \in \mathcal{T}_h,\ s = 0, 1. \tag{6.6}$$

The constant C in (6.5)–(6.6) depends only on k and the shape of K.

The following result follows from (5.17), (6.5)–(6.6), and Theorems 5.1 and 5.2.

PROPOSITION 6.1. *Let* $(\mathbf{u}; p)$ *be the solution of* (1.1)–(1.3) *and* $(\mathbf{u}_h; p_h) \in V_h \times W_h$ *be obtained from either* (4.3)–(4.4) *or* (4.14)–(4.15). *Assume that* $(\mathbf{u}; p) \in (H^{t+1}(\Omega))^2 \times H^t(\Omega)$ *for some* $1 \le t \le k$. *Then there exists a constant* C *independent of* h *such that for* $BDM_k(K)$, $BDM_{[k]}(K)$, *and* $RT_k(K)$

$$|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\| \le Ch^t(\|\mathbf{u}\|_{t+1} + \|p\|_t). \tag{6.7}$$

Furthermore, if the $H^2 \times H^1$*-regularity property holds true for the Stokes problem, then there is a constant* C *such that the finite element approximation* $(\mathbf{u}_h; p_h)$ *from the symmetric formulation has the following error estimate:*

$$\|\mathbf{u} - \mathbf{u}_h\| \le Ch^{t+1}(\|\mathbf{u}\|_{t+1} + \|p\|_t).$$

We comment that the above error estimates hold true for all of the $H(\mathrm{div})$ elements listed in [8].

6.2. New elements. Stability and accuracy are two main factors in the construction of new finite elements. For the variational schemes presented in this paper, the stability part is realized by a combination of the inf-sup condition and the coercivity for the corresponding bilinear forms. The accuracy part is characterized by Assumption 1 and a balanced pressure space W_h. For example, Proposition 6.1 indicates that the Raviart–Thomas element can be used to approximate the solution of the Stokes equations, which is convergent as the mesh size decreases (note that we do not know any convergence when $RT_0(K)$ is used). However, the Raviart–Thomas elements do not appear to be well balanced, because both the velocity and the pressure unknowns are approximated by polynomials of order k. In contrast, the BDM elements offer a better/optimal combination for the solution of the Stokes problem. But the $BDM_{[k]}(K)$ element on rectangles is constructed in an awkward way by involving the curl of some polynomials. We feel that better constructed elements should be explored on rectangles and cubes for solving the Stokes problem. For this purpose, we would like to propose some alternatives on rectangles and cubes which are suitable for approximating the solution of the Stokes problem. These elements can be used on quadrilaterals through local transformations as described in [26].

6.2.1. A new element on rectangles: $NE1_k(K)$. We illustrate the construction of the new $NE1_k(K)$ element on the unit square $K = [0, 1] \times [0, 1]$. Let $k \ge 1$ be any integer. We define local elements $V_r(K) \times W_m(K)$ by

$$V_k(K) = (Q_k(K))^2, \quad W_{k-1}(K) = Q_{k-1}(K).$$

For the first component of $\mathbf{v} = (v_1, v_2)$, we define an operator $\Pi_{K,1} : H^1(K) \to Q_k(K)$ as follows:

$$\int_e (v_1 - \Pi_{K,1} v_1)\phi ds = 0 \quad \forall \phi \in P_k(e),\ e = \text{west}, \text{east}, \tag{6.8}$$

$$\int_K (v_1 - \Pi_{K,1} v_1)\psi dK = 0 \quad \forall \psi \in P_{k-2,k}(K), \tag{6.9}$$

where $e =$ west means that e is the west edge (i.e., $e = \{(0, x_2) : \ x_2 \in [0, 1]\}$) of the unit square; the east edge is defined accordingly.

The system (6.8) involves exactly $2(k + 1)$ linear equations and (6.9) involves $(k - 1)(k + 1)$ linear equations. The total number of equations is given by

$$2(k + 1) + (k - 1)(k + 1) = (k + 1)^2,$$

which is the same as the total number of degrees of freedom for a polynomial in $Q_k(K)$. The following proposition shows that the linear systems (6.8) and (6.9) uniquely determine the projection $\Pi_{K,1} v_1$.

PROPOSITION 6.2. *Let $v \in Q_k(K)$ be such that*

$$\int_e v\phi ds = 0 \quad \forall \phi \in P_k(e), e = \text{west}, \text{east}, \tag{6.10}$$

$$\int_K v\psi dK = 0 \quad \forall \psi \in P_{k-2,k}(K). \tag{6.11}$$

Then we must have $v \equiv 0$.

Proof. The condition (6.10) implies that $v = 0$ at the east and west edges of the unit square K. Thus, there is a polynomial $g = g(x_1, x_2) \in P_{k-2,k}(K)$ such that $v = x_1(1 - x_1)g$. Substitute $v = x_1(1 - x_1)$ into (6.11), and then let $\psi = g$. It follows that $g \equiv 0$. This shows that $v \equiv 0$. □

The projection of the second component of $\mathbf{v}$, denoted by $\Pi_{K,2} v_2$, can be defined in a similar fashion. The local projection operator is then given by

$$\Pi_K v = (\Pi_{K,1} v_1, \Pi_{K,2} v_2).$$

It is not hard to show that such a defined projection satisfies all of the conditions required in the previous sections. As a result, the element $NE1_k(K)$ can be used to approximate the Stokes problem.

6.2.2. A new element on cubes: $NE2_k(K)$. Again, we shall describe details only on the unit cube $K = [0, 1]^3$. Let $k \geq 1$ be an integer. A straightforward extension of the $NE1_k$ element to three-dimensional space is given by

$$V_k(K) = (Q_k(K))^3, \quad W_{k-1}(K) = Q_{k-1}(K).$$

Our goal here is to show that the above extension actually works. To this end, it suffices to construct a projection operator Π_K which satisfies the required properties.

Let $\mathbf{v} = (v_1, v_2, v_3) \in \left(H^1(\Omega)\right)^3$ be a vector-valued function. For each component v_i, we define its projection to $Q_k(K)$ as follows:

$$\int_{e_i} (v_i - \Pi_{K,i} v_i)\phi ds = 0 \quad \forall \phi \in Q_k(e_i), \tag{6.12}$$

$$\int_K (v_i - \Pi_{K,i} v_i)\psi dK = 0 \quad \forall \psi \in P_{k_1,k_2,k_3}(K), \tag{6.13}$$

where $e_i = \{(x_1, x_2, x_3) : \ x_j \in [0, 1], j \neq i; \ x_i = 0 \text{ or } 1\}$ are the two faces of the cube K which are orthogonal to the x_i-axis, and $k_i = k - 2, k_j = k$ for $j \neq i$.

There are $2(k+1)^2$ linear equations from the condition (6.12) and $(k-1)(k+1)^2$ linear equations from the condition (6.13). The total number of linear equations is then given by

$$2(k + 1)^2 + (k - 1)(k + 1)^2 = (k + 1)^3,$$

which is the same as the total number of degrees of freedom for a polynomial in the space $V_k(K)$.

A similar argument as in the previous subsection for $NE1_k(K)$ can be applied to show that the projection $\Pi_{K,i}v_i$ is uniquely determined by (6.12) and (6.13). Furthermore, the local projection given by

$$\Pi_K \mathbf{v} = (\Pi_{K,1}v_1, \Pi_{K,2}v_2, \Pi_{K,3}v_3)$$

can be verified to satisfy all of the properties required by the convergence theory developed in previous sections for the new finite element methods.

