Note that since $\{\rho_h\}_{h>0}$ is bounded in $L^\infty[0,T;L^\infty(\Omega)]$ and converges in $L^2[0,T;L^2(\Omega)]$ it also converges in $L^p[0,T;L^p(\Omega)]$ for any $1 \le p < \infty$. Similarly, since $\{v_h\}_{h>0}$ is bounded in $L^\infty[0,T;L^2(\Omega)] \cap L^2[0,T;H_0^1(\Omega)]$ and converges in $L^2[0,T;L^2(\Omega)]$, the Sobolev embedding theorem and elementary interpolation show that v_h converges in $L^p[0,T;L^q(\Omega)]$ for any pair p, $q \ge 1$ satisfying $1/2 < 1/q + 2/dp$.

THEOREM 3.7. *Let $\Omega \subset \mathbb{R}^d$, $d = 2$ or 3, be a bounded Lipschitz and $\{\mathcal{T}_h\}_{h>0}$ be a regular family of quasi-uniform triangulations of Ω. Let $f \in L^2[0,T;L^2(\Omega)]$, $v_0 \in L^2(\Omega)$, and $\rho_0 \in L^\infty(\Omega)$ satisfy $0 < c \le \rho_0(x) \le C$ for positive constants c and C. Assume that the viscosity, $\mu : \mathbb{R} \to (0,\infty)$, is a continuous nonnegative function of the density.*

Let $\{(v_h,\rho_h)\}_{h>0}$ be the approximate solution of equations (1.1) *computed using the scheme presented in section* 2.4 *with time steps τ converging to zero as $h \to 0$. In particular, assume that the density is computed using the piecewise constant discontinuous Galerkin method, that the velocity-pressure spaces satisfy the Babuska–Brezzi condition, and that the pressure space contains the piecewise constant functions.*

Then, after passing to a subsequence, the densities $\{\rho_h\}$ converge strongly in $L^2[0,T;L^2(\Omega)]$, and the velocities $\{v_h\}$ converge strongly in $L^2[0,T;L^2(\Omega)]$ and weakly star in $L^\infty[0,T;L^2(\Omega)] \cap L^2[0,T;H_0^1(\Omega)]$ to a weak solution of equations (1.1) *with initial data (v_0,ρ_0) and homogeneous Dirichlet boundary data on the velocity. If the solution of equations* (1.1) *is unique, then the whole sequence $\{(v_h,\rho_h)\}_{h>0}$ converges.*

Proof. Notice that the hypotheses of Lemma 3.1 are satisfied since monotonicity of the scheme (2.2) for computing the density guarantees that $0 < c \le \rho_h(x,t) \le C$. Also, $\mu : \mathbb{R} \to (0,\infty)$ is continuous so $\mu_h = \mu(\rho_h)$ satisfies a similar inequality.

Let $w \in \mathcal{D}([0,T) \times \Omega)$ be divergence free and let w^n be the Stokes projection of $w(t^n)$ onto the space

$$\tilde{V}_h = \left\{ v_h \in V_h \mid \int_\Omega \operatorname{div}(v_h)\, q_h = 0 \,\forall q_h \in P_h \right\},$$

and let $w_h \in L^2[0,T;V_h]$ be the piecewise constant function taking values w^n on $(t^{n-1},t^n]$ and $\hat{w}_h \in C[0,T;V_h]$ be the corresponding piecewise linear interpolant. Since the pair (V_h,P_h) satisfies the Babuska–Brezzi condition, w_h and $\hat{w}_h$ converge to w in $L^\infty[0,T,H_0^1(\Omega)]$ and $W^{1,\infty}[0,T;H_0^1(\Omega)]$, respectively. Selecting w^n as the test function in (2.3) and summing over n gives

$$\begin{aligned}\frac{1}{2}\sum_{n=1}^{N}\int_\Omega (\rho^{n-1}-\rho^n)v^n.w^n + \sum_{n=1}^{N}\int_\Omega (\rho v)^{n-1}.(w^{n-1}-w^n)\\ +\frac{\tau}{2}\sum_{n=1}^{N}\int_\Omega (\rho^n v^{n-1}.\nabla)v^n.w^n - (\rho^n v^{n-1}.\nabla)w^n.v^n\\ +\tau\sum_{n=1}^{N}\int_\Omega \mu^n D(v^n)\cdot D(w^n) = \int_\Omega \rho^0 v^0.w^0 + \tau\sum_{n=1}^{N}\int_\Omega \rho^n f^n.w.\end{aligned}$$

To obtain the first line we used the identity

$$\begin{aligned}&\frac{1}{2}\Big(\rho^{n-1}(v^n-v^{n-1}).w^n + \left((\rho v)^n-(\rho v)^{n-1}\right).w^n\Big)\\ &\quad = \frac{1}{2}(\rho^{n-1}-\rho^n)v^n.w^n + \left((\rho v)^n-(\rho v)^{n-1}\right).w^n,\end{aligned}$$

and summed the second term by parts. The upper limit of the summation vanishes since $w \in \mathcal{D}([0,T)\times\Omega)$ implies $w^N = 0$. Recalling the notation that $v_h(t) \in V_h$ is the function taking on value v^n on $(t^{n-1}, t^n]$, we find that

$$\begin{aligned}\frac{1}{2}\sum_{n=1}^{N}\int_\Omega(\rho^{n-1}-\rho^n)v^n.w^n - \int_0^T\int_\Omega \rho_h(.-\tau)v_h(.-\tau)\hat{w}_t \\ +\frac{1}{2}\int_0^T\int_\Omega \left(\rho_h v_h(.-\tau).\nabla\right)v_h.w_h - \left(\rho_h v_h(.-\tau).\nabla\right)w_h.v_h \\ +\int_0^T\int_\Omega \mu_h D(v_h)\cdot D(w_h) = \int_\Omega \rho^0 v^0.w^0 + \int_0^T\int_\Omega \rho_h f_h.w_h.\end{aligned}$$

Selecting $\psi = v_h.w_h$ in Corollary 3.3 shows that the first term can be rewritten as

$$\sum_{n=1}^{N}\int_\Omega(\rho^{n-1}-\rho^n)v^n.w^n = -\int_0^T\int_\Omega \rho_h v_h(.-\tau).\nabla(v_h.w_h) - e_h,$$

where

$$\begin{aligned}e_h = &\int_0^T\int_\Omega \rho_h(v_h.w_h - \overline{v_h.w_h})\mathrm{div}(v_h(.-\tau)) \\ &+\int_0^T\sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho_h](v_h(.-\tau).n)^-(v_h.w_h - \overline{v_h.w_h})\end{aligned}$$

is the consistency error. Then

$$\begin{aligned}-\int_0^T\int_\Omega \rho_h(.-\tau)v_h(.-\tau)\hat{w}_t + \left(\rho_h v_h(.-\tau)\otimes v_h\right)\cdot\nabla w_h \\ +\int_0^T\int_\Omega \mu_h D(v_h)\cdot D(w_h) = \int_\Omega \rho^0 v^0.w^0 + \int_0^T\int_\Omega \rho_h f_h.w_h + e_h.\end{aligned}$$

Now pass to a subsequence along which v_h and ρ_h converge in $L^2[0,T;L^2(\Omega)]$ and $v_h \rightharpoonup v$ in $L^2[0,T;H_0^1(\Omega)]$. Since ρ_h and μ_h are bounded in $L^\infty[0,T;L^\infty(\Omega)]$, they converge in $L^p[0,T;L^p(\Omega)]$ for $1 \le p < \infty$ and v_h converges in $L^p[0,T;L^4(\Omega)]$ for $p < 8/3$. This is sufficient to pass to the limit term-by-term in the above equation; the theorem will then follow provided $e_h \to 0$.

It suffices to show that the consistency error e_h vanishes as $h \to 0$. The first term in e_h is bounded using classical estimates for piecewise constant approximations [3],

$$\begin{aligned}&\int_0^T\int_\Omega \rho_h(v_h.w_h - \overline{v_h.w_h})\mathrm{div}(v_h(.-\tau)) \\ &\le C\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]}\|\mathrm{div}(v_h)\|_{L^2[0,T;L^2(\Omega)]}\|v_h.w_h - \overline{v_h.w_h}\|_{L^2[0,T;L^2(\Omega)]} \\ &\le C\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]}\|\mathrm{div}(v_h)\|_{L^2[0,T;L^2(\Omega)]}|v_h.w_h|_{L^2[0,T;W^{1,p}(\Omega)}h^{1+d(1/2-1/p)}.\end{aligned}$$

As in the proof of Lemma 3.6

$$\begin{aligned}|v_h.w_h|_{W^{1,4/3}(\Omega)} &\le \|v_h\|_{L^4(\Omega)}\|\nabla w_h\|_{L^2(\Omega)} + \|\nabla v_h\|_{L^2(\Omega)}\|w_h\|_{L^4(\Omega)} \\ &\le C\|v_h\|_{H^1(\Omega)}\|w_h\|_{H^1(\Omega)}.\end{aligned}$$

It follows that $|v_h.w_h|_{L^2[0,T;W^{1,4/3}]} \le \|v_h\|_{L^2[0,T;H^1(\Omega)]}\|w_h\|_{L^\infty[0,T;H^1(\Omega)]}$ is bounded so

$$\begin{aligned}
&\int_0^T \int_\Omega \rho_h(v_h.w_h - \overline{v_h.w_h})\mathrm{div}(v_h(.-\tau))\\
&\le C\|\rho_h\|_{L^\infty[0,T;L^\infty(\Omega)]}\|\mathrm{div}(v_h)\|_{L^2[0,T;L^2(\Omega)]}\|v_h\|_{L^2[0,T;H^1(\Omega)]}\|w_h\|_{L^\infty[0,T;H^1(\Omega)]}h^{1-d/4}\\
&\to 0.
\end{aligned}$$

The second term of e_h is bounded using Lemma 3.4 with $q \le 2$,

$$\begin{aligned}
&\int_0^T \sum_{K\in\mathcal{T}_h}\int_{\partial K}[\rho_h](v_h(.-\tau).n)^-(v_h.w_h - \overline{v_h.w_h})\\
&\le \left(\|\rho_h\|^{q'-2}_{L^\infty[0,T;L^\infty(\Omega)]}\int_0^T\sum_{K\in\mathcal{T}_h}\int_{\partial K}|v_h(.-\tau).n|[\rho_h]^2\right)^{1/q'}\\
&\quad\times\left(\int_0^T\sum_{K\in\mathcal{T}_h}\int_{\partial K}|v_h(.-\tau)|(v_h.w_h-\overline{v_h.w_h})^q\right)^{1/q}\\
&\le C\|\rho_h\|^{1-2/q'}_{L^\infty[0,T;L^\infty(\Omega)]}(J_h^N)^{1/q'}\left(\int_0^T\int_\Omega\|v_h(.-\tau)\|_{L^{p'}(\Omega)}|v_h.w_h|^q_{W^{1,pq}(\Omega)}h^{q-1}\right)^{1/q}\\
&\le C\|\rho_h\|^{1-2/q'}_{L^\infty[0,T;L^\infty(\Omega)]}(J_h^N)^{1/q'}\|v_h\|^{1/q}_{L^{r'}[0,T,L^{p'}(\Omega)]}|v_h.w_h|_{L^{rq}[0,T;W^{1,pq}(\Omega)]}h^{1-1/q},
\end{aligned}$$

where $q' \ge 2$ and

$$J_h^N = \sum_{e\in\mathcal{E}_0}\int_0^T\int_e |v_h(.-\tau).n|\,[\rho_h]^2.$$

J_h^N measures the jumps in the density across the interelement boundaries $e \in \mathcal{E}_0$, and it was shown in [18, Theorem 5.1] that, under the hypotheses assumed above, $J_h^N \to 0$ as h (and τ) tend to zero. The parameters p, q, and r are selected so that the norms of v_h and $v_h.w_h$ are bounded. If

$$p = 26/21,\ p' = 26/5, \qquad q = 14/13,\ q' = 14, \qquad r = 13/7,\ r' = 13/6,$$

then $1/2 = 1/p' + 2/dr'$ when $d = 3$, so the terms $\|v_h\|_{L^{r'}[0,T,L^{p'}(\Omega)]}$ and

$$|v_h.w_h|_{L^{rq}[0,T;W^{1,pq}(\Omega)]} = |v_h.w_h|_{L^2[0,T;W^{1,4/3}(\Omega)]}$$

are bounded, and the second term in e_h vanishes as $h \to 0$. ∎

4. Projections of the velocity field. In order to guarantee that the piecewise constant DG scheme is monotone and convergent, the average divergence of the velocity field in (2.2) must vanish on each simplex $K \in \mathcal{T}_h$. Above we assumed space P_h contains the piecewise constant functions so that solution v_h of the approximate momentum equation (2.3) automatically satisfies this condition. In this section projections of the velocity field $v_h \in V_h$ onto a space $\bar{V}_h \subset H(\Omega;\mathrm{div})$ having average divergence on each element equal to zero are considered when P_h does not contain

the piecewise constant functions. In this case the density and velocity/pressure are approximated by $\rho^n \in \mathcal{R}_h$ satisfying

$$\int_K \rho^n \psi^n + \tau \int_{\partial K} \left(\rho^n_-(\bar{v}^{n-1}.n)^+ + \rho^n_+(\bar{v}^{n-1}.n)^- \right) \psi^n = \int_K \rho^{n-1}\psi^n, \tag{4.1}$$

for $K \in \mathcal{T}_h$ and $\psi^n \in \mathbb{R}$, and $(v^n, p^n) \in V_h \times P_h$ satisfying

$$\begin{aligned} \frac{1}{2}\int_\Omega \rho^{n-1}\left(\frac{v^n - v^{n-1}}{\tau}\right).w + (\rho^n \bar{v}^{n-1}.\nabla)v^n.w \\ + \frac{1}{2}\int_\Omega \left(\frac{(\rho v)^n - (\rho v)^{n-1}}{\tau}\right).w - (\rho^n \bar{v}^{n-1}.\nabla)w.v^n \\ + \int_\Omega -p^n \operatorname{div}(w) + \mu^n D(v^n)\cdot D(w) = \int_\Omega \rho^n f^n.w, \end{aligned} \tag{4.2}$$

$$\int_\Omega \operatorname{div}(v^n)\, q = 0,$$

for all $(w, q) \in V_h \times P_h$.

Writing $\bar{v}^{n-1} = P_{\bar{V}_h} v^{n-1}$, where

$$\bar{V}_h \subset \left\{ v_h \in H(\Omega; \operatorname{div}) \mid \int_K \operatorname{div}(v_h) = 0,\ K \in \mathcal{T}_h \right\},$$

examining the proofs shows that the modified scheme will also converge if the projection $P_{\bar{V}_h} : V_h \to \bar{V}_h$ satisfies the following hypotheses.

ASSUMPTION 4.1.

1. *There exists $\ell \in \mathbb{N}$ independent of h such that $\bar{v}_h|_K \in \mathcal{P}_\ell(K)$ for each $K \in \mathcal{T}_h$.*
2. *For each $\bar{v}_h \in \bar{V}_h$*
$$\int_K \operatorname{div}(\bar{v}_h) = 0, \text{and } \int_{\partial K \cap \partial\Omega} \bar{v}_h.n = 0, \qquad K \in \mathcal{T}_h.$$
3. *If $v_h \in V_h$ and $\bar{v}_h = P_{\bar{V}_h} v_h$, then there exists $C > 0$ independent of h such that $\|\operatorname{div}(\bar{v}_h)\|_{L^2(\Omega)} \le C\|v_h\|_{H^1(\Omega)}$.*
4. *If $v_h \in V_h$ and $\bar{v}_h = P_{\bar{V}_h} v_h$, then there exists $C > 0$ independent of h such that $\|\bar{v}_h\|_{L^2(\Omega)} \le C\|v_h\|_{L^2(\Omega)}$ and $\|\bar{v}_h\|_{L^6(\Omega)} \le C\|\nabla v_h\|_{H^1(\Omega)}$.*
5. *Let $\{v_h\}_{h>0}$, $v_h \in V_h$ be bounded in $L^\infty[0,T;L^2(\Omega)] \cap L^2[0,T;H^1_0(\Omega)]$, and $\bar{v}_h = P_{\bar{V}_h} v_h$. If $v_h \to v$ in $L^2[0,T;L^2(\Omega)]$, then $\bar{v}_h \to v$.*

Stokes projections. If $(\bar{V}_h, \bar{P}_h) \subset H^1_0(\Omega)^d \times L^2(\Omega)/\mathbb{R}$ is a family of finite element spaces constructed on $\mathcal{T}_h$ which satisfies the Babuska–Brezzi condition, and if $\bar{P}_h$ contains the piecewise constant functions, then the Stokes projection $P_{\bar{V}_h} : V_h \to \bar{V}_h$ satisfies Assumption 4.1.

The Stokes projection of $v_h \in V_h$ is computed from the unique solution $(\bar{v}_h, \bar{p}_h) \in (\bar{V}_h, \bar{P}_h)$ of

$$a(\bar{v}_h, \bar{w}_h) + b(\bar{p}_h, \bar{w}_h) + b(\bar{q}_h, \bar{v}_h) = a(v_h, \bar{w}_h) \tag{4.3}$$

for all $(\bar{w}_h, \bar{q}_h) \in (\bar{V}_h, \bar{P}_h)$. The bilinear forms $a : H^1(\Omega) \times H^1(\Omega) \to \mathbb{R}$ and $b : L^2(\Omega) \times H^1(\Omega) \to \mathbb{R}$ are defined by

$$a(v, w) = (v, w)_{H^1(\Omega)}, \qquad b(p, v) = (p, \operatorname{div}(v))_{L^2(\Omega)}.$$

By construction the average of $\operatorname{div}(\bar{v}_h)$ vanishes on each simplex $K \in \mathcal{T}_h$. The next lemma shows that the continuity properties of Assumption 4.1 are also satisfied by this construction.

LEMMA 4.2. *Let $\Omega \subset \mathbb{R}^d$ be sufficiently regular to guarantee $H^2(\Omega)^d \times H^1(\Omega)$ regularity of the Stokes operator, and let $\{\mathcal{T}_h\}_{h>0}$ be a regular quasi-uniform family of triangulations of Ω.*

Let (V_h, P_h) and $(\bar{V}_h, \bar{P}_h) \subset H_0^1(\Omega)^d \times L^2(\Omega)/\mathbb{R}$ be families of finite element spaces constructed on $\mathcal{T}_h$ which satisfy the Babuska–Brezzi condition, and let $(\bar{v}_h, \bar{p}_h) \in (\bar{V}_h, \bar{P}_h)$ be the Stokes projection of a velocity field $v_h \in V_h$ satisfying $b(q_h, v_h) = 0$ for all $q_h \in P_h$. Then

- $\|\bar{v}_h\|_{H^1(\Omega)} \le \|v_h\|_{H^1(\Omega)}$, *and*
- $\|\bar{v}_h - v_h\|_{L^2(\Omega)} \le C\|v_h\|_{H^1(\Omega)} h \le C\|v_h\|_{L^2(\Omega)}$.

The first statement of the lemma follows upon setting $\bar{w}_h = \bar{v}_h$ in (4.3), and the Aubin–Nitsche trick and inverse inequalities are used to establish the second statement. The Sobolev embedding theorem guarantees

$$\|\bar{v}_h\|_{L^6(\Omega)} \le C\|\bar{v}_h\|_{H^1(\Omega)} \le C\|v_h\|_{H^1(\Omega)}.$$

It follows that the Stokes projection $v_h \to \bar{v}_h$ satisfies Assumption 4.1.

Acknowledgment. The authors thank Professor Francisco Guillen-Gonzalez of Universidad de Sevilla, who found a gap in one of the proofs of the original version of this manuscript.

UNIFORM ESTIMATES FOR EULERIAN–LAGRANGIAN METHODS FOR SINGULARLY PERTURBED TIME-DEPENDENT PROBLEMS*

HONG WANG† AND KAIXIN WANG‡

Abstract. We prove a priori optimal-order error estimates in a weighted energy norm for several Eulerian–Lagrangian methods for singularly perturbed, time-dependent convection-diffusion equations with full regularity. The estimates depend only on certain Sobolev norms of the initial and right-hand side data, but not on ε or any norm of the true solution, and so hold uniformly with respect to ε. We use the interpolation of spaces and stability estimates to derive an ε-uniform estimate for problems with minimal or intermediate regularity, where the convergence rates are proportional to certain Besov norms of the initial and right-hand side data.

Key words. characteristic methods, convergence analysis, error estimates, Eulerian–Lagrangian methods, interpolation of spaces, uniform error estimates

1. Introduction.

Time-dependent convection-diffusion equations arise in mathematical models of petroleum reservoir simulation, environmental modeling, and other applications [10, 12]. These problems admit solutions with moving fronts and complex structures and present serious mathematical and numerical difficulties. Classical finite difference or finite element methods tend to generate numerical solutions with nonphysical oscillations, while upwind methods often produce excessive numerical diffusion that smears out fronts and generates spurious grid orientation effects [10].

Eulerian–Lagrangian methods combine the convection and capacity terms in the governing equations to carry out the temporal discretization in a Lagrangian coordinate and discretize the diffusion term on a fixed mesh [6, 8, 16, 17, 19]. These methods symmetrize the governing equation and stabilize their numerical approximations. They generate accurate numerical solutions and significantly reduce the numerical diffusion and grid-orientation effect present in upwind methods, even if large time steps and coarse spatial meshes are used. Eulerian–Lagrangian methods were shown to be very competitive in terms of accuracy and efficiency [6, 17, 19].

Optimal-order error estimates were derived for various Eulerian–Lagrangian methods [1, 7, 8, 15, 18]. This type of estimates has drawn debates for two potential problems: The general constant may depend inversely on the parameter ε. Further, the smoothness norms of the true solutions on the right side depend inversely on the parameter ε. Consequently, these estimates could blow up as ε tends to zero.

The goal of the present paper is to derive a priori optimal-order error estimates in an ε-weighted energy norm for Eulerian–Lagrangian methods for singularly perturbed, time-dependent convection-diffusion equations with full regularity. The estimates depend only on certain Sobolev norms of the initial and right-hand side data but not

on ε or any norm of the true solution. The general constant in the estimate does not depend on ε either. Thus, these estimates avoid the problems in the standard estimates. We then use the interpolation of spaces and stability estimates to derive an ε-uniform estimate for problems with minimal or intermediate regularity, where the convergence rates are proportional to certain Besov norms of the initial and right-hand side data.

This paper is organized as follows. In section 2 we recall preliminary results on Sobolev and Besov spaces and interpolation of spaces. In section 3 we revisit the Eulerian-Lagrangian localized adjoint method (ELLAM), the modified method of characteristics (MMOC), and the modified method of characteristics with adjusted advection (MMOCAA). In section 4 we prove an ε-uniform optimal-order error estimate for problems with full regularity. In section 5 we derive ε-uniform error estimates for problems with minimal or intermediate regularity. In section 6 we prove auxiliary lemmas. In section 7 we prove uniform stability of the true solutions in various smoothness norms. Section 8 contains concluding remarks.

2. Model problem and preliminaries. We consider a singularly perturbed, time-dependent convection-diffusion equation in one space dimension

$$\begin{aligned} u_t + (V(x,t)u - \varepsilon D(x,t)u_x)_x &= f(x,t), \quad (x,t) \in (a,b) \times (0,T), \\ u(x,0) &= u_o(x), \qquad x \in [a,b]. \end{aligned} \tag{2.1}$$

Here $V(x,t)$ is a velocity field, $f(x,t)$ accounts for external sources and sinks, $u_o(x)$ is prescribed initial data, and $u(x,t)$ is the ε-dependent unknown function. $D(x,t)$ is a diffusion coefficient with

$$0 < D_{min} \le D(x,t) \le D_{max} < +\infty \qquad \forall (x,t) \in [a,b] \times [0,T].$$

Here $0 < \varepsilon << 1$ is a parameter that scales the diffusion and characterizes the convection dominance of (2.1).

Such Eulerian–Lagrangian methods as the MMOC [8] and the MMOCAA [6, 7] were developed and analyzed for problem (2.1) with periodic boundary conditions. Other methods, such as the ELLAM [3, 18], could handle more general boundary conditions. We analyze these methods in a unified framework and close problem (2.1) with periodic boundary conditions at $x = a$ and $x = b$. This would require that all data functions in the problem are periodic. The assumption of periodicity of the problem may in principle exclude the appearance of boundary layers.

2.1. Sobolev spaces and approximation properties. Let $W_p^k(a,b)$ consist of functions whose weak derivatives up to order-k are pth Lebesgue integrable in (a,b). Let $H^k(a,b) := W_2^k(a,b)$ and $H_E^1(a,b)$ be a subspace of $H^1(a,b)$ with period $b-a$. We introduce an ε-weighted Sobolev norm for any $v \in H^k(a,b)$

$$\|v\|_{H_\varepsilon^k(a,b)} := \left(\|v\|^2_{H^{k-1}(a,b)} + \varepsilon \left\| \frac{d^k v}{dx^k} \right\|^2_{L^2(a,b)} \right)^{1/2}. \tag{2.2}$$

For any Banach space X, we introduce Sobolev spaces involving time [9]

$$W_p^k(t_1,t_2;X) := \left\{ f : \left\| \frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t) \right\|_X \in L^p(t_1,t_2),\ 0 \le \alpha \le k,\ 1 \le p \le \infty \right\},$$

$$\|f\|_{W_p^k(t_1,t_2;X)} := \begin{cases} \left(\displaystyle\sum_{\alpha=0}^{k} \int_{t_1}^{t_2} \left\| \frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t) \right\|_X^p dt \right)^{1/p}, & 1 \le p < \infty, \\ \displaystyle\max_{0 \le \alpha \le k} \operatorname*{ess\,sup}_{(t_1,t_2)} \left\| \frac{\partial^\alpha f}{\partial t^\alpha}(\cdot,t) \right\|_X, & p = \infty. \end{cases}$$

We define a uniform space-time partition on $[a,b]\times[0,T]$: $x_i := a+ih$ for $0\le i\le I$, with $h := (b-a)/I$, and $t_n := n\Delta t$ for $0\le n\le N$, with $\Delta t := T/N$. If a function $f(x,t)$ is defined only at discrete time steps t_n, we understand that the function f has been extended by constant to the time interval $(t_{n-1},t_n]$. Thus, the preceding space-time norm reduces to the following equivalent discrete norm:

$$\|f\|_{L^p(0,T;X)} := \begin{cases} \Big(\sum_{n=1}^{N} \|f(\cdot,t_n)\|_X^p \Delta t\Big)^{1/p}, & 1\le p<\infty,\\ \max\limits_{0\le n\le N} \|f(\cdot,t_n)\|_X, & p=\infty. \end{cases}$$

We also introduce the following ε-weighted energy norms:

$$\|f\|_{L_\varepsilon(0,T;H^k(a,b))} := \|f\|_{L^\infty(0,T;H^{k-1}(a,b))} + \sqrt{\varepsilon}\|f\|_{L^2(0,T;H^k(a,b))},$$
$$\|f\|_{L_\varepsilon(0,T;H^1_D(a,b))} := \|f\|_{L^\infty(0,T;L^2(a,b))} + \sqrt{\varepsilon}\|D^{1/2}f_x\|_{L^2(0,T;L^2(a,b))}.$$

Let $S_h(a,b)\subset H^1_E(a,b)$ be the finite element space that consists of continuous and piecewise-linear functions with respect to the spatial partition in $[a,b]$. We let $\Pi_h v\in S_h(a,b)$ be the piecewise-linear interpolation of v for any $v\in H^1_E(a,b)$. The following estimates hold [4, 5]:

$$\begin{aligned} \|\Pi_h v - v\|_{H^k(a,b)} &\le C_1 h^{2-k}\ \|v\|_{H^2(a,b)} && \forall v\in H^2(a,b),\ k=0,1,\\ \|v_h\|_{H^1(a,b)} &\le C_2 h^{-1}\|v_h\|_{L^2(a,b)} && \forall v_h\in S_h(a,b),\\ \|v_h\|_{L^\infty(a,b)} &\le C_2 h^{-1/2}\|v_h\|_{L^2(a,b)} && \forall v_h\in S_h(a,b). \end{aligned} \tag{2.3}$$

2.2. Besov spaces and interpolation of operators. The Besov spaces provide a finer scale and characterization of smoothness of functions than the Sobolev spaces do. We cite the results used in this paper and refer readers to [2, 5] for details.

For $\alpha>0$, $k := \lfloor\alpha\rfloor+1$, and $0<q\le\infty$, the Besov space $B^\alpha_q(L^p(a,b))$ consists of functions $f\in L^p(a,b)$ (for $p<\infty$) or $f\in C[a,b]$, the space of continuous functions on $[a,b]$, (for $p=\infty$) such that

$$\|f\|_{B^\alpha_q(L^p(a,b))} := \begin{cases} \|f\|_{L^p(a,b)} + \Big[\int_0^\infty [\theta^{-\alpha}\omega_k(f,\theta)_p]^q \dfrac{d\theta}{\theta}\Big]^{1/q}, & 0<q<\infty,\\ \|f\|_{L^p(a,b)} + \sup\limits_{\theta>0}\ \theta^{-\alpha}\omega_k(f,\theta)_p, & q=\infty, \end{cases}$$

is finite. Here the kth modulus of smoothness of function f is defined as

$$\omega_k(f,\theta)_p := \sup_{|h|\le\theta} \|\Delta_h^k f\|_{L^p(a+k|h|,b-k|h|)} \quad \text{with } \Delta_h f(x) := f(x+h)-f(x).$$

It is known that $B^\alpha_{q_1}(L^p(a,b))\hookrightarrow B^\alpha_{q_2}(L^p(a,b))$ for $q_1<q_2$ and that $B^\alpha_2(L^2(a,b)) = H^\alpha(a,b)$ with equivalent norms.

Let $X_1\hookrightarrow X_0$ be Banach spaces. We define the K-functional for $f\in X_0$ by

$$K(f,s) := K(f,s;X_0,X_1) := \inf_{g\in X_1}\{\|f-g\|_{X_0} + s\|g\|_{X_1}\},\quad s\ge 0.$$

The interpolation space $[X_0,X_1]_{s,q}$ consists of all functions $f\in X_0$ such that

$$\|f\|_{s,q} := \begin{cases} \Big[\int_0^\infty [\theta^{-s}K(f,\theta)]^q \dfrac{d\theta}{\theta}\Big]^{1/q}, & 0<q<\infty,\\ \sup\limits_{\theta>0}\ \theta^{-s}K(f,\theta), & q=\infty. \end{cases}$$

It is known that $X_1 \hookrightarrow [X_0, X_1]_{s,q} \hookrightarrow X_0$. The following lemmas characterize interpolation spaces.

LEMMA 2.1 (interpolation of Sobolev spaces). *Let m be a positive integer and $1 \le p \le \infty$. For any $0 < s < 1$ and $0 < q \le \infty$, the following relations hold:*

$$[L^2(a,b), H^m(a,b)]_{s,q} = B_q^{sm}(L^2(a,b)).$$

LEMMA 2.2 (interpolation of operators). *Let $X_1 \hookrightarrow X_0$ and Y be Banach spaces. If T is a bounded linear operator from X_i to Y with norm $M_i\,(i = 0, 1)$, then T is a bounded linear operator from the interpolation space $[X_0, X_1]_{s,q}$ to Y with a norm not exceeding $M_0^{1-s} M_1^s$ for any $0 < s < 1$ and $0 < q \le \infty$.*

LEMMA 2.3 (reiteration theorem). *Let $Y_i = [X_0, X_1]_{s_i,q_i}\,(i = 0, 1)$, with $0 < s_0 < s_1 < 1,\ 0 < q_0, q_1 \le \infty$. For any $0 < \beta < 1,\ 0 < r \le \infty$, we have*

$$[Y_0, Y_1]_{\beta,r} = [X_0, X_1]_{\beta',r}, \quad \beta' := (1-\beta)s_0 + \beta s_1,$$

with equivalent norms.

3. Revisit of Eulerian–Lagrangian methods. The ELLAM, MMOC, and MMOCAA schemes use a time-marching approach, so we need only to define these methods at the current time interval $[t_{n-1}, t_n]$.

3.1. The ELLAM. In the ELLAM formulation, the space-time test functions $w(x,t)$ are chosen to be continuous and piecewise smooth and to vanish outside the space-time strip $[a,b] \times (t_{n-1}, t_n]$. In particular, the test functions $w(x,t)$ satisfy $w(x,t_n) = \lim_{t \to t_n - 0} w(x,t)$, but $w(x,t_{n-1}) \ne \lim_{t \to t_{n-1}+0} w(x,t)$ in general. In this case, we use the notation $w(x, t_{n-1}^+) = \lim_{t \to t_{n-1}+0} w(x,t)$ to account for the possible discontinuity of $w(x,t)$ in time at time t_{n-1}.

We multiply (2.1) by test functions w and integrate the resulting equation on $[a,b] \times (t_{n-1}, t_n]$ to obtain a weak formulation

$$\begin{aligned} &\int_a^b u(x,t_n) w(x,t_n)\,dx + \int_{t_{n-1}}^{t_n} \int_a^b \varepsilon D(x,t) u_x(x,t) w_x(x,t)\,dx\,dt \\ &\quad - \int_{t_{n-1}}^{t_n} \int_a^b u(x,t)\Big(w_t(x,t) + V(x,t) w_x(x,t)\Big)\,dx\,dt \\ &\quad = \int_a^b u(x,t_{n-1}) w(x,t_{n-1}^+)\,dx + \int_{t_{n-1}}^{t_n} \int_a^b f(x,t) w(x,t)\,dx\,dt. \end{aligned} \tag{3.1}$$

In the ELLAM framework [3] the test functions w are chosen to satisfy the adjoint equation of the hyperbolic part of (2.1) to define the temporal variation of w

$$w_t + V w_x = 0. \tag{3.2}$$

This implies the test functions w to be constant along the characteristic curve $r(t; x, t_n)$. Here $r(t; \bar{x}, \bar{t})$ refers to the characteristic curve passing $\bar{x}$ at time $\bar{t}$ defined by

$$\frac{dr}{dt} = V(r,t), \quad r(t; \bar{x}, \bar{t})\Big|_{t=\bar{t}} = \bar{x}. \tag{3.3}$$

Thus, once the test functions $w(x,t)$ are specified in $[a,b]$ at time step t_n, they are determined completely in the space-time strip $[a,b] \times (t_{n-1}, t_n]$.

3.1.1. Evaluation of diffusion and source terms. Note that $V(x,t)$ is a periodic function with respect to x of the period $b-a$. Thus, the shifted characteristic curve $r^S(t;b,t_n) := r(t;b,t_n) - (b-a)$ satisfies the initial-value problem

$$\begin{aligned} \frac{dr^S(t;b,t_n)}{dt} &= \frac{dr(t;b,t_n)}{dt} = V(r(t;b,t_n),t) = V(r^S(t;b,t_n),t), \\ r^S(t;b,t_n)\Big|_{t=t_n} &= b-(b-a) = a. \end{aligned}$$

Therefore, both $r^S(t;b,t_n)$ and $r(t;a,t_n)$ are the solutions of the same initial-value problem. The uniqueness of such a problem concludes that

$$r(t;b,t_n) - r(t;a,t_n) = b-a \qquad \forall t \in [t_{n-1},t_n]. \tag{3.4}$$

For clarity of presentation, in the evaluation of source and diffusion terms we reserve x for points in $[a,b]$ at time t_n representing the heads of characteristics. We use the variable y to represent the spatial coordinate of an arbitrary point at time $t \in (t_{n-1},t_n)$. We use the relation (3.4) and the periodicity of problem (2.1) to evaluate the source term by the Euler quadrature as follows:

$$\begin{aligned} &\int_{t_{n-1}}^{t_n}\int_a^b f(y,t)w(y,t)dydt \\ &\quad= \int_{t_{n-1}}^{t_n}\int_{r(t;a,t_n)}^{r(t;b,t_n)} f(y,t)w(y,t)dydt \\ &\quad= \int_a^b\int_{t_{n-1}}^{t_n} f(r(t;x,t_n),t)w(r(t;x,t_n),t)r_x(t;x,t_n)dtdx \\ &\quad= \int_a^b\Big[\int_{t_{n-1}}^{t_n} f(r(t;x,t_n),t)r_x(t;x,t_n)dt\Big]w(x,t_n)dx \\ &\quad= \Delta t\int_a^b f(x,t_n)w(x,t_n)dx + E_1(w). \end{aligned} \tag{3.5}$$

Here $E_1(w)$ is the local truncation error defined by

$$E_1(w) := \int_a^b\int_{t_{n-1}}^{t_n}\Big[f(r(t;x,t_n),t)r_x(t;x,t_n) - f(x,t_n)\Big]dt\ w(x,t_n)dx. \tag{3.6}$$

We evaluate the diffusion term similarly

$$\begin{aligned} &\int_{t_{n-1}}^{t_n}\int_a^b \varepsilon D(y,t)u_y(y,t)w_y(y,t)dydt \\ &\quad= \int_{t_{n-1}}^{t_n}\int_{r(t;a,t_n)}^{r(t;b,t_n)} \varepsilon D(y,t)u_y(y,t)w_y(y,t)dydt \\ &\quad= \int_a^b\int_{t_{n-1}}^{t_n} \varepsilon D(r(t;x,t_n),t)u_y(r(t;x,t_n),t)w_y(x,t_n)r_x(t;x,t_n)dtdx \\ &\quad= \int_a^b\int_{t_{n-1}}^{t_n} \varepsilon D(r(t;x,t_n),t)u_y(r(t;x,t_n),t)w_x(x,t_n)dtdx \\ &\quad= \varepsilon\Delta t\int_a^b D(x,t_n)u_x(x,t_n)w_x(x,t_n)dx + \varepsilon E_2(u,w). \end{aligned} \tag{3.7}$$

Here $E_2(u,w)$ is the local truncation error defined by

$$E_2(u,w) := \int_a^b\int_{t_{n-1}}^{t_n}\Big[(Du_x)(r(t;x,t_n),t) - (Du_x)(x,t_n)\Big]dt\ w_x(x,t_n)dx. \tag{3.8}$$

3.1.2. ELLAM formulation and numerical scheme. We substitute (3.5) and (3.7) into (3.1) to obtain an ELLAM formulation for problem (2.1):

$$\begin{aligned}\int_a^b u(x,t_n)w(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)u_x(x,t_n)w_x(x,t_n)dx \\ = \int_a^b u(x^*,t_{n-1})w(x,t_n)r_x(t_{n-1};x,t_n)dx \\ +\Delta t\int_a^b f(x,t_n)w(x,t_n)dx + E_1(w) - \varepsilon E_2(u,w).\end{aligned} \tag{3.9}$$

Here x^* is the foot of the characteristic curve $r(t;x,t_n)$ backtracking from x at time t_n. We also let $\tilde{x}$ be the head of the characteristic curve $r(t;\tilde{x},t_n)$ at time t_n that backtracks to x at time t_{n-1}:

$$x^* = r(t_{n-1};x,t_n), \qquad x = r(t_{n-1};\tilde{x},t_n). \tag{3.10}$$

In (3.9) we have used the periodicity of the problem, a relation similar to (3.4), and the fact that w is constant along the characteristics to rewrite the first integral at time t_{n-1} on the right-hand side of (3.1) as an integral at time t_n in (3.9):

$$\begin{aligned}\int_a^b u(y,t_{n-1})w(y,t_{n-1}^+)dy &= \int_{\tilde{a}}^{\tilde{b}} u(x^*,t_{n-1})w(x,t_n)r_x(t_{n-1};x,t_n)dx \\ &= \int_a^b u(x^*,t_{n-1})w(x,t_n)r_x(t_{n-1};x,t_n)dx.\end{aligned} \tag{3.11}$$

The ELLAM scheme is derived based on (3.9). Note that the characteristics $r(t;x,t_n)$ cannot be tracked exactly, in general, so the test functions w_h in the ELLAM scheme are defined to be constant along the approximate characteristics $r_h(t;x,t_n)$. Here $r_h(t;\bar{x},\bar{t})$ is defined by

$$r_h(t;\bar{x},\bar{t}) = \bar{x} + V(\bar{x},\bar{t})(t-\bar{t}). \tag{3.12}$$

Consequently, the ELLAM scheme states as follows: Find $u_h(x,t_n) \in S_h(a,b)$ for $n = 1,\dots,N$ such that for any $w_h(x,t_n) \in S_h(a,b)$

$$\begin{aligned}\int_a^b u_h(x,t_n)w_h(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)u_{h,x}(x,t_n)w_{h,x}(x,t_n)dx \\ = \int_a^b u_h(x_h^*,t_{n-1})w_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx + \Delta t\int_a^b f(x,t_n)w_h(x,t_n)dx.\end{aligned} \tag{3.13}$$

Here x_h^* and $\tilde{x}_h$ are defined by

$$x_h^* = r_h(t_{n-1};x,t_n), \qquad x = r_h(t_{n-1};\tilde{x}_h,t_n). \tag{3.14}$$

The ELLAM, MMOC, MMOCAA, and virtually any other Eulerian–Lagrangian method typically need to impose the following type of constraint on the time step Δt:

$$\|V\|_{L^\infty(0,T;W^1_\infty)}\Delta t < 1. \tag{3.15}$$

This constraint guarantees that the approximate characteristics defined in (3.12), which are extended from different spatial points, do not intersect with each other during the time period $[t_{n-1},t_n]$. In other words, the traceback operator defined by the approximate characteristic tracking is a diffeomorphism. This condition will be used several times in the error estimates in the subsequent sections without being explicitly stated. This constraint can be alleviated if a micro time step Δt_f is used in the characteristic tracking. In this case, the Δt in (3.15) will be replaced by Δt_f.

3.2. The MMOC and MMOCAA. The MMOC and MMOCAA directly apply to a nonconservative analogue of (2.1):

$$u_t + V(x,t)u_x - (\varepsilon D(x,t)u_x)_x + V_x(x,t)u = f(x,t). \tag{3.16}$$

3.2.1. The MMOC. In the MMOC the capacity and convection terms in (3.16) are combined to form a material derivative at time step t_n, which is approximated by a backward difference quotient along the approximate characteristic $r_h(t;x,t_n)$ in the time stepping procedure [8]

$$\begin{aligned} &u_t(x,t_n) + V(x,t_n)u_x(x,t_n) \\ &\quad = \sqrt{1+V(x,t_n)^2}\frac{du}{dt}(x,t_n) = \frac{u(x,t_n) - u(x^*,t_{n-1})}{\Delta t} \\ &\qquad + \frac{1}{\Delta t}\int_{t_{n-1}}^{t_n} \sqrt{(r_h(t;x,t_n) - x_h^*)^2 + (t-t_{n-1})^2}\frac{d^2u}{dt^2}(r_h(t;x,t_n),t)dt. \end{aligned} \tag{3.17}$$

We incorporate (3.17) into (3.16) and multiply the equation by any test function $w \in H_E^1(a,b)$. We integrate the resulting equation on the interval (a,b), leading to an MMOC reference equation for problem (3.16): Find $u(x,t_n) \in H_E^1(a,b)$ for $n = 1,\dots,N$ such that for any $w(x) \in H_E^1(a,b)$

$$\begin{aligned} &\int_a^b \frac{u(x,t_n) - u(x_h^*,t_{n-1})}{\Delta t}w(x)dx + \int_a^b \varepsilon D(x,t_n)u_x(x,t_n)w_x(x)dx \\ &\quad + \int_a^b V_x(x,t_n)u(x,t_n)w(x)dx = \int_a^b f(x,t_n)w(x)dx - \frac{1}{\Delta t}E_3(u,w). \end{aligned} \tag{3.18}$$

Here $E_3(u,w)$ is the local truncation error of the MMOC reference equation

$$E_3(u,w) = \int_a^b w(x)\int_{t_{n-1}}^{t_n} \sqrt{(r_h(t;x,t_n) - x_h^*)^2 + (t-t_{n-1})^2}\frac{d^2u}{dt^2}(r_h(t;x,t_n),t)dtdx.$$

The MMOC scheme reads: Find $u_h(x,t_n) \in S_h(a,b)$ for $n = 1,\dots,N$ such that for any $w_h(x) \in S_h(a,b)$

$$\begin{aligned} &\int_a^b \frac{u_h(x,t_n) - u_h(x_h^*,t_{n-1})}{\Delta t}w_h(x)dx + \int_a^b \varepsilon D(x,t_n)u_{h,x}(x,t_n)w_{h,x}(x)dx \\ &\quad + \int_a^b V_x(x,t_n)u_h(x,t_n)w_h(x)dx = \int_a^b f(x,t_n)w_h(x)dx. \end{aligned} \tag{3.19}$$

3.2.2. The MMOCAA. The MMOCAA [6, 7] aims at eliminating the mass balance error in the MMOC [8]. Summing the MMOC scheme (3.19) for all of the test functions yields a mass balance satisfied by the MMOC solution $u_h(x,t_n)$:

$$\int_a^b (1 + \Delta t V_x(x,t_n))u_h(x,t_n)dx = \int_a^b u_h(x_h^*,t_{n-1})dx + \Delta t\int_a^b f(x,t_n)dx. \tag{3.20}$$

If we integrate (3.16) with $u(x,t_{n-1}) = u_h(x,t_{n-1})$ on $(a,b)\times[t_{n-1},t_n]$ and apply Euler quadrature at time t_n to the source term, we obtain a mass balance equation satisfied by the exact solution (up to the order of truncation error)

$$\int_a^b u(x,t_n)dx = \int_a^b u_h(x,t_{n-1})dx + \Delta t\int_a^b f(x,t_n)dx.$$

Let $Q_{n-1} = \int_a^b u_h(x,t_{n-1})dx$ and $Q^*_{n-1} = \int_a^b u_h(x^*_h,t_{n-1})dx - \Delta t \int_a^b V_x(x,t_n)$ $u_h(x,t_n)dx$. The MMOC scheme conserves mass if and only if $Q_{n-1} = Q^*_{n-1}$. To correct the mass balance error of the MMOC when $Q_{n-1} \neq Q^*_{n-1}$, we set for some fixed constant $\kappa > 0$

$$
\begin{aligned}
x^*_{h,+} &= x^*_h + \kappa V(x,t_n)(\Delta t)^2, \qquad x^*_{h,-} = x^*_h - \kappa V(x,t_n)(\Delta t)^2,\\
u^{\#}_h(x^*_h,t_{n-1}) &= \begin{cases} \max\{u_h(x^*_{h,+},t_{n-1}), u_h(x^*_{h,-},t_{n-1})\} \text{ if } Q^*_{n-1} \le Q_{n-1},\\ \min\{u_h(x^*_{h,+},t_{n-1}), u_h(x^*_{h,-},t_{n-1})\} \text{ if } Q^*_{n-1} > Q_{n-1}, \end{cases}\\
Q^{\#}_{n-1} &= \int_a^b u^{\#}_h(x^*_h,t_{n-1})dx.
\end{aligned} \tag{3.21}
$$

If Q_{n-1} can be expressed as a convex combination of Q^*_{n-1} and $Q^{\#}_{n-1}$, then $\check{u}_h(x^*_h,t_{n-1})$ defined by the same convex combination of $u_h(x^*_h,t_{n-1})$ and $u^{\#}_h(x^*_h,t_{n-1})$ will have mass Q_{n-1}. The $u_h(x^*_h,t_{n-1})$ in the MMOC scheme (3.19) is replaced by $\check{u}_h(x^*_h,t_{n-1})$ in the MMOCAA scheme with all other terms unchanged.

4. Error estimates for problem (2.1) with full regularity. We prove a priori optimal-order error estimates for the ELLAM, MMOC, and MMOCAA schemes for problem (2.1), which hold uniformly with respect to ε.

4.1. An optimal-order error estimate for the ELLAM scheme. Let the Courant number $\mathrm{Cr} := \max_{(x,t)\in[0,1]\times[0,T]} |V(x,t)|\Delta t/h$ and $\lambda = 1$ if $\mathrm{Cr} < 1$ or $= 0$ otherwise. The main result is given in the theorem below.

THEOREM 4.1. *Assume $D, V \in L^\infty(0,T;W^{3+\lambda}_\infty(a,b))$, $f \in L^2(0,T;H^{2+\lambda}(a,b))$, and $u_o \in H^{2+\lambda}(a,b)$. Then the following optimal-order error estimate of the ELLAM scheme holds uniformly with respect to ε:*

$$
\begin{aligned}
&\|u_h - u\|_{L_\varepsilon(0,T;H^1_D)}\\
&\quad \le C\Delta t\Big(\|u_o\|_{H^2_\varepsilon} + \Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} + \|f\|_{L^2(0,T;H^1)}\Big)\\
&\qquad + C(\min\{h,\Delta t\} + h^2)\|u_o\|_{H^2} + C\lambda h^2(\|u_o\|_{H^3} + \|f\|_{L^2(0,T;H^3)}).
\end{aligned} \tag{4.1}
$$

Here the constant C is independent of u and the parameter ε.

Proof. We let $e = u_h - u$ and choose the test function $w(\cdot,t_n)$ in (3.9) to be $w_h(\cdot,t_n) \in S_h(a,b)$. We then subtract (3.13) from the ELLAM reference equation (3.9) to obtain an ELLAM error equation for any $w_h(x,t_n) \in S_h(a,b)$:

$$
\begin{aligned}
&\int_a^b e(x,t_n)w_h(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)e_x(x,t_n)w_{h,x}(x,t_n)dx\\
&= \int_a^b (u(x^*_h,t_{n-1})r_{h,x}(t_{n-1};x,t_n) - u(x^*,t_{n-1})r_x(t_{n-1};x,t_n))w_h(x,t_n)dx\\
&\quad + \int_a^b e(x^*_h,t_{n-1})w_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx - E_1(w_h) + \varepsilon E_2(u,w_h).
\end{aligned} \tag{4.2}
$$

Let $\Pi_h u \in S_h(a,b)$ be the interpolation of the true solution u, $\xi_h = u_h - \Pi_h u \in S_h(a,b)$, and $\eta = \Pi_h u - u$. The error estimates for η are given in (2.3), so we need

only to estimate ξ_h. We choose $w_h(x,t_n)=\xi_h(x,t_n)$ in (4.2) and rewrite the error equation in terms of ξ_h and η as follows:

$$
\begin{aligned}
&\int_a^b \xi_h^2(x,t_n)dx+\varepsilon\Delta t\int_a^b D(x,t_n)\xi_{h,x}^2(x,t_n)dx\\
&\quad=\int_a^b \xi_h(x_h^*,t_{n-1})\xi_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx\\
&\qquad+\int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx-\int_a^b \eta(x,t_n)\xi_h(x,t_n)dx\\
&\qquad-\varepsilon\Delta t\int_a^b D(x,t_n)\eta_x(x,t_n)\xi_{h,x}(x,t_n)dx-E_1(\xi_h)+\varepsilon E_2(u,\xi_h)\\
&\qquad+\int_a^b u(x^*,t_{n-1})(r_{h,x}(t_{n-1};x,t_n)-r_x(t_{n-1};x,t_n))\xi_h(x,t_n)dx\\
&\qquad+\int_a^b (u(x_h^*,t_{n-1})-u(x^*,t_{n-1}))r_{h,x}(t_{n-1};x,t_n)\xi_h(x,t_n)dx.
\end{aligned}
\tag{4.3}
$$

We bound the first term on the right-hand side of (4.3) by

$$
\begin{aligned}
&\Big|\int_a^b \xi_h(x_h^*,t_{n-1})\xi_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx\Big|\\
&\quad\le\frac{1+C\Delta t}{2}\int_a^b \xi^2(x,t_n)dx+\frac{1+C\Delta t}{2}\int_a^b \xi^2(x_h^*,t_{n-1})dx\\
&\quad\le\frac{1+C\Delta t}{2}\int_a^b \xi^2(x,t_n)dx+\frac{1+C\Delta t}{2}\int_{a_h^*}^{b_h^*} \xi^2(x_h^*,t_{n-1})\Big|\frac{dx_h^*}{dx}\Big|^{-1}dx_h^*\\
&\quad\le\frac{1+C\Delta t}{2}\|\xi_h(\cdot,t_n)\|_{L^2}^2+\frac{1+C\Delta t}{2}\|\xi_h(\cdot,t_{n-1})\|_{L^2}^2.
\end{aligned}
\tag{4.4}
$$

Here the constant C depends on $\|V\|_{L^\infty(0,T;W^1_\infty)}$. In the second term after the second inequality, we used the substitution of variables from x to x_h^* given by the first equation in (3.14) and changed the limits a and b of the integral to a_h^* and b_h^*, respectively. We also utilized (3.12) and the periodicity of V to conclude that

$$
\begin{aligned}
r_{h,x}(t_{n-1};x,t_n)&=1-V_x(x,t_n)\Delta t,\\
r_{h,x}^{-1}(t_{n-1};x,t_n)&=(1-V_x(x,t_n)\Delta t)^{-1}=1+O(\Delta t),\\
b_h^*-a_h^*&=(b-a)-(V(b,t_n)-V(a,t_n))\Delta t=b-a.
\end{aligned}
\tag{4.5}
$$

The estimate of the second and third terms on the right-hand side of (4.3) presents one of the major difficulties. Standard techniques yield

$$
\begin{aligned}
&\Big|\int_a^b (\eta(x,t_{n-1})-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx\Big|\\
&\quad=\Big|\int_a^b\int_{x_h^*}^x \eta_y(y,t_{n-1})dy\ \xi_h(x,t_n)dx\Big|\\
&\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2+C\Delta t\ h^2\|u\|^2_{L^\infty(0,T;W^2_\infty)},
\end{aligned}
$$

leading to a suboptimal-order error estimate of order $O(h+\Delta t)$ for the ELLAM scheme. This does not coincide with the optimal-order convergence rates observed numerically. A delicate analysis shows an optimal-order error estimate of the second and third terms on the right-hand side of (4.3). For clarity of exposition, the proof is

presented in Lemma 6.2; there we obtain

$$
\begin{aligned}
&\Big|\int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx - \int_a^b \eta(x,t_n)\xi_h(x,t_n)dx\Big| \\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C\Delta t(\min\{h^2,(\Delta t)^2\}+h^4)\|u\|_{L^\infty(0,T;H^2)}^2 \\
&\quad + C(\Delta t)^3\|u\|_{L^\infty(0,T;H^1)}^2 + C\lambda\, h^4(\|u\|_{H^1(t_{n-1},t_n;H^2)}^2 + \Delta t\|u\|_{L^\infty(0,T;H^3)}^2).
\end{aligned} \tag{4.6}
$$

Let $x_{i-1/2}$ be the middle point of the interval $[x_{i-1},x_i]$. Note that $\xi_{h,x}(x,t_n)$ is constant on each interval $[x_{i-1},x_i]$ and that η satisfies $\eta(x_{i-1},t_n)=\eta(x_i,t_n)=0$ for $i=1,\dots,I$. We bound the fourth term on the right-hand side of (4.3):

$$
\begin{aligned}
&\Big|\varepsilon\Delta t\int_a^b D(x,t_n)\eta_x(x,t_n)\xi_{h,x}(x,t_n)dx\Big| \\
&= \Big|\varepsilon\Delta t\sum_{i=1}^I \xi_{h,x}(x_{i-1/2},t_n)\int_{x_{i-1}}^{x_i}(D(x,t_n)-D(x_{i-1/2},t_n))\eta_x(x,t_n)dx\Big| \\
&\le \varepsilon\Delta t\ h\ \|D\|_{L^\infty(0,T;W^1_\infty)}\ \|\xi_{h,x}(\cdot,t_n)\|_{L^2}\ \|\eta_x(\cdot,t_n)\|_{L^2} \\
&\le \frac{1}{4}\varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|_{L_D^2}^2 + C\varepsilon\Delta t\, h^4\|u\|_{L^\infty(0,T;H^2)}^2.
\end{aligned} \tag{4.7}
$$

Here $\|\cdot\|_{L_D^2} = \|D^{1/2}\cdot\|_{L^2}$.

We use the estimate (6.1) to bound the fifth term on the right side of (4.3):

$$
\begin{aligned}
&\Big|\int_a^b\int_{t_{n-1}}^{t_n}\Big[f(r(t;x,t_n),t)r_x(t;x,t_n)-f(x,t_n)\Big]dt\,\xi_h(x,t_n)dx\Big| \\
&\le \int_a^b\int_{t_{n-1}}^{t_n}|f(x,t_n)-f(r(t;x,t_n),t)|dt\ |\xi_h(x,t_n)|dx \\
&\quad + \int_a^b\int_{t_{n-1}}^{t_n}|f(r(t;x,t_n),t)|\ |1-r_x(t;x,t_n)|dt\ |\xi_h(x,t_n)|dx \\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C(\Delta t)^2\Big(\Big\|\frac{df}{dt}\Big\|_{L^2(t_{n-1},t_n;L^2)}^2 + \|f\|_{L^2(t_{n-1},t_n;L^2)}^2\Big).
\end{aligned} \tag{4.8}
$$

We similarly bound the sixth term on the right-hand side of (4.3) by

$$
\begin{aligned}
&\Big|\varepsilon\int_a^b\int_{t_{n-1}}^{t_n}[(D\ u_x)(x,t_n)-(D\ u_x)(r(t;x,t_n),t)]dt\ \xi_{h,x}(x,t_n)dx\Big| \\
&= \Big|\varepsilon\int_a^b \xi_{h,x}(x,t_n)\Big[\int_{t_{n-1}}^{t_n}\int_t^{t_n}\frac{d}{d\theta}(D\ u_x)(r(\theta;x,t_n),\theta)d\theta dt\Big]dx\Big| \\
&\le \frac{1}{4}\varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|_{L_D^2}^2 + C\varepsilon(\Delta t)^2\Big(\Big\|\frac{du}{dt}\Big\|_{L^2(t_{n-1},t_n;H^1)}^2 + \|u\|_{L^2(t_{n-1},t_n;H^1)}^2\Big).
\end{aligned} \tag{4.9}
$$

We use the estimate (6.2) to bound the seventh term on the right side of (4.3) in a similar way to the estimate (4.4) to get

$$
\begin{aligned}
&\Big|\int_a^b u(x^*,t_{n-1})(r_{h,x}(t_{n-1};x,t_n)-r_x(t_{n-1};x,t_n))\xi_h(x,t_n)dx\Big| \\
&\le C(\Delta t)^2\|\xi_h(\cdot,t_n)\|_{L^2}\Big(\int_a^b u^2(x^*,t_{n-1})dx\Big)^{1/2} \\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C(\Delta t)^3\|u\|_{L^\infty(0,T;L^2)}^2.
\end{aligned} \tag{4.10}
$$

Let $\chi_{(\alpha,\beta)}$ be the indicator function of the interval (α,β), which is 1 on (α,β) or 0 elsewhere. We use the estimate (6.1) to bound the last term on the right-hand side

of (4.3):

$$
\begin{aligned}
&\Big|\int_a^b (u(x_h^*,t_{n-1})-u(x^*,t_{n-1}))r_{h,x}(t_{n-1};x,t_n)\xi_h(x,t_n)dx\Big|\\
&\quad\le C\int_a^b\Big|\int_{x^*}^{x_h^*}|u_y(y,t_{n-1})|dy\Big|\,|\xi_h(x,t_n)|dx\\
&\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\Big(\int_a^b\int_a^b \chi(y)_{(x^*-C(\Delta t)^2,x^*+C(\Delta t)^2)}u_y^2(y,t_{n-1})dydx\Big)^{1/2}\\
&\quad= C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\Big(\int_a^b\int_a^b \chi(x)_{(y-C(\Delta t)^2,y+C(\Delta t)^2)}dx\ u_y^2(y,t_{n-1})dy\Big)^{1/2}\\
&\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2+C(\Delta t)^3\|u\|^2_{L^\infty(0,T;H^1)}.
\end{aligned}
\tag{4.11}
$$

We substitute estimates (4.4)–(4.11) for the corresponding terms in (4.3) to obtain the following estimate:

$$
\begin{aligned}
&\|\xi_h(\cdot,t_n)\|_{L^2}^2+\varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|^2_{L^2_D}\\
&\quad\le\frac{1+C\Delta t}{2}\Big(\|\xi_h(\cdot,t_n)\|_{L^2}^2+\|\xi_h(\cdot,t_{n-1})\|_{L^2}^2\Big)+\frac{1}{2}\varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|^2_{L^2_D}\\
&\qquad+C(\Delta t)^2\Big(\varepsilon\Big\|\frac{du}{dt}\Big\|^2_{L^2(t_{n-1},t_n;H^1)}+\Delta t\|u\|^2_{L^\infty(0,T;H^1)}+\Big\|\frac{df}{dt}\Big\|^2_{L^2(t_{n-1},t_n;L^2)}\\
&\qquad\quad+\|f\|^2_{L^2(t_{n-1},t_n;L^2)}\Big)+C\Delta t\min\{h^2,(\Delta t)^2\}\|u\|^2_{L^\infty(0,T;H^2)}\\
&\qquad+Ch^4\Big(\Delta t\|u\|^2_{L^\infty(0,T;H^2)}+\lambda(\|u\|^2_{H^1(t_{n-1},t_n;H^2)}+\Delta t\|u\|^2_{L^\infty(0,T;H^3)})\Big).
\end{aligned}
$$

We sum the estimate for $n=1,\dots,N_1(\le N)$ and cancel like terms to obtain

$$
\begin{aligned}
&\|\xi_h(\cdot,t_{N_1})\|_{L^2}^2+\varepsilon\Delta t\sum_{n=1}^{N_1}\|\xi_{h,x}(\cdot,t_n)\|^2_{L^2_D}\\
&\quad\le C\Delta t\sum_{n=0}^{N_1-1}\|\xi_h(\cdot,t_n)\|_{L^2}^2+C(\Delta t)^2\Big(\varepsilon\Big\|\frac{du}{dt}\Big\|^2_{L^2(0,T;H^1)}+\|u\|^2_{L^\infty(0,T;H^1)}\\
&\qquad+\Big\|\frac{df}{dt}\Big\|^2_{L^2(0,T;L^2)}+\|f\|^2_{L^2(0,T;L^2)}\Big)+C(\min\{h^2,(\Delta t)^2\}+h^4)\|u\|^2_{L^\infty(0,T;H^2)}\\
&\qquad+C\lambda h^4(\|u\|^2_{H^1(0,T;H^2)}+\|u\|^2_{L^\infty(0,T;H^3)}).
\end{aligned}
$$

We then apply the Gronwall inequality to conclude

$$
\begin{aligned}
&\|\xi_h\|_{L_\varepsilon(0,T;H^1_D(a,b))}\\
&\quad\le C\Delta t\Big(\sqrt{\varepsilon}\Big\|\frac{du}{dt}\Big\|_{L^2(0,T;H^1)}+\|u\|_{L^\infty(0,T;H^1)}+\Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)}+\|f\|_{L^2(0,T;L^2)}\Big)\\
&\qquad+C(\min\{h,\Delta t\}+h^2)\|u\|_{L^\infty(0,T;H^2)}+C\lambda h^2(\|u\|_{H^1(0,T;H^2)}+\|u\|_{L^\infty(0,T;H^3)}).
\end{aligned}
$$

The general constant C depends exponentially on the final time T in problem (2.1), due to the application of the Gronwall inequality, but does not depend on the parameter ε. We combine this estimate with (2.3) and the stability estimate of the true solution in Theorem 7.2 to finish the proof. ∎

4.2. The optimal-order error estimate for the MMOC and MMOCAA schemes. We prove an optimal-order error estimate for the MMOC scheme (3.19) and outline a similar estimate for the MMOCAA scheme.

THEOREM 4.2. *Assume $D, V \in L^\infty(0,T;W^4_\infty(a,b))$, $f \in L^2(0,T;H^3(a,b))$, and $u_o \in H^3(a,b)$. Then the following optimal-order error estimate of the MMOC scheme holds uniformly with respect to ε:*

$$\begin{aligned}
&\|u_h - u\|_{L_\varepsilon(0,T;H^1_D)} \\
&\quad \le C\Delta t\Big(\|u_o\|_{H^2_\varepsilon} + \varepsilon\|u_o\|_{H^3_\varepsilon} + \Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} + \|f\|_{L^2(0,T;H^2)}\Big) \\
&\qquad + C(\min\{h,\Delta t\} + h^2)\|u_o\|_{H^2} + C\lambda h^2(\|u_o\|_{H^3} + \|f\|_{L^2(0,T;H^3)}).
\end{aligned} \tag{4.12}$$

Here the constant C is independent of u and the parameter ε.

Proof. We let $e(x,t_n)$, $\xi_h(x,t_n)$, and $\eta(x,t_n)$ be defined as in section 4.1 and choose $w_h(x) = \xi_h(x,t_n)$ in the MMOC reference equation (3.18) and the MMOC scheme (3.19). We subtract the latter from the former and rewrite the equation in terms of ξ and η as follows:

$$\begin{aligned}
&\int_a^b \xi_h^2(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)\xi_{h,x}^2(x,t_n)dx + \Delta t\int_a^b V_x(x,t_n)\xi_h^2(x,t_n)dx \\
&\quad = \int_a^b \xi_h(x_h^*,t_{n-1})\xi_h(x,t_n)dx + \int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)dx \\
&\qquad - \int_a^b \eta(x,t_n)\xi_h(x,t_n)dx - \varepsilon\Delta t\int_a^b D(x,t_n)\eta_x(x,t_n)\xi_{h,x}(x,t_n)dx \\
&\qquad - \Delta t\int_a^b V_x(x,t_n)\eta(x,t_n)\xi_h(x,t_n)dx + E_3(u,\xi_h).
\end{aligned} \tag{4.13}$$

The first through fourth terms on the right-hand side of (4.13) were already bounded in (4.4)–(4.7). We need only to bound the remaining two terms on the right-hand side. The fifth term on the right-hand side is bounded by

$$\begin{aligned}
\Big|\Delta t\int_a^b V_x(x,t_n)\eta(x,t_n)\xi_h(x,t_n)dx\Big| &\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\ \|\eta(\cdot,t_n)\|_{L^2} \\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C\Delta t\ h^4\|u\|^2_{L^\infty(0,T;H^2)}.
\end{aligned}$$

We use the expression of $E_3(u,\xi_h)$ (below (3.18)) to bound this term by

$$\begin{aligned}
E_3(u,\xi_h) &\le C(\Delta t)^{3/2}\|\xi_h(\cdot,t_n)\|_{L^2}\Big\|\frac{d^2u}{dt^2}\Big\|_{L^2(t_{n-1},t_n;L^2)} \\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C(\Delta t)^2\Big\|\frac{d^2u}{dt^2}\Big\|^2_{L^2(t_{n-1},t_n;L^2)}.
\end{aligned}$$

We combine these estimates and the estimates (4.4)–(4.7) to get

$$\begin{aligned}
&\|\xi_h(\cdot,t_n)\|_{L^2}^2 + \varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|^2_{L^2_D} \\
&\quad \le \frac{1+C\Delta t}{2}(\|\xi_h(\cdot,t_n)\|_{L^2}^2 + \|\xi_h(\cdot,t_{n-1})\|_{L^2}^2) + \frac{1}{4}\varepsilon\Delta t\|\xi_{h,x}(\cdot,t_n)\|^2_{L^2_D} \\
&\qquad + C(\Delta t)^2\Big\|\frac{d^2u}{dt^2}\Big\|^2_{L^2(t_{n-1},t_n;L^2)} + C\Delta t\min\{h^2,(\Delta t)^2\}\|u\|^2_{L^\infty(0,T;H^2)} \\
&\qquad + Ch^4(\Delta t\|u\|^2_{L^\infty(0,T;H^2)} + \lambda(\|u\|^2_{H^1(t_{n-1},t_n;H^2)} + \Delta t\|u\|^2_{L^\infty(0,T;H^3)})).
\end{aligned}$$

The rest of the proof is the same as that in Theorem 4.1. ∎

The MMOCAA scheme corrects the MMOC scheme by replacing $u_h(x_h^*, t_{n-1})$ by $\check{u}_h(x_h^*, t_{n-1}) = u_h(x_h^{**}, t_{n-1})$, where x_h^{**} is an order $O((\Delta t)^2)$ perturbation to x_h^*. This does not affect the order of each term in the error analysis but introduces extra differences of the same term at x_h^* and x_h^{**} and slightly complicates the analysis.

5. Error estimates for problem (2.1) with minimal or intermediate regularity. We prove a uniform stability estimate for the ELLAM, MMOC, and MMOCAA schemes, assuming minimal regularity of problem (2.1). We then use the theory of interpolation of operators to derive a priori error estimates, which hold uniformly with respect to ε, for problem (2.1) with minimal or intermediate regularity.

5.1. A uniform stability estimate. In this subsection we prove a uniform stability estimate for the ELLAM, MMOC, and MMOCAA schemes.

THEOREM 5.1. *Assume $V \in L^\infty(0,T;W^1_\infty(a,b))$, $D \in L^\infty(0,T;L^\infty(a,b))$, $u_o \in L^2(a,b)$, and $f \in L^2(0,T;L^2(a,b))$. Let $u_h(x,0)$ in the ELLAM scheme* (3.13)*, the MMOC scheme* (3.19)*, or the MMOCAA scheme be the L^2 projection of $u_o(x)$. Then an uniform stability estimate holds:*

$$\|u_h\|_{L_\varepsilon(0,T;H^1_D)} \le C(\|u_o\|_{L^2} + \|f\|_{L^2(0,T;L^2)}). \tag{5.1}$$

Proof. We choose $w_h(x,t_n)$ in the ELLAM scheme (3.13) to be $u_h(x,t_n)$ to get

$$\begin{aligned} &\int_a^b u_h^2(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)u_{h,x}^2(x,t_n)dx \\ &\quad = \int_a^b u_h(x_h^*,t_{n-1})u_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx + \Delta t\int_a^b f(x,t_n)u_h(x,t_n)dx. \end{aligned} \tag{5.2}$$

We bound the first term on the right-hand side similarly to estimate (4.4) and incorporate the estimate into (5.2). We cancel like terms and sum the resulting inequalities for $n = 1,\dots,N_1(\le N)$ to get

$$\begin{aligned} &\|u_h(\cdot,t_{N_1})\|_{L^2}^2 + \varepsilon\sum_{n=1}^{N_1}\Delta t\|u_{h,x}(\cdot,t_n)\|_{L^2_D}^2 \\ &\quad \le C\Delta t\sum_{n=0}^{N_1}(\|u_h(\cdot,t_n)\|_{L^2}^2 + \|f(\cdot,t_n)\|_{L^2(0,T;L^2)}^2) + \|u_o\|_{L^2}^2. \end{aligned}$$

We choose $C\Delta t \le 1/2$ and apply the Gronwall inequality to finish the proof of (5.1) in the context of the ELLAM scheme.

We similarly choose $w_h(x) = u_h(x,t_n)$ in the MMOC scheme (3.19) to get

$$\begin{aligned} &\int_a^b u_h^2(x,t_n)dx + \varepsilon\Delta t\int_a^b D(x,t_n)u_{h,x}^2(x,t_n)dx \\ &\quad = \int_a^b u_h(x_h^*,t_{n-1})u_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx \\ &\qquad -\Delta t\int_a^b V_x(x,t_n)u_h^2(x,t_n)dx + \Delta t\int_a^b f(x,t_n)u_h(x,t_n)dx. \end{aligned} \tag{5.3}$$

Compared with (5.2), the only extra term is the second term on the right-hand side of (5.3) that can be bounded by

$$\left|\Delta t\int_a^b V_x(x,t_n)u_h^2(x,t_n)dx\right| \le C\Delta t\|u_h(\cdot,t_n)\|_{L^2}^2.$$

Thus, we can prove the stability estimate (5.1) for the MMOC as we did for the ELLAM. As for the MMOCAA, the only difference is the accumulation term at the time step t_{n-1}, in which the foot of the approximate characteristics is a perturbation of order $O((\Delta t)^2)$ to the Euler tracking. Therefore, the estimate (5.1) is still true. ∎

5.2. Error estimates for problems with minimal or intermediate regularity. We apply the theory of interpolation of spaces to derive a priori error estimates for the ELLAM, MMOC, and MMOCAA schemes, which hold uniformly with respect to ε, for problem (2.1) with minimal or intermediate regularity.

THEOREM 5.2. *Let u be the true solution to problem* (2.1) *and u_h be the numerical solution of the ELLAM scheme* (3.13). *Then the following error estimate holds uniformly with respect to ε for $0 < s < 1$:*

$$\begin{aligned}\|u_h - u\|_{L_\varepsilon(0,T;H^1_D)} \le{}& C(\Delta t)^s \Big(\|u_o\|_{B^s_q(L^2)} + \sqrt{\varepsilon}\|u_o\|_{B^{2s}_q(L^2)} + \Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} \\ &+ \|f\|_{L^2(0,T;B^s_q(L^2))} \Big) + C\min\{h^s, (\Delta t)^s\}\|u_o\|_{B^{2s}_q(L^2)} \\ &+ Ch^{2s}(\|u_o\|_{B^{3s}_q(L^2)} + \lambda\|f\|_{L^2(0,T;B^{3s}_q(L^2))}).\end{aligned} \tag{5.4}$$

Proof. We split $u_h - u = (u_h^{(1)} - u^{(1)}) + (u_h^{(2)} - u^{(2)})$. Here $u_h^{(1)}$ and $u^{(1)}$ are the numerical and true solutions, respectively, to a homogeneous version of problem (2.1), whereas $u_h^{(2)}$ and $u^{(2)}$ are, respectively, the numerical and true solutions to problem (2.1) with zero initial data.

We combine the stability of the numerical solution $u_h^{(1)}$ and the true solution $u^{(1)}$, which is proved in Theorem 7.1, to obtain

$$\|u_h^{(1)} - u^{(1)}\|_{L_\varepsilon(0,T;H^1_D)} \le C\|u_o\|_{L^2}. \tag{5.5}$$

Theorem 4.1 gives an optimal-order error estimate assuming full regularity:

$$\begin{aligned}&\|u_h^{(1)} - u^{(1)}\|_{L_\varepsilon(0,T;H^1_D)} \\ &\quad \le C\Delta t\|u_o\|_{H^2_\varepsilon} + C(\min\{h, \Delta t\} + h^2)\|u_o\|_{H^2} + C\lambda h^2\|u_o\|_{H^3}.\end{aligned} \tag{5.6}$$

We use Lemma 2.1 with $m = 3$ to interpolate $L^2(a,b)$ and the Sobolev space $H^3(a,b)$:

$$[L^2(a,b), H^3(a,b)]_{s,q} = B^{3s}_q(L^2(a,b)), \quad 0 < s < 1.$$

Note that $[L^2(a,b), H^3(a,b)]_{k/3,1} \subset H^k(a,b) \subset [L^2(a,b), H^3(a,b)]_{k/3,\infty}$ for $k = 1, 2$. We apply Lemma 2.3 to reiterate the interpolation process on both ends to get

$$[L^2(a,b), H^k(a,b)]_{s,q} = [L^2(a,b), H^3(a,b)]_{ks/3,q} = B^{ks}_q(L^2(a,b)),\ 0 < s < 1,\ k = 1, 2.$$

We apply Lemma 2.2 to the estimates (5.5) and (5.6) to conclude

$$\begin{aligned}&\|u_h^{(1)} - u^{(1)}\|_{L_\varepsilon(0,T;H^1_D)} \\ &\quad \le C\lambda h^{2s}\|u_o\|_{B^{3s}_q(L^2)} + C(\min\{h^s, (\Delta t)^s\} + h^{2s})\|u_o\|_{B^{2s}_q(L^2)} \\ &\qquad + C(\Delta t)^s(\|u_o\|_{B^s_q(L^2)} + \sqrt{\varepsilon}\|u_o\|_{B^{2s}_q(L^2)}), \quad 0 < s < 1.\end{aligned} \tag{5.7}$$

We use (5.1), (7.2), and (4.1) to bound $u_h^{(2)} - u^{(2)}$ by

$$\|u_h^{(2)} - u^{(2)}\|_{L_\varepsilon(0,T;H^1_D)} \le C\|f\|_{L^2(0,T;L^2)} \tag{5.8}$$

and

$$\|u_h^{(2)} - u^{(2)}\|_{L_\varepsilon(0,T;H_D^1)} \le C\Delta t\Big(\Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} + \|f\|_{L^2(0,T;H^1)}\Big) + C\lambda h^2\|f\|_{L^2(0,T;H^3)}. \tag{5.9}$$

We then use the interpolation to derive the following estimate:

$$\|u_h^{(2)} - u^{(2)}\|_{L_\varepsilon(0,T;H_D^1)} \le C(\Delta t)^s\Big(\Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} + \|f\|_{L^2(0,T;B_q^s(L^2))}\Big) + C\lambda h^{2s}\|f\|_{L^2(0,T;B_q^{3s}(L^2))}. \tag{5.10}$$

We combine the estimates (5.7) and (5.10) to finish the proof of (5.4). ∎

In the theorem, the coefficients are required to be in the appropriate interpolation spaces with proper fine tuning. An analogue can be proved for the MMOC and MMOCAA schemes in a similar manner.

THEOREM 5.3. *Let u be the true solution to problem* (2.1) *and u_h be the numerical solution of the MMOC scheme* (3.19) *or the MMOCAA scheme. Then, for $0 < s < 1$, the following error estimate holds uniformly with respect to ε:*

$$\begin{aligned}
&\|u_h - u\|_{L_\varepsilon(0,T;H_D^1)}\\
&\quad\le C(\Delta t)^s\Big(\|u_o\|_{B_q^s(L^2)} + \sqrt{\varepsilon}\|u_o\|_{B_q^{2s}(L^2)} + \varepsilon^{3/2}\|u_o\|_{B_q^{3s}(L^2)}\\
&\qquad + \Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)} + \|f\|_{L^2(0,T;B_q^{2s}(L^2))}\Big) + C\min\{h^s,(\Delta t)^s\}\|u_o\|_{B_q^{2s}(L^2)}\\
&\qquad + Ch^{2s}(\|u_o\|_{B_q^{3s}(L^2)} + \lambda\|f\|_{L^2(0,T;B_q^{3s}(L^2))}).
\end{aligned} \tag{5.11}$$

6. Auxiliary lemmas. We prove two auxiliary lemmas in this section. The first lemma addresses error bounds on the approximate characteristics to the true characteristics. The second lemma proves the optimal-order error bound in (4.6).

6.1. Estimates on approximations to characteristics. We prove several bounds on the differences between the approximate and true characteristics.

LEMMA 6.1. *Let $r(t;x,t_n)$ and $r_h(t;x,t_n)$ be the true and approximate characteristics defined in* (3.3) *and* (3.12)*, respectively. Assume that V, $\frac{dV}{dt} \in L^\infty(0,T;W_\infty^1(a,b))$. Then the following estimates hold:*

$$\begin{aligned}
&|x_h^* - x^*| \le \frac{(\Delta t)^2}{2}\Big\|\frac{dV}{dt}\Big\|_{L^\infty(0,T;L^\infty)} = O((\Delta t)^2),\\
&|r_x(t;x,t_n) - 1| \le \int_t^{t_n} |V_x(r(\theta;x,t_n),\theta)|d\theta e^{\int_t^{t_n}|V_x(r(\theta;x,t_n),\theta)|d\theta} = O(t_n - t),
\end{aligned} \tag{6.1}$$

and

$$\begin{aligned}
&|r_{h,x}(t_{n-1};x,t_n) - r_x(t_{n-1};x,t_n)|\\
&\quad\le \frac{(\Delta t)^2}{2}\Big(\Big\|\frac{dV}{dt}\Big\|_{L^\infty(0,T;W_\infty^1)} + \|V\|^2_{L^\infty(0,T;W_\infty^1)}\Big)e^{\int_{t_{n-1}}^{t_n}|V_x(r(\theta;x,t_n),\theta)|d\theta}\\
&\quad= O((\Delta t)^2).
\end{aligned} \tag{6.2}$$

Proof. The definition (3.3) directly yields

$$r(t;x,t_n) = x - \int_t^{t_n} V(r(\theta;x,t_n),\theta)d\theta. \tag{6.3}$$

We subtract this equation from (3.12) to get the following, which directly leads to the first inequality in (6.1):

$$\begin{aligned}|x_h^* - x^*| &= \Big|\int_{t_{n-1}}^{t_n} V(r(t;x,t_n),t)dt - V(x,t_n)\Delta t\Big| \\ &= \Big|\int_{t_{n-1}}^{t_n} [V(r(t;x,t_n),t) - V(x,t_n)]dt\Big| \\ &\le \int_{t_{n-1}}^{t_n}\int_{\theta}^{t_n} \Big|\frac{dV(r(\theta;x,t_n),\theta)}{d\theta}\Big| d\theta dt.\end{aligned}$$

Differentiating (6.3) leads to

$$\begin{aligned}r_x(t;x,t_n) - 1 &= -\int_t^{t_n} V_x(r(\theta;x,t_n),\theta) r_x(\theta;x,t_n)d\theta \\ &= -\int_t^{t_n} V_x(r(\theta;x,t_n),\theta)d\theta \\ &\quad -\int_t^{t_n} V_x(r(\theta;x,t_n),\theta)\ (r_x(\theta;x,t_n)-1)d\theta.\end{aligned} \tag{6.4}$$

Application of the Gronwall inequality leads to the second estimate in (6.1).

We differentiate (3.12) and use (6.4) to get

$$\begin{aligned}&r_{h,x}(t_{n-1};x,t_n) - r_x(t_{n-1};x,t_n) \\ &= \int_{t_{n-1}}^{t_n} [V_x(r(t;x,t_n),t) - V_x(x,t_n)]dt \\ &\quad -\int_{t_{n-1}}^{t_n} V_x(r(t;x,t_n),t)[r_{h,x}(t;x,t_n) - r_x(t;x,t_n) + V_x(x,t_n)(t_n - t)]dt.\end{aligned}$$

Application of the Gronwall inequality to the following proves (6.2):

$$\begin{aligned}&|r_{h,x}(t_{n-1};x,t_n) - r_x(t_{n-1};x,t_n)| \\ &\quad \le \frac{(\Delta t)^2}{2}\Big(\Big\|\frac{dV}{dt}\Big\|_{L^\infty(0,T;W^1_\infty)} + \|V\|^2_{L^\infty(0,T;W^1_\infty)}\Big) \\ &\qquad + \int_{t_{n-1}}^{t_n} |V_x(r(t;x,t_n),t)|\ |r_{h,x}(t;x,t_n) - r_x(t;x,t_n)|dt. \qquad \square\end{aligned}$$

6.2. A superconvergent estimate on interpolation. We prove the following superconvergence estimate on the interpolation error.

LEMMA 6.2. *Assume $u \in L^\infty(0,T;H^3(a,b)) \cap H^1(0,T;H^2(a,b))$. Let $\Pi_h u \in S_h(a,b)$ be the interpolation of u and $\eta = \Pi_h u - u$. Let λ be the parameter defined in Theorem* 4.1. *Then the following superconvergence estimate holds:*

$$\begin{aligned}&\Big|\int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n) r_{h,x}(t_{n-1};x,t_n)dx - \int_a^b \eta(x,t_n)\xi_h(x,t_n)dx\Big| \\ &\quad \le C\Delta t\|\xi_h(\cdot,t_n)\|^2_{L^2} + C\Delta t(\min\{h^2,(\Delta t)^2\} + h^4)\|u\|^2_{L^\infty(0,T;H^2)} \\ &\qquad + C(\Delta t)^3\|u\|^2_{L^\infty(0,T;H^1)} + C\lambda\, h^4(\|u\|^2_{H^1(t_{n-1},t_n;H^2)} + \Delta t\|u\|^2_{L^\infty(0,T;H^3)}).\end{aligned} \tag{6.5}$$

Proof. We rewrite the left-hand side of (6.5) as

$$\begin{aligned}&\int_a^b \eta(x,t_n)\xi_h(x,t_n)dx - \int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)r_{h,x}(t_{n-1};x,t_n)dx\\ &\quad=\int_a^b (\eta(x,t_n)-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx\\ &\qquad+\Delta t\int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)V_x(x,t_n)dx.\end{aligned}\tag{6.6}$$

We bound the second term on the right-hand side in a similar way to (4.4):

$$\begin{aligned}&\Big|\Delta t\int_a^b \eta(x_h^*,t_{n-1})\xi_h(x,t_n)V_x(x,t_n)dx\Big|\\ &\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\ \|\eta(x_h^*,t_{n-1})\|_{L^2(a,b)}\\ &\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\ \|\eta(\cdot,t_{n-1})\|_{L^2}\\ &\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C\Delta t\ h^4\|u\|^2_{L^\infty(0,T;H^2)}.\end{aligned}\tag{6.7}$$

When $\mathrm{Cr}\ge 1$ that implies $h\le C\Delta t$, we bound the first term in (6.6) by

$$\begin{aligned}&\Big|\int_a^b (\eta(x,t_n)-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx\Big|\\ &\quad\le C\|\xi_h(\cdot,t_n)\|_{L^2}(\|\eta(\cdot,t_n)\|_{L^2}+\|\eta(\cdot,t_{n-1})\|_{L^2})\\ &\quad\le Ch^2\|\xi_h(\cdot,t_n)\|_{L^2}\ \|u\|_{L^\infty(0,T;H^2)}\\ &\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + C\Delta t\min\{h^2,(\Delta t)^2\}\|u\|^2_{L^\infty(0,T;H^2)}.\end{aligned}\tag{6.8}$$

For $\mathrm{Cr}<1$, we decompose this term as follows:

$$\begin{aligned}&\int_a^b (\eta(x,t_n)-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx\\ &\quad=\int_a^b\int_{t_{n-1}}^{t_n}\eta_t(x,t)dt\ \xi_h(x,t_n)dx\\ &\qquad+\int_a^b (\eta(x,t_{n-1})-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx.\end{aligned}\tag{6.9}$$

The first term on the right-hand side is bounded by

$$\begin{aligned}&\Big|\int_a^b\int_{t_{n-1}}^{t_n}\eta_t(x,t)dt\ \xi_h(x,t_n)dx\Big|\\ &\quad\le(\Delta t)^{1/2}\|\xi_h(\cdot,t_n)\|_{L^2}\ \|\eta\|_{H^1(t_{n-1},t_n;L^2)}\\ &\quad\le\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2 + Ch^4\|u\|^2_{H^1(t_{n-1},t_n;H^2)}.\end{aligned}\tag{6.10}$$

We use the following expressions in the second term on the right side of (6.9):

$$\begin{aligned}\eta(x,t_{n-1})-\eta(x_h^*,t_{n-1}) &= \int_0^1 \frac{d}{d\theta}\eta(x_h^*+\theta(x-x_h^*),t_{n-1})d\theta\\ &= \int_0^1 \eta_x(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)d\theta,\\ \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big) &= \eta_x(x_h^*+\theta(x-x_h^*),t_{n-1})(x_{h,x}^*+\theta(1-x_{h,x}^*))\\ &= \eta_x(x_h^*+\theta(x-x_h^*),t_{n-1})(1-(1-\theta)V_x(x,t_n)\Delta t)\end{aligned}$$

and then integrate the resulting term by parts to yield

$$
\begin{aligned}
&\int_a^b (\eta(x,t_{n-1})-\eta(x_h^*,t_{n-1}))\xi_h(x,t_n)dx\\
&\quad=\int_a^b\int_0^1 \eta_x(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)d\theta\ \xi_h(x,t_n)dx\\
&\quad=\int_a^b\int_0^1 \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big)\\
&\qquad\qquad (1-(1-\theta)V_x(x,t_n)\Delta t)^{-1}(x-x_h^*)d\theta\ \xi_h(x,t_n)dx\\
&\quad=\int_a^b\int_0^1 \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big)(x-x_h^*)d\theta\ \xi_h(x,t_n)dx\\
&\qquad+\int_a^b\int_0^1 \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big)O((\Delta t)^2)d\theta\ \xi_h(x,t_n)dx\\
&\quad=-\int_0^1\int_a^b \eta(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)_x\xi_h(x,t_n)dxd\theta\\
&\qquad-\int_0^1\int_a^b \eta(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)\xi_{h,x}(x,t_n)dxd\theta\\
&\qquad+\int_a^b\int_0^1 \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big)O((\Delta t)^2)d\theta\ \xi_h(x,t_n)dx.
\end{aligned}
\tag{6.11}
$$

Let $y=x_h^*+\theta(x-x_h^*)$. We bound the first and third terms on the right side by

$$
\begin{aligned}
&\Big|\int_0^1\int_a^b \eta(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)_x\xi_h(x,t_n)dxd\theta\\
&\qquad+\int_a^b\int_0^1 \frac{\partial}{\partial x}\Big(\eta(x_h^*+\theta(x-x_h^*),t_{n-1})\Big)O((\Delta t)^2)d\theta\ \xi_h(x,t_n)dx\Big|\\
&\le \Delta t\int_0^1\int_a^b |V_x(x,t_n)||\eta(x_h^*+\theta(x-x_h^*),t_{n-1})||\xi_h(x,t_n)|dxd\theta\\
&\qquad+C(\Delta t)^2\int_0^1\int_a^b |\eta_x(x_h^*+\theta(x-x_h^*),t_{n-1})||\xi_h(x,t_n)|dxd\theta\\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}\Big[\Big(\int_0^1\int_a^b \eta^2(y,t_{n-1})(\theta+(1-\theta)x_{h,x}^*)^{-1}dyd\theta\Big)^{1/2}\\
&\qquad+\Delta t\Big(\int_0^1\int_a^b \eta_x^2(y,t_{n-1})(\theta+(1-\theta)x_{h,x}^*)^{-1}dyd\theta\Big)^{1/2}\Big]\\
&\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2+C\Delta t h^4\|u\|_{L^\infty(0,T;H^2)}^2+C(\Delta t)^3\|u\|_{L^\infty(0,T;H^1)}^2.
\end{aligned}
\tag{6.12}
$$

We decompose the second term on the right-hand side of (6.11) as

$$
\begin{aligned}
&\int_0^1\int_a^b \eta(x_h^*+\theta(x-x_h^*),t_{n-1})(x-x_h^*)\xi_{h,x}(x,t_n)dxd\theta\\
&\quad=\Delta t\int_a^b V(x,t_n)\xi_{h,x}(x,t_n)\Big(\eta(x,t_{n-1})\\
&\qquad+\int_0^1\int_0^1 \frac{d}{d\gamma}\eta(x+\gamma(1-\theta)(x_h^*-x),t_{n-1})d\gamma d\theta\Big)dx\\
&\quad=\Delta t\int_a^b V(x,t_n)\xi_{h,x}(x,t_n)\eta(x,t_{n-1})dx\\
&\qquad+\Delta t\int_0^1\int_0^1\int_a^b V(x,t_n)\xi_{h,x}(x,t_n)(1-\theta)(x_h^*-x)\\
&\qquad\quad\times\eta_x(x+\gamma(1-\theta)(x_h^*-x),t_{n-1})dxd\gamma d\theta.
\end{aligned}
\tag{6.13}
$$

We use the inverse inequality (2.3) to bound the second term by

$$\begin{aligned}(6.14)\qquad &\Big|\Delta t\int_0^1\int_0^1\int_a^b V(x,t_n)\xi_{h,x}(x,t_n)(1-\theta)(x_h^*-x)\\ &\qquad\times\eta_x(x+\gamma(1-\theta)(x_h^*-x),t_{n-1})dxd\gamma d\theta\Big|\\ &\le C(\Delta t)^2h\|\xi_{h,x}(\cdot,t_n)\|_{L^2}\|u(\cdot,t_{n-1})\|_{H^2}\\ &\le C\Delta t\ \|\xi_h(\cdot,t_n)\|_{L^2}^2+C(\Delta t)^3\ \|u\|_{L^\infty(0,T;H^2)}^2.\end{aligned}$$

A standard estimate of the first term on the right-hand side of (6.13) yields

$$\begin{aligned}\Big|\Delta t\int_a^b V(x,t_n)\eta(x,t_{n-1})\xi_{h,x}(x,t_n)dx\Big| &\le C\Delta t\|\xi_{h,x}(\cdot,t_n)\|_{L^2}\|\eta(\cdot,t_{n-1})\|_{L^2}\\ &\le C\Delta t\,h^2\|\xi_{h,x}(\cdot,t_n)\|_{L^2}\|u(\cdot,t_{n-1})\|_{H^2}\\ &\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2+C\Delta t\,h^2\|u(\cdot,t_{n-1})\|_{H^2}.\end{aligned}$$

This will result in a suboptimal-order estimate of order $O(h+\Delta t)$ for the ELLAM scheme. To derive an optimal-order estimate, we sum this term by parts to obtain

$$\begin{aligned}(6.15)\qquad &\Delta t\int_a^b V(x,t_n)\eta(x,t_{n-1})\xi_{h,x}(x,t_n)dx\\ &=-\frac{\Delta t}{h}\sum_{i=1}^I\int_{x_{i-1}}^{x_i}(V(x+h,t_n)-V(x,t_n))\eta(x,t_{n-1})\xi_h(x_i,t_n)dx\\ &\quad-\frac{\Delta t}{h}\sum_{i=1}^I\int_{x_{i-1}}^{x_i}(\eta(x+h,t_{n-1})-\eta(x,t_{n-1}))V(x+h,t_n)\xi_h(x_i,t_n)dx.\end{aligned}$$

We bound the first term on the right-hand side of (6.15) by

$$\begin{aligned}(6.16)\qquad &\Big|\frac{\Delta t}{h}\sum_{i=1}^I\int_{x_{i-1}}^{x_i}(V(x+h,t_n)-V(x,t_n))\eta(x,t_{n-1})\xi_h(x_i,t_n)dx\Big|\\ &\le C\Delta t\ \|\xi_h(\cdot,t_n)\|_{L^2}\ \|\eta(\cdot,t_{n-1})\|_{L^2}\\ &\le C\Delta t\ \|\xi_h(\cdot,t_n)\|_{L^2}^2+C\Delta t\ h^4\ \|u\|_{L^\infty(0,T;H^2)}^2,\end{aligned}$$

where we have used the equivalence between the discrete and continuous L^2 norms.

However, if we similarly bound the second term on the right side of (6.15), we can obtain only a suboptimal-order estimate. To derive an optimal-order estimate, we introduce an auxiliary function $\psi(x,t)$ by

$$\psi(x,t)=u(x+h,t)-u(x,t)=\int_0^h u_\alpha(\alpha+x,t)d\alpha.$$

Because $\eta(x+h,t_{n-1})$ is a shift of $\eta(x,t_{n-1})$ by one grid point, so the forward difference operator and the shift operator are commutative:

$$\begin{aligned}\eta(x+h,t_{n-1})-\eta(x,t_{n-1}) &=(\Pi_h-\mathrm{I})u(x+h,t_{n-1})-(\Pi_h-\mathrm{I})u(x,t_{n-1})\\ &=(\Pi_h-\mathrm{I})(u(x+h,t_{n-1})-u(x,t_{n-1}))\\ &=(\Pi_h-\mathrm{I})\psi(x,t_{n-1}).\end{aligned}$$

Inserting this identity into the second term on the right-hand side of (6.15) gives

$$\begin{aligned}&\Big|\frac{\Delta t}{h}\sum_{i=1}^{I}\int_{x_{i-1}}^{x_i}(\eta(x+h,t_n)-\eta(x,t_n))V(x+h,t_n)\xi_h(x_i,t_n)dx\Big|\\&\quad\le\frac{C\Delta t}{h}\|\xi_h(\cdot,t_n)\|_{L^2}\ \|(\Pi_h-\mathrm{I})\psi(\cdot,t_{n-1})\|_{L^2}\le C\Delta t\ h\|\xi_h(\cdot,t_n)\|_{L^2}\|\psi(\cdot,t_{n-1})\|_{H^2}\\&\quad\le C\Delta t\|\xi_h(\cdot,t_n)\|_{L^2}^2+C\Delta t\ h^4\|u\|^2_{L^\infty(0,T;H^3)}.\end{aligned}\tag{6.17}$$

Combining all of these estimates, we have proved (6.5). ∎

7. Uniform stability estimates of the exact solutions. The existence, uniqueness, and stability estimates for problem (2.1) can be found, e.g., in [9]. We derive a priori stability estimates for problem (2.1) in ε-weighted norms, which hold uniformly with respect to ε, under different regularity assumptions.

7.1. A generic stability estimate with minimal regularity assumption. We prove a priori stability estimates for a slightly more general initial-boundary value problem than problem (2.1) with minimal regularity assumption:

$$\begin{aligned}&z_t+(\bar V(x,t)z-\varepsilon\bar D(x,t)z_x)_x+\bar R(x,t)z=\bar f(x,t),\quad (x,t)\in(a,b)\times(0,T],\\&\qquad\qquad z(x,0)=z_o(x),\end{aligned}\tag{7.1}$$

which is closed by a periodic boundary condition at $x=a$ and $x=b$.

THEOREM 7.1. *Assume $\bar D\in L^\infty(0,T;L^\infty)$, $\bar R\in L^1(0,T;L^\infty)$, $\bar V\in L^1(0,T;W^1_\infty)$, $z_o\in L^2(a,b)$, and $\bar f\in L^2(0,T;L^2)$. Then the following estimate holds:*

$$\begin{aligned}\|z\|_{L_\varepsilon(0,T;H^1_D)}&\le 2(\|z_o\|_{L^2}+\|\bar f\|_{L^2(0,T;L^2)})e^{\frac12\|(1-2\bar R-\bar V_x)^+\|_{L^1(0,T;L^\infty)}}\\&\le C(\|z_o\|_{L^2}+\|\bar f\|_{L^2(0,T;L^2)}).\end{aligned}\tag{7.2}$$

Here C depends on $\|(1-2\bar R-\bar V_x)^+\|_{L^1(0,T;L^\infty)}$ but not on ε, $g^+(x,t)=\max\{g(x,t),0\}$.

Proof. We combine $z_t+\bar V z_x$ in (7.1) to form a material derivative $\frac{dz}{dt}$ along the characteristics $x=r(t;\bar x,\bar t)$ defined by (3.3) with V being replaced by $\bar V$. We multiply the equation by $z(x,t)$ and integrate the resulting equation to get

$$\int_a^b\frac{dz}{dt}zdx+\varepsilon\int_a^b\bar D(x,t)z_x^2dx+\int_a^b(\bar R(x,t)+\bar V_x(x,t))z^2dx=\int_a^b\bar f(x,t)zdx.$$

We apply the Reynolds transport theorem

$$\frac{d}{dt}\int_{r(t;a,\bar t)}^{r(t;b,\bar t)}gdx=\int_{r(t;a,\bar t)}^{r(t;b,\bar t)}\Big(\frac{dg}{dt}+\bar V_xg\Big)dx$$

to $g=z^2(x,t)$ at $t=\bar t$ to rewrite the weak formulation as

$$\frac12\frac{d}{dt}\int_a^bz^2dx+\varepsilon\int_a^b\bar Dz_x^2dx+\int_a^b\Big(\bar R+\frac12\bar V_x\Big)z^2dx=\int_a^bfzdx.$$

Integrating this equation from $t = 0$ to $t = \bar{t}$ yields

$$\begin{aligned}
&\int_a^b z^2(x,\bar{t})dx + 2\varepsilon \int_0^{\bar{t}} \int_a^b \bar{D}(x,t) z_x^2(x,t) dx dt \\
&\quad = \int_a^b z^2(x,\bar{t})dx + 2\varepsilon \int_0^{\bar{t}} \int_{r(t;a,\bar{t})}^{r(t;b,\bar{t})} \bar{D}(x,t) z_x^2(x,t) dx dt \\
&\quad \le \int_{r(0;a,\bar{t})}^{r(0;b,\bar{t})} z_o^2(x) dx + \int_0^{\bar{t}} \int_{r(t;a,\bar{t})}^{r(t;b,\bar{t})} \bar{f}^2(x,t) dx dt \\
&\qquad + \int_0^{\bar{t}} \|(1 - 2\bar{R} - \bar{V}_x)^+(\cdot,t)\|_{L^\infty(a,b)} \int_{r(t;a,\bar{t})}^{r(t;b,\bar{t})} z^2(x,t) dx dt \\
&\quad = \|z_o\|_{L^2}^2 + \int_0^{\bar{t}} \|\bar{f}(\cdot,t)\|_{L^2}^2 dt + \int_0^{\bar{t}} \|(1 - 2\bar{R} - \bar{V}_x)^+(\cdot,t)\|_{L^\infty(a,b)} \, \|z(\cdot,t)\|_{L^2}^2 dt.
\end{aligned}$$

Here we have used the fact that $\int_{r(t;a,\bar{t})}^{r(t;b,\bar{t})} g(x)dx = \int_a^b g(x)dx$. Applying the Gronwall inequality finishes the proof of (7.2). ∎

7.2. Uniform stability estimates for problem (2.1). In this subsection we prove a priori stability estimates for problem (2.1) in different Sobolev norms.

THEOREM 7.2. *Assume $D, V \in L^\infty(0,T; W_\infty^{k+1}(a,b))$, $u_o \in H^k(a,b)$, and $f \in L^2(0,T; H^k(a,b))$. Then the following stability estimate holds for problem* (2.1)*:*

$$\|u\|_{L_\varepsilon(0,T;H^{k+1})} \le C(\|u_o\|_{H^k} + \|f\|_{L^2(0,T;H^k)}), \tag{7.3}$$

where $C = C(\|D\|_{L^\infty(0,T;W_\infty^{k+1})}, \|V\|_{L^\infty(0,T;W_\infty^{k+1})})$, but not on ε. Further, if $D, V \in L^\infty(0,T; W_\infty^4(a,b))$, $u_o \in H^3(a,b)$, and $f \in L^2(0,T; H^3(a,b))$, we have

$$\|u\|_{H^1(0,T;H^2)} \le C(\|u_o\|_{H^3} + \|f\|_{L^2(0,T;H^3)}) \tag{7.4}$$

and

$$\left\|\frac{d^2u}{dt^2}\right\|_{L^2(0,T;L^2)} \le C\Big(\varepsilon\|u_o\|_{H_\varepsilon^3} + \|u_o\|_{H_\varepsilon^1} + \|f\|_{L^2(0,T;H^2)} + \left\|\frac{df}{dt}\right\|_{L^2(0,T;L^2)}\Big). \tag{7.5}$$

Here $C = C(\|D\|_{L^\infty(0,T;W_\infty^4)}, \|V\|_{L^\infty(0,T;W_\infty^4)})$, but not on ε. Finally, assume $D, V \in L^\infty(0,T; W_\infty^{l+1}(a,b))$, $u_o \in H^l(a,b)$, and $f \in L^2(0,T; H^l(a,b))$ for $l = 0, 1$. We have

$$\left\|\frac{du}{dt}\right\|_{L^2(0,T;H^l)} \le C(\|u_o\|_{H_\varepsilon^{l+1}} + \|f\|_{L^2(0,T;H^l)}). \tag{7.6}$$

Proof. (7.3) for $k = 0$ is a direct consequence of (7.2). To prove (7.3) for $k = 1$, we differentiate problem (2.1) with respect to x. The resulting equation corresponds to (7.1) with $z = u_x$, $\bar{D} = D$, $\bar{V} = V - \varepsilon D_x$, $\bar{R} = V_x$, and $\bar{f} = f_x - V_{xx}$. The estimate (7.2) yields (7.3) with $k = 1$. We prove (7.3) for $k \ge 2$ by induction.

To prove the estimate (7.4) we use the governing equation in (2.1) to express u_t in terms of spatial derivatives and bound these spatial derivatives by the estimate (7.3). We similarly bound $\frac{du}{dt}$ in terms of spatial derivatives as follows:

$$\left\|\frac{du}{dt}\right\|_{L^2(0,T;H^l)} \le C(\varepsilon\|(Du_x)_x\|_{L^2(0,T;H^l)} + \|V_x u\|_{L^2(0,T;H^l)} + \|f\|_{L^2(0,T;H^l)}).$$

This together with (7.3) proves the estimate of $\frac{du}{dt}$. We similarly express $\frac{d^2u}{dt^2}$ as

$$\begin{aligned}
&\Big\|\frac{d^2u}{dt^2}\Big\|_{L^2(0,T;L^2)}\\
&\quad=\Big\|\varepsilon[D(\varepsilon(Du_x)_x-V_xu+f)_x]_x+\varepsilon\Big(\frac{dD}{dt}u_x\Big)_x-V_x\frac{du}{dt}-\frac{dV_x}{dt}u+\frac{df}{dt}\Big\|_{L^2(0,T;L^2)}\\
&\quad\le\varepsilon^2\|u\|_{L^2(0,T;H^4)}+\varepsilon\|u\|_{L^2(0,T;H^2)}+\|u\|_{L^2(0,T;L^2)}+\|f\|_{L^2(0,T;H^2)}\\
&\qquad+\Big\|\frac{du}{dt}\Big\|_{L^2(0,T;L^2)}+\Big\|\frac{df}{dt}\Big\|_{L^2(0,T;L^2)}.
\end{aligned}$$

We combine this inequality with estimates (7.3) and (7.6) to finish the proof. ∎

8. Concluding remarks. In this section we summarize the main results in this paper and address several related issues. We also carry out numerical example runs to verify the theoretical estimates numerically. We conclude the paper by briefly discussing the directions of future work.

8.1. The ε-weighted energy norm and L^∞ norm. In the context of stationary convection-diffusion equations, the location of internal and boundary layers is known a priori. A piecewise-uniform mesh was proposed and analyzed by Shishkin to resolve the boundary and internal layers. Moreover, an ε-uniform L^∞ error estimate was proved for numerical methods with Shishkin mesh [11, 14]. However, in the context of transient convection-diffusion equations, the fronts are dynamic and do not always coincide with the spatial mesh. Thus, although an ε-uniform error estimate in the L^∞ norm is ideal, it is generally impossible especially in the context of multiple space dimensions and in the limiting case of $\varepsilon=0$. This is why the L^∞ norm is not used in the numerical methods for hyperbolic conservation laws [13].

In this paper we derived ε-uniform error estimates in the ε-weighted energy norm $\|\cdot\|_{H^1_\varepsilon}$. We now discuss the relation between the error estimates measured in $\|\cdot\|_{L^\infty}$ and in $\|\cdot\|_{H^1_\varepsilon}$. In the context of an exponential layer (say, located at $x=1$), the approximation error e is expected to be of the form [11, 14]

$$e=\exp\Big(\frac{-(1-x)}{\varepsilon}\Big),\qquad 0\le x\le 1. \tag{8.1}$$

$\|e\|_{L^\infty}=O(1)$ and $\|e\|_{H^1_\varepsilon(0,1)}=\|e\|_{L^2(0,1)}+\sqrt{\varepsilon}\|e_x\|_{L^2(0,1)}=\sqrt{\varepsilon}+\sqrt{\varepsilon}\cdot(1/\sqrt{\varepsilon})=O(1)$. Thus, $\|e\|_{L^\infty}$ is comparable to $\|e\|_{H^1_\varepsilon(0,1)}$, and both norms recognize the exponential layer. When problem (2.1) has a smooth solution, $\|e\|_{L^\infty}=O(h^2)$ and $\|e\|_{H^1_\varepsilon(0,1)}=\|e\|_{L^2(0,1)}+\sqrt{\varepsilon}\|e_x\|_{L^2(0,1)}=O(h^2+\sqrt{\varepsilon}h)=O(h^2)$ for $\varepsilon<h^2$. Thus, $\|e\|_{L^\infty}$ is still comparable to $\|e\|_{H^1_\varepsilon(0,1)}$.

In the context of a parabolic layer (say, located at $x=1$), the approximation error e is expected to be of the form [11, 14]

$$e=\exp\Big(\frac{-(1-x)}{\sqrt{\varepsilon}}\Big),\qquad 0\le x\le 1. \tag{8.2}$$

For a parabolic layer, $\|e\|_{L^\infty}=O(1)$ and $\|e\|_{H^1_\varepsilon(0,1)}=\|e\|_{L^2(0,1)}+\sqrt{\varepsilon}\|e_x\|_{L^2(0,1)}=\varepsilon^{1/4}+\sqrt{\varepsilon}\cdot\varepsilon^{-1/4}=O(\varepsilon^{1/4})$. In this case, the L^∞ norm still recognizes the parabolic layer, but the ε-weighted norm does not recognize the layer.

In summary, the ε-weighted norm is comparable to the L^∞ norm in the cases of a smooth solution or an exponential layer. An exponential layer exhibits the strongest layer behavior and is of the major concern from a numerical and analysis viewpoint.

On the other hand, in the context of a parabolic layer, $\|\cdot\|_{H^1_\varepsilon}$ is somewhat weaker than $\|\cdot\|_{L^\infty}$. Thus, the ε-weighted norm is the most feasible measure for transient convection-diffusion equations and is closely related to the L^∞ norm. The L^∞ norm is an ideal but impossible measure in this context.

8.2. Measurements in Besov spaces. In Theorems 5.2 and 5.3, we used the interpolation theory and stability estimates to derive an ε-uniform estimate for problem (2.1) with minimal or intermediate regularity, where the initial and right-hand side data were measured in Besov spaces that generate a refined scale of smoothness and convergence rate. As an example, we consider an initial configuration that contains interior layers. Note that the indicator function $\chi_{(0.4,0.8)}$ (introduced before estimate (4.11)) satisfies $\chi_{(0.4,0.8)} \in H^{1/2-\delta}(0,1)$ for any $0 < \delta \le 1/2$ but $\notin H^{1/2}(0,1)$. Direct calculation shows that

$$\|\chi_{(0.4,0.8)}\|_{H^{1/2-\delta}(0,1)} = O(\delta^{-1/2}) \to \infty \quad \text{as } \delta \to 0. \tag{8.3}$$

Consequently, the convergence rate in the estimates (5.4) and (5.11) will be $s = 1/4 - \delta/2$ in the case of $\mathrm{Cr} \ge 1$, and the norm will blow up as $\delta \to 0$, if the initial configuration is measured in the Sobolev spaces. On the other hand, it can be verified that $\chi_{(0.4,0.8)} \in B^{1/2}_\infty(L^2(0,1))$ but $\notin B^{1/2}_q(L^2(0,1))$ for $q < \infty$. With this measure of the same initial data, the estimates (5.4) and (5.11) yield a sharp convergence rate of order $s = 1/4$ in the case of $\mathrm{Cr} \ge 1$.

8.3. Numerical experiments. Various numerical experiments were reported in the literature, which confirmed spatial and temporal convergence rates of Eulerian–Lagrangian methods (see, e.g., [7, 15, 18]). In this section we conduct numerical experiments to observe the convergence behavior of the truncation error $u_h - u$ and its dependence on ε. We simulate the transport of a Gaussian pulse subject to (2.1) with the initial configuration being given by

$$u_o(x) = \exp\Big(-\frac{(x - x_c)^2}{2\sigma^2}\Big), \tag{8.4}$$

where x_c and σ are the centered and standard deviations, respectively, of the Gaussian pulse. The analytical solution $u(x,t)$ for a homogeneous equation (2.1) is given by

$$u(x,t) = \frac{\sqrt{2}\sigma}{\sqrt{2\sigma^2 + 4\varepsilon t}} \exp\Big(-\frac{(x - x_c - Vt)^2}{2\sigma^2 + 4\varepsilon t}\Big). \tag{8.5}$$

In the numerical example runs, the spatial domain is $(a,b) = (0,3)$, and the time interval is $(0,T) = (0,1)$. We select $V = 1$ and $D = 1$ so the convection dominance is controlled by the magnitude of ε, which is chosen to be 0.001, 0.0001, and 0. We also choose $x_c = 0.5$, and $\sigma = 0.1$. We fix a small time step Δt and use a linear regression to fit the convergence rates and the associated constants in the weighted energy norm

$$\|u_h - u\| \le C_\alpha h^\alpha. \tag{8.6}$$

The results are presented in Table 8.1, which shows that the ELLAM scheme maintains second-order accuracy in space. Moreover, these convergence rates hold uniformly as ε tends to zero, even in the limiting case of $\varepsilon = 0$, as predicted by the theorems proved in this paper.

TABLE 8.1
Spatial convergence rates in the ε-weighted energy norm with $\Delta t = 1/100$.

h	$\varepsilon = 0.001$	$\varepsilon = 0.0001$	$\varepsilon = 0$
1/10	5.74×10^{-2}	7.52×10^{-2}	7.76×10^{-2}
1/20	7.99×10^{-3}	1.02×10^{-2}	1.05×10^{-2}
1/30	2.68×10^{-3}	3.10×10^{-3}	3.15×10^{-3}
1/40	1.24×10^{-3}	1.36×10^{-3}	1.37×10^{-3}
1/60	4.01×10^{-4}	4.31×10^{-4}	4.32×10^{-4}
1/80	1.86×10^{-4}	2.12×10^{-4}	2.15×10^{-4}
	$C_\alpha = 32$, $\alpha = 2.75$	$C_\alpha = 51$, $\alpha = 2.84$	$C_\alpha = 54$, $\alpha = 2.86$

8.4. Summary and discussions. In this paper we proved ε-uniform error estimates in the ε-weighted energy norm for the ELLAM, MMOC, and MMOCAA schemes for one-dimensional singularly perturbed, time-dependent convection-diffusion equations with periodic boundary conditions. The estimates were derived on a uniform space-time partition with no upstream weighting or local grid refinement or any other special arrangements of the grid, so these estimates justify the strength of Eulerian–Lagrangian methods. The analysis fully utilizes the simplicity of the one space dimension and the periodic boundary conditions.

However, a multidimensional analogue of problem (2.1) with general boundary conditions presents much more severe challenges, due to the complication of multiple space dimensions, the solution structures, and the appearance of boundary and interior layers. These issues will be investigated in the near future.

Acknowledgments. This work was done during the visit of the first author to Shandong University. The authors express their sincere thanks to the referees for their very helpful comments and suggestions, which greatly improved the quality of this paper.

UNIFIED CONVERGENCE RESULTS ON A MINIMAX ALGORITHM FOR FINDING MULTIPLE CRITICAL POINTS IN BANACH SPACES*

XUDONG YAO† AND JIANXIN ZHOU‡

Abstract. A minimax method for finding multiple critical points in Banach spaces is successfully developed in [X. Yao and J. Zhou, *SIAM J. Sci. Comput.*, 26 (2005), pp. 1796–1809] by using a projected pseudogradient as a search direction. Since several different techniques can be used to compute a projected pseudogradient, the uniform stepsize and the continuity of a search direction, two key properties for the convergence results in [Y. Li and J. Zhou, *SIAM J. Sci. Comput.*, 24 (2002), pp. 865–885], get lost. In this paper, instead of proving convergence results of the algorithm for each technique, unified convergence results are obtained with a weaker stepsize assumption. An abstract existence-convergence result is also established. It is independent of the algorithm and explains why function values always converge faster than their gradients do. The weaker stepsize assumption is then verified for several different cases. As an illustration to the new results, the Banach space $W_0^{1,p}(\Omega)$ is considered and the conditions posed in the new results are verified for a quasi-linear elliptic PDE.

Key words. multiple critical points, Banach space, pseudogradient, convergence, min-orthogonal characterization

1. Introduction. Let B be a Banach space, B^* its topological dual, $\langle , \rangle$ the dual relation, and $\|\cdot\|$ the norm in B. Let $J \in C^1(B, R)$ and $\nabla J \in B^*$ be its (Fréchet) gradient. A point $u^* \in B$ is a critical point of J if u^* solves the Euler–Lagrange equation $\nabla J(u^*) = 0$. The first candidates for a critical point are the local extrema. Traditional numerical algorithms focus on finding such *stable solutions*. Critical points that are not local extrema are *unstable* and called *saddle points*. In physical systems, saddle points appear as *unstable equilibria* or *transient excited states*. Multiple critical points exist in many nonlinear problems in applications (see, e.g., [3, 6, 7, 8, 10, 11]). Choi and McKenna [1] in 1993 and Ding, Costa, and Chen [2] in 1999 devised two algorithms for finding critical points of (the Morse index) MI = 1 and MI = 2, respectively. But no mathematical justification or convergence of the algorithms is established. Based on a local minimax characterization of saddle points, Li and Zhou [4] developed a local minimax algorithm (LMM) for finding critical points of MI $= 1, 2, \ldots, n$ and proved its convergence in [5]. All those algorithms are formulated in Hilbert spaces, where the gradient $\nabla J(u)$ played a key role in constructing a search direction. In order to find multiple solutions in Banach spaces [3, 10], Yao and Zhou successfully developed the first LMM in Banach spaces and solved several quasi-linear elliptic PDEs for multiple solutions [12]. The method is also modified to solve the nonlinear p-Laplacian operator for multiple eigenpairs [13]. The key to the success of Yao and Zhou's algorithm is to replace the gradient with

a projected pseudogradient (PPG). The purpose of this paper is to establish some convergence results for the algorithm.

Compared to those results in Hilbert spaces [5], there are several significant differences. When B is a Hilbert space, the gradient $\nabla J(u)$, which played the key role in constructing a search direction in the LMM in [5], is uniquely determined in B and naturally continuous if J is C^1 and $B = L \oplus L^\perp$ holds for any closed subspace L. When B is a Banach space, however, the gradient $\nabla J(u)$ is in B^*, not B, and cannot be directly used as a search direction in B. Thus a PPG is introduced to the LMM. Although theoretically a Lipschitz continuous PPG flow exists, for most cases no explicit formula is available. On the other hand, there are many different ways to select a PPG. When PPGs are numerically computed in an implementation, they may belong to different PPG flows. We lost the uniform stepsize property and the continuity of a search direction, two key conditions in proving the convergence results in [5]. To make up the first loss, we design a weaker stepsize condition, called Assumption (H), to replace the old uniform stepsize property; to make up the second loss, we generalize the notion of a peak selection to that of an L-$\perp$ selection with which its continuity or smoothness can be verified. Thus corresponding modifications in the LMM [12] have to be made.

To simplify our approach, in this paper we assume $B = L \oplus L'$. When L is finite-dimensional, such an L' always exists. In particular, for the commonly used Banach space $W_0^{1,p}(\Omega)$, we present an explicit formula for obtaining L' and a practical technique to compute a PPG.

Instead of proving convergence results of the algorithm for each of the techniques used to compute a PPG, in this paper we establish some unified convergence results. To do so, in section 2 we generalize a peak selection to an L-$\perp$ selection and prove the existence of a PPG at a value of an L-$\perp$ selection. A new LMM and its mathematical foundation are also presented there. Section 3 is devoted to proving unified convergence results. We introduce a new stepsize assumption, (H), and then prove a subsequence convergence result, Theorem 3.4, under some very reasonable assumptions. An abstract existence-convergence result, Theorem 3.5, is then established. This result is actually independent of any algorithms. It also explains why in our LMM, function values always converge faster than their gradients do. Based on this abstract result, another convergence result, Corollary 3.6, is proved to show that under certain conditions, a convergent subsequence implies a point-to-set convergence. Assumption (H) is then verified for several different cases, in particular, for the commonly used Banach space $W_0^{1,p}(\Omega)$. In the last section, we discuss how to check other conditions we posed in the convergence results. In particular, we present a quasi-linear elliptic PDE and verify those conditions.

2. A min-$\perp$ method. Let L be a closed subspace of B. For a subspace $A \subseteq B$, denote $S_A = \{v \in A \mid \|v\| = 1\}$. For a point $v \in S_B$, let $[L, v] = \{tv + w \mid w \in L, t \in \mathbb{R}\}$. Since $\nabla J(u) \in B^*$, not B, it cannot be used as a search direction in B. Thus a pseudogradient is used instead.

DEFINITION 2.1. *Let $J : B \to \mathbb{R}$ be Fréchet differentiable at $u \in B$ with $\nabla J(u) \neq 0$ and let $0 < \theta \leq 1$ be given. A point $\Psi(u) \in B$ is a* pseudogradient *of J at u w.r.t. θ if*

$$\|\Psi(u)\| \leq 1, \quad \langle \nabla J(u), \Psi(u) \rangle \geq \theta \|\nabla J(u)\|. \tag{2.1}$$

A pseudogradient flow *of J w.r.t. θ is a continuous mapping $\mathcal{F} : B \to B$ such that $\forall u \in B$ with $\nabla J(u) \neq 0$, $\mathcal{F}(u)$ is a pseudogradient of J at u w.r.t. θ.*

In Definition 2.1, the condition $\|\Psi(u)\| \le 1$ is not essential. It can be replaced with any bound $M \ge 1$, since after a normalization, θ can always be replaced with $\frac{\theta}{M}$. It is known [9] that a C^1 functional has a locally Lipschitz continuous pseudogradient flow. Pseudogradients have been used in the literature to find a minimum of a functional in Banach spaces. However, as saddle points are concerned, such pseudogradients do not help much, since they lead to a local minimum point. Thus we introduce a new notion, called a projected pseudogradient (PPG), which plays a key role in the success of our LMM in Banach spaces.

DEFINITION 2.2. *An L'-PPG $G(u)$ of J is a pseudogradient of J at u such that $G(u) \in L'$.*

The motivation for defining a PPG is twofold. First, as a pseudogradient, it provides a proper searching termination criterion, i.e., with (2.1), $G(u) = 0$ implies $\nabla J(u) = 0$. Second, the condition $G(u) \in L'$ is meant to prevent a pseudogradient search from entering the subspace L, which is spanned by previously found critical points. The existence of such an L'-PPG of J at $u = \mathcal{P}(v)$ is established by Lemma 2.1 in [12], where $\mathcal{P}$ is a peak selection defined below.

DEFINITION 2.3 (see [12]). *A set-valued mapping $P : S_{L'} \to 2^B$ is called the* peak mapping *of J w.r.t. L if*

$$P(v) = \Big\{ w = \arg \textit{local-} \max_{u \in [L,v]} J(u) \Big\} \quad \forall v \in S_{L'}.$$

A mapping $\mathcal{P} : S_{L'} \to B$ is called a peak selection *of J w.r.t. L if $\mathcal{P}(v) \in P(v)$ $\forall v \in S_{L'}$. If a* peak selection $\mathcal{P}$ *is* locally *defined near a point $v \in S_{L'}$, we say that J has a* local peak selection $\mathcal{P}$ *at v.*

By using a peak selection and a PPG, an LMM is successfully developed in [12] for computing multiple saddle points in Banach spaces. However, as convergence analysis is concerned, such an algorithm has an ill-condition; i.e., the graph defined by a peak selection is not closed. In other words, a limit of a sequence of local maxima is not necessarily a local maximum point. Consequently, we cannot talk about a limit, or continuity, or do convergence analysis within the context of a peak selection. We introduce a generalized notion.

DEFINITION 2.4. *A set-valued mapping $P : S_{L'} \to 2^B$ is called the L-$\perp$* mapping *of J if*

$$P(v) = \{ u \in [L, v] : \langle \nabla J(u), w \rangle = 0 \ \forall w \in [L, v] \} \quad \forall v \in S_{L'}.$$

A mapping $\mathcal{P} : S_{L'} \to B$ is called an L-$\perp$ selection *of J if $\mathcal{P}(v) \in P(v)$ $\forall v \in S_{L'}$. If an L-$\perp$* selection $\mathcal{P}$ *is* locally *defined near a given $v \in S_{L'}$, we say that J has a* local L-$\perp$ selection $\mathcal{P}$ *at v.*

LEMMA 2.5. *If J is C^1, then the graph $Gr = \{(u, v) : v \in S_{L'},\ u \in P(v) \ne \emptyset\}$ is closed.*

Proof. Let $(u_n, v_n) \in Gr$ and $(u_n, v_n) \to (u_0, v_0)$. We have $u_n \in [L, v_n]$, $\nabla J(u_n) \perp [L, v_n]$. Since $v_n \to v_0 \in S_{L'}$, for each $w \in [L, v_0]$ there are $w_n \in [L, v_n]$ such that $w_n \to w$. Thus $\nabla J(u_n) \perp w_n$. But J is C^1, $u_n \to u_0$ and $w_n \to w$ lead to $\nabla J(u_0) \perp w$, i.e., $\nabla J(u_0) \perp [L, v_0]$. Thus $v_0 \in S_{L'}$ and $u_0 \in P(v_0)$, i.e., $(u_0, v_0) \in Gr$. ∎

It is clear that if $\mathcal{P}$ is a peak selection of J w.r.t. L, then $\mathcal{P}$ is an L-$\perp$ selection of J. The generalization not only removes the ill-condition and makes it possible to check the continuity of $\mathcal{P}$ but also exceeds the scope of a minimax principle, the most popular approach in critical point theory. It enables us to treat nonminimax-type

saddle points, such as the monkey saddles, or a problem without a mountain pass structure; see Example 2.1 in [14]. By a similar argument as in Lemma 2.1 of [12] we can prove the following existence of an L'-PPG.

LEMMA 2.6. *Assume $B = L \oplus L'$ and let $0 < \theta < 1$ be given. For $v_0 \in S_{L'}$, if $\mathcal{P}$ is a local L-$\perp$ selection of J at v_0 such that $\nabla J(\mathcal{P}(v_0)) \neq 0$ and $\Psi(\mathcal{P}(v_0)) \in B$ is a pseudogradient of J at $\mathcal{P}(v_0)$ w.r.t. θ, then there exists an L'-PPG $G(\mathcal{P}(v_0))$ of J at $\mathcal{P}(v_0)$ w.r.t. θ s.t.*

(a) *$G(\mathcal{P}(v_0)) \in L'$, $0 < \|G(\mathcal{P}(v_0))\| \leq M := \|\mathbb{P}\|$, where $\mathbb{P} : B \to L'$ is the linear projection.*
(b) *$\langle \nabla J(\mathcal{P}(v_0)), G(\mathcal{P}(v_0))\rangle = \langle \nabla J(\mathcal{P}(v_0)), \Psi(\mathcal{P}(v_0))\rangle$.*
(c) *If $\Psi(\mathcal{P}(v_0))$ is the value of a pseudogradient flow $\Psi(\cdot)$ of J at $\mathcal{P}(v_0)$, then $G(\cdot)$ is continuous and $G(\mathcal{P}(v_0))$ is called the value of an L'-PPG flow of J at $\mathcal{P}(v_0)$.*

We now establish some mathematical foundations for our new algorithm.

LEMMA 2.7 (see [12]).

$$\left\| v - \frac{v-w}{\|v-w\|} \right\| \leq \frac{2\|w\|}{\|v-w\|} \quad \forall v \in B,\ \|v\| = 1,\ \forall w \in B.$$

LEMMA 2.8. *For $v_0 \in S_{L'}$, if J has a local L-$\perp$ selection $\mathcal{P}$ at v_0 satisfying (1) $\mathcal{P}$ is continuous at v_0, (2) $d(\mathcal{P}(v_0), L) > 0$, and (3) $\nabla J(\mathcal{P}(v_0)) \neq 0$, then there exists $s_0 > 0$ such that for $0 < s < s_0$*

$$J(\mathcal{P}(v_0(s))) - J(\mathcal{P}(v_0)) < -\frac{\theta s}{4}|t_0|\|\nabla J(\mathcal{P}(v_0))\|, \tag{2.2}$$

where $\mathcal{P}(v_0) = t_0 v_0 + w_0$ for some

$$t_0 \in \mathbb{R}, \quad w_0 \in L, \quad v_0(s) = \frac{v_0 - sign(t_0) s G(\mathcal{P}(v_0))}{\|v_0 - sign(t_0) s G(\mathcal{P}(v_0))\|},$$

and $G(\mathcal{P}(v_0))$ is an L'-PPG of J w.r.t. θ at $\mathcal{P}(v_0)$.

The proof of Lemma 2.8 can follow a similar argument of Lemma 2.4 in [12]. The inequality (2.2) will be used to define a stepsize rule for the algorithm and establish convergence results. With Lemma 2.8, the following characterization of saddle points is clear.

THEOREM 2.9. *Let $v_0 \in S_{L'}$. Assume that J has a local L-$\perp$ selection $\mathcal{P}$ at v_0 such that (1) $\mathcal{P}$ is continuous at v_0, (2) $d(\mathcal{P}(v_0), L) > 0$, and (3) v_0 is a local minimum point of $J(\mathcal{P}(v))$. Then $\mathcal{P}(v_0)$ is a critical point of J.*

2.1. A min-orthogonal algorithm.

DEFINITION 2.10. *Let $v_0 \in S_{L'}$ and $\mathcal{P}$ be a local L-$\perp$ selection of J at v_0 with $\nabla J(\mathcal{P}(v_0)) \neq 0$. A point $w \in L'$ is a* descent direction *of $J(\mathcal{P}(\cdot))$ at v_0 if there is $s_0 > 0$ such that*

$$J(\mathcal{P}(v_0(s))) < J(\mathcal{P}(v_0)) \quad \forall\, 0 < s < s_0, \quad \text{where} \quad v_0(s) = \frac{v_0 + sw}{\|v_0 + sw\|}.$$

By Theorem 2.9, a descent direction method to approximate a local minimum of $J(\mathcal{P}(v))$ leads to the following min-$\perp$ algorithm.

Assume that $L = [u^1, u^2, \ldots, u^{n-1}]$, where $u^1, u^2, \ldots, u^{n-1}$ are $n-1$ previously found critical points of J and L' is a subspace of B such that $B = L \oplus L'$. For given positive numbers $\lambda, \theta \in (0,1)$ and ε.

Step 1: Let $v_1 \in S_{L'}$ be an ascent-descent direction at u^{n-1}.

Step 2: Set $k = 1$. Solve for $u_k \equiv \mathcal{P}(v_k) \equiv t_0^k v_k + t_1^k u^1 + \cdots + t_{n-1}^k u^{n-1}$ such that $t_0^k > 0$,

$$\langle \nabla J(\mathcal{P}(v_k)), v_k \rangle = 0 \quad \text{and} \quad \langle \nabla J(\mathcal{P}(v_k)), u^i \rangle = 0, \quad i = 1, 2, \ldots, n-1.$$

Step 3: Find a descent direction $w_k \in L'$ of $J(\mathcal{P}(\cdot))$ at v_k.

Step 4: If $\|\nabla J(u_k)\| \le \varepsilon$, then output $u_k = \mathcal{P}(v_k)$, stop. Otherwise, do Step 5.

Step 5: For each $s > 0$, denote

$$v_k(s) = \frac{v_k + s w_k}{\|v_k + s w_k\|}$$

and set $v_{k+1} = v_k(s_k)$, where

$$s_k = \max_{m \in \mathbb{N}} \left\{ \frac{\lambda}{2^m} \;\middle|\; 2^m > \|w_k\|,\ J\left(\mathcal{P}\left(v_k\left(\frac{\lambda}{2^m}\right)\right)\right) - J(u_k) < -\frac{\theta |t_0^k|}{4}\left(\frac{\lambda}{2^m}\right)\|\nabla J(u_k)\| \right\}.$$

Step 6: Update $k = k + 1$ and go to Step 3.

Remark 2.1.

(1) The constant $\lambda \in (0, 1)$ is used to prevent the stepsize from being too large to lose search stability. From now on we always assume that λ is such a constant.

(2) In Step 2, one way to solve the equations while satisfying the nondegenerate condition $t_0^k > 0$ is to find a local maximum point u_k of J in the subspace $[L, v_k]$, i.e., $u_k = \mathcal{P}(v_k)$ and $\mathcal{P}$ is a peak selection of J w.r.t. L.

(3) In Step 3, we may assume $\|w_k\| \le M$ for some $M \ge 1$. There are many different ways to select a descent direction w_k. However, when a descent direction is selected, a corresponding stepsize rule in Step 5 has to be designed so that it can be achieved and lead to a convergence. For example, when a negative L'-PPG flow, or a negative L'-PPG, is used as a descent direction, we have $v_k \in S_{L'}$, and a positive stepsize s_k for the current stepsize rule in Step 5 can always be obtained. In some cases, when $-\nabla J(\mathcal{P}(v_k))$ is used to construct a descent direction, the stepsize rule in Step 5 has to be modified as in Case 3 below.

3. Unified convergence results.

DEFINITION 3.1. *For each $v \in S_{L'}$ with $\|\nabla J(\mathcal{P}(v))\| \ne 0$, write $\mathcal{P}(v) = t_v v + v_L$ for some $v_L \in L$ and define the stepsize $s(v)$ at v as*

$$s(v) = \max_{m \in \mathbb{N}} \left\{ s = \frac{\lambda}{2^m} \;\middle|\; 2^m > \|w\|,\ J(\mathcal{P}(v(s))) - J(\mathcal{P}(v)) < -\frac{1}{4}\theta |t_v| s \|\nabla J(\mathcal{P}(v))\| \right\},$$

where w is a descent direction J at $\mathcal{P}(v)$ and

$$v(s) = \frac{v + sw}{\|v + sw\|}.$$

Let $\{u_k\}$ be the sequence generated by the algorithm, where $u_k = \mathcal{P}(v_k)$. Since a PPG can be computed many different ways, we lost the uniform stepsize, one of the key conditions in [5]. Here we design a new stepsize assumption, (H), to establish unified convergence results. This condition is weaker than the uniform stepsize assumption in [5] and will be verified for several different cases.

Assumption (H). If $v_0 \in S_{L'}$ with $\nabla J(\mathcal{P}(v_0)) \neq 0$ and $v_k \to v_0$, then there is $s_0 > 0$ such that $s_k = s(v_k) \geq s_0$ when k is large.

We need the following Palais–Smale (PS) condition and Ekeland's variational principle [10].

DEFINITION 3.2. *A function $J \in C^1(B, \mathbb{R})$ is said to satisfy the PS condition if any sequence $\{u_i\} \subset B$ such that $\{J(u_i)\}$ is bounded and $\nabla J(u_i) \to 0$ possesses a convergent subsequence.*

LEMMA 3.3 (Ekeland's variational principle). *Let X be a complete metric space and $J : X \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function bounded from below. Then, for any $\varepsilon > 0$ and $x_0 \in X$ with $J(x_0) < +\infty$, there is $\bar{x} \in X$ such that*

$$J(\bar{x}) + \varepsilon d(x_0, \bar{x}) \leq J(x_0) \text{ and } J(x) + \varepsilon d(x, \bar{x}) > J(\bar{x}) \quad \forall x \in X \text{ and } x \neq \bar{x}.$$

First, we prove a subsequence convergence result, the conditions of which will be verified with an application problem in section 4.

THEOREM 3.4. *Let $J \in C^1(B, \mathbb{R})$ satisfy the PS condition. If an L-$\perp$ selection $\mathcal{P}$ of J satisfies that*

(1) *$\mathcal{P}$ is continuous on $S_{L'}$,*
(2) *$d(\mathcal{P}(v_k), L) \geq \alpha > 0$ $\forall k = 1, 2, \ldots,$*
(3) *$\inf_{1 \leq k < \infty} J(\mathcal{P}(v_k)) > -\infty$,*
(4) *Assumption* (H) *is satisfied,*

then

(a) *$\{v_k\}$ has a subsequence $\{v_{k_i}\}$ such that $u_{k_i} = \mathcal{P}(v_{k_i})$ converges to a critical point of J;*
(b) *if a subsequence $v_{k_i} \to v_0$ as $i \to \infty$, then $u_0 = \mathcal{P}(v_0)$ is a critical point of J.*

Proof. (a) By the stepsize rule and Lemma 2.7, for $k = 1, 2, \ldots,$ we have

$$\begin{aligned} J(u_{k+1}) - J(u_k) &\leq -\frac{1}{4}\theta\alpha s_k \|\nabla J(\mathcal{P}(v_k))\| \\ &\leq -\frac{|1-\lambda|}{4M}\theta\alpha \|v_{k+1} - v_k\| \|\nabla J(\mathcal{P}(v_k))\|. \end{aligned} \tag{3.1}$$

Suppose there is $\delta > 0$ such that $\|\nabla J(\mathcal{P}(v_k))\| \geq \delta$ for any k. From (3.1), we have

$$J(u_{k+1}) - J(u_k) \leq -\frac{|1-\lambda|}{4M}\theta\alpha\delta \|v_{k+1} - v_k\| \quad \forall k = 0, 1, 2, \ldots. \tag{3.2}$$

Adding up the two sides of (3.2) gives

$$\lim_{k\to\infty} J(u_k) - J(u_0) = \sum_{k=0}^{\infty} [J(u_{k+1}) - J(u_k)] \leq -\frac{|1-\lambda|}{4M}\theta\alpha\delta \sum_{k=0}^{\infty} \|v_{k+1} - v_k\|; \tag{3.3}$$

i.e., $\{v_k\}$ is a Cauchy sequence. Thus $v_k \to \hat{v} \in S_{L'}$. By the continuity of $\mathcal{P}$, $\|\nabla J(\mathcal{P}(\hat{v}))\| \geq \delta > 0$. On the other hand, adding up the two sides of (3.1) gives

$$\lim_{k\to\infty} J(u_k) - J(u_0) \leq -\frac{1}{4}\theta\alpha \sum_{k=0}^{\infty} s_k \|\nabla J(\mathcal{P}(v_k))\| \leq -\frac{1}{4}\theta\alpha\delta \sum_{k=0}^{\infty} s_k,$$

or $s_k \to 0$ as $k \to \infty$. It contradicts Assumption (H). Therefore, there is a subsequence $\{v_{k_i}\}$ such that $\|\nabla J(\mathcal{P}(v_{k_i}))\| \to 0$ as $i \to \infty$ and $\{J(\mathcal{P}(v_{k_i}))\}$ is convergent. By the PS condition, $\{\mathcal{P}(v_{k_i})\}$ has a subsequence that converges to a critical point u_0.

(b) Suppose $u_0 = \mathcal{P}(v_0)$ is not a critical point. Then there is $\delta > 0$ such that $\|\nabla J(u_{k_i})\| > \delta$, $i = 1, 2, \ldots$. Similar to (3.1), we have

$$J(u_{k_i+1}) - J(u_{k_i}) \le -\frac{1}{4}\theta\alpha s_{k_i}\|\nabla J(u_{k_i})\| < -\frac{1}{4}\theta\alpha\delta s_{k_i}.$$

Since $\sum_{k=0}^{\infty}[J(u_{k+1}) - J(u_k)] = \lim_{k\to\infty} J(u_k) - J(u_0)$, it leads to $\lim_{i\to\infty}(J(u_{k_i+1}) - J(u_{k_i})) = 0$. Hence $\lim_{i\to\infty} s_{k_i} = 0$. It contradicts Assumption (H). Thus u_0 is a critical point. ∎

Next we prove an abstract existence-convergence result that is actually independent of the algorithm and also explains why function values always converge faster than the gradients do. Denote $K_c = \{u \in B \mid \nabla J(u) = 0,\ J(u) = c\}$. By the PS condition, K_c is compact.

THEOREM 3.5. *Let $B = L \oplus L'$, $V \subset B$ be open, and $U = V \cap S_{L'} \neq \emptyset$. Assume that $J \in C^1(B, \mathbb{R})$ satisfies the PS condition and*

(1) *$\mathcal{P}$ is a continuous L-$\perp$ selection of J in $\bar{U}$, where $\bar{U}$ is the closure of U on $S_{L'}$.*
(2) *$\inf_{v\in U} d(\mathcal{P}(v), L) > \alpha > 0$.*
(3) *$\inf_{v\in\partial\bar{U}} J(\mathcal{P}(v)) > c = \inf_{v\in U} J(\mathcal{P}(v)) > -\infty$, where $\partial\bar{U}$ is the boundary of $\bar{U}$ on $S_{L'}$.*

Then $K_c^p = \mathcal{P}(U) \cap K_c \neq \emptyset$, and for any $\{v_k\} \subset U$ with $J(u_k) \to c$, where $u_k = \mathcal{P}(v_k)$,

(a) *$\forall \varepsilon > 0$, there is $\bar{k} > 0$ such that $d(K_c^p, u_k) < \varepsilon$ $\forall k > \bar{k}$.*
(b) *if in addition, $\nabla J(\mathcal{P}(\cdot))$ is Lipschitz continuous in U, then there is a constant C such that $\|\nabla J(u_k)\| \le C(J(u_k) - c)^{\frac{1}{2}}$.*

Proof. Define

$$\hat{J}(\mathcal{P}(v)) = \begin{cases} J(\mathcal{P}(v)), & v \in \bar{U}, \\ +\infty, & v \notin \bar{U}. \end{cases}$$

Then, $\hat{J}(\mathcal{P}(\cdot))$ is lower semicontinuous and bounded from below on the complete metric space $S_{L'}$. Let $\{v_k\} \subset U$ be any sequence such that $J(\mathcal{P}(v_k)) \to c$. By our assumption (3), such a sequence always exists. Denote $u_k = \mathcal{P}(v_k)$. Applying Ekeland's variational principle to $\hat{J}(\mathcal{P}(\cdot))$, for every $v_k \in U$ and $\delta_k = (J(u_k) - c)^{\frac{1}{2}}$ there is $\bar{v}_k \in S_{L'}$ such that

$$\hat{J}(\mathcal{P}(\bar{v}_k)) - \hat{J}(\mathcal{P}(v)) \le \delta_k\|\bar{v}_k - v\| \qquad \forall v \in S_{L'}, \tag{3.4}$$

$$\hat{J}(\mathcal{P}(\bar{v}_k)) - \hat{J}(\mathcal{P}(v_k)) \le -\delta_k\|\bar{v}_k - v_k\|. \tag{3.5}$$

By the definition of $\hat{J}(\mathcal{P}(\cdot))$ and assumptions on $\mathcal{P}$, we have $\bar{v}_k \in \bar{U}$,

$$J(\mathcal{P}(\bar{v}_k)) - J(\mathcal{P}(v)) \le \delta_k\|\bar{v}_k - v\| \qquad \forall v \in U, \tag{3.6}$$

$$J(\mathcal{P}(\bar{v}_k)) - J(\mathcal{P}(v_k)) \le -\delta_k\|\bar{v}_k - v_k\|. \tag{3.7}$$

It follows that $c \le J(\mathcal{P}(\bar{v_k})) \le J(u_k) - \delta_k\|\bar{v_k} - v_k\|$, or

$$\|\bar{v}_k - v_k\| \le \delta_k, \tag{3.8}$$

and $d(L, \mathcal{P}(\bar{v}_k)) > \alpha$ when k is large. Then $J(\mathcal{P}(v_k)) \to c$ implies $J(\mathcal{P}(\bar{v}_k)) \to c$. By assumption (3), we have $\bar{v}_k \in U$ for large k. For those large k, if $\nabla J(\mathcal{P}(\bar{v}_k)) \neq 0$, by applying Lemma 2.8 and then Lemma 2.7, when s is small, we have

$$J(\mathcal{P}(\bar{v}_k(s))) - J(\mathcal{P}(\bar{v}_k)) \le -\frac{\theta s}{4}|t_0^k|\|\nabla J(\mathcal{P}(\bar{v}_k))\| \le -\frac{\alpha\theta}{8M}\|\nabla J(\mathcal{P}(\bar{v}_k))\|\|\bar{v}_k(s) - \bar{v}_k\|,$$

where $\bar{v}_k(s) = \frac{\bar{v}_k + s\bar{w}_k}{\|\bar{v}_k + s\bar{w}_k\|} \in U$, $\bar{w}_k = -\,sign(t_0^k) G(\mathcal{P}(\bar{v}_k))$, $\mathcal{P}(\bar{v}_k) = t_0^k \bar{v}_k + u_L^k$ for some $u_L^k \in L$, $G(\mathcal{P}(\bar{v}_k))$ is an L'-PPG of J at $\mathcal{P}(\bar{v}_k)$ with $\|G(\mathcal{P}(\bar{v}_k))\| \le M$; see Lemma 2.6 and $|t_0^k| > \alpha$ by our assumption (2). Hence by (3.6), we get

$$\|\nabla J(\mathcal{P}(\bar{v}_k))\| \le \frac{8M}{\alpha\theta}\delta_k, \tag{3.9}$$

which implies $\nabla J(\mathcal{P}(\bar{v}_k)) \to 0$ and then $\nabla J(\mathcal{P}(v_k)) \to 0$ by (3.8). $\{J(\mathcal{P}(v_k))\}$ is already bounded. By the PS condition, $\{u_k\}$ has a subsequence that converges to a critical point u^*. By assumptions (3) and (1), it is clear that $u^* \in K_c^p \neq \emptyset$. Let β be any limit point of $\{d(K_c^p, u_k)\}$ and $u_{k_i} = \mathcal{P}(v_{k_i}) \in \{u_k\}$ such that $\lim_{i\to\infty} d(K_c^p, u_{k_i}) = \beta$. By the PS condition, $\{\mathcal{P}(v_{k_i})\}$ has a subsequence that converges to a critical point $\bar{u}$. Again $\bar{u} \in K_c^p$, i.e., $\beta = 0$. Thus conclusion (a) holds.

If in addition, $\nabla J(\mathcal{P}(\cdot))$ is Lipschitz continuous in U with a Lipschitz constant ℓ_1, then by (3.8) and (3.9), conclusion (b) follows from

$$\begin{aligned}\|\nabla J(\mathcal{P}(v_k))\| &\le \|\nabla J(\mathcal{P}(\bar{v}_k))\| + \|\nabla J(\mathcal{P}(v_k)) - \nabla J(\mathcal{P}(\bar{v}_k))\| \\ &\le \frac{16M}{\alpha\theta}\delta_k + \ell_1\|\bar{v}_k - v_k\| \le \left(\frac{16M}{\alpha\theta} + \ell_1\right)(J(u_k) - c)^{\frac{1}{2}}. \qquad \square\end{aligned}$$

COROLLARY 3.6. *Let $J \in C^1(B, \mathbb{R})$ satisfy the PS condition, and let V_1 and V_2 be open in L' with $\emptyset \neq U_2 \equiv V_2 \cap S_{L'} \subset V_1 \cap S_{L'} \equiv U_1$. If $\mathcal{P}$ is a continuous L-$\perp$ selection of J in U_1 with*

(1) $\inf_{v\in U_1} d(\mathcal{P}(v), L) \ge \alpha > 0$, $c = \inf_{v\in U_1} J(\mathcal{P}(v)) > -\infty$, *and* $K_c^p = \mathcal{P}(U_1) \cap K \subset K_c$,
(2) *a* $d > 0$ *with* $\inf_{v\in U_1}\{J(\mathcal{P}(v)) \mid d(v, \partial U_1) \le d\} = a > b = \sup_{v\in U_2}\{J(\mathcal{P}(v))\}$,
(3) *given* $\{v_k\}$ *such that* $v_1 \in U_2$, $\|v_{k+1} - v_k\| < d$, $J(u_{k+1}) < J(u_k)$ *and* $\{u_k\}$ *has a subsequence that converges to a critical point* u_0, *where* $u_k = \mathcal{P}(v_k)$,

then

(a) $\forall \varepsilon > 0$, *there is* $\bar{k} > 0$ *such that* $d(K_c^p, u_k) < \varepsilon$ $\forall k > \bar{k}$,
(b) *if in addition,* $\nabla J(\mathcal{P}(\cdot))$ *is Lipschitz continuous in* U_1, *then there is a constant* C *such that* $\|\nabla J(u_k)\| \le C(J(u_k) - c)^{\frac{1}{2}}$.

Proof. First, we prove that $v_k \in U_1$ and $d(v_k, \partial U_1) > d$, $k = 1, 2, \ldots$. In fact, if $v_k \in U_1$, $d(v_k, \partial U_1) > d$, and $J(u_k) \le b$, then $v_{k+1} \in U_1$ and $J(u_{k+1}) < b$, i.e., $v_{k+1} \in U_1$ and $d(v_{k+1}, \partial U_1) > d$. Thus, for $v_1 \in U_2$, $v_k \in U_1$ and $d(v_k, \partial U_1) > d$, $k = 1, 2, \ldots$. Since $K_c^p = \mathcal{P}(U_1) \cap K \subset K_c$ and $\{u_k\}$ has a subsequence that converges to a critical point u_0, we have $u_0 \in K_c^p \neq \emptyset$. Denote $U = \{v \in U_1 \mid d(v, \partial U_1) > d\}$. Then by the monotonicity of $\{J(u_k)\}$, we have $J(u_k) \to c = \inf_{v\in U} J(\mathcal{P}(v))$ as $k \to \infty$, and

$$\inf_{v\in\partial\bar{U}} J(\mathcal{P}(v)) \ge a > b \ge J(\mathcal{P}(v_1)) \ge c = \inf_{v\in U} J(\mathcal{P}(v)).$$

Thus all the assumptions of Theorem 3.5 are satisfied and the conclusions follow. $\square$

Remark 3.1. There are two types of conditions posed in our convergence results. One is used in the literature to guarantee the existence of multiple solutions. The other is what we posed to ensure a convergence for the algorithm. We will focus on verification of the latter.

(1) In Theorem 3.5, condition (3) can be simplified as $c = \inf_{v\in S_{L'}} J(\mathcal{P}(v)) > -\infty$ if $U = S_{L'}$.

(2) In Corollary 3.6, condition (2) is, or its variants are, frequently used in the literature to form a topological linking for applying a deformation lemma to prove an existence of multiple solutions. It is clear that condition (3) in Theorem 3.5 is much weaker. It is used to trap a descending flow away from critical points at other levels. Condition (3) in Corollary 3.6 is designed for our algorithm to cover several different cases in Banach spaces and is guaranteed by our Assumption (H) and Theorem 3.4.

(3) Note that when K_c^p contains only one point, Theorem 3.5 can be easily stated as a point-to-point convergence result. Theorem 3.5, together with its Corollary 3.6, improves a convergence result, Theorem 3.3 in [5], in Hilbert space in several directions, which (a) cover several different cases in Banach spaces, (b) do not require $\mathcal{P}$ to be a homeomorphism, and (c) contain a new result on relative convergence rate, i.e., inequality (2), which explains why in our numerical computations, $J(\mathcal{P}(v_n^k))$ always converges much faster than $\|\nabla J(\mathcal{P}(v_n^k))\| \to 0$.

Next we verify Assumption (H) for several different cases. This is done in Lemmas 3.8, 3.9, 3.11, and 3.12 below. Cases 1 and 2 are general, so we assume $B = L \oplus L'$, where L' is a closed subspace of B and $\mathbb{P} : B \to L'$ is the corresponding projection. In Step 3 of the algorithm, we choose $w_k = -\,sign(t_0)G(\mathcal{P}(v_k))$, where G is either an L'-PPG of J or the value of an L'-PPG flow of J. Then $\|w_k\| \le M = \|\mathbb{P}\|$. By Lemma 2.8 we obtain the following.

LEMMA 3.7. *If $\mathcal{P}$ is a local L-$\perp$ selection of J at $v \in S_{L'}$ such that* (1) *$\mathcal{P}$ is continuous at v,* (2) *$d(\mathcal{P}(v), L) > 0$, and* (3) *$\nabla J(\mathcal{P}(v)) \neq 0$, then $s(v) > 0$.*

Case 1. Use the value of a negative PPG flow G as a descent direction.

Here $G(\mathcal{P}(v_k))$ is the value of an L'-PPG flow of J at $\mathcal{P}(v_k) = t_0^k v_k + v_k^L$ for some $v_k^L \in L$.

LEMMA 3.8. *If $\mathcal{P}$ is a local L-$\perp$ selection of J at $v_0 \in S_{L'}$ such that* (1) *$\mathcal{P}$ is continuous at v_0,* (2) *$d(\mathcal{P}(v_0), L) > 0$, and* (3) *$\nabla J(\mathcal{P}(v_0)) \neq 0$, then there exist $\varepsilon > 0$ and $s_0 = \frac{\lambda}{2^m}$ for some integer m such that for each $v \in S_{L'}$ with $\|v - v_0\| < \varepsilon$, $\lambda \ge s_0\|G(\mathcal{P}(v))\|$ and*

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) < -\frac{s_0\theta|t_v|}{4}\|\nabla J(\mathcal{P}(v))\|, \quad v(s_0) = \frac{v + sign(t_v)s_0 G(\mathcal{P}(v))}{\|v + sign(t_v)s_0 G(\mathcal{P}(v))\|},$$

$\mathcal{P}(v) = t_v v + w_v$ for some $w_v \in L$, and $G(\mathcal{P}(v))$ is the value of an L'-PPG flow of J at $\mathcal{P}(v)$ w.r.t. the constant θ.

Proof. By Lemma 2.8, there is $\bar{s} > 0$ such that as $0 < s < \bar{s}$,

$$J(\mathcal{P}(v_0(s))) - J(\mathcal{P}(v_0)) < -\frac{s\theta|t_0|}{4}\|\nabla J(\mathcal{P}(v_0))\|, \tag{3.10}$$

where

$$v_0(s) = \frac{v_0 - sign(t_0)sG(\mathcal{P}(v_0))}{\|v_0 - sign(t_0)sG(\mathcal{P}(v_0))\|}, \quad \mathcal{P}(v_0) = t_0 v_0 + w_0$$

for some $w_0 \in L$. Actually, for each fixed s, the two sides of (3.10) are continuous in v_0. Thus, there are $\varepsilon > 0$, $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda \ge s_0\|G(\mathcal{P}(v))\|$ and

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) < -\frac{s_0\theta|t_v|}{4}\|\nabla J(\mathcal{P}(v))\|$$

$\forall v \in S_{L'}$ with $\|v - v_0\| \le \varepsilon$. ∎

Case 2. Use a negative PPG G as a descent direction.

Here $G(\mathcal{P}(v_k))$ is an L'-PPG of J at $\mathcal{P}(v_k) = t_0^k v_k + v_k^L$ for some $v_k^L \in L$. Since an L'-PPG may be chosen from different L'-PPG flows, we lost the continuity. To compensate for the loss, we assume that an L-$\perp$ selection $\mathcal{P}$ of J is locally Lipschitz continuous.

LEMMA 3.9. *Let $\mathcal{P}$ be a local L-$\perp$ selection of J at $v_0 \in S_{L'}$. If (1) $\mathcal{P}$ is Lipschitz continuous in a neighborhood of v_0, (2) $d(\mathcal{P}(v_0), L) > 0$, and (3) $\nabla J(\mathcal{P}(v_0)) \neq 0$, then there are $\varepsilon > 0$ and $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda \ge s_0 \|G(\mathcal{P}(v))\|$ and*

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) < -\frac{1}{4} s_0 \theta |t_v| \|\nabla J(\mathcal{P}(v))\|$$

$\forall v \in S_{L'}$ with $\|v - v_0\| < \varepsilon$, where

$$v(s) = \frac{v - sign(t_v) s G(\mathcal{P}(v))}{\|v - sign(t_v) s G(\mathcal{P}(v))\|},\ s > 0, \quad \mathcal{P}(v) = t_v v + w_v \text{ for some } w_v \in L,$$

and $G(\mathcal{P}(v))$ is an L'-PPG of J at $\mathcal{P}(v)$ w.r.t. the constant θ.

Proof. First, denote $\mathcal{P}(v(s)) = t_v^s v(s) + w_v(s)$ for some $w_v(s) \in L$. We have

$$\begin{aligned} &J(\mathcal{P}(v(s))) - J(\mathcal{P}(v)) \\ &\quad = \langle \nabla J(\mathcal{P}(v)) + (\nabla J(\zeta(v,s)) - \nabla J(\mathcal{P}(v))),\, \mathcal{P}(v(s)) - \mathcal{P}(v) \rangle, \end{aligned} \tag{3.11}$$

where $\zeta(v,s) = (1-\eta)\mathcal{P}(v) + \eta \mathcal{P}(v(s))$ for some $\eta \in [0,1]$. By assumption (1) and Lemma 2.7, as s is small and for any v close to v_0,

$$\|\mathcal{P}(v(s)) - \mathcal{P}(v)\| \le \ell \|v(s) - v\| \le \frac{2\ell s \|G(\mathcal{P}(v))\|}{\|v - sign(t_v) s G(\mathcal{P}(v))\|} \le 4\ell M s. \tag{3.12}$$

On the other hand, by the definition of an L-$\perp$ selection of J, we have

$$\begin{aligned} \langle \nabla J(\mathcal{P}(v)), \mathcal{P}(v(s)) - \mathcal{P}(v) \rangle &= -\frac{sign(t_v) t_v^s s \langle \nabla J(\mathcal{P}(v)), G(\mathcal{P}(v)) \rangle}{\|v - sign(t_v) s G(\mathcal{P}(v))\|} \\ &= -\frac{|t_v^s| s \langle \nabla J(\mathcal{P}(v)), \Psi(\mathcal{P}(v)) \rangle}{\|v - sign(t_v) s G(\mathcal{P}(v))\|} \le -\frac{s\theta |t_v| \|\nabla J(\mathcal{P}(v))\|}{2} < 0 \end{aligned} \tag{3.13}$$

and

$$\begin{aligned} &|\langle \nabla J(\zeta(v,s)) - \nabla J(\mathcal{P}(v)),\, \mathcal{P}(v(s)) - \mathcal{P}(v) \rangle| \\ &\quad \le \|\nabla J(\zeta(v,s)) - \nabla J(\mathcal{P}(v))\|\, \|\mathcal{P}(v(s)) - \mathcal{P}(v)\| \le \frac{s\theta |t_v| \|\nabla J(\mathcal{P}(v))\|}{4}, \end{aligned} \tag{3.14}$$

where in the last inequality, since J is C^1 and by assumptions (2) and (3), we have

$$\|\nabla J(\zeta(v,s)) - \nabla J(\mathcal{P}(v))\| \le \frac{\theta |t_v| \|\nabla J(\mathcal{P}(v))\|}{16 \ell M}. \tag{3.15}$$

By (3.11) and the boundedness of L'-PPGs, there exist $\varepsilon > 0$ and $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda \ge s_0 \|G(\mathcal{P}(v))\|$ and

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) \le -\frac{s_0 \theta |t_v| \|\nabla J(\mathcal{P}(v))\|}{4} \quad \forall v \in S_{L'} \text{ with } \|v - v_0\| < \varepsilon. \quad ∎$$

Case 3. Use a practical technique for a descent direction in $B = W_0^{1,p}(\Omega)$.

Let $B = W_0^{1,p}(\Omega)$ where $\Omega \subset \mathbb{R}^n$ is open and bounded, $p > 1$, $B^* = W^{-1,q}(\Omega)$ with $\frac{1}{p} + \frac{1}{q} = 1$. The usual gradient $\delta J(u) \in B^* = W^{-1,q}(\Omega)$ cannot be used as a search direction. Thus $d = \Delta_p^{-1}(\delta J(u)) \in B$ has been used in the literature as a descent direction to find a local minimum of $J : B \to \mathbb{R}$, where Δ_p is the p-Laplacian operator defined in (4.1) and Δ_p^{-1} is its inverse. It leads to solving a sequence of quasi-linear elliptic equations $\Delta_p d_k = \delta J(u_k)$. But such a d is not a PPG and does not help much in finding a saddle point. A practical technique is used in [12] for numerical implementation to compute a PPG. The results are very promising. Here we wish to provide some mathematical justification. This technique is based on the understanding that when a nice smooth initial guess v_0 is used, we may expect that "nice" functions are actually used to approximate a critical point. Let $\mathcal{P}$ be an L-$\perp$ selection of J. For $v \in S_{L'}$, $u = \mathcal{P}(v)$, by the definition of $\mathcal{P}$, $\delta J(u) \perp L$. But $\delta J(u) \in W^{-1,q}(\Omega)$, and its smoothness is poor. We first lift its smoothness by computing $d := \nabla J(u) = \Delta^{-1}(-\delta J(u)) \in W_0^{1,q}(\Omega)$, i.e., $d_k = \nabla J(u_k)$ is solved from

$$\Delta d_k(x) = -\delta J(u_k)(x),\ x \in \Omega, \quad d_k(x)|_{\partial\Omega} = 0.$$

Observe that notationally for any $w \in B$,

$$\begin{aligned}\langle d, w\rangle_{W_0^{1,q}\times W_0^{1,p}} &\equiv \langle \nabla d, \nabla w\rangle_{L^q\times L^p} \equiv \int_\Omega \nabla d(x)\cdot\nabla w(x)\,dx \\ &= \int_\Omega -\Delta d(x) w(x)\,dx = \int_\Omega \delta J(u)(x) w(x)\,dx \equiv \langle \delta J(u), w\rangle_{W^{-1,q}\times W_0^{1,p}}.\end{aligned}$$

This suggests that $d = \nabla J(u)$ be used as a gradient of J at u. In particular when $u = \mathcal{P}(v)$,

$$\langle \nabla J(u), w\rangle_{W_0^{1,q}\times W_0^{1,p}} = \langle \delta J(u), w\rangle_{W^{-1,q}\times W_0^{1,p}} = 0 \quad \forall w \in [L, v], \tag{3.16}$$

or $\nabla J(u) \perp [L, v]$. This suggests a natural way to choose L'. We will discuss it later. Since

$$\begin{aligned}\|\delta J(u)\|_{W^{-1,q}} &= \sup_{\|w\|_{W_0^{1,p}}=1} \langle \delta J(u), w\rangle_{W^{-1,q}\times W_0^{1,p}} \\ &= \sup_{\|w\|_{W_0^{1,p}}=1} \langle d, w\rangle_{W_0^{1,q}\times W_0^{1,p}} = \sup_{\|\nabla w\|_{L^p}=1} |\langle \nabla d, \nabla w\rangle_{L^q\times L^p}| \le \|d\|_{W_0^{1,q}},\end{aligned} \tag{3.17}$$

the PS condition of J in terms of δJ implies the PS condition of J in terms of ∇J. In our convergence analysis of the algorithm, the first order approximation contains a term

$$\begin{aligned}\langle \delta J(v_0), \nabla J(v_0)\rangle_{W^{-1,q}\times W_0^{1,p}} &= \int_\Omega \delta J(v_0)\nabla J(v_0)\,dx \\ &= \int_\Omega -\Delta(\nabla J(v_0))\nabla J(v_0)\,dx = \int_\Omega \nabla(\nabla J(v_0))\cdot\nabla(\nabla J(v_0))\,dx = \|\nabla J(v_0)\|_{W^{1,2}}^2,\end{aligned}$$

which will be used to design a new stepsize rule. Next we let $u_k = \mathcal{P}(v_k)$ and check the ratio

$$1 \ge \theta_k \equiv \frac{\|\nabla J(u_k)\|_2^2}{\|\nabla J(u_k)\|_q \|\nabla J(u_k)\|_p} \ge \theta > 0 \quad \forall k = 1, 2, \ldots, \tag{3.18}$$

where $\|\cdot\|_r$ is the norm in $W_0^{1,r}(\Omega)$ with $r > 1$. Let

$$G(u_k) = \frac{\nabla J(u_k)}{\|\nabla J(u_k)\|_p}.$$

We have $\|G(u_k)\|_p \le M = 1$ and

$$\begin{aligned}\langle \delta J(u_k), G(u_k)\rangle &= \frac{\|\nabla J(u_k)\|_2^2}{\|\nabla J(u_k)\|_p} = \theta_k \|\nabla J(u_k)\|_q \\ &\ge \theta_k \|\delta J(u_k)\|_{W^{-1,q}} \ge \theta \|\delta J(u_k)\|_{W^{-1,q}},\end{aligned}$$

where the last inequality holds if (3.18) is satisfied, i.e., $G(u_k)$ is a pseudogradient of J at u_k. Then (3.16) suggests that $G(u_k)$ is also an L'-PPG of J at $u_k = \mathcal{P}(v_k)$ if $L' = L^\perp$, where $L^\perp$ is given in (3.19), $L = [w_1, \dots, w_{n-1}]$, and $w_1, \dots, w_{n-1}$ are linearly independent. To show $B = L \oplus L^\perp$, we need further assume that when $1 < p < 2$, $w_1, \dots, w_{n-1}$ are $n-1$ previously found nice critical points, or at least they are nice approximations of some exact critical points such that $L \subset W_0^{1,q}(\Omega)$. Such an assumption holds automatically when $2 \le p$. Thus

$$L' := L^\perp = \left\{ u \in B \;\middle|\; \int_\Omega \nabla u(x) \cdot \nabla v(x)\, dx = 0 \ \forall v \in L \right\} \tag{3.19}$$

is well defined and $L \cap L' = \{0\}$ holds. For any $w \in B$, we compute

$$w_L := \sum_{i=1}^{n-1} \alpha_i w_i$$

from

$$\int_\Omega \nabla w_L(x) \cdot \nabla w_j(x)\, dx = \int_\Omega \nabla w(x) \cdot \nabla w_j(x)\, dx, \quad j = 1, \dots, n-1.$$

Thus $w_L \in L$ and $w - w_L \in L^\perp$, i.e., $B = L \oplus L'$.

But we cannot assume that such a $G(u_k)$ is the value of a PPG flow of J at $u_k = \mathcal{P}(v_k)$, because we do not know the ratio at other points. In all our numerical examples, (3.18) is satisfied. But we note that the ratio is stable for $1 < p \le 2$ and gets closer to 0 as $p \to +\infty$. Thus we treat those two cases differently in our convergence analysis. For $1 < p \le 2$, we assume that (3.18) is satisfied. But for $p > 2$, we only assume $\|\nabla J(u_k)\|_p \le M$ for some $M > 0$. Either one of the assumptions implies $\nabla J(u_k) \in L^\perp \subset B$. By comparing $G(u_k)$ and $\nabla J(u_k)$, Step 3 and the stepsize rule in Step 5 need to be modified as below.

Step 3: Find a descent direction w_k of J at $u_k = \mathcal{P}(v_k)$, $w_k = -\,sign(t_0^k)\nabla J(u_k)$. Compute the ratio

$$\theta_k = \frac{\|w_k\|_2^2}{\|w_k\|_p \|w_k\|_q} > 0.$$

Since $\langle \delta J(u_k), \nabla J(u_k)\rangle = \|\nabla J(u_k)\|_2^2$, the stepsize rule in Step 5 has to be changed to

$$s_k = \max_{m \in \mathbb{N}} \left\{ s = \frac{\lambda}{2^m} \;\middle|\; 2^m > \|w_k\|,\ J(\mathcal{P}(v_k(s))) - J(u_k) \le \frac{|t_0^k| s}{-4} \|\nabla J(u_k)\|_2^2 \right\}, \tag{3.20}$$

where $0 < \lambda < 1$. Note that if $\theta_k > \theta > 0$, theoretically the term $\|\nabla J(u_k)\|_2^2$ in the above stepsize rule can be replaced with $\theta\|\nabla J(u_k)\|_q$, i.e., we use

$$G(\mathcal{P}(v_k)) = \frac{\nabla J(u_k)}{\|\nabla J(u_k)\|_p}$$

as an L'-PPG of J at $u_k = \mathcal{P}(v_k)$. Then this case can be covered by Case 2. But in implementation, the lower bound θ of the ratio is usually not known beforehand. In particular, we do not known whether or not the ratio is satisfied at a limit point of the sequence. Thus the current stepsize rule (3.20) has to be used in implementation. First, we show that if $0 < \|\nabla J(\mathcal{P}(v_0))\|_p < +\infty$, then a positive stepsize can always be attained.

LEMMA 3.10. *For $v_0 \in S_{L'}$, if J has a local L-$\perp$ selection $\mathcal{P}$ at v_0 satisfying (1) $\mathcal{P}$ is continuous at v_0, (2) $d(\mathcal{P}(v_0), L) > 0$, and (3) $0 < \|\nabla J(\mathcal{P}(v_0))\|_2 < +\infty$, then there exists $s_0 > 0$ such that as $0 < s < s_0$*

$$J(\mathcal{P}(v_0(s))) - J(\mathcal{P}(v_0)) < -\frac{|t_0|s}{4}\|\nabla J(\mathcal{P}(v_0))\|_2^2, \tag{3.21}$$

where

$$v_0(s) = \frac{v_0 - sign(t_0)s\nabla J(\mathcal{P}(v_0))}{\|v_0 - sign(t_0)s\nabla J(\mathcal{P}(v_0))\|}$$

and $\mathcal{P}(v_0) = t_0 v_0 + w_0$ for some $t_0 \in \mathbb{R}$, $w_0 \in L$.

Proof. Since $\|\mathcal{P}(v_0(s)) - \mathcal{P}(v_0)\| \to 0$ as $s \to 0$, we have

$$\begin{aligned}
&J(\mathcal{P}(v_0(s)) - J(\mathcal{P}(v_0)) \\
&\quad = \langle \delta J(\mathcal{P}(v_0)), \mathcal{P}(v_0(s)) - \mathcal{P}(v_0)\rangle + o(\|\mathcal{P}(v_0(s)) - \mathcal{P}(v_0)\|) \\
&\quad = -\frac{sign(t_0)t_0^s s\|\nabla J(\mathcal{P}(v_0))\|_2^2}{\|v_0 - sign(t_0)s\nabla J(\mathcal{P}(v_0))\|} + o(\|\mathcal{P}(v_0(s)) - \mathcal{P}(v_0)\|) < -\frac{|t_0|s}{4}\|\nabla J(\mathcal{P}(v_0))\|_2^2,
\end{aligned}$$

where $\mathcal{P}(v_0(s)) = t_0^s v_0(s) + w_0^s$ and $w_0^s \in L$, when $s > 0$ is very small. ∎

Next we verify Assumption (H).

Subcase $p < 2$ (we assume (3.18) holds). We have $\nabla J(u_k) \in W_0^{1,q}(\Omega) \subset B$. The conclusion in the next lemma is actually stronger than Assumption (H).

LEMMA 3.11. *Let $J \in C^1(B, \mathbb{R})$ and $v_0 \in S_{L^\perp}$. Let $\mathcal{P}$ be a local L-$\perp$ selection of J at v_0 such that $\mathcal{P}$ is continuous at v_0 and $d(\mathcal{P}(v_0), L) > 0$. If $\delta J(\mathcal{P}(v_0)) \neq 0$, then there are $\varepsilon > 0$ and $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda \geq s_0\|\nabla J(\mathcal{P}(v))\|_p$ and*

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) < -\frac{|t_v|s_0}{4}\|\nabla J(\mathcal{P}(v))\|_2^2 \quad \forall v \in S_{L'},\ \|v - v_0\| < \varepsilon,$$

where $\mathcal{P}(v) = t_v v + w$, $w \in L$, and

$$v(s_0) = \frac{v - sign(t_v)s_0\nabla J(\mathcal{P}(v))}{\|v - sign(t_v)s_0\nabla J(\mathcal{P}(v))\|}.$$

Proof. By Lemma 3.10, we have

$$J(\mathcal{P}(v_0(s))) - J(\mathcal{P}(v_0)) < -\frac{|t_0|s}{4}\|\nabla J(\mathcal{P}(v_0))\|_2^2. \tag{3.22}$$

When $p < 2$, we have $q > 2$. J is C^1 implies that ∇J is continuous in the $\|\cdot\|_2$-norm. For fixed s, all the terms in (3.22) are continuous in v_0. Thus there exist $\varepsilon > 0$ and $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda \geq s_0\|\nabla J(\mathcal{P}(v))\|_p$ since J is C^1 and

$$J(\mathcal{P}(v(s_0))) - J(\mathcal{P}(v)) < -\frac{|t_v|s_0}{4}\|\nabla J(\mathcal{P}(v))\|_2^2 \quad \forall v \in S_{L'},\ \|v - v_0\| < \varepsilon. \qquad \square$$

With the new stepsize rule and the uniform stepsize result, Lemma 3.11, if $\theta_k > \theta > 0$ holds in Step 3. We can verify Theorem 3.4. The proof is similar. We need only replace (3.1) with

$$\begin{aligned} J(u_{k+1}) - J(u_k) &< -\frac{\alpha s_k}{4}\|\nabla J(u_k)\|_2^2 \quad \text{(by (3.18))} \\ &< -\frac{\alpha\theta s_k}{4}\|\nabla J(u_k)\|_p\|\nabla J(u_k)\|_q < -\frac{\alpha\theta|1-\lambda|}{4M}\|v_{k+1} - v_k\|\|\nabla J(u_k)\|_q, \end{aligned} \tag{3.23}$$

where $0 < \lambda < 1$ is given in (3.20), and then follow the proof.

Subcase $p > 2$ (we assume only $\|\nabla J(u_k)\|_p \leq M$ for some $M > 0$). We have $B = W_0^{1,p}(\Omega) \subset W_0^{1,2}(\Omega)$. To verify Assumption (H) and prove the convergence of the algorithm, we note that in this case, $\nabla J(u_k) \in L' = L^\perp$ still holds; i.e., $-\nabla J(u_k)$ can be used as a search direction. But "J is C^1" means that δJ is continuous in the $\|\cdot\|_{(-1,q)}$-norm and ∇J is continuous in the $\|\cdot\|_q$-norm, but not necessarily in the $\|\cdot\|_2$-norm. Thus we need an L-$\perp$ selection $\mathcal{P}$ to be locally Lipschitz continuous.

LEMMA 3.12. *Let $J \in C^1(B, \mathbb{R})$ and $v_0 \in S_{L'}$. Assume that $\mathcal{P}$ is a local L-$\perp$ selection of J at v_0 such that* (1) *$\mathcal{P}$ is locally Lipschitz continuous,* (2) *$d(\mathcal{P}(v_0), L) > 0$, and* (3) *$\delta J(\mathcal{P}(v_0)) \neq 0$. Then for any $v_k \in S_{L'}$ with $\lim_{k\to\infty} v_k = v_0$ and $\|\nabla J(\mathcal{P}(v_k))\|_p \leq M$, there are $\bar{k}$, $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda > s_0\|\nabla J(\mathcal{P}(v_k))\|_p$ and*

$$J(\mathcal{P}(v_k(s_0))) - J(\mathcal{P}(v_k)) \leq -\frac{s_0|t_k|\|\nabla J(\mathcal{P}(v_k))\|_2^2}{4} \quad \forall k > \bar{k},$$

where

$$v_k(s) = \frac{v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))}{\|v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))\|}$$

and $\mathcal{P}(v_k) = t_k v_k + v_k^L$, $v_k^L \in L$.

Proof. Denote $\mathcal{P}(v_k(s)) = t_k^s v_k(s) + v_k^L(s)$ for some $v_k^L(s) \in L$. Then, by the mean value theorem, we have

$$\begin{aligned} &J(\mathcal{P}(v_k(s))) - J(\mathcal{P}(v_k)) \\ &\quad = \langle \delta J(\mathcal{P}(v_k)) + (\delta J(\zeta(v_k, s)) - \delta J(\mathcal{P}(v_k))),\ \mathcal{P}(v_k(s)) - \mathcal{P}(v_k)\rangle, \end{aligned} \tag{3.24}$$

where $\zeta(v_k, s) = (1 - \lambda_k)\mathcal{P}(v_k) + \lambda_k\mathcal{P}(v_k(s))$ for some $\lambda_k \in [0, 1]$. By assumption (1) and Lemma 2.7,

$$\|\mathcal{P}(v_k(s)) - \mathcal{P}(v_k)\| \leq \ell\|v_k(s) - v_k\| \leq \frac{2\ell s\|\nabla J(\mathcal{P}(v_k))\|_p}{\|v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))\|}.$$

On the other hand, by the definition of an L-$\perp$ selection of J, as $s > 0$ is small and k is large, we have

$$\begin{aligned} \langle \delta J(\mathcal{P}(v_k)), \mathcal{P}(v_k(s)) - \mathcal{P}(v_k)\rangle &= -\frac{sign(t_k)t_k^s s\|\nabla J(\mathcal{P}(v_k))\|_2^2}{\|v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))\|} \\ &\leq -\frac{s|t_k|}{2}\|\nabla J(\mathcal{P}(v_k))\|_2^2 < 0. \end{aligned} \tag{3.25}$$

Since J is C^1 and $1 < q < 2$ in this case, by assumptions (2) and (3) and applying inequality (3.17), there exists $\delta > 0$ such that when s is small and k is large,

$$\frac{|t_k|\|v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))\|\|\nabla J(\mathcal{P}(v_k))\|_2^2}{8\ell\|\nabla J(\mathcal{P}(v_k))\|_p} > \delta > 0.$$

Thus we can choose $s > 0$ small and k large such that

$$\|\delta J(\zeta(v_k, s)) - \delta J(\mathcal{P}(v_k))\| \le \frac{|t_k|\|v_k - sign(t_k)s\nabla J(\mathcal{P}(v_k))\|\|\nabla J(\mathcal{P}(v_k))\|_2^2}{8\ell\|\nabla J(\mathcal{P}(v_k))\|_p}.$$

Hence

$$\begin{aligned} &|\langle \delta J(\zeta(v_k, s)) - \delta J(\mathcal{P}(v_k)),\, \mathcal{P}(v_k(s)) - \mathcal{P}(v_k)\rangle| \\ &\le \|\delta J(\zeta(v_k, s)) - \delta J(\mathcal{P}(v_k))\|\|\mathcal{P}(v_k(s)) - \mathcal{P}(v_k)\| \le \frac{s|t_k|\|\nabla J(\mathcal{P}(v_k))\|_2^2}{4}. \end{aligned} \tag{3.26}$$

Applying inequalities (3.25) and (3.26) to (3.24), we see that there exist $\bar{k}$, $s_0 = \frac{\lambda}{2^m}$ for some integer m such that $\lambda > s_0\|\nabla J(\mathcal{P}(v_k))\|_p$ and

$$J(\mathcal{P}(v_k(s_0))) - J(\mathcal{P}(v_k)) \le -\frac{s_0|t_k|\|\nabla J(\mathcal{P}(v_k))\|_2^2}{4} \quad \forall k > \bar{k}. \qquad \square$$

With the new stepsize rule (3.20) and the assumption $\|\nabla J(u_k)\|_p < M$, the conclusion of Lemma 3.12 implies Assumption (H), i.e., $s(v_k) \ge s_0$. Then the convergence result, Theorem 3.4, can be verified. The proof is similar. Note that when $\|\nabla J(u_k)\|_q > \delta_0$ for some $\delta_0 > 0$, $\|\nabla J(u_k)\|_2 > \delta$ for some $\delta > 0$. We need only replace (3.1) and (3.2) with

$$\begin{aligned} J(u_{k+1}) - J(u_k) &< -\frac{\alpha s_k}{4}\|\nabla J(u_k)\|_2^2 \le -\frac{\alpha s_k}{4}\delta^2 \\ &\le -\frac{\alpha s_k \delta^2}{4M}\|\nabla J(u_k)\|_p \le -\frac{\alpha\delta^2|1-\lambda|}{4M}\|v_{k+1} - v_k\|_p, \end{aligned}$$

where $0 < \lambda < 1$ is given in (3.20) and the last inequality follows from Lemma 2.7. Then following the proof, the unified convergence result, Theorem 3.4, is also obtained.

4. An application to the nonlinear p-Laplacian equation. As an application, let us consider the following quasi-linear elliptic boundary-value problem on a bounded smooth domain $\Omega \subset \mathbb{R}^n$:

$$\begin{cases} \Delta_p u(x) + f(x, u(x)) = 0, & x \in \Omega, \\ u(x) = 0, & x \in \partial\Omega, \end{cases} \qquad u \in B \equiv W^{1,p}(\Omega),\ p > 1, \tag{4.1}$$

where Δ_p defined by $\Delta_p u(x) = \mathrm{div}(|\nabla u(x)|^{p-2}\nabla u(x))$ is the p-Laplacian operator which has a variety of applications in physical fields, such as in fluid dynamics when the shear stress and the velocity gradient are related in a certain manner, where $p = 2$, $p < 2$, $p > 2$ if the fluid is Newtonian, pseudoplastic, or dilatant, respectively. The p-Laplacian operator also appears in the study of flow in porous media ($p = \frac{3}{2}$), nonlinear elasticity ($p > 2$), and glaciology ($p \in (1, \frac{4}{3})$). Under certain standard conditions on f, it can be shown that a point $u^* \in W_0^{1,p}(\Omega)$ is a weak solution of (4.1) if and only if u^* is a critical point of the functional

$$J(u) = \frac{1}{p}\int_\Omega |\nabla u(x)|^p\, dx - \int_\Omega F(x, u(x))\, dx, \quad \text{where} \quad F(x,t) = \int_0^t f(x,s)\, ds. \tag{4.2}$$

Many multiple solutions to the above quasi-linear elliptic PDE have been numerically computed in [12, 13] for $p < 2$ and $p > 2$. Convergence results obtained in section 3 can be applied; see Case 3. Since conditions (1), (2), and (3) in Theorem 3.4 are basic assumptions in our results and new in the literature, we focus on verifying them in this section. Other conditions, such as the PS condition, have been studied in the literature and therefore will not be discussed here. Let us assume some of the standard growth and regularity conditions in the literature. Denote the Sobolev exponent $p^* = \frac{np}{n-p}$ for $p < n$ and $p^* = \infty$ for $p \geq n$. Assume

(a) $f \in C^1(\bar{\Omega} \times \mathbb{R}, \mathbb{R})$, $f(x,0) = 0$, $\frac{f(x,t\xi)}{|t\xi|^{p-2}t\xi}$ monotonically increases to $+\infty$ in t.

(b) For each $\varepsilon > 0$, there is $c_1 = c_1(\varepsilon) > 0$ such that $f(x,t)t < \varepsilon|t|^p + c_1|t|^{p^*}$ $\forall t \in \mathbb{R}$, $x \in \Omega$.

It is clear that $u = 0$ is a critical point of the least critical value of J and $f(x,u) = |u|^{q-2}u$ for $q > p$ satisfies condition (a). For each $v \in B$ with $\|v\| = 1$ and $t > 0$, let $g(t) = J(tv)$. We have

$$\begin{aligned} g'(t) = \langle \nabla J(tv), v\rangle &= \int_\Omega \left(t^{p-1}|\nabla v(x)|^p - f(x, tv(x))v(x)\right) dx \\ &= t^{p-1}\left(1 - \int_\Omega \frac{f(x,tv(x))|v(x)|^p}{|tv(x)|^{p-2}tv(x)}\right) dx. \end{aligned}$$

Thus, by condition (a), there is a unique $t_v > 0$ such that $g'(t_v) = 0$; i.e., for $L = \{0\}$ and each $v \in S_B$, the L-$\perp$ selection (actually a peak selection) $\mathcal{P}(v) = t_v v$ is uniquely determined with $J(\mathcal{P}(v)) > 0$. By taking a derivative of condition (a) w.r.t. t, we have

$$\begin{aligned} g''(t) &= (p-1)t^{(p-2)} - \int_\Omega f'_u(x, tv(x))v^2(x)\, dx \\ &< (p-1)t^{(p-2)} - \int_\Omega \frac{(p-1)}{t} f(x, tv(x))v(x)\, dx = \frac{p-1}{t} g'(t). \end{aligned} \tag{4.3}$$

Thus condition (3) in Theorem 3.4 is always satisfied for any L. Next let us recall that when $L = [u^1, u^2, \ldots, u^{n-1}]$, by the definition of an L-$\perp$ selection, $\mathcal{P}(v) = t_0 v + t_1 u^1 + \cdots + t_{n-1}u^{n-1}$ is solved from

$$\begin{aligned} &\frac{\partial}{\partial t_0} g(t_0, \ldots, t_{n-1}) = \langle \nabla J(t_0 v + t_1 u^1 + \cdots + t_{n-1}u^{n-1}), v\rangle = 0, \\ &\frac{\partial}{\partial t_i} g(t_0, \ldots, t_{n-1}) = \langle \nabla J(t_0 v + t_1 u^1 + \cdots + t_{n-1}u^{n-1}), u^i\rangle = 0, \quad i = 1, \ldots, n-1, \end{aligned} \tag{4.4}$$

where $g(t_0, \ldots, t_{n-1}) = J(t_0 v + t_1 u^1 + \cdots + t_{n-1}u^{n-1})$. If $u = \mathcal{P}(v) = t_0 v + t_1 u^1 + \cdots + t_{n-1}u^{n-1}$ satisfies (4.4) and at u, the $n \times n$ matrix

$$\begin{aligned} Q &= \left[\frac{\partial^2}{\partial t_i \partial t_j} g(t_0, \ldots, t_{n-1}) \right] \\ &= \begin{bmatrix} \langle J''(u)v, v\rangle & \langle J''(u)u^1, v\rangle & \cdots & \langle J''(u)u^{n-1}, v\rangle \\ \langle J''(u)v, u^1\rangle & \langle J''(u)u^1, u^1\rangle & \cdots & \langle J''(u)u^{n-1}, u^{n-1}\rangle \\ \cdots & & \cdots & \\ \langle J''(u)v, u^{n-1}\rangle & \langle J''(u)u^1, u^{n-1}\rangle & \cdots & \langle J''(u)u^{n-1}, u^{n-1}\rangle \end{bmatrix} \end{aligned}$$

is invertible, i.e., $|Q| \neq 0$, then by the implicit function theorem, around u, the L-$\perp$ selection $\mathcal{P}$ is well-defined and continuously differentiable. The condition $|Q| \neq 0$ can be easily and numerically checked. For the current case $L = \{0\}$, by (4.3), we have $Q = g''(t_v) < 0$. Thus the L-$\perp$ selection $\mathcal{P}$ is C^1. To show that $d(\mathcal{P}(v), L) > \alpha > 0$ for all $v \in S_B$, by (b), for any $\varepsilon > 0$, there is $c_1 = c_1(\varepsilon)$ such that $f(x, v(x))v(x) < \varepsilon|v(x)|^p + c_1|v(x)|^{p^*}$. It follows that

$$\begin{aligned}\int_\Omega f(x, v(x))v(x)\,dx &< \varepsilon \int_\Omega |v(x)|^p\,dx + c_1 \int_\Omega |v(x)|^{p^*}\,dx \\ &\qquad \text{(by the Poincaré and Sobolev inequalities)} \\ &\leq \varepsilon c_0(\Omega) \int_\Omega |\nabla v(x)|^p\,dx + c_1 c_2(\Omega) \left(\int_\Omega |\nabla v(x)|^p\,dx \right)^{\frac{p^*}{p}} \\ &= \left[\varepsilon c_0(\Omega) + c_1 c_2(\Omega) \left(\int_\Omega |\nabla v(x)|^p\,dx \right)^{\frac{p^*}{p}-1} \right] \int_\Omega |\nabla v(x)|^p\,dx.\end{aligned}$$

Thus

$$\begin{aligned}\langle \nabla J(v), v \rangle &\geq \left[1 - \varepsilon c_0(\Omega) - c_1 c_2(\Omega) \left(\int_\Omega |\nabla v(x)|^p\,dx \right)^{\frac{p^*}{p}-1} \right] \int_\Omega |\nabla v(x)|^p\,dx \\ &= \left[1 - \varepsilon c_0(\Omega) - c_1 c_2(\Omega) \|v\|^{p^*-p} \right] \|v\|^p.\end{aligned}$$

It follows that for any small $\varepsilon > 0$, c_1, $c_0(\Omega)$, and $c_2(\Omega)$, there is a $t_0 > 0$ such that when $0 < \|v\| = t < t_0$, we have $\langle \nabla J(v), v \rangle \geq \left[1 - \varepsilon c_0(\Omega) - c_1 c_2(\Omega) t^{p^*-p} \right] t^p > 0$. Therefore the L-$\perp$ selection $\mathcal{P}(v)$ satisfies $\|\mathcal{P}(v)\| > t_0$ or $d(\mathcal{P}(v), L) > t_0 > 0\ \forall v \in S_B$, where $L = \{0\}$.

Acknowledgment. The authors would like to thank two anonymous referees for their helpful suggestions.

ERROR ANALYSIS OF A CONTINUOUS-DISCONTINUOUS GALERKIN FINITE ELEMENT METHOD FOR GENERALIZED 2D VORTICITY DYNAMICS*

JAAP J. W. VAN DER VEGT†, FERENC IZSÁK‡, AND ONNO BOKHOVE†

Abstract. A detailed a priori error estimate is provided for a continuous-discontinuous Galerkin finite element method for the generalized two-dimensional vorticity dynamics equations. These equations describe several types of geophysical flows, including the Euler equations. The algorithm consists of a continuous Galerkin finite element method for the stream function and a discontinuous Galerkin finite element method for the (potential) vorticity. Since this algorithm satisfies a number of invariants, such as energy and enstrophy conservation, it is possible to provide detailed error estimates for this nonlinear problem. The main result of the analysis is a reduction in the smoothness requirements on the vorticity field from $H^2(\Omega)$, obtained in a previous analysis, to $W_p^r(\Omega)$ with $r > \frac{1}{p}$ and $p > 2$. In addition, sharper estimates for the dependence of the error on time and numerical examples on a model problem are provided.

Key words. generalized vorticity dynamics, continuous-discontinuous Galerkin finite element methods, a priori error estimates

1. Introduction.

The accurate numerical simulation of geophysical flows over long periods of time frequently requires the preservation of invariants of the flow field, such as energy and enstrophy conservation. These requirements are nontrivial and an active area of research in numerical analysis. A promising new technique for geophysical flows is provided by the recently developed continuous-discontinuous Galerkin (CDG) finite element method [3, 9, 10], which is capable of preserving important invariants of the flow field also at the discrete level. The accuracy of the CDG finite element method is discussed in [3, 9], but the a priori error analysis requires quite strong smoothness assumptions, which often are not realistic. The main objective of this paper is to analyze the CDG finite element method for geophysical flows under only very weak smoothness assumptions. In addition, we aim at obtaining sharper estimates for the dependence of the error on time than obtained in [3, 9]. These results will significantly extend the range of applications covered by the error estimates.

The geophysical problems studied in this paper can be described by a hyperbolic equation for the (potential) vorticity ξ and an elliptic equation for the stream function ψ. The coupled set of equations in a simply connected bounded domain $\Omega \times (t_0, T) \subset$

$\mathbb{R}^2 \times (t_0, T)$ is defined as

$$(1/A)\partial_t \xi + \boldsymbol{\nabla} \cdot (\xi \mathbf{U}) = 0, \tag{1.1a}$$

$$\mathbf{U} = \boldsymbol{\nabla}^{\perp} \psi, \tag{1.1b}$$

$$\boldsymbol{\nabla} \cdot (A \boldsymbol{\nabla} \psi) - B\psi + D = (1/A)\, \xi, \tag{1.1c}$$

with t representing time, where t_0 and T denote the initial and final time, respectively, and $A, B, D : \Omega \to \mathbb{R}$ given functions satisfying $0 \leq B(x)$ and $0 < A_0 \leq A(x) \leq A_1 < \infty$ for some finite $A_0, A_1 \in \mathbb{R}^+$. The gradient operator is given by $\boldsymbol{\nabla} = (\partial_x, \partial_y)^T$ and the two-dimensional curl operator by $\boldsymbol{\nabla}^{\perp} = (-\partial_y, \partial_x)^T$. At the domain boundary $\partial\Omega$, a slip flow condition is imposed at $\partial\Omega_D \subseteq \partial\Omega$,

$$\mathbf{U} \cdot \mathbf{n} = 0, \tag{1.2}$$

with $\mathbf{n} = (n_x, n_y)^T$ the outward unit vector normal to the boundary $\partial\Omega$, and periodic boundary conditions at $\partial\Omega \backslash \partial\Omega_D$. The slip flow boundary condition (1.2) is equivalent with the condition $\frac{\partial \psi}{\partial \tau} = 0$ at $\partial\Omega_D$, with $\tau = (-n_y, n_x)^T$ the tangential vector at the domain boundary. This implies that $\psi = c_D(t)$ at $\partial\Omega_D$ for a smooth ψ, with c_D a function which can depend only on time. The boundary conditions for ψ are completed by setting $c_D = 0$ when $B = 0$, almost everywhere. In case $B \neq 0$ for all $x \in \Omega_0 \subseteq \Omega$, where Ω_0 has a nonzero measure, then the circulation $\mathcal{C}$ around the boundary of the domain is imposed as an additional boundary condition, which is defined as

$$\mathcal{C} = \int_{\partial\Omega} A\mathbf{U} \cdot \tau d\Gamma = \int_{\partial\Omega} A \boldsymbol{\nabla} \psi \cdot \mathbf{n} d\Gamma. \tag{1.3}$$

Initial conditions are provided by specifying the initial vorticity field ξ_0. The generalized system (1.1) serves as a model for several fluid flow problems by choosing A, B, and D to yield the incompressible two-dimensional (2D) Euler equations [7], the quasi-geostrophic equations [12], and the rigid-lid equations [8], often used in atmosphere and ocean dynamics. An overview of the specific values of the coefficients A, B, D for these different problems can be found in [3]. In all these cases, ξ represents the (potential) vorticity of the fluid, $\mathbf{u} = A\mathbf{U}$ the velocity, and $\mathbf{U}$ the (mass transport) velocity of the fluid.

The CDG finite element method was introduced in [9, 10] for the 2D Euler equations and extended in [3] to the generalized 2D vorticity dynamics equations (1.1) in multiple connected domains. Apart from detailed numerical experiments, an a priori error analysis was also given in [3] for the CDG finite element discretization of (1.1) under slightly less restrictive assumptions than the analysis for the 2D Euler equations discussed in [9]. The analysis requires, however, that the vorticity field belongs at least to $H^2(\Omega)$, which is frequently not valid. Also, the analyses in [3, 9], which both use Gronwall's inequality, provide only an exponentially growing upper bound for the error in time.

In order to alleviate these restrictions, we provide in this paper an error analysis which imposes only weak smoothness requirements on the (generalized) vorticity field. This analysis extends the work in [10], which proves convergence of the CDG finite element algorithm for the 2D Euler equations when the initial vorticity field is in $L^2(\Omega)$, in two ways. In the first place, we consider the generalized 2D vorticity dynamics equations (1.1) instead of the 2D Euler equations, and in the second place, we provide detailed a priori error estimates in terms of the mesh size and initial vorticity. This result shows that the CDG finite element method in [3] is applicable

to a wide range of geophysical problems, with only weak smoothness requirements on the vorticity.

The outline of the paper is as follows. After some preliminaries in section 2, we briefly state in section 3 the CDG finite element method for (1.1). Next, we recall in section 4 some important properties of the CDG finite element method regarding energy conservation and enstrophy stability. These properties are essential in order to prove the main result of this paper, an a priori error estimate for the CDG finite element method with limited smoothness requirements, which we discuss in section 5. This analysis also requires an upper bound on the stream function and its trace at the boundary, which we provide in a separate lemma. In section 6, we discuss the evolution of a concentrated patch of vorticity as an example of a model problem in geophysical flows where the vorticity field has limited smoothness. Finally, in Appendix A, we analyze the smoothness of this vorticity field.

2. Preliminaries.

2.1. Function spaces. We denote with Ω a simply connected bounded domain $\Omega \subset \mathbb{R}^2$ with Lipschitz boundary $\partial\Omega$. For any nonnegative integer k, $C^k(\Omega)$ denotes the space of all functions w which, together with all their partial derivatives $D^\alpha w$ of order $|\alpha| \leq k$, are continuous in Ω. For $0 < \lambda \leq 1$, we define $C^{k,\lambda}(\overline{\Omega})$ to be the subspace of $C^k(\overline{\Omega})$, with $\overline{\Omega}$ the closure of Ω, consisting of those functions w for which for $0 \leq |\alpha| \leq k$, $D^\alpha w$ satisfies in Ω a Hölder condition of exponent λ. That is, there exists a constant C, such that

$$|D^\alpha w(x) - D^\alpha w(y)| \leq C|x-y|^\lambda \qquad \forall x, y \in \Omega.$$

The Lebesgue measure is also denoted with $|\cdot|$, while for the Lebesgue spaces we use the notation $L^p(\Omega)$, for $1 \leq p \leq \infty$. These spaces are equipped with the norm $\|w\|_{p,\Omega} = (\int_\Omega |w|^p d\Omega)^{\frac{1}{p}}$ for $1 \leq p < \infty$ and $\|w\|_{\infty,\Omega} = \operatorname{ess\,sup}_{x\in\Omega}|w(x)|$. In addition, we define the Sobolev spaces $W_p^s(\Omega)$, with the norm indicated as $\|w\|_{s,p,\Omega}$. For s integer, $s \geq 0$, and $1 \leq p < \infty$, the Sobolev norm is defined as $\|w\|_{s,p,\Omega} = (\sum_{|\alpha|\leq s} \|D^\alpha w\|_{p,\Omega}^p)^{\frac{1}{p}}$ and the seminorm as $|w|_{s,p,\Omega} = (\sum_{|\alpha|=s} \|D^\alpha w\|_{p,\Omega}^p)^{\frac{1}{p}}$, whereas for s integer, $s \geq 0$, and $p = \infty$, we have $\|w\|_{s,\infty,\Omega} = \max_{|\alpha|\leq s} \|D^\alpha w\|_{\infty,\Omega}$, with the usual modification for the seminorm. For noninteger values $s > 0$, we use Banach space interpolation to define the fractional order Sobolev spaces $W_p^s(\Omega)$. For a detailed discussion, we refer the reader to [4, Chapter 14.2]. For $s = 0$, we have $W_p^0(\Omega) = L^p(\Omega)$. The $L^2(\Omega)$ and $(L^2(\Omega))^2$ spaces are equipped with the inner product $(u,v)_\Omega = \int_\Omega uv\, d\Omega$ and $(u,v)_\Omega = \int_\Omega u \cdot v\, d\Omega$, respectively, and we use the shorthand notation $\|w\|_\Omega$ for the $L^2(\Omega)$ norm $\|w\|_{0,2,\Omega}$. We also use the notation $H^s(\Omega)$ for $W_2^s(\Omega)$, with $s \in \mathbb{R}$. For $1 < p < \infty$ and $s \in \mathbb{R}$, $s \geq 0$, the Sobolev spaces with a negative index $W_p^{-s}(\Omega)$ are defined as the dual spaces of $W_p^s(\Omega)$, see [1, p. 65], equipped with the norm $\|w\|_{-s,p,\Omega} = \sup_{0\neq v\in W_{p'}^s(\Omega)} \frac{(w,v)_\Omega}{\|v\|_{s,p',\Omega}}$, where $1/p + 1/p' = 1$, and $(w,v)_\Omega$ denotes the duality pairing between w and v with $L^2(\Omega)$ as pivot space. All the above definitions also apply with the domain Ω replaced by the element K or its boundary ∂K. Finally, we define the broken Sobolev spaces $W_p^s(\mathcal{T}_h)$ for all $s \in \mathbb{R}$, with $\mathcal{T}_h$ a tessellation covering Ω, as the space of functions such that their restriction to each $K \in \mathcal{T}_h$ belongs to $W_p^s(K)$.

2.2. Interpolation operators. In the error analysis, we assume a quasi-uniform mesh (see [4, section 4.4]) with tessellation $\mathcal{T}_h$. Since the vorticity field is not necessarily continuous, we use the more general Clément-type interpolation operator defined

in [2]. Let $\mathcal{T}_h$ be a regular partition of Ω into triangles or quadrilaterals; then the macroelement $\tilde{K}$, associated with element $K \in \mathcal{T}_h$, consists of those elements which share at least one vertex with K, and hence $\tilde{K} = \text{int}\left\{\cup K', K' \in \mathcal{T}_h \,|\, \overline{K'} \cap \overline{K} \neq \emptyset\right\}$, where the overbar denotes the closure of a set and int the interior. The n elements $K \in \mathcal{T}_h$ constituting the macroelement $\tilde{K}$ are denoted $\tilde{K}_i$, with $1 \leq i \leq n$. With each element $\tilde{K}_i$ we associate a reference element $\widehat{\tilde{K}}_i$ using the continuous and invertible mapping $F_{\tilde{K}_i} : \widehat{\tilde{K}}_i \rightarrow \tilde{K}_i$. We denote with $\widehat{\tilde{K}} = \cup_{i=1}^n \widehat{\tilde{K}}_i$ the reference macroelement associated with $\tilde{K}$. Both elements are connected with the mapping $F_{\tilde{K}} : \widehat{\tilde{K}} \rightarrow \tilde{K}$, which consists of the individual mappings $F_{\tilde{K}_i}$, with $1 \leq i \leq n$. Next, we define the local finite element spaces on the macroelement $\tilde{K}$ and its reference macroelement $\widehat{\tilde{K}}$ as follows:

$$\Theta_h^k\left(\widehat{\tilde{K}}\right) = \left\{\hat{v} \in C^0\left(\widehat{\tilde{K}}\right) \,|\, \forall \widehat{\tilde{K}}_i \subset \widehat{\tilde{K}},\, \hat{v}_{|\widehat{\tilde{K}}_i} \in \mathcal{P}_k\right\},$$
$$\Theta_h^k(\tilde{K}) = \left\{v \in C^0(\tilde{K}) \,|\, \forall \tilde{K}_i \subset \tilde{K},\, v_{|\tilde{K}_i} = \hat{v}_{|\widehat{\tilde{K}}_i} \circ F_{\tilde{K}_i}^{-1},\, \hat{v}_{|\widehat{\tilde{K}}_i} \in \mathcal{P}_k\right\},$$

with $\mathcal{P}_k$ polynomials of total degree less than or equal to k on triangles and of degree less than or equal to k in each coordinate direction on quadrilaterals. For any function $\hat{u}$ in $L^1(\widehat{\tilde{K}})$, we define the projection $\widehat{\mathcal{P}}_{\widehat{\tilde{K}}}\hat{u}$ in $\Theta_h^k(\widehat{\tilde{K}})$ by

$$\int_{\widehat{\tilde{K}}} \left(\widehat{\mathcal{P}}_{\widehat{\tilde{K}}}\hat{u} - \hat{u}\right)\hat{v}\, d\hat{x} = 0 \qquad \forall \hat{v} \in \Theta_h^k\left(\widehat{\tilde{K}}\right), \tag{2.1}$$

and for any function u in $L^1(\tilde{K})$, we define the projection $\mathcal{P}_{\tilde{K}}u$ on $\Theta_h^k(\tilde{K})$ by

$$\mathcal{P}_{\tilde{K}}u \circ F_{\tilde{K}} = \widehat{\mathcal{P}}_{\widehat{\tilde{K}}}(u \circ F_{\tilde{K}}). \tag{2.2}$$

The following lemma on the interpolation error is proved in Theorem 2.2 and Remark 4 in [2] for triangles and Theorem 3.5 and Remark 5 in [2] for quadrilaterals.

LEMMA 2.1. *For any integers $k \geq 1$ and any real number t, with $0 \leq t \leq 1$, provided the function u belongs to $W_p^s(\tilde{K})$, there exists a constant C, depending only on the regularity of $\mathcal{T}_h$, such that for any element $\tilde{K}_i \subset \tilde{K}$*

$$|u - \mathcal{P}_{\tilde{K}}u|_{t,p,\tilde{K}_i} \leq C h_K^{s-t} |u|_{s,p,\tilde{K}}, \qquad \text{with } t \leq s \leq k+1,\ 1 \leq p \leq \infty, \tag{2.3}$$

and

$$|u - \mathcal{P}_{\tilde{K}}u|_{t,p,\partial\tilde{K}_i} \leq C h_K^{s-t-\frac{1}{p}} |u|_{s,p,\tilde{K}}, \quad \text{with } t + \frac{1}{p} < s \leq k+1,\ 1 \leq p < \infty, \tag{2.4}$$

with h_K the diameter of elements $K \in \mathcal{T}_h$.

3. Finite element method. The potential vorticity equation (1.1a) and the generalized stream function equation (1.1c) are discretized with a discontinuous and a continuous Galerkin finite element method, respectively. The key benefit of this approach is that we can ensure under certain conditions that the discretization satisfies important constraints, such as energy conservation and enstrophy stability, which are summarized in section 4. In this section, we summarize the CDG finite element method for the system (1.1). More details can be found in [3].

3.1. Continuous Galerkin discretization for generalized stream function. The definition of the weak formulation for (1.1c) requires the treatment of the nonstandard boundary conditions for ψ given by (1.2)–(1.3), which are a mixture of essential and natural boundary conditions. The slip flow boundary condition (1.2) is equivalent with the condition $\frac{\partial \psi}{\partial \tau} = 0$ at $\partial\Omega_D$, which implies that $\gamma(\psi)|_{\partial\Omega_D} = c_D(t)$, with $\gamma : H^1(\Omega) \to H^{\frac{1}{2}}(\partial\Omega)$ the trace operator. The value of c_D, however, still depends on time and is determined implicitly by the circulation condition (1.3), which arises as a natural boundary condition in the weak formulation (3.3). Introduce now the space

$$H^1_{0,D}(\Omega) := \left\{ w \in H^1(\Omega) \,\middle|\, \gamma(w)|_{\partial\Omega_D} = 0 \right\}, \tag{3.1}$$

and split ψ into

$$\psi = \psi_0 + c_D \cdot \mathbf{1}, \tag{3.2}$$

where $\mathbf{1} : \Omega \to 1$ is the constant function. The weak formulation for (1.1c) at time t can then be straightforwardly derived and is equal to the following:

Find a $\psi_0 \in H^1_{0,D}(\Omega)$ such that for all $w_0 \in H^1_{0,D}(\Omega)$ the following relation is satisfied:

$$L(\psi_0, w_0) = F_\xi(w_0) - L(c_D, w_0), \tag{3.3}$$

with the operators $L : H^1(\Omega) \times H^1(\Omega) \to \mathbb{R}$ and $F_\xi : H^{-1}(\Omega) \to \mathbb{R}$ defined as

$$L(\psi, w) := \left(\sqrt{A}\boldsymbol{\nabla}\psi, \sqrt{A}\boldsymbol{\nabla}w\right)_\Omega + \left(\sqrt{B}\psi, \sqrt{B}w\right)_\Omega, \tag{3.4}$$

$$F_\xi(w) := -\left(\xi/A, w\right)_\Omega + (D, w)_\Omega + \gamma(w)\mathcal{C}, \tag{3.5}$$

and $\mathcal{C}$ given by (1.3). Choosing $w = \mathbf{1}$ in (3.3), we obtain that

$$c_D = \frac{F_\xi(\mathbf{1}) - (\psi_0\sqrt{B}, \sqrt{B})_\Omega}{\|\sqrt{B}\|^2_\Omega}. \tag{3.6}$$

For the finite element discretization, we introduce the spaces

$$X^k_h := \left\{ w \in C^0(\Omega) \mid w|_K \in \mathcal{P}_k(K) \, \forall K \in \mathcal{T}_h \right\}$$

and $\mathsf{W}^k_h = H^1_{0,D}(\Omega) \cap X^k_h$. By restricting ψ and w to the finite-dimensional space W^k_h, we obtain the following continuous finite element formulation:

Find a $\psi_h \in \mathsf{W}^k_h$ such that for all $w \in \mathsf{W}^k_h$ the following relation is satisfied:

$$L(\psi_h, w) = F_{\xi_h}(w) - L(c_D, w), \tag{3.7}$$

with ξ_h the discrete vorticity field computed with the discontinuous Galerkin finite element discretization specified in the next section.

3.2. Discontinuous Galerkin space discretization. The weak formulation (in space) for the (potential) vorticity equation (1.1a), with U replaced by (1.1b), can be defined straightforwardly as follows:

Find a $\xi \in L^1((t_0, T), W^r_p(\Omega))$, with $r > \frac{1}{p}$ and $p > 2$, such that for all $v \in H^1(\Omega)$ the following relation is satisfied:

$$\frac{d}{dt}\left(\frac{\xi}{A}, v\right)_\Omega = \left(\xi\boldsymbol{\nabla}^\perp\psi, \boldsymbol{\nabla}v\right)_\Omega - \left(\xi\boldsymbol{\nabla}^\perp\psi \cdot \mathbf{n}, v\right)_{\partial\Omega}, \tag{3.8}$$

where the boundary contribution should be interpreted in the sense of traces and ψ is given by (3.2). For the discontinuous Galerkin (DG) discretization, we define the following space of discontinuous functions:

$$\mathsf{V}_h^k := \left\{ v_h \in L^2(\Omega) \,\middle|\, v_h|_K \in \mathcal{P}_k(K) \quad \forall K \in \mathcal{T}_h \right\}. \tag{3.9}$$

Note that conservation of energy of the numerical solution requires $\mathsf{W}_h^k \subset \mathsf{V}_h^k$ (see [3]). The DG weak formulation is now equal to the following:

Find a $\xi_h \in \mathsf{V}_h^k$ such that for all $v \in \mathsf{V}_h^k$ the following relation holds:

$$\sum_{K\in\mathcal{T}_h} \frac{d}{dt}\Big(\frac{\xi_h}{A}, v\Big)_K = \sum_{K\in\mathcal{T}_h} R_K(\xi_h, \psi_h, v), \tag{3.10}$$

with the operator $R_K : \mathsf{V}_h^k \times \mathsf{W}_h^k \times \mathsf{V}_h^k \to \mathbb{R}$ defined by

$$R_K(\xi_h, \psi_h, v) = \Big(\xi_h \boldsymbol{\nabla}^\perp \psi_h, \boldsymbol{\nabla} v\Big)_K - \int_{\partial K} v^- \hat{f}(\xi_h^+, \xi_h^-, \boldsymbol{\nabla}^\perp \psi_h \cdot \mathbf{n})\, d\Gamma, \tag{3.11}$$

where the superscripts $^-$ and $^+$ denote the trace values at the boundary point ∂K taken from the inside and outside of the element, respectively. Here, $\hat{f}$ denotes the numerical flux which is necessary to account for the discontinuity in the DG basis functions at the element boundaries. The numerical flux is defined as

$$\text{central} \quad \hat{f}(\xi^+, \xi^-, U_n) = \frac{\xi^+ + \xi^-}{2} U_n, \tag{3.12a}$$

$$\text{upwind} \quad \hat{f}(\xi^+, \xi^-, U_n) = U_n \begin{cases} \xi^+ & \text{if } U_n < 0, \\ \xi^- & \text{if } U_n \geq 0, \end{cases} \tag{3.12b}$$

$$\text{Lax–Friedrichs} \quad \hat{f}(\xi^+, \xi^-, U_n) = \frac{1}{2}\left(U_n(\xi^+ + \xi^-) - \alpha_{LF}(\xi^+ - \xi^-)\right), \tag{3.12c}$$

with $U_n = \mathbf{U}_h \cdot \mathbf{n} = \boldsymbol{\nabla}^\perp \psi_h \cdot \mathbf{n}$ and $\alpha_{LF} \geq 0$. For ease of notation, we also write the numerical flux as

$$\hat{\xi}_h = \hat{f}(\xi^+, \xi^-, U_n)/U_n.$$

A common choice for α_{LF} is $\alpha_{LF} = \max|U_n|$ with a local or global maximum. For $\alpha_{LF} = 0$ and $\alpha_{LF} = |U_n|$, we obtain the central and upwind flux, respectively.

4. Conservation of energy and enstrophy. The equations for generalized 2D vorticity dynamics (1.1) and the numerical discretization given by (3.7) and (3.10) satisfy a number of important invariants and constraints, including energy and enstrophy conservation. These invariants are essential for the error analysis discussed in section 5, and we summarize them here for completeness. Define for $A(x, y) > 0$ and $B(x, y) \geq 0$ the total energy E and enstrophy S of the flow field as

$$E(\psi, t) = \frac{1}{2}\|\sqrt{A}\boldsymbol{\nabla}\psi(\cdot, t)\|_\Omega^2 + \frac{1}{2}\|\sqrt{B}\psi(\cdot, t)\|_\Omega^2, \tag{4.1}$$

$$S(\xi, t) = \frac{1}{2}\left\|\frac{\xi(\cdot, t)}{\sqrt{A}}\right\|_\Omega^2. \tag{4.2}$$

The system of equations for generalized 2D vorticity dynamics (1.1) satisfies the following invariants.

LEMMA 4.1. *Assume that $A, B \in L^\infty(\Omega)$, with $A > 0$ and $B \geq 0$; then the energy E and enstrophy S of system* (1.1) *subject to slip flow boundary conditions* (1.2) *and constant circulation* (1.3) *is conserved:*

$$\frac{dE(\psi,t)}{dt} = 0, \qquad \frac{dS(\xi,t)}{dt} = 0. \tag{4.3}$$

For a proof, see, e.g., [3]. The numerical solution of the generalized 2D vorticity dynamics equations (1.1) obtained with the CDG method (partly) satisfies the same invariants.

LEMMA 4.2. *Consider the solution of* (3.7) *and* (3.10) *subject to slip flow boundary conditions* (1.2). *The energy E associated with this numerical solution is a conserved quantity, and the enstrophy S is bounded:*

$$\frac{dE(\psi_h,t)}{dt} = 0, \qquad \frac{dS(\xi_h,t)}{dt} \leq 0. \tag{4.4}$$

For the central flux (3.12a), *the relation for the enstrophy becomes an equality.*

For a proof, see [3].

5. Error analysis. In this section, we will prove an a priori error estimate for the CDG finite element discretization (3.7) and (3.10) for the generalized 2D vorticity dynamics equations (1.1). The key objective is to minimize the requirements imposed on the smoothness of the vorticity field ξ in order to extend the validity of the analysis and the numerical method to a much larger range of physically relevant problems. The error estimate provides a significant extension of the error estimate Theorem 11 in [3], which required the vorticity field ξ to belong to $H^2(\Omega)$ and provided only an exponentially growing upper bound for the growth of the error in time.

The main result of this paper is provided by the following error estimate for the velocity field $\mathbf{u}_h$ and the vorticity field ξ_h computed with the CDG method.

THEOREM 5.1. *Assume that Ω is a polyhedral simply connected bounded domain and that the vorticity field satisfies the condition $\xi \in L^1((t_0,T), W_p^r(\Omega))$, with $r \in \mathbb{R}$, $r > \frac{1}{p}$, and $p > 2$. In addition, we assume that the coefficients in* (1.1c) *satisfy $A, B \in C^{r,1}(\overline{\Omega})$, $D \in L^\infty(\Omega)$, with $0 \leq B(x)$ and $0 < A_0 \leq A(x) \leq A_1 < \infty$ for some finite $A_0, A_1 \in \mathbb{R}^+$; then the error in the CDG finite element discretization* (3.7) *and* (3.10) *on a quasi-uniform mesh $\mathcal{T}_h$, with $h < 1$, can be estimated as*

$$\|(\mathbf{u} - \mathbf{u}_h)/A\|_{0,q,\Omega} + \|(\xi - \xi_h)/A\|_{-1,q',\mathcal{T}_h} \leq Ch^s \|\xi_0\|_\Omega \int_{t_0}^{T} \|\xi(\cdot,t)\|_{r,p,\Omega} dt,$$

where ξ_0 denotes the initial vorticity field, $q = \frac{2p}{p-2}$, $q' = \frac{q}{q-1}$, $\frac{1}{p} < s \leq \min(k-1, r + \frac{2}{p} - \epsilon_0)$, with k the order of the polynomial basis functions, $\epsilon_0 > 0$ an arbitrary small constant, and C a positive constant, independent of h, $\mathbf{u}$, and ξ.

The proof of Theorem 5.1 is split into several parts. Since the weak formulation (3.3) has nonstandard boundary conditions, we first need to show that it has a unique solution. Moreover, we need an upper bound for the stream function ψ and $c_D(t)$, the trace of ψ at $\partial\Omega_D$, for the regularity estimate in the second part of the proof.

LEMMA 5.2. *The variational problem* (3.3) *is well posed in $H^1_{0,D}(\Omega) \oplus \mathbb{R}$, and the*

$H^1(\Omega)$ norm of the stream function can be estimated as

$$\|\psi(\cdot,t)\|_{1,2,\Omega} \leq \left(\gamma + \frac{\sqrt{|\Omega|}}{\|B\|_{1,\Omega}}\left(\sqrt{|\Omega|} + \gamma\|B\|_\Omega\right)\right)\left(\frac{1}{\sqrt{A_0}}\left\|\frac{\xi_0}{\sqrt{A}}\right\|_\Omega + \|D\|_\Omega\right)$$
$$+ \frac{1}{\|B\|_{1,\Omega}}\left(\sqrt{|\Omega|} + \gamma\|B\|_\Omega\right)|\mathcal{C}|, \tag{5.1}$$

with ξ_0 the initial vorticity, $\gamma = \frac{1}{\alpha}(1 + \frac{\sqrt{|\Omega|}\|B\|_\Omega}{\|B\|_{1,\Omega}})$, and $\alpha = \frac{1}{2}\min(A_0/C_p, A_0)$, with C_p the Poincaré constant of Ω. For the case $\|B\|_{1,\Omega} = 0$, this can be simplified into

$$\|\psi(\cdot,t)\|_{1,2,\Omega} \leq \frac{1}{\alpha}\left(\frac{1}{\sqrt{A_0}}\|\xi_0/\sqrt{A}\|_\Omega + \|D\|_\Omega\right). \tag{5.2}$$

Proof. First, assume $\|B\|_{1,\Omega} > 0$. If we introduce the relation for c_D (3.6) into (3.3), then we obtain the following weak formulation:

Find a $\psi_0 \in H^1_{0,D}(\Omega)$ such that for all $w_0 \in H^1_{0,D}(\Omega)$ the following relation is satisfied:

$$\tilde{L}(\psi_0, w_0) = \tilde{F}_\xi(w_0), \tag{5.3}$$

with the operators $\tilde{L} : H^1(\Omega) \times H^1(\Omega) \to \mathbb{R}$ and $\tilde{F}_\xi : H^{-1}(\Omega) \to \mathbb{R}$ defined as

$$\tilde{L}(\psi_0, w_0) := (\sqrt{A}\boldsymbol{\nabla}\psi_0, \sqrt{A}\boldsymbol{\nabla}w_0)_\Omega + (\sqrt{B}\psi_0, \sqrt{B}w_0)_\Omega$$
$$- \frac{1}{\|\sqrt{B}\|^2_\Omega}(\sqrt{B}\psi_0, \sqrt{B})_\Omega(\sqrt{B}w_0, \sqrt{B})_\Omega, \tag{5.4}$$

$$\tilde{F}_\xi(w_0) := F_\xi(w_0) - \frac{1}{\|\sqrt{B}\|^2_\Omega}(\sqrt{B}F_\xi(\mathbf{1}), \sqrt{B}w_0)_\Omega. \tag{5.5}$$

Next, we consider the coercivity of $\tilde{L}$ in $H^1_{0,D}(\Omega)$. Taking $w_0 = \psi_0$ in (5.4) and using the Schwarz inequality $(\sqrt{B}\psi_0, \sqrt{B})_\Omega \leq \|\sqrt{B}\psi_0\|_\Omega\|\sqrt{B}\|_\Omega$, we obtain for all $\psi_0 \in H^1_{0,D}(\Omega)$

$$\tilde{L}(\psi_0,\psi_0) = (\sqrt{A}\boldsymbol{\nabla}\psi_0, \sqrt{A}\boldsymbol{\nabla}\psi_0)_\Omega + (\sqrt{B}\psi_0, \sqrt{B}\psi_0)_\Omega - \frac{1}{\|\sqrt{B}\|^2_\Omega}(\psi_0\sqrt{B}, \sqrt{B})^2_\Omega$$
$$\geq A_0\|\boldsymbol{\nabla}\psi_0\|^2_\Omega.$$

Finally, using the Poincaré inequality $\|\psi_0\|^2_\Omega \leq C_p\|\boldsymbol{\nabla}\psi_0\|^2_\Omega$ for all $\psi_0 \in H^1_{0,D}(\Omega)$, we obtain the coercivity estimate:

$$\tilde{L}(\psi_0,\psi_0) \geq \alpha\|\psi_0\|^2_{1,2,\Omega} \qquad \forall\psi_0 \in H^1_{0,D}(\Omega),$$

with $\alpha = \frac{1}{2}\min(\frac{A_0}{C_p}, A_0)$. The boundedness of $\tilde{L}$ in $H^1_{0,D}(\Omega)$ follows from a straightforward application of the Schwarz inequality:

$$\tilde{L}(\psi_0, w_0) \leq (A_1 + 2\|\sqrt{B}\|^2_{\infty,\Omega})\|\psi_0\|_{1,2,\Omega}\|w_0\|_{1,2,\Omega} \qquad \forall\psi_0, w_0 \in H^1_{0,D}(\Omega).$$

Since $\tilde{L}$ is coercive and bounded on $H^1_{0,D}(\Omega)$, the Lax–Milgram theorem (see, e.g., [4]) states that (5.3) has a unique solution $\psi_0 \in H^1_{0,D}(\Omega)$, provided $\tilde{F}_\xi \in H^{-1}(\Omega)$ and we have the following upper bound for ψ_0:

$$\|\psi_0\|_{1,2,\Omega} \leq \frac{1}{\alpha}\|\tilde{F}_\xi\|_{-1,2,\Omega} \qquad \forall\psi_0 \in H^1_{0,D}(\Omega). \tag{5.6}$$

The right-hand side of (5.6) can be estimated directly using (5.5) and the definition of the dual norm

$$\|\tilde{F}_\xi\|_{-1,2,\Omega} \leq \frac{1}{\sqrt{A_0}} \left\| \frac{\xi}{\sqrt{A}} \right\|_\Omega + \|D\|_\Omega + \frac{\|B\|_\Omega |F_\xi(\mathbf{1})|}{\|B\|_{1,\Omega}}, \tag{5.7}$$

where we used the relations $\|\sqrt{B}\|_\Omega^2 = \|B\|_{1,\Omega}$ and $\|\xi/A\|_\Omega \leq \frac{1}{\sqrt{A_0}} \|\xi/\sqrt{A}\|_\Omega$. The contribution $F_\xi(\mathbf{1})$ can be estimated from (3.5):

$$F_\xi(\mathbf{1}) \leq \sqrt{|\Omega|} \left(\frac{1}{\sqrt{A_0}} \left\| \frac{\xi}{\sqrt{A}} \right\|_\Omega + \|D\|_\Omega \right) + |\mathcal{C}|. \tag{5.8}$$

Combining (5.6)–(5.8) yields the following upper bound for ψ_0:

$$\|\psi_0\|_{1,2,\Omega} \leq \gamma \left(\frac{1}{\sqrt{A_0}} \left\| \frac{\xi}{\sqrt{A}} \right\|_\Omega + \|D\|_\Omega \right) + \frac{\|B\|_\Omega}{\alpha \|B\|_{1,\Omega}} |\mathcal{C}|. \tag{5.9}$$

The coefficient c_D in (3.6) can be estimated using (5.8)–(5.9), yielding

$$\begin{aligned} \|c_D \cdot \mathbf{1}\|_\Omega \leq & \frac{\sqrt{|\Omega|}}{\|B\|_{1,\Omega}} \left(\sqrt{|\Omega|} + \gamma \|B\|_\Omega \right) \left(\frac{1}{\sqrt{A_0}} \left\| \frac{\xi}{\sqrt{A}} \right\|_\Omega + \|D\|_\Omega \right) \\ & + \frac{\sqrt{|\Omega|}}{\|B\|_{1,\Omega}} \left(1 + \frac{\|B\|_\Omega^2}{\alpha \|B\|_{1,\Omega}} \right) |\mathcal{C}|. \end{aligned} \tag{5.10}$$

Combining the estimates for ψ_0 and c_D, given by (5.9)–(5.10), respectively, and using the triangle inequality and the enstrophy conservation (4.3) gives after some algebraic manipulations the estimate (5.1) for the stream function in the $H^1(\Omega)$ norm.

Finally, for the case $\|B\|_{1,\Omega} = 0$, a straightforward calculation gives (5.2). ∎

As a direct consequence of (5.10), we have the following corollary.

COROLLARY 5.3. *The trace $\gamma(\psi)|_{\partial\Omega_D} = c_D(t)$ of $\psi = \psi_0 + c_D$, with ψ_0 satisfying* (3.3)*, is bounded by*

$$\begin{aligned} \|c_D\|_{\infty,(t_0,T)} \leq & \frac{1}{\|B\|_{1,\Omega}} \left(\sqrt{|\Omega|} + \gamma \|B\|_\Omega \right) \left(\frac{1}{\sqrt{A_0}} \left\| \frac{\xi_0}{\sqrt{A}} \right\|_\Omega + \|D\|_\Omega \right) \\ & + \frac{1}{\|B\|_{1,\Omega}} \left(1 + \frac{\|B\|_\Omega^2}{\alpha \|B\|_{1,\Omega}} \right) |\mathcal{C}|. \end{aligned} \tag{5.11}$$

For the error analysis, we now introduce the errors $\epsilon = \xi - \xi_h$ and $\delta = \psi - \psi_h$ in the vorticity field and stream function, respectively, and their $\mathcal{P}_{\tilde{K}}$ projection

$$\epsilon_h = \mathcal{P}_{\tilde{K}} \epsilon = \mathcal{P}_{\tilde{K}} \xi - \xi_h, \qquad \delta_h = \mathcal{P}_{\tilde{K}} \delta = \mathcal{P}_{\tilde{K}} \psi - \psi_h. \tag{5.12}$$

Proof of Theorem 5.1. We start with an analysis of the error in the DG finite element discretization for the vorticity equation, where we initially assume that $\psi \in C^0(\Omega) \cap H^1(\Omega)$, which will be confirmed in the second part of the proof by a regularity estimate. This also implies that $\boldsymbol{\nabla}^\perp \psi \cdot \mathbf{n} = -\frac{\partial \psi}{\partial \tau}$, with τ the tangential vector at ∂K, has the same trace when taking the limit either from the inside or the outside of element K.

First, we consider the error at a fixed time t. Subtracting the discretized weak formulation (3.10) from (3.8), with Ω restricted to K and v to V_h^k, yields the error

equation

$$\begin{aligned}\frac{d}{dt}\Big(\frac{\epsilon}{A},v\Big)_K &= \Big(\xi\boldsymbol{\nabla}^\perp\psi-\xi_h\boldsymbol{\nabla}^\perp\psi_h,\boldsymbol{\nabla}v\Big)_K\\ &\quad-\Big(\xi^-\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}-\hat{\xi}_h\boldsymbol{\nabla}^\perp\psi_h\cdot\mathbf{n},v^-\Big)_{\partial K}\qquad\forall v\in\mathsf{V}_h^k,\forall K\in\mathcal{T}_h.\end{aligned}\tag{5.13}$$

Adding and subtracting the projections $\mathcal{P}_{\tilde{K}}\psi$ and $\mathcal{P}_{\tilde{K}}\xi$ yields the following relation for the error in the vorticity field:

$$\begin{aligned}\frac{d}{dt}\Big(\frac{\epsilon}{A},v\Big)_K =&\big((\xi-\mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi+(\mathcal{P}_{\tilde{K}}\xi-\xi_h)\boldsymbol{\nabla}^\perp\psi\\ &+\ \xi_h\boldsymbol{\nabla}^\perp(\psi-\mathcal{P}_{\tilde{K}}\psi)+\xi_h\boldsymbol{\nabla}^\perp(\mathcal{P}_{\tilde{K}}\psi-\psi_h),\boldsymbol{\nabla}v\big)_K\\ &-\big((\xi^--\mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}+(\mathcal{P}_{\tilde{K}}\xi-\hat{\xi}_h)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}\\ &+\ \hat{\xi}_h\boldsymbol{\nabla}^\perp(\psi-\mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n}+\hat{\xi}_h\boldsymbol{\nabla}^\perp(\mathcal{P}_{\tilde{K}}\psi-\psi_h)\cdot\mathbf{n},v^-\big)_{\partial K}.\end{aligned}\tag{5.14}$$

Note that, since the projection $\mathcal{P}_{\tilde{K}}\xi$ is continuous on the macroelement $\tilde{K}$ and $K\subset\mathrm{int}(\tilde{K})$, we have $\mathcal{P}_{\tilde{K}}\xi^-=\mathcal{P}_{\tilde{K}}\xi^+=\mathcal{P}_{\tilde{K}}\xi$ at ∂K. Introducing the definitions for ϵ_h and δ_h given by (5.12) results in the error equation

$$\begin{aligned}\frac{d}{dt}\Big(\frac{\epsilon}{A},v\Big)_K =&\big((\xi-\mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi+\epsilon_h\boldsymbol{\nabla}^\perp\psi+\xi_h\boldsymbol{\nabla}^\perp(\psi-\mathcal{P}_{\tilde{K}}\psi)\\ &+\xi_h\boldsymbol{\nabla}^\perp\delta_h,\boldsymbol{\nabla}v\big)_K-\big((\xi^--\mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}\\ &+(\mathcal{P}_{\tilde{K}}\xi-\hat{\xi}_h)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}+\hat{\xi}_h\boldsymbol{\nabla}^\perp(\psi-\mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n}\\ &+\hat{\xi}_h\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n},v^-\big)_{\partial K}.\end{aligned}\tag{5.15}$$

We can simplify (5.15) for the central flux $\hat{\xi}_h=\frac{1}{2}(\xi_h^-+\xi_h^+)$ using the following relations:

$$\begin{aligned}&(\epsilon_h\boldsymbol{\nabla}^\perp\psi,\boldsymbol{\nabla}v)_K-((\mathcal{P}_{\tilde{K}}\xi-\hat{\xi}_h)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n},v^-)_{\partial K}\\ &\quad=-(\boldsymbol{\nabla}\cdot(\epsilon_h\boldsymbol{\nabla}^\perp\psi),v)_K+(\epsilon_h^-\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n},v^-)_{\partial K}\\ &\qquad-((\epsilon_h^-+\xi_h^--\hat{\xi}_h)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n},v^-)_{\partial K}\\ &\quad=-(\boldsymbol{\nabla}\epsilon_h\cdot\boldsymbol{\nabla}^\perp\psi,v)_K-\frac{1}{2}((\xi_h^--\xi_h^+)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n},v^-)_{\partial K},\end{aligned}\tag{5.16}$$

where in the first step we integrated by parts and introduced $\mathcal{P}_{\tilde{K}}\xi=\epsilon_h^-+\xi_h^-$ and in the second step we used $\boldsymbol{\nabla}\cdot(\epsilon_h\boldsymbol{\nabla}^\perp\psi)=\boldsymbol{\nabla}\epsilon_h\cdot\boldsymbol{\nabla}^\perp\psi$, since $\boldsymbol{\nabla}\cdot\boldsymbol{\nabla}^\perp\psi=0$. Similarly, we obtain

$$\begin{aligned}&(\xi_h\boldsymbol{\nabla}^\perp\delta_h,\boldsymbol{\nabla}v)_K-(\hat{\xi}_h\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n},v^-)_{\partial K}\\ &\quad=-(\boldsymbol{\nabla}\cdot(\xi_h\boldsymbol{\nabla}^\perp\delta_h),v)_K+(\xi_h^-\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n},v^-)_{\partial K}\\ &\qquad-(\hat{\xi}_h\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n},v^-)_{\partial K}\\ &\quad=-(\boldsymbol{\nabla}\xi_h\cdot\boldsymbol{\nabla}^\perp\delta_h,v)_K+\frac{1}{2}((\xi_h^--\xi_h^+)\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n},v^-)_{\partial K}.\end{aligned}\tag{5.17}$$

For the upwind flux, we obtain a similar relation with $\frac{1}{2}(\xi_h^--\xi_h^+)$ replaced by $\frac{1}{2}(\xi_h^--\xi_h^+)\big(1-\mathrm{sign}(\boldsymbol{\nabla}^\perp\psi_h\cdot\mathbf{n})\big)$ in (5.16) and (5.17), where sign is the sign function, with

$\operatorname{sign}(x) = -1$ if $x < 0$ and $\operatorname{sign}(x) = 1$ if $x \geq 0$. If we introduce (5.16) and (5.17) into (5.15) and use the relation

$$-\frac{1}{2}(\xi_h^- - \xi_h^+)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n} + \frac{1}{2}(\xi_h^- - \xi_h^+)\boldsymbol{\nabla}^\perp\delta_h\cdot\mathbf{n} \\ = -\frac{1}{2}(\xi_h^- - \xi_h^+)\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n} - \frac{1}{2}(\xi_h^- - \xi_h^+)\boldsymbol{\nabla}^\perp\psi_h\cdot\mathbf{n},$$

then we obtain the following relation for ϵ for all $v \in V_h^k$:

$$\begin{aligned}\frac{d}{dt}\Big(\frac{\epsilon}{A}, v\Big)_K &+ (\boldsymbol{\nabla}\epsilon_h\cdot\boldsymbol{\nabla}^\perp\psi, v)_K + (\boldsymbol{\nabla}\xi_h\cdot\boldsymbol{\nabla}^\perp\delta_h, v)_K \\ &+\frac{1}{2}((\epsilon_h^+ - \epsilon_h^-)\boldsymbol{\nabla}^\perp\psi_h\cdot\mathbf{n}, v^-)_{\partial K} \\ &=((\xi - \mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi + \xi_h\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi), \boldsymbol{\nabla}v)_K \\ &-\Bigg((\xi^- - \mathcal{P}_{\tilde{K}}\xi)\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n} \\ &+\left(\hat{\xi}_h + \frac{1}{2}(\xi_h^- - \xi_h^+)\right)\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n}, v^-\Bigg)_{\partial K} \\ &=: \mathcal{Q}_K(\xi, \xi_h, \psi; v), \end{aligned} \tag{5.18}$$

where we used for the fourth term on the left-hand side $\xi_h^- - \xi_h^+ = \mathcal{P}_{\tilde{K}}\xi - \xi_h^+ - (\mathcal{P}_{\tilde{K}}\xi - \xi_h^-) = \epsilon_h^+ - \epsilon_h^-$. Note that the right-hand side depends only on ξ_h, ψ, and the interpolation errors $\xi - \mathcal{P}_{\tilde{K}}\xi$ and $\psi - \mathcal{P}_{\tilde{K}}\psi$ but is independent of ϵ, ϵ_h, and δ_h. Using the generalized Hölder inequality (see [1, Cor. 2.6, p. 25]), we can estimate $\mathcal{Q}_K$ as

$$\begin{aligned}\mathcal{Q}_K(\xi, \xi_h, \psi; v) \leq &\|\xi - \mathcal{P}_{\tilde{K}}\xi\|_{p,K}\|\boldsymbol{\nabla}^\perp\psi\|_K\|\boldsymbol{\nabla}v\|_{q,K} \\ &+\|\xi_h\|_K\|\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\|_{p,K}\|\boldsymbol{\nabla}v\|_{q,K} \\ &+\|\xi^- - \mathcal{P}_{\tilde{K}}\xi\|_{p,\partial K}\|\boldsymbol{\nabla}^\perp\psi\cdot\mathbf{n}\|_{p',\partial K}\|v^-\|_{\infty,\partial K} \\ &+\left\|\hat{\xi}_h + \frac{1}{2}(\xi_h^- - \xi_h^+)\right\|_{\partial K}\|\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n}\|_{\partial K}\|v^-\|_{\infty,\partial K}, \end{aligned} \tag{5.19}$$

with $p > 2$, $q = \frac{2p}{p-2}$, and $p' = \frac{p}{p-1}$. Using the interpolation estimate (2.3) given by Lemma 2.1, we can directly estimate the interpolation errors in (5.19):

$$\|\xi - \mathcal{P}_{\tilde{K}}\xi\|_{p,K} = |\xi - \mathcal{P}_{\tilde{K}}\xi|_{0,p,K} \leq Ch_K^s|\xi|_{s,p,\tilde{K}}, \tag{5.20}$$

$$\|\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\|_{p,K} = |\psi - \mathcal{P}_{\tilde{K}}\psi|_{1,p,K} \leq Ch_K^t|\psi|_{t+1,p,\tilde{K}}, \tag{5.21}$$

with $0 \leq s \leq k+1$, $0 \leq t \leq k$, and $p > 2$. Similarly, using (2.4), together with the fact that the normal vector $\mathbf{n}$ has length one and the triangle inequality, we can estimate the boundary contributions in (5.19):

$$\|\xi^- - \mathcal{P}_{\tilde{K}}\xi\|_{p,\partial K} \leq Ch_K^{s-\frac{1}{p}}|\xi|_{s,p,\tilde{K}}, \tag{5.22}$$

$$\|\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi)\cdot\mathbf{n}\|_{\partial K} \leq Ch_K^t|\psi|_{t+\frac{3}{2},2,\tilde{K}}, \tag{5.23}$$

with $0 < \frac{1}{p} < s \leq k+1$ and $0 < t \leq k - \frac{1}{2}$. Since $\xi_h \in \mathsf{V}_h^k$, which is a finite-dimensional space, we can directly use the equivalence of norms in a finite-dimensional space to obtain the inverse estimate (see, e.g., [5, p. 137])

$$\|\xi_h\|_{\partial K} \leq \frac{C}{\sqrt{h}}\|\xi_h\|_K,$$

which, combined with the triangle inequality, gives for the central flux

$$\left\| \hat{\xi}_h + \frac{1}{2}(\xi_h^- - \xi_h^+) \right\|_{\partial K} \leq \frac{C}{\sqrt{h}} \|\xi_h\|_{\tilde{K}}, \tag{5.24}$$

and a similar relation in the case of the upwind flux. If we choose $t = s + \frac{1}{2}$ in (5.23) and use (5.24), then we obtain

$$\left\| \hat{\xi}_h + \frac{1}{2}(\xi_h^- - \xi_h^+) \right\|_{\partial K} \|\boldsymbol{\nabla}^\perp(\psi - \mathcal{P}_{\tilde{K}}\psi) \cdot \mathbf{n}\|_{\partial K} \leq C h_K^s \|\xi_h\|_{\tilde{K}} |\psi|_{s+2,2,\tilde{K}}, \tag{5.25}$$

with $-\frac{1}{2} < s \leq k-1$. Next, we provide an upper bound for $\|\boldsymbol{\nabla}^\perp\psi \cdot \mathbf{n}\|_{p',\partial K}$ appearing in the third term of (5.19). For this, in the first line of (5.26), we use the Hölder inequality (see [1, Cor. 2.6, p. 25]) with $\frac{1}{p'} = \frac{1}{2} + \frac{1}{w}$. In the second line, we use $\|\mathbf{1}\|_{w,\partial K} \leq C h_K^{\frac{1}{w}}$, with h_K the element diameter, and the trace is estimated for $\frac{1}{2} < t < \frac{3}{2}$ using Theorem 3.38 in [11]:

$$\begin{aligned} \|\boldsymbol{\nabla}^\perp\psi \cdot \mathbf{n}\|_{p',\partial K} &\leq \|\boldsymbol{\nabla}^\perp\psi\|_{p',\partial K} \leq \|\boldsymbol{\nabla}^\perp\psi\|_{2,\partial K} \|\mathbf{1}\|_{w,\partial K} \\ &\leq C h_K^{\frac{1}{w}} \|\boldsymbol{\nabla}^\perp\psi\|_{t-\frac{1}{2},2,\partial K} \leq C h_K^{\frac{1}{w}} \|\boldsymbol{\nabla}^\perp\psi\|_{t,2,K} \leq C h_K^{\frac{1}{w}} \|\psi\|_{t+1,2,K}. \end{aligned} \tag{5.26}$$

We can further sharpen this estimate by introducing $\epsilon = t - \frac{1}{2}$, with $0 < \epsilon \leq \frac{1}{2}$, in the last term of (5.26) and using the imbedding $W^2_{\frac{4}{3-2\epsilon}}(\Omega) \to W_2^{\frac{3}{2}+\epsilon}(\Omega)$, with Ω a Lipschitz domain (see [6, Theorem 1.4.4.1, p. 27]):

$$\|\boldsymbol{\nabla}^\perp\psi \cdot \mathbf{n}\|_{p',\partial K} \leq C h_K^{\frac{1}{w}} \|\psi\|_{\frac{3}{2}+\epsilon,2,K} \leq C h_K^{\frac{1}{w}} \|\psi\|_{2,\frac{4}{3-2\epsilon},K}.$$

This relation can be further evaluated using again the Hölder inequality with $\frac{1}{\frac{4}{3-2\epsilon}} = \frac{1}{2} + \frac{1-2\epsilon}{4}$ and the inequality $(\sum_{i=1}^m a_i^\beta)^{\frac{1}{\beta}} \leq \sum_{i=1}^m a_i$ for $a_i \geq 0$ and $\beta \geq 1$, which give

$$\begin{aligned} \|\boldsymbol{\nabla}^\perp\psi \cdot \mathbf{n}\|_{p',\partial K} &\leq C h_K^{\frac{1}{w}} \left(\sum_{|\alpha|\leq 2} \|D^\alpha\psi\|^{\frac{4}{3-2\epsilon}}_{\frac{4}{3-2\epsilon},K} \right)^{\frac{3-2\epsilon}{4}} \\ &\leq C h_K^{\frac{1}{w}} \left[\sum_{|\alpha|\leq 2} (\|D^\alpha\psi\|_{2,K} \|\mathbf{1}\|_{\frac{4}{1-2\epsilon},K})^{\frac{4}{3-2\epsilon}} \right]^{\frac{3-2\epsilon}{4}} \\ &\leq C h_K^{\frac{1}{w}+\frac{1-2\epsilon}{2}} \left[\sum_{|\alpha|\leq 2} \|D^\alpha\psi\|^{\frac{4}{3-2\epsilon}}_{2,K} \right]^{\frac{3-2\epsilon}{4}} \leq C h_K^{\frac{1}{w}+\frac{1}{2}-\epsilon} \|\psi\|_{2,2,K}. \end{aligned} \tag{5.27}$$

If we introduce (5.20)–(5.22), (5.25), and (5.27) into (5.19) and choose $0 < \epsilon \leq \frac{1}{2}$ such that the relation $s - \frac{1}{p} + \frac{1}{w} + \frac{1}{2} - \epsilon = s - \frac{1}{p} + \frac{1}{p'} - \epsilon = s + \frac{p-2}{p} - \epsilon \geq s$ holds for $p > 2$, then we obtain

$$\begin{aligned} \mathcal{Q}_K(\xi, \xi_h, \psi; v) \leq C h_K^s \big(&\big(|\xi|_{s,p,\tilde{K}} \|\boldsymbol{\nabla}^\perp\psi\|_K + \|\xi_h\|_K |\psi|_{s+1,p,\tilde{K}}\big) \|\boldsymbol{\nabla} v\|_{q,K} \\ &+ \big(|\xi|_{s,p,\tilde{K}} \|\psi\|_{2,2,K} + \|\xi_h\|_{\tilde{K}} |\psi|_{s+2,2,\tilde{K}}\big) \|v^-\|_{\infty,\partial K} \big), \end{aligned} \tag{5.28}$$

with $q = \frac{2p}{p-2}$ and $\frac{1}{p} < s \leq k-1$ determined by the smoothness of ξ and the order k of the polynomial basis functions. Note that, due to the condition $\mathsf{W}_h^k \subset \mathsf{V}_h^k$, which is necessary to ensure conservation of energy as stated in Lemma 4.2, we have to use at least the same polynomial order for ξ_h as for ψ_h. This condition is, however, not essential for the present proof, which requires only polynomials of order $k-2$ for the vorticity field ξ_h when polynomials of order k are used for the stream function ψ_h, but then the discrete energy is no longer conserved.

Next, we further estimate the right-hand side of (5.28). Using Lemmas 4.1 and 4.2, we can also bound the L^2 norm of the vorticity by the initial vorticity

$$\|\xi(\cdot,t)/\sqrt{A}\|_\Omega = \|\xi(\cdot,0)/\sqrt{A}\|_\Omega = \|\xi_0/\sqrt{A}\|_\Omega, \tag{5.29}$$

$$\|\xi_h(\cdot,t)/\sqrt{A}\|_\Omega \leq \|\xi_h(\cdot,0)/\sqrt{A}\|_\Omega = \|\xi_0/\sqrt{A}\|_\Omega, \tag{5.30}$$

with ξ_0 the initial vorticity. An upper bound for the norms of ψ is obtained by first considering ψ_0 defined in (3.2). As shown in the proof of Lemma 5.2, the operator $\tilde{L}$ in (5.4) is coercive and bounded in $H^1_{0,D}(\Omega)$, and together with the condition $A, B \in C^{s,1}(\overline{\Omega})$, the regularity estimate Theorem 4.18(i) on pages 137–138 in [11] implies that for ψ_0 satisfying (5.3) we have the estimate

$$\|\psi_0\|_{s+2,2,\Omega_1} \leq C\big(\|\psi_0\|_{1,2,\Omega_2} + \|\xi\|_{s,2,\Omega_2}\big), \qquad s \geq 0, \tag{5.31}$$

where $\Omega_1 = G_1 \cap \Omega$, $\Omega_2 = G_2 \cap \Omega$, with G_1 and G_2 open subsets of $\mathbb{R}^2$ such that $\overline{G}_1$ is a compact subset of G_2, and $\Gamma_2 = G_2 \cap \partial\Omega$ with Γ_2 a $C^{s+1,1}$ function. Here, G_1 intersects the boundary of Ω, and G_2 has a smooth boundary not necessarily completely contained in Ω. Note that the constant C in (5.31) does not depend on ξ. An estimate for $\|\psi_0\|_{1,2,\Omega}$ satisfying (5.3) is given by (5.9). Combining this result with (5.31) and the estimate for $\|c_D \cdot \mathbf{1}\|_\Omega$ given by (5.10), we obtain

$$\|\psi\|_{s+2,2,\Omega} \leq C\|\xi\|_{s,2,\Omega}, \qquad s \geq 0, \tag{5.32}$$

where we used that Ω can be covered by a finite number of sets Ω_1. Note that the regularity estimate (5.32) also applies for $K \in \mathcal{T}_h$, which follows directly if we set $\Omega_1 = K$. Since $W_2^{s+2}(\Omega)$, $s \geq 0$, is embedded in $C^0(\overline{\Omega})$ (see [1, Theorem 4.12, p. 85]), this also confirms the assumption made at the start of the proof, namely, that ψ is continuous.

In order to estimate $\|\boldsymbol{\nabla}^\perp \psi(\cdot,t)\|_K$, we first use the Hölder inequality with $\frac{1}{2} = \frac{1}{2+\epsilon} + \frac{\epsilon}{2(2+\epsilon)}$ ($\epsilon > 0$), the imbedding Theorem 4.12, Case B in [1] with $j = m = 1$, $p = n = 2$, $q = \frac{2(2+\epsilon)}{\epsilon}$, and (5.32) together with (5.29) to obtain the estimate

$$\begin{aligned}
\|\boldsymbol{\nabla}^\perp \psi(\cdot,t)\|_K &\leq \|\boldsymbol{\nabla}^\perp \psi(\cdot,t)\|_{2(2+\epsilon)/\epsilon,K} \|\mathbf{1}\|_{2+\epsilon,K} \\
&\leq C h_K^{\frac{2}{2+\epsilon}} \|\psi(\cdot,t)\|_{1,2(2+\epsilon)/\epsilon,K} \leq C h_K^{\frac{2}{2+\epsilon}} \|\psi(\cdot,t)\|_{2,2,K} \\
&\leq C h_K^{\frac{2}{2+\epsilon}} \|\xi(\cdot,t)\|_{2,\Omega} \leq C h_K^{\frac{2}{2+\epsilon}} \|\xi_0\|_\Omega.
\end{aligned} \tag{5.33}$$

In a similar way, using the Hölder inequality with $\frac{1}{p} = \frac{1}{p+\epsilon} + \frac{\epsilon}{p(p+\epsilon)}$ ($\epsilon > 0$) and the imbedding $W_2^{s+2}(\Omega) \to W^{s+1}_{p(p+\epsilon)/\epsilon}(\Omega)$ (see Theorem 1.4.4.1 in [6]), we obtain

$$\begin{aligned}
|\psi(\cdot,t)|_{s+1,p,\tilde{K}} &\leq |\psi(\cdot,t)|_{s+1,p(p+\epsilon)/\epsilon,\tilde{K}} \|\mathbf{1}\|_{p+\epsilon,\tilde{K}} \\
&\leq C h_K^{\frac{2}{p+\epsilon}} |\psi(\cdot,t)|_{s+1,p(p+\epsilon)/\epsilon,\tilde{K}} \\
&\leq C h_K^{\frac{2}{p+\epsilon}} \|\psi(\cdot,t)\|_{s+2,2,\Omega} \leq C h_K^{\frac{2}{p+\epsilon}} \|\xi(\cdot,t)\|_{s,2,\Omega}.
\end{aligned} \tag{5.34}$$

We also use the imbedding $W^1_{2+\epsilon}(K) \to L_\infty(K)$ for all $\epsilon > 0$, which is a consequence of Theorem 4.12, Case A in [1]. Applying this for the partial derivatives of v together with the Hölder inequality for $0 < \epsilon < q-2$ with $\frac{1}{2+\epsilon} = \frac{1}{q} + \frac{q-2-\epsilon}{q(2+\epsilon)}$, we obtain

$$\begin{aligned}\|v^-\|_{\infty,\partial K} &\leq C\|v\|_{\infty,K} \leq C\|v\|_{1,2+\epsilon,K} \leq C\|v\|_{1,q,K}\|1\|_{\frac{q(2+\epsilon)}{q-2-\epsilon},K} \\ &\leq Ch_K^{\frac{2(q-2-\epsilon)}{q(2+\epsilon)}}\|v\|_{1,q,K}. \qquad (5.35)\end{aligned}$$

If we introduce (5.30) and (5.32)–(5.35) into (5.28) and use the relation

$$\lim_{\epsilon\to 0} \min\left\{\frac{2(q-2-\epsilon)}{q(2+\epsilon)}, \frac{2}{p+\epsilon}\right\} = \min\left\{\frac{q-2}{q}, \frac{2}{p}\right\} = \frac{2}{p},$$

since $q = \frac{2p}{p-2}$, then we obtain, when $h_K \leq 1$ and for $\epsilon_0 > 0$ arbitrary, the following estimate for $\mathcal{Q}_K$ only in terms of the vorticity field:

$$\begin{aligned}\mathcal{Q}_K(\xi,\xi_h,\psi;v) &\leq Ch_K^{s+\frac{2}{p}-\epsilon_0}\Big(|\xi|_{s,p,\tilde{K}}\|\xi_0\|_\Omega + \|\xi_0\|_\Omega\|\xi\|_{s,2,\Omega} + \|\xi\|_{s,p,\tilde{K}}\|\xi_0\|_\Omega \\ &\quad + \|\xi_0\|_\Omega\|\xi\|_{s,2,\Omega}\Big)\|v\|_{1,q,K} \\ &\leq Ch_K^{s+\frac{2}{p}-\epsilon_0}\|\xi_0\|_\Omega\|\xi\|_{s,p,\Omega}\|v\|_{1,q,K}, \qquad (5.36)\end{aligned}$$

with $\frac{1}{p} < s \leq k-1$ and $q > 2$, which follows directly from the relation $q = \frac{2p}{p-2}$ and the condition $p > 2$.

We now introduce (5.36) into (5.18) and divide this expression by $\|v\|_{1,q,K}$. Finally, we take the supremum over all $v \in W^1_q(K)\backslash\{0\}$, sum over all elements $K \in \mathcal{T}_h$, integrate in time, and obtain an expression for ϵ in the norm of the $W^{-1}_{q'}(\mathcal{T}_h)$ Sobolev space with $\frac{1}{q} + \frac{1}{q'} = 1$, which is dual to $W^1_q(\mathcal{T}_h)$:

$$\begin{aligned}\left\|\frac{\epsilon}{A}\right\|_{-1,q',\mathcal{T}_h} &+ \int_{t_0}^T \Bigg(\|\boldsymbol{\nabla}\epsilon_h\cdot\boldsymbol{\nabla}^\perp\psi\|_{-1,q',\mathcal{T}_h} + \|\boldsymbol{\nabla}\xi_h\cdot\boldsymbol{\nabla}^\perp\delta_h\|_{-1,q',\mathcal{T}_h} \\ &+ \frac{1}{2}\sum_{K\in\mathcal{T}_h}\sup_{0\neq v\in W^1_q(K)}\frac{((\epsilon_h^+ - \epsilon_h^-)\boldsymbol{\nabla}^\perp\psi_h\cdot\mathbf{n}, v^-)_{\partial K}}{\|v\|_{1,q,K}}\Bigg)dt \\ &\leq Ch^{s+\frac{2}{p}-\epsilon_0}\|\xi_0\|_\Omega\int_{t_0}^T\|\xi(\cdot,t)\|_{s,p,\Omega}dt, \qquad (5.37)\end{aligned}$$

with $h = \max_{K\in\mathcal{T}_h} h_K$, $\frac{1}{q'} + \frac{1}{q} = 1$. Note that $1 < q' < 2$, since $q > 2$, and $\frac{1}{p} < s \leq k-1$, with k the order of the polynomial basis functions. Since all terms are positive on the left-hand side of (5.37), we obtain the following negative index Sobolev norm estimate for ϵ/A:

$$\|\epsilon/A\|_{-1,q',\mathcal{T}_h} \leq Ch^{s+\frac{2}{p}-\epsilon_0}\|\xi_0\|_\Omega\int_{t_0}^T\|\xi(\cdot,t)\|_{s,p,\Omega}dt. \qquad (5.38)$$

The error equation for ψ is obtained by subtracting (3.7) from (3.3) and restricting w to W^k_h:

$$L(\delta,w) = (A\boldsymbol{\nabla}\delta,\boldsymbol{\nabla}w)_\Omega + (B\delta,w)_\Omega = -\sum_{K\in\mathcal{T}_h}(\epsilon/A,w)_K. \qquad (5.39)$$

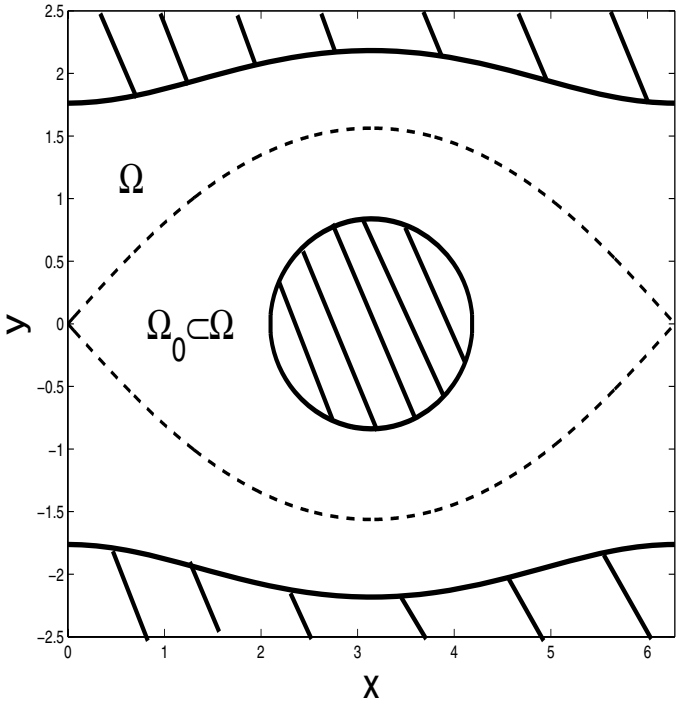

FIG. 1. *Domain used for model problem.*

The operator $L : W_q^1(\Omega) \times W_q^1(\Omega) \to \mathbb{R}$ is coercive on $W_q^1(\Omega)$ with $q > 2$, which follows directly from Theorem 5.3.3 in [4], which also applies to the case $q \neq 2$ (see the remark at the end of page 135 in [4], and the fact that (1.2)–(1.3) are equivalent to a Dirichlet boundary condition on ψ. Using the coercivity of L in $W_q^1(\Omega)$ and (5.39), we obtain the following relation:

$$\begin{aligned}\|\delta\|_{1,q,\Omega} &\leq \frac{1}{\alpha_\delta} \sup_{0\neq w\in W_q^1(\Omega)} \frac{L(\delta, w)}{\|w\|_{1,q,\Omega}} \\ &\leq \frac{1}{\alpha_\delta} \sum_{K\in\mathcal{T}_h} \sup_{0\neq w\in W_q^1(K)} \frac{(\epsilon/A, w)_K}{\|w\|_{1,q,K}} \\ &= \frac{1}{\alpha_\delta} \left\| \frac{\epsilon}{A} \right\|_{-1,q',\mathcal{T}_h}, \end{aligned} \tag{5.40}$$

with α_δ the coercivity constant.

The proof is completed by combining (5.38) and (5.40) and using the relation $\mathbf{u} = A\mathbf{U} = A\boldsymbol{\nabla}^\perp\psi$, and hence $\|\mathbf{u} - \mathbf{u}_h\|_{0,q,\Omega} \leq C\|\psi - \psi_h\|_{1,q,\Omega} = C\|\delta\|_{1,q,\Omega}$. ∎

6. Application to a geophysical model problem. In this section, we consider the flow field generated by a concentrated patch of vorticity in a 2D geophysical flow. The flow field is described by (1.1) with $A = 1$, $B = D = 0$. The flow domain Ω and the subdomain Ω_0 are shown in Figure 1. The domain Ω has an island in the middle, and periodic boundary conditions are applied at $x = 0$ and $x = 2\pi$. Solid walls are hatched and the slip flow boundary condition (1.2) is applied at these

surfaces. We define in Ω the initial vorticity ξ_0 as

$$\xi_0 = \chi_{\Omega_0},$$

with χ_{Ω_0} the characteristic function of Ω_0, which is *one* inside of Ω_0 and *zero* elsewhere. In Appendix A, we prove that $\xi_0 \in W_p^{\frac{1}{p}-\epsilon}(\Omega)$, with $1 \leq p < \infty$ and ϵ an arbitrary positive number, but $\xi_0 \notin H^2(\Omega)$, as is required to apply the error estimates discussed in [3]. The present test case is thus an excellent example of a nonsmooth flow which has the minimal amount of smoothness required by the theory developed in this article.

At first sight, the initial vorticity field appears, however, to be just outside the range of validity for Theorem 5.1, but using the continuity of the Clément interpolation in Lemma 2.1, we can assume that the initial vorticity field $\xi_0 \in W_p^{\frac{1}{p}-\epsilon}$ is equivalent to a slightly smoother field $\tilde{\xi}_0 \in W_p^{\frac{1}{p}+\epsilon}$ which has been taken such that for all macroelements $\tilde{K}$

$$\mathcal{P}_{\tilde{K}}\tilde{\xi_0} = \mathcal{P}_{\tilde{K}}\xi_0 \quad \text{and} \quad \lim_{\epsilon\to 0} \|\xi_0\|_{\frac{1}{p}-2\epsilon,p,\tilde{K}} = \lim_{\epsilon\to 0} \|\tilde{\xi}_0\|_{\frac{1}{p}+\epsilon,p,\tilde{K}}.$$

Since in Theorem 5.1 we must have $p > 2$, we choose $p = 2+\epsilon$, $r = \frac{1}{2+\epsilon} - \epsilon$, which gives that $q = \frac{2(2+\epsilon)}{\epsilon}$, $q' = \frac{2(2+\epsilon)}{2(2+\epsilon)-\epsilon}$, and therefore $s \leq \min\{k-1, \frac{3}{2+\epsilon} - \epsilon\}$. Taking the limits $\epsilon \to 0$, we should then investigate the $L^\infty(\Omega)$ norm for the error in the velocity field and the $W_1^{-1}(\mathcal{T}_h)$ norm for the vorticity field.

In the computations, we used second order polynomials ($k = 2$), and therefore we expect based on Theorem 5.1 a first order convergence in the L^∞ norm for the velocity and in the $W_1^{-1}(\mathcal{T}_h)$ norm for the vorticity. The time integration is conducted with a third order Runge–Kutta method with such a small time step that it does not influence the spatial accuracy. Since we do not know the exact solution, we use a sequence of unstructured uniformly refined meshes, see Figure 2, to obtain an accurate estimate for the norm of the error and the rate of convergence s. The finest mesh is denoted as reference mesh, with mesh size h_{ref} and solution u_{ref}. The meshes satisfy $h_{\text{ref}} < h_3 < h_2 < h_1$, with the mesh size approximately doubling for each mesh; see Table 1. Assuming the following asymptotic behavior of the error,

$$\|u - u_h\| \leq \|u - u_{\text{ref}}\| + \|u_{\text{ref}} - u_h\| \cong C_r h^s, \tag{6.1}$$

we can eliminate the unknown contribution $\|u - u_{\text{ref}}\|$ by considering (6.1) for three meshes with mesh sizes h_1, h_2, and h_3, respectively. This results in the following relation for the rate of convergence s:

$$\frac{h_1^s - h_2^s}{h_2^s - h_3^s} = \frac{\|u_{\text{ref}} - u_{h_1}\| - \|u_{\text{ref}} - u_{h_2}\|}{\|u_{\text{ref}} - u_{h_2}\| - \|u_{\text{ref}} - u_{h_3}\|}, \tag{6.2}$$

which is solved numerically. The constant C_r can be computed easily from

$$C_r = \frac{1}{h_2^s - h_3^s}\Big(\|u_{\text{ref}} - u_{h_2}\| - \|u_{\text{ref}} - u_{h_3}\|\Big), \tag{6.3}$$

and (6.1) then provides an estimate the norm of the error.

In Table 1, we present the estimated L_2-error $\|\xi_0 - \xi_{0h}\|_{\mathcal{T}_h}$ and convergence rate $\hat{s}_\xi$ for the initial vorticity field for different numbers of elements and mesh sizes, obtained

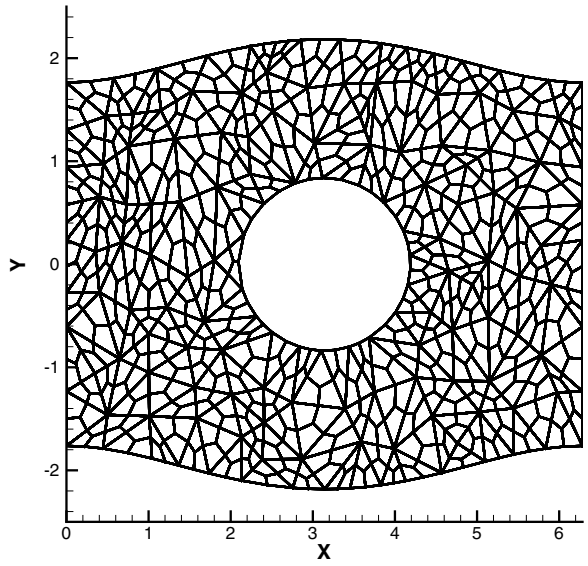

FIG. 2. *Unstructured mesh in the domain* Ω.

TABLE 1
Estimated L_2*-error and rate of convergence in the initial vorticity field.*

Number of elements	h	$\|\xi_0 - \xi_{0h}\|_{\mathcal{T}_h}$	$\hat{s}_\xi$
782	0.0850288	0.5799913	-
3004	0.0434386	0.3982912	0.5596
11768	0.0219504	0.2886455	0.4717

185312	0.0055309	0.1433234	0.5034

from (6.1)–(6.3). For $p = 2 + \epsilon$, with $\epsilon > 0$ arbitrary small, the initial vorticity field satisfies $\xi_0 \in W_{2+\epsilon}^{\frac{1}{2+\epsilon}-\epsilon}$, and we expect a convergence rate $\hat{s}_\xi \cong 0.5$, which is closely confirmed by the results in Table 1.

In the time dependent computations, the initial vorticity field evolves into a complex pattern of continuously thinner shear layers which wrap around each other, but since there is no viscosity in the fluid, the smoothness of the vorticity field does not increase. The vorticity field at several instances in time is shown in Figures 3–5. Note that, since the element boundaries are not aligned with the jumps in vorticity, we see a slight distortion in the plots near these discontinuities.

In Table 2, the estimated L_∞-error in the velocity field $\|\mathbf{u} - \mathbf{u}_h\|_{\infty,\Omega}$ and the estimated convergence rate $\hat{s}_\mathbf{u}$ as a function of the number of elements and mesh size are presented. These results show that the convergence rate for the velocity field is close to one, as was predicted by Theorem 5.1. For the vorticity, we would have to compute the $W_1^{-1}(\mathcal{T}_h)$ norm of the error, but unfortunately it was not possible to obtain accurate numerical estimates for this norm, since this requires meshes beyond our computational means.

Considering the results on the order of accuracy of the CDG scheme summarized in Table 2, we can conclude that the analysis is sharp for this type of nonsmooth flow and also that the CDG scheme behaves properly for this nonsmooth flow field. More

the characteristic function of Ω_0, $\chi_{\Omega_0} : \Omega \to \mathbb{R}$ *(which is* one *inside of* Ω_0 *and* zero *elsewhere) belongs to the space* $W_p^{\frac{1}{p}-\epsilon}(\Omega)$, *with* $1 \le p < \infty$ *and* $\epsilon > 0$.

Proof. We use the definition of fractional order Sobolev spaces $W_p^s(\Omega)$ in [4] (with $n = 2$ and $1 \le p < \infty$), and, accordingly, we have to determine s such that

$$\int_\Omega \int_\Omega \frac{|\chi_{\Omega_0}(x) - \chi_{\Omega_0}(y)|^p}{|x-y|^{2+ps}} \,\mathrm{d}x\,\mathrm{d}y \tag{A.1}$$

is finite. In the consecutive estimates, d_Ω denotes the diameter of Ω. The distance of two sets $S_1, S_2 \subset \mathbb{R}^2$ is denoted with $d(S_1, S_2) = \inf\{|x_1 - x_2| : x_1 \in S_1, x_2 \in S_2\}$, while $B(x, r)$ yields the open ball $\{y \in \mathbb{R}^2 : |x - y| < r\}$. Using the definition of χ_{Ω_0}, it is clear that $\chi_{\Omega_0}(x) - \chi_{\Omega_0}(y) = 0$ whenever $x, y \in \Omega_0$ or $x, y \in \Omega \setminus \Omega_0$. Therefore, we can estimate the double integral in (A.1) as follows:

$$\begin{aligned}
\int_\Omega \int_\Omega \frac{|\chi_{\Omega_0}(x) - \chi_{\Omega_0}(y)|^p}{|x-y|^{2+ps}} \,\mathrm{d}x\,\mathrm{d}y &= 2\int_{\Omega_0}\int_{\Omega\setminus\Omega_0} \frac{1}{|x-y|^{2+ps}} \,\mathrm{d}x\,\mathrm{d}y \\
&\le 2\int_{\Omega_0}\int_{B(y,d_\Omega)\setminus B(y,d(y,\partial\Omega_0))} \frac{1}{|x-y|^{2+ps}} \,\mathrm{d}x\,\mathrm{d}y \\
&= -\frac{4\pi}{ps} d_\Omega^{-ps}|\Omega_0| + \frac{4\pi}{ps}\int_{\Omega_0} d(y,\partial\Omega_0)^{-ps} \,\mathrm{d}y, \qquad \text{(A.2)}
\end{aligned}$$

with $|\Omega_0|$ the Lebesgue measure of Ω_0. For an upper bound of the integral in (A.2), we use the definition of the Lipschitz domain as given in [11, Definition 3.28] and the consecutive analysis. According to this, there is a finite cover $\cup W_j$ of $\partial\Omega_0$ with open sets W_j and a finite collection of open sets Ω_j such that $W_j \cap \Omega_0 = W_j \cap \Omega_j$ for all indices j and Ω_j can be considered as a Lipschitz hypograph (applying a measure preserving transformation).

Since $\cup W_j$ is an open set containing $\partial\Omega_0$, there is a positive number ϵ such that for all $y \in \Omega_0 \setminus \cup_j W_j$ the relation $d(y, \partial\Omega_0) > \epsilon$ holds. Accordingly, we split the integral in (A.2) as

$$\begin{aligned}\int_{\Omega_0} d(y,\partial\Omega_0)^{-ps}\,\mathrm{d}y &= \int_{\Omega_0\setminus\cup_j W_j} d(y,\partial\Omega_0)^{-ps}\,\mathrm{d}y + \int_{\Omega_0\cap\cup_j W_j} d(y,\partial\Omega_0)^{-ps}\,\mathrm{d}y \\ &\le \int_{\Omega_0\setminus\cup_j W_j} \epsilon^{-ps}\,\mathrm{d}y + \sum_j \int_{\Omega_j\cap W_j} d(y,\partial\Omega_0)^{-ps}\,\mathrm{d}y. \qquad \text{(A.3)}\end{aligned}$$

The first integral in (A.3) is obviously finite; therefore, in the consecutive analysis we give an upper estimate for an individual term in the sum.

Since Ω_j is a Lipschitz hypograph and W_j is bounded, we get the inclusion

$$\Omega_j \cap W_j \subset \{y = (y', y_n) \in \mathbb{R}^{n-1} \times \mathbb{R}^+ : y' \in \Omega_j^*, y_n \le f_j(y')\} \qquad \text{(A.4)}$$

in an appropriate coordinate system with the Lipschitz function f_j, where $\Omega_j^* \subset \mathbb{R}^{n-1}$ such that $\operatorname{diam}\Omega_j^* \le \operatorname{diam}\Omega_0$. For an arbitrary point $z = (z', f_j(z')) = (z', z_n)$ on $\partial\Omega_j \cap \partial\Omega_0$, we have

$$\begin{aligned}|f_j(y') - y_n| &= |z_n - y_n + f_j(y') - f_j(z')| \le |z_n - y_n| + M_j|z' - y'| \\ &\le |z_n - y_n| + M_j|z' - y'| \le \sqrt{1 + M_j^2}|z - y|, \qquad \text{(A.5)}\end{aligned}$$

with the Lipschitz constant M_j of f_j. In this way, for any j and any $y \in \Omega_j \cap W_j$, taking the infimum over all $z \in \partial\Omega_j \cap \partial\Omega_0$, the estimate $d(y, \partial\Omega_0) \ge \frac{f_j(y') - y_n}{\sqrt{1+M^2}}$ holds, where $M = \max_j M_j$. Accordingly, using (A.4) we obtain for all indices j that

$$\begin{aligned}\int_{\Omega_j\cap W_j} d(y,\partial\Omega_0)^{-ps}\,\mathrm{d}y &\le (1+M^2)^{\frac{ps}{2}} \int_{\Omega_j\cap W_j} (f_j(y') - y_n)^{-ps}\,\mathrm{d}y \\ &= (1+M^2)^{\frac{ps}{2}} \int_{\Omega_j^*}\int_0^{f_j(y')} (f_j(y') - y_n)^{-ps}\,\mathrm{d}y_n\,\mathrm{d}y',\end{aligned}$$

which is finite when $ps < 1$. ∎

Acknowledgment. It is a pleasure to thank M.Sc. Erik Bernsen for getting JvdV involved with the error analysis of CDG methods, pointing out reference [10], and for providing assistance with the computations.

DISCONTINUOUS GALERKIN FINITE ELEMENT APPROXIMATION OF NONLINEAR SECOND-ORDER ELLIPTIC AND HYPERBOLIC SYSTEMS*

CHRISTOPH ORTNER† AND ENDRE SÜLI†

Abstract. We develop the convergence analysis of discontinuous Galerkin finite element approximations to symmetric second-order quasi-linear elliptic and hyperbolic systems of partial differential equations in divergence form in a bounded spatial domain in $\mathbb{R}^d$, subject to mixed Dirichlet–Neumann boundary conditions. Optimal-order asymptotic bounds are derived on the discretization error in each case without requiring the global Lipschitz continuity or uniform monotonicity of the stress tensor. Instead, only local smoothness and a Gårding inequality are used in the analysis.

Key words. nonlinear elliptic and hyperbolic systems of partial differential equations, discontinuous Galerkin methods, Legendre–Hadamard condition, broken Gårding inequality

1. Introduction.

Second-order nonlinear elliptic and hyperbolic systems of partial differential equations arise in numerous applications, and a substantial body of research has been devoted to their analytical and computational study. This paper is concerned with the construction and convergence analysis of a class of numerical algorithms—discontinuous Galerkin finite element methods—for the approximate solution of quasi-linear elliptic and hyperbolic systems. Nonlinear elasticity is a particularly fertile source of equations of this type, and our results are phrased with this particular application area in mind, although the ideas and techniques developed are valid generally, provided the structural hypotheses on the nonlinearity assumed herein are satisfied.

In order to motivate the discussion that will follow, we begin by formulating a static problem from nonlinear elasticity which results in a mixed Dirichlet–Neumann boundary-value problem for a system of second-order quasi-linear elliptic partial differential equations. We shall then state the corresponding dynamic problem, which is a mixed initial-boundary-value problem for a second-order quasi-linear hyperbolic system.

Suppose that Ω is a bounded open set in $\mathbb{R}^d$, $d \in \{2, 3\}$, with Lipschitz continuous boundary $\partial\Omega$. We shall seek a displacement field $u : \overline{\Omega} \to \mathbb{R}^d$ such that u is a stationary point of the energy functional

$$J : v \mapsto J(v) := \int_\Omega [W(\nabla v(x)) - f(x) \cdot v(x)] \, \mathrm{d}x - \int_{\Gamma_\mathrm{N}} g_\mathrm{N}(s) \cdot v(s) \, \mathrm{d}s, \tag{1.1}$$

defined over the set of all (sufficiently smooth) d-component vector functions v on $\overline{\Omega}$ satisfying the boundary condition $v = g_\mathrm{D}$ on Γ_D, where $\Gamma_\mathrm{D} \subset \Gamma = \partial\Omega$ has positive

†University of Oxford, Computing Laboratory, Wolfson Building, Parks Road, Oxford OX1 3QD, United Kingdom (Christoph.Ortner@comlab.ox.ac.uk, Endre.Suli@comlab.ox.ac.uk).

$(d-1)$-dimensional surface measure $\mathcal{H}^{d-1}(\Gamma_{\rm D})$, $\Gamma_{\rm N} = \Gamma \setminus \Gamma_{\rm D}$, $W \in {\rm C}^4(\mathbb{R}^{d\times d};\mathbb{R})$ is the stored energy function, $f \in {\rm L}^2(\Omega)^d$ is a given body force, and $g_{\rm N} \in {\rm L}^2(\Gamma_{\rm N})^d$. Let us define the Piola–Kirchhoff stress tensor S as the gradient of W, that is,

$$S_{i\alpha}(\eta) := \frac{\partial}{\partial \eta_{i\alpha}} W(\eta), \qquad \eta \in \mathbb{R}^{d\times d},$$

and let

$$A_{i\alpha j\beta}(\eta) := \frac{\partial}{\partial \eta_{j\beta}} S_{i\alpha}(\eta) = \frac{\partial^2}{\partial \eta_{i\alpha}\partial \eta_{j\beta}} W(\eta), \qquad \eta \in \mathbb{R}^{d\times d}.$$

Clearly, $A_{i\alpha j\beta}(\eta) = A_{j\beta i\alpha}(\eta)$ for all $\eta \in \mathbb{R}^{d\times d}$ and $i,\alpha,j,\beta = 1,\dots,d$.

Formal calculations show that sufficiently smooth stationary points $u = u(x)$ of the functional J satisfy the following Euler–Lagrange equation:

$$-\sum_{\alpha=1}^{d} \partial_{x_\alpha} S_{i\alpha}(\nabla u(x)) = f_i(x), \qquad i = 1,\dots,d, \qquad x \in \Omega, \tag{1.2}$$

subject to the boundary conditions

$$u = g_{\rm D} \quad \text{on } \Gamma_{\rm D} \qquad \text{and} \qquad S(\nabla u)\nu = g_{\rm N} \quad \text{on } \Gamma_{\rm N}, \tag{1.3}$$

on the Dirichlet and Neumann parts $\Gamma_{\rm D}$ and $\Gamma_{\rm N}$ of the boundary Γ, respectively. Here ν is the unit outward normal vector to Γ, and $\partial_{x_\alpha} = \partial/\partial x_\alpha$. We note that, except in section 7, we do not use the fact that (1.2) is an Euler–Lagrange equation but only require the symmetry of the tensor $A_{i\alpha j\beta}$.

The weak formulation of the boundary-value problem (1.2), (1.3) is posed as follows: Find the function $u \in {\rm H}^1_{{\rm D},g_{\rm D}}(\Omega)^d = \{v \in {\rm H}^1(\Omega)^d \,:\, v|_{\Gamma_{\rm D}} = g_{\rm D}\}$ such that

$$\int_\Omega S(\nabla u) : \nabla v \,{\rm d}x = \int_\Omega f \cdot v \,{\rm d}x + \int_{\Gamma_{\rm N}} g_{\rm N} \cdot v \,{\rm d}s \qquad \forall v \in {\rm H}^1_{{\rm D},0}(\Omega)^d.$$

We shall assume that this problem has a solution $u \in {\rm H}^{m+1}(\Omega)^d \cap {\rm H}^1_{{\rm D},g_{\rm D}}(\Omega)^d$, with $m > d/2$. By the Sobolev embedding theorem u is then, in fact, contained in ${\rm C}^{1,\hat\alpha}(\overline{\Omega})^d$ for some $\hat\alpha \in (0,1)$.

For future reference we also define the bilinear form $a(\Phi;\cdot,\cdot)$, $\Phi \in {\rm L}^\infty(\Omega)^{d\times d}$, by

$$a(\Phi;v,w) := \sum_{i,\alpha,j,\beta=1}^{d} \int_\Omega A_{i\alpha j\beta}(\Phi)\partial_{x_\alpha} v_i \partial_{x_\beta} w_j \,{\rm d}x \qquad \forall v,w \in {\rm H}^1_{{\rm D},0}(\Omega)^d. \tag{1.4}$$

Formally at least, $a(\nabla u;\cdot,\cdot)$ defines the hessian of J at u; more generally, we shall consider $a(\Phi;\cdot,\cdot)$ for Φ in a certain neighborhood of ∇u which we shall now define.

For $\delta > 0$, let

$$\mathcal{Z}_\delta := \big\{\Phi \in {\rm C}_{\rm pw}(\overline{\Omega})^{d\times d} \,:\, \|\Phi - \nabla u\|_{{\rm L}^\infty(\Omega)} \le \delta\big\}, \tag{1.5}$$

where ${\rm C}_{\rm pw}(\overline{\Omega})$ denotes the set of bounded piecewise continuous functions defined on $\overline{\Omega}$. The set $\mathcal{Z}_\delta$ will be required in the convergence analysis of the finite element method: We will show that, for sufficiently small h, it contains the *piecewise gradients* (relative to the finite element subdivision $\mathcal{T}_h$ of the computational domain Ω) of discontinuous

Galerkin finite element approximations to u. Their point values must therefore be contained in the set

$$\mathcal{M}_\delta := \mathrm{conv}\big\{\eta \in \mathbb{R}^{d\times d} : \inf_{x\in\Omega} |\eta - \nabla u(x)| \le \delta\big\},$$

where $|\cdot|$ denotes the Frobenius norm on $\mathbb{R}^{d\times d}$ defined, for $\eta \in \mathbb{R}^{d\times d}$, by $|\eta| = (\eta : \eta)^{1/2}$. Clearly, as it is the convex hull of a closed and bounded set, $\mathcal{M}_\delta$ is itself closed, bounded, and, of course, convex.

We note here that we do not require S to be globally Lipschitz continuous, but we will use the local Lipschitz constant of S in $\mathcal{M}_\delta$, defined by

$$K_\delta := \sup_{\eta\in\mathcal{M}_\delta} \left(\sum_{i,\alpha,j,\beta=1}^{d} |A_{i\alpha j\beta}(\eta)|^2 \right)^{1/2}, \tag{1.6}$$

and the local Lipschitz constant of the fourth-order elasticity tensor $A = \nabla S$, defined by

$$L_\delta := \sup_{\eta,\sigma\in\mathcal{M}_\delta,\eta\neq\sigma} |\eta-\sigma|^{-1} \left(\sum_{i,\alpha,j,\beta=1}^{d} |A_{i\alpha j\beta}(\eta) - A_{i\alpha j\beta}(\sigma)|^2 \right)^{1/2}. \tag{1.7}$$

Since, for every $\delta > 0$, the set $\mathcal{M}_\delta$ is compact in $\mathbb{R}^{d\times d}$ and $A \in \mathrm{C}^2(\mathcal{M}_\delta)^{d\times d\times d\times d}$, it follows that K_δ and L_δ are finite.

We shall also consider the dynamic counterpart of the boundary-value problem (1.2), (1.3)—the initial-boundary-value problem for the second-order nonlinear evolution equation

$$\partial_t^2 u_i - \sum_{\alpha=1}^{d} \partial_{x_\alpha} S_{i\alpha}(\nabla u) = f_i(t,x), \qquad i = 1,\dots,d, \qquad x \in \Omega, \quad t \in (0,T], \tag{1.8}$$

subject to the initial conditions $u(0,x) = u_0(x)$, $\partial_t(0,x) = u_1(x)$, $x \in \Omega$, and the same boundary conditions as in the static problem above. Here $\partial_t^2 u = \frac{\partial^2 u}{\partial t^2}$; we shall also write $\ddot{u}$ instead of $\partial_t^2 u$ and $\dot{u}$ instead of $\partial_t u = \frac{\partial u}{\partial t}$. For a detailed discussion concerning the physical background to these equations in the field of nonlinear elasticity, we refer to [11, 1], for example. Suitable generalizations of the sets $\mathcal{M}_\delta$ and $\mathcal{Z}_\delta$ for the hyperbolic case are given in section 6.

We now formulate our structual hypotheses on the stress tensor S. For most constitutive laws in solid mechanics and many other applications, the mapping $\eta \mapsto S(\eta)$ satisfies the *axiom of frame indifference*, that is,

$$S(F - \mathrm{id}) = S(QF - \mathrm{id}) \qquad \forall Q \in SO(d), \quad \forall F \in \mathbb{R}^{d\times d}, \tag{1.9}$$

where id is the $d \times d$ identity matrix and $SO(d)$ is the group of special orthogonal $d \times d$ matrices. Note that the form of (1.9) is slighly nonstandard, as our partial differential equation is formulated in terms of displacement rather than deformation. If S satisfies (1.9), then, except in trivial cases, S cannot be monotone; for a detailed discussion of this point, we refer to pages 490–491 in the monograph of Antman [1]. Hence, the *uniform monotonicity* condition which hypothesizes the existence of a real number $M_1 > 0$ such that

$$(S(F) - S(G)) : (F - G) \ge M_1 |F - G|^2 \qquad \forall F, G \in \mathbb{R}^{d\times d}, \tag{1.10}$$

which is commonly assumed in the analysis of finite element approximations to quasi-linear elliptic problems, is inappropriate in the context of nonlinear elasticity and needs to be relaxed in order to cover physically meaningful problems.

In fact, the condition (1.10) can be relaxed in several ways in order to capture the physics while still recovering some of the theory available in the uniformly elliptic setting which stems from the uniform monotonicity condition (1.10). It is reasonable, for example, to assume that a metastable state of the elastic energy functional (1.1) is not merely a critical point satisfying the Euler–Lagrange equation but that the hessian of J is positive definite at this point. Thus, in the static case, we shall replace (1.10) by the following condition, which requires the existence of a real number $M_1 = M_1(u) > 0$ such that

$$a(\nabla u; v, v) \geq M_1 \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} \qquad \forall v \in \mathrm{H}^1_{\mathrm{D},0}(\Omega)^d. \tag{1.11}$$

Similarly, for the dynamic case, it was shown in [8] that, if S satisfies the strong Legendre–Hadamard condition

$$\sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\eta)\zeta_i\zeta_j\xi_\alpha\xi_\beta \geq M_1|\zeta|^2|\xi|^2 \qquad \forall \zeta, \xi \in \mathbb{R}^d, \quad \forall \eta \in \mathbb{R}^{d\times d}, \tag{1.12}$$

for some constant $M_1 > 0$, then a smooth solution to (1.8) is guaranteed to exist locally in time, subject to given initial conditions and the same boundary conditions as in the static case (at least when $\Gamma_{\mathrm{N}} = \emptyset$ and $g_{\mathrm{D}} = 0$). Condition (1.12) is satisfied by most constitutive laws for elastic materials. In this case, the semilinear form a defined in (1.4) satisfies the following Gårding inequality: For any $\varphi \in \mathrm{C}^1(\overline{\Omega})^d$, there exists $M_0 = M_0(\varphi) \geq 0$ such that

$$a(\nabla\varphi; v, v) \geq \tfrac{1}{2}M_1\|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - M_0(\varphi)\|v\|^2_{\mathrm{L}^2(\Omega)} \qquad \forall v \in \mathrm{H}^1_0(\Omega)^d; \tag{1.13}$$

cf. Theorem 6.5.1 on p. 253 in [16]. Even this weaker inequality is, to the best of our knowledge, known only for $v \in \mathrm{H}^1_0(\Omega)^d$. As we shall see, (1.13) is sufficient for the convergence analysis in the dynamic case.

In the case of classical conforming finite element methods based on finite-dimensional subspaces of $\mathrm{H}^1_{\mathrm{D},0}(\Omega)^d$ or $\mathrm{H}^1_0(\Omega)^d$, as the case may be, consisting of continuous piecewise polynomial functions of degree $p \geq 1$ defined over a family of subdivisions $\{\mathcal{T}_h\}_{h>0}$ of the computational domain Ω, the inequalities (1.11) and (1.13) will automatically hold in such subspaces. Discontinuous Galerkin finite element methods which are the focus of this paper are, however, built over finite-dimensional spaces consisting of discontinuous piecewise polynomial functions defined on Ω, which are, clearly, *not* contained in $\mathrm{H}^1(\Omega)^d$, let alone $\mathrm{H}^1_{\mathrm{D},0}(\Omega)^d$ or $\mathrm{H}^1_0(\Omega)^d$. As a matter of fact, both (1.11) and (1.13) are global conditions and, unlike uniform monotonicity (1.10), do not automatically translate to the space $S^p(\Omega, \mathcal{T}_h, \mathbf{F})$, defined in section 2, of discontinuous piecewise polynomial functions of degree p on $\mathcal{T}_h$. Thus, in section 3, we shall derive the "broken" versions of these inequalities which hold over $S^p(\Omega, \mathcal{T}_h, \mathbf{F})$. To the best of our knowledge, the analysis of discontinuous Galerkin finite element approximations to second-order quasi-linear systems of partial differential equations has not been previously considered in the literature under such weak structural assumptions.

In recent years there has been considerable interest in discontinuous Galerkin finite element methods for the numerical solution of a wide range of partial differential equations which arise from continuum mechanics. We shall not attempt to

give a detailed review of this area of research: The reader is referred to [7] for a comprehensive historical survey of the field and [2, 13] for convergence analyses of the method for second-order linear elliptic problems and partial differential equations with nonnegative characteristic form. Discontinuous Galerkin finite element methods were introduced in the early 1970s for the numerical solution of first-order hyperbolic problems. Simultaneously, but quite independently, they were proposed as nonstandard schemes for the approximation of second-order elliptic equations. The recent upsurge of interest in this class of techniques has been stimulated by the computational convenience of discontinuous Galerkin methods due to their high degree of locality and the presence of associated local conservation properties, as well as the need to accommodate high-order *hp* and spectral element discretizations on irregular finite element meshes. The present work has been stimulated by our ongoing research on discontinuous Galerkin methods in the field of fracture mechanics.

The paper is structured as follows. The next section is devoted to the construction of the discontinuous Galerkin method for the nonlinear elliptic boundary-value problem (1.2), (1.3). In section 3, we derive broken Gårding inequalities to aid us in our subsequent analysis. In section 4 we develop the linearization of the semilinear form appearing in the definition of the finite element method. In section 5 we perform the convergence analysis of the discontinuous Galerkin finite element approximation of the elliptic boundary-value problem (1.2), (1.3) under hypothesis (1.11). We note, in particular, that our analysis does not assume the global Lipschitz continuity of the functions $S_{i\alpha}$, $i, \alpha = 1, \ldots, d$, with respect to ∇u, nor do we explicitly require the uniform monotonicity condition (1.10). Building on the work of Makridakis [15] for classical conforming methods, in section 6 we develop the convergence analysis of semidiscrete discontinuous Galerkin finite element approximations of mixed Dirichlet–Neumann initial-boundary-value problems for systems of second-order quasi-linear hyperbolic equations of the form (1.8). This analysis requires a nonlinear projection operator whose approximation properties are analyzed, closely following section 5, in Appendix A. Extensions of our analysis to fully discrete approximations of the hyperbolic problem would proceed along the same lines as in [15] in the case of conforming methods; thus, we do not consider these here. In section 7 we show how our framework can be used to derive optimal error estimates for discontinuous Galerkin finite element methods other than the formulation which we have adopted in this paper.

2. Finite element spaces. For $h \in (0, 1]$, let $\mathcal{T}_h$ be a subdivision of Ω into disjoint open *element domains* (or, simply, *elements*) κ such that $\overline{\Omega} = \cup_{\kappa \in \mathcal{T}_h} \overline{\kappa}$. Here $h = \max_{\kappa \in \mathcal{T}_h} h_\kappa$, where $h_\kappa = \mathrm{diam}(\kappa)$. Each $\kappa \in \mathcal{T}_h$ is assumed to be the image of the open reference simplex under a bijective affine mapping or of the open unit hypercube under a bilinear mapping, denoted by F_κ. We shall denote either master element by $\hat{\kappa}$.

For a nonnegative integer k, we denote by $\mathcal{P}_k(\hat{\kappa})$ the set of polynomials of total degree k on $\hat{\kappa}$. When $\hat{\kappa}$ is the unit hypercube, we also consider $\mathcal{Q}_k(\hat{\kappa})$, the set of all tensor-product polynomials on $\hat{\kappa}$ of degree k in each coordinate direction. We collect the F_κ in the vector $\mathbf{F} = \{F_\kappa : \kappa \in \mathcal{T}_h\}$ and consider, for $p \geq 1$, the finite element space

$$S^p(\Omega, \mathcal{T}_h, \mathbf{F}) := \{v \in \mathrm{L}^2(\Omega)^d : \ v|_\kappa \circ F_\kappa \in \mathcal{R}_p(\hat{\kappa})^d \quad \forall \kappa \in \mathcal{T}_h\},$$

where $\mathcal{R}$ is either $\mathcal{P}$ or $\mathcal{Q}$.

Let us consider the set $\mathcal{E}$ of all $(d-1)$-dimensional open faces—or, simply, *faces*—of all elements $\kappa \in \mathcal{T}_h$. Since hanging nodes are permitted (cf. Figure 2.1), $\mathcal{T}_h$ may be

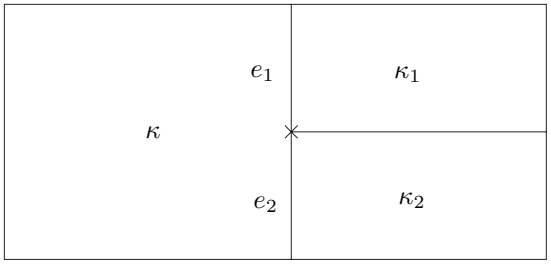

FIG. 2.1. *Hanging node* $\times$ *and faces* $e_1, e_2 \in \mathcal{E}_{\rm int}$.

irregular, and therefore $\mathcal{E}$ will be understood to contain the smallest common $(d-1)$-dimensional open faces of neighboring elements. Further, we denote by $\mathcal{E}_{\rm int}$ the set of all e in $\mathcal{E}$ that are contained in Ω, we let $\Gamma_{\rm int} = \{x \in \Omega : x \in e \text{ for some } e \in \mathcal{E}_{\rm int}\}$, and we introduce the set $\mathcal{E}_{\rm D}$ of $(d-1)$-dimensional boundary faces contained in the subset $\Gamma_{\rm D}$ of Γ. Implicit in these definitions is the assumption that $\mathcal{T}_h$ respects the decomposition of Γ in the sense that each $e \in \mathcal{E}$ that lies on Γ belongs to the interior of exactly one of $\Gamma_{\rm D}$ or $\Gamma_{\rm N}$. Given $e \in \mathcal{E}$, we define $h_e := \mathrm{diam}(e)$.

In the convergence analyses of the discontinuous Galerkin finite element approximations to the partial differential equations considered here, we shall adopt the following hypotheses on the family $\{\mathcal{T}_h\}_{h>0}$, the first of which controls the number of hanging nodes which any one element may have, the second is the standard quasi-uniformity assumption, while the third is a technical condition on the lowest polynomial degree which our analysis admits. **H2** and **H3** are required in order to deduce, by the use of inverse inequalities from bounds in a broken H^1 norm, that the element-wise gradient of the numerical solution lies in $\mathcal{Z}_\delta$. Finally, the fourth hypothesis is required for the definition of the *continuous reconstruction operator* in section 3. We assume that the assumptions **H1**–**H4** hold throughout the remainder of the article.

H1. The family of subdivisions $\{\mathcal{T}_h\}_{h>0}$ is *contact regular*; i.e., there exist positive constants c_d and c_e independent of h such that, for each $\kappa \in \mathcal{T}_h$,

$$\sharp\{\kappa' \in \mathcal{T}_h : \kappa' \neq \kappa,\ \mathcal{H}^{d-1}(\overline{\kappa'} \cap \overline{\kappa}) > 0\} \leq c_d, \quad \text{and} \quad c_e h_\kappa \leq h_e \quad \text{for every face } e \text{ of } \kappa.$$

H2. The family of subdivisions $\{\mathcal{T}_h\}_{h>0}$ is *quasi-uniform*; i.e., there exist positive constants c_0 and c_1, independent of h, such that for each $\kappa \in \mathcal{T}_h$ there exist open balls $B(x_0, c_0 h)$ and $B(x_1, c_1 h)$ such that $B(x_0, c_0 h) \subset \kappa \subset B(x_1, c_1 h)$.

H3. In the case of the elliptic problem (1.2) the polynomial degree $p > d/2$, and in the case of the hyperbolic problem (1.8) the polynomial degree $p > (d/2) + 1$ (viz. $p \geq 2$ for $d = 2, 3$, and $p \geq 3$ for $d = 2, 3$, respectively).

H4. The family of subdivisions $\{\mathcal{T}_h\}_{h>0}$ is *uniformly simplicially reducible*; i.e., for each $h > 0$ there exists a regular (no hanging nodes) simplicial mesh $\tilde{\mathcal{T}}_h$ such that the closure of each element in $\mathcal{T}_h$ is a union of closures of elements of $\tilde{\mathcal{T}}_h$ and such that there exist positive constants θ and C, independent of h, such that the smallest angle between any two edges in $\tilde{\mathcal{T}}_h$ is greater than or equal to θ and $h/\min_{\kappa \in \tilde{\mathcal{T}}_h} h_\kappa \leq C$.

Suppose that e is a $(d-1)$-dimensional open face of an element $\kappa \in \mathcal{T}_h$, and recall the notation introduced above: $h_\kappa = \mathrm{diam}(\kappa)$ and $h_e = \mathrm{diam}(e)$. The following *inverse inequalities* hold: There exists a positive constant C_3, independent of the

discretization parameter h, such that

$$\begin{aligned} \|\nabla w\|_{\mathrm{L}^\infty(\kappa)} &\leq \frac{C_3}{h_\kappa^{d/2}}\|\nabla w\|_{\mathrm{L}^2(\kappa)}, \quad \|\nabla w\|^2_{\mathrm{L}^2(\kappa)} \leq \frac{C_3}{h_\kappa^2}\|w\|^2_{\mathrm{L}^2(\kappa)}, \\ \|w\|^2_{\mathrm{L}^2(e)} &\leq \frac{C_3}{h_e}\|w\|^2_{\mathrm{L}^2(\kappa)}, \qquad \|\nabla w\|^2_{\mathrm{L}^2(e)} \leq \frac{C_3}{h_e}\|\nabla w\|^2_{\mathrm{L}^2(\kappa)}, \end{aligned} \tag{2.1}$$

for all $w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$. In the case of the first two inverse inequalities C_3 depends only on the shape-regularity parameters of $\mathcal{T}_h$, while in the case of the other two inequalities it also depends on the contact-regularity parameter c_e. In fact, h_e in the last two inequalities can be replaced by h_κ at the expense of possibly altering the value of the constant C_3.

In the discussion that follows, we shall frequently need to consider the elementwise weak derivative (called the broken derivative) and the elementwise weak gradient (called the broken gradient) of a function that belongs to a broken Sobolev space. In order to simplify the presentation, our notation will not distinguish these from weak derivatives and weak gradients; the implied meaning of the notation will always be clear from the context. Thus, we adopt the following definition.

