CONVERGENCE ANALYSIS OF A COLOCATED FINITE VOLUME SCHEME FOR THE INCOMPRESSIBLE NAVIER–STOKES EQUATIONS ON GENERAL 2D OR 3D MESHES*

R. EYMARD†, R. HERBIN‡, AND J. C. LATCHÉ§

Abstract. We study a colocated cell-centered finite volume method for the approximation of the incompressible Navier–Stokes equations posed on a 2D or 3D finite domain. The discrete unknowns are the components of the velocity and the pressure, all of them colocated at the center of the cells of a unique mesh; such a configuration is known to lead to stability problems, hence the need for a stabilization technique, which we choose of the Brezzi–Pitkäranta type. The scheme features two essential properties: the discrete gradient is the transpose of the divergence terms, and the discrete trilinear form associated to nonlinear advective terms vanishes on discrete divergence free velocity fields. As a consequence, the scheme is proved to be unconditionally stable and convergent for the Stokes problem and for the transient and the steady Navier–Stokes equations. In this latter case, for a given sequence of approximate solutions computed on meshes the size of which tends to zero, we prove, up to a subsequence, the L^2-convergence of the components of the velocity, and, in the steady case, the weak L^2-convergence of the pressure. The proof relies on the study of space and time translates of approximate solutions, which allows the application of Kolmogorov's theorem. The limit of this subsequence is then shown to be a weak solution of the Navier–Stokes equations. Numerical examples are performed to obtain numerical convergence rates in both the linear and nonlinear cases.

1. Introduction.

In this paper we are interested in finding an approximation of the fields $\bar{u} = (\bar{u}^{(i)})_{i=1,\dots,d} : \Omega \times [0,T] \to \mathbb{R}^d$, and $\bar{p} : \Omega \times [0,T] \to \mathbb{R}$, weak solution to the incompressible Navier–Stokes equations which we write

$$\begin{aligned} &\partial_t \bar{u}^{(i)} - \nu \Delta \bar{u}^{(i)} + \partial_i \bar{p} + \sum_{j=1}^{d} \bar{u}^{(j)} \partial_j \bar{u}^{(i)} = f^{(i)} \text{ in } \Omega \times (0,T), \quad \text{for } i = 1, \dots, d, \\ &\operatorname{div} \bar{u} = \sum_{i=1}^{d} \partial_i \bar{u}^{(i)} = 0 \text{ in } \Omega \times (0,T), \end{aligned} \tag{1.1}$$

with a homogeneous Dirichlet boundary condition for $\bar{u}$ and the initial condition

$$\bar{u}^{(i)}(\cdot, 0) = \bar{u}^{(i)}_{\text{ini}} \text{ in } \Omega \text{ for } i = 1, \dots, d. \tag{1.2}$$

In the above equations, $\bar{u}^{(i)}$, $i = 1, \dots, d$, denotes the components of the velocity of a fluid which flows in a domain Ω during the time $(0,T)$, $\bar{p}$ denotes the pressure, and

$\nu > 0$ stands for the viscosity of the fluid. We make the following assumptions:

$$\Omega \text{ is a polygonal open bounded connected subset of } \mathbb{R}^d,\ d = 2 \text{ or } 3, \tag{1.3}$$

$$T > 0 \text{ is the finite duration of the flow,} \tag{1.4}$$

$$\nu \in (0, +\infty), \tag{1.5}$$

$$\bar{u}_{\rm ini} \in L^2(\Omega)^d, \tag{1.6}$$

$$f^{(i)} \in L^2(\Omega \times (0,T)), \quad \text{for } i = 1, \ldots, d. \tag{1.7}$$

Numerical schemes for the Stokes equations and the Navier–Stokes equations have been extensively studied; see [21, 33, 34, 35, 23, 22] and the references therein. Among different schemes, finite element schemes and finite volume schemes are frequently used for mathematical or engineering studies. An advantage of finite volume schemes is that the unknowns are approximated by piecewise constant functions: this makes it easy to take into account additional nonlinear phenomena or the coupling with algebraic or differential equations, for instance in the case of reactive flows; in particular, one can find in [33, 25] the presentation of the classical finite volume scheme on rectangular meshes, which has been the basis of several industrial applications. However, the use of rectangular grids makes an important limitation to the type of domain which can be gridded and, more recently, finite volume schemes for the Navier–Stokes equations on triangular grids have been presented; see, for example, [24] where the vorticity formulation is used and [4] where primal variables are used with a Chorin-type projection method to ensure the divergence condition. Proofs of convergence for finite volume-type schemes for the Stokes and steady-state Navier–Stokes equations have recently been given for staggered grids [7, 24, 18, 3, 19, 2], following the pioneering work of Nicolaides [31] and Nicolaides and Wu [32].

In this paper, we propose the mathematical and numerical analysis of a discretization method which uses the primitive variables, that is the velocity and pressure, both approximated by piecewise constant functions on the cells of a 2D or 3D mesh. We emphasize that the approximate velocity and pressure are colocated, and therefore no dual grid is needed. The only requirement on the mesh is a geometrical assumption needed for the consistency of the approximate diffusion flux (see [13] and section 2 for a precise definition of the admissible discretizations).

As far as we know, this work is a first proof of the convergence of a finite volume scheme, which is of large interest in industry. Indeed, industrial computational fluid dynamics (CFD) codes (see, e.g., [29, 1]) use colocated cell-centered finite volume schemes; leaving aside implementation considerations, the principle of these schemes seems to differ from the present scheme only by the stabilization choice. The main reasons why this scheme is so popular in industry are

- a colocated arrangement of the unknowns,
- a very cheap assembling step (no numerical integration to perform),
- an easy coupling with other systems of equations.

The finite volume scheme studied here is based on three basic ingredients. First, a stabilization technique à la Brezzi–Pitkäranta [6] is used to cope with the instability of colocated velocity/pressure approximation spaces. Second, the discretization of the pressure gradient in the momentum balance equation is performed to ensure, by construction, that it is the transpose of the divergence term of the continuity constraint. Finally, the contribution of the discrete nonlinear advection term to the kinetic energy balance vanishes for discrete divergence free velocity fields, as in the continuous case. These features appear to be essential in the proof of convergence.

We are then able to prove the stability of the scheme and the convergence of discrete solutions towards a solution of the continuous problem when the size of the mesh tends to zero, for the steady linear case (generalized Stokes problem) and the stationary and transient Navier–Stokes equations, in two and three dimensions. Our results are valid for general meshes and do not require any assumption on the regularity of the continuous solution nor, in the nonlinear case, any small data condition. We emphasize that the convergence of the fully discrete (time and space) approximation is proven here, using an original estimate for the time translates, which yields, combined with a classical estimate on the space translates, a sufficient relative compactness property.

An error analysis is performed in the steady linear case, under regularity assumptions on the solution. An error bound of order 0.5 with respect to the step size is obtained in the discrete H^1 norm and the L^2 norm for, respectively, the velocity and the pressure. Of course, this is probably not a sharp estimate, as can be seen from the numerical results shown in section 5. Indeed, a better rate of convergence can be proven under additional assumptions on the mesh [20].

This paper is organized as follows. In section 2, we introduce the discretization tools together with some discrete functional analysis tools. Section 3 is devoted to the linear steady problem (Stokes problem), for which the finite volume scheme is given and convergence analysis and error estimates are detailed. The complete finite volume scheme for the nonlinear case is presented in section 4, in both the steady and transient cases. We then develop the analysis of its convergence to a weak solution of the continuous problem. We give some numerical results in section 5, and finally conclude with some remarks on open problems in section 6.

2. Spatial discretization and discrete functional analysis.

2.1. Admissible discretization of Ω. We first recall the notion of admissible discretization for a finite volume method, which is given in [13].

DEFINITION 2.1 (admissible discretization, steady case). *Let Ω be an open bounded polygonal (polyhedral if $d = 3$) subset of $\mathbb{R}^d$, and $\partial\Omega = \overline{\Omega}\backslash\Omega$ its boundary. An admissible finite volume discretization of Ω, denoted by $\mathcal{D}$, is given by $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P})$, where*

- *$\mathcal{M}$ is a finite family of nonempty open polygonal convex disjoint subsets of Ω (the "control volumes") such that $\overline{\Omega} = \cup_{K\in\mathcal{M}}\overline{K}$. For any $K \in \mathcal{M}$, let $\partial K = \overline{K} \setminus K$ be the boundary of K and $\mathrm{m}_K > 0$ denote the area of K.*
- *$\mathcal{E}$ is a finite family of disjoint subsets of $\overline{\Omega}$ (the "edges" of the mesh) such that, for all $\sigma \in \mathcal{E}$, there exists a hyperplane E of $\mathbb{R}^d$, $K \in \mathcal{M}$ with $\overline{\sigma} = \partial K \cap E$, and σ is a nonempty open subset of E. We then denote by $\mathrm{m}_\sigma > 0$ the $(d-1)$-dimensional measure of σ. We assume that, for all $K \in \mathcal{M}$, there exists a subset $\mathcal{E}_K$ of $\mathcal{E}$ such that $\partial K = \cup_{\sigma\in\mathcal{E}_K}\overline{\sigma}$. It then results from the previous hypotheses that, for all $\sigma \in \mathcal{E}$, either $\sigma \subset \partial\Omega$ or there exists $(K, L) \in \mathcal{M}^2$ with $K \neq L$ such that $\overline{K} \cap \overline{L} = \overline{\sigma}$; we denote in the latter case $\sigma = K|L$.*
- *$\mathcal{P}$ is a family of points of Ω indexed by $\mathcal{M}$, denoted by $\mathcal{P} = (x_K)_{K\in\mathcal{M}}$. The coordinates of x_K are denoted by $x_K^{(i)}$, $i = 1, \ldots, d$. The family $\mathcal{P}$ is such that, for all $K \in \mathcal{M}$, $x_K \in K$. Furthermore, for all $\sigma \in \mathcal{E}$ such that there exists $(K, L) \in \mathcal{M}^2$ with $\sigma = K|L$, it is assumed that the straight line (x_K, x_L) going through x_K and x_L is orthogonal to $K|L$. For all $K \in \mathcal{M}$ and all $\sigma \in \mathcal{E}_K$, let z_σ be the orthogonal projection of x_K on σ. We suppose that $z_\sigma \in \sigma$.*

An example of two neighboring control volumes K and L of $\mathcal{M}$ is depicted in

Figure 2.1.

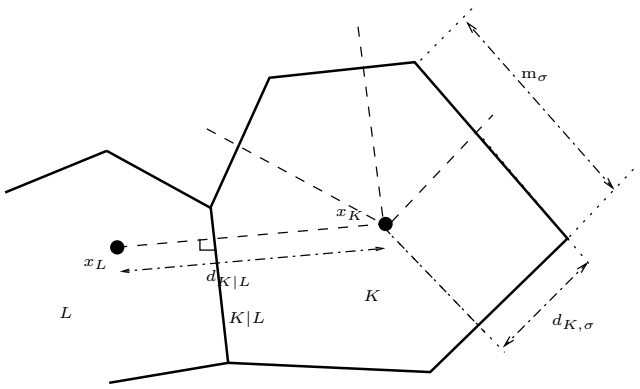

FIG. 2.1. *Notations for an admissible mesh.*

The following notations are used. The size of the discretization is defined by

$$\text{size}(\mathcal{D}) = \sup\{\text{diam}(K), K \in \mathcal{M}\}.$$

For all $K \in \mathcal{M}$ and $\sigma \in \mathcal{E}_K$, we denote by $\mathbf{n}_{K,\sigma}$ the unit vector normal to σ outward to K. We denote by $d_{K,\sigma}$ the Euclidean distance between x_K and σ. The set of interior (resp., boundary) edges is denoted by $\mathcal{E}_{\text{int}}$ (resp., $\mathcal{E}_{\text{ext}}$), that is, $\mathcal{E}_{\text{int}} = \{\sigma \in \mathcal{E};\ \sigma \not\subset \partial\Omega\}$ (resp., $\mathcal{E}_{\text{ext}} = \{\sigma \in \mathcal{E};\ \sigma \subset \partial\Omega\}$). For all $K \in \mathcal{M}$, we denote by $\mathcal{N}_K$ the subset of $\mathcal{M}$ of the neighboring control volumes. For all $K \in \mathcal{M}$ and $L \in \mathcal{N}_K$, we set $\mathbf{n}_{KL} = \mathbf{n}_{K,K|L}$, and we denote by $d_{K|L}$ the Euclidean distance between x_K and x_L.

We shall measure the regularity of the mesh through the function regul($\mathcal{D}$) defined by

$$\begin{aligned}\text{regul}(\mathcal{D}) = \inf&\left\{\frac{d_{K,\sigma}}{\text{diam}(K)},\ K \in \mathcal{M},\ \sigma \in \mathcal{E}_K\right\}\\ &\cup\left\{\frac{d_{K,K|L}}{d_{K|L}},\ L \in \mathcal{N}_K\right\} \cup \left\{\frac{1}{\text{card}(\mathcal{E}_K)},\ K \in \mathcal{M}\right\}.\end{aligned} \tag{2.1}$$

2.2. Discrete functional properties. Finite volume schemes are discrete balance equations with an adequate approximation of the fluxes; see, e.g., [13]. Recent works dealing with cell-centered finite volume methods for elliptic problems [16, 14, 19] introduce an equivalent variational formulation in adequate functional spaces. Here we shall follow this latter path, also introducing discrete analogues of the continuous Laplace, gradient, divergence, and transport operators, each of them featuring properties similar to their continuous counterparts.

DEFINITION 2.2. *Let Ω be an open bounded polygonal subset of $\mathbb{R}^d$, with $d \in \mathbb{N}^*$. Let $\mathcal{D} = (\mathcal{M}, \mathcal{E}, \mathcal{P})$ be an admissible finite volume discretization of Ω in the sense of Definition* 2.1. *We denote by $H_{\mathcal{D}}(\Omega) \subset L^2(\Omega)$ the space of functions which are piecewise constant on each control volume $K \in \mathcal{M}$. For all $w \in H_{\mathcal{D}}(\Omega)$ and for all $K \in \mathcal{M}$, we denote by w_K the constant value of w in K. The space $H_{\mathcal{D}}(\Omega)$ is equipped with the following Euclidean structure. For $(v, w) \in (H_{\mathcal{D}}(\Omega))^2$, we first define the following inner product (corresponding to Neumann boundary conditions):*

$$\langle v, w\rangle_{\mathcal{D}} = \frac{1}{2}\sum_{K\in\mathcal{M}}\sum_{L\in\mathcal{N}_K}\frac{\text{m}_{K|L}}{d_{K|L}}(v_L - v_K)(w_L - w_K). \tag{2.2}$$

We then define another inner product (corresponding to Dirichlet boundary conditions),

$$[v,w]_{\mathcal{D}} = \langle v,w\rangle_{\mathcal{D}} + \sum_{K\in\mathcal{M}} \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\rm ext}} \frac{\mathrm{m}_\sigma}{d_{K,\sigma}} v_K w_K. \tag{2.3}$$

Next, we define a seminorm and a norm in $H_{\mathcal{D}}(\Omega)$ (thanks to the discrete Poincaré inequality (2.4) *given below) by*

$$|w|_{\mathcal{D}} = \left(\langle w,w\rangle_{\mathcal{D}}\right)^{1/2}, \qquad \|w\|_{\mathcal{D}} = \left([w,w]_{\mathcal{D}}\right)^{1/2}.$$

We define the interpolation operator $P_{\mathcal{D}} : C(\Omega)\to H_{\mathcal{D}}(\Omega)$ by $(P_{\mathcal{D}}\varphi)_K = \varphi(x_K)$ for all $K\in\mathcal{M}$ and for all $\varphi\in C(\Omega)$.

Similarly, for $u=(u^{(i)})_{i=1,\dots,d}\in H_{\mathcal{D}}(\Omega)^d$, $v=(v^{(i)})_{i=1,\dots,d}\in H_{\mathcal{D}}(\Omega)^d$, and $w=(w^{(i)})_{i=1,\dots,d}\in H_{\mathcal{D}}(\Omega)^d$, we define

$$\|u\|_{\mathcal{D}} = \left(\sum_{i=1}^d [u^{(i)},u^{(i)}]_{\mathcal{D}}\right)^{1/2}, \qquad [v,w]_{\mathcal{D}} = \sum_{i=1}^d [v^{(i)},w^{(i)}]_{\mathcal{D}},$$

and $P_{\mathcal{D}} : C(\Omega)^d\to H_{\mathcal{D}}(\Omega)^d$ by $(P_{\mathcal{D}}\varphi)_K = \varphi(x_K)$ for all $K\in\mathcal{M}$ and for all $\varphi\in C(\Omega)^d$.

The following discrete Poincaré inequalities (see [13]) hold,

$$\|w\|_{L^2(\Omega)} \le \mathrm{diam}(\Omega)\|w\|_{\mathcal{D}} \ \forall w\in H_{\mathcal{D}}(\Omega), \tag{2.4}$$

and there exists $C_\Omega>0$, depending only on Ω, such that

$$\|w\|^2_{L^2(\Omega)} \le C_\Omega |w|^2_{\mathcal{D}} \ \forall w\in H_{\mathcal{D}}(\Omega) \text{ with } \int_\Omega w(x)\mathrm{d}x = 0. \tag{2.5}$$

Remark 2.1 (on the choice of the inner product). Before we go on with the definition of the discrete divergence and gradient operators, let us explain on the simple Laplace equation why the inner product defined by (2.3) is adequate for the approximation of the diffusion term. The discretization of the Laplace equation using finite volume methods is now classical (see [26, 13]) and is usually written in terms of fluxes; more recently [15, 27], a weak form of the scheme was introduced, which leads to more compact notations. For the sake of completeness, let us recall these two formulations for the Laplace equation $-\Delta w = f$ with homogeneous Dirichlet boundary conditions on Ω. Integrating this equation on a control volume K yields $\int_{\partial K} -\nabla w\cdot\mathbf{n} = \mathrm{m}_K f_K$. Decomposing the boundary of K into edges and approximating the diffusive flux through an edge $\sigma = K|L$ by a two-point finite difference scheme yields

$$\sum_{\sigma\in\mathcal{E}_K} F_{K,\sigma}\mathrm{m}_K f_K, \tag{2.6}$$

with $F_{K,\sigma} = \frac{\mathrm{m}_\sigma}{d_{K|L}}(w_K - w_L)$ if $\sigma = K|L$ is an internal edge separating the control volumes K and L, and $F_{K,\sigma} = \frac{\mathrm{m}_\sigma}{d_{K,\sigma}} w_K$ if σ is a boundary edge. Let $\varphi\in H_{\mathcal{D}}(\Omega)$, $\varphi = \sum_{K\in\mathcal{M}}\varphi_K 1_K$. Multiplying (2.6) by φ_K, summing over K, and reordering the summations yields

$$[w,\varphi]_{\mathcal{D}} = \int_\Omega f(x)\varphi(x)\mathrm{d}x. \tag{2.7}$$

Conversely, taking $\varphi = 1_K$ in (2.7) yields (2.6). The flux form (2.6) of the scheme is therefore equivalent to the weak form (2.7) featuring the inner product (2.3).

Let us also remark that a given function $u \in H_{\mathcal{D}}(\Omega)$, considered only as an element of $L^2(\Omega)$, does not have a trace on $\partial\Omega$. However, since u is constant per control volume, one may define $u_\sigma = u_K$ for any edge $\sigma \in \mathcal{E}_{\rm ext}$, where K is the unique cell of which σ is an edge. One can then immediately deduce from the definition (2.3) of the inner product that $\sum_{\sigma\in\mathcal{E}_{\rm ext}} {\rm m}_\sigma u_\sigma^2 \le h_{\mathcal{D}}\|u\|_{\mathcal{D}}^2$. Therefore, if $(\mathcal{D}_n, u_{\mathcal{D}_n})_{n\in\mathbb{N}}$ is a sequence such that $h_{\mathcal{D}_n} \to 0$ as $n \to +\infty$, and $u_{\mathcal{D}_n} \in H_{\mathcal{D}_n}(\Omega)$ is such that $\|u_{\mathcal{D}_n}\|_{\mathcal{D}_n}$ remains bounded, then $\sum_{\sigma\in\mathcal{E}_{\rm ext}} {\rm m}_\sigma (u_{\mathcal{D}_n})_\sigma^2 \to 0$ as $n \to +\infty$. We then recover, "at the limit," the homogeneous Dirichlet boundary condition.

We define a discrete divergence operator ${\rm div}_{\mathcal{D}} : H_{\mathcal{D}}(\Omega)^d \to H_{\mathcal{D}}(\Omega)$, by

$$\text{(2.8)}\qquad {\rm div}_{\mathcal{D}}(u)(x) = \frac{1}{{\rm m}_K} \sum_{L\in\mathcal{N}_K} A_{KL}\cdot(u_K + u_L), \quad \text{for a.e. } x \in K\ \forall K \in \mathcal{M},$$

with

$$\text{(2.9)}\qquad A_{KL} = \frac{{\rm m}_{K|L}}{d_{K|L}}\frac{x_L - x_K}{2} = \frac{1}{2}\ {\rm m}_{K|L}\ \mathbf{n}_{KL}\ \forall K \in \mathcal{M} \text{ and } \forall L \in \mathcal{N}_K.$$

We then set $E_{\mathcal{D}}(\Omega) = \{u \in H_{\mathcal{D}}(\Omega)^d, {\rm div}_{\mathcal{D}}(u) = 0\}$.

Remark 2.2. Thanks to the conservative formulation (2.8), the function ${\rm div}_{\mathcal{D}}(u)$ satisfies $\int_\Omega {\rm div}_{\mathcal{D}}(u)(x){\rm d}x = 0$.

Remark 2.3. Any definition of A_{KL} such that $A_{KL} = {\rm m}_{K|L} a_{KL}\mathbf{n}_{KL}$ with $a_{KL} \ge 0$ and $a_{KL} + a_{LK} = 1$, combined with the definition ${\rm div}_{\mathcal{D}}(u)(x) = \frac{1}{{\rm m}_K}\sum_{L\in\mathcal{N}_K}(A_{KL}\cdot u_K - A_{LK}\cdot u_L)$, yields a consistent approximation of the normal fluxes, and thus the same results of convergence as those which are proven in this paper, namely an order $h^{1/2}$ error estimate. On particular meshes, one can prove a better error estimate by choosing $a_{KL} = d(x_L, K|L)/d_{KL}$ (see [20]), which yields an order 2 consistent approximation of the normal flux, and therefore an order h error estimate. Nevertheless, in the general framework of this paper, there is no specific choice which improves the convergence result nor the error estimate. Therefore, we set in this paper $a_{KL} = 1/2$, which corresponds to (2.9). The advantage of this choice is that it leads to simpler notations and shorter equations.

The adjoint of this discrete divergence defines a discrete gradient $\nabla_{\mathcal{D}} : H_{\mathcal{D}}(\Omega) \to H_{\mathcal{D}}(\Omega)^d$:

$$\text{(2.10)}\qquad (\nabla_{\mathcal{D}}u)_K = \frac{1}{{\rm m}_K}\sum_{L\in\mathcal{N}_K} A_{KL}(u_L - u_K)\ \forall K \in \mathcal{M} \text{ and } \forall u \in H_{\mathcal{D}}(\Omega).$$

This operator $\nabla_{\mathcal{D}}$ then satisfies the following property.

LEMMA 2.3. *Let $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition* 2.1*, such that $\lim_{m\to\infty} {\rm size}(\mathcal{D}^{(m)}) = 0$. Let us assume that there exists $C > 0$ and $\alpha \in [0, 2)$, a sequence $(u^{(m)})_{m\in\mathbb{N}}$ such that $u^{(m)} \in H_{\mathcal{D}^{(m)}}(\Omega)$, and $|u^{(m)}|_{\mathcal{D}_m}^2 \le C\ {\rm size}(\mathcal{D}^{(m)})^{-\alpha}$ for all $m \in \mathbb{N}$.*

Then the following property holds:

$$\text{(2.11)}\qquad \lim_{m\to+\infty}\int_\Omega \Big(P_{\mathcal{D}_m}\varphi(x)\nabla_{\mathcal{D}_m}u^{(m)}(x) + u^{(m)}(x)\nabla\varphi(x)\Big)\,{\rm d}x = 0\ \forall\varphi \in C_c^\infty(\Omega),$$

and therefore

$$\text{(2.12)}\qquad \lim_{m\to+\infty}\int_\Omega \nabla_{\mathcal{D}_m}u^{(m)}(x)\cdot P_{\mathcal{D}_m}\psi(x){\rm d}x = 0\ \forall\psi \in C_c^\infty(\Omega)^d \cap E(\Omega),$$

where $E(\Omega)$ is defined by (3.5).

Proof. Under the hypotheses stated in Lemma 2.3, let $i = 1, \dots, d$ and $\varphi \in C_c^\infty(\Omega)$ be given. Let us study, for $m \in \mathbb{N}$, the term

$$T_1^{(m)} = \int_\Omega \left(P_{\mathcal{D}_m}\varphi(x) \nabla_{\mathcal{D}_m} u^{(m)}(x) + u^{(m)}(x) \nabla\varphi(x) \right) dx.$$

From (2.9) and (2.10), we get that

$$T_1^{(m)} = \sum_{\sigma \in \mathcal{E}_{\rm int}, \sigma = K|L} (u_L^{(m)} - u_K^{(m)}) \mathrm{m}_{K|L} \, R_{KL}^{(m)},$$

where

$$R_{KL}^{(m)} = \left(\frac{1}{2}(\varphi(x_K) + \varphi(x_L)) - \frac{1}{\mathrm{m}_{K|L}} \int_{K|L} \varphi(x) \mathrm{d}\gamma(x) \right) \mathbf{n}_{KL}.$$

Thanks to the Cauchy–Schwarz inequality,

$$|T_1^{(m)}|^2 \le |u^{(m)}|_{\mathcal{D}_m}^2 \sum_{\sigma \in \mathcal{E}_{\rm int}, \sigma = K|L} \left| R_{KL}^{(m)} \right|^2 \mathrm{m}_{K|L} d_{KL}.$$

One has $\sum_{\sigma \in \mathcal{E}_{\rm int}, \sigma = K|L} \mathrm{m}_{K|L} d_{KL} \le d \ \mathrm{m}(\Omega)$. Thanks to the existence of $C_\varphi > 0$, which depends only on φ such that $|R_{KL}^{(m)}| \le C_\varphi \mathrm{size}(\mathcal{D}^{(m)})$, and since $\alpha < 2$, we then get that

$$\lim_{m \to \infty} T_1^{(m)} = 0,$$

which yields (2.11).

Consider now $\psi \in C_c^\infty(\Omega)^d \cap E(\Omega)$. One may write (2.11) componentwise and take $\varphi = \psi_i$ in the ith equation. Summing the d resulting equations and using the fact that $\psi \in E(\Omega)$ yields (2.12). ∎

Lemma 2.4 (discrete Rellich theorem). *Let $(\mathcal{D}^{(m)})_{m \in \mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition* 2.1*, such that $\lim_{m \to \infty} \mathrm{size}(\mathcal{D}^{(m)}) = 0$. Let us assume that there exist $C > 0$ and a sequence $(u^{(m)})_{m \in \mathbb{N}}$ such that $u^{(m)} \in H_{\mathcal{D}^{(m)}}(\Omega)$ and $\|u^{(m)}\|_{\mathcal{D}_m} \le C$ for all $m \in \mathbb{N}$.*

Then, there exist $\bar{u} \in H_0^1(\Omega)$ and a subsequence of $(u^{(m)})_{m \in \mathbb{N}}$, again denoted by $(u^{(m)})_{m \in \mathbb{N}}$, such that

1. *the sequence $(u^{(m)})_{m \in \mathbb{N}}$ converges in $L^2(\Omega)$ to $\bar{u}$ as $m \to +\infty$,*
2. *for all $\varphi \in C_c^\infty(\Omega)$, we have*

$$\lim_{m \to +\infty} [u^{(m)}, P_{\mathcal{D}_m}\varphi]_{\mathcal{D}_m} = \int_\Omega \nabla\bar{u}(x) \cdot \nabla\varphi(x) \mathrm{d}x, \tag{2.13}$$

3. *$\nabla_{\mathcal{D}_m} u^{(m)}$ weakly converges to $\nabla\bar{u}$ in $L^2(\Omega)^d$ as $m \to +\infty$ and* (2.11) *holds.*

Proof. The proof of the first two items is given in [13, proof of Theorem 9.1, pp. 773–774]. Since we have $|u^{(m)}|_{\mathcal{D}_m} \le \|u^{(m)}\|_{\mathcal{D}_m}$, we can apply Lemma 2.3, which gives the third item. ∎

Remark 2.4. Following [10], if we denote

$$\mathcal{D}_{K,\sigma} = \{ tx_K + (1-t)y, \ t \in (0,1), \ y \in \sigma \} \ \forall K \in \mathcal{M} \text{ and } \forall \sigma \in \mathcal{E}_K,$$

we may alternatively define a discrete gradient $\tilde{\nabla}_{\mathcal{D}} : H_{\mathcal{D}}(\Omega) \to L^2(\Omega)^d$ by

$$\forall\, K \in \mathcal{M},$$

$$\tilde{\nabla}_{\mathcal{D}} u(x) = \frac{d}{d_{KL}}(u_L - u_K)\mathbf{n}_{KL}, \text{ for a.e. } x \in \mathcal{D}_{K,K|L} \cup \mathcal{D}_{L,K|L}\ \forall L \in \mathcal{N}_K,$$
$$\tilde{\nabla}_{\mathcal{D}} u(x) = \frac{d}{d_{K,\sigma}}(0 - u_K)\mathbf{n}_{K,\sigma}, \text{ for a.e. } x \in \mathcal{D}_{K,\sigma}\ \forall \sigma \in \mathcal{E}_K \cap \mathcal{E}_{\text{ext}}.$$

A result similar to that of Lemma 2.4 holds with this definition of a discrete gradient, and in fact it can be shown that the weak convergence of $\tilde{\nabla}_{\mathcal{D}_m} u^{(m)}$ is equivalent to the weak convergence of $\nabla_{\mathcal{D}_m} u^{(m)}$.

LEMMA 2.5. *Let $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition* 2.1*, such that* $\lim_{m\to\infty} \operatorname{size}(\mathcal{D}^{(m)}) = 0$.

Let us assume that there exist two sequences, $(u^{(m)})_{m\in\mathbb{N}}$ and $(v^{(m)})_{m\in\mathbb{N}}$, such that

1. *for all $m \in \mathbb{N}$, $u^{(m)}$ belongs to $H_{\mathcal{D}^{(m)}}(\Omega)$ and there exists $\bar{u} \in H_0^1(\Omega)$ such that the sequence $(u^{(m)})_{m\in\mathbb{N}}$ converges in $L^2(\Omega)$ to $\bar{u}$ as $m \to +\infty$ and*

$$\lim_{m\to\infty} \|u^{(m)}\|^2_{\mathcal{D}^{(m)}} = \|\nabla \bar{u}\|^2_{L^2(\Omega)^d}; \tag{2.14}$$

2. *for all $m \in \mathbb{N}$, $v^{(m)}$ belongs to $H_{\mathcal{D}^{(m)}}(\Omega)$ and there exists $C > 0$ and $\bar{v} \in H_0^1(\Omega)$ such that $\|v^{(m)}\|_{\mathcal{D}^{(m)}} \le C$ for all $m \in \mathbb{N}$ and the sequence $(v^{(m)})_{m\in\mathbb{N}}$ converges in $L^2(\Omega)$ to $\bar{v}$ as $m \to +\infty$.*

Then the following convergence result holds:

$$\lim_{m\to+\infty} [u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} = \int_\Omega \nabla \bar{u}(x) \cdot \nabla \bar{v}(x) \mathrm{d}x. \tag{2.15}$$

Proof. Under the assumptions of the lemma, let $\varphi \in C_c^\infty(\Omega)$. We have

$$[u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} = [u^{(m)} - P_{\mathcal{D}^{(m)}}\varphi, v^{(m)}]_{\mathcal{D}^{(m)}} + [P_{\mathcal{D}^{(m)}}\varphi, v^{(m)}]_{\mathcal{D}^{(m)}},$$

and therefore, thanks to the Cauchy–Schwarz inequality, we get

$$[u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} \ge [P_{\mathcal{D}_m}\varphi, v^{(m)}]_{\mathcal{D}^{(m)}} - \|u^{(m)} - P_{\mathcal{D}^{(m)}}\varphi\|_{\mathcal{D}^{(m)}} \|v^{(m)}\|_{\mathcal{D}^{(m)}}$$

and

$$[u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} \le [P_{\mathcal{D}_m}\varphi, v^{(m)}]_{\mathcal{D}^{(m)}} + \|u^{(m)} - P_{\mathcal{D}^{(m)}}\varphi\|_{\mathcal{D}^{(m)}} \|v^{(m)}\|_{\mathcal{D}^{(m)}}.$$

From (2.14) and thanks to Lemma 2.4, we get that

$$\lim_{m\to+\infty} \|u^{(m)} - P_{\mathcal{D}^{(m)}}\varphi\|^2_{\mathcal{D}^{(m)}} = \|\nabla \bar{u} - \nabla\varphi\|^2_{L^2(\Omega)^d},$$

and thus, passing to the limit $m \to \infty$ in the two above inequalities, we get that

$$\liminf_{m\to\infty} [u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} \ge \int_\Omega \nabla\varphi(x) \cdot \nabla \bar{v}(x) \mathrm{d}x - C\|\nabla \bar{u} - \nabla\varphi\|_{L^2(\Omega)^d}$$

and

$$\limsup_{m\to\infty} [u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} \le \int_\Omega \nabla\varphi(x) \cdot \nabla \bar{v}(x) \mathrm{d}x + C\|\nabla \bar{u} - \nabla\varphi\|_{L^2(\Omega)^d}.$$

Letting φ tend to $\bar{u}$ in $H_0^1(\Omega)$ in the two above inequalities completes the proof. ∎

3. Approximation of the linear steady problem.

3.1. The Stokes problem. We first study the following linear steady problem: Find an approximation of $\bar{u}$ and $\bar{p}$, weak solution to the generalized Stokes equations with homogeneous boundary conditions on $\partial\Omega$, which read

$$\begin{aligned} &\eta\bar{u} - \nu\Delta\bar{u} + \nabla\bar{p} = f \text{ in } \Omega, \\ &\mathrm{div}\bar{u} = 0 \text{ in } \Omega, \\ &\bar{u} = 0 \text{ on } \partial\Omega. \end{aligned} \tag{3.1}$$

For this problem, the following assumptions are made:

$$\Omega \text{ is a polygonal open bounded connected subset of } \mathbb{R}^d,\ d = 2 \text{ or } 3, \tag{3.2}$$

$$\nu \in (0, +\infty),\ \eta \in [0, +\infty), \tag{3.3}$$

$$f \in L^2(\Omega)^d. \tag{3.4}$$

We then consider the following weak sense for problem (3.1).

Definition 3.1 (weak solution to the steady Stokes equations). *Under hypotheses* (3.2)–(3.4)*, let* $E(\Omega)$ *be defined by*

$$E(\Omega) := \{\bar{v} = (\bar{v}^{(i)})_{i=1,\dots,d} \in H_0^1(\Omega)^d, \mathrm{div}\bar{v} = 0 \text{ a.e. in } \Omega\}. \tag{3.5}$$

Then $(\bar{u}, \bar{p})$ *is called a weak solution of* (3.1) *(see, e.g.,* [36] *or* [5]*) if*

$$\left\{ \begin{array}{l} \bar{u} \in E(\Omega),\ \bar{p} \in L^2(\Omega) \text{ with } \displaystyle\int_\Omega \bar{p}(x)\mathrm{d}x = 0, \\ \eta \displaystyle\int_\Omega \bar{u}(x)\cdot\bar{v}(x)\mathrm{d}x + \nu \int_\Omega \nabla\bar{u}(x) : \nabla\bar{v}(x)\mathrm{d}x \\ \qquad\qquad - \displaystyle\int_\Omega \bar{p}(x)\mathrm{div}\bar{v}(x)\mathrm{d}x = \int_\Omega f(x)\cdot\bar{v}(x)\mathrm{d}x \quad \forall \bar{v} \in H_0^1(\Omega)^d, \end{array} \right. \tag{3.6}$$

where, for all $\bar{u}, \bar{v} \in H_0^1(\Omega)^d$ *and for a.e.* $x \in \Omega$*, we use the following notation:*

$$\nabla\bar{u}(x) : \nabla\bar{v}(x) = \sum_{i=1}^{d} \nabla\bar{u}^{(i)}(x)\cdot\nabla\bar{v}^{(i)}(x).$$

The existence and uniqueness of the weak solution of (3.1) in the sense of the above definition is a classical result (see, e.g., [36] or [5]).

3.2. The finite volume scheme. Under hypotheses (3.2)–(3.4), let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition 2.1. It is then natural to write an approximate problem to the Stokes problem (3.6) in the following way (recall that $E_\mathcal{D}(\Omega) = \{u \in H_\mathcal{D}(\Omega)^d, \mathrm{div}_\mathcal{D}(u) = 0\}$):

$$\left\{ \begin{array}{l} u \in E_\mathcal{D}(\Omega),\ p \in H_\mathcal{D}(\Omega) \text{ with } \displaystyle\int_\Omega p(x)\mathrm{d}x = 0, \\ \eta \displaystyle\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u, v]_\mathcal{D} \\ \qquad\qquad - \displaystyle\int_\Omega p(x)\mathrm{div}_\mathcal{D}(v)(x)\mathrm{d}x = \int_\Omega f(x)\cdot v(x)\mathrm{d}x \qquad \forall v \in H_\mathcal{D}(\Omega)^d. \end{array} \right. \tag{3.7}$$

As we use a colocated approximation for the velocity and the pressure fields, the scheme must be stabilized. Using a nonconsistent stabilization à la Brezzi–Pitkäranta [6], we then look for (u,p) such that

$$
\left\{
\begin{array}{l}
(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega) \text{ with } \displaystyle\int_\Omega p(x)\mathrm{d}x = 0, \\
\eta \displaystyle\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu [u,v]_{\mathcal{D}} \\
\qquad\qquad - \displaystyle\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x = \int_\Omega f(x)\cdot v(x)\mathrm{d}x \qquad\qquad \forall v \in H_{\mathcal{D}}(\Omega)^d, \\
\displaystyle\int_\Omega \mathrm{div}_{\mathcal{D}}(u)(x) q(x)\mathrm{d}x = -\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,q\rangle_{\mathcal{D}} \qquad\qquad \forall q \in H_{\mathcal{D}}(\Omega),
\end{array}
\right. \tag{3.8}
$$

where $\lambda > 0$ and $\alpha \in (0,2)$ are adjustable parameters of the scheme which will have to be tuned in order to make a balance between accuracy and stability.

System (3.8) is equivalent to finding the family of vectors of $\mathbb{R}^d$, $(u_K)_{K\in\mathcal{M}}$, and scalars, $(p_K)_{K\in\mathcal{M}}$, solution to the system of equations obtained by writing for each control volume K of $\mathcal{M}$

$$
\left\{
\begin{array}{l}
\eta\ \mathrm{m}_K\ u_K - \nu \displaystyle\sum_{L\in\mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}}(u_L - u_K) - \nu \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{ext}}} \frac{\mathrm{m}_\sigma}{d_{K,\sigma}}(0-u_K) \\
\qquad\qquad + \displaystyle\sum_{L\in\mathcal{N}_K} A_{KL}\ (p_L - p_K) = \int_K f(x)\mathrm{d}x, \\
\displaystyle\sum_{L\in\mathcal{N}_K} A_{KL}\cdot(u_K+u_L) - \lambda\ \mathrm{size}(\mathcal{D})^\alpha \sum_{L\in\mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}}(p_L - p_K) = 0,
\end{array}
\right. \tag{3.9}
$$

supplemented by the relation

$$
\sum_{K\in\mathcal{M}} \mathrm{m}_K\ p_K = 0. \tag{3.10}
$$

Defining $p_\sigma = (p_K + p_L)/2$ if $\sigma = K|L$, and $p_\sigma = p_K$ if $\sigma \in \mathcal{E}_{\mathrm{ext}} \cap \mathcal{E}_K$, and using the fact that $\sum_{\sigma\in\mathcal{E}_K} \mathrm{m}_\sigma \mathbf{n}_{K,\sigma} = 0$, one notices that $\sum_{L\in\mathcal{N}_K} A_{KL}\ (p_L - p_K)$ is in fact equal to $\sum_{\sigma\in\mathcal{E}_K} \mathrm{m}_\sigma p_\sigma \mathbf{n}_{K,\sigma}$, thus yielding a conservative form, which shows that (3.9) is indeed a finite volume scheme.

The existence of a solution to (3.8) will be proven below.

3.3. Study of the scheme in the linear case. We first prove a stability estimate for the velocity.

LEMMA 3.2 (discrete H_0^1 estimate for the velocity). *Under hypotheses* (3.2)–(3.4)*, let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1*. Let* $\lambda \in (0,+\infty)$ *and* $\alpha \in (0,2)$ *be given. Let* $(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ *be a solution to* (3.8)*. Then the following inequalities hold:*

$$
\nu \|u\|_{\mathcal{D}} \le \mathrm{diam}(\Omega) \|f\|_{L^2(\Omega)^d} \tag{3.11}
$$

and

$$
\nu\ \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|_{\mathcal{D}}^2 \le \mathrm{diam}(\Omega)^2 \|f\|_{L^2(\Omega)^d}^2. \tag{3.12}
$$

Proof. Setting $v = u$ and $q = p$ in (3.8), we get

$$
\eta \int_\Omega u(x)^2 \mathrm{d}x + \nu \|u\|_{\mathcal{D}}^2 - \int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(u)(x)\mathrm{d}x = \int_\Omega f(x)\cdot u(x)\mathrm{d}x.
$$

Since $\eta \geq 0$, the second equation of (3.8) with $q = p$ and Young's inequality yields

$$\begin{aligned}&\eta \int_\Omega u(x)^2 \mathrm{d}x + \nu \|u\|_{\mathcal{D}}^2 + \lambda \ \mathrm{size}(\mathcal{D})^\alpha \ |p|_{\mathcal{D}}^2 \\ &\leq \frac{\mathrm{diam}(\Omega)^2}{2\nu} \|f\|_{L^2(\Omega)^d}^2 + \frac{\nu}{2 \, \mathrm{diam}(\Omega)^2} \|u\|_{L^2(\Omega)^d}^2.\end{aligned}$$

Using the Poincaré inequality (2.4) gives

$$\nu \|u\|_{\mathcal{D}}^2 + \lambda \ \mathrm{size}(\mathcal{D})^\alpha \ |p|_{\mathcal{D}}^2 \leq \frac{\mathrm{diam}(\Omega)^2}{2\nu} \|f\|_{L^2(\Omega)^d}^2 + \frac{\nu}{2} \|u\|_{\mathcal{D}}^2,$$

which leads to (3.11) and (3.12). ∎

We can now state the existence and uniqueness of a discrete solution to (3.8).

Corollary 3.3 (existence and uniqueness of a solution to the finite volume scheme). *Under hypotheses* (3.2)–(3.4)*, let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1*. Let* $\lambda \in (0, +\infty)$ *and* $\alpha \in (0, 2)$ *be given. Then there exists a unique solution to* (3.8)*.*

Proof. Let us define the finite dimensional vector space

$$V = \left\{ (u, p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega), \ \int_\Omega p(x) \ \mathrm{d}x = 0 \right\}.$$

Let $(u, p) \in V$ be given, and let us define $(\widetilde{u}, \widetilde{p}) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ by

$$\left\{ \begin{array}{l} \displaystyle \int_\Omega \widetilde{u}(x) \cdot v(x) \mathrm{d}x = \eta \int_\Omega u(x) \cdot v(x) \mathrm{d}x + \nu [u, v]_{\mathcal{D}} - \int_\Omega p(x) \mathrm{div}_{\mathcal{D}}(v)(x) \mathrm{d}x \\ \qquad \forall v \in H_{\mathcal{D}}(\Omega)^d, \\ \displaystyle \int_\Omega \widetilde{p}(x) q(x) \mathrm{d}x = \int_\Omega \mathrm{div}_{\mathcal{D}}(u)(x) q(x) \mathrm{d}x + \lambda \ \mathrm{size}(\mathcal{D})^\alpha \ \langle p, q \rangle_{\mathcal{D}} \ \forall q \in H_{\mathcal{D}}(\Omega). \end{array} \right.$$

Taking $q = 1_\Omega$ shows that $\int_\Omega \widetilde{p}(x) \ \mathrm{d}x = 0$ (see Remark 2.2), and therefore $(\widetilde{u}, \widetilde{p}) \in V$. Hence we define the linear mapping $\Psi : V \to V$ such that $\Psi(u, p) = (\widetilde{u}, \widetilde{p})$. From Lemma 3.2, we get that $\Psi(u, p) = 0$ implies $u = 0$ and $p = 0$. This proves that $\Psi(\cdot)$ is one to one. This concludes the proof of existence and uniqueness of the (u, p) solution to (3.8), since $\widetilde{u}_K = \frac{1}{\mathrm{m}_K} \int_K f(x) \mathrm{d}x$ and $\widetilde{p}_K = 0$ for all $K \in \mathcal{M}$ obviously define an element of V. ∎

We then prove the following strong estimate for the pressure.

Lemma 3.4 (L^2 estimate for the pressure). *Under hypotheses* (3.2)–(3.4)*, let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1 *and let* $\zeta > 0$ *be such that* $\mathrm{regul}(\mathcal{D}) > \zeta$*. Let* $\lambda \in (0, +\infty)$ *and* $\alpha \in (0, 2)$ *be given. Let* $(u, p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ *be a solution to* (3.8)*. Then there exists* C_1 *, depending only on* d*,* Ω*,* η*,* ν*,* λ*,* α*, and* ζ*, and not on* $\mathrm{size}(\mathcal{D})$*, such that the following inequality holds:*

$$\|p\|_{L^2(\Omega)} \leq C_1 \, \|f\|_{L^2(\Omega)^d}. \tag{3.13}$$

Proof. We first apply a result by Nečas [30]: thanks to $\int_\Omega p(x) \mathrm{d}x = 0$, there exists $C_2 > 0$, which depends only on d and Ω, and $\bar{v} \in H_0^1(\Omega)^d$ such that $\mathrm{div} \bar{v}(x) = p(x)$ for a.e. $x \in \Omega$ and

$$\|\bar{v}\|_{H_0^1(\Omega)^d} \leq C_2 \, \|p\|_{L^2(\Omega)}. \tag{3.14}$$

We then set

$$v_\sigma = \frac{1}{\mathrm{m}_\sigma}\int_\sigma \bar{v}(x)\mathrm{d}\gamma(x)\ \forall \sigma \in \mathcal{E}$$

(note that $v_\sigma = 0$ for all $\sigma \in \mathcal{E}_{\rm ext}$) and define $v \in H_{\mathcal{D}}(\Omega)^d$ by

$$v_K = \frac{1}{\mathrm{m}_K}\int_K \bar{v}(x)\mathrm{d}x\ \forall K \in \mathcal{M}. \tag{3.15}$$

Applying the results given in [13, p. 777], we get that there exists $C_3 > 0$, depending only on d and ζ, such that

$$(v_K^{(i)} - v_\sigma^{(i)})^2 \leq C_3\,\frac{\mathrm{diam}(K)}{\mathrm{m}_\sigma}\int_K (\nabla \bar{v}^{(i)}(x))^2\mathrm{d}x\ \forall i = 1,\ldots,d, \tag{3.16}$$

and

$$\|v\|_{\mathcal{D}} \leq C_3\,\|\bar{v}\|_{H_0^1(\Omega)^d} \leq C_3\,C_2\,\|p\|_{L^2(\Omega)}. \tag{3.17}$$

We then have

$$\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}v(x)\mathrm{d}x = \sum_{K\in\mathcal{M}} p_K \sum_{L\in\mathcal{N}_K} A_{KL}\cdot(v_K + v_L) = T_2 + T_3,$$

where

$$\begin{aligned} T_2 &= \sum_{K\in\mathcal{M}} p_K \sum_{L\in\mathcal{N}_K} 2A_{KL}\cdot v_{K|L} \\ &= \sum_{K\in\mathcal{M}} p_K \sum_{L\in\mathcal{N}_K} \int_{K|L} \bar{v}(x)\cdot \mathbf{n}_{KL}\mathrm{d}\gamma(x) \\ &= \int_\Omega p(x)\mathrm{div}\bar{v}(x)\mathrm{d}x = \|p\|^2_{L^2(\Omega)}, \end{aligned}$$

and

$$\begin{aligned} T_3 &= \sum_{K\in\mathcal{M}} p_K \sum_{L\in\mathcal{N}_K} \mathrm{m}_{K|L}\left(\frac{1}{2}(v_K + v_L) - v_{K|L}\right)\cdot \mathbf{n}_{KL} \\ &= \sum_{\sigma = K|L\in\mathcal{E}_{\rm int}} \mathrm{m}_{K|L}(p_K - p_L)\left(\frac{1}{2}(v_K + v_L) - v_{K|L}\right)\cdot \mathbf{n}_{KL}. \end{aligned}$$

We then have, thanks to the Cauchy–Schwarz inequality,

$$T_3^2 \leq |p|^2_{\mathcal{D}} \sum_{\sigma = K|L\in\mathcal{E}_{\rm int}} \mathrm{m}_{K|L} d_{KL}\left(\frac{1}{2}(v_K + v_L) - v_{K|L}\right)^2.$$

Applying inequality (3.16) and thanks to $(\frac{1}{2}(v_K + v_L) - v_{K|L})^2 \leq \frac{1}{2}((v_K - v_{K|L})^2 + (v_L - v_{K|L})^2)$, we get that

$$T_3^2 \leq \frac{1}{2}\,|p|^2_{\mathcal{D}} \sum_{\sigma = K|L\in\mathcal{E}_{\rm int}} d_{KL}C_3\,\mathrm{size}(\mathcal{D})\int_{K\cup L}\sum_{i=1}^d (\nabla \bar{v}^{(i)}(x))^2\mathrm{d}x.$$

This in turn implies the existence of $C_4 > 0$, depending only on d and ζ, such that

$$T_3^2 \leq C_4 \,\mathrm{size}(\mathcal{D})^2 |p|_{\mathcal{D}}^2 \|\bar{v}\|_{H_0^1(\Omega)^d}^2.$$

Thanks to (3.14), we then get, by gathering the previous results,

$$\int_\Omega p(x)\mathrm{div}_{\mathcal{D}} v(x)\mathrm{d}x \geq \|p\|_{L^2(\Omega)}^2 - C_4 \,\mathrm{size}(\mathcal{D})|p|_{\mathcal{D}} C_2 \,\|p\|_{L^2(\Omega)}. \tag{3.18}$$

We then introduce v as a test function in (3.8). We get

$$\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x = \eta \int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u,v]_{\mathcal{D}} - \int_\Omega f(x)\cdot v(x)\mathrm{d}x. \tag{3.19}$$

Applying the discrete Poincaré inequality, (3.17), and (3.18), we get the existence of C_5 , depending only on d, Ω, f, η, ν, and ζ, such that

$$\|p\|_{L^2(\Omega)}^2 - C_4 \,\mathrm{size}(\mathcal{D})|p|_{\mathcal{D}} C_2 \,\|p\|_{L^2(\Omega)} \leq C_5 \,\left(\|u\|_{\mathcal{D}} + \|f\|_{L^2(\Omega)^d}\right) \|p\|_{L^2(\Omega)}.$$

We now apply (3.11) and (3.12). Since $\mathrm{size}(\mathcal{D})^2 \leq \mathrm{size}(\mathcal{D})^\alpha \mathrm{diam}(\Omega)^{2-\alpha}$, the condition $\alpha \leq 2$ is sufficient to yield (3.13) from the above inequality, a factor $1/\lambda$ being introduced in the expression of C_1 (it is therefore not possible to let λ tend to 0 in (3.13)). □

We then have the following result, which states the convergence of the scheme (3.8).

Lemma 3.5 (convergence in the linear case). *Under hypotheses* (3.2)–(3.4)*, let* $(\bar{u},\bar{p})$ *be the unique weak solution of the Stokes problem* (3.1) *in the sense of Definition* 3.1*. Let* $\lambda \in (0,+\infty)$*,* $\alpha \in (0,2)$*, and* $\zeta > 0$ *be given, and let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1 *such that* $\mathrm{regul}(\mathcal{D}) \geq \zeta$*. Let* $(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ *be the unique solution to* (3.8)*.*

Then u *converges to* $\bar{u}$ *in* $L^2(\Omega)^d$*,* $\|u^{(i)}\|_{\mathcal{D}}$ *converges to* $\|\nabla \bar{u}^{(i)}\|_{L^2(\Omega)^d}$ *for all* $i = 1,\ldots,d$*, and* p *converges to* $\bar{p}$ *in* $L^2(\Omega)$ *as* $\mathrm{size}(\mathcal{D})$ *tends to* 0*.*

Remark 3.1. The convergence of $\|u^{(i)}\|_{\mathcal{D}}$ to $\|\nabla \bar{u}^{(i)}\|_{L^2(\Omega)^{d\times d}}$ as $\mathrm{size}(\mathcal{D})$ tends to 0 is sufficient to prove the convergence of some discrete gradient of $u^{(i)}$ to $\nabla \bar{u}^{(i)}$ in $L^2(\Omega)^d$ (see [15]).

Proof. Under the hypotheses of the above lemma, let $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition 2.1 such that

$$\lim_{m\to\infty} \mathrm{size}(\mathcal{D}^{(m)}) = 0$$

and such that $\mathrm{regul}(\mathcal{D}^{(m)}) \geq \zeta$ for all $m \in \mathbb{N}$.

Let $(u^{(m)},p^{(m)}) \in H_{\mathcal{D}^{(m)}}(\Omega)^d \times H_{\mathcal{D}^{(m)}}(\Omega)$ be given by (3.8) for all $m \in \mathbb{N}$. We shall prove in a first step the existence of a subsequence of $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ such that the corresponding sequence $(u^{(m)})_{m\in\mathbb{N}}$ converges in $L^2(\Omega)^d$ to some function $\bar{u}$ and the sequence $(p^{(m)})_{m\in\mathbb{N}}$ weakly converges in $L^2(\Omega)^d$ to some function $\bar{p}$, as $m \to \infty$. We then show that $(\bar{u},\bar{p})$ is the solution of (3.8). Then, in a second step, following some ideas of [15], we again extract a subsequence such that $\|u^{(m)}\|_{\mathcal{D}^{(m)}}$ converges to $\|\nabla \bar{u}\|_{L^2(\Omega)^{d\times d}}$ and $p^{(m)}$ strongly converges to $\bar{p}$ in $L^2(\Omega)$ as $m \to \infty$. The proof is then complete since the solution $(\bar{u},\bar{p})$ of (3.8) is unique and therefore the convergence property holds for the whole sequence.

Step 1. Convergence of the velocity.

Using (3.11), we obtain (see [12, 13]) an estimate for the translates of $u^{(m)}$: for all $m \in \mathbb{N}$, there exists $C_6 > 0$, depending only on Ω, ν, f, and g, such that

$$\int_\Omega (u^{(m,k)}(x+\xi) - u^{(m,k)}(x))^2 \mathrm{d}x \leq C_6\, |\xi|(|\xi| + 4\,\mathrm{size}(\mathcal{D}^{(m)})), \quad \text{for } k = 1, \ldots, d\ \forall \xi \in \mathbb{R}^d, \tag{3.20}$$

where $u^{(m,k)}$ denotes the kth component of $u^{(m)}$. We may then apply Kolmogorov's theorem and obtain the existence of a subsequence of $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ and of $\bar{u} \in H_0^1(\Omega)^d$ such that $(u^{(m)})_{m\in\mathbb{N}}$ converges to $\bar{u}$ in $L^2(\Omega)^d$. Thanks to Lemma 3.4, we extract from this subsequence another one (still denoted by $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$) such that $(p^{(m)})_{m\in\mathbb{N}}$ weakly converges to some function $\bar{p}$ in $L^2(\Omega)$. In order to conclude the proof of the convergence of the scheme, there only remains to prove that $(\bar{u}, \bar{p})$ is the solution of (3.6).

Let $\varphi \in C_c^\infty(\Omega)^d$. For m large enough, and thus size$(\mathcal{D}^{(m)})$ small enough, $\partial K \cap \partial\Omega = \emptyset$ holds for all $K \in \mathcal{M}$ such that $K \cap \mathrm{support}(\varphi) \neq \emptyset$. Let us take $v = P_{\mathcal{D}^{(m)}}\varphi$ in (3.8). Applying Lemma 2.4, we get

$$\lim_{m\to\infty} [u^{(m)}, P_{\mathcal{D}^{(m)}}\varphi]_{\mathcal{D}^{(m)}} \int_\Omega \nabla\bar{u}(x) : \nabla\varphi(x)\mathrm{d}x.$$

Moreover, it is clear that

$$\lim_{m\to\infty} \int_\Omega f(x) \cdot P_{\mathcal{D}^{(m)}}\varphi(x)\mathrm{d}x \int_\Omega f(x)\cdot\varphi(x)\mathrm{d}x,$$

and

$$\lim_{m\to\infty} \eta \int_\Omega u^{(m)}(x) \cdot P_{\mathcal{D}^{(m)}}\varphi(x)\mathrm{d}x \eta \int_\Omega \bar{u}(x)\cdot\varphi(x)\mathrm{d}x.$$

Thanks to the weak convergence of the sequence of approximate pressures, to (3.12) and to the hypothesis $\alpha < 2$ we now apply Lemma 2.3, which gives

$$\lim_{m\to\infty} \int_\Omega p^{(m)}(x)\mathrm{div}_{\mathcal{D}^{(m)}}(P_{\mathcal{D}^{(m)}}\varphi)(x)\mathrm{d}x = \int_\Omega \bar{p}(x)\mathrm{div}\varphi(x)\mathrm{d}x. \tag{3.21}$$

Let us now prove that $\mathrm{div}(\bar{u}) = 0$ almost everywhere in Ω. Let $\varphi \in C_c^\infty(\Omega)$ be given and let us take $q = P_{\mathcal{D}^{(m)}}\varphi$ in (3.8). We get $T_4^{(m)} = -T_5^{(m)}$, where

$$T_4^{(m)} = \int_\Omega \mathrm{div}_{\mathcal{D}^{(m)}}(x)(u^{(m)})P_{\mathcal{D}^{(m)}}\varphi(x)\mathrm{d}x$$

and

$$T_5^{(m)} = \lambda\ \mathrm{size}(\mathcal{D}^{(m)})^\alpha \langle p^{(m)}, P_{\mathcal{D}^{(m)}}\varphi\rangle_{\mathcal{D}}.$$

On one hand, the third item of Lemma 2.4 yields

$$\lim_{m\to\infty} T_4^{(m)} = \sum_{i=1}^d \int_\Omega \varphi(x)\partial_i\bar{u}^{(i)}\mathrm{d}x.$$

On the other hand, using the Cauchy–Schwarz inequality, we get

$$T_5^{(m)} \leq \lambda \mathrm{size}(\mathcal{D}^{(m)})^\alpha |p^{(m)}|_{\mathcal{D}^{(m)}} |P_{\mathcal{D}^{(m)}}\varphi|_{\mathcal{D}^{(m)}}.$$

Therefore, thanks to (3.12) and to the regularity of φ (that implies that $|P_{\mathcal{D}^{(m)}}\varphi|_{\mathcal{D}}$ remains bounded independently of size$(\mathcal{D}^{(m)})$) we obtain $\lim_{m\to\infty} T_5^{(m)} = 0$. This in turn implies that

$$\sum_{i=1}^{d} \int_\Omega \varphi(x)\partial_i \bar{u}^{(i)}(x)\mathrm{d}x = 0 \ \forall\ \varphi \in C_c^\infty(\Omega), \tag{3.22}$$

which proves that $\bar{u} \in E(\Omega)$.

Step 2. Strong convergence of the pressure.