6.2.3. Another new element on rectangles: $NE3_k(K)$. Again for simplicity, we shall describe the new element on the unit square $K = [0,1]^2$. This element will be a simplified version of $NE1_k(K)$ but with the same order of accuracy.

Let $k \geq 1$ be any integer, and define

$$\begin{aligned} V_k(K) &= (P_k(K) \oplus \{x_1 x_2^k\}) \times (P_k(K) \oplus \{x_2 x_1^k\}), \\ W_{k-1}(K) &= P_{k-1}(K). \end{aligned}$$

For the first component of $\mathbf{v} = (v_1, v_2)$, we define its projection $\Pi_{K,1}v_1 \in P_k(K) \oplus \{x_1 x_2^k\}$ by using the following equations:

$$\int_e (v_1 - \Pi_{K,1}v_1)\phi ds = 0 \quad \forall \phi \in P_k(e), e = \text{west}, \text{east}, \tag{6.14}$$

$$\int_K (v_1 - \Pi_{K,1}v_1)\psi dK = 0 \quad \forall \psi \in P_{k-2}(K). \tag{6.15}$$

There are $2(k+1)$ equations from the condition (6.14) and $\frac{1}{2}(k-1)k$ equations from the condition (6.15). The total number of linear equations is given by

$$2(k+1) + \frac{1}{2}(k-1)k = \frac{1}{2}(k+1)(k+2) + 1,$$

which is the same as the total number of degrees of freedom for functions in the space $P_k(K) \oplus \{x_1 x_2^k\}$. Using the same technique as in the analysis for $NE1_k(K)$, it can be proved that $\Pi_{K,1}v_1$ is uniquely determined by (6.14) and (6.15). The projection of the second component of $\mathbf{v}$ can be determined in a similar way. The resulting local projection $\Pi_K \mathbf{v} = (\Pi_{K,1}v_1, \Pi_{K,2}v_2)$ satisfies all of the properties required in the convergence theory.

6.2.4. Error estimates for the new elements. First, we define the velocity space V_h by

$$V_h = \{\mathbf{v} \in H(\text{div}; \Omega) : \ \mathbf{v}|_K \in V_r(K) \quad \forall K \in \mathcal{T}_h; \ \mathbf{v} \cdot \mathbf{n}|_{\partial\Omega} = 0\} \tag{6.16}$$

and the pressure space W_h by

$$W_h = \{q \in L_0^2(\Omega) : \ q|_K \in W_m(K) \quad \forall K \in \mathcal{T}_h\}, \tag{6.17}$$

where $V_r(K) = NE1_k(K), NE2_k(K)$, or $NE3_k(K)$ and $W_m(K) = Q_{k-1}(K), Q_{k-1}(K)$, or $P_{k-1}(K)$, respectively. For any $\mathbf{v} \in (H_0^1(\Omega))^d$, with $d = 2, 3$, define $\Pi_h \mathbf{v} \in V_h$ by

$$(\Pi_h \mathbf{v})|_K = \Pi_K \mathbf{v} \quad \forall\, K \in \mathcal{T}_h, \tag{6.18}$$

where Π_K is the corresponding local projection operator on each element. From the construction of Π_K, it is easy to see that it is indeed true that $\Pi_h \mathbf{v} \in V_h$, and, moreover, one has

$$b(\mathbf{v} - \Pi_h \mathbf{v}, q) = 0 \quad \forall q \in W_h \tag{6.19}$$

and that properties B1–B2 are satisfied for the three new elements $NE1_k(K)$, $NE2_k(K)$, and $NE3_k(K)$. Similar to Proposition 6.1, we have the following convergence estimates.

PROPOSITION 6.3. *Let* $(\mathbf{u}; p)$ *be the solution of* (1.1)–(1.3) *and* $(\mathbf{u}_h; p_h) \in V_h \times W_h$ *be obtained from either* (4.3)–(4.4) *or* (4.14)–(4.15) *by using the new elements described in this subsection. Assume that* $(\mathbf{u}; p) \in (H^{t+1}(\Omega))^d \times H^t(\Omega)$ *for some* $\frac{1}{2} < t \leq k$. *Then there exists a constant* C *independent of* h *such that*

$$|||\mathbf{u} - \mathbf{u}_h||| + \|p - p_h\| \leq Ch^t(\|\mathbf{u}\|_{t+1} + \|p\|_t),$$

and for the symmetric formulation we also have

$$\|\mathbf{u} - \mathbf{u}_h\| \leq Ch^{t+1}(\|\mathbf{u}\|_{t+1} + \|p\|_t),$$

provided that the $H^2 \times H^1$*-regularity property holds true for the Stokes problem.*

We point out that, unlike the existing $H(\mathrm{div})$ elements, the new $H(\mathrm{div})$ elements described in this section do not yield numerical velocities that satisfy the continuity equation (1.4) in the classical sense. However, the numerical approximations arising from the new elements indeed conserve mass locally on each element.

CONVERGENCE OF NUMERICAL APPROXIMATIONS OF THE INCOMPRESSIBLE NAVIER–STOKES EQUATIONS WITH VARIABLE DENSITY AND VISCOSITY*

CHUN LIU† AND NOEL J. WALKINGTON‡

Abstract. We consider numerical approximations of incompressible Newtonian fluids having variable, possibly discontinuous, density and viscosity. Since solutions of the equations with variable density and viscosity may not be unique, numerical schemes may not converge. If the solution is unique, then approximate solutions computed using the discontinuous Galerkin method to approximate the convection of the density and stable finite element approximations of the momentum equation converge to the solution. If the solution is not unique, a subsequence of these approximate solutions will converge to a solution.

Key words. Navier–Stokes equations, transport equations, Taylor–Hood approximations

1. Introduction.

We consider numerical approximations of the incompressible Navier–Stokes equations with variable density and viscosity,

$$\begin{aligned} \rho\left(v_t + (v\cdot\nabla)v\right) + \nabla p - \operatorname{div}\left(\mu(\rho)D(v)\right) &= \rho f, \\ \operatorname{div}(v) &= 0, \\ \rho_t + \operatorname{div}(\rho v) &= 0, \end{aligned} \tag{1.1}$$

on a bounded domain $\Omega \subset \mathbb{R}^d$ with initial and boundary conditions

$$v|_{\partial\Omega} = 0, \qquad v|_{t=0} = v_0, \qquad \rho|_{t=0} = \rho_0.$$

These equations model the motion of mixtures of immiscible fluids having different densities and viscosities. The density and viscosity may be discontinuous, so, in general, the solutions will not enjoy any regularity beyond that given by the basic estimates

$$\frac{d}{dt}\int_\Omega (\rho/2)|v|^2\,dx + \int_\Omega \mu(\rho)|D(v)|^2\,dx = \int_\Omega \rho f\cdot v\,dx$$

and $\rho \in L^\infty[0,T;L^\infty(\Omega)]$; in particular, ρ does not have bounded variation. In this situation we can establish convergence of approximate numerical solutions; however, in the absence of additional regularity no rates of convergence can be guaranteed.