DEFINITION 1. *Let the* broken Sobolev space $\mathrm{H}^1(\Omega, \mathcal{T}_h)$ *be defined by*

$$\mathrm{H}^1(\Omega, \mathcal{T}_h) := \left\{ v \in \mathrm{L}^2(\Omega) : v|_\kappa \in \mathrm{H}^1(\kappa) \quad \forall \kappa \in \mathcal{T}_h \right\}.$$

For $v \in \mathrm{H}^1(\Omega, \mathcal{T}_h)$, we use ∇v to denote the piecewise weak gradient of v (relative to $\mathcal{T}_h$), i.e.,

$$\nabla v(x) := \nabla v|_\kappa(x) \qquad \forall x \in \kappa, \quad \forall \kappa \in \mathcal{T}_h,$$

where, on the right-hand side, $\nabla v|_\kappa$ denotes the weak gradient of $v|_\kappa \in \mathrm{H}^1(\kappa)$. The broken partial derivative $\partial_{x_j} v_i = \partial v_i / \partial x_j$ of $v \in \mathrm{H}^1(\Omega, \mathcal{T}_h)^d$ is the (i, j) component of its broken gradient ∇v.

For each $e \in \mathcal{E}_{\mathrm{int}}$ there exist indices i and j such that $i > j$ and κ_i and κ_j share the face e; we define the (element-numbering-dependent) *jump* of $v \in \mathrm{H}^1(\Omega, \mathcal{T}_h)^d$ across e and the *mean value* of v on e by

$$[\![v]\!]_e := v|_{\partial\kappa_i \cap e} - v|_{\partial\kappa_j \cap e} \quad \text{and} \quad \langle v \rangle_e := \tfrac{1}{2}\left(v|_{\partial\kappa_i \cap e} + v|_{\partial\kappa_j \cap e} \right),$$

respectively. If $e \in \mathcal{E}_{\mathrm{D}}$ is a face on the Dirichlet boundary, contained in the boundary $\partial\kappa$ of an element $\kappa \in \mathcal{T}_h$, it is also customary to define

$$[\![v]\!]_e := v|_{\partial\kappa \cap e} \quad \text{and} \quad \langle v \rangle_e := v|_{\partial\kappa \cap e}.$$

These definitions will enable us to condense our notation. For the sake of simplicity, the subscript e will be suppressed, and we shall simply write $[\![v]\!]$ and $\langle v \rangle$; the implied choice of e will be clear from the context. In addition, we associate with the face e the unit normal vector ν which points from κ_i to κ_j, $i > j$.

Suppose that σ is a positive, piecewise constant function defined on $\Gamma_{\mathrm{D}} \cup \Gamma_{\mathrm{int}}$ (to be defined below). We equip the space $\mathrm{H}^1(\Omega, \mathcal{T}_h)$ with the *broken Sobolev norm* $\|\cdot\|_{1,h}$ defined by

$$\|v\|_{1,h} := \left(\int_\Omega |\nabla v|^2 \, \mathrm{d}x + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma |[\![v]\!]|^2 \, \mathrm{d}s \right)^{1/2}.$$

For the definition of the discontinuous Galerkin method, we introduce the semilinear form

$$B(w,v) := \int_\Omega S(\nabla w) : \nabla v \,\mathrm{d}x - \int_{\Gamma_\mathrm{D}} S(\nabla w)\nu \cdot v \,\mathrm{d}s - \int_{\Gamma_\mathrm{int}} \langle S(\nabla w)\nu\rangle \cdot [\![v]\!] \,\mathrm{d}s$$
$$+ \int_{\Gamma_\mathrm{int}\cup\Gamma_\mathrm{D}} \sigma [\![w]\!]\cdot[\![v]\!]\,\mathrm{d}s, \qquad w \in \mathrm{C}^1(\overline{\Omega},\mathcal{T}_h)^d, \quad v \in \mathrm{H}^1(\Omega,\mathcal{T}_h)^d, \tag{2.2}$$

and the linear functional

$$\ell(v) := \int_\Omega f\cdot v\,\mathrm{d}x + \int_{\Gamma_\mathrm{D}} \sigma g_\mathrm{D}\cdot v\,\mathrm{d}s + \int_{\Gamma_\mathrm{N}} g_\mathrm{N}\cdot v\,\mathrm{d}s, \qquad v\in \mathrm{H}^1(\Omega,\mathcal{T}_h)^d. \tag{2.3}$$

Here $h^{-1}|_e = h_e^{-1}$ for all $e \subset \Gamma_\mathrm{int}\cup\Gamma_\mathrm{D}$. Let $\kappa \in \mathcal{T}_h$, and let e be a $(d-1)$-dimensional face of $\partial\kappa$. The function σ, referred to as the *discontinuity penalization parameter*, featured in $B(\cdot,\cdot)$ and $\ell(\cdot)$ above, is defined by

$$\sigma|_e := \sigma_e = \frac{\alpha}{h_e} \qquad \text{for } e \subset \Gamma_\mathrm{int}\cup\Gamma_\mathrm{D}. \tag{2.4}$$

Here α is a positive constant whose size will be fixed later.

The discontinuous Galerkin finite element approximation of problem (1.2), (1.3) is posed as follows: Find $u_\mathrm{DG} \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ such that

$$B(u_\mathrm{DG},v) = \ell(v) \qquad \forall v \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}). \tag{2.5}$$

If the problem were linear, our discretization would correspond to the incomplete interior penalty method (see, for example, [9, 18]).

3. Broken Gårding inequality. The proofs of the broken versions of the Gårding inequalities (1.11) and (1.13) rely on the construction of a recovery operator, which connects each discontinuous piecewise polynomial function from $S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ to a continuous relative. Such an operator has been used previously in similar contexts, for example, by Karakashian and Pascal [14] for deriving residual-based a posteriori error estimates and by Brenner [4] for the proof of broken Korn inequalities.

Here we follow the construction used by Karakashian and Pascal [14], though we will slightly reformulate their result. By our hypothesis **H4**, the family of meshes $(\mathcal{T}_h)_{h>0}$ is uniformly simplicially reducible, meaning that, for each h there exists a regular simplicial mesh $\tilde{\mathcal{T}}_h$ which refines $\mathcal{T}_h$. For example, quasi-uniform families of 1-irregular meshes in two dimensions satisfy this property (cf. Figure 3.1 and Proposition 2 in [17]). Another important class are quasiuniform quadrilateral meshes obtained by hierarchical refinement (cf. Proposition 3 in [17]). For such families of meshes, we have the following result. For a proof we refer to Theorems 2.2 and 2.3 in [14] or section 7.1 in [17].

LEMMA 3.1. *There exists a constant C_r, independent of h, and a linear operator $\mathcal{R}\colon S^p(\Omega,\mathcal{T}_h,\mathbf{F}) \to \mathrm{H}^1_{\mathrm{D},0}(\Omega)^d$ such that, for all $u \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ and $k\in\{0,1\}$,*

$$\|\nabla^k(u-\mathcal{R}u)\|_{\mathrm{L}^2(\Omega)} \le C_r \int_{\Gamma_\mathrm{int}\cup\Gamma_\mathrm{D}} h^{1-2k}|[\![u]\!]|^2 \,\mathrm{d}s, \tag{3.1}$$

where $\nabla^0 = \mathrm{id}$ and $\nabla^1 = \nabla$.

Lemma 3.1 provides a link between discontinuous piecewise polynomial functions and functions in $\mathrm{H}^1_{\mathrm{D},0}(\Omega)^d$. Thus, to establish a broken Gårding inequality, we replace the test function v by its continuous representative $\mathcal{R}v$ and estimate the error

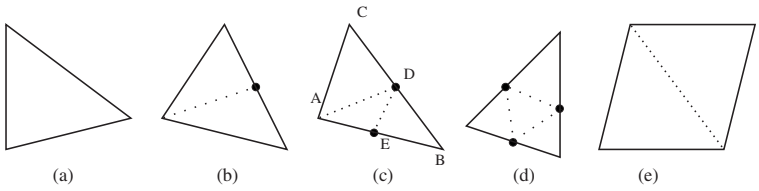

FIG. 3.1. *Refinement of triangular elements in the presence of hanging nodes in order to obtain the mesh $\tilde{\mathcal{T}}_h$ featured in hypothesis* **H4**.

committed in doing so in terms of the jumps of v. This procedure yields the following result.

LEMMA 3.2. *Let $u \in \mathrm{C}^1(\overline{\Omega})^d$ be such that the following Gårding inequality holds:*

$$a(\nabla u; v, v) \geq M_1 \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} \qquad \forall v \in \mathrm{H}^1_{\mathrm{D},0}(\Omega)^d, \tag{3.2}$$

where $M_1 > 0$ and $M_0 \geq 0$. Assume furthermore that $\delta \leq M_1/(4L_\delta)$. Then, for all $\Phi \in \mathcal{Z}_\delta$ and $h \leq 1$, the following broken Gårding inequality holds:

$$\begin{aligned} a(\Phi; v, v) \geq{}& \tfrac{1}{2} M_1 \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} \\ & - C_1 \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} h^{-1} |[\![v]\!]|^2 \, \mathrm{d}s \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \end{aligned} \tag{3.3}$$

where $C_1 = C_1(M_0, M_1, K_\delta, C_r)$ is independent of h.

Proof. Note that the definition (1.6) of K_δ implies that

$$a(\nabla u; v, w) \leq K_\delta \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\nabla w\|_{\mathrm{L}^2(\Omega)} \qquad \forall v, w \in \mathrm{H}^1(\Omega, \mathcal{T}_h)^d.$$

Step 1. We begin by assuming that $\Phi = \nabla u$. In this case, we then have that

$$\begin{aligned} a(\nabla u; v, v) &= a(\nabla u; \mathcal{R}v, \mathcal{R}v) + a(\nabla u; v - \mathcal{R}v, v - \mathcal{R}v) + 2a(\nabla u; v - \mathcal{R}v, \mathcal{R}v) \\ &\geq M_1 \|\nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} - M_0 \|\mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} - K_\delta \|\nabla v - \nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} \\ &\quad - 2K_\delta \|\nabla v - \nabla \mathcal{R}v\|_{\mathrm{L}^2(\Omega)} \|\nabla \mathcal{R}v\|_{\mathrm{L}^2(\Omega)} \\ &\geq M_1 \|\nabla v + (\nabla \mathcal{R}v - \nabla v)\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|\mathcal{R}v - v\|^2_{\mathrm{L}^2(\Omega)} \\ &\quad - 3K_\delta \|\nabla v - \nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} - 2K_\delta \|\nabla v - \nabla \mathcal{R}v\|_{\mathrm{L}^2(\Omega)} \|\nabla v\|_{\mathrm{L}^2(\Omega)}. \end{aligned}$$

Using the inverse triangle inequality in the first term on the right-hand side of the last inequality gives

$$\begin{aligned} a(\nabla u; v, v) \geq{}& M_1 (\|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - 2\|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\nabla v - \nabla \mathcal{R}v\|_{\mathrm{L}^2(\Omega)} + \|\nabla v - \nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)}) \\ & - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|\mathcal{R}v - v\|^2_{\mathrm{L}^2(\Omega)} \\ & - 3K_\delta \|\nabla v - \nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} - 2K_\delta \|\nabla v - \nabla \mathcal{R}v\|_{\mathrm{L}^2(\Omega)} \|\nabla v\|_{\mathrm{L}^2(\Omega)}. \end{aligned}$$

We use the ε-inequality, $ab \leq \frac{\varepsilon}{2} a^2 + \frac{1}{2\varepsilon} b^2$, $\varepsilon > 0$, twice, with $\varepsilon = \varepsilon_1 > 0$ and $\varepsilon = \varepsilon_2 > 0$, to obtain

$$\begin{aligned} a(\nabla u; v, v) \geq{}& (M_1 - \varepsilon_1 M_1 - \varepsilon_2 K_\delta) \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v - \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)} \\ & - (3K_\delta - M_1 + \varepsilon_1^{-1} M_1 + \varepsilon_2^{-1} K_\delta) \|\nabla v - \nabla \mathcal{R}v\|^2_{\mathrm{L}^2(\Omega)}. \end{aligned} \tag{3.4}$$

Step 2. Next, for each $\Phi \in \mathcal{Z}$, and $v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$, we can use the Lipschitz condition (1.7), which immediately implies that

$$a(\Phi; v, v) \geq a(\nabla u; v, v) - L_\delta \|\nabla u - \Phi\|_{\mathrm{L}^\infty(\Omega)} \|\nabla v\|^2_{\mathrm{L}^2(\Omega)}.$$

As, by hypothesis, $\|\nabla u - \Phi\|_{\mathrm{L}^\infty(\Omega)} \leq \delta$, with $\delta \leq M_1/(4L_\delta)$, it is straightforward to choose ε_1 and ε_2 in (3.4) and to apply (3.1) in order to obtain (3.3). ☐

4. Linearization. Before embarking on the analysis of the discontinuous Galerkin finite element method (2.5), we prove some auxiliary results about its linearization. We begin by noting that for any $\eta, \zeta \in \mathbb{R}^{d\times d}$ we have that

$$\begin{aligned} S_{i\alpha}(\eta) - S_{i\alpha}(\zeta) &= \sum_{j,\beta=1}^{d} (\eta_{j\beta} - \zeta_{j\beta}) \int_0^1 \frac{\partial S_{i\alpha}}{\partial \eta_{j\beta}}(\tau\eta + (1-\tau)\zeta)\,\mathrm{d}\tau \\ &= \sum_{j,\beta=1}^{d} (\eta_{j\beta} - \zeta_{j\beta}) \int_0^1 A_{i\alpha j\beta}(\tau\eta + (1-\tau)\zeta)\,\mathrm{d}\tau. \end{aligned} \tag{4.1}$$

Let $\mathrm{C}^1(\overline{\Omega}, \mathcal{T}_h)^d$ denote the space of all d-component piecewise C^1 functions, relative to the subdivision $\mathcal{T}_h$, defined on $\overline{\Omega}$. Taking (4.1) as a starting point, a straightforward computation shows that for any $w_i \in \mathrm{C}^1(\overline{\Omega}, \mathcal{T}_h)^d$, $i = 1, 2$, we have that

$$B(w_1, v) - B(w_2, v) = \int_0^1 \tilde{b}(w_2 + \tau(w_1 - w_2); w_1 - w_2, v)\,\mathrm{d}\tau \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \tag{4.2}$$

where, for $\varphi \in \mathrm{C}^1(\overline{\Omega}, \mathcal{T}_h)^d$, $\tilde{b}(\varphi; \cdot, \cdot)$ is the bilinear form defined by

$$\begin{aligned} \tilde{b}(\varphi; v, w) := &\int_\Omega \sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\nabla\varphi) \frac{\partial w_i}{\partial x_\alpha} \frac{\partial v_j}{\partial x_\beta}\,\mathrm{d}x - \int_{\Gamma_{\mathrm{D}}} \sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\nabla\varphi) w_i \nu_\alpha \frac{\partial v_j}{\partial x_\beta}\,\mathrm{d}s \\ &- \int_{\Gamma_{\mathrm{int}}} \sum_{i,\alpha,j,\beta=1}^{d} \left\langle A_{i\alpha j\beta}(\nabla\varphi)\nu_\alpha \frac{\partial v_j}{\partial x_\beta} \right\rangle [\![w_i]\!]\,\mathrm{d}s + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma [\![v]\!] \cdot [\![w]\!]\,\mathrm{d}s. \end{aligned}$$

In the next section, we shall use $\tilde{b}$ to perform a convergence analysis of the method (2.5), where the Gårding inequality (3.2) and the local Lipschitz continuity of $\tilde{b}$ w.r.t. its first argument are crucial. We prove these three results in the following three lemmas.

LEMMA 4.1. *Suppose that $u \in \mathrm{C}^1(\overline{\Omega})^d$ satisfies the Gårding inequality* (3.2). *Then there exists $\alpha_0 > 0$, independent of h, such that for all $\alpha \geq \alpha_0$, for all $h \in (0, 1]$, and for all $\varphi \in \mathrm{C}^1(\overline{\Omega}, \mathcal{T}_h)^d$, with $\nabla\varphi \in \mathcal{Z}_\delta$,*

$$\tilde{b}(\varphi; v, v) \geq \tilde{M}_1 \|v\|^2_{1,h} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \tag{4.3}$$

where $\tilde{M}_1 := \frac{1}{4}\min(1, M_1)$.

Proof. For $\nabla\varphi \in \mathcal{Z}_\delta$ fixed and $v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ we consider

$$\begin{aligned} \tilde{b}(\varphi; v, v) = &\int_\Omega \sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\nabla\varphi) \frac{\partial v_i}{\partial x_\alpha} \frac{\partial v_j}{\partial x_\beta}\,\mathrm{d}x - \int_{\Gamma_{\mathrm{D}}} \sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\nabla\varphi) v_i \nu_\alpha \frac{\partial v_j}{\partial x_\beta}\,\mathrm{d}s \\ &- \int_{\Gamma_{\mathrm{int}}} \sum_{i,\alpha,j,\beta=1}^{d} \left\langle A_{i\alpha j\beta}(\nabla\varphi)\nu_\alpha \frac{\partial v_j}{\partial x_\beta} \right\rangle [\![v_i]\!]\,\mathrm{d}s + \int_{\Gamma_{\mathrm{D}}} \sigma |v|^2\,\mathrm{d}s + \int_{\Gamma_{\mathrm{int}}} \sigma |[\![v]\!]|^2\,\mathrm{d}s \\ \equiv\ & T_1 + T_2 + T_3 + T_4 + T_5. \end{aligned}$$

Lemma 3.2 implies that

$$T_1 \geq \tfrac{1}{2} M_1 \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} - C_1 \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} h^{-1} |[\![v]\!]|^2 \, \mathrm{d}s,$$

where C_1 is independent of h and φ.

Next, we bound T_2. Since we assumed that $\nabla\varphi \in \mathcal{Z}_\delta$, it follows that $\nabla\varphi(x) \in \mathcal{M}_\delta$ for a.e. $x \in \Omega$. Hence,

$$\begin{aligned} |\mathrm{T}_2| &\leq K_\delta \int_{\Gamma_{\mathrm{D}}} \left(\sum_{i,\alpha,j,\beta=1}^{d} |v_i|^2 |\nu_\alpha|^2 \left| \frac{\partial v_j}{\partial x_\beta} \right|^2 \right)^{1/2} \mathrm{d}s \\ &\leq K_\delta \left(\int_{\Gamma_{\mathrm{D}}} \sigma^{-1} |\nabla v|^2 \, \mathrm{d}s \right)^{1/2} \left(\int_{\Gamma_{\mathrm{D}}} \sigma |v|^2 \, \mathrm{d}s \right)^{1/2}, \end{aligned}$$

where K_δ is defined in (1.6). Using the third of the inverse inequalities (2.1) and recalling the definition of the penalty parameter σ_e on $e \subset \Gamma_{\mathrm{D}}$, we have that

$$|\mathrm{T}_2| \leq K_\delta (C_3 \alpha^{-1} 2d)^{1/2} \left(\int_\Omega |\nabla v|^2 \, \mathrm{d}x \right)^{1/2} \left(\int_{\Gamma_{\mathrm{D}}} \sigma |v|^2 \, \mathrm{d}s \right)^{1/2},$$

where $2d$ stands for the maximum number of faces any one element may have on Γ_{D}.

Analogously,

$$|\mathrm{T}_3| \leq K_\delta \int_{\Gamma_{\mathrm{int}}} \langle |\nabla v| \rangle \, |[\![v]\!]| \, \mathrm{d}s \leq K_\delta \left(\int_{\Gamma_{\mathrm{int}}} \sigma^{-1} \langle |\nabla v| \rangle^2 \, \mathrm{d}s \right)^{1/2} \left(\int_{\Gamma_{\mathrm{int}}} \sigma [\![v]\!]^2 \, \mathrm{d}s \right)^{1/2}.$$

Let us note that

$$\int_{\Gamma_{\mathrm{int}}} \sigma^{-1} \langle |\nabla v| \rangle^2 \, \mathrm{d}s = \sum_{e \in \mathcal{E}_{\mathrm{int}}} \sigma_e^{-1} \int_e \langle |\nabla v| \rangle^2 \, \mathrm{d}s,$$

and, for $e \in \mathcal{E}_{\mathrm{int}}$, let κ and κ' be the two elements that share e. Then

$$\begin{aligned} \int_e \langle |\nabla v| \rangle^2 \, \mathrm{d}s &\leq \frac{1}{2} \int_e |\nabla v|_\kappa|^2 \, \mathrm{d}s + \frac{1}{2} \int_e |\nabla v|_{\kappa'}|^2 \, \mathrm{d}s \\ &\leq \frac{C_3}{2h_e} \int_\kappa |\nabla v|^2 \, \mathrm{d}x + \frac{C_3}{2h_e} \int_{\kappa'} |\nabla v|^2 \, \mathrm{d}x \\ &\leq \frac{C_3}{h_e} \max \left\{ \int_\kappa |\nabla v|^2 \, \mathrm{d}x, \int_{\kappa'} |\nabla v|^2 \, \mathrm{d}x \right\}. \end{aligned}$$

On recalling from the definition of σ that $\sigma_e = \alpha / h_e$ for $e \in \mathcal{E}_{\mathrm{int}}$, we have that

$$\sum_{e \in \mathcal{E}_{\mathrm{int}}} \sigma_e^{-1} \int_e \langle |\nabla v| \rangle^2 \, \mathrm{d}s \leq C_3 \alpha^{-1} \sum_{e \in \mathcal{E}_{\mathrm{int}}} \max_{\{\kappa \,:\, e \subset \partial\kappa\}} \int_\kappa |\nabla v|^2 \, \mathrm{d}x.$$

Thanks to our assumption **H1** of contact regularity, it follows that no element κ can have more than c_d faces, where c_d is a finite number independent of h. We have that

$$\sum_{e \in \mathcal{E}_{\mathrm{int}}} \sigma_e^{-1} \int_e \langle |\nabla v| \rangle^2 \, \mathrm{d}s \leq C_3 \alpha^{-1} c_d \sum_{\kappa \in \mathcal{T}_h} \int_\kappa |\nabla v|^2 \, \mathrm{d}x,$$

and therefore

$$|\mathrm{T}_3| \le K_\delta (C_3 \alpha^{-1} c_d)^{1/2} \left(\int_\Omega |\nabla v|^2 \,\mathrm{d}x \right)^{1/2} \left(\int_{\Gamma_{\mathrm{int}}} \sigma [\![v]\!]^2 \,\mathrm{d}s \right)^{1/2}. \tag{4.4}$$

Using the lower bound on T_1 and the upper bounds on T_2 and T_3, we thus deduce that

$$\begin{aligned} \int_0^1 \tilde{b}(\varphi; v, v) \,\mathrm{d}\tau \;\ge\; & \tfrac{1}{2} M_1 \|\nabla v\|^2_{\mathrm{L}^2(\Omega)} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\mathrm{D}}} \sigma |v|^2 \,\mathrm{d}s + \int_{\Gamma_{\mathrm{int}}} \sigma |[\![v]\!]|^2 \,\mathrm{d}s \\ & - K_\delta (C_3 \alpha^{-1} 2d)^{1/2} \left(\int_\Omega |\nabla v|^2 \,\mathrm{d}x \right)^{1/2} \left(\int_{\Gamma_{\mathrm{D}}} \sigma |v|^2 \,\mathrm{d}s \right)^{1/2} \\ & - K_\delta (C_3 \alpha^{-1} c_d)^{1/2} \left(\int_\Omega |\nabla v|^2 \,\mathrm{d}x \right)^{1/2} \left(\int_{\Gamma_{\mathrm{int}}} \sigma |[\![v]\!]|^2 \,\mathrm{d}s \right)^{1/2}. \end{aligned}$$

Applying Cauchy's inequality $ab \le \frac{1}{2}a^2 + \frac{1}{2}b^2$ to the last two terms on the right-hand side and defining $C_d = c_d + 2d$, we have that

$$\int_0^1 \tilde{b}(\varphi; v, v) \,\mathrm{d}\tau \ge \frac{M_1}{2} \left(1 - \frac{K_\delta^2 C_3 C_d}{2 M_1 \alpha} \right) \int_\kappa |\nabla v|^2 \,\mathrm{d}x + \frac{1}{2} \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![v]\!]^2 \,\mathrm{d}s - 2M_0 \|v\|^2_{\mathrm{L}^2}.$$

On selecting α such that $\alpha \ge K_\delta^2 M_1^{-1} C_3 C_d \equiv \alpha_0$, we deduce that, for all $h \in (0, 1]$, (4.3) holds. ∎

LEMMA 4.2. *For each $\delta > 0$ there exists a constant $\tilde{K}_\delta$ depending only on K_δ, C_3, and c_d such that, for all $\varphi \in \mathrm{C}^1(\Omega, \mathcal{T}_h)^d$ with $\nabla \varphi \in \mathcal{Z}_\delta$,*

$$\left| \tilde{b}(\varphi; v, w) \right| \le \tilde{K}_\delta \|v\|_{1,h} \|w\|_{1,h} \qquad \forall v, w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).$$

Proof. By the definition of K_δ, for $\nabla \varphi \in \mathcal{Z}_\delta$, we have that

$$\sum_{i,\alpha,j,\beta=1}^{d} \int_\Omega |A_{i\alpha j\beta}(\nabla \varphi)| |\partial_{x_\alpha} v_i| |\partial_{x_\beta} w_j| \,\mathrm{d}x \le K_\delta \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\nabla w\|_{\mathrm{L}^2(\Omega)},$$

and, using also the fourth inverse inequality from (2.1),

$$\begin{aligned} \sum_{i,\alpha,j,\beta=1}^{d} \int_{\Gamma_{\mathrm{D}}} |A_{i\alpha j\beta}(\nabla \varphi)| |w_i| |\nu_\alpha| |\partial_{x_\beta} v_j| \,\mathrm{d}s &\le K_\delta \int_{\Gamma_{\mathrm{D}}} |w| |\nabla v| \,\mathrm{d}s \\ &\le K_\delta \left[\int_{\Gamma_{\mathrm{D}}} \sigma |w|^2 \,\mathrm{d}s \right]^{1/2} \left[\int_{\Gamma_{\mathrm{D}}} \sigma^{-1} |\nabla v|^2 \,\mathrm{d}s \right]^{1/2} \\ &\le K_\delta C(C_3, c_d) \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\sigma^{1/2} w\|_{\mathrm{L}^2(\Gamma_{\mathrm{D}})}. \end{aligned}$$

Using a similar argument, we can deduce that

$$\sum_{i,\alpha,j,\beta=1}^{d} \int_{\Gamma_{\mathrm{int}}} \left| \left\langle A_{i\alpha j\beta}(\nabla \varphi) \nu_\alpha \partial_{x_\beta} v \right\rangle \right| \left| [\![w_i]\!] \right| \,\mathrm{d}s \le K_\delta C(C_3, c_d) \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\sigma^{1/2} [\![w]\!]\|_{\mathrm{L}^2(\Gamma_{\mathrm{int}})}.$$

The result follows by inserting these three estimates into the definition of $\tilde{b}$. ∎

LEMMA 4.3. *For every $\delta > 0$ there exists a constant $\tilde{L}_\delta$, depending only on L_δ, C_3, and c_d such that, for all $\varphi, \psi \in \mathrm{C}^1(\Omega, \mathcal{T}_h)^d$ with $\nabla\varphi, \nabla\psi \in \mathcal{Z}_\delta$,*

$$\left|\tilde{b}(\varphi; v, w) - \tilde{b}(\psi; v, w)\right| \leq \tilde{L}_\delta \|\nabla\varphi - \nabla\psi\|_{\mathrm{L}^\infty(\Omega)} \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|w\|_{1,h} \quad \forall v, w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).$$

Proof. The proof follows precisely that of Lemma 4.2. Using the fact that the integrands in $\tilde{b}$ are linear in the tensor, we can replace $A_{i\alpha j\beta}(\nabla\varphi)$ by $(A_{i\alpha j\beta}(\nabla\varphi) - A_{i\alpha j\beta}(\nabla\psi))$ and use the Lipschitz condition (1.7) instead of the bound (1.6). Furthermore, the penalty terms cancel each other out, which gives $\|\nabla v\|_{\mathrm{L}^2(\Omega)}$ instead of $\|v\|_{1,h}$; see [17] for additional details. ∎

5. The elliptic case. Throughout this section, we assume that $u \in \mathrm{H}^{m+1}(\Omega)^d$, with $m > d/2$, is a solution of (1.2), (1.3), satisfying the Gårding inequality (1.11); in our analysis of the discontinuous Galerkin finite element approximation to the corresponding hyperbolic problem (1.8), we shall suppose that the weaker inequality (3.2) holds.

The convergence analysis will be based on Banach's fixed point theorem. We begin by constructing a nonlinear mapping whose unique fixed point in a neighborhood of u is the numerical solution u_{DG}. For this purpose, let $\Pi_h u$ denote the finite element interpolant, from $S^p(\Omega, \mathcal{T}_h, \mathbf{F})$, of the analytical solution u, defined by $(\Pi_h u)|_\kappa := \Pi_p^{\hat{\kappa}}(u|_\kappa \circ F_\kappa) \in \mathcal{R}_p(\hat{\kappa})$, where $\Pi_p^{\hat{\kappa}}(u|_\kappa \circ F_\kappa)$ is the classical finite element interpolant of $u|_\kappa \circ F_\kappa$ from $\mathcal{R}_p(\hat{\kappa})$. We can take $w_1 = u_{\mathrm{DG}}$ and $w_2 = \Pi_h u$ in the identity (4.2) above, which gives

$$B(u_{\mathrm{DG}}, v) - B(\Pi_h u, v) = \int_0^1 \tilde{b}(\Pi_h u + \tau(u_{\mathrm{DG}} - \Pi_h u); u_{\mathrm{DG}} - \Pi_h u, v)\, \mathrm{d}\tau \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).$$

Let us write

$$u - u_{\mathrm{DG}} = (u - \Pi_h u) - (u_{\mathrm{DG}} - \Pi_h u) \equiv \eta - \xi.$$

Note that since $u \in \mathrm{C}^1(\overline{\Omega})^d \cap \mathrm{H}^2(\Omega)^d$, we have that $B(u, v) = \ell(v)$ for all v in $S^p(\Omega, \mathcal{T}_h, \mathbf{F})$. Hence,

$$B(u_{\mathrm{DG}}, v) - B(\Pi_h u, v) = \ell(v) - B(\Pi_h u, v) = B(u, v) - B(\Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}),$$

and therefore, for all $v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$,

$$\int_0^1 \tilde{b}(\Pi_h u + \tau(u_{\mathrm{DG}} - \Pi_h u); u_{\mathrm{DG}} - \Pi_h u, v)\, \mathrm{d}\tau = \int_0^1 \tilde{b}(\Pi_h u + \tau(u - \Pi_h u); u - \Pi_h u, v)\, \mathrm{d}\tau. \tag{5.1}$$

Upon defining the bilinear form $\tilde{B}(\varphi; \cdot, \cdot)$ by

$$\tilde{B}(\varphi; v, w) := \int_0^1 \tilde{b}(\Pi_h u + \tau(\varphi - \Pi_h u); v, w)\, \mathrm{d}\tau,$$

we may rewrite (5.1) as

$$\tilde{B}(u_{\mathrm{DG}}; u_{\mathrm{DG}} - \Pi_h u, v) = \tilde{B}(u; u - \Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{5.2}$$

Lemmas 4.1–4.3 immediately imply that

$$\tilde{B}(\varphi; v, v) \geq \tilde{M}_1 \|v\|_{1,h}^2, \tag{5.3}$$

$$\left|\tilde{B}(\varphi; v, w)\right| \leq \tilde{K}_\delta \|v\|_{1,h} \|w\|_{1,h}, \quad \text{and} \tag{5.4}$$

$$\left|\tilde{B}(\varphi; v, w) - \tilde{B}(\psi; v, w)\right| \leq \tilde{L}_\delta \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|w\|_{1,h} \tag{5.5}$$

for all $v, w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ and $\varphi, \psi \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ such that $\nabla\varphi, \nabla\psi \in \mathcal{Z}_\delta$.

Let us recall our hypotheses that $u \in \mathrm{H}^{m+1}(\Omega)^d$, with $m > d/2$, and that the polynomial degree $p > d/2$. Let $d/2 < r \leq \min(m, p)$, and define the following subset of the broken Sobolev space $\mathrm{H}^1(\Omega, \mathcal{T}_h)^d$:

$$\mathcal{J} := \left\{ \varphi \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}) \,:\, \|\varphi - \Pi_h u\|_{1,h} \leq C_* h^r \|u\|_{\mathrm{H}^{r+1}(\Omega)} \right\},$$

where C_* is a fixed positive constant, independent of h, whose actual value will be fixed below. We note that, since $\Pi_h u \in \mathcal{J}$, the set $\mathcal{J}$ is nonempty. Further, $\mathcal{J}$ is a closed, convex subset of $\mathrm{H}^1(\Omega, \mathcal{T}_h)^d$ in the topology induced by the norm $\|\cdot\|_{1,h}$. Finally, we note that for each $v \in \mathcal{J}$, using the first inverse inequality in (2.1) and the approximation properties of Π_h (see, for example, [6]), we have that

$$\begin{aligned}
\|\nabla v - \nabla u\|_{\mathrm{L}^\infty(\Omega)} &\leq \|\nabla v - \nabla \Pi_h u\|_{\mathrm{L}^\infty(\Omega)} + \|\nabla \Pi_h u - \nabla u\|_{\mathrm{L}^\infty(\Omega)} \\
&\leq C_* C_3 h^{r-d/2} \|u\|_{\mathrm{H}^{r+1}(\Omega)} + \|\nabla \Pi_h u - \nabla u\|_{\mathrm{L}^\infty(\Omega)} \\
&\leq C_* C_3 h^{r-d/2} \|u\|_{\mathrm{H}^{r+1}(\Omega)} + C_5 h^{r-d/2} \|u\|_{\mathrm{H}^{r+1}(\Omega)}.
\end{aligned}$$

Since $r > d/2$ by hypothesis, given $\delta > 0$, there exists $h_0 \in (0, 1]$ such that, for all $h \in (0, h_0]$,

$$\varphi \in \mathcal{J} \;\Rightarrow\; \nabla \varphi \in \mathcal{Z}_\delta. \tag{5.6}$$

Motivated by the form of (5.2), we define the fixed point mapping $\mathcal{N}$ on $\mathcal{J}$ as follows. Given $\varphi \in \mathcal{J}$, we denote by $\mathcal{N}(\varphi) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ the solution to the following linear variational problem: Find $\mathcal{N}(\varphi) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ such that

$$\tilde{B}(\varphi; \mathcal{N}(\varphi) - \Pi_h u, v) = \tilde{B}(u; u - \Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{5.7}$$

Equivalently, we can restate this as follows: Find $\mathcal{N}(\varphi) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ such that

$$\tilde{B}(\varphi; \mathcal{N}(\varphi), v) = \tilde{B}(u; u - \Pi_h u, v) + \tilde{B}(\varphi; \Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).$$

Since $S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ is a finite-dimensional linear space, the existence and uniqueness of a solution $\mathcal{N}(\varphi) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ to problem (5.7) follows immediately from (5.3).

To prove that $\mathcal{N}$ maps $\mathcal{J}$ into itself, we test (5.7) with $v = \mathcal{N}(\varphi) - \Pi_h u$ and use (5.3) and (5.4) to obtain

$$\begin{aligned}
\tilde{M}_1 \|\mathcal{N}(\varphi) - \Pi_h u\|_{1,h}^2 &\leq \tilde{B}(\varphi; \mathcal{N}(\varphi) - \Pi_h u, \mathcal{N}(\varphi) - \Pi_h u) \\
&= \tilde{B}(u; u - \Pi_h u, \mathcal{N}(\varphi) - \Pi_h u) \\
&\leq \tilde{K}_\delta \|u - \Pi_h u\|_{1,h} \|\mathcal{N}(\varphi) - \Pi_h u\|_{1,h}.
\end{aligned}$$

Using the approximation properties of the projector $\Pi_h u$, we deduce that

$$\|\mathcal{N}(\varphi) - \Pi_h u\|_{1,h} \leq \tilde{M}_1^{-1} \tilde{K}_\delta C_6 h^r \|u\|_{\mathrm{H}^{r+1}(\Omega)}.$$

If we define $C_* = \tilde{M}_1^{-1} \tilde{C}_\delta C_6$, then $\mathcal{N}$ indeed maps $\mathcal{J}$ into itself. Note that, while h_0 depends on C_*, the constant C_* does not depend on h_0, and hence this seemingly implicit construction of C_* is correct.

It remains to show that $\mathcal{N}$ is a contraction of $\mathcal{J}$ in the norm $\|\cdot\|_{1,h}$. To do so, let us suppose that φ and ψ belong to $\mathcal{J}$. Then

$$\begin{aligned}
&\tilde{B}(\varphi; \mathcal{N}(\varphi) - \Pi_h u, v) = \tilde{B}(u; u - \Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}) \;\text{ and} \\
&\tilde{B}(\psi; \mathcal{N}(\psi) - \Pi_h u, v) = \tilde{B}(u; u - \Pi_h u, v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).
\end{aligned}$$

Upon subtracting the second line from the first, choosing $v = \mathcal{N}(\varphi) - \mathcal{N}(\psi)$, and using (5.3) and (5.5), we deduce that

$$\begin{aligned}\tilde{M}_1\|\mathcal{N}(\varphi)-\mathcal{N}(\psi)\|_{1,h}^2 &\le \tilde{B}(\varphi;\mathcal{N}(\varphi)-\mathcal{N}(\psi),\mathcal{N}(\varphi)-\mathcal{N}(\psi))\\ &= \tilde{B}(\psi;\mathcal{N}(\psi)-\Pi_h u,\mathcal{N}(\varphi)-\mathcal{N}(\psi)) - \tilde{B}(\varphi;\mathcal{N}(\psi)-\Pi_h u,\mathcal{N}(\varphi)-\mathcal{N}(\psi))\\ &\le \tilde{L}_\delta\|\nabla\psi-\nabla\varphi\|_{\mathrm{L}^\infty(\Omega)}\|\mathcal{N}(\psi)-\Pi_h u\|_{1,h}\|\mathcal{N}(\varphi)-\mathcal{N}(\psi)\|_{1,h}.\end{aligned}$$

Using the first inverse inequality in (2.1), and the fact that $\mathcal{N}(\psi) \in \mathcal{J}$, we have that

$$\|\mathcal{N}(\varphi)-\mathcal{N}(\psi)\|_{1,h} \le \tilde{M}_1^{-1}\tilde{L}_\delta C_3 C_* h^{r-d/2}\|\nabla\varphi-\nabla\psi\|_{\mathrm{L}^2(\Omega)} \le c(h)\|\varphi-\psi\|_{1,h},$$

where $c(h) = \tilde{M}^{-1}\tilde{L}_\delta C_3 C_* h^{r-d/2}$. Since $r > d/2$ by hypothesis **H3**, there exists a positive constant $h_1 \in (0,1]$ such that $c(h) < 1$. Thus, for $h \in (0, \min(h_0, h_1)]$, the mapping $\mathcal{N}$ is a contraction in the norm $\|\cdot\|_{1,h}$ of the closed set $\mathcal{J}$. By Banach's fixed point theorem, $\mathcal{N}$ has a unique fixed point u_{DG} in $\mathcal{J}$; in particular, by the definition of the set $\mathcal{J}$, the finite element approximation u_{DG} of u satisfies the bound

$$\|u_{\mathrm{DG}} - \Pi_h u\|_{1,h} \le C_* h^r \|u\|_{\mathrm{H}^{r+1}(\Omega)}, \qquad d/2 < r \le \min(m,p); \tag{5.8}$$

furthermore, $\nabla u_{\mathrm{DG}} \in \mathcal{Z}_\delta$ for all $h \in (0, \min(h_0, h_1)]$.

Let us write $a \lesssim b$ to express the fact that, for real numbers a and b, there exists a positive constant C, depending on the analytical solution u but *independent* of the discretization parameter h, such that $a \le Cb$ for all h in a closed subinterval of $[0,1]$ containing 0. We shall write $a \approx b$ if and only if $a \lesssim b$ and $b \lesssim a$. Since

$$\|u - \Pi_h u\|_{1,h} \le C_6 h^r \|u\|_{\mathrm{H}^{r+1}(\Omega)}, \qquad d/2 < r \le \min(m,p), \tag{5.9}$$

we deduce from (5.8) and (5.9) via the triangle inequality that, for all $h \in (0, \min(h_0, h_1)]$,

$$\|u - u_{\mathrm{DG}}\|_{1,h} \lesssim h^r \|u\|_{\mathrm{H}^{r+1}(\Omega)}, \qquad d/2 < r \le \min(m,p), \tag{5.10}$$

which is the required optimal bound on the error in the discontinuous Galerkin finite element method.

6. The hyperbolic problem. Now consider the hyperbolic problem

$$\partial_t^2 u_i - \sum_{\alpha=1}^{d} \partial_{x_\alpha}(S_{i\alpha}(\nabla u)) = f_i(t,x), \qquad i = 1,\dots,d, \qquad t \in (0,T], \quad x \in \Omega,$$

subject to the pair of initial conditions $u(0,x) = u_0(x)$, $\partial_t u(0,x) = u_1(x)$, $x \in \Omega$, where $u_0, u_1 \in \mathrm{H}^{m+1}(\Omega)^d$, and analogous boundary conditions as in the case of the static problem considered earlier; that is,

$$u(t,x) = g_{\mathrm{D}}(t,x) \quad \text{on } (0,T]\times\Gamma_{\mathrm{D}} \qquad \text{and} \qquad S(\nabla u(t,x))\nu = g_{\mathrm{N}}(t,x) \quad \text{on } (0,T]\times\Gamma_{\mathrm{N}}. \tag{6.1}$$

Since g_{D} and g_{N} now depend on t, so does the linear functional, which we denote by $\ell(t,\cdot)$ and is otherwise defined as in (2.3).

We refer to [8, 5] for theoretical results concerning the existence of a unique local (in time) solution to (6.1), subject to the given initial conditions, in the special case of a homogeneous Dirichlet boundary condition on Γ.

It will be assumed throughout that

$$u \in \mathrm{C}^2([0,T];\mathrm{H}^{m+1}(\Omega)^d), \qquad m > (d/2) + 1.$$

For simplicity, when there is no danger of confusion, we shall suppress the x-dependence in our notation and write $u(t)$, $v(t)$, etc., instead of $u(t,x)$, $v(t,x)$, etc.; we shall, on occasion, suppress both the x- and the t-dependence and write u, v, and so on. We shall further suppose that, for all $t \in [0,T]$, $u(t,\cdot)$ satisfies the Gårding inequality (3.2) for some $M_0 \geq 0$ and $M_1 > 0$, both independent of t. If one assumes the uniform monotonicity condition (1.10), then this is always true with $M_0 = 0$. If, on the other hand, one adopts the (considerably weaker) strong Legendre–Hadamard condition (1.12) and $\Gamma_{\rm D} = \Gamma$, then the Gårding inequality (3.2) holds with $M_1 > 0$ for some $M_0 \geq 0$ which may depend on $u(t)$; however, since $u \in {\rm C}^2([0,T] \times \overline{\Omega})$ by the Sobolev embedding theorem, M_0 can be chosen independent of t; cf. Theorem 6.5.1 on p. 253 of Morrey [16].

As in the elliptic case, let $\mathcal{M}_\delta$ be defined by

$$\mathcal{M}_\delta := {\rm conv}\big\{\eta \in \mathbb{R}^{d\times d} : \inf_{x\in\Omega, t\in[0,T]} |\eta - \nabla u(t,x)| \leq \delta\big\},$$

and define the constants K_δ and L_δ by the formulas (1.6) and (1.7). The set $\mathcal{Z}_\delta$ is now given by

$$\mathcal{Z}_\delta := \big\{\Phi \in {\rm C}_{\rm pw}(\overline{\Omega})^{d\times d} : \min_{t\in[0,T]} \|\Phi - \nabla u(t)\|_{{\rm L}^\infty(\Omega)} \leq \delta\big\}.$$

Let us consider, for $t \in [0,T]$ and $p > (d/2)+1$, the (semidiscrete) discontinuous Galerkin finite element approximation $u_{\rm DG}(t,\cdot) \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ to $u(t,\cdot)$ such that

$$(\ddot{u}_{\rm DG}, v) + B(u_{\rm DG}, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{u}_{\rm DG}]\!]\cdot[\![v]\!]\,{\rm d}s = \ell(t,v) + \int_{\Gamma_{\rm D}} \sigma\dot{g}_{\rm DG}\cdot v\,{\rm d}s \tag{6.2}$$

for all for $v \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ and all $t \in (0,T]$, and

$$u_{\rm DG}(0,x) = u^0_{\rm DG}(x), \qquad \dot{u}_{\rm DG}(0,x) = u^1_{\rm DG}(x), \qquad x \in \Omega,$$

with $u^0_{\rm DG}$ and $u^1_{\rm DG}$ in $S^p(\Omega,\mathcal{T}_h,\mathbf{F})$.

We highlight the presence of the last term on the left-hand side and the second term on the right-hand side of (6.2) which did not feature in the definition of our discontinuous Galerkin approximation of the elliptic problem considered in the earlier sections. The inclusion of these terms does not affect the consistency of the method. On the other hand, they play a crucial role in ensuring the validity of energy estimates in sufficiently strong norms. In order to highlight this point further, note that, in an energy analysis of the discontinuous Galerkin approximation (2.5) to the elliptic problem (1.2), (1.3), the natural choice of test function is $v = u_{\rm DG}$, while in the case of (6.2) it is $v = \dot{u}_{\rm DG}$, which, in turn, motivates the inclusion of the additional terms in (6.2) compared to the elliptic case.

Let $M_0 \geq 0$ be the constant from (3.2). We denote by $W(t) \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ the nonlinear projection of $u(t)$ defined by

$$B(W(t),v) + 2M_0(W(t),v) = B(u(t),v) + 2M_0(u(t),v) \qquad \forall v \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}), \qquad 0 \leq t \leq T,$$

and we select $u^0_{\rm DG}$ and $u^1_{\rm DG}$ in $S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ such that

$$\|u^0_{\rm DG} - W(0)\|_{1,h} + \|u^1_{\rm DG} - \dot{W}(0)\|_{{\rm L}^2(\Omega)} \lesssim h^r, \qquad (d/2)+1 < r \leq \min(m,p).$$

The existence, uniqueness, approximation properties, and differentiability with respect to t of $W(t)$ are established in Appendix A, in Lemma A.1. For the sake of simplicity of presentation, we choose $u^0_{\rm DG} = W(0)$ and $u^1_{\rm DG} = \dot{W}(0)$ here. By using an argument based on Banach's fixed point theorem, similar to the one presented in the previous section, and stimulated by the ideas in [15], we will show the existence and uniqueness of $u_{\rm DG}$. We shall also show that $u_{\rm DG}$ converges to the analytical solution u with optimal order as the spatial discretization parameter h converges to 0.

6.1. Definition of the fixed point map. We decompose

$$u - u_{\rm DG} = (u - W) - (u_{\rm DG} - W) \equiv \eta - \xi.$$

Then, with our choice of the numerical initial conditions $u^0_{\rm DG}$ and $u^1_{\rm DG}$, we have $\xi(0) = 0$ and $\dot{\xi}(0) = 0$. Hence,

$$\begin{aligned}(\ddot{\xi}, v) + B(u_{\rm DG}, v) - B(W, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\xi}]\!]\cdot[\![v]\!]\,{\rm d}s \\ = (\ddot{\eta}, v) - 2M_0(\eta, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\eta}]\!]\cdot[\![v]\!]\,{\rm d}s \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).\end{aligned}$$

Upon linearization of the term $B(u_{\rm DG}, v) - B(W, v)$, in terms of our earlier notation, we have that

$$\begin{aligned}(\ddot{\xi}, v) + \int_0^1 \tilde{b}(W + \tau(u_{\rm DG} - W); u_{\rm DG} - W, v)\,{\rm d}\tau + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\xi}]\!]\cdot[\![v]\!]\,{\rm d}s \\ = (\ddot{\eta}, v) - 2M_0(\eta, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\eta}]\!]\cdot[\![v]\!]\,{\rm d}s \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}).\end{aligned} \tag{6.3}$$

As in the case of the elliptic problem, we can simplify the notation considerably by defining the bilinear form $\tilde{B}(t, \varphi; \cdot, \cdot)$ by

$$\tilde{B}(t, \varphi; v, w) := \int_0^1 \tilde{b}(W(t) + \tau(\varphi - W(t)); v, w)\,{\rm d}t$$

and the linear functional $\rho(t; \cdot)$ by

$$\rho(t; v) := (\ddot{\eta}, v) - 2M_0(\eta, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\eta}]\!]\cdot[\![v]\!]\,{\rm d}s,$$

which allows us to rewrite (6.3) as

$$(\ddot{\xi}, v) + \tilde{B}(t, u_{\rm DG}(t); \xi, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\xi}]\!]\cdot[\![v]\!]\,{\rm d}s = \rho(t; v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{6.4}$$

We consider the set $\mathcal{J} \subset {\rm C}^1([0, T]; S^p(\Omega, \mathcal{T}_h, \mathbf{F})) \equiv Y$ defined by

$$\begin{aligned}\mathcal{J} :=& \big\{\psi \in Y \,:\, \|\psi - W\|_Y \\ :=& \max_{t\in[0,T]} \Big(\|\psi(t) - W(t)\|_{1,h} + \|\dot{\psi}(t) - \dot{W}(t)\|_{{\rm L}^2(\Omega)}\Big) \le C_*(u)h^r\big\},\end{aligned}$$

where $C_*(u)$ is a positive constant and $(d/2) + 1 < r \le \min(m, p)$. As in the elliptic case, by the first inverse inequality in (2.1), there exists $h_0 > 0$ such that, for all $h \in (0, h_0]$,

$$\psi \in \mathcal{J} \;\Rightarrow\; \nabla\psi(t) \in \mathcal{Z}_\delta \;\forall\; t \in [0, T]. \tag{6.5}$$

In addition, $\mathcal{J}$ is a closed, convex subset of Y.

Now, motivated by the form of (6.4) and the definition of ξ, similarly as in the case of the elliptic problem, we are led to the following definition of the fixed point map $\mathcal{N}$ on $\mathcal{J}$: If $\varphi \in \mathcal{J}$, the image $u_\varphi = \mathcal{N}(\varphi) \in \mathrm{C}^2([0,T]; S^p(\Omega, \mathcal{T}_h, \mathbf{F}))$ is defined as the solution to the following linear problem:

$$(\ddot{u}_\varphi - \ddot{W}, v) + \tilde{B}(t, \varphi(t); u_\varphi - W, v) + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![\dot{u}_\varphi - \dot{W}]\!] \cdot [\![v]\!] \, \mathrm{d}s = \rho(t; v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \tag{6.6}$$

with $u_\varphi(0) = u^0_{\mathrm{DG}}$, $\dot{u}_\varphi(0) = u^1_{\mathrm{DG}}$. Clearly, this variational form can be rewritten as an explicit linear ordinary differential equation for u_φ, and hence $\mathcal{N}$ is well-defined. Our objective now is to show, via Banach's fixed point theorem, that the nonlinear mapping $\varphi \in \mathcal{J} \mapsto \mathcal{N}(\varphi)$ has a unique fixed point $u_{\mathrm{DG}} \in \mathcal{J}$.

6.2. Auxiliary results. In the analysis of the linear problem (6.6), it will be crucial to replace a term of the form

$$\tilde{B}(t, \varphi(t); \xi(t), \dot{\xi}(t))$$

by a total derivative. Since $\tilde{B}(t, \varphi(t); \cdot, \cdot)$ is not symmetric in its last two arguments, we split $\tilde{B}$ into a symmetric term and a remainder which can be controlled:

$$\tilde{B}(t, \varphi(t); v, w) = \tilde{B}^{(S)}(t, \varphi(t); v, w) + \tilde{B}^{(A)}(t, \varphi(t); v, w), \tag{6.7}$$

where

$$\tilde{B}^{(S)}(t, \varphi(t); v, w) := \int_0^1 \int_\Omega \sum_{i,\alpha,j,\beta=1}^{d} A^\tau_{i\alpha j\beta} \partial_{x_\alpha} w_i \partial_{x_\beta} v_j \, \mathrm{d}x \, \mathrm{d}\tau + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![v]\!] \cdot [\![w]\!] \, \mathrm{d}s,$$

and

$$\tilde{B}^{(A)}(t, \varphi(t); v, w) := - \int_0^1 \sum_{i,\alpha,j,\beta=1}^{d} \left[\int_{\Gamma_{\mathrm{int}}} \left\langle A^\tau_{i\alpha j\beta} \nu_\alpha \partial_{x_\beta} v_j \right\rangle [\![w_i]\!] \, \mathrm{d}s + \int_{\Gamma_{\mathrm{D}}} A^\tau_{i\alpha j\beta} \nu_\alpha w_i \partial_{x_\beta} v_j \, \mathrm{d}s \right] \mathrm{d}\tau,$$

where $A^\tau_{i\alpha j\beta} := A_{i\alpha j\beta}(\nabla W(t) + \tau(\nabla \varphi(t) - \nabla W(t)))$. Note that $\tilde{B}^{(A)}(t, \varphi; \cdot, \cdot)$ is not skew-symmetric but asymmetric, i.e., simply, *not symmetric*.

Following the proof of Lemma 4.1 closely, we obtain for all $\varphi \in \mathcal{J}$ and for all $\alpha \geq \alpha_0$, where α_0 is as in Lemma 4.1,

$$\tilde{B}^{(S)}(t, \varphi(t); v, v) \geq \tfrac{1}{2} M_1 \|v\|^2_{1,h} - 2M_0 \|v\|^2_{\mathrm{L}^2(\Omega)} \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \tag{6.8}$$

and

$$\left| \tilde{B}^{(A)}(t, \varphi(t); v, w) \right| \lesssim \|\nabla v\|_{\mathrm{L}^2(\Omega)} \left(\int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma |[\![w]\!]|^2 \, \mathrm{d}s \right)^{1/2} \qquad \forall v, w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{6.9}$$

In addition, we shall require an estimate on the expression

$$\tilde{B}^{(S)}_t(t, \varphi(t); v, w) := \int_0^1 \int_\Omega \sum_{i,\alpha,j,\beta=1}^{d} \left[\frac{\mathrm{d}}{\mathrm{d}t} A^\tau_{i\alpha j\beta} \right] \partial_{x_\alpha} w_i \partial_{x_\beta} v_j \, \mathrm{d}x \, \mathrm{d}\tau, \qquad v, w \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}),$$

where $A^\tau_{i\alpha j\beta}$ is as defined above. Upon setting

$$K'_\delta := \operatorname*{ess.sup}_{x\in\Omega,\tau\in[0,1]} \left(\sum_{i,\alpha,j,\beta=1}^{d} \left| \frac{\mathrm{d}}{\mathrm{d}t} A^\tau_{i\alpha j\beta} \right|^2 \right)^{1/2},$$

we deduce that

$$\left|\tilde{B}^{(S)}_t(t,\varphi(t);v,w)\right| \le K'_\delta \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\nabla w\|_{\mathrm{L}^2(\Omega)}.$$

To estimate K'_δ, consider

$$\begin{aligned} K'_\delta &= \operatorname*{ess.sup}_{x\in\Omega,\tau\in[0,1]} \left(\sum_{i,\alpha,j,\beta=1}^{d} \left|\nabla A_{i\alpha j\beta}(\nabla\psi(t,x))\right|^2 |\nabla\dot{W}(t) + \tau(\nabla\dot{\varphi}(t) - \nabla\dot{W}(t))|^2 \right)^{1/2} \\ &\le L_\delta \big(\|\nabla\dot{W}(t)\|_{\mathrm{L}^\infty(\Omega)} + \|\nabla\dot{\varphi}(t) - \nabla\dot{W}(t)\|_{\mathrm{L}^\infty(\Omega)} \big). \end{aligned}$$

As $\varphi \in \mathcal{J}$, the first of the inverse inequalities (2.1), the bound (A.2), and the definition of the set $\mathcal{J}$ yield

$$K'_\delta \lesssim \|\nabla\dot{W}(t)\|_{\mathrm{L}^\infty(\Omega)} + h^{-d/2} \|\nabla\dot{\varphi}(t) - \nabla\dot{W}(t)\|_{\mathrm{L}^2(\Omega)} \lesssim 1 + h^{r-d/2}.$$

Combining these estimates and recalling that, by hypothesis $r > (d/2) + 1$ and, a fortiori, $r > d/2$, we obtain for all $\varphi \in \mathcal{J}$, for all $t \in [0,T]$, and for all $h \in (0,1]$

$$\left|\tilde{B}^{(S)}_t(t,\varphi(t);v,w)\right| \lesssim \|\nabla v\|_{\mathrm{L}^2(\Omega)} \|\nabla w\|_{\mathrm{L}^2(\Omega)} \qquad \forall v,w \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}). \tag{6.10}$$

Finally, we shall require an estimate on the right-hand side $\rho(t;v)$ in (6.4). A straightforward computation gives

$$\begin{aligned} |\rho(t,v)| &\le \left(2\|\ddot{\eta}\|^2_{\mathrm{L}^2(\Omega)} + 8M_0^2 \|\eta\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma |[\![\dot{\eta}]\!]|^2 \,\mathrm{d}s \right)^{1/2} \\ &\qquad \left(\|v\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma |[\![v]\!]|^2 \,\mathrm{d}s \right)^{1/2} \\ &\lesssim h^r \left(\|v\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma |[\![v]\!]|^2 \,\mathrm{d}s \right)^{1/2}, \end{aligned} \tag{6.11}$$

where we used (A.2) and (A.7) to bound the different norms of η.

6.3. Convergence analysis. For the sake of notational simplicity, we define

$$\xi_\varphi = u_\varphi - W.$$

Testing (6.6) with $v = \dot{\xi}_\varphi$, and using the decomposition (6.7), we deduce that

$$(\ddot{\xi}_\varphi, \dot{\xi}_\varphi) + \tilde{B}^{(S)}(t,\varphi(t);\xi_\varphi,\dot{\xi}_\varphi) + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma |[\![\dot{\xi}_\varphi]\!]|^2 \,\mathrm{d}s = \rho(t;\dot{\xi}_\varphi) - \tilde{B}^{(A)}(t,\varphi(t);\xi_\varphi,\dot{\xi}_\varphi),$$

which can be rewritten as

$$\begin{aligned} &\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\Big[\|\dot{\xi}_\varphi\|^2_{\mathrm{L}^2(\Omega)} + \tilde{B}^{(S)}(t,\varphi(t);\xi_\varphi,\xi_\varphi) \Big] + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma |[\![\dot{\xi}_\varphi]\!]|^2 \,\mathrm{d}s \\ &\qquad = \rho(t;\dot{\xi}_\varphi) - \tilde{B}^{(A)}(t,\varphi(t);\xi_\varphi,\dot{\xi}_\varphi) - \frac{1}{2}\tilde{B}^{(S)}_t(t,\varphi;\xi_\varphi,\xi_\varphi). \end{aligned} \tag{6.12}$$

On noting that $\xi_\varphi(0) = 0$ and $\dot{\xi}_\varphi(0) = 0$, integrating the above identity in t, and multiplying by 2, we deduce from (6.8) that, for $\alpha \geq \alpha_0$ and $h \in (0, h_0]$,

$$\begin{aligned}
&\|\dot{\xi}_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} + \tfrac{1}{2}M_1\|\xi_\varphi(t)\|^2_{1,h} - 2M_0\|\xi_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} + 2\int_0^t \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma|[\![\dot{\xi}_\varphi(\tau)]\!]|^2 \,\mathrm{d}s\,\mathrm{d}\tau \\
&\leq \int_0^t \Big[2|\rho(\tau;\dot{\xi}_\varphi(\tau))| + 2\big|\tilde{B}^{(A)}(\tau,\varphi(\tau);\xi_\varphi(\tau),\dot{\xi}_\varphi(\tau))\big| + \big|\tilde{B}^{(S)}_t(\tau;\varphi(\tau);\xi_\varphi,\xi_\varphi)\big|\Big]\,\mathrm{d}\tau. \qquad (6.13)
\end{aligned}$$

Next we estimate the terms on the right-hand side, using (6.11), (6.9), and (6.10). Transferring the term $2M_0\|\xi_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)}$ to the right-hand side, we obtain

$$\begin{aligned}
&\|\dot{\xi}_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} + \tfrac{1}{2}M_1\|\xi_\varphi(t)\|^2_{1,h} + 2\int_0^t \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma|[\![\dot{\xi}_\varphi(\tau)]\!]|^2 \,\mathrm{d}s\,\mathrm{d}\tau \\
&\quad\lesssim \|\xi_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} + h^r \int_0^t \Big[\|\dot{\xi}_\varphi(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma|[\![\dot{\xi}_\varphi(\tau)]\!]|^2 \,\mathrm{d}s\Big]^{1/2} \mathrm{d}\tau \\
&\quad + \int_0^t \|\nabla\xi_\varphi(\tau)\|_{\mathrm{L}^2(\Omega)} \Big[\int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma|[\![\dot{\xi}_\varphi(\tau)]\!]|^2 \,\mathrm{d}s\Big]^{1/2} \mathrm{d}\tau + \int_0^t \|\nabla\xi_\varphi(\tau)\|^2_{\mathrm{L}^2(\Omega)} \,\mathrm{d}\tau. \qquad (6.14)
\end{aligned}$$

Using $\xi_\varphi(0) = 0$, the first term on the right-hand side can be estimated by

$$\|\xi_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} = \Big\|\int_0^t \dot{\xi}_\varphi(\tau)\,\mathrm{d}\tau\Big\|^2_{\mathrm{L}^2(\Omega)} \leq T\int_0^t \|\dot{\xi}_\varphi(\tau)\|^2_{\mathrm{L}^2(\Omega)}\,\mathrm{d}\tau.$$

Terms containing integrals over $[0,t]\times(\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}})$ in (6.14) can be absorbed into the third term on the left-hand side of (6.14) by apply the ε-inequality with sufficiently small ε (but independent of h). After normalization, we obtain

$$\begin{aligned}
&\|\dot{\xi}_\varphi(t)\|^2_{\mathrm{L}^2(\Omega)} + \|\xi_\varphi(t)\|^2_{1,h} + \int_0^t \int_{\Gamma_{\mathrm{int}}\cup\Gamma_{\mathrm{D}}} \sigma|[\![\dot{\xi}_\varphi(\tau)]\!]|^2 \,\mathrm{d}s\,\mathrm{d}\tau \\
&\qquad\lesssim h^{2r} + \int_0^t \Big[\|\dot{\xi}_\varphi(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \|\nabla\xi_\varphi(\tau)\|^2_{\mathrm{L}^2(\Omega)}\Big]\,\mathrm{d}\tau. \qquad (6.15)
\end{aligned}$$

Hence, an application of Gronwall's lemma gives

$$\max_{t\in[0,T]} \|\mathcal{N}(\varphi)(t) - W(t)\|_Y \lesssim h^r,$$

which allows us to deduce the existence of a constant $C_* = C_*(u)$, independent of h, such that, for $h \leq h_0$, $\mathcal{N}$ maps $\mathcal{J}$ into itself.

Remark 1. Since our strategy for proving that $\mathcal{N}$ maps $\mathcal{J}$ into itself was very similar to the one presented for the case of the quasi-linear elliptic problem considered earlier, we were more concise here than in the corresponding discussion for the elliptic problem. In particular, unlike our detailed analysis in the case of the elliptic problem where we made a deliberate effort to carefully track the constants in the bounds so as to be able to explicitly specify the value of the constant C_* featured in the definition of the set $\mathcal{J}$, here, for the sake of brevity, we refrained from doing so. As a matter of fact, the corresponding constant C_* can be found in an identical manner as in the case of the elliptic problem.

Next we prove that $\mathcal{N}$ is a contraction of $\mathcal{J}$ in the norm $\|\cdot\|_Y$. For this purpose, consider $u_\varphi = \mathcal{N}(\varphi) \in \mathcal{J}$ and $u_\psi = \mathcal{N}(\psi) \in \mathcal{J}$ defined analogously. Setting $\xi_\varphi = u_\varphi - W$ and $\xi_\psi = u_\psi - W$, we have that

$$(\ddot{\xi}_\varphi, v) + \tilde{B}(t, \varphi; \xi_\varphi, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\xi}_\varphi]\!] \cdot [\![v]\!] \,\mathrm{d}s = \rho(t; v), \quad \text{and}$$
$$(\ddot{\xi}_\psi, v) + \tilde{B}(t, \psi; \xi_\psi, v) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma[\![\dot{\xi}_\psi]\!] \cdot [\![v]\!] \,\mathrm{d}s = \rho(t; v) \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}),$$

subject to $\xi_\varphi(0) = \xi_\psi(0) = 0$ and $\dot{\xi}_\varphi(0) = \dot{\xi}_\psi(0) = 0$. By subtracting the second line from the first line, and testing with

$$v = \dot{\xi}_\varphi - \dot{\xi}_\psi = \dot{u}_\varphi - \dot{u}_\psi \equiv \dot{e},$$

where $e = u_\varphi - u_\psi$, we obtain

$$(\ddot{e}, \dot{e}) + \tilde{B}(t, \varphi; e, \dot{e}) + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}]\!]|^2 \,\mathrm{d}s = \tilde{B}(t, \psi; \xi_\psi, \dot{e}) - \tilde{B}(t, \varphi; \xi_\psi, \dot{e}).$$

By virtue of Lemma 4.3,

$$\left|\tilde{B}(t, \psi; \xi_\psi, \dot{e}) - \tilde{B}(t, \varphi; \xi_\psi, \dot{e})\right| \lesssim \|\nabla\varphi - \nabla\psi\|_{\mathrm{L}^\infty(\Omega)} \|\xi_\psi\|_{1,h} \|\dot{e}\|_{1,h}.$$

Thus, by using the same procedure as in the proof of the inclusion $\mathcal{N}(\mathcal{J}) \subset \mathcal{J}$, we obtain

$$\begin{aligned} &\|\dot{e}(t)\|^2_{\mathrm{L}^2(\Omega)} + \|e(t)\|^2_{1,h} + \int_0^t \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}(\tau)]\!]|^2 \,\mathrm{d}s \,\mathrm{d}\tau \\ &\quad\lesssim \int_0^t \left[\|\dot{e}(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \|\nabla e(\tau)\|^2_{\mathrm{L}^2(\Omega)}\right] \mathrm{d}\tau \\ &\quad\quad + \int_0^t \|\nabla\varphi(\tau) - \nabla\psi(\tau)\|_{\mathrm{L}^\infty(\Omega)} \|\xi_\psi(\tau)\|_{1,h} \|\dot{e}(\tau)\|_{1,h} \,\mathrm{d}\tau. \end{aligned} \tag{6.16}$$

As $u_\psi \in \mathcal{J}$, we have $\max_{t\in[0,T]} \|\xi_\psi(t)\|_{1,h} \le C_* h^r$, and, by the first inequality in (2.1), we also have that

$$\|\nabla\varphi(\tau) - \nabla\psi(\tau)\|_{\mathrm{L}^\infty(\Omega)} \lesssim h^{-d/2} \|\nabla\varphi(\tau) - \nabla\psi(\tau)\|_{\mathrm{L}^2(\Omega)}.$$

The only term on the right-hand side of (6.16) which cannot be directly controlled by any of the terms featured on the left-hand side of (6.16) is $\|\dot{e}(\tau)\|_{1,h}$. Employing the second inverse inequality in (2.1), we handle this term as follows:

$$\begin{aligned} \|\dot{e}(\tau)\|^2_{1,h} &= \|\nabla\dot{e}(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}(\tau)]\!]|^2 \,\mathrm{d}s \\ &\lesssim h^{-2} \|\dot{e}(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}(\tau)]\!]|^2 \,\mathrm{d}s. \end{aligned}$$

Inserting these bounds into (6.16), we obtain

$$\begin{aligned} &\|\dot{e}(t)\|^2_{\mathrm{L}^2(\Omega)} + \|e(t)\|^2_{1,h} + \int_0^t \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}(\tau)]\!]|^2 \,\mathrm{d}s \,\mathrm{d}\tau \\ &\quad\lesssim \int_0^t \left[\|\dot{e}(\tau)\|^2_{\mathrm{L}^2(\Omega)} + \|e(\tau)\|^2_{1,h}\right] \mathrm{d}\tau + h^{r-d/2-1} \int_0^t \|\nabla\varphi(\tau) - \nabla\psi(\tau)\|_{\mathrm{L}^2(\Omega)} \\ &\quad\quad \times \left[\|\dot{e}(\tau)\|^2_{\mathrm{L}^2(\Omega)} + h \int_{\Gamma_{\rm int}\cup\Gamma_{\rm D}} \sigma|[\![\dot{e}(\tau)]\!]|^2 \,\mathrm{d}s\right]^{1/2} \mathrm{d}\tau. \end{aligned}$$

Thus, by applying to the two last terms on the right-hand side of the ε-inequality $ab \le \frac{\varepsilon}{2}a^2 + \frac{1}{2\varepsilon}b^2$, with $\varepsilon > 0$ sufficiently small, we deduce from Gronwall's lemma that

$$\begin{aligned}\|\dot{u}_\varphi(t) - \dot{u}_\psi(t)\|^2_{\mathrm{L}^2(\Omega)} + \|u_\varphi(t) - u_\psi(t)\|^2_{1,h} &\lesssim h^{2(r-d/2-1)} \int_0^t \|\nabla\varphi(\tau) - \nabla\psi(\tau)\|^2_{\mathrm{L}^2(\Omega)}\,\mathrm{d}\tau \\ &\lesssim h^{2(r-d/2-1)}\|\varphi - \psi\|^2_Y,\end{aligned}$$

and thereby

$$\|\mathcal{N}(\varphi) - \mathcal{N}(\psi)\|_Y \lesssim h^{r-d/2-1}\|\varphi - \psi\|_Y \qquad \forall \varphi, \psi \in \mathcal{J},$$

which, in turn, implies that, for h sufficiently small, $\mathcal{N}$ is a contraction of $\mathcal{J}$ into itself in the norm $\|\cdot\|_Y$. Therefore, by Banach's fixed point theorem, for h sufficiently small, $\mathcal{N}$ has a unique fixed point, $u_{\mathrm{DG}} \in \mathcal{J}$, the semidiscrete discontinuous Galerkin finite element approximation to u defined by (6.2). In other words, for h sufficiently small,

$$\max_{t\in[0,T]} \Big(\|\dot{u}_{\mathrm{DG}}(t) - \dot{W}(t)\|_{\mathrm{L}^2(\Omega)} + \|u_{\mathrm{DG}}(t) - W(t)\|_{1,h}\Big) \le C_*(u)h^r, \qquad (d/2)+1 < r \le \min(m,p).$$

Combining the last bound with (A.1) and (A.7) we then deduce, for h sufficiently small, that

$$\max_{t\in[0,T]} \big(\|\dot{u}(t) - \dot{u}_{\mathrm{DG}}(t)\|_{\mathrm{L}^2(\Omega)} + \|u(t) - u_{\mathrm{DG}}(t)\|_{1,h}\big) \lesssim h^r, \qquad (d/2)+1 < r \le \min(m,p),$$

which is the desired optimal convergence estimate.

7. Extensions to other methods. It is straightforward to extend our error analysis to different discontinuous finite element methods. Note, for example, that in the elliptic case only Lemmas 4.1–4.3 are method-dependent. Once they are established, the remaining analysis is independent of the particular form of discretization used. We shall demonstrate this through the example of the discontinuous Galerkin finite element method (DGFEM) of Eyck and Lew [10], which is a particularly attractive candidate for variational problems since it is defined via a discrete energy principle.

The idea is to use the lifting operator introduced in [2] to find a gradient representation for the jumps across element interfaces to define a *discontinuous Galerkin (DG) gradient operator*. More precisely, for $v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$, let

$$\nabla_{\mathrm{DG}} v = \nabla v + \mathbf{R}(v),$$

where $\mathbf{R} : S^p(\Omega, \mathcal{T}_h, \mathbf{F}) \to \mathrm{C}_{\mathrm{pw}}(\overline{\Omega})^{d\times d}$ is defined by

$$\int_\Omega \mathbf{R}(v) : F\,\mathrm{d}x = -\int_{\Gamma_{\mathrm{int}}} [\![v]\!] \cdot \langle F\,\nu_{\mathrm{int}}\rangle\,\mathrm{d}s \qquad \forall F \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})^d.$$

We shall also use $\nabla^{i\alpha}_{\mathrm{DG}}$ to denote the (i,α) component of ∇_{DG}. It is straightforward to show that $\mathbf{R}$ is a bounded operator; more precisely,

$$\|\mathbf{R}(v)\|_{\mathrm{L}^2(\Omega)} \le C_L \left(\int_{\Gamma_{\mathrm{int}}} \sigma |[\![v]\!]|^2\,\mathrm{d}x\right)^{1/2} \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}), \tag{7.1}$$

where C_L is independent of h. Using the definition of the DG gradient, we define the discrete functional $J_h : S^p(\Omega, \mathcal{T}_h, \mathbf{F}) \to \mathbb{R}$ by

$$J_h(v) = \int_\Omega \left[W(\nabla_{\mathrm{DG}} v) - f \cdot v\right] \,\mathrm{d}x - \int_{\Gamma_{\mathrm{N}}} g_{\mathrm{N}} \cdot v \,\mathrm{d}s + \int_{\Gamma_{\mathrm{int}}} \sigma |[\![v]\!]|^2 \,\mathrm{d}s + \int_{\Gamma_{\mathrm{D}}} \sigma |v - g_{\mathrm{D}}|^2 \,\mathrm{d}s,$$

as an approximation to the functional J defined in (1.1). The resulting DGFEM for (1.2) is simply the Euler–Lagrange equation $\delta J_h(u_{\mathrm{DG}}) = 0$, where δJ_h, the first variation of J_h, is given by

$$\delta J_h(\varphi; v) = \int_\Omega \sum_{i,\alpha=1}^{d} S_{i\alpha}(\nabla_{\mathrm{DG}}\varphi) \nabla_{\mathrm{DG}}^{i,\alpha} v \,\mathrm{d}x + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![\varphi]\!] \cdot [\![v]\!] \,\mathrm{d}s - \ell(v),$$

where $\ell(v)$ is defined as in (2.3). Since $\mathbf{R}(u) = 0$ if u is continuous on $\overline{\Omega}$, the method is consistent. Similarly, the second variation of J_h is defined by

$$\delta^2 J_h(\varphi; v, w) = \int_\Omega \sum_{i,\alpha,j,\beta=1}^{d} A_{i\alpha j\beta}(\nabla_{\mathrm{DG}}\varphi) \nabla_{\mathrm{DG}}^{i,\alpha} v \; \nabla_{\mathrm{DG}}^{j,\beta} w \,\mathrm{d}x + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![v]\!] \cdot [\![w]\!] \,\mathrm{d}s.$$

Suppose that $u \in \mathrm{C}^1(\overline{\Omega})$ satisfies (3.2). While Lemma 3.2 cannot be applied directly, it is nevertheless straightforward to modify its proof to obtain for $h \le 1$, $\alpha \ge \alpha_0 = \alpha_0(C_r, K_\delta, M_1, M_0)$, and for all $\varphi \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ such that $\|\nabla_{\mathrm{DG}}\varphi - \nabla u\|_{\mathrm{L}^\infty(\Omega)} \le \delta \le M_1/(4L_\delta)$

$$\delta^2 J_h(\varphi; v, v) \ge \tfrac{1}{2} M_1 \|v\|_{1,h}^2 - 2M_0 \|v\|_{\mathrm{L}^2(\Omega)}^2 \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{7.2}$$

The boundedness and Lipschitz continuity of $\varphi \mapsto \delta^2 J_h(\varphi; \cdot, \cdot)$ over the set of all φ such that $\nabla_{\mathrm{DG}}\varphi \in \mathcal{M}_\delta$ can be obtained precisely as in Lemma 4.2 and 4.3. Using (7.1) we can again deduce that for $h \le h_0$

$$\varphi \in \mathcal{J} \;\Rightarrow\; \|\nabla_{\mathrm{DG}}\varphi - \nabla u\|_{\mathrm{L}^\infty(\Omega)} \le \delta,$$

and thus, the convergence analysis of section 5 can be repeated verbatim to obtain the existence of a solution u_{DG} to $\delta J_h(u_{\mathrm{DG}}; v) = 0$ for all $v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$, satisfying the optimal-order error estimate (5.10).

The analysis in the hyperbolic case can be generalized just as easily. The DGFEM based on the energy principle outlined above reads: For $t \in (0, T]$ find $u_{\mathrm{DG}}(t, \cdot) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ such that

$$(\ddot{u}_{\mathrm{DG}}, v) + \delta J_h(u_{\mathrm{DG}}; v) + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma [\![\dot{u}_{\mathrm{DG}}]\!] \cdot [\![v]\!] \,\mathrm{d}s = \int_{\Gamma_{\mathrm{D}}} \sigma \dot{g}_{\mathrm{D}} \cdot v \,\mathrm{d}s \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{7.3}$$

Upon defining

$$\tilde{B}(t, \varphi(t); v, w) = \int_0^1 \delta^2 J_h(W(t) + \tau(\varphi(t) - W(t)); v, w) \,\mathrm{d}\tau,$$

the analysis proceeds almost exactly as in section 6. The only difference now is that, since $\tilde{B}(t, \varphi(t); \cdot, \cdot)$ is symmetric, we do not have to split it into a symmetric and an asymmetric part. Instead of (6.12), we will obtain

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\left[\|\dot{\xi}_\varphi\|_{\mathrm{L}^2}^2 + \tilde{B}(t, \varphi(t); \xi_\varphi, \xi_\varphi)\right] + \int_{\Gamma_{\mathrm{int}} \cup \Gamma_{\mathrm{D}}} \sigma |[\![\dot{\xi}_\varphi]\!]|^2 \,\mathrm{d}s = \rho(t; \dot{\xi}_\varphi) - \frac{1}{2}\tilde{B}_t(t, \varphi(t); \xi_\varphi, \xi_\varphi).$$

From the Lipschitz continuity of $\varphi \mapsto \delta^2 J_h(\varphi;\cdot,\cdot)$ on $\mathcal{J}$, we immediately obtain the bound on $\tilde{B}_t$ equivalent to (6.10), and we can thus proceed as in section 6.3 to prove the existence of a solution to (7.3) and an optimal error bound, identical to the one we had previously established.

8. Conclusions. We derived optimal-order convergence estimates in the broken H^1 norm for discontinuous Galerkin finite element approximations to second-order quasi-linear elliptic and hyperbolic systems of partial differential equations, using piecewise polynomials of degree $p > d/2$ in the elliptic case and of degree $p > d/2+1$ in the (spatially semidiscrete) hyperbolic case, where d is the spatial dimension of the problem. In the physically relevant cases of $d = 2$ and $d = 3$, these correspond to assuming that $p \geq 2$ and $p \geq 3$, respectively. These technical restrictions were also present in the work of Makridakis [15], whose techniques we have employed here. They occur, since we have used the inverse estimate (2.1) in order to obtain L^∞ bounds for elements of the set $\mathcal{J}$ defined, respectively, in sections 5 and 6.1, which in turn are required to obtain the uniform Gårding inequality of Lemma 3.2. However, we have reason to believe that the methods considered remain optimally convergent in the energy norm in these excluded cases as well; certainly, this is true for the nonlinear elliptic problem in the special case when the nonlinearity $\eta \mapsto S(\eta)$ is globally Lipschitz continuous and uniformly monotone (see [12]). The same statement would also follow immediately if one could prove directly, without involving the first inverse inequality in (2.1), that ∇u_{DG} is sufficiently close to ∇u in the L^∞-norm.

The main contribution of the paper is that these optimal-order, $\mathcal{O}(h^p)$, convergence rates have been proved without assuming that the nonlinear coefficient $S(\nabla u)$ appearing in the principal part of the operator is globally Lipschitz continuous or uniformly monotone (cf. (1.10)); instead, we assumed only local Lipschitz continuity of S and the Gårding inequality (3.2).

The main body of the paper was devoted to an analysis of the incomplete interior penalty method [9, 18]. However, we have demonstrated in section 7, where we showed how to extend all results to the variational DGFEM of Eyck and Lew [10], that the framework which we had developed should apply to virtually any discontinuous Galerkin discretization of the quasi-linear elliptic and hyperbolic equations considered. The crucial step is a proof of the coercivity estimate (5.3), using (a variation of) the broken Gårding inequality, stated in Lemma 3.2.

We note that all of our results can be straightforwardly extended to quasi-linear elliptic and hyperbolic partial differential equations where $S(\nabla u)$ is replaced by $S(u, \nabla u)$ under the same hypotheses; the presence of the lower-order nonlinearity causes no additional technical difficulties.

As our key objective here was to understand the analysis of discontinuous Galerkin approximations of locally Lipschitz spatial nonlinearities in quasi-linear elliptic and hyperbolic systems, we did not discuss fully discrete discontinuous Galerkin finite element approximations of quasi-linear hyperbolic problems. The convergence analysis of fully discrete schemes can be carried out using very similar theoretical tools to those presented here. We refer to [15], for example, for the corresponding analysis in the case of spatially H^1_0-conforming finite element methods which may serve as a starting point for further analytical considerations in that direction.

Appendix A. Bounds on the nonlinear projection error. The purpose of this section is to derive the required bounds on the error between a function u and its nonlinear elliptic projection W.

LEMMA A.1. *Let $u \in \mathrm{C}^2([0,T];\mathrm{H}^{m+1}(\Omega)^d)$, $m > d/2+1$, satisfy (3.2) with constants $M_1 > 0$ and $M_0 \geq 0$ which are independent of t. Suppose also that the family $\{\mathcal{T}_h\}_{h>0}$ satisfies* **H1**–**H4** *of section 2. Then there exists $h_0 > 0$ such that for $h \leq h_0$ there exists a solution $W(t) \in S^p(\Omega, \mathcal{T}_h, \mathbf{F})$ to the nonlinear equation*

$$B(W(t);v) + 2M_0(W(t),v) = B(u(t);v) + 2M_0(u(t),v) \qquad \forall v \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}).$$

Furthermore, $t \mapsto W(t)$ is twice differentiable in $[0,T]$ and satisfies

$$\|u(t) - W(t)\|_{1,h} \leq C_p h^r, \tag{A.1}$$

$$\|\dot{u}(t) - \dot{W}(t)\|_{1,h} \leq C_p'' h^r, \quad \text{and} \tag{A.2}$$

$$\|\ddot{u}(t) - \ddot{W}(t)\|_{1,h} \leq C_p'' h^r, \tag{A.3}$$

where C_p, C_p', and C_p'' are constants independent of h and t.

We skip the proof of existence of $W(t)$ and of the bound (A.1) which can be established by identical arguments to those in section 5 (see [17] for details). The proofs of (A.2) and (A.3) are given in the following two sections.

A.1. Bounds on $\dot{u} - \dot{W}$. Having established the existence of the nonlinear projection $W(t)$ of $u(t)$ for $t \in [0,T]$, we next prove the differentiability of the mapping $t \mapsto W(t)$. Suppose that $U \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ and $t \in [0,T]$. The mapping $V \mapsto B(U,V) - B(u(t),V) + 2M_0(U-u(t),V)$ is a bounded linear functional on $S^p(\Omega,\mathcal{T}_h,\mathbf{F})$; hence, by the Riesz representation theorem, there exists a unique (Riesz representer) $\mathcal{B}(t,U) \in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$ such that

$$(\mathcal{B}(t,U),V) = B(U,V) - B(u(t),V) + 2M_0(U-u(t),V) \qquad \forall V \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}).$$

This defines the (nonlinear) mapping

$$\mathcal{B} : (t,U) \in [0,T] \times S^p(\Omega,\mathcal{T}_h,\mathbf{F}) \mapsto \mathcal{B}(t,U) \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}).$$

It follows from the linearization process in section 4 and from Lemma 4.1 that the derivative of $(t,U) \mapsto \mathcal{B}(t,U)$ with respect to U, evaluated at $U = W(t)$, exists and is invertible for any $t \in [0,T]$. Note, furthermore, that $\mathcal{B}(t,W(t)) = 0$. Since $t \mapsto u(t)$ is differentiable, it follows that $(t,U) \mapsto \mathcal{B}(t,U)$ is differentiable in a neighborhood of $(t_0,W(t_0))$ for any $t_0 \in (0,T)$. We then deduce from the implicit function theorem that $t \mapsto W(t)$ is differentiable in $(0,T)$.

Set

$$u(t) - W(t) = (u(t) - \Pi_h u(t)) - (W(t) - \Pi_h u(t)) \equiv \eta - \xi.$$

We begin by noting that, according to the definition of $W(t)$,

$$\tilde{B}(t,W(t);\xi,v) + 2M_0(\xi,v) = \tilde{B}(t,u(t);\eta,v) + 2M_0(\eta,v) \qquad \forall v \in S^p(\Omega,\mathcal{T}_h,\mathbf{F}),$$

where

$$\tilde{B}(t,\varphi;v,w) = \int_0^t \tilde{b}(\Pi_h u(t) + \tau(\varphi - \Pi_h u(t));v,w)\,\mathrm{d}\tau.$$

After differentiation with respect to t, we obtain

$$\begin{aligned}\tilde{B}(t,W(t);\dot{\xi}(t),v) + 2M_0(\dot{\xi}(t),v) = \tilde{B}(t,u(t);\dot{\eta}(t),v) - \tilde{B}_t(t,W(t);\xi(t),v)\\ + \tilde{B}_t(t,u(t);\eta(t),v),\end{aligned} \tag{A.4}$$

where

$$\tilde{B}_t(t,\varphi(t);v,w)=\frac{\mathrm{d}}{\mathrm{d}t}\tilde{B}(t,\varphi(t);v,w)=\int_0^1\int_\Omega\sum_{i,\alpha,j,\beta=1}^{d}\Big[\frac{\mathrm{d}}{\mathrm{d}t}A^\tau_{i\alpha j\beta}\Big]\partial_{x_\alpha}w_i\partial_{x_\beta}v_j\ \mathrm{d}x\ \mathrm{d}\tau$$

for $v,w\in S^p(\Omega,\mathcal{T}_h,\mathbf{F})$, and $A^\tau_{i\alpha j\beta}$ is as before.

Arguing as in the proof of the bound (6.10), we obtain

(A.5)
$$\big|\tilde{B}_t(t,\varphi(t);v,w)\big|\lesssim\big(\|\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}+\|\nabla\dot{\varphi}(t)-\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}\big)\|v\|_{1,h}\|w\|_{1,h}$$

for all $\varphi\in\mathcal{Z}_\delta$. We note that

$$\|\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}\le\|\nabla\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}+C_5h^{r-d/2}\|\dot{u}\|_{\mathrm{H}^{r+1}(\Omega)}\lesssim 1,$$

where, in the last inequality, we made use of hypothesis **H3** whereby $r>(d/2)+1$, and, a fortiori, $r>d/2$.

In order to bound the last two terms in (A.4) we shall need to consider two specific choices of φ in (A.5): $\varphi=W$ and $\varphi=u$. For the case of $\varphi=W$ in (A.5), we shall use the following bound, which results on applying the first inverse inequality in (2.1):

$$\begin{aligned}\|\nabla\dot{W}(t)-\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}&\lesssim h^{-d/2}\|\nabla\dot{W}(t)-\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^2(\Omega)}\\&\lesssim h^{-d/2}\|\dot{W}(t)-\Pi_h\dot{u}(t)\|_{1,h}\approx h^{-d/2}\|\dot{\xi}\|_{1,h}.\end{aligned}$$

On the other hand, for the case of $\varphi=u$, we shall use the bound

$$\|\nabla\dot{u}(t)-\nabla\Pi_h\dot{u}(t)\|_{\mathrm{L}^\infty(\Omega)}\lesssim C_5h^{r-d/2}\|\dot{u}(t)\|_{\mathrm{H}^1(\Omega)}.$$

Thus, we obtain

$$\begin{aligned}&\big|\tilde{B}_t(t,W(t);\xi,v)\big|\lesssim\Big(1+h^{-d/2}\|\dot{\xi}\|_{1,h}\Big)\|\xi\|_{1,h}\|v\|_{1,h}\quad\text{and}\\&\big|\tilde{B}_t(t,u(t);\eta,v)\big|\lesssim\|\eta\|_{1,h}\|v\|_{1,h}.\end{aligned}$$

Upon testing (A.4) with $v=\dot{\xi}(t)$ and using (5.4) on the first term on its right-hand side, we obtain

$$\begin{aligned}\|\dot{\xi}(t)\|^2_{1,h}&\lesssim\|\dot{\eta}\|_{1,h}\|\dot{\xi}\|_{1,h}+\|\eta\|_{1,h}\|\dot{\xi}\|_{1,h}+\|\xi\|_{1,h}\|\dot{\xi}\|_{1,h}+h^{-d/2}\|\xi\|_{1,h}\|\dot{\xi}\|^2_{1,h}\\&\lesssim h^r\|\dot{\xi}\|_{1,h}+h^{r-d/2}\|\dot{\xi}\|^2_{1,h},\end{aligned}$$

where we also used the approximation properties of Π_h and estimate (A.1). Since $r>d/2$, there exists $h_2\in(0,\min(h_0,h_1)]$ such that for $h\in(0,h_2]$ the coefficient of $\|\dot{\xi}\|^2_{1,h}$ on the right-hand side is less than or equal to $\frac{1}{2}$. We can therefore bring this term to the left-hand side and divide by $\frac{1}{2}\|\dot{\xi}\|_{1,h}$ to finally obtain

$$\|\dot{\xi}\|_{1,h}=\|\dot{W}(t)-\Pi_h\dot{u}(t)\|_{1,h}\lesssim h^r$$

for $(d/2)+1<r\le\min(m,p)$, from which (A.2) follows immediately on invoking the approximation properties of Π_h.

A.2. Bounds on $\ddot{\eta} = \ddot{u} - \ddot{W}$. By proceeding in an identical manner as in the previous section we find that the mapping $t \mapsto \dot{W}(t)$ is differentiable on $(0,T)$, and we get, for $(d/2)+1 < r \leq \min(m,p)$, that

$$\|\ddot{W}(t) - \Pi_h \ddot{u}(t)\|_{1,h} \lesssim h^r \left(\|u(t)\|_{\mathrm{H}^{r+1}(\Omega)} + \|\dot{u}(t)\|_{\mathrm{H}^{r+1}(\Omega)} + \|\ddot{u}(t)\|_{\mathrm{H}^{r+1}(\Omega)} \right), \ h \in (0, h_2].$$

Invoking, once again, the approximation properties of Π_h, we deduce from the triangle inequality that, for $(d/2)+1 < r \leq \min(m,p)$, (A.3) holds.

Technically, the only additional step in this argument in comparison with that in the previous section is to establish a bound, similar to (A.5), on the term

$$\tilde{B}_{tt}(t, \varphi(t); v, w) = \frac{\mathrm{d}^2}{\mathrm{d}t^2} \tilde{B}(t, \varphi(t); v, w)$$

for $\varphi \in \mathcal{Z}_\delta$. Here we require a uniform bound on the fourth derivative of W, i.e., on the second derivatives

$$\frac{\partial^2}{\partial \eta_{\gamma k} \partial \eta_{\iota m}} A_{i\alpha j\beta}(\eta)$$

for $\eta \in \mathcal{M}_\delta$ and can otherwise argue similarly as in the proof of (6.10); hence our assumption $W \in \mathrm{C}^4(\mathbb{R}^{d\times d}; \mathbb{R})$ on the regularity of the stored energy function W was adopted in the introductory section of the paper.

A.3. $\mathbf{L^2}$-bounds. Since, by hypothesis **H4**, the family $\{\mathcal{T}_h\}_{h>0}$ is uniformly simplicially reducible (cf. also section 3), the broken Friedrichs inequality (cf. [3]) implies the existence of a positive constant C, independent of h, such that

$$\|v\|^2_{\mathrm{L}^2(\Omega)} \leq C \|v\|^2_{1,h} \qquad \forall v \in S^p(\Omega, \mathcal{T}_h, \mathbf{F}). \tag{A.6}$$

Here the constant C depends only on certain shape-regularity properties of the family $\{\mathcal{T}_h\}_{h>0}$, the penalty parameter α, and the Friedrichs constant for $\mathrm{H}^1_{\mathrm{D},0}(\Omega)$.

In fact, (A.6) can also be obtained from Lemma 3.1, in which case the corresponding constant C would depend on the constant C_r, the penalty parameter α, and the Friedrichs constant for $\mathrm{H}^1_{\mathrm{D},0}(\Omega)$.

Either way, on applying (A.6) to (A.1)–(A.3), we obtain

$$\|W(t) - u(t)\|_{\mathrm{L}^2(\Omega)} + \|\dot{W}(t) - u(t)\|_{\mathrm{L}^2(\Omega)} + \|\ddot{W}(t) - \ddot{u}(t)\|_{\mathrm{L}^2(\Omega)} \lesssim h^r. \tag{A.7}$$

While this bound is not optimal (the optimal rate would be $r+1$ rather than r), it is entirely adequate for the purposes of deriving an optimal bound on $u - u_{\mathrm{DG}}$ in the *energy norm* $\|\cdot\|_Y$.

VALIDATED CONTINUATION FOR EQUILIBRIA OF PDEs*

SARAH DAY†, JEAN-PHILIPPE LESSARD‡, AND KONSTANTIN MISCHAIKOW§‡

Abstract. One of the most efficient methods for determining the equilibria of a continuous parameterized family of differential equations is to use predictor-corrector continuation techniques. In the case of partial differential equations this procedure must be applied to some finite-dimensional approximation, which of course raises the question of the validity of the output. We introduce a new technique that combines the information obtained from the predictor-corrector steps with ideas from rigorous computations and verifies that the numerically produced equilibrium for the finite-dimensional system can be used to explicitly define a set which contains a unique equilibrium for the infinite-dimensional partial differential equation. Using the Cahn–Hilliard and Swift–Hohenberg equations as models we demonstrate that the cost of this new validated continuation is less than twice the cost of the standard continuation method alone.

1. Introduction.

The first step in understanding the dynamics of a nonlinear system of differential equations

$$u_t = f(u, \nu) \tag{1.1}$$

on a Hilbert space is to identify the set of equilibria $\mathcal{E} := \{(u, \nu) \mid f(u, \nu) = 0\}$. For many applications this can only be done using numerical methods. In particular, continuation provides an efficient technique for determining elements on branches of $\mathcal{E}$. Recall that this method involves a predictor and corrector step: given, within a prescribed tolerance, an equilibrium u_0 at parameter value ν_0, the predictor step produces an approximate equilibrium $\tilde{u}_1$ at nearby parameter value ν_1, and the corrector step, often based on a Newton-like operator, takes $\tilde{u}_1$ as its input and produces, once again within the prescribed tolerance, an equilibrium u_1 at ν_1.

With any numerical method there is the question of validity of the output as compared with the cost of computation. The goal of this paper is to argue that for a large and important class of partial differential equations (PDEs) the cost of validating the existence and uniqueness of equilibria is small when compared to the cost of identifying potential equilibria by means of a continuation method. Our interest in this question was motivated by the increasing development of computer-assisted proofs in the dynamics of infinite-dimensional systems (see [3], [10] and the references therein). As mathematicians we are willing to argue forcefully for the importance of rigorous verification and thus marginalize the cost. However, in reality for many

applications, researchers are often interested in investigating a variety of model PDEs at a multitude of parameter values to gain scientific insight rather than an answer to a particular question. This places a premium on minimizing computational cost, often leading to acceptance of the validity of numerical results simply based upon the reproducibility of the result at different levels of refinement. As we shall argue, the results of this paper suggest that this dichotomy need not exist, and we provide examples wherein it is demonstrated that by judicious use of the computations involved in the continuation method it is cheaper to validate the results than to reperform the continuation computation. We refer to the method we propose as *validated continuation*. As is made clear towards the end of the introduction, validated continuation is slightly weaker and computationally cheaper than rigorous continuation.

To the best of our knowledge this is the first attempt to integrate the techniques of rigorous computations with a continuation method; thus we focus on a clear presentation of the ideas as opposed to presenting the results in the most general possible setting. We make use of spectral methods, as they provide us with considerable control on truncation errors. To be more precise, assume that (1.1) takes the form

$$u_t = L(u,\nu) + \sum_{p=0}^{d} c_p(\nu) u^p, \tag{1.2}$$

where $L(\cdot,\nu)$ is a linear operator at parameter value ν and d is the degree of the polynomial nonlinearity. Typically, $c_1(\nu) = 0$ since linear terms are grouped under $L(\cdot,\nu)$. Expanding (1.2) using an orthogonal basis chosen appropriately in terms of the eigenfunctions of the linear operator $L(\cdot,\nu)$, the particular domain, and the boundary conditions results in a countable system of differential equations on the coefficients of the expanded solution.

To simplify the exposition, let us assume the expansion takes the form

$$\dot{u}_k = f_k(u,\nu) := \mu_k u_k + \sum_{p=0}^{d} \sum_{\sum n_i = k} (c_p)_{n_0} u_{n_1} \cdots u_{n_p}, \quad k = 0,1,2,\ldots, \tag{1.3}$$

where $\mu_k = \mu_k(\nu)$ are the parameter-dependent eigenvalues of $L(\cdot,\nu)$, and $\{u_n\}$ and $\{(c_p)_n\}$ are the coefficients of the corresponding expansions of the functions u and $c_p(\nu)$, respectively, with $u_n = u_{-n}$ and $(c_p)_n = (c_p)_{-n}$ for all n. In order to simplify the notation, for a fixed parameter ν, we use $f(u)$ to denote $f(u,\nu)$. The continuation method is applied to the m-dimensional system of ordinary differenial equations (ODEs) of the form

$$\dot{u}_k = \mu_k u_k + \sum_{p=0}^{d} \sum_{\substack{\sum n_i = k \\ |n_i| < m}} (c_p)_{n_0} u_{n_1} \cdots u_{n_p}, \quad k = 0,1,\ldots,m-1, \tag{1.4}$$

obtained by performing a Galerkin projection on (1.3). It is this truncation that introduces the most substantial concern for the validity of the results of the continuation method. In section 3 we present estimates that provide us with bounds on the errors. We obtain these bounds under the assumption of power decay rates in the coefficients $\{u_n\}$. Of course, such decay rates are directly related to the spatial smoothness of the equilibria, which in turn is governed, at least in part, by the linear operator $L(\cdot,\nu)$.

The theoretical justification for our proof of existence and uniqueness of equilibria is based on a componentwise version of the Banach fixed point theorem (see

Theorem 2.1), which itself represents a minor modification of a result of Yamamoto [9, Theorem 2.1]. A similar formulation can also be found in [4]. Recall that to apply the Banach fixed point theorem one must have a contraction mapping $T : X \to X$. With this in mind, we can state that it is appropriate to view our approach as a method by which the Newton-like iteration of the corrector step in the continuation process is used to construct a set X and the above estimates are used to verify that an appropriate generalization of the Newton-like operator is in fact a contraction. More precisely, let $\bar{u}$ be a numerical zero obtained from (1.4). In the orthogonal basis used to obtain (1.3) consider the set $X = \bar{u} + W(r)$ of $\bar{u}$, where $W(r)$ is of the form

$$W(r) = \prod_{k=0}^{m-1} [-r, r] \times \prod_{k=m}^{\infty} \left[-\frac{A_s}{k^s}, \frac{A_s}{k^s} \right].$$

Observe that s indicates the decay rate of the coefficients and r is referred to as the *validation radius*. Our strategy, described in detail in section 3, is to produce a set of *radii polynomials*, $\{P_k(r)\}_{k=0,1,\ldots}$, whose coefficients are given explicitly in terms of the constants A_s, s, and (1.3). Theorem 3.4 guarantees that if there exists a validation radius $r > 0$ such that $P_k(r) < 0$ for all k, then there exists a unique equilibrium solution to (1.2) in the set $X = \bar{u} + W(r)$ built around the numerical equilibrium $\bar{u}$ produced by the continuation procedure. It is important to note that the conditions of Theorem 3.4 can be checked with a finite number of calculations.

As is indicated above the focus of this paper is on the computational efficacy of validated continuation and hence the following organization of the material. Section 2 contains the statement and proof of the aforementioned componentwise version of the Banach fixed point theorem, Theorem 2.1, without any indication of how this result can be used in practice. Section 3 provides the opposite extreme, an explicit set of formulas and steps and the assertion that their successful implementation leads, via Theorem 3.4, to the existence of a unique equilibrium in a specified set. The justification of this assertion and the relationship between Theorems 2.1 and 3.4 is presented in section 6. However, presenting the formulae in this fashion has two advantages. First, they contain all the necessary information should the reader wish to independently code and test the techniques suggested in this paper. Second, it allows for the presentation in section 4 of the comparison of the computational costs between traditional and validated continuation.

It should be emphasized that how one should best compare the costs between the two methods of continuation is not completely clear. In the standard approach m, the dimension of the system on which continuation is performed, is fixed. Thus traditionally a particular Galerkin projection dimension is chosen and continuation is performed. The results are checked by choosing a higher-dimensional projection, reperforming the continuation, and then deciding if the two calculations agree within a certain level of numerical tolerance. In validated continuation, m becomes a variable. In particular, if validation fails, then one has the option of choosing a higher-dimensional Galerkin projection. Equally important, failure of validation may be an indication that a higher-dimensional projection is necessary. In summary, validated continuation provides an internal check of consistency on the dimension of truncation from the infinite- to finite-dimensional problem, a feature which is not present in the traditional application of continuation methods.

With this in mind we have chosen to compare the computational costs as follows. First we restrict our attention to cubic nonlinearities. As is made clear by the formulae of section 3, in this case the cost of evaluating the nonlinearities and performing

Newton's method are both of order m^3. Thus, we can obtain a rough bound on the ratio of the cost of traditional versus validated continuation by counting the number of m^3 operations which need to be performed. These calculations suggest that for fixed m the cost of validated continuation is less than twice the cost of traditional continuation, that is, *it appears that it is cheaper to perform validated continuation than to perform traditional continuation and then check it against continuation performed on a higher-dimensional projection.* In section 5 this estimate is tested against actual computations for the Swift–Hohenberg equation and the Cahn–Hilliard equation. To ensure that these comparisons are fair, we employ standard floating point computations in both cases.

This last point raises an important distinction: validated continuation versus rigorous continuation. Using floating point calculations at all steps of the validated continuation does not allow one to control for roundoff errors, and hence one cannot rigorously conclude the existence of an equilibrium. Because the current computer technology treats floating point and interval arithmetic differently we chose not to make and present timed comparisons between the two for this paper. However, if specific steps in the validation argument are performed using interval arithmetic, then one obtains rigorous results on the existence of equilibria. Results of this type are presented in section 5 for a branch of equilibria of the Swift–Hohenberg equation.

We see the results of this paper as a first step in the direction of combining continuation methods with rigorous computations. With this in mind we conclude the paper in section 7 with a discussion of open questions and ongoing work. In particular, we return to the issue of the necessity of interval arithmetic computations.

2. Computational proofs for equilibria. Assume that following the expansion of a PDE into an appropriate orthogonal basis, we have a system of the form (1.3). Our goal is to prove that there is a unique equilibrium for (1.3) which lies in a small set containing a computed numerical equilibrium. Suppose $\bar{u}_F$ is a numerical equilibrium computed using an m-dimensional continuation procedure (as described in section 3) and $\bar{u} := (\bar{u}_F, 0, \dots)$ is the corresponding point in the infinite-dimensional space. We will consider a set of the form $\bar{u} + W$, where $W = \Pi_k \tilde{w}_k$,

$$\tilde{w}_k = \begin{cases} [-r, r], & 0 \le k < m, \\ \left[-\frac{A_s}{k^s}, \frac{A_s}{k^s}\right], & k \ge m, \end{cases} \tag{2.1}$$

for some constants $r, A_s > 0$ and $s \ge 2$.

A particularly nice norm to use for this set (similar to the one used by Yamamoto in [9]) is the normalized sup norm

$$\|u\|_W := \sup_k \left\{ \frac{|u_k|}{|\tilde{w}_k|} \right\},$$

where $|\tilde{w}_k| := \max\{|x| \mid x \in \tilde{w}_k\}$. In this norm, $W = B(0,1)$ is the unit ball around 0, and $\bar{u} + W = B(\bar{u}, 1)$ is the unit ball around $\bar{u}$.

We will now reformulate our problem of studying equilibria for (1.3) by establishing an equivalent fixed point problem on $\bar{u} + W$. Suppose J is an invertible operator. Then u is an equilibrium solution of (1.3) if and only if u is a fixed point of

$$T(u) = u - Jf(u), \tag{2.2}$$

where f is given by (1.3). In practice, T is constructed to be a contraction (Newton-like) operator with $J \approx (Df(\bar{u}))^{-1}$ so that we may use Banach's fixed point theorem. We now frame this fixed point theorem in a more computational setting.

In the process of showing that T is a contraction, we first consider the following Lipschitz condition on $\bar{u} + W$:

$$\|T(x) - T(y)\|_W \leq K\|x - y\|_W \quad \text{for } x, y \in \bar{u} + W. \tag{2.3}$$

The question now becomes whether we can compute a contraction constant $K < 1$ satisfying (2.3). We begin by computing Lipschitz constants, K_n, for the component functions T_n on $\bar{u} + W$ satisfying

$$|T_n(x) - T_n(y)| \leq K_n\|x - y\|_W \quad \text{for } x, y \in \bar{u} + W. \tag{2.4}$$

If T is C^1, we may take K_n to be a bound on the derivative of T_n over $\bar{u} + W$. More explicitly,

$$\begin{aligned} K_n &\geq \sup |DT_n(\bar{u} + W) \cdot W| \\ &:= \sup_{b,c \in W} |DT_n(\bar{u} + b) \cdot c| . \end{aligned}$$

A constant K_n computed in this manner satisfies (2.4) by the following argument. For $x, y \in \bar{u} + W$, let $g_n(s) := T_n[sx + (1 - s)y]$. Applying the mean value theorem to g_n, we get the existence of $s_n \in [0, 1]$ such that $g_n(1) - g_n(0) = g'(s_n)$. Since the set $\bar{u} + W$ is convex, we get the existence of $z_n := s_n x + (1 - s_n)y \in \bar{u} + W$ such that

$$\begin{aligned} |T_n(x) - T_n(y)| &= |DT_n(z_n)(x - y)| \\ &= \left| DT_n(z_n) \frac{x - y}{\|x - y\|_W} \right| \|x - y\|_W. \end{aligned}$$

By construction of $\|\cdot\|_W$, $\frac{x-y}{\|x-y\|_W} \in W$. Now if $K := \sup_n \frac{K_n}{|\tilde{w}_n|} < \infty$, then, as the following argument shows, it satisfies (2.3):

$$\begin{aligned} \|T(x) - T(y)\|_W &= \sup_n \frac{|T_n(x) - T_n(y)|}{|\tilde{w}_n|} \\ &= \sup_n \frac{\left| DT_n(z_n) \frac{x-y}{\|x-y\|_W} \right| \|x - y\|_W}{|\tilde{w}_n|} \\ &\leq \sup_n \frac{K_n}{|\tilde{w}_n|} \|x - y\|_W \\ &= K\|x - y\|_W. \end{aligned}$$

THEOREM 2.1 (existence and uniqueness). *If for all n there exist bounds $Y_n \geq |T_n(\bar{u}) - \bar{u}_n|$ and K_n satisfying (2.4) such that*

$$Y_n + K_n - |\tilde{w}_n| < 0 \tag{2.5}$$

and

$$K := \sup_n \frac{K_n}{|\tilde{w}_n|} < 1, \tag{2.6}$$

then there exists a unique fixed point of T in $\bar{u} + W$.

Proof. The first inequality ensures that $T(\bar{u} + W) \subset \bar{u} + W$. This is true if and only if for every $u \in \bar{u} + W$, $\|T(u) - \bar{u}\|_W \leq 1$ or, equivalently, $\frac{|T_n(u) - \bar{u}_n|}{|\tilde{w}_n|} < 1$ for all n.

Let $u \in \bar{u} + W$. Then $\|u - \bar{u}\|_W \leq 1$ and for each n,

$$\begin{aligned} |T_n(u) - \bar{u}_n| &= |T_n(u) - T_n(\bar{u}) + T_n(\bar{u}) - \bar{u}_n| \\ &\leq |T_n(u) - T_n(\bar{u})| + |T_n(\bar{u}) - \bar{u}_n| \\ &\leq K_n \|u - \bar{u}\|_W + Y_n \\ &\leq Y_n + K_n \\ &< |\tilde{w}_n| \end{aligned}$$

by assumption (2.5). Therefore, $T(\bar{u}+W) \subset \bar{u}+W$. The second inequality guarantees that T is also a contraction. Thus, the result follows from Banach's fixed point theorem. ∎

Let us make the comment here that sufficient regularity of the equilibrium solutions will effectively reduce the infinite set of conditions listed in Theorem 2.1 to a finite list. In essence, the strong decay in the higher modes may be used to verify (2.5) simultaneously for all $n > N$ for some N. (In our case N is determined by the dimension used for continuation and the degree of the nonlinearity.) Furthermore, regularity of the equilibria may also be used to show that $K_n|\tilde{w}_n|^{-1}$ becomes a decreasing sequence. Therefore, (2.6) follows automatically from (2.5).

Perhaps an even more important point to make for our intended algorithmic approach in this paper is that $Y_n + K_n - |\tilde{w}_n|$ will be given as a polynomial in the validation radius r, the width of the set W in the low modes. Therefore, validating the existence of a unique equilibrium near $\bar{u}$ will amount to showing that it is possible to simultaneously solve a (finite) list of polynomial inequalities in r.

3. Validated continuation. The ideas outlined in section 2 for proving the existence of unique equilibria fit naturally with traditional continuation techniques for following branches of numerical equilibria. In particular, an approximation of a projection of the Newton operator given in (2.2) onto the appropriate m-dimensional subspace is an intrinsic element of the continuation algorithm. In this section, we discuss exploiting this relationship to automatically produce a validation of the existence of unique equilibria at each step of the continuation procedure.

Recall that following the expansion of the system in the appropriate basis, we have

$$\dot{u} = f(u, \nu), \tag{3.1}$$

where for $k = 0, 1, 2, \ldots$, $\mu_k = \mu_k(\nu)$, $(c_p)_n = (c_p(\nu))_n$, and

$$\dot{u}_k = f_k(u) = \mu_k u_k + \sum_{p=0}^{d} \sum_{\sum n_i = k} (c_p)_{n_0} u_{n_1} \cdots u_{n_p}. \tag{3.2}$$

A first step for implementing a continuation algorithm for studying a PDE is to perform a Galerkin projection. Let m be a fixed projection dimension and consider the following truncated version of our original expansion of the PDE given in (3.2). For $u_F := (u_0, \ldots, u_{m-1}) \in \mathbb{R}^m$, define $f^{(m)} : \mathbb{R}^m \to \mathbb{R}^m$ by $f^{(m)}(u_F) = (f_0^{(m)}(u_F), \ldots, f_{m-1}^{(m)}(u_F))$, where for $k = 0, \ldots, m-1$,

$$f_k^{(m)}(u_F) = \mu_k u_k + \sum_{p=0}^{d} \sum_{\substack{\sum n_i = k \\ |n_i| < m}} (c_p)_{n_0} u_{n_1} \cdots u_{n_p}.$$

The corresponding Galerkin projection of the original system (3.1) is then

$$\dot{u}_F = f^{(m)}(u_F, \nu). \tag{3.3}$$

This is the m-dimensional system to be studied numerically. Intuitively, we expect that if m is sufficiently large, (3.3) will capture the essential dynamics for the original system (3.1). In particular, given an equilibrium $\bar{u}_F$ for (3.3) we expect that there is a small set around $\bar{u} := (\bar{u}_F, 0, \dots)$ which contains a unique equilibrium solution for (3.1). Our approach is to study this relationship via the tools outlined in section 2.

3.1. Continuation for ODEs and Newton-like operator. A traditional continuation procedure involves iteration of predictor and corrector steps to trace out branches of equilibria. Under the assumption that at some parameter $\nu = \nu_0$ we have an equilibrium solution for (3.3), we want to continue the equilibrium as we vary ν.

(1) *Euler predictor:* Given an approximate equilibrium x_0 at ν_0, the *predictor* at $\nu_1 = \nu_0 + \Delta\nu$ is $x_1^{(0)} = x_0 + \dot{x}_0 \Delta\nu$, where

$$\dot{x}_0 = -f_x^{(m)}(x_0, \nu_0)^{-1} f_\nu^{(m)}(x_0, \nu_0). \tag{3.4}$$

(2) *Quasi-Newton corrector:* We now use the following quasi-Newton iterative scheme to improve our approximation at ν_1:

$$x_1^{(n+1)} = x_1^{(n)} - f_x^{(m)}({x_1}^{(0)}, \nu_1)^{-1} f^{(m)}(x_1^{(n)}, \nu_1). \tag{3.5}$$

If k is the total number of iterations of (3.5), then $\bar{u}_F := x_1^{(k)}$ and $f^{(m)}(\bar{u}_F, \nu_1) \approx 0$.

As before, define the corresponding point $\bar{u} = (\bar{u}_F, 0, \dots)$ in the infinite-dimensional space. We now use the information required for the next predictor step, the numerical inverse of $f_x^{(m)}(\bar{u}_F, \nu_1)$, to construct a Newton-like operator near $\bar{u}$ at the parameter value ν_1. Let $J_{F\times F}$ be the numerical inverse of $f_x^{(m)}(\bar{u}_F, \nu_1)$ and define the Newton-like operator T by

$$T(u) = u - Jf(u), \tag{3.6}$$

where

$$J := \begin{bmatrix} J_{F\times F} & & 0 & \\ & \mu_m^{-1} & & \\ 0 & & \mu_{m+1}^{-1} & \\ & & & \ddots \end{bmatrix}$$

is the block diagonal matrix which we expect to be close to $(Df(\bar{u}, \nu_1))^{-1}$. Note that T, J, and f all depend on the parameter ν. As in section 2, we will attempt to show that T is a contraction on a set of the form $\bar{u} + W$, where W has the form (2.1). We now emphasize the dependence of this set $W = W(r)$ on the validation radius r since this approach relies on finding an appropriate $r > 0$ to satisfy a set of conditions. The constants A_s and s may be determined by regularity arguments or otherwise set prior to the computations. As seen in the definition of $W(r)$, these constants determine the size of the region in which we are attempting to show the unique existence of an equilibrium solution.

3.2. Radii polynomials. We now present the formulae for *radii polynomials*. In order to focus on the applicability of validated continuation, the justification that these polynomials do, in fact, encode the required bounds Y_n and K_n in (2.5) for the Newton-like operator constructed in (3.6) is delayed to section 6.

Since the formulae for the polynomials are rather ungainly, let us begin by explicitly stating the information that is used to construct the coefficients.

- d is the degree of the nonlinearity of (1.2).
- m is the number of modes used in the Galerkin projection.
- $M \geq m$ is a computational parameter that allows for the use of explicit values for coefficients of $M - m$ additional modes to decrease truncation error bounds.
- $m_+ \geq m$ is a computational parameter that allows for the use of an additional structure in the model to get tighter truncation error bounds.
- $\bar{u}_F \in \mathbb{R}^m$ is the numerical zero produced by the predictor-corrector step.
- $J_{F\times F}$ is the numerical inverse obtained from the predictor-corrector step.
- $(c_p)_n$, $|n| < m$, are the coefficients from the expansion (1.3).
- μ_k, $k \geq 0$, are the eigenvalues for the linear operator L as expressed in (1.3) and

$$\bar{\mu} := \inf_{n \geq m_+} \{|\mu_n|\}.$$

  Note that if $|\mu_n|$ is monotonically increasing for $n \geq m_+$, then $\bar{\mu} = |\mu_{m_+}|$.
- s and A_s are positive constants that are related to the regularity of the equilibria.

Observe that given this information we can evaluate the vector

$$f_F(\bar{u}) := \begin{bmatrix} f_0(\bar{u}) \\ \vdots \\ f_{m-1}(\bar{u}) \end{bmatrix},$$

where

$$f_n(\bar{u}) = \mu_n \bar{u}_n + \sum_{p=0}^{d} \sum_{\substack{n_0+\cdots+n_p=n \\ |n_1|,\ldots,|n_p|<m}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_p} \ .$$

We can also set

$$Y_k \geq \begin{cases} |J_{F\times F} f_F(\bar{u})|_k & \text{if } 0 \leq k < m, \\ \frac{|\sum_{p=2}^{d} (c_p \bar{u}^p)_k|}{|\mu_k|} & \text{if } k \geq m, \end{cases} \tag{3.7}$$

where

$$(c_p \bar{u}^p)_k = \sum_{\sum n_i = k} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_p}.$$

The following constants are all related to asymptotic bounds on the expansions of the numerical equilibrium $\bar{u}$ and the set $\bar{u} + W$. As such they are related to the

regularity of the equilibrium and the coefficients of (1.2). Define

$$\begin{aligned}
\alpha &:= \frac{2}{s-1} + 2 + 3.5 \cdot 2^s, \\
C_p &:= \max_k \{|(c_p)_0|, |(c_p)_k||k|^s\}, \\
\bar{A} &:= \max_{1 \le k < m} \{|\bar{u}_0|, |\bar{u}_k||k|^s\}, \\
A = A(r) &:= \max\{A_s, r(m-1)^s\}, \\
C(\bar{A}, A) &:= \sum_{l=1}^{d} \sum_{p=\max\{2,l\}}^{d} l\binom{p}{l} \alpha^p C_p \bar{A}^{p-l} A(r)^l, \\
C_+(\bar{A}, A) &:= \begin{cases} \sum_{l=1}^{d} \sum_{p=2}^{d} l\binom{p}{l} \alpha^p C_p \bar{A}^{p-l} A^l & \text{if } Y_k, R_k = 0 \text{ for all } k \ge m_+, \\ \sum_{p=0}^{d} \alpha^p C_p \bar{A}^p + \sum_{l=1}^{d} \sum_{p=\max\{2,l\}}^{d} l\binom{p}{l} \alpha^p C_p \bar{A}^{p-l} A^l & \text{otherwise}, \end{cases} \\
V_F^{(0)} &:= |J_{F\times F}|\, R_F, \qquad V_F^{(1)} := \left| I_{F\times F} - J_{F\times F} \cdot Df^{(m)}(\bar{u}_F) \right| \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix},
\end{aligned}$$

where $|\cdot|$ denotes the entrywise absolute value and for $k \in \{0, \dots, m-1\}$,

$$R_k := \sum_{\substack{\bar{n}=-\infty \\ |k-\bar{n}| \ge m}}^{\infty} \left| \sum_{p=1}^{d} p \sum_{\sum n_i = \bar{n}} (c_p)_{n_0} \bar{u}_{n_1} \dots \bar{u}_{n_{p-1}} \right| \frac{A_s}{|k-\bar{n}|^s} \ .$$

Note that if all c_p have finite expansions, then $V_F^{(0)}$ requires only a finite computation. Observe also that the above implies that $\bar{u}_k \in \frac{\bar{A}}{k^s}[-1,1]$ and $\tilde{w}_k \subset \frac{A}{k^s}[-1,1]$ for all k.

The validation procedure also requires bounds on the errors due to truncating modes $k \ge m$. These bounds come in the following form:

$$\epsilon_n := \sum_{l=1}^{d} \sum_{p=l}^{d} l\binom{p}{l} \epsilon_n(p,l,M), \tag{3.8}$$

where

$$\begin{aligned}
&\epsilon_n(p,l,M) \\
&:= \min\left\{ \frac{p\alpha^{p-1} C_p \bar{A}^{p-l} A^l}{(M-1)^{s-1}(s-1)} \left[\frac{1}{(M-n)^s} + \frac{1}{(M+n)^s} \right], \frac{\alpha^p C_p \bar{A}^{p-l} A^l}{n^s} \right\}
\end{aligned} \tag{3.9}$$

and

$$\begin{aligned}
&C_n(p,j,l,M) \\
&:= \sum_{|\bar{n}| < (p-l)(m-1)+M} \left| \sum_{\substack{\sum n_i = \bar{n} \\ |n_0| < M \\ |n_1|, \dots, |n_{p-l}| < m}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right| \left(\sum_{\substack{\sum n_i + \bar{n} = n \\ m \le |n_1|, \dots, |n_j| < M}} \frac{A_s^j}{|n_1|^s \cdots |n_j|^s} \right).
\end{aligned} \tag{3.10}$$

For notational purposes, we also define m-vectors containing these bounds for modes $n = 0, \ldots, m-1$ as follows:

$$\epsilon_F := \begin{bmatrix} \epsilon_0 \\ \vdots \\ \epsilon_{m-1} \end{bmatrix} \quad \text{and} \quad C_F(p,j,l,M) := \begin{bmatrix} C_0(p,j,l,M) \\ \vdots \\ C_{m-1}(p,j,l,M) \end{bmatrix}.$$

Note that these bounds are computable in that they require only a finite number of computations. In addition, increasing the computational parameter M has the effect of increasing the computational work in order to decrease the bounds.

We now use bounds (3.9) and (3.10) to define radii polynomials, $P_n(r)$. These polynomials are designed to encode the bounds required by Theorem 2.1. More specifically, as is demonstrated in section 6, the polynomials are constructed so that $P_n(r) < 0$ implies that $Y_n + K_n - |\tilde{w}_n| < 0$ on the set

$$\bar{u} + W(r) = \bar{u} + \left(\prod_{k=0}^{m-1} [-r, r] \times \prod_{k=m}^{\infty} \left[-\frac{A_s}{k^s}, \frac{A_s}{k^s} \right] \right). \tag{3.11}$$

DEFINITION 3.1. *To simplify notation, the* finite radii polynomials, $P_0, \ldots, P_{m-1}$, *are given as an* m*-vector* $P_F(r) = (P_0(r), \ldots, P_{m-1}(r))^t$. *Define*

$$P_F(r) := \sum_{n=0}^{d} C_F(n) r^n, \tag{3.12}$$

where the coefficients are

$$C_F(n) := \begin{cases} C_F^Y + C_F^K(0), & n = 0, \\ C_F^K(1) - 1, & n = 1, \\ C_F^K(n), & n = 2, \ldots, d. \end{cases}$$

The right-hand terms are defined as follows. The individual terms of the vectors $C_F^K(i)$ *are chosen to satisfy*

$$\begin{aligned} C_k^K(i) \geq & \left(\sum_{l=\max\{2,i\}}^{d} \sum_{p=l}^{d} l \binom{p}{l} \binom{l}{i} |J_{F\times F}| C_F(p, l-i, l, M) \right. \\ & \left. + \begin{cases} |J_{F\times F}| \epsilon_F + V_F^{(0)}, & i = 0, \\ V_F^{(1)}, & i = 1, \\ 0, & \textit{otherwise} \end{cases} \right)_k \end{aligned} \tag{3.13}$$

and similarly

$$C_F^Y = Y_F, \tag{3.14}$$

where $|\cdot|$ *and the bounds are computed componentwise.*

Observe, again, that determining these bounds requires only a finite number of computations.

DEFINITION 3.2. *For $k \geq m$, the* tail radii polynomial *is*

$$P_k(r) = \begin{cases} \frac{|\sum_{p=0}^{d}(c_p \bar{u}^p)_k|}{|\mu_k|} + \frac{C(\bar{A},A(r))}{|\mu_k|k^s} - \frac{A_s}{k^s}, & m \leq k < m_+, \\ \frac{C_+(\bar{A},A)}{|\mu_k|k^s} - \frac{A_s}{k^s}, & k \geq m_+, \end{cases}$$

where, again,

$$(c_p \bar{u}^p)_k = \sum_{\sum n_i = k} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_p}.$$

DEFINITION 3.3. *Consider the radii polynomials consisting of the finite radii polynomials P_k, $k = 0, \ldots, m-1$, and the tail radii polynomials, P_k, $k \geq m$. A positive real number r is a* validation radius *if $P_k(r) < 0$ for all $k \geq 0$.*

The proof of the following theorem is presented in section 6.

THEOREM 3.4. *If there exists a validation radius $r > 0$ and the eigenvalues μ_k satisfy $|\mu_k| \to \infty$, then there exists a unique equilibrium solution of (3.1) in $\bar{u}+W(r)$.*

We now present a procedure for computing a validation radius that satisfies the hypotheses of Theorem 3.4. In particular, this procedure describes a natural order for defining the decay constants A_s, s, and A. The constants A_s and s reflect regularity properties of the equation and should be chosen either from numerical simulations or analysis. In this approach, we choose to treat $A = A(r)$ as a constant. The rationale for this choice is that from a computational perspective, we would like to find $r > 0$ solving simple constructions of the finite radii inequalities $P_0(r) < 0, \ldots, P_{m-1}(r) < 0$ without having to simultaneously control the more complicated effects from A on the coefficients of these polynomials as well as on the tail polynomials P_k, $k \geq m$. A practical way to achieve this goal is to set $A = A_s$ at the beginning of the procedure and then check in the end that a solution $r > 0$ to $P_0(r) < 0, \ldots, P_{m-1}(r) < 0$ also satisfies $r(m-1)^s \leq A_s$.

Here, for the sake of simplicity, we set $M = m$. If the truncation error bounds prove too large for the computations, then M should be increased as described in Remark 6.3 in section 6. Finally, we add a condition which reduces the check of the tail polynomials $P_k(r) < 0$, $k > m$, to a finite number of computations. The following procedure outlines this approach.

PROCEDURE 3.5. *Suppose that the eigenvalues μ_k are such that $|\mu_k| \to \infty$. Suppose further that we may choose $m, m_+, \bar{m} \in \mathbb{N}$, $\bar{m} \geq m_+ \geq m$, and $\bar{\mu} > 0$ such that*

1. *m is the Galerkin projection dimension used for numerical continuation;*
2. *m_+ is the parameter used in the computation of $C_+(\bar{A}, A)$; and*
3. *$\bar{m}$ measures where the tail terms are bounded from below by $\bar{\mu}$ as follows: for all $k \geq \bar{m}$, $|\mu_k| \geq |\bar{\mu}|$.*

Set $M = m$.

Remark: m should be chosen to give the expected nonzero modes along the bifurcation branch under study, and $\bar{m} = m_+ = (2d+1)(m-1)+1$ if $(c_p)_n = 0$ for all $n \neq 0$ and the eigenvalues μ_k are monotonically increasing in magnitude after $k = (2d+1)(m-1)$.

Fix the decay constants

$$s \geq 2 \quad \text{and} \quad A_s > 0. \tag{3.15}$$

Remark: In practice, A_s and s should be determined by regularity properties of the equation.

Set $A := A_s$. *Using the finite radii polynomials given in Definition* 3.1, *for* $k = 0, \ldots, m-1$, *numerically compute* $I_k := \{r > 0 \mid P_k(r) < 0\}$ *and*

$$\mathcal{I} := \bigcap_{k=0}^{m-1} I_k \ . \tag{3.16}$$

Check that $\mathcal{I} \neq \emptyset$.

Remark: If $\mathcal{I} = \emptyset$, *begin the procedure again either by choosing* m *larger or by choosing* s *larger and/or* A_s *smaller in* (3.15).

Check that there exists $\bar{r} \in \mathcal{I}$ *such that*

$$\bar{r} \leq \frac{A_s}{(m-1)^s} \ . \tag{3.17}$$

Remark: If such an $\bar{r}$ *exists, then* $A = A_s = \max\{A_s, \bar{r}(m-1)^s\}$. *This in turn implies that componentwise* $P_F(\bar{r}) < 0$. *If* $\bar{r}$ *does not exist, then begin the procedure again either by choosing* m *larger or by choosing* s *larger and/or* A_s *smaller in* (3.15).

Check the inequalities

$$P_m(\bar{r}) < 0, \ \ldots, \ P_{\bar{m}-1}(\bar{r}) < 0 \quad \text{and} \quad \frac{C(\bar{A}, A)}{|\bar{\mu}|} - A_s < 0.$$

Remark: If any of these inequalities fails, begin the procedure again either by choosing m *larger or by choosing* s *larger and/or* A_s *smaller in* (3.15).

Observe that if Procedure 3.5 is successful, the hypotheses of Theorem 3.4 are satisfied with validation radius $\bar{r}$.

4. Computational cost. We now provide a rough comparison of the cost of continuation with the cost of validated continuation for PDEs of the form

$$u_t = L(u, \nu) - u^3 \ . \tag{4.1}$$

Since the degree of the polynomial nonlinearity in (4.1) is cubic and we use a Newton-like operator in the continuation procedure, the most expensive terms of the computation involve m^3 operations, where m is the number of modes used in the Galerkin projection

$$f_k^{(m)}(u_F, \nu) = \mu_k(\nu) u_k - \sum_{\substack{n_1+n_2+n_3=k \\ |n_i|<m}} u_{n_1} u_{n_2} u_{n_3}, \qquad k = 0, \ldots, m-1. \tag{4.2}$$

With this in mind we count the number of m^3 operations for both approaches to obtain an estimate for the asymptotic costs and conclude with statistics obtained from calculations for the Swift–Hohenberg and Cahn–Hilliard equations.

4.1. Cost of continuation. We decompose the analysis of the cost of continuation into four steps, assuming that we begin with an approximate zero x_0 at ν_0.

Step 1. In order to get the Euler predictor (3.4), we need to evaluate the vector $-f_x^{(m)}(x_0, \nu_0)^{-1} f_\nu^{(m)}(x_0, \nu_0)$. This requires computing the m by m matrix $f_x^{(m)}(x_0^{(0)}, \nu_0)$, where for $0 \leq i, j < m$,

$$\left[f_x^{(m)}(x_0^{(0)}, \nu_0)\right]_{i+1,j+1} = \delta_{i,j}\mu_i - 3\Bigg(\sum_{\substack{n_1+n_2+j=i \\ |n_i|<m}} [x_0^{(0)}]_{|n_1|} [x_0^{(0)}]_{|n_2|} + \sum_{\substack{n_1+n_2-j=i \\ |n_i|<m}} [x_0^{(0)}]_{|n_1|} [x_0^{(0)}]_{|n_2|} \Bigg).$$

This involves the evaluation of $2m^2$ sums demanding $2m-1$ multiplications and $2m-2$ additions each. Therefore, determining $f_x^{(m)}(x_0^{(0)}, \nu_0)$ requires $8m^3$ operations. Next, we compute the LU decomposition of $f_x^{(m)}(x_0^{(0)}, \nu_0)$ in order to compute the action of its inverse on $f_\nu^{(m)}(x_0, \nu_0)$. This involves $\frac{2}{3}m^3$ operations. In our case, $f_\nu^{(m)}(x_0, \nu_0) = x_0$, requiring no additional cost. The predictor is then

$$\begin{cases} x_1^{(0)} = x_0 - \Delta\nu f_x^{(m)}(x_0, \nu_0)^{-1} x_0, \\ \nu_1 \quad = \nu_0 + \Delta\nu. \end{cases}$$

Step 2. We now start the corrector. To construct the quasi-Newton operator (3.5), we need the action of the inverse of $f_x^{(m)}$ at the predictor $(x_1^{(0)}, \nu_1)$. As seen before, it costs $8m^3$ to evaluate $f_x^{(m)}(x_1^{(0)}, \nu_1)$ and $\frac{2}{3}m^3$ to compute its inverse using LU decomposition. Note that we need to compute the LU decomposition only at the first step.

Step 3. At the jth iteration of (3.5), we need to evaluate $f^{(m)}(x_1^{(j-1)}, \nu_1)$. Its ith component is

$$[f^{(m)}(x_1^{(j-1)}, \nu_1)]_i = \mu_i(\nu_1)[x_1^{(j-1)}]_i - \sum_{\substack{n_1+n_2+n_3=i \\ |n_i|<m}} [x_1^{(j-1)}]_{|n_1|}[x_1^{(j-1)}]_{|n_2|}[x_1^{(j-1)}]_{|n_3|},$$

which requires at least $3m^2$ operations to evaluate. Since $f^{(m)}$ has m components, we get a total of $3m^3$. If k is the total number of iterations of the corrector, then this step requires $3km^3$ operations.

Step 4. The corrector ends when $||f^{(m)}(x_1^{(k)}, \nu_1)|| < \texttt{tolerance}$. Let $\bar{a}_F := x_1^{(k)}$. Evaluating the function at $(\bar{u}_F, \nu_1)$ is another $3m^3$. Now, note that we have to compute the action of the inverse of $f_x^{(m)}(\bar{u}_F, \nu_1)$ to get the predictor for the next step. Recall $J_{F\times F}$ is the numerical inverse of $f_x^{(m)}(\bar{u}_F, \nu_1)$ computed as before using an LU decomposition. Explicitly computing all the coefficients in $f_x^{(m)}(\bar{u}_F, \nu_1)$ requires an extra $2m^3$ operations. We do not count the m^3 involved to get the next predictor, since that is part of the next predictor-corrector step.

Combining the costs of the four above-mentioned steps suggests that the cost of one application of the predictor-corrector algorithm is on the order of $(20+3k)m^3$, where k is the number of iterations in the quasi-Newton corrector.

4.2. Cost of validation. We now show that the extra cost of performing validation for a cubic function ($d=3$) with constant function coefficients is of the order of $6m^3$ operations, where m is the projection dimension used for continuation. The additional cost comes primarily from computing the coefficients of the radii polynomials. In the following, we construct $m_+ = d(m-1)+1 = 3m-2$ polynomials $P_0, \ldots, P_{3m-3}$ using Procedure 3.5 and calculate the associated computational cost. Both to simplify the presentation and because this is what is used to perform the computations presented in section 5, we set $\bar{m} = m_+ = d(m-1)+1$, with $|\mu_k| \geq |\mu_{\bar{m}}|$ for all $k \geq \bar{m}$, and $M = m$. As described in Procedure 3.5, $A = A_s$ and we consider fixed $s > 2$ and $A_s > 0$.

The only nonlinear term of (4.1) is a monomial of degree 3. Thus, if $p \neq 3$, then $C_k(p, j, l, M) = 0$. In addition, we have set $M = m$. Hence, if $j \neq 0$, then $C_k(p, j, l, M) = 0$ (see Remark 6.3). Therefore, the only nonzero terms of this form

are

$$C_k(3,0,l,m) = \left| \sum_{\substack{n_1+n_2+n_3=k \\ |n_1|,|n_2|,|n_3|<m}} \bar{u}_{n_1} \cdots \bar{u}_{n_{3-l}} \right|. \tag{4.3}$$

Hence, by (3.13) we set

$$C_k^K(0) \geq (|J_{F\times F}|\epsilon_F)_k + V_k^{(0)} \tag{4.4}$$

for $0 \leq k < m$, and $|\cdot|$ denotes the componentwise absolute value. Note that it is possible to get an analytic upper bound on $V_k^{(0)}$ using Lemma 6.2, in which case computing $V_k^{(0)}$ doesn't require any m^3 operations. Hence, all necessary computations for $C_F^K(0)$ are of order less than m^3. Using (3.13),

$$C_k^K(1) \geq V_k^{(1)}$$

for $0 \leq k < m$ and evaluating $V_F^{(1)}$ does not require any m^3 operations.

Finally, combining (3.13) and (4.3),

$$C_F^K(2) \geq 6|J_{F\times F}|C_F(3,0,2,m),$$

where $C_n(3,0,2,m) = |\bar{u}_n|$, and

$$C_F^K(3) \geq 3|J_{F\times F}|C_F(3,0,3,m),$$

where $C_n(3,0,3,m) = 1$.

The last coefficient to compute to get all the finite radii polynomials (3.14) is

$$C_F^Y \geq |J_{F\times F} f_F(\bar{u})|,$$

where again $|\cdot|$ denotes the componentwise absolute value. This comes with no extra m^3 cost since $f_F(\bar{u}) = f^{(m)}(\bar{u}_F, \nu_1)$ was computed in Step 4 of the predictor-corrector algorithm.

The next step in Procedure 3.5 is checking for the existence of a validation radius $r > 0$. This requires finding the numerical zeros of each of the cubic polynomials $P_0, \ldots, P_{m-1}$, constructing $I_0, \ldots, I_{m-1}$, where I_k are closed intervals such that $I_k \subsetneq \{r > 0 | P_k(r) < 0\}$, and finally checking for a nonempty intersection $\mathcal{I} = \cap_{k=0}^{m-1} I_k$. All of these steps are of order less than m^3.

Assuming there exists a positive $\bar{r} \in \mathcal{I}$ such that $\bar{r}(m-1)^s \leq A_s$, we construct and evaluate the tail radii polynomials $P_m, \ldots, P_{3m-1}$ at $\bar{r}$. We compute Y_k using (3.7), which requires $6m^3$ operations since we need to evaluate $f_k(\bar{u})$ for $k = m, \ldots, 3m-3$.

Using Definition 3.2 and the assumption that $A = A_s$, we compute

$$C(\bar{A}, A) = \sum_{l=1}^{3} l \binom{3}{l} \alpha^3 \bar{A}^{3-l} A^l = 3\alpha^3 A_s (\bar{A} + A_s)^2.$$

This latter step and the remaining computations for Procedure 3.5 are all of order less than m^3.

In summary, the m^3 cost of computing the coefficients of the radii polynomials is $6m^3$. Thus the additional cost of validation is on the order of $6m^3$ operations.

4.3. Relative cost. Combining the results of sections 4.1 and 4.2 suggests that asymptotically the ratio of the cost of validated continuation to the cost of traditional continuation is

$$\frac{26+3k}{20+3k},$$

where k is the number of iterations performed in the corrector step. We tested this hypothesis again on two fourth order PDEs with cubic nonlinearities, Swift–Hohenberg and Cahn–Hilliard. The results are discussed in greater detail in section 5. For the moment we are interested only in the relative times of computation.

We performed validated continuation for 46 predictor-corrector steps involving a total of 90 quasi-Newton iterations for the cubic Swift–Hohenberg equation. We repeated the computations without validation. The ratio of elapsed time for validated continuation to the time used for continuation alone was ≈ 1.156. Given that we had an average of 90/46 iterations per predictor-corrector step, this is close to the rough estimate of $\frac{26+3\cdot 90/46}{20+3\cdot 90/46} \approx 1.232$ given by the above arguments.

Similarly, we performed validated continuation for 15 predictor-corrector steps involving a total of 37 quasi-Newton iterations for Cahn–Hilliard. Again, we repeated the computations without validation. The ratio of elapsed time for validated continuation to the time used for continuation alone was ≈ 1.173. Given that we had an average of 37/15 iterations per predictor-corrector step, the asymptotic ratio is $\frac{26+3\cdot 37/15}{20+3\cdot 37/15} \approx 1.219$.

The results of these computations are summarized in Table 4.1.

TABLE 4.1
Comparison of the asymptotic ratios.

PDE	m	$\frac{\#\text{ iterations}}{\#\text{ steps}}$	Experimental ratio	Estimated ratio $\frac{26+3k}{20+2k}$
Swift–Hohenberg	27	1.96	1.156	1.232
Cahn–Hilliard	60	1.65	1.173	1.219

5. Sample results. To demonstrate the practical applicability of validated continuation we turn to two model problems, Cahn–Hilliard and Swift–Hohenberg. In both cases we follow a branch of equilibria and validate at each parameter value of the continuation. In the case of Swift–Hohenberg we also use interval arithmetic to evaluate the radii polynomials, thus allowing us to rigorously verify the existence and uniqueness of the equilibria.

5.1. Cahn–Hilliard. The Cahn–Hilliard equation was introduced in [1] as a model for the process of phase separation of a binary alloy at a fixed temperature. On a one-dimensional domain it takes the form

$$\begin{aligned} u_t &= -\left(\frac{1}{\nu}u_{xx} + u - u^3\right)_{xx}, \quad x \in [0,1], \\ u_x &= u_{xxx} = 0 \quad \text{at } x = 0, 1. \end{aligned} \tag{5.1}$$

The assumption of an equal concentration of both alloys is formulated as

$$\int_0^1 u(x,\cdot)\,dx = 0.$$

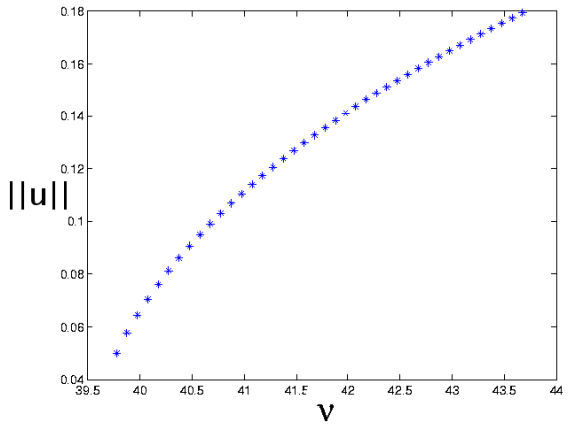

FIG. 5.1. *Validated continuation in ν for the Cahn–Hilliard equation on* $[0,1]$.

Note that when looking for the equilibrium solutions of (5.1), it is sufficient to work with the Allen–Cahn equation

$$\begin{aligned} &\frac{1}{\nu}u_{xx} + u - u^3 = 0, \\ &u_x = 0 \quad \text{at } x = 0, 1. \end{aligned} \tag{5.2}$$

Rewriting (5.2) in the form of (1.2), the linear operator is $L(\cdot,\nu) = \frac{1}{\nu}\frac{\partial^2}{\partial x^2} + 1$ and the polynomial nonlinearity is of degree $d = 3$ with coefficient functions

$$(c_p)_n = \begin{cases} -1, & p = 3 \text{ and } n = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Applying Procedure 3.5 with $M = m = 60$, $s = 3$, and $A_s = 0.01$ results in the branch of equilibria indicated in Figure 5.1, where each point represents the center of the infinite-dimensional validation set of the form $\bar{u} + W(\bar{r})$, containing a unique equilibrium of (5.1). These are the points used to obtain the cost estimates presented in Table 4.1. To avoid drowning the reader in large lists of numbers, we only provide the detailed numerical output at one parameter value.

VALIDATED RESULT 5.1. *Let* $\nu = 43.57415358799057$. *Then*

$$\bar{r} = 4.846104201261526 \times 10^{-8}$$

is a validation radius for the numerical zero $\bar{u}_F$ *given in Table* 5.1. *Thus, there exists a unique equilibrium for* (5.1) *in the validation set*

$$(\bar{u}_F, 0) + \prod_{k=0}^{59}[-\bar{r}, \bar{r}] \times \prod_{k=60}^{\infty}\left[-\frac{0.01}{k^3}, \frac{0.01}{k^3}\right].$$

5.2. Swift–Hohenberg. The Swift–Hohenberg equation

$$\begin{aligned} &u_t = f(u,\nu) = \left\{\nu - \left(1 + \frac{\partial^2}{\partial x^2}\right)^2\right\} u - u^3, \qquad u(\cdot,t) \in L^2\left(0, \frac{2\pi}{L_0}\right), \\ &u(x,t) = u\left(x + \frac{2\pi}{L_0}, t\right), \qquad u(-x,t) = u(x,t), \qquad \nu > 0, \end{aligned} \tag{5.3}$$

was originally introduced to describe the onset of Rayleigh–Bénard heat convection [8], where L_0 is a fundamental wave number for the system size $2\pi/L_0$. The parameter ν corresponds to the Rayleigh number, and its increase is associated with the appearance of multiple solutions that exhibit complicated patterns. For the computations presented here we fixed $L_0 = 0.65$.

Rewriting (5.3) in the form of (1.2), the linear operator is $L(\cdot, \nu) = \nu - (1 + \frac{\partial^2}{\partial x^2})^2$ and the polynomial nonlinearity is of degree $d = 3$ with coefficient functions

$$(c_p)_n = \begin{cases} -1, & p = 3 \text{ and } n = 0, \\ 0, & \text{otherwise.} \end{cases}$$

Applying Procedure 3.5 with $M = m = 27$, $s = 4$, and $A_s = 0.002$ results in the branch of equilibria indicated in Figure 5.2, where each point represents the center of the infinite-dimensional validation set of the form $\bar{u} + W(\bar{r})$, containing a unique equilibrium of (5.3). Again, these are the points used to obtain the cost estimates presented in Table 4.1.

As in the case of the Cahn–Hilliard equation, we only include the output at one point on the branch of Figure 5.2.

VALIDATED RESULT 5.2. *Let $\nu = 0.6674701641462312$. Then*

$$\bar{r} = 1.998167170445973 \ \times \ 10^{-9}$$

is a validation radius for the numerical zero $\bar{u}_F$ whose coefficient values are indicated in Table 5.2. *Thus, there exists a unique equilibrium solution for* (5.3) *in the validation set*

$$(\bar{u}_F, 0) + \prod_{k=0}^{26} [-\bar{r}, \bar{r}] \times \prod_{k=27}^{\infty} \left[-\frac{0.002}{k^4}, \frac{0.002}{k^4} \right].$$

Observe that in all the above-mentioned calculations, floating point roundoff errors have not been controlled; thus at this point one cannot claim that the validation results presented above are rigorous. However, with additional computational effort a computer-assisted proof can be obtained. To be more precise, our technique relies on the existence of a validation radius $\bar{r}$ making all radii polynomials strictly negative.

Hence, rigorous validation follows if the inequalities are satisfied when one includes bounds to control the possibility of floating point errors. The first step in checking these inequalities on this level is to obtain floating point outer bounds for the coefficients of the polynomials. This can be done by defining each entry of

$$\bar{u}_F,\ f^{(m)}(\bar{u}_F,\nu),\ J_{F\times F},\ f_x^{(m)}(\bar{u}_F,\nu),\ \mu_k(\nu),\ A_s,\ \text{and } s$$

to be an interval and then computing (3.13), (3.14), and the quantities in Definition 3.2 using interval arithmetic. The resulting radii polynomials, which we denote by $\tilde{P}_k$, have interval coefficients. Let $\bar{r}$ be the smallest representable number such that using interval arithmetic, the corresponding finite radii polynomials may be shown to be strictly contained in $(-\infty,0)$. Assume such an $\bar{r}$ exists. If, again using interval arithmetic, $\bar{r}(m-1)-A_s\subset(-\infty,0)$ and the intervals obtained from evaluating tail radii polynomials at $\bar{r}$ are strictly contained in $(-\infty,0)$, i.e., $\tilde{P}_k(\bar{r})\subset(-\infty,0)$ for all $k\geq m$, then the hypotheses of Theorem 3.4 are satisfied and we obtain a proof.

The above-mentioned computations were performed using the interval arithmetic package in MATLAB. Thus, we can state the following theorem.

THEOREM 5.3. *Each point in Figure* 5.2 *represents the center of an infinite-dimensional set of the form*

$$\bar{u}_F+\prod_{k=0}^{26}[-\bar{r},\bar{r}]\times\prod_{k=27}^{\infty}\left[-\frac{0.002}{k^4},\frac{0.002}{k^4}\right]$$

containing a unique equilibrium to (5.3).

The actual values for the various numerical zeros and validation radii are of limited interest and thus not presented. Of greater interest is understanding how large the errors induced by the floating point computations are as opposed to the magnitudes of the floating point computations of $P_k(\bar{r})$, $k\geq 0$, where $\bar{r}$ is the validation radius.

Let us restrict our attention to the equilibrium described by Validated Result 5.2. Following Procedure 3.5 at this parameter value, beginning using radii polynomials with interval coefficients, and performing the computations with interval arithmetic leads to an interval of potential validation radii

$$\mathcal{I}=[3.373873850437414\times10^{-9},9.003755731999980\times10^{-4}].$$

Hence, we choose $\bar{r}=3.373873850437415\times10^{-9}$. There are 53 inclusions that need to be satisfied, those arising from the $2m-2=52$ tail radii polynomials with interval coefficients and the one associated with inequality (3.17). The fact that the inclusions are satisfied leads to the conclusion of Theorem 5.3 at this parameter value. Again, rather than listing all 53 inclusions, let us focus on the two extremes, the interval closest to 0,

$$\tilde{P}_{27}(\bar{r})=-3.191484496597115\times10^{-11}\pm7.037497555236307\times10^{-24},$$

and the interval the farthest from 0,

$$-1.973098298147102\times10^{-3}\pm8.673617379884037\times10^{-19},$$

corresponding to inequality (3.17). Observe that in both cases, the width of the interval induced by the floating point errors is more than ten orders of magnitude smaller than the value of the center. Furthermore, this behavior is typical for all the validation computations that were performed. This suggests that it is reasonably safe to assume that a validated equilibrium is a true equilibrium.

6. Justification of radii polynomials. In this section, we describe the construction of the radii polynomials that were defined in section 3.2 and encode the bounds required for Theorem 2.1. We begin by computing the required bounds Y_n and K_n in (2.5) for the Newton-like operator constructed in (3.6).

Using a Taylor expansion of the Newton-like operator $T(u) = u - Jf(u)$ around the numerical equilibrium $\bar{u} = (\bar{u}_F, 0, 0, \dots)$ leads to

$$\begin{aligned}
&DT(\bar{u}+w')w = [I - J\cdot Df(\bar{u}+w')]\,w \\
&= \left(I - J\left(Df(\bar{u}) + D^2f(\bar{u})(w') + \cdots + \frac{D^l f(\bar{u})}{(l-1)!}(w')^{l-1} + \cdots + \frac{D^d f(\bar{u})}{(d-1)!}(w')^{d-1}\right)\right) w \\
&= [I - J\cdot Df(\bar{u})]w - J\left(\sum_{l=2}^{d}\frac{D^l f(\bar{u})}{(l-1)!}(w')^{l-1}\right) w \\
&= [I - J\cdot Df(\bar{u})]\,w - J\left(\sum_{l=2}^{d}\sum_{p=l}^{d}\frac{p!c_p\bar{u}^{p-l}(w')^{l-1}}{(l-1)!(p-l)!}\right) w \\
&= [I - J\cdot Df(\bar{u})]\,w - J\left(\sum_{l=2}^{d}\sum_{p=l}^{d} l\binom{p}{l}c_p\bar{u}^{p-l}(w')^{l-1}\right) w\ .
\end{aligned}$$

In the rest of the section, we will make use of the discrete convolution of bi-infinite vectors, i.e., considering two bi-infinite vectors $(a_j)_{j\in\mathbb{Z}}$, $(b_j)_{j\in\mathbb{Z}}$, we define their convolution by

$$(a*b)_k = \sum_{n=-\infty}^{\infty} a_n b_{k-n} = \sum_{\substack{k_1+k_2=k\\ k_i\in\mathbb{Z}}} a_{k_1}b_{k_2}, \quad k\in\mathbb{Z}\ .$$

Expanding into Fourier modes, we can write the nonlinear part in terms of convolution:

$$\begin{aligned}
DT(\bar{u}+w')w &= [I - J\cdot Df(\bar{u})]\,w - J\left(\sum_{l=2}^{d}\sum_{p=l}^{d} l\binom{p}{l}c_p\bar{u}^{p-l}(w')^{l-1}\right) * w \\
&= [I - J\cdot Df(\bar{u})]\,w - J\left(\sum_{l=2}^{d}\sum_{p=l}^{d} l\binom{p}{l}(c_p\bar{u}^{p-l}) * (w')^{l-1} * w\right)\ . \qquad (6.1)
\end{aligned}$$

Thus,

$$(c_p\bar{u}^{p-l})*((w')^{l-1})*w = \left[\sum_{\bar{n}}\left(\sum_{\sum n_i=\bar{n}}(c_p)_{n_0}\bar{u}_{n_1}\cdots\bar{u}_{n_{p-l}}\right)\left(\sum_{\sum n_i=n-\bar{n}} w'_{n_1}\cdots w'_{n_{l-1}}w_{n_l}\right)\right]_n .$$

Here, $[\cdot]_n$ denotes the bi-infinite vector indexed by $n\in\mathbb{Z}$ and $(\cdot)_k$ denotes the entry at index k.

We use this expansion to compute the bounds

$$\begin{aligned}
K_k &\geq \max|(DT(\bar{u}+W)W)_k| \\
&\geq \max\left|[I - J\cdot Df(\bar{u})]\tilde{w} - J\left(\sum_{l=2}^{d}\sum_{p=l}^{d} l\binom{p}{l}(c_p\bar{u}^{p-l}) * \tilde{w}^l\right)\right|,
\end{aligned}$$

where, as in section 2, W has the form (2.1).

The block diagonal structure of J allows us to decompose (6.1) into a finite, m-dimensional piece and the infinite-dimensional tail terms. For the following, we adopt the notation $[\cdot]_F$ to denote the m-vector whose nth entry is computed at index value $n-1$ for $1 \le n \le m$, the subscript $\tilde{F}$ to denote the bi-infinite vector in which the kth entries for $|k| \ge m$ are set equal to 0, and the subscript $\tilde{I}$ to denote the bi-infinite vector in which the kth entries for $|k| < m$ are set equal to 0. We begin with the following decomposition of the finite part of the linear term:

$$\begin{aligned}
\{[I - J \cdot Df(\bar{u})]w\}_F &= w_F - [J \cdot Df(\bar{u})w]_F \\
&= w_F - J_{F\times F}\,[Df(\bar{u})w]_F \\
&= w_F - J_{F\times F} \cdot Df_F(\bar{u})w \\
&= w_F - J_{F\times F} \cdot \left[Df^{(m)}(\bar{u}_F)w_F + R_F(\bar{u}, w)\right] \\
&= \left[I_{F\times F} - J_{F\times F} \cdot Df^{(m)}(\bar{u}_F)\right] w_F - J_{F\times F} \cdot R_F(\bar{u}, w)\ , \qquad (6.2)
\end{aligned}$$

where for $k \in \{0, \dots, m-1\}$,

$$\begin{aligned}
R_k(\bar{u}, w) &:= \sum_{i=m}^{\infty} \frac{\partial f_k}{\partial u_i}(\bar{u}) w_i \\
&= \sum_{\substack{\bar{n}=-\infty \\ |k-\bar{n}|\ge m}}^{\infty} \left| \sum_{p=1}^{d} p \sum_{\sum n_i = \bar{n}} (c_p)_{n_0} \bar{u}_{n_1} \dots \bar{u}_{n_{p-1}} \right| \frac{A_s}{|k-\bar{n}|^s}\ . \qquad (6.3)
\end{aligned}$$

It follows that

$$\begin{aligned}
[DT(\bar{u}+W)W]_F \subseteq &\left[I_{F\times F} - J_{F\times F} \cdot Df^{(m)}(\bar{u}_F)\right] \tilde{w}_F - J_{F\times F} \cdot R_F(\bar{u}, w) \\
&- \left(J_{F\times F} \sum_{l=2}^{d} \sum_{p=l}^{d} l \binom{p}{l} [(c_p \bar{u}^{p-l}) * \tilde{w}^l]_F \right). \qquad (6.4)
\end{aligned}$$

For $k \ge m$,

$$(DT(\bar{u}+W)W)_k \subseteq -J(k,k) \sum_{l=1}^{d} \sum_{p=l}^{d} l \binom{p}{l} ((c_p \bar{u}^{p-l}) * \tilde{w}^l)_k. \qquad (6.5)$$

We now focus on finding bounds on the terms given in (6.4) and (6.5). First consider

$$((c_p \bar{u}^{p-l}) * \tilde{w}^l)_k = \sum_{\bar{n}} \left(\sum_{\sum n_i = \bar{n}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right) \left(\sum_{\sum n_i + \bar{n} = k} \tilde{w}_{n_1} \cdots \tilde{w}_{n_l} \right), \qquad (6.6)$$

where p is the degree of the original monomial term of f and $l \in \{1, \dots, p\}$ is the order of the derivative being taken. One upper bound for (6.6) is given in the following lemma, which uses asymptotic bounds first listed in section 3.2.

LEMMA 6.1. *Let* $\alpha = \frac{2}{s-1} + 2 + 3.5 \cdot 2^s$, $\bar{u}_k \in \frac{\bar{A}}{k^s}[-1,1]$, $(c_p)_k \in \frac{C_p}{k^s}[-1,1]$, *and* $\tilde{w}_k \subset \frac{A}{k^s}[-1,1]$ *for all* k. *Then*

$$((c_p \bar{u}^{p-l}) * \tilde{w}^l)_k \subseteq \begin{cases} \frac{\alpha^p C_p \bar{A}^{p-l} A^l}{|k|^s}[-1,1], & k \ne 0, \\ \alpha^p C_p \bar{A}^{p-l} A^l [-1,1], & k = 0. \end{cases}$$

Proof. Note that

$$\sum_{\bar{n}} \left(\sum_{\sum n_i = \bar{n}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right) \left(\sum_{\sum n_i + \bar{n} = k} \tilde{w}_{n_1} \cdots \tilde{w}_{n_l} \right)$$
$$\subseteq \sum_{\sum n_i = k} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \tilde{w}_{n_{p-l+1}} \cdots \tilde{w}_{n_p}$$
$$\subseteq \sum_{\sum n_i = k} \frac{C_p}{|n_0|^s} \frac{\bar{A}}{|n_1|^s} \cdots \frac{\bar{A}}{|n_{p-l}|^s} \frac{A}{|n_{p-l+1}|^s} \cdots \frac{A}{|n_p|^s} [-1, 1].$$

The remainder of the proof is a modification of [2, Lemma 5.8]. ∎

In most cases, especially when l is small relative to p, this bound will be too large to use for the low modes. In particular, $\bar{u}$ may be far from zero, resulting in a large constant $\bar{A}$. By taking k sufficiently large, the contraction given by $J(k,k) \approx {\mu_k}^{-1}$ will overcome the large bound. A more practical approach for obtaining bounds for the low modes is given by the following lemma. For flexibility in balancing numerical computations (requiring a finite number of operations) with analysis (to obtain truncation bounds), we choose $M \geq m$ to be the dimension used to split these sums.

LEMMA 6.2. *For $M \geq m$,*

$$((c_p \bar{u}^{p-l}) * \tilde{w}^l)_k \subseteq \left(\sum_{j=0}^{l} \binom{l}{j} C_k(p, j, l, M) r^{l-j} + \epsilon_k(p, l, M) \right) [-1, 1].$$

Proof. This lemma is a modification of [2, Lemma 5.10] combined with Lemma 6.1. In [2, Lemma 5.10], the bound is split into finite sums and the tail term, bounded by

$$\frac{p \alpha^{p-1} C_p \bar{A}^{p-l} A^l}{(M-1)^{s-1}(s-1)} \left[\frac{1}{(M-k)^s} + \frac{1}{(M+k)^s} \right] [-1, 1].$$

We obtain a polynomial in r by rewriting the finite sums as follows:

$$\sum_{\bar{n}} \left(\sum_{\substack{\sum n_i = \bar{n} \\ |n_i| < M}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right) \left(\sum_{\substack{\sum n_i + \bar{n} = k \\ |n_i| < M}} \tilde{w}_{n_1} \cdots \tilde{w}_{n_l} \right)$$
$$= \sum_{\bar{n}} \left(\sum_{\substack{\sum n_i = \bar{n} \\ |n_1|, \ldots, |n_{p-l}| < m \\ |n_0| < M}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right) \left(\sum_{\substack{\sum n_i + \bar{n} = k \\ |n_i| < M}} \tilde{w}_{n_1} \cdots \tilde{w}_{n_l} \right)$$
$$= \sum_{\bar{n}} \left(\sum_{\substack{\sum n_i = \bar{n} \\ |n_1|, \ldots, |n_{p-l}| < m \\ |n_0| < M}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right) \left(\sum_{j=0}^{l} \binom{l}{j} \sum_{\substack{\sum n_i + \bar{n} = k \\ m \leq |n_1|, \ldots, |n_j| < M \\ |n_{j+1}|, \ldots, |n_l| < m}} \tilde{w}_{n_1} \cdots \tilde{w}_{n_l} \right)$$
$$= \sum_{\bar{n}} \left(\sum_{\substack{\sum n_i = \bar{n} \\ |n_1|, \ldots, |n_{p-l}| < m \\ |n_0| < M}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right)$$

$$\times \left(\sum_{j=0}^{l} \binom{l}{j} r^{l-j} [-1,1] \sum_{\substack{\sum n_i + \bar{n} = k \\ m \le |n_1|, \ldots, |n_j| < M \\ |n_{j+1}|, \ldots, |n_l| < m}} \frac{A_s^j}{|n_1|^s \cdots |n_j|^s} \right)$$

$$= \sum_{j=0}^{l} \binom{l}{j} r^{l-j} \sum_{|\bar{n}| < (p-l)(m-1)+M} [-1,1] \left| \sum_{\substack{\sum n_i = \bar{n} \\ |n_1|, \ldots, |n_{p-l}| < m \\ |n_0| < M}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right|$$

$$\times \left(\sum_{\substack{\sum n_i + \bar{n} = k \\ m \le |n_1|, \ldots, |n_j| < M \\ |n_{j+1}|, \ldots, |n_l| < m}} \frac{A_s^j}{|n_1|^s \cdots |n_j|^s} \right). \qquad \square$$

REMARK 6.3. *Note that in Lemma* 6.2*, $C_k(p,j,l,M)$ captures the contribution to the $(l-j)$th polynomial coefficient from the lth derivative of the pth monomial term of f in the Taylor expansion. If $M = m$, then $C_k(p,j,l,M) = 0$ for all $j > 0$ and*

$$C_k(p,0,l,m) = \left| \sum_{\substack{n_0 + \cdots + n_{p-l} = k \\ |n_0|, \ldots, |n_{p-l}| < m}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_{p-l}} \right| .$$

For $M > m$ there is also a (small) contribution to the coefficients of higher degrees of r in the polynomials, while simultaneously decreasing the ϵ_k term. This offers a method for using additional computations to decrease the bound ϵ_k if this bound proves to be too large for the validation procedure.

For notational purposes, set ϵ_F, $C_F(p,j,l,M)$, $V_F^{(0)}$, and $V_F^{(1)}$, to be the m-vectors as defined in section 3.2. For $0 \le k < m$, we substitute the bounds from Lemma 6.2 into (6.4),

$$\begin{aligned}
&(DT(\bar{u}+W)W)_k \subseteq r V_k^{(1)}[-1,1] + V_k^{(0)}[-1,1] \\
&\quad + \left(-J_{F\times F} \sum_{l=2}^{d} \sum_{p=l}^{d} l \binom{p}{l} \left(\sum_{j=0}^{l} \binom{l}{j} (C_F(p,j,l,M) r^{l-j} + \epsilon_F(p,l,M)) \right) [-1,1] \right)_k \\
&= \left(|J_{F\times F}| \epsilon_F \right)_k [-1,1] + r V_k^{(1)}[-1,1] + V_k^{(0)}[-1,1] \\
&\quad + \left(\sum_{l=2}^{d} \sum_{p=l}^{d} \sum_{j=0}^{l} r^{l-j} l \binom{p}{l} \binom{l}{j} |J_{F\times F}| C_F(p,j,l,M) \right)_k [-1,1] \\
&= \left(|J_{F\times F}| \epsilon_F + V_F^{(0)} \right)_k [-1,1] + r V_k^{(1)}[-1,1] \\
&\quad + \left(\sum_{i=0}^{d} r^i \sum_{l=\max\{2,i\}}^{d} \sum_{p=l}^{d} l \binom{p}{l} \binom{l}{i} |J_{F\times F}| C_F(p,l-i,l,M) \right)_k [-1,1],
\end{aligned}$$

where $|\cdot|$ denotes entrywise absolute value. For $0 \le k < m$, set K_k to be

$$K_k := \sum_{i=0}^{d} C_k^K(i) r^i \ge |(DT(\bar{u}+W)W)_k|,$$

where $C_k^K(i)$ satisfies (3.13).

Recall that our goal is to find a polynomial bound for $Y_k + K_k - |\tilde{w}_k|$ for Theorem 2.1. This requires also computing the bounds for Y_k satisfying the following equation:

$$\begin{aligned} Y_k &\geq |(T(\bar{u}) - \bar{u})_k| \\ &= |[-Jf(\bar{u})]_k| \\ &= \left| \left(-J \left[\mu_n \bar{u}_n + \sum_{p=0}^{d} \sum_{\substack{n_0+\cdots+n_p=n \\ |n_1|,\ldots,|n_p|<m}} (c_p)_{n_0} \bar{u}_{n_1} \cdots \bar{u}_{n_p} \right]_n \right)_k \right|. \end{aligned} \tag{6.7}$$

Therefore, for $k < m$, set $Y_k = C_k^Y$, where C_F^Y is given by (3.14). Note that these terms involve the Galerkin projection of f at $\bar{u}$ onto the first m modes and, therefore, are expected to be small.

For $0 \leq k < m$, we now combine our bounds for Y_k with the bounds for K_k to compute the coefficients of the polynomials $P_k(r)$ giving the bounds $Y_k + K_k - |\tilde{w}_k|$. This leads us to the definition of the finite radii polynomials presented in Definition 3.1.

In modes $k \geq m$, we use Lemma 6.1 and (6.5) to obtain

$$\begin{aligned} (DT(\bar{u}+W)W)_k &\subseteq -J(k,k) \sum_{l=1}^{d} \sum_{p=\max\{2,l\}}^{d} l \binom{p}{l} ((c_p \bar{u}^{p-l}) * \tilde{w}^l)_k \\ &\subseteq \frac{1}{|\mu_k| k^s} \sum_{l=1}^{d} \sum_{p=\max\{2,l\}}^{d} l \binom{p}{l} \alpha^p C_p \bar{A}^{p-l} A^l [-1,1]. \end{aligned} \tag{6.8}$$

Therefore, set K_k, $k \geq m$, such that

$$K_k \geq \frac{C(\bar{A}, A)}{|\mu_k| k^s}. \tag{6.9}$$

Recall (6.7). For $k \geq m$, choose Y_k (compare with (3.7)) such that

$$\begin{aligned} Y_k &\geq |(T(\bar{u}) - \bar{u})_k| \\ &= |-J(k,k)(f_k(\bar{u}))| \\ &= \frac{|\sum_{p=2}^{d} (c_p \bar{u}^p)_k|}{|\mu_k|}. \end{aligned} \tag{6.10}$$

Using Lemma 6.1,

$$\frac{|\sum_{p=2}^{d} (c_p \bar{u}^p)_k|}{|\mu_k|} \subseteq \sum_{p=2}^{d} \frac{\alpha C_p \bar{A}^p}{|\mu_k||k|^s} [-1,1]. \tag{6.11}$$

These bounds are overestimates and should only be used for large k. In fact, if the coefficient functions c_p have finite Fourier expansions (as in the examples we consider in section 5), then $Y_k = 0$ for k sufficiently large.

We may now define the polynomial bounds for $Y_k + K_k - |\tilde{w}_k|$ in the tail modes. Suppose the bounds Y_k are numerically or analytically computed for $m \leq k < m_+$.

Then for $k \geq m$, the tail radii polynomial (see Definition 3.2) satisfies

$$P_k(r) = Y_k + K_k(r) - \frac{A_s}{k^s}$$
$$= \begin{cases} \frac{|\sum_{p=2}^{d}(c_p \bar{u}^p)_k|}{|\mu_k|} + \frac{C(\bar{A},A)}{|\mu_k|k^s} - \frac{A_s}{k^s}, & m \leq k < m_+, \\ \frac{C_+(\bar{A},A)}{|\mu_k|k^s} - \frac{A_s}{k^s}, & k \geq m_+, \end{cases}$$

Checking that $P_k < 0$ for $k \geq m$ reduces to checking the inequalities $P_m < 0, \ldots, P_{m_+-1} < 0$ and, by rearranging terms,

$$C_+(\bar{A}, A) < |\mu_k| A_s. \tag{6.12}$$

Therefore, the assumption that $|\mu_k|$ is growing in k ensures that (6.12) may be verified for all $k \geq m$ with only a finite number of checks. More explicitly, computing a lower bound on $|\mu_k|$, $k \geq m_+$, would allow us to verify all inequalities of type (6.12), $k \geq m_+$, in one step. Indeed, since $\frac{C_+(\bar{A},A)}{|\bar{\mu}|} - A_s < 0$, and $f_k(\bar{u}) = 0$ and $|\mu_k| \geq |\bar{\mu}|$ for all $k \geq \bar{m} \geq m_+$,

$$\begin{aligned} P_k(\bar{r}) &= Y_k + K_k - \frac{A_s}{k^s} \\ &= \frac{C_+(\bar{A},A)}{|\mu_k|k^s} - \frac{A_s}{k^s} \\ &\leq \frac{C_+(\bar{A},A)}{|\bar{\mu}|k^s} - \frac{A_s}{k^s} \\ &< 0. \end{aligned}$$

We have now constructed the radii polynomials to give the bounds required for Theorem 2.1.

Recall that $r > 0$ is a *validation radius* if $P_k(r) < 0$ for all radii polynomials P_k as defined in Definitions 3.1 and 3.2. We may now prove Theorem 3.4 from section 3.2.

Proof of Theorem 3.4. The radii polynomials have been constructed so that $P_k(r) < 0$ for all k ensures that the first condition of Theorem 2.1 is satisfied. Since the first condition is satisfied, we also have that $\frac{K_k}{|\tilde{w}_k|} < 1$ for all k. Finally, since $|\mu_k| \to \infty$,

$$\frac{K_k}{|\tilde{w}_k|} = \frac{\frac{C_+(\bar{A},A)}{|\mu_k|k^s}}{\frac{A_s}{k^s}} = \frac{C_+(\bar{A},A)}{A_s|\mu_k|} \to 0.$$

Therefore, $K := \sup\left\{\frac{K_k}{|\tilde{w}_k|}\right\} < 1$ and the second and final hypothesis in Theorem 2.1 is also satisfied.

7. Concluding remarks. As is indicated in the introduction, the purpose of this paper is to communicate the essential ideas of our proposed validation method. As such we have presented it in a somewhat limited setting. Thus, we conclude with a range of comments, beginning with obvious generalizations describing ongoing work and ending with some open questions.

The particular choice of the abstract expression for the expansion of the PDE (1.3) was chosen because it was appropriate for the application to Cahn–Hilliard (5.1) and Swift–Hohenberg (5.3). Hopefully it is clear that a different choice of boundary conditions or symmetries does not affect the essential estimates. It is expected,

but remains to be checked, that the form of the estimates can be lifted to parabolic PDEs on rectangular domains (see [6], where similar estimates were used to study the equilibria of the Cahn–Hilliard equation on the unit square) and to systems of such PDEs. We also believe that generalizing this technique to pseudoarclength continuation should be fairly straightforward. Furthermore, treating the parameter ν as an interval allows us to prove the existence and uniqueness of a branch of solutions over the interval $\tilde{\nu}$. By adapting the predictor step length, this approach may be used to prove existence and uniqueness along continuous, finite branches of equilibria.

While there are numerous directions in which our validation technique can be expanded or improved, we focus on the following four.

- Observe that if (1.2) has a polynomial nonlinearity of order d, then straightforward evaluation of the nonlinear term in (1.4) involves on the order of m^d operations. In a forthcoming work [5], this computational cost is reduced by the use of the fast Fourier transform.
- For the computations presented in this paper, we fixed $M = m$. This was done for the sake of simplicity of presentation. Clearly, the success of validation strongly depends on upper bounds presented in Lemma 6.2. In general, for fixed m, choosing $M > m$ increases the computational cost but provides a smaller bound for the truncation error ϵ_k. Improved bounds should facilitate validated continuation with a smaller projection dimension m, which decreases the computational cost. The exact tradeoff is currently being explored.
- The computational strategy adopted for this work is to fix A_s and s throughout the continuation procedure. In particular, in the Swift–Hohenberg example we obtained 40 successful predictor-corrector steps with $A_s = 0.002$ and $s = 4$ held constant over a parameter range of length 0.4. We were able to do this because we chose a projection dimension $m = 27$, which is unnecessarily large. For example, with $m = 11$, $A_s = 0.002$, and $s = 4.52$ we were able to perform a validated continuation over a parameter range of length 0.01. In this case, we obtained $s = 4.52$ by fixing A_s and seeking a successful s by trial and error. This suggests that it is worthwhile to develop a method for choosing A_s and s adaptively during the validated continuation procedure.
- As pointed out in section 5, the floating point errors are many orders of magnitude smaller than the magnitude of the radii polynomials evaluated at the validation radius. This suggests that it might be possible to compute a priori bounds on the floating point errors from which one could conclude that the validation computations are in fact rigorous computations. The techniques in [7] might prove useful for this purpose.

Acknowledgments. The authors would like to thank L. Dieci for numerous helpful conversations concerning continuation methods and M. Gameiro, R. Beardmore, and the referees for helpful comments on the layout of the paper.

CONVERGENCE OF A NUMERICAL METHOD FOR SOLVING DISCONTINUOUS FOKKER–PLANCK EQUATIONS*

HONGYUN WANG†

Abstract. In studies of molecular motors, the stochastic motion is modeled using the Langevin equation. If we consider an ensemble of motors, the probability density is governed by the corresponding Fokker–Planck equation. Average quantities, such as average velocity, effective diffusion coefficient, and randomness parameter, can be calculated from the probability density. A numerical method was previously developed to solve Fokker–Planck equations [H. Wang, C. Peskin, and T. Elston, *J. Theoret. Biol.*, 221 (2003), pp. 491–511]. It preserves detailed balance, which ensures that if the system is forced to an equilibrium, the numerical solution will be the same as the Boltzmann distribution. Here we study the convergence of this numerical method when the potential has a finite number of discontinuities at half numerical grid points. We prove that this numerical method is stable and is consistent with the differential equation. Based on the consistency analysis, we propose a modified version of this numerical method to eliminate the first order error term caused by the discontinuity. We also show that in the presence of discontinuities, detailed balance is a necessary condition for converging to the correct solution. This explains why the central difference method converges to a wrong solution.

1. Introduction.

Molecular motors operate in an environment dominated by thermal fluctuations [1]. In general, a molecular motor has many internal and external degrees of freedom. Of these degrees of freedom, there is one associated with the main function of the motor, its unidirectional motion. For example, the γ shaft of an F_1 ATPase rotates with respect to the hexamer formed by three pairs of α and β subunits [2, 3, 4], and a kinesin dimer walks along a microtubule [5, 6]. In studies of molecular motors, it is natural to follow the motor along the dimension of its unidirectional motion [7, 8, 9]. The effects of the other degrees of freedom are modeled in the mean field potential affecting the unidirectional motion.

To introduce the governing equations for molecular motors, we start with the one-dimensional motion of a small particle in a fluid environment subject to a potential, $V(x)$, where x is the coordinate along the dimension of motion. The particle is subject to the viscous drag force, the force derived from the potential, and the Brownian force. Both the drag force and the Brownian force are the results of bombardments by surrounding fluid molecules. The drag force is the mean, and the Brownian force is the fluctuation part of the random force caused by bombardments. The particle is governed by Newton's second law:

$$m\frac{dv}{dt} = -\zeta v - V'(x) + \sqrt{2k_BT\zeta}\,\frac{dW(t)}{dt}, \tag{1.1}$$

where m is the mass and v the velocity of the particle. In (1.1), $W(t)$ is the Weiner process. The drag force on the particle, ζv, is proportional to the velocity, and ζ is

†Department of Applied Mathematics and Statistics, Mail Stop SOE2, University of California Santa Cruz, Santa Cruz, CA 95064 (hongwang@ams.ucsc.edu).

called the drag coefficient. The magnitude of the Brownian force is related to the drag coefficient and is given by $\sqrt{2k_BT\zeta}$, which is a result of the fluctuation-dissipation theorem [11, 13]. Here k_B is the Boltzmann constant and T the absolute temperature.

For a bead of radius a, the drag coefficient and the mass, respectively, are [1]

$$\zeta = 6\pi\eta a, \qquad m = \frac{4}{3}\pi\rho a^3, \tag{1.2}$$

where ρ is the density and η the viscosity of the surrounding fluid. Equation (1.1) can be written as

$$\frac{dv}{dt} = -\frac{\zeta}{m}\left(v - \left[-\frac{1}{\zeta}V'(x) + \sqrt{2D}\frac{dW(t)}{dt}\right]\right), \tag{1.3}$$

where $D = \frac{k_BT}{\zeta}$ is the diffusion constant [1]. It is important to notice that the ratio $\frac{\zeta}{m}$ is inversely proportional to the square of the radius of particle

$$\frac{\zeta}{m} = \frac{9\eta}{2\rho a^2} = O\left(\frac{1}{a^2}\right). \tag{1.4}$$

Thus, for a small particle, $\frac{\zeta}{m}$ is very large. In this case, (1.3) is well approximated by

$$v = \left[-\frac{1}{\zeta}V'(x) + \sqrt{2D}\frac{dW(t)}{dt}\right]. \tag{1.5}$$

The reduction from (1.3) to (1.5) in the limit of large $\frac{\zeta}{m}$ is called the Kramers–Smoluchowski approximation. Writing (1.5) as a stochastic differential equation for x, we have

$$\frac{dx}{dt} = -\frac{1}{\zeta}V'(x) + \sqrt{2D}\frac{dW(t)}{dt}. \tag{1.6}$$

This is the Langevin equation without the inertia term, governing the stochastic motion of a small particle subject to potential $V(x)$ [12].

In molecular motors, the mechanical motion is coupled to the chemical reaction. The general mathematical framework used in modeling molecular motors is a system of coupled Langevin equations. Each Langevin equation in the coupled system has the form of (1.6) with a periodic potential $V_S(x)$, where S represents the current chemical state of the motor system [7, 9, 4]:

$$\frac{dx}{dt} = -\frac{1}{\zeta}V_S'(x) + \sqrt{2D}\frac{dW(t)}{dt}. \tag{1.7}$$

Here $1 \le S \le N$, and N is the number of possible chemical states of the motor system. The period of these potentials is usually determined by the step size of the motor. For example, a kinesin dimer walks on a microtubule with 8-nm steps [6]. The chemical reaction of the motor system (the stochastic jumping of the motor system among the chemical states) is governed by a discrete Markov process (a jump process).

The motor behavior (such as the average velocity) can be calculated by following the stochastic evolution (mechanical motion and chemical reaction) of the motor in Monte Carlo simulations. However, results obtained with Monte Carlo simulations have statistical errors and converge very slowly. If we calculate the ensemble average

by following a large number of motors, then the statistical error is inversely proportional to the square root of the number of motors in the ensemble. Furthermore, when the potential $\psi(x)$ is not smooth, there are numerical difficulties in Monte Carlo simulations. Fortunately, average quantities can be calculated more efficiently by following the probability density of the motor.

Let us consider an ensemble of motors, each evolving in time independently and stochastically according to Langevin equation (1.7). Let $\rho_S(x,t)$ be the probability density that the motor is at position x and in chemical state S at time t. The time evolution of $\rho_S(x,t)$ is governed by the Fokker–Planck equation corresponding to Langevin equation (1.7) [12]:

$$\frac{\partial \rho_S}{\partial t} = D\frac{\partial}{\partial x}\left[\frac{V_S'(x)}{k_BT}\rho_S + \frac{\partial \rho_S}{\partial x}\right] + \sum_{j=1}^{N} k_{j\to S}(x)\rho_j, \qquad S = 1, 2, \ldots, N, \tag{1.8}$$

where, for $j \neq S$, $k_{j\to S}(x)$ is the chemical transition rate from state j to state S. $k_{S\to S}(x)$ is the total rate of jumping out of state S and is given by

$$k_{S\to S}(x) \equiv -\sum_{j\neq S} k_{S\to j}(x). \tag{1.9}$$

A simple way to model molecular motors is to average $V_S'(x)$ over all chemical states weighted by the steady state probability density functions of these states [10]. Let $\psi'(x)$ be the weighted average of $V_S'(x)$ over all chemical states:

$$\psi'(x) \equiv \frac{1}{\sum_{S=1}^{N}\rho_S(x)}\sum_{S=1}^{N}\rho_S(x)V_S'(x). \tag{1.10}$$

$\psi(x)$ can be viewed as the motor's mean field free energy landscape. The mechanical motion of the motor can be modeled using Langevin equation (1.6) with potential $\psi(x)$. Let L denote the period of $V_S(x)$. We immediately see that $\psi'(x)$ is also periodic with period L. However, $\psi(x)$ may not be periodic. As a matter of fact, for a molecular motor undergoing a unidirectional motion powered by a chemical reaction, $\psi(x)$ must not be periodic. If $\psi(x)$ is periodic, then there is no energy available to drive the motor forward because there is no free energy change going from one period to the next. For the motor to go forward, there must be a free energy drop going from one period to the next. Since $\psi'(x)$ is periodic, the energy landscape $\psi(x)$ is a tilted periodic potential:

$$\psi(x+L) = \psi(x) - \Delta\psi, \tag{1.11}$$

where $\Delta\psi > 0$ is the energy made available from the chemical reaction to drive the motor forward in one period. An example of tilted periodic potential is shown in Figure 1.1. This is also the potential we will use in numerical simulations in section 7. If the energy landscape $\psi(x)$ is simply a constant slope downhill, then the energy $\Delta\psi$ is utilized uniformly in one period to generate a constant motor force. If the slope of $\psi(x)$ is not a constant, then the motor force varies with the motor position within one period. As shown in Figure 1.1, the energy landscape $\psi(x)$ may not be monotonic. In that case, the motor depends on the Brownian fluctuations from the surrounding fluid to get over the free energy barrier. Of course, the energy source for driving the motor forward eventually comes from the free energy drop $\Delta\psi$, which rectifies

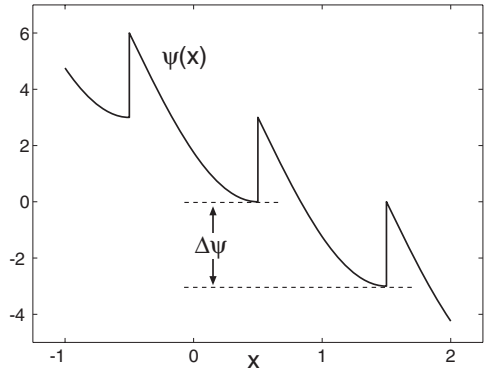

FIG. 1.1. *Graph of the tilted periodic potential used in numerical simulations in section 7.*

the forward fluctuations. This mechanism of driving the motor forward by rectifying thermal fluctuations is called ratchet [22].

If we use the mean field potential (1.10), then the mechanical motion of the motor is governed by the Langevin equation:

$$\frac{dx}{dt} = -\frac{1}{\zeta}\psi'(x) + \sqrt{2D}\frac{dW(t)}{dt}. \tag{1.12}$$

Equation (1.12) has been used in studies of motors [14, 15]. In addition to its mathematical simplicity, another advantage of using (1.12) is that the energy landscape $\psi(x)$ can be extracted from single molecule experimental data [10]. The Fokker–Planck equation corresponding to Langevin equation (1.12) is [12]

$$\frac{\partial \rho}{\partial t} = D\frac{\partial}{\partial x}\left[\frac{\psi'(x)}{k_B T}\rho + \frac{\partial \rho}{\partial x}\right]. \tag{1.13}$$

In [16], a robust numerical method (hereafter referred to as Method 1) was designed for solving Fokker–Planck equations (1.8) and (1.13). When the potential is smooth, the proof of convergence of Method 1 is straightforward [16]. But that does not provide an accurate theoretical explanation for the robust performance of Method 1. The strength of Method 1 is that it works fairly well even if the potential is discontinuous. In this paper, we are going to prove the convergence of Method 1 for the model equation (1.13) when the potential is piecewise smooth and has a finite number of discontinuities at half numerical grid points. First, we nondimensionalize (1.13). The dimensionless independent variables and functions are defined as

$$\tilde{x} = x\frac{1}{L}, \qquad \tilde{t} = t\frac{D}{L^2},$$

$$\tilde{\psi}(\tilde{x}) = \psi(x)\frac{1}{k_B T}, \qquad \tilde{\rho}(\tilde{x}) = \rho(x)L, \qquad \Delta\tilde{\psi} = \Delta\psi\frac{1}{k_B T}.$$

Since we are going to work with the dimensionless variables and functions, let us drop $\sim$ from the notations. The dimensionless version of (1.13) is

$$\frac{\partial \rho}{\partial t} = \frac{\partial}{\partial x}\left[\psi'(x)\rho + \frac{\partial \rho}{\partial x}\right], \tag{1.14}$$

where $\psi(x)$ satisfies

$$\psi(x+1) = \psi(x) - \Delta\psi, \qquad \Delta\psi > 0.$$

Equation (1.14) can be viewed as a special case of (1.13) with $L = 1$, $D = 1$, and $k_B T = 1$.

The rest of the paper is organized as follows. In section 2, we discuss the two conditions that the exact solution of a discontinuous Fokker–Planck equation must satisfy at a discontinuity. We derive the two conditions for the exact solution at a discontinuity by rewriting the Fokker–Planck equation as a heat equation with discontinuous heat conductivity and discontinuous specific heat capacity. The first condition is the continuity of the "heat flux," which corresponds to the conservation of heat. The second condition is the continuity of the "temperature," which follows from the regularizing properties of the heat equation. In section 3, we describe the construction and properties of Method 1 developed in [16]. The most important property of Method 1 is that it preserves detailed balance. In section 4, we prove that Method 1 is stable with respect to a norm that is equivalent to the 2-norm. We start by showing that the steady state solution of the half discrete method is unique and all positive. This allows us to define a weighted 2-norm using the steady state solution as the weight function. We proceed to show that the steady state solution is bounded away from 0 and from infinity, independent of the numerical grid size. It follows that the weighted 2-norm is equivalent to the standard 2-norm. We then show that with respect to the weighted 2-norm, Method 1 is unconditionally stable. In section 5, we analyze the consistency of Method 1 when the potential is discontinuous. We show that away from the discontinuity, the local truncation error of Method 1 on the exact solution is $O(k(k^2+h^2))$. At the discontinuity, the local truncation error on the exact solution is $O(1)$. However, if we perturb the exact solution by a term of the order $O(h)$, then the local truncation error on the perturbed solution is $O(k(k^2+h))$. Once we have both the stability and consistency, the Lax equivalence theorem [17] implies that Method 1 converges to the correct solution of the differential equation. In section 6, we propose a modified version of Method 1 to eliminate the first order error term caused by the discontinuity (hereafter referred to as Method 2). As a result, the modified method (Method 2) is second order accurate even in the presence of discontinuities. In section 7, we carry out numerical simulations using a discontinuous potential to compare the performance of the central difference method, Method 1, and Method 2. The central difference method converges to a wrong solution. Both Method 1 and Method 2 converge to the correct solution. We also show that in the presence of discontinuities, detailed balance is a necessary condition for converging to the correct solution. This explains the defect of the central difference method.

2. Exact solution of a discontinuous Fokker–Planck equation and conditions at the discontinuity. In this section, we discuss the two conditions that the exact solution of a discontinuous Fokker–Planck equation must satisfy at a discontinuity. We derive the two conditions for the exact solution at a discontinuity by rewriting the Fokker–Planck equation as a heat equation with discontinuous heat conductivity and discontinuous specific heat capacity. The first condition is the continuity of the "heat flux." The second condition is the continuity of the "temperature."

We study the case where potential $\psi(x)$ is piecewise smooth and has a finite number of discontinuities in one period. Without loss of generality, we assume that there is only one discontinuity at x_d in $[0, 1]$. More specifically, we assume that $\psi(x)$ is two smooth functions connected by the discontinuity. That is, $\psi(x)$ is smooth in

$[0, x_d]$ if $\psi(x_d)$ is redefined as $\psi(x_d) = \lim_{x \to x_d^-} \psi(x)$, and $\psi(x)$ is smooth in $[x_d, 1]$ if $\psi(x_d)$ is redefined as $\psi(x_d) = \lim_{x \to x_d^+} \psi(x)$. For simplicity, in this paper a smooth function means it is infinitely differentiable, and so we can use as many terms of its Taylor expansion as we want.

When $\psi(x)$ is discontinuous at x_d, $\psi'(x)$ is not a regular function. If the system is brought to an equilibrium, the equilibrium solution is given by the Boltzmann distribution:

$$\rho(x) = \frac{1}{Z} e^{-\psi(x)}, \qquad Z = \int_0^1 e^{-\psi(x)} dx,$$

which is discontinuous at x_d. Thus, we should expect $\rho(x,t)$ to be discontinuous as a function of x at x_d. In modeling molecular motors, a discontinuous potential is simply a mathematical abstraction. In reality, the discontinuity represents a very narrow transition region in which the potential is smooth but changes dramatically. When the potential is smooth, we can rewrite Fokker–Planck equation (1.14) as

$$\frac{\partial \rho}{\partial t} = \frac{\partial}{\partial x} \left(e^{-\psi(x)} \frac{\partial e^{\psi(x)} \rho}{\partial x} \right). \tag{2.1}$$

Let us introduce $u(x,t) \equiv e^{\psi(x)} \rho(x,t)$. The equation above can be written in the form

$$\frac{\partial e^{-\psi(x)} u}{\partial t} = \frac{\partial}{\partial x} \left(e^{-\psi(x)} \frac{\partial u}{\partial x} \right). \tag{2.2}$$

Equation (2.2) has the form of a heat equation. In (2.2), $u(x,t)$ can be viewed as the "temperature," $e^{-\psi(x)}$ on the right-hand side as the heat conductivity, $e^{-\psi(x)}$ on the left-hand side as the specific heat capacity, and $e^{-\psi(x)} u(x,t) = \rho(x,t)$ as the heat. Equation (2.2) is equivalent to Fokker–Planck equation (1.14) when the potential is smooth. So it is natural for us to use the exact solution of (2.2) to define the exact solution of Fokker–Planck equation (1.14) when the potential is discontinuous. The biggest advantage of using (2.2) is that we can avoid the nonconservative product $\psi'(x)\rho(x,t)$ in Fokker–Planck equation (1.14). When both $\psi(x)$ and $\rho(x,t)$ are discontinuous, it is highly nontrivial to interpret the nonconservative product $\psi'(x)\rho(x,t)$ in Fokker–Planck equation (1.14) (for example, in [23], nonconservative product of the form $\frac{dw}{dx} g(w)$ is defined as a Borel measure).

In (2.2), when $\psi(x)$ is discontinuous, both the heat conductivity and the specific heat capacity are discontinuous. Away from the discontinuity, the exact solution of (2.2) satisfies differential equation (2.2) in the classical sense. At the discontinuity, the exact solution of (2.2) is constrained by two conditions. The first condition is the continuity of the "heat flux," which corresponds to the conservation of heat. The second condition is the continuity of the "temperature," which follows from the regularizing properties of the heat equation. The continuity of the "temperature" also reflects the physical nature of the heat conduction process: temperature gradient is relaxed by the heat flow that is induced by the temperature gradient. In particular, any isolated discontinuity in temperature will be removed immediately by heat conduction.

Now we write the two conditions in terms of $\rho(x,t)$ and $\psi(x)$. The first condition (continuity of "heat flux") is

$$\left(\psi'(x)\rho + \frac{\partial \rho}{\partial x} \right) \Big|_{x = x_d^-} = \left(\psi'(x)\rho + \frac{\partial \rho}{\partial x} \right) \Big|_{x = x_d^+}. \tag{2.3}$$

For Fokker–Planck equation (1.14), condition (2.3) means that the probability flux into the discontinuity is the same as the probability flux out of the discontinuity (i.e., the conservation of probability at the discontinuity), which corresponds to the well-known Rankine–Hugoniot condition for weak solutions of hyperbolic equations [24]. The second condition (continuity of "temperature") is

$$\left(e^{\psi(x)}\rho(x,t)\right)\Big|_{x=x_d^-} = \left(e^{\psi(x)}\rho(x,t)\right)\Big|_{x=x_d^+}. \tag{2.4}$$

Equations (2.3) and (2.4) are the two conditions that the exact solution of a discontinuous Fokker–Planck equation must satisfy at the discontinuity. If a numerical method is based on conservation of probability, then the numerical solution will automatically satisfy condition (2.3). As we will see in section 7, condition (2.4) is related to detailed balance. If a numerical method does not preserve detailed balance, then the numerical solution may converge to a wrong solution that does not satisfy condition (2.4).

3. The numerical method. In this section, we summarize Method 1 proposed in [16]. In the spatial discretization of (1.14), we divide the period $[0,1]$ into M subintervals of size $h = 1/M$. Each subinterval is represented by its center (a site), and the numerical grid is formed as

$$h = \frac{1}{M}, \qquad x_j = \frac{h}{2} + jh, \qquad x_{j-1/2} = \frac{h}{2} + \left(j - \frac{1}{2}\right) h.$$

Since the underlying stochastic evolution (1.12) is a continuous Markov process, we discretize it as a jump process (discrete Markov process). The idea of using a jump process on discrete sites to approximate a continuous Markov process was originated in [18] and in an unpublished result by C. Peskin. As shown in Figure 3.1, in the spatial discretization, subinterval j is $\left[x_{j-1/2}, x_{j+1/2}\right]$ and its center is x_j. The motor system can reside only on a set of discrete sites $\{x_j\}$. In a single jump, it can jump only to one of the two adjacent sites. Let $h \cdot p_j(t)$ be the probability that the motor system is at site x_j at time t in the jump process. $p_j(t)$ can be viewed as

$$p_j(t) \approx \frac{1}{h}\int_{x_{j-1/2}}^{x_{j+1/2}} \rho(x,t)dx \approx \rho(x_j,t). \tag{3.1}$$

Let $F_{j+1/2}$ be the rate of jumping from x_j to x_{j+1} (forward jump) and $B_{j+1/2}$ the rate of jumping from x_{j+1} to x_j (backward jump). The numerical probability flux through $x_{j+1/2}$ is

$$J_{j+1/2} = h\left(F_{j+1/2}\, p_j - B_{j+1/2}\, p_{j+1}\right). \tag{3.2}$$

The time evolution of $p_j(t)$ is governed by the conservation of probability:

$$\begin{aligned} \frac{dp_j}{dt} &= \frac{1}{h}\left(J_{j-1/2} - J_{j+1/2}\right) \\ &= \left(F_{j-1/2}\, p_{j-1} - B_{j-1/2}\, p_j\right) - \left(F_{j+1/2}\, p_j - B_{j+1/2}\, p_{j+1}\right). \end{aligned} \tag{3.3}$$

Before we describe how the jump rates $F_{j+1/2}$ and $B_{j+1/2}$ are calculated in Method 1, we would like to point out that (3.3) is a very general framework. It can even accommodate the central difference method, which can be cast into the form of (3.3) with

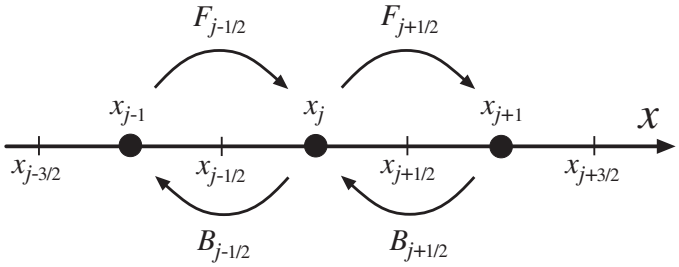

FIG. 3.1. *Spatial discretization of* (1.14). *The motor system is restricted to a set of discrete sites* $\{x_j\}$ *and can jump only to adjacent sites.*

jump rates

$$F_{j+1/2}^{(CD)} = \frac{1}{h^2}\left(1 - \frac{\delta\psi_{j+1/2}}{2}\right),$$
$$B_{j+1/2}^{(CD)} = \frac{1}{h^2}\left(1 + \frac{\delta\psi_{j+1/2}}{2}\right), \tag{3.4}$$

where

$$\delta\psi_{j+1/2} = \psi(x_{j+1}) - \psi(x_j). \tag{3.5}$$

Notice, however, that the jump rates (3.4) associated with the central difference method may be negative. Even in the limit of $h \to 0$, the jump rates (3.4) may be negative when the potential $\psi(x)$ is discontinuous. This explains why the central difference method converges to a wrong solution (as we will see in section 7).

In Method 1 [16], the jump rates are calculated based on local approximate solutions. In calculating $F_{j+1/2}$ and $B_{j+1/2}$, we make two assumptions:

1. In $[x_{j-1/2}, x_{j+3/2}]$, potential $\psi(x)$ is linear with slope $\delta\psi_{j+1/2}/h$. This assumption is to make the method simple and easy to implement. Under this assumption, the potential in $[x_{j-1/2}, x_{j+3/2}]$ is given by

$$\psi(x) = C + \frac{\delta\psi_{j+1/2}}{h} \cdot x, \tag{3.6}$$

   where $\delta\psi_{j+1/2}$ is defined in (3.5).

2. Let $\rho_{j+1/2}(x)$ be the steady state solution of (1.14) in $[x_{j-1/2}, x_{j+3/2}]$ with linear potential (3.6) and subject to the condition

$$\frac{1}{h}\int_{x_{j-1/2}}^{x_{j+1/2}} \rho_{j+1/2}(x)dx = p_j,$$
$$\frac{1}{h}\int_{x_{j+1/2}}^{x_{j+3/2}} \rho_{j+1/2}(x)dx = p_{j+1}. \tag{3.7}$$

   In the jump process, the probability flux through $x_{j+1/2}$ is given by that of $\rho_{j+1/2}(x)$. This assumption is a key component of Method 1 [16]. Instead of using the Taylor expansion, the numerical approximation is based on local approximate solutions. The consequence of this approach is that detailed balance is preserved, and Method 1 works well even if the potential is discontinuous.

The probability flux of $\rho_{j+1/2}(x)$ is derived in [16] and is given by

$$J = \frac{1}{h} \cdot \frac{\delta\psi_{j+1/2}}{e^{\delta\psi_{j+1/2}} - 1} \left(p_j - e^{\delta\psi_{j+1/2}}\, p_{j+1} \right). \tag{3.8}$$

Comparing the theoretical flux (3.8) with the numerical flux (3.2), we immediately obtain

$$\begin{aligned} F_{j+1/2} &= \frac{1}{h^2} \frac{\delta\psi_{j+1/2}}{e^{\delta\psi_{j+1/2}} - 1}, \\ B_{j+1/2} &= \frac{1}{h^2} \frac{\delta\psi_{j+1/2}\, e^{\delta\psi_{j+1/2}}}{e^{\delta\psi_{j+1/2}} - 1}, \end{aligned} \tag{3.9}$$

where $\delta\psi_{j+1/2} = \psi(x_{j+1}) - \psi(x_j)$, as defined in (3.5). It is important to notice that the jump rates (3.9) are always positive. It is straightforward to verify that $F_{j+1/2}$ and $B_{j+1/2}$ are both positive when $\delta\psi_{j+1/2} \neq 0$. When $\psi_{j+1/2} = 0$, we have

$$\begin{aligned} F_{j+1/2} &= \lim_{\delta\psi \to 0} \frac{1}{h^2} \frac{\delta\psi}{e^{\delta\psi} - 1} = \frac{1}{h^2}, \\ B_{j+1/2} &= \lim_{\delta\psi \to 0} \frac{1}{h^2} \frac{\delta\psi\, e^{\delta\psi}}{e^{\delta\psi} - 1} = \frac{1}{h^2}. \end{aligned}$$

The property that the jump rates given in (3.9) are always positive will be used in the stability analysis below. The jump rates given in (3.9) also satisfy detailed balance [16]:

$$\frac{F_{j+1/2}}{B_{j+1/2}} = e^{\psi(x_j) - \psi(x_{j+1})}. \tag{3.10}$$

In the time dimension, (3.3) is discretized using a Crank–Nicolson-type method [19]. Let p_j^n be the numerical approximation for $p_j(nk)$, where k is the time step. The fully discrete method is

$$\begin{aligned} p_j^{n+1} = p_j^n + k \Bigg\{ & \left(F_{j-1/2} \frac{p_{j-1}^n + p_{j-1}^{n+1}}{2} - B_{j-1/2} \frac{p_j^n + p_j^{n+1}}{2} \right) \\ & - \left(F_{j+1/2} \frac{p_j^n + p_j^{n+1}}{2} - B_{j+1/2} \frac{p_{j+1}^n + p_{j+1}^{n+1}}{2} \right) \Bigg\}. \end{aligned} \tag{3.11}$$

In the calculation of average velocity and/or effective diffusion coefficient, (1.14) is solved with the periodic boundary condition [16]. In the analysis of subsequent sections, we always assume the periodic boundary condition:

$$p_j^n = p_{j+M}^n, \qquad \psi(x+1) = \psi(x) - \Delta\psi.$$

We will prove the stability and consistency of (3.11) when potential $\psi(x)$ is piecewise smooth and has a finite number of discontinuities at half numerical grid points.

4. Stability of the numerical method. In this section, we prove the stability of Method 1 [16]. We first show that the steady state solution of the half discrete method (3.3) is unique and is all positive. Furthermore, we show that the maximum of the steady state solution is bounded by the minimum multiplied by a constant that

is determined by the underlying physical problem but is independent of the numerical grid size. Thus, we can define a weighted 2-norm using the steady state solution as the weighting function, and the weighted 2-norm so defined is equivalent to the 2-norm. Then we prove that the fully discrete method (3.11) is unconditionally stable with respect to the weighted 2-norm.

For the convenience of mathematical discussion, we introduce vector notations for numerical solutions in one period:

$$\begin{aligned}\vec{p}^{\,n} &\equiv (p_1^n,\ p_2^n,\ \ldots,\ p_M^n)\,,\\ \vec{q} &\equiv (q_1,\ q_2,\ \ldots,\ q_M)\,,\\ \vec{r} &\equiv (r_1,\ r_2,\ \ldots,\ r_M)\,.\end{aligned}$$

Here the superscript n denotes the time level. Remember all solutions are periodic. Let $\vec{q}$ be the steady state solution of (3.3). $\vec{q}$ satisfies the equation

$$(F_{j-1/2}\,q_{j-1} - B_{j-1/2}\,q_j) - (F_{j+1/2}\,q_j - B_{j+1/2}\,q_{j+1}) = 0, \qquad j = 1, 2, \ldots, M, \tag{4.1}$$

and satisfies the constraint

$$h\sum_{j=1}^{M} q_j = 1. \tag{4.2}$$

Condition (4.2) corresponds to $\int_0^1 \rho(x)dx = 1$. We now show that $\vec{q}$ is unique, is all positive, and is bounded away from 0 and from infinity, independent of the numerical grid size.

THEOREM 4.1. *Suppose $\vec{q}$ satisfies* (4.1). *Then $\vec{q}$ is either all zeros or all positive or all negative.*

Proof. Suppose $\vec{q}$ is not all zeros. Otherwise, there is no need to continue. Without loss of generality, we assume that there is an index j_0 such that $q_{j_0} > 0$. Otherwise, we simply consider $-\vec{q}$, which also satisfies (4.1). Starting at j_0, we first search to the left for a nonpositive element. If we cannot find a nonpositive element over a distance of M grid points, then all elements are positive because the solution is periodic.

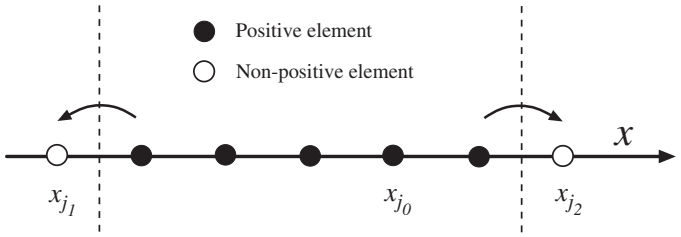

FIG. 4.1. *Starting from a positive element, $q_{j_0} > 0$, we either find that all elements are positive or find a positive region bounded by nonpositive elements. The latter leads to a contradiction.*

Suppose q_{j_1} is the first nonpositive element found in the search to the left and q_{j_2} is the first nonpositive element found in the search to the right. As shown in Figure 4.1, we have a positive region bounded by nonpositive elements:

$$q_{j_1} \le 0, \qquad q_{j_2} \le 0, \qquad \text{and } q_j > 0 \qquad \text{for } j_1 < j < j_2.$$

We are going to show that this leads to a contradiction. Summing (4.1) from $j = j_1+1$ to $j = j_2 - 1$, we obtain

$$\left(B_{j_1+1/2}\, q_{j_1+1} - F_{j_1+1/2}\, q_{j_1}\right) + \left(F_{j_2-1/2}\, q_{j_2-1} - B_{j_2-1/2}\, q_{j_2}\right) = 0. \tag{4.3}$$

The two terms on the left-hand side of (4.3) are the net probability fluxes to the outside of the region. Recall that the jump rates in Method 1 are always positive. Because $q_{j_1+1} > 0$ and $q_{j_1} \le 0$, the first term is positive. Similarly, the second term is also positive. Thus, the total net probability flux to the outside of the region is positive. This contradicts that $\vec{q}$ is a steady state. Mathematically, the contradiction arises in (4.3), where the two positive terms sum to zero. Therefore, if one element is positive, then all elements must be positive. ∎

Remark. The proof presented here can be extended to Fokker–Planck equations of higher dimensions, in which the positive region is bounded by a combination of nonpositive elements and a periodic boundary. The total net probability flux to the outside of the region is positive, which contradicts the steady state assumption.

THEOREM 4.2. *Suppose $\vec{q}$ satisfies* (4.1) *and* (4.2). *Then $\vec{q}$ is unique and all positive.*

Proof. Suppose both $\vec{q}$ and $\vec{p}$ satisfy (4.1) and (4.2). Let $\vec{r} = \vec{q} - \vec{p}$. Then $\vec{r}$ satisfies (4.1). Applying Theorem 4.1 to $\vec{r}$ yields that $\vec{r}$ is either all zeros or all positive or all negative. Since $\vec{r}$ also satisfies $h\sum_{j=1}^{M} r_j = 0$, $\vec{r}$ must be all zeros. Consequently, $\vec{q}$ is unique. Applying Theorem 4.1 to $\vec{q}$ and using (4.2), we obtain that $\vec{q}$ is all positive. ∎

Remark. This theorem shows that the solution of (4.1) with condition (4.2) is unique and all positive. In other words, Method 1 yields a unique steady state solution and preserves the positivity of probability. As pointed above, this result can be extended to Fokker–Planck equations of higher dimensions.

Now we consider the 2-norm and the weighted 2-norm defined as

$$\|\vec{p}\|_2 \equiv \left(h\sum_{j=1}^{M} (p_j)^2\right)^{\frac{1}{2}},$$

$$\|\vec{p}\|_\psi \equiv \left(h\sum_{j=1}^{M} \frac{1}{q_j}\,(p_j)^2\right)^{\frac{1}{2}}, \qquad h = \frac{1}{M}, \tag{4.4}$$

where $\vec{q} = (q_1,\ q_2,\ \ldots,\ q_M)$ is the solution of (4.1) with condition (4.2). In the analysis below, $\vec{q} = (q_1,\ q_2,\ \ldots,\ q_M)$ is reserved to denote this steady state solution. The 2-norm is denoted by $\|\bullet\|_2$. The weighted 2-norm is denoted by $\|\bullet\|_\psi$ because the weighting function $\vec{q}$ depends on potential $\psi(x)$.

THEOREM 4.3. *Suppose the free energy drop satisfies $\Delta\psi = \psi(x) - \psi(x+1) > 0$. Then the steady state probability flux of* (4.1), *$\tilde{J} = h\left(F_{j+1/2}\, q_j - B_{j+1/2}\, q_{j+1}\right)$, must be positive.*

Proof. We use proof by contradiction. Suppose $\tilde{J} \le 0$. Recall that Method 1 satisfies detailed balance (3.10). It follows that

$$q_{j+1} \ \ge\ \frac{F_{j+1/2}}{B_{j+1/2}}\, q_j = e^{\psi(x_j)-\psi(x_{j+1})}\, q_j.$$

Applying the inequality for $j,\ j+1,\ \ldots$, we obtain

$$q_{j+M} \ \ge\ e^{\psi(x_j)-\psi(x_{j+M})}\, q_j = e^{\Delta\psi}\, q_j > q_j,$$

which contradicts the periodic condition $q_{j+M} = q_j$. In the above, we have used the condition $\Delta\psi > 0$. Therefore, when $\Delta\psi$ is positive, $\tilde{J}$ must be positive. ∎

Remark. The key component in the proof of this theorem is detailed balance (3.10). A method preserving detailed balance has the advantage that the direction of chemical reaction and mechanical motion is preserved in numerical results. That is, the method will not produce a numerical result in which the motor system goes upward along the free energy landscape. This property is very important in studies of molecular motors.

THEOREM 4.4. *Suppose $\Delta\psi > 0$, and $\vec{q}$ satisfies* (4.1) *and* (4.2). *Then we have*

$$\max_j q_j \le e^{C_\psi}, \qquad \min_j q_j \ge e^{-C_\psi}, \tag{4.5}$$

where C_ψ depends on potential $\psi(x)$ but is independent of the numerical grid size.

Proof. Equation (4.1) implies that

$$\left(F_{j+1/2}\, q_j - B_{j+1/2}\, q_{j+1}\right) = \frac{\tilde{J}}{h}, \quad \text{independent of } j, \tag{4.6}$$

where $\tilde{J}$ is the steady state probability flux. Applying Theorem 4.3, we have $\tilde{J} > 0$, and (4.6) becomes

$$\left(F_{j+1/2}\, q_j - B_{j+1/2}\, q_{j+1}\right) \ge 0.$$

Recall that Method 1 satisfies detailed balance (3.10). It follows that

$$q_{j+1} \;\le\; \frac{F_{j+1/2}}{B_{j+1/2}}\, q_j = e^{\psi(x_j)-\psi(x_{j+1})}\, q_j. \tag{4.7}$$

Let $q_l = \min_j q_j$. Applying inequality (4.7) for $j = l$, $j = l+1$, ..., we get

$$q_j \;\le\; e^{\psi(x_l)-\psi(x_j)}\, q_l \quad \text{for } j \ge l. \tag{4.8}$$

Let $C_\psi = \max_x \max_{x\le y\le x+1} (\psi(x) - \psi(y))$. C_ψ is a constant independent of the numerical grid size. Taking the maximum of both sides of (4.8) over $l \le j \le l + M$, and noticing that $\vec{q}$ is periodic, we obtain

$$\max_j q_j \;\le\; e^{C_\psi}\, q_l = e^{C_\psi} \min_j q_j. \tag{4.9}$$

Since $\vec{q}$ also satisfies (4.2), we have

$$\min_j q_j \le h \sum_{j=1}^{M} q_j = 1, \qquad \max_j q_j \ge h \sum_{j=1}^{M} q_j = 1. \tag{4.10}$$

Equations (4.9) and (4.10) lead immediately to (4.5). ∎

Remark. This theorem shows that the weighted 2-norm is equivalent to the 2-norm

$$e^{-C_\psi} \|\vec{p}\|_2 \;\le\; \|\vec{p}\|_\psi \;\le\; e^{C_\psi} \|\vec{p}\|_2. \tag{4.11}$$

The extension of this theorem to Fokker–Planck equations of higher dimensions is still an open problem (we believe the theorem is valid for Fokker–Planck equations of higher dimensions, but the proof is still an open problem). We are going to use the weighted 2-norm to study the stability of the fully discrete method (3.11).

THEOREM 4.5. *Let $\vec{p}^{\,n} = (p_1^n, p_2^n, \ldots, p_M^n)$ denote the solution of the fully discrete method* (3.11) *at time level n. Then we have*

$$\|\vec{p}^{\,n+1}\|_\psi \le \|\vec{p}^{\,n}\|_\psi. \tag{4.12}$$

Proof. First, we write (3.11) as

$$p_j^{n+1} - p_j^n = \frac{k}{h}\left(J_{j-1/2}^{n+1/2} - J_{j+1/2}^{n+1/2}\right), \tag{4.13}$$

where

$$J_{j+1/2}^{n+1/2} = h\left(F_{j+1/2}\, p_j^{n+1/2} - B_{j+1/2}\, p_{j+1}^{n+1/2}\right), \tag{4.14}$$

$$p_j^{n+1/2} = \frac{p_j^{n+1} + p_j^n}{2}.$$

Multiplying both sides of (4.13) by $2\,h\,p_j^{n+1/2}$, dividing by q_j, and summing over j yields

$$h\sum_{j=1}^{M}\frac{1}{q_j}\,(p_j^{n+1})^2 - h\sum_{j=1}^{M}\frac{1}{q_j}\,(p_j^n)^2 = 2k\sum_{j=1}^{M}\frac{1}{q_j}p_j^{n+1/2}\left(J_{j-1/2}^{n+1/2} - J_{j+1/2}^{n+1/2}\right).$$

Applying summation by parts and using the periodic condition, we get

$$\|\vec{p}^{\,n+1}\|_\psi^2 - \|\vec{p}^{\,n}\|_\psi^2 = -2k\sum_{j=1}^{M}\left(\frac{1}{q_j}p_j^{n+1/2} - \frac{1}{q_{j+1}}p_{j+1}^{n+1/2}\right)J_{j+1/2}^{n+1/2}. \tag{4.15}$$

Let $r_j = \frac{p_j^{n+1/2}}{q_j}$. Here, for simplicity and without causing confusion, we have dropped the superscript $(n+1/2)$ from r_j. We write the probability flux $J_{j+1/2}^{n+1/2}$ as

$$\begin{aligned} J_{j+1/2}^{n+1/2} &= h\left(F_{j+1/2}\, p_j^{n+1/2} - B_{j+1/2}\, p_{j+1}^{n+1/2}\right) \\ &= h\left(F_{j+1/2}\, q_j\, r_j - B_{j+1/2}\, q_{j+1}\, r_{j+1}\right) \\ &= h\left(\frac{F_{j+1/2}\, q_j + B_{j+1/2}\, q_{j+1}}{2}\right)(r_j - r_{j+1}) + \tilde{J}\cdot\frac{r_j + r_{j+1}}{2}. \end{aligned}$$

Here $\tilde{J} = h\left(F_{j+1/2}\, q_j - B_{j+1/2}\, q_{j+1}\right)$ is the steady state probability flux, which is a constant independent of j. Substituting $J_{j+1/2}^{n+1/2}$ into (4.15), we have

$$\begin{aligned} \|\vec{p}^{\,n+1}\|_\psi^2 - \|\vec{p}^{\,n}\|_\psi^2 = &-kh\sum_{j=1}^{M}\left(F_{j+1/2}\, q_j + B_{j+1/2}\, q_{j+1}\right)(r_j - r_{j+1})^2 \\ &- k\sum_{j=1}^{M}\tilde{J}\left((r_j)^2 - (r_{j+1})^2\right). \end{aligned} \tag{4.16}$$

Recall that in Method 1, the steady state solution $\vec{q}$ is all positive and jump rates are all positive. Consequently, the first term on the right-hand side of (4.16) is nonpositive.

Applying summation by parts and using the periodic condition, we obtain that the second term on the right-hand side of (4.16) is zero. Thus, we conclude that

$$\|\vec{p}^{\,n+1}\|_\psi^2 - \|\vec{p}^{\,n}\|_\psi^2 \le 0, \tag{4.17}$$

which immediately leads to (4.12). □

Remark 1. This theorem shows that the fully discrete method (3.11) is unconditionally stable with respect to the weighted 2-norm $\| \bullet \|_\psi$ even if potential $\psi(x)$ is discontinuous.

Remark 2. This theorem can be extended to Fokker–Planck equations of higher dimensions.

5. Consistency and convergence of the numerical method. We study the consistency of Method 1 when potential $\psi(x)$ is piecewise smooth and has a finite number of discontinuities in one period at half numerical grid points. Without loss of generality, we assume that there is only one discontinuity at x_d in $[0,1]$, where $x_d = x_{l+1/2}$ is a half numerical grid point (that is, x_d is at the boundary between two numerical subintervals). Below we will show that away from the discontinuity, the local truncation error of Method 1 on the exact solution is $O\left(k(k^2+h^2)\right)$. At the discontinuity, the local truncation error on the exact solution is $O(1)$. However, if we perturb the exact solution by a term of the order $O(h)$, then the local truncation error on the perturbed solution (instead of the exact solution) is $O\left(k(k^2+h)\right)$.

5.1. Local truncation error away from the discontinuity. We rewrite the fully discrete method (3.11) in the flux form

$$p_j^{n+1} = p_j^n + \frac{k}{h}\left(\frac{J_{j-1/2}^n + J_{j-1/2}^{n+1}}{2} - \frac{J_{j+1/2}^n + J_{j+1/2}^{n+1}}{2}\right), \tag{5.1}$$

where the numerical probability flux is

$$J_{j+1/2}^n = h\left(F_{j+1/2}\, p_j^n - B_{j+1/2}\, p_{j+1}^n\right). \tag{5.2}$$

Let $\rho(x,t)$ be the exact solution of (1.14) subject to conditions (2.3) and (2.4). Let ρ_j^n denote the exact solution on the numerical grid:

$$\rho_j^n = \rho(x_j, t_n).$$

The local truncation error is defined as the residual term when the numerical method is applied to the exact solution ρ_j^n. Integrating the differential equation (1.14) over $[x_{j-1/2}, x_{j+1/2}] \times [t_n, t_{n+1}]$, we have

$$\begin{aligned}\int_{x_{j-1/2}}^{x_{j+1/2}} \rho(x,t_{n+1})dx - \int_{x_{j-1/2}}^{x_{j+1/2}} \rho(x,t_n)dx \\ = \int_{t_n}^{t_{n+1}} J(x_{j-1/2},t)dt - \int_{t_n}^{t_{n+1}} J(x_{j+1/2},t)dt,\end{aligned} \tag{5.3}$$

where $J(x,t) = -\left(\psi'\rho + \frac{\partial \rho}{\partial x}\right)$ is the exact probability flux in (1.14). Using the trapezoidal rule to approximate the integrals on the right-hand side yields

$$\begin{aligned}\int_{t_n}^{t_{n+1}} J(x_{j+1/2},t)dt = k\left(\frac{J(x_{j+1/2},t_n) + J(x_{j+1/2},t_{n+1})}{2}\right) \\ - \frac{k^3}{12}\frac{\partial^2}{\partial t^2} J(x_{j+1/2}, t_{n+1/2}) + O(k^5).\end{aligned}$$

Since the probability flux, $J(x,t)$, is continuous across the discontinuity, the time derivatives of $J(x,t)$ are also continuous across the discontinuity. Suppose $x_{j+1/2}$ is the location of discontinuity. Then we have

$$\frac{\partial^2}{\partial t^2} J(x^+_{j+1/2}, t_{n+1/2}) = \frac{\partial^2}{\partial t^2} J(x^-_{j+1/2}, t_{n+1/2}).$$

Using the assumption that everything is smooth on both sides of the discontinuity, we obtain

$$\begin{aligned}\frac{\partial^2}{\partial t^2} J(x^-_{j+1/2}, t_{n+1/2}) - \frac{\partial^2}{\partial t^2} J(x_{j-1/2}, t_{n+1/2}) \\ = h \frac{\partial^3}{\partial t^2 \partial x} J(\xi, t_{n+1/2}) = O(h),\end{aligned}$$

where $x_{j-1/2} < \xi < x_{j+1/2}$. Expanding the integrals on the left-hand side of (5.3), using the results we just derived for the integrals on the right-hand side of (5.3), and then dividing (5.3) by h, we arrive at

$$\begin{aligned}\rho_j^{n+1} - \rho_j^n = \frac{k}{h} \Bigg(& \frac{J(x_{j-1/2}, t_n) + J(x_{j-1/2}, t_{n+1})}{2} \\ & - \frac{J(x_{j+1/2}, t_n) + J(x_{j+1/2}, t_{n+1})}{2} \Bigg) + O\left(k(k^2 + h^2)\right).\end{aligned} \tag{5.4}$$

Let $J^n_{j+1/2}\{\rho\}$ denote the numerical probability flux on the exact solution $\rho(x,t)$:

$$J^n_{j+1/2}\{\rho\} = h\left(F_{j+1/2}\, \rho_j^n - B_{j+1/2}\, \rho_{j+1}^n\right). \tag{5.5}$$

We expand $F_{j+1/2}$, $B_{j+1/2}$, ρ_j^n, and ρ_j^{n+1} around $x = x_{j+1/2}$ to obtain the following expansion for $J^n_{j+1/2}\{\rho\}$ away from the discontinuity:

$$J^n_{j+1/2}\{\rho\} = J(x_{j+1/2}, t_n) - h^2\, u(x_{j+1/2}, t_n) + O\left(h^3\right), \tag{5.6}$$

where $u(x,t)$ is a function consisting of various derivatives of $\psi(x)$ and $\rho(x,t)$. The derivation of (5.6) is presented in Appendix A. Notice that $u(x,t)$ is smooth in the region where $\psi(x)$ and $\rho(x,t)$ are smooth. Away from the discontinuity, $u(x,t)$ satisfies

$$u(x_{j+1/2}, t_n) - u(x_{j-1/2}, t_n) = O(h).$$

Substituting (5.6) into (5.4), we obtain that, away from the discontinuity, ρ_j^n satisfies

$$\begin{aligned}\rho_j^{n+1} = \rho_j^n + \frac{k}{h} \left(\frac{J^n_{j-1/2}\{\rho\} + J^{n+1}_{j-1/2}\{\rho\}}{2} - \frac{J^n_{j+1/2}\{\rho\} + J^{n+1}_{j+1/2}\{\rho\}}{2} \right) \\ + O\left(k(k^2 + h^2)\right).\end{aligned} \tag{5.7}$$

That is, away from the discontinuity, the local truncation error on the exact solution $\rho(x,t)$ is $O\left(k(k^2 + h^2)\right)$.

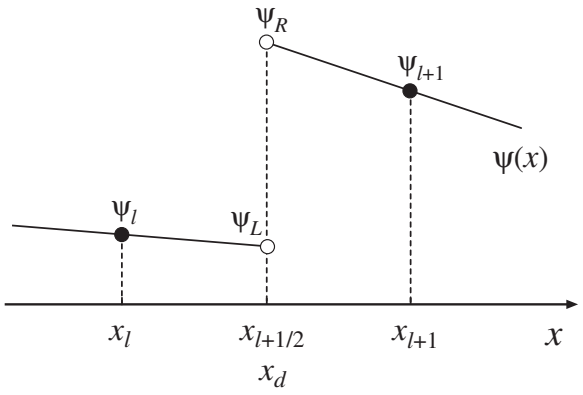

FIG. 5.1. *Schematic diagram of the discontinuity at* $x_d = x_{l+1/2}$.

5.2. Local truncation error on the perturbed solution. Now let us look at the numerical probability flux at the discontinuity. As shown in Figure 5.1, the discontinuity is at $x_d = x_{l+1/2}$. We introduce several shorthand notations:

$$\rho_L^n = \rho(x,t_n)|_{x=x_d^-}\,, \qquad \rho_R^n = \rho(x,t_n)|_{x=x_d^+}\,,$$

$$\psi_L = \psi(x)|_{x=x_d^-}\,, \qquad \psi_R = \psi(x)|_{x=x_d^+}\,.$$

The numerical probability flux on the exact solution $\rho(x,t)$ is

$$\begin{aligned} J_{l+1/2}^n\{\rho\} &= h\left(F_{l+1/2}\rho_l^n - B_{l+1/2}\rho_{l+1}^n\right) \\ &= \frac{1}{h}\,\frac{\psi_{l+1}-\psi_l}{e^{\psi_{l+1}}-e^{\psi_l}}\left(e^{\psi_l}\rho_l^n - e^{\psi_{l+1}}\rho_{l+1}^n\right) \\ &= \frac{1}{h}\,\frac{\psi_{l+1}-\psi_l}{e^{\psi_{l+1}}-e^{\psi_l}}\left(e^{\psi_l}\rho_l^n - e^{\psi_L}\rho_L^n + e^{\psi_R}\rho_R^n - e^{\psi_{l+1}}\rho_{l+1}^n\right). \end{aligned} \tag{5.8}$$

Here we have used condition (2.4): $e^{\psi_L}\rho_L^n = e^{\psi_R}\rho_R^n$. Expanding $e^{\psi_l}\rho_l^n$ around $x = x_d^-$ and $e^{\psi_{l+1}}\rho_{l+1}^n$ around $x = x_d^+$, we get

$$\begin{aligned} &e^{\psi_l}\rho_l^n - e^{\psi_L}\rho_L^n \\ &\quad= -\frac{h}{2}e^{\psi_L}\left(\psi'(x)\rho + \frac{\partial\rho}{\partial x}\right)\bigg|_{x=x_d^-} + h^2\,v_L(t_n) + h^3\,w_L(t_n) + O(h^4) \\ &\quad= \frac{h}{2}e^{\psi_L}J(x_{l+1/2},t_n) + h^2\,v_L(t_n) + h^3\,w_L(t_n) + O(h^4), \end{aligned}$$

$$\begin{aligned} &e^{\psi_R}\rho_R^n - e^{\psi_{l+1}}\rho_{l+1}^n \\ &\quad= \frac{h}{2}e^{\psi_R}J(x_{l+1/2},t_n) + h^2\,v_R(t_n) + h^3\,w_R(t_n) + O(h^4), \end{aligned}$$

where $v_L(t)$, $v_R(t)$, $w_L(t)$, and $w_R(t)$ are smooth functions of t. Substituting these two expansions into (5.8), we have

$$J_{l+1/2}^n\{\rho\} = J(x_{l+1/2},t_n) + v_0(t_n) + h\,v_1(t_n) + h^2\,v_2(t_n) + O(h^3), \tag{5.9}$$

where

$$v_0(t) = \left[\frac{\psi_R - \psi_L}{e^{\psi_R} - e^{\psi_L}}\left(\frac{e^{\psi_L} + e^{\psi_R}}{2}\right) - 1\right] J(x_{l+1/2}, t_n). \tag{5.10}$$

Again, $v_0(t)$, $v_1(t)$, and $v_2(t)$ are smooth functions of t. Combining (5.9), which gives numerical flux at the discontinuity, and (5.6), which is valid away from the discontinuity, we obtain

$$\begin{aligned} J^n_{j-1/2}\{\rho\} - J^n_{j+1/2}\{\rho\} &= \big(J(x_{j-1/2}, t_n) - J(x_{j+1/2}, t_n)\big) + O(h^3) \\ &+ h^2\left(u(x_d^+, t_n) - u(x_d^-, t_n)\right) a_j + h\left(v_0(t_n) + h\, v_1(t_n) + h^2 \tilde{v}_2(t_n)\right) b_j, \end{aligned} \tag{5.11}$$

where

$$a_j = \begin{cases} \frac{1}{2}, & j = l, \\ \frac{1}{2}, & j = l+1, \\ -h\frac{M}{M-2} & \text{otherwise}, \end{cases} \tag{5.12}$$

$$b_j = \begin{cases} -\frac{1}{h}, & j = l, \\ +\frac{1}{h}, & j = l+1, \\ 0 & \text{otherwise}, \end{cases} \tag{5.13}$$

and

$$\tilde{v}_2(t) = v_2(t) + \frac{u(x_d^+, t) + u(x_d^-, t)}{2}. \tag{5.14}$$

In (5.11), the first term on the right-hand side is the desired result; the second term is of the order $O(h^3)$; the third term is of the order $O(h^2)$ at the discontinuity and of the order $O(h^3)$ elsewhere; the fourth term is of the order $O(1)$, which is the term we need to deal with.

Terms in (5.11) contribute to the local truncation error. In general, the global error is one order lower than the local truncation error. However, the $O(1)$ term in (5.11) does not necessarily imply that the error in the numerical solution is $O(1/h)$ or is $O(1)$. As we will see below, the $O(1)$ term in (5.11) actually leads to an $O(h)$ term in the global error. The key is that the $O(1)$ term in (5.11) can be eliminated by perturbing the exact solution by an $O(h)$ term. So if we use the perturbed exact solution to calculate the local truncation error, then the $O(1)$ term in (5.11) disappears. In other words, the numerical method is consistent with the perturbed exact solution and the perturbed exact solution converges to the exact solution. The successful elimination of the $O(1)$ term in (5.11) by perturbing the exact solution by an $O(h)$ term depends on the special structure of vector $\{b_j\}$ given in (5.13). For that purpose, we have the theorem below.

THEOREM 5.1. *Suppose $\vec{r}$ is periodic, satisfies the equation*

$$h\left(F_{j-1/2}\, r_{j-1} - B_{j-1/2}\, r_j\right) - h\left(F_{j+1/2}\, r_j - B_{j+1/2}\, r_{j+1}\right) = b_j, \tag{5.15}$$

and satisfies the condition

$$\sum_{j=1}^{M} r_j = 0, \tag{5.16}$$

where b_j is defined in (5.13). *Then there exists a constant C_b, independent of the numerical grid size, such that*

$$\max_j |r_j| \le C_b.$$

Proof. The proof of Theorem 5.1 is presented in Appendix B. ∎

Now we use the result of Theorem 5.1 to eliminate the $O(1)$ error term in (5.11), and we consider the perturbed solution given below:

$$\tilde{\rho}_j^n \equiv \rho_j^n - h\left(v_0(t_n) + h\, v_1(t_n) + h^2\, \tilde{v}_2(t_n)\right) r_j = \rho_j^n + O(h), \tag{5.17}$$

where r_j is the solution of (5.15) and (5.16) in Theorem 5.1. It is straightforward to verify that the perturbed solution $\tilde{\rho}_j^n$ satisfies

$$J_{j-1/2}^n\{\tilde{\rho}\} - J_{j+1/2}^n\{\tilde{\rho}\} = \left(J(x_{j-1/2}, t_n) - J(x_{j+1/2}, t_n)\right) + O(h^2), \tag{5.18}$$

$$\tilde{\rho}_j^{n+1} - \tilde{\rho}_j^n = \rho_j^{n+1} - \rho_j^n + O(kh). \tag{5.19}$$

Substituting (5.18) and (5.19) into (5.4), we obtain

$$\begin{aligned}\tilde{\rho}_j^{n+1} = \tilde{\rho}_j^n + \frac{k}{h}\left(\frac{J_{j-1/2}^n\{\tilde{\rho}\} + J_{j-1/2}^{n+1}\{\tilde{\rho}\}}{2} - \frac{J_{j+1/2}^n\{\tilde{\rho}\} + J_{j+1/2}^{n+1}\{\tilde{\rho}\}}{2}\right)\\ + O\left(k(k^2+h)\right).\end{aligned} \tag{5.20}$$

That is, the local truncation error on the perturbed solution $\tilde{\rho}_j^n$ is $O\left(k(k^2+h)\right)$.

5.3. Convergence of the numerical method. Once we have both the stability and the consistency, the convergence follows, in principle, from the Lax equivalence theorem [17]. More specifically, we write the numerical method (3.11) in the vector-operator form

$$\vec{p}^{\,n+1} = L\,\vec{p}^{\,n}, \tag{5.21}$$

where L is the linear operator representing the numerical method. Stability (4.12) implies

$$\|L\|_\psi \le 1, \tag{5.22}$$

where $\|L\|_\psi$ is the induced operator norm defined by

$$\|L\|_\psi \equiv \max_{\|\vec{p}\|_\psi = 1} \|L\vec{p}\|_\psi.$$

Consistency (5.20) on the perturbed solution implies

$$\vec{\tilde{\rho}}^{\,n+1} = L\,\vec{\tilde{\rho}}^{\,n} + O\left(k(k^2+h)\right), \tag{5.23}$$

where $\vec{\tilde{\rho}}^{\,n}$ is the perturbed solution given in (5.17). Subtracting (5.23) from (5.21) yields

$$\vec{p}^{\,n+1} - \vec{\tilde{\rho}}^{\,n+1} = L\left[\vec{p}^{\,n} - \vec{\tilde{\rho}}^{\,n}\right] + O\left(k(k^2+h)\right). \tag{5.24}$$

Taking $\| \bullet \|_\psi$ norm of the both sides, using the stability, and summing over n, we have

$$\|\vec{p}^{\,n} - \vec{\tilde{\rho}}^{\,n}\|_\psi \le T \cdot O(k^2 + h), \qquad nk \le T. \tag{5.25}$$

Using the fact that $\vec{\tilde{\rho}}^{\,n} - \vec{\rho}^{\,n} = O(h)$, we obtain

$$\|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_\psi \le T \cdot O(k^2 + h). \tag{5.26}$$

Using Theorem 4.4, we see that (5.26) implies the convergence in the 2-norm:

$$\|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_2 \le e^{C_\psi} \|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_\psi \le e^{C_\psi}\, T \cdot O(k^2 + h). \tag{5.27}$$

If $k \le O(h)$, then (5.26) also implies the pointwise convergence

$$\|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_\infty \le \frac{1}{\sqrt{h}} \|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_2 \le e^{C_\psi}\, T \cdot O(\sqrt{h}). \tag{5.28}$$

6. The modified numerical method. In the consistency analysis of the previous section, we see the connection between the leading term in the local truncation error and the jump rates. Based on the lessons we learned in the consistency analysis, we will design a new set of jump rates to eliminate the first order error term caused by the discontinuity. The modified numerical method (hereafter referred to as Method 2) is as simple as Method 1. We will show that Method 2 is second order accurate even if the potential is discontinuous.

In the local truncation error in (5.20), the leading term $O(kh)$ comes from the term $v_0(t_n)$ in (5.9). At the discontinuity, if we use Method 1 defined in (3.9), then we have

$$v_0(t_n) = \left[\frac{\psi_R - \psi_L}{e^{\psi_R} - e^{\psi_L}} \left(\frac{e^{\psi_L} + e^{\psi_R}}{2} \right) - 1 \right] J(x_{l+1/2}, t_n) \neq 0.$$

This suggests a way of improving the performance of Method 1. We need to design the jump rates such that $v_0(t_n) = 0$ at the discontinuity. For that purpose, we propose Method 2:

$$\begin{aligned} F_{j+1/2} &= \frac{1}{h^2} \frac{2e^{\psi_j}}{e^{\psi_j} + e^{\psi_{j+1}}}, \\ B_{j+1/2} &= \frac{1}{h^2} \frac{2e^{\psi_{j+1}}}{e^{\psi_j} + e^{\psi_{j+1}}}. \end{aligned} \tag{6.1}$$

If we use Method 2 defined in (6.1), then we have

$$v_0(t_n) = \left[\frac{2}{e^{\psi_L} + e^{\psi_R}} \left(\frac{e^{\psi_L} + e^{\psi_R}}{2} \right) - 1 \right] J(x_{l+1/2}, t_n) = 0.$$

It can be shown that expansion (5.6) is still valid for Method 2. Consequently, expansion (5.11) is valid for Method 2 where $v_0(t_n) = 0$. Recall that for Method 1, the $O(1)$ term in (5.11) leads to an $O(h)$ error term in the numerical solution. For Method 2, $v_0(t_n) = 0$ kills the $O(1)$ term in (5.11). The third term in (5.11) is $O(h^2)$, and the remaining part of the fourth term in (5.11) is $O(h)$. Because of the special structures of vector $\{b_j\}$ in (5.13) and vector $\{a_j\}$ in (5.12), both the third term and the remaining part of the fourth term in (5.11) can be eliminated by perturbing the

exact solution by an $O(h^2)$ term. The elimination of these two terms by a perturbation of $O(h^2)$ makes Method 2 a second order method. For eliminating the third term in (5.11), we have the theorem below.

THEOREM 6.1. *Suppose $\vec{\sigma}$ is periodic, satisfies the equation*

$$h\left(F_{j-1/2}\,\sigma_{j-1} - B_{j-1/2}\,\sigma_j\right) - h\left(F_{j+1/2}\,\sigma_j - B_{j+1/2}\,\sigma_{j+1}\right) = a_j, \tag{6.2}$$

and satisfies the condition

$$\sum_{j=1}^{M} \sigma_j = 0, \tag{6.3}$$

where a_j is defined in (5.12). *Then there exists a constant C_a, independent of the numerical grid size, such that*

$$\max_j |\sigma_j| \le C_a.$$

Proof. The proof of Theorem 6.1 is similar to that of Theorem 5.1 and is skipped. ∎

Now we use the results of Theorems 5.1 and 6.1 to eliminate the third and fourth terms in (5.11). For Method 2, we consider the perturbed solution:

$$\begin{aligned} \hat{\rho}_j^n &\equiv \rho_j^n - h^2\left(v_1(t_n) + h\,\tilde{v}_2(t_n)\right) r_j - h^2\left(u(x_d^+, t_n) - u(x_d^-, t_n)\right)\sigma_j \\ &= \rho_j^n + O(h^2), \end{aligned} \tag{6.4}$$

where r_j is the solution of (5.15) and (5.16), and σ_j is the solution of (6.2) and (6.3). Theorems 5.1 and 6.1 guarantee that both r_j and σ_j are bounded by a constant, independent of the numerical grid size. The perturbed solution $\hat{\rho}_j^n$ satisfies

$$J_{j-1/2}^n\{\hat{\rho}\} - J_{j+1/2}^n\{\hat{\rho}\} = \left(J(x_{j-1/2}, t_n) - J(x_{j+1/2}, t_n)\right) + O(h^3), \tag{6.5}$$

$$\hat{\rho}_j^{n+1} - \hat{\rho}_j^n = \rho_j^{n+1} - \rho_j^n + O(kh^2). \tag{6.6}$$

Thus, the local truncation error on the perturbed solution $\hat{\rho}_j^n$ is $O\left(k(k^2+h^2)\right)$. Repeating the derivation from (5.21) to (5.28), we obtain

$$\|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_2 \le e^{C_\psi}\, T \cdot O(k^2 + h^2), \tag{6.7}$$

$$\|\vec{p}^{\,n} - \vec{\rho}^{\,n}\|_\infty \le e^{C_\psi}\, T \cdot O(h^{\frac{3}{2}}). \tag{6.8}$$

The error bound for the ∞-norm (6.8) is derived assuming the worst case scenario. As we will see in the numerical example below, the ∞-norm of the error is usually of the same order as the 2-norm of the error.

Method 2 defined in (6.1) can be viewed as constructed by using the standard finite difference on (2.1) with a special approximation for the heat conductivity:

$$e^{-\psi(x_{j+1/2})} \approx \frac{2}{e^{\psi(x_j)} + e^{\psi(x_{j+1})}}.$$

This special approximation is essential for Method 2 to achieve second order accuracy at discontinuities. Method 1 developed in [16] can be viewed as constructed by using the standard finite difference on (2.1) with approximation

$$e^{-\psi(x_{j+1/2})} \approx \frac{\psi(x_{j+1}) - \psi(x_j)}{e^{\psi(x_{j+1})} - e^{\psi(x_j)}}.$$

The numerical method previously developed by Elston and Doering in [18] can be viewed as constructed by using the standard finite difference on (2.1) with approximation

$$e^{-\psi(x_{j+1/2})} \approx e^{-\left(\frac{\psi(x_j)+\psi(x_{j+1})}{2}\right)}.$$

7. Numerical results and discussions. Now we compare the performance of three numerical methods on a model problem with discontinuous potential. For the model problem, we select the potential

$$\psi(x) = \begin{cases} 6 - 6\sin\left(\frac{\pi}{2}(x+0.5)\right), & 0 < x < 0.5, \\ 3 - 6\sin\left(\frac{\pi}{2}(x-0.5)\right), & 0.5 < x < 1. \end{cases} \tag{7.1}$$

The graph of this discontinuous potential is shown in Figure 1.1. It has a discontinuity of amplitude 3 at $x = 0.5$. We use the initial condition

$$\rho(x, 0) = 1 + \cos(2\pi x). \tag{7.2}$$

We run simulations to $t = 1$ with a wide range of values for spatial step h, and we use time step $k = h$. We compare the performance of the central difference method (3.4), Method 1 (3.9), and Method 2 (6.1). We define the error as the difference between the numerical solution obtained with a finite value of h and the converged target (the converged target is not necessarily the correct solution of the differential equation). The behavior of the error so defined tells us whether or not a method converges. However, it does not tell us whether or not the converged target is the correct solution. We estimate the error as follows. Suppose $\vec{p}^{\,n}(h)$ is the numerical solution obtained with spatial step h and time step $k = h$. The error of $\vec{p}^{\,n}(h)$ is estimated as

$$\text{error}(h) \approx C_p \left\| \vec{p}^{\,n}(h) - \vec{p}^{\,n}\left(\frac{h}{2}\right) \right\|, \tag{7.3}$$

where C_p is a constant depending on the order of the method. For methods of first order or higher, C_p is between 1 and 2. Here we simply use $C_p = 1$ (in the worst case scenario, we underestimate the error by a factor of 2). The order of a method is estimated as

$$\text{order}(h) \approx \log_2 \left(\frac{\text{error}(h)}{\text{error}\left(\frac{h}{2}\right)} \right). \tag{7.4}$$

Figure 7.1 shows the estimated errors and estimated orders for the three methods. We follow the behavior of both the 2-norm and the ∞-norm of the estimated error. Here we are solving a nondimensionalized Fokker–Planck equation. Both the time step and the spatial step are dimensionless. So $k = h$ is just a convenient choice. Strictly speaking, the error shown in Figure 7.1 is the total error in time and space estimated by comparing the numerical solution obtained using (h, k) to that of $(\frac{h}{2}, \frac{k}{2})$. However, we find that the difference in numerical solution between (h, k) and $(h, \frac{k}{2})$ is much smaller than that between (h, k) and $(\frac{h}{2}, \frac{k}{2})$ (results not shown), which indicates that the error shown in Figure 7.1 is mainly due to the spatial discretization.

For Method 1 (the second row in Figure 7.1), the estimated error decreases as $k = h$ is reduced. From the convergence analysis in the previous sections, we know that

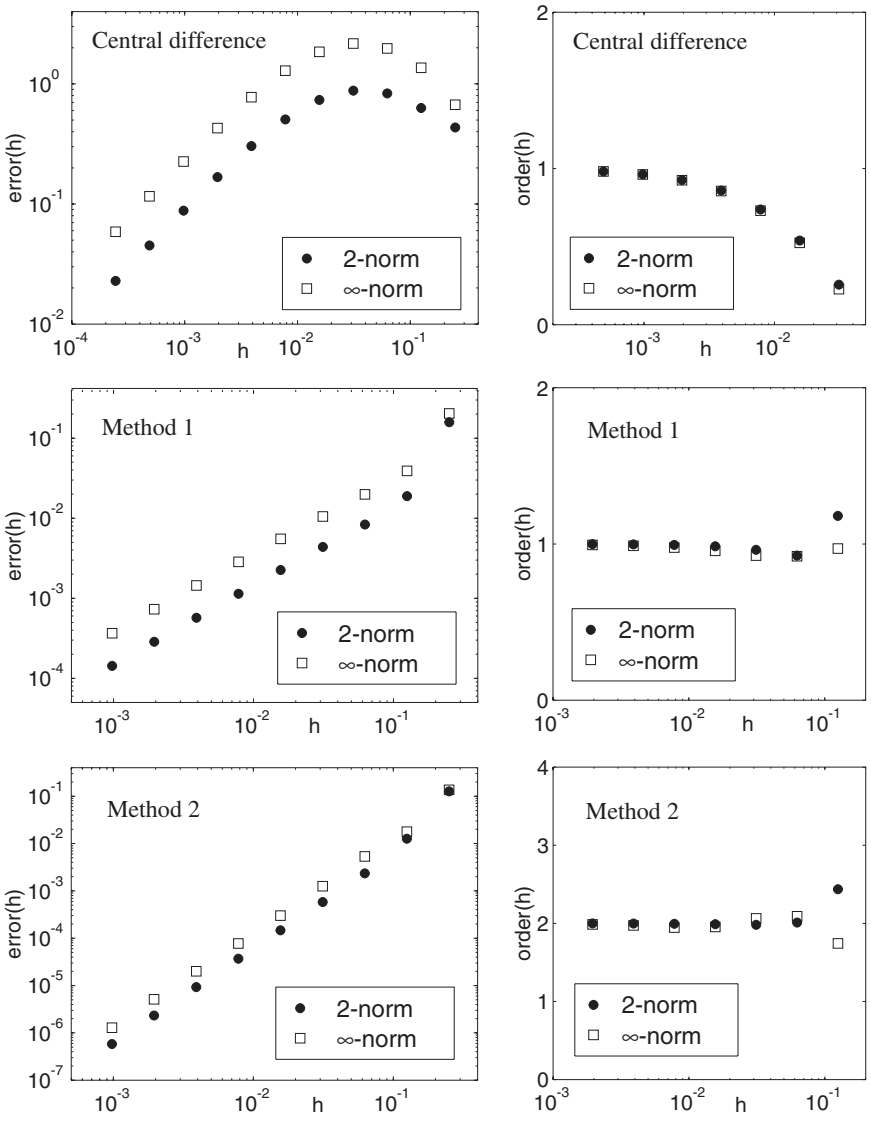

FIG. 7.1. *Estimated errors (first column) and estimated orders (second column) for the central difference method (first row), Method* 1 *(second row), and Method* 2 *(third row).*

the converged target must be the correct solution of the Fokker–Planck equation. In the presence of a discontinuity, the estimated order of accuracy of Method 1 developed in [16] is 1 for both the 2-norm and the ∞-norm. This result is consistent with the error bounds (5.27) and (5.28) derived in the previous sections. Notice that the 2-norm and the ∞-norm of the estimated error are of the same order. This tells us that although the first order error is caused by the discontinuity, it is spread to the whole region by diffusion.

For Method 2 (the third row in Figure 7.1), the estimated error decreases more rapidly as $k = h$ is reduced. The convergence analysis in the previous sections guarantees that Method 2 converges to the correct solution of the Fokker–Planck equation.

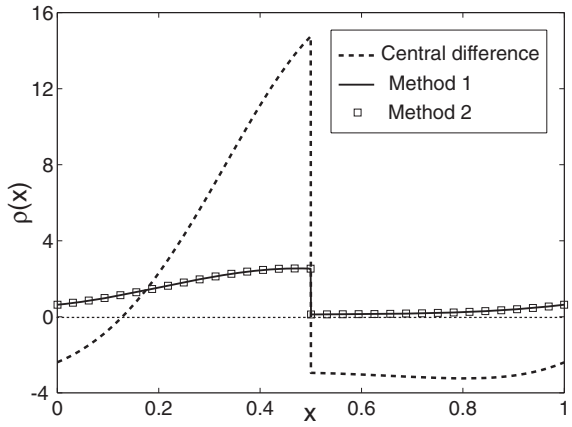

FIG. 7.2. *Numerical probability densities at $t = 1$ obtained with spatial and time steps $h = k = \frac{1}{4096}$ using, respectively, the central difference method, Method* 1*, and Method* 2*.*

Even in the presence of a discontinuity, the estimated order of accuracy for Method 2 is 2 for both the 2-norm and the ∞-norm. This result is consistent with the error bounds (6.7) and (6.8) derived in the previous section.

For the central difference method (the first row in Figure 7.1), it appears that the estimated error converges to zero as $k = h$ goes to zero. The convergence to the target is very slow. Even with $k = h = \frac{1}{4096}$, both the 2-norm and the ∞-norm of the error are still above 10^{-2}. But this is not the only defect of the central difference method. The fatal defect of the central difference method is that it converges to a wrong solution that does not satisfies condition (2.4) at the discontinuity. Figure 7.2 shows the numerical probability densities at $t = 1$ for the three methods. Notice that the probability density obtained using the central difference method is *negative* for $x > 0.5$. This is definitely wrong because the probability can never be negative. This defect of the central difference method is caused by the fact that the jump rates (3.4) may be negative at the discontinuity. Suppose the discontinuity is at $x_{l+1/2}$. The numerical probability flux at $x_{l+1/2}$ is

$$\begin{aligned} J_{l+1/2} &= h\left(F_{l+1/2}\, p_l - B_{l+1/2}\, p_{l+1}\right) \\ &= h\, B_{l+1/2}\, p_l \left[\frac{F_{l+1/2}}{B_{l+1/2}} - \frac{p_{l+1}}{p_l}\right]. \end{aligned} \tag{7.5}$$

A necessary condition for converging to the correct solution is

$$\begin{aligned} &\lim_{h\to 0} p_l = \rho(x_d^-, t), \\ &\lim_{h\to 0} p_{l+1} = \rho(x_d^+, t), \\ &\lim_{h\to 0} J_{l+1/2} = \text{finite}. \end{aligned}$$

Applying condition (2.4) yields

$$\lim_{h\to 0} \frac{p_{l+1}}{p_l} = \frac{\rho(x_d^+, t)}{\rho(x_d^-, t)} = e^{\psi(x_d^-) - \psi(x_d^+)}.$$

Multiplying (7.5) by h, using $h^2 B_{l+1/2} = O(1)$, and taking the limit as $h \to 0$, we obtain

$$\lim_{h\to 0} \frac{F_{l+1/2}}{B_{l+1/2}} = e^{\psi(x_d^-)-\psi(x_d^+)},$$

which reduces to detailed balance (3.10). Therefore, in the presence of discontinuities, detailed balance is a necessary condition for converging to the correct solution of the differential equation. Both Method 1 developed in [16] and Method 2 proposed in this paper satisfy detailed balance. The central difference method does not. For the model problem (7.1), we have

$$e^{\psi(x_d^-)-\psi(x_d^+)} = e^{-3},$$
$$\lim_{h\to 0} \frac{F^{(CD)}_{l+1/2}}{B^{(CD)}_{l+1/2}} = \frac{1 - \frac{\psi(x_d^+)-\psi(x_d^-)}{2}}{1 + \frac{\psi(x_d^+)-\psi(x_d^-)}{2}} = \frac{-1}{5} < 0.$$

The negative value of $\frac{F_{l+1/2}}{B_{l+1/2}}$ will force the ratio $\frac{p_{l+1}}{p_l}$ to be negative, which leads to negative probability in the numerical solution of the central difference method.

In conclusion, we have proved that Method 1 developed in [16] is stable and is consistent with the Fokker–Planck equation. Method 1 converges to the correct solution of the Fokker–Planck equation, and the 2-norm of the error behaves like $O(k^2 + h)$ when the potential is discontinuous. Numerical results indicate that the ∞-norm of the error is of the same order. Based on the consistency analysis, we proposed a modified version of Method 1 to eliminate the first order error caused by the discontinuity. The modified numerical method (Method 2) is guaranteed to converge to the correct solution, and the 2-norm of the error behaves like $O(k^2 + h^2)$ even in the presence of discontinuities. Again, numerical results indicate that the ∞-norm of the error is of the same order.

In stochastic ratchets with discontinuous force [20], also known as sharp stochastic ratchets [21], the potential is continuous, but the derivative of the potential is discontinuous. Originally in [20] and subsequently in [21], the transport in stochastic ratchets was studied where a particle is driven by a continuous piecewise linear potential, the Brownian noise (white noise), and an additional colored noise. They derived analytic expressions for the steady state particle current for various asymptotic limits. Now we look at the convergence of numerical methods in the case of sharp stochastic ratchets. When the potential is continuous and piecewise smooth, both Method 1 and Method 2 (the modified numerical method) converge, and the error behaves like $O(k^2 + h^2)$. This can be seen by going back to section 5. In the local truncation error in (5.20), the leading term $O(kh)$ comes from the term $v_0(t_n)$ in (5.9). $v_0(t_n)$ is nonzero only at discontinuities. For Method 1, $v_0(t_n)$ is given in (5.10). At a discontinuity on the derivative of a continuous function, we have $\psi_L = \psi_R$ and consequently $v_0(t_n) = 0$. Thus, Method 1 is second order when the potential is continuous. Method 2 (the modified numerical method) is already second order even when the potential is discontinuous.

All of the conclusions above for Method 1 are also true for the numerical method previously developed by Elston and Doering [18]. More specifically, the numerical stability proved in section 4 depends on two main features of the numerical method, (i) all jump rates being positive and (ii) detailed balance being preserved, which are satisfied in the method of [18]. The numerical consistence away from the discontinuities is obtained by doing Taylor expansion. The key feature we utilized in section 5

to derive the numerical consistence at the discontinuities is again detailed balance. Therefore, all the analysis in sections 4 and 5 for Method 1 can be extended to the method in [18].

In the numerical simulations above, we also examined the behavior of the central difference method. We found that in the presence of discontinuities, the central difference method converges to a wrong solution that does not satisfy condition (2.4). We showed that in the presence of discontinuities, detailed balance is a necessary condition for converging to the correct solution. Both Method 1 and Method 2 satisfy detailed balance. The central difference method does not, which explains the fatal defect of the central difference method.

Appendix A. In this appendix, we derive (5.6). We start by expanding function $\frac{x}{e^x-1}$ around $x=0$:

$$\frac{x}{e^x-1} = 1 - \frac{1}{2}x + \frac{1}{12}x^2 + 0 \times x^3 + O\left(x^4\right). \tag{A.1}$$

Using (A.1) to expand jump rates $F_{j+1/2}$ and $B_{j+1/2}$ in terms of $\delta\psi_{j+1/2}$, we get

$$\begin{aligned} F_{j+1/2} &= \frac{1}{h^2}\frac{\delta\psi_{j+1/2}}{e^{\delta\psi_{j+1/2}}-1} \\ &= \frac{1}{h^2}\left[1 - \frac{1}{2}\delta\psi_{j+1/2} + \frac{1}{12}(\delta\psi_{j+1/2})^2 + O\left((\delta\psi_{j+1/2})^4\right)\right], \end{aligned} \tag{A.2}$$

$$\begin{aligned} B_{j+1/2} &= \frac{1}{h^2}\frac{\delta\psi_{j+1/2}\, e^{\delta\psi_{j+1/2}}}{e^{\delta\psi_{j+1/2}}-1} \\ &= \frac{1}{h^2}\frac{(-\delta\psi_{j+1/2})}{e^{-\delta\psi_{j+1/2}}-1} \\ &= \frac{1}{h^2}\left[1 + \frac{1}{2}\delta\psi_{j+1/2} + \frac{1}{12}(\delta\psi_{j+1/2})^2 + O\left((\delta\psi_{j+1/2})^4\right)\right]. \end{aligned} \tag{A.3}$$

Substituting $F_{j+1/2}$, $B_{j+1/2}$, ρ_j^n, and ρ_{j+1}^n into (5.2) yields

$$\begin{aligned} J_{j+1/2}^n &= h\left(F_{j+1/2}\,\rho_j^n - B_{j+1/2}\,\rho_{j+1}^n\right) \\ &= \frac{1}{h}\left[\left(\rho_j^n - \rho_{j+1}^n\right) - \frac{1}{2}\delta\psi_{j+1/2}\left(\rho_j^n + \rho_{j+1}^n\right)\right. \\ &\qquad \left. + \frac{1}{12}(\delta\psi_{j+1/2})^2\left(\rho_j^n - \rho_{j+1}^n\right) + O\left((\delta\psi_{j+1/2})^4\right)\right]. \end{aligned} \tag{A.4}$$

Expanding $\delta\psi_{j+1/2}$, ρ_j^n, and ρ_{j+1}^n around $x = x_{j+1/2}$, we have

$$\delta\psi_{j+1/2} = h\,\psi'_{j+1/2} + \frac{h^3}{24}\psi'''_{j+1/2} + O\left(h^5\right),$$

$$\rho_j^n - \rho_{j+1}^n = -h\left(\frac{\partial\rho}{\partial x}\right)_{j+1/2}^n - \frac{h^3}{24}\left(\frac{\partial^3\rho}{\partial x^3}\right)_{j+1/2}^n + O\left(h^5\right),$$

$$\rho_j^n + \rho_{j+1}^n = 2\left(\rho(x,t)\right)_{j+1/2}^n + \frac{h^2}{4}\left(\frac{\partial^2\rho}{\partial x^2}\right)_{j+1/2}^n + O\left(h^4\right).$$

Here we used the shorthand notation $(g(x,t))_j^n = g(x_j, t_n)$. Substituting these expansions into (A.4), we obtain the expansion for the probability flux

$$J_{j+1/2}^n = -\left(\psi'\rho + \frac{\partial \rho}{\partial x}\right)_{j+1/2}^n - h^2\left(\frac{1}{24}\frac{\partial^3 \rho}{\partial x^3} + \frac{1}{8}\psi'\frac{\partial^2 \rho}{\partial x^2} + \frac{1}{12}(\psi')^2\frac{\partial \rho}{\partial x} + \frac{1}{24}\psi'''\rho\right)_{j+1/2}^n + O\left(h^3\right),$$

which corresponds to (5.6).

Appendix B. In this appendix, we prove Theorem 5.1. We first rewrite the numerical probability flux as

$$\begin{aligned} J_{j+1/2} &= h\left(F_{j+1/2}\, r_j - B_{j+1/2}\, r_{j+1}\right) \\ &= \frac{1}{h}\,\frac{\psi_{j+1}-\psi_j}{e^{\psi_{j+1}}-e^{\psi_j}} e^{\psi_j}\, r_j - \frac{1}{h}\,\frac{\psi_{j+1}-\psi_j}{e^{\psi_{j+1}}-e^{\psi_j}} e^{\psi_{j+1}}\, r_{j+1} \\ &= \frac{1}{h}\,\frac{\psi_{j+1}-\psi_j}{e^{\psi_{j+1}}-e^{\psi_j}}\left(e^{\psi_j}\, r_j - e^{\psi_{j+1}}\, r_{j+1}\right). \end{aligned} \tag{B.1}$$

Suppose r_j is the solution of (5.15) and (5.16). Let $\tilde{r}_j = e^{\psi_j}\, r_j$. $\tilde{r}_j$ satisfies the equation

$$\frac{1}{h}\,\frac{\psi_j-\psi_{j-1}}{e^{\psi_j}-e^{\psi_{j-1}}}\left(\tilde{r}_{j-1}-\tilde{r}_j\right) - \frac{1}{h}\,\frac{\psi_{j+1}-\psi_j}{e^{\psi_{j+1}}-e^{\psi_j}}\left(\tilde{r}_j-\tilde{r}_{j+1}\right) = b_j \tag{B.2}$$

and the condition

$$\sum_{j=1}^{M} e^{-\psi_j}\,\tilde{r}_j = 0. \tag{B.3}$$

We construct $\tilde{r}_j$ starting at $j = l+1$ with

$$\tilde{r}_{l+1} = -c_1 \quad \text{and} \quad \frac{1}{h}\,\frac{\psi_{l+2}-\psi_{l+1}}{e^{\psi_{l+2}}-e^{\psi_{l+1}}}\left(\tilde{r}_{l+1}-\tilde{r}_{l+2}\right) = -c_2,$$

where c_1 and c_2 are two coefficients to be determined. Because b_j, as defined in (5.13), satisfies $b_j = 0$ for $j = l+2, \ldots, M+l-1$, we immediately obtain that

$$\frac{1}{h}\,\frac{\psi_{j+1}-\psi_j}{e^{\psi_{j+1}}-e^{\psi_j}}\left(\tilde{r}_j-\tilde{r}_{j+1}\right) = -c_2 \quad \text{for } j = l+2, \ldots, M+l-1.$$

This allows us to write $\tilde{r}_{j+1}$ in terms of $\tilde{r}_j$:

$$\tilde{r}_{j+1} = \tilde{r}_j + c_2\left(h\frac{e^{\psi_{j+1}}-e^{\psi_j}}{\psi_{j+1}-\psi_j}\right).$$

Summing over j, we get

$$\tilde{r}_i = -c_1 + c_2\sum_{j=l+1}^{i-1}\left(h\frac{e^{\psi_{j+1}}-e^{\psi_j}}{\psi_{j+1}-\psi_j}\right) \quad \text{for } i = l+2, \ldots, M+l. \tag{B.4}$$

For $\tilde{r}_j$ to solve (B.2), it needs to satisfy

$$\frac{1}{h}\,\frac{\psi_{l+1}-\psi_l}{e^{\psi_{l+1}}-e^{\psi_l}}\left(\tilde{r}_l-\tilde{r}_{l+1}\right) = \frac{1}{h} - c_2. \tag{B.5}$$

Using the fact that $\tilde{r}_j$ is periodic and substituting (B.4) into (B.5) yields an equation for c_2:

$$c_2 \frac{\psi_{l+1} - \psi_l}{e^{\psi_{l+1}} - e^{\psi_l}} \sum_{j=l+1}^{M+l-1} \left(h \frac{e^{\psi_{j+1}} - e^{\psi_j}}{\psi_{j+1} - \psi_j} \right) = 1 - c_2 h. \tag{B.6}$$

It follows that

$$c_2 = \left[h + \frac{\psi_{l+1} - \psi_l}{e^{\psi_{l+1}} - e^{\psi_l}} \sum_{j=l+1}^{M+l-1} \left(h \frac{e^{\psi_{j+1}} - e^{\psi_j}}{\psi_{j+1} - \psi_j} \right) \right]^{-1}. \tag{B.7}$$

The sum in (B.7) is approximately an integral

$$\sum_{j=l+1}^{M+l-1} \left(h \frac{e^{\psi_{j+1}} - e^{\psi_j}}{\psi_{j+1} - \psi_j} \right) = \int_0^1 e^{\psi(x)} dx + O(h).$$

Substituting this result into (B.7), we have

$$c_2 = \frac{e^{\psi_R} - e^{\psi_L}}{\psi_R - \psi_L} \left[\int_0^1 e^{\psi(x)} dx \right]^{-1} + O(h). \tag{B.8}$$

Thus, for h small enough, c_2 is positive and bounded.

c_1 is determined by condition (B.3). Notice that $\tilde{r}_j$, as given in (B.4), is monotonically increasing for $j = l+1, \ldots, M+l$. If $c_1 = 0$, then we have $\tilde{r}_{l+1} = 0$ and $\tilde{r}_j > 0$ for $j = l+2, \ldots, M+l$. Consequently, we have $\sum_{j=1}^{M} e^{-\psi_j} \tilde{r}_j > 0$. Now we select c_1 to make $\tilde{r}_{M+l} = 0$:

$$\hat{c}_1 = c_2 \sum_{j=l+1}^{M+l-1} \left(h \frac{e^{\psi_{j+1}} - e^{\psi_j}}{\psi_{j+1} - \psi_j} \right) = \frac{e^{\psi_R} - e^{\psi_L}}{\psi_R - \psi_L} + O(h).$$

In this case, we have $\tilde{r}_{M+l} = 0$ and $\tilde{r}_j < 0$ for $j = l+1, \ldots, M+l-1$. Consequently, we have $\sum_{j=1}^{M} e^{-\psi_j} \tilde{r}_j < 0$. The value of c_1 that satisfies condition (B.3) is between 0 and $\hat{c}_1$. Thus, for h small enough, c_1 is positive and bounded:

$$0 < c_1 < \frac{e^{\psi_R} - e^{\psi_L}}{\psi_R - \psi_L} + O(h). \tag{B.9}$$

Substituting (B.8) and (B.9) into (B.4), we conclude that

$$\max_j |\tilde{r}_j| \leq \frac{e^{\psi_R} - e^{\psi_L}}{\psi_R - \psi_L} + O(h), \tag{B.10}$$

which leads directly to the conclusion of Theorem 5.1.

Acknowledgment. The author would like to thank anonymous referees for their constructive comments and suggestions in improving the manuscript.

ON CONVERGENCE OF A DOMAIN DECOMPOSITION METHOD FOR A SCALAR CONSERVATION LAW*

HUAZHONG TANG† AND GERALD WARNECKE‡

Abstract. In this paper, we prove convergence of a domain decomposition method for one-dimensional scalar conservation laws by dealing carefully with nonconservative terms at the interface of subdomains. The method consists of an explicit scheme in some subdomains and an implicit scheme in other subdomains with a numerical flux being the same as the one used in the explicit scheme. Although such a multidomain algorithm is not strictly conservative, the conservation error $CE(0, N\Delta t)$ is equal to $\mathcal{O}(\Delta t)$ regardless of the smoothness of the solution. Finally, two test examples are given to validate convergence and the computational efficiency of the present method.

Key words. hyperbolic conservation laws, domain decomposition method, explicit scheme, implicit scheme, convergence

1. Introduction.

This paper is devoted to the study of convergence of a domain decomposition method (DDM) or multidomain algorithm for scalar conservation laws

$$\frac{\partial u}{\partial t} + \frac{\partial f(u)}{\partial x} = 0, \tag{1.1}$$

with initial data

$$u(x, 0) = u_0(x), \tag{1.2}$$

where $x \in \mathbb{R}$, $t \geq 0$, and we assume that u_0 has compact support. We are considering admissible weak solutions to this initial value problem that satisfy entropy conditions such as the Kružkov entropy inequalities [20].

Hyperbolic conservation laws are of great practical importance since they arise in fluid flows, for example, reactive flows, groundwater flows, non-Newtonian flows, traffic flows, and two-phase flows in oil reservoirs. They also govern a variety of physical phenomena that appear in aeronautics, astrophysics, meteorology, semiconductors, financial modeling, front propagation, and other areas.

During the past few decades there has been a considerable amount of activity related to the construction of finite difference schemes for equations of type (1.1) and applications; see, for instance, [10, 13, 17, 19, 21, 22, 28, 29, 35] and the references therein. Explicit methods have been proved to be very efficient in capturing moving discontinuities or fronts, such as shock waves, detonation waves, and contact

discontinuities. However, they need a small time step size satisfying a Courant–Friedrichs–Lewy (CFL) condition to guarantee stability. For an implicit scheme, the time step size is also often constrained by convergence. An implicit scheme usually requires solving a nonlinear equation by some iteration method, and thus it is very time-consuming. Even for the same time step size as used in the explicit case, unsteady solutions of the implicit schemes are less accurate; see [19]. However, the implicit scheme is very attractive in simulating steady state solutions. The spatial step sizes and the "signal" speeds are the two main elements that limit a choice of the time step size. Hence, when solving numerically some initial boundary value problems (IBVP) for nonlinear partial differential equations (PDEs), it may occur that in some spatial regions there is the need for a smaller time step than in other regions. Typical examples are numerical simulations of viscous fluid flows on nonuniform meshes and other computations of solutions to PDEs on an adaptive mesh [2, 25]. Due to the above reason, the large time step schemes [23, 36, 37] and the local time step schemes [2, 7, 25, 32, 33] become attractive. The large time step schemes satisfy the CFL condition by automatically increasing the stencil with the size of the time step. They can correctly give the location of shocks with virtually no smearing, but they seem to be inconvenient in practical applications, especially in treating boundary conditions.

The local time step schemes are restricted only by a local stability condition rather than the traditional global stability condition dominated by the smallest cells. The schemes studied in [2, 25] are conservative, but they suffer a loss of consistency near a time grid interface in terms of truncation errors. The schemes proposed in [32] are consistent but slightly nonconservative. Recently, Berger, Helzel, and LeVeque [3] presented an h-box method approximating hyperbolic conservation laws on irregular grids that had a time step restriction based on a reference grid cell length that could be orders of magnitude larger than the smallest grid cell arising in the discretization.

The discrete conservation of a numerical algorithm for (1.1) is important in order to keep the correct location of the discontinuities. Hou and LeFloch [16] showed that if a nonconservative scheme for (1.1) converges, it converges to a solution of $\partial_t u + \partial_x f(u) = \mu$, where μ is a Borel measure source term that is expected to be zero in the region where the solution u is smooth and concentrated where u is not smooth. Tang and Zhou [30] analyzed the conservation error of a numerical solution caused by a nonconservative interface matching for grid interfaces and showed that the error had an upper bound when the solution itself was bounded. Even so, nonconservative schemes are also valuable in some practical applications and have been implemented successfully, for example, in computations of compressible multifluids [1] and fluid flows on an overlapping grid [26].

The DDM has been widely used in solving elliptic or parabolic equations and parallel computation of some large-scale problems. There also exist some works on applications in solving hyperbolic conservation laws. For example, Quarteroni [27] used DDMs for systems of conservation laws in connection with a spectral approximation. Grott, Chernigovskij, and Glatzel [14] applied an implicit scheme with vastly different time scales to the numerical simulation of stellar instabilities by using a DDM. However, due to a possible loss of conservation, there seems to be no theoretical analysis of a DDM for hyperbolic conservation laws.

This paper attempts to conduct a study of convergence of a DDM for hyperbolic conservation laws. The DDM we consider consists of an explicit scheme in some subdomains and an implicit scheme in other subdomains. Due to the local implicit character, such a multidomain algorithm can be used to reduce the CFL restriction

on the time step size and improve efficiency of simulating numerically some problems with multitime scale phenomena. The DDM is not strictly conservative, but we can prove that under a local stability condition for the explicit schemes, the approximate solutions constructed by the DDM will converge to the unique entropy solution to the scalar conservation laws. The main technical point in our convergence proof is to treat nonconservative terms suitably.

This paper is organized as follows. In section 2, we introduce the DDM. We consider only one space dimension. Section 3 is devoted to a study of nonlinear stability of the algorithm introduced in section 2, including the maximum principle, total variation (TV) stability, and L^1-continuity in time. In section 4 we give a proof of a cell entropy inequality. In section 5 we focus on a study of convergence of the approximate solutions constructed by the DDM. Section 6 presents numerical experiments to validate the theoretical results derived in sections 3–5.

2. A domain decomposition method. We define the domains $\Omega^1 = \{x | x \le a \text{ or } x \ge b\}$ and $\Omega^2 = \{x | a \le x \le b\}$, where a and b are two given constants, $-\infty < a < b < \infty$. Each of them is equipped with an individual mesh with a varying space step size $\Delta x_{j+\frac{1}{2}} = x_{j+1} - x_j$, where x_j denotes the coordinate of the jth grid point. We also discretize in time. Define $\Delta t_n = t_{n+1} - t_n > 0$, $n \ge 0$. As a measure of refinement we introduce $\delta = \max_{j\in\mathbb{Z},n\ge 0}\{\Delta x_{j+\frac{1}{2}}, \Delta t_n\}$. Moreover, throughout this paper, we will also use the following notation: $x_{j+\frac{1}{2}} = \frac{1}{2}(x_{j+1} + x_j)$, $\Omega^1_\delta = \{j | j < j_1 \text{ or } j \ge j_2, j \in \mathbb{Z}\}$, and $\Omega^2_\delta = \{j | j_1 \le j < j_2, j \in \mathbb{Z}\}$, where $j_1 = j_1(\delta), j_2 = j_2(\delta)$, $x_{j_1} = a$, and $x_{j_2} = b$. We also assume that $\Delta x_{j+\frac{1}{2}}/\Delta x_{j-\frac{1}{2}} = 1 + \mathcal{O}(\delta^\alpha)$ for all $j \in \mathbb{Z}$, or $\Delta t_{n-1}/\Delta t_n = 1 + \mathcal{O}(\delta^\alpha)$ for all $n \in \mathbb{N}$, where α is a positive number.

The initial condition in (1.2) is projected onto the space of piecewise constant functions as

$$u^0_{j+\frac{1}{2}} = \frac{1}{\Delta x_{j+\frac{1}{2}}} \int_{x_j}^{x_{j+1}} u_0(x)\, dx, \quad j \in \mathbb{Z}. \tag{2.1}$$

Our DDM is described as follows. A three-point explicit conservative scheme,

$$u^{n+1}_{j+\frac{1}{2}} = u^n_{j+\frac{1}{2}} - \lambda^n_{j+\frac{1}{2}} \left(h(u^n_{j+\frac{1}{2}}, u^n_{j+\frac{3}{2}}) - h(u^n_{j-\frac{1}{2}}, u^n_{j+\frac{1}{2}}) \right), \tag{2.2}$$

is used in the subdomain Ω^1, while a three-point implicit conservative scheme,

$$u^{n+1}_{j+\frac{1}{2}} = u^n_{j+\frac{1}{2}} - \lambda^n_{j+\frac{1}{2}} \left(h(u^{n+1}_{j+\frac{1}{2}}, u^{n+1}_{j+\frac{3}{2}}) - h(u^{n+1}_{j-\frac{1}{2}}, u^{n+1}_{j+\frac{1}{2}}) \right), \tag{2.3}$$

is adopted in the subdomain Ω^2, where $\lambda^n_{j+\frac{1}{2}} = \Delta t_n/\Delta x_{j+\frac{1}{2}}$. The numerical flux $h(u, v)$ is assumed to be $C^1(\mathbb{R}^2)$ and satisfy $|h_1(u, v)|, |h_2(u, v)| \le L < \infty$ for all $u, v \in \mathbb{R}$, where $h_1(\cdot, \cdot)$ and $h_2(\cdot, \cdot)$ denote the partial derivatives of $h(\cdot, \cdot)$ with respect to its first and second arguments, respectively. Moreover, we also assume that the numerical flux $h(u, v)$ is monotone; that is to say, $h(u, v)$ is nondecreasing in the first variable and nonincreasing in the second variable. The numerical flux $h(u, v)$ satisfies the consistency condition

$$h(u, u) = f(u). \tag{2.4}$$

Obviously, conservation of the total mass cannot be preserved exactly; for example, if we assume that u approaches the same constant when $j \to \pm\infty$, then we

have

$$\sum_{j\in\mathbb{R}} u^{n+1}_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}} \equiv \sum_{j<j_1} u^{n+1}_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}} + \sum_{j\geq j_2} u^{n+1}_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}} + \sum_{j_1\leq j<j_2} u^{n+1}_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}}$$
$$= \sum_{j\in\mathbb{R}} u^{n}_{j+\frac{1}{2}}\Delta x_{j+\frac{1}{2}} + CE(t_n, t_{n+1}), \tag{2.5}$$

where the additional term $CE(t_n, t_{n+1})$ is defined by

$$CE(t_n,t_{n+1}) := \Delta t_n\Big(h(u^{n+1}_{j_1-\frac{1}{2}}, u^{n+1}_{j_1+\frac{1}{2}}) - h(u^{n}_{j_1-\frac{1}{2}}, u^{n}_{j_1+\frac{1}{2}}) + h(u^{n}_{j_2-\frac{1}{2}}, u^{n}_{j_2+\frac{1}{2}})$$
$$- h(u^{n+1}_{j_2-\frac{1}{2}}, u^{n+1}_{j_2+\frac{1}{2}})\Big) \leq L\Delta t_n\Big(|u^{n}_{j_1-\frac{1}{2}} - u^{n+1}_{j_1-\frac{1}{2}}| + |u^{n}_{j_1+\frac{1}{2}} - u^{n+1}_{j_1+\frac{1}{2}}|$$
$$+ |u^{n}_{j_2-\frac{1}{2}} - u^{n+1}_{j_2-\frac{1}{2}}| + |u^{n}_{j_2+\frac{1}{2}} - u^{n+1}_{j_2+\frac{1}{2}}|\Big),$$

which is generated by the DDM algorithm at the interfaces of two subdomains. It can be considered as a measure of conservation error. It is obvious that the term $CE(t_n, t_{n+1})$ will be $\mathcal{O}(\Delta t_n^2)$ in the smooth regions of the solution, but it is only $\mathcal{O}(\Delta t_n)$ if a discontinuity is interacting with the corresponding interface $\{x = x_{j_1}, t_n \leq t \leq t_{n+1}\}$ or $\{x = x_{j_2}, t_n \leq t \leq t_{n+1}\}$. If we assume that the time step size is a constant, i.e., $\Delta t_n = \Delta t$, then the conservation error $CE(0, N\Delta t)$ is equal to

$$CE(0,N\Delta t) = \sum_{n=0}^{N-1} CE\big((n-1)\Delta t, n\Delta t\big) = \Delta t\Big(h(u^{N}_{j_1-\frac{1}{2}}, u^{N}_{j_1+\frac{1}{2}})$$
$$- h(u^{0}_{j_1-\frac{1}{2}}, u^{0}_{j_1+\frac{1}{2}})\Big) + \Delta t\left(h(u^{0}_{j_2-\frac{1}{2}}, u^{0}_{j_2+\frac{1}{2}}) - h(u^{N}_{j_2-\frac{1}{2}}, u^{N}_{j_2+\frac{1}{2}})\right)$$
$$\leq L\Delta t_n\Big(|u^{N}_{j_1-\frac{1}{2}} - u^{0}_{j_1-\frac{1}{2}}| + |u^{N}_{j_1+\frac{1}{2}} - u^{0}_{j_1+\frac{1}{2}}|$$
$$+ |u^{N}_{j_2-\frac{1}{2}} - u^{0}_{j_2-\frac{1}{2}}| + |u^{N}_{j_2+\frac{1}{2}} - u^{0}_{j_2+\frac{1}{2}}|\Big). \tag{2.6}$$

From (2.6), we may conclude that the conservative error $CE(0, N\Delta t)$ is generally $\mathcal{O}(\Delta t)$ if the solution is smooth, or a discontinuity with a finite strength is interacting with the interface $x = x_{j_1}$ or x_{j_2}. It means that the above DDM is not a bad approximation to (1.1). It is worth noting that the conservation error $CE(0, N\Delta t)$ of a general nonconservative scheme is usually equal to $\mathcal{O}(\Delta t)$ in the smooth regions of the solution and to $\mathcal{O}(1)$ when the solution is discontinuous. In practical applications, we can generally avoid the interaction of discontinuities with the interface of subdomains by decomposing the domains appropriately at the different times. In test cases where the shock position is known, for instance, one can avoid decomposing there. In applications where this is not the case an approximate estimate of shock positions, e.g., by a numerical shock indicator, would have to be used. Nevertheless, it seems to be difficult to improve the total nonconservation error $CE(0, N\Delta t)$ in theory because

$$CE(0,N\Delta t) = \sum_{n=0}^{N-1} CE\big((n-1)\Delta t, n\Delta t\big) = N\mathcal{O}(\Delta t^2) = \mathcal{O}(\Delta t).$$

Remark 2.1. The two numerical fluxes adopted in (2.2) and (2.3) have been assumed to be the same. This will be crucial to get convergence of the approximate

solutions constructed by the present algorithm. However, we may use a θ-scheme to replace the above fully implicit scheme (2.3), for example,

$$u_{j+\frac{1}{2}}^{n+1} = u_{j+\frac{1}{2}}^{n} + \lambda_{j+\frac{1}{2}}^{n}\Delta_+\left(\theta h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}) + (1-\theta)h(u_{j-\frac{1}{2}}^{n}, u_{j+\frac{1}{2}}^{n})\right), \tag{2.7}$$

where θ is a given constant, $0 \le \theta \le 1$, and Δ_+ denotes the forward difference operator in space. When $\theta = 0$, we have a trivial case: the explicit scheme (2.2) is exploited in the whole computational domain. For this trivial case, the time step size is constrained by the global CFL condition; convergence of the nonoverlapping DDM can be obtained by following the proof of convergence of a single domain method.

The motivation of using different schemes within different subdomains is to relax the CFL restriction and improve the efficiency of simulating numerically some problems with multitime scale phenomena. Moreover, the results derived in the following are also analogously valid if the number of subdomains is any finite number m. Further, they hold for any multipoint monotone scheme when the fluxes are interpreted accordingly.

3. The main properties. In this section we shall analyze mainly the nonlinear stability of the DDM (2.2) and (2.3) introduced in the last section. Before doing this, we first show existence of a solution of (2.3) with given boundary conditions at x_{j_1} and x_{j_2}. A similar question has been discussed by several authors; see, e.g., [9, 11, 24]. By using the inverse positivity property and Brouwer's fixed point theorem, Fuhrmann [11] gave a proof of existence and uniqueness of solutions of certain systems of algebraic equations with off-diagonal nonlinearity, which arise, e.g., from stable finite volume discretizations of viscous conservation laws; see [12]. Lucier [24], as well as Evje and Karlsen [9], used the theory of accretive operators introduced in [4, 18] and the Crandall–Liggett theorem [5] to prove the existence and uniqueness of solutions of their system of algebraic equations, too.

LEMMA 3.1. *Assume that the initial data* $\{u_{j+\frac{1}{2}}^{0} | j \in \mathbb{Z}\}$ *are given by* (2.1)*, that* $\{u_{j+\frac{1}{2}}^{n+1} | j \in \Omega_\delta^1\}$ *is the explicit solution of* (2.2) *at* $t = t_{n+1}$*, and that* $\{u_{j+\frac{1}{2}}^{n+1} | j \in \Omega_\delta^2\}$ *is defined by the implicit equation* (2.3)*. Then the solution* $\{u_{j+\frac{1}{2}}^{n+1} | j \in \Omega_\delta^2\}$ *exists uniquely; that is, the boundary value problem of* (2.3) *with boundary conditions at* x_{j_1} *and* x_{j_2} *computed by the explicit scheme* (2.2) *admits a unique solution. Moreover, if we assume that the initial data* $\{u_{j+\frac{1}{2}}^{0} | j \in \mathbb{Z}\}$ *are bounded, a bound for* $u_{j+\frac{1}{2}}^{n+1}$ *for all* $j \in \Omega_\delta^2$ *exists for fixed* δ *and independent of* n*.*

Proof. We consider the boundary value problem of the implicit scheme (2.3), where the boundary values are obtained from the computed values of the explicit scheme (2.2) at x_{j_1} and x_{j_2}. It can be written in a matrix form as follows:

$$\begin{cases} \boldsymbol{u}^{n+1} + \Delta t_n A(\boldsymbol{u}^{n+1}) = \boldsymbol{u}^n, \\ u_{j_1-\frac{1}{2}}^{n+1} \text{ and } u_{j_2+\frac{1}{2}}^{n+1} \text{ are given by the explicit scheme (2.2)}, \end{cases} \tag{3.1}$$

where $\boldsymbol{u} = (u_{j_1+\frac{1}{2}}, \dots, u_{j_2-\frac{1}{2}})^T$, $A(\boldsymbol{u}) = \left(\frac{1}{\Delta x_{j_1+\frac{1}{2}}} a_{j_1+\frac{1}{2}}(\boldsymbol{u}), \dots, \frac{1}{\Delta x_{j_2-\frac{1}{2}}} a_{j_2-\frac{1}{2}}(\boldsymbol{u})\right)^T$, and

$$a_{j+\frac{1}{2}}(\boldsymbol{u}) = h(u_{j+\frac{1}{2}}, u_{j+\frac{3}{2}}) - h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}}), \quad j \in \Omega_\delta^2.$$

It remains to show the existence of a solution of the scheme (3.1) following [9] which is based on [24]. The existence needed here is on a finite dimensional space. If the

domain is semi-infinite or infinite by switching the two domains, we have to consider a suitable version of ℓ^1 as our solution space. It suffices to show that the operator $A : \ell^1 \longrightarrow \ell^1$ is accretive; i.e., the operator A satisfies

$$\mathcal{I} := \sum_{j\in\Omega_\delta^2} \operatorname{sign}(w_{j+\frac{1}{2}})\big(a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})\big) \geq 0$$

for all $\boldsymbol{u}$ and $\boldsymbol{v}$ under consideration, e.g., satisfying $u_{j_1-\frac{1}{2}} = v_{j_1-\frac{1}{2}}$ and $u_{j_2+\frac{1}{2}} = v_{j_2+\frac{1}{2}}$, where $w_{j+\frac{1}{2}} = u_{j+\frac{1}{2}} - v_{j+\frac{1}{2}}$. In fact, because for each $j \in \Omega_\delta^2$ and a positive constant $c \geq 2L$, the inequality

$$\begin{aligned}\Big|cw_{j+\frac{1}{2}} - \big(a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})\big)\Big| &\equiv \Big|c|w_{j+\frac{1}{2}}| - \operatorname{sign}(w_{j+\frac{1}{2}})\big(a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})\big)\Big| \\ &\geq c|w_{j+\frac{1}{2}}| - \operatorname{sign}(w_{j+\frac{1}{2}})\big(a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})\big)\end{aligned}$$

holds, we have

$$\mathcal{I} \geq -\sum_{j\in\Omega_\delta^2} \Big|cw_{j+\frac{1}{2}} - \big(a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})\big)\Big| + c\sum_{j\in\Omega_\delta^2} |w_{j+\frac{1}{2}}|.$$

Define

$$a_j = \begin{cases} \frac{h(u_{j-\frac{1}{2}},u_{j+\frac{1}{2}}) - h(v_{j-\frac{1}{2}},u_{j+\frac{1}{2}})}{u_{j-\frac{1}{2}} - v_{j-\frac{1}{2}}} & \text{if } u_{j-\frac{1}{2}} \neq v_{j-\frac{1}{2}}, \\ h_1(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}}) & \text{otherwise,} \end{cases}$$

$$b_j = \begin{cases} \frac{h(v_{j-\frac{1}{2}},u_{j+\frac{1}{2}}) - h(v_{j-\frac{1}{2}},v_{j+\frac{1}{2}})}{u_{j+\frac{1}{2}} - v_{j+\frac{1}{2}}} & \text{if } u_{j+\frac{1}{2}} \neq v_{j+\frac{1}{2}}, \\ h_2(v_{j-\frac{1}{2}}, v_{j+\frac{1}{2}}) & \text{otherwise.} \end{cases}$$

Obviously, we have $a_j \geq 0$ and $b_j \leq 0$, because the numerical flux $h(\cdot,\cdot)$ is monotone. Moreover, we can rewrite $a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v})$ as follows:

$$\begin{aligned}a_{j+\frac{1}{2}}(\boldsymbol{u}) - a_{j+\frac{1}{2}}(\boldsymbol{v}) &= h(u_{j+\frac{1}{2}}, u_{j+\frac{3}{2}}) - h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}}) - h(v_{j+\frac{1}{2}}, v_{j+\frac{3}{2}}) + h(v_{j-\frac{1}{2}}, v_{j+\frac{1}{2}}) \\ &= (a_{j+1} - b_j)w_{j+\frac{1}{2}} + b_{j+1}w_{j+\frac{3}{2}} - a_j w_{j-\frac{1}{2}}.\end{aligned}$$

Because of $c \geq (a_{j+1} - b_j) \geq 0$ and $w_{j_1-\frac{1}{2}} = w_{j_2+\frac{1}{2}} = 0$, we have

$$\begin{aligned}\mathcal{I} &\geq c\sum_{j\in\Omega_\delta^2} |w_{j+\frac{1}{2}}| - \sum_{j\in\Omega_\delta^2} (c - a_{j+1} + b_j)\,|w_{j+\frac{1}{2}}| + \sum_{j\in\Omega_\delta^2} b_{j+1}|w_{j+\frac{3}{2}}| - \sum_{j\in\Omega_\delta^2} a_j|w_{j-\frac{1}{2}}| \\ &= a_{j_1+1}|w_{j_1+\frac{1}{2}}| - b_{j_2-1}|w_{j_2-\frac{1}{2}}| \geq 0.\end{aligned}$$

Therefore, the operator A is accretive.

On the other hand, because the numerical flux $h(u,v) \in C^1(\mathbb{R}^2)$, the operator A is not only accretive but also m-accretive; i.e., for all positive numbers λ, $I + \lambda A$ is a surjection, where I denotes the identity operator. Therefore, in view of the well-known results of Lucier [24] as well as Crandall and Liggett [5], we can conclude the existence of a unique solution of (3.1).

Since for fixed δ there is only a finite number of real terms in (3.1), $u_{j+\frac{1}{2}}^{n+1}$, $j_1 \leq j < j_2$, can be computed if $u_{j+\frac{1}{2}}^{n} \in \mathbb{R}$. Moreover, if we assume that the initial data

$\{u^0_{j+\frac{1}{2}} | j \in \mathbb{Z}\}$ are bounded, a bound for $u^{n+1}_{j+\frac{1}{2}}$ for all $j \in \Omega^2_\delta$ exists for fixed δ and independent of n, which will be proved later. □

Mimicking the proof of Lemma 3.1, the following result is easily proved.

LEMMA 3.2. *Assuming that* $\{u^{n+1}_{j_1-\frac{1}{2}}, u^{n+1}_{j_2+\frac{1}{2}}, u^n_{j+\frac{1}{2}}, j = j_1, \ldots, j_2 - 1\}$ *and* $\{v^{n+1}_{j_1-\frac{1}{2}}, v^{n+1}_{j_2+\frac{1}{2}}, v^n_{j+\frac{1}{2}}, j = j_1, \ldots, j_2 - 1\}$ *are two arbitrarily given initial data and boundary conditions, then the two corresponding solutions of* (3.1), $\boldsymbol{u}^{n+1}$ *and* $\boldsymbol{v}^{n+1}$, *satisfy*

$$\begin{aligned}\sum_{j=j_1}^{j_2-1} |u^{n+1}_{j+\frac{1}{2}} - v^{n+1}_{j+\frac{1}{2}}| \Delta x_{j+\frac{1}{2}} &\le \sum_{j=j_1}^{j_2-1} |u^n_{j+\frac{1}{2}} - v^n_{j+\frac{1}{2}}| \Delta x_{j+\frac{1}{2}} \\ &\quad + \Delta t_n L \left(|u^{n+1}_{j_1-\frac{1}{2}} - v^{n+1}_{j_1-\frac{1}{2}}| + |u^{n+1}_{j_2+\frac{1}{2}} - v^{n+1}_{j_2+\frac{1}{2}}| \right). \end{aligned} \tag{3.2}$$

Moreover, if $u^{n+1}_{j_1-\frac{1}{2}}$, $u^{n+1}_{j_2+\frac{1}{2}}$, *and* $u^n_{j+\frac{1}{2}}$, $j = j_1, \ldots, j_2 - 1$, *are bounded, so is* $u^{n+1}_{j+\frac{1}{2}}$ *for all* $j \in \Omega^2_\delta$.

Remark 3.1. If we assume that the time step sizes satisfy a suitable restriction, then we may also present a proof of Lemma 3.1 by using the uniform monotonicity theorem of Dekker and Verwer; see page 147 of the book [8].

3.1. Maximum principle. In this subsection we show the existence of a maximum principle satisfied by the solutions of the DDM (2.2) and (2.3).

LEMMA 3.3. *If the initial data* $\{u^0_{j+\frac{1}{2}}\}_{j\in\mathbb{Z}}$ *satisfy*

$$m \le u^0_{j+\frac{1}{2}} \le M \quad \forall j \in \mathbb{Z}, \tag{3.3}$$

then under the local CFL condition

$$\lambda^n_{j+\frac{1}{2}} \max_{u,v,w,z\in\mathcal{A}} \{|h_1(u,v)| + |h_2(w,z)|\} \le 1 \tag{3.4}$$

for all $j \in \Omega^1_\delta$, *where* $\mathcal{A} = \{w \in L^\infty(\mathbb{R}) \big| ||w||_{L^\infty(\mathbb{R})} \le ||u^0||_{L^\infty(\mathbb{R})}\}$, *we have*

$$m \le u^{n+1}_{j+\frac{1}{2}} \le M \quad \forall j \in \mathbb{Z},\ n \ge 0. \tag{3.5}$$

Proof. Assume that $m \le u^n_{j+\frac{1}{2}} \le M$ for all $j \in \mathbb{Z}$. First, we consider the solutions in the domain Ω^1_δ. We obtain the estimate

$$\begin{aligned} u^{n+1}_{j+\frac{1}{2}} - m &= u^n_{j+\frac{1}{2}} - m - \lambda^n_{j+\frac{1}{2}} \left(h(u^n_{j+\frac{1}{2}}, u^n_{j+\frac{3}{2}}) - h(m, u^n_{j+\frac{3}{2}}) + h(m,m) - h(m, u^n_{j+\frac{1}{2}}) \right) \\ &\quad - \lambda^n_{j+\frac{1}{2}} \left(h(m, u^n_{j+\frac{3}{2}}) - h(m,m) + h(m, u^n_{j+\frac{1}{2}}) - h(u^n_{j-\frac{1}{2}}, u^n_{j+\frac{1}{2}}) \right) \ge 0 \end{aligned}$$

for all $j \in \Omega^1_\delta$ by applying the CFL condition (3.4) to the right-hand side (RHS) of the first line and by using the monotonicity property of the flux h in the second line. Similarly, we can also get that $u^{n+1}_{j+\frac{1}{2}} \le M$ for all $j \in \Omega^1_\delta$ under the hypotheses of the lemma.