As in the proof of Lemma 3.2, we set $v = u^{(m)}$ and $q = p^{(m)}$ in (3.8). We get

$$\eta \int_\Omega u^{(m)}(x)^2\mathrm{d}x + \nu\|u^{(m)}\|^2_{\mathcal{D}^{(m)}} + \lambda\ \mathrm{size}(\mathcal{D}^{(m)})^\alpha\ |p|^2_{\mathcal{D}^{(m)}} = \int_\Omega f(x)\cdot u^{(m)}(x)\mathrm{d}x.$$

Passing to the limit in the above equation provides

$$\eta \int_\Omega \bar{u}(x)^2\mathrm{d}x + \nu \limsup_{m\to\infty} \|u^{(m)}\|^2_{\mathcal{D}^{(m)}} \le \int_\Omega f(x)\cdot \bar{u}(x)\mathrm{d}x,$$

and therefore, since $\bar{u}$ is the solution of the continuous problem (3.6), we have

$$\limsup_{m\to\infty} \|u^{(m)}\|^2_{\mathcal{D}^{(m)}} \le \int_\Omega (\nabla \bar{u}(x))^2\mathrm{d}x.$$

Thanks to the fact that

$$\liminf_{m\to\infty} \|u^{(i,m)}\|^2_{\mathcal{D}^{(m)}} \ge \int_\Omega (\nabla \bar{u}^{(i)}(x))^2\mathrm{d}x\ \forall i = 1,\dots,d,$$

proved in [28, Lemma 2.2], we get that

$$\lim_{m\to\infty} \|u^{(i,m)}\|^2_{\mathcal{D}^{(m)}} = \int_\Omega (\nabla \bar{u}^{(i)}(x))^2\mathrm{d}x\ \forall i = 1,\dots,d. \tag{3.23}$$

Following the same line as in the proof of Lemma 3.4, we now consider a function $\bar{v}^{(m)} \in H_0^1(\Omega)^d$ such that $\mathrm{div}\bar{v}^{(m)}(x) = p^{(m)}(x)$ for a.e. $x \in \Omega$ and

$$\|\bar{v}^{(m)}\|_{H_0^1(\Omega)^d} \le C_2\, \|p^{(m)}\|_{L^2(\Omega)}.$$

We then define $v^{(m)} \in H_{\mathcal{D}^{(m)}}(\Omega)^d$ by

$$v_K^{(m)} = \frac{1}{\mathrm{m}_K} \int_K \bar{v}^{(m)}(x)\mathrm{d}x\ \forall K \in \mathcal{M}.$$

Thanks to (3.13) and applying Lemma 2.4, we get the existence of a subsequence of $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$, and of $\bar{v} \in H_0^1(\Omega)^d$ such that $(v^{(m)})_{m\in\mathbb{N}}$ converges to $\bar{v}$ in $L^2(\Omega)^d$. Passing to the limit $m \to \infty$ shows that $\mathrm{div}\bar{v}(x) = \bar{p}(x)$ for a.e. $x \in \Omega$.

Using the relations (3.18) and (3.19) obtained in the proof of Lemma 3.4, we get

$$\begin{aligned}\|p^{(m)}\|^2_{L^2(\Omega)} &- C_4\,\mathrm{size}(\mathcal{D}^{(m)})|p^{(m)}|_{\mathcal{D}^{(m)}} C_2\, \|p^{(m)}\|_{L^2(\Omega)} \\ &\le \eta \int_\Omega u^{(m)}(x)\cdot v^{(m)}(x)\mathrm{d}x + \nu[u^{(m)}, v^{(m)}]_{\mathcal{D}^{(m)}} - \int_\Omega f(x)\cdot v^{(m)}(x)\mathrm{d}x.\end{aligned}$$

Thanks to (3.12) and (3.13), we have

$$\lim_{m\to\infty} C_4\,\mathrm{size}(\mathcal{D}^{(m)})|p^{(m)}|_{\mathcal{D}^{(m)}} C_2\,\|p^{(m)}\|_{L^2(\Omega)} = 0.$$

In addition, using (3.23), we have from Lemma 2.5 that

$$\lim_{m\to+\infty}[u^{(m)},v^{(m)}]_{\mathcal{D}^{(m)}} = \int_\Omega \nabla\bar{u}(x):\nabla\bar{v}(x)\mathrm{d}x.$$

Therefore, passing to the limit $m\to\infty$ in the above inequality yields

$$\limsup_{m\to\infty}\|p^{(m)}\|^2_{L^2(\Omega)} \le \eta\int_\Omega \bar{u}(x)\cdot\bar{v}(x)\mathrm{d}x + \nu\int_\Omega \nabla\bar{u}(x):\nabla\bar{v}(x)\mathrm{d}x - \int_\Omega f(x)\cdot\bar{v}(x)\mathrm{d}x.$$

Taking $\bar{v}$ as test function in (3.6) gives

$$\eta\int_\Omega \bar{u}(x)\cdot\bar{v}(x)\mathrm{d}x + \nu\int_\Omega \nabla\bar{u}(x):\nabla\bar{v}(x)\mathrm{d}x - \int_\Omega \bar{p}(x)^2\mathrm{d}x = \int_\Omega f(x)\cdot\bar{v}(x)\mathrm{d}x,$$

and therefore $\limsup_{m\to\infty}\|p^{(m)}\|^2_{L^2(\Omega)} \le \|\bar{p}\|^2_{L^2(\Omega)}$. Since, classically, we get from the weak convergence of $p^{(m)}$ to $\bar{p}$ in $L^2(\Omega)$ that $\liminf_{m\to\infty}\|p^{(m)}\|^2_{L^2(\Omega)} \ge \|\bar{p}\|^2_{L^2(\Omega)}$, we thus obtain that $\lim_{m\to\infty}\|p^{(m)}\|^2_{L^2(\Omega)} = \|\bar{p}\|^2_{L^2(\Omega)}$. This completes the proof of the strong convergence of $p^{(m)}$ to $\bar{p}$ in $L^2(\Omega)$. □

3.4. An error estimate. The following result states an error estimate for the scheme (3.8).

LEMMA 3.6 (error estimate in the linear case). *Under hypotheses* (3.2)–(3.4)*, we assume that the weak solution* $(\bar{u},\bar{p})$ *of the Stokes problem* (3.1) *in the sense of Definition* 3.1 *is such that* $(\bar{u},\bar{p})\in H^2(\Omega)^d\times H^1(\Omega)$*. Let* $\lambda\in(0,+\infty)$ *and* $\alpha\in(0,2)$ *be given, let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1*, and let* $\zeta>0$ *such that* $\mathrm{regul}(\mathcal{D}^{(m)})\ge\zeta$*. Let* $(u,p)\in H_{\mathcal{D}}(\Omega)^d\times H_{\mathcal{D}}(\Omega)$ *be the solution to* (3.8)*. Then there exists* C_7*, which depends only on* d*,* Ω*,* ν*,* η*, and* ζ *such that*

$$\|u-P_{\mathcal{D}}\bar{u}\|^2_{\mathcal{D}} \le C_7\,\varepsilon(\lambda,\mathrm{size}(\mathcal{D}),\bar{p},\bar{u}), \tag{3.24}$$

$$\|u-\bar{u}\|^2_{L^2(\Omega)} \le C_7\,\varepsilon(\lambda,\mathrm{size}(\mathcal{D}),\bar{p},\bar{u}), \tag{3.25}$$

$$\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|^2_{\mathcal{D}} \le C_7\,\varepsilon(\lambda,\mathrm{size}(\mathcal{D}),\bar{p},\bar{u}), \tag{3.26}$$

$$\|p-\bar{p}\|^2_{L^2(\Omega)} \le C_7\,\varepsilon(\lambda,\mathrm{size}(\mathcal{D}),\bar{p},\bar{u}), \tag{3.27}$$

where

$$\varepsilon(\lambda,\mathrm{size}(\mathcal{D}),\bar{p},\bar{u}) = \max\left(\lambda\mathrm{size}(\mathcal{D})^\alpha, \frac{1}{\lambda}\mathrm{size}(\mathcal{D})^{2-\alpha}\right)\left(\|\bar{p}\|^2_{H^1(\Omega)}+\|\bar{u}\|^2_{H^2(\Omega)}\right). \tag{3.28}$$

Proof. The proof is divided into three steps: we first state the equation controlling the errors, then we prove the estimates (3.24)–(3.26) and, finally, (3.27).

Step 1. Statement of the control equation for the errors.

We define $(\widehat{u},\widehat{p})\in H_{\mathcal{D}}(\Omega)^d\times H_{\mathcal{D}}(\Omega)$ by $\widehat{u}=P_{\mathcal{D}}\bar{u}$, which means $\widehat{u}_K=\bar{u}(x_K)$ for all $K\in\mathcal{M}$, and $\widehat{p}_K=\frac{1}{\mathrm{m}_K}\int_K\bar{p}(x)\mathrm{d}x$ for all $K\in\mathcal{M}$.

Integrating the first equation of (3.1) on $K \in \mathcal{M}$ gives

$$\eta \int_K \bar{u}(x)\mathrm{d}x + \sum_{\sigma\in\mathcal{E}_K} \left(-\nu \int_\sigma \nabla\bar{u}(x)\cdot\mathbf{n}_{K,\sigma}\mathrm{d}\gamma(x) + \int_\sigma \bar{p}(x)\mathbf{n}_{K,\sigma}\mathrm{d}\gamma(x)\right) = \int_K f(x)\mathrm{d}x. \tag{3.29}$$

We introduce for $K \in \mathcal{M}$ the following consistency residuals:

$$\begin{aligned}
&R_{\mathrm{o},K} = \widehat{u}_K - \frac{1}{\mathrm{m}_K}\int_K \bar{u}(x)\mathrm{d}x,\\
&\text{for } L\in\mathcal{N}_K, \quad R_{\Delta,K|L} = \frac{1}{d_{K|L}}(\widehat{u}_L - \widehat{u}_K) - \frac{1}{\mathrm{m}_{K|L}}\int_{K|L}\nabla\bar{u}(x)\cdot\mathbf{n}_{K,K|L}\mathrm{d}\gamma(x),\\
&\text{for } \sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{ext}}, \quad R_{\Delta,\sigma} = \frac{1}{d_{K,\sigma}}(0 - \widehat{u}_K) - \frac{1}{\mathrm{m}_\sigma}\int_\sigma \nabla\bar{u}(x)\cdot\mathbf{n}_{K,\sigma}\mathrm{d}\gamma(x),\\
&\text{for } L\in\mathcal{N}_K, \quad R_{\nabla,K|L} = \frac{1}{2}(\widehat{p}_K + \widehat{p}_L) - \frac{1}{\mathrm{m}_{K|L}}\int_{K|L}\bar{p}(x)\mathrm{d}\gamma(x),\\
&\text{for } \sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{ext}}, \quad R_{\nabla,\sigma} = \widehat{p}_K - \frac{1}{\mathrm{m}_\sigma}\int_\sigma \bar{p}(x)\mathrm{d}\gamma(x).
\end{aligned}$$

Using these notations and the relation $\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\mathbf{n}_{K,\sigma} = 0$, we get from (3.29)

$$\eta\ \mathrm{m}_K\widehat{u}_K - \nu\left(\sum_{L\in\mathcal{N}_K}\frac{\mathrm{m}_{K|L}}{d_{K|L}}(\widehat{u}_L - \widehat{u}_K) + \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{ext}}}\frac{\mathrm{m}_\sigma}{d_{K,\sigma}}(0-\widehat{u}_K)\right) + \sum_{L\in\mathcal{N}_K} A_{KL}\ (\widehat{p}_L - \widehat{p}_K) = \int_K f(x)\mathrm{d}x + \mathrm{m}_K R_K,$$

with

$$R_K = \eta\ R_{\mathrm{o},K} - \nu\frac{1}{\mathrm{m}_K}\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma R_{\Delta,\sigma} + \frac{1}{\mathrm{m}_K}\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\ R_{\nabla,\sigma}\mathbf{n}_{K,\sigma}.$$

We set $\delta u = \widehat{u} - u$ and $\delta p = \widehat{p} - p$. We then get, subtracting the first relation of the scheme (3.9) from the above equation, for all $v \in H_{\mathcal{D}}(\Omega)^d$,

$$\eta\int_\Omega \delta u(x)v(x)\mathrm{d}x + \nu[\delta u, v]_{\mathcal{D}} - \int_\Omega \delta p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x = \int_\Omega R(x)v\mathrm{d}x, \tag{3.30}$$

and, setting $v = \delta u$ in this relation,

$$\eta\int_\Omega \delta u(x)^2\mathrm{d}x + \nu\|\delta u\|_{\mathcal{D}}^2 - \int_\Omega \delta p(x)\mathrm{div}_{\mathcal{D}}(\delta u)(x)\mathrm{d}x = \int_\Omega R(x)\delta u(x)\mathrm{d}x.$$

We now integrate the second equation of (3.1) on $K \in \mathcal{M}$. This gives

$$\sum_{\sigma\in\mathcal{E}_K}\int_\sigma \bar{u}(x)\cdot\mathbf{n}_{K,\sigma}\mathrm{d}\gamma(x) = 0.$$

Since $\bar{u}$ vanishes on the boundary of Ω, we then obtain

$$\sum_{L\in\mathcal{N}_K} A_{KL}\cdot(\widehat{u}_K + \widehat{u}_L) = \sum_{L\in\mathcal{N}_K}\mathrm{m}_{K|L}R_{\mathrm{div},K|L}\ \forall K\in\mathcal{M}$$

with

$$R_{\mathrm{div},K|L} = \left(\frac{1}{2}(\widehat{u}_K + \widehat{u}_L) - \frac{1}{\mathrm{m}_{K|L}}\int_{K|L}\bar{u}(x)\mathrm{d}\gamma(x)\right)\cdot\mathbf{n}_{KL}\ \forall K\in\mathcal{M}\ \text{and}\,\forall L\in\mathcal{N}_K.$$

We then have, subtracting the second relation of the scheme (3.9) from the above equation,

$$\int_\Omega \mathrm{div}_\mathcal{D}(\delta u)(x)\delta p(x)\mathrm{d}x = \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,\widehat{p}-p\rangle_\mathcal{D} + \sum_{\sigma\in\mathcal{E}_{\mathrm{int}}}\mathrm{m}_\sigma R_{\mathrm{div},\sigma}(\delta p_K - \delta p_L).$$

Gathering the above results, we get

$$\begin{aligned}&\eta\int_\Omega \delta u(x)^2\mathrm{d}x + \nu\|\delta u\|_\mathcal{D}^2 + \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|_\mathcal{D}^2\\ &= \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,\widehat{p}\rangle_\mathcal{D} + \int_\Omega R(x)\cdot\delta u(x)\mathrm{d}x + \sum_{\sigma\in\mathcal{E}_{\mathrm{int}}}\mathrm{m}_\sigma R_{\mathrm{div},\sigma}(\delta p_K - \delta p_L).\end{aligned}\tag{3.31}$$

Step 2. Proof of the bounds (3.24)–(3.26).

Let us study the terms at the right-hand side of the above equation. We have, using the Young inequality,

$$\langle p,\widehat{p}\rangle_\mathcal{D} \le \frac{1}{4}|p|_\mathcal{D}^2 + |\widehat{p}|_\mathcal{D}^2 \le \frac{1}{4}|p|_\mathcal{D}^2 + C_8\,\|\bar{p}\|_{H^1(\Omega)}^2.\tag{3.32}$$

We then decompose $\int_\Omega R(x)\cdot\delta u(x)\mathrm{d}x$ as $\int_\Omega R(x)\cdot\delta u(x)\mathrm{d}x = T_6+T_7+T_8$, with

$$\begin{aligned}T_6 &= \eta\ \int_\Omega R_{\mathrm{o}}(x)\cdot\delta u(x)\mathrm{d}x,\\ T_7 &= \nu\sum_{K\in\mathcal{M}}\left(\sum_{L\in\mathcal{N}_K}\mathrm{m}_{K|L}R_{\Delta,K|L} + \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\mathrm{ext}}}\mathrm{m}_\sigma R_{\Delta,\sigma}\right)\cdot\delta u_K,\\ T_8 &= \sum_{K\in\mathcal{M}}\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\ R_{\nabla,\sigma}\mathbf{n}_{K,\sigma}\cdot\delta u_K.\end{aligned}$$

Thanks to interpolation results proven in [13] and to (2.4) (see also [20] for a comprehensive exposition of consistency estimates, although with slightly different projection operators), we obtain

$$\begin{aligned}T_6 &\le C_9\,\mathrm{size}(\mathcal{D})^2\|\bar{u}\|_{H^2(\Omega)^d}^2 + \frac{\nu}{4}\|\delta u\|_\mathcal{D}^2,\\ T_7 &\le C_{10}\,\mathrm{size}(\mathcal{D})^2\|\bar{u}\|_{H^2(\Omega)^d}^2 + \frac{\nu}{4}\|\delta u\|_\mathcal{D}^2,\\ T_8 &\le C_{11}\,\mathrm{size}(\mathcal{D})^2\|\bar{p}\|_{H^1(\Omega)}^2 + \frac{\nu}{4}\|\delta u\|_\mathcal{D}^2.\end{aligned}\tag{3.33}$$

We then have

$$\sum_{\sigma\in\mathcal{E}_{\mathrm{int}}}\mathrm{m}_\sigma R_{\mathrm{div},\sigma}(\delta p_K - \delta p_L) = T_9 - T_{10}$$

with

$$T_9 = \sum_{\sigma\in\mathcal{E}_{\mathrm{int}}}\mathrm{m}_\sigma R_{\mathrm{div},\sigma}(\widehat{p}_K - \widehat{p}_L) \le C_{12}\,\mathrm{size}(\mathcal{D})\left(\|\bar{p}\|_{H^1(\Omega)}^2 + \|\bar{u}\|_{H^2(\Omega)^d}^2\right),\tag{3.34}$$

and

$$
\begin{aligned}
T_{10} &= \sum_{\sigma\in\mathcal{E}_{\rm int}} \mathrm{m}_\sigma R_{{\rm div},\sigma}(p_K - p_L) \\
&\leq \frac{1}{4}\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|_{\mathcal{D}}^2 + C_{13}\,\frac{1}{\lambda}\mathrm{size}(\mathcal{D})^{2-\alpha}\|\bar{u}\|_{H^2(\Omega)^d}^2.
\end{aligned} \tag{3.35}
$$

Gathering equations (3.31)–(3.35) gives

$$
\|\delta u\|_{\mathcal{D}}^2 + \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|_{\mathcal{D}}^2 \leq C_{14}\,\varepsilon(\lambda, \mathrm{size}(\mathcal{D}), \bar{p}, \bar{u}),
$$

where $\varepsilon(\lambda, \mathrm{size}(\mathcal{D}), \bar{p}, \bar{u})$ is defined by (3.28). This in turn yields (3.24) (and thus (3.25) thanks to the Poincaré inequality) and (3.26).

Step 3. Proof of the bound (3.27).

We then again follow the method used in the proof of Lemma 3.4.

Using $\int_\Omega \widehat{p}(x)\mathrm{d}x = 0$, and therefore $\int_\Omega \delta p(x)\mathrm{d}x = 0$, let $\bar{v} \in H_0^1(\Omega)^d$ be given such that $\mathrm{div}\bar{v}(x) = \delta p(x)$ for a.e. $x \in \Omega$ and

$$
\|\bar{v}\|_{H_0^1(\Omega)^d} \leq C_2\,\|\delta p\|_{L^2(\Omega)}. \tag{3.36}
$$

We again set

$$
v_\sigma^{(i)} = \frac{1}{\mathrm{m}_\sigma}\int_\sigma \bar{v}^{(i)}(x)\mathrm{d}\gamma(x)\ \forall\sigma\in\mathcal{E} \text{ and } \forall i = 1,\dots,d,
$$

and we define $v \in H_{\mathcal{D}}(\Omega)^d$ by

$$
v_K^{(i)} = \frac{1}{\mathrm{m}_K}\int_K \bar{v}^{(i)}(x)\mathrm{d}x\ \forall K\in\mathcal{M} \text{ and } \forall i = 1,\dots,d.
$$

The same method gives

$$
\begin{aligned}
\|\delta p\|_{L^2(\Omega)}^2 &\leq \int_\Omega \delta p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + C_4\,\mathrm{size}(\mathcal{D})|p|_{\mathcal{D}}\|\bar{v}\|_{H_0^1(\Omega)^d} \\
&\leq \int_\Omega \delta p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + C_{15}\,\mathrm{size}(\mathcal{D})^2|p|_{\mathcal{D}}^2 + \frac{1}{4}\|\delta p\|_{L^2(\Omega)}^2.
\end{aligned}
$$

We now use v as test function in (3.30). We get

$$
\int_\Omega \delta p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x = \eta\int_\Omega \delta u(x)v(x)\mathrm{d}x + \nu[\delta u, v]_{\mathcal{D}} + \int_\Omega R(x)v\mathrm{d}x.
$$

Gathering the two above relations, (3.33) and (3.36) yield

$$
\begin{aligned}
\|\delta p\|_{L^2(\Omega)}^2 \leq \frac{1}{2}\|\delta p\|_{L^2(\Omega)}^2 &+ C_{16}\,\mathrm{size}(\mathcal{D})^2\left(\|\bar{p}\|_{H^1(\Omega)}^2 + \|\bar{u}\|_{H^2(\Omega)^d}^2\right) \\
&+ C_{17}\,\|\delta u\|_{\mathcal{D}}^2 + C_{15}\,\mathrm{size}(\mathcal{D})^2|p|_{\mathcal{D}}^2.
\end{aligned}
$$

Applying (3.25) and (3.26) then gives (3.27). □

Remark 3.2. In the above result, letting $\alpha = 1$, we get an order 1/2 for the convergence of the scheme. We recall that this result is not sharp, and that the numerical results show a much better order of convergence.

4. The finite volume scheme for the Navier–Stokes equations. Before handling the transient nonlinear case, we first address in the following section the steady-state case.

4.1. The steady-state case. For the continuous equations

$$\begin{aligned} &\eta\bar{u}^{(i)} - \nu\Delta\bar{u}^{(i)} + \partial_i\bar{p} + \sum_{j=1}^{d}\bar{u}^{(j)}\partial_j\bar{u}^{(i)} = f^{(i)} \text{ in } \Omega, \quad \text{for } i = 1,\dots,d, \\ &\mathrm{div}\bar{u} = \sum_{i=1}^{d}\partial_i\bar{u}^{(i)} = 0 \text{ in } \Omega \end{aligned} \tag{4.1}$$

with homogeneous Dirichlet boundary conditions for the velocity, we define the following weak sense.

DEFINITION 4.1 (weak solution to the steady Navier–Stokes equations). *Under hypotheses* (3.2)–(3.4)*, let* $E(\Omega)$ *be defined by* (3.5)*. Then* $(\bar{u},\bar{p})$ *is called a weak solution of* (4.1) *if*

$$\left\{\begin{array}{l} \bar{u}\in E(\Omega),\ \bar{p}\in L^2(\Omega) \text{ with } \displaystyle\int_\Omega \bar{p}(x)\mathrm{d}x = 0, \\ \eta\displaystyle\int_\Omega \bar{u}(x)\cdot\bar{v}(x)\mathrm{d}x + \nu\int_\Omega \nabla\bar{u}(x):\nabla\bar{v}(x)\mathrm{d}x \\ \quad -\displaystyle\int_\Omega \bar{p}(x)\mathrm{div}\bar{v}(x)\mathrm{d}x + b(\bar{u},\bar{u},\bar{v}) = \int_\Omega f(x)\cdot\bar{v}(x)\mathrm{d}x \qquad \forall\bar{v}\in H_0^1(\Omega)^d, \end{array}\right. \tag{4.2}$$

where the trilinear form $b(\cdot,\cdot,\cdot)$ *is defined, for all* $\bar{u},\bar{v},\bar{w}\in H_0^1(\Omega)^d$*, by*

$$b(\bar{u},\bar{v},\bar{w}) = \sum_{k=1}^{d}\sum_{i=1}^{d}\int_\Omega \bar{u}^{(i)}(x)\partial_i\bar{v}^{(k)}(x)\bar{w}^{(k)}(x)\,\mathrm{d}x.$$

The existence of a weak solution of (4.2) in the sense of the above definition, in two or three dimensions, is a classical result (again, see, e.g., [36]). Note that the uniqueness of the solution holds only under small data conditions.

We now give the finite volume scheme for this problem. Under hypotheses (3.2)–(3.4), let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition 2.1. We introduce Bernoulli's pressure $p+\frac{1}{2}u^2$ instead of p, again denoted by p, and for any real value $\lambda>0$ and $\alpha\in(0,2)$ we look for (u,p) such that

$$\left\{\begin{array}{l} (u,p)\in H_{\mathcal{D}}(\Omega)^d\times H_{\mathcal{D}}(\Omega) \text{ with } \displaystyle\int_\Omega p(x)\mathrm{d}x = 0, \\ \eta\displaystyle\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u,v]_{\mathcal{D}} + \frac{1}{2}\int_\Omega u(x)^2\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x \\ \quad -\displaystyle\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + b_{\mathcal{D}}(u,u,v) = \int_\Omega f(x)\cdot v(x)\mathrm{d}x \quad \forall v\in H_{\mathcal{D}}(\Omega)^d, \\ \displaystyle\int_\Omega \mathrm{div}_{\mathcal{D}}(u)(x)q(x)\mathrm{d}x = -\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,q\rangle_{\mathcal{D}} \qquad \forall q\in H_{\mathcal{D}}(\Omega), \end{array}\right. \tag{4.3}$$

where, for $u,v,w\in H_{\mathcal{D}}(\Omega)^d$, we define the following approximation for $b(u,v,w)$:

$$b_{\mathcal{D}}(u,v,w) = \frac{1}{2}\sum_{K\in\mathcal{M}}\sum_{L\in\mathcal{N}_K}(A_{KL}\cdot(u_K+u_L))\,((v_L-v_K)\cdot w_K). \tag{4.4}$$

System (4.3) is equivalent to finding the family of vectors of $\mathbb{R}^d$, $(u_K)_{K\in\mathcal{M}}$, and scalars, $(p_K)_{K\in\mathcal{M}}$, solution to the system of equations obtained by writing for each control volume K of $\mathcal{M}$

$$
\left\{\begin{array}{l}
\eta\ \mathrm{m}_K\ u_K - \nu \displaystyle\sum_{L\in\mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}}(u_L-u_K) - \nu \sum_{\sigma\in\mathcal{E}_K\cap\mathcal{E}_{\rm ext}} \frac{\mathrm{m}_\sigma}{d_{K,\sigma}}(0-u_K) \\
+ \displaystyle\sum_{L\in\mathcal{N}_K} \left(A_{KL}\cdot\left(\frac12(u_K+u_L)\right)\right)\ (u_L-u_K) \\
+ \displaystyle\sum_{L\in\mathcal{N}_K} A_{KL}\ (p_L-p_K) - \frac12 \sum_{L\in\mathcal{N}_K} A_{KL}\ (u_L^2-u_K^2) = \int_K f(x)\mathrm{d}x, \\
\displaystyle\sum_{L\in\mathcal{N}_K} A_{KL}\cdot(u_K+u_L) - \lambda\ \mathrm{size}(\mathcal{D})^\alpha \sum_{L\in\mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}}(p_L-p_K) = 0,
\end{array}\right. \tag{4.5}
$$

supplemented by the relation

$$
\sum_{K\in\mathcal{M}} \mathrm{m}_K\ p_K = 0.
$$

Defining $\tilde p_K = p_K - u_K^2/2$ and $\tilde p_\sigma = (\tilde p_K + \tilde p_L)/2$ if $\sigma = K|L$, $\tilde p_\sigma = \tilde p_K$ if $\sigma\in\mathcal{E}_{\rm ext}\cap\mathcal{E}_K$, and using the fact that $\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\mathbf{n}_{K,\sigma}=0$, one again notices that $\sum_{L\in\mathcal{N}_K} A_{KL}\ (\tilde p_L-\tilde p_K)$ is in fact equal to $\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\tilde p_\sigma\mathbf{n}_{K,\sigma}$, thus yielding a conservative form for the fifth and sixth terms of the left-hand side of the discrete momentum equation in (4.5). Defining $u_\sigma=(u_K+u_L)/2$ if $\sigma=K|L$, $u_\sigma=0$ if $\sigma\in\mathcal{E}_{\rm ext}\cap\mathcal{E}_K$, one obtains that the nonlinear advective term $\sum_{L\in\mathcal{N}_K}(A_{KL}\cdot(\frac12(u_K+u_L)))\ (u_L-u_K)$ is equal to $\sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma(\mathbf{n}_{K,\sigma}\cdot u_\sigma)u_\sigma - \mathrm{m}_K u_K(\mathrm{div}_\mathcal{D}u)_K$; one may note that $(\mathrm{div}_\mathcal{D}u)_K = \sum_{\sigma\in\mathcal{E}_K}\mathrm{m}_\sigma\mathbf{n}_{K,\sigma}\cdot u_\sigma$. Hence the nonlinear advective term is the sum of a conservative form and a source term due to the stabilization (this source term vanishes for a discrete divergence free function u).

Let us then study some properties of the trilinear form $b_\mathcal{D}(\cdot,\cdot,\cdot)$. First note that the quantity $b_\mathcal{D}(u,v,w)$ also states that

$$
b_\mathcal{D}(u,v,w) = \frac12 \sum_{K|L\in\mathcal{E}_{\rm int}} (A_{KL}\cdot(u_K+u_L))\ ((v_L-v_K)\cdot(w_L+w_K)). \tag{4.6}
$$

We thus get that, for all $u,v\in H_\mathcal{D}(\Omega)^d$,

$$
\begin{aligned}
b_\mathcal{D}(u,v,v) &= \frac12 \sum_{K|L\in\mathcal{E}_{\rm int}} (A_{KL}\cdot(u_K+u_L))((v_L)^2-(v_K)^2) \\
&= -\frac12 \int_\Omega v(x)^2\ \mathrm{div}_\mathcal{D}(u)(x)\ \mathrm{d}x.
\end{aligned} \tag{4.7}
$$

We get, in particular, that, for all $u\in E_\mathcal{D}(\Omega)$, $b_\mathcal{D}(u,u,u)=0$, which is the discrete equivalent of the continuous property.

Remark 4.1 (upstream weighting versions of the scheme). The results of this paper are still valid setting $F_{KL}(u)=A_{KL}\cdot(u_K+u_L)$ and considering, for $u,v,w\in H_\mathcal{D}(\Omega)^d$,

$$
b_\mathcal{D}^{\rm ups}(u,v,w) = b_\mathcal{D}(u,v,w) + \frac12 \sum_{K|L\in\mathcal{E}_{\rm int}} \Theta_{KL}|F_{KL}(u)|\ (v_L-v_K)\cdot(w_L-w_K),
$$

with, for example, $\Theta_{KL} = \max(1 - 2\nu \frac{\mathrm{m}_{K|L}}{d_{K|L}} |F_{KL}(u)|, 0)$.

We then get, for all $u, v \in H_{\mathcal{D}}(\Omega)^d$, the inequality

$$b_{\mathcal{D}}^{\mathrm{ups}}(u, v, v) \geq -\frac{1}{2} \int_\Omega v(x)^2 \mathrm{div}_{\mathcal{D}}(u)(x) \mathrm{d}x,$$

which is sufficient to get all the estimates of this paper, together with the convergence properties of the scheme. The use of such a local upwinding technique may help avoid the development of nonphysical oscillations only when meshes are too coarse.

The following technical estimates are crucial to prove the convergence properties of the scheme.

LEMMA 4.2 (estimates on $b_{\mathcal{D}}(\cdot,\cdot,\cdot)$ by discrete Sobolev norms). *Under hypotheses* (1.3)–(1.7)*, let* $\mathcal{D}$ *be an admissible discretization of* Ω *in the sense of Definition* 2.1*, and* $\zeta > 0$ *such that* $\mathrm{regul}(\mathcal{D}) \geq \zeta$*. Then there exist* $C_{18} > 0$ *and* $C_{19} > 0$*, depending only on* d*,* ζ*, and* Ω*, such that*

$$b_{\mathcal{D}}(u, v, w) \leq C_{18} \ \|u\|_{L^4(\Omega)^d} \ \|v\|_{\mathcal{D}} \ \|w\|_{L^4(\Omega)^d} \leq C_{19} \ \|u\|_{\mathcal{D}} \ \|v\|_{\mathcal{D}} \ \|w\|_{\mathcal{D}}. \tag{4.8}$$

Proof. The quantity $b_{\mathcal{D}}(u, v, w)$ reads

$$b_{\mathcal{D}}(u, v, w) = \frac{1}{4} \sum_{K \in \mathcal{M}} \sum_{L \in \mathcal{N}_K} (w_K \cdot (v_L - v_K)) \ \frac{\mathrm{m}_{K|L}}{d_{K|L}} \ ((x_L - x_K) \cdot (u_K + u_L)).$$

Applying the Cauchy–Schwarz inequality twice and using the fact that $(x_L - x_K)^2 = d_{KL}^2$, and that, for any admissible discretization, $\sum_{L \in \mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}} \ d_{KL}^2 \leq d \ \frac{m_K}{\zeta}$, yields

$$\begin{aligned} b_{\mathcal{D}}(u, v, w)^2 \quad &\leq C_{20} \quad \left(\sum_{K \in \mathcal{M}} \sum_{L \in \mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}} (w_K)^2 (x_L - x_K)^2 (2(u_K)^2 + 2(u_L)^2) \right) \\ &\qquad \left(\sum_{K \in \mathcal{M}} \sum_{L \in \mathcal{N}_K} \frac{\mathrm{m}_{K|L}}{d_{K|L}} (v_L - v_K)^2 \right) \\ &\leq C_{21} \quad \left(\sum_{K \in \mathcal{M}} m_K |w_K|^4 \right)^{1/2} \left(\sum_{K \in \mathcal{M}} m_K |u_K|^4 \right)^{1/2} \|v\|_{\mathcal{D}}^2. \end{aligned}$$

The inequality (4.8) is now a straightforward consequence of the following discrete Sobolev inequality, which holds under the same regularity assumptions on the mesh (see proof in [8] or [13, pp. 790–791]):

$$\|u\|_{L^4(\Omega)} \leq C_{22} \ \|u\|_{\mathcal{D}}. \tag{4.9}$$ ∎

Remark 4.2 (2D case). In the case $d = 2$, it may be proven setting $\alpha = 2, p = p' = 2$ in the proof of [13, p. 791] that

$$\|u\|_{L^4(\Omega)^d} \leq C_{23} \|u\|_{L^2(\Omega)^d}^{1/2} \|u\|_{\mathcal{D}}^{1/2}$$

and therefore that there exists $C_{24} > 0$, depending only on d and Ω, such that

$$b_{\mathcal{D}}(u, v, w) \leq C_{24} \|v\|_{\mathcal{D}} \left(\|u\|_{\mathcal{D}} \ \|u\|_{L^2(\Omega)^d} \ \|w\|_{\mathcal{D}} \ \|w\|_{L^2(\Omega)^d} \right)^{1/2}.$$

This is a discrete analogue to the classical continuous estimate for the trilinear form.

The existence of a solution to the scheme (4.3) is obtained through a so-called "topological degree" argument. For the sake of completeness, we recall this argument (which was first used for numerical schemes in [11]) in the finite dimensional case in the following theorem and refer to [9] for the general case.

THEOREM 4.3 (application of the topological degree, finite dimensional case). *Let V be a finite dimensional vector space on $\mathbb{R}$, and g be a continuous function from V to V. Let us assume that there exists a continuous function F from $V \times [0,1]$ to V satisfying the following:*

1. *$F(\cdot,1) = g$, $F(\cdot,0)$ is an affine function.*
2. *There exists $R > 0$ such that, for any $(v,\rho) \in V \times [0,1]$, if $F(v,\rho) = 0$, then $\|v\|_V \neq R$.*
3. *The equation $F(v,0) = 0$ has a solution $v \in V$ such that $\|v\|_V < R$.*

Then there exists at least a solution $v \in V$ such that $g(v) = 0$ and $\|v\|_V < R$.

Here $g(v) = 0$ represents the nonlinear system (4.3), and we are now going to construct the function F and show the required estimates. Note that here the use of Bernouilli's pressure leads to simpler calculations.

LEMMA 4.4 (discrete H_0^1 estimate for the velocity). *Under hypotheses* (3.2)–(3.4)*, let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition* 2.1*. Let $\lambda \in (0,+\infty)$ and $\alpha \in (0,2)$ be given. Let $\rho \in [0,1]$ be given, and let $(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ be a solution to the following system of equations (which reduces to* (4.3) *as $\rho = 1$ and to* (3.8) *as $\rho = 0$):*

$$\left\{\begin{array}{ll} (u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega) \text{ with } \displaystyle\int_\Omega p(x)\mathrm{d}x = 0, & \\ \eta \displaystyle\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u,v]_{\mathcal{D}} + \frac{\rho}{2}\int_\Omega u(x)^2 \mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x & \\ + \rho\ b_{\mathcal{D}}(u,u,v) - \displaystyle\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x = \int_\Omega f(x)\cdot v(x)\mathrm{d}x & \forall v \in H_{\mathcal{D}}(\Omega)^d, \\ \displaystyle\int_\Omega \mathrm{div}_{\mathcal{D}}(u)(x)q(x)\mathrm{d}x = -\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,q\rangle_{\mathcal{D}} & \forall q \in H_{\mathcal{D}}(\Omega). \end{array}\right. \tag{4.10}$$

Then u and p satisfy the following estimates, which are the same inequalities as obtained in the linear case (inequalities (3.11) *and* (3.12)*):*

$$\nu\|u\|_{\mathcal{D}} \leq \mathrm{diam}(\Omega)\|f\|_{L^2(\Omega)^d},$$
$$\nu\ \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ |p|_{\mathcal{D}}^2 \leq \mathrm{diam}(\Omega)^2\|f\|_{L^2(\Omega)^d}^2.$$

Proof. The proof is similar to that of Lemma 3.2, using the property (4.7) on the discrete trilinear form. □

We are now in position to prove the existence of at least one solution to scheme (4.3).

LEMMA 4.5 (existence of a discrete solution). *Under hypotheses* (3.2)–(3.4)*, let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition* 2.1*. Let $\lambda \in (0,+\infty)$ and $\alpha \in (0,2)$ be given. Then there exists at least one $(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$, solution to* (4.3)*.*

Proof. Let us define $V = \{(u,p) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega)$ s.t. $\int_\Omega p(x)\mathrm{d}x = 0\}$. Consider the continuous mapping $F : V \times [0,1] \to V$ such that, for a given $(u,p) \in V$ and

$\rho \in [0,1]$, $(\widehat{u},\widehat{p}) = F(u,p,\rho)$ is defined by

$$\begin{aligned}\int_\Omega \widehat{u}(x)\cdot v(x)\mathrm{d}x &= \eta\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u,v]_{\mathcal{D}} - \int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x\\ &\quad+\rho\left(\frac{1}{2}\int_\Omega u(x)^2\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + b_{\mathcal{D}}(u,u,v)\right)\\ &\quad-\int_\Omega f(x)\cdot v(x)\mathrm{d}x \qquad\qquad \forall v\in H_{\mathcal{D}}(\Omega)^d,\\ \int_\Omega \widehat{p}(x)\cdot q(x)\mathrm{d}x &= \int_\Omega \mathrm{div}_{\mathcal{D}}(u)(x)q(x)\mathrm{d}x + \lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p,q\rangle_{\mathcal{D}} \qquad \forall q\in H_{\mathcal{D}}(\Omega).\end{aligned}$$

It is easily checked that the two above relations uniquely define the function $F(\cdot,\cdot,\cdot)$. Indeed, the value of $\widehat{u}_K^{(i)}$ and $\widehat{p}_K$ for a given $K\in\mathcal{M}$ and $i=1,\dots,d$ are readily obtained by setting $v^{(i)} = 1_K$, $v^{(j)}=0$ for $j\neq i$, and $q = 1_K$.

The mapping $F(.,.,.)$ is continuous, and, for a given (u,p) such that $F(u,p,\rho) = (0,0)$, we can apply Lemma 4.4, which proves that (u,p) is bounded independently on ρ. Since $F(u,p,0)$ is an affine function of (u,p) and $F(u,p,0)=0$ admits one solution (see Corollary 3.3), we may apply Theorem 4.3 and conclude the existence of at least one solution (u,p) to (4.3). ∎

We then have the following strong estimate for the pressure.

LEMMA 4.6 ($L^2(\Omega)$ estimate for the pressure). *Under hypotheses* (3.2)–(3.4)*, let $\mathcal{D}$ be an admissible discretization of Ω in the sense of Definition* 2.1*, and let $\zeta>0$ such that* $\mathrm{regul}(\mathcal{D})>\zeta$*. Let $\lambda\in(0,+\infty)$ and $\alpha\in(0,2)$ be given. Let $(u,p)\in H_{\mathcal{D}}(\Omega)^d\times H_{\mathcal{D}}(\Omega)$ be a solution to* (4.3)*. Then there exists C_{25}, depending only on d, Ω, η, ν, λ, α, and ζ, and not on* $\mathrm{size}(\mathcal{D})$*, such that the following inequality holds:*

$$\|p\|_{L^2(\Omega)} \le C_{25}\left(\|f\|_{L^2(\Omega)^d} + \left(\|f\|_{L^2(\Omega)^d}\right)^2\right). \tag{4.11}$$

Proof. We may follow the proof of Lemma 3.4 until (3.19), which is changed to

$$\begin{aligned}\int_\Omega p(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x &= \eta\int_\Omega u(x)\cdot v(x)\mathrm{d}x + \nu[u,v]_{\mathcal{D}} - \int_\Omega f(x)\cdot v(x)\mathrm{d}x\\ &\quad+\frac{1}{2}\int_\Omega u(x)^2\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + b_{\mathcal{D}}(u,u,v).\end{aligned} \tag{4.12}$$

We again apply the discrete Poincaré inequality (2.4), (3.17), (3.18), and we use (4.8). We get the existence of C_{26}, depending only on d, Ω, f, η, ν, λ, and ζ, such that

$$\begin{aligned}\|p\|_{L^2(\Omega)}^2 - C_4\,\mathrm{size}(\mathcal{D})|p|_{\mathcal{D}}C_2\,\|p\|_{L^2(\Omega)}&\\ \le C_{26}\left(\|u\|_{\mathcal{D}} + \|f\|_{L^2(\Omega)^d} + \|u\|_{\mathcal{D}}^2\right)\|p\|_{L^2(\Omega)}.&\end{aligned}$$

We now apply (3.11) and (3.12), which yields the conclusion. ∎

We now can state the convergence of scheme (4.3).

THEOREM 4.7 (convergence of the scheme). *Under hypotheses* (3.2)–(3.4)*, let $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ be a sequence of admissible discretizations of Ω in the sense of Definition* 2.1*, such that* $\mathrm{size}(\mathcal{D}^{(m)})$ *tends to* 0 *as $m\to\infty$ and such that there exists $\zeta>0$ with* $\mathrm{regul}(\mathcal{D}^{(m)})\ge\zeta$ *for all $m\in\mathbb{N}$. Let $\lambda\in(0,+\infty)$ and $\alpha\in(0,2)$ be given. Let, for all*

$m \in \mathbb{N}$, $(u^{(m)}, p^{(m)}) \in H_{\mathcal{D}^{(m)}}(\Omega)^d \times H_{\mathcal{D}^{(m)}}(\Omega)$ be a solution to (4.3) *with $\mathcal{D} = \mathcal{D}^{(m)}$. Then there exists a weak solution $(\bar{u}, \bar{p})$ of* (4.1) *in the sense of Definition* 4.1 *and a subsequence of $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$, again denoted by $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$, such that the corresponding subsequence of solutions $(u^{(m)})_{m\in\mathbb{N}}$ converges to $\bar{u}$ in $L^2(\Omega)$ and $(p^{(m)} - \frac{1}{2}(u^{(m)})^2)_{m\in\mathbb{N}}$ weakly converges to $\bar{p}$ in $L^2(\Omega)$.*

Proof. Since the same estimates as in the linear case are available in the steady nonlinear case, the first step of the proof of Lemma 3.5 holds for all the terms of (4.2), which are present in (3.6). We have to prove only that for a given $\varphi \in C_c^\infty(\Omega)^d$, as $m \to +\infty$,

$$T_{11}^{(m)} = \int_\Omega u^{(m)}(x)^2 \mathrm{div}_{\mathcal{D}^{(m)}}(P_{\mathcal{D}^{(m)}}\varphi)(x)\mathrm{d}x \quad \text{tends to} \quad \int_\Omega \bar{u}(x)^2 \mathrm{div}\varphi(x)\mathrm{d}x$$

and

$$T_{12}^{(m)} = b_{\mathcal{D}}(u^{(m)}, u^{(m)}, P_{\mathcal{D}^{(m)}}\varphi) \quad \text{tends to} \quad b(\bar{u}, \bar{u}, \varphi).$$

Thanks to the convergence in $L^2(\Omega)^d$ of $(u^{(m)})_{m\in\mathbb{N}}$ to $\bar{u}$ and to the discrete Sobolev inequalities $\|v\|_{L^q(\Omega)} \le C_{27}\|v\|_{\mathcal{D}^{(m)}}$ for all $v \in H_{\mathcal{D}^{(m)}}(\Omega)$ and all $q \le 6$ (see [13, p. 790]), we get, using the first stability estimate of Lemma 4.4, the convergence in $L^2(\Omega)$ of $((u^{(m)})^2)_{m\in\mathbb{N}}$ to $\bar{u}^2$. We now remark that for $i = 1, \dots, d$ the sequence $(P_{\mathcal{D}^{(m)}}\varphi^{(i)})_{m\in\mathbb{N}}$ satisfies the hypotheses of Lemma 2.4. Hence, $\nabla_{\mathcal{D}^{(m)}} P_{\mathcal{D}^{(m)}}\varphi^{(i)}$ weakly converges to $\nabla\varphi^{(i)}$ in $L^2(\Omega)^d$. One has $\mathrm{div}_{\mathcal{D}} u = \sum_{i=1}^d \nabla_{\mathcal{D}}^{(i)} u^{(i)}$ for all $u \in H_{\mathcal{D}}(\Omega)^d$ such that $u_K = 0$ if $\mathcal{E}_K \cap \mathcal{E}_{\mathrm{ext}} \neq \emptyset$. Hence $\mathrm{div}_{\mathcal{D}^{(m)}}(P_{\mathcal{D}^{(m)}}\varphi)$ weakly converges to $\mathrm{div}\varphi$ in $L^2(\Omega)$, thus providing the limit of $T_{11}^{(m)}$.

Thanks to (4.6), dropping for short some indices (m), we have

$$b_{\mathcal{D}}(u, u, P_{\mathcal{D}}\varphi) = T_{13}^{(m)} - T_{14}^{(m)},$$

with

$$\begin{aligned} T_{13}^{(m)} &= \sum_{K\in\mathcal{M}} \sum_{L\in\mathcal{N}_K} (A_{KL}\cdot u_K)((u_L - u_K)\cdot\varphi(x_K)) \\ &= \sum_{k=1}^d \sum_{i=1}^d \int_\Omega u^{(i)}(x)\nabla_{\mathcal{D}}^{(i)}(u^{(k)})(x) P_{\mathcal{D}}\varphi^{(k)}(x)\mathrm{d}x, \\ T_{14}^{(m)} &= \frac{1}{2} \sum_{K|L\in\mathcal{E}_{\mathrm{int}}} (A_{KL}\cdot(u_L - u_K))((u_L - u_K)\cdot(\varphi(x_K) - \varphi(x_L))). \end{aligned}$$

Thanks to the convergence in $L^2(\Omega)$ of $(u^{(m)(i)} P_{\mathcal{D}^{(m)}}\varphi^{(j)})_{m\in\mathbb{N}}$ to $\bar{u}^{(i)}\varphi^{(j)}$, $i, j = 1, \dots, d$, we get from Lemma 2.4 that

$$\lim_{m\to\infty} T_{13}^{(m)} = \sum_{k=1}^d \sum_{i=1}^d \int_\Omega \bar{u}^{(i)}(x)\partial_i\bar{u}^{(k)}(x)\bar{\varphi}^{(k)}(x)\mathrm{d}x = b(\bar{u}, \bar{u}, \varphi).$$

We have

$$T_{14}^{(m)} = \frac{1}{4} \sum_{K|L\in\mathcal{E}_{\mathrm{int}}} d_{KL}\left(\frac{\mathrm{m}_{K|L}}{d_{K|L}}\mathbf{n}_{KL}\cdot(u_L - u_K)\right)((u_L - u_K)\cdot(\varphi(x_K) - \varphi(x_L))),$$

and therefore, since $|\varphi(x_K)-\varphi(x_L)| \le d_{KL} C_\varphi \mathrm{size}(\mathcal{D})$, where C_φ is a bound of $\nabla\varphi$ in $L^\infty(\Omega)^{d\times d}$, and since $d_{KL} \le 2\ \mathrm{size}(\mathcal{D})$, the following estimate holds:

$$|T_{14}^{(m)}| \le 4\ \mathrm{size}(\mathcal{D})^2 C_\varphi \|u\|_{\mathcal{D}}^2.$$

Therefore, the second estimate of Lemma 4.4 yields

$$\lim_{m\to\infty} T_{14}^{(m)} = 0,$$

which concludes the proof of convergence. □

4.2. The transient case. We now turn to the study of the finite volume scheme for the transient Navier–Stokes equations, the weak formulation of which is in the following definition.

DEFINITION 4.8 (weak solution to the transient Navier–Stokes equations). *Under hypotheses* (1.3)–(1.7)*, let* $E(\Omega)$ *be defined by* (3.5)*. Then* $\bar u$ *is called a weak solution of* (1.1)–(1.2) *if* $\bar u \in L^2(0,T;E(\Omega)) \cap L^\infty(0,T;L^2(\Omega)^d)$ *and*

$$\left\{\begin{array}{l} \forall \varphi \in L^2(0,T;E(\Omega)) \cap C_c^\infty(\Omega\times(-\infty,T))^d, \\ \\ \displaystyle -\int_0^T\int_\Omega \bar u(x,t)\cdot\partial_t\varphi(x,t)\,\mathrm{d}x\,\mathrm{d}t - \int_\Omega \bar u_{\mathrm{ini}}(x)\cdot\varphi(x,0)\,\mathrm{d}x \\ \displaystyle +\nu\int_0^T\int_\Omega \nabla\bar u(x,t):\nabla\varphi(x,t)\,\mathrm{d}x\,\mathrm{d}t \ + \int_0^T b(\bar u(\cdot,t),\bar u(\cdot,t),\varphi(\cdot,t))\,\mathrm{d}t \\ \displaystyle = \int_0^T\int_\Omega f(x)\cdot\varphi(x,t)\,\mathrm{d}x\,\mathrm{d}t. \end{array}\right. \tag{4.13}$$

The existence of a weak solution of (4.13) in the sense of the above definition, in two or three dimensions, is a classical result (again, see, e.g., [36] or [5]). Note that the uniqueness of the solution holds in two dimensions, and that it has only been proven in three dimensions under small data conditions.

Remark 4.3. From (4.13), we get that a weak solution u of (1.1)–(1.2) in the sense of Definition 4.8 satisfies $\partial_t\bar u \in L^{4/d}(0,T;E(\Omega)')$ and is therefore a weak solution in the classical sense, such that $\bar u(\cdot,0)$ is the orthogonal L^2-projection of $\bar u_{\mathrm{ini}}$ on $\{\bar v \in L^2(\Omega)^d, \mathrm{div}\bar v = 0, \mathrm{trace}(\bar v\cdot n_{\partial\Omega},\partial\Omega)=0\}$ (see, for example, [36] or [5]).

We first give the definition of an admissible discretization for a space-time domain.

DEFINITION 4.9 (admissible discretization, transient case). *Let* Ω *be an open bounded polygonal (polyhedral if* $d=3$*) subset of* $\mathbb{R}^d$*, and* $\partial\Omega = \overline{\Omega}\setminus\Omega$ *its boundary, and let* $T>0$*. An admissible finite volume discretization of* $\Omega\times(0,T)$*, denoted by* $\mathcal{D}$*, is given by* $\mathcal{D}=(\mathcal{M},\mathcal{E},\mathcal{P},N)$*, where* $(\mathcal{M},\mathcal{E},\mathcal{P})$ *is an admissible discretization of* Ω *in the sense of Definition* 2.1 *and* $N\in\mathbb{N}^*$ *is given. We then define* $\delta t = T/N$*, and we denote by* $\mathrm{size}(\mathcal{D}) = \max(\mathrm{size}(\mathcal{M},\mathcal{E},\mathcal{P}),\delta t)$ *and* $\mathrm{regul}(\mathcal{D}) = \mathrm{regul}(\mathcal{M},\mathcal{E},\mathcal{P})$.

Under hypotheses (1.3)–(1.7), let $\mathcal{D}$ be an admissible discretization of $\Omega\times(0,T)$ in the sense of Definition 4.9 and let $\lambda\in(0,+\infty)$ and $\alpha\in(0,2)$ be given. We write a Crank–Nicolson scheme for the time discretization, and follow the nonlinear steady-state case for the space discretization; the finite volume scheme for the approximation of the solution (1.1)–(1.2) is then

$$\begin{array}{l} u_0 \in H_{\mathcal{D}}(\Omega)^d, \\ \displaystyle u_{0,K} = \frac{1}{\mathrm{m}_K}\int_K u_{\mathrm{ini}}(x)\mathrm{d}x\ \forall K\in\mathcal{M}, \end{array} \tag{4.14}$$

and, again using Bernoulli's pressure $p + \frac{1}{2}u^2$ instead of p, again still denoted by p,

$$\begin{aligned}
&\text{for } n = 0, \dots, N-1, \text{ find } (u_{n+1}, p_{n+\frac{1}{2}}) \in H_{\mathcal{D}}(\Omega)^d \times H_{\mathcal{D}}(\Omega),\\
&\text{such that } \int_\Omega p_{n+\frac{1}{2}}(x)\mathrm{d}x = 0 \text{ and } \forall v \in H_{\mathcal{D}}(\Omega)^d, \forall q \in H_{\mathcal{D}}(\Omega),
\end{aligned}$$

$$\left\{\begin{aligned}
&\int_\Omega (u_{n+1}(x) - u_n(x)) \cdot v(x)\mathrm{d}x + \nu\delta t [u_{n+\frac{1}{2}}, v]_{\mathcal{D}}\\
&\qquad - \delta t \int_\Omega p_{n+\frac{1}{2}}(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x + \frac{\delta t}{2}\int_\Omega u_{n+\frac{1}{2}}(x)^2 \mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x\\
&\qquad + \delta t\ b_{\mathcal{D}}(u_{n+\frac{1}{2}}, u_{n+\frac{1}{2}}, v) = \int_{n\delta t}^{(n+1)\delta t}\int_\Omega f(x,t)\cdot v(x)\mathrm{d}x\mathrm{d}t,\\
&\int_\Omega \mathrm{div}_{\mathcal{D}}(u_{n+\frac{1}{2}})(x) q(x)\mathrm{d}x = -\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p_{n+\frac{1}{2}}, q\rangle_{\mathcal{D}},
\end{aligned}\right. \tag{4.15}$$

where $u_{n+\frac{1}{2}}$ stands for $\frac{1}{2}(u_{n+1} + u_n)$.

In (4.15), we consider the approximation of $b_{\mathcal{D}}(\cdot,\cdot,\cdot)$ given by (4.4). We then define the set $H_{\mathcal{D}}(\Omega\times(0,T))$ of piecewise constant functions in each $K\times(n\delta t,(n+1)\delta t)$, $K \in \mathcal{M}$, $n = 0, \dots, N-1$, and we define $(u,p) \in H_{\mathcal{D}}(\Omega\times(0,T))^d \times H_{\mathcal{D}}(\Omega\times(0,T))$ by, for $n = 1, \dots, N-1$,

$$\left\{\begin{aligned}
&u(x,t) = u_{n+\frac{1}{2}}(x),\\
&p(x,t) = p_{n+\frac{1}{2}}(x),
\end{aligned}\right. \quad \text{for a.e. } (x,t) \in \Omega \times (n\delta t, (n+1)\delta t). \tag{4.16}$$

Remark 4.4 (time discretization). If, instead of the Crank–Nicolson scheme, we use the θ scheme, $u_{n+\frac{1}{2}} = \theta u_{n+1} + (1-\theta)u_n$, with $\theta \in [1/2, 1]$, the convergence proof which follows applies with a few minor changes. However, this is not so if θ is smaller than $1/2$; in particular, the estimate of Lemma 4.10 does not seem to be obtained easily in this case. Note that variable time steps may also be considered.