The existence of a weak solutions to (1.1) has been established by Lions [15]. Some additional regularity was proven by Antontsev, Kazhikhov, and Monakhov [1] and

Fujita and Kato [6] when the viscosity is constant and the initial density is bounded from below. In [4], Desjardins provides similar results under weaker assumptions; for instance, when the viscosity does not vary too much with the density. To establish the existence of solutions of the Navier–Stokes equations with discontinuous density and viscosity, sharp results for the convection equation governing the density are required. These were developed by DiPerna and Lions [5], who showed that the weak solutions of convection equations were unique even when the velocity was not Lipschitz, so that characteristics may not exist. They also showed that the solutions would converge strongly when the velocities converged weakly in $L^2[0,T;H^1_0(\Omega)]$. For technical reasons they only considered velocity fields v vanishing[1] on $\partial\Omega$, and for this reason we only consider Dirichlet boundary data for v. Currently, uniqueness of solutions to the coupled system can only be established if the velocity and density satisfy $\nabla v \in L^2[0,T;L^\infty(\Omega)]$, $v_t \in L^2[0,T;L^\infty(\Omega)]$, and $\nabla\rho \in L^2[0,T;L^\infty(\Omega)]$; see [15], so, in general, uniqueness is not expected. In this situation we can only show that subsequences of approximate solutions converge to solutions of the Navier–Stokes equations.

While there is a rich body of literature on numerical approximation of the classical (constant density and viscosity) Navier–Stokes equations, very few results are available for the situation considered here. Algorithms proposed for the approximation of (1.1) include front tracking techniques [7, 8] and level set/phase field methods [2, 16, 17]. Recall that level set methods seek a smooth function ϕ satisfying $\phi_t + \operatorname{div}(\phi v) = 0$ and compute $\rho = H(\phi)$, where $H(.)$ is a suitable translation of the Heaviside graph. Numerical approximations typically approximate the Heaviside graph to give a smooth transition over several grid points. Since ϕ is "smooth," accurate approximations can be computed; however, difficulties arise when attempting to estimate the accuracy of $\rho = H(\phi)$. Indeed, it is difficult to write down the approximate equation satisfied by ρ in this context. For this reason we chose to compute ρ directly using the discontinuous Galerkin method [9, 12]. Below we use the results of Walkington [18], which show that approximations of the density computed using the discontinuous Galerkin method converge strongly in $L^2[0,T;L^2(\Omega)]$. Traditionally the analysis of schemes for hyperbolic equations is based upon the (nonlinear) theory of Kruzkov [10], which requires the coefficients to be C^1. This guarantees that the solutions are regular, in the sense that they have bounded variation, and rates of convergence can be established [11]. This theory fails for the problem considered here since v is not C^1 and ρ does not have bounded variation. This problem was circumvented in [18] by drawing upon the (linear) DiPerna–Lions theory [5]. We refer to [18] for further discussion and references on this topic.

It will be assumed that the viscosity can be determined as a continuous function of the density, $\mu = \mu(\rho)$. Physically each material particle has an associated viscosity, so μ should satisfy the convection equation $\mu_t + v.\nabla\mu = 0$. If $\mu = \mu(\rho)$, then this equation is satisfied when $\rho_t + \operatorname{div}(\rho v) = 0$ and the fluid is incompressible, $\operatorname{div}(v) = 0$. In order to model a mixture of fluids where different components have the same density but different viscosities, the convection equation for μ may be approximated independently. This does not change the analysis below where the major difficulties are due to the coupling between the density and velocity in the convection terms.

1.1. Weak solutions and the energy estimate. Since the solutions of equations (1.1) are not smooth we consider weak solutions. A pair (v,ρ) is a weak solution

[1] Lions and DiPerna also considered the periodic problem and the convection equation on all of $\mathbb{R}^d$.

of (1.1) with initial data $(v_0, \rho_0) \in L^2(\Omega) \times L^\infty(\Omega)$ if

$$v \in V = \{v \in L^\infty[0,T; L^2(\Omega)] \cap L^2[0,T; H_0^1(\Omega)] \mid \operatorname{div}(v) = 0\},$$

$\rho \in \mathcal{R} = L^\infty[0,T; L^\infty(\Omega)]$, and

$$\int_0^T \int_\Omega -\rho v.w_t - (\rho v \otimes v) \cdot \nabla w + \mu(\rho) D(v) \cdot D(w) = \int_\Omega \rho_0 v_0.w(0) + \int_0^T \int_\Omega \rho f.w,$$

$$\int_0^T \int_\Omega \rho(\psi_t + v.\nabla\psi) = \int_\Omega \rho_0 \psi(0), \tag{1.2}$$

for all $w \in \{w \in \mathcal{D}([0,T) \times \Omega) \mid \operatorname{div}(w) = 0\}$ and $\psi \in \mathcal{D}([0,T) \times \Omega)$. DiPerna and Lions [5] and Lions [15] established existence of solutions of this weak problem when ρ_0 is nonnegative. Their weak solutions satisfy the natural energy estimate

$$\frac{d}{dt} \int_\Omega (\rho/2)|v|^2 + \int_\Omega \mu(\rho)|D(v)|^2 \le \int_\Omega \rho f.v, \tag{1.3}$$

which may be derived by formally setting $w = v$ in the weak statement of the momentum equation and $\psi = |v|^2/2$ in the weak statement of the density equation.

1.2. Outline. In the next section we motivate and then state the numerical scheme used to approximate the Navier–Stokes equations with variable density and viscosity (1.1). The requirement of stability, consistency, and nonnegativity of the density, give rise to conflicting requirements. The scheme presented in section 2.4 satisfies these requirements and is subsequently analyzed in section 3.

1.3. Notation. Below, $\Omega \subset \mathbb{R}^d$ will be a bounded domain with unit outward normal n. We will consider a regular family of finite element meshes $\{\mathcal{T}_h\}_{h>0}$, each of which is assumed to triangulate Ω exactly. It is assumed that the finite elements have uniformly bounded aspect ratio, and the parameter $h > 0$ represents the diameter of the largest element in $\mathcal{T}_h$. The space of polynomials of degree k on an element $K \in \mathcal{T}_h$ is denoted $\mathcal{P}_k(K)$. For simplicity we assume that for each $h > 0$ a uniform partition of $[0,T]$ used with $t^n = n\tau$, where $\tau = T/N$, $N \in \mathbb{N}$, is assumed to converge to zero as h tends to zero. We will denote the approximate solutions by (v_h, ρ_h); in particular, the dependence upon τ is implicit. If $a \in \mathbb{R}$, then the positive and negative parts are denoted by $a^\pm$ with $a^+ = \max(a, 0)$ and $a^- = \min(a, 0)$.

Divergences of vectors and matrices are denoted $\operatorname{div}(v) = v_{i,i}$ and $\operatorname{div}(T)_i = T_{ij,j}$, and gradients of vector valued quantities are interpreted as matrices, $(\nabla v)_{ij} = v_{i,j}$. Here indices after the comma represent partial derivatives and the summation convention is used. The symmetric part of the velocity gradient (stretching tensor) is written as $D(v)$. Inner products of vectors v, $w \in \mathbb{R}^d$ are written as $v.w$ and their tensor product $v \otimes w$ is the matrix having components $v_i w_j$. The Frobenius inner product of two matrices A, $B \in \mathbb{R}^{d\times d}$ is denoted by $A \cdot B = \sum_{i,j} A_{ij} B_{ij}$; we frequently use the elementary identities $AB \cdot C = A \cdot CB^T = B \cdot A^T C$.