Next, we show $m \le u^{n+1}_{j+\frac{1}{2}} \le M$ for all $j \in \Omega^2_\delta$. To do this, we introduce a small positive constant, $0 < \beta \ll 1$, and rewrite (2.3) in the following form:

$$(1+\beta) u^{n+1}_{j+\frac{1}{2}} = \beta u^n_{j+\frac{1}{2}} + \widetilde{u}^{n+1}_{j+\frac{1}{2}}, \tag{3.6}$$

where

$$\widetilde{u}_{j+\frac{1}{2}}^{n+1} = u_{j+\frac{1}{2}}^{n+1} - \beta\lambda_{j+\frac{1}{2}}^{n}\left(h(u_{j+\frac{1}{2}}^{n+1}, u_{j+\frac{3}{2}}^{n+1}) - h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1})\right). \tag{3.7}$$

Define $\widetilde{M} = \max_{j\in\Omega_\delta^2}\{u_{j+\frac{1}{2}}^{n+1}\}$ and $\widetilde{m} = \min_{j\in\Omega_\delta^2}\{u_{j+\frac{1}{2}}^{n+1}\}$. They are all finite, due to Lemma 3.2. Following the analysis for $j \in \Omega_\delta^1$, we may prove

$$\min\{\widetilde{m}, m\} \le \widetilde{u}_{j+\frac{1}{2}}^{n+1} \le \max\{\widetilde{M}, M\} \quad \forall j \in \Omega_\delta^2$$

under the CFL-type condition

$$\beta\lambda_{j+\frac{1}{2}}^{n} \max_{u,v,w,z\in\widetilde{\mathcal{A}}}\{|h_1(u,v)| + |h_2(w,z)|\} \le 1 \tag{3.8}$$

for all $j \in \Omega_\delta^2$, where $\widetilde{\mathcal{A}} := [\min\{\widetilde{m}, m\}, \max\{\widetilde{M}, M\}]$. Note that (3.8) is slightly more general than (3.4), but since β may be arbitrarily small there is essentially no further restriction to the time step. From (3.6), we get

$$\beta m + \min\{\widetilde{m}, m\} \le (1+\beta)u_{j+\frac{1}{2}}^{n+1} \le \beta M + \max\{\widetilde{M}, M\}, \quad j \in \Omega_\delta^2. \tag{3.9}$$

If $\widetilde{M} > M$, then we have from (3.9)

$$(1+\beta)\widetilde{M} \le \beta M + \widetilde{M}, \quad \widetilde{M} = \max_{j\in\Omega_\delta^2}\{u_{j+\frac{1}{2}}^{n+1}\}.$$

This leads to a contradiction. Therefore, $u_{j+\frac{1}{2}}^{n+1} \le M, j \in \mathbb{Z}$. Similarly, we can also get $u_{j+\frac{1}{2}}^{n+1} \ge m$ for all $j \in \mathbb{Z}$. The proof is completed. □

LEMMA 3.4. *Under the local CFL condition*

$$\lambda_j^n \max_{u,v,w,z\in\mathcal{A}}\{|h_1(u,v)| + |h_2(w,z)|\} \le 1 \tag{3.10}$$

for all $j \in \Omega_\delta^1$, *where* $\lambda_j^n = \max\{\lambda_{j+\frac{1}{2}}^n, \lambda_{j-\frac{1}{2}}^n\}$, *the DDM* (2.2) *and* (2.3) *is total variation diminishing; i.e.,*

$$TV(u^{n+1}) \le TV(u^n) \equiv \sum_{j\in\mathbb{Z}} |\Delta_+ u_{j-\frac{1}{2}}^n|, \quad n \ge 0, \tag{3.11}$$

where Δ_+ *denotes the forward difference operator in space.*

Proof. First, we rewrite (2.2) and (2.3) in an incremental form as follows:

$$u_{j+\frac{1}{2}}^{n+1} = u_{j+\frac{1}{2}}^n + C_{j+1}^n\Delta_+ u_{j+\frac{1}{2}}^n - D_j^n\Delta_+ u_{j-\frac{1}{2}}^n, \ j \in \Omega_\delta^1, \tag{3.12}$$

$$u_{j+\frac{1}{2}}^{n+1} = u_{j+\frac{1}{2}}^n + C_{j+1}^{n+1}\Delta_+ u_{j+\frac{1}{2}}^{n+1} - D_j^{n+1}\Delta_+ u_{j-\frac{1}{2}}^{n+1}, \ j \in \Omega_\delta^2, \tag{3.13}$$

where the incremental coefficients are defined by

$$C_{j+1}^\nu = \lambda_{j+\frac{1}{2}}^n \begin{cases} \frac{f(u_{j+\frac{1}{2}}^\nu) - h(u_{j+\frac{1}{2}}^\nu, u_{j+\frac{3}{2}}^\nu)}{\Delta_+ u_{j+\frac{1}{2}}^\nu}, & \Delta_+ u_{j+\frac{1}{2}}^\nu \ne 0, \\ h_2(u_{j+\frac{1}{2}}^\nu, u_{j+1/2}^\nu) & \text{otherwise}, \end{cases}$$

$$D_j^\nu = \lambda_{j+\frac{1}{2}}^n \begin{cases} \frac{f(u_{j+\frac{1}{2}}^\nu) - h(u_{j-\frac{1}{2}}^\nu, u_{j+\frac{1}{2}}^\nu)}{\Delta_+ u_{j-\frac{1}{2}}^\nu}, & \Delta_+ u_{j-\frac{1}{2}}^\nu \ne 0, \\ h_1(u_{j-\frac{1}{2}}^\nu, u_{j+\frac{1}{2}}^\nu) & \text{otherwise}, \end{cases}$$

where $\nu = n$ or $n+1$. Subtracting (3.12) (or (3.13)) at $j-\frac{1}{2}$ from (3.12) (or (3.13)) at $j+\frac{1}{2}$ for $j < j_1$ and $j > j_2$ (or $j_2 > j > j_1$) gives

$$\Delta_+ u^{n+1}_{j-\frac{1}{2}} = (1 - C^n_j - D^n_j)\Delta_+ u^n_{j-\frac{1}{2}} + C^n_{j+1}\Delta_+ u^n_{j+\frac{1}{2}} + D^n_{j-1}\Delta_+ u^n_{j-\frac{3}{2}}, \tag{3.14}$$

$$(1 + C^{n+1}_j + D^{n+1}_j)\Delta_+ u^{n+1}_{j-\frac{1}{2}} = \Delta_+ u^n_{j-\frac{1}{2}} + C^{n+1}_{j+1}\Delta_+ u^{n+1}_{j+\frac{1}{2}} + D^{n+1}_{j-1}\Delta_+ u^{n+1}_{j-\frac{3}{2}}. \tag{3.15}$$

We also subtract (3.12) at $j_1 - \frac{1}{2}$ from (3.13) at $j_1 + \frac{1}{2}$, and have

$$(1 + D^{n+1}_{j_1})\Delta_+ u^{n+1}_{j_1-\frac{1}{2}} = (1 - C^n_{j_1})\Delta_+ u^n_{j_1-\frac{1}{2}} + C^{n+1}_{j_1+1}\Delta_+ u^{n+1}_{j_1+\frac{1}{2}} + D^n_{j_1-1}\Delta_+ u^n_{j_1-\frac{3}{2}}. \tag{3.16}$$

Similarly, near the interface $x = x_{j_2}$, we have

$$(1 + C^{n+1}_{j_2})\Delta_+ u^{n+1}_{j_2-\frac{1}{2}} = (1 - D^n_{j_2})\Delta_+ u^n_{j_2-\frac{1}{2}} + C^n_{j_2+1}\Delta_+ u^n_{j_2+\frac{1}{2}} + D^{n+1}_{j_2-1}\Delta_+ u^{n+1}_{j_2-\frac{3}{2}}. \tag{3.17}$$

Under (3.10) and the monotonicity property of the numerical flux $h(u,v)$, the coefficients C^ν_j and D^ν_j in (3.14)–(3.17) are all nonnegative; i.e.,

$$C^\nu_j \geq 0, \quad D^\nu_j \geq 0 \quad \text{for all } j \in \mathbb{Z} \text{ and } \nu = n \text{ or } n+1,$$
$$C^n_j + D^n_j \leq \lambda^n_j \max\{|h_1| + |h_2|\} \leq 1.$$

Thus, taking the absolute value of (3.14)–(3.17) and using the triangle inequality, we get

$$\begin{aligned} |\Delta_+ u^{n+1}_{j-\frac{1}{2}}| \leq{}& \big(1 - (C^n_j + D^n_j)\big)|\Delta_+ u^n_{j-\frac{1}{2}}| + C^n_{j+1}|\Delta_+ u^n_{j+\frac{1}{2}}| \\ &+ D^n_{j-1}|\Delta_+ u^n_{j-\frac{3}{2}}|, \ j < j_1 \text{ or } j > j_2, \end{aligned} \tag{3.18}$$

$$\begin{aligned} (1 + C^{n+1}_j + D^{n+1}_j)|\Delta_+ u^{n+1}_{j-\frac{1}{2}}| \leq{}& |\Delta_+ u^n_{j-\frac{1}{2}}| + C^{n+1}_{j+1}|\Delta_+ u^{n+1}_{j+\frac{1}{2}}| \\ &+ D^{n+1}_{j-1}|\Delta_+ u^{n+1}_{j-\frac{3}{2}}|, \ j_1 < j < j_2, \end{aligned} \tag{3.19}$$

$$\begin{aligned} (1 + D^{n+1}_{j_1})|\Delta_+ u^{n+1}_{j_1-\frac{1}{2}}| \leq{}& (1 - C^n_{j_1})|\Delta_+ u^n_{j_1-\frac{1}{2}}| \\ &+ C^{n+1}_{j_1+1}|\Delta_+ u^{n+1}_{j_1+\frac{1}{2}}| + D^n_{j_1-1}|\Delta_+ u^n_{j_1-\frac{3}{2}}|, \end{aligned} \tag{3.20}$$

$$\begin{aligned} (1 + C^{n+1}_{j_2})|\Delta_+ u^{n+1}_{j_2-\frac{1}{2}}| \leq{}& (1 - D^n_{j_2})|\Delta_+ u^n_{j_2-\frac{1}{2}}| + C^n_{j_2+1}|\Delta_+ u^n_{j_2+\frac{1}{2}}| \\ &+ D^{n+1}_{j_2-1}|\Delta_+ u^{n+1}_{j_2-\frac{3}{2}}|. \end{aligned} \tag{3.21}$$

Summing (3.18) from $j = -\infty$ to $j_1 - 1$ and from $j = j_2 + 1$ to ∞, (3.19) from $j_1 + 1$ to $j_2 - 1$, (3.20), and (3.21), we get by shifting indices

$$TV(u^{n+1}) \leq TV(u^n).$$

This completes the proof. ∎

Remark 3.2. Let us take the following numerical flux [32]:

$$h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}}) = \frac{\Delta x_{j+\frac{1}{2}} f(u_{j-\frac{1}{2}}) + \Delta x_{j-\frac{1}{2}} f(u_{j+\frac{1}{2}})}{\Delta x_{j+\frac{1}{2}} + \Delta x_{j-\frac{1}{2}}} - Q_j \frac{u_{j+\frac{1}{2}} - u_{j-\frac{1}{2}}}{\Delta x_{j+\frac{1}{2}} + \Delta x_{j-\frac{1}{2}}}, \tag{3.22}$$

where the numerical viscosity coefficient $Q_j = Q(u_{j+\frac{1}{2}}, u_{j-\frac{1}{2}}; \Delta x_{j+\frac{1}{2}}, \Delta x_{j-\frac{1}{2}})$ is chosen such that $h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}})$ is monotone. As an example, we define Q_j by

$$Q_j = \max_u \{|f'(u)|\} \max\{\Delta x_{j+\frac{1}{2}}, \Delta x_{j-\frac{1}{2}}\}. \tag{3.23}$$

For this special numerical flux $h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}})$ given by (3.22) and (3.23), we have

$$C_j + D_j = \frac{\Delta t_n}{\Delta x_{j-\frac{1}{2}} \Delta x_{j+\frac{1}{2}}} Q_j = \frac{\Delta t_n}{\min\{\Delta x_{j-\frac{1}{2}}, \Delta x_{j+\frac{1}{2}}\}} \max_u\{|f'(u)|\}.$$

Thus, the TV-stability condition now becomes

$$\frac{\Delta t_n}{\min\{\Delta x_{j-\frac{1}{2}}, \Delta x_{j+\frac{1}{2}}\}} \max_u\{|f'(u)|\} \le 1 \quad \forall j \in \Omega_\delta^1.$$

3.2. L^1-continuity in time.

LEMMA 3.5. *Let $\mu > 1$ and assume $C_j^{n+1} + D_j^{n+1} \le \mu$ for all $j \in \Omega_2^\delta$, $n \in \mathbb{Z}$. Under the hypothesis of Lemma* 3.4*, we have*

$$||u^m - u^n||_{L^1(\mathbb{R})} \equiv \sum_{j\in\mathbb{Z}} |u_{j+\frac{1}{2}}^m - u_{j+\frac{1}{2}}^n| \Delta x_{j+\frac{1}{2}} \le \frac{1+\mu}{\lambda}(t_m - t_n) TV(u_0), \tag{3.24}$$

where $\frac{1}{\lambda} = \max_{j,n}\{\frac{1}{\lambda_{j+\frac{1}{2}}^n}\}$.

Note that due to the larger time step in a part of the domain, i.e., Ω_δ^2, the term $C_j^{n+1} + D_j^{n+1}$ is not necessarily bounded by 1. For this purpose we introduce the constant $\mu \ge 1$ as in the formulation of the lemma. This constant is assumed to be chosen independently of spatial and time step sizes.

Proof. From (3.12)–(3.13), we have

$$(u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n)\Delta x_{j+\frac{1}{2}} = \frac{\Delta t_n}{\lambda_{j+\frac{1}{2}}^n}(C_{j+1}^n \Delta_+ u_{j+\frac{1}{2}}^n - D_j^n \Delta_+ u_{j-\frac{1}{2}}^n),\ j \in \Omega_\delta^1, \tag{3.25}$$

$$(u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n)\Delta x_{j+\frac{1}{2}} = \frac{\Delta t_n}{\lambda_{j+\frac{1}{2}}^n}(C_{j+1}^{n+1} \Delta_+ u_{j+\frac{1}{2}}^{n+1} - D_j^{n+1} \Delta_+ u_{j-\frac{1}{2}}^{n+1}),\ j \in \Omega_\delta^2. \tag{3.26}$$

Taking the absolute value of these equations and using the triangle inequality, we get

$$|u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n| \Delta x_{j+\frac{1}{2}} \le \frac{\Delta t_n}{\lambda_{j+\frac{1}{2}}^n}(C_{j+1}^n |\Delta_+ u_{j+\frac{1}{2}}^n| + D_j^n |\Delta_+ u_{j-\frac{1}{2}}^n|),\ j \in \Omega_\delta^1, \tag{3.27}$$

$$|u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n| \Delta x_{j+\frac{1}{2}} \le \frac{\Delta t_n}{\lambda_{j+\frac{1}{2}}^n}(C_{j+1}^{n+1} |\Delta_+ u_{j+\frac{1}{2}}^{n+1}| + D_j^{n+1} |\Delta_+ u_{j-\frac{1}{2}}^{n+1}|),\ j \in \Omega_\delta^2. \tag{3.28}$$

Summing (3.27) from $j = -\infty$ to $j_1 - 1$ and from j_2 to ∞, and (3.28) from j_1 to $j_2 - 1$, we get by shifting indices

$$\sum_{j=-\infty}^{\infty} |u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n| \Delta x_{j+\frac{1}{2}} \le \frac{\Delta t_n}{\lambda}\left(TV(u^n) + \mu TV(u^{n+1})\right) \le \frac{(1+\mu)\Delta t_n}{\lambda} TV(u^n). \tag{3.29}$$

Here the conclusion of Lemma 3.4 has been used. From this inequality, we may complete the proof. ∎

4. A cell entropy inequality. This section concerns the study of a cell entropy inequality satisfied by the solutions of the DDM (2.2) and (2.3). In our analysis we will make use of the Kruzkov entropy pairs (U,F): $U(u;k)=|u-k|$, $F(u;k)=\operatorname{sign}(u-k)\big(f(u)-f(k)\big)$ for any $k\in\mathbb{R}$, and the notation "$\vee$" and "$\wedge$" defined by $a\vee b=\max\{a,b\}$, and $a\wedge b=\min\{a,b\}$.

LEMMA 4.1. *The solutions of the scheme* (2.2) *satisfy the cell entropy inequality*

$$U(u^{n+1}_{j+\frac12};k)-U(u^n_{j+\frac12};k)+\lambda^n_{j+\frac12}\Delta_+H(u^n_{j-\frac12},u^n_{j+\frac12};k)\le 0,\quad j\in\Omega^1_\delta, \tag{4.1}$$

under the CFL condition (3.4)*, while the solutions of the scheme* (2.3) *satisfy*

$$U(u^{n+1}_{j+\frac12};k)-U(u^n_{j+\frac12};k)+\lambda^n_{j+\frac12}\Delta_+H(u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac12};k)\le 0,\quad j\in\Omega^2_\delta, \tag{4.2}$$

where the numerical entropy flux is defined by $H(u^\nu_{j-\frac12},u^\nu_{j+\frac12};k)=h(u^\nu_{j-\frac12}\vee k,u^\nu_{j+\frac12}\vee k)-h(u^\nu_{j-\frac12}\wedge k,u^\nu_{j+\frac12}\wedge k)$*, which satisfies the consistency condition*

$$H(u,u;k)=F(u;k).$$

Proof. Mimicking the proof of Crandall and Majda given in [6], we can deduce the cell entropy inequality (4.1). Rewrite the difference equation (2.2) as

$$u^{n+1}_{j+\frac12}=G(u^n_{j-\frac12},u^n_{j+\frac12},u^n_{j+\frac32}).$$

Because $G(u,v,w)$ satisfies $k=G(k,k,k)$ and is monotonously increasing with respect to its arguments, under the CFL condition (3.4), we find that

$$\begin{aligned}
u^{n+1}_{j+\frac12}\vee k&=G(u^n_{j-\frac12},u^n_{j+\frac12},u^n_{j+\frac32})\vee G(k,k,k)\le G(k\vee u^n_{j-\frac12},k\vee u^n_{j+\frac12},k\vee u^n_{j+\frac32}),\\
-u^{n+1}_{j+\frac12}\wedge k&=-G(u^n_{j-\frac12},u^n_{j+\frac12},u^n_{j+\frac32})\wedge G(k,k,k)\le -G(k\wedge u^n_{j-\frac12},k\wedge u^n_{j+\frac12},k\wedge u^n_{j+\frac32}).
\end{aligned}$$

Adding these two inequalities gives (4.1), i.e.,

$$\begin{aligned}
|u^{n+1}_{j+\frac12}-k|&\le G(k\vee u^n_{j-\frac12},k\vee u^n_{j+\frac12},k\vee u^n_{j+\frac32})-G(k\wedge u^n_{j-\frac12},k\wedge u^n_{j+\frac12},k\wedge u^n_{j+\frac32})\\
&=|u^n_{j+\frac12}-k|-\beta\lambda^n_{j+\frac12}\Delta_+H(u^n_{j-\frac12},u^n_{j+\frac12};k).
\end{aligned}$$

If using the CFL-type condition (3.8), we can get the inequality (4.2) from the difference equations (3.7) and (3.6) in a similar way. In the following we begin to prove the inequality (4.2) by a case-by-case procedure, without using the condition (3.8).

Case 1. $u^{n+1}_{j+\frac12},u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac32}\ge k$. From the scheme (2.3), we have

$$|u^{n+1}_{j+\frac12}-k|-(u^n_{j+\frac12}-k)+\lambda^n_{j+\frac12}\Delta_+\Big(h(u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac12})-h(k,k)\Big)=0$$

and get (4.2); i.e.,

$$|u^{n+1}_{j+\frac12}-k|-|u^n_{j+\frac12}-k|+\lambda^n_{j+\frac12}\Delta_+\Big(h(u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac12})-h(k,k)\Big)\le 0.$$

Case 2. $u^{n+1}_{j+\frac12},u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac32}\le k$. From the scheme (2.3), we have

$$|k-u^{n+1}_{j+\frac12}|-(k-u^n_{j+\frac12})+\lambda^n_{j+\frac12}\Delta_+\Big(h(k,k)-h(u^{n+1}_{j-\frac12},u^{n+1}_{j+\frac12})\Big)=0$$

and get (4.2); i.e.,

$$|u^{n+1}_{j+\frac{1}{2}}-k|-|u^{n}_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Delta_+\Big(h(k,k)-h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})\Big)\le 0.$$

Case 3. $u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j+\frac{3}{2}}\ge k\ge u^{n+1}_{j-\frac{1}{2}}$. Substituting (2.3) into the left-hand side (LHS) of (4.2), we have

$$\begin{aligned}\text{LHS}(4.2)&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|-\lambda^n_{j+\frac{1}{2}}\Delta_+h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})\\&\quad+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j+\frac{3}{2}})-h(k,k)-h(k,u^{n+1}_{j+\frac{1}{2}})+h(u^{n+1}_{j-\frac{1}{2}},k)\Big)\\&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})-h(k,u^{n+1}_{j+\frac{1}{2}})\\&\quad+h(u^{n+1}_{j-\frac{1}{2}},k)-h(k,k)\Big)\le 0,\end{aligned}$$

where we have used the monotonicity property of the numerical flux $h(u,v)$.

Case 4. $u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j-\frac{1}{2}}\ge k\ge u^{n+1}_{j+\frac{3}{2}}$. This case is similar to Case 3. We have

$$\begin{aligned}\text{LHS}(4.2)&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|-\lambda^n_{j+\frac{1}{2}}\Delta_+h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})\\&\quad+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},k)-h(k,u^{n+1}_{j+\frac{3}{2}})-h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})+h(k,k)\Big)\\&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},k)-h(u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j+\frac{3}{2}})\\&\quad+h(k,k)-h(k,u^{n+1}_{j+\frac{3}{2}})\Big)\le 0.\end{aligned}$$

Case 5. $u^{n+1}_{j+\frac{3}{2}},u^{n+1}_{j-\frac{1}{2}}\ge k\ge u^{n+1}_{j+\frac{1}{2}}$. Similarly, we have

$$\begin{aligned}\text{LHS}(4.2)&=(k-u^n_{j+\frac{1}{2}})-|u^n_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Delta_+h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})\\&\quad+\lambda^n_{j+\frac{1}{2}}\Big(h(k,u^{n+1}_{j+\frac{3}{2}})-h(u^{n+1}_{j+\frac{1}{2}},k)-h(u^{n+1}_{j-\frac{1}{2}},k)+h(k,u^{n+1}_{j+\frac{1}{2}})\Big)\\&=(k-u^n_{j+\frac{1}{2}})-|u^n_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j+\frac{3}{2}})-h(u^{n+1}_{j+\frac{1}{2}},k)\\&\quad+h(k,u^{n+1}_{j+\frac{1}{2}})-h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})+h(k,u^{n+1}_{j+\frac{3}{2}})-h(k,k)\\&\quad+h(k,k)-h(u^{n+1}_{j-\frac{1}{2}},k)\Big)\le 0.\end{aligned}$$

Case 6. $u^{n+1}_{j+\frac{1}{2}}\ge k\ge u^{n+1}_{j+\frac{3}{2}},u^{n+1}_{j-\frac{1}{2}}$. This case is similar to Case 5. We have

$$\begin{aligned}\text{LHS}(4.2)&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|-\lambda^n_{j+\frac{1}{2}}\Delta_+h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})\\&\quad+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},k)-h(k,u^{n+1}_{j+\frac{3}{2}})-h(k,u^{n+1}_{j+\frac{1}{2}})+h(u^{n+1}_{j-\frac{1}{2}},k)\Big)\\&=(u^n_{j+\frac{1}{2}}-k)-|u^n_{j+\frac{1}{2}}-k|+\lambda^n_{j+\frac{1}{2}}\Big(h(u^{n+1}_{j+\frac{1}{2}},k)-h(u^{n+1}_{j+\frac{1}{2}},u^{n+1}_{j+\frac{3}{2}})\\&\quad+h(u^{n+1}_{j-\frac{1}{2}},u^{n+1}_{j+\frac{1}{2}})-h(k,u^{n+1}_{j+\frac{1}{2}})+h(u^{n+1}_{j-\frac{1}{2}},k)-h(k,k)\\&\quad+h(k,k)-h(k,u^{n+1}_{j+\frac{3}{2}})\Big)\le 0.\end{aligned}$$

Case 7. $u_{j-\frac{1}{2}}^{n+1} \geq k \geq u_{j+\frac{3}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}$. We have

$$\begin{aligned}\text{LHS}(4.2) &= (k-u_{j+\frac{1}{2}}^n) - |u_{j+\frac{1}{2}}^n - k| + \lambda_{j+\frac{1}{2}}^n \Delta_+ h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}) \\ &\quad + \lambda_{j+\frac{1}{2}}^n \Big(h(k,k) - h(u_{j+\frac{1}{2}}^{n+1}, u_{j+\frac{3}{2}}^{n+1}) - h(u_{j-\frac{1}{2}}^{n+1}, k) + h(k, u_{j+\frac{1}{2}}^{n+1}) \Big) \\ &= (k-u_{j+\frac{1}{2}}^n) - |u_{j+\frac{1}{2}}^n - k| + \lambda_{j+\frac{1}{2}}^n \Big(h(k, u_{j+\frac{1}{2}}^{n+1}) - h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}) \\ &\quad + h(k,k) - h(u_{j-\frac{1}{2}}^{n+1}, k) \Big) \leq 0.\end{aligned}$$

Case 8. $u_{j+\frac{3}{2}}^{n+1} \geq k \geq u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}$. It is similar to Case 7. We have

$$\begin{aligned}\text{LHS}(4.2) &= (k-u_{j+\frac{1}{2}}^n) - |u_{j+\frac{1}{2}}^n - k| + \lambda_{j+\frac{1}{2}}^n \Delta_+ h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}) \\ &\quad + \lambda_{j+\frac{1}{2}}^n \Big(h(k, u_{j+\frac{3}{2}}^{n+1}) - h(u_{j+\frac{1}{2}}^{n+1}, k) - h(k,k) + h(u_{j-\frac{1}{2}}^{n+1}, u_{j+\frac{1}{2}}^{n+1}) \Big) \\ &= (k-u_{j+\frac{1}{2}}^n) - |u_{j+\frac{1}{2}}^n - k| + \lambda_{j+\frac{1}{2}}^n \Big(h(u_{j+\frac{1}{2}}^{n+1}, u_{j+\frac{3}{2}}^{n+1}) - h(u_{j+\frac{1}{2}}^{n+1}, k) \\ &\quad h(k, u_{j+\frac{3}{2}}^{n+1}) - h(k,k) \Big) \leq 0.\end{aligned}$$

The proof is completed. ∎

5. Convergence of the algorithm. We focus in this section on the study of the convergence of the DDM (2.2) and (2.3) introduced in section 2. Treating the nonconservative terms carefully is the key.

Let $L^1_{loc}(\Omega)$ denote the space of all functions u that are integrable on compact subsets of Ω, and define the step function u_δ as follows:

$$u_\delta(x,t) = u_{j+\frac{1}{2}}^n \quad \text{for } (x,t) \in (x_j, x_{j+1}) \times [t_n, t_{n+1}) \tag{5.1}$$

if $j \in \Omega_\delta^1 \cup \Omega_\delta^2$.

Using Lemmas 3.3–3.5, we can prove the following theorem.

THEOREM 5.1. *If $u_0(x) \in L^\infty(\mathbb{R}) \cap L^1(\mathbb{R}) \cap BV(\mathbb{R})$, then the approximate family of solutions u_δ constructed by the DDM algorithm converges as δ tends to zero. The limit is a function u in $L^1_{loc}(\mathbb{R} \times \mathbb{R}^+)$ which is a weak solution of* (1.1) *with initial data* (1.2).

Proof. From Lemmas 3.3–3.5, the sequence $\{u_\delta\}$ is bounded in $L^\infty(\mathbb{R}) \cap L^1(\mathbb{R}) \cap BV(\mathbb{R})$. Then by Helly's compactness theorem, we can extract a subsequence still labeled $\{u_\delta\}$ which converges towards a function u in $L^1_{loc}(\mathbb{R}\times\mathbb{R}^+)$. In the following we shall prove that the function u is a weak solution of (1.1) and (1.2). We mimic the proof of the Lax–Wendroff theorem. For the sake of clarity throughout the proof, we still use $u_{j+\frac{1}{2}}^\nu$ to denote $u_\delta(x_{j+\frac{1}{2}}, t_\nu)$, and h_j^ν to denote $h\big(u_\delta(x_{j-\frac{1}{2}}, t_\nu), u_\delta(x_{j+\frac{1}{2}}, t_\nu)\big)$, where $\nu = n$ or $n+1$. Multiplying (2.2) and (2.3) by a smooth test function $\phi(x_{j+\frac{1}{2}}, t_n) \in C_0^\infty(\mathbb{R}^2)$ and summing it with respect to n and j gives

$$\begin{aligned}&\sum_{j=-\infty}^{\infty} \left\{ \sum_{n=0}^{\infty} \big(u_{j+\frac{1}{2}}^{n+1} - u_{j+\frac{1}{2}}^n\big) \phi(x_{j+\frac{1}{2}}, t_n) \right\} \Delta x_{j+\frac{1}{2}} + \sum_{n=0}^{\infty} \left\{ \sum_{j=-\infty}^{j_1-1} (h_{j+1}^n - h_j^n) \phi(x_{j+\frac{1}{2}}, t_n) \right. \\ &\left. + \sum_{j=j_1}^{j_2-1} (h_{j+1}^{n+1} - h_j^{n+1}) \phi(x_{j+\frac{1}{2}}, t_n) + \sum_{j=j_2}^{\infty} (h_{j+1}^n - h_j^n) \phi(x_{j+\frac{1}{2}}, t_n) \right\} \Delta t_n = 0.\end{aligned} \tag{5.2}$$

Now, we use I_0 to denote the first term at the LHS of (5.2), and I_i, $i = 1, 2, 3$, to denote the ith term in braces in the second term at the LHS of (5.2). If we use "summation by parts," then the term I_0 becomes

$$I_0 = \sum_{j=-\infty}^{\infty} \left\{ -u^0_{j+\frac{1}{2}} \phi(x_{j+\frac{1}{2}}, t_0) - \sum_{n=1}^{\infty} u^n_{j+\frac{1}{2}} \Delta^t_+ \phi(x_{j+\frac{1}{2}}, t_{n-1}) \right\} \Delta x_{j+\frac{1}{2}}, \tag{5.3}$$

where Δ^t_+ denotes the forward difference operator in time. Similarly, we also have

$$I_1 = h^n_{j_1} \phi(x_{j_1-\frac{1}{2}}, t_n) - \sum_{j=-\infty}^{j_1-1} h^n_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n), \tag{5.4}$$

$$I_2 = \left\{ h^{n+1}_{j_2} \phi(x_{j_2-\frac{1}{2}}, t_n) - h^{n+1}_{j_1} \phi(x_{j_1-\frac{1}{2}}, t_n) \right\} - \sum_{j=j_1}^{j_2-1} h^{n+1}_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n), \tag{5.5}$$

where the term $h^{n+1}_{j_1} \phi(x_{j_1-\frac{1}{2}}, t_n)$ has been added and subtracted above, and

$$I_3 = - h^n_{j_2} \phi(x_{j_2-\frac{1}{2}}, t_n) - \sum_{j=j_2}^{\infty} h^n_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n). \tag{5.6}$$

Here we have similarly added and subtracted the term $h^n_{j_2} \phi(x_{j_2-\frac{1}{2}}, t_n)$. Hence, (5.2) becomes, after using summation by parts as above,

$$\begin{aligned} 0 = & \sum_{j=-\infty}^{\infty} \left\{ -u^0_{j+\frac{1}{2}} \phi(x_{j+\frac{1}{2}}, t_0) - \sum_{n=1}^{\infty} u^n_{j+\frac{1}{2}} \Delta^t_+ \phi(x_{j+\frac{1}{2}}, t_{n-1}) \right\} \Delta x_{j+\frac{1}{2}} \\ & - \sum_{n=0}^{\infty} \left\{ \sum_{j=-\infty}^{j_1-1} h^n_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n) + \sum_{j=j_1}^{j_2-1} h^{n+1}_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n) + \sum_{j=j_2}^{\infty} h^n_j \Delta_+ \phi(x_{j-\frac{1}{2}}, t_n) \right\} \\ & + \sum_{n=0}^{\infty} \left\{ \phi(x_{j_2-\frac{1}{2}}, t_n) \Delta t_n \Delta^t_+ h^n_{j_2} - \phi(x_{j_1-\frac{1}{2}}, t_n) \Delta t_n \Delta^t_+ h^n_{j_1} \right\}. \end{aligned} \tag{5.7}$$

Again using summation by parts, we can rewrite the third term at the RHS of (5.7) as follows:

$$\begin{aligned} I_4 := & \phi(x_{j_1-\frac{1}{2}}, t_0) \Delta t_0 - \phi(x_{j_2-\frac{1}{2}}, t_0) \Delta t_0 - \sum_{n=1}^{\infty} \left\{ h^n_{j_2} \Delta^t_+ (\phi(x_{j_2-\frac{1}{2}}, t_{n-1}) \Delta t_{n-1}) \right. \\ & \left. - h^n_{j_1} \Delta^t_+ (\phi(x_{j_1-\frac{1}{2}}, t_{n-1}) \Delta t_{n-1}) \right\}. \end{aligned} \tag{5.8}$$

Under the assumption that $\Delta t_n = \Delta t_{n-1} + \mathcal{O}(\delta^{1+\alpha})$, we have

$$\begin{aligned} & \sum_{n=1}^{\infty} h^n_{\hat{j}} \Delta^t_+ \left(\phi(x_{\hat{j}-\frac{1}{2}}, t_{n-1}) \Delta t_{n-1} \right) \\ & \quad = \sum_{n=1}^{\infty} h^n_{\hat{j}} \left\{ \phi(x_{\hat{j}-\frac{1}{2}}, t_n) \left(\Delta t_{n-1} + \mathcal{O}(\delta^{1+\alpha}) \right) - \phi(x_{\hat{j}-\frac{1}{2}}, t_{n-1}) \Delta t_{n-1} \right\} \\ & \quad = \sum_{n=1}^{\infty} h^n_{\hat{j}} \left\{ \Delta t^2_{n-1} \phi_t(x_{\hat{j}-\frac{1}{2}}, \eta_{n-1}) + \phi(x_{\hat{j}-\frac{1}{2}}, t) \mathcal{O}(\delta^{1+\alpha}) \right\} \longrightarrow 0 \end{aligned} \tag{5.9}$$

as $\delta \longrightarrow 0$, where $\hat{j} = j_2$ or j_1, and $\eta_{n-1} \in [t_{n-1}, t_n]$. Therefore, it follows that the term $\lim_{\delta \to 0} I_4 = 0$ uniformly.

Taking into account the above results, we prove that (5.7) gives

$$-\int_{\mathbb{R}} u_0(x)\phi(x,0)\,dx = \int_{\mathbb{R}\times\mathbb{R}^+} \left(u\frac{\partial \phi}{\partial t} + f(u)\frac{\partial \phi}{\partial x}\right)\,dxdt, \tag{5.10}$$

as δ tends to zero. The proof is completed. □

THEOREM 5.2. *Let u be a weak solution to the initial value problem* (1.1) *and* (1.2). *Further, let u_δ be a sequence of approximate solutions constructed by* (2.2) *and* (2.3). *Suppose that u is the limit in $L^1_{loc}(\mathbb{R}\times\mathbb{R}^+)$ of the sequence of the approximate solutions u_δ for $\delta \to 0$. Then u is the unique entropy solution to* (1.1) *and* (1.2) *satisfying the entropy condition*

$$-\int_{\mathbb{R}\times\mathbb{R}^+} \left(|u-k|\frac{\partial \phi}{\partial t} + sign(u-k)(f(u)-f(k))\frac{\partial \phi}{\partial x}\right)\,dxdt \le 0 \tag{5.11}$$

for all nonnegative test function $\phi \in C_0^\infty(\mathbb{R}\times\mathbb{R}^+)$ and all real numbers k.

The proof of this theorem is analogous to that of the previous procedure in the proof of the last theorem and will be omitted here.

6. Numerical experiments. In this section we present two numerical experiments to validate the previous results of the domain decomposition method given in section 2.

Example 1. We use our algorithm (2.2) and (2.3) to solve the following initial value problem of the inviscid Burgers equation:

$$\frac{\partial u}{\partial t} + \frac{\partial\left(\frac{1}{2}u^2\right)}{\partial x} = 0, \tag{6.1}$$

$$u(x,0) = \begin{cases} 1 & \text{if } -1 \le x \le 0, \\ 0.1 & \text{otherwise.} \end{cases} \tag{6.2}$$

The numerical flux is taken as $h(u_{j-\frac{1}{2}}, u_{j+\frac{1}{2}}) = \frac{1}{2}(u_{j-\frac{1}{2}})^2$, because $u(x,t)$ is nonnegative for all $x \in \mathbb{R}$ and $t \ge 0$. The computational domain $[-2,2]$ is divided into two subdomains: $\Omega^1 = \{x|x < -1\} \cup \{x|x > 1\}$ and $\Omega^2 = \{x| -1 \le x \le 1\}$. Each subdomain is again partitioned into small cells with length $\Delta x = 0.01$. It means that the global domain is divided into 400 cells. In Figure 1, we show the numerical solutions at $t = 1$ obtained by two single domain algorithms: the fully explicit upwind scheme and the fully implicit upwind scheme, respectively. The time step size $\Delta t = 9.5 \times 10^{-3}$ has been used. The solid line is the exact solution obtained by the method of characteristics and the jump condition.

Figure 2 gives the numerical solutions at $t = 1$ calculated by our multidomain algorithm (2.2) and (2.3) with two different time step sizes $\Delta t = 9.5 \times 10^{-3}$ and $\Delta t = 9.5 \times 10^{-2}$, respectively. The results show that the correct location of discontinuities has been obtained; it is in accordance with the exact solution. The numerical solutions at $t = 1$ and 2 shown in Figure 3 are calculated by our multidomain algorithm (2.2) and (2.3) with the time step sizes $\Delta t = 9.5 \times 10^{-3}$ as well as $\Omega^1 = \{x|x < -1\} \cup \{x|x > 0\}$ and $\Omega^2 = \{x| -1 \le x \le 0\}$. The discontinuities have also been resolved correctly. In this case, the shock wave is passing through the interface of Ω^1 and Ω^2.

However, from Figures 1 and 2, we observe that the solutions calculated by using the fully implicit upwind scheme are more dissipative than those of the explicit upwind

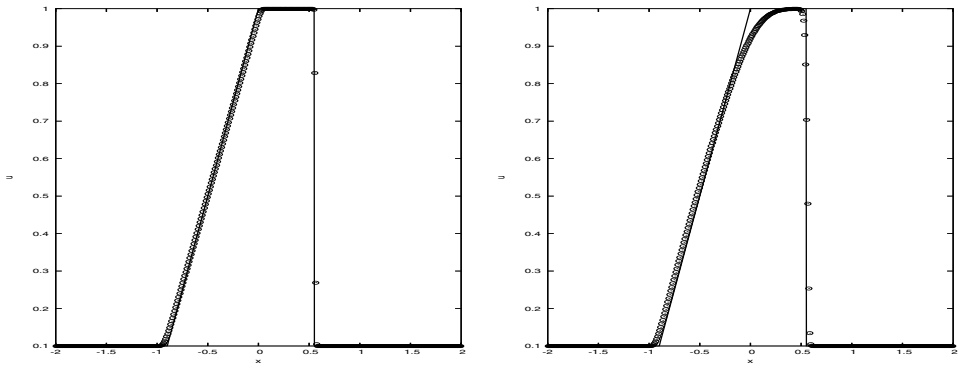

FIG. 1. *Example* 1: *Comparison of the single-domain solutions ("circle") with the exact solutions. Left: explicit upwind scheme; right: implicit upwind scheme.*

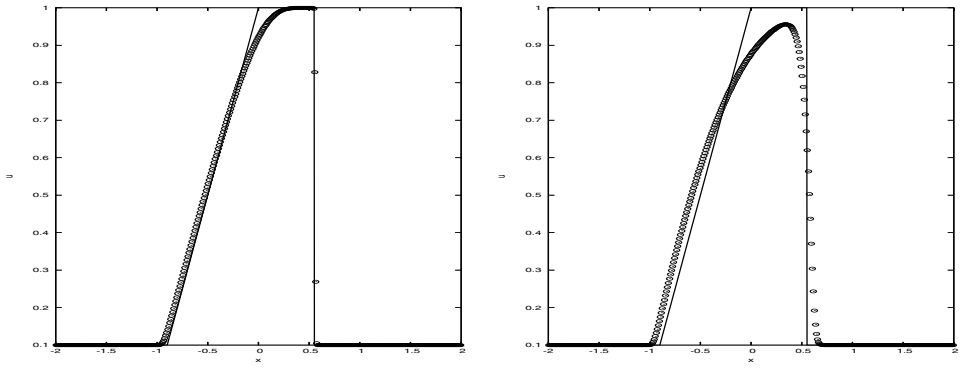

FIG. 2. *Example* 1: *Comparison of multidomain solutions ("circle") with the exact solutions. Left:* $\Delta t = 9.5 \times 10^{-3}$*; right:* $\Delta t = 9.5 \times 10^{-2}$.

scheme. If the time step size is taken larger, resolution of numerical solutions will be decreased; see, e.g., Figure 2. Therefore, it will be meaningful to develop high resolution DDMs for hyperbolic conservation laws.

Even though the numerical solutions obtained by using the DDM (2.2) and (2.3) are less accurate in the above example, this DDM is still very attractive in relaxing the restriction of the time step size and improving the computational efficiency of the DDM algorithm when we solve the steady state problem. In the following, we give a simple example to demonstrate this.

Example 2. This example is to solve the following IBVP of the Burgers equation subject to the periodic data [19]:

$$u(x,0) = \sin(\pi(x+1)), \quad x \in [-1,1). \tag{6.3}$$

The numerical flux $h(u,v)$ is taken as the traditional upwind flux, but an entropy fix should be used to avoid the sonic point glitch [31]. The computational domain $[-1,1]$ is first divided into two subdomains: $\Omega^1 = \{x|x < -0.5\} \cup \{x|x > 0.5\}$ and $\Omega^2 = \{x| -0.5 \le x \le 0.5\}$. The domain Ω^2 is chosen in the region where $f'(u) = u$ is largest and leads to the most severe time step restriction. On the other hand, there the shock appears, and we expect to need a fine spatial resolution for accuracy. The subdomain Ω^1 is then partitioned into 20 large cells, and Ω^2 is divided into 2000 small cells. We now give a comparison of our partitioning method on the two domains with an explicit computation using an explicit method.

The computed solutions at $t = 3$ are shown in Figure 4. We see that the steady state solution of the DDM is slightly more accurate than the explicit upwind scheme. Here we used a fine mesh as in Ω^2 on the whole domain for the explicit scheme with the usual CFL condition. The CFL number used was 0.9. It spent the CPU time of 1.06s. When we use the DDM, the time step size is determined only by the explicit part, and a CPU time of 0.06s is needed.

7. Concluding remarks. The use of DDMs for conservation laws is an emerging field. The potential payoff will lie in a reduction of computing time possibly in conjunction with parallelization and the use of different solvers in different regions of the computational domain. The second author is pursuing the latter approach for

advection-diffusion equations and reaction-diffusion systems in parallel work, e.g., in [15].

A sound analytical foundation of the DDMs is needed. For conservation laws it is currently very difficult to obtain numerical analysis for systems of equations, even impossible for real multidimensional systems and for methods that are higher than first order. The entropy consistency in conjunction with the need to use limiters is the key problem for higher order methods. For conservation laws the most important issue is conservativity. This and other essential properties need careful study in the scalar case, as was done in this paper. The method described in this paper is already an improvement over previous approaches. An important further step is to find a practical solution for the multidimensional systems appearing in practical applications. This development must be guided by the type of analysis we presented in our paper, especially concerning the issue of conservativity.

The analysis and the computational results in this paper suggest that the approach of mixing implicit and explicit methods should be considered further from a computational point of view. Next to considering variants of the computations in this paper, methods of at least second order are needed for practical purposes, even if their analytical basis is still incomplete.

Acknowledgment. The authors would like to thank the referees for many helpful suggestions during the revision of the paper.

WHY FINITE ELEMENT DISCRETIZATIONS CAN BE FACTORED BY TRIANGULAR HIERARCHICAL MATRICES*

MARIO BEBENDORF†

Abstract. Although the asymptotic complexity of direct methods for the solution of large sparse finite element systems arising from second-order elliptic partial differential operators is far from being optimal, these methods are often preferred over modern iterative methods. This is mainly due to their robustness. In this article it is shown that an approximate LU decomposition exists which can be computed in the algebra of hierarchical matrices with almost linear complexity and with the same robustness as the classical LU decomposition. Low-precision approximations may be used for preconditioning iterative solvers. As a byproduct we prove that Schur complements of stiffness matrices can be approximated with almost linear complexity.

Key words. approximate LU decomposition, fast direct solution, preconditioning, hierarchical matrices

1. Introduction.

The finite element discretization of Dirichlet boundary value problems

$$\begin{aligned} Du &= f \quad \text{in } \Omega, \\ u &= g \quad \text{on } \partial\Omega \end{aligned}$$

with general second-order elliptic partial differential operators

$$Du = -\operatorname{div}\left[C\nabla u + c'u\right] + c'' \cdot \nabla u + c_0 u \tag{1}$$

and possibly rough coefficients $c_{ij}, c_i', c_j'', c_0 \in L^\infty(\Omega)$, $i,j = 1,\dots,d$, on a bounded Lipschitz domain $\Omega \subset \mathbb{R}^d$ leads to large sparse linear systems

$$Ax = b, \quad A \in \mathbb{R}^{n\times n}. \tag{2}$$

In this article we assume that for the discretization of (1) quasi-uniform finite elements are used.

The numerical solution of linear systems (2) is usually done iteratively by Krylov subspace methods. The sparse coefficient matrix A enters these solvers only through the matrix-vector product. Iterative methods are particularly efficient if an approximate solution of relatively low accuracy is sought. However, the number of iterations may be large depending on the distribution of the eigenvalues of A. For instance, the spectral condition number of finite element discretizations of the second-order operator D from (1) grows like $n^{2/d}$ for large n but also depends significantly on the coefficients of D. Hence, an appropriate preconditioner has to be employed in order to improve the convergence properties. This usually requires tailoring the preconditioner to the respective application.

The lack of robustness of iterative methods is the reason for the fact that direct solvers are still in use even for large-scale problems. The latter are based on factorizations of the coefficient matrix A into easily invertible matrices. The disadvantage of direct methods is that these factors suffer from so-called *fill-in*; i.e., compared with the sparsity of A considerably more entries of the factors will be nonzero. This usually happens to all entries within the bandwidth of the original matrix, which for Galerkin matrices of operators (1) scales like $n^{1-1/d}$ even if the bandwidth has been reduced, for instance, by the *reverse Cuthill–McKee* (RCM) algorithm [9]. Hence, the fill-in will lead to a computational complexity of order $n^{3-2/d}$. Instead of reducing the bandwidth, the aim of the *minimum degree algorithm* [26, 15] and *nested dissection* [13] is to reduce fill-in. When $d = 2$, the fill-in for nested dissection is of the order $n \log n$, and the complexity is $n^{3/2}$; see [14]. For $d > 2$ the complexity scales like $n^{3-3/d}$; cf. [23]. Constants, however, are attractively small, making direct methods the methods of choice if n is not too large or if we are to solve problems in two spatial dimensions. Here, recent multifrontal solvers (see [1] and the references therein) can be used.

In the last decade many fast algorithms for the direct solution of boundary value problems have been proposed. If Ω is an interval, then the Green function G of ordinary differential operators has the property that

$$G(x,y) = \begin{cases} u_1(x)v_1(y), & x \geq y, \\ u_2(x)v_2(y), & x \leq y, \end{cases}$$

with appropriately chosen functions u_1, v_1, u_2, and v_2. This fact is, for instance, exploited by the algorithm in [30]. The algebraic analogue of the above property are *semiseparable matrices*, which can be factored with linear complexity; cf. [11, 12, 8, 32]. The presence of such structures, which allow an exact factorization, is, however, restricted to one-dimensional problems. For higher dimensions, fast algorithms require approximation; see, for instance, [21] in which the inverse is generated in compressed form.

The aim of this article is to present a new approach that merges the advantages of direct and iterative methods. This will be achieved by generalizing the classical LU decomposition to an approximate LU decomposition, which on one side inherits the robustness of the classical LU decomposition, while on the other side has logarithmic-linear complexity independently of the spatial dimension. The efficiency of this approximate LU decomposition will, however, depend on the accuracy ε although the dependence is only logarithmic. In the limiting case $\varepsilon = 0$, the proposed hierarchical LU decomposition is nothing but a partitioned LU decomposition of a matrix thereby inheriting its $n^{3-2/d}$ asymptotic complexity. Hence, the proposed method aims at applications which admit an approximation of low accuracy. Since the discretization of (1) introduces an approximation error which cannot be removed no matter how accurately the linear system (2) is solved, it is sufficient to compute an LU decomposition with a precision which is of the same order of magnitude as the discretization error. Another application is approximate inverse preconditioning. The results of [4] on approximate preconditioners also hold for approximate inverses obtained by approximate LU decomposition.

Since fill-in will also occur during an approximate LU decomposition, we make use of the structure of hierarchical matrices, by which appropriate dense matrices can be treated with almost linear complexity. Consequently, the bandwidths of the factors L and U will not be an issue. In recent years fast methods for the treatment of large

dense matrices $M \in \mathbb{R}^{n\times n}$ have considerably spread. After the introduction of the *fast multipole method* [25] and the *panel-clustering method* [19], numerous methods have been developed based on low-rank approximations

$$M_{ts} \approx VW^T$$

of appropriate subblocks M_{ts} in the rows and columns $t, s \subset \{1, \dots, n\}$ of M, where $V \in \mathbb{R}^{t\times k}$, $W \in \mathbb{R}^{s\times k}$, and k is small compared with $|t|$ and $|s|$. While the fast multipole method was aiming at an efficient approximate evaluation of matrix-vector products, by the structure of *hierarchical matrices* ($\mathcal{H}$-matrices) (see [17, 18]), one efficiently approximates the matrix entries. Basically, $\mathcal{H}$-matrices are matrices that are of low rank on each block of a certain partition resulting from a recursive subdivision of the set of matrix indices. In addition to the efficient matrix-vector multiplication (also with the transposed matrix) this structure provides approximate operations such as matrix addition, matrix-matrix multiplication, and matrix inversion of fully populated matrices with almost linear complexity. Furthermore, $\mathcal{H}$-matrices can be stored in an almost linear amount of units of memory. In the case of matrices arising from the discretization of integral equations, $\mathcal{H}$-matrices can be efficiently constructed from few of the original matrix entries; see [5, 6]. The existence of $\mathcal{H}$-matrix approximants of almost linear complexity is not self-evident. Recently [7, 2] it was shown that the inverse of finite element discretizations of operators of type (1) can be approximated by $\mathcal{H}$-matrices with a blockwise rank that depends logarithmically on both the number of unknowns n and the accuracy ε. Interestingly, this approximation is very robust with respect to nonsmooth coefficients. The aim of this article is to extend the existence theory to the factors of the LU decomposition. Compared with the $\mathcal{H}$-inverse, the presented $\mathcal{H}$-LU decomposition can be computed in significantly less time while keeping the same robustness with respect to the coefficients of D.

The hierarchical LU decomposition differs conceptually from the so-called *incomplete LU factorization* (ILU); see [27]. The ILU overcomes the problem of fill-in by setting to zero entries in the factors L and U outside of the sparsity pattern of A. Although the ILU can be equipped with a thresholding parameter, it will always result in more or less sparse factors, while the hierarchical LU decomposition is a data-sparse representation of fully (up to the bandwidth) populated matrix approximants.

The structure of this article is as follows: In section 2 a brief review of the structure of $\mathcal{H}$-matrices will be given. The existence of $\mathcal{H}$-matrix approximants, which was proved in [7, 2], will be used to show existence of $\mathcal{H}$-matrix approximants to the factors L and U in section 3. In contrast to the inverse of a finite element Galerkin matrix A, its LU decomposition has no analytic equivalent. It is thus surprising that the matrix partition which has proved useful for elliptic problems can also be used for the approximation of the factors L and U. For the proof of this main result of the article, we first show that each Schur complement in A can be approximated by $\mathcal{H}$-matrices. It will be seen that this knowledge will be sufficient to show that the factors L and U have $\mathcal{H}$-matrix approximants. The complexity estimates show the same dependence on the coefficients of operator (1) as the estimates for the $\mathcal{H}$-inverse. Hence, the asymptotic complexity and the robustness of the hierarchical inverse are inherited by the $\mathcal{H}$-LU decomposition. The ideas of nested dissection can also be used to improve the efficiency of $\mathcal{H}$-matrices; cf. [24]. As for the classical LU decomposition, the $\mathcal{H}$-LU decomposition preserves zero blocks introduced by this special kind of ordering. We remark that the approximation results of this article are obviously valid for the induced matrix partition although we will confine ourselves to standard partitions.

In section 4 the existence result for the factors L and U is used to lay theoretical ground to an algorithm for the approximate factorization. This algorithm uses the $\mathcal{H}$-matrix arithmetic and is related to the partitioned LU decomposition procedure. As a consequence of the partitioned approach, only a limited version of pivoting is possible. Once the matrix partition has been generated from the mesh information, an approximate LU decomposition can be obtained from any Galerkin matrix in a purely algebraic way. Finally, in section 5 numerical results for elliptic partial differential operators with nonsmooth coefficients will confirm our analysis. It will be seen that the proposed approximate LU decomposition can be computed, stored, and used during forward/backward substitution with almost linear complexity. The comparison with MUMPS (see [1]) shows that the exact and the approximate LU decompositions scale similarly for two-dimensional problems. The reduced asymptotic complexity of the $\mathcal{H}$-LU decomposition will be observable in three spatial dimensions.

2. Hierarchical matrices. In this section we will briefly review the structure of $\mathcal{H}$-matrices originally introduced by Hackbusch [17] and Hackbusch and Khoromskij [18]. We will describe the two principles on which the efficiency of $\mathcal{H}$-matrices is based. These are the hierarchical partitioning of the matrix into blocks and the blockwise restriction to low-rank matrices. These principles were also used in the mosaic-skeleton method [31].

In this article we will consider matrices $A \in \mathbb{R}^{n\times n}$ with entries

$$a_{ij} = a(\varphi_j, \varphi_i), \quad i,j = 1,\dots,n, \tag{3}$$

where a is a bilinear form and φ_i are basis functions with supports $X_i := \operatorname{supp} \varphi_i$, $i \in I := \{1,\dots,n\}$. Here, it is crucial that the basis functions φ_i are locally supported. Matrices of type (3) arise, for instance, from the Galerkin method, which is frequently used to discretize operators of type (1). If a arises from the variational formulation of differential operators, then A is a sparse matrix. A will, however, be fully populated in general if a incorporates a nonlocal operator.

In order to be able to approximate each block $t \times s$, $t, s \subset I$, of A by a matrix of low rank, i.e.,

$$A_{ts} \approx VW^T, \quad V \in \mathbb{R}^{t\times k}, W \in \mathbb{R}^{s\times k},$$

where k is small compared with $|t|$ and $|s|$, $t\times s$ has to satisfy a certain condition which is caused by the operator D hidden in a. In the field of elliptic partial differential operators the corresponding Green function $G(x,y)$ has an algebraic singularity for $x = y$. Hence, the following condition on $t \times s$ has proved useful:

$$\min\{\operatorname{diam} X_t, \operatorname{diam} X_s\} < \eta \operatorname{dist}(X_t, X_s), \tag{4}$$

where $\eta > 0$ is a given real number which typically is chosen from the interval $[0.5, 1.5]$. Blocks $t \times s$ satisfying (4) will be called *admissible*. The support X_t of a cluster t is the union of the supports of the basis functions corresponding to the indices contained in t:

$$X_t := \bigcup_{i\in t} X_i.$$

The *far-field* $\mathcal{F}_\eta(t)$ of $t \subset I$ is defined as

$$\mathcal{F}_\eta(t) := \{i \in I : \eta \operatorname{dist}(X_i, X_t) > \operatorname{diam} X_t\},$$

and by $\mathcal{N}_\eta(t) := I \setminus \mathcal{F}_\eta(t)$ we denote the *near-field* of t. As usual we set

$$\operatorname{diam} X = \sup_{x,y\in X} |x-y| \quad \text{and} \quad \operatorname{dist}(X,Y) = \inf_{x\in X,\, y\in Y} |x-y|$$

for two bounded sets $X, Y \subset \mathbb{R}^d$. Hence, (4) is equivalent to the condition $s \subset \mathcal{F}_\eta(t)$ or $t \subset \mathcal{F}_\eta(s)$. Note that (4) implies that the partition we are looking for has to be refined towards the diagonal of A, since the diagonal entries arise from the interaction of the same basis functions; i.e., $\operatorname{dist}(X_t, X_s) = 0$ for all blocks $t \times s$ containing the diagonal.

The construction of a partition P of the matrix indices $I \times I$ consisting of admissible blocks or blocks which are small enough is usually based on cluster trees. A tree T_I satisfying the following conditions is called a *cluster tree* for I:

(i) I is the root of T_I;

(ii) if $t \in T_I$ is not a leaf, then t has sons $t_1, t_2 \in T_I$, so that $t = t_1 \dot\cup t_2$.[1]

The set of sons of $t \in T_I$ is denoted by $\mathcal{S}(t)$, while $\mathcal{L}(T_I)$ stands for the set of leaves of the tree T_I.

A cluster tree is usually generated by recursive subdivision of I. For practical purposes the recursion should be stopped if a certain cardinality $n_{\min}$ of the clusters is reached, rather than subdividing the clusters until only one index is left. The depth of T_I, i.e., the maximum distance of a vertex to the root of the tree increased by one, will be denoted by p, which for quasi-uniform grids can be guaranteed to be of the order $\log n$.

Note that by moving the indices of the first son t_1 to the beginning of t we can always obtain contiguous clusters; i.e., for $t \in T_I$ there are $t_{\min}, t_{\max} \in \mathbb{N}$ such that

$$t = \{i \in I : t_{\min} \le i \le t_{\max}\}.$$

This rearrangement induces a reordering of the index set I.

Remark 2.1. Since for each subdivision we have only two possibilities for arranging the indices, i.e., $t = [t_1, t_2]$ or $t = [t_2, t_1]$, the above construction leaves room for only $2^p n_{\min}!$ permutations of I (the size of the leaves in T_I is assumed to be exactly $n_{\min}$). Hence, building the cluster tree determines the numbering of the indices in I up to $\mathcal{O}(n)$ permutations.

Using a cluster tree, which contains a hierarchy of partitions of I, a block cluster tree $T_{I\times I}$ is constructed by recursively subdividing each block $t \times s$ into four disjoint subblocks $t_1 \times s_1$, $t_1 \times s_2$, $t_2 \times s_1$ and $t_2 \times s_2$, $t_1, t_2 \in \mathcal{S}(t)$, $s_1, s_2 \in \mathcal{S}(s)$, starting from the set of matrix indices $I \times I$. This recursion stops in blocks which satisfy (4) or are small enough. The resulting set of leaves $P := \mathcal{L}(T_{I\times I})$ is a partition with the desired properties. For a detailed description of the partitioning of a matrix into admissible subblocks the reader is referred to [4]. An important property of P is that a constant $c_{\mathrm{sp}} > 0$ exists such that for each set of indices $t \subset I$ there are at most c_{sp} blocks $t \times s \in P$ and at most c_{sp} blocks $s \times t \in P$ with some set of indices $s \subset I$; cf. [16].

On P we define the set of $\mathcal{H}$-matrices (see Figure 1) with blockwise rank k by

$$\mathcal{H}(T_{I\times I}, k) := \{M \in \mathbb{R}^{I\times I} : \operatorname{rank} M_b \le k \text{ for all } b \in \mathcal{L}(T_{I\times I})\}.$$

Note that $\mathcal{H}(T_{I\times I}, k)$ is not a linear space since the sum of two rank-k matrices exceeds rank k in general.

[1] In the case of nested dissection a subdivision into three sons is required.

Remark 2.2. For a block $B \in \mathbb{R}^{t\times s}$ the low-rank representation $B = VW^T$, $V \in \mathbb{R}^{t\times k}$, $W \in \mathbb{R}^{s\times k}$, is advantageous compared with the entrywise representation only if $k(|t| + |s|) \leq |t|\,|s|$. For the sake of simplicity in this article we will, however, assume that each block has the low-rank representation. Employing the entrywise representation for appropriate blocks will accelerate the algorithms.

Exploiting the hierarchical structure of $M \in \mathcal{H}(T_{I\times I}, k)$, it can be shown that the storage requirement for $M \in \mathcal{H}(T_{I\times I}, k)$ is of the order $kn \log n$. Multiplying M by a vector can be done with $\mathcal{O}(kn \log n)$ arithmetical operations. Two $\mathcal{H}$-matrices from $\mathcal{H}(T_{I\times I}, k)$ can be added with complexity $\mathcal{O}(k^2 n \log n)$ provided that the sum can be approximated with the desired accuracy by a matrix having blockwise rank at most k. The complexity of computing a rounded product of two $\mathcal{H}$-matrices is $\mathcal{O}(k^2 n(\log n)^2)$; see [17, 18, 16]. It was already mentioned in [17] that LU decompositions can be computed in the algebra of $\mathcal{H}$-matrices with complexity $k^2 n(\log n)^2$ assuming that arising blocks are approximated by rank-k matrices. In order to be able to deduce almost linear complexity from these complexity estimates it is crucial to know how the blockwise rank k depends on the accuracy ε of the approximation or, conversely, which accuracy is associated with a given k. In the extreme case $k \sim n$ the $\mathcal{H}$-matrix operations would be as expensive as the usual ones. Analyzing the relation between k and ε is the main purpose of this article. It will turn out that k depends logarithmically on both ε and n.

2.1. Bandwidth and $\mathcal{H}$-matrices. Although $\mathcal{H}$-matrices are primarily aiming at dense matrices, the stiffness matrix A of the differential operator D from (1) is in $\mathcal{H}(T_{I\times I}, n_{\min})$ and can be stored in this format with complexity $\mathcal{O}(n)$. This can be seen by the following arguments. If $b \in P$ is admissible, then the supports of the basis functions are pairwise disjoint. Hence, the matrix entries in this block vanish. In the remaining case, b does not satisfy (4). Then the size of one of the clusters is less than or equal to $n_{\min}$. In either case, the rank of A_b does not exceed $n_{\min}$. The last observation is of particular importance since it will allow us to compute an LU decomposition using approximate arithmetical operations on the set of $\mathcal{H}$-matrices; see section 4.

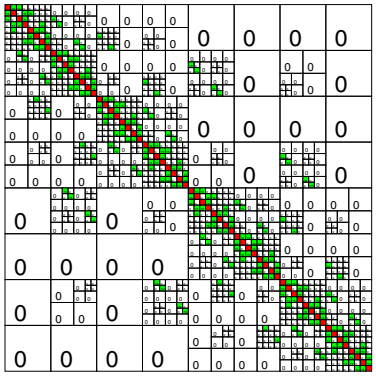

FIG. 1. *A sparse $\mathcal{H}$-matrix with its rank distribution.*

The efficiency of the usual LU decomposition is determined by the bandwidth of A unless special reordering techniques such as nested dissection are employed. The reason for this is that although A is sparse, the factors L and U will in general be fully

populated up to the bandwidth. Since $\mathcal{H}$-matrices are able to handle dense matrices with almost linear complexity, the bandwidth of A is not an issue when using this structure. Due to the reordering of indices required when building the cluster tree, we even obtain a bandwidth which is of order n. This will result in an enormous fill-in and is unavoidable as can be seen by the following example.

A matrix entry a_{ij} in the Galerkin matrix A will in general be nonzero if the supports of the associated basis functions φ_i and φ_j have a nonempty intersection. For simplicity we investigate the situation which occurs for a regular triangulation of the unit square in $\mathbb{R}^2$. Assume that after two subdivision steps this square has been subdivided into four smaller squares of the same size each containing $n/4$ supports. During the subdivision, the indices are reordered so that the kth square contains the indices $(k-1)n/4+1$ to $kn/4$, $k=1,\dots,4$. Hence, the first and the last square contain indices which differ by at least $n/2$. These squares intersect in the center of the original square. Therefore, at this point the supports of two basis functions φ_i and φ_j with $|i-j|\geq n/2$ intersect. This situation persists when the subdivision is continued since the indices are rearranged only within each subsquare.

2.2. Where can $\mathcal{H}$-matrices be applied? One of the first applications of the structure of $\mathcal{H}$-matrices was the acceleration of both the building process and the matrix-vector multiplication of discrete integral operators with smooth kernels having an algebraic singularity at $x=y$. This kind of integral operator arises, for instance, from the boundary element method. For such operators the adaptive cross approximation (ACA) algorithm [5, 6] can be used to generate the low-rank approximants from few of the original matrix entries.

In addition to discretizations of integral operators with smooth kernel functions, in [7, 2] it was shown that inverses of discrete elliptic differential operators with measurable coefficients can be approximated on partitions satisfying (4). Since the analysis of this article will be based on approximations of the inverse, we state the main result of [2]. Let the operator D from (1) be uniformly elliptic; i.e., for the coefficient $C(x)\in\mathbb{R}^{d\times d}$ of D it holds that C is symmetric with $c_{ij}\in L^\infty(\Omega)$ and

$$0<\lambda\leq\lambda(x)\leq\Lambda$$

for all eigenvalues $\lambda(x)$ of $C(x)$ and almost all $x\in\Omega$. Furthermore, let $e_h(u):=\|u-P_hu\|_{L^2(\Omega)}$ be the finite element error, where $P_h: H^1_0(\Omega)\to V_h$ is the Ritz projector mapping $u\in H^1_0(\Omega)$ to its finite element solution u_h; i.e., the solution of $a(u_h,v_h)=\ell(v_h)$ for all $v_h\in V_h$ with a linear form ℓ. We assume that the finite element method converges in the following sense:

$$e_h(u)\leq\varepsilon_h\|f\|_{L^2(\Omega)}\quad\text{for all } u=D^{-1}f,\ f\in L^2(\Omega), \tag{5}$$

where $\varepsilon_h\to 0$ as $h\to 0$. Note that due to a possible lack of regularity of D one cannot guarantee a specific rate of convergence.

THEOREM 2.3. *Let p be the depth of the cluster tree T_I defined in the beginning of section 2. Then there is $C_{\mathcal{H}}\in\mathcal{H}(T_{I\times I},k)$ with $k:=p^2\log^{d+1}(p/\varepsilon_h)$ such that*

$$\|A^{-1}-C_{\mathcal{H}}\|_2<c\,\varepsilon_h\|A^{-1}\|_2,$$

where $c=c(D,\Omega,\eta)>0$ depends on the size of coefficients of D, the diameter of Ω, and the cluster parameter η. If $\varepsilon_h=\mathcal{O}(h^\beta)$ for some $\beta>0$, then $k=\mathcal{O}(\log^{d+3}n)$ holds.

Remark 2.4. Since the proof of Theorem 2.3 is based on the finite element error estimate (5), we were only able to show existence of approximants with an accuracy which is of the order of the finite element error ε_h. This is not a restriction since a higher accuracy in the approximation of the inverse would be superposed by the finite element error in the solution anyhow. However, numerical experiments show that the above result is true for any accuracy. Therefore, in this article we assume that for any $\varepsilon > 0$ there is $C_{\mathcal{H}} \in \mathcal{H}(T_{I\times I}, k)$ with $k := |\log \varepsilon|^{d+1}(\log n)^2$ such that

$$\|A^{-1} - C_{\mathcal{H}}\|_2 < c\,\varepsilon \|A^{-1}\|_2,$$

where $c > 0$ depends on the size of the coefficients of D, the diameter of Ω, and η.

2.3. Schur complements. Among other applications, the efficient treatment of Schur complements is of particular importance for domain decomposition methods (see, for instance, [29]). In this section it will be shown that Schur complements of subblocks of A can be approximated by $\mathcal{H}$-matrices. This result will lay ground to our main aim, the approximation of the factors L and U arising from the LU decomposition of A.

Assume that the Galerkin stiffness matrix $A \in \mathbb{R}^{n\times n}$ is partitioned in the following way:

$$A = \begin{bmatrix} A_{rr} & A_{rr'} \\ A_{r'r} & A_{r'r'} \end{bmatrix}, \tag{6}$$

where $r \subset I$ and $r' := I \setminus r$. We will show that the Schur complement

$$S := A_{r'r'} - A_{r'r} A_{rr}^{-1} A_{rr'}$$

of A_{rr} in A can be approximated by an $\mathcal{H}$-matrix with blockwise rank k, where k depends only logarithmically on both the approximation accuracy ε and n. For this purpose it is crucial to notice that A_{rr} in (6) is nothing but the Galerkin matrix of D if we replace Ω by the subdomain X_r. Hence, Theorem 2.3 guarantees that an $\mathcal{H}$-matrix approximant for A_{rr}^{-1} exists. Additionally, we assume that there is a constant $c > 0$ such that

$$\|A_{rr}^{-1}\|_2 \le c\|A^{-1}\|_2. \tag{7}$$

The previous estimate holds, for instance, if D is self-adjoint and its associated bilinear form a is V_h-coercive in the sense that there is $\alpha > 0$ satisfying

$$\alpha = \inf_{v_h \in V_h} \frac{a(v_h, v_h)}{\|v_h\|_{H^1}^2}.$$

Then

$$\|A_{rr}^{-1}\|_2 = \sup_{x\in\mathbb{R}^I} \frac{\|Rx\|_2^2}{a(JRx, JRx)} \le \frac{1}{c_1 h^d} \sup_{x\in\mathbb{R}^I} \frac{\|JRx\|_{H^1}^2}{a(JRx, JRx)} \le \frac{1}{\alpha c_1 h^d} \tag{8a}$$

$$= \frac{1}{c_1 h^d} \sup_{u\in H^1(\Omega)} \frac{\|Jx\|_{H^1}^2}{a(Jx, Jx)} \le c' \frac{c_2}{c_1} \sup_{x\in\mathbb{R}^I} \frac{\|x\|_2^2}{a(Jx, Jx)} = c' \frac{c_2}{c_1} \|A^{-1}\|_2, \tag{8b}$$

where R denotes the restriction of $\mathbb{R}^I$ to $\mathbb{R}^r$ and $Jx := \sum_{i\in I} x_i \varphi_i$ with the finite element basis functions φ_i. In (8) we have used that for quasi-uniform discretizations it holds that

$$c_1 \|x\|_2^2 \le h^{-d} \|Jx\|_{L^2}^2 \le c_2 \|x\|_2^2 \quad \text{for all } x \in \mathbb{R}^I$$

and that $\|\cdot\|_{H^1} \le c'\|\cdot\|_{L^2}$ on $H_0^1(\Omega)$.

Let $t \in T_I$ be a cluster. By

$$N(t) = \{i \in I : \operatorname{dist}(X_i, X_t) = 0\} \tag{9}$$

we denote a neighborhood of t. Furthermore, we define the ratios

$$q := \frac{\max_{i\in I} \operatorname{diam} X_i}{\min_{t\in T_I} \operatorname{diam} X_t} \quad \text{and} \quad \bar q := \max_{t\in T_I} \frac{\operatorname{diam} X_{N(t)}}{\operatorname{diam} X_t} \le 1 + 2q.$$

Since the minimal cluster size $n_{\min}$ is usually chosen larger than 20, one can expect that realistic values for $\bar q$ are close to 1. The size of q depends on the uniformity of $\{X_i\}_{i\in I}$. We need the following basic lemma, which states that the neighborhood of t is in the far-field of the neighborhood of s if t is in the far-field of s.

LEMMA 2.5. *Let $0 < \eta < (q+\bar q)^{-1}$. If $t \subset \mathcal{F}_\eta(s)$, then*

$$N(t) \subset \mathcal{F}_{\tilde\eta}(N(s)), \quad \textit{where} \quad \tilde\eta = \frac{\bar q\eta}{1-(q+\bar q)\eta}.$$

Proof. Since $\max_{i\in I} \operatorname{diam} X_i \le q \operatorname{diam} X_s$, we obtain for $x \in X_{N(t)}$ and $y \in X_{N(s)}$ that

$$\begin{aligned} |x-y| &\ge \operatorname{dist}(X_t, X_s) - \max_{i\in I} \operatorname{diam} X_i - \operatorname{diam} X_{N(s)} \\ &> \left(\frac{1}{\eta} - q\right) \operatorname{diam} X_s - \operatorname{diam} X_{N(s)} \\ &\ge \left[\frac{1}{\bar q}\left(\frac{1}{\eta} - q\right) - 1\right] \operatorname{diam} X_{N(s)}, \end{aligned}$$

which proves the assertion. ∎

Approximation results for $\mathcal{H}$-matrices are usually derived for each block of the partition. By the following estimates it is possible to relate the blockwise norms of an $\mathcal{H}$-matrix to its global norm. If we are interested in the Frobenius norm, estimates for each block E_b, $b \in P$, immediately lead to an estimate for $E \in \mathbb{R}^{I\times I}$ due to

$$\|E\|_F^2 = \sum_{b\in P} \|E_b\|_F^2.$$

For the spectral norm the situation is a bit more difficult. We can, however, use the following lemma together with the structure of P.

LEMMA 2.6. *We consider the $\nu \times \nu$ block matrix*

$$E = \begin{bmatrix} E_{11} & \dots & E_{1\nu} \\ \vdots & & \vdots \\ E_{\nu 1} & \dots & E_{\nu\nu} \end{bmatrix} \tag{10}$$

with $E_{ij} \in \mathbb{R}^{m_i\times n_j}$, $i,j = 1,\dots,\nu$. Then it holds that

$$\max_{i,j=1,\dots,\nu} \|E_{ij}\|_2 \le \|E\|_2 \le \left(\max_{i=1,\dots,\nu} \sum_{j=1}^{\nu} \|E_{ij}\|_2\right)^{1/2} \left(\max_{j=1,\dots,\nu} \sum_{i=1}^{\nu} \|E_{ij}\|_2\right)^{1/2}. \tag{11}$$

Proof. Let $u = [u_1, \dots, u_\nu]^T \in \mathbb{R}^n$, where $n = \sum_{j=1}^{\nu} n_j$. Observe that

$$\|Eu\|_2^2 = \sum_{i=1}^{\nu} \left\| \sum_{j=1}^{\nu} E_{ij} u_j \right\|_2^2 \le \sum_{i=1}^{\nu} \left(\sum_{j=1}^{\nu} \|E_{ij}\|_2 \|u_j\|_2 \right)^2 = \|\hat{E}\hat{u}\|_2^2,$$

where $\hat{E} \in \mathbb{R}^{\nu\times\nu}$ has the entries $\hat{E}_{ij} = \|E_{ij}\|_2$ and $\hat{u} \in \mathbb{R}^\nu$ is the vector with components $\hat{u}_j = \|u_j\|_2$, $j = 1, \dots, \nu$. It is well known that $\|\hat{E}\|_2^2 \le \|\hat{E}\|_1 \|\hat{E}\|_\infty$. Hence,

$$\|\hat{E}\hat{u}\|_2^2 \le \|\hat{E}\|_1 \|\hat{E}\|_\infty \|\hat{u}\|_2^2 = \|\hat{E}\|_1 \|\hat{E}\|_\infty \|u\|_2^2$$

gives the first part of the assertion. The lower bound follows from the fact that the spectral norm of any subblock of E is bounded by the spectral norm of E. ∎

An important consequence of (11) is that for matrices (10) vanishing in all but μ blocks in each row and each column it follows that

$$\max_{i,j=1,\dots,\nu} \|E_{ij}\|_2 \le \|E\|_2 \le \mu \max_{i,j=1,\dots,\nu} \|E_{ij}\|_2.$$

The previous estimate was also proved in [16] with a different technique. This equivalence of the global and the blockwise spectral norm is useful in translating a blockwise error to a global one. When relative error estimates are to be derived, we will additionally need to estimate how a blockwise norm relation is carried over to the whole matrix.

LEMMA 2.7. *Let P be the leaves of a block cluster tree $T_{I\times I}$. Then for $E, F \in \mathcal{H}(T_{I\times I}, k)$ it holds that*

(i) $\max_{b\in P} \|E_b\|_2 \le \|E\|_2 \le c_{\mathrm{sp}} p \max_{b\in P} \|E_b\|_2$;

(ii) $\|E\|_2 \le c_{\mathrm{sp}} p \|F\|_2$ *provided* $\max_{b\in P} \|E_b\|_2 \le \max_{b\in P} \|F_b\|_2$.

Proof. Let E_ℓ denote the part of E which corresponds to the blocks of P from the ℓth level $T_{I\times I}^{(\ell)}$ of $T_{I\times I}$; i.e.,

$$(E_\ell)_b = \begin{cases} E_b, & b \in T_{I\times I}^{(\ell)} \cap P, \\ 0, & \text{else.} \end{cases}$$

Since E_ℓ has tensor structure with at most c_{sp} blocks per row or block column, Lemma 2.6 gives $\|E_\ell\|_2 \le c_{\mathrm{sp}} \max_{b\in T_{I\times I}^{(\ell)}\cap P} \|E_b\|_2$ such that

$$\|E\|_2 \le \sum_{\ell=0}^{p-1} \|E_\ell\|_2 \le c_{\mathrm{sp}} \sum_{\ell=0}^{p-1} \max_{b\in T_{I\times I}^{(\ell)}\cap P} \|E_b\| \le c_{\mathrm{sp}} p \max_{b\in P} \|E_b\|_2.$$

The estimate

$$\max_{b\in P} \|E_b\|_2 \le \max_{b\in P} \|F_b\|_2 \le \|F\|_2$$

gives the second part of the assertion. ∎

Using the last three lemmas, we can now prove that the Schur complement S of finite element Galerkin matrices A can be approximated with almost linear complexity.

THEOREM 2.8. *Let the finite element Galerkin matrix $A \in \mathbb{R}^{n\times n}$ be partitioned as in* (6). *Then for the Schur complement*

$$S = A_{r'r'} - A_{r'r} A_{rr}^{-1} A_{rr'}$$

of A_{rr}, $r \neq \emptyset$, in A and all $\varepsilon > 0$ there is $S_{\mathcal{H}} \in \mathcal{H}(T_{r'\times r'}, k_S)$, where $k_S \sim |\log\varepsilon|^{d+1}(\log|r|)^2$, such that

$$\|S - S_{\mathcal{H}}\|_2 < \kappa p\varepsilon\|A\|_2, \tag{12}$$

where $\kappa := \|A\|_2\|A^{-1}\|_2$ denotes the spectral condition number of A.

Proof. We have to show that for each admissible subblock $t \times s \in P$ of $r' \times r'$ and any prescribed accuracy $\varepsilon > 0$ we can find a low-rank matrix which approximates S_{ts} with accuracy ε. Since $t \times s$ is admissible, $(A_{r'r'})_{ts} = 0$ holds. Hence,

$$S_{ts} = -A_{tr}A_{rr}^{-1}A_{rs} = -\sum_{i,j\in r} A_{ti}(A_{rr}^{-1})_{ij}A_{js}.$$

If $i \notin N(t)$, where $N(t)$ is defined in (9), then $A_{ti} = 0$. If, on the other hand, $j \notin N(s)$, then $A_{js} = 0$. With the notation $N'(t) := N(t) \cap r$, we have

$$S_{ts} = -\sum_{i\in N'(t),\, j\in N'(s)} A_{ti}(A_{rr}^{-1})_{ij}A_{js}.$$

Since $t \times s$ is admissible, $t \subset \mathcal{F}_\eta(s)$ or $s \subset \mathcal{F}_\eta(t)$ holds. According to Lemma 2.5, it follows that $N(t) \subset \mathcal{F}_{\tilde\eta}(N(s))$ or $N(s) \subset \mathcal{F}_{\tilde\eta}(N(t))$ is valid. Following Theorem 2.3 (with η replaced by $\tilde\eta$), there are $X \in \mathbb{R}^{N'(t)\times k}$ and $Y \in \mathbb{R}^{N'(s)\times k}$ with $k \sim |\log\varepsilon|^{d+1}(\log|r|)^2$ such that

$$\|(A_{rr}^{-1})_{N'(t)N'(s)} - XY^T\|_2 < \varepsilon\|A_{rr}^{-1}\|_2.$$

Let X and Y be extended to $\hat X \in \mathbb{R}^{r\times k}$ and $\hat Y \in \mathbb{R}^{r\times k}$ by adding zero rows. Observe that

$$\begin{aligned} A_{tr}\hat X\hat Y^T A_{rs} &= \sum_{i\in N'(t),\, j\in N'(s)} \sum_{\ell=1}^{k} A_{ti}X_{i\ell}Y_{j\ell}A_{js} \\ &= \sum_{\ell=1}^{k} \left(\sum_{i\in N'(t)} A_{ti}X_{i\ell}\right)\left(\sum_{j\in N'(s)} Y_{j\ell}A_{js}\right) =: VW^T, \end{aligned}$$

where $V \in \mathbb{R}^{t\times k}$, $W \in \mathbb{R}^{s\times k}$ have the entries

$$V_{t\ell} := \sum_{i\in N'(t)} A_{ti}X_{i\ell} \quad\text{and}\quad W_{s\ell} := \sum_{j\in N'(s)} Y_{j\ell}A_{js}, \qquad \ell = 1,\dots,k.$$

Define $B \in \mathbb{R}^{r\times r}$ with entries

$$b_{ij} = \begin{cases} (A_{rr}^{-1})_{ij} & \text{if } i \in N'(t) \text{ and } j \in N'(s), \\ 0 & \text{else;} \end{cases}$$

then using (7) it follows that

$$\begin{aligned} \|S_{ts} - VW^T\|_2 &= \|A_{tr}(B - \hat X\hat Y^T)A_{rs}\|_2 \le \|A_{tr}\|_2\|(A_{rr}^{-1})_{N'(t)N'(s)} - XY^T\|_2\|A_{rs}\|_2 \\ &\le \varepsilon\|A_{tr}\|_2\|A_{rr}^{-1}\|\|A_{rs}\|_2 < c\kappa\varepsilon\|A\|_2. \end{aligned}$$

The assertion follows from Lemma 2.7. ∎

Since the spectral condition number κ grows polynomially with n and since the accuracy ε enters the complexity estimate only through the logarithm, we can get rid of the factor κ in (12) if the rank k_S is increased by adding a logarithmic factor.

3. Hierarchical *LU* decomposition. Assume that all minors of A are nonzero. Then A can be factored as

$$A = LU,$$

where L is a unit lower triangular and U is an upper triangular matrix. In this section it will be shown that the factors L and U can be approximated by $\mathcal{H}$-matrices $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$ if any Schur complement in A has this property. Note that the following proof consists of algebraic arguments only. Hence, the LU decompositions can be accelerated also for problems that do not stem from finite element applications as long as the Schur complements are known to have an approximant in the set of $\mathcal{H}$-matrices.

When computing pointwise LU decompositions, usually pivoting is performed in order to avoid zero or almost zero pivots. For block versions of the LU algorithm the possibilities of pivoting are limited if the blocking is given. In our case we can choose from only two possible pivots, block $t_1 \times t_1$ or block $t_2 \times t_2$, if the LU decomposition of a block $t \times t$, $t = t_1 \cup t_2$, is to be computed. Hence, the accuracy analysis cannot rely on the advantages of pivoting.

In order to show that L and U can be approximated by $\mathcal{H}$-matrices it seems natural to define the approximants

$$\tilde{L} = \begin{bmatrix} \tilde{L}_{11} & \\ \tilde{L}_{21} & \tilde{L}_{22} \end{bmatrix} \quad \text{and} \quad \tilde{U} = \begin{bmatrix} \tilde{U}_{11} & \tilde{U}_{12} \\ & \tilde{U}_{22} \end{bmatrix}$$

recursively as

$$\tilde{L}_{11}\tilde{U}_{11} = A_{11} + E_{11}, \tag{13a}$$

$$\tilde{L}_{11}\tilde{U}_{12} = A_{12} + E_{12}, \tag{13b}$$

$$\tilde{L}_{21}\tilde{U}_{11} = A_{21} + E_{21}, \tag{13c}$$

$$\tilde{L}_{22}\tilde{U}_{22} = A_{22} - \tilde{L}_{21}\tilde{U}_{12} + E_{22}, \tag{13d}$$

replacing appropriate subblocks of the arising Schur complements with low-rank matrices thereby introducing the error terms E_{12} and E_{21}. The errors E_{11} and E_{22} could then be estimated by the error analysis of the block LU decomposition; see [10]. The problem with this approach is that the arising Schur complements (see (13d)) are not the original complements but complements that contain the perturbations from all previous approximation steps. Since it cannot be guaranteed that these perturbed complements can be approximated by $\mathcal{H}$-matrices and since their distance to the exact complements leads to unattractive estimates, we have to go a different way for the proof. In the following subsection we first find a recursive relation between the Schur complement of a block b and the complements of its subblocks.

3.1. A hierarchy of Schur complements. Let $A \in \mathbb{R}^{n\times n}$ and $t, s \subset I$. With the notations $\hat{t} = \{i \in I : i \le \max t\}$ and $\hat{s} = \{j \in I : j \le \max s\}$ the Schur complement for the block $t \times s$ in $A_{\hat{t}\hat{s}}$ is defined as

$$S(t,s) = A_{ts} - A_{tr}A_{rr}^{-1}A_{rs}, \tag{14}$$

where $r = \{i \in I : i < \min t \cup s\}$; see Figure 2. Note that in the case $r = \emptyset$ this definition is meant to result in $S(t,s) = A_{ts}$. For $t = s$ the expression $S(t,s)$ is the usual Schur complement of A_{rr} in $A_{\hat{t}\hat{t}}$. Note that if t_1, t_2 are the sons of t, then

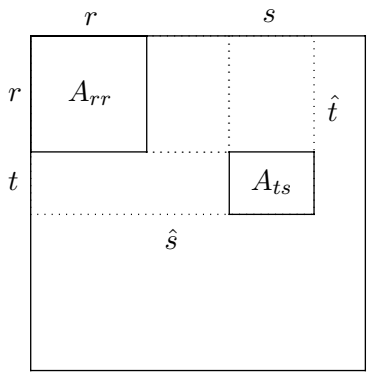

FIG. 2. *Schur complement of a block* $t \times s$.

$S(t_2, t_2)$ does not coincide with the subblock in the rows t_2 and columns t_2 of $S(t, t)$ in general. The following lemma will show the right relation between the complement of a block and the complements of its subblocks. For the ease of notation we first consider the case of blocks on the diagonal.

LEMMA 3.1. *Let* $t \in T_I$ *and let* t_1, t_2 *be its sons. Then*

$$S(t,t) = \begin{bmatrix} S(t_1,t_1) & S(t_1,t_2) \\ S(t_2,t_1) & S(t_2,t_2) + S(t_2,t_1)S(t_1,t_1)^{-1}S(t_1,t_2) \end{bmatrix}.$$

Proof. Let $S(t, t)$ be decomposed in the following way:

$$S(t,t) = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix}.$$

For the blocks (t_1, t_1), (t_1, t_2), and (t_2, t_1) the definition of r from (14) results in $r = \{i \in I : i < \min t\}$. Hence, we obtain

$$S(t_1,t_2) = A_{t_1t_2} - A_{t_1r}A_{rr}^{-1}A_{rt_2} = S_{12}.$$

Similarly, one sees that $S(t_1, t_1) = S_{11}$ and $S(t_2, t_1) = S_{21}$. It remains to show that

$$S_{22} = S(t_2,t_2) + S_{21}S_{11}^{-1}S_{12}.$$

Let $\bar{r} = \{i \in I : i < \min t\}$. Then from the definition of $S(t, t)$ it follows that

$$S(t_2,t_2) = A_{t_2t_2} - \begin{bmatrix} A_{t_2\bar{r}} & A_{t_2t_1} \end{bmatrix} \begin{bmatrix} A_{\bar{r}\bar{r}} & A_{\bar{r}t_1} \\ A_{t_1\bar{r}} & A_{t_1t_1} \end{bmatrix}^{-1} \begin{bmatrix} A_{\bar{r}t_2} \\ A_{t_1t_2} \end{bmatrix}.$$

Since

$$\begin{bmatrix} A_{\bar{r}\bar{r}} & A_{\bar{r}t_1} \\ A_{t_1\bar{r}} & A_{t_1t_1} \end{bmatrix}^{-1} = \begin{bmatrix} A_{\bar{r}\bar{r}}^{-1} & -A_{\bar{r}\bar{r}}^{-1}A_{\bar{r}t_1}S_{11}^{-1} \\ 0 & S_{11}^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -A_{t_1\bar{r}}A_{\bar{r}\bar{r}}^{-1} & I \end{bmatrix},$$

we have

$$\begin{aligned} S(t_2,t_2) &= A_{t_2t_2} - \begin{bmatrix} A_{t_2\bar{r}} & A_{t_2t_1} \end{bmatrix} \begin{bmatrix} A_{\bar{r}\bar{r}}^{-1} & -A_{\bar{r}\bar{r}}^{-1}A_{\bar{r}t_1}S_{11}^{-1} \\ 0 & S_{11}^{-1} \end{bmatrix} \begin{bmatrix} I & 0 \\ -A_{t_1\bar{r}}A_{\bar{r}\bar{r}}^{-1} & I \end{bmatrix} \begin{bmatrix} A_{\bar{r}t_2} \\ A_{t_1t_2} \end{bmatrix} \\ &= A_{t_2t_2} - \begin{bmatrix} A_{t_2\bar{r}} & A_{t_2t_1} \end{bmatrix} \begin{bmatrix} A_{\bar{r}\bar{r}}^{-1} & -A_{\bar{r}\bar{r}}^{-1}A_{\bar{r}t_1}S_{11}^{-1} \\ 0 & S_{11}^{-1} \end{bmatrix} \begin{bmatrix} A_{\bar{r}t_2} \\ S_{12} \end{bmatrix} \\ &= A_{t_2t_2} - \begin{bmatrix} A_{t_2\bar{r}}A_{\bar{r}\bar{r}}^{-1} & S_{21}S_{11}^{-1} \end{bmatrix} \begin{bmatrix} A_{\bar{r}t_2} \\ S_{12} \end{bmatrix} = S_{22} - S_{21}S_{11}^{-1}S_{12}, \end{aligned}$$

which proves the assertion. ∎

Since each block $t \times s$ in the upper triangular part, i.e., $\max t \le \min s$, can be embedded into the block $r \times r$, $r = \{i \in I : \min t \le i \le \max s\}$, Lemma 3.1 gives

$$S(t,s) = \begin{bmatrix} S(t_1,s) \\ S(t_2,s_1) + S(t_2,t_1)S(t_1,t_1)^{-1}S(t_1,s) \end{bmatrix}. \tag{15}$$

Similarly, for each block $t \times s$ in the lower triangular part, i.e., $\max s \le \min t$, it holds that

$$S(t,s) = \begin{bmatrix} S(t,s_1) & S(t,s_2) + S(t_1,s_1)S(s_1,s_1)^{-1}S(s_1,s_2) \end{bmatrix}.$$

3.2. Constructing the factors $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$. We assume that the corresponding Schur complement $S(t,s)$ for each admissible block $t \times s \in \mathcal{L}(T_{I\times I})$ can be approximated by a matrix of low rank with arbitrary accuracy; i.e, for all $\varepsilon > 0$ there is $\tilde{S}(t,s) \in \mathbb{R}^{t\times s}$ of rank $k_S \sim (\log n)^{\alpha} |\log \varepsilon|^{\beta}$ with some $\alpha, \beta > 0$ such that

$$\|S(t,s) - \tilde{S}(t,s)\|_2 \le \varepsilon \|A\|_2. \tag{16}$$

According to Theorem 2.8, this assumption is fulfilled, for instance, in the case of finite element stiffness matrices.

In order to define the factors $L(t)$ and $U(t)$ of $S(t,t) = L(t)U(t)$, $t \in T_I \setminus \mathcal{L}(T_I)$, we set

$$L(t) := \begin{bmatrix} L(t_1) & 0 \\ S(t_2,t_1)U(t_1)^{-1} & L(t_2) \end{bmatrix} \quad \text{and} \quad U(t) := \begin{bmatrix} U(t_1) & L(t_1)^{-1}S(t_1,t_2) \\ 0 & U(t_2) \end{bmatrix}, \tag{17}$$

where

$$L(t_1)U(t_1) = S(t_1,t_1), \qquad L(t_2)U(t_2) = S(t_2,t_2),$$

and t_1, t_2 are the sons of t. If $t \in \mathcal{L}(T_I)$, then $L(t)$ and $U(t)$ are defined by the pointwise LU decomposition. Note that since

$$L(t)U(t) = \begin{bmatrix} L(t_1)U(t_1) & S(t_1,t_2) \\ S(t_2,t_1) & L(t_2)U(t_2) + S(t_2,t_1)S(t_1,t_1)^{-1}S(t_1,t_2) \end{bmatrix},$$

we obtain $L(t)U(t) = S(t,t)$ due to Lemma 3.1. The following lemma shows that the off-diagonal blocks in (17) can be approximated by hierarchical matrices. For its proof we will make use of

$$\|S(t,t)^{-1}\|_2 \le \|A_{\hat{t}\hat{t}}^{-1}\|_2 \le c\|A^{-1}\|_2, \tag{18}$$

where $\hat{t} := \{i \in I : i \le \max t\}$. Estimate (18) follows from (7) and the fact that $S(t,t)^{-1}$ is the $t \times t$ subblock of $A_{\hat{t}\hat{t}}^{-1}$.

LEMMA 3.2. *Let X, Y solve $L(t)X = S(t,s)$ and $YU(t) = S(s,t)$, where $\max t \le \min s$. Then X and Y can be approximated by $\tilde{X} \in \mathcal{H}(T_{t\times s}, k_S)$ and $\tilde{Y} \in \mathcal{H}(T_{s\times t}, k_S)$ such that*

$$\|X - \tilde{X}\|_2 \le c\kappa p\varepsilon \|U(t)\|_2 \quad \text{and} \quad \|Y - \tilde{Y}\|_2 \le c\kappa p\varepsilon \|L(t)\|_2.$$

The bound k_S on the blockwise rank was defined in (16).

Proof. We first prove by induction that X can be approximated by a matrix $\tilde{X} \in \mathcal{H}(T_{t\times s}, k_S)$ such that on each admissible subblock $t' \times s'$ of $t \times s$ it holds that

$$\|X_{t's'} - \tilde{X}_{t's'}\|_2 \le c\kappa\varepsilon\|U(t')\|_2. \tag{19}$$

If $t \times s$ is an admissible leaf in T_I, then we have assumed (see (16)) that $S(t,s)$ can be approximated by a matrix $\tilde{S}(t,s) \in \mathbb{R}^{t\times s}$ of rank at most k_S. Hence, the rank of $\tilde{X} := L(t)^{-1}\tilde{S}(t,s)$ cannot exceed k_S, and we have that

$$\begin{aligned}\|X - \tilde{X}\|_2 &= \|L(t)^{-1}[S(t,s) - \tilde{S}(t,s)]\|_2 = \|U(t)S(t,t)^{-1}[S(t,s) - \tilde{S}(t,s)]\|_2\\ &\le \varepsilon\|S(t,t)^{-1}\|_2\|A\|_2\|U(t)\|_2 \le c\kappa\varepsilon\|U(t)\|_2\end{aligned}$$

due to (18). If $t \times s$ is not a leaf, then t has sons t_1, t_2 and s has sons s_1, s_2. Define $X_{11} \in \mathbb{R}^{t_1\times s_1}$, $X_{12} \in \mathbb{R}^{t_1\times s_2}$, $X_{21} \in \mathbb{R}^{t_2\times s_1}$, and $X_{22} \in \mathbb{R}^{t_2\times s_2}$ by

$$L(t_1)X_{11} = S(t_1, s_1), \quad L(t_1)X_{12} = S(t_1, s_2)$$

and

$$L(t_2)X_{21} = S(t_2, s_1), \quad L(t_2)X_{22} = S(t_2, s_2),$$

respectively. By induction we know that X_{11}, X_{12}, X_{21}, and X_{22} can be approximated by $\mathcal{H}$-matrices $\tilde{X}_{11}$, $\tilde{X}_{12}$, $\tilde{X}_{21}$, and $\tilde{X}_{22}$ to the subtrees of $T_{I\times I}$ with roots $t_1 \times s_1$, $t_1 \times s_2$, $t_2 \times s_1$, and $t_2 \times s_2$, respectively. Hence,

$$X = \begin{bmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{bmatrix}$$

satisfies

$$\begin{aligned}L(t)X &= \begin{bmatrix} L(t_1) & 0 \\ S(t_2,t_1)U(t_1)^{-1} & L(t_2) \end{bmatrix}\begin{bmatrix} X_{11} & X_{12} \\ X_{21} & X_{22} \end{bmatrix}\\ &= \begin{bmatrix} S(t_1,s) \\ S(t_2,s) + S(t_2,t_1)S(t_1,t_1)^{-1}S(t_1,s) \end{bmatrix} = S(t,s)\end{aligned}$$

due to the definition (17) of $L(t)$ and (15) and can be approximated by

$$\tilde{X} := \begin{bmatrix} \tilde{X}_{11} & \tilde{X}_{12} \\ \tilde{X}_{21} & \tilde{X}_{22} \end{bmatrix} \in \mathcal{H}(T_{t\times s}, k_S)$$

satisfying (19). The assertion follows from Lemma 2.7, because

$$\|X - \tilde{X}\|_2 \le c_{\mathrm{sp}} p \max_{t'\times s' \in T_{t\times s}} \|X_{t's'} - \tilde{X}_{t's'}\|_2 \le cc_{\mathrm{sp}}\kappa p\varepsilon \max_{t'\in T_t} \|U(t')\|_2 \le cc_{\mathrm{sp}}\kappa p\varepsilon\|U(t)\|_2.$$

The proof for Y can be done analogously. ∎

The following theorem is the main result of this article. Although the proved error estimates have a Wilkinson style, these theorems are not meant as estimates on the backward stability of an algorithm for the approximation by $\mathcal{H}$-matrices. However, they show that $\mathcal{H}$-matrix approximants exist and that their complexity depends logarithmically on the accuracy $\varepsilon \to 0$. A similar estimate obviously holds for the Cholesky decomposition.

THEOREM 3.3. *Assume that* (16) *holds and let L and U be the unique unit lower and upper triangular factors of A. Then there are unit lower and upper triangular matrices $L_{\mathcal{H}}, U_{\mathcal{H}} \in \mathcal{H}(T_{I\times I}, k_S)$ such that*

$$\|A - L_{\mathcal{H}}U_{\mathcal{H}}\|_2 \le c\kappa p\varepsilon\|L\|_2\|U\|_2 + \mathcal{O}(\varepsilon^2).$$

Proof. Since $A = S(I,I) = L(I)U(I)$, it follows from the uniqueness of the LU decomposition that $L = L(I)$ and $U = U(I)$. According to Lemma 3.2, there are $\mathcal{H}$-matrices $L_{\mathcal{H}}, U_{\mathcal{H}} \in \mathcal{H}(T_{I\times I}, k_S)$ satisfying

$$\|L - L_{\mathcal{H}}\|_2 \le c\kappa p\varepsilon\|L\|_2 \quad \text{and} \quad \|U - U_{\mathcal{H}}\|_2 \le c\kappa p\varepsilon\|U\|_2.$$

As a consequence we have

$$\begin{aligned}\|A - L_{\mathcal{H}}U_{\mathcal{H}}\|_2 &\le \|(L - L_{\mathcal{H}})U\|_2 + \|L(U - U_{\mathcal{H}})\|_2 + \|(L - L_{\mathcal{H}})(U - U_{\mathcal{H}})\|_2\\ &\le \|L - L_{\mathcal{H}}\|_2\|U\|_2 + \|L\|_2\|U - U_{\mathcal{H}}\|_2 + \|L - L_{\mathcal{H}}\|_2\|U - U_{\mathcal{H}}\|_2\\ &\le [2c\kappa p\varepsilon + c^2\kappa^2p^2\varepsilon^2]\|L\|_2\|U\|_2,\end{aligned}$$

which proves the assertion. ∎

Since the complexity depends logarithmically on the accuracy ε, the blockwise rank of the factors $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$ compared with the rank of the inverse bears an additional logarithmic factor. However, from the following numerical experiments it will be seen that the complexity of the $\mathcal{H}$-LU decomposition is much smaller than the complexity of the $\mathcal{H}$-inverse in practice.

4. Computing the hierarchical *LU* decomposition. In the last section we have seen that the factors L and U from an LU decomposition of A can be approximated by $\mathcal{H}$-matrices $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$ whenever the Schur complements in A possess this property. Although the construction used for the proof could in principle be used to compute $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$, for an improved efficiency, we prefer to use another method which is based on the partitioned LU decomposition.

On the set $\mathcal{H}(T_{I\times I}, k)$ of hierarchical matrices approximate versions of the usual matrix operations such as addition, matrix-matrix multiplication, and inversion can be defined; cf. [17, 18, 16]. The rounding precision these operations are performed with will be denoted by $\varepsilon_{\mathcal{H}}$. The hierarchical LU decomposition can then be computed using these operations during the block LU decomposition instead of the usual ones. The LU decomposition of $\mathcal{H}$-matrices in a format that does not account for general $\mathcal{H}$-matrices has already been used in [22]. The first algorithm for the factorization of general $\mathcal{H}$-matrices was published in [3]; the ideas of nested dissection were first applied to $\mathcal{H}$-matrices in [24].

In order to define the $\mathcal{H}$-LU decomposition we exploit the hierarchical block structure of a block A_{tt}, $t \in T_I \setminus \mathcal{L}(T_I)$:

$$A_{tt} = \begin{bmatrix} A_{t_1t_1} & A_{t_1t_2} \\ A_{t_2t_1} & A_{t_2t_2}\end{bmatrix} = \begin{bmatrix} L_{t_1t_1} & \\ L_{t_2t_1} & L_{t_2t_2}\end{bmatrix}\begin{bmatrix} U_{t_1t_1} & U_{t_1t_2} \\ & U_{t_2t_2}\end{bmatrix},$$

where $t_1, t_2 \in T_I$ denote the sons of t in T_I. Hence, the LU decomposition of a block A_{tt} is reduced to the following four problems on the sons of $t \times t$:

(i) Compute $L_{t_1t_1}$ and $U_{t_1t_1}$ from the LU decomposition $L_{t_1t_1}U_{t_1t_1} = A_{t_1t_1}$.
(ii) Compute $U_{t_1t_2}$ from $L_{t_1t_1}U_{t_1t_2} = A_{t_1t_2}$.
(iii) Compute $L_{t_2t_1}$ from $L_{t_2t_1}U_{t_1t_1} = A_{t_2t_1}$.

(iv) Compute $L_{t_2t_2}$ and $U_{t_2t_2}$ from the LU decomposition $L_{t_2t_2}U_{t_2t_2} = A_{t_2t_2} - L_{t_2t_1}U_{t_1t_2}$.

If a block $t \times t \in \mathcal{L}(T_{I\times I})$ is a leaf, the usual pivoted LU decomposition is employed. For (i) and (iv) two LU decompositions of half the size have to be computed. In order to solve (ii), i.e., solve a problem of the structure $L_{tt}B_{ts} = A_{ts}$ for B_{ts}, where L_{tt} is a lower triangular matrix and $t \times s \in T_{I\times I}$, we use a recursive block forward substitution: If the block $t \times s$ is not a leaf in $T_{I\times I}$, from the decompositions of the blocks A_{ts}, B_{ts}, and L_{tt} into their subblocks (t_1, t_2 and s_1, s_2 are again the sons of t and s, respectively)

$$\begin{bmatrix} L_{t_1t_1} & \\ L_{t_2t_1} & L_{t_2t_2} \end{bmatrix} \begin{bmatrix} B_{t_1s_1} & B_{t_1s_2} \\ B_{t_2s_1} & B_{t_2s_2} \end{bmatrix} = \begin{bmatrix} A_{t_1s_1} & A_{t_1s_2} \\ A_{t_2s_1} & A_{t_2s_2} \end{bmatrix},$$

one observes that B_{ts} can be found from the equations

$$\begin{aligned} L_{t_1t_1}B_{t_1s_1} &= A_{t_1s_1}, \\ L_{t_1t_1}B_{t_1s_2} &= A_{t_1s_2}, \\ L_{t_2t_2}B_{t_2s_1} &= A_{t_2s_1} - L_{t_2t_1}B_{t_1s_1}, \\ L_{t_2t_2}B_{t_2s_2} &= A_{t_2s_2} - L_{t_2t_1}B_{t_1s_2}, \end{aligned}$$

which are again of type (ii). If, on the other hand, $t \times s$ is a leaf, the usual forward substitution is applied. Similarly, one can solve (iii) by recursive block backward substitution.

The complexity of the above recursions is mainly determined by the complexity of the hierarchical matrix-matrix multiplication, which can be estimated as $\mathcal{O}(k^2n(\log n)^2)$ for two matrices from $\mathcal{H}(T_{I\times I}, k)$; cf. [16]. Each operation is carried out with precision $\varepsilon_{\mathcal{H}}$. A result [10] on the stability analysis of the block LU decomposition states that the product LU is backward stable in the following sense:

$$\|A - LU\|_2 < c(n)\varepsilon_{\mathcal{H}}(\|A\|_2 + \|L\|_2\|U\|_2).$$

Provided that $\|L\|_2\|U\|_2 \approx \|A\|_2$, the relative accuracy of LU will hence be of order $\varepsilon_{\mathcal{H}}$. Employing the $\mathcal{H}$-matrix arithmetic, it is therefore possible to generate an approximate LU decomposition of an $\mathcal{H}$-matrix $A \in \mathcal{H}(T_{I\times I}, k)$ to any prescribed accuracy with almost linear complexity.

Remark 4.1. Although the intermediate results of the presented algorithm (i)–(iv) are guaranteed to be $\mathcal{H}$-matrices, the blockwise rank k is not known. Note that our theory cannot be applied to this construction of the LU decomposition since the computed Schur complements in (iv) are approximate ones. Nevertheless, it will be seen from the numerical experiments that k still depends logarithmically on both the accuracy ε and the number of unknowns n.

In the case of positive definite matrices A it is possible to define an $\mathcal{H}$-version of the Cholesky decomposition of a block A_{tt}, $t \in T_I \setminus \mathcal{L}(T_I)$:

$$A_{tt} = \begin{bmatrix} A_{t_1t_1} & A_{t_1t_2} \\ A_{t_1t_2}^T & A_{t_2t_2} \end{bmatrix} = \begin{bmatrix} L_{t_1t_1} & \\ L_{t_2t_1} & L_{t_2t_2} \end{bmatrix} \begin{bmatrix} L_{t_1t_1} & \\ L_{t_2t_1} & L_{t_2t_2} \end{bmatrix}^T.$$

This factorization is recursively computed by

$$\begin{aligned} L_{t_1t_1}L_{t_1t_1}^T &= A_{t_1t_1}, \\ L_{t_1t_1}L_{t_2t_1}^T &= A_{t_1t_2}, \\ L_{t_2t_2}L_{t_2t_2}^T &= A_{t_2t_2} - L_{t_2t_1}L_{t_2t_1}^T, \end{aligned}$$

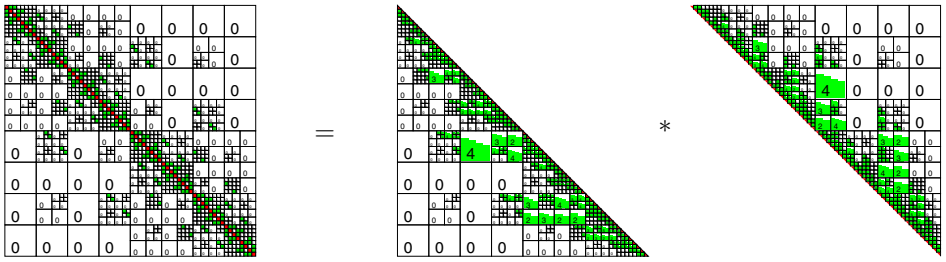
using the usual Cholesky decomposition on the leaves of $T_{I\times I}$. The second equation $L_{t_1t_1}L_{t_2t_1}^T = A_{t_1t_2}$ is solved for $L_{t_2t_1}$ in a way similar to how $U_{t_1t_2}$ was previously obtained in the LU decomposition.

Once A has been decomposed, the solution of $Ax = b$ can be found by forward/backward substitution: $L_{\mathcal{H}}y = b$ and $U_{\mathcal{H}}x = y$. Since $L_{\mathcal{H}}$ and $U_{\mathcal{H}}$ are $\mathcal{H}$-matrices, y_t, $t \in T_I \setminus \mathcal{L}(T_I)$, can be computed recursively by solving the following systems for y_{t_1} and y_{t_2}:

$$L_{t_1t_1}y_{t_1} = b_{t_1} \quad \text{and} \quad L_{t_2t_2}y_{t_2} = b_{t_2} - L_{t_2t_1}y_{t_1}.$$

If $t \in \mathcal{L}(T_I)$ is a leaf, a usual triangular solver is used. The backward substitution can be done analogously. The complexity of this forward/backward substitution is determined by the complexity of the hierarchical matrix-vector multiplication, which is $\mathcal{O}(kn\log n)$ if a matrix from $\mathcal{H}(T_{I\times I}, k)$ is multiplied by a vector.

5. Numerical results. In this section we make use of the above algorithms for the computation of approximate LU decompositions of finite element stiffness matrices in two and three spatial dimensions. The emphasis in these tests is laid on robustness with respect to varying coefficients of the underlying operator.



All computations were carried out on an Athlon64 PC (2 GHz) with 4 GB of core memory. For compiling the $\mathcal{H}$-matrix library,[2] the Intel compiler version 9.0 was used.

5.1. Two-dimensional diffusion. As a first set of tests we consider the Dirichlet boundary value problem

$$\begin{aligned} -\operatorname{div}\alpha(x)\nabla u &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{aligned}$$

where $\Omega := (0,1)^2$ is the unit square in $\mathbb{R}^2$ and $\alpha(x)$ is a random number from the interval $[0,a]$ for each $x = (x_1, x_2) \in \Omega$ satisfying $x_1 > x_2$. In the remaining part of Ω the coefficient α is set to 1. The amplitude a will be used to demonstrate that the presented method is not sensitive to nonsmooth coefficients.

The main aim of these two-dimensional tests is to show that the computational complexity of the presented hierarchical LU decomposition is almost linear, thereby confirming our estimates. In the following tables we compare for different problem sizes n and for different amplitudes a the computational effort to decompose the stiffness matrix of the problem from above. Since the discrete operator is symmetric positive definite, we actually compute the Cholesky decomposition LL^T. Table 1

[2] A C++ implementation of the $\mathcal{H}$-matrix structure can be obtained from the following web site: http://www.mathematik.uni-leipzig.de/~bebendorf/AHMED.html.

shows the time T_{LL^T} for computing the hierarchical Cholesky decomposition in seconds, its memory consumption (MB), the maximum rank k among the blocks, and the backward error

$$\mathcal{E}_A := \frac{\|A - L_{\mathcal{H}} L_{\mathcal{H}}^T\|_2}{\|A\|_2}.$$

The minimal block size (see section 2) was chosen to be $n_{\min} = 50$. Apparently, the computational effort grows almost linearly with n, while the backward error seems to be independent of n. Increasing the rounding precision $\varepsilon_{\mathcal{H}}$ directly results in a smaller backward error. Table 2 shows the same values for $a = 10^9$ with only slight changes of the results. The dependence of the computational effort and of the backward error on the amplitude a is surprisingly weak, demonstrating the robustness of this approximate LU decomposition.

5.2. Convection-diffusion problems. In the next tests operators of type

$$D = -\Delta + c \cdot \nabla$$

are considered. The convection coefficient c is randomly chosen, i.e., $c(x) \in [-a, a]^2$ for each $x \in \Omega = (0, 1)^2$. Since the standard finite element method becomes unstable for large a (i.e., the stiffness matrix may become singular), we have restricted ourselves to the cases $a = 10, 100$. In the convection dominant case the *streamline diffusion finite element method* (cf. [20]) has to be used. Note that the limiting case $a \to \infty$ is not covered by the present theory but will be treated in a forthcoming article.

Tables 3 and 4 show the same quantities as Tables 1 and 2. Note that in this case symmetry of the stiffness matrix could not be exploited.

Due to memory limitations the example with $n = 1\,276\,900$ and $\varepsilon_{\mathcal{H}} = 1_{10}{-}6$ failed to compute. Although the computational effort has increased compared with

the diffusion problem, it still scales almost linearly. A dependence on the coefficient c can hardly be observed.

Table 5 shows the time T_{LU} and the amount of memory needed to compute the exact LU decomposition using MUMPS version 4.6.3; cf. [1]. Both methods seem to scale in a similar way with n while MUMPS is 5 times faster than the $\mathcal{H}$-LU factorization.

1 276 900	72.1	1564

5.3. Three-dimensional diffusion. As we have mentioned in section 2, the structure of $\mathcal{H}$-matrices can be equally applied to any quasi-uniform finite element discretization of Ω given by just the grid information. In order to demonstrate that the $\mathcal{H}$-LU decomposition is also efficient for three-dimensional problems, we test the proposed method on three tetrahedral discretizations ($n = 25\,011$, $n = 217\,225$, and $n = 1\,848\,951$ of unknowns) of the volume shown in Figure 3. The meshes were generated using NETGEN [28].

We consider the Dirichlet boundary value problem

$$\begin{aligned} -\operatorname{div} C(x)\nabla u &= f \quad \text{in } \Omega, \\ u &= 0 \quad \text{on } \partial\Omega, \end{aligned}$$

where $C(x) \in \mathbb{R}^{3\times 3}$ is a symmetric positive definite matrix for all $x \in \Omega$. The

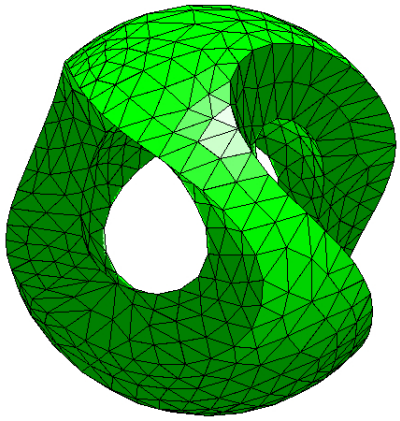

FIG. 3. *The computational domain.*

coefficients c_{ij}, $i,j = 1,2,3$, are set to one in the left half-space and to a random number from the interval $[0,1]$ in each point of the right half-space.

In Table 6 we compare the numerical effort for generating a hierarchical Cholesky decomposition. The minimal cluster size was chosen to be $n_{\min} = 50$. In the second column the time that was needed to compute the approximate Cholesky decomposition is shown for different rounding precisions $\varepsilon_{\mathcal{H}}$. The memory consumption can be found in the third column. Columns four and five contain the maximum rank among the blocks and the backward error. Compared with the two-dimensional problems from section 5.1, the CPU time for decomposing the matrix has increased. However, a behavior similar to that in the two-dimensional tests can be observed: The computational complexity scales almost linearly, and the backward error does not seem to depend on n. Again, the proposed method is able to adapt itself to the varying coefficients.

TABLE 6
Decompositions for three-dimensional diffusion.

	$n = 25\,011$				$n = 217\,225$				$n = 1\,848\,951$			
$\varepsilon_{\mathcal{H}}$	T_{LL^T}	MB	k	$\mathcal{E}_A$	T_{LL^T}	MB	k	$\mathcal{E}_A$	T_{LL^T}	MB	k	$\mathcal{E}_A$
$1_{10}{-}1$	1.7s	14	35	$3.0_{10}{-}2$	39.4s	173	35	$3.3_{10}{-}2$	869.9s	2029	187	$4.7_{10}{-}2$
$1_{10}{-}2$	2.6s	18	41	$3.3_{10}{-}3$	65.7s	261	47	$5.3_{10}{-}3$	1662.1s	3323	206	$5.9_{10}{-}3$
$1_{10}{-}3$	3.4s	21	46	$3.3_{10}{-}4$	97.2s	344	58	$5.7_{10}{-}4$	–	–	–	–
$1_{10}{-}4$	4.2s	25	47	$3.4_{10}{-}5$	137.4s	434	82	$4.5_{10}{-}5$	–	–	–	–
MUMPS	1.8s	26			85.6s	547			–	–		

The comparison with MUMPS shows that the $\mathcal{H}$-LU decomposition is as fast as this direct solver for the smallest problem. The situation changes, however, for larger problems. The $\mathcal{H}$-LU factorization becomes more efficient. MUMPS was not able to compute the problem with $n = 1\,848\,951$ unknowns on our system. Here, the higher asymptotic complexity of direct solvers is revealed. The proposed approximate LU decomposition still scales linearly and hence becomes more efficient. This is especially true for low-precision approximations which are sufficient if the LU decomposition is used for preconditioning.

Table 7 contains the time T_S required to solve a linear system by forward/backward

TABLE 7
Time for solving and solution error.

substitution. The third column contains the error

$$\mathcal{E}_x := \frac{\|\tilde{x} - x\|_2}{\|x\|_2}$$

of the solution vector $\tilde{x}$ compared with the exact solution x.

6. Conclusion. We have laid theoretical ground for the approximation of the factors L and U of the LU decomposition of discrete elliptic operators by $\mathcal{H}$-matrices. Furthermore, an algorithm for the computation of an approximate LU decomposition with almost linear complexity was presented. The comparison with MUMPS shows that an improved asymptotic complexity of the approximate LU decomposition can be observed for problems posed in three spatial dimensions. The hierarchical LU decomposition is robust with respect to varying coefficients of the differential operator and is especially efficient for low-precision applications. Hence, it is well suited, for instance, for computing black-box preconditioners at least for the class of second-order elliptic operators.

MESH INDEPENDENT SUPERLINEAR PCG RATES VIA COMPACT-EQUIVALENT OPERATORS*

OWE AXELSSON† AND JÁNOS KARÁTSON‡

Abstract. The subject of the paper is the mesh independent convergence of the preconditioned conjugate gradient (PCG) method for nonsymmetric elliptic problems. The approach of equivalent operators is involved, in which one uses the discretization of another suitable elliptic operator as preconditioning matrix. By introducing the notion of compact-equivalent operators, it is proved that for a wide class of elliptic problems the superlinear convergence of the obtained PCG method is mesh independent under finite element discretizations; that is, the rate of superlinear convergence is given in the form of a sequence which is mesh independent and is determined only by the elliptic operators.

Key words. nonsymmetric elliptic problems, conjugate gradient method, preconditioning, equivalent operators, superlinear convergence, mesh independence

1. Introduction.

The conjugate gradient (CG) method is a widespread way of solving large linear algebraic systems, such as those arising from discretized elliptic problems, in particular when combined with a suitable preconditioning. For nonsymmetric systems several CG algorithms exist [2, 4], including the common CGN method based on normal equations. Since its first presentation in [21] the convergence of the CG method has been well established, as summarized in [4]. The convergence theory of the CG method often involves linear operators in Hilbert space; see both classical and recent results [14, 15, 20, 27, 31, 32] and the authors' papers [6, 7, 8, 22, 24]. A basic reason to use Hilbert space theory is to derive mesh independence of the convergence estimates, by which it can be shown that the preconditioned CG (PCG) method can be competitive with multigrid methods [14].

The theory of equivalent operators in Hilbert space has proved to provide an efficient clear framework for the convergence study of the PCG method for elliptic problems [14, 18, 26]. Thereby one uses the discretization of a suitable linear elliptic operator as preconditioning matrix; see also [10, 12, 32]. As a main result, mesh independence of linear convergence rates is rigorously characterized in [14, 26]. We note that in [18], for proper boundary conditions, when the preconditioned operator is a compact perturbation of the identity, then convergence is expected to be faster than any linear rate.

Our goal is to complete the above results on the preconditioned CGN (PCGN) method by showing that for a class of elliptic problems, the superlinear convergence of the iteration is mesh independent under finite element method (FEM) discretizations. This means that a bound on the rate of superlinear convergence is given in the form of a sequence which is mesh independent and is determined only by the

elliptic operators. To describe the suitable class of problems, we introduce the notion of compact-equivalent operators, which expresses that preconditioning one with the other yields a compact perturbation of the identity. This notion and the convergence result give a refinement of the case of equivalent operators: roughly speaking, if the two operators (the original and preconditioner) are equivalent, then the corresponding PCG method provides mesh independent linear convergence, whereas if the two operators are compact-equivalent, then the PCG method provides mesh independent superlinear convergence.

Our present results are extensions of the earlier ones [8, 24], where such mesh independence was proved for the generalized conjugate gradient-least squares (GCG-LS) method for elliptic Dirichlet problems, but with severe restrictions: except for some special cases, both the original and preconditioning operators had to contain constant coefficients. Now we show that two elliptic operators, with homogeneous Dirichlet conditions on the same portion of the boundary, are compact-equivalent if and only if their principal parts coincide up to a constant factor. Within this class, the proof of the mesh independence result then contains no restrictions except standard smoothness and coercivity assumptions on the operators.

Our characterization of compact-equivalence provides, in fact, a limitation on the scope of the mesh independent superlinear convergence property. Since the principal parts of compact-equivalent operators must coincide (up to a constant), preconditioning methods like replacing rough diffusion coefficients by simpler, e.g., constant, ones are not covered by this setting except, of course, the case when the variable coefficient problem can be easily rewritten by suitable scaling to a constant coefficient problem, as for scalar coefficients. In fact, one cannot expect superlinear convergence for such non–compact-equivalent operators since, as shown in [15], convergence of the CG method may be only linear if an operator is not a compact perturbation of a constant times the identity.

The paper is organized as follows: the required background is given in section 2, compact-equivalent operators are introduced and characterized in section 3, and the mesh independence result is proved in section 4. Some closing remarks are found in section 5.

2. Background.

2.1. Conjugate gradient algorithms.

Let us consider a linear system

$$Bu = f \tag{1}$$

with a given nonsingular matrix $B \in \mathbf{R}^{n\times n}$, $f \in \mathbf{R}^n$ and solution u. Let $\langle .,. \rangle$ be a given inner product on $\mathbf{R}^n$ and, denoting by B^* the adjoint of B w.r.t. this inner product, assume that $B + B^* > 0$, i.e., is positive definite.

If B is self-adjoint, then the standard CG method reads as follows [4, 31]: let $u_0 \in \mathbf{R}^n$ be arbitrary, $d_0 := Bu_0 - f$; for given u_k and d_k, with $\hat{r}_k := Bu_k - f$, we let

$$u_{k+1} = u_k - \alpha_k d_k, \text{ where } \alpha_k = \frac{\langle \hat{r}_k, d_k \rangle}{\langle Bd_k, d_k \rangle}; \quad d_{k+1} = \hat{r}_{k+1} + \beta_k d_k, \text{ where } \beta_k = \frac{\|\hat{r}_{k+1}\|^2}{\|\hat{r}_k\|^2}. \tag{2}$$

Then, using the error vector $e_k = u_k - u$ and its energy norm $\|e_k\|_B = \langle Be_k, e_k \rangle^{1/2}$, respectively, and with the decomposition $B = I + C$ (where I is the identity matrix),

the following celebrated estimate holds [4, 31]:

$$\left(\frac{\|e_k\|_B}{\|e_0\|_B}\right)^{1/k} \le \frac{2}{k}\,\|B^{-1}\|\sum_{j=1}^{k}|\lambda_j(C)| \qquad (k=1,2,\dots,n), \tag{3}$$

which shows superlinear convergence if the eigenvalues $|\lambda_1(C)| \ge |\lambda_2(C)| \ge \cdots$ approach zero.

Since this result is basic for the whole paper, and for completeness, we present a derivation of (3) following [4]. The optimality of the CG method implies

$$\frac{\|e_k\|_B}{\|e_0\|_B} \le \min_{P_k\in\pi_k^1}\max_{\lambda\in\sigma(B)\}}|P_k(\lambda)|,$$

where π_k^1 denotes the set of polynomials P_k of degree k with $P_k(0)=1$. Let $\lambda_j := \lambda_j(B)$ and $\mu_j := \lambda_j(C)\,(=\lambda_j-1)$. Then the polynomials $P_k(\lambda) := \prod_{j=1}^{k}(1-\frac{\lambda}{\lambda_j})$ satisfy $P_k(\lambda_i)=0$ $(i=1,\dots,k)$ and

$$\max_{\lambda\in\sigma(B)\}}|P_k(\lambda)| = \max_{i\ge k+1}\prod_{j=1}^{k}\left|1-\frac{\lambda_i}{\lambda_j}\right| = \max_{i\ge k+1}\prod_{j=1}^{k}\frac{|\mu_j-\mu_i|}{|1+\mu_j|} \le \max_{i\ge k+1}\prod_{j=1}^{k}\frac{2|\mu_j|}{|1+\mu_j|}\,;$$

hence, using the arithmetic-geometric inequality,

$$\max_{\lambda\in\sigma(B)\}}|P_k(\lambda)|^{1/k} \le \frac{2}{k}\sum_{j=1}^{k}\frac{|\mu_j|}{|1+\mu_j|} \le \frac{2}{k}\left(\sup\frac{1}{|\lambda_j|}\right)\sum_{j=1}^{k}|\mu_j|,$$

which yields (3).

For nonsymmetric B, several CG algorithms exist (see, e.g., [2, 4, 13]). The GCG-LS method [3, 4] is defined directly for (1) and produces an estimate similar to that of (3) if B is normal. Mesh independent bounds in [8, 24] for (3) for some elliptic problems have been given using the GCG-LS method. Alternatively, one can consider the normal equation and apply a symmetric CG algorithm, which we will do in this paper. For clearness, let us hereby consider a nonsymmetric linear system

$$Au = b \tag{4}$$

with a given nonsingular matrix $A\in\mathbf{R}^{n\times n}$ and vector $b\in\mathbf{R}^n$. Let us apply the iteration (2) for the equation $A^*Au = A^*b$, i.e., with $B=A^*A$ and $f=A^*b$. Then, with notations $s_k=\hat r_k$ and $r_k = A^{-*}\hat r_k$, we obtain the following algorithmic form, often called the CGN method: let $u_0\in\mathbf{R}^n$ be arbitrary, $r_0 := Au_0-b$, $s_0 := d_0 := A^*r_0$; for given d_k, u_k, r_k, and s_k, we let

$$\begin{cases} z_k = Ad_k, \\ \alpha_k = \dfrac{\langle r_k, z_k\rangle}{\|z_k\|^2}\,, \quad u_{k+1} = u_k - \alpha_k d_k\,, \quad r_{k+1} = r_k - \alpha_k z_k\,; \\ s_{k+1} = A^*r_{k+1}, \\ \beta_k = \dfrac{\|s_{k+1}\|^2}{\|s_k\|^2}\,, \quad d_{k+1} = s_{k+1} + \beta_k d_k. \end{cases} \tag{5}$$

Let us consider the decomposition

$$A = I + K.$$

Then, using the relations $B = I + (K^* + K + K^*K)$, $\|e_k\|_B = \|Ae_k\| = \|r_k\|$, and $\|B^{-1}\| \le \nu^{-1}$, where $\nu := \min_{x\in\mathbf{R}^n} \frac{\|Ax\|^2}{\|x\|^2}$, estimate (3) can be reformulated as

$$\left(\frac{\|r_k\|}{\|r_0\|}\right)^{1/k} \le \frac{2}{k\nu} \sum_{i=1}^{k} \Big(\big|\lambda_i(K^*+K)\big| + \lambda_i(K^*K) \Big) \qquad (k = 1, 2, \dots, n). \tag{6}$$

The goal of this paper is to derive a mesh independent bound for (6) when (4) comes from a preconditioned discretized elliptic PDE using suitable equivalent operators.

2.2. Singular values of compact operators. Let H be a real Hilbert space. We shall consider compact operators, i.e., operators C such that the image (Cv_i) of any bounded sequence (v_i) contains a convergent subsequence.

DEFINITION 2.1. (i) We call $\lambda_i(F)$ $(i = 1, 2, \dots)$ the *ordered eigenvalues* of a compact self-adjoint linear operator F in H if each of them is repeated as many times as its multiplicity and $|\lambda_1(F)| \ge |\lambda_2(F)| \ge \cdots$.

(ii) The *singular values* of a compact operator C in H are

$$s_i(C) := \lambda_i(C^*C)^{1/2} \qquad (i = 1, 2, \dots),$$

where $\lambda_i(C^*C)$ are the ordered eigenvalues of C^*C. In particular, if C is self-adjoint, then $s_i(C) = |\lambda_i(C)|$.

Some useful properties of compact operators are listed below.

PROPOSITION 2.2. *Let C be a compact operator in H. Then the following properties hold.*

(a) *For any $k \in \mathbf{N}^+$ and any orthonormal vectors $u_1, \dots, u_k \in H$,*

$$\sum_{i=1}^{k} \big|\langle Cu_i, u_i\rangle\big| \le \sum_{i=1}^{k} s_i(C)\,.$$

(b) *If B is a bounded linear operator in H, then*

$$s_i(BC) \le \|B\|\, s_i(C) \qquad (i = 1, 2, \dots).$$

(c) *(Variational characterization of the eigenvalues.) If C is also self-adjoint, then*

$$\big|\lambda_i(C)\big| = \min_{H_{i-1}\subset H} \max_{\substack{u\perp H_{i-1}\\ u\neq 0}} \frac{\big|\langle Cu, u\rangle\big|}{\|u\|^2}\,,$$

where H_{i-1} stands for an arbitrary $(i-1)$-dimensional subspace.

(d) *If a sequence $(u_i) \subset H$ satisfies $\langle u_i, u_j\rangle = \langle Cu_i, u_j\rangle = 0$ $(i \neq j)$, then*

$$\inf_i\, |\langle Cu_i, u_i\rangle| / \|u_i\|^2 = 0.$$

Proof. Statements (a) and (b) are the consequences of [16, Chap. VI, Corollary 3.3 and Proposition 1.3, resp.]; for statement (c), see [17, Theorem III.9.1]. To prove (d), assume the contrary that the infimum equals $\delta > 0$. We may assume that $\langle Cu_i, u_i\rangle$ has constant sign (otherwise we can consider a subsequence that has constant sign). Then the orthonormal sequence $v_i := u_i/\|u_i\|$ satisfies for all $i \neq j$

$$\begin{aligned} 2\delta &\le |\langle Cv_i, v_i\rangle + \langle Cv_j, v_j\rangle| = |\langle C(v_i - v_j), v_i - v_j\rangle| \\ &\le \|C(v_i - v_j)\|\,\|v_i - v_j\| = \sqrt{2}\|C(v_i - v_j)\|; \end{aligned}$$

hence the image (Cv_i) of the bounded sequence (v_i) contains no convergent subsequence (i.e., C is not compact). ∎

3. Compact-equivalent operators in Hilbert space. In this section we introduce and characterize compact-equivalent operators. Roughly speaking, the compact-equivalence of the unbounded operators N and L expresses that $N^{-1}L$ is a compact perturbation of a constant times the identity. To avoid difficulties with domains and ranges, our definition will use a weak form of the operators in a suitable energy space H_S. In particular, no regularity is required in the case of elliptic operators.

The fact that a compact perturbation of a constant times identity is a bounded operator implies that compact-equivalent operators are equivalent in the sense of [14]. Hence, when we characterize compact-equivalent elliptic operators (under standard smoothness and coercivity assumptions), we can a priori assume that they have homogeneous Dirichlet conditions on the same portion of the boundary [26]. Within this class, compact-equivalence will hold if and only if the principal parts of the operators coincide up to some constant.

3.1. Basic definitions. In what follows, let H be a real Hilbert space. Let S be a (generally unbounded) linear symmetric operator in H which is coercive; i.e., there exists $p > 0$ such that $\langle Su, u\rangle \ge p\|u\|^2$ $(u \in D(S))$. Then the energy space H_S is the completion of $D(S)$ under the inner product $\langle u, v\rangle_S = \langle Su, v\rangle$, and the coercivity implies $H_S \subset H$. The corresponding S-norm is denoted by $\|u\|_S$, and the space of bounded linear operators on H_S by $B(H_S)$.

DEFINITION 3.1. *Let S be a linear symmetric coercive operator in H. We say that a linear operator L in H is S-bounded and S-coercive, and write $L \in BC_S(H)$ if the following properties hold:*

(i) *$D(L) \subset H_S$ and $D(L)$ is dense in H_S in the S-norm;*

(ii) *there exists $M > 0$ such that*

$$|\langle Lu, v\rangle| \le M\|u\|_S\|v\|_S \qquad (u, v \in D(L));$$

(iii) *there exists $m > 0$ such that*

$$\langle Lu, u\rangle \ge m\|u\|_S^2 \qquad (u \in D(L)).$$

DEFINITION 3.2. *For any $L \in BC_S(H)$, let $L_S \in B(H_S)$ be defined by*

$$\langle L_S u, v\rangle_S = \langle Lu, v\rangle \qquad (u, v \in D(L)).$$

Remark 1.

(a) The above definition makes sense since L_S is the bounded linear operator on H_S that represents the unique extension to H_S of the densely defined S-bounded bilinear form $u, v \mapsto \langle Lu, v\rangle$.

(b) L_S is coercive on H_S.
(c) If in particular $R(L) \subset R(S)$ (where $R(.)$ denotes the range), then $L_S\big|_{D(L)} = S^{-1}L$.

Remark 2. Definition 3.2 uses the idea of weak form of operators from [26]. Namely, if H_S is a subspace of $H^1(\Omega)$ consisting of functions vanishing on a fixed portion of the boundary, then L_S coincides with the weak operator L_w using (2.15) in [26].

Now let us consider an operator equation

$$Lu = g, \tag{7}$$

where $L \in BC_S(H)$ and $g \in H$.

DEFINITION 3.3. *We call $u \in H_S$ the weak solution of equation* (7) *if*

$$\langle L_S u, v\rangle_S = \langle g, v\rangle \qquad (v \in H_S). \tag{8}$$

Remark 3.
(a) For all $g \in H$ the weak solution of (7) exists and is unique. This follows in the usual way from the Lax–Milgram theorem, since $v \mapsto \langle g, v\rangle$ is a bounded linear functional on H_S by the coercivity of S.
(b) If $u \in D(L)$, then u satisfies (7) (i.e., it is a strong solution) if and only if u is a weak solution.

3.2. Compact-equivalent operators. We can introduce the notion of compact-equivalence within the previously described setting as follows.

DEFINITION 3.4. *Let L and N be S-bounded and S-coercive operators in H. We call L and N compact-equivalent in H_S if*

$$L_S = \mu N_S + Q_S \tag{9}$$

for some constant $\mu > 0$ and compact operator $Q_S \in B(H_S)$.

Remark 4. (i) It follows in a straightforward way that the property compact-equivalence is an equivalence relation.

(ii) In the special case $R(L) \subset R(N)$, compact-equivalence of L and N means that $N^{-1}L$ is a compact perturbation of a constant times the identity in the space H_S. Indeed, it is easy to see that here $N^{-1}L = N_S^{-1}L_S\big|_{D(L)}$, and by definition the latter is the perturbation of μI with the operator $N_S^{-1}Q_S\big|_{D(L)}$, which is compact since N_S^{-1} is bounded. (In the general case the "weakly preconditioned" form $N_S^{-1}L_S$ is also a compact perturbation.)

Now we characterize compact-equivalence for elliptic operators. Let $H = L^2(\Omega)$ and let us define the operators

$$N_1 u \equiv -\mathrm{div}\,(A_1 \nabla u) + \mathbf{b}_1 \cdot \nabla u + c_1 u \qquad \text{for } u_{|\Gamma_D} = 0,\ \tfrac{\partial u}{\partial \nu_{A_1}} + \alpha_1 u_{|\Gamma_N} = 0,$$
$$N_2 u \equiv -\mathrm{div}\,(A_2 \nabla u) + \mathbf{b}_2 \cdot \nabla u + c_2 u \qquad \text{for } u_{|\Gamma_D} = 0,\ \tfrac{\partial u}{\partial \nu_{A_2}} + \alpha_2 u_{|\Gamma_N} = 0,$$

where $\frac{\partial u}{\partial \nu_{A_i}} = A_i\,\nu \cdot \nabla u$ denotes the weighted normal derivative. (The formal domain of N_i to be used in Definition 3.2 consists of those $u \in H^2(\Omega)$ that satisfy the above boundary conditions; however, this is used nowhere else.) The following properties hold, where $i = 1, 2$.

ASSUMPTIONS 3.2.

(i) $\Omega \subset \mathbf{R}^d$ is a bounded piecewise C^1 domain; Γ_D, Γ_N are disjoint open measurable subparts of $\partial\Omega$ such that $\partial\Omega = \overline{\Gamma}_D \cup \overline{\Gamma}_N$.

(ii) $A_i \in C^1(\overline{\Omega}, \mathbf{R}^{d\times d})$ and for all $x \in \overline{\Omega}$ the matrix $A_i(x)$ is symmetric; $\mathbf{b}_i \in C^1(\overline{\Omega})^d$, $c_i \in L^\infty(\Omega)$, $\alpha_i \in L^\infty(\Gamma_N)$.

(iii) We have the coercivity properties $\min_{\lambda\in\sigma(A_i(x))} \lambda \geq p > 0$ with p independent of x, $\hat{c}_i := c_i - \frac{1}{2}\operatorname{div}\mathbf{b}_i \geq 0$ in Ω and $\hat{\alpha}_i := \alpha_i + \frac{1}{2}(\mathbf{b}_i \cdot \nu) \geq 0$ on Γ_N.

(iv) Either $\Gamma_D \neq \emptyset$, or $\hat{c}_i$ or $\hat{\alpha}_i$ has a positive lower bound.

For the study of such operators we define the space

$$H^1_D(\Omega) := \{u \in H^1(\Omega) : u_{|\Gamma_D} = 0\} \quad \text{with } \langle u, v\rangle_S := \int_\Omega (G\,\nabla u\cdot\nabla v + huv) + \int_{\Gamma_N} \beta uv\, d\sigma, \tag{10}$$

where G has the same properties as A_i above in (ii)–(iii), and $h \in L^\infty(\Omega)$, $h \geq 0$, if $\Gamma_D \neq \emptyset$ and $h \geq \delta_0 > 0$ if $\Gamma_D = \emptyset$, and further, $\beta \in L^\infty(\Gamma_N)$ and $\beta \geq 0$. Then $H^1_D(\Omega)$ is the energy space H_S of the operator $Su := -\operatorname{div}(G\nabla u) + hu$ on $D(S) := \{u \in H^2(\Omega) : u_{|\Gamma_D} = 0,\ \frac{\partial u}{\partial \nu_{G+\beta u}}{}_{|\Gamma_N} = 0\}$. It is easy to check the properties in Definition 3.1 from the above assumptions, which means that $N_1, N_2 \in BC_S(L^2(\Omega))$.

PROPOSITION 3.5. *The elliptic operators N_1 and N_2 are compact-equivalent in $H^1_D(\Omega)$ if and only if their principal parts coincide up to some constant $\mu > 0$, i.e., $A_1 = \mu A_2$.*

Proof. We have for all $u, v \in H^1_D(\Omega)$

$$\langle (N_i)_S u, v\rangle_S = \int_\Omega \Big(A_i\ \nabla u \cdot \nabla v + (\mathbf{b}_i \cdot \nabla u)v + c_i uv\Big)\, dx + \int_{\Gamma_N} \alpha_i uv\, d\sigma\,.$$

Hence

$$(N_1)_S - \mu(N_2)_S = J_S + Q_S,$$

where, using notations $\mathbf{b} := \mathbf{b}_1 - \mu\mathbf{b}_2$, $c := c_1 - \mu c_2$, and $\alpha := \alpha_1 - \mu\alpha_2$, we have

$$\begin{aligned} \langle J_S u, v\rangle_S &= \int_\Omega (A_1 - \mu A_2)\ \nabla u \cdot \nabla v\, dx\,, \\ \langle Q_S u, v\rangle_S &= \int_\Omega \Big((\mathbf{b}\cdot\nabla u)v + cuv\Big)\, dx + \int_{\Gamma_N} \alpha uv\, d\sigma\,. \end{aligned} \tag{11}$$

Here Q_S is compact, which is known [18] when N_1 and N_2 have the same boundary conditions. Otherwise we use the equality

$$\begin{aligned} \int_\Omega (\mathbf{b}\cdot\nabla u)v\, dx &= -\int_\Omega u(\mathbf{b}\cdot\nabla v)\, dx - \int_\Omega (\operatorname{div}\mathbf{b})uv\, dx \\ &\quad + \int_{\Gamma_N} (\mathbf{b}\cdot\nu)\, uv\, d\sigma \quad (u, v \in H^1_D(\Omega)) \end{aligned} \tag{12}$$

whence, using notations $\tilde{c} := c - \operatorname{div}\mathbf{b}$ and $\tilde{\alpha} := \alpha + \mathbf{b}\cdot\nu$,

$$\|Q_S u\|_S = \sup_{\substack{v\in H^1_D(\Omega)\\ \|v\|_S=1}} |\langle Q_S u, v\rangle_S| = \sup_{\substack{v\in H^1_D(\Omega)\\ \|v\|_S=1}} \left| -\int_\Omega u(\mathbf{b}\cdot\nabla v)\, dx + \int_\Omega \tilde{c}uv\, dx + \int_{\Gamma_N} \tilde{\alpha}\, uv\, d\sigma \right|.$$

Using the embedding estimates

$$\|v\|_{L^2(\Omega)} \le C_\Omega \|v\|_S\,, \qquad \|v\|_{L^2(\Gamma_N)} \le C_{\Gamma_N}\|v\|_S \qquad (v \in H^1_D(\Omega)) \tag{13}$$

(where $C_\Omega, C_{\Gamma_N} > 0$) and $\|\nabla v\|_{L^2(\Omega)} \le p^{-1/2}\|v\|_S$, and letting $K_1 := p^{-1/2}\|\mathbf{b}\|_{L^\infty(\Omega)} + C_\Omega\|\tilde{c}\|_{L^\infty(\Omega)}$, $K_2 := C_{\Gamma_N}\|\tilde{\alpha}\|_{L^\infty(\Gamma_N)}$, we obtain

$$\|Q_S u\|_S \le K_1\|u\|_{L^2(\Omega)} + K_2\|u\|_{L^2(\Gamma_N)} \tag{14}$$

whence Q_S is compact.

It remains to prove that if $A_1 \ne \mu A_2$, then J_S is not compact. Using Proposition 2.2(d), it suffices to find a sequence $(u_i) \subset H^1_0(\Omega) \subset H^1_D(\Omega)$ satisfying

$$\langle u_i, u_j\rangle_S = \langle J_S u_i, u_j\rangle_S = 0 \qquad (i \ne j), \tag{15}$$

$$\inf_i\, |\langle J_S u_i, u_i\rangle_S|/\|u_i\|_S^2 = \delta > 0. \tag{16}$$

Let $A := A_1 - \mu A_2$. Since A is not identically zero, there is $x_0 \in \Omega$ such that $A_0 := A(x_0) \ne 0$. Here A_0 is symmetric; hence there is $u_0 \in H^1_0(\Omega)$ such that $\int_\Omega A_0\ \nabla u_0 \cdot \nabla u_0 \ne 0$. Let

$$\varepsilon := \left|\int_\Omega A_0\ \nabla u_0 \cdot \nabla u_0\right| \Big/ \left(\int_\Omega |\nabla u_0|^2\right), \qquad \Omega_{\varepsilon/2} := \{x \in \Omega :\ \|A(x) - A_0\| < \varepsilon/2\},$$

which is an open set since A is continuous. Fix $z' \in \Omega$, and for any $z \in \Omega$ and $R > 0$ let $\Omega_{z,R} := \{x \in \mathbf{R}^d :\ z' + R(x - z) \in \Omega\}$. Let $z_i \in \Omega$, $R_i > 0$ $(i \in \mathbf{N}^+)$ such that $\Omega_i := \Omega_{z_i,R_i} \subset \Omega_{\varepsilon/2}$ and $\overline{\Omega}_i$ are pairwise disjoint sets. We define $u_i \in H^1_0(\Omega)$ by $u_i(x) := u_0\big(z' + R_i(x - z_i)\big)$ for $x \in \Omega_i$ and $u_i(x) := 0$ for $x \in \Omega \setminus \Omega_i$. Since $\operatorname{supp} u_i = \overline{\Omega}_i$ are disjoint, (15) is satisfied. Further, using the fact $\Omega_i \subset \Omega_{\varepsilon/2}$ and a linear transformation $\Omega_i \to \Omega$ in the integral, we obtain

$$\begin{aligned}\frac{|\langle J_S u_i, u_i\rangle_S|}{\int_{\Omega_i}|\nabla u_i|^2} &= \frac{\left|\int_{\Omega_i} A\ \nabla u_i \cdot \nabla u_i\right|}{\int_{\Omega_i}|\nabla u_i|^2} \ge \frac{\left|\int_{\Omega_i} A_0\ \nabla u_i \cdot \nabla u_i\right|}{\int_{\Omega_i}|\nabla u_i|^2} - \frac{\varepsilon}{2}\\ &= \frac{\left|\int_\Omega A_0\ \nabla u_0 \cdot \nabla u_0\right|}{\int_\Omega |\nabla u_0|^2} - \frac{\varepsilon}{2} = \frac{\varepsilon}{2}.\end{aligned}$$

Since for $u \in H^1_0(\Omega)$ we have $\|u\|_S^2 \le C \cdot \int_\Omega |\nabla u|^2$, the above estimate yields (16) with $\delta = \frac{\varepsilon}{2C} > 0$. ∎

4. Compact-equivalent preconditioning and mesh independent superlinear convergence rates. We prove the mesh independent convergence results for the PCG method in four stages. First we consider symmetric preconditioning operators, which are more straightforward to handle. Then, by suitable modifications of the proof, we turn to arbitrary preconditioning operators (in the studied coercive framework) where the general result is obtained. In both the symmetric and nonsymmetric cases we first consider an abstract Hilbert space level and then derive the corresponding estimates for elliptic problems.

For simplicity we will consider compact-equivalence with $\mu = 1$ in (9), which is clearly no restriction, since if a preconditioner N_S satisfies $L_S = \mu N_S + Q_S$, then we can consider the preconditioner μN_S instead.

4.1. The abstract operator equation and its discretization. Let us consider the operator equation

$$Lu = g, \tag{17}$$

where $L \in BC_S(H)$ and $g \in H$, and let $u \in H_S$ be the weak solution as in Definition 3.3. Equation (17) will be solved numerically using a Galerkin discretization: let

$$V_h = span\{\varphi_1, \ldots, \varphi_n\} \subset H_S\,,$$

where φ_i are linearly independent, be a given finite-dimensional subspace and let

$$\mathbf{L}_h := \Big\{ \langle L_S \varphi_i, \varphi_j \rangle_S \Big\}_{i,j=1}^{n}.$$

Finding the discrete solution $u_h \in V_h$ requires solving the $n \times n$ system

$$\mathbf{L}_h\, \mathbf{c} = \mathbf{b} \tag{18}$$

with $\mathbf{b} = \{\langle g, \varphi_j \rangle\}_{j=1}^{n}$. Since $L \in BC_S(H)$, the symmetric part of $\mathbf{L}_h$ is positive definite; hence system (18) has a unique solution. Moreover, if a sequence of such subspaces V_h satisfies $\inf_{v \in V_h} \|u - v\|_S \to 0$ for all $u \in H_S$, then the coercivity of L_S implies in the standard way [9] that u_h converges to the exact weak solution in the H_S-norm.

4.2. Symmetric preconditioning in Hilbert space. We introduce the stiffness matrix of S,

$$\mathbf{S}_h = \Big\{ \langle \varphi_i, \varphi_j \rangle_S \Big\}_{i,j=1}^{n}, \tag{19}$$

as preconditioner for system (18), and wish to solve

$$\mathbf{S}_h^{-1} \mathbf{L}_h\, \mathbf{c} = \tilde{\mathbf{b}} \tag{20}$$

(with $\tilde{\mathbf{b}} = \mathbf{S}_h^{-1}\mathbf{b}$) using the CG method . Let us endow $\mathbf{R}^n$ with the $\mathbf{S}_h$-inner product $\langle \mathbf{c}, \mathbf{d} \rangle_{\mathbf{S}_h} := \mathbf{S}_h\, \mathbf{c} \cdot \mathbf{d}$. Then the $\mathbf{S}_h$-adjoint of $\mathbf{S}_h^{-1}\mathbf{L}_h$ is $\mathbf{S}_h^{-1}\mathbf{L}_h^T$; hence we apply the CG algorithm (5) with $A = \mathbf{S}_h^{-1}\mathbf{L}_h$ and $A^* = \mathbf{S}_h^{-1}\mathbf{L}_h^T$.

Let us now assume that L and S are compact-equivalent with $\mu = 1$. In this special case (9) holds with $N_S = I$:

$$L_S = I + Q_S\,. \tag{21}$$

Hence, letting

$$\mathbf{Q}_h = \Big\{ \langle Q_S \varphi_i, \varphi_j \rangle_S \Big\}_{i,j=1}^{n},$$

system (20) takes the form

$$(\mathbf{I}_h + \mathbf{S}_h^{-1}\mathbf{Q}_h)\, \mathbf{c} = \tilde{\mathbf{b}}, \tag{22}$$

where $\mathbf{I}_h$ is the $n \times n$ identity matrix. Using (6), the CG algorithm (5) thus provides the estimate

$$\left(\frac{\|r_k\|_{\mathbf{S}_h}}{\|r_0\|_{\mathbf{S}_h}} \right)^{1/k} \le \frac{2}{k\nu_h} \sum_{i=1}^{k} \Big(\big|\lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T + \mathbf{S}_h^{-1}\mathbf{Q}_h)\big| + \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T\mathbf{S}_h^{-1}\mathbf{Q}_h) \Big) \tag{23}$$

$(k = 1, 2, \dots, n)$, where

$$\nu_h = \min_{\substack{\mathbf{c}\in\mathbf{R}^n \\ \mathbf{c}\neq\mathbf{0}}} \frac{\|\mathbf{S}_h^{-1}\mathbf{L}_h\mathbf{c}\|_{\mathbf{S}_h}^2}{\|\mathbf{c}\|_{\mathbf{S}_h}^2}\,. \tag{24}$$

Our goal is to give a bound on (23) that is independent of the subspace V_h.

PROPOSITION 4.1. *Let L be S-bounded and S-coercive. Let $\mathbf{S}_h$, $\mathbf{Q}_h$ be defined as above and let $s_i(Q_S)$ and $\lambda_i(Q_S^* + Q_S)$ $(i = 1, 2, \dots)$ denote the corresponding singular values, respectively, ordered eigenvalues where Q_S, defined in* (21)*, is compact on H_S. Then the following relations hold:*

(a) $$\sum_{i=1}^{k} \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T\,\mathbf{S}_h^{-1}\mathbf{Q}_h) \le \sum_{i=1}^{k} s_i(Q_S)^2 \qquad (k = 1, \dots, n),$$

(b) $$\sum_{i=1}^{k} \big|\lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T + \mathbf{S}_h^{-1}\mathbf{Q}_h)\big| \le \sum_{i=1}^{k} \big|\lambda_i(Q_S^* + Q_S)\big| \qquad (k = 1, \dots, n),$$

(c) $$\nu_h \ge m^2 \quad \textit{for } \nu_h \textit{ in } (24), \quad \textit{where} \quad m := \inf_{\substack{u\in D(L) \\ u\neq 0}} \frac{\langle Lu, u\rangle}{\|u\|_S^2}\,.$$

Proof. (a) Let $\lambda_i := \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T\,\mathbf{S}_h^{-1}\mathbf{Q}_h)$ $(i = 1, \dots, n)$ and let $\mathbf{c}^i = (c_1^i, \dots, c_n^i) \in \mathbf{R}^n$ be corresponding eigenvectors such that

$$\mathbf{S}_h\,\mathbf{c}^i \cdot \mathbf{c}^l = \delta_{il} \qquad (i, l = 1, \dots, n), \tag{25}$$

where $\cdot$ denotes the ordinary inner product on $\mathbf{R}^n$. Then

$$\mathbf{S}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i \cdot \mathbf{Q}_h\,\mathbf{c}^i = \lambda_i \qquad (i = 1, \dots, n). \tag{26}$$

Let $\mathbf{d}^i := \mathbf{S}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i$ for all i; that is,

$$\mathbf{S}_h\,\mathbf{d}^i = \mathbf{Q}_h\,\mathbf{c}^i, \tag{27}$$

which turns (26) into

$$\mathbf{S}_h\mathbf{d}^i \cdot \mathbf{d}^i = \lambda_i\,. \tag{28}$$

Now let $u_i = \sum_{j=1}^n c_j^i\varphi_j \in V_h$ and $z_i = \sum_{j=1}^n d_j^i\varphi_j \in V_h$ $(i = 1, \dots, n)$. Then (28) yields

$$\|z_i\|_S^2 = \lambda_i\,. \tag{29}$$

Further, for all $v = \sum_{j=1}^n p_j\varphi_j \in V_h$, with notation $\mathbf{p} = (p_1, \dots, p_n) \in \mathbf{R}^n$, (27) yields $\mathbf{S}_h\,\mathbf{d}^i \cdot \mathbf{p} = \mathbf{Q}_h\,\mathbf{c}^i \cdot \mathbf{p}$, which implies

$$\langle z_i, v\rangle_S = \langle Q_S u_i, v\rangle_S \qquad (v \in V_h);$$

i.e., z_i is the orthogonal projection of $Q_S u_i \in H_S$ into V_h. Therefore $\|z_i\|_S \le \|Q_S u_i\|_S$, and (29) provides

$$\sum_{i=1}^{k} \lambda_i \le \sum_{i=1}^{k} \|Q_S u_i\|_S^2 = \sum_{i=1}^{k} \langle Q_S^* Q_S u_i, u_i\rangle_S. \tag{30}$$

Here $\langle u_i, u_l\rangle_S = \mathbf{S}_h\,\mathbf{c}^i \cdot \mathbf{c}^l$ for all $i,l = 1,\dots,n$; hence by (25) the vectors u_i are orthonormal in H_S. Therefore Proposition 2.2(a) for the operator $C = Q_S^* Q_S$ in the space H_S yields the desired estimate.

(b) The proof is similar to that of (a). Now let $\lambda_i := \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T + \mathbf{S}_h^{-1}\mathbf{Q}_h)$ and let $\mathbf{c}^i = (c_1^i,\dots,c_n^i) \in \mathbf{R}^n$ be corresponding eigenvectors with property (25). Then

$$(\mathbf{Q}_h^T + \mathbf{Q}_h)\,\mathbf{c}^i = \lambda_i\,\mathbf{S}_h\,\mathbf{c}^i \qquad (i = 1,\dots,n),$$

and (25) yields

$$\lambda_i \;=\; (\mathbf{Q}_h^T + \mathbf{Q}_h)\,\mathbf{c}^i \cdot \mathbf{c}^i = 2\,\mathbf{Q}_h\,\mathbf{c}^i \cdot \mathbf{c}^i.$$

For $u_i = \sum_{j=1}^n c_j^i \varphi_j \in V_h$ we thus obtain

$$\sum_{i=1}^k \big|\lambda_i\big| \;= 2\sum_{i=1}^k \big|\langle Q_S u_i, u_i\rangle_S\big| = \sum_{i=1}^k \big|\langle (Q_S^* + Q_S)u_i, u_i\rangle_S\big|, \tag{31}$$

and Proposition 2.2(a) for the operator $C = Q_S^* + Q_S$ in the space H_S yields the desired estimate.

(c) We have

$$\min_{\substack{\mathbf{c}\in\mathbf{R}^n\\ \mathbf{c}\neq\mathbf{0}}} \frac{\|\mathbf{S}_h^{-1}\mathbf{L}_h\mathbf{c}\|_{\mathbf{S}_h}}{\|\mathbf{c}\|_{\mathbf{S}_h}} = \min_{\substack{\mathbf{c}\in\mathbf{R}^n\\ \mathbf{c}\neq\mathbf{0}}} \frac{\|\mathbf{S}_h^{-1}\mathbf{L}_h\mathbf{c}\|_{\mathbf{S}_h}\|\mathbf{c}\|_{\mathbf{S}_h}}{\|\mathbf{c}\|^2_{\mathbf{S}_h}} \geq \min_{\substack{\mathbf{c}\in\mathbf{R}^n\\ \mathbf{c}\neq\mathbf{0}}} \frac{\langle \mathbf{S}_h^{-1}\mathbf{L}_h\mathbf{c},\mathbf{c}\rangle_{\mathbf{S}_h}}{\|\mathbf{c}\|^2_{\mathbf{S}_h}}$$

$$= \min_{\substack{\mathbf{c}\in\mathbf{R}^n\\ \mathbf{c}\neq\mathbf{0}}} \frac{\mathbf{L}_h\,\mathbf{c}\cdot\mathbf{c}}{\mathbf{S}_h\,\mathbf{c}\cdot\mathbf{c}} = \min_{\substack{u\in V_h\\ u\neq 0}} \frac{\langle L_S u, u\rangle_S}{\|u\|_S^2} \geq \inf_{\substack{u\in H_S\\ u\neq 0}} \frac{\langle L_S u, u\rangle_S}{\|u\|_S^2}$$

$$= \inf_{\substack{u\in D(L)\\ u\neq 0}} \frac{\langle L_S u, u\rangle_S}{\|u\|_S^2} = \inf_{\substack{u\in D(L)\\ u\neq 0}} \frac{\langle Lu, u\rangle}{\|u\|_S^2} = m,$$

where the density of $D(L)$ in H_S has been used. □

In virtue of (23) and Proposition 4.1, we have proved the following theorem.

THEOREM 4.2. *Let L be S-bounded and S-coercive, and let L and S be compact-equivalent with $\mu = 1$. Let the compact operator Q_S be as in* (21). *Then for any subspace $V_h = span\{\varphi_1,\dots,\varphi_n\} \subset H_S$, the CG algorithm* (5) *with $\mathbf{S}_h$-inner product, applied for the $n \times n$ preconditioned system* (20), *yields*

$$\left(\frac{\|r_k\|_{\mathbf{S}_h}}{\|r_0\|_{\mathbf{S}_h}}\right)^{1/k} \leq\; \varepsilon_k \qquad (k = 1,2,\dots,n), \tag{32}$$

$$\textit{where}\quad \varepsilon_k = \frac{2}{km^2}\sum_{i=1}^k \Big(\big|\lambda_i(Q_S^* + Q_S)\big| + s_i(Q_S)^2\Big) \;\to 0 \qquad (\textit{as } k\to\infty) \tag{33}$$

and $(\varepsilon_k)_{k\in\mathbf{N}^+}$ is a sequence independent of n and V_h.

4.3. Symmetric preconditioning for discretized elliptic problems.

4.3.1. General elliptic equations. Let us consider an elliptic problem

$$\begin{cases} Lu \equiv -\mathrm{div}\,(A\,\nabla u) + \mathbf{b}\cdot\nabla u + cu = g, \\ u_{|\Gamma_D} = 0, \qquad \frac{\partial u}{\partial \nu_A} + \alpha u_{|\Gamma_N} = 0, \end{cases} \tag{34}$$

where L satisfies Assumptions 3.2 and $g \in L^2(\Omega)$. We define $H^1_D(\Omega) = \{u \in H^1(\Omega) : u_{|\Gamma_D} = 0\}$; then Assumptions 3.2 ensure that problem (34) has a unique weak solution $u \in H^1_D(\Omega)$. Now let $V_h = span\{\varphi_1, \dots, \varphi_n\} \subset H^1_D(\Omega)$ be a given FEM subspace. We seek the FEM solution $u_h \in V_h$, which requires solving the $n \times n$ system

$$\mathbf{L}_h\,\mathbf{c} = \mathbf{b}, \tag{35}$$

where

$$\big(\mathbf{L}_h\big)_{i,j} = \int_\Omega \Big(A\,\nabla\varphi_i \cdot \nabla\varphi_j + (\mathbf{b}\cdot\nabla\varphi_i)\varphi_j + c\varphi_i\varphi_j \Big) \; + \int_{\Gamma_N} \alpha\varphi_i\varphi_j \, d\sigma$$

and $\mathbf{b}_j = \int_\Omega g\varphi_j$ $(j = 1, \dots, n)$. Following subsection 4.2, we define a preconditioner for system (35) as the discretization of a suitable symmetric elliptic operator. Let

$$Su := -\mathrm{div}\,(A\,\nabla u) + hu \qquad \text{for } \; u \in H^2(\Omega) : \; u_{|\Gamma_D} = 0, \; \tfrac{\partial u}{\partial \nu_A} + \beta u_{|\Gamma_N} = 0, \tag{36}$$

where $h \in L^\infty(\Omega)$ and $h \geq 0$ if $\Gamma_D \neq \emptyset$ and $h \geq \delta_0 > 0$ if $\Gamma_D = \emptyset$, and, further, $\beta \in L^\infty(\Gamma_N)$ and $\beta \geq 0$. The corresponding inner product on $H^1_D(\Omega)$ is

$$\langle u, v\rangle_S := \int_\Omega (A\;\nabla u \cdot \nabla v + huv) + \int_{\Gamma_N} \beta uv \, d\sigma\,. \tag{37}$$

We introduce the matrix

$$\mathbf{S}_h = \Big\{ \langle \varphi_i, \varphi_j\rangle_S \Big\}_{i,j=1}^n \tag{38}$$

as preconditioner for system (35), and then solve system (20) using the CG algorithm (5) with the $\mathbf{S}_h$-inner product and with $A = \mathbf{S}_h^{-1}\mathbf{L}_h$ and $A^* = \mathbf{S}_h^{-1}\mathbf{L}_h^T$.

THEOREM 4.3. *Let $V_h \subset H^1_D(\Omega)$ be an arbitrary FEM subspace and consider the FEM discretization* (35) *of problem* (34)*, using the stiffness matrix $\mathbf{S}_h$ as preconditioner. Then the superlinear convergence of the preconditioned CG method is mesh independent in the sense of Theorem* 4.2*; i.e., we have*

$$\left(\frac{\|r_k\|_{\mathbf{S}_h}}{\|r_0\|_{\mathbf{S}_h}} \right)^{1/k} \leq \; \varepsilon_k \qquad (k = 1, 2, \dots, n) \tag{39}$$

for the mesh independent sequence $\varepsilon_k \to 0$ from (33).

Proof. The coercivity and boundedness assumptions on the coefficients of L and S imply in a standard way that L is S-bounded and S-coercive. Proposition 3.5 yields that L and S are compact-equivalent in $H^1_D(\Omega)$ if the latter is endowed with the inner product (37). Therefore Theorem 4.2 is valid with the compact operator Q_S defined via

$$\langle Q_S u, v\rangle_S = \int_\Omega \Big((\mathbf{b}\cdot\nabla u)v + (c-h)uv \Big) + \int_{\Gamma_N} (\alpha-\beta)uv \, d\sigma \qquad (u, v \in H^1_D(\Omega)), \tag{40}$$

which satisfies (21). □

We note that the above result is an extension of [8], where the mesh independence property has been proved for Dirichlet boundary conditions when either S is the symmetric part of L, or both L and S have constant coefficients.

Remark 5. Finding the correction terms in algorithm (5) with the present choice $A = \mathbf{S}_h^{-1}\mathbf{L}_h$ and $A^* = \mathbf{S}_h^{-1}\mathbf{L}_h^T$ is equivalent to the auxiliary problems

$$\begin{aligned} &\text{find } z_k \in V_h: \qquad \langle z_k, v\rangle_S = \langle L_S d_k, v\rangle_S \qquad (v \in V_h),\\ &\text{find } s_{k+1} \in V_h: \qquad \langle s_{k+1}, v\rangle_S = \langle L_S^* r_{k+1}, v\rangle_S \qquad (v \in V_h); \end{aligned}$$

i.e., z_k and s_{k+1} are the FEM solutions in V_h of the symmetric elliptic problems of the form $Sz_k = Ld_k$ and $Ss_{k+1} = L^* r_{k+1}$ with the boundary conditions of (36).

PROPOSITION 4.4. *Under the conditions of Theorem* 4.3*, the sequence* ε_k *in* (39) *satisfies*

$$\varepsilon_k \le \frac{4s}{k} \sum_{i=1}^{k} \frac{1}{\mu_i}, \tag{41}$$

where μ_i $(i \in \mathbf{N}^+)$ *are the solutions of the eigenvalue problem*

$$Su = \mu u, \quad u_{|\Gamma_D} = 0, \quad r\left(\frac{\partial u}{\partial \nu_A} + \beta u\right)_{|\Gamma_N} = \mu u \tag{42}$$

and $s, r > 0$ *are constants defined below. When the asymptotics* $\mu_i = O(i^{2/d})$ *holds (in particular, for Dirichlet boundary conditions),*

$$\varepsilon_k \le O\left(\frac{\log k}{k}\right) \quad \text{if } d = 2 \quad \text{and} \quad \varepsilon_k \le O\left(\frac{1}{k^{2/d}}\right) \quad \text{if } d \ge 3. \tag{43}$$

Proof. From (40) and (12) for $v = u$, letting $d = c - h$ and $\gamma = \alpha - \beta$, we obtain

$$\begin{aligned} \langle Q_S u, u\rangle_S &= \int_\Omega \left(d - \frac{1}{2}(\operatorname{div}\mathbf{b})\right) u^2 \; + \int_{\Gamma_N} \left(\gamma + \frac{1}{2}(\mathbf{b}\cdot\nu)\right) u^2 \, d\sigma \\ &\le C_1 \|u\|^2_{L^2(\Omega)} + C_2 \|u\|^2_{L^2(\Gamma_N)}. \end{aligned}$$

We have $\big|\langle (Q_S^* + Q_S)u, u\rangle_S\big| = 2\big|\langle Q_S u, u\rangle_S\big|$; hence the variational characterization of the eigenvalues yields

$$\big|\lambda_i(Q_S^* + Q_S)\big| = \min_{H_{i-1}\subset H_S} \max_{\substack{u \perp H_{i-1} \\ u \neq 0}} \frac{\big|\langle (Q_S^* + Q_S)u, u\rangle_S\big|}{\|u\|_S^2}$$

$$\le 2 \min_{H_{i-1}\subset H_S} \max_{\substack{u \perp H_{i-1} \\ u \neq 0}} \frac{C_1\|u\|^2_{L^2(\Omega)} + C_2\|u\|^2_{L^2(\Gamma_N)}}{\|u\|_S^2},$$

where H_{i-1} stands for an arbitrary $(i-1)$-dimensional subspace. On the other hand, here Q_S falls into the type (11), and hence (14) implies

$$\|Q_S u\|_S^2 \le 2K_1^2 \|u\|^2_{L^2(\Omega)} + 2K_2^2 \|u\|^2_{L^2(\Gamma_N)}.$$

Since $s_i(Q_S)^2 = \lambda_i(Q_S^* Q_S)$ and $\langle Q_S^* Q_S u, u\rangle_S = \|Q_S u\|_S^2$, we obtain as above that

$$s_i(Q_S)^2 = \min_{H_{i-1}\subset H_S} \max_{\substack{u\perp H_{i-1}\\ u\neq 0}} \frac{\langle Q_S^* Q_S u, u\rangle_S}{\|u\|_S^2}$$

$$\leq \min_{H_{i-1}\subset H_S} \max_{\substack{u\perp H_{i-1}\\ u\neq 0}} \frac{2K_1^2\|u\|_{L^2(\Omega)}^2 + 2K_2^2\|u\|_{L^2(\Gamma_N)}^2}{\|u\|_S^2}\,.$$

Altogether, letting $s := \frac{C_1+K_1^2}{m^2}$, $r := \frac{C_1+K_1^2}{C_2+K_2^2}$, formula (33) implies

$$\varepsilon_k \leq \frac{4s}{k}\sum_{i=1}^{k}\hat{\mu}_i, \qquad \text{where } \hat{\mu}_i = \min_{H_{i-1}\subset H_S} \max_{\substack{u\perp H_{i-1}\\ u\neq 0}} \frac{\|u\|_{L^2(\Omega)}^2 + \frac{1}{r}\|u\|_{L^2(\Gamma_N)}^2}{\|u\|_S^2},$$

in which the fraction equals $1/\mu$ for (42); hence the equality $\hat{\mu}_i = \frac{1}{\mu_i}$ follows from the variational characterization of the eigenvalues.

Estimate (43) follows from the asymptotics $\mu_i = O(i^{2/d})$ by an elementary calculation. For Dirichlet boundary conditions, this asymptotic behavior can be found in [11]. ∎

Remark 6. To the authors' knowledge the asymptotic behavior $\mu_i = O(i^{2/d})$ is not known for general (other than Dirichlet) boundary conditions. However, for the simple special case $-\Delta u = \mu u$, $\frac{\partial u}{\partial \nu}\big|_{\partial\Omega} = \mu u$, where Ω is a disc in $\mathbf{R}^2$, one can easily verify via the sign properties of the Bessel functions that μ_i are asymptotic to the Dirichlet eigenvalues and hence also satisfy $\mu_i = O(i^{2/d})$. This suggests a wider validity of this asymptotic rate.

Remark 7. It is of interest to compare the estimates (43), obtained in the context of the CGN method, to those valid for the GCG-LS method. In [8] we have proved $\varepsilon_k \leq O\big(k^{-1/2}\big)$ in two dimensions on the unit square for the GCG-LS method under the same preconditioning (for Dirichlet boundary conditions, and using explicit formulae for the eigenvalues). Using the same technique, one can similarly derive $\varepsilon_k \leq O\big(k^{-1/d}\big)$ in d dimensions (on the unit cube). That is, comparing with (43), we see that the decay rate of ε_k for the CGN method is almost or exactly (in two or more dimensions, respectively) the square of the decay rate for the GCG method, which compensates for the extra work of solving two auxiliary problems in the preconditioned CGN iteration.

4.3.2. An example: Convection-diffusion equations with Helmholtz preconditioners. As a special case of the preceding subsection, let us consider the case of a convection-diffusion operator L in (34) and a preconditioning operator S with constant coefficients. Namely, if $A \equiv I$ in (34), then we have the problem

$$\text{(44)} \qquad \begin{cases} Lu \equiv -\Delta u + \mathbf{b}(x)\cdot\nabla u + c(x)u = g(x), \\ u_{|\Gamma_D} = 0, \qquad \frac{\partial u}{\partial \nu} + \alpha(x)u_{|\Gamma_N} = 0, \end{cases}$$

where for clearness, the dependence of the coefficients on x has now been indicated unlike before. Let us define the preconditioning operator

$$\text{(45)} \qquad Su := -\Delta u + hu \qquad \text{for } u \in H^2(\Omega):\ u_{|\Gamma_D} = 0,\ \frac{\partial u}{\partial \nu} + \beta u_{|\Gamma_N} = 0,$$

where $h, \beta \in \mathbf{R}$ are constants such that $h \geq 0$ if $\Gamma_D \neq \emptyset$ and $h > 0$ if $\Gamma_D = \emptyset$, and further, $\beta \geq 0$. (For constant $\mathbf{b}$ and Dirichlet boundary conditions, the analysis of linear convergence in [25] proposes $h = O(|\mathbf{b}|^2)$ as an efficient choice.)

Then the auxiliary problems with this preconditioning are discrete Helmholtz problems with constant coefficients. For such problems various fast solvers are available (like fast Fourier transform, cyclic reduction, or multigrid; see, e.g., [19, 28, 30]), which, together with the mesh independence result of Theorem 4.3, turns $\mathbf{S}_h$ into an efficient preconditioner. We point out that this is an extension of [8], where the mesh independence property has been proved for Dirichlet boundary conditions under the strong restriction that the operator L itself has constant coefficients.

4.3.3. Elliptic systems. Analogously to subsection 4.3.1, we can consider elliptic systems

$$\left.\begin{array}{l} L_i u \equiv -\mathrm{div}\,(A_i \nabla u_i) + \mathbf{b}_i \cdot \nabla u_i + \sum_{j=1}^{l} V_{ij} u_j = g_i, \\ u_{i\,|\Gamma_D} = 0, \qquad \frac{\partial u_i}{\partial \nu_A} + \alpha_i u_{i\,|\Gamma_N} = 0 \end{array}\right\} \qquad (i = 1, \ldots, l), \tag{46}$$

where Ω, A_i, and α_i are as in Assumptions 3.2, $\mathbf{b}_i \in C^1(\overline{\Omega})^N$, $g_i \in L^2(\Omega)$, $V_{ij} \in L^\infty(\Omega)$. We assume that $\mathbf{b}_i$ and the matrix $V = \left\{V_{ij}\right\}_{i,j=1}^{l}$ satisfy the coercivity property

$$\lambda_{min}(V + V^T) - \max_i \mathrm{div}\,\mathbf{b}_i \geq 0$$

pointwise on Ω, where λ_{min} denotes the smallest eigenvalue; then system (46) has a unique weak solution $u \in H_D^1(\Omega)^l$. Such systems arise, e.g., from suitable time discretization and Newton linearization of transport systems, which often consist of a huge number of equations [33]. Now we choose an FEM subspace $V_h \subset H_D^1(\Omega)^l$ and look for the solution of the corresponding algebraic system $\mathbf{L}_h\,\mathbf{c} = \mathbf{b}$. We define the preconditioning operator $S = (S_1, \ldots, S_l)$ as the l-tuple of independent operators

$$S_i u_i := -\mathrm{div}\,(A_i \nabla u) + h_i u \qquad \text{for } u_i \in H^2(\Omega) :\ u_{i\,|\Gamma_D} = 0,\ \frac{\partial u_i}{\partial \nu_A} + \beta_i u_{i\,|\Gamma_N} = 0 \tag{47}$$

$(i = 1, \ldots, l)$ with the conditions of (36), and let $\mathbf{S}_h$ be the stiffness matrix of S in $H_D^1(\Omega)^l$.

Then, similarly to subsection 4.3.1, one can verify that the superlinear convergence of the preconditioned CG method is mesh independent in the sense of Theorem 4.2; i.e., (32)–(33) hold.

This result is an extension of [24] where the above preconditioning has been introduced and its efficient parallelizability has been demonstrated; on the other hand, the mesh independence property was proved there for Dirichlet boundary conditions under strong restrictions on the matrix V (antisymmetric, or normal when the operator L itself has constant coefficients).

4.4. Nonsymmetric preconditioning in Hilbert space. Now let N be a general (possibly nonsymmetric) S-bounded and S-coercive operator which is compact-equivalent to L with $\mu = 1$; i.e., (9) becomes

$$L_S = N_S + Q_S\,. \tag{48}$$

We introduce the stiffness matrix of N_S,

$$\mathbf{N}_h = \Big\{ \langle N_S \varphi_i, \varphi_j \rangle_S \Big\}_{i,j=1}^{n},$$

as preconditioner for system (18), and wish to solve

$$\mathbf{N}_h^{-1} \mathbf{L}_h \, \mathbf{c} = \hat{\mathbf{b}} \tag{49}$$

(with $\hat{\mathbf{b}} = \mathbf{N}_h^{-1}\mathbf{b}$) using the CG method . Since N is nonsymmetric, in order to define an inner product on $\mathbf{R}^n$ we preserve the stiffness matrix of S on V_h; i.e., using (19) we endow $\mathbf{R}^n$ with the $\mathbf{S}_h$-inner product $\langle \mathbf{c}, \mathbf{d} \rangle_{\mathbf{S}_h} := \mathbf{S}_h \, \mathbf{c} \cdot \mathbf{d}$ as earlier. Then the $\mathbf{S}_h$-adjoint of $\mathbf{N}_h^{-1}\mathbf{L}_h$ is $\mathbf{S}_h^{-1}\mathbf{L}_h^T \, \mathbf{N}_h^{-T}\mathbf{S}_h$; hence we apply the CG algorithm (5) with $A = \mathbf{N}_h^{-1}\mathbf{L}_h$ and $A^* = \mathbf{S}_h^{-1}\mathbf{L}_h^T \mathbf{N}_h^{-T}\mathbf{S}_h$.

Letting

$$\mathbf{Q}_h = \Big\{ \langle Q_S \varphi_i, \varphi_j \rangle_S \Big\}_{i,j=1}^{n},$$

system (20) takes the form

$$(\mathbf{I}_h + \mathbf{N}_h^{-1}\mathbf{Q}_h) \, \mathbf{c} = \hat{\mathbf{b}}, \tag{50}$$

where $\mathbf{I}_h$ is the $n \times n$ identity matrix. Using (6), the CG algorithm (5) thus provides

$$\left(\frac{\|r_k\|_{\mathbf{S}_h}}{\|r_0\|_{\mathbf{S}_h}} \right)^{1/k} \le \frac{2}{k\nu_h} \sum_{i=1}^{k} \Big(\lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T \, \mathbf{N}_h^{-T}\mathbf{S}_h + \mathbf{N}_h^{-1}\mathbf{Q}_h) + \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T \, \mathbf{N}_h^{-T}\mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h) \Big) \tag{51}$$

$(k = 1, 2, \ldots, n)$, where

$$\nu_h = \min_{\mathbf{c} \in \mathbf{R}^n} \frac{\|\mathbf{N}_h^{-1}\mathbf{L}_h\mathbf{c}\|_{\mathbf{S}_h}^2}{\|\mathbf{c}\|_{\mathbf{S}_h}^2} \, . \tag{52}$$

Again, our goal is to give a bound on (51) that is independent of V_h.

PROPOSITION 4.5. *Let L and N be S-bounded and S-coercive operators, in particular,*

$$m := \inf_{\substack{u \in D(L) \\ u \neq 0}} \frac{\langle Lu, u \rangle}{\|u\|_S^2} > 0, \qquad \hat{m} := \inf_{\substack{u \in D(N) \\ u \neq 0}} \frac{\langle Nu, u \rangle}{\|u\|_S^2} > 0,$$
$$\hat{M} := \sup_{\substack{u \in D(N) \\ u \neq 0}} \frac{|\langle Nu, v \rangle|}{\|u\|_S \|v\|_S} > 0,$$

and let Q_S be a compact operator on H_S. Let $\mathbf{S}_h$, $\mathbf{N}_h$, and $\mathbf{Q}_h$ be defined as above, and let $s_i(Q_S)$ $(i = 1, 2, \ldots)$ denote the singular values of Q_S. Then the following relations hold:

(a) $$\sum_{i=1}^{k} \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T \, \mathbf{N}_h^{-T}\mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h) \le \frac{1}{\hat{m}^2} \sum_{i=1}^{k} s_i(Q_S)^2 \qquad (k = 1, \ldots, n),$$

(b) $$\sum_{i=1}^{k} \big| \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T \, \mathbf{N}_h^{-T}\mathbf{S}_h + \mathbf{N}_h^{-1}\mathbf{Q}_h) \big| \le \frac{2}{\hat{m}} \sum_{i=1}^{k} s_i(Q_S) \qquad (k = 1, \ldots, n),$$

(c) $$\nu_h \geq \frac{m^2}{\hat{M}^2}\,.$$

Proof. (a) We proceed in a manner similar to that of Proposition 4.1. Let $\lambda_i := \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T\,\mathbf{N}_h^{-T}\mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h)$ $(i=1,\ldots,n)$ and let $\mathbf{c}^i = (c_1^i,\ldots,c_n^i) \in \mathbf{R}^n$ be corresponding eigenvectors with property (25). Then

$$\mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i \cdot \mathbf{N}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i = \lambda_i \qquad (i=1,\ldots,n). \tag{53}$$

Let $\mathbf{d}^i := \mathbf{N}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i$ for all i; that is,

$$\mathbf{N}_h\,\mathbf{d}^i = \mathbf{Q}_h\,\mathbf{c}^i\,. \tag{54}$$

For this $\mathbf{d}^i$ and λ_i, similarly to Proposition 4.1, we have (28) and, letting $u_i = \sum_{j=1}^n c_j^i\varphi_j \in V_h$ and $z_i = \sum_{j=1}^n d_j^i\varphi_j \in V_h$, we obtain (29). Further, for all $v = \sum_{j=1}^n p_j\varphi_j \in V_h$, with notation $\mathbf{p} = (p_1,\ldots,p_n) \in \mathbf{R}^n$, (54) yields $\mathbf{N}_h\,\mathbf{d}^i \cdot \mathbf{p} = \mathbf{Q}_h\,\mathbf{c}^i \cdot \mathbf{p}$, which means

$$\langle N_S z_i, v\rangle_S = \langle Q_S u_i, v\rangle_S \qquad (v \in V_h).$$

From this we have

$$\|z_i\|_S^2 \leq \frac{1}{\hat{m}}\,\langle N_S z_i, z_i\rangle_S = \frac{1}{\hat{m}}\,\langle Q_S u_i, z_i\rangle_S \leq \frac{1}{\hat{m}}\,\|Q_S u_i\|_S\|z_i\|_S;$$

hence $\|z_i\|_S \leq \frac{1}{\hat{m}}\,\|Q_S u_i\|_S$. Then from (29)

$$\sum_{i=1}^k \lambda_i \leq \frac{1}{\hat{m}^2}\sum_{i=1}^k \|Q_S u_i\|_S^2 = \frac{1}{\hat{m}^2}\sum_{i=1}^k \langle Q_S^* Q_S u_i, u_i\rangle_S, \tag{55}$$

whence the desired estimate follows in the same way as from (30) in Proposition 4.1.

(b) Now let $\lambda_i := \lambda_i(\mathbf{S}_h^{-1}\mathbf{Q}_h^T\,\mathbf{N}_h^{-T}\mathbf{S}_h + \mathbf{N}_h^{-1}\mathbf{Q}_h)$ and let $\mathbf{c}^i = (c_1^i,\ldots,c_n^i) \in \mathbf{R}^n$ be corresponding eigenvectors with property (25). Then

$$\lambda_i = \lambda_i\,\mathbf{S}_h\,\mathbf{c}^i\cdot\mathbf{c}^i = \mathbf{Q}_h^T\,\mathbf{N}_h^{-T}\mathbf{S}_h\,\mathbf{c}^i\cdot\mathbf{c}^i + \mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i\cdot\mathbf{c}^i = 2\,\mathbf{S}_h\mathbf{N}_h^{-1}\mathbf{Q}_h\,\mathbf{c}^i\cdot\mathbf{c}^i = 2\,\mathbf{Q}_h\,\mathbf{c}^i\cdot\mathbf{e}^i,$$

where $\mathbf{e}^i := \mathbf{N}_h^{-T}\mathbf{S}_h\,\mathbf{c}^i$ for all i. Here for all $v = \sum_{j=1}^n p_j\varphi_j \in V_h$, with notation $\mathbf{p} = (p_1,\ldots,p_n) \in \mathbf{R}^n$, we obtain $\mathbf{e}^i\cdot\mathbf{N}_h\,\mathbf{p} = \mathbf{S}_h\,\mathbf{c}^i\cdot\mathbf{p}$, which means $\langle w_i, N_S v\rangle_S = \langle u_i, v\rangle_S$ for all $v \in V_h$, where $w_i = \sum_{j=1}^n e_j^i\varphi_j$ and $u_i = \sum_{j=1}^n c_j^i\varphi_j$, or

$$\langle N_S^* w_i, v\rangle_S = \langle u_i, v\rangle_S \qquad (v \in V_h). \tag{56}$$

Denote by P the orthogonal projection of H_S onto V_h. Then (56) yields $u_i = PN_S^* w_i$. Here the linear mapping $(PN_S^*)_{|V_h} : V_h \to V_h$ is one-to-one, since for all $v \in V_h$

$$\langle PN_S^* v, v\rangle_S = \langle N_S^* v, v\rangle_S = \langle N_S v, v\rangle_S \geq \hat{m}\|v\|_S^2\,. \tag{57}$$

Therefore

$$\mathbf{Q}_h\,\mathbf{c}^i\cdot\mathbf{e}^i = \langle Q_S u_i, w_i\rangle_S = \langle Q_S u_i, (PN_S^*)^{-1}_{|V_h} u_i\rangle_S = \langle u_i,\, Q_S^*(PN_S^*)^{-1}_{|V_h} u_i\rangle_S.$$

Here the operator $(PN_S^*)^{-1}_{|V_h}$ has a norm-preserving extension $\hat{N}$ from V_h onto H_S (namely, with $\hat{N}\big|_{(V_h)\perp} := 0$), and from (57) we have $\|\hat{N}\| \le \frac{1}{\hat{m}}$. Altogether, we obtain

$$\sum_{i=1}^{k} |\lambda_i| = 2\sum_{i=1}^{k} \big|\langle Q_S^*(PN_S^*)^{-1}_{|V_h} u_i,\, u_i\rangle_S\big| \;=\; 2\sum_{i=1}^{k} \big|\langle Q_S^*\hat{N}u_i,\, u_i\rangle_S\big| \;\le\; 2\sum_{i=1}^{k} s_i\big(Q_S^*\hat{N}\big)$$
$$\le \frac{2}{\hat{m}}\sum_{i=1}^{k} s_i\big(Q_S^*\big) = \frac{2}{\hat{m}}\sum_{i=1}^{k} s_i\big(Q_S\big)$$

(where, in the inequalities, statements (a) and (b) of Proposition 2.2 have been used, respectively).

(c) Let $\mathbf{c} \in \mathbf{R}^n$ be arbitrary, $\mathbf{d} := \mathbf{N}_h^{-1}\mathbf{L}_h\mathbf{c}$. Let $u = \sum_{j=1}^n c_j\varphi_j \in V_h$ and $z = \sum_{j=1}^n d_j\varphi_j \in V_h$. Then $m\|u\|_S^2 \le \langle L_S u, u\rangle_S = \mathbf{L}_h\,\mathbf{c}\cdot\mathbf{c} = \mathbf{N}_h\,\mathbf{d}\cdot\mathbf{c} = \langle N_S z, u\rangle_S \le \|N_S z\|_S\|u\|_S$; hence

$$m\|u\|_S \le \|N_S z\|_S$$

and

$$\frac{\|\mathbf{N}_h^{-1}\mathbf{L}_h\mathbf{c}\|^2_{\mathbf{S}_h}}{\|\mathbf{c}\|^2_{\mathbf{S}_h}} = \frac{\mathbf{S}_h\,\mathbf{d}\cdot\mathbf{d}}{\mathbf{S}_h\,\mathbf{c}\cdot\mathbf{c}} = \frac{\|z\|_S^2}{\|u\|_S^2} \ge m^2\,\frac{\|z\|_S^2}{\|N_S z\|_S^2} \ge \frac{m^2}{\hat{M}^2}. \qquad \square$$

By virtue of (51) and Proposition 4.5, we have proved the following theorem.

THEOREM 4.6. *Let L and N be S-bounded and S-coercive operators that are compact-equivalent in H_S with $\mu = 1$. Let the compact operator Q_S be as in* (48)*. Then for any subspace $V_h = span\{\varphi_1, \dots, \varphi_n\} \subset H_S$, the CG algorithm* (5) *with $\mathbf{S}_h$-inner product, applied for the $n \times n$ preconditioned system* (49)*, yields*

$$\left(\frac{\|r_k\|_{\mathbf{S}_h}}{\|r_0\|_{\mathbf{S}_h}}\right)^{1/k} \le\; \varepsilon_k \qquad (k = 1, 2, \dots, n), \tag{58}$$

$$\textit{where}\quad \varepsilon_k = \frac{2\hat{M}^2}{km^2}\sum_{i=1}^{k}\left(\frac{2}{\hat{m}}\,s_i(Q_S) + \frac{1}{\hat{m}^2}\,s_i(Q_S)^2\right) \to 0 \qquad (\textit{as } k\to\infty) \tag{59}$$

and $(\varepsilon_k)_{k\in\mathbf{N}^+}$ is a sequence independent of n and V_h.

Remark 8. When one preconditions L with N, a useful choice for the operator S is the symmetric part of N: i.e., if $D(N) = D(N^*)$, then $S = (N + N^*)/2$, and if $D(N) \ne D(N^*)$, then S is an operator that generates the inner product satisfying $\langle u, v\rangle_S := \frac{1}{2}(\langle Nu, v\rangle + \langle u, Nv\rangle)$ for $u, v \in D(N)$; see [23]. Then in Proposition 4.5 we have $\langle Nu, u\rangle = \|u\|_S^2$ $(u \in D(N))$, and hence $\hat{m} = 1$.

4.5. Nonsymmetric preconditioning for discretized elliptic problems. This section contains our most general result for elliptic operators: in the studied coercive framework, preconditioning with an arbitrary operator N that is compact-equivalent with L provides mesh independent superlinear convergence. Besides its theoretical aspect, the importance of this property will be shown below by some practical examples as well. Let us first consider the elliptic problem (34)

$$\begin{cases} Lu \equiv\; -\mathrm{div}\,(A\,\nabla u) + \mathbf{b}\cdot\nabla u + cu = g, \\ u_{|\Gamma_D} = 0, \qquad \frac{\partial u}{\partial \nu_A} + \alpha u_{|\Gamma_N} = 0, \end{cases} \tag{60}$$

and let us define the nonsymmetric preconditioning operator

(61)
$$Nu := -\mathrm{div}\,(A\,\nabla u) + \mathbf{w}\cdot\nabla u + zu \quad \text{for } u \in H^2(\Omega):\ u_{|\Gamma_D} = 0,\ \frac{\partial u}{\partial \nu_A} + \eta u_{|\Gamma_N} = 0$$

for some properly chosen functions $\mathbf{w}, z, \eta$, where L and N satisfy Assumptions 3.2 in the obvious sense, and further, $g \in L^2(\Omega)$. Accordingly, the preconditioner for the discretized problem (35) is the nonsymmetric stiffness matrix

$$\left(\mathbf{N}_h\right)_{i,j} = \int_\Omega \Big(A\,\nabla\varphi_i\cdot\nabla\varphi_j + (\mathbf{w}\cdot\nabla\varphi_i)\,\varphi_j + z\varphi_i\varphi_j \Big) \ + \int_{\Gamma_N} \eta\varphi_i\varphi_j\,d\sigma\,.$$

We use the same energy space as in the symmetric case, i.e., $H_S = H^1_D(\Omega)$ with inner product (37). We then solve the preconditioned system using the CG algorithm (5) with the $\mathbf{S}_h$-inner product and with $A = \mathbf{N}_h^{-1}\mathbf{L}_h$ and $A^* = \mathbf{S}_h^{-1}\mathbf{L}_h^T\mathbf{N}_h^{-T}\mathbf{S}_h$.

THEOREM 4.7. *Let $V_h \subset H^1_D(\Omega)$ be an arbitrary FEM subspace and consider the FEM discretization* (35) *of problem* (34)*, using the stiffness matrix $\mathbf{N}_h$ as preconditioner. Then the superlinear convergence of the preconditioned CG method is mesh independent in the sense of Theorem* 4.6*; i.e.,* (58)–(59) *hold.*

Proof. The proof is similar to that of Theorem 4.3, but now Theorem 4.6 is applied in $H^1_D(\Omega)$. ∎

Examples. Let us consider problem (44); i.e., when in (60) we have

$$Lu = -\Delta u + \mathbf{b}(x)\cdot\nabla u + c(x)u,$$

where for clarity, the dependence of the coefficients on x has now been indicated. For convection-dominated problems (i.e., when $|\mathbf{b}|$ is large), the inclusion of nonsymmetric terms in N may turn it into a much better approximation of L than a symmetric preconditioner like (45). Although the preconditioner N thus becomes nonsymmetric as is L itself, the solution of the auxiliary problems can still remain considerably simpler than the original one. We illustrate this with two examples.

1. One can propose a preconditioning operator with constant coefficients:

(62)
$$Nu = -\Delta u + \mathbf{w}\cdot\nabla u + zu \qquad \text{for } u \in H^2(\Omega):\ u_{|\Gamma_D} = 0,\ \frac{\partial u}{\partial \nu} + \eta u_{|\Gamma_N} = 0,$$

where $\mathbf{w} \in \mathbf{R}^d$, $z, \eta \in \mathbf{R}$ are constants such that $z \geq 0$ if $\Gamma_D \neq \emptyset$ and $z > 0$ if $\Gamma_D = \emptyset$, and further, $\eta \geq 0$. Owing to the fact that N has constant coefficients, one can rely on efficient solution methods for the auxiliary problems. Here one can use either multigrid or multilevel methods, or (if Ω is rectangular or the boundary conditions allow the problem to be easily embedded into a rectangular domain) fast direct solvers for separable equations are available; see, e.g., [29].

2. The preconditioning operator (62) can be further simplified if one convection coefficient is dominating. Assume that, say, $b_1(x)$ has considerably larger values than $b_j(x)$ $(j \geq 2)$. Then one can include only one nonsymmetric coefficient, i.e., propose the preconditioning operator

(63)
$$Nu = -\Delta u + w_1\frac{\partial u}{\partial x_1} + zu \qquad \text{for } u \in H^2(\Omega):\ u_{|\Gamma_D} = 0,\ \frac{\partial u}{\partial \nu} + \eta u_{|\Gamma_N} = 0,$$

where $w_1, z, \eta \in \mathbf{R}$ are constants with the same properties as those required for (62). In this case (above all, if $b_1(x)$ are large), the presence of the term $w_1 \frac{\partial u}{\partial x_1}$ itself may turn N into a much better approximation of L. Nevertheless, since this term is one-dimensional, the solution of the auxiliary problems remains considerably simpler than the original one, e.g., via local one-dimensional Green's functions [5]. (The above operator N has been proposed in [8], where the mesh independence result of the PCG method has been proved for Dirichlet boundary conditions under the strong restriction that the operator L itself has constant coefficients.)

Analogously to the symmetric case in subsection 4.3.3, the above results can be extended to systems in a straightforward way. Namely, let us consider system (46) and introduce the preconditioning operator N as an l-tuple of decoupled operators N_i, where each N_i is of the type (61). Then the superlinear convergence of the preconditioned CG method is mesh independent in the sense of Theorem 4.6; i.e., (58)–(59) hold. Since N_i are decoupled, the resulting algorithm is parallelizable. This turns it into an efficient method if, for instance, each N_i is like (62), or the problem itself is in one dimension, which may occur, e.g., after using some method of splitting in meteorological models with several components; see [33].

5. Some closing remarks.

5.1. Conclusions and notes on numerical realization. The main results of this paper can be summarized as follows. If two elliptic operators are compact-equivalent (which requires that their principal parts coincide up to a constant factor and they have homogeneous Dirichlet conditions on the same portion of the boundary), then the PCGN method provides mesh independent superlinear convergence; i.e., a bound on the rate of superlinear convergence is given in the form of a sequence which is mesh independent and is determined only by the elliptic operators. The analogous result holds for suitable elliptic systems where, as an additional advantage, the preconditioning operator can be chosen to be decoupled. Various further examples have been shown on the efficient choice of compact-equivalent preconditioners.

For the GCG-LS method we have obtained similar earlier results in [8, 24], but with severe restrictions: except for some special cases, both the original and preconditioning operators had to contain constant coefficients, and further, only Dirichlet boundary conditions have been considered. On the other hand, numerical experiments in [24] suggest that the restrictions are probably mostly technical, since a similar superlinear behavior has been observed for test problems with or without these conditions. Remark 7 suggests that the PCGN and GCG-LS methods require the same order of operations for prescribed accuracy; hence there is no a priori preference for one over the other. In any case, a favorable property for the PCGN iteration is the generality of the underlying theory, clarified in the present paper.

The PCGN algorithm has been applied in the setting of subsection 4.3.3 as an inner iterative solver for Newton's method for nonlinear nonsymmetric elliptic systems in [1]. As in the above-mentioned experiments in [24], an efficient performance of the compact-equivalent preconditioning has been observed. Further numerical experiments are beyond the scope and length of this paper.

When realizing the equivalent operator preconditioning for a problem with a second order operator with variable coefficients, one can use an inner-outer iteration method, i.e., precondition in the outer iterations with the given second order operator and use inner iterations to solve this equation. For the superlinear rate to remain, the inner iteration errors must not be of an order greater than that for the first order part of the operator. For optimal complexity of the overall computations to hold, one

should then solve the arising inner systems with an optimal order of computational complexity, i.e., proportional to the degrees of freedom used in the discretization of the differential equation.

5.2. On singular perturbation problems. For singular perturbation problems such as

$$L_\varepsilon u \equiv -\varepsilon\Delta u + \mathbf{b}\cdot\nabla u + cu = f$$

(plus boundary conditions), where $\varepsilon > 0$ but $\varepsilon \ll \|\mathbf{b}\|$, one cannot neglect the first order term when forming an efficient preconditioner. Such problems are characterized by thin boundary and/or interior layers, and the diffusion term plays a noticeable role only in the layer. This property is not exploited in preconditioners like (62). A possible approach for handling such problems therefore is to use the following defect-correction method:

$$L_{\delta(x)}(u_{k+1} - u_k) = f - L_\varepsilon u \qquad (k \in \mathbf{N}^+),$$

where u_0 is given and in practice only one or two steps need to be performed. Here

$$L_{\delta(x)}u := -\delta(x)\Delta u + \mathbf{b}\cdot\nabla u + cu,$$

where $\delta(x) = 0$ outside the layers and increases continuously along each characteristic line (defined by the velocity vector $\mathbf{b}$) from zero to ε in the layers. The widths of the layers are typically chosen as $\varepsilon\log(1/\varepsilon)$. To solve the correction equation by iteration, one can form a preconditioner S by using the operator $\mathbf{b}\cdot\nabla u + hu$ outside the layers and $-\delta(x)\Delta u + \mathbf{b}\cdot\nabla u + hu$ in the layers for some properly chosen function $h \geq 0$. The analysis of the problem will not be considered further in the present paper.

A FINITE ELEMENT METHOD FOR 3D EXTERIOR OSEEN FLOWS: ERROR ESTIMATES*

PAUL DEURING†

Abstract. Stationary Oseen flows in a 3D exterior domain are discretized by applying a P1-P1 stabilized finite element method to the Oseen system in a truncated exterior domain, with an implicit pointwise artificial boundary condition on the truncating boundary. Error estimates are proved for this discretization. The paper extends an approach which was introduced by Guirguis and Gunzburger [*RAIRO Modél. Math. Anal. Numér.*, 21 (1987), pp. 445–464] for exterior Stokes flows. The stabilized P1-P1 method in question was introduced by Rebollo [*Numer. Math.*, 79 (1998), pp. 283–319].

1. Introduction.

We consider the following Oseen system in an exterior domain Ω, with a Dirichlet boundary condition on $\partial\Omega$ and with zero velocity at infinity:

$$-\Delta u + \tau \cdot \partial_1 u + \nabla \pi = f, \quad \operatorname{div} u = 0 \quad \text{in } \Omega, \tag{1.1}$$
$$u \,|\, \partial\Omega = (-1,0,0), \quad |u(x)| \to 0 \quad \text{for } |x| \to \infty,$$

where $\Omega = \mathbb{R}^3 \backslash \overline{\mathcal{P}}$ for some open bounded polyhedron $\mathcal{P} \subset \mathbb{R}^3$ with Lipschitz boundary. Problem (1.1) arises as a linearization of a mathematical model for the steady motion without rotation of a rigid body in a viscous incompressible fluid. We refer to [6] for more details; here we mention only that $\tau \in (0,\infty)$ is the Reynolds number of the fluid, and the vector $(-1,0,0)$ appearing in the boundary condition on $\partial\Omega$ corresponds to the normalized steady velocity of the rigid body. Under suitable assumptions on f, problem (1.1) admits a unique solution (u,π) with $\nabla u \in L^2(\Omega)^9$ and $\pi \in L^2(\Omega)$. In the following, this solution will be called "exterior flow." We will study a finite element method for computing this exterior flow in a region Ω_S around $\partial\Omega$, for some fixed $S > 0$ with $\mathbb{R}^3 \backslash \Omega \subset B_S$. (For any $r > 0$, we denote by B_r the open ball with center at the origin and with radius r, and we set $\Omega_r := \Omega \cap B_r$.) As computational domains, we consider polyhedrons $P_{h,R}$, which are larger than Ω_S and have parameters $h \in (0,S)$ and $R \in (S,\infty)$ that may be interpreted as follows: The number R indicates that $P_{h,R}$ approximates the truncated exterior domain Ω_R in a suitable sense. As for the parameter h, it refers to the way we decompose $P_{h,R}$ into tetrahedrons. These tetrahedrons are assumed to have a diameter of order h when situated near $\partial\Omega$, and of order $h \cdot R$ when located near ∂B_R. The transition of the mesh size from values of order h near $\partial\Omega$ to about $h \cdot R$ near ∂B_R is performed in such a way that the aspect ratio of our tetrahedrons remains bounded as a function of h and R. We refer to assumptions (A1)–(A8) in section 2 for more details.

On each polyhedron $P_{h,R}$, we define a pair $(V_{h,R}, M_{h,R})$ of P1 finite element spaces. Then, in (2.11)–(2.13) below we introduce a variational problem, which is

†Laboratoire de Mathématiques Pures et Appliquées, Université du Littoral, B.P. 699, F-62228 Calais cédex, France (Paul.Deuring@lmpa.univ-littoral.fr).

based on these spaces and is a variant of the P1-P1 stabilized finite element method proposed by Rebollo [17] for the Navier–Stokes system in a fixed bounded domain. We show that a solution $(u_{h,R}, \pi_{h,R})$ of (2.11)–(2.13) approximates (u, π) in the sense that an error estimate is valid with essential features that may be stated as follows:

$$\|\nabla(u - u_{h,R})\|_2 \ + \ \|(\pi - \pi_{h,R}) \,|\, \Omega_S\|_2 \ \le \ C \cdot (h^t + h \cdot \ln(R/S) + R^{-1}) \tag{1.2}$$

for $h \in (0, h_0)$, $R \in (R_0, \infty)$, where $h_0 \in (0, S/2)$, $R_0 \in (S, \infty)$ are constants depending on Ω, S and on certain mesh parameters. Inequality (1.2) is valid under the assumption that the quantity $h \cdot R$ is bounded by some arbitrary but fixed constant. The exponent $t \in (0, 1]$ in (1.2) describes the regularity of u and π near the Lipschitz boundary $\partial\Omega$. We may take $t = 1$ if u is H^2 and if π is H^1 in a neighborhood of $\partial\Omega$, but this case will not arise in general because Ω is a nonconvex Lipschitz domain. The constant C in (1.2) depends on Ω, S, t, τ, on an upper bound for $h \cdot R$, on some mesh parameters, on certain quantities related to the exterior flow (u, π) (see (2.1)–(2.5)), and on a bilinear form used to stabilize P1-P1 finite elements (see (2.6)). A more detailed version of (1.2) may be found in Theorem 2.1 below.

Our discrete variational problem (2.11)–(2.13) may be considered as a discretization of a boundary value problem in Ω_R consisting of the Oseen system

$$-\Delta u_R + \tau \cdot \partial_1 u_R + \nabla \pi_R = f \,|\, \Omega_R, \quad \operatorname{div} u_R = 0 \quad \text{in } \Omega_R, \tag{1.3}$$

with the same boundary condition on $\partial\Omega$ as in (1.1):

$$u_R \,|\, \partial\Omega = (-1, 0, 0), \tag{1.4}$$

and with the ensuing pointwise "artificial" boundary condition on the sphere ∂B_R:

$$\sum_{j=1}^{3} \Big(\partial_j v_k(x) - \delta_{jk} \cdot \varrho(x) \Big) \cdot (x_j / R) + \Big(R^{-1} + (\tau/2) \cdot (1 - x_1/R) \Big) \cdot v_k(x) = 0 \tag{1.5}$$

for $x \in \partial B_R$, $1 \le k \le 3$. This boundary value problem can be written as a variational problem which admits a unique solution (u_R, π_R) in $H^1(\Omega_R)^3 \times L^2(\Omega_R)$. As was shown in [7, Theorem 7.1 with $\widetilde{\tau} = 0$ (linear case)], this solution satisfies the relation

$$\|\nabla(u_R - u)\|_2 \ = \ O(R^{-1}) \quad \text{for } R \to \infty. \tag{1.6}$$

This result motivated the choice of the discrete equations (2.11)–(2.13), and it explains the term R^{-1} on the right-hand side of (1.2): this term corresponds to the truncation error exhibited in [7]. It should be remarked, however, that relation (1.6) will not be used in the work at hand. Instead the solution $(u_{h,R}, \pi_{h,R})$ of our finite element variational problem (2.11)–(2.13) will be compared directly with the exterior flow (u, π), and no continuous intermediate problem on Ω_R or $P_{h,R}$ will be considered. In this way, we will be better able to exploit the asymptotics of u and π. A crucial feature of this asymptotics is the existence of a "wake region," which means that in the downstream direction, the velocity u converges more slowly than elsewhere to its boundary value at infinity (see [9, p. 374]). This wake region will be taken into consideration in two ways. First, an asymmetric surface integral on the outer boundary of $P_{h,R}$ enters into the definition of the bilinear form a appearing in our

discrete variational problem (2.11)–(2.13). Second, our error estimates involve bounds of u and ∇u with respect to pointwise norms with inhomogeneous weights. We remark that our error bounds additionally depend on homogeneously weighted L^2-norms of the second derivatives of u and of the gradient of π, with the weights being defined in an implicit way: we take the standard L^2-norm over annular domains $B_R \backslash B_{R/2}$ for $R \in (2 \cdot S, \infty)$ and then multiply by powers of R. A complete list of the quantities related to u and π and entering into our error bounds may be found in (2.1)–(2.4).

Of course, the finite element approximation we consider gives rise not only to a truncation error but also to a discretization error. Concerning that latter component of the total error, we indicate that the velocity part u of the exterior flow is assumed to be an H^{1+t}-function near $\partial\Omega$, and an H^2-function far from $\partial\Omega$. Analogous conditions are imposed on the pressure (H^t near $\partial\Omega$, H^1 far from Ω). As a consequence, if the error is measured by the L^2-norm of the gradient of the velocity, we expect our P1-P1 finite element method to give rise to a discretization error of order h^t related to the approximation of u and π near $\partial\Omega$, and to an error of order h which may be ascribed to the discretization of velocity and pressure far from $\partial\Omega$. This explains the terms h^t and $h \cdot \ln(R/S)$ on the right-hand side of (1.2) and indicates that these terms describe the discretization error in an optimal way, except for the factor $\ln(R/S)$. However, we cannot see how to remove this factor.

It might be asked why we have chosen Rebollo's finite element method for our discretization of (1.3)–(1.5). There are essentially two reasons for this choice. First, Rebollo [17] uses P1-P1 elements and circumvents the LBB condition by introducing a stabilization term ("pressure stabilization") which does not involve any parameter. Thus, implementing Rebollo's method is relatively simple. Second, due to [17], optimal error estimates are available when this method is applied to the stationary Navier–Stokes system in a fixed bounded domain. The theory in [17] even covers a streamlined upwind Petrov–Galerkin (SUPG)-type stabilization related to the convective term ("velocity stabilization"). Thus Rebollo's article presents a coherent theory for several aspects of finite element discretizations of stationary Navier–Stokes flows. Such a theory seemed to be a good starting point for attempting to discretize problem (1.3)–(1.5). As it turns out, the principal results from [17] may be generalized to our situation. This generalization takes the form of estimate (1.2), which we establish here for our approximate Oseen flows, but which remains valid when the stationary Navier–Stokes system with Oseen term and with small Reynolds number is considered, and when Rebollo's version of SUPG is included in the discrete problem. These two points—nonlinearity and SUPG—will be the subject of a separate paper. However, the main difficulties of our theory are discussed in the work at hand because they already arise with the discrete Oseen problem (2.11)–(2.13) without velocity stabilization. These difficulties are essentially due to four features: the Oseen term $\tau \cdot \partial_1 u$, the graded mesh, a nonvanishing mean value of the pressure, and the parameter R, which must be controlled in all our estimates, in addition to the quantity h. Since none of these features appear in [17], it is not astonishing that the proofs in that reference do not carry over to our situation. In fact, the present article represents a considerable extension of the theory in [17].

The argument we present here might also work for mixed finite element methods without stabilization, under one condition: the mixed method in question must satisfy the LBB condition on the type of grid considered here, with a constant independent of *h and R*. This condition is fulfilled by P1-P1 finite elements augmented by bubble functions (the "mini element"), as was shown in [3] and is stated in Theorem 3.1 below.

However, it seems to be an open question whether an analogue of Theorem 3.1 is valid for other kinds of LBB-stable finite elements.

Our approach to the discretization of exterior domains was inspired by Guirguis and Gunzburger [14], who approximated exterior Stokes flows by solutions of finite element variational problems in truncated exterior domains; also see [15, sections 16.3 and 16.4]. Guirguis and Gunzburger were led to these finite element problems by discretizing the Stokes system in a truncated exterior domain with a suitable pointwise artificial boundary condition on the truncating surface. This boundary condition determines the quality of the approximation. The error bounds considered in [14] depend on the given exterior Stokes flow via weighted L^2-norms involving second order or higher derivatives of the velocity, as well as the gradient or higher derivatives of the pressure [14, Theorem 5.2].

We further remark that Goldstein [11] introduced the type of graded meshes we consider in the work at hand. Due to these meshes, the complexity of our finite element method (2.11)–(2.13) on $P_{h,R}$ is proportional to $h^{-3} \cdot \ln(R/S)$, and thus exhibits only a logarithmic dependence on R; see [11], [12] in this respect.

Further articles related to the computation of exterior Stokes, Oseen, or Navier–Stokes flows, but not closely linked to the work at hand, are listed in [6]. To our knowledge, there are no previous articles presenting error estimates for discretizations of 3D exterior Oseen or Navier–Stokes flows.

2. Notation. Statement of our finite element variational problem. Main results. For $U \subset \mathbb{R}^3$, put $U^c := \mathbb{R}^3 \backslash U$. If $r \in (0,\infty)$, $x \in \mathbb{R}^3$, put $B_r(x) := \{y \in \mathbb{R}^3 \ : \ |y-x| < r\}$, $B_r := B_r(0)$. If U is (Lebesgue) measurable, we denote the Lebesgue measure of U by $|U|$. Let $V \subset \mathbb{R}^3$ be open. For functions $v : V \mapsto \mathbb{R}$, $w, \widetilde{w} : V \mapsto \mathbb{R}^3$ with appropriate regularity, the notation $\partial_l v$ for $1 \le l \le 3$, $\partial^a v$ for $a \in \mathbb{N}_0^3$, ∇v, Δv, $\operatorname{div} w$, $(\widetilde{w} \cdot \nabla) w$ stands for partial derivatives, with obvious meanings. If $p \in [1,\infty)$, the standard L^p-norm of functions on V is denoted by $\| \ \|_{p,V}$. Let $m \in \mathbb{N}$. We write $H^m(V)$ for the usual Sobolev space of order m and exponent 2. The usual norm of that space is denoted by $\| \ \|_{m,2,V}$. The subspace $H_0^1(V)$ of $H^1(V)$ is defined in the standard way. We write $H^{-1}(V)^3$ for the dual space of $H_0^1(V)^3$. If $s \in (0,2)$ with $s \ne 1$, the symbol $H^s(V)$ stands for the usual fractional-order Sobolev space, with its intrinsic norm denoted by $\| \ \|_{s,2,V}$ (see [1, 7.48]). We will also use the seminorm $| \ |_{m,2,V}$ defined by

$$|v|_{m,2,V} := \left(\sum_{a \in \mathbb{N}_0^3,\, |a|=m} \|\partial^a v\|_{2,V}^2 \right)^{1/2} \qquad \text{for } \ v \in W^{m,p}(V),$$

where $|a| := a_1 + a_2 + a_3$ for $a \in \mathbb{N}_0^3$. We write $H^m_{loc}(V)$ for the space of all functions $v : V \mapsto \mathbb{R}$ such that $v \,|\, K \in H^m(K)$ for any $K \subset \mathbb{R}^3$ open with $\overline{K} \subset V$. If $(\mathcal{H}, \| \ \|)$ is a normed space consisting of functions from V into $\mathbb{R}$, we use the symbol $\| \ \|$ also for the norm $(\sum_{i=1}^3 \|v_i\|^2)^{1/2}$ of fields $v : V \mapsto \mathbb{R}^3$ with $v_i \in \mathcal{H}$ $(1 \le i \le 3)$. Moreover, if $W \subset \mathbb{R}^3$ with $V \subset W$, and if $w : W \mapsto \mathbb{R}$ is a function with $w \,|\, V \in \mathcal{H}$, we write $\|w\|$ instead of $\|w \,|\, V\|$. This convention will not give rise to ambiguities because the notation for our norms is chosen in such a way that the domain of reference is always indicated.

For $R \in (0,\infty)$, put $\Omega_R := B_R \cap \Omega$. We fix some number $S \in (0,\infty)$ with $\Omega^c \subset B_S$. As we already remarked in section 1, the domain Ω_S should be considered as the region where we want to compute the flow (u,π). Denote $U_0 := \Omega_S$, $U_j := B_{2^j \cdot S} \backslash B_{2^{j-1} \cdot S}$ for $j \in \mathbb{N}$. It will be convenient to use the notation $U_{-1} := \emptyset$.

In the rest of this section, we will always assume that the parameter h belongs to $(0,\, S/2)$, and R to (S, ∞), except when indicated otherwise.

For such h and R, we choose an open polyhedron $P_{h,R} \subset \mathbb{R}^3$ and closed tetrahedrons $K_1^{(h,R)}, \ldots, K_{k(h,R)}^{(h,R)} \subset P_{h,R}$, with $k(h,R) \in \mathbb{N}$, such that the following assumptions (A1)–(A8) are valid. (In order to simplify notation, we will always write k instead of $k(h,R)$, and K_l instead of $K_l^{(h,R)}$, for $1 \le l \le k$.):

(A1) $\overline{P_{h,R}} = \bigcup_{l=1}^{k} K_l$.

(A2) $K_l \subset \Omega_R$; $K_l \cap K_m$ is either empty or a common vertex or a common side or a common face of K_l and K_m, for $l, m \in \{1, \ldots, k\}$ with $l \neq m$.

(A3) There is $\sigma_1 > 0$, independent of h and R, such that

$$\sigma_1 \cdot 2^j \cdot h \le \sup\big\{\, r \in (0,\infty) \,:\, B_r(x) \subset K_l \text{ for some } x \in K_l \,\big\},$$

for $l \in \{1, \ldots, k\}$, $j \in \mathbb{N}_0$ with $K_l \cap U_j \neq \emptyset$. Moreover, $diam\, K_l \le 2^j \cdot h$ for such l and j.

(A4) $B_S \cap P_{h,R} = \Omega_S$; if $l \in \{1, \ldots, k\}$ and if $x \in \partial P_{h,R} \backslash \partial\Omega$ is a vertex of K_l, then $x \in \partial B_R$.

(A5) The domain $P_{h,R} \cup \Omega^c$ is convex.

(A6) There is $\sigma_2 \in (0,\infty)$, independent of h and R, such that for $l \in \{1, \ldots, k\}$, the macroelement $(K_l)_\Delta := \cup\big\{\, K_m \,:\, m \in \{1, \ldots, k\} \text{ with } K_m \cap K_l \neq \emptyset \,\big\}$ is star-shaped with respect to the ball $B_{\sigma_2 \cdot diam\, K_l}(x)$, for some $x \in (K_l)_\Delta$. (See [2, (4.2.2)] for the notion "star-shaped with respect to a ball.")

(A7) For any $l \in \{1, \ldots, k\}$, at least one vertex of K_l is located in the (open) set $P_{h,R}$.

(A8) There is $\varphi_1 \in (0, \pi/2)$, independent of h and R, such that the relation

$$x + \big\{\, z \in \mathbb{R}^3 \backslash \{0\} \,:\, |x|^{-1} \cdot |z|^{-1} \cdot (x \cdot z) \ge \cos\varphi_1 \,\big\} \subset \mathbb{R}^3 \backslash (P'_{h,R} \cup \Omega^c)$$

holds for any $x \in \partial P'_{h,R} \backslash \partial\Omega$, where $P'_{h,R}$ denotes the interior of the union of the tetrahedrons K_l with $K_l \subset \Omega_{2\cdot S}$.

Assumptions (A1) and (A2) specify that $P_{h,R}$ is a subset of Ω_R, and $\mathcal{T}_{h,R}$ is a triangulation of $P_{h,R}$ without hanging nodes. By assumption (A3), we specify Goldstein's mesh-grading process and require the aspect ratio of our mesh cells to stay away from zero. Condition (A6) is necessary for constructing interpolation operators of Clément type; see [2, section 4.8], where (A6) is used implicitly. As concerns (A5), (A7), and (A8), these assumptions are needed so that Theorem 3.1 is valid. Moreover, the convexity of $P_{h,R} \cup \Omega^c$ required in (A5) and our assumptions on Ω imply that $P_{h,R}$ is Lipschitz bounded (see [13, Corollary 1.2.2.3]). This means in particular that the outward unit normal to $P_{h,R}$ is well defined [16, pp. 88–89]. We will denote it by n. It will be convenient to use the abbreviation $\partial_{h,R} := \partial P_{h,R} \backslash \partial\Omega$. Thus $\partial_{h,R}$ is the "outer part" of the boundary of $P_{h,R}$, that is, the surface which cuts off the exterior domain Ω. We put

$$W_{h,R} := \big\{\, v \in H^1(P_{h,R})^3 \,:\, v \,|\, \partial\Omega = 0 \,\big\},$$

$$\|v\|^{(h,R)} := \big(\, \|\nabla v\|^2_{2,P_{h,R}} + R^{-1} \cdot \|v\|^2_{2,\partial_{h,R}} \,\big)^{1/2} \quad \text{for } v \in W_{h,R}.$$

It follows from [6, Theorem 3.4] that the mapping $\|\ \|^{(h,R)}$ is a norm on $W_{h,R}$ which is equivalent to the norm $\|\ \|_{1,2,P_{h,R}}$, but this equivalence involves constants depending on R.

Turning to problem (1.1), we fix $\tau \in (0,\infty)$ and a function $f : \Omega \mapsto \mathbb{R}^3$ such that $f \,|\, \Omega_S \in L^2(\Omega_S)^3$ and $\sup\{\, |f(x)| \cdot |x|^\sigma \ : \ x \in B_S^c \,\} < \infty$ for some $\sigma \in (4,\infty)$. By [9, Theorems VII.2.1, VII.1.1; Lemma VII.1.1], [7, Theorem 4.13], there are unique functions $u \in H^2_{loc}(\Omega)^3,\ \pi \in H^1_{loc}(\Omega) \cap L^2(\Omega)$ such that $\nabla u \in L^2(\Omega)^9$ and such that the pair (u,π) verifies (1.1). This pair (u,π) is the exterior flow we will consider in the following. Since $\partial\Omega$ is only Lipschitz bounded, we cannot expect H^2-regularity of u or H^1-regularity of π near $\partial\Omega$. Instead we have only

$$\mathcal{A}_1 := \|u\|_{1+t,2,\Omega_{4\cdot S}} \ + \ \|\pi\|_{t,2,\Omega_{4\cdot S}} \ < \ \infty \quad \text{for some } \ t \in (0,1], \tag{2.1}$$

with $t < 1$ in general. This parameter t will be kept fixed throughout. Of course, the radius $4 \cdot S$ may be replaced by any number $R \in (0,\infty)$ with $\Omega^c \subset B_R$, but the choice $R = 4 \cdot S$ will be convenient in the following. To our knowledge, no direct proof is available for relation (2.1), which, however, follows from regularity results for the Stokes system in Lipschitz domains (see [8]). By [7, Theorem 5.6], we further have

(2.2)

$$\begin{aligned}\mathcal{A}_2 := {} & \sup\{\, |u(x)| \cdot |x| \cdot (1 + \tau \cdot (|x| - x_1)) \ : \ x \in B_S^c \,\} \\ & + \ \sup\{\, |\pi(x)| \cdot |x|^2 \ : \ x \in B_S^c \,\} \\ & + \ \sup\{\, |\nabla u(x)| \cdot \big[\, |x|^{-2} + \tau^{1/2} \cdot |x|^{-3/2} \cdot (1 + \tau \cdot (|x| - x_1))^{-3/2} \,\big]^{-1} \ : \ x \in B_S^c \,\} \\ & < \infty.\end{aligned}$$

Moreover, by [9, Theorem VII.1.1], [5, Theorem 5.2; Theorem 7.1 with $\widetilde{\tau} = 0$], the following relations are valid:

(2.3)

$$\begin{aligned}\mathcal{A}_3 := {} & \sup\{\, \|\, \partial_l \partial_m u\|_{2,\, B_R \setminus B_{\delta\cdot R}} \cdot \big(\, (1-\delta)^{1/2} \cdot R^{-1} + R^{-3/2} \,\big)^{-1} \ : \\ & \qquad\qquad R \in [2\cdot S,\, \infty),\ \delta \in [1/2,\, 1],\ 1 \le l, m \le 3 \,\} \\ & + \ \sup\{\, \|\, \nabla\pi\|_{2,\, B_R \setminus B_{R/2}} \cdot R \ + \ \|\partial_1 u\|_{2,\, B_R \setminus B_{R/2}} \cdot R \ : \ R \in [2\cdot S,\, \infty) \,\} \\ & < \infty,\end{aligned}$$

(2.4)

$$\begin{aligned}\mathcal{A}_4 := {} & \sup\{\, \big(\, \|\nabla u\|_{2,\, \partial_{h,R}} \ + \ \tau \cdot \|\, (1 - n_1) \cdot u\|_{2,\, \partial_{h,R}} \\ & \qquad + \|\pi\|_{2,\, \partial_{h,R}} \,\big)\, / (h + R^{-1}) \ + \ \|u\|_{2,\, \partial_{h,R}} \ : \ R \in [4\cdot S,\, \infty),\ h \in (0, S_0) \,\} \\ & < \infty,\end{aligned}$$

with a constant $S_0 \in (0,\, S/4)$. Put

$$\mathcal{A} := \max\{\, \mathcal{A}_1,\, \ldots,\, \mathcal{A}_4 \,\}. \tag{2.5}$$

This quantity $\mathcal{A}$ characterizes the regularity and the asymptotic behavior near infinity of the exterior flow (u,π) and contains all the information on (u,π) that we will need in the following. Next we introduce the finite element variational problem with solution

assumed to approximate our exterior flow. To this end, we define the following finite element spaces:

$$V_{h,R} := \big\{\, v \in C^0(\overline{P_{h,R}})^3 \;:\; v \,|\, K_l \in P_1(K_l)^3 \;\text{ for }\; 1 \le l \le k \,\big\},$$

$$Y_{h,R} := \big\{\, v \in V_{h,R} \;:\; v|\partial\Omega = 0 \,\big\},$$

$$M_{h,R} := \big\{\, \varrho \in C^0(\overline{P_{h,R}}) \;:\; \varrho \,|\, K_l \in P_1(K_l) \;\text{ for }\quad 1 \le l \le k \,\big\},$$

where $P_1(K_l)$ denotes the space of all polynomials over K_l of degree at most 1 ($l \in \{1, \ldots, k\}$). We write $\mathcal{B}_{h,R}$ for the space of all functions $v : \overline{P_{h,R}} \mapsto \mathbb{R}$ such that for $l \in \{1, \ldots, k\}$, we have $v \,|\, K_l = \alpha_l \cdot b_{K_l}$ for some $\alpha_l \in \mathbb{R}$, where b_{K_l} is the standard bubble function on K_l (that is, the polynomial of order 4 on K_l vanishing on ∂K_l as defined in [17, p. 287]). For $v, w \in H^1(P_{h,R})^3,\ q \in L^2(P_{h,R})$, we set

$$a(v,w) := a_{h,R,\tau}(v,w) := \int_{P_{h,R}} \left(\sum_{k=1}^{3} \partial_k v \cdot \partial_k w + \tau \cdot \partial_1 v \cdot w \right) dx$$

$$+ \int_{\partial_{h,R}} \Big(R^{-1} + \ (\tau/2) \cdot (1 - n_1) \Big) \cdot (v \cdot w)\, do_x,$$

$$c(v,q) := c_{h,R}(v,q) := -\int_{P_{h,R}} \operatorname{div} v \cdot q \, dx.$$

Next, following [17], we want to introduce a stabilization term which allows us to circumvent the LBB condition. To this end, we consider a bilinear symmetric form $A := A_{h,R} : H_0^1(P_{h,R})^3 \times H_0^1(P_{h,R})^3 \mapsto \mathbb{R}$ with

$$A(V,V) \ge \alpha \cdot \|\nabla V\|^2_{2,P_{h,R}}, \quad |\, A(V,W)\,| \le \alpha^{-1} \cdot \|\nabla V\|_{2,P_{h,R}} \cdot \|\nabla W\|_{2,P_{h,R}} \tag{2.6}$$

for $V, W \in \mathcal{B}^3_{h,R}$, where the constant $\alpha \in (0,\infty)$ is to be independent of h and R. Let $H_0^1(P_{h,R})^3$ be equipped with the gradient norm, and denote the corresponding norm of $H^{-1}(P_{h,R})^3$ by $\|\ \|_{-1,2,P_{h,R}}$. Then by (2.6) and the Lax–Milgram theorem, there is a unique operator $\mathcal{R} := \mathcal{R}_A : H^{-1}(P_{h,R})^3 \mapsto \mathcal{B}^3_{h,R}$ such that

$$A\big(\,\mathcal{R}(F),\, W\big) = F(W) \quad \text{for }\ F \in H^{-1}(P_{h,R})^3,\ W \in \mathcal{B}^3_{h,R}, \tag{2.7}$$

and this operator verifies the following inequality:

$$\alpha \cdot \|\nabla \mathcal{R}(F)\|^2_{2,P_{h,R}} \le A\big(\,\mathcal{R}(F), \mathcal{R}(F)\,\big) = F\big(\,\mathcal{R}(F)\,\big) \le \|F\|_{-1,2,P_{h,R}} \cdot \|\nabla \mathcal{R}(F)\|_{2,P_{h,R}}.$$

Hence

$$\|\nabla \mathcal{R}(F)\|_{2,P_{h,R}} \le \alpha^{-1} \cdot \|F\|_{-1,2,P_{h,R}} \quad \text{for }\ F \in H^{-1}(P_{h,R})^3; \tag{2.8}$$

compare [17, p. 288]. In particular, $\mathcal{R}$ is continuous. It is easy to see that $\mathcal{R} \,|\, \mathcal{B}^3_{h,R}$ is one-to-one if a function $W \in \mathcal{B}^3_{h,R}$ is identified with the element F_W of $H^{-1}(P_{h,R})^3$ given by $F_W(v) := \int_{P_{h,R}} W \cdot v \, dx$ for $v \in H_0^1(P_{h,R})^3$. Thus we may think of $\mathcal{R}$ as a kind of interpolation operator from $H^{-1}(P_{h,R})^3$ into $\mathcal{B}^3_{h,R}$.

For $q \in L^2(P_{h,R})$, we may define a functional $\nabla q \in H^{-1}(P_{h,R})^3$ by setting

$$\nabla q(w) := -\int_{P_{h,R}} q \cdot \operatorname{div} w \, dx \quad \text{for }\ w \in H_0^1(P_{h,R})^3.$$

Then

$$\|\nabla q\|_{-1,2,P_{h,R}} \le 3 \cdot \|q\|_{2,P_{h,R}} \quad \text{for } q \in L^2(P_{h,R})^3. \tag{2.9}$$

When we write $\mathcal{R}(\nabla q)$ in the following, for some q in $L^2(P_{h,R})^3$ (in particular for $q \in M_{h,R}$), then the term ∇q is to be understood as a functional in the preceding sense. Observe that by (2.7),

$$A\big(\mathcal{R}(\nabla q), W\big) = -\int_{P_{h,R}} q \cdot \operatorname{div} W \, dx \quad \text{for } q \in M_{h,R},\ W \in \mathcal{B}^3_{h,R}. \tag{2.10}$$

Now we may formulate our finite element problem. It reads as follows: For $F \in Y'_{h,R}$, find $u_{h,R} = u_{h,R,\tau,A,F} \in V_{h,R}$, $\pi_{h,R} = \pi_{h,R,\tau,A,F} \in M_{h,R}$ such that

$$a(u_{h,R}, w) + c(w, \pi_{h,R}) = F(w) \quad \text{for } w \in Y_{h,R}, \tag{2.11}$$

$$c(u_{h,R}, q) = A\big(\mathcal{R}(\nabla \pi_{h,R}), \mathcal{R}(\nabla q)\big) \quad \text{for } q \in M_{h,R}, \tag{2.12}$$

$$u_{h,R} \,|\, \partial\Omega = (-1, 0, 0). \tag{2.13}$$

In [6], it was shown that a solution $(u_{h,R}, \pi_{h,R})$ to (2.11)–(2.13) exists and is unique. The term $A\big(\mathcal{R}(\nabla \pi_{h,R}), \mathcal{R}(\nabla q)\big)$ serves to circumvent the LBB condition ("pressure stabilization") and may be considered as a generalization of the static condensation operator used to eliminate the bubble functions of the mini element. In fact, if we make the most obvious choice for A, that is, $A(v, w) := \int_\Omega \nabla v \cdot \nabla w \, dx$ $(v, w \in H^1_0(P_{h,R})^3)$, then the term $A\big(\mathcal{R}(\nabla \pi_{h,R}), \mathcal{R}(\nabla q)\big)$ corresponds to just that operator (see [17, p. 304]). But instead of restricting ourselves to this special case, we chose the more abstract framework based on the bilinear symmetric form A with (2.6) because such a framework covers at least one more interesting example, namely, the Brezzi–Pitkäranta pressure stabilization (see [17, p. 304]) and may have other applications as well.

Our error estimates may now be stated in the form of the following theorem. Recall that the quantities σ_1, σ_2, φ_1, α, and $\mathcal{A}$ were introduced in (A3), (A6), (A8), (2.6), and (2.5), respectively.

THEOREM 2.1. *Let $h \in (0, h_0)$, $R \in (R_0, \infty)$, where $h_0 \in (0, S/8]$ and $R_0 \in [8 \cdot S, \infty)$ are constants depending only on Ω, S, σ_1, σ_2, and φ_1. Further suppose that $F(w) = \int_{P_{h,R}} f \cdot w \, dx$ for $w \in Y_{h,R}$, and that $(u_{h,R}, \pi_{h,R}) \in V_{h,R} \times M_{h,R}$ is a solution of (2.11)–(2.13). Then*

$$\begin{aligned} &\Big((\|u - u_{h,R}\|^{(h,R)})^2 + \tau \cdot \|u - u_{h,R}\|^2_{2,\partial P_{h,R}} \\ &\qquad + \| \nabla \mathcal{R}(\nabla(\pi - \pi_{h,R})) \|^2_{2,P_{h,R}} + \|\pi - \pi_{h,R}\|^2_{2,\Omega_{2\cdot S}} \Big)^{1/2} \\ &\qquad \le C_1(\tau, h \cdot R) \cdot \max\{1, \tau^{-1/2}\} \cdot \mathcal{A} \cdot (h^t + h \cdot \ln(R/S) + R^{-1}). \end{aligned} \tag{2.14}$$

The constant $C_1(\tau, h \cdot R)$ depends on Ω, S, σ_1, σ_2, φ_1, and α and is an increasing function of τ and $h \cdot R$.

A remark is perhaps in order with respect to our estimate of the pressure error $\pi - \pi_{h,R}$ in (2.14). In that inequality, the restriction of this error to $\Omega_{2\cdot S}$ is evaluated in the L^2-norm, and an interpolation of this error in $\mathcal{B}^3_{h,R}$ is estimated with respect to the H^1-norm. It remains an open problem whether the L^2-norm of $\pi - \pi_{h,R}$ in

$P_{h,R}$—instead of $\Omega_{2\cdot S}$—decays in the same way for $h+R^{-1}\to 0$, as does the left-hand side of (2.14), or whether it decays at all.

We remark that the notation $\partial_{h,R}$, $\mathcal{A}$, $\mathcal{R}$, $u_{h,R}$, $\pi_{h,R}$, $\Gamma_{h,R}$ will be used frequently in the following.

3. Auxiliary results. We will apply the following version of the LBB condition for the mini element.

THEOREM 3.1. *There are constants* $C_0\in(0,\infty)$, $\gamma_0\in(0,\,S/4]$, $R_0\in[8\cdot S,\,\infty)$ *such that for* $h\in(0,\,\gamma_0)$, $R\in(R_0,\infty)$, $\varrho\in M_{h,R}$,

$$\|\varrho\|_{2,P_{h,R}}\le C_0\cdot\sup\Big\{\int_{P_{h,R}}\varrho\cdot\operatorname{div}(w+W)\,dx/\|w+W\|^{(h,R)}\ :\ w\in Y_{h,R},\ W\in B^3_{h,R},\ w+W\neq 0\Big\}.$$

The constants C_0, γ_0, R_0 *depend on the parameters* σ_1, σ_2, *and* φ_1 (*see* (A3), (A6), (A8), *respectively*) *and on* Ω *and* S.

Note that the constant C_0 does not depend on either h or R. Theorem 3.1 is a slightly simplified form of [3, Theorem 4.1]. (The spherical boundary ∂B_R in [3] is replaced here by the polyhedral boundary $\partial_{h,R}$.) By [4, eqs. (2.3), (2.7); Corollary 2.2], there is a constant $S_1\in(0,\,S/8]$ such that

$$\int_{\partial_{h,R}}do\ \le\ 2\cdot\int_{\partial B_R}do\quad\text{for }\ h\in(0,S_1)\ \text{ and for }\ R\in(8\cdot S,\,\infty).\tag{3.1}$$

We put $h_0:=\min\{\gamma_0,S_0,S_1\}$, with S_0 from (2.4) and γ_0 from Theorem 3.1 above. This means in particular that $h_0<S/8$. In the following, we write $\mathcal{C}$ for constants which depend only on Ω, S, and the parameters $\sigma_1,\sigma_2,\varphi_1$, and α from (A3), (A6), (A8), and (2.6), respectively. By $\mathcal{C}(\tau)$ we denote constants which depend on $\Omega,S,\sigma_1,\sigma_2,\varphi_1,\alpha$ and which are increasing functions of τ. We write $\mathcal{C}(\tau,h\cdot R)$ for constants which, in addition, are increasing functions of $h\cdot R$. In the following, the quantities h and R are always assumed to belong to $(0,h_0)$ and (R_0,∞), respectively. We set

$$J:=J_R:=\min\big\{\,j\in\mathbb{N}\ :\ 2^j\cdot S\ge R\,\big\},\tag{3.2}$$

$$A_{h,R}:=\cup\big\{\,K_l\ :\ l\in\{1,\dots,k\}\text{ with }\ K_l\cap\partial B_R\neq\emptyset\,\big\}.$$

In the next lemma, we introduce functions from $M_{h,R}$ with support in a single layer of mesh cells near $\partial_{h,R}$; compare [6, Lemma 3.1] and the remarks on its proof given in [6].

LEMMA 3.1. *Let* $m\in M_{h,R}$. *Denote by* $\overline{m}$ *the uniquely determined element from* $M_{h,R}$ *such that for any* $l\in\{1,\dots,k\}$ *and for any vertex* x *of* K_l, *the relation* $\overline{m}(x)=m(x)$ *holds if* $x\in\partial B_R$, *and* $\overline{m}(x)=0$ *otherwise. Then*

$$m\,|\,\partial_{h,R}=\overline{m}\,|\,\partial_{h,R},\quad \operatorname{supp}(\overline{m})\subset A_{h,R},\quad \|\overline{m}\|_2\le\mathcal{C}\cdot\|m\|_{2,A_{h,R}}.$$

We further note the following consequences of (A3) and (A4). These consequences should be obvious, except perhaps relation (3.5), which may be proved in the same

way as [3, Lemma 4.2]:

$$\text{(3.3)}\quad diam\, K_l \le 2^J \cdot h \le 2 \cdot h \cdot R/S \ \text{ for } 1 \le l \le k; \quad A_{h,R} \subset \overline{P_{h,R}} \backslash B_{R\cdot(1-2\cdot h/S)};$$

$$\text{(3.4)}\quad (K_l)_\Delta \subset \overline{P_{h,R}} \backslash B_{R\cdot(1-4\cdot h/S)} \ \text{ for } \ l \in \{1, \dots, k\} \ \text{ with } \ K_l \cap \partial B_R \ne \emptyset;$$

$$\text{(3.5)}\quad \Omega_{R\cdot(1-h^2/S^2)^{1/2}} \subset P_{h,R} \subset \Omega_R, \quad \text{so } \ B_R \backslash (P_{h,R} \cup \Omega^c) \subset B_R \backslash B_{R\cdot(1-h^2/S^2)^{1/2}};$$

$$\text{(3.6)}\quad \sum_{l=1}^{k} \int_{(K_l)_\Delta} v\, dx \ \le \ \mathcal{C} \cdot \int_{P_{h,R}} v\, dx \quad \text{for any } \ v \in L^1(P_{h,R}) \text{ with } v \ge 0;$$

$$\text{(3.7)}\quad \sum_{l=1,\ K_l \cap U_j \ne \emptyset}^{k} \int_{(K_l)_\Delta} v\, dx \ \le \ \mathcal{C} \cdot \int_{(U_{j-1} \cup U_j \cup U_{j+1}) \cap P_{h,R}} v\, dx$$

$$\text{for } \ v \ \text{ as in } \ (3.6) \ \text{ and for } \ 0 \le j \le J;$$

$$\text{(3.8)}\quad \sum_{l=1,\ K_l \cap \partial B_R \ne \emptyset}^{k} \int_{(K_l)_\Delta} v\, dx \ \le \ \mathcal{C} \cdot \int_{P_{h,R} \backslash B_{R\cdot(1-4\cdot h/S)}} v\, dx \quad \text{for } \ v \ \text{ as in } \ (3.6);$$

$$\text{(3.9)}\quad \int_{P_{h,R}} v\, dx \ = \ \sum_{j=0}^{J} \int_{U_j \cap P_{h,R}} v\, dx \quad \text{for } \ v \in L^1(P_{h,R}).$$

Next we introduce two Clément-type interpolation operators. By [2, section 4.8], (A3), and (A6), there are linear operators $\Pi_{h,R} : H^1(P_{h,R})^3 \mapsto V_{h,R}$, $\widetilde{\Pi}_{h,R} : L^2(P_{h,R}) \mapsto M_{h,R}$ with $\Pi_{h,R}(w) \,|\, \partial\Omega = 0$ for $w \in W_{h,R}$; $\Pi_{h,R}(v) = v$ for $v \in V_{h,R}$; $\widetilde{\Pi}_{h,R}(\varrho) = \varrho$ for $\varrho \in M_{h,R}$,

$$\text{(3.10)}\quad |\Pi_{h,R}(w) - w|_{r,2,K_l} \ \le \ \widetilde{C} \cdot (diam\, K_l)^{\nu - r} \cdot |w|_{\nu,2,(K_l)_\Delta}$$

for $r \in \{0,1\}$, $\nu \in \{1,\, 2\}$, $w \in H^1(P_{h,R})^3$, $1 \le l \le k$ with $w \,|\, (K_l)_\Delta \in H^\nu\big((K_l)_\Delta\big)^3$; and

$$\text{(3.11)}\quad |\widetilde{\Pi}_{h,R}(\varrho) - \varrho|_{r,2,K_l} \ \le \ \widetilde{C} \cdot (diam\, K_l)^{1-r} \cdot |\varrho|_{1,2,(K_l)_\Delta}$$

for $r \in \{0,1\}$, $\varrho \in L^2(P_{h,R})$, $l \in \{1, \dots, k\}$ with $\varrho \,|\, (K_l)_\Delta \in H^1\big((K_l)_\Delta\big)$, where the constant $\widetilde{C}$ depends only on σ_1 and σ_2. For simplicity, we have written K_l and $(K_l)_\Delta$ instead of the interior of K_l and $(K_l)_\Delta$, respectively. Note that since $\Pi_{h,R}(v) \,|\, \partial\Omega = 0$ for $v \in W_{h,R}$, $\Pi_{h,R}(v) = v$ for $v \in V_{h,R}$, and because $u \,|\, \partial\Omega = (-1,0,0)$ on $\partial\Omega$, we have $\Pi_{h,R}(u) \,|\, \partial\Omega = (-1,0,0)$. Let us draw some conclusions from these relations.

Corollary 3.1. *The ensuing estimates are valid:*

$$\text{(3.12)}\quad \|\, \Pi_{h,R}(w) - w\|_{2,\partial_{h,R}} \ \le \ \mathcal{C} \cdot (h \cdot R)^{\nu - 1/2} \cdot |w|_{\nu,2,\, P_{h,R} \backslash B_{R\cdot(1-4\cdot h/S)}}$$

for $\nu \in \{1,\, 2\}$, $w \in W_{h,R}$ *with* $w \,|\, P_{h,R} \backslash B_{R\cdot(1-4\cdot h/S)} \in H^\nu(P_{h,R} \backslash B_{R\cdot(1-4\cdot h/S)})^3$;

$$\text{(3.13)}\quad |\, \Pi_{h,R}(w) - w\,|_{r,2,P_{h,R}} \ \le \ \mathcal{C} \cdot (h \cdot R)^{1-r} \cdot \|\nabla w\|_{2,P_{h,R}}$$

$$\text{for } \ w \in H^1(P_{h,R})^3, \ \ r \in \{0,\, 1\},$$

$$\text{(3.14)}\quad \|\Pi_{h,R}(w) - w\|_{6,K_l} \ \le \ \mathcal{C} \cdot (diam\, K_l) \cdot |w|_{2,2,(K_l)_\Delta}$$

$$\text{for } \ l \in \{1, \dots, k\}, \ w \in H^1(P_{h,R})^3 \ \text{ with } \ w \,|\, (K_l)_\Delta \in H^2((K_l)_\Delta)^3.$$

Proof. For the first inequality, we refer to (3.8) and to the proof of [4, Theorem 3.1]. The second is a consequence of (3.10), (3.6), and (3.3). The third may be proved by transforming its left-hand side into an integral over a standard tetrahedron, then using the Sobolev imbedding of H^1 into L^6 on this tetrahedron, returning to the domain of integration K_l, and finally applying (3.10). Also see [10, (I.A.14)]. ∎

COROLLARY 3.2. *For $r \in \{0,1\}$, $l \in \{1, \ldots, k\}$ with $K_l \cap \Omega_{2\cdot S} \neq \emptyset$, we have*

$$|\Pi_{h,R}(u) - u|_{r,2,K_l} \;\le\; \mathcal{C} \cdot h^{1+t-r} \cdot \|u\|_{1+t,\,2,\,(K_l)_\Delta},$$

$$\|\widetilde{\Pi}_{h,R}(\pi) - \pi\|_{2,K_l} \;\le\; \mathcal{C} \cdot h^{t} \cdot \|\pi\|_{t,2,\,(K_l)_\Delta}.$$

Proof. The corollary follows by interpolation from (3.10), (3.11), and (A3). ∎

COROLLARY 3.3. *Put $w := \Pi(u)_{h,R} - u$. Then, with $\mathcal{A}$ from (2.5),*

$$h^{-1-t} \cdot \|w\|_{2,\Omega_{2\cdot S}} + h^{-1/2-t} \cdot \|w\|_{3,\Omega_{2\cdot S}} + h^{-t} \cdot \|\nabla w\|_{2,\Omega_{2\cdot S}} \;\le\; \mathcal{C} \cdot \mathcal{A}; \tag{3.15}$$

$$(h^2 \cdot 2^j)^{-1} \cdot \|w\|_{2,\,U_j \cap P_{h,R}} \;+\; (h^{3/2} \cdot 2^{j/2})^{-1} \cdot \|w\|_{3,\,U_j \cap P_{h,R}}$$
$$+\; h^{-1} \cdot \big(\|w\|_{6,\,U_j \cap P_{h,R}} + \|\nabla w\|_{2,\,U_j \cap P_{h,R}}\big) \;\le\; \mathcal{C} \cdot \mathcal{A} \qquad \textit{for } j \in \{2, \ldots, J\}; \tag{3.16}$$

$$\|w\|_{6,P_{h,R}} + \|\nabla w\|_{2,P_{h,R}} + \|\widetilde{\Pi}_{h,R}(\pi) - \pi\|_{2,P_{h,R}} \;\le\; \mathcal{C} \cdot \mathcal{A} \cdot \big(\, h^t + h \cdot \ln(R/S)\,\big); \tag{3.17}$$

$$\|w\|_{3,P_{h,R}} \le \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot (h^{3/2} \cdot R^{1/2} + h^{t+1/2});\; \|w\|_{2,P_{h,R}} \le \mathcal{C} \cdot \mathcal{A} \cdot (h^2 \cdot R + h^{t+1}); \tag{3.18}$$

$$\|w\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot \mathcal{A} \cdot h^{3/2}. \tag{3.19}$$

Proof. Denote $\mathcal{I}_0 := \big\{\, l \in \{1, \ldots, k\} \;:\; K_l \cap \Omega_{2\cdot S} \neq \emptyset \,\big\}$. Then

$$\|w\|_{2,\,\Omega_{2\cdot S}} \le \left(\sum_{l \in \mathcal{I}_0} \|w\|^2_{2,K_l}\right)^{1/2} \;\le\; \mathcal{C} \cdot h^{1+t} \cdot \left(\sum_{l \in \mathcal{I}_0} \|u\|^2_{1+t,\,2,\,(K_l)_\Delta}\right)^{1/2} \tag{3.20}$$
$$\le \mathcal{C} \cdot h^{1+t} \cdot \|u\|_{1+t,\,2,\,\Omega_{4\cdot S}} \;\le\; \mathcal{C} \cdot \mathcal{A} \cdot h^{1+t},$$

where we used Corollary 3.2, (3.7), (2.1), and (2.5). The term $\|\nabla w\|_{2,\,\Omega_{2\cdot S}}$ may be evaluated in the same way. Noting that $\|w\|_{6,\,\Omega_{2\cdot S}} \le \mathcal{C} \cdot \|w\|_{1,2,\,\Omega_{2\cdot S}}$ according to a Sobolev inequality, we obtain an estimate of $\|w\|_{3,\,\Omega_{2\cdot S}}$ by interpolation between an L^6- and an L^2-estimate. A similar computation as in (3.20) yields, in view of (3.10), (A3), and (3.7):

$$\|w\|_{2,\,U_j \cap P_{h,R}} \;\le\; \mathcal{C} \cdot 2^{2\cdot j} \cdot h^2 \cdot |u|_{2,\,2,\,U_{j-1} \cup U_j \cup U_{j+1}} \quad \text{for } j \in \{2, \ldots, J\}.$$

It follows by (2.3) and (2.5) that $\|w\|_{2,\,U_j \cap P_{h,R}} \;\le\; \mathcal{C} \cdot \mathcal{A} \cdot h^2 \cdot 2^j$. This explains the estimate of $(h^2 \cdot 2^j)^{-1} \cdot \|w\|_{2,\,U_j \cap P_{h,R}}$ in (3.16). The other terms on the left-hand side of that inequality may be dealt with in a similar way. (Use (3.14) for the L^6-estimate, and use interpolation for the estimate of the L^3-norm.) The estimates of w and ∇w in (3.17) and (3.18) follow from (3.16), (3.15), (3.9), and the inequality $J \le \mathcal{C} \cdot \ln(R/S)$ (see (3.2)). Estimate (3.12) yields $\|w\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot (h \cdot R)^{3/2} \cdot |u|_{2,\,2,\,B_R \setminus B_{R\cdot(1-4\cdot h/S)}}$. This observation, (2.3) with $\delta = 1 - 4 \cdot h/S$, and (2.5) yield inequality (3.19). The term

$\|\widetilde{\Pi}_{h,R}(\pi)-\pi\|_{2,P_{h,R}}$ may be evaluated by using Corollary 3.2, (3.11), an argument as in (3.20), as well as (3.7), (2.1), (2.3), and (2.5). ∎

LEMMA 3.2. *Let* $W \in \mathcal{B}^3_{h,R}$. *Then*

$$\|\nabla W\|_{2,K_l} \;\le\; \mathcal{C}\cdot(\mathit{diam}\, K_l)^{-5/2}\cdot\Big|\int_{K_l} W\; dx\Big| \quad \textit{for } l\in\{1,\dots,k\}; \tag{3.21}$$

$$\|W\|_{2,\,U_j\cap P_{h,R}} \;\le\; \mathcal{C}\cdot 2^j\cdot h\cdot\|\nabla W\|_{2,\,(U_{j-1}\cap U_j\cap U_{j+1})\cap P_{h,R}} \quad \textit{for } 1\le j\le J; \tag{3.22}$$

$$\|W\|_{2,P_{h,R}} \;\le\; \mathcal{C}\cdot h\cdot R\cdot\|\nabla W\|_{2,P_{h,R}}. \tag{3.23}$$

Proof. The lemma may be proved via transformations to a reference tetrahedron; compare [17, Lemma 4.1b]. ∎

4. Estimate of the velocity error by the pressure error. In this section, the velocity error $u-u_{h,R}$ and an interpolation in $\mathcal{B}^3_{h,R}$ of the gradient of the pressure error $\pi-\pi_{h,R}$ are estimated by a quantity depending on $\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)$ (see Theorem 4.1). Since the latter term differs from the pressure error only by the interpolation error $\pi-\widetilde{\Pi}_{h,R}(\pi)$, our result may thus be considered as an estimate of the velocity error by the pressure error.

In the following lemma, the velocity error and the interpolation via $\mathcal{R}$ of $\nabla(\pi-\pi_{h,R})$ in $\mathcal{B}^3_{h,R}$ are estimated by a sum of seven terms $|\mathcal{N}_1|$ to $|\mathcal{N}_7|$; these terms will be evaluated in the proof of Theorem 4.1. The main difficulty consists in dealing with the term $\mathcal{N}_4$, because we were not able to prove that $\|\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}}$ decreases for $h+1/R\to 0$ (section 5). Therefore we had to estimate $|\mathcal{N}_4|$ in such a way that we obtained an upper bound in which the critical quantity $\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)$ is multiplied by negative powers of R and/or positive powers of h.

LEMMA 4.1. *Put*

$$\mathcal{N}_1 := \big(\,\|u-\Pi_{h,R}(u)\|^{(h,R)}\,\big)^2 \;+\; \tau\cdot\|u-\Pi_{h,R}(u)\|^2_{2,\partial_{h,R}},$$

$$\mathcal{N}_2 := a\big(\,\Pi_{h,R}(u)-u,\,\Pi_{h,R}(u)-u_{h,R}\,\big), \quad \mathcal{N}_3 := c\big(\,\Pi_{h,R}(u)-u_{h,R},\,\widetilde{\Pi}_{h,R}(\pi)-\pi\,\big),$$

$$\mathcal{N}_4 := c\big(\,\Pi_{h,R}(u)-u,\,\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)\,\big),$$

$$\mathcal{N}_5 := \big|\,\|\nabla\mathcal{R}\big(\,\nabla(\pi-\pi_{h,R})\,\big)\|^2_{2,P_{h,R}} - \|\nabla\mathcal{R}\big(\,\nabla(\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R})\,\big)\|^2_{2,P_{h,R}}\,\big|,$$

$$\mathcal{N}_6 := A\Big(\,\mathcal{R}\big(\,\nabla\widetilde{\Pi}_{h,R}(\pi)\,\big),\,\mathcal{R}\big(\,\nabla(\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R})\,\big)\,\Big),$$

$$\mathcal{N}_7 := \int_{\partial_{h,R}}\sum_{k=1}^{3}\left(\sum_{j=1}^{3}(\partial_j u_k-\delta_{jk}\cdot\pi)\cdot n_j \;+\; \big(\,R^{-1}+(\tau/2)\cdot(1-n_1)\,\big)\cdot u_k\right)$$
$$\cdot(\Pi_{h,R}(u)-u_{h,R})_k\; do.$$

Then

$$(\|u-u_{h,R}\|^{(h,R)})^2+\tau\cdot\|u-u_{h,R}\|^2_{2,\partial P_{h,R}}+\|\nabla\mathcal{R}\big(\nabla(\pi-\pi_{h,R})\big)\|^2_{2,P_{h,R}}\le\mathcal{C}\cdot\sum_{i=1}^{7}|\mathcal{N}_i|.$$

Proof. Denote

$$z := \Pi_{h,R}(u) - u_{h,R}, \quad I := \big(\|u - u_{h,R}\|^{(h,R)} \big)^2 + \tau \cdot \|u - u_{h,R}\|^2_{2,\partial_{h,R}}.$$

Then

$$I \le 2 \cdot \big(\mathcal{N}_1 + (\|z\|^{(h,R)})^2 + \tau \cdot \|z\|^2_{2,\partial_{h,R}} \big) \ \le \ \mathcal{C} \cdot \big(\mathcal{N}_1 + \mathcal{N}_2 + a(u - u_{h,R},\, z) \big)$$

$$= \mathcal{C} \cdot \left[\mathcal{N}_1 + \mathcal{N}_2 + \mathcal{N}_7 + \int_{P_{h,R}} (-\Delta u + \tau \cdot \partial_1 u + \nabla \pi) \cdot z \; dx - c(z, \pi) - a(u_{h,R}, z) \right].$$

Lemma 4.1 follows from this estimate, (2.6) , (1.1), and (2.11)–(2.13). ∎

Next we establish three auxiliary results which will be needed in order to evaluate $\mathcal{N}_4$ and $\mathcal{N}_6$.

LEMMA 4.2. *Define a function* $W(u) := W_{h,R}(u) \in \mathcal{B}^3_{h,R}$ *by setting*

$$W(u)_i(x) := \left(\int_{K_l} b_{K_l} \, dy \right)^{-1} \cdot \int_{K_l} (\Pi_{h,R}(u) - u)_i \, dy \cdot b_{K_l}(x)$$

for $x \in K_l$, $l \in \{1, \ldots, k\}$, $i \in \{1, 2, 3\}$, *where* b_{K_l} *is as introduced in section* 2. *Then we have for* $m \in M_{h,R}$, *with* $\overline{m}$ *defined in Lemma* 3.1,

$$|c(\Pi_{h,R}(u) - u, \, \overline{m})| \ + \ |c(\, W(u), \, \overline{m}\,)| \ \le \ \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot h \cdot R^{-1/2} \cdot \|\overline{m}\|_{2,P_{h,R}}.$$

Proof. Abbreviate $I(h,R) := \big\{ \, l \in \{1, \ldots, k\} \, : \, K_l \cap \partial B_R \neq \emptyset \, \big\}$. Applying (3.10), (3.3), (3.8), (2.3) with $\delta = 1 - 4 \cdot h/S$, and (2.5), we get

$$|c(\Pi_{h,R}(u) - u, \, \overline{m})| \ \le \ \mathcal{C} \cdot \left(\sum_{l \in I(h,R)} \|\nabla(\Pi_{h,R}(u) - u)\|^2_{2,K_l} \right)^{1/2} \cdot \|\overline{m}\|_{2,P_{h,R}}$$

$$\le \mathcal{C} \cdot h \cdot R \cdot |u|_{2,2,\, P_{h,R} \setminus B_{R \cdot (1 - 4 \cdot h/S)}} \cdot \|\overline{m}\|_{2,P_{h,R}} \ \le \ \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot h \cdot R^{-1/2} \cdot \|\overline{m}\|_{2,P_{h,R}}.$$

We further observe that $|c\big(\, W(u), \, \overline{m}\,\big)| \le \mathcal{C} \cdot \|\nabla W(u)\|_{2,A_{h,R}} \cdot \|\overline{m}\|_{2,P_{h,R}}$, with $A_{h,R}$ as defined in (3.2). Moreover, by (3.21), the definition of $W(u)$, (3.10), (3.3), (3.8), (2.3) with $\delta = 1 - 4 \cdot h/S$, and (2.5), we find

$$\|\nabla W(u)\|^2_{2,A_{h,R}} = \sum_{l \in I(h,R)} \|\nabla W(u)\|^2_{2,K_l} \ \le \ \mathcal{C} \cdot \sum_{l \in I(h,R)} (diam\, K_l)^{-5} \cdot \left| \int_{K_l} W(u) \; dx \right|^2$$

$$= \mathcal{C} \cdot \sum_{l \in I(h,R)} (diam\, K_l)^{-5} \cdot \left| \int_{K_l} (\Pi_{h,R}(u) - u) \; dx \right|^2$$

$$\le \mathcal{C} \cdot \sum_{l \in I(h,R)} (diam\, K_l)^{-2} \cdot \|\Pi_{h,R}(u) - u\|^2_{2,K_l}$$

$$\le \mathcal{C} \cdot h^2 \cdot R^2 \cdot |u|^2_{2,\, 2,\, P_{h,R} \setminus B_{R \cdot (1 - 4 \cdot h/S)}} \ \le \ \mathcal{C}(h \cdot R) \cdot \mathcal{A}^2 \cdot h^2 \cdot R^{-1}.$$

The lemma follows from the preceding inequalities. ∎

LEMMA 4.3. *Define the function $W(u)$ as in Lemma 4.2. Then*

$$|c\big(W(u),\,\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)\big)|$$
$$\leq\ \mathcal{C}\cdot\mathcal{A}\cdot\big(h^t+h\cdot\ln(R/S)\big)\cdot\|\nabla\mathcal{R}\big(\nabla(\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi))\big)\|_{2,P_{h,R}}.$$

Proof. With the abbreviation $\mathcal{T}:=\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)$, we find by (2.10) and (2.6) that

(4.1)
$$\big|\,c\big(W(u),\,\mathcal{T}\big)\big|=|A\big(\mathcal{R}(\nabla\mathcal{T}),\,W(u)\big)|\leq\mathcal{C}\cdot\|\nabla\mathcal{R}(\nabla\mathcal{T})\|_{2,P_{h,R}}\cdot\|\nabla W(u)\|_{2,P_{h,R}}.$$

By the same reasoning as in the proof of Lemma 4.2, we get

$$\|\nabla W(u)\|_{2,P_{h,R}}\ \leq\ \mathcal{C}\cdot\left(\sum_{l=1}^{k}(diam\,K_l)^{-2}\cdot\|\Pi_{h,R}(u)-u\|^2_{2,K_l}\right)^{1/2}. \tag{4.2}$$

Abbreviate $Z:=\big\{\,l\in\{1,\,\dots,\,k\}\ :\ K_l\subset B_{2\cdot S}\,\big\}$. We have $diam\,K_l\geq\mathcal{C}\cdot h$ for $l\in Z$ by (A3), so with (3.15) we get

$$\sum_{l\in Z}(diam\,K_l)^{-2}\cdot\|\Pi_{h,R}(u)-u\|^2_{2,K_l}\ \leq\ \mathcal{C}\cdot h^{-2}\cdot\|\Pi_{h,R}(u)-u\|^2_{2,\Omega_{2\cdot S}}\ \leq\ \mathcal{C}\cdot\mathcal{A}^2\cdot h^{2\cdot t}.$$

On the other hand, using (3.10), (A3), and (3.7), we find

$$\sum_{l=1,\,l\notin Z}^{k}(diam\,K_l)^{-2}\cdot\|\Pi_{h,R}(u)-u\|^2_{2,K_l}\ \leq\ \sum_{l=1,\,l\notin Z}^{k}(diam\,K_l)^{2}\cdot|u|^2_{2,\,2,\,(K_l)_\Delta}$$
$$\leq\ \sum_{j=2}^{J}(2^j\cdot h)^2\cdot\sum_{l=1,\,K_l\cap U_j\neq\emptyset}^{k}\big|u\big|^2_{2,\,2,\,(K_l)_\Delta}\ \leq\ \sum_{j=2}^{J}(2^j\cdot h)^2\cdot\big|u\big|^2_{2,\,2,\,U_{j-1}\cup U_j\cup U_{j+1}}.$$

But for $j\in\{2,\,\dots,\,J\}$, we have $\big|u\big|_{2,\,2,\,U_{j-1}\cup U_j\cup U_{j+1}}\ \leq\ \mathcal{C}\cdot\mathcal{A}\cdot2^{-j}$ by (2.3) and (2.5). Combining the preceding estimates beginning with (4.2), we obtain

$$\|\nabla W(u)\|_{2,P_{h,R}}\ \leq\ \mathcal{C}\cdot\mathcal{A}\cdot(h^t+J\cdot h)\ \leq\ \mathcal{C}\cdot\mathcal{A}\cdot\big(h^t+h\cdot\ln(R/S)\big).$$

Lemma 4.3 now follows with (4.1). ∎

LEMMA 4.4. *Let $W\in\mathcal{B}^3_{h,R}$. Then*

$$\Big|\int_{P_{h,R}}\pi\cdot\operatorname{div}W\,dx\Big|\ \leq\ \mathcal{C}\cdot\mathcal{A}\cdot\big(h^t+h\cdot\ln(R/S)\big)\cdot\|\nabla W\|_{2,P_{h,R}}.$$

Proof. Let B denote the interior of the set $\cup\big\{\,K_l:1\leq l\leq k,\ K_l\cap\overline{\Omega_S}\neq\emptyset\,\big\}$. Note that $\overline{B}\subset\overline{U_0}\cup\overline{U_1}=\overline{\Omega_{2\cdot S}}$ by (A3). Define operators $T_1:L^2(B)\mapsto\mathbb{R}$, $T_2:H^1(B)\mapsto\mathbb{R}$ by $T_i(z):=\int_B z\cdot\operatorname{div}W\,dx$, with $z\in L^2(B)$ in the case $i=1$, and $z\in H^1(B)$ if $i=2$. Observe that

$$T_1\,|\,H^1(B)=T_2,\qquad|T_1(z)|\ \leq\ \mathcal{C}\cdot\|z\|_{2,B}\cdot\|\nabla W\|_{2,P_{h,R}}\quad\text{for }\ z\in L^2(B),$$

$$|T_2(z)|\ =\ \Big|\int_B\nabla z\cdot W\,dx\Big|\ \leq\ \mathcal{C}\cdot\|\nabla z\|_{2,B}\cdot\|W\|_{2,B}\ \leq\ \mathcal{C}\cdot\|\nabla z\|_{2,B}\cdot\|\nabla W\|_{2,P_{h,R}}\cdot h$$

for $z \in H^1(B)$, where we refer to (3.22) for the last inequality. It follows by interpolation (see [2, Theorem 14.2.3, Proposition 14.1.5], for example) that

(4.3)
$$\Big| \int_B \pi \cdot \operatorname{div} W \, dx \Big| \le \mathcal{C} \cdot \|\pi\|_{t,2,B} \cdot \|\nabla W\|_{2,P_{h,R}} \cdot h^t \le \mathcal{C} \cdot \mathcal{A} \cdot \|\nabla W\|_{2,P_{h,R}} \cdot h^t,$$

where we used the relation $\|\pi\|_{t,2,B} \le \|\pi\|_{t,2,\Omega_{2\cdot S}} \le \mathcal{A}$ (see (2.1), (2.5)) in the last inequality. On the other hand, since $P_{h,R}\backslash B \subset P_{h,R}\backslash\Omega_S = P_{h,R}\backslash U_0$, with a partial integration and by (2.3), (2.5) we get

$$\Big| \int_{P_{h,R}\backslash B} \pi \cdot \operatorname{div} W \, dx \Big| \le \sum_{j=1}^{J} \int_{U_j \cap P_{h,R}} |\nabla \pi| \cdot |W| \, dx \le \mathcal{C} \cdot \mathcal{A} \cdot \sum_{j=1}^{J} 2^{-j} \cdot \|W\|_{2,\,U_j \cap P_{h,R}}. \tag{4.4}$$

Combining (4.3), (4.4), and (3.22) yields the lemma. ∎

Now we are in a position to prove the main result of this section.

THEOREM 4.1. *Let $\mathcal{D}_{h,R}$ be an abbreviation of the term*

$$\Big((\|u - u_{h,R}\|^{(h,R)})^2 + \tau \cdot \|u - u_{h,R}\|^2_{2,\partial P_{h,R}} + \| \nabla \mathcal{R}(\nabla(\pi - \pi_{h,R})) \|^2_{2,P_{h,R}} \Big)^{1/2}.$$

Then

$$\begin{aligned} \mathcal{D}^2_{h,R} \le\ & \mathcal{C}(\tau, h \cdot R) \cdot \max\{1, \tau^{-1/2}\} \cdot \mathcal{A} \cdot (h^t + h \cdot \ln(R/S) + R^{-1}) \\ & \cdot \big(\mathcal{D}_{h,R} + \mathcal{A} \cdot (h^t + h \cdot \ln(R/S)) \big) \\ & + \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot h \cdot R^{-1} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_2 \\ & + \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot h \cdot R^{-1/2} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi) - m_{h,R}\|_2, \end{aligned}$$

with $m_{h,R} := |P_{h,R}|^{-1} \cdot \int_{P_{h,R}} (\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)) \, dx$ (mean value of $\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)$). Moreover,

$$\|\nabla \mathcal{R}\big(\nabla \big(\widetilde{\Pi}_{h,R}(\pi) - \pi_{h,R} \big) \big)\|_{2,P_{h,R}} \le \mathcal{C} \cdot \big(\mathcal{D}_{h,R} + \mathcal{A} \cdot (h^t + h \cdot \ln(R/S)) \big). \tag{4.5}$$

Proof. Abbreviate $\mathcal{H} := h^t + h \cdot \ln(R/S)$. Let us estimate the terms $\mathcal{N}_1$ to $\mathcal{N}_7$ introduced in Lemma 4.1. We begin by observing that as a direct consequence of (3.17) and (3.19),

$$|\mathcal{N}_1| \le \mathcal{C}(\tau) \cdot (\mathcal{A} \cdot \mathcal{H})^2.$$

In view of finding an upper bound for $|\mathcal{N}_2|$, we remark that $\|\Pi_{h,R}(u) - u\|^{(h,R)} \le \mathcal{C} \cdot \mathcal{A} \cdot \mathcal{H}$ by (3.17) and (3.19). Hence

$$\|\Pi_{h,R}(u) - u_{h,R}\|^{(h,R)} \le \|u - u_{h,R}\|^{(h,R)} + \mathcal{C} \cdot \mathcal{A} \cdot \mathcal{H} \le \mathcal{D}_{h,R} + \mathcal{C} \cdot \mathcal{A} \cdot \mathcal{H}. \tag{4.6}$$

On the other hand, after a partial integration of the Oseen term, we get

$$\begin{aligned}|\mathcal{N}_2| \;\le\; \mathcal{C}\cdot\big(&\|\nabla\big(\,\Pi_{h,R}(u)-u\,\big)\|_{2,P_{h,R}}\cdot\;\|\nabla\big(\,\Pi_{h,R}(u)-u_{h,R}\,\big)\|_{2,P_{h,R}}\\ &+(R^{-1}+\tau)\cdot\|\Pi_{h,R}(u)-u\|_{2,\partial_{h,R}}\cdot\|\Pi_{h,R}(u)-u_{h,R}\|_{2,\partial_{h,R}}\\ &+\tau\cdot\|\Pi_{h,R}(u)-u\|_{2,P_{h,R}}\cdot\|\nabla\big(\,\Pi_{h,R}(u)-u_{h,R}\,\big)\|_{2,P_{h,R}}\big).\end{aligned}$$

This estimate, (3.17)–(3.19), and (4.6) imply

$$|\mathcal{N}_2| \;\le\; \mathcal{C}(\tau,h\cdot R)\cdot\mathcal{A}\cdot\mathcal{H}\cdot(\mathcal{D}_{h,R}+\mathcal{A}\cdot\mathcal{H}).$$

As an immediate consequence of (3.17) and (4.6), we get

$$|\mathcal{N}_3| \;\le\; \mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}\cdot(\mathcal{D}_{h,R}+\mathcal{A}\cdot\mathcal{H}).$$

In order to deal with $\mathcal{N}_5$ and $\mathcal{N}_6$, denote

$$\begin{aligned}&\mathcal{R}^{(1)}:=\mathcal{R}\big(\,\nabla(\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R})\,\big),\;\;\mathcal{R}^{(2)}:=\mathcal{R}\big(\,\nabla(\pi-\pi_{h,R})\,\big),\\ &\mathcal{R}^{(3)}:=\mathcal{R}\big(\,\nabla(\widetilde{\Pi}_{h,R}(\pi)-\pi)\,\big),\end{aligned}$$

and observe that $\|\nabla\mathcal{R}^{(2)}\|_{2,P_{h,R}}\le\mathcal{D}_{h,R}$. We find

$$\begin{aligned}|\mathcal{N}_5|&=\big(\,\|\nabla\mathcal{R}^{(1)}\|_{2,P_{h,R}}+\|\nabla\mathcal{R}^{(2)}\|_{2,P_{h,R}}\,\big)\cdot\|\nabla\mathcal{R}^{(3)}\|_{2,P_{h,R}}\\ &\le\big(\,2\cdot\|\nabla\mathcal{R}^{(2)}\|_{2,P_{h,R}}+\|\nabla\mathcal{R}^{(3)}\|_{2,P_{h,R}}\,\big)\cdot\|\nabla\mathcal{R}^{(3)}\|_{2,P_{h,R}}.\end{aligned}$$

On the other hand, by (2.8), (2.9), and (3.17),

$$\|\nabla\mathcal{R}^{(3)}\|_{2,P_{h,R}}\le\mathcal{C}\cdot\|\,\widetilde{\Pi}_{h,R}(\pi)-\pi\|_{2,P_{h,R}}\le\mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}.$$

Thus we get

$$|\mathcal{N}_5|\le\mathcal{C}\cdot(\mathcal{D}_{h,R}+\mathcal{A}\cdot\mathcal{H})\cdot\mathcal{A}\cdot\mathcal{H};\quad\|\nabla\mathcal{R}^{(1)}\|_{2,P_{h,R}}\le\mathcal{C}\cdot(\mathcal{D}_{h,R}+\mathcal{A}\cdot\mathcal{H}).$$

In particular we have shown (4.5). By (2.10), the relation

$$|\mathcal{N}_6|=\Big|\int_{P_{h,R}}\widetilde{\Pi}_{h,R}(\pi)\cdot\operatorname{div}\mathcal{R}^{(1)}\,dx\Big|\;\le\;|\mathcal{I}_1|+|\mathcal{I}_2| \tag{4.7}$$

holds, with

$$\mathcal{I}_1:=\int_{P_{h,R}}\big(\,\widetilde{\Pi}_{h,R}(\pi)-\pi\,\big)\cdot\operatorname{div}\mathcal{R}^{(1)}\,dx,\quad\mathcal{I}_2:=\int_{P_{h,R}}\pi\cdot\operatorname{div}\mathcal{R}^{(1)}\,dx.$$

Due to (3.17), we find

$$|\mathcal{I}_1|\;\le\;\mathcal{C}\cdot\|\widetilde{\Pi}_{h,R}(\pi)-\pi\|_{2,P_{h,R}}\cdot\|\nabla\mathcal{R}^{(1)}\|_{2,P_{h,R}}\;\le\;\mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}\cdot\|\nabla\mathcal{R}^{(1)}\|_{2,P_{h,R}}.$$

By combining this inequality with the estimate of $\mathcal{I}_2$ in Lemma 4.4 and then applying (4.5), we obtain

$$|\mathcal{N}_6|\;\le\;\mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}\cdot\|\nabla\mathcal{R}^{(1)}\|_{2,P_{h,R}}\;\le\;\mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}\cdot(\mathcal{A}\cdot\mathcal{H}+\mathcal{D}_{h,R}).$$

Now we turn to the term $\mathcal{N}_4$. For $q \in M_{h,R}$, put $m(q) := |P_{h,R}|^{-1} \cdot \int_{P_{h,R}} q\, dx$ (mean value of q). This means that $m_{h,R} = m(\,\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\,)$, where $m_{h,R}$ is as introduced in Theorem 4.1. Since $R \geq R_0 \geq 8 \cdot S$ (see Theorem 3.1) and $\Omega^c \subset B_S$, and because of (3.5), we have $|P_{h,R}| \geq \mathcal{C} \cdot R^3$. Hence with Hölder's inequality,

$$|m_{h,R}| \leq |P_{h,R}|^{-1/2} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} \leq \mathcal{C} \cdot R^{-3/2} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}}. \tag{4.8}$$

Now by a partial integration we obtain

$$\begin{aligned} |c\big(\,\Pi_{h,R}(u) - u,\, m_{h,R}\,\big)| &= \Big| \int_{\partial_{h,R}} \big(\,(\Pi_{h,R}(u) - u) \cdot n\,\big) \cdot m_{h,R}\; do \Big| \\ &\leq\; \mathcal{C} \cdot |m_{h,R}| \cdot \|\Pi_{h,R}(u) - u\|_{2,\partial_{h,R}} \cdot \left(\int_{\partial_{h,R}} do \right)^{1/2} \\ &\leq\; \mathcal{C} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} \cdot \|\Pi_{h,R}(u) - u\|_{2,\partial_{h,R}} \cdot R^{-1/2}. \end{aligned} \tag{4.9}$$

The last inequality follows from (4.8) and (3.1). Inequalities (4.9) and (3.19) imply

$$\begin{aligned} |c(\Pi_{h,R}(u) - u,\, m_{h,R})| &\leq \mathcal{C} \cdot \mathcal{A} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} \cdot h^{3/2} \cdot R^{-1/2} \\ &\leq \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot \|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} \cdot h/R. \end{aligned} \tag{4.10}$$

Next define $W(u)$ as in Lemma 4.2, and abbreviate $p := \pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi) - m_{h,R}$. Recall that $\mathcal{R}^{(1)}$ is an abbreviation for $\mathcal{R}(\nabla(\widetilde{\Pi}_{h,R}(\pi) - \pi_{h,R}))$. Then

$$\begin{aligned} |\mathcal{N}_4| \leq\; & |c\big(\,\Pi_{h,R}(u) - u,\, p - \overline{p}\,\big)| + |c\big(\,\Pi_{h,R}(u) - u,\, \overline{p}\,\big)| \\ & + |c\big(\,\Pi_{h,R}(u) - u,\, m_{h,R}\,\big)|, \end{aligned} \tag{4.11}$$

with $\overline{p}$ defined as in Lemma 3.1. Using the main trick from the proof of the stability of the mini element, and recalling that $(p - \overline{p})\,|\,\partial_{h,R} = 0$ and $(\Pi_{h,R}(u) - u)\,|\,\partial\Omega = 0$, by a partial integration and by the definition of the function $W(u) \in \mathcal{B}^3_{h,R}$, we get

$$|c\big(\,\Pi_{h,R}(u) - u,\, p - \overline{p}\,\big)| \;=\; \left| \sum_{l=1}^{k} \nabla(p - \overline{p}) \cdot \int_{K_l} W(u)\; dx \right| \;=\; |c\big(\,W(u),\, p - \overline{p}\,\big)|.$$

It follows that

$$\begin{aligned} |c\big(\,\Pi_{h,R}(u) - u,\, p - \overline{p}\,\big)| &\leq |c\big(\,W(u),\, p\,\big)| + |c\big(\,W(u),\, \overline{p}\,\big)| \\ &= |c\big(\,W(u),\, \pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\,\big)| + |c\big(\,W(u),\, \overline{p}\,\big)|, \end{aligned}$$

where the last equation holds since $W(u) \in \mathcal{B}^3_{h,R}$. Now apply Lemmas 4.3 and 4.2 to obtain

$$|c\big(\,\Pi_{h,R}(u) - u,\, p - \overline{p}\,\big)| \;\leq\; \mathcal{C}(h \cdot R) \cdot \mathcal{A} \cdot \big(\,\mathcal{H} \cdot \|\nabla \mathcal{R}^{(1)}\|_{2,P_{h,R}} \;+\; \|\overline{p}\|_{2,P_{h,R}} \cdot h \cdot R^{-1/2}\,\big). \tag{4.12}$$

But the terms $|c\big(\Pi_{h,R}(u)-u,\,\overline{p}\,\big)|$ and $|c\big(\Pi_{h,R}(u)-u,\,m_{h,R}\,\big)|$ were already estimated in Lemma 4.2 and (4.10), respectively. We further take into account that $\|\overline{p}\|_{2,P_{h,R}} \le \|p\|_{2,P_{h,R}}$ by Lemma 3.1. Combining these estimates with (4.5), (4.11), and (4.12), we get

$$|\mathcal{N}_4| \le \mathcal{C}(h\cdot R)\cdot\mathcal{A}\cdot\Big(\mathcal{H}\cdot(\mathcal{A}\cdot\mathcal{H}+\mathcal{D}_{h,r}) + h\cdot R^{-1}\cdot\|\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} + h\cdot R^{-1/2}\cdot\|\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)-m_{h,R}\|_{2,P_{h,R}}\Big).$$

We further observe that by (2.4) and (2.5),

$$|\mathcal{N}_7| \;\le\; \mathcal{C}(h\cdot R)\cdot\mathcal{A}\cdot R^{-1}\cdot\|\Pi_{h,R}(u)-u_{h,R})\|_{2,\partial_{h,R}}.$$

On the other hand, by referring to (3.19) we find

$$\|\Pi_{h,R}(u)-u_{h,R}\|_{2,\partial_{h,R}} \le \|\Pi_{h,R}(u)-u\|_{2,\partial_{h,R}} \;+\; \|u-u_{h,R}\|_{2,\partial_{h,R}} \le \mathcal{C}\cdot\mathcal{A}\cdot h^{3/2}+\tau^{-1/2}\cdot\mathcal{D}_{h,R}.$$

Thus we have

$$|\mathcal{N}_7| \le \mathcal{C}(h\cdot R)\cdot\max\{1,\tau^{-1/2}\}\cdot\mathcal{A}\cdot R^{-1}\cdot(\mathcal{D}_{h,R}+\mathcal{A}\cdot\mathcal{H}).$$

The preceding estimates of $|\mathcal{N}_1|$ to $|\mathcal{N}_7|$ yield the upper bound of $\mathcal{D}_{h,R}^2$ given in Theorem 4.1. ∎

5. A bound for the pressure error. Theorem 4.1 leaves the problem of how to deal with the terms $\|\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}}$ and $\|\pi_{h,R}-\widetilde{\Pi}_{h,R}(\pi)-m_{h,R}\|_{2,P_{h,R}}$. This is the subject of the present section, where these terms will be majorized by bounds containing a factor of R or $h^{-1/2}$ (Corollary 5.1), which seems to pollute our error estimates. However, in view of the factor $h\cdot R^{-1}$ or $h\cdot R^{-1/2}$ with which these critical terms are multiplied in Theorem 4.1, such bounds are just sufficient to obtain the desired decay rate $h^t+h\cdot\ln(R/S)+R^{-1}$ of the velocity error. Concerning the proof of our estimate of the critical terms, we will reduce this estimate to an evaluation of $c(w,\,\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R})$, for $w\in Y_{h,R}$. In the ensuing lemma, we introduce a decomposition of $c(w,\,\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R})$ which will be the starting point of this argument.

LEMMA 5.1. *For $w\in W_{h,R}$, set*

$$\mathcal{M}_1(w) := -a(u-u_{h,R},\,w),\quad \mathcal{M}_2(w) := c(w,\,\widetilde{\Pi}_{h,R}(\pi)-\pi),$$

$$\mathcal{M}_3(w) := \int_{\partial_{h,R}}\sum_{k=1}^{3}\left(\sum_{j=1}^{3}(D_ju_k-\delta_{jk}\cdot\pi)\cdot n_j+(R^{-1}+(\tau/2)\cdot(1-n_1))\cdot u_k\right)\cdot w_k\;do.$$

Then

$$c(w,\,\widetilde{\Pi}_{h,R}(\pi)-\pi_{h,R}) \;=\; \sum_{i=1}^{3}\mathcal{M}_i(w)\quad \textit{for}\;\; w\in W_{h,R}.$$

Proof. The lemma follows from (1.1) and (2.11)–(2.13). ∎

LEMMA 5.2. *Let $q \in M_{h,R}$, and put $\psi := G(q - m(q))$, with the operator G introduced in Theorem A.2, and with $m(q) := |P_{h,R}|^{-1} \cdot \int_{P_{h,R}} q\, dx$. Set $Z := \Pi_{h,R}(\psi)$, $\overline{Z} := (\overline{Z_i})_{1 \le i \le 3}$, with $\overline{Z_i}$ defined as in Lemma* 3.1. *Then*

$$\|\nabla Z\|_{2,P_{h,R}} + \|Z\|_{2,\Omega_S} \;\le\; \mathcal{C} \cdot \|q - m(q)\|_{2,P_{h,R}},$$

$$\|\overline{Z}\|_{2,\partial_{h,R}} \;=\; \|Z\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot R^{1/2} \cdot \|q - m(q)\|_{2,P_{h,R}},$$

$$\|\nabla \overline{Z}\|_{2,P_{h,R}} \;\le\; \mathcal{C} \cdot h^{-1/2} \cdot \|q - m(q)\|_{2,P_{h,R}}.$$

Proof. The first inequality in the lemma follows from (3.13) and Theorem A.2 (estimate of ∇Z), and from (3.10), (3.7), and Theorem A.2 (estimate of $Z \,|\, \Omega_{2 \cdot S}$). Concerning the second, we observe that $\|\overline{Z}\|_{2,\partial_{h,R}} = \|Z\|_{2,\partial_{h,R}}$ by Lemma 3.1, and

$$\|Z\|_{2,\partial_{h,R}} \le \|Z - \psi\|_{2,\partial_{h,R}} + \|\psi\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot (h \cdot R)^{1/2} \cdot \|\nabla \psi\|_{2,P_{h,R}} + R^{1/2} \cdot \|\psi\|^{(h,R)}$$

by (3.12). Now the second inequality stated in the lemma follows with Theorem A.2. Let us finally consider the term $\|\nabla \overline{Z}\|_{2,P_{h,R}}$. The usual technique (transformation to a reference tetrahedron) yields the inverse estimate $\|\nabla \overline{Z}\|_{2,K_l} \le \mathcal{C} \cdot (diam\, K_l)^{-1} \cdot \|\overline{Z}\|_{2,K_l}$ for $1 \le l \le k$. Since $K_l \cap \partial B_R \ne \emptyset$ for any $l \in \{1, \ldots, k\}$ with $\overline{Z} \,|\, K_l \ne 0$, by referring to (A3), (3.2), and Lemma 3.1, we thus obtain

$$\|\nabla \overline{Z}\|_{2,P_{h,R}} \le \mathcal{C} \cdot (h \cdot R)^{-1} \cdot \|\overline{Z}\|_{2,A_{h,R}} \le \mathcal{C} \cdot (h \cdot R)^{-1} \cdot \|Z\|_{2,A_{h,R}}.$$

But the relations in (3.3) and (A.3) yield

$$\|Z\|_{2,A_{h,R}} \;\le\; \mathcal{C} \cdot \big(h \cdot R \cdot \|\nabla Z\|_{2,P_{h,R}} \;+\; (h \cdot R)^{1/2} \cdot \|Z\|_{2,\partial_{h,R}} \big).$$

The last inequality in the lemma follows from the two preceding estimates and from the first and second estimates in the lemma. ∎

LEMMA 5.3. *In the situation of Lemma* 5.2, *we have*

$$\|q - m(q)\|^2_{2,P_{h,R}} \;\le\; |c(Z - \overline{Z},\, q)| \;+\; \mathcal{C} \cdot h^{-1/2} \cdot \|\nabla \mathcal{R}(\nabla q)\|_{2,P_{h,R}} \cdot \|q - m(q)\|_{2,P_{h,R}}.$$

Proof. We define a function $W \in \mathcal{B}^3_{h,R}$ by

$$W_i(x) := \left(\int_{K_l} b_{K_l}\, dy \right)^{-1} \cdot \int_{K_l} \big(\psi \;-\; (Z - \overline{Z}) \big)_i \, dy \cdot b_{K_l}(x)$$

for $x \in K_l$, $1 \le l \le k$, $1 \le i \le 3$. By Theorem A.2, the function ψ introduced in the preceding lemma verifies the equations

$$\operatorname{div} \psi = q - m(q), \quad \psi \,|\, \partial\Omega = 0, \quad \psi \cdot n = 0 \;\text{ on } \partial_{h,R}.$$

Therefore after a partial integration of the integral of the product $m(q) \cdot \operatorname{div} \psi$, we obtain

$$\|q - m(q)\|^2_{2,P_{h,R}} \tag{5.1}$$

$$= \int_{P_{h,R}} q \cdot \operatorname{div} \psi \, dx \;=\; -c(Z - \overline{Z},\, q) + \int_{P_{h,R}} q \cdot \operatorname{div} \big(\psi - (Z - \overline{Z}) \big)\, dx.$$

On the other hand, recalling the properties of ψ and the equation $(Z-\overline{Z})\,|\,\partial_{h,R}=0$ (Lemma 3.1), and applying the trick from the proof of LBB stability of the mini element in a similar way as in the proof of (4.12), we obtain

$$\int_{P_{h,R}} q\cdot \operatorname{div}\big(\,\psi\;-\;(Z-\overline{Z})\,\big)\;dx\;=\;\int_{P_{h,R}} q\cdot \operatorname{div} W\;dx\;=\;-A\big(\,\mathcal{R}(\nabla q),\,W\big).$$

The last equation is valid due to (2.10). With (2.6) it follows that

$$\Big|\int_{P_{h,R}} q\cdot \operatorname{div}\big(\,\psi\;-\;(Z-\overline{Z})\big)\;dx\Big|\;\le\;\mathcal{C}\cdot\|\nabla\mathcal{R}(\nabla q)\|_{2,P_{h,R}}\cdot\|\nabla W\|_{2,P_{h,R}}. \tag{5.2}$$

But with (3.21) and the definition of W,

$$\|\nabla W\|_{2,P_{h,R}}\;\le\;\mathcal{C}\cdot\left(\sum_{l=1}^{k}(diam\,K_l)^{-2}\cdot\|\psi\;-\;(Z-\overline{Z})\|_{2,K_l}^2\right)^{1/2}; \tag{5.3}$$

compare the proof of Lemma 4.2 and (4.2). Put $I(h,R):=\{l\in\{1,\dots,k\}\;:\;K_l\cap\partial B_R\neq\emptyset\}$. Then, referring to Lemma 3.1, (A3), and notation from (3.2), we obtain

$$\begin{aligned}\sum_{l=1}^{k}(diam\,K_l)^{-2}\cdot\|\overline{Z}\|_{2,K_l}^2\;&\le\;\mathcal{C}\cdot\sum_{l\in I(h,R)}(diam\,K_l)^{-2}\cdot\|Z\|_{2,K_l}^2\\
&\le\;\mathcal{C}\cdot\left((h\cdot R)^{-2}\cdot\|\psi\|_{2,A_{h,R}}^2\;+\sum_{l\in I(h,R)}(diam\,K_l)^{-2}\cdot\|\psi-Z\|_{2,K_l}^2\right)\\
&\le\;\mathcal{C}\cdot\Big((h\cdot R)^{-2}\cdot\|\psi\|_{2,A_{h,R}}^2+\|\nabla\psi\|_{2,P_{h,R}}^2\Big)\\
&\le\;\mathcal{C}\cdot\Big((h\cdot R)^{-1}\cdot\|\psi\|_{2,A_{h,R}}+\|q-m(q)\|_{2,P_{h,R}}\Big)^2,\end{aligned} \tag{5.4}$$

where the last two inequalities are a consequence of (3.10), (3.8), and Theorem A.2. Moreover, by (3.3) and (A.3) we find

$$\begin{aligned}\|\psi\|_{2,A_{h,R}}&\le\|\psi\|_{2,\,P_{h,R}\setminus B_{R\cdot(1-2\cdot h/S)}}\\
&\le\mathcal{C}\cdot\big(\,h\cdot R\cdot\|\nabla\psi\|_{2,P_{h,R}}\;+\;(h\cdot R)^{1/2}\cdot\|\psi\|_{2,\partial_{h,R}}\,\big).\end{aligned}$$

Hence $(h\cdot R)^{-1}\cdot\|\psi\|_{2,A_{h,R}}\;\le\;\mathcal{C}\cdot h^{-1/2}\cdot\|q-m(q)\|_{2,P_{h,R}}$ by Theorem A.2. From this estimate, (5.3), (3.10), and (3.6), we may conclude that

$$\|\nabla W\|_{2,P_{h,R}}\le\mathcal{C}\cdot h^{-1/2}\cdot\|q-m(q)\|_{2,P_{h,R}}.$$

This inequality, (5.1), and (5.2) imply the lemma. □

THEOREM 5.1. *In the situation of Lemma* 5.2, *and with the abbreviation* $\mathcal{D}_{h,R}$ *defined in Theorem* 4.1, *we have*

$$\begin{aligned}&|a(u-u_{h,R},\,Z)|\\
&\le\;\mathcal{C}(\tau,h\cdot R)\cdot\big(\,\mathcal{D}_{h,R}+\mathcal{A}\cdot\big(\,h^t+h\cdot\ln(R/S)\,\big)\,\big)\cdot\|q-m(q)\|_{2,P_{h,R}}\cdot R^{1/2};\end{aligned} \tag{5.5}$$

$$|a(u-u_{h,R},\,\overline{Z})|\;\le\;\mathcal{C}(\tau,h\cdot R)\cdot\mathcal{D}_{h,R}\cdot\|q-m(q)\|_{2,P_{h,R}}\cdot h^{-1/2}; \tag{5.6}$$

$$|a(u-u_{h,R},\,w)|\;\le\;\mathcal{C}(\tau)\cdot\mathcal{D}_{h,R}\cdot\|w\|^{(h,R)}\cdot R\quad\textit{for }\;w\in W_{h,R}. \tag{5.7}$$

Proof. For brevity, we put $e_{h,R} := u - u_{h,R}$. We have

$$|a(e_{h,R},\, Z)| \;\le\; \sum_{i=1}^{3} |I_i| \quad \text{with} \quad I_1 := \int_{P_{h,R}} \nabla e_{h,R} \cdot \nabla Z \; dx, \tag{5.8}$$

$$I_2 := \tau \cdot \int_{P_{h,R}} \partial_1 e_{h,R} \cdot Z \; dx, \quad I_3 := \int_{\partial_{h,R}} \big(R^{-1} + (\tau/2) \cdot (1 - n_1) \big) \cdot \big(e_{h,R} \cdot Z \big) \; do.$$

The main difficulty consists in estimating the term I_2. In order to obtain such an estimate, we begin by observing that the function ψ from Lemma 5.2 fulfills the relation $\psi \,|\, P_{h,R} \backslash B_S = \nabla v \,|\, P_{h,R} \backslash B_S$ for some function $v \in H^2(P_{h,R} \cup \Omega^c)$; see Theorem A.2. This means that $\partial_1 \psi(x) = \nabla \psi_1(x)$ for $x \in P_{h,R} \backslash \overline{B_S}$. As a consequence, after some partial integrations, we obtain the decomposition $I_2 = \tau \cdot \sum_{i=1}^{7} J_i$, where

$$J_1 := \int_{\Omega_S} \partial_1 e_{h,R} \cdot Z \; dx, \quad J_2 := \int_{\partial B_S} e_{h,R}(x) \cdot S^{-1} \cdot (-x_1 \cdot \psi(x) + \psi_1(x) \cdot x) \; do_x,$$

$$J_3 := \int_{P_{h,R} \backslash B_S} \partial_1 e_{h,R} \cdot (Z - \psi) \; dx, \quad J_4 := \int_{\partial_{h,R}} e_{h,R} \cdot (n_1 \cdot \psi - \psi_1 \cdot n) \; do,$$

$$J_5 := -\int_{\Omega_S} \operatorname{div} e_{h,R} \cdot \psi_1 \; dx, \quad J_6 := \int_{P_{h,R}} \operatorname{div} e_{h,R} \cdot (\psi - Z)_1 \; dx,$$

$$J_7 := \int_{P_{h,R}} \operatorname{div} u_{h,R} \cdot Z_1 \; dx.$$

By (3.13) and Theorem A.2,

$$\begin{aligned} |J_3| + |J_6| &\le \mathcal{C} \cdot \|\nabla e_{h,R}\|_{2,P_{h,R}} \cdot \|Z - \psi\|_{2,P_{h,R}} \\ &\le \mathcal{C}(h \cdot R) \cdot \|e_{h,R}\|^{(h,R)} \cdot \|q - m(q)\|_{2,P_{h,R}}. \end{aligned} \tag{5.9}$$

A standard trace theorem and Theorems A.1 and A.2 yield

$$|J_2| \;\le\; \mathcal{C} \cdot \|e_{h,R}\|_{1,2,\Omega_S} \cdot \|\psi\|_{1,2,\Omega_S} \;\le\; \mathcal{C} \cdot \|e_{h,R}\|^{(h,R)} \cdot \|q - m(q)\|_{2,P_{h,R}}. \tag{5.10}$$

By Theorem A.2 and Lemma 5.2,

$$\begin{aligned} |J_1| + |J_5| &\le \mathcal{C} \cdot \|\nabla e_{h,R}\|_{2,P_{h,R}} \cdot (\|Z\|_{2,\Omega_S} + \|\psi\|_{2,\Omega_S}) \\ &\le \mathcal{C} \cdot \|e_{h,R}\|^{(h,R)} \cdot \|q - m(q)\|_{2,P_{h,R}}. \end{aligned} \tag{5.11}$$

By Theorem A.2, we further get

$$|J_4| \;\le\; \mathcal{C} \cdot \|e_{h,R}\|_{2,\partial_{h,R}} \cdot \|\psi\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot R^{1/2} \cdot \tau^{-1/2} \cdot \mathcal{D}_{h,R} \cdot \|q - m(q)\|_{2,P_{h,R}}. \tag{5.12}$$

This leaves us to deal with the term J_7. To this end, we observe that $|J_7|$ is bounded by $\mathcal{C} \cdot \|\nabla Z\|_{2,P_{h,R}} \cdot \|\mathcal{R}(\nabla \pi_{h,R})\|_{2,P_{h,R}}$, as follows from (2.12) and (2.10). We may conclude with Lemma 5.2 and (3.23) that

$$|J_7| \;\le\; \mathcal{C}(h \cdot R) \cdot \|\nabla \mathcal{R}(\nabla \pi_{h,R})\|_{2,P_{h,R}} \cdot \|q - m(q)\|_{2,P_{h,R}}.$$

This estimate, the inequality $\|e_{h,R}\|^{(h,R)} \le \mathcal{D}_{h,R}$, and (5.9)–(5.12) imply

$$|I_2| \le \mathcal{C}(\tau, h\cdot R)\cdot R^{1/2}\cdot (\mathcal{D}_{h,R} + \|\nabla\mathcal{R}(\nabla\pi_{h,R})\|_{2,P_{h,R}})\cdot \|q-m(q)\|_{2,P_{h,R}}. \tag{5.13}$$

As for I_3, we have

$$|I_3| \;\le\; \mathcal{C}(\tau)\cdot (\|e_{h,R}\|^{(h,R)} + \tau^{1/2}\cdot \|e_{h,R}\|_{2,\partial_{h,R}})\cdot \|Z\|_{2,\partial_{h,R}}.$$

Hence

$$\begin{aligned} |I_3| &\le \mathcal{C}(\tau)\cdot \mathcal{D}_{h,R}\cdot \|Z\|_{2,\partial_{h,R}} \\ &\le \mathcal{C}(\tau, h\cdot R)\cdot R^{1/2}\cdot \mathcal{D}_{h,R}\cdot \|q-m(q)\|_{2,P_{h,R}}, \end{aligned} \tag{5.14}$$

where we used Lemma 5.2. Observe in addition that by (2.6) and (2.10),

$$\|\nabla\mathcal{R}(\nabla\pi)\|^2_{2,P_{h,R}} \le \alpha^{-1}\cdot A\big(\mathcal{R}(\nabla\pi),\, \mathcal{R}(\nabla\pi)\big) = -\alpha^{-1}\cdot \int_{P_{h,R}} \pi\cdot \operatorname{div}\mathcal{R}(\nabla\pi)\,dx.$$

Hence with Lemma 4.4 and the definition of $\mathcal{D}_{h,R}$,

$$\|\nabla\mathcal{R}(\nabla\pi_{h,R})\|_{2,P_{h,R}} \;\le\; \mathcal{D}_{h,R} + \mathcal{C}\cdot\mathcal{A}\cdot\big(h^t + h\cdot\ln(R/S)\big). \tag{5.15}$$

We finally note that $|I_1|$ is bounded by $\mathcal{C}\cdot\mathcal{D}_{h,R}\cdot\|q-m(q)\|_{2,P_{h,R}}$, where we applied Lemma 5.2 again. This inequality and estimates (5.13)–(5.15) imply (5.5). Turning to the proof of (5.6), we have to estimate the terms I_1, I_2, and I_3 with Z replaced by $\overline{Z}$. Denoting these terms by $\widetilde{I}_i$, for $i\in\{1,\,2,\,3\}$, we use Lemma 3.1, (3.3), (A.3), and Lemma 5.2 to obtain

$$\begin{aligned} |\widetilde{I}_2| &\le \mathcal{C}(\tau)\cdot\|\nabla e_{h,R}\|_{2,P_{h,R}}\cdot\|Z\|_{2,A_{h,R}} \\ &\le \mathcal{C}(\tau, h\cdot R)\cdot R^{1/2}\cdot\|\nabla e_{h,R}\|_{2,P_{h,R}}\cdot\|q-m(q)\|_{2,P_{h,R}}. \end{aligned}$$

Taking account of this inequality, and estimating the terms $\widetilde{I}_1$ and $\widetilde{I}_3$ in a straightforward way (Hölder's inequality, Lemma 5.2; note that $R^{-1/2}\cdot\|e_{h,R}\|_{2,\partial_{h,R}} \le \mathcal{D}_{h,R}$ and $\tau^{1/2}\cdot\|e_{h,R}\|_{2,\partial_{h,R}} \le \mathcal{D}_{h,R}$), we arrive at (5.6). Inequality (5.7) may be established by combining Hölder's inequality, the preceding estimates of $\|e_{h,R}\|_{2,\partial_{h,R}}$, and the inequalities

$$\|w\|_{2,P_{h,R}} \le \mathcal{C}\cdot R\cdot\|w\|_{6,P_{h,R}} \le \mathcal{C}\cdot R\cdot\|w\|^{(h,R)} \;\text{ for }\; w\in W_{h,R}$$

(Theorem A.1). □

Now we are in a position to estimate the terms $\|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi) - m_{h,R}\|_{2,P_{h,R}}$ and $\|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}}$.

Corollary 5.1. *Let $\mathcal{D}_{h,R}$ and $m_{h,R}$ be defined as in Theorem* 4.1. *Then*

$$\begin{aligned} &\|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi) - m_{h,R}\|_{2,P_{h,R}} \\ &\quad\le\; \mathcal{C}(\tau, h\cdot R)\cdot\big(\mathcal{D}_{h,R} + \mathcal{A}\cdot(h^t + h\cdot\ln(R/S) + R^{-1})\big)\cdot h^{-1/2}; \end{aligned} \tag{5.16}$$

$$\begin{aligned} &\|\pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)\|_{2,P_{h,R}} \\ &\quad\le\; \mathcal{C}(\tau, h\cdot R)\cdot\big(\mathcal{D}_{h,R} + \mathcal{A}\cdot(h^t + h\cdot\ln(R/S) + R^{-1})\big)\cdot R. \end{aligned} \tag{5.17}$$

Proof. We use the notation introduced in Lemma 5.2, but suppose that $q = \pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)$. Hence $m(q) = m_{h,R}$. Then, by (4.5) and Lemma 5.3,

$$\|q - m(q)\|^2_{2,P_{h,R}} \le |c(Z - \overline{Z},\, q)| + \mathcal{C}\cdot h^{-1/2}\cdot \Big(\mathcal{D}_{h,R} + \mathcal{A}\cdot\big(h^t + h\cdot\ln(R/S)\big)\Big)\cdot \|q - m(q)\|_{2,P_{h,R}}. \tag{5.18}$$

But by Lemma 5.1, $|c(Z - \overline{Z},\, q)| \le \sum_{i=1}^{3}\big(|\mathcal{M}_i(Z)| + |\mathcal{M}_i(\overline{Z})|\big)$, with the terms $\mathcal{M}_i(Z)$ and $\mathcal{M}_i(\overline{Z})$ ($i \in \{1,\, 2,\, 3\}$) defined as in that lemma. As a consequence of (2.4), (2.5), and Lemma 5.2, we get

$$\begin{aligned}|\mathcal{M}_3(Z)| + |\mathcal{M}_3(\overline{Z})| &\le \mathcal{C}\cdot\mathcal{A}\cdot(h + R^{-1})\cdot R^{1/2}\cdot\|q - m(q)\|_{2,P_{h,R}}\\ &\le \mathcal{C}(h\cdot R)\cdot\mathcal{A}\cdot(h + R^{-1})\cdot\|q - m(q)\|_{2,P_{h,R}}\cdot h^{-1/2}.\end{aligned} \tag{5.19}$$

By (3.17) and Lemma 5.2, we have

$$|\mathcal{M}_2(Z)| + |\mathcal{M}_2(\overline{Z})| \le \mathcal{C}\cdot\mathcal{A}\cdot\big(h^t + h\cdot\ln(R/S)\big)\cdot\|q - m(q)\|_{2,P_{h,R}}\cdot h^{-1/2}. \tag{5.20}$$

The terms $\mathcal{M}_1(Z)$ and $\mathcal{M}_1(\overline{Z})$ were estimated in Theorem 5.1. By combining this observation, inequalities (5.19) and (5.20), the splitting of $|c(Z - \overline{Z},\, q)|$ provided by Lemma 5.1 and indicated above, and estimate (5.18), we obtain (5.16).