LEMMA 4.10 (existence of a discrete solution). *Under hypotheses* (1.3)–(1.7)*, let $\mathcal{D}$ be an admissible discretization of $\Omega \times (0,T)$ in the sense of Definition* 4.9*. Let $\lambda \in (0, +\infty)$ and $\alpha \in (0,2)$ be given. Then there exists at least one $(u,p) \in H_{\mathcal{D}}(\Omega\times(0,T))^d \times H_{\mathcal{D}}(\Omega\times(0,T))$, solution to* (4.14)–(4.16)*.*

Proof. We remark that, for a given $n = 0, \dots, N-1$, taking as unknown $u_{n+\frac{1}{2}}$, and noting that $u_{n+1} = 2u_{n+\frac{1}{2}} - u_n$, scheme (4.15) is under the same form as scheme (4.3), with $\eta = 2/\delta t$ and with a term involving u_n included in the right-hand side. Therefore the existence of at least one solution follows from Lemma 4.5. ∎

LEMMA 4.11 (estimates for the velocity). *Under hypotheses* (1.3)–(1.7)*, let $\mathcal{D}$ be an admissible discretization of $\Omega \times (0,T)$ in the sense of Definition* 4.9*. Let $\lambda \in (0, +\infty)$ and $\alpha \in (0,2)$. Let $(u,p) \in H_{\mathcal{D}}(\Omega\times(0,T))^d \times H_{\mathcal{D}}(\Omega\times(0,T))$ be a solution to* (4.14)–(4.16)*. Then there exists $C_{28} > 0$, depending only on d, Ω, ν, u_0, f, T, such that the following inequalities hold:*

$$\|u\|_{L^\infty(0,T;L^2(\Omega)^d)} \le C_{28}\,, \tag{4.17}$$

$$\|u\|_{L^2(0,T;H_{\mathcal{D}}(\Omega)^d)} \le C_{28}\,, \tag{4.18}$$

and

$$\lambda\ \mathrm{size}(\mathcal{D})^\alpha \sum_{n=0}^{N-1} \delta t |p_{n+\frac{1}{2}}|_{\mathcal{D}}^2 = \lambda\ \mathrm{size}(\mathcal{D})^\alpha \int_0^T |p(\cdot,t)|_{\mathcal{D}}^2 \mathrm{d}t \le C_{28}\,. \tag{4.19}$$

Proof. Let $k = 1, \ldots, N$. Setting $v = u_{n+\frac{1}{2}}$ in the first equation of (4.15), and summing on $K \in \mathcal{M}$ and $n = 0, \ldots, k-1$ in the first equation of (4.15), and using property (4.7), we get.

$$\frac{1}{2}\sum_{n=0}^{k-1}\int_\Omega (u_{n+1}(x)^2 - u_n(x)^2)\mathrm{d}x + \nu\sum_{n=0}^{k-1}\delta t[u_{n+\frac{1}{2}}, u_{n+\frac{1}{2}}]_{\mathcal{D}}$$
$$-\sum_{n=0}^{k-1}\delta t\int_\Omega p_{n+\frac{1}{2}}(x)\mathrm{div}_{\mathcal{D}}(u_{n+\frac{1}{2}})(x)dx = \sum_{n=0}^{k-1}\int_{n\delta t}^{(n+1)\delta t}\int_\Omega f(x,t)\cdot u_{n+\frac{1}{2}}(x)\mathrm{d}x\mathrm{d}t.$$

This leads, setting $q = p_{n+\frac{1}{2}}$ in the second equation of (4.15), to

$$\begin{aligned}&\frac{1}{2}\int_\Omega (u_k(x)^2 - u_0(x)^2)\mathrm{d}x + \nu\sum_{n=0}^{k-1}\delta t[u_{n+\frac{1}{2}}, u_{n+\frac{1}{2}}]_{\mathcal{D}}\\ &+\lambda\ \mathrm{size}(\mathcal{D})^\alpha\sum_{n=0}^{k-1}\delta t|p_{n+\frac{1}{2}}|_{\mathcal{D}}^2 = \int_0^{k\delta t}\int_\Omega f(x,t)\cdot u(x,t)\mathrm{d}x\mathrm{d}t.\end{aligned} \tag{4.20}$$

Setting $k = N$ in (4.20) gives (4.18) and (4.19). The discrete Poincaré inequality (2.4) and the inequality $\|u_0\|_{L^2(\Omega)^d} \le \|u_{\mathrm{ini}}\|_{L^2(\Omega)^d}$ give

$$\|u_k\|_{L^2(\Omega)^d}^2 \le \frac{\mathrm{diam}(\Omega)^2}{2\nu}\|f\|_{L^2(\Omega\times(0,T))^d}^2 + \|u_{\mathrm{ini}}\|_{L^2(\Omega)^d}^2\ \forall k = 1, \ldots, N,$$

which proves (4.17), since $\|u_{n+\frac{1}{2}}\|_{L^2(\Omega)^d} \le \frac{1}{2}(\|u_n\|_{L^2(\Omega)^d} + \|u_{n+1}\|_{L^2(\Omega)^d})$ for all $n = 0, \ldots, N-1$. ∎

LEMMA 4.12 (space and time velocity translate estimates). *Under hypotheses* (1.3)–(1.7), *let* $\mathcal{D}$ *be an admissible discretization of* $\Omega\times(0,T)$ *in the sense of Definition* 4.9. *Let* $\lambda \in (0,+\infty)$, $\alpha \in (0,2)$, *and* $\zeta > 0$, *such that* $\mathrm{regul}(\mathcal{D}) \ge \zeta$. *Let* $(u,p) \in H_{\mathcal{D}}(\Omega\times(0,T))^d \times H_{\mathcal{D}}(\Omega\times(0,T))$ *be a solution to* (4.14)–(4.16). *We still denote by* u *the extension in* $\mathbb{R}^d\times\mathbb{R}$ *of* u *by* 0 *outside of* $\Omega\times(0,T)$. *Then there exists* $C_{29} > 0$ *and* $C_{30} > 0$, *depending only on* d, Ω, ν, λ, α, u_0, f, ζ, *and* T, *such that the following inequalities hold:*

$$\|u(\cdot+\xi,\cdot) - u\|_{L^2(\mathbb{R}^d\times\mathbb{R})^d}^2 \le C_{29}\,|\xi|(|\xi| + 4\,\mathrm{size}(\mathcal{M}))\ \forall \xi \in \mathbb{R}^d \tag{4.21}$$

and

$$\|u(\cdot,\cdot+\tau) - u\|_{L^1(\mathbb{R};L^2(\mathbb{R}^d)^d)} \le C_{30}\,|\tau|^{1/2}\ \forall \tau \in \mathbb{R}. \tag{4.22}$$

Proof. In the following proof, we denote by C_i, where i is an integer, various positive real numbers which can depend only on d, Ω, ν, λ, α, u_0, f, ζ, and T. Inequality (4.21) is obtained from (4.18) (see [13]). Let us prove (4.22). Let $\tau \in (0,T)$ be given. We define the following norms on $H_{\mathcal{D}}(\Omega)^d$,

$$\forall\ w \in H_{\mathcal{D}}(\Omega)^d,$$

$$\begin{aligned}\|w\|_{\mathcal{D},\lambda}^2 &= \|w\|_{\mathcal{D}}^2\\ &+\frac{1}{\lambda\mathrm{size}(\mathcal{D})^\alpha}\left(\sup\left\{\int_\Omega \mathrm{div}_{\mathcal{D}}(w)(x)q(x)\mathrm{d}x,\ q \in H_{\mathcal{D}}(\Omega), |q|_{\mathcal{D}} = 1\right\}\right)^2\end{aligned} \tag{4.23}$$

and

$$\begin{aligned}&\forall\ w \in H_{\mathcal{D}}(\Omega)^d,\\ &\|w\|_{\star,\mathcal{D},\lambda} = \sup\left\{\int_\Omega w(x)\cdot v(x)dx, v \in H_{\mathcal{D}}(\Omega)^d, \|v\|_{\mathcal{D},\lambda} = 1\right\}.\end{aligned} \tag{4.24}$$

We then have, for a.e. $t \in (0,T)$,

$$\|u(\cdot,t+\tau)-u(\cdot,t)\|^2_{L^2(\Omega)^d} \le \|u(\cdot,t+\tau)-u(\cdot,t)\|_{\mathcal{D},\lambda}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\star,\mathcal{D},\lambda},$$

and therefore, thanks to Young's formula,

$$\begin{aligned}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{L^2(\Omega)^d} \le \frac{\sqrt{\tau}}{2}&\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\mathcal{D},\lambda}\\ &+\frac{1}{2\sqrt{\tau}}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\star,\mathcal{D},\lambda}.\end{aligned} \tag{4.25}$$

We get, from (4.15), for all $q \in H_{\mathcal{D}}(\Omega)$ and for a.e. $t \in (0,T)$,

$$\int_\Omega \mathrm{div}_{\mathcal{D}}(u(\cdot,t))(x)q(x)\mathrm{d}x = -\lambda\ \mathrm{size}(\mathcal{D})^\alpha\ \langle p(\cdot,t),q\rangle_{\mathcal{D}},$$

which proves, using (4.23), that

$$\|u(\cdot,t)\|^2_{\mathcal{D},\lambda} \le \|u(\cdot,t)\|^2_{\mathcal{D}} + \lambda\ \mathrm{size}(\mathcal{D})^\alpha |p(\cdot,t)|^2_{\mathcal{D}}.$$

Using the Cauchy–Schwarz inequality, we have

$$\left(\int_0^{T-\tau}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\mathcal{D},\lambda}\mathrm{d}t\right)^2 \le 4T\int_0^T \|u(\cdot,t)\|^2_{\mathcal{D},\lambda}\mathrm{d}t,$$

and therefore, using (4.18) and (4.19),

$$\int_0^{T-\tau}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\mathcal{D},\lambda}\mathrm{d}t \le C_{31}\,. \tag{4.26}$$

We now study $\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\star,\mathcal{D},\lambda}$. We can write, for a.e. $t \in (0,T-\tau)$ and $x \in \Omega$,

$$u(x,t+\tau)-u(x,t) = \frac{1}{2}\sum_{n=0}^{N-1}(\chi_n(t,\tau)+\chi_{n+1}(t,\tau))(u_{n+1}(x)-u_n(x)),$$

where, for all $n \in \mathbb{N}$ and $t \in (0,T)$, $\chi_n(t,\tau) = 1$ if $n\delta t \in [t,t+\tau[$, and $\chi_n(t,\tau) = 0$ otherwise. This implies

$$\begin{aligned}&\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\star,\mathcal{D},\lambda}\\ &\qquad\le \frac{1}{2}\sum_{n=0}^{N-1}(\chi_n(t,\tau)+\chi_{n+1}(t,\tau))\|u_{n+1}-u_n\|_{\star,\mathcal{D},\lambda}.\end{aligned} \tag{4.27}$$

Let us then obtain a bound for $\|u_{n+1}-u_n\|_{\star,\mathcal{D},\lambda}$. Using the definition of the scheme (4.15), we get that, for all $v \in H_{\mathcal{D}}(\Omega)^d$,

$$\begin{aligned}\int_\Omega (u_{n+1}(x)-u_n(x))\cdot v(x)\mathrm{d}x = &\int_{n\delta t}^{(n+1)\delta t}\int_\Omega f(x,t)\cdot v(x)\mathrm{d}x\mathrm{d}t\\ &-\nu\delta t[u_{n+\frac12},v]_{\mathcal{D}} + \delta t\int_\Omega p_{n+\frac12}(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x\\ &-\frac{\delta t}{2}\int_\Omega u^2_{n+\frac12}\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x - \delta t\ b_{\mathcal{D}}(u_{n+\frac12},u_{n+\frac12},v).\end{aligned} \tag{4.28}$$

Using the definition of $\mathrm{div}_{\mathcal{D}}$, the fact that $\sum_{\sigma\in\mathcal{E}_K} \mathrm{m}_\sigma \mathbf{n}_{K,\sigma} = 0$, and the Cauchy–Schwarz inequality, there exists C_{32} such that

$$\int_\Omega u^2_{n+\frac12}(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x \le C_{32}\,\|u^2_{n+\frac12}\|_{L^2(\Omega)}\ \|v\|_{\mathcal{D}}.$$

The discrete Sobolev inequality (4.9) leads to

$$\|u^2_{n+\frac12}\|_{L^2(\Omega)} \le \sum_{i=1}^d \|(u^{(i)}_{n+\frac12})^2\|_{L^2(\Omega)} = \sum_{i=1}^d \|u^{(i)}_{n+\frac12}\|^2_{L^4(\Omega)} \le C_{33}\,\|u_{n+\frac12}\|^2_{\mathcal{D}}.$$

We take $\|v\|_{\mathcal{D},\lambda} = 1$ and note that, from definition (4.23), we obtain that $\|v\|_{\mathcal{D}} \le 1$ and that

$$\int_\Omega p_{n+\frac12}(x)\mathrm{div}_{\mathcal{D}}(v)(x)\mathrm{d}x \le (\lambda\ \mathrm{size}(\mathcal{D})^\alpha)^{1/2}\ \ |p_{n+\frac12}|_{\mathcal{D}}.$$

We then take the supremum in (4.28). Using the Cauchy–Schwarz inequality, the discrete Poincaré inequality, and (4.8), this yields

$$\begin{aligned}\|u_{n+1}-u_n\|_{\star,\mathcal{D},\lambda} \ &\le \sqrt{\delta t}\,\mathrm{diam}(\Omega)\|f\|_{L^2((n\delta t,(n+1)\delta t);L^2(\Omega)^d)}\delta t\\ &+\delta t\,\nu\,\|u_{n+\frac12}\|_{\mathcal{D}} + \ (\lambda\ \mathrm{size}(\mathcal{D})^\alpha)^{1/2}\ \ |p_{n+\frac12}|_{\mathcal{D}}\\ &+\delta t\left(\frac12 C_{32}\,C_{33}\ + C_{19}\right)\|u_{n+\frac12}\|^2_{\mathcal{D}}.\end{aligned}$$

Summing the above equation for $n = 0$ to $N-1$, applying the Cauchy–Schwarz inequality to all terms of the right-hand side except the last one, and using (4.18) and (4.19), we get that there exists C_{34} such that

$$\sum_{n=0}^{N-1}\|u_{n+1}-u_n\|_{\star,\mathcal{D},\lambda} \le C_{34}\,.$$

Hence, noting that for all $n = 0,\dots,N$, $\int_0^{T-\tau}\chi_n(t,\tau)\mathrm{d}t \le \tau$, we have

$$\frac12\int_0^{T-\tau}\sum_{n=0}^{N-1}(\chi_n(t,\tau)+\chi_{n+1}(t,\tau))\|u_{n+1}-u_n\|_{\star,\mathcal{D},\lambda}\mathrm{d}t \le C_{34}\,\tau,$$

which proves, using (4.27),

$$\int_0^{T-\tau}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{\star,\mathcal{D},\lambda}\mathrm{d}t \le C_{34}\,\tau. \tag{4.29}$$

Thanks to (4.25), (4.26), and (4.29), we obtain that

$$\int_0^{T-\tau}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{L^2(\Omega)^d}\mathrm{d}t \le C_{35}\,\sqrt{\tau}.$$

Using (4.17), we have

$$\int_{T-\tau}^{T}\|u(\cdot,t+\tau)-u(\cdot,t)\|_{L^2(\Omega)^d}\mathrm{d}t = \int_{T-\tau}^{T}\|-u(\cdot,t)\|_{L^2(\Omega)^d}\mathrm{d}t \le C_{28}\,\tau \le \sqrt{\tau}\sqrt{T}C_{28}\,,$$

and a similar inequality holds for $\int_{-\tau}^{0} \|u(\cdot,t+\tau)-u(\cdot,t)\|_{L^2(\Omega)^d}\mathrm{d}t$. This thus gives (4.22), for any $\tau \in (0,T)$. The case $\tau \geq T$ is obtained again using (4.17), and the case $\tau \leq 0$ is obtained from $\tau \geq 0$ by the change of variable $s = t+\tau$. This completes the proof of (4.22). □

THEOREM 4.13 (convergence of the scheme). *Under hypotheses* (1.3)–(1.7)*, let* $\zeta > 0$ *be given and let* $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$ *be a sequence of admissible discretizations of* $\Omega \times (0,T)$ *in the sense of Definition* 4.9*, such that* $\mathrm{regul}(\mathcal{D}^{(m)}) \geq \zeta$ *and* $\mathrm{size}(\mathcal{D}^{(m)})$ *tends to* 0 *as* $m \to \infty$*. Let* $\lambda \in (0,+\infty)$ *and* $\alpha \in (0,2)$ *be given. Let, for all* $m \in \mathbb{N}$*,* $(u^{(m)}, p^{(m)}) \in H_{\mathcal{D}^{(m)}}(\Omega\times(0,T))^d \times H_{\mathcal{D}^{(m)}}(\Omega\times(0,T))$ *be a solution to* (4.14)–(4.16) *with* $\mathcal{D} = \mathcal{D}^{(m)}$*. Then there exists a subsequence of* $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$*, again denoted by* $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$*, such that the corresponding subsequence of solutions* $(u^{(m)})_{m\in\mathbb{N}}$ *converges in* $L^2(0,T;L^2(\Omega)^d)$ *to a weak solution* $\bar{u}$ *of* (1.1)–(1.2) *in the sense of Definition* 4.8*.*

Proof. Let us assume that the assumptions of the theorem hold. Using translates estimates (4.21) and (4.22) in the space $L^1(\mathbb{R};L^1(\mathbb{R}^d)^d)$, we can apply Kolmogorov's theorem. We get that there exist $\bar{u} \in L^1(0,T;L^1(\Omega)^d)$ and a subsequence of $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$, again denoted by $(\mathcal{D}^{(m)})_{m\in\mathbb{N}}$, such that the corresponding subsequence of solutions $(u^{(m)})_{m\in\mathbb{N}}$ converges in $L^1(0,T;L^1(\Omega)^d)$ to $\bar{u}$ as $m \to \infty$. Using (4.18), we get $\|u^{(m)}\|_{L^2(0,T;H_{\mathcal{D}_m}(\Omega)^d)} \leq C_{28}$ for all $m \in \mathbb{N}$, which gives, using the discrete Sobolev inequalities, $\|u^{(m)}\|_{L^1(0,T;L^4(\Omega)^d)} \leq C_{36}$ for all $m \in \mathbb{N}$. Using a classical result on spaces $L^p(0,T;L^q(\Omega))$, we get that $(u^{(m)})_{m\in\mathbb{N}}$ converges in $L^1(0,T;L^2(\Omega)^d)$ to $\bar{u}$ as $m \to \infty$. Thanks to (4.17), we have $\|u^{(m)}\|_{L^\infty(0,T;L^2(\Omega)^d)} \leq C_{28}$ for all $m \in \mathbb{N}$. The same result on spaces $L^p(0,T;L^q(\Omega))$ implies that $(u^{(m)})_{m\in\mathbb{N}}$ converges in $L^2(0,T;L^2(\Omega)^d)$ to $\bar{u}$ as $m \to \infty$. We can therefore pass to the limit in (4.21). The resulting inequality implies $\bar{u} \in L^2(0,T;H_0^1(\Omega)^d)$ (see [13]). Passing to the limit in (4.17) leads to $\bar{u} \in L^\infty(0,T;L^2(\Omega)^d)$.

Let us now prove that $\bar{u}$ is a weak solution of (1.1)–(1.2) in the sense of Definition 4.8.

Let $\varphi \in C_c^\infty(\Omega\times(-\infty,T))^d$ be given, with $\mathrm{div}\varphi(x,t) = 0$ for all $(x,t) \in \Omega\times(-\infty,T)$. Let $\mathcal{D}^{(m)}$ be a given admissible discretization extracted from the considered subsequence. Omitting some of the indices m for the simplicity of notation, we then set $v = P_{\mathcal{D}}\varphi(\cdot,n\delta t)$ in (4.15), and we sum for $n = 0,\dots,N-1$. We thus get

$$T_{15}^{(m)} + T_{16}^{(m)} + T_{17}^{(m)} + T_{18}^{(m)} + T_{19}^{(m)} = T_{20}^{(m)}, \tag{4.30}$$

with

$$T_{15}^{(m)} = \sum_{n=0}^{N-1} \int_\Omega (u_{n+1}(x) - u_n(x)) \cdot P_{\mathcal{D}}\varphi(x,n\delta t)\mathrm{d}x,$$

$$T_{16}^{(m)} = \sum_{n=0}^{N-1} \delta t [u_{n+\frac{1}{2}}, P_{\mathcal{D}}\varphi(\cdot,n\delta t)]_{\mathcal{D}},$$

$$T_{17}^{(m)} = -\sum_{n=0}^{N-1} \delta t \int_\Omega p_{n+\frac{1}{2}}(x)\mathrm{div}_{\mathcal{D}}(P_{\mathcal{D}}\varphi(\cdot,n\delta t))(x)\mathrm{d}x,$$

$$T_{18}^{(m)} = \frac{1}{2}\sum_{n=0}^{N-1} \delta t \int_\Omega u_{n+\frac{1}{2}}(x)^2\mathrm{div}_{\mathcal{D}}(P_{\mathcal{D}}\varphi(\cdot,n\delta t))(x)\mathrm{d}x,$$

$$T_{19}^{(m)} = \sum_{n=0}^{N-1} \delta t b_{\mathcal{D}}(u_{n+\frac{1}{2}}, u_{n+\frac{1}{2}}, P_{\mathcal{D}}\varphi(\cdot, n\delta t)),$$

and

$$T_{20}^{(m)} = \sum_{n=0}^{N-1} \int_{n\delta t}^{(n+1)\delta t} \int_{\Omega} f(x,t) \cdot P_{\mathcal{D}}\varphi(x, n\delta t) \mathrm{d}x\mathrm{d}t.$$

In the following, we denote by C_i various positive reals which can depend only on d, Ω, T, u_{ini}, f, ν, ζ, and λ. We first start with the study of T_{16}. We classically have (see [13])

$$\lim_{m\to\infty} T_{16}^{(m)} = \int_0^T \int_{\Omega} \nabla \bar{u}(x,t) : \nabla \varphi(x,t) \mathrm{d}x\mathrm{d}t. \tag{4.31}$$

The proof that

$$\lim_{m\to\infty} T_{17}^{(m)} = 0 \tag{4.32}$$

is a consequence of (4.19) and of a direct adaptation of Lemma 2.3 to time-dependent functions. Let us now prove that

$$\lim_{m\to\infty} T_{18}^{(m)} = 0. \tag{4.33}$$

Since $(u^{(m)})^2$ tend to $\bar{u}^2$ as $m \to \infty$ in $L^1(\Omega \times (0,T))$, the same argument as in the steady-state case (see proof of Theorem 4.7) provides (4.33).

We now turn to the study of T_{19}. Following the proof of Lemma 4.7, the proof that

$$\lim_{m\to\infty} T_{19}^{(m)} = \int_0^T b(\bar{u}(\cdot,t), \bar{u}(\cdot,t), \varphi(\cdot,t)) \mathrm{d}t \tag{4.34}$$

is a direct consequence of the convergence of u to $\bar{u}$ in $L^2(\Omega \times (0,T))^d$ and Lemma 2.3. The study of T_{20} is classical, and we have

$$\lim_{m\to\infty} T_{20}^{(m)} = \int_0^T \int_{\Omega} f(x,t) \cdot \varphi(x,t) \mathrm{d}x\mathrm{d}t. \tag{4.35}$$

Let us now prove that

$$\lim_{m\to\infty} T_{15}^{(m)} = -\int_0^T \int_{\Omega} \bar{u}(x,t) \partial_t \varphi(x,t) \mathrm{d}x\mathrm{d}t - \int_{\Omega} u_{\mathrm{ini}}(x) \varphi(x,0) \mathrm{d}x. \tag{4.36}$$

Indeed, we have

$$T_{15}^{(m)} = -\int_{\Omega} u_0(x) \cdot P_{\mathcal{D}}\varphi(x,0) \mathrm{d}x - T_{21}^{(m)} - \frac{1}{2} T_{22}^{(m)}$$

with

$$T_{21}^{(m)} = \sum_{n=0}^{N-1} \int_{\Omega} u_{n+\frac{1}{2}}(x) \cdot (P_{\mathcal{D}}\varphi(x,(n+1)\delta t) - P_{\mathcal{D}}\varphi(x, n\delta t)) \mathrm{d}x$$

and

$$T_{22}^{(m)} = \sum_{n=0}^{N-1} \int_\Omega (u_{n+1}(x) - u_n(x)) \cdot (P_{\mathcal{D}}\varphi(x,(n+1)\delta t) - P_{\mathcal{D}}\varphi(x,n\delta t))\mathrm{d}x.$$

We classically have

$$\lim_{m\to\infty} \int_\Omega u_0(x) \cdot P_{\mathcal{D}}\varphi(x,0)\mathrm{d}x = \int_\Omega u_{\mathrm{ini}}(x)\varphi(x,0)\mathrm{d}x.$$

We also easily have, thanks to the convergence properties of $u^{(m)}$, that

$$\lim_{m\to\infty} T_{21}^{(m)} = \int_0^T \int_\Omega \bar{u}(x,t)\partial_t\varphi(x,t)\mathrm{d}x\mathrm{d}t.$$

Let us prove that the term $T_{22}^{(m)}$ tends to 0 as $m \to \infty$. We have $T_{22}^{(m)} = T_{23}^{(m)} - T_{15}^{(m)}$, with

$$T_{23}^{(m)} = \sum_{n=0}^{N-1} \int_\Omega (u_{n+1}(x) - u_n(x)) \cdot P_{\mathcal{D}}\varphi(x,(n+1)\delta t)\mathrm{d}x.$$

Thanks to the limits given by (4.31), (4.32), (4.33), (4.34), and (4.35), and thanks to (4.30), we obtain that $\lim_{m\to\infty} T_{15}^{(m)} = T_{24}$, with

$$\begin{aligned} T_{24} = \; & -\nu \sum_{i=1}^{d} \int_0^T \int_\Omega \nabla u^{(i)}(x,t) \cdot \nabla \varphi^{(i)}(x,t)\mathrm{d}x\mathrm{d}t - \int_0^T b(u(\cdot,t), u(\cdot,t), \varphi(\cdot,t))\mathrm{d}t \\ & + \int_0^T \int_\Omega f(x) \cdot \varphi(x,t)\mathrm{d}x\mathrm{d}t. \end{aligned}$$

Since (4.31), (4.32), (4.33), (4.34), and (4.35) are available as well, replacing $P_{\mathcal{D}}\varphi(\cdot,n\delta t)$ by $P_{\mathcal{D}}\varphi(\cdot,(n+1)\delta t)$ in T_{16}, T_{17}, T_{18}, T_{19}, and T_{20}, we also get using (4.15) with $v = P_{\mathcal{D}}\varphi(\cdot,(n+1)\delta t)$, that $\lim_{m\to\infty} T_{23}^{(m)} = T_{24}$. Thus we get that $\lim_{m\to\infty} T_{22}^{(m)} = 0$, which concludes the proof of (4.36). Thanks to (4.30), (4.36), (4.31), (4.32), (4.33), (4.34), and (4.35), we thus obtain (4.13), provided that we can prove that

$$\mathrm{div}\bar{u}(x,t) = 0 \quad \text{for a.e. } (x,t) \in \Omega \times (0,T).$$

This last relation can be shown by following the proof of (3.22). This completes the proof of the above theorem. □

Remark 4.5. Using the above proof of convergence, we get the energy inequality for $d = 2$ or 3 from inequality (4.20), since we have the property

$$\int_0^T \int_\Omega (\nabla u^{(i)}(x,t))^2 \mathrm{d}x\mathrm{d}t \le \liminf_{m\to\infty} \sum_{n=0}^{N^{(m)}-1} \delta t \left[u_{n+\frac{1}{2}}^{(m,i)}, u_{n+\frac{1}{2}}^{(m,i)} \right]_{\mathcal{D}^{(m)}}.$$

5. Numerical results. Some simple numerical experiments are described here to observe the convergence rate of schemes (3.8) and (4.14)–(4.15) with respect to the space and time discretizations. To that purpose, we use a prototype code where the nonlinear equations are solved by an underrelaxed Newton method, and the linear

systems by a direct band Gaussian elimination solver. This code handles Stokes or Navier–Stokes problems with various boundary conditions, using nonuniform rectangular or triangular meshes on general 2D polygonal domains.

The linear Stokes equations are first considered in the case $d = 2$, $\Omega = (0,1) \times (0,1)$, $\nu = 1$, and f is taken to satisfy (3.1) with a solution equal to

$$\begin{aligned} \bar{u}^{(1)}(x^{(1)}, x^{(2)}) &= -\partial^{(2)}\Psi(x^{(1)}, x^{(2)}), \\ \bar{u}^{(2)}(x^{(1)}, x^{(2)}) &= \partial^{(1)}\Psi(x^{(1)}, x^{(2)}), \\ \bar{p}(x^{(1)}, x^{(2)}) &= 100 \ \left((x^{(1)})^2 + (x^{(2)})^2\right), \end{aligned}$$

denoting by $\Psi(x^{(1)}, x^{(2)}) = 1000\ [x^{(1)}(1 - x^{(1)})x^{(2)}(1 - x^{(2)})]^2$. The approximate solution (u, p) is computed with the scheme (3.8). The observed numerical order of convergence, considering the norms $\|u - P_{\mathcal{D}}\bar{u}\|_{L^2(\Omega)^d}$ and $\|p - P_{\mathcal{D}}\bar{p}\|_{L^2(\Omega)}$, is equal to 2 for the velocity components, and to 1 for the pressure in the cases of nonuniform rectangular and square meshes (from 400 to 6400 control volumes). Note that in these cases, there is apparently no need for a significant positive value of the stabilization coefficient λ. The observed numerical order of convergence is similar in the case of triangular meshes (from 1400 to 5600 control volumes), but values such as $\lambda = 10^{-4}$, $\alpha = 1$ have to be used in order to avoid oscillations in the pressure field. This confirms that in the case of triangles, the approximate pressure space is too large to avoid stabilization. In fact, other tests were performed (e.g., the classical backward step) which show that stabilization is also needed in the case of rectangles when more severe problems are considered. Note that in industrial implementations, stabilization may be performed by other means; see [29, 1] (see also [4] in the triangular case).

We then proceed to a similar comparison in the case of transient nonlinear problems. Considering a transient adaptation of the above steady-state analytical solution, the continuous problem is then defined by zero initial and boundary conditions, $T = 0.1$, and the function f is taken to satisfy (1.1) with a solution equal to

$$\begin{aligned} \bar{u}^{(1)}(x^{(1)}, x^{(2)}, t) &= -t\ \partial^{(2)}\Psi(x^{(1)}, x^{(2)}), \\ \bar{u}^{(2)}(x^{(1)}, x^{(2)}, t) &= t\ \partial^{(1)}\Psi(x^{(1)}, x^{(2)}), \\ \bar{p}(x^{(1)}, x^{(2)}, t) &= 100\ t\ \left((x^{(1)})^2 + (x^{(2)})^2\right), \end{aligned}$$

with the same function Ψ as above. We again observe an order 2 of convergence of the approximate solution at times $t = .05$ and $t = .1$, when the space and time discretizations are simultaneously modified with the same ratio (from $\delta t = 0.01$ to $\delta t = 0.0025$ as the size of the mesh is divided by 4). Similar observations are still valid for the classical Green–Taylor example.

6. Conclusions. The above numerical results show that the theoretical error estimate, which is proven in section 3 for the linear Stokes equations, is nonoptimal; a sharper estimate is currently being written [20] under more regularity assumptions on the mesh.

The proof of convergence of the full space-time discrete approximation of (1.1) given by (4.15) uses estimates on the time translates, which were introduced in the $L^2(\Omega \times (0,T))$ framework for the proof of convergence of the finite volume method for degenerate parabolic equations [17, 13] and used for several other cases; see, e.g., [16]. A major difficulty which arises here is the handling on the nonlinear advective term, as in the continuous case, which leads us to establish an estimate for the time translates in $L^1(0,T;L^2(\Omega))$. This new technique may be used for parabolic problems with other types of nonlinearities.

We remarked that industrial codes use other types of stabilizations than the one used here. Further works will be devoted to the mathematical study of such stabilizations, for which, to our knowledge, no proof of convergence is known up to now.

Finally, let us also mention undergoing work on a generalization of the scheme studied here to the full transient Navier–Stokes equations including the energy balance under the Boussinesq approximation.

A REFINED GALERKIN ERROR AND STABILITY ANALYSIS FOR HIGHLY INDEFINITE VARIATIONAL PROBLEMS*

L. BANJAI† AND S. SAUTER†

Abstract. Recently, a refined finite element analysis for highly indefinite Helmholtz problems was introduced by the second author. We generalize the analysis to the Galerkin method applied to an *abstract* highly indefinite variational problem. In the refined analysis, the condition for stability and a quasi-optimal error estimate are expressed in terms of approximation properties $\mathcal{T}(S) \approx S$ and $\mathcal{T}(u+S) \approx S$. Here, u is the solution of the original variational problem, $\mathcal{T}$ is a certain continuous solution operator, and S is the finite dimensional test and trial space. The abstract analysis can be applied to both finite and boundary element solutions of high-frequency Helmholtz problems. We apply the analysis to investigate the properties of the Brakhage–Werner boundary integral formulation of the Helmholtz problem, discretized by a standard Galerkin boundary element method. In the case of scattering by the unit sphere, we derive the explicit dependence of the error and of the stability condition on the wave number k. We show that $hk \lesssim 1$ is a sufficient condition for stability and a quasi-optimal error estimate. Further, we show that the constant of quasioptimality is independent of k, which is an improvement over previously available results. Thus, the boundary element method does not suffer from the *pollution effect*.

Key words. indefinite problems, Helmholtz equation, finite and boundary element methods

1. Introduction.

The numerical solution of high-frequency Helmholtz problems has attracted much interest in recent years; see, for example, [3, 4, 7, 10, 11, 12, 17, 28, 29]. The main aim of this paper is to develop a refined analysis for the error and the stability of the Galerkin discretization of high-frequency Helmholtz problems. The analysis should be general enough to include both boundary and finite element methods and allow for discussion of standard and special finite/boundary elements such as the ones used in [23, 27, 29]. Most importantly, it should be possible to obtain optimal results on the dependence of the error bounds and the stability condition on the wave number k. The explicit dependence on k is rarely given in existing literature; for exceptions, see [8, 11, 13].

It is well known that the Galerkin finite element method with standard piecewise polynomial basis functions suffers from the so-called *pollution effect* [3]. If piecewise linear basis functions are used, the stability condition in the mesh width h is very strong: $hk^2 \lesssim 1$. In [3], a generalized finite element method was presented in one dimension, with the stability condition reduced to $hk \lesssim 1$; see also [17]. The proofs rely on explicit knowledge of the Green's function and, hence, do not carry over to higher dimensions. Further, the general stability and convergence analysis given in [23] does not yield the improved stability condition. With this in mind, in [29] a refined finite element analysis was developed that gives improved stability and error estimates.

In this paper, we generalize the results of [29] to an abstract theory applicable to a general indefinite variational problem. We prove that the condition $\mathcal{T}(S) \approx S$,

†Institut für Mathematik, Universität Zürich, Winterthurerstrasse 190, CH-8057 Zürich, Switzerland (lehelb@math.unizh.ch, stas@math.unizh.ch).

of approximate invariance of the test and trial space S under a certain continuous solution operator $\mathcal{T}$, is sufficient for stability. The quasi-optimal error estimate is proved under a similar condition $\mathcal{T}(u+S) \approx S$, where u is the solution of the continuous variational problem. This new concept is the crux of the abstract analysis we develop. We describe how the abstract analysis can be used to prove the results of [29] for the finite element method. As a further example of its use, we consider the boundary element method for the solution of high-frequency Helmholtz problems using the Brakhage–Werner boundary integral formulation. This problem has already been considered in [13] and recently in [11]. There, the stability condition $hk \lesssim 1$ and a quasi-optimal error estimate, with the constant of quasi-optimality proportional to $k^{1/3}$, was proved for the case of the unit sphere. In [11], the authors consider the problem of high-frequency scattering by a convex object in two dimensions. Known asymptotics of the scattered wave were used to reduce the problem to the computation of unknown amplitudes, which are less oscillatory than the original scattered wave. These were then computed using a Galerkin method for which the quasi-optimal error with constant of $\mathcal{O}(k^{1/3})$ was proved in the case of the unit disk and sphere.

We obtain a sharper error estimate, with the quasi-optimality constant independent of k. More importantly, our paper provides a framework in which to investigate the properties of boundary element methods with special basis elements such as plane waves [27]. For special finite element methods, it was already shown in [29] that the refined analysis obtains results outside the reach of standard analyses. We give reasons to expect the same to be true for boundary element methods. Further, the condition of the approximability of $\mathcal{T}(S)$ and $\mathcal{T}(u+S)$ by the boundary element space can give guidelines for the construction of special boundary elements.

2. A highly indefinite variational problem. Let H and V be Hilbert spaces such that H is continuously imbedded in V and, hence, V' is continuously imbedded in H', where V' and H' are the dual spaces; see [33]. Denote by $(\cdot,\cdot)_H$ and $(\cdot,\cdot)_V$ the respective inner products, and by $\|\cdot\|_H$ and $\|\cdot\|_V$ the induced norms.

We are interested in the following abstract variational problem: Given $f \in H'$, find $u \in H$ such that

$$a(u,v) = \langle f, v\rangle \quad \text{for all } v \in H, \tag{2.1}$$

where $a(\cdot,\cdot) : H \times H \to \mathbb{C}$ and we have written $\langle f, v\rangle = f(v)$ for the value of the functional f at v.

Naturally, we need to place some conditions on the above problem.

Assumptions.

A1: $a(\cdot,\cdot) : H \times H \to \mathbb{C}$ is a bounded sesquilinear form. Thus, $a(u,v)$ is linear in u, conjugate linear in v, and

$$|a(u,v)| \le C_{\mathrm{c}} \|u\|_H \|v\|_H.$$

A2: There exist bounded sesquilinear forms $a_H(\cdot,\cdot) : H \times H \to \mathbb{C}$ and $a_V(\cdot,\cdot) : V \times V \to \mathbb{C}$ such that

$$a(u,v) = a_H(u,v) + a_V(u,v)$$

and

$$|a_H(u,u)| \ge \alpha_H \|u\|_H^2, \quad |a_V(u,v)| \le C_V \|u\|_V \|v\|_V \quad \text{for any } u, v \in H.$$

A3: Problem (2.1) and its adjoint have a unique solution $u \in H$. Further,

$$\|u\|_H \leq C_{\mathrm{reg}} \|f\|_{H'}.$$

The sesquilinear forms $a(\cdot,\cdot)$, $a_H(\cdot,\cdot)$, and $a_V(\cdot,\cdot)$ define the corresponding bounded linear operators:

$$A : H \to H', \quad A_H : H \to H', \quad \text{and } A_V : V \to V'. \tag{2.2}$$

In view of A3, the inverses of A and the adjoint A^* are also bounded linear operators:

$$A^{-1} : H' \to H \quad \text{and} \quad A^{*-1} : H' \to H. \tag{2.3}$$

We now investigate the properties of the Galerkin discretization of (2.1).

2.1. Abstract stability and convergence analysis of the Galerkin method. Let $S \subset H$ be a finite dimensional subspace of H. We wish to consider the Galerkin discretization of problem (2.1): Given $f \in H'$, find $u_S \in S$ such that

$$a(u_S, v) = \langle f, v \rangle \quad \text{for all } v \in S. \tag{2.4}$$

We now derive a condition on S that guarantees the existence and uniqueness of u_S and a quasi-optimal error estimate.

2.1.1. Stability and convergence. For our analysis of the stability and convergence of (2.4), the following continuous dual problem will be crucial: Given $w \in H$, let $z \in H$ be such that

$$a(v, z) = -a_V(w, v) \quad \text{for all } v \in H.$$

From (A2) it follows that $a_V(w,\cdot)$ defines a bounded linear functional on V. Since H is continuously imbedded in V, i.e., the identity mapping $I : H \to V$ is continuous, $a_V(w,\cdot)$ defines also a bounded linear functional on H. Therefore, we can apply (A3) to obtain that the solution $z \in H$ of the above adjoint problem exists and is unique. Consequently, we can define a solution operator by $\mathcal{T} w := z$. Using again the fact that H is continuously imbedded in V and the properties of the operators in (2.2) and (2.3), we conclude that the solution operator $\mathcal{T} = -A^{*-1} A_V$ is a bounded linear operator mapping from H to H. Hence, there exists a constant $C_{\mathcal{T}}$ such that

$$\|\mathcal{T} u\|_H \leq C_{\mathcal{T}} \|u\|_H \quad \text{for all } u \in H. \tag{2.5}$$

Remark 1. *In applications, the operator $\mathcal{T}$ will be a compact operator. Usually it is also a smoothening operator; see Remark* 5 *and* [29].

Let us now define a measure of approximability in the space S. This measure depends on some subset $\widetilde{H} \subseteq H$, which satisfies $S \subset \widetilde{H}$ and $u + S \subset \widetilde{H}$, where u is the exact solution of (2.1). The measure is defined by

$$\eta(S) := \sup_{w \in \widetilde{H} \setminus \{0\}} \inf_{v \in S} \frac{\|\mathcal{T} w - v\|_H}{\|w\|_H}. \tag{2.6}$$

Remark 2.

1. *For a dense sequence $(S_l)_{l \geq 1}$ of spaces, i.e., $\overline{\cup_l S_l}^{\|\cdot\|_H} = H$, we have* $\lim_{l \to \infty} \eta(S_l) = 0$.

2. *We will prove stability of* (2.4) *and a quasi-optimal error estimate, under the condition that* $\eta(S)$ *is small enough.*
3. *Note that the choice* $\widetilde{H} = H$ *is always possible. However, a choice of a smaller set* $\widetilde{H} \subsetneq H$ *might result in a smaller value of* $\eta(S)$ *and a less restrictive stability condition.*

THEOREM 2.1. *Let* S *be such that*

$$\eta(S) \leq \frac{\alpha_H}{2C_c}, \tag{2.7}$$

and let $u \in H$ *be the solution of* (2.1)*. Then there exists a unique solution* $u_S \in S$ *of the discrete problem* (2.4)*. Moreover,*

$$\|u - u_S\|_H \leq \frac{2C_c}{\alpha_H} \inf_{v \in S} \|u - v\|_H.$$

Proof. Since S is finite dimensional, it suffices to prove uniqueness. Given $w_S \in S$, let z_S be the best approximation to $z = \mathcal{T} w_S$ with respect to the H-norm. Then,

$$\begin{aligned} |a(w_S, w_S + z_S)| &= |a_H(w_S, w_S) - a(w_S, z - z_S)| \geq \alpha_H \|w_S\|_H^2 - C_{\mathrm{c}} \|w_S\|_H \|z - z_S\|_H \\ &\geq \alpha_H \|w_S\|_H^2 - C_{\mathrm{c}} \eta(S) \|w_S\|_H^2. \end{aligned}$$

From (2.5) we have that

$$\|z\|_H \leq C_{\mathcal{T}} \|w_S\|_H$$

and hence

$$\|w_S + z_S\|_H \leq \|w_S\|_H + \|z\|_H + \|z - z_S\|_H \leq (1 + C_{\mathcal{T}} + \eta(S)) \|w_S\|_H.$$

Using (2.7), we have that

$$|a(w_S, w_S + z_S)| \geq \frac{\alpha_H}{2} \|w_S\|_H^2 \geq \frac{\alpha_H}{2 + 2C_{\mathcal{T}} + 2\eta(S)} \|w_S\|_H \|w_S + z_S\|_H.$$

Hence, we have the discrete inf-sup condition

$$\inf_{u \in S \setminus \{0\}} \sup_{v \in S \setminus \{0\}} \frac{|a(u, v)|}{\|u\|_H \|v\|_H} \geq \frac{\alpha_H}{2 + 2C_{\mathcal{T}} + 2\eta(S)} > 0,$$

and we have proved that the discrete solution u_S exists and is unique.

Next, let $z' = \mathcal{T} e$, where $e = u - u_S$, and again let z'_S be the best approximation to z' in the H-norm. Then,

$$|a_V(e, e)| = |a(e, z')| = |a(e, z' - z'_S)| \leq C_{\mathrm{c}} \eta(S) \|e\|_H^2.$$

Hence, for any $v \in S$,

$$\begin{aligned} \alpha_H \|e\|_H^2 &\leq |a_H(e, e)| = |a(e, e) - a_V(e, e)| = |a(e, u - v) - a_V(e, e)| \\ &\leq C_{\mathrm{c}} \|e\|_H \|u - v\|_H + C_{\mathrm{c}} \eta(S) \|e\|_H^2. \end{aligned}$$

Therefore, using (2.7),

$$\|e\|_H \leq \frac{2C_{\mathrm{c}}}{\alpha_H} \|u - v\|_H \quad \text{for any } v \in S.$$

Thus, we have also proved the quasioptimality of the Galerkin method. ∎

REMARK 3. *A result on the stability and convergence of the Galerkin finite element method applied to an indefinite PDE can be found in Theorem* 5.7.6 *of* [6]. *The same constant of quasioptimality* $2C_c/\alpha_H$, *as above, is also given in* [6]*; this is an improvement over the usual estimate given by Céa's lemma; see Remark* 6. *The essential novelty of our concept is that for stability and convergence it is sufficient to have* $\mathcal{T}(S) \approx S$ *and* $\mathcal{T}(u+S) \approx S$. *In contrast, the approach taken in* [6] *requires that the adjoint problem have full regularity. Theorem* 2.1 *is a stronger result, which implies the result of* [6]. *In particular, the kind of condition given in* [6] *does not allow for improved stability estimates of* [29]*; for details see* [29].

2.1.2. Error estimate in the V-norm. By using the Aubin–Nitsche technique, we can bound the V-norm of the error by the H-norm of the error. Let $\psi \in H$ be such that

$$a(v,\psi) = (e,v)_V \quad \text{for all } v \in H.$$

Let $\mathcal{S} : H \to H$ be the solution operator defined by $\mathcal{S}e := \psi$, and let

$$\mu(S) := \sup_{w \in \widetilde{H}\setminus\{0\}} \inf_{v\in S} \frac{\|\mathcal{S}w - v\|_H}{\|w\|_V}.$$

If ψ_S is the best approximation to ψ with respect to the H-norm, then

$$\|e\|_V^2 = a(e,\psi) = a(e,\psi-\psi_S) \le C_c\mu(S)\|e\|_H\|e\|_V. \tag{2.8}$$

Hence, we have an estimate of the V-norm of the error in terms of the H-norm of the error. We proceed now to obtain an alternative condition to that given in Theorem 2.1 for the existence of a quasi-optimal error estimate. For any $v \in H$,

$$\begin{aligned}\alpha_H\|e\|_H^2 &\le |a_H(e,e)| = |a(e,e) - a_V(e,e)| \le C_c\|e\|_H\|u-v\|_H + C_V\|e\|_V^2\\ &\le C_c\|e\|_H\|u-v\|_H + C_V\left(C_c\mu(S)\right)^2\|e\|_H^2.\end{aligned}$$

Hence, under the alternative condition

$$C_V\left(C_c\mu(S)\right)^2 < \alpha_H/2,$$

we have obtained the same quasi-optimal estimate as before. The results are collected in the following theorem.

THEOREM 2.2. *Let* $u \in H$ *be the solution of* (2.1) *and* $u_S \in S$ *be a solution of* (2.4). *Then*

$$\|u-u_S\|_V \le C_c\mu(S)\|u-u_S\|_H.$$

Further, if S *is such that* $C_V\left(C_c\mu(S)\right)^2 < \alpha_H/2$, *then*

$$\|u-u_S\|_H \le \frac{2C_c}{\alpha_H}\inf_{v\in S}\|u-v\|_H.$$

REMARK 4. *An abstract indefinite problem similar to the one we investigate here has been considered by Schatz in* [31]. *As an assumption of the abstract problem, Schatz imposes a condition of the type* (2.8) *with* $\mu(S) \to 0$ *for* $\dim(S) \to \infty$*; see* [31, (12)]. *This is not possible if* $V = H$, *which is the case of the boundary integral equation considered in section* 3*; hence the results of* [31] *do not apply, and Theorem* 2.1 *needs to be used. Further in* [31] *the constant of quasioptimality is not investigated.*

2.2. An example application in a finite element setting. The abstract analysis given here is a generalization of the finite element analysis for highly indefinite Helmholtz problems introduced in [29]. The appropriate choice of spaces H and V for the finite element method in [29] is

$$H = H^1(\Omega), \quad V = L^2(\Omega),$$

where the space H is equipped with a weighted norm (cf. [23]):

$$\|u\|_{\mathcal{H}} := \left(|u|_{1,\Omega}^2 + k^2\|u\|_{0,\Omega}^2\right)^{1/2}.$$

With this choice of spaces, the assumptions A1–A3 are proved in [29]. Theorems 2.2 and 2.5 of [29] are then implied by Theorems 2.1 and 2.2, respectively. For details we refer the reader to [29].

We now turn to another case to which the abstract theory can be applied. Namely, we consider the solution of a Helmholtz problem by a Galerkin boundary element method.

3. A Helmholtz scattering problem. Let Ω be a bounded domain in $\mathbb{R}^d$, $d = 2, 3$, with a smooth boundary Γ. We consider the following exterior Helmholtz problem: Given $g \in H^{1/2}(\Gamma)$, find $u \in H^1_{\mathrm{loc}}(\Omega^c)$ such that

$$\begin{aligned} -\Delta u - k^2 u &= 0 && \text{in } \Omega^c, \\ u &= g && \text{on } \Gamma, \\ \lim_{r\to\infty} r^{(d-1)/2}\left(\frac{\partial u}{\partial r} - iku\right) &= 0, && \text{where } r := \|x\|, \end{aligned} \tag{3.1}$$

is satisfied in a weak sense. The equation governs the process of acoustic scattering by a sound soft object; see [25].

Let $G_k(\cdot)$ be the fundamental solution of the Helmholtz equation:

$$G_k(r) = \frac{i}{4}H_0(kr), \quad \text{for } d = 2,$$
$$G_k(r) = \frac{1}{4\pi}\frac{e^{ikr}}{r}, \quad \text{for } d = 3,$$

with $r > 0$. Throughout the paper H_ν is the Hankel function of the first kind of order ν defined by

$$H_\nu(x) := J_\nu(x) + i\,Y_\nu(x), \quad x > 0,$$

where J_ν and Y_ν are the Bessel functions of the first and second kind. Employing the fundamental solution, we define, respectively, the single layer and the double layer integral operators:

$$(S_k\varphi)(x) := \int_\Gamma G_k(\|x-y\|)\varphi(y)d\Gamma_y, \quad x \in \mathbb{R}^d \setminus \Gamma, \tag{3.2}$$

$$(D_k\varphi)(x) := \int_\Gamma \frac{\partial}{\partial n_y}G_k(\|x-y\|)\varphi(y)d\Gamma_y, \quad x \in \mathbb{R}^d \setminus \Gamma, \tag{3.3}$$

where n_y is the unit normal to the surface Γ at the point $y \in \Gamma$. The corresponding boundary integral operators are defined by

$$(V_k\varphi)(x) := \int_\Gamma G_k(\|x-y\|)\varphi(y)d\Gamma_y, \quad x \in \Gamma, \tag{3.4}$$

$$(K_k\varphi)(x) := \int_\Gamma \frac{\partial}{\partial n_y}G_k(\|x-y\|)\varphi(y)d\Gamma_y, \quad x \in \Gamma. \tag{3.5}$$

We now state the well-known mapping properties of the above operators; see [9, 30].

PROPOSITION 3.1. *Let $\Omega \subset \mathbb{R}^d$, $d = 2$ or 3, be a bounded domain with smooth boundary Γ. Then for any $s \in \mathbb{R}$ the following are bounded linear operators:*

(a) $V_k : H^s(\Gamma) \to H^{s+1}(\Gamma)$,

(b) $K_k : H^s(\Gamma) \to H^{s+1}(\Gamma)$.

It is well known that every solution $\varphi \in H^{-1/2}(\Gamma)$ of $V_k\varphi = g$ has the property that $u = S_k\varphi$ satisfies the exterior Helmholtz problem (3.1). However, for countably many wave numbers k the operator V_k is not injective. To avoid this problem Brakhage and Werner [5], Leis [22], and Panič [26], independently suggested representing the solution as a combination of the single and double layer potentials,

$$u = D_k\varphi - i\alpha S_k\varphi, \tag{3.6}$$

for some coupling parameter $\alpha > 0$. The unknown density φ in (3.6) satisfies the boundary integral equation

$$g = \left(\frac{1}{2}I + K_k - i\alpha V_k\right)\varphi, \tag{3.7}$$

where I is the identity operator. We denote by $(\cdot,\cdot)_0$ the $L^2(\Gamma)$ inner product, and by $\|\cdot\|_0$ the corresponding norm, and define

$$a(\varphi, v) := (R_k\varphi, v)_0, \quad \text{where } R_k := \frac{1}{2}I + K_k - i\alpha V_k. \tag{3.8}$$

To be able to apply the abstract theory developed in section 2, we need to prove that the assumptions A1–A3 hold in this case. Proposition 3.1 implies that the condition A1 is satisfied with the choice $H = L^2(\Gamma)$. We can then define

$$a_{_H}(\varphi, v) := \frac{1}{2}(I\varphi, v)_0 \quad \text{and} \quad a_{_V}(\varphi, v) := (\widetilde{R}_k\varphi, v)_0, \qquad \text{where } \widetilde{R}_k := K_k - i\alpha V_k.$$

Therefore, $A := R_k$, $A_{_H} := \frac{1}{2}I$, and $A_{_V} := \widetilde{R}_k$. Again by Proposition 3.1, it follows that the condition A2 holds with the choice $V = L^2(\Gamma)$; trivially, V is then continuously imbedded in H. Furthermore, we can clearly set $\alpha_{_H} = 1/2$. The following proposition deals with assumption A3.

PROPOSITION 3.2. *Let $\Omega \subset \mathbb{R}^d$ be a bounded domain with smooth boundary Γ. Then, for any $g \in L^2(\Gamma)$ there exists a unique $\varphi \in L^2(\Gamma)$ such that*

$$a(\varphi, v) = (g, v)_0 \quad \textit{for all } v \in L^2(\Gamma), \tag{3.9}$$

and there exists a constant $C_{reg} > 0$, which depends on both k and Ω, such that

$$\|\varphi\|_0 \le C_{reg}\|g\|_0.$$

Moreover,

$$u = (D_k\varphi) - i\alpha\,(S_k\varphi)$$

is the solution of the Helmholtz problem (3.1).

Proof. In the original paper of Brakhage and Werner [5], the existence and uniqueness were proved for the classical formulation. To extend the proof to the variational

formulation we proceed as in [13].[1] Since $\widetilde{R}_k$ is a continuous operator from $L^2(\Gamma)$ to $H^1(\Gamma)$, and $H^1(\Gamma)$ is compactly imbedded in $L^2(\Gamma)$, we have that $\widetilde{R}_k$ is a compact operator from $L^2(\Gamma)$ to $L^2(\Gamma)$. Therefore we can apply the Fredholm–Riesz–Schauder theory to the operator $R_k = I/2 + \widetilde{R}_k$, which implies that to prove invertibility it suffices to prove injectivity; i.e., it suffices to prove that $\operatorname{Ker} R_k = \{0\}$.

Let $R_k\varphi = 0$; then $\varphi = -2\widetilde{R}_k\varphi$. Applying the mapping property $\widetilde{R}_k : H^s(\Gamma) \to H^{s+1}(\Gamma)$ twice, we have that $\varphi \in H^2(\Gamma)$ and is hence continuous. For continuous functions the proof of uniqueness given in [5] is applicable, therefore $\varphi = 0$. ∎

To find an approximation to the solution φ numerically, we use the Galerkin discretization. Let S be a finite dimensional subset of $L^2(\Gamma)$. Then, find a $\varphi_S \in S$ such that

$$a(\varphi_S, v) = (g, v)_0 \quad \text{for all } v \in S. \tag{3.10}$$

Since we have checked that all the assumptions of the abstract theory hold, from Theorem 2.1 we immediately obtain the following result.

COROLLARY 3.3. *Let S be such that $C_c\eta(S) \le 1/4$. Then* (3.10) *has a unique solution $\varphi_S \in L^2(\Gamma)$ and*

$$\|\varphi - \varphi_S\|_0 \le 4C_c \inf_{v\in S} \|\varphi - v\|_0,$$

where $\varphi \in L^2(\Gamma)$ is the solution of (3.9).

REMARK 5. *Recall the definition of $\mathcal{T}$ from the previous section. Since $\mathcal{T} = R_k^{*-1}\widetilde{R}_k$, from Proposition* 3.1 *we have that $\mathcal{T} : L^2(\Gamma) \to H^1(\Gamma)$; therefore, $\mathcal{T}$ is a smoothening operator. To emphasize the dependence of $\mathcal{T}$ on k, for the rest of the paper we denote it by $\mathcal{T}_k := \mathcal{T}$.*

We will later show that for the case of $\Omega = \mathbb{S}^2$ and a particular choice of the coupling parameter α, the constant C_c is independent of k. The result of Theorem 2.2 brings little new in this setting, since $V = H$. For the finite element method of [29], Theorem 2.2 is of more interest.

So far we have made no specification for the set S except that it is a finite dimensional subspace of $L^2(\Gamma)$. Next, we consider the special case of the usual piecewise polynomial boundary elements.

3.1. Piecewise polynomial boundary elements. Let $\mathcal{G}$ be a shape-regular triangulation of Γ. We assume that no approximation of the boundary occurs; namely,

$$\Gamma = \bigcup_{\tau\in\mathcal{G}} \tau.$$

The mesh width h is defined to be

$$h := \max\{h_\tau : \tau \in \mathcal{G}\}, \quad \text{where } h_\tau := \sup_{x,y\in\tau} \|x - y\|.$$

The set S is then defined to be a space of piecewise polynomial functions on the triangulation $\mathcal{G}$. In particular we are interested in the space $\mathcal{S}^{0,-1}_{\mathcal{G},h}$ of functions constant on each triangle $\tau \in \mathcal{G}$.

Next we give the well-known approximation property of the piecewise-constant finite element spaces.

[1] In [13] a weaker assumption is made on the smoothness of Γ but stronger on the spaces: $\Gamma \in C^{2,\lambda}$, $0 < \lambda < 1$, and $u, f \in H^{1/2}(\Gamma)$.

THEOREM 3.4. *Let $\varphi \in H^1(\Gamma)$ and $S = \mathcal{S}^{0,-1}_{\mathcal{G},h}$. There exists a constant C_A, which depends only on the minimal angle of the triangulation $\mathcal{G}$, such that*

$$\inf_{v\in S} \|\varphi - v\|_0 \le C_A h \|\varphi\|_1.$$

We now proceed to investigate the dependence of the stability and the Galerkin error on the wave number. To do this, we make the assumption that the derivatives of the solution grow proportionally with the wave number k.

DEFINITION 3.5. *For a given $\rho > 0$, the set $\mathcal{O}_{\rho,k,l}$ contains functions $\varphi \in H^l(\Gamma)$ such that*

$$\|\varphi\|_l \le \rho k^l \|\varphi\|_0.$$

The conditions under which the solution of (3.9) belongs to a class $\mathcal{O}_{\rho,k,l}$ are discussed in [8].

COROLLARY 3.6. *Let $S = \mathcal{S}^{0,-1}_{\mathcal{G},h}$, and let $\varphi \in L^2(\Gamma)$ be the solution of (3.9). If*

$$C_c C_A h \|\mathcal{T}_k\|_{H^1(\Gamma)\leftarrow L^2(\Gamma)} < 1/4,$$

the discrete problem (3.10) has a unique solution $\varphi_S \in S$. If, further, $\varphi \in \mathcal{O}_{\rho,k,1}$ and $\varphi \neq 0$, then the relative error is bounded as

$$\frac{\|\varphi - \varphi_S\|_0}{\|\varphi\|_0} \le 4 C_c C_A h k.$$

Proof. Using the approximation property of the piecewise-constant space and choosing $\widetilde{H} = H = L^2(\Gamma)$, we have that

$$\eta(S) = \sup_{\varphi\in L^2(\Gamma)\setminus\{0\}} \inf_{v\in S} \frac{\|\mathcal{T}_k\varphi - v\|_0}{\|\varphi\|_0} \le C_A \sup_{\varphi\in L^2(\Gamma)\setminus\{0\}} \frac{h\|\mathcal{T}_k\varphi\|_1}{\|\varphi\|_0} \le \frac{1}{4C_c}.$$

Hence, by Corollary 3.3, we have the required stability condition.

Let us now assume that $\varphi \in \mathcal{O}_{\rho,k,l}$. Using Corollary 3.3 again,

$$\|\varphi - \varphi_s\|_0 \le 4C_{\mathrm{c}} \inf_{v\in S} \|\varphi - v\|_0 \le 4C_c C_A h \|\varphi\|_1 \le 4C_c C_A h k \|\varphi\|_0. \qquad \square$$

In the next section we investigate the dependence of C_{c} and of $\|\mathcal{T}_k\|_{H^1(\Gamma)\leftarrow L^2(\Gamma)}$ on the wave number k. Our goal is to state the dependence on k of all the constants in Corollary 3.6 in the case of the sphere.

3.2. The special case of the unit sphere. In this section we restrict our discussion to the case $\Gamma = \mathbb{S}^2$. This case was investigated by Giebermann in [13] and by Domínguez, Graham, and Smyshlyaev in [11]. Our final result will be a slight improvement on the results of [13] and [11]. The improvement is in part due to the abstract theory developed at the start of the paper and in part due to some stronger bounds on the eigenvalues that we prove; the details are stated in Remark 6.

The Fourier coefficients of a function $f \in L^2(\mathbb{S}^2)$ are defined by

$$f_n^m := \int_{\mathbb{S}^2} Y_n^m(\hat{x})\overline{f(\hat{x})} ds_x, \tag{3.11}$$

where Y_n^m are the spherical harmonics; see [1]. Spaces equivalent to the usual Sobolev spaces on $\mathbb{S}^2$ can be defined through the Fourier coefficients.

DEFINITION 3.7. *For any $s \geq 0$, let $\mathcal{H}^s(\mathbb{S}^2)$ be the space containing all functions $f \in L^2(\mathbb{S}^2)$ whose Fourier coefficients satisfy*

$$\sum_{n=0}^{\infty} \sum_{m=-n}^{n} |f_n^m|^2 (1+n^2)^s < \infty.$$

The inner product is defined by

$$\langle f, g \rangle_s := \sum_{n=0}^{\infty} (1+n^2)^s \sum_{m=-n}^{n} f_n^m \overline{g_n^m}.$$

For negative s, $\mathcal{H}^s(\mathbb{S}^2)$ is the dual space of $\mathcal{H}^{-s}(\mathbb{S}^2)$.

In the following, j_n, y_n, and $h_n^{(1)}$ are spherical Bessel functions of the first, second, and third kind, respectively; see [1]. These can be defined through the Bessel functions

$$\begin{aligned} j_n(x) &:= \sqrt{\frac{\pi}{2x}} J_{n+\frac{1}{2}}(x), \\ y_n(x) &:= \sqrt{\frac{\pi}{2x}} Y_{n+\frac{1}{2}}(x), \\ h_n^{(1)}(x) &:= j_n(x) + i y_n(x) = \sqrt{\frac{\pi}{2x}} H_{n+\frac{1}{2}}(x). \end{aligned} \tag{3.12}$$

LEMMA 3.8.