Standard notation is adopted for the Lebesgue spaces, $L^p(\Omega)$, and the Sobolev spaces, $W^{m,p}(\Omega)$ or $H^m(\Omega)$. The dual exponent to p will be denoted by p', $1/p + 1/p' = 1$. Solutions of the evolution equation will be functions from $[0,T]$ into these spaces, and we adopt the usual notion, $L^2[0,T; H^1(\Omega)]$, $C[0,T; H^1(\Omega)]$, etc. to indicate the temporal regularity of such functions. The space of C^∞ test functions having compact

support in Ω is denoted by $\mathcal{D}(\Omega)$. For vector valued quantities, such as the velocity v, we write $v \in L^2(\Omega)$ to indicate that each component lies in the specified space. The space $H(\mathrm{div};\Omega)$ is the set of vector valued functions in $L^2[0,T;L^2(\Omega)]$ with divergence in $L^2[0,T;L^2(\Omega)]$. Strong convergence of a sequence will be indicated as $\rho_h \to \rho$, weak convergence by $\rho_h \rightharpoonup \rho$, and weak $\star$ convergence by $\rho_h \rightharpoonup^* \rho$.

2. Construction of numerical schemes.

2.1. Overview. Convergence proofs of numerical schemes for linear partial differential equations are almost always a variant of the old adage "stability and consistency imply convergence." For nonlinear problems, some form of compactness is usually also required. Our proof of convergence follows this line of argument; in particular, numerical schemes are constructed so that discrete versions of energy estimate (1.3) (and hence stability) hold.

The low regularity of the solution gives rise to many technical problems. If high order approximations of the density are used, Gibbs phenomena arise, and stable approximations of the momentum equation require the density to be truncated or projected onto a set of strictly positive functions. Since the density has low regularity we cannot establish consistency of such schemes. In this situation we are forced to resort piecewise constant approximations of the density which give rise to monotone schemes. Unfortunately, piecewise constant approximations of the density give rise to a different consistency error; specifically, jump terms arise when the test functions are not continuous.

In the current context the key compactness result is that solutions of the equation for the density ρ will converge strongly in $L^2[0,T;L^2(\Omega)]$ when the velocity converges weakly in $L^2[0,T;H_0^1(\Omega)]$, [5, 15]. The analogous statement for discontinuous Galerkin approximations of the density equation was established by Walkington in [18] and this result will be used below. Again the low regularity of the velocity, which appears as a nonconstant coefficient in the density equation, gives rise to technical problems. Specifically, in order to establish strong convergence of the density the (approximate) velocity fields are required to have average divergence equal to zero on each element [18].

2.2. Stability. The natural energy estimate given in (1.3) was derived assuming that the balance of mass is satisfied *exactly*. Since the balance of mass is only approximately satisfied by numerical approximations, the energy estimate is not automatic. Also, numerical approximations of the density may not be nonnegative, so even if an "energy estimate" holds it may not be useful. One way to circumvent these problems is to observe that if $\rho_t + \mathrm{div}(\rho v) = 0$, then

$$\rho\left(v_t + (v.\nabla)v\right) = \frac{1}{2}\Big(\rho v_t + (\rho v.\nabla)v + (\rho v)_t + \mathrm{div}(\rho v \otimes v)\Big).$$

Taking the dot product of the right-hand side with v vanishing on $\partial\Omega$ and integrating gives $(d/dt)\int(\rho|v|^2/2)$. This identity holds independently of the equation for the balance of mass and also holds if different approximations of the velocity are used as coefficients of the convective terms. This motivates the following weak statement of the momentum equation:

$$\frac{1}{2}\int_\Omega \bar\rho v_t.w + (\rho\bar v.\nabla)v.w + (\bar\rho v)_t.w - (\rho\bar v.\nabla)w.v + \int_\Omega -p\,\mathrm{div}(w) + \mu(\rho)D(v)\cdot D(w) = \int_\Omega \bar\rho f.w. \tag{2.1}$$

In the context of a numerical scheme, ρ is an approximation of the density which may not be positive and $\bar{\rho}$ is a nonnegative projection or truncation of ρ. Similarly, in order to obtain stability of the convection equation, a projection, $\bar{v}$, of v onto a suitable subspace of $H(\mathrm{div};\Omega)$ may be required for the convection terms; see [18]. Selecting $w(t) = v(t)$ in the above equation immediately gives

$$\frac{d}{dt}\int_\Omega (1/2)\bar{\rho}|v|^2 + \int_\Omega \mu(\rho)|D(v)|^2 = \int_\Omega \bar{\rho} f.v.$$

2.3. Consistency. While numerical schemes based upon the weak statement (2.1) will "automatically" be stable, they are not "automatically" consistent. Specifically, in the absence of any estimates on v_t it is necessary to integrate the first term by parts. Then

$$\begin{aligned}\int_0^T\int_\Omega \bar{\rho}v_t.w + (\rho\bar{v}.\nabla)v.w &= \int_0^T\int_\Omega -v.(\bar{\rho}w)_t + (\rho\bar{v}.\nabla)v.w \\ &= \int_0^T\int_\Omega -(\bar{\rho}-\rho)_t\, v.w - \bar{\rho}v.w_t - \left(\rho_t(v.w) - (\rho\bar{v}.\nabla)v.w\right).\end{aligned}$$

(1) If a *high order* approximation of the density equation is used it is possible to select $v.w$ as a test function in the Galerkin approximation of $\rho_t + \mathrm{div}(\rho\bar{v}) = 0$. Then

$$\int_0^T\int_\Omega \bar{\rho}v_t.w + (\rho\bar{v}.\nabla)v.w = \int_0^T\int_\Omega -(\bar{\rho}-\rho)_t\, v.w - \bar{\rho}v.w_t - (\rho\bar{v}\otimes v)\cdot\nabla w$$

and consistency requires the first term to vanish in the limit. For the continuous problem ρ is bounded in $L^\infty[0,T;L^\infty(\Omega)]$ so that the momentum, ρv, is bounded in $L^2[0,T;L^2(\Omega)]$. Since $\rho_t + \mathrm{div}(\rho v) = 0$, it follows that ρ_t is bounded in $L^2[0,T;H^{-1}(\Omega)]$. Unfortunately, L^∞ bounds could not be established for high order approximations of the density, so the analogous estimates could not be established for the time derivative of the discrete density. For this reason we could not construct nonnegative approximations, $\bar{\rho}$, for which $(\bar{\rho}-\rho)_t$ converged to zero in $L^2[0,T;H^{-1}(\Omega)]$. In particular, we could not establish consistency of numerical schemes constructed using high order approximations of the density equation.

(2) If *piecewise constant* approximations of the density are used, then numerical approximations of ρ are nonnegative so it is possible to select $\bar{\rho} = \rho$. The first term in (2.1) then becomes

$$\int_0^T\int_\Omega \rho v_t.w + (\rho\bar{v}.\nabla)v.w = \int_0^T\int_\Omega -\rho v.w_t - \rho_t v.w + (\rho\bar{v}.\nabla)v.w.$$

To establish consistency we would like to multiply the Galerkin approximation of $\rho_t + \mathrm{div}(\rho\bar{v}) = 0$ by $v.w$. When the density is approximated using piecewise constant functions we must first approximate $v.w$ by a (discontinuous) piecewise constant function. This leads to an expression of the form

$$\int_0^T\int_\Omega \rho v_t.w + (\rho\bar{v}.\nabla)v.w = \int_0^T\int_\Omega -\rho v.w_t - (\rho\bar{v}\otimes v)\cdot\nabla w + \text{"jump terms,"}$$

and the scheme is consistent provided the "jump terms" vanish in the limit. In section 3 we show that the jump terms do vanish in the limit, which establishes consistency.