The starting point of our proof of (5.17) is the estimate in Theorem 3.1, applied with $\varrho = q$. Due to this inequality, and in view of Lemma 5.1, the problem reduces to estimating the terms $|\mathcal{M}_i(w)|$ for $w \in W_{h,R},\ i \in \{1,\, 2,\, 3\}$, and the term $|c(W, q)|$ for $W \in \mathcal{B}^3_{h,R}$. First take $w \in W_{h,R}$. The relations in (2.4) and (2.5) and the estimate $\|w\|_{2,\partial_{h,R}} \le R^{1/2}\cdot\|w\|^{(h,R)}$ yield

$$|\mathcal{M}_3(w)| \le \mathcal{C}\cdot\mathcal{A}\cdot(h + R^{-1})\cdot\|w\|^{(h,R)}\cdot R^{1/2}.$$

Moreover, inequality (3.17) implies

$$|\mathcal{M}_2(w)| \le \mathcal{C}\cdot\|\nabla w\|_2\cdot\mathcal{A}\cdot\big(h^t + h\cdot\ln(R/S)\big).$$

The term $\mathcal{M}_1(w)$ was estimated in (5.7). Next take $W \in \mathcal{B}^3_{h,R}$. With (2.10), (2.6), and (4.5), we get

$$\begin{aligned}|c(W, q)| = |A\big(\mathcal{R}(\nabla q),\, W\big)| &\le \mathcal{C}\cdot\|\nabla\mathcal{R}(\nabla q)\|_{2,P_{h,R}}\cdot\|\nabla W\|_{2,P_{h,R}}\\ &\le \mathcal{C}\cdot\Big(\mathcal{D}_{h,R} + \mathcal{A}\cdot\big(h^t + h\cdot\ln(R/S)\big)\Big)\cdot\|\nabla W\|_{2,P_{h,R}}.\end{aligned}$$

We note in addition that $\|w\|^{(h,R)} + \|\nabla W\|_{2,P_{h,R}} \le \mathcal{C}\cdot\|w + W\|^{(h,R)}$ for $w \in W_{h,R},\ W \in \mathcal{B}^3_{h,R}$ (see [17, p. 291]). These results taken together yield (5.17). ∎

6. Proof of Theorem 2.1. Let us again use the notation $\mathcal{D}_{h,R}$ introduced in Theorem 4.1. Put $\mathcal{H} := h^t + h\cdot\ln(R/S)$. Theorem 4.1 and Corollary 5.1 imply

$$\mathcal{D}^2_{h,R} \le \mathcal{C}(\tau, h\cdot R)\cdot\max\{1,\, \tau^{-1/2}\}\cdot\mathcal{A}\cdot(\mathcal{H} + R^{-1})\cdot\big(\mathcal{D}_{h,R} + \mathcal{A}\cdot(\mathcal{H} + R^{-1})\big).$$

Hence

$$\mathcal{D}_{h,R} \le \mathcal{C}(\tau, h\cdot R)\cdot\max\{1,\, \tau^{-1/2}\}\cdot\mathcal{A}\cdot(\mathcal{H} + R^{-1}). \tag{6.1}$$

Thus, in order to complete the proof of (2.14), we still have to evaluate $\|\pi-\pi_{h,R}\|_{2,\Omega_{2\cdot S}}$. Denote $q := \pi_{h,R} - \widetilde{\Pi}_{h,R}(\pi)$. By [6, Theorem 3.5], there is a function $w \in H^1(P_{h,R})^3$ with $w \,|\, \partial\Omega = 0,\ \operatorname{div} w(x) = q(x)$ for $x \in \Omega_{2\cdot S},\ \operatorname{div} w(x) = 0$ for $x \in P_{h,R}\backslash B_{2\cdot S}$, and such that $\Pi_{h,R}(w)$ verifies the estimates stated in [6, Lemma 3.4], with g replaced by $q \,|\, \Omega_{2\cdot S}$. For brevity, put $v := \Pi_{h,R}(w)$. By [6, Lemma 4.3], we have

$$\|q\|^2_{2,\Omega_{2\cdot S}} \ \le\ |c(v,q)| \ +\ \mathcal{C}\cdot\big(\,\|\nabla\mathcal{R}(\nabla q)\|_{2,P_{h,R}} \ +\ \|q\|_{2,P_{h,R}}\cdot h^{1/2}\cdot R^{-3/2}\,\big)^2. \tag{6.2}$$

On the other hand, we know by (5.17) that

$$\|q\|_{2,P_{h,R}}\cdot h^{1/2}\cdot R^{-3/2} \le\ \mathcal{C}(\tau, h\cdot R)\cdot\big(\,\mathcal{D}_{h,R} + \mathcal{A}\cdot(\mathcal{H}+R^{-1})\,\big). \tag{6.3}$$

Recall the terms $\mathcal{M}_i(v)$ $(1 \le i \le 3)$ defined in Lemma 5.1. The reference [6, Lemma 3.4] and the definitions in (2.4), (2.5) imply

$$|\mathcal{M}_3(v)| \ \le\ \mathcal{C}\cdot\mathcal{A}\cdot(h+R^{-1})\cdot\|v\|_{2,\partial_{h,R}} \ \le\ \mathcal{C}\cdot\mathcal{A}\cdot(h+R^{-1})\cdot\|q\|_{2,\Omega_{2\cdot S}}. \tag{6.4}$$

Using (3.17) and [6, Lemma 3.4], we get

$$|\mathcal{M}_2(v)| \ \le\ \mathcal{C}\cdot\|\nabla v\|_{2,P_{h,R}}\cdot\mathcal{A}\cdot\mathcal{H} \ \le\ \mathcal{C}\cdot\mathcal{A}\cdot\mathcal{H}\cdot\|q\|_{2,\Omega_{2\cdot S}}. \tag{6.5}$$

Again referring to [6, Lemma 3.4], we obtain

$$\begin{aligned}|\mathcal{M}_1(v)| \ &\le\ \mathcal{C}(\tau)\cdot\big(\,\|u-u_{h,R}\|^{(h,R)} + \tau^{1/2}\cdot\|u-u_{h,R}\|_{2,\partial_{h,R}}\,\big)\\ &\quad\cdot\big(\,\|\nabla v\|_{2,P_{h,R}} + \|v\|_{2,\partial_{h,R}} + \|v\|_{2,P_{h,R}}\,\big) \ \le\ \mathcal{C}(\tau)\cdot\mathcal{D}_{h,R}\cdot\|q\|_{2,\Omega_{2\cdot S}}.\end{aligned} \tag{6.6}$$

As a consequence of (6.4)–(6.6) and Lemma 5.1, we find

$$|c(v,q)| \ \le\ \mathcal{C}(\tau)\cdot\big(\,\mathcal{D}_{h,R} + \mathcal{A}\cdot(\mathcal{H}+R^{-1})\,\big)\cdot\|q\|_{2,\Omega_{2\cdot S}}.$$

Now we combine the preceding inequality with (6.2), (6.3), and (4.5) to obtain, by a simple shoestring argument,

$$\|q\|_{2,\Omega_{2\cdot S}} \ \le\ \mathcal{C}(\tau, h\cdot R)\cdot\big(\,\mathcal{D}_{h,R} + \mathcal{A}\cdot(\mathcal{H}+R^{-1})\,\big). \tag{6.7}$$

From (6.7) and (3.17) we may conclude that

$$\|\pi-\pi_{h,R}\|_{2,\Omega_{2\cdot S}} \ \le\ \mathcal{C}(\tau, h\cdot R)\cdot(\mathcal{D}_{h,R} + \mathcal{A}\cdot(\mathcal{H}+R^{-1})\,\big),$$

so (2.14) follows with (6.1).

Appendix. In this appendix, we prove some results from analysis we applied above. We begin by considering two inequalities already used in [6].

THEOREM A.1. *The following inequalities are valid:*

$$\|v\|_{2,\Omega_{2\cdot S}} + \|v\|_{6,P_{h,R}} \le \mathcal{C}\cdot\|v\|^{(h,R)} \quad \textit{for}\ \ v \in W_{h,R},$$

$$\|v\|_{2,\Omega_{2\cdot S}} \le \mathcal{C}\cdot\big(\,\|v\|_{2,P_{h,R}\cup\Omega^c} + R^{-1/2}\cdot\|v\|_{2,\partial_{h,R}}\,\big) \quad \textit{for}\ \ v \in H^1(P_{h,R}\cup\Omega^c)^3.$$

Proof. For the estimate of $\|v\|_{2,\Omega_{2\cdot S}}$ in both cases $v \in W_{h,R}$ and $v \in H^1(P_{h,R}\cup\Omega^c)^3$, we refer to [4, Theorem 3.4] and [6, Theorem 3.3]. Concerning the term $\|v\|_{6,P_{h,R}}$, it may be evaluated by applying [6, Theorem 3.4]. ∎

In the first three inequalities of the ensuing lemma, functions with domain $P_{h,R}$ are estimated near or on $\partial_{h,R}$. The lemma indicates how the constants in these inequalities depend on h and R.

LEMMA A.1. *Denote* $\widetilde{R} := R \cdot (1 - h^2/S^2)^{1/2}$. *Then, for* $v \in H^1(P_{h,R})^3$,

$$\|v\|_{2,\,P_{h,R}\setminus B_{\widetilde{R}}} \;\le\; \mathcal{C} \cdot \big(h^2 \cdot R \cdot \|\nabla v\|_{2,P_{h,R}} + h \cdot R^{1/2} \cdot \|v\|_{2,\,\partial B_{\widetilde{R}}} \big), \tag{A.1}$$

$$\|v\|_{2,\partial_{h,R}} \;\le\; \mathcal{C} \cdot \big(h \cdot \widetilde{R}^{1/2} \cdot \|\nabla v\|_{2,P_{h,R}} + \|v\|_{2,\,\partial B_{\widetilde{R}}} \big), \tag{A.2}$$

$$\|v\|_{2,\,P_{h,R}\setminus B_{R\cdot(1-4\cdot h/S)}} \;\le\; \mathcal{C} \cdot \big(h \cdot R \cdot \|\nabla v\|_{2,P_{h,R}} + (h \cdot R)^{1/2} \cdot \|v\|_{2,\partial_{h,R}} \big). \tag{A.3}$$

(*Note that* $\Omega_{\widetilde{R}} \subset P_{h,R}$ *by* (3.5).) *Moreover,*

$$\|v\|_{2,\,\widetilde{R}^{-1}\cdot(P_{h,R}\setminus B_{\widetilde{R}})} \;\le\; \mathcal{C} \cdot (\|\nabla v\|_{2,\,\widetilde{R}^{-1}\cdot P_{h,R}} + \|v\|_{2,\,\partial B_1}) \tag{A.4}$$

$$\text{for } v \in H^1(\widetilde{R}^{-1} \cdot P_{h,R}),$$

$$\|v\|_{2,\,\partial B_{\widetilde{R}}} \;\le\; \mathcal{C} \cdot \big(\widetilde{R}^{1/2} \cdot \|\nabla v\|_{2,B_{\widetilde{R}}} + \widetilde{R}^{-1/2} \cdot \|v\|_{2,B_{\widetilde{R}}} \big) \quad \text{for } v \in H^1(B_{\widetilde{R}})^3. \tag{A.5}$$

Proof. Inequalities (A.1)–(A.3) may be proved in the same way as [5, Lemma 7.1] or [4, Theorems 3.2 and 3.3]. We leave the details to the reader. The relation (A.4) may be obtained from (A.1) by a scaling argument, whereas estimate (A.5) may be reduced by a scaling argument to a standard trace estimate for functions from $H^1(B_1)^3$. □

Finally, we consider the divergence equation on $P_{h,R}$, which we solve by using the L^2-theory for the Laplace operator with Neumann boundary conditions on convex domains.

THEOREM A.2. *Let* $g \in L^2(P_{h,R})$ *with* $\int_{P_{h,R}} g\, dx = 0$. *Then there is a function* $G(g) \in H^1(P_{h,R})^3$ *with*

$$\operatorname{div} G(g) = g, \quad G(g)\,|\,\partial\Omega = 0, \quad G(g)\cdot n = 0 \;\text{ on }\; \partial_{h,R},$$

$$G(g)\,|\,P_{h,R}\setminus B_S = \nabla v(g)\,|\,P_{h,R}\setminus B_S \quad \text{for some function } v(g) \in H^2(P_{h,R}\cup\Omega^c),$$

$$\|G(g)\|^{(h,R)} + \|G(g)\|_{2,\Omega_{2\cdot S}} \;\le\; \mathcal{C}\cdot\|g\|_{2,P_{h,R}}.$$

Proof. Denote $\widetilde{R} := R \cdot (1 - h^2/S^2)^{1/2}$, $U := \widetilde{R}^{-1} \cdot \big(P_{h,R} \cup \Omega^c)$, and let $n^{(U)}$ denote the outward unit normal to U. Note that $B_1 \subset U$ (see (3.5)). Put

$$\mathcal{P} := \Big\{ v \in H^2(U) \;:\; \partial u/\partial n^{(U)} = 0 \;\text{ on }\; \partial U, \;\; \int_{B_1} v\, dx = 0 \Big\}.$$

Since U is convex (see (A5)), by [13, Theorem 3.1.2.3, Lemma 3.2.1.1], we have

$$\|v\|_{2,2,U} \;\le\; \mathcal{C} \cdot (\|\Delta v\|_{2,U} + \|v\|_{2,U}) \quad \text{for } v \in H^2(U) \text{ with } \partial v/\partial n^{(U)} = 0. \tag{A.6}$$

This inequality is valid with the same constant for any convex domain in $\mathbb{R}^3$. In particular, it is valid with the same constant for all domains $U = \widetilde{R}^{-1} \cdot (P_{h,R} \cup \Omega^c)$ with $h \in (0, h_0)$, $R \in (R_0, \infty)$. Let us show that

$$\|v\|_{2,2,U} \;\le\; \mathcal{C} \cdot \|\Delta v\|_{2,U} \quad \text{for any } \; v \in \mathcal{P}. \tag{A.7}$$

By first using (A.4) and then estimating $\|v\|_{2,\partial B_1}$ by a standard trace theorem, we get $\|v\|_{2,\,U\setminus B_1} \le \mathcal{C}\cdot(\|\nabla v\|_{2,U}+\|v\|_{2,B_1})$ for $v\in H^1(U)$. By Poincaré's inequality for functions with mean value zero on B_1 (see [9, Theorem II.4.3], for example), we may deduce from the previous estimate that $\|v\|_{2,U}\le \mathcal{C}\cdot\|\nabla v\|_{2,U}$ for $v\in\mathcal{P}$. By partial integration and due to the relation $\partial v/\partial n^{(U)}=0$ for $v\in\mathcal{P}$, the inequality

$$\|\nabla v\|_{2,U}^2 \le \mathcal{C}\cdot\|\Delta v\|_{2,U}\cdot\|v\|_{2,U} \le (\mathcal{C}/\epsilon)\cdot\|\Delta v\|_{2,U}^2+\epsilon\cdot\|v\|_{2,U}^2$$

holds for $\epsilon\in(0,\infty)$, $v\in\mathcal{P}$. By choosing ϵ sufficiently small, we may deduce (A.7) from the two preceding estimates and from (A.6).

Now we return to the function g given in the theorem. Let $\widetilde{g}$ be the zero extension of g to $P_{h,R}\cup\Omega^c$. Recall that $P_{h,R}\cup\Omega^c$ is convex (see (A5)) and $\int_{P_{h,R}} g\,dx=0$. Thus, according to [10, Theorem I.1.9], [13, Theorem 3.2.1.3], there is a function $v(g)\in H^2\big(P_{h,R}\cup\Omega^c\big)$ with $\Delta v(g)=\widetilde{g}$, $\partial v(g)/\partial n=0$ on $\partial_{h,R}$. Without loss of generality, we may suppose that $\int_{B_{\widetilde{R}}} v(g)\,dx=0$. Put $\widetilde{v}(x):=v(g)(\widetilde{R}\cdot x)$ for $x\in U$. Then $\widetilde{v}\in\mathcal{P}$, and hence inequality (A.7) holds with v replaced by $\widetilde{v}$. It follows by a scaling argument that

$$|v(g)|_{2,2,\,P_{h,R}\cup\Omega^c} + R^{-1}\cdot\|\nabla v(g)\|_{2,\,P_{h,R}\cup\Omega^c} \le \mathcal{C}\cdot\|g\|_{2,P_{h,R}}. \tag{A.8}$$

On the other hand, using (A.2) and (A.5) with v replaced by $\nabla v(g)$, and using (A.8) as well, we see that

$$R^{-1/2}\cdot\|\nabla v(g)\|_{2,\partial_{h,R}} \le \mathcal{C}\cdot\|g\|_{2,P_{h,R}}. \tag{A.9}$$

Since $\widetilde{g}\,|\,\Omega=0$, we get $\int_{\partial\Omega}\nabla v(g)\cdot n^{(\Omega)}\,do=0$, where we write $n^{(\Omega)}$ for the exterior unit normal to Ω. Thus, according to [9, Exercise III.3.4], there is a function $\mathcal{F}\in H^1(\Omega_S)^3$ with $\operatorname{div}\mathcal{F}=0$ and

$$\mathcal{F}\,|\,\partial\Omega=-\nabla v(g)\,|\,\partial\Omega,\quad \mathcal{F}\,|\,\partial B_S=0,\quad \|\mathcal{F}\|_{1,2,\Omega_S}\le\mathcal{C}\cdot\|\nabla v(g)\,|\,\partial\Omega\|_{1/2,\,2,\partial\Omega},$$

where $\|\ \|_{1/2,\,2,\partial\Omega}$ denotes an arbitrary but fixed norm of the usual fractional order Sobolev space $H^{1/2}(\partial\Omega)^3$ on the Lipschitz boundary $\partial\Omega$. The last inequality and a standard trace theorem imply

$$\|\mathcal{F}\|_{1,2,\Omega_S}\le\mathcal{C}\cdot\|\nabla v(g)\|_{1,2,\Omega_S}. \tag{A.10}$$

Let $\widetilde{\mathcal{F}}$ denote the zero extension of $\mathcal{F}$ to $P_{h,R}$, and put $G(g):=\widetilde{\mathcal{F}}+\nabla v(g)\,|\,P_{h,R}$. Then the functions $G(g)$ and $v(g)$ verify the properties stated in Theorem A.2. In particular, the inequality at the end of that theorem follows from (A.8)–(A.10) and from the first inequality in Theorem A.1 with v replaced by $\nabla v(g)$. □

hp-VERSION DISCONTINUOUS GALERKIN FINITE ELEMENT METHOD FOR SEMILINEAR PARABOLIC PROBLEMS*

ANDRIS LASIS† AND ENDRE SÜLI‡

Abstract. We consider the *hp*-version discontinuous Galerkin finite element method (*hp*-DGFEM) with interior penalty for semilinear parabolic equations with locally Lipschitz continuous nonlinearity, subject to mixed nonhomogeneous Dirichlet–nonhomogeneous Neumann boundary conditions. Our main concern is the error analysis of the (spatially) semidiscrete *hp*-DGFEM on shape-regular spatial meshes. We derive error bounds under various hypotheses on the regularity of the solution, for both the symmetric and nonsymmetric versions of DGFEM.

Key words. *hp*-finite element methods, discontinuous Galerkin methods, semilinear parabolic PDEs

1. Introduction.

Let Ω be a bounded open polyhedral domain in $\mathbb{R}^d$, $d \geq 2$, with a Lipschitz-continuous boundary. We consider the semilinear parabolic partial differential equation (PDE)

$$u' - \Delta u = f(x,t,u) \quad \text{in} \quad \Omega \times (0,T], \tag{1.1}$$

where $u' := \partial u/\partial t$ and $T > 0$. It will be assumed throughout that f is a real-valued function defined on $\Omega \times (0,T] \times \mathbb{R}$ which satisfies the following assumption:

(**A**) $f(\cdot\,,\cdot\,,v) : (x,t) \in \Omega \times (0,T] \mapsto f(x,t,v) \in \mathbb{R}$ is measurable in $(x,t) \in \Omega \times (0,T]$ for all $v \in \mathbb{R}$, with $f(x,t,0) = 0$ for all $(x,t) \in \Omega \times (0,T]$, and the mapping $f(x,t,\cdot\,) : v \in \mathbb{R} \mapsto f(x,t,v) \in \mathbb{R}$ is locally Lipschitz continuous for a.e. $(x,t) \in \Omega \times (0,T]$, in the sense that there exist real numbers $G_f > 0$ and $\gamma \geq 0$ such that

$$|f(x,t,w) - f(x,t,v)| \leq G_f(1+|w|+|v|)^\gamma\,|w-v| \quad \begin{cases} \forall w,\, v \in \mathbb{R}, \\ \text{a.e. } (x,t) \in \Omega \times (0,T]. \end{cases} \tag{1.2}$$

We shall suppose that $0 \leq \gamma < \infty$ when $d = 2$, and $0 \leq \gamma \leq 2/(d-2)$ when $d \geq 3$. The trivial case of $\gamma = 0$ corresponds to assuming that the function f is globally Lipschitz continuous in its third argument.

Let $\partial\Omega$ denote the union of all $(d-1)$-dimensional open faces of the polyhedron Ω. Upon decomposing $\partial\Omega$ into two parts, $\Gamma_{\rm D}$ and $\Gamma_{\rm N}$, so that $\bar{\Gamma}_{\rm D} \cup \bar{\Gamma}_{\rm N} = \overline{\partial\Omega}$ and $\Gamma_{\rm D}$ has positive $(d-1)$-dimensional Hausdorff measure, and denoting by $\nu = (\nu_1, \ldots, \nu_d)^\top$

the unit outward normal vector to $\partial\Omega$, we impose Dirichlet and Neumann boundary conditions on Γ_{D} and Γ_{N}, respectively:

$$\begin{aligned} u &= g_{\mathrm{D}} \qquad \text{on} \qquad \Gamma_{\mathrm{D}} \times (0,T], \\ \nabla u \cdot \nu &= g_{\mathrm{N}} \qquad \text{on} \qquad \Gamma_{\mathrm{N}} \times (0,T], \end{aligned} \tag{1.3}$$

with $g_{\mathrm{D}} \in \mathrm{H}^{1/2}(\Gamma_{\mathrm{D}})$ and $g_{\mathrm{N}} \in \mathrm{L}^2(\Gamma_{\mathrm{N}})$. Given a function $u_0 \in \mathrm{L}^2(\Omega)$, we supplement (1.1) and (1.3) with the initial condition

$$u = u_0 \quad \text{on} \quad \Omega \times \{0\}\,. \tag{1.4}$$

As the solution to the problem (1.1)–(1.4) may exhibit blowup in finite time, we shall assume that, for the potential blowup time $T^\star \in (0,\infty]$, the time interval $[0,T]$ on which the problem is considered excludes the blowup time, i.e., $T < T^\star$.

Discontinuous Galerkin finite element methods (DGFEMs) were introduced in the early 1970s for the numerical solution of first-order hyperbolic problems (see [33, 28, 26, 25, 10, 11, 12, 15, 34, 35]). Simultaneously, but independently, they were proposed as nonstandard schemes for the numerical approximation of second-order elliptic equations [32, 16, 1]. In recent years there has been renewed interest in this class of methods due to their favorable properties, which include a high degree of locality, stability in the absence of streamline-diffusion stabilization for convection-dominated diffusion problems [22], and the flexibility of locally varying the polynomial degree in adaptive *hp*-version approximations, since no pointwise continuity requirements are imposed at the element interfaces [23]. Much attention has been devoted to the analysis of DG methods applied to scalar nonlinear hyperbolic equations and hyperbolic systems [21, 7, 8], as well as to several other types of nonlinear equations, including the Hamilton–Jacobi equations [24], the nonlinear Schrödinger equation [27], and various other nonlinear problems [9]. The analysis of the spatial discretization of nonlinear parabolic problems by the interior penalty DGFEM (see [1]) was pursued by Rivière and Wheeler in [36], where the nonlinearity was assumed to be *globally* Lipschitz continuous with respect to the unknown solution.

In this work we shall be concerned with the error analysis of the *hp*-version interior penalty discontinuous Galerkin finite element method (*hp*-DGFEM) on shape-regular meshes, for the initial-boundary value problem (1.1)–(1.4). In particular, we focus on the spatial semidiscretization of the problem; however, unlike [1] and [36], we shall suppose that the nonlinearity satisfies only the *local* Lipschitz condition (1.2). As we shall see, this relaxation of the hypothesis on f leads to technical difficulties which are not present in the case when $f(x,t,\,\cdot\,)$ is globally Lipschitz continuous.

The paper is structured as follows. In section 2 we state the broken weak formulation of the problem. The error analysis of the *hp*-DGFEM approximation is discussed in section 3. We begin by establishing the local Lipschitz continuity of the mapping $w \mapsto f(\,\cdot\,,t,w(\,\cdot\,)) : \mathrm{L}^{2(\gamma+1)}(\Omega) \to \mathrm{L}^2(\Omega)$; we then show the continuity and coercivity of the bilinear form $B(\,\cdot\,,\,\cdot\,)$ appearing in the broken weak formulation of the initial-boundary value problem under consideration. Finally, we define the broken elliptic projector induced by $B(\,\cdot\,,\,\cdot\,)$ and state its approximation properties in the L^2 and broken H^1 norms. Section 3.2 contains the error analysis of the nonsymmetric version of the interior penalty *hp*-DGFEM: we prove an a priori error bound in the broken $\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega))$ norm that is h-optimal and p-suboptimal (by half an order of p). Full *hp*-optimality of the error bound in the broken $\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega))$ norm can be easily restored by hypothesizing piecewise regularity of the solution in augmented Sobolev

spaces instead of classical Sobolev spaces, as was done in [17] in the elliptic case; for the sake of brevity we shall not pursue this line of study here since the necessary modifications are quite straightforward. Section 3.3 is concerned with the error analysis of the symmetric version of the interior penalty *hp*-DGFEM, where we derive a priori error bounds in the broken $\mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega))$ norm (which is stronger than the broken $\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega))$ norm, in which the error bound for the nonsymmetric version of the method was derived) as well as in the $\mathrm{L}^\infty(0,T;\mathrm{L}^2(\Omega))$ norm. Unlike the case when the nonlinearity is globally Lipschitz continuous, corresponding to the particular choice of $\gamma = 0$ in (1.2), for $\gamma > 0$ a broken counterpart of the Sobolev–Poincaré inequality has to be used to complete the error analyses of the symmetric and nonsymmetric versions of *hp*-DGFEM. The variant of the Sobolev–Poincaré inequality considered here is inspired by the work of Brenner [5]. A further ingredient of our error analysis is an adaptation to DG methods of a continuity argument due to Thomée and Wahlbin (cf. pages 382–384 in [38]). Section 4 contains some final comments on our results in this work. We remark that the analysis of the fully discrete counterpart of the method considered here, with DGFEM time discretization, proceeds in much the same manner as our analysis of the spatially semidiscrete method and is therefore omitted (cf. [29] for details and exhaustive numerical experiments). We also note that the extension of our arguments to more general second-order semilinear parabolic equations, where the Laplace operator is replaced by a general linear second-order elliptic operator in divergence form, is also straightforward (e.g., by combining the analysis presented here with that in [22]). For an extension of the analysis in this paper to a class of quasi-linear parabolic problems we refer to [29].

2. Broken weak formulation. Throughout the paper, $\mathrm{W}^{s,q}(\Omega)$ will signify the usual Sobolev space on Ω, of differentiability-index s and integrability index q, equipped with the Sobolev norm $\|\cdot\|_{s,q,\Omega}$ and seminorm $|\cdot|_{s,q,\Omega}$. In the case when $q = 2$, we shall write $\mathrm{H}^s(\Omega) := \mathrm{W}^{s,2}(\Omega)$ and suppress the index q in the notation of the norm and seminorm, writing $\|\cdot\|_{s,\Omega}$ and $|\cdot|_{s,\Omega}$, respectively. For a Banach space X equipped with a norm $\|\cdot\|$, the space $\mathrm{L}^q(0,T;X)$ consists of all strongly measurable functions $\mathbf{u} : (0,T) \to X$ with the norm

$$\|\mathbf{u}\|_{\mathrm{L}^q(0,T;X)} := \left(\int_0^T \|\mathbf{u}(t)\|^q \,\mathrm{d}t\right)^{1/q} < \infty \quad \text{for} \quad 1 \le q < \infty,$$

and with

$$\|\mathbf{u}\|_{\mathrm{L}^\infty(0,T;X)} := \operatorname*{ess.\,sup}_{0\le t\le T} \|\mathbf{u}(t)\| < \infty \quad \text{for} \quad q = \infty.$$

The Sobolev space $\mathrm{W}^{1,q}(0,T;X)$ consists of all functions $\mathbf{u} \in \mathrm{L}^q(0,T;X)$ such that $\mathbf{u}'$ exists in the weak sense and belongs to $\mathrm{L}^q(0,T;X)$, with the associated norm

$$\|\mathbf{u}\|_{\mathrm{W}^{1,q}(0,T;X)} := \left(\int_0^T \{\|\mathbf{u}(t)\|^q + \|\mathbf{u}'(t)\|^q\} \,\mathrm{d}t\right)^{1/q} < \infty \quad \text{for} \quad 1 \le q < \infty,$$

and with

$$\|\mathbf{u}\|_{\mathrm{W}^{1,\infty}(0,T;X)} := \operatorname*{ess.\,sup}_{0<t<T} (\|\mathbf{u}(t)\| + \|\mathbf{u}'(t)\|).$$

In the context of the initial-boundary value problem under consideration, $\mathbf{u}(t) = u(\cdot\,,t)$; with a slight abuse of notation, we shall simply write u in place of $\mathbf{u}$. Also, for the sake of brevity, we shall write $\mathrm{H}^1(0,T;X) := \mathrm{W}^{1,2}(0,T;X)$.

Let $\mathcal{T}_h$ be a subdivision of Ω into disjoint open elements κ such that $\bar{\Omega} = \cup_{\kappa\in\mathcal{T}_h}\bar{\kappa}$, where $\mathcal{T}_h$ is regular or 1-irregular; i.e., each face of κ has at most one hanging node. We let $h_\kappa := \mathrm{diam}(\bar{\kappa})$ and $h := \max_{\kappa\in\mathcal{T}_h} h_\kappa$; it will be assumed throughout that $h \le 1$. We assume that the family of subdivisions $\{\mathcal{T}_h\}$ is shape regular (see pages 61, 113, and Remark 2.2 on page 114, in [4]), and require each $\kappa \in \mathcal{T}_h$ to be an affine image $F_\kappa(\hat{\kappa})$ of a fixed master element $\hat{\kappa}$ for all $\kappa \in \mathcal{T}_h$, where $\hat{\kappa}$ is the open unit simplex or the open unit hypercube in $\mathbb{R}^d$. For a nonnegative integer p, we denote by $\mathcal{P}_p(\hat{\kappa})$ the set of all polynomials of degree p or less on $\hat{\kappa}$; if $\hat{\kappa}$ is the open unit hypercube in $\mathbb{R}^d$ we also consider $\mathcal{Q}_p(\hat{\kappa})$, the set of all tensor-product polynomials on $\hat{\kappa}$ of degree p or less in each coordinate direction. To each $\kappa \in \mathcal{T}_h$ we assign a nonnegative integer p_κ (the local polynomial degree) and a nonnegative integer s_κ (the local Sobolev index), collect the p_κ, s_κ, and F_κ into vectors $\mathbf{p} = \{p_\kappa : \kappa \in \mathcal{T}_h\}$, $\mathbf{s} = \{s_\kappa : \kappa \in \mathcal{T}_h\}$, and $\mathbf{F} = \{F_\kappa : \kappa \in \mathcal{T}_h\}$, respectively, and consider the finite element space

$$S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}) := \left\{v \in \mathrm{L}^2(\Omega) : v|_\kappa \circ F_\kappa \in \mathcal{R}_{p_\kappa}(\hat{\kappa}),\, \kappa \in \mathcal{T}_h\right\}, \tag{2.1}$$

where $\mathcal{R}$ is either $\mathcal{P}$ or $\mathcal{Q}$ if $\hat{\kappa}$ is the open unit hypercube in $\mathbb{R}^d$, and $\mathcal{R}$ is $\mathcal{P}$ if $\hat{\kappa}$ is the open unit simplex in $\mathbb{R}^d$.

We shall assume that the polynomial degree vector $\mathbf{p}$, with $p_\kappa \ge 1$ for each $\kappa \in \mathcal{T}_h$, has *bounded local variation*; i.e., there exists a constant $\rho \ge 1$, independent of h, such that, for any pair of elements κ and κ' in $\mathcal{T}_h$ which share a $(d-1)$-dimensional face,

$$\rho^{-1} \le p_\kappa/p_{\kappa'} \le \rho. \tag{2.2}$$

For $q \in [1,\infty)$, we assign to the subdivision $\mathcal{T}_h$ the broken Sobolev space of composite order $\mathbf{s}$,

$$\mathrm{W}^{\mathbf{s},q}(\Omega,\mathcal{T}_h) := \{u \in \mathrm{L}^q(\Omega) : u|_\kappa \in \mathrm{W}^{s_\kappa,q}(\kappa)\ \forall\ \kappa \in \mathcal{T}_h\},$$

equipped with the broken Sobolev norm and seminorm, respectively,

$$\|u\|_{\mathbf{s},q,\mathcal{T}_h} := \left(\sum_{\kappa\in\mathcal{T}_h} \|u\|^q_{s_\kappa,q,\kappa}\right)^{1/q}, \quad |u|_{\mathbf{s},q,\mathcal{T}_h} := \left(\sum_{\kappa\in\mathcal{T}_h} |u|^q_{s_\kappa,q,\kappa}\right)^{1/q}.$$

When $s_\kappa = s$ for all $\kappa \in \mathcal{T}_h$, we write $\mathrm{W}^{s,q}(\Omega,\mathcal{T}_h)$, $\|u\|_{s,q,\mathcal{T}_h}$, $|u|_{s,q,\mathcal{T}_h}$, and for $q = 2$ we let $\mathrm{H}^{\mathbf{s}} := \mathrm{W}^{\mathbf{s},2}$ and omit the index q in the notation of the norm and seminorm.

Let $\mathcal{E}$ denote the set of all open $(d-1)$-dimensional faces of the subdivision $\mathcal{T}_h$, containing the smallest common $(d-1)$-dimensional interfaces e of neighboring elements. We denote by $\mathcal{E}_{\mathrm{int}}$ the set of all faces in $\mathcal{E}$ that are contained in Ω, and we let $\Gamma_{\mathrm{int}} := \{x \in \Omega : x \in e \text{ for some } e \in \mathcal{E}_{\mathrm{int}}\}$. Further, we denote by $\mathcal{E}_\partial$ the set of all $(d-1)$-dimensional boundary faces. Assuming that each $e \in \mathcal{E}_\partial$ is a subset of the interior of exactly one of Γ_{D} and Γ_{N}, we label the associated sets of faces by $\mathcal{E}_{\mathrm{D}}$ and $\mathcal{E}_{\mathrm{N}}$. Given that $e \in \mathcal{E}_{\mathrm{int}}$, there exist positive integers i, j such that $i > j$ and that κ_i and κ_j share the face e; we define the jump of $v \in \mathrm{W}^{\mathbf{s},q}(\Omega,\mathcal{T}_h)$, $s_\kappa > 1/q$, $\kappa \in \mathcal{T}_h$, across e and the mean value of v on e by

$$[\![v]\!]_e := v|_{\partial\kappa_i\cap e} - v|_{\partial\kappa_j\cap e} \quad \text{and} \quad \{\!\{v\}\!\}_e := \tfrac{1}{2}\left(v|_{\partial\kappa_i\cap e} + v|_{\partial\kappa_j\cap e}\right),$$

respectively, with $\partial\kappa$ denoting the union of all open faces of the element κ. With each face e we associate the unit normal vector ν pointing from the element κ_i to κ_j when $i > j$; when the face belongs to $\mathcal{E}_\partial$, we choose ν to be the unit outward normal vector.

With this notation, we introduce the bilinear form

(2.3)
$$B(w,v) := \sum_{\kappa\in\mathcal{T}_h}\int_\kappa \nabla w\cdot\nabla v\,\mathrm{d}x + \int_{\Gamma_\mathrm{D}}\{\theta(\nabla v\cdot\nu)w - (\nabla w\cdot\nu)v\}\,\mathrm{d}s + \int_{\Gamma_\mathrm{D}}\sigma wv\,\mathrm{d}s$$
$$+\int_{\Gamma_\mathrm{int}}\{\theta\{\!\{\nabla v\cdot\nu\}\!\}[\![w]\!] - \{\!\{\nabla w\cdot\nu\}\!\}[\![v]\!]\}\,\mathrm{d}s + \int_{\Gamma_\mathrm{int}}\sigma[\![w]\!][\![v]\!]\,\mathrm{d}s$$

and the linear functional

$$\ell(v) := \int_{\Gamma_\mathrm{N}} g_\mathrm{N} v\,\mathrm{d}s + \theta\int_{\Gamma_\mathrm{D}}(\nabla v\cdot\nu)g_\mathrm{D}\,\mathrm{d}s + \int_{\Gamma_\mathrm{D}}\sigma g_\mathrm{D} v\,\mathrm{d}s. \tag{2.4}$$

Here σ is called the *discontinuity-penalization parameter* and is defined by

$$\sigma|_e = \sigma_e \quad \text{for} \quad e\in\mathcal{E}_\mathrm{int}\cup\mathcal{E}_\partial,$$

where σ_e is a positive constant on the face e. The precise choice of σ_e will be discussed in section 3. The subscript e in these definitions will be suppressed when no confusion is likely to occur. The parameter θ takes its values in the interval $[-1,1]$. Since for $\theta\neq\pm1$ the analysis of the method is similar to that in the case of $\theta=\pm1$, for the sake of brevity we shall suppose throughout that $\theta\in\{-1,1\}$. The choice of $\theta=-1$ leads to a symmetric bilinear form $B(\,\cdot\,,\,\cdot\,)$; we call the associated method the *symmetric interior penalty*, or SIP, method. On the other hand, for $\theta=1$ the bilinear form $B(\,\cdot\,,\,\cdot\,)$ is nonsymmetric, but it is coercive for any $\sigma>0$; we call the corresponding method the *nonsymmetric interior penalty*, or NSIP, method. In order to distinguish between the two methods, we shall label the bilinear form (2.3) and the linear functional (2.4) with indices S and NS in the symmetric and nonsymmetric cases, corresponding to $\theta=-1$ and $\theta=1$, respectively.

Then, the broken weak formulation of the problem (1.1)–(1.4) reads as follows:

(2.5) Find $u\in\mathrm{H}^1(0,T;\mathrm{L}^2(\Omega))\cap\mathrm{L}^2(0,T;\mathfrak{A})$ such that

$$\int_\Omega u'v\,\mathrm{d}x + B(u,v) - \int_\Omega f(x,t,u)v\,\mathrm{d}x = \ell(v)\quad\forall v\in\mathrm{H}^2(\Omega,\mathcal{T}_h),$$
$$u(0)=u_0,$$

where by $\mathfrak{A}$ we denote the function space

$$\mathfrak{A} = \left\{w\in\mathrm{H}^2(\Omega,\mathcal{T}_h) : w,\ \nabla w\cdot\nu \text{ are continuous across each } e\in\mathcal{E}_\mathrm{int}\right\}.$$

Note that if $u\in\mathrm{H}^1(0,T;\mathrm{L}^2(\Omega))\cap\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega))$ is a weak solution of (1.1)–(1.4) and $u\in\mathrm{L}^2(0,T;\mathfrak{A})$, then u also solves (2.5); in what follows we shall always assume that such a u exists.

The *hp*-DGFEM approximation of problem (1.1)–(1.4) is as follows:

(2.6) Find $u_{\mathrm{DG}} \in \mathrm{H}^1(0,T;S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}))$ such that

$$\int_\Omega u'_{\mathrm{DG}} v \,\mathrm{d}x + B(u_{\mathrm{DG}},v) - \int_\Omega f(x,t,u_{\mathrm{DG}})v\,\mathrm{d}x = \ell(v) \quad \forall v \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}),$$

$$u_{\mathrm{DG}}(0) = u_0^{\mathrm{DG}},$$

where u_0^{DG} denotes an approximation of the function u_0 from the finite element space $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$. The purpose of this paper is to quantify the size of the error between the solution u to (2.5) and its *hp*-DGFEM approximation u_{DG} in various norms.

Equation (2.6) can be interpreted as a system of ordinary differential equations (ODEs) for the coefficients in the expansion of $u_{\mathrm{DG}}(\,\cdot\,,t)$ in terms of basis functions of the finite-dimensional space $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$. Thus, (2.6) represents a nonautonomous system of ODEs with locally Lipschitz continuous right-hand side, given that $f(x,t,\,\cdot\,)$ is locally Lipschitz continuous, uniformly in $(x,t) \in \Omega \times (0,T]$, and the other terms are linear. By Carathéodory's theorem (see Theorems II.4.1 and II.4.5 in [39]) this, in turn, implies the existence of a unique local solution to (2.6) on a certain maximal subinterval $[0,t_{\star\star})$ of $[0,T]$. In fact, we shall show below that u_{DG} exists on the whole of $[0,T]$.

3. Error analysis. Before embarking on the analysis of (2.6), we state and prove some preliminary results.

3.1. Preliminary results. We begin by establishing the local Lipschitz-continuity of $w \mapsto f(\,\cdot\,,t,w(\,\cdot\,))$ as a mapping from $\mathrm{L}^{2(\gamma+1)}(\Omega)$ to $\mathrm{L}^2(\Omega)$.

LEMMA 3.1. *Suppose that f satisfies* (**A**). *Then, there exists a positive constant $C_f = C_f(\gamma, G_f, |\Omega|)$ such that*

$$\|f(\,\cdot\,,t,w) - f(\,\cdot\,,t,v)\|_{0,\Omega} \le C_f \|w-v\|_{0,2(\gamma+1),\Omega} \times \left(1 + \|w\|^\gamma_{0,2(\gamma+1),\Omega} + \|v\|^\gamma_{0,2(\gamma+1),\Omega}\right) \tag{3.1}$$

for all w, $v \in \mathrm{L}^{2(\gamma+1)}(\Omega)$ and a.e. $t \in (0,T]$.

Proof. Let $q = 2(\gamma+1)$. Note that if $d = 2$, $0 \le \gamma < \infty$, then $2 \le q < \infty$, and if $d \ge 3$, $0 \le \gamma \le 2/(d-2)$, then $2 \le q \le 2d/(d-2)$. Let us suppose that $\gamma > 0$ and therefore $q > 2$; for $\gamma = 0$, (3.1) trivially holds with $C_f = G_f/3$. Let w, $v \in \mathrm{L}^{2(\gamma+1)}(\Omega)$; from (1.2), by Hölder's inequality, for a.e. $t \in (0,T]$ we have

$$\begin{aligned}\|f(\,\cdot\,,t,w) - f(\,\cdot\,,t,v)\|^2_{0,\Omega} &\le G_f^2 \int_\Omega (w-v)^2(1+|w|+|v|)^{2\gamma}\,\mathrm{d}x \\ &\le G_f^2 \left(\int_\Omega |w-v|^{2\cdot q/2}\,\mathrm{d}x\right)^{2/q} \left(\int_\Omega (1+|w|+|v|)^{2\gamma\cdot(1-2/q)^{-1}}\,\mathrm{d}x\right)^{1-2/q}.\end{aligned}$$

As $1-2/q=(q-2)/q=2\gamma/q$ and $q>2$, we have

$$\begin{aligned}\|f(\,\cdot\,,t,w)-f(\,\cdot\,,t,v)\|_{0,\Omega}^2 &\le G_f^2\|w-v\|_{0,q,\Omega}^2\left(\int_\Omega(1+|w|+|v|)^q\,\mathrm{d}x\right)^{2\gamma/q}\\ &\le G_f^2\|w-v\|_{0,q,\Omega}^2\left(|\Omega|^{1/q}+\|w\|_{0,q,\Omega}+\|v\|_{0,q,\Omega}\right)^{2\gamma}\\ &\le C_f^2\|w-v\|_{0,q,\Omega}^2\left(1+\|w\|_{0,q,\Omega}^{\gamma}+\|v\|_{0,q,\Omega}^{\gamma}\right)^2,\end{aligned}$$

and hence (3.1) for a.e. $t\in(0,T]$ and all $w,v\in\mathrm{L}^q(\Omega)$, $q=2(\gamma+1)$. ∎

We equip $\mathrm{H}^1(\Omega,\mathcal{T}_h)$ with the norm $\|\cdot\|_{1,h}$ defined by

$$\|w\|_{1,h}:=\left(\sum_{\kappa\in\mathcal{T}_h}\|\nabla w\|_{0,\kappa}^2+\int_{\Gamma_{\mathrm{D}}}\sigma w^2\,\mathrm{d}s+\int_{\Gamma_{\mathrm{int}}}\sigma\,[\![w]\!]^2\,\mathrm{d}s\right)^{1/2},\tag{3.2}$$

where σ is the positive discontinuity-penalization parameter which was introduced after (2.4). In addition, we define the norm $|||\cdot|||_{1,h}$ by

$$|||w|||_{1,h}:=\left(\sum_{\kappa\in\mathcal{T}_h}\|\nabla w\|_{0,\kappa}^2+|\Gamma_{\mathrm{D}}|^{-1}\int_{\Gamma_{\mathrm{D}}}w^2\,\mathrm{d}s+\sum_{e\in\mathcal{E}_{\mathrm{int}}}h_e^{-1}\int_e[\![w]\!]^2\,\mathrm{d}s\right)^{1/2}.\tag{3.3}$$

The parameter σ will be chosen so that $\sigma|_e=\sigma_e$ on each face $e\in\mathcal{E}$ and $\sigma_e\ge C_\sigma/h_e$, where C_σ is a positive constant whose value will be fixed later on; here h_e denotes the diameter of the face e. With this choice of σ, by noting that $1\le h_e^{-1}\le\sigma_e/C_\sigma$ (since $h\le1$) and that $|\Gamma_{\mathrm{D}}|^{-1}\int_{\Gamma_{\mathrm{D}}}w^2\,\mathrm{d}s=|\Gamma_{\mathrm{D}}|^{-1}\sum_{e\in\mathcal{E}_{\mathrm{D}}}1\cdot\int_e w^2\,\mathrm{d}s$, we have that

$$|||w|||_{1,h}\le C\|w\|_{1,h}\qquad\forall w\in\mathrm{H}^1(\Omega,\mathcal{T}_h),\tag{3.4}$$

where C is a constant independent of h and w. The next lemma will play a key role.

LEMMA 3.2 (broken Sobolev–Poincaré inequality). *There exists a positive constant C, independent of h, such that for any $q\in[1,\infty)$ when $d=2$ and any $q\in[1,2d/(d-2)]$ when $d\ge3$,*

$$\|w\|_{0,q,\Omega}\le C|||w|||_{1,h}\qquad\forall w\in\mathrm{H}^1(\Omega,\mathcal{T}_h).\tag{3.5}$$

Proof. From [30, Theorem 3.7], using the notation therein, we define Ψ as in Example 3.6 of that paper, with $\psi\in\mathrm{L}^2(\partial\Omega)$, $\psi\equiv0$ on Γ_{N}, to obtain (3.5). ∎

LEMMA 3.3. *Suppose that f satisfies* (**A**). *Then, there exists a positive constant $C_f=C_f(\gamma,G_f,d,|\Omega|)$ such that*

$$|(f(\,\cdot\,,t,u)-f(\,\cdot\,,t,v),w)|\le C_f\|u-v\|_{0,\Omega}\left(1+|||u|||_{1,h}^{\gamma}+|||v|||_{1,h}^{\gamma}\right)\|w\|_{1,h}\tag{3.6}$$

for all u, v, $w\in\mathrm{H}^1(\Omega,\mathcal{T}_h)$ and a.e. $t\in(0,T]$.

Proof. Let $u,v,w\in\mathrm{H}^1(\Omega,\mathcal{T}_h)$. Let $p>1$ and $1/p+1/q=1$. By applying

Hölder's inequality, we obtain that, for a.e. $t \in (0,T]$,

$$\begin{aligned}|(f(\cdot,t,u)-f(\cdot,t,v),w)| &\le G_f \int_\Omega |u-v|\,(1+|u|+|v|)^\gamma\,|w|\,\mathrm{d}x\\ &\le G_f \left(\int_\Omega |u-v|^2\,\mathrm{d}x\right)^{1/2}\left(\int_\Omega (1+|u|+|v|)^{2\gamma}\,|w|^2\,\mathrm{d}x\right)^{1/2}\\ &\le G_f \left(\int_\Omega |u-v|^2\,\mathrm{d}x\right)^{1/2}\left(\int_\Omega (1+|u|+|v|)^{2\gamma p}\,\mathrm{d}x\right)^{1/2p}\left(\int_\Omega |w|^{2q}\,\mathrm{d}x\right)^{1/2q}.\end{aligned}$$

When $d \ge 3$ we take $p = d/2$, $q = d/(d-2)$; while if $d = 2$, we take any $p > 1$ and put $q = p/(p-1)$. The desired inequality then follows by using the broken Sobolev–Poincaré inequality (3.5), with q thus defined, and by applying (3.4). ∎

We recall the following approximation result for the space $S^{\mathbf{P}}(\Omega,\mathcal{T}_h,\mathbf{F})$.

LEMMA 3.4. *Suppose that $\kappa \in \mathcal{T}_h$ with $h_\kappa = \mathrm{diam}(\bar\kappa)$ and $u|_\kappa \in \mathrm{H}^{k_\kappa}(\kappa)$ for some $k_\kappa \ge 0$; then there exists a sequence of algebraic polynomials $z_{p_\kappa}^{h_\kappa}(u) \in \mathcal{R}_{p_\kappa}(\kappa)$, $p_\kappa \ge 1$, such that for any l, with $0 \le l \le s_\kappa$,*

$$\|u - z_{p_\kappa}^{h_\kappa}(u)\|_{l,\kappa} \le C\,\frac{h_\kappa^{s_\kappa - l}}{p_\kappa^{k_\kappa - l}}\,\|u\|_{k_\kappa,\kappa}, \tag{3.7}$$

and when $k_\kappa > 1/2$, then

$$\|u - z_{p_\kappa}^{h_\kappa}(u)\|_{0,e_\kappa} \le C\,\frac{h_\kappa^{s_\kappa - 1/2}}{p_\kappa^{k_\kappa - 1/2}}\,\|u\|_{k_\kappa,\kappa}; \tag{3.8}$$

further, if $k_\kappa > 3/2$, then

$$\|\nabla(u - z_{p_\kappa}^{h_\kappa}(u))\|_{0,e_\kappa} \le C\,\frac{h_\kappa^{s_\kappa - 3/2}}{p_\kappa^{k_\kappa - 3/2}}\,\|u\|_{k_\kappa,\kappa}, \tag{3.9}$$

where e_κ is any face $e_\kappa \subset \partial\kappa$, $s_\kappa = \min\{p_\kappa + 1, k_\kappa\}$, and C is a constant independent of u, h_κ, and p_κ but dependent on $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$.

Proof. For the proof of (3.7), see [3, Lemma 4.5] for $d = 2$ (the argument being analogous when $d > 2$). By using the multiplicative trace inequality

$$\|u\|_{0,\partial\kappa} \le C(d)\left(h_\kappa^{-1/2}\|u\|_{0,\kappa} + \|u\|_{0,\kappa}^{1/2}\|\nabla u\|_{0,\kappa}^{1/2}\right),$$

we obtain (3.8) and (3.9) from (3.7). ∎

Remark 3.5. If the reference element $\hat\kappa$ is the d-dimensional hypercube, instead of the Babuška–Suri projector $z_{p_\kappa}^{h_\kappa}$ we can use the Jackson-type quasi-interpolation operator $J_{p_\kappa}^{k_\kappa}$ (for its definition see [14, Chapter 7]; the error bounds are presented in [31, Theorem A.3]).

We require the following bound on the bilinear form $B(\cdot,\cdot)$ (see [22] for a proof), a key ingredient of which is the inverse inequality

$$\|\nabla w\|_{0,\partial\kappa\cap\Gamma_{\mathrm{D}}}^2 \le C_{\mathrm{inv}}\frac{p_\kappa^2}{h_\kappa}\|\nabla w\|_{0,\kappa}^2, \tag{3.10}$$

where the constant C_{inv} depends only on the shape-regularity constant of the family $\{\mathcal{T}_h\}$ (see Schwab [37, Theorem 4.76, inequality (4.6.4)]).

LEMMA 3.6. *There exists a positive constant C, independent of the discretization parameters, such that the following inequality holds for all $v \in \mathrm{H}^1(\Omega, \mathcal{T}_h)$ and all $w \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$:*

$$
\begin{aligned}
|B(v,w)| \le C\,\|w\|_{1,h} \int_{\Gamma_{\mathrm{D}}} \sigma\,|v|^2\,\mathrm{d}s + \int_{\Gamma_{\mathrm{int}}} \sigma\,[\![v]\!]^2\,\mathrm{d}s + \sum_{\kappa\in\mathcal{T}_h} \|\nabla v\|^2_{0,\kappa} \\
+ \sum_{\kappa\in\mathcal{T}_h} \left(\|\sqrt{\tau} v\|^2_{0,\partial\kappa\cap\Gamma_{\mathrm{D}}} + \|\sigma^{-1/2}\nabla v\|^2_{0,\partial\kappa\cap\Gamma_{\mathrm{D}}}\right) \\
+ \sum_{\kappa\in\mathcal{T}_h} \left(\|\sqrt{\tau}\,[\![v]\!]\,\|^2_{0,\partial\kappa\cap\Gamma_{\mathrm{int}}} + \|\sigma^{-1/2}\nabla v\|^2_{0,\partial\kappa\cap\Gamma_{\mathrm{int}}}\right)^{1/2},
\end{aligned}
\tag{3.11}
$$

where $\tau_e = \{\!\{p^2\}\!\}_e/h_e$ and h_e is the diameter of a face $e \subset \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$; when $e \in \mathcal{E}_{\mathrm{D}}$ the contribution from outside Ω in the definition of τ_e is set to 0.

Next, we shall investigate the coercivity of the bilinear form $B : S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F}) \times S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F}) \to \mathbb{R}$ defined by (2.3). In the nonsymmetric case (with $\theta = 1$) coercivity follows directly as, for any $w \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$, we have $B_{\mathrm{NS}}(w,w) = \|w\|^2_{1,h}$.

Consider now the symmetric bilinear form (2.3) (with $\theta = -1$). We have, for any $w \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$,

$$
\begin{aligned}
B_{\mathrm{S}}(w,w) = \sum_{\kappa\in\mathcal{T}_h} \|\nabla w\|^2_{0,\kappa} + \int_{\Gamma_{\mathrm{D}}} \left(\sigma w^2 - 2w(\nabla w\cdot\nu)\right)\,\mathrm{d}s \\
+ \int_{\Gamma_{\mathrm{int}}} \left(\sigma\,[\![w]\!]^2 - 2\,[\![w]\!]\,\{\!\{\nabla w\cdot\nu\}\!\}\right)\,\mathrm{d}s.
\end{aligned}
$$

Clearly, the integrands in the last two terms need not be positive for $w \neq 0$ unless σ is chosen sufficiently large: the purpose of the analysis that now follows is to assess just how large σ needs to be to ensure coercivity of $B_{\mathrm{S}}(\,\cdot\,,\,\cdot\,)$ over $S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F}) \times S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$.

For any positive number τ_e we have

$$
-2\int_{\Gamma_{\mathrm{D}}} w(\nabla w\cdot\nu)\,\mathrm{d}s \ge -\sum_{e\in\mathcal{E}_{\mathrm{D}}} \left(\int_e \tau_e w^2\,\mathrm{d}s + \int_e \tau_e^{-1}(\nabla w\cdot\nu)^2\,\mathrm{d}s\right).
$$

Omitting the summation sign but retaining the minus sign in front of it, we see that the second term on the right-hand side can be further bounded below by using the inverse inequality (3.10), the shape-regularity condition (to relate h_κ to h_e, where κ is the element whose face $e \in \mathcal{E}_{\mathrm{D}}$ is) and letting $p_e = p_\kappa$ for $e \subset \partial\kappa\cap\Gamma_{\mathrm{D}}$; by absorbing all constants into C_τ, we thus obtain

$$
-\int_e \tau_e^{-1}(\nabla w\cdot\nu)^2\,\mathrm{d}s \ge -\int_e \tau_e^{-1}\,|\nabla w|^2\,|\nu|^2\,\mathrm{d}s \ge -\tau_e^{-1} C_\tau \frac{p_e^2}{h_e}\,\|\nabla w\|^2_{0,\kappa},
$$

and hence

$$
-2\int_{\Gamma_{\mathrm{D}}} w(\nabla w\cdot\nu)\,\mathrm{d}s \ge -\sum_{e\in\mathcal{E}_{\mathrm{D}}} \left(\int_e \tau_e w^2\,\mathrm{d}s + \tau_e^{-1} C_\tau \frac{p_e^2}{h_e}\|\nabla w\|^2_{0,\kappa}\right).
$$

Similarly, for the term involving faces $e \in \mathcal{E}_{\rm int}$, we have, using the bounded local variation condition (to relate p_κ^2 to $\{\!\{p^2\}\!\}_e$),

$$-2\int_{\Gamma_{\rm int}} [\![w]\!]\,\{\!\{\nabla w\cdot\nu\}\!\}\,{\rm d}s \geq -\sum_{e\in\mathcal{E}_{\rm int}}\left(\int_e \tau_e\,[\![w]\!]^2\,{\rm d}s + \tau_e^{-1}C_\tau\frac{\{\!\{p^2\}\!\}_e}{2h_e}\left(\|\nabla w\|^2_{0,\kappa'}+\|\nabla w\|^2_{0,\kappa''}\right)\right);$$

here κ' and κ'' are the two elements that have e as their common face.

Thanks to our assumption that no face e of any element $\kappa\in\mathcal{T}_h$ contains more than one hanging node, it follows that no element κ can have more than $2d\cdot 2^{d-1}=2^d d$ faces if $\hat\kappa$ is the d-dimensional hypercube, or more than $(d+1)d$ faces if $\hat\kappa$ is the d-dimensional simplex. On writing $c_d=\max\left\{2^d d,(d+1)d\right\}=2^d d$, we then let $\tau_e:=c_dC_\tau\{\!\{p^2\}\!\}_e/h_e$ for $e\in\mathcal{E}_{\rm D}\cup\mathcal{E}_{\rm int}$ (with the convention that, for $e\in\mathcal{E}_{\rm D}$, $\{\!\{p^2\}\!\}_e=p_e^2/2=p_\kappa^2/2$ where κ is the element in $\mathcal{T}_h$ with face e); hence,

$$B_{\rm S}(w,w)\geq\frac{1}{2}\sum_{\kappa\in\mathcal{T}_h}\|\nabla w\|^2_{0,\kappa}+\int_{\Gamma_{\rm D}}(\sigma-\tau)w^2\,{\rm d}s+\int_{\Gamma_{\rm int}}(\sigma-\tau)\,[\![w]\!]^2\,{\rm d}s.$$

Choosing σ_e appropriately, i.e., letting $\sigma_e=C_\sigma\{\!\{p^2\}\!\}_e/h_e$ with the penalty constant $C_\sigma>0$ large enough (that is, with $C_\sigma>c_dC_\tau$), will ensure that $\sigma_e>\tau_e$ for all $e\in\mathcal{E}_{\rm int}\cup\mathcal{E}_{\rm D}$, and hence that the symmetric bilinear form $B_{\rm S}(\cdot,\cdot)$ is coercive. When $e\in\mathcal{E}_{\rm D}$ the contribution from outside Ω in the definition of σ_e is set to 0. Thus, we adopt the following hypothesis concerning the choice of the penalty constant C_σ:

(**B**) In the *nonsymmetric* case (when $\theta=1$) we take any $C_\sigma>0$. In the *symmetric* case (when $\theta=-1$) we take $C_\sigma>c_dC_\tau$.

We summarize our findings about the bilinear forms $B_{\rm NS}(\,\cdot\,,\,\cdot\,)$ and $B_{\rm S}(\,\cdot\,,\,\cdot\,)$ in the next lemma.

LEMMA 3.7. *The nonsymmetric bilinear form $B_{\rm NS}(\,\cdot\,,\,\cdot\,)$ is coercive in the norm $\|\,\cdot\,\|_{1,h}$ over the space $\mathrm{H}^1(\Omega,\mathcal{T}_h)\times\mathrm{H}^1(\Omega,\mathcal{T}_h)$; more precisely,*

$$B_{\rm NS}(w,w)=\|w\|^2_{1,h}\qquad\forall w\in\mathrm{H}^1(\Omega,\mathcal{T}_h).$$

With the constant C_σ chosen as in (**B**)*, the symmetric bilinear form $B_{\rm S}(\,\cdot\,,\,\cdot\,)$ induces a norm $\|\,\cdot\,\|_B$ on the finite element space $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$; moreover, there exists a positive constant c_0 such that*

$$B_{\rm S}(w,w)=\|w\|_B^2\geq c_0\|w\|^2_{1,h}\qquad\forall w\in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}),$$

i.e., $B_{\rm S}(\,\cdot\,,\,\cdot\,)$ is coercive in $\|\,\cdot\,\|_{1,h}$ over the space $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})\times S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$.

Let us consider the projection operator Π from $\mathrm{H}^2(\Omega,\mathcal{T}_h)$ onto the finite element space $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ defined (for $u\in\mathrm{H}^2(\Omega,\mathcal{T}_h)$) by

$$B(u-\Pi u,v)=0\qquad\forall v\in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}).\tag{3.12}$$

As $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ is a finite-dimensional linear space, the existence of a unique Πu in $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ for each $u\in\mathrm{H}^2(\Omega,\mathcal{T}_h)$ follows from the coercivity of the bilinear form $B(\,\cdot\,,\,\cdot\,)$ over $S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})\times S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$; Πu will be referred to as the *broken elliptic projection* of u, and $\Pi:\mathrm{H}^2(\Omega,\mathcal{T}_h)\to S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ as the *broken elliptic projector*.

Next, we establish bounds on the approximation error $u-\Pi u$, in the H^1 and L^2 norms, for the broken elliptic projector Π.

Suppose that $\Omega \subset \mathbb{R}^d$, $d \geq 2$, is a bounded open polyhedral domain with Lipschitz-continuous boundary. We shall say that Ω is H^2-*regular* if, for any $u \in \mathrm{H}^1_0(\Omega)$ with $\Delta u \in \mathrm{L}^2(\Omega)$, u belongs to $\mathrm{H}^2(\Omega) \cap \mathrm{H}^1_0(\Omega)$ and there exists a constant $c_* = c_*(\Omega, d) > 0$, independent of u, such that $\|u\|_{\mathrm{H}^2(\Omega)} \leq c_* \|\Delta u\|_{\mathrm{L}^2(\Omega)}$.

LEMMA 3.8. *Suppose that $u|_\kappa \in \mathrm{H}^{k_\kappa}(\kappa)$ for some Sobolev index $k_\kappa \geq 2$ and each $\kappa \in \mathcal{T}_h$. Let Πu be the projection of $u \in \mathrm{H}^2(\Omega, \mathcal{T}_h)$ onto $S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$, defined by (3.12), with $p_\kappa \geq 1$ for each $\kappa \in \mathcal{T}_h$, and*

$$\sigma_e = C_\sigma \{\!\{p^2\}\!\}|_e / h_e,$$

*where C_σ is as in (**B**), and h_e is the diameter of a face $e \in \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$; when $e \in \mathcal{E}_{\mathrm{D}}$, the contribution from outside Ω in the definition of σ_e is set to 0. Then, the following error bound holds:*

$$\|u - \Pi u\|^2_{1,h} \leq C \sum_{\kappa \in \mathcal{T}_h} \frac{h_\kappa^{2s_\kappa - 2}}{p_\kappa^{2k_\kappa - 3}} \|u\|^2_{k_\kappa, \kappa}, \tag{3.13}$$

where $s_\kappa = \min\{p_\kappa + 1, k_\kappa\}$, and the constant C is independent of u, p_κ, and h_κ but depends on $k = \max_{\kappa \in \mathcal{T}_h} k_\kappa$, the parameter ρ in (2.2), and C_σ.

Moreover, if $\theta = -1$, Γ_N is empty (i.e., $\Gamma_{\mathrm{D}} = \partial\Omega$) and Ω is an H^2-regular polyhedral domain, we have

$$\|u - \Pi u\|^2_{0,\Omega} \leq C \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \sum_{\kappa \in \mathcal{T}_h} \frac{h_\kappa^{2s_\kappa - 2}}{p_\kappa^{2k_\kappa - 3}} \|u\|^2_{k_\kappa, \kappa}, \tag{3.14}$$

where $s_\kappa = \min\{p_\kappa + 1, k_\kappa\}$, and the constant C is independent of u, p_κ, and h_κ but depends on $k = \max_{\kappa \in \mathcal{T}_h} k_\kappa$, the parameter ρ in (2.2), the constant C_σ, and Ω.

Proof. By recalling the definition of the norm (3.2) and applying Lemma 3.7, we have that $B(w, w) \geq c_0 \|w\|^2_{1,h}$ for all $w \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$. On writing $u - \Pi u = (u - z^{h_\kappa}_{p_\kappa}(u)) + (z^{h_\kappa}_{p_\kappa}(u) - \Pi u) =: \eta + \xi$, with the projection operator $u \mapsto z^{h_\kappa}_{p_\kappa}(u)$ defined as in Lemma 3.4, and taking $v = \xi$ in the definition of the broken elliptic projector (3.12), we then deduce that

$$c_0 \|\xi\|^2_{1,h} \leq B(\xi, \xi) = B((u - \Pi u) - \eta, \xi) = -B(\eta, \xi) \leq |B(\eta, \xi)|.$$

By Lemma 3.6 with $v = \eta$, $w = \xi$, and the above inequality, noting that $\sigma_e = C_\sigma \{\!\{p^2\}\!\}|_e / h_e > \tau_e$, with h_e the diameter of a face $e \in \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$ and with the contribution from outside Ω in $\{\!\{p^2\}\!\}|_e$ set to 0 for $e \in \mathcal{E}_{\mathrm{D}}$, we have that

$$\|\xi\|^2_{1,h} \leq C \sum_{\kappa \in \mathcal{T}_h} \Big(\|\sqrt{\sigma}\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{D}}} + \|\sqrt{\sigma}\,[\![\eta]\!]\,\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{int}}} + \|\nabla\eta\|^2_{0,\kappa} + \|\sigma^{-1/2}\nabla\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{D}}} + \|\sigma^{-1/2}\nabla\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{int}}} \Big).$$

Using the triangle inequality $\|u - \Pi u\|_{1,h} \leq \|\eta\|_{1,h} + \|\xi\|_{1,h}$ and recalling the definition of the norm $\|\cdot\|_{1,h}$, we then obtain the bound

$$\|u - \Pi u\|^2_{1,h} \leq C \sum_{\kappa \in \mathcal{T}_h} \Big(\|\sqrt{\sigma}\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{D}}} + \|\sqrt{\sigma}\,[\![\eta]\!]\,\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{int}}} + \|\nabla\eta\|^2_{0,\kappa} + \|\sigma^{-1/2}\nabla\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{D}}} + \|\sigma^{-1/2}\nabla\eta\|^2_{0,\partial\kappa \cap \Gamma_{\mathrm{int}}} \Big). \tag{3.15}$$

From Lemma 3.4, inequalities (3.7)–(3.9), we deduce that

$$\|\eta\|^2_{0,\partial\kappa} \le C\frac{h_\kappa^{2s_\kappa-1}}{p_\kappa^{2k_\kappa-1}}\|u\|^2_{k_\kappa,\kappa},\ \|\nabla\eta\|^2_{0,\partial\kappa} \le C\frac{h_\kappa^{2s_\kappa-3}}{p_\kappa^{2k_\kappa-3}}\|u\|^2_{k_\kappa,\kappa},\ \|\eta\|^2_{1,\kappa} \le C\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-2}}\|u\|^2_{k_\kappa,\kappa}.$$

Applying these bounds to the right-hand side of (3.15), choosing σ_e as assumed in the statement of the lemma, and noting the bounded local variation condition (2.2) and the shape-regularity of $\mathcal{T}_h$ to relate h_e to h_κ, we obtain the bound

$$\|u-\Pi u\|^2_{1,h} \le C\sum_{\kappa\in\mathcal{T}_h}\left(\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-2}} + \frac{p_\kappa^2}{h_\kappa}\frac{h_\kappa^{2s_\kappa-1}}{p_\kappa^{2k_\kappa-1}}\right)\|u\|^2_{k_\kappa,\kappa},$$

and hence (3.13).

To estimate $\|u-\Pi u\|_{0,\Omega}$ in the case of $\theta=-1$ and $\Gamma_{\rm D}=\partial\Omega$, when Ω is H^2-regular, we shall use the Aubin–Nitsche duality argument (see [6]). Let $(\,\cdot\,,\,\cdot\,)$ signify the L^2 inner product over Ω. Then,

$$\|u-\Pi u\|_{0,\Omega} = \sup_{\substack{g\in \mathrm{L}^2(\Omega)\\ g\neq 0}} \frac{(u-\Pi u, g)}{\|g\|_{0,\Omega}}. \tag{3.16}$$

For $g\in\mathrm{L}^2(\Omega)$ fixed, $g\neq 0$, let $w=w_g\in\mathrm{H}^1_0(\Omega)$ be the weak solution of the problem

$$\begin{aligned} -\Delta w &= g \qquad \text{in} \qquad \Omega,\\ w &= 0 \qquad \text{on} \qquad \partial\Omega. \end{aligned} \tag{3.17}$$

Since Ω is H^2-regular, we have that $w\in\mathrm{H}^2(\Omega)\cap\mathrm{H}^1_0(\Omega)$, and there exists a positive constant c_*, independent of g and w, such that

$$\|w\|_{2,\Omega} \le c_*\|g\|_{0,\Omega}. \tag{3.18}$$

Moreover, $w\in\mathrm{C}^1(\Omega)$ by [18, Corollary 8.36]. The SIP DGFEM approximation of the problem (3.17) is as follows:

$$\text{Find}\ \ w_{\rm DG}\in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})\ \ \text{such that}\ \ B_{\rm S}(w_{\rm DG},v)=\ell_g(v)\qquad \forall v\in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F}),$$

where $B_{\rm S}(w,v)$ is defined by (2.3) with $\theta=-1$, and $\ell_g(v)=(g,v)+\ell_{\rm S}(v)$, where $\ell_{\rm S}(v)$ is defined by (2.4) with $\theta=-1$ and $g_{\rm D}=0$ on $\Gamma_{\rm D}=\partial\Omega$ (also, as $\Gamma_{\rm N}=\emptyset$, the integral over $\Gamma_{\rm N}$ in (2.4) vanishes); clearly, then, $\ell_{\rm S}(v)=0$ for all v in $\mathrm{H}^2(\Omega,\mathcal{T}_h)$.

Using the fact that $w\in\mathrm{H}^2(\Omega)\cap\mathrm{H}^1_0(\Omega)\cap\mathrm{C}^1(\Omega)$, we deduce that $B_{\rm S}(w,v)=\ell_g(v)$ for all $v\in\mathrm{H}^2(\Omega,\mathcal{T}_h)$. Moreover, by the definition of the broken elliptic projector (3.12), $B_{\rm S}(u-\Pi u,v)=0$ for all $v\in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$, and hence

$$\begin{aligned}(u-\Pi u,g) &= (g,u-\Pi u)=\ell_g(u-\Pi u)=B_{\rm S}(w,u-\Pi u)\\ &= B_{\rm S}(u-\Pi u,w)=B_{\rm S}(u-\Pi u,w-z^{h_\kappa}_{p_\kappa}(w)).\end{aligned}$$

Further, on denoting $\eta_w:=w-z^{h_\kappa}_{p_\kappa}(w)$, by (3.11), and noting that $\sigma_e=C_\sigma\{\!\{p^2\}\!\}|_e/h_e>\tau_e$, with h_e the diameter of a face $e\in\mathcal{E}_{\rm int}\cup\mathcal{E}_{\rm D}$ and with the contribution from outside

Ω in $\{\!\{p^2\}\!\}|_e$ set to 0 for $e \in \mathcal{E}_{\rm D}$, we have that

(3.19)
$$(u-\Pi u, g) = B_{\rm S}(u-\Pi u, \eta_w) \le C\,\|u-\Pi u\|_{1,h} \left\{ \int_{\Gamma_{\rm D}} \sigma\,|\eta_w|^2\,{\rm d}s + \int_{\Gamma_{\rm int}} \sigma\,[\![\eta_w]\!]^2\,{\rm d}s \right.$$
$$\left. + \sum_{\kappa\in\mathcal{T}_h} \left(\|\nabla\eta_w\|^2_{0,\kappa} + \|\sigma^{-1/2}\nabla\eta_w\|^2_{0,\partial\kappa\cap\Gamma_{\rm D}} + \|\sigma^{-1/2}\nabla\eta_w\|^2_{0,\partial\kappa\cap\Gamma_{\rm int}} \right) \right\}^{1/2}.$$

Applying (3.13) and inequalities (3.7)–(3.9) from Lemma 3.4 to the right-hand side of (3.19), choosing σ_e as described in the statement of Lemma 3.8 above, and noting the bounded local variation condition (2.2) and the shape-regularity of $\mathcal{T}_h$ to relate h_e to h_κ, we obtain

$$(u-\Pi u, g) \le C \left(\sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\,\|u\|^2_{k_\kappa,\kappa} \times \sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa}\|w\|^2_{2,\kappa} \right)^{1/2}.$$

By observing that

$$\sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa}\|w\|^2_{2,\kappa} \le \left(\max_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \sum_{\kappa\in\mathcal{T}_h} \|w\|^2_{2,\kappa} = \left(\max_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \|w\|^2_{2,\Omega}$$

and noting (3.18), we obtain

$$(u-\Pi u, g) \le C \left(\left(\max_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\,\|u\|^2_{k_\kappa,\kappa} \right)^{1/2} \|g\|_{0,\Omega},$$

and therefore, for any $g \in {\rm L}^2(\Omega)$, $g \neq 0$,

$$\frac{(u-\Pi u, g)}{\|g\|_{0,\Omega}} \le C \left(\left(\max_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\,\|u\|^2_{k_\kappa,\kappa} \right)^{1/2}.$$

Recalling (3.16), taking the supremum over $g \in {\rm L}^2(\Omega)$, $g \neq 0$, and squaring the resulting expression yields (3.14). ∎

Remark 3.9. When $d \in \{2,3\}$, any convex bounded open polyhedral domain $\Omega \subset \mathbb{R}^d$ is ${\rm H}^2$-regular in the sense defined above (see Theorem 3.1.2.1 on page 139 of [19]). A similar result holds for mixed homogeneous Dirichlet–homogeneous Neumann boundary conditions, provided that the internal angles of the polyhedron are sufficiently small (cf. [13, Chapter 8]), with the definition of ${\rm H}^2$-regularity suitably adjusted. The error bound (3.14) still holds then in this, more general, case. For simplicity, though, we have confined ourselves to the case when $\Gamma_{\rm N} = \emptyset$.

3.2. Error analysis of the nonsymmetric version of DGFEM. Let the bilinear form B be as in (2.3). In this section we shall be concerned with the nonsymmetric version of DGFEM corresponding to $\theta = 1$ in (2.3), so we write $B_{\rm NS}(\,\cdot\,,\,\cdot\,)$ in place of $B(\,\cdot\,,\,\cdot\,)$. Our aim is to derive a bound on the ${\rm H}^1$ norm of the error $u - u_{\rm DG}$. Here $u_{\rm DG}$ is the NSIP DGFEM approximation of the analytical solution u. We decompose the error as $u - u_{\rm DG} = \eta + \xi$, where $\eta := u - \Pi u$ and $\xi := \Pi u - u_{\rm DG}$, with

Π denoting the broken elliptic projector defined in (3.12) with $\theta = 1$. We assume for simplicity that the initial value is chosen as $u_0^{\mathrm{DG}} = \Pi u_0$, and thus $\xi(0) = 0$.

As in (**B**), we shall suppose throughout this section that $\sigma_e = C_\sigma \{\!\{p^2\}\!\}_e / h_e$, where $C_\sigma > 0$ is an arbitrary positive constant, and h_e is the diameter of a face $e \in \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$; when $e \in \mathcal{E}_{\mathrm{D}}$, the contribution from outside Ω in the definition of σ_e is set to 0.

LEMMA 3.10. *Let f satisfy* (**A**) *and assume that $u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega))$. Suppose further that*

(a) *$p_\kappa \geq 2$ and $u|_\kappa \in \mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))$ with $k_\kappa \geq 3\frac{1}{2}$ on each $\kappa \in \mathcal{T}_h$;*

(b) *the hp-mesh is quasi-uniform in the sense that there exists a positive constant C_0 such that*

$$\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2} \leq C_0 \min_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2}. \tag{3.20}$$

Then, there exists $h_0 \in (0,1]$ and a positive constant C independent of the discretization parameters, such that for all $h \in (0,h_0]$, $h = \max_{\kappa \in \mathcal{T}_h} h_\kappa$, and for all $t \in [0,T]$ we have

$$\int_0^t \|(u - u_{\mathrm{DG}})(s)\|_{1,h}^2 \,\mathrm{d}s \leq C \int_0^t \left\{ \|\eta(s)\|_{1,h}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} \mathrm{d}s. \tag{3.21}$$

Proof. Let $t_{\star\star} \in (0,T]$ be such that $u_{\mathrm{DG}}(t) \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$ exists for all $t \in [0, t_{\star\star})$. The existence of such a $t_{\star\star}$ is ensured by Carathéodory's theorem (see [39, Theorems II.4.1 and II.4.5]). Thus, either $t_{\star\star} = T$, or $t_{\star\star} < T$ and $\limsup_{t \to t_{\star\star}} \|u_{\mathrm{DG}}(t)\|_{1,h} = +\infty$. In fact, we shall show below that, for h sufficiently small, $t_{\star\star} = T$.

From the formulation of the *hp*-DGFEM (2.6), for all $v \in S^{\mathbf{p}}(\Omega, \mathcal{T}_h, \mathbf{F})$, we have

$$\int_\Omega u_{\mathrm{DG}}' v \,\mathrm{d}x + B_{\mathrm{NS}}(u_{\mathrm{DG}}, v) = \int_\Omega f(x,t,u_{\mathrm{DG}}) v \,\mathrm{d}x + \ell_{\mathrm{NS}}(v) \tag{3.22}$$

for all $t \in (0, t_{\star\star})$. On the other hand, the broken weak formulation (2.5) implies that

$$\begin{aligned} \int_\Omega (\Pi u') v \,\mathrm{d}x + B_{\mathrm{NS}}(\Pi u, v) &= \int_\Omega f(x,t,u) v \,\mathrm{d}x + \ell_{\mathrm{NS}}(v) \\ &\quad + \int_\Omega (\Pi u' - u') v \,\mathrm{d}x + B_{\mathrm{NS}}(\Pi u - u, v) \end{aligned} \tag{3.23}$$

for all $v \in \mathrm{H}^2(\Omega, \mathcal{T}_h)$ and all $t \in (0,T]$. Upon subtracting (3.22) from (3.23) and taking $v = \xi = \Pi u - u_{\mathrm{DG}}$, we obtain

$$\int_\Omega \xi' \xi \,\mathrm{d}x + B_{\mathrm{NS}}(\xi, \xi) = \int_\Omega \{f(x,t,u) - f(x,t,u_{\mathrm{DG}})\} \xi \,\mathrm{d}x - \int_\Omega \eta' \xi \,\mathrm{d}x - B_{\mathrm{NS}}(\eta, \xi)$$

for all $t \in (0, t_{\star\star})$. By virtue of (3.12) we have $B_{\mathrm{NS}}(\eta, \xi) = 0$. Hence, by noting that $\|\xi\|_{1,h}^2 = B_{\mathrm{NS}}(\xi, \xi)$, we deduce from the above identity that

$$\begin{aligned} \frac{1}{2} \frac{\mathrm{d}}{\mathrm{d}t} \|\xi\|_{0,\Omega}^2 + \|\xi\|_{1,h}^2 &\leq \left| \int_\Omega \{f(x,t,u) - f(x,t,\Pi u)\} \xi \,\mathrm{d}x \right| \\ &\quad + \left| \int_\Omega \{f(x,t,\Pi u) - f(x,t,u_{\mathrm{DG}})\} \xi \,\mathrm{d}x \right| + \left| \int_\Omega \eta' \xi \,\mathrm{d}x \right| \end{aligned} \tag{3.24}$$

for all $t \in (0, t_{\star\star})$. By the Cauchy–Schwarz inequality and Cauchy's inequality, with $\varepsilon_1 > 0$, we have

$$\left| \int_\Omega \eta' \xi \, \mathrm{d}x \right| \leq \|\eta'\|_{0,\Omega} \|\xi\|_{0,\Omega} \leq \frac{\varepsilon_1}{2} \|\eta'\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_1} \|\xi\|_{0,\Omega}^2.$$

By the same argument, with ε_2, $\varepsilon_3 > 0$, we have

$$\left| \int_\Omega \{f(x,t,u) - f(x,t,\Pi u)\} \, \xi \, \mathrm{d}x \right| \leq \frac{\varepsilon_2}{2} \|f(\,\cdot\,,t,u) - f(\,\cdot\,,t,\Pi u)\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_2} \|\xi\|_{0,\Omega}^2,$$

$$\left| \int_\Omega \{f(x,t,\Pi u) - f(x,t,u_{\mathrm{DG}})\} \, \xi \, \mathrm{d}x \right| \leq \frac{\varepsilon_3}{2} \|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_3} \|\xi\|_{0,\Omega}^2.$$

Further, by Lemma 3.1, upon absorbing all constants into C and using the broken Sobolev–Poincaré inequality and (3.4), for a.e. $t \in (0,T]$ we have that

$$\begin{aligned}
&\|f(\,\cdot\,,t,u) - f(\,\cdot\,,t,\Pi u)\|_{0,\Omega}^2 \\
&\quad \leq C_f^2 \|\eta\|_{0,2(\gamma+1),\Omega}^2 \left(1 + \|u\|_{0,2(\gamma+1),\Omega}^{\gamma} + \|\Pi u\|_{0,2(\gamma+1),\Omega}^{\gamma}\right)^2 \\
&\quad \leq C \|\eta\|_{0,2(\gamma+1),\Omega}^2 \left(1 + \|u\|_{0,2(\gamma+1),\Omega}^{2\gamma} + \|\Pi u - u\|_{0,2(\gamma+1),\Omega}^{2\gamma}\right) \\
&\quad = C \|\eta\|_{0,2(\gamma+1),\Omega}^2 \left(1 + \|u\|_{0,2(\gamma+1),\Omega}^{2\gamma} + \|\eta\|_{0,2(\gamma+1),\Omega}^{2\gamma}\right) \\
&\quad \leq C \|\eta\|_{0,2(\gamma+1),\Omega} \left(1 + \|u\|_{0,2(\gamma+1),\Omega}^{2\gamma} + \|\eta\|_{1,h}^{2\gamma}\right) \\
&\quad \leq C \|\eta\|_{0,2(\gamma+1),\Omega}^2,
\end{aligned}$$

where the constant $C > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$. For ease of writing, the dependence of the norms of u, η, and Πu on t in the last chain of inequalities has been suppressed.

Applying these bounds on the right-hand side of (3.24) with $\varepsilon_1 = \varepsilon_2 = 1$ (the value of ε_3 will be fixed below) and absorbing all constants into C_1 and $C_2 = C_2(\varepsilon_3)$, we obtain

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}t} \|\xi(t)\|_{0,\Omega}^2 + 2\|\xi(t)\|_{1,h}^2 \leq C_1 (\|\eta(t)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(t)\|_{0,\Omega}^2) + C_2 \|\xi(t)\|_{0,\Omega}^2 \\
+ \varepsilon_3 \|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2
\end{aligned} \tag{3.25}$$

for a.e. $t \in (0, t_{\star\star})$.

To bound $\|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2$, we first note that, by a very similar argument to the one above, we have, for a.e. $t \in (0, t_{\star\star})$,

$$\|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 \leq C \|\xi(t)\|_{0,2(\gamma+1),\Omega}^2 \left(1 + \|\xi(t)\|_{0,2(\gamma+1),\Omega}^{2\gamma}\right), \tag{3.26}$$

where the constant $C > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$.

For $\mathcal{T}_h$ and the polynomial degree vector $\mathbf{p}$ fixed, let $t_\star = t_\star(\mathcal{T}_h, \mathbf{p}) \in (0, t_{\star\star}]$ be the largest time such that u_{DG} exists for all $t \in [0, t_\star]$ and $\|\xi(t)\|_{1,h}^2 \leq 1$ for all $t \in [0, t_\star]$; the existence of such a $t_\star$ follows from the definition of $t_{\star\star}$, together with the fact that $t \mapsto \|\xi(t)\|_{1,h}^2$ is continuous in the neighborhood of $t = 0$ and $\|\xi(0)\|_{1,h}^2 = 0$. Our aim is to show that $t_\star = T$ for all h, sufficiently small; thereby, we will have also shown that $t_{\star\star} = T$. We have that

$$\|\xi(t)\|_{0,2(\gamma+1),\Omega}^2 \leq \text{Const.}\|\xi(t)\|_{1,h}^2 \qquad \forall t \in [0, t_\star]$$

by the broken Sobolev–Poincaré inequality (see Lemma 3.2) and (3.4); here Const. is a constant that is independent of the discretization parameters and t. This and (3.26), together with the fact that $\|\xi(t)\|_{1,h}^2 \leq 1$ for all $t \in [0, t_\star]$, imply that, for a.e. $t \in (0, t_\star]$,

$$\|f(\,\cdot\,, t, \Pi u) - f(\,\cdot\,, t, u_{\mathrm{DG}})\|_{0,\Omega}^2 \leq \tilde{C}\|\xi(t)\|_{1,h}^2,$$

where the constant $\tilde{C} > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0, t_\star)$.

On choosing $\varepsilon_3 \tilde{C} \leq 1$, after integration from 0 to $t \leq t_\star$ and noting that $\xi(0) = 0$, the inequality (3.25) yields that

$$\begin{aligned}\|\xi(t)\|_{0,\Omega}^2 + \int_0^t \|\xi(s)\|_{1,h}^2 \,\mathrm{d}s \leq & C_1 \int_0^t \left\{\|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2\right\} \mathrm{d}s \\ & + C_2 \int_0^t \|\xi(s)\|_{0,\Omega}^2 \,\mathrm{d}s \qquad \forall t \in [0, t_\star],\end{aligned} \tag{3.27}$$

with the constant $C_1 > 0$ depending only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0, T)$.

We can make the first integral on the right-hand side of (3.27) as small as we like (for example, by fixing the local polynomial degree p_κ on each element $\kappa \in \mathcal{T}_h$ and reducing $h = \max_{\kappa \in \mathcal{T}_h} h_\kappa$). In particular, let us take $h_0 \in (0, 1]$ so small that, for all $h \leq h_0$ and $t \in [0, T]$, the following inequality holds:

$$C_1 \int_0^t \left\{\|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2\right\} \mathrm{d}s < \frac{1}{1+T}\,\mathrm{e}^{-C_2 T} \times C_{\mathrm{inv}}^{-1} C_0^{-2} \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2}\right)^2,$$

where C_{inv} is the constant from the inverse inequality

$$\|\xi(t)\|_{1,h}^2 \leq C_{\mathrm{inv}} \left(\max_{\kappa \in \mathcal{T}_h} \frac{p_\kappa^2}{h_\kappa}\right)^2 \|\xi(t)\|_{0,\Omega}^2 \qquad \forall t \in [0, t_\star]. \tag{3.28}$$

We note in passing that in order to be able to extract the factor $(\max_{\kappa \in \mathcal{T}_h}(h_\kappa/p_\kappa^2))^2$ above from $\|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2$ with *strict* inequality (by using (3.5), (3.4), and (3.13)), we require hypothesis (a) of the lemma; in particular, the desired strict inequality cannot be achieved when $p_\kappa = 1$, and hence we have our assumption that $p_\kappa \geq 2$ for all $\kappa \in \mathcal{T}_h$.

Thereby, (3.27) yields

$$\|\xi(t)\|_{0,\Omega}^2 + \int_0^t \|\xi(s)\|_{1,h}^2 \,\mathrm{d}s < \frac{\mathrm{e}^{-C_2 T}}{1+T} \times C_{\mathrm{inv}}^{-1} C_0^{-2} \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2}\right)^2 + C_2 \int_0^t \|\xi(s)\|_{0,\Omega}^2 \,\mathrm{d}s$$

for all $t \in [0, t_\star]$. The Gronwall–Bellman inequality then implies that

$$\|\xi(t)\|_{0,\Omega}^2 < C_{\rm inv}^{-1} C_0^{-2} \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2} \right)^2 \qquad \forall t \in [0, t_\star].$$

By the inverse inequality (3.28) we have that,

$$\|\xi(t)\|_{1,h}^2 < C_0^{-2} \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2} \right)^2 \left(\max_{\kappa \in \mathcal{T}_h} \frac{p_\kappa^2}{h_\kappa} \right)^2 = C_0^{-2} \left(\max_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2} \right)^2 \left(\min_{\kappa \in \mathcal{T}_h} \frac{h_\kappa}{p_\kappa^2} \right)^{-2}$$

for all $t \in [0, t_\star]$, which, by the quasi-uniformity hypothesis (b) above, is ≤ 1.

Thus, for $h \leq h_0$, we have that $\|\xi(t)\|_{1,h}^2 < 1$ for all $t \in [0, t_\star]$. By continuity of the mapping $t \mapsto \|\xi(t)\|_{1,h}^2$ on $[0, t_\star]$ it follows that $t_\star = t_{\star\star}$, provided that $h \in (0, h_0]$ (otherwise $t_\star$ would *not* be the largest real number in $(0, t_{\star\star}]$ such that $\|\xi(t)\|_{1,h}^2 \leq 1$ for all $t \in [0, t_\star]$). Now, since $\|\xi(t)\|_{1,h}^2 < 1$ for all $t \in [0, t_{\star\star}]$, and hence $\limsup_{t \to t_{\star\star}} \|\xi(t)\|_{1,h} \leq 1$, it follows by the definition of ξ and the triangle inequality that

$$\limsup_{t \to t_{\star\star}} \|u_{\rm DG}(t)\|_{1,h} \leq 1 + \limsup_{t \to t_{\star\star}} \|\Pi u(t)\|_{1,h} \leq \text{Const.}$$

Therefore $t_{\star\star}$ cannot be strictly smaller than T (if it were, then we would have that $\limsup_{t \to t_{\star\star}} \|u_{\rm DG}\|_{1,h} = +\infty$). To summarize, we have shown that, for $h \leq h_0$, $u_{\rm DG}$ exists on the whole of the interval $[0, T]$ and $\|\xi(t)\|_{1,h} \leq 1$ for all $t \in [0, T]$.

From (3.27), by the Gronwall–Bellman inequality, we then obtain

$$\|\xi(t)\|_{0,\Omega}^2 + \int_0^t \|\xi(s)\|_{1,h}^2 \, {\rm d}s \leq C \int_0^t \left\{ \|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} {\rm d}s \quad \forall t \in [0, T],$$

and hence, in particular,

$$\int_0^t \|\xi(s)\|_{1,h}^2 \, {\rm d}s \leq C \int_0^t \left\{ \|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} {\rm d}s \qquad \forall t \in [0, T],$$

with the constant $C > 0$ depending only on the domain Ω, the quasi-uniformity constant C_0, the final time T, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0, T)$.

Employing the triangle inequality and applying the broken Sobolev–Poincaré inequality and (3.4), we deduce that

$$\int_0^t \|(u - u_{\rm DG})(s)\|_{1,h}^2 \, {\rm d}s \leq C \int_0^t \left\{ \|\eta(s)\|_{1,h}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} {\rm d}s \qquad \forall t \in [0, T]. \qquad \square$$

Lemma 3.10 yields the following error bound for the NSIP DGFEM (2.6).

THEOREM 3.11. *Let $\Omega \subset \mathbb{R}^d$, $d \geq 2$, be a bounded polyhedral domain with Lipschitz-continuous boundary, let $\{\mathcal{T}_h\}$ be a family of shape-regular and hp-quasi-uniform subdivisions of Ω (cf.* (b) *in Lemma* 3.10*), and suppose that $\mathbf{p}$ is a polynomial degree vector of bounded local variation. Let each face $e \in \mathcal{E}_{\rm int} \cup \mathcal{E}_{\rm D}$ be assigned a positive real number*

$$\sigma_e = \{\!\{p^2\}\!\}_e / h_e, \tag{3.29}$$

where h_e is the diameter of e, with the convention that for $e \in \mathcal{E}_{\rm D}$ the contributions from outside Ω in the definition of σ_e are set to 0*. Suppose that f satisfies* (**A**) *and*

$u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega))$. *Then, if* $p_\kappa \geq 2$ *and* $u|_\kappa \in \mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))$ *with* $k_\kappa \geq 3\frac{1}{2}$ *on each* $\kappa \in \mathcal{T}_h$, *there exists* $h_0 \in (0,1]$ *such that for all* $h \in (0,h_0]$, $h = \max_{\kappa\in\mathcal{T}_h} h_\kappa$, *and all* $t \in [0,T]$, *the solution* $u_{\mathrm{DG}}(\,\cdot\,,t) \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ *of the NSIP DGFEM* (2.6) *satisfies the following error bound:*

$$\|u-u_{\mathrm{DG}}\|^2_{\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega,\mathcal{T}_h))} \leq C\sum_{\kappa\in\mathcal{T}_h}\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\|u\|^2_{\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))}, \tag{3.30}$$

with $1 \leq s_\kappa \leq \min\{p_\kappa+1,k_\kappa\}$, $p_\kappa \geq 2$ *on each* $\kappa \in \mathcal{T}_h$, *where* C *is a positive constant depending only on the domain* Ω, *the shape-regularity and quasi-uniformity constants of* $\mathcal{T}_h$, *the final time* T, *the exponent* γ *in the growth condition for the function* f, *the parameter* ρ *in* (2.2), $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$, *and the Lebesgue and Sobolev norms of* u *over the time interval* $(0,T)$.

Proof. As before, let us choose the projector Π to be the broken elliptic projector defined by (3.12), with $\theta = 1$. From Lemma 3.8 we have the bound

$$\|\eta(s)\|^2_{1,h} \leq C\sum_{\kappa\in\mathcal{T}_h}\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\|u(s)\|^2_{k_\kappa,\kappa} \qquad \forall s\in[0,T],$$

with $1 \leq s_\kappa \leq \min\{p_\kappa+1,k_\kappa\}$, $p_\kappa \geq 1$, on each $\kappa \in \mathcal{T}_h$.

By differentiating (3.12) with respect to t we deduce that $B(u'-\Pi u',v)=0$ for all $v \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$. Hence, by applying Lemma 3.8 to u', we obtain that

$$\|\eta'(s)\|^2_{1,h} \leq C\sum_{\kappa\in\mathcal{T}_h}\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\|u'(s)\|^2_{k_\kappa,\kappa} \qquad \forall s\in[0,T],$$

and with $1 \leq s_\kappa \leq \min\{p_\kappa+1,k_\kappa\}$, $p_\kappa \geq 1$, on each $\kappa \in \mathcal{T}_h$. Therefore, by the broken Sobolev–Poincaré inequality (3.5) and (3.4), an identical bound holds for the norm $\|\eta'(s)\|_{0,\Omega}$, for all $s \in [0,T]$.

Applying these bounds in the right-hand side of (3.21) for $t \in [0,T]$, we obtain the desired bound, with $1 \leq s_\kappa \leq \min\{p_\kappa+1,k_\kappa\}$ and $p_\kappa \geq 2$ on each $\kappa \in \mathcal{T}_h$, where C is a positive constant depending only on the domain Ω, the shape-regularity and quasi-uniformity constants of $\mathcal{T}_h$, the final time T, the exponent γ in the growth condition for the function f, the parameter ρ in (2.2), $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$. □

When f is *globally* Lipschitz continuous the hypotheses (a) and (b) stated in Lemma 3.10 are redundant, as (3.27) holds automatically for all $t \in [0,T]$, and it is not necessary to separately prove that $\|\xi(t)\|_{1,h} \leq 1$ for all $t \in [0,T]$ and all h sufficiently small. As we shall now see, (a) and (b) also are redundant in the case of the SIP DGFEM.

3.3. Error analysis of the symmetric version of the DGFEM. The symmetric version of the interior penalty DGFEM appeared in the literature much earlier than the nonsymmetric formulation; see Wheeler [16]. It was not widely accepted as an effective numerical method until very recently, due to the additional condition on the minimum size of the penalty parameter which is required to ensure the coercivity of the bilinear form of the method. The renewed interest in the symmetric formulation of the interior penalty DGFEM for second-order elliptic problems can be attributed to the optimality of its convergence rate in the L^2 norm as well as for linear functionals of the solution. Indeed, the nonsymmetric formulation of the interior penalty method

for second-order elliptic problems suffers from a lack of adjoint consistency (see [2]), and, in general, it results in suboptimal a priori error bounds in the L^2 norm and in linear functionals of the solution unless the polynomial degree $p_\kappa = p$, $\kappa \in \mathcal{T}_h$, where p is odd (see [20]). Thanks to its adjoint consistency, the symmetric version of the interior penalty DGFEM does not suffer from these drawbacks.

We state our first result about the accuracy of the symmetric version of the *hp*-DGFEM. We shall assume below that u_{DG} is the SIP DGFEM approximation to the analytical solution u and $u_0^{\mathrm{DG}} = \Pi u_0$, where Π is the broken elliptic projector defined by (3.12) with $\theta = -1$.

THEOREM 3.12. *Let $\Omega \subset \mathbb{R}^d$, $d \geq 2$, be a bounded polyhedral domain with a Lipschitz-continuous boundary. Suppose that $\{\mathcal{T}_h\}$ is a family of shape-regular subdivisions of Ω and $\mathbf{p}$ is a polynomial degree vector of bounded local variation. Let each face $e \in \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$ be assigned the positive real number*

$$\sigma_e = C_\sigma \{\!\{p^2\}\!\}_e / h_e, \tag{3.31}$$

where h_e is the diameter of e, with the convention that for $e \in \mathcal{E}_{\mathrm{D}}$ the contributions from outside Ω in the definition of σ_e are set to 0, and let C_σ be as in (**B**). *Suppose that the function f satisfies* (**A**). *Then, if $u|_\kappa \in \mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))$, $k_\kappa \geq 2$, $\kappa \in \mathcal{T}_h$, and $u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega))$, there exists $h_0 \in (0,1]$ such that, for all $h \in (0,h_0]$, $h = \max_{\kappa\in\mathcal{T}_h} h_\kappa$, and $t \in [0,T]$, the solution $u_{\mathrm{DG}}(\cdot,t) \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ of the SIP DGFEM* (2.6) *satisfies the following error bound:*

$$\operatorname*{ess.\,sup}_{0\leq t\leq T} \|u(t) - u_{\mathrm{DG}}(t)\|_{1,h}^2 \leq C \sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}} \|u\|^2_{\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))}, \tag{3.32}$$

with $1 \leq s_\kappa \leq \min\{p_\kappa+1, k_\kappa\}$, $p_\kappa \geq 1$, for $\kappa \in \mathcal{T}_h$, where C is a positive constant depending only on the domain Ω, the shape-regularity constant of $\mathcal{T}_h$, the final time T, the exponent γ in the growth condition for the function f, the parameter ρ in (2.2), *the Lebesgue and Sobolev norms of u over the interval $(0,T)$, and $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$.*

Proof. Let $t_{\star\star} \in (0,T]$ be such that $u_{\mathrm{DG}}(t) \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ exists for all $t \in [0,t_{\star\star})$. Again, the existence of such a $t_{\star\star}$ is ensured by Carathéodory's theorem (see [39, Theorems II.4.1 and II.4.5]). Thus, either $t_{\star\star} = T$, or $t_{\star\star} < T$ and $\limsup_{t\to t_{\star\star}} \|u_{\mathrm{DG}}(t)\|_{1,h} = +\infty$. In fact, we shall show below that, for h sufficiently small, $t_{\star\star} = T$. Let us write $u - u_{\mathrm{DG}} = (u - \Pi u) + (\Pi u - u_{\mathrm{DG}}) =: \eta + \xi$. By the same argument as in the proof of Lemma 3.10, upon subtracting (3.22) from (3.23) and choosing $v = \xi'$, we obtain for a.e. $t \in (0,t_{\star\star})$ that

$$\|\xi'\|_{0,\Omega}^2 + B_{\mathrm{S}}(\xi,\xi') = \int_\Omega \{f(x,t,u) - f(x,t,u_{\mathrm{DG}})\}\,\xi'\,\mathrm{d}x - \int_\Omega \eta'\xi'\,\mathrm{d}x - B_{\mathrm{S}}(\eta,\xi').$$

By virtue of (3.12), $B_{\mathrm{S}}(\eta,\xi') = 0$. With the constant C_σ in (3.31) chosen large enough, the symmetric bilinear form $B_{\mathrm{S}}(\,\cdot\,,\,\cdot\,)$ is coercive and therefore defines an inner product on $\mathrm{H}^1(\Omega,\mathcal{T}_h)$, which induces the norm $\|\,\cdot\,\|_B$ on this space (cf. Lemma 3.7). Hence we deduce that $B_{\mathrm{S}}(\xi,\xi') = \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_B^2$. We thereby infer from the above equality that

$$\begin{aligned}\|\xi'\|_{0,\Omega}^2 + \frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_B^2 \leq{}& \left|\int_\Omega \eta'\xi'\,\mathrm{d}x\right| + \left|\int_\Omega \{f(x,t,u) - f(x,t,\Pi u)\}\,\xi'\,\mathrm{d}x\right| \\ &+ \left|\int_\Omega \{f(x,t,\Pi u) - f(x,t,u_{\mathrm{DG}})\}\,\xi'\,\mathrm{d}x\right|\end{aligned} \tag{3.33}$$

for a.e. $t \in (0, t_{\star\star})$. By the Cauchy–Schwarz inequality and Cauchy's inequality, we have

$$\left| \int_\Omega \eta' \xi' \, \mathrm{d}x \right| \leq \|\eta'\|_{0,\Omega} \|\xi'\|_{0,\Omega} \leq \frac{\varepsilon_1}{2} \|\eta'\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_1} \|\xi'\|_{0,\Omega}^2,$$

and, similarly,

$$\left| \int_\Omega \{f(x,t,u) - f(x,t,\Pi u)\} \xi' \, \mathrm{d}x \right| \leq \frac{\varepsilon_2}{2} \|f(\,\cdot\,,t,u) - f(\,\cdot\,,t,\Pi u)\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_2} \|\xi'\|_{0,\Omega}^2,$$

$$\left| \int_\Omega \{f(x,t,\Pi u) - f(x,t,u_{\mathrm{DG}})\} \xi' \, \mathrm{d}x \right| \leq \frac{\varepsilon_3}{2} \|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 + \frac{1}{2\varepsilon_3} \|\xi'\|_{0,\Omega}^2,$$

with $\varepsilon_1, \varepsilon_2, \varepsilon_3 > 0$. Also, by the same argument as in the proof of Lemma 3.10, we have, for a.e. $t \in [0,T]$, that

$$\|f(\,\cdot\,,t,u) - f(\,\cdot\,,t,\Pi u)\|_{0,\Omega}^2 \leq C \|\eta(t)\|_{0,2(\gamma+1),\Omega}^2,$$

where the constant $C > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$. Choosing $\varepsilon_1, \varepsilon_2, \varepsilon_3$ such that $\varepsilon_1^{-1} + \varepsilon_2^{-1} + \varepsilon_3^{-1} \leq 2$, and inserting the above bounds into (3.33), we obtain

$$\frac{\mathrm{d}}{\mathrm{d}t} \|\xi\|_B^2 \leq C_1 \left(\|\eta\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'\|_{0,\Omega}^2 \right) + \tilde{C}_2 \|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 \tag{3.34}$$

for all $t \in (0, t_{\star\star})$. To bound $\|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2$ we note that, by the same argument as in (3.26) above, for a.e. $t \in (0, t_{\star\star})$, we have

$$\|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 \leq C \|\xi(t)\|_{0,2(\gamma+1),\Omega}^2 \left(1 + \|\xi(t)\|_{0,2(\gamma+1),\Omega}^{2\gamma} \right),$$

where the constant $C > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$.

For $\mathcal{T}_h$ and the polynomial degree vector $\mathbf{p}$ fixed, let $t_\star = t_\star(\mathcal{T}_h, \mathbf{p})$ denote the largest time $t \in (0, t_{\star\star}]$ such that $u_{\mathrm{DG}}(t)$ exists for all $t \in [0, t_\star]$ and $\|\xi(t)\|_{1,h} \leq 1$ for all $t \in [0, t_\star]$; the existence of such a $t_\star$ is guaranteed by the definition of $t_{\star\star}$, together with the fact that $t \mapsto \|\xi(t)\|_{1,h}$ is continuous in the neighborhood of $t = 0$ and $\|\xi(0)\|_{1,h} = 0$. By the broken Sobolev–Poincaré inequality (3.5) and (3.4), for a.e. $t \in (0, t_\star]$, we have that

$$\|f(\,\cdot\,,t,\Pi u) - f(\,\cdot\,,t,u_{\mathrm{DG}})\|_{0,\Omega}^2 \leq C \|\xi(t)\|_{1,h}^2.$$

Inserting this bound into (3.34), integrating from 0 to $t \leq t_\star$, using Lemma 3.7 to deduce that $c_0 \|\xi(t)\|_{1,h}^2 \leq \|\xi(t)\|_B^2$, and noting that $\xi(0) = 0$, we deduce that

$$c_0 \|\xi(t)\|_{1,h}^2 \leq C_1 \int_0^t \left\{ \|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} \mathrm{d}s + C_2 \int_0^t \|\xi(s)\|_{1,h}^2 \, \mathrm{d}s \tag{3.35}$$

for all $t \in [0, t_\star]$. By Lemma 3.8, the first integral on the right-hand side can be bounded in terms of h_κ and p_κ. We define $h = \max_{\kappa \in \mathcal{T}_h} h_\kappa$, $C_3 = C_2/c_0$, and let $h_0 \in (0,1]$ be small enough so that for all $h \leq h_0$ and $t \in [0, t_\star]$ we have

$$C_1 \int_0^t \left\{ \|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} \mathrm{d}s < \frac{c_0}{1+T} \, \mathrm{e}^{-C_3 T}.$$

Thus, for $h \le h_0$ and all $t \in [0, t_\star]$, from (3.35) we have that

$$\|\xi(t)\|_{1,h}^2 < \frac{1}{1+T}\,\mathrm{e}^{-C_3 T} + C_3 \int_0^t \|\xi(s)\|_{1,h}^2 \,\mathrm{d}s;$$

using the Gronwall–Bellman inequality, we deduce that $\|\xi(t)\|_{1,h}^2 < 1$ for all $t \in [0, t_\star]$ with $h \le h_0$. Therefore, by the same continuity argument as in the proof of Lemma 3.10 applied to the mapping $t \mapsto \|\xi(t)\|_{1,h}^2$, we deduce that $t_\star = t_{\star\star} = T$ for all $h \in (0, h_0]$. Taking this into account, assuming that $h \le h_0$, and applying the Gronwall–Bellman inequality to (3.35) gives us the following bound:

$$\|\xi(t)\|_{1,h}^2 \le C \int_0^t \left\{ \|\eta(s)\|_{0,2(\gamma+1),\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} \mathrm{d}s \qquad \forall t \in [0,T], \tag{3.36}$$

where the constant $C > 0$ depends only on the domain Ω, the exponent γ in the growth condition for the function f, the final time T, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$.

Further, by the broken Sobolev–Poincaré inequality (3.5) and (3.4), we have that $\|\eta\|_{0,2(\gamma+1),\Omega}^2 \le C\|\eta\|_{1,h}^2$; employing the triangle inequality, we thus obtain

$$\|(u - u_{\mathrm{DG}})(t)\|_{1,h}^2 \le C \left(\|\eta(t)\|_{1,h}^2 + \int_0^t \left\{ \|\eta(s)\|_{1,h}^2 + \|\eta'(s)\|_{0,\Omega}^2 \right\} \mathrm{d}s \right) \qquad \forall t \in [0,T].$$

Arguing in the same way as in the proof of Theorem 3.11 to bound $\|\eta'(s)\|_{0,\Omega}^2$ and noting that the embedding $\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa)) \hookrightarrow \mathrm{L}^\infty(0,T;\mathrm{H}^{k_\kappa}(\kappa))$ yields (3.32), with $1 \le s_\kappa \le \min\{p_\kappa + 1, k_\kappa\}$, $p_\kappa \ge 1$, for $\kappa \in \mathcal{T}_h$, where the constant $C > 0$ depends only on the domain Ω, the shape-regularity constant of $\mathcal{T}_h$, the final time T, the parameter ρ in (2.2), the exponent γ in the growth condition for the function f, $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$, and the Lebesgue and Sobolev norms of u over the time interval $(0,T)$. ∎

Let us now prove an error bound in the L^2 norm for the SIP DGFEM.

THEOREM 3.13. *Let $\Omega \subset \mathbb{R}^d$, $d \ge 2$, be an H^2-regular polyhedral domain. Suppose that Γ_{N} is empty, $\{\mathcal{T}_h\}$ is a family of shape-regular subdivisions of Ω, and $\mathbf{p}$ is a polynomial degree vector of bounded local variation. Let each face $e \in \mathcal{E}_{\mathrm{int}} \cup \mathcal{E}_{\mathrm{D}}$ be assigned the positive real number*

$$\sigma_e = C_\sigma \{\!\{p^2\}\!\}_e / h_e,$$

*where h_e is the diameter of e, with the convention that for $e \in \mathcal{E}_{\mathrm{D}}$ the contributions from outside Ω in the definition of σ_e are set to 0, and C_σ is as in (**B**). Suppose that the function f satisfies (**A**). Then, if $u|_\kappa \in \mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))$, $k_\kappa \ge 2$, $\kappa \in \mathcal{T}_h$ and $u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega) \cap \mathrm{C}(\bar\Omega))$, there exists $h_0 \in (0,1]$ such that for all $h \in (0,h_0]$, $h = \max_{\kappa\in\mathcal{T}_h} h_\kappa$, and $t \in (0,T]$, the solution $u_{\mathrm{DG}}(\,\cdot\,,t) \in S^{\mathbf{p}}(\Omega,\mathcal{T}_h,\mathbf{F})$ of the SIP DGFEM (2.6) satisfies the following error bound:*

$$\|u - u_{\mathrm{DG}}\|_{\mathrm{L}^\infty(0,T;\mathrm{L}^2(\Omega))}^2 \le C \left(\max_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^2}{p_\kappa} \right) \sum_{\kappa\in\mathcal{T}_h} \frac{h_\kappa^{2s_\kappa - 2}}{p_\kappa^{2k_\kappa - 3}} \|u\|_{\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))}^2, \tag{3.37}$$

with $1 \le s_\kappa \le \min\{p_\kappa + 1, k_\kappa\}$, $p_\kappa \ge 1$, for $\kappa \in \mathcal{T}_h$, where C is a positive constant depending only on the domain Ω, the shape-regularity constant of $\mathcal{T}_h$, the final time T, the exponent γ in the growth condition for the function f, the parameter ρ in (2.2), the Lebesgue and Sobolev norms of u over the time interval $(0,T)$, and $k = \max_{\kappa\in\mathcal{T}_h} k_\kappa$.

Proof. By the same argument as in the proof of Lemma 3.10, and with ξ and η defined as in the proof of Theorem 3.12, we have

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_{0,\Omega}^2 + \|\xi\|_B^2 \leq \left|\int_\Omega \{f(x,t,u) - f(x,t,\Pi u)\}\,\xi\,\mathrm{d}x\right| + \left|\int_\Omega \{f(x,t,\Pi u) - f(x,t,u_{\mathrm{DG}})\}\,\xi\,\mathrm{d}x\right| + \left|\int_\Omega \eta'\xi\,\mathrm{d}x\right|$$

for a.e. $t \in [0,T]$. Applying (3.6) and the Cauchy–Schwarz inequality to the right-hand side of the above inequality gives, for a.e. $t \in [0,T]$,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_{0,\Omega}^2 + \|\xi\|_B^2 \leq C\|\eta\|_{0,\Omega}(1 + |||u|||_{1,h}^\gamma + |||\Pi u|||_{1,h}^\gamma)\|\xi\|_{1,h} + C\|\xi\|_{0,\Omega}(1 + |||\Pi u|||_{1,h}^\gamma + |||u_{\mathrm{DG}}|||_{1,h}^\gamma)\|\xi\|_{1,h} + \|\eta'\|_{0,\Omega}\|\xi\|_{0,\Omega}.$$

Let us show that $\operatorname{ess.sup}_{0\leq t\leq T} |||\Pi u(t)|||_{1,h}$ and $\operatorname{ess.sup}_{0\leq t\leq T} |||u_{\mathrm{DG}}(t)|||_{1,h}$ are bounded uniformly with respect to $h \in (0,h_0]$. We have that

$$|||\Pi u(t)|||_{1,h} \leq |||(\Pi u - u)(t)|||_{1,h} + |||u(t)|||_{1,h} = |||\eta(t)|||_{1,h} + |||u(t)|||_{1,h} \leq \|\eta(t)\|_{1,h} + |||u(t)|||_{1,h} \leq \text{Const.} \qquad \forall t \in [0,T],$$

where Const. is a positive constant, independent of the discretization parameters and of $t \in [0,T]$. Here, the last inequality follows from (3.13) on observing that $\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa)) \hookrightarrow \mathrm{L}^\infty(0,T;\mathrm{H}^{k_\kappa}(\kappa))$, recalling the definition of the norm $|||\cdot|||_{1,h}$, and noting that $u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega)\cap \mathrm{C}(\bar\Omega))$.

By the above and the fact that $\operatorname{ess.sup}_{0\leq t\leq T}\|\xi(t)\|_{1,h}^2 \leq 1$ uniformly in $h \leq h_0$ (see the proof of Theorem 3.12), we have that

$$|||u_{\mathrm{DG}}(t)|||_{1,h} \leq |||(u_{\mathrm{DG}} - \Pi u)(t)|||_{1,h} + |||\Pi u(t)|||_{1,h} = |||\xi(t)|||_{1,h} + |||\Pi u(t)|||_{1,h} \leq \|\xi(t)\|_{1,h} + |||\Pi u(t)|||_{1,h} \leq \|\xi(t)\|_{1,h} + \|\eta(t)\|_{1,h} + |||u(t)|||_{1,h} \leq \text{Const.}$$

for all $t \in [0,T]$ and uniformly in $h \in (0,h_0]$—again by (3.13) on observing that $\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa)) \hookrightarrow \mathrm{L}^\infty(0,T;\mathrm{H}^{k_\kappa}(\kappa))$, the definition of the norm $|||\cdot|||_{1,h}$ and the fact that $u \in \mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega)\cap\mathrm{C}(\bar\Omega))$; once again, Const. denotes a positive constant, independent of the discretization parameters and of $t \in [0,T]$. Hence we deduce that

$$\operatorname*{ess.sup}_{0\leq t\leq T}\left(1 + |||u(t)|||_{1,h}^\gamma + |||\Pi u(t)|||_{1,h}^\gamma\right) \leq \text{Const.},$$

$$\operatorname*{ess.sup}_{0\leq t\leq T}\left(1 + |||\Pi u(t)|||_{1,h}^\gamma + |||u_{\mathrm{DG}}(t)|||_{1,h}^\gamma\right) \leq \text{Const.},$$

uniformly in $h \in (0,h_0]$. Therefore, by Cauchy's inequality,

$$\frac{1}{2}\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_{0,\Omega}^2 + \|\xi\|_{1,h}^2 \leq C\left(\|\eta\|_{0,\Omega}\|\xi\|_{1,h} + \|\xi\|_{0,\Omega}\|\xi\|_{1,h} + \|\eta'\|_{0,\Omega}\|\xi\|_{0,\Omega}\right) \leq \frac{1}{2}\|\xi\|_{1,h}^2 + \frac{1}{2}C^2\left(\|\eta\|_{0,\Omega}^2 + \|\eta'\|_{0,\Omega}^2 + \|\xi\|_{0,\Omega}^2\right),$$

which yields

$$\frac{\mathrm{d}}{\mathrm{d}t}\|\xi\|_{0,\Omega}^2 + \|\xi\|_{1,h}^2 \le C^2\left(\|\eta\|_{0,\Omega}^2 + \|\eta'\|_{0,\Omega}^2 + \|\xi\|_{0,\Omega}^2\right).$$

Upon integrating from 0 to $t \in (0,T]$ and applying the Gronwall–Bellman inequality, we have

$$\|\xi(t)\|_{0,\Omega}^2 + \int_0^t \|\xi(s)\|_{1,h}^2\,\mathrm{d}s \le C\int_0^T \left\{\|\eta(s)\|_{0,\Omega}^2 + \|\eta'(s)\|_{0,\Omega}^2\right\}\,\mathrm{d}s. \tag{3.38}$$

Applying (3.14) to the right-hand side of (3.38), we deduce that

$$\|\xi(t)\|_{0,\Omega}^2 \le C\left(\max_{\kappa\in\mathcal{T}_h}\frac{h_k^2}{p_\kappa}\right)\sum_{\kappa\in\mathcal{T}_h}\frac{h_\kappa^{2s_\kappa-2}}{p_\kappa^{2k_\kappa-3}}\|u\|_{\mathrm{H}^1(0,T;\mathrm{H}^{k_\kappa}(\kappa))}^2 \qquad \forall t\in[0,T].$$

Employing the triangle inequality $\|u(t)-u_{\mathrm{DG}}(t)\|_{0,\Omega} \le \|\eta(t)\|_{0,\Omega} + \|\xi(t)\|_{0,\Omega}$ and applying (3.14) to $\|\eta(t)\|_{0,\Omega}$ once again, we obtain (3.37). ∎

Remark 3.14. Suppose, for example, that $u \in \mathrm{H}^1(0,T;\mathrm{H}^k(\Omega))$, $k \ge 2$, and that $p_\kappa = p$ for all $\kappa \in \mathcal{T}_h$, and let $h = \max_{\kappa\in\mathcal{T}_h} h_\kappa$. Then, (3.32) and (3.37) take the form

$$\frac{h}{p^{3/2}}\|u-u_{\mathrm{DG}}\|_{\mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega,\mathcal{T}_h))} + \frac{1}{p}\|u-u_{\mathrm{DG}}\|_{\mathrm{L}^\infty(0,T;\mathrm{L}^2(\Omega))} \le C\frac{h^s}{p^k}\,\|u\|_{\mathrm{H}^1(0,T;\mathrm{H}^k(\Omega))},$$

where the constant $C>0$ is as above, $1 \le s \le \min\{p+1,k\}$, and $p \ge 1$. Hence the error bounds (3.32) and (3.37) are fully optimal in h; the error bound (3.32) in the broken H^1 norm is suboptimal in p by half a power of p, while the error bound (3.37) in the L^2 norm is suboptimal in p by a single power of the polynomial degree p.

4. Conclusions. We have been concerned with the error analysis of the spatial discretization of semilinear parabolic initial boundary value problems with mixed Dirichlet and Neumann boundary conditions by interior penalty *hp*-DGFEMs. We developed techniques for handling locally Lipschitz-continuous nonlinearities in the error analysis, which allowed us to perform our proofs on the entire time interval of existence of the solution. We showed that the presence of a locally Lipschitz nonlinearity, satisfying a certain growth condition, does not degrade the convergence rates observed in the case of a linear parabolic PDE. The resulting error bounds are optimal in h and slightly suboptimal in p. As we have noted in the introduction, full *hp*-optimality of the error bounds can be restored by hypothesizing piecewise regularity of the solution in augmented Sobolev spaces instead of classical Sobolev spaces, as was done in [17] in the case of linear elliptic equations. To the best of our knowledge, the error bounds derived in the present paper are the first of this kind for semilinear parabolic equations with locally Lipschitz-continuous nonlinearity. The extension of the analysis of our semidiscrete scheme to simple fully discrete schemes, using DGFEM time discretization, say, would proceed along very similar lines and is, therefore, not considered here (see [29], which also includes numerical experiments).

Our error bound for the nonsymmetric version of the method was established in the broken $\mathrm{L}^2(0,T;\mathrm{H}^1(\Omega))$ norm, while for the symmetric version of the method we derived our error bounds in the broken $\mathrm{L}^\infty(0,T;\mathrm{L}^2(\Omega))$ and $\mathrm{L}^\infty(0,T;\mathrm{H}^1(\Omega))$ norms. As we have noted above, all of these bounds are optimal with respect to h. Due to the fact that the bilinear form featured in the nonsymmetric version of the method is *not* adjoint-consistent, one cannot expect to observe a fully optimal bound for NSIP

DGFEM in the $L^\infty(0,T;L^2(\Omega))$ norm with respect to h—at least not for all p; in fact, it is well documented in the literature that, already in the case of Poisson's equation with a homogeneous Dirichlet boundary condition, the (elliptic) NSIP DGFEM is optimally convergent with respect to h only when $p \geq 1$ is an odd integer (see, for example, [20]). Yet, one may nevertheless wonder whether it is possible to derive, instead of the broken $L^2([0,T],H^1(\Omega))$ norm, an optimal error bound for NSIP DGFEM in the broken $L^\infty([0,T],H^1(\Omega))$ norm, as has been done for SIP DGFEM. This is an open problem: the main technical difficulty is that the bilinear form of NSIP DGFEM is nonsymmetric (as well as adjoint-inconsistent), so the usual testing procedure for convergence analysis in the $L^\infty([0,T],H^1(\Omega))$ norm for second-order parabolic equations of the form $\xi' + A\xi = g$, based on taking the $L^2(\Omega)$ inner product of the equation with ξ', fails to deliver a helpful energy estimate.

Finally, we note that by analogous arguments to those presented above all of our results can be extended to the case of a general locally Lipschitz-continuous nonlinearity which, instead of inequality (1.2), satisfies

$$|f(x,t,w) - f(x,t,v)| \leq C(|w|,|v|)\,|w-v| \quad \begin{cases} \forall w,\, v \in \mathbb{R}, \\ \text{a.e. } (x,t) \in \Omega \times (0,T], \end{cases} \tag{4.1}$$

where $C(\cdot,\cdot)$ is a continuous function on $[0,\infty)^2$. Since, this time, no growth condition of the kind $C(|w|,|v|) \leq G_f(1+|w|+|v|)^\gamma$ is assumed, one cannot rely on the broken Sobolev–Poincaré inequality. In fact, the only way to control terms such as $C(\|u(t)\|_{\infty,\Omega}, \|\Pi u(t)\|_{\infty,\Omega})$ and $C(\|u_{\mathrm{DG}}(t)\|_{\infty,\Omega}, \|\Pi u(t)\|_{\infty,\Omega})$, which will arise in the error analysis, is to show that $\max_{t\in[0,T]} \|\Pi u(t)\|_{\infty,\Omega}$ and $\max_{t\in[0,T]} \|u_{\mathrm{DG}}(t)\|_{\infty,\Omega}$ can be bounded, independent of $\mathbf{p}$ and h. For the first of these, we first note that

$$\|\Pi u(t)\|_{\infty,\Omega} \leq \|u(t)\|_{\infty,\Omega} + \|u(t) - \Pi u(t)\|_{\infty,\Omega}.$$

We then show the smallness of the second term by using the smallness of the projection error $\|u(t) - \Pi u(t)\|_{1,h}$, the smallness of $\|u(t) - z_{p_\kappa}^{h_\kappa}(u(t))\|_{\infty,\kappa}$, and an inverse inequality relating $\|\cdot\|_{\infty,\Omega}$ to $\|\cdot\|_{1,h}$. To bound $\|u_{\mathrm{DG}}(t)\|_{\infty,\Omega}$, we note that

$$\|u_{\mathrm{DG}}(t)\|_{\infty,\Omega} \leq \|\xi(t)\|_{\infty,\Omega} + \|\Pi u(t)\|_{\infty,\Omega}$$

and use an inverse inequality to relate the $\|\cdot\|_{\infty,\Omega}$ norm of ξ to its $\|\cdot\|_{1,h}$ norm. In order to accommodate the use of the inverse inequality, one has then to assume in the analysis of *both* SIP DGFEM and NSIP DGFEM that the mesh is quasi-uniform in the sense of (3.20). For our analysis of SIP DGFEM under hypothesis (1.2), this strong mesh-regularity assumption was not required. Thus, and for reasons of brevity, we chose to base this paper on (1.2) rather than on the more general local Lipschitz condition (4.1) which, at the expense of more restrictive hypotheses on the mesh, makes no assumption on the growth rate of $C(|w|,|v|)$ as $|w|,|v| \to \infty$.

A POSTERIORI ERROR ESTIMATES FOR LOWEST-ORDER MIXED FINITE ELEMENT DISCRETIZATIONS OF CONVECTION-DIFFUSION-REACTION EQUATIONS*

MARTIN VOHRALÍK†

Abstract. We establish residual a posteriori error estimates for lowest-order Raviart–Thomas mixed finite element discretizations of convection-diffusion-reaction equations on simplicial meshes in two or three space dimensions. The upwind-mixed scheme is considered as well, and the emphasis is put on the presence of an inhomogeneous and anisotropic diffusion-dispersion tensor and on a possible convection dominance. Global upper bounds for the approximation error in the energy norm are derived, where in particular all constants are evaluated explicitly, so that the estimators are fully computable. Our estimators give local lower bounds for the error as well, and they hold from the cases where convection or reaction are not present to convection- or reaction-dominated problems; we prove that their local efficiency depends only on local variations in the coefficients and on the local Péclet number. Moreover, the developed general framework allows for asymptotic exactness and full robustness with respect to inhomogeneities and anisotropies. The main idea of the proof is a construction of a locally postprocessed approximate solution using the mean value and the flux in each element, known in the mixed finite element method, and a subsequent use of the abstract framework arising from the primal weak formulation of the continuous problem. Numerical experiments confirm the guaranteed upper bound and excellent efficiency and robustness of the derived estimators.

Key words. convection-diffusion-reaction equation, inhomogeneous and anisotropic diffusion, convection dominance, mixed finite element method, upwind weighting, a posteriori error estimates

1. Introduction.

We consider the convection-diffusion-reaction problem

$$-\nabla \cdot (\mathbf{S}\nabla p) + \nabla \cdot (p\mathbf{w}) + rp = f \quad \text{in } \Omega, \tag{1.1a}$$

$$p = 0 \quad \text{on } \partial\Omega, \tag{1.1b}$$

where $\mathbf{S}$ is in general an inhomogeneous and anisotropic (nonconstant full-matrix) diffusion-dispersion tensor, $\mathbf{w}$ is a (dominating) velocity field, r a reaction function, f a source term, and $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, is a polygonal (polyhedral) domain (open, bounded, and connected set). Our purpose is to derive a posteriori error estimates for the lowest-order Raviart–Thomas mixed finite element discretization of the problem (1.1a)–(1.1b) on simplicial meshes (consisting of triangles if $d = 2$ and of tetrahedra if $d = 3$), as well as for its upwind variant; cf. Douglas and Roberts [17] and Dawson [16].

A posteriori error estimates, pioneered by Babuška and Rheinboldt [7], are nowadays well established for primal discretizations of second-order elliptic problems involving only a diffusion term; cf., for example, the survey by Verfürth [32] for the conforming finite element method. An approach encompassing all conforming, nonconforming, and discontinuous finite element methods was recently proposed by Ainsworth [3], using a Helmholtz-like decomposition of the error in the numerical solution into its conforming and nonconforming parts in order to give a computable error bound. In most cases the analysis is given only for $\mathbf{S}$ being an identity matrix; an in-depth analysis for the general inhomogeneous and anisotropic diffusion tensor in the framework of the finite element method was presented by Bernardi and Verfürth [9]. Similar results have been obtained by Petzoldt [28], for nonconforming finite elements by Ainsworth [4], and some developments for the finite volume box scheme (in the given case actually equivalent to the lowest-order Raviart–Thomas mixed finite element method) are presented by El Alaoui and Ern [19]. In all these references, a hypothesis of the type "monotonicity around vertices" on the distribution of the inhomogeneities is necessary. In recent years a posteriori error estimates have been extended to convection-diffusion problems as well. We cite in particular Verfürth [33], who derived estimates in the energy norm for the conforming Galerkin method and its stabilized SUPG (streamline upwind Petrov–Galerkin) version. His estimates are both reliable (yielding a global upper bound on the error between the exact and approximate solutions) and locally efficient (giving a local lower bound). Moreover, they are semirobust in the sense that the lower and upper bounds differ by constants whose dependence on the local mesh discretization parameter vanishes as this approaches the ratio of the smallest eigenvalue of $\mathbf{S}$ to the local size of the velocity field (i.e., when the local Péclet number gets sufficiently small). Recently, Verfürth [34] improved his results while giving estimates which are fully robust with respect to convection dominance in a norm incorporating a dual norm of the convective derivative. The new norm is not, however, easily computable, there is no local lower bound, and the estimators do not change with respect to [33], and hence the adaptive strategies will remain the same. Finally, a different approach, yielding an estimate in the L^1-norm, independent of the size of the diffusion tensor, is given by Ohlberger [26] in the framework of the vertex-centered finite volume method.

In comparison with primal methods, the literature on a posteriori error estimates in the mixed finite element method is much less extensive. Most of the results have been obtained for the Poisson equation (i.e., $\mathbf{w} = r = 0$ in (1.1a)–(1.1b)) in two space dimensions: Alonso [5] derived estimates for the error in the flux $\mathbf{u} := -\mathbf{S}\nabla p$ of the scalar variable p and either Raviart–Thomas [29] or Brezzi–Douglas–Marini [11] mixed finite elements. Braess and Verfürth [10] proved estimates for both $\mathbf{u}$ and p for Raviart–Thomas elements, based on mesh-dependent norms and a saturation assumption. Carstensen [13] derived rigorous estimates for various mixed finite element schemes and for both $\mathbf{u}$ and p. Achchab et al. [1] can imbed Raviart–Thomas elements in their hierarchical a posteriori error estimates, whereas Carstensen and Bartels [14] give an upper bound using averaging techniques. Kirby [24] proposed simple residual-based estimates for Raviart–Thomas elements, where, however, the flux estimator is not proved to yield a lower bound and is, moreover, obtained under a saturation assumption. Wheeler and Yotov [39] were able to obtain a posteriori error estimates for the mortar version of all families of mixed finite elements, also including the three-dimensional case; a saturation assumption was, however, necessary for the velocity estimate. Recently, Lovadina and Stenberg [25] employed an idea of postprocessing similar to that used in this paper (with, however, the postprocessed

scalar unknown of one degree lower than the one used here) in order to prove reliable and efficient a posteriori error estimates for both the scalar and flux variables in a mesh-dependent norm. Finally, Hoppe and Wohlmuth [22] treat a diffusion-reaction problem in two space dimensions and use the relation of lowest-order Raviart–Thomas mixed finite elements to nonconforming finite elements derived by Arnold and Brezzi in [6] in order to control, under a saturation assumption, the L^2-norm error in the primal variable p.

To the author's knowledge, no a posteriori estimates for mixed finite element discretizations of convection-diffusion(-reaction) problems have been presented in the literature so far. We do this in section 4 of this paper, after stating the assumptions on the data and formulating the continuous problem in section 2 and after defining the schemes in section 3. The estimates are derived in the energy norm for a new locally (on each element) postprocessed scalar variable $\tilde{p}_h$ such that its flux $-\mathbf{S}\nabla\tilde{p}_h$ is equal to $\mathbf{u}_h$ and such that its mean on each element is equal to p_h. By this construction, we actually have the $L^2(\Omega)$ control over both $\mathbf{u}_h-\mathbf{u}$ and $\tilde{p}_h-p$. Our estimates, in contrast to the usual practice, do not include any undetermined multiplicative constants, so that they are fully (and locally and easily) computable. They represent local lower bounds for the error as well, with efficiency constants of the form $c_1+c_2\min\{\mathrm{Pe},\varrho\}$, where Pe (the local Péclet number) and ϱ are given below by (4.8) and where c_1, c_2 depend only on local variations in $\mathbf{S}$ (i.e., on local inhomogeneities and anisotropies), on local variations in $\mathbf{w}$ and r, on the space dimension, on the polynomial degree of f, and on the shape-regularity parameter of the mesh. They hold from the cases where convection or reaction are not present to convection- or reaction-dominated problems and are in particular semirobust as in [33] with respect to convection dominance. Next, in the pure diffusion case, we can write the general framework for our estimators in a form of an infimum over all $H^1_0(\Omega)$ functions plus a higher-order residual term, which yields asymptotic exactness and full robustness with respect to inhomogeneities and anisotropies, and this without any "monotonicity" hypothesis. Although in numerical experiments we use only local discrete evaluations of the estimators, they remain almost asymptotically exact (the ratio of the estimated and actual error is close to one, and this even in the convection-diffusion-reaction case) and quite robust. Finally, as an interesting consequence of our analysis, we find that in the pure diffusion case with piecewise constant coefficients, the lowest-order mixed finite elements represent an exact three-point scheme in one space dimension, and in two or three space dimensions, the postprocessed approximation is exact with respect to some generalized continuous solution. All these issues are discussed in detail in section 5.

Next, section 6 presents some discrete properties of the schemes and of the postprocessed scalar variable $\tilde{p}_h$. Namely, we show that $\tilde{p}_h$ is nonconforming in the sense that it is not included in $H^1_0(\Omega)$, but we prove that the means of its traces are continuous across interior sides (edges if $d=2$, faces if $d=3$) and equal to zero on exterior sides of the mesh; they are, in fact, shown to equal the Lagrange multipliers from the hybridized forms of the schemes. The actual proofs of our a posteriori error estimates and of their local efficiency are then given in section 7. The key element is Lemma 7.1 which states a primal weak formulation-based abstract framework allowing for the above-discussed asymptotic exactness and asymptotic robustness. The nonconformity of $\tilde{p}_h$ is then treated by the techniques developed in [2, 23, 19]. Neither any additional regularity of the weak solution nor any saturation assumption is needed. Finally, we illustrate the accuracy of the derived estimates in section 8 in several numerical experiments.

In this paper we focus only on lowest-order methods since in practice they are

by far the most commonly used and hence we believe they deserve a special treatment; on the other hand, we do cover the three-dimensional case. Moreover, we have shown in [36] that there exists a local flux-expression formula in lowest-order mixed finite elements and that they can namely be implemented with only one unknown per element, which enables us to significantly decrease their traditional increased computational cost. The extension to higher-order schemes is an ongoing work. Finally, we have also generalized the presented type of a posteriori error estimates to the finite volume method in the forthcoming paper [38]. We treat there among other questions a larger variety of meshes and general inhomogeneous Dirichlet or Neumann boundary conditions. This paper is a detailed description of the results previously announced in [37].

2. Notation, assumptions, and the continuous problem. We introduce here the notation, define admissible triangulations to which the space $W_0(\mathcal{T}_h)$ and the data will be related, and finally give details on the continuous problem (1.1a)–(1.1b).

2.1. Notation. For a domain $S \subset \mathbb{R}^d$, we denote by $L^2(S)$ and $\mathbf{L}^2(S) = [L^2(S)]^d$ the Lebesgue spaces, by $(\cdot,\cdot)_S$ the $L^2(S)$ or $\mathbf{L}^2(S)$ inner product, and by $\|\cdot\|_S$ the associated norm; $|S|$ stands for the Lebesgue measure of S. Next, $H^1(S)$ and $H^1_0(S)$ are the Sobolev spaces of functions with square-integrable weak derivatives, $\mathbf{H}(\mathrm{div}, S) = \{\mathbf{v} \in \mathbf{L}^2(S); \nabla\cdot\mathbf{v} \in L^2(S)\}$ is the space of functions with square-integrable weak divergences, and $\langle\cdot,\cdot\rangle_{\partial S}$ stands for $(d-1)$-dimensional inner product on ∂S or for the duality pairing between $H^{-\frac{1}{2}}(\partial S)$ and $H^{\frac{1}{2}}(\partial S)$. We will also use the "broken Sobolev space" $H^1(\mathcal{T}_h) := \{\varphi \in L^2(\Omega); \varphi|_K \in H^1(K)\ \forall K \in \mathcal{T}_h\}$. In what follows we conceptually denote by C_A, c_A constants dependent only on a quantity A.

2.2. Triangulation, Poincaré and Friedrichs inequalities, and the space $\boldsymbol{W_0(\mathcal{T}_h)}$. We suppose that $\mathcal{T}_h$ for all $h > 0$ consists of closed simplices such that $\overline{\Omega} = \bigcup_{K\in\mathcal{T}_h} K$ and such that if $K, L \in \mathcal{T}_h$, $K \neq L$, then $K \cap L$ is either an empty set or a common face, edge, or vertex of K and L. Let h_K denote the diameter of K and let $h := \max_{K\in\mathcal{T}_h} h_K$. We make the following shape-regularity assumption on the family of triangulations $\{\mathcal{T}_h\}_h$, denoting $\kappa_K := |K|/h_K^d$.

Assumption A (shape-regularity of the meshes). There exists a constant $\kappa_{\mathcal{T}} > 0$ such that $\min_{K\in\mathcal{T}_h} \kappa_K \geq \kappa_{\mathcal{T}}$ for all $h > 0$.

Let ρ_K denote the diameter of the largest ball inscribed in K. Then Assumption A is equivalent to the usual requirement of the existence of a constant $\theta_{\mathcal{T}} > 0$ such that $\max_{K\in\mathcal{T}_h} h_K/\rho_K \leq \theta_{\mathcal{T}}$ for all $h > 0$. We next denote by $\mathcal{E}_h$ the set of all sides of $\mathcal{T}_h$, by $\mathcal{E}_h^{\mathrm{int}}$ the set of interior, by $\mathcal{E}_h^{\mathrm{ext}}$ the set of exterior, and by $\mathcal{E}_K$ the set of all the sides of an element $K \in \mathcal{T}_h$. Finally, h_σ stands for the diameter of $\sigma \in \mathcal{E}_h$.

Let $K \in \mathcal{T}_h$ and $\varphi \in H^1(K)$. Two inequalities play an essential role in our analysis. First, the Poincaré inequality states that

$$\|\varphi - \varphi_K\|_K^2 \leq C_{\mathrm{P},d} h_K^2 \|\nabla\varphi\|_K^2\,, \tag{2.1}$$

where φ_K is the mean of φ over K, $\varphi_K := (\varphi, 1)_K/|K|$, and where the constant $C_{\mathrm{P},d}$ can for a simplex (using its convexity) be evaluated as d/π; cf. [27, 8]. Next, the following generalized Friedrichs inequalities have been proved in [35, Lemma 4.1]:

$$(\varphi_K - \varphi_\sigma)^2 \leq C_{\mathrm{F},d} \frac{h_K^2}{|K|} \|\nabla\varphi\|_K^2\,, \qquad \|\varphi - \varphi_\sigma\|_K^2 \leq C_{\mathrm{F},d} h_K^2 \|\nabla\varphi\|_K^2\,. \tag{2.2}$$

Here φ_σ is the mean of φ over $\sigma \in \mathcal{E}_K$, $\varphi_\sigma := \langle\varphi, 1\rangle_\sigma/|\sigma|$, and $C_{\mathrm{F},d} = 3d$.

We finally define the space $W_0(\mathcal{T}_h)$ of functions with mean values of the traces continuous across interior sides and zero on exterior sides,

$$W_0(\mathcal{T}_h) := \big\{\varphi \in L^2(\Omega)\,;\varphi|_K \in H^1(K)\ \forall K \in \mathcal{T}_h, \\ \langle \varphi|_K - \varphi|_L, 1\rangle_{\sigma_{K,L}} = 0\ \forall \sigma_{K,L} \in \mathcal{E}_h^{\mathrm{int}}\,, \\ \langle \varphi, 1\rangle_\sigma = 0\ \forall \sigma \in \mathcal{E}_h^{\mathrm{ext}}\big\}, \tag{2.3}$$

and recall the discrete Friedrichs inequality

$$\|\varphi\|_\Omega^2 \le C_{\mathrm{DF}} \sum_{K\in\mathcal{T}_h} \|\nabla\varphi\|_K^2 \qquad \forall \varphi \in W_0(\mathcal{T}_h),\ \forall h > 0, \tag{2.4}$$

where C_{DF} depends only on $\kappa_{\mathcal{T}}$ and $\inf_{\mathbf{b}\in\mathbb{R}^d}\{\mathrm{thick}_{\mathbf{b}}(\Omega)\}$; cf. [35, Theorem 5.4].

2.3. Data. We suppose that there exists a basic triangulation $\widetilde{\mathcal{T}}_h$ of Ω such that the data of the problem (1.1a)–(1.1b) are related to $\widetilde{\mathcal{T}}_h$ in the following way.

Assumption B (data).

- (B1) $\mathbf{S}_K := \mathbf{S}|_K$ *is a constant, symmetric, bounded, and uniformly positive definite tensor such that* $c_{\mathbf{S},K}\,\mathbf{v}\cdot\mathbf{v} \le \mathbf{S}_K\mathbf{v}\cdot\mathbf{v} \le C_{\mathbf{S},K}\,\mathbf{v}\cdot\mathbf{v}$, $c_{\mathbf{S},K} > 0$, $C_{\mathbf{S},K} > 0$, *for all* $\mathbf{v}\in\mathbb{R}^d$ *and all* $K \in \widetilde{\mathcal{T}}_h$;
- (B2) $\mathbf{w} \in \mathbf{RTN}^0(\widetilde{\mathcal{T}}_h)$ *satisfies* $\big|\mathbf{w}|_K\big| \le C_{\mathbf{w},K}$, $C_{\mathbf{w},K} \ge 0$, *for all* $K \in \widetilde{\mathcal{T}}_h$;
- (B3) $r_K := r|_K$ *is a constant for all* $K \in \widetilde{\mathcal{T}}_h$;
- (B4) $\frac{1}{2}\nabla\cdot\mathbf{w}|_K + r|_K = c_{\mathbf{w},r,K}$ *and* $\big|\nabla\cdot\mathbf{w}|_K + r_K\big| = C_{\mathbf{w},r,K}$, $c_{\mathbf{w},r,K} \ge 0$, $C_{\mathbf{w},r,K} \ge 0$, *for all* $K \in \widetilde{\mathcal{T}}_h$;
- (B5) $f|_K$ *is a polynomial of degree at most* k *for each* $K \in \widetilde{\mathcal{T}}_h$;
- (B6) *if* $c_{\mathbf{w},r,K} = 0$, *then* $C_{\mathbf{w},r,K} = 0$.

The assumptions that $\mathbf{S}$ and r are piecewise constant on $\widetilde{\mathcal{T}}_h$, that $\mathbf{w} \in \mathbf{RTN}^0(\widetilde{\mathcal{T}}_h)$ (cf. section 3.1 below for the definition of this space), and that f is a piecewise polynomial are made for the sake of simplicity and are usually satisfied in practice. If the functions at hand do not fulfill these requirements, interpolation can be used. Finally, note that Assumption (B6) allows $c_{\mathbf{w},r,K} = 0$ but $\mathbf{w}|_K \neq 0$.

2.4. Continuous problem. Let $\mathcal{T}_h$ be, as throughout the whole paper, a refinement of $\widetilde{\mathcal{T}}_h$. We define a bilinear form $\mathcal{B}$ by

$$\mathcal{B}(p,\varphi) := \sum_{K\in\mathcal{T}_h} \big\{(\mathbf{S}\nabla p, \nabla\varphi)_K + (\nabla\cdot(p\mathbf{w}),\varphi)_K + (rp,\varphi)_K\big\}, \qquad p,\varphi \in H^1(\mathcal{T}_h), \tag{2.5}$$

and the corresponding energy (semi)norm by

$$|||\varphi|||_\Omega^2 := \sum_{K\in\mathcal{T}_h} |||\varphi|||_K^2, \quad |||\varphi|||_K^2 := (\mathbf{S}\nabla\varphi,\nabla\varphi)_K + c_{\mathbf{w},r,K}\|\varphi\|_K^2, \qquad \varphi \in H^1(\mathcal{T}_h). \tag{2.6}$$

In this way $\mathcal{B}(\cdot,\cdot)$ and $|||\cdot|||_\Omega$ are well defined for $p,\varphi \in H^1(\Omega)$ as well as for p,φ that are only piecewise regular. Note also that $|||\cdot|||_\Omega$ is a norm on $W_0(\mathcal{T}_h)$ even if there exists $K \in \mathcal{T}_h$ such that $c_{\mathbf{w},r,K} = 0$ because of the discrete Friedrichs inequality (2.4) and Assumption (B1). The weak formulation of the problem (1.1a)–(1.1b) is then to find $p \in H_0^1(\Omega)$ such that

$$\mathcal{B}(p,\varphi) = (f,\varphi)_\Omega \qquad \forall \varphi \in H_0^1(\Omega). \tag{2.7}$$

Assumption B, the Green theorem, and the Cauchy–Schwarz inequality imply that

$$\mathcal{B}(\varphi,\varphi) = |||\varphi|||_\Omega^2 \qquad \forall \varphi \in H_0^1(\Omega), \tag{2.8}$$

$$\mathcal{B}(\varphi,\varphi) = |||\varphi|||_\Omega^2 + \frac{1}{2}\sum_{K\in\mathcal{T}_h} \langle \varphi^2, \mathbf{w}\cdot\mathbf{n}\rangle_{\partial K} \qquad \forall \varphi \in H^1(\mathcal{T}_h), \tag{2.9}$$

$$\begin{aligned}\mathcal{B}(p,\varphi) \le{}& \max\left\{1, \max_{K\in\mathcal{T}_h}\left\{\frac{C_{\mathbf{w},r,K}}{c_{\mathbf{w},r,K}}\right\}\right\} |||p|||_\Omega |||\varphi|||_\Omega \\ &+ \max_{K\in\mathcal{T}_h}\left\{\frac{C_{\mathbf{w},K}}{\sqrt{c_{\mathbf{S},K}}}\right\} |||p|||_\Omega \|\varphi\|_\Omega \qquad \forall p,\varphi \in H^1(\mathcal{T}_h),\end{aligned} \tag{2.10}$$

and problem (2.7) under Assumption B, in particular, admits a unique solution.

Remark 2.1 (notation). In estimate (2.10), if $c_{\mathbf{w},r,K} = 0$, the term $C_{\mathbf{w},r,K}/c_{\mathbf{w},r,K}$ should be evaluated as zero, since Assumption (B6) in this case gives $C_{\mathbf{w},r,K} = 0$. To simplify notation, we systematically use the convention $0/0 = 0$ throughout the text.

3. Mixed finite element schemes. We define in this section the centered and upwind-weighted mixed finite element schemes.

3.1. Function spaces. Let $\mathbf{RTN}^0_{-1}(\mathcal{T}_h)$ be the space of elementwise linear vector functions $\mathbf{u}_h$ such that, on each $K \in \mathcal{T}_h$, $\mathbf{u}_h|_K = (a_K + d_K x, b_K + d_K y)$ if $d = 2$ and $\mathbf{u}_h|_K = (a_K + d_K x, b_K + d_K y, c_K + d_K z)$ if $d = 3$. The Raviart–Thomas–Nédélec space $\mathbf{RTN}^0(\mathcal{T}_h)$ imposes the continuity of the normal trace across all $\sigma \in \mathcal{E}_h^{\rm int}$ and is given by $\mathbf{RTN}^0(\mathcal{T}_h) := \mathbf{RTN}^0_{-1}(\mathcal{T}_h) \cap \mathbf{H}(\mathrm{div},\Omega)$. There is one basis function $\mathbf{v}_\sigma$ associated with each $\sigma \in \mathcal{E}_h$. For $\sigma_{K,L} \in \mathcal{E}_h^{\rm int}$, $\mathbf{v}_{\sigma_{K,L}}(\mathbf{x}) = \frac{1}{d|K|}(\mathbf{x} - V_K)$, $\mathbf{x} \in K$; $\mathbf{v}_{\sigma_{K,L}}(\mathbf{x}) = \frac{1}{d|L|}(V_L - \mathbf{x})$, $\mathbf{x} \in L$; $\mathbf{v}_{\sigma_{K,L}}(\mathbf{x}) = 0$ otherwise, where V_K is the vertex of K opposite to σ and V_L the vertex of L opposite to σ. We suppose that the orientation of $\mathbf{v}_{\sigma_{K,L}}$, i.e., the order of K and L, is fixed. For a boundary side σ, the support of $\mathbf{v}_\sigma$ consists only of $K \in \mathcal{T}_h$ such that $\sigma \in \mathcal{E}_K$. Next, the space $\Phi(\mathcal{T}_h)$ consists of elementwise constant scalar functions; we denote $p_h|_K = p_K$ for $p_h \in \Phi(\mathcal{T}_h)$. Recall also that $\nabla\cdot\mathbf{u}_h \in \Phi(\mathcal{T}_h)$ for each $\mathbf{u}_h \in \mathbf{RTN}^0_{-1}(\mathcal{T}_h)$.

3.2. Centered scheme. The centered mixed finite element scheme (cf. [17]) reads: find $\mathbf{u}_h \in \mathbf{RTN}^0(\mathcal{T}_h)$ and $p_h \in \Phi(\mathcal{T}_h)$ such that

$$(\mathbf{S}^{-1}\mathbf{u}_h, \mathbf{v}_h)_\Omega - (p_h, \nabla\cdot\mathbf{v}_h)_\Omega = 0 \qquad \forall\, \mathbf{v}_h \in \mathbf{RTN}^0(\mathcal{T}_h), \tag{3.1a}$$

$$(\nabla\cdot\mathbf{u}_h, \phi_h)_\Omega - (\mathbf{S}^{-1}\mathbf{u}_h\cdot\mathbf{w}, \phi_h)_\Omega + ((r + \nabla\cdot\mathbf{w})p_h, \phi_h)_\Omega = (f,\phi_h)_\Omega \qquad \forall \phi_h \in \Phi(\mathcal{T}_h). \tag{3.1b}$$

3.3. Upwind-weighted scheme. The upwind-weighted mixed finite element scheme reads: find $\mathbf{u}_h \in \mathbf{RTN}^0(\mathcal{T}_h)$ and $p_h \in \Phi(\mathcal{T}_h)$ such that

$$(\mathbf{S}^{-1}\mathbf{u}_h, \mathbf{v}_h)_\Omega - (p_h, \nabla\cdot\mathbf{v}_h)_\Omega = 0 \qquad \forall\, \mathbf{v}_h \in \mathbf{RTN}^0(\mathcal{T}_h), \tag{3.2a}$$

$$(\nabla\cdot\mathbf{u}_h, \phi_h)_\Omega + \sum_{K\in\mathcal{T}_h}\sum_{\sigma\in\mathcal{E}_K} \hat{p}_\sigma w_{K,\sigma}\phi_K + (rp_h,\phi_h)_\Omega = (f,\phi_h)_\Omega \qquad \forall \phi_h \in \Phi_h(\mathcal{T}_h), \tag{3.2b}$$

where $w_{K,\sigma} := \langle \mathbf{w}\cdot\mathbf{n}, 1\rangle_\sigma$, $\sigma \in \mathcal{E}_K$, with $\mathbf{n}$ being the unit normal vector of the side σ, outward to K, and where $\hat{p}_\sigma$ is the weighted upwind value defined by

$$\hat{p}_\sigma := \begin{cases} (1-\nu_\sigma)p_K + \nu_\sigma p_L & \text{if } w_{K,\sigma} \geq 0, \\ (1-\nu_\sigma)p_L + \nu_\sigma p_K & \text{if } w_{K,\sigma} < 0, \end{cases} \tag{3.3}$$

if σ is an interior side between elements K and L, and

$$\hat{p}_\sigma := \begin{cases} (1-\nu_\sigma)p_K & \text{if } w_{K,\sigma} \geq 0, \\ \nu_\sigma p_K & \text{if } w_{K,\sigma} < 0, \end{cases} \tag{3.4}$$

if σ is a boundary side. Here, $\nu_\sigma \in [0, 1/2]$ is the coefficient of the amount of upstream weighting which may be, in order to reduce the excessive numerical diffusion added by the full upstream weighting used in [16], chosen as

$$\nu_\sigma := \begin{cases} \min\left\{ c_{\mathbf{S},\sigma}\dfrac{|\sigma|}{h_\sigma |w_{K,\sigma}|}, \dfrac{1}{2}\right\} & \text{if } w_{K,\sigma} \neq 0 \text{ and } \sigma \in \mathcal{E}_h^{\text{int}}, \\ & \text{or if } \sigma \in \mathcal{E}_h^{\text{ext}} \text{ and } w_{K,\sigma} > 0, \\ 0 & \text{if } w_{K,\sigma} = 0 \text{ or if } \sigma \in \mathcal{E}_h^{\text{ext}} \text{ and } w_{K,\sigma} < 0, \end{cases} \tag{3.5}$$

where $c_{\mathbf{S},\sigma}$ is the harmonic average of $c_{\mathbf{S},K}$ and $c_{\mathbf{S},L}$ if $\sigma = \partial K \cap \partial L$ and $c_{\mathbf{S},K}$ otherwise.

4. A posteriori error estimates. We summarize in this section our a posteriori estimates on the error between the weak solution p and a postprocessed variable $\tilde{p}_h$, which we shall define first, along with its modified Oswald interpolate.

4.1. A postprocessed scalar variable $\tilde{p}_h$. In standard mixed finite element theory (see, e.g., Brezzi and Fortin [12] or Roberts and Thomas [31]) the two variables p_h and $\mathbf{u}_h$ are considered as independent. In contrast, the basis for our a posteriori error estimates is a construction of a postprocessed scalar variable $\tilde{p}_h$ which links p_h and $\mathbf{u}_h$ on each simplex in the following way:

$$-\mathbf{S}_K \nabla \tilde{p}_h|_K = \mathbf{u}_h|_K \quad \forall K \in \mathcal{T}_h, \tag{4.1a}$$

$$\frac{(\tilde{p}_h, 1)_K}{|K|} = p_K \quad \forall K \in \mathcal{T}_h. \tag{4.1b}$$

Note that, in particular, if $\mathbf{S} = Id$, $\tilde{p}_h|_K = -d_K/2\,(x^2+y^2) - a_K x - b_K y - e_K$ if $d = 2$ and $\tilde{p}_h|_K = -d_K/2\,(x^2+y^2+z^2) - a_K x - b_K y - c_K z - e_K$ if $d = 3$. Here a_K–d_K are the coefficients from section 3.1, and e_K is given so that (4.1b) was satisfied. If $\mathbf{S} \neq Id$, then $\tilde{p}_h$ verifying (4.1a)–(4.1b) still exists due to the symmetry of $\mathbf{S}$ and is this time a full second-order polynomial on each $K \in \mathcal{T}_h$. The new variable $\tilde{p}_h$ is nonconforming, $\tilde{p}_h \notin H_0^1(\Omega)$, but, by Lemma 6.1 below, $\tilde{p}_h \in W_0(\mathcal{T}_h)$; i.e., its means on interior sides are continuous and its means on exterior sides are equal to zero. In fact, by Lemma 6.4 below, these means coincide with the Lagrange multipliers of hybridized schemes. Moreover, the centered scheme can equivalently be rewritten with the help of $\tilde{p}_h$ (see Lemma 6.2 below), which corresponds to the employment of the Lagrange multipliers in the convection term. Note that the proposed postprocessing is local on each element and its cost is negligible.

4.2. A modified Oswald interpolation operator. Let $\mathbb{P}_l(\mathcal{T}_h)$ denote the space of polynomials of degree at most l on each simplex, not necessary continuous. The Oswald interpolation operator $\mathcal{I}_{\rm Os} : \mathbb{P}_l(\mathcal{T}_h) \to \mathbb{P}_l(\mathcal{T}_h) \cap H^1_0(\Omega)$ has been considered, e.g., in [2, 23, 19]. Given a function $\varphi_h \in \mathbb{P}_l(\mathcal{T}_h)$, $\mathcal{I}_{\rm Os}(\varphi_h)$ is prescribed at the Lagrangian nodes (degrees of freedom; cf. [15, section 2.2]) of $\mathbb{P}_l(\mathcal{T}_h) \cap H^1_0(\Omega)$ by the average of the values of φ_h at this node. We will now construct its modification which preserves the means of $\tilde{p}_h$ over the sides, since this will appear crucial when convection is present.

The modified Oswald interpolation operator $\mathcal{I}_{\rm MO} : \mathbb{P}_2(\mathcal{T}_h) \cap W_0(\mathcal{T}_h) \to \mathbb{P}_d(\mathcal{T}_h) \cap H^1_0(\Omega)$ is defined as follows: at all Lagrangian nodes of $\mathbb{P}_d(\mathcal{T}_h) \cap H^1_0(\Omega)$, except for those lying at the barycenters of the sides, the value of $\mathcal{I}_{\rm MO}(\varphi_h)$ is given by the average of the values of φ_h at this node (as in the standard Oswald interpolation operator). The values at the barycenters of the sides are then established so that the means of $\mathcal{I}_{\rm MO}(\varphi_h)$ over the sides were given by the means of φ_h. (The space $\mathbb{P}_2(\mathcal{T}_h) \cap H^1_0(\Omega)$ in three space dimensions does not have Lagrangian nodes at side barycenters; this is the reason to use $\mathbb{P}_3(\mathcal{T}_h) \cap H^1_0(\Omega)$ in this case.) It is easily verified that, as in the case of the Oswald interpolation operator, $\mathcal{I}_{\rm MO}(\varphi_h)$ is a uniquely defined piecewise polynomial continuous function. Let $[\varphi_h]$ be the jump of a function φ_h across a side σ: if $\sigma = \partial K \cap \partial L$, then $[\varphi_h]$ is the difference of the value of φ_h in K and L (the order of K and L has no influence on what follows), and if $\sigma \in \mathcal{E}_h^{\rm ext}$, then $[\varphi_h] = \varphi_h$. Then the following lemma is an easy modification of [23, Theorem 2.2] ($\sigma \cap K \neq \emptyset$ when σ contains a vertex of K).

LEMMA 4.1 (modified Oswald interpolation operator). *Let $\varphi_h \in \mathbb{P}_2(\mathcal{T}_h) \cap W_0(\mathcal{T}_h)$, and let $\mathcal{I}_{\rm MO}(\varphi_h) \in \mathbb{P}_d(\mathcal{T}_h) \cap H^1_0(\Omega)$ be constructed as described above. Then*

$$\|\nabla(\varphi_h - \mathcal{I}_{\rm MO}(\varphi_h))\|_K^2 \le C_1 \sum_{\sigma;\sigma\cap K\neq\emptyset} h_\sigma^{-1} \|[\varphi_h]\|_\sigma^2 ,$$

where the constant C_1 depends only on d and $\kappa_{\mathcal{T}}$.

4.3. A posteriori error estimates. We now finally state the a posteriori error estimates. Let $K \in \mathcal{T}_h$. Let us first set

$$m_K^2 := \min\left\{ C_{{\rm P},d} \frac{h_K^2}{c_{\mathbf{S},K}}, \frac{1}{c_{\mathbf{w},r,K}} \right\}.$$

We define the *residual estimator* $\eta_{{\rm R},K}$ by

$$\eta_{{\rm R},K} := m_K \|f + \nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h\|_K . \tag{4.2}$$

Next, denote $v := \tilde{p}_h - \mathcal{I}_{\rm MO}(\tilde{p}_h)$. The *nonconformity estimator* $\eta_{{\rm NC},K}$ is given by

$$\eta_{{\rm NC},K} := |||v|||_K \tag{4.3}$$

and the *convection estimator* $\eta_{{\rm C},K}$ by

$$\eta_{{\rm C},K} := \min\left\{ \frac{\|\nabla\cdot(v\mathbf{w}) - \frac{1}{2}v\nabla\cdot\mathbf{w}\|_K}{\sqrt{c_{\mathbf{w},r,K}}}, \left(\frac{C_{{\rm P},d} h_K^2 \|\nabla v\cdot\mathbf{w}\|_K^2}{c_{\mathbf{S},K}} + \frac{9\|v\nabla\cdot\mathbf{w}\|_K^2}{4c_{\mathbf{w},r,K}} \right)^{\frac{1}{2}} \right\}. \tag{4.4}$$

Finally, let

$$m_\sigma^2 := \min\left\{ \max_{K;\,\sigma\in\mathcal{E}_K} \left\{ C_{{\rm F},d} \frac{|\sigma| h_K^2}{|K| c_{\mathbf{S},K}} \right\}, \max_{K;\,\sigma\in\mathcal{E}_K} \left\{ \frac{|\sigma|}{|K| c_{\mathbf{w},r,K}} \right\} \right\} \tag{4.5}$$

for all $\sigma \in \mathcal{E}_h$. We set $\tilde{p}_\sigma := \langle \tilde{p}_h, 1\rangle_\sigma/|\sigma|$, the mean of the postprocessed scalar variable $\tilde{p}_h$ over a side $\sigma \in \mathcal{E}_h$; recall that $\hat{p}_\sigma$ is the upwind value given by (3.3) or (3.4); and define the *upwinding estimator* $\eta_{\mathrm{U},K}$ by

$$\eta_{\mathrm{U},K} := \sum_{\sigma\in\mathcal{E}_K} m_\sigma \|(\hat{p}_\sigma - \tilde{p}_\sigma)\mathbf{w}\cdot\mathbf{n}\|_\sigma \,. \tag{4.6}$$

We have the following a posteriori error estimates.

THEOREM 4.2 (a posteriori error estimate for the centered mixed finite element scheme). *Let p be the weak solution of the problem* (1.1a)–(1.1b) *given by* (2.7)*, and let $\tilde{p}_h$ be the postprocessed solution of the centered mixed finite element scheme* (3.1a)–(3.1b) *given by* (4.1a)–(4.1b)*. Then*

$$|||p - \tilde{p}_h|||_\Omega \le \left\{ \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{NC},K}^2 \right\}^{\frac12} + \left\{ \sum_{K\in\mathcal{T}_h} (\eta_{\mathrm{R},K} + \eta_{\mathrm{C},K})^2 \right\}^{\frac12} . \tag{4.7}$$

THEOREM 4.3 (a posteriori error estimate for the upwind-weighted mixed finite element scheme). *Let p be the weak solution of the problem* (1.1a)–(1.1b) *given by* (2.7)*, and let $\tilde{p}_h$ be the postprocessed solution of the upwind-weighted mixed finite element scheme* (3.2a)–(3.2b) *given by* (4.1a)–(4.1b)*. Then*

$$|||p - \tilde{p}_h|||_\Omega \le \left\{ \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{NC},K}^2 \right\}^{\frac12} + \left\{ \sum_{K\in\mathcal{T}_h} (\eta_{\mathrm{R},K} + \eta_{\mathrm{C},K} + \eta_{\mathrm{U},K})^2 \right\}^{\frac12} .$$

4.4. Local efficiency of the estimates. Let the local Péclet number Pe_K and ϱ_K be given by

$$\mathrm{Pe}_K := h_K \frac{C_{\mathbf{w},K}}{c_{\mathbf{S},K}} , \quad \varrho_K := \frac{C_{\mathbf{w},K}}{\sqrt{c_{\mathbf{w},r,K}}\sqrt{c_{\mathbf{S},K}}} . \tag{4.8}$$

Next, let, for $\varphi \in H^1(K)$,

$$\alpha_{*,K} := c_{\mathbf{S},K}\left(\frac{C_{\mathbf{S},K}}{c_{\mathbf{S},K}} + 2\varrho_K^2\right) , \quad \beta_{*,K} := c_{\mathbf{w},r,K} + \frac{\left|\nabla\cdot\mathbf{w}|_K\right|^2}{2c_{\mathbf{w},r,K}} ,$$

$$\alpha_{\#,K} := c_{\mathbf{S},K}\left(\frac{C_{\mathbf{S},K}}{c_{\mathbf{S},K}} + C_{\mathrm{P},d}\mathrm{Pe}_K^2\right) , \quad \beta_{\#,K} := c_{\mathbf{w},r,K} + \frac{9\left|\nabla\cdot\mathbf{w}|_K\right|^2}{4c_{\mathbf{w},r,K}} ,$$

$$|||\varphi|||_{*,K}^2 := \alpha_{*,K}\|\nabla\varphi\|_K^2 + \beta_{*,K}\|\varphi\|_K^2 , \quad |||\varphi|||_{\#,K}^2 := \alpha_{\#,K}\|\nabla\varphi\|_K^2 + \beta_{\#,K}\|\varphi\|_K^2 .$$

Finally, let

$$c_{\mathbf{S},\omega_K} := \min_{L;L\cap K\neq\emptyset} c_{\mathbf{S},L}, \quad c_{\mathbf{w},r,\omega_K} := \min_{L;L\cap K\neq\emptyset} c_{\mathbf{w},r,L}, \quad c_{\mathbf{S},\Omega} := \min_{K\in\mathcal{T}_h} c_{\mathbf{S},K}. \tag{4.9}$$

The theorem below discusses the local efficiency of our a posteriori error estimators.

THEOREM 4.4 (local efficiency of the a posteriori error estimators). *Let p be the weak solution of the problem* (1.1a)–(1.1b) *given by* (2.7)*, and let $\tilde{p}_h$ be the postprocessed solution of the centered mixed finite element scheme* (3.1a)–(3.1b) *or of the*

upwind-weighted mixed finite element scheme (3.2a)–(3.2b) *given by* (4.1a)–(4.1b). *Then, for the residual estimator* $\eta_{\mathrm{R},K}$ *on each* $K \in \mathcal{T}_h$, *there holds*

(4.10)
$$\eta_{\mathrm{R},K} \le C_2 |||p - \tilde{p}_h|||_K \left\{ \sqrt{\frac{C_{\mathbf{S},K}}{c_{\mathbf{S},K}}} \max\left\{1, \frac{C_{\mathbf{w},r,K}}{c_{\mathbf{w},r,K}}\right\} + \min\left\{ \mathrm{Pe}_K, \sqrt{\frac{C_{\mathbf{S},K}}{c_{\mathbf{S},K}}}\varrho_K \right\} \right\},$$

where the constant C_2 *depends only on the space dimension* d, *on the shape-regularity parameter* $\kappa_{\mathcal{T}}$, *and on the polynomial degree* k *of* f *(see Lemma* 7.6 *below). Next, for the nonconformity and velocity estimators* $\eta_{\mathrm{NC},K}$ *and* $\eta_{\mathrm{C},K}$ *on each* $K \in \mathcal{T}_h$, *we have*

$$\begin{aligned} \eta_{\mathrm{NC},K}^2 + \eta_{\mathrm{C},K}^2 \le C_3 \min\Bigg\{ & \frac{\alpha_{*,K}}{c_{\mathbf{S},\omega_K}} + \min\left\{ \frac{\beta_{*,K}}{c_{\mathbf{w},r,\omega_K}}, \frac{\beta_{*,K}h_K^2}{c_{\mathbf{S},\omega_K}} \right\}, \\ & \frac{\alpha_{\#,K}}{c_{\mathbf{S},\omega_K}} + \min\left\{ \frac{\beta_{\#,K}}{c_{\mathbf{w},r,\omega_K}}, \frac{\beta_{\#,K}h_K^2}{c_{\mathbf{S},\omega_K}} \right\} \Bigg\} \sum_{L;L\cap K\neq\emptyset} |||p - \tilde{p}_h|||_L^2 \\ & + C_3\beta_{\#,K} \inf_{s_h \in \mathbb{P}_2(\mathcal{T}_h)\cap H_0^1(\Omega)} \sum_{L;L\cap K\neq\emptyset} \|p - s_h\|_L^2, \end{aligned} \tag{4.11}$$

where the constant C_3 *depends only on* d *and* $\kappa_{\mathcal{T}}$ *(see Lemma* 7.7 *below). Finally, the upwinding estimator* $\eta_{\mathrm{U},K}$ *is not efficient and we have only*

$$\sum_{K\in\mathcal{T}_h} \eta_{\mathrm{U},K}^2 \le C_4 \max_{\sigma\in\mathcal{E}_h} \varrho_\sigma \max_{K\in\mathcal{T}_h} \tilde{\varrho}_K \min\left\{ \frac{1}{2} \sum_{K\in\mathcal{T}_h} \frac{\|f\|_K^2}{c_{\mathbf{w},r,K}}, \|f\|_\Omega^2 \frac{C_{\mathrm{DF}}}{c_{\mathbf{S},\Omega}} \right\}, \tag{4.12}$$

where C_{DF} *is the constant from the discrete Friedrichs inequality* (2.4), *the constant* C_4 *depends only on* d *and* $\kappa_{\mathcal{T}}$ *(see Lemma* 7.8 *below), and*

$$\varrho_\sigma := \left(\frac{\max_{K;\sigma\in\mathcal{E}_K} c_{\mathbf{S},K}}{\min_{K;\sigma\in\mathcal{E}_K} c_{\mathbf{S},K}} \right)^2, \quad \tilde{\varrho}_K := \min\left\{ (\mathrm{Pe}_K)^2, (\varrho_K)^2 \frac{\max_{L;L\cap K\in\mathcal{E}_h} c_{\mathbf{w},r,L}}{\min_{L;L\cap K\in\mathcal{E}_h} c_{\mathbf{w},r,L}} \right\}.$$

5. Various remarks. We give several remarks in this section.

5.1. Nature of the estimates. The basis of the a posteriori error estimates derived in this paper is the construction of the postprocessed scalar variable $\tilde{p}_h$ and the consequent application of the abstract framework arising from the primal weak formulation (2.7) of the continuous problem; cf. Lemmas 7.1 and 7.2 below. Compared to Galerkin finite element approximations, the crucial advantage is that $\tilde{p}_h$, an elementwise quadratic polynomial, has the normal traces of its flux $-\mathbf{S}\nabla\tilde{p}_h$ (which is, by (4.1a), nothing else than the mixed finite element vector variable $\mathbf{u}_h$) continuous across interior sides. Hence the side error estimators penalizing the mass balance common in Galerkin finite element methods (cf. [33]) do not appear here at all. This advantage is, however, compensated by the fact that $\tilde{p}_h \notin H_0^1(\Omega)$, so that the estimators known from nonconforming and discontinuous Galerkin finite elements (cf. [19, 23]) appear. Next, whereas in the lowest-order Galerkin finite element method $\nabla\cdot(\mathbf{S}_K\nabla p_h)|_K$ is always equal to zero on all $K \in \mathcal{T}_h$, the element residuals (4.2) give

a very good sense. We also notice that using (2.6), (4.1a), and (2.4),

(5.1)
$$|||p-\tilde{p}_h|||_\Omega^2 = \sum_{K\in\mathcal{T}_h} \left\{ \|\mathbf{S}^{-\frac{1}{2}}(\mathbf{u}-\mathbf{u}_h)\|_K^2 + c_{\mathbf{w},r,K}\|p-\tilde{p}_h\|_K^2 \right\}$$
$$\geq \sum_{K\in\mathcal{T}_h} \left\{ \frac{1}{2}\|\mathbf{S}^{-\frac{1}{2}}(\mathbf{u}-\mathbf{u}_h)\|_K^2 + c_{\mathbf{w},r,K}\|p-\tilde{p}_h\|_K^2 \right\} + \frac{c_{\mathbf{S},\Omega}}{2C_{\mathrm{DF}}}\|p-\tilde{p}_h\|_\Omega^2 ,$$

so that we have the usual mixed finite element $L^2(\Omega)$ control over the error in both the scalar and vector unknowns even if $c_{\mathbf{w},r,K}=0$ for some $K\in\mathcal{T}_h$.

5.2. The estimates and their local efficiency with respect to S and w. We discuss here our a posteriori error estimates and their local efficiency that we have been able to prove in Theorem 4.4. For further remarks, see the next section.

The minimum in the definition of the residual estimator $\eta_{\mathrm{R},K}$ (4.2) prevents it from growing to extreme values on coarse elements with a small value $c_{\mathbf{S},K}$ when $c_{\mathbf{w},r,K}>0$. Its local efficiency depends only on anisotropy in its element expressed by the ratio $\sqrt{C_{\mathbf{S},K}/c_{\mathbf{S},K}}$ and there is no dependency on inhomogeneities. Next, under the given assumptions, $C_{\mathbf{w},r,K}/c_{\mathbf{w},r,K}\leq 2$ whenever r_K is nonnegative. Finally, the minimum of the local Péclet number Pe_K and ϱ_K ensures boundedness if $c_{\mathbf{w},r,K}\neq 0$ and if h_K is large and optimal efficiency as Pe_K becomes small.

The minimum in the definition of the convection estimator $\eta_{\mathrm{C},K}$ (4.4) prevents it from exploding when $c_{\mathbf{w},r,K}=0$ but $C_{\mathbf{w},K}\neq 0$. Together with the nonconformity estimator $\eta_{\mathrm{NC},K}$ (4.3), they give local efficiency, up to higher-order terms if $c_{\mathbf{w},r,K}\neq 0$ (the part $\inf_{s_h\in\mathbb{P}_2(\mathcal{T}_h)\cap H_0^1(\Omega)}$), which is shown to be a function of a local (meaning all elements sharing a vertex with the given one) maximal ratio of inhomogeneities (the term $\sqrt{\alpha_{*,K}/c_{\mathbf{S},\omega_K}}$) and of $\sqrt{C_{\mathbf{S},K}/c_{\mathbf{S},K}}$ in each element concerning anisotropy. For further remarks, see the next section. Finally, the efficiency gets into optimal values with respect to convection dominance as Pe_K gets sufficiently small. We note also that the estimate is robust (up to the higher-order term) in the reaction-dominated case as well, since the quantities $C_{\mathbf{w},r,K}/c_{\mathbf{w},r,K}$ and $\sqrt{\beta_{*,K}/c_{\mathbf{w},r,\omega_K}}$ remain well bounded in the limit.

The fact that the upwinding estimator $\eta_{\mathrm{U},K}$ (4.6) cannot in general give a lower bound for the error is quite obvious: it is not difficult to imagine a situation where $p=\tilde{p}_h$, whereas $(\hat{p}_\sigma-\tilde{p}_\sigma)$, the difference of the mean value of $\tilde{p}_h$ on a side σ and of the combination of the mean values of $\tilde{p}_h$ on the elements sharing σ, is generally nonzero. However, we at least show that there is an upper bound for the contributions of this estimator, which moreover decreases with the local Péclet numbers as $O(h)$. It should be noted that this estimator does not change the limit optimality of the schemes and estimates—see section 5.5 below for a remark on this point.

5.3. Asymptotic exactness and asymptotic robustness with respect to inhomogeneities and anisotropies. We show in this remark that the (global asymptotic) efficiency of our estimates is indeed even better than that proved in Theorem 4.4 and discussed in the previous section.

5.3.1. Pure diffusion problems. Let us first consider a pure diffusion problem, i.e., $r=\mathbf{w}=0$ in (1.1a)–(1.1b). Using that in this case $-\nabla\cdot(\mathbf{S}_K\nabla\tilde{p}_h|_K)=\nabla\cdot\mathbf{u}_h|_K=f_K$ for all $K\in\mathcal{T}_h$, where f_K is the mean value of f over K, the analysis for the general

case simplifies to the a posteriori error estimate (4.7) with $\eta_{\mathrm{C},K} = 0$ and

$$\eta_{\mathrm{R},K}^2 := C_{\mathrm{P},d} \frac{h_K^2}{c_{\mathbf{S},K}} \|f - f_K\|_K^2 , \tag{5.2}$$

$$\eta_{\mathrm{NC},K}^2 := \|\mathbf{S}^{\frac{1}{2}} \nabla(\tilde{p}_h - s)\|_K^2 , \tag{5.3}$$

where in particular $s \in H_0^1(\Omega)$ can be chosen arbitrarily (cf. Lemma 7.2 below). Examples are the Oswald or the modified Oswald interpolates of $\tilde{p}_h$—in the pure diffusion case, all the presented results hold similarly for these two operators. Also note that since $\nabla \cdot (\mathbf{u} - \mathbf{u}_h)|_K = f - f_K$ is fully computable for all $K \in \mathcal{T}_h$, the control over $\|\mathbf{u} - \mathbf{u}_h\|_\Omega + \|\nabla \cdot (\mathbf{u} - \mathbf{u}_h)\|_\Omega$ immediately follows using (5.1).

Our main point is, however, that the above developments in fact imply

$$|||p - \tilde{p}_h|||_\Omega \leq \inf_{s \in H_0^1(\Omega)} |||\tilde{p}_h - s|||_\Omega + \left\{ \sum_{K \in \mathcal{T}_h} C_{\mathrm{P},d} \frac{h_K^2}{c_{\mathbf{S},K}} \|f - f_K\|_K^2 \right\}^{\frac{1}{2}} , \tag{5.4}$$

which, in the case where f is piecewise constant, by virtue of

$$\inf_{s \in H_0^1(\Omega)} |||\tilde{p}_h - s|||_\Omega \leq |||\tilde{p}_h - p|||_\Omega,$$

gives asymptotic global efficiency of such an estimator with a constant 1, i.e., asymptotic exactness and asymptotic full robustness with respect to inhomogeneities and anisotropies (asymptotic with respect to the approximation of $\tilde{p}_h$ by some, e.g., polynomial, $s \in H_0^1(\Omega)$ on a fixed grid $\mathcal{T}_h$). In the general case, if, e.g., $f \in H^1(\mathcal{T}_h)$, then $\|f - f_K\|_K^2 \leq C_{\mathrm{P},d} h_K^2 \|\nabla f\|_K^2$, and asymptotic exactness and asymptotic robustness still hold true (this time asymptotic also with respect to $h \to 0$). Although we use only the Oswald or the modified Oswald interpolates of $\tilde{p}_h$ instead of evaluating or approximating the infimum in (5.4), the numerical experiments of section 8.1 below show that estimators of section 4.3 remain almost asymptotically exact and robust with respect to inhomogeneities and anisotropies.

5.3.2. Convection-diffusion-reaction problems. The above considerations roughly extend to the convection-diffusion-reaction case in the following sense: for the centered mixed finite element scheme (3.1a)–(3.1b), one has (7.4) and consequently a superconvergence of the residual estimators $\eta_{\mathrm{R},K}$ (4.2) to zero. Next, for divergence-free velocity fields $\mathbf{w}$, the second arguments of the convection estimators $\eta_{\mathrm{C},K}$ in (4.4) again superconverge to zero since $\tilde{p}_h \in W_0(\mathcal{T}_h)$ (both as $h \to 0$). Hence the estimate will be asymptotically given only by the nonconformity estimators $\eta_{\mathrm{NC},K}$ of (4.3) and thus by the best approximation of $\tilde{p}_h$ by $s \in H_0^1(\Omega)$ such that its means are given by the means of $\tilde{p}_h$. (This property is needed when convection is present; see Lemma 7.4 below.) This asymptotic almost optimal efficiency is again observed below in numerical experiments in section 8.2.

5.4. Pure diffusion problems: Mixed finite elements and a generalized weak solution. Let us in this remark consider $r = \mathbf{w} = 0$ in (1.1a)–(1.1b) and generalize the classical weak solution to a function $\tilde{p} \in W_0(\mathcal{T}_h)$ such that

$$\mathcal{B}(\tilde{p}, \varphi) = (f, \varphi)_\Omega \qquad \forall \varphi \in W_0(\mathcal{T}_h) . \tag{5.5}$$

(In)equalities (2.9) and (2.10) together with the discrete Friedrichs inequality (2.4) ensure the existence of a unique solution of (5.5).

We thus have

$$|||\tilde{p}-\tilde{p}_h|||_\Omega = \frac{\mathcal{B}(\tilde{p}-\tilde{p}_h,\tilde{p}-\tilde{p}_h)}{|||\tilde{p}-\tilde{p}_h|||_\Omega} \le \sup_{\varphi\in W_0(\mathcal{T}_h),\,|||\varphi|||_\Omega=1} \mathcal{B}(\tilde{p}-\tilde{p}_h,\varphi)$$

and develop, similarly as in the proof of Lemma 7.2 below,

$$\begin{aligned}\mathcal{B}(\tilde{p}-\tilde{p}_h,\varphi) &= (f,\varphi)_\Omega + \sum_{K\in\mathcal{T}_h}\left\{(\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h),\varphi)_K - \langle\mathbf{S}\nabla\tilde{p}_h\cdot\mathbf{n},\varphi\rangle_{\partial K}\right\}\\ &= \sum_{K\in\mathcal{T}_h}(f-\nabla\cdot\mathbf{u}_h,\varphi)_K + \sum_{\sigma\in\mathcal{E}_h}\langle\mathbf{u}_h\cdot\mathbf{n},[\varphi]\rangle_\sigma\\ &= \sum_{K\in\mathcal{T}_h}(f-\nabla\cdot\mathbf{u}_h,\varphi)_K = \sum_{K\in\mathcal{T}_h}(f-f_K,\varphi-\varphi_K)_K,\end{aligned}$$

using the bilinearity of $\mathcal{B}(\cdot,\cdot)$, the definition (5.5) of the generalized weak solution $\tilde{p}$, the Green theorem in each $K\in\mathcal{T}_h$, the relation (4.1a) between $\tilde{p}_h$ and $\mathbf{u}_h$, reordering the summation over the boundaries of elements to the summation over the sides, using the continuity of the normal trace of $\mathbf{u}_h$ expressed by $\mathbf{u}_h|_K\cdot\mathbf{n}_K = -\mathbf{u}_h|_L\cdot\mathbf{n}_L$ on $\sigma_{K,L}\in\mathcal{E}_h^{\mathrm{int}}$, the fact that $\mathbf{u}_h\cdot\mathbf{n}$ is constant on all sides $\sigma\in\mathcal{E}_h$ and the definition (2.3) of the space $W_0(\mathcal{T}_h)$, and finally the equation (3.1b) of the definition of the mixed finite element scheme (φ_K is the mean of φ over K). Next, estimate (7.5) given below holds true also in this case, so that finally the Cauchy–Schwarz inequality leads to

$$|||\tilde{p}-\tilde{p}_h|||_\Omega \le \left\{\sum_{K\in\mathcal{T}_h}\eta_{\mathrm{R},K}^2\right\}^{\frac12}$$

with $\eta_{\mathrm{R},K}$ given by (5.2).

First, this is a completely data-dependent a posteriori error estimate, and second, this is in fact an a priori error estimate as well: it shows that the mixed finite element solutions $\tilde{p}_h$ and $\mathbf{u}_h$ (cf. (5.1), which still holds true) converge both as $O(h^2)$ in the $L^2(\Omega)$, $\mathbf{L}^2(\Omega)$, respectively, norms to the generalized weak solution $\tilde{p}$ given by (5.5) and its flux $\tilde{\mathbf{u}}$, $\tilde{\mathbf{u}}|_K := -\mathbf{S}\nabla\tilde{p}|_K$ (for $f\in H^1(\mathcal{T}_h)$). Moreover, as soon as f is piecewise constant, $\tilde{p}_h$ is directly equal to the generalized solution! We emphasize that these results hold true for $\mathbf{S}$ piecewise constant but arbitrarily inhomogeneous and anisotropic; they apparently confirm the observations of a very good behavior of mixed methods in these circumstances. There are also very interesting consequences in one space dimension; cf. section 5.6 below.

5.5. A combination of the centered and upwind-weighted schemes. The scheme (3.2a)–(3.2b) guarantees stability in the convection-dominated case, but the additional upwinding estimator $\eta_{\mathrm{U},K}$ given by (4.6) is unfortunately not efficient. On the other hand, the scheme (3.1a)–(3.1b), however precise if h is sufficiently small, may give completely wrong results on coarse meshes. Hence a good idea may be a smooth transition from the upwind-weighted to the centered scheme under the form

$$(\mathbf{S}^{-1}\mathbf{u}_h,\mathbf{v}_h)_\Omega - (p_h,\nabla\cdot\mathbf{v}_h)_\Omega = 0 \qquad \forall\,\mathbf{v}_h\in\mathbf{RTN}^0(\mathcal{T}_h),$$

$$(\nabla\cdot\mathbf{u}_h,\phi_K)_K + \sum_{\sigma\in\mathcal{E}_K}\left\{(\mu_\sigma\hat{p}_\sigma+(1-\mu_\sigma)\tilde{p}_\sigma)w_{K,\sigma}\phi_K\right\} + (rp_h,\phi_K)_K = (f,\phi_K)_K \qquad \forall K\in\mathcal{T}_h,$$

where $\hat{p}_\sigma$ is the upstream value and μ_σ is set to $1-2\nu_\sigma$ with ν_σ given by (3.5). Notice that such a scheme is fully rewritable in terms of the original unknowns p_h, $\mathbf{u}_h$, using that $\sum_{\sigma\in\mathcal{E}_K}\tilde{p}_\sigma w_{K,\sigma}\phi_K = \langle\tilde{p}_h\mathbf{w}\cdot\mathbf{n},\phi_K\rangle_{\partial K}$ and Lemma 6.2 below.

5.6. The estimates in one space dimension. As the last remark, it appears that the above results have interesting particular consequences in one space dimension, where the two schemes (3.1a)–(3.1b) and (3.2a)–(3.2b) can likewise be defined.

5.6.1. One dimension: No nonconformity. First of all, Lemma 6.1 below reduces in one space dimension to the assertion that the postprocessed variable $\tilde{p}_h$ given by (4.1a)–(4.1b) is continuous, i.e., that in this case $\tilde{p}_h \in H_0^1(\Omega)$. An immediate consequence is that the parts of the a posteriori error estimates of Theorems 4.2–4.3 related to nonconformity disappear.

5.6.2. Lowest-order mixed finite elements: An exact three-point scheme for one-dimensional diffusion problems with piecewise constant coefficients. Another quite interesting consequence is related to the remark of section 5.4 and results of [36]. As there is no nonconformity, the superconvergence $O(h^2)$ of both $\tilde{p}_h$ and $\mathbf{u}_h$ (this time towards the weak solution and its flux, coinciding with the generalized one) always holds true, and, moreover, it appears that in one space dimension, one can always rewrite the schemes with only p_K, $K\in\mathcal{T}_h$, as unknowns. Hence the lowest-order mixed finite elements represent a scheme with a three-point stencil which is exact for one-dimensional pure diffusion problems, where the diffusion tensor $\mathbf{S}$ (this time a scalar function) and the right-hand side f are piecewise constant (and hence possibly arbitrarily discontinuous). This should be compared to the known results for the finite volume/finite difference method. In particular, the (best known?) scheme proposed by Ewing, Iliev, and Lazarov in [21] is exact only when the right-hand side is constant (the diffusion tensor may be piecewise constant); cf. Remark 2.4 in [21].

6. Discrete properties of the schemes. In this section we prove different properties of the schemes (3.1a)–(3.1b) and (3.2a)–(3.2b) and of the postprocessed scalar variable $\tilde{p}_h$ needed in the paper.

LEMMA 6.1 (continuity of the means of traces of $\tilde{p}_h$). *It holds that $\tilde{p}_h\in W_0(\mathcal{T}_h)$; i.e.,*

$$\langle\tilde{p}_h|_K-\tilde{p}_h|_L,1\rangle_{\sigma_{K,L}}=0\qquad\forall\sigma_{K,L}\in\mathcal{E}_h^{\mathrm{int}},$$

$$\langle\tilde{p}_h,1\rangle_\sigma=0\qquad\forall\sigma\in\mathcal{E}_h^{\mathrm{ext}}.$$

Proof. Let us consider a side $\sigma_{K,L}\in\mathcal{E}_h^{\mathrm{int}}$. Then taking $\mathbf{v}_h$ equal to the basis function $\mathbf{v}_{\sigma_{K,L}}$ (cf. section 3.1) in (3.1a) or (3.2a) yields

$$\begin{aligned}0&=-(\nabla\tilde{p}_h,\mathbf{v}_{\sigma_{K,L}})_{K\cup L}-(\tilde{p}_h,\nabla\cdot\mathbf{v}_{\sigma_{K,L}})_{K\cup L}\\&=-\langle\mathbf{v}_{\sigma_{K,L}}\cdot\mathbf{n},\tilde{p}_h\rangle_{\partial K}-\langle\mathbf{v}_{\sigma_{K,L}}\cdot\mathbf{n},\tilde{p}_h\rangle_{\partial L}=\langle\mathbf{v}_{\sigma_{K,L}}\cdot\mathbf{n}_K,\tilde{p}_h|_L-\tilde{p}_h|_K\rangle_{\sigma_{K,L}},\end{aligned}$$

using the definition (4.1a)–(4.1b) of $\tilde{p}_h$, the fact that $\nabla\cdot\mathbf{v}_h$ for $\mathbf{v}_h\in\mathbf{RTN}^0(\mathcal{T}_h)$ is constant in each simplex (which allows us to replace p_h by $\tilde{p}_h$), the Green theorem, and the fact that $\mathbf{v}_{\sigma_{K,L}}$ has a nonzero normal flux only through $\sigma_{K,L}$. The first assertion of the lemma follows by the fact that $\mathbf{v}_h\cdot\mathbf{n}$ for $\mathbf{v}_h\in\mathbf{RTN}^0(\mathcal{T}_h)$ is constant on each side $\sigma\in\mathcal{E}_h$. The proof for boundary sides is completely similar. ∎

LEMMA 6.2 (equivalent form of the centered scheme). *The scheme* (3.1a)–(3.1b) *can be equivalently written: find* $\mathbf{u}_h \in \mathbf{RTN}^0(\mathcal{T}_h)$ *and* $p_h \in \Phi(\mathcal{T}_h)$ *such that*

$$(\mathbf{S}^{-1}\mathbf{u}_h, \mathbf{v}_h)_\Omega - (\tilde{p}_h, \nabla\cdot\mathbf{v}_h)_\Omega = 0 \qquad \forall\, \mathbf{v}_h \in \mathbf{RTN}^0(\mathcal{T}_h), \tag{6.1a}$$

$$(\nabla\cdot\mathbf{u}_h, \phi_K)_K + \langle \tilde{p}_h\mathbf{w}\cdot\mathbf{n}, \phi_K\rangle_{\partial K} + (r\tilde{p}_h, \phi_K)_K = (f, \phi_K)_K \qquad \forall K \in \mathcal{T}_h, \tag{6.1b}$$

where $\tilde{p}_h$ *is defined by* (4.1a)–(4.1b).

Proof. Since $\nabla\cdot\mathbf{v}_h$ for $\mathbf{v}_h \in \mathbf{RTN}^0(\mathcal{T}_h)$ is constant in each simplex and since r was in Assumption (B3) supposed piecewise constant as well, one can replace p_h by $\tilde{p}_h$ in the terms $(p_h, \nabla\cdot\mathbf{v}_h)_\Omega$ and $(rp_h, \phi_K)_K$ using (4.1b). Similarly, using in addition the Green theorem,

$$\begin{aligned}-(\mathbf{S}_K^{-1}\mathbf{u}_h\cdot\mathbf{w}, \phi_K)_K + (p_K\nabla\cdot\mathbf{w}, \phi_K)_K &= (\nabla\tilde{p}_h\cdot\mathbf{w}, \phi_K)_K + (\tilde{p}_h\nabla\cdot\mathbf{w}, \phi_K)_K \\ &= (\nabla\cdot(\tilde{p}_h\mathbf{w}), \phi_K)_K = \langle \tilde{p}_h\mathbf{w}\cdot\mathbf{n}, \phi_K\rangle_{\partial K}. \qquad \square\end{aligned}$$

Remark 6.3 (hybridization of the schemes). Mixed finite element schemes can equivalently be reformulated while relaxing the continuity of the normal trace of $\mathbf{u}_h$ required in the definition of the space $\mathbf{RTN}^0(\mathcal{T}_h)$ and imposing it instead with the help of Lagrange multipliers λ_σ, $\sigma \in \mathcal{E}_h^{\rm int}$; cf. [12, section V.1.2]. The centered scheme (3.1a)–(3.1b), taking into account its equivalent form given by Lemma 6.2, then changes to: find $\mathbf{u}_h \in \mathbf{RTN}^0_{-1}(\mathcal{T}_h)$, $p_h \in \Phi(\mathcal{T}_h)$, and λ_σ, $\sigma \in \mathcal{E}_h^{\rm int}$, with $\tilde{p}_h$ defined by (4.1a)–(4.1b), such that

$$\sum_{K\in\mathcal{T}_h}\left\{(\mathbf{S}^{-1}\mathbf{u}_h, \mathbf{v}_h)_K - (\tilde{p}_h, \nabla\cdot\mathbf{v}_h)_K + \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_h^{\rm int}}\langle \mathbf{v}_h\cdot\mathbf{n}, \lambda_\sigma\rangle_\sigma\right\} = 0 \tag{6.2a}$$

$$\forall\, \mathbf{v}_h \in \mathbf{RTN}^0_{-1}(\mathcal{T}_h),$$

$$(\nabla\cdot\mathbf{u}_h, \phi_K)_K + \langle \tilde{p}_h\mathbf{w}\cdot\mathbf{n}, \phi_K\rangle_{\partial K} + (r\tilde{p}_h, \phi_K)_K = (f, \phi_K)_K \qquad \forall K \in \mathcal{T}_h, \tag{6.2b}$$

$$\langle (\mathbf{u}_h\cdot\mathbf{n})|_K + (\mathbf{u}_h\cdot\mathbf{n})|_L, 1\rangle_{\sigma_{K,L}} = 0 \qquad \forall \sigma_{K,L} \in \mathcal{E}_h^{\rm int}, \tag{6.2c}$$

whereas the upwind-weighted scheme (3.2a)–(3.2b) becomes: find $\mathbf{u}_h \in \mathbf{RTN}^0_{-1}(\mathcal{T}_h)$, $p_h \in \Phi(\mathcal{T}_h)$, and λ_σ, $\sigma \in \mathcal{E}_h^{\rm int}$ such that

$$\sum_{K\in\mathcal{T}_h}\left\{(\mathbf{S}^{-1}\mathbf{u}_h, \mathbf{v}_h)_K - (p_h, \nabla\cdot\mathbf{v}_h)_K + \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_h^{\rm int}}\langle \mathbf{v}_h\cdot\mathbf{n}, \lambda_\sigma\rangle_\sigma\right\} = 0 \tag{6.3a}$$

$$\forall\, \mathbf{v}_h \in \mathbf{RTN}^0_{-1}(\mathcal{T}_h),$$

$$(\nabla\cdot\mathbf{u}_h, \phi_K)_K + \sum_{\sigma\in\mathcal{E}_K}\hat{p}_\sigma w_{K,\sigma}\phi_K + (rp_h, \phi_K)_K = (f, \phi_K)_K \qquad \forall K \in \mathcal{T}_h, \tag{6.3b}$$

$$\langle (\mathbf{u}_h\cdot\mathbf{n})|_K + (\mathbf{u}_h\cdot\mathbf{n})|_L, 1\rangle_{\sigma_{K,L}} = 0 \qquad \forall \sigma_{K,L} \in \mathcal{E}_h^{\rm int}. \tag{6.3c}$$

LEMMA 6.4 (relation of $\tilde{p}_h$ to the Lagrange multipliers λ_σ). *It holds that*

$$\lambda_\sigma = \tilde{p}_\sigma = \frac{\langle \tilde{p}_h, 1\rangle_\sigma}{|\sigma|} \qquad \forall \sigma \in \mathcal{E}_h^{\rm int}.$$

Proof. The proof is similar to that of Lemma 6.1. Let $K \in \mathcal{T}_h$ and $\sigma \in \mathcal{E}_K \cap \mathcal{E}_h^{\rm int}$. Then taking $\mathbf{v}_h = \mathbf{v}_\sigma$ in (6.2a) or (6.3a), we have

$$0 = -(\nabla \tilde{p}_h, \mathbf{v}_\sigma)_K - (\tilde{p}_h, \nabla \cdot \mathbf{v}_\sigma)_K + \langle \mathbf{v}_\sigma \cdot \mathbf{n}, \lambda_\sigma \rangle_\sigma = \langle \mathbf{v}_\sigma \cdot \mathbf{n}, \lambda_\sigma - \tilde{p}_h \rangle_\sigma \,,$$

using the definition (4.1a)–(4.1b) of $\tilde{p}_h$, the fact that $\nabla \cdot \mathbf{v}_\sigma$ is constant in each simplex, the fact that $\mathbf{v}_\sigma$ has a nonzero normal flux only through σ, and the Green theorem. The assertion of the lemma follows by the fact that $\mathbf{v}_\sigma \cdot \mathbf{n}$ is constant on σ. ∎

LEMMA 6.5 (a priori estimate for the upwind-weighted scheme). *Let $\mathbf{u}_h$, p_h be the solutions of the upwind-weighted scheme* (3.2a)–(3.2b)*, and let $\tilde{p}_h$ be the postprocessed scalar variable given by* (4.1a)–(4.1b)*. Then*

$$\sum_{K \in \mathcal{T}_h} \left\{ c_{\mathbf{S},K} \|\nabla \tilde{p}_h\|_K^2 + \frac{1}{2} c_{\mathbf{w},r,K} \, \|p_h\|_K^2 \right\} \le \frac{1}{2} \sum_{K \in \mathcal{T}_h} \frac{\|f\|_K^2}{c_{\mathbf{w},r,K}}$$

if $c_{\mathbf{w},r,K} > 0$ for all $K \in \mathcal{T}_h$ and

$$\sum_{K \in \mathcal{T}_h} \left\{ \frac{1}{2} c_{\mathbf{S},K} \|\nabla \tilde{p}_h\|_K^2 + c_{\mathbf{w},r,K} \, \|p_h\|_K^2 \right\} \le \frac{\|f\|_\Omega^2}{2} \frac{C_{\rm DF}}{c_{\mathbf{S},\Omega}},$$

where $c_{\mathbf{S},\Omega}$ is given by (4.9) *and $C_{\rm DF}$ is the constant from the discrete Friedrichs inequality* (2.4).

Proof. Let us set $\phi_h = p_h$ in (3.2b). We then can rewrite the first term of the left-hand side of (3.2b) as

$$\sum_{K \in \mathcal{T}_h} (\nabla \cdot \mathbf{u}_h, p_K)_K = \sum_{K \in \mathcal{T}_h} \left\{ -(\mathbf{u}_h, \nabla \tilde{p}_h)_K + \langle \mathbf{u}_h \cdot \mathbf{n}, \tilde{p}_h \rangle_{\partial K} \right\} = \sum_{K \in \mathcal{T}_h} (\mathbf{S}_K \nabla \tilde{p}_h, \nabla \tilde{p}_h)_K$$

$$+ \sum_{\sigma_{K,L} \in \mathcal{E}_h^{\rm int}} \langle \mathbf{u}_h \cdot \mathbf{n}_K, \tilde{p}_h|_K - \tilde{p}_h|_L \rangle_{\sigma_{K,L}} + \sum_{\sigma \in \mathcal{E}_h^{\rm ext}} \langle \mathbf{u}_h \cdot \mathbf{n}, \tilde{p}_h \rangle_\sigma \ge \sum_{K \in \mathcal{T}_h} c_{\mathbf{S},K} \|\nabla \tilde{p}_h\|_K^2 \,,$$

using the fact that $\nabla \cdot \mathbf{u}_h$ is constant on each $K \in \mathcal{T}_h$ and we thus can replace p_h by $\tilde{p}_h$ employing (4.1b), the Green theorem, (4.1a), the fact that $\mathbf{u}_h \cdot \mathbf{n}$ is constant on each $\sigma \in \mathcal{E}_h$, the continuity of the means of the traces of $\tilde{p}_h$ given by Lemma 6.1, and finally Assumption (B1). Next,

$$\sum_{K \in \mathcal{T}_h} \sum_{\sigma \in \mathcal{E}_K} \hat{p}_\sigma w_{K,\sigma} p_K = \sum_{\sigma_{K,L} \in \mathcal{E}_h^{\rm int}} \{ \hat{p}_\sigma w_{K,\sigma} p_K + \hat{p}_\sigma w_{L,\sigma} p_L \} + \sum_{\sigma_K \in \mathcal{E}_h^{\rm ext}} \hat{p}_\sigma w_{K,\sigma} p_K$$

$$= \sum_{\sigma_{K,L} \in \mathcal{E}_h^{\rm int},\, w_{K,\sigma} \ge 0} w_{K,\sigma} \left(p_K (p_K - p_L) - \nu_\sigma (p_L - p_K)^2 \right) + \sum_{\sigma_K \in \mathcal{E}_h^{\rm ext}} \hat{p}_\sigma w_{K,\sigma} p_K$$

$$= \frac{1}{2} \sum_{\sigma_{K,L} \in \mathcal{E}_h^{\rm int},\, w_{K,\sigma} \ge 0} w_{K,\sigma} (p_K^2 - p_L^2) + \sum_{\sigma_{K,L} \in \mathcal{E}_h^{\rm int}} |w_{K,\sigma}| (p_L - p_K)^2 \left(\frac{1}{2} - \nu_\sigma \right)$$

$$+ \sum_{\sigma_K \in \mathcal{E}_h^{\rm ext}} \left\{ \frac{1}{2} p_K^2 w_{K,\sigma} + |w_{K,\sigma}| p_K^2 \left(\frac{1}{2} - \nu_\sigma \right) \right\} \ge \frac{1}{2} \sum_{K \in \mathcal{T}_h} p_K^2 (\nabla \cdot \mathbf{w}, 1)_K,$$

where we have rewritten the summation over the sides and fixed denotation of $K, L \in \mathcal{T}_h$ sharing a side $\sigma_{K,L} \in \mathcal{E}_h^{\rm int}$ such that $w_{K,\sigma} \ge 0$; used that $w_{K,\sigma} = -w_{L,\sigma}$, the

definition (3.3)–(3.4) of $\hat{p}_\sigma$, and the relation $2a(a-b) = (a-b)^2 + a^2 - b^2$; estimated using $0 \le \nu_\sigma \le 1/2$, which follows from (3.5); rewritten the summation back over the elements and their sides; and finally employed the Green theorem, giving $\sum_{\sigma\in\mathcal{E}_K} w_{K,\sigma} = (\nabla\cdot\mathbf{w},1)_K$. Finally, $(rp_h,p_h)_\Omega = \sum_{K\in\mathcal{T}_h} p_K^2 (r,1)_K$.

The right-hand side of (3.2b) with $\phi_h = p_h$ can be estimated either by

$$(f,p_h)_\Omega \le \sum_{K\in\mathcal{T}_h} \|f\|_K \frac{\sqrt{c_{\mathbf{w},r,K}}}{\sqrt{c_{\mathbf{w},r,K}}} \|p_h\|_K \le \frac{1}{2}\sum_{K\in\mathcal{T}_h} \frac{\|f\|_K^2}{c_{\mathbf{w},r,K}} + \frac{1}{2}\sum_{K\in\mathcal{T}_h} c_{\mathbf{w},r,K}\|p_h\|_K^2$$

or by

$$(f,p_h)_\Omega \le \|f\|_\Omega \|p_h\|_\Omega \le \frac{\|f\|_\Omega^2}{2}\frac{C_{\mathrm{DF}}}{c_{\mathbf{S},\Omega}} + \frac{c_{\mathbf{S},\Omega}}{C_{\mathrm{DF}}}\frac{\|\tilde{p}_h\|_\Omega^2}{2} \le \frac{\|f\|_\Omega^2}{2}\frac{C_{\mathrm{DF}}}{c_{\mathbf{S},\Omega}} + \frac{c_{\mathbf{S},\Omega}}{2}\sum_{K\in\mathcal{T}_h}\|\nabla\tilde{p}_h\|_K^2,$$

using the Cauchy–Schwarz, $ab \le \varepsilon a^2/2 + b^2/(2\varepsilon)$, $\varepsilon > 0$, $\|p_h\|_K \le \|\tilde{p}_h\|_K$, and the discrete Friedrichs (2.4) inequalities. The assertion follows by combining the above estimates. ∎

Remark 6.6 (existence and uniqueness for the upwind-weighted scheme). From Lemma 6.5, existence and uniqueness for the upwind-weighted scheme (3.2a)–(3.2b) easily follows. Indeed, let $f = 0$. Then $p_h = 0$ and $\mathbf{u}_h = -\mathbf{S}\nabla\tilde{p}_h = 0$ for all $K \in \mathcal{T}_h$.

Remark 6.7 (existence and uniqueness for the centered scheme). In contrast with the upwind-weighted scheme, existence and uniqueness for the centered scheme (3.1a)–(3.1b) is in [17] guaranteed only for "h sufficiently small." Alternatively, there exists a unique solution if $C_{\mathbf{w},K} \le 2(1-\mu)\sqrt{c_{\mathbf{S},K}}\sqrt{\tilde{c}_{\mathbf{w},r,K}}$ for some $\mu \in (0,1)$ and all $K \in \mathcal{T}_h$, where $(\nabla\cdot\mathbf{w} + r)|_K = \tilde{c}_{\mathbf{w},r,K} > 0$, which corresponds to the case that is not convection-dominated.

7. Proofs of the a posteriori error estimates and of their local efficiency. We shall prove in this section the a posteriori error estimates stated by Theorems 4.2–4.3, as well as their local efficiency discussed in Theorem 4.4.

7.1. Proofs of the a posteriori error estimates. To begin with, we state the following result, the purpose of which is to give an optimal abstract bound on the error between $p \in H^1(\Omega)$ and $\tilde{p} \in H^1(\mathcal{T}_h)$ in the energy (semi)norm $|||\cdot|||_\Omega$. ($H^1_{\mathrm{D}}(\Omega)$ is the subspace of $H^1(\Omega)$ of functions with traces vanishing on $\Gamma_{\mathrm{D}} \subset \partial\Omega$.)

LEMMA 7.1 (abstract framework). *Let $\Gamma_{\mathrm{D}} \subset \partial\Omega$, $|\Gamma_{\mathrm{D}}| \neq 0$, let $\Gamma_{\mathrm{in}} := \{\mathbf{x} \in \partial\Omega; \mathbf{w}\cdot\mathbf{n} < 0\} \subset \Gamma_{\mathrm{D}}$, let $p, s \in H^1(\Omega)$ be such that $p - s \in H^1_{\mathrm{D}}(\Omega)$, and let $\tilde{p} \in H^1(\mathcal{T}_h)$ be arbitrary. Then*

$$|||p-\tilde{p}|||_\Omega \le |||\tilde{p}-s|||_\Omega + \left| \mathcal{B}\left(p-\tilde{p}, \frac{p-s}{|||p-s|||_\Omega}\right) + \sum_{K\in\mathcal{T}_h}\left(\nabla\cdot((\tilde{p}-s)\mathbf{w}) - \frac{1}{2}(\tilde{p}-s)\nabla\cdot\mathbf{w}, \frac{p-s}{|||p-s|||_\Omega}\right)_K \right|.$$

Proof. Let us set, for $p, \varphi \in H^1(\mathcal{T}_h)$,

$$\mathcal{B}_{\mathrm{S}}(p,\varphi) := \sum_{K\in\mathcal{T}_h}\left\{(\mathbf{S}\nabla p, \nabla\varphi)_K + \left(\left(\frac{1}{2}\nabla\cdot\mathbf{w} + r\right)p, \varphi\right)_K\right\},$$

$$\mathcal{B}_{\mathrm{A}}(p,\varphi) := \sum_{K\in\mathcal{T}_h}\left(\nabla\cdot(p\mathbf{w}) - \frac{1}{2}p\nabla\cdot\mathbf{w}, \varphi\right)_K,$$

so that

$$\mathcal{B}(p,\varphi) = \mathcal{B}_{\mathrm{S}}(p,\varphi) + \mathcal{B}_{\mathrm{A}}(p,\varphi) \qquad \forall p,\varphi \in H^1(\mathcal{T}_h), \tag{7.1}$$

$$\mathcal{B}_{\mathrm{S}}(\varphi,\varphi) = |||\varphi|||_\Omega^2 \qquad \forall \varphi \in H^1(\mathcal{T}_h), \tag{7.2}$$

$$\mathcal{B}_{\mathrm{A}}(\varphi,\varphi) \geq 0 \qquad \forall \varphi \in H^1_{\mathrm{D}}(\Omega), \tag{7.3}$$

using (2.9) and $\sum_{K\in\mathcal{T}_h}\langle\varphi^2, \mathbf{w}\cdot\mathbf{n}\rangle_{\partial K} \geq 0$ for $\varphi \in H^1_{\mathrm{D}}(\Omega)$ in the estimate.

We then have, using that $p - s \in H^1_{\mathrm{D}}(\Omega)$,

$$\begin{aligned}
|||p-s|||_\Omega^2 &\leq \mathcal{B}(p-s,p-s) = \mathcal{B}(p-\tilde{p},p-s) + \mathcal{B}(\tilde{p}-s,p-s)\\
&= \mathcal{B}_{\mathrm{S}}(\tilde{p}-s,p-s) + \mathcal{B}(p-\tilde{p},p-s) + \mathcal{B}_{\mathrm{A}}(\tilde{p}-s,p-s)\\
&\leq |||\tilde{p}-s|||_\Omega |||p-s|||_\Omega + |||p-s|||_\Omega \mathcal{B}\left(p-\tilde{p}, \frac{p-s}{|||p-s|||_\Omega}\right)\\
&\quad + |||p-s|||_\Omega \mathcal{B}_{\mathrm{A}}\left(\tilde{p}-s, \frac{p-s}{|||p-s|||_\Omega}\right),
\end{aligned}$$

employing the Cauchy–Schwarz inequality in the first term. If $|||p-\tilde{p}|||_\Omega \leq |||p-s|||_\Omega$, this concludes the proof. In general, we could use the triangle inequality $|||p-\tilde{p}|||_\Omega \leq |||p-s|||_\Omega + |||s-\tilde{p}|||_\Omega$ and the above bound for $|||p-s|||_\Omega$, but this would lead to an estimate which is not optimal (the term $|||\tilde{p}-s|||_\Omega$ would be replaced by $2|||\tilde{p}-s|||_\Omega$). We thus show below that the same bound holds true also when $|||p-s|||_\Omega \leq |||p-\tilde{p}|||_\Omega$.

We have, using (7.3) and the Cauchy–Schwarz inequality,

$$\begin{aligned}
|||p-\tilde{p}|||_\Omega^2 &= \mathcal{B}_{\mathrm{S}}(p-\tilde{p},p-\tilde{p}) = \mathcal{B}_{\mathrm{S}}(p-\tilde{p},p-s) + \mathcal{B}_{\mathrm{S}}(p-\tilde{p},s-\tilde{p})\\
&= \mathcal{B}_{\mathrm{S}}(p-\tilde{p},s-\tilde{p}) + \mathcal{B}(p-\tilde{p},p-s) - \mathcal{B}_{\mathrm{A}}(p-\tilde{p},p-s)\\
&= \mathcal{B}_{\mathrm{S}}(p-\tilde{p},s-\tilde{p}) + \mathcal{B}(p-\tilde{p},p-s) - \mathcal{B}_{\mathrm{A}}(p-s,p-s) + \mathcal{B}_{\mathrm{A}}(\tilde{p}-s,p-s)\\
&\leq \mathcal{B}_{\mathrm{S}}(p-\tilde{p},s-\tilde{p}) + \mathcal{B}(p-\tilde{p},p-s) + \mathcal{B}_{\mathrm{A}}(\tilde{p}-s,p-s)\\
&\leq |||p-\tilde{p}|||_\Omega |||s-\tilde{p}|||_\Omega + |||p-s|||_\Omega \mathcal{B}\left(p-\tilde{p}, \frac{p-s}{|||p-s|||_\Omega}\right)\\
&\quad + |||p-s|||_\Omega \mathcal{B}_{\mathrm{A}}\left(\tilde{p}-s, \frac{p-s}{|||p-s|||_\Omega}\right),
\end{aligned}$$

which, by virtue of $|||p-s|||_\Omega \leq |||p-\tilde{p}|||_\Omega$ supposed in this second case, concludes the proof. ∎

Consequently, the following bound for the error $|||p-\tilde{p}_h|||_\Omega$ holds.

LEMMA 7.2 (abstract error estimate). *Let p be the weak solution of the problem* (1.1a)–(1.1b) *given by* (2.7), *and let $s \in H^1_0(\Omega)$ be arbitrary. If $\tilde{p}_h$ is the post-processed solution of the centered mixed finite element scheme* (3.1a)–(3.1b) *given by* (4.1a)–(4.1b), *then*

$$|||p-\tilde{p}_h|||_\Omega \leq |||\tilde{p}_h - s|||_\Omega + \sup_{\varphi\in H^1_0(\Omega),\, |||\varphi|||_\Omega = 1} \big\{T_{\mathrm{R}}(\varphi) + T_{\mathrm{C}}(\varphi)\big\},$$

and if $\tilde{p}_h$ is the postprocessed solution of the upwind-weighted mixed finite element scheme (3.2a)–(3.2b), *given by* (4.1a)–(4.1b), *then*

$$|||p-\tilde{p}_h|||_\Omega \le |||\tilde{p}_h - s|||_\Omega + \sup_{\varphi\in H^1_0(\Omega),\, |||\varphi|||_\Omega=1} \big\{T_{\mathrm{R}}(\varphi)+T_{\mathrm{C}}(\varphi)+T_{\mathrm{U}}(\varphi)\big\},$$

where

$$T_{\mathrm{R}}(\varphi) := \sum_{K\in\mathcal{T}_h} \big(f+\nabla\cdot\mathbf{S}\nabla\tilde{p}_h - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h, \varphi-\varphi_K\big)_K,$$

$$T_{\mathrm{C}}(\varphi) := \sum_{K\in\mathcal{T}_h} \left(\nabla\cdot((\tilde{p}_h-s)\mathbf{w}) - \frac{1}{2}(\tilde{p}_h-s)\nabla\cdot\mathbf{w}, \varphi\right)_K,$$

$$T_{\mathrm{U}}(\varphi) := \sum_{K\in\mathcal{T}_h}\sum_{\sigma\in\mathcal{E}_K} \langle(\hat{p}_\sigma-\tilde{p}_h)\mathbf{w}\cdot\mathbf{n}, \varphi_K\rangle_\sigma,$$

and where φ_K is the mean of φ over $K\in\mathcal{T}_h$, $\varphi_K := (\varphi,1)_K/|K|$.

Proof. Let us consider an arbitrary $\varphi\in H^1_0(\Omega)$. We have, using the bilinearity of $\mathcal{B}(\cdot,\cdot)$, the definition (2.7) of the weak solution p, and the Green theorem in each $K\in\mathcal{T}_h$,

$$\begin{aligned}\mathcal{B}(p-\tilde{p}_h,\varphi) &= (f,\varphi)_\Omega - \sum_{K\in\mathcal{T}_h}\big\{(\mathbf{S}\nabla\tilde{p}_h,\nabla\varphi)_K + \big(\nabla\cdot(\tilde{p}_h\mathbf{w}),\varphi\big)_K + (r\tilde{p}_h,\varphi)_K\big\}\\ &= \sum_{K\in\mathcal{T}_h}\big\{\big(f+\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h,\varphi\big)_K - \langle\mathbf{S}\nabla\tilde{p}_h\cdot\mathbf{n},\varphi\rangle_{\partial K}\big\}\\ &= \sum_{K\in\mathcal{T}_h}\big(f+\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h,\varphi\big)_K.\end{aligned}$$

Note that we have, in particular, used the continuity of the normal trace of $\mathbf{S}\nabla\tilde{p}_h$ (i.e., by (4.1a), the mixed finite element continuity of the normal trace of $\mathbf{u}_h$), yielding

$$\langle(\mathbf{S}\nabla\tilde{p}_h\cdot\mathbf{n})|_K + (\mathbf{S}\nabla\tilde{p}_h\cdot\mathbf{n})|_L, \varphi\rangle_{\sigma_{K,L}} = \langle 0,\varphi\rangle_{\sigma_{K,L}} = 0 \qquad \forall\sigma_{K,L}\in\mathcal{E}_h^{\mathrm{int}}$$

(the fact that $\langle\mathbf{S}\nabla\tilde{p}_h\cdot\mathbf{n},\varphi\rangle_\sigma = 0$ for $\sigma\in\mathcal{E}_h^{\mathrm{ext}}$ follows by $\varphi\in H^1_0(\Omega)$).

Now the equation (6.1b) of the equivalent form of the centered scheme by the definition of $\tilde{p}_h$ (4.1a)–(4.1b) and by the Green theorem implies that (recall that φ_K is the constant mean of φ over K)

$$\big(f+\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h,\varphi_K\big)_K = 0 \qquad \forall K\in\mathcal{T}_h. \tag{7.4}$$

Hence in the case of the centered scheme,

$$\mathcal{B}(p-\tilde{p}_h,\varphi) = \sum_{K\in\mathcal{T}_h}\big(f+\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h,\varphi-\varphi_K\big)_K = T_{\mathrm{R}}(\varphi).$$

For the upwind-weighted scheme, we have

$$\mathcal{B}(p-\tilde{p}_h,\varphi) = T_{\mathrm{R}}(\varphi) + T_{\mathrm{U}}(\varphi).$$

To conclude the proof, if now suffices to use Lemma 7.1. ∎

We now estimate the terms T_{R}, T_{C}, and T_{U} separately, setting $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$ in Lemma 7.2.

LEMMA 7.3 (residual estimate). *Let $\varphi \in H_0^1(\Omega)$ be arbitrary. Then*

$$T_{\mathrm{R}}(\varphi) \le \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{R},K} |||\varphi|||_K,$$

where $\eta_{\mathrm{R},K}$ is given by (4.2).

Proof. The Poincaré inequality (2.1) and the definition of $|||\cdot|||_K$ by (2.6) imply

$$\|\varphi - \varphi_K\|_K^2 \le C_{\mathrm{P},d} h_K^2 \|\nabla\varphi\|_K^2 \le C_{\mathrm{P},d} \frac{h_K^2}{c_{\mathbf{S},K}} |||\varphi|||_K^2 . \tag{7.5}$$

Next, the estimate

$$\|\varphi - \varphi_K\|_K^2 \le \|\varphi\|_K^2 \le \frac{1}{c_{\mathbf{w},r,K}} |||\varphi|||_K^2$$

is obvious using the definition of $|||\cdot|||_K$ by (2.6). Thus the Schwarz inequality implies

$$\begin{aligned} T_{\mathrm{R}}(\varphi) &\le \sum_{K\in\mathcal{T}_h} \left\| f + \nabla\cdot(\mathbf{S}\nabla\tilde{p}_h) - \nabla\cdot(\tilde{p}_h\mathbf{w}) - r\tilde{p}_h \right\|_K \|\varphi - \varphi_K\|_K \\ &\le \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{R},K} |||\varphi|||_K. \qquad \square \end{aligned}$$

LEMMA 7.4 (convection estimate). *Let $\varphi \in H_0^1(\Omega)$ be arbitrary. Then*

$$T_{\mathrm{C}}(\varphi) \le \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{C},K} |||\varphi|||_K,$$

where $\eta_{\mathrm{C},K}$ is given by (4.4).

Proof. Denote $v := \tilde{p}_h - \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$. Then, for each $K \in \mathcal{T}_h$,

$$\left(\nabla\cdot(v\mathbf{w}) - \frac{1}{2} v\nabla\cdot\mathbf{w}, \varphi\right)_K \le \frac{\|\nabla\cdot(v\mathbf{w}) - \frac{1}{2}v\nabla\cdot\mathbf{w}\|_K}{\sqrt{c_{\mathbf{w},r,K}}} |||\varphi|||_K .$$

Note that this estimate is valid for an arbitrary $s \in H_0^1(\Omega)$ instead of $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$.

Next, the fact that the modified Oswald interpolation operator of section 4.2 preserves the means of $\tilde{p}_h$ over the sides and that $\mathbf{w}\cdot\mathbf{n}$ is constant on all sides implies

$$(\nabla\cdot(v\mathbf{w}), \varphi_K)_K = \langle v\mathbf{w}\cdot\mathbf{n}, \varphi_K\rangle_{\partial K} = 0, \tag{7.6}$$

where again $\varphi_K := (\varphi, 1)_K/|K|$. Thus we also have an alternative estimate

$$\begin{aligned} &\left(\nabla\cdot(v\mathbf{w}) - \frac{1}{2}v\nabla\cdot\mathbf{w}, \varphi\right)_K \\ &= (\nabla v\cdot\mathbf{w}, \varphi - \varphi_K)_K + \left(\frac{1}{2}v\nabla\cdot\mathbf{w}, \varphi\right)_K - (v\nabla\cdot\mathbf{w}, \varphi_K)_K \\ &\le \frac{\sqrt{C_{\mathrm{P},d}}h_K\|\nabla v\cdot\mathbf{w}\|_K}{\sqrt{c_{\mathbf{S},K}}} \sqrt{c_{\mathbf{S},K}}\|\nabla\varphi\|_K + \frac{3\|v\nabla\cdot\mathbf{w}\|_K}{2\sqrt{c_{\mathbf{w},r,K}}} \sqrt{c_{\mathbf{w},r,K}}\|\varphi\|_K \\ &\le \left(\frac{C_{\mathrm{P},d}h_K^2\|\nabla v\cdot\mathbf{w}\|_K^2}{c_{\mathbf{S},K}} + \frac{9\|v\nabla\cdot\mathbf{w}\|_K^2}{4c_{\mathbf{w},r,K}}\right)^{\frac{1}{2}} |||\varphi|||_K, \end{aligned}$$

using the Cauchy–Schwarz inequality and the Poincaré inequality (2.1). ∎

Finally, the proof of the following lemma can be found in [38].

LEMMA 7.5 (upwinding estimate). *Let $\varphi \in H^1_0(\Omega)$ be arbitrary. Then*

$$T_{\mathrm{U}}(\varphi) \leq \sum_{K\in\mathcal{T}_h} \eta_{\mathrm{U},K} |||\varphi|||_K,$$

where $\eta_{\mathrm{U},K}$ is given by (4.6).

Lemmas 7.1–7.5 and the Cauchy–Schwarz inequality prove Theorems 4.2–4.3.

7.2. Proofs of the local efficiency of the estimates.

LEMMA 7.6 (local efficiency of the residual estimator). *Let $K \in \mathcal{T}_h$ and let $\eta_{\mathrm{R},K}$ be the residual estimator given by* (4.2). *Then* (4.10) *holds true.*

Proof. The proof follows that given in [33]. Let ψ_K be the bubble function on K, given as the product of the $d+1$ linear functions that take the value 1 at one vertex of K and vanish at the other vertices, and let us denote $v := (f+\nabla\cdot(\mathbf{S}\nabla\tilde{p}_h)-\nabla\cdot(\tilde{p}_h\mathbf{w})-r\tilde{p}_h)$ on a given $K \in \mathcal{T}_h$. Note that v is a polynomial in K by Assumption B. Then the equivalence of norms on finite-dimensional spaces, the inverse inequality (cf., e.g., [15, Theorem 3.2.6]), and the definition of $|||\cdot|||_K$ by (2.6) give

$$\begin{aligned} c\,\|v\|_K^2 &\leq (v,\psi_K v)_K,\\ \|\psi_K v\|_K &\leq \|v\|_K,\\ |||\psi_K v|||_K &\leq C \min\left\{\frac{h_K}{\sqrt{C_{\mathbf{S},K}}}, \frac{1}{\sqrt{c_{\mathbf{w},r,K}}}\right\}^{-1} \|v\|_K, \end{aligned}$$

with the constants c and C depending only on the polynomial degree k of f, d, and κ_K. Next, we immediately have (cf. the proof of Lemma 7.2)

$$\mathcal{B}(p-\tilde{p}_h,\psi_K v) = (v,\psi_K v)_K,$$

and, using (2.10),

$$\begin{aligned} \mathcal{B}(p-\tilde{p}_h,\psi_K v) \leq{}& \max\left\{1, \frac{C_{\mathbf{w},r,K}}{c_{\mathbf{w},r,K}}\right\} |||p-\tilde{p}_h|||_K |||\psi_K v|||_K\\ &+ \frac{C_{\mathbf{w},K}}{\sqrt{c_{\mathbf{S},K}}} |||p-\tilde{p}_h|||_K \|\psi_K v\|_K. \end{aligned}$$

Combining the above estimates, one comes to

$$\begin{aligned} c\|v\|_K^2 \leq{}& |||p-\tilde{p}_h|||_K \|v\|_K\\ &\cdot\left\{\max\left\{1, \frac{C_{\mathbf{w},r,K}}{c_{\mathbf{w},r,K}}\right\} C \min\left\{\frac{h_K}{\sqrt{C_{\mathbf{S},K}}}, \frac{1}{\sqrt{c_{\mathbf{w},r,K}}}\right\}^{-1} + \frac{C_{\mathbf{w},K}}{\sqrt{c_{\mathbf{S},K}}}\right\}. \end{aligned}$$

Considering the definition of $\eta_{\mathrm{R},K}$ by (4.2) and that of Pe_K and ϱ_K by (4.8) concludes the proof. ∎

LEMMA 7.7 (local efficiency of the nonconformity and velocity estimators). *Let $K \in \mathcal{T}_h$ and let $\eta_{\mathrm{NC},K}$ and $\eta_{\mathrm{C},K}$ be the nonconformity and velocity estimators given, respectively, by* (4.3) *and* (4.4). *Then* (4.11) *holds true.*

Proof. One shows easily that (with $|||\cdot|||_{*,K}$ and $|||\cdot|||_{\#,K}$ defined in section 4.4)

$$\eta_{\mathrm{NC},K}^2+\eta_{\mathrm{C},K}^2\le\min\left\{|||\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)|||_{*,K}^2,|||\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)|||_{\#,K}^2\right\}.$$

Throughout the rest of the proof, let C denote a constant depending only on d and on $\kappa_{\mathcal{T}}$, not necessarily the same at each occurrence. We first show that

(7.7)
$$|||\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)|||_{*,K}^2\le C\left(\alpha_{*,K}\sum_{\sigma;\sigma\cap K\neq\emptyset}h_\sigma^{-1}\|[\tilde p_h]\|_\sigma^2+\beta_{*,K}\sum_{\sigma;\sigma\cap K\neq\emptyset}h_\sigma\|[\tilde p_h]\|_\sigma^2\right).$$

The first part of the estimate follows directly from Lemma 4.1 and the definition of $|||\cdot|||_{*,K}$. To estimate $\beta_{*,K}\|\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)\|_K^2$, we notice that the means of $\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)$ over all sides of a simplex $K\in\mathcal{T}_h$ are by the construction of the modified Oswald interpolation operator equal to 0. Hence

$$\|\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)\|_K^2\le C_{\mathrm{F},d}h_K^2\|\nabla(\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h))\|_K^2$$

by the generalized Friedrichs inequality (2.2). The fact that h_K/h_σ for $K\cap\sigma\neq\emptyset$ depends only on $\kappa_{\mathcal{T}}$, which will be used in what follows as well, and another use of Lemma 4.1 proves the second part of the estimate.

We will next use the inequality

$$h_\sigma^{-\frac12}\|[\tilde p_h]\|_\sigma\le C\sum_{L;\sigma\in\mathcal{E}_L}\|\nabla(\tilde p_h-\varphi)\|_L$$

established in [2, Theorem 10] for $\sigma\in\mathcal{E}_h^{\mathrm{int}}$ and an arbitrary $\varphi\in H^1(\Omega)$. It generalizes easily to the case $\sigma\in\mathcal{E}_h^{\mathrm{ext}}$ and $\varphi\in H_0^1(\Omega)$. This inequality implies that

$$h_\sigma^\gamma\|[\tilde p_h]\|_\sigma^2\le C\frac{h_\sigma^{\gamma+1}}{\min_{L;\sigma\in\mathcal{E}_L}c_{\mathbf{S},L}}\sum_{L;\sigma\in\mathcal{E}_L}c_{\mathbf{S},L}\|\nabla(\tilde p_h-p)\|_L^2,\tag{7.8}$$

where we set $\gamma=-1,1$. Next, for an arbitrary $s_h\in\mathbb{P}_2(\mathcal{T}_h)\cap H_0^1(\Omega)$,

$$\begin{aligned}h_\sigma^{\frac12}\|[\tilde p_h]\|_\sigma&\le h_\sigma C\sum_{L;\sigma\in\mathcal{E}_L}\|\nabla(\tilde p_h-s_h)\|_L\le C\sum_{L;\sigma\in\mathcal{E}_L}h_L\|\nabla(\tilde p_h-s_h)\|_L\\&\le C\sum_{L;\sigma\in\mathcal{E}_L}\|\tilde p_h-s_h\|_L\le C\sum_{L;\sigma\in\mathcal{E}_L}\|\tilde p_h-p\|_L+C\sum_{L;\sigma\in\mathcal{E}_L}\|p-s_h\|_L,\end{aligned}$$

by the inverse inequality (cf. [15, Theorem 3.2.6]) and the triangle inequality. Hence

$$h_\sigma\|[\tilde p_h]\|_\sigma^2\le C\frac{1}{\min_{L;\sigma\in\mathcal{E}_L}c_{\mathbf{w},r,L}}\sum_{L;\sigma\in\mathcal{E}_L}c_{\mathbf{w},r,L}\|\tilde p_h-p\|_L^2+C\sum_{L;\sigma\in\mathcal{E}_L}\|p-s_h\|_L^2\tag{7.9}$$

holds as well, which gives a sense when all $c_{\mathbf{w},r,L}$ for L such that $\sigma\in\mathcal{E}_L$ are nonzero. Combining estimates (7.7)–(7.9) while estimating $\min_{L;\sigma\in\mathcal{E}_L}c_L$ for a side σ such that $\sigma\cap K\neq\emptyset$ from below by $\min_{L;L\cap K\neq\emptyset}c_L$ concludes the proof for $|||\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)|||_{*,K}$. The proof for $|||\tilde p_h-\mathcal{I}_{\mathrm{MO}}(\tilde p_h)|||_{\#,K}$ is completely similar. ∎

LEMMA 7.8 ((non)efficiency of the upwinding estimator). *Let $K\in\mathcal{T}_h$ and let $\eta_{\mathrm{U},K}$ be the upwinding estimator given by* (4.6). *Then* (4.12) *holds true.*

Proof. Let $K \in \mathcal{T}_h$, $\varphi \in H^1(K)$, and $\varphi_\sigma := \langle \varphi, 1\rangle_\sigma/|\sigma|$. Let us set $\tilde{\varphi} := \varphi - \varphi_\sigma$ and $\tilde{\varphi}_K := (\tilde{\varphi}, 1)_K/|K|$. We now note that $\tilde{\varphi}_\sigma := \langle \tilde{\varphi}, 1\rangle_\sigma/|\sigma| = 0$ and that $\nabla\tilde{\varphi} = \nabla\varphi$, which allows us to estimate

$$\|\varphi_K - \varphi_\sigma\|_\sigma^2 = \tilde{\varphi}_K^2|\sigma| \le \frac{|\sigma|}{|K|}\|\tilde{\varphi}\|_K^2 \le C_{\mathrm{F},d}\frac{|\sigma|h_K^2}{|K|}\|\nabla\varphi\|_K^2,$$

employing the generalized Friedrichs inequality (2.2). Now using the definition of $\hat{p}_\sigma$ for $\sigma \in \mathcal{E}_h^{\mathrm{int}}$ by (3.3), the fact that $0 \le \nu_\sigma \le 1/2$, (4.1b), and the above estimate,

$$\begin{aligned}\|\hat{p}_\sigma - \tilde{p}_\sigma\|_\sigma &= \|(1-\nu_\sigma)(p_K - \tilde{p}_\sigma) + \nu_\sigma(p_L - \tilde{p}_\sigma)\|_\sigma \\ &\le \max_{M;\sigma\in\mathcal{E}_M}\left\{\frac{C_{\mathrm{F},d}|\sigma|h_M^2}{|M|}\right\}^{\frac{1}{2}}(\|\nabla\tilde{p}_h\|_K + \|\nabla\tilde{p}_h\|_L)\end{aligned}$$

for suitable denotation K, L of the two elements sharing σ. For $\sigma \in \mathcal{E}_h^{\mathrm{ext}}$, a similar estimate holds. The assertion of the lemma follows by using the above estimate, (4.5), (4.6), the definition of κ_K, the estimate $|\sigma| \le h_K^{d-1}/(d-1)$, the Cauchy–Schwarz inequality, and estimating the term $\sum_{K\in\mathcal{T}_h} c_{\mathbf{S},K}\|\nabla\tilde{p}_h\|_K^2$ using Lemma 6.5. ∎

Lemmas 7.6–7.8 together prove Theorem 4.4.

8. Numerical experiments. We test our a posteriori error estimates on two model problems in this section. The first problem contains a strongly inhomogeneous diffusion-dispersion tensor, and the second one is convection-dominated; in both cases, the analytical solution is known. Estimators for inhomogeneous Dirichlet (and Neumann) boundary conditions are adapted from [38].

8.1. Model problem with strongly inhomogeneous diffusion-dispersion tensor. This model problem is taken from [30, 18] and is motivated by the fact that in real-life applications, the diffusion-dispersion tensor $\mathbf{S}$ may be discontinuous and strongly inhomogeneous. We consider in particular $\Omega = (-1,1)\times(-1,1)$ and (1.1a) with $\mathbf{w} = 0$, $r = 0$, and $f = 0$. We suppose that Ω is divided into four subdomains Ω_i corresponding to the axis quadrants (in the counterclockwise direction) and that $\mathbf{S}$ is constant and equal to $s_i\,Id$ in Ω_i. Under such conditions, an analytical solution writing

$$p(r,\theta) = r^\alpha(a_i\sin(\alpha\theta) + b_i\cos(\alpha\theta))$$

in each Ω_i can be found. Here (r,θ) are the polar coordinates in Ω, a_i and b_i are constants depending on Ω_i, and α is a parameter. This solution is continuous across the interfaces, but only the normal component of its flux $\mathbf{u} = -\mathbf{S}\nabla p$ is continuous; it finally exhibits a singularity at the origin. We assume Dirichlet boundary conditions given by this solution and consider two sets of the coefficients, with $s_1 = s_3 = 5$, $s_2 = s_4 = 1$ in the first case and $s_1 = s_3 = 100$, $s_2 = s_4 = 1$ in the second one:

$\alpha = 0.53544095$		$\alpha = 0.12690207$	
$a_1 = 0.44721360$	$b_1 = 1$	$a_1 = 0.1$	$b_1 = 1$
$a_2 = -0.74535599$	$b_2 = 2.33333333$	$a_2 = -9.60396040$	$b_2 = 2.96039604$
$a_3 = -0.94411759$	$b_3 = 0.55555556$	$a_3 = -0.48035487$	$b_3 = -0.88275659$
$a_4 = -2.40170264$	$b_4 = -0.48148148$	$a_4 = 7.70156488$	$b_4 = -6.45646175$

The original grid consisted of 24 right-angled triangles, and we have refined it either uniformly (up to five refinements) or adaptively on the basis of our estimator.

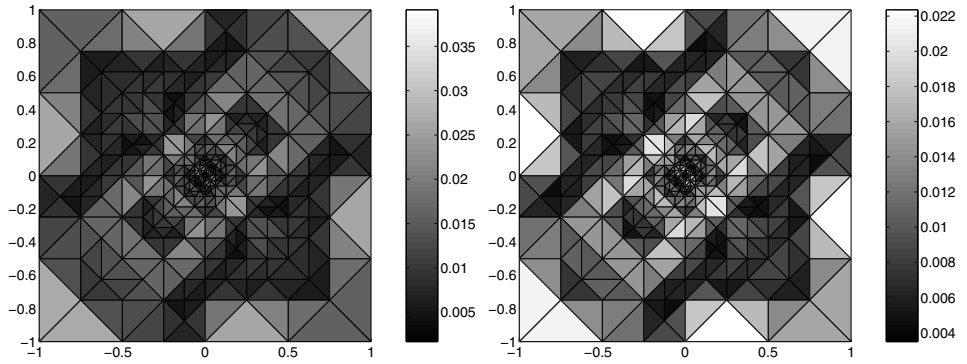

FIG. 8.1. *Estimated (left) and actual (right) error distribution,* $\alpha = 0.53544095$ *(the maximum is attained at the origin).*

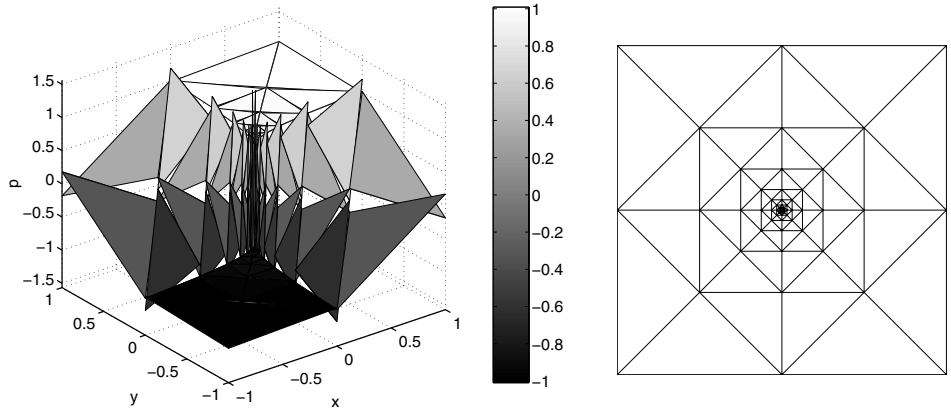

FIG. 8.2. *Approximate solution and the corresponding adaptively refined mesh,* $\alpha = 0.12690207$.

In the latter case, we refine each element where the estimated $|||\cdot|||_\Omega$-error is greater than the half of the maximum of the estimators regularly into four subelements and then use the "longest edge" refinement to recover an admissible mesh. In the given case, the residual estimators $\eta_{\mathrm{R},K}$ of (5.2) are zero for each $K \in \mathcal{T}_h$, and hence the a posteriori error estimate is entirely given by the nonconformity estimators $\eta_{\mathrm{NC},K}$ in (5.3). We have done numerical experiments with two choices, $s = \mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$ and $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$, and present the results with the first one, which gives a slightly better efficiency.

We can see in Figure 8.1 that the predicted error distribution on an adaptively refined mesh for the first test case is excellent. In particular, even if the solution is smoother, the singularity is well recognized. Next, Figure 8.2 gives an example of the approximate solution on an adaptively refined mesh and this mesh in the second test case. Here, the singularity is much more important, and consequently the grid is highly refined around the origin (for 1800 triangles, the diameter of the smallest ones is 10^{-16}, and 73% of them are contained in the circle of radius 0.1). Figure 8.3 then reports the estimated and actual errors of the numerical solutions on uniformly/adaptively refined grids in the two test cases. The energy norm (2.6) was approximated with a 7-point quadrature formula in each triangle. It can be seen

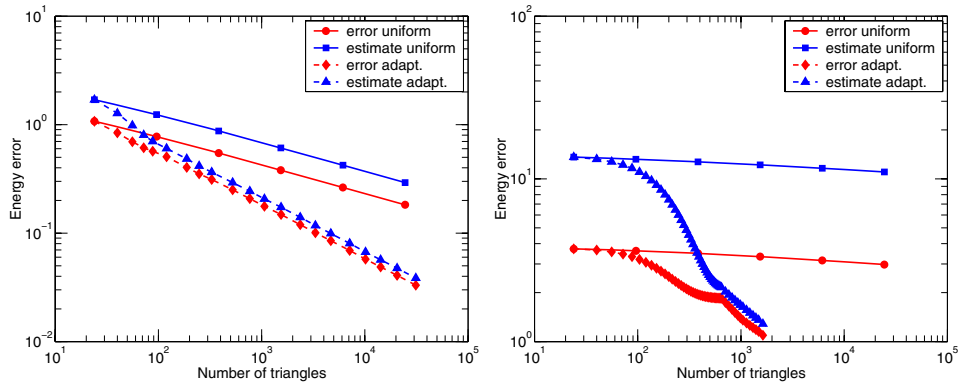

FIG. 8.3. *Estimated and actual error against the number of elements in uniformly/adaptively refined meshes for* $\alpha = 0.53544095$ *(left) and* $\alpha = 0.12690207$ *(right).*

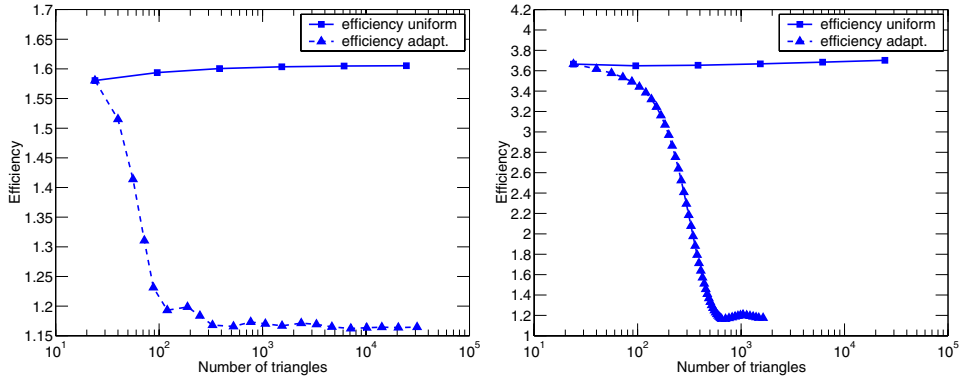

FIG. 8.4. *Overall efficiency of the a posteriori error estimates against the number of elements in uniformly/adaptively refined meshes for* $\alpha = 0.53544095$ *(left) and* $\alpha = 0.12690207$ *(right).*

from these plots that one can substantially reduce the number of unknowns necessary to attain the prescribed precision using the derived a posteriori error estimates and adaptively refined grids. Finally, Figure 8.4 gives the efficiency plots for the two cases, i.e., the ratio of the estimated $|||\cdot|||_\Omega$-error to the actual $|||\cdot|||_\Omega$-error. This quantity simply expresses how many times we have overestimated the error—recall that there are no undetermined multiplicative constants in our estimates. These plots confirm the theoretical results of section 5.3. Even while only using $\mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$ instead of evaluating the infimum in (5.4), (approximate) asymptotic exactness and robustness with respect to inhomogeneities is confirmed.

8.2. Convection-dominated model problem. This problem is a modification of a problem considered in [20]. We set $\Omega = (0,1) \times (0,1)$, $\mathbf{w} = (0,1)$, and $r = 1$ in (1.1a) and consider three cases with $\mathbf{S} = \varepsilon\, Id$ and ε equal to, respectively, 1, 10^{-2}, and 10^{-4}. The right-hand-side term f, Neumann boundary conditions on the upper side, and Dirichlet boundary conditions elsewhere are chosen so that

$$p(x,y) = 0.5\left(1 - \tanh\left(\frac{0.5 - x}{a}\right)\right)$$

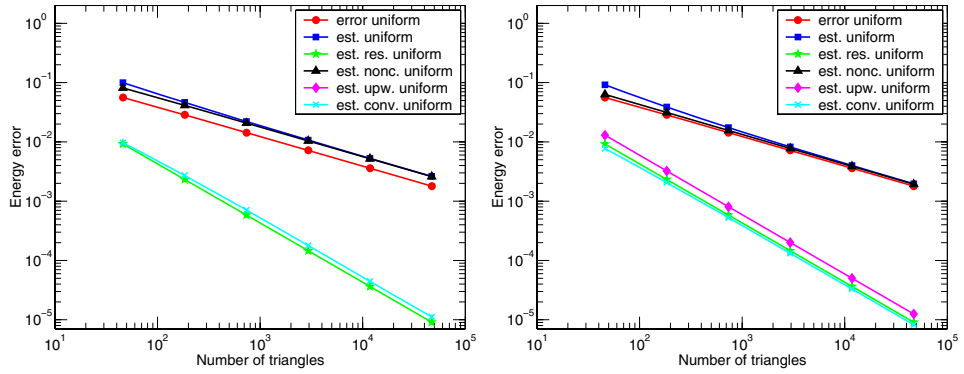

FIG. 8.5. *Estimated and actual error using* $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$ *(left) and* $s = \mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$ *(right) against the number of elements,* $\varepsilon = 1$, $a = 0.5$.

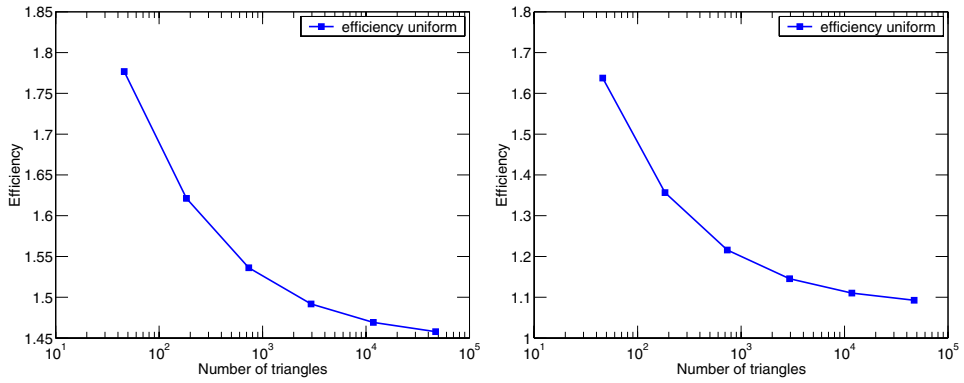

FIG. 8.6. *Overall efficiency using* $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$ *(left) and* $s = \mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$ *(right) against the number of elements,* $\varepsilon = 1$, $a = 0.5$.

was the exact solution. It is, in fact, one-dimensional and possesses an internal layer of width a which we set, respectively, equal to 0.5, 0.05, and 0.02. We start the computations from an unstructured grid of Ω consisting of 46 triangles and refine it either uniformly (up to five refinements) or adaptively. We use the scheme described in section 5.5.

We first compare, for $\varepsilon = 1$ and $a = 0.5$, the estimates with $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$ as proposed in section 4.3 and a modification with $s = \mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$, corresponding to the approach chosen in [38, 37], on uniformly refined grids. In the latter case, we no longer have the important property (7.6), and consequently there is an additional term which we associate with the upwinding estimator; it, however, turns out to be of higher order; see Figure 8.5. Note that the (approximate) asymptotic exactness observed in Figure 8.6 is in full correspondence with the theoretical considerations of section 5.3.2. In this case, $s = \mathcal{I}_{\mathrm{Os}}(\tilde{p}_h)$ gives a slightly better efficiency. In the following examples, however, we use $s = \mathcal{I}_{\mathrm{MO}}(\tilde{p}_h)$, since it turns out to be the better choice.

For $\varepsilon = 10^{-2}$ and $a = 0.05$ (convection-dominated regime on coarse meshes and diffusion-dominated regime with progressive refinement), still the distribution of the error is predicted very well; cf. Figure 8.7. Note in particular the correct localization of

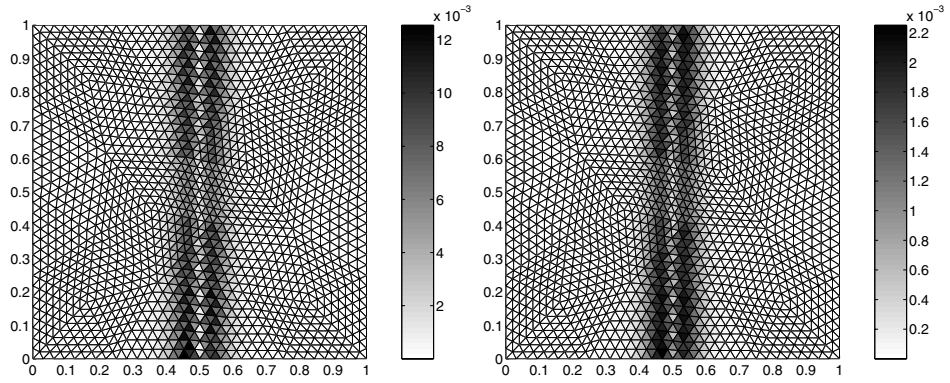

FIG. 8.7. *Estimated (left) and actual (right) error distribution,* $\varepsilon = 10^{-2}$, $a = 0.05$.

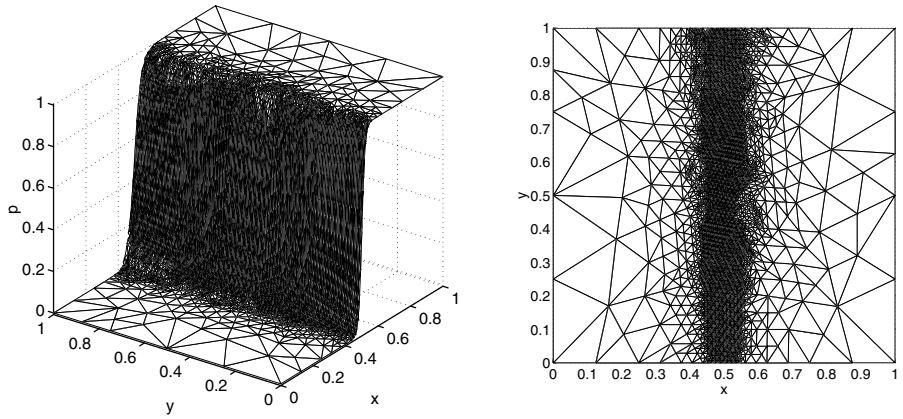

FIG. 8.8. *Approximate solution and the corresponding adaptively refined mesh,* $\varepsilon = 10^{-4}$, $a = 0.02$.

the error away from the center of the shock, as well as the sensitivity of our estimator to the shape of the elements. Next, an example of an adaptively refined mesh and of the corresponding solution for $\varepsilon = 10^{-4}$ and $a = 0.02$ is given in Figure 8.8. For these two test cases, we have used as a refinement criterion 0.2- and 0.05-times the maximum of the estimators, respectively. The estimated and actual errors are plotted against the number of elements in uniformly/adaptively refined meshes in Figure 8.9. Again, one can see that we can substantially reduce the number of unknowns necessary to attain the prescribed precision using the derived estimators and adaptively refined grids. Finally, the efficiency plots are given in Figure 8.10. In the first case, the efficiency is almost optimal for finest grids, whereas in the second one, only the elements in the refined shock region start to leave the convection-dominated regime, and thus the efficiency starts to decrease.

Acknowledgments. The author would like to thank Prof. Alexandre Ern from the CERMICS laboratory of the Ecole Nationale des Ponts et Chaussées, Marne la Vallée, France, for pointing out the compact form of the proof of Lemma 7.1.

ERROR ANALYSIS OF IMEX RUNGE–KUTTA METHODS DERIVED FROM DIFFERENTIAL-ALGEBRAIC SYSTEMS*

SEBASTIANO BOSCARINO†

Abstract. In this paper we present an error analysis of the IMEX Runge–Kutta methods when applied to stiff problems containing a nonstiff term and a stiff term, characterized by a small stiffness parameter ε. In this analysis we expand the global error in powers of ε and show that the coefficients of the error are the global errors of the IMEX Runge–Kutta method applied to a differential-algebraic system. Interesting convergence results of these errors and of the remainder of the expansion allow us to determine sharp error bounds for stiff problems. As a representative example of stiff problems we have chosen the van der Pol equation. We illustrate that the theoretical prediction is confirmed by the numerical test. Specifically, an order reduction phenomenon is observed when the problem becomes increasingly stiff. In particular, making several assumptions, we try to improve global error estimates of several IMEX Runge–Kutta methods existing in the literature.

1. Introduction.

Several physical phenomena of great importance for applications are described by stiff systems of differential equations in the form

$$U' = F(U) + \frac{1}{\varepsilon}G(U), \tag{1}$$

where $U = U(t) \in R^m$, F,$G : R^m \to R^m$, and $\varepsilon > 0$ is the stiffness parameter.

Systems of such form, with a large number of equations, often arise from the discretization of partial differential equations, such as convection-diffusion problems and hyperbolic systems with relaxation (i.e., discrete kinetic theory of rarefied gases, hydrodynamical models for semiconductors, etc., see [8], [17], [19], [18], [15], [6], [9]), where a method of lines approach is usually used.

In order to be able to treat problems of the form (1), it is important to develop suitable numerical schemes that work in an accurate and efficient way. A general approach to the solution of problem (1) is based on implicit-explicit (IMEX) multistep methods [14], [10], [3] or IMEX Runge–Kutta (R-K) methods [8], [17], [19], [18], [1], [2].

We consider here IMEX R-K methods. An IMEX R-K method consists of applying an implicit discretization for G and an explicit one for F. In general, in order to guarantee simplicity and efficiency in solving the algebraic equations corresponding to the implicit part of the discretization at each step of problem (1), we will consider diagonally implicit R-K (DIRK) methods.

In this paper we show that most of the popular IMEX R-K methods presented in the literature suffer from the phenomenon of order reduction in the stiff regime

($\Delta t \gg \varepsilon$) when the classical order is greater than two [8], [17], [18], [1]. To this aim, we investigate this phenomenon and give an answer through a theoretical error analysis using typical techniques of differential-algebraic equations (DAEs) [12], [13], [7], [11].

We observe that system (1) can be written as a system of $2m$ equations in the form

$$\begin{aligned} y' &= f(y,z), \\ \varepsilon z' &= g(y,z) \end{aligned} \tag{2}$$

once we set $U = y+z$, $F(U) = f(y,z)$, and $G(U) = g(y,z)$. On the other hand, system (2) is a particular case of system (1) when $F(U) = (f(y,z),0)$, $G(U) = (0, g(y,z))$. Now, restricting our attention to system (2), such a problem is called a *singular perturbation problem* (SPP). Classical books on this subject are [20] and [16]. These SPPs give us the possibility of studying the dependence of the global error of IMEX R-K methods on the stiffness parameter ε. Then in system (2) we suppose that $0 < \varepsilon \ll 1$ and the functions f and g are sufficiently differentiable, with f, g and the initial values $y(0)$, $z(0)$ that may depend smoothly on ε. For simplicity of notation we suppress this dependence.

When the parameter ε in system (2) is small, the corresponding differential equation is stiff, and when ε tends to zero, the differential equation becomes differential algebraic. A sequence of differential-algebraic systems arises in the study of SPPs. Our analysis is based on the assumption of a smooth solution of system (2) and applies to the stiff case ($\Delta t \gg \varepsilon$).

The paper is organized as follows. In the next section we introduce a description and classification of the different types of IMEX R-K methods present in the literature, based on the structure of the matrix of the implicit part. In section 3 we state our main results, presenting convergence proofs which give sharp error bounds for such methods. On the van der Pol equation, moreover, we provide numerical confirmation of the theoretical analysis and compare the performances of several types of IMEX R-K schemes. Also, these numerical results suggest how we can improve error estimates of some IMEX R-K methods through straightforward assumptions. In section 4 we consider the asymptotic expansion of the exact and numerical solution in terms of the stiffness parameter ε. Sections 5 and 6 are devoted to examining the results obtained when we apply IMEX R-K methods to DAEs of index 1 (zeroth-order expansion) and higher (higher-order expansion). In particular, in section 7 we estimate the remainder of the expansion. Finally, in section 8, conclusions are drawn and work in progress is mentioned.

2. Description and classification of IMEX R-K methods. We consider an IMEX R-K method applied to system (2),

$$\begin{pmatrix} y_{n+1} \\ z_{n+1} \end{pmatrix} = \begin{pmatrix} y_n \\ z_n \end{pmatrix} + h \sum_{i=1}^{s} \begin{pmatrix} \tilde{b}_i k_{ni} \\ b_i \ell_{ni} \end{pmatrix}, \tag{3}$$

where

$$\begin{pmatrix} k_{ni} \\ \varepsilon \ell_{ni} \end{pmatrix} = \begin{pmatrix} f(Y_{ni}, Z_{ni}) \\ g(Y_{ni}, Z_{ni}) \end{pmatrix} \tag{4}$$

and the internal stages are given by

$$\begin{pmatrix} Y_{ni} \\ Z_{ni} \end{pmatrix} = \begin{pmatrix} y_n \\ z_n \end{pmatrix} + h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} k_{nj} \\ \sum_{j=1}^{i} a_{ij} \ell_{nj} \end{pmatrix}. \tag{5}$$

The matrices $(\tilde{a}_{ij})$, with $\tilde{a}_{ij} = 0$ for $j \geq i$, and (a_{ij}) are $s \times s$ matrices such that the resulting method is explicit in f and implicit in g. We use a diagonally implicit scheme for g, i.e., $a_{ij} = 0$ for $j > i$. This will guarantee that f is always evaluated explicitly.

Such methods are characterized by the coefficient matrices $\tilde{A} = (\tilde{a}_{ij})$, $A = (a_{ij})$ and vectors $\tilde{c} = (\tilde{c}_1, \ldots, \tilde{c}_s)^T$, $\tilde{b} = (\tilde{b}_1, \ldots, \tilde{b}_s)^T$, $c = (c_1, \ldots, c_s)^T$, $b = (b_1, \ldots, b_s)^T$. They can be represented by a double *tableau* in the usual Butcher notation,

$$\begin{array}{c|c} \tilde{c} & \tilde{A} \\ \hline & \tilde{b}^T \end{array} \qquad \begin{array}{c|c} c & A \\ \hline & b^T \end{array}.$$

The coefficients $\tilde{c}$ and c are given by the usual relation,

$$\tilde{c}_i = \sum_{j=1}^{i-1} \tilde{a}_{ij}, \quad c_i = \sum_{j=1}^{i} a_{ij}, \tag{6}$$

which allows the results of our analysis to be extended to nonautonomous systems. We shall use the notation Name(s, σ, p), where this triplet characterizes the number s of the stages of the implicit scheme, the number σ of stages of the explicit scheme and the combined order of the method, p. Now we give some definitions that we will use later.

DEFINITION 2.1. *We call q_i the stage order of the ith stage of an R-K method if and only if for a problem $\dot{y}(t) = f(t, y(t))$, with $0 \leq t \leq T$ and f a smooth function, the intermediate local errors $y(t_n + c_i h) - Y_i = \mathcal{O}(h^{q_i+1})$, where $Y_i = y(t_n) + h \sum_{j=1}^{s} a_{ij} f(t_n + c_j h, Y_j)$ $(1 \leq i \leq s)$.*

Remark. For stiff differential equations the *stage order* q is an essential ingredient. It is defined by the condition $C(q)$ (see [12] and [13, sect. IV.5]), i.e.,

$$\sum_{j=1}^{s} a_{ij} c_j^{k-1} = \frac{c_i^k}{k} \quad \text{for } k = 1, \ldots, q \quad \text{and all } \ i. \tag{7}$$

For an s-stage DIRK method, the stage order is 1.

DEFINITION 2.2. *Methods that satisfy the condition $a_{sj} = b_j$, $j = 1, \ldots, s$, are called stiffly accurate.*

Remark. In our analysis we indicate $R(\infty) = \lim_{z \to \infty} R(z)$, with $R(z)$ *the stability function* of the implicit scheme, defined by $R(z) = 1 + z b^T (I - zA)^{-1} \mathbf{1}$ (see [13, sect. IV.3]), with $b^T = (b_1, \ldots, b_s)$ and $\mathbf{1} = (1, \ldots, 1)^T$. From the expression of $R(z)$ follows $R(\infty) = 1 - \sum_{i,j=1}^{s} b_i \omega_{ij}$ with ω_{ij} elements of the inverse of (a_{ij}). Moreover, if the implicit method is stiffly accurate and the matrix A is invertible, one has always $R(\infty) = 0$. We shall use the notation $\tilde{q}_i$, with $\tilde{q}_i \geq 1$, to indicate the *stage order* of the ith stage of the explicit part of the IMEX R-K method, and with q_i, $q_i \geq 1$, the *stage order* of the ith stage of the implicit one. IMEX R-K methods present in the literature can be classified in three different types characterized by the structure of the matrix $A = (a_{ij})_{i,j=1}^{s}$ of the implicit scheme.

DEFINITION 2.3. *We call an IMEX R-K method* type A *(see* [18]*) if the matrix $A \in R^{s \times s}$ is invertible.*

DEFINITION 2.4. *We call an IMEX R-K method* type CK *(see* [8]*) if the matrix $A \in R^{s \times s}$ can be written as*

$$A = \begin{pmatrix} 0 & 0 \\ a & \hat{A} \end{pmatrix}$$

with the submatrix $\hat{A} \in R^{(s-1)\times(s-1)}$ *invertible.*

Remark. IMEX R-K methods of type ARS (see [1]) are a special case of type CK with the vector $a = 0$.

3. Main results. Motivated by the procedure first suggested by Hairer, Lubich, and Roche [12] (see also [13]), we extend this analysis to different types of IMEX R-K methods. The main results of this paper are summarized in this section in the form of theorems. The aim of these theorems is to present convergence results of these methods when applied to SPP (2). We suppose that the initial values lie on a suitable manifold that allows smooth solutions even in the limit of infinite stiffness and the step size $h = \Delta t \gg \varepsilon$. In fact, arbitrary initial values introduce in the solution a fast transient. One possible way to overcome this difficulty is simply to ensure that the numerical method resolves the transient phase by taking time step $h \ll \varepsilon$ in the first few steps. Then the following results are obtained assuming that the transient phase is over.

An essential ingredient to obtaining these results is to assume that the system is dissipative. More precisely, we assume that

$$\mu\left(g_z(y,z)\right) \le -1 \tag{8}$$

in an ε-independent neighborhood of the solution, where μ denotes the logarithmic norm with respect to some inner product. Condition (8) guarantees the existence of an ε-expansion of problem (2) (see [13, p. 390]).

The proof of the theorems below will be a consequence of the results of sections 5 to 7. We start by considering the limit case $\varepsilon = 0$ (*the reduced problem* or *problems of index* 1) for problem (2).

THEOREM 3.1 (type A). *Consider the stiff problem* (2), (8) *with initial values* $y(0)$, $z(0)$ *admitting a smooth solution. Apply the type-A IMEX R-K method* (3)–(5) *and let* p *be the order of explicit scheme. Assume that the method with coefficients* b_i *and* a_{ij} *is A-stable, that the stability function satisfies* $|R(\infty)| < 1$, *and that* $a_{ii} > 0$ *for all* i. *Furthermore, assume that the weights satisfy the condition* $\tilde{b}_i = b_i$ *for* $i = 1, \dots, s$.

Then if $\sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1$, *with* ω_{ij} *elements of the inverse matrix of* A, *for any fixed constant* $C > 0$, *the global error satisfies*

$$y_n - y(t_n) = \mathcal{O}(h^p) + \mathcal{O}(\varepsilon h^2), \quad z_n - z(t_n) = \mathcal{O}(h^2)$$

for $\varepsilon \le Ch$; *otherwise, we obtain*

$$y_n - y(t_n) = \mathcal{O}(h^p) + \mathcal{O}(\varepsilon h), \quad z_n - z(t_n) = \mathcal{O}(h).$$

If in addition $a_{si} = b_i$ *and* $\tilde{a}_{si} = \tilde{b}_i$ *for all* i, *we have* $z_n - z(x_n) = \mathcal{O}(h^p) + \mathcal{O}(\varepsilon h^2)$. *The estimates hold uniformly for* $h \le h_0$ *and* $nh \le$ Const.

THEOREM 3.2 (type CK). *Consider the stiff problem* (2), (8) *with initial values* $y(0)$, $z(0)$ *admitting a smooth solution. Apply the type-CK IMEX R-K method* (3)–(5) *with invertible matrix* $\hat{A}$ *and let* p *be the order of the explicit scheme. Assume that the method, with coefficients* b_i *and* a_{ij}, *is A-stable, that the stability function satisfies* $|R(\infty)| < 1$, *and that* $a_{ii} > 0$ *for all* i. *Assume that the weights satisfy the condition* $\tilde{b}_i = b_i$ *for* $i = 1, \dots, s$ *and that the method is stiffly accurate. Then, for any fixed constant* $C > 0$, *the global error satisfies, for* $\varepsilon \le Ch$,

$$y_n - y(x_n) = \mathcal{O}(h^{\tilde{q}+2} + h^p) + \mathcal{O}(\varepsilon h^2), \quad z_n - z(x_n) = \mathcal{O}(h^{\tilde{q}+1} + h^p) + \mathcal{O}(\varepsilon h) \tag{9}$$

with $\tilde{q} = \min\{\tilde{q}_s,\ \tilde{q}_i + 1$ *for all* $i = 2, \dots, s-1\}$. *The estimates hold uniformly for* $h \le h_0$ *and* $nh \le$ Const.

COROLLARY 3.1 (type ARS). *Under the same assumptions of Theorem* 3.2 *and with* $b_1 = 0$, *the global error satisfies* (9). *These estimates hold uniformly for* $h \le h_0$ *and* $nh \le$ Const.

Remark. Next, we shall show that if the method of type ARS is not *stiffly accurate*, one obtains the following estimates:

$$y_n - y(x_n) = \mathcal{O}(h^p + h^3) + \mathcal{O}(\varepsilon h^2), \quad z_n - z(x_n) = \mathcal{O}(h^p + h^2) + \mathcal{O}(\varepsilon h).$$

3.1. Numerical evidence. Before we provide proof of the main theorems, we present numerical results for the different types of IMEX R-K methods developed in the literature (see, e.g., [8], [1], [18], [19]), which confirm the theoretical prediction. Specifically, we will conduct convergence tests to compare the performance of different types of methods. As an example of a stiff problem (2) we consider one of the simplest nonlinear equations (describing nonlinear oscillations) in the stiff literature, the *van der Pol equation*

$$y' = z, \quad \varepsilon z' = (1 - y^2)z - y \tag{10}$$

with $0 \le \varepsilon \ll 1$. When the stiffness parameter ε is sufficiently small, numerical results confirm order reduction especially for the algebraic z-component. In our experiment, errors are computed by choosing initial values

$$y(0) = 2, \qquad z(0) = -\frac{2}{3} + \frac{10}{81}\varepsilon - \frac{292}{2187}\varepsilon^2 - \frac{1814}{19683}\varepsilon^3 + \mathcal{O}(\varepsilon^4) \tag{11}$$

such that the solution is smooth, and $\varepsilon = 10^{-6}$. In the following figures we have plotted the relative global error at $t_{end} = 0.55139$ as a function of the step size h, which was taken to be a constant over the considered interval $[0, t_{end}]$. We use logarithmic scales in both directions. The relative global error behaves like $C \cdot h^r$, where r is the slope of the straight line and C is a constant. We have indicated this behavior in all figures.

Table 1 shows the different types of IMEX R-K methods together with the global errors predicted by Theorems 3.1 and 3.2 and Corollary 3.1. Several conclusions are drawn from the numerical tests.

3.2. Discussion. (a) In Figures 1–7 we see that whenever p is small or h is very large the $\mathcal{O}(h^p)$ term is dominant in the z-component, whereas the other terms can be seen behaving otherwise. Furthermore the estimates in Table 1 demonstrate order reduction for the algebraic component in every type of method for a sufficiently stiff parameter ($\varepsilon = 10^{-6}$).

(b) An important ingredient, suggested by the analysis, is the condition $\tilde{b}_i = b_i$ for all i. Such a choice provides a significant benefit for the differential y-component. In fact the ARS$(4, 4, 3)$ method does not satisfy this condition, and for the y-component the global error drops to first order for a range of the step h. Note, however, that in Theorems 6.1 and 6.2 a satisfactory theoretical explanation of this fact is given.

In particular, the ARS$(4, 4, 3)$ method satisfies the conditions $\tilde{a}_{si} = \tilde{b}_i$ $\tilde{a}_{si} = \tilde{b}_i$ for all i, and in the next sections we shall observe that as a consequence of the above the z-component has the same estimate of the convergence rate as the y-component, justifying the behavior shown in Figure 3.

TABLE 1
Global errors predicted by theorems for the van der Pol equation.

Method	Stiffly accurate	y-comp.	z-comp.
ARS$(3,4,3)$, [1]	yes	$h^3+\varepsilon h^2$	h^2
MARS$(3,4,3)$	yes	$h^3+\varepsilon h^2$	$h^3+\varepsilon h$
ARS$(4,4,3)$, [1]	yes	$h^3+\varepsilon h$	$h^3+\varepsilon h$
ARK3(2)4L[2]SA, [8]	yes	h^3	h^2
ARK5(4)8L[2]SA, [8]	yes	$h^4+\varepsilon h^2$	$h^3+\varepsilon h$
ARK4(3)6L[2]SA, [8]	yes	h^4	$h^3+\varepsilon h$
MARK3(2)4L[2]SA	yes	h^3	$h^3+\varepsilon h$
IMEX-SSP2$(3,3,2)$, [18]	yes	h^2	h^2
IMEX-SSP3$(3,3,2)$, [18]	no	$h^3+\varepsilon h$	h
IMEX-SSP3$(4,3,3)$, [18]	no	$h^3+\varepsilon h$	h

(c) As noted in [8], according to the estimated convergence rates for differential and algebraic variables in [8, Table 12], several IMEX ARK_2 methods confirm the theoretical estimates given in Theorem 3.2. For instance, in order to justify the behavior observed in Figure 6, several pertinent assumptions are satisfied: $b_2 = \tilde{b}_2 = 0$ as well as the formula

$$\sum_{j=1}^{s} \tilde{a}_{ij} c_j = \frac{c_i^2}{2} \tag{12}$$

for $i = 3, \ldots, s$. Thus, using these assumptions, we achieve the estimates in Theorem 3.2.

(d) Finally, it is worth mentioning that the IMEX-SSP3$(4,3,3)$ scheme, as shown in Figure 7, exhibits order reduction both in the differential and algebraic components. Similarly, plots for the IMEX-SSP3$(3,3,2)$ scheme yield similar results. This behavior appears since the IMEX-SSP3$(3,3,2)$ and IMEX-SSP3$(4,3,3)$ schemes don't satisfy the condition $\sum_{ij} b_i \omega_{ij} \tilde{c}_j = 1$ required in Theorem 3.1. On the other hand, the IMEX-SSP2(3,3,2) scheme satisfies this condition so it achieves the anticipated convergence rate.

Improvements of existing schemes. A most relevant point demonstrated by this test is that methods such as *modified* ARK3(2)4L[2]SA (MARK3(2)4L[2]SA) and *modified* ARS$(3,4,3)$ (MARS$(3,4,3)$) produce an estimate for the z-component of the following form:

$$z_n - z(t_n) = \mathcal{O}(h^3) + \mathcal{O}(\varepsilon h) + \mathcal{O}(\varepsilon^2). \tag{13}$$

In this result the term $\mathcal{O}(\varepsilon^2)$ can be neglected since $\varepsilon \ll h$. Furthermore, to illustrate the results shown in Figures 2 and 5, we note that if the step size $h > \varepsilon^{1/2}$, the $\mathcal{O}(h^3)$ term is dominant; otherwise the term $\mathcal{O}(\varepsilon h)$ can be observed. A singularity appears in the neighborhood of $h \approx \varepsilon^{1/2}$ where we have a cancellation of error terms $\mathcal{O}(h^3)$ and $\mathcal{O}(\varepsilon h)$ with error constants of an opposite sign.

Therefore, the modified schemes give an improvement in the error estimate for the z-component when compared to the ARK3(2)4L[2]SA and ARS$(3,4,3)$ methods. In the following sections we will see that the global error estimates of these methods depend on $\tilde{q} = \min\{\tilde{q}_s,\ \tilde{q}_i + 1 \text{ for all } i = 2,\dots,s-1\}$. This fact enables us to construct methods with more accuracy. Notice the following:

(i) For the MARS$(3,4,3)$ method, a natural way to achieve the error estimate (13) is to increase from 1 to 2 the stage order in the sth stage of the explicit scheme so that $\tilde{q} = 2$.

(ii) In order to reach estimate (13) in the case of the MARK3(2)4L[2]SA method, we suggest using formula (12), for $i = 3,\dots,s$, in the explicit scheme accompanied by the assumption $\tilde{b}_2 = 0$. The assumption $\tilde{b}_2 = 0$ is necessary because the assumption (12) cannot be satisfied for $i = 2$; otherwise we would have $c_2 = 0$ and the method would be equivalent to one with fewer stages.

4. Asymptotic expansion. To obtain our main results in a general setting, we start from the ε-expansion of the exact solution of problem (2). Here, in particular, we are interested in smooth solutions which are of the form

$$\begin{aligned} y(t) &= y_0(t) + \varepsilon y_1(t) + \varepsilon^2 y_2(t) + \cdots, \\ z(t) &= z_0(t) + \varepsilon z_1(t) + \varepsilon^2 z_2(t) + \cdots, \end{aligned} \tag{14}$$

where $y_i(t)$ and $z_i(t)$ are ε-independent functions, which are solutions of a sequence of DAEs of arbitrary index.

The aim in this section is to analyze the ε-expansion of the numerical solution for problem (2) and verify how a sequence of differential-algebraic systems arise in the study of such a problem. A general and detailed investigation about the ε-expansion of the exact solution for problem (2) is given in [13] and [16].

We consider the IMEX R-K method (3), (5). We formally expand the quantities Y_{ni}, k_{ni}, y_n, Z_{ni}, ℓ_{ni}, and z_n into powers of ε with ε-independent coefficients:

$$y_n = y_n^0 + \varepsilon y_n^1 + \varepsilon^2 y_n^2 + \cdots, \tag{15a}$$

$$Y_{ni} = Y_{ni}^0 + \varepsilon Y_{ni}^1 + \varepsilon^2 Y_{ni}^2 + \cdots, \tag{15b}$$

$$k_{ni} = k_{ni}^0 + \varepsilon k_{ni}^1 + \varepsilon^2 k_{ni}^2 + \cdots, \tag{15c}$$

$$z_n = z_n^0 + \varepsilon z_n^1 + \varepsilon^2 z_n^2 + \cdots, \tag{15d}$$

$$Z_{ni} = Z_{ni}^0 + \varepsilon Z_{ni}^1 + \varepsilon^2 Z_{ni}^2 + \cdots, \tag{15e}$$

$$\ell_{ni} = \varepsilon^{-1}\ell_{ni}^{-1} + \ell_{ni}^0 + \varepsilon \ell_{ni}^1 + \varepsilon^2 \ell_{ni}^2 + \cdots. \tag{15f}$$

Because of the linearity of relations (3) and (5) we have to order ε^ν, with $\nu = -1$,

$$0 = h\sum_{j=1}^{i} a_{ij}\ell_{nj}^{-1}, \quad 0 = h\sum_{i=1}^{s} b_i\ell_{ni}^{-1} \tag{16}$$

and, for $\nu \geq 0$,

$$\begin{pmatrix} y_{n+1}^\nu \\ z_{n+1}^\nu \end{pmatrix} = \begin{pmatrix} y_n^\nu \\ z_n^\nu \end{pmatrix} + h\sum_{i=1}^{s} \begin{pmatrix} \tilde{b}_i k_{ni}^\nu \\ b_i \ell_{ni}^\nu \end{pmatrix}, \tag{17}$$

$$\begin{pmatrix} Y_{ni}^\nu \\ Z_{ni}^\nu \end{pmatrix} = \begin{pmatrix} y_n^\nu \\ z_n^\nu \end{pmatrix} + h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} k_{nj}^\nu \\ \sum_{j=1}^{i} a_{ij} \ell_{nj}^\nu \end{pmatrix}. \tag{18}$$

Inserting (15b), (15c), (15e), and (15f) into (4) and comparing equal powers of ε, we obtain

$$\varepsilon^0 : \begin{cases} k_{ni}^0 = f(Y_{ni}^0, Z_{ni}^0), \\ \ell_{ni}^{-1} = g(Y_{ni}^0, Z_{ni}^0), \end{cases} \tag{19a}$$

$$\varepsilon^1 : \begin{cases} k_{ni}^1 = f_y(Y_{ni}^0, Z_{ni}^0)Y_{ni}^1 + f_z(Y_{ni}^0, Z_{ni}^0)Z_{ni}^1, \\ \ell_{ni}^0 = g_y(Y_{ni}^0, Z_{ni}^0)Y_{ni}^1 + g_z(Y_{ni}^0, Z_{ni}^0)Z_{ni}^1, \end{cases} \tag{19b}$$

$$\cdots\cdots$$

$$\varepsilon^\nu : \begin{cases} k_{ni}^\nu = f_y(Y_{ni}^0, Z_{ni}^0)Y_{ni}^\nu + f_z(Y_{ni}^0, Z_{ni}^0)Z_{ni}^\nu + \varphi_\nu(Y_{ni}^0, Z_{ni}^0, \ldots, Y_{ni}^{\nu-1}, Z_{ni}^{\nu-1}), \\ \ell_{ni}^{\nu-1} = g_y(Y_{ni}^0, Z_{ni}^0)Y_{ni}^\nu + g_z(Y_{ni}^0, Z_{ni}^0)Z_{ni}^\nu + \psi_\nu(Y_{ni}^0, Z_{ni}^0, \ldots, Y_{ni}^{\nu-1}, Z_{ni}^{\nu-1}). \end{cases} \tag{19c}$$

Since (4) has a similar form to (2), the formulas (19a), (19b), and (19c) are exactly the same as those of the expansion in powers of ε for the exact solution (see [13] and [12]). In response to this fact, it follows that the coefficients y_n^0, z_n^0, y_n^1, z_n^1, ... represent the numerical solution of an arbitrary IMEX R-K method applied to DAEs of arbitrary index. Finally, subtracting (15a) and (15d) from (14), we get formally

$$y_n - y(t_n) = \sum_{\nu\geq 0} \varepsilon^\nu (y_n^\nu - y_\nu(t_n)), \quad z_n - z(t_n) = \sum_{\nu\geq 0} \varepsilon^\nu (z_n^\nu - z_\nu(t_n)). \tag{20}$$

Hence, the error of the numerical solution possesses an ε-expansion whose coefficients are the errors of the method applied to the differential-algebraic system. Clearly, in order to study this error, one will investigate only the differences $y_n^\nu - y_\nu(t_n)$, $z_n^\nu - z_\nu(t_n)$.

5. Zeroth-order expansion (index 1). From an arbitrary SPP (2) now we want to study the behavior of the global error of different types of IMEX R-K schemes for $\varepsilon \to 0$. In this section we start by studying the limiting case $\varepsilon = 0$. This gives us the corresponding *reduced* problem

$$\begin{aligned} y' &= f(y, z), \\ 0 &= g(y, z). \end{aligned} \tag{21}$$

We assume that $g_z(y,z)$ is invertible in a neighborhood of the solution of (21). This assumption guarantees the solvability of (21) and that the equation $g(y,z)=0$ possesses a locally unique solution (implicit function theorem). Furthermore, the same assumption guarantees that system (21) is a differential-algebraic one of *index* 1 [13]. Therefore, our first goal is to consider the different types of schemes applied to the reduced problem.

Type A. An IMEX R-K method of type A applied to the reduced problem has the form

$$Y_{ni} = y_n + h\sum_{j=1}^{i-1} \tilde{a}_{ij} f(Y_{nj}, Z_{nj}), \tag{22a}$$

$$0 = g(Y_{ni}, Z_{ni}), \tag{22b}$$

$$y_{n+1} = y_n + h\sum_{i=1}^{s} \tilde{b}_i f(Y_{ni}, Z_{ni}), \tag{22c}$$

$$z_{n+1} = R(\infty) z_n + \sum_{i,j=1}^{s} b_i \omega_{ij} Z_{nj}. \tag{22d}$$

Remarks. (a) By the implicit function theorem applied to (22b), we have $Z_{ni} = G(Y_{ni})$ for $i=1,\dots,s$. Consequently, by $Y_{ni} = y(t_n + \tilde{c}_i h) + \mathcal{O}(h^{\tilde{q}_i+1})$, it follows that the *internal stages* Z_{ni} depend on the coefficients $\tilde{c}_i$ of the explicit scheme.

(b) Concerning system (21), the y-component can be interpreted as the numerical solution of the ordinary differential equation $y' = f(y, H(y))$ with $z = H(y)$ (implicit function theorem). Therefore, for the method (22a)–(22d) we have

$$y_n - y(t_n) = \mathcal{O}(h^p),$$

because the formulas (22a), (22b), and (22c) are independent of z_n with p the order of the explicit scheme. Thus, we have only to prove a convergence result for the z-component.

Type CK. By Definition 2.4, we assume submatrix $\hat{A}$ is invertible. By (16), we have $0 = ha_{i1}\ell_{n1}^{-1} + h\sum_{j=2}^{i} a_{ij}\ell_{nj}^{-1}$ for $i=2,\dots,s$. Now, by the fact that $\ell_{n1}^{-1} = g(y_n, z_n)$, we obtain

$$\ell_{ni}^{-1} = \alpha_i g(y_n, z_n), \tag{23}$$

where $\alpha_i = -\sum_{i,j=2}^{s} \hat{\omega}_{ij} a_{j1}$ for $i=2,\dots,s$, with $\hat{\omega}_{ij}$ elements of the inverse matrix of $\hat{A}$.

Now, looking at (16), Lemma 5.1 follows from (23) and $\ell_{n1}^{-1} = g(y_n, z_n)$.

LEMMA 5.1. *The condition*

$$b_1 + \sum_{i=2}^{s} b_i \alpha_i = 0 \tag{24}$$

is automatically satisfied if the IMEX R-K method of type CK is stiffly accurate.

Therefore we assume that the method is stiffly accurate in the implicit part. This, moreover, yields $z_{n+1} = Z_{ns}$. Next we will use this lemma.

Then for the reduced problem a type-CK IMEX R-K scheme is defined by

$$Y_{ni} = y_n + h\sum_{j=1}^{i-1} \tilde{a}_{ij} f(Y_{nj}, Z_{nj}), \tag{25a}$$

$$y_{n+1} = y_n + h\sum_{i=1}^{s} \tilde{b}_i f(Y_{ni}, Z_{ni}), \tag{25b}$$

$$g(Y_{ni}, Z_{ni}) = \alpha_i g(y_n, z_n), \quad i = 2, \dots, s-1, \tag{25c}$$

$$g(Y_{ns}, z_{n+1}) = \alpha_s g(y_n, z_n). \tag{25d}$$

Type ARS. Since this is a particular case of CK with $a_{i1} = 0$ it follows that $\alpha_i = 0$ and $G(Y_{ni}, Z_{ni}) = 0$ for $i = 2, \dots, s$. As an immediate consequence, we get explicitly $z_{n+1} = R(\infty)z_n + \sum_{i,j=2}^{s} b_j \hat{\omega}_{ij} Z_{nj}$. In particular, if the method is stiffly accurate, $z_{n+1} = Z_{ns}$. In particular more theoretical insight into this type ARS shows that if we have $a_{si} = b_i$ and $\tilde{a}_{si} = \tilde{b}_i$ for $i = 1, \dots, s$, it also follows that $g(y_{n+1}, z_{n+1}) = 0$. Thus if $g_z(y, z)$ is invertible, we may express z_{n+1} as a function of y_{n+1}, and therefore we can declare that the z-component has the same asymptotic error estimate as the y-component.

After having understood the structure of each method, we are now in a position to prove the following results. All the theorems below are built on the assumption that the reduced problem satisfies (8) in a neighborhood of the exact solution $(y(t), z(t))$, and we assume that the initial values are *consistent*, i.e., $g(y_0, z_0) = 0$.

THEOREM 5.1 (type A). *Consider an IMEX R-K method of type A. Let p be the classical order of the explicit R-K method. Assume that the stability function of the implicit scheme satisfies $|R(\infty)| < 1$. Then the numerical solution of* (22a)–(22d) *has global error*

$$z_n - z(t_n) = \begin{cases} \mathcal{O}(h^2) & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1, \\ \mathcal{O}(h) & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j \neq 1. \end{cases} \tag{26}$$

The estimates (26) *hold uniformly for $t_n - t_0 = nh \leq$ Const.*

Proof. We denote the global error by $\Delta z_n = z_n - z(t_n)$ and $R(\infty) = \rho$. By remark (b), we get $Z_{ni} = z(t_n) + \tilde{c}_i h z'(t_n) + \mathcal{O}(h^2)$. Now, inserting it into (22d) and considering $z(t_{n+1}) = z(t_n) + h z'(t_n) + \mathcal{O}(h^2)$, one obtains

$$\Delta z_{n+1} = \rho \Delta z_n + \left(\sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j - 1 \right) h z'(t_n) + \mathcal{O}(h^2),$$

which allows us to conclude that

$$\Delta z_{n+1} = \begin{cases} \rho \Delta z_n + \delta_{n+1} & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1, \\ \rho \Delta z_n + \delta_{n+1} & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j \neq 1, \end{cases} \tag{27}$$

where

$$\delta_{n+1} = \begin{cases} O(h^2) & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1, \\ O(h) & \text{if } \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j \neq 1. \end{cases} \tag{28}$$

Finally, repeated insertion of these formulas gives

$$\Delta z_n = \begin{cases} \sum_{i=1}^{n} \rho^{n-j}\delta_j & \text{if } \sum_{i,j=1}^{s} b_i\omega_{ij}\tilde{c_j} = 1, \\ \sum_{i=1}^{n} \rho^{n-j}\delta j & \text{if } \sum_{i,j=1}^{s} b_i\omega_{ij}\tilde{c_j} \neq 1 \end{cases} \tag{29}$$

because $\Delta z_0 = 0$. Thus, by the hypothesis $|\rho| < 1$, we obtain

$$\Delta z_n = \begin{cases} \mathcal{O}(h^2) & \text{if } \sum_{i,j=1}^{s} b_i\omega_{ij}\tilde{c_j} = 1, \\ \mathcal{O}(h) & \text{if } \sum_{i,j=1}^{s} b_i\omega_{ij}\tilde{c_j} \neq 1. \end{cases} \tag{30}$$

□

Remark. If the IMEX R-K method is stiffly accurate, it follows by (22b) that $z_{n+1} = Z_{ns} = G(Y_{ns})$. By remark (b), since we get $Z_{ns} - z(t_n + \tilde{c}_s h) = G(Y_{ns}) - G(y(t_n + \tilde{c}_s h)) = \mathcal{O}(h^{\tilde{q}_s+1})$, if $\tilde{c}_s = 1$, this proves the following estimate: $z_n - z(t_n) = \mathcal{O}(h^{\tilde{q}_s+1})$. Moreover, if in the explicit part we also have $\tilde{a}_{si} = \tilde{b}_i$ for $i = 1, \dots, s$, this yields $y_{n+1} = Y_{ns}$. Therefore, by $g(y_{n+1}, z_{n+1}) = 0$ and by the implicit function theorem, it follows that $z_{n+1} = G(y_{n+1})$, and in this situation the estimate is $z_n - z(t_n) = \mathcal{O}(h^p)$.

THEOREM 5.2 (type CK). *Consider an IMEX R-K method of type KC stiffly accurate with invertible matrix $\hat{A}$ and weights $\tilde{b}_i = b_i$ for $i = 1, \dots, s$. Let p be the order of explicit scheme. Assume that the stability function of the implicit scheme satisfies $|R(\infty)| < 1$ and $\delta = |\alpha_s| < 1$. Then the numerical solution of* (25a)–(25d) *has global error*

$$y_n - y(t_n) = \mathcal{O}(h^{\tilde{q}+2}) + \mathcal{O}(h^p), \qquad z_n - z(t_n) = \mathcal{O}(h^{\tilde{q}+1}) + \mathcal{O}(h^p) \tag{31}$$

with $\tilde{q} = \min\{\tilde{q}_s, \tilde{q}_i + 1,\ i = 2, \dots, s-1\}$. These estimates holds uniformly for $nh \leq$ Const.

Proof. By the relation (23), it follows that

$$g(Y_{ni}, Z_{ni}) = \alpha_i g(y_n, z_n), \tag{32}$$

so that Z_{ni} is a function of Y_{ni}, y_n, and z_n for $i = 2, \dots, s$. On the other hand, to provide an optimal estimate for the local error of the y-component we introduce the internal stages U_{ni}, V_{ni} that satisfy the relation

$$g(U_{ni}, V_{ni}) = \alpha_i g(y(t_n), z(t_n)) \tag{33}$$

for $i = 2, \dots, s$. Of course, this implies that V_{ni} is a function of U_{ni}, $y(t_n)$, and $z(t_n)$. Also, the internal stage U_{ni} is defined as

$$U_{ni} = y(t_n) + h\left(\tilde{a}_{i1}y'(t_n) + \sum_{j=2}^{i-1} \tilde{a}_{ij} f(U_{nj}, V_{ni})\right), \tag{34}$$

where $y'(t_n) = f(y(t_n), z(t_n))$ is the exact solution of $y(t)$ in t_n.

Next we shall use the abbreviation $g_z(t_n) = g_z(y(t_n), z(t_n))$, $f_y(t_n) = f_y(y(t_n), z(t_n))$ and denote $\Delta y_n = y_n - y(t_n)$ and $\Delta z_n = z_n - z(t_n)$.

Our proof proceeds in two parts, referred to as (a) and (b).

(a) We first estimate the differences $\|Z_{ni} - V_{ni}\|$, $\|Y_{ni} - U_{ni}\|$ of the internal stages. For this, we subtract $Y_{ni} = y_n + h(\tilde{a}_{i1} f(y_n, z_n) + \sum_{j=2}^{i-1} \tilde{a}_{ij} f(Y_{nj}, Z_{nj}))$ from (34) to obtain

$$\|Y_{ni} - U_{ni}\| \leq \|\Delta y_n\| + \mathcal{O}(h\|y_n\| + h\|\Delta z_n\|) + Ch\sum_{j=2}^{i-1} |\tilde{a}_{ij}| \, \|Z_{nj} - V_{nj}\| \tag{35}$$

for $i = 2, \ldots, s$ by the use of a Lipschitz condition for f.

We now linearize (32) and (33). Subtracting the two quantities, by the use of (35) and the condition $g_z^{-1}(t_n + c_i h) g_z(t_n) = I + \mathcal{O}(h)$, we obtain

$$\|Z_{ni} - V_{ni}\| \le |\alpha_i| \, \|\Delta z_n\| + \mathcal{O}(h \, \|\Delta z_n\|) + \mathcal{O}(\|\Delta y_n\|). \tag{36}$$

(b) Our next aim is to prove the recursion

$$\begin{pmatrix} \|\Delta y_{n+1}\| \\ \|\Delta z_{n+1}\| \end{pmatrix} \le \begin{pmatrix} 1 + \mathcal{O}(h) & \mathcal{O}(h^2) \\ \mathcal{O}(1) & \delta + \mathcal{O}(h) \end{pmatrix} \begin{pmatrix} \|\Delta y_n\| \\ \|\Delta z_n\| \end{pmatrix} + \begin{pmatrix} \mathcal{O}(h^{p+1}) \\ \mathcal{O}(h^{\tilde{q}+1}) \end{pmatrix}. \tag{37}$$

For the verification of the first relation in (37) we again linearize the quantities $y(t_n+h)$ and y_{n+1} to obtain

$$\begin{aligned} \Delta y_{n+1} = \Delta y_n + h\tilde{b}_1 (f_y(t_n) \Delta y_n + f_z(t_n) \Delta z_n) + h \sum_{i=2}^{s} \tilde{b}_i (f_y(t_n) \, (Y_{ni} - U_{ni}) \\ + f_z(t_n) \, (Z_{ni} - V_{ni})) + \mathcal{O}(h^2 \, \|y_n\| + h^2 \, \|z_n\|) + \mathcal{O}(h^{p+1}), \end{aligned} \tag{38}$$

and inserting (35) and (36) into (38), we get

$$\|\Delta y_{n+1}\| \le (1 + C_1 h) \, \|\Delta y_n\| + C_2 h^2 \, \|\Delta z_n\| + \mathcal{O}(h^{p+1}). \tag{39}$$

In (39), we applied the statement of Lemma 5.1.

Now we compute the second relation in (37) from (25d) and its exact expression $g(y(t_n + \tilde{c}_s h), z(t_{n+1})) = \alpha_s g(y(t_n), z(t_n))$. Linearizing and subtracting the two quantities, respectively, we obtain

$$\begin{aligned} \Delta z_{n+1} = -g_z^{-1}(t_n + \tilde{c}_s h) g_y(t_n) \Delta Y_{ns} + \alpha_s g_z^{-1}(t_n + \tilde{c}_s h) g_y(t_n) y_n \\ + \alpha_s g_z^{-1}(t_n + \tilde{c}_s h) g_z(t_n) z_n + \mathcal{O}\left(\|\Delta y_n\|^2 + \|\Delta z_n\|^2 \right). \end{aligned}$$

We now assume that

$$\|\Delta y_n\| \le Ch, \quad \|\Delta z_n\| \le Ch, \tag{40}$$

with some fixed constant C.[1] Therefore, by $g_z^{-1}(t_n + h) g_z(t_n) = I + \mathcal{O}(h)$, it follows that

$$\|\Delta z_{n+1}\| \le |\alpha_s| \, \|\Delta z_n\| + \mathcal{O}\left(\|\Delta y_n\| + h \, \|\Delta z_n\| \right) + \mathcal{O}(\|\Delta Y_{ns}\|) \tag{41}$$

as long as assumption (40) is satisfied. Now, using

$$\Delta Y_{ni} = \Delta y_n + h \sum_{j=1}^{i-1} \tilde{a}_{ij} \Delta k_{nj} + \mathcal{O}(h^{\tilde{q}_i + 1}) \tag{42}$$

and a Lipschitz condition for f gives

$$\|\Delta k_{ni}\| \le M \, \|\Delta Y_{ni}\| + N \, \|\Delta Z_{ni}\| \, . \tag{43}$$

[1] This statement should be interpreted to mean that if h is sufficiently small, the numerical solution will never violate the conditions (40).

In order to find an optimal estimate of (41) we proceed as follows. The linearization of (32) and the exact expression $g(y(t_n+\tilde{c}_ih),z(t_n+\tilde{c}_ih))=\alpha_i g(y(t_n),z(t_n))$ yields

$$\|\Delta Z_{ni}\| \le |\alpha_i|\,\|\Delta z_n\| + \mathcal{O}\left(h\,\|\Delta z_n\| + \|\Delta y_n\|\right) + \mathcal{O}(\|\Delta Y_{ni}\|).$$

Inserted into (43), with the help of (42) after repeated insertions of $\|\Delta Y_{ni}\|$, and setting $i=s$, we obtain

$$\|\Delta Y_{ns}\| \le \|\Delta y_n\| + hC_1\left(\|\Delta y_n\| + \|\Delta z_n\|\right) + hC_2(|\alpha_s|\,\|\Delta z_n\| + \|\Delta y_n\|) + \mathcal{O}(h^{\tilde{q}+1})$$

with $\tilde{q}=\min\{\tilde{q}_s,\ \tilde{q}_i+1,\ i=2,\dots,s-1\}$. Now putting the previous formula into (41), it follows that

$$\|\Delta z_{n+1}\| \le C\,\|\Delta y_n\| + (\delta + Ch)\,\|\Delta z_n\| + \mathcal{O}(h^{\tilde{q}+1}), \tag{44}$$

where $\delta=|\alpha_s|$. This completes the proof of formula (37).