(a) *The space $\mathcal{H}^s(\mathbb{S}^2)$ is a Hilbert space and is equivalent to $H^s(\mathbb{S}^2)$. Namely, the norms induced by the inner products are equivalent, and the sets $\mathcal{H}^s(\mathbb{S}^2)$ and $H^s(\mathbb{S}^2)$ coincide.*

(b) *The spherical harmonics form a complete orthogonal system in $\mathcal{H}^s(\mathbb{S}^2)$ and are the eigenfunctions of operators V_k, K_k, R_k, and $\mathcal{T}_k$. We have that*

$$\begin{aligned} V_k Y_n^m &= \lambda_{n,k}^{(V)} Y_n^m, \quad \text{with } \lambda_{n,k}^{(V)} := 2ikh_n^{(1)}(k) j_n(k), \\ K_k Y_n^m &= \lambda_{n,k}^{(K)} Y_n^m, \quad \text{with } \lambda_{n,k}^{(K)} := -1/2 + ik^2 h_n^{(1)}(k) j_n'(k), \\ R_k Y_n^m &= \lambda_{n,k}^{(R)} Y_n^m, \quad \text{with } \lambda_{n,k}^{(R)} := 1/2 + \lambda_{n,k}^{(K)} - i\alpha \lambda_{n,k}^{(V)} \\ &\qquad\qquad = ik^2 h_n^{(1)}(k) j_n'(k) + 2\alpha k h_n^{(1)}(k) j_n(k). \\ \mathcal{T}_k Y_m^n &= R_k^{*-1} \widetilde{R}_k Y_m^n = \lambda_{n,k}^{(\mathcal{T})} Y_n^m, \quad \text{with } \lambda_{n,k}^{(\mathcal{T})} := \frac{\lambda_{n,k}^{(K)} - i\alpha \lambda_{n,k}^{(V)}}{1/2 + \overline{\lambda_{n,k}^{(K)}} + i\alpha \overline{\lambda_{n,k}^{(V)}}}. \end{aligned}$$

(c) *For $s \geq 0$,*

$$\|R_k\|_{\mathcal{H}^s(\mathbb{S}^2) \leftarrow \mathcal{H}^s(\mathbb{S}^2)} = \sup_{n \in \mathbb{N}_0} |\lambda_{n,k}^{(R)}|, \quad \|\mathcal{T}_k\|_{\mathcal{H}^{s+1}(\mathbb{S}^2) \leftarrow \mathcal{H}^s(\mathbb{S}^2)} = \sup_{n \in \mathbb{N}_0} \sqrt{1+n^2} |\lambda_{n,k}^{(\mathcal{T})}|.$$

Proof. For the proof of (a) see [24]. The eigenvalues of the operators V_k and K_k are given in [19]. From these it is easy to derive the eigenvalues of the remaining two operators. A proof of (c) can be found in [13]; see also [24]. ∎

The above result justifies our writing $H^s(\mathbb{S}^2)$ for both $H^s(\mathbb{S}^2)$ and $\mathcal{H}^s(\mathbb{S}^2)$. We now prove some results on the Bessel functions that, in view of (3.12) and Lemma 3.8, have direct use in bounding eigenvalues $\lambda_{n,k}^{(R)}$. Recall that the Bessel functions $J_\nu(x)$ and $Y_\nu(x)$ are real valued for $\nu \in \mathbb{R}$ and $x \geq 0$.

LEMMA 3.9.
(a) $J_\nu(x), J'_\nu(x), Y'_\nu(x) > 0$, $Y_\nu(x) < 0$, *for* $0 < x < \nu$,
(b) $J_\nu(x)$ *and* $xJ'_\nu(x)$ *are positive increasing functions of* x, *for* $0 < x < \nu$,
(c) *for* $x > 0$ *the product* $x\left[J_\nu^2(x) + Y_\nu^2(x)\right]$, *as a function of* x, *decreases monotonically if* $\nu > 1/2$, *and increases monotonically if* $\nu < 1/2$.

Proof. Parts (a) and (b) are proved in Watson [32, section 15.3]. A proof of part (c) can also be found in Watson [32, section 13.74]. ∎

PROPOSITION 3.10. *There exists a constant* $C > 0$ *such that for any* $x \geq 1$ *and* $\nu \in [1/2, \infty) \cup \{0\}$,
(a) $|J_\nu(x)H_\nu(x)| \leq Cx^{-2/3}$,
(b) $|xJ'_\nu(x)H_\nu(x)| \leq C$.

Proof. A proof of part (a) for $\nu > 1/2$ is given in [13] and [11], where also a bound that is less sharp than what we prove here is given for part (b).

In the proof we make use of the following asymptotic expansions [1, (9.3.31)–(9.3.34)]:

$$\begin{aligned} J_\nu(\nu) &= a\nu^{-1/3} + O(\nu^{-5/3}), \\ Y_\nu(\nu) &= -\sqrt{3}a\nu^{-1/3} + O(\nu^{-5/3}), \\ J'_\nu(\nu) &= b\nu^{-2/3} - c\nu^{-4/3} + O(\nu^{-8/3}), \\ Y'_\nu(\nu) &= \sqrt{3}\big(b\nu^{-2/3} + c\nu^{-4/3}\big) + O(\nu^{-8/3}), \end{aligned} \tag{3.13}$$

where a, b, and c are certain positive constants.

We divide the proof into two cases, as follows.

Case 1: $\nu > x \geq 0$. Using the identity $J_\nu(x)Y'_\nu(x) - J'_\nu(x)Y_\nu(x) = 2/(\pi x)$ [1, (9.1.16)], we have that

$$0 \overset{\text{Lemma 3.9(a)}}{\leq} J_\nu(x)Y'_\nu(x) \overset{[1,\ (9.1.16)]}{=} \frac{2}{\pi x} + J'_\nu(x)Y_\nu(x).$$

Therefore,

$$|xJ'_\nu(x)Y_\nu(x)| \overset{\text{Lemma 3.9(a)}}{=} -xJ'_\nu(x)Y_\nu(x) \leq \frac{2}{\pi}.$$

Also,

$$|xJ'_\nu(x)J_\nu(x)| = xJ'_\nu(x)J_\nu(x) \overset{\text{Lemma 3.9(b)}}{\leq} \nu J'_\nu(\nu)J_\nu(\nu) \overset{(3.13)}{\leq} C,$$

where C is independent of x and ν. Combining the last two results, we have that

$$|xJ'_\nu(x)H_\nu(x)| \leq |xJ'_\nu(x)J_\nu(x)| + |xJ'_\nu(x)Y_\nu(x)| \leq C + \frac{2}{\pi} \quad \text{for } x < \nu. \tag{3.14}$$

Case 2: $1/2 < \nu \leq x$. We use the following definitions:

$$M_\nu(x) := |H_\nu(x)| \quad \text{and} \quad N_\nu(x) := |H'_\nu(x)|.$$

We have that

$$x^2|J'_\nu(x)H_\nu(x)|^2 \leq x^2N_\nu^2(x)M_\nu^2(x) \overset{[1,\ (9.2.22)]}{=} x^2{M'_\nu}^2(x)M_\nu^2(x) + \frac{4}{\pi}. \tag{3.15}$$

Next,

$$\begin{aligned} x\frac{d}{dx}\{-xM_\nu'(x)\} &\overset{[1,\ (9.2.25)]}{=} (x^2-\nu^2)M_\nu(x) - \frac{4}{\pi^2}\frac{1}{M_\nu^3(x)} = M_\nu(x)\left(x^2-\nu^2-\frac{4}{\pi^2}M_\nu^{-4}(x)\right) \\ &\overset{[14,\ (8.479)]}{\leq} M_\nu(x)\left(x^2-\nu^2-x^2\right) \leq 0. \end{aligned}$$

Hence, $-xM_\nu'(x)$ is a monotonically decreasing function. From Lemma 3.9(c) we have that, for $\nu > 1/2$, $xM_\nu^2(x)$ is monotonically decreasing, and hence $M_\nu'(x) \leq 0$. It is now not difficult to see that $xM_\nu'^2(x)$ is also a monotonically decreasing function. Therefore,

$$xM_\nu'^2(x)xM_\nu^2(x) \leq \nu^2 M_\nu'^2(\nu)M_\nu(\nu)^2 \overset{(3.13)}{\leq} C \quad \text{for } x \geq \nu > \frac{1}{2}. \tag{3.16}$$

Combining this last result with (3.14) and (3.15) gives the required bound for $\nu > 1/2$. The result for $\nu = 1/2$ is obtained by the continuity of Bessel functions in the argument ν.

Finally we prove (a) and (b) for $\nu = 0$.

$$|J_0(k)H_0(k)| \leq \frac{1}{k}kM_0^2(k) \overset{\text{Lemma 3.9(c)}}{\leq} \frac{1}{k}\lim_{k\to\infty} kM_0^2(k) \overset{[1,\ (9.2.3)]}{\leq} C\frac{1}{k} \leq Ck^{-2/3}.$$

Similarly,

$$\begin{aligned} k|J_0'(k)H_0(k)| = k|J_1(k)H_0(k)| &\leq \sqrt{k}M_1(k)\sqrt{k}M_0(k) \\ &\overset{\text{Lemma 3.9(c)}}{\leq} M_1(1)\lim_{k\to\infty}\sqrt{k}M_0(k) \overset{[1,\ (9.2.3)]}{\leq} C. \qquad \square \end{aligned}$$

COROLLARY 3.11. *Let $R_k : L^2(\mathbb{S}^2) \to L^2(\mathbb{S}^2)$ be the operator defined, as in* (3.8)*, by*

$$R_k = I/2 + K_k - i\alpha V_k.$$

Then R_k is bounded, and there exists a constant $C > 0$ independent of k such that

$$\|R_k\|_{L^2(\mathbb{S}^2)\leftarrow L^2(\mathbb{S}^2)} \leq C(1+\alpha k^{-2/3}).$$

Proof. In view of Lemma 3.8, to prove the statement we need to find bounds on the eigenvalues of the operator R_k. Using the definition of spherical Bessel functions (3.12) and Proposition 3.10, we have that

$$\left|\lambda_{n,k}^{(V)}\right| = \left|2kh_n^{(1)}(k)j_n(k)\right| = \left|\pi H_{n+\frac{1}{2}}(k)J_{n+\frac{1}{2}}(k)\right| \leq Ck^{-2/3},$$

and

$$\begin{aligned} \left|\frac{1}{2}+\lambda_{n,k}^{(K)}\right| = \left|k^2h_n^{(1)}(k)j_n'(k)\right| &= \left|\frac{\pi}{2}kH_{n+\frac{1}{2}}(k)\left(J_{n+\frac{1}{2}}'(k)+\frac{1}{2k}J_{n+\frac{1}{2}}(k)\right)\right| \\ &\leq \left|\frac{\pi}{2}kH_{n+\frac{1}{2}}(k)J_{n+\frac{1}{2}}'(k)\right| + \left|\frac{\pi}{4}H_{n+\frac{1}{2}}(k)J_{n+\frac{1}{2}}(k)\right| \leq C(1+k^{-2/3}). \end{aligned}$$

The result now follows from the identity

$$\|R_k\|_{\mathcal{H}^s(\mathbb{S}^2)\leftarrow\mathcal{H}^s(\mathbb{S}^2)} = \sup_{n\in\mathbb{N}_0}\left|\lambda_{n,k}^{(R)}\right| = \sup_{n\in\mathbb{N}_0}\left|1/2+\lambda_{n,k}^{(K)}-i\alpha\lambda_{n,k}^{(V)}\right|. \qquad \square$$

Note that for $\alpha \le k^{2/3}$, $\|R_k\|_{L^2(\mathbb{S}^2)\leftarrow L^2(\mathbb{S}^2)}$ is bounded by a constant independent of k. Numerical experiments suggest $C_c = \|R_k\|_{L^2(\mathbb{S}^2)\leftarrow L^2(\mathbb{S}^2)} \le 1.76$, for $\alpha = k^{2/3}$.

DEFINITION 3.12. *Let $\alpha := k^{2/3}$ in the definition of R_k; see* (3.8).

REMARK 6. *The choice $\alpha \propto k$ is prevalent in the literature; see* [2, 11, 13, 21]. *In* [2] *and* [21] *the choice was made to minimize the condition number of the matrices arising from the discretization of boundary integral operators in the case of the unit sphere and the unit disk. The same choice maximizes the inf-sup constant and hence optimizes the error estimate given by Céa's lemma; see* [13]. *The error estimate in Corollary* 3.3 *is not affected by the inf-sup constant, and with the choice $\alpha = k^{2/3}$ the constant of quasioptimality C_c is independent of k. Céa's lemma gives a more pessimistic bound, with the quasioptimality constant growing as $k^{1/3}$; see* [11, 13].

It remains now to find the dependence on k of the continuity constant of the operator $\mathcal{T}_k = R_k^{*-1}\widetilde{R}$. From Lemma 3.8 we have that

$$\|\mathcal{T}_k\|_{H^1(\mathbb{S}^2)\leftarrow L^2(\mathbb{S}^2)} = \sup_n \sqrt{1+n^2}|\lambda_{n,k}^{\mathcal{T}}| = \sup_n \sqrt{1+n^2}\left|\frac{\lambda_{n,k}^{(K)}-i\alpha\lambda_{n,k}^{(V)}}{1/2+\overline{\lambda_{n,k}^{(K)}}+i\alpha\overline{\lambda_{n,k}^{(V)}}}\right|.$$

By taking into account the properties of the zeros of Bessel functions (see [1, (9.5)]), it can be seen that the denominator in the above expression is never zero; however, a proof of a useful upper bound for the whole expression is beyond the scope of this paper. Instead, we consider the three asymptotic cases: k fixed and $n\to\infty$, $n\approx k$, and n fixed and $k\to\infty$.

PROPOSITION 3.13.

(a) *For fixed ν and $k\to\infty$ we have, for $\alpha \le k$,*

$$\left|\lambda_{\nu,k}^{\mathcal{T}}\right| = \left|1-\frac{1}{2e^{i\chi}\left(-\frac{2\alpha}{k}\cos\chi + i\sin\chi\right)}+O(k^{-1})\right|,$$

where $\chi = k-\nu\pi/2-\pi/2$.

(b) *For $\nu+1/2 = k$ and $\alpha \le k^{4/3}$ we have*

$$|\lambda_{\nu,k}^{\mathcal{T}}| = 1+\left|i\pi ab(1+\sqrt{3}i)+2\pi a^2(1-\sqrt{3}i)\alpha k^{-2/3}+O(k^{-2/3})\right|^{-1},$$

where a and b are constants from the asymptotic expansions (3.13).

(c) *For fixed k and $\nu\to\infty$ we have*

$$\lambda_{\nu,k}^{\mathcal{T}} = O(\nu^{-1}).$$

Proof. Part (a). We first use the definition of spherical functions to write the eigenvalues in terms of Bessel functions and then make use of asymptotic expansions given in [1, (9.2)]. From (3.12), as in proof of Corollary 3.11, we have for ν fixed and

$k \to \infty$ that

$$\begin{aligned}
\left|\lambda_{\nu,k}^{\mathcal{T}}\right| &= \left|\frac{-\frac{1}{2} + i\frac{\pi}{2}kH_{\nu+\frac{1}{2}}(k)J'_{\nu+\frac{1}{2}}(k) - \frac{\pi}{2}(\frac{i}{2} - 2\alpha)H_{\nu+\frac{1}{2}}(k)J_{\nu+\frac{1}{2}}(k)}{i\frac{\pi}{2}kH_{\nu+\frac{1}{2}}(k)J'_{\nu+\frac{1}{2}}(k) - \frac{\pi}{2}(\frac{i}{2} - 2\alpha)H_{\nu+\frac{1}{2}}(k)J_{\nu+\frac{1}{2}}(k)}\right| \\
&= \left|1 - \frac{1}{i\pi kH_{\nu+\frac{1}{2}}(k)J'_{\nu+\frac{1}{2}}(k) - \pi(\frac{i}{2} - 2\alpha)H_{\nu+\frac{1}{2}}(k)J_{\nu+\frac{1}{2}}(k)}\right| \\
&\overset{[1,\ (9.2)]}{=} \left|1 - \frac{1}{2e^{i\chi}\left(-\frac{2\alpha}{k}\cos\chi + i\sin\chi\right) - \frac{\alpha}{k}O(k^{-1}) + O(k^{-1})}\right|,
\end{aligned}$$

where $\chi = k - (\nu + 1/2)\pi/2 - \pi/4 = k - \nu\pi/2 - \pi/2$. The result now follows from the assumption $\alpha \le k$.

Part (b). Using the asymptotic expansions (3.13), we obtain that

$$\begin{aligned}
\lambda_{\nu,k}^{\mathcal{T}} = 1 + \Big|& i\pi kab\left((1+\sqrt{3}i)k^{-1} + O(k^{-5/3})\right) \\
&- \pi a^2(i/2 - 2\alpha)\left((1-\sqrt{3}i)k^{-2/3} + O(k^{-2})\right)\Big|^{-1} \\
= 1 + \Big|& i\pi ab(1+\sqrt{3}i) + 2\pi a^2(1-\sqrt{3}i)\alpha k^{-2/3} + O(k^{-2/3}) + \alpha O(k^{-2})\Big|^{-1}.
\end{aligned}$$

Part (c). For the proof, we use the asymptotic expansions given in [1, (9.3)]:

$$J_\nu(k)H_\nu(k) \overset{[1,\ (9.3.1)]}{\sim} \frac{1}{2\pi\nu}\left(\frac{ek}{2\nu}\right)^{2\nu} - i\frac{1}{\pi\nu} = O(\nu^{-1}). \tag{3.17}$$

We also make use of Stirling's approximation to the Gamma function [1, (6.1.39)]:

$$\begin{aligned}
J'_\nu(k) &\overset{[1,\ (9.1.10)]}{=} \nu\frac{(\frac{1}{2}k)^\nu}{\Gamma(\nu+1)}\left(\frac{1}{k} - \frac{2+\nu}{2\nu}\left(\frac{1}{2}k\right)\frac{1}{\nu+1} + \cdots\right) \\
&\overset{[1,\ (6.1.39)]}{\sim} \sqrt{\frac{\nu}{2\pi}}\left(\frac{ke}{2\nu}\right)^\nu\left(\frac{1}{k} + O(\nu^{-1})\right).
\end{aligned}$$

Hence,

$$J'_\nu(k)H_\nu(k) \overset{[1,\ (9.3.1)]}{\sim} -i\frac{1}{\pi k} + O(\nu^{-1}). \tag{3.18}$$

Finally,

$$\lambda_{\nu,k}^{\mathcal{T}} \overset{(3.17),\,(3.18)}{\sim} \frac{-1/2 + 1/2 + O(\nu^{-1})}{1/2 + O(\nu^{-1})} = O(\nu^{-1}). \qquad \square$$

Part (c) in the above proposition merely confirms that $\mathcal{T}_k$ is a pseudodifferential operator of order -1. From part (b) we conclude that for $n + 1/2 = k$,

$$\sqrt{1+n^2}|\lambda_{n,k}^{\mathcal{T}}| \sim O(k). \tag{3.19}$$

The denominator in the expression of part (a) is clearly never 0; however, it becomes arbitrarily close to zero for certain large enough values of k and for $\alpha < k$. Nevertheless, note that $|-\frac{2\alpha}{k}\cos\chi + i\sin\chi| \ge 2\alpha/k$, for $k > 2\alpha$. Thus,

$$|\lambda_{\nu,k}^{\mathcal{T}}| = O(k/\alpha) \quad \text{for } k > 2\alpha.$$

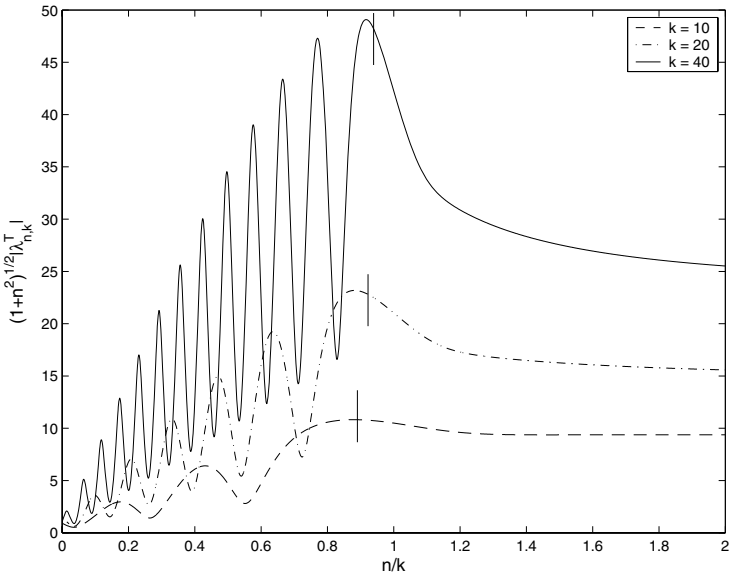

FIG. 3.1. *Plot of* $\sqrt{1+n^2}|\lambda^{\mathcal{T}}_{n,k}|$ *for different values of* n *and* k. *The vertical lines denote the positions at which* $n + 1/2 = k$.

Since $\alpha = k^{2/3}$, the condition $k > 2\alpha$ is equivalent to $k > 8$.

To see how relevant these asymptotic cases are for estimating the continuity constant, in Figure 3.1 we plot $\sqrt{1+n^2}|\lambda^{\mathcal{T}}_{n,k}|$ for different values of k and n. The picture suggests that the maximum occurs for $n + 1/2 \approx k$. Hence, in view of (3.19), we are lead to the following heuristic:

$$\|\mathcal{T}_k\|_{H^1(\mathbb{S}^2)\leftarrow L^2(\mathbb{S}^2)} \leq C_X k \tag{3.20}$$

for some constant $C_X > 0$ independent of k. Numerical experiments suggest that $C_X \leq 1.7$. In [11], it was proved that, in two dimensions with the coupling parameter $\alpha = k$ and large enough k, the eigenvalues of R_k are bounded below by $1/2$. This further supports our claim (3.20).

Now we are in a position to give estimates of the dependence on k of the stability and the accuracy of the boundary element method.

3.2.1. Piecewise-constant Galerkin boundary element method.

PROPOSITION 3.14. *Let* $\Gamma = \mathbb{S}^2$, $S = \mathcal{S}^{0,-1}_{\mathcal{G},h}$, $\varphi \in L^2(\Gamma)$ *be the solution of* (3.9), *and let* (3.20) *hold. There exists a constant* c *independent of* k *such that if* $hk < c$, *the discrete problem* (3.10) *has a unique solution* $\varphi_S \in S$. *If, further,* $\varphi \in \mathcal{O}_{\rho,k,1}$, *then there exists a constant* C *independent of* k *such that*

$$\|\varphi - \varphi_S\|_0 \leq Chk\|\varphi\|_0.$$

Therefore, the boundary element method does not suffer from the pollution effect, and a condition $hk \lesssim 1$ is sufficient to guarantee stability and a quasi-optimal error estimate.

REMARK 7. *Let us consider the two dimensional case,* $\Gamma = \{x \in \mathbb{R}^2 : \|x\| = 1\}$. *The Sobolev space* $H^s(\Gamma)$ *can be identified with the space* $H^s([0, 2\pi])$ *of* 2π *periodic*

distributions; see [2, 20]. *Periodic functions,* $e^{\pm in\theta}$, $n \in \mathbb{N}_0$, *are then the eigenfunctions of the operators* V_k *and* K_k *with eigenvalues given by*

$$\lambda_{n,k}^{(V)} = \frac{i\pi}{2} J_n(k) H_n(k), \qquad \lambda_{n,k}^{(K)} = -\frac{1}{2} + \frac{i\pi}{2} k J_n'(k) H_n(k).$$

Comparing these with the case of the sphere, it is clear that the analogous analysis of this section holds for the two dimensional case as well. In particular, the statement of Proposition 3.14 *also holds for the case of the unit ball in two dimensions.*

3.2.2. The *h*-*p* version of the Galerkin method. Just as in the finite element method [17, 18], the use of higher order polynomials improves the stability condition of the boundary element method. Let $S = \mathcal{S}_{\mathcal{G},h}^{p,1}$ be the usual boundary element space of continuous piecewise polynomial functions of order p. Using the approximation properties of such spaces proved in [15, 16, 17, 18], we proceed as in the case of piecewise-constant basis functions. Assuming that $\widetilde{H} = \mathcal{O}_{\rho,k,l}$, where $1 \le l \le p$, we obtain the estimate

$$\begin{aligned}
\eta(S) &= \sup_{\psi \in \widetilde{H}\setminus\{0\}} \inf_{v \in S} \frac{\|\mathcal{T}_k\psi - v\|_0}{\|\psi\|_0} \overset{[15,\,17]}{\le} C_A(l) \sup_{\psi \in \widetilde{H}\setminus\{0\}} \frac{\|\mathcal{T}_k\psi\|_{l+1}}{\|\psi\|_0} \left(\frac{h}{2p}\right)^{l+1} \\
&\le C_A(l) C_X k \sup_{\psi \in \widetilde{H}\setminus\{0\}} \frac{\|\psi\|_l}{\|\psi\|_0} \left(\frac{h}{2p}\right)^{l+1} \\
&\le \rho C_A(l) C_X \left(\frac{kh}{2p}\right)^{l+1},
\end{aligned}$$

where $C(l)$ is a constant depending only on l. Therefore, the condition for stability and the quasi-optimal error estimate reduces to $hk \lesssim 2p$. Thus, higher order elements allow for a coarser mesh and the following error estimate:

$$\|\varphi - \varphi_s\|_0 \le C \left(\frac{kh}{2p}\right)^{l+1} \|\varphi\|_0.$$

TIME SPLITTING ERROR IN DSMC SCHEMES FOR THE SPATIALLY HOMOGENEOUS INELASTIC BOLTZMANN EQUATION*

SERGEJ RJASANOW† AND WOLFGANG WAGNER‡

Abstract. The paper is concerned with the numerical treatment of the uniformly heated inelastic Boltzmann equation by the direct simulation Monte Carlo (DSMC) method. This technique is presently the most widely used numerical method in kinetic theory. We consider three modifications of the DSMC method and study them with respect to their efficiency and convergence properties. Convergence is investigated with respect to both the number of particles and the time step. The main issue of interest is the time step discretization error due to various splitting strategies. A scheme based on the Strang-splitting strategy is shown to be of second order with respect to time step, while there is only first order for the commonly used Euler-splitting scheme. On the other hand, a no-splitting scheme based on appropriate Markov jump processes does not produce any time step error. It is established in numerical examples that the no-splitting scheme is about two orders of magnitude more efficient than the Euler-splitting scheme. The Strang-splitting scheme reaches almost the same level of efficiency as that of the no-splitting scheme, since the deterministic time step error vanishes sufficiently fast.

1. Introduction.

A basic tool for modeling low-density flows of granular materials is the inelastic Boltzmann equation. We refer to the conference proceedings [17], [16] and to the monograph [5] for details concerning applications and an appropriate physical justification. In this paper we consider the spatially homogeneous uniformly heated inelastic Boltzmann equation

$$\partial_t f - \beta \, \Delta_v \, f = Q_\alpha(f, f) \tag{1.1}$$

with initial condition

$$f(0, v) = f_0(v). \tag{1.2}$$

Equation (1.1) describes the time evolution of a function $f(t, v)$ representing the average number of particles at time t having a velocity close to v. The symbol Δ denotes the Laplace operator and the parameter $\beta > 0$ determines the strength of the random forcing. The collision integral is most conveniently written in the weak form

$$\begin{aligned} &\int_{\mathbb{R}^3} Q_\alpha(f, f)(v) \, \varphi(v) \, dv \\ &\quad = \frac{1}{2} \int_{\mathbb{R}^3} \int_{\mathbb{R}^3} \int_{S^2} B(v, w, e) \, [\varphi(v'_\alpha) + \varphi(w'_\alpha) - \varphi(v) - \varphi(w)] \, f(v) \, f(w) \, de \, dw \, dv, \end{aligned} \tag{1.3}$$

where φ is a test function and S^2 denotes the unit sphere in the Euclidean space $\mathbb{R}^3$. The function B is called the collision kernel. The postcollisional velocities are defined by

$$
\begin{aligned}
v'_\alpha = v'_\alpha(v,w,e) &= \frac{1}{2}(v+w) + \frac{1-\alpha}{4}(v-w) + \frac{1+\alpha}{4}|v-w|\,e,\\
w'_\alpha = w'_\alpha(v,w,e) &= \frac{1}{2}(v+w) - \frac{1-\alpha}{4}(v-w) - \frac{1+\alpha}{4}|v-w|\,e.
\end{aligned}
\tag{1.4}
$$

The parameter $0 < \alpha \le 1$ is called the restitution coefficient. For $\alpha = 1$ the collisions are elastic and $Q_1(f,f)$ coincides with the classical Boltzmann collision operator. A discussion of the relevance of (1.1), as well as more references, can be found in [10].

In this paper we address the issue of the numerical treatment of (1.1) by the direct simulation Monte Carlo (DSMC) method. This technique is presently the most widely used numerical method in kinetic theory (cf. [2], [6]). It is based on a system of particles performing a random evolution that imitates the behavior of the underlying physical model. As to inelastic collisions, the homogeneous cooling state of a low-density granular flow was studied by the DSMC method in [4]. A DSMC method for uniformly heated granular fluids, described by (1.1), was introduced in [13]. Related studies were performed in [1], [21]. We refer to [8] for an account of deterministic numerical methods for the elastic Boltzmann equation and to [9] concerning a deterministic numerical approach to (1.1).

The purpose of this paper is to study three modifications of the DSMC method for the uniformly heated inelastic Boltzmann equation with respect to their efficiency and convergence properties. The main issue of interest is the time step discretization error due to various splitting strategies. The first method, from [13], implements a straightforward Euler-type splitting in analogy with the classical Bird scheme for the spatially inhomogeneous elastic Boltzmann equation. The second method follows the Strang-splitting strategy (cf. [20]). The third method, previously used in [11], avoids any time step discretization error, since no splitting is used. Convergence is studied with respect to both the number of particles and the time step. All methods are of first order with respect to the inverse number of particles. The Strang-splitting scheme is of second order with respect to the time step, while the Euler-splitting scheme is of first order. In the numerical examples, the no-splitting scheme is about two orders of magnitude more efficient than the Euler-splitting scheme. It is observed that the Strang-splitting scheme reaches almost the same level of efficiency compared to the no-splitting scheme, since the deterministic time step error vanishes sufficiently fast.

The paper is organized as follows. In section 2 we describe a Markovian particle system approximating (1.1). In section 3 we define the three DSMC algorithms mentioned above. In section 4 we introduce a test example and present the results of numerical experiments. Here we study efficiency and convergence properties of the algorithms both in the transient and in the steady state cases. Section 5 contains some concluding remarks.

2. The direct simulation process. Here we describe the time evolution of a Markovian particle system

$$
\Big(v_1(t),\dots,v_n(t)\Big), \qquad t \ge 0, \tag{2.1}
$$

where each particle is characterized by its velocity. The process (2.1) corresponds to (1.1) in the sense that the family of empirical measures

$$\nu^{(n)}(t, dv) = \frac{1}{n} \sum_{j=1}^{n} \delta_{v_j(t)}(dv) \tag{2.2}$$

converges (as $n \to \infty$) to the measures $f(t, v)\, dv$. We refer to [14], [12] concerning rigorous convergence results for a wide class of Boltzmann-type models (see also [19, section 2.3.3]).

Roughly speaking, the system interacts through binary inelastic collisions. In addition, the particles continuously gain kinetic energy due to Gaussian white noise forcing. More precisely, we assume

$$\int_{S^2} B(v, w, e)\, de \le B_{max} \qquad \forall\, v, w \in \mathbb{R}^3. \tag{2.3}$$

Then the evolution of system (2.1) is determined via the following steps.

Initial measure. System (2.1) at $t = 0$ is chosen in such a way that the empirical measure $\nu^{(n)}(0, dv)$ (cf. (2.2)) approximates the initial measure $f_0(v)\, dv$ (cf. (1.2)).

Time counter. Given system (2.1) at time t, the next interaction (collision) takes place at a random time $t + \tau$, where

$$\text{Prob}\,\{\tau \ge s\} = \exp\left(-\frac{n-1}{2} B_{max}\, s\right), \qquad s \ge 0. \tag{2.4}$$

Brownian motion. The particle velocities perform individual Brownian motions between the collisions. After some time τ without collisions, the particle velocities are given by

$$v_j(t + \tau) = v_j(t) + \sqrt{2\,\beta\,\tau}\;\xi_j, \qquad j = 1, \ldots, n, \tag{2.5}$$

where $\xi_j \in \mathbb{R}^3$ are independent standard Gaussian random variables.

Collision partners. The indices i and j of the collision partners are chosen uniformly on the set $\{1 \le i \ne j \le n\}$.

Fictitious collision. Given i and j, the collision is fictitious (the system does not change) with probability

$$1 - \frac{\int_{S^2} B(v_i, v_j, e)\, de}{B_{max}}. \tag{2.6}$$

Collision. With the remaining probability, a direction vector e is generated according to the density

$$\frac{B(v_i, v_j, e)}{\int_{S^2} B(v_i, v_j, e)\, de}, \qquad e \in S^2, \tag{2.7}$$

and the postcollisional velocities

$$v'_\alpha(v_i, v_j, e), \qquad w'_\alpha(v_i, v_j, e) \tag{2.8}$$

are computed according to the collision transformation (1.4).

3. DSMC algorithms. Here we describe three algorithms based on the Markov process introduced in the previous section. They differ in the way time splitting is carried out.

The algorithms perform the time evolution of a particle system $(v_1, \dots, v_n)$. At some observation points

$$s_m, \qquad m = 0, 1 \dots, M, \tag{3.1}$$

functionals of the system

$$\xi^{(n)} = \frac{1}{n} \sum_{j=1}^{n} \varphi(v_j) \tag{3.2}$$

are computed, where φ is an appropriate test function. The random variable (3.2) approximates the functional

$$\int_{\mathbb{R}^3} \varphi(v)\, f(s_m, v)\, dv \tag{3.3}$$

of the solution of (1.1).

In order to reduce the random fluctuations of the estimator (3.2), a number N of independent ensembles of particles is generated. The corresponding values of the random variable are denoted by $\xi_1^{(n)}, \dots, \xi_N^{(n)}$. The empirical mean value of the random variable (3.2)

$$\eta^{(n,N)} = \frac{1}{N} \sum_{j=1}^{N} \xi_j^{(n)} \tag{3.4}$$

is used as an approximation to the functional (3.3). The independent ensembles of particles are also used to estimate the random fluctuations by means of confidence intervals. For details we refer, e.g., to [19, section 3.1.4].

3.1. Euler-splitting scheme. First we describe the DSMC method introduced in [13]. It implements the idea of standard (elastic) DSMC, where the free flow and collision simulation are separated (cf. [2]). The simulation of random "kicking" and collisions is split over a time step Δt. The state of the particle system is calculated at the discrete time points

$$t_k = k\, \Delta t, \qquad k = 0, 1, \dots, \tag{3.5}$$

until all observation points (3.1) (assumed to be multiples of the time step) are reached.

ALGORITHM 3.1.

1. Initialization
   - 1.1 set system time $t = t_0$
   - 1.2 generate v_j, $j = 1, \dots, n$, according to $f_0(v)$
2. Simulation (for $k = 1, 2, \dots$)
   - 2.1 Collision step of length Δt
     - 2.1.1 compute τ according to (2.4)
     - 2.1.2 update the system time $t := t + \tau$
     - 2.1.3 if $t \geq t_k$ then go to Step 2.2

2.1.4 generate the indices $i \neq j$
2.1.5 go to Step 2.1.1 with probability (2.6)
2.1.6 generate e according to (2.7)
2.1.7 replace v_i and v_j according to (2.8)
2.2 Kicking step of length Δt
2.2.1 update all velocities (cf. (2.5))

$$v_i := v_i + \sqrt{2\beta\,\Delta t}\,\xi_i, \qquad i = 1, \dots, n$$

2.2.2 set system time $t = t_k$
3. Compute functional (3.2) at all s_m

3.2. Strang-splitting scheme. Next we describe a modification of the algorithm from the previous section. We apply the idea of the Strang splitting. This has been introduced in the context of the elastic Boltzmann equation in [15]. Its application to equations with rather general operators was studied in [3].

ALGORITHM 3.2.
1. Initialization
2. Simulation (for $k = 1, 2, \dots$)
2.1 Collision step of length $\Delta t/2$
2.2 Kicking step of length Δt
2.3 Collision step of length $\Delta t/2$
3. Computation of functionals

3.3. No-splitting scheme. Finally we recall a DSMC algorithm that was introduced in [11]. The symbols σ_j denote the last time, at which the particle j was kicked.

ALGORITHM 3.3.
1. Initialization
1.1 set system time $t = 0$
1.2 generate v_j, $j = 1, \dots, n$, according to $f_0(v)$
1.3 set $\sigma_j = 0$, $j = 1, \dots, n$
2. Simulation (for $m = 0, 1, \dots, M$)
2.1 compute τ according to (2.4)
2.2 update the system time $t := t + \tau$
2.3 if $t \geq s_m$ then go to Step 3
2.4 generate the indices $i \neq j$
2.5 update the velocities v_i and v_j (cf. (2.5))

$$v_i := v_i + \sqrt{2\beta\,(t - \sigma_i)}\,\xi_i, \quad v_j := v_j + \sqrt{2\beta\,(t - \sigma_j)}\,\xi_j$$

2.6 update the times of last kicking $\sigma_i = \sigma_j := t$
2.7 go to Step 2.1 with probability (2.6)
2.8 generate e according to (2.7)
2.9 replace v_i and v_j according to (2.8) and go to Step 2.1
3. Calculation of functionals
3.1 update the velocities of all particles (cf. (2.5))

$$v_i := v_i + \sqrt{2\beta\,(s_m - \sigma_i)}\,\xi_i, \qquad i = 1, \dots, n$$

3.2 compute (3.2)
3.3 set system time $t = s_m$ and go to Step 2.1

3.4. Comments. In Algorithms 3.1 and 3.2, the kicking step is computed accurately, i.e., without any further time discretization. Particles are just moved according to Brownian motion. The collision step contains the random interaction times distributed according to (2.4). Its accuracy depends on the number of particles. In Algorithm 3.3 particles perform Brownian motion between collisions so that any splitting errors are avoided.

One might use deterministic interaction times obtained as the expectation of the distribution (2.4). This would introduce another error, which is small for large n. We refer to [19, section 3.5.2] concerning a discussion of various time counting procedures.

Unbounded collision kernels. The *variable hard sphere model*

$$B(v,w,e) = C_\lambda\,|v-w|^\lambda, \qquad 0 \le \lambda \le 1, \tag{3.6}$$

is widely used in applications (cf. [2, Chapter 2]). Particular cases are the models of *hard spheres* ($\lambda = 1$) and of *pseudo-Maxwell molecules* ($\lambda = 0$). The kernel (3.6) does not satisfy condition (2.3), unless $\lambda = 0$. In order to fit into the framework of section 2, one has to truncate the kernel using some maximal relative velocity U_{max}. The truncated kernel

$$\hat{B}(v,w,e) = \begin{cases} B(v,w,e) & \text{if} \quad |v-w| \le U_{max}, \\ C_\lambda\, U_{max}^\lambda & \text{otherwise} \end{cases} \tag{3.7}$$

satisfies (2.3) with $B_{max} = 4\pi\, C_\lambda\, U_{max}^\lambda$. Correspondingly, the parameter of the waiting time distribution (2.4) takes the form

$$2\pi\,(n-1)\,C_\lambda\,U_{max}^\lambda. \tag{3.8}$$

The probability of a fictitious collision (2.6) is

$$1 - \left(\frac{|v_i - v_j|}{U_{max}}\right)^\lambda.$$

The density (2.7) is constant so that the vector e is distributed uniformly on the unit sphere.

Adapting majorants. There are two aspects related to the choice of the truncation parameter U_{max}. If it is small, then the solution of (1.1) for the kernel (3.7) will significantly differ from the solution for the original kernel B. If, on the other hand, the parameter U_{max} is big, then the time steps between collisions are small (inverse of parameter (3.8)) and the algorithms are time consuming. Therefore, the parameter U_{max} is usually derived from the particle system used in the simulation.

In the classical (elastic) DSMC algorithm (cf. [2]) the starting value of U_{max} is based on the temperature of the initial particle system. Then this value is adapted during the process of calculation each time the relative velocity of a pair of particles exceeds the stored quantity. This procedure works well in steady state calculations. The error related to this procedure in transient calculations was studied in [18].

A problem with finding the maximum relative velocity in a particle system is related to the fact that the effort is quadratic in the number of particles. However, this can easily be reduced to a linear effort by using the estimate

$$\max_{i,j} |v_i - v_j| \le \max_{i,j} \Big(|v_i - V| + |V - v_j| \Big) = 2 \max_i |v_i - V|,$$

where V is any fixed vector. A particular choice is the numerical bulk velocity

$$V = \frac{1}{n} \sum_{j=1}^{n} v_j.$$

Thus, one may start with $U_{max} = 2 \max_i |v_i - V|$ and update the majorant after each collision

$$U_{max} := \max \Big\{ U_{max}, |v_i - V|, |v_j - V| \Big\}. \tag{3.9}$$

This procedure is used in Algorithms 3.1 and 3.2. The situation in Algorithm 3.3 is slightly more difficult, since particle velocities change continuously as a result of the kicking process. Here we implemented the above procedure of adapting the majorant, but in addition the quantity U_{max} was updated according to (3.9) after each Step 2.5. The error caused by this truncation does not seem to be significant, as shown by the very precise tail calculations in [11].

4. Numerical examples. Here we test the algorithms introduced in the previous section with respect to their convergence properties and efficiency.

We consider the case of a constant collision kernel, namely, (3.6), with

$$\lambda = 0, \qquad C_0 = \frac{1}{\pi}. \tag{4.1}$$

Note that other values of the constant C_0 can be handled by an appropriate time scaling, since the function $f(c\,t, v)$ solves (1.1) with diffusion coefficient $c\,\beta$ and collision kernel $c\,B$, where $c > 0$ is some constant. Furthermore, we assume

$$\int_{\mathbb{R}^3} f_0(v)\, dv = 1, \qquad \int_{\mathbb{R}^3} v\, f_0(v)\, dv = 0.$$

Note the conservation properties

$$\int_{\mathbb{R}^3} f(t,v)\, dv = \int_{\mathbb{R}^3} f_0(v)\, dv, \qquad \int_{\mathbb{R}^3} v\, f(t,v)\, dv = \int_{\mathbb{R}^3} v\, f_0(v)\, dv,$$

which can be derived easily from the weak form of the equation (cf. (1.3)).

In this case the relaxation of the temperature

$$T(t) = \frac{1}{3} \int_{\mathbb{R}^3} |v|^2 f(t,v)\, dv \tag{4.2}$$

is known analytically. Assuming $0 < \alpha < 1$, one obtains (cf. [11])

$$\begin{aligned} T(t) = T_{\alpha,\beta}(t) &= T_0\, e^{-(1-\alpha^2)\,t} + T_{\alpha,\beta}(\infty) \left(1 - e^{-(1-\alpha^2)\,t} \right) \\ &= T_{\alpha,\beta}(\infty) + [T_0 - T_{\alpha,\beta}(\infty)]\, e^{-(1-\alpha^2)\,t}, \end{aligned} \tag{4.3}$$

where

$$T_0 = \frac{1}{3} \int_{\mathbb{R}^3} |v|^2 f_0(v)\, dv$$

and

$$T_{\alpha,\beta}(\infty) = \frac{2\,\beta}{1-\alpha^2}. \tag{4.4}$$

Note that

$$\lim_{\alpha\to 1} T_{\alpha,\beta}(t) = T_0 + 2\beta\, t.$$

According to (4.1), the collision kernel is bounded so that the only sources of error are the number of particles n, the time step Δt (in Algorithms 3.1 and 3.2), and the number of independent samples N (cf. (3.4)). First order of convergence with respect to n has been established under rather general assumptions (cf. [14], [12] concerning the transient case and [7] concerning the steady state case). Convergence with respect to Δt for Euler splitting (first order) and Strang splitting (second order) was studied in [3] in the context of rather general operator equations. We refer to [19, section 3.5.5] for more details.

4.1. Approximation on a finite time interval (transient case). Here we use the Maxwell distribution

$$f_0(v) = \frac{1}{(2\,\pi)^{3/2}}\, e^{-\frac{|v|^2}{2}} \tag{4.5}$$

as the initial condition. For the parameters

$$\alpha = \frac{1}{2}, \qquad \beta = 1, \tag{4.6}$$

one obtains from (4.3), (4.4)

$$T(t) = e^{-\frac{3}{4}\,t} + \frac{8}{3}\left(1 - e^{-\frac{3}{4}\,t}\right). \tag{4.7}$$

We approximate the evolution of the temperature (4.2) on the time interval $[0, 8.0]$, using (3.2) with $\varphi(v) = \frac{1}{3}\,|v|^2$ (cf. (3.3)). The time step in the splitting schemes (cf. (3.5)) is chosen in the form

$$\Delta t = \frac{8}{K}, \qquad K \geq 4.$$

Unless indicated otherwise, the results are averaged over $N = 10\,000$ independent ensembles (cf. (3.4)).

Particle number convergence. Figure 4.1 illustrates the approximation of the analytical solution (4.7) (dashed line) by confidence bands (solid lines) computed using the no-splitting scheme with two different values of n. A "zoom" on the time interval $[5.0, 8.0]$ of the no-splitting scheme for two higher values of n is shown in Figure 4.2. The analytical solution (4.7) is mostly covered by the confidence interval for $n = 4\,096$ and completely covered for $n = 65\,536$. More detailed results are given in Table 4.1. The errors are computed as

$$E_{end} = \left|\frac{T(t_K) - T_K}{T(t_K)}\right|, \qquad E_{max} = \max_{0\leq k\leq K}\left|\frac{T(t_k) - T_k}{T(t_k)}\right|,$$

where $T(t_k)$ are the exact values (4.7) of the temperature at time point t_k and T_k is the computed temperature. The convergence factors (quotients of subsequent values) are denoted by CF. The results in Table 4.1 clearly indicate the expected convergence order $O(n^{-1})$ of the error. Note that the width Conf_{end} of the confidence interval at t_K is proportional to $\frac{1}{\sqrt{n\,N}}$, since the variance of the estimator (3.2) has the order $\frac{1}{n}$.

Time step convergence. Similar convergence behavior with respect to the particle number is observed for the Euler- and Strang-splitting schemes, except that the n-limits contain an error depending on Δt. The corresponding numerical results are collected in Table 4.2. The linear convergence of the Euler-splitting scheme as well as the quadratic convergence of the Strang-splitting scheme are clearly indicated.

For $n = 4\,096$ and $K = 32$ the error of the Strang-splitting scheme is comparable to that of the no-splitting scheme, while the error of the Euler-splitting scheme is about 70 times larger. We note that for these parameters the numerical work of all

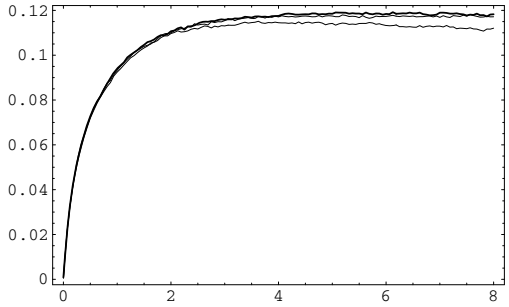

FIG. 4.3. *No-splitting scheme for* $n = 256$, 1 024, *and* 4 096 *(from below).*

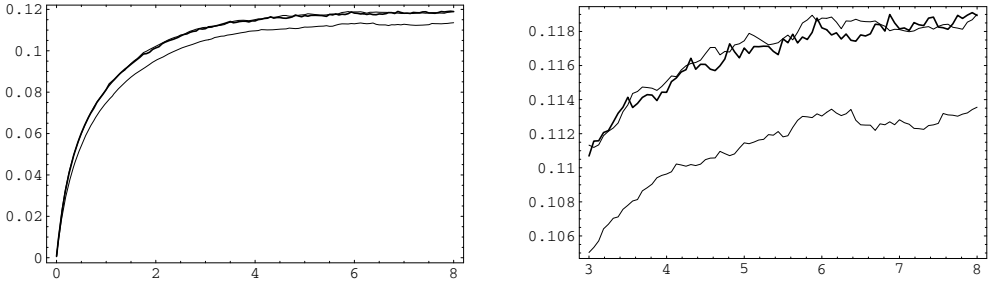

FIG. 4.4. *No-splitting scheme (thick line), Strang-splitting scheme (upper thin line), and Euler-splitting scheme (lower thin line) for* $n = 4\,096$.

schemes is roughly the same. A more detailed study of the efficiency will be made in section 4.2.

Deviation from the Maxwellian state. An interesting feature of the inelastic Boltzmann equation (1.1) is a non-Maxwellian steady state. A specific "criterion" for detecting deviations from the Maxwellian state has the form (cf. [19, section 1.8])

$$Crit(t) = \frac{1}{T(t)} \left(\frac{1}{2} \|P(t) - p(t)\, I\|_F^2 + \frac{2}{5\,T(t)} \|q(t)\|^2 + \frac{1}{120\,T(t)^2} \gamma(t)^2 \right)^{1/2}, \tag{4.8}$$

where $P(t)$ is the pressure tensor, $p(t)$ is the scalar pressure, $q(t)$ is the heat flux vector, I denotes the identity matrix, $\|A\|_F$ denotes the Frobenius norm of a matrix A, and

$$\gamma(t) = \int_{\mathcal{R}^3} \|v\|^4 f(t,v)\, dv - 15\, T(t)^2$$

is a fourth moment of the distribution function.

In Figure 4.3 we show the criterion (4.8) obtained by the no-splitting scheme with different values of n. The curves were calculated using, respectively, $N = 65\,536$, 16 192, and 4 096 repetitions. The functional starts from zero, according to (4.5), and tends to a strictly positive stationary value as $t \to \infty$. So it allows one to quantify the deviation from the Maxwellian state.

For comparison the corresponding curves for the splitting schemes with $K = 32$, $n = 4\,096$, and $N = 4\,096$ are provided in Figure 4.4. Similar to what was observed

TABLE 4.3
Euler-splitting scheme for $n = 65\,536$.

T_∞	Error	Conf	CPU
2.6684	0.0017	0.0040	1.0

for the temperature, the Strang-splitting scheme gives basically the same accuracy as the no-splitting scheme, while the error of the Euler-splitting scheme is significantly larger.

4.2. Approximation of the stationary value (steady state case). Here we consider the same example as in section 4.1 (cf. (4.7)). Figures 4.1 and 4.2 show that the stationary value $T(\infty) \sim 2.6667$ has almost been reached. So we start averaging at $s_0 = 8$ (cf. (3.1)). The quantity of interest is measured after each $\Delta t_{\max} = 2$ so that

$$s_m = s_0 + m\,\Delta t_{\max}, \qquad m = 1, \ldots, M.$$

This time step (corresponding to $K = 4$ in the context of the previous subsection) is big enough to assure almost independent observations. Confidence intervals are constructed over $M = 64$ observation points, so that $s_M = 136$.

Time step error. We choose $n = 65\,536$ so that the particle number error is negligible. Results for the different methods are given in Tables 4.3–4.5. As above, Conf denotes the width of the confidence interval and CF denotes the convergence factors (quotients of subsequent values). The CPU times for the splitting schemes are measured relative to the CPU time for the no-splitting scheme.

First order of the time step error is observed for the Euler-splitting scheme, while the Strang-splitting scheme provides second order. The no-splitting scheme avoids any time step error. Note that 0.0267 would be a 1% error.

Efficiency. The effort is roughly determined by the sum of the mean number of collisions N_{coll} and the mean number of kicks N_{kick}. These quantities can be predicted rather accurately.

The mean number of collisions is (cf. (3.8), (4.1))

$$N_{\mathrm{coll}}(n) = 2\,(n-1)\,s_M.$$

TABLE 4.6
Example (4.9) *for* $n = 65\,536$.

Method	T_∞	Error	Conf
Euler	109.596	9.596	0.1711
Strang	99.739	0.261	0.1425
no-split	99.981	0.019	0.1877

This quantity does not depend on the particular splitting procedure. The number of kicks is easily calculated from the other parameters. In the no-splitting scheme one obtains

$$N_{\text{kick}}^{\text{nosplit}}(n) = 2\,N_{\text{coll}}(n) + n\,M, \qquad M = \frac{s_M - s_0}{\Delta t_{\max}},$$

since at each collision both partners are kicked and, in addition, all particles are kicked before making a measurement. In the other methods one obtains

$$N_{\text{kick}}^{\text{split}}(n) = \frac{s_M}{\Delta t}\,n,$$

independently of the particular way of splitting. Accordingly, the effort is roughly the same for the splitting and no-splitting schemes if

$$4\,(n-1)\,s_M + n\,\frac{s_M - s_0}{\Delta t_{\max}} \;\sim\; \frac{s_M}{\Delta t}\,n$$

or

$$\frac{1}{\Delta t} \sim 4 + \frac{1}{\Delta t_{\max}}.$$

Thus, all methods have a similar effort for $\Delta t \sim \frac{1}{4}$, i.e., $K \sim 32$. In general, the effort for the splitting schemes increases inversely proportional to the time step. Note that these predictions are confirmed by the CPU measurements in Tables 4.3–4.5.

In conclusion, the Euler-splitting scheme needs running time about 100 times longer than the no-splitting scheme to cover the correct temperature by the confidence interval. The Strang-splitting scheme needs running time only about two times longer. Alternatively, with the same effort, the error for the Euler-splitting scheme is 100 times bigger than that for the no-splitting scheme, while the error for the Strang-splitting scheme is two times bigger.

These conclusions are qualitatively confirmed by a rough test for another parameter configuration, namely,

$$\alpha = 0.5, \qquad \beta = 37.5 \tag{4.9}$$

instead of (4.6). In this case the exact asymptotic value of the temperature is $T(\infty) = 100$ (cf. (4.4)). All other parameters are as above, in particular, $K = 32$, so that all three methods have approximately the same effort. The results are given in Table 4.6.

5. Concluding remarks. The direct simulation Monte Carlo (DSMC) method is one of the basic tools for the numerical treatment of nonlinear kinetic equations so that improvements of its efficiency are of significant practical importance. In this paper we considered a particular application, namely, the uniformly heated inelastic Boltzmann equation. We investigated the performance of two new DSMC algorithms

compared to a commonly used procedure. The order of convergence with respect to the numerical parameters (number of particles, time step) as well as the computational efficiency of the algorithms were studied both in the transient case (approximation of the solution on a finite time interval) and in the steady state case (approximation of the stationary solution). One scheme uses the Strang-splitting strategy instead of the Euler-splitting scheme. It provides second order time step convergence instead of first order. The other scheme is based on an appropriate Markov process avoiding any splitting procedure. It can be considered as providing infinite order time step convergence. All schemes are of first order with respect to the inverse particle number. In our particular numerical test cases, both the Strang-splitting scheme and the no-splitting scheme were up to two orders of magnitude more efficient than the Euler-splitting scheme.

Here we comment on the relevance of the results for more general applications. The first direction of generalization concerns the type of the driving force in (1.1). The adaptation of the schemes to other mechanisms instead of Brownian motion, e.g., to deterministic force terms as in [13], is rather obvious. We expect that the main messages of the paper concerning "Strang versus Euler" and "no-splitting scheme" remain valid.

It should be emphasized that in the case of inelastic collisions the spatially homogeneous situation is of independent interest, since there is some "nontrivial" behavior as, for example, a non-Maxwellian steady state. This issue has been intensively studied in recent years. The no-splitting scheme is very useful for investigating "fine" properties of the solution, as higher moments or tails of the steady state distribution. It is remarkable that the no-splitting scheme not only avoids the time step discretization error, but also is usually even more efficient than the other schemes. The quantitative value of the efficiency gain depends on the concrete example, in particular, on the level of "acceptable" time step error: if big time steps are sufficient, there is less or no efficiency gain; if small time steps are required, the efficiency gain may be rather significant.

Another interesting aspect of the present study is that it throws some additional light on the controversial issue about the order of the time step error in the elastic case ($\beta = 0$, $\alpha = 1$). Without going into detail, we refer to [19, section 3.5.5] concerning a discussion of this matter for the DSMC method in rarefied gas dynamics. Since temperature is not conserved, it provides a simple nontrivial test example in the inelastic situation. This is in contrast to the elastic case, where the time step issue can be studied only in spatially inhomogeneous examples.

A second direction of further study concerns the spatially inhomogeneous situation. In this case a term (v, ∇_x) is added to (1.1) and the solution $f(t, x, v)$ depends on three more variables (position coordinates x). The direct simulation process introduced in section 2 can be adapted to this situation. In addition to being accelerated by a random force, particles change their positions between collisions. However, DSMC algorithms in engineering applications [6] are based on splitting. The point is that it would be computationally too expensive to take into account the relative positions for the whole system at all times. The splitting should be performed by the Strang strategy, moreover, since the Strang and Euler schemes have basically the same effort per trajectory. The no-splitting approach provides alternatives for the splitting procedure in the spatially inhomogeneous situation. For example, the acceleration term might be combined either with the motion term or with the collision term. Additional time step errors should be avoided, whenever this is possible, and the no-splitting idea may help to do so.

FRAMEWORK FOR THE A POSTERIORI ERROR ANALYSIS OF NONCONFORMING FINITE ELEMENTS*

CARSTEN CARSTENSEN†, JUN HU‡, AND ANTONIO ORLANDO§

Abstract. This paper establishes a unified framework for the a posteriori error analysis of a large class of nonconforming finite element methods. The theory assures reliability and efficiency of explicit residual error estimates up to data oscillations under the conditions (H1)–(H2) and applies to several nonconforming finite elements: the Crouzeix–Raviart triangle element, the Han parallelogram element, the nonconforming rotated (NR) parallelogram element of Rannacher and Turek, the constrained NR parallelogram element of Hu and Shi, the P_1 element on parallelograms due to Park and Sheen, and the DSSY parallelogram element. The theory is extended to include 1-irregular meshes with at most one hanging node per edge.

Key words. nonconforming quadrilateral finite elements, a posteriori error analysis

AMS subject classifications. 65N30, 65R20, 73C50

DOI. 10.1137/050628854

1. Introduction.

Nonconforming finite element methods are very appealing for the numerical approximation of partial differential equations, for they enjoy better stability properties compared to the conforming finite elements. While the study of the approximation properties of nonconforming triangular and quadrilateral elements has reached a certain level of maturity [3, 18, 27], the a posteriori error analysis of nonconforming quadrilateral finite element approximations is still in its infancy.

Following the contribution of [16, 15] the a posteriori error analysis for the L^2 norm of the piecewise gradient of the error, $\|\nabla_h e\|_{L^2(\Omega)}$, has been carried out successfully for triangular elements [9, 1] on the basis of two arguments: (a) the Helmholtz decomposition of $\nabla_h e$, and (b) some orthogonality with respect to some conforming finite element space V_h^c. Condition (b) fails for some quadrilateral nonconforming finite elements, e.g., the nonconforming rotated quadrilateral element of Rannacher and Turek, referred to as the NR element [25]. As a result, the a posteriori error analysis of $\|\nabla_h e\|_{L^2(\Omega)}$ for nonconforming quadrilateral elements appears as a minefield. For the NR element, for instance, the work [23] bypasses condition (b) by some enlargement of V_h^{nc} with local bubble trial functions, but their analysis applies only to goal-oriented error control and cannot be extended to the control of $\|\nabla_h e\|_{L^2(\Omega)}$. Another inherent mathematical difficulty for the NR element functions results from the nonequivalence of the continuity at midpoints *and* the equality of integral averages along edges. This makes the operator Π in [2] *not* well defined (while correct for all triangular elements of [1]).