2.4. Scheme. In light of the above discussion we will consider approximations of equations (1.1) where the density is approximated using piecewise constant approximations in space and time, and the momentum equation is approximated using the implicit Euler scheme with velocity-pressure spaces satisfying the Babuska–Brezzi condition. In order to minimize the technicalities it will be assumed that the pressure space contains the (discontinuous) piecewise constant functions on each triangulation. Relaxing this condition is considered in section 4. Since the accuracy of the piecewise constant approximation of the density is formally first order, at each discrete time we can first advance the density and then the velocity and pressure without further loss of accuracy. In this situation the linear systems for the density and velocity/pressure can be decoupled.

Given a triangulation $\mathcal{T}_h$ of Ω and time step $\tau = T/N$, let

$$\mathcal{R}_h = \{\rho \in L^2(\Omega) \mid \rho|_K \in \mathbb{R}\, \forall K \in \mathcal{T}_h\}.$$

If ρ^0 is the projection of $\rho(0)$ onto $\mathcal{R}_h$, then the (piecewise constant) discontinuous Galerkin approximation of $\rho(t^n)$ satisfies $\rho^n \in \mathcal{R}_h$ and

$$\int_K \rho^n \psi^n + \tau \int_{\partial K} \left(\rho^n_-(v^{n-1}.n)^+ + \rho^n_+(v^{n-1}.n)^-\right)\psi^n = \int_K \rho^{n-1}\psi^n, \tag{2.2}$$

for $K \in \mathcal{T}_h$ and $\psi^n \in \mathbb{R}$. Here $v.n = (v.n)^+ + (v.n)^-$ are the positive and negative parts of $v.n$ and $\rho^n_\pm(x) = \lim_{s\searrow 0} \rho^n(x \pm sn)$ so that the middle term gives the "upwind" value of $\rho^n v^{n-1}.n$.

To march the velocity forward, let

$$V_h \subset \{v \in H^1_0(\Omega) \mid v|_K \in \mathcal{P}_k(K),\, K \in \mathcal{T}_h\},$$

and

$$P_h \subset \{p \in L^2(\Omega)/\mathbb{R} \mid p|_K \in \mathcal{P}_\ell(K),\, K \in \mathcal{T}_h\},$$

be a pair of spaces satisfying the Babuska–Brezzi condition and let v^0 be the $L^2(\Omega)$ projection of $v(0)$ onto V_h. Then the approximations, $(v^n, p^n) \in V_h \times P_h$, of $(v(t^n), p(t^n))$ are the solution of

$$\begin{aligned}
&\frac{1}{2}\int_\Omega \left\{ \rho^{n-1}\left(\frac{v^n - v^{n-1}}{\tau}\right).w + (\rho^n v^{n-1}.\nabla)v^n.w \right. \\
&\qquad \left. + \left(\frac{(\rho v)^n - (\rho v)^{n-1}}{\tau}\right).w - (\rho^n v^{n-1}.\nabla)w.v^n \right\} \\
&\qquad + \int_\Omega -p^n\, div(w) + \mu^n D(v^n)\cdot D(w) = \int_\Omega \rho^n f^n.w,
\end{aligned} \tag{2.3}$$

$$\int_\Omega \operatorname{div}(v^n)\, q = 0$$

for all $(w, q) \in V_h \times P_h$. In the above equation, f^n is an approximation of the average of f on $(t^{n-1}, t^n]$ and $\mu^n = \mu(\rho^n)$.

3. Analysis of the numerical scheme.

3.1. Estimates. To establish stability of the scheme (2.2)–(2.3) we first state the natural energy estimate the scheme was designed to satisfy.

Notation: If $\{v_n\}_{n=0}^N \subset V_h$ and $\{\rho^n\}_{n=0}^N \subset \mathcal{R}_h$, then we let $v_h \in L^2[-\tau, T; V_h]$ and $\rho_h \in L^2[-\tau, T; \mathcal{R}_h]$ denote the piecewise constant functions taking values v^n and ρ^n on $(t^{n-1}, t^n]$, respectively.

LEMMA 3.1. *Let (ρ_h, v_h, p_h) be the approximate solution of equations* (1.1) *computed using the scheme* (2.2)–(2.3). *Then*

$$\frac{1}{2}\int_\Omega \rho^n|v^n|^2 + \frac{1}{2}\sum_{i=1}^n \int_\Omega \rho^{n-1}|v^n - v^{n-1}|^2 + \sum_{i=1}^n \tau \int_\Omega \mu^n |D(v^n)|^2 = \frac{1}{2}\int_\Omega \rho^0|v^0|^2 + \sum_{i=1}^n \tau \int_\Omega \rho^n f^n.v^n.$$

Let the pressure space contain the piecewise constant functions. If $0 < c \le \rho(0) \le C$ and $0 < c \le \mu(\rho) \le C$ for constants c, $C \in \mathbb{R}$, $v_0 \in L^2(\Omega)$, and $f \in L^2[0, T; L^2(\Omega)]$, then $\{v_h\}_{h>0}$ is bounded in $L^\infty[0, T; L^2(\Omega)] \cap L^2[0, T; H_0^1(\Omega)]$ and

$$\int_\tau^T \|v_h(t) - v_h(t-\tau)\|^2_{L^2(\Omega)} \le C(v_0, f)\tau.$$

The first estimate follows directly upon substituting $w = v^n$ and $q = p^n$ into equations (2.3). The assumption on the pressure space guarantees that the scheme for the density is monotone [18, Theorem 6.1], so the bounds on the initial data are preserved,

$$\min_\Omega \rho^0 \le \rho^n(x) \le \max_\Omega \rho^0, \qquad x \in \Omega. \tag{3.1}$$

The bounds on $\{v_h\}_{h>0}$ then follow from the energy estimate.

3.2. Consistency of the density equation. To establish compactness of the sequence $\{v_h\}_{h>0}$ in $L^2[0, T; L^2(\Omega)]$, it is necessary to use test functions ψ in the discrete density equation (2.2) which are not piecewise constant. This gives rise to consistency errors which are estimated in this section. The following lemma provides explicit expressions for these errors.

LEMMA 3.2. *Let $\rho_h \in \mathcal{R}_h$ satisfy* (2.2). *If $\psi \in H_0^1(\Omega)$ and $\bar\psi \in \mathcal{R}_h$ is the function taking the average value of ψ on each element $K \in \mathcal{T}_h$, then*

$$\int_\Omega (\rho^n - \rho^{n-1})\psi - \tau\int_\Omega \rho^n v^{n-1}.\nabla\psi = \tau\int_\Omega \rho^n(\psi - \bar\psi)\mathrm{div}(v^{n-1}) + \tau\sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho^n](v^{n-1}.n)^-(\psi - \bar\psi),$$

where the value of $\bar\psi$ on ∂K is taken as $\bar\psi|_K$ (that is, the trace from inside K) and $[\rho^n] = \rho^n_+ - \rho^n_-$.