Now applying Lemma 5.2 below to (37) gives the estimates (31) for $nh\le \text{Const}$, completing the proof. □

LEMMA 5.2. *Let $\{u_n\}$ and $\{v_n\}$ be two sequences of nonnegative numbers satisfying (componentwise)*

$$\begin{pmatrix} u_{n+1} \\ v_{n+1} \end{pmatrix} \le \begin{pmatrix} 1+\mathcal{O}(h) & \mathcal{O}(h^2) \\ \mathcal{O}(1) & \delta+\mathcal{O}(h) \end{pmatrix} \begin{pmatrix} u_n \\ v_n \end{pmatrix} + \begin{pmatrix} \mathcal{O}(h^{p+1}) \\ \mathcal{O}(h^{\tilde{q}+1}) \end{pmatrix} \tag{45}$$

with $0\le\delta<1$. Then the following estimate holds for $nh\le\text{Const}$ and $h\le h_0$:

$$\begin{aligned} u_n &\le C(u_0 + h^2v_0 + h^{\tilde{q}+2} + h^p), \\ v_n &\le C(u_0 + (\delta^n + h)\,v_0 + h^{\tilde{q}+1} + h^p). \end{aligned} \tag{46}$$

The proof is similar to that of Lemma 3.9 in [13].

Remarks. It is worth noting that if $b_i=\tilde{b}_i$ for $i=1,\dots,s$, then inserting (35) and (36) into (38) yields the nonzero quantity $\tilde{b}_1+\sum_{i=2}^s \tilde{b}_i\alpha_i$. For the y-component this implies $y_n-y(t_n)=\mathcal{O}(h^p)+\mathcal{O}(h^{\tilde{q}+1})$.

COROLLARY 5.1 (type ARS). *Suppose that the assumptions of Theorem 5.2 are satisfied and $b_1=0$. Then the numerical solution has global error satisfying* (31).

Remarks. We now suppose that the ARS method is not stiffly accurate. In order to obtain an optimal evaluation of Δz_n, we proceed as follows. Since $g(Y_{ni},Z_{ni})=0$, we get $Z_{ni}=G(Y_{ni})$ for $i=2,\dots,s$. By the Lipschitz condition for G, it follows that $\|\Delta Z_{ni}\|\le C\,\|\Delta Y_{ni}\|$. Using (42) and (43), we get

$$\|\Delta Y_{ni}\| \le \|\Delta y_n\| + h\,|\tilde{a}_{i1}|\,(\|\Delta y_n\| + \|\Delta z_n\|) + \mathcal{O}(h^{\tilde{r}_i+1}) \tag{47}$$

with $\tilde{r}_i=\min\{\tilde{q}_i,\tilde{q}_j+1,\ \ j=1,\dots,i-1\}$. It thus follows from the numerical and exact solution that

$$\|\Delta z_{n+1}\| \le |\rho|\,\|\Delta z_n\| + C\sum_{i,j=2}^{s} |b_i\hat{\omega}_{ij}|\,\|\Delta Y_{nj}\| + \mathcal{O}(h^{q+1}), \tag{48}$$

where $\rho=1-\sum_{i,j=2}^s b_i\hat{\omega}_{ij}$ and $q=\min_{i\le s}q_i$. Now, inserting (47) into (48) yields

$$\|\Delta z_{n+1}\| \le (|\rho|+C_2h)\,\|\Delta z_n\| + C_1\,\|\Delta y_n\| + \mathcal{O}(h^{\tilde{r}+1}) + \mathcal{O}(h^{q+1}), \tag{49}$$

where $\tilde{r} = \min\{\tilde{r}_2, \ldots, \tilde{r}_s\}$ with $|\rho| < 1$. We now solve (39) and (49), applying again Lemma 5.2, thus obtaining for the global error

$$y_n - y(t_n) = \mathcal{O}(h^p) + \mathcal{O}(h^3), \quad z_n - z(t_n) = \mathcal{O}(h^p) + \mathcal{O}(h^2).$$

Observe that the estimates obtained above are given since $q = 1$.

It is interesting to note that if $\tilde{b}_1 \neq 0$, in (39) we get $\|\Delta y_{n+1}\| \leq (1+C_1 h)\,\|\Delta y_n\| + C_2 h\,\|\Delta z_n\| + \mathcal{O}(h^{p+1})$ and the proof follows as above.

6. Higher-order expansion (higher index). Now we study the global error of IMEX R-K methods when applied to the SPP (2). To this end, we are interested in studying the differences $y_n^\nu - y_\nu(t_n)$ and $z_n^\nu - z_\nu(t_n)$ from (20). All the theorems below are built on the assumption that the stability function of the implicit scheme satisfies $|R(\infty)| < 1$ and the weights $\tilde{b}_i = b_i$ for all i. In what follows, when we use the superscript 0 in the quantities Y_{ni}, Z_{ni}, k_{ni}, ℓ_{ni}, y_n, z_n, we are treating the behavior of the numerical solution of the *reduced* problem.

THEOREM 6.1 (type A). *Consider an IMEX R-K method of type A such that (a_{ij}) is invertible. Assume* (8) *holds and the initial values of the differential-algebraic system of index $\nu + 1$ are consistent. Then if $\sum_{ij}^{s} b_i \omega_{ij} \tilde{c}_j = 1$, the global error of method* (17)–(19c) *satisfies, for $\nu = 1, 2$,*

$$y_n^\nu - y_\nu(t_n) = \mathcal{O}(h^{3-\nu}), \quad z_n^\nu - z_\nu(t_n) = \mathcal{O}(h^{2-\nu}); \tag{50}$$

otherwise

$$y_n^\nu - y_\nu(t_n) = \mathcal{O}(h^{2-\nu}), \quad z_n^\nu - z_\nu(t_n) = \mathcal{O}(h^{1-\nu}). \tag{51}$$

Proof. Here we emphasize some straightforward differences with respect to Theorem 3.4 in [13].

(a) We begin by denoting the differences to the exact solution values:

$$\begin{aligned} \Delta y_n^\nu &= y_n^\nu - y_\nu(t_n), & \Delta z_n^\nu &= z_n^\nu - z_\nu(t_n), \\ \Delta Y_{ni}^\nu &= Y_{ni}^\nu - y_\nu(t_n + \tilde{c}_i h), & \Delta Z_{ni}^\nu &= Z_{ni}^\nu - Z_\nu(t_n + c_i h), \\ \Delta k_{ni}^\nu &= k_{ni}^\nu - y_\nu'(t_n + \tilde{c}_i h), & \Delta \ell_{ni}^\nu &= \ell_{ni}^\nu - z_\nu'(t_n + c_i h). \end{aligned} \tag{52}$$

Furthermore we have for an IMEX R-K method

$$\begin{pmatrix} \Delta Y_{ni}^\nu \\ \Delta Z_{ni}^\nu \end{pmatrix} = \begin{pmatrix} \Delta y_n^\nu \\ \Delta z_n^\nu \end{pmatrix} + h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} \Delta k_{nj}^\nu \\ \sum_{j=1}^{i} a_{ij} \Delta \ell_{nj}^\nu \end{pmatrix} + \begin{pmatrix} \mathcal{O}(h^{\tilde{q}_i+1}) \\ \mathcal{O}(h^{q_i+1}) \end{pmatrix}. \tag{53}$$

From Theorem 5.1 it follows that

$$\begin{aligned} \Delta y_n^0 &= \mathcal{O}(h^p), & \Delta Y_{ni}^0 &= \mathcal{O}(h^{\tilde{q}_i+1}), \\ \Delta k_{ni}^0 &= \mathcal{O}(h^{\tilde{q}_i+1}), & \Delta Z_{ni}^0 &= \mathcal{O}(h^{\tilde{q}_i+1}), \end{aligned} \tag{54}$$

and

$$\Delta z_n^0 = \begin{cases} \mathcal{O}(h^2) & \text{if} \quad \sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1, \\ \mathcal{O}(h) & \text{otherwise.} \end{cases} \tag{55}$$

We also have

$$\Delta \ell_{ni}^0 = \begin{cases} \mathcal{O}(h) & \text{if} \quad \sum_{i,j=1}^{s} \omega_{ij} \tilde{c}_j = 1, \\ \mathcal{O}(1) & \text{otherwise.} \end{cases} \tag{56}$$

Here ω_{ij} are the elements of the inverse of matrix A.

(b) We first consider the case $\nu = 1$. In analogy to the proof of Theorem 3.4 in [13], using the estimates (54), we deduce the following expressions:

$$\begin{aligned}
\Delta k^1_{ni} &= f_y(t_n + \tilde{c}_i h)\Delta Y^1_{ni} + f_z(t_n + \tilde{c}_i h)\Delta Z^1_{ni} \\
&\qquad + \mathcal{O}(h^{\tilde{q}_i+1} + h^{\tilde{q}_i+1}\left\|\Delta Y^1_{ni}\right\| + h^{\tilde{q}_i+1}\left\|\Delta Z^1_{ni}\right\|), \\
\Delta \ell^0_{ni} &= g_y(t_n + \tilde{c}_i h)\Delta Y^1_{ni} + g_z(t_n + \tilde{c}_i h)\Delta Z^1_{ni} \\
&\qquad + \mathcal{O}(h^{\tilde{q}_i+1} + h^{\tilde{q}_i+1}\left\|\Delta Y^1_{ni}\right\| + h^{\tilde{q}_i+1}\left\|\Delta Z^1_{ni}\right\|).
\end{aligned} \tag{57}$$

Here we have used the abbreviations $f_y(t) = f_y(y_0(t), z_0(t))$, $g_y(t) = g_y(y_0(t), z_0(t))$. Now, we compute ΔZ^1_{ni} from the second relation in (57). Therefore, inserting it into the first one and using (53), we can eliminate ΔY^1_{ni} and obtain

$$\begin{aligned}
&\Delta k^1_{ni} - (f_z g_z^{-1})(t_n + \tilde{c}_i h)\Delta \ell^0_{ni} = \mathcal{O}(\left\|\Delta y^1_n\right\|) \\
&+ (f_y - f_z g_z^{-1} g_y)(t_n + \tilde{c}_i h) h \sum_{j=1}^{i-1} \left((f_z g_z^{-1})(t_n + \tilde{c}_j h)\tilde{a}_{ij}\Delta \ell^0_{nj} + \mathcal{O}(h^{\tilde{q}_j+1})\right) + \mathcal{O}(h^{\tilde{q}_i+1}).
\end{aligned}$$

By (56), it follows that $\Delta k_{ni} = \mathcal{O}(\left\|\Delta y^1_n\right\|) + \mathcal{O}(h)$ if $\sum_{i,j=1}^{i} b_i \omega_{ij} \tilde{c}_j = 1$; otherwise $\Delta k_{ni} = \mathcal{O}(\left\|\Delta y^1_n\right\|) + \mathcal{O}(1)$. A direct estimation of Δy^1_n proves that $\Delta y^1_n = \mathcal{O}(h)$ if $\sum_{i,j=1}^{s} b_i \omega_{ij} \tilde{c}_j = 1$; otherwise $\Delta y^1_n = \mathcal{O}(1)$. However, these estimations are not optimal.

Following the argument in Theorem 3.4 in [13], we now introduce the new variable

$$\Delta u^1_n = \Delta y^1_n - (f_z g_z^{-1})(t_n)\Delta z^0_n. \tag{58}$$

At this point the only difference is that we have to treat more carefully the quantity $\Delta k^1_{ni} - f_z g_z^{-1}(t_n)\Delta \ell^0_{ni}$ for all i. For details we refer to [4]. Using the hypothesis $\tilde{b}_i = b_i$ for $i = 1, \ldots, s$, we obtain

$$\begin{aligned}
\Delta u^1_{n+1} &= \Delta u^1_n + h \sum_{i=1}^{s} b_i \Big(\mathcal{O}(\left\|\Delta y^1_n\right\|) + \mathcal{O}(h\left\|\Delta \ell^0_{ni}\right\|) \\
&+ (f_y - f_z g_z^{-1} g_y)(t_n + \tilde{c}_i h) h \sum_{j=1}^{i-1} \left((f_y - f_z g_z^{-1} g_y)(t_n + \tilde{c}_j h)\tilde{a}_{ij}\Delta \ell^0_{nj} + \mathcal{O}(h^{\tilde{q}_j+1})\right) \\
&\qquad + \mathcal{O}(h^{\tilde{q}_i+1}) \Big) - ((f_z g_z^{-1})(t_n + h) - (f_z g_z^{-1})(t_n))\Delta z^0_{n+1} + \mathcal{O}(h^{p+1}),
\end{aligned}$$

where $\mathcal{O}(h\left\|\Delta \ell^0_{ni}\right\|) = ((f_z g_z^{-1})(t_n + \tilde{c}_i h) - (f_z g_z^{-1})(t_n))\Delta \ell^0_{ni}$. Consequently, the first relations in (56) and (55) and the fact that $((f_z g_z^{-1})(t_n + h) - (f_z g_z^{-1})(t_n)) = \mathcal{O}(h)$ imply that

$$\left\|\Delta u^1_{n+1}\right\| \le (1 + Ch)\left\|\Delta u^1_n\right\| + \mathcal{O}(h^3). \tag{59}$$

Then we have $\Delta u^1_n = \mathcal{O}(h^2)$ for $nh \le \text{Const}$ (observe that the initial values are assumed to be consistent, i.e., $\Delta u^1_0 = 0$), so that by (58) and (55) we also have $\Delta y^1_n = \mathcal{O}(h^2)$. This implies $\Delta k^1_{ni} = \mathcal{O}(h)$ and $\Delta Y^1_{ni} = \mathcal{O}(h^2)$. The second relation in (57) proves that $\Delta Z^1_{ni} = \mathcal{O}(h)$.

In order to estimate Δz_n^1 we proceed as in Theorem 3.4 in [13] and, because $|R(\infty)| < 1$, we thus obtain $\Delta z_n^1 = \mathcal{O}(h)$. In particular, we emphasize that if we consider the second relation in (56) and (55) in a similar way, we get $\Delta y_n^1 = \mathcal{O}(h)$ with $\Delta k_{ni}^1 = \mathcal{O}(1)$ and, in addition, it follows from $\Delta Z_{ni}^1 = \mathcal{O}(1)$ that $\Delta z_n^1 = \mathcal{O}(1)$.

(c) The proof for general ν is similar to that of Theorem 3.4 in [13]. It is worth commenting that the only difference arises in the quantity $\Delta \ell_{ni}^{\nu-1} = \mathcal{O}(h^{2-\nu})$ if $\sum_{ij}^{s} b_i \omega_{ij} \tilde{c}_j = 1$; otherwise $\Delta \ell_{ni}^{\nu-1} = \mathcal{O}(h^{1-\nu})$. Thus the statement follows with

$$\begin{aligned} &\text{if } \sum_{ij}^{s} b_i \omega_{ij} \tilde{c}_j = 1, \ \Delta Y_{ni}^{\nu} = \mathcal{O}(h^{3-\nu}), \quad \Delta Z_{ni}^{\nu} = \mathcal{O}(h^{2-\nu}); \\ &\text{otherwise} \qquad\qquad \Delta Y_{ni}^{\nu} = \mathcal{O}(h^{2-\nu}), \quad \Delta Z_{ni}^{\nu} = \mathcal{O}(h^{1-\nu}). \end{aligned} \tag{60}$$

∎

THEOREM 6.2 (type CK). *Consider an IMEX R-K method of type CK which is stiffly accurate and such that* $(\hat{a}_{ij})$ *is invertible. If* (8) *holds and if the initial values of the differential-algebraic system of index* $\nu + 1$ *are consistent, then the global error of method* (17)–(19c) *satisfies, for* $\nu = 1, 2$,

$$y_n^{\nu} - y_{\nu}(t_n) = \mathcal{O}(h^{3-\nu}), \qquad z_n^{\nu} - z_{\nu}(t_n) = \mathcal{O}(h^{2-\nu}). \tag{61}$$

Proof. From Theorem 5.2 it follows that

$$\begin{aligned} &\Delta y_n^0 = \mathcal{O}(h^{\tilde{q}+2} + h^p), \quad \Delta Y_{ni}^0 = \mathcal{O}(h^{\tilde{q}_i+1}), \quad \Delta k_{ni}^0 = \mathcal{O}(h^{\tilde{q}_i+1}), \\ &\Delta z_n^0 = \mathcal{O}(h^{\tilde{q}+1} + h^p), \quad \Delta Z_{ni}^0 = \mathcal{O}(h^{\tilde{q}_i+1}), \end{aligned} \tag{62}$$

with $\tilde{q} = \min\{\tilde{q}_s, \tilde{q}_i + 1, i = 2, \ldots, s-1\}$.

Again we consider the case $\nu = 1$. Here the study of convergence needs further investigation. We start by computing the difference $\Delta \ell_{n1}^0$. From (19b), we have $\ell_{n1}^0 = g_y(y_n^0, z_n^0) y_n^1 + g_z(y_n^0, z_n^0) z_n^1$, and this implies $\|\Delta \ell_{n1}^0\| \le C(\|\Delta y_n^0\| + \|\Delta z_n^0\| + \|\Delta y_n^1\| + \|\Delta z_n^1\|)$. Consequently, using (53), we have

$$\Delta \ell_{ni}^0 = \mathcal{O}(\|\Delta y_n^1\| + \|\Delta z_n^1\|) + h^{-1} \hat{\omega}_{i2} (\Delta Z_{n2}^0 - \Delta z_n^0) + \mathcal{O}(h^{\tilde{q}_i}) + \mathcal{O}(h^{q_i}), \tag{63}$$

where $\hat{\omega}_{ij}$ are the elements of the inverse matrix of $\hat{A}$. Therefore, inserting (63) into the quantity $\Delta k_{ni}^1 - (f_z g_z^{-1})(t_n + \tilde{c}_i h) \Delta \ell_{ni}^0$ computed in the previous theorem, we obtain

$$\begin{aligned} \Delta k_{ni}^1 = {} & h^{-1} \hat{\omega}_{i2} (f_z g_z^{-1})(t_n + \tilde{c}_i h)(\Delta Z_{n2}^0 - \Delta z_n^0) \\ & + \mathcal{O}(\|\Delta y_n^1\| + \|\Delta z_n^1\|) + \mathcal{O}(h^{\tilde{q}_i}) + \mathcal{O}(h^{q_i}). \end{aligned}$$

By (62) and $\tilde{q}_2 = 1$, we have $\Delta Y_{n2}^0 = \mathcal{O}(h^2)$ and $\Delta Z_{n2}^0 = \mathcal{O}(h^2)$. Hence, this implies $\Delta k_{ni}^1 = \mathcal{O}(\|\Delta y_n^1\| + \|\Delta z_n^1\|) + \mathcal{O}(h)$, and a direct estimation of Δy_n^1 leads to

$$\|\Delta y_n^1\| \le (1 + Ch) \|\Delta y_n^1\| + Ch \|\Delta z_n^1\| + \mathcal{O}(h^2). \tag{64}$$

Now, using (53), this gives $\Delta \ell_{ni}^1 = \alpha_i \Delta \ell_{n1}^1 + h^{-1} \sum_{j \ge 2} \hat{\omega}_{ij} (\Delta Z_{nj}^1 - \Delta z_n^1) + \mathcal{O}(h^{q_i})$ for $i = 2, \ldots, s$. Since the method is stiffly accurate and $\tilde{b}_i = b_i$ for $i = 1, \ldots, s$, the statement of Lemma 5.1 is satisfied, and from $\Delta z_{n+1}^1 = \Delta z_n^1 + h(b_1 + \sum_{i \ge 2} b_i \alpha_i) \Delta \ell_{n1}^1 + \sum_{i,j \ge 2} b_i \hat{\omega}_{ij} (\Delta Z_{nj}^1 - \Delta z_n^1) + \mathcal{O}(h^{q_i+1})$ we obtain

$$\|\Delta z_{n+1}^1\| \le |\rho| \, \|\Delta z_n^1\| + \sum_{i,j \ge 2} |b_i \hat{\omega}_{ij}| \, \|\Delta Z_{nj}^1\| + \mathcal{O}(h^{q_i+1}) \tag{65}$$

with $|\rho| = |R(\infty)| < 1$. By (63) and $\Delta Z_{ni}^0 = \mathcal{O}(h^2)$, it follows that $\Delta \ell_{ni}^0 = \mathcal{O}(\|\Delta y_n^1\| + \|\Delta z_n^1\|) + \mathcal{O}(h)$. Thus, the second relation of (57) proves that $\Delta Z_{ni}^1 = \mathcal{O}(\|\Delta y_n^1\| + \|\Delta z_n^1\|) + \mathcal{O}(h(\|\Delta y_n^1\| + \|\Delta z_n^1\|)) + \mathcal{O}(h)$. Inserting (65), we obtain

$$\left\|\Delta z_{n+1}^1\right\| \le \left\|\Delta y_n^1\right\| + (|\rho| + Ch)\left\|\Delta z_n^1\right\| + \mathcal{O}(h). \tag{66}$$

Now applying Lemma 5.2 to inequalities (64) and (66) gives $\Delta y_n^1 = \mathcal{O}(h)$, $\Delta z_n^1 = \mathcal{O}(h)$. Again, we can conclude that the estimate about Δy_n^1 is not optimal. Therefore, introducing the new variable (58), we obtain

$$\left\|\Delta u_{n+1}^1\right\| \le (1 + Ch)\left\|\Delta u_n^1\right\| + Ch^2\left\|\Delta z_n^1\right\| + \mathcal{O}(h^3). \tag{67}$$

We now apply Lemma 5.2 again, replacing the inequality (64) with (67). Then by (58) and (62) we have $\Delta y_n^1 = \mathcal{O}(h^2)$. Obviously, the proof for general ν is similar to the one presented in Theorem 6.1. This completes the proof of the theorem. ∎

Remark. Of course, concerning type ARS, under the same assumptions as Theorem 6.2 (with also $b_1 = 0$), we again deduce the estimates (61).

7. Estimates on the remainder. In order to estimate the remainder in the expansion (20), we require the same detailed analysis previously developed by Hairer, Lubich, and Roche in [12] (see also [13, sect. VI.3]). The main purpose in this section is to extend the same results presented in [13, sect. VI.3] to the different types of IMEX R-K methods.

Let us introduce existence and local uniqueness of the numerical solution of (4), (5). Next we shall discuss the influence of perturbations in (5) to the numerical solution.

We shall consider two steps in succession. First, we suppose that (y_n, z_n) are known, denoted by (η, ζ), and prove the existence and uniqueness of (y_{n+1}, z_{n+1}). We assume that $g(\eta, \zeta) = \mathcal{O}(h)$, $\mu(g_z(\eta, \zeta)) \le 1$ and that $a_{ii} > 0$ for all i. Thus we have the nonlinear system for the stage values

$$\begin{pmatrix} Y_i - \eta \\ \varepsilon\,(Z_i - \zeta) \end{pmatrix} = h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} f(Y_j, Z_j) \\ \sum_{j=1}^{i} a_{ij} g(Y_j, Z_j) \end{pmatrix}. \tag{68}$$

It is significant to note that if we restrict ourselves to the use of a particular type of IMEX R-K method, for instance, type A, where the matrix A is invertible, we immediately obtain the statement of Theorem 3.5 in [13]. Instead, for type CK, it is worth commenting that the second equation in (68) becomes

$$\frac{\varepsilon}{h}(Z_i - \zeta) - a_{i1} g(\eta, \zeta) - \sum_{j=2}^{i} \hat{a}_{ij} g(Y_j, Z_j) = 0,$$

whereas for type ARS we have $a_{i1} = 0$ for all i. Therefore, we easily find again the statement of Theorem 3.5 in [13].

We now study the influence of perturbations in (68) to the numerical solution. For the perturbed IMEX R-K method

$$\begin{pmatrix} \widehat{Y}_i - \widehat{\eta} \\ \varepsilon\left(\widehat{Z}_i - \widehat{\zeta}\right) \end{pmatrix} = h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} f(\widehat{Y}_j, \widehat{Z}_j) \\ \sum_{j=1}^{i} a_{ij} g(\widehat{Y}_j, \widehat{Z}_j) \end{pmatrix} + h \begin{pmatrix} \delta_i \\ \theta_i \end{pmatrix} \tag{69}$$

we allow the following remarks.

Remarks. For an IMEX R-K scheme of type A the statement and the proof is similar to that of Theorem 3.6 in [13]. Extra care must to be taken to properly handle type CK. First observe that in addition to the assumptions of Theorem 3.5 in [13] we suppose that $\widehat{\eta} - \eta = \mathcal{O}(h)$, $\widehat{\zeta} - \zeta = \mathcal{O}(h)$, $\delta_i = \mathcal{O}(1)$, and $\theta_i = \mathcal{O}(h)$ for $i = 2, \dots, s$ with $\delta_1 = 0$ and $\theta_1 = 0$. Then we have for $h \le h_0$ the following estimates:

$$\begin{aligned} &\|\widehat{Y}_i - Y_i\| \le C(\|\widehat{\eta} - \eta\| + h\|\widehat{\zeta} - \zeta\|) + hC(\|\delta\| + \|\theta\|), \\ &\|\widehat{Z}_i - Z_i\| \le C\left(\|\widehat{\eta} - \eta\| + \left(\frac{\varepsilon}{h} + h\right)\|\widehat{\zeta} - \zeta\|\right) + C(h\,\|\delta\| + \|\theta\|), \end{aligned} \tag{70}$$

where $\delta = (\delta_1, \dots, \delta_s)^T$ and $\theta = (\theta_1, \dots, \theta_s)^T$. Later, we note that we have to treat the following homotopy more carefully:

$$\begin{pmatrix} Y_i - \eta \\ \varepsilon\,(Z_i - \zeta) \end{pmatrix} - h \begin{pmatrix} \sum_{j=1}^{i-1} \tilde{a}_{ij} f(Y_j, Z_j) \\ \sum_{j=1}^{i} \hat{a}_{ij} g(Y_j, Z_j) \end{pmatrix} = \tau \begin{pmatrix} \widehat{\eta} - \eta + h\delta_i \\ \varepsilon(\widehat{\zeta} - \zeta) + h a_{i1}(g(\widehat{\eta}, \widehat{\zeta}) - g(\eta, \zeta)) + h\theta_i \end{pmatrix},$$

which relates system (68) for $\tau = 0$ to the perturbed system (71) for $\tau = 1$. Furthermore, we denote by $\hat{a}_{ij}$ the elements of the submatrix $\hat{A}$, and, by the Lipschitz condition for g, we have the inequality

$$\|(g(\widehat{\eta}, \widehat{\zeta}) - g(\eta, \zeta))\| \le L\|\widehat{\eta} - \eta\| + L\|\widehat{\zeta} - \zeta\|.$$

Then, in this situation, the same conclusions of Theorem 3.6 in [13] hold. In particular, if $a_{i1} = 0$ for all i, the same also follows for type ARS.

Following [13], we finally estimate the remainder of the expansion (20).

THEOREM 7.1 (type A). *Under the same hypotheses as those of Theorem* 3.1*, for any fixed constant $c > 0$ and $\varepsilon \le ch$, the global error satisfies*

$$\begin{aligned} &y_n - y(t_n) = \Delta y_n^0 + \varepsilon \Delta y_n^1 + \varepsilon^2 \Delta y_n^2 + \mathcal{O}(\varepsilon^3), \\ &z_n - z(t_n) = \Delta z_n^0 + \varepsilon \Delta z_n^1 + \varepsilon^2 \Delta z_n^2 + \mathcal{O}(\varepsilon^3/h), \end{aligned} \tag{71}$$

where $\Delta y_n^0 = y_n^0 - y_0(t_n)$, $\Delta z_n^0 = z_n^0 - z_0(t_n), \dots$ are the global errors of the method applied to differential-algebraic system. The estimates (71) *hold uniformly for $h \le h_0$ and $nh \le$ Const.*

Remark. In order to enable a direct comparison with Theorem 3.8 in [13] (see also [12]), by Theorem 6.1, and by (50) and (60), if $\sum_{ij}^{s} b_i \omega_{ij} \tilde{c}_j = 1$, it suffices to prove the result for $\nu = 2$; otherwise it must be proven for $\nu = 1$. Therefore, the result follows directly by applying Theorem 3.8 in [13].

THEOREM 7.2 (type CK). *Under the same hypotheses as those of Theorem* 3.2*, then, for any fixed constant $c > 0$ and $\varepsilon \le ch$, the global error satisfies the estimates* (71) *uniformly for $h \le h_0$ and $nh \le$ Const.*

Remark. It is interesting, of course, to know how in the proof of Theorem 7.2 several formulas are related to those of Theorem 3.8 in [13]. For instance, by (19a)–(19c) it follows from (60) and $\nu = 2$ that

$$\begin{aligned} &\widehat{k}_{ni} = f(\widehat{Y}_{ni}, \widehat{Z}_{ni}) + \mathcal{O}(\varepsilon^3), \\ &\varepsilon\widehat{\ell}_{ni} = g(\widehat{Y}_{ni}, \widehat{Z}_{ni}) + \varepsilon^3 \ell_{ni}^2 + \mathcal{O}(\varepsilon^3). \end{aligned} \tag{72}$$

Using $Z_{ni}^{\nu} = z_n^{\nu} + ha_{i1}\ell_{n1}^{\nu} + h\sum_{j=2}^{i}\ell_{nj}^{\nu}$, from (61) and

$$\ell_{n1}^{\nu} = g_y(y_n^0, z_n^0)y_n^{\nu+1} + g_z(y_n^0, z_n^0)z_n^{\nu+1} + \psi_{\nu+1}(y_n^0, z_n^0, \dots, y_n^{\nu}, z_n^{\nu}),$$

we get $\ell_{ni}^2 = \mathcal{O}(h^{-1})$. Together with (18), and by (72), it follows that we obtain a perturbed IMEX R-K method which is of the form (69). Therefore, in the case of Theorem 3.8 in [13], this yields

$$\begin{aligned} &\|\Delta Y_{ni}\| \le C(\|\Delta y_n\| + h\|\Delta z_n\|) + \mathcal{O}(\varepsilon^3), \\ &\|\Delta Z_{ni}\| \le C\left(\|\Delta y_n\| + \left(\frac{\varepsilon}{h} + h\right)\|\Delta z_n\|\right) + \mathcal{O}(\varepsilon^3/h), \end{aligned} \tag{73}$$

provided that Δy_n and Δz_n are of size $\mathcal{O}(h)$. The justification of these assumptions follows by induction on n where $\Delta y_0 = \mathcal{O}(\varepsilon^3)$ and $\Delta z_0 = \mathcal{O}(\varepsilon^3)$ and from $\Delta y_n = \mathcal{O}(\varepsilon^3/h)$, $\Delta z_n = \mathcal{O}(\varepsilon^3/h)$, because $\nu = 2$.

Moreover, we prove the recursion

$$\begin{pmatrix} \|\Delta y_{n+1}\| \\ \|\Delta z_{n+1}\| \end{pmatrix} \le \begin{pmatrix} 1 + \mathcal{O}(h) & \mathcal{O}(\varepsilon + h^2) \\ \mathcal{O}(1) & \alpha + \mathcal{O}(h) \end{pmatrix} \begin{pmatrix} \|\Delta y_n\| \\ \|\Delta z_n\| \end{pmatrix} + \begin{pmatrix} \mathcal{O}(\varepsilon^3) \\ \mathcal{O}(\varepsilon^3/h) \end{pmatrix}. \tag{74}$$

The value $\alpha < 1$ is justified in [4] (see also [13]).

Second, in solving the second relation in (74) we use the result of Lemma 5.1 where we emphasize that the method is stiffly accurate and $\tilde{b}_i = b_i$ for all i. Of course, for type ARS, we have again the estimates (71).

Now by combining Theorems 5.1, 6.1, and 7.1, Theorem 3.1 follows. Theorem 3.2 follows from Theorems 5.2, 6.2, and 7.2. Finally, Corollary 3.1 follows from Corollary 5.1 and from the remarks of Theorems 6.2 and 7.2.

8. Conclusions. A study of the global error for different types of IMEX R-K methods has been investigated for a class of singular perturbation problems (SPPs). This asymptotic analysis enables us to obtain convergence results, based on the smoothness of the solution, giving error bounds for several classes of IMEX R-K methods. In particular, the use of DAE techniques, when applied to the stiff case $\Delta t \gg \varepsilon$, was found to give optimal estimates describing the structure of the solutions of SPPs. Concerning the van der Pol equation, numerical results reveal order reduction for all methods in the second (algebraic) component of the solution for small values of the stiffness parameter ε and likewise an order reduction in the first (differential) component when $\tilde{b}_i$ is not equal to b_i for all i. In fact, the hypothesis $\tilde{b}_i = b_i$ represents the only remedy for preserving the classical order for the differential component of the solution. Also, when ε is sufficiently small, and for a given set of suitable assumptions, we obtain numerical results which display improved error estimates in the algebraic component for some IMEX R-K methods appearing in the literature. These results lead us to develop new IMEX R-K methods that work uniformly for a wide range of values of the stiffness parameter ε. In future work we shall introduce new order conditions for the construction of these IMEX R-K methods (see [5]) and study their stability properties.

Acknowledgments. The author wishes to express his gratitude and appreciation to Prof. Ernst Hairer, who generously spent his time to guide him in this work through numerous suggestions and enlightening discussions, during the author's stay at the mathematics department of the University of Geneva. He also thanks the two unknown referees for their critical remarks on the first draft of this paper.

AN ENERGY- AND HELICITY-CONSERVING FINITE ELEMENT SCHEME FOR THE NAVIER–STOKES EQUATIONS*

LEO G. REBHOLZ†

Abstract. We present a new finite element scheme for solving the Navier–Stokes equations that exactly conserves both energy ($\int_\Omega u^2$) and helicity ($\int_\Omega u \cdot (\nabla \times u)$) in the absence of viscosity and external force. We prove stability, exact conservation, and convergence for the scheme. Energy and helicity are exactly conserved by using a combination of the usual (convective) form with the rotational form of the nonlinearity and solving for both velocity and a projected vorticity in a trapezoidal time discretization. Numerical results are presented that compare the scheme to the usual trapezoidal schemes.

Key words. Navier–Stokes, conservation, helicity, energy, rotational form, fully discrete

1. Introduction.

It is well known that the Navier–Stokes equations (NSE) conserve energy ($E = \frac{1}{2}\int_\Omega |u|^2$) in the absence of viscosity and external force. Conserving energy in numerical schemes for the NSE not only leads to stability for the scheme, but also is necessary for physical relevance of solutions. In rotational flows, however, other integral invariants are also important. In two dimensions enstrophy ($Ens = \frac{1}{2}\int_\Omega |\nabla \times u|^2$) and in three dimensions helicity ($H = \int_\Omega u \cdot (\nabla \times u)$) are also conserved quantities of the NSE when viscosity and external force are not present [4], [6].

Although the importance of enstrophy in two-dimensional flow has been known for many years, the importance of helicity in understanding three-dimensional turbulent phenomena has only recently been recognized. The inviscid invariance of helicity was discovered by Moreau in 1961 [15], and a famous 1992 review paper [14] of Moffatt and Tsoniber finds helicity to have a status of importance comparable to energy for three-dimensional flows. Hence, accurate helicity treatment, in addition to accurate energy treatment, should be a goal for numerical schemes for three-dimensional rotational flows.

Helicity in true fluid flow is created and dissipated only by viscous and body forces, and thus for a numerical scheme for the NSE to have physical relevance, the nonlinearity in the scheme should not create or dissipate helicity. If a scheme conserves helicity in the inviscid case (even though an NSE scheme is typically designed for viscous flows only), then under viscous conditions the scheme's nonlinearity will not nonphysically create or dissipate helicity.

For two-dimensional flows, schemes such as the classical Arakawa scheme [1] have existed for over forty years which conserve both energy and enstrophy (this and all future references to E/H/Ens conservation implicitly refer to the case of no viscosity or external force). By conserving energy and enstrophy for inviscid flows, the Arakawa

scheme is accurate over longer time intervals because it ensures only viscosity and external force (and not the nonlinearity) create and dissipate energy and enstrophy. For three-dimensional flows, however, it was not until 2004 that Liu and Wang developed the first scheme that conserves both energy and helicity. In [13], they present an energy- and helicity-preserving scheme for axisymmetric flows and show that this dual conservation eliminates the need for excessive numerical viscosity. It is their work which motivated this article.

In this report, we present a new finite element scheme that conserves both energy and helicity for general, viscous flows. Our development of the scheme herein is for periodic boundaries (and hence we use a box for the domain Ω). The key features that allow the scheme to conserve both energy and helicity are the use of the projection of the vorticity in the scheme and a new variational formulation of the nonlinearity that vanishes when tested against either the velocity or projected vorticity. For nonperiodic boundary conditions, helicity is not necessarily globally conserved. On the other hand, helicity generation and helicity flux are equally important for nonperiodic problems, and a numerical method should not generate spurious helicity through its discretization of the nonlinear term.

Remark 1.1. Helicity is not necessarily globally conserved for more general boundary conditions. Consider the Euler equations on $\Omega = (0, L)^3$. Multiply by the vorticity $w := (\nabla \times u)$ and integrate over the domain:

$$\int_\Omega u_t \cdot w + \int_\Omega \left(\frac{1}{2}\nabla u^2 - u \times w\right) \cdot w + \int_\Omega \nabla p \cdot w = 0. \tag{1}$$

This reduces via integration by parts and vector identities to

$$\int_\Omega u_t \cdot w + \int_{\partial\Omega} \left(p + \frac{1}{2}u^2\right)(w \cdot n) = 0. \tag{2}$$

The boundary integral in (2) can vanish without periodicity (e.g., if $w \cdot n = 0$ is imposed), but the resulting equation, $\int_\Omega u_t \cdot w = 0$, still does not imply the conservation of helicity since integrating by parts with u decomposed as $u := \langle u_1, u_2, u_3\rangle$ shows

$$\begin{aligned} H(T) - H(0) &= \int_0^T \frac{d}{dt}H(t) = \int_0^T \frac{d}{dt}\int_\Omega u \cdot w = \int_0^T \int_\Omega (u_t \cdot w + u \cdot w_t) \\ &= \left(\int_0^L \int_0^L \left(\left(u_1 u_3|_{y=0}^{y=L}\, dz\, dx\right) + \left(u_1 u_2|_{z=0}^{z=L}\, dy\, dx\right) + \left(u_2 u_3|_{x=0}^{x=L}\, dz\, dy\right)\right)\right)|_{t=0}^{t=T}. \end{aligned} \tag{3}$$

Thus we see that helicity is conserved for periodic boundary conditions or for zero (Dirichlet) boundary conditions (with $w \cdot n = 0$ imposed on the boundary), but not necessarily conserved in general.

This article is arranged as follows: We present the energy- and helicity-conserving scheme in section 3, after providing the necessary notation in section 2. Section 4 gives a rigorous numerical analysis for the scheme, section 5 presents numerical results, and section 6 presents conclusions.

2. Notation and preliminaries. $(\cdot, \cdot)$ and $\|\cdot\|$ denote the usual L^2 inner product and norm, respectively, and $\|\cdot\|_k$ the $H^k(\Omega)$ norm. $\|\cdot\|_\infty$ will denote the usual $L^\infty(\Omega)$ norm, and all other norms that appear in this article will be clearly labeled with subscripts. The domain Ω we use is the box $(0, L)^3$.

DEFINITION 2.1. *The Hilbert space $H^1_\#(\Omega)$ will be defined as*

$$H^1_\# := \left(v \in H^1 \ : \ v \text{ periodic on } \Omega, \ \int_\Omega v \ dx = 0 \right).$$

This is the natural velocity space for the NSE with periodic boundary conditions, as discussed in [11] and [12]. Note that velocities in this space automatically conserve momentum ($\int_\Omega u$), i.e., if $u \in H^1_\#$, then $\frac{d}{dt}\int_\Omega u = 0$. This is physically important because the NSE (with periodic boundary conditions) also conserve momentum [6].

Let $T^h = T^h(\Omega)$ be a conforming finite element mesh on Ω. Define the spaces $(X^h, Q^h) \subset (H^1_\#, L^2_0)$ to be conforming velocity, pressure finite element spaces (see, e.g., [3], [5], or [7] for examples) that satisfy the discrete inf-sup condition (also known as the LBB condition)

$$0 < \beta \leq \inf_{q \in Q^h} \sup_{v \in X^h} \frac{(q, \nabla \cdot v)}{\|v\|_1 \|q\|}. \tag{4}$$

Define V^h to be the space of discretely divergence-free, zero-mean, periodic functions.

$$V^h = \{ v \in X^h \ : \ (\nabla \cdot v, q) = 0 \ \forall q \in Q^h \}.$$

Since V^h is a closed subspace of $H^1_\#(\Omega)$, we have also that V^h is a Hilbert space, hence the following result.

LEMMA 2.2. *Let $u^h \in V^h$. Then there exists a unique $w^h \in V^h$ satisfying*

$$(w^h, v) = (\nabla \times u^h, v) \ \forall v \in V^h. \tag{5}$$

Proof. Since $u^h \in V^h \subset H^1(\Omega)$, it follows that $\nabla \times u^h \in L^2(\Omega)$. Since V^h is a closed subset of the Hilbert space $L^2(\Omega)$, the Riesz representation theorem implies the existence and uniqueness of a solution w^h to (5). ∎

The next lemma shows how an elementary property of the cross product can be used for double skew-symmetry of a trilinear term.

LEMMA 2.3. *Let $u^h, w^h \in X^h$. Then*

$$(u^h \times w^h, u^h) = (u^h \times w^h, w^h) = 0.$$

Proof. This follows from an elementary property of the cross product; the cross product of two vectors is perpendicular to each of them. ∎

The significance of this lemma is that in a finite element scheme, the trilinear form $(u^h \times w^h, v^h)$ will vanish when $v^h = u^h$ or w^h. Such a trilinear form has significance in the NSE if the rotational form of the nonlinearity is used (see, e.g., [6, p. 461] or [17]). Our scheme uses this form and exploits the double skew-symmetry to show the scheme conserves both energy and helicity.

The discrete Gronwall lemma will also be an essential tool in the error analysis; we present it now.

LEMMA 2.4 (discrete Gronwall). *Let Δt, H, and a_n, b_n, c_n, d_n (for integers $n \geq 0$) be nonnegative numbers such that*

$$a_l + \Delta t \sum_{n=0}^{l} b_n \leq \Delta t \sum_{n=0}^{l} d_n a_n + \Delta t \sum_{n=0}^{l} c_n + H \text{ for } l \geq 0. \tag{6}$$

Suppose that $\Delta t d_n < 1\ \forall n$. *Then*

$$a_l + \Delta t \sum_{n=0}^{l} b_n \le exp\left(\Delta t \sum_{n=0}^{l} \frac{d_n}{1-\Delta t d_n}\right)\left(\Delta t \sum_{n=0}^{l} c_n + H\right) \text{ for } l \ge 0. \tag{7}$$

Proof. See [9], for example, for the proof of this well-known lemma. □

We end this section with definitions for discrete energy and helicity.

DEFINITION 2.5. *We define the discrete energy* E *and helicity* H *to be, at time* t^k,

$$E_h(t^k) = \frac{1}{2}\|u_h^k\|^2,$$
$$H_h(t^k) = (u_h^k, \nabla \times u_h^k).$$

We are now ready to present the scheme.

3. An energy- and helicity-preserving scheme for periodic flows. The energy- and helicity-preserving finite element scheme we study is composed of a trapezoidal time discretization with a nonlinearity that is doubly skew-symmetric. Let Δt denote the timestep, $t^k = k\Delta t$, $t^{k+1/2} = (k+\frac{1}{2})\Delta t$, and u_h^k the approximation to $u(x,t^k)$. $u_h^{k+1/2}$ will denote

$$u_h^{k+1/2} := \frac{1}{2}(u_h^{k+1} + u_h^k),$$

and $f^{n+1/2}(x) := f(t^{n+1/2},x) \in V^{h,*}$. $T = Nk$ denotes the final time. Given $u_h^0 \in V^h$, define w_h^0 to be the (unique in V^h by Lemma 2.2) solution of $(w_h^0, v) = (\nabla \times u_h^0, v)\ \forall v \in V^h$, and find $(u_h^k; w_h^k; p_h^k) \in X_h \times V_h \times Q_h$ for $k = 1, \ldots, N$, satisfying

$$\frac{1}{\Delta t}(u_h^{n+1}, v) + (u_h^{n+1/2} \times w_h^{n+1/2}, v) - (p_h^{n+1/2}, \nabla \cdot v) + \frac{\nu}{2}(\nabla u_h^{n+1/2}, \nabla v) + \frac{\nu}{2}(w_h^{n+1/2}, \nabla \times v) = (f^{n+1/2}, v) + \frac{1}{\Delta t}(u_h^n, v)\ \forall v \in X^h, \tag{8}$$

$$(\nabla \cdot u_h^{n+1}, q) = 0\ \forall q \in Q^h, \tag{9}$$

$$(w_h^{n+1} - \nabla \times u_h^{n+1}, \chi) = 0\ \forall \chi \in V^h. \tag{10}$$

We now prove the conservation properties of the scheme: energy and helicity are exactly conserved in the absence of viscosity and external force.

LEMMA 3.1. *The scheme* (8)–(10) *conserves energy and helicity in the absence of viscosity and body force, that is,* $E_h(t^n) = E_h(t^0)$ *and* $H_h(t^n) = H_h(t^0)\ \forall n \le N$, *provided* $\nu = f = 0$.

Proof. For the conservation of energy, set $v = u_h^{n+1/2}$ and $\nu = f = 0$ in (8). This gives

$$(u_h^{n+1}, u_h^{n+1/2}) = (u_h^n, u_h^{n+1/2}). \tag{11}$$

By expanding the $u_h^{n+1/2}$ terms in (11), we have

$$\frac{1}{2}\|u_h^{n+1}\|^2 + \frac{1}{2}(u_h^{n+1}, u_h^n) = \frac{1}{2}\|u_h^n\|^2 + \frac{1}{2}(u_h^n, u_h^{n+1}), \tag{12}$$

$$E_h(t^{n+1}) = E_h(t^n), \tag{13}$$

which implies that $E_h(t^n) = E_h(t^0)$.

For helicity conservation, set $v = w_h^{n+1/2}$ in (8). The pressure term vanishes since $w_h^n, w_h^{n+1} \in V^h$, and so after setting $\nu = f = 0$, we are left with

$$\frac{1}{2}(u_h^{n+1}, w_h^{n+1}) + \frac{1}{2}(u_h^{n+1}, w_h^n) = \frac{1}{2}(u_h^n, w_h^n) + \frac{1}{2}(u_h^n, w_h^{n+1}). \tag{14}$$

Using (10) and integrating by parts, we have the following identities for the terms in (14):

$$(u_h^{n+1}, w_h^{n+1}) = (u_h^{n+1}, \nabla \times u_h^{n+1}) = H_h(t^{n+1}), \tag{15}$$

$$(u_h^n, w_h^n) = (u_h^n, \nabla \times u_h^n) = H_h(t^n), \tag{16}$$

$$(u_h^{n+1}, w_h^n) = (u_h^n, w_h^{n+1}). \tag{17}$$

Thus (14) can be rewritten as

$$H_h(t^{n+1}) = H_h(t^n), \tag{18}$$

which implies that $H_h(t^n) = H_h(t^0)$. ∎

Lemma 3.1 shows that only viscous and external forces create and dissipate energy and helicity in the scheme when $\nu > 0$ and nonzero f. This is qualitatively important for the physical relevance of the scheme's solution because this is also true for helicity in the NSE (true fluid flow):

$$H(T) = H(0) + \int_0^T ((f(t), \nabla \times u(t)) + \nu(\nabla u(t), \nabla(\nabla \times u(t)))) \, dt. \tag{19}$$

In the energy- and helicity-conserving scheme, we have that

$$H_h^N = H_h^0 + \sum_{n=0}^{N-1} (f(t^{n+1/2}), w_h^{n+1/2}) + \frac{\nu}{2}(\nabla u_h^{n+1/2}, \nabla w_h^{n+1/2}) + \frac{\nu}{2}(w_h^{n+1/2}, \nabla \times w_h^{n+1/2}). \tag{20}$$

However, schemes that do not conserve helicity will not necessarily share this physical property. For example, in a trapezoidal scheme for the NSE that does not conserve helicity (e.g., usual Crank–Nicholson in rotational form (67)), the nonlinear term will not vanish when the test function is chosen to be the projection of the curl. In this scheme,

$$\begin{aligned} H_h^N = H_h^0 &+ \sum_{n=0}^{N-1} (f(t^{n+1/2}), w_h^{n+1/2}) + \nu(\nabla u_h^{n+1/2}, \nabla w_h^{n+1/2}) \\ &+ (u_h^{n+1/2} \times ((\nabla \times u_h^{n+1/2}) - w_h^{n+1/2}), w_h^{n+1/2}). \end{aligned} \tag{21}$$

It is the last term in (21) that is nonphysical and thus can cause numerical errors and a loss of physical fidelity over long time intervals in the usual trapezoidal scheme.

The following lemma shows that the energy- and helicity-conserving scheme is also bounded by its data.

LEMMA 3.2. *Solutions to the discrete scheme* (8)–(10) *satisfy*

$$\|u_h^N\|^2 + \Delta t \sum_{n=0}^{N-1} \left(\frac{\nu}{2} \|\nabla u_h^{n+1/2}\|^2 + \nu \|w_h^{n+1/2}\|^2 \right) \leq \|u_h^0\|^2 + \frac{2\Delta t}{\nu} \sum_{n=0}^{N-1} \|f^{n+1/2}\|_*^2. \tag{22}$$

Proof. Set $v = u_h^{n+1/2}$ in (8), $q = p_h^{n+1/2}$ in (9), and add the equations. This gives

$$\frac{1}{2\Delta t}\|u_h^{n+1}\|^2 + \frac{1}{2\Delta t}(u_h^{n+1}, u_h^n) + \frac{\nu}{2}\|\nabla u_h^{n+1/2}\|^2 + \frac{\nu}{2}(w_h^{n+1/2}, \nabla \times u^{n+1/2}) = (f^{n+1/2}, u_h^{n+1/2}) + \frac{1}{2\Delta t}\|u_h^n\|^2 + \frac{1}{2\Delta t}(u_h^n, u_h^{n+1}). \tag{23}$$

Note that $(w_h^{n+1/2}, \nabla \times u_h^{n+1/2}) = \|w_h^{n+1/2}\|^2$ since (10) must hold for $(n+1)$ replaced by (n), and thus also for $(n+1)$ replaced by $(n+1/2)$. By making this substitution, (23) reduces to

$$\frac{1}{2\Delta t}\|u_h^{n+1}\|^2 + \frac{\nu}{2}\|\nabla u_h^{n+1/2}\|^2 + \frac{\nu}{2}\|w_h^{n+1/2}\|^2 = (f^{n+1/2}, u_h^{n+1/2}) + \frac{1}{2\Delta t}\|u_h^n\|^2. \tag{24}$$

Next we use the bound $(f^{n+1/2}, u_h^{n+1/2}) \le \frac{\nu}{4}\|\nabla u_h^{n+1/2}\|^2 + \frac{1}{\nu}\|f^{n+1/2}\|_*^2$, and sum from $n = 0, \ldots, (N-1)$, yielding

$$\frac{1}{2\Delta t}\|u_h^N\|^2 + \sum_{n=0}^{N-1}\left(\frac{\nu}{2}\|\nabla u_h^{n+1/2}\|^2 + \nu\|w_h^{n+1/2}\|^2\right) \le \frac{1}{2\Delta t}\|u_h^0\|^2 + \frac{1}{\nu}\sum_{n=0}^{N-1}\|f^{n+1/2}\|_*^2. \tag{25}$$

Now multiplying both sides by $(2\Delta t)$ proves the lemma. ∎

3.1. Existence of solutions for the scheme. Given $u_h^n, w_h^n \in V^h$, a nonlinear system must be solved for the approximations at time level $n+1$. The question arises, Does that system have a solution? In other words, does imposing two integral invariants overdetermine the system for u_h^{n+1}, w_h^{n+1}? The answer is that solutions to (8)–(10) do exist, as we will show in this section.

For clarity, we show existence for the equivalent nonlinear problem: Given $\nu, \Delta t > 0$, $f^{n+1/2} \in V^{h,*}$, and $u_h^n \in V^h$, find $(u_h; w_h) \in V^h \times V^h$ satisfying

$$\frac{2}{\Delta t}(u_h, v) + (u_h \times w_h, v) + \frac{\nu}{2}(\nabla u_h, \nabla v) + \frac{\nu}{2}(w_h, \nabla \times v) = (f^{n+1/2}, v) + \frac{2}{\Delta t}(u_h^n, v)\ \forall v \in V^h, \tag{26}$$

$$(w_h - \nabla \times u_h, \chi) = 0\ \forall \chi \in V^h. \tag{27}$$

This form of the scheme is derived from (8)–(10) by defining $u_h := u_h^{n+1/2}$, $w_h := w_h^{n+1/2}$ and restricting the test functions to V^h. Equations (26)–(27) are equivalent to (8)–(10). To show solutions exist, we formulate (26)–(27) as a fixed point problem, $y = F(y)$, and use the Leray–Schauder fixed point theorem. We will first prove several preliminary lemmas, followed by a theorem which proves that a solution to (26)–(27) exists.

LEMMA 3.3. *For $\nu, \Delta t > 0$, there exists a unique solution (u_h, w_h) to the following: Given $g \in V^{h,*}$, find $(u_h; w_h) \in V^h \times V^h$ satisfying*

$$\frac{2}{\Delta t}(u_h, v) + \frac{\nu}{2}(\nabla u_h, \nabla v) + \frac{\nu}{2}(w_h, \nabla \times v) = (g, v)\ \forall v \in V^h, \tag{28}$$

$$(w_h - \nabla \times u_h, \chi) = 0\ \forall \chi \in V^h. \tag{29}$$

Proof. We will prove uniqueness of solutions to (28)–(29) by showing only that the trivial solution solves the homogeneous problem, which will also imply the existence of solutions to the finite-dimensional problem. Since the space V^h includes only zero-mean functions, functions and operators are uniquely solvable, and thus we need not consider the adjoint problem. Choose $v = u_h$ in (28), $\chi = w_h$ in (29), and substitute (29) into (28). This gives

$$\frac{2}{\Delta t}\|u_h\|^2 + \frac{\nu}{2}\|\nabla u_h\|^2 + \frac{\nu}{2}\|w_h\|^2 = 0, \tag{30}$$

which implies $u_h = w_h = 0$, i.e., uniqueness. ∎

This lemma allows us to define a solution operator to (28)–(29).

DEFINITION 3.4. *We define the solution operator $T : V^{h,*} \to (V^h \times V^h)$ to be the solution operator of* (28)–(29)*: if $g \in V^{h,*}$, then $T(g) = (u_h; w_h)$ solves* (28)–(29).

We have that T is well defined by the previous lemma, and we now prove it is also bounded and linear.

LEMMA 3.5. *The solution operator T is linear, bounded, and continuous.*

Proof. The linearity of T follows from the fact that T is a solution operator to a linear problem. To see that T is bounded (and thus continuous since it is linear), we let $v = u_h,\ \chi = w_h$ in (28)–(29), multiply (29) by $\frac{\nu}{2}$, and add the equations. This gives

$$\frac{2\|u_h\|^2}{\Delta t} + \frac{\nu}{4}\|\nabla u_h\|^2 + \frac{\nu}{2}\|w_h\|^2 \le \frac{1}{\nu}\|g\|_*^2.$$

Then since u_h, w_h are finite-dimensional, $\|u_h, w_h\|_{V^h \times V^h} \le C\|g\|_*$. Hence,

$$\|T\| = \sup_{g \in V_*^h} \frac{\|T(g)\|}{\|g\|_*} = \sup_{g \in V_*^h} \frac{\|u_h, w_h\|_{V^h \times V^h}}{\|g\|_*} \le C. \qquad ∎$$

We next define the operator N. The function F that will be used in the formulation of the fixed point problem will be a composition of T and N.

DEFINITION 3.6. *We define the operator N on $(V^h \times V^h)$ by*

$$N(u_h; w_h) := f^{n+1/2} + \frac{2}{\Delta t}u_h^n + u_h \times w_h.$$

We now prove properties for N necessary for use in Leray–Schauder.

LEMMA 3.7. *For the nonlinear operator N, we have that $N : V^h \times V^h \to V^{h,*}$, N is bounded, and N is continuous.*

Proof. To show N maps as stated, we let $(u_h, w_h) \in V^h \times V^h$ and write

$$\|N(u_h; w_h)\|_* = \sup_{v \in V^h} \frac{(N(u_h; w_h), v)}{\|v\|_1}.$$

From the definition of N, we have that $\frac{(f^{n+1/2}, v) + (2(\Delta t)^{-1}u_h^n, v)}{\|v\|_1} \le \|f\|_* + C_1\|u_h^n\| \le C_2$, and that

$$\frac{(u_h \times w_h, v)}{\|v\|_1} \le \|u_h\|_\infty \|w_h\| \le C_3$$

since u_h and w^h are given to be in V^h, and all norms are equivalent in finite dimension. Hence $\|N(u_h, w_h)\|_* < C$, and so N maps as stated. Note we have also proven that N is bounded.

The equivalence of norms in finite dimension is also key in showing that N is continuous, as

$$\|N(u;w) - N(u_k;w_k)\|_* \le \|u \times (w - w_k)\|_* + \|(u - u_k) \times w_k\|_* \tag{31}$$

$$\le \|u\|_\infty \|w - w_k\| + \|w_k\|_\infty \|u - u_k\|, \tag{32}$$

and thus $\to 0$ as $\|(u;w) - (u_k;w_k)\| \to 0$. ∎

We are now ready to define the operator F, which will formulate (26)–(27) as a fixed point problem.

DEFINITION 3.8. *Define the operator $F : (V^h \times V^h) \to (V^h \times V^h)$ to be the composition of T and N: $F(y) = T(N(Y))$.*

LEMMA 3.9. *F is well defined and compact, and a solution to $y = F(y)$ solves* (26)–(27).

Proof. F is well defined because N and T are. The fact that F is compact follows from the fact that both N and T are continuous and bounded. It can easily be seen that a fixed point of F solves (26)–(27) by expanding F. ∎

We are now ready to prove existence to (26)–(27).

THEOREM 3.10. *Let $y_\lambda = (u_\lambda; w_\lambda) \in V^h \times V^h$ and consider the family of fixed point problems $y_\lambda = \lambda F(y_\lambda)$, $0 \le \lambda \le 1$. A solution y_λ to any of these fixed point problems satisfies $\|y_\lambda\| < K$, independent of λ. Since F is compact, and fixed points of F solve* (26)–(27)*, by the Leray–Schauder theorem there exist solutions to* (26)–(27).

Proof. All we have to show to prove this theorem is that solutions to $y_\lambda = \lambda F(y_\lambda)$ are bounded independent of λ. Using the definition of F and the linearity of T we have that

$$y_\lambda = \lambda F(y_\lambda) = \lambda T(N(y_\lambda)) = T\left(\lambda N\left(y_\lambda\right)\right) = T\left(\lambda\left(f^{n+1/2} + \frac{2}{\Delta t}u_h^n + u_\lambda \times w_\lambda\right)\right),$$

which implies that

$$\frac{2}{\Delta t}(u_\lambda, v) - \lambda(u_\lambda \times w_\lambda, v) + \frac{\nu}{2}(\nabla u_\lambda, \nabla v) + \frac{\nu}{2}(w_\lambda, \nabla \times v) = (\lambda f^{n+1/2}, v) + \frac{2\lambda}{\Delta t}(u_h^n, v)\ \forall v \in V^h, \tag{33}$$

$$(w_\lambda - \nabla \times u_\lambda, \chi) = 0\ \forall \chi \in V^h. \tag{34}$$

Multiply (34) by $\frac{\nu}{2}$, let $\chi = w_\lambda$ in (34), $v = u_\lambda$ in (33), and add the equations. Similarly to the stability estimate, this gives

$$\frac{1}{\Delta t}\|u_\lambda\|^2 + \frac{\nu}{4}\|\nabla u_\lambda\|^2 + \frac{\nu}{2}\|w_\lambda\|^2 \le \lambda^2\left(\frac{1}{\nu}\|f^{n+1/2}\|^2 + \frac{1}{\Delta t}\|u_h^n\|^2\right) \le \left(\frac{1}{\nu}\|f^{n+1/2}\|^2 + \frac{1}{\Delta t}\|u_h^n\|^2\right) \le C, \tag{35}$$

which is a bound independent of λ. Thus the theorem is proven. ∎

We have now shown that the scheme (8)–(10) preserves energy and helicity when $\nu = f = 0$, that it is stable, and that it admits solutions. The final step is an error analysis for the scheme.

4. Error analysis of the scheme. This section presents a theorem for the convergence of the scheme, followed by the proof. The restriction that the theorem places on the timestep is for the use of the discrete Gronwall lemma. Although we found its use necessary in the proof, it is widely believed that it gives a gross underestimate of the largest timestep one can use, and we expect the same asymptotic error. Without the projection step, the proof of the theorem is fairly standard; the smoothness assumptions we make are also fairly standard and are similar to those found in, for example, [10], [18].

THEOREM 4.1. *For* $u \in L^\infty(0,T;W_4^{k+1}) \cap W_2^3(0,T;L^2) \cap W_4^2(O,T,W_2^1)$, $p \in L^4(0,T;W^k) \cap W_2^2(0,T;L^2)$, $f \in L^2(0,T,V^{h,*})$ *satisfying the NSE on the periodic box* $\Omega = (0,L)^3$, $(u_h^n; w_h^n)$ *given by* (8)–(10) *with velocity-pressure spaces chosen as* P_k, P_{k-1} $(k > 1)$, *and timestep* Δt *sufficiently small (for Gronwall's inequality), we have that*

(36)
$$\|u(T) - u_h^N\|^2 + \frac{3\nu\Delta t}{4}\sum_{n=0}^{N-1}\left(\frac{1}{2}\|\nabla(u^{n+1/2} - u_h^{n+1/2})\|^2 + \|w^{n+1/2} - w_h^{n+1/2}\|^2\right) \leq C(u,p,\nu^{-3},\Omega,T)(\Delta t^4 + h^{2k}).$$

Remark 4.2. Under the smoothness assumptions of the theorem, the constant in the error estimate can be prohibitively large for small ν, as the constant contains ν^{-3} terms. This constant can be improved (i.e., to contain ν^{-1} instead of ν^{-3}), but requires the data to be assumed very smooth.

Remark 4.3. Under the assumptions of the theorem, a pressure estimate can also be obtained: $\frac{1}{\Delta t}\sum_{n=0}^{N-1}\|p(t^{n+1/2}) - p_h^{n+1/2}\| \leq C(u,p,\nu^{-3},\Omega,\beta,T)(\Delta t^2 + h^k)$. Enforcing helicity conservation in this setting does not improve this estimate versus the pressure estimate in the usual trapezoidal scheme; that is, this is the expected result and its proof (which is omitted) follows in the standard way (see, e.g., [8], [9]).

Proof. The proof of the theorem is divided into the following parts. We first develop the error equations by subtracting our scheme from the NSE. The error is then split into parts in and out of the finite element spaces. This is followed by bounding the error in the space by interpolation error, and the proof concludes by bounding the total error. Note that we require that the spaces X^h, Q^h satisfy the discrete inf-sup condition; with such spaces, and since $(w_h^0 - \nabla\times u_h^0, v) = 0\ \forall v \in V^h$, the energy- and helicity-conserving scheme is equivalent to finding solutions $u^n, w^n \in V^h$, $n = 0,\ldots,N$, satisfying

(37)
$$\frac{1}{\Delta t}(u_h^{n+1} - u_h^n, v) - (u_h^{n+1/2}\times w_h^{n+1/2}, v) + \frac{\nu}{2}(\nabla u_h^{n+1/2}, \nabla v) + \frac{\nu}{2}(w_h^{n+1/2}, \nabla\times v) = (f^{n+1/2}, v)\ \ \forall v \in V^h,$$

(38)
$$(w_h^{n+1/2} - \nabla\times u_h^{n+1/2}, \chi) = 0\ \ \forall \chi \in V^h.$$

Using the identity $u\cdot\nabla u = \frac{1}{2}\nabla(u^2) - u\times(\nabla\times u)$, and grouping the usual pressure gradient with the $\frac{1}{2}\nabla(u^2)$ term to form the Bernoulli pressure, a periodic solution

$(u;p)$ and $w := \nabla \times u$ of the NSE satisfies

(39)
$$\begin{aligned}
&\frac{1}{\Delta t}(u^{n+1}-u^n,v)-(u^{n+1/2}\times w^{n+1/2},v)+\frac{\nu}{2}(\nabla u^{n+1/2},\nabla v)+\frac{\nu}{2}(w^{n+1/2},\nabla\times v)\\
&-(p(t^{n+1/2}),\nabla\cdot v)=(f^{n+1/2},v)+\left(\frac{u^{n+1}-u^n}{\Delta t}-u_t(t^{n+1/2}),v\right)\\
&-(u^{n+1/2}\times w^{n+1/2}-u(t^{n+1/2})\times w(t^{n+1/2}),v)\\
&+\frac{\nu}{2}(\nabla(u^{n+1/2}-u(t^{n+1/2})),\nabla v)\\
&+\frac{\nu}{2}(w^{n+1/2}-w(t^{n+1/2}),\nabla\times v)\quad\forall v\in V^h.
\end{aligned}$$

Define $e^i := u^i - u_h^i$ and $E^i := w^i - w_h^i$ for $i = n, n+1, n+1/2$, and form the error equations by subtracting the scheme (37), (38) from (39) and $w = \nabla \times u$ to get

(40)
$$\begin{aligned}
&\frac{1}{\Delta t}(e^{n+1}-e^n,v)-(u^{n+1/2}\times E^{n+1/2},v)-(e^{n+1/2}\times w_h^{n+1/2},v)+\frac{\nu}{2}(\nabla e^{n+1/2},\nabla v)\\
&\qquad+\frac{\nu}{2}(E^{n+1/2},\nabla\times v)-(p(t^{n+1/2}),\nabla\cdot v)=IERR(u^n;w^n;v)\quad\forall v\in V^h,
\end{aligned}$$

$$(E^{n+1/2},\chi)-(\nabla\times e^{n+1/2},\chi)=0\quad\forall\chi\in V^h, \tag{41}$$

where the interpolation error in time, $IERR$, is defined by

$$\begin{aligned}
IERR(u^n,w^n,v) &:= \left(\frac{u^{n+1}-u^n}{\Delta t}-u_t(t^{n+1/2}),v\right)\\
&-(u^{n+1/2}\times w^{n+1/2}-u(t^{n+1/2})\times w(t^{n+1/2}),v)\\
&+\frac{\nu}{2}(\nabla(u^{n+1/2}-u(t^{n+1/2})),\nabla v)+\frac{\nu}{2}(w^{n+1/2}-w(t^{n+1/2}),\nabla\times v).
\end{aligned} \tag{42}$$

Next we split the error terms into pieces in and out of V^h. Let U^i and W^i be the projections of u^i and w^i, respectively, into V^h. Then the error terms can be decomposed as

$$e^i=(u^i-U^i)-(u_h^i-U^i)=:\eta^i-\phi_h^i, \tag{43}$$

$$E^i=(w^i-W^i)-(w_h^i-W^i)=:r^i-s_h^i. \tag{44}$$

Note that $(\eta^i, v) = 0$ for $v \in V^h$ by the definition of η^i. Rewriting (40), (41) with this decomposition gives

$$\begin{aligned}
&\frac{1}{\Delta t}(\phi_h^{n+1}-\phi_h^n,v)-(\phi_h^{n+1/2}\times w_h^{n+1/2},v)+\frac{\nu}{2}(\nabla\phi_h^{n+1/2},\nabla v)\\
&+\frac{\nu}{2}(s_h^{n+1/2},\nabla\times v)=(u^{n+1/2}\times s_h^{n+1/2},v)-(u^{n+1/2}\times r^{n+1/2},v)\\
&-(\eta^{n+1/2}\times w_h^{n+1/2},v)+\frac{\nu}{2}(\nabla\eta^{n+1/2},\nabla v)\\
&+\frac{\nu}{2}(r^{n+1/2},\nabla\times v)-(p(t^{n+1/2}),\nabla\cdot v)+IERR(u^n;w^n;v)\quad\forall v\in V^h,
\end{aligned} \tag{45}$$

$$(\nabla\times\phi_h^{n+1},\chi)=(s_h^{n+1/2},\chi)-(r^{n+1/2},\chi)+(\nabla\times\eta^{n+1/2},\chi)=0\quad\forall\chi\in V^h. \tag{46}$$

Let $v = \phi_h^{n+1/2}$ and $\chi = s_h^{n+1/2}$ and combine (45) and (46) to get

$$\begin{aligned}(47)\quad &\frac{1}{2\Delta t}\left(\|\phi_h^{n+1}\|^2 - \|\phi_h^n\|^2\right) + \frac{\nu}{2}\|\nabla\phi_h^{n+1/2}\|^2 + \frac{\nu}{2}\|s_h^{n+1/2}\|^2 \\ &= (u^{n+1/2}\times s_h^{n+1/2}, \phi_h^{n+1/2}) - (u^{n+1/2}\times r^{n+1/2}, \phi_h^{n+1/2}) \\ &\quad - (\eta^{n+1/2}\times w_h^{n+1/2}, \phi_h^{n+1/2}) + \frac{\nu}{2}(\nabla\eta^{n+1/2}, \nabla\phi_h^{n+1/2}) \\ &\quad + \frac{\nu}{2}(r^{n+1/2}, \nabla\times\phi_h^{n+1/2}) + \frac{\nu}{2}(r^{n+1/2}, s_h^{n+1/2}) + \frac{\nu}{2}(\nabla\times\eta^{n+1/2}, s_h^{n+1/2}) \\ &\quad - (p(t^{n+1/2}), \nabla\cdot\phi_h^{n+1/2}) + IERR(u^n; w^n; \phi_h^{n+1/2}).\end{aligned}$$

The terms on the right-hand side of (47) are now majorized in the usual way, using Cauchy–Schwarz and Young's inequalities, and the bound $(u\times w, v) \le C\|a\|_0\|b\|_1\|c\|_{1/2}$. Note that this inequality holds no matter the order of u, w, v (provided the norms exist) due to a well-known vector identity from calculus. We first bound the following right-hand side terms:

$$(48)\quad \frac{\nu}{2}\left|(\nabla\eta^{n+1/2}, \nabla\phi_h^{n+1/2})\right| \le \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2 + C\nu^{-1}\|\nabla\eta^{n+1/2}\|^2,$$

$$(49)\quad \frac{\nu}{2}\left|(r^{n+1/2}, \nabla\times\phi_h^{n+1/2})\right| \le \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2 + C\nu^{-1}\|r^{n+1/2}\|^2,$$

$$(50)\quad \frac{\nu}{2}\left|(r^{n+1/2}, s_h^{n+1/2})\right| \le \frac{\nu}{32}\|s_h^{n+1/2}\|^2 + C\nu^{-1}\|r^{n+1/2}\|^2,$$

$$(51)\quad \frac{\nu}{2}\left|(\nabla\eta^{n+1/2}, s_h^{n+1/2})\right| \le \frac{\nu}{32}\|s_h^{n+1/2}\|^2 + C\nu^{-1}\|\nabla\eta^{n+1/2}\|^2,$$

$$(52)\quad \left|(p(t^{n+1/2}), \nabla\cdot\phi_h^{n+1/2})\right| \le \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2 + C\nu^{-1}\inf_{q\in Q^h}\|p(t^{n+1/2}) - q\|^2.$$

The first of the trilinear terms is bounded by

$$\begin{aligned}(53)\quad \left|(u^{n+1/2}\times s_h^{n+1/2}, \phi_h^{n+1/2})\right| &\le C\|\nabla u^{n+1/2}\|\|s_h^{n+1/2}\|\|\phi_h^{n+1/2}\|^{1/2}\|\nabla\phi_h^{n+1/2}\|^{1/2} \\ &\le \frac{\nu}{32}\|s_h^{n+1/2}\|^2 + \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2 + C\nu^{-3}\|\nabla u^{n+1/2}\|^4\|\phi_h^{n+1/2}\|^2.\end{aligned}$$

Similarly, the second of the trilinear terms is bounded by

$$\begin{aligned}(54)\quad \left|(u^{n+1/2}\times r^{n+1/2}, \phi_h^{n+1/2})\right| &\le \frac{\nu}{32}\|r^{n+1/2}\|^2 + \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2 \\ &\quad + C\nu^{-3}\|\nabla u^{n+1/2}\|^4\|\phi_h^{n+1/2}\|^2.\end{aligned}$$

The third of the trilinear terms is expanded by adding and subtracting $w^{n+1/2}$ to $w_h^{n+1/2}$ to form $w^{n+1/2} - E^{n+1/2}$, followed by decomposing $E^{n+1/2}$, and bounding each of the three resulting trilinear terms to get

$$\begin{aligned}(55)\quad &\left|(\eta^{n+1/2}\times w_h^{n+1/2}, \phi_h^{n+1/2})\right| \le \frac{3\nu}{32}\|\phi_h^{n+1/2}\|^2 + \frac{\nu}{32}\|s_h^{n+1/2}\|^2 \\ &+ C\nu^{-1}\|r^{n+1/2}\|^2\|\nabla\eta^{n+1/2}\|^2 + \frac{1}{2}\|\nabla\eta^{n+1/2}\|^2\|w^{n+1/2}\|^2 \\ &+ C\nu^{-1}\|\phi_h^{n+1/2}\|^2 + C\nu^{-3}\|\nabla\eta^{n+1/2}\|^4\|\phi_h^{n+1/2}\|^2.\end{aligned}$$

Three of the four terms in $IERR(u^n; w^n; \phi_h^{n+1/2})$ are majorized as

$$(56)\quad \left|\left(\frac{u^{n+1}-u^n}{\Delta t} - u_t(t^{n+1/2}), \phi_h^{n+1/2}\right)\right| \le \frac{1}{2}\|\phi_h^{n+1/2}\|^2 + \frac{1}{2}\left\|\frac{u^{n+1}-u^n}{\Delta t} - u_t(t^{n+1/2})\right\|^2,$$

(57)
$$\left|\frac{\nu}{2}(\nabla(u^{n+1/2}-u(t^{n+1/2})),\nabla\phi_h^{n+1/2})\right| \le \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2+C\nu\|\nabla(u^{n+1/2}-u(t^{n+1/2}))\|^2,$$

(58)
$$\left|\frac{\nu}{2}(w^{n+1/2}-w(t^{n+1/2}),\nabla\times\phi_h^{n+1/2})\right| \le \frac{\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2+C\nu\|w^{n+1/2}-w(t^{n+1/2})\|^2,$$

with the remaining term bounded by

(59)
$$\begin{aligned}(u^{n+1/2}&\times w^{n+1/2}-u(t^{n+1/2})\times w(t^{n+1/2}),\phi_h^{n+1/2})\\ &\le \frac{2\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2+C\nu^{-1}\|\nabla u^{n+1/2}\|^2\|w^{n+1/2}-w(t^{n+1/2})\|^2\\ &\quad+C\nu^{-1}\|w(t^{n+1/2})\|^2\|\nabla(u^{n+1/2}-u(t^{n+1/2}))\|^2.\end{aligned}$$

We may now rewrite (47) as

(60)
$$\begin{aligned}&\frac{1}{2\Delta t}(\|\nabla\phi_h^{n+1}\|^2-\|\nabla\phi_h^n\|^2)+\frac{3\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2+\frac{12\nu}{32}\|s_h^{n+1/2}\|^2\\ &\le C\nu^{-1}\|\nabla\eta^{n+1/2}\|^2+C(\nu^{-1}+\nu)\|r^{n+1/2}\|^2+C\nu^{-1}\inf_{q\in Q^h}\|p(t^{n+1/2})-q\|^2\\ &+C\nu^{-3}\|\nabla u^{n+1/2}\|^4\|\phi_h^{n+1/2}\|^2+C\nu^{-1}\|r^{n+1/2}\|^2\|\nabla\eta^{n+1/2}\|^2\\ &+\frac{1}{2}\|\nabla\eta^{n+1/2}\|^2\|w^{n+1/2}\|^2+C\nu^{-3}\|\nabla\eta^{n+1/2}\|^4\|\phi_h^{n+1/2}\|^2\\ &+C\nu^{-1}\|\phi_h^{n+1/2}\|^2+\frac{1}{2}\left\|\frac{u^{n+1}-u^n}{\Delta t}-u_t(t^{n+1/2})\right\|^2+C\nu\|\nabla(u^{n+1/2}-u(t^{n+1/2}))\|^2\\ &+C\nu\|w^{n+1/2}-w(t^{n+1/2})\|^2+C\nu^{-1}\|\nabla u^{n+1/2}\|^2\|w^{n+1/2}-w(t^{n+1/2})\|^2\\ &+C\nu^{-1}\|w(t^{n+1/2})\|^2\|\nabla(u^{n+1/2}-u(t^{n+1/2}))\|^2.\end{aligned}$$

Taylor series can be used to bound the interpolation in time terms, and thus (60) can be reduced to

(61)
$$\begin{aligned}&\frac{1}{2\Delta t}(\|\nabla\phi_h^{n+1}\|^2-\|\nabla\phi_h^n\|^2)+\frac{3\nu}{32}\|\nabla\phi_h^{n+1/2}\|^2+\frac{12\nu}{32}\|s_h^{n+1/2}\|^2\\ &\le C\nu^{-1}\|\nabla\eta^{n+1/2}\|^2+C(\nu^{-1}+\nu)\|r^{n+1/2}\|^2+C\nu^{-1}\inf_{q\in Q^h}\|p^{n+1/2}-q\|^2\\ &+C\nu^{-1}\|r^{n+1/2}\|^2\|\nabla\eta^{n+1/2}\|^2+\frac{1}{2}\|\nabla\eta^{n+1/2}\|^2\|w^{n+1/2}\|^2\\ &+C(\Delta t)^3\int_{t^n}^{t^{n+1}}\|u_{ttt}\|^2\,dt\;+C\nu(\Delta t)^3\int_{t^n}^{t^{n+1}}\|\nabla u_{tt}\|^2\,dt\\ &+C\nu(\Delta t)^3\int_{t^n}^{t^{n+1}}\|w_{tt}\|^2\,dt\;+C\nu^{-1}(\Delta t)^3\|\nabla u^{n+1/2}\|^2\int_{t^n}^{t^{n+1}}\|w_{tt}\|^2\,dt\\ &+C\nu^{-1}(\Delta t)^3\|w(t^{n+1/2})\|^2\int_{t^n}^{t^{n+1}}\|\nabla u_{tt}\|^2\,dt\\ &+C(\nu^{-1}+\nu^{-3}\|\nabla u^{n+1/2}\|^4+\nu^{-3}\|\nabla\eta^{n+1/2}\|^4)\|\phi_h^{n+1/2}\|^2.\end{aligned}$$

Next we sum from $n=0,\dots,N-1$, multiply both sides by $2\Delta t$, recall $\phi_h^0=0$ and the smoothness assumptions, and reduce. With the choice of P_k, P_{k-1} velocity-pressure

spaces, (61) reduces to

$$
\begin{aligned}
(62)\qquad & \|\phi_h^N\|^2 + \sum_{n=0}^{N-1}\left(\frac{3\nu\Delta t}{16}\|\nabla\phi_h^{n+1/2}\|^2 + \frac{3\nu\Delta t}{4}\|s_h^{n+1/2}\|^2\right)\\
&\le C((\Delta t)^4 + \nu^{-1}h^{2k} + (\nu^{-1}+\nu)h^{2k+2} + \nu^{-1}h^{2k} + h^{4k+2})\\
&+ \Delta t\sum_{n=0}^{N-1}\|\nabla\eta^{n+1/2}\|^2\|w^{n+1/2}\|^2 + C\nu^{-1}(\Delta t)^4\sum_{n=0}^{N-1}\|\nabla u^{n+1/2}\|^2\int_{t^n}^{t^{n+1}}\|w_{tt}\|^2\,dt\\
&+ C\nu^{-1}(\Delta t)^4\sum_{n=0}^{N-1}\|w(t^{n+1/2})\|^2\int_{t^n}^{t^{n+1}}\|\nabla u_{tt}\|^2\,dt\\
&+ C\Delta t\sum_{n=0}^{N-1}(\nu^{-1}+\nu^{-3}\|\nabla u^{n+1/2}\|^4 + \nu^{-3}\|\nabla\eta^{n+1/2}\|^4)\|\phi_h^{n+1/2}\|^2.
\end{aligned}
$$

Since $w = \nabla\times u$, we reduce (62) to

$$
\begin{aligned}
(63)\qquad & \|\phi_h^N\|^2 + \sum_{n=0}^{N-1}\left(\frac{3\nu\Delta t}{16}\|\nabla\phi_h^{n+1/2}\|^2 + \frac{3\nu\Delta t}{4}\|s_h^{n+1/2}\|^2\right)\\
&\le C((\Delta t)^4 + \nu^{-1}h^{2k} + (\nu^{-1}+\nu)h^{2k+2} + \nu^{-1}h^{2k} + h^{4k+2})\\
&+ \Delta t\sum_{n=0}^{N-1}\|\nabla\eta^{n+1/2}\|^2\|\nabla u^{n+1/2}\|^2 + C\nu^{-1}(\Delta t)^4\sum_{n=0}^{N-1}\|\nabla u(t^{n+1/2})\|^2\int_{t^n}^{t^{n+1}}\|\nabla u_{tt}\|^2\,dt\\
&+ C\Delta t\sum_{n=0}^{N-1}(\nu^{-1}+\nu^{-3}\|\nabla u^{n+1/2}\|^4 + \nu^{-3}\|\nabla\eta^{n+1/2}\|^4)\|\phi_h^{n+1/2}\|^2.
\end{aligned}
$$

We bound the third and second to last terms with Holder's inequality and the smoothness assumptions, then reduce by assuming $\Delta t,\ \nu\ \le 1$. This yields

$$
\begin{aligned}
(64)\quad & \|\phi_h^N\|^2 + \sum_{n=0}^{N-1}\left(\frac{3\nu\Delta t}{16}\|\nabla\phi_h^{n+1/2}\|^2 + \frac{3\nu\Delta t}{4}\|s_h^{n+1/2}\|^2\right)\\
&\le C((\Delta t)^4+\nu^{-1}h^{2k}) + C\Delta t\sum_{n=0}^{N-1}(\nu^{-1}+\nu^{-3}\|\nabla u^{n+1/2}\|^4+\nu^{-3}\|\nabla\eta^{n+1/2}\|^4)\|\phi_h^{n+1/2}\|^2.
\end{aligned}
$$

Now with Δt chosen sufficiently small, we use the discrete Gronwall inequality to get

(65)
$$
\|\phi_h^N\|^2 + \sum_{n=0}^{N-1}\left(\frac{3\nu\Delta t}{16}\|\nabla\phi_h^{n+1/2}\|^2 + \frac{3\nu\Delta t}{4}\|s_h^{n+1/2}\|^2\right) \le C(u,p,\nu,\Omega)((\Delta t)^4 + h^{2k}).
$$

Using the triangle inequality with (65) completes the proof. ∎

5. Numerical experiments. We now present numerical experiments for the energy- and helicity-conserving scheme. This section makes several comparisons between this scheme and the usual convective form of the trapezoidal (Crank–Nicholson) scheme for the NSE

$$
\begin{aligned}
(66)\quad \frac{1}{\Delta t}(u_h^{n+1}-u_h^n, v) + \frac{1}{2}(u_h^{n+1/2}\cdot\nabla u_h^{n+1/2}, v) - \frac{1}{2}(u_h^{n+1/2}\cdot\nabla v, u_h^{n+1/2})&\\
+ \nu(\nabla u_h^{n+1/2}, \nabla v) = (f^{n+1/2}, v)\ \ \forall v\in V^h,&
\end{aligned}
$$

and the rotational form

$$\frac{1}{\Delta t}(u_h^{n+1} - u_h^n, v) - (u_h^{n+1/2} \times (\nabla \times u_h^{n+1/2}), v) + \nu(\nabla u_h^{n+1/2}, \nabla v) = (f^{n+1/2}, v) \quad \forall v \in V^h. \tag{67}$$

All of the schemes were implemented in MATLAB using Taylor–Hood elements and periodic boundary conditions and uniform meshes on the unit cube. Simple fixed point iterations were used to solve the nonlinear problem in each timestep.

5.1. Computational cost of the schemes. The energy- and helicity-conserving scheme is more computationally expensive than the usual trapezoidal schemes (66) and (67). It solves for velocity and a projected vorticity, both in V^h, and results in linear systems that are double the size of those arising from the usual schemes. Hence, the energy- and helicity-conserving scheme would be more practical if a linearization or decoupling of the system could be found that would still conserve both energy and helicity. At this point, we do not know if such a linearization can be found. It is possible that an (effective and reliable) iteration between decoupled equations could be discovered. Since the energy- and helicity-conserving scheme, when decoupled, will take a form much like that of (67), one may even be able to take advantage of more efficient solvers designed for rotational-form Navier–Stokes schemes such as those described by Benzi and Liu in [2] or Olshanskii in [16].

5.2. Experiment 1: Helicity conservation for $\nu = f = 0$. The first numerical experiment is a comparison of helicity treatment in the three schemes when $\nu = f = 0$. This is the case where helicity is exactly conserved in the true physics, and thus for physical fidelity should also be conserved in the numerical schemes. Using

$$u^0 = \langle \cos(2\pi z), \sin(2\pi z), \sin(2\pi x) \rangle \tag{68}$$

for the initial condition (since it is simple and has nonzero helicity), we set $\nu = f = 0$ in each scheme and computed from $(0, 1]$ on the (periodic) unit cube. The energy- and helicity-conserving scheme was run on an $h = 1/8$ uniform mesh, and the other two schemes were run on $h = 1/8$ and $h = 1/16$ uniform meshes. Timesteps were chosen to be 0.025 and 0.01 for the two meshes, respectively. Figure 1 shows a plot of each solution's helicity on $[0, 1]$, and from here it is clear that the usual trapezoidal schemes do not conserve helicity, and that the energy- and helicity-conserving scheme, as expected, does.

5.3. Experiment 2: Accuracy comparison for a known solution. Given the true solution

$$u = ((2-t)\cos(2\pi z),\ (1+t)\sin(2\pi z),\ (1-t)\sin(2\pi x)),\ p = \sin(2\pi(x+y+t)), \tag{69}$$

we calculated f from u and p and implemented each of the schemes on an $h = 1/8$ mesh with $T = 2$, $\Delta t = 0.025$, and $\nu = 1$. Shown below are the plots of helicity error, L^2 error, and H^1 error vs. time for the three schemes. We see from the plots that the usual trapezoidal schemes (66) and (67) give nearly identical results, and that these schemes have a better H^1 error but worse L^2 error and helicity error than the energy- and helicity-conserving scheme. Similar experiments should be conducted for smaller ν (and thus finer meshes) to verify that the results will hold in a setting with less viscosity.

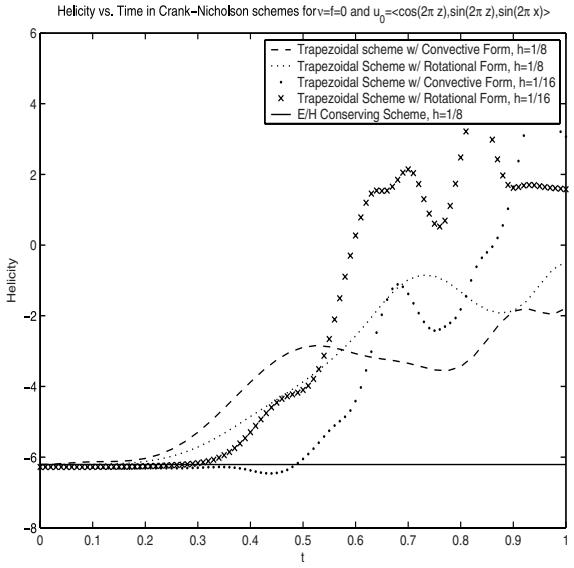

FIG. 1. *Helicity conservation in different trapezoid schemes for the NSE with* $\nu = f = 0$ *and* $u_0 = (\cos(2\pi z), \sin(2\pi z), \sin(2\pi x))$.

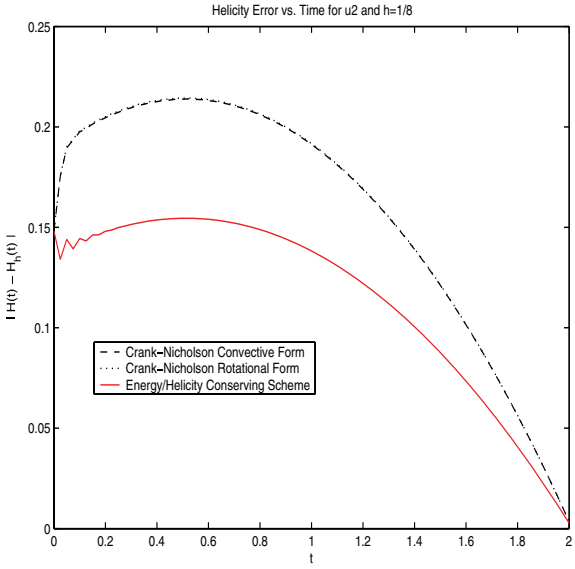

FIG. 2. *Helicity error in the schemes.*

We believe the oscillations near $t = 0$ (seen in Figures 2 and 3) are a result of using Crank–Nicholson schemes, and we offer the following possibility for the more pronounced oscillations in the new scheme: On such a coarse mesh, the different schemes treat the viscous term(s) significantly differently, as the new scheme employs a vorticity projection. We believe the error introduced (by such a coarse mesh projection) may amplify initial oscillations, and thus we expect the difference in magnitude of the schemes' oscillations to decrease with finer meshes.

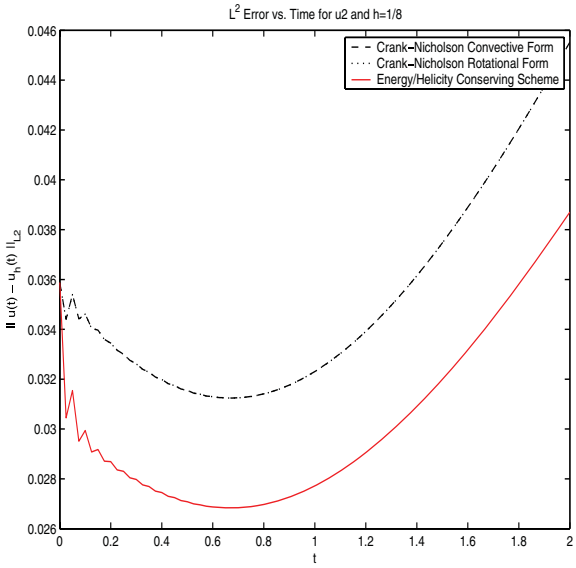

FIG. 3. *L^2 error in the schemes.*

6. Conclusions. In an effort to find more physically relevant solutions to the NSE, we have developed an energy- and helicity-conserving finite element scheme for periodic flows which is second order in time and converges optimally in space. The scheme is able to conserve two inviscid invariants by using the rotational form of the nonlinearity with a projected vorticity. The scheme retains the asymptotic velocity convergence rates of the usual trapezoidal finite element method. Numerical evidence suggests that the scheme can predict helicity more accurately than the usual

trapezoidal scheme. However, each linear system that needs to be solved is double the size of those in usual trapezoidal scheme, and thus further work must be done to make this promising scheme more practical.

UNIFIED ANALYSIS OF FINITE VOLUME METHODS FOR SECOND ORDER ELLIPTIC PROBLEMS*

SO-HSIANG CHOU† AND XIU YE‡

Abstract. We establish a general framework for analyzing the class of finite volume methods which employ continuous or totally discontinuous trial functions and piecewise constant test functions. Under the framework, optimal order convergence in the H^1 and L^2 norms can be obtained in a natural and systematic way for classical finite volume methods and new finite volume methods such as discontinuous finite volume methods applied to second order elliptic problems.

Key words. finite element methods, finite volume methods, discontinuous Galerkin methods, finite volume element

1. Introduction.

Due to the local conservation property and other attractive properties such as robustness with unstructured meshes, the finite volume method is widely used in computational fluid dynamics. Numerical analysis of a finite volume method is more difficult than that of a finite element method, since in general a finite volume method uses two different function spaces: one for the trial space and one for the test space. For example, obtaining the optimal L^2 error estimates is a common practice for finite element methods. They are very difficult to obtain for the finite volume methods. Because of this reason, the optimal L^2 estimates have not been derived for the finite volume methods proposed in [8, 9, 10, 13, 25]. The main motivation of this paper is to propose a general framework under which we can systematically give a thorough analysis for finite volume methods to second order elliptic problems and obtain the optimal error estimates in energy norm and L^2 norm.

In recent years, there have appeared different approaches in the convergence and stability analysis of the finite volume method; see, for example, [2, 5, 6, 12, 13, 16, 15, 17, 18, 22], among others. Motivated by the popularity of discontinuous Galerkin methods, Ye [25] proposed a finite volume method with a totally discontinuous trial function space for elliptic problems. Our general framework covers the finite volume methods (continuous or discontinuous) developed in all of the papers mentioned above in a unified way, and previously hard-to-obtain optimal L^2 estimates [8, 10, 9, 13, 25] can now be derived naturally.

For simplicity in this paper we will treat only finite volume methods applied to the self-adjoint elliptic equations. To illustrate the idea, we consider the model problem

$$\mathcal{L}u := -\nabla \cdot \mathcal{A}\nabla u = f \quad \text{in } \Omega, \quad u = 0 \quad \text{on } \partial\Omega, \tag{1.1}$$

where $\Omega \subset R^2$ is a bounded polygonal domain and $\mathcal{A}$ is in either $W^{1,\infty}$ or $W^{2,\infty}$. A typical finite volume method uses piecewise constant functions as test functions, and,

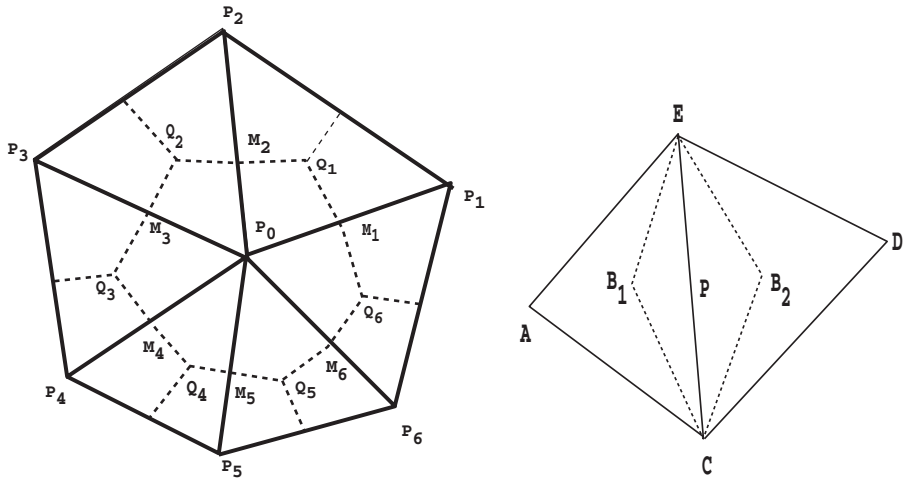

FIG. 1. *Primal and dual grids. Left figure: Conforming finite volume method. Right figure: Nonconforming finite volume method.*

to keep the same dimension for the spaces of the trial functions and test functions, two different partitions of the domain Ω are needed: one called the primal partition is associated with the trial space, and one called the dual partition is associated with the test space. For example, in Figure 1, on the left the primal partition is made up of the standard triangular finite elements, and the dual partition is the usual barycentric subdivision consisting of polygons around P_i's obtained by connecting midpoints M_i's of edges and barycenters Q_i's of the triangles. Thus $M_1Q_1M_2Q_2M_3Q_3M_4Q_4M_5Q_5M_6Q_6$ is a typical dual volume around P_0. On the other hand, in the right figure of Figure 1 we use triangles in the primal partition, and for each midpoint of an edge in the triangles we define a quadrilateral element that serves as an element in the dual partition. So, for example, in Figure 1 the quadrilateral EB_1CB_2 around midpoint P (B_i barycenters of triangles) is in the dual partition.

Figure 2 shows two more possible configurations of primal (solid lines) and dual (dashed lines) partitions. In particular, the partitions in the right figure will be used for the discontinuous finite volume method in section 3.3. Here we use standard triangular elements in the primal partition, and each triangular element then generates three dual triangular volumes (AB_1D and two others) by connecting its barycenter and vertices.

Denote by $\mathcal{T}_h$ the primal triangulation of Ω, by $\mathcal{T}_h^*$ the dual partition of $\mathcal{T}_h$, and by $P_l(T)$ the space of all polynomials on T whose degree is at most l. The finite dimensional trial space V_h associated with $\mathcal{T}_h$ is a subspace of piecewise linears, i.e.,

$$V_h \subset \{v \in V : \ v|_T \in P_1(T) \ \forall T \in \mathcal{T}_h\}, \tag{1.2}$$

where V is either $H_0^1(\Omega)$ or $L^2(\Omega)$ (standard Sobolev spaces notation will be adopted throughout the paper). Examples of such space are continuous P_1 conforming space, the Crouzeix–Raviart P_1 nonconforming space [14] (continuous at midpoints), and totally discontinuous P_1 space to be used in conjunction with the discontinuous finite volume method in section 3.3. The test function space Q_h associated with the dual partition $\mathcal{T}_h^*$ is

$$Q_h = \{q \in L^2(\Omega) : \ q|_K \in P_0(K) \ \ \forall K \in \mathcal{T}_h^*\}. \tag{1.3}$$

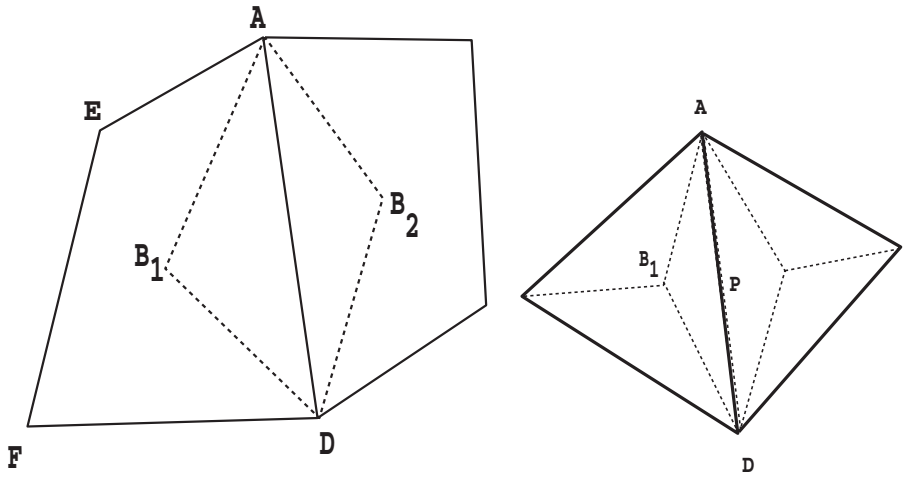

FIG. 2. *Primal and dual grids. Left figure: Nonconforming finite volume method. Right figure: Discontinuous finite volume method.*

We mention in passing that classical finite volume methods adopt piecewise P_0 shape functions, and their applications abound. The present (and newer) finite volume methods using piecewise P_1 shape functions also find many practical applications in heat transfer and fluid flow problems [7, 21] and the references therein. These methods are also natural when combined with the multilevel adaptive methods [19, 20].

Due to the efforts of several authors [6, 12, 15, 17], especially [6, 15, 17], it is now recognized that, for finite volume methods applied to second order elliptic problems on polygonal domains, it is to be expected that, for the exact solution u and approximate solution u_h, the best form of the L^2 estimates is

$$||u - u_h|| \leq Ch^2(||u||_2 + ||f||_1).$$

(We use $||\cdot||_p$ for the standard Sobolev H^p norm and drop the subindex for the L^2 norm.) One notes that this is not the same as assuming u in $H^3(\Omega)$. For example, the solution of the boundary value problem $\Delta u = 1$ on the unit square and $u = 0$ on the boundary belongs to $H^2(\Omega)$ but not to $H^3(\Omega)$. While it is easy and natural to deduce the above error estimates under our present framework, it should be pointed out that there are other ways to view finite volume methods, depending on how one views what the distinctive traits of a finite volume method are. For example, one may consider the so-called mixed finite volume method in which the flux can be recovered by a simple formula [11]. On the other hand, in other finite volume methods the flux itself plays an important role in the derivation of the method. For instance, in [16], finite volume methods are based on considering averages of solutions on the control volumes which coincide with the supports of the test functions in the present paper. The stiffness matrix is calculated from a difference approximation of the fluxes between two neighboring elements. Compactness methods are used to prove the convergence. While this approach can be generalized consistently to convection-diffusion and hyperbolic problems, it shows considerable difficulties when error estimates are to be obtained. Our approach focuses on a narrower elliptic problem class and explores its natural relation to the Galerkin finite element method. Consequently, optimal order error estimates are easier to obtain.

The organization of the paper is as follows. In section 2 we present our general finite volume framework and its stability and convergent analysis. Under this framework, in section 3 we systematically derive for the new as well as the old finite volume methods the optimal H^1 estimates of the usual form and optimal L^2 estimates of the above form.

Let e be an interior edge common to elements T_1 and T_2 in $\mathcal{T}_h$, and let $\mathbf{n}_1$ and $\mathbf{n}_2$ be the unit normal vectors on e exterior to K_1 and K_2, respectively. For a scalar q and a vector $\mathbf{w}$ we define their average $\{\cdot\}$ on e and jump $[\![\cdot]\!]$ across e, respectively, as

$$\{q\} = \frac{1}{2}(q|_{\partial T_1} + q|_{\partial T_2}), \quad [\![q]\!] = q|_{\partial T_1}\mathbf{n}_1 + q|_{\partial T_2}\mathbf{n}_2,$$

$$\{\mathbf{w}\} = \frac{1}{2}(\mathbf{w}|_{\partial T_1} + \mathbf{w}|_{\partial T_2}), \quad [\![\mathbf{w}]\!] = \mathbf{w}|_{\partial T_1} \cdot \mathbf{n}_1 + \mathbf{w}|_{\partial T_2} \cdot \mathbf{n}_2.$$

Note that the jump of a vector is a scalar, whereas the jump of a scalar is a vector. If e is an edge on the boundary of Ω, we define

$$\{q\} = q, \quad [\![\mathbf{w}]\!] = \mathbf{w} \cdot \mathbf{n}.$$

The quantities $[\![q]\!]$ and $\{\mathbf{w}\}$ on boundary edges are defined analogously. Let $\mathcal{E}_h$ denote the union of the boundaries of the triangles T of $\mathcal{T}_h$ and $\mathcal{E}_h^0 := \mathcal{E}_h \backslash \partial\Omega$ the collection of all interior edges.

Following [8, 12], we assume the existence of a transfer operator γ from $V(h) := V_h + H^2(\Omega) \cap H_0^1(\Omega)$ to the test space Q_h. In particular, γ connects the trial space V_h with the test space Q_h. Throughout the paper, the operator γ is required to satisfy the following sets of assumptions.

Assumption 1. Quadraturelike and restriction assumptions for γ:

$$\int_T (v - \gamma v)dx = 0 \quad \forall v \in V_h, \ \ \forall T \in \mathcal{T}_h, \tag{1.4}$$

$$\int_e (v - \gamma v)ds = 0 \quad \forall v \in H^2(\mathcal{T}_h), \ \ \forall e \in \partial T, \ \forall T \in \mathcal{T}_h, \tag{1.5}$$

$$\text{if} \quad [\![v]\!] = 0, \quad \text{then} \ \ [\![\gamma v]\!] = 0, \tag{1.6}$$

where $H^2(\mathcal{T}_h) := \{v \in L^2(\Omega) : v|_T \in H^2(T) \qquad \forall T \in \mathcal{T}_h\}$.

Equations (1.4)–(1.5) have been observed in [12, 13] and perhaps can be viewed as a type of quadrature condition. Equation (1.6) is our new observation in this paper regarding to the jump.

Assumption 2. Approximation property of γ:

$$||\gamma w - w||_{0,T} \le Ch_T|w|_{1,T} \qquad \forall T \in \mathcal{T}_h. \tag{1.7}$$

Then the solution of (1.1) necessarily satisfies

$$\mathcal{L}u = -\nabla \cdot \mathcal{A}\nabla u = f \quad \text{ on } K \quad \forall K \in \mathcal{T}_h^*, \tag{1.8}$$

$$[\![\gamma u]\!]_e = 0 \quad \forall e \in \mathcal{E}_h, \tag{1.9}$$

$$[\![\mathcal{A}\nabla u]\!]_e = 0 \quad \forall e \in \mathcal{E}_h^0. \tag{1.10}$$

2. Finite volume formulation. In this section, we will derive a general formulation for finite volume methods. The formulation is based on enforcing (1.8)–(1.10) by testing with "element" test functions for (1.8) and "edge" test functions for (1.9)

and (1.10). To this end, we further assume the existence of two linear operators $B_1 : V(h) \to L^2(\mathcal{E}_h)$ and $B_2 : V(h) \to L^2(\mathcal{E}_h^0)$ (they will be defined shortly). Testing (1.8), (1.9), and (1.10) by γv, $B_1 v$, and $B_2 v$, respectively, and adding them up, we obtain the "global" equation

$$(\mathcal{L}u, \gamma v)_{\mathcal{T}_h^*} + ([\![\gamma u]\!], B_1 v)_{\mathcal{E}_h} + ([\![\mathcal{A}\nabla u]\!], B_2 v)_{\mathcal{E}_h^0} = (f, \gamma v), \tag{2.1}$$

where each inner product obviously means the sum of its local inner products. *A remark is in order here.* Interpreting PDEs and jump conditions such as (1.8)–(1.10) as residual equations and testing them with test functions of different levels is, of course, quite common in finite element and finite volume methods. However, the fact that summing them up as equal weight relations can lead to fruitful analysis is more recent. In fact, using this technique Brezzi et al. [4] have demonstrated stabilization mechanisms in discontinuous Galerkin methods in a unified way.

Integrating (2.1) by parts and using the fact that γv is constant on K, we have

$$\begin{aligned}
(\mathcal{L}u, \gamma v)_{\mathcal{T}_h^*} &= -\sum_{K\in\mathcal{T}_h^*} \int_K \nabla\cdot\mathcal{A}\nabla u \gamma v dx \\
&= -\sum_{K\in\mathcal{T}_h^*} \int_{\partial K} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds \\
&= \left(-\sum_{K\in\mathcal{T}_h^*} \int_{\partial K} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds + \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds \right) \\
&\quad - \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds,
\end{aligned}$$

where we have added and subtracted the last term to bring in the effect of primal triangulation.

Define the bilinear form $a : V(h)\times V(h) \to R$

$$a(u,v) := -\sum_{K\in\mathcal{T}_h^*} \int_{\partial K} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds + \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds.$$

Recall the following easily derived identity (or see [1]): For all $q \in \prod_{T\in\mathcal{T}_h} L^2(\partial T)$ and for all $\mathbf{v} \in [\prod_{T\in\mathcal{T}_h} L^2(\partial T)]^2$,

$$\sum_{T\in\mathcal{T}_h} \int_{\partial T} q\mathbf{v}\cdot\mathbf{n} ds = \int_{\mathcal{E}_h} [\![q]\!]\{\mathbf{v}\} ds + \int_{\mathcal{E}_h^0} \{q\}[\![\mathbf{v}]\!] ds. \tag{2.2}$$

In particular,

$$\sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds = \sum_{e\in\mathcal{E}_h} \int_e [\![\gamma v]\!]\cdot\{\mathcal{A}\nabla u\} ds + \sum_{e\in\mathcal{E}_h^0} \int_e \{\gamma v\}[\![\mathcal{A}\nabla u]\!] ds, \tag{2.3}$$

and hence (2.1) becomes

$$\begin{aligned}
&a(u,v) - ([\![\mathcal{A}\nabla u]\!], \{\gamma v\})_{\mathcal{E}_h^0} - (\{\mathcal{A}\nabla u\}, [\![\gamma v]\!])_{\mathcal{E}_h} \\
&\qquad + ([\![\gamma u]\!], B_1 v)_{\mathcal{E}_h} + ([\![\mathcal{A}\nabla u]\!], B_2 v)_{\mathcal{E}_h^0} = (f, \gamma v).
\end{aligned}$$

The choice of $B_2 v = \{\gamma v\}$ leads to

$$a(u,v) - (\{\mathcal{A}\nabla u\}, [\![\gamma v]\!])_{\mathcal{E}_h} + ([\![\gamma u]\!], B_1 v)_{\mathcal{E}_h} = (f, \gamma v).$$

Furthermore, if we take the common pick of $B_1 v = \alpha h^{-1}[\![\gamma v]\!] + \delta\{\mathcal{A}\nabla v\}$, where α is a positive number and $\delta = 1, -1$, the above equation becomes

$$a(u,v) - (\{\mathcal{A}\nabla u\}, [\![\gamma v]\!])_{\mathcal{E}_h} + \delta([\![\gamma u]\!], \{\mathcal{A}\nabla v\})_{\mathcal{E}_h} + \alpha h^{-1}([\![\gamma u]\!], [\![\gamma v]\!])_{\mathcal{E}_h} = (f, \gamma v).$$

For simplicity, we will fix our choices and take $B_1 v = \alpha h^{-1}[\![\gamma v]\!] + \delta\{\mathcal{A}\nabla v\}$ and $B_2 v = \{\gamma v\}$ in the remaining part of the paper. However, our analysis carries through for other choices in [4] as well.

Let

$$A(u,v) := a(u,v) - (\{\mathcal{A}\nabla u\}, [\![\gamma v]\!])_{\mathcal{E}_h} + \delta([\![\gamma u]\!], \{\mathcal{A}\nabla v\})_{\mathcal{E}_h} + \alpha h^{-1}([\![\gamma u]\!], [\![\gamma v]\!])_{\mathcal{E}_h}, \tag{2.4}$$

and consider the following class of finite volume methods: Find $u_h \in V_h$

$$A(u_h, v) = (f, \gamma v) \qquad \forall v \in V_h. \tag{2.5}$$

The formulation (2.5) is consistent; i.e., the true solution u satisfies

$$A(u,v) = (f, \gamma v) \quad \forall v \in V_h. \tag{2.6}$$

Subtracting (2.5) from (2.6) gives

$$A(u - u_h, v) = 0 \quad \forall v \in V_h. \tag{2.7}$$

We define a norm $|\!|\!| \cdot |\!|\!|$ on $V(h)$ as

$$|\!|\!| v |\!|\!|^2 = |u|_{1,h}^2 + \sum_{e \in \mathcal{E}_h} [\![\gamma v]\!]_e^2 + \sum_{T \in \mathcal{T}_h} h_T^2 |v|_{2,T}^2.$$

We assume the bilinear for $A(\cdot,\cdot)$ is bounded and coercive:

Assumption 3.

$$|A(v,w)| \le C_1 |\!|\!| v |\!|\!| |\!|\!| w |\!|\!| \qquad \forall v, w \in V(h) \times V(h), \tag{2.8}$$

$$A(v,v) \ge C_2 |\!|\!| v |\!|\!|^2 \qquad \forall v \in V_h. \tag{2.9}$$

Then we have the following theorem that is the counterpart of Céa's lemma [3] in the finite element theory.

THEOREM 2.1. *Let u and u_h be the solutions of* (1.1) *and* (2.5). *Then*

$$|\!|\!| u - u_h |\!|\!| \le C \inf_{v \in V_h} |\!|\!| u - v |\!|\!|.$$

Proof. From (2.9) and (2.7), we have that for any $v \in V_h$

$$C_1 |\!|\!| u_h - v |\!|\!|^2 \le A(u_h - v, u_h - v) = A(u - v, u_h - v) \le C_2 |\!|\!| u - v |\!|\!| |\!|\!| u_h - v |\!|\!|.$$

Hence by the triangle inequality we have

$$|\!|\!| u - u_h |\!|\!| \le C \inf_{v \in V_h} |\!|\!| u - v |\!|\!|.$$

This completes the proof. ∎

To obtain the L^2 error estimate for our general finite volume formulation (2.5), we assume that the bilinear form $a(v,w)$ satisfies the following equations.

Assumption 4. For any $v, w \in V(h)$,

$$a(v,w) = (\mathcal{A}\nabla_h v, \nabla_h w) + \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla v \cdot \mathbf{n}(\gamma w - w)ds + \sum_{T\in\mathcal{T}_h} (\nabla\cdot\mathcal{A}\nabla v, w-\gamma w)_T. \tag{2.10}$$

For this reason, we shall take $\delta = -1$ in the following analysis.

THEOREM 2.2. *Let $u \in H^2(\Omega)\cap H_0^1(\Omega)$ and $u_h \in V_h$ be the solutions of* (1.1) *and* (2.5) *with $\delta = -1$, respectively. Assume that $\mathcal{A} \in W^{2,\infty}(\Omega)$ and that* (1.4), (1.5), (1.7), *and* (2.10) *hold. Then*

$$\|u - u_h\| \le Ch(|\!|\!| u - u_h |\!|\!| + h\|f\|_1).$$

Proof. Let $w \in H_0^1(\Omega)\cap H^2(\Omega)$ be the solution of the dual problem

$$-\nabla\cdot\mathcal{A}\nabla w = u - u_h \quad \text{in } \Omega, \tag{2.11}$$

$$w = 0 \quad \text{on } \partial\Omega, \tag{2.12}$$

so that the following estimate holds:

$$\|w\|_2 \le C\|u - u_h\|. \tag{2.13}$$

Let $w_I \in V_h$ be the usual *continuous* piecewise linear Lagrange interpolant of w, so that

$$|\!|\!| w - w_I |\!|\!| \le Ch|w|_2. \tag{2.14}$$

From (2.11) we deduce that

$$\begin{aligned}\|u-u_h\|^2 &= -(u-u_h, \nabla\cdot\mathcal{A}\nabla w)\\ &= (\mathcal{A}\nabla_h(u-u_h), \nabla_h w) - \sum_{T\in\mathcal{T}_h}\int_{\partial T}\mathcal{A}\nabla w\cdot\mathbf{n}(u-u_h)ds\\ &= (\mathcal{A}\nabla_h(u-u_h), \nabla_h w) - \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\}, [\![u-u_h]\!])_e, \end{aligned} \tag{2.15}$$

where we have used (2.3) and the fact that $[\![\mathcal{A}\nabla w]\!]_e = 0$ on all interior edges e.

On the one hand, (2.10) implies

$$a(u-u_h, w_I) = (\mathcal{A}\nabla_h(u-u_h), \nabla_h w_I) + \sum_{T\in\mathcal{T}_h}(\mathcal{A}\nabla(u-u_h)\cdot\mathbf{n}, \gamma w_I - w_I)_{\partial T} + \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla(u-u_h), w_I - \gamma w_I)_T, \tag{2.16}$$

and, on the other hand, it follows from (2.7) that

$$a(u-u_h, w_I) = \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w_I\}, [\![\gamma(u-u_h)]\!])_e. \tag{2.17}$$

Thus, subtracting (2.16) from the sum of (2.15) and (2.17), we have

$$\begin{aligned}\|u-u_h\|^2 &= (\mathcal{A}\nabla_h(u-u_h),\nabla_h(w-w_I)) - \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla(u-u_h),w_I-\gamma w_I)_T \\ &\quad + \left(\sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w_I\},[\![\gamma(u-u_h)]\!])_e - \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\},[\![u-u_h]\!])_e\right) \\ &\quad - \sum_{T\in\mathcal{T}_h}(\mathcal{A}\nabla(u-u_h)\cdot\mathbf{n},\gamma w_I-w_I)_{\partial T} \\ &:= I_1+I_2+I_3+I_4. \end{aligned} \tag{2.18}$$

The four I terms can be estimated as follows. Using (2.14) and (2.13), we have

$$\begin{aligned} I_1 &= (\mathcal{A}\nabla_h(u-u_h),\nabla(w-w_I)) \le C|||u-u_h|||w-w_I|_1 \\ &\le Ch\|u-u_h\|\,|||u-u_h|||. \end{aligned}$$

As for the I_2 term, first it follows from (1.1), (1.4), (1.7), and (2.13) that

$$\begin{aligned}\sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla u,w_I-\gamma w_I)_T &= \sum_{T\in\mathcal{T}_h}(\bar f-f,w_I-\gamma w_I)_T \\ &\le Ch^2\|f\|_1\|u-u_h\|, \end{aligned}$$

where $\bar f$ is the average of f over each element. Next,

$$\begin{aligned}\sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla u_h,w_I-\gamma w_I)_T &= \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla u_h-\overline{\nabla\cdot\mathcal{A}\nabla u_h},w_I-\gamma w_I)_T \\ &\le Ch||\mathcal{A}||_{2,\infty}|u_h|_{1,h}\|u-u_h\| \\ &\le Ch||\mathcal{A}||_{2,\infty}(|||u-u_h|||+||f||)\,\|u-u_h\|, \end{aligned} \tag{2.19}$$

where $\overline{\nabla\cdot\mathcal{A}\nabla u_h}$ is the average of $\nabla\cdot\mathcal{A}\nabla u_h$ over each element T.

For the I_3 term, using (1.5) and (2.13), we have

$$\begin{aligned}&\sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w_I\},[\![\gamma(u-u_h)]\!])_e - \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\},[\![(u-u_h)]\!])_e \\ &\quad= \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w_I\},[\![\gamma(u-u_h)]\!])_e - \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\},[\![\gamma(u-u_h)]\!])_e \\ &\qquad+ \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\},[\![\gamma(u-u_h)]\!])_e - \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w\},[\![(u-u_h)]\!])_e \\ &\quad= \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla(w_I-w)\},[\![\gamma(u-u_h)]\!])_e \\ &\qquad- \sum_{e\in\mathcal{E}_h}(\{\mathcal{A}\nabla w-\overline{\mathcal{A}\nabla w}\},[\![(u-u_h)-\gamma(u-u_h)]\!])_e \\ &\quad:= J_1+J_2 \\ &\quad\le Ch|||u-u_h|||\|u-u_h\|, \end{aligned}$$

where $\overline{\mathcal{A}\nabla w}$ is the average of $\mathcal{A}\nabla w$ over each edge and the J terms are estimated as follows. In fact, the J_i terms can be estimated using the following easily derived trace inequality [12]: For $\phi\in H^1(T)$ and for an edge e of T with h_e the length of e,

$$\|\phi\|_e^2 \le C(h_e^{-1}|\phi|_{0,T}^2 + h_e|\phi|_{1,T}^2), \tag{2.20}$$

where C depends on the shape parameter of T such as the minimal angle of T in the triangular case. For instance,

$$\begin{aligned}
J_1 &= \sum_{e\in\mathcal{E}_h} (\{\mathcal{A}\nabla(w_I - w)\}, [\![\gamma(u-u_h)]\!])_e \\
&\le \sum_{e\in\mathcal{E}_h} |\{\mathcal{A}\nabla(w_I - w)\}|_{0,e} |[\![\gamma(u-u_h)]\!]|_{0,e} \\
&= \sum_{e\in\mathcal{E}_h} |\{\mathcal{A}\nabla(w_I - w)\}|_{0,e}\, h_e^{1/2} [\![\gamma(u-u_h)]\!]_e \\
&\le \sum_{e\in\mathcal{E}_h} h_e^{1/2} \left(h_e^{-1/2} |\{\mathcal{A}\nabla(w_I - w)\}|_T + h_e^{1/2} |\{\mathcal{A}\nabla(w_I - w)\}|_{1,T} \right) [\![\gamma(u-u_h)]\!]_e \\
&\le Ch||\mathcal{A}||_{0,\infty} \|u-u_h\| \, |||u-u_h|||,
\end{aligned}$$

where we have used (2.20) in the last inequality. The term J_2 can be handled similarly.

For the I_4 term first observe that, for any matrix-valued function $\mathcal{M}$ such that $\mathcal{M}$ is constant on each $e \in \mathcal{E}_h$,

$$\begin{aligned}
\sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{M}\nabla(u-u_h)\cdot\mathbf{n}(\gamma w_I - w_I)ds &= \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{M}\nabla u\cdot\mathbf{n}(\gamma w_I - w_I)ds \\
&\quad - \sum_{T\in\mathcal{T}_h} \int_{\partial T} \mathcal{M}\nabla u_h\cdot\mathbf{n}(\gamma w_I - w_I)ds \\
&= I_1 + I_2 = 0,
\end{aligned}$$

where $I_1 = 0$ due to $[\![\mathcal{M}\nabla u]\!] = 0$, and $[\![w_I - \gamma w_I]\!] = 0$ and $I_2 = 0$ due to the fact that $\mathcal{M}\nabla u_h \cdot \mathbf{n}$ is a constant on e and (1.5). Now define $\mathcal{M}$ so that on each $e \in \mathcal{E}_h$, $\mathcal{M} = \mathcal{A}(m)$, the value of $\mathcal{A}$ at the midpoint:

$$\begin{aligned}
|I_4| &= \left| \sum_{T\in\mathcal{T}_h} ((\mathcal{A}-\mathcal{M})\nabla(u-u_h)\cdot\mathbf{n}, \gamma w_I - w_I)_{\partial T} \right| \\
&\le Ch||A||_{1,\infty} \sum_{T\in\mathcal{T}_h} (|\nabla(u-u_h)\cdot\mathbf{n}|, |\gamma w_I - w_I|)_{\partial T} \\
&\le Ch||\mathcal{A}||_{1,\infty} |||u-u_h||| \, ||u-u_h||_0, \qquad (2.21)
\end{aligned}$$

where the last inequality was obtained via the trace inequality (2.20) as before.

Combining the above four estimates with (2.18), we obtain

$$\|u-u_h\| \le Ch(|||u-u_h||| + h\|f\|_1).$$

This completes the proof. □

The counterexamples in [15, 17] show that the assumption of $f \in H^1(\Omega)$ is necessary for finite volume methods.

3. Applications to finite volume and discontinuous finite volume methods. In this section, we will illustrate how our general theory can be applied to analyze different finite volume schemes.

3.1. Finite volume method with conforming trial functions. The finite volume discussed in this subsection is the classical finite volume method. For a given regular subdivision $\mathcal{T}_h$ of triangles, its dual partition $\mathcal{T}_h^*$ is the union of the convex hulls. These convex hulls in $\mathcal{T}_h^*$ are obtained by connecting the barycenters of the triangles and the midpoints of the edges of the triangles in $\mathcal{T}_h$ as shown in Figure 1.

The trial function space associated with $\mathcal{T}_h$ for the traditional finite volume method is defined as

$$V_h = \{v \in H_0^1(\Omega) : \ v|_T \in P_1(T) \ \forall T \in \mathcal{T}^h\},$$

with $V = H_0^1(\Omega)$ in (1.2). The test function space is defined as in (1.3).

Let $\mathcal{N}$ be a set containing all of the interior nodal points associated with the partition $\mathcal{T}^h$. The operator $\gamma : V(h) \to Q_h$ is defined by

$$\gamma v(x) \equiv \sum_{P \in \mathcal{N}} v(P)\chi_P(x) \quad \forall x \in \Omega, \tag{3.1}$$

where χ_P is the characteristic function of the dual element K_P^* associated with the node P. It can be easily verified that γ defined in (3.1) satisfies (1.4)–(1.7).

The traditional conforming finite volume method is to find $u_h \in V_h$ such that for any $v \in V_h$

$$a(u_h, v) = (f, \gamma v). \tag{3.2}$$

The bilinear form $A(v, w)$ in (2.5) reduces to $a(v, w)$ and

$$a(u, v) = -\sum_{K \in \mathcal{T}_h^*} \int_{\partial K} \mathcal{A}\nabla u \cdot \mathbf{n}\gamma v ds.$$

LEMMA 3.1. *For any $v, w \in V(h)$,*

$$\begin{aligned} a(v, w) = (\mathcal{A}\nabla v, \nabla w) &+ \sum_{T \in \mathcal{T}_h} \int_{\partial T} \mathcal{A}\nabla v \cdot \mathbf{n}(\gamma w - w) ds \\ &+ \sum_{T \in \mathcal{T}_h} (\nabla \cdot \mathcal{A}\nabla v, w - \gamma w)_T. \end{aligned} \tag{3.3}$$

Proof. Equation (3.3) appeared in [12, 15, 24], and for completeness we include a short proof here. For ease of proof, a typical primal triangle in Figure 1 is isolated and indexed as in Figure 3. For $j = 1, 2, 3$, let $\square_j$ denote the quadrilaterals formed by the four corner nodes Q, M_j, P_{j+1}, M_{j+1} as shown in Figure 3; when out of bound we use $M_4 = M_1$ and $P_4 = P_1$. Using the divergence theorem on each quadrilateral,

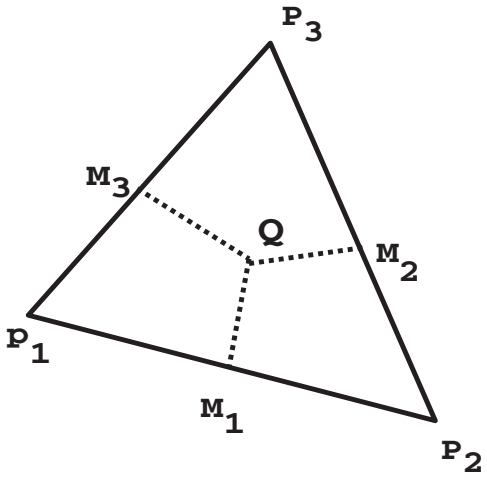

FIG. 3. *Partial primal and dual grids for integration.*

we have

$$
\begin{aligned}
a(v,w) &= -\sum_{T\in\mathcal{T}_h}\sum_{j=1}^{3}\int_{M_{j+1}QM_j}\mathcal{A}\nabla v\cdot\mathbf{n}\gamma w ds\\
&= \sum_{T\in\mathcal{T}_h}\sum_{j=1}^{3}\int_{M_jP_{j+1}M_{j+1}}\mathcal{A}\nabla v\cdot\mathbf{n}\gamma w ds - \sum_{T\in\mathcal{T}_h}\sum_{\square_j}(\nabla\cdot\mathcal{A}\nabla v,\gamma w)\\
&= \sum_{T\in\mathcal{T}_h}\sum_{j=1}^{3}\int_{M_jP_{j+1}M_{j+1}}\mathcal{A}\nabla v\cdot\mathbf{n}(\gamma w - w) ds + \sum_{T\in\mathcal{T}_h}\int_{\partial T} w\mathcal{A}\nabla v\cdot\mathbf{n} ds\\
&\quad - \sum_{T\in\mathcal{T}_h}\sum_{\square_j}(\nabla\cdot\mathcal{A}\nabla v,\gamma w)\\
&= \sum_{T\in\mathcal{T}_h}\int_{\partial T}\mathcal{A}\nabla v\cdot\mathbf{n}(\gamma w - w) ds + \sum_{T\in\mathcal{T}_h}(\mathcal{A}\nabla v,\nabla w)_T + \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla v, w)_T\\
&\quad - \sum_{T\in\mathcal{T}_h}\sum_{\square_j}(\nabla\cdot\mathcal{A}\nabla v,\gamma w)\\
&= (\mathcal{A}\nabla v,\nabla w) + \sum_{T\in\mathcal{T}_h}\int_{\partial T}\mathcal{A}\nabla v\cdot\mathbf{n}(\gamma w - w) ds + \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla v, w-\gamma w)_T. \qquad \square
\end{aligned}
$$

This lemma implies that Assumption 3 holds: The boundedness of $a(v,w)$ is straightforward. For the proof of coercivity (2.9) on V_h, notice the following. First of all, $|\!|\!| v |\!|\!| = |v|_{1,h}$, and so $C|\!|\!| v |\!|\!| \le (\mathcal{A}\nabla v,\nabla v)$ for all $v\in V_h$. The last two terms in the right side of (3.3) are the $O(h|v|_{1,h}^2)$ term when $v=w$. In fact, just as in estimating the I_4 term of (2.21), we have

$$
\sum_{T\in\mathcal{T}_h}\int_{\partial T}\mathcal{A}\nabla v\cdot\mathbf{n}(\gamma v - v) ds \le Ch\|A\|_{1,\infty}|v|_{1,h}^2
$$

and

$$\sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla v, v-\gamma v)_T = \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\cdot\nabla v, v-\gamma v)_T \le Ch\|A\|_{1,\infty}|v|_{1,h}^2, \tag{3.4}$$

where $\nabla\cdot\mathcal{A}$ is the vector obtained by applying the divergence rowwise. Thus for h small enough we have the coercivity. Note that this last term could be handled like (2.19), but this would require $\mathcal{A}$ to be in $W^{2,\infty}$, which is unnecessary.

Applying Theorems 2.1 and 2.2, we have the following results.

THEOREM 3.1. *If $u\in H_0^1(\Omega)\cap H^2(\Omega)$ and $f\in H^1(\Omega)$, then*

$$|||u-u_h||| \le Ch\|u\|_2,$$
$$\|u-u_h\| \le Ch^2(\|u\|_2+\|f\|_1),$$

where the L^2 estimate requires $\mathcal{A}\in W^{2,\infty}(\Omega)$.

The same conclusions hold for the conforming bilinear trial function case [9], and we omit the details.

3.2. Finite volume method with nonconforming trial functions. For a given regular triangulation $\mathcal{T}_h$, its dual partition $\mathcal{T}_h^*$ is the union of quadrilaterals. Each quadrilateral in $\mathcal{T}_h^*$ is made up of two subtriangles which share a common edge (see Figure 1). These subtriangles are formed by connecting the barycenter and the three corners of the triangles.

The trial function space associated with $\mathcal{T}_h$ for the nonconforming finite volume method is defined as

$$\begin{aligned} V_h = \{&v\in L^2(\Omega):\ v|_T\in P_1(T)\ \ \forall T\in\mathcal{T}_h,\\ &\text{is continuous at the midpoint of } e\in\mathcal{E}_h^0\\ &\text{and is zero at the midpoint of boundary edges } e \text{ on } \partial\Omega\}. \end{aligned}$$

The test function space is defined as in (1.3).

Let $\mathcal{M}$ be a set containing all of the midpoints of the interior edges associated with the triangulation $\mathcal{T}^h$. The operator $\gamma: V(h)\to Q_h$ is defined by

$$\gamma v(x) \equiv \sum_{P\in\mathcal{M}} v(P)\chi_P(x) \quad \forall x\in\Omega, \tag{3.5}$$

where χ_P is the characteristic function of dual element K_P^* associated with the node P. The mapping γ satisfies Assumptions 1 and 2 (see [8]). Finite volume methods using the above nonconforming trial functions were considered in [8, 6].

Our version [8] is to find $u_h\in V_h$ such that for any $v\in V_h$

$$a(u_h,v) = (f,\gamma v). \tag{3.6}$$

The bilinear form $A(v,w)$ in (2.5) reduces to $a(v,w)$ and

$$a(u,v) = -\sum_{K\in\mathcal{T}_h^*}\int_{\partial K}\mathcal{A}\nabla u\cdot\mathbf{n}\gamma v ds.$$

LEMMA 3.2. *For any $v,w\in V(h)$,*

$$\begin{aligned} a(v,w) = (\mathcal{A}\nabla_h v,\nabla_h w) &+ \sum_{T\in\mathcal{T}_h}\int_{\partial T}\mathcal{A}\nabla v\cdot\mathbf{n}(\gamma w - w)ds\\ &+ \sum_{T\in\mathcal{T}_h}(\nabla\cdot\mathcal{A}\nabla v, w-\gamma w)_T. \end{aligned}$$

Proof. See Lemma 3.2 in [24]. ∎

Using the above lemma, as before we can prove that (2.8) and (2.9) hold easily. Then we have the following estimates.

THEOREM 3.2. *If $u \in H_0^1(\Omega) \cap H^2(\Omega)$ and $f \in H^1(\Omega)$, then*

$$|||u - u_h||| \le Ch\|u\|_2$$
$$\|u - u_h\| \le Ch^2(\|u\|_2 + \|f\|_1),$$

where the L^2 estimate requires $\mathcal{A} \in W^{2,\infty}$.

The same conclusions hold for the finite volume method [10] using the rotated bilinear trial functions, i.e., the nonconforming Q_1 elements on rectangular grids [23]. We omit the details here.

3.3. Finite volume method with totally discontinuous trial functions. The finite volume method using totally discontinuous trial functions was first proposed in [24].

Let $\mathcal{T}_h$ be a quasiuniform triangulation of Ω. We define the dual partition $\mathcal{T}_h^*$ of $\mathcal{T}_h$ for the test function space as follows. We divide each $T \in \mathcal{T}_h$ into three triangles by connecting the barycenter and the three corners of the triangle as shown in Figure 2. Let $\mathcal{T}_h^*$ consist of all of these triangles T_j, $j = 1, 2, 3$.

We define the finite dimensional space associated with $\mathcal{T}_h$ for the trial functions as

$$V_h = \{v \in L^2(\Omega) : \ v|_T \in P_1(T) \ \forall T \in \mathcal{T}_h\}. \tag{3.7}$$

The test function space is defined as in (1.3). The operator $\gamma : V(h) \to Q_h$ is defined as

$$\gamma v|_T = \frac{1}{h_e}\int_e v|_T ds \quad \forall T \in \mathcal{T}_h, \tag{3.8}$$

where h_e is the length of the edge e. The operator γ satisfies (1.4)–(1.7) (see [25]).

The discontinuous finite volume method is to find $u_h \in V_h$ such that

$$A(u_h, v) = (f, \gamma v) \qquad \forall v \in V_h. \tag{3.9}$$

LEMMA 3.3. *For any $v, w \in V(h)$,*

$$a(v, w) = (\mathcal{A}\nabla_h v, \nabla_h w) + \sum_{T\in\mathcal{T}_h}\int_{\partial T} \mathcal{A}\nabla v \cdot \mathbf{n}(\gamma w - w)ds$$
$$+ \sum_{T\in\mathcal{T}_h} (\nabla \cdot \mathcal{A}\nabla v, w - \gamma w)_T. \tag{3.10}$$

Proof. See Lemma 2.1 in [25]. ∎

Using the above lemma, one can prove coercivity and boundedness.

LEMMA 3.4. *There is a constant C independent of h such that*

$$A(v, v) \ge C|||v|||^2 \qquad \forall v \in V_h \tag{3.11}$$

for any positive α if $\delta = 1$ and for α larger enough if $\delta = -1$.

Proof. See Lemma 2.2 in [25]. ∎

LEMMA 3.5. *For $v, w \in V(h)$, we have*

$$A(v,w) \le C|||v|||\,|||w|||. \tag{3.12}$$

Proof. See Lemma 2.3 in [25]. □

Since all of the conditions for Theorems 2.1 and 2.2 are satisfied, we have the following error estimates for the discontinuous finite volume method.

THEOREM 3.3. *If $u \in H_0^1(\Omega) \cap H^2(\Omega)$ and $f \in H^1(\Omega)$, then*

$$|||u - u_h||| \le Ch\|u\|_2,$$
$$\|u - u_h\| \le Ch^2(\|u\|_2 + \|f\|_1).$$

We point out that the above L^2 estimate was not obtained in [25].

THE RESIDUAL-FREE-BUBBLE FINITE ELEMENT METHOD ON ANISOTROPIC PARTITIONS*

ANDREA CANGIANI† AND ENDRE SÜLI‡

Abstract. The subject of this work is the analysis and implementation of stabilized finite element methods on anisotropic meshes. We develop the anisotropic a priori error analysis of the residual-free-bubble (RFB) method applied to elliptic convection-dominated convection-diffusion problems in two dimensions, with finite element spaces of type Q_k, $k \geq 1$. In the case of P_1 finite elements, relying on the equivalence of the RFB method to classical stabilized finite element methods, we propose a new rule, justified through the analysis of the RFB method, for selecting the stabilization parameter in classical stabilized methods on two-dimensional anisotropic triangulations.

Key words. residual-free-bubble finite element method, convection-dominated diffusion problems, stabilized finite element methods

1. Introduction.

Elliptic convection-diffusion problems arise in a vast number of applications, and their stable, accurate, and efficient solution is of significant theoretical and practical interest. From the computational point of view, problems of this kind become particularly challenging when convection dominates diffusion in the sense that the Péclet number, which measures the magnitude of the convective vector field over the length scale of the computational domain relative to the size of the diffusion coefficient, is large. Convection-dominated diffusion equations exhibit features which resemble those of the *reduced*, first-order hyperbolic equation arising from the second-order elliptic convection-diffusion equation on neglecting the diffusion term. For example, the solution may contain thin internal layers within the computational domain; also, due to the singular perturbation nature of an elliptic convection-dominated diffusion problem, the solution may exhibit thin boundary layers along sections of the boundary of the computational domain which correspond to the outflow part of the boundary for the reduced problem. As a result of this, on meshes which do not resolve internal and boundary layers, standard Galerkin finite element methods have poor stability and accuracy properties. The difficulties typically manifest themselves as large, maximum-principle-violating, oscillations in the numerical solution which occur predominantly along the characteristics of the reduced problem.

The situation may be remedied by using a classical stabilized finite element method (such as a streamline-diffusion method or a Galerkin least-squares method) or a residual-free-bubble (RFB) finite element method; we refer to the monograph [28] for an extensive survey of the literature. Due to the presence of anisotropic numerical dissipation terms in the direction of the characteristics of the reduced equation whose role is to suppress undesirable numerical oscillations, these methods are capable of delivering accurate numerical solutions even on shape-regular computational meshes

whose granularity is relatively coarse compared to the thickness of internal and boundary layers. Alternatively, motivated by the fact that internal and boundary layers are highly localized and anisotropic, one may choose to use a standard Galerkin finite element method, albeit on a stretched, anisotropic, or layer-adapted (and, certainly, non-shape-regular) computational mesh (see, for example, the discussion in [28] on Shishkin-type meshes).

In recent years, there have been attempts to employ these remedies simultaneously; see, for example, the work of Apel and Lube [3] and Micheletti, Perotto, and Picasso [25] concerning classical stabilized finite element methods on anisotropic meshes. The developments in the present article are in a similar spirit.

The objective of this paper is twofold. We aim to develop the a priori error analysis of the RFB method for two-dimensional elliptic convection-dominated diffusion equations on anisotropic partitions. Specifically, we aim to bound the error by appropriately weighted norms of directional derivatives of the solution, so as to incorporate the anisotropic nature of the solution into the bounds. On the one hand, our results complement the work in [3, 25] on the a priori error analysis of classical stabilized finite element methods over anisotropic meshes; on the other hand, they extend earlier results by Brezzi, Marini, and Süli [7], Brezzi and Marini [8], and Sangalli [29] on the a priori error analysis of RFB methods on shape-regular triangulations.

Anisotropy also has to be taken into account in the selection of parameters appearing in stabilized finite element methods, such as *streamline-diffusion-type* methods. The second key objective of the paper is to use the stabilizing term derived from the RFB method to redefine the mesh Péclet number and propose a new choice of the streamline-diffusion (SD) parameter that is suitable for use on anisotropic partitions. The proposed choice of the SD parameter improves earlier suggestions based on the a priori analysis of the streamline-diffusion method (cf. [3, 23, 25]).

The paper is structured as follows. The first part of this work is concerned with the analysis of stabilized finite element methods on anisotropic computational meshes: We consider the anisotropic a priori error analysis of the RFB method applied to elliptic convection-dominated convection-diffusion problems in two dimensions. In the second part of the paper, in the case of P_1 finite elements on triangular meshes, appealing to the equivalence of the RFB method to classical stabilized finite element methods, we propose a new rule, justified through the analysis of the RFB method, for selecting the stabilization parameter in classical stabilized methods on two-dimensional anisotropic triangulations; we then relate our work to existing developments on classical stabilized finite element methods on anisotropic meshes, including [3, 23, 25].

2. Statement of the problem. Let $\Omega \subset \mathbb{R}^2$ be a bounded open polygonal domain. We consider the model elliptic boundary-value problem

$$\left\{ \begin{array}{l} \text{find } u \in V = \mathrm{H}_0^1(\Omega) \text{ such that} \\ Lu := -\varepsilon \Delta u + \boldsymbol{a} \cdot \nabla u = f \qquad \text{in } \Omega, \end{array} \right. \tag{2.1}$$

where ε is a positive parameter, $\boldsymbol{a} \in [\mathrm{W}^{1,\infty}(\Omega)]^2$, with $\mathrm{div}(\boldsymbol{a}) \leq 0$ in Ω, and f belongs to $\mathrm{L}^2(\Omega)$. The homogeneous Dirichlet boundary condition $u|_{\partial\Omega} = 0$ has been assumed here only for ease of presentation. We normalize the problem by requiring that $\|\boldsymbol{a}\|_{\mathrm{L}^\infty(\Omega)} \leq 1$. Our focus of interest is the convection-dominated regime, namely, when $0 < \varepsilon \ll 1$; thus we assume, without loss of generality, that $\varepsilon \in (0, 1]$. The extension of the results of this paper to the, more general, convection-diffusion-reaction equation $-\varepsilon\Delta u + \mathbf{a} \cdot \nabla u + cu = f$ in Ω, subject to a homogeneous Dirichlet boundary

condition on $\partial\Omega$, is straightforward, provided that $\mathrm{div}(\mathbf{a}) - 2c \leq 0$ in Ω. Below, we shall briefly comment on the case when $\mathrm{div}(\mathbf{a}) - 2c \leq -2c_0$ in Ω, where c_0 is a positive constant.

The variational formulation of the boundary-value problem (2.1) is

$$\left\{ \begin{array}{l} \text{find } u \in V \text{ such that} \\ \mathcal{L}(u,v) = (f,v) \qquad \forall v \in V, \end{array} \right. \tag{2.2}$$

where

$$\mathcal{L}(w,v) := \varepsilon \int_\Omega \nabla w \cdot \nabla v \, \mathrm{d}\boldsymbol{x} + \int_\Omega (\boldsymbol{a} \cdot \nabla w)\, v \, \mathrm{d}\boldsymbol{x} \tag{2.3}$$

is a continuous and coercive bilinear form on $V \times V$ and $(\cdot,\cdot)$ denotes the L^2 inner product over Ω.

The existence and uniqueness of a solution to (2.2) (that is, of a weak solution to (2.1)) are well-known consequences of the Lax–Milgram lemma; for a more general existence and uniqueness result, see [19, Theorem 8.6].

We consider finite element discretizations of (2.2) over *conforming* partitions $\mathcal{T}_h$ of $\overline{\Omega}$ consisting of affine-equivalent quadrilateral or triangular elements. We shall not assume that the family of partitions $\{\mathcal{T}_h\}_{h>0}$ is *shape-regular*, because we wish to allow anisotropic local refinements in parts of the computational domain where special features of the exact solution, such as thin layers, are detected. Our only assumption will be the existence of a positive constant $c \leq 1$ such that

$$\varepsilon \leq c h_\gamma, \tag{2.4}$$

for all element edges γ in the partition; here h_γ represents the length of γ. This is a reasonable assumption when dealing with the analysis of stabilized finite element methods for convection-dominated diffusion problems such as our model problem, which exhibits boundary layers whose thickness is commensurate with $\varepsilon \ll 1$: For, if we could afford to solve the problem on meshes whose granularity is smaller than ε, then we would not need to use a stabilized method in the first place. Thus, our a priori error bounds, developed under the hypothesis (2.4), will be of a *preasymptotic* nature: Since the lower bound $\varepsilon \ll 1$ on ch_γ is fixed, we will *not* let h_γ tend to zero.

An optimal mesh (in terms of the number of degrees of freedom required to obtain a given accuracy) must mimic the behavior of the solution to (2.1). Such an optimal mesh would, in general, be designed through successive mesh refinements/derefinements. In early stages of the mesh adaptation process, the use of a stabilized finite element method is mandatory, since on coarse meshes classical Galerkin finite element approximations of (2.1) will exhibit large maximum-principle-violating numerical oscillations when $\varepsilon \ll 1$, hence the need for sharp preasymptotic error bounds for stabilized finite element methods. In later stages of the mesh refinement process, when the mesh has been adapted to the solution, the stabilized method could be simplified, for instance, by omitting the stabilization term, as was done in [10].

We denote by λ_1 and λ_2 some characteristic dimensions of a generic element $T \in \mathcal{T}_h$, to be defined on a case-by-case basis; λ_1 and λ_2 are used to group the elements according to the following rule (which defines the subpartitions $\mathcal{T}_1$ and $\mathcal{T}_2$):

1. $T \in \mathcal{T}_1$ if $\lambda_1 \leq \lambda_2$;
2. $T \in \mathcal{T}_2$ if $\lambda_2 < \lambda_1$.

An admissible structured mesh and its subpartitions are shown in Figure 2.1.

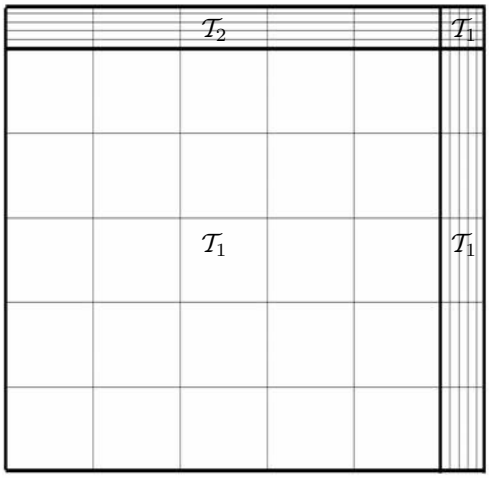

FIG. 2.1. *A locally anisotropic partition and its subpartitions $\mathcal{T}_1$ and $\mathcal{T}_2$.*

Given $k \geq 1$, let $\mathcal{P}_k$ denote the space of algebraic polynomials of degree $\leq k$, and let $\mathcal{Q}_k$ denote the space of algebraic polynomials of degree $\leq k$ with respect to each variable. Further, let $F_T : \widehat{T} \to T$ be the affine transformation mapping the reference element onto $T \in \mathcal{T}_h$.

The *residual-free-bubble* space is defined as follows (see [7]):

$$V_{\mathrm{RFB}} := \left\{ v \in V : v_{|_e} \in \mathcal{P}_k \text{ for each edge } e \text{ of } T \text{ and any element } T \in \mathcal{T}_h \right\}. \tag{2.5}$$

We note that the space V_{RFB} is infinite-dimensional, admitting the representation

$$V_{\mathrm{RFB}} = V_h^k + B_h, \tag{2.6}$$

where V_h^k is the classical finite element space given by

$$V_h^k := \left\{ v_h \in \mathrm{H}_0^1(\Omega) : \left\{ \begin{array}{ll} v_{h|_T} \in \mathcal{P}_k & \text{if } T \text{ is a triangle} \\ v_{h|_T} \circ F_T \in \mathcal{Q}_k & \text{if } T \text{ is a parallelogram} \end{array} \right. \right\},$$

and

$$B_h := \bigoplus_{T \in \mathcal{T}_h} \mathrm{H}_0^1(T) \tag{2.7}$$

is the space of all *bubble functions* in V; i.e., all function with zero trace on the skeleton of the partition $\mathcal{T}_h$.

The RFB approximation of (2.2) is defined as the Galerkin approximation of (2.2) in the space V_{RFB}:

$$\left\{ \begin{array}{l} \text{find } u_{\mathrm{RFB}} \in V_{\mathrm{RFB}} \text{ such that} \\ \mathcal{L}(u_{\mathrm{RFB}}, v) = (f, v) \qquad \forall v \in V_{\mathrm{RFB}}. \end{array} \right. \tag{2.8}$$

Since V_{RFB} is infinite-dimensional, the formulation (2.8) does not represent a numerical method in the classical sense. In fact, a numerical algorithm can be devised from (2.8) through *static condensation* of the bubble component u_b of the solution u_{RFB},

which belongs to the infinite-dimensional space B_h, and then discretizing the resulting infinite-dimensional problem over the finite-dimensional space V_h^k. For instance, if $k \leq 2$, the sum in (2.7) is direct, and hence we then have the following unique decomposition of the RFB solution:

$$u_{\mathrm{RFB}} = u_h + u_b.$$

Consequently, by testing in V_h^k and then in B_h, we can split (2.8) into the following two problems:

$$\mathcal{L}(u_h, v_h) + \mathcal{L}(u_b, v_h) = (f, v_h) \qquad \forall v_h \in V_h^k, \tag{2.9}$$

$$\mathcal{L}(u_h, v_b) + \mathcal{L}(u_b, v_b) = (f, v_b) \qquad \forall v_b \in B_h. \tag{2.10}$$

Equation (2.10) is referred to as a *bubble equation* as it is equivalent to solving, in each element $T \in \mathcal{T}_h$, the boundary-value problem

$$\begin{cases} Lu_b = f - Lu_h & \text{in } T, \\ u_b = 0 & \text{on } \partial T \end{cases} \tag{2.11}$$

for the "fine-scale" bubble component u_b of the approximate solution u_{RFB} in terms of the "coarse-scale" piecewise polynomial component u_h of u_{RFB}. The static condensation procedure corresponds to eliminating u_b from (2.9) in favor of u_h using (2.11). This can be done by numerically solving a finite number of independent local problems such as (2.11); this then leads to a (fully discrete) numerical algorithm. An instance of such a procedure is discussed in section 6 of this paper. For further details, we refer the reader to [9, 7].

The general a priori error analysis of the RFB method on shape-regular partitions is due to Brezzi, Marini, and Süli [7]; it was shown there that if $u \in \mathrm{H}^{k+1}(\Omega)$, then the numerical solution u_{RFB} delivered by the RFB method satisfies the following optimal asymptotic error bound in the energy norm:

$$\varepsilon^{1/2}|u - u_{\mathrm{RFB}}|_{1,\Omega} \leq Ch^{k+1/2}\|u\|_{\mathrm{H}^{k+1}(\Omega)}, \tag{2.12}$$

where h represents the characteristic size of the partition.

The technique used here to extend the a priori error analysis of the RFB method to anisotropic partitions is different from the one employed in [7]. Instead, we follow the approach adopted by Sangalli [29] to subsequently rederive and localize the results presented in [7]. The key idea of Sangalli's approach, and of the analysis below, is to exploit the approximation properties of the space V_{RFB}. To do so, Sangalli explicitly constructs a projector from H^1 onto the RFB space in a certain ε-weighted H^1 norm. A similar approach is followed by Risch in [27].

A second key ingredient of our analysis is the use of anisotropic approximation results. These must be employed in order to derive an a priori error bound in terms of appropriately weighted norms of directional derivatives of the exact solution u.

3. Structured quadrilateral partitions. We begin with the case of axiparallel rectangular elements, leaving the treatment of more general partitions to subsequent sections.

In this case it is natural to define $\lambda_1 = h_1$ and $\lambda_2 = h_2$, where h_1 and h_2 denote the dimensions of the generic element $T \in \mathcal{T}$ in the x_1 and x_2 coordinate directions, respectively.

3.1. Notations and preliminary results. Let $\widehat{T} = (-1,1)^2$ be the master element. Given a function $v \in \mathrm{H}^1(T)$, we consider $\hat{v} \in \mathrm{H}^1(\widehat{T})$, the function associated to v through the affine transformation F_T which maps $\widehat{T}$ into T; hence $\hat{v} := v \circ F_T$. Further, we denote by $i^* = 3 - i$ the complementary index to i with respect to the set $\{1,2\}$.

Since T is a rectangle, the usual scaling properties for functions $v \in \mathrm{H}^1(T)$ yield

$$\|v\|_{0,T}^2 = \frac{1}{4} h_1 h_2 \|\hat{v}\|_{0,\widehat{T}}^2, \tag{3.1}$$

$$\left\| \frac{\partial v}{\partial x_i} \right\|_{0,T}^2 = \frac{h_{i^*}}{h_i} \left\| \frac{\partial \hat{v}}{\partial \widehat{x}_i} \right\|_{0,\widehat{T}}^2, \qquad i \in \{1,2\}. \tag{3.2}$$

We will also need some scaling properties for functions defined over edges of the elements $T \in \mathcal{T}_h$. The trace of a function belonging to the space $\mathrm{H}^1(T) = \mathrm{W}^{1,2}(T)$ and, more generally, to the Sobolev space $\mathrm{W}^{1,p}(T)$, $1 \le p < \infty$, is characterized in terms of the *fractional-order* Sobolev space $\mathrm{W}^{1-1/p,p}(\partial T)$, which, for $p > 1$, can be defined using the real method of function space interpolation; see, e.g., Adams [1].

The space $\mathrm{W}^{s,p}(\partial T)$, $0 < s < 1$, can also be characterized in terms of an intrinsically defined norm. For instance, for every $s \in (0,1)$, the norm $\|\cdot\|_{s,\partial T}$ and seminorm $|\cdot|_{s,\partial T}$ of the Sobolev space $\mathrm{H}^s(\partial T) = \mathrm{W}^{s,2}(\partial T)$ of fractional order s are defined by

$$\begin{aligned} \|v\|_{s,\partial T} &:= \left\{ \|v\|_{0,\partial T}^2 + \int_{\partial T} \int_{\partial T} \frac{|v(\boldsymbol{x}) - v(\boldsymbol{y})|^2}{|\boldsymbol{x} - \boldsymbol{y}|^{1+2s}} \, \mathrm{d}\sigma(\boldsymbol{x}) \, \mathrm{d}\sigma(\boldsymbol{y}) \right\}^{1/2} \\ &= \left\{ \|v\|_{0,\partial T}^2 + |v|_{s,\partial T}^2 \right\}^{1/2}, \end{aligned} \tag{3.3}$$

where $\mathrm{d}\sigma$ denotes the one-dimensional Hausdorff measure of ∂T. This definition can be extended to portions of ∂T.

The trace theorem (again, see [1]) ensures that the trace of a function $v \in \mathrm{H}^s(T)$ belongs to $\mathrm{H}^{s-1/2}(\partial T)$, $s \in (1/2, 1]$, and that there exists a constant C, independent of v, such that

$$\|v\|_{s-1/2,\partial T} \le C \|v\|_{s,T} \qquad \forall v \in \mathrm{H}^s(T). \tag{3.4}$$

Let γ be an edge of $T \in \mathcal{T}_h$ and $\widehat{\gamma} = F_T^{-1}(\gamma)$ the corresponding edge of $\widehat{T}$. Scaling the Sobolev seminorm $|\cdot|_{s,\gamma}$, $0 \le s \le 1$, from $\widehat{\gamma}$ to γ, we have

$$|v|_{s,\gamma}^2 = \left(\frac{h_\gamma}{2} \right)^{1-2s} |\hat{v}|_{s,\widehat{\gamma}}^2 \qquad \forall v \in \mathrm{H}^s(\gamma), \tag{3.5}$$

where, as before, $h_\gamma = |\gamma|$. The scaling property (3.5) will be used to prove the following anisotropic trace inequalities which are refinements of the usual ones valid for axiparallel domains.

LEMMA 3.1. *Let $v \in \mathrm{H}^1(T)$, where T is an axiparallel rectangle in $\mathbb{R}^2$, and let γ_i be an edge of T parallel to the ith coordinate axis, with $h_i = |\gamma_i|$, $i = 1,2$. The following trace inequalities hold:*

$$\|v\|_{0,\gamma_i}^2 \le \frac{1}{h_{i^*}} \|v\|_{0,T}^2 + 2 \|v\|_{0,T} \|v_{x_{i^*}}\|_{0,T}, \qquad i = 1,2; \tag{3.6}$$

$$|v|_{1/2,\partial T}^2 \le C \left(\frac{1}{h_1 h_2} \|v\|_{0,T}^2 + \frac{h_1}{h_2} \|v_{x_1}\|_{0,T}^2 + \frac{h_2}{h_1} \|v_{x_2}\|_{0,T}^2 \right), \tag{3.7}$$

where the constant C is independent of h_1 and h_2.

Proof. The proof of (3.6) can be found, for instance, in [17]. To prove (3.7), we apply (3.5) with $s = 1/2$ to scale from ∂T to $\partial\widehat{T}$ and the trace inequality (3.4) to shift from $\partial\widehat{T}$ to $\widehat{T}$, and, finally, we use (3.1) and (3.2) to scale back from $\widehat{T}$ to T:

$$\begin{aligned}|v|^2_{1/2,\partial T} &= |\hat{v}|^2_{1/2,\partial\widehat{T}} \leq \|\hat{v}\|^2_{1/2,\partial\widehat{T}} \leq C\,\|\hat{v}\|^2_{1,\widehat{T}}\\ &= C\left(\|\hat{v}\|^2_{0,\widehat{T}} + \|\hat{v}_{x_1}\|^2_{0,\widehat{T}} + \|\hat{v}_{x_2}\|^2_{0,\widehat{T}}\right)\\ &= C\left(\frac{1}{h_1h_2}\,\|v\|^2_{0,T} + \frac{h_1}{h_2}\,\|v_{x_1}\|^2_{0,T} + \frac{h_2}{h_1}\,\|v_{x_2}\|^2_{0,T}\right)\end{aligned}$$

and hence the desired result for any $v \in \mathrm{H}^1(T)$. ∎

We shall also require the following trace-lifting lemma (see, e.g., Sangalli [29]).

LEMMA 3.2. *Given a function $\hat{w}_0 \in \mathrm{H}^{1/2}(\partial\widehat{T})$ and a real parameter t, with $0 < t \leq 1$, there exists $\hat{w} \in \mathrm{H}^1(\widehat{T})$ such that $\hat{w} = \hat{w}_0$ on $\partial\widehat{T}$ and*

$$t\,|\hat{w}|^2_{1,\widehat{T}} + t^{-1}\,\|\hat{w}\|^2_{0,\widehat{T}} \leq C\left(t\,|\hat{w}_0|^2_{1/2,\partial\widehat{T}} + \|\hat{w}_0\|^2_{0,\partial\widehat{T}}\right), \tag{3.8}$$

where the constant C is independent of t and $\hat{w}_0$.

3.2. The projection error. Let us consider the function space $\mathrm{H}^{r_1,r_2}(T)$ of dominant mixed smoothness, defined by

$$\mathrm{H}^{r_1,r_2}(T) := \left\{v \in \mathrm{L}^2(T) : D^{r_1}_{x_1}v,\ D^{r_2}_{x_2}v,\ D^{r_1}_{x_1}D^{r_2}_{x_2} \in \mathrm{L}^2(T)\right\}.$$

It is known that if $r_i > 1/2$, $i = 1, 2$, then $\mathrm{H}^{r_1,r_2}(T)$ is continuously embedded into the space $\mathrm{C}(\overline{T})$ of uniformly continuous functions on $\overline{T}$ (see, for example, [32, Chapter 2, Theorem 2.2.3]). Trivially, $\mathrm{H}^{r+1}(T)$ is continuously embedded into $\mathrm{H}^{1,1}(T)$ for any $r \geq 1$.

We begin by introducing a suitable interpolant from $\mathcal{Q}_k$ of a generic function in $\mathrm{H}^{1,1}(T)$— the tensor-product H^1-projection operator Π_k, as has been defined in [17] (see also [31, 18]), by means of truncated Legendre expansions.

DEFINITION 3.3. *Let L_n denote the Legendre polynomial of degree n on the open interval $I = (-1, 1)$. We define the* L^2-projection operator

$$\tilde{\pi}_k : \mathrm{L}^2(I) \to \mathcal{P}_k(I)$$

by

$$\tilde{\pi}_k v(x) := \sum_{n=0}^{k} a_n L_n(x),$$

where

$$a_n := \frac{2n+1}{2}\int_I v(x)L_n(x)\,\mathrm{d}x.$$

Further, we define the H^1-projection operator

$$\hat{\pi}_k : \mathrm{H}^1(I) \to \mathcal{P}_k(I)$$

by setting, for any $v \in \mathrm{H}^1(I)$,

$$\hat{\pi}_k v(x) := \int_{-1}^{x} \tilde{\pi}_{k-1}(v')(\eta)\,\mathrm{d}\eta + v(-1), \qquad x \in (-1, 1).$$

A convenient feature of the above definition is that it can be easily extended to the multidimensional setting by means of a tensor-product construction; this is achieved at the cost of assuming additional regularity (viz. assuming $\mathrm{H}^{1,1}$-regularity instead of H^1-regularity).

DEFINITION 3.4. *Let $\widehat{T} = (-1,1)^2$. We define the* tensor-product projection operator

$$\widehat{\Pi}_k : \mathrm{H}^{1,1}(\widehat{T}) \to \mathcal{Q}_k(\widehat{T})$$

by

$$\widehat{\Pi}_k := \hat{\pi}_k^{x_1} \circ \hat{\pi}_k^{x_2},$$

where $\hat{\pi}_k^{x_1}$, $\hat{\pi}_k^{x_2}$ denote the one-dimensional H^1-projection operators from Definition 3.3, and the superscripts x_i, $i = 1, 2$, indicate the directions in which the one-dimensional projections are applied.

The above definition is easily extended to a generic axiparallel rectangle T as follows.

DEFINITION 3.5. *Let $T \in \mathcal{T}_h$. We define the* tensor-product projection operator

$$\Pi_k : \mathrm{H}^{1,1}(T) \to \mathcal{Q}_k(T)$$

by setting, for any $v \in \mathrm{H}^{1,1}(T)$,

$$\Pi_k v := \widehat{\Pi}_k \hat{v} \circ F_T^{-1}.$$

By virtue of being of tensor-product type, the projection Π_k admits anisotropic error bounds. As a matter of fact, it is better-behaved than the L^2-projection operator when bounds on the derivatives of the interpolation error are needed. The relevant approximation properties of Π_k are summarized in the next lemma.

LEMMA 3.6. *Suppose that T is an axiparallel rectangle and $v \in \mathrm{H}^{r+1}(T)$, with $1 \le r \le k$—and thereby $v \in \mathrm{H}^{1,1}(T)$. Then, for any s with $0 \le s \le r$, the following error bound holds:*

$$\|v - \Pi_k v\|_{0,T}^2 \le \Phi_2(k,s) \left(\left(\frac{h_1}{2}\right)^{2s+2} \|\partial_{x_1}^{s+1} v\|_{0,T}^2 + \left(\frac{h_2}{2}\right)^{2s+2} \|\partial_{x_2}^{s+1} v\|_{0,T}^2 \right) + \Phi_2(k,s-1) \min_{\substack{i,\, j \,=\, 1,\, 2 \\ i \,\neq\, j}} \left(\frac{h_i}{2}\right)^2 \left(\frac{h_j}{2}\right)^{2s} \|\partial_{x_j}^s \partial_{x_i} v\|_{0,T}^2,$$

and, for any $i = 1, 2$,

$$\|\partial_{x_i}(v - \Pi_k v)\|_{0,T}^2 \le \Phi_1(k,s) \left(\frac{h_i}{2}\right)^{2s} \|\partial_{x_i}^{s+1} v\|_{0,T}^2 + \Phi_2(k,s-1) \left(\frac{h_{i^*}}{2}\right)^{2s} \|\partial_{x_{i^*}}^s \partial_{x_i} v\|_{0,T}^2,$$

where

$$\Phi_1(k,s) := \left(\frac{\Gamma(k-s+1)}{\Gamma(k+s+1)}\right)^{1/2}, \qquad \Phi_2(k,s) := \frac{\Phi_1(k,s)}{\sqrt{k(k+1)}},$$

and Γ is the Gamma function.

The proof of the interpolation error bounds stated in the above lemma has been given by Georgoulis in [17] (see also [18]), where such results are presented in a much more general setting.

Remark. Interpolation error bounds similar to those in Lemma 3.6 are provided, although for a different interpolation operator, by Apel [2, Theorem 2.7]. These, too, are limited to rectangular elements and are obtained as improvements of the general but slightly less sharp bounds presented in earlier sections of [2]; see also section 4 (especially Theorem 4.10) in the recent work of Georgoulis, Hall, and Houston [16] concerning interpolation results on anisotropic nonaxiparallel meshes. For a recent survey of anisotropic mesh adaptivity and anisotropic interpolation error estimates, particularly on triangular meshes, we refer to the work of Huang [21].

3.3. Error bound. Suppose that the bounded polygonal domain $\Omega \subset \mathbb{R}^2$ is a finite union of axiparallel rectangles. We begin the error analysis with the construction of a suitable projector $P : \mathrm{H}^1_0(\Omega) \cap \mathrm{H}^2(\Omega) \to V_{\mathrm{RFB}}$, whose definition is based on the $\mathrm{H}^{1,1}$-projection operator Π_k described above and the trace-lifting lemma, Lemma 3.2.

Given $\hat{v} \in \mathrm{H}^{1,1}(\widehat{T}) \subset \mathrm{H}^1(\widehat{T})$, let $\hat{w} \in \mathrm{H}^1(\widehat{T})$ be the function obtained by applying Lemma 3.2 with

$$\hat{w}_0 = (\hat{v} - \widehat{\Pi}_k \hat{v})_{|_{\partial \widehat{T}}}, \qquad t = \frac{\varepsilon}{h_i}.$$

We note that $t \leq 1$ due to assumption (2.4). We define $P_{\widehat{T}} \hat{v} \in \mathrm{H}^1(\hat{T})$ by

$$P_{\widehat{T}} \hat{v} := \hat{v} - \hat{w}, \tag{3.9}$$

and let $P_T v = P_{\widehat{T}} \hat{v} \circ F_T^{-1}$. Finally, for $v \in \mathrm{H}^1_0(\Omega) \cap \mathrm{H}^2(\Omega)$, we define $Pv \in \mathrm{H}^1_0(\Omega)$ elementwise by $(Pv)|_T = P_T(v|_T)$, $T \in \mathcal{T}_h$; recall that $v|_T \in \mathrm{H}^2(T) \subset \mathrm{H}^{1,1}(T)$, so this definition is meaningful. It is clear from this construction that, for every element $T \in \mathcal{T}_h$, $P_T : \mathrm{H}^{1,1}(T) \to V_{\mathrm{RFB}}|_T$, and $P : \mathrm{H}^1_0(\Omega) \cap \mathrm{H}^2(\Omega) \to V_{\mathrm{RFB}}$.

The main task in the a priori error analysis is to bound the quantity $\mathcal{E}^P_T(v)$ defined for $v \in \mathrm{H}^{1,1}(T)$ by

$$\mathcal{E}^P_T(v) := \varepsilon |v - P_T v|^2_{1,T} + \varepsilon^{-1} \|v - P_T v\|^2_{0,T}. \tag{3.10}$$

To this end, let us assume that $T \in \mathcal{T}_i$, with $i \in \{1, 2\}$. Using (3.1) and (3.2), and noting that for $T \in \mathcal{T}_i$ we have $h_i \leq h_{i^*}$, it follows that

$$\begin{aligned} \mathcal{E}^P_T(v) &= \varepsilon \frac{h_i}{h_{i^*}} \|(\hat{v} - P_{\widehat{T}} \hat{v})_{\hat{x}_{i^*}}\|^2_{0,\widehat{T}} + \varepsilon \frac{h_{i^*}}{h_i} \|(\hat{v} - P_{\widehat{T}} \hat{v})_{\hat{x}_i}\|^2_{0,\widehat{T}} + \frac{\varepsilon^{-1} h_{i^*} h_i}{4} \|\hat{v} - P_{\widehat{T}} \hat{v}\|^2_{0,\widehat{T}} \\ &\leq C h_{i^*} \left(\frac{\varepsilon}{h_i} |\hat{v} - P_{\widehat{T}} \hat{v}|^2_{1,\widehat{T}} + \left(\frac{\varepsilon}{h_i} \right)^{-1} \|\hat{v} - P_{\widehat{T}} \hat{v}\|^2_{0,\widehat{T}} \right). \end{aligned} \tag{3.11}$$

Hence, by applying (3.8) in (3.11) with $\hat{w} = \hat{v} - P_{\widehat{T}} \hat{v}$, we have

$$\mathcal{E}^P_T(v) \leq C \left(\varepsilon \frac{h_{i^*}}{h_i} |\hat{v} - \widehat{\Pi}_k \hat{v}|^2_{1/2,\partial\widehat{T}} + h_{i^*} \|\hat{v} - \widehat{\Pi}_k \hat{v}\|^2_{0,\partial\widehat{T}} \right). \tag{3.12}$$

We are now in a position to prove the following result which justifies our choice of the projector P.

LEMMA 3.7. *Let $T \in \mathcal{T}$ and $v \in \mathrm{H}^{r+1}(T)$, with $1 \le r \le k$, and consider the quantity $\mathcal{E}_T^P(v)$ defined by* (3.10). *If $T \in \mathcal{T}_i$, $i \in \{1,2\}$, then*

$$\begin{aligned}\mathcal{E}_T^P(v) \le & \frac{C}{2^{2r+1}}\left(\Phi_{12}(k,r)\left(h_i^{2r+1}\|\partial_{x_i}^{r+1}v\|_{0,T}^2 + \frac{h_{i^*}^{2r+2}}{h_i}\|\partial_{x_{i^*}}^{r+1}v\|_{0,T}^2\right)\right.\\ &\left. + \frac{5}{2}\Phi_2(k,r-1)\left(h_i^{2r-1}h_{i^*}^2\|\partial_{x_i}^r\partial_{x_{i^*}}v\|_{0,T}^2 + h_ih_{i^*}^{2r}\|\partial_{x_i}\partial_{x_{i^*}}^r v\|_{0,T}^2\right)\right),\end{aligned} \tag{3.13}$$

where $\Phi_{12}(k,r) := 2\Phi_1(k,r) + \Phi_2(k,r)/2$.

Proof. Assume that $T \in \mathcal{T}_i$, $i \in \{1,2\}$, and let $\partial_{x_i}T$ and $\partial_{x_{i^*}}T$ be the collection of the edges of T parallel to the x_i and x_{i^*} coordinate directions, respectively. From (3.12), upon returning to ∂T using (3.5) and applying the trace inequalities of Lemma 3.1, we have

$$\begin{aligned}\mathcal{E}_T^P(v) &\le C\left(\varepsilon\frac{h_{i^*}}{h_i}|v-\Pi_k v|_{1/2,\partial T}^2 + 4\|v-\Pi_k v\|_{0,\partial_{x_{i^*}}T}^2 + 4\frac{h_{i^*}}{h_i}\|v-\Pi_k v\|_{0,\partial_{x_i}T}^2\right)\\ &\le C\left(\left(\frac{\varepsilon}{h_i^2}+\frac{1}{h_i}\right)\|v-\Pi_k v\|_{0,T}^2 + \varepsilon\frac{h_{i^*}^2}{h_i^2}\|(v-\Pi_k v)_{x_{i^*}}\|_{0,T}^2 + \varepsilon\|(v-\Pi_k v)_{x_i}\|_{0,T}^2\right.\\ &\quad\left. + \frac{h_{i^*}}{h_i}\|v-\Pi_k v\|_{0,T}\|(v-\Pi_k v)_{x_{i^*}}\|_{0,T} + \|v-\Pi_k v\|_{0,T}\|(v-\Pi_k v)_{x_i}\|_{0,T}\right)\\ &\le C\left(\left(\frac{\varepsilon}{h_i^2}+\frac{1}{h_i}\right)\|v-\Pi_k v\|_{0,T}^2\right.\\ &\quad\left. + \left(\varepsilon\frac{h_{i^*}^2}{h_i^2}+\frac{h_{i^*}^2}{h_i}\right)\|(v-\Pi_k v)_{x_{i^*}}\|_{0,T}^2 + (\varepsilon+h_i)\|(v-\Pi_k v)_{x_i}\|_{0,T}^2\right).\end{aligned}$$

With assumption (2.4) this bound may be written

$$\mathcal{E}_T^P(v) \le C\left(\frac{1}{h_i}\|v-\Pi_k v\|_{0,T}^2 + \frac{h_{i^*}^2}{h_i}\|(v-\Pi_k v)_{x_{i^*}}\|_{0,T}^2 + h_i\|(v-\Pi_k v)_{x_i}\|_{0,T}^2\right).$$

Thus, we have bounded $\mathcal{E}_T^P(v)$ in terms of the H^1-projection error. The required bound (3.13) follows by applying the projection error bounds from Lemma 3.6. ∎

We are ready to prove the following a priori error bound for the RFB method in the energy norm $\varepsilon^{1/2}|\cdot|_{1,\Omega}$.

THEOREM 3.8. *Let $u \in V$ be the solution of* (2.2) *and $u_{\mathrm{RFB}} \in V_{\mathrm{RFB}}$ the RFB solution defined by* (2.8). *Assume that the partition $\mathcal{T}_h$ consists of axiparallel rectangles and that there exists a constant $c \in (0,1]$ such that, for any $T \in \mathcal{T}_h$, $\varepsilon \le c\min\{h_1,h_2\}$. Finally, let $\mathcal{T}_1$ be the subpartition given by all $T \in \mathcal{T}_h$ such that $h_1 \le h_2$, and let $\mathcal{T}_2 := \mathcal{T}_h \setminus \mathcal{T}_1$.*

If $u \in \mathrm{H}_0^1(\Omega) \cap \mathrm{H}^{k+1}(\Omega)$, then there exists a positive constant C, independent of ε, k and of the mesh dimensions, such that for any $1 \le r \le k$

$$\begin{aligned}\varepsilon^{1/2}|u-u_{\mathrm{RFB}}|_{1,\Omega} \le C\frac{\bar{\Phi}(k,r)}{2^{r+1/2}}\sum_{i=1}^{2}\left(\sum_{T\in\mathcal{T}_i}\left(h_i^{2r+1}\|\partial_{x_i}^{r+1}u\|_{0,T}^2 + \frac{h_{i^*}^{2r+2}}{h_i}\|\partial_{x_{i^*}}^{r+1}u\|_{0,T}^2\right.\right.\\ \left.\left. + h_ih_{i^*}^{2r}\|\partial_{x_i}\partial_{x_{i^*}}^r u\|_{0,T}^2 + h_i^{2r-1}h_{i^*}^2\|\partial_{x_i}^r\partial_{x_{i^*}}u\|_{0,T}^2\right)\right)^{1/2},\end{aligned} \tag{3.14}$$

where $\bar{\Phi}(r,k) := \max\{\Phi_{12}(k,r), \frac{5}{2}\Phi_2(k,r-1)\}$. *The constant* C *depends only on the constant in the trace inequality* (3.7) *and on the constant in Lemma* 3.2.

Proof. We consider the decomposition

$$u - u_{\mathrm{RFB}} = (u - Pu) + (Pu - u_{\mathrm{RFB}}),$$

where P is the approximation operator described in the previous section. By employing the coercivity of $\mathcal{L}$ and the Galerkin orthogonality property, on recalling that $Pu \in V_{\mathrm{RFB}}$, we have that

$$\begin{aligned}\varepsilon|u - u_{\mathrm{RFB}}|^2_{1,\Omega} &\le \mathcal{L}(u - u_{\mathrm{RFB}}, u - u_{\mathrm{RFB}})\\ &= \mathcal{L}(u - u_{\mathrm{RFB}}, u - Pu).\end{aligned}$$

Thus, on applying the Cauchy–Schwarz inequality to $\mathcal{L}(u-u_{\mathrm{RFB}}, u-Pu)$ after rewriting it explicitly using the definition of the bilinear form (2.3), we get

$$\begin{aligned}\varepsilon|u - u_{\mathrm{RFB}}|^2_{1,\Omega} &\le \sum_{T\in\mathcal{T}_h}\left(\varepsilon\int_T \nabla(u - u_{\mathrm{RFB}})\cdot\nabla(u - P_T u)\ \mathrm{d}\boldsymbol{x}\right.\\ &\qquad\left. + \int_T \boldsymbol{a}\cdot\nabla(u - u_{\mathrm{RFB}})(u - P_T u)\ \mathrm{d}\boldsymbol{x}\right)\\ &\le \sum_{T\in\mathcal{T}_h}\left(\varepsilon^{1/2}|u - u_{\mathrm{RFB}}|_{1,T}\right)\left(\varepsilon^{1/2}|u - P_T u|_{1,T} + \varepsilon^{-1/2}\|u - P_T u\|_{0,T}\right)\\ &\le \varepsilon^{1/2}|u - u_{\mathrm{RFB}}|_{1,\Omega}\left(\sum_{T\in\mathcal{T}_h}\left(\varepsilon^{1/2}|u - P_T u|_{1,T} + \varepsilon^{-1/2}\|u - P_T u\|_{0,T}\right)^2\right)^{1/2}.\end{aligned}$$

Next, we split the sum on the right-hand side between the subpartitions $\mathcal{T}_1$ and $\mathcal{T}_2$ to obtain

$$\varepsilon^{1/2}|u - u_{\mathrm{RFB}}|_{1,\Omega} \le C\sum_{i=1,2}\left(\sum_{T\in\mathcal{T}_i}\mathcal{E}_T^P(u)\right)^{1/2},$$

with $\mathcal{E}_T^P(u)$ as in (3.10). The required bound now follows from (3.13). ∎

Remark. When the problem (2.1) is strongly convection-dominated, the solution is highly anisotropic locally. For this reason it is crucial that the error is bounded by appropriately weighted norms of directional derivatives of the solution, as in our error bound (3.14). We also observe that, if the partition is shape-regular, our error bound collapses to the isotropic error estimate (2.12).

We conclude the section with a remark on the extension of the above bound to the case when, in addition to diffusion and convection terms, the equation also contains a reaction term. Suppose therefore that $-\varepsilon\Delta u + \mathbf{a}\cdot\nabla u + cu = f$ in Ω, subject to $u = 0$ on $\partial\Omega$, with $2c - \mathrm{div}(\mathbf{a}) \le -2c_0$ in Ω, where c_0 is a positive constant. Arguing similarly as in the proof above, we then obtain

$$
\begin{aligned}
&\varepsilon|u-u_{\mathrm{RFB}}|_{1,\Omega}^2+c_0\|u-u_{\mathrm{RFB}}\|_{0,\Omega}^2\\
&\quad\le \varepsilon^{1/2}|u-u_{\mathrm{RFB}}|_{1,\Omega}\left(\sum_{T\in\mathcal{T}_h}\left(\varepsilon^{1/2}|u-P_Tu|_{1,T}+\varepsilon^{-1/2}\|u-P_Tu\|_{0,T}\right)^2\right)^{1/2}\\
&\qquad+\|c\|_{\mathrm{L}^\infty(\Omega)}\|u-u_{\mathrm{RFB}}\|_{0,\Omega}\left(\sum_{T\in\mathcal{T}_h}\|u-P_Tu\|_{0,T}^2\right)^{1/2}\\
&\quad\le \left(\varepsilon|u-u_{\mathrm{RFB}}|_{1,\Omega}^2+c_0\|u-u_{\mathrm{RFB}}\|_{0,\Omega}^2\right)^{1/2}\\
&\qquad\times\left(\sum_{T\in\mathcal{T}_h}\left(\varepsilon^{1/2}|u-P_Tu|_{1,T}+\varepsilon^{-1/2}\|u-P_Tu\|_{0,T}\right)^2+\frac{\|c\|_{\mathrm{L}^\infty(\Omega)}^2}{c_0}\|u-P_Tu\|_{0,T}^2\right)^{1/2}.
\end{aligned}
$$

The rest of the argument, based on bounding the second factor on the right-hand side in the final inequality, proceeds as in the proof of Theorem 3.8.

4. Affine partitions. We now discuss the case of partitions $\mathcal{T}_h$ consisting of affine-equivalent (triangular or quadrilateral) elements. As before, our assumptions on the partition are conformity and that (2.4) holds.

The following a priori error analysis is based on Lemma 3.2 and on the technique introduced by Formaggia and Perotto [14] (see also the references therein and Micheletti, Perotto, and Picasso [25]) to prove anisotropic error estimates for the interpolation error. More precisely, we will employ suitable scaling properties derived in [14] in terms of certain characteristic quantities of the affine transformation F_T. A limitation of the approach is that only an a priori error bound in terms of the H^2-seminorm can be obtained, so this analysis applies only in the case when $k=1$. An extension of the bounds presented here to the case when $k\ge 1$ can be carried out using the techniques developed in section 2.2 of the paper of Huang [20].

Let $F_T(\hat{\boldsymbol{x}})=M\hat{\boldsymbol{x}}+\boldsymbol{t}$ (we omit the dependence of M and t on T to simplify the notation). As the matrix M is invertible, it admits a unique *polar decomposition* $M=BZ$, where B is symmetric and positive definite and Z is orthonormal.

Further, B is factorized as $B=R^{\mathrm{T}}\Lambda R$, where Λ is diagonal with positive decreasing entries (the eigenvalues of B) and R is orthonormal (with rows which are the eigenvectors of B). Hence,

$$
\Lambda=\begin{bmatrix}\lambda_1 & 0\\ 0 & \lambda_2\end{bmatrix},\qquad R=\begin{bmatrix}\boldsymbol{r}_1^{\mathrm{T}}\\ \boldsymbol{r}_2^{\mathrm{T}}\end{bmatrix},
$$

where $\lambda_1\ge\lambda_2$ and $\boldsymbol{r}_1$, $\boldsymbol{r}_2$ are the eigenvalues and eigenvectors of B, respectively. The above decomposition corresponds to the singular value decomposition $M=R^{\mathrm{T}}\Lambda Q$, with $Q=RZ$: The reference element $\widehat{T}$ is rotated using Q, stretched by Λ, and then rotated again by R^{T}. The translation $\boldsymbol{t}$ finally gives the correct location of T. The eigenvalues λ_1 and λ_2 of Λ thus give the element dimensions in a rotated orthogonal frame and hence are used to replace h_1 and h_2 from the previous section as the characteristic dimensions of the element T.

With this new notation, we get the following scaling rules, which are the counterparts of (3.1) and (3.2):

$$
\|v\|_{0,T}^2=\lambda_1\lambda_2\|\hat{v}\|_{0,\widehat{T}}^2, \tag{4.1}
$$

$$
|v|_{1,T}^2\le\frac{\lambda_1}{\lambda_2}|\hat{v}|_{1,\widehat{T}}^2. \tag{4.2}
$$

The equality (4.1) is elementary, while (4.2) is proved in [14] as Lemma 2.2.

To scale back from the reference element we shall use the following identity which is Lemma 2.2 in [25] (see also the proof of Lemmas 2.1 and 2.2 in [14]):

$$|\hat{v}|^2_{2,\widehat{T}} = \frac{\lambda_1^3}{\lambda_2} L_{11} v + \frac{\lambda_2^3}{\lambda_1} L_{22} v + 2\lambda_1\lambda_2 L_{12} v, \tag{4.3}$$

where

$$L_{ij} v := \int_T \left(\boldsymbol{r}_i^{\mathrm{T}} H(v) \boldsymbol{r}_j \right)^2 \mathrm{d}\boldsymbol{x}, \qquad \text{with } i,j = 1,2, \tag{4.4}$$

and $H(v)$ is the Hessian matrix associated with the function v; that is,

$$H(v) := \begin{bmatrix} \frac{\partial^2 v}{\partial x_1^2} & \frac{\partial^2 v}{\partial x_1 \partial x_2} \\ \frac{\partial^2 v}{\partial x_1 \partial x_2} & \frac{\partial^2 v}{\partial x_2^2} \end{bmatrix}.$$

THEOREM 4.1. *Let $u \in V$ be the solution of (2.2) and $u_{\mathrm{RFB}} \in V_{\mathrm{RFB}}$ the RFB solution defined by (2.8). Consider a conforming affine-equivalent partition $\mathcal{T}_h$ assuming that there exists a constant $c \in (0,1]$ such that, for every $T \in \mathcal{T}_h$, $\varepsilon \le c\lambda_2$, where $\lambda_1 \ge \lambda_2$ are the characteristic dimensions of T defined above.*

If $u \in \mathrm{H}^1_0(\Omega) \cap \mathrm{H}^2(\Omega)$, then there exists a positive constant C, independent of the mesh dimensions and of ε, such that

$$\varepsilon^{1/2} |u - u_{\mathrm{RFB}}|_{1,\Omega} \le C \left(\sum_{T \in \mathcal{T}_h} \left(\frac{\lambda_1^4}{\lambda_2} L_{11} u + \lambda_2^3 L_{22} u + 2\lambda_1^2 \lambda_2 L_{12} u \right) \right)^{1/2}, \tag{4.5}$$

where the terms L_{ij}, $i,j = 1,2$, are defined elementwise as in (4.4) in terms of the Hessian of the function u.

Proof. Let $T \in \mathcal{T}_h$. As in the previous section, we need to bound the quantity given by (3.10); that is,

$$\mathcal{E}_T^I(v) = \varepsilon |v - P_T v|^2_{1,T} + \varepsilon^{-1} \|v - P_T v\|^2_{0,T},$$

where $v \in \mathrm{H}^1(T)$. As before, we start by scaling $\mathcal{E}_T^I(v)$ to the reference element $\widehat{T}$. Using (4.1) and (4.2) we get

$$\begin{aligned} \mathcal{E}_T^I(v) &\le \varepsilon \frac{\lambda_1}{\lambda_2} |\hat{v} - P_{\widehat{T}} \hat{v}|^2_{1,\widehat{T}} + \varepsilon^{-1} \lambda_1 \lambda_2 \|\hat{v} - P_{\widehat{T}} \hat{v}\|^2_{0,\widehat{T}} \\ &= \lambda_1 \left(\frac{\varepsilon}{\lambda_2} |\hat{v} - P_{\widehat{T}} \hat{v}|^2_{1,\widehat{T}} + \left(\frac{\varepsilon}{\lambda_2} \right)^{-1} \|\hat{v} - P_{\widehat{T}} \hat{v}\|^2_{0,\widehat{T}} \right). \end{aligned} \tag{4.6}$$

We then apply Lemma 3.2, this time with $\hat{w}_0 = (\hat{v} - \hat{\pi}_1 \hat{v})_{|\partial\widehat{T}}$, where $\hat{\pi}_1$ is the standard linear Lagrange interpolant (that is, $\hat{\pi}_k$, with $k = 1$) defined on the reference triangle $\widehat{T}$, and with $t = \varepsilon/\lambda_2$. In this way we get

$$\mathcal{E}_T^I(v) \le C \left(\varepsilon \frac{\lambda_1}{\lambda_2} |\hat{v} - \hat{\pi}_1 \hat{v}|^2_{1/2,\partial\widehat{T}} + \lambda_1 \|\hat{v} - \hat{\pi}_1 \hat{v}\|^2_{0,\partial\widehat{T}} \right).$$

Instead of scaling back to the boundary of the element T as was done previously, we now proceed by applying the trace inequality (3.4) and the standard Lagrange

interpolation error bounds on $\widehat{T}$ (see Ciarlet [13]). Since $\lambda_2 \leq \lambda_1$ and $\varepsilon \leq c\lambda_2$, with $c \in (0,1]$, we get

$$\begin{aligned}\mathcal{E}_T^I(v) &\leq C\left(\varepsilon\frac{\lambda_1}{\lambda_2}+\lambda_1\right)\|\hat{v}-\hat{\pi}_1\hat{v}\|_{1,\widehat{T}}^2\\ &\leq C\lambda_1|\hat{v}|_{2,\widehat{T}}^2\\ &\leq C\left(\frac{\lambda_1^4}{\lambda_2}L_{11}v+\lambda_2^3L_{22}v+2\lambda_1^2\lambda_2L_{12}v\right),\end{aligned}\tag{4.7}$$

the last bound being a consequence of (4.3). The desired error bound now follows by repeating the steps in the proof of Theorem 3.8. ∎

If the partition $\mathcal{T}_h$ is axiparallel, then $\lambda_i = h_i/c_i$, with h_i and c_i, $i = 1, 2$, being the dimensions along the coordinate axes of T and $\widehat{T}$, respectively. In this case Theorem 4.1 collapses to the a priori error bound (3.14), with $r = 1$.

5. Numerical examples. As discussed in section 1, a fully discrete RFB method is obtained after approximating the bubble space. In the following experiment, the local bubble problem on each element is solved using the standard Galerkin finite element method (FEM) on an 8×8 Shishkin partition. This is a piecewise uniform mesh with half of the nodes in each coordinate direction lying in the boundary-layer region of the element; see [24] and references therein. This choice abundantly ensures that the subgrid discretization error is of higher order than the RFB error controlled by our error analysis. In fact, in the case of P_1 shape-regular finite elements, it has been proved by Brezzi and Marini [8] that a subgrid consisting of a single internal node placed inside the boundary layer of the bubble problem is sufficient; see also [4]. This is the fully discrete method that we suggest for practical implementations.

Another possibility, exploited in further experiments presented later on, is to discretize the convection field with piecewise constants and then approximate the solution of each local bubble problem by the solution of the corresponding reduced (hyperbolic) elemental problem [9]. This procedure is computationally inexpensive, as it amounts to the calculation of the volume of a pyramid on each element. Moreover, when the problem is convection-dominated, such an approximation does not compromise the accuracy of the method (a choice that is optimal in all regimes is the link-cutting bubble proposed in [4] for one-dimensional problems). Indeed, the discretization of the bubble functions need not be particularly accurate as long as the elemental average

$$\frac{\int_T b_T \,\mathrm{d}\boldsymbol{x}}{|T|}$$

of the bubble b_T has been sufficiently accurately approximated; the reason, as is shown later on in this paper (see also [5]), is that only the elemental averages of the bubbles enter into the fully discrete method. The behavior of the above term on shape-regular partitions, as a function of the mesh Péclet number $\mathtt{Pe}_T = h_T|\boldsymbol{a}|/\varepsilon$, is analyzed in [5], where it is also shown that the average of the solution of the reduced bubble problem behaves similarly in the convection-dominated regime to the average of the exact bubble b_T. Lemma 6.1 below extends the analysis from [5] to anisotropic partitions, thus suggesting that this simple recipe for full discretization is still viable on anisotropic partitions.

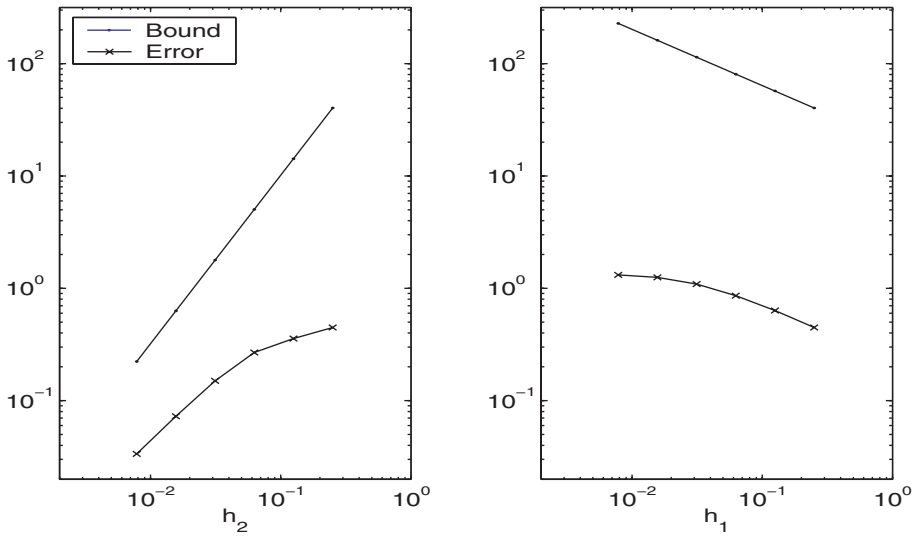

FIG. 5.1. *$\varepsilon^{1/2}$-weighted H^1-seminorm error and error bound under (the correct) h_2-refinement (left) and (the incorrect) h_1-refinement (right); $\varepsilon = 10^{-2}$. In both cases, we start from the 4×4 uniform square mesh.*

We consider the following simple boundary-value problem

$$(5.1)\qquad \begin{cases} -\varepsilon\Delta u + u_{x_2} = 0 & \text{in } \Omega = (0,1)^2, \\ u(x_1,0) = 0; \quad u(x_1,1) = 1, & x_1 \in [0,1], \\ u_{x_1} = 0 & \text{on } \Gamma_{\mathrm{N}} = (\{0\}\times(0,1)) \cup (\{1\}\times(0,1)), \end{cases}$$

whose solution is given by

$$u(x_1,x_2) = \frac{\mathrm{e}^{x_2/\varepsilon} - 1}{\mathrm{e}^{1/\varepsilon} - 1}.$$

We consider discretizations of this problem with respect to axiparallel uniform rectangular grids of dimensions h_1 and h_2 in the respective coordinate directions. For this problem the error bound (3.14) reduces to

$$\varepsilon^{1/2}|u - u_{\mathrm{RFB}}|_{1,\Omega} \le C \begin{cases} h_2^3 ||\partial_{x_2}^2 u||_{0,\Omega}^2 & \text{if } h_2 \le h_1, \\ \dfrac{h_2^4}{h_1} ||\partial_{x_2}^2 u||_{0,\Omega}^2 & \text{if } h_2 > h_1. \end{cases}$$

We verify the validity of the bound by performing the following tests. Starting from the uniform 4×4 mesh, we either

- fix h_1 while halving h_2 (*correct refinement*) or
- fix h_2 while halving h_1 (*incorrect refinement*).

The relevant energy norm errors and error bounds are shown in the log-log plot in Figure 5.1 (left-hand panel) for $\varepsilon = 10^{-2}$.

Performing the correct refinement is, of course, not too different from solving the related sequence of one-dimensional problems. The similarity of the numerical solution of the two-dimensional problem to the numerical solution of the related one-dimensional problem is lost when the incorrect refinement is performed (notice that

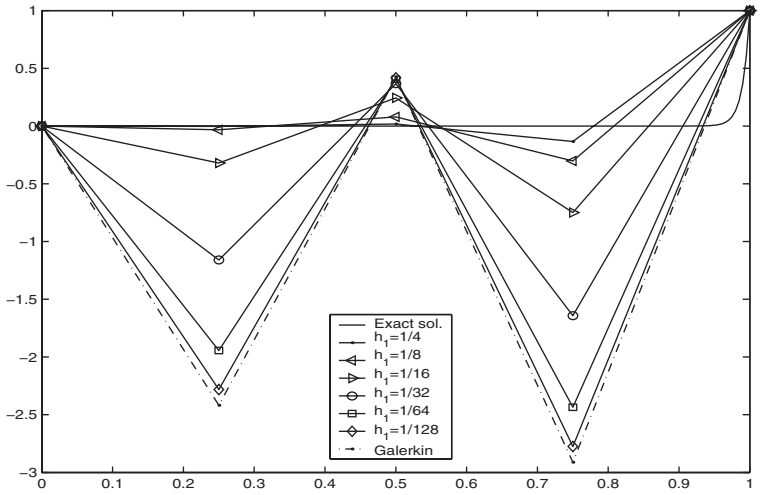

FIG. 5.2. *Profile of the solution along $x_1 = 1/2$ under h_1-refinement (as in the right-hand panel in Figure* 5.1*), while $h_2 = 1/4$. The lowest profile represents the piecewise $\mathcal{Q}_1$ standard Galerkin FEM solution computed on a uniform 4×4 mesh. The exact solution is also plotted for comparison.*

this does not happen when applying the standard Galerkin method with linear elements). As predicted by the error bound, the accuracy of the solution actually deteriorates under the incorrect refinement; see the log-log plot in Figure 5.1 (right-hand panel). This is due to the peculiar definition of the RFB finite element space. Mesh refinement corresponds to a relative impoverishment of the bubble subspace and an enrichment of the piecewise polynomial subspace. If the latter enrichment, as is the case with our incorrect refinement, is ineffective, then the overall approximation properties of V_{RFB} will be worse than on a coarser mesh. The detailed error analysis of the RFB method on shape-regular partitions presented in our recent work [12] aims to clarify the approximation properties of the method in the preasymptotic regime when $\varepsilon \leq ch$. In particular, in [12], we relate the phenomenon just observed to the inadequacy of V_h^k to capture the exponential behavior of the solution along element edges contained in the boundary layer.

In the limit of $h_1 \to 0$, the solution becomes constant along x_1. That is, it tends to the piecewise $\mathcal{Q}_1$ standard Galerkin solution, which is unaffected by the reduction of h_1; see Figure 5.2. Asymptotically, in the case of the incorrect refinement (with $h_1 \to 0$), the error is of order $O(1)$ (cf. Figure 5.1 (right)). In other words, since the bubble part of the solution is forced to tend to zero as $h_1 \to 0$, its stabilizing effect is diminished until, in the limit, it vanishes and the RFB method collapses to the standard Galerkin FEM. This fact shows that the stabilization properties of stabilized FEMs are affected by the anisotropy of the partition.

The use of anisotropic partitions for the solution of highly convection-dominated problems can become mandatory if resolution of thin layers in the solution is paramount. Let us consider, for example, the boundary-value problem

$$\begin{cases} -\varepsilon \Delta u + (2,1)^{\mathrm{T}} \cdot \nabla u = 0 & \text{in } \Omega = (0,1)^2, \\ u(x_1, 0) = u(1, x_2) = 0, & x_1, x_2 \in (0,1), \\ u(x_1, 1) = u(0, x_2) = 1, & x_1, x_2 \in [0,1]. \end{cases} \tag{5.2}$$

The solution of (5.2) exhibits an internal layer emanating from the origin of the coor-

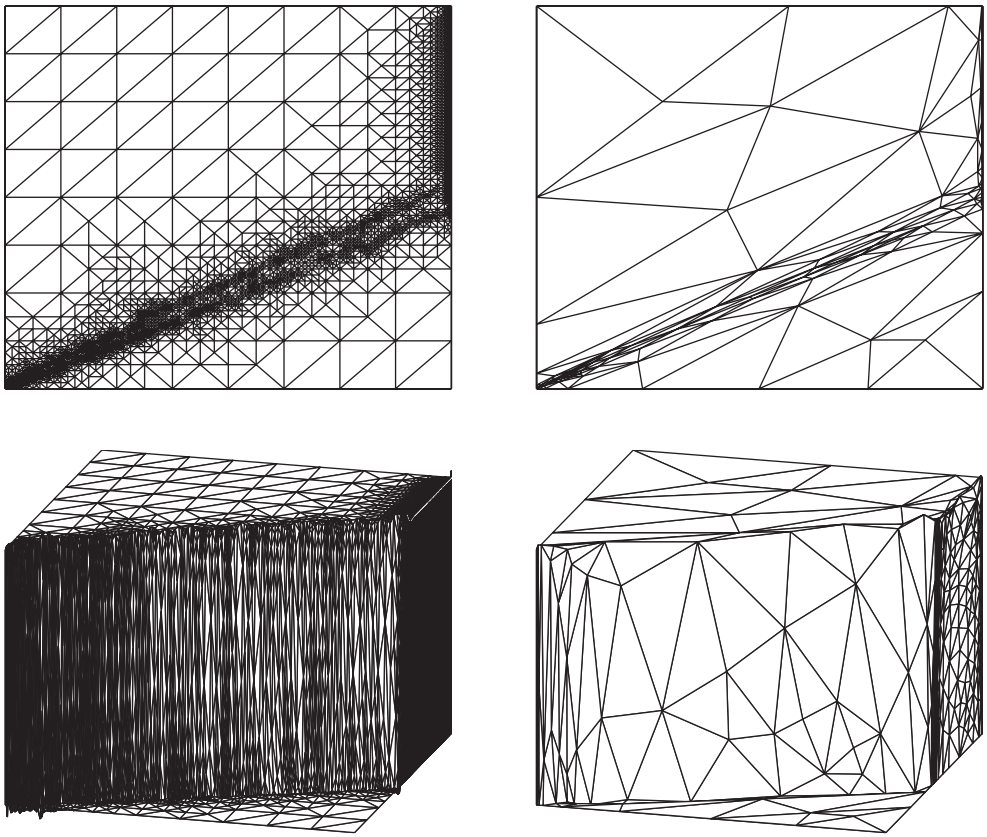

FIG. 5.3. *The solution of* (5.2) *with* $\varepsilon = 10^{-4}$ *on* ad hoc-*refined triangulations. Left: Shape-regular mesh (*23256 *elements,* 12693 *nodes) and the corresponding solution. Right: Anisotropic mesh (*478 *elements,* 263 *nodes) and the corresponding solution.*

dinate system and a boundary layer situated along $x_1 = 1$. The RFB approximation of (5.2) is shown in Figure 5.3. The bubble solution is approximated by the solution of the related reduced (hyperbolic) elemental problem [9]. We compute the RFB solution using, respectively, a shape-regular triangulation (left-hand panels in the figure) and an anisotropic triangulation (right-hand panels in the figure). The anisotropic triangulation has been generated by Picasso [26], by applying a ZZ-type error indicator for the gradient error to the classical stabilized Galerkin least-squares (GLS) method, until the stopping criterion ZZ-indicator $\leq 1/4$ was satisfied in all elements. The triangulation was then used to compute the RFB solution shown in the bottom right-hand panel of Figure 5.3. The computation on the shape-regular triangulation was performed by applying the residual-based L^2-error indicator proposed in [10] for the RFB method. For the sake of consistency, the adaptation was stopped when the error indicator fell below 1/4 in all elements. The RFB solution computed on the anisotropic triangulation is clearly superior, as the triangulation consists of only 263 nodes instead of the 12693 nodes, with comparable accuracy, in the case of the shape-regular partition.

6. Tuning of the SD parameter. The RFB method is closely related to classical stabilized finite element methods (streamline upwind Petrov–Galerkin (SUPG),

GLS, etc.). For instance, in the case of piecewise constant coefficients and linear finite elements, RFB is equivalent to SUPG and GLS (the latter methods coincide in this case with what Johnson, Nävert, and Pitkäranta [22] refer to as the *streamline-diffusion finite element method* (SDFEM)). Here we exploit this identification to obtain a theoretically justified value of the user-selected stabilization parameter in stabilized finite element methods.

We consider the RFB method (2.8), assuming that $\mathcal{T}_h$ consists of triangles, and fix $k = 1$. In this case, $V_{\mathrm{RFB}} = V_h^1 \oplus B_h$, where V_h^1 is the space of linear finite elements.

Let us also assume that $\boldsymbol{a}$ and f are constant on every element of $\mathcal{T}_h$. Then the right-hand side of (2.11) is constant, and the bubble part of the RFB solution is given locally on T by $u_b|_T = (f - Lu_h)|_T b_T$, where $b_T \in \mathrm{H}_0^1(T)$ satisfies

$$-\varepsilon \Delta b_T + \boldsymbol{a} \cdot \nabla b_T = 1. \tag{6.1}$$

Substituting u_b into (2.9) it follows that $u_h \in V_h^1$ is the solution of

$$\mathcal{L}(u_h, v_h) + \sum_{T \in \mathcal{T}_h} \frac{\int_T b_T \,\mathrm{d}\boldsymbol{x}}{|T|} (\boldsymbol{a} \cdot \nabla u_h - f, \boldsymbol{a} \cdot \nabla v_h)_T = (f, v_h) \qquad \forall v_h \in V_h^1. \tag{6.2}$$

The formulation (6.2) coincides with the SDFEM with the particular choice of the SD parameter given by

$$\tau_b := \frac{\int_T b_T \,\mathrm{d}\boldsymbol{x}}{|T|}. \tag{6.3}$$

Thus, as anticipated, the RFB method and the SDFEM are, in this case, equivalent. This well-known fact was first observed by Brezzi and Russo [9].

A numerical method is obtained from the RFB formulation by considering (6.2) where the quantity τ_b has been suitably approximated (examples are given in [9, 15, 6, 8, 4, 30, 11]). As discussed in [5] in the case of shape-regular triangulations, the crucial property is that the approximated value of τ_b scales as τ_b with respect to the mesh size and the coefficients ε and $\mathbf{b}$.

Specifically, let h_a indicate the length of the longest segment parallel to $\boldsymbol{a}$ contained in T. On shape-regular partitions, i.e., assuming that the minimal angle of T is bounded below by a fixed positive constant, we know from [5] that

$$C \frac{h_T}{|\boldsymbol{a}|} \min\left\{ \frac{h|\boldsymbol{a}|}{\varepsilon}, 1 \right\} \le \tau_b \le \frac{h_a}{|\boldsymbol{a}|}. \tag{6.4}$$

In practice, $\tau_b \sim \frac{h_T}{|\boldsymbol{a}|} \min\{\frac{h|\boldsymbol{a}|}{\varepsilon}, 1\}$, which is qualitatively the value of the SD parameter suggested by the a priori error analysis of the SDFEM (see, e.g., [28]).

The situation is less clear when considering anisotropic elements. Attempts have been made to derive the optimal behavior of the SD parameter through a priori analysis; see, e.g., [3, 23, 25]. The outcome of the investigations in these papers is that the stabilization parameter should depend on the smaller dimension of the element.

For instance, assume that T is a right-angled triangle of dimensions h_1, h_2, and let $h_{\min} = \min\{h_1, h_2\}$. Then, according to [25], we should choose the SD parameter as

$$\tau_{\mathrm{sd}} := C \frac{h_{\min}}{2|\boldsymbol{a}|} \min\left\{ \frac{h_{\min}|\boldsymbol{a}|}{6\varepsilon}, 1 \right\}. \tag{6.5}$$

This choice seems less favorable when the mesh is not aligned with the solution (as in the incorrect refinement in our example above). We notice that in this case the a priori analysis does not predict convergence anyway.

By appropriately modifying the argument employed in [5] to derive (6.4), we shall now obtain a new lower bound for τ_b that takes the two characteristic dimensions of T into account. This result is then used to provide a new rule for selecting the SD parameter.

LEMMA 6.1. *Suppose that T is a right-angled triangle, oriented along the coordinate axes, of dimensions h_1, h_2; then the quantity τ_b given by* (6.3)*, where b_T solves* (6.1)*, satisfies*

$$C\frac{h_a}{|\boldsymbol{a}|}\min\{\mathtt{Pe}_T,1\}\le\tau_b\le\frac{h_a}{|\boldsymbol{a}|}, \tag{6.6}$$

with $C=1/45$ and with the following definition of the element Péclet number:

$$\mathtt{Pe}_T:=h_{\min}^2\frac{|\boldsymbol{a}|}{8\varepsilon h_a}. \tag{6.7}$$

Proof. The upper bound is already given in (6.4). Assume that $h_2<h_1$, so that $h_{\min}=h_2$. To prove the lower bound, we map T into the right-angled triangle $\widehat{T}$ with its two orthogonal edges of length h_ah_1/h_2^2 and h_a/h_2 aligned with the positive semiaxes of the coordinate system $(\hat{x}_1,\hat{x}_2)$. The image $\hat{b}$ of $b_T\in\mathrm{H}_0^1(\widehat{T})$ satisfies

$$-\varepsilon\frac{h_a}{h_2^2}\Delta\hat{b}+\boldsymbol{a}\cdot\nabla\hat{b}=\frac{h_2^2}{h_a}\quad\text{in }\widehat{T},$$

and we have

$$\tau_b=\frac{2h_2^3}{h_1h_a^2}\int_{\widehat{T}}\hat{b}\,\mathrm{d}\hat{\boldsymbol{x}}. \tag{6.8}$$

To bound the integral in (6.8) we proceed as in [5]. We let $\hat{\lambda}_1$, $\hat{\lambda}_2$, and $\hat{\lambda}_3$ be the barycentric coordinates on $\widehat{T}$, define $\hat{b}_3:=\hat{\lambda}_1\hat{\lambda}_2\hat{\lambda}_3$, and note that

$$\int_{\widehat{T}}\hat{b}_3\,\mathrm{d}\hat{\boldsymbol{x}}=\frac{h_a^2h_1}{120h_2^3}. \tag{6.9}$$

Since $h_2<h_1$, we have

$$M_\Delta:=\frac{1}{8}\max_{\widehat{T}}|\Delta\hat{b}_3|=\frac{1}{4}\frac{h_2^5}{h_a^3h_1}\max_{\widehat{T}}\left(\frac{\hat{x}_1}{h_2}+\frac{\hat{x}_2}{h_1}\right)=\frac{1}{4}\frac{h_2^2}{h_a^2}, \tag{6.10}$$

the maximum being attained at the vertex $(h_a h_1/h_2^2, 0)$, and

$$\begin{aligned} M_g &:= \frac{1}{|\boldsymbol{a}|}\max_{\widehat{T}}|\boldsymbol{a}\cdot\nabla\hat{b}_3| \\ &= \frac{h_2^3}{|\boldsymbol{a}|h_a^2h_1}\max_{\widehat{T}}\left|a_1\left(\hat{x}_2-2\frac{h_2^2}{h_ah_1}\hat{x}_1\hat{x}_2-\frac{h_2}{h_a}\hat{x}_2^2\right)\right. \\ &\quad \left.+a_2\left(\hat{x}_1-\frac{h_2^2}{h_ah_1}\hat{x}_1^2-2\frac{h_2}{h_a}\hat{x}_1\hat{x}_2\right)\right| \\ &\le \frac{h_2^3}{|\boldsymbol{a}|h_a^2h_1}\left(|a_1|\max_{\widehat{T}}\left|\hat{x}_2-2\frac{h_2^2}{h_ah_1}\hat{x}_1\hat{x}_2-\frac{h_2}{h_a}\hat{x}_2^2\right|\right. \\ &\quad \left.+|a_2|\max_{\widehat{T}}\left|\hat{x}_1-\frac{h_2^2}{h_ah_1}\hat{x}_1^2-2\frac{h_2}{h_a}\hat{x}_1\hat{x}_2\right|\right) \\ &= \frac{h_2^3}{|\boldsymbol{a}|h_a^2h^1}\left(|a_1|\frac{h_a}{4h_2}+|a_2|\frac{h_ah_1}{4h_2^2}\right) \\ &= \frac{1}{4|\boldsymbol{a}|}\left(|a_1|\frac{h_2^2}{h_ah_1}+|a_2|\frac{h_2}{h_a}\right), \end{aligned} \tag{6.11}$$

both maxima being attained at the midpoint of the hypotenuse. We note that if $\operatorname{sign}(a_1)=\operatorname{sign}(a_2)$, the above bound reduces to an equality.

We now define

$$\gamma := \frac{1}{M_\Delta+M_g}\min\left\{\frac{h_2^2}{8\varepsilon h_a},\frac{1}{|\boldsymbol{a}|}\right\}, \qquad \hat{w}:=\gamma\hat{b}_3, \qquad \hat{v}:=\frac{h_a}{h_2^2}\hat{b},$$

and introduce the differential operator

$$\widehat{L}\varphi := -\varepsilon\frac{h_a}{h_2^2}\Delta\varphi+\boldsymbol{a}\cdot\nabla\varphi.$$

By the definition of γ, $\hat{w}$, M_Δ, and M_g, we have

$$|\widehat{L}\hat{w}|\le\gamma\left(\varepsilon\frac{h_a}{h_2^2}M_\Delta+|\boldsymbol{a}|M_g\right)\le 1.$$

Thus, by the definition of $\hat{v}$, we have

$$\widehat{L}(\hat{v}-\hat{w})=\frac{h_a}{h_2^2}\widehat{L}\hat{b}-\widehat{L}\hat{w}=1-\widehat{L}\hat{w}\ge 0,$$

and, since both $\hat{v}$ and $\hat{w}$ vanish on $\partial\widehat{T}$, using the maximum principle, we conclude that $\hat{v}\ge\hat{w}$ in $\widehat{T}$. We are now ready to bound τ_b. Recalling (6.8) and (6.9), we have

$$\tau_b=\frac{2h_2^5}{h_a^3h_1}\int_{\widehat{T}}\hat{v}\,\mathrm{d}\hat{\boldsymbol{x}}\ge\frac{2h_2^5}{h_a^3h_1}\gamma\int_{\widehat{T}}\hat{b}_3\,\mathrm{d}\hat{\boldsymbol{x}}=\frac{h_2^2}{60h_a}\gamma.$$

Further, using the definition of γ, and inserting (6.10) and (6.11), we have

$$\tau_b\ge\frac{1}{15\left(\frac{|\boldsymbol{a}|}{h_a}+\frac{|a_1|}{h_1}+\frac{|a_2|}{h_2}\right)}\min\left\{\frac{|\boldsymbol{a}|h_2^2}{8\varepsilon h_a},1\right\}.$$

We distinguish between the following two cases.

- If $\mathrm{sign}(a_1) = \mathrm{sign}(a_2)$, then h_a is the length of the line segment oriented with $\boldsymbol{a}$ which joins the hypotenuse of T with the opposite vertex. Thus,

$$h_a = \sqrt{\frac{h_2^2}{\left(\frac{a_2}{a_1} + \frac{h_2}{h_1}\right)^2}\left(1 + \frac{a_2^2}{a_1^2}\right)} = \frac{|\boldsymbol{a}|}{\frac{|a_1|}{h_1} + \frac{|a_2|}{h_2}}.$$

  It follows that $|a_1|/h_1 + |a_2|/h_2 = |\boldsymbol{a}|/h_a$.
- If $\mathrm{sign}(a_1) \neq \mathrm{sign}(a_2)$ and $|a_2|/h_2 > |a_1|/h_1$, then h_a is the length of the line segment oriented with $\boldsymbol{a}$ which joins the edge of T parallel to the x_1-axis with the opposite vertex. Thus,

$$h_a = \sqrt{h_2^2 + \frac{a_1^2}{a_2^2}h_2^2} = \frac{h_2|\boldsymbol{a}|}{|a_2|},$$

  and so $|a_2|/h_2 = |\boldsymbol{a}|/h_a$. Similarly, if $|a_2|/h_2 > |a_1|/h_1$, then $|a_1|/h_1 = |\boldsymbol{a}|/h_a$.

It follows that

$$\frac{|\boldsymbol{a}|}{h_a} + \frac{|a_1|}{h_1} + \frac{|a_2|}{h_2} \leq C\frac{|\boldsymbol{a}|}{h_a},$$

with $C = 2$ or 3, depending on the cases listed above, respectively.

Since the above argument can be repeated in the case $h_1 \leq h_2$ by interchanging the role of h_1 and h_2, we conclude that the bound (6.6) holds with $C = 1/45$. ∎

To verify the bound obtained, we compare the behavior of

$$\tau_a := C\frac{h_a}{|\boldsymbol{a}|}\min\left\{\mathtt{Pe}_T, 1\right\},$$

with that of τ_b with respect to the dimensions of T. We let $h_1 = 1$ while halving h_2 starting from $h_2 = 1$. We do this twice in succession, with $\boldsymbol{a} = (1, 0)$ and then with $\boldsymbol{a} = (0, 1)$. The results are shown in Figure 6.1 (τ_b is calculated by solving (6.1) very accurately). The superimposition of the graphs is obtained by renormalizing τ_a (the factor is always around 3) so that its first values coincide with that of τ_b. As we can see in Figure 6.1, τ_a and τ_b are very close to each other.

Figure 6.1 also reports the results obtained with the choice τ_{sd} given by (6.5), which was proposed as a SD parameter in [3, 23, 25]. We notice that the two choices τ_a and τ_{sd} have different turning points, particularly when $\boldsymbol{a}$ is aligned with the longest edge of T. This is due to the fact that our definition of the element Péclet number depends not only on the magnitude of the convective field, but also on its direction. We believe that this should indeed be the case when anisotropic partitions are considered, and hence we propose τ_a as the appropriate SD parameter. The definition of τ_a easily extends to a general element by substituting h_1 and h_2 by the characteristic dimensions λ_1 and λ_2.

We assess experimentally our new choice of the SD parameter τ_a by comparing its performance with that of τ_{sd} on some model problems. From the discussion above we know that the two choices τ_a and τ_{sd} differ the most when the stretching of the element is aligned with the direction of convection. We must also take into account, though, that the magnitude of the SDFEM stabilization term depends on the alignment of the convection with the gradient of the solution; cf. (6.2); see also section 3 in [20]. We therefore consider two test problems: (5.1), whose solution exhibits a boundary layer,

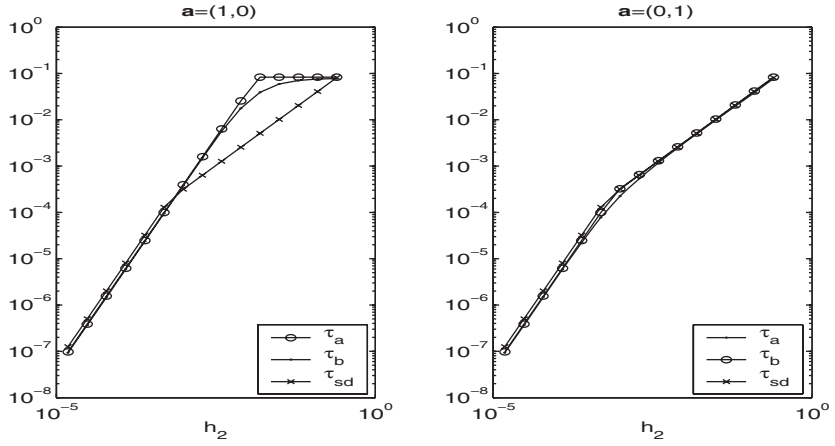

FIG. 6.1. *Comparisons of τ_b with τ_a and $\tau_{\rm sd}$ on a rectangle of dimensions 1 and h_2 for $\varepsilon = 10^{-4}$.*

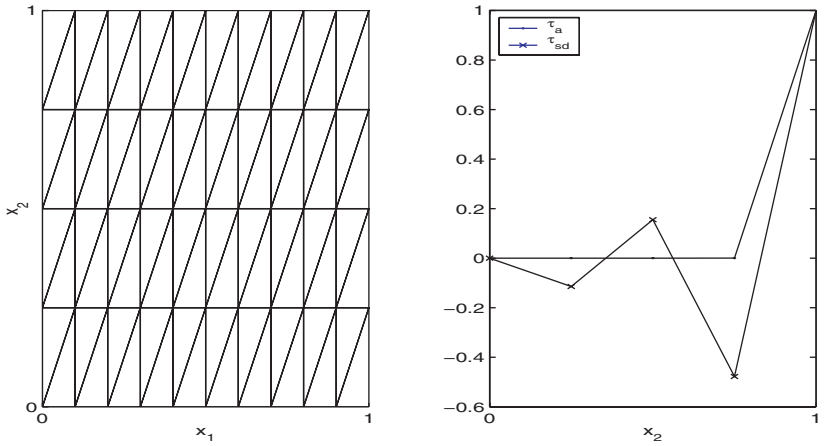

FIG. 6.2. *Mesh and SDFEM solution profile along $x_1 = 1/2$ for the model problem* (5.1) *with $\varepsilon = 10^{-4}$.*

and a modification of (5.2) obtained by imposing a Neumann boundary condition on the outflow boundary, so that the solution of the problem contains an internal layer. In all tests we solved the problem on a slightly stretched uniform partition of aspect ratio 4/10.

We start with (5.1). We compare the two different choices of the SD parameter τ_a and $\tau_{\rm sd}$ by solving the model problem (5.1) with $\varepsilon = 10^{-4}$ by means of the SDFEM. In both cases, the constant factors C in the definitions of the two parameters are tuned by solving the problem on a uniform partition. We apply the SDFEM on the partition depicted in the left-hand panel of Figure 6.2. The solution profile at $x_1 = 1/2$ is shown in the right-hand panel of Figure 6.2. While the solution obtained using τ_a correctly reproduces the exact solution, the one obtained using $\tau_{\rm sd}$ is corrupted by oscillations, indicating that the stabilization parameter $\tau_{\rm sd}$ is too small. The difference is due to the fact that, while $\tau_{\rm sd}$ always depends on $h_{\min}$, the parameter τ_a is linked to $h_{\max}$ as long as $\mathtt{Pe}_T > 1$. Eventually, if the mesh is further stretched in the incorrect direction, the

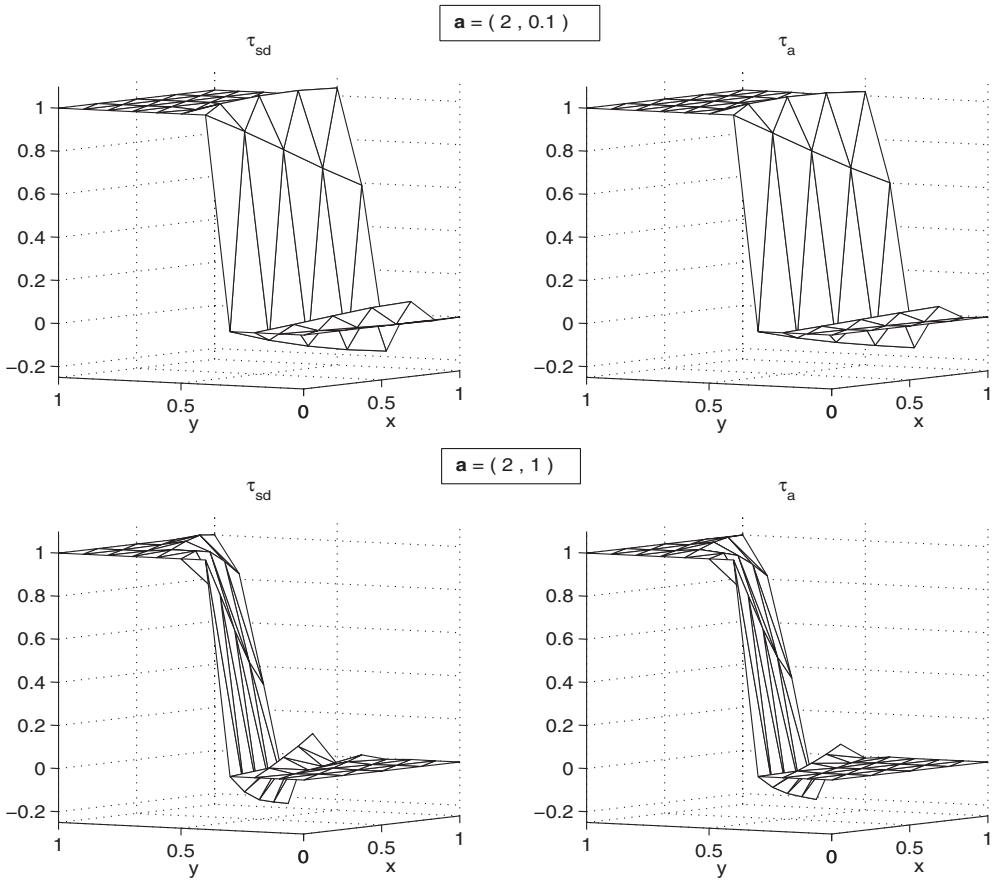

FIG. 6.3. *SDFEM solution of the model problem* (6.12) *with* $\varepsilon = 10^{-4}$.

use of τ_a will also lead to maximum-principle-violating oscillations in the numerical solution, but this happens for partitions with significantly higher aspect ratios than for $\tau_{\rm sd}$; for the present model problem, $\mathtt{Pe}_T > 1$ for $h_{\min} > 2^{5/2}10^{-2} \approx 0.05$, corresponding to an aspect ratio of 1/5. In conclusion, our choice will guarantee stability for any, *not too unreasonably* designed, partition, such as the one used in the experiment.

We finally consider the following boundary-value problem:

$$\begin{cases} -\varepsilon\Delta u + \boldsymbol{a}\cdot\nabla u = 0 & & \text{in } \Omega = (0,1)^2, \\ u(x_1,0) = 0; & u(x_1,1) = 1, & x_1 \in (0,1), \\ u(0,x_2) = \chi_{[1/3,1]}(x_2); & \frac{\partial u}{\partial x_1}(1,x_2) = 0, & x_2 \in [0,1], \end{cases} \tag{6.12}$$

which exhibits an internal layer emanating from the boundary-value discontinuity in $(0,1/3)$ in the direction of $\boldsymbol{a}$. We fix the partition to be a uniform 4×10 partition and test the different choices of the SD parameter as functions of the convection direction by setting $\boldsymbol{a} = (2,1)$ as in (5.2) and then $\boldsymbol{a} = (2,0.1)$, i.e., aligned with the partition. The SDFEM solutions are shown in Figure 6.3. The solutions obtained using τ_a are slightly less oscillatory, particularly in the case $\boldsymbol{a} = (2,1)$, where we observe differences in the solutions at the outflow up to a factor of 1.6. This latter fact may seem counterintuitive, as τ_a and $\tau_{\rm sd}$ differ the most in the case $\boldsymbol{a} = (2,0.1)$

when convection is aligned with the stretching of the partition, but the alignment improves the performance of the method and reduces the need for stabilization.

7. Conclusions. When a convection-diffusion problem is strongly convection-dominated, the solution is often highly anisotropic, exhibiting large gradients in specific directions. In this paper we have developed the a priori error analysis of the RFB method, in the energy norm, on anisotropic partitions. The error is bounded by appropriately weighted norms of directional derivatives of the solution, so as to respect the anisotropic nature of the solution to the problem. The error bound established is an extension of that obtained by Sangalli [29] for shape-regular partitions.

Anisotropy also has to be taken into account in the tuning of the parameters appearing in *streamline-diffusion*-type methods. We have used the stabilizing term derived from the RFB method to redefine the mesh Péclet number and proposed a new choice of the SD parameter which is suitable for use on anisotropic partitions. Our choice improves the choices of the SD parameter presented in previous works based on the a priori analysis of the SD method (cf. [3, 23, 25]).

Acknowledgment. We are grateful to Professor Marco Picasso (Ecole Polytechnique Fédérale de Lausanne) for supplying the anisotropic triangulation that was used to generate the right-hand panels in Figure 5.3.

FINITE ELEMENT DISCRETIZATION ERROR ANALYSIS OF A SURFACE TENSION FORCE IN TWO-PHASE INCOMPRESSIBLE FLOWS*

SVEN GROSS† AND ARNOLD REUSKEN†

Abstract. We consider a standard model for a stationary two-phase incompressible flow with surface tension. In the variational formulation of the model a linear functional which describes the surface tension force occurs. This functional depends on the location and the curvature of the interface. In a finite element discretization method the functional has to be approximated. For an approximation method based on a Laplace–Beltrami representation of the curvature we derive sharp bounds for the approximation error. A new modified approximation method with a significantly smaller error is introduced.

1. Introduction.

Let $\Omega \subset \mathbb{R}^3$ be a polyhedral domain that contains a flow of two different immiscible incompressible newtonian phases (fluid-fluid or fluid-gas). At the interface between the two phases there are surface tension forces that are significant and cannot be neglected. An example is a (rising) liquid drop contained in a surrounding fluid. The standard model to describe such a flow problem consists of instationary Navier–Stokes equations with certain coupling conditions at the interface which describe the effect of surface tension. In this paper we analyze errors that are due to the discretization of the surface tension force that occurs in the continuous model. To simplify the presentation and the analysis we assume a *stationary* flow.

The domains which contain the phases are denoted by Ω_1 and Ω_2 with $\overline{\Omega}_1 \cup \overline{\Omega}_2 = \overline{\Omega}$ and $\partial\Omega_1 \cap \partial\Omega = \emptyset$. The interface between the two phases $(\partial\Omega_1 \cap \partial\Omega_2)$ is denoted by Γ. To model the forces at the interface we make the standard assumption that the surface tension balances the jump of the normal stress on the interface; i.e., we have an interface condition

$$[\boldsymbol{\sigma}\mathbf{n}]_\Gamma = \tau\mathcal{K}\mathbf{n},$$

with $\mathbf{n} = \mathbf{n}_\Gamma$ the unit normal at the interface (pointing from Ω_1 in Ω_2), τ the surface tension coefficient (material parameter), $\mathcal{K}$ the curvature of Γ, and $\boldsymbol{\sigma}$ the stress tensor, i.e.,

$$\boldsymbol{\sigma} = -p\mathbf{I} + \mu\mathbf{D}(\mathbf{u}), \quad \mathbf{D}(\mathbf{u}) = \nabla\mathbf{u} + (\nabla\mathbf{u})^T,$$

with $p = p(x,t)$ the pressure, $\mathbf{u} = \mathbf{u}(x,t)$ the velocity vector, and μ the viscosity. We assume continuity of the velocity across the interface. In combination with the

†Institut für Geometrie und Praktische Mathematik, RWTH Aachen, D-52056 Aachen, Germany (gross@igpm.rwth-aachen.de, reusken@igpm.rwth-aachen.de).

conservation laws of mass and momentum this yields the following standard model (cf., for example, [23, 22, 26, 25]):

$$\begin{cases} -\operatorname{div}(\mu_i \mathbf{D}(\mathbf{u})) + \rho_i(\mathbf{u}\cdot\nabla)\mathbf{u} - \nabla p = \rho_i \mathbf{g} & \text{in } \Omega_i \\ \operatorname{div}\mathbf{u} = 0 & \text{in } \Omega_i \end{cases} \quad \text{for } i = 1,2, \tag{1.1}$$

$$[\boldsymbol{\sigma}\mathbf{n}]_\Gamma = \tau\mathcal{K}\mathbf{n}, \quad [\mathbf{u}]_\Gamma = 0. \tag{1.2}$$

The vector $\mathbf{g}$ is a known external force (gravity). In addition we need boundary conditions for $\mathbf{u}$ at $\partial\Omega$. For simplicity we take homogeneous Dirichlet boundary conditions. The *two* Navier–Stokes equations in (1.1) and the coupling conditions at the interface in (1.2) can be reformulated into *one* Navier–Stokes equation in the whole domain in which the effect of the surface tension is expressed in terms of a localized force at the interface; cf. the so-called continuum surface force (CSF) model [5, 6]. We consider this alternative formulation in a standard weak form (as in [12, 27, 28, 29, 30]) in the spaces

$$\mathbf{V} := H_0^1(\Omega)^3, \quad Q := L_0^2(\Omega) = \left\{ q \in L^2(\Omega) \mid \int_\Omega q\,dx = 0 \right\}.$$

For the L^2 scalar product we use the notation $(f,g) := \int_\Omega fg\,dx$ (and similarly for vector functions). The standard norm in $\mathbf{V}$ is denoted by $\|\cdot\|_1$. The weak formulation is as follows: Determine $(\mathbf{u},p) \in \mathbf{V}\times Q$ such that

$$\begin{aligned} &\int_\Omega \frac{\mu}{2}\,\mathbf{D}(\mathbf{u}) : \mathbf{D}(\mathbf{v})\,dx + (\rho\,\mathbf{u}\cdot\nabla\mathbf{u},\mathbf{v}) + (\operatorname{div}\mathbf{v},p) = (\rho\,\mathbf{g},\mathbf{v}) + f_\Gamma(\mathbf{v}) \quad \text{for all } \mathbf{v}\in\mathbf{V}, \\ &(\operatorname{div}\mathbf{u},q) = 0 \quad \text{for all } q \in Q, \end{aligned} \tag{1.3}$$

with

$$f_\Gamma(\mathbf{v}) = \tau \int_\Gamma \mathcal{K}\mathbf{n}_\Gamma \cdot \mathbf{v}\,ds, \tag{1.4}$$

and $\mathbf{D}(\mathbf{u}) : \mathbf{D}(\mathbf{v}) = \operatorname{tr}\big(\mathbf{D}(\mathbf{u})\mathbf{D}(\mathbf{v})\big)$. The functions μ and ρ are strictly positive and piecewise constant in $\Omega_i,\ i=1,2$. For Γ sufficiently smooth we have $\sup_{x\in\Gamma}|\mathcal{K}(x)| \le c < \infty$, and thus

$$|f_\Gamma(\mathbf{v})| \le c\,\tau \int_\Gamma |\mathbf{n}_\Gamma\cdot\mathbf{v}|\,ds \le c\,\|\mathbf{v}\|_{L^2(\Gamma)} \le c\|\mathbf{v}\|_1 \quad \text{for all } \ \mathbf{v}\in\mathbf{V}. \tag{1.5}$$

Here and in the remainder we use the notation c for a generic constant. From (1.5) we see that $f_\Gamma \in \mathbf{V}'$, and thus under the usual assumptions (cf. [13]) the stationary Navier–Stokes equations (1.3) have a unique solution. We emphasize that the location of the interface is in general unknown and has to be determined (approximated) before the Navier–Stokes equations (1.3) can be solved. In this paper we assume that the unknown interface is captured using a level set technique. For a discussion of level set methods in incompressible two-phase flow problems we refer to the literature [6, 14, 21, 24]. We assume that the interface Γ is characterized as the zero level of the level set function d, which locally (close to the interface) is a signed distance function.

We now turn to the discretization of (1.3). We assume that $\mathcal{S}$ is a triangulation of Ω consisting of tetrahedra. With this triangulation we associate a mesh size parameter H. Let $\mathbf{V}_H \subset \mathbf{V}$, $Q_H \subset Q$ be standard polynomial finite element spaces corresponding to the triangulation $\mathcal{S}$, for example, the Hood–Taylor P_2-P_1 pair. In practice, the triangulation $\mathcal{S}$ is locally refined close to the interface Γ but *not* aligned with this interface; cf. Figures 2.1 and 6.1. The Galerkin discretization is as follows: Determine $(\mathbf{u}_H, p_H) \in \mathbf{V}_H \times Q_H$ such that

$$
\begin{aligned}
&\int_\Omega \frac{\mu}{2}\, \mathbf{D}(\mathbf{u}_H) : \mathbf{D}(\mathbf{v}_H)\, dx + (\rho\, \mathbf{u}_H \cdot \nabla \mathbf{u}_H, \mathbf{v}_H) + (\operatorname{div} \mathbf{v}_H, p_H) \\
&= (\rho\, \mathbf{g}, \mathbf{v}_H) + f_\Gamma(\mathbf{v}_H) \quad \text{for all } \ \mathbf{v}_H \in \mathbf{V}_H, \\
&(\operatorname{div} \mathbf{u}_H, q_H) = 0 \quad \text{for all } \ q_H \in Q_H.
\end{aligned} \tag{1.6}
$$

For this discrete problem, many important theoretical issues are still unsolved. For example, regarding iterative solvers there is the issue of robustness w.r.t. large jumps in the density and viscosity coefficients (results for Stokes equations are given in [20, 19, 18]). A second example is the effect of errors in the approximation of $f_\Gamma(\mathbf{v}_H)$ on the accuracy of the flow variables. In this paper we treat the latter topic.

As mentioned above, the interface Γ has to be approximated. Furthermore, to evaluate the integral in (1.4) the curvature of Γ has to be approximated and a quadrature rule may be needed. Thus the term $f_\Gamma(\mathbf{v}_H)$ on the right-hand side in (1.6) will be replaced by an approximation $\tilde{f}(\mathbf{v}_H)$. For the effect of the surface tension force approximation error on the accuracy of the velocity and pressure variables, the quantity

$$
\sup_{\mathbf{v} \in \mathbf{V}_H} \frac{f_\Gamma(\mathbf{v}_H) - \tilde{f}(\mathbf{v}_H)}{\|\mathbf{v}_H\|_1} \tag{1.7}
$$

is crucial (Strang lemma). The two main ingredients in the approximation method that we use are the following. First, a Laplace–Beltrami characterization of the curvature is used. This technique has been applied in mean curvature flows (cf. [7]) and in flows with a free capillary surface (cf. [3, 4]). Application of this technique in two-phase incompressible flows can be found in [12, 11, 14, 17]. Second, the unknown interface Γ (zero level of d) is approximated as the zero level Γ_h of a finite element approximation d_h of d. The approximate interface Γ_h consists of triangular faces. The parameter h is the maximal diameter of these faces and is not necessarily of the same order of magnitude as H. For this approximation technique we derive a sharp bound for the quantity in (1.7). The main result of this paper is the $\mathcal{O}(\sqrt{h})$ bound given in Corollary 4.8. We do not know of any literature in which, for this technique or for any other technique for approximating $f_\Gamma(\mathbf{v}_H)$, rigorous bounds for the quantity in (1.7) are derived. A numerical experiment (given in section 6) indicates that the $\mathcal{O}(\sqrt{h})$ is sharp. Our analysis reveals how the approximation method can be improved. A modified new approach, resulting in an $\mathcal{O}(h)$ bound, is presented in section 5.

2. Approximation of the surface tension force $f_\Gamma(\mathbf{v}_H)$. In this section we explain how the localized surface tension force term, $f_\Gamma(\mathbf{v}_H)$ in (1.6), is approximated. For this we first need some notions from differential geometry.

Let U be an open subset in $\mathbb{R}^3$ and Γ a connected C^2 compact hypersurface contained in U. For a sufficiently smooth function $g : U \to \mathbb{R}$ the tangential derivative

(along Γ) is defined by projecting the derivative on the tangent space of Γ, i.e.,

$$\nabla_\Gamma g = \nabla g - \nabla g \cdot \mathbf{n}_\Gamma \, \mathbf{n}_\Gamma. \tag{2.1}$$

The *Laplace–Beltrami operator* of g on Γ is defined by

$$\Delta_\Gamma g := \nabla_\Gamma \cdot \nabla_\Gamma g.$$

It can be shown that $\nabla_\Gamma g$ and $\Delta_\Gamma g$ depend only on values of g on Γ. For vector valued functions f, $g : \Gamma \to \mathbb{R}^3$ we define

$$\Delta_\Gamma f := (\Delta_\Gamma f_1, \Delta_\Gamma f_2, \Delta_\Gamma f_3)^T, \qquad \nabla_\Gamma f \cdot \nabla_\Gamma g := \sum_{i=1}^{3} \nabla_\Gamma f_i \cdot \nabla_\Gamma g_i.$$

We recall the following basic result from differential geometry.

THEOREM 2.1. *Let* $\mathrm{id}_\Gamma : \Gamma \to \mathbb{R}^3$ *be the identity on* Γ *and* $\mathcal{K} = \kappa_1 + \kappa_2$ *the sum of the principal curvatures. For all sufficiently smooth vector functions* $\mathbf{v}$ *on* Γ *the following holds:*

$$\int_\Gamma \mathcal{K}\, \mathbf{n}_\Gamma \cdot \mathbf{v}\, ds = -\int_\Gamma (\Delta_\Gamma \,\mathrm{id}_\Gamma) \cdot \mathbf{v}\, ds = \int_\Gamma \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma \mathbf{v}\, ds. \tag{2.2}$$

In a finite element setting (which is based on a weak formulation) it is natural to use the expression on the right-hand side of (2.2) as a starting point for the discretization. This idea is used in, for example, [10, 4, 12, 14]. In this discretization we use *an approximation* Γ_h *of* Γ.

For the formulation of assumptions on the approximate interface Γ_h it is convenient to introduce the signed distance function $d : U \to \mathbb{R}$, $|d(x)| := \mathrm{dist}(x, \Gamma)$ for all $x \in U$. Thus Γ is the zero level set of d. We assume $d < 0$ on the interior of Γ (that is, in Ω_1) and $d > 0$ on the exterior. Note that $\mathbf{n}_\Gamma = \nabla d$ on Γ. We define $\mathbf{n}(x) := \nabla d(x)$ for all $x \in U$. Thus $\mathbf{n} = \mathbf{n}_\Gamma$ on Γ and $\|\mathbf{n}(x)\| = 1$ for all $x \in U$. Here and in the remainder $\|\cdot\|$ denotes the Euclidean norm. The Hessian of d is denoted by $\mathbf{H}$:

$$\mathbf{H}(x) = D^2 d(x) \in \mathbb{R}^{3\times 3} \quad \text{for all} \quad x \in U. \tag{2.3}$$

The eigenvalues of $\mathbf{H}(x)$ are denoted by $\kappa_1(x), \kappa_2(x)$, and 0. For $x \in \Gamma$ the eigenvalues $\kappa_i(x)$, $i = 1, 2$, are the principal curvatures.

We will need the orthogonal projection

$$\mathbf{P}(x) = \mathbf{I} - \mathbf{n}(x)\mathbf{n}(x)^T \quad \text{for} \quad x \in U.$$

Note that the tangential derivative can be written as $\nabla_\Gamma g = \mathbf{P}\nabla g$.

Using the distance function d we now introduce assumptions on the approximate interface Γ_h. In Remark 2 below we indicate how in practice an approximate interface Γ_h can be constructed which satisfies these assumptions. Let $\{\Gamma_h\}_{h>0}$ be a family of polygonal approximations of Γ. Each Γ_h is contained in U and consists of a set $\mathcal{F}_h$ of triangular faces: $\Gamma_h = \cup_{T\in\mathcal{F}_h} T$. For $T_1, T_2 \in \mathcal{F}_h$ with $T_1 \neq T_2$ we assume that $T_1 \cap T_2$ is either empty or a common edge or a common vertex. The parameter h denotes the maximal diameter of the triangles in $\mathcal{F}_h$: $h = \max_{T\in\mathcal{F}_h} \mathrm{diam}(T)$. By $\mathbf{n}_h$ we denote the outward pointing unit normal on Γ_h. This normal is piecewise constant with possible discontinuities at the edges of the triangles in $\mathcal{F}_h$.

The approximation Γ_h is assumed to be close to Γ in the following sense:

$$|d(x)| \leq ch^2 \quad \text{for all} \quad x \in \Gamma_h, \tag{2.4}$$

$$\operatorname{ess\,inf}_{x\in\Gamma_h} \mathbf{n}(x)^T \mathbf{n}_h(x) \geq c > 0, \tag{2.5}$$

$$\operatorname{ess\,sup}_{x\in\Gamma_h} \|\mathbf{P}(x)\mathbf{n}_h(x)\| \leq ch. \tag{2.6}$$

Here c denotes a generic constant independent of h.

Remark 1. The conditions (2.5), (2.6) are satisfied if

$$\operatorname{ess\,sup}_{x\in\Gamma_h} \|\mathbf{n}(x) - \mathbf{n}_h(x)\| \leq \min\{c_0, ch\} \quad \text{with} \quad c_0 < \sqrt{2} \tag{2.7}$$

holds. This easily follows from

$$\|\mathbf{n}(x) - \mathbf{n}_h(x)\|^2 = 2\big(1 - \mathbf{n}(x)^T \mathbf{n}_h(x)\big)$$

and

$$\|\mathbf{P}(x)\mathbf{n}_h(x)\| = \|\mathbf{P}(x)\big(\mathbf{n}(x) - \mathbf{n}_h(x)\big)\| \leq \|\mathbf{n}(x) - \mathbf{n}_h(x)\|.$$

Remark 2. We briefly explain the approach that is used in [14] (cf. also [9]) for computing Γ_h. Let $\mathcal{S}$ be the (locally refined) triangulation of Ω, consisting of tetrahedra, that is used for the discretization of the flow variables with finite elements; cf. (1.6) (in our approach we use the Hood–Taylor P_2-P_1 pair). The level set equation for d is discretized with continuous piecewise quadratic finite elements on a triangulation $\mathcal{T}$. This triangulation is either equal to $\mathcal{S}$ or obtained from one or a few regular refinements of $\mathcal{S}$ (the subdivision of each tetrahedron in eight child tetrahedra). The piecewise *quadratic* finite element approximation of d on $\mathcal{T}$ is denoted by d_h. We now introduce one further regular refinement of $\mathcal{T}$, resulting in $\mathcal{T}'$. Let $I(d_h)$ be the continuous piecewise *linear* function on $\mathcal{T}'$ which interpolates d_h at all vertices of all tetrahedra in $\mathcal{T}'$. The approximation of the interface Γ is defined by

$$\Gamma_h := \{\, x \in \Omega \mid I(d_h)(x) = 0 \,\}$$

which consists of piecewise planar segments. The mesh size parameter h is the maximal diameter of these segments. This (maximal) diameter is approximately the (maximal) diameter of the tetrahedra in $\mathcal{T}'$ that contain the discrete interface; i.e., h is approximately the maximal diameter of the tetrahedra in $\mathcal{T}'$ *that are close to the interface*. In Figure 2.1 we illustrate this construction for the two-dimensional case.

Each of the planar segments of Γ_h is either a triangle or a quadrilateral. The quadrilaterals can (formally) be divided into two triangles. Thus Γ_h consists of a set $\mathcal{F}_h$ of triangular faces. For the example considered in section 6, in which Γ is a sphere, the resulting polygonal approximations Γ_h for $h = \frac{1}{5}$ and $h = \frac{1}{10}$, resp., are shown in Figure 2.2.

We note the following related to the assumptions (2.4)–(2.6). If we assume $|I(d_h)(x) - d(x)| \leq c\,h^2$ for all x in a neighborhood of Γ, which is reasonable for a smooth d and piecewise quadratic d_h, then for $x \in \Gamma_h$ we have $|d(x)| = |d(x) - I(d_h)(x)| \leq c\,h^2$, and thus (2.4) is satisfied. Instead of (2.5), (2.6) we consider the sufficient condition (2.7). We assume $\|\nabla d(x) - \nabla I(d_h)(x)\| \leq c\,h$ for all x in a neighborhood of Γ (x not on an edge), which again is reasonable for a smooth d and

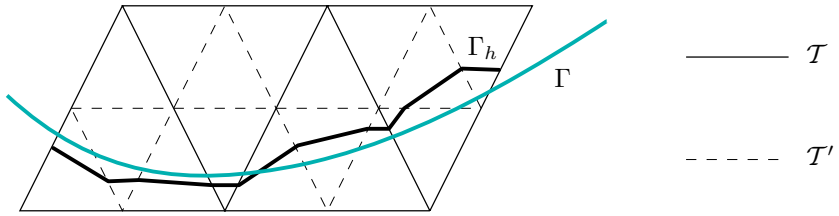

FIG. 2.1. *Construction of approximate interface for the two-dimensional case.*

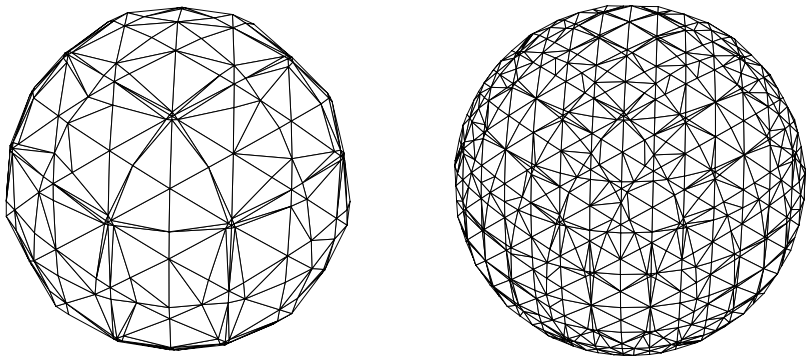

FIG. 2.2. *Approximate interface Γ_h for the example from section 6 on a coarse grid (left) and after one refinement (right).*

piecewise quadratic d_h. Due to $\|\nabla d\| = 1$ we then also have $\|\nabla I(d_h)(x)\| = 1 + \mathcal{O}(h)$ in a neighborhood of Γ. For $x \in \Gamma_h$ (not on an edge) we obtain

$$\begin{aligned}\|\mathbf{n}_h(x) - \mathbf{n}(x)\| &= \Big\| \frac{\nabla I(d_h)(x)}{\|\nabla I(d_h)(x)\|} - \nabla d(x) \Big\| \\ &\leq \Big| \frac{1}{\|\nabla I(d_h)(x)\|} - 1 \Big| \cdot \|\nabla I(d_h)(x)\| + \|\nabla I(d_h)(x) - \nabla d(x)\| \leq c\, h,\end{aligned}$$

and thus (2.7) is satisfied (for h sufficiently small).

Given an approximate interface Γ_h, the localized force term $f_\Gamma(\mathbf{v}_H)$ is approximated by

$$\tilde{f}(\mathbf{v}_H) = f_{\Gamma_h}(\mathbf{v}_H) := \tau \int_{\Gamma_h} \nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} \cdot \nabla_{\Gamma_h} \mathbf{v}_H \, ds, \qquad \mathbf{v}_H \in \mathbf{V}_H. \tag{2.8}$$

Under the assumptions (2.4)–(2.6) on the family $\{\Gamma_h\}_{h>0}$ in section 4 we will derive a bound for the approximation error

$$\sup_{\mathbf{v}_H \in \mathbf{V}_H} \frac{f_\Gamma(\mathbf{v}_H) - f_{\Gamma_h}(\mathbf{v}_H)}{\|\mathbf{v}_H\|_1} \quad \text{with} \quad f_{\Gamma_h}(\mathbf{v}_H) \quad \text{as in (2.8)}. \tag{2.9}$$

Remark 3. From Theorem 2.1, the fact that $f_\Gamma(\mathbf{v}) = \tau \int_\Gamma \mathcal{K}\mathbf{v} \cdot \mathbf{n}\, ds$ is a bounded linear functional on $\mathbf{V}$, and a density argument, it follows that the linear functional

$$f_\Gamma : \ \mathbf{v} \to \tau \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma \mathbf{v} \, ds \ , \qquad \mathbf{v} \in \left(C_0^\infty(\Omega)\right)^3, \tag{2.10}$$

has a unique bounded extension to $\mathbf{V}$. Therefore, for $f_\Gamma : \mathbf{V} \to \mathbb{R}$ we can use both the representation in (1.4) and the one in (2.10) (these are the same on a dense subset). This, however, is *not* the case for f_{Γ_h}. Because Γ_h is not sufficiently smooth, a partial integration result as in Theorem 2.1 does not hold. The linear functional

$$\mathbf{v} \to \tau \int_{\Gamma_h} \nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} \cdot \nabla_{\Gamma_h} \mathbf{v}\, ds$$

is *not* necessarily bounded on $\mathbf{V}$. For this reason the restriction to $\mathbf{v}_H$ from the finite element space $\mathbf{V}_H$ in (2.9) is essential.

Remark 4. At many places in this section, for example in (2.2), (2.3) and (implicitly) in (2.4), and also in the analysis presented in the next section, the assumption that Γ is a C^2 smooth interface plays a crucial role. We do not know of any literature in which smoothness properties of the interface are analyzed for a Navier–Stokes incompressible two-phase flow problem with surface tension. In [2] and [1] a two-phase Stokes flow problem without surface tension, in which the evolution is driven by the gravity force, is analyzed. In [2] it is proved that if the initial configuration has a C^2 smooth interface $\Gamma = \Gamma(0)$, then for arbitrary finite time $t > 0$ the interface $\Gamma(t)$ is a surface of class $C^{2-\varepsilon}$ for arbitrary $\varepsilon \in (0, 2]$. In [1] it is shown that if $\Gamma(0)$ is a $C^{2+\ell}$ smooth surface, with $\ell > 0$, then $\Gamma(t)$ is of class $C^{2+\ell}$, too, for all $t \in [0, T]$ and $T > 0$ sufficiently small.

3. Preliminaries. In this section we collect some results that will be used in the analysis in section 4. The techniques that we use come from the paper [8]. For proofs of certain results we will refer to that paper.

We introduce a locally (in a neighborhood of Γ) orthogonal coordinate system by using the projection $\mathbf{p} : U \to \Gamma$:

$$\mathbf{p}(x) = x - d(x)\mathbf{n}(x) \quad \text{for all} \quad x \in U.$$

We assume that the decomposition $x = \mathbf{p}(x) + d(x)\mathbf{n}(x)$ is unique for all $x \in U$. Note that

$$\mathbf{n}(x) = \mathbf{n}(\mathbf{p}(x)) \quad \text{for all} \quad x \in U.$$

We use an extension operator defined as follows. For a (scalar) function v defined on Γ we define

$$v_\Gamma^e(x) := v(x - d(x)\mathbf{n}(x)) = v(\mathbf{p}(x)) \quad \text{for all} \quad x \in U;$$

i.e., v is extended along normals on Γ. We will also need extensions of functions defined on Γ_h to U. This is done again by extending along normals $\mathbf{n}(x)$. For v defined on Γ_h we define, for $x \in \Gamma_h$,

$$v_{\Gamma_h}^e(x + \alpha\mathbf{n}(x)) := v(x) \quad \text{for all} \quad \alpha \in \mathbb{R} \quad \text{with} \quad x + \alpha\mathbf{n}(x) \in U. \tag{3.1}$$

The projection $\mathbf{p}$ and the extensions v_Γ^e, $v_{\Gamma_h}^e$ are illustrated in Figure 3.1.

We define a discrete analogue of the orthogonal projection $\mathbf{P}$:

$$\mathbf{P}_h(x) := \mathbf{I} - \mathbf{n}_h(x)\mathbf{n}_h(x)^T \quad \text{for} \quad x \in \Gamma_h,\ x \text{ not on an edge.}$$

The tangential derivative along Γ_h can be written as $\nabla_{\Gamma_h} g = \mathbf{P}_h \nabla g$. In the analysis a further technical assumption is used, namely that the neighborhood U of Γ is

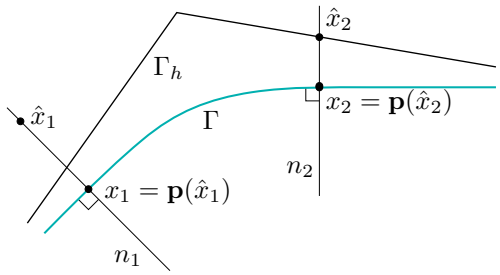

FIG. 3.1. *Example for projection* $\mathbf{p}$ *and construction of extension operators.* n_1 *and* n_2 *are straight lines perpendicular to* Γ. *For* v *defined on* Γ *we have* $v_\Gamma^e \equiv v(x_1)$ *on* n_1. *For* v_h *defined on* Γ_h *we have* $v_{\Gamma_h}^e \equiv v_h(\hat{x}_2)$ *on* n_2.

sufficiently small in the following sense. We assume that U is a strip of width $\delta > 0$ with

$$\delta^{-1} > \max_{i=1,2} \|\kappa_i(x)\|_{L^\infty(\Gamma)}. \tag{3.2}$$

Assumption 1. In the remainder of the paper we assume that (2.4), (2.5), (2.6), and (3.2) hold.

We present two lemmas from [8]. Proofs are elementary and can be found in [8].

LEMMA 3.1. *For the projection operator* $\mathbf{P}$ *and the Hessian* $\mathbf{H}$ *the relation*

$$\mathbf{P}(x)\mathbf{H}(x) = \mathbf{H}(x)\mathbf{P}(x) = \mathbf{H}(x) \quad \text{for all} \quad x \in U$$

holds. For v *defined on* Γ *and sufficiently smooth the following holds:*

$$\nabla_{\Gamma_h} v_\Gamma^e(x) = \mathbf{P}_h(x)\big(\mathbf{I} - d(x)\mathbf{H}(x)\big)\mathbf{P}(x)\nabla_\Gamma v(\mathbf{p}(x)) \quad \text{a.e. on} \quad \Gamma_h. \tag{3.3}$$

Proof. A proof is given in section 2.3 in [8]. ∎

In (3.3) (and also below) we have the result "a.e. on Γ_h" because quantities (derivatives, $\mathbf{P}_h$, etc.) are not well defined on the edges of the triangulation Γ_h.

LEMMA 3.2. *For* $x \in \Gamma_h$ *(not on an edge) define*

$$\mu(x) = \big[\Pi_{i=1}^2 (1 - d(x)\kappa_i(x))\big]\mathbf{n}(x)^T\mathbf{n}_h(x), \tag{3.4}$$

$$\mathbf{A}(x) = \frac{1}{\mu(x)}\mathbf{P}(x)\big[\mathbf{I} - d(x)\mathbf{H}(x)\big]\mathbf{P}_h(x)\big[\mathbf{I} - d(x)\mathbf{H}(x)\big]\mathbf{P}(x). \tag{3.5}$$

Let $\mathbf{A}_{\Gamma_h}^e$ *be the extension of* $\mathbf{A}$ *as in* (3.1). *The following identity holds for functions* v *and* ψ *that are defined on* Γ_h *and sufficiently smooth:*

$$\int_{\Gamma_h} \nabla_{\Gamma_h} v \cdot \nabla_{\Gamma_h} \psi \, ds = \int_\Gamma \mathbf{A}_{\Gamma_h}^e \nabla_\Gamma v_{\Gamma_h}^e \cdot \nabla_\Gamma \psi_{\Gamma_h}^e \, ds. \tag{3.6}$$

Proof. A proof is given in section 2.3 in [8]. ∎

Due to the assumptions in (2.5) and (3.2) we have $\operatorname{ess\,inf}_{x\in\Gamma_h} \mu(x) > 0$, and thus $\mathbf{A}(x)$ is well defined.

We now derive two further results that are needed in the analysis in section 4.

LEMMA 3.3. *There exists a constant* c *independent of* h *such that*

$$\|\nabla_\Gamma v_{\Gamma_h}^e\|_{L^2(\Gamma)} \le c\,\|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \text{for all} \quad v \in H^1(\Gamma_h) \cap C(\Gamma_h).$$

Proof. Due to Lemma 3.2 we have

$$\|\nabla_{\Gamma_h} v\|^2_{L^2(\Gamma_h)} = \int_\Gamma \mathbf{A}^e_{\Gamma_h}(y)\nabla_\Gamma v^e_{\Gamma_h}(y)\cdot\nabla_\Gamma v^e_{\Gamma_h}(y)\,ds(y)$$

with $ds(y)$ the surface measure on Γ. Take $x\in\Gamma_h$ with $\mathbf{p}(x)=y$. If x does not lie on an edge, we have $\mathbf{A}^e_{\Gamma_h}(y)=\mathbf{A}(x)$ with $\mathbf{A}(x)$ as in (3.5). We drop the symbol x in the notation and write $\mathbf{A}(x)=\mathbf{A}=\frac{1}{\mu}\mathbf{P}(\mathbf{I}-d\mathbf{H})\mathbf{P}_h(\mathbf{I}-d\mathbf{H})\mathbf{P}$. Decompose $\mathbf{n}_h$ as $\mathbf{n}_h=\alpha\mathbf{n}+\beta\mathbf{n}^\perp$ with $\|\mathbf{n}^\perp\|=1$ and $\mathbf{n}^T\mathbf{n}^\perp=0$. From (2.5) is follows that $\alpha\geq c>0$ and thus $\beta^2\leq 1-c^2<1$. Take $z\in\operatorname{range}(\mathbf{P})$ with $\|z\|=1$. We then have $\|\mathbf{P}_h z\|\geq\|z\|-|z^T\mathbf{n}_h|=\|z\|-|\beta||z^T\mathbf{n}^\perp|\geq(1-|\beta|)\|z\|$. Hence, there is a constant $c>0$ such that

$$\|\mathbf{P}_h\mathbf{P}w\|\geq c\,\|\mathbf{P}w\|\quad\text{for all}\ \ w\in\mathbb{R}^3.$$

Using (3.2) it follows that there is a constant $c>0$ such that $\|(\mathbf{I}-d\mathbf{H})w\|\geq c\,\|w\|$ for all $w\in\mathbb{R}^3$. Note that $\mu=\mu(x)\geq c>0$ holds. From these results we obtain, using $\mathbf{PH}=\mathbf{HP}$ (Lemma 3.1),

$$\begin{aligned} w^T\mathbf{A}w &= \frac{1}{\mu}w^T\mathbf{P}(\mathbf{I}-d\mathbf{H})\mathbf{P}_h(\mathbf{I}-d\mathbf{H})\mathbf{P}w\\ &= \frac{1}{\mu}\|\mathbf{P}_h\mathbf{P}(\mathbf{I}-d\mathbf{H})w\|^2\geq c\,\|\mathbf{P}w\|^2\quad\text{for all}\ \ w\in\mathbb{R}^3, \end{aligned}$$

with a constant $c>0$. This yields, using $\mathbf{n}(x)=\mathbf{n}(\mathbf{p}(x))=\mathbf{n}(y)$,

$$\mathbf{A}^e_{\Gamma_h}(y)w\cdot w = w^T\mathbf{A}(x)w\geq c\,\|\mathbf{P}(x)w\|^2=\|\mathbf{P}(y)w\|^2,$$

with $c>0$. For $w=\nabla_\Gamma v^e_{\Gamma_h}(y)$ we have $\mathbf{P}(y)w=\mathbf{P}(y)\nabla_\Gamma v^e_{\Gamma_h}(y)=\nabla_\Gamma v^e_{\Gamma_h}(y)$, and thus we get

$$\begin{aligned} \|\nabla_{\Gamma_h} v\|^2_{L^2(\Gamma_h)} &= \int_\Gamma \mathbf{A}^e_{\Gamma_h}(y)\nabla_\Gamma v^e_{\Gamma_h}(y)\cdot\nabla_\Gamma v^e_{\Gamma_h}(y)\,ds(y)\\ &\geq c\int_\Gamma \nabla_\Gamma v^e_{\Gamma_h}(y)\cdot\nabla_\Gamma v^e_{\Gamma_h}(y)\,ds(y)=c\,\|\nabla_\Gamma v^e_{\Gamma_h}\|^2_{L^2(\Gamma)}, \end{aligned}$$

with a constant $c>0$. ∎

LEMMA 3.4. *The following holds:*

$$\operatorname{ess\,sup}_{y\in\Gamma}\|\big(\mathbf{A}^e_{\Gamma_h}(y)-\mathbf{I}\big)\mathbf{P}(y)\|\leq ch^2.$$

Proof. Take $y\in\Gamma$ and a corresponding $x\in\Gamma_h$ such that $\mathbf{p}(x)=y$. Assume that x does not lie on an edge of the triangulation Γ_h, which is true for almost all $y\in\Gamma$. Then we have

$$(\mathbf{A}^e_{\Gamma_h}(y)-\mathbf{I})\mathbf{P}(y)=(\mathbf{A}(x)-\mathbf{I})\mathbf{P}(x).$$

We drop the symbol x in the notation and write $\mathbf{A}(x)=\mathbf{A}=\frac{1}{\mu}\mathbf{P}(\mathbf{I}-d\mathbf{H})\mathbf{P}_h(\mathbf{I}-d\mathbf{H})\mathbf{P}$. Note that $|\mu|=\mu(x)\geq c>0$ holds. Decompose $\mathbf{n}_h$ as $\mathbf{n}_h=\alpha\mathbf{n}+\beta\mathbf{n}^\perp$ with $\|\mathbf{n}^\perp\|=1$ and $\mathbf{n}^T\mathbf{n}^\perp=0$. Due to (2.5) we have $\alpha=\mathbf{n}^T\mathbf{n}_h\geq c>0$. From (2.6) we get $\|\mathbf{P}\mathbf{n}_h\|=|\beta|\leq ch$. Hence,

$$|\mathbf{n}^T\mathbf{n}_h-1|=1-\alpha=\frac{1-\alpha^2}{1+\alpha}\leq 1-\alpha^2=\beta^2\leq c\,h^2. \tag{3.7}$$

Using this and $|d(x)| \leq ch^2,\ |\kappa_i(x)| \leq c$, we obtain $|\mu - 1| \leq c\,h^2$. Thus

$$\left|\frac{1}{\mu} - 1\right| = \frac{|\mu - 1|}{\mu} \leq c\,h^2 \tag{3.8}$$

holds. We have

$$\begin{aligned}(\mathbf{A} - \mathbf{I})\mathbf{P} &= \frac{1}{\mu}\mathbf{P}(\mathbf{I} - d\mathbf{H})\mathbf{P}_h(\mathbf{I} - d\mathbf{H})\mathbf{P} - \mathbf{P} \\ &= \left[\left(\frac{1}{\mu} - 1\right)\mathbf{P}(\mathbf{I} - d\mathbf{H})\mathbf{P}_h(\mathbf{I} - d\mathbf{H})\mathbf{P}\right] + \left[\mathbf{P}(\mathbf{I} - d\mathbf{H})\mathbf{P}_h(\mathbf{I} - d\mathbf{H})\mathbf{P} - \mathbf{P}\right]\end{aligned}$$

and consider the two terms on the right-hand side separately. For the first term we get, using (3.8),

$$\left\|\left(\frac{1}{\mu} - 1\right)\mathbf{P}(\mathbf{I} - d\mathbf{H})\mathbf{P}_h(\mathbf{I} - d\mathbf{H})\mathbf{P}\right\| \leq \left|\frac{1}{\mu} - 1\right|(1 + c\,h^2)(1 + c\,h^2) \leq c\,h^2.$$

For the second term we obtain, using (2.6),

$$\begin{aligned}\|\mathbf{P}(\mathbf{I} - d\mathbf{H})\mathbf{P}_h(\mathbf{I} - d\mathbf{H})\mathbf{P} - \mathbf{P}\| &\leq \|\mathbf{P}\mathbf{P}_h\mathbf{P} - \mathbf{P}\| + c\,h^2 \\ &= \|\mathbf{P}\mathbf{n}_h\mathbf{n}_h^T\mathbf{P}\| + c\,h^2 = \|\mathbf{P}\mathbf{n}_h\|^2 + c\,h^2 \leq c\,h^2.\end{aligned}$$

Combination of these bounds completes the proof. ∎

4. Approximation error analysis. We are interested in the difference between the terms

$$\tau \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma \mathbf{v}_H\, ds \quad \text{and} \quad \tau \int_{\Gamma_h} \nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} \cdot \nabla_{\Gamma_h} \mathbf{v}_H\, ds \quad \text{for} \quad \mathbf{v}_H \in \mathbf{V}_H.$$

Since $\nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma \mathbf{v}_H = \sum_{i=1}^3 \nabla_\Gamma(\mathrm{id}_\Gamma)_i \cdot \nabla_\Gamma(\mathbf{v}_H)_i$ we consider only one term in this sum, say the ith. We write id_Γ and v for the *scalar* functions $(\mathrm{id}_\Gamma)_i$ and $(\mathbf{v}_H)_i$, respectively. We write id_{Γ_h} for $(\mathrm{id}_{\Gamma_h})_i$. Note that

$$\nabla_\Gamma \mathrm{id}_\Gamma = \mathbf{P}\nabla \mathrm{id}_\Gamma = \mathbf{P}e_i, \quad \nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} = \mathbf{P}_h \nabla \mathrm{id}_{\Gamma_h} = \mathbf{P}_h e_i,$$

with e_i the ith basis vector in $\mathbb{R}^3$. We introduce scalar versions of the functionals f_Γ and f_{Γ_h} defined in (2.10) and (2.8) (without loss of generality we can take $\tau := 1$):

$$g(v) := \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma v\, ds, \quad g_h(v) := \int_{\Gamma_h} \nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} \cdot \nabla_{\Gamma_h} v\, ds.$$

As noted in Remark 3, g is a bounded linear functional on $H^1(U)$. To guarantee that g_h and the extension operator in (3.1) are well defined we assume $v \in H^1(\Gamma_h) \cap C(\Gamma_h)$. Therefore, in the analysis in this section we use the subspace W of $H^1(U)$ consisting of functions whose restriction to Γ_h belongs to $H^1(\Gamma_h) \cap C(\Gamma_h)$.

Remark 5. If we use a Hood–Taylor pair $\mathbf{V}_H \times Q_H$ in the discretization of the Navier–Stokes equations, then the ith component $v \in V_H$ of $\mathbf{v}_H \in \mathbf{V}_H = (V_H)^3$ is continuous and piecewise polynomial (on the tetrahedral triangulation $\mathcal{S}$). Thus $v \in W$ holds.

In this section we first derive, for $v \in W$, a bound for $|g(v) - g_h(v)|$ in terms of $\|v\|_{1,U} := \|v\|_{H^1(U)}$ and $\|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)}$. This bound is given in Corollary 4.4. Using this bound we then derive a bound for

$$\sup_{v \in V_H} \frac{g(v) - g_h(v)}{\|v\|_1};$$

cf. Theorem 4.7. This immediately implies a bound for the approximation error as in (2.9); cf. Corollary 4.8.

The analysis is based on the following splitting:

$$\begin{aligned}
&g(v) - g_h(v) \\
&= \int_\Gamma \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v \, ds - \int_{\Gamma_h} \nabla_{\Gamma_h} \,\mathrm{id}_\Gamma^e \cdot \nabla_{\Gamma_h} v \, ds + \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds \\
&\overset{(3.6)}{=} \int_\Gamma \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v \, ds - \int_\Gamma \mathbf{A}_{\Gamma_h}^e \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v_{\Gamma_h}^e \, ds + \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds \\
&= \int_\Gamma \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma (v - v_{\Gamma_h}^e) \, ds + \int_\Gamma (\mathbf{I} - \mathbf{A}_{\Gamma_h}^e) \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v_{\Gamma_h}^e \, ds \\
&\qquad + \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds. \qquad (4.1)
\end{aligned}$$

In the lemmas below we derive bounds for the three terms in (4.1). Note that the first two terms do *not* involve id_{Γ_h}.

LEMMA 4.1. *The following holds:*

$$\left| \int_\Gamma (\mathbf{I} - \mathbf{A}_{\Gamma_h}^e) \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v_{\Gamma_h}^e \, ds \right| \leq c\, h^2 \, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \textit{for all} \quad v \in W.$$

Proof. Using the Cauchy–Schwarz inequality and the results in Lemmas 3.3 and 3.4 we obtain

$$\begin{aligned}
&\left| \int_\Gamma (\mathbf{I} - \mathbf{A}_{\Gamma_h}^e) \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v_{\Gamma_h}^e \, ds \right| = \left| \int_\Gamma (\mathbf{I} - \mathbf{A}_{\Gamma_h}^e) \mathbf{P} \nabla_\Gamma \,\mathrm{id}_\Gamma \cdot \nabla_\Gamma v_{\Gamma_h}^e \, ds \right| \\
&\leq \operatorname{ess\,sup}_{y \in \Gamma} \|(\mathbf{I} - \mathbf{A}_{\Gamma_h}^e(y)) \mathbf{P}(y)\| \, \|\nabla_\Gamma \,\mathrm{id}_\Gamma\|_{L^2(\Gamma)} \, \|\nabla_\Gamma v_{\Gamma_h}^e\|_{L^2(\Gamma)} \\
&\leq c\, h^2 \, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)},
\end{aligned}$$

and thus the result holds. ∎

LEMMA 4.2. *The following holds:*

$$\left| \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds \right| \leq c\, h \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \textit{for all} \quad v \in W.$$

Proof. From Lemma 3.1 we get for $x \in \Gamma_h$ (not on an edge),

$$\begin{aligned}
\nabla_{\Gamma_h} \,\mathrm{id}_\Gamma^e(x) &= \mathbf{P}_h(x) \big(\mathbf{I} - d(x) \mathbf{H}(x)\big) \mathbf{P}(x) \nabla_\Gamma \,\mathrm{id}_\Gamma(\mathbf{p}(x)) \\
&= \mathbf{P}_h(x) \big(\mathbf{I} - d(x) \mathbf{H}(x)\big) \mathbf{P}(x) e_i.
\end{aligned}$$

We also have $\nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h} = \mathbf{P}_h \nabla \mathrm{id}_{\Gamma_h} = \mathbf{P}_h e_i$. Hence,

$$\left| \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds \right| \tag{4.2}$$

$$= \left| \int_{\Gamma_h} \big(\mathbf{P}_h (\mathbf{I} - d\mathbf{H}) \mathbf{P} e_i - \mathbf{P}_h e_i \big) \cdot \nabla_{\Gamma_h} v \, ds \right|$$

$$\leq c \, \mathrm{ess\,sup}_{x \in \Gamma_h} \| \mathbf{P}_h(x) \big(\mathbf{I} - d(x) \mathbf{H}(x) \big) \mathbf{P}(x) - \mathbf{P}_h(x) \| \, \| \nabla_{\Gamma_h} v \|_{L^2(\Gamma_h)}$$

$$\leq c \, \mathrm{ess\,sup}_{x \in \Gamma_h} \big(\| \mathbf{P}_h(x) \mathbf{P}(x) - \mathbf{P}_h(x) \| \tag{4.3}$$

$$+ |d(x)| \| \mathbf{P}_h(x) \mathbf{H}(x) \mathbf{P}(x) \| \big) \| \nabla_{\Gamma_h} v \|_{L^2(\Gamma_h)}. \tag{4.4}$$

Note that $|d(x)| \leq c\, h^2$ for $x \in \Gamma_h$, and

$$\mathrm{ess\,sup}_{x \in \Gamma_h} \| \mathbf{P}_h(x) \mathbf{H}(x) \mathbf{P}(x) \| \leq \mathrm{ess\,sup}_{x \in \Gamma_h} \| \mathbf{H}(x) \| \leq c.$$

For the term in (4.3) we have (we drop x in the notation)

$$\| \mathbf{P}_h \mathbf{P} - \mathbf{P}_h \| = \| \mathbf{P}_h \mathbf{n} \mathbf{n}^T \| \leq \| \mathbf{P}_h \mathbf{n} \| \leq \| \mathbf{P}_h \mathbf{n} + \mathbf{P} \mathbf{n}_h \| + \| \mathbf{P} \mathbf{n}_h \|.$$

For the first term we get, using (3.7),

$$\| \mathbf{P}_h \mathbf{n} + \mathbf{P} \mathbf{n}_h \| = \big\| (1 - \mathbf{n}^T \mathbf{n}_h)(\mathbf{n} + \mathbf{n}_h) \big\| \leq 2 |1 - \mathbf{n}^T \mathbf{n}_h| \leq c\, h^2.$$

From (2.6) we get $\| \mathbf{P} \mathbf{n}_h \| \leq c\, h$ (a.e. on Γ_h). Thus $\| \mathbf{P}_h(x) \mathbf{P}(x) - \mathbf{P}_h(x) \| \leq c\, h$ holds a.e. on Γ_h. As an upper bound for (4.2) we obtain $ch \, \| \nabla_{\Gamma_h} v \|_{L^2(\Gamma_h)}$. ∎

LEMMA 4.3. *The following holds:*

$$\left| \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma (v - v^e_{\Gamma_h}) \, ds \right| \leq ch \| v \|_{1,U} \quad \textit{for all} \;\; v \in W.$$

Proof. We take $v \in C^1(U)$. For $y \in \Gamma$ we have $v^e_{\Gamma_h}(y) = v(y \pm \delta(y) \mathbf{n}(y))$ with a unique $\delta(y) \geq 0$ such that $y \pm \delta(y) \mathbf{n}(y) \in \Gamma_h$. Note that $\delta(y) \leq c\, h^2$ holds. Let $U_m \subset U$ be a strip around Γ that contains Γ_h and has width $m \leq c\, h^2$. We now have

$$\left| \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma (v - v^e_{\Gamma_h}) \, ds(y) \right| = \left| \int_\Gamma \Delta_\Gamma \mathrm{id}_\Gamma \, \big(v(y) - v(y \pm \delta(y) \mathbf{n}(y)) \big) \, ds(y) \right|$$

$$\leq \int_\Gamma |\Delta_\Gamma \mathrm{id}_\Gamma| \left| \int_0^{\delta(y)} \frac{\partial v}{\partial t}(y \pm t \mathbf{n}(y)) \, dt \right| ds(y)$$

$$\leq c \int_\Gamma \int_0^{\delta(y)} \left| \frac{\partial v}{\partial t}(y \pm t \mathbf{n}(y)) \right| dt \, ds(y).$$

For $x = y \pm t \mathbf{n}(y)$ with $0 \leq t \leq \delta(y)$ we use $\mathbf{n}(x) = \mathbf{n}(\mathbf{p}(x)) = \mathbf{n}(y)$ and obtain

$$\left| \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma (v - v^e_{\Gamma_h}) \, ds(y) \right| \leq c \int_{U_m} |\mathbf{n}(x) \cdot \nabla v(x)| \, dx$$

$$\leq c \left(\int_{U_m} 1 \, dx \right)^{\frac{1}{2}} \left(\int_{U_m} (\nabla v)^2 \, dx \right)^{\frac{1}{2}} \leq c\, h \, \| v \|_{1,U}.$$

A density argument yields the same bound for all $v \in W$. ∎

A direct consequence of the previous three lemmas is the following corollary.

COROLLARY 4.4. *The three terms in* (4.1) *can be bounded by*

$$\left| \int_\Gamma \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma (v - v^e_{\Gamma_h})\, ds \right| \leq c\, h\, \|v\|_{1,U}, \tag{4.5}$$

$$\left| \int_\Gamma (\mathbf{I} - \mathbf{A}^e_{\Gamma_h}) \nabla_\Gamma \mathrm{id}_\Gamma \cdot \nabla_\Gamma v^e_{\Gamma_h}\, ds \right| \leq c\, h^2\, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)}, \tag{4.6}$$

$$\left| \int_{\Gamma_h} \nabla_{\Gamma_h} (\mathrm{id}^e_\Gamma - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v\, ds \right| \leq c\, h\, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)}, \tag{4.7}$$

and thus

$$|g(v) - g_h(v)| \leq c\, h\, \|v\|_{1,U} + c\, h^2\, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} + c\, h\, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \textit{for all} \;\; v \in W$$

holds.

In view of Corollary 4.4 and the error measure in (2.9), we want to derive a bound for $\|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)}$ in terms of $\|v\|_1$ for v from the scalar finite element space V_H. An obvious approach is to apply an inverse inequality combined with a trace theorem, resulting in

$$\|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \leq c\, h_{\min}^{-1} \|v\|_{L^2(\Gamma_h)} \leq c\, h_{\min}^{-1} \|v\|_1 \quad \text{for all} \;\; v \in V_H. \tag{4.8}$$

This, however, is too crude (cf. the bound in Corollary 4.4). To derive a better bound than the one in (4.8) we have to introduce some further assumptions related to the family of triangulations $\{\Gamma_h\}_{h>0}$. We assume that to each triangulation $\Gamma_h = \cup_{T \in \mathcal{F}_h} T$ there can be associated a set of tetrahedra $\mathcal{S}_h$ with the following properties:

(4.9) For each $T \in \mathcal{F}_h$ there is a corresponding $S_T \in \mathcal{S}_h$ with $T \subset S_T$.

(4.10) For $T_1, T_2 \in \mathcal{F}_h$ with $T_1 \neq T_2$ we have $\mathrm{meas}_3(S_{T_1} \cap S_{T_2}) = 0$.

(4.11) The family $\{\mathcal{S}_h\}_{h>0}$ is shape-regular.

(4.12) $c_0 h \leq \mathrm{diam}(S_T) \leq ch$ for all $T \in \mathcal{F}_h$ with $c_0 > 0$ (quasi-uniformity).

(4.13) For each $S_T \in \mathcal{S}_h$ there is a tetrahedron $S \in \mathcal{S}$ such that $S_T \subset S$.

Recall that $\mathcal{S}$ is the (fixed) tetrahedral triangulation that is used in the finite element discretization of the Navier–Stokes problem in (1.6). Note that the set of tetrahedra $\mathcal{S}_h$ has to be defined only close to the approximate interface Γ_h and that this set does not necessarily form a regular tetrahedral triangulation of Ω. Furthermore, it is *not* assumed that the family $\{\Gamma_h\}_{h>0}$is shape-regular or quasi-uniform.

Remark 6. Consider the construction of $\{\Gamma_h\}_{h>0}$ as in Remark 2. The approximate interface Γ_h is the zero level of the function $I(d_h)$, which is continuous piecewise linear on the tetrahedral triangulation $\mathcal{T}'$:

$$\Gamma_h = \cup_T T.$$

Each T is a triangle or a quadrilateral. To each T there can be associated a tetrahedron $S_T \in \mathcal{T}'$ such that $T \subset S_T$. If T is a quadrilateral, then we can subdivide T and

S_T in two disjoint triangles T_1, T_2 and two disjoint tetrahedra S_{T_1}, S_{T_2}, respectively, such that $T_i \subset S_{T_i} \subset S_T$ for $i = 1, 2$. One can check that this construction results in a family $\{\mathcal{S}_h\}_{h>0}$ that satisfies conditions (4.9)–(4.13).

In the following lemma we consider a standard affine mapping between a tetrahedron $S_T \in \mathcal{S}_h$ and the reference unit tetrahedron and apply it to the triangle $T \subset S_T$.

LEMMA 4.5. *Assume that the family $\{\Gamma_h\}_{h>0}$ is such that for the associated family of sets of tetrahedra $\{\mathcal{S}_h\}_{h>0}$ conditions* (4.9)–(4.13) *are satisfied. Take $T \in \mathcal{F}_h$ and the corresponding $S_T \in \mathcal{S}_h$. Let $\hat{S}$ be the reference unit tetrahedron and $F(x) = \mathbf{J}x + \mathbf{b}$ an affine mapping such that $F(\hat{S}) = S_T$. Define $\hat{T} := F^{-1}(T)$. The following holds:*

$$\|\mathbf{J}\|^2 \frac{\mathrm{meas}_3(\hat{S})}{\mathrm{meas}_3(S_T)} \leq c\, h^{-1}, \tag{4.14}$$

$$\|\mathbf{J}^{-1}\|^2 \frac{\mathrm{meas}_2(T)}{\mathrm{meas}_2(\hat{T})} \leq c, \tag{4.15}$$

with constants c independent of T and h.

Proof. Let $\rho(S_T)$ be the diameter of the maximal ball contained in S_T and similarly for $\rho(\hat{S})$. From standard finite element theory we have

$$\|\mathbf{J}\| \leq \frac{\mathrm{diam}(S_T)}{\rho(\hat{S})}, \quad \|\mathbf{J}^{-1}\| \leq \frac{\mathrm{diam}(\hat{S})}{\rho(S_T)}.$$

Using (4.11) and (4.12) we then get

$$\|\mathbf{J}\|^2 \frac{\mathrm{meas}_3(\hat{S})}{\mathrm{meas}_3(S_T)} \leq c\, \frac{\mathrm{diam}(S_T)^2}{\mathrm{meas}_3(S_T)} \leq c\ \mathrm{diam}(S_T)^{-1} \leq c\, h^{-1},$$

and thus the result in (4.14) holds.

The vertices of $\hat{T} = F^{-1}(T)$ are denoted by $\hat{V}_i$, $i = 1, 2, 3$. Let $\hat{V}_1\hat{V}_2$ be a longest edge of $\hat{T}$ and $\hat{M}$ the point on this edge such that $\hat{M}\hat{V}_3$ is perpendicular to $\hat{V}_1\hat{V}_2$. Define $V_i := F(\hat{V}_i)$, $i = 1, 2, 3$, and $M := F(\hat{M})$. Then V_i, $i = 1, 2, 3$, are the vertices of T and M lies on the edge V_1V_2. We then have

$$\mathrm{meas}_2(\hat{T}) = \frac{1}{2}\|\hat{V}_1 - \hat{V}_2\|\|\hat{V}_3 - \hat{M}\| = \frac{1}{2}\|\mathbf{J}^{-1}(V_1 - V_2)\|\|\mathbf{J}^{-1}(V_3 - M)\|$$

$$\geq \frac{1}{2}\|\mathbf{J}\|^{-2}\|V_1 - V_2\|\|V_3 - M\| \geq c\, \frac{\rho(\hat{S})^2}{\mathrm{diam}(S_T)^2}\, \mathrm{meas}_2(T),$$

with a constant $c > 0$. Thus we obtain

$$\|\mathbf{J}^{-1}\|^2 \frac{\mathrm{meas}_2(T)}{\mathrm{meas}_2(\hat{T})} \leq c\, \frac{\mathrm{diam}(\hat{S})^2}{\rho(S_T)^2} \frac{\mathrm{diam}(S_T)^2}{\rho(\hat{S})^2} \leq c,$$

which completes the proof. ∎

THEOREM 4.6. *Assume that the family $\{\Gamma_h\}_{h>0}$ is such that for the associated family of sets of tetrahedra $\{\mathcal{S}_h\}_{h>0}$ conditions* (4.9)–(4.13) *are satisfied. The following holds:*

$$\|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \leq c\, h^{-\frac{1}{2}} \|v\|_1 \quad \textit{for all} \quad v \in V_H.$$

Proof. Note that

$$\|\nabla_{\Gamma_h} v\|^2_{L^2(\Gamma_h)} = \sum_{T\in\mathcal{F}_h} \|\nabla_T v\|^2_{L^2(T)}.$$

Take $T \in \mathcal{F}_h$ and let S_T be the associated tetrahedron as explained above. Let $\hat{S}$ be the reference unit tetrahedron and $F : \hat{S} \to S_T$ as in Lemma 4.5. Define $\hat{v} := v \circ F$. Using standard transformation rules and Lemma 4.5 we get

$$\begin{aligned}
\|\nabla_T v\|^2_{L^2(T)} = \|\mathbf{P}_h \nabla v\|^2_{L^2(T)} &\le \|\nabla v\|^2_{L^2(T)} = \sum_{|\alpha|=1} \|\partial^\alpha v\|^2_{L^2(T)} \\
&\le c\,\|\mathbf{J}^{-1}\|^2 \sum_{|\alpha|=1} \|(\partial^\alpha \hat{v}) \circ F^{-1}\|^2_{L^2(T)} \\
&\le c\,\|\mathbf{J}^{-1}\|^2 \frac{\mathrm{meas}_2(T)}{\mathrm{meas}_2(\hat{T})} \sum_{|\alpha|=1} \|\partial^\alpha \hat{v}\|^2_{L^2(\hat{T})} \le c \sum_{|\alpha|=1} \|\partial^\alpha \hat{v}\|^2_{L^2(\hat{T})} \\
&\le c \sum_{|\alpha|=1} \max_{x\in\hat{T}} \left|\partial^\alpha \hat{v}(x)\right|^2 \le c \sum_{|\alpha|=1} \max_{x\in\hat{S}} \left|\partial^\alpha \hat{v}(x)\right|^2,
\end{aligned}$$

with a constant c independent of T. From (4.13) it follows that $\hat{v}$ is a polynomial on $\hat{S}$ of maximal degree k, where k depends only on the choice of the finite element space $\mathbf{V}_H$. On $P_k^* := \{\, p \in P_k \mid p(0) = 0 \,\}$ we have, due to equivalence of norms,

$$\sum_{|\alpha|=1} \max_{x\in\hat{S}} \left|\partial^\alpha \hat{v}(x)\right|^2 \le c \sum_{|\alpha|=1} \|\partial^\alpha \hat{v}\|^2_{L^2(\hat{S})} \quad \text{for all} \;\; \hat{v} \in P_k^*.$$

Because $\partial^\alpha \hat{v}$ is independent of $\hat{v}(0)$ for $\hat{v} \in P_k$ and $|\alpha| = 1$, the same inequality holds for all $\hat{v} \in P_k$. Thus we get

$$\begin{aligned}
\|\nabla_T v\|^2_{L^2(T)} &\le c \sum_{|\alpha|=1} \|\partial^\alpha \hat{v}\|^2_{L^2(\hat{S})} \le c\,\|\mathbf{J}\|^2 \sum_{|\alpha|=1} \|(\partial^\alpha v) \circ F\|^2_{L^2(\hat{S})} \\
&= c\,\|\mathbf{J}\|^2 \frac{\mathrm{meas}_3(\hat{S})}{\mathrm{meas}_3(S_T)} \sum_{|\alpha|=1} \|\partial^\alpha v\|^2_{L^2(S_T)} \le c\,h^{-1} \|\nabla v\|^2_{L^2(S_T)},
\end{aligned}$$

with a constant c independent of T and h. Using (4.10) we finally obtain

$$\begin{aligned}
\|\nabla_{\Gamma_h} v\|^2_{L^2(\Gamma_h)} &\le c\,h^{-1} \sum_{T\in\mathcal{F}_h} \|\nabla v\|^2_{L^2(S_T)} \\
&\le c\,h^{-1} \int_\Omega (\nabla v)^2\,dx \le c\,h^{-1} \|v\|^2_1,
\end{aligned}$$

which proves the result. ∎

We now present the main result of this paper.

THEOREM 4.7. *Let the assumptions be as in Theorem* 4.6. *The following holds:*

$$\sup_{v\in V_H} \frac{g(v) - g_h(v)}{\|v\|_1} \le c\sqrt{h}.$$

Proof. Combine the result in Corollary 4.4 with that in Theorem 4.6. ∎

As a direct consequence we obtain the following.

COROLLARY 4.8. *Let the assumptions be as in Theorem* 4.6. *For* f_Γ *and* f_{Γ_h} *as defined in section* 2 *the following holds:*

$$\sup_{\mathbf{v}\in\mathbf{V}_H} \frac{f_\Gamma(\mathbf{v}_H) - f_{\Gamma_h}(\mathbf{v}_H)}{\|\mathbf{v}_H\|_1} \leq \tau c \sqrt{h}.$$

Proof. Note that

$$f_\Gamma(\mathbf{v}_H) - f_{\Gamma_h}(\mathbf{v}_H)$$
$$= \tau \sum_{i=1}^{3} \left(\int_\Gamma \nabla_\Gamma(\mathrm{id}_\Gamma)_i \cdot \nabla_\Gamma(\mathbf{v}_H)_i \, ds - \int_{\Gamma_h} \nabla_{\Gamma_h}(\mathrm{id}_{\Gamma_h})_i \cdot \nabla_{\Gamma_h}(\mathbf{v}_H)_i \, ds \right),$$

and use the result in Theorem 4.7. ∎

An upper bound $\mathcal{O}(\sqrt{h})$ as in Corollary 4.8 for the error in the approximation of the localized force term may seem rather pessimistic, because Γ_h is an $\mathcal{O}(h^2)$ accurate approximation of Γ. Numerical experiments in section 6, however, indicate that the bound is sharp.

5. Improved approximation of the localized force term $f_\Gamma(\mathbf{v}_h)$. In this section we show how the approximation of the localized force term can be improved, resulting in an improved error bound of the form $\mathcal{O}(h)$ (instead of $\mathcal{O}(\sqrt{h})$). From Corollary 4.4 and Theorem 4.6 we see that the $\sqrt{h}$ behavior is caused by the estimate in (4.7):

$$\left| \int_{\Gamma_h} \nabla_{\Gamma_h}(\mathrm{id}_\Gamma^e - \mathrm{id}_{\Gamma_h}) \cdot \nabla_{\Gamma_h} v \, ds \right| \leq c\, h \, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)}. \tag{5.1}$$

The term $\nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h}$ that is used in $g_h(v)$ occurs in (5.1) but not in the other two terms of the splitting; cf. (4.5), (4.6). We consider

$$\tilde{g}_h(v) = \int_{\Gamma_h} m_h \cdot \nabla_{\Gamma_h} v \, ds$$

and try to find a function $m_h = m_h(x)$ such that $\tilde{g}_h(v)$ remains easily computable and the bound in (5.1) is improved if we use m_h instead of $\nabla_{\Gamma_h} \mathrm{id}_{\Gamma_h}$. The latter condition is trivially satisfied for $m_h = \nabla_{\Gamma_h} \mathrm{id}_\Gamma^e$ (leading to a bound 0 in (5.1)). This choice, however, does not satisfy the first condition, because Γ is not known. We now discuss another possibility that is used in the experiments in section 6.

Due to $|d(x)| \leq ch^2$ we get from Lemma 3.1, for $x \in \Gamma_h$:

$$\nabla_{\Gamma_h} \mathrm{id}_\Gamma^e(x) = \mathbf{P}_h(x)\mathbf{P}(x)\nabla_\Gamma \mathrm{id}_\Gamma(\mathbf{p}(x)) + \mathcal{O}(h^2) = \mathbf{P}_h(x)\mathbf{P}(x)e_i + \mathcal{O}(h^2).$$

In the construction of the interface Γ_h (cf. Remark 2), we have available a piecewise *quadratic* function $d_h \approx d$. Define

$$\tilde{\mathbf{n}}_h(x) := \frac{\nabla d_h(x)}{\|\nabla d_h(x)\|}, \qquad \tilde{\mathbf{P}}_h(x); = \mathbf{I} - \tilde{\mathbf{n}}_h(x)\tilde{\mathbf{n}}_h(x)^T, \quad x \in \Gamma_h.$$

Thus an obvious modification is based on the choice $m_h(x) = \mathbf{P}_h(x)\tilde{\mathbf{P}}_h(x)e_i$, i.e.,

$$\tilde{g}_h(v) := \int_{\Gamma_h} \mathbf{P}_h(x)\tilde{\mathbf{P}}_h(x)e_i \cdot \nabla_{\Gamma_h} v \, ds = \int_{\Gamma_h} \tilde{\mathbf{P}}_h(x)e_i \cdot \nabla_{\Gamma_h} v \, ds. \tag{5.2}$$

In this approach the approximate interface Γ_h is *not* changed (piecewise planar). For piecewise quadratics d_h and v, the function $\nabla_{\Gamma_h} v = \mathbf{P}_h \nabla v$ is piecewise linear and $\tilde{\mathbf{P}}_h e_i$ is piecewise (very) smooth on the segments of Γ_h. Hence, the functional in (5.2) can be evaluated easily.

Under reasonable assumptions the modified functional indeed yields a better error bound, as the following lemma shows.

LEMMA 5.1. *Assume that there exists $p > 0$ such that*

$$\|\nabla d_h(x) - \nabla d(x)\| \leq c\, h^p \quad \textit{for} \;\; x \in \Gamma_h. \tag{5.3}$$

Then the following holds:

$$\left| \int_{\Gamma_h} \left(\nabla_{\Gamma_h} \mathrm{id}_\Gamma^e - \mathbf{P}_h \tilde{\mathbf{P}}_h e_i \right) \cdot \nabla_{\Gamma_h} v \, ds \right| \leq c\, h^{\min\{p,2\}} \, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \textit{for all} \;\; v \in W.$$

Proof. Using $\|\nabla d\| = 1$ it follows that $\|\nabla d_h\| = 1 + \mathcal{O}(h^p)$ holds. We can use the same line of reasoning as in the proof of Lemma 4.2. The term in (4.4) remains the same. Instead of the term in (4.3) we now get $\|\mathbf{P}_h(x)\mathbf{P}(x) - \mathbf{P}_h(x)\tilde{\mathbf{P}}_h(x)\|$. We drop x in the notation, and using the assumption we obtain

$$\begin{aligned}
\|\mathbf{P}_h\mathbf{P} - \mathbf{P}_h\tilde{\mathbf{P}}_h\| = \|\mathbf{P}_h(\mathbf{P} - \tilde{\mathbf{P}}_h)\| &\leq \|\mathbf{n}\mathbf{n}^T - \tilde{\mathbf{n}}_h\tilde{\mathbf{n}}_h^T\| \\
&\leq \|(\mathbf{n} - \tilde{\mathbf{n}}_h)\mathbf{n}^T\| + \|\tilde{\mathbf{n}}_h(\mathbf{n} - \tilde{\mathbf{n}}_h)^T\| = 2\|\mathbf{n} - \tilde{\mathbf{n}}_h\| \\
&= 2 \left\| \nabla d - \frac{\nabla d_h}{\|\nabla d_h\|} \right\| \\
&\leq 2\big|1 - \|\nabla d_h\|^{-1}\big| \|\nabla d_h\| + 2\|\nabla d - \nabla d_h\| \leq c\, h^p.
\end{aligned}$$

Thus we get an estimate $\|\mathbf{P}_h\mathbf{P} - \mathbf{P}_h\tilde{\mathbf{P}}_h\| \leq c\, h^p$. Combined with the inequality $|d(x)|\|\mathbf{P}_h(x)\mathbf{H}(x)\mathbf{P}(x)\| \leq c\, h^2$ for the term in (4.4) this proves the result. ∎

If we assume that the condition in (5.3) is satisfied for $p = 2$, which is reasonable for a piecewise quadratic approximation d_h of d, we get the following improvement due to the modified functional $\tilde{g}_h$ (cf. Corollary 4.4):

$$|g(v) - \tilde{g}_h(v)| \leq c\, h \, \|v\|_{1,U} + c\, h^2 \, \|\nabla_{\Gamma_h} v\|_{L^2(\Gamma_h)} \quad \text{for all} \;\; v \in W.$$

Combining this with the result in Theorem 4.6 yields (under the assumption as in Theorem 4.6)

$$|g(v) - \tilde{g}_h(v)| \leq c\, h \, \|v\|_{1,U} + c\, h^{\frac{3}{2}} \, \|v\|_1 \quad \text{for all} \;\; v \in V_H.$$

Hence, using this modified functional $\tilde{g}_h$ we have an $\mathcal{O}(h)$ error bound. This significant improvement (compared to the $\mathcal{O}(\sqrt{h})$ error bound for the functional g_h) is confirmed by the numerical experiments in the next section.