This paper aims to clarify and develop a unified framework for the a posteriori error analysis of nonconforming finite element methods based on properties for meshes obtained through affine mappings. The resulting framework is exemplified in the two-dimensional elliptic model problem

$$\operatorname{div} \nabla u = f \text{ in } \Omega, \quad u = u_D \text{ on } \Gamma_D, \quad \nabla u \cdot \nu = g \text{ on } \Gamma_N \tag{1.1}$$

on some Lipschitz domain $\Omega \subset \mathbb{R}^2$ with the outward unit normal ν along $\partial\Omega := \Gamma_D \cup \Gamma_N$. Let $V := \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\}$ denote the space of the test functions approximated by conforming, $V_{h,0}^c$, and nonconforming, $V_{h,0}^{nc}$, finite element spaces associated with a shape regular triangulation $\mathcal{T}$, with $\mathcal{E}$ the set of the edges and $\mathcal{E}(\Omega)$ and $\mathcal{E}(\Gamma_D)$ the interior and boundary edges, respectively. Also, define $[v_h]$ as the jump across $E \in \mathcal{E}(\Omega)$ of the general discontinuous $v_h \in V_h^{nc}$ and $\mathbb{P}_k(\omega)$ the polynomials of total degree k on the domain ω. Throughout the paper, the hypotheses (H1)–(H2) characterize some class of nonconforming finite elements allowing for efficient and reliable error control.

(H1) For all $v_h \in V_h^{nc}$ there holds

$$\int_E [v_h]\, ds = 0 \text{ for } E \in \mathcal{E}(\Omega) \quad \text{and} \quad \int_E (v_h - u_D)\, ds = 0 \text{ for } E \in \mathcal{E}(\Gamma_D). \tag{1.2}$$

(H2) There exists some bounded, linear operator $\Pi : V \mapsto V_{h,0}^{nc}$ and some mesh size independent constant C with the properties (1.3)–(1.5) for every $v_h \in V_{h,0}^c$, $K \in \mathcal{T}$, and $E \in \mathcal{E}$,

$$\int_K \nabla w_h \cdot \nabla (v_h - \Pi v_h)\, dx = 0 \quad \text{for all } w_h \in V_h^{nc}; \tag{1.3}$$

$$\int_K (v_h - \Pi v_h)\, dx = 0; \quad \int_E (v_h - \Pi v_h)\, ds = 0; \tag{1.4}$$

$$\|\nabla \Pi v_h\|_{L^2(K)} \le C \|\nabla v_h\|_{L^2(K)}. \tag{1.5}$$

The main result of the paper (Theorem 3.1 below) establishes the reliability of

$$\eta^2 := \sum_{K \in \mathcal{T}} \eta_K^2 + \sum_{E \in \mathcal{E}} \eta_E^2, \quad \text{with} \tag{1.6}$$

$$\eta_K^2 := h_K^2 \|f + \operatorname{div} \nabla u_h\|_{L^2(K)}^2 \text{ for } K \in \mathcal{T}; \tag{1.7}$$

$$\eta_E^2 := h_E \big(\|J_{E,\nu}\|_{L^2(E)}^2 + \|J_{E,\tau}\|_{L^2(E)}^2 \big) \text{ for } E \in \mathcal{E}, \tag{1.8}$$

up to the data oscillations $\operatorname{osc}(f)$ and $\operatorname{osc}(g)$ (see section 2.5 below):

$$\|\nabla_h (u - u_h)\|_{L^2(\Omega)} \le C(\eta + \operatorname{osc}(f) + \operatorname{osc}(g)), \tag{1.9}$$

with $J_{E,\nu}$ and $J_{E,\tau}$ defined by (2.9) and (2.10), respectively.

The weak continuity condition (H1) is met by quite a large class of nonconforming finite elements proposed in the literature [14, 19, 25, 17, 24, 21]. However, there are also elements that fail the above condition, for instance, the version of the Rannacher–Turek element [25] with local degree of freedom equal to the value of the function at the midside nodes of each edge, and the nonconforming quadrilateral element of Wilson et al. [29]. Both elements are therefore ruled out by the present analysis.

Condition (H2) represents a key assumption of the theory. It weakens the orthogonality condition (b) mentioned above (see Lemma 3.3 below) by means of an estimate depending on data oscillations and allows the analysis of nonconforming finite elements obtained through affine mappings.

The efficiency of η in the sense that there exists a mesh size–independent constant C such that

$$\eta \leq C(\|\nabla_h e\|_{L^2(\Omega)} + \operatorname{osc}(f) + \operatorname{osc}(u_D) + \operatorname{osc}(g)), \tag{1.10}$$

with $\operatorname{osc}(u_D)$ defined in section 2.5, can be proved by adapting the arguments from [28, pp. 15–18] and [16, 9].

An outline of the remaining parts of the paper is as follows. Section 2 displays the setup of the model problem (1.1), and introduces the conforming and nonconforming finite element spaces as well as the a posteriori error estimate (1.6) and the data oscillations in (1.9). Theorem 3.1 shows that the abstract conditions (H1)–(H2) imply the reliability in the sense of (1.9). This is stated and proved in section 3 in the abstract framework, while the relevant examples follow in section 4. Namely, applications of the theory are given for the Crouzeix–Raviart element, the Han element [19], the NR element [25] with local degrees of freedom equal to the average value over the edges, the constrained NR element of Hu and Shi [21], the P_1 quadrilateral element of Park and Sheen [24], and the DSSY element [17]. Section 4 concludes with a discussion of the applicability of the theory to 1-irregular meshes, with at most one hanging node per edge, and its generalization to elliptic systems. Section 5 describes an adaptive finite element method and a numerical example for the NR element with hanging nodes.

2. Notation and preliminaries.

2.1. Model problem. Let Ω be a polygonal domain in $\mathbb{R}^2$ with boundary $\Gamma := \partial\Omega$ split into a closed Dirichlet boundary $\Gamma_D \subseteq \Gamma$ with positive surface measure and the remaining Neumann boundary $\Gamma_N := \Gamma \setminus \Gamma_D$. Given $f \in L^2(\Omega)$, $g \in L^2(\Gamma_N)$, $u_D \in H^{1/2}(\Gamma_D)$, and $V := \{v \in H^1(\Omega) : v = 0 \text{ on } \Gamma_D\}$, the solution of (1.1) satisfies

$$\int_\Omega \nabla u \cdot \nabla v \, dx = \int_\Omega f v \, dx + \int_{\Gamma_N} g v \, ds \quad \text{for every } v \in V, \tag{2.1}$$

where the symbol $\cdot$ is the scalar product in the Euclidean space $\mathbb{R}^2$. Furthermore, we denote by L^2 the Lebesgue space of square integrable functions, and by H^s with $s > 0$ the Sobolev space defined in the usual way [18]. For the corresponding norm we use the symbols $\|\cdot\|_{L^2}$ and $\|\cdot\|_{H^s}$, respectively, with explicit indication of the domain of integration. With Ω an open set of $\mathbb{R}^2$, and $\varphi \in H^1(\Omega)$, the curl and gradient operators are given as

$$\operatorname{curl}\varphi = (-\partial\varphi/\partial x_2, \, \partial\varphi/\partial x_1), \quad \nabla\varphi = (\partial\varphi/\partial x_1, \, \partial\varphi/\partial x_2), \tag{2.2}$$

whereas for an $\mathbb{R}^2$-valued function $v = (v_1, v_2)$ the divergence is

$$\operatorname{div} v = \partial v_1/\partial x_1 + \partial v_2/\partial x_2. \tag{2.3}$$

Throughout the paper, the letter C denotes a generic constant, not necessarily the same at each occurrence.

2.2. Conforming finite element spaces. For approximating (2.1) by the finite element method, we introduce a regular triangulation $\mathcal{T}$ of $\bar{\Omega} \subset \mathbb{R}^2$ in the sense of Ciarlet [12, 6] into closed triangles, and/or convex quadrilaterals, such that $\bigcup_{K\in\mathcal{T}} K = \bar{\Omega}$, two distinct elements K and K' in $\mathcal{T}$ are either disjoint, or share the common edge E, or a common vertex; that is, hanging nodes at this stage are not allowed, and we refer to section 4.6 and [11] for further discussion. Let $\mathcal{E}$ denote the set of all edges in $\mathcal{T}$, $\mathcal{N}$ the set of vertices of the elements $K \in \mathcal{T}$, and $\mathcal{N}_m$ the set of the midside nodes m_E of the edges $E \in \mathcal{E}$. The set of interior edges of Ω are denoted by $\mathcal{E}(\Omega)$, the set of edges of the element K by $\mathcal{E}(K)$, whereas those that belong to the Dirichlet and Neumann boundary are denoted by $\mathcal{E}(\Gamma_D)$ and $\mathcal{E}(\Gamma_N)$, respectively. For the set of midpoints of the edges $E \in \mathcal{E}(\Gamma_D)$ we use the notation $\mathcal{N}_m(\Gamma_D)$. By h_K and h_E we denote the diameter of the element $K \in \mathcal{T}$ and of the edge $E \in \mathcal{E}$, respectively. Also, we denote by ω_K the patch of elements $K' \in \mathcal{T}$ that share an edge with K, and by ω_E the patch of elements having in common the edge E. Given any edge $E \in \mathcal{E}$ we assign one fixed unit normal ν_E; if (ν_1, ν_2) are its components, τ_E denotes the orthogonal vector of components $(-\nu_2, \nu_1)$. For $E \in \mathcal{E}(\Gamma_D) \cup \mathcal{E}(\Gamma_N)$ on the boundary we choose $\nu_E = \nu$, the unit outward normal to Ω, and concordantly the unit tangent vector τ. Once ν_E and τ_E have been fixed on E, in relation to ν_E one defines the elements $K_{in} \in \mathcal{T}$ and $K_{out} \in \mathcal{T}$, with $E = K_{out} \cap K_{in}$, as depicted in Figure 1.

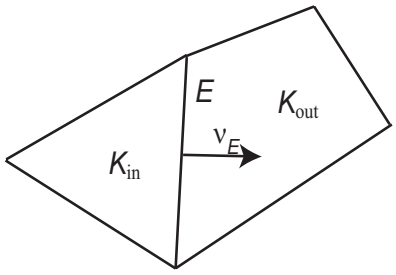

FIG. 1. *Definition of the elements K_{in} and K_{out} in relation to ν_E.*

Given $E \in \mathcal{E}(\Omega)$ and an $\mathbb{R}^d$-valued function v defined in Ω, with $d = 1, 2$, we denote by $[v]_E$ the jump of v across E, that is,

$$[v]_E(x) = (v|_{K_{out}}(x) - v|_{K_{in}}(x)) \quad \text{for } x \in E = K_{in} \cap K_{out};$$

the subscript E will be omitted whenever it is clear from the context.

With the triangulation $\mathcal{T}$ we associate, moreover, the space $H^1(\mathcal{T})$ defined as

$$H^1(\mathcal{T}) = \{v \in L^2(\Omega) : \forall K \in \mathcal{T},\, v|_K \in H^1(K)\},$$

and for $v \in H^1(\mathcal{T})$, we denote by $\nabla_h v$ the gradient operator defined piecewise with respect to $\mathcal{T}$, i.e.,

$$\nabla_h v|_K := \nabla(v|_K).$$

Whenever it is clear from the context that we are considering the restriction of v to an element $K \in \mathcal{T}$, then we clearly write only ∇v in lieu of $\nabla_h v$.

For a nonnegative integer k the space $Q_k(\omega)$ consists of polynomials of total degree at most k defined over ω in the case in which $\omega = K$ is a triangle, whereas it denotes polynomials of degree at most k in each variable in the case in which K is a

quadrilateral. For this presentation it will suffice to assume $k = 1$. The corresponding conforming space will be denoted by

$$V_h^c := \{v \in H^1(\Omega) : v|_K \in Q_1(K)\} \quad \text{and} \quad V_{h,0}^c := \{v \in V_h^c : v = 0 \text{ on } \Gamma_D\}.$$

Throughout the paper, for triangular elements, $V_{h,0}^c$ stands for the conforming space of P_1 elements, whereas for quadrilateral elements it denotes the conforming space of bilinear elements.

Given the conforming finite element space $V_{h,0}^c$, we consider the Clément interpolation operator or any other regularized conforming finite element approximation operator $\mathcal{J} : H^1(\Omega) \mapsto V_h^c$ with the property

$$\|\nabla \mathcal{J}\varphi\|_{L^2(K)} + \|h_K^{-1}(\varphi - \mathcal{J}\varphi)\|_{L^2(K)} \le C\|\nabla\varphi\|_{L^2(\omega_K)}, \tag{2.4}$$

$$\|h_E^{-1/2}(\varphi - \mathcal{J}\varphi)\|_{L^2(E)} \le C\|\nabla\varphi\|_{L^2(\omega_E)} \tag{2.5}$$

for all $K \in \mathcal{T}$, $E \in \mathcal{E}$, and $\varphi \in H^1(\Omega)$. The existence of such operators is guaranteed, for instance, in [13, 26, 7, 5].

2.3. Nonconforming finite element spaces and a posteriori error estimator. A nonconforming finite element approximation is defined by a finite-dimensional trial space $V_h^{nc} \subset H^1(\mathcal{T})$ along with the test space $V_{h,0}^{nc}$ corresponding to the discrete homogeneous Dirichlet boundary conditions. The nonconforming finite element approximation $u_h \in V_h^{nc}$ of (2.1) then satisfies

$$\int_\Omega \nabla_h u_h \cdot \nabla_h v_h \, dx = \int_\Omega f v_h \, dx + \int_{\Gamma_N} g v_h \, ds \quad \text{for every } v_h \in V_{h,0}^{nc}. \tag{2.6}$$

The Helmholtz decomposition is a well-established tool in the a posteriori error analysis of nonconforming finite element methods [16, 9].

LEMMA 2.1. *Given any $e \in V + V_h^{nc}$ such that $\nabla_h e \in L^2(\Omega;\mathbb{R}^2)$ there exist w, $\varphi \in H^1(\Omega)$ with $w = 0$ on Γ_D, and $\nabla\varphi \cdot \tau = \operatorname{curl}\varphi \cdot \nu = 0$ on Γ_N such that*

$$\nabla_h e = \nabla w + \operatorname{curl}\varphi, \tag{2.7}$$

$$\|\nabla_h e\|_{L^2(\Omega)}^2 = \|\nabla w\|_{L^2(\Omega)}^2 + \|\operatorname{curl}\varphi\|_{L^2(\Omega)}^2. \tag{2.8}$$

2.4. A posteriori error estimator. For each edge $E \in \mathcal{E}$, define $J_{E,\nu}$ the jump of $\nabla_h u_h$ across E in direction ν_E, i.e.,

$$J_{E,\nu} := \begin{cases} [\nabla_h u_h]_E \cdot \nu_E & \text{if } E \in \mathcal{E}_\Omega, \\ g - \nabla u_h \cdot \nu & \text{if } E \in \mathcal{E}_N, \\ 0 & \text{if } E \in \mathcal{E}_D, \end{cases} \tag{2.9}$$

and $J_{E,\tau}$ the jump of $\nabla_h u_h$ across E in direction t_E, i.e.,

$$J_{E,\tau} := \begin{cases} [\nabla_h u_h]_E \cdot \tau_E & \text{if } E \in \mathcal{E}_\Omega, \\ 0 & \text{if } E \in \mathcal{E}_N, \\ (\nabla u_D - \nabla u_h) \cdot \tau & \text{if } E \in \mathcal{E}_D, \end{cases} \tag{2.10}$$

and recall η from (1.6) with the local contributions η_K (1.7) and η_E (1.8) for each $K \in \mathcal{T}$ and $E \in \mathcal{E}$, respectively.

2.5. Data oscillations. For $f \in L^2(\Omega)$ and its piecewise constant approximation f_h with respect to $\mathcal{T}$, we refer to $\operatorname{osc}(f)$ as the oscillation of f [28],

$$\operatorname{osc}^2(f) := \sum_{K\in\mathcal{T}} h_K^2 \|f - f_h\|^2_{L^2(K)}, \tag{2.11}$$

with $\operatorname{osc}(f)$ being a higher order term if $f \in H^1(\Omega)$. Similar definitions hold for the oscillations $\operatorname{osc}(u_D)$ and $\operatorname{osc}(g)$ of the Dirichlet and Neumann boundary data, $u_D \in H^{1/2}(\Gamma_D)$ and $g \in L^2(\Gamma_N)$, and their piecewise affine and constant approximations $u_{D,h}$ and g_h, respectively, as [28, 8]

$$\operatorname{osc}^2(u_D) := \sum_{E\in\mathcal{E}(\Gamma_D)} h_E \left\| \frac{\partial}{\partial s}(u_D - u_{D,h}) \right\|^2_{L^2(E)},$$

$$\operatorname{osc}^2(g) := \sum_{E\in\mathcal{E}(\Gamma_N)} h_E \|g - g_h\|^2_{L^2(E)}.$$

3. Reliability of η. This section presents the main result of this paper, that is, (H1)–(H2) imply the reliability of η. Throughout this section, let u solve (2.1), let u_h solve (2.6), and set $e := u - u_h$.

THEOREM 3.1. *Assume that the space V_h^{nc} along with the corresponding $V_{h,0}^{nc}$ satisfy* (H1)–(H2). *Then there exists a positive constant C depending only on the minimum angle of $\mathcal{T}$ such that η is reliable in the sense that*

$$\|\nabla_h e\|_{L^2(\Omega)} \le C\big(\eta + \operatorname{osc}(f) + \operatorname{osc}(g)\big). \tag{3.1}$$

The remainder of this section is devoted to the proof of Theorem 3.1.

We establish first some interpolation error estimates for the operator Π in (H2).

LEMMA 3.2. *Given the operator Π meeting* (H2), *there then exists some mesh size–independent constant C such that there holds*

$$\begin{aligned} h_K^{-1}\|v_h - \Pi v_h\|_{L^2(K)} + \|\nabla(v_h - \Pi v_h)\|_{L^2(K)} &\le C\|\nabla v_h\|_{L^2(K)}, \\ h_E^{-1/2}\|v_h - \Pi v_h\|_{L^2(E)} &\le C\|\nabla v_h\|_{L^2(\omega_E)}. \end{aligned} \tag{3.2}$$

Proof. Let Π_0^K denote the mean average operator over K. Using condition $(1.4)_1$ with $\Pi_0^K v_h = \Pi_0^K \Pi\, v_h$, the triangular inequality, and (1.5), one obtains

$$\begin{aligned} \|v_h - \Pi v_h\|_{L^2(K)} &\le \|v_h - \Pi_0^K v_h\|_{L^2(K)} + \|\Pi_0^K \Pi v_h - \Pi v_h\|_{L^2(K)} \\ &\le C(h_K\|\nabla v_h\|_{L^2(K)} + h_K\|\nabla v_h\|_{L^2(K)}). \end{aligned} \tag{3.3}$$

A triangular inequality and (1.5) also gives

$$\|\nabla v_h - \nabla\,\Pi v_h\|_{L^2(K)} \le C\|\nabla v_h\|_{L^2(K)},$$

which, combined with (3.3), finally yields $(3.2)_1$. Arguing in a similar way and using the trace theorem [6, 12] one obtains $(3.2)_2$. ∎

Here and throughout, f_h and g_h denote piecewise constant approximations of f and g, respectively. From (H2) and for every $v_h \in V_{h,0}^c$, the following holds:

$$\int_\Omega \nabla_h u_h \cdot \nabla v_h\, dx = \int_\Omega f\,\Pi v_h\, dx + \int_{\Gamma_N} g\,\Pi v_h\, ds. \tag{3.4}$$

LEMMA 3.3. *There exists a mesh size–independent constant C such that, for every $v_h \in V_{h,0}^c$, the following holds:*

$$\int_\Omega \nabla_h e \cdot \nabla v_h \, dx \le C(\mathrm{osc}(f) + \mathrm{osc}(g)) \, \|\nabla v_h\|_{L^2(\Omega)}. \tag{3.5}$$

Proof. From (2.1) and (3.4), for every $v_h \in V_{h,0}^c$ it follows that

$$\int_\Omega \nabla_h e \cdot \nabla v_h \, dx = \sum_{K\in\mathcal{T}} \Big(\int_K (f - f_h)(v_h - \Pi v_h) \, dx + \int_K f_h(v_h - \Pi v_h) \, dx \Big) + \sum_{E\in\mathcal{E}(\Gamma_N)} \Big(\int_E (g - g_h)(v_h - \Pi v_h) \, ds + \int_E g_h(v_h - \Pi v_h) \, ds \Big).$$

Since (1.4), this equals

$$\int_\Omega (f - f_h)(v_h - \Pi v_h) \, dx + \int_{\Gamma_N} (g - g_h)(v_h - \Pi v_h) \, ds.$$

The combination of Cauchy inequalities with (3.2) yields its upper bound:

$$C\bigg(\Big(\sum_{K\in\mathcal{T}} h_K^2 \|f - f_h\|_{L^2(K)}^2 \Big)^{1/2} + \Big(\sum_{E\in\mathcal{E}(\Gamma_N)} h_E \|g - g_h\|_{L^2(E)}^2 \Big)^{1/2} \bigg) \|\nabla v_h\|_{L^2(\Omega)}. \qquad \square$$

Remark 1. If $V_{h,0}^c$ is a subspace of $V_{h,0}^{nc}$, then (H1)–(H2) hold for $\Pi = I$ and (3.5) recovers the L^2-orthogonality of $\nabla_h e$ and ∇v_h for every $v_h \in V_{h,0}^c$ (because $C = 0$ in (3.2)).

The following orthogonality condition (3.6) is well established in the literature on a posteriori error estimates for nonconforming finite element schemes.

LEMMA 3.4. *For every $v_h \in V_h^c$ such that $\partial v_h/\partial s = 0$ on Γ_N, it holds that*

$$\int_\Omega \nabla_h e \cdot \mathrm{curl}\, v_h \, dx = 0. \tag{3.6}$$

Proof. The proof is along the lines of [16, eqn. (3.4)] for the Crouzeix–Raviart element. An integration by parts over each element gives

$$\int_\Omega \nabla_h e \cdot \mathrm{curl}\, v_h \, dx = \sum_{E\in\mathcal{E}} \int_E [u - u_h] \frac{\partial v_h}{\partial s} \, ds. \tag{3.7}$$

Since for $v_h \in V_h^c$, $\partial v_h/\partial s$ is constant over each edge $E \in \mathcal{E}(\Omega) \cup \mathcal{E}(\Gamma_D)$, or is zero on $E \in \mathcal{E}(\Gamma_N)$, accounting for (H1), one obtains (3.6). $\square$

The proof of (3.1) starts with the decomposition (2.7), the interpolation operator $\mathcal{J}$ of Clément, and Lemma 3.4. Without loss of generality one can choose φ in (2.7) to be equal to a constant on Γ_N, and $\mathcal{J}\varphi|_{\Gamma_N} = \varphi|_{\Gamma_N}$. Then it follows that

$$\|\nabla_h e\|_{L^2(\Omega)}^2 = \int_\Omega \nabla_h e \cdot (\nabla w + \mathrm{curl}\, \varphi) \, dx = \int_\Omega \nabla_h e \cdot \nabla(w - \mathcal{J}w) \, dx + \int_\Omega \nabla_h e \cdot \mathrm{curl}(\varphi - \mathcal{J}\varphi) \, dx + \int_\Omega \nabla_h e \cdot \nabla \mathcal{J} w \, dx.$$

From Lemma 3.3 and the estimate (2.4), one obtains

$$\begin{aligned}\int_\Omega \nabla_h e \cdot \nabla \mathcal{J} w \, dx &\le C\big(\operatorname{osc}(f) + \operatorname{osc}(g)\big)\|\nabla \mathcal{J} w\|_{L^2(\Omega)} \\ &\le C\big(\operatorname{osc}(f) + \operatorname{osc}(g)\big)\|\nabla w\|_{L^2(\Omega)}.\end{aligned} \tag{3.8}$$

Since $(w - \mathcal{J}w)$ and $(\varphi - \mathcal{J}\varphi)$ belong to $H^1(\Omega)$, the use of the Stokes theorem and Green's formula over each element gives, after some rearrangements,

$$\begin{aligned}&\int_\Omega \nabla_h e \cdot \nabla(w - \mathcal{J}w)\, dx + \int_\Omega \nabla_h e \cdot \operatorname{curl}(\varphi - \mathcal{J}\varphi)\, dx \\ &= \sum_{E\in\mathcal{E}} \left(\int_E J_{E,\tau}(\varphi - \mathcal{J}\varphi)\, ds + \int_E J_{E,\nu}(w - \mathcal{J}w)\, ds \right) \\ &+ \sum_{K\in\mathcal{T}} \int_K (f + \operatorname{div} \nabla u_h)\,(w - \mathcal{J}w)\, dx.\end{aligned}$$

It is a standard argument with Cauchy inequalities and (2.4)–(2.5) to bound this by

$$C\eta\big(\|\nabla w\|_{L^2(\Omega)} + \|\nabla \varphi\|_{L^2(\Omega)}\big),$$

with η from (1.6). The combination of the aforementioned estimates with (2.8) concludes the proof of (3.1).

4. Examples. In this section, we verify (H1)–(H2) for several nonconforming finite elements proposed in the literature and discuss the applicability of the theory to 1-irregular meshes and to elliptic systems in divergence form. For the following examples, the operator Π that enters (H2) is the interpolation operator of V associated with $V_{h,0}^{nc}$.

4.1. The Crouzeix–Raviart element. The nonconforming finite element space associated with the Crouzeix–Raviart element [14] reads

$$\begin{aligned}V_h^{nc} := \big\{ v_h \in H^1(\mathcal{T}) :\ & v_h|_K \in P_1(K) \quad \forall K \in \mathcal{T},\ v_h \text{ is continuous at each} \\ & m_E \in \mathcal{N}_m \setminus \mathcal{N}_m(\Gamma_D),\ \text{and } v_h(m_E) = u_D(m_E) \text{ for } m_E \in \mathcal{N}_m(\Gamma_D)\big\},\end{aligned} \tag{4.1}$$

and $V_{h,0}^{nc}$ denotes the space corresponding to the discrete homogeneous Dirichlet boundary conditions. For this element, it is trivial to check that the space V_h^{nc} meets (H1). Furthermore, since $V_{h,0}^c \subset V_{h,0}^{nc}$, (H2) follows immediately (see Remark 1) and Theorem 3.1 recovers the results of [16, 9].

4.2. The Han element. With respect to the global coordinate system (x_1, x_2), the nonparametric formulation of rectangular and parallelogram elements proposed by Han in [19] is obtained by introducing the local space

$$\mathcal{Q}_{\mathcal{H}}^{nc} = \operatorname{span}\left\{ 1,\, x_1,\, x_2,\, x_1^2 - \frac{5}{3}x_1^4,\, x_2^2 - \frac{5}{3}x_2^4 \right\}, \tag{4.2}$$

and the $\mathcal{Q}_{\mathcal{H}}^{nc}$-unisolvent set of linearly independent linear forms [12, 19] reads

$$\mathcal{F}_E(v) = \frac{1}{h_E}\int_E v\, ds, \quad \mathcal{F}_K(v) = \frac{1}{|K|}\int_K v\, dx \text{ with } E \in \mathcal{E}(K), \quad K \in \mathcal{T}. \tag{4.3}$$

This defines the five degrees of freedom for the Han element. In (4.3), $|K|$ denotes the area of the element. Recall from [12] that, given $E = K \cap K'$ for K, $K' \in \mathcal{T}$, and $v \in H^1(\mathcal{T})$ such that $v|_K \in \mathcal{Q}^{nc}_{\mathcal{H}}(K)$ and $v|_{K'} \in \mathcal{Q}^{nc}_{\mathcal{H}}(K')$, we say that v is continuous with respect to $\mathcal{F}_E$ if $\mathcal{F}_E(v|_K) = \mathcal{F}_E(v|_{K'})$. The nonconforming finite element space V_h^{nc} is then defined as

(4.4)
$$V_h^{nc} := \big\{ v \in H^1(\mathcal{T}) : v|_K \in \mathcal{Q}^{nc}_{\mathcal{H}}(K) \text{ for each } K \in \mathcal{T},\ v \text{ continuous with respect to } \mathcal{F}_E\ \forall\ E \in \mathcal{E}(\Omega), \text{ and } \mathcal{F}_E(v) = \mathcal{F}_E(u_D)\ \forall\ E \in \mathcal{E}(\Gamma_D) \big\},$$

whereas $V_{h,0}^{nc}$ denotes the space corresponding to the discrete homogeneous Dirichlet boundary conditions in (4.4). For $v_h \in V_h^{nc}$, the definition (4.4) of V_h^{nc} and (4.3) yield

(4.5)
$$\int_E [v_h]\, ds = 0 \ \text{ for all } E \in \mathcal{E}(\Omega) \quad \text{and} \quad \int_E (v_h - u_D)\, ds = 0 \ \text{ for all } E \in \mathcal{E}(\Gamma_D),$$

and so V_h^{nc} verifies (H1). Let V_h^c be the conforming space of the bilinear elements constructed from the local spaces $\mathcal{Q}^c(K) = \text{span}\{1, x_1, x_2, x_1x_2\}$. Consider then the interpolation operator $\Pi : V \mapsto V_{h,0}^{nc}$ defined by the following conditions: For all $E \in \mathcal{E}(K)$ and $K \in \mathcal{T}$,

$$\Pi v \in V_{h,0}^{nc}, \quad \mathcal{F}_E(\Pi v|_K) = \mathcal{F}_E(v|_K), \quad \mathcal{F}_K(\Pi v|_K) = \mathcal{F}_K(v|_K). \tag{4.6}$$

Given $v \in V_{h,0}^c$, the restriction of v to $K \in \mathcal{T}$ has the following representation:

$$v = a_0 + a_1x_1 + a_2x_2 + a_3x_1x_2 \tag{4.7}$$

for some interpolation constants a_i, $i = 0, \ldots, 3$. Since the degrees of freedom (4.3) vanish over the nonconforming bubble function $x_1x_2 \in \mathcal{Q}^c(K)$, it follows that the restriction of Π to $V_{h,0}^c$ yields [21]

$$\Pi v|_K = a_0 + a_1x_1 + a_2x_2. \tag{4.8}$$

By a scaling argument, one can verify that Π meets (1.5) and therefore the estimates (3.2). Furthermore, for every $v_h \in V_{h,0}^c$ a direct evaluation of the integrals shows (1.3)–(1.4) over rectangular and parallelogram element domains, i.e., the space V_h^{nc} meets (H2).

4.3. The quadrilateral rotated nonconforming element. In [25] Rannacher and Turek introduced two types of quadrilateral nonconforming elements referred to as NR elements. The corresponding local finite element spaces are obtained by rotating the mixed term of the bilinear element, and assuming as local degree of freedom either the average of the function over the edge or its value at the midside node. In this section we consider the nonparametric formulation for rectangular and parallelogram elements with the first choice of degree of freedom. More precisely, for each element $K \in \mathcal{T}$ and with respect to the global coordinate system (x_1, x_2), we set [25]

$$\mathcal{Q}^{nc}_{\mathcal{R}} = \text{span}\{\, 1,\, x_1,\, x_2,\, x_1^2 - x_2^2 \,\} \tag{4.9}$$

and introduce the four degrees of freedom as

$$\mathcal{F}_E(v) = \frac{1}{h_E} \int_E v\, ds \text{ with } E \in \mathcal{E}(K). \tag{4.10}$$

With the corresponding nonconforming finite element space defined as in (4.4) and concordantly $V_{h,0}^{nc}$, it follows that V_h^{nc} meets (H1).

For any $v \in V$, the interpolation operator $\Pi v \in V_{h,0}^{nc}$ is defined as in [25, 21]: For all $E \in \mathcal{E}(K)$ and $K \in \mathcal{T}$,

$$\Pi v \in V_{h,0}^{nc} \quad \text{and} \quad \mathcal{F}_E(\Pi v|_K) = \mathcal{F}_E(v|_K), \tag{4.11}$$

and, hence, as with the Han element, since $\mathcal{F}_E$ vanishes over the nonconforming bubble function $x_1x_2 \in \mathcal{Q}^c(K)$, the restriction of Π to $V_{h,0}^c \subset V$ is represented locally by (4.8) [21]. Therefore, the above arguments verify (H2).

Remark 2. For the version of the NR element with function evaluation at the midpoints as degree of freedom, (H1) is not satisfied and we refer to section 4.5 for a modification of the NR element.

Remark 3. The proof of Lemma 3.4 for the NR element can be found in [20, 22].

Remark 4. The interpolation operator $\Pi_{\mathcal{P}}$ defined in [2, eqn. (6)] does not, in general, map into the space $X_{\mathcal{P},E}$ of the NR element functions continuous at the midside nodes [2, p. 4]. This results in a gap in the analysis of [2] for this finite element; the remaining assertions in [2] seem to be correct.

Remark 5. The present analysis shows that the augmentation of V_h^{nc} with local bubble trial functions proposed in [23] is not necessary for the error control of $\|\nabla_h e\|$.

Remark 6. The flux $\nabla_h u|_K \cdot \nu_E$ is not required to be constant over each edge E with normal ν_E as in [2]. The latter hypothesis would in fact restrict the analysis to only rectangular meshes.

4.4. The constrained NR element and the P_1-quadrilateral element. The constrained NR finite element (referred to as the CNR element) introduced in [20, 21] is obtained by enforcing a constraint on the degree of freedom of the NR element described in section 4.3. With $\mathcal{Q}_{\mathcal{R}}^{nc}$ denoting here the space of the global trial functions defined over Ω and corresponding to the NR element, the space of the CNR element is then defined as follows:

$$\begin{aligned}\mathcal{Q}_{\mathcal{J}}^{nc} := \Bigg\{ v \in \mathcal{Q}_{\mathcal{R}}^{nc} : \forall K \in \mathcal{T} \int_{E_1} v\,ds + \int_{E_3} v\,ds = \int_{E_2} v\,ds + \int_{E_4} v\,ds \\ \text{with } E_i, \quad 1 \le i \le 4, \text{ edges of } K \in \mathcal{T} \text{ numbered counterclockwise} \Bigg\}.\end{aligned} \tag{4.12}$$

For rectangular and parallelogram element domains, considered here, the element is equivalent to the P_1-quadrilateral element of [24]. For homogeneous Dirichlet boundary conditions, it is trivial to check that the space V_h^{nc} meets (H1) for being the CNR space, a subspace of NR. Furthermore, in [20, 21] it is also proved that on the generic element $K \in \mathcal{T}$ with vertices 1, 2, 3, 4 labeled counterclockwise, the interpolation $\Pi v \in V_{h,0}^{nc}$ defined as in (4.11) and for $v \in V_{h,0}^c$ has the representation

$$\Pi v|_K = v_1\phi_1 + v_2\phi_2 + v_3\phi_3 + v_4\phi_4, \tag{4.13}$$

with v_i nodal value of $v \in V_{h,0}^c$ and

$$\begin{aligned}\phi_1(x_1,x_2) &= \frac{1}{4}(1 - x_1 - x_2), \quad \phi_2(x_1,x_2) = \frac{1}{4}(1 - x_1 + x_2), \\ \phi_3(x_1,x_2) &= \frac{1}{4}(1 + x_1 + x_2), \quad \phi_4(x_1,x_2) = \frac{1}{4}(1 - x_1 + x_2)\end{aligned} \tag{4.14}$$

associated with each of such vertices. The arguments of section 4.3 finally show (H2).

4.5. The DSSY element. The main motivation for the definition of this element is to obtain a quadrilateral element with approximation properties similar to those of the Crouzeix–Raviart element. For parallelogram elements these properties were identified in [17] by (i) continuity at the midpoints of each edge, (ii) value of the function at these points as degrees of freedom, and (iii) validity of the orthogonality condition [17, eqn. (6.1)]: For all $v_h \in V_{h,0}^{nc}$ there holds

$$\int_E [v_h]\, ds = 0 \quad \text{for } E \in \mathcal{E}(\Omega). \tag{4.15}$$

The latter condition plays a crucial role in the proof of optimal error estimates as realized in [17], for instance, by two spaces of local basis obtained by an ad hoc modification of the local basis of the Rannacher–Turek element. Set

$$\theta_\ell(t) = \begin{cases} t^2 - \frac{5}{3}t^4 & \text{for } \ell = 1, \\ t^2 - \frac{25}{6}t^4 + \frac{7}{2}t^6 & \text{for } \ell = 2. \end{cases} \tag{4.16}$$

Then the local space reads

$$\mathcal{Q}_{\mathcal{D}}^{nc} = \operatorname{span}\{1,\, x_1,\, x_2,\, \theta_\ell(x_1) - \theta_\ell(x_2)\} \quad \text{for } \ell = 1, 2, \tag{4.17}$$

and the $\mathcal{Q}_{\mathcal{D}}^{nc}$-unisolvent linear forms read

$$\mathcal{F}_{E_i}(v_h|_K) = v_h|_K(m_{E_i}) \quad \text{for } E_i \in \mathcal{E}(K),\ 1 \le i \le 4,\ v_h \in \mathcal{Q}_{\mathcal{D}}^{nc}, \tag{4.18}$$

with m_{E_i} midside nodes of the edge E_i. The nonconforming finite element spaces V_h^{nc} and $V_{h,0}^{nc}$ are then defined as in (4.4) with $\mathcal{Q}_{\mathcal{H}}^{nc}$ replaced by $\mathcal{Q}_{\mathcal{D}}^{nc}$. Following [17], one can show that (H1) holds. Furthermore, with the interpolation operator $\Pi : V \mapsto V_{h,0}^{nc}$ defined as in (4.11), one obtains

$$\Pi v \in V_{h,0}^{nc}, \quad \Pi v|_K(m_E) = \frac{1}{h_E}\int_E v\, ds \quad \text{for each edge } E \in \mathcal{E}(K), \quad K \in \mathcal{T}, \tag{4.19}$$

with the restriction of Π to the space $V_{h,0}^c$ having the local representation (4.8) that implies (H2).

4.6. Hanging nodes. This section discusses 1-irregular meshes and refers to [11] for further details and technicalities. Given an initial regular mesh $\mathcal{T}_0$ of Ω in the sense of Ciarlet [12, 6], a 1-irregular mesh $\mathcal{T}_\ell$ is obtained from $\mathcal{T}_{\ell-1}$ by refining some elements K into four congruent elements by connecting the midside points of the edges of K [4].

Let $\mathcal{N}_H$ denote the set of hanging nodes, $\mathcal{N}_E$ the set of the endpoints of the edges containing one hanging node, $\mathcal{E}_C$ the set of edges with one endpoint in $\mathcal{N}_H$, and $\mathcal{E}_H$ the set of edges containing one hanging node, hereafter referred to as hanging edges. We define the set $\mathcal{N}_R$ of regular nodes as $\mathcal{N}_R = \mathcal{N} \setminus (\mathcal{N}_H \cup \mathcal{N}_E)$ and the set $\mathcal{E}_R$ of regular edges as $\mathcal{E}_R = (\mathcal{E}(\Omega) \setminus \mathcal{E}_C) \cup \mathcal{E}(\Gamma_D)$. It is then possible to construct a partition of unity $(\varphi_z)_{z\in\mathcal{N}_E\cup\mathcal{N}_R}$ on Ω that forms a basis for $V_{h,0}^c$ and define a regularized operator $\mathcal{J} : H^1(\Omega) \mapsto V_h^c$ meeting (2.4)–(2.5) [11].

Under proper constraints for the degrees of freedom for the hanging edges we have the following result that controls the nonconforming part of the error [11]:

$$\min_{\substack{v\in H^1(\Omega)\\ v=u_D \text{ on } \Gamma_D}} \|\nabla_h(u_h - v)\|_{L^2(\Omega)} \le C\left(\sum_{E\in\mathcal{E}_R} h_E \|J_{E,\tau}\|_{L^2(E)}^2\right)^{1/2} + C\operatorname{osc}(u_D). \tag{4.20}$$

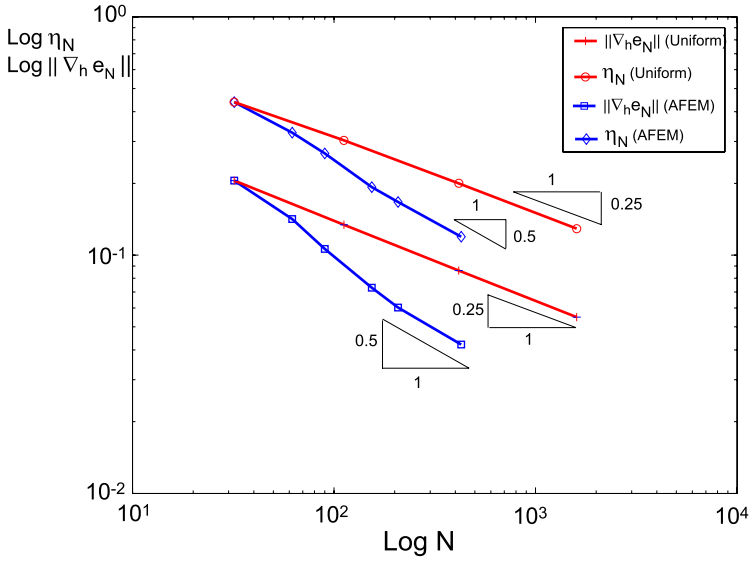

FIG. 2. *Experimental convergence rate of η_N and the exact error $\|\nabla_h e_N\|$ with respect to the number N of degrees of freedom for the adaptive and uniform refinement based on η_N and with the NR finite element. The displayed results show $2.13 \le \eta_N/\|\nabla_h e_N\| \le 2.83$ for adaptive and $2.13 \le \eta_N/\|\nabla_h e_N\| \le 2.35$ for uniform mesh refinement.*

An integration by parts, use of Young's inequality, the properties of the operator $\mathcal{J}$, and (4.20) finally prove (3.1) with $\eta + \operatorname{osc}(f) + \operatorname{osc}(g) + \operatorname{osc}(u_D)$ and corresponding modifications for the contribution to η from the hanging edges [11].

4.7. Generalizations. If $A \in L^\infty(\Omega; \mathbb{R}^{2\times 2})$ denotes a symmetric positive definite matrix piecewise constant with respect to $\mathcal{T}$, then Theorem 3.1 with corresponding modifications for the definition of η applies also to the elliptic PDE $\operatorname{div} A\nabla u = f$ with boundary conditions $u = u_D$ on Γ_D and $(A\nabla u)\cdot\nu = g$ on Γ_N.

5. Numerical experiment. This section concludes the paper with an example of an adaptive finite element model for the Poisson problem.

5.1. Adaptive finite element method. By rewriting η from (1.6) as $\eta^2 = \sum_{K\in\mathcal{T}} \eta_K^2$, with

$$\eta_K^2 := h_K^2 \|f + \operatorname{div}\nabla u_h\|_{L^2(K)}^2 + \frac{1}{2}\sum_{E\in\mathcal{E}(K)} h_E\big(\|J_{E,\nu}\|_{L^2(E)}^2 + \|J_{E,\tau}\|_{L^2(E)}^2\big),$$

the estimate η and the elemental contributions η_K can be used to generate the triangulations $\{\mathcal{T}_\ell\}_{\ell\in\mathbb{N}}$ in an adaptive way using the following algorithm.

ALGORITHM 1. *Input a coarse mesh $\mathcal{T}_0$ with rectangular and/or triangular elements, and set $\ell = 0$.*

(a) *Solve the discrete problem on $\mathcal{T}_\ell$ with N degrees of freedom.*
(b) *Compute η_K for all $K \in \mathcal{T}_\ell$ and $\eta_N := (\sum_{K\in\mathcal{T}} \eta_K^2)^{1/2}$.*
(c) *Mark $K \in \mathcal{M} \subset \mathcal{T}_\ell$ for refinement into four congruent elements by connecting the midside points of its edges if $\theta \max_{T\in\mathcal{T}_\ell} \eta_T \le \eta_K$.*
(d) *Mark further elements to ensure at most one hanging node per edge. Define the resulting mesh as the actual mesh $\mathcal{T}_{\ell+1}$, update ℓ, and go to* (a).

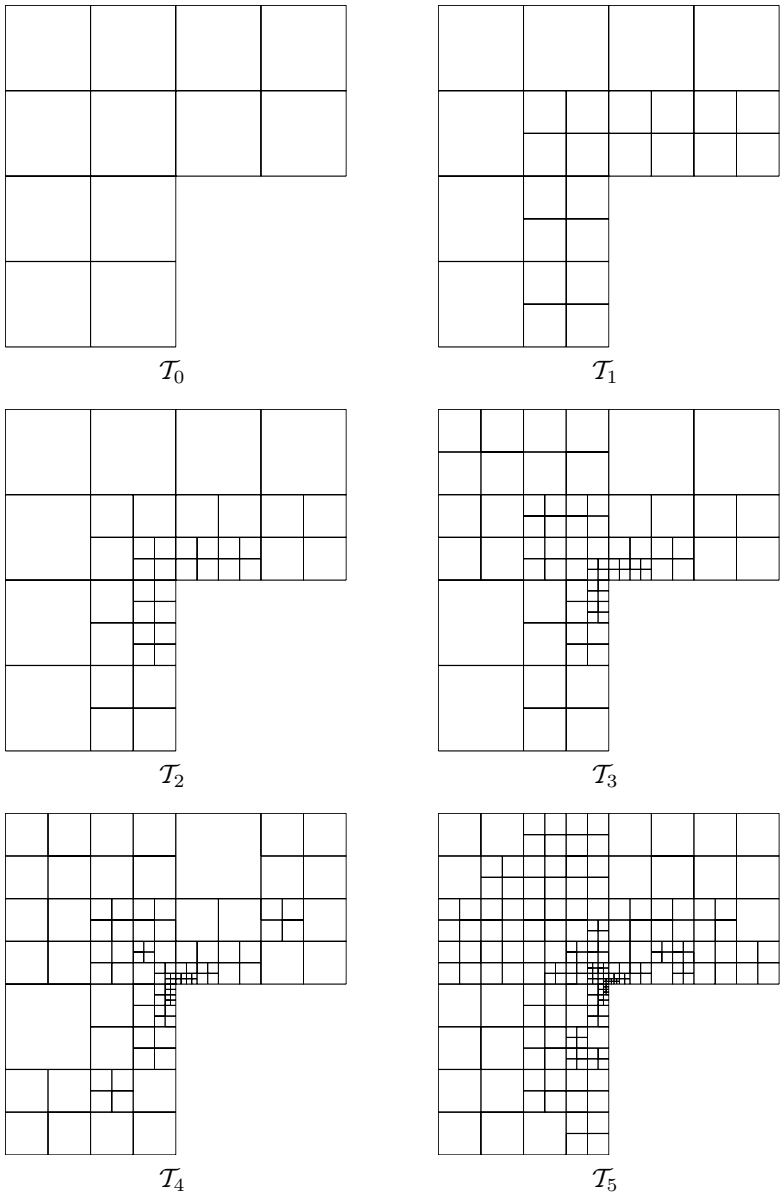

FIG. 3. *Adapted triangulations $\mathcal{T}_0, \ldots, \mathcal{T}_5$ generated with Algorithm 1 with $\theta = 1/2$. Notice a local higher refinement towards the reentrant corner.*

The triangulations $\mathcal{T}$ generated by Algorithm 1 are 1-irregular meshes. Error reduction and convergence of the adaptive finite element method based on the bulk criterion has been established in [10] for the Crouzeix–Raviart element.

5.2. Numerical example. On the L-shaped domain $\Omega = [0, 1]^2 \setminus [0.5, 1.0]^2$, we use the NR element defined in section 4.3 to approximate the Poisson problem (1.1) with $f \equiv 0$, $\Gamma_D = \partial\Omega$, $\Gamma_N = \emptyset$, and u_D a smooth function such that in polar coordinates

$$u(r, \theta) = r^{2/3} \sin\left(\frac{2}{3}\theta\right)$$

is the exact solution of (1.1). Figure 2 displays experimental convergence rates for the exact error and the estimate η_N for uniform and adaptive refinement with the corresponding triangulations depicted in Figure 3. The adaptive refinement improves the convergence rate of uniform refinement to the optimal one, $O(N^{-1/2})$, with respect to the number of degrees of freedom, and the convergence rate of the estimate mirrors that of the exact error for both uniform and adaptive refinement.

FAST SWEEPING METHODS FOR EIKONAL EQUATIONS ON TRIANGULAR MESHES*

JIANLIANG QIAN†, YONG-TAO ZHANG‡, AND HONG-KAI ZHAO‡

Abstract. The original fast sweeping method, which is an efficient iterative method for stationary Hamilton–Jacobi equations, relies on natural ordering provided by a rectangular mesh. We propose novel ordering strategies so that the fast sweeping method can be extended efficiently and easily to any unstructured mesh. To that end we introduce multiple reference points and order all the nodes according to their l^p-metrics to those reference points. We show that these orderings satisfy the two most important properties underlying the fast sweeping method: (1) these orderings can cover all directions of information propagating efficiently; (2) any characteristic can be decomposed into a finite number of pieces and each piece can be covered by one of the orderings. We prove the convergence of the new algorithm. The computational complexity of the algorithm is nearly optimal in the sense that the total computational cost consists of $O(M)$ flops for iteration steps and $O(M\log M)$ flops for sorting at the predetermined initialization step which can be efficiently optimized by adopting a linear time sorting method, where M is the total number of mesh points. Extensive numerical examples demonstrate that the new algorithm converges in a finite number of iterations independent of mesh size.

1. Introduction.

The eikonal equation in its simplest form says that the magnitude of the gradient of the eikonal is constant: $|\nabla T| = 1$, where T is the so-called eikonal. Because it appears in a variety of applications, it is essential to develop fast and efficient numerical methods to solve such an equation. In this work, we design a class of fast sweeping methods on triangulated domains for an eikonal equation of the following form:

$$\begin{cases} |\nabla T(\mathbf{x})| = f(\mathbf{x}), & \mathbf{x} \in \Omega \setminus \Gamma, \\ T(\mathbf{x}) = g(\mathbf{x}), & \mathbf{x} \in \Gamma \subset \Omega, \end{cases} \tag{1.1}$$

where $f(\mathbf{x})$ is a nonnegative function, Ω is an open, bounded polygonal domain in R^d, and Γ is a subset of Ω.

Two key points in designing an efficient numerical algorithm for solving such a nonlinear boundary value problem of hyperbolic type are (1) a numerical discretization that is both consistent with the causality of the PDE and able to deal with singularities in the solution gradient, and (2) a fast algorithm to solve the resulting large nonlinear system of equations. There are usually two types of methods for solving the nonlinear system: time marching methods and direct methods. Time marching methods add to the equation a pseudo–time variable which transforms the problem into

a time dependent one and evolve the solution to the steady state. Due to the finite speed of propagation and the Courant–Friedrichs–Lewy (CFL) condition for stability, many iterations are needed to reach the steady state solution. The last two decades have witnessed much effort towards solving the eikonal equation directly: upwinding schemes [32, 31], dynamic programming sweeping methods [27], Jacobi iterations [26], semi-Lagrangian schemes [8], fast marching-type methods [30, 10, 28, 13], down-n-out approaches [7], wavefront expanding methods [23], adaptive upwinding methods [19, 21], fast sweeping methods [2, 37, 29, 35, 12, 34, 11, 36, 33]; see also the references therein. Accuracy of numerical solutions is determined by the discretization scheme. For example, if a first-order monotone scheme is used, in general only the $h^{1/2}$ convergence rate can be shown [6] and the $h \log h$ convergence rate is optimal for the eikonal equation [35].

Among all these methods, both the fast marching method and the fast sweeping method are designed to solve the nonlinear discretized system directly and efficiently by exploiting causality of the underlying PDE. In terms of complexity, the fast marching method [30, 10, 28, 13] has the complexity of $O(M \log M)$, where M is the total number of mesh points and the $\log M$ factor comes from the heapsort algorithm needed for sorting out the causality order at each step, while the fast sweeping method has the complexity of $O(M)$, where the constant in O depends on the equation, and this was proved in [35] for eikonal equations on rectangular grids. For a particular problem on a fixed grid, one method could be faster than the other. When the grid is more refined the fast sweeping method will be faster eventually. In [9], concrete and detailed comparisons are presented for various numerical examples. In terms of accuracy there is no difference since they are two different ways of solving the same nonlinear discretized equation. The main difference between these two methods lies in the use of causality. The fast marching method enforces the causality sequentially and on the fly during each update step; that is why a heapsort algorithm is needed to order all possible candidates and pick up the correct one by the causality at each step; once a point is accepted it cannot be revisited and its value cannot be changed afterwards. On the other hand the fast sweeping method is an iterative method of Gauss–Seidel type which is extremely simple to implement; such a simple iterative method for a nonlinear problem is able to achieve an optimal complexity because it can capture the causality of the PDE in a parallel way, as shown in [35]. Since it is an iterative method by nature the fast sweeping method is applicable to other situations such as higher order schemes with ease [34, 33], nonconvex Hamiltonians [12], and parallel implementation [36].

On the other hand, most of these methods are based on rectangular meshes. However, it is important to design fast methods on triangulated meshes as well. For example, in seismics a subsurface velocity model usually consists of several irregular interfaces, and in robotic path planning an obstacle may have an irregular boundary. Thus, for applications involving irregular boundaries or interfaces, it is much desired to triangulate a computational domain into irregular meshes to fit with boundaries or interfaces. Kimmel and Sethian [13] extended the fast marching method to triangulated domains to compute geodesics on manifolds.

In this work, we extend the fast sweeping method to triangulated domains by introducing novel ordering processes into the sweeping strategy. The resulting method is proved to be convergent, and numerical examples demonstrate that the method converges in a finite number of iterations independent of mesh size. The computational complexity of the new algorithm is nearly optimal in the sense that the total

computational cost consists of $O(M)$ flops for iteration steps and $O(M\log M)$ flops for sorting at the predetermined initialization step, which can be efficiently optimized by adopting a linear time sorting method.

An essential property of the eikonal equation is that it is hyperbolic, and a stable scheme must look for information by following characteristics in an upwind fashion, which is equivalent to the simple causality for the eikonal equation in that its solution is always increasing (or decreasing) along a characteristic. To satisfy such a property, it is crucial for a scheme of computing viscosity solutions to be based on a monotone numerical Hamiltonian [1, 17]. Once we have in place such a discretization for eikonal equations, the problem reduces to one of solving the resulting nonlinear system efficiently; the fast sweeping method is designed to do exactly that. The original fast sweeping method was inspired by the work in [2]. The fast sweeping method uses Gauss–Seidel iterations with alternate sweeping orderings to solve the nonlinear system. The fact that the iterative algorithm for a nonlinear system can converge in a finite number of iterations independent of mesh size is quite remarkable; even for a linear system, such as the discretized system for the Laplace equation, this is not true.

The crucial idea underlying the fast sweeping method is the following [35]: all directions of characteristics can be divided into a finite number of groups; any characteristic can be decomposed into a finite number of pieces that belong to one of the above groups; there are systematic orderings that can follow the causality of each group of directions simultaneously.

On a rectangular grid there are natural orderings of all grid points. For example, in the two-dimensional (2-D) case, all directions of the characteristics can be partitioned into four groups, up-right, up-left, down-right, and down-left, and it is very natural to order all the nodes according to their indexes in ascent or descent orders [2, 37, 29, 11, 35, 12, 34], which yields four possible orderings to cover all those four directions of characteristics.

However, on an unstructured mesh, only local connection of the nodes is available and natural ordering no longer exists. To overcome these difficulties we propose general ordering strategies by introducing multiple reference points and ordering all the nodes according to their l^p-distances to those reference points. For example, information is propagated as plane waves in different directions when the l^1-metric is used or as spherical waves with different centers when the l^2-metric is used. We show that these orderings satisfy the key properties essential for the fast sweeping method to converge and numerically demonstrate that the fast sweeping method converges in a finite number of iterations independent of mesh size. Although it may still cost $O(M\log M)$ by a comparison-based sorting method, the ordering step in our algorithm may be made to be $O(M)$ by a linear time sorting method since we know the distribution of nodes at the initial step. For example, the radix sorting method [4] may be used for such a purpose. Moreover this initial ordering is done for a fixed mesh once and for all. This is different from other methods based on heap sorting to maintain a dynamic data structure. Therefore the methods proposed here are very efficient and extremely easy to write in any number of dimensions.

The rest of the paper is organized as follows. In section 2, we construct local solvers at each node on a triangulated mesh, propose novel ordering strategies, and detail fast sweeping algorithms. In section 3, we analyze the new algorithm and prove convergence results. In section 4, we present various numerical examples to illustrate the efficiency and the accuracy of the new method. We conclude the paper in section 5.

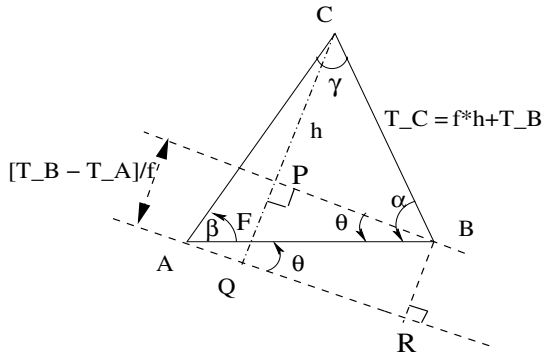

FIG. 2.1. *Update the value at C in a triangle when causality is satisfied.*

2. Fast sweeping methods on unstructured meshes.

2.1. 2-D local solvers. Take $d = 2$ in (1.1):

$$\begin{cases} \sqrt{T_x^2 + T_y^2} = f(x,y), & (x,y) \in \Omega \subset R^2, \\ T(x,y) = g(x,y), & (x,y) \in \Gamma \subset \Omega, \end{cases} \tag{2.1}$$

where $f(\mathbf{x})$ is a nonnegative function, Ω is an open, bounded polygonal domain in R^d, and Γ is a subset of Ω.

We consider a triangulation $\mathcal{T}_h$ of Ω which consists of nonoverlapping, nonempty, and closed triangles $\mathcal{T}$, with diameter $h_{\mathcal{T}}$, such that $\bar{\Omega} = \cup_{\mathcal{T} \in \mathcal{T}_h} \mathcal{T}$. We assume that $\mathcal{T}_h$ satisfies the following conditions:

- No more than μ triangles have a common vertex; $h = \sup_{\mathcal{T} \in \mathcal{T}_h} h_{\mathcal{T}} < 1$.
- $\mathcal{T}_h$ is regular; there exists a constant ω_0 independent of h such that if $\rho_{\mathcal{T}}$ is the diameter of the largest ball $B \subset \mathcal{T}$, then for all $\mathcal{T} \in \mathcal{T}_h$, $h_{\mathcal{T}} \le \omega_0 \rho_{\mathcal{T}}$.

For a given triangle $\triangle ABC$, we denote $\angle A = \beta$, $\angle B = \alpha$, and $\angle C = \gamma$; $\overline{AB} = c$, $\overline{AC} = b$, and $\overline{BC} = a$ are the lengths of the edges AB, AC, and BC, respectively.

During the solution process we need a local solver at vertex C for each triangle; see Figure 2.1. Given the values T_A and T_B at A and B of triangle $\triangle ABC$, we want to calculate the value T_C at C.

To make the description specific, we introduce the definition of causality.

DEFINITION 2.1. *Under the above regular triangulation we consider a local scheme based on piecewise linear reconstructions. By the causality condition of isotropic wave propagation for updating the travel-time at the node C from travel-times T_A and T_B, we mean that the ray which is orthogonal to the wavefront and passes through C must fall inside the triangle $\triangle ABC$.*

We notice that in isotropic wave propagation the ray direction is the same as the gradient direction of the travel-time field and thus it is the same as the outward normal of the wavefront.

First we assume that $\triangle ABC$ is acute. To construct a first-order scheme we determine a planar wavefront from the known values T_A and T_B. Suppose that the angle is θ between the incoming wavefront and the edge AB.