Proof. Select $\psi^n = \bar\psi|_K$ in (2.2) and sum over all of the simplices $K \in \mathcal{T}_h$ to get

$$\int_\Omega \rho^n\psi + \tau\sum_{K\in\mathcal{T}_h}\int_{\partial K}\left(\rho^n_-(v^{n-1}.n)^+ + \rho^n_+(v^{n-1}.n)^-\right)\bar\psi = \int_\Omega \rho^{n-1}\psi. \tag{3.2}$$

In the middle term $\rho^n_\pm(x) = \lim_{s\searrow 0}\rho^n(x \pm n)$ and $\bar\psi|_{\partial K} = \bar\psi|_K$. If $\mathcal{E}_0$ denotes all of the interior edges (faces in $3d$) of the elements, then the middle term may be written as

$$\sum_{K\in\mathcal{T}_h}\int_{\partial K}\left(\rho^n_-(v^{n-1}.n)^+ + \rho^n_+(v^{n-1}.n)^-\right)\bar\psi$$
$$= \sum_{e\in\mathcal{E}_0}\int_e -\left(\rho^n_-(v^{n-1}.N)^+ + \rho^n_+(v^{n-1}.N)^-\right)[\bar\psi].$$

Here N is one of the normals to e, $\rho^n_\pm(x) = \lim_{s\searrow 0}\rho^n(x \pm sN)$ and $[\bar\psi] = \bar\psi_+ - \bar\psi_-$. Integrals over the edges $e \subset \partial\Omega$ vanish since $\int_e v.n = 0$ on boundary edges. If $\psi : \bar\Omega \to \mathbb{R}$ is continuous and vanishes on $\partial\Omega$, then $[\psi] = 0$ on each edge $e \in \mathcal{E}_0$, so $[\bar\psi] = [\bar\psi - \psi]$. Reversing the above calculation shows

$$\sum_{K\in\mathcal{T}_h}\int_{\partial K}\left(\rho^n_-(v^{n-1}.n)^+ + \rho^n_+(v^{n-1}.n)^-\right)\bar\psi$$
$$= \sum_{K\in\mathcal{T}_h}\int_{\partial K}\left(\rho^n_-(v^{n-1}.n)^+ + \rho^n_+(v^{n-1}.n)^-\right)(\bar\psi - \psi)$$
$$= \sum_{K\in\mathcal{T}_h}\int_{\partial K}\left(\rho^n_-(v^{n-1}.n) + (\rho^n_+ - \rho^n_-)(v^{n-1}.n)^-\right)(\bar\psi - \psi)$$
$$= \sum_{K\in\mathcal{T}_h}\int_K \operatorname{div}\left(\rho^n v^{n-1}(\bar\psi - \psi)\right) + \sum_{K\in\mathcal{T}_h}\int_{\partial K}(\rho^n_+ - \rho^n_-)(v^{n-1}.n)^-(\bar\psi - \psi)$$
$$= -\int_\Omega\left(\rho^n v^{n-1}.\nabla\psi + \rho^n(\psi - \bar\psi)\operatorname{div}(v^{n-1})\right) - \sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho^n](v^{n-1}.n)^-(\psi - \bar\psi).$$

The last step used the property that ρ^n and ψ^n are constant on each element $K \in \mathcal{T}_h$. The lemma follows upon substituting this expression into (3.2). ∎

The following corollary expresses the weak statement satisfied by the discrete density ρ_h in a more convenient form. Given a sequence of functions $\{\psi^n\}_{n=0}^N \subset \mathcal{R}_h$, recall the convention that $\psi_h : (-\tau, T] \to \mathcal{R}_h$ is the function taking values $\psi_h(t) = \psi^n$ for $t \in (n-1)\tau, n\tau]$.

COROLLARY 3.3. *Let $\rho_h \in \mathcal{R}_h$ satisfy (2.2), $\{\psi^n\}_{n=0}^N \subset H^1_0(\Omega)$, and let $\{\bar\psi^n\}_{n=0}^N \subset \mathcal{R}_h$ be the piecewise constant approximations of $\{\psi^n\}_{n=0}^N$. Then*

$$\sum_{j=m+1}^n\int_\Omega(\rho^j - \rho^{j-1})\psi^j - \int_{t^m}^{t^n}\int_\Omega \rho_h v_h(.-\tau).\nabla\psi_h \tag{3.3}$$
$$= \int_{t^m}^{t^n}\int_\Omega \rho_h(\psi_h - \bar\psi_h)\operatorname{div}(v_h(.-\tau)) + \int_{t^m}^{t^n}\sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho_h](v_h(.-\tau).n)^-(\psi_h - \bar\psi_h),$$

where the value of $\bar\psi_h$ on ∂K is taken as $\bar\psi_h|_K$.

The two terms on the right-hand side represent the consistency error of the piecewise constant DG scheme. The first term is easy to bound, and the following lemma will be used to bound the last one.

LEMMA 3.4. *Let $K \subset \mathbb{R}^d$ be a simplex, $v \in \mathcal{P}_\ell(K)^d$, $\psi \in \mathcal{P}_\ell(K)$ and p, $q \geq 1$. Then there exists a constant C depending only upon d, p, q, ℓ and the aspect ratio of*

K such that

$$\int_{\partial K} |v.n||\psi - \bar{\psi}|^q \le C\|v\|_{L^{p'}(K)} h_K^{q-1} |\psi|^q_{W^{1,pq}(K)},$$

where $\bar{\psi} = (1/|K|)\int_K \psi$ is the average of ψ on K and h_K is the diameter of K.

Proof. Let $\hat{K}$ be the usual reference simplex and $\chi(\xi) = x_0 + B\xi$ be an affine mapping of $\hat{K}$ onto K. We use a hat to denote the natural correspondence between functions defined on K and $\hat{K}$, $\hat{\psi} = \psi \circ \chi$. Writing the integral over the boundary as the sum over the faces $e \subset \partial K$ gives

$$\begin{aligned}
\int_{\partial K} |v.n||\psi - \bar{\psi}|^q &= \sum_{e\subset\partial K} \int_e |v.n||\psi - \bar{\psi}|^q \\
&= \sum_{\hat{e}\subset\partial\hat{K}} \frac{|e|}{|\hat{e}|} \int_{\hat{e}} |\hat{v}.n||\hat{\psi} - \bar{\psi}|^q \\
&\le C \sum_{\hat{e}\subset\partial\hat{K}} |e| \|\hat{v}\|_{L^{p'}(\hat{K})} \|\hat{\psi} - \bar{\psi}\|^q_{L^{qp}(\hat{K})} \\
&\le C \sum_{\hat{e}\subset\partial\hat{K}} |e| \|\hat{v}\|_{L^{p'}(\hat{K})} |\hat{\psi}|^q_{W^{1,pq}(\hat{K})}.
\end{aligned}$$

To obtain the third line the trace theorem was used and the finite dimensionality of $\mathcal{P}_\ell(\hat{K})$ allowed the use of the indicated norms. The last line follows from the Poincaré inequality and the observation that the average of ψ is the average of $\hat{\psi}$.