6. Numerical experiments. In this section we present results of a numerical experiment which indicates that the $\mathcal{O}(\sqrt{h})$ bound in Corollary 4.8 is sharp. Furthermore, for the improved approximation described in section 5 the $\mathcal{O}(h)$ bound will be confirmed numerically.

We consider the domain $\Omega := [-1, 1]^3$, where the ball $\Omega_1 := \{\mathbf{x} \in \Omega \mid \|\mathbf{x}\| < R\}$ is located in the center of the domain. In our experiments we take $R = \frac{1}{2}$.

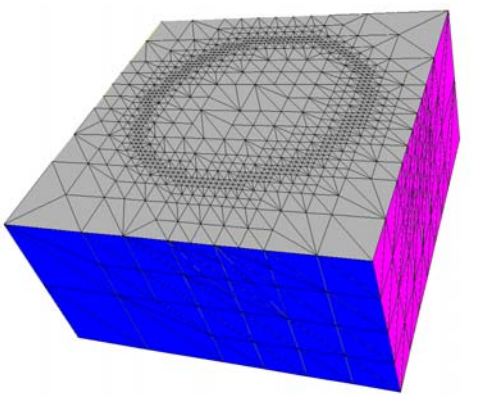

FIG. 6.1. *Lower half of the four times refined mesh* $\mathcal{T}_4$.

For the discretization a uniform tetrahedral mesh $\mathcal{T}_0$ is used, where the vertices form a $6 \times 6 \times 6$ lattice; hence $h_0 = \frac{1}{5}$. This coarse mesh $\mathcal{T}_0$ is locally refined in the vicinity of $\Gamma = \partial\Omega_1$ using an adaptive refinement algorithm presented in [15]. This repeated refinement process yields the gradually refined meshes $\mathcal{T}_1, \mathcal{T}_2, \ldots$ with *local* (i.e., close to the interface) mesh sizes $h_i = \frac{1}{5} \cdot 2^{-i}, i = 1, 2, \ldots$. Part of the tetrahedral triangulation $\mathcal{T}_4$ is shown in Figure 6.1. The corresponding finite element spaces $\mathbf{V}_i := \mathbf{V}_{h_i} = (V_{h_i})^3$ consist of vector functions where each component is a continuous piecewise quadratic function on $\mathcal{T}_i$.

The interface $\Gamma = \partial\Omega_1$ is a sphere, and thus the curvature $\mathcal{K} = \frac{2}{R}$ is constant. If we discretize the flow problem using $\mathbf{V}_i$ as a discrete velocity space, we have to approximate the surface tension force

$$f_\Gamma(\mathbf{v}) = \frac{2\tau}{R} \int_\Gamma \mathbf{n}_\Gamma \cdot \mathbf{v}\, ds = \tau \int_\Gamma \nabla_\Gamma \operatorname{id}_\Gamma \cdot \nabla_\Gamma \mathbf{v}\, ds, \qquad \mathbf{v} \in \mathbf{V}_i. \tag{6.1}$$

To simplify notation, we take a fixed $i \geq 0$, and the corresponding local mesh size parameter is denoted by $h = h_i$. For the approximation of the interface we use the following approach (cf. Remark 2). The interface Γ is the zero level of the signed distance function d. In this test problem, d is known. For the finite element approximation $d_h \in V_h$ of d we take the continuous piecewise *quadratic* function on $\mathcal{T}_i$ that interpolates d at the vertices and midpoints of edges. Then $I(d_h)$ is the continuous piecewise *linear* function on $\mathcal{T}_i'$ that interpolates d_h at the vertices of all tetrahedra in $\mathcal{T}_i'$; cf. Remark 2 (note that in this test problem, d_h also can be computed by piecewise linear interpolation of d on $\mathcal{T}_i'$). The approximation of Γ is defined by

$$\Gamma_h = \{\, x \in \Omega \mid I(d_h)(x) = 0 \,\}$$

and is illustrated in Figure 2.2. The discrete approximation of the surface tension force is

$$f_{\Gamma_h}(\mathbf{v}) = \tau \int_{\Gamma_h} \nabla_{\Gamma_h} \operatorname{id}_{\Gamma_h} \cdot \nabla_{\Gamma_h} \mathbf{v}\, ds, \qquad \mathbf{v} \in \mathbf{V}_i.$$

We are interested in (cf. Corollary 4.8)

$$\|f_\Gamma - f_{\Gamma_h}\|_{\mathbf{V}_i'} := \sup_{\mathbf{v} \in \mathbf{V}_i} \frac{f_\Gamma(\mathbf{v}) - f_{\Gamma_h}(\mathbf{v})}{\|\mathbf{v}\|_1}. \tag{6.2}$$

The evaluation of $f_\Gamma(\mathbf{v})$, for $\mathbf{v} \in \mathbf{V}_i$, requires the computation of integrals on curved triangles or quadrilaterals $\Gamma \cap S$, where S is a tetrahedron from the mesh $\mathcal{T}_i$. We are not able to compute these exactly. Therefore, we introduce an artificial force term which, in this model problem with a known constant curvature, is computable and sufficiently close to f_Γ.

LEMMA 6.1. *For* $\mathbf{v} \in \mathbf{V} = (H_0^1(\Omega))^3$ *define*

$$\hat{f}_{\Gamma_h}(\mathbf{v}) := \frac{2\tau}{R} \int_{\Gamma_h} \mathbf{n}_h \cdot \mathbf{v}\, ds$$

($\mathbf{n}_h$ *denotes the piecewise constant outward unit normal on* Γ_h*). Then the following inequality holds:*

$$\|f_\Gamma - \hat{f}_{\Gamma_h}\|_{\mathbf{V}'} \le ch. \tag{6.3}$$

Proof. Let $\Omega_{1,h} \subset \Omega$ be the domain enclosed by Γ_h, i.e., $\partial\Omega_{1,h} = \Gamma_h$. We define $D_h^+ := \Omega_1 \setminus \Omega_{1,h}$, $D_h^- := \Omega_{1,h} \setminus \Omega_1$, and $D_h := D_h^+ \cup D_h^-$. Due to the Stokes theorem, for $\mathbf{v} \in \mathbf{V}$ we have

$$|f_\Gamma(\mathbf{v}) - \hat{f}_{\Gamma_h}(\mathbf{v})| = \frac{2\tau}{R} \left| \int_{\Omega_1} \operatorname{div} \mathbf{v}\, dx - \int_{\Omega_{1,h}} \operatorname{div} \mathbf{v}\, dx \right| \tag{6.4}$$

$$= \frac{2\tau}{R} \left| \int_{D_h^+} \operatorname{div} \mathbf{v}\, d\mathbf{x} - \int_{D_h^-} \operatorname{div} \mathbf{v}\, dx \right| \tag{6.5}$$

$$\le \frac{2\tau}{R} \int_{D_h} |\operatorname{div} \mathbf{v}|\, dx. \tag{6.6}$$

Using the Cauchy–Schwarz inequality, we get the estimate

$$|f_\Gamma(\mathbf{v}) - \hat{f}_{\Gamma_h}(\mathbf{v})| \le c\sqrt{|D_h|}\|\mathbf{v}\|_1 \quad \text{for all} \quad \mathbf{v} \in \mathbf{V}.$$

For the piecewise planar approximation Γ_h of the interface Γ we have $|D_h| = \mathcal{O}(h^2)$, and thus (6.3) holds. ∎

From Lemma 6.1 we obtain $\|f_\Gamma - \hat{f}_{\Gamma_h}\|_{\mathbf{V}_j'} \le c\,h$ with a constant c independent of j. Thus we have

$$\|\hat{f}_{\Gamma_h} - f_{\Gamma_h}\|_{\mathbf{V}_i'} - ch \le \|f_\Gamma - f_{\Gamma_h}\|_{\mathbf{V}_i'} \le \|\hat{f}_{\Gamma_h} - f_{\Gamma_h}\|_{\mathbf{V}_i'} + ch. \tag{6.7}$$

The term $\|\hat{f}_{\Gamma_h} - f_{\Gamma_h}\|_{\mathbf{V}_i'}$ can be evaluated as follows. Since Γ_h is piecewise planar and $\mathbf{v} \in \mathbf{V}_i$ is a piecewise quadratic function, for $\mathbf{v} \in \mathbf{V}_i$, both $\hat{f}_{\Gamma_h}(\mathbf{v})$ and $f_{\Gamma_h}(\mathbf{v})$ can be computed exactly (up to machine accuracy) using suitable quadrature rules. For the evaluation of the dual norm $\|\cdot\|_{\mathbf{V}_i'}$ we proceed as follows. Let $\{\boldsymbol{\phi}_j\}_{j=1,\dots,n}$ be the standard nodal basis in $\mathbf{V}_i$ and $J : \mathbb{R}^n \to \mathbf{V}_i$ the isomorphism $J\vec{x} = \sum_{k=1}^n x_k \boldsymbol{\phi}_k$. Let M_h be the mass matrix and A_h the stiffness matrix of the Laplacian:

$$\begin{aligned} (M_h)_{i,j} &:= \int_\Omega \boldsymbol{\phi}_i \cdot \boldsymbol{\phi}_j\, dx, \\ (A_h)_{i,j} &:= \int_\Omega \nabla\boldsymbol{\phi}_i \cdot \nabla\boldsymbol{\phi}_j\, dx. \end{aligned} \qquad 1 \le i, j \le n.$$

TABLE 6.1
Error norms and numerical order of convergence for different refinement levels.

i	$\|\hat{f}_{\Gamma_h} - f_{\Gamma_h}\|_{\mathbf{V}_i'}$	order	$\|\hat{f}_{\Gamma_h} - \tilde{f}_{\Gamma_h}\|_{\mathbf{V}_i'}$	order
0	1.79 E-1	–	1.32 E-1	–
1	1.40 E-1	0.35	4.43 E-2	1.57
2	1.03 E-1	0.45	1.46 E-2	1.61
3	7.22 E-2	0.51	5.06 E-3	1.52
4	5.02 E-2	0.53	1.78 E-3	1.51

Define $C_h = A_h + M_h$. Note that for $\mathbf{v} = J\vec{x} \in \mathbf{V}_i$ we have $\|\mathbf{v}\|_1^2 = \langle C_h\vec{x}, \vec{x}\rangle$. Take $e \in \mathbf{V}_i'$ and define $\vec{e} \in \mathbb{R}^n$ by $e_j := e(\boldsymbol{\phi}_j)$, $j = 1, \ldots, n$. Due to

$$\|e\|_{\mathbf{V}_i'} = \sup_{\mathbf{v}\in\mathbf{V}_i} \frac{|e(\mathbf{v})|}{\|\mathbf{v}\|_1} = \sup_{\vec{x}\in\mathbb{R}^n} \frac{|\sum_{j=1}^n x_j e(\boldsymbol{\phi}_j)|}{\sqrt{\langle C_h\vec{x}, \vec{x}\rangle}}$$

we obtain

$$\|e\|_{\mathbf{V}_i'} = \sup_{\vec{x}\in\mathbb{R}^n} \frac{\langle \vec{x}, \vec{e}\rangle}{\sqrt{\langle C_h\vec{x}, \vec{x}\rangle}} = \|C_h^{-1/2}\vec{e}\| = \sqrt{\langle C_h^{-1}\vec{e}, \vec{e}\rangle}. \tag{6.8}$$

Thus for the computation of $\|e\|_{\mathbf{V}_i'}$ we proceed in the following way:

1. Compute $\vec{e} = \big(e(\boldsymbol{\phi}_j)\big)_{j=1}^n$.
2. Solve the linear system $C_h\vec{z} = \vec{e}$ up to machine accuracy.
3. Compute $\|e\|_{\mathbf{V}_i'} = \sqrt{\langle \vec{z}, \vec{e}\rangle}$.

We applied this strategy to $e := \hat{f}_{\Gamma_h} - f_{\Gamma_h}$. The results are given in the second column in Table 6.1. The numerical order of convergence in the third column of this table clearly indicates an $\mathcal{O}(\sqrt{h})$ behavior. Due to (6.7) this implies the same $\mathcal{O}(\sqrt{h})$ convergence behavior for $\|f_\Gamma - f_{\Gamma_h}\|_{\mathbf{V}_i'}$. This indicates that the $\mathcal{O}(\sqrt{h})$ bound in Corollary 4.8 is sharp.

The same procedure can be applied with f_{Γ_h} replaced by the modified (improved) approximate surface tension force

$$\tilde{f}_{\Gamma_h}(\mathbf{v}) = \tau \sum_{i=1}^3 \tilde{g}_{h,i}(v_i)$$

with $\tilde{g}_{h,i}$ as defined in (5.2). This yields the results in the fourth column in Table 6.1. For this modification the numerical order of convergence is significantly better, namely, at least first order in h. From (6.7) it follows that for $\|f_\Gamma - \tilde{f}_{\Gamma_h}\|_{\mathbf{V}_i'}$ we can expect $\mathcal{O}(h^p)$ with $p \geq 1$.

Summarizing, we conclude that the results of these numerical experiments confirm the theoretical $\mathcal{O}(\sqrt{h})$ error bound derived in the analysis in section 4 and show that the modified approximation indeed leads to (much) better results.

Results of numerical experiments for a Stokes two-phase flow problem using both f_{Γ_h} and $\tilde{f}_{\Gamma_h}$ are presented in [16].

CAN WE HAVE SUPERCONVERGENT GRADIENT RECOVERY UNDER ADAPTIVE MESHES?*

HAIJUN WU† AND ZHIMIN ZHANG‡

Abstract. We study adaptive finite element methods for elliptic problems with domain corner singularities. Our model problem is the two-dimensional Poisson equation. Results of this paper are twofold. First, we prove that there exists an adaptive mesh (gauged by a discrete mesh density function) under which the recovered gradient by the polynomial preserving recovery (PPR) is superconvergent. Second, we demonstrate by numerical examples that an adaptive procedure with an a posteriori error estimator based on PPR does produce adaptive meshes that asatisfy our mesh density assumption, and the recovered gradient by PPR is indeed superconvergent in the adaptive process.

Key words. finite element method, adaptive, superconvergence, gradient recovery

1. Introduction.

Let $\Omega \subset R^2$ be a bounded polygon with boundary $\partial\Omega$. Consider the following Dirichlet boundary problem: Find $u \in H^1(\Omega)$ such that $u = g$ on $\partial\Omega$ and

$$A(u,v) = \int_\Omega \nabla u \cdot \nabla v = f(v) \quad \forall v \in H_0^1(\Omega), \tag{1.1}$$

where $f \in H^{-1}(\Omega)$.

It is well known that the solution u may have singularities at corners of Ω. Since the treatment of multiple singular points is no different from a simple one, without loss of generality we assume that the solution u has a singularity at the origin O and can be decomposed as a sum of a singular part and a smooth part:

$$u = v + w, \tag{1.2}$$

where

$$\left|\frac{\partial^m v}{\partial x^i \partial y^{m-i}}\right| \lesssim r^{\delta - m} \text{ and } \left|\frac{\partial^m w}{\partial x^i \partial y^{m-i}}\right| \lesssim 1, \quad m = 1, \ldots, k+2,\ i = 0, \ldots, m, \tag{1.3}$$

where $r = \sqrt{x^2 + y^2}$ and $0 < \delta < k + 1$ is a constant. Here $k = 1$ for linear finite element methods and $k = 2$ for quadratic finite element methods.

Next, we briefly explain the rationale of the above regularity assumption. When Ω is a polygonal domain, the solution of the Poisson equation with the Dirichlet

boundary condition,

$$-\Delta u = f \quad \text{in} \quad \Omega, \qquad u|_{\partial\Omega} = g,$$

with sufficiently smooth data f and g, has the following decomposition (see, e.g., [3] and [11]), at a corner with angle ω:

$$u(r,\theta) = \sum_{j=1}^{J} c_j r^{\alpha_j} \ln^{s_j} r \sin \alpha_j \theta + w, \quad \alpha_j = \frac{j\pi}{\omega},$$

where w is smoother than the terms in the sum, and

$$s_j = \begin{cases} 1 & \alpha_j \text{ is an integer,} \\ 0 & \text{otherwise.} \end{cases}$$

Especially for the L-shaped domain, $\omega = 3\pi/2$ at the re-entrance corner, and the expansion is

$$u = c_1 r^{2/3} \sin \frac{2}{3}\theta + c_2 r^{4/3} \sin \frac{4}{3}\theta + c_3 r^2 \ln r \sin 2\theta + c_4 r^{8/3} \sin \frac{8}{3}\theta + w,$$

with $w \in W^3_\infty(\Omega)$. For a cracked domain, $\omega = 2\pi$ at the crack tip and the expansion is

$$\begin{aligned} u = {} & c_1 r^{1/2} \sin \frac{1}{2}\theta + c_2 2r \ln r \sin \theta + c_3 r^{3/2} \sin \frac{3}{2}\theta \\ & + c_4 r^2 \ln r \sin 2\theta + c_5 r^{5/2} \sin \frac{5}{2}\theta + c_6 r^3 \ln r \sin 3\theta + w, \end{aligned}$$

with $w \in W^3_\infty(\Omega)$. More terms are needed in the expansion if we want higher regularity on w. These are the two cases we shall test numerically in the last section.

Let $\mathcal{M}_h$ be a regular triangulation of the domain Ω, $\mathcal{E}_h$ be the set of all interior edges, and $\mathcal{N}_h$ be the set of all nodal points. Assume that the origin $O \in \mathcal{N}_h$. Remember that any triangle $\tau \in \mathcal{M}_h$ is considered to be closed. Let

$$V_h^k = \left\{ v_h : \ v_h \in H^1(\Omega), v_h|_\tau \in P_k(\tau) \right\}, \quad k = 1, 2,$$

be the conforming finite element space associated with $\mathcal{M}_h$, and let $\overset{\circ}{V}{}_h^k = V_h^k \bigcap H_0^1(\Omega)$. Here P_k denotes the set of polynomials with degree $\leq k$. Denote by $I_h^k : C(\bar{\Omega}) \to V_h^k$ the standard finite element interpolation operator. The finite element solution $u_h \in V_h^k$ satisfies $u_h = I_h^k u$ on $\partial\Omega$ and

$$A(u_h, v_h) = \int_\Omega \nabla u_h \cdot \nabla v_h = f(v_h) \quad \forall v_h \in \overset{\circ}{V}{}_h^k. \tag{1.4}$$

In adaptive finite element methods, the convergence rate is measured by the total number of degrees of freedom N, since the mesh is not quasi-uniform. For a two-dimensional second-order elliptic equation, the optimal convergence rates are

$$\|\nabla(u - u_h)\|_{L^2(\Omega)} \lesssim \begin{cases} N^{-1/2}, & k = 1, \\ N^{-1}, & k = 2, \end{cases} \tag{1.5}$$

where $k = 1$ for the linear element and $k = 2$ for the quadratic.

The theoretical development of residual-type error estimates is now in its maturity. For the early literature, readers are referred to [1, 4, 10, 21] and references therein. Starting from the fundamental work of [9], in the last decade the convergence proof of residual-based adaptive finite element method has been well established; see, e.g., [2, 8, 17, 19]. On the contrary, there is no convergence proof for using recovery-based error estimators. Nevertheless, by shifting the error estimator from residual based to recovery based, we have obtained the same numerical convergence rate following the same mark-up and refinement procedure for two model problems—the Poisson equation on the L-shaped domain and cracked square. Theoretically, we are able to prove that there exists an adaptive mesh satisfying a discrete mesh density condition such that the convergence rate (1.5) can be established. Moreover, under the same mesh density condition, the recovered gradient $G_h u_h$ is superconvergent in the sense that

$$\|\nabla u - G_h u_h\|_{L^2(\Omega)} \lesssim \begin{cases} N^{-1/2-\rho}, & k = 1, \\ N^{-1-\rho}, & k = 2, \end{cases} \tag{1.6}$$

where $\rho > 0$ is a constant, which depends on the quality of the adaptive mesh, and $G_h : V_h^k \to V_h^k \times V_h^k$ is the recovery operator. Now the question is: Is the condition required by our theory practical? We demonstrate that the meshes generated by the standard adaptive procedure in both of our model problems indeed satisfies the mesh density condition.

In recent years there have been some superconvergence results for a recovered gradient [5, 15, 8, 16, 20, 23, 24, 25, 26, 28]. All of them assumed at least $u \in H^3(\Omega) \cap W_\infty^2(\Omega)$ (a condition that rules out domains with a re-entrant corner) and required some stronger (than we required here) mesh conditions. Our current work fills in this gap. To the best of our knowledge, this is the first theoretical superconvergence proof for real-life adaptive meshes.

Some further theoretical results about recovery techniques and recovery-type error estimators can be found in [1, 7, 22, 13].

Based on the estimate (1.6), we suggest that, even for residual-type adaptive method, a gradient recovery procedure at the very last mesh would dramatically improve the numerical gradient.

Throughout the paper, we use the notation $A \lesssim B$ to represent the inequality $A \leq \textit{constant} \times B$, where the *constant* may depend only on the minimum angle of the triangles in the mesh $\mathcal{M}_h$, the constant δ, and the domain Ω. The notation $A \eqsim B$ is equivalent to the statement $A \lesssim B$ and $B \lesssim A$.

2. Preliminaries. Following the discussion in [8], we consider in Figure 2.1 an edge e, two elements τ and τ' sharing e, and $\Omega_e = \tau \cup \tau'$ the patch of e. For an element $\tau \subset \Omega_e$, θ_e denotes the angle opposite of the edge e, h_e, h_{e+1}, and h_{e-1} denote the lengths of the three edges of τ. The subscript $e+1$ or $e-1$ is for orientation. All triangles in the triangulation are orientated counterclockwise. $\boldsymbol{t}_e$ is the unit tangent vector of e with counterclockwise orientation and $\boldsymbol{n}_e$ is the unit outward normal vector. An index $'$ is added for the corresponding quantities in τ'. Notice that $\boldsymbol{t}_e = -\boldsymbol{t}'_e$ and $\boldsymbol{n}_e = -\boldsymbol{n}'_e$ because of the orientation. For any $\tau \in \mathcal{M}_h$, we denote by h_τ its diameter and by r_τ the distance from the origin to the barycenter of τ, and by $|\tau|$ the area of the triangle τ. For any $e \in \mathcal{E}_h$, let r_e be the distance from the origin O to the midpoint of e.

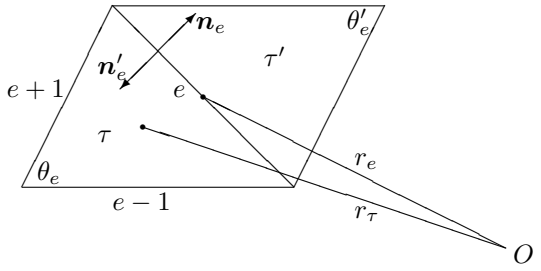

FIG. 2.1. *Notation in the patch* Ω_e.

Let $e \in \mathcal{E}_h$ be an interior edge. Recall that Ω_e, the patch of e, consists of two adjacent triangles sharing e. We say that Ω_e is an ε approximate parallelogram if the lengths of any two opposite edges differ by at most ε.

Definition. *The triangulation* $\mathcal{M}_h$ *is said to satisfy* Condition (α, σ, μ) *if there exist constants* $\alpha > 0$, $\sigma \geq 0$, *and* $\mu > 0$ *such that the interior edges can be separated into two parts* $\mathcal{E}_h = \mathcal{E}_{1,h} \oplus \mathcal{E}_{2,h}$: Ω_e *forms an* $O\big(h_e^{1+\alpha}/r_e^{\alpha+\mu(1-\alpha)}\big)$ *parallelogram for* $e \in \mathcal{E}_{1,h}$ *and the number of edges in* $\mathcal{E}_{2,h}$ *satisfies* $\#\mathcal{E}_{2,h} \lesssim N^\sigma$.

Remark 2.1. The meaning of *Condition* (α, σ, μ) is the following. The edges can be grouped into "good" ($\mathcal{E}_{1,h}$) and "bad" ($\mathcal{E}_{2,h}$), where the number of bad edges is much smaller than that of good edges. The ratio is

$$\frac{\#\mathcal{E}_{2,h}}{\#\mathcal{E}_{1,h}} \lesssim \frac{N^\sigma}{N} = \frac{1}{N^{1-\sigma}}.$$

When $r_e = O(1)$, i.e., an edge e is far away from the singular point O, more restrictions are put on the adjacent triangles with the common edge e. This condition requires that they form an $O(h_e^{1+\alpha})$ parallelogram, which is the same as in previous works [20, 23, 25, 26]. When e is in a neighborhood of O, where $r_e^{1+\mu(1-\alpha)/\alpha} \lesssim h_e$, the condition $O(h_e)$ implies $O\big(h_e^{1+\alpha}/r_e^{\alpha+\mu(1-\alpha)}\big)$. In other words, two adjacent triangles that share e are allow to distort $O(h_e)$ from a parallelogram, which implies no restriction on them. Roughly speaking, the number of edges in $\mathcal{E}_{1,h}$ that have no restriction imposed is $O(N^{1-\alpha})$ if $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^\mu$ for any $\tau \in \mathcal{M}_h$. Here $\underline{h}$ and μ are positive constants. An explanation is given below after Lemma 2.1.

We see from the above discussion that the closer we are to the singular point, the less restriction is imposed on the mesh. Indeed, for an adaptively refined mesh, the closer we are to the singular point, the worse the mesh quality is in terms of forming parallelogram triangular pairs.

LEMMA 2.1. *Assume that* $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^\mu$ *for any* $\tau \in \mathcal{M}_h$, *where* $\underline{h}$ *and* μ *are positive constants. Then the total number of degrees of freedom* N *of the finite element equation* (1.4) *satisfies*

$$N \eqsim \frac{1}{\underline{h}^{2\mu}}. \tag{2.1}$$

Proof.

$$N \eqsim \sum_{\tau\in\mathcal{M}_h} \frac{h_\tau^2}{h_\tau^2} \eqsim \frac{1}{\underline{h}^{2\mu}} \sum_{\tau\in\mathcal{M}_h} \frac{1}{r_\tau^{2-2\mu}} \cdot |\tau|$$

$$\eqsim \frac{1}{\underline{h}^{2\mu}} \int_\Omega \frac{1}{r^{2-2\mu}} \eqsim \frac{1}{\underline{h}^{2\mu}} \int_0^1 \frac{1}{r^{2-2\mu}} \cdot r \,\mathrm{d}r \eqsim \frac{1}{\underline{h}^{2\mu}}.$$

This completes the proof of the lemma. ∎

Remark 2.2. For the linear element, $\mu = \delta/2$, $N \eqsim 1/\underline{h}^{\delta}$, and for the quadratic element $\mu = \delta/3$, $N \eqsim 1/\underline{h}^{2\delta/3}$. The condition $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^{\mu}$ can be viewed as a discrete mesh density function. The positive number $\underline{h} \eqsim \min_{\tau\in\mathcal{M}_h} h_\tau$, is the size of the minimum element because for an element τ neighboring O, $r_\tau \eqsim h_\tau$ and the condition $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^{\mu}$ implies that $h_\tau \eqsim \underline{h}$. It is clear that the condition $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^{\mu}$ for any $\tau \in \mathcal{M}_h$ is equivalent to the condition $h_e \eqsim r_e^{1-\mu}\underline{h}^{\mu}$ for any $e \in \mathcal{E}_h$. We recall that *Condition* (α, σ, μ) means no restriction on Ω_e if $r_e^{1+\mu(1-\alpha)/\alpha} \lesssim h_e$. Furthermore, if $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^{\mu}$, i.e., $h_e \eqsim r_e^{1-\mu}\underline{h}^{\mu}$, then $r_e \lesssim \underline{h}^{\alpha}$. Therefore if the mesh $\mathcal{M}_h$ satisfies *Condition* (α, σ, μ) and $h_\tau \eqsim r_\tau^{1-\mu}\underline{h}^{\mu}$, then no restriction is imposed on edges within the ball of radius $R \lesssim \underline{h}^{\alpha}$. The number of edges in the ball is $O(N^{1-\alpha})$ by an argument similar to the proof of Lemma 2.1.

3. Superconvergence between the finite element solution and linear interpolant. We now define a quadratic interpolant of ϕ based on moment conditions on edges. Let $\phi_Q = \Pi_Q\phi$ be a quadratic element defined by

$$(\Pi_Q\phi)(z) = \phi(z), \quad \text{and} \quad \int_e \Pi_Q\phi = \int_e \phi \quad \forall z \in \mathcal{N}_h, e \in \mathcal{E}_h. \tag{3.1}$$

The following fundamental identity is proved in [8] for $v_h \in P_1(\tau)$:

$$\int_\tau \nabla(\phi - \phi_I)\cdot\nabla v_h = \sum_{e\subset\partial\tau}\left(\beta_e \int_e \frac{\partial^2\phi_Q}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e \int_e \frac{\partial^2\phi_Q}{\partial \boldsymbol{t}_e \partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}\right), \tag{3.2}$$

where

$$\beta_e = \frac{1}{12}\cot\theta_e(h_{e+1}^2 - h_{e-1}^2), \quad \gamma_e = \frac{1}{3}\cot\theta_e\,|\tau|\,, \tag{3.3}$$

and $\phi_I \in P_1(\tau)$ is the linear interpolant of ϕ on τ. The following lemma is a simple modification of [8, Lemma 2.13].

LEMMA 3.1. *Let $\boldsymbol{m}_e$ denote $\boldsymbol{t}_e$ or $\boldsymbol{n}_e$. Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/2)$ *with $0 < \alpha \le 1$ and $0 \le \sigma < 1$. For any interior edge $e \in \mathcal{M}_h$ and two elements τ, $\tau' \subset \Omega_e$, we have*

$$|\beta_e| + |\beta_e'| \lesssim h_e^2, \quad |\gamma_e| + |\gamma_e'| \lesssim h_e^2 \quad \forall e \in \mathcal{E}_h; \tag{3.4}$$

$$|\beta_e - \beta_e'| \lesssim h_e^{2+\alpha}/r_e^{\alpha+\delta(1-\alpha)/2}, \quad |\gamma_e - \gamma_e'| \lesssim h_e^{2+\alpha}/r_e^{\alpha+\delta(1-\alpha)/2} \quad \forall e \in \mathcal{E}_{1,h}; \tag{3.5}$$

$$\int_e \frac{\partial^2\phi}{\partial \boldsymbol{t}_e\partial \boldsymbol{m}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e} \lesssim |\phi|_{W^{2,\infty}(e)}\,\|\nabla v_h\|_{L^2(\tau)}\,; \tag{3.6}$$

$$\int_e \frac{\partial^2(\phi - \phi_Q)}{\partial \boldsymbol{t}_e\partial \boldsymbol{m}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e} \lesssim |\phi|_{H^3(\tau)}\,\|\nabla v_h\|_{L^2(\tau)}\,. \tag{3.7}$$

Proof. The arguments for (3.4), (3.5), and (3.6) are trivial, and that for (3.7) follows from the trace theorem and the standard error estimate $|\phi - \phi_Q|_{H^2(\tau)} \lesssim h_\tau\,|\phi|_{H^3(\tau)}$. ∎

To deal with the singularity at the origin O we introduce the following lemma. Recall that v is the singular part of the decomposition $u = v + w$.

LEMMA 3.2. *Let $\mathcal{M}^O = \{\tau \in \mathcal{M}_h : \text{the origin } O \in \partial\tau\}$ be the set of elements with one vertex at O. Then,*

$$\|\nabla v - \nabla v_I\|_{L^2(\tau)} \lesssim h_\tau^\delta \quad \forall \tau \in \mathcal{M}^O,$$

where $v_I = I_h^1 v$ is the linear interpolant of v.

Proof.

$$\|\nabla v - \nabla v_I\|_{L^2(\tau)} \lesssim \|\nabla v\|_{L^2(\tau)} + \|\nabla v_I\|_{L^2(\tau)}. \tag{3.8}$$

It follows from (1.3) that

$$\|\nabla v\|_{L^2(\tau)} = \left(\int_\tau |\nabla v|^2\right)^{1/2} \lesssim \left(\int_\tau r^{2\delta-2}\right)^{1/2} \lesssim \left(\int_0^{h_\tau} r^{2\delta-2} r\,\mathrm{d}r\right)^{1/2} \lesssim h_\tau^\delta. \tag{3.9}$$

Since $\nabla C = 0$, for any constant C, we have,

$$\begin{aligned}\|\nabla v_I\|_{L^2(\tau)} = \|\nabla(v_I - v(O))\|_{L^2(\tau)} &\lesssim h_\tau \max_{z\in\mathcal{N}_h\cap\tau} \big|\nabla\big(v_I - v(O)\big)(z)\big| \\ &\lesssim h_\tau \frac{1}{h_\tau} \max_{z\in\mathcal{N}_h\cap\tau} |v(z) - v(O)| \\ &= \max_{z\in\mathcal{N}_h\cap\tau} \left|\int_0^1 \frac{d}{dt} v(zt)\mathrm{d}t\right| = \max_{z\in\mathcal{N}_h\cap\tau} \left|\int_0^1 z\cdot\nabla v(zt)\mathrm{d}t\right|.\end{aligned}$$

Noting that $|z| \lesssim h_\tau$ for $\tau \in \mathcal{M}^O$, it follows from assumption (1.3) that

$$\|\nabla v_I\|_{L^2(\tau)} \lesssim \int_0^1 h_\tau \cdot (h_\tau t)^{\delta-1}\mathrm{d}t \lesssim h_\tau^\delta. \tag{3.10}$$

The proof is completed by combining (3.8)–(3.10). ∎

LEMMA 3.3. *Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/2)$ *with $0 < \alpha \le 1$ and $0 \le \sigma < 1$, and that $h_\tau \eqsim r_\tau^{1-\delta/2}\underline{h}^{\delta/2}$ for any $\tau \in \mathcal{M}_h$. Then for any $v_h \in \mathring{V}_h^1$,*

$$\left|\int_\Omega \nabla(u - u_I)\cdot\nabla v_h\right| \lesssim \frac{1 + (\ln N)^{1/2}}{N^{1/2+\rho}} \|\nabla v_h\|_{L^2(\Omega)}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right), \tag{3.11}$$

where $u_I = I_h^1 u \in V_h^1$ is the piecewise linear interpolant of u.

Proof. From the decomposition $u = v + w$,

$$\int_\Omega \nabla(u - u_I)\cdot\nabla v_h = \int_\Omega \nabla(v - v_I)\cdot\nabla v_h + \int_\Omega \nabla(w - w_I)\cdot\nabla v_h, \tag{3.12}$$

where $v_I = I_h^1 v$ and $w_I = I_h^1 w$ are the linear interpolants of v and w, respectively.

We first estimate $\int_\Omega \nabla(v - v_I)\cdot\nabla v_h$. Let $\mathcal{E}^O = \{e \in \mathcal{E}_h : e \subset \partial\tau \text{ the origin } O \in \tau\}$ and $\partial\mathcal{E}^O = \big\{e \in \mathcal{E}^O : O \notin e\big\}$. Recall that $\mathcal{M}^O$ is the set of elements with one vertex at O. Applying (3.2),

$$\begin{aligned}\int_\Omega \nabla(v - v_I)\cdot\nabla v_h &= \sum_{\tau\in\mathcal{M}_h} \int_\tau \nabla(v - v_I)\cdot\nabla v_h = \sum_{\tau\in\mathcal{M}^O} \int_\tau \nabla(v - v_I)\cdot\nabla v_h \\ &\quad + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^O} \sum_{e\subset\partial\tau} \left(\beta_e \int_e \frac{\partial^2 v_Q}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e \int_e \frac{\partial^2 v_Q}{\partial \boldsymbol{t}_e \partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}\right) \\ &= I_1 + I_2 + I_3 + I_4,\end{aligned} \tag{3.13}$$

where

$$I_j = \sum_{e\in\mathcal{E}_{j,h}\backslash\mathcal{E}^O}\Big[(\beta_e-\beta_e')\int_e \frac{\partial^2 v}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + (\gamma_e-\gamma_e')\int_e \frac{\partial^2 v}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}$$
$$+\beta_e\int_e \frac{\partial^2 (v_Q-v)}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e\int_e \frac{\partial^2 (v_Q-v)}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}$$
$$+\beta_e'\int_e \frac{\partial^2 (v-v_Q)}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e'\int_e \frac{\partial^2 (v-v_Q)}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}\Big], \quad j=1,2,$$

$$I_3 = \sum_{\tau\in\mathcal{M}^O}\int_\tau \nabla(v-v_I)\cdot\nabla v_h,$$

$$I_4 = \sum_{e\in\partial\mathcal{E}^O}\left(\beta_e\int_e \frac{\partial^2 v_Q}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e\int_e \frac{\partial^2 v_Q}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}\right).$$

First, I_3 can be estimated by Lemma 3.2 and the fact that $h_\tau \eqsim \underline{h}$ for $\tau\in\mathcal{M}^O$:

$$|I_3| \lesssim \underline{h}^\delta \sum_{\tau\in\mathcal{M}^O}\|\nabla v_h\|_{L^2(\tau)} \lesssim \underline{h}^\delta \|\nabla v_h\|_{L^2(\Omega)}. \tag{3.14}$$

Second, I_4 can be estimated by Lemma 3.1, assumption (1.3), and the fact that $h_e \eqsim r_e \eqsim \underline{h}$ for $e\in\partial\mathcal{E}^O$:

$$\begin{aligned}|I_4| &\lesssim \sum_{e\in\partial\mathcal{E}^O} h_e^2\left(|v|_{W^{2,\infty}(e)} + |v|_{H^3(\tau:\,\tau\in\Omega_e,\tau\notin\mathcal{M}^O)}\right)\|\nabla v_h\|_{L^2(\tau:\,\tau\in\Omega_e,\tau\notin\mathcal{M}^O)}\\ &\lesssim \sum_{e\in\partial\mathcal{E}^O} h_e^2\big(r_e^{\delta-2}+h_e r_e^{\delta-3}\big)\|\nabla v_h\|_{L^2(\tau:\,\tau\in\Omega_e,\tau\notin\mathcal{M}^O)} \qquad (3.15)\\ &\lesssim \underline{h}^\delta \sum_{e\in\partial\mathcal{E}^O}\|\nabla v_h\|_{L^2(\tau:\,\tau\in\Omega_e,\tau\notin\mathcal{M}^O)} \lesssim \underline{h}^\delta\|\nabla v_h\|_{L^2(\Omega)}.\end{aligned}$$

Next we estimate I_1. Notice that $h_e \eqsim h_\tau$ and $r_e \eqsim r_\tau$ for $\tau\subset\Omega_e$ and $e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O$. It follows from Lemma 3.1 and assumption (1.3) that

$$\begin{aligned}|I_1| &\lesssim \sum_{e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O}\left[\frac{h_e^{2+\alpha}}{r_e^{\alpha+\delta(1-\alpha)/2}}r_e^{\delta-2} + h_e^2 h_\tau r_\tau^{\delta-3}\right]\|\nabla v_h\|_{L^2(\tau:\,\tau\in\Omega_e)}\\ &\lesssim \sum_{e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O}\left[h_e^{2+\alpha}r_e^{\delta-2-\alpha-\delta(1-\alpha)/2} + h_e^3 r_e^{\delta-3}\right]\|\nabla v_h\|_{L^2(\tau:\,\tau\in\Omega_e)}\\ &\lesssim \left\{\sum_{e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O}\left[h_e^2 h_e^{2+2\alpha}r_e^{2\delta-4-2\alpha-\delta(1-\alpha)} + h_e^2 h_e^4 r_e^{2\delta-6}\right]\right\}^{1/2}\|\nabla v_h\|_{L^2(\Omega)}\\ &\lesssim \left\{\sum_{e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O}\left[h_e^2\underline{h}^{\delta(1+\alpha)}r_e^{(2-\delta)(1+\alpha)}r_e^{2\delta-4-2\alpha-\delta(1-\alpha)} + h_e^2\underline{h}^{2\delta}r_e^{4-2\delta}r_e^{2\delta-6}\right]\right\}^{1/2}\\ &\quad\times\|\nabla v_h\|_{L^2(\Omega)}.\end{aligned}$$

Here we have used $h_e \eqsim r_e^{1-\delta/2}\underline{h}^{\delta/2}$ to derive the last inequality. Therefore

(3.16)
$$\begin{aligned} I_1 &\lesssim \left\{\underline{h}^{\delta(1+\alpha)} \sum_{e\in\mathcal{E}_{1,h}\setminus\mathcal{E}^O} h_e^2 r_e^{-2}\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)} \lesssim \left\{\underline{h}^{\delta(1+\alpha)} \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^O} h_\tau^2 r_\tau^{-2}\right\}^{1/2} \\ &\quad \times \|\nabla v_h\|_{L^2(\Omega)} \\ &\lesssim \left\{\underline{h}^{\delta(1+\alpha)} \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^O} \int_\tau r^{-2}\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)} \lesssim \left\{\underline{h}^{\delta(1+\alpha)} \int_{\underline{h}}^1 r^{-1}\,\mathrm{d}r\right\}^{1/2} \\ &\quad \times \|\nabla v_h\|_{L^2(\Omega)} \\ &\lesssim \underline{h}^{\delta(1+\alpha)/2}(|\ln \underline{h}|^{1/2}) \|\nabla v_h\|_{L^2(\Omega)}. \end{aligned}$$

Finally, we estimate I_2. Notice that $h_e \lesssim r_e$ for $e \notin \mathcal{E}^O$. It follows from Lemma 3.1 and assumption (1.3) that

$$\begin{aligned} |I_2| &\lesssim \sum_{e\in\mathcal{E}_{2,h}\setminus\mathcal{E}^O} \left[h_e^2 r_e^{\delta-2} + h_e^2 h_\tau r_\tau^{\delta-3}\right] \|v_h\|_{L^2(\tau:\,\tau\in\Omega_e)} \\ &\lesssim \sum_{e\in\mathcal{E}_{2,h}\setminus\mathcal{E}^O} h_e^2 r_e^{\delta-2} \|v_h\|_{L^2(\tau:\,\tau\in\Omega_e)} \\ &\lesssim \left\{\sum_{e\in\mathcal{E}_{2,h}\setminus\mathcal{E}^O} h_e^4 r_e^{2\delta-4}\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)} \\ &\lesssim \underline{h}^\delta \left\{\sum_{e\in\mathcal{E}_{2,h}\setminus\mathcal{E}^O} 1\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)}. \end{aligned}$$

Here we have used $h_e \eqsim r_e^{1-\delta/2}\underline{h}^{\delta/2}$ to derive the last inequality. Therefore

$$|I_2| \lesssim \underline{h}^\delta \left\{\#\mathcal{E}_{2,h}\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)} \lesssim \underline{h}^\delta \left\{N^\sigma\right\}^{1/2} \|\nabla v_h\|_{L^2(\Omega)}. \tag{3.17}$$

From Lemma 2.1, $\underline{h}^\delta \eqsim 1/N$, $|\ln \underline{h}| \eqsim \ln N$. Combining (3.13)–(3.17) we have

$$\begin{aligned} \left|\int_\Omega \nabla(v - v_I)\cdot\nabla v_h\right| &\lesssim \left(\underline{h}^{\delta(1+\alpha)/2}(|\ln \underline{h}|^{1/2}) + \underline{h}^\delta \left\{N^\sigma\right\}^{1/2}\right) \|\nabla v_h\|_{L^2(\Omega)} \\ &\lesssim \frac{1+(\ln N)^{1/2}}{N^{1/2+\rho}} \|\nabla v_h\|_{L^2(\Omega)}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \end{aligned} \tag{3.18}$$

Now we turn to the estimate for $\int_\Omega \nabla(w - w_I)\cdot\nabla v_h$. Since w is smooth, we do not exclude the point O. From (3.2),

$$\int_\Omega \nabla(w - w_I)\cdot\nabla v_h = \sum_{\tau\in\mathcal{M}_h} \int_\tau \nabla(w - w_I)\cdot\nabla v_h = J_1 + J_2, \tag{3.19}$$

where

$$J_j = \sum_{e\in\mathcal{E}_{j,h}} \Big[(\beta_e-\beta_e')\int_e \frac{\partial^2 w}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + (\gamma_e-\gamma_e')\int_e \frac{\partial^2 w}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}$$
$$+\beta_e\int_e \frac{\partial^2 (w_Q-w)}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e\int_e \frac{\partial^2 (w_Q-w)}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}$$
$$+\beta_e'\int_e \frac{\partial^2 (w-w_Q)}{\partial \boldsymbol{t}_e^2}\frac{\partial v_h}{\partial \boldsymbol{t}_e} + \gamma_e'\int_e \frac{\partial^2 (w-w_Q)}{\partial \boldsymbol{t}_e\partial \boldsymbol{n}_e}\frac{\partial v_h}{\partial \boldsymbol{t}_e}\Big], \quad j=1,2.$$

By a similar argument as for I_1 and I_2, we can prove that

$$\left|\int_\Omega \nabla(w-w_I)\cdot\nabla v_h\right| \lesssim \frac{1}{N^{1/2+\rho}}\left\|\nabla v_h\right\|_{L^2(\Omega)}. \tag{3.20}$$

Now, the proof of the lemma follows from (3.12), (3.18), and (3.20). ∎

Applying Lemma 3.3 we obtain the following superconvergence result between the finite element solution u_h and the linear interpolant u_I of the solution of (1.1).

THEOREM 3.4. *Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha,\sigma,\delta/2)$ *with $0<\alpha\le 1$ and $0\le\sigma<1$ and that $h_\tau \eqsim r_\tau^{1-\delta/2}\underline{h}^{\delta/2}$ for any $\tau\in\mathcal{M}_h$. Then*

$$\left\|\nabla(u_h-u_I)\right\|_{L^2(\Omega)} \lesssim \frac{1+(\ln N)^{1/2}}{N^{1/2+\rho}}, \quad \rho=\min\left(\frac{\alpha}{2},\frac{1-\sigma}{2}\right). \tag{3.21}$$

Proof. Taking $v_h=u_h-u_I$ in Lemma 3.3 we have

$$\left\|\nabla(u_h-u_I)\right\|_{L^2(\Omega)}^2 = A(u_h-u_I,v_h) = A(u-u_I,v_h) = \int_\Omega \nabla(u-u_I)\cdot\nabla v_h$$
$$\lesssim \frac{1+(\ln N)^{1/2}}{N^{1/2+\rho}}\left\|\nabla v_h\right\|_{L^2(\Omega)} = \frac{1+(\ln N)^{1/2}}{N^{1/2+\rho}}\left\|\nabla(u_h-u_I)\right\|_{L^2(\Omega)}.$$

The proof is completed by canceling $\left\|\nabla(u_h-u_I)\right\|_{L^2(\Omega)}$ on both sides of the inequality. ∎

4. Superconvergence between the finite element solution and quadratic interpolation. Most parts of the proof are similar to those for linear elements and therefore are omitted. We emphasize only the differing parts. In this section u_h is the solution of (1.4) with $k=2$, that is, the quadratic finite element approximation of u.

We first introduce some estimates over triangles from [14]. Recall that $\phi_Q=\Pi_Q\phi$ is the quadratic interpolant defined in (3.1) based on the moment conditions.

LEMMA 4.1. *Assume that $\phi\in H^4(\tau)$; then there holds*

$$\int_\tau \nabla(\phi-\Pi_Q\phi)\cdot\nabla v_h = \sum_{e\subset\partial\tau}\sum_{s=0}^{3}\left(a_e^s(\tau)\frac{|\tau|}{h_e}+b_e^s(\tau)\right)\int_e \frac{\partial^3\phi}{\partial \boldsymbol{n}_e^s\partial \boldsymbol{t}_e^{3-s}}\frac{\partial^2 v_h}{\partial \boldsymbol{t}_e^2}$$
$$+O(h_\tau^3)\left|\phi\right|_{H^4(\tau)}\left\|v_h\right\|_{H^1(\tau)} \quad \forall v_h\in P_2(\tau), \tag{4.1}$$

where for $s = 0, 1, 2, 3$,

(4.2)

$$|a_e^s(\tau)| + |a_e^s(\tau')| \lesssim h_e^3, \quad |b_e^s(\tau)| + |b_e^s(\tau')| \lesssim h_e^4 \quad \text{if } e \in \mathcal{E}_h;$$

(4.3)

$$|a_e^s(\tau)|\tau| - a_e^s(\tau')|\tau'|| \lesssim h_e^{5+\alpha}/r_e^{\alpha+\delta(1-\alpha)/3}, |b_e^s(\tau) - b_e^s(\tau')| \lesssim h_e^{4+\alpha}/r_e^{\alpha+\delta(1-\alpha)/3}$$

if $\mathcal{M}_h$ *satisfies* Condition $(\alpha, \sigma, \delta/3)$ *with* $0 < \alpha \le 1$ *and* $0 \le \sigma < 1$, *and if* $e \in \mathcal{E}_{1,h}$.

To obtain the superconvergence of $\left\|\nabla(u_h - I_h^2 u)\right\|_{L^2(\Omega)}$, we estimate the difference between two quadratic interpolation operators Π_Q and I_h^2. It is easy to check that [27]

$$\Pi_Q p - I_h^2 p = 0 \quad \forall p \in P_3.$$

By the Bramble–Hilbert lemma, we have

$$\int_\tau (\nabla \Pi_Q \phi - \nabla I_h^2 \phi) \cdot \nabla v_h \lesssim h_\tau^3 \left|\phi\right|_{H^4(\tau)} \left\|\nabla v_h\right\|_{L^2(\tau)}.$$

Therefore we have the following lemma from (4.1).

LEMMA 4.2. *Assume that* $\phi \in H^4(\tau)$, *then there holds*

$$\int_\tau \nabla(\phi - I_h^2\phi) \cdot \nabla v_h = \sum_{e \subset \partial\tau} \sum_{s=0}^{3} \left(a_e^s(\tau) \frac{|\tau|}{h_e} + b_e^s(\tau) \right) \int_e \frac{\partial^3 \phi}{\partial \boldsymbol{n}_e^s \partial \boldsymbol{t}_e^{3-s}} \frac{\partial^2 v_h}{\partial \boldsymbol{t}_e^2} + O(h_\tau^3) \left|\phi\right|_{H^4(\tau)} \left\|v_h\right\|_{H^1(\tau)} \quad \text{for } v_h \in P_2(\tau). \tag{4.4}$$

Recall from Lemma 2.1 that, in the quadratic case, if $h_\tau \eqsim r_\tau^{1-\delta/3} \underline{h}^{\delta/3}$ for any $\tau \in \mathcal{M}_h$, then the total number of degrees of freedom N of the finite element equation (1.4) satisfies

$$N \eqsim \frac{1}{\underline{h}^{2\delta/3}}. \tag{4.5}$$

The following lemma is analogous to Lemma 3.2. We omit the proof.

LEMMA 4.3. *For* v *in decomposition* (1.2),

$$\left\|\nabla v - \nabla I_h^2 v\right\|_{L^2(\tau)} \lesssim h_\tau^\delta \quad \forall \tau \in \mathcal{M}^O.$$

The following lemma is the counterpart of Lemma 3.3 for the quadratic case.

LEMMA 4.4. *Assume that* $\mathcal{M}_h$ *satisfies* Condition $(\alpha, \sigma, \delta/3)$ *with* $0 < \alpha \le 1$ *and* $0 \le \sigma < 1$, *and that* $h_\tau \eqsim r_\tau^{1-\delta/3} \underline{h}^{\delta/3}$ *for any* $\tau \in \mathcal{M}_h$. *Then for any* $v_h \in \overset{\circ}{V}{}_h^2$,

$$\left| \int_\Omega \nabla(u - I_h^2 u) \cdot \nabla v_h \right| \lesssim \frac{1 + (\ln N)^{1/2}}{N^{1+\rho}} \left\|\nabla v_h\right\|_{L^2(\Omega)}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \tag{4.6}$$

Proof. From the decomposition $u = v + w$,

$$\int_\Omega \nabla(u - I_h^2 u) \cdot \nabla v_h = \int_\Omega \nabla(v - I_h^2 v) \cdot \nabla v_h + \int_\Omega \nabla(w - I_h^2 w) \cdot \nabla v_h. \tag{4.7}$$

We first estimate the term $\int_\Omega \nabla(v - I_h^2 v)\cdot\nabla v_h$. It follows from Lemma 4.2 that

$$\int_\Omega \nabla(v - I_h^2 v)\cdot\nabla v_h = \sum_{\tau\in\mathcal{M}_h}\int_\tau \nabla(v - I_h^2 v)\cdot\nabla v_h = I_1 + I_2 + I_3 + I_4, \tag{4.8}$$

where

$$I_j = \sum_{e=\tau\cap\tau'\in\mathcal{E}_{j,h}\setminus\mathcal{E}^O}\left\{\sum_{s=0}^{3}\left\{\frac{a_e^s(\tau)\,|\tau| - a_e^s(\tau')\,|\tau'|}{h_e} + \left[b_e^s(\tau) - b_e^s(\tau')\right]\right\}\int_e \frac{\partial^3 v}{\partial \boldsymbol{n}_e^s \partial \boldsymbol{t}_e^{3-s}}\frac{\partial^2 v_h}{\partial \boldsymbol{t}_e^2}\right.$$
$$\left. + O(h_e^3)\,|v|_{H^4(\Omega_e)}\,\|v_h\|_{H^1(\Omega_e)}\right\},\quad j = 1, 2,$$

$$I_3 = \sum_{\tau\in\mathcal{M}^O}\int_\tau \nabla(v - I_h^2 v)\cdot\nabla v_h,$$

$$I_4 = \sum_{e\in\partial\mathcal{E}^O}\left[\sum_{s=0}^{3}\left(a_e^s(\tau)\frac{|\tau|}{h_e} + b_e^s(\tau)\right)\int_e \frac{\partial^3 v}{\partial \boldsymbol{n}_e^s \partial \boldsymbol{t}_e^{3-s}}\frac{\partial^2 v_h}{\partial \boldsymbol{t}_e^2} + O(h_\tau^3)\,|v|_{H^4(\tau)}\,\|v_h\|_{H^1(\tau)}\right].$$

Notice that the τ in I_4 is not in $\mathcal{M}^O$.

From Lemma 4.3,

$$|I_3| \lesssim \underline{h}^\delta\,\|\nabla v_h\|_{L^2(\Omega)}. \tag{4.9}$$

It follows from (4.2) and assumption (1.3) that

$$\begin{aligned} |I_4| &\lesssim \sum_{e\in\partial\mathcal{E}^O}\left(h_e^5 r_e^{\delta-3}\,|v_h|_{W^{2,\infty}(\tau)} + h_\tau^3 h_\tau r_e^{\delta-4}\,\|v_h\|_{H^1(\tau)}\right)\\ &\lesssim \sum_{e\in\partial\mathcal{E}^O}\left(h_e^3 r_e^{\delta-3}\,\|v_h\|_{H^1(\tau)}\right) + h_e^4 r_e^{\delta-4}\,\|v_h\|_{H^1(\tau)} \lesssim \underline{h}^\delta\,\|v_h\|_{H^1(\Omega)}. \end{aligned} \tag{4.10}$$

Here we have used the inverse estimate $|v_h|_{W^{2,\infty}(\tau)} \lesssim h_e^{-2}\,\|v_h\|_{H^1(\tau)}$ and the fact that $h_e \eqsim r_e \eqsim \underline{h}$ for $e\in\partial\mathcal{E}^O$.

Next we estimate I_1. It follows from Lemma 4.1 and assumption (1.3) that

$$\begin{aligned} |I_1| &\lesssim \sum_{e\in\mathcal{E}_{1,h}\setminus\mathcal{E}^O}\left[\frac{h_e^{5+\alpha}}{r_e^{\alpha+\delta(1-\alpha)/3}} r_e^{\delta-3}\,|v_h|_{W^{2,\infty}(\tau)} + h_e^3 h_\tau r_\tau^{\delta-4}\,\|v_h\|_{H^1(\Omega_e)}\right]\\ &\lesssim \sum_{e\in\mathcal{E}_{1,h}\setminus\mathcal{E}^O}\left[h_e^{3+\alpha} r_e^{\delta-3-\alpha-\delta(1-\alpha)/3} + h_e^4 r_e^{\delta-4}\right]\|v_h\|_{H^1(\Omega_e)}\\ &\lesssim \left\{\sum_{e\in\mathcal{E}_{1,h}\setminus\mathcal{E}^O}\left[h_e^2 h_e^{4+2\alpha} r_e^{2\delta-6-2\alpha-2\delta(1-\alpha)/3} + h_e^2 h_e^6 r_e^{2\delta-8}\right]\right\}^{1/2}\|v_h\|_{H^1(\Omega)}\\ &\lesssim \left\{\sum_{e\in\mathcal{E}_{1,h}\setminus\mathcal{E}^O}\left[h_e^2 \underline{h}^{2\delta(2+\alpha)/3} r_e^{(4+2\alpha)(1-\delta/3)} r_e^{2\delta-6-2\alpha-2\delta(1-\alpha)/3}\right.\right.\\ &\qquad\left.\left. + h_e^2 \underline{h}^{2\delta} r_e^{6-2\delta} r_e^{2\delta-8}\right]\right\}^{1/2}\|v_h\|_{H^1(\Omega)}. \end{aligned}$$

Here we have used $h_e \eqsim r_e^{1-\delta/3}\underline{h}^{\delta/3}$ to derive the last inequality. Therefore

(4.11)

$$I_1 \lesssim \left\{\underline{h}^{2\delta(2+\alpha)/3}\sum_{e\in\mathcal{E}_{1,h}\backslash\mathcal{E}^O} h_e^2 r_e^{-2}\right\}^{1/2}\|v_h\|_{H^1(\Omega)} \lesssim \left\{\underline{h}^{2\delta(2+\alpha)/3}\sum_{\tau\in\mathcal{M}_h\backslash\mathcal{M}^O} h_\tau^2 r_\tau^{-2}\right\}^{1/2}$$
$$\times \|v_h\|_{H^1(\Omega)}$$
$$\lesssim \left\{\underline{h}^{2\delta(2+\alpha)/3}\sum_{\tau\in\mathcal{M}_h\backslash\mathcal{M}^O}\int_\tau r^{-2}\right\}^{1/2}\|v_h\|_{H^1(\Omega)} \lesssim \underline{h}^{\delta(2+\alpha)/3}\left|\ln\underline{h}\right|^{1/2}\|v_h\|_{H^1(\Omega)}.$$

By a similar argument for (3.17) we can show that

$$|I_2| \lesssim \underline{h}^{\delta}\left\{\#\mathcal{E}_{2,h}\right\}^{1/2}\|v_h\|_{H^1(\Omega)} \lesssim \underline{h}^{\delta}\left\{N^\sigma\right\}^{1/2}\|v_h\|_{H^1(\Omega)}. \tag{4.12}$$

Notice that $\|v_h\|_{H^1(\Omega)} \lesssim \|\nabla v_h\|_{L^2(\Omega)}$ from Poincaré's inequality. Combining (4.8)–(4.12), we have

$$\begin{aligned}\left|\int_\Omega \nabla(v-v_I)\cdot\nabla v_h\right| &\lesssim \left(\underline{h}^{\delta(2+\alpha)/3}\left|\ln\underline{h}\right|^{1/2} + \underline{h}^{\delta}\left\{N^\sigma\right\}^{1/2}\right)\|\nabla v_h\|_{L^2(\Omega)}\\ &\lesssim \frac{1+(\ln N)^{1/2}}{N^{1+\rho}}\|\nabla v_h\|_{L^2(\Omega)}, \quad \rho=\min\left(\frac{\alpha}{2},\frac{1-\sigma}{2}\right).\end{aligned} \tag{4.13}$$

The estimate for the term $\int_\Omega \nabla(w-I_h^2 w)\cdot\nabla v_h$ is similar to (4.13). It follows from Lemma 4.2 that

$$\int_\Omega \nabla(w-I_h^2 w)\cdot\nabla v_h = \sum_{\tau\in\mathcal{M}_h}\int_\tau \nabla(w-I_h^2 w)\cdot\nabla v_h = J_1+J_2, \tag{4.14}$$

where

$$J_j = \sum_{e=\tau\cap\tau'\in\mathcal{E}_{j,h}}\left\{\sum_{s=0}^{3}\left\{\frac{a_e^s(\tau)\,|\tau| - a_e^s(\tau')\,|\tau'|}{h_e} + \left[b_e^s(\tau)-b_e^s(\tau')\right]\right\}\int_e \frac{\partial^3 w}{\partial \boldsymbol{n}_e^s\partial \boldsymbol{t}_e^{3-s}}\frac{\partial^2 v_h}{\partial \boldsymbol{t}_e^2}\right.$$
$$\left. + O(h_e^3)\,|w|_{H^4(\Omega_e)}\|v_h\|_{H^1(\Omega_e)}\right\}, \quad j=1,2.$$

There holds

$$\left|\int_\Omega \nabla(w-w_I)\cdot\nabla v_h\right| \lesssim \frac{1}{N^{1+\rho}}\|\nabla v_h\|_{L^2(\Omega)}. \tag{4.15}$$

Now, the conclusion follows from (4.7), (4.13), and (4.15). ∎

Applying Lemma 4.4 we obtain the following superconvergence result between the quadratic finite element approximation u_h and the quadratic interpolant $I_h^2 u$ of the solution of problem (1.1).

THEOREM 4.5. *Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha,\sigma,\delta/3)$ *with $0<\alpha\le 1$ and $0\le\sigma<1$, and that $h_\tau \eqsim r_\tau^{1-\delta/3}\underline{h}^{\delta/3}$ for any $\tau\in\mathcal{M}_h$. Then*

$$\left\|\nabla(u_h - I_h^2 u)\right\|_{L^2(\Omega)} \lesssim \frac{1+(\ln N)^{1/2}}{N^{1+\rho}}, \quad \rho=\min\left(\frac{\alpha}{2},\frac{1-\sigma}{2}\right). \tag{4.16}$$

5. The asymptotically exact a posteriori error estimators. In this section, we apply a newly developed gradient recovery operator, called polynomial preserving recovery (PPR) [20, 26, 28], to define an a posteriori error estimator. We further prove some superconvergence properties of the recovery operator. As a consequence, the error estimator based on PPR is asymptotically exact under a mesh density assumption.

5.1. The gradient recovery operator G_h and its superconvergence. Given a node $z \in \mathcal{N}_h$, we select $n \geq m = (k+2)(k+3)/2$ sampling points $z_j \in \mathcal{N}_h$, $j = 1, 2, \ldots, n$, in an element patch ω_z containing z (z is one of z_j) and fit a polynomial of degree $k+1$, in the least squares sense, with values of u_h at those sampling points. In other words, we are looking for $p_{k+1} \in \mathcal{P}_{k+1}$ such that

$$\sum_{j=1}^{n} (p_{k+1} - u_h)^2(z_j) = \min_{q \in \mathcal{P}_{k+1}} \sum_{j=1}^{n} (q - u_h)^2(z_j). \tag{5.1}$$

The recovered gradient at of z is then defined as

$$G_h u_h(z) = (\nabla p_{k+1})(z). \tag{5.2}$$

It was proved in [20] that the above least squares fitting procedure has a unique solution as long as those n sampling points are not on the same conic curve for the linear element. Conditions for higher order elements were given as well. Furthermore, the gradient recovery operator $G_h : C(\Omega) \mapsto V_h^k \times V_h^k$, $k = 1$ or 2, has the following properties:

(i) $\|G_h v_h\|_{L^2(\Omega)} \lesssim \|\nabla v_h\|_{L^2(\Omega)} \quad \forall v_h \in V_h^k$.
(ii) For any nodal point z, $(G_h p)(z) = \nabla p(z)$ if $p \in P_{k+1}(\omega_z)$.
(iii) $|(G_h\phi)(z)| \lesssim \frac{1}{h_\tau} \max_{z' \in \mathcal{N}_h \cap \omega_z} |\phi(z')|$ for any node z in an element $\tau \in \mathcal{M}_h$.
(iv) $G_h\phi = G_h I_h^k \phi$.

Since $I_h^k\phi$ and ϕ have the same nodal values and G_h uses only nodal values, (iv) is clear. The polynomial preserving property (ii) can be established easily by the least squares procedure [28]. A key observation is that G_h provides a finite difference scheme at each node $z \in \mathcal{N}_h$; therefore, (iii) is obvious. Under a very mild mesh condition, "the sum of any two adjacent angles in $\mathcal{M}_h$ is at most π," the boundedness property (i) can be proved, though it is not trivial. The reader is referred to [20, 26, 28] for more details.

We first consider the case of linear finite elements and then state the corresponding results for quadratic elements since the proofs are similar. We have from (i),

$$\begin{aligned} \|G_h u_h - \nabla u\|_{L^2(\Omega)} &\leq \|G_h u_h - G_h u_I\|_{L^2(\Omega)} + \|G_h u_I - \nabla u\|_{L^2(\Omega)} \\ &\lesssim \|\nabla(u_h - u_I)\|_{L^2(\Omega)} + \|G_h u_I - \nabla u\|_{L^2(\Omega)}. \end{aligned} \tag{5.3}$$

Here u_I is the linear interpolant of u. The estimate for the first term of the right hand side of the inequality (5.3) is given in Theorem 3.4. To estimate the second term we need the following lemma.

LEMMA 5.1. *Under properties* (ii)–(iii)*, for any element $\tau \in \mathcal{M}_h$ and any function $\phi \in W^{3,\infty}(\tilde{\tau})$,*

$$\|G_h\phi_I - \nabla\phi\|_{L^2(\tau)} \lesssim h_\tau^3 |\phi|_{W^{3,\infty}(\tilde{\tau})},$$

where $\tilde{\tau} = \bigcup \{\omega_z : z \in \mathcal{N}_h \cap \tau\}$ and ϕ_I is the linear interpolant of ϕ.

Proof. Let $(\nabla\phi)_I$ be the linear interpolant of $\nabla\phi$. Then

$$\|G_h\phi_I - \nabla\phi\|_{L^2(\tau)} \le \|G_h\phi_I - (\nabla\phi)_I\|_{L^2(\tau)} + \|(\nabla\phi)_I - \nabla\phi\|_{L^2(\tau)}\,. \tag{5.4}$$

The standard theory of finite element interpolation estimates says that [6]

$$\|(\nabla\phi)_I - \nabla\phi\|_{L^2(\tau)} \lesssim h_\tau^2\,|\phi|_{H^3(\tau)} \lesssim h_\tau^3\,|\phi|_{W^{3,\infty}(\tilde\tau)}\,. \tag{5.5}$$

For a node $z \in \tau$, let $\phi_2(x,y)$ be the 2nd-degree Taylor expansion of ϕ at the point z. It is clear that

$$|\phi(x,y) - \phi_2(x,y)| \lesssim h_\tau^3\,|\phi|_{W^{3,\infty}(\tilde\tau)} \quad \forall (x,y) \in \tilde\tau.$$

By properties (ii) and (iii),

$$\begin{aligned}\big|\big(G_h\phi_I - (\nabla\phi)_I\big)(z)\big| &= \big|\big(G_h\phi_I - \nabla\phi\big)(z)\big| = \big|\big(G_h(\phi_I - \phi_2) - (\nabla\phi - \nabla\phi_2)\big)(z)\big| \\ &= \big|\big(G_h(\phi_I - \phi_2)\big)(z)\big| \lesssim \frac{1}{h_\tau}\max_{z'\in\mathcal{N}_h\cap\omega_z}|(\phi-\phi_2)(z')| \\ &\lesssim h_\tau^2\,|\phi|_{W^{3,\infty}(\omega_z)}\,.\end{aligned}$$

Therefore

$$\|G_h\phi_I - (\nabla\phi)_I\|_{L^2(\tau)} \lesssim h_\tau \max_{z\in\mathcal{N}_h\cap\tau}\big|\big(G_h\phi_I - (\nabla\phi)_I\big)(z)\big| \lesssim h_\tau^3\,|\phi|_{W^{3,\infty}(\tilde\tau)}\,. \tag{5.6}$$

The proof of the lemma is completed by combining (5.4)–(5.6). ∎

The following theorem is devoted to the estimate of the second term of (5.3).

THEOREM 5.2. *Assume that* $h_\tau \eqsim r_\tau^{1-\delta/2}\underline{h}^{\delta/2}$ *for any* $\tau \in \mathcal{M}_h$. *Then*

$$\|G_hu_I - \nabla u\|_{L^2(\Omega)} \lesssim \frac{1+(\ln N)^{1/2}}{N}. \tag{5.7}$$

Proof. Recall the decomposition (1.2) $u = v + w$, we have, by the triangular inequality,

$$\|G_hu_I - \nabla u\|_{L^2(\Omega)} \le \|G_hv_I - \nabla v\|_{L^2(\Omega)} + \|G_hw_I - \nabla w\|_{L^2(\Omega)}\,, \tag{5.8}$$

where $v_I = I_h^1 v$ and $w_I = I_h^1 w$ are the linear interpolants of v and w, respectively.

We first estimate the singular part $\|G_hv_I - \nabla v\|_{L^2(\Omega)}$. Introduce the set of triangles $\mathcal{M}^{\tilde O} = \{\tau \in \mathcal{M}_h :$ the origin $O \in \tilde\tau\}$. For any $\tau \in \mathcal{M}^{\tilde O}$,

$$\|G_hv_I - \nabla v\|_{L^2(\tau)} \le \|G_hv_I\|_{L^2(\tau)} + \|\nabla v\|_{L^2(\tau)}\,. \tag{5.9}$$

By property (ii), $G_hC = 0$ for any constant C. Thus, from property (iii),

$$\begin{aligned}\|G_hv_I\|_{L^2(\tau)} = \|G_h(v_I - v(O))\|_{L^2(\tau)} &\lesssim h_\tau \max_{z\in\mathcal{N}_h\cap\tau}\big|G_h\big(v_I - v(O)\big)(z)\big| \\ &\lesssim h_\tau\frac{1}{h_\tau}\max_{z'\in\mathcal{N}_h\cap\tilde\tau}|v(z') - v(O)| \\ &= \max_{z'\in\mathcal{N}_h\cap\tilde\tau}\left|\int_0^1 \frac{d}{dt}v(z't)\mathrm{d}t\right| = \max_{z'\in\mathcal{N}_h\cap\tilde\tau}\left|\int_0^1 z'\cdot\nabla v(z't)\mathrm{d}t\right|.\end{aligned}$$

Since $\tau \in \mathcal{M}^{\widetilde{O}}$, $|z'| \lesssim \underline{h}$. It follows from assumption (1.3) that

$$\|G_h v_I\|_{L^2(\tau)} \lesssim \int_0^1 \underline{h} \cdot (\underline{h}t)^{\delta-1} \mathrm{d}t \lesssim \underline{h}^{\delta}. \tag{5.10}$$

On the other hand,

$$\|\nabla v\|_{L^2(\tau)} \lesssim \left(\int_\tau |\nabla v|^2\right)^{1/2} \lesssim \left(\int_\tau r^{2\delta-2}\right)^{1/2} \lesssim \left(\int_0^{c\underline{h}} r^{2\delta-2} r \,\mathrm{d}r\right)^{1/2} \lesssim \underline{h}^{\delta}. \tag{5.11}$$

Here $c\underline{h}$ is the diameter of $\tilde{\tau}$. Combining (5.9), (5.10), and (5.11), we obtain

$$\|G_h v_I - \nabla v\|_{L^2(\tau)} \lesssim \underline{h}^{\delta} \quad \text{for } \tau \in \mathcal{M}^{\widetilde{O}}. \tag{5.12}$$

It follows from Lemma 5.1 and (1.3) that

$$\|G_h v_I - \nabla v\|_{L^2(\tau)} \lesssim h_\tau^3 \, |v|_{W^{3,\infty}(\tilde{\tau})} \lesssim h_\tau^3 r_\tau^{\delta-3} \quad \text{for } \tau \in \mathcal{M}_h \setminus \mathcal{M}^{\widetilde{O}}, \tag{5.13}$$

where r_τ is the distance form O to the barycenter of τ. Therefore from $h_\tau \eqsim r_\tau^{1-\delta/2} \underline{h}^{\delta/2}$,

$$\begin{aligned}
\|G_h v_I - \nabla v\|_{L^2(\Omega)}^2 &= \sum_{\tau\in\mathcal{M}_h} \|G_h v_I - \nabla v\|_{L^2(\tau)}^2 \lesssim \underline{h}^{2\delta} + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^{\widetilde{O}}} h_\tau^6 r_\tau^{2\delta-6} \\
&\lesssim \underline{h}^{2\delta} + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^{\widetilde{O}}} h_\tau^2 r_\tau^{4-2\delta} \underline{h}^{2\delta} r_\tau^{2\delta-6} \lesssim \underline{h}^{2\delta} + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^{\widetilde{O}}} \underline{h}^{2\delta} h_\tau^2 r_\tau^{-2} \\
&\lesssim \underline{h}^{2\delta} + \underline{h}^{2\delta} \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^{\widetilde{O}}} \int_\tau r^{-2} \lesssim \underline{h}^{2\delta} + \underline{h}^{2\delta} \int_{\underline{h}}^1 r^{-1} \,\mathrm{d}r \lesssim \underline{h}^{2\delta} \\
&\quad + \underline{h}^{2\delta} \left|\ln \underline{h}\right|.
\end{aligned}$$

Therefore Lemma 2.1 implies that

$$\|G_h v_I - \nabla v\|_{L^2(\Omega)} \lesssim \underline{h}^{\delta} \left(1 + |\ln \underline{h}|^{1/2}\right) \lesssim \frac{1 + (\ln N)^{1/2}}{N}. \tag{5.14}$$

Next we estimate the term $\|G_h w_I - \nabla w\|_{L^2(\Omega)}$ in (5.8). Since w is smooth, we do not have to divide $\mathcal{M}_h$ into two parts as above. From Lemma 5.1 and assumption (1.3),

$$\begin{aligned}
\|G_h w_I - \nabla w\|_{L^2(\Omega)} &\lesssim \left(\sum_{\tau\in\mathcal{M}_h} \|G_h w_I - \nabla w\|_{L^2(\tau)}^2\right)^{1/2} \lesssim \left(\sum_{\tau\in\mathcal{M}_h} h_\tau^6\right)^{1/2} \\
&\lesssim \left(\sum_{\tau\in\mathcal{M}_h} h_\tau^2 r_\tau^{4-2\delta} \underline{h}^{2\delta}\right)^{1/2} \lesssim \underline{h}^{\delta} \left(\int_\Omega r^{4-2\delta}\right)^{1/2} \lesssim \underline{h}^{\delta} \lesssim \frac{1}{N}.
\end{aligned} \tag{5.15}$$

The proof of the theorem is completed by inserting estimates (5.14) and (5.15) into inequality (5.8). ∎

The following superconvergence result of the gradient recovery operator G_h can be proved by combining (5.3), Theorem 3.4, and Theorem 5.2.

THEOREM 5.3. *Let u_h be the linear finite element approximation of u. Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/2)$ *with $0 < \alpha \leq 1$ and $0 \leq \sigma < 1$, and that $h_\tau \eqsim r_\tau^{1-\delta/2} \underline{h}^{\delta/2}$ for any $\tau \in \mathcal{M}_h$. Then*

$$\|G_h u_h - \nabla u\|_{L^2(\Omega)} \lesssim \frac{1 + (\ln N)^{1/2}}{N^{1/2+\rho}}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \tag{5.16}$$

We remark that the result of Theorem 5.3 is a superconvergence result since the asymptotically optimal convergence rate of $\|\nabla(u - u_h)\|_{L^2(\Omega)}$ is $O(1/N^{1/2})$.

Next we state the results for quadratic finite elements. The following theorem provides the estimate for the gradient recovery operator G_h. The proof is similar to that of Theorem 5.2 and therefore is omitted.

THEOREM 5.4. *Assume that $h_\tau \eqsim r_\tau^{1-\delta/3} \underline{h}^{\delta/3}$ for any $\tau \in \mathcal{M}_h$. Then*

$$\left\|G_h I_h^2 u - \nabla u\right\|_{L^2(\Omega)} \lesssim \frac{1 + (\ln N)^{1/2}}{N^{3/2}}. \tag{5.17}$$

The superconvergence of the gradient recovery operator G_h is presented in the following theorem which is parallel to Theorem 5.3.

THEOREM 5.5. *Let u_h be the quadratic finite element approximation of u. Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/3)$ *with $0 < \alpha \leq 1$ and $0 \leq \sigma < 1$ and that $h_\tau \eqsim r_\tau^{1-\delta/3} \underline{h}^{\delta/3}$ for any $\tau \in \mathcal{M}_h$. Then*

$$\|G_h u_h - \nabla u\|_{L^2(\Omega)} \lesssim \frac{1 + (\ln N)^{1/2}}{N^{1+\rho}}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \tag{5.18}$$

5.2. The a posteriori error estimators. With preparation from the previous subsections, it is now straightforward to prove the asymptotic exactness of error estimators based on the recovery operator G_h. The global error estimator is naturally defined by

$$\eta_h = \|G_h u_h - \nabla u_h\|_{L^2(\Omega)}. \tag{5.19}$$

THEOREM 5.6. *Let u_h be the linear finite element approximation of u. Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/2)$ *with $0 < \alpha \leq 1$ and $0 \leq \sigma < 1$, and that $h_\tau \eqsim r_\tau^{1-\delta/2} \underline{h}^{\delta/2}$ for any $\tau \in \mathcal{M}_h$. Furthermore, assume that*

$$\frac{1}{N^{1/2}} \lesssim \|\nabla(u - u_h)\|_{L^2(\Omega)}. \tag{5.20}$$

Then

$$\left|\frac{\eta_h}{\|\nabla(u - u_h)\|_{L^2(\Omega)}} - 1\right| \lesssim \frac{1 + (\ln N)^{1/2}}{N^{\rho}}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \tag{5.21}$$

The following lemma says that $\|\nabla(u - u_h)\|_{L^2(\Omega)}$ is the asymptotically optimal on the mesh $\mathcal{M}_h$ satisfying $h_\tau \eqsim r_\tau^{1-\delta/2} \underline{h}^{\delta/2}$ as the total number of degrees of freedom $N \to \infty$.

LEMMA 5.7. *Let u_h be the linear finite element approximation of u. Assume that $h_\tau \eqsim r_\tau^{1-\delta/2}\underline{h}^{\delta/2}$ for any $\tau \in \mathcal{M}_h$. Then*

$$\|\nabla(u-u_I)\|_{L^2(\Omega)} \lesssim \frac{1}{N^{1/2}} \text{ and hence } \|\nabla(u-u_h)\|_{L^2(\Omega)} \lesssim \frac{1}{N^{1/2}}.$$

Proof. Recall that u is decomposed as $u = v + w$ satisfying (1.3). Noticing that

$$\|\nabla(v-v_I)\|_{L^2(\tau)} \lesssim h_\tau |v|_{H^2(\tau)} \lesssim h_\tau^2 r_\tau^{\delta-2} \quad \forall \tau \in \mathcal{M}_h \setminus \mathcal{M}^O,$$

and that

$$\|\nabla(w-w_I)\|_{L^2(\tau)} \lesssim h_\tau |w|_{H^2(\tau)} \lesssim h_\tau^2 \quad \forall \tau \in \mathcal{M}_h,$$

we have, by Lemma 3.2,

$$\begin{aligned}
\|\nabla(u-u_I)\|_{L^2(\Omega)}^2 &\lesssim \|\nabla(v-v_I)\|_{L^2(\Omega)}^2 + \|\nabla(w-w_I)\|_{L^2(\Omega)}^2 \\
&= \sum_{\tau\in\mathcal{M}_h} \left(\|\nabla(v-v_I)\|_{L^2(\tau)}^2 + \|\nabla(w-w_I)\|_{L^2(\tau)}^2 \right) \\
&\lesssim \underline{h}^{2\delta} + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^O} h_\tau^4 r_\tau^{2\delta-4} \lesssim \underline{h}^{2\delta} + \sum_{\tau\in\mathcal{M}_h\setminus\mathcal{M}^O} h_\tau^2 r_\tau^{2-\delta}\underline{h}^{\delta} r_\tau^{2\delta-4} \\
&\lesssim \underline{h}^{2\delta} + \underline{h}^{\delta}\int_\Omega r^{\delta-2} \lesssim \underline{h}^{2\delta} + \underline{h}^{\delta}.
\end{aligned}$$

In light of Lemma 2.1, we obtain

$$\|\nabla(u-u_I)\|_{L^2(\Omega)}^2 \lesssim \frac{1}{N^2} + \frac{1}{N},$$

which completes the proof of the lemma. ∎

The following lemma says that, for the quadratic finite element approximation u_h, $\|\nabla(u-u_h)\|_{L^2(\Omega)}$ is asymptotically optimal on the mesh $\mathcal{M}_h$ satisfying $h_\tau \eqsim r_\tau^{1-\delta/3}\underline{h}^{\delta/3}$ as the total number of degrees of freedom $N \to \infty$.

LEMMA 5.8. *Let u_h be the quadratic finite element approximation of u. Assume that $h_\tau \eqsim r_\tau^{1-\delta/3}\underline{h}^{\delta/3}$ for any $\tau \in \mathcal{M}_h$. Then*

$$\left\|\nabla(u-I_h^2 u)\right\|_{L^2(\Omega)} \lesssim \frac{1}{N} \text{ and hence } \|\nabla(u-u_h)\|_{L^2(\Omega)} \lesssim \frac{1}{N}.$$

By Theorem 5.5, we can prove the asymptotic exactness of error estimators based on the recovery operator G_h for quadratic elements.

THEOREM 5.9. *Let u_h be the quadratic finite element approximation of u. Assume that $\mathcal{M}_h$ satisfies* Condition $(\alpha, \sigma, \delta/3)$ *with $0 < \alpha \le 1$ and $0 \le \sigma < 1$ and that $h_\tau \eqsim r_\tau^{1-\delta/3}\underline{h}^{\delta/3}$ for any $\tau \in \mathcal{M}_h$. Furthermore, assume that*

$$\frac{1}{N} \lesssim \|\nabla(u-u_h)\|_{L^2(\Omega)}. \tag{5.22}$$

Then

$$\left| \frac{\eta_h}{\|\nabla(u-u_h)\|_{L^2(\Omega)}} - 1 \right| \lesssim \frac{1+(\ln N)^{1/2}}{N^\rho}, \quad \rho = \min\left(\frac{\alpha}{2}, \frac{1-\sigma}{2}\right). \tag{5.23}$$

6. Implementation and numerical examples. In this section we present some numerical examples to verify the asymptotic exactness of the error estimator η_h based on the recovery operator G_h using quadratic finite elements. For examples on linear elements we refer to [12].

Implementation of the adaptive algorithm in this section is based on FEMLAB.[1] We define the local a posteriori error estimator on element τ as

$$\eta_\tau = \|G_h u_h - \nabla u_h\|_{L^2(\tau)},$$

and the global error estimator as

$$\eta_h = \left(\sum_{\tau \in \mathcal{M}_h} \eta_\tau^2 \right)^{1/2}.$$

Now we describe the adaptive algorithm used in this paper.

ALGORITHM. Given the tolerance $\texttt{TOL} > 0$,

- generate an initial mesh $\mathcal{M}_h$ over Ω;
- while $\eta_h > \texttt{TOL}$ do
  - choose a set of elements $\widehat{\mathcal{M}}_h \subset \mathcal{M}_h$ such that

$$\left(\sum_{\tau \in \widehat{\mathcal{M}}_h} \eta_\tau^2 \right)^{1/2} > 0.7 \left(\sum_{\tau \in \mathcal{M}_h} \eta_\tau^2 \right)^{1/2},$$

    then refine the elements in $\widehat{\mathcal{M}}_h$. Update the mesh $\mathcal{M}_h$.
  - solve the discrete problem (1.4) on $\mathcal{M}_h$.
  - compute error estimators on $\mathcal{M}_h$.

  end while

Remark 6.1. The marking strategy, that is, the method of how to choose $\widehat{\mathcal{M}}_h$ for refinements used in our algorithm, is well known in the adaptive finite element community. Actually, it was used, e.g., in [9, 18] to design convergent finite element algorithms. In our implementation of the algorithm, the elements in $\widehat{\mathcal{M}}_h$ are chosen from the elements which have larger local a posteriori error estimators η_τ.

Example 1. The Laplace equation on the L-shaped domain of Figure 6.1 with the Dirichlet boundary condition is chosen so that the true solution is $r^{2/3}\sin(2\theta/3)$ in polar coordinates.

Figure 6.1 plots the initial mesh and the adaptively refined mesh of 3565 elements after 15 adaptive iterations. Figure 6.2 demonstrates asymptotic exactness of the error estimator $\eta_h = \|G_h u_h - \nabla u_h\|_{L^2(\Omega)}$ for the Laplace equation on the L-shaped domain. We see that

$$\|\nabla u_h - \nabla u\|_{L^2(\Omega)} \approx O(N^{-1}), \quad \|G_h u_h - \nabla u\|_{L^2(\Omega)} \approx O(N^{-1.2}),$$

and

$$\|G_h u_h - \nabla u_h\|_{L^2(\Omega)} \Big/ \|\nabla u - \nabla u_h\|_{L^2(\Omega)} \approx 1 + O(N^{-0.5}).$$

[1] http://ecs.rutgers.edu/eitlab/femlab.php.

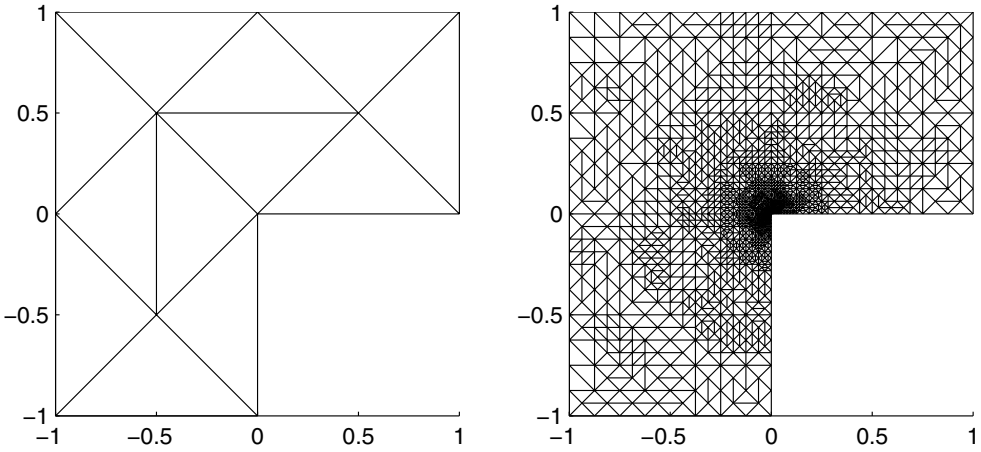

FIG. 6.1. *The initial mesh (left) and the adaptively refined mesh (right) of* 3565 *elements after* 15 *adaptive iterations for the Laplace equation on the L-shaped domain.*

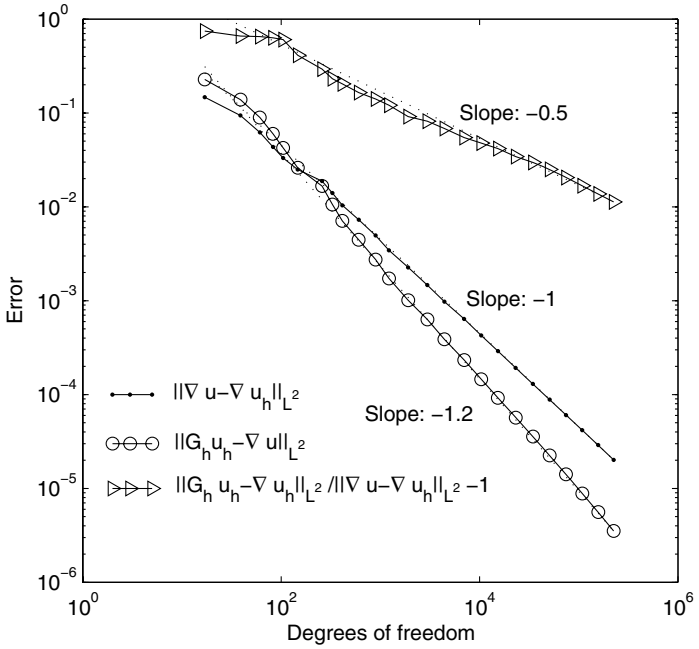

FIG. 6.2. $\|\nabla u - \nabla u_h\|_{L^2(\Omega)}$, $\|\nabla u - G_h u_h\|_{L^2(\Omega)}$, *and* $\|G_h u_h - \nabla u_h\|_{L^2(\Omega)} / \|\nabla u - \nabla u_h\|_{L^2(\Omega)} - 1$ *versus the total number of degrees of freedom for the Laplace equation on the L-shaped domain. Dotted lines give reference slopes.*

Notice that the decay of $\|\nabla u_h - \nabla u\|_{L^2(\Omega)}$ is quasi-optimal, $\|G_h u_h - \nabla u\|_{L^2(\Omega)}$ is superconvergent with order $O(N^{-1.2})$, and $\eta_h / \|\nabla u - \nabla u_h\|_{L^2(\Omega)}$ approaches 1 at the rate of $O(N^{-0.5})$. In this paper, the L^2 norms are calculated by the six points Gauss quadrature rule over triangles.

Let us have a close look at the mesh density assumption $h_\tau \approx r_\tau^{1-\delta/3} \underline{h}^{\delta/3} = r_\tau^{7/9} \underline{h}^{2/9}$ for $\delta = 2/3$. We shall verify this on the final mesh, which has 112880

elements after 24 adaptive iterations. We choose $\underline{h} = \min_{\tau\in\mathcal{M}_h} h_\tau \approx 5.96 \times 10^{-8}$ and have

$$0.44 \le \frac{h_\tau}{r_\tau^{7/9}\underline{h}^{2/9}} \le 2.35$$

for all elements $\tau \in \mathcal{M}_h$. Note that the ratio between the upper and lower bounds is less than 6. This fact indicates that all elements in the final mesh satisfy the mesh density assumption.

Next, let us examine the condition (α, σ, μ) on the final mesh. Here $\mu = \delta/3 = 2/9$. It is shown that, for every $e \in \mathcal{E}_h$, Ω_e is a $3.92 \times h_e^{1+0.4}/r_e^{0.4+\mu(1-0.4)}$ approximate parallelogram. That is, the final mesh satisfies Condition $(0.4, 0, 2/9)$.

Example 2. Let $\Omega = \{(x_1, x_2) : |x_1|, |x_2| < 0.5\}\backslash\{(x_1, 0) : 0 \le x_1 < 0.5\}$ be the domain with a crack. We consider the Poisson equation

$$-\Delta u = 1$$

with a Dirichlet boundary condition chosen so that the true solution is $r^{1/2}\sin(\theta/2) - \frac{1}{4}r^2$ in polar coordinates.

Figure 6.3 plots the initial mesh and the adaptively refined mesh of 3353 elements after 16 adaptive iterations. Figure 6.4 shows asymptotic exactness of the error estimator $\eta_h = \|G_h u_h - \nabla u_h\|_{L^2(\Omega)}$ for the crack problem. We see that

$$\|\nabla u_h - \nabla u\|_{L^2(\Omega)} \approx O(N^{-1}), \quad \|G_h u_h - \nabla u\|_{L^2(\Omega)} \approx O(N^{-1.1}),$$

and

$$\|G_h u_h - \nabla u_h\|_{L^2(\Omega)} \Big/ \|\nabla u - \nabla u_h\|_{L^2(\Omega)} \approx 1 + O(N^{-0.3}).$$

Notice that the decay of $\|\nabla u_h - \nabla u\|_{L^2(\Omega)}$ is quasi-optimal, $\|G_h u_h - \nabla u\|_{L^2(\Omega)}$ is superconvergent at an order $O(N^{-1.1})$, and $\eta_h / \|\nabla u - \nabla u_h\|_{L^2(\Omega)}$ approaches 1 at the rate of $O(N^{-0.3})$.

Let us take a close look at the mesh density assumption $h_\tau \eqsim r_\tau^{1-\delta/3}\underline{h}^{\delta/3} = r_\tau^{5/6}\underline{h}^{1/6}$ for $\delta = 1/2$. We verify this on the final mesh, which has 110563 elements after 27 adaptive iterations. We choose $\underline{h} = \min_{\tau\in\mathcal{M}_h} h_\tau \approx 3.67 \times 10^{-9}$ and have

$$0.32 < \frac{h_\tau}{r_\tau^{5/6}\underline{h}^{1/6}} < 1.92$$

for all elements $\tau \in \mathcal{M}_h$. Note that the ratio between the upper and lower bounds is 6. This fact indicates that all elements in the final mesh satisfy the mesh density assumption.

Next, let us examine the condition (α, σ, μ) on the final mesh. Here $\mu = \delta/3 = 1/6$. It is shown that, for every $e \in \mathcal{E}_h$, Ω_e is a $1.49 \times h_e^{1+0.2}/r_e^{0.2+\mu(1-0.2)}$ approximate parallelogram. That is, the final mesh satisfies Condition $(0.2, 0, 1/6)$.

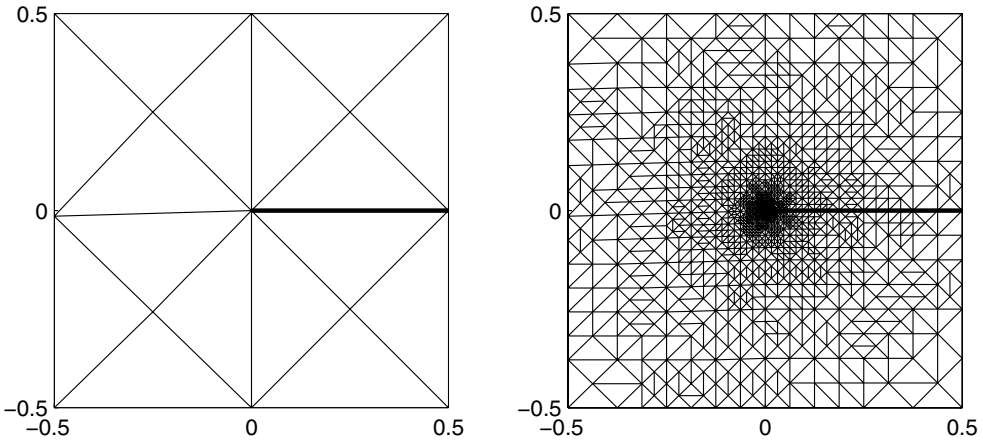

FIG. 6.3. *The initial mesh (left) and the adaptively refined mesh (right) of* 3353 *elements after* 16 *adaptive iterations for the crack problem.*

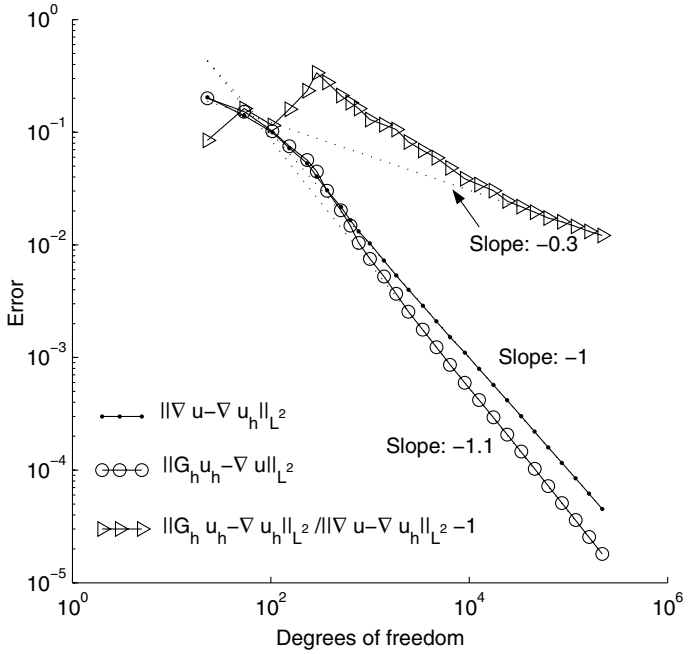

FIG. 6.4. $\|\nabla u - \nabla u_h\|_{L^2(\Omega)}$, $\|\nabla u - G_h u_h\|_{L^2(\Omega)}$, *and* $\|G_h u_h - \nabla u_h\|_{L^2(\Omega)} / \|\nabla u - \nabla u_h\|_{L^2(\Omega)} - 1$ *versus the total number of degrees of freedom for the crack problem. Dotted lines give reference slopes.*

Acknowledgments. The authors would like to thank a referee and the editor for many constructive and valuable suggestions, which considerably improved the presentation of the paper.

MESHLESS COLLOCATION: ERROR ESTIMATES WITH APPLICATION TO DYNAMICAL SYSTEMS*

PETER GIESL† AND HOLGER WENDLAND‡

Abstract. In this paper, we derive error estimates for generalized interpolation, in particular collocation, in Sobolev spaces. We employ our estimates in collocation problems using radial basis functions and extend and improve previously known results for elliptic problems. Finally, we use meshless collocation to approximate Lyapunov functions for dynamical systems.

Key words. partial differential equation, radial basis function, error estimates, Lyapunov function

AMS subject classifications. 65N15, 65N35, 37B25

DOI. 10.1137/060658813

1. Introduction. Meshless collocation methods for the numerical solution of partial differential equations have recently become more and more popular. They provide a greater flexibility when it comes to adaptivity and time-dependent changes of the underlying region.

Radial basis functions or, more generally, (conditionally) positive definite kernels are one of the mainstream methods in the field of meshless collocation. There are, in principle, two different approaches to collocation using radial basis functions. The *unsymmetric* approach by Kansa [14, 15] has the advantage that less derivatives have to be formed but has the drawback of an unsymmetric collocation matrix, which can even be singular [13]. Despite this drawback unsymmetric collocation has been used frequently and successfully in several applications.

In this paper, however, we will concentrate on *symmetric* collocation methods based on radial basis functions, as they have been introduced in the context of *generalized interpolation* in [28, 17] and used for elliptic problems in [4, 5, 7, 6].

Radial basis functions, in general, are a powerful tool for reconstruction processes from scattered data (see, for example, [3, 26]).

In this paper, we study a general linear partial differential equation of the form

$$Lu = f \text{ on } \Omega, \tag{1}$$

where Ω is a domain in $\mathbb{R}^n$ and L is a linear differential operator of the form

$$Lu(x) = \sum_{|\alpha| \le m} c_\alpha(x) D^\alpha u(x), \tag{2}$$

where the coefficients have a certain smoothness $c_\alpha \in C^\sigma(\overline{\Omega}, \mathbb{R})$; i.e., the derivatives of order β with $|\beta| \le \sigma$ exist and are continuous on $\overline{\Omega}$.

Moreover, we consider boundary value problems, where in addition to (1), u is required to satisfy the following boundary condition:

$$u(x) = F(x) \text{ for } x \in \partial\Omega. \tag{3}$$

The numerical solution of such boundary value problems by collocation using radial basis functions has been studied by several authors. First error estimates have been given in [7, 6]. However, despite following a rather general approach, the authors of those papers show that the problems are well-posed and provide error estimates only for differential operators with *constant coefficients* c_α. A generalization to nonconstant coefficients without zeros, including also a more thorough discussion of the boundary estimates, can be found in [26]. However, in that book the approximation orders are, to a certain extent, not optimal. Moreover, the restriction to nonzero coefficients is not sufficient for our applications in dynamical systems.

Our goals in this paper are to investigate well-posedness of the collocation problem for the differential operator (2) with *nonconstant* coefficients and to state error estimates with optimal orders in Sobolev spaces. To this end we will put the setting in the general framework of generalized interpolation in reproducing kernel Hilbert spaces and then use a recent result [18] on error estimates in Sobolev spaces for *arbitrary* scattered data reconstruction methods.

Next, we will apply the general estimates to derive error estimates in Sobolev spaces for elliptic partial differential equations. Another major and new application will be the approximation of Lyapunov functions in dynamical systems. Here, the differential operator is given by the *orbital derivative* of a function u with respect to the ordinary differential equation $\dot{x} = g(x)$, i.e., by

$$Lu(x) := \langle \nabla u(x), g(x) \rangle = \sum_{j=1}^{n} g_j(x) \partial_j u(x).$$

This operator L is a first-order differential operator of the form (2) with $c_{e^j}(x) = g_j(x)$. The approximation of the orbital derivative for Lyapunov functions has been studied in [11, 8, 9, 10]. However, the approximation orders of those results can be improved significantly with the results of this paper.

This paper is organized as follows. In the rest of this section we will introduce notation which is necessary throughout the paper. Section 2 deals with generalized interpolation and is mainly a collection of known results, which will be helpful in this paper. In section 3 we investigate collocation by radial basis functions, derive our new estimates, and apply these results to elliptic problems. The final section deals with applications to dynamical systems. In particular, we describe a method to calculate Lyapunov functions and thus to calculate the basin of attraction of an equilibrium.

1.1. Notation. We will need to work with a variety of Sobolev spaces. Let $\Omega \subseteq \mathbb{R}^n$ be a domain. For $k \in \mathbb{N}_0$, and $1 \le p < \infty$, the Sobolev spaces $W_p^k(\Omega)$ consist, as usual, of all u with weak derivatives $D^\alpha u \in L_p(\Omega)$, $|\alpha| \le k$. Associated with these spaces are the (semi-)norms

$$|u|_{W_p^k(\Omega)} = \left(\sum_{|\alpha|=k} \|D^\alpha u\|_{L_p(\Omega)}^p \right)^{1/p} \text{ and } \|u\|_{W_p^k(\Omega)} = \left(\sum_{|\alpha|\le k} \|D^\alpha u\|_{L_p(\Omega)}^p \right)^{1/p}.$$

The case $p = \infty$ is defined in the obvious way:

$$|u|_{W_\infty^k(\Omega)} = \sup_{|\alpha|=k} \|D^\alpha u\|_{L_\infty(\Omega)} \quad \text{and} \quad \|u\|_{W_\infty^k(\Omega)} = \sup_{|\alpha|\le k} \|D^\alpha u\|_{L_\infty(\Omega)}.$$

We also need fractional order Sobolev spaces. However, it will not be necessary to discuss them in detail. We just remind the reader that there are different ways of introducing fractional order Sobolev spaces. For our purposes, interpolation theory in Sobolev spaces as it has, for example, been discussed in [1, 23, 2] will be sufficient.

Let $X := \{x_1, \dots, x_N\}$ be a finite, discrete subset of Ω, which we now assume to be bounded. There are two quantities that we associate with X: the *separation radius* and the *mesh norm* or *fill distance*. Respectively, these are given by

$$q_X := \frac{1}{2} \min_{j \neq k} \|x_j - x_k\|_2, \quad h_{X,\Omega} := \sup_{x \in \Omega} \min_{x_j \in X} \|x - x_j\|_2,$$

where $\|\cdot\|_2$ denotes the Euclidean distance in $\mathbb{R}^n$.

The first is half the smallest distance between points in X, and the second measures the maximum distance which a point in Ω can be from any point in X. Frequently, when it is clear from the context what the set Ω (or X) is, we will drop subscripts and write h_X or h. Other notation will be introduced along the way.

2. Generalized interpolation.

2.1. Reproducing kernel Hilbert spaces. Let $H \subseteq C(\Omega)$ be a Hilbert space of functions $f : \Omega \to \mathbb{R}$ and let H^* be its dual. We consider a generalized interpolation problem of the following form.

DEFINITION 2.1. *Given N linearly independent functionals $\lambda_1, \dots, \lambda_N \in H^*$ and N function values $f_1, \dots, f_N \in \mathbb{R}$, a generalized interpolant is a function $s \in H$ satisfying $\lambda_j(s) = f_j$, $1 \leq j \leq N$. The norm-minimal interpolant s^* is the interpolant that, in addition, minimizes the norm of the Hilbert space; i.e., s^* is the solution of*

$$\min\{\|s\|_H : \lambda_j(s) = f_j, 1 \leq j \leq N\}. \tag{4}$$

It is well known that the norm-minimal generalized interpolant is a linear combination of the Riesz representers of the functionals and that the coefficients can be computed by solving a linear system. Such problems can be best solved if H is a reproducing kernel Hilbert space (RKHS), i.e., if there exists a unique kernel $\Phi : \Omega \times \Omega \to \mathbb{R}$, satisfying

1. $\Phi(\cdot, x) \in H$ for all $x \in \Omega$,
2. $f(x) = (f, \Phi(\cdot, x))_H$ for all $x \in \Omega$ and all $f \in H$.

Here, the Riesz representer of a functional $\lambda \in H^*$ is simply given by applying it to one argument of the kernel, i.e., by $\lambda^y \Phi(\cdot, y)$.

LEMMA 2.2 (see [26, Theorem 16.1]). *If H is a reproducing kernel Hilbert space, then the solution s^* of (4) is given by*

$$s^* = \sum_{j=1}^{N} \alpha_j \lambda_j^y \Phi(\cdot, y),$$

where $\alpha \in \mathbb{R}^N$ is the solution of the linear system $A_{\Lambda,\Phi}\alpha = f$ with $A_{\Lambda,\Phi} = (\lambda_i^x \lambda_j^y \Phi(x, y))$ and $f = (f_j)$.

Note that the matrix $A_{\Lambda,\Phi} = (a_{ij})$ is a Gramian matrix because of

$$a_{ij} = \lambda_i^x \lambda_j^y \Phi(x, y) = (\lambda_i^x \Phi(\cdot, x), \lambda_j^y \Phi(\cdot, y))_H = (\lambda_i, \lambda_j)_{H^*}$$

and hence is positive semidefinite. Since the functionals are assumed to be linearly independent the matrix is even positive definite.

Looking at point evaluations $\lambda_j(f) = \delta_{x_j}(f) = f(x_j)$ alone, we see that the kernel of a reproducing kernel Hilbert space is *positive definite* in the sense that all the matrices

$$(\Phi(x_i, x_j))_{1\le i,j\le N}$$

are positive definite, provided that point evaluation functionals are linearly independent.

Now, it is easy to see that the kernel of a reproducing kernel Hilbert space is uniquely determined. On the other hand, the Hilbert space is also uniquely determined by the kernel. Moreover, every positive definite kernel generates a unique Hilbert space to which it is the reproducing kernel. More details about this fact and the construction of such *native* function spaces can be found in [26]. Here, the only thing that matters is that two *different* kernels can generate the *same* function Hilbert space H but with different, yet equivalent, inner products. In such a situation we will say that both kernels are reproducing kernels of H, thus relaxing the definition of a reproducing kernel Hilbert space. Moreover, it will be helpful to consider kernels defined on all $\mathbb{R}^n$ instead of on only $\Omega \subseteq \mathbb{R}^n$. Such kernels are often *translation-invariant*, meaning $\Phi(x, y) = \Phi(x - y)$, and are often even *radial*, meaning $\Phi(x, y) = \Phi(\|x - y\|_2)$.

This will be very useful when it comes to Sobolev spaces. Remember that the Sobolev embedding theorem states that $W_2^\tau(\mathbb{R}^n)$ can be embedded into $C(\mathbb{R}^n)$ provided that $\tau > n/2$. Hence, in this situation $W_2^\tau(\mathbb{R}^n)$ is a reproducing kernel Hilbert space. Unfortunately, the reproducing kernel involves some modified Bessel functions of the third kind.

However, it is well known that other reproducing kernels of $W_2^\tau(\mathbb{R}^n)$ can be characterized by their Fourier transform

$$\widehat{\Phi}(\omega) = (2\pi)^{-n} \int_{\mathbb{R}^n} \Phi(x) e^{-ix^T\omega} dx.$$

To be more precise, the following result holds.

LEMMA 2.3 (see [26, Corollary 10.13]). *Let $\tau > n/2$. Suppose the Fourier transform of an integrable function $\Phi : \mathbb{R}^n \to \mathbb{R}$ satisfies*

$$c_1(1 + \|\omega\|_2^2)^{-\tau} \le \widehat{\Phi}(\omega) \le c_2(1 + \|\omega\|_2^2)^{-\tau}, \qquad \omega \in \mathbb{R}^n, \tag{5}$$

with two constants $c_2 \ge c_1 > 0$. Then, the kernel Φ is also a reproducing kernel of $W_2^\tau(\mathbb{R}^n)$, and the inner product defined by

$$(f, g) := \int_{\mathbb{R}^n} \frac{\widehat{f}(\omega)\overline{\widehat{g}(\omega)}}{\widehat{\Phi}(\omega)} d\omega$$

is equivalent to the usual inner product on $W_2^\tau(\mathbb{R}^n)$.

The following observation will be of use. It follows directly from the Fourier inversion theorem.

Remark 2.4. If $\Phi \in L_1(\mathbb{R}^n)$ satisfies (5) with $\tau > m + n/2$, then $\Phi \in C^{2m}(\mathbb{R}^n)$.

The most prominent examples of kernels satisfying (5) are the Wendland functions [24, 25]. They are positive definite and radial functions with compact support. On its support, each function can be represented by a univariate polynomial. Here it is mainly important that they satisfy (5) with $\tau = k + (n + 1)/2$, where k is a given smoothness index. Hence, they belong to $C^{2k}(\mathbb{R}^n)$ and generate integer order Sobolev

spaces in odd space dimensions, while for even space dimensions the order is integer plus one half.

Although most kernels which generate Sobolev spaces are radial, there exist also kernels which are not even translation invariant; cf. [21, 20]. Our results will hold regardless of whether the kernels are translation invariant or not.

We end this section by citing a general convergence result from [18] in its improved form (see the remarks in [19]) using also the fact that a region with a Lipschitz boundary automatically satisfies a cone condition (see [27]).

THEOREM 2.5. *Let $\Omega \subseteq \mathbb{R}^n$ be a bounded domain with a Lipschitz continuous boundary. Let $1 \leq p < \infty$, $1 \leq q \leq \infty$, and let $m \in \mathbb{N}_0$ and $\tau \in \mathbb{R}$ satisfying $\lfloor \tau \rfloor > m + n/p$ if $p > 1$, or $\lfloor \tau \rfloor \geq m + n$ if $p = 1$. Also, let $X \subseteq \Omega$ be a discrete set with a sufficiently small mesh norm h. If $u \in W_p^\tau(\Omega)$ satisfies $u|X = 0$, then*

$$|u|_{W_q^m(\Omega)} \leq C h^{\tau - m - n(1/p - 1/q)_+} |u|_{W_p^\tau(\Omega)}, \tag{6}$$

where $(x)_+ = \max\{x, 0\}$.

3. Partial differential equations (PDEs).

3.1. General PDE operators. It is now time to look at specific collocation problems. We start with the PDE (1). Following the general approach of the previous section, we define functionals

$$\lambda_j(u) := \delta_{x_j} \circ L(u) = (Lu)(x_j)$$

with scattered points $X = \{x_1, \ldots, x_N\} \subseteq \Omega$. Hence, employing a sufficiently smooth kernel $\Phi : \Omega \times \Omega \to \mathbb{R}$ results in the approximating function

$$s = \sum_{k=1}^{N} \alpha_k (\delta_{x_k} \circ L)^y \Phi(\cdot, y). \tag{7}$$

Applying the interpolation conditions yields the following interpolation problem.

DEFINITION 3.1 (interpolation problem, operator). *Let $X = \{x_1, \ldots, x_N\}$ be a set of pairwise distinct points in $\Omega \subseteq \mathbb{R}^n$ and $u : \Omega \to \mathbb{R}$. Let L be a linear differential operator. Then, the* reconstruction s of u with respect to the set X and the operator L *is given by* (7)*, where the coefficient vector α is the solution of $A\alpha = f = (f_j)$ with the interpolation matrix $A = (a_{jk})_{j,k=1,\ldots,N}$ given by*

$$a_{jk} = (\delta_{x_j} \circ L)^x (\delta_{x_k} \circ L)^y \Phi(x, y) \tag{8}$$

and $f_j = (\delta_{x_j} \circ L)^x u(x) = Lu(x_j)$.

According to Lemma 2.2, the generalized interpolation matrix is positive definite, provided that the involved functionals are linearly independent.

DEFINITION 3.2 (singular points of L). *The point $x \in \mathbb{R}^n$ is called a* singular point of L *if $\delta_x \circ L = 0$, i.e., $c_\alpha(x) = 0$ for all $|\alpha| \leq m$.*

PROPOSITION 3.3. *Suppose $\Phi : \mathbb{R}^n \to \mathbb{R}$ is a reproducing kernel of $W_2^\tau(\mathbb{R}^n)$ with $\tau > m + n/2$. Let L be a linear differential operator of degree m. Let $X = \{x_1, \ldots, x_N\}$ be a set of pairwise distinct points, which are not singular points of L. Then, the functionals $\lambda_j = \delta_{x_j} \circ L$ are linearly independent over $W_2^\tau(\mathbb{R}^n)$.*

Proof. First of all note that, according to Remark 2.4, (8) is well defined for reproducing kernels of $W_2^\tau(\mathbb{R}^n)$ even with $\tau > m + n/2$. Moreover, the functionals are indeed in the dual space to $W_2^\tau(\mathbb{R}^n)$.

Next, suppose that

$$\sum_{k=1}^{N} d_k \lambda_k = 0 \tag{9}$$

on $W_2^\tau(\mathbb{R}^n)$ with certain coefficients $d_1, \dots, d_N$.

Then we choose a flat bump function $g \in C_0^\infty(\mathbb{R}^n)$, i.e., a nonnegative, compactly supported function with support $B(0,1) = \{x \in \mathbb{R}^n : \|x\|_2 \le 1\}$ which is nonvanishing and satisfies $g(x) = 1$ on $B(0,1/2)$. Fix $1 \le j \le N$. Since x_j is not a singular point of L, there exists a $\beta \in \mathbb{N}_0^n$ with minimal $|\beta| \le m$ such that $c_\beta(x_j) \neq 0$. Employing the separation radius q_X, the function

$$g_j(x) = \frac{1}{\beta!}(x - x_j)^\beta g\left(\frac{x - x_j}{q_X}\right)$$

then satisfies $D^\alpha g_j(x_k) = 0$ for all $|\alpha| \le m$ and $x_k \neq x_j$. Furthermore, we have $D^\alpha g_j(x_j) = 0$ if $\alpha \neq \beta$ and $D^\beta g_j(x_j) = 1$. Hence, (9) gives, in particular,

$$0 = \sum_{k=1}^{N} d_k \lambda_k(g_j) = \sum_{|\alpha| \le m} \sum_{k=1}^{N} d_k c_\alpha(x_k) D^\alpha g_j(x_k) = d_j c_\beta(x_j),$$

which implies $d_j = 0$. Since j was chosen arbitrarily, this shows that the functionals are linearly independent. ∎

This proposition is a generalization of the results in [6], where only constant coefficients have been allowed, and of the results in [26], where also variable coefficients without zeros were treated.

Note also that the reproducing kernel Hilbert space does not have to be a Sobolev space at all. It is necessary only that the Hilbert space contains bump functions of the described form. Hence, the results remain true, if, for example, function spaces associated with Gaussians or (inverse) multiquadrics are considered.

Next we turn to error estimates. We need a simple auxiliary result.

LEMMA 3.4. *Fix $\tau \in \mathbb{R}$ with $k = \lfloor \tau \rfloor > n/2 + m$, where m is the order of the differential operator L. Suppose that the coefficients c_α of the differential operator L belong to $W_\infty^{k-m+1}(\Omega)$. Then L is a bounded operator from $W_2^\tau(\Omega)$ to $W_2^{\tau-m}(\Omega)$, i.e.,*

$$\|Lu\|_{W_2^{\tau-m}(\Omega)} \le C \|u\|_{W_2^\tau(\Omega)}, \qquad u \in W_2^\tau(\Omega).$$

Proof. Take a multi-index $\alpha \in \mathbb{N}_0^n$ with $|\alpha| \le k + 1 - m$. Then

$$\begin{aligned} |D^\alpha(Lu)| &= \left| \sum_{|\beta| \le m} \sum_{\gamma \le \alpha} \binom{\alpha}{\gamma} (D^{\alpha-\gamma} c_\beta)(D^{\gamma+\beta} u) \right| \\ &\le C \sum_{|\beta| \le m} \sum_{\gamma \le \alpha} |D^{\gamma+\beta} u|, \end{aligned}$$

where we used the boundedness of the derivatives of the coefficients. This shows that

$$\|D^\alpha(Lu)\|_{L_2(\Omega)} \le C \|u\|_{W_2^{m+|\alpha|}(\Omega)},$$

and hence

$$\|Lu\|_{W_2^{k-m}(\Omega)} \le C \|u\|_{W_2^k(\Omega)}, \qquad \|Lu\|_{W_2^{k+1-m}(\Omega)} \le C \|u\|_{W_2^{k+1}(\Omega)}.$$

From this, the result for fractional order Sobolev spaces $W_2^\tau(\Omega)$ follows by interpolation theory. ∎

THEOREM 3.5. *Suppose Φ is a reproducing kernel of $W_2^\tau(\mathbb{R}^n)$ with $k := \lfloor \tau \rfloor > m + n/2$. Let $\Omega \subseteq \mathbb{R}^n$ be a bounded domain having a Lipschitz boundary. Let L be a linear differential operator of order m with coefficients c_α in $W_\infty^{k-m+1}(\Omega)$. Finally, let s be the generalized interpolant to $u \in W_2^\tau(\Omega)$ from Definition 3.1. If $X \subseteq \Omega$ has a sufficiently small mesh norm h_X, then for $1 \le p \le \infty$, the error estimate*

$$\|Lu - Ls\|_{L_p(\Omega)} \le C h_X^{\tau - m - n(1/2 - 1/p)_+} \|u\|_{W_2^\tau(\Omega)}$$

is satisfied.

Proof. Note that $u \in W_2^\tau(\Omega) \subseteq C^m(\mathbb{R}^n)$ by assumption, while $s \in C^m(\mathbb{R}^n)$ by Remark 2.4. Hence, application of L is feasible.

Since $Lu|X = Ls|X$ by definition, we can apply Theorem 2.5 to derive

$$\begin{aligned}\|Lu - Ls\|_{L_p(\Omega)} &\le C h_X^{\tau - m - n(1/2 - 1/p)_+} \|Lu - Ls\|_{W_2^{\tau - m}(\Omega)} \\ &\le C h_X^{\tau - m - n(1/2 - 1/p)_+} \|u - s\|_{W_2^\tau(\Omega)},\end{aligned}$$

where we have also used Lemma 3.4.

Next, we follow the ideas in [18]. Our assumptions on the region Ω allow us to extend the function $u \in W_2^\tau(\Omega)$ to a function $Eu \in W_2^\tau(\mathbb{R}^n)$. Moreover, since $X \subseteq \Omega$ and $Eu|\Omega = u|\Omega$, the generalized interpolant $s = s_u$ to u coincides with the generalized interpolant s_{Eu} to Eu on Ω. Finally, the Sobolev space norm on $W_2^\tau(\mathbb{R}^n)$ is equivalent to the norm induced by the kernel Φ on $W_2^\tau(\mathbb{R}^n)$ (Lemma 2.3) and the generalized interpolant is norm-minimal (Lemma 2.2). This all gives

$$\begin{aligned}\|u - s\|_{W_2^\tau(\Omega)} = \|Eu - s_{Eu}\|_{W_2^\tau(\Omega)} &\le \|Eu - s_{Eu}\|_{W_2^\tau(\mathbb{R}^n)} \\ &\le C \|Eu\|_{W_2^\tau(\mathbb{R}^n)} \le C \|u\|_{W_2^\tau(\Omega)},\end{aligned}$$

which establishes the stated error estimate. ∎

The most important choices of $p = 2$ and $p = \infty$ yield

$$\|Lu - Ls\|_{L_2(\Omega)} \le C h_X^{\tau - m} \|u\|_{W_2^\tau(\Omega)},$$

$$\|Lu - Ls\|_{L_\infty(\Omega)} \le C h_X^{\tau - m - n/2} \|u\|_{W_2^\tau(\Omega)}.$$

As a consequence, using Wendland's compactly supported functions, we have to set $\tau = k + (n+1)/2$, where k is the smoothness index of the compactly supported functions, i.e., $\Phi = \psi_{\ell,k}(c\|\cdot\|_2) \in C^{2k}(\mathbb{R}^n)$. Note that this k is different from the k in Theorem 3.5. As a matter of fact the k in that theorem is given by $\lfloor \tau \rfloor = k + \lfloor (n+1)/2 \rfloor$.

COROLLARY 3.6. *Denote by k the smoothness index of the compactly supported Wendland function. Let $k > m - \frac{1}{2}$ if n is odd or $k > m$ if n is even. Let $c_\alpha \in W_\infty^{k-m+1+\lfloor \frac{n+1}{2} \rfloor}$. Suppose $u \in W_2^{k+(n+1)/2}(\Omega)$. Then, employing this basis function yields*

$$\|Lu - Ls\|_{L_\infty(\Omega)} \le C h_X^{k-m+1/2} \|u\|_{W_2^{k+(n+1)/2}(\Omega)}.$$

3.2. Boundary value problems. The collocation problem of the previous section will already be useful in its form in our application to dynamical systems; however, boundary value problems also will occur; cf. section 4. Furthermore, for applications such as solving elliptic PDEs, incorporating boundary values is crucial.

In order to solve a boundary value problem of the form (1) and (3), we need two linear operators L and $L^0 = \mathrm{id}$, the values of which are given on Ω, $\partial\Omega$, respectively. The ansatz for the approximating function s reflects this. We choose two sets of points, $X_1 := \{x_1, \dots, x_N\} \subseteq \Omega$ and $X_2 := \{x_{N+1}, \dots, x_{N+M}\} \subseteq \partial\Omega$, and define the functionals by

$$\lambda_j = \begin{cases} \delta_{x_j} \circ L & \text{for } 1 \le j \le N, \\ \delta_{x_j} \circ L^0 & \text{for } N+1 \le j \le N+M. \end{cases} \tag{10}$$

The mixed ansatz for the approximant s of the function u is then given by

$$\begin{aligned} s(x) &= \sum_{k=1}^{N+M} \alpha_k \lambda_k^y \Phi(x,y) \\ &= \sum_{k=1}^{N} \alpha_k (\delta_{x_k} \circ L)^y \Phi(x,y) + \sum_{k=N+1}^{N+M} \alpha_k (\delta_{x_k} \circ L^0)^y \Phi(x,y), \end{aligned} \tag{11}$$

where we will assume that $L^0 = \mathrm{id}$. The coefficient vector $\alpha \in \mathbb{R}^{N+M}$ is determined by the interpolation conditions

$$(\delta_{x_j} \circ L)(s) = (\delta_{x_j} \circ L)(u) = f(x_j), \quad 1 \le j \le N, \tag{12}$$

$$(\delta_{x_j} \circ L^0)(s) = (\delta_{x_j} \circ L^0)(u) = F(x_j), \quad N+1 \le j \le N+M. \tag{13}$$

Plugging the ansatz (11) into both (12) and (13) gives the following.

DEFINITION 3.7 (mixed interpolation problem). *Let $u\colon \Omega \to \mathbb{R}$ be the solution of* (1) *and* (3). *Let $X_1 = \{x_1, \dots, x_N\} \subseteq \Omega$ and $X_2 := \{x_{N+1}, \dots, x_{N+M}\} \subseteq \partial\Omega$ be two sets of pairwise distinct points. Then the* collocation reconstruction *s of u based upon X_1 and X_2 and the kernel Φ is given by* (11), *where the coefficient vector is determined by solving the linear system $\widetilde{A}\alpha = \beta$, with the interpolation matrix*

$$\widetilde{A} := \begin{pmatrix} A & C \\ C^T & A^0 \end{pmatrix} \in \mathbb{R}^{(N+M)\times(N+M)} \tag{14}$$

having submatrices $A = (a_{ij}) \in \mathbb{R}^{N\times N}$, $C = (c_{ij}) \in \mathbb{R}^{N\times M}$, and $A^0 = (a^0_{ij}) \in \mathbb{R}^{M\times M}$ with elements

$$\begin{aligned} a_{i,j} &= (\delta_{x_i} \circ L)^x (\delta_{x_j} \circ L)^y \Phi(x,y), \\ c_{i,\ell-N} &= (\delta_{x_i} \circ L)^x (\delta_{x_\ell} \circ L^0)^y \Phi(x,y), \\ a^0_{k-N,\ell-N} &= (\delta_{x_k} \circ L^0)^x (\delta_{x_\ell} \circ L^0)^y \Phi(x,y) \end{aligned}$$

for $1 \le i, j \le N$, $N+1 \le k, \ell \le N+M$.

The right-hand side of the linear system is determined by $\beta_j = f(x_j)$ for $1 \le j \le N$ and $\beta_j = F(x_j)$ for $N+1 \le j \le N+M$, respectively.

As in the case of one operator, it is easy to show that the functionals λ_j, this time defined by (10), are linearly independent.

PROPOSITION 3.8. *Suppose $\Phi : \mathbb{R}^n \to \mathbb{R}$ is a reproducing kernel of $W_2^\tau(\mathbb{R}^n)$ with $\tau > m + n/2$. Let L be a linear differential operator of degree m. Let $X_1 = \{x_1, \dots, x_N\} \subseteq \Omega$ and $X_2 = \{x_{N+1}, \dots, x_{N+M}\} \subseteq \partial\Omega$ be two sets of pairwise distinct points such that X_1 contains no singular point of L. Then, the functionals $\Lambda = \{\lambda_1, \dots, \lambda_{N+M}\}$ with $\lambda_j = \delta_{x_j} \circ L$ for $1 \le j \le N$ and $\lambda_j = \delta_{x_j}$ for $N+1 \le j \le N+M$ are linearly independent over $W_2^\tau(\mathbb{R}^n)$.*

Next we turn to error estimates. To this end we have to make certain further assumptions on the boundary.

We will assume that the bounded region $\Omega \subseteq \mathbb{R}^n$ has a $C^{k,s}$-boundary $\partial\Omega$, where $\tau = k + s$ with $k \in \mathbb{N}_0$ and $s \in [0, 1)$. This means, in particular, that $\partial\Omega$ is an $n-1$ dimensional $C^{k,s}$-submanifold of $\mathbb{R}^n$. It also means that Ω is Lipschitz continuous and satisfies the cone condition. For details, we refer the reader to [27].

We will represent the boundary $\partial\Omega$ by a finite atlas consisting of $C^{k,s}$-diffeomorphisms with a slight abuse of terminology. To be more precise, we assume that $\partial\Omega \subseteq \cup_{j=1}^K V_j$, where $V_j \subseteq \mathbb{R}^n$ are open sets. Moreover, the sets V_j are images of $C^{k,s}$-diffeomorphisms

$$\varphi_j : B \to V_j,$$

where $B = B(0, 1)$ denotes the unit ball in $\mathbb{R}^{n-1}$. Finally, suppose $\{w_j\}$ is a partition of unity with respect to $\{V_j\}$. Then the Sobolev norms on $\partial\Omega$ can be defined via

$$\|u\|^p_{W_p^\mu(\partial\Omega)} = \sum_{j=1}^K \|(uw_j) \circ \varphi_j\|^p_{W_p^\mu(B)}.$$

It is well known that this norm is independent of the chosen atlas $\{V_j, \varphi_j\}$, but this is of less importance here since we will assume that the atlas is fixed. For us, the next well known result will play a crucial role.

LEMMA 3.9 (trace theorem [27, Theorem 8.7]). *Suppose $\Omega \subseteq \mathbb{R}^n$ is a bounded region with a $C^{k,s}$-boundary $\partial\Omega$. Then, the restriction of $u \in W_2^\tau(\Omega)$ with $\tau = k + s$ to $\partial\Omega$ is well defined, belongs to $W_2^{\tau-1/2}(\partial\Omega)$, and satisfies*

$$\|u\|_{W_2^{\tau-1/2}(\partial\Omega)} \le C\|u\|_{W_2^\tau(\Omega)}.$$

Moreover, we now have two different mesh norms, $h_{X_1,\Omega}$ for the domain part and $h_{X_2,\partial\Omega}$ for the boundary part. Using the atlas $\{V_j, \varphi_j\}$, we simply define the latter to be

$$h_{X_2,\partial\Omega} := \max_{1 \le j \le K} h_{T_j,B}$$

with $T_j = \varphi_j^{-1}(X_2 \cap V_j) \subseteq B$. As mentioned before, we will assume the atlas is fixed and hence will not be concerned about the dependence of $h_{X_2,\partial\Omega}$ on the atlas.

THEOREM 3.10. *Suppose Φ is the reproducing kernel of $W_2^\tau(\mathbb{R}^n)$ with $k := \lfloor\tau\rfloor > m + n/2$. Let $\Omega \subseteq \mathbb{R}^n$ be a bounded domain having a $C^{k,s}$-boundary. Let L be a linear differential operator of order m with coefficients c_α in $W_\infty^{k-m+1}(\Omega)$. Finally, let s be the generalized interpolant to $u \in W_2^\tau(\Omega)$ from Definition 3.7. If the data sets have sufficiently small mesh norms, then for $1 \le p \le \infty$, the error estimates*

$$\|Lu - Ls\|_{L_p(\Omega)} \le Ch^{\tau-m-n(1/2-1/p)_+}_{X_1,\Omega}\|u\|_{W_2^\tau(\Omega)}, \tag{15}$$

$$\|u - s\|_{L_p(\partial\Omega)} \le Ch^{\tau-1/2-(n-1)(1/2-1/p)_+}_{X_2,\partial\Omega}\|u\|_{W_2^\tau(\Omega)} \tag{16}$$

are satisfied.

Proof. Estimate (15) follows as in Theorem 3.5. For the second estimate, note that the functions $u_j = ((u-s)w_j) \circ \varphi_j$ belong to $W_2^{\tau-1/2}(B)$ and vanish on T_j. Hence, using the definition of the Sobolev norm on $\partial\Omega$ and Theorem 2.5 yields

$$\begin{aligned}\|u-s\|_{L_p(\partial\Omega)}^p &= \sum_{j=1}^K \|u_j\|_{L_p(B)}^p \\ &\le C \sum_{j=1}^K h_{T_j,B}^{p(\tau-1/2-(n-1)(1/2-1/p)_+)} \|u_j\|_{W_2^{\tau-1/2}(B)}^p \\ &\le C h_{X_2,\partial\Omega}^{p(\tau-1/2-(n-1)(1/2-1/p)_+)} \|u-s\|_{W_2^{\tau-1/2}(\partial\Omega)}^p \\ &\le C h_{X_2,\partial\Omega}^{p(\tau-1/2-(n-1)(1/2-1/p)_+)} \|u-s\|_{W_2^{\tau}(\Omega)}^p\end{aligned}$$

for $1 \le p < \infty$, and the case $p = \infty$ is treated in the same fashion. Finally, since s is a norm-minimal interpolant, the norm in the last expression can again be bounded by the norm of u. ∎

The two most important estimates for the boundary part are hence

$$\|u-s\|_{L_\infty(\partial\Omega)} \le C h_{X_2,\partial\Omega}^{\tau-n/2} \|u\|_{W_2^\tau(\Omega)},$$

$$\|u-s\|_{L_2(\partial\Omega)} \le C h_{X_2,\partial\Omega}^{\tau-1/2} \|u\|_{W_2^\tau(\Omega)}.$$

The proof of Theorem 3.10 shows that the following alternative version of Theorem 3.10 is also true.

COROLLARY 3.11. *Suppose $\Gamma \subseteq \partial\Omega$ is a part of the boundary satisfying*

$$\Gamma = \bigcup_{j=1}^J (V_j \cap \partial\Omega). \tag{17}$$

This means, that the first J charts $\{V_j, \varphi_j\}_{j=1}^J$ are exclusive for Γ, or that, for $1 \le j \le J$, $V_j \cap (\partial\Omega \setminus \Gamma) = 0$. Suppose further that the boundary collocation points X_2 are chosen only on Γ, while the interior points are still chosen in Ω; then estimate (15) *remains valid and* (16) *becomes*

$$\|u-s\|_{L_p(\Gamma)} \le C h_{X_2,\Gamma}^{\tau-1/2-(n-1)(1/2-1/p)_+} \|u\|_{W_2^\tau(\Omega)}, \tag{18}$$

where $h_{X_2,\Gamma} = \max_{1\le j\le L} h_{T_j,B}$ with T_j defined as before.

As a matter of fact, neither condition (17) nor the fact that $X_2 \subseteq \Gamma$ are necessary to derive (18). But if (17) is not satisfied, the fill distance $h_{X_2,\Gamma}$ might be larger than necessary if X_2 is chosen only from Γ. On the other hand, if X_2 is dense on all of $\partial\Omega$, then, of course, (16) implies (18).

Considering again the compactly supported functions $\Phi = \psi_{\ell,k}(\|\cdot\|_2)$, i.e., choosing $\tau = k + (n+1)/2$, gives this time the following corollary.

COROLLARY 3.12. *Let $k > m - 1/2$ if n is odd or $k > m$ if n is even. Let $c_\alpha \in W_\infty^{k-m+1+\lfloor \frac{n+1}{2} \rfloor}$. Suppose $u \in W_2^{k+(n+1)/2}(\Omega)$. Then, employing Wendland's*

compactly supported basis functions yields

$$\|Lu - Ls\|_{L_\infty(\Omega)} \le C h_{X_1,\Omega}^{k-m+1/2} \|u\|_{W_2^{k+(n+1)/2}(\Omega)}, \tag{19}$$

$$\|u - s\|_{L_\infty(\partial\Omega)} \le C h_{X_2,\partial\Omega}^{k+1/2} \|u\|_{W_2^{k+(n+1)/2}(\Omega)}. \tag{20}$$

A similar statement holds also for $\Gamma \subset \partial\Omega$; cf. Corollary 3.11.

3.3. Elliptic PDEs. We now consider the following elliptic operator of second order in a bounded domain $\Omega \subset \mathbb{R}^n$ with a sufficiently smooth boundary

$$Lu(x) := \sum_{i,j=1}^{n} a_{ij}(x)\partial_{i,j}u(x) + \sum_{i=1}^{n} b_i(x)\partial_i u(x) + c(x)u(x), \tag{21}$$

where a, b, and c are bounded, $a_{ij}(x) = a_{ji}(x)$ (symmetry), and $c(x) \le 0$ holds for all $x \in \Omega$. Moreover, let L be strictly elliptic; i.e., there is a constant $\lambda > 0$ such that

$$\lambda \|\xi\|_2^2 \le \sum_{i,j=1}^{n} a_{ij}(x)\xi_i\xi_j$$

for all $x \in \Omega$ and $\xi \in \mathbb{R}^n$. Then, if $u \in C^0(\overline{\Omega}) \cap C^2(\Omega)$ is the solution of (1) and (3), it enjoys the following estimate (see [12, Theorem 3.7]):

$$\|u\|_{L_\infty(\Omega)} \le \|F\|_{L_\infty(\partial\Omega)} + \frac{C}{\lambda}\|f\|_{L_\infty(\Omega)}, \tag{22}$$

where the constant C depends on the diameter of Ω and on $\|b\|_{L_\infty(\Omega)}/\lambda$. This, together with Theorem 3.10, immediately yields the next result.

COROLLARY 3.13. *Assume that the solution u belongs to $W_2^\tau(\Omega)$ with $\lfloor\tau\rfloor > 2+n/2$. Then, the error between u and its collocation approximation s can be bounded by*

$$\begin{aligned}\|u - s\|_{L_\infty(\Omega)} &\le C\left(h_{X_1,\Omega}^{\tau-2-n/2} + h_{X_2,\partial\Omega}^{\tau-n/2}\right)\|u\|_{W_2^\tau(\Omega)} \\ &\le C h_X^{\tau-2-n/2}\|u\|_{W_2^\tau(\Omega)},\end{aligned}$$

where $h_X = \max\{h_{X_1,\Omega}, h_{X_2,\partial\Omega}\}$.

Note that this result unfortunately means that we have to choose a higher data density in the interior than on the boundary.

The result for the compactly supported functions is

$$\|u - s\|_{L_\infty(\Omega)} \le C\left(h_{X_1,\Omega}^{k-3/2} + h_{X_2,\partial\Omega}^{k+1/2}\right)\|u\|_{W_2^{k+(n+1)/2}(\Omega)}.$$

In the case of constant coefficients, i.e., $a_{ij}(x) = a_{ij}$, $b_i(x) = b_i$ and $c(x) = c$ for all $x \in \Omega$, this result was obtained in [6] using a transformation theorem. Our result, however, also holds for nonconstant coefficients and is mainly a simple application of Theorem 3.10.

4. Dynamical systems.

4.1. A short introduction. Consider the ordinary differential equation

$$\dot{x} = \frac{dx}{dt} = g(x), \tag{23}$$

where $g \in C^\sigma(\mathbb{R}^n, \mathbb{R}^n)$, $\sigma \geq 1$, and $x(t) \in \mathbb{R}^n$. We search for solutions $x(t)$, $t \geq 0$, of the initial value problem (23), $x(0) = \xi$. We denote these solutions also by $S_t\xi := x(t)$. Since g is at least C^1, we have existence and uniqueness of solutions of this initial value problem locally in time.

Since one cannot calculate the solutions of (23) in general, from the viewpoint of dynamical systems theory we are interested in the qualitative long-time behavior of solutions. Therefore, one studies simple solutions such as equilibria, i.e., solutions which are constant in time.

DEFINITION 4.1. *$x_0 \in \mathbb{R}^n$ is called an equilibrium for* (23) *if $g(x_0) = 0$. Then $S_t x_0 = x_0$ for all $t \geq 0$; i.e., the constant function $x(t) = x_0$ is a solution of* (23).

The concept of stability describes the behavior of solutions near the equilibrium x_0. Stability can be analyzed using the linearization of g at x_0.

PROPOSITION 4.2. *Let $x_0 \in \mathbb{R}^n$ be an equilibrium for* (23). *If all eigenvalues of the Jacobian $Dg(x_0)$ have a negative real part, then x_0 is asymptotically stable.*

For the rest of this section we assume that x_0 is an equilibrium such that all eigenvalues of $Dg(x_0)$ have a negative real part. For such an asymptotically stable equilibrium x_0 we can define the basin of attraction $A(x_0)$. Note that $A(x_0) \neq \varnothing$ and $A(x_0)$ is open.

DEFINITION 4.3. *Let $x_0 \in \mathbb{R}^n$ be an asymptotically stable equilibrium for* (23). *Then we define the basin of attraction as $A(x_0) := \{\xi \in \mathbb{R}^n \mid \lim_{t\to\infty} S_t\xi = x_0\}$.*

A method to determine subsets of the basin of attraction is the method of Lyapunov functions; cf. [16]. The main characteristic of a Lyapunov function $V \in C^1(\mathbb{R}^n, \mathbb{R})$ is that its orbital derivative $V'(x)$ is negative.

DEFINITION 4.4. *Given a function $V \in C^1(\mathbb{R}^n, \mathbb{R})$ its orbital derivative with respect to* (23) *is defined as $V'(x) := \langle \nabla V(x), g(x)\rangle = \sum_{j=1}^n \partial_j V(x) g_j(x)$.*

The orbital derivative is the derivative along a solution of (23) due to the chain rule:

$$\frac{d}{dt} V(x(t)) = \langle \nabla V(x(t)), \dot{x}(t)\rangle = \sum_{j=1}^n (\partial_j V)(x(t)) g_j(x(t)) = V'(x(t)).$$

Note that the orbital derivative is a linear differential operator of first order of the form (2):

$$LV(x) = V'(x) = \sum_{i=1}^n g_i(x) \partial_i V(x).$$

Here, the singular points, i.e., those points where $(\delta_x \circ L) = 0$, are simply the equilibrium points, i.e., those points satisfying $g(x) = 0$.

The following theorem explains the use of Lyapunov functions for the determination of the basin of attraction.

THEOREM 4.5 (see [11, Theorem 2.24]). *Let $s \in C^1(\mathbb{R}^n, \mathbb{R})$ and $K \subset \mathbb{R}^n$ be a compact set with neighborhood B such that $x_0 \in \overset{\circ}{K}$. Furthermore, let*

1. *$K = \{x \in B \mid s(x) \leq R\}$ with an $R \in \mathbb{R}$; i.e., K is a sublevel set of s.*

2. *$s'(x) < 0$ for all $x \in K \setminus \{x_0\}$; i.e., s is decreasing along solutions in $K \setminus \{x_0\}$.*

Then $K \subset A(x_0)$.

Hence, a Lyapunov function provides information on the basin of attraction through its sublevel sets. However, it is not easy to find a Lyapunov function for a general system (23). Although existence of several types of Lyapunov functions is known, their construction is not easy.

However, for linear differential equations, i.e., $g(x)$ is linear, one can easily calculate a Lyapunov function. For a nonlinear system we consider the linearized system at the equilibrium point, namely, $\dot{x} = Dg(x_0)(x - x_0)$. This is a linear system and, thus, one can easily calculate a Lyapunov function of the form $v(x) = (x - x_0)^T C(x - x_0)$, where the positive definite matrix C is the unique solution of the matrix equation $Dg(x_0)^T C + CDg(x_0) = -I$; cf. [22]. The function v is a Lyapunov function not only for the linearized system but also for the nonlinear system in a neighborhood of x_0; for details, cf. [11].

LEMMA 4.6 (local Lyapunov function). *Let x_0 be an equilibrium of $\dot{x} = g(x)$ such that all eigenvalues of $Dg(x_0)$ have a negative real part. Denote by $C \in \mathbb{R}^{n \times n}$ the unique solution of the matrix equation $Dg(x_0)^T C + CDg(x_0) = -I$ and define the local Lyapunov function*

$$v(x) = (x - x_0)^T C(x - x_0).$$

Then there is a compact set K with a neighborhood B such that $x_0 \in \overset{\circ}{K}$. Moreover, $v'(x) < 0$ holds for all $x \in K \setminus \{x_0\}$ and $K = \{x \in B \mid v(x) \leq R\}$ with $R > 0$.

We return to Lyapunov functions which have a negative orbital derivative for all $x \in A(x_0) \setminus \{x_0\}$. We consider special Lyapunov functions satisfying certain equations for their orbital derivatives. In the first part of Theorem 4.8 below, a feasible candidate is given by $p(x) = \|x - x_0\|_2^2$. For the second part we need the following definition.

DEFINITION 4.7 (noncharacteristic hypersurface [11, Definition 2.36]). *Let $h \in C^\sigma(\mathbb{R}^n, \mathbb{R})$. The set $\Gamma \subset \mathbb{R}^n$ is called a* noncharacteristic hypersurface *if*

- *Γ is compact,*
- *$h(x) = 0$ holds if and only if $x \in \Gamma$,*
- *$h'(x) < 0$ holds for all $x \in \Gamma$, and*
- *for each $x \in A(x_0) \setminus \{x_0\}$ there is a time $\theta(x) \in \mathbb{R}$ such that $S_{\theta(x)} x \in \Gamma$.*

An example of a noncharacteristic hypersurface is a level set of the local Lyapunov function; cf. Lemma 4.6.

THEOREM 4.8 (see [11, Theorems 2.38 and 2.46]). *Consider (23) with $g \in C^\sigma(\mathbb{R}^n, \mathbb{R}^n)$ and let x_0 be an equilibrium such that all eigenvalues of $Dg(x_0)$ have a negative real part.*

1. *Let $p(x) \in C^\sigma(\mathbb{R}^n, \mathbb{R})$ satisfy the following conditions:*
   (a) *$p(x) > 0$ for $x \neq x_0$.*
   (b) *$p(x) = O(\|x - x_0\|_2^\eta)$ with $\eta > 0$ for $x \to x_0$.*
   (c) *For all $\epsilon > 0$, p has a lower positive bound on $\mathbb{R}^n \setminus B(x_0, \epsilon)$.*

   Then there exists a Lyapunov function $V_1 \in C^\sigma(A(x_0), \mathbb{R})$ such that $V_1(x_0) = 0$ and

$$LV_1(x) = f_1(x) := -p(x) \text{ for all } x \in A(x_0).$$

2. *Let $c > 0$, let Γ be a noncharacteristic hypersurface (see Definition 4.7), and let $F \in C^\sigma(\Gamma, \mathbb{R})$. Then there is a Lyapunov function $V_2 \in C^\sigma(A(x_0) \setminus \{x_0\}, \mathbb{R})$ such that*

$$LV_2(x) = f_2(x) := -c \text{ for all } x \in A(x_0) \setminus \{x_0\},$$

$$V_2(x) = F(x) \text{ for all } x \in \Gamma.$$

4.2. Approximating Lyapunov functions. Theorem 4.8 shows two possibilities for approximating Lyapunov functions. We can use the first part to approximate V_1 by solving the problem

$$Ls_1(x) = LV_1(x) = -p(x), \qquad x \in A(x_0).$$

This is an example of an operator problem of type (1), and our theory from section 3.1 applies.

On the other hand, the second part of Theorem 4.8 implies to solve the boundary value problem

$$Ls_2(x) = f_2(x) = -c, \qquad x \in A(x_0) \setminus \{x_0\},$$

$$s_2(x) = F(x), \qquad x \in \Gamma,$$

such that we can use our theory from section 3.2.

However, in both cases the application of our error estimates now has a different character. An error bound of the form $|LV(x) - Ls(x)| = |V'(x) - s'(x)| < \epsilon$ leads to $s'(x) \leq V'(x) + \epsilon < 0$, provided that ϵ is sufficiently small. Remember that V, as a Lyapunov function, satisfies $V'(x) < 0$. Hence, in this case s is itself a Lyapunov function.

However, for the specific choices of Lyapunov functions from Theorem 4.8 we have a problem if x is close to x_0. In the first case, $V_1'(x) = f_1(x) = -p(x)$ and $p(x) \to 0$ as $x \to x_0$. Hence, this estimate will not hold near x_0 and thus s_1' may be positive near x_0. The same problem arises for the approximation s_2 of V_2, since V_2 is not defined in x_0. Fortunately, locally it is easy to determine the basin of attraction by linearization; cf. Lemma 4.6.

Before we can apply the results of this paper to the calculation of Lyapunov functions, we need some information about the level sets of Lyapunov functions. We assume that g is bounded in $A(x_0)$. This can easily be achieved by considering the system $\dot{x} = h(x) := \frac{g(x)}{1+\|g(x)\|^2}$. Note that $\|h(x)\| \leq \frac{1}{2}$. This system has the same equilibria and basins of attraction as system (23) since $h(x)$ is obtained by multiplication of $g(x)$ by a positive, scalar factor; i.e., the orbits of both systems are the same, but the velocities are different.

THEOREM 4.9 (see [11, Corollary 2.43, Proposition 2.44, and Theorem 2.46]). *Let x_0 be an equilibrium of $\dot{x} = g(x)$, $g \in C^\sigma(\mathbb{R}^n, \mathbb{R}^n)$, $\sigma \geq 1$, and let the maximal real part of all eigenvalues of $Dg(x_0)$ be negative. Let g be bounded in $A(x_0)$ and let $V = V_i$, $i = 1, 2$, be one of the functions of Theorem 4.8.*

Then for all $r > 0$ the set $\{x \in A(x_0) \setminus \{x_0\} \mid V(x) \leq r\} \cup \{x_0\}$ is compact. Moreover, there is a C^σ-diffeomorphism

$$\phi \in C^\sigma(S^{n-1}, \{x \in A(x_0) \mid V(x) = r\}),$$

where $S^{n-1} = \{x \in \mathbb{R}^n \mid \|x\|_2 = 1\}$. For V_2 we have $\lim_{x \to x_0} V_2(x) = -\infty$.

In the second case V_2, one first has to link the function V_2 to a local Lyapunov function to obtain the above theorem. For details, see [11].

In order to apply the results of section 3 to approximate the functions V_1, V_2 of Theorem 4.8, we have to choose a set Ω in an appropriate way such that Ω has a smooth boundary.

THEOREM 4.10. *Let $k := \lfloor \tau \rfloor > 1 + n/2$ and $\sigma := \lceil \tau \rceil$. Consider the dynamical system defined by the ordinary differential equation $\dot{x} = g(x)$, where $g \in C^\sigma(\mathbb{R}^n, \mathbb{R}^n)$. Let $x_0 \in \mathbb{R}^n$ be an equilibrium such that the real parts of all eigenvalues of $Dg(x_0)$ are negative. Let g be bounded in $A(x_0)$ and denote by $V_1 \in W_2^\tau(A(x_0), \mathbb{R})$, $V_2 \in W_2^\tau(A(x_0) \setminus \{x_0\}, \mathbb{R})$ the Lyapunov functions of Theorem* 4.8.

1. *The reconstruction s_1 of the Lyapunov function V_1 with respect to the operator $Lu(x) = \langle \nabla u(x), g(x) \rangle$ and a set $X \subseteq \Omega := \{x \in A(x_0) \mid V_1(x) \le r\} \setminus \{x_0\}$, $r > 0$, satisfies*

$$\|s_1' - V_1'\|_{L_\infty(\Omega)} = \|s_1' + p\|_{L_\infty(\Omega)} \le C h_X^{\tau - 1 - n/2} \|V_1\|_{W_2^\tau(\Omega)}.$$

2. *Let $\Gamma = \{x \in A(x_0) \setminus \{x_0\} \mid h(x) = 0\}$ be a noncharacteristic hypersurface and set $\Omega = \{x \in A(x_0) \setminus \{x_0\} \mid V_2(x) \le r$ and $h(x) \ge 0\}$, where $r > 0$ is large enough such that $\{x \in A(x_0) \setminus \{x_0\} \mid V_2(x) = r\} \cap \Gamma = \varnothing$. The reconstruction s_2 of V_2 with respect to the boundary value problem $Lu(x) = \langle \nabla u(x), g(x) \rangle$, $u(x) = 0 = F(x)$ for Γ and the data sites $X_1 \subset \Omega$ and $X_2 \subset \Gamma$ satisfies*

$$\|s_2' - V_2'\|_{L_\infty(\Omega)} = \|s_2' + c\|_{L_\infty(\Omega)} \le C h_{X_1,\Omega}^{\tau - 1 - n/2} \|V_2\|_{W_2^\tau(\Omega)},$$

$$\|s_2 - V_2\|_{L_\infty(\Gamma)} = \|s_2\|_{L_\infty(\Gamma)} \le C h_{X_2,\Gamma}^{\tau - n/2} \|V_2\|_{W_2^\tau(\Omega)}.$$

Proof. Note that the data sites x_j, $1 \le j \le N$, are no singular points, i.e., $g(x_j) \ne 0$ or equilibria in this case, since there are no equilibria in $A(x_0) \setminus \{x_0\}$.

1. We apply Theorem 3.5 with $m = 1$. The set Ω is bounded and has a smooth boundary by Theorem 4.9 and thus satisfies the conditions of Theorem 3.5; cf. [27]. The functions c_α are $g_j \in C^\sigma(\mathbb{R}^n, \mathbb{R})$ and thus are in $W_\infty^k(\Omega)$.
2. We apply Corollary 3.11 with $m = 1$. The sets Ω and $\Gamma \subset \partial\Omega$ are bounded and Ω has a smooth boundary by Theorem 4.9 (see also [27]). Thus the conditions of Corollary 3.11 are satisfied. The functions c_α are $g_j \in C^\sigma(\mathbb{R}^n, \mathbb{R})$ and thus are in $W_\infty^k(\Omega)$. ∎

The calculation of the interpolation matrix A in Definition 3.1 can easily be achieved for radial basis functions, in particular for Wendland's compactly supported ones; cf. [11, Proposition 3.5 and Table 3.1].

COROLLARY 4.11. *Denote by k the smoothness index of the compactly supported Wendland function. Let $k > \frac{1}{2}$ if n is odd or $k > 1$ if n is even. Set $\tau = k + (n+1)/2$ and $\sigma = \lceil \tau \rceil$. Consider the dynamical system defined by the ordinary differential equation $\dot{x} = g(x)$, where $g \in C^\sigma(\mathbb{R}^n, \mathbb{R}^n)$. Let $x_0 \in \mathbb{R}^n$ be an equilibrium such that all eigenvalues of $Dg(x_0)$ have a negative real part. Let g be bounded in $A(x_0)$ and denote by $V_1 \in W_2^\tau(A(x_0), \mathbb{R})$ and $V_2 \in W_2^\tau(A(x_0) \setminus \{x_0\}, \mathbb{R})$ the Lyapunov functions of Theorem* 4.8.

1. *The reconstruction s_1 of the Lyapunov function V_1 with respect to the operator $Lu(x) = \langle \nabla u(x), g(x) \rangle$ and a set $X \subseteq \Omega := \{x \in A(x_0) \mid V_1(x) \le r\} \setminus \{x_0\}$, $r > 0$, satisfies*

$$\|s_1' - V_1'\|_{L_\infty(\Omega)} = \|s_1' + p\|_{L_\infty(\Omega)} \le C h_X^{k - \frac{1}{2}} \|V_1\|_{W_2^{k+(n+1)/2}(\Omega)}. \tag{24}$$

2. *Let* $\Gamma = \{x \in A(x_0)\setminus\{x_0\} \mid h(x) = 0\}$ *be a noncharacteristic hypersurface and set* $\Omega = \{x \in A(x_0) \setminus \{x_0\} \mid V_2(x) \le r$ *and* $h(x) \ge 0\}$, *where* $r > 0$ *is large enough such that* $\{x \in A(x_0) \setminus \{x_0\} \mid V_2(x) = r\} \cap \Gamma = \varnothing$. *The reconstruction* s_2 *of* V_2 *with respect to the boundary value problem* $Lu(x) = \langle \nabla u(x), g(x)\rangle$, $u(x) = 0 = F(x)$, *for* Γ *and the sets of data sites* $X_1 \subset \Omega$ *and* $X_2 \subset \Gamma$ *satisfies*

$$\|s_2' - V_2'\|_{L_\infty(\Omega)} \le C h_{X_1,\Omega}^{k-\frac{1}{2}} \|V_2\|_{W_2^{k+(n+1)/2}(\Omega)}, \tag{25}$$

$$\|s_2 - V_2\|_{L_\infty(\Gamma)} \le C h_{X_2,\Gamma}^{k+\frac{1}{2}} \|V_2\|_{W_2^{k+(n+1)/2}(\Omega)}. \tag{26}$$

Proof. Apply Corollaries 3.6, 3.11, and 3.12, respectively, with $m = 1$. ∎

The method described in this paper has already been used in [8, 9, 10, 11]. However, the approximation orders derived in those papers were based on Taylor approximation of first order, and hence the results in those papers were significantly worse than the results of Corollary 4.11.

The theorems and corollaries of this section, in particular (24) and (25), ensure that the approximation of the Lyapunov functions V_1 and V_2 produces functions s_1, s_2, respectively, with negative orbital derivatives in Ω if the data sites are dense enough. For the remaining neighborhood of the equilibrium x_0 we use a local Lyapunov function; cf. Lemma 4.6. We can combine the approximated function s and the local Lyapunov function v to a new Lyapunov function $\tilde{s}$ such that $\tilde{s}'(x) < 0$ holds for all $x \in \Omega \setminus \{x_0\}$ and such that level sets of s are level sets of $\tilde{s}$.

However, since Theorem 4.5 requires a sublevel set of s within the region where $s'(x) < 0$, we need information about the level sets of the approximants s. Here we make use of the estimate for s_2 on Γ; cf. (26). The following theorem shows that we can cover each compact subset $\tilde{K}$ of the basin of attraction with a sublevel set of s, and thus the approximation method finds every compact subset of the basin of attraction, provided that the sets Ω and Γ are chosen appropriately and the data sites are dense enough.

THEOREM 4.12 (see [11, Theorems 5.1 and 5.3]).

1. *Let* $\tilde{K}$ *be a compact set with* $x_0 \in \overset{\circ}{\tilde{K}} \subset \tilde{K} \subset A(x_0)$. *Let* s_1 *be an approximation of* V_1 *as in Corollary* 4.11 *with* $\Omega := \{x \in A(x_0) \mid V_1(x) \le r\} \setminus \{x_0\}$, *where* $r > 0$ *is large enough and* h_X *is small enough.*
   Then there is a $\rho \in \mathbb{R}$ *with* $\tilde{K} \subset \{x \in \Omega \mid s_1(x) \le \rho\}$.
2. *Let* $\tilde{K}$ *be a compact set with* $x_0 \in \overset{\circ}{\tilde{K}} \subset \tilde{K} \subset A(x_0)$. *Let* s_2 *be an approximation of* V_2 *as in Corollary* 4.11 *with* $\Omega = \{x \in A(x_0) \setminus \{x_0\} \mid V_2(x) \le r$ *and* $h(x) \ge 0\}$, *where* $r > 0$ *is large enough and* h_{X_1} *and* h_{X_2} *are small enough. Set* $U = \{x \in A(x_0) \mid h(x) \le 0\}$.
   Then there is a $\rho \in \mathbb{R}$ *with* $\tilde{K} \subset U \cup \{x \in \Omega \mid s_2(x) \le \rho\}$.

The proof of 2 compares level sets of s_2 with level sets of V_2 using estimate (26) on Γ and (25) along solutions. For 1 we can derive an estimate near x_0 since V_1 is defined and smooth at x_0; then we use the estimate (24) along solutions.

4.3. Example. As an example we consider the dynamical system given by

$$\begin{cases} \dot{x} &= -x - 2y + x^3, \\ \dot{y} &= -y + \frac{1}{2}x^2 y + x^3 \end{cases}$$

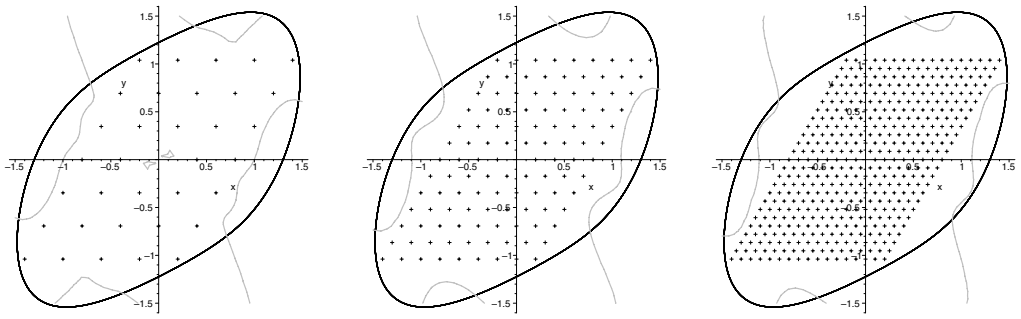

FIG. 1. *The grid X_N (plus signs), the basin of attraction bounded by the black periodic orbit, and the set $\{(x,y) \in \mathbb{R}^2 \mid s'(x,y) = 0\}$ (grey dotted lines) with the approximation s of the function V, where $V'(x,y) = -x^2 - y^2$ with the Wendland function $\psi_{4,2}(2/3\|x\|_2)$ and the grid distance α. Left: $\alpha = 0.4$; middle: $\alpha = 0.2$; right: $\alpha = 0.1$.*

and denote the right-hand side by $g(x,y)$. The system has an asymptotically stable equilibrium at $(0,0)$ with Jacobian

$$Dg(0,0) = \begin{pmatrix} -1 & -2 \\ 0 & -1 \end{pmatrix}.$$

For a local Lyapunov function (cf. Lemma 4.6), we calculate the unique solution C of the matrix equation $Dg(0,0)^T C + CDg(0,0) = -I$, which is given by

$$C = \begin{pmatrix} \frac{1}{2} & -\frac{1}{2} \\ -\frac{1}{2} & \frac{3}{2} \end{pmatrix}.$$

The basin of attraction $A(0,0)$ is bounded by an unstable periodic orbit which we have calculated numerically. We approximate the function V_1 satisfying $V_1'(x,y) = -x^2 - y^2$. We use a hexagonal grid of the form $\alpha[j\,(1,0)^T + k(\frac{1}{2}, \frac{\sqrt{3}}{2})^T]$ for the data sites. Then the mesh norm is $h = \alpha/2$. Since we have to avoid singular points we must exclude the origin. We use three different grids with parameters $\alpha_1 = 0.1$, $\alpha_2 = 0.2$, and $\alpha_3 = 0.4$ and two different Wendland functions as radial basis functions $\Phi(x) = \psi_{k,l}(c\|x\|_2)$ with $c = 2/3$ and $k = 2, 3$; cf. Figures 1 and 2.

We consider the grid $0.1[j\,(1,0)^T + k(\frac{1}{2}, \frac{\sqrt{3}}{2})^T + (\frac{3}{4}, \frac{\sqrt{3}}{4})^T]$. These grid points are in between the grid points of the smallest grid above. We calculate the maximal error on this grid. By our error analysis the errors $e_{k,\alpha}$ and $e_{k,2\alpha}$ should behave as

$$\frac{e_{k,2\alpha}}{e_{k,\alpha}} \approx \frac{(2\alpha)^{k-1/2}}{(\alpha)^{k-1/2}} = 2^{k-1/2}$$

(cf. (24)), which is approximately reflected in our numerical results; see Table 1.

For the basin of attraction, however, the level sets of s are also important. Even if the set, where s' is negative, is large, a subset of the basin of attraction is given only by a sublevel set of s within this region. For one example we have calculated such a sublevel set and have compared it to the sublevel set of the local Lyapunov function; see Figure 3. If the function g is bounded in the basin of attraction, then one can cover each given compact set in $A(x_0)$ with a sublevel set of s, where the data sites are dense enough; see Theorem 4.12.

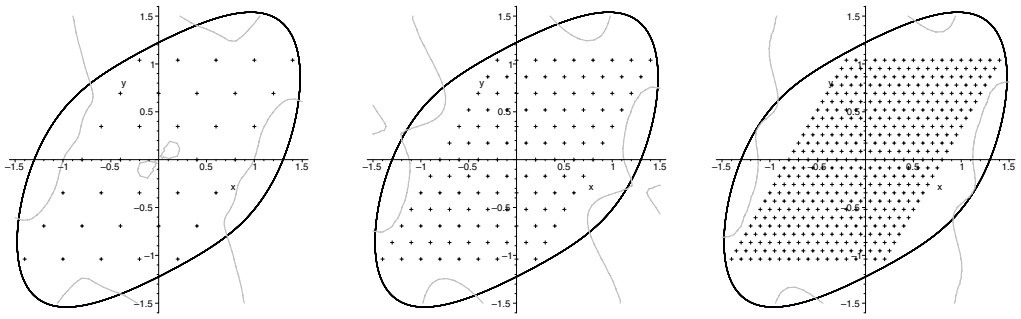

FIG. 2. *The grid X_N (plus signs), the basin of attraction bounded by the black periodic orbit, and the set $\{(x,y) \in \mathbb{R}^2 \mid s'(x,y) = 0\}$ (grey dotted lines) with the approximation s of the function V, where $V'(x,y) = -x^2 - y^2$ with the Wendland function $\psi_{5,3}(2/3\|x\|_2)$ and the grid distance α. Left: $\alpha = 0.4$; middle: $\alpha = 0.2$; right: $\alpha = 0.1$.*

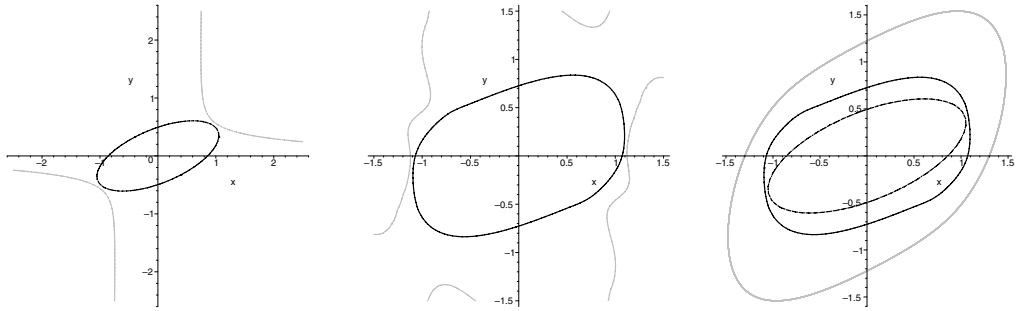

FIG. 3. *Left: The local Lyapunov function $v(x) = x^T Cx$: level set $v'(x) = 0$ (grey dotted lines) and a sublevel set $\{x \in \mathbb{R}^2 \mid v(x) \leq 0.37\}$ which is a subset of the basin of attraction. Middle: The calculated Lyapunov function s ($k = 3$, $\alpha = 0.1$): level set $s'(x) = 0$ (grey dotted lines) and a sublevel set $\{x \in \mathbb{R}^2 \mid s(x) \leq -0.5\}$ which is a subset of the basin of attraction. Right: Comparison of the subsets obtained by the local Lyapunov function v (small black ellipse), the calculated Lyapunov function s (large black set), and the whole basin of attraction (grey dotted lines).*

TABLE 1

The approximation error $e_\alpha = \max_{x \in X_3} \|s_1'(x) - V_1'(x)\|_2$, where X_3 is a dense grid for different Wendland functions $\psi_{k+2,k}$ and different grids with mesh norm α for the example discussed in this section. The ratio of the errors e_α is compared to the theoretical bound $2^{k-1/2}$ of Corollary 4.11, (24).

k / α	0.4	0.2	0.1	$e_{0.4}/e_{0.2}$	$e_{0.2}/e_{0.1}$	$2^{k-1/2}$
2	0.8862	0.4641	0.1814	1.9094	2.5592	2.8284
3	1.1308	0.4265	0.1041	2.6516	4.0960	5.6569

LOCALLY CONSERVATIVE FLUXES FOR THE CONTINUOUS GALERKIN METHOD*

BERNARDO COCKBURN†, JAYADEEP GOPALAKRISHNAN‡, AND HAIYING WANG†

Abstract. The standard continuous Galerkin (CG) finite element method for second order elliptic problems suffers from its inability to provide conservative flux approximations, a much needed quantity in many applications. We show how to overcome this shortcoming by using a two-step postprocessing. The first step is the computation of a numerical flux trace defined on element interfaces and is motivated by the structure of the numerical traces of discontinuous Galerkin methods. This computation is nonlocal in that it requires the solution of a symmetric positive definite system, but the system is well conditioned independently of mesh size, so it can be solved at asymptotically optimal cost. The second step is a local element-by-element postprocessing of the CG solution incorporating the result of the first step. This leads to a conservative flux approximation with continuous normal components. This postprocessing applies for the CG method in its standard form or for a hybridized version of it. We present the hybridized version since it allows easy handling of variable-degree polynomials and hanging nodes. Furthermore, we provide an a priori analysis of the error in the postprocessed flux approximation and display numerical evidence suggesting that the approximation is competitive with the approximation provided by the Raviart–Thomas mixed method of corresponding degree.

1. Introduction.

In this paper, we revisit the classical finite element method [13, 20], otherwise known as the continuous Galerkin (CG) method, for second order elliptic problems, with the intention of showing how to overcome what is perhaps its main disadvantage, namely, the discontinuity of the normal component of the approximate flux across element interfaces. We show how to achieve this by means of an efficient postprocessing of the approximate solution provided by the CG method. We also show that the postprocessed flux is competitive with the flux provided by the Raviart–Thomas mixed method of corresponding degree.

We illustrate our technique in the framework of the model second order elliptic boundary value problem

$$-\nabla \cdot (a\nabla u) = f \qquad \text{on } \Omega, \tag{1.1a}$$

$$u = g \qquad \text{on } \Gamma_D, \tag{1.1b}$$

$$-a\nabla u \cdot \boldsymbol{n} = \mathsf{q}_{\mathsf{N}} \qquad \text{on } \Gamma_N. \tag{1.1c}$$

Here $\Omega \subset \mathbb{R}^N$ is a polyhedral domain ($N \geq 2$) with boundary $\partial\Omega$, $f \in L^2(\Omega)$, and $a = a(\boldsymbol{x})$ is a symmetric $N \times N$ matrix function that is uniformly positive definite

on Ω with components in $L^\infty(\Omega)$. The boundary conditions are given by functions g and $\mathsf{q_N}$ on disjoint subsets Γ_D and Γ_N of $\partial\Omega$, upon which further assumptions will be placed shortly. Here and elsewhere we use $\boldsymbol{n}$ to denote the unit outward normal on the boundary of some domain—the domain will be clear from the context, e.g., in (1.1c) it is Ω. As is well known, this boundary value problem models a wide range of problems of practical interest from electromagnetics to heat dissipation and flow in porous media.

To facilitate the discussion of the results, let us introduce our notation for the CG method right away. Let $\mathcal{T}_h$ denote a triangulation of the domain Ω, which for simplicity we assume consists of simplices. Define the space

$$\mathsf{V}_h = \left\{ v \in \mathcal{C}^0(\Omega) : v|_K \in \mathcal{P}_k(K) \text{ for } K \in \mathcal{T}_h \right\}, \tag{1.2}$$

where $\mathcal{C}^0(D)$ denotes the space of continuous functions on a domain D. We assume that Γ_D is the union of some mesh faces (edges if $N = 2$) lying on $\partial\Omega$ and that $\Gamma_N = \partial\Omega \setminus \Gamma_D$. We assume that g is in the space of traces on Γ_D of functions in V_h and set $\mathsf{V}_h(g) = \{v \in \mathsf{V}_h : v = g \text{ on } \Gamma_D\}$. If a Dirichlet data that is not polynomial is given, one can proceed by approximating it as usual, but we shall not consider this case. As is well known, the approximate solution u_h of the CG method is the function in $\mathsf{V}_h(g)$ determined by

$$(a\nabla u_h, \nabla v)_\Omega = (f,\ v)_\Omega - \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N} \quad \text{for all } v \in \mathsf{V}_h(0). \tag{1.3}$$

Here we have used common notation for innerproducts: For scalar functions w and v on some domain $\mathcal{D} \subset \mathbb{R}^N$, $(w, v)_\mathcal{D} = \int_\mathcal{D} w\, v\, dx$; for vector functions $(\boldsymbol{p}, \boldsymbol{q})_\mathcal{D} = \int_\mathcal{D} \boldsymbol{p} \cdot \boldsymbol{q}\, dx$; and for functions on domains B formed by lower-dimensional objects like union of a few mesh faces, $\langle \eta, \zeta\rangle_B = \int_B \eta\, \zeta\, d\gamma$.

It is well known that the CG approximation given by $-a\nabla u_h$ to the flux $\boldsymbol{q} = -a\nabla u$ is not conservative. The root of the problem is evident once we write (1.1a) in conservation form as $\operatorname{div} \boldsymbol{q} = f$. While the flux approximations from mixed and discontinuous Galerkin (DG) methods satisfy a discrete analogue of this equation, the CG flux $-a\nabla u_h$ does not. We say that a discrete flux $\boldsymbol{q}_h$ approximating the exact flux $\boldsymbol{q}$ is *conservative* if the total outward flux across any "discrete subdomain" as measured by $\boldsymbol{q}$ and $\boldsymbol{q}_h$ coincides, or more precisely,

$$\int_{\partial D_h} \boldsymbol{q} \cdot \boldsymbol{n}\, ds = \int_{\partial D_h} \boldsymbol{q}_h \cdot \boldsymbol{n}\, ds \tag{1.4}$$

for any domain D_h formed by the union of some mesh elements in $\mathcal{T}_h$ (where $\boldsymbol{n}$ is unit outward normal on the boundary of D_h). Conservative flux approximations are very important in many applications, e.g., in oil recovery simulations, more generally in flows through porous media, and indeed in computational fluid dynamics in general. The same is true in computational structural mechanics, where mixed and hybrid methods were devised to cope with its absence in the so-called one-field displacement method for linear elasticity (which is the CG method for elasticity); see, e.g., the first paragraph of section 3.3 in [31].

Many researchers have attempted to overcome the lack of conservativity of the CG flux by generating a better flux through postprocessing. However, a conservative $\boldsymbol{H}(\operatorname{div}, \Omega)$-conforming flux approximation has eluded their efforts for more than three decades. Let us briefly review what has been achieved to date. In [33], J. Wheeler showed how to postprocess the CG solution to obtain approximations to the normal component of $\boldsymbol{q}$ at the boundary of the computational domain. In one space

dimension, this procedure can be extended to compute approximations to $\boldsymbol{q}$ at all the nodes. In fact, such approximations were proven by M. Wheeler in [34] to superconverge with order $2\,k$ when using polynomial approximations of degree k. This solves the problem in the one-dimensional case. In the multidimensional case, however, the situation is rather different and no $\boldsymbol{H}(\mathrm{div},\Omega)$-conforming approximation of $\boldsymbol{q}$ has been constructed so far. Moreover, there are only a few theoretical and numerical studies of the approximation given by J. Wheeler's procedure. In [23], it was shown that such a procedure provides an approximation that superconverges in the $L^2(\partial\Omega)$-norm with order $k+1$ for $a\equiv 1$, and with order $k+1/2$ when a is smooth (under the assumption that Ω is a square endowed with a Cartesian mesh). In [3], the integral of the normal component of the flux on the whole boundary was proven to superconverge with order $k+1$ when Ω is a curved domain and isoparametric elements are used, and with order $2k$ when it is a polyhedron. For numerical studies, see the references cited in [25]. More importantly, in [25] the CG method was argued to have the property of local conservativity; see also [26] for an extension of this approach to the advection-diffusion and incompressible Navier–Stokes equations. In [9], the so-called *superconvergent integral flux postprocessing formula* was revisited. The conservation property was proven and a relation to a Lagrange multiplier mixed formulation and the associated consistency implications were established. See also [10] for further work on conservative projections involving multipliers in a different context. However, none of the approaches used in [25, 9] can be employed to construct an $\boldsymbol{H}(\mathrm{div},\Omega)$-conforming approximation of the flux, rendering the CG method locally conservative. (The precise relation between this approach and ours is displayed right before section 3.2.) In [7], this approach was used (for $a=1$ and $N=2$) to obtain an approximation of the integral of the normal component of the flux on an internal boundary which splits the domain in two; an order of convergence of $2\,k$ was proven for such an approximation.

In this paper, we show how to obtain a conservative flux approximation $\boldsymbol{q}_h$ in $\boldsymbol{H}(\mathrm{div},\Omega)$ that renders the CG method locally conservative. This is done by postprocessing the CG solution u_h in two steps. The objective of the first is to compute a numerical trace $\widehat{\boldsymbol{q}}_h$ of the flux whose normal component is single-valued on the interelement boundaries and *renders locally conservative the CG method*, that is, it satisfies

$$-\sum_{K\in\mathcal{T}_h}(a\,\nabla u_h,\nabla v)_K+\sum_{K\in\mathcal{T}_h}\langle\widehat{\boldsymbol{q}}_h\cdot\boldsymbol{n},v\rangle_{\partial K}=(f,v)_\Omega$$

for all v such that $v|_K\in\mathcal{P}_\ell(K)$ for all $K\in\mathcal{T}_h$ for some $\ell\le k$. The form of this numerical trace is similar to that of the corresponding numerical traces of the DG methods. However, unlike the DG numerical traces, the crucial *stabilization* term cannot have the form of a parameter times the jump of the u_h, since in our case such a jump is identically equal to zero. Instead, it is a quantity that belongs to a certain nonstandard space of *jumps* and that depends globally on the CG approximation u_h. While the need for this term is far from obvious when approaching from the standard CG formulation, it becomes clearer from the hybridized form of the CG method, which uses a space of discontinuous functions that generate the above-mentioned space of jumps on mesh faces. Because of this, we now face difficulties not encountered in DG methods: the computation of $\widehat{\boldsymbol{q}}_h$ requires (i) a local basis representation of the space of jumps, and (ii) the solution of a global system in that space. We are able to overcome the former difficulty by extending some techniques developed in [17, 18].

Although the latter difficulty persists, it turns out that the stiffness matrix of the global system is symmetric, positive definite, and well conditioned. In particular, we prove that its condition number is bounded independently of mesh size, so it can be solved iteratively at asymptotically optimal cost. In [27] a similar but different way of computing a numerical trace has been proposed; see the discussion before section 3.3.

The second step in the postprocessing is the local element-by-element recovery of a conservative flux approximation $\boldsymbol{q}_h$ throughout the computational domain by a variation of the so-called Raviart–Thomas (RT) projection [29]. Similar techniques have been used by [4] in the framework of DG methods for Darcy's law and by [19] in the context of DG methods for the Navier–Stokes equations. The flux approximation $\boldsymbol{q}_h$ *coincides* with the numerical trace $\widehat{\boldsymbol{q}}_h$ on element boundaries supplied by the previous step and is lifted to the interior of each element by using the $a\,\nabla u_h$ in such a way that

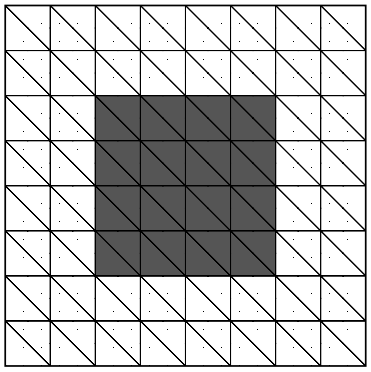
$$-\sum_{K\in\mathcal{T}_h}(a\,\nabla u_h,\nabla v)_K+\sum_{K\in\mathcal{T}_h}\langle\widehat{\boldsymbol{q}}_h\cdot\boldsymbol{n},v\rangle_{\partial K}=\sum_{K\in\mathcal{T}_h}(\nabla\cdot\boldsymbol{q}_h,v)_K=(f,v)_\Omega$$

for all v such that $v|_K\in\mathcal{P}_\ell(K)$ for all $K\in\mathcal{T}_h$ for some $\ell\le k$. We prove that the resulting approximation $\boldsymbol{q}_h$ converges to the exact flux $\boldsymbol{q}$ at the *same* order of convergence as the approximation provided by the RT mixed method of corresponding order. Moreover, since the computation of the CG solution requires solving a system that is smaller in size than the corresponding RT system, our flux computation becomes a competitive alternative.

In [32], a technique is proposed for computing a locally conservative flux approximation in the domain Ω from its exact divergence in Ω and an approximation of its normal component on the interelement boundaries. It also proceeds in two steps. In the first, a locally conservative approximation to the normal component is obtained by solving a global constrained minimization problem. Then, on each element, the data on the border is lifted to the interior to obtain the desired flux; a local mixed element method is used to achieve this. The application of this technique to the CG method differs from ours in several respects. First of all, the resulting numerical trace does not render locally conservative the CG method, in the sense defined above. Moreover, to obtain it, a global constrained minimization problem is to be solved; this has to be contrasted with our unconstrained minimization problem whose stiffness matrix has a condition number bounded independently of the mesh size. Finally, to obtain what we call $\boldsymbol{q}_h$, the approximation u_h given by the CG method is not used.

Let us compare our flux $\boldsymbol{q}_h$ with the RT flux obtained for the model problem (1.1) with $f=0$, $\Omega=(0,1)\times(0,1)$ and boundary conditions as indicated in Figure 1. Here $a=0.001\mathrm{Id}$ in the region $(.25,.75)\times(.25,.75)$ and $a=\mathrm{Id}$ elsewhere (Id denotes the identity matrix); see Figure 1. We can think of this problem as modeling the steady state flow of a fluid through a porous medium with permeability given by a. In Figure 2 we display the streamlines of the approximations to the velocity field $-a\nabla u$ for the approximation given by the RT mixed method of order 1 (left) as well as that given by a postprocessing of the CG method of order 2 (right). The results are very similar. Notice that the singularity of the flow around the corners of the low permeability region $(.25,.25)\times(.75,.75)$ makes this a hard test problem.

We discuss the postprocessing procedure for a hybridized version of the CG method, although it can be applied directly to the standard CG formulation. This is not only because it is easier to understand the first step of the postprocessing using the hybridized formulation (as mentioned previously), but also because the hybridized



Boundary conditions:

$$u = 0 \quad \text{on } \{(1,y) : y \in [0,1]\},$$

$$\boldsymbol{q}\cdot\boldsymbol{n} = \begin{cases} -1 & \{(0,y) : y \in [0,.5)\}, \\ 0 & \{(0,y) : y \in [.5,1]\}, \\ 0 & \{(x,1) : x \in [0,1]\}, \\ 0 & \{(x,0) : x \in [0,1]\}. \end{cases}$$

method has interesting features in its own right. The hybridized CG method is obtained as a natural extension of the new perspective introduced in [15] for hybridizing mixed methods. It can be briefly described in two steps. First, we express the approximate solution of the CG method u_h in terms of the data components (g and f) and a *Lagrange multiplier* λ_h. It turns out that for the CG method, λ_h is nothing but the restriction of u_h to the faces of the elements of the triangulation. The second step consists in showing that λ_h can be characterized as the only element of certain set $M_h(g)$ satisfying a weak formulation of the form

$$a_h(\lambda_h, \mu) = b_h(\mu) \qquad \text{for all } \mu \in M_h(0). \tag{1.5}$$

This formulation was also obtained in [5] with the purpose of devising efficient substructuring preconditioners for the CG method.

Hybridization in the context of mixed methods is different from what goes by the name of static condensation in the engineering literature, because the former gives extra information through the Lagrange multiplier, a solution component absent in

static condensation. However, in the hybridized CG case, the fact that the Lagrange multiplier λ_h equals u_h on the element interfaces implies that hybridization and static condensation coincide, except when we have variable degree elements and hanging nodes. In the static condensation approach, the degrees of freedom of the approximate solution u_h must be very carefully chosen in order to ensure the required continuity across interelement boundaries. The data structures needed to enforce such continuity for variable-degree approximations and hanging nodes have attained a high degree of sophistication; see, for example, [21, 22]. On the other hand, if we use the hybridized version of the CG method (1.5), there is no need to enforce any continuity constraint at all. We apply CG on each element without caring about continuity restrictions, as the continuity is automatically enforced by the equations of the method, provided we pick a suitable Lagrange multiplier space $M_h(0)$.

The paper is organized as follows. In section 2, we present the hybridized CG method and briefly discuss the result characterizing λ_h as the unique solution of (1.5). We also discuss extensions to the variable-degree case and hanging nodes. In section 3, we describe the construction of $\boldsymbol{H}(\mathrm{div}, \Omega)$-conforming approximation to the flux. We state the error estimates of the flux approximation and the results on the relationship between our method and the corresponding RT mixed method. We explain how to explicitly construct a local basis for the space required to compute a single-valued numerical flux trace. An estimate of the conditioning of the global system that arises also appears in this section. In section 4, we give all the proofs of the theorems. A numerical study of the approximation properties of these approximations is presented in section 5. We end with some concluding remarks in section 6.

2. Characterization of the Lagrange multiplier. We begin this section by hybridizing the CG method. We then state, discuss, and prove the main result of this section, Theorem 2.1, which characterizes the Lagrange multiplier.

2.1. The hybridized CG method. To hybridize the CG method, we relax the continuity restriction and impose it back through suitably chosen new equations. Since the continuity restriction is enforced in the sets $\mathsf{V}_h(\cdot)$, to relax it means to work instead with the space

$$V_h = \left\{ v \in L^2(\Omega) : v|_K \in \mathcal{P}_k(K) \quad \text{for all} \quad K \in \mathcal{T}_h \right\}. \tag{2.1a}$$

The new approximation U_h in V_h must, however, coincide with u_h, which means, in particular, that it has to be continuous. To enforce the continuity of U_h across interelement boundaries, we force U_h to be equal to the Lagrange multiplier λ_h, which we take in

$$M_h(g) = \{\mu \in \mathcal{C}^0(\mathcal{E}_h) : \ \mu|e \in \mathcal{P}_k(e) \quad \text{for all } e \in \mathcal{E}_h, \mu = g \text{ on } \Gamma_D\}, \tag{2.1b}$$

where

$$\mathcal{E}_h = \{e : e \text{ is a face of } K \text{ for all } K \in \mathcal{T}_h\}. \tag{2.1c}$$

Notice that we are implicitly assuming that the triangulation $\mathcal{T}_h$ does not have hanging nodes. To ensure that $U_h = u_h$, we are going to use an auxiliary variable which approximates $\boldsymbol{q} \cdot \boldsymbol{n} = -a\nabla u \cdot \boldsymbol{n}$ on ∂K for each element K. This additional variable is denoted by $q_{n,h}$ and will be taken in the space

$$W_h = \left\{ p \in L^2(\{\partial K : \ K \in \mathcal{T}_h\}) : \ p|_{\partial K} = v|_{\partial K} \quad \text{for } v \in V_h \right\}. \tag{2.1d}$$

Note that $p \in W_h$ is double-valued in the interior faces of the elements $K \in \mathcal{T}_h$. Thus the hybridized method seeks an approximation to $(u|_{K\in\mathcal{T}_h}, u|_{\mathcal{E}_h}, \boldsymbol{q}\cdot\boldsymbol{n}|_{\partial K, K\in\mathcal{T}_h})$, $(U_h, \lambda_h, q_{n,h})$ in the space $V_h \times M_h(g) \times W_h$. It is defined by

$$\sum_{K\in\mathcal{T}_h} (a\nabla U_h, \nabla v)_K + \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} = (f, v)_\Omega \qquad \text{for all } v \in V_h, \tag{2.2a}$$

$$U_h = \lambda_h \qquad \text{on } \mathcal{E}_h, \tag{2.2b}$$

$$\sum_{K\in\mathcal{T}_h} \langle q_{n,h}, \mu\rangle_{\partial K} = \langle \mathsf{q_N}\,,\, \mu\rangle_{\Gamma_N} \qquad \text{for all } \mu \in M_h(0). \tag{2.2c}$$

Notice that, by the definition of the space $M_h(0)$, (2.1b), $\mu = v|_{\mathcal{E}_h}$ belongs to $M_h(0)$ whenever $v \in \mathsf{V}_h(0)$. This implies that the last equation can be rewritten as

$$\langle [\![q_{n,h}]\!], v\rangle_{\mathcal{E}_h} = \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N} \qquad \text{for all } v \in \mathsf{V}_h(0),$$

where the *jump* of the approximate normal component of the flux is

$$[\![q_{n,h}]\!] := \begin{cases} q_{n,h}|_{\partial K^+} + q_{n,h}|_{\partial K^-} & \text{on the face } e = \partial K^+ \cap \partial K^-, \\ q_{n,h} & \text{on the face } e = \partial K \cap \partial\Omega. \end{cases}$$

We thus see that it enforces a weak continuity of the interelement boundary of the jump of this variable; this is why we call it the *jump condition*. Next, we see that this condition ensures that $U_h = u_h$.

PROPOSITION 2.1. *There exists a unique function $(U_h, \lambda_h, q_{n,h})$ in the space $V_h \times M_h(g) \times W_h$ satisfying the formulation* (2.2)*. Moreover,*

$$U_h = u_h \text{ on } \Omega \quad \text{and} \quad \lambda_h = u_h \text{ on } \mathcal{E}_h.$$

Proof. Since $\lambda_h \in M_h(g)$ and $U_h \in V_h$, we have that $U_h \in \mathsf{V}_h(g)$. Moreover, since $\mathsf{V}_h(0) \subset V_h$, by (2.2a) we have

$$(a\nabla U_h, \nabla v)_\Omega + \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} = (f, v)_\Omega \qquad \text{for all } v \in \mathsf{V}_h(0),$$

and, by the jump condition (2.2c),

$$(a\nabla U_h, \nabla v)_\Omega = (f, v)_\Omega - \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N} \qquad \text{for all } v \in \mathsf{V}_h(0).$$

By the uniqueness of the approximate of the CG method, we immediately obtain that $U_h = u_h$ on Ω and, as a consequence, that $\lambda_h = u_h$ on $\mathcal{E}_h$.

It only remains to prove that the function $q_{n,h}$ exists and is unique. This is equivalent to proving that the trivial solution is the only solution of

$$\sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} = 0 \qquad \text{for all } v \in V_h\,.$$

Since $q_{n,h} \in W_h$, there is a $w \in V_h$ such that $q_{n,h} = w$. Taking $v = w$ in the above equation, we conclude that $q_{n,h} \equiv 0$, as desired. This completes the proof. ∎

2.2. Characterization of the Lagrange multiplier $\boldsymbol{\lambda_h}$. Next, we show how to eliminate the unknowns U_h and $q_{n,h}$ from (2.2) and obtain a formulation only for λ_h. The discussion here is a straightforward generalization of well-known results in domain decomposition [5] to the case when subdomains are reduced to elements. Analogous to the discrete harmonic extensions of [5], we now define a local lifting.

The lifting associates to each $\mathsf{m} \in M_h(\cdot)$ the pair of functions $(\,\mathcal{U}\mathsf{m}\,, \boldsymbol{\mathcal{Q}_n}\mathsf{m}\,) \in \mathcal{P}_k(K) \times \{v|_{\partial K} : v \in \mathcal{P}_k(K)\}$ defined by requiring that

$$(a\nabla\,\mathcal{U}\mathsf{m}\,, \nabla v)_K + \langle \boldsymbol{\mathcal{Q}_n}\mathsf{m}\,, v\rangle_{\partial K} = 0 \qquad \text{for all } v \in \mathcal{P}_k(K), \tag{2.3a}$$

$$\mathcal{U}\mathsf{m} = \mathsf{m} \qquad \text{on } \partial K. \tag{2.3b}$$

In addition, we define a second local mapping that associates to the function $f \in L^2(\Omega)$ the pair of functions $(\,\mathcal{U}f\,, \boldsymbol{\mathcal{Q}_n}f\,) \in \mathcal{P}_k(K) \times \{v|_{\partial K},\ v \in \mathcal{P}_k(K)\}$ defined by

$$(a\nabla\,\mathcal{U}f\,, \nabla v)_K + \langle \boldsymbol{\mathcal{Q}_n}f\,, v\rangle_{\partial K} = (f, v)_K \qquad \text{for all } v \in \mathcal{P}_k(K), \tag{2.4a}$$

$$\mathcal{U}f = 0 \qquad \text{on } \partial K. \tag{2.4b}$$

Notice that $(\,\mathcal{U}\mathsf{m}\,, \boldsymbol{\mathcal{Q}_n}\mathsf{m}\,)$ and $(\,\mathcal{U}f\,, \boldsymbol{\mathcal{Q}_n}f\,)$ are approximations to the solutions of

$$-\operatorname{div}(a\nabla u) = 0, \qquad -\operatorname{div}(a\nabla u) = f \qquad \text{on } K, \tag{2.5a}$$

$$u = \mathsf{m}, \qquad u = 0 \qquad \text{on } \partial K. \tag{2.5b}$$

We are now ready to state the characterization of the CG solution in terms of the Lagrange multiplier, whose proof is at the end of this section.

THEOREM 2.1. *Let $(U_h, \lambda_h, q_{n,h})$ be the solution of the hybridized version of the* CG *method. Then*

$$U_h = \mathcal{U}\lambda_h + \mathcal{U}f \quad \textit{and} \quad q_{n,h} = \boldsymbol{\mathcal{Q}_n}\lambda_h + \boldsymbol{\mathcal{Q}_n}f\,.$$

Moreover, the Lagrange multiplier $\lambda_h \in M_h(g)$ is the unique solution of

$$\sum_{K\in\mathcal{T}_h} (a\,\nabla\,\mathcal{U}\lambda_h, \nabla\,\mathcal{U}\mu\,)_K = (f,\,\mathcal{U}\mu\,)_\Omega - \langle \mathsf{q_N}\,,\,\mu\rangle_{\Gamma_N} \qquad \textit{for all } \mu \in M_h(0).$$

Like other hybridized formulations, the utility of such a result lies in its ease of computation of a "stiffness matrix" for the Lagrange multiplier. Furthermore, once λ_h has been obtained, U_h and $q_{n,h}$ can be easily computed element by element using the local mappings (2.3) and (2.4).

It is interesting to note that $q_{n,h}|_{\partial K}$ is strongly related to what was denoted by $H^h(K)$ in [25]; in fact, when the element K does not have a face lying on the boundary, these two quantities are identical. However, in [25] they are used to uncover a local conservativity property of the CG method, whereas here we use them as an auxiliary means to hybridize it.

Finally, notice that Theorem 2.1 states that the functions $q_{n,h}|_{\partial K}$ need *not* be actually computed to construct the matrix equations for the multiplier λ_h. Indeed, from the definition of the lifting (2.3), we see that we can independently compute $\mathcal{U}\mathsf{m}$ on the element K by solving

$$(a\nabla\,\mathcal{U}\mathsf{m}\,, \nabla v)_K = 0 \qquad \text{for all } v \in \mathcal{P}_k(K) \text{ such that } v = 0 \text{ on } \partial K,$$

$$\mathcal{U}\mathsf{m} = \mathsf{m} \qquad \text{on } \partial K.$$

This implies that $\mathcal{U}\mathsf{m}$ can be written as a linear combination of

$$\dim \mathcal{P}_k(K) - \dim \mathcal{P}_{k-3}(K) = \binom{k+N}{N} - \binom{k-3+N}{N}$$

basis functions, when $k \geq 3$, of course. In two space dimensions ($N = 2$), this means that instead of working with a basis of $(k+2)(k+1)/2$ functions, we can work with a basis of only $3\,k$ functions. In three space dimensions, it means that instead of working with $(k+3)(k+2)(k+1)/6$ basis functions, we only have to work with $(3k^2+3k+2)/2$. Thus, the computation of $\mathcal{U}\mathsf{m}$ can be rendered extremely efficient, especially for high polynomial degrees k. This is especially true if the exact solution is harmonic, that is, if $f = 0$.

2.3. Variable-degree approximations and hanging nodes. The hybridized CG formulation is particularly attractive for variable-degree approximate spaces and meshes with hanging nodes.

We begin by briefly showing how to extend our previous results to the variable-degree case, that is, to the case in which the approximate solution u_h belongs to

$$\mathsf{V}_h(s) = \left\{ v \in \mathcal{C}^0(\Omega) : \ v|_K \in \mathcal{P}_{k(K)}(K), \ v = s \text{ on } \Gamma_D \right\},$$

where the polynomial degree $k(K)$ now varies with as K varies within $\mathcal{T}_h$. We can then hybridize the resulting CG method, just as we hybridized the uniform-degree CG method, if we take

$$\begin{aligned} M_h(g) &= \left\{ \mu \in \mathcal{C}^0(\mathcal{E}_h) : \ \mu|e \in \mathcal{P}_{k(e)}(e) \quad \text{for all } e \in \mathcal{E}_h, \mu = g \text{ on } \Gamma_D \right\}, \\ W_h &= \left\{ w \in L^2(\mathcal{E}_h) : w = v|_{\partial K}, \ \ v \in \mathcal{P}_{k(K)}(K) \quad \text{for all } K \in \mathcal{T}_h \right\}, \\ V_h &= \left\{ v \in L^2(\mathcal{T}_h) : v|_K \in \mathcal{P}_{k(K)}(K) \quad \text{for all } K \in \mathcal{T}_h \right\}. \end{aligned} \tag{2.6}$$

With this, the burden of enforcing the continuity constraint is automatically dealt with by the local mappings which are defined *exactly* as before with k replaced by $k(K)$. While the current practice for implementing variable-degree methods is via transitional basis functions and the minimum degree rule [21], the above hybridization approach removes the continuity matching considerations from the design of shape functions.

To end this subsection, let us briefly address the case of hanging nodes, which is also surprisingly simple to handle by hybridization, even in three dimensions. We only have to define the multiplier space $M_h(g)$ in a suitable way. In fact, we can continue to define $M_h(g)$ by (2.6) provided we redefine the set $\mathcal{E}_h$ there. To do this, we need to introduce the notion of a *maximal face*. A face e of an element $K \in \mathcal{T}_h$ is said to be a maximal face of the triangulation $\mathcal{T}_h$ if it lies on $\partial\Omega$ or whenever there is another element $K' \in \mathcal{T}_h$ such that $e \cap \partial K'$ has nonzero $(N-1)$-Lebesgue measure, $e \cap \partial K'$ is a face of K'. An illustration is given in Figure 3. The new definition of $\mathcal{E}_h$ is simply

$$\mathcal{E}_h = \{ e : e \text{ is a maximal face of the triangulation } \mathcal{T}_h \}. \tag{2.7}$$

2.4. Proof of Theorem 2.1. To prove this result, we need the following lemma.

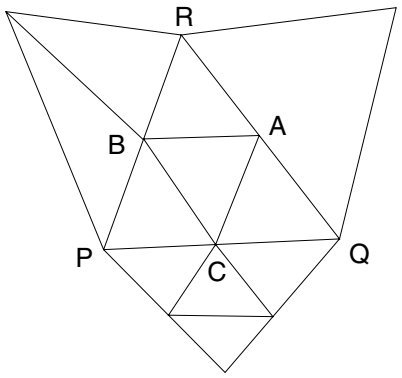

FIG. 3. *Detail of a triangulation. The faces RQ, BR, and AB are maximal, whereas the faces RA and AQ are not.*

LEMMA 2.2 (elementary identities). *We have, for any* $\mathsf{m} \in M_h(\cdot)$, $\mu \in M_h(0)$, *and* $f \in L^2(\Omega)$,

$$\text{(i)} \quad -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n}\mathsf{m}\,,\mu\rangle_{\partial K} = \sum_{K\in\mathcal{T}_h} (a\nabla\,\mathcal{U}\mathsf{m}\,,\nabla\,\mathcal{U}\mu\,)_K\,,$$

$$\text{(ii)} \quad -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n} f\,,\mu\rangle_{\partial K} = -\,(f,\,\mathcal{U}\mu\,)_\Omega\,.$$

Proof. We have

$$\begin{aligned} -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n}\mathsf{m}\,,\mu\rangle_{\partial K} &= -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n}\mathsf{m}\,,\,\mathcal{U}\mu\,\rangle_{\partial K} \qquad \text{by (2.3b)},\\ &= \sum_{K\in\mathcal{T}_h} (a\nabla\,\mathcal{U}\mathsf{m}\,,\nabla\,\mathcal{U}\mu\,)_K \qquad \text{by (2.3a)}. \end{aligned}$$

This proves the first identity.

Let us prove the second identity. We have

$$\begin{aligned} -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n} f\,,\mu\rangle_{\partial K} &= -\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n} f\,,\,\mathcal{U}\mu\,\rangle_{\partial K} && \text{by (2.3b)},\\ &= -\,(f,\,\mathcal{U}\mu\,)_\Omega + \sum_{K\in\mathcal{T}_h} (a\nabla\,\mathcal{U}f\,,\nabla\,\mathcal{U}\mu\,)_K && \text{by (2.4a)},\\ &= -\,(f,\,\mathcal{U}\mu\,)_\Omega + \sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n}\mu\,,\,\mathcal{U}f\,\rangle_{\partial K} && \text{by (2.3a)},\\ &= -\,(f,\,\mathcal{U}\mu\,)_\Omega && \text{by (2.4b)}. \end{aligned}$$

This completes the proof. ∎

Proof of Theorem 2.1. By the definition of the local mappings, we have that

$$U_h = \mathcal{U}\lambda_h + \mathcal{U}f \quad \text{and} \quad q_{n,h} = \boldsymbol{\Omega_n}\lambda_h + \boldsymbol{\Omega_n} f\,.$$

This implies that the third equation in the definition of the hybridized version of the CG method (2.2c) can be rewritten as

$$\sum_{K\in\mathcal{T}_h} \langle \boldsymbol{\Omega_n}\lambda_h + \boldsymbol{\Omega_n} f\,,\mu\rangle_{\partial K} = \langle \mathsf{q_N}\,,\,v\rangle_{\Gamma_N} \quad \text{for all } \mu \in M_h(0),$$

or, by Lemma 2.2, as

$$-\sum_{K\in\mathcal{T}_h} (a\nabla\,\mathcal{U}\lambda_h\,,\nabla\,\mathcal{U}\mu\,)_K + (f,\,\mathcal{U}\mu\,)_\Omega = \langle \mathsf{q_N}\,,\,v\rangle_{\Gamma_N}.$$

This completes the proof. □.

3. An $\boldsymbol{H}(\mathrm{div},\Omega)$-conforming approximation of the flux. In this section, we define an $\boldsymbol{H}(\mathrm{div},\Omega)$-conforming approximation, $\boldsymbol{q}_h$, to the flux $\boldsymbol{q} = -a\nabla u$. Then we state, discuss, and prove a theorem about the quality of the resulting approximation as well as the complexity of the algorithm needed to compute it. Although all considerations in this section hold for the variable degree case, for simplicity we restrict ourselves to the uniform degree case spaces defined in (2.1) with no hanging nodes.

3.1. The new approximation to the flux. The key step in the construction of an $\boldsymbol{H}(\mathrm{div},\Omega)$-conforming approximation $\boldsymbol{q}_h$ is the definition of its normal component on the element interfaces. The function $q_{n,h}$ represents an approximation to the normal component of the flux, but unfortunately it is not a single-valued function in general. Notice, however, that by (2.2a), we have

$$\sum_{K\in\mathcal{T}_h} (a\nabla U_h,\nabla v)_K + \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} = (f,v)_\Omega \quad \text{for all } v\in V_h,$$

so the possibility of constructing a single-valued function $\widehat{\boldsymbol{q}}_h$ satisfying

$$\sum_{K\in\mathcal{T}_h} \langle \widehat{\boldsymbol{q}}_h\cdot\boldsymbol{n},\, v\rangle_{\partial K} = \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} \quad \text{for all } v\in V_h \tag{3.1}$$

opens up. If such a $\widehat{\boldsymbol{q}}_h$ could be constructed, we could then define the approximate flux $\boldsymbol{q}_h$ as follows: On any simplicial element K, we can set $\boldsymbol{q}_h$ in the RT space

$$V_{RT_\ell}(K) := \mathcal{P}_\ell(K)^N + \boldsymbol{x}\,\mathcal{P}_\ell(K) \tag{3.2a}$$

by requiring that

$$\langle \boldsymbol{q}_h\cdot\boldsymbol{n}, v\rangle_e = \langle \widehat{\boldsymbol{q}}_h\cdot\boldsymbol{n}, v\rangle_e \qquad \text{for all } v\in\mathcal{P}_\ell(e) \text{ for any face } e\subset\partial K, \tag{3.2b}$$

$$(\boldsymbol{q}_h,\boldsymbol{v})_K = -(a\nabla U_h,\boldsymbol{v})_K \quad \text{for all } \boldsymbol{v}\in\mathcal{P}_{\ell-1}(K)^N. \tag{3.2c}$$

Note that the definition (3.2) is a modification of the well-known RT projection, (see (3.12) later). A similar projection was suggested in [4] in the framework of the interior penalty method for Darcy's law and in [19] in the framework of local discontinuous Galerkin methods for the Navier–Stokes equations. It is not difficult to show that a $\boldsymbol{q}_h$ constructed by (3.2b) belongs to $\boldsymbol{H}(\mathrm{div},\Omega)$, thanks to the single-valuedness of the normal component of the numerical trace $\widehat{\boldsymbol{q}}_h$.

Such a construction will yield a flux $\boldsymbol{q}_h$ that is conservative whenever $\ell\le k$. Indeed, we can rewrite (2.2a) as

$$-\sum_{K\in\mathcal{T}_h} (\boldsymbol{q}_h,\nabla v)_K + \sum_{K\in\mathcal{T}_h} \langle \boldsymbol{q}_h\cdot\boldsymbol{n}, v\rangle_{\partial K} = (f,v)_\Omega$$

for all v such that $v|_K\in\mathcal{P}_\ell(K)$ for all $K\in\mathcal{T}_h$. Hence, if we take v to be the characteristic function of a discrete subdomain D_h formed by the union of some elements $K\in\mathcal{T}_h$, we obtain

$$\langle \boldsymbol{q}_h\cdot\boldsymbol{n}, 1\rangle_{\partial D_h} = (f,1)_{D_h},$$

which is the same as the exact conservation property (1.4).

It is interesting to see that there is an extremely simple relation between the normal component of $\boldsymbol{q}_h$ and the approximation $H^h(\cdot)$ defined in [25] or, equivalently, what is called $\tilde{\sigma}_h$ in [9]. Indeed, if D is any union of elements $K \in \mathcal{T}_h$, then from the definition of $\boldsymbol{q}_h$ and that of $H^h(D)$ (see equations (47) and (57) in [25]), we have that

$$\langle \boldsymbol{q}_h \cdot \boldsymbol{n} - H^h(D)\,,\, v\rangle_{\partial D} = 0 \quad \text{for all } v \in V_{h,D} := \{v \in V_h \cap \mathcal{C}^0(D)\}.$$

Since $H^h(D)|_{\partial D}$ belongs to the space of traces on ∂D of the functions in $V_{h,D}$, we see that $H^h(D)$ is the L^2-projection of $\boldsymbol{q}_h \cdot \boldsymbol{n}$ into such space.

3.2. The numerical trace $\widehat{\boldsymbol{q}}_h$. It remains to find the numerical trace $\widehat{\boldsymbol{q}}_h$. To do that, we first notice that if $\widehat{\boldsymbol{q}}_h$ is single valued, then (3.1) takes the form

$$\langle \widehat{\boldsymbol{q}}_h\,,\, [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h} = \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} \quad \text{for all } v \in V_h.$$

Since the flux on Γ_N is given to be $\mathsf{q_N}$, incorporating this information into the above equation, we get

$$\langle \widehat{\boldsymbol{q}}_h\,,\, [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} = \sum_{K\in\mathcal{T}_h} \langle q_{n,h}, v\rangle_{\partial K} - \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N} \quad \text{for all } v \in V_h. \tag{3.3}$$

In the one-dimensional case $\Omega = (0,1)$, this equation can be readily solved. Indeed, we have that

$$\widehat{\boldsymbol{q}}_h(x_i) = \begin{cases} q_{n,h}(1^-) & \text{if } x_i = 1,\\ q_{n,h}(x_i^-) = -q_{n,h}(x_i^+) & \text{if } x_i \text{ is an interior node},\\ -q_{n,h}(0^+) & \text{if } x_i = 0, \end{cases}$$

where we have used the fact that, by (2.2c), $q_{n,h}(x_i^-) + q_{n,h}(x_i^+) = 0$ on all interior nodes x_i. Let us find expressions for $q_{n,h}$ in terms of the data f and u_h. By (2.2c), $q_{n,h} = \mathsf{q_N}$ on Γ_N, and we get that

$$\widehat{\boldsymbol{q}}_h = \mathsf{q_N} \quad \text{on } \Gamma_N.$$

To find $q_{n,h}$ in the remaining nodes, we simply use (2.2a). Thus, if we let x_i be any node not lying on Γ_N, and let φ_i^+ (resp., φ_i^-) be the linear function with support the interval $I_i^+ = (x_i, x_{i+1})$ (resp., $I_i^- = (x_{i-1}, x_i)$) such that $\varphi_i^+(x_i) = 1$ and $\varphi_i^+(x_{i+1}) = 0$ (resp., $\varphi_i^-(x_i) = 1$ and $\varphi_i^-(x_{i-1}) = 0$), we obtain that

$$\widehat{\boldsymbol{q}}_h(x_i) = \mp\left(a\frac{d}{dx}u_h, \frac{d}{dx}\varphi_i^{\pm}\right)_{I_i^{\pm}} \pm (f, \varphi_i^{\pm})_{I_i^{\pm}}.$$

These expressions have been known for a long time; see the work by J. Wheeler [33] and M. Wheeler [34]. Moreover, in [34], it was shown that the approximation $\widehat{\boldsymbol{q}}_h$ superconverges with order $2\,k$ if the CG method uses polynomials of degree k and is exact, that is,

$$\widehat{\boldsymbol{q}}_h(x_i) = -a\frac{d}{dx}u(x_i),$$

whenever a is a constant.

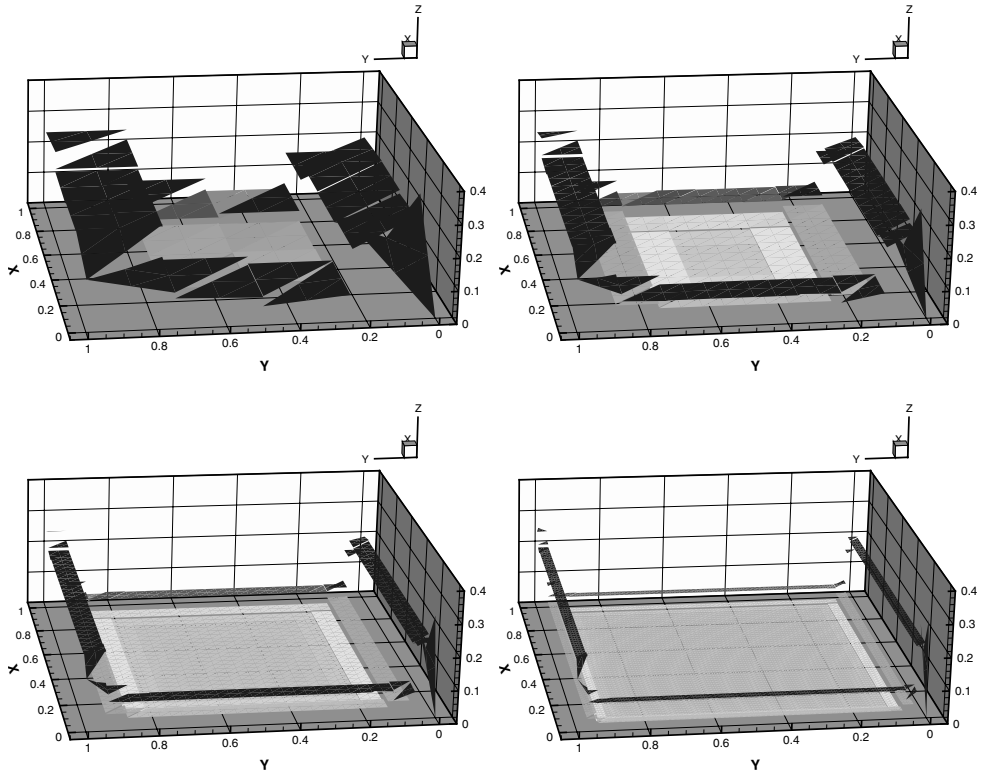

FIG. 4. *Plots of the error* $|\boldsymbol{q} - \boldsymbol{q}_h|$ *with the wrong flux trace choice on successively refined meshes. Computational details: Here* $\boldsymbol{q}_h$ *is obtained by* (3.2) *with* $\widehat{\boldsymbol{q}}_h$ *chosen as the unique function in* $\mathfrak{J}_h$ *satisfying* (3.3). *The parameters are* $a = \mathrm{Id}$, $f = 0$, $\Omega = (0,1) \times (0,1)$, $\Gamma_D = \{0\} \times (0,1)$, *the polynomial degrees are* $k = 1$ *and* $\ell = k - 1$ *(for postprocessing), and the boundary conditions are set in such a way that the exact solution is* $u(x,y) = 1 + x$. *We see that while the error is small far from the boundary, near the boundary the error remains of order one. Therefore, we expect to see an order of convergence of* $1/2$ *in the* L^2*-norm. This is confirmed in Table* 1.

Extensions of the above approach to the multidimensional case for obtaining approximations to the normal component of $\widehat{\boldsymbol{q}}_h$ have been explored by many authors. See [9] for an overview and recent developments, [8] for early computational tricks, [11] for a fully developed technique, and [14, 28] for rigorous error estimates.

Here, we do not use this approach. Instead, we begin by noting that from the formulation (3.3) it is clear that we can only obtain a projection of $\widehat{\boldsymbol{q}}_h$ into the space of jumps

$$\mathfrak{J}_h = \{ [\![w\boldsymbol{n}]\!] |_{\mathcal{E}_h \setminus \Gamma_N} : w \in V_h \}. \tag{3.4}$$

This may seem to suggest choosing $\widehat{\boldsymbol{q}}_h$ in $\mathfrak{J}_h$. We have experimented with such a choice. The results of one such experiment are reported in Figure 4 and Table 1. We found that such a flux approximation is often reasonable away from the boundary, but near $\partial\Omega$ the degradation of the approximation is clearly evident for some problems. Furthermore, from a theoretical standpoint, such a choice appears dubious as the space $\mathfrak{J}_h$ does not contain the constant function. For these reasons, we do *not* advocate it.

The solution we found practically acceptable as well as theoretically sound proceeds by borrowing ideas from the development of the DG method. We select the

TABLE 1
The L^2-norm of the error $\boldsymbol{q} - \boldsymbol{q}_h$ when the wrong flux trace is used. The parameters are the same as those described in Figure 4.

	$k=1$		$k=2$		$k=3$	
h	Error	Order	Error	Order	Error	Order
1/8	0.11E+00	0.46	0.62E-01	0.41	0.40E-01	0.46
1/16	0.77E-01	0.48	0.45E-01	0.46	0.29E-01	0.48
1/32	0.55E-01	0.49	0.32E-01	0.48	0.21E-01	0.49
1/64	0.39E-01	0.50	0.23E-01	0.49	0.15E-01	0.50

following form for the numerical trace:

$$\widehat{\boldsymbol{q}}_h = \begin{cases} \mathsf{q}_{\mathsf{N}} \boldsymbol{n} & \text{on } \Gamma_N, \\ -a\nabla U_h + \alpha\, \boldsymbol{J}_h & \text{on } \Gamma_D, \\ -\{\!\{a\nabla U_h\}\!\} - \boldsymbol{\beta}\, [\![a\nabla U_h \cdot \boldsymbol{n}]\!] + \alpha\, \boldsymbol{J}_h & \text{on } \mathcal{E}_h \setminus \partial\Omega, \end{cases} \tag{3.5}$$

where α and $\boldsymbol{\beta}$ are single-valued bounded (resp., scalar and vector) functions on $\mathcal{E}_h \setminus \partial\Omega$, $\alpha > 0$, and $\boldsymbol{J}_h$ is an element of the space of jumps $\mathfrak{J}_h$ to be determined. A typical choice of the parameters that we have found adequate in our numerical experiments (on uniform meshes) is $\boldsymbol{\beta} \equiv \boldsymbol{0}$ and $\alpha \equiv 1$ (also see Theorem 3.2 for better choices of α on highly nonuniform meshes). Here, we have used the now standard DG notation (cf., e.g., [2]),

$$\{\!\{v\}\!\} = \begin{cases} \frac{1}{2}\,(v^+ + v^-) & \text{on } \mathcal{E}_h^\circ, \\ v & \text{on } \partial\Omega \end{cases} \tag{3.6a}$$

and

$$[\![v\,\boldsymbol{n}]\!] = \begin{cases} v^+\,\boldsymbol{n}^+ + v^-\,\boldsymbol{n}^- & \text{on } \mathcal{E}_h^\circ, \\ v\,\boldsymbol{n} & \text{on } \partial\Omega, \end{cases} \tag{3.6b}$$

where for a piecewise smooth function v, the traces from either side of a mesh face (edge) e are denoted by $v^\pm(\boldsymbol{x}) = \lim_{\epsilon \downarrow 0} v(\boldsymbol{x} - \epsilon\,\boldsymbol{n}^\pm)$ for all $\boldsymbol{x}$ in e (and $\boldsymbol{n}^\pm$ denotes the corresponding unit outward normal on e from either side).

Next, we insert the expression we have selected in (3.5) for the numerical flux $\widehat{\boldsymbol{q}}_h$ into (3.3). This gives us an equation for $\boldsymbol{J}_h$:

$$\begin{aligned} \langle \alpha\, \boldsymbol{J}_h,\ [\![v\boldsymbol{n}]\!] \rangle_{\mathcal{E}_h \setminus \Gamma_N} = {} & \langle\, \{\!\{a\nabla U_h\}\!\} + \boldsymbol{\beta}\, [\![a\nabla U_h \cdot \boldsymbol{n}]\!],\ [\![v\boldsymbol{n}]\!] \rangle_{\mathcal{E}_h \setminus \partial\Omega} \\ & + \langle a\nabla U_h,\, v\boldsymbol{n} \rangle_{\Gamma_D} + \sum_{K \in \mathcal{T}_h} \langle q_{n,h}, v \rangle_{\partial K} - \langle \mathsf{q}_{\mathsf{N}}\,,\, v \rangle_{\Gamma_N}. \end{aligned} \tag{3.7}$$

The computation of $\boldsymbol{J}_h$ from this equation requires solving a global, but well-conditioned, system. The details involved are discussed in the next subsection. For the moment, observe that if we are using the hybridized form of the CG method and have already computed U_h and $q_{n,h}$, the right-hand side of (3.7) can be computed using integrations only on element boundaries.

On the other hand, if we have computed U_h using a standard CG implementation without hybridization (and so do not have access to $q_{n,h}$), we can still use the above

postprocessing. Indeed, by using (2.2a), we can transform (3.7) into an equation that is more convenient for this case:

(3.8)
$$\langle \alpha \boldsymbol{J}_h,\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} = \langle\, \{\!\{a\nabla U_h\}\!\} + \boldsymbol{\beta}\, [\![a\nabla U_h\cdot\boldsymbol{n}]\!],\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\partial\Omega} + \langle a\nabla U_h,\, v\boldsymbol{n}\rangle_{\Gamma_D} - \sum_{K\in\mathcal{T}_h} (a\nabla U_h, \nabla v)_K + (f,v)_\Omega - \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N}.$$

Observe that whenever $[\![v\boldsymbol{n}]\!] = 0$ on $\mathcal{E}_h\setminus\Gamma_N$, i.e., whenever $v\in \mathsf{V}_h(0)$, the right-hand side of the above equation is equal to zero by the definition of the CG method, by (1.3), and by Proposition 2.1. Therefore, this equation defines $\boldsymbol{J}_h$ uniquely. When using spaces of high polynomial degrees, it is preferable to use (3.7) instead of (3.8), as the former involves faster quadratures.

This completes the definition of the numerical trace $\widehat{\boldsymbol{q}}_h$. To summarize, $\widehat{\boldsymbol{q}}_h$ is defined by (3.3), wherein $\boldsymbol{J}_h$ is the unique function in $\boldsymbol{\mathfrak{J}}_h$ satisfying (3.7) or (3.8). Let us point out that this definition of the numerical trace reproduces constant fluxes. More precisely, if $-a\nabla U_h$ is a constant vector, say $\boldsymbol{c}$, then $\widehat{\boldsymbol{q}}_h$ is also $\boldsymbol{c}$. To see this, note that in this case we must have $\mathsf{q_N} = \boldsymbol{c}\cdot\boldsymbol{n}$ and $f=0$, so that (3.8) becomes

$$\langle \alpha \boldsymbol{J}_h,\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} = -\langle \boldsymbol{c},\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} + \sum_{K\in\mathcal{T}_h} (\boldsymbol{c},\nabla v)_K - \langle \boldsymbol{c}\cdot\boldsymbol{n}\,,\, v\rangle_{\Gamma_N} = 0.$$

This implies $\boldsymbol{J}_h\equiv\boldsymbol{0}$, and hence $\widehat{\boldsymbol{q}}_h = \boldsymbol{c}$, as claimed.

Let us end this subsection by relating our approach to compute $\widehat{\boldsymbol{q}}_h$ to that proposed in [27]. In such an approach, the numerical trace $\widehat{\boldsymbol{q}}_h$ is taken as in (3.5) with $\beta=0$ and $\alpha = 1/h$, where $\boldsymbol{J}_h$ is taken in the space

$$\boldsymbol{\mathfrak{J}}_{h,0} = \{\, [\![w\boldsymbol{n}]\!]|_{\mathcal{E}_h\setminus\Gamma_N} : w|_K\in\mathcal{P}_0(K)\ \text{ for all } K\in\mathcal{T}_h\}$$

and is defined by requiring that

$$\langle \alpha \boldsymbol{J}_h,\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} = \langle\, \{\!\{a\nabla U_h\}\!\},\ [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\partial\Omega} + \langle a\nabla U_h,\, v\boldsymbol{n}\rangle_{\Gamma_D} + (f,v)_\Omega - \langle \mathsf{q_N}\,,\, v\rangle_{\Gamma_N}$$

be satisfied for all $v\in\boldsymbol{\mathfrak{J}}_{h,0}$. Note that our $\boldsymbol{J}_h$ also satisfies this formulation, in the case in which $\beta=0$ and $\alpha=1/h$, since the formulation (3.8) reduces to the one under consideration when $v\in\boldsymbol{\mathfrak{J}}_h$ is restricted to $v\in\boldsymbol{\mathfrak{J}}_{h,0}$.

3.3. The computation of $\boldsymbol{J_h}$. Next, we discuss the computation of $\boldsymbol{J}_h$ through solution of (3.7) or (3.8). First, in order to represent $\boldsymbol{J}_h$ in computations we need a basis for the space $\boldsymbol{\mathfrak{J}}_h$ of jumps. We construct a local basis for $\boldsymbol{\mathfrak{J}}_h$ extending a similar construction carried out in [17, 18] in the context of Stokes flow. Second, we need to solve for $\boldsymbol{J}_h$ from (3.7) or (3.8). We show that this can be accomplished by solving a square system whose matrix is well conditioned. Thus, we conclude that the computational complexity needed to solve for $\boldsymbol{J}_h$ is negligible with respect to that required to solve for the multiplier λ_h. Proofs of all results here are given in section 4.

The basis is easiest to see in the lowest order case (i.e., when $k=1$). In two dimensions, this basis is closely related to the "wedge" basis functions obtained in [17]. However, in three dimensions, it is different from that given in [18], so let us begin by describing our lowest order basis in three dimensions. For a mesh vertex $\boldsymbol{z}$ and a mesh element K having $\boldsymbol{z}$ as a vertex, let $\lambda_{\boldsymbol{z},K}$ denote the linear function on K which equals one on $\boldsymbol{z}$ and zero at all other vertices of K and let $\phi_{\boldsymbol{z},K}$ denote its extension

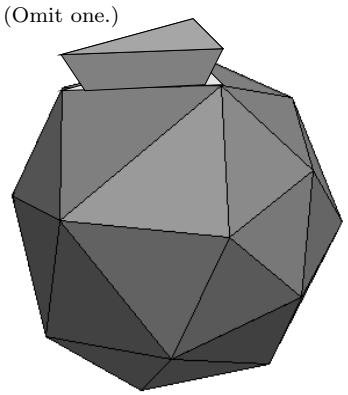

FIG. 5. *Illustration of the elements connected to one vertex* $\boldsymbol{z}$ *and the omission of one* $\phi_{z,K}$ *to construct a basis.*

by zero from K to all Ω. Then clearly the restrictions of $[\![\phi_{\boldsymbol{z},K}\boldsymbol{n}]\!]$ on $\mathcal{E}_h\backslash\Gamma_N$ are in $\mathfrak{J}_h$. However, they are not all linearly independent, because for any vertex $\boldsymbol{z}$ not on Γ_D, the sum of the functions $[\![\phi_{\boldsymbol{z},K}\boldsymbol{n}]\!]|_{\mathcal{E}_h\backslash\Gamma_N}$ over all K sharing $\boldsymbol{z}$ vanishes. Therefore, we must omit one function per vertex to get a basis: For each $\boldsymbol{z}$, we define $V_{\boldsymbol{z}}$ as the set of functions $\phi_{\boldsymbol{z},K}$ for all K having $\boldsymbol{z}$ as a vertex. Then for vertices $\boldsymbol{z}$ not on $\overline{\Gamma}_D$, we define $V_{\boldsymbol{z}}^\star$ as the set obtained by omitting (any) one member of $V_{\boldsymbol{z}}$ (see Figure 5), while for vertices on $\overline{\Gamma}_D$, we define $V_{\boldsymbol{z}}^\star = V_{\boldsymbol{z}}$. Then, by a straightforward generalization of the arguments in [17, Proposition 4.2], one can prove that the set

$$\mathfrak{B}^1 = \{\, [\![\phi\,\boldsymbol{n}]\!]\big|_{\mathcal{E}_h\backslash\Gamma_N} :\ \phi \in V_{\boldsymbol{z}}^\star \text{ for all mesh vertices } \boldsymbol{z}\}$$

is linearly independent, so it forms a basis for $\mathfrak{J}_h$.

Next, we describe one possible extension of this basis construction to the higher order case. For any given simplex $S \in \mathbb{R}^N$ with vertices $\boldsymbol{x}_{i,S}$, $i = 1, \ldots, N+1$, we define the points in its principal lattice (of order k) [13] by

$$\boldsymbol{x}_{\boldsymbol{\alpha},S} = \sum_{j=1}^{N+1} \alpha_j\, \boldsymbol{x}_{j,S},$$

where $\boldsymbol{\alpha}$ is taken in $\mathcal{A}_N^k = \{(\alpha_1, \ldots, \alpha_{N+1}) :\ k\,\alpha_j \in \{0, 1, \ldots, k\} \text{ and } \sum_{j=1}^{N+1} \alpha_j = 1\}$. We associate to each point $\boldsymbol{x}_{\boldsymbol{\alpha},S}$ the standard Lagrange finite element basis function $v_{\boldsymbol{\alpha},S}$ defined as the unique function in $\mathcal{P}_k(S)$ satisfying

$$v_{\boldsymbol{\alpha},S}(\boldsymbol{x}_{\boldsymbol{\beta},S}) = \begin{cases} 1 & \text{if } \boldsymbol{\alpha} = \boldsymbol{\beta}, \\ 0 & \text{otherwise} \end{cases}$$

for all $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ in $\mathcal{A}_N^k$. Let $\phi_{\boldsymbol{\alpha},S}$ be the extension by zero to Ω of $v_{\boldsymbol{\alpha},S}$. Since the basis will be constructed using the jumps of these functions across element interfaces, we will need to separate the functions associated to the points on element interfaces, which we collect in

$$\mathcal{G}_h^k = \{\boldsymbol{x}_{\boldsymbol{\alpha},S} \in \partial K : K \in \mathcal{T}_h, \boldsymbol{\alpha} \in \mathcal{A}_N^k\}. \tag{3.9}$$

To any $\boldsymbol{z}$ in $\mathcal{G}_h^k$, we associate more than one $\phi_{\boldsymbol{\alpha},K}$ if more than one simplex shares $\boldsymbol{z}$. We collect these functions in $V_{\boldsymbol{z}} = \{\phi_{\boldsymbol{\alpha},K} : \boldsymbol{x}_{\boldsymbol{\alpha},K} = \boldsymbol{z}\}$ and define

$$V_{\boldsymbol{z}}^\star = \begin{cases} V_{\boldsymbol{z}} & \text{if } \boldsymbol{z} \in \overline{\Gamma}_D, \\ V_{\boldsymbol{z}} \setminus \{\phi_{\boldsymbol{\alpha}^\star,K^\star} \text{ for some } \boldsymbol{x}_{\boldsymbol{\alpha}^\star,K^\star} = \boldsymbol{z}\} & \text{otherwise,} \end{cases}$$

where, as in the lowest order case, we have selected (arbitrarily) one degree of freedom (represented by the multi-index $\boldsymbol{\alpha}^\star$ and $K^\star$) for every $\boldsymbol{z}$ in $\mathcal{G}_h^k \setminus \overline{\Gamma}_D$ and omitted the corresponding Lagrange function $\phi_{\boldsymbol{\alpha}^\star,K^\star}$. With this notation, we have the following result, whose proof follows by generalizing the above-mentioned arguments for the lowest order case.

THEOREM 3.1. *The set*

$$\mathfrak{B}^k = \{ [\![\phi\, \boldsymbol{n}]\!]\big|_{\mathcal{E}_h \setminus \Gamma_N} : \phi \in V_{\boldsymbol{z}}^\star \text{ for all } \boldsymbol{z} \in \mathcal{G}_h^k\}$$

is a basis for $\mathfrak{J}_h$.

Now that a local basis of the jump space $\mathfrak{J}_h$ has been constructed, we can compute the representation of the jump function $\boldsymbol{J}_h$ in the basis $\mathfrak{B}^k$ by using (3.7) or (3.8). For example, to solve for $\boldsymbol{J}_h$ using (3.7), we begin by introducing an extension operator T_h from the space of jumps $\mathfrak{J}_h$ to the space V_h, constructed in such a way that we have

$$[\![T_h(\boldsymbol{J}_h)\, \boldsymbol{n}]\!] = \boldsymbol{J}_h \qquad \text{on } \mathcal{E}_h \setminus \Gamma_N, \tag{3.10a}$$

$$T_h(\boldsymbol{J}_h)\big|_{K^\star,\, \boldsymbol{x}_{\boldsymbol{\alpha}^\star,K^\star}} = 0. \tag{3.10b}$$

Here and elsewhere, we use the notation $w|_{K,\boldsymbol{r}}$ to denote the limit of the function $w(\boldsymbol{x})$ as $\boldsymbol{x}$ approaches $\boldsymbol{r}$ from within K. One can easily verify that the choice

$$T_h(\boldsymbol{J}_h) = \sum_{\boldsymbol{z} \in \mathcal{G}_h^k} \sum_{\phi \in V_{\boldsymbol{z}}^\star} c_\phi\, \phi \quad \text{whenever} \quad \boldsymbol{J}_h = \sum_{\boldsymbol{z} \in \mathcal{G}_h^k} \sum_{\phi \in V_{\boldsymbol{z}}^\star} c_\phi\, [\![\phi\, \boldsymbol{n}]\!] \tag{3.11}$$

satisfies both properties of (3.10). Then, for any $\boldsymbol{Y}_h \in \mathfrak{J}_h$, setting $v = T_h(\boldsymbol{Y}_h)$ in (3.7) and using (3.10a), we get that $\boldsymbol{J}_h$ satisfies

$$\begin{aligned} \langle \alpha\, \boldsymbol{J}_h,\, \boldsymbol{Y}_h \rangle_{\mathcal{E}_h \setminus \Gamma_N} &= \langle\, \{\!\{ a \nabla U_h \}\!\} + \boldsymbol{\beta}\, [\![a \nabla U_h \cdot \boldsymbol{n}]\!],\ [\![T_h(\boldsymbol{Y}_h) \boldsymbol{n}]\!] \rangle_{\mathcal{E}_h \setminus \partial\Omega} \\ &\quad + \langle a \nabla U_h,\, T_h(\boldsymbol{Y}_h) \boldsymbol{n} \rangle_{\Gamma_D} + \sum_{K \in \mathcal{T}_h} \langle q_{n,h}, T_h(\boldsymbol{Y}_h) \rangle_{\partial K} - \langle \mathsf{q}_{\mathsf{N}}\, ,\, T_h(\boldsymbol{Y}_h) \rangle_{\Gamma_N} \\ &\quad \equiv F(\boldsymbol{Y}_h). \end{aligned}$$

This shows that $\boldsymbol{J}_h$ is the unique solution of a square system.

The next result shows that this square system is well conditioned. Let $[\boldsymbol{J}_h]$ denote the vector of coefficients in the expansion of $\boldsymbol{J}_h$ in the basis $\mathfrak{B}^k$. We place some minimal assumptions on the mesh from now on. As per standard terminology, we say that the mesh $\mathcal{T}_h$ is shape regular if, letting ρ_K be the diameter of the largest ball contained in K, the ratios $\gamma_K = \operatorname{diam}(K)/\rho_K$ are uniformly bounded by some fixed constant γ for all K. If we use the parameter α on every mesh face e to scale by the measure of the face, namely, $|e|$, then we obtain a well-conditioned matrix as stated in the following theorem.

THEOREM 3.2. *Let M be the matrix defined by*

$$[\boldsymbol{Y}_h]^t M [\boldsymbol{Z}_h] = \langle \alpha\, \boldsymbol{Z}_h, \boldsymbol{Y}_h \rangle_{\mathcal{E}_h \setminus \Gamma_N} \qquad \textit{for all } \boldsymbol{Y}_h \textit{ and } \boldsymbol{Z}_h \in \mathfrak{J}_h\,.$$

TABLE 2
Condition number of M with $\alpha \equiv 1$ for different mesh levels using different polynomial approximations.

h	1	1/2	1/4	1/8	1/16	1/32
$k=1$	3.4	5.7	6.8	7.3	7.5	7.5
$k=2$	2.0	3.4	5.9	7.5	8.7	10.4
$k=3$	2.1	5.8	5.7	8.6	11.8	10.9

Then, whenever

$$\alpha|_e = \frac{\zeta|_e}{|e|} \quad \text{on } e \in \mathcal{E}_h \setminus \Gamma_N$$

for some piecewise constant function ζ on $\mathcal{E}_h \setminus \Gamma_N$ satisfying $0 < \zeta_\star \le \zeta \le \zeta^\star$, the spectral condition number of M, namely, κ_M, is uniformly bounded by

$$\kappa_M \le C_0\, \zeta^\star/\zeta_\star,$$

where $C_0 > 0$ is independent of the number of mesh elements (but depends on the space dimension N, the polynomial degree k, and the shape regularity constant γ).

This theorem implies that to compute the solution $\boldsymbol{J}_h$ of (3.7) by the method of conjugate gradients, we need a number of iterations that is independent of the number of unknowns. In Table 2, we numerically verify this fact for $k = 1, 2$, and 3 on a sequence of uniform meshes. Since the meshes are uniform, we have simply taken $\alpha \equiv 1$ for this computation. Notice that, as expected, the condition numbers observed do not vary significantly as the mesh size h is reduced. For practical computations, one often uses the method of conjugate gradients to solve for the Lagrange multiplier λ_h. Since the system for λ_h has condition number $O(h^{-2})$ (cf. [24]) without any preconditioner, it is clear that the cost of computing $\boldsymbol{J}_h$ is a negligible addition to the cost of solving for λ_h.

3.4. Error analysis. In this subsection, we give a priori error estimates for our new postprocessed flux approximation $\boldsymbol{q}_h$. Recall that $\boldsymbol{q}_h$ is computed by the following steps:

1. Compute the CG solution U_h.
2. Using this U_h in (3.7), compute the unique function $\boldsymbol{J}_h$ in $\mathfrak{J}_h$ satisfying (3.7).
3. Set the flux trace $\widehat{\boldsymbol{q}}_h$ by substituting the $\boldsymbol{J}_h$ computed above in (3.3).
4. Solve for $\boldsymbol{q}_h$ element by element using (3.2), with the data set by the U_h and $\widehat{\boldsymbol{q}}_h$ computed above.

Notice that the last step involves equations very similar to the well-known RT projection defined as follows: We denote by $\pi_\ell\, \boldsymbol{q}$ the RT projection [29] of the function $\boldsymbol{q}$, which is the unique function in

$$V_{RT_\ell}(K) := \mathcal{P}_\ell(K)^N + \boldsymbol{x}\, \mathcal{P}_\ell(K), \tag{3.12a}$$

satisfying

$$\langle \pi_\ell\, \boldsymbol{q} \cdot \boldsymbol{n}, v\rangle_e = \langle \boldsymbol{q} \cdot \boldsymbol{n}, v\rangle_e \text{ for all } v \in \mathcal{P}_\ell(e) \text{ for any face } e \subset \partial K, \tag{3.12b}$$

$$(\pi_\ell\, \boldsymbol{q}, \boldsymbol{v})_K = (\boldsymbol{q}, \boldsymbol{v})_K \quad \text{for all } \boldsymbol{v} \in \mathcal{P}_{\ell-1}(K)^N. \tag{3.12c}$$

It is well known [6] that the domain of definition of π_ℓ is slightly smaller than $\boldsymbol{H}(\mathrm{div},\Omega)$. We shall tacitly assume that the exact flux $\boldsymbol{q}$ is smooth enough so that π_ℓ can be applied to it (e.g., $\boldsymbol{q}$ in $\boldsymbol{H}(\mathrm{div},\Omega)\cap L^p(\Omega)$ with $p>2$ is enough when $N=2$). Because of the similarity of (3.12) to (3.2), we shall refer to our flux approximation $\boldsymbol{q}_h$ as the *RT_ℓ-postprocessed CG_k flux.*

To describe our error estimates for this flux approximation, we need the following notation. We set $\mathrm{diam}(K)=h_K$, and h is the maximum of h_K over all K in $\mathcal{T}_h$. For Sobolev norms, we denote by $\|\cdot\|_{\ell,\mathcal{D}}$ and $|\cdot|_{\ell,\mathcal{D}}$ the H^ℓ-norm and seminorm, respectively, on $\mathcal{D}$. We also set

(3.13a)
$$\boldsymbol{\mathcal{V}}^0_{h,\ell} := \{\boldsymbol{v}\in\boldsymbol{H}(\mathrm{div},\Omega):\ \nabla\cdot\boldsymbol{v}=0, \boldsymbol{v}|_K\in\mathcal{P}_\ell(K)^N \text{ for all } K\in\mathcal{T}_h, \boldsymbol{v}\cdot\boldsymbol{n}|_{\Gamma_N}=0\},$$

and denote by $\mathbb{P}_\ell$ the weighted L^2-projection into $\boldsymbol{\mathcal{V}}^0_{h,\ell}$ defined by

(3.13b)
$$(a^{-1}(\mathbb{P}_\ell\,\boldsymbol{q}-\boldsymbol{q}),\boldsymbol{v})_\Omega=0 \qquad \text{for all } \boldsymbol{v}\in\boldsymbol{\mathcal{V}}^0_{h,\ell}.$$

Finally, we set $\alpha^\star := \max_{e\in\mathcal{E}_h\setminus\Gamma_N}\alpha|_e$ and $\alpha_\star := \min_{e\in\mathcal{E}_h\setminus\Gamma_N}\alpha|_e$. With these notations, we have the following result.

THEOREM 3.3. *Let $\boldsymbol{q}_h$ be the RT_ℓ-postprocessed CG_k flux for an integer $0\le\ell\le k$. Then the following statements hold:*

1. *The RT_ℓ-postprocessed CG_k flux $\boldsymbol{q}_h$ is in $\boldsymbol{H}(\mathrm{div},\Omega)$ and satisfies*
$$\mathrm{div}(\pi_\ell\,\boldsymbol{q}-\boldsymbol{q}_h)=0.$$
In particular, it satisfies the exact conservativity property (1.4).
2. *If $\ell>1$ and $a(\boldsymbol{x})$ is constant on each mesh element, $\mathbb{P}_{\ell-1}(\pi_\ell\,\boldsymbol{q}-\boldsymbol{q}_h)=0$.*
3. *The divergence of the flux approximation satisfies*
$$\|\nabla\cdot(\boldsymbol{q}-\boldsymbol{q}_h)\|_{0,\Omega}\le C_1 h^{\min(\ell,s)+1}\,|\,f\,|_{s+1,\Omega}.$$
4. *If $a(\boldsymbol{x})|_K$ is in $W^{1,\infty}(K)$ for all mesh elements K, and the mesh $\mathcal{T}_h$ is quasi uniform, then the following error estimate holds:*
$$\|\boldsymbol{q}-\boldsymbol{q}_h\|_{0,\Omega}\ \le\ C_2 h^{\min(k,\,\ell+1,s)}\big(|\,\boldsymbol{q}\,|_{s,\Omega}+|u|_{s,\Omega}\big).$$

In the inequalities above, C_1 and $C_2/(1+\alpha^\star/\alpha_\star)$ are independent of $\boldsymbol{q}$ and h (but dependent on k, N, $\boldsymbol{\beta}$, a, and γ).

The first identity of the theorem can be interpreted as a superconvergence property for the divergence. Indeed, if the load f is a piecewise polynomial satisfying $f|_K\in\mathcal{P}_\ell(K)$, then the exact and discrete divergences coincide, i.e., $\mathrm{div}(\boldsymbol{q}-\boldsymbol{q}_h)=0$, because of a well-known commutativity property of π_ℓ. In one space dimension, it states that the difference between $\pi_\ell\boldsymbol{q}$ and $\boldsymbol{q}_h$ is just a constant; moreover, if the Neumann boundary is not empty, $\pi_\ell\boldsymbol{q}$ and $\boldsymbol{q}_h$ are *identical*. This implies that at each node x_i we have that

$$\boldsymbol{q}_h(x_i)=\boldsymbol{q}(x_i),$$

by definition of the projection π_ℓ. The fact that this holds independently of how we chose the parameter $\boldsymbol{\beta}$ in (3.5) is remarkable, although this fits very well with similar results obtained in [12]. Notice also that when the Neumann boundary is empty but

a is piecewise constant, the second identity states that $\pi_\ell \boldsymbol{q}$ and $\boldsymbol{q}_h$ are also identical, provided $\ell \geq 1$.

Next, we compare our approximation $\boldsymbol{q}_h$ to the corresponding RT approximation. We begin by recalling the standard result that *all statements of Theorem* 3.3 *continue to hold if we replace* $\boldsymbol{q}$ *by the approximation to the flux given by the* RT_ℓ *method;* i.e., both the standard RT_{k-1} method and our new RT_{k-1}-postprocessed CG_k method produce $H(\mathrm{div})$-conforming approximations to the flux $\boldsymbol{q}$ that converge at the same order. This indicates that the RT_{k-1}-postprocessed CG_k method is competitive with the RT_{k-1} method. Indeed, to compare their computational complexities, we recall the earlier observation that the cost of the computation of our approximation $\boldsymbol{q}_h$ is negligible compared to that of solving for the Lagrange multiplier λ_h. The condition number of the Lagrange multiplier system in the CG case as well as the RT case [24] is $O(h^{-2})$, so in both cases, the cost of solving for λ_h dominates the cost of the computation of $\boldsymbol{q}_h$. Thus the relative size of the stiffness matrices for the Lagrange multiplier becomes the deciding factor.

It is not difficult to see that this matrix for the CG_k method has smaller size than that of the RT_{k-1} method. Let us show this in the case of a two-dimensional simply connected domain Ω. We denote the number of mesh vertices, edges, and triangles by n_e, n_v, and n_t, respectively. The number of degrees of freedom of the Lagrange multipliers for the CG_k method is $(k-1)n_e + n_v$, whereas it is kn_e for the RT_{k-1} method. Since $n_v - n_e + n_t = 1$, we see that the Lagrange multipliers of the CG_k method have $(n_t - 1)$ fewer degrees of freedom than RT_{k-1}. This is a significant difference in practice. The numerical experiments of section 5 show that for the same mesh, the approximations given by the RT_{k-1}-postprocessed CG_k method and the RT_{k-1} method are very similar. This shows that the former method may be better than the latter. A final point reinforcing this conclusion is obtained by comparing the approximation to u given by both methods. The u_h of the CG_k method converges in the L^2-norm with order $k+1$ when the exact solution is smooth. However, the approximation to u given by the RT_{k-1} method converges only with order k. Of course, following [1], we can use the Lagrange multipliers to obtain a locally postprocessed approximation that also converges with order $k+1$, but such postprocessing is not available for arbitrary values of k. Moreover, our numerical results show that for $k \in \{0, 1, 2\}$, the CG_k and the postprocessed RT_{k-1} methods produce roughly similar approximations to u.

4. Proofs.

4.1. Norm equivalences. In this subsection, we will prove the condition number estimate of Theorem 3.2 using certain norm equivalences. Recall that the extension operator T_h is defined in (3.10) and that $[\boldsymbol{J}_h]$ is the vector representation of the function $\boldsymbol{J}_h$ in the basis $\mathfrak{B}^k$. Define the norms

$$\|\boldsymbol{J}_h\|_S = \left(\sum_{e \in \mathcal{E}_h \setminus \Gamma_N} \frac{1}{|e|} \|\boldsymbol{J}_h\|_{0,e}^2 \right)^{1/2} \quad \text{and} \quad \|\boldsymbol{J}_h\|_T = \left(\sum_{K \in \mathcal{T}_h} \frac{1}{|K|} \|T(\boldsymbol{J}_h)\|_{0,K}^2 \right)^{1/2},$$

where $|K|$ and $|e|$ denote the measures (in their respective dimensions) of an element K and face e, respectively. The following lemma shows that the three norms $\|\boldsymbol{J}_h\|_S$, $\|\boldsymbol{J}_h\|_T$, and $\|\,[\boldsymbol{J}_h]\,\|_{\ell^2}^2$ are equivalent.

LEMMA 4.1. *There is a constant C independent of the mesh size (but depending on the degree k, dimension N, and the shape regularity constant γ) such that*

$$\frac{1}{C}\,\|\boldsymbol{J}_h\|_T^2 \;\le\; \|\boldsymbol{J}_h\|_S^2 \;\le\; C\,\|\boldsymbol{J}_h\|_T^2 \tag{4.1}$$

and

$$\frac{1}{C}\,\|\boldsymbol{J}_h\|_S^2 \;\le\; \big\|\,[\boldsymbol{J}_h]\,\big\|_{\ell^2}^2 \;\le\; C\,\|\boldsymbol{J}_h\|_S^2 \tag{4.2}$$

for all $\boldsymbol{J}_h \in \mathfrak{J}_h$.

Proof. First, let us prove the upper bound of (4.1). Recall that by (3.10a), $\boldsymbol{J}_h$ and $[\![T_h(\boldsymbol{J}_h)\,\boldsymbol{n}]\!]$ coincide for any $\boldsymbol{J}_h$ in $\mathfrak{J}_h$, so by standard trace inequalities,

$$\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2 \le C\sum_{K\in\mathcal{K}_e}\frac{1}{|K|}\big\|T_h(\boldsymbol{J}_h)\big\|_{0,K}^2, \tag{4.3}$$

where $\mathcal{K}_e$ denotes the set of elements $K \in \mathcal{T}_h$ such that e is a face of K. Since $\mathcal{K}_e$ has at most two elements for any mesh face e, summing over all edges in $\mathcal{E}_h \setminus \Gamma_N$, we obtain the upper bound in (4.1).

Next, let us prove the lower bound of (4.1). By standard scaling arguments using the principal lattice $\mathcal{A}_N^k$ on any mesh element K, we have

$$\begin{aligned}\frac{C}{|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2 &\le \sum_{\boldsymbol{\alpha}\in\mathcal{A}_N^k}\big|(T_h(\boldsymbol{J}_h))(\boldsymbol{x}_{\boldsymbol{\alpha},K})\big|^2\\ &= \sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K} T_h(\boldsymbol{J}_h)\big|_{K,\boldsymbol{z}}^2,\end{aligned} \tag{4.4}$$

where, as before, $w|_{K,\boldsymbol{z}}$ denote the limit of $w(\boldsymbol{x})$ as $\boldsymbol{x}$ approaches $\boldsymbol{z}$ from within K.

We need to bound each of the terms in (4.4) using norms of $\boldsymbol{J}_h$. Let us first consider the case when $\boldsymbol{z}$ is not on Γ_D. For such a $\boldsymbol{z}$, recalling the way we constructed the basis of Theorem 3.1, note that there is a mesh element $K^\star$ such that $\boldsymbol{z} = \boldsymbol{x}_{\boldsymbol{\alpha}^\star,K^\star}$, where the limit $T_h(\boldsymbol{J}_h)|_{K^\star,\,\boldsymbol{z}}$ is zero; see (3.10b). Using this fact, it is easy to see that we can write $T_h(\boldsymbol{J}_h)\big|_{K,\boldsymbol{z}}$ as the telescoping sum

$$T_h(\boldsymbol{J}_h)\big|_{K,\boldsymbol{z}} = \sum_{i=1}^{m}\Big[T_h(\boldsymbol{J}_h)\big|_{K_i,\boldsymbol{z}} - T_h(\boldsymbol{J}_h)\big|_{K_{i+1},\boldsymbol{z}}\Big] \tag{4.5}$$

for some collection of mesh elements K_i such that $\boldsymbol{z}$ is in $\bar{K}_i$, $K_1 = K$, $K_{m+1} = K^\star$, and $K_i \cap K_{i+1}$ is a mesh face in $\mathcal{E}_h \setminus \Gamma_N$. If $\boldsymbol{z}$ lies on Γ_D, we can still write a similar sum as long as we omit the last term (as there is no $K^\star$ for such $\boldsymbol{z}$) and choose K_m such that it has a face on $\partial\Omega$. By (3.10a), the absolute value of the ith summand inside the square brackets in (4.5) equals the magnitude of the limit of $\boldsymbol{J}_h$ as we approach $\boldsymbol{z}$ from within the mesh face $K_i \cap K_{i+1}$. Expressing each of the terms in the sum in (4.4) in terms of $\boldsymbol{J}_h$ this way, we obtain

$$\frac{C}{|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2 \;\le\; \sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K}\;\sum_{e\in\mathcal{F}_{\boldsymbol{z}}}\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2, \tag{4.6}$$

where $\mathcal{F}_{\boldsymbol{z}}$ denotes the set of all mesh faces e in $\mathcal{E}_h \setminus \Gamma_N$ such that $\boldsymbol{z} \in \bar{e}$. Note that in obtaining the above inequality, we have used the fact that for every $\boldsymbol{z}$, the number

m in (4.5) can be bounded uniformly in terms of the shape regularity constants. Summing over all mesh elements K, we obtain the lower bound of (4.1).

It now remains to prove (4.2). Recall that a standard norm equivalence asserts the existence of a constant C (depending on the shape regularity of K, but otherwise independent of K) such that for all $w \in \mathcal{P}_k(K)$,

$$\frac{1}{C|K|}\|w\|_{0,K}^2 \le \sum_{\boldsymbol{\alpha}\in\mathcal{A}_N^k} |w(\boldsymbol{x}_{\boldsymbol{\alpha},K})|^2 \le \frac{C}{|K|}\|w\|_{0,K}^2.$$

Applying this with $w = T_h(\boldsymbol{J}_h)|_K$, and observing that in the expansion for $T_h(\boldsymbol{J}_h)$ in (3.11), the coefficients $\{c_\phi\}$ are the nonzero values of $T_h(\boldsymbol{J}_h)$ at the points $\boldsymbol{x}_{\boldsymbol{\alpha},K}$, we obtain

$$\frac{1}{C|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2 \;\le \sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K}\sum_{\phi\in V_{\boldsymbol{z}}^\star} c_\phi^2 \;\le\; \frac{C}{|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2. \tag{4.7}$$

The upper inequality above implies

$$\begin{aligned}\sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K}\sum_{\phi\in V_{\boldsymbol{z}}^\star} c_\phi^2 \;&\le \frac{C}{|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2 && \text{by (4.7)}\\ &\le\; C\sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K}\sum_{e\in\mathcal{F}_{\boldsymbol{z}}}\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2 && \text{by (4.6).}\end{aligned}$$

If we sum this inequality over all mesh elements K, the resulting left-hand side dominates $\|\,[\boldsymbol{J}_h]\,\|_{\ell^2}^2$. Hence we have proven that

$$\big\|\,[\boldsymbol{J}_h]\,\big\|_{\ell^2}^2 \le\; C\sum_{e\in\mathcal{E}_h\setminus\Gamma_N}\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2. \tag{4.8}$$

Returning to (4.7) and using its lower inequality, we also have

$$\begin{aligned}\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2 &\le C\sum_{K\in\mathcal{K}_e}\frac{1}{|K|}\|T_h(\boldsymbol{J}_h)\|_{0,K}^2 && \text{by (4.3)}\\ &\le C\sum_{K\in\mathcal{K}_e}\sum_{\boldsymbol{z}\in\mathcal{G}_h^k\cap\partial K}\sum_{\phi\in V_{\boldsymbol{z}}^\star} c_\phi^2 && \text{by (4.7).}\end{aligned}$$

Summing this inequality over all edges e in $\mathcal{E}_h \setminus \Gamma_N$ and noting that the resulting number of repetitions in c_ϕ^2 can be uniformly bounded, we obtain

$$\sum_{e\in\mathcal{E}_h\setminus\Gamma_N}\frac{1}{|e|}\|\boldsymbol{J}_h\|_{0,e}^2 \le C\big\|\,[\boldsymbol{J}_h]\,\big\|_{\ell^2}^2. \tag{4.9}$$

Combining (4.9) and (4.8), the proof of (4.2) is finished. ∎

Proof of Theorem 3.2. Since the matrix M is symmetric and positive definite, its spectral condition number κ_M is given by

$$\kappa_M = \left(\max_{\boldsymbol{Y}_h\in\mathfrak{Z}_h}\frac{\langle\alpha\,\boldsymbol{Y}_h\,,\,\boldsymbol{Y}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N}}{\|\,[\boldsymbol{Y}_h]\,\|_{\ell^2}^2}\right)\Big/\left(\min_{\boldsymbol{Y}_h\in\mathfrak{Z}_h}\frac{\langle\alpha\,\boldsymbol{Y}_h\,,\,\boldsymbol{Y}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N}}{\|\,[\boldsymbol{Y}_h]\,\|_{\ell^2}^2}\right). \tag{4.10}$$

By the assumptions in the theorem on α,

$$\zeta_\star\Big(\sum_{e\in\mathcal{E}_h\setminus\Gamma_N}\frac{1}{|e|}\|\boldsymbol{Y}_h\|_{0,e}^2\Big)\le\langle\alpha\,\boldsymbol{Y}_h\,,\,\boldsymbol{Y}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N}\le\zeta^\star\Big(\sum_{e\in\mathcal{E}_h\setminus\Gamma_N}\frac{1}{|e|}\|\boldsymbol{Y}_h\|_{0,e}^2\Big).$$

Applying (4.2) of Lemma 4.1 to the above inequality, we obtain

$$\frac{\zeta_\star}{C}\,\|\,[\boldsymbol{Y}_h]\,\|^2\le\langle\alpha\,\boldsymbol{Y}_h\,,\,\boldsymbol{Y}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N}\le\;C\zeta^\star\|\,[\boldsymbol{Y}_h]\,\|^2.$$

Using this in (4.10), we find that $\kappa_M\le C^2\zeta^\star/\zeta_\star$. ∎

4.2. Proof of the flux error estimates. This subsection is devoted to proving the error estimates of Theorem 3.3. The error in the divergence is easy to analyze, but the proof of the L^2-estimate is more involved. Proceeding as in [16] in the analysis of the hybridized RT method, we start with the error equations.

Proof of Theorem 3.3. We divide this proof into seven steps.

Step 1. *Obtaining the error equations.* If we set $\boldsymbol{q}_{\nabla,h}:=-a\nabla U_h$, on each element $K\in\mathcal{T}_h$, from (2.2a) and (2.2b) defining the hybridized continuous Galerkin method and from (3.1) relating $q_{n,h}$ with the numerical trace $\widehat{\boldsymbol{q}}_h$, it follows that

$$\begin{aligned}&\big(a^{-1}\boldsymbol{q}_{\nabla,h},\,\boldsymbol{v}\big)_K-(U_h,\,\nabla\cdot\boldsymbol{v})_K=-\langle\lambda_h,\,\boldsymbol{v}\cdot\boldsymbol{n}\rangle_{\partial K},\\&-\big(\boldsymbol{q}_{\nabla,h},\,\nabla w\big)_K+\langle\widehat{\boldsymbol{q}}_h,\,w\boldsymbol{n}\rangle_{\partial K}=(f,\,w)_K\end{aligned}$$

for any $(\boldsymbol{v},w)\in\mathcal{P}_k(K)^N\times\mathcal{P}_k(K)$. As a consequence, by the definition of $\boldsymbol{q}_h$ given by (3.2), we obtain that for $\ell\le k$,

$$\big(a^{-1}\boldsymbol{q}_h,\,\boldsymbol{v}\big)_K-(U_h,\,\nabla\cdot\boldsymbol{v})_K=-\langle\lambda_h,\,\boldsymbol{v}\cdot\boldsymbol{n}\rangle_{\partial K}+\big(a^{-1}(\boldsymbol{q}_h-\boldsymbol{q}_{\nabla,h}),\,\boldsymbol{v}\big)_K\,,\tag{4.11a}$$

$$-\,(\boldsymbol{q}_h,\,\nabla w)_K+\langle\boldsymbol{q}_h,\,w\boldsymbol{n}\rangle_{\partial K}=(f,\,w)_K\tag{4.11b}$$

for any $(\boldsymbol{v},w)\in\mathcal{P}_k(K)^N\times\mathcal{P}_\ell(K)$. The error equations are derived by comparing these equations to the equations satisfied by the exact solution $(\boldsymbol{q},u)$, namely,

$$\begin{aligned}&\big(a^{-1}\boldsymbol{q},\,\boldsymbol{v}\big)_K-(u,\,\nabla\cdot\boldsymbol{v})_K=-\langle u,\,\boldsymbol{v}\cdot\boldsymbol{n}\rangle_{\partial K},\\&-\,(\boldsymbol{q},\,\nabla w)_K+\langle\boldsymbol{q},\,w\boldsymbol{n}\rangle_{\partial K}=(f,\,w)_K\end{aligned}$$

for any $(\boldsymbol{v},w)\in V_{RT_\ell}(K)\times\mathcal{P}_\ell(K)$. They imply, as a consequence of the definition of the RT projection π_ℓ given in (3.12), that

$$\big(a^{-1}\pi_\ell\,\boldsymbol{q},\,\boldsymbol{v}\big)_K-(u,\,\nabla\cdot\boldsymbol{v})_K=-\langle u,\,\boldsymbol{v}\cdot\boldsymbol{n}\rangle_{\partial K}+\big(a^{-1}(\pi_\ell\,\boldsymbol{q}-\boldsymbol{q}),\,\boldsymbol{v}\big)_K\,,\tag{4.12a}$$

$$-\,(\pi_\ell\,\boldsymbol{q},\,\nabla w)_K+\langle\pi_\ell\,\boldsymbol{q},\,w\boldsymbol{n}\rangle_{\partial K}=(f,\,w)_K\tag{4.12b}$$

for any $(\boldsymbol{v},w)\in V_{RT_\ell}(K)\times\mathcal{P}_\ell(K)$.

Thus, if we define the errors of the approximation as

$$\boldsymbol{e}_{\boldsymbol{q}}=\pi_\ell\,\boldsymbol{q}-\boldsymbol{q}_h,\quad e_u=u-U_h,\quad e_\lambda=u-\lambda_h,$$

we see, after subtracting (4.11) from (4.12), that they satisfy

$$\begin{aligned}\big(a^{-1}\boldsymbol{e}_{\boldsymbol{q}},\,\boldsymbol{v}\big)_K-(e_u,\,\nabla\cdot\boldsymbol{v})_K=&-\langle e_\lambda,\,\boldsymbol{v}\cdot\boldsymbol{n}\rangle_{\partial K}\\&-\big(a^{-1}(\boldsymbol{q}_h-\boldsymbol{q}_{\nabla,h}),\,\boldsymbol{v}\big)_K\\&+\big(a^{-1}(\pi_\ell\,\boldsymbol{q}-\boldsymbol{q}),\,\boldsymbol{v}\big)_K\,,\end{aligned}\tag{4.13a}$$

$$-(\boldsymbol{e}_{\boldsymbol{q}},\,\nabla w)_K+\langle\boldsymbol{e}_{\boldsymbol{q}}\cdot\boldsymbol{n},\,w\rangle_{\partial K}=0\tag{4.13b}$$

for any $(\boldsymbol{v}, w) \in (V_{RT_\ell}(K) \cap \mathcal{P}_k(K)^N) \times \mathcal{P}_\ell(K)$ for $\ell \leq k$.

Step 2. *Analyzing errors in the divergence of the flux.* Integrating (4.13b) by parts, we obtain

$$(\nabla \cdot \boldsymbol{e_q},\, w)_K = 0 \quad \text{for all } w \in \mathcal{P}_\ell(K).$$

Since $\nabla \cdot \boldsymbol{e_q} \in \mathcal{P}_\ell(K)$, we immediately get that

$$\nabla \cdot \boldsymbol{e_q} \equiv 0 \quad \text{on } K,$$

which is the first identity of Theorem 3.3. (It is obvious that $\boldsymbol{e_q}$ is in $\boldsymbol{H}(\mathrm{div}, \Omega)$.)

The first inequality of Theorem 3.3 follows from the fact that

$$\nabla \cdot (\boldsymbol{q} - \boldsymbol{q}_h) = \nabla \cdot (\boldsymbol{q} - \pi_\ell\, \boldsymbol{q}) = (\mathrm{Id} - \mathsf{P}_\ell)\, f,$$

where P_ℓ is the L^2-projection into the space of functions w such that $w_K \in \mathcal{P}_\ell(K)$ for all $K \in \mathcal{T}_h$. Notice that in the last step, we used the commutativity property $\nabla \cdot \pi_\ell = \mathrm{P}_\ell \nabla \cdot$ (see, e.g., [6, 16, 22]).

Step 3. *Establishing the second identity.* If in the error equation (4.13a) we select $\boldsymbol{v} \in \mathcal{P}_{\ell-1}^N(K)$, we find that whenever $a(\boldsymbol{x})$ is constant on K,

$$\left(a^{-1}\boldsymbol{e_q},\, \boldsymbol{v}\right)_K - (e_u,\, \nabla \cdot \boldsymbol{v})_K = -\langle e_\lambda,\, \boldsymbol{v} \cdot \boldsymbol{n} \rangle_{\partial K},$$

where we used (3.2c) of the definition of $\boldsymbol{q}_h$ and (3.12c) of the definition of π_ℓ. This readily implies that

$$\left(a^{-1}\boldsymbol{e_q},\, \boldsymbol{v}\right)_\Omega - \sum_{K \in \mathcal{T}_h} (e_u,\, \nabla \cdot \boldsymbol{v})_K = - \sum_{e \in \mathcal{E}_h} \langle e_\lambda,\, [\![\boldsymbol{v} \cdot \boldsymbol{n}]\!] \rangle_e,$$

and so

$$\left(a^{-1}\boldsymbol{e_q},\, \boldsymbol{v}\right)_\Omega = -\langle e_\lambda\,,\, \boldsymbol{v} \cdot \boldsymbol{n} \rangle_{\Gamma_D} = 0 \quad \text{for all } \boldsymbol{v} \in \boldsymbol{\mathcal{V}}_{h,\ell-1}^0,$$

since we are assuming that $g|_e \in \mathcal{P}_k(e)$ for each face e on Γ_D. The second identity of Theorem 3.3 immediately follows from this and the definition of the projection $\mathbb{P}_{\ell-1}$ given by (3.13).

Step 4. *Splitting errors in the flux.* It remains to prove the second inequality of Theorem 3.3. To do this, we begin by noting that since $\boldsymbol{e_q} \in \boldsymbol{\mathcal{V}}_{h,\ell}^0$, we can choose $\boldsymbol{v} = \boldsymbol{e_q}$ in the error equation (4.13a). Doing this and summing over all the elements $K \in \mathcal{T}_h$, we obtain

$$(a^{-1}e_{\boldsymbol{q}}, e_{\boldsymbol{q}})_\Omega = -\left(a^{-1}(\boldsymbol{q}_h - \boldsymbol{q}_{\nabla,h}),\, \boldsymbol{e_q}\right)_\Omega + \left(a^{-1}(\pi_\ell\, \boldsymbol{q} - \boldsymbol{q}),\, \boldsymbol{e_q}\right)_\Omega.$$

Introducing $\pi_\ell \boldsymbol{q}_{\nabla,h}$ into the right-hand side,

$$\begin{aligned}(a^{-1}e_{\boldsymbol{q}}, e_{\boldsymbol{q}})_\Omega &= -\left(a^{-1}(\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h}),\, \boldsymbol{e_q}\right)_\Omega - \left(a^{-1}(\pi_\ell \boldsymbol{q}_{\nabla,h} - \boldsymbol{q}_{\nabla,h}),\, \boldsymbol{e_q}\right)_\Omega \\ &\quad + \left(a^{-1}(\pi_\ell\, \boldsymbol{q} - \boldsymbol{q}),\, \boldsymbol{e_q}\right)_\Omega \\ &= -\left(a^{-1}(\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h}),\, \boldsymbol{e_q}\right)_\Omega - \left(a^{-1}(Id - \pi_\ell)(\boldsymbol{q} - \boldsymbol{q}_{\nabla,h}),\, \boldsymbol{e_q}\right)_\Omega.\end{aligned}$$

Applying the Cauchy–Schwarz inequality,

$$C\|\boldsymbol{e_q}\|_{0,\Omega} \leq \|\boldsymbol{q}_h - \pi_\ell\, \boldsymbol{q}_{\nabla,h}\|_{0,\Omega} + \|(\mathrm{Id} - \pi_\ell)(\boldsymbol{q} - \boldsymbol{q}_{\nabla,\mathrm{h}})\|_{0,\Omega}. \tag{4.14}$$

We now estimate each of the terms on the right-hand side separately in the next two steps.

Step 5. *Estimating* $\|\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h}\|_{0,\Omega}$. In order to estimate this term, we rewrite (3.2b) and (3.2c) defining $\boldsymbol{q}_h$ as

$$\begin{aligned}
&(\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h},\, \boldsymbol{v})_K = 0 && \text{for all } \boldsymbol{v} \in \mathcal{P}_{\ell-1}(K)^N,\\
&\langle (\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h})\cdot \boldsymbol{n},\, w\rangle_e = \langle (\widehat{\boldsymbol{q}}_h - \boldsymbol{q}_{\nabla,h})\cdot \boldsymbol{n},\, w\rangle_e && \text{for all } w \in \mathcal{P}_\ell(e) \text{ and all faces } e \subset \partial K.
\end{aligned}$$

Then a standard scaling argument gives

$$\|\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h}\|_{0,K}^2 \le C h_K \|(\widehat{\boldsymbol{q}}_h - \boldsymbol{q}_{\nabla,h})\cdot \boldsymbol{n}\|_{0,\partial K}^2.$$

Summing over all mesh elements and using the definition of the numerical trace $\widehat{\boldsymbol{q}}_h$ given (3.5), we obtain

$$\begin{aligned}
\|\boldsymbol{q}_h - \pi_\ell \boldsymbol{q}_{\nabla,h}\|_{0,\Omega}^2 \le C \sum_{K\in\mathcal{T}_h} h_K \Bigg(&\left\| \left(\boldsymbol{\beta}\cdot\boldsymbol{n} - \frac{1}{2}\right) [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!] + \alpha\, \boldsymbol{J}_h\cdot\boldsymbol{n} \right\|_{0,\partial K\setminus\,\partial\Omega}^2 \\
&+ \left\|\alpha\, \boldsymbol{J}_h\cdot\boldsymbol{n}\right\|_{0,\partial K\cap\Gamma_D}^2 + \left\|\mathsf{q}_{\mathsf{N}} - \boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}\right\|_{0,\partial K\cap\Gamma_N}^2 \Bigg)\\
&\le C\, h\, (T_1 + T_2), \qquad (4.15)
\end{aligned}$$

where

$$T_1 := \left\| [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n} - \pi_\ell \boldsymbol{q}\cdot\boldsymbol{n}]\!] \right\|_{0,\mathcal{E}_h\setminus\Gamma_D}^2 \quad \text{and} \quad T_2 := \|\alpha\, \boldsymbol{J}_h\cdot\boldsymbol{n}\|_{0,\mathcal{E}_h\setminus\Gamma_N}^2.$$

The term T_1 can be easily estimated by an inverse inequality:

$$T_1 \le C h^{-1} \|\boldsymbol{q}_{\nabla,h} - \pi_\ell \boldsymbol{q}\|_{0,\Omega}^2 \le C h^{-1} \big(|u - U_h|_{1,\Omega}^2 + \|\boldsymbol{q} - \pi_\ell \boldsymbol{q}\|_{0,\Omega}^2\big). \qquad (4.16)$$

The other term T_2 requires more work.

To estimate T_2, we rewrite the definition of the jump $\boldsymbol{J}_h$, namely, (3.8), as

$$\begin{aligned}
\langle \alpha\, \boldsymbol{J}_h,\, [\![v\boldsymbol{n}]\!]\rangle_{\mathcal{E}_h\setminus\Gamma_N} &= \big\langle [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!],\, \{\!\{v\}\!\} - \boldsymbol{\beta}\cdot [\![v\boldsymbol{n}]\!]\big\rangle_{\mathcal{E}_h\setminus\partial\Omega}\\
&\quad + \sum_{K\in\mathcal{T}_h} (f - \nabla\cdot\boldsymbol{q}_{\nabla,h}, v)_K\\
&= \big\langle [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!],\, \{\!\{v\}\!\} - \boldsymbol{\beta}\cdot [\![v\boldsymbol{n}]\!]\big\rangle_{\mathcal{E}_h\setminus\partial\Omega}\\
&\quad + \sum_{K\in\mathcal{T}_h} (\nabla\cdot(\pi_k\boldsymbol{q} - \boldsymbol{q}_{\nabla,h}), v)_K
\end{aligned}$$

for all $v \in V_h$. Choosing $v = T_h(\boldsymbol{J}_h)$ and using the property (3.10a) of the operator T_h, we get

$$\begin{aligned}
\langle \alpha\, \boldsymbol{J}_h\,,\, \boldsymbol{J}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N} = \langle [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!],\, \{\!\{T_h(\boldsymbol{J}_h)\}\!\}\rangle_{\mathcal{E}_h^\circ} - \langle [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!],\, \boldsymbol{\beta}\cdot\boldsymbol{J}_h)\rangle_{\mathcal{E}_h^\circ}\\
+ \sum_{K\in\mathcal{T}_h} (\nabla\cdot(\pi_k\boldsymbol{q} - \boldsymbol{q}_{\nabla,h}),\, T_h(\boldsymbol{J}_h))_K.
\end{aligned}$$

Using (4.1) of Lemma 4.1 after applying suitable inverse inequalities, we obtain

$$\langle \alpha\, \boldsymbol{J}_h\,,\, \boldsymbol{J}_h\rangle_{\mathcal{E}_h\setminus\Gamma_N} \le C \left(\left\| [\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!] \right\|_{0,\mathcal{E}_h^\circ} + h^{1/2} \|\nabla\cdot(\pi_k\boldsymbol{q} - \boldsymbol{q}_{\nabla,h})\|_{0,\Omega} \right) \|\boldsymbol{J}_h\|_{0,\mathcal{E}_h\setminus\Gamma_N}.$$

This implies that

$$T_2 \leq C\,\frac{\alpha^\star}{\alpha_\star}\,\Big(\big\|\,[\![\boldsymbol{q}_{\nabla,h}\cdot\boldsymbol{n}]\!]\,\big\|^2_{0,\mathcal{E}_h^\circ} + h\,\|\nabla\cdot(\pi_k\boldsymbol{q}-\boldsymbol{q}_{\nabla,h})\|^2_{0,\Omega}\Big).$$

Treating the first term inside the parentheses above as in the proof of (4.16), and applying an inverse inequality to the second, we get

$$T_2 \leq C\,h^{-1}\big(|u-U_h|^2_{1,\Omega} + \|\boldsymbol{q}-\pi_\ell\boldsymbol{q}\|^2_{0,\Omega} + \|\boldsymbol{q}-\pi_k\boldsymbol{q}\|^2_{0,\Omega}\big).$$

Using the estimates for T_1 and T_2 in (4.15), we conclude that

$$C\,\|\boldsymbol{q}_h-\pi_\ell\boldsymbol{q}_{\nabla,h}\|^2_{0,\Omega} \leq |u-U_h|^2_{1,\Omega} + \|\boldsymbol{q}-\pi_\ell\boldsymbol{q}\|^2_{0,\Omega} + \|\boldsymbol{q}-\pi_k\boldsymbol{q}\|^2_{0,\Omega}. \tag{4.17}$$

Step 6. *Estimating* $\|(Id-\pi_\ell)(\boldsymbol{q}-\boldsymbol{q}_{\nabla,h})\|_{0,\Omega}$. On an element K, using the well-known approximation property of π_ℓ [6, 29], we obtain

$$\begin{aligned}\|(Id-\pi_\ell)(\boldsymbol{q}-\boldsymbol{q}_{\nabla,h})\|_{0,K} &\leq Ch_K|\boldsymbol{q}-\boldsymbol{q}_{\nabla,h}|_{1,K}\\ &\leq Ch_K\|a\|_{W^1_\infty(K)}\|\nabla u-\nabla U_h\|_{1,K}.\end{aligned}$$

Now using any projector Π_K well defined on $L^2(K)^N$ with standard approximation properties, e.g., the one constructed in [30], we have

$$\begin{aligned}\|(Id-\pi_\ell)(\boldsymbol{q}-\boldsymbol{q}_{\nabla,h})\|_{0,K} &\leq Ch_K\big(\|\nabla u-\Pi_K\nabla u\|_{1,K} + \|\Pi_K(\nabla u-\nabla U_h)\|_{1,K}\big)\\ &\leq C\big(h_K\|\nabla u-\Pi_K\nabla u\|_{1,K} + \|\Pi_K(\nabla u-\nabla U_h)\|_{0,K}\big)\\ &\leq C\big(h_K\|\nabla u-\Pi_K\nabla u\|_{1,K} + \|\nabla u-\nabla U_h\|_{0,K}\big).\end{aligned}$$

Thus, we obtain

$$\|(\mathrm{Id}-\pi_\ell)(\boldsymbol{q}-\boldsymbol{q}_{\nabla,\mathrm{h}})\|_{0,\Omega} \leq \mathrm{Ch}^{\min(\mathrm{s},\mathrm{k})}|\mathrm{u}|_{\mathrm{s}+1,\Omega}. \tag{4.18}$$

Step 7. *Completing the proof of Theorem* 3.3. Now we use the results of the previous two steps, namely, (4.17) and (4.18), in the splitting (4.14) of the error term. Then we obtain

$$C\|\boldsymbol{e}_{\boldsymbol{q}}\|_{0,\Omega} \leq |u-U_h|_{1,\Omega} + \|\boldsymbol{q}-\pi_\ell\,\boldsymbol{q}\|_{0,\Omega} + \|\boldsymbol{q}-\pi_k\boldsymbol{q}\|_{0,\Omega} + h^{\min(s,k)}|u|_{s+1,\Omega},$$

and the estimate of $\boldsymbol{q}_h$ immediately follows from the standard approximation results:

$$\begin{aligned}|u-U_h|_{1,\Omega} &\leq Ch^{\min\{k,s\}}|u|_{s+1,\Omega},\\ \|\boldsymbol{q}-\pi_m\boldsymbol{q}\|_{0,\Omega} &\leq Ch^{\min\{m+1,s\}}|\boldsymbol{q}|_{s,\Omega}.\end{aligned}$$

This concludes the proof. ∎

5. Numerical results. In this section, we carry out some numerical experiments to verify the theoretical results when the exact solution is smooth (Test 1) and to test the performance of the method when the exact solution has a singularity (Test 2). For the sake of simplicity, we use uniform meshes and pick $\boldsymbol{\beta}=\mathbf{0}$ in the definition of the numerical trace $\widehat{\boldsymbol{q}}_h$, (3.5).

In what follows, by the approximation given by the "RT$_\ell$ method" we mean the pair $(\boldsymbol{q}_h, U_h)$ obtained as follows. The function $(\boldsymbol{q}_h, u_h, \lambda_h)$ is the solution of the hybridized RT method whose Lagrange multipliers are piecewise polynomials of

degree ℓ. The function U_h is obtained from (u_h, λ_h) by using the local postprocessing described in [1]. The resulting pair $(\boldsymbol{q}_h, U_h)$ is then compared to the solution of our RT_ℓ-postprocessed CG_k method, for which $\boldsymbol{q}_h$ is the RT_ℓ-postprocessed CG_k flux and U_h is the solution of the CG method with piecewise polynomials of degree k.

Test 1. We take

$$a = \begin{pmatrix} x+2 & x+y \\ x+y & y+2 \end{pmatrix}$$

and then g and f so that the exact solution is

$$u(x,y) = \sin(\pi x)\,\sin(\pi y).$$

The history of convergence of the approximations given by the RT_{k-1} and the RT_ℓ-postprocessed CG_k methods, for $\ell \in \{k-1, k\}$, are displayed in Tables 3, 4, and 5 for $k = 1, 2,$ and 3, respectively. Plots of these results are also displayed in Figure 6 for an easier comparison.

We see that the approximation given by the RT_ℓ-postprocessed CG_k method converges with the orders predicted by Theorem 3.3. Observe that the errors of the

divergence between the RT_{k-1} and the RT_{k-1}-postprocessed CG_k methods are exactly the same, as predicted by the theory. Moreover, as can be clearly seen from Figure 6, the approximations of the RT_{k-1} and the RT_{k-1}-postprocessed CG_k methods are comparable in accuracy. We also see that the approximate flux provided by the RT_{k-1}-postprocessed CG_k is better than the approximation $-a\nabla U_h$ provided by the CG_k method. Finally, note that if we increase ℓ by one more degree than $k-1$ in RT_ℓ-postprocessing, there is no improvement—in fact, the approximate flux given by the RT_k-postprocessed CG_k method produces an approximate flux that is worse than that provided by the RT_{k-1}-postprocessed CG_k method.

Test 2. Now we work on a problem in which the solution has singularities produced by drastic changes in the permeability a; see Figure 1 in the introduction. We compare the streamlines of the approximate flux obtained by the RT_{k-1}-postprocessed CG_k method and that of the RT_{k-1} method around the upper left corner of the rock in Figures 7, 8, and 9. We see that the presence of the singularity at the corner induces small distortions in the streamlines. However, even in this hard case, the flux produced by the RT_{k-1} method and the solution given by the RT_{k-1}-postprocessed CG_k method are remarkably similar.

6. Concluding remarks. We have shown that a new postprocessing of the CG_k solution gives rise to an $H(\mathrm{div})$-conforming approximation to the flux which renders the CG method locally conservative. The postprocessing belongs to the RT space of degree $k-1$ and displays convergence properties similar to the approximation given by the RT method of degree $k-1$ itself. By counting the degrees of freedom we have established that the computational effort needed to obtain the new postprocessed flux is less than that of the RT method.

We have also shown how to hybridize the CG method, making it easier to treat variable degree approximation spaces and hanging nodes.

The study of the effect of the numerical trace parameter $\boldsymbol{\beta}$ on the quality of the approximation and the extension of this approach to linear elasticity are subjects of ongoing research.

A POSTERIORI ERROR ESTIMATION FOR DISCONTINUOUS GALERKIN FINITE ELEMENT APPROXIMATION*

MARK AINSWORTH†

Abstract. It is shown that the interelement discontinuities in a discontinuous Galerkin finite element approximation are subordinate to the error measured in the broken H^1-seminorm. One consequence is that the DG-norm of the error is equivalent to the broken energy seminorm. Computable a posteriori error bounds are obtained for the error measured in both the DG-norm and the broken energy seminorm and are shown to be efficient in the sense that they also provide lower bounds up to a constant and higher order data oscillation terms. The estimators are completely free of unknown constants and provide guaranteed numerical bounds for the error.

Key words. a posteriori error estimation, discontinuous Galerkin method, computable error bounds

1. Introduction.

Discontinuous Galerkin finite element methods for the approximation of elliptic problems were pioneered in the late 1970s [4, 6, 18] but lay virtually dormant until recently, when they became the subject of intense research activity. The reader is referred to [5, 9] for an overview of developments in the formulation of the methods and their a priori error analysis.

The theory of a posteriori error bounds for discontinuous Galerkin methods in energy-type norms is considerably less developed in comparison with the huge literature on such methods for conforming finite element schemes. Explicit a posteriori estimators for the error in the discontinuous Galerkin approximation measured in mesh-dependent energy-type norms were developed in [7, 12, 14, 15] and later in [11, 16, 19]. Explicit estimators take the form of norms of residuals and jump discontinuities in the finite element approximation, weighted in terms of the local mesh-size and involving unknown generic constants. As noted in [14], the presence of such unknown constants means that one does not actually have numerical bounds on the error, and this limits the practical usage of the estimators to error indication for the purposes of, say, adaptive mesh refinement, as opposed to actual quantitative error control.

In the present work, we wish to derive a posteriori error estimators that are free of any unknown constants, provide actual error bounds, and give local error indicators suitable for driving adaptive refinement procedures. Of course, if one aims to provide error bounds, then the question of the choice of norm in which the error should be bounded naturally arises. Traditionally, a priori error analysis of discontinuous Galerkin methods has been carried out in a mesh-dependent "DG-norm" defined by

$$|||e|||_{DG}^2 = \sum_{K\in\mathcal{P}} \|a^{1/2}\,\mathbf{grad}\, e\|_K^2 + \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \frac{\kappa}{|\gamma|}\|[e]\|_\gamma^2$$

*Received by the editors July 25, 2006; accepted for publication (in revised form) February 27, 2007; published electronically August 24, 2007. This work was partially supported by the Engineering and Physical Sciences Research Council of Great Britain under grant GR/S35103.

using standard notation (see (11)), which incorporates a term involving the jump discontinuity in the error $[e]$ across element interfaces weighted with the interior penalty parameter κ. However, when it comes to a posteriori error estimation, the practical relevance of a bound for the error measured in a parameter-dependent DG-norm is less clear cut. Of course, the jump term has to be included to ensure that $|||\cdot|||_{DG}$ defines a norm on the discontinuous finite element space, but one may hope that if the jumps have been appropriately penalized, then their contribution should be dominated by the first term; i.e., for κ "sufficiently large" one may hope that

$$\sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D}\frac{\kappa}{|\gamma|}\|[e]\|_\gamma^2\le C\sum_{K\in\mathcal{P}}\|a^{1/2}\,\mathbf{grad}\,e\|_K^2$$

for a positive constant C depending on κ. At first sight, the validity of such a bound hardly seems credible since the bounding term vanishes if e is piecewise constant, while the jump term does not. Nevertheless, in Theorem 3 we show that such a bound does indeed hold (modulo data oscillation which we ignore in this introductory discussion). Moreover, we quantify precisely how "sufficiently large" κ must be and show that the threshold is consistent with the value of κ that must be chosen to ensure the discrete problem itself is uniquely solvable. This result seems to be of some interest in its own right—quite apart from its significance for a posteriori error estimation. In particular, the following equivalence holds:

$$\sum_{K\in\mathcal{P}}\|a^{1/2}\,\mathbf{grad}\,e\|_K^2\le|||e|||_{DG}^2\le C\sum_{K\in\mathcal{P}}\|a^{1/2}\,\mathbf{grad}\,e\|_K^2.$$

As a consequence, we see that it makes sense to estimate and control the error in the broken energy seminorm safe in the knowledge that the jumps are controlled implicitly.

Finally, returning to the issue of a posteriori error bounds, we derive computable upper bounds for the error in the symmetric interior penalty discontinuous Galerkin approximation in both the DG- and broken energy norms. In addition, we obtain local lower bounds which imply that our upper bounds are also lower bounds up to a positive constant. We restrict our attention to the symmetric interior penalty discontinuous Galerkin scheme, although we believe the extension of our results to other variants of discontinuous Galerkin is possible. Some of the results in the present work were announced previously in [2].

2. Preliminaries.

2.1. Model problem.

Consider the model problem

$$\left.\begin{aligned}-\mathbf{div}\,\boldsymbol{\sigma}(u)&=f\in L_2(\Omega)\\ \boldsymbol{\sigma}(u)-a\,\mathbf{grad}\,u&=0\end{aligned}\right\}\ \text{in }\Omega \tag{1}$$

subject to $u=u_D$ on Γ_D and $\sigma_\nu(u)=\boldsymbol{\nu}\cdot\boldsymbol{\sigma}(u)=g\in L_2(\Gamma_N)$ on Γ_N, where $\boldsymbol{\nu}$ is the unit outward normal. The domain Ω is assumed to be a plane polygon, and the disjoint sets Γ_D and Γ_N form a partitioning of the boundary $\Gamma=\partial\Omega$ of the domain. The datum a is assumed to be strictly positive and, for simplicity, is assumed piecewise constant on subdomains of Ω, while u_D is assumed to be continuous, piecewise linear on Γ_D.

The standard variational formulation of the problem consists of seeking $u \in H^1(\Omega)$ such that $u = u_D$ on Γ_D, with

$$(a\,\mathbf{grad}\,u, \mathbf{grad}\,v) = (f, v) + \int_{\Gamma_N} gv\,\mathrm{d}s \quad \forall v \in H^1_E(\Omega), \tag{2}$$

where $H^1_E(\Omega)$ denotes the space $\{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\}$. Throughout, we use the notation $(\cdot,\cdot)_\omega$ to denote the integral inner product over a region ω, and omit the subscript in the case where ω is the physical domain Ω.

2.2. Discontinuous Galerkin formulation. We consider a family of partitions $\{\mathcal{P}\}$ of the domain Ω into the union of nonoverlapping, triangular elements such that the nonempty intersection of a distinct pair of elements is a single common node or single common edge. The family of partitions is assumed to be locally quasi-uniform in the sense that the ratio of the diameters of any pair of neighboring elements is uniformly bounded above and below over the whole family. Furthermore, it is assumed that the partitioning is compatible with the data so that a is piecewise constant on each element and u_D is piecewise linear on an element edge.

The set of all edges of the elements is denoted by $\mathcal{E}$, which we partition into subsets $\mathcal{E}_D$, $\mathcal{E}_N$, and $\mathcal{E}_I$ consisting of edges lying on the Dirichlet boundary Γ_D, the Neumann boundary Γ_N, and the interior edges, respectively. Likewise, the corresponding quantities relative to an individual element K are denoted by $\mathcal{E}(K)$, $\mathcal{E}_D(K)$, $\mathcal{E}_N(K)$, and $\mathcal{E}_I(K)$, respectively. The set of element nodes is denoted by $\mathcal{N}$, while the nodes on a particular element K or edge γ are denoted by $\mathcal{N}(K)$ or $\mathcal{N}(\gamma)$, respectively. For each edge $\gamma \in \mathcal{E}$, the set $\widetilde{\gamma}$ consists of those elements for which γ is an edge,

$$\widetilde{\gamma} = \{K' \in \mathcal{P} : \gamma \in \mathcal{E}(K')\}, \tag{3}$$

while for each element $K \in \mathcal{P}$, the set $\widetilde{K}$ consists of those elements having an edge in common with K,

$$\widetilde{K} = \{K' \in \mathcal{P} : \mathcal{E}(K) \cap \mathcal{E}(K') \text{ is nonempty}\}. \tag{4}$$

Let $X_{\mathcal{P}}$ denote the finite-dimensional space relative to the partition defined by

$$X_{\mathcal{P}} = \{v \in L_2(\Omega) : v_{|K} \in \mathbb{P}_1(K) \quad \forall v \in \mathcal{P}\},$$

where $\mathbb{P}_1(K)$ denotes the set of polynomials of degree at most one in each variable. We now describe the so-called *discontinuous Galerkin finite element method* for the approximation of the solution of the model problem (2) using the space $X_{\mathcal{P}}$. Observe that membership of the space $X_{\mathcal{P}}$ carries no interelement continuity constraints or boundary conditions. Instead, these will be enforced indirectly in the variational scheme. For this purpose, we shall need some notation and conventions to describe jumps and averages of functions associated with the space $X_{\mathcal{P}}$ across interelement edges. For each element $K \in \mathcal{P}$, we let $\mu_K : \partial K \to \{+1, -1\}$ denote a sign function that is piecewise constant on the edges of element K and chosen such that $\mu_K + \mu_{K'} = 0$ on $\partial K \cap \partial K'$ and $\mu_K = 1$ on $\partial K \cap \partial\Omega$. For $v \in X_{\mathcal{P}}$, we define the jump and average values of v on the edges $\mathcal{E}$ by

$$[v] = \begin{cases} \mu_K v_K + \mu_{K'} v_{K'} & \text{on } \gamma = \partial K \cap \partial K', \\ v_K & \text{on } \gamma = \partial K \cap \Gamma_D \end{cases} \tag{5}$$

and

$$\langle v\rangle = \begin{cases} \frac{1}{2}(v_K + v_{K'}) & \text{on } \gamma = \partial K \cap \partial K', \\ v_K & \text{on } \gamma = \partial K \cap \Gamma_D. \end{cases} \tag{6}$$

The sign functions $\{\mu_K\}$ may be used to define a unique, unit normal vector $\boldsymbol{\nu}$ on any given edge $\gamma \in \mathcal{E}$ according to the formula $\boldsymbol{\nu} = \mu_K \boldsymbol{\nu}_K$, $\gamma \subset \partial K$, where $\boldsymbol{\nu}_K$ denotes the unit outward normal relative to element K. This definition is independent of the choice of element K sharing the γ. The jump and average in the flux of a function $v \in X_{\mathcal{P}}$ on individual edges may then be defined by $[\sigma_\nu(v)] = \boldsymbol{\nu} \cdot [\boldsymbol{\sigma}(v)]$ and $\langle \sigma_\nu(v)\rangle = \boldsymbol{\nu} \cdot \langle \boldsymbol{\sigma}(v)\rangle$.

For a given positive constant κ to be specified later, we define the bilinear form $\mathcal{B}_{\mathcal{P}} : X_{\mathcal{P}} \times X_{\mathcal{P}} \to \mathbb{R}$ by the rule

$$\begin{aligned} \mathcal{B}_{\mathcal{P}}(v,w) &= \sum_{K\in\mathcal{P}} (a\,\mathbf{grad}\, v, \mathbf{grad}\, w)_K \\ &\quad - \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \int_\gamma \left(\langle\sigma_\nu(v)\rangle\,[w] + [v]\,\langle\sigma_\nu(w)\rangle\right) \mathrm{d}s + \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \frac{\kappa}{|\gamma|}\int_\gamma [v]\,[w]\,\mathrm{d}s \end{aligned} \tag{7}$$

and the linear form $\mathcal{L}_{\mathcal{P}} : X_{\mathcal{P}} \to \mathbb{R}$ by

$$\begin{aligned} \mathcal{L}_{\mathcal{P}}(w) &= \sum_{K\in\mathcal{P}} (f, w_K)_K \\ &\quad + \sum_{\gamma\in\mathcal{E}_N} \int_\gamma g w\,\mathrm{d}s - \sum_{\gamma\in\mathcal{E}_D}\int_\gamma u_D\,\langle\sigma_\nu(w)\rangle\,\mathrm{d}s + \sum_{\gamma\in\mathcal{E}_D}\frac{\kappa}{|\gamma|}\int_\gamma u_D w\,\mathrm{d}s, \end{aligned} \tag{8}$$

where $|\gamma|$ is used to denote the length of an edge γ.

An approximation of the true solution u is obtained by seeking $U_{\mathcal{P}} \in X_{\mathcal{P}}$ such that

$$\mathcal{B}_{\mathcal{P}}(U_{\mathcal{P}}, v) = \mathcal{L}_{\mathcal{P}}(v) \quad \forall v \in X_{\mathcal{P}}. \tag{9}$$

This type of scheme is often referred to as the *symmetric interior penalty discontinuous Galerkin finite element method*. The quantity $|||\cdot|||$ defined by

$$|||v||| = \left\{ \sum_{K\in\mathcal{P}} (a\,\mathbf{grad}\, v, \mathbf{grad}\, v)_K \right\}^{1/2} \tag{10}$$

is sometimes dubbed the *broken energy or H^1-seminorm* (note that $|||v|||$ vanishes whenever v is a piecewise constant function), while the quantity $|||\cdot|||_{DG}$ given by

$$|||v|||_{DG} = \left\{ |||v|||^2 + \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \frac{\kappa}{|\gamma|}\int_\gamma [v]^2\,\mathrm{d}s \right\}^{1/2} \tag{11}$$

is generally referred to as the *DG-norm* and plays an important role in the a priori error analysis of the method.

For a sufficiently large choice of parameter κ, it may be shown (see, for example, section 4.2 of [5]) that (9) has a unique solution. In view of the developments in section 4, where bounds on the residuals are obtained under an assumption on the size of the interior penalty parameter κ, it is of practical importance that the bound assumed there is consistent with the values of interior penalty for which the method itself is well-posed. Therefore, we shall give a simple quantitative bound on the choice of the interior penalty parameter κ.

The bound on the interior penalty parameter is stated in terms of the spectral radius of the element stiffness matrix $\boldsymbol{S}_K$ obtained using the standard barycentric coordinates $\{\lambda_n : n \in \mathcal{N}(K)\}$ on element K, i.e.,

$$[\boldsymbol{S}_K]_{mn} = (a\,\mathbf{grad}\,\lambda_m, \mathbf{grad}\,\lambda_n)_K. \tag{12}$$

Obviously, $\boldsymbol{S}_K$ is positive semidefinite and has a largest eigenvalue $\varrho(\boldsymbol{S}_K)$ that depends on the shape of the element but not on the mesh-size.

LEMMA 1. *Suppose that the interior penalty parameter appearing in the bilinear form $\mathcal{B}_{\mathcal{P}}(\cdot,\cdot)$ is chosen so that*

$$\kappa > 4 \max_{K\in\mathcal{P}} \varrho(\boldsymbol{S}_K). \tag{13}$$

Then there exists a unique $U_{\mathcal{P}} \in X_{\mathcal{P}}$ such that

$$\mathcal{B}_{\mathcal{P}}(U_{\mathcal{P}}, v) = \mathcal{L}_{\mathcal{P}}(v) \quad \forall v \in X_{\mathcal{P}}. \tag{14}$$

Proof. Thanks to the finite dimensionality, it suffices to show that the only solution to the homogeneous problem vanishes. Let $\delta > 0$ be a constant to be determined and let $v \in X_{\mathcal{P}}$ be arbitrary. Then, for each edge $\gamma \in \mathcal{E}_I \cup \mathcal{E}_D$,

$$2\int_\gamma \langle \sigma_\nu(v)\rangle\,[v]\;\mathrm{d}s \le \delta \int_\gamma |\gamma|\,\langle \sigma_\nu(v)\rangle^2\;\mathrm{d}s + \delta^{-1}\int_\gamma |\gamma|^{-1}\,[v]^2\;\mathrm{d}s.$$

If $\gamma \in \mathcal{E}_I$ is an interior edge shared by elements K and K', then

$$\int_\gamma |\gamma|\,\langle \sigma_\nu(v)\rangle^2\;\mathrm{d}s \le \frac{1}{2}|\gamma|^2\left\{(\boldsymbol{\nu}_K\cdot\boldsymbol{\sigma}_K(v)_{|\gamma})^2 + (\boldsymbol{\nu}_{K'}\cdot\boldsymbol{\sigma}_{K'}(v)_{|\gamma})^2\right\},$$

where we have exploited the fact that $\boldsymbol{\sigma}(v)$ is constant on each element. Likewise, if $\gamma \in \mathcal{E}_D$ is an edge of element K, then

$$\int_\gamma |\gamma|\,\langle \sigma_\nu(v)\rangle^2\;\mathrm{d}s \le |\gamma|^2(\boldsymbol{\nu}_K\cdot\boldsymbol{\sigma}_K(v)_{|\gamma})^2.$$

Hence, by including nonnegative contributions from the edges on the Neumann boundary, we deduce that

$$\sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D}\int_\gamma |\gamma|\,\langle \sigma_\nu(v)\rangle^2\;\mathrm{d}s \le \sum_{K\in\mathcal{P}}\sum_{\gamma\subset\partial K}|\gamma|^2(\boldsymbol{\nu}_K\cdot\boldsymbol{\sigma}_K(v))^2_{|\gamma}.$$

Making use of the relationship $\mathbf{grad}\,\lambda_{n(\gamma)} = -|\gamma|\boldsymbol{\nu}_K/2|K|$ between the barycentric coordinate $\lambda_{n(\gamma)}$ associated with the vertex opposite edge γ and the unit outward normal $\boldsymbol{\nu}_K$ on the edge, we deduce that

$$\sum_{\gamma\subset\partial K}|\gamma|^2(\boldsymbol{\nu}_K\cdot\boldsymbol{\sigma}_K(v))^2_{|\gamma} = 4\vec{v}_K^{\top}\boldsymbol{S}_K^2\vec{v}_K,$$

where $\vec{v}_K$ is the vector of values of v at the vertices of element K, and hence

$$|\gamma|^2(\boldsymbol{\nu}_K \cdot \boldsymbol{\sigma}_K(v))^2_{|\gamma} \le 4\varrho(\boldsymbol{S}_K)\vec{v}_K^{\top}\boldsymbol{S}_K\vec{v}_K = 4\varrho(\boldsymbol{S}_K)(a\,\mathbf{grad}\,v, \mathbf{grad}\,v)_K.$$

These estimates imply that

$$\mathcal{B}_{\mathcal{P}}(v,v) \ge \sum_{K\in\mathcal{P}} (1 - 4\delta\varrho(\boldsymbol{S}_K))(a\,\mathbf{grad}\,v, \mathbf{grad}\,v)_K$$

$$+ \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} (\kappa - \delta^{-1})|\gamma|^{-1}\int_\gamma [v]^2\,\mathrm{d}s.$$

By selecting δ such that $\kappa > \delta^{-1} > 4\max_{K\in\mathcal{P}}\varrho(\boldsymbol{S}_K)$, we ensure that $1 - 4\delta\varrho(\boldsymbol{S}_K)$ and $\kappa - \delta^{-1}$ are positive. Consequently, in the case of homogeneous data $\mathcal{L}_{\mathcal{P}}(\cdot)$, any solution $U_{\mathcal{P}}$ of (14) satisfies $(a\,\mathbf{grad}\,U_{\mathcal{P}}, \mathbf{grad}\,U_{\mathcal{P}})_K = 0$ on every element K, and $\int_\gamma [U_{\mathcal{P}}]^2\,\mathrm{d}s = 0$ on the interior and Dirichlet edges. Consequently, $U_{\mathcal{P}}$ must vanish identically. This completes the proof. □

3. A posteriori error analysis. Various a priori error bounds are available for the approximation scheme described above [5]. However, the issues that we wish to focus on in the present work are (i) *can one obtain computable a posteriori estimates for the error $u - U_{\mathcal{P}}$, and if so,* (ii) *in what norms?* One complication is caused by the fact that the error $e = u - U_{\mathcal{P}}$ in the finite element approximation generally fails to belong to the natural space $H^1_E(\Omega)$ for the original variational problem (2). The following result, due to Dari et al. [10], will be useful in this respect, where, for a discontinuous function v, we define the broken gradient by the rule $\mathbf{grad}_{\mathcal{P}}\,v = (\mathbf{grad}\,v)_{|K}$ and the broken flux by the rule $\boldsymbol{\sigma}_{\mathcal{P}}(v) = (a\,\mathbf{grad}\,v)_{|K}$ on element K.