Without loss of generality, we further assume that $T_B \ge T_A$. If T_C is determined by both T_A and T_B, then by the Huygens principle the wavefront must first pass through the vertex A, then B, and finally C. To guarantee this, the following conditions must be satisfied:

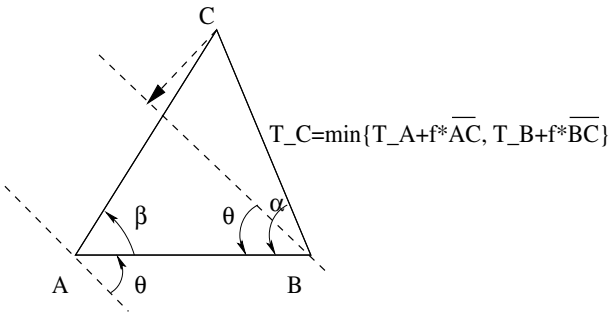

FIG. 2.2. *Update the value at vertex C in a triangle when causality is not satisfied.*

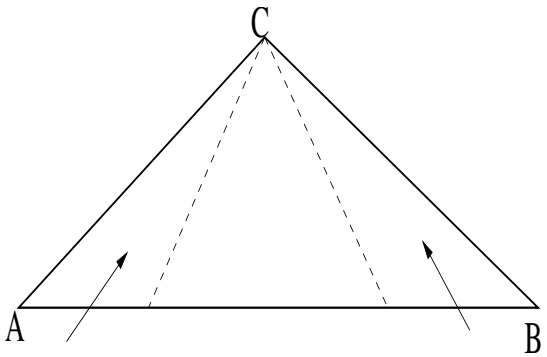

FIG. 2.3. *C and its obtuse triangle.*

- $[T_B - T_A]/f_C \le \overline{AB} = c$; i.e., it is possible for the wavefront to propagate from A to B with the given speed, where f_C is the value of $f(C)$, the inverse of the speed at C.
- $\theta \le \alpha$ so that the wavefront passes through B first rather than C.
- $\theta + \beta < \frac{\pi}{2}$; otherwise the causality is violated since the vertical line from C to the wavefront does *not* fall inside the triangle; see Figure 2.2.

If all n triangles $\mathcal{T}_1, \mathcal{T}_2, \ldots, \mathcal{T}_n$ around C are acute, the wavefront can be captured well in one of these triangles, no matter which direction the wave comes from. However, if one of the triangles is obtuse and the wavefront comes in just from this obtuse angle, then the situation is different; there are two possible cases: (i) if the normal of the wavefront is contained between those two dotted lines in Figure 2.3, then the value at C can be updated using values at A and B even though the accuracy will be degraded; (ii) otherwise, the value at C cannot be updated by A and B correctly [25]. These will be shown in numerical examples in section 4.

In order to treat obtuse triangles, we adopt the strategy used in [25]. As illustrated in Figure 2.4, if $\angle C$ is obtuse, then we connect C to a vertex D of a neighboring triangle to cut the obtuse angle into two smaller angles. If these two angles are both acute, then we are done, as shown in Figure 2.4(a); otherwise, if one of the smaller angles is still obtuse, then we keep connecting C to the vertexes of the neighboring triangles of the next level until all new angles at C are acute, as shown in Figure 2.4(b). All these added edges are "virtual"; i.e., they exist only when the value at C is updated. Because such a treatment depends on a given mesh, we only need to do that once before the iteration in the algorithm begins; the resulting algorithm is

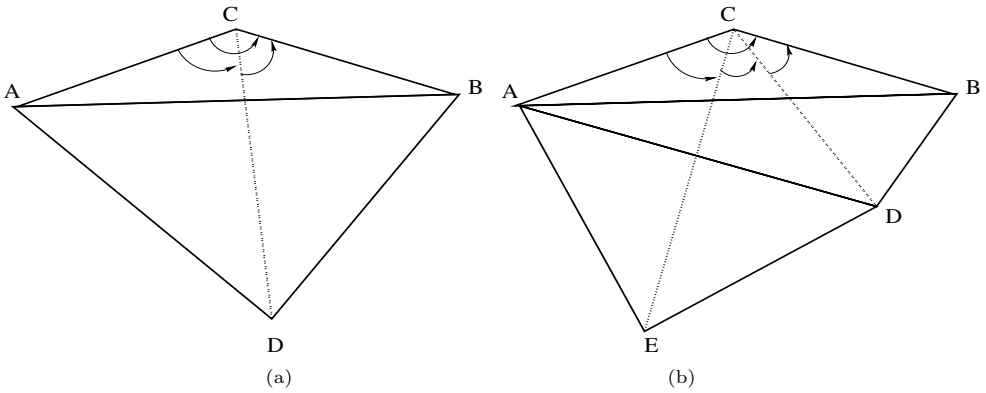

FIG. 2.4. *A strategy to treat obtuse angles.*

simple with almost no extra computational cost, as shown by numerical examples in section 4. This construction is different from the one used in [13].

We first give a geometric version of our local solvers.

A 2-D LOCAL SOLVER (Version 1: given $T_A \le T_B$, determine $T_C = T_C(T_A, T_B)$).

1. If $[T_B - T_A] \le c\, f_C$, then

$$\theta = \arcsin\left(\frac{[T_B - T_A]}{c\, f_C}\right);$$

   (a) if $\max(0, \alpha - \frac{\pi}{2}) \le \theta \le \frac{\pi}{2} - \beta$, then

$$h = \overline{CP} = a\sin(\alpha - \theta); T_C = \min\{T_C, h\, f_C + T_B\};$$

   (b) else

$$T_C = \min\{T_C, T_A + b\, f_C, T_B + a\, f_C\};$$

2. else

$$T_C = \min\{T_C, T_A + b\, f_C, T_B + a\, f_C\}.$$

The angle condition,

$$\max\left(0, \alpha - \frac{\pi}{2}\right) \le \theta \le \frac{\pi}{2} - \beta,$$

can be obtained in the following way:

1. If $\beta > \frac{\pi}{2}$, then the causality condition is not valid.
2. If $\beta < \frac{\pi}{2}$, then we must have $\theta \le \frac{\pi}{2} - \beta$; otherwise, the causality is violated since the vertical line from C to the wavefront does *not* fall inside the triangle. Furthermore,
   (a) from this condition we can directly deduce that $\alpha \ge \theta$, since $\angle C = \gamma < \frac{\pi}{2}$ by construction;
   (b) if $\alpha \ge \frac{\pi}{2}$, then we must have $\alpha - \theta \le \frac{\pi}{2}$ so that the ray from C reaching the wavefront is located inside the triangle.

The following algorithm unifies all the cases into one.

A 2-D LOCAL SOLVER (Version 2: given T_A and T_B, determine $T_C = T_C(T_A, T_B)$).

1. If $|T_B - T_A| \le c\, f_C$, then

$$\theta = \arcsin\left(\frac{[T_B - T_A]}{c\, f_C}\right);$$

(a) if $\max(0, \alpha - \frac{\pi}{2}) \le \theta \le \frac{\pi}{2} - \beta$ or $\alpha - \frac{\pi}{2} \le \theta \le \min(0, \frac{\pi}{2} - \beta)$, then

$$h = \overline{CP} = a\, \sin(\alpha - \theta); H = \overline{CQ} = b\, \sin(\beta + \theta);$$

$$T_C = \min\{T_C, 0.5\, (h\, f_C + T_B) + 0.5\, (H\, f_C + T_A)\};$$

(b) else

$$T_C = \min\{T_C, T_A + b\, f_C, T_B + a\, f_C\};$$

2. else

$$T_C = \min\{T_C, T_A + b\, f_C, T_B + a\, f_C\}.$$

In the special case that a given mesh is rectangular and $\alpha = \beta = \frac{\pi}{4}$, it is straightforward to verify that the above local solver reduces to the one given in [35]. Therefore, the local solver is consistent with the one on rectangular meshes.

If a triangle is acute, then the angle conditions in Version 2 reduce to one condition:

$$\alpha - \frac{\pi}{2} \le \theta \le \frac{\pi}{2} - \beta;$$

otherwise, the two angle conditions cannot be combined into one, since there are gaps corresponding to one of the angles α or β being obtuse. See Figures 2.1 and 2.2 for illustrations.

We emphasize that both updating algorithms require that $\angle C = \gamma < \frac{\pi}{2}$, but one of the other two angles may be obtuse.

2.2. A 3-D local solver. A local solver in three dimensions can be derived similarly. Take $d = 3$ in (1.1):

$$\begin{cases} \sqrt{T_x^2 + T_y^2 + T_z^2} = f(x, y, z), & (x, y, z) \in \Omega \subset R^3, \\ T(x, y, z) = g(x, y, z), & (x, y, z) \in \Gamma \subset \Omega. \end{cases} \tag{2.2}$$

Equation (2.2) is solved in the domain Ω, which has a triangulation $\mathcal{T}_h$ consisting of tetrahedrons. We consider every vertex and all tetrahedrons which are associated to this vertex. Again the question reduces to one of calculating the numerical solution at the current central vertex for each tetrahedron; see Figure 2.5.

Given the values T_A, T_B, and T_C at A, B, and C of the tetrahedron $ABCD$, we need to calculate the value T_D at the current central vertex D. The key is to determine the normal direction $\vec{\mathbf{n}}$ of the wavefront and determine whether the causality condition is satisfied or not. Analogous to Definition 2.1, the ray which has direction $\vec{\mathbf{n}}$ and passes through D must fall inside the tetrahedron $ABCD$ so as to satisfy the causality condition. To check the causality condition numerically, we first compute the coordinates of the point E at which the ray passing through D with direction $\vec{\mathbf{n}}$ intersects the plane spanned by A, B, and C; afterwards, we check to see whether E is inside $\triangle ABC$ or not.

Without loss of generality, we assume that $T_A = \min\{T_A, T_B, T_C\}$.

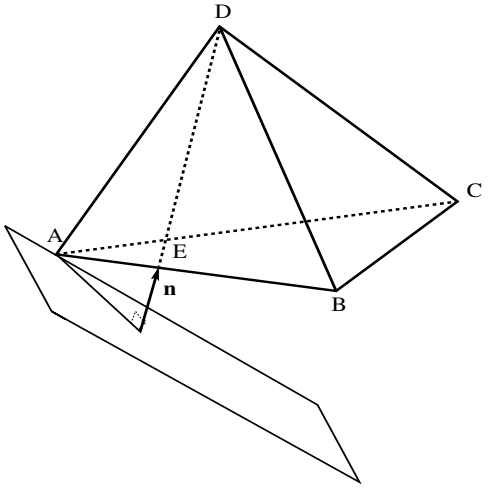

FIG. 2.5. *A 3-D local solver.*

A 3-D LOCAL SOLVER (given T_A, T_B, and T_C, determine $T_D = T_D(T_A, T_B, T_C)$).

1. If $[T_B - T_A] \le \overline{AB} \cdot f_D$ and $[T_C - T_A] \le \overline{AC} \cdot f_D$, then we solve the quadratic equation for the normal direction $\vec{\mathbf{n}}$ of the wavefront:

$$\begin{cases} \overrightarrow{AB} \cdot \vec{\mathbf{n}} = [T_B - T_A]/f_D, \\ \overrightarrow{AC} \cdot \vec{\mathbf{n}} = [T_C - T_A]/f_D, \\ \quad |\vec{\mathbf{n}}| = 1; \end{cases} \tag{2.3}$$

   (a) if there exist solutions $\vec{\mathbf{n}}^{(i)}, i = 1, 2$, for the quadratic equation (2.3) and the area $|\triangle EAB| + |\triangle EAC| + |\triangle EBC| = |\triangle ABC|$ for an $\vec{\mathbf{n}}^{(i)}$, then

$$T_D = \min\{T_D, T_A + (|\overrightarrow{AD} \cdot \vec{\mathbf{n}}^{(i)}|) \cdot f_D\};$$

   (b) else, apply the 2-D local solver on surfaces $\triangle ABD, \triangle ACD$, and $\triangle BCD$ and take the minimal one;

2. else, apply the 2-D local solver on surfaces $\triangle ABD, \triangle ACD$, and $\triangle BCD$ and take the minimal one.

2.3. Sweeping orders and a complete algorithm. An essential ingredient for making the fast sweeping method [35] successful is a systematic ordering that covers all directions of characteristics efficiently. With a causality preserving discretization in place, information along characteristics of certain directions is captured simultaneously in each sweeping ordering. Moreover, once the solution at a node gets its correct value, i.e., the smallest possible value, it will not change in later iterations. There are natural orderings on rectangular meshes. For example, in 2-D cases [35], all directions can be divided into four groups, up-right, up-left, down-left, and down-right, which can be covered by the orderings $i = 1 : I, j = 1 : J$; $i = 1 : I, j = J : 1$; $i = I : 1, j = 1 : J$; $i = I : 1, j = J : 1$, respectively, where i and j are the running indexes in the x- and y-directions, respectively. However, such natural orderings no longer exist on an unstructured mesh.

To devise efficient fast sweeping methods on unstructured meshes, we propose systematic orderings by introducing multiple reference points and sorting all the nodes according to their l^p-distances to each individual reference point. In this paper we

focus on $p = 1$ and 2 and give explicit geometric interpretation. The argument works for all other p's.

The l^p-metric for a vector $\mathbf{x} = (x_1, x_2, \ldots, x_n) \in R^n$ is defined as $|\mathbf{x}|_p = (\sum_{j=1}^{n} |x_j|^p)^{1/p}$. Without abuse of notation we also use $|\mathbf{x}|$ to denote the 2-norm of a vector $\mathbf{x}$. For example, in two dimensions, we first fix a reference point $\mathbf{x}_{\text{ref}}$; if we sweep through all nodes according to $|\mathbf{x} - \mathbf{x}_{\text{ref}}|_1$ in the ascent (or descent) order, then the sweeping wavefront is an outgoing (or incoming) plane wave since the unit ball of the l^1-metric is a tilted square. If we use $|\mathbf{x} - \mathbf{x}_{\text{ref}}|_2$ to order all nodes, then the sweeping wavefront is an outgoing (or incoming) spherical wave.

Next we address the following questions:

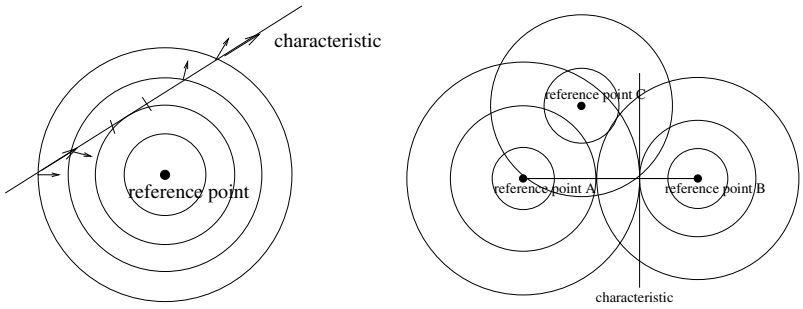
1. How many references points are needed in a systematic ordering that can cover all directions of information propagating?
2. How many iterations are needed for the algorithm to converge?

To address the first question, we have to understand the directional relation between a sweeping wavefront and a characteristic. In the continuous case the following is a basic fact: if the propagating direction of the sweeping wavefront forms an acute angle with the direction of the characteristic, then the causality along this characteristic can be captured in this ordering. As illustrated in Figure 2.6, if we use the l^2-metric, i.e., with a spherical sweeping wavefront, a straight characteristic in any direction can be partitioned into two pieces by the tangent point to a particular spherical sweeping wavefront, and each piece forms an acute angle to the outgoing or incoming sweeping wavefront. If all characteristics are straight lines, which is the case when the right-hand side of the eikonal equation is constant, we cover almost all characteristics by sweeping all nodes according to the l^2-distance to a single reference point in both ascent and descent orders alternately. However, for all characteristics at the tangent point, the normal of the sweeping wavefront is orthogonal to the direction of characteristics. So information will not propagate across the tangent point from one piece to other pieces effectively. To remedy this problem we introduce another reference point. Now all directions of characteristics can be covered effectively by the four orderings except one direction, which is orthogonal to the line connecting these two reference points, as shown in Figure 2.6. Therefore we need at least three noncollinear reference points and we sweep through all the nodes according to their l^2-distances to these reference points in ascent and descent orderings; a total of six orderings cover all directions of information propagating along characteristics. It can be easily seen that four noncoplanar reference points are needed in three dimensions.

If we use the l^1-metric, the sweeping wavefront is a tilted square. For each reference point, as shown in Figure 2.7, the whole plane can be divided into four quadrants, and each quadrant can be covered by one planar sweeping wavefront. If we choose two reference points such that the computational domain lies in different quadrants of these two reference points, all directions of characteristics can be covered by the four orderings corresponding to the ascent and descent sorting according to the l^1-metric; see Figure 2.7.

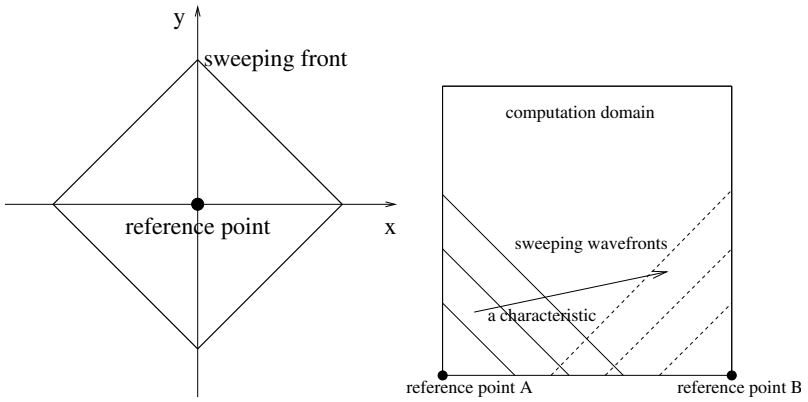
When characteristics are not straight lines, any characteristic can be divided into a finite number of pieces so that each piece can be covered effectively by one of the orderings, as shown in [35]. The total number of sweepings is increased due to curved characteristics, but it is still finite. The number of iterations will be estimated in section 3.

In terms of numerical implementation on a particular mesh some remarks are in order.



(a) one reference point (b) three reference points

FIG. 2.6. *Reference points and sweeping wavefronts for the l^2-metric.*



(a) one reference point (b) two reference points

FIG. 2.7. *Reference points and sweeping wavefronts for the l^1-metric.*

The domain of dependence for a node in the discrete case is a region rather than only the characteristic that passes through the node in the continuous case. On a triangular mesh, the propagating direction of a sweeping wavefront has to fall into the triangle which satisfies the causality criterion in Definition 2.1 so that the two neighbors that determine the current vertex have already been updated in the current sweeping. Numerically this means that the normal of the sweeping wavefront has to make an acute angle with the characteristic that passes through this vertex.

The criterion for an optimal choice of reference points and their locations on a triangular mesh is that all directions of characteristics should be covered with minimal redundancy. In practice, it is better if these reference points are evenly spaced both spatially and angularly with respect to the data set or boundary where the solution is prescribed. In our numerical tests we use the corners as reference points if the computational domain is rectangular. Other points, such as the center point of the domain or middle points of each edge, can be used as well. The number of iterations needed for convergence may be different for different choices of reference points but it will be finite.

If we have only a point source as the boundary condition on a rectangular mesh and we use that point as the single reference point, then the square wave sweeping accesses nodes in the ascent order in the same way that the down-n-out model does

[32, 7], and the spherical wave sweeping shares some similarities with the expanding wavefront model proposed in [31, 23]. However, we are not aware of any work accessing the nodes in the way similar to the plane wave sweeping proposed here.

The above isotropic metrics are suitable for ordering nodes in solving isotropic eikonal equations. For general anisotropic eikonal equations considered in [24, 18, 20], we may introduce anisotropic Riemannian metrics [5] to sort all the nodes, derive a local solver to update solutions at each node by using phase velocity and group velocity, as illustrated in [24, 18], and design fast sweeping methods accordingly; see [22] for a recent work along this direction.

Now we summarize local solvers and sweeping orderings into a complete algorithm.

THE FAST SWEEPING ALGORITHM ON A TRIANGULAR MESH.

1. Initialization:
   (a) Triangulate the computational domain Ω. Add virtual edges to cut obtuse angles if there are any.
   (b) Choose multiple reference points: $\mathbf{x}_{\text{ref}}^i$, $i = 1, \ldots, R$.
   (c) Sort all nodes according to their l^p-distances to the reference points in ascent and descent orders, and put them into arrays:

$$\begin{aligned} &S_i^+ : \text{ascent order}, i = 1, 2, \ldots, R; \\ &S_i^- : \text{descent order}, i = 1, 2, \ldots, R. \end{aligned} \tag{2.4}$$

   (d) Assign exact values or interpolated values $T^{(0)}$ at vertexes on or near the given boundary Γ, and keep these values fixed during the iterations. At all other vertexes, assign large positive values N to $T^{(0)}$, where N should be larger than the maximum of the true solution, and these values will be updated in later iterations.
2. Gauss–Seidel iteration for $k = 0, 1, \ldots$:
   (a) For $i = 1, \ldots, R$:
      i. For $j = +, -$:
         A. To every vertex $C \in S_i^j$ and every triangle associated with C, f_C=$f(C)$, apply the local solver;
         B. Convergence test: $\|T^{(k+1)} - T^{(k)}\| \le \epsilon$ for $\epsilon > 0$ given, where $\|\cdot\|$ is some specified norm.

We remark that during the Gauss–Seidel iteration the numerical solution at C is calculated using the current values of its neighbors in every triangle. The smallest one will be taken as the possible new value. If this smallest new value is smaller than the current value at C, then the numerical solution at C is updated to be the smallest new value.

In passing we point out that the sorting procedure in the above algorithm can cost $O(M\log M)$ flops if a comparison-based sorting method is used; however, to achieve an optimal $O(M)$ complexity for the algorithm, we may use a radix sorting method [4] in that we know the distribution of nodes. Radix sorting runs an $O(M)$ counting sort on each digit of the key, starting with the least significant and working for bounded integers. For general distances computed in the above algorithm, we argue that a fixed number of digits is sufficient because in some sense the order of updates does not matter too much for two nodes sufficiently close to each other. Moreover, this initial ordering is done for a fixed mesh once and for all.

3. Convergence results. In this section we prove convergence of the fast sweeping algorithm on triangular meshes. In the following analysis, we consider a regular

triangulation $\mathcal{T}_h$ of Ω with the property that all the inner angles of the triangles in $\mathcal{T}_h$ satisfy $\leq \frac{\pi}{2}$.

Considering a triangle $\triangle ABC$ in which T_A and T_B are given, we update the travel-time T_C at the vertex C. Denoting

$$p_1 = \frac{T_C - T_A}{b}, \;\; p_2 = \frac{T_C - T_B}{a}, \;\; p_3 = \frac{T_B - T_A}{c},$$

we adopt the framework in [3] to show consistency and monotonicity of the Godunov numerical Hamiltonian resulting from the local solver introduced in section 2.

LEMMA 3.1 (Godunov numerical Hamiltonian). *Assuming that the causality condition holds, the updating formula for the local solver is one of the solutions for the following equations:*

$$\text{(3.1)} \qquad \begin{cases} \frac{(T_C-T_A)^2}{b^2} - 2\frac{(T_C-T_A)(T_C-T_B)}{a\,b}\cos\gamma + \frac{(T_C-T_B)^2}{a^2} = f_C^2\,\sin^2\gamma \\ \qquad\qquad \textit{if } |p_3| \leq f_C \textit{ and } \alpha - \frac{\pi}{2} \leq \arcsin(\frac{p_3}{f_C}) \leq \frac{\pi}{2} - \beta; \\ \max\left(\frac{T_C-T_A}{b}, \frac{T_C-T_B}{a}\right) = f_C \quad \textit{otherwise.} \end{cases}$$

Here $\angle C = \gamma$, $\angle A = \beta$, $\angle B = \alpha$, and $f_C = f(C)$. This discretization for the eikonal equation is based on the Godunov numerical Hamiltonian:

$$\text{(3.2)} \qquad \hat{H}_C\left(\frac{T_C - T_A}{b}, \frac{T_C - T_B}{a}\right) = f_C,$$

where

$$\text{(3.3)} \quad \hat{H}_C(p_1, p_2) = \begin{cases} \frac{1}{\sin\gamma}\sqrt{p_1^2 - 2p_1\,p_2\cos\gamma + p_2^2} \\ \qquad\qquad \textit{if } |p_3| \leq f_C \textit{ and } \alpha - \frac{\pi}{2} \leq \arcsin(\frac{p_3}{f_C}) \leq \frac{\pi}{2} - \beta; \\ \max(p_1, p_2) \quad \textit{otherwise.} \end{cases}$$

Proof. By Version 2 of the local solver, we have

$$\text{(3.4)} \quad T_C = \begin{cases} \frac{1}{2}(T_A + T_B) + \frac{\sin(\alpha-\beta)}{2\sin\gamma}(T_B - T_A) + \frac{\sin\alpha\,\sin\beta}{\sin\gamma}\sqrt{c^2 f_C^2 - (T_B - T_A)^2} \\ \qquad \text{if } |p_3| \leq f_C \text{ and } \alpha - \frac{\pi}{2} \leq \arcsin(\frac{p_3}{f_C}) \leq \frac{\pi}{2} - \beta; \\ \min(T_A + bf_C, T_B + af_C) \quad \text{otherwise.} \end{cases}$$

By solving (3.1), we have

$$\text{(3.5)} \quad T_C = \begin{cases} \frac{1}{2}(T_A + T_B) + \frac{b^2-a^2}{2c^2}(T_B - T_A) \pm \frac{a\,b\sin\gamma}{c^2}\sqrt{c^2 f_C^2 - (T_B - T_A)^2} \\ \qquad \text{if } |p_3| \leq f_C \text{ and } \alpha - \frac{\pi}{2} \leq \arcsin(\frac{p_3}{f_C}) \leq \frac{\pi}{2} - \beta; \\ \min(T_A + bf_C, T_B + af_C) \quad \text{otherwise;} \end{cases}$$

one of the two roots corresponds to (3.4).

Next we derive the numerical Hamiltonian. Denote $A : (x_A, y_A)$, $B : (x_B, y_B)$, and $C : (x_C, y_C)$. Since the causality condition holds, we have

$$\text{(3.6)} \qquad \frac{T_C - T_A}{b} = \nabla T(C) \cdot \left(\frac{x_C - x_A}{b}, \frac{y_C - y_A}{b}\right)^t + o(h^2),$$

$$\text{(3.7)} \qquad \frac{T_C - T_B}{a} = \nabla T(C) \cdot \left(\frac{x_C - x_B}{a}, \frac{y_C - y_B}{a}\right)^t + o(h^2),$$

where t denotes the transpose of vectors. Furthermore we have

$$\begin{pmatrix} \frac{T_C - T_A}{b} \\ \frac{T_C - T_B}{a} \end{pmatrix} = \mathbf{P}\nabla T(C) + o(h^2), \tag{3.8}$$

where

$$\mathbf{P} = \begin{pmatrix} \frac{x_C - x_A}{b} & \frac{y_C - y_A}{b} \\ \frac{x_C - x_B}{a} & \frac{y_C - y_B}{a} \end{pmatrix}.$$

Ignoring higher-order terms and solving for ∇T_C, we have

$$|\nabla T(C)| \approx \begin{cases} \frac{1}{\sin\gamma}\sqrt{\frac{(T_C - T_A)^2}{b^2} - 2\frac{(T_C - T_A)(T_C - T_B)}{a\,b}\cos\gamma + \frac{(T_C - T_B)^2}{a^2}} \\ \qquad \text{if } |p_3| \le f_C \text{ and } \alpha - \frac{\pi}{2} \le \arcsin(\frac{p_3}{f_C}) \le \frac{\pi}{2} - \beta; \\ \max\left(\frac{T_C - T_A}{b}, \frac{T_C - T_B}{a}\right) \quad \text{otherwise;} \end{cases} \tag{3.9}$$

this is the Godunov numerical Hamiltonian for the eikonal equation. ∎

LEMMA 3.2 (consistency and causality). *The Godunov numerical Hamiltonian*

$$\hat{H}_C(p_1, p_2) = \begin{cases} \frac{1}{\sin\gamma}\sqrt{p_1^2 - 2p_1\,p_2\cos\gamma + p_2^2} \\ \qquad \textit{if } |p_3| \le f_C \textit{ and } \alpha - \frac{\pi}{2} \le \arcsin(\frac{p_3}{f_C}) \le \frac{\pi}{2} - \beta; \\ \max(p_1, p_2) \quad \textit{otherwise} \end{cases} \tag{3.10}$$

is consistent; namely,

$$\hat{H}_C\left(\frac{T_C - T_A}{b}, \frac{T_C - T_B}{a}\right) = |\mathbf{p}| \tag{3.11}$$

if $\nabla T_h = \mathbf{p} \in \mathcal{R}^2$. *It is monotone if the causality condition holds:* $0 \le \gamma_1 \le \gamma$, *where* γ_1 *is the angle from the edge CA to the ray (i.e., the vertical line to the wavefront) CQ counterclockwise; see Figure* 2.1.

Proof. By $\nabla T_h = \mathbf{p} \in \mathcal{R}^2$, we have

$$\begin{pmatrix} \frac{T_C - T_A}{b} \\ \frac{T_C - T_B}{a} \end{pmatrix} = \mathbf{P}\mathbf{p}. \tag{3.12}$$

Inserting this into the numerical Hamiltonian, we have (3.11).

Differentiating $\hat{H}_C(p_1, p_2)$ with respect to p_1 and p_2, the monotonicity of the Hamiltonian requires

$$\frac{\partial \hat{H}_C}{\partial p_1} \ge 0, \qquad \frac{\partial \hat{H}_C}{\partial p_2} \ge 0; \tag{3.13}$$

these can be satisfied if and only if $\cos\gamma \le \frac{p_2}{p_1} \le \frac{1}{\cos\gamma}$. By

$$p_1 = \frac{T_C - T_A}{b} = f_C \sin(\beta + \theta), \tag{3.14}$$

$$p_2 = \frac{T_C - T_B}{a} = f_C \sin(\alpha - \theta), \tag{3.15}$$

where $\theta = \arcsin(\frac{p_3}{f_C})$, we have

$$\cos\gamma \le \frac{\sin(\beta + \theta)}{\sin(\alpha - \theta)} \le \frac{1}{\cos\gamma}, \tag{3.16}$$

which is equivalent to the causality condition $0 \le \gamma_1 \le \gamma$, since $\gamma_1 = \frac{\pi}{2} - (\beta + \theta)$ and $\gamma_1 = (\gamma + \alpha - \theta) - \frac{\pi}{2}$. ∎

LEMMA 3.3 (monotonicity). *The fast sweeping algorithm is monotone and Lipschitz continuous, i.e.,*

$$1 \ge \frac{\partial T_C}{\partial T_B} \ge 0, \quad 1 \ge \frac{\partial T_C}{\partial T_A} \ge 0, \tag{3.17}$$

and

$$\frac{\partial T_C}{\partial T_B} + \frac{\partial T_C}{\partial T_A} = 1. \tag{3.18}$$

Proof. Consider the case that $T_A \le T_B$. We need only verify that the above inequalities hold when T_C is updated by

$$T_C = h\, f_C + T_B, \tag{3.19}$$

which is the case that the causality condition is satisfied. From Version 1 of the local solver we have

$$\frac{\partial T_C}{\partial T_B} = 1 + a f_C \cos(\alpha - \theta) \left(-\frac{\partial \theta}{\partial T_B} \right) \tag{3.20}$$

$$= 1 - \frac{a \cos(\alpha - \theta)}{c \cos\theta}; \tag{3.21}$$

$$\frac{\partial T_C}{\partial T_A} = a f_C \cos(\alpha - \theta) \left(-\frac{\partial \theta}{\partial T_A} \right) \tag{3.22}$$

$$= \frac{a \cos(\alpha - \theta)}{c \cos\theta}. \tag{3.23}$$

From Figure 2.1, we have $a\cos(\alpha - \theta) = \overline{PB}$, $c\cos(\theta) = \overline{AR}$, and $\overline{PB} \le \overline{AR}$; therefore, $1 \ge \frac{\partial T_C}{\partial T_B} \ge 0$, $1 \ge \frac{\partial T_C}{\partial T_A} \ge 0$, and $\frac{\partial T_C}{\partial T_B} + \frac{\partial T_C}{\partial T_A} = 1$. ∎

LEMMA 3.4 (maximum change principle). *In the Gauss–Seidel iteration for the fast sweeping algorithm, the maximum change of T_h at any vertex is less than or equal to the maximum change of T_h at its neighboring points.*

Proof. This follows from the above monotonicity property proved in Lemma 3.3. ∎

LEMMA 3.5 (order preserving). *The fast sweeping algorithm is monotone in the initial data.*

Proof. By the monotonicity property of the solution, if $T_h(C) \le R_h(C)$ at all vertexes initially, then $T_h(C) \le R_h(C)$ at all vertexes after any number of Gauss–Seidel iterations. ∎

LEMMA 3.6 (nonincreasing). *The solution of the fast sweeping algorithm is nonincreasing with each Gauss–Seidel iteration.*

Proof. This is evident from the updating formula, which updates the current value only if it is larger than the newly computed value during the Gauss–Seidel iteration. ∎

LEMMA 3.7 (l^∞-contraction). *Let $T^{(k)}$ and $R^{(k)}$ be two numerical solutions at the kth iteration of the fast sweeping algorithm. Let $\|\cdot\|_\infty$ be the maximum norm. Then*

$$\|T^{(k)} - R^{(k)}\|_\infty \le \|T^{(k-1)} - R^{(k-1)}\|_\infty; \tag{3.24}$$

$$0 \le \max_C \left\{ T_C^{(k)} - T_C^{(k+1)} \right\} \le \max_C \left\{ T_C^{(k-1)} - T_C^{(k)} \right\}. \tag{3.25}$$

Proof. Assume that the first update at the kth iteration is at C,

$$T_C^{(k)} = \min\{T_C^{(k-1)}, \bar{T}\},$$

where $\bar{T}$ is the solution computed from its neighbors $T_A^{(k-1)}$ and $T_B^{(k-1)}$. The same is true for $R_C^{(k)}$. By the maximum change principle, we have

$$|T_C^{(k)} - R_C^{(k)}| \le \|T^{(k-1)} - R^{(k-1)}\|_\infty. \tag{3.26}$$

For an update at any other node later in the iteration, the neighboring values used for the update are either from the previous iteration or from an earlier update in the current iteration, both of which satisfy the above bound. By induction, we have l^∞-contraction (3.24). By the monotonicity of the fast sweeping algorithm and (3.24), setting $R^{(k)} = T^{(k-1)}$ we conclude (3.25). ∎

THEOREM 3.8 (convergence). *The solution of the fast sweeping algorithm converges monotonically to the solution of the discretized system.*

Proof. Denote the numerical solution after the kth iteration by $T_C^{(k)}$. Since $T_C^{(k)}$ is bounded below by 0 and is nonincreasing with Gauss–Seidel iterations, $T_C^{(k)}$ is convergent for all C. After each sweep for each C at each triangle, we have by the monotonicity of the numerical Hamiltonian

$$\frac{(T_C^{(k)} - T_A^{(k)})^2}{b^2 \sin^2\gamma} - 2\frac{(T_C^{(k)} - T_A^{(k)})(T_C^{(k)} - T_B^{(k)})}{a\, b \sin^2\gamma}\cos\gamma + \frac{(T_C^{(k)} - T_B^{(k)})^2}{a^2 \sin^2\gamma} \ge f_C^2 \tag{3.27}$$

because any later update of neighbors of $T_C^{(k)}$ in the same iteration is nonincreasing. Moreover, it is easy to see that after $T_C^{(k)}$ is updated, the function

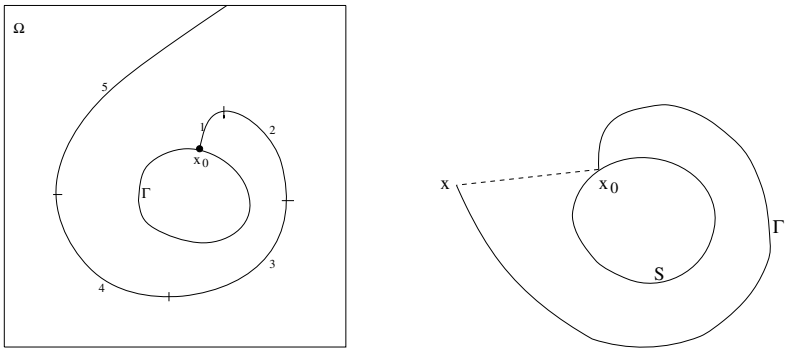
$$\begin{aligned} F(T_A^{(k)}, T_B^{(k)}) = {} & \frac{(T_C^{(k)} - T_A^{(k)})^2}{b^2 \sin^2\gamma} - 2\frac{(T_C^{(k)} - T_A^{(k)})(T_C^{(k)} - T_B^{(k)})}{a\, b \sin^2\gamma}\cos\gamma \\ & + \frac{(T_C^{(k)} - T_B^{(k)})^2}{a^2 \sin^2\gamma} - f_C^2 \end{aligned} \tag{3.28}$$

is Lipschitz continuous in $T_A^{(k)}$ and $T_B^{(k)}$, and the Lipschitz constant is bounded by

$$2\max\left\{ \frac{|T_C^{(k)} - T_A^{(k)}|}{b^2 \sin^2\gamma} + \frac{|T_C^{(k)} - T_B^{(k)}|}{a\, b \sin^2\gamma}\cos\gamma, \frac{|T_C^{(k)} - T_B^{(k)}|}{a^2 \sin^2\gamma} + \frac{|T_C^{(k)} - T_A^{(k)}|}{a\, b \sin^2\gamma}\cos\gamma \right\}.$$

Since $T_C^{(k)}$ is monotonically convergent for all C, we can have an upper bound $Z > 0$ for the Lipschitz constant. Let $\delta^{(k)} = \max\{T_C^{(k-1)} - T_C^{(k)}\}$ be the maximum change at all grid points during the kth iteration. By the l^∞-contraction property and the convergence property of $T_C^{(k)}$, $\delta^{(k)}$ converges monotonically to zero. After the kth iteration, we have

$$\begin{aligned} 0 \le {} & \frac{(T_C^{(k)} - T_A^{(k)})^2}{b^2 \sin^2\gamma} - 2\frac{(T_C^{(k)} - T_A^{(k)})(T_C^{(k)} - T_B^{(k)})}{a\, b \sin^2\gamma}\cos\gamma + \frac{(T_C^{(k)} - T_B^{(k)})^2}{a^2 \sin^2\gamma} - f_C^2 \\ & \le Z\delta^{(k)}. \end{aligned} \tag{3.29}$$



(a) (b)

FIG. 3.1. *Partitioning of a characteristic.*

Thus $T^{(k)}$ converges to the solution to (3.1). □

Note that the monotone convergence is very important during iterations. Once the solution at a node reaches the minimal value that it can get, it is the correct value at that node and will not change in later iterations.

Next we show the estimate for the total number of iterations needed for convergence. As pointed out above, given a systematic ordering, any characteristic can be partitioned into a finite number of pieces and each piece will be covered correctly by one of the sweeping orderings, as shown in Figure 3.1(a). Since these pieces have to be captured sequentially the total number of iterations needed is proportional to the number of pieces. Finally the number of pieces needed to partition a characteristic is related to the directional change of the characteristic. We now give an estimate on the total variation of the tangent direction of any characteristic in a fixed domain Ω.

Denote $H(\mathbf{p}, \mathbf{x}) = |\mathbf{p}| - f(\mathbf{x})$, where $\mathbf{p} = \nabla T$. The characteristic equation for the eikonal equation is

$$\begin{cases} \dot{\mathbf{x}} = \nabla_{\mathbf{p}} H = \frac{\nabla T}{f(\mathbf{x})}, \\ \dot{\mathbf{p}} = -\nabla_{\mathbf{x}} H = \nabla f(\mathbf{x}), \\ \dot{T} = \nabla T \cdot \dot{\mathbf{x}} = f(\mathbf{x}), \end{cases}$$

where $\dot{}$ denotes the derivative along characteristics parametrized by the arc length s.

Since $|\dot{\mathbf{x}}| = 1$, it was shown in [35] that the curvature bound along a characteristic is

$$|\ddot{\mathbf{x}}| \le \left| \frac{\nabla f(\mathbf{x})}{f(\mathbf{x})} \right|. \tag{3.30}$$

LEMMA 3.9. *Assuming that $f(\mathbf{x})$ is strictly positive and C^1 in Ω, the total variation of the tangent direction of the shortest characteristic L from an initial point $\mathbf{x}_0 \in \Gamma$ to a point $\mathbf{x} \in \Omega$ is bounded by*

$$\int_L |\ddot{\mathbf{x}}| ds \le \frac{DKf_M}{f_m}, \tag{3.31}$$

where s is the arc-length along the characteristic L, D is the diameter of domain Ω, and

$$K = \sup_{\mathbf{x}\in\Omega} \left| \frac{\nabla f(\mathbf{x})}{f(\mathbf{x})} \right|, \qquad f_M = \sup_{\mathbf{x}\in\Omega} f(\mathbf{x}), \qquad f_m = \inf_{\mathbf{x}\in\Omega} f(\mathbf{x}).$$

Proof. The existence of the shortest path L, yielding the first-arrival travel-time from an initial point $\mathbf{x}_0 \in \Gamma$ to a point $\mathbf{x} \in \Omega$, is guaranteed by the results in [14, 16]. If L is a single characteristic curve, then from (3.30) we have

$$\int_L |\ddot{\mathbf{x}}| ds \leq \int_L \frac{|\nabla f(\mathbf{x})|}{f(\mathbf{x})} ds \leq K \int_L ds, \tag{3.32}$$

where s is the arc-length; see Figure 3.1(b). The travel-time at $\mathbf{x}$ is $T(\mathbf{x}) = \int_L f(s)ds$. This travel-time, which is the first arrival time at $\mathbf{x}$, is smaller than the travel-time along the direct path from $\mathbf{x}_0$ to $\mathbf{x}$. So we have

$$f_m \int_L ds \leq \int_L f(s)ds = T(\mathbf{x}) \leq \int_{\mathbf{x}_0}^{\mathbf{x}} f(s)ds \leq f_M |\mathbf{x} - \mathbf{x}_0|. \tag{3.33}$$

Hence

$$\text{length}(L) = \int_L ds \leq \frac{D f_M}{f_m}. \tag{3.34}$$

Together with (3.32) we finish the proof. In general L may be composed of several pieces of characteristic curves. The above integral may be broken into several parts accordingly, but the same proof goes through. □

According to the above lemma the maximal number of sweeping needed to cover all characteristics can be bounded by $C \times \frac{DKf_M}{f_m}$, where the constant C may depend on the number of reference points and orderings.

Here is a discrete version of the above argument [36]. For an appropriate upwind scheme the corresponding discretized nonlinear system of equations has a solution (see Theorem 3.8). We can classify all nodes into a few groups according to the solution. All nodes in each group have a dependence pattern similar to their neighbors. For example, on a rectangular grid in two dimensions, almost all grid points can be divided into simply connected regions. In each region the value at a grid point depends on two of its neighbors in the following ways: (1) left and down neighbors; (2) left and up neighbors; (3) right and down neighbors; (4) right and up neighbors. By the Gauss–Seidel iteration each connected region can be covered by one of the orderings simultaneously when the ordering is in the upwind direction of the dependence pattern. The number of connected regions is proportional to the number of directional changes of characteristics which is bounded above. This relates the number of iterations for the fast sweeping method to the above bound. On a triangular mesh, because an arbitrary unstructured mesh may accommodate much more information flowing directions than a rectangular mesh, the situation is more complicated. However, given a triangulation and a choice of the reference points, all nodes can be partitioned into a finite number of connected regions. In each region the nodal dependence follows one of the orderings according to the increase/decrease of the distance to the reference points. For example, all those connected nodes, whose values depend on neighboring nodes that are closer to one of the reference points, belong to one region. The number of regions is proportional to the bound above. Although the triangulation and the choice of the reference points may affect the number of iterations, it is finite for a fixed setup.

4. Numerical examples. Now we show numerical examples in both two and three dimensions to illustrate the efficiency and the accuracy of our algorithm. In all the examples we have used the quick-sort method to order the nodes, though a radix sorting method may be implemented as well.

Our computational experience indicates that for an acute triangulation, using four corners in 2-D rectangular domains or eight corners in 3-D rectangular domains as the reference points is sufficient for the algorithm to converge in a finite number of iterations. For a triangulation with some obtuse triangles, more reference points may be needed. However, if the virtual splitting of obtuse angles as described in section 2.1 is used, then no extra reference point is needed; the results in convergence and accuracy are similar to those with all triangles being acute.

In all the presented examples the number of iterations is independent of the mesh size. The convergence of iteration is measured as full convergence in terms of the l^∞-norm; i.e., the iteration stops when the successive error reaches machine zero. On the other hand, the convergence order of the method is measured in the l^1-norm, as advocated by Lin and Tadmor [15].

We note that in our implementation, the convergence test is checked for every sweeping; here one sweeping is defined as passing through each node once according to a given ordering of nodes. So the iteration numbers reported in numerical examples are, in fact, the sweeping numbers needed for the algorithm to converge.

4.1. 2-D acute triangulation. We first triangulate the computational domain into acute triangles, then we refine the mesh uniformly by cutting each triangle in the coarse mesh into four smaller similar ones. We have chosen the four corners as the reference points in Examples 1, 2, and 3, with both the l^1- and l^2-metric–based sortings.

Example 1 (two-circle problem). The eikonal equation (2.1) with $f(x, y) = 1$. The computational domain is $\Omega = [-2, 2] \times [-2, 2]$; Γ consists of two circles of equal radius 0.5 with centers located at $(-1, 0)$ and $(\sqrt{1.5}, 0)$, respectively. The exact solution is the distance function to Γ. An acute triangulation is used in the computation. The solution is shown in Figure 4.1(a).

Example 2 (shape-from-shading). This example is taken from [26], in which

$$f(x, y) = 2\pi\sqrt{[\cos(2\pi x)\sin(2\pi y)]^2 + [\sin(2\pi x)\cos(2\pi y)]^2}. \tag{4.1}$$

$\Gamma = \{(\frac{1}{4}, \frac{1}{4}),\ (\frac{3}{4}, \frac{3}{4}),\ (\frac{1}{4}, \frac{3}{4}),\ (\frac{3}{4}, \frac{1}{4}),\ (\frac{1}{2}, \frac{1}{2})\}$, consisting of five isolated points. The computational domain is $\Omega = [0, 1] \times [0, 1]$. $T(x, y) = 0$ is prescribed on the boundary of the unit square. The solution to this problem is the shape function, which has the brightness $I(x, y) = 1/\sqrt{1 + f(x, y)^2}$ under vertical lighting. We have used acute triangulations for the following two cases.

Case a.

$$g\left(\frac{1}{4},\ \frac{1}{4}\right) = g\left(\frac{3}{4},\ \frac{3}{4}\right) = 1, \quad g\left(\frac{1}{4},\ \frac{3}{4}\right) = g\left(\frac{3}{4},\ \frac{1}{4}\right) = -1, \quad g\left(\frac{1}{2},\ \frac{1}{2}\right) = 0.$$

The exact solution for this case is smooth,

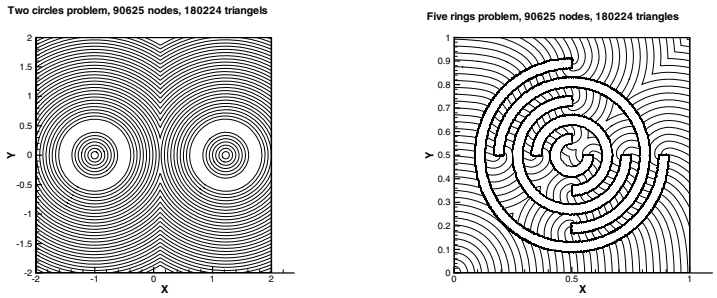
$$T(x, y) = \sin(2\pi x)\sin(2\pi y).$$

Case b.

$$g\left(\frac{1}{4},\ \frac{1}{4}\right) = g\left(\frac{3}{4},\ \frac{3}{4}\right) = g\left(\frac{1}{4},\ \frac{3}{4}\right) = g\left(\frac{3}{4},\ \frac{1}{4}\right) = 1, \quad g\left(\frac{1}{2},\ \frac{1}{2}\right) = 2.$$

The exact solution for this case is nonsmooth,

$$T(x, y) = \begin{cases} \max(|\sin(2\pi x)\sin(2\pi y)|,\ 1 + \cos(2\pi x)\cos(2\pi y)) \\ \qquad\qquad \text{if } |x + y - 1| < \frac{1}{2} \text{ and } |x - y| < \frac{1}{2}; \\ |\sin(2\pi x)\sin(2\pi y)| \qquad \text{otherwise.} \end{cases}$$



(a) (b)

Example 3 (five-ring). The computational domain is $\Omega = [0,1] \times [0,1]$, Γ is a point source at $(0,0)$, and a five-ring obstacle is placed in the computational domain. This example is borrowed from [9]. Here we also use an acute triangulation. The solution is shown in Figure 4.1(b).

From Table 4.1, we can see that the accuracy of the algorithm for Examples 1 and 2 is first order. Although the same discretized nonlinear system is solved, no matter which ordering metric is used, different ordering strategies may result in different numbers of iterations, as illustrated in Tables 4.2 and 4.3, where we have applied orderings based on l^1- and l^2-metrics, respectively. Certainly, the two tables also indicate that the iteration number does not depend on the mesh size as the mesh is refined.

Table 4.4 shows the number of iterations needed using the l^1-metric with only two reference points. The two reference points are two corners that are not diagonal to each other.

On the other hand, Table 4.5 shows that a simple extension of the ordering strategy used for rectangular meshes, i.e., sorting all vertexes according to the ascent and descent orders of their x- and y-coordinates, may result in more iterations.

4.2. 2-D obtuse triangulation. We test our strategy for treating a triangulation which has obtuse angles. The obtuse triangulations are constructed by perturbing randomly the x-coordinates of vertexes (Figure 4.2(a)) or perturbing randomly both the x-coordinates and the y-coordinates of vertexes (Figure 4.2(b)) in a uniform triangulation. The uniform triangulation, in turn, is obtained by connecting the diagonal line in every rectangle of a rectangular mesh and cutting every rectangle into two equivalent isosceles triangles. The perturbation range is $[-0.5h, 0.5h]$, where h is the length of an isosceles triangle. We use Example 1 in section 4.1 as a test example and apply spherical-wave sweepings.

As a first test, we use the obtuse triangulation as in Figure 4.2(a), choose four corners of the computational domain as the reference points, and sweep through all the nodes according to both ascent and descent sortings. The accuracy and the number of iterations for the algorithm without and with the obtuse-angle treatment are listed in Table 4.6.

As a second test, we use eight reference points which include both the four corners and four middle points of the four edges of the computational domain, and we use only ascent orders. The accuracy and the number of iterations for the algorithm without and with the obtuse-angle treatment are listed in Table 4.7 for the obtuse triangulation as in Figure 4.2(a) and in Table 4.8 for the obtuse triangulation as in Figure 4.2(b). Comparing Tables 4.6, 4.7, and 4.8, we can see that more reference points may help us reduce the number of sweepings needed in the algorithm. Roughly speaking, for different meshes the errors from the algorithm with the obtuse-angle treatment are decreased $2 \sim 4$ times in comparison to the errors from the algorithm without such a treatment, as shown in both Table 4.7 and Table 4.8. The first-order

accuracy with the obtuse-angle treatment is more regular than that without the treatment. Moreover, comparing the errors in Table 4.6 with those in Table 4.7, we can observe that without the obtuse-angle treatment different sweeping ordering strategies yield slightly different numerical solutions, and with the obtuse-angle treatment different sweeping ordering strategies yield the same solutions up to machine zero. This indicates that the causality of PDEs may *not* be captured accurately if obtuse angles are *not* treated.

4.3. A 3-D example. We test our 3-D fast sweeping methods on tetrahedral meshes. We use a two-sphere problem as an example: the eikonal equation (2.3) with $f(x, y, z) = 1$.

The computational domain is $\Omega = [0, 1] \times [0, 1] \times [0, 1]$; Γ consists of two spheres of equal radius 0.1 with centers located at $(0.25, 0.25, 0.25)$ and $(0.75, 0.75, 0.75)$, respectively. The exact solution is the distance function to Γ.

We first partition the computational domain into identical rectangular cubes. Then a tetrahedral mesh is obtained by cutting each cube into six tetrahedrons.

The results in Figure 4.3 are obtained by using a tetrahedral mesh which consists of $40 \times 40 \times 40 \times 6 = 384000$ tetrahedrons. We choose the eight corners of the computational domain as the reference points. Both ascent and descent orderings are used, and the ordering strategy is based on the l^2-metric. Figure 4.3(a) shows contours of the solution on the surface of the domain, and Figure 4.3(b) shows 3-D plots of the contour $T = 0.17$.

In Table 4.9, we present the accuracy and numbers of iterations when the tetrahedral mesh is refined. To calibrate the result, we apply the same sweeping ordering to the rectangular mesh from which the tetrahedral mesh is obtained. For the rectangular mesh we use the local solver for rectangular grids as in [35]. Although the

nodes are the same, the local solvers at each node are different so that the discretized nonlinear systems of the equation are different. The comparison results are also shown in Table 4.9. It is obvious from the table that the local solver on unstructured meshes can achieve higher accuracy than that on structured meshes since the former uses more neighboring points at each node and captures directions of characteristics more accurately than the latter.

Also we can see from Table 4.9 that if the l^2-metric is used for ordering, the number of iterations on an unstructured mesh can be less than that on a structured one. However, the local solver at each node for an unstructured mesh is more expensive than that for a rectangular mesh. Most importantly, we see that both iteration numbers do not change as the mesh is refined. So our ordering strategy works for both cases.

A similar comparison for a 2-D case, Example 1 of section 4.1, is presented in Table 4.10; again the local solver on unstructured meshes achieves higher accuracy than that on structured meshes.

4.4. Typical convergence behavior. Figure 4.4 shows the typical behavior of convergence error of the fast sweeping method in terms of the difference between two consecutive iterations in maximum norm. It demonstrates that the exact solution (up to machine error) to the discretized system is achieved in a finite number of iterations independent of mesh size.

5. Conclusion. We propose novel ordering strategies to extend the fast sweeping method to unstructured meshes. To that end we introduce multiple reference points and order all the nodes according to their l^p-metrics to those reference points. Information propagating along all characteristics can be covered efficiently by the

systematic orderings. We prove that the new algorithm converges and numerical examples demonstrate that the algorithm converges in a finite number of iterations independent of mesh size. The computational complexity of the new algorithm is nearly optimal in the sense that the total computational cost consists of $O(M)$ flops for iteration steps and $O(M\log M)$ flops for sorting at the predetermined initialization step, which can be efficiently optimized by adopting a linear time sorting method, where M is the total number of mesh points. Extensive numerical examples demonstrate the accuracy and the efficiency of the new fast sweeping method.

Acknowledgment. Qian thanks Profs. Stan Osher, William W. Symes, and Eitan Tadmor for encouragement in this project. Qian also thanks Prof. Ian Mitchell for comments related to sorting algorithms. The authors would like to thank the anonymous referees for constructive comments on the paper.

APPROXIMATION AND RECONSTRUCTION FROM ATTENUATED RADON PROJECTIONS*

YUAN XU†, OLEG TISCHENKO‡, AND CHRISTOPH HOESCHEN‡

Abstract. Attenuated Radon projections with respect to the weight function $W_\mu(x,y) = (1 - x^2 - y^2)^{\mu-1/2}$ are shown to be closely related to the orthogonal expansion in two variables with respect to W_μ. This leads to an algorithm for reconstructing two-dimensional functions (images) from attenuated Radon projections. Similar results are established for reconstructing functions on the sphere from projections described by integrals over circles on the sphere, and for reconstructing functions on the three-dimensional ball and cylinder domains.

Key words. approximation, reconstruction of images, Radon projections, polynomials of several variables, algorithms

1. Introduction.

Computer tomography (CT) offers a noninvasive method for two-dimensional (2D) cross-sectional or three-dimensional (3D) imaging of an object. In a typical CT application, the distribution of the attenuation coefficient through a body from measurements of x-ray transmission is estimated and used to reconstruct an image of the object. The mathematical foundation of CT is the Radon transform. Let f be a function defined on the unit disk B^2 of the $\mathbb{R}^2$ plane. A Radon transform of f is a line integral,

$$\mathcal{R}_\theta(f;t) := \int_{I(\theta,t)} f(x,y)dx\,dy, \qquad 0 \le \theta \le 2\pi, \quad -1 \le t \le 1, \tag{1.1}$$

where $I(\theta,t) = \{(x,y) : x\cos\theta + y\sin\theta = t\} \cap B^2$ is a line segment inside B^2. An essential problem in CT is to reconstruct the function f from its Radon projections. An algorithm amounts to an approximation to f that uses values of $\mathcal{R}_\theta(f;t)$ from a finite set of parameters (θ,t).

The attenuation of an x-ray beam is dependent on the energy of each photon. A line integral as defined in (1.1) represents a monochromatic x-ray. In practice, however, an x-ray is usually polychromatic, meaning that it consists of photons with different energies. This could lead to artifacts in the reconstruction; see, for example, [4, Chap. 4]. A polychromatic x-ray is represented by the so-called attenuated Radon projections for which the integral is taken against $\exp\{-\alpha_\theta(x,y)\}dx\,dy$, where $\alpha_\theta(x,y)$ is a given function, instead of $dx\,dy$. The attenuated Radon transform appears in, for example, emission tomography [7]. The reconstruction algorithms for attenuated Radon data have been derived from Novikov's inversion formula; see [10] and [8]. See also the recent survey in [3] in this direction.

In the present paper we consider the special case that $\exp\{-\alpha_\theta(x,y)\}$ is given, or

can be approximated, by the function

$$W_\mu(x,y) = (1-x^2-y^2)^{\mu-1/2}, \qquad (x,y)\in B^2, \tag{1.2}$$

where $\mu \ge 0$; in other words, $\alpha_\theta(x,y) = -(\mu-1/2)\log(1-x^2-y^2)$. The attenuated Radon transform, denoted by $\mathcal{R}_\theta^\mu$, then takes the form

$$\mathcal{R}_\theta^\mu(f;t) := \int_{I(\theta,t)} f(x,y)W_\mu(x,y)dx\,dy, \qquad 0\le\theta\le 2\pi, \quad -1\le t\le 1. \tag{1.3}$$

Clearly this is just a special case of the attenuated Radon transform. This case, however, appears to be useful in understanding the effect of monochromatic and polychromatic x-rays. In this regard let us mention the classical example of the water phantom in a skull in [4, p. 121], which demonstrated that beam hardening causes an elevation in CT numbers for tissues close to the skull bone. The attenuated Radon transform defined in (1.3) models the boundary behavior of the x-rays differently.

Our approach is based on orthogonal polynomial expansions on B^2. Let $\mathcal{V}_n^2(W_\mu)$ denote the space of orthogonal polynomials with respect to the weight function W_μ on B^2. It is well known that

$$L^2(B^2,W_\mu) = \sum_{k=0}^\infty \oplus \mathcal{V}_k^2 : \qquad f = \sum_{k=1}^\infty \operatorname{proj}_k^\mu f,$$

where $\operatorname{proj}_k^\mu f$ is the projection of f on $\mathcal{V}_k^2(W_\mu)$. The infinite series holds in the sense that the sequence of the partial sums

$$S_n^\mu(f;x,y) := \sum_{k=0}^n \operatorname{proj}_k^\mu f(x,y), \qquad n\ge 0,$$

converges to f as $n\to\infty$ in $L^2(B^2,W_\mu)$ norm. The partial sum S_nf provides a natural approximation to f. It turns out that there is a remarkable connection between $S_n^\mu f$ and the attenuated Radon transforms, which states that

$$S_{2m}f(x,y) = \sum_{\nu=0}^{2m}\int_{-1}^1 \mathcal{R}_{\phi_\nu}^\mu(f;t)\Phi_\nu(t;x,y)dt, \qquad \phi_\nu = \frac{2\nu\pi}{2m+1}, \tag{1.4}$$

where Φ_ν are polynomials of two variables given by explicit formulas. This representation provides a simple and direct access to attenuated Radon data. For the ordinary Radon transforms ($\mu = 1/2$), this was discovered recently in [16]. Applying an appropriate quadrature formula to the integrals in the expression leads to an approximation to f that uses discrete attenuated Radon projections. One important feature of the algorithm is that polynomials up to a certain degree are reconstructed exactly, which guarantees that the algorithm has a fast rate of convergence. Such an algorithm can be easily implemented numerically. For the ordinary Radon transforms, the algorithm is named OPED (orthogonal polynomial expansion on the disk) and has proved to be a highly effective method [17, 18].