Since

$$\|\hat{v}\|_{L^{p'}(\hat{K})} = (|\hat{K}|/|K|)^{1/p'} \|v\|_{L^{p'}(K)}, \qquad |\hat{\psi}|_{W^{1,pq}(\hat{K})} \le C(|\hat{K}|/|K|)^{1/pq} h_K |\psi|_{W^{1,pq}(K)},$$

and $|e| \le C|K|/h_K$, where C depends upon the aspect ratio of K, the lemma follows. ∎

3.3. Compactness. The energy estimate shows that $\{v_h\}_{h>0}$ is bounded in $L^\infty[0,T;L^2(\Omega)] \cap L^2[0,T;H_0^1(\Omega)]$. A result of Lions [13] and Lions and Magenes [14] states that compactness of the sequence in $L^2[0,T;L^2(\Omega)]$ will follow if

$$\int_\delta^T \|v_h(t) - v_h(t-\delta)\|_{L^2(\Omega)} \le C\delta^\alpha,$$

for $0 \le \delta \le T$ and some $\alpha > 0$.

We recall Lions' argument [13] which shows that weak solutions of the Navier–Stokes equations with variable density and viscosity satisfy this inequality. This proof carries over to Galerkin approximations with a few modifications which will be considered subsequently.

Lions' compactness argument. Beginning with the weak statement of the momentum equation (cf. (2.3))

$$\begin{aligned}
\int_\Omega \Big\{ &(1/2)\left(\rho v_t + (\rho v)_t\right).w + (1/2)(\rho v.\nabla)v.w - (1/2)(\rho v.\nabla)w.v \\
&- p\,\mathrm{div}(w) + \mu D(v)\cdot D(w) \Big\} = \int_\Omega \rho f.w,
\end{aligned}$$

the identity $\rho v_t = (\rho v)_t - \rho_t v$ is used to obtain

$$\int_\Omega (\rho v)_t.w = \int_\Omega \Big\{\rho f.w + (1/2)\rho_t(v.w) - (1/2)(\rho v.\nabla)v.w \\ + (1/2)(\rho v.\nabla)w.v + p\,\mathrm{div}(w) - \mu D(v)\cdot D(w)\Big\}.$$

The second term on the right-hand side can be eliminated upon writing the weak statement of the balance of mass as

$$\int_\Omega \rho_t \psi = \int_\Omega \rho v.\nabla\psi, \tag{3.4}$$

and selecting $\psi = v.w$, to give

$$\int_\Omega (\rho v)_t.w = \int_\Omega \rho f.w + (\rho v.\nabla)w.v + p\,\mathrm{div}(w) - \mu D(v)\cdot D(w).$$

Integrating this expression with respect to $s \in (t-\delta, t)$ and letting $w = w(t)$ be independent of s gives

$$\int_\Omega \rho v|_{t-\delta}^t .w(t) = \int_{t-\delta}^t \int_\Omega \rho f.w(t) + (\rho v.\nabla)w(t).v + p\,\mathrm{div}(w(t)) - \mu D(v)\cdot D(w(t))\,ds.$$

Integrating the weak statement of the balance of mass (3.4) with respect to $s \in (t-\delta, t)$ and setting $\psi = v(t).w(t)$ shows

$$\int_\Omega \rho|_{t-\delta}^t v(t).w(t) = \int_{t-\delta}^t \int_\Omega \rho v.\nabla(v(t).w(t)).$$

Subtracting this equation from the previous one and observing that

$$\rho v|_{t-\delta}^t .w(t) - \rho|_{t-\delta}^t v(t).w(t) = \rho(t-\delta)(v(t) - v(t-\delta)).w(t)$$

gives

$$\int_\Omega \rho(t-\delta)(v(t)-v(t-\delta)).w(t) = \int_{t-\delta}^t \int_\Omega \Big\{\rho f.w(t) + (\rho v.\nabla)w(t).v \\ + p\,\mathrm{div}(w(t)) - \mu D(v)\cdot D(w(t)) - \rho v.\nabla(v(t).w(t))\Big\}\,ds. \tag{3.5}$$

Upon electing $w(t) = v(t) - v(t-\delta)$ the left-hand side dominates $\|v(t) - v(t-\delta)\|^2_{L^2(\Omega)}$ when ρ is bounded below by $c > 0$. The right-hand side is estimated using the following lemma.

LEMMA 3.5. *Let $\Omega \subset \mathbb{R}^d$ with $d = 2$ or 3 and $v, w \in L^2[0,T; H_0^1(\Omega)] \cap L^\infty[0,T; L^2(\Omega)]$, $\rho, \mu \in L^\infty[0,T; L^\infty(\Omega)]$, and $f \in L^2[0,T; L^2(\Omega)]$. Then there exists a constant $C > 0$ and $\alpha \in (0,1)$ such that*

$$\left| \int_\delta^T \int_{t-\delta}^t \int_\Omega \rho f.w(t) + (\rho v.\nabla)w(t).v - \mu D(v)\cdot D(w(t)) - \rho v.\nabla(v(t).w(t))\,ds\,dt \right| \le C\delta^\alpha,$$

for $0 < \delta < T$. Here C depends only upon d, T, and f, ρ, μ, v, and w through the norms stated in the hypotheses.

This lemma follows from elementary applications of Holder's inequality and the Sobolev embedding theorem, $\|v\|_{L^4(\Omega)} \le \|v\|^\beta_{L^2(\Omega)} \|\nabla v\|^{1-\beta}_{L^2(\Omega)}$, where $\beta = 1/2$ and $\beta = 1/4$ for $d = 2$ and 3, respectively.

Compactness for the discrete problem. The calculations above can be replicated for numerical solutions computed using (2.2)–(2.3) provided the discrete weak statement of the balance of mass (3.3) is used in place of (3.4). This gives rise to four extra terms on the right-hand side of (3.5).

LEMMA 3.6. *Let $\{(\rho_h, v_h)\}_{h>0}$ be numerical approximations of the Navier–Stokes equations with variable density and viscosity computed using (2.2)–(2.3) over a quasi-regular family of triangulations $\{\mathcal{T}_h\}_{h>0}$ of $\Omega \subset \mathbb{R}^d$ with $d = 2$ or $= 3$. Assume the following:*

- *$v^0 \in L^2(\Omega)$, $\rho^0 \in L^\infty(\Omega)$ satisfies $0 < c \le \rho^0(x) \le C$, and $f \in L^2[0,T;L^2(\Omega)]$.*
- *$\mu : \mathbb{R} \to \mathbb{R}^+$ is continuous.*
- *The spaces for the velocity and pressure satisfy the Babuska–Brezzi condition and the pressure space contains the piecewise constant functions.*

Then there exists a constant $C > 0$ independent of h and $\alpha \in (0,1)$ such that

$$\int_\delta^T \|v_h(t) - v_h(t-\delta)\|^2_{L^2(\Omega)} \le C\delta^\alpha,$$

for $0 < \delta < T$.