THEOREM 1. *Let $\mathcal{H}$ denote the space*

$$\mathcal{H} = \{w \in H^1(\Omega) : \partial w/\partial s = 0 \text{ on } \Gamma_N\}. \tag{15}$$

Then the error in the flux may be decomposed into the form

$$\boldsymbol{\sigma}_{\mathcal{P}}(e) = \boldsymbol{\sigma}(\chi) + \mathbf{curl}\,\psi, \tag{16}$$

where $\chi \in H^1_E(\Omega)$ satisfies

$$(a\,\mathbf{grad}\,\chi, \mathbf{grad}\,v) = (a\,\mathbf{grad}_{\mathcal{P}}\,e, \mathbf{grad}\,v) \quad \forall v \in H^1_E(\Omega) \tag{17}$$

and $\psi \in \mathcal{H}$ satisfies

$$(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,w) = (a^{-1}\boldsymbol{\sigma}_{\mathcal{P}}(e), \mathbf{curl}\,w) = (\mathbf{grad}_{\mathcal{P}}\,e, \mathbf{curl}\,w) \quad \forall w \in \mathcal{H}. \tag{18}$$

This splitting is orthogonal in the sense that

$$(a^{-1}\boldsymbol{\sigma}_{\mathcal{P}}(e), \boldsymbol{\sigma}_{\mathcal{P}}(e)) = (a^{-1}\boldsymbol{\sigma}(\chi), \boldsymbol{\sigma}(\chi)) + (a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi). \tag{19}$$

A proof of this result can be found in [10], while a proof of a slightly more general version is given in [1]. The function χ constitutes the orthogonal projection of the total error onto the conforming space $H^1_E(\Omega)$ and is referred to as the *conforming error*, while the remaining part ψ is referred to as the *nonconforming error*. The orthogonality of the splitting means that it suffices to estimate the contribution of each part to the total error independently.

3.1. Statement of the a posteriori error bounds. The treatment of the nonconforming part of the error forms the subject of section 6, where it is shown in Lemma 9 that

$$(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi) \leq \sum_{K\in\mathcal{P}} \eta_{\mathsf{NC},K}^2,$$

where $\eta_{\mathsf{NC},K} = \|a^{1/2}\,\mathbf{grad}_{\mathcal{P}}(U_{\mathcal{P}}^* - U_{\mathcal{P}})\|_K$ and $U_{\mathcal{P}}^*$ is defined in section 6. The conforming part of the error is dealt with in section 5, where it is shown in Lemma 8 that

$$(a\,\mathbf{grad}\,\chi, \mathbf{grad}\,\chi) \leq \sum_{K\in\mathcal{P}} \eta_{\mathsf{CF},K}(\beta)^2,$$

where

$$\eta_{\mathsf{CF},K}(\beta) = a_K^{-1/2}\sqrt{\|\boldsymbol{\rho}_K\|_K^2 - \mathcal{C}_K^\star(\beta)^2|K|\|\mathrm{curl}\,\boldsymbol{\rho}_K\|_K^2}$$
$$+ \mathcal{C}_p(K)a_K^{-1/2}\|f - \overline{f}_K\|_K + \sum_{\gamma\in\mathcal{E}_N(K)} \mathcal{C}_t(K,\gamma)a_K^{-1/2}\|g - \overline{g}_\gamma\|_\gamma,$$

a_K denotes the restriction of the data a to element K, and $\overline{f}_K = |K|^{-1}\int_K f\,\mathrm{d}\boldsymbol{x}$ and $\overline{g}_\gamma = |\gamma|^{-1}\int_\gamma g\,\mathrm{d}s$ denote average values of the data over an element or edge, respectively.

We emphasize that *all* of these quantities are given explicitly and are fully computable in terms of the discontinuous Galerkin approximation $U_{\mathcal{P}}$, the data f and g_N, and geometrical information on the element. The final two terms often represent higher order contributions measuring the oscillation in the data f and g_N but are nevertheless included in the estimator, using values for the multiplicative constants $\mathcal{C}_p$ and $\mathcal{C}_t$ given explicitly in (61) and (64), so that one has a guaranteed upper bound on the error even if the terms turn out not to be of higher order. The principal part of the estimator involves the function $\boldsymbol{\rho}_K$ defined in Lemma 6, where an easily computable closed form expression for its norm is given. The quantity $\mathcal{C}_K^\star(\beta)$ defined in (49) involves an arbitrarily chosen "bubble" function $\beta \in H_0^1(K)$. One possibility is to choose $\beta = 0$. The best choice, in terms of maximizing $\mathcal{C}_K^\star$, satisfies $-\Delta\beta = 1$ in K and vanishes on the element boundary. In general such a function is not available in closed form and in practice a simple cubic polynomial approximation of the function is found to be sufficient, for which one may show that

$$\mathcal{C}_K^\star(\beta)^2 = \frac{a_K}{20\,\mathrm{trace}(\boldsymbol{S}_K)}, \tag{20}$$

where $\boldsymbol{S}_K$ is the element stiffness matrix in terms of the barycentric coordinates defined earlier.

Lemmas 8 and 9 also assert that $\eta_{\mathsf{CF},K}(\beta)$ and $\eta_{\mathsf{NC},K}$ provide local lower bounds for the conforming and nonconforming parts of the error up to data oscillation. Consequently, by combining Theorem 1 and the above lemmas we obtain computable bounds for the error measured in both the broken energy seminorm and DG-norm, along with corresponding lower bounds.

THEOREM 2. *Let $e = U_{\mathcal{P}} - u$ denote the error in the discontinuous Galerkin approximation. Then*

$$|||e|||^2 \leq \sum_{K\in\mathcal{P}} (\eta_{\mathsf{CF},K}(\beta)^2 + \eta_{\mathsf{NC},K}^2) \tag{21}$$

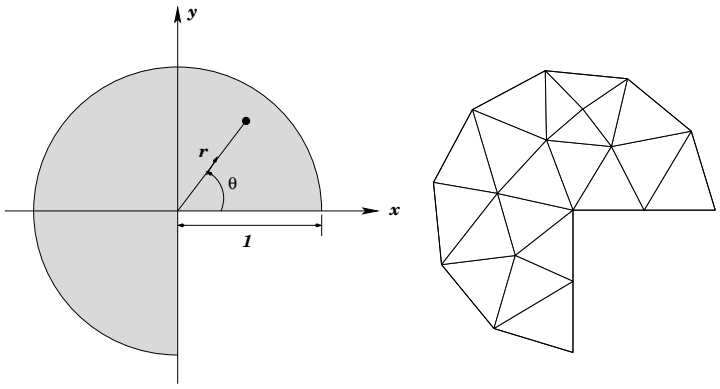

FIG. 1. (a) *Domain* Ω *and* (b) *initial mesh used in numerical example.*

and

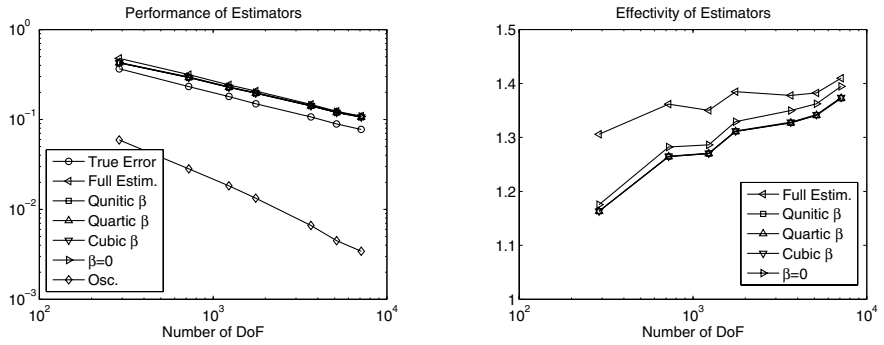
$$\|\!|e|\!\|_{DG}^2 \leq \sum_{K\in\mathcal{P}} (\eta_{\mathsf{CF},K}(\beta)^2 + \eta_{\mathsf{NC},K}^2) + \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \frac{\kappa}{|\gamma|}\|[U_{\mathcal{P}}]\|_\gamma^2, \tag{22}$$

where $\eta_{\mathsf{CF},K}(\beta)$ *and* $\eta_{\mathsf{NC},K}$ *are defined in Lemmas* 8 *and* 9*, respectively. Moreover, if the interior penalty parameter* $\kappa > 4\max_{K\in\mathcal{P}} \varrho(\boldsymbol{S}_K)$*, then the above bounds are efficient up to data oscillation and a positive constant independent of any mesh-size and the solution.*

3.2. Numerical example. In order to illustrate the theoretical results, we consider a simple Poisson problem with homogeneous Dirichlet data on the domain Ω as shown in Figure 1, with the source term f chosen so that the true solution is given by $u(r,\theta) = (r^3 - r^{2/3})\sin(2\theta/3)$. The problem is approximated using discontinuous Galerkin with an interior penalty parameter $\kappa = 10$, which was observed to be consistent with the bound given in Lemma 1, using a sequence of adaptively refined meshes obtained starting with the mesh shown in Figure 1 and selecting those elements for which the "full" local error indicator exceeds 30% of the value of the largest local error indicator. In Figure 2 we compare the values of the a posteriori error estimator corresponding to the choice $\beta = 0$, or to choosing β to be the cubic, quartic, or quintic polynomial that maximizes the value of $\mathcal{C}_K^\star(\beta)$. In order to illustrate the influence of the choice of the bubble more clearly, the data oscillation term in (57) is not included but rather is shown separately, where it is seen to be of higher order. The "full" estimator, with optimal quintic bubble and including data oscillation, is also shown separately.

The results obtained in this particular example are typical. In particular, we observe that the use of a cubic bubble β provides a marked improvement over the raw estimator ($\beta = 0$), while the use of higher order bubbles provides marginal further improvement at best. Therefore, the use of a cubic bubble seems to be merited in general practical computations, particularly in view of the ease with which it may be implemented.

4. Jumps in DGFEM are subordinate to the error in the broken H^1-seminorm. As usual, we define the oscillation of the data $f \in L_2(\Omega)$ over a collection



(a) (b)

FIG. 2. (a) *Values of a posteriori estimators and data oscillation, and* (b) *ratio of estimated error to true error obtained for numerical example.*

$\mathcal{P}'$ of elements by

$$\operatorname{osc}(f,\mathcal{P}')^2 = \sum_{K\subset\mathcal{P}'} |K| \|f - \overline{f}_K\|_K^2, \tag{23}$$

where $\overline{f}_K$ is the average value of f over element K. Likewise, the oscillation of the Neumann data g over a collection $\mathcal{E}' \subset \mathcal{E}_N$ of edges is defined by

$$\operatorname{osc}(g,\mathcal{E}')^2 = \sum_{\gamma\subset\mathcal{E}'} |\gamma| \|g - \overline{g}_\gamma\|_\gamma^2, \tag{24}$$

where $\overline{g}_\gamma$ denotes the average value of g on the edge γ. The main result of this section may be stated as follows.

THEOREM 3. *Suppose that* $\kappa > 4\max_{K\in\mathcal{P}} \varrho(\boldsymbol{S}_K)$, *and* $e = U_\mathcal{P} - u$ *denote the error in the discontinuous Galerkin approximation. Then*

$$\begin{aligned}\sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \frac{\kappa}{|\gamma|}\int_\gamma [e]^2 \,\mathrm{d}s \\ \le C\kappa \left[\frac{\kappa}{\kappa - 4\max_{K\in\mathcal{P}}\varrho(\boldsymbol{S}_K)}\right]^2 \left[\sum_{K\in\mathcal{P}} \|a^{1/2}\,\mathbf{grad}\, e\|_K^2 + \operatorname{osc}(f,\mathcal{P})^2 + \operatorname{osc}(g,\mathcal{E}_N)^2\right],\end{aligned} \tag{25}$$

where C *is a positive constant independent of any mesh-size.*

This result shows, up to terms involving oscillation of the data, that the contributions from the jump terms to the value of $\|\!|e|\!\|_{DG}$ may be bounded in terms of the contributions from the broken H^1-seminorm $\|\!|e|\!\|$. At first glance, this result is somewhat surprising in the sense that it does not hold for an arbitrary function. Note, for example, that (ignoring oscillation terms) the expression appearing in the bound vanishes when applied to a piecewise constant function, while the left-hand side is nonzero for such a function. There is of course no paradox here, since the estimate is claimed to hold only in the case of the error in a discontinuous Galerkin approximation.

This type of estimate seems to be of wider significance for discontinuous Galerkin finite element schemes, confirming that the jump discontinuities in the approximation

are properly controlled through the interior penalty term and, as a result, play a subordinate role to that of the error measured in the broken H^1-seminorm.

The proof of Theorem 3 is postponed until the end of this section. We begin by deriving estimates for the element volume residuals and jumps in function values and fluxes across interelement edges in terms of the error in a neighborhood of the entity.

The bounds given in the following result for the volume residuals and interelement fluxes are more or less standard and we confine ourselves to a statement of the results.

LEMMA 2. *Let $\chi \in H^1_E(\Omega)$ denote the conforming part of the error defined in* (17). *Then there exist positive constants c, independent of any mesh-size, such that on every element $K \in \mathcal{P}$,*

$$ch_K\|f\|_K \le \|a^{1/2}\,\mathbf{grad}\,\chi\|_K + \operatorname{osc}(f,K); \tag{26}$$

on every edge $\gamma \in \mathcal{E}_I$,

$$c|\gamma|^{1/2}\|[\sigma_\nu(U_{\mathcal{P}})]\|_\gamma \le \|a^{1/2}\,\mathbf{grad}\,\chi\|_{\widetilde{\gamma}} + \operatorname{osc}(f,\widetilde{\gamma}); \tag{27}$$

and, on every edge $\gamma \in \mathcal{E}_N$,

$$c|\gamma|^{1/2}\|g - \sigma_\nu(U_{\mathcal{P}})\|_\gamma \le \|a^{1/2}\,\mathbf{grad}\,\chi\|_{\widetilde{\gamma}} + \operatorname{osc}(f,\widetilde{\gamma}) + \operatorname{osc}(g,\gamma). \tag{28}$$

Let $\psi \in \mathcal{H}$ denote the nonconforming part of the error defined in (18). *Then, on every edge $\gamma \in \mathcal{E}_I$,*

$$c|\gamma|^{1/2}\|[\partial U_{\mathcal{P}}/\partial s]\|_\gamma \le \|a^{-1/2}\,\mathbf{curl}\,\psi\|_{\widetilde{\gamma}}, \tag{29}$$

and on every edge $\gamma \in \mathcal{E}_D$,

$$c|\gamma|^{1/2}\|\partial(u_D - U_{\mathcal{P}})/\partial s\|_\gamma \le \|a^{-1/2}\,\mathbf{curl}\,\psi\|_{\widetilde{\gamma}}. \tag{30}$$

Proof. The first three estimates are obtained by applying a standard "bubble" function argument to (17) (see, e.g., [3, section 2.3] or [17]). The remaining estimates are obtained in a similar fashion (see, e.g., [10]) using (18). ∎

The above estimates give only bounds on the jumps in the gradient of the approximation across element boundaries. Our objective here is to obtain bounds on the jumps in actual values. The next result gives bounds on the average value of the jump in the approximation across edges provided that the choice of the penalty parameter κ is consistent with the bound obtained in Lemma 1 that was shown to be sufficient to ensure that the discrete scheme is well-posed.

LEMMA 3. *Suppose that $\kappa > 4\varrho(\boldsymbol{S}_K)$. Then*

$$\begin{aligned}&\sum_{\gamma\in\mathcal{E}_I(K)}\left||\gamma|^{-1}\int_\gamma [U_{\mathcal{P}}]\,\mathrm{d}s\right| + \sum_{\gamma\in\mathcal{E}_D(K)}\left||\gamma|^{-1}\int_\gamma (U_{\mathcal{P}} - u_D)\,\mathrm{d}s\right| \\ &\le C(\kappa - 4\varrho(\boldsymbol{S}_K))^{-1}\Big[\|a^{1/2}\,\mathbf{grad}\,\chi\|_{\widetilde{K}} + \operatorname{osc}(f,\widetilde{K}) \\ &\qquad + \kappa\|a^{-1/2}\,\mathbf{curl}\,\psi\|_{\widetilde{K}} + \operatorname{osc}(g,\mathcal{E}_N(K))\Big],\end{aligned} \tag{31}$$

where C is a positive constant independent of any mesh-size.

Proof. Fix an element $K \in \mathcal{P}$ and, for each edge $\gamma \in \mathcal{E}_I(K) \cup \mathcal{E}_D(K)$, define

$$\alpha_\gamma = \begin{cases} \dfrac{1}{|\gamma|} \displaystyle\int_\gamma \mu_K \, [U_\mathcal{P}] \, \mathrm{d}s, & \gamma \in \mathcal{E}_I(K), \\ \dfrac{1}{|\gamma|} \displaystyle\int_\gamma (U_\mathcal{P} - u_D) \, \mathrm{d}s, & \gamma \in \mathcal{E}_D(K). \end{cases}$$

Let $\gamma^* \in \mathcal{E}_I(K) \cup \mathcal{E}_D(K)$ and define $\varphi_{\gamma^*} \in \mathbb{P}_1(K)$ by the rule $\varphi_{\gamma^*} = 1 - 2\lambda_*$, where λ_* is the barycentric coordinate associated with the vertex in element K that is opposite to the edge γ^*. Observe that φ_{γ^*} has constant value (unity) on the edge γ^* and satisfies

$$\frac{1}{|\gamma|} \int_\gamma \varphi_{\gamma^*} \, \mathrm{d}s = \delta_{\gamma^*\gamma}, \quad \gamma \in \mathcal{E}(K). \tag{32}$$

The lack of any interelement continuity requirements on the test functions means that the function φ_{γ^*}, extended onto the remaining elements by zero, is admissible.

Inserting the test function into the variational statement (9), integrating the volumetric term in the bilinear form (7) by parts, and simplifying, we arrive at the identity

$$\begin{aligned} &(f, \varphi_{\gamma^*})_K + \sum_{\gamma \in \mathcal{E}_N(K)} \int_\gamma (g - \sigma_\nu(U_\mathcal{P})) \varphi_{\gamma^*} \, \mathrm{d}s - \frac{1}{2} \sum_{\gamma \in \mathcal{E}_I(K)} \int_\gamma [\sigma_\nu(U_\mathcal{P})] \, \varphi_{\gamma^*} \, \mathrm{d}s \\ &= \sum_{\gamma \in \mathcal{E}_D(K)} \frac{\kappa}{|\gamma|} \int_\gamma (U_\mathcal{P} - u_D) \varphi_{\gamma^*} \, \mathrm{d}s + \sum_{\gamma \in \mathcal{E}_I(K)} \frac{\kappa}{|\gamma|} \int_\gamma \mu_K \, [U_\mathcal{P}] \, \varphi_{\gamma^*} \, \mathrm{d}s \\ &\quad - \sum_{\gamma \in \mathcal{E}_D(K)} \int_\gamma (U_\mathcal{P} - u_D) \sigma_{\nu_K}(\varphi_{\gamma^*}) \, \mathrm{d}s - \frac{1}{2} \sum_{\gamma \in \mathcal{E}_I(K)} \int_\gamma \mu_K \, [U_\mathcal{P}] \, \sigma_{\nu_K}(\varphi_{\gamma^*}) \, \mathrm{d}s. \end{aligned} \tag{33}$$

It will be useful to express several of the terms appearing on the right-hand side in an alternative form. In view of (32), for $\gamma \in \mathcal{E}_I(K)$ there holds

$$\frac{\kappa}{|\gamma|} \int_\gamma \mu_K \, [U_\mathcal{P}] \, \varphi_{\gamma^*} \, \mathrm{d}s = \begin{cases} \kappa \alpha_{\gamma^*} & \text{if } \gamma^* = \gamma, \\ \dfrac{\kappa}{|\gamma|} \displaystyle\int_\gamma \mu_K ([U_\mathcal{P}] - c_\gamma) \varphi_{\gamma^*} \, \mathrm{d}s & \text{otherwise,} \end{cases}$$

while for $\gamma \in \mathcal{E}_D(K)$,

$$\frac{\kappa}{|\gamma|} \int_\gamma (U_\mathcal{P} - u_D) \varphi_{\gamma^*} \, \mathrm{d}s = \begin{cases} \kappa \alpha_{\gamma^*} & \text{if } \gamma^* = \gamma, \\ \dfrac{\kappa}{|\gamma|} \displaystyle\int_\gamma (U_\mathcal{P} - u_D - c_\gamma) \varphi_{\gamma^*} \, \mathrm{d}s & \text{otherwise,} \end{cases}$$

where c_γ is an arbitrary constant (to be chosen later).

By observing that $\sigma_{\nu_K}(\varphi_{\gamma^*})$ is piecewise constant on the element boundary and again using property (32), we see that

$$|\gamma| \, \sigma_{\nu_K}(\varphi_{\gamma^*})|_\gamma = \int_{\partial K} \varphi_\gamma \sigma_{\nu_K}(\varphi_{\gamma^*}) \, \mathrm{d}s = (a \, \mathbf{grad} \, \varphi_{\gamma^*}, \mathbf{grad} \, \varphi_\gamma)_K$$

for any edge $\gamma \subset \partial K$. By further exploiting the fact that $\sigma_{\nu_K}(\varphi_{\gamma^*})$ is piecewise constant and by the definition of α_γ, we deduce that

$$\int_\gamma (U_{\mathcal{P}} - u_D)\sigma_{\nu_K}(\varphi_{\gamma^*})\,\mathrm{d}s = (a\,\mathbf{grad}\,\varphi_{\gamma^*}, \mathbf{grad}\,\varphi_\gamma)_K\ \alpha_\gamma, \quad \gamma \in \mathcal{E}_D(K),$$

and

$$\int_\gamma \mu_K\,[U_{\mathcal{P}}]\,\sigma_{\nu_K}(\varphi_{\gamma^*})\,\mathrm{d}s = (a\,\mathbf{grad}\,\varphi_{\gamma^*}, \mathbf{grad}\,\varphi_\gamma)_K\ \alpha_\gamma, \quad \gamma \in \mathcal{E}_I(K).$$

It is convenient to express these quantities in terms of entries in the element stiffness matrix $\boldsymbol{S}_K$ relative to the barycentric coordinates defined earlier:

$$(a\,\mathbf{grad}\,\varphi_\gamma, \mathbf{grad}\,\varphi_{\gamma'})_K = 4[\boldsymbol{S}_K]_{\gamma\gamma'}.$$

Inserting the above alternative forms into expression (33) and rearranging, we obtain the following relation for each edge $\gamma^* \in \mathcal{E}_I(K) \cup \mathcal{E}_D(K)$:

$$\kappa\alpha_{\gamma^*} - 4\sum_{\gamma\in\mathcal{E}_D(K)} [\boldsymbol{S}_K]_{\gamma^*\gamma}\ \alpha_\gamma - 2\sum_{\gamma\in\mathcal{E}_I(K)} [\boldsymbol{S}_K]_{\gamma^*\gamma}\ \alpha_\gamma = r^K_{\gamma^*},$$

where

$$\begin{aligned} r^K_{\gamma^*} &= (f, \varphi_{\gamma^*})_K \\ &+ \sum_{\gamma\in\mathcal{E}_N(K)} \int_\gamma (g - \sigma_\nu(U_{\mathcal{P}}))\varphi_{\gamma^*}\,\mathrm{d}s - \frac{1}{2}\sum_{\gamma\in\mathcal{E}_I(K)} \int_\gamma [\sigma_\nu(U_{\mathcal{P}})]\,\varphi_{\gamma^*}\,\mathrm{d}s \\ &- \sum_{\gamma\in\mathcal{E}_D(K)\setminus\gamma^*} \frac{\kappa}{|\gamma|}\int_\gamma (U_{\mathcal{P}} - u_D - c_\gamma)\varphi_{\gamma^*}\,\mathrm{d}s \\ &- \sum_{\gamma\in\mathcal{E}_I(K)\setminus\gamma^*} \frac{\kappa}{|\gamma|}\int_\gamma \mu_K([U_{\mathcal{P}}] - c_\gamma)\varphi_{\gamma^*}\,\mathrm{d}s. \end{aligned}$$

Introducing a diagonal matrix $\boldsymbol{\Lambda}_K \in \mathbb{R}^{m\times m}$, where m is the number of Dirichlet and internal edges on K, with entries

$$\Lambda_{\gamma\gamma} = \begin{cases} 1 & \text{if } \gamma \in \mathcal{E}_D(K), \\ \frac{1}{2} & \text{if } \gamma \in \mathcal{E}_I(K), \end{cases}$$

we may write the above equations in the form

$$\kappa\boldsymbol{\alpha}_K - 4\boldsymbol{S}_K\boldsymbol{\Lambda}_K\boldsymbol{\alpha}_K = \boldsymbol{r}_K,$$

where $[\boldsymbol{\alpha}_K]_\gamma = \alpha_\gamma$ and $[\boldsymbol{r}_K]_\gamma = r^K_\gamma$. Observing that

$$(\boldsymbol{\Lambda}_K\boldsymbol{\alpha}_K)^\top \boldsymbol{S}_K\boldsymbol{\Lambda}_K\boldsymbol{\alpha}_K \le \varrho(\boldsymbol{S}_K)\boldsymbol{\alpha}_K^\top\boldsymbol{\Lambda}_K^2\boldsymbol{\alpha}_K \le \varrho(\boldsymbol{S}_K)\boldsymbol{\alpha}_K^\top\boldsymbol{\Lambda}_K\boldsymbol{\alpha}_K,$$

we obtain

$$(\kappa - 4\varrho(\boldsymbol{S}_K))\boldsymbol{\alpha}_K^\top\boldsymbol{\Lambda}_K\boldsymbol{\alpha}_K \le \boldsymbol{\alpha}_K^\top\boldsymbol{\Lambda}_K\boldsymbol{r}_K$$

and hence, with the aid of a Cauchy–Schwarz inequality,

$$(\kappa - 4\varrho(\boldsymbol{S}_K))^2 \boldsymbol{\alpha}_K^\top \boldsymbol{\Lambda}_K \boldsymbol{\alpha}_K \leq \boldsymbol{r}_K^\top \boldsymbol{\Lambda}_K \boldsymbol{r}_K.$$

It remains to bound the terms appearing in the entries $r_{\gamma^*}^K$ of the vector $\boldsymbol{r}_K$. Observing that φ_{γ^*} satisfies $\|\varphi_{\gamma^*}\|_K \sim h_K$ and $\|\varphi_{\gamma^*}\|_\gamma \sim |\gamma|^{1/2}$, we obtain

$$\begin{aligned} c|r_{\gamma^*}^K| &\leq h_K \|f\|_K \\ &+ \sum_{\gamma \in \mathcal{E}_N(K)} |\gamma|^{1/2} \|g - \sigma_\nu(U_{\mathcal{P}})\|_\gamma + \frac{1}{2} \sum_{\gamma \in \mathcal{E}_I(K)} |\gamma|^{1/2} \|[\sigma_\nu(U_{\mathcal{P}})]\|_\gamma \\ &+ \sum_{\gamma \in \mathcal{E}_D(K) \setminus \gamma^*} \kappa |\gamma|^{-1/2} \|U_{\mathcal{P}} - u_D - c_\gamma\|_\gamma \\ &+ \sum_{\gamma \in \mathcal{E}_I(K) \setminus \gamma^*} \kappa |\gamma|^{-1/2} \|[U_{\mathcal{P}}] - c_\gamma\|_\gamma, \end{aligned}$$

where c is a positive constant independent of κ and any mesh-size. The above estimate holds for all choices of constants $\{c_\gamma\}$ and hence, taking c_γ to be appropriate averages and using a scaling argument, we may arrange that

$$\|U_{\mathcal{P}} - u_D - c_\gamma\|_\gamma \leq C|\gamma| \|\partial(U_{\mathcal{P}} - u_D)/\partial s\|_\gamma, \quad \gamma \in \mathcal{E}_D(K),$$

and

$$\|[\sigma_\nu(U_{\mathcal{P}})] - c_\gamma\|_\gamma \leq C|\gamma| \|[\partial U_{\mathcal{P}}/\partial s]\|_\gamma, \quad \gamma \in \mathcal{E}_I(K).$$

In view of the estimates in Lemma 2, we conclude that

$$c|\boldsymbol{r}_K| \leq \|a^{1/2} \operatorname{\mathbf{grad}} \chi\|_{\widetilde{K}} + \kappa \|a^{-1/2} \operatorname{\mathbf{curl}} \psi\|_{\widetilde{K}} + \operatorname{osc}(f, \widetilde{K}) + \operatorname{osc}(g, \mathcal{E}_N(K)),$$

and the result then follows as claimed. ∎

We are now in a position to give bounds on the norms of the jumps in the discontinuous Galerkin approximation in terms of the local conforming and nonconforming parts of the error.

LEMMA 4. *Suppose that $\kappa > 4\varrho(\boldsymbol{S}_K)$. Then*

$$\begin{aligned} |\gamma|^{-1/2} \|[U_{\mathcal{P}}]\|_\gamma \leq & C(\kappa - 4\varrho(\boldsymbol{S}_K))^{-1} \Big[\|a^{1/2} \operatorname{\mathbf{grad}} \chi\|_{\widetilde{K}} + \operatorname{osc}(f, \widetilde{K}) \\ & + \kappa \|a^{-1/2} \operatorname{\mathbf{curl}} \psi\|_{\widetilde{K}} + \operatorname{osc}(g, \mathcal{E}_N(K)) \Big] \end{aligned} \tag{34}$$

for $\gamma \in \mathcal{E}_I(K)$, and

$$\begin{aligned} |\gamma|^{-1/2} \|U_{\mathcal{P}} - u_D\|_\gamma \leq & C(\kappa - 4\varrho(\boldsymbol{S}_K))^{-1} \Big[\|a^{1/2} \operatorname{\mathbf{grad}} \chi\|_{\widetilde{K}} + \operatorname{osc}(f, \widetilde{K}) \\ & + \kappa \|a^{-1/2} \operatorname{\mathbf{curl}} \psi\|_{\widetilde{K}} + \operatorname{osc}(g, \mathcal{E}_N(K)) \Big] \end{aligned} \tag{35}$$

for $\gamma \in \mathcal{E}_D(K)$, where C is a positive constant independent of any mesh-size.

Proof. It is not difficult to show that for any function $F \in H^1(0, h)$ we have

$$h^{-1} \|F - \overline{F}\|_{L_2(0,h)}^2 \leq Ch \|F'\|_{L_2(0,h)}^2,$$

where the prime denotes the derivative, and $\overline{F}$ is the average value of F. Observing that the left-hand side may be rewritten as

$$h^{-1}\|F\|^2_{L_2(0,h)} - |\overline{F}|^2,$$

we deduce that

$$h^{-1}\|F\|^2_{L_2(0,h)} \le |\overline{F}|^2 + Ch\|F'\|^2_{L_2(0,h)}.$$

Choosing $F = [U_{\mathcal{P}}]$, we obtain

$$|\gamma|^{-1}\|[U_{\mathcal{P}}]\|^2_\gamma \le \left||\gamma|^{-1}\int_\gamma [U_{\mathcal{P}}]\ \mathrm{d}s\right|^2 + C|\gamma|\|[\partial U_{\mathcal{P}}/ds]\|^2_\gamma,$$

while choosing $F = U_{\mathcal{P}} - u_D$, we obtain

$$|\gamma|^{-1}\|U_{\mathcal{P}} - u_D\|^2_\gamma \le \left||\gamma|^{-1}\int_\gamma (U_{\mathcal{P}} - u_D)\,\mathrm{d}s\right|^2 + C|\gamma|\|\partial(U_{\mathcal{P}} - u_D)/ds\|^2_\gamma.$$

The assertions then follow at once from Lemmas 2 and 3. ∎

Finally, we come to the proof of Theorem 3.

Proof. The result follows at once from Theorem 1 and Lemma 4 on observing that $[e]$ coincides with $[U_{\mathcal{P}}]$ on an interior edge and with $U_{\mathcal{P}} - u_D$ on an edge $\gamma \in \mathcal{E}_D$. ∎

5. Estimation of conforming error.

5.1. Equilibrated fluxes. Given the finite element approximation $U_{\mathcal{P}}$, we introduce a set of piecewise linear *flux functions* $\{g_K : K \in \mathcal{P}\}$ on the element boundaries $g_K : \partial K \to \mathbb{R}$ as follows:

$$g_{K|\gamma} = \begin{cases} \mu_K\left(\langle\sigma_\nu(U_{\mathcal{P}})\rangle - \kappa|\gamma|^{-1}\,[U_{\mathcal{P}}]\right) & \text{on } \gamma \in \mathcal{E}_I(K), \\ \sigma_\nu(U_{\mathcal{P}}) - \kappa|\gamma|^{-1}(U_{\mathcal{P}} - u_D) & \text{on } \gamma \in \mathcal{E}_D(K), \\ \overline{g}_\gamma & \text{on } \gamma \in \mathcal{E}_N(K), \end{cases} \tag{36}$$

where $\overline{g}_\gamma$ denotes the average value of g on edge γ.

The fluxes $\{g_K\}$ have the following useful properties, referred to as *equilibration conditions* in [3].

LEMMA 5. *Let $\{g_K : K \in \mathcal{P}\}$ be defined as in* (36). *Then*

$$\sum_{K\in\mathcal{P}}\int_{\partial K} g_K v\,\mathrm{d}s = \int_{\Gamma_N} gv\,\mathrm{d}s - \sum_{\gamma\in\mathcal{E}_N}\int_\gamma (g - \overline{g}_\gamma)v\,\mathrm{d}s \quad \forall v \in H^1_E(\Omega) \tag{37}$$

and

$$\int_{\partial K} g_K\,\mathrm{d}s + \int_K f\,\mathrm{d}\boldsymbol{x} = 0 \tag{38}$$

for each element $K \in \mathcal{P}$.

Proof. The presence of the sign function μ_K in definition (36) means that, on any given interior edge $\gamma \in \mathcal{E}_I(K) \cap \mathcal{E}_I(K')$, the fluxes satisfy $g_K + g_{K'} = 0$. The first identity is an easy consequence of this fact, the definition of the fluxes on Γ_N, and the vanishing of the trace of the test function v on Γ_D. Let χ_K denote the piecewise constant function supported on element K, where it takes the value unity. The second

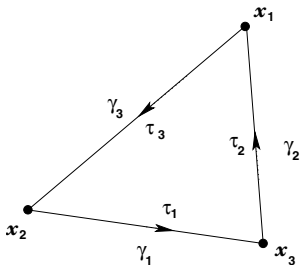


FIG. 3. *Locations of vertices and associated tangent vectors on triangle.*

assertion follows by inserting the expression for the flux function and simplifying to obtain

$$\begin{aligned}
&\int_{\partial K} g_K \,\mathrm{d}s + \int_K f \,\mathrm{d}\boldsymbol{x} \\
&= \sum_{\gamma\in\mathcal{E}_N} \int_\gamma g\chi_K \,\mathrm{d}s + (f,\chi_K) + \sum_{\gamma\in\mathcal{E}_D} \kappa|\gamma|^{-1} \int_\gamma u_D\chi_K \,\mathrm{d}s \\
&\quad + \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \int_\gamma \langle\sigma_\nu(U_\mathcal{P})\rangle\,[\chi_K] - \sum_{\gamma\in\mathcal{E}_I\cup\mathcal{E}_D} \kappa|\gamma|^{-1} \int_\gamma [U_\mathcal{P}]\,[\chi_K] \\
&= \mathcal{L}_\mathcal{P}(\chi_K) - \mathcal{B}_\mathcal{P}(U_\mathcal{P},\chi_K) = 0,
\end{aligned}$$

where we have used the facts that $[\chi_K] = \mu_K\chi_K$, that $\mathbf{grad}_\mathcal{P}\,\chi_K$ and $\langle\sigma_\nu(\chi_K)\rangle$ both vanish, and that $U_\mathcal{P}$ satisfies (9). ∎

The data appearing in the definition of the conforming part of the error may be rewritten, using (2), as

$$(a\,\mathbf{grad}\,\chi, \mathbf{grad}\,v) = (f,v) + \int_{\Gamma_N} gv \,\mathrm{d}s - (a\,\mathbf{grad}_\mathcal{P}\,U_\mathcal{P}, \mathbf{grad}\,v) \quad \forall v \in H^1_E(\Omega). \tag{39}$$

Then, exploiting property (37), we may split the right-hand side into contributions from individual elements, arriving at the identity

$$\begin{aligned}
&(a\,\mathbf{grad}\,\chi, \mathbf{grad}\,v) \\
&= \sum_{K\in\mathcal{P}} \left\{ (\overline{f}_K, v)_K + \int_{\partial K} g_K v \,\mathrm{d}s - (a\,\mathbf{grad}\,U_\mathcal{P}, \mathbf{grad}\,v)_K \right\} \\
&\quad + \sum_{K\in\mathcal{P}} (f-\overline{f}_K, v)_K + \sum_{\gamma\in\mathcal{E}_N} \int_\gamma (g-\overline{g}_\gamma) v \,\mathrm{d}s \quad \forall v \in H^1_E(\Omega).
\end{aligned} \tag{40}$$

The next step is to construct a computable local representation of the functionals appearing in parentheses.

5.2. Construction of local representer. Let $K \in \mathcal{P}$ be any element and, without loss of generality, assume that the vertices and edges are enumerated as shown in Figure 3, where $\boldsymbol{\tau}_n$ are the nonnormalized tangent vectors shown. The following result gives an explicit construction for the local representer and a closed form for its norm.

LEMMA 6. *For $K \in \mathcal{P}$, let*

$$\boldsymbol{\rho}_K = \frac{1}{2|K|} \sum_{n \in \mathcal{N}(K)} \boldsymbol{\rho}_n^{(K)} \lambda_n, \tag{41}$$

where $|K|$ is the area of the element,

$$\begin{aligned} \boldsymbol{\rho}_1^{(K)} &= |\gamma_3| \Delta_3^{(K)}(\boldsymbol{x}_1)\boldsymbol{\tau}_2 - |\gamma_2| \Delta_2^{(K)}(\boldsymbol{x}_1)\boldsymbol{\tau}_3, \\ \boldsymbol{\rho}_2^{(K)} &= |\gamma_1| \Delta_1^{(K)}(\boldsymbol{x}_2)\boldsymbol{\tau}_3 - |\gamma_3| \Delta_3^{(K)}(\boldsymbol{x}_2)\boldsymbol{\tau}_1, \\ \boldsymbol{\rho}_3^{(K)} &= |\gamma_2| \Delta_2^{(K)}(\boldsymbol{x}_3)\boldsymbol{\tau}_1 - |\gamma_1| \Delta_1^{(K)}(\boldsymbol{x}_3)\boldsymbol{\tau}_2, \end{aligned} \tag{42}$$

and

$$\Delta_n^{(K)} = (g_K - \sigma_{\nu_K}(U_{\mathcal{P}}))_{|\gamma_n}, \quad \gamma_n \subset \mathcal{E}(K). \tag{43}$$

Then

$$(\boldsymbol{\rho}_K, \mathbf{grad}\, v)_K = (\overline{f}_K, v)_K + \int_{\partial K} g_K v \, \mathrm{d}s - (a \,\mathbf{grad}\, U_{\mathcal{P}}, \mathbf{grad}\, v)_K \quad \forall v \in H^1_E(K) \tag{44}$$

and

$$\|\boldsymbol{\rho}_K\|_K^2 = \frac{1}{48|K|} \left[\left| \sum_{n \in \mathcal{N}(K)} \boldsymbol{\rho}_n^{(K)} \right|^2 + \sum_{n \in \mathcal{N}(K)} \left| \boldsymbol{\rho}_n^{(K)} \right|^2 \right]. \tag{45}$$

Proof. Let $\boldsymbol{\nu}_1$ denote the unit normal on edge γ_1. Then

$$\boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_K = \frac{1}{2|K|} \left[\boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_2^{(K)} \lambda_2 + \boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_3^{(K)} \lambda_3 \right] \quad \text{on } \gamma_1.$$

Elementary algebra reveals that $\boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_n^{(K)} = 2|K| \Delta_1^{(K)}(\boldsymbol{x}_n)$ for $n = 2$ and 3, and hence

$$\boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_K = \Delta_1^{(K)}(\boldsymbol{x}_2)\lambda_2 + \Delta_1^{(K)}(\boldsymbol{x}_3)\lambda_3 \quad \text{on } \gamma_1.$$

Since $\Delta^{(K)}$ is piecewise linear on the element edges, we have $\boldsymbol{\nu}_1 \cdot \boldsymbol{\rho}_K = \Delta_1^{(K)}$ on γ_1. The same argument applies equally well to the remaining edges, and we conclude that

$$\boldsymbol{\nu}_K \cdot \boldsymbol{\rho}_K = g_K - \sigma_{\nu_K}(U_{\mathcal{P}}) \quad \text{on } \partial K.$$

Furthermore, since $\mathbf{div}\, \boldsymbol{\rho}_K$ is constant, we have

$$\mathbf{div}\, \boldsymbol{\rho}_K = \frac{1}{|K|} \int_K \mathbf{div}\, \boldsymbol{\rho}_K \, \mathrm{d}\boldsymbol{x} = \frac{1}{|K|} \int_{\partial K} \boldsymbol{\nu}_K \cdot \boldsymbol{\rho}_K \, \mathrm{d}s.$$

Then inserting the expression for the normal components and integrating by parts, we obtain

$$\mathbf{div}\, \boldsymbol{\rho}_K = \frac{1}{|K|} \int_{\partial K} g_K \, \mathrm{d}s - \frac{1}{|K|} \int_K \mathbf{div}\, \boldsymbol{\sigma}(U_{\mathcal{P}}) \, \mathrm{d}\boldsymbol{x},$$

and, thanks to (38), we deduce that

$$-\mathbf{div}\, \boldsymbol{\rho}_K = \overline{f}_K + \mathbf{div}\, \boldsymbol{\sigma}(U_{\mathcal{P}}) \quad \text{on } K.$$

Given $v \in H^1(K)$, we have

$$(\boldsymbol{\rho}_K, \mathbf{grad}\, v)_K = \int_{\partial K} v \boldsymbol{\nu}_K \cdot \boldsymbol{\rho}_K \,\mathrm{d}s - (v, \mathbf{div}\, \boldsymbol{\rho}_K)_K,$$

and by again inserting the expressions for the normal components and divergence of $\boldsymbol{\rho}_K$, integrating by parts, and simplifying, we arrive at the identity (44). Finally, recalling that

$$\int_K \lambda_m \lambda_n \,\mathrm{d}\boldsymbol{x} = \frac{1}{12}|K|(1+\delta_{mn}), \quad m, n \in \mathcal{N}(K),$$

we have

$$\|\boldsymbol{\rho}_K\|_K^2 = \frac{1}{48|K|} \sum_{m\in\mathcal{N}(K)} \sum_{n\in\mathcal{N}(K)} (1+\delta_{mn}) \boldsymbol{\rho}_m^{(K)} \cdot \boldsymbol{\rho}_n^{(K)},$$

which simplifies to give (45). ∎

The following result gives an alternative representer having in general a smaller norm than the previous one.

LEMMA 7. *Let $K \in \mathcal{P}$ and define $\boldsymbol{\rho}_K$ as in Lemma 6. Let $\beta \in H_0^1(K)$ be arbitrary. Then*

$$\boldsymbol{\rho}_K^\star = \boldsymbol{\rho}_K - c_K^\star \,\mathbf{curl}\, \beta, \tag{46}$$

where

$$c_K^\star = \frac{\int_K \beta \,\mathrm{d}\boldsymbol{x}}{\|\mathbf{curl}\, \beta\|_K^2} \operatorname{curl} \boldsymbol{\rho}_K \tag{47}$$

satisfies (44) *(with $\boldsymbol{\rho}_K$ replaced by $\boldsymbol{\rho}_K^\star$) and*

$$\|\boldsymbol{\rho}_K^\star\|_K^2 = \|\boldsymbol{\rho}_K\|_K^2 - \mathcal{C}_K^\star(\beta)^2 |K| \|\operatorname{curl} \boldsymbol{\rho}_K\|_K^2, \tag{48}$$

where

$$\mathcal{C}_K^\star(\beta) = \frac{\int_K \beta \,\mathrm{d}\boldsymbol{x}}{|K| \|\mathbf{curl}\, \beta\|_K}. \tag{49}$$

Proof. The fact that $\boldsymbol{\rho}_K^\star$ satisfies the identity follows at once from Lemma 6 after noting that $\operatorname{curl} \boldsymbol{\rho}_K$ is constant and then observing that $(\mathbf{curl}\, \beta, \mathbf{grad}\, v)_K$ vanishes for $v \in H^1(K)$. Equally well, again using the fact that $\operatorname{curl} \boldsymbol{\rho}_K$ is constant, we find

$$\operatorname{curl} \boldsymbol{\rho}_K \int_K \beta \,\mathrm{d}\boldsymbol{x} = \int_K \beta \operatorname{curl} \boldsymbol{\rho}_K \,\mathrm{d}\boldsymbol{x} = (\boldsymbol{\rho}_K, \mathbf{curl}\, \beta)_K, \tag{50}$$

and so $c_K^\star = (\boldsymbol{\rho}_K, \mathbf{curl}\, \beta)_K / \|\mathbf{curl}\, \beta\|_K^2$. Direct calculation then gives

$$\|\boldsymbol{\rho}_K^\star\|_K^2 = \|\boldsymbol{\rho}_K\|_K^2 - \left[\frac{(\boldsymbol{\rho}_K, \mathbf{curl}\, \beta)_K}{\|\mathbf{curl}\, \beta\|_K} \right]^2$$

and the result then follows thanks to (50). ∎

Note that the quantity $\mathcal{C}_K^\star(\beta)$ depends on the shape of the element K but not on its size. The choice of the bubble function β was discussed in section 3.

5.3. Bounds on the conforming error. With the above representation result in hand, we resume the argument following (40) by inserting the representation (44) for the terms in parentheses, giving

$$\begin{aligned}&(a\,\mathbf{grad}\,\chi,\mathbf{grad}\,v)\\ &=\sum_{K\in\mathcal{P}}(\boldsymbol{\rho}_K^\star,\mathbf{grad}\,v)_K+\sum_{K\in\mathcal{P}}(f-\overline{f}_K,v)_K+\sum_{\gamma\in\mathcal{E}_N}(g-\overline{g}_\gamma,v)_\gamma\end{aligned}\tag{51}$$

for all $v\in H^1_E(\Omega)$. The following result gives a computable upper bound on the conforming error and a local lower bound up to a positive constant independent of any mesh-size.

LEMMA 8. *Let $K\in\mathcal{P}$ and define $\boldsymbol{\rho}_K$ as above. Then*

$$(a\,\mathbf{grad}\,\chi,\mathbf{grad}\,\chi)\le\sum_{K\in\mathcal{P}}\eta_{\mathsf{CF},K}(\beta)^2,\tag{52}$$

where

$$\begin{aligned}\eta_{\mathsf{CF},K}(\beta)&=a_K^{-1/2}\sqrt{\|\boldsymbol{\rho}_K\|_K^2-\mathcal{C}_K^\star(\beta)^2|K|\|\mathrm{curl}\,\boldsymbol{\rho}_K\|_K^2}\\ &+\mathcal{C}_p(K)a_K^{-1/2}\|f-\overline{f}_K\|_K+\sum_{\gamma\in\mathcal{E}_N(K)}\mathcal{C}_t(K,\gamma)a_K^{-1/2}\|g-\overline{g}_\gamma\|_\gamma,\end{aligned}\tag{53}$$

with $\mathcal{C}_K^\star$, $\mathcal{C}_p$, and $\mathcal{C}_t$ as defined in Lemma 7, Theorem 4, and Lemma 11, respectively. Moreover,

$$c\eta_{\mathsf{CF},K}(\beta)\le\|a^{1/2}\,\mathbf{grad}\,\chi\|_{\widetilde{K}}+\|a^{-1/2}\,\mathbf{curl}\,\psi\|_{\widetilde{K}}+\mathrm{osc}(g,\{\gamma\in\mathcal{E}_N(K)\})+\mathrm{osc}(f,\widetilde{K}),\tag{54}$$

where c is a positive constant independent of any mesh-size.

Proof. The first term in (51) is simply estimated using

$$(\boldsymbol{\rho}_K^\star,\mathbf{grad}\,v)_K\le\|\boldsymbol{\rho}_K^\star\|_K\|\mathbf{grad}\,v\|_K,$$

while the remaining terms are estimated using Theorem 4 and Lemma 11 to obtain for each element $K\in\mathcal{P}$

$$(f-\overline{f}_K,v)_K=\inf_{c\in\mathbb{R}}(f-\overline{f}_K,v-c)_K\le\mathcal{C}_p(K)\|f-\overline{f}_K\|_K\|\mathbf{grad}\,v\|_K$$

and

$$(g-\overline{g}_\gamma,v)_\gamma=\inf_{c\in\mathbb{R}}(g-\overline{g}_K,v-c)_\gamma\le\mathcal{C}_t(K,\gamma)\|g-\overline{g}_\gamma\|_\gamma\|\mathbf{grad}\,v\|_K\quad\forall\gamma\in\mathcal{E}_N(K).$$

Choosing $v=\chi$ and applying the Cauchy–Schwarz inequality results in the claimed upper bound.

It suffices to prove the lower bound for the choice $\beta=0$. Let $K\in\mathcal{P}$ and note that

$$\|\boldsymbol{\rho}_K\|_K^2\le C|K|^{-1}\sum_{n\in\mathcal{N}(K)}|\boldsymbol{\rho}_n^{(K)}|^2$$

and

$$|\boldsymbol{\rho}_1^{(K)}|\le|\gamma_2||\gamma_3|[|\Delta_2^{(K)}(\boldsymbol{x}_1)|+|\Delta_3^{(K)}(\boldsymbol{x}_1)|]\le C|K|[\Delta_2^{(K)}(\boldsymbol{x}_1)^2+\Delta_3^{(K)}(\boldsymbol{x}_1)^2]^{1/2},$$

with similar bounds for $\boldsymbol{\rho}_2^{(K)}$ and $\boldsymbol{\rho}_3^{(K)}$. Since the flux $\Delta^{(K)}$ is piecewise linear, it follows that

$$\|\boldsymbol{\rho}_K\|_K^2 \leq C|K| \sum_{\gamma\in\mathcal{E}(K)} |\gamma|^{-1}\|\Delta^{(K)}\|_\gamma^2 \leq C \sum_{\gamma\in\mathcal{E}(K)} |\gamma|\|\Delta^{(K)}\|_\gamma^2.$$

Then

$$\Delta^{(K)} = g_K - \sigma_{\nu_K}(U_{\mathcal{P}}) = \begin{cases} -\frac{1}{2}\left[\sigma_\nu(U_{\mathcal{P}})\right] - \kappa|\gamma|^{-1}\mu_K\left[U_{\mathcal{P}}\right], & \gamma\in\mathcal{E}_I(K), \\ -\kappa|\gamma|^{-1}(U_{\mathcal{P}} - u_D), & \gamma\in\mathcal{E}_D(K), \\ g - \sigma_\nu(U_{\mathcal{P}}), & \gamma\in\mathcal{E}_N(K), \end{cases}$$

and hence, applying the triangle inequality and the estimates of Lemma 4, we may bound the quantity $|\gamma|^{1/2}\|g_K - \sigma_{\nu_K}\|_\gamma$ by

$$|\gamma|^{1/2}\|[\sigma_\nu(U_{\mathcal{P}})]\|_\gamma + \kappa\left||\gamma|^{-1}\int_\gamma [U_{\mathcal{P}}]\ \mathrm{d}s\right| + \kappa|\gamma|^{1/2}\|[\partial U_{\mathcal{P}}/ds]\|_\gamma$$

for edges $\gamma\in\mathcal{E}_I(K)$, by

$$\kappa\left||\gamma|^{-1}\int_\gamma (U_{\mathcal{P}} - u_D)\,\mathrm{d}s\right| + \kappa|\gamma|^{1/2}\|[\partial(U_{\mathcal{P}} - u_D)/ds]\|_\gamma$$

for edges $\gamma\in\mathcal{E}_D(K)$, and by

$$|\gamma|^{1/2}\|g - \sigma_\nu(U_{\mathcal{P}})\|_\gamma$$

for edges $\gamma\in\mathcal{E}_N(K)$. Squaring and summing these bounds over all edges γ of the element, then using the estimates in Lemmas 2 and 3, we deduce that

$$c\eta_{\mathsf{CF},K}(0) \leq \|a^{1/2}\,\mathbf{grad}\,\chi\|_{\widetilde{K}} + \|a^{-1/2}\,\mathbf{curl}\,\psi\|_{\widetilde{K}} + \mathrm{osc}(g,\{\gamma\in\mathcal{E}_N(K)\}) + \mathrm{osc}(f,\widetilde{K}),$$

where c is a positive constant that is independent of any mesh-size, since the shape regularity of the elements means that the diameter of the element and the lengths of its edges means that all such dimensions are equivalent up to constants that depend only on the shape of the element. ∎

6. Estimation of nonconforming error. The estimation of the nonconforming part of the error is based on the following identity:

$$(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi) = \min_{u^*\in H^1_{u_D}(\Omega)} (a\,\mathbf{grad}_{\mathcal{P}}(u^* - U_{\mathcal{P}}), \mathbf{grad}_{\mathcal{P}}(u^* - U_{\mathcal{P}})), \tag{55}$$

where $H^1_{u_D}(\Omega) = \{v\in H^1(\Omega) : v = u_D \text{ on } \Gamma_D\}$. A proof of this can be found in [1]. In order to make use of the bound, we construct an admissible function $u^*\in H^1_{u_D}(\Omega)$ by smoothing the finite element approximation $U_{\mathcal{P}}$. Specifically, take u^* to be a piecewise affine function $U^*_{\mathcal{P}}$ on $\mathcal{P}$ with nodal values given by

$$U^*_{\mathcal{P}}(\boldsymbol{x}_n) = \begin{cases} \dfrac{1}{\#\Omega_n}\displaystyle\sum_{K\subset\Omega_n} U_{\mathcal{P}|K}(\boldsymbol{x}_n) & \text{if } \boldsymbol{x}_n\notin\Gamma_D, \\ u_D(\boldsymbol{x}_n) & \text{if } \boldsymbol{x}_n\in\Gamma_D, \end{cases} \tag{56}$$

where Ω_n is the set of elements that have a vertex at the point $\boldsymbol{x}_n$, and $\#\Omega_n$ denotes its cardinality. Inserting the function into the above statement shows that the estimator

$$\eta^2_{\mathsf{NC},K} = (a\,\mathbf{grad}_{\mathcal{P}}(U^*_{\mathcal{P}} - U_{\mathcal{P}}), \mathbf{grad}_{\mathcal{P}}(U^*_{\mathcal{P}} - U_{\mathcal{P}}))_K \tag{57}$$

provides a computable upper bound on the nonconforming part of the error.

The next result asserts that the estimator provides two-sided bounds on the error.

LEMMA 9. *Let $\eta_{\mathsf{NC},K}$ denote the estimator defined in* (57). *Then*

$$(a^{-1}\,\mathbf{curl}\,\psi, \mathbf{curl}\,\psi) \le \sum_{K\in\mathcal{P}} \eta^2_{\mathsf{NC},K} \tag{58}$$

and, for each element $K \in \mathcal{P}$,

$$c\eta_{\mathsf{NC},K} \le \|a^{1/2}\,\mathbf{grad}\,\chi\|_{K^*} + \|a^{-1/2}\,\mathbf{curl}\,\psi\|_{K^*} + \mathrm{osc}(g, \{\gamma \in \mathcal{E}_N(K^*)\}) + \mathrm{osc}(f, K^*), \tag{59}$$

where

$$K^* = \cup\{\widetilde{\gamma} : \mathcal{N}(K) \cap \mathcal{N}(\gamma) \text{ is nonempty}\} \tag{60}$$

and c is a positive constant independent of any mesh-size.

Proof. The upper bound follows from the foregoing arguments. A simple scaling argument shows that

$$\eta^2_{\mathsf{NC},K} \le Ca_K \sum_{n\in\mathcal{N}(K)} |U^*_{\mathcal{P}}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)|^2.$$

We distinguish two cases.

Case (i). If $\boldsymbol{x}_n \notin \Gamma_D$, then

$$U^*_{\mathcal{P}}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n) = \frac{1}{\#\Omega_n} \sum_{K'\in\Omega_n} (U_{\mathcal{P}|K'}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)).$$

If elements K and K' share a common edge γ, then

$$|U_{\mathcal{P}|K'}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)| = |\,[U_{\mathcal{P}}]\,(\boldsymbol{x}_n)|$$

and, by writing $[U_{\mathcal{P}}]_\gamma$ in terms of its average value and (constant) gradient on the edge, we deduce that

$$|\,[U_{\mathcal{P}}]\,(\boldsymbol{x}_n)| \le \left|\frac{1}{|\gamma|}\int_\gamma [U_{\mathcal{P}}]\ \mathrm{d}s\right| + \frac{1}{2}|\gamma|^{1/2}\|[\partial U_{\mathcal{P}}/\partial s]\|_\gamma.$$

If K and K' are separated by intervening elements, we write the difference $U_{\mathcal{P}|K} - U_{\mathcal{P}|K'}$ as a telescoping sum of differences between neighboring elements and use the above estimate to deduce that

$$|U_{\mathcal{P}|K'}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)| \le C \sum_{\gamma:\boldsymbol{x}_n\in\gamma} \left|\frac{1}{|\gamma|}\int_\gamma [U_{\mathcal{P}}]\ \mathrm{d}s\right| + \frac{1}{2}|\gamma|^{1/2}\|[\partial U_{\mathcal{P}}/\partial s]\|_\gamma$$

whenever K and $K' \in \Omega_n$.

Case (ii). If $\boldsymbol{x}_n \in \Gamma_D$, then $U^*_{\mathcal{P}}(\boldsymbol{x}_n) = u_D(\boldsymbol{x}_n)$. If K has an edge $\gamma \subset \Gamma_D$, then, arguing as in the previous case, we obtain

$$|U^*_{\mathcal{P}}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)| \le \left| \frac{1}{|\gamma|} \int_\gamma (U_{\mathcal{P}} - u_D)\, \mathrm{d}s \right| + \frac{1}{2}|\gamma|^{1/2} \|\partial(U_{\mathcal{P}} - u_D)/\partial s\|_\gamma.$$

As before, if element K is separated from the Dirichlet boundary by intervening elements, then we write the difference as a telescoping sum of differences between neighboring elements and use the previous estimates.

Finally, making use of the above bounds and the estimates in Lemmas 2 and 3, we conclude that in both cases,

$$c|U^*_{\mathcal{P}}(\boldsymbol{x}_n) - U_{\mathcal{P}|K}(\boldsymbol{x}_n)|$$

$$\le \|a^{1/2}\, \mathbf{grad}\, \chi\|_{K^*} + \|a^{-1/2}\, \mathbf{curl}\, \psi\|_{K^*} + \mathrm{osc}(g, \{\gamma \in \mathcal{E}_N(K^*)\}) + \mathrm{osc}(f, K^*)$$

and the desired result is then a simple consequence of this estimate. ∎

Appendix. Some basic estimates. We collect some basic estimates needed in the upper bounds for the conforming part of the error in section 5. The following optimal Poincaré estimate is proved in [13].

THEOREM 4. *Let $K \in \mathcal{P}$ and $v \in H^1(K)$. Then*

$$\inf_{c \in \mathbb{R}} \|v - c\|_K \le \mathcal{C}_p(K) \|\mathbf{grad}\, v\|_K, \tag{61}$$

where $\mathcal{C}_p(K) = \frac{1}{\pi} \max_{\boldsymbol{x},\boldsymbol{y} \in K} |\boldsymbol{x} - \boldsymbol{y}|$.

The next estimate gives a bound for the L_2-norm of a function over an element edge in terms of the H^1-norm over the element. Again, the bound may be shown to be optimal.

LEMMA 10. *Let γ be any edge of a triangle $K \in \mathcal{P}$. Let $\boldsymbol{x}_\gamma$ denote the vertex of K opposite to edge γ and define $L_\gamma = \max_{\boldsymbol{x} \in \gamma} |\boldsymbol{x} - \boldsymbol{x}_\gamma|$ and $\ell_\gamma = \min_{\boldsymbol{x} \in \gamma} |\boldsymbol{x} - \boldsymbol{x}_\gamma|$. Then, for all $v \in H^1(K)$,*

$$\|v\|^2_\gamma \le \frac{2}{\ell_\gamma} \|v\|_K \left[\|v\|_K + L_\gamma \|\mathbf{grad}\, v\|_K \right]. \tag{62}$$

Proof. Let $\boldsymbol{\nu}$ denote the unit outward normal on ∂K, and observe that the quantity $\boldsymbol{\nu} \cdot (\boldsymbol{x} - \boldsymbol{x}_\gamma)$ equals ℓ_γ on γ and vanishes on the remaining portion of the boundary of K. Hence,

$$\ell_\gamma \|v\|^2_{\partial K} = \int_{\partial K} \boldsymbol{\nu} \cdot (\boldsymbol{x} - \boldsymbol{x}_\gamma) v^2\, \mathrm{d}s = \int_K \mathbf{div}[(\boldsymbol{x} - \boldsymbol{x}_\gamma) v^2]\, \mathrm{d}\boldsymbol{x}$$

$$= 2\|v\|^2_K + 2 \int_K v(\boldsymbol{x} - \boldsymbol{x}_\gamma) \cdot \mathbf{grad}\, v\, \mathrm{d}\boldsymbol{x}.$$

The result then follows by noting that the second term on the right-hand side is bounded by $2L_\gamma \|v\|_K \|\mathbf{grad}\, v\|_K$. In fact, we have proved a slightly stronger estimate whereby $\mathbf{grad}\, v$ could be replaced by the derivative of v in the direction of $\boldsymbol{x} - \boldsymbol{x}_\gamma$. A different argument used in [8] led to the same kind of estimate with a worse constant. ∎

The following simple corollary of the above results will be used in the main text.

LEMMA 11. *Let γ be any edge of a triangle $K \in \mathcal{P}$. Then*

$$\inf_{c\in\mathbb{R}} \|v - c\|_\gamma \leq \mathcal{C}_t(K,\gamma)\|\mathbf{grad}\, v\|_K, \tag{63}$$

where

$$\mathcal{C}_t(K,\gamma)^2 = \frac{2}{\ell_\gamma}\mathcal{C}_p(K)\left(\mathcal{C}_p(K) + L_\gamma\right) \tag{64}$$

and L_γ, ℓ_γ are given in Lemma 10, and $\mathcal{C}_p$ is given in Theorem 4.

ERRATUM: ON A HERMITE INTERPOLATION BY POLYNOMIALS OF TWO VARIABLES*

BORISLAV BOJANOV† AND YUAN XU‡

Abstract. We correct several errors in [*SIAM J. Numer. Anal.,* 39 (2002), pp. 1780–1793] caused by a formula wrongly copied from the literature.

Key words. Hermite interpolation, polynomials, two variables

DOI. 10.1137/060676027

On p. 1789 of [1], the expression $h_{k,0}(r)$ of the basic polynomials in the classical Hermite interpolation was wrongly copied from the literature. It should be

$$h_{k,0}(r) = \left(\frac{1-r}{2}\right)^{s+1} \frac{2^k}{k!} \sum_{j=0}^{s-k} \binom{s+j}{j} \left(\frac{1+r}{2}\right)^{k+j}.$$

This mistake then manifested in some of the formulas in section 3. The corrected formulas are given below:

(1) The formula for $p(r)$ in the statement of Corollary 3.3 should be

$$p(r) = \sum_{k=0}^{[n/2]} \frac{(-1)^k 2^k F_k}{k!} \sum_{j=0}^{[n/2]-k} \binom{[n/2]+j}{j} \times \left[\left(\frac{1-r}{2}\right)^{[n/2]+1} \left(\frac{1+r}{2}\right)^{k+j} + \left(\frac{1+r}{2}\right)^{[n/2]+1} \left(\frac{1-r}{2}\right)^{k+j} \right].$$

(2) The formula for the coefficients Λ_k in Theorem 3.6 should be

$$\Lambda_k = \frac{2\pi}{2m+1} \frac{(-1)^k}{k!} \sum_{j=0}^{s-k} \binom{s+j}{j} \sum_{i=0}^{[(s+1-k-j)/2]} \binom{s+1-k-j}{2i} \times \frac{\Gamma(k+j+1)\Gamma(i+1)}{2^{s+j+1}\Gamma(k+j+i+2)}.$$

Also, on p. 1790, the expression following the product sign in the formula for $g(r)$ should be $r^2 - r_j^2$. We are grateful to M. Gachpazan and S. Serajzadeh for detecting these errors and giving the correct formulas.

We also take this opportunity to mention again that the proof of Theorem 2.5 covers only the case when all $\alpha_1, \ldots, \alpha_\lambda$ are equal. This was pointed out to us by H. Hakopian and was already acknowledged in the paper [2]. For further development in this direction, see [3, 4, 5].

A TWO-GRID METHOD OF A MIXED STOKES–DARCY MODEL FOR COUPLING FLUID FLOW WITH POROUS MEDIA FLOW*

MO MU† AND JINCHAO XU‡

Abstract. We study numerical methods for solving a coupled Stokes–Darcy problem in porous media flow applications. A two-grid method is proposed for decoupling the mixed model by a coarse grid approximation to the interface coupling conditions. Error estimates are derived for the proposed method. Both theoretical analysis and numerical experiments show the efficiency and effectiveness of the two-grid approach for solving multimodeling problems. Potential extensions and future directions are discussed.

1. Introduction.

There are many multimodeling problems in real applications of complex systems. They consist of multiple models in different regions coupled through interface conditions. The local models may be very varied in type, scale, control variable, and many other physical and mathematical properties. The corresponding numerical treatments may, of course, also vary significantly in geometric and PDE discretization, algebraic solution, and so on, in order to cope with local properties. The mixture of coupled models also leads to various mathematical and numerical difficulties. For instance, interface coupling conditions involve different control variables from different local models and may have complex, or even nonlinear, forms. Coupling different models may lead to very singular and complex structures across the interface and strong stiffness due to different scales, which would present considerable numerical difficulties. Examples of coupled multimodel applications include viscous-inviscid flows [5], compressible-incompressible fluids [17], turbulent-laminar flows [9], viscous-porous media flows [11, 16, 21, 27], and inertial confinement fusion with high ratio of density and temperature [31].

In general, there are two types of approaches to solving multimodel problems. One is to solve coupled problems directly, and the other is to first decouple mixed models and then apply appropriate local solvers individually. There are many appealing reasons to use the decoupling approach. First, it allows one to tailor algorithm components flexibly and conveniently in terms of physical, mathematical, and numerical properties for each local model and solver. Second, it is suitable for today's grid computing environment because it can efficiently and effectively exploit the existing computing resources, including both hardware and software, that are distributed

over the Internet and that have been developed by different experts for use in various application fields [26]. As a by-product, it naturally results in parallelism in the conventional sense.

There are various decoupling techniques. Many of them are in the spirit of domain decomposition in general. For instance, Quarteroni and Valli [29] have extensively investigated heterogeneous domain decomposition methods for various coupled models. The Lagrange multiplier approach is also widely used [15, 28] for decoupling multimodel problems. The interface relaxation approach [24, 25] has also been successfully applied in multimodel simulations. We note that two-grid methods were proposed in [34, 35] for discretizing nonsymmetric and indefinite PDEs. The approach was also used for linearizing nonlinear problems [23, 36, 37], for localization and parallelization [38, 39, 40], as well as for many other applications; see, for instance, Axelssson and coworkers [2, 3, 4], Girault and Lions [13], Layton and coworkers [18, 19, 20], and Utnes [32]. In this paper, we demonstrate that the two-grid approach can also be applied successfully to solve multimodel problems.

The rest of the paper is organized as follows. A coupled Stokes–Darcy model is described in the next section as our model problem. A two-grid algorithm is proposed in section 3 for decoupling the mixed model. The basic idea is to first solve a much smaller problem on a coarse grid. The coarse grid solution is then used to interpolate the interface condition, which leads to a decoupled problem on the fine grid. Section 4 contains the error analysis for the two-grid method and discusses its computational aspects as well as potential extensions and future directions. Both theoretical analysis and numerical experiments confirm that approximation accuracy does not deteriorate under the proposed two-grid decoupling technique so that the decoupled discrete problem is of the same accuracy as the couple discrete problem for approximating the mixed Stokes–Darcy model. Concluding remarks follow in section 5.

2. Coupled Stokes–Darcy model. Let us consider a mixed model of Stokes equations and Darcy equations for coupling a fluid flow with a porous media flow. There has been very active research done recently on its applications, mathematical analysis, finite element approximation, and numerical solution; see, e.g., [1, 11, 16, 21, 27] and references therein. In particular, a subdomain iterative method is proposed to decouple the Stokes–Darcy problem by applying the preconditioned Richardson–Franklin method to the interface equation with the Steklov–Poincaré pseudo-PDE operator [11].

We consider a fluid flow in Ω_f coupled with a porous media flow in Ω_p; see Figure 1, where Ω_f and Ω_p are two- or three-dimensional bounded domains, $\Omega_f \bigcap \Omega_p = \emptyset$, and $\overline{\Omega_f} \bigcap \overline{\Omega_p} = \Gamma$. Denote by $\Omega = \Omega_f \bigcup \Omega_p$, $\mathbf{n}_f$, and $\mathbf{n}_p$ as usual the unit outward normal directions on $\partial\Omega_f$ and $\partial\Omega_p$.

The fluid motion is governed by the Stokes equations for the velocity $\mathbf{V}_f$ and the pressure p_f: $\forall t > 0$,

$$(1) \qquad \begin{cases} \dfrac{\partial \mathbf{V}_f}{\partial t} - \mathrm{div}\mathbf{T}(\mathbf{V}_f, p_f) = \mathbf{g}_f & \forall \mathbf{x} \in \Omega_f \text{ (conservation of momentum)}, \\ \mathrm{div}\mathbf{V}_f = 0, & \forall \mathbf{x} \in \Omega_f \text{ (conservation of mass)}, \end{cases}$$

where

$$\mathbf{T}(\mathbf{V}_f, p_f) = -p_f \mathbf{I} + 2\mu \mathbf{D}(\mathbf{V}_f)$$

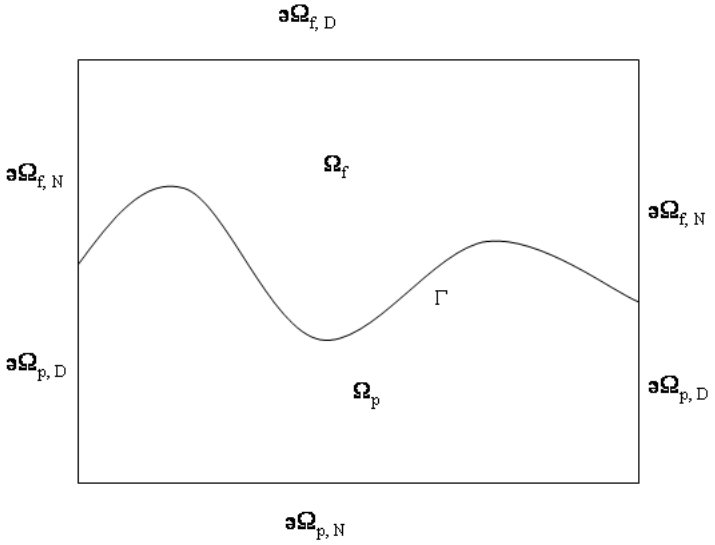

FIG. 1. *A global domain* Ω *consisting of a fluid region* Ω_f *and a porous media region* Ω_p *separated by an interface* Γ.

is the stress tensor, $\mu > 0$ is the kinematic viscosity, $\mathbf{g}_f$ is the external force, and

$$\mathbf{D}(\mathbf{V}_f) = \frac{1}{2}(\nabla \mathbf{V}_f + \nabla^T \mathbf{V}_f)$$

is the deformation rate tensor.

The porous media flow motion is governed by Darcy's law for the *piezometric head* ϕ and the *discharge vector* $\mathbf{q}$ that is proportional to the velocity $\mathbf{V}_p$, namely, $\mathbf{q} = n\mathbf{V}_p$ with n being the volumetric porosity: $\forall t > 0$,

$$\begin{cases} S_0 \dfrac{\partial \phi}{\partial t} + \operatorname{div} \mathbf{q} = g_p & \forall \mathbf{x} \in \Omega_p \text{ (conservation of mass)}, \\ \mathbf{q} = -\mathbf{K} \nabla \phi & \forall \mathbf{x} \in \Omega_p \text{ (Darcy's law)}, \end{cases} \tag{2}$$

where S_0 is the mass storativity, $\mathbf{K}$ is the hydraulic conductivity tensor of the porous medium, and the source g_p satisfies the solvability condition

$$\int_{\Omega_p} g_p = 0,$$

and

$$\phi = z + \frac{p_p}{\rho_f g},$$

where z is the elevation from a reference level, p_p is the pressure in Ω_p, ρ_f is the density, and g is the gravity acceleration.

We consider the following boundary conditions. Denote $\partial\Omega_f \setminus \Gamma = \partial\Omega_{f,D} \bigcup \partial\Omega_{f,N}$ and $\partial\Omega_p \setminus \Gamma = \partial\Omega_{p,D} \bigcup \partial\Omega_{p,N}$, as shown in Figure 1. For the fluid flow, we impose

$$\begin{cases} \mathbf{V}_f = 0 & \text{on } \partial\Omega_{f,D} \text{ with } meas(\partial\Omega_{f,D}) \neq 0, \\ -(\mathbf{T}(\mathbf{V}_f, p_f)) \cdot \mathbf{n}_f = \mathbf{h} & \text{on } \partial\Omega_{f,N}, \end{cases}$$

where $\mathbf{h}$ is a given vector. For the porous medium, we assume

$$\begin{cases} \phi = \phi_p & \text{on } \partial\Omega_{p,D}, \\ \mathbf{V}_p \cdot \mathbf{n}_p = v_p & \text{on } \partial\Omega_{p,N}. \end{cases}$$

A key part in a mixed model is the interface coupling conditions. The following interface conditions have been extensively used and studied in the literature [6, 21, 27]:

$$\begin{cases} \mathbf{V}_f \cdot \mathbf{n}_f + \mathbf{V}_p \cdot \mathbf{n}_p = 0, \\ -[(\mathbf{T}(\mathbf{V}_f, p_f)) \cdot \mathbf{n}_f] \cdot \mathbf{n}_f = \rho_f g \phi, \\ -[(\mathbf{T}(\mathbf{V}_f, p_f)) \cdot \mathbf{n}_f] \cdot \boldsymbol{\tau}_i = \dfrac{\alpha}{\sqrt{\boldsymbol{\tau}_i \cdot \mathbf{K} \cdot \boldsymbol{\tau}_i}} (\mathbf{V}_f - \mathbf{V}_p) \cdot \boldsymbol{\tau}_i, \quad i = 1, \ldots, d-1, \end{cases} \tag{3}$$

where $\{\boldsymbol{\tau}_i\}_{i=1}^{d-1}$ are linearly independent unit tangential vectors on Γ, d is the spacial dimension, and α is a positive parameter depending on the properties of the porous medium and must be experimentally determined. The first interface condition ensures mass conservation across Γ. The second one is a balance of normal forces across the interface. The third one states that the slip velocity along Γ is proportional to the shear stress along Γ. There have been many discussions in the literature on the slip condition along the interface. It is even unclear if the third condition in (3) leads to a well-posed problem. However, it has been observed that in practice the term $\mathbf{V}_p \cdot \boldsymbol{\tau}_i$ on the right-hand side from the porous media flow is much smaller than the other terms. The most accepted interface condition, known as the Beavers–Joseph–Saffman law, is then given by

$$-[2\mu \mathbf{D}(\mathbf{V}_f) \cdot \mathbf{n}_f] \cdot \boldsymbol{\tau}_i = \frac{\alpha}{\sqrt{\boldsymbol{\tau}_i \cdot \mathbf{K} \cdot \boldsymbol{\tau}_i}} \mathbf{V}_f \cdot \boldsymbol{\tau}_i, \ i = 1, \ldots, d-1, \tag{4}$$

which can be justified by a statistical approach and the Brinkman approximation [30]. We note that different interface conditions have been used in numerical studies. For instance, the Beavers–Joseph–Saffman condition is used in [1, 21], while the free-slip condition with $\alpha = 0$ is assumed in [10, 11, 12]. We will assume the Beavers–Joseph–Saffman condition (4) from now on.

For simplicity, let us assume n, ρ_f, and g are constants. We also assume the homogenous boundary condition on ϕ, $\phi_p = 0$, which can be easily handled by a lifting function in the nonhomogenous case.

Denote

$$\begin{aligned} H_f &= \{\mathbf{v} \in (H^1(\Omega_f))^d \mid \mathbf{v} = 0 \text{ on } \partial\Omega_{f,D}\}, \\ H_p &= \{\phi \in H^1(\Omega_p) \mid \phi = 0 \text{ on } \partial\Omega_{p,D}\}, \\ W &= H_f \times H_p, \\ Q &= L^2(\Omega_f). \end{aligned}$$

By integration by parts as in [21], the weak formulation for the above coupled (stationary) Stokes–Darcy problem reads as follows: For $f \in W'$, find $u = (\mathbf{u}, \phi) \in W$, $p \in Q$ such that

$$\begin{cases} a(u,v) + b(v,p) = f(v) & \forall v = (\mathbf{v}, \psi) \in W, \\ b(u,q) = 0 & \forall q \in Q, \end{cases} \tag{5}$$

where

$$a(u,v) = a_\Omega(u,v) + a_\Gamma(u,v),$$

with

$$\begin{aligned} a_\Omega(u,v) &= a_{\Omega_f}(\mathbf{u},\mathbf{v}) + a_{\Omega_p}(\phi,\psi), \\ a_{\Omega_f}(\mathbf{u},\mathbf{v}) &= \int_{\Omega_f} 2n\mu D(\mathbf{u}) \cdot D(\mathbf{v}) + \sum_{i=1}^{d-1} \frac{\alpha n}{\sqrt{\boldsymbol{\tau}_i \cdot \mathbf{K} \cdot \boldsymbol{\tau}_i}} \int_\Gamma (\mathbf{u} \cdot \boldsymbol{\tau}_i)(\mathbf{v} \cdot \boldsymbol{\tau}_i), \\ a_{\Omega_p}(\phi,\psi) &= \int_{\Omega_p} \rho_f g \nabla\psi \cdot \mathbf{K} \nabla\phi, \\ a_\Gamma(u,v) &= \int_\Gamma n\rho_f g[\phi\mathbf{v} - \psi\mathbf{u}] \cdot \mathbf{n}_f \end{aligned}$$

and with

$$b(v,p) \equiv b(\mathbf{v},p) = -\int_{\Omega_f} np \operatorname{div} \mathbf{v}.$$

Similarly to [10], it is easy to verify that (i) $a(\cdot,\cdot)$ is continuous and coercive on W, and that (ii) $b(\cdot,\cdot)$ is continuous on $W \times Q$ and satisfies the well-known Brezzi–Babuska condition as follows: There exists a positive constant $\beta > 0$ such that $\forall q \in Q, \exists w \in W$ such that

$$b(w,q) \geq \beta ||w||_W ||q||_Q. \tag{6}$$

The well-posedness of the model problem (5) then follows from Brezzi's theory for saddle-point problems [7]. The only difference from [10] is that the extension from the free-slip interface condition to the case of nonzero α results in the inclusion of an extra term $\sum_{i=1}^{d-1} \frac{\alpha n}{\sqrt{\boldsymbol{\tau}_i \cdot \mathbf{K} \cdot \boldsymbol{\tau}_i}} \int_\Gamma (\mathbf{u} \cdot \boldsymbol{\tau}_i)(\mathbf{v} \cdot \boldsymbol{\tau}_i)$ in the bilinear form $a_{\Omega_f}(\mathbf{u},\mathbf{v})$. Note that this extension does not affect property (i) for the bilinear form $a(\cdot,\cdot)$. The continuity is obvious, while the coercivity is still a consequence of the well-known Poincaré inequality and Korn inequality as in the free-slip case because α is positive and the corresponding term can thus be ignored in the estimation.

3. A two-grid algorithm. Let $W_h = H_{f,h} \times H_{p,h} \subset W$ and $Q_h \subset Q$ be two finite element spaces. The finite element discretization applied to the model problem (5) leads to a coupled discrete problem as follows: Find $u_h = (\mathbf{u_h}, \phi_h) \in W_h$, $p_h \in Q_h$ such that

$$\begin{cases} a(u_h, v_h) + b(v_h, p_h) = f(v_h) & \forall v_h = (\mathbf{v_h}, \psi_h) \in W_h, \\ b(u_h, q_h) = 0 & \forall q_h \in Q_h. \end{cases} \tag{7}$$

The construction of the finite element spaces W_h and Q_h is described more specifically as follows. Let the triangulation of the global domain be regular, as well as compatible and quasi-uniform on Γ as described in [11]. Furthermore, the finite element spaces $H_{f,h}$ and Q_h approximating the velocity and pressure fields in the fluid region are assumed to satisfy the discrete inf-sup condition as follows: There exists a positive constant $\beta^* > 0$, independent of h, such that $\forall \mathbf{v_h} \in H_{f,h}, q_h \in Q_h$,

$$b(\mathbf{v_h}, q_h) \geq \beta^* ||\mathbf{v_h}||_{H_f} ||q_h||_Q. \tag{8}$$

Several families of finite element spaces designed for the Stokes problem are provided in IV.2 and Chapter VI in [7]. They all satisfy the discrete inf-sup condition (8) and can thus be applied for $H_{f,h}$ and Q_h. Finally, standard finite element approximations of $H^m(\Omega_p)$, such as piecewise linear elements for $m = 1$, can be applied for $H_{p,h}$ in the porous media region. The well-posedness and error analysis of the coupled discrete model (7) can be found in [11].

We now propose a *two-grid algorithm* consisting of the following two steps.

ALGORITHM.

1. Solve a coarse grid problem (7) with spacing H as follows: Find $u_H = (\mathbf{u_H}, \phi_H) \in W_H \subset W_h$, $p_H \in Q_H \subset Q_h$ such that

$$\begin{cases} a(u_H, v_H) + b(v_H, p_H) = f(v_H) & \forall v_H = (\mathbf{v_H}, \psi_H) \in W_H, \\ b(u_H, q_H) = 0 & \forall q_H \in Q_H. \end{cases} \tag{9}$$

2. Solve a modified fine grid problem as follows: Find $u^h = (\mathbf{u^h}, \phi^h) \in W_h$, $p^h \in Q_h$ such that

$$\begin{cases} a_\Omega(u^h, v_h) + b(v_h, p^h) = f(v_h) - a_\Gamma(u_H, v_h) & \forall v_h \in W_h, \\ b(u^h, q_h) = 0 & \forall q_h \in Q_h. \end{cases} \tag{10}$$

It is easy to see that the modified fine grid problem (10) is also well-posed. More important, the discrete model (10) is in fact equivalent to two decoupled problems that correspond to the Stokes problem on Ω_f and the Darcy problem on Ω_p, respectively, with the boundary conditions defined by u_H on Γ. More specifically, the discrete Stokes problem on the fluid region reads as follows: Find $\mathbf{u^h} \in H_{f,h}$, $p^h \in Q_h$ such that

$$\begin{cases} a_{\Omega_f}(\mathbf{u}^h, \mathbf{v}_h) + b(\mathbf{v}_h, p^h) = (n\mathbf{g}_f, \mathbf{v}_h) - \displaystyle\int_\Gamma n\rho_f g \phi_H \mathbf{v}_h \cdot \mathbf{n}_f & \forall \mathbf{v}_h \in H_{f,h}, \\ b(\mathbf{u}^h, q_h) = 0 & \forall q_h \in Q_h. \end{cases} \tag{11}$$

Similarly, the discrete Darcy problem on the porous media region reads as follows: Find $\phi^h \in H_{p,h}$ such that

$$a_{\Omega_p}(\phi^h, \psi_h) = (\rho_f g g_p, \psi_h) + \int_\Gamma n\rho_f g \psi_h \mathbf{u}_H \cdot \mathbf{n}_f \quad \forall \psi_h \in H_{p,h}. \tag{12}$$

4. Error analysis. For convenience, from now on we will use $x \lesssim y$ to denote that there exists a constant C, such that $x \leq Cy$. Let W_h and Q_h be any finite element spaces as described in the previous section. In addition, for illustration assume the regularity $u \in (H^2(\Omega_f))^d \times H^2(\Omega_p)$ and $p \in H^1(\Omega_f)$, and thus finite element spaces as described above of first order approximation $O(h)$ are used for the fluid and

porous media regions. Then the error analysis for the coupled model in [11] yields the estimates

$$\begin{cases} ||u-u_h||_W \lesssim h, \\ ||p-p_h||_Q \lesssim h. \end{cases} \tag{13}$$

Note that estimates (13) apply to the coupled problem (7) but not to the decoupled problem (10). Furthermore, the extended framework of the Aubin–Nitsche duality technique [7] gives the following L^2-norm estimate.

LEMMA 1. *Let $W_- = (L^2(\Omega_f))^d \times L^2(\Omega_p)$. Then under the same assumptions as above, we have*

$$||u-u_h||_{W_-} \lesssim h^2. \tag{14}$$

Proof. As in the Aubin–Nitsche duality technique for the general framework of mixed problems in [7], consider the dual problem defined by the error pair $(u-u_h, p-p_h)$ to be (2.90) and (2.93) from [7]. For the solution (w,s) of the dual problem, from the regularity of the dual problem we have $(w,s) \in W_{++} \times Q_{++} = ((H^2(\Omega_f))^d \times H^2(\Omega_p)) \times H^1(\Omega_f)$ in the particular setting of our problem. Then, Theorem 2.2 (in particular the estimate of (2.100)) in [7] gives

$$||u-u_h||_{W_-} \lesssim m(h)(\|u-u_h\|_W + \|p-p_h\|_Q) + n(h)\|u-u_h\|_W,$$

where

$$\inf_{w_h \in W_h} \|w-w_h\|_W \le m(h)\|w\|_{W_{++}},$$

and

$$\inf_{q_h \in Q_h} \|s-q_h\|_Q \le n(h)\|s\|_{Q_{++}}.$$

Note that both $m(h)$ and $n(h)$ are of the order of $O(h)$ as shown in [7]. Estimate (14) then follows immediately from (13), which completes the proof. ∎

As a consequence, the following estimates, which will be used in the proof of the next theorem, follow immediately from (13) and (14):

$$\begin{cases} ||\mathbf{u}_h - \mathbf{u}_H||_{H_f} \lesssim H, \quad ||\mathbf{u}_h - \mathbf{u}_H||_{(L^2(\Omega_f))^d} \lesssim H^2, \\ \|\phi_h - \phi_H\|_{H_p} \lesssim H, \quad \|\phi_h - \phi_H\|_{L^2(\Omega_p)} \lesssim H^2. \end{cases} \tag{15}$$

THEOREM 2. *Let u_h, p_h and u^h, p^h be defined by the two discrete models* (7) *and* (10) *on the fine grid. The following error estimates hold:*

$$||\phi_h - \phi^h||_{H_p} \lesssim H^2, \tag{16}$$

$$||\mathbf{u}_h - \mathbf{u}^h||_{H_f} \lesssim H^{3/2}, \tag{17}$$

$$||p_h - p^h||_Q \lesssim H^{3/2}. \tag{18}$$

Proof. Note that by comparing the two discrete models (7) and (10) on the fine grid, we have

$$\begin{cases} a_\Omega(u_h - u^h, v_h) + a_\Gamma(u_h - u_H, v_h) + b(v_h, p_h - p^h) = 0 & \forall v_h \in W_h, \\ b(u_h - u^h, q_h) = 0 & \forall q_h \in Q_h. \end{cases} \tag{19}$$

First, taking $v_h = (\mathbf{0}, \psi_h) \in W_h$ in (19), we obtain

$$a_{\Omega_p}(\phi_h - \phi^h, \psi_h) + a_\Gamma(u_h - u_H, v_h) = 0.$$

In particular, when $\psi_h = \phi_h - \phi^h$, it is further reduced to

$$a_{\Omega_p}(\phi_h - \phi^h, \phi_h - \phi^h) = \int_\Gamma n\rho_f g(\phi_h - \phi^h)(\mathbf{u}_h - \mathbf{u}_H) \cdot \mathbf{n}_f.$$

Let $\theta \in H^1(\Omega_f)$ be a harmonic extension of $\phi_h - \phi^h$ to the fluid flow region, satisfying

$$\begin{cases} -\Delta\theta = 0 & \text{in } \Omega_f, \\ \theta = \phi_h - \phi^h & \text{on } \Gamma, \\ \theta = 0 & \text{on } \partial\Omega_f/\Gamma. \end{cases}$$

Let $H_{00}^{1/2}(\Gamma)$ denote the interpolation space [22]

$$H_{00}^{1/2}(\Gamma) = [L^2(\Gamma), H_0^1(\Gamma)]_{1/2}.$$

Apparently,

$$||\theta||_{H^1(\Omega_f)} \lesssim ||\phi_h - \phi^h||_{H_{00}^{1/2}(\Gamma)} \lesssim ||\phi_h - \phi^h||_{H_p}.$$

Note that $\forall q_H \in Q_H$,

$$\begin{aligned} &\int_\Gamma n\rho_f g(\phi_h - \phi^h)(\mathbf{u}_h - \mathbf{u}_H) \cdot \mathbf{n}_f \\ &\quad = \int_{\partial\Omega_f} n\rho_f g\theta(\mathbf{u}_h - \mathbf{u}_H) \cdot \mathbf{n}_f \\ &\quad = \int_{\Omega_f} \mathrm{div}(\mathbf{u}_h - \mathbf{u}_H)(n\rho_f g\theta) + \int_{\Omega_f} (\mathbf{u}_h - \mathbf{u}_H) \cdot \nabla(n\rho_f g\theta) \\ &\quad = n\rho_f g \left(\int_{\Omega_f} (\theta - q_H)\mathrm{div}(\mathbf{u}_h - \mathbf{u}_H) + \int_{\Omega_f} (\mathbf{u}_h - \mathbf{u}_H) \cdot \nabla\theta \right), \end{aligned}$$

where in the last equality we use the discrete divergence-free property for $\mathbf{u}_h$ and $\mathbf{u}_H$,

$$b(u_h - u_H, q_H) = \int_{\Omega_f} nq_H \mathrm{div}(\mathbf{u}_h - \mathbf{u}_H) = 0 \ \forall q_H \in Q_H.$$

Therefore, we have

$$\begin{aligned} &||\phi_h - \phi^h||_{H_p}^2 \\ &\quad \lesssim a_{\Omega_p}(\phi_h - \phi^h, \phi_h - \phi^h) \\ &\quad \lesssim \inf_{\forall q_H \in Q_H} \left| \int_{\Omega_f} (\theta - q_H)\mathrm{div}(\mathbf{u}_h - \mathbf{u}_H) \right| + \left| \int_{\Omega_f} (\mathbf{u}_h - \mathbf{u}_H) \cdot \nabla\theta \right| \\ &\quad \lesssim ||\mathbf{u}_h - \mathbf{u}_H||_{H_f} \inf_{\forall q_H \in Q_H} ||\theta - q_H||_{L^2(\Omega_f)} + ||\mathbf{u}_h - \mathbf{u}_H||_{(L^2(\Omega_f))^d} ||\theta||_{H^1(\Omega_f)} \\ &\quad \lesssim (H||\mathbf{u}_h - \mathbf{u}_H||_{H_f} + ||\mathbf{u}_h - \mathbf{u}_H||_{(L^2(\Omega_f))^d}) ||\theta||_{H^1(\Omega_f)} \\ &\quad \lesssim H^2 ||\phi_h - \phi^h||_{H_{00}^{1/2}(\Gamma)} \\ &\quad \lesssim H^2 ||\phi_h - \phi^h||_{H_p}, \end{aligned}$$

which leads to estimate (16).

To show (17), taking $v_h = (\mathbf{v}_h, 0) \in W_h$ in (19), we obtain

$$a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{v}_h) + a_\Gamma(u_h - u_H, v_h) + b(v_h, p_h - p^h) = 0.$$

In particular, when $\mathbf{v}_h = \mathbf{u}_h - \mathbf{u}^h$, due to the discrete divergence-free property of $\mathbf{u}_h$ and $\mathbf{u}^h$ so that $b(\mathbf{u}_h - \mathbf{u}^h, p_h - p^h) = 0$, we further have

$$a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{u}_h - \mathbf{u}^h) = \int_\Gamma n\rho_f g(\phi_h - \phi_H)(\mathbf{u}_h - \mathbf{u}^h) \cdot \mathbf{n}_f.$$

Hence,

$$\begin{aligned} ||\mathbf{u}_h - \mathbf{u}^h||^2_{H_f} &\lesssim a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{u}_h - \mathbf{u}^h) \\ &= \int_\Gamma n\rho_f g(\phi_h - \phi_H)(\mathbf{u}_h - \mathbf{u}^h) \cdot \mathbf{n}_f \\ &\lesssim \|\phi_h - \phi_H\|_{L^2(\Gamma)} \|\mathbf{u}_h - \mathbf{u}^h\|_{(L^2(\Gamma))^d} \\ &\lesssim \|\phi_h - \phi_H\|_{L^2(\Gamma)} \|\mathbf{u}_h - \mathbf{u}^h\|_{H_f}. \end{aligned} \tag{20}$$

Using a refined trace result (see [33, p. 27], with $\epsilon = H^{1/2}$), we get

$$\|\phi_h - \phi_H\|_{L^2(\Gamma)} \lesssim H^{-1/2}\|\phi_h - \phi_H\|_{L^2(\Omega_p)} + H^{1/2}\|\phi_h - \phi_H\|_{H^1(\Omega_p)} \lesssim H^{3/2}. \tag{21}$$

Applying (21) to (20) then yields estimate (17).

Finally, let us show (18). From the discrete Brezzi–Babuska condition on Ω_f, for $q_h = p_h - p^h \in Q_h, \exists \mathbf{v}_h \in H_{f,h}$ such that

$$||p_h - p^h||_{L^2(\Omega_f)} \lesssim \frac{-\int_{\Omega_f} n(p_h - p^h)\mathrm{div}\mathbf{v}_h}{||\mathbf{v}_h||_{H_f}}.$$

Recall that for $v_h = (\mathbf{v}_h, 0) \in W_h$ in (19), we have

$$a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{v}_h) + a_\Gamma(u_h - u_H, v_h) + b(v_h, p_h - p^h) = 0.$$

The first term above is easy to handle by

$$|a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{v}_h)| \lesssim ||\mathbf{u}_h - \mathbf{u}^h||_{H_f} ||\mathbf{v}_h||_{H_f}.$$

For the second term, we have

$$\begin{aligned} |a_\Gamma(u_h - u_H, v_h)| &= \left| \int_\Gamma n\rho_f g(\phi_h - \phi_H)\mathbf{v}_h \cdot \mathbf{n}_f \right| \\ &\lesssim \|\phi_h - \phi_H\|_{L^2(\Gamma)} \|\mathbf{v}_h\|_{(L^2(\Gamma))^d} \\ &\lesssim \|\phi_h - \phi_H\|_{L^2(\Gamma)} \|\mathbf{v}_h\|_{H_f}. \end{aligned}$$

Using (21) and (17), we have

$$\begin{aligned} ||p_h - p^h||_{L^2(\Omega_f)} &\lesssim \frac{|a_{\Omega_f}(\mathbf{u}_h - \mathbf{u}^h, \mathbf{v}_h)| + |a_\Gamma(u_h - u_H, v_h)|}{||\mathbf{v}_h||_{H_f}} \\ &\lesssim ||\mathbf{u}_h - \mathbf{u}^h||_{H_f} + \|\phi_h - \phi_H\|_{L^2(\Gamma)} \\ &\lesssim H^{3/2}, \end{aligned}$$

which leads to estimate (18). This completes the proof. ∎

COROLLARY 3. *Let $(u^h, p^h) \in W_h \times Q_h$ be the solution of the two-grid algorithm with $H = \sqrt{h}$. We have*

$$||\phi - \phi^h||_{H_p} \lesssim h \tag{22}$$

and

$$||\mathbf{u} - \mathbf{u}^h||_{H_f} + ||p - p^h||_Q \lesssim h^{3/4}. \tag{23}$$

If $H = h^{2/3}$, estimate (23) *is further improved to the optimal order as follows:*

$$||\mathbf{u} - \mathbf{u}^h||_{H_f} + ||p - p^h||_Q \lesssim h. \tag{24}$$

We remark that error estimates (17) and (18) for $\mathbf{u}_h - \mathbf{u}^h$ and $p_h - p^h$ may not be optimal due to technical reasons. These two estimates might be further improved to $O(H^2)$ by a finer analysis, as suggested by numerical experiments in [8], which could then lead to an improvement of (23) to an optimal estimate of the order of $O(h)$ for $\mathbf{u} - \mathbf{u}^h$ and $p - p^h$, yet still with $H = \sqrt{h}$. Furthermore, the error analysis may be extended to finite element spaces with higher order approximation $O(h^m)$, provided that the solution is locally smooth enough within each subdomain. Specifically, if $W_h \subset W$ and $Q_h \subset Q$ are finite element spaces with the approximation order $O(h^m)$, and the solution (u, p) is locally smooth enough within each subdomain, we expect the following estimates to hold:

$$||\phi_h - \phi^h||_{H_p} \lesssim H^{m+1} \tag{25}$$

and

$$||\mathbf{u_h} - \mathbf{u}^h||_{H_f} + ||p_h - p^h||_Q \lesssim H^{m+1}, \tag{26}$$

which implies the optimal error estimates if we take $H = h^{\frac{m}{m+1}}$:

$$||\phi - \phi^h||_{H_p} \lesssim h^m \tag{27}$$

and

$$||\mathbf{u} - \mathbf{u}^h||_{H_f} + ||p - p^h||_Q \lesssim h^m. \tag{28}$$

We refer readers to [8] for more details on this extension.

Comprehensive numerical experiments on various aspects of the proposed theoretical framework are under investigation and will be reported in [8]. For instance, if the well-known Taylor–Hood elements [7], also known as the P2-P1 elements, are applied to the Stokes model, and the P2 elements are applied to the Darcy model, and for convenience we simply take $H = \sqrt{h}$, the numerical approximations of the two-grid algorithm to a locally very smooth solution clearly demonstrate an optimal convergence rate of $O(h^2)$, which confirms our theoretical expectation. For more details, see [8].

Most important, the presented theory suggests that one can effectively and efficiently decouple a coupled multimodel problem by proper multigrid techniques. This allows for different submodel problems to be solved independently by applying the most appropriate numerical techniques individually. In addition, these decoupled local problems can be solved by different processors on a parallel multiprocessor or

by different computing nodes on a traditional cluster or even a remotely distributed computational grid. Furthermore, in a grid computing environment, powerful and efficient local solvers are usually available which were developed at different sites by different experts for various single models. Therefore, substantial coding tasks can also be reduced thanks to resource sharing in grid computing.

We also remark that the proposed two-grid algorithm still requires a coarse grid solver for the coupling purpose. The coarse grid problem usually has a much smaller size, say $H = \sqrt{h}$, and can thus be solved on a front end machine or a client machine. It is also numerically easier to solve than a fine grid problem in various aspects such as approximation accuracy, stiffness, and so on.

In addition, iterative strategies such as preconditioned error correction can be applied for the coarse grid solver by restricting the computed fine grid approximation to the coarse grid so that the coarse grid problem is also similarly decoupled. This then leads to a fully decoupled iterative two-grid algorithm. Finally, we remark that the same strategy can be applied recursively to the coarse grid problem, if necessary, which then leads to a multigrid algorithm.

5. Conclusions. We have proposed a two-grid method for solving the coupled Stokes–Darcy problem. Error estimates are obtained, which suggests that multigrid can provide a general framework for solving multimodeling problems. It is promising to extend this approach to more general settings, such as other boundary and interface conditions, Navier–Stokes/Darcy coupling, time-dependent problems, as well as other coupling applications. It is also possible to generalize the framework to other versions, including iterative two-grid methods and multilevel methods.

Acknowledgments. The authors would like to thank M. C. Cai for implementing the two-grid algorithm and conducting the numerical experiments. They also thank the referees very much for helpful comments and suggestions, which led to substantial improvements in the presentation.

SPECIALIZED PARTITIONED ADDITIVE RUNGE–KUTTA METHODS FOR SYSTEMS OF OVERDETERMINED DAES WITH HOLONOMIC CONSTRAINTS*

LAURENT O. JAY†

Abstract. We consider a general class of systems of overdetermined differential-algebraic equations (ODAEs). We are particularly interested in extending the application of the symplectic Gauss methods to Hamiltonian and Lagrangian systems with holonomic constraints. For the numerical approximation to the solution to these ODAEs, we present specialized partitioned additive Runge–Kutta (SPARK) methods, and in particular the new class of (s, s)-Gauss–Lobatto SPARK methods. These methods not only preserve the constraints, symmetry, symplecticness of the flow, and variational nature of the trajectories of holonomically constrained Hamiltonian and Lagrangian systems, but they also have an optimal order of convergence $2s$.

Key words. differential-algebraic equations, Gauss coefficients, Hamiltonian systems, holonomic constraints, Lagrangian systems, Lobatto coefficients, Runge–Kutta methods, symplecticness, variational integrators

1. Introduction.

Gauss methods for Hamiltonian systems are known to be symplectic [7, 8, 19, 25, 28]. For Lagrangian systems these methods are also known to be of a variational nature [21]. The main objective of this paper is to present extensions of Gauss methods to Hamiltonian and Lagrangian systems with holonomic constraints. For these systems we have found extensions of Gauss methods preserving symplecticness, the manifold of constraints, the variational nature of trajectories, and having an optimal order of convergence. When applied to nonstiff ordinary differential equations (ODEs), Gauss methods have a maximal order of convergence in the class of Runge–Kutta (RK) methods [3, 8]. However, for index 3 differential-algebraic equations (DAEs) such as Hamiltonian systems with holonomic constraints, standard Gauss methods either are divergent or have a very low order of convergence when the underlying differentiated constraints are not taken into account [5]. Gauss methods have thus not been considered of much practical interest for the numerical solution of high index DAEs. Recently, optimal methods based on Gauss coefficients have been obtained for index 2 DAEs [18] and have stirred renewed interest in Gauss methods for DAEs.

In this paper we consider a general class of systems of overdetermined differential-algebraic equations (ODAEs), including a unified formulation of Hamiltonian and Lagrangian systems with holonomic constraints. To approximate numerically the solution to these systems of ODAEs, we present the new class of specialized partitioned additive Runge–Kutta (SPARK) methods. We make great use of the structure of the ODAEs. The new class of (s, s)-Gauss–Lobatto SPARK methods extends to these ODAEs the application of Gauss methods to ODEs. These symmetric methods are

shown to be superconvergent of order $2s$ and constraint preserving. Moreover, for Hamiltonian and Lagrangian systems with holonomic constraints these methods are shown to be symplectic and to satisfy a discrete variational principle.

The paper is organized as follows. In section 2 we introduce the equations of Hamiltonian and Lagrangian systems with holonomic constraints. We state some of their relations and main properties. A unified formulation of Hamiltonian and Lagrangian systems is presented and generalized to a larger class of systems of ODAEs. In section 3 we introduce the new class of SPARK methods. Examples of SPARK methods are given. In section 4 we characterize symplectic SPARK methods and show their variational nature. In section 5 we give results about existence, uniqueness, local error, and global convergence of SPARK methods. Finally, in section 6 some numerical experiments are given to illustrate our theoretical results. A short conclusion is given in section 7.

Regarding notation, we denote by x' the total derivative of x with respect to the independent variable t. For a function $f(x, y)$, we denote by $f_x(x, y)$ its partial derivative with respect to x.

2. Hamiltonian and Lagrangian systems with holonomic constraints. In this section we introduce the equations of Hamiltonian and Lagrangian systems with holonomic constraints. For these systems some important relations and properties are stated [1, 4, 20]. A unified and generalized formulation of Hamiltonian and Lagrangian systems is presented.

2.1. Hamiltonian systems with holonomic constraints. The Hamiltonian system with Hamiltonian $H : \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}$ and holonomic constraints $g : \mathbb{R}^n \longrightarrow \mathbb{R}^m$ $(m < n)$ is given by

$$q' = H_p^T(q, p), \tag{2.1a}$$

$$p' = -H_q^T(q, p) - g_q^T(q)\lambda, \tag{2.1b}$$

$$0 = g(q). \tag{2.1c}$$

Differentiating (2.1c) once with respect to the independent variable t, we obtain $g_q(q)q' = 0$, and from (2.1a) this leads to

$$0 = g_q(q)H_p^T(q, p). \tag{2.1d}$$

We assume that $g_q(q)$ is of full row rank m and that the Hessian matrix

$$H_{pp}^T(q, p) \text{ is invertible.} \tag{2.2}$$

For example, $H_{pp}^T(q, p)$ is generally assumed to be (strictly) positive definite. Equations (2.1a,b,c) are DAEs of index 3 in Hessenberg form [2, 6, 9, 12, 15]. The whole system (2.1) can be considered as a system of index 2 ODAEs. For consistent initial values, i.e., for $(q_0, p_0) \in V$, where

$$V := \left\{(q, p) \in \mathbb{R}^n \times \mathbb{R}^n \mid 0 = g(q),\ 0 = g_q(q)H_p^T(q, p)\right\}, \tag{2.3}$$

we have existence and uniqueness of a solution.

2.2. Lagrangian systems with holonomic constraints. The Lagrangian system with Lagrangian $L : \mathbb{R}^n \times \mathbb{R}^n \longrightarrow \mathbb{R}$ and holonomic constraints $g : \mathbb{R}^n \longrightarrow \mathbb{R}^m$ $(m < n)$ is given by

$$q' = v, \tag{2.4a}$$

$$(L_v^T(q,v))' = L_q^T(q,v) - g_q^T(q)\lambda, \tag{2.4b}$$

$$0 = g(q). \tag{2.4c}$$

Differentiating (2.4c) once with respect to t, we obtain $g_q(q)q' = 0$, and from (2.4a) this leads to

$$0 = g_q(q)v. \tag{2.4d}$$

We assume that $g_q(q)$ is of full row rank m and that the Hessian matrix

$$L_{vv}^T(q,v) \text{ is invertible,} \tag{2.5}$$

for example, $L_{vv}^T(q,v)$ is generally assumed to be (strictly) positive definite. Equations (2.4a,b,c) are usually called *Euler–Lagrange equations* and are DAEs of index 3 [15]. The whole system (2.4) can be considered as a system of index 2 ODAEs. For consistent initial values, i.e., for $(q_0, v_0) \in W$, where

$$W := \{(q,v) \in \mathbb{R}^n \times \mathbb{R}^n \mid 0 = g(q),\ 0 = g_q(q)v\}, \tag{2.6}$$

we have existence and uniqueness of a solution. For Lagrangian systems with holonomic constraints (2.4), it is advantageous to consider directly the formulation (2.4b) instead of

$$L_{vv}^T(q,v)v' = -L_{vq}^T(q,v)v + L_q^T(q,v) - g_q^T(q)\lambda, \tag{2.7}$$

since this formulation (2.7) requires an extra term $L_{vq}^T(q,v)v$ which usually corresponds to Coriolis forces; see [14, 15]. Moreover, preserving the Lagrangian symplectic 2-form (2.10) for numerical methods is certainly more problematic with formulation (2.7) than with (2.4b); see also Corollary 4.2.

2.3. Relations and properties of Hamiltonian and Lagrangian systems with holonomic constraints. Lagrangian systems are closely related to Hamiltonian systems. The momenta p of a Lagrangian system are defined by

$$p := L_v^T(q,v). \tag{2.8}$$

From (2.5), the relation $p - L_v^T(q,v) = 0$ defines v as an implicit function $v(q,p)$. Under assumption (2.5) the Lagrangian system (2.4) is equivalent by the change of variables (2.8) to the Hamiltonian system (2.1) with Hamiltonian

$$H(q,p) := p^T v(q,p) - L(q, v(q,p)).$$

This is known as a Legendre transform. Assumption (2.5) is equivalent to (2.2). The velocities of a Hamiltonian system are defined by

$$v := H_p^T(q,p). \tag{2.9}$$

From (2.2), the relation $v - H_p^T(q,p) = 0$ defines p as an implicit function $p(q,v)$. Under assumption (2.2) Hamiltonian system (2.1) is equivalent by the change of variables (2.9) to Lagrangian system (2.4) with Lagrangian

$$L(q,v) := p^T(q,v)v - H(q,p(q,v)).$$

This is also a Legendre transform. Under the equivalent assumptions (2.2) and (2.5) we have the following symmetric relations between Lagrangian systems and their Hamiltonian counterparts:

$$p^T v = H(q,p) + L(q,v),$$

$$p = L_v^T(q,v),$$

$$v = H_p^T(q,p),$$

$$I_n = H_{pp}^T(q,p)L_{vv}^T(q,v).$$

Properties of Lagrangian systems can thus be transferred to Hamiltonian systems, and vice versa. Hence, here we state only five important properties of Lagrangian systems with holonomic constraints as follows:

1. Any solution to (2.4) must lie on the manifold of constraints W (2.6). In particular, any initial conditions (q_0, v_0) at t_0 must belong to W.

2. The energy function $E(q,v) := L_v(q,v)v - L(q,v)$ is invariant along a solution, i.e.,

$$E(q(t), v(t)) = \text{Const.}$$

3. The flow $\varphi_\tau : (q(t), v(t)) \mapsto (q(t+\tau), v(t+\tau))$ on the manifold of constraints W preserves the Lagrangian symplectic 2-form

$$\sum_{i=1}^{n} dq^i \wedge dL_{v^i}(q,v) = \sum_{i=1}^{n}\sum_{j=1}^{n}(L_{v^i q^j}(q,v)dq^i \wedge dq^j + L_{v^i v^j}(q,v)dq^i \wedge dv^j). \tag{2.10}$$

4. The *action* of the Lagrangian

$$\int_{t_a}^{t_b} L(q(t), v(t)) - g^T(q(t))\lambda(t)dt$$

is stationary. This is *Hamilton's variational principle*. The algebraic variables λ are Lagrange multipliers associated with the holonomic constraints (2.4c).

5. The flow may be γ-*reversible*, i.e., $\varphi_\tau = \gamma^{-1} \circ \varphi_\tau^{-1} \circ \gamma$ for some transformation γ of the variables (q,v). For example, for *conservative mechanical systems* in Lagrangian form, the Lagrangian is given by $L(q,v) = T(q,v) - U(q)$, where $T(q,v) = \frac{1}{2}v^T M(q)v$ is the *kinetic energy* with $M(q)$ being the (strictly) positive definite symmetric generalized mass matrix, and $U(q)$ is the *potential energy*. The flow is γ-reversible with respect to a reflection of the velocities $\gamma : (q,v) \mapsto (q,-v)$.

2.4. Unification and generalization of the formulation of Hamiltonian and Lagrangian systems with holonomic constraints. We present here a unified and generalized formulation of Hamiltonian and Lagrangian systems with holonomic constraints, consisting of a set of implicit ODAEs

$$y' = v(y,z), \tag{2.11a}$$

$$(p(y,z))' = f(y,z) + r(y,\lambda), \tag{2.11b}$$

$$0 = g(y), \tag{2.11c}$$

$$0 = g_y(y)v(y,z). \tag{2.11d}$$

These equations encompass the formulation of conservative mechanical systems with constraints of holonomic and scleronomic types [10, 22, 26, 27]. In mechanics the quantities y, v, p, f, r usually represent, respectively, generalized coordinates, generalized velocities, generalized momenta, generalized forces, and reaction forces due to the holonomic constraints (2.11c). These equations include Hamiltonian systems with holonomic constraints (2.1) and Lagrangian systems with holonomic constraints (2.4). For Hamiltonian systems (2.1) we have $q = y$, $p(y,z) = z$, $v(y,z) = H_z^T(y,z)$, $f(y,z) = -H_y^T(y,z)$, and $r(y,\lambda) = -g_y^T(y)\lambda$. For Lagrangian systems (2.4) we have $q = y$, $v(y,z) = z$, $p(y,z) = L_z^T(y,z)$, $f(y,z) = L_y^T(y,z)$, and $r(y,\lambda) = -g_y^T(y)\lambda$. Equation (2.11d) corresponds to $0 = (g(y))' = g_y(y)y'$. The variable $t \in \mathbb{R}$ is the independent variable and

$$\begin{aligned}
&y = (y^1, \ldots, y^{n_y})^T \in \mathbb{R}^{n_y},\\
&z = (z^1, \ldots, z^{n_z})^T \in \mathbb{R}^{n_z},\\
&\lambda = (\lambda^1, \ldots, \lambda^{n_\lambda})^T \in \mathbb{R}^{n_\lambda},\\
&p \,:\, \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R}^{n_z} \longrightarrow \mathbb{R}^{n_z},\\
&g \,:\, \mathbb{R} \times \mathbb{R}^{n_y} \longrightarrow \mathbb{R}^{n_\lambda},\\
&v \,:\, \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R}^{n_z} \longrightarrow \mathbb{R}^{n_y},\\
&f \,:\, \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R}^{n_z} \longrightarrow \mathbb{R}^{n_z},\\
&r \,:\, \mathbb{R} \times \mathbb{R}^{n_y} \times \mathbb{R}^{n_\lambda} \longrightarrow \mathbb{R}^{n_z}.
\end{aligned}$$

The variables y, z are called the *differential* variables and the variables λ are called the *algebraic* variables. The latter correspond to Lagrange multipliers when the DAEs are derived from a constrained variational principle [10, 22]. The initial values y_0, z_0 at t_0 are assumed to be given and consistent, i.e., (2.11c) and (2.11d) must be satisfied. Some differentiability conditions on the above functions are also assumed to ensure existence and uniqueness of the solution. In a neighborhood of the solution the following conditions are assumed to be satisfied:

$$p_z \text{ is invertible,} \tag{2.12a}$$

$$\begin{pmatrix} p_z & -r_\lambda \\ g_y v_z & O \end{pmatrix} \text{ is invertible.} \tag{2.12b}$$

Differentiating the left-hand side of (2.11b), under the assumption (2.12a) we obtain the following expression:

$$z' = p_z(y,z)^{-1}\left(f(y,z) + r(y,\lambda) - p_y(y,z)v(y,z)\right). \tag{2.13}$$

Differentiating the constraints (2.11d) leads to

$$0 = g_{yy}(y)\left(v(y,z), v(y,z)\right) + g_y(y)(v_y(y,z)v(y,z) + v_z(y,z)z'). \tag{2.14}$$

Introducing the expression for z' from (2.13) into (2.14), we see that under assumption (2.12b) equations (2.14) form an implicit system of equations for λ whose solution exists and is locally unique by application of the implicit function theorem.

Introducing the new variables q, p and the relations

$$q = y, \qquad p = p(y,z), \tag{2.15}$$

under the assumption (2.12a) we can formally express the differential variables y and z as (implicit) functions of (q,p), i.e.,

$$y = q, \qquad z = z(q,p).$$

Defining

$$V(q,p) := v\left(q, z\left(q,p\right)\right), \; F(q,p) := f\left(q, z\left(q,p\right)\right), \; R(q,\lambda) := r\left(q,\lambda\right), \; G(q) := g\left(q\right),$$

the whole system (2.11) can be reformulated in an equivalent way as

$$q' = V(q,p), \tag{2.16a}$$

$$p' = F(q,p) + R(q,\lambda), \tag{2.16b}$$

$$0 = G(q), \tag{2.16c}$$

$$0 = G_q(q)V(q,p), \tag{2.16d}$$

and assumption (2.12b) is equivalent to

$$G_q V_p R_\lambda \text{ is invertible.} \tag{2.17}$$

There is no implicit derivative in (2.16b). Since the application of SPARK methods (3.2) below is invariant under the change of variables (2.15), for the analysis in section 5 we can simply consider $p(y,z) = z$ in (2.11b).

3. SPARK methods. After briefly considering the class of standard RK methods, we introduce the new class of SPARK methods for the ODAEs (2.11). Examples of SPARK methods are then given.

3.1. Standard RK methods. The standard application of RK methods to the system of index 3 DAEs (2.11a,b,c) with $p(y,z) = z$ is as follows [6]:

$$Y_i = y_0 + h\sum_{j=1}^{s} a_{ij} v(Y_j, Z_j) \quad \text{for } i = 1,\dots,s,$$

$$Z_i = z_0 + h\sum_{j=1}^{s} a_{ij}\left(f(Y_j, Z_j) + r(Y_j, \Lambda_j)\right) \quad \text{for } i = 1,\dots,s,$$

$$0 = g(Y_i) \quad \text{for } i = 1, \dots, s,$$

$$y_1 = y_0 + h \sum_{j=1}^{s} b_j v(Y_j, Z_j),$$

$$z_1 = z_0 + h \sum_{j=1}^{s} b_j \left(f(Y_j, Z_j) + r(Y_j, \Lambda_j) \right).$$

For example, the standard $s = 1$-stage Gauss RK method for Hamiltonian systems with holonomic constraints (2.1a,b,c), based on the implicit midpoint rule for ODEs, reads as

$$Q_1 = q_0 + h\frac{1}{2} H_p^T(Q_1, P_1) = \frac{1}{2}(q_1 + q_0),$$

$$P_1 = p_0 - h\frac{1}{2} H_q^T(Q_1, P_1) - h\frac{1}{2} g_q^T(q_1)\Lambda_1 = \frac{1}{2}(p_1 + p_0),$$

$$0 = g(Q_1),$$

$$q_1 = q_0 + h H_p^T(Q_1, P_1),$$

$$p_1 = p_0 - h H_q^T(Q_1, P_1) - h g_q^T(q_1)\Lambda_1.$$

Unfortunately, this method is in general divergent. More generally, the standard definition of RK methods does not take advantage of the additive structure of (2.11b) and of the presence of the two sets of constraints (2.11c,d). A different extension of the implicit midpoint rule, convergent even for the more general system of ODAEs (2.11), can be found within the class of SPARK methods (3.2) to be discussed hereafter. When $p(y, z) = z$, this extension is given by

$$Y_1 = y_0 + h\frac{1}{2} v(Y_1, Z_1) = \frac{1}{2}(y_1 + y_0), \tag{3.1a}$$

$$Z_1 = z_0 + h\frac{1}{2} f(Y_1, Z_1) + h\frac{1}{2} r(y_0, \Lambda_0), \tag{3.1b}$$

$$y_1 = y_0 + h v(Y_1, Z_1), \tag{3.1c}$$

$$0 = g(y_1), \tag{3.1d}$$

$$z_1 = z_0 + h f(Y_1, Z_1) + h\frac{1}{2} r(y_0, \Lambda_0) + h\frac{1}{2} r(y_1, \Lambda_1), \tag{3.1e}$$

$$0 = g_y(y_1) v(y_1, z_1) \tag{3.1f}$$

and is named a $(1, 1)$-Gauss–Lobatto SPARK method; see subsection 3.3. Note that the quantity Λ_0 is local to the current step and does not come from the previous step. For Hamiltonian systems with holonomic constraints (2.1), we obtain

$$Q_1 = q_0 + h\frac{1}{2} H_p^T(Q_1, P_1) = \frac{1}{2}(q_1 + q_0),$$

$$P_1 = p_0 - h\frac{1}{2} H_q^T(Q_1, P_1) - h\frac{1}{2} g_q^T(q_0)\Lambda_0,$$

$$q_1 = q_0 + hH_p^T(Q_1, P_1),$$

$$0 = g(q_1),$$

$$p_1 = p_0 - hH_q^T(Q_1, P_1) - h\frac{1}{2}g_q^T(q_0)\Lambda_0 - h\frac{1}{2}g_q^T(q_1)\Lambda_1,$$

$$0 = g_q(q_1)H_p^T(q_1, p_1).$$

For separable Hamiltonian systems of the form $H(q,p) = \frac{1}{2}p^T M^{-1}p + U(q)$, this method is equivalent to a method proposed by Reich in [24].

3.2. Definition of SPARK methods. We propose here a class of methods based on RK coefficients taking advantage of the structure of (2.11), in particular of the additive and partitioned structure of (2.11a,b) and of the presence of the two sets of constraints (2.11c,d). The definition of SPARK methods is given below. A similar application of SPARK methods has been proposed for the numerical solution of mechanical systems in [15]; see also [16].

DEFINITION 3.1. *One step of an* $(s, \widetilde{s})$-SPARK method *applied to the system of implicit overdetermined partitioned DAEs* (2.11) *with consistent initial values* (y_0, z_0) *at* t_0 *and stepsize* h *is given as follows:*

$$Y_i = y_0 + h\sum_{j=1}^{s} a_{ij}v(Y_j, Z_j) \quad \text{for } i = 1, \ldots, s, \tag{3.2a}$$

$$p(Y_i, Z_i) = p_0 + h\sum_{j=1}^{s} \widehat{a}_{ij}f(Y_j, Z_j) + h\sum_{j=0}^{\widetilde{s}} \widetilde{a}_{ij}r(\widetilde{Y}_j, \Lambda_j) \quad \text{for } i = 1, \ldots, s, \tag{3.2b}$$

$$\widetilde{Y}_i = y_0 + h\sum_{j=1}^{s} \overline{a}_{ij}v(Y_j, Z_j) \quad \text{for } i = 0, 1, \ldots, \widetilde{s}, \tag{3.2c}$$

$$0 = g(\widetilde{Y}_i) \quad \text{for } i = 0, 1, \ldots, \widetilde{s}, \tag{3.2d}$$

$$y_1 = y_0 + h\sum_{j=1}^{s} b_j v(Y_j, Z_j), \tag{3.2e}$$

$$p(y_1, z_1) = p_0 + h\sum_{j=1}^{s} \widehat{b}_j f(Y_j, Z_j) + h\sum_{j=0}^{\widetilde{s}} \widetilde{b}_j r(\widetilde{Y}_j, \Lambda_j), \tag{3.2f}$$

$$0 = g(y_1), \tag{3.2g}$$

$$0 = g_y(y_1)v(y_1, z_1), \tag{3.2h}$$

where $p_0 := p(y_0, z_0)$. *We have four sets of coefficients* (b_j, a_{ij}, c_i), $(\widehat{b}_j, \widehat{a}_{ij})$, $(\widetilde{b}_j, \widetilde{a}_{ij})$, $(\overline{a}_{ij}, \widetilde{c}_i)$, *where we have defined*

$$c_i := \sum_{j=1}^{s} a_{ij} \quad \text{for } i = 1, \ldots, s, \qquad \widetilde{c}_i := \sum_{j=1}^{s} \overline{a}_{ij} \quad \text{for } i = 0, 1, \ldots, \widetilde{s}.$$

Notice that the coefficients $(b_j, c_j)_{j=1}^{s}$ *and* $(\widetilde{b}_j, \widetilde{c}_j)_{j=0}^{\widetilde{s}}$ *are generally two distinct quadrature formulas. The SPARK coefficients can be expressed concisely in four Butcher-style tableaux:*

$$\begin{array}{c|c} c_i & a_{ij} \\ \hline A & b_j \end{array} \qquad \begin{array}{c|c} & \widehat{a}_{ij} \\ \hline \widehat{A} & \widehat{b}_j \end{array} \qquad \begin{array}{c|c} & \widetilde{a}_{ij} \\ \hline \widetilde{A} & \widetilde{b}_j \end{array} \qquad \begin{array}{c|c} \widetilde{c}_i & \overline{a}_{ij} \\ \hline \overline{A} & \end{array}.$$

When the RK matrix $A = (a_{ij})_{i,j=1}^{s}$ is invertible we can express the values $\widetilde{Y}_i$ for $i = 0, 1, \ldots, \widetilde{s}$ and y_1 as linear combinations of y_0 and Y_j for $j = 1, \ldots, s$ as follows:

$$\widetilde{Y}_i = y_0 + \sum_{j=1}^{s} \eta_{ij}(Y_j - y_0), \qquad y_1 = y_0 + \sum_{j=1}^{s} \nu_j(Y_j - y_0),$$

where $\eta := \overline{A}A^{-1}$ and $\nu^T := b^T A^{-1}$. An $(s, \widetilde{s})$-SPARK method (3.2) can be seen as an extension of an s-stage standard (partitioned) RK method for partitioned ODEs

$$y' = v(y, z), \qquad z' = f(y, z).$$

To ensure existence and uniqueness of the SPARK solution (see Theorem 5.1), we assume the SPARK coefficients satisfy the following conditions:

(3.3a) $\overline{a}_{0j} = 0 \quad$ for $j = 1, \ldots, s$,

(3.3b) $\overline{a}_{\widetilde{s}j} = b_j \quad$ for $j = 1, \ldots, s$,

(3.3c) $$\sum_{j=1}^{s} \overline{a}_{ij} c_j = \sum_{j=1}^{s}\sum_{k=1}^{s} \overline{a}_{ij}\widehat{a}_{jk} = \sum_{j=1}^{s}\sum_{k=0}^{\widetilde{s}} \overline{a}_{ij}\widetilde{a}_{jk} = \frac{\widetilde{c}_i^2}{2} \quad \text{for } i = 0, 1, \ldots, \widetilde{s},$$

(3.3d) $$\overline{A}\widetilde{A} =: \begin{pmatrix} 0 & \cdots & 0 \\ & N & \end{pmatrix}, \qquad \begin{pmatrix} N \\ \widetilde{b}^T \end{pmatrix} \text{ is invertible.}$$

Condition (3.3a) implies that $\widetilde{c}_0 = 0$ and $\widetilde{Y}_0 = y_0$. Therefore $g(\widetilde{Y}_0) = 0$ is automatically satisfied since we assume $g(y_0) = 0$. Such SPARK methods generally do not require the evaluation of $v(y_0, z_0)$ and $f(y_0, z_0)$. However, $r(y_0, \Lambda_0)$ is required. Condition (3.3b) implies that $g(y_1) = 0$ is automatically satisfied since $g(\widetilde{Y}_{\widetilde{s}}) = 0$ from (3.2d) for $i = \widetilde{s}$ and $y_1 = \widetilde{Y}_{\widetilde{s}}$.

3.3. The (s, s)-Gauss–Lobatto SPARK methods. We are especially interested in extending Gauss RK methods for ODEs without constraints to corresponding (s, s)-SPARK methods (3.2) for the ODAEs (2.11) having an optimal order of convergence $2s$. The Gauss RK coefficients $\widehat{a}_{ij} = a_{ij}, \widehat{b}_j = b_j$ can be found, e.g., in [3, 7]. The Gauss RK coefficients satisfy

$$\sum_{i=1}^{s} b_i c_i^{k-1} = \frac{1}{k}, \qquad k = 1, \ldots, 2s,$$

$$\sum_{j=1}^{s} a_{ij} c_j^{k-1} = \frac{c_i^k}{k}, \qquad i = 1, \ldots, s, \quad k = 1, \ldots, s.$$

For the coefficients $\widetilde{b}_i$ and $\widetilde{c}_i$, we take the coefficients of the $(s+1)$-stage Lobatto quadrature formula ($\widetilde{c}_0 = 0, \widetilde{c}_s = 1$) of order $2s$ which satisfy

$$\sum_{i=0}^{s} \widetilde{b}_i \widetilde{c}_i^{k-1} = \frac{1}{k}, \qquad k = 1, \ldots, 2s.$$

The coefficients $\overline{a}_{ij}$ can be taken according to

$$\sum_{j=1}^{s} \overline{a}_{ij} c_j^{k-1} = \frac{\widetilde{c}_i^k}{k}, \qquad i = 0, 1, \ldots, s, \quad k = 1, \ldots, s,$$

and the coefficients $\widetilde{a}_{ij}$ are then simply determined by

$$\widetilde{a}_{ij} = \widetilde{b}_j \left(1 - \frac{\overline{a}_{ji}}{b_i}\right), \qquad i = 1, \ldots, s, \quad j = 0, 1, \ldots, s.$$

These methods are called (s, s)-*Gauss–Lobatto SPARK methods*. They have order $2s$ of convergence; see Corollary 5.4. It can be shown that these methods satisfy conditions (3.3) and

$$\widetilde{a}_{i0} = \widetilde{b}_0, \quad \widetilde{a}_{is} = 0, \quad i = 1, \ldots, s.$$

The algebraic variable Λ_s appears only in (3.2f) and is thus determined by (3.2h).

The $(1, 1)$-Gauss–Lobatto SPARK method corresponds to the following Butcher-style tableaux of SPARK coefficients:

$$\begin{array}{c|c} 1/2 & 1/2 \\ \hline A & 1 \end{array} \qquad \begin{array}{c|c} & 1/2 \\ \hline \widehat{A} & 1 \end{array} \qquad \begin{array}{c|cc} & 1/2 & 0 \\ \hline \widetilde{A} & 1/2 & 1/2 \end{array} \qquad \begin{array}{c|c} 0 & 0 \\ 1 & 1 \\ \hline \overline{A} & \end{array}.$$

We have $\widetilde{Y}_0 = y_0$ and $\widetilde{Y}_1 = y_1$. When $p(y, z) = z$ in (2.11b) the method simplifies to (3.1) for $Y_1, y_1, Z_1, z_1, \Lambda_0, \Lambda_1$.

The $(2, 2)$-Gauss–Lobatto SPARK method corresponds to the following Butcher-style tableaux of SPARK coefficients:

$$\begin{array}{c|cc} 1/2 - \sqrt{3}/6 & 1/4 & 1/4 - \sqrt{3}/6 \\ 1/2 + \sqrt{3}/6 & 1/4 + \sqrt{3}/6 & 1/4 \\ \hline A & 1/2 & 1/2 \end{array} \qquad \begin{array}{c|cc} & 1/4 & 1/4 - \sqrt{3}/6 \\ & 1/4 + \sqrt{3}/6 & 1/4 \\ \hline \widehat{A} & 1/2 & 1/2 \end{array}$$

$$\begin{array}{c|ccc} & 1/6 & 1/3 - \sqrt{3}/6 & 0 \\ & 1/6 & 1/3 + \sqrt{3}/6 & 0 \\ \hline \widetilde{A} & 1/6 & 2/3 & 1/6 \end{array} \qquad \begin{array}{c|cc} 0 & 0 & 0 \\ 1/2 & 1/4 + \sqrt{3}/8 & 1/4 - \sqrt{3}/8 \\ 1 & 1/2 & 1/2 \\ \hline \overline{A} & & \end{array}.$$

We have $\widetilde{Y}_0 = y_0$ and $\widetilde{Y}_2 = y_1$.

3.4. The Lobatto IIIA-B partitioned RK (PRK) methods. SPARK methods (3.2) include the Lobatto IIIA-B PRK methods of [12, 13]. For example, the

$(2,1)$-Lobatto IIIA-B SPARK method of order 2 (an extension of the Störmer/leap-frog/Verlet/RATTLE/ SHAKE methods) corresponds to the following Butcher-style tableaux of SPARK coefficients:

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1/2 & 1/2 \\ \hline A & 1/2 & 1/2 \end{array} \qquad \begin{array}{c|cc} & 1/2 & 0 \\ & 1/2 & 0 \\ \hline \widehat{A} & 1/2 & 1/2 \end{array} \qquad \begin{array}{c|cc} & 1/2 & 0 \\ & 1/2 & 0 \\ \hline \widetilde{A} & 1/2 & 1/2 \end{array} \qquad \begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1/2 & 1/2 \\ \hline \overline{A} & & \end{array}.$$

For this method we have $Y_1 = \widetilde{Y}_0 = y_0$ and $Y_2 = \widetilde{Y}_1 = y_1$. When $p(y,z) = z$ in (2.11b) the method simplifies to the following equations for $y_1, Z_1 = Z_2, z_1, \Lambda_0, \Lambda_1$:

$$\begin{aligned} y_1 &= y_0 + h\frac{1}{2}v(y_0, Z_1) + h\frac{1}{2}v(y_1, Z_2), \\ Z_1 &= z_0 + h\frac{1}{2}f(y_0, Z_1) + h\frac{1}{2}r(y_0, \Lambda_0), \\ 0 &= g(y_1), \\ z_1 &= z_0 + h\frac{1}{2}f(y_0, Z_1) + h\frac{1}{2}f(y_1, Z_2) + h\frac{1}{2}r(y_0, \Lambda_0) + h\frac{1}{2}r(y_1, \Lambda_1) \\ &= Z_1 + h\frac{1}{2}f(y_1, Z_2) + h\frac{1}{2}r(y_1, \Lambda_1), \\ 0 &= g_y(y_1)v(y_1, z_1). \end{aligned}$$

3.5. The symplectic Euler method. For Hamiltonian systems with holonomic constraints (2.1), the symplectic Euler method [7, 9, 23] is defined as follows:

$$P_1 = p_0 - hH_q^T(q_0, P_1) - hg_q^T(q_0)\Psi_0, \tag{3.4a}$$

$$q_1 = q_0 + hH_p^T(q_0, P_1), \tag{3.4b}$$

$$0 = g(q_1), \tag{3.4c}$$

$$p_1 = p_0 - hH_q^T(q_0, P_1) - hg_q^T(q_0)\Psi_0 - hg_q^T(q_1)\Psi_1 = P_1 - hg_q^T(q_1)\Psi_1, \tag{3.4d}$$

$$0 = g_q(q_1)H_p^T(q_1, p_1). \tag{3.4e}$$

It is a method of order 1 and the two quantities Ψ_0, Ψ_1 are locally determined by these equations. The symplectic Euler method can be interpreted as a SPARK method (3.2) with coefficients

$$\begin{array}{c|c} 0 & 0 \\ \hline A & 1 \end{array} \qquad \begin{array}{c|c} & 1 \\ \hline \widehat{A} & 1 \end{array} \qquad \begin{array}{c|cc} & \alpha & 0 \\ \hline \widetilde{A} & \alpha & 1-\alpha \end{array} \qquad \begin{array}{c|c} 0 & 0 \\ 1 & 1 \\ \hline \overline{A} & \end{array},$$

which we call the *"natural" symplectic Euler method*. The quantities Ψ_0 and Ψ_1 correspond to $\Psi_0 = \alpha\Lambda_0$ and $\Psi_1 = (1-\alpha)\Lambda_1$. Unfortunately, this method does not satisfy (3.3c), and when applied to the more general problem (2.11) this SPARK method is generally not convergent [17] when $r(y,\lambda)$ is nonlinear in λ. A convergent

extension of the symplectic Euler method to (2.11) (here given when $p(y,z)=z$ in (2.11b)) is as follows:

$$\begin{aligned}
Z_1 &= z_0 + hf(y_0, Z_1) + h\alpha r(y_0, \Lambda_0),\\
y_1 &= y_0 + hv(y_0, Z_1),\\
0 &= g(y_1),\\
z_1 &= z_0 + hf(y_0, Z_1) + h\alpha(r(y_0,\Lambda_0) - r(y_1,\Lambda_0)) + hr(y_1, \widetilde{\Lambda}_1)\\
&= Z_1 - h\alpha r(y_1,\Lambda_0) + hr(y_1,\widetilde{\Lambda}_1),\\
0 &= g_y(y_1)v(y_1, z_1),
\end{aligned}$$

with $\alpha \neq 0$. We call this method the *"true" symplectic Euler method*. It is convergent of order 1 [17]. It cannot be expressed in the format of a SPARK method (3.2) when $r(y,\lambda)$ is nonlinear in λ. When $r(y,\lambda)$ is affine in λ it is equivalent to the natural symplectic Euler method, which is symplectic for Hamiltonian systems with holonomic constraints (2.1) and for Lagrangian systems with holonomic constraints (2.4); see Theorems 4.1 and 4.2.

4. Symplecticness and variational properties of SPARK methods. The preservation of the symplecticness of the flow of Hamiltonian and Lagrangian systems with holonomic constraints by SPARK methods is considered in this section. The variational properties of the discrete trajectories of symplectic SPARK methods are also examined.

4.1. Symplectic SPARK methods. For Hamiltonian systems with holonomic constraints (2.1), SPARK methods whose numerical flow preserves (locally) the symplecticness property are characterized as follows.

THEOREM 4.1. *We consider Hamiltonian systems with holonomic constraints* (2.1) *satisfying the assumptions given in section* 2.1. *If the SPARK method* (3.2) *applied to* (2.1) *satisfies*

$$\widehat{b}_i = b_i \qquad \text{for } i = 1,\dots,s, \tag{4.1a}$$

$$\widehat{b}_i a_{ij} + b_j \widehat{a}_{ji} - \widehat{b}_i b_j = 0 \qquad \text{for } i,j = 1,\dots,s, \tag{4.1b}$$

$$\widetilde{b}_i \overline{a}_{ij} + b_j \widetilde{a}_{ji} - \widetilde{b}_i b_j = 0 \qquad \text{for } i = 0,1,\dots,\widetilde{s},\quad j = 1,\dots,s, \tag{4.1c}$$

then the numerical flow $(q_0,p_0)\mapsto(q_1,p_1)$ *preserves on* V (2.3) *the symplectic* 2*-form* $\sum_{i=1}^n dq^i \wedge dp^i$.

Proof. We denote

$$V_j := H_p^T(Q_j,P_j), \quad F_j := -H_q^T(Q_j,P_j), \quad R_j := -g_q^T(\widetilde{Q}_j)\Lambda_j.$$

We have

$$\begin{aligned}
dq_1^J \wedge dp_1^J - dq_0^J \wedge dp_0^J = {} & h\sum_{i=1}^{s} \widehat{b}_i dq_0^J \wedge dF_i^J + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i dq_0^J \wedge dR_i^J + h\sum_{j=1}^{s} b_j dV_j^J \wedge dp_0^J\\
& + h^2 \sum_{j=1}^{s} b_j dV_j^J \wedge \sum_{i=1}^{s} \widehat{b}_i dF_i^J + h^2 \sum_{j=1}^{s} b_j dV_j^J \wedge \sum_{i=0}^{\widetilde{s}} \widetilde{b}_i dR_i^J.
\end{aligned}$$

Introducing in the first three terms the following three relations for q_0 and p_0, respectively:

$$q_0 = Q_i - h\sum_{j=1}^{s} a_{ij}V_j, \quad q_0 = \widetilde{Q}_i - h\sum_{j=1}^{s} \overline{a}_{ij}V_j, \quad p_0 = P_j - h\sum_{i=1}^{s} \widehat{a}_{ji}F_i - h\sum_{i=0}^{\widetilde{s}} \widetilde{a}_{ji}R_i,$$

we obtain

$$\begin{aligned}\sum_{J=1}^{n} dq_1^J \wedge dp_1^J - \sum_{J=1}^{n} dq_0^J \wedge dp_0^J = {} & h\sum_{i=1}^{s}\left(\widehat{b}_i \sum_{J=1}^{n} dQ_i^J \wedge dF_i^J + b_i \sum_{J=1}^{n} dV_i^J \wedge dP_i^J\right) \\ & + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i \left(\sum_{J=1}^{n} d\widetilde{Q}_i^J \wedge dR_i^J\right) \\ & + h^2 \sum_{J=1}^{n}\sum_{j=1}^{s}\sum_{i=1}^{s}\left(b_j\widehat{b}_i - b_j\widehat{a}_{ji} - \widehat{b}_i a_{ij}\right) dV_j^J \wedge dF_i^J \\ & + h^2 \sum_{J=1}^{n}\sum_{j=1}^{s}\sum_{i=0}^{\widetilde{s}}\left(b_j\widetilde{b}_i - b_j\widetilde{a}_{ji} - \widetilde{b}_i\overline{a}_{ij}\right) dV_j^J \wedge dR_i^J.\end{aligned}$$

The first term vanishes by assumption (4.1a) and

$$\sum_{J=1}^{n}(dQ_i^J \wedge dF_i^J + dV_i^J \wedge dP_i^J) = 0;$$

see [8, Formula (II.16.18)]. The last two terms also vanish by assumptions (4.1b,c). It remains to show that the second term also vanishes. We have

$$dR_i^J = -\sum_{L=1}^{m}\sum_{K=1}^{n} \frac{\partial^2 g^L}{\partial q^K \partial q^J}(\widetilde{Q}_i)\Lambda_i^L d\widetilde{Q}_i^K - \sum_{L=1}^{m} \frac{\partial g^L}{\partial q^J}(\widetilde{Q}_i) d\Lambda_i^L.$$

We thus get

$$\begin{aligned}\sum_{J=1}^{n} d\widetilde{Q}_i^J \wedge dR_i^J = {} & -\sum_{L=1}^{m} \Lambda_i^L \left(\sum_{J=1}^{n}\sum_{K=1}^{n} \frac{\partial^2 g^L}{\partial q^K \partial q^J}(\widetilde{Q}_i) d\widetilde{Q}_i^J \wedge d\widetilde{Q}_i^K\right) \\ & - \sum_{L=1}^{m}\left(\sum_{J=1}^{n} \frac{\partial g^L}{\partial q^J}(\widetilde{Q}_i) d\widetilde{Q}_i^J\right) \wedge d\Lambda_i^L.\end{aligned}$$

Since the second derivative of g^L is symmetric the expression in brackets in the first term vanishes. Moreover, since $g^L(\widetilde{Q}_i) = 0$ the expression in brackets in the second term also vanishes. This concludes the proof. ∎

Notice that by adding the terms $\overline{a}_{i0}v(y_0, z_0)$ in (3.2c) and $b_0 v(y_0, z_0)$ in (3.2e), we obtain in Theorem 4.1 the additional condition (4.1c) for $j = 0$. For $b_0 = 0$ this implies $\overline{a}_{i0} = 0$ if $\widetilde{b}_i \neq 0$ $(i = 0, 1, \ldots, \widetilde{s})$.

A consequence of Theorem 4.1 is the following.

COROLLARY 4.2. *We consider Lagrangian systems with holonomic constraints* (2.4) *satisfying the assumptions given in section* 2.2. *If the SPARK method* (3.2)

applied to (2.4) *satisfies* (4.1)*, then the numerical flow* $(q_0, v_0) \mapsto (q_1, v_1)$ *preserves on* W (2.6) *the Lagrangian symplectic* 2*-form* (2.10).

Proof. For systems without constraints this result was stated in [14]. The result follows from the equivalence between Hamiltonian and Lagrangian systems as described in section 2.3. Under assumption (2.5), Lagrangian system (2.4) with variables (q, v) can be reformulated in terms of an equivalent Hamiltonian system (2.1) with variables (q, p). A SPARK method (3.1) can be formally applied to this Hamiltonian system (2.1) and then rewritten in terms of the variables (q, v) of the Lagrangian form. This is in fact equivalent to applying a SPARK method (3.1) with the same coefficients directly to Lagrangian system (2.4). ∎

Assuming coefficients (b_i, a_{ij}) and $(\widehat{b}_i)$ are given, to satisfy the symplecticness conditions (4.1b) we must have

$$\widehat{a}_{ij} = \widehat{b}_j \left(1 - \frac{a_{ji}}{b_i}\right) \quad \text{for } i, j = 1, \dots, s, \quad \text{when } b_i \neq 0.$$

Assuming coefficients $(\widetilde{b}_i, \overline{a}_{ij})$ and (b_i) are given, to satisfy the symplecticness conditions (4.1c) we must have

$$\widetilde{a}_{ij} = \widetilde{b}_j \left(1 - \frac{\overline{a}_{ji}}{b_i}\right) \quad \text{for } i = 1, \dots, s, \quad j = 0, 1, \dots, \widetilde{s}, \quad \text{when } b_i \neq 0.$$

From the symplecticness condition (4.1c), the assumption $\overline{a}_{0j} = 0$ (3.3a) implies $b_j = 0$ or $\widetilde{a}_{j0} = \widetilde{b}_0$. We are thus particularly interested in SPARK methods satisfying

$$\widetilde{a}_{i0} = \widetilde{b}_0 \quad \text{for } i = 1, \dots, s. \tag{4.2}$$

From the symplecticness condition (4.1c), the assumption $\overline{a}_{\widetilde{s}j} = b_j$ implies $b_j = 0$ or $\widetilde{a}_{j\widetilde{s}} = 0$. We are thus particularly interested in SPARK methods satisfying

$$\widetilde{a}_{i\widetilde{s}} = 0 \quad \text{for } i = 1, \dots, s. \tag{4.3}$$

From this condition the algebraic variable $\Lambda_{\widetilde{s}}$ appears only in (3.2f) and is determined by (3.2h).

4.2. Symplectic SPARK methods are variational integrators. The application of a SPARK method to Lagrangian systems (2.4) with holonomic constraints and consistent initial values q_0, v_0 at t_0, i.e., $g(q_0) = 0$ and $g_q(q_0)v_0 = 0$, reads as

$$Q_i = q_0 + h \sum_{j=1}^{s} a_{ij} V_j \quad \text{for } i = 1, \dots, s, \tag{4.4a}$$

$$P_i = p_0 + h \sum_{j=1}^{s} \widehat{a}_{ij} F_j + h \sum_{j=0}^{\widetilde{s}} \widetilde{a}_{ij} R_j \quad \text{for } i = 1, \dots, s, \tag{4.4b}$$

$$\widetilde{Q}_i = q_0 + h \sum_{j=1}^{s} \overline{a}_{ij} V_j \quad \text{for } i = 0, 1, \dots, \widetilde{s}, \tag{4.4c}$$

$$0 = g(\widetilde{Q}_i) \quad \text{for } i = 0, 1, \dots, \widetilde{s}, \tag{4.4d}$$

$$q_1 = q_0 + h\sum_{j=1}^{s} b_j V_j, \tag{4.4e}$$

$$p_1 = p_0 + h\sum_{j=1}^{s} \widehat{b}_j F_j + h\sum_{j=0}^{\widetilde{s}} \widetilde{b}_j R_j, \tag{4.4f}$$

$$0 = g(q_1), \tag{4.4g}$$

$$0 = g_q(q_1)v_1, \tag{4.4h}$$

where

$$p_0 := L_v^T(q_0, v_0), \quad p_1 := L_v^T(q_1, v_1), \quad P_i := L_v^T(Q_i, V_i) \quad \text{for } i = 1, \dots, s,$$

$$F_i := L_q^T(Q_i, V_i) \quad \text{for } i = 1, \dots, s, \qquad R_i := -g_q^T(\widetilde{Q}_i)\Lambda_i \quad \text{for } i = 0, 1, \dots, \widetilde{s}.$$

When the SPARK coefficients satisfy symplecticness conditions (4.1), SPARK method (4.4) can also be derived from a variational point of view following the ideas introduced by Marsden and West [21]. Notice that the variational property in a backward analysis sense of symplectic PRK integrators was derived in [14]. The nonequivalent derivation of [7] would consider $V_1, \dots, V_s$ as independent variables and would remove the constraints (4.4b). This derivation would be difficult to apply in our context due to the presence of holonomic constraints.

Following Marsden and West [21], instead of considering the unknown quantities in (3.2) as implicit functions of q_0, v_0, and h, we consider them as implicit functions of q_0, q_1, and h. More precisely, assuming $g(q_0) = 0$ and $g(q_1) = 0$ we implicitly define as functions of q_0, q_1, and h the quantities $p_0, p_1, v_0, v_1, Q_i, P_i, V_i, F_i$ for $i = 1, \dots, s$ and $\widetilde{Q}_i, R_i, \Lambda_i$ for $i = 0, 1, \dots, \widetilde{s}$ by (4.4), except that we replace (4.4g) $g(q_1) = 0$ by $0 = g_q(q_0)v_0$. Formally speaking, we should make a distinction between the solution of (4.4) and the solution of (4.4) with the equation $g(q_1) = 0$ replaced by $0 = g_q(q_0)v_0$. In any case, the solution to one system is also the solution to the other under the assumptions $g(q_0) = 0$ and $g_q(q_0)v_0 = 0$ for the first system of equations and $g(q_0) = 0$ and $g(q_1) = 0$ for the second system of equations.

Considering the discrete action

$$A_d(q_0, q_1, h) := h\sum_{i=1}^{s} b_i L(Q_i, V_i) - h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i \Lambda_i g(\widetilde{Q}_i),$$

we can show after some lengthy calculations (see the proof of Theorem 4.3) that when the SPARK coefficients satisfy the symplecticness assumptions (4.1), we have the relations

$$p_0 = -\nabla_1 A_d(q_0, q_1, h), \qquad p_1 = \nabla_2 A_d(q_0, q_1, h).$$

Therefore, the discrete Euler–Lagrange equations

$$\nabla_2 A_d(q_{n-1}, q_n, h) + \nabla_1 A_d(q_n, q_{n+1}, h) = 0$$

are satisfied for $n = 1, \dots, N-1$. This implies stationarity of the total discrete action

$$\sum_{n=1}^{N} A_d(q_{n-1}, q_n, h) \tag{4.5}$$

with respect to q_n for $n = 1, \ldots, N-1$. This is nothing else but a discrete version of Hamilton's principle applied to this sum (4.5). Therefore a SPARK symplectic integrator is also a variational integrator in this sense; more precisely, we have the following.

THEOREM 4.3. *For Lagrangian systems with holonomic constraints* (2.4) *and a corresponding SPARK method* (4.4)*, assume q_0 and q_N are fixed and consistent. Replace $0 = g(q_{n+1})$ for $n = 0, 1, \ldots, N-1$ by $0 = g_q(q_n)v_n$. If the SPARK coefficients satisfy symplecticness assumptions* (4.1)*, then we have a variational integrator in the sense of Marsden and West* [21]*; i.e., we have stationarity of the total discrete action* (4.5) *with respect to q_n for $n = 1, \ldots, N-1$.*

Proof. We show now the relation $-\nabla_1 A_d(q_0, q_1, h) = p_0$. We have

$$
\begin{aligned}
-\frac{\partial A_d}{\partial q_0}(q_0,q_1,h) &= -h\sum_{i=1}^{s} b_i L_q(Q_i,V_i)\frac{\partial Q_i}{\partial q_0} - h\sum_{i=1}^{s} b_i L_v(Q_i,V_i)\frac{\partial V_i}{\partial q_0} \\
&\quad + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i \Lambda_i^T \left(g_q(\widetilde{Q}_i)\frac{\partial \widetilde{Q}_i}{\partial q_0}\right) + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i g^T(\widetilde{Q}_i)\frac{\partial \Lambda_i}{\partial q_0} \\
&= -h\sum_{i=1}^{s} b_i F_i^T \left(I + h\sum_{j=1}^{s} a_{ij}\frac{\partial V_j}{\partial q_0}\right) - h\sum_{i=1}^{s} b_i P_i^T \frac{\partial V_i}{\partial q_0} \\
&\quad + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i \Lambda_i^T g_q(\widetilde{Q}_i) \left(I + h\sum_{j=1}^{s} \overline{a}_{ij}\frac{\partial V_j}{\partial q_0}\right) + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i g^T(\widetilde{Q}_i)\frac{\partial \Lambda_i}{\partial q_0} \\
&= -h\sum_{i=1}^{s} b_i F_i^T I - h^2 \sum_{i=1}^{s}\sum_{j=1}^{s} b_i a_{ij} F_i^T \frac{\partial V_j}{\partial q_0} \\
&\quad - h\sum_{i=1}^{s} b_i \left(p_0^T + h\sum_{j=1}^{s} \widehat{a}_{ij} F_j^T + h\sum_{j=0}^{\widetilde{s}} \widetilde{a}_{ij} R_j^T \right) \frac{\partial V_i}{\partial q_0} - h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i R_i^T I \\
&\quad - h^2 \sum_{i=0}^{\widetilde{s}}\sum_{j=1}^{s} \widetilde{b}_i \overline{a}_{ij} R_i^T \frac{\partial V_j}{\partial q_0} + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i g^T(\widetilde{Q}_i)\frac{\partial \Lambda_i}{\partial q_0} \\
&= -h\sum_{j=1}^{s} b_j F_j^T I - h^2 \sum_{i=1}^{s}\sum_{j=1}^{s} (b_j a_{ji} + b_i \widehat{a}_{ij}) F_j^T \frac{\partial V_i}{\partial q_0} \\
&\quad - p_0^T h\sum_{i=1}^{s} b_i \frac{\partial V_i}{\partial q_0} - h^2 \sum_{i=1}^{s}\sum_{j=0}^{\widetilde{s}} b_i \widetilde{a}_{ij} R_j^T \frac{\partial V_i}{\partial q_0} - h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i R_i^T I \\
&\quad - h^2 \sum_{i=0}^{\widetilde{s}}\sum_{j=1}^{s} \widetilde{b}_i \overline{a}_{ij} R_i^T \frac{\partial V_j}{\partial q_0} + h\sum_{i=0}^{\widetilde{s}} \widetilde{b}_i g^T(\widetilde{Q}_i)\frac{\partial \Lambda_i}{\partial q_0}.
\end{aligned}
$$

From (4.4e) we have

$$
0 = I + h\sum_{i=1}^{s} b_i \frac{\partial V_i}{\partial q_0};
$$

hence

$$-\frac{\partial A_d}{\partial q_0}(q_0,q_1,h) = -h^2\sum_{i=1}^{s}\sum_{j=1}^{s}(b_j a_{ji} + b_i\widehat{a}_{ij} - b_j b_i)F_j^T\frac{\partial V_i}{\partial q_0} + p_0^T$$

$$-h^2\sum_{i=0}^{\widetilde{s}}\sum_{j=1}^{s}(b_j\widetilde{a}_{ji} + \widetilde{b}_i\overline{a}_{ij} - \widetilde{b}_i b_j)R_i^T\frac{\partial V_j}{\partial q_0} + h\sum_{i=0}^{\widetilde{s}}\widetilde{b}_i g^T(\widetilde{Q}_i)\frac{\partial \Lambda_i}{\partial q_0}.$$

From (4.4d) and symplecticness assumptions (4.1) we obtain the desired result of

$$-\frac{\partial A_d}{\partial q_0}(q_0,q_1,h) = p_0^T.$$

The relation $\nabla_2 A_d(q_0,q_1,h) = p_1$ can be shown in a similar way; thus we skip its proof. ∎

A consequence of Theorem 4.3 is the following.

COROLLARY 4.4. *For Hamiltonian systems with holonomic constraints* (2.1)*, assume q_0 and q_N are fixed and consistent. Replace the equations $0 = g(q_{n+1})$ for $n = 0,1,\ldots,N-1$ by $0 = g_q(q_n)H_p(q_n,p_n)$. If the SPARK coefficients satisfy symplecticness assumptions* (4.1)*, then we have a variational integrator in the sense of Marsden and West* [21]*; i.e., we have stationarity of the total discrete action*

$$\sum_{n=1}^{N} A_d(q_{n-1},q_n,h)$$

with respect to q_n for $n = 1,\ldots,N-1$, where

$$A_d(q_0,q_1,h) := h\sum_{i=1}^{s} b_i\ell(Q_i,P_i) - h\sum_{i=0}^{\widetilde{s}}\widetilde{b}_i\Lambda_i^T g(\widetilde{Q}_i)$$

and where $\ell(q,p) := p^T H_p^T(q,p) - H(q,p)$.

Proof. The result follows from the equivalence between Hamiltonian and Lagrangian systems described in section 2.3. Under assumption (2.2), Hamiltonian system (2.1) with variables (q,p) can be reformulated in terms of an equivalent Lagrangian system (2.4) with variables (q,v). A SPARK method (3.1) can be formally applied to this Lagrangian system (2.1) and then rewritten in terms of the variables (q,p) of the Hamiltonian form. This is in fact equivalent to applying a SPARK method (3.1) with the same coefficients directly to Hamiltonian system (2.1). ∎

5. Analysis of SPARK methods. In this section we give results about existence, uniqueness, local error, and global convergence of SPARK methods. Since SPARK methods are invariant under the change of variables (2.15) (see (2.16) and (2.17)), for the analysis we can simply consider $p(y,z) = z$ in (2.11b), under the assumption

$$g_y v_z r_\lambda \text{ is invertible.}$$

5.1. Existence and uniqueness. Generally there does not exist a solution to the nonlinear system of Definition 3.1 without any assumption on the coefficients of the SPARK method. For consistent SPARK methods satisfying (3.3), existence and

uniqueness for the nonlinear system can be shown under some additional assumptions (see Theorem 5.1). A very accurate value for λ_1 may be unnecessary. For a consistent SPARK method, by (3.3b) we have $\widetilde{c}_{\widetilde{s}} = 1$. Hence, a fairly good choice for λ_1 is given by $\lambda_1 := \Lambda_{\widetilde{s}}$ if one is not interested in enforcing constraints (2.14). The accuracy of the numerical λ-component does not influence the convergence of the (y, z)-components and the properties of the SPARK method. Existence and uniqueness for the system of nonlinear equations of SPARK methods (3.1) are shown in the following theorem.

THEOREM 5.1. *Suppose that* $y_0 = y_0(h), z_0 = z_0(h), \lambda_0 = \lambda_0(h)$ *satisfy*

$$0 = g(y_0), \tag{5.1a}$$

$$O(h^2) = g_y(y_0)v(y_0, z_0), \tag{5.1b}$$

$$\begin{aligned} O(h) = {} & g_{yy}(y_0)(v(y_0, z_0), v(y_0, z_0)) + g_y(y_0)v_y(y_0, z_0)v(y_0, z_0) \\ & + g_y(y_0)v_z(y_0, z_0)(f(y_0, z_0) + r(y_0, \lambda_0)), \end{aligned} \tag{5.1c}$$

where (2.12) *is satisfied in a neighborhood of* (y_0, z_0, λ_0). *Then for SPARK methods satisfying* (3.3) *and* $|h| \le h_0$ *there exists a locally unique SPARK solution of*

$$0 = Y_i - y_0 - h\sum_{j=1}^{s} a_{ij}v(Y_j, Z_j) \quad \text{for } i = 1, \dots, s, \tag{5.2a}$$

$$0 = Z_i - z_0 - h\sum_{j=1}^{s} \widehat{a}_{ij}f(Y_j, Z_j) - h\sum_{j=0}^{\widetilde{s}} \widetilde{a}_{ij}r(\widetilde{Y}_j, \Lambda_j) \quad \text{for } i = 1, \dots, s, \tag{5.2b}$$

$$0 = \widetilde{Y}_i - y_0 - h\sum_{j=1}^{s} \overline{a}_{ij}v(Y_j, Z_j) \quad \text{for } i = 0, 1, \dots, \widetilde{s}, \tag{5.2c}$$

$$0 = g(\widetilde{Y}_i) \quad \text{for } i = 0, 1, \dots, \widetilde{s}, \tag{5.2d}$$

$$0 = y_1 - y_0 - h\sum_{j=1}^{s} b_j v(Y_j, Z_j), \tag{5.2e}$$

$$0 = z_1 - z_0 - h\sum_{j=1}^{s} \widehat{b}_j f(Y_j, Z_j) - h\sum_{j=0}^{\widetilde{s}} \widetilde{b}_j r(\widetilde{Y}_j, \Lambda_j), \tag{5.2f}$$

$$0 = g(y_1), \tag{5.2g}$$

$$0 = g_y(y_1)v(y_1, z_1), \tag{5.2h}$$

which satisfies

$$\begin{aligned} & & Y_i - y_0 = O(h) \quad & \text{for } i = 1, \dots, s, & & \\ \widetilde{Y}_0 = y_0, \quad & \widetilde{Y}_i - y_0 = O(h) \quad & \text{for } i = 1, \dots, \widetilde{s}, \quad & y_1 = \widetilde{Y}_{\widetilde{s}}, \\ & Z_i - z_0 = O(h) \quad & \text{for } i = 1, \dots, s, \quad & z_1 - z_0 = O(h), \\ & \Lambda_i - \lambda_0 = O(h) \quad & \text{for } i = 0, 1, \dots, \widetilde{s}. & \end{aligned}$$

Proof. The proof of this theorem can be done by application of the implicit function theorem, as in the proof of [12, Theorem V.4.1]. We have $\widetilde{Y}_0 = y_0$; hence $g(\widetilde{Y}_0) = 0$ is automatically satisfied by assumption. We have $\widetilde{Y}_{\widetilde{s}} = y_1$; hence (5.2g) can be removed since it is equivalent to (5.2d) for $i = \widetilde{s}$. We expand $g(\widetilde{Y}_i)$ for $i = 1, \dots, \widetilde{s}$ and $v(Y_i, Z_i)$ for $i = 1, \dots, s$ into Taylor series around y_0

$$
\begin{aligned}
g(\widetilde{Y}_i) &= g(y_0) + g_y(y_0)(\widetilde{Y}_i - y_0) \\
&\qquad + \int_0^1 (1-\tau) g_{yy}(y_0 + \tau(\widetilde{Y}_i - y_0)) d\tau (\widetilde{Y}_i - y_0, \widetilde{Y}_i - y_0), \\
v(Y_i, Z_i) &= v(y_0, z_0) + \int_0^1 v_y(y_0 + \tau(Y_i - y_0), z_0 + \tau(Z_i - z_0)) d\tau (Y_i - y_0) \\
&\qquad + \int_0^1 v_z(y_0 + \tau(Y_i - y_0), z_0 + \tau(Z_i - z_0)) d\tau (Z_i - z_0) \\
&= v(y_0, z_0) + h \int_0^1 v_y(y_0 + \tau(Y_i - y_0), z_0 + \tau(Z_i - z_0)) d\tau \sum_{j=1}^{s} a_{ij} v(Y_j, Z_j) \\
&\quad + h \int_0^1 v_z(y_0 + \tau(Y_i - y_0), z_0 + \tau(Z_i - z_0)) d\tau \left(\sum_{j=1}^{s} \widehat{a}_{ij} f(Y_j, Z_j) + \sum_{j=0}^{\widetilde{s}} \widetilde{a}_{ij} r(\widetilde{Y}_j, \Lambda_j) \right).
\end{aligned}
$$

Dividing $g(\widetilde{Y}_i)$ by h^2 and replacing the terms $\widetilde{Y}_i - y_0$, $Y_i - y_0$, and $Z_i - z_0$ by using (5.2a,b,c), we obtain

$$
\begin{aligned}
\frac{1}{h^2} g(\widetilde{Y}_i) &= \frac{1}{h^2} g(y_0) + \frac{1}{h} \sum_{j=1}^{s} \overline{a}_{ij} g_y(y_0) v(Y_j, Z_j) \\
&\qquad + \sum_{j=1}^{s} \sum_{k=1}^{s} \overline{a}_{ij} \overline{a}_{ik} \int_0^1 (1-\tau) g_{yy}(y_0 + \tau(\widetilde{Y}_i - y_0)) d\tau (v(Y_j, Z_j), v(Y_k, Z_k)) \\
&= \frac{1}{h^2} g(y_0) + \frac{1}{h} \sum_{j=1}^{s} \overline{a}_{ij} g_y(y_0) v(y_0, z_0) \\
&\quad + \sum_{j=1}^{s} \sum_{k=1}^{s} \overline{a}_{ij} a_{jk} g_y(y_0) \int_0^1 v_y(y_0 + \tau(Y_j - y_0), z_0 + \tau(Z_j - z_0)) d\tau v(Y_k, Z_k) \\
&\quad + \sum_{j=1}^{s} \sum_{k=1}^{s} \overline{a}_{ij} \widehat{a}_{jk} g_y(y_0) \int_0^1 v_z(y_0 + \tau(Y_j - y_0), z_0 + \tau(Z_j - z_0)) d\tau f(Y_k, Z_k) \\
&\quad + \sum_{j=1}^{s} \sum_{k=0}^{\widetilde{s}} \overline{a}_{ij} \widetilde{a}_{jk} g_y(y_0) \int_0^1 v_z(y_0 + \tau(Y_j - y_0), z_0 + \tau(Z_j - z_0)) d\tau r(\widetilde{Y}_k, \Lambda_k) \\
&\quad + \sum_{j=1}^{s} \sum_{k=1}^{s} \overline{a}_{ij} \overline{a}_{ik} \int_0^1 (1-\tau) g_{yy}(y_0 + \tau(\widetilde{Y}_i - y_0)) d\tau (v(Y_j, Z_j), v(Y_k, Z_k)).
\end{aligned}
$$

By (3.3c), for the values $Y_i := y_0$, $\widetilde{Y}_i := y_0$, $Z_i := z_0$, and $\Lambda_i = \lambda_0$ we obtain

$$\frac{1}{h^2}g(\widetilde{Y}_i) = \frac{\widetilde{c}_i^2}{2}\big(g_y(y_0)v_y(y_0,z_0)v(y_0,z_0) + g_y(y_0)v_z(y_0,z_0)f(y_0,z_0) + g_y(y_0)v_z(y_0,z_0)r(y_0,\lambda_0) + g_{yy}(y_0)(v(y_0,z_0),v(y_0,z_0))\big) = O(h).$$

Hence the values $Y_i(0) := y_0(0)$, $\widetilde{Y}_i(0) := y_0(0)$, $Z_i(0) := z_0(0)$, and $\Lambda_i(0) = \lambda_0(0)$ satisfy (5.2a,b,c) and

$$0 = \frac{1}{h^2}g(\widetilde{Y}_i) \tag{5.3}$$

$$= \sum_{j=1}^{s}\sum_{k=1}^{s}\overline{a}_{ij}a_{jk}g_y(y_0)\int_0^1 v_y(y_0+\tau(Y_j-y_0),z_0+\tau(Z_j-z_0))d\tau v(Y_k,Z_k) + \cdots.$$

Similarly we have

$$g_y(y_1) = g_y(y_0) + \int_0^1 g_{yy}(y_0+\tau(y_1-y_0))d\tau(y_1-y_0,\cdot)$$

$$= g_y(y_0) + h\sum_{j=1}^{s} b_j\int_0^1 g_{yy}(y_0+\tau(y_1-y_0))d\tau(v(Y_j,Z_j),\cdot),$$

$$v(y_1,z_1) = v(y_0,z_0) + \int_0^1 v_y(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau(y_1-y_0) + \int_0^1 v_z(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau(z_1-z_0)$$

$$= v(y_0,z_0) + h\int_0^1 v_y(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau\sum_{j=1}^{s} b_j v(Y_j,Z_j)$$

$$+ h\int_0^1 v_z(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau\left(\sum_{j=1}^{s}\widehat{b}_j f(Y_j,Z_j) + \sum_{j=0}^{\widetilde{s}}\widetilde{b}_j r(\widetilde{Y}_j,\Lambda_j)\right).$$

Hence, dividing $g_y(y_1)v(y_1,z_1)$ by h, we obtain

$$\frac{1}{h}g_y(y_1)v(y_1,z_1) = \frac{1}{h}g_y(y_0)v(y_0,z_0) + \sum_{j=1}^{s} b_j g_y(y_0)\int_0^1 v_y(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau v(Y_j,Z_j)$$

$$+ \sum_{j=1}^{s}\widehat{b}_j\int_0^1 v_z(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau f(Y_j,Z_j)$$

$$+ \sum_{j=0}^{\widetilde{s}}\widetilde{b}_j\int_0^1 v_z(y_0+\tau(y_1-y_0),z_0+\tau(z_1-z_0))d\tau r(\widetilde{Y}_j,\Lambda_j)$$

$$+ \sum_{j=1}^{s} b_j\int_0^1 g_{yy}(y_0+\tau(y_1-y_0))d\tau(v(Y_j,Z_j),v(y_1,z_1)).$$

By consistency $\sum_{j=1}^{s} b_j = 1$, $\sum_{j=1}^{s} \widehat{b}_j = 1$, $\sum_{j=0}^{\widetilde{s}} \widetilde{b}_j = 1$, for the values $Y_i := y_0$, $\widetilde{Y}_i := y_0$, $y_1 := y_0$, $Z_i := z_0$, $z_1 := z_0$, and $\Lambda_i = \lambda_0$, we obtain

$$\frac{1}{h} g_y(y_1) v(y_1, z_1) = g_y(y_0) v_y(y_0, z_0) v(y_0, z_0) + g_y(y_0) v_z(y_0, z_0) f(y_0, z_0) + g_y(y_0) v_z(y_0, z_0) r(y_0, \lambda_0) + g_{yy}(y_0)(v(y_0, z_0), v(y_0, z_0)) = O(h).$$

Hence the values $Y_i(0) := y_0(0)$, $\widetilde{Y}_i(0) := y_0(0)$, $y_1(0) := y_0(0)$, $Z_i(0) := z_0(0)$, $z_1(0) := z_0(0)$, and $\Lambda_i(0) = \lambda_0(0)$ satisfy

$$0 = \frac{1}{h} g_y(y_1) v(y_1, z_1) = \sum_{j=1}^{s} b_j g_y(y_0) \int_0^1 v_y(y_0 + \tau(y_1 - y_0), z_0 + \tau(z_1 - z_0)) d\tau v(Y_j, Z_j) + \cdots . \tag{5.4}$$

Replacing y_1 and z_1 in (5.3)–(5.4) by using (5.2e,f), and using tensor matrix product notations, we see that the Jacobian of (5.2a,b,c), (5.3), and (5.4) with respect to Y_i $(i = 1, \ldots, s)$, Z_i $(i = 1, \ldots, s)$, $\widetilde{Y}_i$ $(i = 1, \ldots, \widetilde{s})$, and Λ_i $(i = 0, 1, \ldots, \widetilde{s})$ is of the form

$$\begin{pmatrix} I_{sn_y} + O(h) & O & O(h) & O \\ O(h) & I_{sn_z} + O(h) & O(h) & O(h) \\ O(h) & O(h) & I_{\widetilde{s}n_y} & O \\ O(1) & O(1) & O(1) & \begin{pmatrix} N \\ \widetilde{b}^T \end{pmatrix} \otimes g_y(y_0) v_z(y_0, z_o) r_\lambda(y_0, \lambda_0) + O(h) \end{pmatrix}$$

with N as defined in (3.3d). This Jacobian matrix is invertible for $|h| \le h_0$ sufficiently small. Therefore, the implicit function theorem yields the existence of a locally unique solution to (5.2a,b,c), (5.3), and (5.4), and hence to the corresponding SPARK method (5.2). ∎

5.2. Local error of the (s, s)-Gauss–Lobatto SPARK methods. A thorough local error analysis of the whole class of SPARK methods (3.2) based on using simplifying assumptions is beyond the scope of this paper. SPARK methods include a class of PRK methods whose local error analysis based on trees is long and technical [12, 13]. For Lobatto IIIA-B methods, an alternative proof using the idea of discontinuous collocation can be found in [7, section VII.1]. Here we will analyze only the local error of the (s, s)-Gauss–Lobatto SPARK methods as defined in subsection 3.3.

THEOREM 5.2. *Consider the system of ODAEs* (2.11), *consistent initial values* y_0, z_0 *at* t_0, *where* (2.12) *is satisfied in a neighborhood of* (y_0, z_0, λ_0). *Then for* $|h| \le h_0$ *the local error of the* (s, s)*-Gauss–Lobatto SPARK methods satisfies*

$$y_1 - y(t_0 + h) = O(h^{2s+1}), \quad z_1 - z(t_0 + h) = O(h^{2s+1}). \tag{5.5}$$

Proof. For the proof we can consider $p(y, z) = z$ in (2.11b). To prove this theorem we use the same techniques of proof as used in [11] for collocation methods. We define the polynomials $Y(t)$, $\widetilde{Y}(t)$, $Z(t)$, and $\Lambda(t)$ of degree s by

$$Y(t) = \sum_{i=0}^{s} \ell_i \left(\frac{t - t_0}{h} \right) Y_i, \qquad \widetilde{Y}(t) = \sum_{i=0}^{s} \widetilde{\ell}_i \left(\frac{t - t_0}{h} \right) \widetilde{Y}_i,$$

$$Z(t)=\sum_{i=0}^{s}\ell_i\left(\frac{t-t_0}{h}\right)Z_i,\qquad \Lambda(t)=\sum_{i=0}^{s}\widetilde{\ell}_i\left(\frac{t-t_0}{h}\right)\Lambda_i,$$

where

$$\ell_i(\tau):=\prod_{\substack{j=0\\ j\neq i}}^{s}\left(\frac{\tau-c_j}{c_i-c_j}\right),\qquad \widetilde{\ell}_i(\tau):=\prod_{\substack{j=0\\ j\neq i}}^{s}\left(\frac{\tau-\widetilde{c}_j}{\widetilde{c}_i-\widetilde{c}_j}\right),$$

$c_0:=0$, $Y_0:=y_0$, and $Z_0:=z_0$. We have $Y(t_0)=\widetilde{Y}(t_0)=y_0$, $Z(t_0)=z_0$, $Y(t_0+h)=\widetilde{Y}(t_0+h)=y_1$, $Z(t_0+h)=z_1$, and

$$Y'(t)=v(Y(t),Z(t))+\delta(t), \tag{5.6a}$$

$$\widetilde{Y}'(t)=v(Y(t),Z(t))+\widetilde{\delta}(t), \tag{5.6b}$$

$$Z'(t)=f(Y(t),Z(t))+r(\widetilde{Y}(t),\Lambda(t))+\mu(t), \tag{5.6c}$$

$$0=g(\widetilde{Y}(t))+\widetilde{\theta}(t), \tag{5.6d}$$

$$0=g_y(\widetilde{Y}(t))(v(Y(t),Z(t))+\widetilde{\delta}(t))+\widetilde{\theta}'(t), \tag{5.6e}$$

with defects $\delta(t)$, $\widetilde{\delta}(t)$, $\mu(t)$, $\widetilde{\theta}(t)$ satisfying

$$\begin{aligned}
\delta(t_0+c_ih)&=0 \quad \text{for } i=1,\dots,s,\\
\widetilde{\delta}(t_0+\widetilde{c}_ih)&=0 \quad \text{for } i=0,1,\dots,s,\\
\mu(t_0+c_ih)&=0 \quad \text{for } i=1,\dots,s,\\
\widetilde{\theta}(t_0+\widetilde{c}_ih)&=0 \quad \text{for } i=0,1,\dots,s,\\
\widetilde{\theta}'(t_0)&=-g_y(\widetilde{Y}(t_0))\widetilde{\delta}(t_0)=0,\\
\widetilde{\theta}'(t_0+h)&=-g_y(\widetilde{Y}(t_0+h))\widetilde{\delta}(t_0+h)=0.
\end{aligned}$$

The exact solution $(y(t),y(t),z(t),\lambda(t))$ satisfies the same above relations (5.6) with $\delta(t)\equiv 0$, $\widetilde{\delta}(t)\equiv 0$, $\mu(t)\equiv 0$, and $\widetilde{\theta}(t)\equiv 0$. One more differentiation of (5.6e) yields

$$\begin{aligned}
0=&\,g_{yy}(\widetilde{Y}(t))(v(Y(t),Z(t))+\widetilde{\delta}(t),v(Y(t),Z(t))+\widetilde{\delta}(t))\\
&+g_y(\widetilde{Y}(t))v_y(Y(t),Z(t))(v(Y(t),Z(t))+\delta(t))\\
&+g_y(\widetilde{Y}(t))v_z(Y(t),Z(t))(f(Y(t),Z(t))+r(\widetilde{Y}(t),\Lambda(t))+\mu(t))\\
&+g_y(\widetilde{Y}(t))\widetilde{\delta}'(t)+\widetilde{\theta}''(t).
\end{aligned}$$

We can express $\Lambda(t)$ from this equation as an implicit function

$$\Lambda(t)=\Upsilon(Y(t),\widetilde{Y}(t),Z(t),\delta(t),\widetilde{\delta}(t),\widetilde{\delta}'(t),\mu(t),\widetilde{\theta}''(t)).$$

Inserting this relation into (5.6c), we obtain the system of ODEs

$$Y'(t) = v(Y(t), Z(t)) + \delta(t),$$

$$\widetilde{Y}'(t) = v(Y(t), Z(t)) + \widetilde{\delta}(t),$$

$$Z'(t) = f(Y(t), Z(t)) + r(\widetilde{Y}(t), \Upsilon(Y(t), \widetilde{Y}(t), Z(t), \delta(t), \widetilde{\delta}(t), \widetilde{\delta}'(t), \mu(t), \widetilde{\theta}''(t))) + \mu(t).$$

To apply the Gröbner–Alekseev formula [8, Theorem I.14.5] we need the defect $d(t) := (d_1(t), d_2(t), d_3(t))^T$:

$$d_1(t) := Y'(t) - v(Y(t), Z(t)) = \delta(t),$$

$$d_2(t) := \widetilde{Y}'(t) - v(Y(t), Z(t)) = \widetilde{\delta}(t),$$

$$d_3(t) := Z'(t) - f(Y(t), Z(t)) - r(\widetilde{Y}(t), \Upsilon(Y(t), \widetilde{Y}(t), Z(t), 0, 0, 0, 0, 0)).$$

We have

$$d_3(t) = \Phi_3(t, 1) - \Phi_3(t, 0) = \int_0^1 \frac{\partial \Phi_3}{\partial \tau}(t, \tau) d\tau,$$

where

$$\Phi_3(t, \tau) := r(\widetilde{Y}(t), \Upsilon(Y(t), \widetilde{Y}(t), Z(t), \tau\delta(t), \tau\widetilde{\delta}(t), \tau\widetilde{\delta}'(t), \tau\mu(t), \tau\widetilde{\theta}''(t))) + \tau\mu(t).$$

Hence, we get

$$d_3(t) = Q_1(t)\delta(t) + Q_2(t)\widetilde{\delta}(t) + Q_3(t)\widetilde{\delta}'(t) + (I + Q_4(t))\mu(t) + Q_5(t)\widetilde{\theta}''(t),$$

where we give only the expressions of $Q_3(t)$ and $Q_5(t)$:

$$Q_3(t) = -\int_0^1 (r_\lambda (g_y v_z r_\lambda)^{-1} g_y)(Y(t), \widetilde{Y}(t), Z(t), \Upsilon(Y(t), \widetilde{Y}(t), Z(t), \tau\delta(t), \tau\widetilde{\delta}(t), \tau\widetilde{\delta}'(t), \tau\mu(t), \tau\widetilde{\theta}''(t)) d\tau,$$

$$Q_5(t) = -\int_0^1 (r_\lambda (g_y v_z r_\lambda)^{-1}(Y(t), \widetilde{Y}(t), Z(t), \Upsilon(Y(t), \widetilde{Y}(t), Z(t), \tau\delta(t), \tau\widetilde{\delta}(t), \tau\widetilde{\delta}'(t), \tau\mu(t), \tau\widetilde{\theta}''(t)) d\tau.$$

We denote the resolvent of the exact solution

$$R(t, s) := R(t, s, y_s, \widetilde{Y}_s, z_s) = \frac{\partial(y, \widetilde{Y}, z)}{\partial(y_s, \widetilde{Y}_s, z_s)}(t, s, y_s, \widetilde{Y}_s, z_s).$$

From the Gröbner–Alekseev formula we have

$$\begin{pmatrix} Y(t) - y(t) \\ \widetilde{Y}(t) - y(t) \\ Z(t) - z(t) \end{pmatrix} = \int_{t_0}^t R(t, s) d(s) ds$$

$$= \int_{t_0}^t S_1(t, s)\delta(s) + S_2(t, s)\widetilde{\delta}(s) + S_3(t, s)\widetilde{\delta}'(s) + S_4(t, s)\mu(s) + S_5(t, s)\widetilde{\theta}''(s) ds,$$

where

$$S_1(t,s)=R(t,s)\begin{pmatrix} I \\ O \\ Q_1(s) \end{pmatrix}, \qquad S_2(t,s)=R(t,s)\begin{pmatrix} O \\ I \\ Q_2(s) \end{pmatrix},$$

$$S_3(t,s)=R(t,s)\begin{pmatrix} O \\ O \\ Q_3(s) \end{pmatrix}, \qquad S_4(t,s)=R(t,s)\begin{pmatrix} O \\ O \\ I+Q_4(s) \end{pmatrix},$$

$$S_5(t,s)=R(t,s)\begin{pmatrix} O \\ O \\ Q_5(s) \end{pmatrix}.$$

Hence, by integration by parts, we obtain

$$\begin{pmatrix} Y(t)-y(t) \\ \widetilde{Y}(t)-y(t) \\ Z(t)-z(t) \end{pmatrix} = S_3(t,s)\widetilde{\delta}(s) - \frac{\partial S_5}{\partial s}(t,s)\widetilde{\theta}(s) + S_5(t,s)\widetilde{\theta}'(s)\Big|_{s=t_0}^{t}$$

$$+\int_{t_0}^{t}\sigma(t,s)ds+\int_{t_0}^{t}\widetilde{\sigma}(t,s)ds,$$

where

$$\sigma(t,s):=S_1(t,s)\delta(s)+S_4(t,s)\mu(s),$$

$$\widetilde{\sigma}(t,s):=\left(S_2(t,s)-\frac{\partial S_3}{\partial s}(t,s)\right)\widetilde{\delta}(s)+\frac{\partial^2 S_5}{\partial s^2}(t,s)\widetilde{\theta}(s).$$

We have $\widetilde{\delta}(t_0)=0=\widetilde{\delta}(t_0+h)$, $\widetilde{\theta}(t_0)=0=\widetilde{\theta}(t_0+h)$, $\widetilde{\theta}'(t_0)=0=\widetilde{\theta}'(t_0+h)$; hence at $t=t_0+h$ we are left with

$$\begin{pmatrix} y_1-y(t_0+h) \\ y_1-y(t_0+h) \\ z_1-z(t_0+h) \end{pmatrix} = \int_{t_0}^{t_0+h}\sigma(t_0+h,s)ds+\int_{t_0}^{t_0+h}\widetilde{\sigma}(t_0+h,s)ds.$$

Applying the Gauss quadrature formula with s nodes of order $2s$ for the first integral, and the Lobatto quadrature formula with $s+1$ nodes of order $2s$ for the second integral, we obtain

$$\int_{t_0}^{t_0+h}\sigma(t_0+h,s)ds=h\sum_{i=1}^{s}\sigma(t_0+h,t_0+c_ih)+O(h^{2s+1}),$$

$$\int_{t_0}^{t_0+h}\widetilde{\sigma}(t_0+h,s)ds=h\sum_{i=0}^{s}\widetilde{\sigma}(t_0+h,t_0+\widetilde{c}_ih)+O(h^{2s+1}),$$

and since $\sigma(t,t_0+c_ih)=0$ for $i=1,\dots,s$ and $\widetilde{\sigma}(t,t_0+\widetilde{c}_ih)=0$ for $i=0,1,\dots,s$, this leads to the desired result (5.5). □

5.3. Global convergence of SPARK methods. Once local error estimates of SPARK methods are known, global convergence results can be obtained without too much difficulty.

THEOREM 5.3. *Consider the system of ODAEs* (2.11) *under assumptions* (2.12) *and a SPARK method* (3.2) *of local order p satisfying assumptions* (3.3). *Then it is globally convergent of order p, i.e.,*

$$y_n - y(t_n) = O(h^p), \quad z_n - z(t_n) = O(h^p)$$

for $t_n - t_0 = nh \leq \text{Const}$.

Proof. For the proof we can consider $p(y,z) = z$ in (2.11b). Replacing (5.2d,g,h), respectively, by

$$\begin{aligned} g(\widetilde{Y}_i) &= g(y_0) + h\widetilde{c}_i g_y(y_0)v(y_0,z_0) \quad \text{for } i = 0,1,\dots,\widetilde{s}, \\ g(y_1) &= g(y_0) + h g_y(y_0)v(y_0,z_0), \\ g_y(y_1)v(y_1,z_1) &= g_y(y_0)v(y_0,z_0) \end{aligned}$$

extends the definition of SPARK methods to a neighborhood of (y_0,z_0) in $\mathbb{R}^{n_y}\times\mathbb{R}^{n_z}$; i.e., SPARK methods are not restricted to just the manifold of constraints $\{(y,z)\in \mathbb{R}^{n_y}\times\mathbb{R}^{n_z} | 0 = g(y), 0 = g_y(y)v(y,z)\}$. Hence, SPARK methods can be locally expressed as a mapping

$$\begin{pmatrix} y_{n+1} \\ z_{n+1} \end{pmatrix} = \begin{pmatrix} y_n \\ z_n \end{pmatrix} + h_n \Phi(h_n, y_n, z_n)$$

from $\mathbb{R}^{n_y}\times\mathbb{R}^{n_z}$ to $\mathbb{R}^{n_y}\times\mathbb{R}^{n_z}$. Hence, classical convergence results, like those for RK methods applied to ODEs, can then be applied [8]. ∎

For the (s,s)-Gauss–Lobatto SPARK methods, as a consequence of Theorem 4.1, Corollary 4.2, Theorem 4.3, Corollary 4.4, and Theorems 5.2 and 5.3, we can now state a major result of this paper.

COROLLARY 5.4. *Consider the system of ODAEs* (2.11) *under assumptions* (2.12). *The* (s,s)*-Gauss–Lobatto SPARK method* (3.2) *is constraint-preserving, symmetric, and of maximal order* $2s$, *i.e.,*

$$y_n - y(t_n) = O(h^{2s}), \quad z_n - z(t_n) = O(h^{2s})$$

for $|t_n - t_0| \leq \text{Const}$ *and* $h := \max(|h_1|,\dots,|h_n|)$. *For holonomically constrained Hamiltonian systems* (2.1) *and Lagrangian systems* (2.4) *these methods are also symplectic and variational.*

6. Numerical experiments. Figure 6.3

To illustrate Corollary 5.4, we have applied (s,s)-Gauss–Lobatto SPARK methods with constant stepsize h to the following system of ODAEs:

$$\begin{pmatrix} y_1' \\ y_2' \end{pmatrix} = \begin{pmatrix} 2z_1 \\ -z_2 \end{pmatrix}, \tag{6.1a}$$

$$\begin{pmatrix} z_1' \\ z_2' \end{pmatrix} = \begin{pmatrix} 2y_1y_2z_1z_2 - y_1z_1z_2 \\ z_1 - y_1z_2^3 \end{pmatrix} + \begin{pmatrix} y_1y_2\lambda_1^2 \\ -\sqrt{y_1}\lambda_1 \end{pmatrix}, \tag{6.1b}$$

$$0 = y_1y_2^2 - 1, \tag{6.1c}$$

$$0 = 2y_2(z_1y_2 - y_1z_2). \tag{6.1d}$$

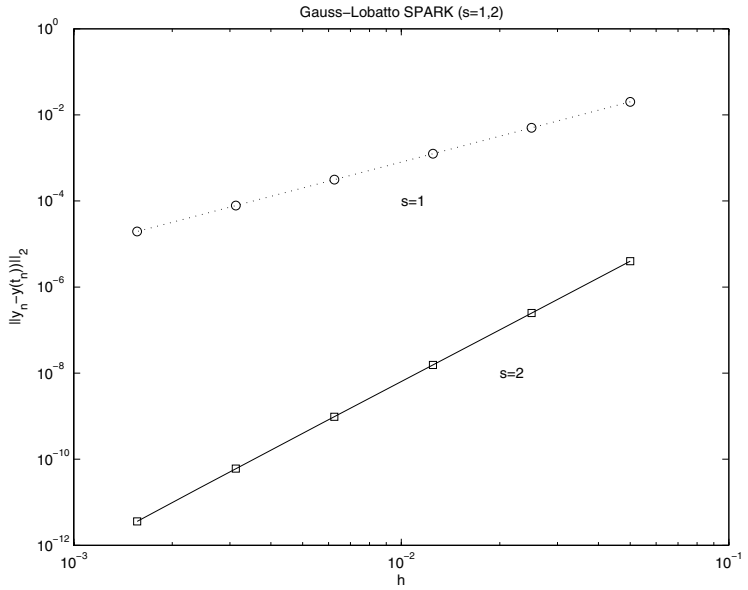

FIG. 6.1. *Global error in y at $t_n = 1$ of (s,s)-Gauss–Lobatto SPARK methods $(s = 1, 2)$ applied with various constant stepsizes h to the test problem* (6.1).

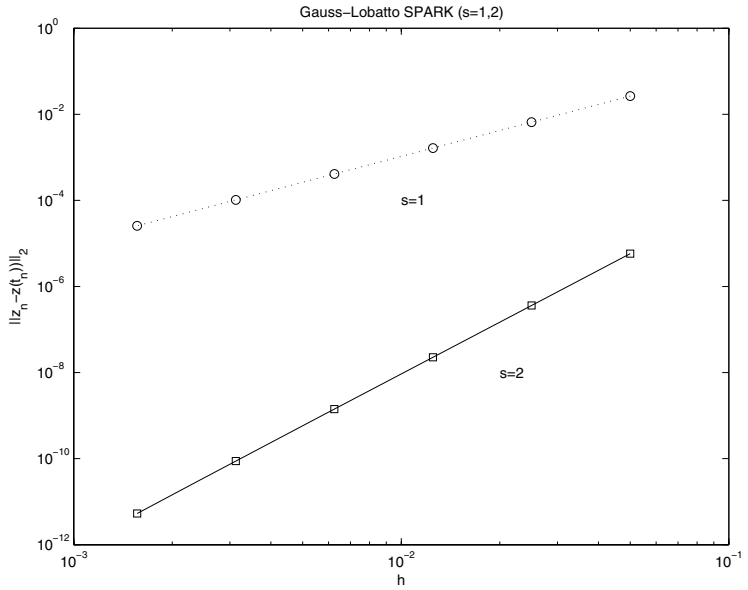

FIG. 6.2. *Global error in z at $t_n = 1$ of (s,s)-Gauss–Lobatto SPARK methods $(s = 1, 2)$ applied with various constant stepsizes h to the test problem* (6.1).

For the initial conditions $y_1(0) = y_2(0) = z_1(0) = z_2(0) = 1$ at $t_0 = 0$, the exact solution to this test problem is given by $y_1(t) = z_1(t) = e^{2t}$, $y_2(t) = z_2(t) = e^{-t}$, $\lambda_1(t) = e^t$. We have plotted in Figures 6.1 and 6.2 the global errors for the y- and z-components at $t_n = 1$ with respect to various constant stepsizes h. Logarithmic scales have been used so that a curve appears as a straight line of slope k whenever

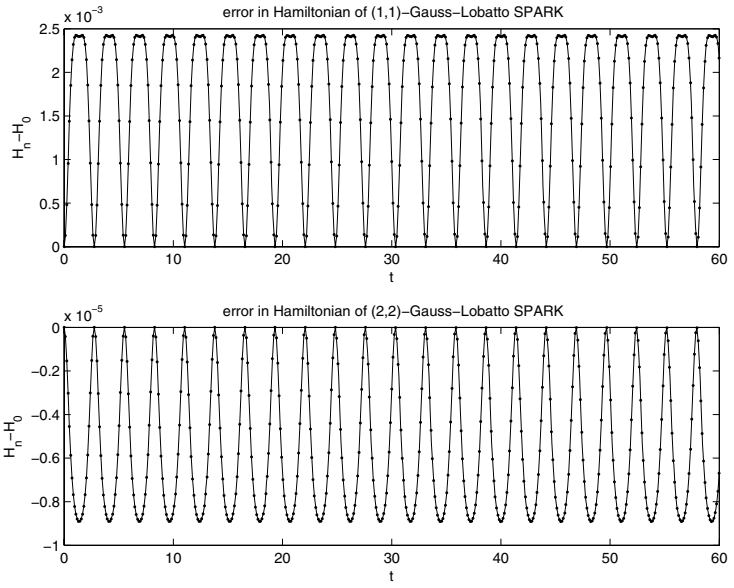

FIG. 6.3. *Error in Hamiltonian of* (s,s)*-Gauss–Lobatto SPARK methods* $(s=1,2)$ *applied with constant stepsize* $h=0.12$ *to the test problem* (6.2).

the leading term of the global error is of order k, i.e., when $\|y_n - y(t_n)\| = O(h^k)$. For the (s,s)-Gauss–Lobatto SPARK methods with $s=1,2$ of order $2s=2,4$ we observe straight lines of slope $2s=2,4$, thus confirming the orders of convergence predicted by Corollary 5.4.

As a second test problem, we consider the motion of a particle of mass m and electric charge e under the influence of an electric field $(0,0,E)^T$ and a magnetic field $(0,0,B)^T$ and restricted to a sphere of radius R [4, Problem 7.16]. This system can be described in term of Cartesian coordinates $(q_1,q_2,q_3)^T$ and generalized momenta $(p_1,p_2,p_3)^T$ with a nonseparable Hamiltonian

$$H = \frac{1}{2m}((p_1+m\omega q_2)^2 + (p_2 - m\omega q_1)^2 + p_3^2) - eEq_3 \tag{6.2a}$$

with $\omega := eB/(2mc)$ and holonomic constraint

$$\sqrt{q_1^2+q_2^2+q_3^2} - R = 0. \tag{6.2b}$$

We choose the parameters

$$m=1, \quad \omega=1, \quad R=1, \quad eE=1$$

and initial conditions

$$q_1(0)=0.2,\ q_2(0)=0.2,\ q_3(0)=\sqrt{0.92},\ p_1(0)=1,\ p_2(0)=-1,\ p_3(0)=0.$$

In Figure 6.3 we plot the Hamiltonian error of (s,s)-Gauss–Lobatto SPARK methods $(s=1,2)$ applied with constant stepsize $h=0.12$ to this system. As expected for a symplectic integrator, we observe that the Hamiltonian error remains bounded and small over long-time intervals.

7. Conclusion. We have considered a general class of ODAEs, and, more particularly, a unified formulation of Hamiltonian and Lagrangian systems with holonomic constraints. We have defined the application of SPARK methods for these systems, including in particular the new (s, s)-Gauss–Lobatto SPARK methods and also well-known schemes such as the Lobatto IIIA-B PRK methods. SPARK methods preserve the constraints. The (s, s)-Gauss–Lobatto SPARK methods have been proved to be of optimal order of convergence $2s$. For Hamiltonian and Lagrangian systems with holonomic constraints, these methods have also been shown to be symplectic and to preserve the variational nature of trajectories.

A SMALL EDDY CORRECTION METHOD FOR A 3D NAVIER–STOKES-TYPE SYSTEM OF EQUATIONS RELATED TO THE PRIMITIVE EQUATIONS OF THE OCEAN*

T. TACHIM MEDJO†

Abstract. Considering the interaction between the baroclinic and barotropic flows and using the idea of the Newton iteration, a small eddy correction method is proposed for approximating and numerically solving the primitive equations of the ocean. We assume that the barotropic approximation to the solution is known. Formally applying the Newton iterative procedure to the baroclinic flow equation, we then generate approximate systems. It is shown that the first step leads to the well-known quasi-geostrophic equations. The convergence analysis is presented and the results show that the small eddy correction method can greatly improve the accuracy of the quasi-geostrophic approximate solution. More precisely, we prove that the approximate system derived from the procedure converges to the original primitive equations, and we estimate the rate of convergence as a function of the aspect ratio of the domain. Some numerical simulations are presented to illustrate the method.

Key words. primitive equations, barotropic flow, baroclinic flow, small eddy

1. Introduction. In dynamical systems theory the objective is to study the long-term behavior of solutions of an evolution equation. When the equation is dissipative all solutions converge as $t \longmapsto \infty$ to a complicated set $\mathcal{A}$, the global attractor, which may be a fractal set. This set embodies the large-time dynamics of the equations, corresponding to all sorts of regimes, including turbulent ones. Although this set may be fairly complicated, in general it has finite dimension [26]. Despite the considerable increase in available computing power during the past few years, the numerical approximation of the global attractor remains a difficult task especially for important systems such as the Navier–Stokes equations or the primitive equations (PEs) of the ocean. For the Navier–Stokes flows, there are some approaches to deriving simplified behavioral laws for the smallest structure set in motion with the aim of reducing the computational cost [9, 24]. In the nonlinear Galerkin (NLG) method introduced in [24], the small scales are given as a function of the large scales, and the nonlinear interaction between the large and the small scales is only approximately modeled. In [13], the authors presented a small eddy correction method for the two-dimensional (2D) Navier–Stokes equations. It is shown that the first step of this iterative method leads to the standard Galerkin method and the second step yields the NLG method.

Although the source of the extensive scale variability differs for the Navier–Stokes and the PE models (the scale variability in the Navier–Stokes system is mainly the result of the nonlinear term, while the sources are more varied for the PE model), there exists an energy cascade that is similar for the two models, and for which one can apply the main principle of description given by Charney [5].

Every mode undergoes constraints due to wind. Even for a fairly constant wind, there is still an infinite number of modes stimulated by the boundary conditions. These modes will exhibit different behaviors with respect to the stimulations based on their position in the spectrum. They can be grouped into three categories:

- At the largest scales, geophysical flows such as the ocean and the atmosphere are essentially 2D (barotropic component). These barotropic modes transmit their energy in the following two ways:
  - (i) at modes of greater dimension, through an inverse kinetic energy cascade; the surplus energy is then dissipated by the boundary conditions;
  - (ii) at modes of smaller dimension, through an entropy barotropic cascade.
- At the medium scales, we have the baroclinic modes. These modes will redistribute their energy as a baroclinic energy cascade, thus transporting the energy to the viscous dispersal area. This cascade is similar to the energy cascade predicted by Kolmogorov for the Navier–Stokes system [9, 8].
- At the very small scales, the energy provided by the surface forces is insufficient to oppose the viscous dispersion constraint.

Given the similarities with the Navier–Stokes system and inspired by the results obtained for the 2D Navier–Stokes equations with the small eddy correction method [13] and the NLG method [24, 12, 11], we present in this article a small eddy correction method for the PEs of the ocean. Considering the interaction between the baroclinic and barotropic flows and using the idea of the Newton iteration, a small eddy correction method is proposed for approximating and numerically solving the PEs of the ocean. We assume that the barotropic approximation to the solution is known. Formally applying the Newton iterative procedure to the baroclinic flow equation, we then generate approximate systems. It is shown that the first step leads to the well-known quasi-geostrophic equations. The convergence analysis is presented and the results show that the small eddy correction method can greatly improve the accuracy of the quasi-geostrophic approximate solution. More precisely, we prove that the approximate system derived from the procedure converges to the PEs of the ocean with a rate of convergence $O((\delta^{1/2})^{2^{l-1}})$, where δ is the shape ratio of the ocean and l is the number of small eddy iterations.

The article is organized as follows. In section 2, we recall the PEs of the ocean and their mathematical setting. The third section of this article presents the small eddy correction method. We prove the existence and uniqueness of solutions to the small eddy correction method when the aspect ratio is small enough. The fourth section is devoted to the convergence of small eddy correction models to the PEs as the aspect ratio goes to zero. We derive an estimate to the rate of convergence as a power of the aspect ratio of the ocean. Although the approach used here is similar to that of [13], there are several differences between the work of [13] and that presented here. First, our model is more complicated. In fact, the PEs of the ocean possess some specific difficulties to circumvent; for instance, the nonlocal constraint (incompressible condition) and the integral expression of the vertical velocity lead to a strong nonlinear term

$$\left(\int_z^0 \operatorname{div} v\, ds\right) \frac{\partial v}{\partial z}. \tag{1.1}$$

More importantly, in [13] the authors used the eigenvalues of the Stokes operator to split the solution between the large and small scales, while in this article the large scale is the depth average (barotropic mode) of the solution and the small scale is the

deviation (baroclinic mode), a decomposition commonly used in ocean modeling. To illustrate the method, some numerical simulations are presented in the last section of this article.

Let us recall that despite advances in the study of the PEs, the mathematical theory of the PEs is far from complete [15, 16, 19, 20, 21, 22, 23, 29, 4]. In [16], the authors prove the existence and uniqueness of global strong solutions of the PEs in thin domains for a broad class of data which include the most physically relevant ones. The most recent result appears in [3], in which the authors prove the existence and uniqueness of global strong solutions without any restriction on the size of the data and the domain occupied by the fluid. It is also worth mentioning that the existence and regularity of solutions to the primitive equations are also studied in [1, 2]. In all these works, the model is a 2D primitive equations, while this article deals with a three-dimensional (3D) problem. Another model of a fluid under the effect of a Coriolis force is studied in [6, 7]. In these articles, the model is a 3D Navier–Stokes equation with a Coriolis force. The authors proved in [6] the existence and uniqueness of strong solutions when the domain is the whole space $\Re^3$ and the Rossby number is small enough. In [7], the authors studied the convergence of the model when the Rossby number goes to zero.

2. The primitive equations and its mathematical setting.

2.1. Governing equations. We first recall the primitive equations. In the nondimensional form, the equations read

$$\begin{cases} \dfrac{\partial v}{\partial t} - \dfrac{1}{R_{e_1}}\Delta v - \dfrac{1}{R_{e_2}}\dfrac{\partial^2 v}{\partial z^2} + f k_0 \times v + (v\cdot\nabla)v + w\dfrac{\partial v}{\partial z} + \operatorname{grad} p = F_1, \\ \dfrac{\partial \rho}{\partial t} - \dfrac{1}{R_{t_1}}\Delta \rho - \dfrac{1}{R_{t_2}}\dfrac{\partial^2 \rho}{\partial z^2} + (v\cdot\nabla)\rho + w\dfrac{\partial \rho}{\partial z} = F_2, \\ \operatorname{div} v + \dfrac{\partial w}{\partial z} = 0, \\ \dfrac{\partial p}{\partial z} = -\rho. \end{cases} \tag{2.1}$$

The boundary conditions are given by

$$\begin{cases} \dfrac{\partial v}{\partial z} = \dfrac{\partial \rho}{\partial z} = 0,\ w = 0 \text{ at } z = -\delta, 0, \\ v, w, \rho \ \text{ periodic in the direction } x, y \text{ with period } \omega. \end{cases} \tag{2.2}$$

In (2.1)–(2.2), the unknown functions are the horizontal velocity v, the vertical velocity w, and the density ρ of the fluid. The constants $R_{e_1} = \frac{\mu}{L_1 U_1} > 0$, $R_{e_2} = \frac{\nu}{L_1 U_1} > 0$, $R_{t_1} = \frac{\mu_T}{L_1 U_1} > 0$, and $R_{t_2} = \frac{\nu_T}{L_1 U_1} > 0$ are the nondimensional Reynolds numbers, $\delta = \frac{H_1}{L_1}$ is the aspect ratio, p is the pressure of the fluid, F_1, F_2 are the volume forces, and k_0 is the unit vector in the vertical direction. Here U_1 is the reference value for the horizontal velocity, L_1 is the reference value for the horizontal length scale, H_1 is the reference value for the vertical length scales, ν and μ are the effective molecular dissipation in the horizontal and vertical directions, and μ_T and ν_T reflect the heat diffusion [19, 20, 21].

The Coriolis parameter f is defined by $f = f_0 + \beta y$, where $\beta > 0$, $f_0 > 0$ are positive constants.

Throughout this article, we use Δ, ∇, div to denote the 2D gradient, Laplacian, and divergence operators on the horizontal plane. The nondimensional domain $\mathcal{M}$ occupied by the fluid is given by

$$\mathcal{M} = \omega \times (-\delta, 0), \tag{2.3}$$

where $\omega \subset \Re^2$ is a smooth convex, bounded open set of $\Re^2$ with boundary $\partial\omega$, and $\delta > 0$ is a constant.

From $(2.1)_{3,4}$ we derive that

$$\begin{cases} W(v) = -\displaystyle\int_{-\delta}^{z} \text{div } v ds, \\ p = p_s + \displaystyle\int_{z}^{0} \rho ds, \\ \text{div} \displaystyle\int_{-\delta}^{0} u \, dz = 0. \end{cases} \tag{2.4}$$

Therefore, (2.1) becomes

$$\begin{cases} \dfrac{\partial v}{\partial t} - \dfrac{1}{R_{e_1}}\Delta v - \dfrac{1}{R_{e_2}}\dfrac{\partial^2 v}{\partial z^2} + f k_0 \times v + (u \cdot \nabla)v \\ \qquad + W(v)\dfrac{\partial v}{\partial z} + \text{grad } p_s + \text{grad} \displaystyle\int_{z}^{0} \rho ds = F_1, \\ \dfrac{\partial \rho}{\partial t} - \dfrac{1}{R_{t_1}}\Delta \rho - \dfrac{1}{R_{t_2}}\dfrac{\partial^2 \rho}{\partial z^2} + (v \cdot \nabla)\rho + W(v)\dfrac{\partial \rho}{\partial z} = F_2, \\ \text{div} \displaystyle\int_{-\delta}^{0} v \, dz = 0. \end{cases} \tag{2.5}$$

Remark 2.1. As in [14], on the surface $z = 0$ of the ocean, we consider a simplified boundary condition. A more physical boundary conditions should be

$$\frac{\partial v}{\partial z} + \alpha_v v = 0, \ \frac{\partial \rho}{\partial z} + \alpha_\rho \rho = 0 \ \text{ at } z = 0. \tag{2.6}$$

In [14], the author pointed out that his existence and uniqueness results cannot be easily extended to the boundary conditions (2.6). Since we extensively used some results given in [14], we will restrict ourselves to the boundary conditions (2.2).

2.2. Mathematical setting. In this section we first recall from [14] the functional spaces suitable for the mathematical setting of (2.5)–(2.2). Let $\mathcal{C}^\infty(\mathcal{M})$ be the usual infinitely differentiable function space in $\mathcal{M}$. Let $H^s(\mathcal{M})$, for $s \in \Re$, be the Sobolev spaces constructed on $L^2(\mathcal{M})$. Motivated by the boundary conditions (2.2), we define

$$\mathcal{C}^\infty_{l,per}(\mathcal{M}) = \{v \in \mathcal{C}^\infty(\mathcal{M}), \ v \text{ periodic in the } x, y \text{ direction with period } \omega\}, \tag{2.7}$$

where the subscript "l" represents the lateral boundary.

Let

$$\mathcal{V}_1 = \left\{ v \in \mathcal{C}^\infty_{l,per}(\mathcal{M}), \ \ \text{div} \int_{-\delta}^{0} v ds = 0 \right\}, \tag{2.8}$$

$$H_1 = \text{ closure of } \mathcal{V}_1 \text{ in } (L^2(\mathcal{M}))^2, \ H_2 = L^2(\mathcal{M}), H = H_1 \times H_2, \tag{2.9}$$

and

$$V_1 = \text{ closure of } \mathcal{V}_1 \text{ in the } (H^1(\mathcal{M}))^2 - \text{norm},\ V_2 = H^1(\mathcal{M}),\ V = V_1 \times V_2. \tag{2.10}$$

The scalar product in H is simply denoted by $(\cdot,\cdot)$, the one in V is denoted by $((\cdot,\cdot))$, and the associated norms are denoted by $|\cdot|_{L^2}$ and $\|\cdot\|$, respectively.

We define the function spaces X_1 and X_2 by

$$X_1 = \left\{ \bar{u} = (\bar{v}, \bar{q}),\ \text{for } u = (v,q) \in L^2(0,T;D(A)),\ \frac{du}{dt} \in L^2(0,T;H) \right\},$$

$$X_2 = \left\{ u^\flat = (v^\flat, q^\flat),\ \text{for } u = (v,q) \in L^2(0,T;D(A)),\ \frac{du}{dt} \in L^2(0,T;H) \right\},$$

where $\bar{u} = Mu$, $u^\flat = N$ are defined by (2.22)–(2.24).

The spaces X_1 and X_2 are endowed with the norms

$$\|\bar{u}\|_{X_1} = \left(\|\bar{u}\|^2_{L^2(0,T;D(A))} + \left| \frac{d\bar{u}}{dt} \right|^2_{L^2(0,T;H)} \right)^{\frac{1}{2}},$$

$$\|u^\flat\|_{X_2} = \left(\|u^\flat\|^2_{L^2(0,T;D(A))} + \left| \frac{dv^\flat}{dt} \right|^2_{L^2(0,T;H)} \right)^{\frac{1}{2}}.$$

We define the bilinear forms $a : V \times V \to \Re$, $a_i : V_i \times V_i \to \Re, i = 1,2$, and the corresponding linear operators $A : V \to V'$, $A_i : V_i \to V_i'$, $i = 1,2$, by

$$\begin{aligned} a_1(v,\tilde{v}) &= \langle A_1 v, \tilde{v} \rangle = \int_{\mathcal{M}} \left[\frac{1}{R_{e_1}} \nabla v \nabla \tilde{v} + \frac{1}{R_{e_2}} \frac{\partial v}{\partial z} \frac{\partial \tilde{v}}{\partial z} \right] dxdydz, \\ a_2(\rho,\tilde{\rho}) &= \langle A_2 \rho, \tilde{\rho} \rangle = \int_{\mathcal{M}} \left[\frac{1}{R_{t_1}} \nabla \rho \nabla \tilde{\rho} + \frac{1}{R_{t_2}} \frac{\partial \rho}{\partial z} \frac{\partial \tilde{\rho}}{\partial z} \right] dxdydz, \\ a(u,\tilde{u}) &= \langle Au, \tilde{u} \rangle = \langle A_1 v, \tilde{v} \rangle + \langle A_2 \rho, \tilde{\rho} \rangle \end{aligned} \tag{2.11}$$

for $u = (v,\rho), \tilde{u} = (\tilde{v},\tilde{\rho}) \in V$.

We have the following characterization of the operators A_i and their domains (see [14] for the details):

$$\begin{aligned} D(A_1) &= \left\{ v \in (H^2(\mathcal{M}))^2 \cap V_1;\ \frac{\partial v}{\partial z} = 0 \ \text{ at } z = -\delta, 0 \right\}, \\ D(A_2) &= \left\{ \rho \in H^2(\mathcal{M}) \cap V_2;\ \frac{\partial \rho}{\partial z} = 0 \ \text{ at } z = -\delta, 0 \right\}, \end{aligned} \tag{2.12}$$

and

$$\begin{aligned} A_1 v &= -\mathcal{P} \left[\frac{1}{R_{e_1}} \Delta v + \frac{1}{R_{e_2}} \frac{\partial^2 v}{\partial z^2} \right] \ \forall v \in D(A_1), \\ A_2 \rho &= -\left[\frac{1}{R_{t_1}} \Delta \rho + \frac{1}{R_{t_2}} \frac{\partial^2 \rho}{\partial z^2} \right] \ \forall \rho \in D(A_2), \end{aligned} \tag{2.13}$$

where $\mathcal{P}$ is the orthogonal projection from $(L^2(\mathcal{M}))^2$ onto H_1.

The linear operators A_i, $i = 1, 2$, which are isomorphisms from V_i onto V_i' are unbounded, self-adjoint linear operators on H_i; they are positive operators and admit compact inverses, so that the fractional power of A_i can also be defined; see [14] and also [28] in which the regularity of A_1 has been studied in a different context.

Note that there exist constants $m_1 > 0$ and $m_2 > 0$ such that

$$m_1\|w\|^2 \leq \langle Aw, w\rangle \leq m_2\|w\|^2 \ \forall w \in V. \tag{2.14}$$

For the nonlinear term, we define the following trilinear functionals and associated operators

$$\begin{aligned} b_1(v,\tilde{v},v') &= \langle B_1(v,\tilde{v}),v'\rangle = \int_{\mathcal{M}} \left[(v\cdot\nabla)\tilde{v} + W(v)\frac{\partial\tilde{v}}{\partial z}\right]\cdot v' dxdydz,\\ b_2(v,\tilde{\rho},\rho') &= \langle B_2(v,\tilde{\rho}),\rho'\rangle = \int_{\mathcal{M}} \left[(v\cdot\nabla)\tilde{\rho} + W(v)\frac{\partial\tilde{\rho}}{\partial z}\right]\cdot \rho' dxdydz,\\ b(u,\tilde{u},u') &= \langle B(u,\tilde{u}),u'\rangle = b_1(v,\tilde{v},v') + b_2(v,\tilde{\rho},\rho') \end{aligned} \tag{2.15}$$

for $u = (v, \rho)$, $\tilde{u} = (\tilde{v}, \tilde{\rho})$, $u' = (v', \rho')$ in V.

For the Coriolis term, we define the bilinear functional $e : H_1 \times H_1 \to \Re$ and the associated operator $E : H_1 \to H_1$ by

$$e(u,\tilde{u}) = \langle E(u),\tilde{u}\rangle = \int_{\mathcal{M}} (f_0 k\times v)\cdot\tilde{v}dxdydz \ \forall u = (v,\rho), \tilde{u} = (\tilde{v},\tilde{\rho}) \in H. \tag{2.16}$$

Finally we define γ and Λ by

$$\Lambda u = \int_z^0 \text{grad}\rho ds, \ \gamma(u,\tilde{u}) = \langle \Lambda u,\tilde{v}\rangle \ \forall u = (v,\rho), \tilde{u} = (\tilde{v},\tilde{\rho}) \in V. \tag{2.17}$$

With these notations, we have the following weak formulation of (2.5)–(2.2) (see page 431 of [14] for the details):

(2.18)

Find $u = (v, \rho) \in L^\infty(0, T; H) \cap L^2(0, T; V)$ $\forall T > 0$, such that

$$\frac{d}{dt}(u,u') + a(u,u') + b(u,u,u') + e(u,u') + \gamma(u,u') = (F,u') \ \forall u' = (v',\rho') \in V,$$

$$u(0) = a \in H.$$

The following result concerning the existence of weak solutions for the PEs is proved in [18, 19].

THEOREM 2.1. *For $T > 0$, there exists at least one solution $u = (v, \rho)$ for (2.18) defined on $(0, T)$ and such that*

$$u \in C([0,T]; H_w), \ \frac{du}{dt} \in L^2(0,T;(V\cap H^3(\mathcal{M}))'),$$

where H_w is the space H equipped with the weak topology and $(V \cap H^3(\mathcal{M}))'$ is the dual space of $V \cap H^3(\mathcal{M})$.

Let us recall that the existence and uniqueness of strong solutions to the PEs was recently proved in [3] without any restriction on the size of the data and the domain

occupied by the fluid. However, in this article, we restrict ourselves to the framework given in [14].

To state the results of [14], we introduce a monotone increasing function $R_0(\delta)$ which satisfies

$$\lim_{\delta\to 0} \delta^{1/2} R_0^2(\delta) = 0. \tag{2.19}$$

THEOREM 2.2. *Assume that the initial condition $a \in H$ and the forcing $F \in H$ satisfy*

$$\|a^\flat\|^2 + |F^\flat|_{L^2}^2 \le \delta^{1/4} R_0^2(\delta), \quad \|\bar a\|^2 + |\bar F|_{L^2}^2 \le \delta R_0^2(\delta). \tag{2.20}$$

Then there exist a constant δ_0 which depends on $R_{e_i}, R_{t_i}, i = 1, 2$, ω and a constant $\sigma > 1$ independent of δ such that, whenever $\delta \in (0, \delta_0)$, the strong solution $u = (v, \rho)$ of (2.18) exists and is unique for all times. More precisely, for all $T > 0$, $u \in L^\infty(0, \infty; V) \cap L^2(0, T; D(A))$ and the following estimates hold:

$$\|v^\flat\|^2 + \|\rho^\flat\|^2 \le \sigma\delta^{1/2} R_0^2(\delta), \quad \|\bar v\|^2 \le \sigma\delta R_0^2(\delta), \quad \|\bar\rho\|^2 \le \sigma R_0^2(\delta), \tag{2.21}$$

where $u^\flat = Nu$, $\bar u = Mu$. The operator M and N which are, respectively, the average operator in the thin direction and its complementary part are defined in (2.22).

Proof. See page 436 of [14]. □

Remark 2.2. The restriction (2.19) on the data is still physically relevant. In fact the baroclinic components $a^\flat$ and $F^\flat$ of the data can be of order $O(\delta^{-1/4})$, while the baroclinic components $\bar a$ and $\bar F$ are of order $O(1)$.

2.2.1. Functional inequalities in thin domains. We recall from [28] (see also [14]) some functional inequalities in thin domains. First we define average operator M in the thin direction and its complementary N as follows:

$$M\psi(x, y) = \frac{1}{\delta}\int_{-\delta}^{0} \psi(x, y, z)dz, \ N\psi(x, y, z) = \psi(x, y, z) - M\psi(x, y). \tag{2.22}$$

Clearly, M and N are orthogonal projections on $L^2(\mathcal{M})$. They commute with the partial derivatives $\frac{\partial}{\partial x}$, $\frac{\partial}{\partial y}$, and $\frac{\partial}{\partial z}$.

It follows that (see [14])

$$MPv = PMv \ \forall v \in (L^2(\mathcal{M}))^2, \qquad MA_1 v = A_1 Mv \ \forall v \in D(A_1). \tag{2.23}$$

Hereafter, we will also use the following notation:

$$\bar v = Mv, \qquad v^\flat = Nv. \tag{2.24}$$

We also have the Poincaré inequalities

$$\begin{aligned} &|v^\flat|_{L^2} \le \delta \left|\frac{\partial v^\flat}{\partial z}\right|_{L^2} \ \forall v \in V_1, \\ &|v^\flat|_{L^2} \le \delta^2 |Av^\flat|_{L^2} \ \forall v \in D(A_1). \end{aligned} \tag{2.25}$$

The following lemma is borrowed from [28] (see also [14]).

LEMMA 2.3. *Let $k \in (0,1/2)$. Then there exists $c_1 = c_1(k)$ independent of δ such that*

(2.26)
$$|b_1(\bar{u}, v^\flat, w)| \le c_1 \delta^k \|\bar{u}\| |A_1 v^\flat|_{L^2} |w|_{L^2} \ \forall u \in V_1, v \in D(A_1), w \in (L^2(\mathcal{M}))^2,$$

$$|b_1(u^\flat, \bar{v}, w)| \le c_1 \delta^{1/2} \|\bar{v}\| |A_1 u^\flat|_{L^2} |w|_{L^2} \ \forall u \in D(A_1), v \in V_1, w \in (L^2(\mathcal{M}))^2,$$

$$|b_1(u^\flat, v^\flat, w)| \le c_1 \delta^{1/2} \|v^\flat\| |A_1 u^\flat|_{L^2} |w|_{L^2} \ \forall u \in D(A_1), v \in V_1, w \in (L^2(\mathcal{M}))^2,$$

$$|b_2(\bar{v}, \rho^\flat, w)| \le c_1 \delta^k \|\bar{v}\| |A_2 \rho^\flat|_{L^2} |w|_{L^2} \ \forall v \in V_1, \rho \in D(A_2), w \in (L^2(\mathcal{M}))^2,$$

$$|b_2(v^\flat, \bar{\rho}, w)| \le c_1 \delta^{1/2} \|\bar{\rho}\| |A_1 v^\flat|_{L^2} |w|_{L^2} \ \forall v \in D(A_1), \rho \in V_2, w \in (L^2(\mathcal{M}))^2,$$

$$|b_2(v^\flat, \rho^\flat, w)| \le c_1 \delta^{1/2} \|\rho^\flat\| |A_1 v^\flat|_{L^2} |w|_{L^2} \ \forall v \in D(A_1), \rho \in V_2, w \in (L^2(\mathcal{M}))^2,$$

$$|\Lambda w|_{L^2}^2 \le c\delta^2 |Aw|_{L^2}^2 \ \forall w \in D(A),$$

$$|Ew|_{L^2}^2 \le c|w|_{L^2}^2 \ \forall w \in H.$$

We also recall the following well-known estimate on the trilinear form of the 2D Navier–Stokes equations (see [26]):

$$\begin{aligned}
&b(\bar{u}, \bar{v}, \bar{v}) = 0 \quad \forall u, v \in V,\\
&|b(\bar{u}, \bar{v}, \bar{w})| \le c_0 |\bar{u}|_{L^2}^{\frac{1}{2}} \|\bar{u}\|^{\frac{1}{2}} \|\bar{v}\|^{\frac{1}{2}} |A\bar{v}|_{L^2}^{\frac{1}{2}} |\bar{w}|_{L^2} \quad \forall u \in V, v \in D(A), w \in H,\\
&|b(\bar{u}, \bar{v}, \bar{w})| \le c_0 |\bar{u}|_{L^2}^{\frac{1}{2}} |A\bar{u}|_{L^2}^{\frac{1}{2}} \|\bar{v}\| |\bar{w}|_{L^2} \quad \forall u \in D(A), v \in V, w \in H,\\
&|b(\bar{u}, \bar{v}, \bar{w})| \le c_0 |\bar{u}|_{L^2}^{\frac{1}{2}} \|\bar{u}\|^{\frac{1}{2}} \|\bar{v}\| |\bar{w}|_{L^2}^{\frac{1}{2}} \|\bar{w}\|^{\frac{1}{2}} \quad \forall u, v, w \in V.
\end{aligned} \tag{2.27}$$

In [14, p. 436], the author derived the following weak formulation for the M and N components $\bar{u}$ and $u^\flat$ of u (note that $\gamma(u, \bar{\theta}) = 0$ for all $\theta \in V$ since for $\theta = (w, \phi) \in V$, div $\bar{w} = 0$):

$$\begin{aligned}
&\frac{d}{dt}(\bar{u}, \bar{\theta}) + a(\bar{u}, \bar{\theta}) + e(\bar{u}, \bar{\theta}) + b(\bar{u}, \bar{u}, \bar{\theta}) + b(u^\flat, u^\flat, \bar{\theta}) = (\bar{F}, \bar{\theta}) \ \forall \theta \in V,\\
&\bar{u}(0) = \bar{a} \in H,
\end{aligned} \tag{2.28}$$

$$\begin{aligned}
&\frac{d}{dt}(u^\flat, \theta^\flat) + a(u^\flat, \theta^\flat) + e(u^\flat, \theta^\flat) + b(\bar{u}, u^\flat, \theta^\flat) + b(u^\flat, \bar{u}, \theta^\flat)\\
&\qquad + b(u^\flat, u^\flat, \theta^\flat) + \gamma(\bar{u} + u^\flat, \theta^\flat) = (F^\flat, \theta^\flat) \ \forall \theta \in V,\\
&u^\flat(0) = a^\flat \in H.
\end{aligned} \tag{2.29}$$

Hereafter, $c_0 = c_0(\omega, T)$ will denote constants that depend only on the horizontal domain ω and T, $c_2 = c_2(\omega, k, T)$ will denote a constant that depends on ω, T, and k, and $c_1 = c_1(k, T)$ will denote a constant that depend on k and T. Finally c will denote a generic constant.

2.2.2. The 2D Navier–Stokes. We first recall the following 2D Navier–Stokes equations (with a Coriolis force) and an associated transport equation:

$$\begin{cases} \dfrac{\partial \bar{w}_1}{\partial t} - \dfrac{1}{R_{e_1}}\Delta \bar{w}_1 + fk_0 \times \bar{w}_1 + (\bar{U}_1 \cdot \nabla)\bar{w}_1 + (\bar{w}_1 \cdot \nabla)\bar{U}_1 \\ \qquad + (\bar{w}_1 \cdot \nabla)\bar{w}_1 + \text{grad } p_s = \bar{F}_1, \\ \dfrac{\partial \bar{q}_1}{\partial t} - \dfrac{1}{R_{t_1}}\Delta \bar{q}_1 + (\bar{U}_1 \cdot \nabla)\bar{q}_1 + (\bar{w}_1 \cdot \nabla)\bar{\psi} + (\bar{v}_1 \cdot \nabla)\bar{q} = \bar{F}_2, \\ \text{div } \bar{w}_1 = 0, \end{cases} \tag{2.30}$$

with the initial and boundary conditions

$$\begin{aligned} &\bar{v}_1 = (\bar{w}_1, \bar{q}) \text{ is periodic in the } x \text{ and } y \text{ direction with period } \omega, \\ &\bar{v}_1(0) = \bar{a}, \text{ at } t = 0. \end{aligned} \tag{2.31}$$

It is clear that $\bar{v}_1 = (\bar{w}_1, \bar{q}_1)$ satisfies

$$\begin{aligned} &\frac{d}{dt}(\bar{v}_1, \bar{\theta}) + a(\bar{v}_1, \bar{\theta}) + e(\bar{v}_1, \bar{\theta}) + b(\bar{U}, \bar{v}_1, \bar{\theta}) + b(\bar{v}_1, \bar{U}, \bar{\theta}) + b(\bar{v}_1, \bar{v}_1, \bar{\theta}) \\ &\qquad = (\bar{F}, \bar{\theta}) \ \forall \theta \in V, \ \bar{v}_1(0) = \bar{a}, \end{aligned} \tag{2.32}$$

where $\bar{U} = (\bar{U}_1, \bar{\psi}_1)$, $\bar{F} = (\bar{F}_1, \bar{F}_2)$, $\bar{a} = (\bar{a}_1, \bar{a}_2)$.

In (2.30), the unknown functions are the velocity $\bar{w}$, the temperature $\bar{q}_1$, and the surface pressure p_s. The volume force $\bar{F}$ and the initial condition $\bar{a}$ are given.

We assume the following regularity conditions:

$$\bar{F} \in L^2(0,T;H) \ \forall T > 0, \ \bar{a} \in V; \qquad \bar{U} \in L^\infty(0,T;V) \cap L^2(0,T;D(A)). \tag{2.33}$$

The domain ω occupied by the fluid is a smooth convex, bounded open set of $\Re^2$ with boundary $\partial\omega$. Finally the constant $R_{e_1} > 0$ is the nondimensional Reynolds number.

PROPOSITION 2.4. *The system* (2.30) *has a unique solution* $\bar{v}_1 \in L^2(0,T;D(A)) \cap L^\infty(0,T;V)$. *Moreover, we have the estimates*

$$\begin{aligned} &|\bar{v}_1(t)|_{L^2}^2 + \int_0^T \|\bar{v}_1\|^2 dt \le e^{M_0(T)} \left(|\bar{a}|_{L^2}^2 + \int_0^T |\bar{F}|_{L^2}^2 ds \right), \\ &\|\bar{v}_1(t)\|^2 + \int_0^T |A\bar{v}_1|_{L^2}^2 dt \le e^{M_1(T)} \left(\|\bar{a}\|^2 + \int_0^T |\bar{F}|_{L^2}^2 ds \right), \\ &\int_0^T \left| \frac{d\bar{v}_1}{dt} \right|_{L^2}^2 dt \le e^{M_1(T)} \left(\|\bar{a}\|^2 + \int_0^T |\bar{F}|_{L^2}^2 ds \right), \end{aligned} \tag{2.34}$$

where

$$\begin{aligned} M_0(t) = c_0 \int^t \|\bar{U}\|^2 ds, \ M_1(t) = c_0 \int_0^t |\bar{U}|_{L^2} |A_1 \bar{U}|_{L^2} ds \\ + e^{2M_0(t)} \left(|\bar{a}|_{L^2}^2 + \int_0^T |\bar{F}|_{L^2}^2 ds \right)^2. \end{aligned} \tag{2.35}$$

Proof. For the existence and uniqueness of solutions to (2.32), (2.30), see, for instance, [26]. The estimates (2.34) are also standard, but for the sake of clarity, we give a sketch of the proof.

For $(2.34)_1$, multiplying (2.30) by $\bar{v}_1$ and using (2.27) yield

$$\frac{d}{dt}|\bar{v}_1|_{L^2}^2 + c_0\|\bar{v}_1\|^2 \leq c_0|\bar{v}_1|_{L^2}^2\|\bar{U}\|^2 + c_0|\bar{F}|_{L^2}^2, \tag{2.36}$$

and $(2.34)_1$ follows from the Gronwall lemma [26].

For $(2.34)_2$, we first note that (see (2.27))

$$\begin{aligned}
|b(\bar{v}_1, \bar{U}, A\bar{v}_1)| &\leq c_0|\bar{v}_1|_{L^2}^{1/2}|A\bar{v}_1|_{L^2}^{3/2}\|\bar{U}\| \\
&\leq \frac{1}{8}|A\bar{v}_1|_{L^2}^2 + c_0|\bar{v}_1|_{L^2}^2\|\bar{U}\|^4, \\
|b(\bar{U}, \bar{v}_1, A\bar{v}_1)| &\leq \frac{1}{8}|A\bar{v}_1|_{L^2}^2 + c_0|\bar{U}|_{L^2}|A\bar{U}|_{L^2}, \\
|b(\bar{v}_1, \bar{v}_1, A\bar{v})| &\leq \frac{1}{8}|A\bar{v}_1|_{L^2}^2 + c_0|\bar{v}_1|_{L^2}^2\|\bar{v}_1\|^4, \\
|e(\bar{v}_1, A\bar{v}_1)| &\leq \frac{1}{8}|A\bar{v}_1|_{L^2}^2 + c_0|\bar{v}_1|_{L^2}^2.
\end{aligned} \tag{2.37}$$

Now multiplying (2.30) by $A\bar{v}$ and using (2.37) yield

$$\frac{d}{dt}\|\bar{v}_1\|^2 + |A\bar{v}_1|_{L^2}^2 \leq c_0|\bar{F}|_{L^2}^2 + c_0|\bar{v}_1|_{L^2}^2 + h(t)\|\bar{v}_1\|^2, \tag{2.38}$$

where

$$h(t) = c_0|\bar{U}|_{L^2}|A\bar{U}|_{L^2} + c_0|\bar{v}_1|_{L^2}^2\|\bar{v}_1\|^2 + c_0\|\bar{U}\|^4$$

and

$$\begin{aligned}
\int_0^t h(s)ds &\leq c_0\int_0^t |\bar{U}|_{L^2}|A\bar{U}|_{L^2}ds + \sup_s |\bar{v}_1(s)|_{L^2}^2\int_0^t \|\bar{v}_1\|^2 ds \\
&\quad + c_0\int_0^t \|\bar{U}\|^4 ds \equiv M_1(t),
\end{aligned} \tag{2.39}$$

and $(2.34)_2$ follows from the standard Gronwall lemma.

For $(2.34)_3$, we note that

$$\begin{aligned}
\left|\frac{d\bar{v}_1}{dt}\right|_{L^2}^2 &\leq c|A\bar{v}_1|_{L^2}^2 + c|E\bar{v}_1|_{L^2}^2 + c|B(\bar{U}, \bar{v}_1)|_{L^2}^2 \\
&\quad + c|B(\bar{v}_1, \bar{U})|_{L^2}^2 + c|B(\bar{v}_1, \bar{v}_1)|_{L^2}^2 \\
&\leq c|A\bar{v}_1|_{L^2}^2 + c_0|\bar{v}_1|_{L^2}^2 + c_0|\bar{U}|_{L^2}|A\bar{U}|_{L^2}\|\bar{v}_1\|^2 + c_0|\bar{v}_1|_{L^2}|A\bar{v}_1|_{L^2}\|\bar{U}\|^2 \\
&\quad + c_0|\bar{v}_1|_{L^2}|A\bar{v}_1|_{L^2}\|\bar{v}_1\|^2,
\end{aligned} \tag{2.40}$$

and $(2.34)_3$ follows from $(2.34)_2$. ∎

2.2.3. The 3D linear system. We also consider the following 3D heat-type equations:

$$\frac{d}{dt}(v^\flat,\theta^\flat)+a(v^\flat,\theta^\flat)+e(v^\flat,\theta^\flat)+\gamma(v^\flat,\theta^\flat)=(F^\flat,\theta^\flat)\ \forall\theta\in V,\ v^\flat(0)=a^\flat. \tag{2.41}$$

In (2.41), the unknown function $v^\flat=(v_1^\flat,q_1^\flat)$, the volume force $F^\flat=(F^\flat,F_2^\flat)$, and the initial condition $a^\flat=(a_1^\flat,a_2^\flat)$ are given. We assume the following regularity condition:

$$a^\flat\in V,\qquad F^\flat\in L^2(0,T;H). \tag{2.42}$$

PROPOSITION 2.5. *The heat-type equation* (2.41) *has a unique solution* $v^\flat\in L^2(0,T;D(A))\cap L^\infty(0,T;V)$. *Moreover, we have the estimates*

$$\begin{aligned}&\|v^\flat(t)\|^2\le c\left(\|a^\flat\|^2+\int_0^T|F^\flat|_{L^2}^2ds\right)\equiv c_5,\ \int_0^T|Av^\flat|_{L^2}^2dt\le c_5,\\&\int_0^T\left|\frac{dv^\flat}{dt}\right|_{L^2}^2dt\le c_5,\ |v^\flat(t)|_{L^2}^2\le\delta^2c_5.\end{aligned} \tag{2.43}$$

Proof. Multiplying (2.41) by $v^\flat$ gives

$$|v^\flat(t)|_{L^2}^2+\int_0^t\|v^\flat\|^2ds+\le c\left(|a^\flat|_{L^2}^2+\int_0^t|F^\flat|_{L^2}^2ds\right). \tag{2.44}$$

Now, multiplying (2.41) by $Av^\flat$ yields

$$\|v^\flat(t)\|^2+\int_0^t|Av^\flat|_{L^2}^2ds\le c\left(\|a^\flat\|^2+\int_0^t|F^\flat|_{L^2}^2ds\right) \tag{2.45}$$

and $(2.43)_{2,3}$ follow. Note that $(2.43)_4$ follows from (2.25).

3. A small eddy correction method. Hereafter we set

$$\begin{aligned}(\mathcal{F}(\bar u,u^\flat),\theta^\flat)=&\frac{d}{dt}(u^\flat,\theta^\flat)+a(u^\flat,\theta^\flat)+e(u^\flat,\theta^\flat)+\gamma(\bar u+u^\flat,\theta^\flat)+b(\bar u,u^\flat,\theta^\flat)\\&+b(u^\flat,\bar u,\theta^\flat)+b(u^\flat,u^\flat,\theta^\flat)-(F^\flat,\theta^\flat).\end{aligned} \tag{3.1}$$

Then $(2.29)_1$ is equivalent to

$$(\mathcal{F}(\bar u,u^\flat),\theta^\flat)=0\ \forall\theta\in V,\ u^\flat(0)=a^\flat. \tag{3.2}$$

Supposing that the barotropic flow $\bar u$ is known, and formally applying the Newton iteration to (3.2), we get the following iterative procedure: assuming that the initial guess for the baroclinic (or the small eddy) component $u_0^\flat=0$ and the $(j-1)$th approximation $u_{j-1}^\flat$ is known for some integer j, find the jth approximation $u_j^\flat$ such that

$$D_{u^\flat}\mathcal{F}(\bar u,u^\flat)(u_j^\flat-u_{j-1}^\flat)=-\mathcal{F}(\bar u,u_{j-1}^\flat). \tag{3.3}$$

Simple calculation shows that (3.3) reduces to

$$\begin{aligned}&\frac{d}{dt}(u_j^\flat,\theta^\flat)+a(u_j^\flat,\theta^\flat)+e(u_j^\flat,\theta^\flat)+\gamma(v+u_j^\flat,\theta^\flat)+b(\bar u,u_j^\flat,\theta^\flat)+b(u_j^\flat,\bar u,\theta^\flat)\\&\quad+b(u_{j-1}^\flat,u_j^\flat,\theta^\flat)+b(u_j^\flat,u_{j-1}^\flat,\theta^\flat)+b(u_{j-1}^\flat,u_{j-1}^\flat,\theta^\flat)\\&=(F^\flat,\theta^\flat)\ \forall\theta\in V,\ u_j^\flat(0)=a^\flat.\end{aligned} \tag{3.4}$$

Combining (3.4) with the barotropic equation (2.29) (with $\bar{u}$ replaced by v and $u_j^\flat$ replaced by w_j), we obtain the following small eddy correction method: let $w_0 = 0$ and let l be a fixed positive integer:

$$\frac{d}{dt}(v,\bar{\theta}) + a(v,\bar{\theta}) + e(v,\bar{\theta}) + b(v,v,\bar{\theta}) + b(w_l,w_l,\bar{\theta}) = (\bar{F},\bar{\theta})\ \forall \theta \in V,\ v(0) = \bar{a}, \tag{3.5}$$

$$\begin{aligned}&\frac{d}{dt}(w_j,\theta^\flat) + a(w_j,\theta^\flat) + e(w_j,\theta^\flat) + \gamma(v+w_j,\theta^\flat) + b(v,w_j,\theta^\flat) + b(w_j,v,\theta^\flat)\\ &\qquad + b(w_{j-1},u_j^\flat,\theta^\flat) + b(w_j,w_{j-1},\theta^\flat) + b(w_{j-1},w_{j-1},\theta^\flat)\\ &\quad = (F^\flat,\theta^\flat)\ \forall \theta \in V,\ w_j(0) = a^\flat\end{aligned} \tag{3.6}$$

for $j = 1, 2, \ldots, l$.

Remark 3.1. For $l = 0$, (3.5)–(3.6) reduce (since $w_0 = 0$) to

$$\frac{d}{dt}(v,\bar{\theta}) + a(v,\bar{\theta}) + e(v,\bar{\theta}) + b(v,v,\bar{\theta}) = (\bar{F},\bar{\theta})\ \forall \theta \in V,\ v(0) = \bar{a}, \tag{3.7}$$

which is the well-known quasi-geostrophic model.

For $l = 1$, (3.5)–(3.6) become

$$\frac{d}{dt}(v,\bar{\theta}) + a(v,\bar{\theta}) + e(v,\bar{\theta}) + b(v,v,\bar{\theta}) + b(w_1,w_1,\bar{\theta}) = (\bar{F},\bar{\theta})\ \forall \theta \in V,\ v(0) = \bar{a}, \tag{3.8}$$

$$\begin{aligned}&\frac{d}{dt}(w_1,\theta^\flat) + a(w_1,\theta^\flat) + e(w_1,\theta^\flat) + \gamma(v+w_1,\theta^\flat) + b(v,w_1,\theta^\flat) + b(w_1,v,\theta^\flat)\\ &\quad = (F^\flat,\theta^\flat)\ \forall \theta \in V,\ w_1(0) = a^\flat,\end{aligned} \tag{3.9}$$

which is similar to the NLG method studied in [27, 17, 24, 25] for the 2D Navier–Stokes equations.

3.1. Some a priori estimates. In this part, we prove the existence and uniqueness of a strong solution to (3.5)–(3.6) when δ is small enough.

Hereafter we set $\mathbf{X} = X_1 \times (X_2)^l$. For $v = (\bar{v}, w_1, w_2, \ldots, w_l) \in \mathbf{X}$, we set

$$\|v\|_{\mathbf{X}}^2 = \|\bar{v}\|_{X_1}^2 + \sup_i \|w_i\|_{X_2}^2. \tag{3.10}$$

3.1.1. Linear problems. To (3.5)–(3.6) we associate the following system: Find $(\bar{v}^0, w_1^0, w_2^0, \ldots, w_l^0) \in \mathbf{X}$ such that

$$\frac{d}{dt}(v^0,\bar{\theta}) + a(v^0,\bar{\theta}) + e(v^0,\bar{\theta}) = (\bar{F},\bar{\theta})\ \forall \theta \in V,\ v^0(0) = \bar{a}, \tag{3.11}$$

and for $j = 1, 2, \ldots, l$

$$\frac{d}{dt}(w_j^0,\theta^\flat) + a(w_j^0,\theta^\flat) + e(w_j^0,\theta^\flat) = (F^\flat,\theta^\flat)\ \forall \theta \in V,\ w_j^0(0) = a^\flat. \tag{3.12}$$

Following Propositions 2.4 and 2.5, the unique strong solution $(v^0, w_1^0, w_2^0, \ldots, w_l^0) \in \mathbf{X}$ to (3.11)–(3.12) satisfies

$$\|v^0\|_{X_1}^2 \le \alpha_1^2, \quad \sup_j \|w_j^0\|_{X_2}^2 \le \alpha_2^2, \quad \sup_j |w_j^0(t)|_{L^2}^2 \le \delta^2\alpha_2^2, \tag{3.13}$$

where

$$
\begin{aligned}
&\alpha_1^2 \equiv c\left(\|\bar{a}\|^2 + \int_0^T |\bar{F}|_{L^2}^2 ds\right) \le c\delta^{1/2} R_0^2(\delta),\\
&\alpha_2^2 \equiv c\left(\|a^\flat\|^2 + \int_0^T |F^\flat|_{L^2}^2 ds\right) \le c\delta^{1/4} R_0^2(\delta),\ \alpha_0^2 = \alpha_1^2 + \alpha_2^2.
\end{aligned} \tag{3.14}
$$

Note that from (2.19)–(2.20), α_1^2 goes to zero as δ goes to zero.

3.1.2. Nonlinear problems. Now let us set $\vartheta = v - v^0$, $\eta_j = w_j - w_j^0$. Then ϑ and η_j satisfy

$$
\begin{aligned}
&\frac{d}{dt}(\vartheta, \bar{\theta}) + a(\vartheta, \bar{\theta}) + e(\vartheta, \bar{\theta}) + b(\vartheta, v^0, \bar{\theta}) + b(v^0, \vartheta, \bar{\theta}) + b(\vartheta, \vartheta, \bar{\theta}) + (S_1, \bar{\theta})\\
&\qquad = 0\ \forall \theta \in V,\ \vartheta(0) = 0,
\end{aligned} \tag{3.15}
$$

$$
\frac{d}{dt}(\eta_j, \theta^\flat) + a(\eta_j, \theta^\flat) + e(\eta_j, \theta^\flat) + (S_2, \theta^\flat) = 0\ \forall \theta \in V,\ \eta_j(0) = 0, \tag{3.16}
$$

where

$$
\begin{aligned}
&S_1 = B(v^0, v^0) + B(\eta_l + w_l^0, \eta_l + w_l^0),\\
&S_2 = B(\vartheta + v^0, \eta_j + w_j^0) + B(\eta_j + w_j^0, \vartheta + v^0) + B(\eta_{j-1} + w_{j-1}^0, \eta_j + w_j^0)\\
&\qquad + B(\eta_j + w_j^0, \eta_{j-1} + w_{j-1}^0) - B(\eta_{j-1} + w_{j-1}^0, \eta_{j-1} + w_{j-1}^0) + \Lambda(\vartheta + \eta_j).
\end{aligned} \tag{3.17}
$$

To solve (3.15)–(3.16), we consider the following iterative process:

$$
\begin{aligned}
&\frac{d}{dt}(\vartheta^{n+1}, \bar{\theta}) + a(\vartheta^{n+1}, \bar{\theta}) + e(\vartheta^{n+1}, \bar{\theta}) + b(\vartheta^{n+1}, v^0, \bar{\theta}) + b(v^0, \vartheta^{n+1}, \bar{\theta})\\
&\qquad + b(\vartheta^{n+1}, \vartheta^{n+1}, \bar{\theta}) + (S_1^n, \bar{\theta}) = 0\ \forall \theta \in V,\ \vartheta^{n+1}(0) = 0,
\end{aligned} \tag{3.18}
$$

$$
\frac{d}{dt}(\eta_j^{n+1}, \theta^\flat) + a(\eta_j^{n+1}, \theta^\flat) + e(\eta_j^{n+1}, \theta^\flat) + (S_2^n, \theta^\flat) = 0\ \forall \theta \in V,\ \eta_j^{n+1}(0) = 0, \tag{3.19}
$$

where

$$
\begin{aligned}
&S_1^n = B(v^0, v^0) + B(\eta_l^n + w_l^0, \eta_l^n + w_l^0),\\
&S_2^n = B(\vartheta^n + v^0, \eta_j^n + w_j^0) + B(\eta_j^n + w_j^0, \vartheta^n + v^0) + B(\eta_{j-1}^n + w_{j-1}^0, \eta_j^n + w_j^0)\\
&\qquad + B(\eta_j^n + w_j^0, \eta_{j-1}^n + w_{j-1}^0) - B(\eta_{j-1}^n + w_{j-1}^0, \eta_{j-1}^n + w_{j-1}^0) + \Lambda(\vartheta^n + \eta_j^n)
\end{aligned} \tag{3.20}
$$

for $(v^0, \eta_1^0, \eta_2^0, \dots, \eta_l^0) \in \mathbf{X}$ such that

$$
\|\vartheta^0\|_{X_1}^2 + \sup_j \|\eta_j^0\|_{X_2}^2 \le R^2, \qquad \sup_j |\eta_j^0(t)|_{L^2}^2 \le \delta^2 R^2, \tag{3.21}
$$

where $R = R(a, g, T, R_{e_1}, R_{e_2}) > 0$ is given by (3.34).

The goal is to prove (using a fixed-point argument) that the sequence (ϑ^n, η_j^n) is convergent for δ small enough.

PROPOSITION 3.1. *Let $k \in (0, 1/2)$. We assume that*

$$\|\vartheta^n\|_{X_1}^2 + \sup_j \|\eta_j^n\|_{X_2}^2 \leq R^2, \tag{3.22}$$

where R will be made precise later. Then the following estimates hold true for S_1^n and S_2^n:

(3.23)
$$\int_0^T (|S_1^n|_{L^2}^2 + |S_2^n|_{L^2}^2)dt \leq c_2\delta^{2k}(R^2(\|\vartheta^n\|_{X_1}^2 + \sup_j \|\eta_j^n\|_{X_2}^2) + R^4 + \alpha_0^4 + R^2) + c_0\alpha_1^4.$$

Proof. The proof follows from the inequalities (see (2.26)–(2.27))

$$|S_1^n|_{L^2}^2 \leq c_0|v^0|_{L^2}|Av^0|_{L^2}\|v^0\|^2 + c_1\delta\|\eta_l^n + w_l^0\|^2|A(\eta_l^n + w_l^0)|_{L^2}^2, \tag{3.24}$$

which gives

$$\begin{aligned}\int_0^T |S_1^n|_{L^2}^2 dt &\leq c_0\alpha_1^4 + c_1\delta \sup_s \|\eta_l^n(s) + w_l^0(s)\|^2 \int_0^T |A(\eta_l^n + w_l^0)|_{L^2}^2 ds \\ &\leq c_0\alpha_1^4 + c_1\delta(R^2 \sup_j \|\eta_j^n\|_{X_2}^2 + \alpha_0^4 + R^4).\end{aligned} \tag{3.25}$$

We also have

(3.26)
$$\begin{aligned}|S_2^n|_{L^2}^2 \leq{}& c_1\delta^{2k}\|\vartheta^n + v^0\|^2|A(\eta_j^n + w_j^0)|_{L^2}^2 + c_1\delta\|\vartheta^n + v^0\|^2|A(\eta_j^n + w_j^0)|_{L^2}^2 \\ &+ c_1\delta\|\eta_j^n + w_j^0\|^2|A(\eta_{j-1}^n + w_{j-1}^0)|_{L^2}^2 + c_1\delta\|\eta_{j-1}^n + w_{j-1}^0\|^2|A(\eta_j^n + w_j^0)|_{L^2}^2 \\ &+ c_1\delta\|\eta_{j-1}^n + w_{j-1}^0\|^2|A(\eta_{j-1}^n + w_{j-1}^0)|_{L^2}^2 + c_1\delta^2\|\eta_j^n + \vartheta^n\|^2,\end{aligned}$$

which gives

$$\begin{aligned}\int_0^T |S_2^n|_{L^2}^2 dt \leq{}& c_1\delta^{2k} \sup_s \|\vartheta^n(s) + v^0(s)\|^2 \int_0^T |A(\eta_j^n + w_j^0)|_{L^2}^2 ds \\ &+ c_1\delta \sup_s \|\vartheta^n + v^0\|^2 + c_1\delta \sup_s \|\eta_j^n + w_j^0\|^2 \int_0^T |A(\eta_{j-1}^n + w_{j-1}^0)|_{L^2}^2 ds \\ &+ c_1\delta \sup_s \|\eta_{j-1}^n + w_{j-1}^0\|^2 \int_0^T |A(\eta_j^n + w_j^0)|_{L^2}^2 ds \\ &+ c_1\delta \sup_s \|\eta_{j-1}^n + w_{j-1}^0\|^2 \int_0^T |A(\eta_{j-1}^n + w_{j-1}^0)|_{L^2}^2 ds + c_1\delta^2 R^2\end{aligned} \tag{3.27}$$

and

$$\int_0^T |S_2^n|_{L^2}^2 dt \leq c_1\delta^{2k}(R^2(\|\vartheta^n\|^2 + \sup_j \|\eta_j^n\|^2) + \alpha_0^4 + R^4) + c_1\delta^2 R^2. \tag{3.28}$$

Therefore (3.23) follows from (3.25) and (3.28). ∎

PROPOSITION 3.2. *Let $k \in (1/4, 1/2)$. We assume that* (3.22) *holds true.* Then for δ small enough, we have

$$\|\vartheta^{n+1}\|^2_{X_1} + \sup_j \|\eta_j^{n+1}\|^2_{X_2} \le R^2, \qquad \sup_j |\eta_j^{n+1}(t)|^2_{L^2} \le \delta^2 R^2. \tag{3.29}$$

Proof. It clearly follows from Proposition 2.4 and the estimate (3.25) that

$$\begin{aligned}
&|\vartheta^{n+1}(t)|^2_{L^2} \le c_2 e^{N_0(T)}(\delta R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \delta\alpha_0^4 + \delta R^4 + \alpha_1^4),\\
&\|\vartheta^{n+1}(t)\|^2_{X_1} \le c_2 e^{N_1(T)}(\delta R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \delta\alpha_0^4 + \delta R^4 + \alpha_1^4),\\
&\int_0^T |A\vartheta^{n+1}|^2_{L^2} dt \le c_2 e^{N_1(T)}(\delta R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \delta\alpha_0^4 + \delta R^4 + \alpha_1^4),\\
&\int_0^T \left|\frac{d\vartheta^{n+1}}{dt}\right|^2_{L^2} dt \le c_2 e^{N_1(T)}(\delta R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \delta\alpha_0^4 + \delta R^4 + \alpha_1^4).
\end{aligned} \tag{3.30}$$

The exact form of $N_0(T)$ and $N_1(T)$ can be obtained, respectively, from (2.35) by replacing $\bar{U}$ by v^0; i.e., $N_0(T) = N_0(T, \alpha_1)$ and $N_1(T) = N_1(T, \alpha_1)$.

It also follows from Proposition 2.5 and the estimate (3.28) that

$$\begin{aligned}
&\sup_j |\eta_j^{n+1}(t)|^2_{L^2} \le c_1\delta^{2k}(R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \alpha_0^4 + R^4) + c_1\delta^2 R^2,\\
&\sup_j \|\eta_j^{n+1}(t)\|^2 \le c_1\delta^{2k}(R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \alpha_0^4 + R^4) + c_1\delta^2 R^2,\\
&\sup_j \int_0^T |A\eta_j^{n+1}|^2_{L^2} dt \le c_1\delta^{2k}(R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \alpha_0^4 + R^4) + c_1\delta^2 R^2,\\
&\sup_j \int_0^T \left|\frac{d\eta_j^{n+1}}{dt}\right|^2_{L^2} dt \le c_1\delta^{2k}(R^2(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + \alpha_0^4 + R^4) + c_1\delta^2 R^2.
\end{aligned} \tag{3.31}$$

From (3.30) and (3.31) we can write

$$\|\vartheta^{n+1}\|^2_{X_1} + \sup_j \|\eta_j^{n+1}\|^2_{X_2} \le \epsilon(\|\vartheta^n\|^2_{X_1} + \sup_j \|\eta_j^n\|^2_{X_2}) + L_0, \tag{3.32}$$

where

$$\epsilon = c_2\delta^{2k}R^2, \qquad L_0 = c_2\delta^{2k}(\alpha_0^4 + R^4) + c_2\delta^2 R^2 + c_0\alpha_1^4. \tag{3.33}$$

Let

$$R^2 = 8c_2\alpha_0^4, \tag{3.34}$$

where c_2 is the constant that appears in (3.33). Note that from (2.19) and (3.14), R does not go to zero as δ goes to zero.

Now we choose δ small enough such that

$$L_0 \le R^2/4, \qquad \epsilon \le \frac{1}{2}. \tag{3.35}$$

This is possible since from (2.19)–(2.20) and (3.14), all the quantities $\delta^2 R^2$, α_1^4, $\delta^{2k} R^2$, and

$$\frac{\delta^{2k}(\alpha_0^4 + R^4)}{R^2} = c_2 \delta^{2k}(1 + \alpha_0^4) \tag{3.36}$$

go to zero as δ goes to zero for $k \in (1/4, 1/2)$.

Therefore, using inequality (3.32) successively, we get

$$\begin{aligned} \|\vartheta^{n+1}\|_{X_1}^2 + \sup_j \|\eta_j^{n+1}\|_{X_2}^2 &\le \epsilon^n (\|\vartheta^0\|_{X_1}^2 + \sup_j \|\eta_j^0\|_{X_2}^2) + \frac{1-\epsilon^n}{1-\epsilon} L_0, \\ &\le R^2/2 + 2L_0 \le R^2, \end{aligned} \tag{3.37}$$

and $(3.29)_1$ follows. Note that $(3.29)_2$ follows from $(3.29)_1$ and (2.25). □

PROPOSITION 3.3. *Let $k \in (1/4, 1/2)$. Let R be given by* (3.34). *We assume that δ is small enough so that* (3.35) *is satisfied. Let $(\vartheta^0, \eta_1^0, \dots, \eta_l^0) \in \mathbf{X}$ such that* (3.21) *is satisfied. Then the sequence $(\vartheta^n, \eta_1^n, \eta_2^n, \dots, \eta_l^n) \in \mathbf{X}$ given by* (3.18)–(3.19) *satisfies the estimates*

$$\|\vartheta^n\|_{X_1}^2 + \sup_j \|\eta_j^n\|_{X_2}^2 \le R^2, \qquad \sup_j |\eta_j^n(t)|_{L^2}^2 \le \delta^2 R^2. \tag{3.38}$$

Proof. The proof follows by induction from (3.21) and Proposition 3.2. □

Now, let us set $\theta^{n+1} = \vartheta^{n+1} - \vartheta^n$, $q_j^{n+1} = \eta_j^{n+1} - \eta_j^n$. Then $(\theta^{n+1}, q_j^{n+1})$ satisfy

$$\begin{aligned} &\frac{d}{dt}(\theta^{n+1}, \bar\zeta) + a(\theta^{n+1}, \bar\zeta) + e(\theta^{n+1}, \bar\zeta) + b(\theta^{n+1}, \vartheta^{n+1} + v^0, \bar\zeta) \\ &+ b(\vartheta^n + v^0, \theta^{n+1}, \bar\zeta) + (K_1^n, \bar\zeta) = 0 \ \forall \zeta \in V, \ \theta^{n+1}(0) = 0, \end{aligned} \tag{3.39}$$

$$\frac{d}{dt}(q_j^{n+1}, \zeta^\flat) + a(q_j^{n+1}, \zeta^\flat) + e(q_j^{n+1}, \zeta^\flat) + (K_2^n, \zeta^\flat) = 0 \ \forall \zeta \in V, \quad q_j^{n+1}(0) = 0, \tag{3.40}$$

where

$$K_n^1 = B(q_l^n, \eta_l^{n-1} + w_l^0) + B(\eta_l^n + w_l^0, q_l^n) \tag{3.41}$$

and

$$\begin{aligned} K_n^2 &= B(\theta^n, \eta_j^n + w_j^0) + B(q_j^n, \vartheta^n + v^0) + B(q_j^n, \eta_j^n + w_j^0) \\ &\quad + B(\vartheta^{n-1} + v^0, q_j^n) + B(\eta_j^{n-1} + w_j^0, \theta^n) + B(\eta_j^{n-1} + w_j^0, q_j^n) + \Lambda(\theta^n + q_j^n). \end{aligned} \tag{3.42}$$

PROPOSITION 3.4. *Let $k \in (1/4, 1/2)$. We assume that δ is small enough so that* (3.35) *holds. Then the following estimate holds:*

$$\int_0^T (|K_n^1|_{L^2}^2 + |K_n^2|_{L^2}^2) dt \le c_3 \delta^{2k} (\|\theta^n\|_{X_1}^2 + \sup_j \|q_j^n\|_{X_2}^2). \tag{3.43}$$

Proof. The proof follows from the following estimates:

$$|K_n^1|_{L^2}^2 \le c_1 \delta \|\eta_l^n + w_l^0\|^2 |A q_l^n|_{L^2}^2 + c_1 \delta \|q_l^n\|^2 |A(\eta_l^n + w_l^0)|_{L^2}^2 \tag{3.44}$$

and

$$\begin{aligned}\int_0^T |K_n^1|_{L^2}^2 dt &\le c_1\delta \sup_s \|\eta_l^n(s)+w_l^0(s)\|^2 \int_0^T |Aq_l^n|_{L^2}^2 ds \\ &\quad + c_1\delta \sup_s \|q_l^n(s)\|^2 \int_0^T |A(\eta_l^n+w_l^0)|_{L^2}^2 ds \\ &\le c_3\delta \sup_j \|q_j^n\|_{X_2}^2.\end{aligned} \tag{3.45}$$

We also have

$$\begin{aligned}|K_n^2|_{L^2}^2 &\le c_1\delta^{2k}\|\theta^n\|^2|A(\eta_j^n+w_j^0)|_{L^2}^2 + c_1\delta\|\vartheta^n+v^0\|^2|Aq_j^n|_{L^2}^2 \\ &\quad + c_1\delta\|\eta_j^n+w_j^0\|^2|Aq_j^n|_{L^2}^2 + c_1\delta^{2k}\|\vartheta^{n-1}+v^0\|^2|Aq_j^n|_{L^2}^2 \\ &\quad + c_1\delta\|\theta^n\|^2|A(\eta_j^{n-1}+w_j^0)|_{L^2}^2 \\ &\quad + c_1\delta\|q_j^n\|^2|A(\eta_j^{n-1}+w_j^0)|_{L^2}^2 + c_1\delta^2|A(\theta^n+q_j^n)|_{L^2}^2\end{aligned} \tag{3.46}$$

and

$$\begin{aligned}\int_0^T |K_n^2|_{L^2}^2 dt &\le c_1\delta^{2k}\sup_s \|\theta^n(s)\|^2 \int_0^T |A(\eta_j^n+w_j^0)|_{L^2}^2 ds + c_1\delta \sup_s \|\vartheta^n(s) \\ &\quad + v^0(s)\|^2 \int_0^T |Aq_j^n|_{L^2}^2 dt + c_1\delta \sup_s \|\eta_j^n(s)+w_j^0(s)\|^2 \int_0^T |Aq_j^n|_{L^2}^2 dt \\ &\quad + c_1\delta^{2k}\sup_s \|\vartheta^{n-1}(s)+v^0(s)\|^2 \int_0^T |Aq_j^n|_{L^2}^2 dt \\ &\quad + c_1\delta \sup_s \|\theta^n(s)\|^2 \int_0^T |A(\eta_j^{n-1}+w_j^0)|_{L^2}^2 dt \\ &\quad + c_1\delta \sup_s \|q_j^n(s)\|^2 \int_0^T |A(\eta_j^{n-1}+w_j^0)|_{L^2}^2 dt \\ &\quad + c_1\delta^2 \int_0^T |A(\theta^n+q_j^n)|_{L^2}^2 dt \le c_3\delta^{2k}(\|\theta^n\|_{X_1}^2 + \sup_j \|q_j^n\|_{X_2}^2).\end{aligned} \tag{3.47}$$

Finally (3.43) follows from (3.45) and (3.47). ∎

Note that from the previous estimates, c_3 has the form

$$c_3 = c(\alpha_2^2 + R^2). \tag{3.48}$$

It follows from (2.20) and (3.14) that $\delta^{2k}c_3$ goes to zero as δ goes to zero. Hereafter, we choose δ small enough such that

$$\delta_1 = \delta^{2k}c_3 < 1. \tag{3.49}$$

PROPOSITION 3.5. *Let $k \in (1/4, 1/2)$. We assume that δ is small enough so that* (3.35), (3.49) *hold. Then the following estimate holds:*

$$\|\theta^{n+1}\|_{X_1}^2 + \sup_j \|q_j^{n+1}\|_{X_2}^2 \le c_3\delta^{2k}\left(\|\theta^n\|_{X_1}^2 + \sup_j \|q_j^n\|_{X_2}^2\right). \tag{3.50}$$

Proof. The proof, which is similar to those of Propositions 2.4 and 2.5, follows from (3.43). Moreover, the following result is proved.

PROPOSITION 3.6. *Let $k \in (1/4, 1/2)$. We assume that δ is small enough so that* (3.35) *and* (3.49) *are satisfied. Then the sequence $(\vartheta^n, \eta_1^n, \eta_2^n, \dots, \eta_l^n) \in \mathbf{X}$ defined by* (3.18), (3.19) *converges to a solution $(\vartheta, \eta_1, \eta_2, \dots, \eta_l)$ to* (3.18)–(3.19) *in* $\mathbf{X}$. *Moreover, $(\vartheta, \eta_1, \eta_2, \dots, \eta_l)$ is the unique solution to* (3.15)–(3.16) *in* $\mathbf{X}$ *that satisfies*

$$\|\vartheta^n - \vartheta\|_{X_1}^2 + \sup_j \|\eta_j^n - \eta_j\|_{X_2}^2 \le R^2.$$

Furthermore the following convergence rate holds true:

$$\|\vartheta^n - \vartheta\|_{X_1}^2 + \sup_j \|\eta_j^n - \eta_j\|_{X_2}^2 \le \frac{\delta_1^n}{1-\delta_1}, \tag{3.51}$$

where $\delta_1 < 1$ is given by (3.49).

4. Convergence of the method. In this part, we study the convergence of the small eddy correction method presented in the previous section. We prove that the method converges, and we estimate the rate of convergence with respect to the aspect ratio δ.

Hereafter, we set $u_l = v + w_l$, $\zeta = u - u_l$, $\varepsilon_j = w_j - w_{j-1}$. In particular, $\varepsilon_1 = w_1$.

Using (2.18) and (3.5)–(3.6), it is clear that u_l and ζ satisfy (see [13])

$$\begin{aligned}\frac{d}{dt}(u_l,\theta) + a(u_l,\theta) + e(u_l,\theta) + \gamma(u_l,\theta) + b(u_l,u_l,\theta) - (NB(\varepsilon_l,\varepsilon_l),\theta)\\ = (F,\theta)\ \forall\theta\in V,\ u_l(0) = a,\end{aligned} \tag{4.1}$$

$$\begin{aligned}\frac{d}{dt}(\zeta,\theta) + a(\zeta,\theta) + e(\zeta,\theta) + \gamma(\zeta,\theta) + b(\zeta,u,\theta) + b(u_l,\zeta,\theta)\\ + (NB(\varepsilon_l,\varepsilon_l),\theta) = 0\ \forall\theta\in V,\ \zeta(0) = 0.\end{aligned} \tag{4.2}$$

Taking the vertical average of (4.2), we derive that the barotropic and baroclinic flows $\bar\zeta$ and $\zeta^\flat$ satisfy

$$\begin{aligned}\frac{d}{dt}(\bar\zeta,\bar\theta) + a(\bar\zeta,\bar\theta) + e(\bar\zeta,\bar\theta) + b(\bar\zeta,\bar u,\bar\theta) + b(v,\bar\zeta,\bar\theta) + b(\zeta^\flat,u^\flat,\bar\theta)\\ + b(w_l,\zeta^\flat,\bar\theta) = 0\ \forall\theta\in V,\ \bar\zeta(0) = 0,\end{aligned} \tag{4.3}$$

$$\begin{aligned}&\frac{d}{dt}(\zeta^\flat,\theta^\flat) + a(\zeta^\flat,\theta^\flat) + e(\zeta^\flat,\theta^\flat) + \gamma(\bar\zeta+\zeta^\flat,\theta^\flat) + b(\bar\zeta,u^\flat,\theta^\flat) + b(\zeta^\flat,\bar u,\theta^\flat)\\ &\quad + b(v,\zeta^\flat,\theta^\flat) + b(w_l,\bar\zeta,\theta^\flat) + b(\zeta^\flat,u^\flat,\theta^\flat)\\ &\quad + b(w_l,\zeta^\flat,\theta^\flat) + b(\varepsilon_l,\varepsilon_l,\theta^\flat) = 0\ \forall\theta\in V,\ \zeta^\flat(0) = 0.\end{aligned} \tag{4.4}$$

Note that

$$|b(\bar\zeta,\bar u,A\bar\zeta)| \le c_0|\bar\zeta|_{L^2}^{1/2}\|\bar u\||A\bar\zeta|_{L^2}^{3/2} \le \frac{1}{8}|A\bar\zeta|_{L^2}^2 + c_0|\bar\zeta|_{L^2}^2\|\bar u\|^4, \tag{4.5}$$

$$|b(\zeta^\flat, u^\flat, A\bar{\zeta})| \le c_1\delta^{1/2}\|u^\flat\||A\zeta^\flat|_{L^2}|A\bar{\zeta}|_{L^2} \le \frac{1}{8}|A\bar{\zeta}|_{L^2}^2 + c_1\delta\|u^\flat\|^2|A\zeta^\flat|_{L^2}^2, \tag{4.6}$$

$$|b(w_l, \zeta^\flat, A\bar{\zeta})| \le c_1\delta^{1/2}\|\zeta^\flat\||Aw_l|_{L^2}|A\bar{\zeta}|_{L^2} \le \frac{1}{8}|A\bar{\zeta}|_{L^2}^2 + c_1\delta\|\zeta^\flat\|^2|Aw_l|_{L^2}^2, \tag{4.7}$$

$$|e(\bar{\zeta}, A\bar{\zeta})| \le c_0\|\bar{\zeta}\||A\bar{\zeta}|_{L^2} \le \frac{1}{8}|A\bar{\zeta}|_{L^2}^2 + c_0\|\bar{\zeta}\|^2. \tag{4.8}$$

We also have

$$|b(\bar{\zeta}, u^\flat, A\zeta^\flat)| \le c_1\delta^k\|\bar{\zeta}\||Au^\flat|_{L^2}|A\zeta^\flat|_{L^2} \le \frac{1}{8}|A\zeta^\flat|_{L^2}^2 + c_1\delta^{2k}\|\bar{\zeta}\|^2|Au^\flat|_{L^2}^2, \tag{4.9}$$

$$|b(\zeta^\flat, \bar{u}, A\zeta^\flat)| \le c_1\delta^{1/2}\|\bar{u}\||A\zeta^\flat|_{L^2}^2, \tag{4.10}$$

$$|b(v, \zeta^\flat, A\zeta^\flat)| \le c_1\delta^k\|v\||A\zeta^\flat|_{L^2}^2, \tag{4.11}$$

$$|b(w_l, \bar{\zeta}, A\zeta^\flat)| \le c_1\delta^{1/2}\|\bar{\zeta}\||Aw_l|_{L^2}|A\zeta^\flat|_{L^2} \le \frac{1}{8}|A\zeta^\flat|_{L^2}^2 + c_1\delta|Aw_l|_{L^2}^2\|\bar{\zeta}\|^2, \tag{4.12}$$

$$|b(\zeta^\flat, u^\flat, A\zeta^\flat)| \le c_1\delta^{1/2}\|u^\flat\||A\zeta^\flat|_{L^2}^2, \tag{4.13}$$

$$|b(w_l, \zeta^\flat, A\zeta^\flat)| \le c_1\delta^{1/2}\|\zeta^\flat\||Aw_l|_{L^2}|A\zeta^\flat|_{L^2} \le \frac{1}{8}|A\zeta^\flat|_{L^2}^2 + c_1\delta|Aw_l|_{L^2}^2\|\zeta^\flat\|^2, \tag{4.14}$$

$$|b(\varepsilon_l, \varepsilon_l, A\zeta^\flat)| \le c_1\delta^{1/2}\|\varepsilon_l\||A\varepsilon_l|_{L^2}|A\zeta^\flat|_{L^2} \le \frac{1}{8}|A\zeta^\flat|_{L^2}^2 + c_1\delta|A\varepsilon_l|_{L^2}^2\|\varepsilon_l\|^2, \tag{4.15}$$

$$|e(\zeta^\flat, A\zeta^\flat)| \le c_1\delta|A\zeta^\flat|_{L^2}^2, \tag{4.16}$$

$$|\gamma(\bar{\zeta} + \zeta^\flat, A\zeta^\flat)| \le c\delta|A(\bar{\zeta} + \zeta^\flat)|_{L^2}|A\zeta^\flat|_{L^2} \le c\delta(|A\bar{\zeta}|_{L^2}^2 + |A\zeta^\flat|_{L^2}^2). \tag{4.17}$$

Let

$$\beta_1 = 1 - c_1\delta\|u^\flat\|^2 - c_1\delta^{2k}\|\bar{\zeta}\|^2 - c_1\delta^{1/2}\|\bar{u}\| - c_1\delta^k\|v\| - c_1\delta^{1/2}\|u^\flat\| - c_1\delta - c\delta. \tag{4.18}$$

We choose $k \in (1/4, 1/2)$ and δ small enough such that

$$\beta_1 > \frac{1}{2}. \tag{4.19}$$

This choice is possible since

$$\begin{aligned}
&\|\bar{u}\|^2 \le 2\sigma(\delta R_0^2(\delta) + \sigma R_0^2(\delta)),\\
&\|v\|^2 \le 2(R^2 + \alpha_1^2),\\
&\|\bar{\zeta}\|^2 \le 2\|\bar{u}\|^2 + 2\|v\|^2 \le 4(R^2 + \alpha_1^2 + \sigma\delta R_0^2(\delta) + \sigma R_0^2(\delta)),\\
&\|u^\flat\|^2 \le \sigma\delta^{1/4}R_0^2(\delta),
\end{aligned} \tag{4.20}$$

and (2.19)–(2.20) are satisfied.

Therefore, multiplying (4.3) by $A\bar{\zeta}$, (4.4) by $A\zeta^\flat$, and using (4.5)–(4.19) yield

$$\begin{aligned}&\frac{d}{dt}(\|\bar{\zeta}\|^2+\|\zeta^\flat\|^2)+\frac{1}{2}(|A\bar{\zeta}|_{L^2}^2+|A\zeta^\flat|_{L^2}^2)\\&\quad\le c_1\delta^{2k}\|\bar{\zeta}\|^2|Au^\flat|_{L^2}^2+c_0\|\bar{\zeta}\|^2+c_0\|\bar{\zeta}\|^2\|\bar{u}\|^4\\&\qquad+c_1\delta(\|\zeta^\flat\|^2|Aw_l|_{L^2}^2+\|\bar{\zeta}\|^2|Au^\flat|_{L^2}^2+\|\varepsilon_l\|^2|A\varepsilon_l|_{L^2}^2+|Aw_l|_{L^2}^2\|\bar{\zeta}\|^2),\end{aligned}\tag{4.21}$$

which gives

$$\|\bar{\zeta}(t)\|^2+\|\zeta^\flat(t)\|^2+\frac{1}{2}\int_0^t(|A\bar{\zeta}|_{L^2}^2+|A\zeta^\flat|_{L^2}^2)ds\le c_1\delta\sup_s\|\varepsilon_l(s)\|^2\int_0^t|A\varepsilon_l|_{L^2}^2ds.\tag{4.22}$$

The next step is to derive some a priori estimates on ε_k.

Note that ε_j satisfies (for $2\le j\le l$)

$$\begin{aligned}&\frac{d}{dt}(\varepsilon_j,\theta^\flat)+a(\varepsilon_j,\theta^\flat)+e(\varepsilon_j,\theta^\flat)+\gamma(\varepsilon_j,\theta^\flat)+b(v,\varepsilon_j,\theta^\flat)+b(\varepsilon_j,v,\theta^\flat)\\&+b(w_{j-1},\varepsilon_j,\theta^\flat)+b(\varepsilon_j,w_{j-1},\theta^\flat)+b(\varepsilon_{j-1},\varepsilon_{j-1},\theta^\flat)=0\ \forall\theta\in V,\ \varepsilon_j(0)=0.\end{aligned}\tag{4.23}$$

We have

$$|b(v,\varepsilon_j,A\varepsilon_j)|\le c_1\delta^k\|v\||A\varepsilon_j|_{L^2}^2.\tag{4.24}$$

$$|b(\varepsilon_j,v,A\varepsilon_j)|\le c_1\delta^{1/2}\|v\||A\varepsilon_j|_{L^2}^2.\tag{4.25}$$

$$\begin{aligned}|b(w_{j-1},\varepsilon_j,A\varepsilon_j)|&\le c_1\delta^{1/2}\|\varepsilon_j\||Aw_{j-1}|_{L^2}|A\varepsilon_j|_{L^2}\\&\le\frac{1}{8}|A\varepsilon_j|_{L^2}^2+c_1\delta\|\varepsilon_j\|^2|Aw_{j-1}|_{L^2}^2,\end{aligned}\tag{4.26}$$

$$|b(\varepsilon_j,w_{j-1},A\varepsilon_j)|\le c_1\delta^{1/2}\|w_{j-1}\||A\varepsilon_j|_{L^2}^2,\tag{4.27}$$

$$\begin{aligned}|b(\varepsilon_{j-1},\varepsilon_{j-1},A\varepsilon_j)|&\le c_1\delta^{1/2}\|\varepsilon_{j-1}\||A\varepsilon_{j-1}|_{L^2}|A\varepsilon_j|_{L^2}\\&\le\frac{1}{8}|A\varepsilon_j|_{L^2}^2+c_1\delta\|\varepsilon_{j-1}\|^2|A\varepsilon_{j-1}|_{L^2}^2.\end{aligned}\tag{4.28}$$

Let

$$\beta_2=1-c_1\delta^{1/2}\|v\|-c_1\delta^k\|v\|.\tag{4.29}$$

We choose δ small enough such that

$$\beta_2>\frac{1}{2}.\tag{4.30}$$

This choice is possible since $\|v\|^2\le 2R^2+2\alpha_1^2$, which shows that $\delta^k\|v\|$ and $\delta^{1/2}\|v\|$ go to zero as δ goes to zero for $k\in(1/4,1/2)$.

Therefore, multiplying (4.23) by $A\varepsilon_j$ and using (4.25)–(4.28) yield

$$\|\varepsilon_j(t)\|^2 + \int_0^t |A\varepsilon_j|_{L^2}^2 ds \le c_1\delta \sup_s \|\varepsilon_{j-1}(s)\|^2 \int_0^t |A\varepsilon_{j-1}|_{L^2}^2 ds. \tag{4.31}$$

Therefore

$$\sup_s \|\varepsilon_j(s)\|^2 \int_0^T |A\varepsilon_j|_{L^2}^2 ds \le c_1\delta^2 \left(\sup_s \|\varepsilon_{j-1}(s)\|^2\right)^2 \left(\int_0^T |A\varepsilon_{j-1}|_{L^2}^2 ds\right)^2. \tag{4.32}$$

THEOREM 4.1. *We assume that the data satisfy* (2.20). *Then for δ small enough, the error $\zeta(t) = u(t) - u_l(t)$ satisfies*

$$\|\bar{\zeta}(t)\|^2 + \|\zeta^\flat(t)\|^2 + \int_0^t (|A\bar{\zeta}(s)|_{L^2}^2 + |A\zeta^\flat(s)|_{L^2}^2) ds \le c_4(\delta^{1/2})^{2^{l-1}}, \tag{4.33}$$

where c_4 is a constant that is independent of δ for δ small enough.

Proof. Let us set

$$\begin{aligned} E(t) &= \|\bar{\zeta}(t)\|^2 + \|\zeta^\flat(t)\|^2 + \int_0^t (|A\bar{\zeta}(s)|_{L^2}^2 + |A\zeta^\flat(s)|_{L^2}^2) ds, \\ x_j &= \sup_s \|\varepsilon_j(s)\|^2 \int_0^T |A\varepsilon_j|_{L^2}^2 ds. \end{aligned} \tag{4.34}$$

It follows from (4.22) and (4.31) that

$$E(t) \le c\delta x_l, \quad x_j \le c\delta^2 x_{j-1}^2 = \delta_2^2 x_{j-1}^2, \quad \delta_2 = \sqrt{c}\delta. \tag{4.35}$$

By iteration we derive that

$$x_j \le \delta_2^{(2^{j-1}-1)2} x_1^{2^{j-1}}. \tag{4.36}$$

Let us now estimate $\varepsilon_1 = w_1$ and x_1. Note that (see (2.26))

$$\begin{aligned} |e(w_1, Aw_1)| &\le c\delta^2 |Aw_1|_{L^2}^2, \\ |\gamma(v + w_1, Aw_1)| &\le c_1\delta |A(v + w_1)|_{L^2} |Aw_1|_{L^2} \\ &\le \frac{1}{4}|Aw_1|_{L^2}^2 + c_1\delta^2 |Av|_{L^2}^2 + c_1\delta |Aw_1|_{L^2}^2, \\ |b(v, w_1, Aw_1)| &\le c_1\delta^k \|v\| |Aw_1|_{L^2}^2, \\ |b(w_1, v, Aw_1)| &\le c_1\delta^{1/2} \|v\| |Aw_1|_{L^2}^2. \end{aligned} \tag{4.37}$$

Let us set

$$\beta_3 = 1 - c_1\delta^2 - c_1\delta - c_1\delta^k \|v\| - c_1\delta^{1/2} \|v\|. \tag{4.38}$$

Now we assume that δ is small enough (using an argument similar to that of β_2) such that

$$\beta_3 > \frac{1}{4}. \tag{4.39}$$

Then using (3.9) and (4.37)–(4.39) we derive that

$$\frac{d}{dt}\|w_1\|^2 + |Aw_1|_{L^2}^2 \leq c_1\delta^2|Av|_{L^2}^2 + c_1|F^\flat|_{L^2}^2, \tag{4.40}$$

which gives

$$\begin{aligned}\|w_1(t)\|^2 + \int_0^t |Aw_1|_{L^2}^2 &\leq \|a^\flat\|^2 + c\delta^2\int_0^t |Av|_{L^2}^2 ds + c_1\int_0^t |F^\flat|_{L^2}^2 ds \\ &\leq c_1(\delta^{1/4}R_0^2(\delta) + \delta^2R^2 + \delta^2\alpha_1^2)\end{aligned} \tag{4.41}$$

and

$$x_1 \leq c(\delta^{1/4}R_0^2(\delta) + \delta^2R^2 + \delta^2\alpha_1^2)^2. \tag{4.42}$$

From (2.19)–(2.20), it is clear that $\sqrt{c}\delta^{1/2}x_1$ goes to zero as δ goes to zero, where c is the constant that appears in (4.22). Finally from (4.35)–(4.36), we have

$$E(t) \leq c_4(\delta^{1/2})^{2^{l-1}}, \tag{4.43}$$

where $c_4 > 0$ is a constant independent of δ for δ small enough.

5. Numerical results. In this section, we present some numerical simulations obtained with the models (2.18) and (3.5)–(3.6). The goal is to compare the solution obtained with (2.18) to that of the small eddy correction method. Hereafter we restrict ourselves to $l = 1$, and (3.8)–(3.9) will be referred to hereafter as the reduced model. More simulations for larger values of l will be presented elsewhere. To avoid dealing with the divergence-free condition, we first rewrote the barotropic equations in the vorticity streamfunction formulation.

In our experiments, the basin configuration is the (nondimensional) cube $[0,1] \times [0,1] \times [-1,0]$. Let us simply recall that this is a two-gyre, wind-driven ocean-type problem with steady sinusoidal wind stress (maximum $\tau_0 = 1$ dyne cm^{-4}) in a basin that is $L_1 \times L_1 \times H_1$ km (east-west $\times$ north-south $\times$ bottom-surface extent). The Coriolis parameter is given by $f = f_0 + \beta y$, $f_0 = 9.3\times10^{-5}\text{s}^{-1}$, $\beta = 2.\times10^{-11}$ m^{-1}s^{-1}. The model does not include bottom topography. The ocean is forced by a steady wind stress $\tau_0 = (\tau_0^x, \tau_0^y) = (-10^{-4}\cos(2\pi y/L_1), 0)$. Other dimensional quantities are given by $U_1 = 10^{-1}$m s^{-1}, $g = 9.8$m s^{-2}, $L_1 = 2.10^6$ m, and $H_1 = 4000$m, which gives $\delta = H_1/L_1 = 2.10^{-3}$. The initial condition is given by $u = 0$ at $t = 0$. All the operators in (2.18) and (3.8)–(3.9) are discretized using a second-order central difference scheme. The Jacobian operator is approximated using Arakawa's method [30]. For the time integration, we use a fourth-order Adams–Bashforth method. For the space discretization, we take 100×100 points in the x-y plane and 10 points on the vertical direction. For the boundary conditions, we replace (2.2) by the following physically more acceptable boundary conditions:

$$\begin{cases} \dfrac{\partial v}{\partial z} = 0,\ \dfrac{\partial \rho}{\partial z} = -\alpha_T\rho \text{ at } z = 0, \\ \dfrac{\partial v}{\partial z} = 0,\ \dfrac{\partial \rho}{\partial z} = 0 \text{ at } z = -\delta, \\ v = 0,\ \dfrac{\partial \rho}{\partial n} = 0 \text{ on } \partial\omega \times (-\delta, 0). \end{cases} \tag{5.1}$$

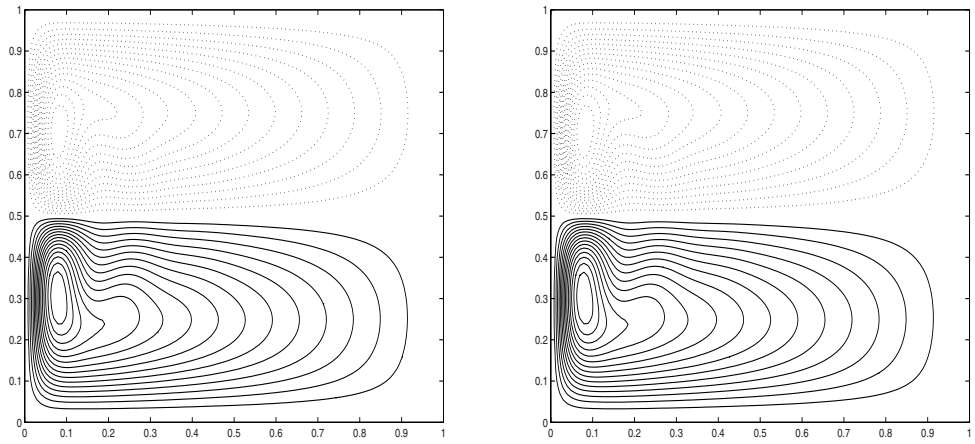

FIG. 1. *Barotropic streamfunction at the steady state. Original model* (2.18) *on the left and reduced model* (3.8)–(3.9) *on the right.*

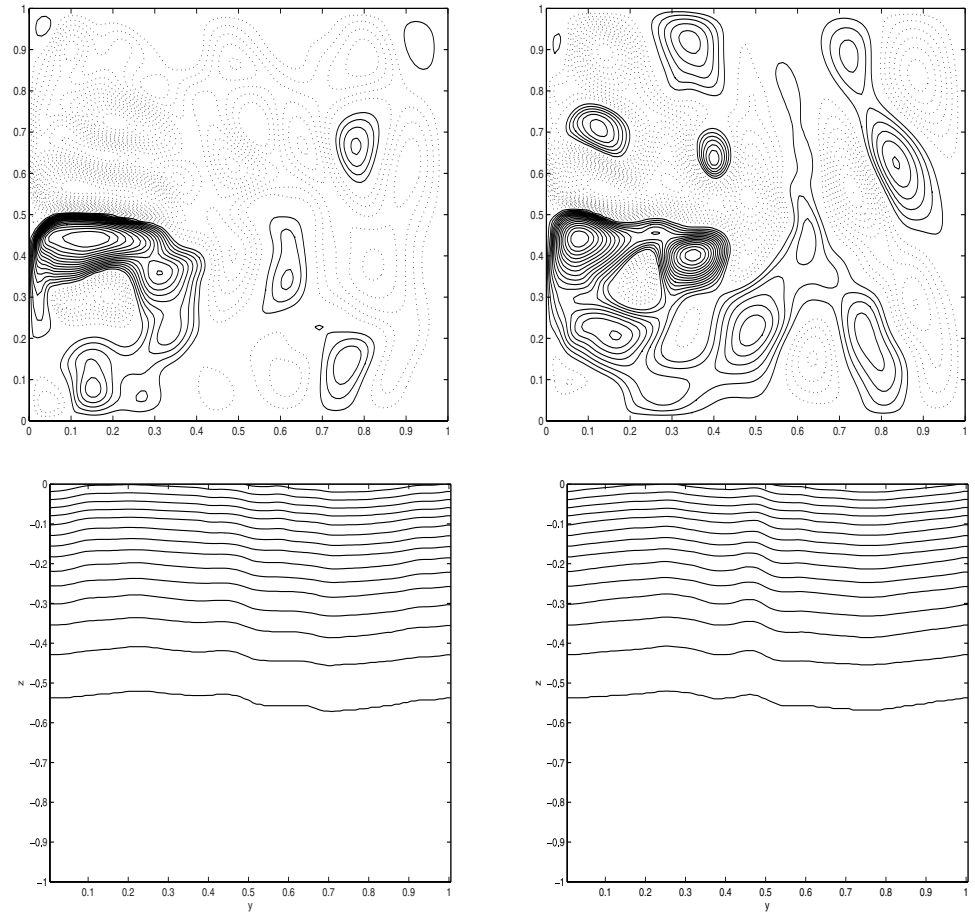

FIG. 2. *Snapshot at the (nondimensional) time* $t = 5$ *of the barotropic streamfunction and the total density at* $x = 0.25$. *PEs on the left and reduced model* (3.8)–(3.9) *on the right.*

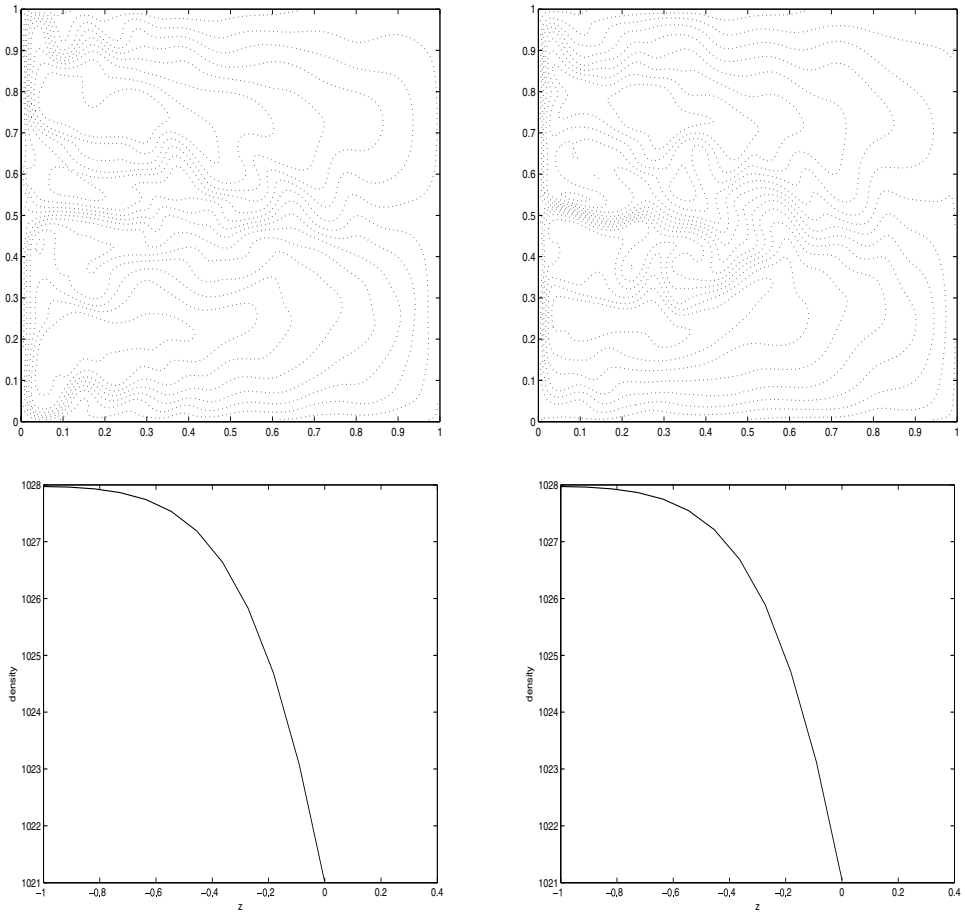

FIG. 3. *Snapshot at the (nondimensional) time $t = 5$ of the surface density deviation and the total density at $(x, y) = (0.5, 0.5)$. PEs on the left and reduced model* (3.8)–(3.9) *on the right.*

The forcing term $F = (F_1, F_2)$ in (2.5) is defined by

$$F_1 = c(g(z)\tau_0, 0), \qquad F_2(z) = c\frac{\partial^2 \rho_s}{\partial z^2}/\rho_0, \tag{5.2}$$

where $g(z)$ and ρ_s are given by

$$g(z) = 0.5(1 + \tanh((z/H_1 + z_1)/\epsilon_1)), \qquad \rho_s(z) = 1028 - 3\exp(10z/H_1). \tag{5.3}$$

In (5.2)–(5.3), z_1 and ϵ_1 are very small constants chosen such that the forcing F_1 is nonzero only on the first couple layers from the surface of the ocean and c is a constant.

Simulation 1: Steady state solutions.

In this simulation, we compare the two models (2.18) and (3.8)–(3.9) when the solution converges to a steady state. For $R_{e_1} = R_{e_2} = 100$, the solutions obtained with the two models converge to a steady state. Figure 1 shows the barotropic streamfunctions obtained with the two models. As one can see, model (3.8)–(3.9) approximates very well the original model (2.18).

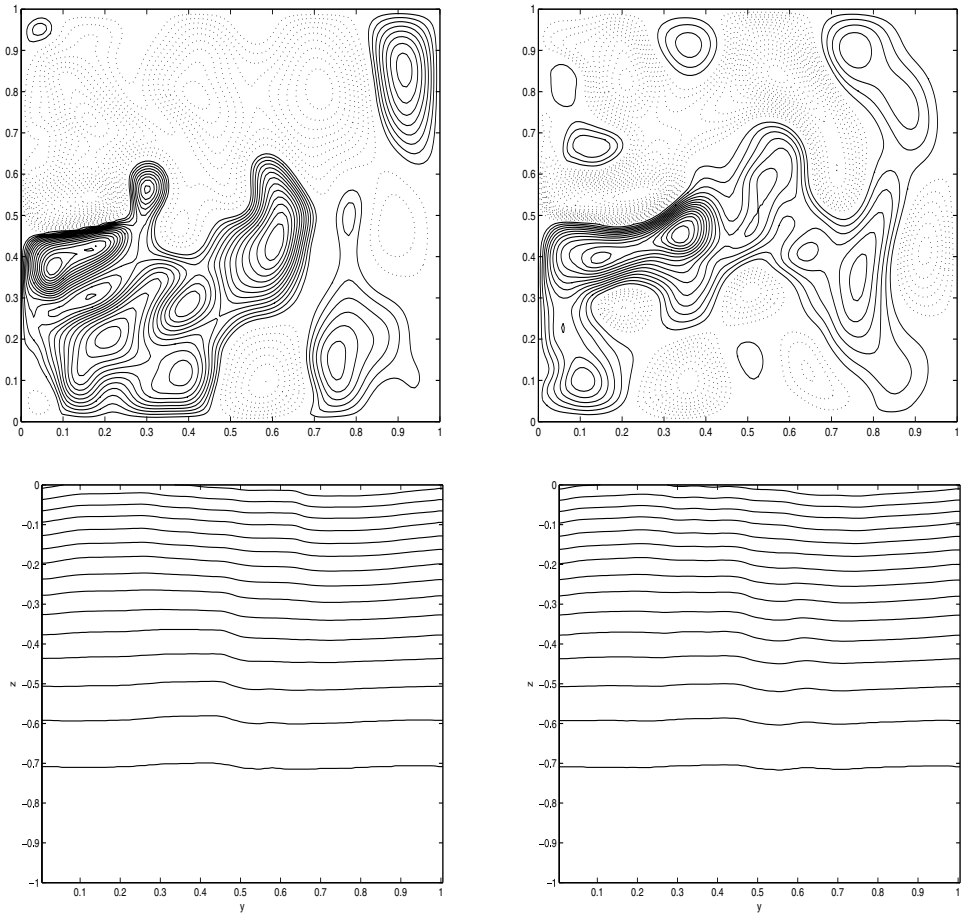

FIG. 4. *Snapshot at the (nondimensional) time* $t = 10$ *of the barotropic streamfunction and the total density at* $x = 0.25$. *PEs on the left and reduced model* (3.8)–(3.9) *on the right.*

Simulation 2: Time-dependent solutions.