There are other expressions in the spirit of (1.4). In order to prove them, we need to study orthogonal expansions in terms of orthogonal polynomials with respect to $W_\mu(x,y)$ on B^2. The case $\mu = 1/2$ is easier since an orthonormal basis for $\mathcal{V}_k^2(W_{1/2})$ is known to be $U_k(x\cos\frac{j\pi}{k+1} + y\sin\frac{j\pi}{k+1})$, $0\le j\le k$. No such convenient orthonormal basis is available for $\mu\ne 1/2$.

There is another advantage for considering the attenuated Radon transform $\mathcal{R}_\theta^\mu(f;t)$. It is known that there is a close relation between orthogonal polynomials on the unit ball and those on the unit sphere, which allows us to establish analogous results on the unit sphere S^2. In particular, the case $\mu = 0$ on B^2 can be used to show that we can reconstruct a function f from its integral projections:

$$Qf(\zeta;t) = \int_{\langle \mathbf{x},\zeta\rangle = t} f(\mathbf{x}) d\omega(\mathbf{x}), \qquad 0 \neq \zeta \in S^2, \quad -1 \le t \le 1, \tag{1.5}$$

where $\mathbf{x} = (x_1, x_2, x_3)$ and $d\omega$ is the surface measure on S^2. Reconstruction from such spherical transforms has been studied in the literature; see [9].

From the disk B^2 we can also extend the results to the unit ball B^3 and to cylinder domains in $\mathbb{R}^3$, taking Radon projections on parallel disks in each case. It turns out, however, that there is an important difference between the ball and the cylinder. For the cylinder domain, all results obtained in the disk can be extended without problem. For the unit ball, however, we still have an analogue of (1.4), but the reconstruction algorithm may no longer work as efficiently as in the cylinder case. The problem is that the operator produced by the algorithm no longer preserves polynomials.

For the algorithm on B^2, we provide a numerical example in section 2, which reconstructs a 2D phantom image for three different values of μ. For the transform on the sphere and the 3D transforms on the ball and on the cylinder domain, we will be content with deriving the algorithms and will not discuss convergence or the performance of the algorithms at this time.

The paper is organized as follows. In the following section we consider the reconstruction and approximation on the unit disk B^2 from attenuated Radon projections. This section is divided into several subsections, the last one including the numerical example. In section 3 the results on B^2 are transplanted to those on the surface S^2, while the attenuated Radon projections become weighted spherical transforms. The analogous results are then established for the unit ball B^3 in section 4 and for the cylinder domain in section 5.

2. Reconstruction and approximation on the unit disk. Let Π^d denote the space of polynomials of d variables and let Π_n^d denote the subspace of polynomials of total degree n in Π^d, which has dimension $\dim \Pi_n^d = \binom{n+d}{d}$. We set $\Pi_n := \Pi_n^1$. In this section we mainly work with the case $d = 2$.

2.1. Orthogonal polynomials on the unit disk. Let W_μ be the weight function defined in (1.2). Let $\mathcal{V}_k^2(W_\mu)$ denote the space of orthogonal polynomials of degree k on B^2 with respect to the inner product

$$\langle P, Q\rangle_\mu = a_\mu \int_{B^2} P(x,y)Q(x,y)W_\mu(x,y)dx\,dy, \qquad a_\mu = (\mu + 1/2)/\pi,$$

where a_μ is the normalization constant of W_μ, $a_\mu = 1/\int_{B^2} W_\mu(x)dx$. Thus, $P \in \mathcal{V}_k^2(W_\mu)$ if P is of degree k and $\langle P, Q\rangle_\mu = 0$ for all $Q \in \Pi_{k-1}^2$. We note that elements in a basis for $\mathcal{V}_k^2(W_\mu)$ may not be orthogonal with respect to each other according to our definition. A basis for $\mathcal{V}_k^2(W_\mu)$ is called orthonormal if the elements in the basis are mutually orthogonal and $\langle P, P\rangle_\mu = 1$.

The reproducing kernel of the space $\mathcal{V}_k^2(W_\mu)$ plays an important role in our development. In terms of an orthonormal basis $\{P_j^k : 0 \le j \le k\}$ of $\mathcal{V}_k^2(W_\mu)$, the

reproducing kernel satisfies

$$P_k(W_\mu; \mathbf{x}, \mathbf{y}) = \sum_{j=0}^{k} P_j^k(\mathbf{x}) P_j^k(\mathbf{y}). \tag{2.1}$$

The kernel is independent of the choice of the bases of $\mathcal{V}_k^2(W_\mu)$. In fact, a compact formula for this kernel can be given in terms of the Gegenbauer polynomial [13],

$$\begin{aligned} P_k(W_\mu; \mathbf{x}, \mathbf{y}) = \frac{k+\mu+1/2}{\mu+1/2} b_{\mu-1} \int_{-1}^{1} C_k^{\mu+1/2}\Big(\langle \mathbf{x}, \mathbf{y}\rangle \\ + \sqrt{1-\|\mathbf{x}\|^2}\sqrt{1-\|\mathbf{y}\|^2}\, t\Big)(1-t^2)^{\mu-1} dt \end{aligned} \tag{2.2}$$

for $\mu > 0$; the formula also holds for $\mu = 0$ upon taking limit $\mu \to 0$. Here and in the following, the Gegenbauer polynomials $C_k^\lambda(s)$ are orthogonal with respect to $(1-s^2)^{\lambda-1/2}$ on $[-1,1]$,

$$c_{\lambda-1/2} \int_{-1}^{1} C_k^\lambda(s) C_l^\lambda(s)(1-s^2)^{\lambda-1/2} ds = \frac{\lambda(2\lambda)_k}{(k+\lambda)k!}\delta_{k,l} := h_k \delta_{k,l}, \tag{2.3}$$

where $c_{\lambda-1/2} := \Gamma(\lambda+1)/(\sqrt{\pi}\Gamma(\lambda+1/2))$ is the normalization constant of the weight function $(1-s^2)^{\lambda-1/2}$ on $[-1,1]$, and $(a)_k := a(a+1)\cdots(a+k-1)$. For $\mu = 1/2$, $C_k^{\mu+1/2}(s) = U_k(s)$ is the Chebyshev polynomial of the second kind.

For the weight function $W_{1/2}(x) = 1$, it is known [5] that the set

$$\{U_k(x\cos\theta_{j,k} + y\sin\theta_{j,k}) : 0 \le j \le k\}$$

forms an orthonormal basis of $\mathcal{V}_k^2(W_{1/2})$. The elements of this basis are the so-called ridge functions. In general, given an angle ϕ and a polynomial $p \in \Pi_k := \Pi_k^1$, a ridge polynomial is defined by

$$p(\phi; x, y) := p(x\cos\phi + y\sin\phi), \qquad \phi \in [0, 2\pi].$$

It is easy to see that $p(\phi; x, y)$ is a polynomial in Π_k^2 as well. The functions $\{C_k^{\mu+1/2}(\theta_{j,k}; x, y) : 0 \le j \le k\}$, where $\theta_{j,k} = j\pi/(k+1)$, form a basis for $\mathcal{V}_k^2(W_\mu)$, albeit not a mutually orthogonal one (see, for example, [14]). The lack of an orthonormal ridge basis in the case of $\mu \ne 1/2$ makes the results for the attenuated Radon transform more difficult, as we shall see below.

We call a polynomial $P \in \Pi_k$ of one variable *symmetric* with respect to the origin if P is even when k is even, and if P is odd when k is odd. It is known that $C_k^{\mu+1/2}(t)$ is symmetric with respect to the origin. The ridge polynomials arising from such a polynomial turn out to satisfy a remarkable relation.

PROPOSITION 2.1. *For $n \ge 0$ and $k \le n$, the identity*

$$\frac{1}{n+1}\sum_{\nu=0}^{n} U_k\left(\frac{\nu\pi}{n+1}; \cos\theta, \sin\theta\right) P_k\left(\frac{\nu\pi}{n+1}; x, y\right) = P_k(\theta; x, y) \tag{2.4}$$

holds for all polynomials $P_k \in \Pi_k$ that are symmetric with respect to the origin.

Proof. The proof uses the elementary trigonometric identities

$$\sum_{\nu=0}^{n} \sin k\frac{2\nu\pi}{n+1} = 0 \quad \text{and} \quad \sum_{\nu=0}^{n} \cos k\frac{2\nu\pi}{n+1} = \begin{cases} n+1 & \text{if } k = 0 \mod n+1, \\ 0 & \text{otherwise,} \end{cases} \tag{2.5}$$

which hold for all nonnegative integers k. Let us prove the case $k = 2l$. We follow the proof of Proposition 2.3 in [16]. The polynomial P_k can be written as a linear combination of U_{k-2j} for $0 \le 2j \le k$. Consequently, we can write $P_{2l}(\theta; x, y)$ as

$$P_{2l}(\theta; x, y) = P_{2l}(r\cos(\theta - \phi)) = \sum_{j=0}^{l} b_j(r) \cos 2j(\theta - \phi) \tag{2.6}$$

in polar coordinates $x = r\cos\phi$ and $y = r\sin\phi$, where $b_j(r)$ is a polynomial of degree $2j$ in r. Furthermore, we know that

$$U_{2l}(\theta; \cos\phi, \sin\phi) = U_{2l}(\cos(\theta - \phi)) = \sum_{j=0}^{l} d_j \cos 2j(\theta - \phi),$$

where $d_0 = 1$ and $d_j = 2$ for $j \ge 1$. The identities (2.5) and the product formula of the cosine function show that

$$\frac{1}{n+1} \sum_{\nu=0}^{n} \cos 2i\left(\theta - \frac{\nu\pi}{n+1}\right) \cos 2j\left(\phi - \frac{\nu\pi}{n+1}\right) = \begin{cases} 0 & \text{if } i \ne j, \\ \frac{1}{2}\cos 2j(\theta - \phi) & \text{if } 0 < i = j \le n, \\ 1 & \text{if } i = j = 0. \end{cases}$$

Let us denote by I_k the left-hand side of (2.4). The above trigonometric identity implies immediately that, for $0 \le 2l \le n$,

$$\begin{aligned} I_{2l} &= \sum_{i=0}^{l} d_i \sum_{j=0}^{l} b_j(r) \frac{1}{n+1} \sum_{\nu=0}^{n} \cos 2i\left(\theta - \frac{\nu\pi}{n+1}\right) \cos 2j\left(\phi - \frac{\nu\pi}{n+1}\right) \\ &= \sum_{j=0}^{l} b_j(r) \cos 2j(\theta - \phi) = P_{2l}(r\cos(\theta - \phi)) = P_{2l}(\theta; x, y). \end{aligned}$$

This completes the proof for the case $k = 2l \le n$. The case $k = 2l - 1$ is similar. □

In (2.4) the summation is over angles, $\nu\pi/(n+1)$, that are equally spaced in the interval $[0, \pi)$. In the case that n is even, the angles can be arranged as equally spaced angles in $[0, 2\pi]$ by using the fact that

$$\cos\frac{(2k+1)\pi}{2m+1} = -\cos\frac{(2m+2k)\pi}{2m+1} \quad \text{and} \quad \sin\frac{(2k+1)\pi}{2m+1} = -\sin\frac{(2m+2k)\pi}{2m+1}. \tag{2.7}$$

The result is the following proposition proved in [16] for P_k being the Chebyshev polynomial of the second kind.

PROPOSITION 2.2. *For $m \ge 0$ and $k \le 2m$, the identity*

$$\frac{1}{2m+1} \sum_{\nu=0}^{2m} U_k\left(\frac{2\nu\pi}{2m+1}; \cos\theta, \sin\theta\right) P_k\left(\frac{2\nu\pi}{2m+1}; x, y\right) = P_k(\theta; x, y) \tag{2.8}$$

holds for all polynomials $P_k \in \Pi_k$ that are symmetric with respect to the origin.

There are many orthonormal bases of $\mathcal{V}_k^2(W_\mu)$ that are known explicitly (see [2]). One that is particularly useful for us is given in terms of the polar coordinates

$$x = r\cos\phi, y = r\sin\phi, \qquad 0 \le r \le 1, \quad 0 \le \phi \le 2\pi,$$

and Jacobi polynomials [2, Prop. 2.3.1]. Let $p_n^{(\alpha,\beta)}(t)$ denote the orthonormal Jacobi polynomials, that is,

$$c_{\alpha,\beta}\int_{-1}^{1} p_n^{(\alpha,\beta)}(t)p_m^{(\alpha,\beta)}(t)(1-t)^\alpha(1+t)^\beta dt = \delta_{m,n}, \quad m,n = 0,1,2,\ldots,$$

where $c_{\alpha,\beta}$ is the normalized constant so that $c_{\alpha,\beta}\int_{-1}^{1}(1-t)^\alpha(1+t)^\beta dt = 1$.

PROPOSITION 2.3. *For $\varepsilon = 0$ or 1, define the polynomials $P_{l,\varepsilon}^k$ by*

$$P_{l,\varepsilon}^k(x,y) = h_{l,k}p_l^{(\mu-\frac{1}{2},k-2l)}(2r^2-1)r^{k-2l}S_{k-2l,\varepsilon}(\phi), \tag{2.9}$$

where

$$\begin{aligned} S_{k-2l,0}(\phi) &= \cos(k-2l)\phi \quad \text{for } 0 \le 2l \le k,\\ S_{k-2l,1}(\phi) &= \sin(k-2l)\phi \quad \text{for } 0 \le 2l \le k-1, \end{aligned}$$

and

$$[h_{l,k}]^2 := \frac{\Gamma(k-2l+\mu+3/2)}{\Gamma(\mu+3/2)\Gamma(k-2l+1)}.$$

Then these polynomials form an orthonormal basis for $\mathcal{V}_k^2(W_\mu)$.

By the definition of the reproducing kernel (2.1) and formula (2.2), it follows that the above orthonormal basis satisfies

$$\sum_{\varepsilon=0,1}\sum_{0\le 2l\le k} P_{l,\varepsilon}^k(x,y)P_{l,\varepsilon}^k(\cos\phi,\sin\phi) = \frac{k+\lambda}{\lambda}C_k^\lambda(\phi;x,y), \tag{2.10}$$

where $\lambda = \mu + 1/2$. This formula will play an important role below. It shows, in particular, the expansion of $C_k^{\mu+1/2}(\phi;x,y)$ in terms of our orthonormal basis. The following lemma shows the converse.

LEMMA 2.4. *Let $\theta_{j,k} = j\pi/(k+1)$. Then for $0 \le 2l \le k$ if $\varepsilon = 0$ and $0 \le 2l \le k-1$ if $\varepsilon = 1$,*

$$\frac{1}{k+1}\sum_{j=0}^{k} S_{k-2l,\varepsilon}(\theta_{j,k})C_k^{\mu+1/2}(\theta_{j,k};x,y) = \frac{\mu+\frac{1}{2}}{k+\mu+\frac{1}{2}}H_{l,k}^\mu d_{l,k}P_{l,\varepsilon}^k(x,y),$$

where $d_{l,k} = 1/2$ if $2l < k$ and $d_{l,k} = 1$ if $2l = k$, $H_{l,k}^\mu := h_{l,k}^\mu p_l^{(\mu+1/2,k-2l)}(1)$ and

$$\left[H_{l,k}^\mu\right]^2 = \frac{(\mu+\frac{1}{2})_l(\mu+\frac{3}{2})_{k-l}(k+\mu+\frac{3}{2})}{l!(k-l)!(k-l+\mu+\frac{3}{2})}.$$

Proof. Using the identities (2.5) it is easy to verify that

$$\frac{1}{k+1}\sum_{j=0}^{k} S_{k-2l,\varepsilon}(\theta_{j,k})S_{k-2l',\varepsilon}(\theta_{j,k}) = d_{l,k}\delta_{l,l'}. \tag{2.11}$$

Using (2.9) and the fact that $P^k_{l,\varepsilon}(\cos\theta_{j,k}, \sin\theta_{l,k}) = H^\mu_{l,k} S_{k-2l,\varepsilon}(\theta_{j,k})$, we obtain

$$\begin{aligned}
&\frac{1}{k+1}\sum_{j=0}^{k} S_{k-2l,\varepsilon}(\theta_{j,k}) C_k^{\mu+1/2}(\theta_{j,k}; x, y) \\
&\quad = \frac{\mu+\frac12}{k+\mu+\frac12} \sum_{0\le l\le 2k} P^k_{l,\varepsilon}(x,y) \frac{1}{k+1}\sum_{l=0}^{k} P^k_{l,\varepsilon}(\cos\theta_{j,k}, \sin\theta_{j,k}) S_{k-2l,\varepsilon}(\theta_{j,k}) \\
&\quad = \frac{\mu+\frac12}{k+\mu+\frac12} H^\mu_{l,k} d_{l,k} P^k_l(x,y)
\end{aligned}$$

upon using (2.11). Finally, the expression of $[H^\mu_{l,k}]^2$ is derived from the well-known formula of $p_l^{\alpha,\beta}(1)$ (see [11]) and the formula of $h^\mu_{l,k}$. □

LEMMA 2.5. *Let $\theta_{j,k}$ be as above. Then*

$$\frac{1}{k+1}\sum_{j=0}^{k} S_{k-2l,\varepsilon}(\theta_{j,k}) U_k(\theta_{j,k}; \cos\phi, \sin\phi) = d_{l,k} S_{k-2l,\varepsilon}(\phi).$$

Proof. Using (2.6) and the analogous formula for U_{2l-1}, the identity is an easy consequence of (2.11). □

2.2. Attenuated Radon transforms. Let θ be an angle measured counterclockwise from the positive x-axis. Let ℓ denote the line perpendicular to the direction $(\cos\theta, \sin\theta)$ and passing through the point $(t\cos\theta, t\sin\theta)$. The equation of the line is $\ell(\theta, t) = \{(x, y) : x\cos\theta + y\sin\theta = t\}$ for $-1 \le t \le 1$. We use

$$I(\theta, t) = \ell(\theta, t) \cap B^2, \qquad 0 \le \theta < 2\pi, \quad -1 \le t \le 1, \tag{2.12}$$

to denote the line segment of ℓ inside B^2. Let W_μ be the weight function defined in (1.2). The attenuated Radon projection of a function f, with respect to W_μ, in the direction θ with parameter $t \in [-1, 1]$ is defined in (1.3). It can be written as

$$\mathcal{R}^\mu_\theta(f; t) = \int_{-\sqrt{1-t^2}}^{\sqrt{1-t^2}} f(t\cos\theta - s\sin\theta, t\sin\theta + s\cos\theta) W_\mu(s, t) ds, \tag{2.13}$$

using the fact that the mapping $(s, t) \mapsto (x, y)$ defined by $x = t\cos\theta - s\sin\theta$ and $y = t\sin\theta + s\cos\theta$ amounts to a rotation. When $\mu = 1/2$, this is the usual Radon projection, which is also called an x-ray transform. The definition (1.3) or (2.13) shows that $\mathcal{R}^\mu_\theta(f; t) = \mathcal{R}^\mu_{\pi+\theta}(f; -t)$.

The ridge polynomials are particularly useful for studying Radon transforms, as seen in the following result.

PROPOSITION 2.6. *For $f \in L^1(B^2)$ and $p \in \Pi_k$,*

$$\int_{B^2} f(x, y) p(\phi; x, y) W_\mu(x, y) dx\, dy = \int_{-1}^{1} \mathcal{R}^\mu_\phi(f; t) p(t) dt. \tag{2.14}$$

Proof. Since the change of variables $t = x\cos\phi + y\sin\phi$ and $s = -x\sin\phi + y\cos\phi$

amounts to a rotation, we have

$$\begin{aligned}\int_{B^2} & f(x,y)p_k(\phi;x,y)W_\mu(x,y)dx\,dy \\ &= \int_{B^2} f(t\cos\phi - s\sin\phi, t\sin\phi + s\cos\phi)p_k(t)W_\mu(t,s)dt\,ds \\ &= \int_{-1}^{1}\int_{-\sqrt{1-t^2}}^{\sqrt{1-t^2}} f(t\cos\phi - s\sin\phi, t\sin\phi + s\cos\phi)W_\mu(t,s)ds p_k(t)dt,\end{aligned}$$

and the inner integral is exactly $\mathcal{R}^\mu_\phi(f;t)$ by (2.13). ∎

In particular, attenuated Radon transforms of the orthogonal polynomials in $\mathcal{V}^2_n(W_\mu)$ can be explicitly computed.

LEMMA 2.7. *If $P \in \mathcal{V}^2_k(W_\mu)$, then for each $t \in (-1,1)$, $0 \le \theta \le 2\pi$,*

$$\mathcal{R}^\mu_\theta(P;t) = b_\mu(1-t^2)^\mu \frac{C_k^{\mu+1/2}(t)}{C_k^{\mu+1/2}(1)} P(\cos\theta,\sin\theta), \tag{2.15}$$

where $b_\mu = c_\mu^{-1}$ for c_μ defined in (2.3).

Proof. Changing variables in (2.13) shows that

$$\begin{aligned} Q(t) &:= (1-t^2)^{-\mu}\mathcal{R}^\mu_\theta(P;t) \\ &= \int_{-1}^{1} P\left(t\cos\theta - s\sqrt{1-t^2}\sin\theta, t\sin\theta + s\sqrt{1-t^2}\cos\theta\right)(1-s^2)^{\mu-1/2}ds.\end{aligned}$$

Since an odd power of $\sqrt{1-t}$ in the integrand is always attached to an odd power of s, which has integral zero, $Q(t)$ is a polynomial of t of degree at most k. Furthermore, the integral shows that $Q(1) = b_\mu P(\cos\theta,\sin\theta)$. Equation (2.14) in Proposition 2.6 shows that

$$\int_{-1}^{1} \frac{\mathcal{R}^\mu_\theta(P;t)}{(1-t^2)^\mu} C_j^{\mu+1/2}(t)(1-t^2)^\mu dt = \int_{B^2} P(x,y)C_j^{\mu+1/2}(\theta;x,y)dx\,dy = 0$$

for $j = 0,1,\ldots,k-1$, since $P \in \mathcal{V}_k(B^2)$. In particular, this shows that $Q(t)$ is in fact orthogonal to all polynomials in Π_{k-1} with respect to the weight function $(1-t^2)^\mu$ on $[-1,1]$. Since Q is of degree k, it must be an orthogonal polynomial of degree k with respect to this weight function. Hence, we conclude that $Q(t) = cC_k^{\mu+1/2}(t)$ for some constant c independent of t. Setting $t = 1$ shows that $c = b_\mu P(\cos\theta,\sin\theta)/C_k^{\mu+1/2}(1)$. ∎

In the case of $\mu = 1/2$, the above lemma appeared first in [6].

2.3. Orthogonal expansion and attenuated Radon projections. The standard Hilbert space theory shows that any function in $L^2(W_\mu;B^2)$ can be expanded as a Fourier orthogonal series in terms of $\mathcal{V}^2_n(W_\mu)$. More precisely,

$$L^2(W_\mu;B^2) = \sum_{k=1}^{\infty}\oplus \mathcal{V}^2_k(W_\mu): \qquad f = \sum_{k=1}^{\infty} \operatorname{proj}^\mu_k f, \tag{2.16}$$

where $\operatorname{proj}^\mu_k f$ is the orthogonal projection of f from $L^2(W_\mu;B^2)$ onto the subspace

$\mathcal{V}_k^2(W_\mu)$. It is well known that $\operatorname{proj}_k^\mu f$ can be written as an integral operator in terms of the reproducing kernel $P_k(W_\mu;\cdot,\cdot)$ of $\mathcal{V}_k(B^2)$ in $L^2(B^2)$; that is,

$$\operatorname{proj}_k^\mu f(\mathbf{x}) = \int_{B^2} P_k(W_\mu;\mathbf{x},\mathbf{y}) f(\mathbf{y}) W_\mu(\mathbf{y}) d\mathbf{y}, \tag{2.17}$$

where $\mathbf{x} = (x_1, x_2)$ and $\mathbf{y} = (y_1, y_2)$.

This formula plays an essential role in studying the convergence behavior of the orthogonal expansions; see, for example, [13, 15]. For our purposes, we need a different expression for $\operatorname{proj}_k f$. This is the following remarkable formula that relates $\operatorname{proj}_k f$ to the attenuated Radon transforms of f directly. Let

$$\xi_\nu = \frac{\nu\pi}{n+1}, \qquad 0 \le \nu \le n.$$

THEOREM 2.8. *For $n \ge 0$ and $k \le n$, the operator $\operatorname{proj}_k^\mu f$ can be written as*

$$\operatorname{proj}_k^\mu f(x,y) = \frac{1}{n+1} \sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}^\mu(f;t) D_k^{\mu+1/2}(\xi_\nu, t; x, y) dt \tag{2.18}$$

$$= \frac{1}{2n+2} \sum_{\nu=0}^{2n+1} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}^\mu(f;t) D_k^{\mu+1/2}(\xi_\nu, t; x, y) dt, \tag{2.19}$$

where

$$D_k^{\mu+1/2}(\xi, t; x, y) = \frac{k+\mu+1/2}{\mu+1/2} C_k^{\mu+1/2}(t) D_k^{\mu+1/2}(\xi; x, y) \tag{2.20}$$

with $\lambda_{l,k}^\mu = [H_{l,k}^\mu]^{-2}$ and

$$D_k^{\mu+1/2}(\xi_\nu; x, y) := \sum_{l=0}^{k} \lambda_{l,k}^\mu P_l^k(\cos\xi_\nu, \sin\xi_\nu) P_l^k(x,y).$$

Proof. Since $C_k^{\mu+1/2}$ is symmetric with respect to the origin, using Propositions 2.1 and 2.6, we have

$$\begin{aligned}
a_\mu &\int_{B^2} f(x,y) C_k^{\mu+1/2}(\theta_{j,k}; x, y) W_\mu(x,y) dx\, dy \\
&= \frac{1}{n+1} \sum_{\nu=0}^{n} U_k(\xi_\nu; \cos\theta_{j,k}, \sin\theta_{j,k}) \\
&\quad \times a_\mu \int_{B^2} f(x,y) C_k^{\mu+1/2}(\xi_\nu; x, y) W_\mu(x,y) dx\, dy \\
&= \frac{1}{n+1} \sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}(f;t) C_k^{\mu+1/2}(t) dt U_k(\xi_\nu; \cos\theta_{j,k}, \sin\theta_{j,k}).
\end{aligned}$$

Using Lemmas 2.4 and 2.5 we conclude that

$$\begin{aligned}
a_\mu &\int_{B^2} f(x,y) P_{l,\varepsilon}^k(x,y) W_\mu(x,y)\,dx\,dy \\
&= \frac{1}{n+1}\sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}(f;t) C_k^{\mu+1/2}(t)\,dt \frac{k+\mu+\frac{1}{2}}{\mu+\frac{1}{2}} [H_{l,k}^\mu]^{-1} \\
&\quad \times d_{l,k}^{-1} \frac{1}{k+1}\sum_{j=0}^{k} S_{k-2l,\varepsilon}(\theta_{j,k}) U_k(\xi_\nu; \cos\theta_{j,k}, \sin\theta_{j,k}) \\
&= \frac{1}{n+1}\sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}(f;t) C_k^{\mu+1/2}(t)\,dt \frac{k+\mu+\frac{1}{2}}{\mu+\frac{1}{2}} [H_{l,k}^\mu]^{-1} S_{k-2l,\varepsilon}(\xi_\nu).
\end{aligned}$$

Multiplying by $P_{l,\varepsilon}^k(x,y)$ and summing up, it follows from the definition of the reproducing kernel that

$$\begin{aligned}
\operatorname{proj}_k^\mu f(x,y) &= \frac{1}{n+1}\sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}(f;t) C_k^{\mu+1/2}(t)\,dt \frac{k+\mu+\frac{1}{2}}{\mu+\frac{1}{2}} \\
&\quad \times \sum_{l=0}^{k} [H_{l,k}^\mu]^{-1} \left[S_{k-2l,0}(\xi_\nu) P_{l,0}^k(x,y) + S_{k-2l,1}(\xi_\nu) P_{l,1}^k(x,y) \right] \\
&= \frac{1}{n+1}\sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_\nu}(f;t) C_k^{\mu+1/2}(t)\,dt \frac{k+\mu+\frac{1}{2}}{\mu+\frac{1}{2}} D_k^{\mu+1/2}(\xi_\mu; x, y),
\end{aligned}$$

since $P_{l,\varepsilon}^k(\cos\xi_\nu, \sin\xi_\nu) = H_{l,k}^\mu S_{k-2l,\varepsilon}(\xi_\nu)$ and $\lambda_{l,k}^\mu = [H_{l,k}^\mu]^{-2}$. This proves the first identity.

We now prove the second equation, (2.19). Using the fact that $\xi_{n+\nu+1} = \xi_\nu + \pi$,

$$\cos(k-2l)\xi_{n+\nu+1} = (-1)^k \cos(k-2l)\xi_\nu, \quad \sin(k-2l)\xi_{n+\nu+1} = (-1)^k \sin(k-2l)\xi_\nu,$$

we conclude that $D_k^{\mu+1/2}(\xi_\nu; x, y) = (-1)^k C_k^{\mu+1/2}(\xi_{n+1+\nu}; x, y)$. Hence, using the fact that $\mathcal{R}_{\xi_\nu+\pi}^\mu(f;t) = \mathcal{R}_{\xi_\nu}^\mu(f;-t)$, we conclude that

$$\operatorname{proj}_k^\mu f(x,y) = \frac{1}{n+1}\sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} \mathcal{R}_{\xi_{n+1+\nu}}^\mu(f;t) D_k^{\mu+1/2}(\xi_{n+1+\nu}, t; x, y)\,dt.$$

Adding this equation and the first equation of (2.18) and dividing the result by 2, we then have (2.19). □

In the case of $\mu = 1/2$, it is easy to see that $\lambda_{l,k}^{\frac{1}{2}} = 1/(k+1)$, independent of l. Hence, for $\mu = 1/2$, (2.10) shows that

$$D_k^{\mu+1/2}(\xi_\nu; x, y) = \frac{1}{k+1}(k+1) C_k^1(\xi_\nu; x, y) = U_k(\xi_\nu; x, y),$$

and formulas (2.18) and (2.19) are of a particular simple form. This case was studied in [16].

The two expressions of $\operatorname{proj}_k f$ look similar but are different in one important point: the first expression consists of Radon projections in equally spaced directions along half of the circumference of the circle, while the second expression uses Radon

projections in equally spaced directions along the entire circumference of the circle. This distinction is meaningful for reconstruction algorithms for Radon data.

If n is even, then we can use Proposition 2.2 instead of Proposition 2.1 in the proof. The result is another identity that uses Radon projections over equally spaced angles in $[0, 2\pi]$. Let

$$\phi_\nu = \frac{2\nu\pi}{2m+1}, \qquad 0 \le \nu \le 2m.$$

THEOREM 2.9. *For $m \ge 0$ and $k \le 2m$, the operator $\operatorname{proj}_k^\mu f$ can be written as*

$$\operatorname{proj}_k^\mu f(x,y) = \frac{1}{2m+1} \sum_{\nu=0}^{2m} a_\mu \int_{-1}^1 \mathcal{R}_{\phi_\nu}^\mu(f;t) D_k^{\mu+1/2}(\phi_\nu, t; x, y)dt. \tag{2.21}$$

This expression of $\operatorname{proj}_k f$ is not a special case of (2.19), even though both use equally spaced angles. In fact, setting $n = 2m$ shows that (2.19) uses exactly twice as many Radon projections in equally spaced directions. For $\mu = 1/2$ the identity (2.21) has appeared in [16]. Equation (2.21) can be deduced from (2.18) by using the fact that $\mathcal{R}_{\phi+\pi} f(t) = \mathcal{R}_\phi(f; -t)$ and changing variable $t \mapsto -t$ in the integral whenever $\phi = \xi_{2\nu-1}$ in (2.18), then making use of the equations in (2.7) and the fact that the Gegenbauer polynomial is symmetric.

Let $S_n^\mu f$ denote the nth partial sum of the expansion (2.16); that is,

$$S_n^\mu(f; x, y) = \sum_{k=0}^n \operatorname{proj}_k^\mu f(x,y).$$

The operator S_n^μ is a projection operator from $L^2(W_\mu; B^2)$ onto Π_n^2. An immediate consequence of Theorem 2.8 is the following corollary.

COROLLARY 2.10. *For $n \ge 0$, the partial sum operator $S_n^\mu f$ can be written as*

$$\begin{aligned} S_n^\mu(f; x, y) &= \frac{1}{n+1} \sum_{\nu=0}^n a_\mu \int_{-1}^1 \mathcal{R}_{\xi_\nu}^\mu(f;t) \Phi_n^\mu(\xi_\nu, t; x, y)dt \\ &= \frac{1}{2n+2} \sum_{\nu=0}^{2n+1} a_\mu \int_{-1}^1 \mathcal{R}_{\xi_\nu}^\mu(f;t) \Phi_n^\mu(\xi_\nu, t; x, y)dt, \end{aligned} \tag{2.22}$$

where

$$\Phi_n^\mu(\xi, t; x, y) = \sum_{k=0}^n \frac{k+\mu+1/2}{\mu+1/2} C_k^{\mu+1/2}(t) D_k^{\mu+1/2}(\xi; x, y). \tag{2.23}$$

Likewise, an immediate consequence of Theorem 2.9 is the following corollary.

COROLLARY 2.11. *For $m \ge 0$, the partial sum operator $S_{2m}^\mu f$ can be written as*

$$S_{2m}^\mu(f; x, y) = \frac{1}{2m+1} \sum_{\nu=0}^{2m} a_\mu \int_{-1}^1 \mathcal{R}_{\phi_\nu}^\mu(f;t) \Phi_{2m}^\mu(\phi_\nu, t; x, y)dt. \tag{2.24}$$

2.4. Discretization and reconstruction algorithm. Equation (2.22) expresses the partial sum of the Fourier orthogonal expansion as the integrals of attenuated Radon projections in the equally spaced directions. In order to derive an

algorithm that uses only values of attenuated Radon projections on a set of finite line segments, we approximate the integrals by a quadrature formula. If f is a polynomial, then $\mathcal{R}^\mu_\phi(f;t)/(1-t^2)^\mu$ is a polynomial of the same degree by Lemma 2.7, which shows that we should use a quadrature formula with respect to the weight function $(1-t^2)^\mu$; that is,

$$\int_{-1}^{1} g(t)(1-t^2)^\mu dt \approx \sum_{j=1}^{N} \lambda_j g(t_j),$$

where t_j are real numbers and λ_j are chosen so that the quadrature produces exact values of the integrals for polynomials of degree at least M. Such a quadrature is said to be of N points and of precision M. A Gaussian quadrature of N points has the highest precision $M = 2N-1$ among all quadrature formulas of N points.

For our purpose we are interested in quadrature formulas of precision $2n$ that use $n+1$ points. A class of such formulas is given in the following proposition, which is based on the zeros of the quasi-orthogonal polynomial $C_{n+1}^{\mu+1/2}(t) + aC_n^{\mu+1/2}(t)$, where a is a real number [11]. For a certain range of a, such a polynomial has $n+1$ real distinct zeros in the interval $[-1,1]$.

PROPOSITION 2.12. *Let $t_{j,n}$, $0 \le j \le n$, be the distinct zeros of a quasi-orthogonal polynomial $C_{n+1}^{\mu+1/2}(t) + aC_n^{\mu+1/2}(t)$. Then there are positive numbers $\lambda_{j,n}$ such that the quadrature*

$$\int_{-1}^{1} g(t)(1-t^2)^\mu dt \approx \sum_{j=0}^{n} \lambda_{j,n} g(t_{j,n}) := \mathcal{I}_n^\mu(g) \tag{2.25}$$

has precision $2n$ if $a \neq 0$. If $a = 0$, then the quadrature has precision $2n+1$.

Using an appropriate quadrature on the integrals in (2.22) we obtain a reconstruction algorithm for the attenuated Radon data. We state such an algorithm only in the case of the quadrature formula in (2.25).

ALGORITHM 2.13. *Let $\mu \ge 0$ and $n \ge 0$. Let $t_{j,n}$ and $\lambda_{j,n}$ be as in* (2.25). *For $(x,y) \in B^2$ define*

$$\mathcal{A}_n^\mu(f;x,y) = \sum_{\nu=0}^{n} \sum_{j=0}^{n} \mathcal{R}^\mu_{\xi_\nu}(f;t_{j,n}) T^\mu_{j,\nu}(x,y), \tag{2.26}$$

where

$$T^\mu_{j,\nu}(x,y) = \frac{a_\mu \lambda_{j,n}}{n+1} (1-t_{j,n}^2)^{-\mu} \Phi_n^\mu(\xi_\nu, t_{j,n}; x, y).$$

For a given f, the approximation process $\mathcal{A}_n^\mu f$ uses attenuated Radon data

$$\left\{ \mathcal{R}^\mu_{\xi_\nu}(f;t_{j,n}) : 0 \le \nu \le n, \quad 0 \le j \le n \right\}$$

of f. The data consist of Radon projections on $n+1$ equally spaced directions (specified by ξ_ν) along the circumference of a half circle, and there are $n+1$ parallel lines (specified by $t_{j,n}$) in each direction. The algorithm produces a polynomial $\mathcal{A}_n^\mu f$ which is an approximation to f. In the case of $\mu = 1/2$ the algorithm (2.13) appeared earlier in [1]; the connection to the orthogonal partial sums, however, was neither established nor used there.

THEOREM 2.14. *The operator $\mathcal{A}_n^\mu$ is a projection operator on Π_n^2. In other words, $\mathcal{A}_n^\mu f \in \Pi_n^2$ and $\mathcal{A}_n^\mu P = P$ for $P \in \Pi_n^2$.*

Proof. The function $\Phi^\mu(\xi_\nu, t_{j,n}; x, y)$ is evidently an element in Π_n^2. It follows immediately that $\mathcal{A}_n^\mu f \in \Pi_n^2$. By definition, S_n^μ is a projection operator on Π_n^2. The operator $\mathcal{A}_n^\mu f$ is obtained from $S_n^\mu f$ by applying the quadrature (2.25), exactly for polynomials in Π_{2n}^2, on $(1-t^2)^{-\mu}\mathcal{R}_{\xi_\nu}^\mu(f;t)\Phi_n^\mu(\xi_\nu, t; \cdot)$, which is a polynomial of degree $2n$ in t variable by Lemma 2.7 and (2.23) whenever $f \in \Pi_n^2$. Hence, the quadrature (2.25) is exact. Thus, $\mathcal{A}_n^\mu f = S_n^\mu f = f$ if $f \in \Pi_n^2$. ∎

Alternatively, we can use a quadrature formula of proper order on the second expression of (2.22) to derive an algorithm that uses Radon projections on $2n+2$ directions equally distributed along the circumference of the entire circle. Instead of stating such an algorithm we consider the case of $n = 2m$ and use the expression (2.24). This leads to an algorithm that sums over $2m+1$ angles that are equally spaced over $[0, 2\pi]$, as we shall discuss in the following subsection.

2.5. Reconstruction algorithm using attenuated Radon projections. For practical applications in CT, the discretization described in Algorithm 2.13 needs to be further specified or simplified. In fact, one has to take into consideration what scan geometry is used in practice. For example, the zeros of quasi-orthogonal polynomials will not coincide with the discrete measurement of the attenuated Radon projections in the usual scan geometry. If these points were used, then it would be necessary to introduce an interpolation process, which would introduce new errors. As an alternative, we suggest using a different discretization, which amounts to using a different quadrature formula.

For the ordinary Radon projections ($\mu = 1/2$), Gaussian quadrature formulas for the weight function $\sqrt{1-x^2}$ are used for the integrals in (2.24) to generate algorithms. For practical implementation in CT, the quadrature formula

$$\frac{1}{\pi}\int_{-1}^{1} f(t)\frac{dt}{\sqrt{1-t^2}} = \frac{1}{n+1}\sum_{j=0}^{n} f\left(\cos\frac{(2j+1)\pi}{2n+2}\right), \tag{2.27}$$

based on zeros of $T_{n+1}(x) = \cos(n+1)\theta$, $x = \cos\theta$, is used [17]. The reason for such a choice lies in the scanning geometry of the input data. It turns out that for $n = 2m$, such a choice allows us to adopt fan beam geometry and use it as parallel geometry in a straightforward way.

It is possible to use the quadrature formula (2.27) for attenuated Radon transforms $\mathcal{R}_\phi^\mu(f;t)$, especially when μ is a half integer. The resulting $\mathcal{A}_{2m}$ will no longer be a projection operator, but it still reproduces polynomials of degree slightly less than n when μ is a half integer.

ALGORITHM 2.15. *For $m \ge 0$, $(x, y) \in B^2$,*

$$\mathcal{A}_{2m}^\mu(f; x, y) = \sum_{\nu=0}^{2m}\sum_{j=0}^{2m} \mathcal{R}_{\phi_\nu}^\mu\left(f; \cos\psi_j\right) T_{j,\nu}^\mu(x, y), \tag{2.28}$$

where

$$T_{j,\nu}^\mu(x, y) = \frac{\mu + 1/2}{(2m+1)^2}\sin\psi_j \Phi_{2m}^\mu(\phi_\nu, \cos\psi_j; x, y), \qquad \psi_j = \frac{(2j+1)\pi}{4m+2}.$$

The constant $\mu + 1/2$ in $T_{j,\nu}^\mu$ comes from the fact that $a_\mu = (\mu + 1/2)/\pi$.

This algorithm provides an approximation for the reconstruction of a function $f(x, y)$ from a set of attenuated Radon projections

$$\big\{\mathcal{R}^\mu_{\phi_\nu}(f; \cos\psi_j), \quad 0 \le \nu \le 2m, \quad 1 \le j \le 2m\big\}.$$

The set $\{\phi_\nu : 0 \le \nu \le 2m\}$ consists of equally spaced angles along the circumference of the disk. For $\mu = 1/2$ it has appeared in [16]. The advantage of this algorithm lies in the fact that it can be used with attenuated Radon data obtained from the fan beam geometry directly; see the discussion in [17]. The operator, however, reproduces polynomials up to a lower degree.

THEOREM 2.16. *Let μ be a half integer, $\mu + 1/2 \in \mathbb{N}$. Then the operator $\mathcal{A}^\mu_{2m}$ in Algorithm* 2.15 *preserves polynomials of degree $2m - 2\mu$; that is, $\mathcal{A}^\mu_{2m} P = P$ for $P \in \Pi^2_{2m-2\mu}$.*

Proof. The algorithm is obtained by using the Gaussian quadrature formula (2.27) to discretize the integrals in (2.24); that is,

$$\begin{aligned}\int_{-1}^1 \mathcal{R}^\mu_{\phi_\nu}(f;t) C_k^{\mu+1/2}(t)dt &= \int_{-1}^1 \frac{\mathcal{R}^\mu_{\phi_\nu}(f;t)}{\sqrt{1-t^2}} C_k^{\mu+1/2}(t)\sqrt{1-t^2}dt \\ &\approx \frac{\pi}{2m+1}\sum_{k=0}^{2m} \sin\psi_j \mathcal{R}^\mu_{\phi_\nu}(f;\cos\psi_j) C_k^{\mu+1/2}(\cos\psi_j).\end{aligned}$$

If $f \in \Pi^2_{2m-2\mu}$, then using the fact that $\mathcal{R}^\mu_\phi(f;t)/(1-t^2)^\mu$ is a polynomial of degree $2m - 2\mu$, the assumption that μ is a half integer shows that

$$\mathcal{R}_{\phi_\nu}(f;t)/\sqrt{1-t^2} = (1-t^2)^{\mu-1/2}\mathcal{R}_{\phi_\nu}(f;t)/(1-t^2)^\mu$$

is a polynomial of $2\mu - 1 + 2m - 2\mu = 2m - 1$. Since $\Phi^\mu_{2m}(\xi_\nu, t; \cdot)$ is of degree $2m$ and the quadrature (2.27) is of precision $4m - 1$, the discretization becomes exact in this case and we conclude that $\mathcal{A}^\mu_{2m} f = f$ if $f \in \Pi^2_{2m-2\mu}$. ∎

Let $C(B^2)$ denote the space of continuous function on B^2 with the uniform norm $\|\cdot\|_\infty$ and let $\|\mathcal{A}^\mu_n\|$ denote the operator norm of $\mathcal{A}^\mu_n$ under the uniform norm. By $A \sim B$ we mean that there are two constants c_1 and c_2 such that $c_1 A \le B \le c_2 A$. Evidently the convergence of the algorithm depends on $\|\mathcal{A}^\mu_n\|$. In fact, since $\mathcal{A}^\mu_n$ in Algorithm 2.13 preserves Π_n, it is easy to see that

$$\|f - \mathcal{A}^\mu_n f\| \le c_f\,(1 + \|\mathcal{A}^\mu_n\|)\,E_n(f),$$

where $E_n(f) := \inf\{\|f - P\| : P \in \Pi^2_n\}$ is the error of the best approximation of f by polynomials on B^2. If f has rth order continuous derivatives, then $E_n(f) \le c_f n^{-r}$, in which c_f depends on the norm of the rth derivatives of f. The same applies to $\mathcal{A}^\mu_{2m}$ in Algorithm 2.15, which preserves $\Pi_{2m-2\mu}$. Using the formula in (2.13), the proof of Proposition 5.1 of [16] gives the following formula of the norm of $\mathcal{A}^\mu_{2m}$ in Algorithm 2.15.

PROPOSITION 2.17. *The operator norm $\|\mathcal{A}^\mu_{2m}\|$ of $C(B^2)$ to $C(B^2)$ is given by*

$$\|\mathcal{A}^\mu_{2m}\| = \max_{(x,y)\in B^2} \Lambda_m(x,y), \qquad \Lambda_m(x,y) := \sum_{\nu=0}^{2m}\sum_{j=0}^{2m} (\sin\theta_{j,m})^\mu |T^\mu_{j,\nu}(x,y)|.$$

As $m \to \infty$, the norm grows in an essentially polynomial order of m. Hence, the algorithm converges uniformly if f is sufficiently smooth. Estimating the exact order

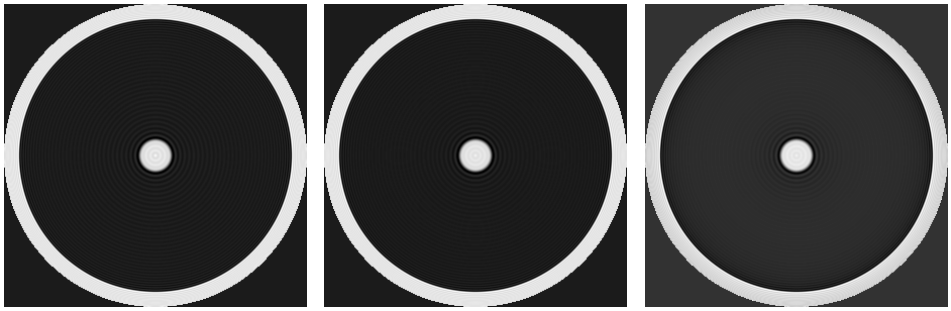

FIG. 1. *From left to right,* $\mu = 0, 1/2, 3/2$.

of $\mathcal{A}_{2m}^{\mu}$ is difficult. In the case of $\mu = 1/2$, it is carried out in [16] and the order is $\|\mathcal{A}_{2m}\| \sim m \log(m+1)$. Based on this fact, we conjecture that the operator norm of $\mathcal{A}_{2m}^{\mu}$ is of the the order

$$\|\mathcal{A}_{2m}^{\mu}\| \sim m^{\mu+1/2} \log(m+1) \qquad \text{as } m \to \infty,$$

which is only slightly worse than the norm $\|S_n^{\mu}\| \sim n^{\mu+1/2}$ (see [15]). If the conjecture holds, then the algorithm will converge uniformly for smooth $f \in C^r(B^2)$ with $r > \mu + 1/2$. In most applications, however, the function or image could have jumps; that is, there is not even continuity. The numerical tests in the case of ordinary Radon data shows that the algorithm is stable and yields fairly accurate results even when the data are highly singular (see [17]). See also the example given in the following subsection.

2.6. Numerical example. For the numerical examples we use Algorithm 2.15, for which the scan geometry is easy to implement. The data required are $g_{j,\nu} := \mathcal{R}_{\phi_\nu}^{\mu}(f; \cos\psi_j)$, where $\phi_\nu = 2\nu\pi/(2m+1)$ stands for the $2m+1$ views equally spaced along the circumference of the region to be reconstructed and $\psi_j = (2j+1)/(4m+2)$ means that the x-rays in each view are distributed according to the zeros of the Chebyshev polynomial T_{2m+1}. In this case the fan data can be resorted into parallel data (see [17]).

We reconstruct a simple analytical phantom defined by the function

$$f(x,y) = \begin{cases} 1 & \text{if } 0.9 \le r \le 1 \ \text{ or } \ 0 \le r \le 0.1, \\ 0 & \text{if } 0.1 < r < 0.9, \end{cases}$$

where $r = \sqrt{x^2+y^2}$ on the unit disk. This phantom contains strong singularity along the circles $r = 0.9$ and $r = 0.1$. The rotationally invariant nature of the function allows certain simplification of the algorithm.

For the reconstruction, we choose three values of the parameter μ, $\mu = 0, 1/2, 3/2$. The case $\mu = 1/2$ means the ordinary Radon transform. The case $\mu = 0$ means that the Radon transform is attenuated by the weight function $(1-x^2-y^2)^{-1/2}$, which is infinity at the boundary of the disk. The case $\mu = 3/2$ means that the Radon transform is attenuated by the weight function $1-x^2-y^2$, which is zero at the boundary. In each case, the Radon data are computed analytically.

For each of the three values of μ, we use Algorithm 2.15 for the reconstruction with a moderate $m = 100$. The reconstructed image is evaluated on a 300×300 grid. The result is shown in Figure 1.

These images show that the function is reconstructed rather faithfully in each of the three cases, even though the function has strong singularity. The case $\mu = 1/2$ has been tested extensively and compared with the FBP (filtered back-projection) algorithm (see [17, 18]). The above is our first attempt to test the algorithm for attenuated Radon transforms.

3. Reconstruction and approximation on the unit sphere. It is known that orthogonal polynomials on the unit ball and on the unit sphere are closely related (see [12]). Since the approximation and the reconstruction in the previous section are based on orthogonal expansions on the unit disk, the relation suggests analogous results on the unit sphere $S^2 = \{(x, y, z) : x^2 + y^2 + z^2 = 1\}$, which we explore in this section.

On the sphere we consider the attenuated spherical transform defined by

$$Q^\mu f(\zeta; t) = \int_{\langle \mathbf{x}, \zeta \rangle = t} f(\mathbf{x}) |x_3|^{2\mu} d\omega,$$

where $\mathbf{x} = (x_1, x_2, x_3) \in S^2$, $\zeta \in \mathbb{R}^3$, and $\xi \neq 0$, and $d\omega$ is the measure on the subset $\{x \in S^2 : \langle \mathbf{x}, \zeta \rangle = t\}$, which is the circle on the sphere. When $\mu = 0$, this is the usual spherical transform (1.5); see, for example, [9, p. 33]. We will mainly work with the case that $\zeta_3 = 0$. We say that a function is even in x_3 if $f(x_1, x_2, x_3) = f(x_1, x_2, -x_3)$.

PROPOSITION 3.1. *Let f be even in x_3. If $\zeta = (\cos\theta, \sin\theta, 0)$, then*

$$Q^\mu f(\zeta; t) = \mathcal{R}^\mu_\theta(F; t), \qquad F(x_1, x_2) = f\Big(x_1, x_2, \sqrt{1 - x_1^2 - x_2^2}\Big). \tag{3.1}$$

Proof. Since f is even in x_3 we have $f(\mathbf{x}) = F(x_1, x_2)$ for $\mathbf{x} \in S^2$. The definition of ζ shows that $\langle \mathbf{x}, \zeta \rangle = x_1 \cos\theta + x_2 \sin\theta = I(\theta, t)$. In terms of x_1 and x_2, $d\omega = dx_1 dx_2 / \sqrt{1 - x_1^2 - x_2^2}$. Thus,

$$Q^\mu f(\zeta; t) = \int_{x_1 \cos\theta + x_2 \sin\theta = t} F(x_1, x_2) \left(1 - x_1^2 - x_2^2\right)^\mu \frac{dx_1 dx_2}{\sqrt{1 - x_1^2 - x_2^2}},$$

which is precisely $\mathcal{R}^\mu_\theta(F; t)$. ∎

Let $H_\mu(\mathbf{x}) = |x_3|^\mu$. The space $L^2(H_\mu; S^2)$ has an orthogonal decomposition

$$L^2(H_\mu; S^2) = \sum_{k=0}^{\infty} \oplus \mathcal{H}^\mu_k, \tag{3.2}$$

where the subspace $\mathcal{H}^\mu_k$ contains homogeneous polynomials of degree k that are orthogonal to lower degree polynomials with respect to $H_\mu d\omega$ on S^2. For $\mu = 0$, $\mathcal{H}^0_k$ is the space of ordinary spherical harmonics. Let

$$\mathrm{proj}_{\mathcal{H}^\mu_k} f : L^2(H_\mu; S^2) \mapsto \mathcal{H}^\mu_k$$

be the orthogonal projection from $L^2(H_\mu; S^2)$ onto $\mathcal{H}^\mu_k$. The space $\mathcal{H}^\mu_k$ is closely related to the space $\mathcal{V}^2_k(W_\mu)$ discussed in the previous section (see [12]). For our purpose, we only need the following relation on the orthogonal projections: if f is even in x_3, then

$$\mathrm{proj}_{\mathcal{H}^\mu_n} f(\mathbf{x}) = \mathrm{proj}^\mu_n F(x_1, x_2), \tag{3.3}$$

where F is the function defined in (3.1). This relation, together with (3.1), allows us to express the projection operator on the sphere in terms of spherical transforms. Using these relations and Theorem 2.8 we obtain the following result.

THEOREM 3.2. *Let f be even in x_3. For $n \ge 0$ and $k \le n$, the operator* $\mathrm{proj}_{\mathcal{H}_k^\mu}$ *can be written as*

$$\mathrm{proj}_{\mathcal{H}_k^\mu} f(\mathbf{x}) = \frac{1}{n+1} \sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} Q^\mu f(\zeta_\nu; t) D_k^{\mu+1/2}(\xi_\nu, t; x_1, x_2) dt, \tag{3.4}$$

where $\xi_\nu = \frac{\nu\pi}{n+1}$, $\zeta_\nu = (\cos\xi_\nu, \sin\xi_\nu, 0)$, and $D_k^{\mu+1/2}(\xi, t; x, y)$ is defined in (2.20).

Let $Y_n^\mu f$ denote the nth partial sum of the expansion (3.2); that is,

$$Y_n^\mu(f; \mathbf{x}) = \sum_{k=0}^{n} \mathrm{proj}_{\mathcal{H}_k^\mu} f(x_1, x_2).$$

The operator Y_n^μ is a projection operator from $L^2(H_\mu; S^2)$ onto $\Pi_n(S^2)$, the restriction of Π_n^3 on S^2. An immediate consequence of Theorem 3.2 is the following.

COROLLARY 3.3. *Let f be even in x_3. For $n \ge 0$, the partial sum operator $Y_n^\mu f$ can be written as*

$$\begin{aligned} Y_n^\mu(f; \mathbf{x}) &= \frac{1}{n+1} \sum_{\nu=0}^{n} a_\mu \int_{-1}^{1} Q^\mu f(\zeta_\nu; t) \Phi_n^\mu(\xi_\nu, t; x_1, x_2) dt \\ &= \frac{1}{2n+2} \sum_{\nu=0}^{2n+1} a_\mu \int_{-1}^{1} Q^\mu f(\zeta_\nu; t) \Phi_n^\mu(\xi_\nu, t; x_1, x_2) dt, \end{aligned} \tag{3.5}$$

where Φ_n^μ is the function defined in (2.23).

For $n = 2m$ we can also use Theorem 2.9 to derive an expression for $Y_{2m}^\mu(f)$, which leads to the following corollary.

COROLLARY 3.4. *Let f be even in x_3. For $m \ge 0$, the partial sum operator $Y_{2m}^\mu f$ can be written as*

$$Y_{2m}^\mu(f; \mathbf{x}) = \frac{1}{2m+1} \sum_{\nu=0}^{2m} a_\mu \int_{-1}^{1} Q^\mu f(\zeta_\nu; t) \Phi_{2m}^\mu(\phi_\nu, t; x_1, x_2) dt, \tag{3.6}$$

where $\phi_\nu = \frac{2\nu\pi}{2m+1}$, $\zeta_\nu = (\cos\phi_\nu, \sin\phi_\nu, 0)$, and Φ_{2m}^μ is the function defined in (2.23).

In the case of $\mu = 0$, equations (3.5) and (3.6) are representations of the partial sums of ordinary spherical harmonic expansions, which are expressed in terms of the Legendre polynomial $P_k(t) = C_k^{1/2}(t)$.

Just like the case of orthogonal expansions on the unit disk, we can use a quadrature formula to obtain a reconstruction algorithm using spherical transforms. For example, using the quadrature formula with respect to $(1-t^2)^\mu$ in Proposition 2.12 as in the case of Algorithm 2.13, we get the following result.

ALGORITHM 3.5. *Let f be even in x_3. Let $\mu \ge 0$. For $n \ge 0$, $\mathbf{x} \in S^2$,*

$$\mathcal{S}_n^\mu(f; \mathbf{x}) = \sum_{\nu=0}^{n} \sum_{j=0}^{n} Q^\mu f(\zeta_\nu; t_{j,n}) T_{j,\nu}^\mu(x_1, x_2), \tag{3.7}$$

where $t_{j,n}$ are as in the quadrature (2.25) *and $T_{j,\nu}^\mu$ are defined in Algorithm* 2.13.

This algorithm reconstructs a function $f(\mathbf{x})$ from a set of spherical transforms

$$\{Q^\mu f(\zeta_\nu; t_j), \quad \zeta_\nu = (\cos\xi_\nu, \sin\xi_\mu, 0), \quad 0 \le \nu \le 2m, \quad 1 \le j \le 2m\},$$

which consists of integrals over a number of circles on the sphere. These circles lie on planes that are parallel to the x_3-axis. The circles intersect the circumference of a disk perpendicular to the x_3-axis at equally spaced angles. The distance between these parallel circles depends on the values of $t_{j,n}$. In the case $\mu = 0$, the algorithm provides an approximation to the function based on ordinary spherical transforms. The assumption that f is even in x_3 implies that we can use the algorithm to reconstruct a function defined on the upper hemisphere from spherical transforms that are integrals over half circles parallel to the x_3-axis on the upper hemisphere.

If μ is a half integer, we can also state an algorithm using the quadrature (2.27), as in Algorithm 2.15, so that $t_{j,n} = \cos j\pi/(2m+1)$. However, in the most interesting case of $\mu = 0$, we do not have such a somewhat simplified algorithm.

4. Reconstruction and approximation on the unit ball. In this section we consider reconstruction of functions on a unit ball B^3 in $\mathbb{R}^3$ based on the attenuated Radon projections.

4.1. Radon projections and orthogonal polynomials. We will work with attenuated Radon projections that are integrals on line segments inside B^3 with respect to the weight function

$$W_\mu(\mathbf{x}) = (1 - \|\mathbf{x}\|^2)^{\mu - 1/2}, \quad \mathbf{x} = (x_1, x_2, x_3) \in B^3, \quad \mu \ge 0.$$

For our purpose, however, we will consider only those lines lying on the planes that are perpendicular to the x_3-axis. Let $x_3 = w$ be such a plane. Its intersection with the unit ball B^3 is a disk $\{\mathbf{x} : x_1^2 + x_2^2 \le \sqrt{1-w^2}, x_3 = w\}$. A line on this disk is given by the equation

$$\ell : \quad x\cos\theta + y\sin\theta = t\sqrt{1-w^2}, \qquad -1 \le t \le 1.$$

Let $I(\theta, w; t)$ denote the intersection of ℓ with B^3. The attenuated Radon projection on such a line is then defined by

$$\mathcal{R}_\theta^\mu(f; t, w) := \int_{I(\theta,w;t)} f(\mathbf{x}) W_\mu(\mathbf{x}) d\mathbf{x}. \tag{4.1}$$

The case $\mu = 1/2$ again corresponds to the usual Radon projection.