Proof. Since $\{v_h\}_{h>0}$ are piecewise constant in time it suffices to consider δ a multiple of the time step τ. Writing $(t-\delta, t) = (t^m, t^n)$ and $w(t) = v^n - v^m = w^{mn}$, the discrete analogue of (3.5) is

$$\begin{aligned}
\int_\Omega \rho^m (v^n - v^m).w^{mn} = \int_{t^m}^{t^n} \int_\Omega \Big\{ & \rho_h f.w^{mn} + (\rho_h v_h(.-\tau).\nabla) w^{mn}.v_h \\
& - \mu_h D(v_h) \cdot D(w^{mn}) - \rho_h v_h.\nabla(v^n.w^{mn}) \Big\}\, ds \\
+ \int_{t^m}^{t^n} \int_\Omega \Big\{ & \rho_h (v_h.w^{mn} - \overline{v_h.w^{mn}}) \operatorname{div}(v_h(.-\tau)) \\
& - \rho_h (v^n.w^{mn} - \overline{v^n.w^{mn}}) \operatorname{div}(v_h(.-\tau)) \Big\}\, ds \\
+\tau \sum_{j=m+1}^{n} \sum_{K \in \mathcal{T}_h} \int_{\partial K} \Big\{ & [\rho^j](v^{j-1}.n)^- \quad (v^j.w^{mn} - \overline{v^j.w^{mn}}) \\
& - [\rho^j](v^{j-1}.n)^- (v^n.w^{mn} - \overline{v^n.w^{mn}}) \Big\}.
\end{aligned}$$

The last four terms represent the consistency errors associated with the density equation and the term involving the pressure vanishes since $w^{mn} = v^n - v^m$ is discreetly divergence free. (Recall that $\bar\psi$ is the piecewise constant function having average value of ψ on each element $K \in \mathcal{T}_h$.)

We bound the first term in each of the last two lines since the second is bounded similarly. Since $\|\bar\psi\|_{L^p(\Omega)} \le \|\psi\|_{L^p(\Omega)}$ for any $\psi \in L^p(\Omega)$, the first term on the second to last line may be bounded as

$$\begin{aligned}
& \int_{t^m}^{t^n} \int_\Omega \rho_h (v_h.w^{mn} - \overline{v_h.w^{mn}}) \operatorname{div}(v_h(.-\tau))\, ds \\
& \le 2\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]} \int_{t^m}^{t^n} \|v_h\|_{L^4(\Omega)} \|w^{mn}\|_{L^4(\Omega)} \|\operatorname{div}(v_h(.-\tau))\|_{L^2(\Omega)}\, ds \\
& \le C \int_{t^m}^{t^n} \|\nabla v_h\|^{1-\beta}_{L^2(\Omega)} \|\operatorname{div}(v_h(.-\tau))\|_{L^2(\Omega)}\, ds\, \|\nabla w^{mn}\|^{1-\beta}_{L^2(\Omega)}
\end{aligned}$$

$$\le C\int_{t^m}^{t^n}\|\nabla v_h\|_{L^2(\Omega)}^{1-\beta}\|\nabla v_h(.-\tau)\|_{L^2(\Omega)}\,ds\,\|\nabla w^{mn}\|_{L^2(\Omega)}^{1-\beta}$$
$$\le C\|\nabla v_h\|_{L^2[0,T;L^2(\Omega)]}^{2-\beta}(t^n-t^m)^{\beta/2}\|\nabla w^{mn}\|_{L^2(\Omega)}^{1-\beta}$$

(here $\beta = 1/2$ or $1/4$ for $d = 2$ or 3, respectively). Since v_h, $w^{mn} \in L^\infty[0,T;L^2(\Omega)]$, quantities involving $\|v_h\|_{L^2(\Omega)}$ and $\|w^{mn}\|_{L^2(\Omega)}$ have been absorbed into the constant C. Integrating with respect to $t^n \in (\delta, T)$ and recalling that $t^m = t^n - \delta$ and $w^{mn} = v_h(t^n) - v_h(t^n - \delta)$ shows that this term may be bounded by a constant of the form $C\delta^{\beta/2}$ with C independent of h.

To estimate the first jump term use Lemma 3.4 with $q = 1$ to obtain

$$\tau\sum_{j=m+1}^{n}\sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho^j](v^{j-1}.n)^-(v^j.w^{mn}-\overline{v^j.w^{mn}})$$
$$\le C\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]}\tau\sum_{j=m+1}^{n}\sum_{K\in\mathcal{T}_h}\int_K\|v^{j-1}\|_{L^{p'}(K)}|v^j.w^{mn}|_{W^{1,p}(K)}$$
$$\le C\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]}\int_{t^m}^{t^n}\|v_h(.-\tau)\|_{L^{p'}(\Omega)}|v_h.w^{mn}|_{W^{1,p}(\Omega)}.$$

When $p < 2$ the terms of the form $\nabla(v.w)$ can be estimated as

$$\begin{aligned}|\nabla(v.w)|_{W^{1,p}(\Omega)} &\le \||v||\nabla w| + |\nabla v||w|\|_{L^p(\Omega)}\\ &\le \||v||\nabla w|\|_{L^p(\Omega)} + \||\nabla v||w|\|_{L^p(\Omega)}\\ &\le \|v\|_{L^{2p/(2-p)}(\Omega)}\|\nabla w\|_{L^2(\Omega)} + \|\nabla v\|_{L^2(\Omega)}\|w\|_{L^{2p/(2-p)}(\Omega)}.\end{aligned}$$

Letting $p = 4/3$ so that $2p/(2-p) = 4$, the first jump term becomes

$$\tau\sum_{j=m+1}^{n}\sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho^j](v^{j-1}.n)^-(v^j.w^{mn}-\overline{v^j.w^{mn}})$$
$$\le C\int_{t^m}^{t^n}\|v_h(.-\tau)\|_{L^4(\Omega)}\left(\|v_h\|_{L^4(\Omega)}\|\nabla w^{mn}\|_{L^2(\Omega)} + \|\nabla v_h\|_{L^2(\Omega)}\|w^{mn}\|_{L^4(\Omega)}\right)ds$$
$$\le C\int_{t^m}^{t^n}\|\nabla v_h(.-\tau)\|_{L^2(\Omega)}^{1-\beta}\Big(\|\nabla v_h\|_{L^2(\Omega)}^{1-\beta}\|\nabla w^{mn}\|_{L^2(\Omega)} + \|\nabla v_h\|_{L^2(\Omega)}\|\nabla w^{mn}\|_{L^2(\Omega)}^{1-\beta}\Big)ds$$
$$\le C\Big(\|\nabla v_h\|_{L^2[0,T;L^2(\Omega)]}^{2(1-\beta)}(t^n-t^m)^{\beta}\|\nabla w^{mn}\|_{L^2(\Omega)}$$
$$+\|\nabla v_h\|_{L^2[0,T;L^2(\Omega)]}^{2-\beta}(t^n-t^m)^{\beta/2}\|\nabla w^{mn}\|_{L^2(\Omega)}^{1-\beta}\Big).$$

Integration with respect to $t^n \in (\delta, T)$ bounds this term by a constant of the form $C\delta^{\beta/2}$ with C independent of h. □

3.4. Convergence. The bound on the sequence $\{v_h\}_{h>0}$ and the compactness result of Lions [13] and Lions and Magenes [14] allows passage to a subsequence for which

$$v_h \rightharpoonup^* v \text{ in } L^\infty[0,T;L^2(\Omega)]\cap L^2[0,T;H_0^1(\Omega)] \qquad \text{and} \qquad v_h \to v \text{ in } L^2[0,T;L^2(\Omega)].$$

In this situation, Theorem 5.1 of [18] states that the corresponding densities $\{\rho_h\}_{h>0}$ converge in $L^2[0,T;L^2(\Omega)]$ to a limit which we denote by ρ. We will show that the pair (v,ρ) is a solution of (1.1).