For the two models (2.18) and (3.8)–(3.9), Figure 2 (resp., Figure 4) shows the barotropic streamfunction and the total density $\rho + \rho_s$ at $x = 0.25$ for the Reynolds number $R_{e_1} = 2.10^3, R_{e_2} = 10^2$ and at the time $t = 5$ (resp., $t = 10$). For the same values of the Reynolds number, Figure 3 (resp., Figure 5) shows the surface density deviation ρ and the total density $\rho + \rho_s$ at the point $(x, y) = (0.5, 0.5)$ and at the time $t = 5$ (resp., $t = 10$). For these values of the Reynolds number, the flow remains time-dependent. From these figures, we observe that the solutions obtained with the two models present some differences. However, Figure 6 shows that the time-averages of the two flows are very similar. This seems to confirm what is already believed in oceanography: from the climate point of view (where the main focus is on the time-average of the flow), the interactions between the baroclinic and the barotropic modes do not need to be accurately represented [10]. From an efficiency point of view, it was noticed that the reduced model (3.8)–(3.9) allows a larger time step than the original model (2.18). With $100 \times 100 \times 10$ grid points, for instance, the maximum time step allowed for (2.18) was around 10^{-4}, while the reduced model was still stable with $\triangle t = 3 \times 10^{-4}$. This result is not surprising. In fact, since the equation for the

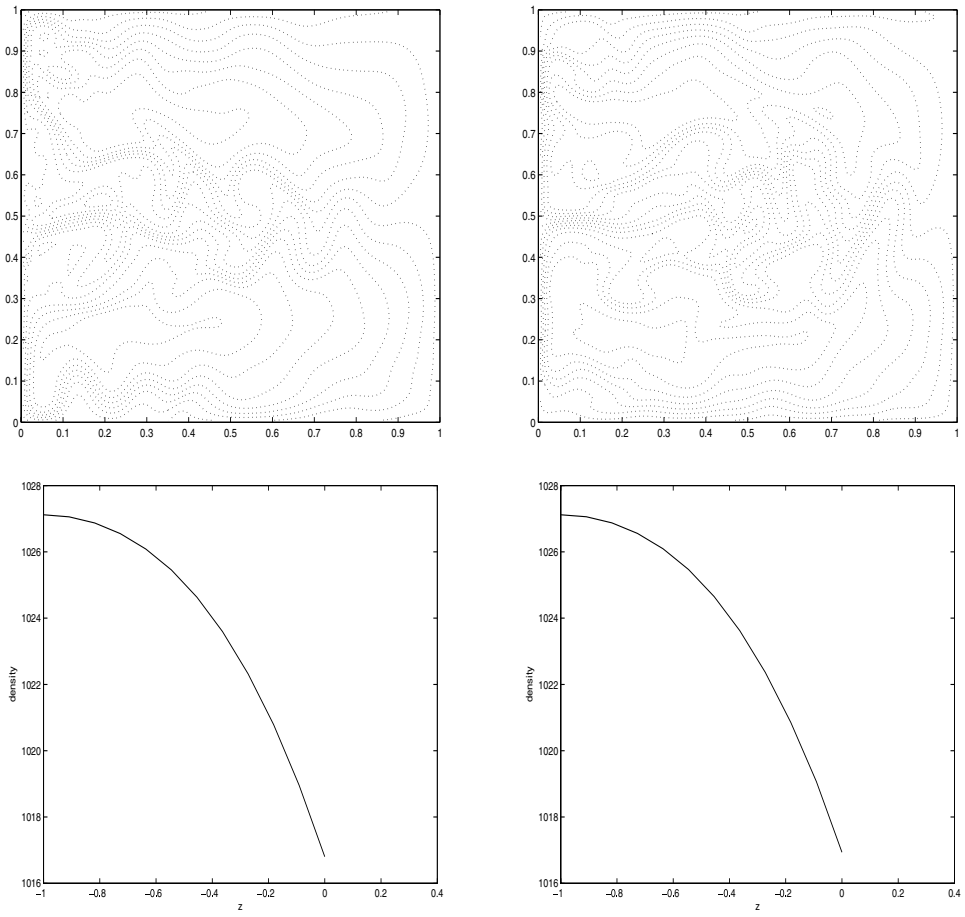

FIG. 5. *Snapshot at the (nondimensional) time* $t = 10$ *of the surface density deviation and the total density at* $(x, y) = (0.5, 0.5)$. *PEs on the left and reduced model* (3.8)–(3.9) *on the right.*

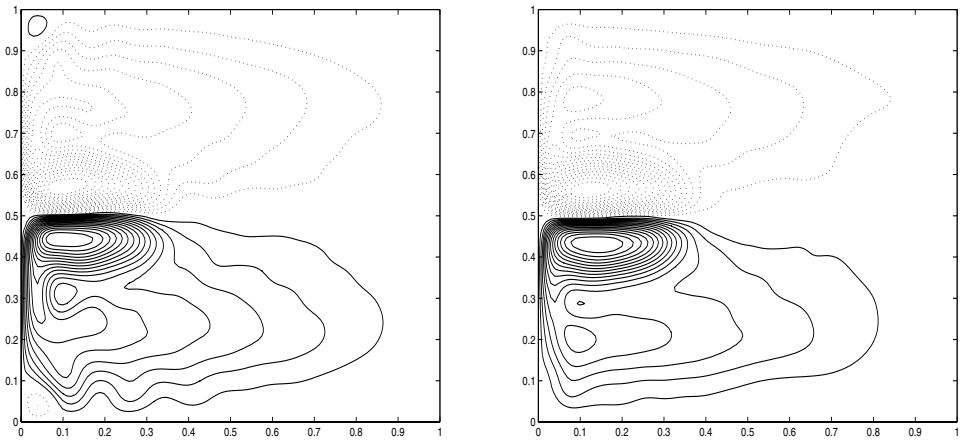

FIG. 6. *Time-average (over* $[0, 10]$*) of the barotropic streamfunction. PEs on the left and reduced model* (3.8)–(3.9) *on the right.*

small scales is (highly) nonlinear for the model (2.18) and linearized in the model (3.8)–(3.9), it is expected that the small scales will greatly influence the time step in (2.18) more than in (3.8)–(3.9), especially for turbulent flows.

6. Conclusion. The purpose of this article was to present a small eddy correction method for the numerical solution to (2.5). Considering the interaction between the baroclinic and barotropic flows and using the idea of the Newton iteration, a small eddy correction method was proposed for (2.5). We assume that the barotropic approximation to the solution is known. Formally applying the Newton iterative procedure to the baroclinic flow equation, we then generate approximate systems. It was shown that the initial step ($l = 0$) leads to the well-known quasi-geostrophic equations and the next step ($l = 1$) yields an NLG-type approximation. Some numerical simulations for $l = 1$ show that the method can accurately approximate the PEs system of (2.18). For the simulation presented in this article, it was observed that with the same time discretization, the reduced model allows a larger time step (about three times larger) than the original model. An efficient time discretization of the model presented in this article may lead to even more considerable savings in calculation costs. In fact, such method should take advantage of the time scale differences between the barotropic and baroclinic modes. For instance,

- one can use different time steps for the small and large scales;
- one can use different schemes for the small and large scales;
- one can freeze the small scales over an interval of time.

These approaches, already used with success (considerable reduction in CPU cost) in the context of the NLG method and the Navier–Stokes equations (see [9, 17]), are currently under development by the author. Let us also recall that in climate research, it would be extremely useful to be able to parameterize the nonlinear effects of the small scales on big scales, using simplified models that do not require costly solutions of the whole ocean model at high resolution. We believe that the research presented in this article is a step in this direction.

LINEAR INSTABILITY OF THE FIFTH-ORDER WENO METHOD*

RONG WANG† AND RAYMOND J. SPITERI†

Abstract. The weighted essentially nonoscillatory (WENO) methods are popular spatial discretization methods for hyperbolic partial differential equations. In this paper we show that the combination of the widely used fifth-order WENO spatial discretization (WENO5) and the forward Euler time integration method is linearly unstable when numerically integrating hyperbolic conservation laws. Consequently it is not convergent. Furthermore we show that all two-stage, second-order explicit Runge–Kutta (ERK) methods are linearly unstable (and hence do not converge) when coupled with WENO5. We also show that all optimal first- and second-order strong-stability-preserving (SSP) ERK methods are linearly unstable when coupled with WENO5. Moreover the popular three-stage, third-order SSP(3,3) ERK method offers no linear stability advantage over non-SSP ERK methods, including ones with negative coefficients, when coupled with WENO5. We give new linear stability criteria for combinations of WENO5 with general ERK methods *of any order*. We find that a sufficient condition for the combination of an ERK method and WENO5 to be linearly stable is that the linear stability region of the ERK method should include the part of the imaginary axis of the form $[-\iota\mu, \iota\mu]$ for some $\mu > 0$. The linear stability analysis also provides insight into the behavior of ERK methods applied to nonlinear problems and problems with discontinuous solutions. We confirm the assertions of our analysis by means of numerical tests.

1. Introduction.

The method of lines (MOL) is a general approach for the treatment of time-dependent partial differential equations (PDEs) [24]. The standard MOL involves two steps. The first step is to discretize the spatial variables of the PDE to obtain a large set of initial-value ordinary differential equations (ODEs). The second step is to integrate the ODEs using a time integration method such as a linear multistep or Runge–Kutta (RK) method [4, 5].

The essentially nonoscillatory (ENO) methods [6, 7] and the weighted essentially nonoscillatory (WENO) methods [15, 11] are popular and effective nonlinear spatial discretizations for hyperbolic PDEs. These methods are adept at handling the nonsmooth features that arise in the solutions to hyperbolic PDEs. For example, although these methods are formally first-order accurate once a shock is present, they still have uniform high-order accuracy right up to the location of the shock [11]. Specifically, the fifth-order WENO spatial discretization (WENO5) [11], which uses a convex combination of three third-order ENO stencils, is a widely used and robust spatial discretization for numerical solution of hyperbolic conservation laws.

The three-stage, third-order strong-stability-preserving (SSP) explicit RK (ERK) method, which has most recently been referred to as SSP(3,3) [21], is generally viewed as the time integration method of choice to couple with WENO5; see, e.g., [16] and references therein. Numerical results are generically stable and satisfactory [11, 20].

Because of this, it is generally believed that, when WENO5 is used as the spatial discretization for hyperbolic PDEs, the SSP property is a necessary (or advantageous) property for the time integration method to possess [16, 20]. However, for ERK methods applied to hyperbolic conservation laws spatially discretized by WENO5, our work shows that there is a different property, i.e., linear stability, that must be considered.

In this paper we analyze the linear stability of some ERK methods when coupled with WENO5 to solve hyperbolic conservation laws. First we show that the forward Euler method is linearly unstable when coupled with WENO5; i.e., the corresponding CFL number is 0. Consequently the numerical solution does not converge to the true solution for any time step. This means that the stability of WENO5 in general is a product of its nonlinear nature and the particular time integration method with which it is coupled. Furthermore SSP ERK methods [18, 3] derived based on the SSP property of forward Euler cannot be SSP when coupled with WENO5. In fact, there is no guarantee for stability of any kind. In section 3 we show that any optimal s-stage, first- or second-order SSP ERK method [21] is linearly unstable when coupled with WENO5. This result is surprising and contrary to expectation based on existing literature; see, e.g., [16, 20, 25] and references therein. Moreover, we show that, in our analysis, the success of the SSP(3,3) method for the time integration of hyperbolic PDEs spatially discretized by WENO5 is not due to its SSP property; indeed any three-stage, third-order ERK method (even with negative coefficients or that is provably non-SSP) possesses the same linear stability properties. We demonstrate all of these results by means of numerical experiments.

For linear spatial discretizations of linear, constant-coefficient PDE problems posed on unbounded or periodic domains, linear instability guarantees *global* instability; the instability typically leads to spurious oscillations in the numerical solution that ultimately become unbounded [23]. However, WENO methods are not linear spatial discretizations; see, e.g., [9, p. 59] for a definition of linear spatial discretizations for periodic advection problems. Therefore, the behavior of a numerical solution computed from linearly unstable combinations of WENO methods and certain time integration methods for solving hyperbolic conservation laws is more subtle. Such a combination arises, for example, when using the combination of WENO5 and the forward Euler method; see Theorem 3.1 below. In such cases, the linear instability again manifests itself as spurious oscillations in the numerical solution. However, WENO methods attempt to adapt to the instability by changing the associated ENO stencil weights; see section 2 below. The spurious oscillations may still grow to large magnitudes; however, they do not necessarily become unbounded. In other words, the nonlinear nature of WENO methods may be successful in controlling potential instabilities, and this process may take a significant length of time to assert itself. It is important to note that, because they are linearly unstable, these combined methods are not convergent. Hence, although the discussions in this paper are phrased mainly in terms of linear stability analysis, an immediate corollary of every result presented regarding linear instability is the nonconvergence of the combined method. We offer further discussion and illustration of this in section 4; see also Example 1.

The remainder of this paper proceeds as follows. In section 2 we give a brief review of WENO5. In section 3 we prove that, when coupled with WENO5, the forward Euler method and all two-stage, second-order ERK methods are linearly unstable. We then provide criteria for the linear stability of general ERK methods of orders 1 and 2. Immediate consequences of these criteria are that the optimal s-stage ($s \geq 2$), first-order or s-stage ($s \geq 3$), second-order SSP ERK methods are linearly

unstable when coupled with WENO5. It is also easy to show that all three-stage, third-order ERK methods (including SSP(3,3)) and all four-stage, fourth-order ERK methods (including the classical four-stage, fourth-order ERK method) are linearly stable when coupled with WENO5. Finally we find that a sufficient condition for the combination of any ERK time integration method with WENO5 to be linearly stable is that the linear stability region of the ERK method must include the part of the imaginary axis in the form $[-\iota\mu, \iota\mu]$ for some $\mu > 0$. In section 4 we confirm our theoretical results by means of numerical experiments. We also derive and test four new non-SSP ERK methods (a two-stage, first-order method; a three-stage, second-order method; a three-stage, third-order method with negative coefficients; and a low-storage five-stage, third-order method) that are stable according to our linear stability analysis. Numerical results for both linear and nonlinear problems, as well as problems with continuous and discontinuous solutions, demonstrate the relevance of our analysis.

2. The WENO5 method. WENO methods are widely used for the spatial discretization of hyperbolic conservation laws. They were first introduced in [15] as an improvement to ENO methods. ENO methods are based on polynomial interpolation of solution data to define numerical fluxes. They were originally designed to suppress instabilities that lead to spurious oscillations in other commonly used spatial discretizations. To achieve this, ENO methods choose stencils that are adapted to the directions where the solution has an increased order of smoothness. WENO methods take a convex combination of r candidate ENO stencils of order r to produce a method of order $2r-1$ in regions where the solution is smooth while retaining the ENO property in regions where the solution exhibits discontinuous behavior. Specifically, for a given cell, the WENO5 method consists of a convex combination of the three possible third-order ENO stencils containing that cell [11]. Although in practice ENO or WENO methods are very robust, there are very few theoretical results for them [20]. We note that no proof of the stability of either family of methods has yet been given. The WENO5 method is perhaps the most commonly used of the WENO family of methods. We now give a brief summary of some theoretical aspects of WENO methods, with specific implementational details given for the WENO5 method.

Consider the one-dimensional scalar hyperbolic conservation law

$$u_t = -f_x(u), \qquad 0 < x < 1,\ t > 0. \tag{2.1}$$

Assume a uniform spatial mesh, i.e., $x_j = j\Delta x$, $j = 0, 1, \ldots, N$, where $\Delta x = \frac{1}{N}$, and define cells by $I_j = [x_{j-1}, x_j]$, $i = 1, 2, \ldots, N$. We use a conservative finite difference scheme in a MOL approach to write

$$\frac{du_j}{dt} = -\frac{1}{\Delta x}\left(\hat{f}_{j+\frac{1}{2}} - \hat{f}_{j-\frac{1}{2}}\right),$$

where $u_j(t) \approx u(x_j, t)$, $j = 0, 1, \ldots, N$. The term $\hat{f}_{j+\frac{1}{2}} = \hat{f}\left(u_{j-R}, \ldots, u_{j+S}\right)$ is the numerical flux. The numerical flux must be consistent with $f(u)$; i.e., $\hat{f}(u, \ldots, u) = f(u)$. The specification of $\hat{f}(u)$ determines the particular numerical method and its properties. We now derive the specific form of the numerical flux $\hat{f}(u)$ for WENO5.

We first split the flux into positive and negative parts

$$f(u) = f^+(u) + f^-(u). \tag{2.2}$$

This can be accomplished in different ways. In this paper we consider only the Lax–Friedrichs flux splitting [20]

$$f^+(u) = \frac{1}{2}\left(f(u) + mu\right), \qquad f^-(u) = \frac{1}{2}\left(f(u) - mu\right),$$

where $m = \max|f'(u)|$. It is easy to show that $\frac{df^+}{du} \geq 0$ and $\frac{df^-}{du} \leq 0$. However, we note that the same analysis and conclusions apply to other flux-splitting methods.

As in [11], we now calculate the indicators of smoothness IS_i, $i = 0, 1, \ldots, r-1$, associated with the ith stencil. For IS_i^+ we use

$$IS_i^+ = \sum_{m=1}^{r-1} \int_{x_{j-\frac{1}{2}}}^{x_{j+\frac{1}{2}}} \Delta x^{2m-1} \left(\frac{\partial^m p_i(x)}{\partial x^m}\right)^2 dx, \quad i = 0, 1, \ldots, r-1,$$

where $p_i(x)$ is the interpolating polynomial of order r to solution data on r cells; i.e., $I_{j+i-r+1}$, $\ldots$, I_{j+i}. In the case of WENO5, $r = 3$, this leads to

$$IS_0^+ = \frac{13}{12}\left(f_{j-2}^+ - 2f_{j-1}^+ + f_j^+\right)^2 + \frac{1}{4}\left(f_{j-2}^+ - 4f_{j-1}^+ + 3f_j^+\right)^2, \tag{2.3}$$

$$IS_1^+ = \frac{13}{12}\left(f_{j-1}^+ - 2f_j^+ + f_{j+1}^+\right)^2 + \frac{1}{4}\left(f_{j-1}^+ - f_{j+1}^+\right)^2, \tag{2.4}$$

$$IS_2^+ = \frac{13}{12}\left(f_j^+ - 2f_{j+1}^+ + f_{j+2}^+\right)^2 + \frac{1}{4}\left(3f_j^+ - 4f_{j+1}^+ + f_{j+2}^+\right)^2, \tag{2.5}$$

and, using an analagous formula for IS_i^-, we have

$$\begin{aligned}
IS_0^- &= \frac{13}{12}\left(f_{j+1}^- - 2f_{j+2}^- + f_{j+3}^-\right)^2 + \frac{1}{4}\left(3f_{j+1}^- - 4f_{j+2}^- + f_{j+3}^-\right)^2,\\
IS_1^- &= \frac{13}{12}\left(f_j^- - 2f_{j+1}^- + f_{j+2}^-\right)^2 + \frac{1}{4}\left(f_j^- - f_{j+2}^-\right)^2,\\
IS_2^- &= \frac{13}{12}\left(f_{j-1}^- - 2f_j^- + f_{j+1}^-\right)^2 + \frac{1}{4}\left(f_{j-1}^- - 4f_j^- + 3f_{j+1}^-\right)^2.
\end{aligned}$$

Next the (nonnormalized) stencil weights take the form

$$\alpha_i^{\pm} = \frac{d_i}{(\epsilon + IS_i)^2}, \quad i = 0, 1, \ldots, r-1,$$

where ϵ is a small positive number that is introduced to avoid the denominator becoming zero. In the numerical experiments of this paper, we choose $\epsilon = 10^{-6}$, which is the value recommended in [11]. In the case of the WENO5 method, we have $d_0 = \frac{1}{10}$, $d_1 = \frac{6}{10}$, $d_2 = \frac{3}{10}$ (see, e.g., [11] for a derivation of the d_i), and

$$\alpha_0^{\pm} = \frac{1}{10}\left(\frac{1}{\epsilon + IS_0^{\pm}}\right)^2, \quad \alpha_1^{\pm} = \frac{6}{10}\left(\frac{1}{\epsilon + IS_1^{\pm}}\right)^2, \quad \alpha_2^{\pm} = \frac{3}{10}\left(\frac{1}{\epsilon + IS_2^{\pm}}\right)^2. \tag{2.6}$$

In order to a achieve a convex combination of ENO stencils, the WENO stencil weights are normalized according to

$$w_i^{\pm} = \frac{\alpha_i}{\sum_{m=0}^{r-1} \alpha_m}, \quad i = 0, 1, \ldots, r-1,$$

to give

$$w_0^{\pm} = \frac{\alpha_0^{\pm}}{\alpha_0^{\pm} + \alpha_1^{\pm} + \alpha_2^{\pm}}, \quad w_1^{\pm} = \frac{\alpha_1^{\pm}}{\alpha_0^{\pm} + \alpha_1^{\pm} + \alpha_2^{\pm}}, \quad w_2^{\pm} = \frac{\alpha_2^{\pm}}{\alpha_0^{\pm} + \alpha_1^{\pm} + \alpha_2^{\pm}}. \tag{2.7}$$

We note that $w_j^{\pm} \in (0,1)$, $j = 0,1,2$, and $w_0^{\pm} + w_1^{\pm} + w_2^{\pm} = 1$, as required.

The numerical fluxes for WENO5 are given by

$$\begin{aligned} \hat{f}^+_{j+\frac{1}{2}} &= w_0^+ \left(\frac{2}{6} f^+_{j-2} - \frac{7}{6} f^+_{j-1} + \frac{11}{6} f^+_j \right) + w_1^+ \left(-\frac{1}{6} f^+_{j-1} + \frac{5}{6} f^+_j + \frac{2}{6} f^+_{j+1} \right) \\ &\quad + w_2^+ \left(\frac{2}{6} f^+_j + \frac{5}{6} f^+_{j+1} - \frac{1}{6} f^+_{j+2} \right) \end{aligned} \tag{2.8}$$

and

$$\begin{aligned} \hat{f}^-_{j+\frac{1}{2}} &= w_2^- \left(-\frac{1}{6} f^-_{j-1} + \frac{5}{6} f^-_j + \frac{2}{6} f^-_{j+1} \right) + w_1^- \left(\frac{2}{6} f^-_j + \frac{5}{6} f^-_{j+1} - \frac{1}{6} f^-_{j+2} \right) \\ &\quad + w_0^- \left(\frac{11}{6} f^-_{j+1} - \frac{7}{6} f^-_{j+2} + \frac{2}{6} f^-_{j+3} \right). \end{aligned}$$

Noting (2.2), the WENO5 method takes the final form

$$\frac{du_j}{dt} = -\frac{1}{\Delta x} \left[\left(\hat{f}^+_{j+\frac{1}{2}} - \hat{f}^+_{j-\frac{1}{2}} \right) + \left(\hat{f}^-_{j+\frac{1}{2}} - \hat{f}^-_{j-\frac{1}{2}} \right) \right]. \tag{2.9}$$

We refer the interested reader to [20] and references therein for further details and discussion of WENO methods.

3. Linear stability analysis. We consider the linear stability properties of various ERK methods when coupled with WENO5 to solve hyperbolic conservation laws (2.1). The CFL number associated with a uniform discretization in both space and time of (2.1) is defined as $\sigma = (\max \frac{\partial f}{\partial u}) \frac{\Delta t}{\Delta x}$. As is usual when performing linear stability analysis, we linearize and freeze coefficients to write

$$u_t = -\lambda u_x.$$

The corresponding CFL number σ is then $\sigma = \frac{\lambda \Delta t}{\Delta x}$. For the purposes of our analysis, it is sufficient to consider the one-dimensional scalar advection equation

$$u_t = -u_x;$$

i.e., $f(u) = u$; any CFL number appearing in our analysis can then be scaled appropriately for more general interpretations.

We begin this section by showing that the combination of WENO5 and the forward Euler ERK method is linearly unstable.

The Lax–Friedrichs flux splitting yields

$$f^+(u) = u, \quad f^-(u) = 0;$$

i.e., the negative part of the flux is zero. Thus, (2.8) takes the form

$$\begin{aligned} \hat{f}^+_{j+\frac{1}{2}} &= w_0^+ \left(\frac{2}{6} u_{j-2} - \frac{7}{6} u_{j-1} + \frac{11}{6} u_j \right) + w_1^+ \left(-\frac{1}{6} u_{j-1} + \frac{5}{6} u_j + \frac{2}{6} u_{j+1} \right) \\ &\quad + w_2^+ \left(\frac{2}{6} u_j + \frac{5}{6} u_{j+1} - \frac{1}{6} u_{j+2} \right). \end{aligned} \tag{3.1}$$

When the exact solution is smooth, it is well known that

$$w_0^+ = \frac{1}{10} + \epsilon_1, \quad w_1^+ = \frac{6}{10} + \epsilon_2, \quad w_2^+ = \frac{3}{10} + \epsilon_3, \tag{3.2}$$

where ϵ_1, ϵ_2, ϵ_3 are all $\mathcal{O}((\Delta x)^2)$, and $\epsilon_1+\epsilon_2+\epsilon_3 = 0$ [11]. We now prove the following theorem using von Neumann analysis.

THEOREM 3.1. *The combination of WENO5 and forward Euler is linearly unstable.*

Proof. Assuming periodic boundary conditions, we can expand the approximate solution $\{u_j\}_{j=0}^N$ as a finite Fourier series

$$u_j = \sum_{k=-\lfloor N/2 \rfloor}^{\lceil N/2 \rceil} \hat{u}_k e^{\iota j \xi_k \, \Delta x},$$

where ι is the imaginary unit, i.e., $\iota^2 = -1$, and ξ_k is the spatial frequency associated with $\hat{u}_k$. Because the wave equation is linear and has constant coefficients, it is sufficient to consider only one individual Fourier mode; i.e.,

$$u_j = \hat{u} e^{\iota j \xi \, \Delta x}.$$

Defining $\phi = \xi \, \Delta x$, we thus have

$$u_j = \hat{u} e^{\iota j \phi}. \tag{3.3}$$

By using (3.2), (3.1), and (3.3), we now obtain

$$\begin{aligned} \hat{f}^+_{j+\frac{1}{2}} = u_j \Bigg[& w_0^+ \left(\frac{2}{6} e^{-2\iota\phi} - \frac{7}{6} e^{-\iota\phi} + \frac{11}{6} \right) + \; w_1^+ \left(-\frac{1}{6} e^{-\iota\phi} + \frac{5}{6} + \frac{2}{6} e^{\iota\phi} \right) \\ & + w_2^+ \left(\frac{2}{6} + \frac{5}{6} e^{\iota\phi} - \frac{1}{6} e^{2\iota\phi} \right) \Bigg]. \end{aligned} \tag{3.4}$$

When the forward Euler method is used, the WENO5 method becomes

$$u_j^{n+1} = u_j^n - \frac{\Delta t}{\Delta x} L\left(u_{j-3}^n, u_{j-2}^n, \ldots, u_{j+2}^n\right), \tag{3.5}$$

where

$$L\left(u_{j-3}^n, u_{j-2}^n, \ldots, u_{j+2}^n\right) = \hat{f}^{+,n}_{j+\frac{1}{2}} - \hat{f}^{+,n}_{j-\frac{1}{2}}.$$

From (3.4) we see that $\frac{\hat{f}^{+,n}_{j+\frac{1}{2}} - \hat{f}^{+,n}_{j-\frac{1}{2}}}{u_j^n}$ is a function of ϕ. Thus we define $z(\phi) = \frac{\hat{f}^{+,n}_{j+\frac{1}{2}} - \hat{f}^{+,n}_{j-\frac{1}{2}}}{u_j^n}$ and obtain

$$L\left(u_{j-3}^n, u_{j-2}^n, \ldots, u_{j+2}^n\right) = z(\phi) u_j^n.$$

Defining the CFL number $\sigma = \frac{\Delta t}{\Delta x}$, (3.5) becomes

$$\begin{aligned} u_j^{n+1} &= u_j^n - \sigma z(\phi) u_j^n \\ &= u_j^n \left(1 - \sigma z(\phi)\right). \end{aligned} \tag{3.6}$$

Define the *amplification factor* $g(\sigma z(\phi)) = 1 - \sigma z(\phi)$. In order to prove the theorem, we need to show that for any $\sigma > 0$, there exists a ϕ such that $|g| > 1$. Let ϕ be a small positive number. Using the Taylor expansion of $\sin\phi$ and $\cos\phi$ in (2.3)–(2.5), we obtain

$$
\begin{aligned}
IS_0^+ &= u_j^2\phi^2\left(-1 + \frac{5}{12}\phi^2 - \frac{89}{40}\phi^4 + \frac{4889}{4032}\phi^6 - \frac{5}{3}\,\iota\phi^3 + \frac{17}{9}\,\iota\phi^5 + \mathcal{O}(\phi^7)\right),\\
IS_1^+ &= u_j^2\phi^2\left(-1 + \frac{17}{12}\phi^2 - \frac{9}{40}\phi^4 + \frac{337}{20160}\phi^6 + \mathcal{O}(\phi^7)\right),\\
IS_2^+ &= u_j^2\phi^2\left(-1 + \frac{5}{12}\phi^2 - \frac{89}{40}\phi^4 + \frac{4889}{4032}\phi^6 + \frac{5}{3}\,\iota\phi^3 - \frac{17}{9}\,\iota\phi^5 + \mathcal{O}(\phi^7)\right).
\end{aligned}
$$

For $0 < \epsilon \ll 1$, we can choose $\phi = \phi(\epsilon) = \mathcal{O}(\epsilon^{1/9})$ sufficiently small such that the α_i^+, $i = 0, 1, 2$, in (2.6) can be estimated as follows:

$$
\begin{aligned}
\alpha_0^+ &= \frac{1}{u_j^4\phi^4}\left(\frac{1}{10} + \frac{1}{12}\phi^2 - \frac{943}{2400}\phi^4 - \frac{7879}{4320}\phi^6 - \frac{1}{3}\,\iota\phi^3 - \frac{5}{9}\,\iota\phi^5 + \mathcal{O}(\phi^7)\right),\\
\alpha_1^+ &= \frac{1}{u_j^4\phi^4}\left(\frac{6}{10} + \frac{17}{10}\phi^2 + \frac{1337}{400}\phi^4 + \frac{19057}{3600}\phi^6 + \mathcal{O}(\phi^7)\right),\\
\alpha_2^+ &= \frac{1}{u_j^4\phi^4}\left(\frac{3}{10} + \frac{1}{4}\phi^2 - \frac{943}{800}\phi^4 - \frac{7879}{1440}\phi^6 + \,\iota\phi^3 + \frac{5}{3}\,\iota\phi^5 + \mathcal{O}(\phi^7)\right).
\end{aligned}
$$

Substituting the above expressions into (2.7), we obtain

$$
\begin{aligned}
w_0^+ &= \frac{1}{10} - \frac{3}{25}\phi^2 - \frac{163}{500}\phi^4 - \frac{30449}{30000}\phi^6 - \frac{2}{5}\,\iota\phi^3 + \frac{17}{75}\,\iota\phi^5 + \mathcal{O}(\phi^7),\\
w_1^+ &= \frac{6}{10} + \frac{12}{25}\phi^2 + \frac{163}{125}\phi^4 + \frac{20449}{7500}\phi^6 - \frac{2}{5}\,\iota\phi^3 - \frac{13}{75}\,\iota\phi^5 + \mathcal{O}(\phi^7),\\
w_2^+ &= \frac{3}{10} - \frac{9}{25}\phi^2 - \frac{489}{500}\phi^4 - \frac{51347}{30000}\phi^6 + \frac{4}{5}\,\iota\phi^3 - \frac{4}{75}\,\iota\phi^5 + \mathcal{O}(\phi^7).
\end{aligned}
$$

Thus the real and imaginary parts of $\hat{f}^{+,n}_{j+\frac{1}{2}}$ are

$$
\operatorname{Re}\hat{f}^{+,n}_{j+\frac{1}{2}} = u_j^n\left(1 - \frac{1}{12}\phi^2 - \frac{1}{720}\phi^4 + \frac{241}{21600}\phi^6 + \mathcal{O}(\phi^8)\right), \tag{3.7}
$$

$$
\operatorname{Im}\hat{f}^{+,n}_{j+\frac{1}{2}} = u_j^n\left(\frac{1}{2}\phi - \frac{7}{60}\phi^5 + \mathcal{O}(\phi^7)\right). \tag{3.8}
$$

Similarly it can be shown that

$$
\operatorname{Re}\hat{f}^{+,n}_{j-\frac{1}{2}} = u_j^n\left(1 - \frac{1}{12}\phi^2 - \frac{1}{720}\phi^4 - \frac{2279}{21600}\phi^6 + \mathcal{O}(\phi^8)\right), \tag{3.9}
$$

$$
\operatorname{Im}\hat{f}^{+,n}_{j-\frac{1}{2}} = u_j^n\left(-\frac{1}{2}\phi - \frac{7}{60}\phi^5 + \mathcal{O}(\phi^7)\right). \tag{3.10}
$$

Using (3.7)–(3.10), we obtain

$$
z(\phi) = \frac{7}{60}\phi^6 + \mathcal{O}(\phi^8) + \iota\left(\phi + \mathcal{O}(\phi^7)\right). \tag{3.11}
$$

The amplification factor becomes

$$g = 1 - \sigma\left(\mathcal{O}(\phi^6) + \iota\left(\phi + \mathcal{O}(\phi^7)\right)\right).$$

A simple calculation now shows that

$$\begin{aligned} |g|^2 &= \left(1 - \sigma\mathcal{O}(\phi^6)\right)^2 + \sigma^2\,\left(\phi + \mathcal{O}(\phi^7)\right)^2 \\ &= 1 + \sigma^2\,\phi^2 + \mathcal{O}(\phi^6) \\ &> 1 \qquad \forall\,\sigma > 0. \end{aligned}$$

This completes the proof. □

Remark 1. Equation (3.11) is valid only when ϕ is a small positive number. The general form of $z(\phi)$ for any ϕ is given later in (3.21).

Remark 2. This form of analysis applies to any linear finite difference method for $\frac{du_j}{dt} = -\frac{1}{\Delta x}L(u_{j-R}, \ldots, u_{j+S})$, where $L(u_{j-R}, \ldots, u_{j+S})$ can be written in the form

$$L(u_{j-R}, \ldots, u_{j+S}) = u_j z(\phi),$$

where $z(\phi)$ is uniquely determined by the spatial operator.

Remark 3. It should be noted that, although this instability argument applies to the WENO spatial discretization, it does not necessarily apply to the ENO spatial discretization. The reason is that this analysis needs to have a known stencil, and ENO methods may choose any of a number of candidate stencils even if the solution is smooth. Moreover, such a "randomly" chosen stencil may lead to an unstable method. This is why a biased choice for choosing ENO stencils is suggested in [19], and this strategy has been very successful for ENO methods in practice.

Remark 4. It follows immediately that, for the class of problems considered in this analysis, the combination of the forward Euler method and the WENO5 spatial discretization is not SSP for any step size $\Delta t > 0$. Because every ERK generates its second stage by a forward Euler step, this second stage cannot be SSP, and hence *in this framework, no ERK method can be SSP.*[1] Hence the SSP property offers no stability advantage.

Consider the general s-stage ERK method written in standard form:

$$\begin{aligned} y_n^{(1)} &= y_n, \\ y_n^{(k)} &= y_n + \Delta t \sum_{i=1}^{k-1} a_{k,i} f\left(t_n + c_i\Delta t, y_n^{(i)}\right), \quad k = 2, \ldots, s, \\ y_{n+1} &= y_n + \Delta t \sum_{i=1}^{s} b_i f\left(t_n + c_i\Delta t, y_n^{(i)}\right), \end{aligned}$$

where the c_k satisfy the conditions

$$c_k = a_{k1} + a_{k2} + \cdots + a_{k,k-1}$$

for $k = 1, \ldots, s$.

Its Butcher tableau is of the form given in Table 3.1.

[1] Recall that an ERK method written in Shu–Osher form is SSP if all of its stages i on step n of the numerical solution $Y_n^{(i)}$ satisfy $\|Y_n^{(i)}\| \le \|Y_n\|$, for all $i = 1, 2, \ldots, s$ and $n \ge 1$, for some suitable seminorm $\|\cdot\|$, where $Y_n^{(1)} = Y_n$ and $Y_n^{(s)} = Y_{n+1}$; see, e.g., [2, 8].

TABLE 3.1
Butcher tableau for s-stage ERK methods.

0						
c_2	a_{21}					
c_3	a_{31}	a_{32}				
c_4	a_{41}	a_{42}	a_{43}			
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$		
c_s	a_{s1}	a_{s2}	a_{s3}	$\cdots$	$a_{s,s-1}$	
	b_1	b_2	b_3	$\cdots$	b_{s-1}	b_s

We have the following theorem and corollary [12].

THEOREM 3.2. *The amplification factor for an s-stage ERK method is*

$$g(\hat{z}) = 1 + \sum_{l=1}^{s} \left(\sum_{j=l}^{s} b_j \left(\sum_{j>m_1>\cdots>m_{l-1}\geq 1} a_{j,m_1} a_{m_1,m_2} \dots a_{m_{l-2},m_{l-1}} \right) \right) \hat{z}^l \tag{3.12}$$

$$= 1 + \hat{z} b^T (I - \hat{z}A)^{-1} e, \tag{3.13}$$

where I is the unit matrix, $A = (a_{ij})_{1\leq i,j\leq s}$ and $b = (b_1, b_2, \dots, b_s)$ are the coefficients of the Butcher tableau, $e = (1, 1, \dots, 1)$, $z(\phi)$ is determined by the spatial operator, and $\hat{z} = -\sigma z$.

Combining the order conditions for ERK methods with (3.12) or (3.13), we easily obtain the following corollary [14, 22].

COROLLARY 3.3. *The amplification factor of an s-stage, order-p ERK method is*

$$\begin{aligned} g(\hat{z}) &= 1 + \sum_{l=1}^{p} \frac{1}{l!} \hat{z}^l \\ &\quad + \sum_{l=p+1}^{s} \left(\sum_{j=l}^{s} b_j \left(\sum_{j>m_1>\cdots>m_{l-1}\geq 1} a_{j,m_1} a_{m_1,m_2} \dots a_{m_{l-2},m_{l-1}} \right) \right) \hat{z}^l \\ &= 1 + \sum_{l=1}^{p} \frac{\hat{z}^l}{l!} + \sum_{l=p+1}^{s} \hat{z}^l b^T A^{l-1} e. \end{aligned} \tag{3.14}$$

Therefore, a spatial discretization scheme combined with a given ERK method is linearly stable if and only if g in (3.12) satisfies $|g| \leq 1$ for all $\phi \in [0, 2\pi]$.

We can now prove the following theorem for any two-stage, second-order ERK method.

THEOREM 3.4. *The combination of WENO5 with any two-stage, second-order ERK method is linearly unstable.*

Proof. From (3.14), the amplification factor is given by

$$g(\hat{z}) = 1 - \sigma z + \frac{1}{2}(\sigma z)^2.$$

Choosing ϕ to be a small positive number and using (3.11), a simple calculation shows

$$\begin{aligned} |g|^2 &= \left(1 - \frac{1}{2}\sigma^2\phi^2 + \mathcal{O}(\phi^6)\right)^2 + \left(-\sigma\phi + \mathcal{O}(\phi^7)\right)^2 \\ &= 1 + \frac{1}{4}\sigma^4\phi^4 + \mathcal{O}(\phi^6) \\ &> 1. \end{aligned}$$

This finishes the proof. ∎

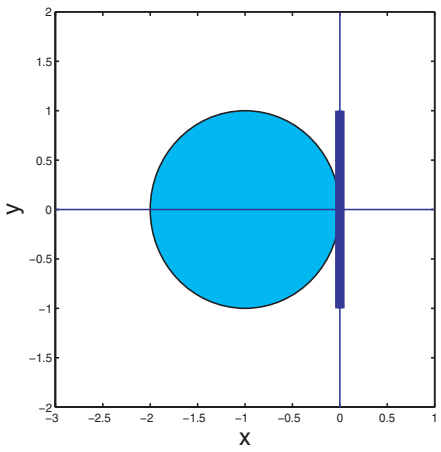

FIG. 1. *D_2 for the upwind (circle) and central (line segment) spatial discretizations.*

Before we derive the theorem for general ERK methods, we give a geometric interpretation for the CFL number σ [1, 10, 14, 22].

DEFINITION 3.5. *Let D_1 denote the classical (linear) stability domain of any ERK method, and let D_2 denote the region interior to the boundary $\{-z(\phi) : 0 \le \phi \le 2\pi\}$ in the complex domain. The CFL number σ is the largest nonnegative real number such that the scaled region σD_2 is contained in D_1.*

It is well known that (3.13) is the stability function for an ERK method; see, e.g., [5]. Thus $D_1 = \{\hat{z} : \ |g(\hat{z})| \le 1\}$. Note that the set $\{\hat{z} = -\sigma z(\phi) : 0 \le \phi \le 2\pi\}$ represents the boundary of the scaled region σD_2. It is clear that, in order to have $\hat{z} \in D_1$, the scaled region σD_2 must be contained in D_1. We now give two simple examples for the purposes of illustration. The first example is for the upwind spatial discretization; i.e., $du_j/dt = L(u_{j-1}, u_j) = -\frac{1}{\Delta x}(u_j - u_{j-1})$. Using von Neumann analysis, we obtain $z(\phi) = 1 - e^{-\iota\phi}$. It is easy to see that the set $\{-z(\phi) : 0 \le \phi \le 2\pi\}$ represents a circle in the complex plane with center $(-1, 0)$ and radius 1; i.e., D_2 is the shaded area shown in Figure 1.

If the forward Euler method is used for the time discretization, its classical linear stability domain D_1 is $\{z : |1 + z| \le 1\}$. In other words, D_1 is exactly the same as D_2 in this case. It is trivial to conclude therefore that $\sigma = 1$ is the largest number such that $\sigma D_2 \subseteq D_1$. Hence the CFL number is 1.

The second example is for the central finite difference spatial discretization; i.e., $du_j/dt = L(u_{j-1}, u_j, u_{j+1}) = -\frac{1}{\Delta x}\frac{u_{j+1} - u_{j-1}}{2}$. Using von Neumann analysis, we obtain $z(\phi) = \frac{1}{2}(e^{\iota\phi} - e^{-\iota\phi}) = \iota \sin\phi$. It is easy to see that the set $\{-z(\phi) : 0 \le \phi \le 2\pi\} = \{(0, y) : -1 \le y \le 1\}$; i.e., D_2 now represents a finite segment of the imaginary axis. If the forward Euler method is used for the time discretization, $\sigma D_2 \not\subseteq D_1$, no matter how small $\sigma > 0$ is chosen. Therefore, the central finite difference spatial discretization is linearly unstable when it is coupled with the forward Euler method.

We now derive the following lemma for any consistent ERK method. Lemma 3.6 is important for all of the theorems in this paper.

LEMMA 3.6. *The classical (linear) stability domain of any consistent ERK method contains a rectangle $[-\eta, 0] \times [-\iota\hat{\mu}, \iota\hat{\mu}]$ for some η, $\hat{\mu} > 0$ if and only if it has an intersection with the imaginary axis of the form $[-\iota\mu, \iota\mu]$ for some $\mu \ge \hat{\mu} > 0$.*

Proof. $\Longrightarrow$ If the rectangle $[-\eta, 0] \times [-\hat{\mu}, \hat{\mu}]$ is inside the classical (linear) stability domain of any consistent ERK method, by definition the part of the imaginary axis

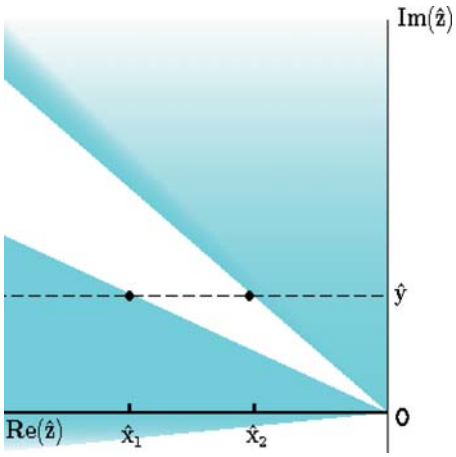

FIG. 2. *A schematic of the topology of the classical stability domain in a sufficiently small neighborhood of the origin if a rectangle* $[-\nu, 0] \times [-\hat{\mu}, \hat{\mu}]$ *is not contained in it. Shaded areas are inside in the stability domain.*

$[-\iota\hat{\mu}, \iota\hat{\mu}]$ is also inside the stability domain. In other words, the stability domain of the ERK method intersects the imaginary axis at $[-\iota\mu, \iota\mu]$ for some $\mu \geq \hat{\mu} > 0$.

$\Longleftarrow$ Assume that the stability domain of the ERK method intersects the imaginary axis at $[-\iota\mu, \iota\mu]$ for some $\mu > 0$. We first prove that the stability domain of the ERK method intersects the part of the (negative) real axis at $[-\hat{\eta}, 0]$ for some $\hat{\eta} > 0$. Recall that the stability function of any consistent ERK method is of the form

$$g(\hat{z}) = 1 + \hat{z} + \text{higher-order terms}.$$

Let $\hat{z} = -\gamma$, where γ is a small, positive real number. In other words, choose $\hat{z}$ to be close to the origin and on the negative real axis. It is easy to see $g(-\gamma) = 1-\gamma+\mathcal{O}(\gamma^2)$. It is obvious that $0 < |g(-\gamma)| < 1$ as $\gamma \to 0+$. That is, there is an intersection of the stability domain with the negative real axis. Assume the intersection is of the form $[-\hat{\eta}, 0]$ for some real $\hat{\eta} > 0$.

Now by contradiction assume that no rectangle $[-\eta, 0]\times[-\hat{\mu}, \hat{\mu}]$ is contained inside the stability domain. Using the facts that the stability domain intersects the negative real axis at $[-\hat{\eta}, 0]$ and that it intersects the imaginary axis at $[-\iota\mu, \iota\mu]$, we give a schematic representation of the topology of a sufficiently small neighborhood of the origin in Figure 2. In the figure, areas inside the stability domain are shaded. For simplicity we focus on the second quadrant in the complex plane, and we show only one region not contained in the stability domain. Thus, if we define $\hat{z} = \hat{x} + \iota\hat{y}$, where $\hat{x}$, $\hat{y}$ are sufficiently small real numbers, there are at least two numbers $\hat{x}_1$ and $\hat{x}_2$ for each $\hat{y}$ such that $|g(\hat{x}_1 + \iota\hat{y})| = |g(\hat{x}_2 + \iota\hat{y})| = 1$. Therefore, the equation $R(\hat{x}, \hat{y}) = |g(\hat{x} + \iota\hat{y})|^2 - 1 = 0$ must have more than one solution $\hat{x} = \hat{x}(\hat{y})$ in the neighborhood of $(0, 0)$.

We now obtain a contradiction by using the implicit function theorem to prove that, in fact, $\hat{x}(\hat{y})$ is a unique solution to $R(\hat{x}, \hat{y}) = 0$ in a small neighborhood of the origin. It is easy to see that

$$g(\hat{x} + \iota\hat{y}) = 1 + \hat{x} + \iota\hat{y} + Q_1(\hat{x}, \hat{y}) + \iota Q_2(\hat{x}, \hat{y}), \tag{3.15}$$

where $Q_1(\hat{x},\hat{y})$ and $Q_2(\hat{x},\hat{y})$ are two real polynomials of the form

$$Q_1(\hat{x},\hat{y}) = \sum_{\substack{l,k\geq 0,\\ l+k\geq 2}} \xi_{l,k}\hat{x}^l\hat{y}^k, \tag{3.16}$$

$$Q_2(\hat{x},\hat{y}) = \sum_{\substack{l,k\geq 0,\\ l+k\geq 2}} \zeta_{l,k}\hat{x}^l\hat{y}^k, \tag{3.17}$$

with real coefficients $\xi_{l,k}$, $\zeta_{l,k}$. Using (3.15)–(3.17), we obtain

$$R(\hat{x},\hat{y}) = (1+\hat{x}+Q_1(\hat{x},\hat{y}))^2 + (\hat{y}+Q_2(\hat{x},\hat{y}))^2 - 1.$$

A simple calculation shows that

$$\frac{\partial R}{\partial \hat{x}}(0,0) = 2 \neq 0.$$

From the implicit function theorem, we know that there is a unique solution $\hat{x} = \hat{x}(\hat{y})$ to $R(\hat{x},\hat{y}) = 0$ in a small neighborhood of the origin, yielding the desired contradiction. ∎

Remark 5. The result of Lemma 3.6 can be generalized to any consistent one-step method with very little modification of the proof.

Remark 6. Because of this result, the prospect that the spectra of the spatially discretized system may contain negative real components is not problematic.

Remark 7. This result is the equivalent of the result of [13] for *local stability*. In particular, the regions of stability described for ERK methods are equivalent.

Using Definition 3.5 and Lemma 3.6, we have the following theorem for first-order ERK methods.

THEOREM 3.7. *There exists a CFL number σ such that the combination of WENO5 with a first-order ERK method is linearly stable for $\Delta t/\Delta x \leq \sigma$ provided the first-order ERK method satisfies*

$$\sum_{1\leq i<j\leq s} b_j a_{ji} > \frac{1}{2}; \tag{3.18}$$

on the other hand, this combination is linearly unstable if

$$\sum_{1\leq i<j\leq s} b_j a_{ji} < \frac{1}{2}.$$

Note 1. When $\sum_{1\leq i<j\leq s} b_j a_{ji} = \frac{1}{2}$, the ERK method is second order. The corresponding results are given in Theorem 3.9.

Proof. We first prove the linearly unstable case. Let $\tau_2 = \sum_{1\leq i<j\leq s} b_j a_{ji}$; i.e., τ_2 is the coefficient of $\hat{z}^2$ in (3.12). For $\phi > 0$ sufficiently small, from (3.11) it is easy to show that

$$\begin{aligned} z^l &= \iota^l\phi^l + \mathcal{O}(\phi^6) + \iota\mathcal{O}(\phi^6) \qquad \text{if } 2\leq l<6,\\ z^l &= \mathcal{O}(\phi^6) \qquad \text{if } l\geq 6. \end{aligned}$$

From (3.12), we obtain

$$\begin{aligned} g(-\sigma z(\phi)) &= 1-\sigma z+\tau_2(\sigma z)^2+\mathcal{O}(z^3)\\ &= \left(1-\tau_2\sigma^2\phi^2+\mathcal{O}(\phi^4)\right) - \iota\left(\sigma\phi+\mathcal{O}(\phi^3)\right). \end{aligned}$$

A simple calculation shows that

$$\begin{aligned}|g|^2 &= \left(1-\tau_2\sigma^2\phi^2+\mathcal{O}(\phi^4)\right)^2+\left(\sigma\phi+\mathcal{O}(\phi^3)\right)^2\\ &= 1+(1-2\tau_2)\sigma^2\phi^2+\mathcal{O}(\phi^4)\\ &> 1,\end{aligned}$$

if $\tau_2 < \frac{1}{2}$. Therefore, the combined method is linearly unstable.

Now let us assume $\tau_2 > \frac{1}{2}$. We first show that the stability domain D_1 of the corresponding ERK intersects the imaginary axis. Later (in Theorem 3.14) we show that, in fact, this is a sufficient condition for linear stability of any ERK method when combined with WENO5. Recall that the stability function of the ERK method is of the form

$$g(\hat{z}) = 1+\hat{z}+\tau_2\,\hat{z}^2+\cdots.$$

Let $\hat{z}=\iota\gamma$, where γ is a small real number. In other words, choose $\hat{z}$ to be close to the origin and on the imaginary axis. It is easy to see

$$\begin{aligned}|g(\iota\gamma)|^2 &= \left(1-\tau_2\gamma^2+\mathcal{O}(\gamma^4)\right)^2+\left(\gamma+\mathcal{O}(\gamma^3)\right)^2\\ &= \left(1-2\tau_2\gamma^2+\mathcal{O}(\gamma^4)\right)+\left(\gamma^2+\mathcal{O}(\gamma^4)\right)\\ &= 1+(1-2\tau_2)\gamma^2+\mathcal{O}(\gamma^4).\end{aligned}$$

Using the condition $\tau_2 > \frac{1}{2}$, we obtain that $|g(\iota\gamma)| < 1$ as $\gamma \to 0+$. That is, there is an intersection of D_1 with the imaginary axis. Assume the intersection is the interval $[-\iota\mu, \iota\mu]$ for some real $\mu > 0$. Then from Lemma 3.6 there exists a rectangle $D_3 = [-\eta, 0]\times[-\hat{\mu},\hat{\mu}] \subseteq D_1$ for some $\eta > 0$, $0 < \hat{\mu} \le \mu$.

It is easy to derive the expression for $\hat{f}^+_{j+\frac{1}{2}}$ from (3.4) and (3.2):

$$\begin{aligned}\hat{f}^+_{j+\frac{1}{2}} = u_j\Bigg[&\left(\frac{2}{60}e^{-2\iota\phi}-\frac{13}{60}e^{-\iota\phi}+\frac{47}{60}+\frac{27}{60}e^{\iota\phi}-\frac{3}{60}e^{2\iota\phi}\right)\\ &+\epsilon_1\left(\frac{2}{6}e^{-2\iota\phi}-\frac{7}{6}e^{-\iota\phi}+\frac{11}{6}\right)\\ &+\epsilon_2\left(-\frac{1}{6}e^{-\iota\phi}+\frac{5}{6}+\frac{2}{6}e^{\iota\phi}\right)+\epsilon_3\left(\frac{2}{6}+\frac{5}{6}e^{\iota\phi}-\frac{1}{6}e^{2\iota\phi}\right)\Bigg].\end{aligned} \tag{3.19}$$

Similarly we obtain the expression for $\hat{f}^+_{j-\frac{1}{2}}$:

$$\begin{aligned}\hat{f}^+_{j-\frac{1}{2}} = u_j\Bigg[&\left(\frac{2}{60}e^{-3\iota\phi}-\frac{13}{60}e^{-2\iota\phi}+\frac{47}{60}e^{-\iota\phi}+\frac{27}{60}-\frac{3}{60}e^{\iota\phi}\right)\\ &+\epsilon_4\left(\frac{2}{6}e^{-3\iota\phi}-\frac{7}{6}e^{-2\iota\phi}+\frac{11}{6}e^{-\iota\phi}\right)\\ &+\epsilon_5\left(-\frac{1}{6}e^{-2\iota\phi}+\frac{5}{6}e^{-\iota\phi}+\frac{2}{6}\right)+\epsilon_6\left(\frac{2}{6}e^{-\iota\phi}+\frac{5}{6}-\frac{1}{6}e^{\iota\phi}\right)\Bigg],\end{aligned} \tag{3.20}$$

where ϵ_4, ϵ_5, and ϵ_6 are all $\mathcal{O}((\Delta x)^2)$, and $\epsilon_4+\epsilon_5+\epsilon_6 = 0$.

Using (3.19), (3.20), and the definition $z(\phi) = \frac{\hat{f}^{+,n}_{j+\frac{1}{2}}-\hat{f}^{+,n}_{j-\frac{1}{2}}}{u^n_j}$, we obtain

$$z(\phi) = \tilde{z} + M(\epsilon_1,\epsilon_2,\ldots,\epsilon_6,\phi), \tag{3.21}$$

where

$$\tilde{z} = -\frac{1}{30}e^{-3\iota\phi} + \frac{1}{4}e^{-2\iota\phi} - e^{-\iota\phi} + \frac{1}{3} + \frac{1}{2}e^{\iota\phi} - \frac{1}{20}e^{2\iota\phi}, \tag{3.22}$$

and

$$\begin{aligned} M(\epsilon_1,\epsilon_2,\ldots,\epsilon_6,\phi) &= \epsilon_1\left(\frac{2}{6}e^{-2\iota\phi} - \frac{7}{6}e^{-\iota\phi} + \frac{11}{6}\right) + \epsilon_2\left(-\frac{1}{6}e^{-\iota\phi} + \frac{5}{6} + \frac{2}{6}e^{\iota\phi}\right) \\ &\quad + \epsilon_3\left(\frac{2}{6} + \frac{5}{6}e^{\iota\phi} - \frac{1}{6}e^{2\iota\phi}\right) - \epsilon_4\left(\frac{2}{6}e^{-3\iota\phi} - \frac{7}{6}e^{-2\iota\phi} + \frac{11}{6}e^{-\iota\phi}\right) \\ &\quad - \epsilon_5\left(-\frac{1}{6}e^{-2\iota\phi} + \frac{5}{6}e^{-\iota\phi} + \frac{2}{6}\right) - \epsilon_6\left(\frac{2}{6}e^{-\iota\phi} + \frac{5}{6} - \frac{1}{6}e^{\iota\phi}\right). \end{aligned} \tag{3.23}$$

We note that M is made up of two pairs of three terms, corresponding to each of the ENO stencils associated with each of the flux terms. We now bound each of the terms that comprise M. Because $\operatorname{Re}\left(\frac{2}{6}e^{-2\iota\phi} - \frac{7}{6}e^{-\iota\phi} + \frac{11}{6}\right) = \frac{2}{6}\cos 2\phi - \frac{7}{6}\cos\phi + \frac{11}{6}$, and $-1 \le \cos\phi \le 1$ for all ϕ, we can write

$$\frac{1}{3} \le \operatorname{Re}\left(\frac{2}{6}e^{-2\iota\phi} - \frac{7}{6}e^{-\iota\phi} + \frac{11}{6}\right) \le \frac{10}{3}.$$

(In fact, the lower bound can be tightened to 95/96, but the proof is not sensitive to this value.)

Thus

$$\operatorname{Re}\left|\epsilon_1\left(\frac{2}{6}e^{-2\iota\phi} - \frac{7}{6}e^{-\iota\phi} + \frac{11}{6}\right)\right| \le \frac{10}{3}\left|\epsilon_1\right|.$$

Similarly we can bound the remaining terms of $M(\epsilon_1,\epsilon_2,\ldots,\epsilon_6,\phi)$. Finally we can obtain an expression of the form

$$\left|\operatorname{Re} M(\epsilon_1,\epsilon_2,\ldots,\epsilon_6,\phi)\right| \le \Gamma_1 \max_{1\le m\le 6}\left|\epsilon_m\right|, \tag{3.24}$$

where Γ_1 is a positive constant that is determined by the stencils. Applying the same analysis, we can write

$$\left|\operatorname{Im} M(\epsilon_1,\epsilon_2,\ldots,\epsilon_6,\phi)\right| \le \Gamma_2 \max_{1\le m\le 6}\left|\epsilon_m\right|, \tag{3.25}$$

where Γ_2 is a positive constant that is determined by the stencils.

We now examine the real and imaginary parts of $\tilde{z}$:

$$\begin{aligned} \operatorname{Re}\tilde{z} &= -\frac{1}{30}\cos 3\phi + \frac{1}{5}\cos 2\phi - \frac{1}{2}\cos\phi + \frac{1}{3} \\ &= -\frac{1}{30}\left(4\cos^3\phi - 3\cos\phi\right) + \frac{1}{5}\left(2\cos^2\phi - 1\right) - \frac{1}{2}\cos\phi + \frac{1}{3} \\ &= \frac{2}{15}(1-\cos\phi)^3; \end{aligned} \tag{3.26}$$

$$\operatorname{Im}\ \tilde{z} = \frac{1}{30}\sin 3\phi - \frac{3}{10}\sin 2\phi + \frac{3}{2}\sin\phi. \tag{3.27}$$

Let $D_4 = [-\frac{31}{15}, 0] \times [-\frac{17}{6}, \frac{17}{6}]$, and let $\sigma_0 > 0$ be such that the rectangle $\sigma_0 D_4 \subseteq D_3 = [-\eta, 0] \times [-\hat{\mu}, \hat{\mu}]$ defined previously. We now use D_3 and D_4 to prove that

$\sigma_0 D_2 \subseteq D_1$; i.e., the combination of an s-stage, first-order ERK method where $\tau_2 > \frac{1}{2}$ with WENO5 is linearly stable if $\frac{\Delta t}{\Delta x} \leq \sigma_0$. (Note that σ_0 may not be the same as the CFL number σ; in fact, we know only that $0 < \sigma_0 \leq \sigma$. However, this proves the existence of $\sigma > 0$.)

Using a similar analysis to the first part of this theorem, we conclude that, given σ_0, we can choose ϕ small enough such that $|g| < 1$. In other words, $\exists\, \alpha > 0$, such that the scaled domain $\{-\sigma_0 z(\phi) : 0 \leq \phi \leq \alpha \text{ or } 2\pi - \alpha \leq \phi \leq 2\pi\} \subseteq D_1$. We now complete the proof by showing that $D_5 = \{-\sigma_0 z(\phi) : \alpha \leq \phi \leq 2\pi - \alpha\} \subseteq D_1$.

Using (3.24) and (3.26), we obtain

$$\frac{2}{15}(1-\cos\phi)^3 - \Gamma_1 \max_{1\leq m\leq 6} |\epsilon_m| \leq \operatorname{Re} z(\phi) \leq \frac{2}{15}(1-\cos\phi)^3 + \Gamma_1 \max_{1\leq m\leq 6} |\epsilon_m|.$$

Because $\alpha \leq \phi \leq 2\pi - \alpha$, we see

$$\frac{2}{15}(1-\cos\alpha)^3 - \Gamma_1 \max_{1\leq m\leq 6} |\epsilon_m| \leq \operatorname{Re} z(\phi) \leq \frac{16}{15} + \Gamma_1 \max_{1\leq m\leq 6} |\epsilon_m|.$$

Note the ϵ_m, $m = 1, 2, \ldots, 6$, are $\mathcal{O}((\Delta x)^2)$, and Γ_1 is a constant. We can choose Δx small enough such that $\Gamma_1 \max_{1\leq m\leq 6} |\epsilon_m| \leq \min\left(\frac{2}{15}(1-\cos\alpha)^3, 1\right)$. Therefore,

$$0 \leq \operatorname{Re} z(\phi) \leq \frac{16}{15} + 1 = \frac{31}{15}. \tag{3.28}$$

From (3.27), using the fact that $-1 \leq \sin\phi \leq 1$ for all ϕ, we see that $-\frac{11}{6} \leq \operatorname{Im} \tilde{z} \leq \frac{11}{6}$. Again, we can choose Δx small enough such that $\Gamma_2 \max_{1\leq m\leq 6} |\epsilon_m| \leq 1$. Using (3.25) and (3.27), we have

$$-\frac{17}{6} = -\frac{11}{6} - 1 \leq \operatorname{Im} z(\phi) \leq \frac{11}{6} + 1 = \frac{17}{6}. \tag{3.29}$$

From (3.28) and (3.29), we conclude that $D_5 \subseteq D_4$. Because $\sigma_0 D_4 \subseteq D_3 = [-\eta, 0] \times [-\hat{\mu}, \hat{\mu}]$, and $D_3 \subseteq D_1$, we conclude that $\sigma_0 D_5 \subseteq D_1$.

This completes the proof. ∎

COROLLARY 3.8. *The combination of WENO5 and any optimal, s-stage, first-order SSP ERK method as in* [21] *is linearly unstable.*

Proof. The Butcher tableau of the optimal, s-stage, first-order SSP ERK method is of the form shown in Table 3.2.

The corresponding stability function is

$$\left(1 + \frac{1}{s}\hat{z}\right)^s = 1 + \hat{z} + \frac{s-1}{2s}\hat{z}^2 + \cdots.$$

Because $\frac{s-1}{2s} < \frac{1}{2}$ for all $s \geq 1$, linear instability follows from Theorem 3.7. ∎

TABLE 3.2
Butcher tableau for optimal s-stage, order-1 SSP ERK methods.

0						
$\frac{1}{s}$	$\frac{1}{s}$					
$\frac{2}{s}$	$\frac{1}{s}$	$\frac{1}{s}$				
$\frac{3}{s}$	$\frac{1}{s}$	$\frac{1}{s}$	$\frac{1}{s}$			
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$		
$\frac{s-1}{s}$	$\frac{1}{s}$	$\frac{1}{s}$	$\frac{1}{s}$	$\cdots$	$\frac{1}{s}$	
	$\frac{1}{s}$	$\frac{1}{s}$	$\frac{1}{s}$	$\cdots$	$\frac{1}{s}$	$\frac{1}{s}$

Using the same analysis of Theorem 3.7, we obtain the following theorem for s-stage, second-order order ERK methods.

THEOREM 3.9. *Assume the ERK method is at least second order. Its stability function is of the form*

$$1 + \hat{z} + \frac{1}{2}\hat{z}^2 + \tau_3\hat{z}^3 + \tau_4\hat{z}^4 + \tau_5\hat{z}^5 + \tau_6\hat{z}^6 + \cdots . \tag{3.30}$$

Then there exists a CFL number σ such that the combination of this ERK method and WENO5 is linearly stable for $\Delta t/\Delta x \le \sigma$ if the ERK method satisfies

$$\tau_3 - \tau_4 > \frac{1}{8}; \tag{3.31}$$

on the other hand, the combination is linearly unstable if

$$\tau_3 - \tau_4 < \frac{1}{8}.$$

Proof. First we note that (3.30) is the amplification factor g if $\hat{z} = -\sigma z$. Now choosing ϕ to be a small positive number, we use (3.11) and have

$$\begin{aligned}
z &= \left(\frac{7}{60}\phi^6 + \mathcal{O}(\phi^8)\right) + \iota\ \left(\phi + \mathcal{O}(\phi^7)\right),\\
z^2 &= \left(-\phi^2 + \mathcal{O}(\phi^8)\right) + \iota\ \mathcal{O}(\phi^7),\\
z^3 &= \mathcal{O}(\phi^8) + \iota\ \left(-\phi^3 + \mathcal{O}(\phi^9)\right),\\
z^4 &= \left(\phi^4 + \mathcal{O}(\phi^{10})\right) + \iota\ \mathcal{O}(\phi^9),\\
z^5 &= \mathcal{O}(\phi^{10}) + \iota\ \left(\phi^5 + \mathcal{O}(\phi^{11})\right),\\
z^6 &= \left(-\phi^6 + \mathcal{O}(\phi^{12})\right) + \iota\ \mathcal{O}(\phi^{11}),
\end{aligned}$$

and $z^l = \mathcal{O}(\phi^7)$, $l \ge 7$. We now calculate $|g|^2$:

$$\begin{aligned}
|g|^2 &= \left(1 - \frac{1}{2}\sigma^2\phi^2 + \tau_4\sigma^4\phi^4 - \frac{7}{60}\sigma\phi^6 - \tau_6\sigma^6\phi^6 + \mathcal{O}(\phi^8)\right)^2\\
&\quad + \left(-\sigma\phi + \tau_3\sigma^3\phi^3 - \tau_5\sigma^5\phi^5 + \mathcal{O}(\phi^7)\right)^2\\
&= \left(1 - \sigma^2\phi^2 + \left(\frac{1}{4} + 2\tau_4\right)\sigma^4\phi^4 - \frac{7}{30}\sigma\phi^6 - \left(\tau_4 + 2\tau_6\right)\sigma^6\phi^6 + \mathcal{O}(\phi^8)\right)\\
&\quad + \left(\sigma^2\phi^2 - 2\tau_3\sigma^4\phi^4 + \left(\tau_3^2 + 2\tau_5\right)\sigma^6\phi^6 + \mathcal{O}(\phi^8)\right)\\
&= 1 + \left(\frac{1}{4} + 2\tau_4 - 2\tau_3\right)\sigma^4\phi^4 + \left(-\frac{7}{30}\sigma + \left(\tau_3^2 + 2\tau_5 - \tau_4 - 2\tau_6\right)\sigma^6\right)\phi^6 + \mathcal{O}(\phi^8).
\end{aligned} \tag{3.32}$$

If $(\frac{1}{4} + 2\tau_4 - 2\tau_3) > 0$, i.e., $\tau_3 - \tau_4 < \frac{1}{8}$, we have $|g| > 1$ as $\phi \to 0+$. Therefore, in this case the combination is linearly unstable.

However, if $(\frac{1}{4} + 2\tau_4 - 2\tau_3) < 0$, i.e., $\tau_3 - \tau_4 > \frac{1}{8}$, we have $|g| < 1$ as $\phi \to 0^+$. Moreover, there is an intersection between the stability domain of the ERK method and the imaginary axis. The rest of the proof of stability is similar to that of Theorem 3.7. ∎

COROLLARY 3.10. *The combination of WENO5 with any optimal s-stage, second-order SSP ERK method as in* [21] *is linearly unstable.*

TABLE 3.3
Butcher tableau for optimal s-stage, second-order SSP ERK methods.

0						
$\frac{1}{s-1}$	$\frac{1}{s-1}$					
$\frac{2}{s-1}$	$\frac{1}{s-1}$	$\frac{1}{s-1}$				
$\frac{3}{s-1}$	$\frac{1}{s-1}$	$\frac{1}{s-1}$	$\frac{1}{s-1}$			
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\ddots$		
$\frac{s-1}{s-1}$	$\frac{1}{s-1}$	$\frac{1}{s-1}$	$\frac{1}{s-1}$	$\cdots$	$\frac{1}{s-1}$	
	$\frac{1}{s}$	$\frac{1}{s}$	$\frac{1}{s}$	$\cdots$	$\frac{1}{s}$	$\frac{1}{s}$

Proof. The Butcher tableau of the optimal s-stage, second-order SSP ERK method is of the form given in Table 3.3.

The corresponding stability function is

$$\frac{1}{s}+\frac{s-1}{s}\left(1+\frac{1}{s-1}\hat{z}\right)^s=1+\hat{z}+\frac{1}{2}\hat{z}^2+\frac{s-2}{6(s-1)}\hat{z}^3+\frac{(s-2)(s-3)}{24(s-1)^2}\hat{z}^4+\cdots.$$

Because $\tau_3-\tau_4=\frac{s(s-2)}{(s-1)^2}(\frac{1}{8}-\frac{1}{24s})<\frac{1}{8}$, the linear instability follows from Theorem 3.9. ∎

Note that the stability function of any three-stage, third-order ERK method is $1+\hat{z}+\frac{1}{2}\hat{z}^2+\frac{1}{6}\hat{z}^3$. Because $\tau_3-\tau_4=\frac{1}{6}>\frac{1}{8}$, *the combination of WENO5 and any three-stage, third-order ERK method is linearly stable.* Furthermore, we have the following theorem for s-stage, third-order ERK methods.

THEOREM 3.11. *Assume the ERK method is third order. Its stability function is of the form*

$$1+\hat{z}+\frac{1}{2}\hat{z}^2+\frac{1}{6}\hat{z}^3+\tau_4\hat{z}^4+\cdots.$$

Then there exists a CFL number σ such that the combination of WENO5 and the ERK method is linearly stable for $\Delta t/\Delta x\le\sigma$ if the ERK method satisfies

$$\tau_4<\frac{1}{24}; \tag{3.33}$$

on the other hand, the combination is linearly unstable if

$$\tau_4>\frac{1}{24}.$$

When $\tau_4=\frac{1}{24}$, the ERK method has the same linear stability as the fourth-order ERK methods. The corresponding results are given in Theorem 3.12.

Proof. The proof is similar to that of Theorem 3.9. ∎

Note that, if the ERK method is at least fourth order, we have $\tau_3-\tau_4=\frac{1}{8}$. From (3.32), we obtain the following.

THEOREM 3.12. *Assume that the ERK method is at least order* 4. *Its stability function is of the form*

$$1+\hat{z}+\frac{1}{2}\hat{z}^2+\frac{1}{6}\hat{z}^3+\frac{1}{24}\hat{z}^4+\tau_5\hat{z}^5+\tau_6\hat{z}^6+\cdots.$$

Then there exists a CFL number σ such that the combination of the ERK method and WENO5 is linearly stable for $\Delta t/\Delta x\le\sigma$ if the ERK method satisfies

$$\tau_5-\tau_6<\frac{1}{144}.$$

Proof. From (3.32) we conclude that $-\frac{7}{30}\sigma + \left(\tau_3^2 + 2\tau_5 - \tau_4 - 2\tau_6\right)\sigma^6 < 0$ for σ sufficiently small. Therefore, $|g|^2 < 1$ for ϕ sufficiently small and positive. In other words, $\exists\, \sigma_0, \alpha > 0$, such that the scaled domain $\{-\sigma_0 z(\phi) : 0 \le \phi \le \alpha \text{ or } 2\pi - \alpha \le \phi \le 2\pi\}$ is inside the stability domain D_1 of the ERK method.

The stability function of the ERK method is now of the form

$$g(\hat{z}) = 1 + \hat{z} + \frac{1}{2}\hat{z}^2 + \frac{1}{6}\hat{z}^3 + \frac{1}{24}\hat{z}^4 + \tau_5\hat{z}^5 + \tau_6\hat{z}^6 + \cdots.$$

Let $\hat{z} = \iota\gamma$, where γ is a small real number. In other words, choose $\hat{z}$ to be close to the origin and on the imaginary axis. It is easy to see

$$|g|^2 = 1 + 2\left(\tau_5 - \tau_6 - \frac{1}{144}\right)\gamma^6 + \mathcal{O}(\gamma^8).$$

Using the condition $\tau_5 - \tau_6 < \frac{1}{144}$, we obtain that $|g(\iota\gamma)| < 1$ as $\gamma \to 0+$. In other words, there is an intersection between the stability domain D_1 of the ERK method and the imaginary axis if $\tau_5 - \tau_6 < \frac{1}{144}$. The rest of the proof is similar to the proof of linear stability for second-order ERK methods from Theorem 3.9. ∎

From Theorem 3.12, we see that $\tau_5 = \tau_6 = 0$ for the classical four-stage, fourth-order ERK method. Therefore, its combination with WENO5 is linearly stable.

Remark 8. There is no corresponding result for linear instability as in Theorem 3.9 if the ERK method is fourth order. This is because, regardless of the values of τ_5 and τ_6, $|g|^2 < 1$ whenever ϕ is a small positive number, and σ is sufficiently small. On the other hand, if the stability domain D_1 of the ERK method does not intersect the imaginary axis (i.e., $\tau_5 - \tau_6 > \frac{1}{144}$), linear instability cannot be proved as in Theorem 3.9.

Following immediately from Theorem 3.12 with $\tau_5 = \frac{1}{120}$, we have the following theorem for s-stage, fifth-order ERK methods.

THEOREM 3.13. *Assume that the ERK method is at least order* 5. *Its stability function is of the form*

$$1 + \hat{z} + \frac{1}{2}\hat{z}^2 + \frac{1}{6}\hat{z}^3 + \frac{1}{24}\hat{z}^4 + \frac{1}{120}\hat{z}^5 + \tau_6\hat{z}^6 + \cdots.$$

*Then there exists a CFL number σ such that the combination of the ERK method and WENO*5 *is linearly stable for $\Delta t/\Delta x \le \sigma$ if the ERK method satisfies*

$$\tau_6 > \frac{1}{720}.$$

Finally we have the more general result for s-stage, order-$p \ge 4$ ERK methods as follows.

THEOREM 3.14. *Assume that the ERK method is at least order $p \ge 4$. Its stability function is of the form*

$$1 + \hat{z} + \frac{1}{2}\hat{z}^2 + \frac{1}{6}\hat{z}^3 + \frac{1}{24}\hat{z}^4 + \cdots.$$

*Then there exists a CFL number σ such that the combination of the ERK method and WENO*5 *is linearly stable for $\Delta t/\Delta x \le \sigma$ if the stability domain of the ERK method includes the part of the imaginary axis of the form $[-\iota\mu, \iota\mu]$ for some $\mu > 0$.*

The proof is similar that of Theorem 3.12.

Remark 9. We note that the presence of an intersection of the stability domain of an ERK method with the imaginary axis of the form $[-\iota\mu, \iota\mu]$ for some $\mu > 0$ has been used to prove stability of s-stage methods of orders 1, 2, and 3 already. Combining this with the result in Theorem 3.14 allows us to conclude that the intersection of the stability domain with the imaginary axis in the form $[-\iota\mu, \iota\mu]$ for some $\mu > 0$ is a sufficient condition for linear stability of any ERK method when coupled with WENO5.

4. Numerical results. In this section, we study two classical scalar hyperbolic conservation laws: the (linear) advection equation and the (nonlinear) inviscid Burgers equation. In both cases, the problems are posed in one dimension, and WENO5 is employed as the spatial discretization. We use a uniform mesh with N spatial subintervals. Both SSP and non-SSP ERK time integration methods are considered. We illustrate the linear instability of some well-known first- and second-order SSP ERK methods by plotting the solution at a given time T_{out} with a specified Courant number $\sigma = \frac{\Delta t}{\Delta x}$. Extensive numerical tests have shown that smaller values of σ require larger values of T_{out} for the effect of the instability to clearly manifest itself.

4.1. ERK methods. In order to illustrate our theory, we consider the following four well-known ERK methods. Under appropriate assumptions, these methods can be SSP. The first three are linearly unstable when coupled with WENO5 and are used to solve hyperbolic conservation laws; the fourth is arguably the most widely used time integration method used with WENO spatial discretizations.

(1) The forward Euler (FE) method.

(2) The optimal two-stage, second-order SSP ERK method (which we call SSP(2,2)) with Butcher tableau (cf. Table 3.1)

$$\begin{array}{c|cc} 0 & 0 & 0 \\ 1 & 1 & 0 \\ \hline & \frac{1}{2} & \frac{1}{2} \end{array}.$$

(3) The optimal three-stage, second-order SSP ERK method [21] (which we call SSP(3,2)) with Butcher tableau

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \frac{1}{2} & \frac{1}{2} & 0 & 0 \\ 1 & \frac{1}{2} & \frac{1}{2} & 0 \\ \hline & \frac{1}{3} & \frac{1}{3} & \frac{1}{3} \end{array}.$$

(4) The (optimal) three-stage, third-order SSP ERK method, SSP(3,3) [3, 21], with Butcher tableau

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ 1 & 1 & 0 & 0 \\ \frac{1}{2} & \frac{1}{4} & \frac{1}{4} & 0 \\ \hline & \frac{1}{6} & \frac{1}{6} & \frac{2}{3} \end{array}.$$

We also consider four ERK methods that are linearly stable according to our analysis when coupled with WENO5. These methods are provably not SSP for any time step $\Delta t > 0$. Stated differently, these methods have a radius of contractivity of 0 (see, e.g., [12]); this fact is obvious because each method has a 0 in its $\mathbf{b}$ vector (or *quadrature weights*) of the Butcher tableau.

(5) A two-stage, order-1 non-SSP ERK method (which we call NSSP(2,1)) with Butcher tableau

$$\begin{array}{c|cc} 0 & 0 & 0 \\ \frac{3}{4} & \frac{3}{4} & 0 \\ \hline & 0 & 1 \end{array}.$$

Because $b_2 a_{21} = \frac{3}{4}$, it is a stable ERK method for WENO5 according to Theorem 3.7. Its CFL number can be directly estimated to be $\sigma = 0.80$; see, e.g., [9, p. 150].

(6) A three-stage, second-order non-SSP ERK method (which we call NSSP(3,2)) with Butcher tableau

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ \frac{1}{3} & \frac{1}{3} & 0 & 0 \\ 1 & 0 & 1 & 0 \\ \hline & \frac{1}{2} & 0 & \frac{1}{2} \end{array}.$$

It is easy to show that the linear stability function (and hence the amplification factor) of this ERK method is the same as SSP(3,3) and indeed all three-stage, third-order ERK methods. According to our analysis, it has the same linear stability properties, and in particular CFL number $\sigma = 1.43$, as SSP(3,3); see [11].

(7) A three-stage, third-order non-SSP ERK method (which we call NSSP(3,3)) with Butcher tableau

$$\begin{array}{c|ccc} 0 & 0 & 0 & 0 \\ -\frac{4}{9} & -\frac{4}{9} & 0 & 0 \\ \frac{2}{3} & \frac{7}{6} & -\frac{1}{2} & 0 \\ \hline & \frac{1}{4} & 0 & \frac{3}{4} \end{array}.$$

This method has negative coefficients. It is sometimes necessary to specially treat right-hand side function evaluations $\hat{f}(u)$ that correspond to negative coefficients, e.g., by downwinding [18, 17]. However, according to our analysis, the linear stability properties of NSSP(3,3) are identical to SSP(3,3) (and all other three-stage, third-order ERK methods). We show that, even for a nonlinear problem (Example 2), it has the same stability performance as SSP(3,3).

(8) A five-stage, third-order non-SSP ERK method (which we call NSSP(5,3)) with Butcher tableau

$$\begin{array}{c|ccccc} 0 & 0 & 0 & 0 & 0 & 0 \\ \frac{1}{7} & \frac{1}{7} & 0 & 0 & 0 & 0 \\ \frac{3}{16} & 0 & \frac{3}{16} & 0 & 0 & 0 \\ \frac{1}{3} & 0 & 0 & \frac{1}{3} & 0 & 0 \\ \frac{2}{3} & 0 & 0 & 0 & \frac{2}{3} & 0 \\ \hline & \frac{1}{4} & 0 & 0 & 0 & \frac{3}{4} \end{array}.$$

This is a new, low-storage ERK method, whose stability function is $1 + \hat{z} + \frac{1}{2}\hat{z}^2 + \frac{1}{6}\hat{z}^3 + \frac{1}{32}\hat{z}^4 + \frac{1}{224}\hat{z}^5$. It is a linearly stable ERK method for WENO5 according to Theorem 3.11. Its CFL number can be directly estimated to be

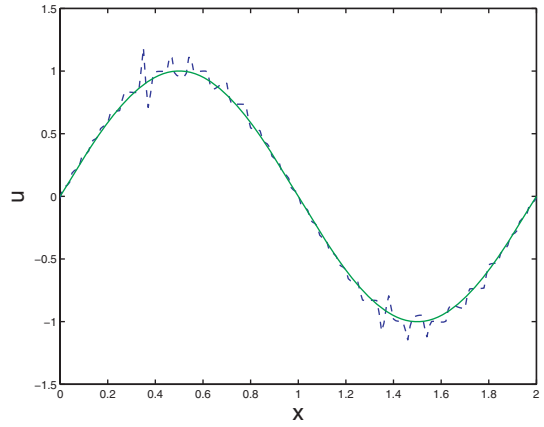

FIG. 3. *FE for* $u(x,0) = \sin(\pi x)$.

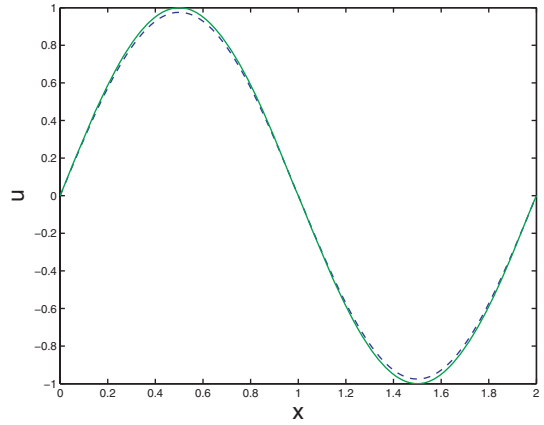

FIG. 4. *NSSP*(2,1) *for* $u(x,0) = \sin(\pi x)$.

$\sigma = 2.56$. Defining the effective CFL number to be $\frac{\sigma}{s}$, it is easy to see that a larger effective CFL number leads to more efficient time integration. The effective CFL number is 0.512 for NSSP(5,3), which is larger than 0.477 for SSP(3,3). We choose this scheme to illustrate that the theoretical principles described in this paper give us the ability to develop more efficient schemes than the popular SSP(3,3). We report on the results for the optimal ERK schemes for WENO5 elsewhere.

Example 1. The first example is the linear advection equation

$$u_t + u_x = 0, \qquad 0 < x < 2,\ t > 0,$$

with periodic boundary conditions. We consider three different initial conditions: (a) the smooth initial condition $u(x,0) = \sin(\pi x)$, (b) the smooth but more spatially varying initial condition $u(x,0) = \sin^9(\pi x)$, and (c) the discontinuous initial condition

$$u(x,0) = \begin{cases} 1 & \text{if } 0 < x < 0.5 \text{ or } 1.5 < x < 2, \\ 0 & \text{if } 0.5 \le x \le 1.5. \end{cases} \tag{4.1}$$

(a) Figures 3 and 4 show the performance of FE and NSSP(2,1) for the problem with the smooth initial condition $u(x,0) = \sin(\pi x)$. The solid lines in the figures are the

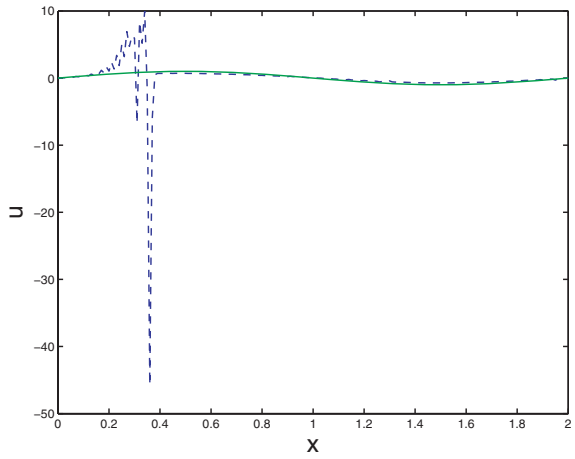

FIG. 5. *SSP*(2,2) *for* $u(x,0) = \sin(\pi x)$ *at* $T_{out} = 16$.

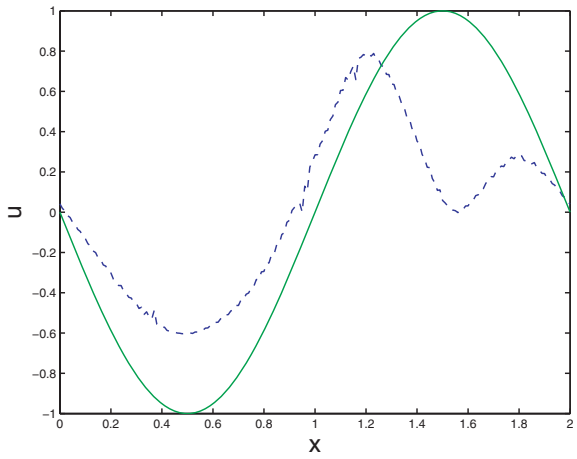

FIG. 6. *SSP*(2,2) *for* $u(x,0) = \sin(\pi x)$ *at* $T_{out} = 25$.

exact solutions, and the dashed lines are the computed solutions. Both solutions are computed with $N = 200$, $\sigma = 0.5$, and they are plotted at $T_{out} = 2$.

As expected, spurious oscillations due to linear instability are present when the FE method is used, whereas there is no instability exhibited for NSSP(2,1). Although we show only the numerical result for $\sigma = 0.5$, we emphasize that *the linear instability of the FE method appears for every* $\sigma > 0$*, no matter how small*. We observe the linear instability of the FE method for any of the later problems, whereas NSSP(2,1) is stable when $\sigma \leq 0.8$, which agrees with our expectation. However, the dissipation of NSSP(2,1) is very strong; this makes it unsuitable for computation in practice.

We now show an example of the nonconvergence effect of linear instability. Figures 5 and 6 show the result of the numerical integration using WENO5 coupled with SSP(2,2) at two different output times. The solutions are computed with $N = 200$ and $\sigma = 1.32$. Figure 5 gives the solution at $T_{out} = 16$, while Figure 6 gives it at $T_{out} = 25$. We note that oscillations are generated almost immediately at the start of the integration. By $T_{out} = 16$, Figure 5 shows significant oscillation. However, the

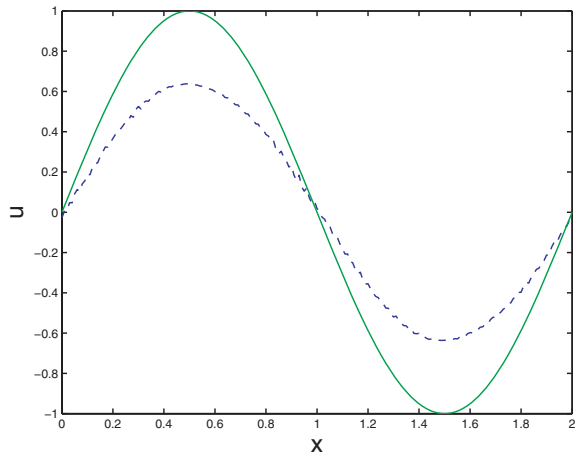

FIG. 7. *SSP*(3,3) *with* $\sigma = 1.5$ *for* $u(x,0) = \sin(\pi x)$.

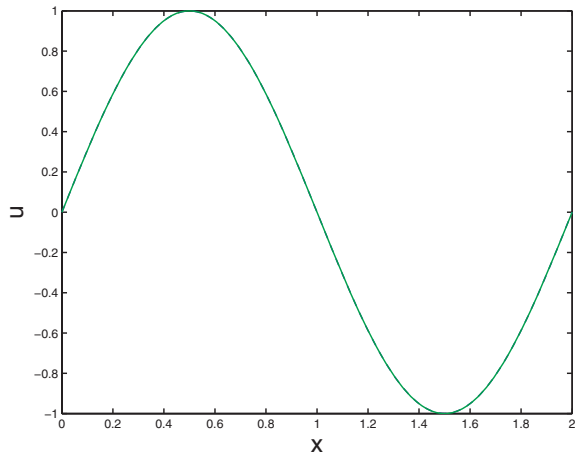

FIG. 8. *NSSP*(5,3) *with* $\sigma = 2.5$ *for* $u(x,0) = \sin(\pi x)$.

solution does not become unbounded, as can be seen in Figure 6 for $T_{out} = 25$; i.e., WENO5 has successfully adapted to the oscillations, not allowing them to become unbounded. However, with $N = 1000$ and the same σ, the solution quickly becomes unbounded. In other words, the spurious oscillations confirm the linear instability, but due to the nonlinear nature of WENO5, the numerical solution does not necessarily become unbounded. However, we point out that the linear instability of the combined method precludes convergence to the true solution; *i.e., irrespective of the long-term boundedness, the error of the numerical solution in such cases can at best be expected to be* $\mathcal{O}(1)$.

We now compare the performance of SSP(3,3) and NSSP(5,3). Figure 7 shows the performance of SSP(3,3) with $\sigma = 1.5$ for the problem just described, while Figure 8 shows the performance of NSSP(5,3) with $\sigma = 2.5$. The solid lines in the figures are the exact solutions, and the dashed lines are the computed solutions. Both solutions are computed with $N = 200$ and plotted at $T_{out} = 30$. We choose the two CFL numbers to make the computational costs equal for both experiments. Note that

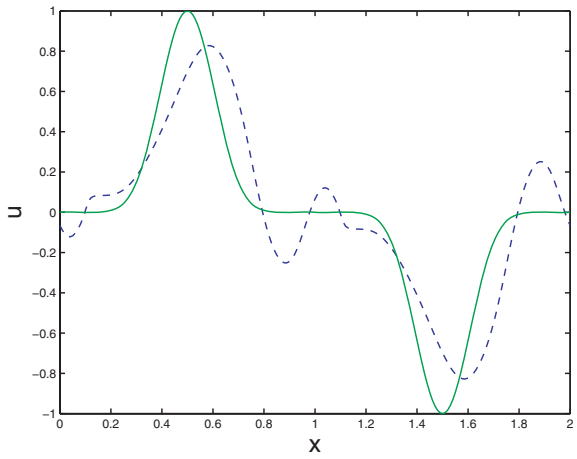

FIG. 9. *SSP*(2,2) *for* $u(x,0) = \sin^9(\pi x)$.

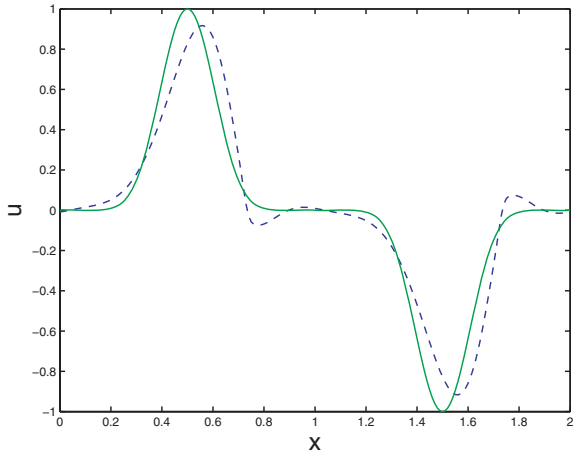

FIG. 10. *SSP*(3,2) *for* $u(x,0) = \sin^9(\pi x)$.

the difference between the computed solution by NSSP(5,3) and the exact solution is negligible. On the other hand, spurious oscillations appear for SSP(3,3) because it is linearly stable only for CFL numbers less than about 1.43. Once again we note that the solution does not become unbounded. Another interesting observation is that, when we choose $\sigma = 1.4$ for SSP(3,3), the difference between the computed solution and the exact solution is also negligible. This means that the solution by SSP(3,3) with $\sigma = 1.5$ is inaccurate due only to linear instability. The experiment clearly favors NSSP(5,3) for its larger effective CFL number.

Our experiments show that when SSP(2,2) and SSP(3,2) are used for the above problem with a small value for σ, the instability requires a long time to develop. In many cases the oscillations are not conspicuous in a relatively short time.

(b) We can introduce more spatial difficulty by using $u(x,0) = \sin^9(\pi x)$. Figures 9–12 show the performance of SSP(2,2), SSP(3,2), NSSP(3,2), and NSSP(3,3), respectively. The solid lines in the figures are the exact solutions, and the dashed lines are the computed solutions. All solutions are computed with $N = 200$, $\sigma = 0.5$, and they are plotted at $T_{out} = 150$.

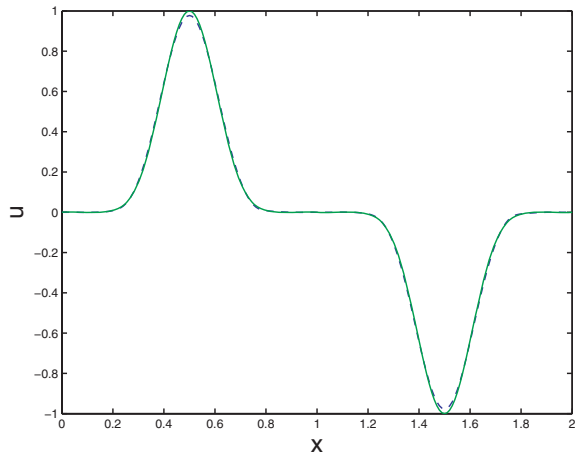

FIG. 11. *NSSP*(3,2) *for* $u(x,0) = \sin^9(\pi x)$.

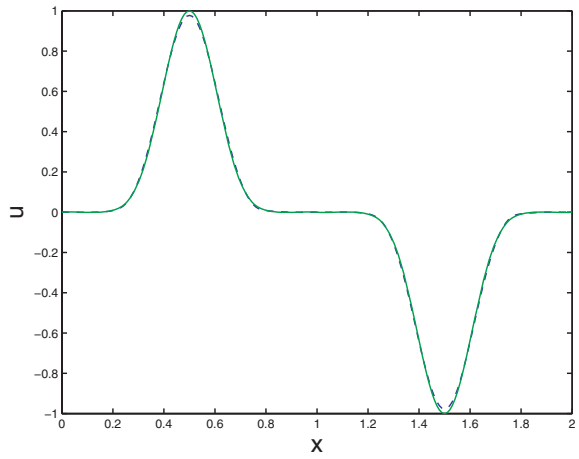

FIG. 12. *NSSP*(3,3) *for* $u(x,0) = \sin^9(\pi x)$.

The linear instability of WENO5 coupled with SSP(2,2) or SSP(3,2) takes a long time to become conspicuous for this problem, whereas NSSP(3,2) and NSSP(3,3) are stable. Moreover, smaller values of σ tend to delay the manifestation of the instability even further. We also observe that the linear instability of the combination of WENO5 and SSP(3,2) develops more slowly than that of WENO5 and SSP(2,2). This can be explained by the fact that the classical (linear) stability domain of SSP(3,2) includes the classical stability domain of SSP(2,2).

(c) The final initial condition is the step function (4.1). As we know, WENO5 is widely used in the numerical simulations of discontinuous solutions of hyperbolic PDEs. If the solution has only a few discontinuities and the wave speed is not zero, i.e., there is no stationary shock, the WENO5 stencil weights at any given point are the same as for the continuous case (3.2) for the majority of the time. That is, only the points close to the discontinuity use different discretizations because some stencil weights approach zero. However, the discretization at these points returns to those of the continuous case after the discontinuity passes through. Therefore, we

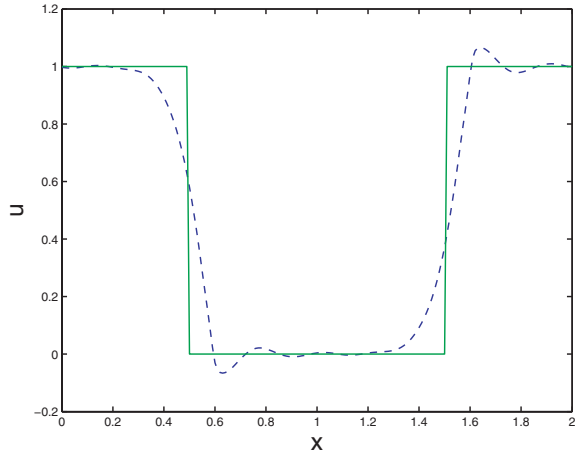

FIG. 13. *SSP*(2,2) *for* (4.1).

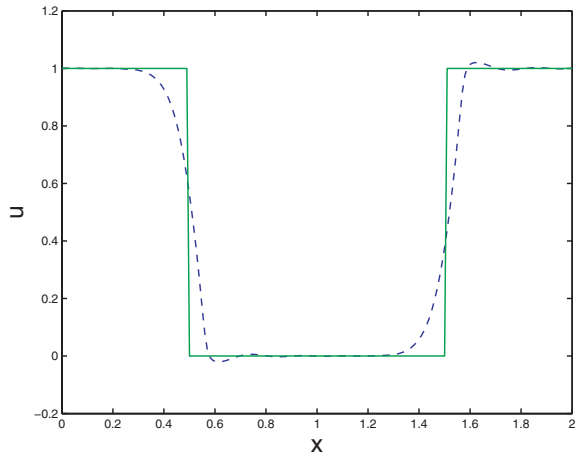

FIG. 14. *SSP*(3,2) *for* (4.1).

expect that our analysis for the continuous case is also relevant to such discontinuous problems. Figures 13–16 show the performance of SSP(2,2), SSP(3,2), NSSP(3,2), and NSSP(3,3), respectively, for the discontinuous initial condition (4.1). The solid lines in the figures are the exact solutions, and the dashed lines are the computed solutions. All solutions are computed with $N = 200$, $\sigma = 0.5$, and they are plotted at $T_{out} = 50$.

We again make the observation that NSSP(3,2) and NSSP(3,3) are stable, whereas SSP(2,2) and SSP(3,2) exhibit oscillations.

We now compare SSP(3,3) with NSSP(5,3) for the discontinuous initial condition (4.1). Figures 17 and 18 show the performance of SSP(3,3) with $\sigma = 1.11$ and NSSP(5,3) with $\sigma = 1.85$. We choose the two CFL numbers to make the computational costs equal for both experiments. The solid lines in the figures are the exact solutions, and the dashed lines are the computed solutions. All solutions are computed with $N = 200$, and they are plotted at $T_{out} = 10$. Spurious oscillations appear when we use SSP(3,3) with $\sigma = 1.11$, whereas there is no problem with NSSP(5,3) with

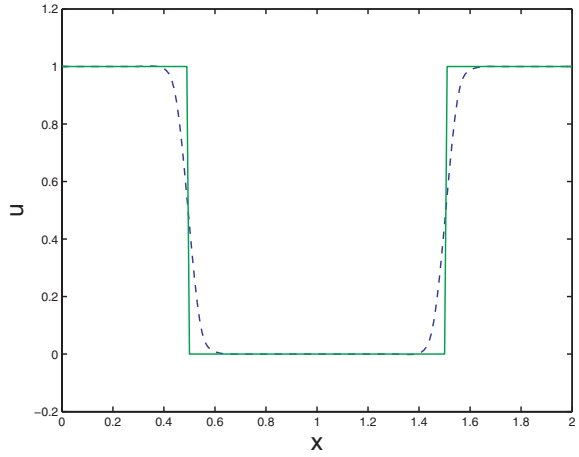

FIG. 15. *NSSP*(3,2) *for* (4.1).

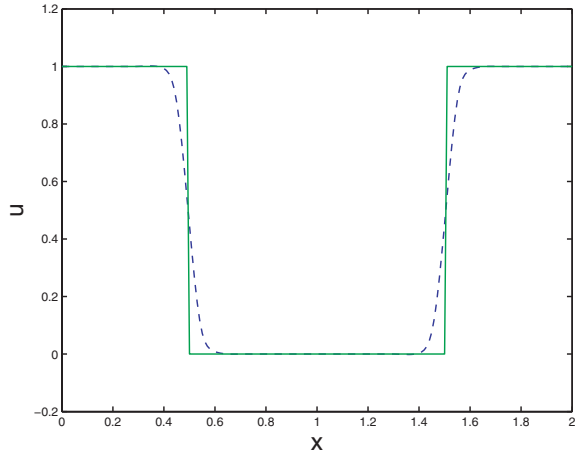

FIG. 16. *NSSP*(3,3) *for* (4.1).

$\sigma = 1.85$. These numerical experiments show that WENO5 coupled with SSP(3,3) is stable when $\sigma \leq 1$ for the discontinuous initial condition (4.1), whereas NSSP(5,3) is stable when $\sigma \leq 1.9$. This example shows that larger time steps can be used with NSSP(5,3) than with SSP(3,3) even when the solutions have discontinuities.

Example 2. The second example is the inviscid Burgers equation

$$u_t + \left(\frac{u^2}{2}\right)_x = 0, \qquad 0 < x < 2,\ t > 0,$$

with periodic boundary conditions and the initial condition $u(x,0) = 2 + \sin^9(\pi x)$. This is a nonlinear problem with $f(u) = u^2/2$. Thus $\partial f/\partial u = u$. For a given σ, Δt is chosen as $\Delta t = \sigma \Delta x(\max_j u_j)$. Figures 19–22 show the performance of SSP(2,2), SSP(3,2), NSSP(3,2), and NSSP(3,3), respectively. The solid lines in the figures represent the reference solution, which is generated using WENO5 with SSP(3,3), $N = 1000$, and $\sigma = 0.5$. The dashed lines are the computed solutions, all of which have $N = 100$, $\sigma = 0.5$, and they are plotted at $T_{out} = 40$. Again we see that NSSP(3,2)

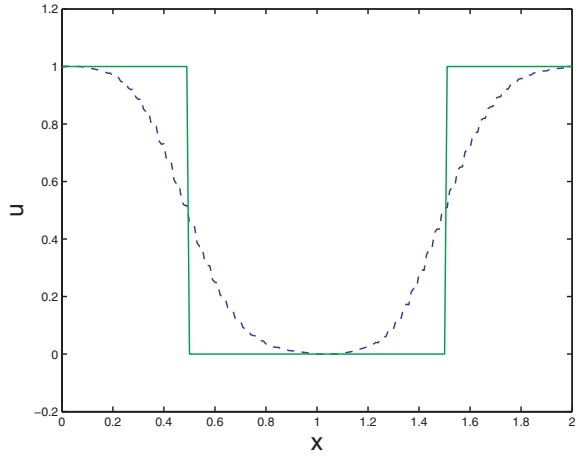

FIG. 17. *SSP*(3,3) *with* $\sigma = 1.11$ *for* (4.1).

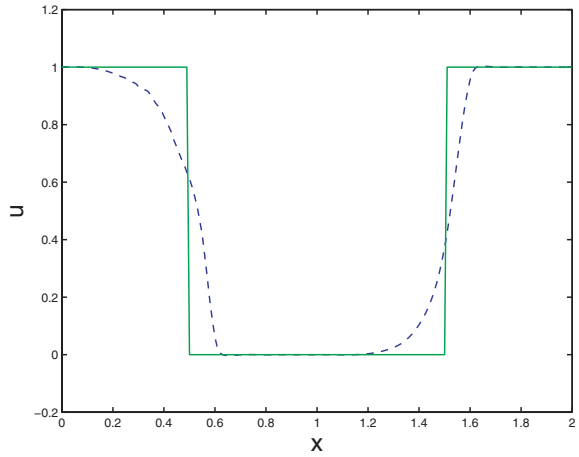

FIG. 18. *NSSP*(5,3) *with* $\sigma = 1.85$ *for* (4.1).

and NSSP(3,3) are stable, whereas SSP(2,2) and SSP(3,3) exhibit oscillations. This is a compelling illustration that our analysis accurately predicts the linear stability of ERK methods *even with negative coefficients and even when applied to a nonlinear problem whose solution develops a discontinuity.*

5. Conclusions. In this paper we employ a linear stability analysis for ERK time integration methods coupled with the WENO5 spatial discretization. We prove that the forward Euler method, all two-stage, second-order ERK methods, and all optimal SSP ERK methods of up to second order are linearly unstable when coupled with WENO5 and used for solving hyperbolic conservation laws. Hence all of these combined methods are also not convergent. Moreover, we show that, in our analysis, the success of the popular SSP(3,3) method is not due to the SSP property; indeed all three-stage, third-order ERK methods, including those with negative coefficients or those that are provably non-SSP, have precisely the same linear stability performance according to our analysis, and this has translated to very similar performance in

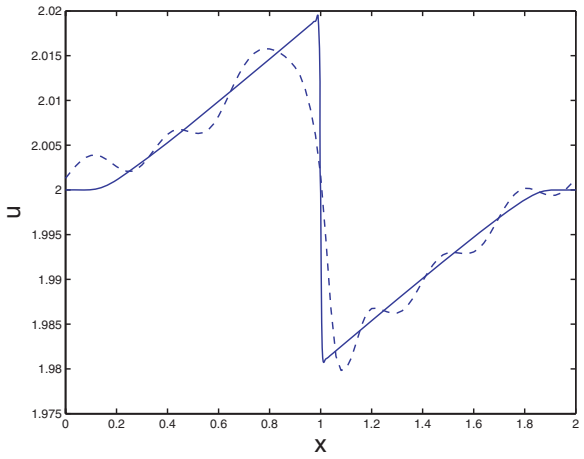

FIG. 19. *SSP*(2,2) *for the Burgers equation.*

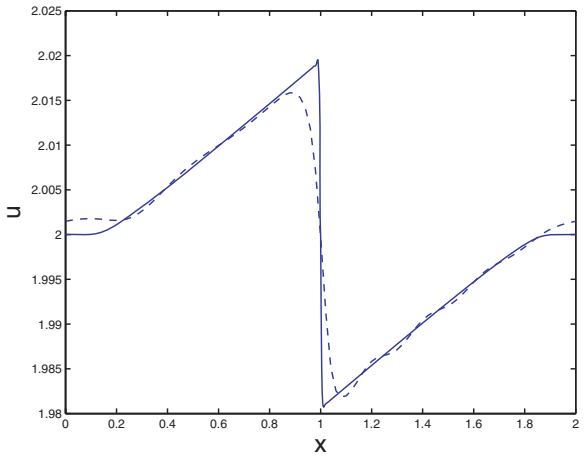

FIG. 20. *SSP*(3,2) *for the Burgers equation.*

the examples we have presented. New stability criteria are derived for general ERK methods *of any order*. Numerical experiments demonstrate that, although the analysis is strictly valid only for linear constant-coefficient problems with continuous initial conditions and periodic boundary conditions, it is relevant to both linear and nonlinear problems with continuous and discontinuous solutions. It is also relevant to ERK methods with negative coefficients without a special treatment (downwinding) of the spatial operator. For linear stability of an ERK time integration method coupled with WENO5, we show that it is sufficient that the classical linear stability region of the ERK method include a piece of the imaginary axis. The analysis techniques described in this paper apply to other WENO methods such as the seventh- or higher-order WENO methods. From this analysis it is also possible to derive optimal ERK methods in terms of the CFL number for WENO5. In particular, it is possible to derive methods such as NSSP(5,3) that are more efficient (i.e., have larger effective CFL numbers) than the benchmark method SSP(3,3). We report on these results elsewhere.

STABLE DIFFERENCE APPROXIMATIONS FOR THE ELASTIC WAVE EQUATION IN SECOND ORDER FORMULATION*

STEFAN NILSSON†, N. ANDERS PETERSSON†, BJÖRN SJÖGREEN†, AND HEINZ-OTTO KREISS‡

Abstract. We consider the three-dimensional elastic wave equation for an isotropic heterogeneous material subject to a stress-free boundary condition. Building on our recently developed theory for difference methods for second order hyperbolic systems [H.-O. Kreiss, N. A. Petersson, J. Yström, *SIAM J. Numer. Anal.*, 40 (2002), pp. 1940–1967], we develop an explicit, second order accurate technique which is stable for all ratios of longitudinal over transverse phase velocities. The spatial discretization is self-adjoint, and the stability is obtained through an energy estimate. Seismic events are often modeled using singular source terms, and we devise a technique to place sources independently of the grid while retaining second order accuracy away from the source. Several numerical examples are given.

1. Introduction.

As a model for seismic wave propagation, we consider the elastic wave equation for an isotropic heterogeneous material in a three-dimensional domain Ω:

$$\rho \frac{\partial^2 \mathbf{u}}{\partial t^2} = \nabla \cdot \mathfrak{T} + \mathbf{f}, \quad \mathbf{x} \in \Omega,\ t \geq 0, \tag{1}$$
$$\mathfrak{T} = \lambda (\nabla \cdot \mathbf{u}) \mathbf{I} + \mu \left(\nabla \mathbf{u} + \nabla \mathbf{u}^T \right),$$

subject to initial data

$$\mathbf{u}(\mathbf{x}, 0) = \mathbf{U}_0(\mathbf{x}), \quad \mathbf{u}_t(\mathbf{x}, 0) = \mathbf{U}_1(\mathbf{x}), \quad \mathbf{x} \in \Omega.$$

Here $\mathfrak{T}$ is the stress tensor, $\mathbf{u} = \mathbf{u}(\mathbf{x}, t)$ is the displacement vector with Cartesian components $\mathbf{u} = (u, v, w)^T$, where $\mathbf{x} = (x, y, z)^T$ is the location, and t is time. $\mathbf{f}$ is the external (volume) forcing, and the material properties are characterized by the density $\rho(\mathbf{x}) > 0$ and the Lamé parameters $\lambda(\mathbf{x}) > 0$ and $\mu(\mathbf{x}) \geq 0$. The degenerate case $\mu = 0$ corresponds to acoustic wave propagation and will not be discussed here. We henceforth assume $\mu(\mathbf{x}) > 0$.

Common boundary conditions include a Dirichlet condition for $\mathbf{u}$ or a normal stress condition

$$\mathfrak{T} \cdot \hat{\mathbf{n}} = \lambda (\nabla \cdot \mathbf{u}) \hat{\mathbf{n}} + \mu (\nabla \mathbf{u} + \nabla \mathbf{u}^T) \cdot \hat{\mathbf{n}} = \mathbf{g}, \tag{2}$$

which prescribes the stresses on a boundary with unit normal $\hat{\mathbf{n}}$. When $\mathbf{g} = \mathbf{0}$, this boundary condition is often called a free surface or stress-free condition. The system (1) admits longitudinal (P, or primary) and transverse (S, or secondary) waves which propagate at phase velocities

$$c_p = \sqrt{(2\mu + \lambda)/\rho} \quad \text{and} \quad c_s = \sqrt{\mu/\rho},$$

respectively. There can also be surface waves, which travel along a free surface, as well as waves which travel along internal material discontinuities.

Finite difference approximations of the elastodynamic equations in second order formulation have been around for a long time [2, 3]. Early methods, based on explicit centered difference approximations, were initially very successful but suffered from instability problems when a free surface boundary condition was imposed, and the ratio between the P- and S-wave velocities

$$\nu = \frac{c_p}{c_s}$$

became too large [13] (note that $\nu > \sqrt{2}$). Ilan [14] proposed a remedy which applied only to materials with constant properties normal to the boundary, and an implicit boundary update technique was suggested by Vidale and Clayton [25]. However, no generally applicable, stable, explicit discretization was found for the second order formulation which worked for high values of ν. Due to the instability problems, alternative formulations were explored where the elastic wave equation was rewritten as a larger first order system for the three velocity and six stress components and discretized on a staggered grid [21]. Most current finite difference methods for seismic wave propagation are based on the staggered grid technique. It is, however, difficult to handle complex geometry (e.g., topography) with these staggered grid methods, so there has been recent interest in more expensive methods based on unstructured meshes, such as the spectral element technique described by Komatitsch and Tromp [15].

In this paper we revisit the problem of devising an explicit finite difference method for the elastic wave equation in second order formulation, subject to a free surface boundary condition. Building on our recently developed theory for difference methods for second order hyperbolic systems [18], we develop a technique which is stable for all ratios c_p/c_s. We focus on the long-wave approximation where topography is neglected, and the stress-free boundary condition is enforced on a flat surface which is aligned with a grid surface. However, our longer term goal is to extend the embedded boundary technique [19, 17, 16] to the elastic wave equation for handling general domains. In seismic applications, the material parameters ρ, μ, and λ often vary on a length scale which is significantly smaller than the wavelength of the elastic waves. Hence the material parameters can vary rapidly on the computational grid, and to guarantee stability it is desirable to develop a numerical method which satisfies an energy estimate. For a hyperbolic system in second order formulation, the key to an energy estimate is a spatial discretization which is self-adjoint, i.e., corresponds to a symmetric or symmetrizable matrix. In this paper, we present a discretization which makes the spatial approximation second order accurate, self-adjoint, and explicit. The self-adjoint property also implies that the method is conservative.

In section 1.1 we introduce the basic ideas behind our spatial discretization by studying the scalar wave equation with a cross term in two space dimensions. The discretization technique is generalized to the elastic wave equation in section 2, where

we present a theory proving that the method is second order accurate and stable for all values of c_p/c_s. The stability and accuracy of the new method are also illustrated with computational experiments. Seismic events (for example, earthquakes) are often modeled using singular source terms applied at points, along lines, or over surfaces in the three-dimensional domain. In section 3 we devise a technique to place sources independently of the grid while retaining second order accuracy away from the source. We also study how the temporal smoothness of a point source affects the spatial smoothness of the solution. In section 4 we first study how the phase velocity of surface waves depends on the number of grid points per wavelength. Thereafter, we solve a benchmark problem for a simplified earthquake where the sources are distributed along a plane. Some comments on our implementation of nonreflecting boundary conditions for truncating unbounded domains are also given.

1.1. A model problem. We introduce our discretization technique on the half-plane problem for the scalar wave equation with a cross term in two dimensions:

$$\frac{\partial^2 u}{\partial t^2} = \nabla \cdot \mathbf{F}, \quad x \geq 0,\ 0 \leq y \leq 2\pi,\ t \geq 0, \tag{3}$$
$$\mathbf{F} = \begin{pmatrix} u_x + \alpha u_y \\ u_y + \alpha u_x \end{pmatrix},$$

with 2π-periodic solutions in the y-direction, subject to the boundary condition

$$\mathbf{F} \cdot \hat{\mathbf{n}} = u_x + \alpha u_y = 0, \quad x = 0,\ 0 \leq y \leq 2\pi,\ t \geq 0, \quad \text{when} \quad \hat{\mathbf{n}} = (1,0)^T. \tag{4}$$

Here α is a real constant. Similar to the elastic wave equation, the problem (3)–(4) conserves an energy:

$$\|u_t\|^2 + \|u_x\|^2 + \|u_y\|^2 + 2\alpha(u_x, u_y) = \text{const},$$

where (u, v) is the L_2 scalar product and $\|u\|^2 = (u, u)$. We have

$$\|u_x\|^2 + \|u_y\|^2 + 2\alpha(u_x, u_y) \geq (1 - |\alpha|)\left(\|u_x\|^2 + \|u_y\|^2\right) > 0, \quad |\alpha| < 1.$$

Hence the conserved quantity is a norm, and the problem (3)–(4) is well-posed, when $|\alpha| < 1$. Conversely, it can be shown that the problem becomes ill-posed for $|\alpha| > 1$.

We introduce a grid with points $x_i = (i-1)h$, $y_j = (j-1)h$, $i = 0, 1, 2, \ldots$, $j = 1, 2, \ldots, N_y$, where $h = 2\pi/(N_y - 1)$ is the grid size. We denote a two-dimensional grid function by $u_{i,j}(t) = u(x_i, y_j, t)$. The time dependence will be suppressed when the meaning is obvious. We use the usual definitions of divided difference operators

$$D_+^x v_{i,j} = \frac{1}{h}(v_{i+1,j} - v_{i,j}), \quad D_-^x v_{i,j} = D_+^x v_{i-1,j}, \quad D_0^x = \frac{1}{2}\left(D_+^x + D_-^x\right)$$

and corresponding expressions in the y-direction.

A second order accurate centered spatial discretization of (3) is given by

$$\frac{d^2 u_{i,j}}{dt^2} = \left(D_-^x D_+^x + D_-^y D_+^y + 2\alpha D_0^x D_0^y\right) u_{i,j}, \quad i \geq 1, \quad 1 \leq j \leq N_y - 1. \tag{5}$$

There are several ways to discretize the boundary condition (4) to second order accuracy. As we shall see, a good choice is

$$D_0^x u_{1,j} + \alpha D_0^y \left(\frac{u_{2,j} + u_{0,j}}{2} \right) = 0, \quad 1 \le j \le N_y - 1. \tag{6}$$

After Fourier transforming in the y-direction (with dual variable ω), using the boundary condition (6) to eliminate the ghost point values at $i = 0$, and introducing the vector notation $\hat{\mathbf{u}} = (\hat{u}_1, \hat{u}_2, \dots)^T$, we can write the Fourier-transformed semidiscrete problem in matrix form

$$h^2 \frac{d^2 \hat{\mathbf{u}}}{dt^2} = (A + B)\hat{\mathbf{u}}, \tag{7}$$

where

$$A = \begin{pmatrix} -\left(2 + 4\sin^2 \frac{\omega h}{2}\right) & 2 & & \\ 1 & -\left(2 + 4\sin^2 \frac{\omega h}{2}\right) & 1 & \\ & \ddots & \ddots & \ddots \end{pmatrix},$$

$$B = \imath\alpha \sin(\omega h) \begin{pmatrix} 0 & 2 & & \\ -1 & 0 & 1 & \\ & \ddots & \ddots & \ddots \end{pmatrix},$$

and $\imath = \sqrt{-1}$. We can symmetrize (7) by the diagonal scaling

$$S = \begin{pmatrix} 1/\sqrt{2} & 0 & & \\ 0 & 1 & 0 & \\ & \ddots & \ddots & \ddots \end{pmatrix}, \quad \hat{\mathbf{w}} = S\hat{\mathbf{u}},$$

$$h^2 \frac{d^2 \hat{\mathbf{w}}}{dt^2} = (\tilde{A} + \tilde{B})\hat{\mathbf{w}}, \quad \tilde{A} + \tilde{B} = S(A + B)S^{-1},$$

where $\tilde{A} + \tilde{B}$ is self-adjoint. As we shall see in section 2, the semidiscrete problem is stable if $\tilde{A} + \tilde{B}$ also is negative definite. Furthermore, when $\tilde{A} + \tilde{B}$ is self-adjoint, it is straightforward to discretize time such that the fully discrete problem becomes stable and conserves a discrete energy which is a second order accurate approximation of the conserved energy in the continuous case.

Note that it is not necessary to solve a linear system to update the ghost points. Instead of (6), we can change the boundary condition to be

$$D_0^x u_{1j} + \alpha D_0^y u_{1j} = 0, \quad 1 \le j \le N_y - 1, \tag{8}$$

if we also modify the difference approximation on the boundary by taking the cross term one-sided in the direction normal to the boundary

$$\frac{d^2 u_{1,j}}{dt^2} = \left(D_-^x D_+^x + D_-^y D_+^y + 2\alpha D_+^x D_0^y \right) u_{1,j}, \quad 1 \le j \le N_y - 1. \tag{9}$$

After Fourier transforming (9) in the y-direction and eliminating the ghost point by use of (8), we obtain the same matrix representation as before, showing that the two formulations are equivalent.

2. The elastic wave equation. In Cartesian component form, the system (1) is

$$\rho u_{tt} = \frac{\partial}{\partial x}\left((2\mu+\lambda)u_x + \lambda v_y + \lambda w_z\right) + \frac{\partial}{\partial y}\left(\mu v_x + \mu u_y\right) + \frac{\partial}{\partial z}\left(\mu u_z + \mu w_x\right) + f^{(x)}, \tag{10}$$

$$\rho v_{tt} = \frac{\partial}{\partial x}\left(\mu v_x + \mu u_y\right) + \frac{\partial}{\partial y}\left((2\mu+\lambda)v_y + \lambda u_x + \lambda w_z\right) + \frac{\partial}{\partial z}\left(\mu v_z + \mu w_y\right) + f^{(y)}, \tag{11}$$

$$\rho w_{tt} = \frac{\partial}{\partial x}\left(\mu u_z + \mu w_x\right) + \frac{\partial}{\partial y}\left(\mu v_z + \mu w_y\right) + \frac{\partial}{\partial z}\left((2\mu+\lambda)w_z + \lambda u_x + \lambda v_y\right) + f^{(z)}. \tag{12}$$

In this paper, we consider box-shaped domains $0 \le x \le a$, $0 \le y \le b$, $0 \le z \le c$ and impose a normal stress boundary condition at $z = 0$. In component form, the boundary condition (2) is

$$\mu u_z + \mu w_x = g^{(x)}, \tag{13}$$

$$\mu v_z + \mu w_y = g^{(y)}, \quad z = 0,\ 0 \le x \le a,\ 0 \le y \le b,\ t \ge 0, \tag{14}$$

$$(2\mu+\lambda)w_z + \lambda u_x + \lambda v_y = g^{(z)}. \tag{15}$$

For the purpose of discussing the stability properties of our method, we impose homogeneous Dirichlet conditions at $z = c$

$$\mathbf{u}(x, y, c, t) = 0, \quad 0 \le x \le a,\ 0 \le y \le b,\ t \ge 0, \tag{16}$$

and periodic boundary conditions in the x- and y-directions. Note that the stability results can be extended to the case of Dirichlet conditions in the x- and y-directions.

To simplify our notation, we assume zero volume and boundary forcings ($\mathbf{f} = \mathbf{0}$ and $\mathbf{g} = \mathbf{0}$) throughout sections 2.1–2.3.

2.1. Spatial discretization. The conclusion from the model problem in section 1.1 is that a stable second order accurate discretization of (3)–(4) can be obtained by discretizing the differential equation with centered differences, except for the cross terms on the boundary, which should be taken one-sided in the direction normal to the boundary. The resulting approximation will be second order accurate, and the ghost points can be updated explicitly if the tangential derivatives in the boundary conditions are discretized by centered differences along the boundary. We shall use these principles to define the difference scheme for the three-dimensional elastic wave equation and proceed by verifying that the resulting approximation is stable and second order accurate. The underlying ideas are the same as for the model problem, even though the algebra gets more complicated.

We define a three-dimensional grid with points $x_i = (i-1)h$, $y_j = (j-1)h$, $z_k = (k-1)h$, $0 \le i \le N_x$, $0 \le j \le N_y$, $0 \le k \le N_z$, where $h > 0$ is the grid size, $x_{N_x} = a$, $y_{N_y} = b$, and $z_{N_z} = c$. Time is discretized with step size $\delta_t > 0$ on a grid $t_n = n\delta_t$, $n = 0, 1, \ldots$, and we denote a grid function by $u^n_{i,j,k} = u(x_i, y_j, z_k, t_n)$. The superscript for time will be supressed when the meaning is obvious. Apart from the difference operators already defined, we also introduce

$$\widetilde{D^z_0} v_{i,j,k} = \begin{cases} D^z_+ v_{i,j,1}, & k = 1, \\ D^z_0 v_{i,j,k}, & k \ge 2, \end{cases}$$

and the averaging operators

$$E^x_{1/2}(\gamma_{i,j,k}) = \gamma_{i+1/2,j,k} := \frac{\gamma_{i+1,j,k} + \gamma_{i,j,k}}{2},$$
$$E^y_{1/2}(\gamma_{i,j,k}) = \gamma_{i,j+1/2,k} := \frac{\gamma_{i,j+1,k} + \gamma_{i,j,k}}{2},$$
$$E^z_{1/2}(\gamma_{i,j,k}) = \gamma_{i,j,k+1/2} := \frac{\gamma_{i,j,k+1} + \gamma_{i,j,k}}{2}.$$

We form the spatially discrete equations at the grid points $1 \le i \le N_x - 1$, $1 \le j \le N_y - 1$, $1 \le k \le N_z - 1$,

$$\rho \frac{d^2u}{dt^2} = D^x_- \left(E^x_{1/2}(2\mu+\lambda) D^x_+ u \right) + D^y_- \left(E^y_{1/2}(\mu) D^y_+ u \right) + D^z_- \left(E^z_{1/2}(\mu) D^z_+ u \right)$$
$$+ D^x_0 \left(\lambda D^y_0 v + \lambda \widetilde{D^z_0} w \right) + D^y_0 \left(\mu D^x_0 v \right) + \widetilde{D^z_0} \left(\mu D^x_0 w \right) =: L^{(u)}(u,v,w), \tag{17}$$

$$\rho \frac{d^2v}{dt^2} = D^x_- \left(E^x_{1/2}(\mu) D^x_+ v \right) + D^y_- \left(E^y_{1/2}(2\mu+\lambda) D^y_+ v \right) + D^z_- \left(E^z_{1/2}(\mu) D^z_+ v \right)$$
$$+ D^x_0 \left(\mu D^y_0 u \right) + D^y_0 \left(\lambda D^x_0 u + \lambda \widetilde{D^z_0} w \right) + \widetilde{D^z_0} \left(\mu D^y_0 w \right) =: L^{(v)}(u,v,w), \tag{18}$$

$$\rho \frac{d^2w}{dt^2} = D^x_- \left(E^x_{1/2}(\mu) D^x_+ w \right) + D^y_- \left(E^y_{1/2}(\mu) D^y_+ w \right) + D^z_- \left(E^z_{1/2}(2\mu+\lambda) D^z_+ w \right)$$
$$+ D^x_0 \left(\mu \widetilde{D^z_0} u \right) + D^y_0 \left(\mu \widetilde{D^z_0} v \right) + \widetilde{D^z_0} \left(\lambda D^x_0 u + \lambda D^y_0 v \right) =: L^{(w)}(u,v,w), \tag{19}$$

where grid point indices have been suppressed to improve readability. The free surface boundary conditions (13)–(15) are discretized by

$$\frac{1}{2} \left(\mu_{i,j,3/2} D^z_+ u_{i,j,1} + \mu_{i,j,1/2} D^z_+ u_{i,j,0} \right) + \mu_{i,j,1} D^x_0 w_{i,j,1} = 0, \tag{20}$$

$$\frac{1}{2} \left(\mu_{i,j,3/2} D^z_+ v_{i,j,1} + \mu_{i,j,1/2} D^z_+ v_{i,j,0} \right) + \mu_{i,j,1} D^y_0 w_{i,j,1} = 0, \tag{21}$$

$$\frac{1}{2} \left((2\mu+\lambda)_{i,j,3/2} D^z_+ w_{i,j,1} + (2\mu+\lambda)_{i,j,1/2} D^z_+ w_{i,j,0} \right) + \lambda_{i,j,1} \left(D^x_0 u_{i,j,1} + D^y_0 v_{i,j,1} \right) = 0 \tag{22}$$

for $1 \le i \le N_x - 1$, $1 \le j \le N_y - 1$. The Dirichlet boundary condition (16) is discretized by

$$\mathbf{u}_{i,j,N_z} = \mathbf{0}, \quad 1 \le i \le N_x,\ 1 \le j \le N_y. \tag{23}$$

The discrete counterparts of the periodic boundary conditions are

$$\mathbf{u}_{N_x,j,k} = \mathbf{u}_{1,j,k}, \quad \mathbf{u}_{0,j,k} = \mathbf{u}_{N_x-1,j,k}, \tag{24}$$

$$\mathbf{u}_{i,N_y,k} = \mathbf{u}_{i,1,k}, \quad \mathbf{u}_{i,0,k} = \mathbf{u}_{i,N_y-1,k} \tag{25}$$

for $1 \le i \le N_x$, $1 \le j \le N_y$, $1 \le k \le N_z$.

In (17)–(19), z-derivatives in the cross terms are made one-sided at the grid line $k = 1$. Nevertheless, the semidiscrete approximation is a second order accurate approximation as demonstrated in the following theorem.

THEOREM 1. *The semidiscrete scheme* (17)–(19) *subject to the boundary conditions* (20)–(25) *is a second order accurate approximation of the continuous equation* (10)–(12) *subject to the boundary conditions* (13)–(16).

Proof. See Appendix A. ∎

We will show that the above scheme satisfies an energy estimate. The energy estimate relies on the spatial discretization being self-adjoint and negative definite (elliptic). These properties are stated in three lemmas below. The main stability estimate is stated after the lemmas.

The diagonal scaling S which was used to symmetrize the spatial discretization for the model problem in section 1.1 is related to a weighted scalar product for the unscaled problem. For the three-dimensional elastic wave equation, the appropriate scalar product and norm are

$$(w,v)_h = h^2 \sum_{i=1}^{N_x-1} \sum_{j=1}^{N_y-1} \left(\frac{h}{2} w_{i,j,1} v_{i,j,1} + h \sum_{k=2}^{N_z-1} w_{i,j,k} v_{i,j,k} \right), \quad \|v\|_h^2 = (v,v)_h.$$

The self-adjoint property is expressed in the following lemma.

LEMMA 1. *For all real-valued grid functions* (u^0, v^0, w^0), (u^1, v^1, w^1) *which satisfy the discrete boundary conditions* (20)–(25), *the spatial operator* $(L^{(u)}, L^{(v)}, L^{(w)})$ *is self-adjoint; i.e.,*

$$\begin{aligned} &\left(u^0, L^{(u)}(u^1,v^1,w^1)\right)_h + \left(v^0, L^{(v)}(u^1,v^1,w^1)\right)_h + \left(w^0, L^{(w)}(u^1,v^1,w^1)\right)_h \\ &\quad = \left(u^1, L^{(u)}(u^0,v^0,w^0)\right)_h + \left(v^1, L^{(v)}(u^0,v^0,w^0)\right)_h + \left(w^1, L^{(w)}(u^0,v^0,w^0)\right)_h. \end{aligned} \tag{26}$$

Proof. See Appendix B. ∎

From the self-adjoint property it follows that there exists a conserved quantity.

LEMMA 2. *All real-valued solutions* (u,v,w) *of the semidiscrete scheme* (17)–(19) *subject to the boundary conditions* (20)–(25) *satisfy*

$$\begin{aligned} &\|\rho^{1/2} u_t\|_h^2 + \|\rho^{1/2} v_t\|_h^2 + \|\rho^{1/2} w_t\|_h^2 - (u, L^{(u)}(u,v,w))_h - (v, L^{(v)}(u,v,w))_h \\ &\quad -(w, L^{(w)}(u,v,w))_h = C, \end{aligned} \tag{27}$$

where C *is a constant which depends on the initial data.*

Proof. Lemma 1 gives

$$\begin{aligned} \frac{1}{2}\frac{d}{dt} &\left(\|\rho^{1/2} u_t\|_h^2 + \|\rho^{1/2} v_t\|_h^2 + \|\rho^{1/2} w_t\|_h^2 \right) \\ &= (u_t, L^{(u)}(u,v,w))_h + (v_t, L^{(v)}(u,v,w))_h + (w_t, L^{(w)}(u,v,w))_h \\ &= \frac{1}{2}\left((u_t, L^{(u)}(u,v,w))_h + (v_t, L^{(v)}(u,v,w))_h + (w_t, L^{(w)}(u,v,w))_h \right) \\ &+ \frac{1}{2}\left((u, L^{(u)}(u_t,v_t,w_t))_h + (v, L^{(v)}(u_t,v_t,w_t))_h + (w, L^{(w)}(u_t,v_t,w_t))_h \right) \\ &= \frac{1}{2}\frac{d}{dt}\left((u, L^{(u)}(u,v,w))_h + (v, L^{(v)}(u,v,w))_h + (w, L^{(w)}(u,v,w))_h \right). \end{aligned}$$

Integrating the above relation in time starting at $t = 0$ gives (27) and shows that the constant C depends on the initial data. ∎

To prove that the semidiscrete scheme is stable, we need to show that the conserved quantity in (27) is a norm; i.e., we need to show that the spatial operator is negative definite. In particular, we need to show that the sum of the mixed terms in $(u, L^{(u)})_h$, $(v, L^{(v)})_h$, and $(w, L^{(w)})_h$ (such as $\left(D_0^x w, \mu \widetilde{D_0^z} u\right)_h$) is dominated by the sum of the strictly positive terms (such as $\left(D_+^x w, E_{1/2}^x(\mu) D_+^x w\right)_h$). This is straightforward in the corresponding continuous case and leads to the well-known formula for

the elastic energy. What makes the discrete case more challenging is that all derivatives in the strictly positive terms are discretized by operators such as $D_+^x D_-^x$, while they are discretized by centered differences (such as $D_0^x D_0^y$) in all mixed terms. We have the following.

LEMMA 3. *For all real-valued grid functions (u, v, w) which satisfy the boundary conditions* (20)–(25)*, we have*

(28)
$$\begin{aligned}(u, L^{(u)}(u,v,w))_h + (v, L^{(v)}(u,v,w))_h + (w, L^{(w)}(u,v,w))_h &= -2\|(E^x_{1/2}(\mu))^{1/2} D_+^x u\|_h^2 \\ - 2\|(E^y_{1/2}(\mu))^{1/2} D_+^y v\|_h^2 - 2\|(E^z_{1/2}(\mu))^{1/2} D_+^z w\|_h^2 &- \|\lambda^{1/2}(D_0^x u + D_0^y v + \widetilde{D_0^z} w)\|_h^2 \\ - \|\mu^{1/2}(D_0^x u + D_0^y v)\|_h^2 - \|\mu^{1/2}(\widetilde{D_0^z} v + D_0^y w)\|_h^2 &- \|\mu^{1/2}(\widetilde{D_0^z} u + D_0^x w)\|_h^2 - \frac{h^2}{4} R - B.\end{aligned}$$

The operator $\left(L^{(u)}, L^{(v)}, L^{(w)}\right)$ is negative definite when $\mu > 0$ and $\lambda > 0$. It is semidefinite when $\mu = 0$ and $\lambda > 0$. The remainder term R and the boundary term B are both positive. They are given by

$$\begin{aligned}R = \|\lambda^{1/2} D_+^x D_-^x u\|_h^2 + \|\mu^{1/2} D_+^y D_-^y u\|_h^2 + \|\mu^{1/2} D_+^z D_-^z u\|_{hr}^2 \\ + \|\mu^{1/2} D_+^x D_-^x v\|_h^2 + \|\lambda^{1/2} D_+^y D_-^y v\|_h^2 + \|\mu^{1/2} D_+^z D_-^z v\|_{hr}^2 \\ + \|\mu^{1/2} D_+^x D_-^x w\|_h^2 + \|\mu^{1/2} D_+^y D_-^y w\|_h^2 + \|\lambda^{1/2} D_+^z D_-^z w\|_{hr}^2\end{aligned} \tag{29}$$

and

(30)
$$B = h \sum_{j=1}^{N_y} \sum_{i=1}^{N_x} \Big(\frac{\lambda_{i,j,N_z}}{2} w^2_{i,j,N_z-1} + \frac{\mu_{i,j,N_z}}{2} (u^2_{i,j,N_z-1} + v^2_{i,j,N_z-1}) + h^2 \mu_{i,j,3/2} (D_+^z w_{i,j,1})^2 \Big),$$

respectively.

Note: The reduced scalar product $(u, v)_{hr}$ is similar to the standard scalar product, except that it starts the summation from $k = 2$:

$$(w, v)_{hr} = h^3 \sum_{i=1}^{N_x - 1} \sum_{j=1}^{N_y - 1} \sum_{k=2}^{N_z - 1} w_{i,j,k} v_{i,j,k}, \quad \|v\|_{hr}^2 = (v, v)_{hr}.$$

Proof. The identity (28) is derived in Appendix C. All terms on the right-hand side of (28) are nonpositive when the functions μ and λ are nonnegative. Therefore the operator is at least negative semidefinite. Negative definiteness is proved by showing that

$$(u, L^{(u)}(u,v,w))_h + (v, L^{(v)}(u,v,w))_h + (w, L^{(w)}(u,v,w))_h = 0 \tag{31}$$

implies $u_{i,j,k} = 0$, $v_{i,j,k} = 0$, and $w_{i,j,k} = 0$ at all grid points.

Assume that $\mu_{i,j,k} > 0$ and $\lambda_{i,j,k} > 0$ for all i, j, k and that (31) holds. The right-hand side of (28) is a sum of nonpositive terms. Therefore, each term must be zero to make the sum zero. Hence the third scalar product term on the right-hand side of (28) gives

$$D_+^z w_{i,j,k} = 0, \quad 1 \le i \le N_x - 1, \ \ 1 \le j \le N_y - 1, \ \ 1 \le k \le N_z - 1.$$

Together with the boundary condition $w_{i,j,N_z} = 0$, this gives

$$0 = w_{i,j,N_z} = w_{i,j,N_z-1} = \cdots = w_{i,j,1}.$$

Thus $w_{i,j,k} = 0$ everywhere, except possibly at $k = 0$. Next we show that $u_{i,j,k} = 0$ for all i, j, k except possibly for $k = 0$. The seventh scalar product term on the right-hand side of (28) gives

$$\widetilde{D_0^z} u_{i,j,k} + D_0^x w_{i,j,k} = 0, \quad 1 \le i \le N_x - 1, \ \ 1 \le j \le N_y - 1, \ \ 1 \le k \le N_z - 1. \tag{32}$$

Because $w_{i,j,k} = 0$, (32) gives

$$u_{i,j,N_z} = u_{i,j,N_z-2} = u_{i,j,N_z-4} = \ldots, \tag{33}$$

$$u_{i,j,N_z-1} = u_{i,j,N_z-3} = u_{i,j,N_z-5} = \ldots . \tag{34}$$

The boundary term B contains u^2_{i,j,N_z-1}, which therefore must be zero. Hence, (33) and (34) together with the boundary condition $u_{i,j,N_z} = 0$ give

$$0 = u_{i,j,N_z} = u_{i,j,N_z-1} = \ldots = u_{i,j,1}.$$

We have shown that $u_{i,j,k} = 0$ for all i, j, k except possibly for $k = 0$. The property $v_{i,j,k} = 0$, except possibly for $k = 0$, follows in exactly the same way as for $u_{i,j,k}$ by studying the sixth term on the right-hand side of (28). The possibilities $u_{i,j,0} \neq 0$, $v_{i,j,0} \neq 0$, or $w_{i,j,0} \neq 0$ remain. However, when (u, v, w) is zero for $1 \le k \le N_z$, the boundary conditions (20)–(22) give $u_{i,j,0} = v_{i,j,0} = w_{i,j,0} = 0$. We have now proved that the operator $(L^{(u)}, L^{(v)}, L^{(w)})$ is negative definite when μ and λ are positive functions.

If $\mu = 0$ and $\lambda > 0$, the operator has a nontrivial null space. Take, for example, $u_{i,j,k} = f_{j,k}$, $v_{i,j,k} = g_{i,k}$, and $w_{i,j,k} = 0$, with $f_{j,k}, g_{i,k}$ satisfying $f_{j,N_z} = g_{i,N_z} = 0$ and periodic in the j- and i-directions, respectively, but otherwise arbitrary. Because $\mu = 0$, these functions satisfy the free surface boundary conditions (20)–(22). It is an easy exercise to show that these functions make (28) equal to zero when $\mu = 0$ everywhere. Hence the operator $(L^{(u)}, L^{(v)}, L^{(w)})$ is negative semidefinite when $\mu = 0$ and $\lambda > 0$. ∎

The findings in Lemmas 1–3 are summarized in the following main theorem, showing that the semidiscrete problem is well-posed.

THEOREM 2. *The solution of the semidiscrete scheme* (17)–(19) *subject to the boundary conditions* (20)–(25) *satisfies*

$$\|\rho^{1/2} u_t\|_h^2 + \|\rho^{1/2} v_t\|_h^2 + \|\rho^{1/2} w_t\|_h^2 - (u, L^{(u)}(u,v,w))_h - (v, L^{(v)}(u,v,w))_h - (w, L^{(w)}(u,v,w))_h = C,$$

where C is a constant that depends on the initial data. The quantity

$$-(u, L^{(u)}(u,v,w))_h - (v, L^{(v)}(u,v,w))_h - (w, L^{(w)}(u,v,w))_h$$

is positive definite when $\mu > 0$ and $\lambda > 0$ and is therefore a norm.

2.2. Fully discrete equations. Following the theory in [18], we discretize (17)–(19) in time according to

$$\rho\left(\frac{u^{n+1}-2u^n+u^{n-1}}{\delta_t^2}\right)=L^{(u)}(u^n,v^n,w^n), \tag{35}$$

$$\rho\left(\frac{v^{n+1}-2v^n+v^{n-1}}{\delta_t^2}\right)=L^{(v)}(u^n,v^n,w^n), \tag{36}$$

$$\rho\left(\frac{w^{n+1}-2w^n+w^{n-1}}{\delta_t^2}\right)=L^{(w)}(u^n,v^n,w^n). \tag{37}$$

To simplify the notation, we introduce the weighted ρ-norm

$$(w,v)_\rho = h^2\sum_{i=1}^{N_x-1}\sum_{j=1}^{N_y-1}\left(\frac{h}{2}\rho_{i,j,1}w_{i,j,1}v_{i,j,1}+h\sum_{k=2}^{N_z-1}\rho_{i,j,k}w_{i,j,k}v_{i,j,k}\right),\quad \|v\|_\rho^2=(v,v)_\rho\,.$$

Trivial calculations give

$$\left(w,\rho^{-1}v\right)_\rho=(w,v)_h\,. \tag{38}$$

To show that the fully discrete scheme is energy conserving, we consider the quantity

$$\begin{aligned}C_e(t_{n+1}) &= \left\|D_+^t u^n\right\|_\rho^2+\left\|D_+^t v^n\right\|_\rho^2+\left\|D_+^t w^n\right\|_\rho^2-\left(u^{n+1},\rho^{-1}L^{(u)}(u^n,v^n,w^n)\right)_\rho\\ &\quad-\left(v^{n+1},\rho^{-1}L^{(v)}(u^n,v^n,w^n)\right)_\rho-\left(w^{n+1},\rho^{-1}L^{(w)}(u^n,v^n,w^n)\right)_\rho\\ &= \left\|D_+^t u^n\right\|_\rho^2+\left\|D_+^t v^n\right\|_\rho^2+\left\|D_+^t w^n\right\|_\rho^2\\ &\quad-\left(u^{n+1},D_+^tD_-^t u^n\right)_\rho-\left(v^{n+1},D_+^tD_-^t v^n\right)_\rho-\left(w^{n+1},D_+^tD_-^t w^n\right)_\rho\,.\end{aligned} \tag{39}$$

We have the following energy conservation result for the difference scheme.

THEOREM 3. *The solution computed by the difference scheme* (35)–(37) *together with the boundary conditions* (20)–(25) *satisfies*

$$C_e(t_{n+1})=C_e(t_n);$$

i.e., $C_e(t_n)$ is a conserved quantity for the fully discrete scheme.

Proof. Expanding the square in the term $||D_+^t u^n||_\rho^2$ (and similarly for v and w) gives the identity

$$\begin{aligned}\delta_t^2 C_e(t_{n+1}) &= \|u^{n+1}\|_\rho^2+\|u^n\|_\rho^2-\left(u^{n+1},2u^n+\delta_t^2\rho^{-1}L^{(u)}(u^n,v^n,w^n)\right)_\rho\\ &\quad+\|v^{n+1}\|_\rho^2+\|v^n\|_\rho^2-\left(v^{n+1},2v^n+\delta_t^2\rho^{-1}L^{(v)}(u^n,v^n,w^n)\right)_\rho\\ &\quad+\|w^{n+1}\|_\rho^2+\|w^n\|_\rho^2-\left(w^{n+1},2w^n+\delta_t^2\rho^{-1}L^{(w)}(u^n,v^n,w^n)\right)_\rho\,.\end{aligned} \tag{40}$$

We have

$$u^{n+1}+u^{n-1}=2u^n+\delta_t^2\rho^{-1}L^{(u)}(u^n,v^n,w^n)$$

and corresponding expressions for v and w. Hence,

$$\begin{aligned}\delta_t^2 C_e(t_{n+1}) &= \|u^{n+1}\|_\rho^2 + \|u^n\|_\rho^2 - \left(u^{n+1}, u^{n+1} + u^{n-1}\right)_\rho + \|v^{n+1}\|_\rho^2 + \|v^n\|_\rho^2 \\ &\quad - \left(v^{n+1}, v^{n+1} + v^{n-1}\right)_\rho + \|w^{n+1}\|_\rho^2 + \|w^n\|_\rho^2 - \left(w^{n+1}, w^{n+1} + w^{n-1}\right)_\rho \\ &= \|u^n\|_\rho^2 + \|u^{n-1}\|_\rho^2 - \left(u^{n-1}, 2u^n + \delta_t^2 \rho^{-1} L^{(u)}(u^n, v^n, w^n)\right)_\rho \\ &\quad + \|v^n\|_\rho^2 + \|v^{n-1}\|_\rho^2 - \left(v^{n-1}, 2v^n + \delta_t^2 \rho^{-1} L^{(v)}(u^n, v^n, w^n)\right)_\rho \\ &\quad + \|w^n\|_\rho^2 + \|w^{n-1}\|_\rho^2 - \left(w^{n-1}, 2w^n + \delta_t^2 \rho^{-1} L^{(w)}(u^n, v^n, w^n)\right)_\rho .\end{aligned}$$

The relation (38) gives

$$\left(u^{n-1}, \delta_t^2 \rho^{-1} L^{(u)}(u^n, v^n, w^n)\right)_\rho = \left(u^{n-1}, \delta_t^2 L^{(u)}(u^n, v^n, w^n)\right)_h ,$$

so Lemma 1 yields

$$\begin{aligned}&\left(u^{n-1}, \delta_t^2 \rho^{-1} L^{(u)}(u^n, v^n, w^n)\right)_\rho + \left(v^{n-1}, \delta_t^2 \rho^{-1} L^{(v)}(u^n, v^n, w^n)\right)_\rho \\ &\qquad + \left(w^{n-1}, \delta_t^2 \rho^{-1} L^{(w)}(u^n, v^n, w^n)\right)_\rho \\ &= \left(u^n, \delta_t^2 \rho^{-1} L^{(u)}(u^{n-1}, v^{n-1}, w^{n-1})\right)_\rho + \left(v^n, \delta_t^2 \rho^{-1} L^{(v)}(u^{n-1}, v^{n-1}, w^{n-1})\right)_\rho \\ &\qquad + \left(w^n, \delta_t^2 \rho^{-1} L^{(w)}(u^{n-1}, v^{n-1}, w^{n-1})\right)_\rho .\end{aligned} \tag{41}$$

We conclude that

$$C_e(t_{n+1}) = C_e(t_n);$$

i.e., $C_e(t_n)$ is a conserved quantity for the fully discrete scheme. ∎

To obtain an energy estimate we need to show that $C_e > 0$. This was done in [18] for approximations of the scalar wave equation. We here perform a similar analysis for the scheme (35)–(37). To make the presentation more compact, we introduce the vector notation

$$\begin{aligned}(\mathbf{u}^{n+1}, \mathbf{L}(\mathbf{u}^n))_h =: &(u^{n+1}, L^{(u)}(u^n, v^n, w^n))_h + (v^{n+1}, L^{(v)}(u^n, v^n, w^n))_h \\ &+ (w^{n+1}, L^{(w)}(u^n, v^n, w^n))_h.\end{aligned} \tag{42}$$

As we shall see below, it is natural to study the scaled eigenvalue problem

$$\rho^{-1}\mathbf{L}(\mathbf{w}) = \zeta \mathbf{w}, \tag{43}$$

where $\mathbf{w}$ satisfies the boundary conditions (20)–(25). We know from Lemma 1 that $\mathbf{L}$ is self-adjoint with respect to $(\cdot,\cdot)_h$. Therefore, $\rho^{-1}\mathbf{L}$ is self-adjoint with respect to $(\cdot,\cdot)_\rho$ because

$$(\mathbf{v}, \rho^{-1}\mathbf{L}(\mathbf{w}))_\rho = (\mathbf{v}, \mathbf{L}(\mathbf{w}))_h = (\mathbf{L}(\mathbf{v}), \mathbf{w})_h = (\rho^{-1}\mathbf{L}(\mathbf{v}), \mathbf{w})_\rho.$$

Hence, the eigenvalues of (43) are real and Lemma 3 implies that they are negative, i.e.,

$$-\max_m |\zeta_m| \|\mathbf{w}\|_\rho^2 \le (\mathbf{w}, \rho^{-1}\mathbf{L}(\mathbf{w}))_\rho \le -\min_m |\zeta_m| \|\mathbf{w}\|_\rho^2. \tag{44}$$

We have the following stability result.

THEOREM 4. *If the eigenvalues ζ_m of (43) satisfy the CFL condition*

$$\frac{\delta_t^2}{4}\max_m|\zeta_m| < 1, \tag{45}$$

then the conserved quantity $C_e(t_{n+1})$ is a norm which is bounded from below by

$$C_e(t_{n+1}) \geq \left(1 - \frac{\delta_t^2}{4}\max_m|\zeta_m|\right)\|D_+^t\mathbf{u}^n\|_\rho^2 + \frac{\min_m|\zeta_m|}{4}\|\mathbf{u}^{n+1}+\mathbf{u}^n\|_\rho^2. \tag{46}$$

Proof. Using the vector notation (42), we can write the conserved quantity (39) as follows:

$$C_e(t_{n+1}) = \left\|D_+^t\mathbf{u}^n\right\|_\rho^2 - \left(\mathbf{u}^{n+1},\mathbf{L}(\mathbf{u}^n)\right)_h.$$

Because the operator $\mathbf{L}$ is self-adjoint (Lemma 1),

$$(\mathbf{u}^{n+1},\mathbf{L}(\mathbf{u}^n))_h = \frac{1}{2}(\mathbf{u}^{n+1},\mathbf{L}(\mathbf{u}^n))_h + \frac{1}{2}(\mathbf{u}^n,\mathbf{L}(\mathbf{u}^{n+1}))_h.$$

Furthermore,

$$\begin{aligned}&(\mathbf{u}^{n+1}+\mathbf{u}^n,\mathbf{L}(\mathbf{u}^{n+1}+\mathbf{u}^n))_h - (\mathbf{u}^{n+1}-\mathbf{u}^n,\mathbf{L}(\mathbf{u}^{n+1}-\mathbf{u}^n))_h\\ &\quad = 2(\mathbf{u}^n,\mathbf{L}(\mathbf{u}^{n+1}))_h + 2(\mathbf{u}^{n+1},\mathbf{L}(\mathbf{u}^n))_h,\end{aligned}$$

and $(\mathbf{w},\mathbf{L}(\mathbf{w}))_h = (\mathbf{w},\rho^{-1}\mathbf{L}(\mathbf{w}))_\rho$. Hence,

$$\begin{aligned}\delta_t^2 C_e(t_{n+1}) = ||\mathbf{u}^{n+1}-\mathbf{u}^n||_\rho^2 &- \frac{\delta_t^2}{4}(\mathbf{u}^{n+1}+\mathbf{u}^n,\rho^{-1}\mathbf{L}(\mathbf{u}^{n+1}+\mathbf{u}^n))_\rho\\ &+ \frac{\delta_t^2}{4}(\mathbf{u}^{n+1}-\mathbf{u}^n,\rho^{-1}\mathbf{L}(\mathbf{u}^{n+1}-\mathbf{u}^n))_\rho.\end{aligned} \tag{47}$$

The eigenvalue bound (44) gives

$$\delta_t^2 C_e(t_{n+1}) \geq \left(1 - \frac{\delta_t^2}{4}\max_m|\zeta_m|\right)\|\mathbf{u}^{n+1}-\mathbf{u}^n\|_\rho^2 + \frac{\delta_t^2}{4}\min_m|\zeta_m|\|\mathbf{u}^{n+1}+\mathbf{u}^n\|_\rho^2. \tag{48}$$

Hence, $C_e(t_{n+1})$ is a norm when

$$1 - \frac{\delta_t^2}{4}\max_m|\zeta_m| > 0,$$

i.e., when the CFL condition (45) is satisfied. ∎

2.3. Time step restrictions. In the case of constant ρ, μ, λ, and periodic boundary conditions in all three directions, a von Neumann analysis gives the maximum eigenvalue

$$\zeta_{vN} = \begin{cases} -\dfrac{4}{h^2}\dfrac{4\mu+\lambda}{\rho}, & \lambda < 2\mu,\\ -\dfrac{9}{2h^2}\dfrac{(2\mu+\lambda)^2}{\rho(\mu+\lambda)}, & \lambda \geq 2\mu.\end{cases} \tag{49}$$

(We mention in passing that the largest eigenvalue occurs for the highest wave number on the grid ($\omega h = \pi$) when $\lambda < 2\mu$, while it arises for $\omega h = 2\pi/3$ when $\lambda \geq 2\mu$.

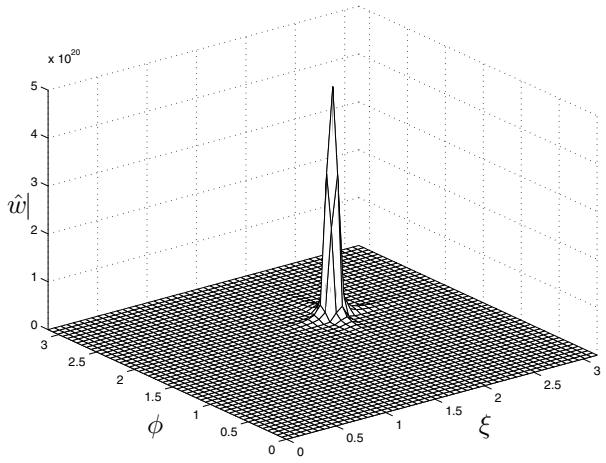

FIG. 1. *Magnitude of the two-dimensional discrete Fourier transform of w at $t = 1.78$, along the $z = 0$ (stress-free) surface calculated with a time step allowed by the von Neumann analysis, which underestimates the largest eigenvalue of the spatial operator. In this calculation, $\rho = 1$, $\mu = 1$, $\lambda = 79$, $h = 0.04$, $\delta_t = 0.95\delta_{tvN}$, and the initial data were given by* (66). *Note that all energy is concentrated around the wave numbers $\omega_x h \approx \omega_y h \approx 2\pi/3$.*

This behavior is different from the corresponding two-dimensional problem, where the largest eigenvalue always happens when $\omega h = \pi$.) If ζ_{vN} is used to estimate the largest eigenvalue $\max_m |\zeta_m|$, we get the time step restriction $\delta_t < \delta_{tvN}$, where

$$\delta_{tvN} = \begin{cases} h\sqrt{\dfrac{\rho}{4\mu+\lambda}} = \dfrac{h}{\sqrt{c_p^2+2c_s^2}}, & c_p < 2c_s, \\ \dfrac{\sqrt{8}h}{3}\dfrac{\sqrt{\rho(\mu+\lambda)}}{2\mu+\lambda} = \dfrac{\sqrt{8}h}{3}\dfrac{\sqrt{c_p^2-c_s^2}}{c_p^2}, & c_p \geq 2c_s. \end{cases} \tag{50}$$

Unfortunately, numerical simulations using a time step smaller but close to the limit (50) become unstable when a stress-free boundary is imposed and the ratio $\nu = c_p/c_s$ is large; see Figure 1.

To estimate how the free-surface boundary condition modifies the time step restriction, we study the stability of the discrete half-plane problem with constant values of ρ, μ, λ. In this approximation, we assume a 2π-periodic solution in the x- and y-directions, expand the grid in the z-direction by taking $N_z \to \infty$, and replace the Dirichlet boundary condition (23) by

$$\lim_{k\to\infty} |\mathbf{u}_{i,j,k}^n| = 0. \tag{51}$$

Several stability definitions for difference approximations are possible, and we refer to [11] for a discussion. Here we use a normal-mode approach and define the half-plane problem to be stable if there are no solutions of the form

$$\mathbf{u}(x_i, y_j, z_k, t_n) = \chi^n e^{\imath(\omega_x x_i + \omega_y y_j)}\hat{\mathbf{u}}_k, \quad \sum_{k=1}^{\infty} |\hat{\mathbf{u}}_k|^2 < \infty, \quad |\chi| > 1, \tag{52}$$

where $\imath = \sqrt{-1}$. For simplicity we assume that $N_x = N_y$ is odd. Then $\omega_x, \omega_y = 0, \pm 1, \pm 2, \ldots, \pm(N_x - 1)/2$.

It is straightforward to perform the stability analysis if we first rewrite our scheme (17)–(19) into an equivalent form, where the one-sided discretization of the cross-derivatives at $k = 1$ are replaced by the centered discretization used for $k \geq 2$, i.e., replace $\widetilde{D_0^z}$ by D_0^z in (17)–(19). We arrive at an equivalent problem by introducing compensating terms in the boundary conditions; see Appendix A. In the case of constant coefficients, the compensated stress-free boundary conditions are

$$D_0^z u_{i,j,1} + D_0^x \left(w_{i,j,1} + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z w_{i,j,1} \right) = 0, \tag{53}$$

$$D_0^z v_{i,j,1} + D_0^y \left(w_{i,j,1} + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z w_{i,j,1} \right) = 0, \tag{54}$$

$$\begin{aligned} \nu^2 D_0^z w_{i,j,1} &+ D_0^x \left((\nu^2 - 2) u_{i,j,1} + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z u_{i,j,1} \right) \\ &+ D_0^y \left((\nu^2 - 2) v_{i,j,1} + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z v_{i,j,1} \right) = 0. \end{aligned} \tag{55}$$

After inserting the ansatz (52) into the modified version of (17)–(19), we arrive at the eigenvalue problem

$$\begin{aligned} \frac{\zeta_{hp}}{c_s^2} \hat{\mathbf{u}}_k := \frac{\chi - 2 + \chi^{-1}}{\delta_t^2 c_s^2} \hat{\mathbf{u}}_k &= -\frac{4}{h^2} \left(\sin^2 \frac{\xi}{2} + \sin^2 \frac{\phi}{2} \right) \hat{\mathbf{u}}_k + D_+^z D_-^z \hat{\mathbf{u}}_k \\ &+ (\nu^2 - 1) \begin{pmatrix} -\frac{4}{h^2} \sin^2 \frac{\xi}{2} & -\frac{1}{h^2} \sin\xi \sin\phi & \frac{\imath}{h} \sin\xi D_0^z \\ -\frac{1}{h^2} \sin\xi \sin\phi & -\frac{4}{h^2} \sin^2 \frac{\phi}{2} & \frac{\imath}{h} \sin\phi D_0^z \\ \frac{\imath}{h} \sin\xi D_0^z & \frac{\imath}{h} \sin\phi D_0^z & D_+^z D_-^z \end{pmatrix} \hat{\mathbf{u}}_k, \end{aligned} \tag{56}$$

where $\xi = \omega_x h$ and $\phi = \omega_y h$ satisfy $-\pi \leq \xi \leq \pi$, $-\pi \leq \phi \leq \pi$. Inserting the ansatz (52) into the boundary conditions (53)–(55) gives

$$D_0^z \hat{u}_1 + \frac{\imath}{h} \sin\xi \left(\hat{w}_1 + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z \hat{w}_1 \right) = 0, \tag{57}$$

$$D_0^z \hat{v}_1 + \frac{\imath}{h} \sin\phi \left(\hat{w}_1 + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z \hat{w}_1 \right) = 0, \tag{58}$$

$$\begin{aligned} \nu^2 D_0^z \hat{w}_1 &+ \frac{\imath}{h} \sin\xi \left((\nu^2 - 2)\hat{u}_1 + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z \hat{u}_1 \right) \\ &+ \frac{\imath}{h} \sin\phi \left((\nu^2 - 2)\hat{v}_1 + (\nu^2 - 1)\frac{h^2}{4} D_+^z D_-^z \hat{v}_1 \right) = 0. \end{aligned} \tag{59}$$

The eigenvalue problem (56) can be solved using the ansatz

$$\hat{\mathbf{u}}_k = \mathbf{U}\kappa^k, \quad \text{where } |\kappa| < 1. \tag{60}$$

Lemma 1 is straightforward to generalize to the half-plane problem, so the spatial operator is self-adjoint, and the generalization of Lemma 3 shows that the spatial operator is negative semidefinite. All eigenvalues ζ_{hp} are therefore real and nonpositive.

Next we study the relation between ζ_{hp} and χ in (56). The roots of the quadratic equation $\chi^2 - (2 - |\zeta_{hp}|\delta_t^2)\chi + 1 = 0$ are given by

$$\chi_{1,2} = 1 - \frac{|\zeta_{hp}|\delta_t^2}{2} \pm \sqrt{\Delta}, \quad \Delta = -|\zeta_{hp}|\delta_t^2 \left(1 - \frac{|\zeta_{hp}|\delta_t^2}{4} \right).$$

If $\Delta < 0$, the roots are complex conjugates. Since the product of the roots equals one, both roots satisfy $|\chi_{1,2}| = 1$. If $\Delta = 0$, $\chi_{1,2} = -1$ is a double root. Finally, if $\Delta > 0$, both roots are real. One root will have magnitude greater than one and one less than one. Hence, the condition $|\chi| > 1$ in the normal-mode ansatz (52) is equivalent to $\Delta > 0$. Conversely, there are no solutions of the form (52) if all eigenvalues ζ_{hp} satisfy

$$-|\zeta_{hp}|\delta_t^2\left(1 - \frac{|\zeta_{hp}|\delta_t^2}{4}\right) \leq 0, \quad \text{i.e.,} \quad \frac{\delta_t^2}{4}|\zeta_{hp}| \leq 1.$$

Hence the normal-mode stability definition leads to the same type of time step restriction as in the energy method (Theorem 4), and we can use the most negative eigenvalue ζ_{hp} to approximate the eigenvalue in (45). This approximation will lead to a more restrictive time step limitation than in the von Neumann analysis if there are any eigenvalues ζ_{hp} such that

$$|\zeta_{hp}| > |\zeta_{vN}|.$$

Inserting (60) into (56) gives

$$Q\mathbf{U} = 0, \tag{61}$$

$$Q = \begin{pmatrix} \begin{matrix}-4(\nu^2\sin^2\frac{\xi}{2} + \sin^2\frac{\phi}{2}) + \\ \kappa - 2 + \kappa^{-1} - \tilde{\zeta}\end{matrix} & -(\nu^2-1)\sin\xi\sin\phi & (\nu^2-1)\imath\sin\xi(\kappa-\kappa^{-1}) \\ -(\nu^2-1)\sin\xi\sin\phi & \begin{matrix}-4(\sin^2\frac{\xi}{2} + \nu^2\sin^2\frac{\phi}{2}) + \\ \kappa - 2 + \kappa^{-1} - \tilde{\zeta}\end{matrix} & (\nu^2-1)\imath\sin\phi(\kappa-\kappa^{-1}) \\ (\nu^2-1)\imath\sin\xi(\kappa-\kappa^{-1}) & (\nu^2-1)\imath\sin\phi(\kappa-\kappa^{-1}) & \begin{matrix}-4(\sin^2\frac{\xi}{2} + \sin^2\frac{\phi}{2}) + \\ \nu^2(\kappa - 2 + \kappa^{-1}) - \tilde{\zeta}\end{matrix} \end{pmatrix},$$

where $\tilde{\zeta} = \zeta_{hp}h^2/c_s^2$. Multiply (61) by κ, and let

$$P(\tilde{\zeta}, \kappa, \xi, \phi, \nu) = 0 \tag{62}$$

be the corresponding characteristic equation. Here P is a cubic polynomial in $\tilde{\zeta}$ and a polynomial of degree six in κ. For fixed ν, ξ, and ϕ there are six roots κ for each $\tilde{\zeta}$. The following lemma is a standard result (see, e.g., [12]), which we here formulate for our discretization of the elastic wave equation.

LEMMA 4. *The characteristic equation $P = 0$ has six roots κ_l. For $\tilde{\zeta} < -|\tilde{\zeta}_{vN}| = -|\zeta_{vN}|h^2/c_s^2$, three of these roots have $|\kappa| < 1$ and three have $|\kappa| > 1$.*

Proof. A polynomial of degree six has six roots (counting multiplicity). If any κ is such that $|\kappa| = 1$, then $\kappa = e^{i\alpha}$ for some real α, and (62) becomes identical to the relation obtained in the von Neumann analysis of the fully periodic problem. We know that there are no eigenvalues with magnitude greater than $|\tilde{\zeta}_{vN}|$ in this case. Therefore there can be no κ on the unit circle when $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$. Second, take $\phi = \xi = 0$. It is not hard to see that the characteristic equation $P = 0$ becomes

$$\left[\kappa^2 - (2+\tilde{\zeta})\kappa + 1\right]\left[\kappa^2 - (2+\tilde{\zeta})\kappa + 1\right]\left[\kappa^2 - \left(2 + \frac{\tilde{\zeta}}{\nu^2}\right)\kappa + 1\right] = 0.$$

Therefore the six roots κ satisfy the pairwise relations $\kappa_1\kappa_4 = 1$, $\kappa_2\kappa_5 = 1$, and $\kappa_3\kappa_6 = 1$. Since no root can be on the unit circle when $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$, there must be three roots inside the unit circle and three roots outside of it. Furthermore, the roots

κ are smooth functions of ϕ, ξ, ν, and $\tilde{\zeta}$. Because they cannot move across the unit circle when $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$, the roots are always divided into these two groups for all values of ϕ, ξ, ν, and for any $\tilde{\zeta}$ such that $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$. □

It follows from Lemma 4 that the general solution of (56) subject to the boundary condition (51) is

$$\hat{\mathbf{u}}_k = C_1\mathbf{U}_1\kappa_1^k + C_2\mathbf{U}_2\kappa_2^k + C_3\mathbf{U}_3\kappa_3^k, \quad |\kappa_l| < 1, \quad l = 1, 2, 3, \tag{63}$$

where $\mathbf{U}_l$ are the eigenvectors corresponding to κ_l, $l = 1, 2, 3$, respectively. For each $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$, $\mathbf{U}_l$ is the null vector of the linear system (61) when the root κ_l is substituted for κ.

Inserting the general solution (63) into the stress-free boundary conditions (57)–(59) leads to a homogeneous linear system for the coefficients C_1, C_2, and C_3:

$$A \begin{pmatrix} C_1 \\ C_2 \\ C_3 \end{pmatrix} = \mathbf{0}, \tag{64}$$

where $A = A(\tilde{\zeta}, \xi, \phi, \nu)$ is a three by three matrix. There are nontrivial solutions of (64) if and only if $\det A = 0$. If (64) has a nontrivial solution $(C_1, C_2, C_3)^T$ for some $\tilde{\zeta}$, then the corresponding ζ_{hp} is an eigenvalue of (56).

Since the algebra involved in forming $\det A$ is rather complicated, we have resolved to calculate the roots of $\det A = 0$ numerically. The determinant depends on four parameters, where $\nu = c_p/c_s$ is a material constant and the angles ξ, ϕ satisfy $-\pi \leq \xi, \phi \leq \pi$. For each fixed ν, we need to find the angles ξ, ϕ that give the most negative solution $\tilde{\zeta}$ of $\det A = 0$. A straightforward approach is to discretize ξ, ϕ on a fine mesh:

$$\xi_p = -\pi + p\frac{2\pi}{N_\xi}, \quad p = 0, 1, 2, \ldots, N_\xi,$$
$$\phi_q = -\pi + q\frac{2\pi}{N_\phi}, \quad q = 0, 1, 2, \ldots, N_\phi.$$

At each mesh point $\det A$ is a complex-valued function of the real variable $\tilde{\zeta}$, and we need to consider only $\tilde{\zeta} < -|\tilde{\zeta}_{vN}|$, since only such eigenvalues can restrict the time step beyond the von Neumann limit. At each point (ξ_p, η_q), we apply a numerical root-finding routine to locate the most negative solution $\tilde{\zeta}_{p,q}$ of $\det A = 0$. We then use $\min_{p,q} \tilde{\zeta}_{p,q}$ as an approximation of the most negative solution $\tilde{\zeta}$ corresponding to ν. The fundamental operation when applying a numerical root-finding routine is to evaluate $\det A$ at a given value of $\tilde{\zeta}$, which can be broken down into the following steps:

1. Solve the characteristic equation (62) for κ. Select the three roots with $|\kappa_l| < 1$;
2. find the three eigenvectors $\mathbf{U}_l$ by solving (61) for each κ_l, $l = 1, 2, 3$;
3. form the matrix A by inserting (63) into (57)–(59);
4. compute the determinant of A.

Using the numerical root-finding procedure outlined above, we calculated the ratio between the largest stable time step for the half-plane problem with a stress-free boundary and the largest stable time step for the fully periodic case; see Figure 2. The numerical root-finding procedure located the largest eigenvalue $|\zeta_{hp}|$ at $\phi = \xi = 2\pi/3$. Hence, the spatial frequencies $\omega_x h = \omega_y h = 2\pi/3$ should grow the fastest if the time

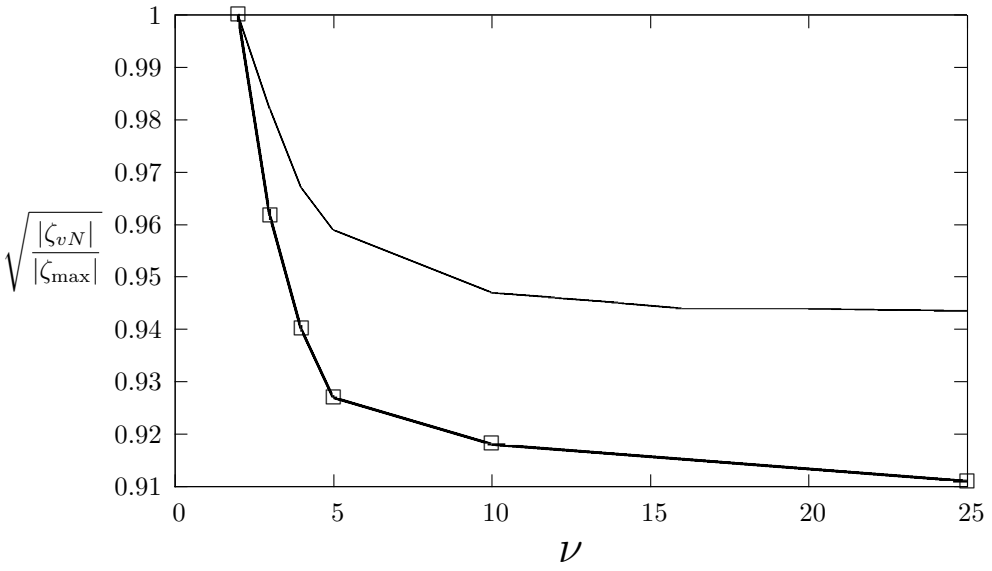

FIG. 2. *Ratio between the maximum stable time step for the half-plane problem with a free surface and that of the fully periodic problem. The line with boxes corresponds to the three-dimensional problem, and the two-dimensional case is shown with a solid line.*

step exceeds the stability limit and ν is large. This prediction was confirmed by spatially Fourier transforming an unstable numerical solution; see Figure 1.

For large ν, the solutions of $\det A = 0$ corresponding to the largest $|\tilde{\zeta}|$ were numerically found to occur when κ_1 is real with $-1 < \kappa_1 < 0$ and $\kappa_2 = \bar{\kappa_3}$ with $-1 < \mathrm{Re}(\kappa_{2,3}) < 0$. Thus, the eigenfunction corresponding to the largest eigenvalue oscillates in the z-direction with two different frequencies: the fastest frequency on the mesh $|\kappa_1|^k(-1)^k$ and more slowly $|\kappa_2|^k(\exp(\pm\imath \arg\kappa_2))^k$, where $\arg(\kappa_2) \approx 2\pi/3$ for large ν. This boundary layer behavior has been observed in numerical solutions when the time step exceeds the stability limit.

Note that the limitations imposed on the time step by the stress-free boundary are very moderate even for extreme ν values (most solid materials occuring in nature have $c_p/c_s \leq 3$). As ν gets large, the largest stable time step for the half-plane problem tends to a factor exceeding 0.91 of that for the fully periodic problem. Our practical experience with the time-stepping algorithm on bounded domains with variable coefficients and a free surface boundary condition on one side indicates that it is stable when the half-plane problem with constant coefficients is stable, using the smallest time step obtained by evaluating c_p and c_s at all grid points. Hence, we can handle all values of c_p/c_s by reducing the time step by less than 9% compared to the von Neumann value. This makes our method practically useful for all isotropic materials.

The additional time-step restriction due to the free surface boundary condition indicates that there are numerical surface waves which travel faster than any volume waves on the grid. In the continuous problem, Rayleigh (surface) waves always have a phase velocity which is smaller than c_s. Hence, it is likely that the numerical phase velocity for Rayleigh waves will depend on the grid resolution in terms of the number of grid points per wavelength. Numerical experiments along these lines are presented in section 4.1.

We also analyzed the two-dimensional version of the scheme by assuming that the solution does not depend on y. Here a von Neumann analysis of the doubly periodic case (ρ, μ, and λ constant) gives a time step restriction

$$\delta_t < \frac{h\sqrt{\rho}}{\sqrt{3\mu+\lambda}} = \frac{h}{\sqrt{c_p^2+c_s^2}}. \tag{65}$$

The stability restriction on the time step with the free surface boundary condition can be obtained using the above root-finding procedure with $\phi = 0$. The results are given in Figure 2 together with the three-dimensional case. When ν becomes large, the largest stable time step for the half-plane problem tends to a factor exceeding 0.94 of that for the fully periodic case (i.e., 6% smaller). As in the three-dimensional problem, the largest eigenvalue occurs for the spatial frequency $\omega_x h = 2\pi/3$.

2.4. Numerical tests of the scheme. In order to test the implementation of our method we first ran a number of computations without forcing with decreasing grid size h to evaluate the discrete energy C_e as a function of time. We took $\mu = 0.16$, $\lambda = 0.49$, $\rho = 1$, and started the computations with the initial data in spherical coordinates:

$$\begin{aligned} \mathbf{U}_0(r) = \nabla\left(\frac{P_{10}(r)}{r}\right), \quad \mathbf{U}_1(r) = -c_p\nabla\left(\frac{P'_{10}(r)}{r}\right), \\ r = \sqrt{(x-2)^2+(y-1.5)^2+(z-1.5)^2}, \end{aligned} \tag{66}$$

where $P_{10}(\xi)$ is the four times continously differentiable function

$$P_{10}(\xi) = \begin{cases} 0, & \xi <= 0, \\ 1024\xi^5\left(1-5\xi+10\xi^2-10\xi^3+5\xi^4-\xi^5\right), & 0<\xi<1, \\ 0, & \xi \geq 1. \end{cases} \tag{67}$$

(We note in passing that $\mathbf{u}(r,t) = \nabla(P_{10}(r-c_pt)/r)$ is an analytic solution of the free space problem.) We impose a stress-free boundary condition at $z = 0$ and enforce zero displacement conditions on all other boundaries. The size of the computational domain was $a = 4$, $b = 3$, and $c = 3$. Since there is no forcing, the discrete energy $C_e(t_n)$ should remain constant. The energy in the continuous problem is often decomposed into its kinematic and potential components

$$E(t) = K(t) + U(t),$$

where

$$\begin{aligned} K(t) =& \frac{1}{2}\int_\Omega \rho(u_t^2+v_t^2+w_t^2)\,d\Omega, \\ U(t) =& \frac{1}{2}\int_\Omega \lambda(u_x+v_y+w_z)^2 + 2\mu(u_x^2+v_y^2+w_z^2) \\ &+ \mu\left((u_y+v_x)^2+(u_z+w_x)^2+(v_z+w_y)^2\right)\,d\Omega. \end{aligned}$$

In the absence of forcing, $E(t) = \text{const}$. By dividing (47) by δ_t^2 it is straightforward to see that

$$C_e(t_{n+1}) = 2E(t_{n+1/2}) + \mathcal{O}(h^2).$$

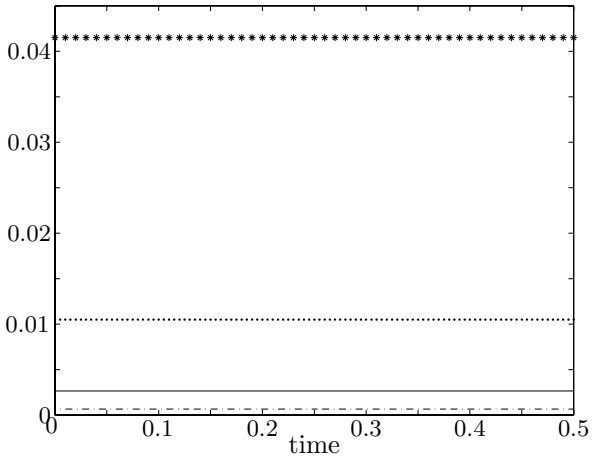

FIG. 3. *Time evolution of the relative error in the discrete energy* $(C_e(t) - 2E(t))/2E(t)$ *for different grid sizes. The discrete energy is conserved to within roundoff errors for all cases. As can be seen, the discrete energy converges towards the continuous value at the expected* $\mathcal{O}(h^2)$ *rate. Here* $h = 0.04\,(*)$, $0.02\,(\cdot)$, $0.01\,(-)$, *and* $0.005\,(-\cdot)$.

Hence, the discrete energy C_e should not only be conserved in time, but its value should also converge to $2E(t)$ as the grid is refined. Both of these properties are confirmed by our calculations; see Figure 3.

As a second test of our implementation, we check the order of accuracy of the scheme using the *method of analytical solutions* (also known as *twilight-zone* forcing [5]). The idea is to construct forcing functions $\mathbf{f}$ and $\mathbf{g}$ so that the solution of the test problem becomes a known function $\mathbf{u}^{\text{true}}(\mathbf{x}, t)$. We then solved the test problem using our implementation of the method and compared our numerical results to the known solution on a succession of finer grids in order to check the convergence properties. Our constructed solution was

$$\begin{aligned} u^{\text{true}}(\mathbf{x}, t) &= \sin(\omega(x - ct)) \sin(\omega y) \sin(\omega z), \\ v^{\text{true}}(\mathbf{x}, t) &= \sin(\omega x) \sin(\omega(y - ct)) \sin(\omega z), \\ w^{\text{true}}(\mathbf{x}, t) &= \sin(\omega x) \sin(\omega y) \sin(\omega(z - ct)), \end{aligned}$$

where ω and c are constants. The material properties were chosen to vary smoothly according to

$$\begin{aligned} \mu(\mathbf{x}) &= 1 + \cos^2(\pi x) \cos^2(\pi y) \cos^2(\pi z), \\ \lambda(\mathbf{x}) &= 1 + \sin^2(\pi x) \sin^2(\pi y) \sin^2(\pi z), \\ \rho(\mathbf{x}) &= 1. \end{aligned}$$

A normal stress condition was imposed on the $z = 0$ surface, and inhomogeneous Dirichlet conditions were imposed on all other boundaries. The computational domain had sizes $a = 2$, $b = 2$, and $c = 2$. A number of calculations with increasingly fine grid spacing were run, and the errors were evaluated in the discrete max-norm. (The discrete max-norm of a vector grid function $\mathbf{v}_h = (u_h, v_h, w_h)$ is defined as $||\mathbf{v}_h||_\infty = \max(\max_{i,j,k} |u_h|, \max_{i,j,k} |v_h|, \max_{i,j,k} |w_h|)$.) As expected we obtained second order convergence when both the forcing and the solution are smooth; see Table 1. Nonsmooth forcings and solutions will be discussed in section 3.

TABLE 1
Errors in max-norm for decreasing h and smooth analytical solution $\mathbf{u}^{\text{true}}$. Convergence rate indicates second order convergence. Here $c = 1$ and $\omega = 2\pi$.

	$t = 1$	
h	$\|\|\mathbf{v}_h - \mathbf{u}^{\text{true}}\|\|_\infty$	Rate

0.02	0.01062	4.079
0.01	0.002654	4.00
0.005	0.0006627	4.00

3. Singular source terms. In seismic wave propagation the source term is often applied at a point, along a line, or over a surface in three-dimensional space. Sources along lines or surfaces are commonly decomposed into a number of point sources distributed along the corresponding line or surface:

$$\mathbf{f}(\mathbf{x},t) = \sum_r \mathbf{f}_r^{(F)}(\mathbf{x},t) + \sum_r \mathbf{f}_r^{(M)}(\mathbf{x},t). \tag{68}$$

Two types of point sources occur in seismic applications. Point forces ($\mathbf{f}_r^{(F)}$) are, for example, used to model internal forcings due to volcanic eruptions or external forcings applied to the free surface

$$\mathbf{f}_r^{(F)}(\mathbf{x},t) = g_r(t)\mathbf{F}_r\delta(\mathbf{x}-\mathbf{x}_r), \tag{69}$$

where $\delta(\mathbf{x})$ is the Dirac distribution and $\mathbf{F}_r$ is a constant vector. The second type of point source is the point moment (or double couple), denoted by $\mathbf{f}_r^{(M)}$ in (68). Point moments are often used to model earthquakes and explosions [4] and are of the form

$$\mathbf{f}_r^{(M)}(\mathbf{x},t) = g_r(t)\,\mathfrak{M}_r \cdot \nabla\delta(\mathbf{x}-\mathbf{x}_r), \tag{70}$$

where $\nabla\delta(\mathbf{x})$ is the gradient of the Dirac distribution, and $\mathfrak{M}_r$ is a constant symmetric tensor.

Each term in (68) is applied at a location (x_r, y_r, z_r), and it is desirable to make this location independent of the grid so that the numerical modeling can be made as accurate as possible and no artifacts are generated by "stair stepping" the point sources along a smooth line or surface in three-dimensional space. Due to the singular nature of point sources, we can only expect the numerical solution to converge away from the location of the sources. Furthermore, we can expect that different numerical techniques are necessary for handling the two types of sources, since the point force depends on the Dirac distribution while the point moment depends on its gradient, which is a more singular function.

The analyses of Waldén [26] and Tornberg and Engquist [24] demonstrate that it is possible to derive regularized approximations of the Dirac distribution and its gradient, which result in pointwise convergence of the solution away from the sources. Based on these analyses, we define a hat function

$$\delta_{\text{hat}}(x) = \frac{1}{h}\begin{cases} 1-|x|/h, & |x|<h, \\ 0, & \text{elsewhere}, \end{cases} \tag{71}$$

and use $\delta_{\text{hat}}(x-x_r)\delta_{\text{hat}}(y-y_r)\delta_{\text{hat}}(z-z_r)$ to approximate $\delta(\mathbf{x})$ in (69). To approximate the gradient of a Dirac distribution, we start from the piecewise cubic function

$$\delta_{\text{cube}}(x) = \frac{1}{h}\begin{cases} 1-|x/h|/2-|x/h|^2+|x/h|^3/2, & |x|<h, \\ 1-11|x/h|/6+|x/h|^2-|x/h|^3/6, & h\le|x|<2h, \\ 0, & \text{elsewhere}. \end{cases} \tag{72}$$

We then use

$$\begin{pmatrix} \delta'_{\rm cube}(x-x_r)\delta_{\rm hat}(y-y_r)\delta_{\rm hat}(z-z_r) \\ \delta_{\rm hat}(x-x_r)\delta'_{\rm cube}(y-y_r)\delta_{\rm hat}(z-z_r) \\ \delta_{\rm hat}(x-x_r)\delta_{\rm hat}(y-y_r)\delta'_{\rm cube}(z-z_r) \end{pmatrix}$$

to approximate the Cartesian components of $\nabla\delta(\mathbf{x}-\mathbf{x}_r)$ in (70). Note that neither (71) nor (72) need to be aligned with the grid.

3.1. Spatial regularity. To study the relation between smoothness of the time function $g(t)$ in the source term and smoothness in the space of the solution, we analyze the related problem of the scalar wave equation with a singular source term. In particular, we study the problem on an infinite domain with the forcing term applied at the point $(0,0,0)$ with homogeneous initial data:

$$\begin{aligned} p_{tt} &= \nabla^2 p + g(t)\delta(\mathbf{x}), \quad \mathbf{x}\in R^3, \quad t\geq 0, \\ p(\mathbf{x},0) &= p_t(\mathbf{x},0) = 0. \end{aligned}$$

The Fourier transform of this equation is

$$\frac{d^2\hat{p}}{dt^2} = -(k_x^2+k_y^2+k_z^2)\hat{p} + g(t), \quad t\geq 0, \tag{73}$$

$$\hat{p}(k_x,k_y,k_z,0) = \hat{p}_t(k_x,k_y,k_z,0) = 0, \tag{74}$$

where the Fourier transform is given by

$$\hat{p}(k_x,k_y,k_z,t) = \int\int\int p(x,y,z,t)e^{-i(xk_x+yk_y+zk_z)}\,dx\,dy\,dz.$$

Equations (73)–(74) are solved by

$$\hat{p}(k_x,k_y,k_z,t) = \begin{cases} \int_0^t \int_0^\tau g(\tau')\,d\tau'\,d\tau, & k=0, \\ \frac{1}{k}\left(\sin(kt)\int_0^t \cos(k\tau)g(\tau)\,d\tau - \cos(kt)\int_0^t \sin(k\tau)g(\tau)\,d\tau\right), & k>0, \end{cases} \tag{75}$$

where $k=\sqrt{k_x^2+k_y^2+k_z^2}$. If $g(t)$ is continuously differentiable, we can integrate (75) by parts:

$$\begin{aligned} \hat{p}(k_x,k_y,k_z,t) = \frac{1}{k^2}\Bigg(g(t) - \cos(kt)g(0) - \sin(kt)\int_0^t \sin(k\tau)g'(\tau)d\tau \\ - \cos(kt)\int_0^t \cos(k\tau)g'(\tau)d\tau\Bigg). \end{aligned}$$

By assuming that $g(t)$ has compact support, i.e., $g(t)\equiv 0$ for $t\leq 0$ and $t\geq T$, we get

$$\begin{aligned} \hat{p}(k_x,k_y,k_z,t) = \frac{1}{k^2}\Bigg(-\sin(kt)\int_0^t \sin(k\tau)g'(\tau)\,d\tau \\ -\ \cos(kt)\int_0^t \cos(k\tau)g'(\tau)\,d\tau\Bigg), \quad t\geq T. \end{aligned}$$

The Fourier transform decays as $1/k^2$. We can continue integrating by parts as long as $g(t)$ is sufficiently differentiable, gaining one order of k for each integration. This

shows that the solution $p(\mathbf{x},t)$ has a Fourier transform that decays as $1/k^q$ for $t > T$ if $g(t)$ has compact support and is $q-1$ times differentiable in time. Furthermore, $\hat{p}$ is bounded because the singularity at $k = 0$ is removable:

$$\lim_{k\to 0} \hat{p}(k_x, k_y, k_z, t) = \int_0^t (t-\tau) g(\tau)\, d\tau = \int_0^t \int_0^\tau g(\tau')\, d\tau'\, d\tau.$$

Therefore,

$$\int\int\int (1 + k^{2q'}) |\hat{p}|^2\, dk_x\, dk_y\, dk_z < \infty$$

for $q' < q - 3/2$. By the Sobolev lemma [10], p can be identified with a function that has m continous derivatives for $m < q' - 3/2 < q - 3$. We conclude that for $t > T$ the solution $p(\mathbf{x},t)$ will have m continuous derivatives if g is compactly supported and smooth. Here m can be made arbitrarily large by choosing $g(t)$ sufficiently smooth.

If $g(t)$ does not tend to zero for large t, the solution will remain singular at the location of the point source but will be smooth away from it.

3.2. Free space solutions. Let the free space Green's (dyadic) function for the elastic wave equation in a homogeneous material be $\mathfrak{G}(\mathbf{x},t)$; see [4]. Assuming homogeneous initial data, the analytical solution of the elastic wave equation due to a source function $\mathbf{f}(\mathbf{x},\mathbf{t})$ follows as the space and time convolution between the Green's function and the source term

$$\mathbf{u}(\mathbf{x},t) = \int_t \int_\Omega \mathbf{f}(\mathbf{x}',t') \cdot \mathfrak{G}(\mathbf{x}-\mathbf{x}', t-t')\, d\mathbf{x}'\, dt'.$$

In the special case when the source is a point force, the spatial convolution becomes trivial due to the Dirac distributions in $\mathbf{f}_r^{(F)}$, and the expression reduces to a time integral over t'. Near the source, the solution behaves like $1/|\mathbf{x}-\mathbf{x}_r|$. A closed form solution can be obtained when the time integration can be performed analytically, for instance, when $g(t)$ is a polynomial function.

For a point moment source term $\mathbf{f}_r^{(M)}$, the analytical solution can be written

$$\begin{aligned}\mathbf{u}(\mathbf{x},t) &= \int_0^t \int_\Omega g_r(t') \left(\mathfrak{M}_r \cdot \nabla\delta(\mathbf{x}'-\mathbf{x}_r)\right) \cdot \mathfrak{G}(\mathbf{x}-\mathbf{x}', t-t')\, d\mathbf{x}'\, dt' \\ &= \int_0^t g_r(t')\, \mathfrak{M}_r : \nabla\mathfrak{G}(\mathbf{x}-\mathbf{x}_r, t-t')\, dt',\end{aligned}$$

where the colon represents the tensor contraction over two indices. Near the point moment, the solution behaves like $1/|\mathbf{x}-\mathbf{x}_r|^2$, so it is more singular than in the point force case.

To investigate how the numerical solution converges when the source function is singular, we ran a number of tests with point forces and point moments using the time function $g(t) = P_{10}(t)$ defined in (67). This function has compact support in $0 \le t \le 1$ and is four times continuously differentiable. We took a computational domain with $a = 2$, $b = 2$, $c = 2$, and used the material parameters $\rho = 1$, $\lambda = 0.32$, $\mu = 0.16$. Dirichlet boundary conditions were enforced on all boundaries, but the boundaries have no influence on the solution until $t > 1.25$ since $c_p = 0.8$ and the point sources were centered at $\mathbf{x}_r = (1,1,1)$. The errors were measured at two different times in discrete max-, 2-, and 1-norms. Since the analytical solution is singular

TABLE 2

Relative error in the numerical solution of the free space problem at time $t = 0.5$ (singular solution) due to a point force (top) and a point moment (bottom), measured in max-, 2-, and 1-norms. Here $\mathbf{v}_h$ and $\mathbf{u}$ denote the numerical and analytical solutions, respectively.

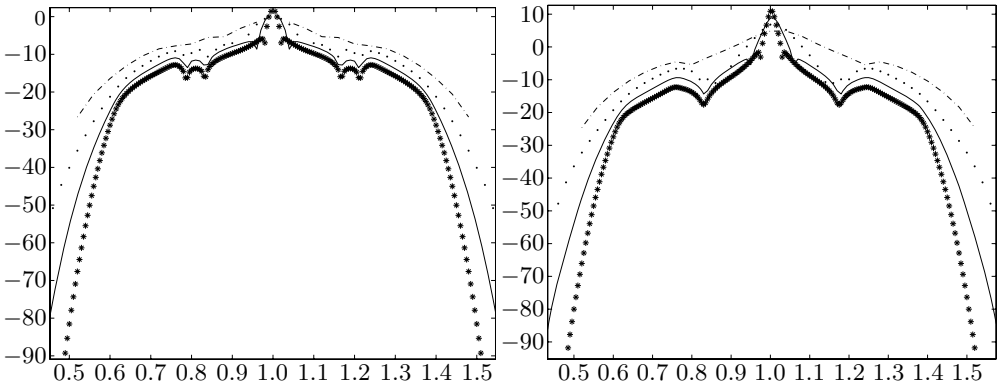

FIG. 4. *The 2-logarithm of the error along a line going through the source point for a point force (left) and a point moment source (right), both located at $x = 1$. Note that the error decays as $\mathcal{O}(h^2)$ away from the source but not near it. Near the source, the error is about $2^{11} \approx 2000$ times larger for the point moment than for the point force. The grid sizes were $h = 0.04\,(-\cdot)$, $0.02\,(\cdot)$, $0.01\,(-)$, and $0.005\,(*)$.*

at the point where the source applies, that point was excluded from the calculation of the norms. (The 2- and 1-norms for a vector grid function $\mathbf{u}$ are defined as $||\mathbf{u}||_2^2 = h^3 \sum_{i,j,k}(|u_{i,j,k}|^2+|v_{i,j,k}|^2+|w_{i,j,k}|^2)$ and $||\mathbf{u}||_1 = h^3 \sum_{i,j,k}(|u_{i,j,k}|+|v_{i,j,k}|+|w_{i,j,k}|)$.) First we evaluated the errors at $t = 0.5$ when $g(t) > 0$; see Table 2. As expected we did not achieve second order convergence because the solution of the continuous problem is singular. Also note that the convergence rate is slower for the point moment source than in the less singular point force case. In Figure 4, we show the errors as a function of the distance from the singularity. Away from the singularity, the errors are smooth in space and decay like $\mathcal{O}(h^2)$ as the grid size tends to zero. However, near the source the errors do not decay as the grid is refined, and this explains the convergence numbers in Table 2. Second, we evaluated the errors at $t = 1.2$, when $g(t) = 0$; see Table 3. After the source term has vanished the solution becomes smooth everywhere, and our results show the proper second order convergence rate in accordance with theory.

We remark that in the point moment source case it is important to use the δ'_{cube} approximation in the gradient of the Dirac distribution, as opposed to δ'_{hat}. Otherwise

TABLE 3

Relative error in the numerical solution of the free space problem at time $t = 1.2$ (smooth solution) due to a point force (top) and a point moment (bottom), measured in max-, 2-, and 1-norms. Here $\mathbf{v}_h$ and $\mathbf{u}$ denote the numerical and analytical solutions, respectively.

the convergence rate will be slower than second order in the grid size (example not shown to conserve space).

3.3. Half spaces and Lamb's problem. Point forcing on the boundary of a half space is referred to as Lamb's problem [20]. Analytical solutions for the three-dimensional problem have been presented by a number of authors with different degrees of applicability. For the case of a point force directed normal to the free surface $z = 0$, the general solution can be found in [22] or [9]. To test the accuracy of the numerical solutions, we performed a grid refinement study on a computational domain with sizes $a = 4$, $b = 4$, $c = 2$, enforcing a free surface boundary condition along $z = 0$ and Dirichlet conditions on all other boundaries. We assumed a Poisson material with $\rho = 1$, $\mu = 1$, and $\lambda = 1$, i.e., $c_p/c_s = \sqrt{3}$, and used the same time function $g(t)$ as in the free space case. In this experiment, the point force was applied at $\mathbf{x}_r = (2, 2, 0)$, so the Dirichlet boundaries should not affect the solution until $t > 1.15$. The error in the numerical solution was evaluated both at $t = 0.5$, when the solution of the continuous problem is singular, and at $t = 1.1$, when the solution is smooth. We report only the error along the free surface, because the analytical solution is difficult to evaluate in the interior of the domain. As in the free space problem, we observe second order convergence only when the solution is smooth in space; see Table 4.

4. Applications and extensions of the method.

4.1. Surface waves. The elastodynamic equations together with the stress-free boundary condition admit solutions in the form of surface waves, i.e., waves propagating along the surface with amplitude decaying exponentially away from the surface. For the homogeneous two-dimensional half-plane problem in $z \geq 0$, these solutions are commonly referred to as Rayleigh waves and have the form

$$u(x,z,t) = A\left(e^{-\eta_p \omega z} - \left(1 - \frac{c_r^2}{2c_s^2}\right) e^{-\eta_s \omega z}\right) \sin(\omega(c_r t - x)), \tag{76}$$

$$w(x,z,t) = A\left(1 - \frac{c_r^2}{c_p^2}\right)^{1/2} \left(-e^{-\eta_p \omega z} + \left(1 - \frac{c_r^2}{2c_s^2}\right)^{-1} e^{-\eta_s \omega z}\right) \cos(\omega(c_r t - x)), \tag{77}$$

where

$$\eta_p = \left(1 - \frac{c_r^2}{c_p^2}\right)^{1/2}, \quad \eta_s = \left(1 - \frac{c_r^2}{c_s^2}\right)^{1/2}.$$

Here c_r is the phase velocity of the wave, which is the real root of the Rayleigh equation

$$\left(2 - \frac{c_r^2}{c_s^2}\right)^2 - 4\left(1 - \frac{c_r^2}{c_p^2}\right)^{1/2} \left(1 - \frac{c_r^2}{c_s^2}\right)^{1/2} = 0, \quad 0 < c_r < c_s.$$

The waves described by (76)–(77) are nondispersive; i.e., c_r is independent of ω. However, the discretization introduces errors that can be interpreted as a numerical dispersion relation where the phase velocity depends on the resolution on the grid. The numerical dispersion relation for our interior difference stencil coincides with previous central difference schemes which were analyzed by Cohen [7]. For surface waves, the numerical dispersion relation provides the numerical phase velocity c_r^* as a function of the resolution ωh, which often is expressed in terms of the number of grid points per wavelength

$$\mathrm{PPW} = \frac{2\pi}{\omega h}.$$

Since it is very complicated to analytically derive the numerical dispersion relation for surface waves, we instead investigate the relation by numerical experiments using a two-dimensional version of our method. A free surface condition was imposed at $z = 0$, and periodic boundary conditions were used in the x-direction. We enforced (76)–(77) as initial data, which contains only a single spatial frequency ω. Hence, the numerical solution should essentially advect the initial data with a modified phase velocity c_r^*. We determined c_r^* by visually inspecting the solution along the surface at time $t = 1/c_r$ and comparing the positions of the numerical and analytical solutions; see Table 5. Note that the visual inspection is not very precise when the solution is poorly resolved on the grid (PPW < 5), so these results should be interpreted accordingly. Despite this uncertainty, it is clear that the numerical phase velocity increases rapidly as ωh approaches $2\pi/3$ and $\nu \geq 3$. It is interesting to note that this value of ωh coincides with the spatial frequency of the fast surface waves which determine the stability limit of the time step; cf. section 2.3.

TABLE 5

Numerical dispersion relation for the finite difference scheme applied to Rayleigh waves. The table shows the ratio between the estimated phase velocity in the numerical solution and its continuous value, using different number of grid points per wavelength (PPW) and ν.

	c_r^*/c_r			
PPW	$\nu = 2$	$\nu = 3$	$\nu = 5$	$\nu = 10$
40	1.0028	1.0065	1.017	1.055
20	1.011	1.022	1.052	1.12
10	1.031	1.06	1.11	1.2
8	1.043	1.083	1.13	1.5
6	1.049	1.095	1.35	1.63
5	1.07	1.11	1.4	1.72
4	1.095	1.14	1.65	1.78
3.5	1.16	1.4	2.76	2.9

4.2. Nonreflecting boundary conditions. When modeling seismic events such as the simplified earthquake in section 4.3, it is desirable to truncate the computational domain without causing significant amounts of artificial reflections. Many different methods, including absorbing, nonreflecting, and perfectly matching techniques have been proposed in the literature. Here we will use the first order nonreflecting boundary conditions developed by Clayton and Engquist [6]. The well-known idea behind these boundary conditions is to impose a differential equation on the boundary which allows wave propagation only in the outward direction. For boundaries with $x = \text{const}$, the boundary conditions are

$$u_t = \pm c_p u_x,\ v_t = \pm c_s v_x,\ w_t = \pm c_s w_x, \tag{78}$$

where the positive signs are taken for the lower boundary $x = 0$ and the negative signs for the upper boundary $x = a$. Similar advection equations are imposed at boundaries with $y = \text{const}$ or $z = \text{const}$.

Away from edges in the computational domain, we have found that the box scheme discretization [6] of the boundary condition (78) works well. At the edges of the domain, i.e., where two nonreflecting boundaries meet, Clayton and Engquist suggested applying the nonreflecting boundary condition in a diagonal direction. However, we have found that imposing compatibility conditions along the edges results in a more rubust method which also is easier to implement. We examplify the compatibility conditions on the edge where $x = 0$ and $y = 0$. Along the boundary $x = 0$, we impose (78) (with the positive sign). The corresponding boundary conditions along $y = 0$ are

$$u_t = c_s u_y,\ v_t = c_p v_y,\ w_t = c_s w_y, \quad y = 0,\ 0 \le x \le a,\ 0 \le z \le c,\ t \ge 0.$$

Equating the time derivatives along the edge gives

$$\begin{aligned} c_p u_x &= c_s u_y, \\ c_s v_x &= c_p v_y, \quad y = 0,\ x = 0,\ 0 \le z \le c,\ t \ge 0, \\ c_s w_x &= c_s w_y. \end{aligned}$$

Similar relations can easily be derived for the other edges.

4.3. A simplified earthquake. The Pacific Earthquake Engineering Center and the Southern California Earthquake Center have defined a set of seismic model problems in an effort to evaluate and validate wave propagation software [8]. We have computed solutions to several of these problems, but in order to save space we report

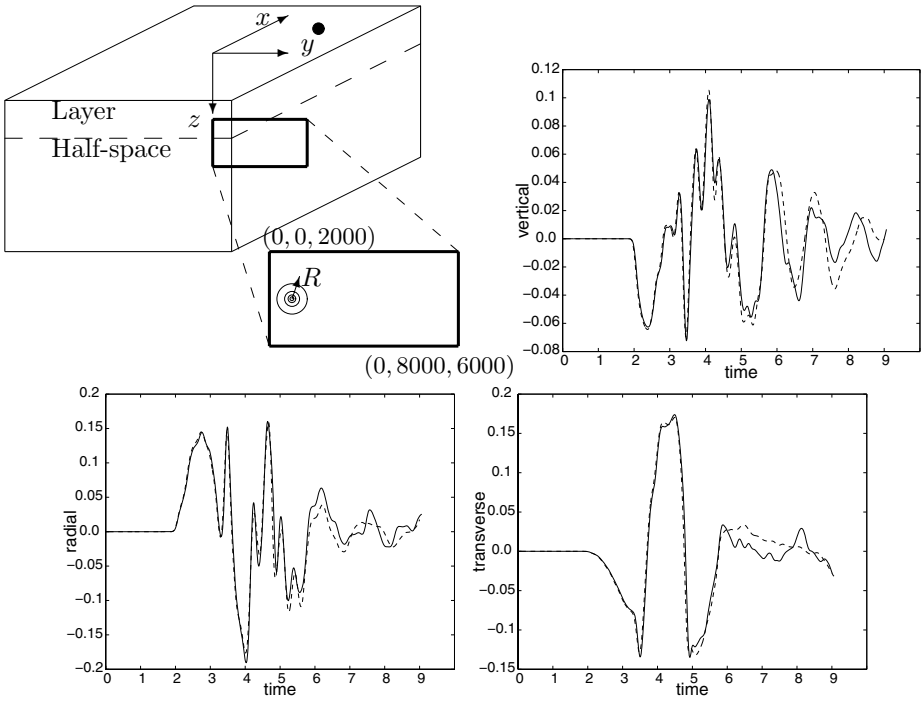

FIG. 5. *The computational domain and fault surface for the simplified earthquake problem LOH.2 (upper left). The • indicates the measurement station, and the magnified plane shows the fault surface, where the slip starts at the hypocenter indicated by concentric circles. Our results are shown with solid lines for the vertical (top right), radial (bottom left), and transverse (bottom right) velocity components, and the dashed lines are the results from the UCSB code; see* [8].

only our results for problem LOH.2, which models a simplified earthquake with slip on an extended fault surface; see Figure 5. The material in this model consists of a layer over a half-space, where the layer extends from depth $z = 0$ to $z = 1000$. The velocities and density in the layer are $c_p = 4000$, $c_s = 2000$, $\rho = 2600$. The half-space $z \geq 1000$ has the material properties $c_p = 6000$, $c_s = 3464$, $\rho = 2700$.

The slip on the extended fault is modeled by distributing point moment sources on a regular grid with size δ_s (which is independent of the grid size h) over the fault surface $x = 0$, $0 \leq y \leq 8000$, $2000 \leq z \leq 6000$. In this case, the fault slips by a constant amount in the y-direction, which means that the Cartesian components of the moment tensor $\mathfrak{M}_r$ in each source term (70) equal

$$\mathfrak{M}_r = \delta_s^2 \mu S_0 \begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad S_0 = 1.$$

The modeled earthquake starts at the hypocenter $\mathbf{x}_H = (0, 1000, 4000)$, and the rupture propagates along the fault surface with a uniform rupture velocity of 3000. The propagation of the rupture is modeled by letting the source time function $g_r(t)$ depend on the distance between the hypocenter and the location of each source

$$R_r = |\mathbf{x}_r - \mathbf{x}_H|.$$

The time dependence of source number r is

$$g_r(t) = \begin{cases} 0, & t < R_r/3000, \\ 1 - \left(1 + \dfrac{\tau_r(t)}{T}\right) e^{-\tau_r(t)/T}, & t \geq R_r/3000, \end{cases} \qquad \tau_r(t) = t - R_r/3000,$$

where $T = 0.1$ is related to the rise time of the slip, i.e., how quickly the fault slips at each fixed point along the fault surface.

In our calculation, the extent of the computational domain was $-15000 \leq x \leq 15000$, $-15000 \leq y \leq 15000$, $0 \leq z \leq 17000$, and nonreflecting boundary conditions were imposed on all boundaries except at $z = 0$, where a free surface condition was enforced. The grid size was $h = 50$, corresponding to about 1.23×10^8 grid points, and 1742 time steps were taken to reach time $t = 9$. We discretized the fault surface with $\delta_s = 100$, giving 3200 point moment sources. Results for this problem are available from a number of finite difference and finite element codes [8]. To compare our results, we recorded the time evolution of the velocity (i.e., the time derivative of the displacement) at a number of stations along a line on the free surface. Since all codes predicted similar results, we show only the comparison with the UCSB code (using notation from [8]). This code solves the elastic wave equation as a first order system in velocity-stress formulation using a staggered grid finite difference method. Since the source time functions $g_r(t)$ trigger high frequency motions which are not resolvable on the mesh, the results from both our code and the UCSB code were low-pass filtered in time using a Gaussian with filter width $\sigma = 0.05$. In Figure 5 we compare solutions at a station located at $\mathbf{x} = (6000, 8000, 0)$. Velocities are given in a cylindrical coordinate system (radial, transverse, up) with the origin at $(0, 0, 0)$. Note that the nonreflecting boundary conditions affects the solution only after $t \approx 5$ and that our results compare especially well with the other code before that time. One way of determining the accuracy of the solution after $t \approx 5$ would be to repeat the simulation on a larger domain, but the computational cost was too great to perform that experiment.

5. Conclusions. We have described a stable, second order accurate finite difference method for the elastic wave equation in second order formulation subject to a stress-free boundary condition on a flat surface. We have proven that the method is stable even when the coefficients are discontinuous in space, as long as $\mu > 0$, $\lambda > 0$, and $\rho > 0$ at all grid points. The stability limit on the time step has been studied in detail, and we have shown that all values of $c_p/c_s > \sqrt{2}$ can be handled if the time step is reduced by 9% compared to the von Neumann value. We have also described a way to discretize point forces and moments on the mesh so that the solution becomes second order accurate away from the singularity in the solution.

In seismic applications it is common to have water (e.g., a lake or an ocean) in parts of the domain. Only compressional (P) waves can travel through water, and the acoustic wave propagation can be modeled by setting $\mu = 0$ in the elastic wave equation. We have generalized our scheme to handle the mixed elastic/acoustic case, and this scheme was used as part of a simulation effort coordinated by the U.S. Geological Survey to model ground motions during the great 1906 San Francisco earthquake [23]. Our results showed good agreement with other codes and measured Mercalli intensities. More details will be described in a forthcoming paper [1].

Future plans include generalizing our embedded boundary technique for the scalar wave equation [19, 17, 16] to the elastic wave equation. In the seismic application, embedded boundaries will allow us to include effects of topography and more accurately treat internal material discontinuities. We are also exploring generalizations to fourth order accuracy and curvilinear coordinates.

Appendix A. Accuracy (Theorem 1). We will prove the accuracy of the semidiscrete equations by showing that they are equivalent to another approximation which clearly is second order accurate. In particular, we want to analyze the accuracy of the spatial discretization (17)–(19) at the $z = 0$ boundary, where the free surface boundary condition is applied. At this boundary, the operator $\widetilde{D_0^z}$ simplifies to D_+^z, which would appear to give only a first order accurate difference formula. However, we proceed to show that this difference formula, in combination with the discrete free surface boundary condition, indeed results in a second order approximation.

We start by eliminating the ghost points above the free surface from the semidiscrete system (17)–(19), subject to the boundary conditions (20)–(22). To save space, we go through only the details for (17) subject to (20). The terms in $L^{(u)}$ that contain z-differences on the $z = 0$ grid line are

$$T_{i,j} =: D_-^z \left(\mu_{i,j,3/2} D_+^z u_{i,j,1}\right) + D_0^x \left(\lambda_{i,j,1} D_+^z w_{i,j,1}\right) + D_+^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right).$$

The free surface boundary condition (20) gives

$$\mu_{i,j,1/2} D_+^z u_{i,j,0} = -\mu_{i,j,3/2} D_+^z u_{i,j,1} - 2\mu_{i,j,1} D_0^x w_{i,j,1}.$$

Hence,

(79)
$$T_{i,j} = \frac{2}{h}\left[\mu_{i,j,3/2} D_+^z u_{i,j,1} + \mu_{i,j,1} D_0^x w_{i,j,1}\right] + D_0^x \left(\lambda_{i,j,1} D_+^z w_{i,j,1}\right) + D_+^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right).$$

We compare the spatial discretization to a fully centered scheme where the terms in $L^{(u)}$ that contain z-differences on the $z = 0$ grid line:

$$\widetilde{T}_{i,j} =: D_-^z \left(\mu_{i,j,3/2} D_+^z u_{i,j,1}\right) + D_0^x \left(\lambda_{i,j,1} D_0^z w_{i,j,1}\right) + D_0^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right). \tag{80}$$

We can perturb the free surface boundary condition (20) by a second order term

$$\frac{1}{2}\left(\mu_{i,j,3/2} D_+^z u_{i,j,1} + \mu_{i,j,1/2} D_+^z u_{i,j,0}\right) + \mu_{i,j,1} D_0^x w_{i,j,1} = h^2 R_{i,j}. \tag{81}$$

The resulting spatial discretization will be second order accurate as long as R is a difference operator which is bounded independently of h for smooth functions. We will determine R such that (80) subject to (81) is equivalent to (79). The boundary condition (81) gives

$$\mu_{i,j,1/2} D_+^z u_{i,j,0} = -\mu_{i,j,3/2} D_+^z u_{i,j,1} - 2\mu_{i,j,1} D_0^x w_{i,j,1} + 2h^2 R_{i,j}. \tag{82}$$

Using (82), (80) can be written

$$\begin{aligned}\widetilde{T}_{i,j} = \frac{2}{h}\left[\mu_{i,j,3/2} D_+^z u_{i,j,1} + \mu_{i,j,1} D_0^x w_{i,j,1}\right] + D_0^x \left(\lambda_{i,j,1} D_0^z w_{i,j,1}\right) \\ + D_0^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right) + 2hR_{i,j}.\end{aligned}$$

Hence, $T = \widetilde{T}$ if

$$\begin{aligned}&D_0^x \left(\lambda_{i,j,1} D_+^z w_{i,j,1}\right) + D_+^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right) \\ &\quad = D_0^x \left(\lambda_{i,j,1} D_0^z w_{i,j,1}\right) + D_0^z \left(\mu_{i,j,1} D_0^x w_{i,j,1}\right) + 2hR_{i,j}.\end{aligned}$$

We have

$$D_0^z w = D_+^z w - \frac{h}{2} D_+^z D_-^z w,$$

which gives

$$R_{i,j} = \frac{1}{4} D_0^x (\lambda_{i,j,1} D_+^z D_-^z w_{i,j,1}) + \frac{1}{4} D_+^z D_-^z (\mu_{i,j,1} D_0^x w_{i,j,1}).$$

Similar calculations show that the boundary conditions (21) and (22) can be perturbed by second order terms to account for the difference between a fully centered and a one-sided spatial discretization in $L^{(v)}$ and $L^{(w)}$, respectively.

This proves that the semidiscrete approximation (17)–(19) subject to the boundary conditions (20)–(22) is second order accurate. ∎

Note. Inserting the expression for $R_{i,j}$ into (81) shows that the fully centered approximation couples all ghost points ($k = 0$) along the free surface. Hence, using this formulation would require a linear system to be solved to obtain the ghost point values at each time step. As we have demonstrated, the same solution can be obtained without solving a linear system by using our one-sided formula on the boundary.

Appendix B. Self-adjointness of the spatial operator (Lemma 1). It is straightforward to show the following summation by parts identities:

(83)
$$(w, D_-^z v)_h = -(D_+^z w, v)_h - \frac{h^2}{2} \sum_{i,j} (w_{i,j,2} v_{i,j,1} + w_{i,j,1} v_{i,j,0}) + h^2 \sum_{i,j} w_{i,j,N_z} v_{i,j,N_z-1},$$

(84)
$$(w, \widetilde{D_0^z} v)_h = -(\widetilde{D_0^z} w, v)_h - h^2 \sum_{i,j} w_{i,j,1} v_{i,j,1} + \frac{h^2}{2} \sum_{i,j} \left(w_{i,j,N_z-1} v_{i,j,N_z} + w_{i,j,N_z} v_{i,j,N_z-1} \right),$$

where $\sum_{i,j} = \sum_{i=1}^{N_x-1} \sum_{j=1}^{N_y-1}$. Since the solution satisfies periodic boundary conditions in the x- and y-directions, we have

$$(w, D_-^x v)_h = -(D_+^x w, v)_h, \quad (w, D_0^x v)_h = -(D_0^x w, v)_h, \tag{85}$$

$$(w, D_-^y v)_h = -(D_+^y w, v)_h, \quad (w, D_0^y v)_h = -(D_0^y w, v)_h. \tag{86}$$

Consider the three terms in the left-hand side of (26): LHS := I + II + III,

$$\mathrm{I} = \left(u^0, L^{(u)}(u^1, v^1, w^1)\right)_h, \quad \mathrm{II} = \left(v^0, L^{(v)}(u^1, v^1, w^1)\right)_h,$$
$$\mathrm{III} = \left(w^0, L^{(w)}(u^1, v^1, w^1)\right)_h.$$

Applying the summation by parts identities (83)–(86) on the first term gives

$$\begin{aligned} \mathrm{I} = &- \left(D_+^x u^0, E_{1/2}^x (2\mu + \lambda) D_+^x u^1\right)_h - \left(D_+^y u^0, E_{1/2}^y (\mu) D_+^y u^1\right)_h \\ &- \left(D_+^z u^0, E_{1/2}^z (\mu) D_+^z u^1\right)_h - \left(D_0^x u^0, \lambda D_0^y v^1 + \lambda \widetilde{D_0^z} w^1\right)_h \\ &- \left(D_0^y u^0, \mu D_0^x v^1\right)_h - \left(\widetilde{D_0^z} u^0, \mu D_0^x w^1\right)_h + B^{(u)}, \end{aligned} \tag{87}$$

where the boundary terms are

$$\begin{aligned} B^{(u)} = &- \frac{h^2}{2} \sum_{i,j} \left(u^0_{i,j,2} \mu_{i,j,3/2} D^z_+ u^1_{i,j,1} + u^0_{i,j,1} \mu_{i,j,1/2} D^z_+ u^1_{i,j,0} \right) \\ &- h^2 \sum_{i,j} u^0_{i,j,1} \mu_{i,j,1} D^x_0 w^1_{i,j,1} + h^2 \sum_{i,j} u^0_{i,j,N_z} \mu_{i,j,N_z-1/2} D^z_+ u^1_{i,j,N_z-1} \\ &+ \frac{h^2}{2} \sum_{i,j} \left(u^0_{i,j,N_z-1} \mu_{i,j,N_z} D^x_0 w^1_{i,j,N_z} + u^0_{i,j,N_z} \mu_{i,j,N_z-1} D^x_0 w^1_{i,j,N_z-1} \right). \end{aligned}$$

The homogeneous Dirichlet boundary condition (23) gives

$$u^0_{i,j,N_z} = 0, \quad D^x_0 w^1_{i,j,N_z} = 0.$$

Hence, the third and fourth terms in $B^{(u)}$ vanish. To analyze the first term, we note that

$$u^0_{i,j,2} = u^0_{i,j,1} + h D^z_+ u^0_{i,j,1}.$$

Therefore,

$$\begin{aligned} B^{(u)} = -\frac{h^2}{2} \sum_{i,j} u^0_{i,j,1} \left(\mu_{i,j,3/2} D^z_+ u^1_{i,j,1} + \mu_{i,j,1/2} D^z_+ u^1_{i,j,0} + 2\mu_{i,j,1} D^x_0 w^1_{i,j,1} \right) \\ - \frac{h^3}{2} \sum_{i,j} \mu_{i,j,3/2} D^z_+ u^0_{i,j,1} D^z_+ u^1_{i,j,1}. \end{aligned} \tag{88}$$

The first term in (88) vanishes because of the free surface boundary condition (20), and we arrive at

$$B^{(u)} = -\frac{h^3}{2} \sum_{i,j} \mu_{i,j,3/2} D^z_+ u^0_{i,j,1} D^z_+ u^1_{i,j,1}.$$

The second term in LHS can be analyzed in the same way, giving

$$\begin{aligned} \mathrm{II} = &- \left(D^x_+ v^0, E^x_{1/2}(\mu) D^x_+ v^1 \right)_h - \left(D^y_+ v^0, E^y_{1/2}(2\mu+\lambda) D^y_+ v^1 \right)_h \\ &- \left(D^z_+ v^0, E^z_{1/2}(\mu) D^z_+ v^1 \right)_h - \left(D^x_0 v^0, \mu D^y_0 u^1 \right)_h \\ &- \left(D^y_0 v^0, \lambda D^x_0 u^1 + \lambda \widetilde{D^z_0} w^1 \right)_h - \left(\widetilde{D^z_0} v^0, \mu D^y_0 w^1 \right)_h + B^{(v)}, \end{aligned} \tag{89}$$

where

$$B^{(v)} = -\frac{h^3}{2} \sum_{i,j} \mu_{i,j,3/2} D^z_+ v^0_{i,j,1} D^z_+ v^1_{i,j,1}.$$

For the third term in LHS, we get

$$\begin{aligned} \mathrm{III} = &- \left(D^x_+ w^0, E^x_{1/2}(\mu) D^x_+ w^1 \right)_h - \left(D^y_+ w^0, E^y_{1/2}(\mu) D^y_+ w^1 \right)_h \\ &- \left(D^z_+ w^0, E^z_{1/2}(2\mu+\lambda) D^z_+ w^1 \right)_h - \left(D^x_0 w^0, \mu \widetilde{D^z_0} u^1 \right)_h \\ &- \left(D^y_0 w^0, \mu \widetilde{D^z_0} v^1 \right)_h - \left(\widetilde{D^z_0} w^0, \lambda D^x_0 u^1 + \lambda D^y_0 v^1 \right)_h + B^{(w)}, \end{aligned} \tag{90}$$

where

$$B^{(w)} = -\frac{h^3}{2}\sum_{i,j}(2\mu_{i,j,3/2}+\lambda_{i,j,3/2})D_+^z w^0_{i,j,1} D_+^z w^1_{i,j,1}.$$

After applying the same summation by parts rules to the right-hand side of (26), it is straightforward to verify that the right-hand side equals the left-hand side. ∎

Appendix C. Ellipticity of the spatial operator (Lemma 3). We will mimic the construction of the energy in the continuous case by exploring the identity

$$D_-^x E_{1/2}^x(\mu) D_+^x u = D_0^x\left(\mu D_0^x u\right) - \frac{h^2}{4} D_+^x D_-^x\left(\mu D_+^x D_-^x u\right) \tag{91}$$

in the periodic x- and y-directions. The problem is not periodic in the z-direction. We will use the following summation-by-parts form of the above identity instead ($N = N_z$ in this appendix)

$$\begin{aligned}\left(u, D_-^z E_{1/2}^z(\mu) D_+^z u\right)_h &= -\left(\widetilde{D_0^z} u, \mu \widetilde{D_0^z} u\right)_h - \frac{h^2}{4}\left(D_+^z D_-^z u, \mu D_+^z D_-^z u\right)_{hr} \\ &+ h^2 \sum_{i,j}\left(-\frac{1}{2}\mu_{i,j,1/2} u_{i,j,1} D_+^z u_{i,j,0} - \frac{1}{2}\mu_{i,j,3/2} u_{i,j,1} D_+^z u_{i,j,1}\right. \\ &\left. + \frac{\mu_{i,j,N}}{2} u_{i,j,N-1} D_+^z u_{i,j,N-1} + \frac{\mu_{i,j,N-1}}{2} u_{i,j,N} D_+^z u_{i,j,N-1}\right).\end{aligned} \tag{92}$$

We obtain, by use of (91) in the periodic directions,

$$\begin{aligned}L^{(u)}(u,v,w) &= 2D_-^x\left(E_{1/2}^x(\mu) D_+^x u\right) + D_-^z\left(E_{1/2}^z(\mu) D_+^z u\right) \\ &+ D_0^x\left(\lambda(D_0^x u + D_0^y v + \widetilde{D_0^z} w)\right) + D_0^y\left(\mu(D_0^y u + D_0^x v)\right) + \widetilde{D_0^z}\left(\mu D_0^x w\right) \\ &- \frac{h^2}{4}\left(D_+^x D_-^x(\lambda D_+^x D_-^x u) + D_+^y D_-^y(\mu D_+^y D_-^y u)\right), \\ L^{(v)}(u,v,w) &= 2D_-^y\left(E_{1/2}^y(\mu) D_+^y v\right) + D_-^z\left(E_{1/2}^z(\mu) D_+^z v\right) \\ &+ D_0^y\left(\lambda(D_0^x u + D_0^y v + \widetilde{D_0^z} w)\right) + D_0^x\left(\mu(D_0^y u + D_0^x v)\right) + \widetilde{D_0^z}\left(\mu D_0^y w\right) \\ &- \frac{h^2}{4}\left(D_+^x D_-^x(\mu D_+^x D_-^x v) + D_+^y D_-^y(\lambda D_+^y D_-^y v)\right), \\ L^{(w)}(u,v,w) &= 2D_-^z\left(E_{1/2}^z(\mu) D_+^z w\right) + D_-^z\left(E_{1/2}^z(\lambda) D_+^z w\right) \\ &+ \widetilde{D_0^z}\left(\lambda(D_0^x u + D_0^y v)\right) + D_0^x\left(\mu(\widetilde{D_0^z} u + D_0^x w)\right) + D_0^y\left(\mu(\widetilde{D_0^z} v + D_0^y w)\right) \\ &- \frac{h^2}{4}\left(D_+^x D_-^x(\mu D_+^x D_-^x w) + D_+^y D_-^y(\mu D_+^y D_-^y w)\right).\end{aligned}$$

Identities (92) and (84) give

$$\begin{aligned}(u, L^{(u)})_h = &-2(D_+^x u, E_{1/2}^x(\mu) D_+^x u)_h - (\widetilde{D_0^z} u, \mu \widetilde{D_0^z} u)_h \\ &- \left(D_0^x u, \lambda(D_0^x u + D_0^y v + \widetilde{D_0^z} w)\right)_h - \left(D_0^y u, \mu(D_0^y u + D_0^x v)\right)_h \\ &- \left(\widetilde{D_0^z} u, \mu D_0^x w\right)_h - \frac{h^2}{4}\left[(D_+^x D_-^x u, \lambda D_+^x D_-^x u)_h\right. \\ &\left. + (D_+^y D_-^y u, \mu D_+^y D_-^y u)_h + (D_+^z D_-^z u, \mu D_+^z D_-^z u)_{hr}\right] + T_1^{(u)} + T_N^{(u)},\end{aligned}$$

where $T_1^{(u)}$ and $T_N^{(u)}$ are the boundary terms that correspond to the boundary at $k = 1$ and at $k = N$, respectively. The periodic directions do not contribute with any boundary terms as seen from (85) and (86). We have

$$\begin{aligned} T_1^{(u)} &= h^2 \sum_{i,j} \left(-\frac{1}{2}\mu_{i,j,1/2} u_{i,j,1} D_+^z u_{i,j,0} - \frac{1}{2}\mu_{i,j,3/2} u_{i,j,1} D_+^z u_{i,j,1} - u_{i,j,1}\mu_{i,j,1} D_0^x w_{i,j,1} \right) \\ &= h^2 \sum_{i,j} u_{i,j,1} \left(-\frac{1}{2}\mu_{i,j,1/2} D_+^z u_{i,j,0} - \frac{1}{2}\mu_{i,j,3/2} D_+^z u_{i,j,1} - \mu_{i,j,1} D_0^x w_{i,j,1} \right). \end{aligned}$$

It follows directly from the free surface boundary condition (20) that $T_1^{(u)} = 0$. The boundary terms at $k = N$ are given by

$$\begin{aligned} T_N^{(u)} = h^2 \sum_{i,j} \Big(&\frac{\mu_{i,j,N-1}}{2} u_{i,j,N} D_0^x w_{i,j,N-1} + \frac{\mu_{i,j,N} u_{i,j,N-1}}{2} D_0^x w_{i,j,N} \\ &+ \frac{\mu_{i,j,N}}{2} u_{i,j,N-1} D_-^z u_{i,j,N} + \frac{\mu_{i,j,N-1}}{2} u_{i,j,N} D_-^z u_{i,j,N} \Big). \end{aligned}$$

The Dirichlet boundary condition at $k = N$ gives

$$T_N^{(u)} = -h \sum_{i,j} \frac{\mu_{i,j,N}}{2} u_{i,j,N-1}^2.$$

Similarly, we obtain

$$\begin{aligned} (v, L^{(v)})_h = &- 2(D_+^y v, E_{1/2}^y(\mu) D_+^y v)_h - (\widetilde{D_0^z} v, \mu \widetilde{D_0^z} v)_h \\ &- \left(D_0^y v, \lambda (D_0^x u + D_0^y v + \widetilde{D_0^z} w) \right)_h - (D_0^x v, \mu (D_0^y u + D_0^x w))_h \\ &- \left(\widetilde{D_0^z} v, \mu D_0^y w \right)_h - \frac{h^2}{4} \left[(D_+^x D_-^x v, \mu D_+^x D_-^x v)_h \right. \\ &\left. + (D_+^y D_-^y v, \lambda D_+^y D_-^y v)_h + (D_+^z D_-^z v, \mu D_+^z D_-^z v)_{hr} \right] \\ &- h \sum_{i,j} \frac{\mu_{i,j,N}}{2} v_{i,j,N-1}^2. \end{aligned}$$

In the z-direction, we make use of (84) and (92) as well as

$$\begin{aligned} &\left(w, D_+^z \left(E_{1/2}^z(\mu) D_-^z w \right) \right)_h = - \left(D_+^z w, E_{1/2}^z(\mu) D_+^z w \right)_h \\ &+ h^2 \sum_{i,j} -\frac{1}{2}\mu_{i,j,1/2} w_{i,j,1} D_+^z w_{i,j,0} - \frac{1}{2}\mu_{i,j,3/2} w_{i,j,1} D_+^z w_{i,j,1} - \frac{h}{2}\mu_{i,j,3/2} (D_+^z w_{i,j,1})^2 \\ &\qquad + \mu_{i,j,N-1/2} w_{i,j,N} D_+^z w_{i,j,N-1}. \end{aligned}$$

We have

$$\begin{aligned} (w, L^{(w)})_h = &-2(D_+^z w, E_{1/2}^z(\mu) D_+^z w)_h - (\widetilde{D_0^z} w, \lambda \widetilde{D_0^z} w)_h - (\widetilde{D_0^z} w, \lambda (D_0^x u + D_0^y v))_h \\ &- (D_0^x w, \mu (D_0^x w + \widetilde{D_0^z} u))_h - (D_0^y w, \mu (D_0^y w + \widetilde{D_0^z} v))_h \\ &- \frac{h^2}{4} \left[(D_+^x D_-^x w, \mu D_+^x D_-^x w)_h + (D_+^y D_-^y w, \mu D_+^y D_-^y w)_h + (D_+^z D_-^z w, \lambda D_+^z D_-^z w)_{hr} \right] \\ &+ T_1^{(w)} + T_N^{(w)}, \end{aligned}$$

where $T_1^{(w)}$ are the boundary terms that belong to the free surface boundary, and $T_N^{(w)}$ are the boundary terms that belong to the Dirichlet boundary. We have

$$\begin{aligned}
T_1^{(w)} &= h^2 \sum_{i,j} -\frac{1}{2}\lambda_{i,j,1/2} w_{i,j,1} D_+^z w_{i,j,0} - \frac{1}{2}\lambda_{i,j,3/2} w_{i,j,1} D_+^z w_{i,j,1} \\
&\quad - w_{i,j,1}\lambda_{i,j,1}(D_0^x u_{i,j,1} + D_0^y v_{i,j,1}) - \mu_{i,j,1/2} w_{i,j,1} D_+^z w_{i,j,0} \\
&\quad - \mu_{i,j,3/2} w_{i,j,1} D_+^z w_{i,j,1} - h\mu_{i,j,3/2}(D_+^z w_{i,j,1})^2 \\
&= h^2 \sum_{i,j} w_{i,j,1} \left(-\frac{1}{2}\lambda_{i,j,1/2} D_+^z w_{i,j,0} - \frac{1}{2}\lambda_{i,j,3/2} D_+^z w_{i,j,1} \right. \\
&\quad - \lambda_{i,j,1}(D_0^x u_{i,j,1} + D_0^y v_{i,j,1}) - \mu_{i,j,1/2} D_+^z w_{i,j,0} \\
&\quad \left. - \mu_{i,j,3/2} D_+^z w_{i,j,1} \right) - h\mu_{i,j,3/2}(D_+^z w_{i,j,1})^2.
\end{aligned}$$

The free surface boundary condition (22) gives

$$T_1^{(w)} = -h^3 \sum_{i,j} \mu_{i,j,3/2}(D_+^z w_{i,j,1})^2.$$

At the Dirichlet boundary we have

$$\begin{aligned}
T_N^{(w)} &= h^2 \sum_{i,j} 2\mu_{i,j,N-1/2} w_{i,j,N} D_+^z w_{i,j,N-1} + \frac{1}{2} w_{i,j,N-1}\lambda_{i,j,N}(D_0^x u_{i,j,N} + D_0^y v_{i,j,N}) \\
&\quad + \frac{1}{2} w_{i,j,N}\lambda_{i,j,N-1}(D_0^x u_{i,j,N-1} + D_0^y v_{i,j,N-1}) + \frac{\lambda_{i,j,N}}{2} w_{i,j,N-1} D_+^z w_{i,j,N-1} \\
&\quad + \frac{\lambda_{i,j,N-1}}{2} w_{i,j,N} D_+^z w_{i,j,N-1} = -h \sum_{i,j} \frac{\lambda_{i,j,N}}{2} w_{i,j,N-1}^2.
\end{aligned}$$

Adding the expressions for $(u, L^{(u)})$, $(v, L^{(v)})$, and $(w, L^{(w)})$ results in (28)–(30).

CONVERGENCE OF A FINITE ELEMENT APPROXIMATION TO A STATE-CONSTRAINED ELLIPTIC CONTROL PROBLEM*

KLAUS DECKELNICK† AND MICHAEL HINZE‡

Abstract. We consider an elliptic optimal control problem with pointwise state constraints. The cost functional is approximated by a sequence of functionals which are obtained by discretizing the state equation with the help of linear finite elements and enforcing the state constraints in the nodes of the triangulation. The corresponding minima are shown to converge in L^2 to the exact control as the discretization parameter tends to zero. Furthermore, error bounds for the control and the state are obtained in both two and three space dimensions. Finally, we present numerical examples which confirm our analytical findings.

Key words. elliptic optimal control problem, state constraints, error estimates

1. Introduction.

The aim of this paper is to analyze a finite element discretization of a control problem with pointwise state constraints. Let $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ be a bounded domain with a smooth boundary. For a given function $u \in L^2(\Omega)$ we denote by $y = \mathcal{G}(u)$ the solution of the Neumann problem

$$\begin{aligned} -\Delta y + y &= u \quad \text{in } \Omega, \\ \partial_\nu y &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Here ν denotes the outward pointing unit normal to $\partial\Omega$. It is well known that $y \in H^2(\Omega)$ and

$$\|y\|_{H^2} \le C\|u\|_{L^2}. \tag{1.1}$$

We now consider the following control problem:

$$\min_{u \in L^2(\Omega)} J(u) = \frac{1}{2}\int_\Omega |y - y_0|^2 + \frac{\alpha}{2}\int_\Omega |u - u_0|^2$$

$$\text{subject to } y = \mathcal{G}(u) \text{ and } y(x) \le b(x) \text{ in } \Omega. \tag{1.2}$$

Here $\alpha > 0$ and $y_0, u_0 \in H^1(\Omega)$ as well as $b \in W^{2,\infty}(\Omega)$ are given functions. We denote by $\mathcal{M}(\bar\Omega)$ the space of Radon measures, which is defined as the dual space of $C^0(\bar\Omega)$ and endowed with the norm

$$\|\mu\|_{\mathcal{M}(\bar\Omega)} = \sup_{f \in C^0(\bar\Omega), |f| \le 1} \int_{\bar\Omega} f\, d\mu.$$

The analysis of (1.2) is well understood and sketched in [16, section 6.2.1] for the problem under consideration. Since the state constraints form a convex set and the

‡Department Mathematik, Schwerpunkt Optimierung und Approximation, Universität Hamburg, Bundesstraße 55, D-20146 Hamburg, Germany (michael.hinze@uni-hamburg.de).

cost functional is quadratic, it is not difficult to establish the existence of a unique solution $u \in L^2(\Omega)$ to this problem. Moreover, from [3, Theorem 5.2] we infer (compare also [2, Theorem 2]) the following.

THEOREM 1.1. *A function $u \in L^2(\Omega)$ is a solution of (1.2) if and only if there exist $\mu \in \mathcal{M}(\bar\Omega)$ and $p \in L^2(\Omega)$ such that with $y = \mathcal{G}(u)$ there holds,*

$$\int_\Omega p\big(-\Delta v + v\big) = \int_\Omega (y - y_0)v + \int_{\bar\Omega} v\,d\mu \qquad \forall v \in H^2(\Omega) \text{ with } \partial_\nu v = 0 \text{ on } \partial\Omega, \tag{1.3}$$

$$p + \alpha(u - u_0) = 0 \qquad \text{a.e. in } \Omega, \tag{1.4}$$

$$\mu \ge 0,\ y(x) \le b(x) \text{ a.e. in } \Omega \text{ and } \int_{\bar\Omega} (b - y)\,d\mu = 0. \tag{1.5}$$

The study of (1.2) is complicated by the presence of the measure μ on the right-hand side of (1.3). As a consequence, the solution p of this problem is no longer in $H^1(\Omega)$ but only in $W^{1,s}(\Omega)$ for all $1 \le s < \frac{d}{d-1}$. This fact also accounts for the form of the weak formulation (1.3).

The aim of the present paper is to develop a finite element approximation of problem (1.2). The underlying idea consists in approximating the cost functional J by a sequence of functionals J_h, where h is a mesh parameter related to a sequence of triangulations. The definition of J_h involves the approximation of the state equation by linear finite elements and enforces constraints on the state in the nodes of the triangulation. We shall prove that the minima of J_h converge in L^2 to the minimum of J as $h \to 0$ and that the states convergence strongly in H^1 as well as uniformly and derive corresponding error bounds.

To our knowledge only a few attempts have been made to develop a finite element analysis for state-constrained elliptic control problems. In [4] Casas proves convergence of finite element approximations to optimal control problems for semilinear elliptic equations with finitely many state constraints. Casas and Mateos extend these results in [5] to a less regular setting for the states and prove convergence of finite element approximations to semilinear distributed and boundary control problems.

Let us comment on further approaches that tackle optimization problems for PDEs with state constraints. A *Lavrentiev-type regularization* of problem (1.2) is investigated in [11]. In this approach the state constraint $y \le b$ in (1.2) is replaced by the mixed constraint $\epsilon u + y \le b$, with $\epsilon > 0$ denoting a regularization parameter. It turns out that the associated Lagrange multiplier μ_ϵ belongs to $L^2(\Omega)$. The resulting optimization problems are solved by either interior-point methods or primal-dual active set strategies; compare [10]. The development of numerical approaches to tackle (1.2) is ongoing. An excellent overview can be found in [8, 9], where further references are also given.

The paper is organized as follows: In section 2 we describe our discretization and establish convergence of controls and states to their continuous counterparts for two- and three-dimensional domains. An error analysis is carried out in section 3. We obtain

$$\|u - u_h\|_{L^2},\ \|y - y_h\|_{H^1} = \begin{cases} O(h^{1-\epsilon}) & \text{if } d = 2, \\ O(h^{\frac{1}{2}-\epsilon}) & \text{if } d = 3 \end{cases}$$

($\epsilon > 0$ arbitrary), where u_h and y_h are the discrete control and state, respectively. Roughly speaking, the idea is to insert the discrete solution into the continuous functional and vice versa. An important tool in the analysis is the use of L^∞-error esti-

mates for finite element approximations of the Neumann problem developed in [13]. The need for uniform estimates is due to the presence of the measure μ in (1.3).

2. Finite element discretization. Let $\mathcal{T}_h$ be a triangulation of Ω with maximum mesh size $h := \max_{T\in\mathcal{T}_h} \operatorname{diam}(T)$ and vertices $x_1, \dots, x_m$. We suppose that $\bar{\Omega}$ is the union of the elements of $\mathcal{T}_h$; boundary elements are allowed to have one curved face. In addition, we assume that the triangulation is quasi-uniform in the sense that there exists a constant $\kappa > 0$ (independent of h) such that each $T \in \mathcal{T}_h$ is contained in a ball of radius $\kappa^{-1}h$ and contains a ball of radius κh. Let us define the space of linear finite elements:

$$X_h := \{v_h \in C^0(\bar{\Omega}) \,|\, v_h \text{ is a linear polynomial on each } T \in \mathcal{T}_h\}.$$

We have the following approximation and inverse properties:

(a) There exists an interpolation operator $\Pi_h : W^{l,p}(\Omega) \to X_h$ $(l = 1, 2; 1 \le p \le \infty)$ such that for $T \in \mathcal{T}_h$

$$\|v - \Pi_h v\|_{W^{m,p}(T)} \le Ch^{l-m}\|v\|_{W^{l,p}(S_T)}, \quad 0 \le m \le l, \tag{2.1}$$

where $S_T = \cup\{\tilde{T} \in \mathcal{T}_h \,|\, \tilde{T} \cap T \neq \emptyset\}$.

(b) If $p > d$, the usual nodal interpolate satisfies

$$\|v - I_h v\|_{W^{1,\infty}(T)} \le Ch^{1-\frac{d}{p}}\|v\|_{W^{2,p}(T)}, \quad T \in \mathcal{T}_h. \tag{2.2}$$

(c) For $v_h \in X_h$, $m = 0, 1, l \ge 0$, and $1 \le q \le p \le \infty$ we have

$$\|v_h\|_{W^{m,p}(T)} \le Ch^{-(\frac{d}{q}-\frac{d}{p})-m-l}\|v_h\|_{W^{-l,q}(T)}, \quad T \in \mathcal{T}_h, \tag{2.3}$$

where, for $l \ge 1$, $W^{-l,q}(T)$ is the dual of $W_0^{l,q'}(T)$, $\frac{1}{q} + \frac{1}{q'} = 1$.

The interpolation operator Π_h in (a) can be defined as in [15] using averages over $(d-1)$-simplices σ_i. Since boundary elements are allowed to have only one curved face we can associate with a boundary node x_i a straight $(d-1)$-simplex σ_i such that $x_i \in \sigma_i$. It turns out that the arguments presented in [15] for a polydedral domain can be used with small changes in order to derive (2.1) for boundary elements T. Note that functions $v_h \in X_h$ do not have to satisfy boundary conditions. The estimates (2.2) and (2.3) can be proved similarly as in [14, pp. 685–686].

In what follows it is convenient to introduce a discrete approximation of the solution operator $\mathcal{G}$. For a given function $v \in L^2(\Omega)$ we denote by $z_h = \mathcal{G}_h(v) \in X_h$ the solution of the discrete Neumann problem

$$\int_\Omega \big(\nabla z_h \cdot \nabla v_h + z_h v_h\big) \;=\; \int_\Omega v v_h \quad \text{for all } v_h \in X_h.$$

It is well known that for all $v \in L^2(\Omega)$

$$\|\mathcal{G}(v) - \mathcal{G}_h(v)\| \le Ch^2\|v\|, \tag{2.4}$$

$$\|\mathcal{G}(v) - \mathcal{G}_h(v)\|_{L^\infty} \le Ch^{2-\frac{d}{2}}\|v\|. \tag{2.5}$$

Here $\|\cdot\|$ denotes the L^2-norm. We propose the following approximation of the control problem (1.2):

$$\min_{u\in L^2(\Omega)} J_h(u) := \frac{1}{2}\int_\Omega |y_h - P_h y_0|^2 + \frac{\alpha}{2}\int_\Omega |u - P_h u_0|^2$$

$$\text{subject to } \; y_h = \mathcal{G}_h(u) \text{ and } y_h(x_j) \le b(x_j) \text{ for } j = 1, \dots, m. \tag{2.6}$$

Here P_h denotes the L^2-projection, i.e.,

$$\int_\Omega P_h z\, v_h = \int_\Omega z\, v_h \qquad \forall v_h \in X_h. \tag{2.7}$$

It is well known that

$$\|z - P_h z\| \le Ch\|z\|_{H^1} \qquad \forall z \in H^1(\Omega). \tag{2.8}$$

Problem (2.6) represents a convex infinite-dimensional optimization problem of similar structure as problem (1.2) but with only finitely many equality and inequality constraints which form a convex admissible set. Again we can apply [3, Theorem 5.2] which together with [2, Corollary 1] yields (compare also the analysis of problem (P) in [4]) the following.

LEMMA 2.1. *Problem* (2.6) *has a unique solution* $u_h \in L^2(\Omega)$. *There exist* $\mu_1, \dots, \mu_m \in \mathbb{R}$ *and* $p_h \in X_h$ *such that with* $y_h = \mathcal{G}_h(u_h)$ *and* $\mu_h = \sum_{j=1}^m \mu_j \delta_{x_j}$ *we have*

$$\int_\Omega \big(\nabla p_h \cdot \nabla v_h + p_h v_h\big) = \int_\Omega (y_h - P_h y_0) v_h + \int_{\bar\Omega} v_h d\mu_h \quad \text{for all } v_h \in X_h, \tag{2.9}$$

$$p_h + \alpha(u_h - P_h u_0) = 0 \text{ in } \Omega, \tag{2.10}$$

$$\mu_j \ge 0,\ y_h(x_j) \le b(x_j), j = 1, \dots, m, \text{ and } \int_{\bar\Omega} \big(I_h b - y_h\big) d\mu_h = 0. \tag{2.11}$$

Here δ_x denotes the Dirac measure concentrated at x, and I_h is the usual Lagrange interpolation operator.

Remark 2.2. From (2.10) we deduce that in problem (2.6) it is sufficient to minimize over controls $u \in X_h$ instead of $u \in L^2(\Omega)$ in order to obtain the same unique solution u_h. For the resulting finite-dimensional optimization problem the result of Lemma 2.1 then follows from, e.g., [12, Theorem 12.1].

We have the following convergence result.

THEOREM 2.3. *Let* $u_h \in L^2(\Omega)$ *be the optimal solution of* (2.6) *with corresponding state* $y_h \in X_h$ *and adjoint variables* $p_h \in X_h$ *and* $\mu_h \in \mathcal{M}(\bar\Omega)$. *Then as* $h \to 0$ *we have*

$$u_h \to u \text{ in } L^2(\Omega), \quad y_h \to y \text{ in } H^1(\Omega) \text{ and in } C^0(\bar\Omega),$$

where u *is the solution of* (1.2) *with corresponding state* y.

Proof. Let $\underline{b} := \min_{x \in \bar\Omega} b(x)$. Since $\underline{b} = \mathcal{G}_h(\underline{b})$ and $\underline{b} \le b(x_j)$ for $j = 1, \dots, m$ we have

$$\frac{1}{2}\int_\Omega |y_h - P_h y_0|^2 + \frac{\alpha}{2}\int_\Omega |u_h - P_h u_0|^2 = J_h(u_h) \le J_h(\underline{b}) \le C(y_0, u_0, \underline{b}).$$

This implies that there exists a constant C which is independent of h such that

$$\|y_h\|,\ \|u_h\|,\ \|p_h\| \le C \qquad \text{for all } 0 < h \le 1. \tag{2.12}$$

Note that the bound on p_h follows from (2.10). In order to estimate μ_h we use $v_h \equiv 1$ in (2.9) and obtain for every $f \in C^0(\bar\Omega), |f| \le 1$,

$$\int_{\bar\Omega} f d\mu_h \le \sum_{j=1}^m \mu_j |f(x_j)| \le \sum_{j=1}^m \mu_j = \int_{\bar\Omega} 1 d\mu_h = \int_\Omega \big(p_h + P_h y_0 - y_h\big) \le C$$

by (2.12). This yields

$$\|\mu_h\|_{\mathcal{M}(\bar\Omega)} \le C \qquad \text{for all } 0 < h \le 1. \tag{2.13}$$

In view of (2.12) and (2.13) there exists a sequence $h \to 0$ and $\hat u, \hat p \in L^2(\Omega)$ as well as $\hat\mu \in \mathcal{M}(\bar\Omega)$ such that

$$u_h \rightharpoonup \hat u, \quad p_h \rightharpoonup \hat p \text{ in } L^2(\Omega), \quad \text{and } \mu_h \rightharpoonup \hat\mu \text{ in } \mathcal{M}(\bar\Omega). \tag{2.14}$$

Since $\mathcal{G}$ is compact as an operator from $L^2(\Omega)$ into $C^0(\bar\Omega)$ we have, after passing to a further subsequence if necessary,

$$\mathcal{G}(u_h) \to \mathcal{G}(\hat u) \qquad \text{in } C^0(\bar\Omega) \tag{2.15}$$

and hence

$$\begin{aligned}\|y_h - \mathcal{G}(\hat u)\|_{L^\infty} &\le \|\mathcal{G}_h(u_h) - \mathcal{G}(u_h)\|_{L^\infty} + \|\mathcal{G}(u_h) - \mathcal{G}(\hat u)\|_{L^\infty}\\ &\le Ch^{2-\frac{d}{2}}\|u_h\| + \|\mathcal{G}(u_h) - \mathcal{G}(\hat u)\|_{L^\infty}\end{aligned}$$

so that $y_h \to \mathcal{G}(\hat u) =: \hat y$ in $C^0(\bar\Omega)$ as $h \to 0$ by (2.12) and (2.15). A similar argument shows that $y_h \to \hat y$ in $H^1(\Omega)$.

Let us now pass to the limit in (2.9)–(2.11). To begin, let $v \in H^2(\Omega)$ with $\partial_\nu v = 0$ on $\partial\Omega$ and denote by $R_h v$ the Ritz projection of v. Recalling (2.14) and (2.9) and the fact that $R_h v \to v$ in $C^0(\bar\Omega)$ we obtain

$$\begin{aligned}\int_\Omega \hat p\big(-\Delta v + v\big) &\leftarrow \int_\Omega p_h\big(-\Delta v + v\big) = \int_\Omega \big(\nabla p_h \cdot \nabla v + p_h v\big)\\ &= \int_\Omega \big(\nabla p_h \cdot \nabla R_h v + p_h R_h v\big) = \int_\Omega (y_h - P_h y_0) R_h v + \int_{\bar\Omega} R_h v\, d\mu_h\\ &\to \int_\Omega (\hat y - y_0) v + \int_{\bar\Omega} v\, d\hat\mu.\end{aligned}$$

Using (2.14) we may pass to the limit in (2.10) and deduce $\hat p + \alpha(\hat u - u_0) = 0$ a.e. in Ω. Clearly, $\hat\mu \ge 0$; since $y_h \le I_h b$ in $\bar\Omega$ and $y_h \to \hat y$ in $C^0(\bar\Omega)$ we have $\hat y \le b$ in $\bar\Omega$. Furthermore, recalling that $\int_{\bar\Omega}(I_h b - y_h)\, d\mu_h = 0$ we obtain in the limit

$$\int_{\bar\Omega} (b - \hat y)\, d\hat\mu = 0.$$

Theorem 1.1 now implies that $\hat u$ is a solution of (1.2); as the solution of this problem is unique we must have $u = \hat u$ and hence $y = \hat y$, and the whole sequence is convergent.

Let us finally prove that $u_h \to u$ in $L^2(\Omega)$. To begin, note that by (2.5)

$$\mathcal{G}_h\big(u - \gamma h^{2-\frac{d}{2}}\big) = \mathcal{G}_h(u) - \mathcal{G}(u) + \mathcal{G}(u) - \gamma h^{2-\frac{d}{2}} \le Ch^{2-\frac{d}{2}}\|u\| + b - \gamma h^{2-\frac{d}{2}} \le b$$

in $\bar\Omega$, provided that γ is large enough. Evaluating the above inequality at the nodes $x_1, \dots, x_m$ we see that $\mathcal{G}_h(u - \gamma h^{2-\frac{d}{2}})$ is admissible for the discrete problem, and hence $J_h(u_h) \le J_h(u - \gamma h^{2-\frac{d}{2}})$ or

$$\frac{\alpha}{2}\|u_h - P_h u_0\|^2 \le \frac{\alpha}{2}\|u - \gamma h^{2-\frac{d}{2}} - P_h u_0\|^2 + \frac{1}{2}\|\mathcal{G}_h(u) - \gamma h^{2-\frac{d}{2}} - P_h y_0\|^2 - \frac{1}{2}\|y_h - P_h y_0\|^2.$$

Since $y_h \to y$, $\mathcal{G}_h(u) \to \mathcal{G}(u) = y$ in $L^2(\Omega)$ we infer that

$$\limsup_{h\to 0} \|u_h - P_h u_0\|^2 \le \|u - u_0\|^2 \le \liminf_{h\to 0} \|u_h - P_h u_0\|^2,$$

where the second inequality is a consequence of the weak convergence $u_h - P_h u_0 \rightharpoonup u - u_0$. Thus, $\|u_h - P_h u_0\|^2 \to \|u - u_0\|^2$, which implies $u_h - P_h u_0 \to u - u_0$ in L^2 and hence $u_h \to u_0$ in L^2. ∎

Remark 2.4. The above convergence result also holds if Ω is assumed to be a bounded, convex, and polyhedral domain in $\mathbb{R}^d$. To see this we note that (1.1) still holds in this case, and hence both Theorem 1.1 (see [2]) and the estimates (2.4), (2.5) remain true. An inspection of the proof of Theorem 2.3 then shows that this is sufficient in order to carry out the analysis.

3. Error analysis. Let us now turn to the error analysis and start with a couple of auxiliary results.

LEMMA 3.1. *Suppose that $u, u_h \in L^2(\Omega)$ are the optimal solutions of* (1.2) *and* (2.6)*, respectively, with corresponding states $y \in H^2(\Omega), y_h \in X_h$. Let $v \in L^2(\Omega)$ and $z = \mathcal{G}(v), z_h = \mathcal{G}_h(v)$. Then*

$$J(u) + \frac{1}{2}\int_\Omega |z - y|^2 + \frac{\alpha}{2}\int_\Omega |v - u|^2 + \int_{\bar\Omega} (b - z)\, d\mu = J(v), \tag{3.1}$$

$$J_h(u_h) + \frac{1}{2}\int_\Omega |z_h - y_h|^2 + \frac{\alpha}{2}\int_\Omega |v - u_h|^2 + \int_{\bar\Omega} \big(I_h b - z_h\big)\, d\mu_h = J_h(v). \tag{3.2}$$

Proof. An elementary calculation using (1.3) shows

$$\begin{aligned} J(v) - J(u) &= \frac{1}{2}\int_\Omega |z - y|^2 + \frac{\alpha}{2}\int_\Omega |v - u|^2 + \int_\Omega (z - y)(y - y_0) + \alpha \int_\Omega (u - u_0)(v - u) \\ &= \frac{1}{2}\int_\Omega |z - y|^2 + \frac{\alpha}{2}\int_\Omega |v - u|^2 + \int_\Omega p\big(-\Delta(z - y) + (z - y)\big) \\ &\quad - \int_{\bar\Omega} (z - y)\, d\mu + \alpha \int_\Omega (u - u_0)(v - u). \end{aligned}$$

Since $z = \mathcal{G}(v), y = \mathcal{G}(u)$ we have

$$\int_\Omega p\big(-\Delta(z - y) + (z - y)\big) = \int_\Omega p(v - u),$$

so that (1.4) and (1.5) finally imply

$$J(v) - J(u) = \frac{1}{2}\int_\Omega |z - y|^2 + \frac{\alpha}{2}\int_\Omega |v - u|^2 + \int_{\bar\Omega} (b - z)\, d\mu.$$

The second claim follows in a similar way. ∎

Remark 3.2. Note that in the above $z = \mathcal{G}(v), z_h = \mathcal{G}_h(v)$ do not necessarily have to be admissible for the minimization problems.

The next lemma examines in more detail the approximation of J by J_h.

LEMMA 3.3. *Suppose that $v \in W^{1,s}(\Omega)$ for some $\frac{2d}{d+2} \le s \le 2$. Then*

$$|J(v) - J_h(v)| \le C h^{2 + \frac{d}{2} - \frac{d}{s}} \big(\|u_0\|_{H^1}\|v\|_{W^{1,s}} + \|v\|^2 + \|y_0\|_{H^1}^2 + \|u_0\|_{H^1}^2\big).$$

Proof. Let $z = \mathcal{G}(v), z_h = \mathcal{G}_h(v)$. Then

$$J(v) - J_h(v) = \frac{1}{2}\int_\Omega \big(|z - y_0|^2 - |z_h - P_h y_0|^2\big) + \frac{\alpha}{2}\int_\Omega \big(|v - u_0|^2 - |v - P_h u_0|^2\big).$$

Using (2.7), (2.8), (2.4), and (1.1) we obtain

$$\begin{aligned}
&\left|\int_\Omega \big(|z-y_0|^2-|z_h-P_hy_0|^2\big)\right| = \left|\int_\Omega (z-y_0-z_h+P_hy_0)(z-y_0+z_h-P_hy_0)\right| \\
&= \left|\int_\Omega \big((z-z_h)(z-y_0+z_h-P_hy_0)-(y_0-P_hy_0)(z-y_0-P_h(z-y_0)\big)\right| \\
&\le C\|z-z_h\|\big(\|z\|+\|z_h\|+\|y_0\|\big)+Ch^2\|y_0\|_{H^1}\big(\|z\|_{H^1}+\|y_0\|_{H^1}\big) \\
&\le Ch^2\big(\|v\|^2+\|y_0\|_{H^1}^2\big).
\end{aligned}$$

For the second term we obtain in a similar way

$$\int_\Omega \big(|v-u_0|^2-|v-P_hu_0|^2\big)=\int_\Omega (u_0-P_hu_0)w=\int_\Omega (u_0-P_hu_0)(w-P_hw),$$

where $w=u_0+P_hu_0-2v$ and where we have used (2.7). Applying Lemma 5.1 from the appendix we infer

$$\begin{aligned}
\left|\int_\Omega \big(|v-u_0|^2-|v-P_hu_0|^2\big)\right| &\le Ch^{2+\frac{d}{2}-\frac{d}{s}}\|u_0\|_{H^1}\|w\|_{W^{1,s}} \\
&\le Ch^{2+\frac{d}{2}-\frac{d}{s}}\|u_0\|_{H^1}\big(\|u_0\|_{H^1}+\|v\|_{W^{1,s}}\big).
\end{aligned}$$

This proves the lemma. ∎

LEMMA 3.4. *Suppose that $v\in W^{1,s}(\Omega)$ for some $1<s<\frac{d}{d-1}$. Then*

$$\|\mathcal{G}(v)-\mathcal{G}_h(v)\|_{L^\infty}\le Ch^{3-\frac{d}{s}}|\log h|\ \|v\|_{W^{1,s}}.$$

Proof Let $z=\mathcal{G}(v)$, $z_h=\mathcal{G}_h(v)$. From a well-known embedding theorem we infer that $v\in L^q(\Omega)$, with $q=\frac{ds}{d-s}$. Hence, elliptic regularity theory implies that $z\in W^{2,q}(\Omega)$ and

$$\|z\|_{W^{2,q}}\le C\|v\|_{L^q}\le C\|v\|_{W^{1,s}}. \tag{3.3}$$

Using Theorem 2.2 and the ensuing Remark in [13] we have

$$\|z-z_h\|_{L^\infty}\le C|\log h|\inf_{\chi\in X_h}\|z-\chi\|_{L^\infty}. \tag{3.4}$$

The result in [13] holds under certain approximation and inverse properties (see A.1–A.4 on pp. 883–884) on the finite element space X_h which follow from (2.1)–(2.3). Combining (3.4) with a well-known interpolation estimate yields

$$\|z-z_h\|_{L^\infty}\le Ch^{2-\frac{d}{q}}|\log h|\|z\|_{W^{2,q}}\le Ch^{3-\frac{d}{s}}|\log h|\|v\|_{W^{1,s}}$$

in view of (3.3) and the relation between s and q. ∎

Our next aim is to derive a uniform bound on $\|u_h\|_{W^{1,s}}$ for $s<\frac{d}{d-1}$.

LEMMA 3.5. *Let $1<s<\frac{d}{d-1}$. Then there exists a constant c, which is independent of h, such that*

$$\|u_h\|_{W^{1,s}}\le c \qquad \text{for all } 0<h\le 1.$$

Proof. In view of (2.10) we have

$$\|u_h\|_{W^{1,s}}\le\frac{1}{\alpha}\|p_h\|_{W^{1,s}}+\|P_hu_0\|_{H^1}\le\frac{1}{\alpha}\|p_h\|_{W^{1,s}}+c,$$

so that it is sufficient to bound $\|p_h\|_{W^{1,s}}$.

Let s' be such that $\frac{1}{s}+\frac{1}{s'}=1$, and suppose that $\phi\in L^{s'}(\Omega)$. Let us denote by $\psi\in W^{2,s'}(\Omega)$ the unique solution of the Neumann problem

$$\begin{aligned} -\Delta\psi+\psi &= \phi \quad \text{in } \Omega,\\ \partial_\nu\psi &= 0 \quad \text{on } \partial\Omega. \end{aligned}$$

Integration by parts and (2.9) yield

$$\begin{aligned} \int_\Omega p_h\,\phi &= \int_\Omega \big(\nabla p_h\cdot\nabla\psi + p_h\psi\big) = \int_\Omega \big(\nabla p_h\cdot\nabla R_h\psi + p_h R_h\psi\big)\\ &= \int_\Omega (y_h-P_hy_0)R_h\psi + \int_{\bar\Omega} R_h\psi\, d\mu_h, \end{aligned} \tag{3.5}$$

where $R_h\psi$ is the Ritz projection of ψ. Arguing similarly as in Theorem 1 of [1] one shows that there exists a unique solution $p^h\in W^{1,s}(\Omega)$ of the problem

$$\int_\Omega p^h\big(-\Delta v+v\big) = \int_\Omega (y_h-P_hy_0)v + \int_{\bar\Omega} v\,d\mu_h \quad \forall v\in H^2(\Omega) \text{ with } \partial_\nu v=0 \text{ on } \partial\Omega. \tag{3.6}$$

Furthermore, there exists a constant $c=c(s)>0$ such that

$$\|p^h\|_{W^{1,s}} \le c\big(\|y_h-P_hy_0\|+\|\mu_h\|_{\mathcal{M}(\bar\Omega)}\big)\le C \tag{3.7}$$

uniformly in h in view of (2.12) and (2.13). If we use $v=\psi$ in (3.6) and combine it with (3.5), we obtain

$$\begin{aligned} \int_\Omega (p^h-p_h)\phi &= \int_\Omega (y_h-P_hy_0)(\psi-R_h\psi) + \int_{\bar\Omega}(\psi-R_h\psi)d\mu_h\\ &\le Ch^2\|\psi\|_{H^2}\big(\|y_h\|+\|P_hy_0\|\big) + \|\psi-R_h\psi\|_{L^\infty}\|\mu_h\|_{\mathcal{M}(\bar\Omega)}\\ &\le Ch^2\|\psi\|_{H^2} + ch^{2-\frac{d}{s'}}|\log h|\|\psi\|_{W^{2,s'}}\\ &\le Ch^{2-\frac{d}{s'}}|\log h|\|\phi\|_{L^{s'}}. \end{aligned}$$

Note that we have again applied (3.4) in order to control $\|\psi-R_h\psi\|_{L^\infty}$. Since $\phi\in L^{s'}(\Omega)$ is arbitrary we infer

$$\|p^h-p_h\|_{L^s}\le Ch^{2-\frac{d}{s'}}|\log h|.$$

Interpolation and inverse estimates then give

$$\|\nabla p_h\|_{L^s}\le C\|\nabla p^h\|_{L^s} + ch^{1-\frac{d}{s'}}|\log h|\le C$$

by (3.7) and since $1-\frac{d}{s'}=\frac{d-1}{s}\big(\frac{d}{d-1}-s\big)>0$. ∎

Let us finally turn to an error estimate for the optimal controls and the optimal states.

THEOREM 3.6. *Let u and u_h be the solutions of* (1.2) *and* (2.6)*, respectively. For every $\epsilon>0$ there exists $C_\epsilon>0$ such that*

$$\|u-u_h\|+\|y-y_h\|_{H^1}\le C_\epsilon h^{2-\frac{d}{2}-\epsilon}.$$

Proof. Let us define $\tilde y^h:=\mathcal{G}(u_h)\in H^2(\Omega)$ and $\tilde y_h:=\mathcal{G}_h(u)\in X_h$. Then Lemma 3.1 implies

$$\begin{aligned} J(u)+\frac12\int_\Omega|\tilde y^h-y|^2+\frac{\alpha}{2}\int_\Omega|u_h-u|^2+\int_{\bar\Omega}(b-\tilde y^h)d\mu = J(u_h),\\ J_h(u_h)+\frac12\int_\Omega|\tilde y_h-y_h|^2+\frac{\alpha}{2}\int_\Omega|u-u_h|^2+\int_{\bar\Omega}\big(I_hb-\tilde y_h\big)d\mu_h = J_h(u). \end{aligned}$$

Since $u = u_0 - \frac{1}{\alpha}p \in W^{1,s}(\Omega)$ for all $\frac{2d}{d+2} \le s < \frac{d}{d-1}$ we obtain with the help of Lemma 3.3

$$\begin{aligned}
&\frac{1}{2}\int_\Omega |\tilde{y}^h - y|^2 + \frac{1}{2}\int_\Omega |\tilde{y}_h - y_h|^2 + \alpha\int_\Omega |u_h - u|^2 \\
&= J(u_h) - J(u) + J_h(u) - J_h(u_h) - \int_{\bar\Omega}(b - \tilde{y}^h)d\mu - \int_{\bar\Omega}\big(I_h b - \tilde{y}_h\big)d\mu_h \\
&\le Ch^{2+\frac{d}{2}-\frac{d}{s}}\Big(\|u_0\|_{H^1}\big(\|u\|_{W^{1,s}} + \|u_h\|_{W^{1,s}}\big) + \|u\|^2 + \|u_h\|^2 + \|y_0\|^2_{H^1} + \|u_0\|^2_{H^1}\Big) \\
&\qquad + \int_{\bar\Omega}(\tilde{y}^h - b)d\mu + \int_{\bar\Omega}(\tilde{y}_h - I_h b)d\mu_h. \qquad (3.8)
\end{aligned}$$

Let us first consider the last two integrals. We have for $x \in \bar\Omega$

$$\begin{aligned}
\tilde{y}^h(x) - b(x) &= (\tilde{y}^h(x) - y_h(x)) + (y_h(x) - (I_h b)(x)) + ((I_h b)(x) - b(x)) \\
&\le \|\mathcal{G}(u_h) - \mathcal{G}_h(u_h)\|_{L^\infty} + \|I_h b - b\|_{L^\infty},
\end{aligned}$$

since $y_h(x_j) \le b(x_j), j = 1, \dots, m$, implies that $y_h \le I_h b$ in $\bar\Omega$. If we combine Lemma 3.4 with Lemma 3.5 we infer

$$\int_{\bar\Omega}(\tilde{y}^h - b)d\mu \le Ch^{3-\frac{d}{s}}|\log h|\,\|u_h\|_{W^{1,s}} + Ch^2|b|_{W^{2,\infty}} \le Ch^{3-\frac{d}{s}}|\log h|.$$

Similarly we have from (1.5)

$$\begin{aligned}
\tilde{y}_h(x) - (I_h b)(x) &= (\tilde{y}_h(x) - y(x)) + (y(x) - b(x)) + (b(x) - (I_h b)(x)) \\
&\le \|\mathcal{G}_h(u) - \mathcal{G}(u)\|_{L^\infty} + \|b - I_h b\|_{L^\infty},
\end{aligned}$$

so that (2.13) and Lemma 3.4 give

$$\int_{\bar\Omega}\big(y_h - I_h b\big)d\mu_h \le Ch^{3-\frac{d}{s}}|\log h|\,\|u\|_{W^{1,s}} + Ch^2|b|_{W^{2,\infty}} \le Ch^{3-\frac{d}{s}}|\log h|.$$

Inserting these estimates into (3.8) and applying again Lemma 3.5 we derive

$$\|u - u_h\|^2 + \|y - y_h\|^2 \le Ch^{3-\frac{d}{s}}|\log h|.$$

If we now choose s sufficiently close to $\frac{d}{d-1}$ we obtain

$$\|u - u_h\|^2 + \|y - y_h\|^2 \le C_\epsilon h^{4-d-2\epsilon}.$$

Finally, in order to obtain the error bound for y in H^1 we note that

$$\int_\Omega\big(\nabla(y - y_h)\cdot\nabla v_h + (y - y_h)v_h\big) = \int_\Omega (u - u_h)v_h$$

for all $v_h \in X_h$, from which one derives the desired estimate using standard finite element techniques and the bound on $\|u - u_h\|$. ∎

In general we expect only weak convergence of μ_h to μ. Nevertheless, we have the following partial result.

COROLLARY 3.7. *Let $K \subset \bar\Omega$ be compact with $K \cap \operatorname{supp}\mu = \emptyset$. For every $\epsilon > 0$ there exists a constant C_ϵ such that*

$$\mu_h(K) \le C_\epsilon h^{2-\frac{d}{2}-\epsilon}.$$

Proof. By Lemma 5.2 in the appendix there exists a nonnegative function $\phi \in C^2(\bar\Omega)$ which satisfies

$$\phi \geq 1 \text{ on } K,\ \phi = 0 \text{ on } \operatorname{supp}\mu,\ \partial_\nu \phi = 0 \text{ on } \partial\Omega.$$

Since $\mu_h \geq 0$ we obtain from (2.9)

$$\begin{aligned}
\mu_h(K) &\leq \int_{\bar\Omega} \phi \, d\mu_h = \int_{\bar\Omega} (\phi - R_h\phi) d\mu_h + \int_{\bar\Omega} R_h\phi \, d\mu_h \\
&= \int_{\bar\Omega} (\phi - R_h\phi) d\mu_h + \int_\Omega \big(\nabla p_h \cdot \nabla R_h\phi + p_h R_h\phi\big) - \int_\Omega (y_h - P_h y_0) R_h\phi \\
&= \int_{\bar\Omega} (\phi - R_h\phi) d\mu_h + \int_\Omega \big(\nabla p_h \cdot \nabla \phi + p_h \phi\big) - \int_\Omega (y_h - P_h y_0) R_h\phi \\
&= \int_{\bar\Omega} (\phi - R_h\phi) d\mu_h + \int_\Omega p_h(-\Delta\phi + \phi) - \int_\Omega (y_h - P_h y_0) R_h\phi,
\end{aligned}$$

where R_h is again the Ritz projection. On the other hand, (1.3) and the fact that $\phi = 0$ on $\operatorname{supp}\mu$ imply

$$\int_\Omega (y - y_0)\phi - \int_\Omega p(-\Delta\phi + \phi) = 0.$$

Combining this relation with the first estimate we derive

$$\begin{aligned}
\mu_h(K) &\leq \int_{\bar\Omega} (\phi - R_h\phi) d\mu_h + \int_\Omega (p_h - p)(-\Delta\phi + \phi) + \int_\Omega (y_h - P_h y_0)(\phi - R_h\phi) \\
&\qquad + \int_\Omega (y - y_h - y_0 + P_h y_0)\phi \\
&\leq \|\phi - R_h\phi\|_{L^\infty} \|\mu_h\|_{\mathcal{M}(\bar\Omega)} + \|p - p_h\| \|\phi\|_{H^2} + \big(\|y_h\| + \|P_h y_0\|\big)\|\phi - R_h\phi\| \\
&\qquad + \big(\|y - y_h\| + \|y_0 - P_h y_0\|\big)\|\phi\| \\
&\leq C\|\phi - R_h\phi\|_{L^\infty} + C_\epsilon h^{2-\frac{d}{2}-\epsilon} \leq C_\epsilon h^{2-\frac{d}{2}-\epsilon}
\end{aligned}$$

in view of (1.4), (2.10), and Theorem 3.6. ∎

Remark 3.8. We mention here a second approach that differs from the one discussed above in the way in which the inequality constraints are realized. Denote by $D_1, \dots, D_m$ the cells of the dual mesh. Each cell D_i is associated with a vertex x_i of $\mathcal{T}_h$, and we have

$$\bar\Omega = \cup_{i=1}^m D_i, \quad \operatorname{int}(D_i) \cap \operatorname{int}(D_j) = \emptyset, i \neq j.$$

In (2.6), we now impose the constraints

$$\fint_{D_j} (y_h - I_h b) \leq 0 \text{ for } j = 1, \dots, m \tag{3.9}$$

on the discrete solution $y_h = \mathcal{G}_h(u)$. Here we have abbreviated $\fint_{D_j} f = \frac{1}{|D_j|}\int_{D_j} f$. The measure μ_h that appears in Lemma 2.1 now has the form $\mu_h = \sum_{j=1}^m \mu_j \fint_{D_j} \cdot\, dx$, and the pointwise constraints in (2.11) are replaced by those of (3.9). The error analysis for the resulting numerical method can be carried out in the same way as

shown above with the exception of Theorem 3.6, where the bounds on $\tilde{y} - b$ and $\tilde{y}_h - I_h b$ require a different argument. In this case, additional terms of the form

$$\left\| f - \fint_{D_j} f \right\|_{L^\infty(D_j)}$$

have to be estimated. Since these will, in general, be only of order $O(h)$, this analysis would only give $\|u-u_h\|, \|y-y_h\|_{H^1} = O(\sqrt{h})$. The numerical test example in section 4 suggests that at least $\|u - u_h\| = O(h)$, but we are presently unable to prove such an estimate.

4. Numerical examples.

Example 4.1. The following test problem is taken—in a slightly modified form—from [10, Example 6.2]. Let $\Omega := B_1(0)$, $\alpha > 0$,

$$y_0(x) := 4 + \frac{1}{\pi} - \frac{1}{4\pi}|x|^2 + \frac{1}{2\pi}\log|x|, \quad u_0(x) := 4 + \frac{1}{4\alpha\pi}|x|^2 - \frac{1}{2\alpha\pi}\log|x|,$$

and $b(x) := |x|^2 + 4$. We consider the cost functional

$$J(u) := \frac{1}{2}\int_\Omega |y - y_0|^2 + \frac{\alpha}{2}\int_\Omega |u - u_0|^2,$$

where $y = \mathcal{G}(u)$. By checking the optimality conditions of first order, one verifies that $u \equiv 4$ is the unique solution of (1.2) with corresponding state $y \equiv 4$ and adjoint states

$$p(x) = \frac{1}{4\pi}|x|^2 - \frac{1}{2\pi}\log|x| \quad \text{and} \quad \mu = \delta_0.$$

The finite element counterparts of y, u, p, and μ are denoted by y_h, u_h, p_h, and μ_h, respectively.

For an error functional $E(h)$ we define the experimental order of convergence as

$$\text{EOC} \ = \frac{\ln E(h_1) - \ln E(h_2)}{\ln h_1 - \ln h_2}.$$

To investigate EOCs for our model problem we choose a sequence of uniform partitions of Ω containing five refinement levels, starting with eight triangles forming a uniform octagon as the initial triangulation of the unit disc. The corresponding grid sizes are $h_i = 2^{-i}$ for $i = 1, \ldots, 5$. As error functionals we take $E(h) = \|(u, y) - (u_h, y_h)\|$ and $E(h) = \|(u, y) - (u_h, y_h)\|_{H^1}$ and note that the error $p - p_h$ is related to $u - u_h$ via (2.10). We solve problems (2.6) using the QUADPROG routine of the MATLAB OPTIMIZATION TOOLBOX. The required finite element matrices for the discrete state and adjoint systems are generated with the help of the MATLAB PDE TOOLBOX. Furthermore, for discontinuous functions f we use the quadrature rule

$$\int_\Omega f(x)dx \approx \sum_{T \in \mathcal{T}_h} f\left(x_{s(T)}\right)|T|,$$

where $x_{s(T)}$ denotes the barycenter of T. In all computations we set $\alpha = 1$.

In Table 1, we present EOCs for problem (2.6) (case $S = D$) and the approach sketched in Remark 3.8 (case $S = M$). As one can see, the error $\|u - u_h\|$ behaves in the case $S = D$ as predicted by Theorem 3.6, whereas the errors $\|y - y_h\|$ and

TABLE 1
Experimental order of convergence.

Level	$(S=D)$ $\|u-u_h\|$	$(S=M)$ $\|u-u_h\|$	$(S=D)$ $\|y-y_h\|$	$(S=M)$ $\|y-y_h\|$	$(S=D)$ $\|y-y_h\|_{H^1}$	$(S=M)$ $\|y-y_h\|_{H^1}$
1	0.97615	0.65403	0.53646	0.69030	0.86051	0.68853

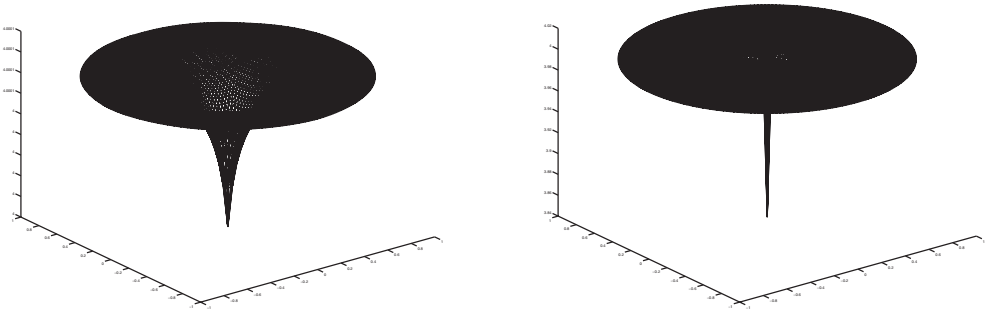

FIG. 1. *Numerically computed state y_h (left) and control u_h (right) for $h = 2^{-5}$ in the case $S = D$.*

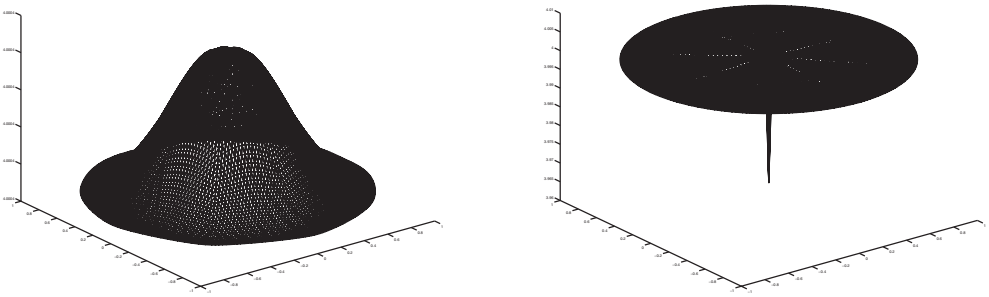

FIG. 2. *Numerically computed state y_h (left) and control u_h (right) for $h = 2^{-5}$ in the case $S = M$.*

$\|y-y_h\|_{H^1}$ show a better convergence behavior. On the finest level we have $\|u-u_h\| = 0.003117033$, $\|y-y_h\| = 0.000123186$, and $|y-y_h|_{H^1} = 0.000083757$. Furthermore, all coefficients of μ_h are equal to zero, except the one in front of δ_0, whose value is 0.99946494. The errors $\|u-u_h\|$, $\|y-y_h\|$, and $\|y-y_h\|_{H^1}$ in the case $S = M$ show a better EOC than in the case $S = D$. This can be explained by the facts that the exact solutions y and u are very smooth and that the relaxed form of the state constraints introduce a smearing effect on the numerical solutions at the origin. On the finest level we have $\|u-u_h\| = 0.001020918$, $\|y-y_h\| = 0.000652006$, and $|y-y_h|_{H^1} = 0.000037656$. Furthermore, the coefficient of μ_h corresponding to the patch containing the origin has the value 0.66505911271141.

Figures 1 and 2 present the numerical solutions y_h and u_h for $h = 2^{-5}$ in the case $S = D$ and $S = M$, respectively. We note that using equal scales on all axes would give completely flat graphs in all four figures.

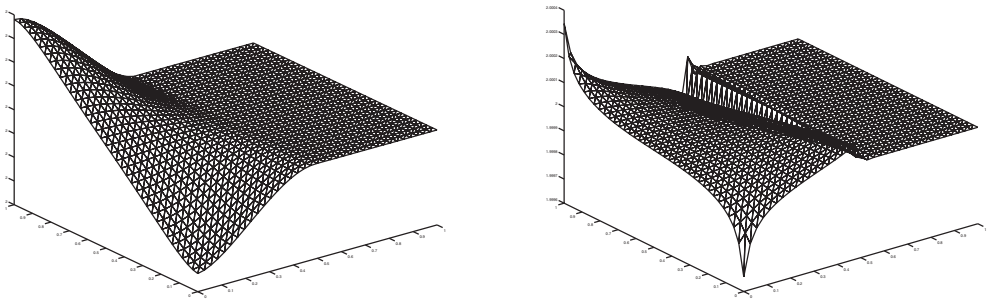

FIG. 3. *Numerically computed state y_h (left) and control u_h (right) for $h = \frac{\sqrt{2}}{36}$ in the case $S = D$.*

Example 4.2. The second test problem is taken from [11, Example 2]. It reads

$$\min_{u \in L^2(\Omega)} J(u) = \frac{1}{2}\int_\Omega |y - y_0|^2 + \frac{1}{2}\int_\Omega |u - u_0|^2$$
$$\text{subject to } y = \mathcal{G}(u) \text{ and } y(x) \geq b(x) \text{ in } \Omega.$$

Here Ω denotes the unit square,

$$b(x) = \begin{cases} 2x_1 + 1, & x_1 < \frac{1}{2}, \\ 2, & x_1 \geq \frac{1}{2}, \end{cases} \quad y_0(x) = \begin{cases} x_1^2 - \frac{1}{2}, & x_1 < \frac{1}{2}, \\ \frac{1}{4}, & x_1 = \frac{1}{2}, \\ \frac{3}{4}, & x_1 > \frac{1}{2}, \end{cases}$$

and

$$u_0(x) = \begin{cases} \frac{5}{2} - x_1^2, & x_1 < \frac{1}{2}, \\ \frac{9}{4}, & x_1 \geq \frac{1}{2}. \end{cases}$$

We remark that the inequality sign in the state constraint has been reversed in order to construct the example. The exact solution is given by $y \equiv 2$ and $u \equiv 2$ in Ω. The corresponding Lagrange multiplier $p \in H^1(\Omega)$ is given by

$$p(x) = \begin{cases} \frac{1}{2} - x_1^2, & x_1 < \frac{1}{2}, \\ \frac{1}{4}, & x_1 \geq \frac{1}{2}. \end{cases}$$

The multiplier μ has the form

$$\int_{\bar\Omega} f d\mu = \int_{\{x_1 = \frac{1}{2}\}} f ds + \int_{\{x_1 > \frac{1}{2}\}} f dx, \qquad f \in C^0(\bar\Omega). \tag{4.1}$$

In our numerical computations we use uniform grids generated with the POIMESH function of the MATLAB PDE TOOLBOX. Integrals containing y_0, u_0 are numerically evaluated by substituting y_0, u_0 by their piecewise linear, continuous finite element interpolations $I_h y_0, I_h u_0$. The grid size of a grid containing l horizontal and l vertical lines is given by $h_l = \frac{\sqrt{2}}{l+1}$. Figure 3 presents the numerical results for a grid with $h = \frac{\sqrt{2}}{36}$ in the case $(S = D)$. The corresponding values of μ_h on the same grid are presented in Figure 4. They reflect the fact that the measure consists of a lower dimensional part which is concentrated on the line $\{x \in \Omega \,|\, x_1 = \frac{1}{2}\}$ and a regular

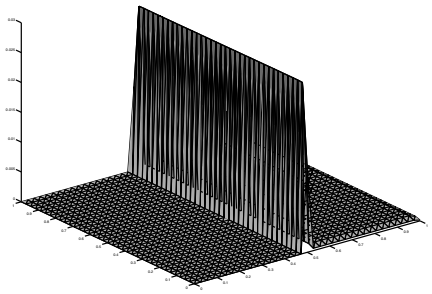

FIG. 4. *Numerically computed multiplier* μ_h *for* $h = \frac{\sqrt{2}}{36}$ *in the case* $S = D$.

part with a density $\chi_{|\{x_1>\frac{1}{2}\}}$. We again note that using equal scales on all axes would give completely flat graphs for y_h as well as for u_h.

We compute EOCs for the two different sequences of grid sizes $s_o = \{h_1, h_3, \dots, h_{19}\}$ and $s_e = \{h_0, h_2, \dots, h_{18}\}$. We note that the grids corresponding to s_o contain the line $x_1 = \frac{1}{2}$. Table 2 presents EOCs for s_o, and Table 3 presents EOCs for s_e. For the sequence s_o we observe superconvergence in the case $(S = D)$, although the discontinuous function y_0 for the quadrature is replaced by its piecewise linear, continuous finite element interpolant $I_h y_0$. Let us note that further numerical experiments show that the use of the quadrature rule (4.1) for integrals containing the function y_0 decreases the EOC for $\|u-u_h\|$ to $\frac{3}{2}$, whereas EOCs remain close to 2 for the other two errors $\|y-y_h\|$ and $\|y-y_h\|_{H^1}$. For this sequence also the case $(S = M)$ behaves twice as good as expected by our arguments in Remark 3.8. For the sequence s_e the

TABLE 4
Approximation of the multiplier in the case ($S = D$), $x_1 = \frac{1}{2}$ grid line.

8	1.01359012331610	0.48637773715316
9	1.01198410389649	0.48799027450619

error $\|u - u_h\|$ in the case ($S = D$) approximately behaves as predicted by our theory; in the case ($S = M$) it behaves as for the sequence s_o. The errors $\|y - y_h\|$ and $\|y - y_h\|_{H^1}$ behave that well, since the the exact solutions y and u are very smooth. For h_{19} we have in the case ($S = D$) $\|u - u_h\| = 0.000103428$, $\|y - y_h\| = 0.000003233$, and $|y - y_h|_{H^1} = 0.000015155$, and in the case ($S = M$) $\|u - u_h\| = 0.011177577$, $\|y - y_h\| = 0.000504815$, and $|y - y_h|_{H^1} = 0.001547907$. We observe that the errors in the case $S = M$ are two magnitudes larger than in the case ($S = D$). This can be explained by the fact that an ansatz for the multiplier μ with a linear combination of Dirac measures is better suited to approximate measures concentrated on singular sets than a piecewise constant ansatz as in the case ($S = M$). Finally, Table 4 presents $\sum_{x_i \in \{x_1 = 1/2\}} \mu_i$ and $\sum_{x_i \in \{x_1 > 1/2\}} \mu_i$ for s_o in the case ($S = D$). As one can see $\sum_{x_i \in \{x_1 = 1/2\}} \mu_i$ tends to 1, the length of $\{x_1 = 1/2\}$, and $\sum_{x_i \in \{x_1 > 1/2\}} \mu_i$ tends to $1/2$, the area of $\{x_1 > 1/2\}$. These numerical findings indicate that $\mu_h = \sum_{i=1}^m \mu_i \delta_{x_i}$ well approximates μ, since $\int_{\bar{\Omega}} d\mu_h = \sum_{i=1}^m \mu_i$, and that μ_h also well resolves the structure of μ; see (4.1). For all numerical computations of this example we have $\mu_i = 0$ for $x_i \in \{x_1 < 1/2\}$.

5. Appendix.

LEMMA 5.1. *Let $\frac{2d}{d+2} \le s \le 2$ and $v \in W^{1,s}(\Omega)$. Then*

$$\|v - P_h v\| \le C h^{1 + \frac{d}{2} - \frac{d}{s}} \|v\|_{W^{1,s}}.$$

Proof. The assertion is clear if $s = \frac{2d}{d+2}$ or if $s = 2$ so that we may assume $\frac{2d}{d+2} < s < 2$. Let us write

$$\int_\Omega |v - P_h v|^2 = \int_\Omega |v - P_h v|^{\frac{sd - 2d + 2s}{s}} |v - P_h v|^{\frac{d(2-s)}{s}}$$

and apply Hölder's inequality with $p = \frac{s^2}{sd - 2d + 2s}$, $q = \frac{s^2}{(d-s)(2-s)}$, which implies

$$\begin{aligned} \|v - P_h v\|^2 &\le \|v - P_h v\|_{L^s}^{\frac{sd-2d+2s}{s}} \|v - P_h v\|_{L^{\frac{ds}{d-s}}}^{\frac{d(2-s)}{s}} \\ &\le \|v - P_h v\|_{L^s}^{\frac{sd-2d+2s}{s}} \left(\|v\|_{L^{\frac{ds}{d-s}}} + \|P_h v\|_{L^{\frac{ds}{d-s}}} \right)^{\frac{d(2-s)}{s}}. \end{aligned}$$

We infer from [6] that

$$\|v - P_h v\|_{L^s} \le C h \|v\|_{W^{1,s}}, \quad \|P_h v\|_{L^{\frac{ds}{d-s}}} \le C \|v\|_{L^{\frac{ds}{d-s}}},$$

which, together with the continuous embedding $W^{1,s}(\Omega) \hookrightarrow L^{\frac{ds}{d-s}}(\Omega)$, gives

$$\|v - P_h v\|^2 \le C h^{\frac{sd-2d+2s}{s}} \|v\|^2_{W^{1,s}}$$

so that the assertion follows. ∎

LEMMA 5.2. *Suppose that K and $\tilde{K}$ are two disjoint compact subsets of $\bar{\Omega}$. Then there exists a nonnegative function $\phi \in C^2(\bar{\Omega})$ which satisfies*

$$\partial_\nu \phi = 0 \text{ on } \partial\Omega, \quad \phi \ge 1 \text{ on } K, \quad \phi = 0 \text{ on } \tilde{K}.$$

Proof. For $r > 0$ let us define $\Omega_r := \{x \in \bar{\Omega} \,|\, \operatorname{dist}(x, \partial\Omega) < r\}$. In view of the smoothness of $\partial\Omega$ there exists $\delta > 0$ such that for each $x \in \Omega_\delta$ there exists a unique point $y = y(x) \in \partial\Omega$, with

$$x = y - \operatorname{dist}(x, \partial\Omega)\nu(y)$$

(see [7, Section 14.6]). Since $K \cap \tilde{K} = \emptyset$ we may assume that $\operatorname{dist}(K, \tilde{K}) > \delta$. Let us define

$$\Gamma_K := \{y(x) \,|\, x \in K \cap \overline{\Omega_{\frac{\delta}{2}}}\}, \quad \Gamma_{\tilde{K}} := \{y(x) \,|\, x \in \tilde{K} \cap \overline{\Omega_{\frac{\delta}{2}}}\}.$$

Γ_K and $\Gamma_{\tilde{K}}$ are disjoint, compact subsets of $\partial\Omega$, since $\operatorname{dist}(K, \tilde{K}) > \delta$ and $x \mapsto y(x)$ is continuous. Let $\phi_1 \in C^2(\partial\Omega)$ be a nonnegative function satisfying $\phi_1 \ge 1$ on Γ_K, $\phi_1 = 0$ on $\Gamma_{\tilde{K}}$. By setting $\phi_1(x) = \phi_1(y(x))$ we extend ϕ_1 as a C^2 function to Ω_δ. Clearly, $\partial_\nu \phi_1 = 0$ on $\partial\Omega$. Let $\psi \in C^2(\bar{\Omega})$ be a nonnegative cutoff function, with $\psi = 1$ in $\Omega_{\frac{\delta}{4}}$ and $\psi = 0$ in $\bar{\Omega} \setminus \Omega_{\frac{\delta}{2}}$. Then $\phi_2 := \psi\phi_1$ satisfies

$$\partial_\nu \phi_2 = 0 \text{ on } \partial\Omega, \quad \phi_2 \ge 1 \text{ on } K \cap \Omega_{\frac{\delta}{4}}, \quad \phi_2 = 0 \text{ on } \tilde{K}.$$

Finally, choose a nonnegative function $\phi_3 \in C^2(\bar{\Omega})$, with

$$\phi_3 \ge 1 \text{ on } K \cap (\bar{\Omega} \setminus \Omega_{\frac{\delta}{4}}), \quad \phi_3(x) = 0 \text{ if } \operatorname{dist}(x, K \cap (\bar{\Omega} \setminus \Omega_{\frac{\delta}{4}})) \ge \frac{\delta}{8}.$$

Then $\partial_\nu \phi_3 = 0$ on $\partial\Omega$, $\phi_3 = 0$ on $\tilde{K}$, and $\phi := \phi_2 + \phi_3$ has the required properties. ∎

Acknowledgments. We thank Ulrich Matthes (TU Dresden) for coding the numerical examples and Alan Demlow (University of Kentucky) for pointing out reference [13] to us.

ANALYSIS OF A SPECTRAL-GALERKIN APPROXIMATION TO THE HELMHOLTZ EQUATION IN EXTERIOR DOMAINS*

JIE SHEN† AND LI-LIAN WANG‡

Abstract. An error analysis is presented for the spectral-Galerkin method to the Helmholtz equation in 2- and 3-dimensional exterior domains. The problem in unbounded domains is first reduced to a problem on a bounded domain via the Dirichlet-to-Neumann operator, and then a spectral-Galerkin method is employed to approximate the reduced problem. The error analysis is based on exploring delicate asymptotic behaviors of the Hankel functions and on deriving a priori estimates with explicit dependence on the wave number for both the continuous and the discrete problems. Explicit error bounds with respect to the wave number are derived, and some illustrative numerical examples are also presented.

Key words. Helmholtz equation, wave scattering, error analysis, spectral-Galerkin, unbounded domain

1. Introduction.

We consider in this paper the acoustic wave scattering from a bounded obstacle $D \subset \mathbb{R}^d$, $d = 2, 3$. In this case, the scattered wave satisfies the Helmholtz equation

$$-\Delta U - k^2 U = F \quad \text{in } \mathbb{R}^d \backslash \bar{D}, \tag{1.1}$$

along with the Sommerfeld radiation condition at infinity

$$\partial_r U - \mathrm{i}kU = o\big(r^{\frac{1-d}{2}}\big) \quad \text{as } r \to \infty,\ d = 2, 3, \tag{1.2}$$

which ensures that waves do not reflect from the far field. On the surface of the scatterer D, a Dirichlet (sound soft) or Neumann (sound hard) condition is assumed.

Although the Helmholtz equation with (1.2) is linear, its numerical approximation and associated analysis are notoriously difficult due to the following: (i) the domain is unbounded; (ii) the system is not positive definite; and (iii) when the wave number $k \gg 1$, the solution is highly oscillatory. In particular, it remains a challenge to design numerical algorithms which are robust and efficient for moderate to high wave numbers.

There has been extensive research work devoted to overcoming these difficulties (see, for instance, [16, 23, 22] and the references therein). In particular, it has been shown, at least for some simple cases, that errors of pth order numerical methods for the Helmholtz equation behave like $O(k^{p+1}h^p)$ (see, for instance, [18, 4, 30]). Hence, high-order methods are particularly preferable for this type of problem over low-order methods. We note also that some very detailed analyses were carried out in [2, 3]

on the discrete dispersive relation by the hp version of finite element method (FEM) and by the high-order discontinuous Galerkin method. These results indicate, once again, that high-order methods are preferable, if not necessary, for highly oscillatory problems.

On the other hand, the linear system from a discretization of the Helmholtz equation with moderate to high wave numbers is usually highly indefinite and difficult to solve. It is with these considerations in mind that we choose to use the transformed field expansion (TFE) method (cf. [26]), which improves over the classical field expansion method [27, 5, 6], coupled with a fast spectral-Galerkin solution (cf. [28, 29, 24]).

There are a few recent works on wave number independent boundary element methods and on error estimates with explicit dependence on wave numbers for acoustic scattering problems. In [19, 8], the authors introduced a novel Galerkin boundary element method using a graded mesh and special basis functions and derived a quasi-optimal error estimate which is independent of wave number for the Helmholtz equation in a half-plane and exterior of a convex polygon.

We now briefly describe the TFE method for a 2-dimensional (2-D) obstacle enclosed by $\{r = a + g(\theta) : 0 \le \theta < 2\pi\}$. The TFE algorithm consists of the following steps:

- Assuming F is compactly supported and choosing b such that $b > a + \max_{0\le\theta<2\pi} |g(\theta)|$ and $\mathrm{supp}F \subset \Omega_g := \{(r,\theta) : a + g(\theta) < r < b\}$, we then use the Dirichlet-to-Neumann operator T (see [15, 13] and the next section) to reduce the problem in the unbounded domain to

$$\begin{aligned} &-\Delta U - k^2 U = F \quad \text{in } \Omega_g, \\ &U|_{r=a+g(\theta)} = \xi, \qquad (\partial_r U + T(U))|_{r=b} = 0. \end{aligned} \tag{1.3}$$

- Make a change of variables

$$r' = \frac{(b-a)r - bg(\theta)}{(b-a) - g(\theta)}, \qquad \theta' = \theta, \tag{1.4}$$

which maps Ω_g to an annulus Ω_0. To simplify the notation, we still use (r,θ) to denote (r',θ') and U, F, ξ to denote the functions U, F, ξ after the change of variables. Then the problem (1.3) becomes

$$\begin{aligned} &-\Delta U - k^2 U = F + J(g,U) \quad \text{in } \Omega_0, \\ &U(a,\theta) = \xi(\theta), \ \ (\partial_r U + TU)|_{r=b} = \eta(g,U), \end{aligned} \tag{1.5}$$

where $J(g,U)$ and $\eta(g,U)$ contain differential operators with nonconstant coefficients for which a fast direct/iterative solution is not available.

- Consider the obstacle $\{(r,\theta) : r < a + g(\theta)\}$ as a perturbation of the disk $\{r < a\}$; i.e., write $g = \varepsilon h$ and expand u as

$$U(r,\theta;\varepsilon) = \sum_{n=0}^{\infty} U_n(r,\theta)\ \varepsilon^n.$$

Plugging the above expansion into (1.5) and collecting terms with ε^n, we find that [24]

$$\begin{aligned} &-\Delta U_n - k^2 U_n = \delta_{n,0} F + \tilde{J}(g, U_{n-4}, \ldots, U_{n-1}) \quad \text{in } \Omega_0, \\ &U_n(a,\theta) = \delta_{n,0}\xi(\theta), \ \ (\partial_r U_n + TU_n)|_{r=b} = \tilde{\eta}(g, U_{n-1}). \end{aligned} \tag{1.6}$$

- Solve (1.6) for $n = 0, 1, 2, \ldots$, and sum up the series by using a Padé approximation.

It is shown in [25, 26] that this TFE method is stable and robust at high order, and it is demonstrated in [24] that this method, coupled with a spectral-Galerkin solution for (1.6), is very efficient and capable of providing very accurate results for bounded obstacle scattering with moderate to high wave numbers.

Notice that the whole algorithm boils down to solving a sequence of the following nonhomogeneous Helmholtz equation in an annulus (2-D) or a spherical shell (3-D):

$$\begin{aligned} &-\Delta U - k^2 U = F \quad \text{in } \Omega_0, \\ &U(a,\theta) = \xi(\theta), \ \ (\partial_r U + TU)|_{r=b} = \eta(\theta). \end{aligned} \tag{1.7}$$

The purpose of this paper is to present a detailed error analysis of the spectral-Galerkin method for (1.7). The main difficulty here is to obtain error estimates with explicit dependence on the wave number. Among the very few results available in this regard are those in [18, 30], where the Helmholtz equation in bounded domains with a first-order approximation to the radiation boundary condition was considered and error estimates with explicit dependence on the wave numbers were derived. To the authors' best knowledge, there seems to be no rigorous error estimate available with explicit dependence on the wave number for a numerical scheme to bounded obstacle scattering.

We now introduce some notations to be used throughout this paper. Let ϖ be a given positive weight function in $I := (a, b)$. We denote by $L^2_\varpi(I)$ a Hilbert space of real or complex functions with inner product and norm

$$(u, v)_\varpi = \int_I u(r)\overline{v(r)}\varpi(r)dr, \qquad \|u\|_\varpi = \sqrt{(u, u)_\varpi},$$