LEMMA 4.1. *For $f \in L^1(W_\mu; B^3)$ and for a fixed $w \in [-1, 1]$, define a function g_w on B^2 by*

$$g_w(x, y) = f\left(\sqrt{1-w^2}\, x, \sqrt{1-w^2}\, y, w\right).$$

The x-ray transform (4.1) *is related to the 2D Radon transform* (1.3) *by*

$$\mathcal{R}_\theta^\mu(f; t, w) = (1-w^2)^\mu \mathcal{R}_\theta^\mu(g_w; t). \tag{4.2}$$

Proof. Since $I(\theta, w; t)$ can be represented by

$$x_1 = \sqrt{1-w^2}(t\cos\theta - s\sin\theta), \quad x_2 = \sqrt{1-w^2}(t\sin\theta + t\cos\theta), \quad x_3 = w$$

for $s \in [-\sqrt{1-t^2}, \sqrt{1-t^2}]$, which is a rotation around the x_3-axis on the plane defined by $x_3 = w$, we have

$$\mathcal{R}_\theta(f;t,w) = (1-w^2)^\mu \int_{-\sqrt{1-t^2}}^{\sqrt{1-t^2}} g_w(t\cos\theta - s\sin\theta, t\sin\theta + s\cos\theta) W_\mu(s,t) ds.$$

The integral is precisely $\mathcal{R}_\theta^\mu(g_w;t)$ by (2.13). □

Let $\mathcal{V}_n^3(W_\mu)$ denote the space of orthogonal polynomials with respect to W_μ on B^3, which contains polynomials of degree n that are orthogonal to polynomials of lower degrees with respect to the inner product

$$\langle P, Q\rangle = a_{\mu,3} \int_{B^3} P(\mathbf{x}) Q(\mathbf{x}) W_\mu(x) d\mathbf{x}, \qquad a_{\mu,3} = \frac{\Gamma(\mu+2)}{\pi^{3/2}\Gamma(\mu+1/2)},$$

where $a_{\mu,3}$ is the normalization constant of W_μ. We derive a basis for $\mathcal{V}_n^3(W_\mu)$, making use of an orthogonal basis for $\mathcal{V}_n^2(W_\mu)$. We note that the W_μ in these two notations are different: the first one is on B^3 and the second one is on B^2. We denote by $\widetilde{C}_j^\lambda$ the orthonormal Gegenbauer polynomial, which is equal to $C_n^\lambda/\sqrt{h_n}$ by (2.3).

PROPOSITION 4.2. *Let $\{P_j^k : 0 \le j \le k\}$ be an orthonormal basis for $\mathcal{V}_k^2(W_\mu)$. Then the polynomials*

$$Q_{l,k,j}(x,y,z) = h_k (1-z^2)^{k/2} P_j^k\left(\frac{x}{\sqrt{1-z^2}}, \frac{y}{\sqrt{1-z^2}}\right) \widetilde{C}_{l-k}^{k+\mu+1}(z) \tag{4.3}$$

for $0 \le j \le k \le l$, where $h_k^2 = (\mu+2)_k/(\mu+3/2)_k$, form an orthonormal basis for $\mathcal{V}_l^3(W_\mu)$.

Proof. From Proposition 2.3, it is easy to see that P_j^k is a sum of even powers of homogeneous polynomials when k is even, and a sum of odd powers of homogeneous polynomials when k is odd. Thus, it follows that $Q_{l,k,j} \in \Pi_l^3$. Using the fact that P_j^k is orthonormal, it follows from the integral relation

$$\int_{B^3} f(\mathbf{x}) d\mathbf{x} = \int_{-1}^1 \int_{B^2} f\left(x_1\sqrt{1-x_3^2}, x_2\sqrt{1-x_3^2}, x_3\right) dx_1 dx_2 (1-x_3^2) dx_3 \tag{4.4}$$

and the fact that $a_{\mu,3} = a_\mu c_{\mu+1/2}$, where a_μ is the normalization of W_μ on B^2 and c_μ is defined in (2.3), that

$$\begin{aligned} &a_{\mu,3} \int_{B^3} Q_{l,k,j}(\mathbf{x}) Q_{l',k',j'}(\mathbf{x}) W_\mu(\mathbf{x}) d\mathbf{x} \\ &\quad = h_k^2 c_{\mu+1/2} \int_{-1}^1 \widetilde{C}_{l-k}^{k+\mu+1}(t) \widetilde{C}_{l'-k}^{k+\mu+1}(t) (1-t^2)^{k+\mu+1/2} dt \delta_{k,k'} \delta_{j,j'} \\ &\quad = h_k^2 \frac{c_{\mu+1/2}}{c_{k+\mu+1/2}} \delta_{l,l'} \delta_{k,k'} \delta_{j,j'}. \end{aligned}$$

It follows from the definition of c_μ that $c_{\mu+1/2}/c_{k+\mu+1/2} = (\mu+3/2)_k/(\mu+2)_k$, which completes the proof. □

The attenuated Radon transforms of this basis can be computed explicitly.

PROPOSITION 4.3. *Let $\mu \ge 0$ and let $Q_{l,k,j}$ be defined by (4.3). Then*

$$\frac{\mathcal{R}_\phi^\mu(Q_{l,k,j};t,w)}{(1-t^2)^\mu(1-w^2)^\mu} = b_\mu \frac{C_k^{\mu+1/2}(t)}{C_k^{\mu+1/2}(1)} Q_{l,k,j}\left(\sqrt{1-w^2}\cos\phi, \sqrt{1-w^2}\sin\phi, w\right). \tag{4.5}$$

Proof. By Lemma 4.1 and the definition of $Q_{l,k,j}$ we have

$$\mathcal{R}_\phi^\mu(Q_{l,k,j};t,w) = (1-w^2)^\mu \mathcal{R}_\phi^\mu(g_w;t),$$

where $g_w(x,y) = h_k P_j^k(x,y)(1-w^2)^{k/2}\widetilde{C}_{l-k}^{k+\mu+1}(w)$. By Lemma 2.7, it follows that

$$\begin{aligned}\mathcal{R}_\phi^\mu(g_w;t) &= h_k(1-w^2)^{k/2}\widetilde{C}_{l-k}^{k+\mu+1}(w)\mathcal{R}_\phi^\mu(P_j^k;t)\\ &= b_\mu h_k(1-w^2)^{k/2}\widetilde{C}_{l-k}^{k+\mu+1}(w)(1-t^2)^\mu \frac{C_k^{\mu+1/2}(t)}{C_k^{\mu+1/2}(1)} P_j^k(\cos\phi,\sin\phi)\\ &= b_\mu(1-t^2)^\mu \frac{C_k^{\mu+1/2}(t)}{C_k^{\mu+1/2}(1)} Q_{l,k,j}\left(\sqrt{1-w^2}\cos\phi, \sqrt{1-w^2}\sin\phi, w\right)\end{aligned}$$

by the definition of $Q_{l,k,j}$. Putting these equations together completes the proof. ∎

Let $\mathrm{proj}_{l,3}^\mu$ denote the projection operator from $L^2(W_\mu;B^3)$ onto the space $\mathcal{V}_l^3(W_\mu)$. Again we have the decomposition

$$L^2(W_\mu;B^3) = \sum_{k=0}^\infty \oplus \mathcal{V}_k^3(W_\mu): \qquad f = \sum_{k=0}^\infty \mathrm{proj}_{k,3}^\mu f. \tag{4.6}$$

Proposition 4.4. *For $n \ge 0$ and $0 \le l \le n$,*

$$\begin{aligned}\mathrm{proj}_{l,3}^\mu f(\mathbf{x}) &= \frac{1}{n+1}\sum_{\nu=0}^n \int_{-1}^1\int_{-1}^1 \mathcal{R}_{\xi_\nu}^\mu(f;t,w)G_l(\xi_\nu,t,w;\mathbf{x})dt\sqrt{1-w^2}dw\\ &= \frac{1}{2n+2}\sum_{\nu=0}^{2n+1} \int_{-1}^1\int_{-1}^1 \mathcal{R}_{\xi_\nu}^\mu(f;t,w)G_l(\xi_\nu,t,w;\mathbf{x})dt\sqrt{1-w^2}dw,\end{aligned} \tag{4.7}$$

where

$$\begin{aligned}G_l(\xi,t,w;\mathbf{x}) = a_{\mu,3}\sum_{k=0}^l h_k^2 D_k^{\mu+1/2}\left(\xi,t;\frac{x_1}{\sqrt{1-x_3^2}},\frac{x_2}{\sqrt{1-x_3^2}}\right)\\ \times (1-w^2)^{k/2}(1-x_3^2)^{k/2}\widetilde{C}_{l-k}^{k+\mu+1}(w)\widetilde{C}_{l-k}^{k+\mu+1}(x_3).\end{aligned}$$

Proof. The projection operator has an integral expression just as that of (2.17). Furthermore, the kernel function $P(W_\mu;\mathbf{x},\mathbf{y})$ can be written as a sum of an orthonormal basis. In particular,

$$\mathrm{proj}_{l,3}^\mu f(\mathbf{x}) = \sum_{k=0}^l\sum_{j=0}^k \widehat{f}_{l,k,j}Q_{l,k,j}(\mathbf{x}),$$

where $Q_{l,k,j}$ is the orthonormal basis for $\mathcal{V}_l^3(W_\mu)$ defined in (4.3) and

$$\widehat{f}_{l,k,j} = a_{\mu,3}\int_{B^3} f(\mathbf{y})Q_{l,k,j}(\mathbf{y})W_\mu(\mathbf{y})d\mathbf{y}.$$

Using (4.4), the definition of $Q_{k,l,j}$, and the fact that $a_{\mu,3} = a_\mu c_{\mu+1/2}$, we have

$$\begin{aligned}\widehat{f}_{l,k,j} = c_{\mu+1/2}\int_{-1}^1 \left[a_\mu\int_{B^2} g_w(u,v)P_j^k(u,v)W_\mu(u,v)dudv\right]\\ \times h_k\widetilde{C}_{l-k}^{k+\mu+1}(w)(1-w^2)^{k/2+\mu+1/2}dw,\end{aligned}$$

where g_w is defined as in Lemma 4.1. Hence, it follows from (2.17) and (2.1) that

$$\begin{aligned}\operatorname{proj}_{l,3} f(\mathbf{x}) = &\sum_{k=0}^{l} h_k^2 \widetilde{C}_{l-k}^{k+\mu+1}(x_3)(1-x_3^2)^{k/2} c_{\mu+1/2} \\ &\times \int_{-1}^{1} \operatorname{proj}_k^{\mu} g_w\left(\frac{x_1}{\sqrt{1-x_3^2}}, \frac{x_2}{\sqrt{1-x_3^2}}\right) \widetilde{C}_{l-k}^{k+\mu+1}(w)(1-w^2)^{(k+1)/2+\mu} dw.\end{aligned}$$

The identity (4.7) follows from the above equation upon using (2.18) and (4.2). ∎

Let us denote by $S_{n,3}^{\mu} f$ the nth partial sum of the orthogonal expansion (4.6),

$$S_{n,3}^{\mu} f(\mathbf{x}) = \sum_{l=0}^{n} \operatorname{proj}_{l,3}^{\mu} f(\mathbf{x}).$$

As an immediate consequence of Proposition 4.4 we have the following corollary.

COROLLARY 4.5. *For $n \ge 0$,*

$$\begin{aligned}S_{n,3}^{\mu} f(\mathbf{x}) &= \frac{1}{n+1} \sum_{\nu=0}^{n} \int_{-1}^{1} \int_{-1}^{1} \mathcal{R}_{\xi_\nu}^{\mu}(f;t,w) \Phi_n^{\mu}(\xi_\nu, t, w; \mathbf{x}) dt \sqrt{1-w^2} dw \\ &= \frac{1}{2n+2} \sum_{\nu=0}^{2n+1} \int_{-1}^{1} \int_{-1}^{1} \mathcal{R}_{\xi_\nu}^{\mu}(f;t,w) \Phi_n^{\mu}(\xi_\nu, t, w; \mathbf{x}) dt \sqrt{1-w^2} dw,\end{aligned} \tag{4.8}$$

where

$$\Phi_n^{\mu}(\xi, t, w; \mathbf{x}) = \sum_{l=0}^{n} G_l(\xi, t, w; \mathbf{x}).$$

In the case of $n = 2m$ we can use (2.21) instead of (2.18) in the last step of the proof of Proposition 4.4 to get an expression for $\operatorname{proj}_{l,3}^{\mu} f$. The corresponding expression for the partial sum is the following result.

PROPOSITION 4.6. *For $m \ge 0$,*

$$S_{2m,3}^{\mu} f(\mathbf{x}) = \frac{1}{2m+1} \sum_{\nu=0}^{2m} \int_{-1}^{1} \int_{-1}^{1} \mathcal{R}_{\phi_\nu}^{\mu}(f;t,w) \Phi_{2m}(\phi_\nu, t, w; \mathbf{x}) dt \sqrt{1-w^2} dw.$$

From such an expression of $S_{n,3}^{\mu}$ we naturally want to derive an algorithm as in the 2D case. However, there is a problem when we use a quadrature formula. Indeed, in order to obtain an algorithm, we need to discretize the integrals

$$\int_{-1}^{1} \int_{-1}^{1} \mathcal{R}_{\xi_\nu}^{\mu}(f;t,w) \Phi_n^{\mu}(\xi_\nu, t, w; \mathbf{x}) dt \sqrt{1-w^2} dw \tag{4.9}$$

in $S_{n,3}^{\mu} f$ by a quadrature formula. We can use, for example, the quadrature (2.25) of precision $2n$, which we denote by

$$\int_{-1}^{1} f(t)(1-t^2)^{\alpha} dt \approx \sum_{k=0}^{n} \lambda_{k,n}^{\alpha} f(t_{k,n}^{\alpha})$$

to emphasis the dependence of $t_{k,n}$ and $\lambda_{k,n}$ on the weight function. If we follow the 2D case, then (4.5) indicates that we should apply the quadrature with respect to

$(1-t^2)^\mu$ in the t variable, and apply the quadrature with respect to $(1-w^2)^{\mu+1/2}$ in the w variable. The result of using these quadrature formulas gives us the following.

ALGORITHM 4.7. *Let $\mu \ge 0$. For $n \ge 0$, $\mathbf{x} = (x_1, x_2, x_3) \in B^3$,*

$$\mathcal{B}_n^\mu(f;\mathbf{x}) = \sum_{\nu=0}^{n} \sum_{j=0}^{n} \sum_{k=0}^{n} \mathcal{R}_{\phi_\nu}^\mu(f; t_{j,n}^\mu, t_{k,n}^{\mu+1/2}) T_{j,k,\nu}(\mathbf{x}),$$

where

$$T_{j,k,\nu}^\mu(\mathbf{x}) = \frac{\lambda_j^\mu \lambda_k^{\mu+1/2}}{n+1} \Phi_n^\mu(\xi_\nu, t_{j,n}^\mu, t_{k,n}^{\mu+1/2}; \mathbf{x}).$$

However, this is not likely an accurate algorithm. The problem is that the operator $\mathcal{B}_n^\mu$ does not preserve polynomials of degree n. In fact, in order that $\mathcal{B}_n P = P$ for $P \in \Pi_n^3$, we need the discretization of the integrals (4.9) to be exact whenever f is a polynomial of degree at most n. The function

$$F_\mu(t,w) := (1-t^2)^{-\mu}(1-w^2)^{-\mu} \mathcal{R}_{\xi_\nu}^\mu(f;t,w) \Phi_n^\mu(\xi_\nu, t, w; \mathbf{x})$$

is a polynomial of degree $2n$ in variable t whenever f is a polynomial of degree n by the definition of Φ_n^μ and Proposition 4.3, so that the discretization in the t variable is exact. However, the function $F_\mu(t,w)$ is not a polynomial in the w variable. By the definition of $Q_{l,k,j}$ in (4.3), equation (4.5) shows that $F_\mu(t,w)$ with $f = Q_{l,k,j}$ contains $(1-w)^{k/2} \widetilde{C}_{l-k}^{k+\mu+1}(w)$, which is not a polynomial in the w variable if k is odd. The formula of $\Phi_n^\mu(\xi_\nu, t, w; \mathbf{x})$ shows that it is a sum of functions, which is also not a polynomial. This means that the quadrature will not be exact and polynomials are not preserved by $\mathcal{B}_n^\mu$.

An algorithm should have high convergence order if it preserves polynomials up to certain degrees. The fact that $B_n^\mu f$ does not preserve polynomials means that the convergence of the algorithm may not be as desirable.

5. Reconstruction and approximation on the cylinder domain. In contrast to the unit ball in $\mathbb{R}^3$, the reconstruction algorithm on a cylinder domain works well. Let $L > 0$ and let B_L be the cylinder domain defined by

$$B_L = B^2 \times [0, L] = \{(x,y,z) : (x,y) \in B^2, 0 \le z \le L\}.$$

We will show that the partial sum operator of the orthogonal expansions on W_L admits an expression that relates to Radon data, and we will use it to get a reconstruction algorithm.

Let W_μ be defined as in (1.2). Let $W_{\mu,L}$ be the weight function

$$W_{\mu,L}(x,y,z) = W_\mu(x,y) W_L(z), \qquad (x,y,z) \in B_L.$$

We retain the notation $\mathcal{R}_\phi^\mu(g;t)$ for the attenuated Radon projection of a function $g : B^2 \mapsto \mathbb{R}$, as defined in (1.3). For a fixed z in $[0, L]$, we define

$$\mathcal{R}_\phi^\mu(f(\cdot,\cdot,z);t) := \int_{I(\phi,t)} f(x,y,z) W_\mu(x,y)\, dx\, dy, \tag{5.1}$$

which is the attenuated Radon projection of f in a disk that is perpendicular to the z-axis.

We consider the orthogonal polynomials with respect to the inner product

$$\langle f, g\rangle_{B_L} = \frac{1}{\pi}\int_{B_L} f(x,y,z)g(x,y,z)W_{\mu,L}(x,y,z)\,dx\,dy\,dz. \tag{5.2}$$

Let $\mathcal{V}_n^3(W_{\mu,L})$ denote the subspace of orthogonal polynomials of degree n on B_L with respect to the inner product (5.2); that is, $P \in \mathcal{V}_n^3(W_{\mu,L})$ if $\langle P, Q\rangle_{B_L} = 0$ for all polynomial $Q \in \Pi_{n-1}^3$.

Let p_k be the orthonormal polynomial of degree n with respect to W_L on $[0, L]$ and let $\{P_j^k(x,y) : 0 \le j \le k\}$ denote an orthonormal basis of $\mathcal{V}_k^2(W_\mu)$. Since $W_{\mu,L}$ is a product on a product domain, the following proposition is obvious.

PROPOSITION 5.1. *An orthonormal basis for $\mathcal{V}_l^3(W_{\mu,L})$ is given by*

$$\mathbb{P}_l = \left\{P_{l,k,j}^\mu : 0 \le j \le k \le n\right\}, \qquad P_{n,k,j}^\mu(x,y,z) = P_j^k(x,y)p_{n-k}(z).$$

In particular, the set $\{\mathbb{P}_l : 0 \le l \le n\}$ is an orthonormal basis for Π_n^3.

For $f \in L^2(W_{\mu,L}; B_L)$, the Fourier coefficients of f with respect to the orthonormal system $\{\mathbb{P}_l : l \ge 0\}$ are given by

$$\widehat{f}_{l,k,j}^\mu = a_\mu \int_{B_L} f(\mathbf{x})P_{l,k,j}^\mu(\mathbf{x})W_{\mu,L}(\mathbf{x})d\mathbf{x}, \quad 0 \le j \le k \le l.$$

Let $S_{n,L}^\mu f$ denote the Fourier partial sum operator,

$$S_{n,L}^\mu f(\mathbf{x}) = \sum_{l=0}^n \sum_{k=0}^l \sum_{j=0}^k \widehat{f}_{l,k,j}^\mu P_{l,k,j}^\mu(\mathbf{x}).$$

Just like its counterpart in two variables, this is a projection operator. The following is an analogue of Theorem 2.10 for the cylinder domain B_L.

THEOREM 5.2. *For $n \ge 0$,*

$$S_{n,L}^\mu f(\mathbf{x}) = \frac{1}{n+1}\sum_{\nu=0}^n a_\mu \int_{-1}^1 \int_0^L \mathcal{R}_{\xi_\nu}^\mu(f(\cdot,\cdot,w);t)\Phi_n^\mu(\xi_\nu, w, t; \mathbf{x})W_L(w)dw\,dt, \tag{5.3}$$

where

$$\Phi_n^\mu(\xi, w, t; \mathbf{x}) = \sum_{k=0}^n \frac{k+\mu+1/2}{\mu+1/2} D_k^{\mu+1/2}(\xi, t; x_1, x_2)\sum_{l=0}^{n-k} p_l(w)p_l(x_3). \tag{5.4}$$

Proof. By the definition of $\widehat{f}_{l,k,j}^\mu$ we can write

$$\widehat{f}_{l,k,j}^\mu = a_\mu \int_{B^2} f_{l-k}(x,y)P_j^k(x,y)W_\mu(x,y)dx\,dy,$$

where

$$f_{l-k}(x,y) := \int_0^L f(x,y,w)p_{l-k}(w)W_L(w)dw, \qquad l \ge k \ge 0.$$

Consequently, by the definition of proj_k^μ in (2.17), it follows that

$$S_{n,L}^\mu f(\mathbf{x}) = \sum_{l=0}^n \sum_{k=0}^l \mathrm{proj}_k^\mu(f_{l-k}; x_1, x_2)p_{l-k}(x_3).$$

We can then use the expression (2.18) for $\text{proj}_k^\mu f$ and the fact that

$$\mathcal{R}_\xi^\mu(f_{l-k};t) = \int_0^L \mathcal{R}_\xi^\mu(f(\cdot,\cdot,w);t)p_{l-k}(w)W_L(w)dw$$

to complete the proof. □

In the case of $n = 2m$, we can use (2.21) in place of (2.18) in the proof. The result is the following proposition, which has appeared in [16] when $\mu = 1/2$.

PROPOSITION 5.3. *For $m \ge 0$,*

$$S_{2m,L}^\mu f(\mathbf{x}) = \frac{1}{2m+1}\sum_{\nu=0}^{2m} a_\mu \int_{-1}^1 \int_0^L \mathcal{R}_{\xi_\nu}^\mu(f(\cdot,\cdot,w);t)\Phi_{2m}^\mu(\phi_\nu,w,t;\mathbf{x})W_L(w)dw\,dt. \tag{5.5}$$

From the expression (5.3) or (5.5) of $S_{n,L}^\mu f$, we can apply a quadrature formula to get a reconstruction algorithm on B_l for the attenuated Radon data. In [16] the weight function W_L is chosen to be the Chebyshev weight function

$$W_L(z) = \frac{1}{\pi}\frac{1}{\sqrt{z(L-z)}}, \qquad z \in [0,L],$$

normalized to have integral 1 on $[0,L]$. The reason for this choice is that the Gaussian quadrature formula takes a simple form

$$\int_0^L g(z)W_L(z)dz \approx \frac{1}{n+1}\sum_{j=0}^n g(z_i), \qquad z_i = \frac{1}{2}\left(1+\cos\frac{2j+1}{2n+2}\right), \tag{5.6}$$

which is of precision $2n+1$. We can apply this quadrature for the integral with respect to w and use the quadrature (2.25) for the integral with respect to t in (5.3) or (5.5). The result is the following algorithm.

ALGORITHM 5.4. *Let $\mu \ge 0$ and let $\gamma_{\mu,j,i} = \mathcal{R}_{\xi_\nu}^\mu(f(\cdot,\cdot,z_i);t_{j,n})$. For $n \ge 0$*

$$\mathcal{B}_{n,L}^\mu(f;\mathbf{x}) = \sum_{\nu=0}^n\sum_{j=0}^n\sum_{i=0}^n \gamma_{\nu,j,i}T_{\nu,j,i}(\mathbf{x}), \tag{5.7}$$

where

$$T_{\nu,j,i}(\mathbf{x}) = \frac{a_\mu\lambda_{j,n}}{n+1}(1-t_{j,n}^2)^{-\mu}\Phi_n^\mu(\xi_\nu,z_i,t_{j,n};\mathbf{x}).$$

Like the algorithms in the previous sections, this algorithm produces a polynomial as an approximation to the function. It does preserve polynomials of lower degrees.

THEOREM 5.5. *The operator $\mathcal{B}_{n,L}^\mu$ is a projection operator on Π_n^3. In other words, $\mathcal{B}_n f \in \Pi_n^3$ and $\mathcal{B}_{n,L}(f) = f$ if $f \in \Pi_n^3$.*

Proof. Let $P_{n,k,j}^\mu$ be defined as in Proposition 5.1. It follows from the definition in (5.1) that $\mathcal{R}_\phi^\mu(P_{l,k,j}^\mu(\cdot,\cdot,w);t) = \mathcal{R}_\phi^\mu(P_j^k;t)p_{l-k}(w)$. Consequently, it follows from (2.15) that $\mathcal{R}_\phi^\mu(P(\cdot,\cdot,w);t)/(1-t^2)^\mu$ is a polynomial of degree n in both the t variable and the w variable whenever $P \in \Pi_n^3$. By its definition in (5.4), the function $\Phi^\mu(\xi,w,t;\mathbf{x})$ is evidently a polynomial of degree n in both t and w variables. Hence,

we can apply (5.6) for the w variable and apply the quadrature (2.25) of precision $2n$ to the t variable, which are exact on $(1-t^2)^{-\mu}\mathcal{R}^\mu_\phi(P(\cdot,\cdot,w);t)\Phi^\mu(\xi,w,t;\cdot)$. □

The approximation process in Algorithm 5.4 uses the attenuated Radon data

$$\big\{\mathcal{R}^\mu_{\xi_\nu}(f(\cdot,\cdot,z_i);t_{j,n}) : 0 \le \nu \le n,\ 0 \le j \le n,\ 0 \le i \le n\big\},$$

which consists of Radon projections on $n+1$ disks that are parallel to the z-axis. In other words, it consists of reconstructions of the function on $n+1$ planes.

In the case in which $n = 2m$ and μ is a half integer, we can also use the quadrature (2.27) to derive a more explicit algorithm as in Algorithm 2.15. Such an algorithm is given in [17] for $\mu = 1/2$. We shall not elaborate further.

COMPOSITE WAVELET BASES WITH EXTENDED STABILITY AND CANCELLATION PROPERTIES*

ROB STEVENSON†

Abstract. The efficient solution of operator equations using wavelets requires that they generate a Riesz basis for the underlying Sobolev space and that they have cancellation properties of a sufficiently high order. Suitable biorthogonal wavelets were constructed on reference domains as the n-cube. Via a domain decomposition approach, these bases have been used as building blocks to construct biorthogonal wavelets on general domains or manifolds, where, in order to end up with local wavelets, biorthogonality was realized with respect to a modified L_2-scalar product. The use of this modified scalar product restricts the application of these so-called composite wavelets to problems of orders strictly larger than -1. Moreover, those wavelets with supports that extend to more than one patch generally have no cancellation properties. In this paper, we construct local, composite wavelets that are close to being biorthogonal with respect to the standard L_2-scalar product. As a consequence, they generate Riesz bases for the Sobolev spaces H^s for the *full range of* s allowed by the continuous gluing of functions over the patch interfaces, the properties of the primal and dual approximation spaces on the reference domain, and, in the manifold case, by the regularity of the manifold. Moreover, all these wavelets have *cancellation properties of the full order* induced by the approximation properties of the dual spaces on the reference domain. We illustrate our findings by a concrete realization of wavelets on a perturbed sphere.

Key words. wavelets, Riesz bases, cancellation properties, domain decomposition, boundary integral equations

1. Introduction.

The use of wavelet bases for solving operator equations, as *partial differential equations* or *(boundary) integral equations*, has a number of advantages; cf. [9, 3]. Let us assume that the operator is symmetric, and, for H being some Hilbert space, H-bounded and H-coercive, and that the infinite collection of properly scaled wavelets generates a *Riesz basis* for H. Then the stiffness matrix in wavelet coordinates resulting from a Ritz–Galerkin discretization is well conditioned uniformly in its size, guaranteeing a uniform rate of convergence of an iterative method. In case of a differential operator, this stiffness matrix is not truly sparse, but has the well-known "finger structure." For multiplying with this matrix, however, one may switch to a single-scale basis, with respect to which the stiffness matrix is sparse.

For integral operators, the stiffness matrix with respect to both single-scale and wavelet basis is densely populated. Here the second important property of wavelets—that of having vanishing moments or, more generally, *cancellation properties*, meaning that the integral of a wavelet against a smooth function vanishes with a certain order of the length scale of the wavelet—can be exploited. If, depending on the order of the operator and the order of approximation, this order of the cancellation properties is sufficiently large, then the stiffness matrix with respect to the wavelet basis can be a priorily compressed to a sparse one without reducing the order of convergence. With this a method of linear complexity is obtained for solving integral equations [18, 10].

Instead of projecting the operator equation onto a fixed finite dimensional space, and then solving the resulting matrix-vector problem with an iterative method, the availability of a *Riesz basis* for H opens an attractive alternative for approximating the solution by adaptive wavelet methods [4, 5]. By writing this unknown solution in terms of this basis and testing the equation for all basis functions, one obtains an infinite dimensional matrix-vector problem. This problem is *equivalent* to the operator equation, and it is well-posed in ℓ_2-metric, meaning that it can be solved using an iterative method. In each iteration of such a method, the application of the infinite stiffness matrix to the current approximation vector has to be approximated. Here the concept of *adaptivity* enters; the accuracy with which a column is approximated grows with the modulus of the corresponding entry of the vector. The resulting method, extended with a so-called coarsening routine to remove small entries from the approximation vector, can be proven to be optimal in the following sense. Whenever, for a certain range of s, the solution is in a class of functions for which the error of the best N-term approximations from the wavelet basis decays like N^{-s}, the sequence of approximations produced by this adaptive method has the same rate of convergence, whereas the computational cost is equivalent to their support sizes. A necessary condition for this statement to be true is that the stiffness matrix is sufficiently close to a sparse matrix, which depends on the smoothness of the wavelets and, again, on the *order of the cancellation properties* [21]. Recently, it has been shown that an optimal adaptive wavelet method can even be obtained without coarsening [15].

Aiming at the aforementioned applications, this paper deals with *the construction on general n-dimensional domains or manifolds of wavelets that, properly scaled, generate Riesz bases for a range of Sobolev spaces, and satisfy cancellation properties of any required order*. To be able to choose this order independently from the order of approximation, we will consider biorthogonal wavelets. Their construction starts with two nested sequences of approximation spaces that both satisfy Jackson and Bernstein estimates ("multiresolution analyses"). Then the primal and dual wavelets are sought as bases of the biorthogonal complements of successive approximation spaces at primal and dual side, respectively. In case the primal and dual approximation spaces can be equipped with bases of local, biorthogonal scaling functions, local primal wavelets are found by applying the biorthogonal projector onto a local basis of some complement space of two successive primal approximation spaces. In this case, under some mild additional condition, the corresponding dual wavelets are also local. Actually, for constructing only local primal wavelets, a reduced set of assumptions already suffices, which for simplicity we will ignore in this introduction. Note that in algorithms for solving operator equations, usually dual wavelets do not play any role.

Biorthogonal scaling functions have been constructed on the real line [6] and, as adaptations of these, on the interval [11]. By taking tensor products, one obtains biorthogonal scaling functions on the n-dimensional unit cube. To construct biorthogonal scaling functions and wavelets on general domains and manifolds, a domain decomposition approach has been developed by Dahmen and Schneider in [12] (see [1, 7] for related approaches). The domain or manifold of interest is written as a disjoint union of smooth parametric images of the unit cube. The biorthogonal scaling functions on the cube are lifted to the patches, and, assuming that the decomposition satisfies some matching condition, they are continuously connected over the interfaces. With respect to a *modified L_2-scalar product*, defined by ignoring the Jacobian determinants of the parametrizations in the definition of the canonical L_2-scalar product, the resulting collections of scaling functions are biorthogonal. Wavelets, in this setting called *composite wavelets*, can now be constructed using the biorthogonal

projector. There are, however, two principal limitations related to the realization of biorthogonality with respect to the modified L_2-scalar product. First, wavelets with supports that extend to more than one patch generally have *no cancellation properties* with respect to the canonical L_2-scalar product. So results concerning matrix compression do not apply to entries involving such wavelets. Second, with respect to the interpretation of a wavelet as a functional using the duality pairing in terms of the canonical L_2-scalar product, generally the resulting wavelets *cannot* generate a *Riesz basis for* H^s *for* $s \leq -\frac{1}{2}$. So for operators of order $2s \leq -1$, like the single-layer potential operator, neither are the optimal preconditioning results valid, nor can the adaptive wavelet method be applied.

These limitations were already recognized by the authors in [12]. In [13], they developed an elegant approach to construct wavelets on general domains or manifolds that, properly scaled, generate Riesz bases for H^s for in principal any s, and that have cancellation properties of any required order. Unfortunately, so far with this approach it seems not easy to construct wavelets that have competitive quantitative properties. A recent investigation of this approach was made in [16].

In this paper, we reconsider the approach from [12], except that, in view of the aforementioned limitations, we make use of the canonical L_2-scalar product. Although, generally, the lifted and connected scaling functions are not biorthogonal with respect to this scalar product, we can derive a general formula for the corresponding biorthogonal wavelets. Since this formula, however, involves the inverse of the matrix consisting of the L_2-scalar products between all primal and dual scaling functions (this matrix is thus generally not diagonal), these wavelets have global supports. On the other hand, this matrix is nearly diagonal, so that its inverse can be well approximated by sparse matrices, which gives rise to local, approximate wavelets. We derive general conditions under which, properly scaled, such approximate wavelets generate a Riesz basis for H^s for the *full range of* s allowed by the continuous gluing of the scaling functions over the interfaces, by the properties of the primal and dual approximation spaces on the cube, and, in the manifold case, by the regularity of the manifold. We give three possibilities for the construction of approximate wavelets that are local and generate Riesz bases for H^s for the aforementioned full range of s, and *all* have *cancellation properties of the full order* induced by the approximation properties of the dual spaces on the unit cube. First, we show that the approximation of the inverse of the matrix of L_2-scalar products of primal and dual scaling functions by a suitable, fixed number of Jacobi iterations yields such approximate wavelets. In view of the relatively large supports of these wavelets, second, we show that away from the patch interfaces they can be replaced by the wavelets one gets by ignoring the Jacobian determinants, which are the wavelets from [12]. Third, we show that also along the patch interfaces suitable approximate wavelets with smaller supports can be constructed, which, however, will involve solving some local systems. Although several proofs will be quite involved, we emphasize that the implementation of the approximate wavelets is relatively straightforward.

In [14, 20], we constructed wavelet bases for Lagrange finite element spaces based on a subdivision of polygonal domains into n-simplices. In this paper, we include the option that these finite element wavelets, or more precisely the underlying scaling functions, are used as building blocks for wavelets on general (nonpolygonal) domains or manifolds, where then the unit n-cube as reference domain should be replaced by some reference n-simplex.

This paper is organized as follows. In the remainder of this section we fix a few notations. In section 2, we specify the type of domains and manifolds and their

parametrizations that we will consider. We recall the definition of the Sobolev spaces, that may involve zero order Dirichlet boundary conditions, which we are going to equip with Riesz bases. In section 3, we collect all assumptions on the multiresolution analyses on the reference domain. The induced, continuous, multiresolution analyses on the target domain or manifold are defined in section 4. Although put here into a more general framework, the main construction principles from sections 2–4 originate from [12]. Biorthogonal space decompositions and the, generally, globally supported biorthogonal wavelets are constructed in section 5. Sections 6 and 7, which form the main part of this paper, are devoted to the construction of local, approximate wavelets. Finally, in section 8 we show examples of approximate wavelets on a perturbed sphere and give some numerically computed condition numbers.

In order to limit the size of this paper, for some technical (parts of) proofs we will refer to the extended preprint version [22].

In order to avoid the repeated use of generic but unspecified constants, in this paper by $C \lesssim D$ we mean that C can be bounded by a multiple of D, independently of parameters on which C and D may depend. Obviously, $C \gtrsim D$ is defined as $D \lesssim C$, and $C \eqsim D$ as $C \lesssim D$ and $C \gtrsim D$.

Let H be a separable Hilbert space with scalar product $\langle\cdot,\cdot\rangle$ and norm $\|\cdot\|$. For a countable collection Σ of functions in H, which we formally view as a (column) vector, and for $\mathbf{c} = (c_\sigma)_{\sigma\in\Sigma}$ a vector of scalars, with $\mathbf{c}^T\Sigma$ we will mean the expansion $\sum_{\sigma\in\Sigma} c_\sigma\sigma$. The span of Σ will be denoted as $\mathcal{S}(\Sigma)$. For $x \in H$, by $\langle\Sigma, x\rangle$ and $\langle x, \Sigma\rangle$ we will mean the column- and row-vectors with coefficients $\langle\sigma, x\rangle$ and $\langle x, \sigma\rangle$, $\sigma \in \Sigma$. When $\tilde\Sigma$ is another countable collection in H, with $\langle\Sigma, \tilde\Sigma\rangle$ we denote the matrix $(\langle\sigma, \tilde\sigma\rangle)_{\sigma\in\Sigma,\tilde\sigma\in\tilde\Sigma}$. For $V \subset H$ being a dense, continuously embedded Banach space, as usual we will use $\langle\cdot,\cdot\rangle$ sometimes also to denote the duality pairing $\langle\cdot,\cdot\rangle_{V\times V'}$, which, with the aforementioned meaning, can also be applied to collections from V and/or V'.

On the spaces of (possibly infinite) scalar vectors or matrices, we will exclusively use the ℓ_2-scalar product, ℓ_2-norm, or the resulting operator norm, that we therefore simply denote by $\langle\cdot,\cdot\rangle$ or $\|\cdot\|$, respectively. A collection Σ is called a *Riesz system* when $\|\mathbf{c}^T\Sigma\| \eqsim \|\mathbf{c}\|$, i.e., when $\langle\Sigma,\Sigma\rangle$ is boundedly invertible, and Σ is called a *Riesz basis* when it is in addition a basis for H. When Σ depends on a parameter, we will speak about *uniform Riesz systems* (or bases) when the above equivalence holds uniformly over the values this parameter may attain. We set $\|\Sigma\| = \|\langle\Sigma,\Sigma\rangle\|^{\frac12}$ and collect a few properties related to this definition.

PROPOSITION 1.1.
(i) $\sup_{\mathbf{c}\neq0} \frac{\|\mathbf{c}^T\Sigma\|}{\|\mathbf{c}\|} = \|\Sigma\|$,
(ii) $\|\langle\Sigma,\tilde\Sigma\rangle\| \le \|\Sigma\|\|\tilde\Sigma\|$,
(iii) $\|\Sigma+\tilde\Sigma\| \le \|\Sigma\| + \|\tilde\Sigma\|$,
(iv) *for a matrix* $\mathbf{A}$, $\|\mathbf{A}\Sigma\| \le \|\mathbf{A}\|\|\Sigma\|$.

Proof. For (i), use $\|\mathbf{c}^T\Sigma\|^2 = \langle\langle\Sigma,\Sigma\rangle\mathbf{c},\mathbf{c}\rangle$. Part (ii) follows from $|\langle\langle\Sigma,\tilde\Sigma\rangle\mathbf{c},\tilde{\mathbf{c}}\rangle| = |\langle\mathbf{c}^T\Sigma,\tilde{\mathbf{c}}^T\tilde\Sigma\rangle| \le \|\mathbf{c}\|\|\tilde{\mathbf{c}}\|\|\Sigma\|\|\tilde\Sigma\|$ because of (i). Part (iii) follows easily from (ii). For (iv), use $\langle\mathbf{A}\Sigma,\mathbf{A}\Sigma\rangle = \mathbf{A}\langle\Sigma,\Sigma\rangle\mathbf{A}^*$. ∎

2. Domains and function spaces. For some $n' \ge n \ge 1$, let Γ be an n-dimensional bounded manifold in $\mathbb{R}^{n'}$, with or without a boundary. For $\square$ denoting the interior either of the n-cube $[0,1]^n$ or, despite its notation, of some reference n-simplex, we assume that Γ is given as

$$\overline{\Gamma} = \cup_{q=1}^M \overline{\Gamma_q},\ \text{with } \Gamma_q \cap \Gamma_{q'} = \emptyset \text{ when } q \neq q',\ \text{and } \Gamma_q = \kappa_q(\square),$$

where $\kappa_q : \mathbb{R}^n \to \mathbb{R}^{n'}$ are some smooth, regular parametrizations. With Π we will denote the collection of all affine mappings from $\square$ onto $\square$. So in case $\square$ is the interior of an n-simplex, this collection consists of the permutations of the $n+1$ barycentric coordinates, and otherwise it consists of the compositions of any permutation of the n Cartesian coordinates and reflections of type $y \mapsto (y_1, \ldots, y_{i-1}, 1-y_i, y_{i+1}, \ldots, y_n)$ $(1 \le i \le n)$. We assume that the splitting of Γ into the patches Γ_q is conforming in the sense that for any $q \neq q'$, either $\overline{\Gamma_q} \cap \overline{\Gamma_{q'}}$ is empty or

$$\kappa_q^{-1}(\overline{\Gamma_q} \cap \overline{\Gamma_{q'}}) \text{ is a face of } \square.$$

In addition, we assume that the parametrizations can be chosen such that the following matching condition is satisfied: There exists a $\pi \in \Pi$ with

$$\kappa_{q'} \circ \pi \circ \kappa_q^{-1} = Id \quad \text{on } \overline{\Gamma_q} \cap \overline{\Gamma_{q'}}. \tag{$\mathcal{M}$}$$

Here and in the remainder of this paper, by a "face" of $\square$, we mean a (complete, closed) face of any dimension $0 \le k \le n-1$; i.e., for $n=3$, it is a vertex, an edge, or a facet. Note that our setting allows Γ to be a bounded domain in $\mathbb{R}^n$, as well as an open or closed bounded manifold in $\mathbb{R}^{n'}$ for some $n' > n$.

We include the possibility that homogeneous, zero order Dirichlet boundary conditions are prescribed on some part $\partial\Gamma_D \subset \overline{\Gamma}\backslash\Gamma$, for which, for all $1 \le q \le M$,

$$\kappa_q^{-1}(\partial\Gamma_D \cap \overline{\Gamma}_q) \text{ is a, possibly empty, union of faces of } \square; \tag{2.1}$$

see Figure 2.1.

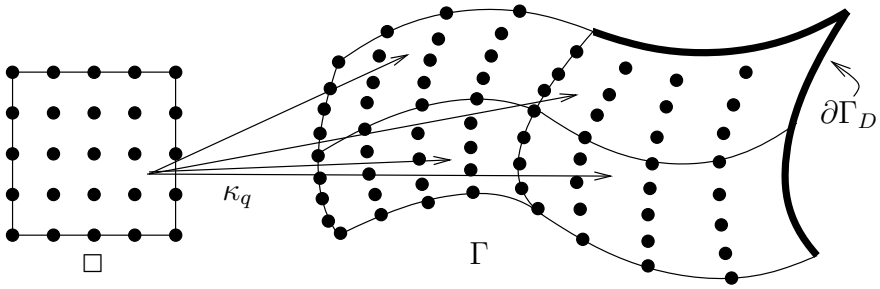

FIG. 2.1. *Illustration of the domain decomposition approach.*

For some $s_\Gamma > 0$, we assume that, globally,

$$\Gamma \in C^{s_\Gamma} \text{ when } s_\Gamma \notin \mathbb{N}, \text{ or } \Gamma \in C^{s_\Gamma - 1,1} \text{ when } s_\Gamma \in \mathbb{N}.$$

This means that for $0 \le s < s_\Gamma \notin \mathbb{N}$, or $0 \le s \le s_\Gamma \in \mathbb{N}$, the Sobolev spaces

$$\mathcal{H}^s(\Gamma) := \begin{cases} H^s_{0,\partial\Gamma_D}(\Gamma) & \text{when } s \le 1, \\ H^s(\Gamma) \cap H^1_{0,\partial\Gamma_D}(\Gamma) & \text{when } s > 1 \end{cases}$$

can be defined in the usual way using a partition of unity relative to some atlas. For $s > 0$ in the above range, $\mathcal{H}^{-s}(\Gamma)$ will be understood as being the dual of $\mathcal{H}^s(\Gamma)$.

With μ being the induced Lebesgue measure on Γ, the inner product on $L_2(\Gamma)$ is given by

$$\langle u, v\rangle_{L_2(\Gamma)} = \int_\Gamma u\overline{v}d\mu = \sum_{q=1}^{M} \langle u \circ \kappa_q, v \circ \kappa_q\rangle_{L_2(\square),|\partial\kappa_q|}. \tag{2.2}$$

Here, for $w \in L^\infty(\square)$ with $w > 0$ a.e., $\langle f, g\rangle_{L_2(\square),w} := \int_\square f(y)\overline{g(y)}w(y)dy$, and $|\partial\kappa_q| : z \mapsto |\partial\kappa_q(z)|$ are the Jacobian determinants of the parametrizations. We will also make use of a modified inner product

$$\langle\!\langle u, v\rangle\!\rangle_0 := \sum_{q=1}^M \langle u\circ\kappa_q, v\circ\kappa_q\rangle_{L_2(\square)}, \tag{2.3}$$

which is the inner product one gets by ignoring the Jacobian determinants. It is equivalent to $\langle\,,\,\rangle_{L_2(\Gamma)}$ in the sense that $|\!|\!|\cdot|\!|\!|_0 := \langle\!\langle\cdot,\cdot\rangle\!\rangle_0^{\frac12} \eqsim \|\cdot\|_{L_2(\Gamma)}$. More generally, for any $s \geq 0$, we define

$$\langle\!\langle u, v\rangle\!\rangle_s = \sum_{q=1}^M \langle u\circ\kappa_q, v\circ\kappa_q\rangle_{H^s(\square)},$$

and let $\mathcal{H}_s(\Gamma)$ denote the closure with respect to $|\!|\!|\cdot|\!|\!|_s := \langle\!\langle\cdot,\cdot\rangle\!\rangle_s^{\frac12}$ of the set all *globally continuous*, and with respect to the subdivision $\overline{\Gamma} = \cup_{q=1}^M \overline{\Gamma_q}$, *piecewise* C^∞ functions on Γ that are *zero on* $\partial\Gamma_D$. For $s > 0$, we define $\mathcal{H}_{-s}(\Gamma) = (\mathcal{H}_s(\Gamma))'$. For $0 \leq s < s_\Gamma \notin \mathbb{N}$ or $0 \leq s \leq s_\Gamma \in \mathbb{N}$, it holds that $\|\cdot\|_{H^s(\Gamma)} \eqsim |\!|\!|\cdot|\!|\!|_s$ on $H^s(\Gamma)$. Furthermore, if $s < \frac32$, then the functions in the aforementioned set generate a dense subset in $\mathcal{H}^s(\Gamma)$. Using in addition duality, we infer that

$$\mathcal{H}^s(\Gamma) \asymp \mathcal{H}_s(\Gamma) \quad (|s| < \tfrac32 \text{ with } |s| < s_\Gamma \notin \mathbb{N} \text{ or } |s| \leq s_\Gamma \in \mathbb{N}), \tag{2.4}$$

meaning that both spaces agree as sets and have equivalent norms. The spaces $\mathcal{H}_s(\Gamma)$ will serve only as auxiliary spaces to prove that the wavelets we are going to construct generate, when properly scaled, a Riesz basis for $\mathcal{H}^s$ for the full range of s; in case this range is limited by the regularity of Γ to a *closed* range $[-s_\Gamma, s_\Gamma]$.

3. Multiresolution analyses on the reference domain. On the reference domain, we will need two nested sequences of approximation spaces (multiresolution analyses) that satisfy Jackson and Bernstein estimates. We will assume that these spaces are equipped with single-scale bases that satisfy certain conditions concerning their supports and symmetry (cf. assumptions ($\mathcal{L}$), ($\mathcal{V}$), ($\mathcal{S}$)), so that after their lifting to the patches, they can be continuously connected over the interfaces. Furthermore, we will assume that the rate of best approximation from these sequences is realized by some concrete projector (cf. ($\mathcal{J}$) and Proposition 3.1), with which it will be shown that the induced approximation spaces on Γ are nested and have the same rate of approximation. We will make some assumptions (($\mathcal{J}1$) and ($\mathcal{J}2$)) connecting primal and dual multiresolution analyses to ensure the existence and uniform boundedness of the biorthogonal projector (cf. Proposition 5.2). Finally, we will assume the existence of a suitable "initial stable completion."

For $j \in \mathbb{N}_0$, let $I_j^\square \subset \overline{\square}$ be some index set with

$$\pi(I_j^\square) = I_j^\square \quad (\pi \in \Pi), \quad \sup_{y\in\square} \#(I_j^\square \cap B(y; 2^{-j})) \lesssim 1$$

(see Figure 2.1). For completeness, for $A \subset \mathbb{R}^n$ and $\delta \geq 0$, by $B(A;\delta)$ we mean $\{y \in \mathbb{R}^n : \mathrm{dist}(y, A) \leq \delta\}$, and $B(\emptyset;\delta) := \emptyset$. For $j \in \mathbb{N}_0$, we assume a collection $\Phi_j^\square = (\phi_{j,x}^\square)_{x\in I_j^\square} \subset C(\overline{\square})$, usually referred to as the set of *scaling functions*, such that the following hold:

($\mathcal{L}$) $\exists$ constant $\varepsilon > 0$, $\operatorname{supp} \phi^{\square}_{j,x} \subset B(x; \varepsilon 2^{-j})$.
($\mathcal{V}$) $\phi^{\square}_{j,x}$ vanishes on any face of $\square$ that does not contain x.
($\mathcal{S}$) $\phi^{\square}_{j,x} = \phi^{\square}_{j,\pi(x)} \circ \pi \quad (\pi \in \Pi)$.
($\mathcal{R}$) $\Phi^{\square}_j$ is a uniform $L_2(\square)$-Riesz system.
($\mathcal{J}$) There exists a collection of functionals $\Lambda^{\square}_j = (\lambda^{\square}_{j,x})_{x \in I^{\square}_j} \subset C(\overline{\square})'$ such that
  (i) $\exists$ constant $\vartheta > 0$, $\operatorname{supp} \lambda^{\square}_{j,x} \subset B(x; \vartheta 2^{-j})$.
  (ii) If $x \in \partial\square$, then $\operatorname{supp} \lambda^{\square}_{j,x}$ is contained in the lowest dimensional face of $\square$ that contains x.
  (iii) $\langle u, \lambda^{\square}_{j,\pi(x)} \rangle_{L_2(\square)} = \langle u \circ \pi, \lambda^{\square}_{j,x} \rangle_{L_2(\square)} \quad (\pi \in \Pi)$.
  (iv) $|\langle u, \lambda^{\square}_{j,x} \rangle_{L_2(\square)}| \lesssim 2^{-jn/2} \|u\|_{L_\infty(\operatorname{supp} \lambda^{\square}_{j,x})}$.
  (v) $\langle \Phi^{\square}_j, \Lambda^{\square}_j \rangle_{L_2(\square)} = Id$.
  (vi) For some $\frac{n}{2} < d \in \mathbb{N}$, $P_{d-1}(\square) \subset \mathcal{S}(\Phi^{\square}_j)$.
($\mathcal{N}$) $\mathcal{S}(\Phi^{\square}_j) \subset \mathcal{S}(\Phi^{\square}_{j+1})$.
($\mathcal{B}$) For some $\gamma > 0$, and any $s \in [0, \gamma)$, it holds that

$$\|u_j\|_{H^s(\square)} \lesssim 2^{sj} \|u_j\|_{L_2(\square)} \quad (u_j \in \mathcal{S}(\Phi^{\square}_j)).$$

Note that, in particular, ($\mathcal{J}$)(ii) implies that for x being a vertex of $\square$, $\langle u, \lambda^{\square}_{j,x} \rangle_{L_2(\square)}$ is a multiple of $u(x)$. Examples of such collections will be given at the end of this section.

PROPOSITION 3.1. *For the projector $P^{\square}_j : u \mapsto \langle u, \Lambda^{\square}_j \rangle_{L_2(\square)} \Phi^{\square}_j$ onto $\mathcal{S}(\Phi^{\square}_j)$, we have*

$$\|u - P^{\square}_j u\|_{L_2(\diamond)} \lesssim 2^{-dj} |u|_{H^d(B(\diamond; (\vartheta + 3\varepsilon) 2^{-j}) \cap \square)} \quad (\diamond \subset \square, u \in H^d(\square)).$$

The proof given in [22] follows standard lines.

Apart from the above collection $\Phi^{\square}_j$ of *primal* scaling functions, for $j \in \mathbb{N}_0$ we assume the existence of a collection $\tilde{\Phi}^{\square}_j = (\tilde{\phi}^{\square}_{j,x})_{x \in I^{\square}_j} \subset C(\overline{\square})$ of *dual* scaling functions. This collection should also satisfy all of ($\mathcal{L}$)–($\mathcal{B}$) with the same index set $I^{\square}_j$, but with generally different parameters and functionals in ($\mathcal{B}$) and ($\mathcal{J}$) that we will denote as $\tilde{\gamma} > 0$, $\tilde{d} > \frac{n}{2}$, $\tilde{\Lambda}^{\square}_j$, and $\tilde{\varepsilon}, \tilde{\vartheta} > 0$. The resulting projector $\tilde{P}^{\square}_j : u \mapsto \langle u, \tilde{\Lambda}^{\square}_j \rangle_{L_2(\square)} \tilde{\Phi}^{\square}_j$ satisfies the analogue of Proposition 3.1 with $(d, \vartheta, \varepsilon)$ replaced by $(\tilde{d}, \tilde{\vartheta}, \tilde{\varepsilon})$.

Since $\Phi^{\square}_j$ and $\tilde{\Phi}^{\square}_j$ are uniform $L_2(\square)$-Riesz systems, the matrix $\langle \Phi^{\square}_j, \tilde{\Phi}^{\square}_j \rangle_{L_2(\square)}$ defines a uniformly bounded linear operator on $\ell_2(I^{\square}_j)$. A relation between $\mathcal{S}(\Phi^{\square}_j)$ and $\mathcal{S}(\tilde{\Phi}^{\square}_j)$ is established by assuming that its real part satisfies

$$\Re \langle \Phi^{\square}_j, \tilde{\Phi}^{\square}_j \rangle_{L_2(\square)} \gtrsim Id. \tag{$\mathcal{J}1$}$$

Finally, for $j \in \mathbb{N}_0$, let $J^{\square}_j \subset \overline{\square}$ be some index set with $\pi(J^{\square}_j) = J^{\square}_j$ $(\pi \in \Pi)$, $\sup_{y \in \square} \#(J^{\square}_j \cap B(y; 2^{-j})) \lesssim 1$, and for e being either $\overline{\square}$ or any face of $\square$, $\#((I^{\square}_j \cup J^{\square}_j) \cap e) = \#(I^{\square}_{j+1} \cap e)$. In case $I^{\square}_j \subset I^{\square}_{j+1}$, a natural candidate is $J^{\square}_j = I^{\square}_{j+1} \backslash I^{\square}_j$. We assume the existence of collections $\Theta^{\square}_j = (\theta^{\square}_{j,x})_{x \in I^{\square}_j}$ with

$$\langle \Theta^{\square}_j, \tilde{\Phi}^{\square}_j \rangle_{L_2(\square)} = Id, \tag{$\mathcal{J}2$}$$

and $\Xi^{\square}_j = (\xi^{\square}_{j,x})_{x \in J^{\square}_j}$ such that the union $\Upsilon^{\square}_{j+1} := \left[(\Theta^{\square}_j)^T \quad (\Xi^{\square}_j)^T \right]^T$ satisfies ($\mathcal{L}$)–($\mathcal{R}$), and $\mathcal{S}(\Upsilon^{\square}_{j+1}) = \mathcal{S}(\Phi^{\square}_{j+1})$.

Remark 3.2. "Classical" wavelet constructions start with assuming biorthogonal scaling functions, i.e., $\langle \Phi_j^\square, \tilde{\Phi}_j^\square \rangle_{L_2(\square)} = Id$, in which case (J1) and (J2) are satisfied with $\Theta_j^\square = \Phi_j^\square$. When there is no need for locally supported dual wavelets, biorthogonality of the scaling functions can be relaxed to the conditions given here, with generally $\Theta_j^\square$ different from $\Phi_j^\square$, and in particular not contained in $\mathcal{S}(\Phi_j)$. For the case that $\Theta_j^\square = \Phi_j^\square$, in the literature the set $\Xi_j^\square$ is sometimes called an initial "stable" completion of $\Phi_j^\square$, that is, a completion of $\tilde{\Phi}_j^\square$ to a uniform $L_2(\square)$-Riesz basis for $\mathcal{S}(\Phi_{j+1}^\square)$. The wavelets to be constructed are then thought of being the target stable completion.

Remark 3.3. The condition (J2) can be further relaxed, which turned out to be useful in [20]. Instead of assuming that $\langle \Theta_j^\square, \tilde{\Phi}_j^\square \rangle_{L_2(\square)}$ is diagonal, more generally it is also sufficient when, for some fixed p, $I_j^\square$ is the union of disjoint sets $I_{j,1}^\square, \ldots, I_{j,p}^\square$, with $\pi(I_{j,i}^\square) = I_{j,i}^\square$ ($\pi \in \Pi$, $1 \le i \le p$), such that, with respect to this partitioning, $\langle \Theta_j^\square, \tilde{\Phi}_j^\square \rangle_{L_2(\square)}$ is a block triangular matrix, with diagonal blocks that are identity matrices. Although all results from this paper are also valid under this relaxed assumption, for ease of presentation we will stick to assumption (J2).

Because of $\mathcal{S}(\Phi_j^\square) \subset \mathcal{S}(\Phi_{j+1}^\square)$, $\mathcal{S}(\tilde{\Phi}_j^\square) \subset \mathcal{S}(\tilde{\Phi}_{j+1}^\square)$, and $\mathcal{S}(\Upsilon_{j+1}^\square) = \mathcal{S}(\Phi_{j+1}^\square)$, it holds that $\Phi_j^\square = \langle \Phi_j^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)} \Phi_{j+1}^\square$, $\tilde{\Phi}_j^\square = \langle \tilde{\Phi}_j^\square, \tilde{\Lambda}_{j+1}^\square \rangle_{L_2(\square)} \tilde{\Phi}_{j+1}^\square$, and $\Upsilon_{j+1}^\square = \langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)} \Phi_{j+1}^\square$, where $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$ is uniformly boundedly invertible.

LEMMA 3.4. *For the matrix* $\mathbf{R}_j^\square$ *being* $\langle \Phi_j^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$, $\langle \tilde{\Phi}_j^\square, \tilde{\Lambda}_{j+1}^\square \rangle_{L_2(\square)}$, $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$, *or* $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}^{-1}$, *it holds that*

(a) $(\mathbf{R}_j^\square)_{\pi(x),\pi(y)} = (\mathbf{R}_j^\square)_{x,y}$ ($\pi \in \Pi$).

(b) $(\mathbf{R}_j^\square)_{x,y} = 0$ *when* y *is on a face of* $\square$ *that does not contain* x.

Proof. Part (a) follows from the assumptions ($\mathcal{S}$) or ($\mathcal{J}$)(iii) for the involved collections of functions and functionals, respectively. Similarly, for the first three matrices, part (b) follows from the assumptions ($\mathcal{V}$) or ($\mathcal{J}$)(ii). Now let e be a face of $\square$. With respect to the partitioning of the index sets for $\Upsilon_{j+1}^\square$ and $\Lambda_{j+1}^\square$ into indices on e and indices not on e, $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$ is a 2×2 upper block triangular matrix with square diagonal blocks, and thus so is its inverse, which shows (b) also for $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}^{-1}$. ∎

By our assumptions, the matrices $\langle \Phi_j^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$ and $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}$ are *uniformly local*, by which we mean that only entries with indices (x, y) with $|x - y| \lesssim 2^{-j}$ might be nonzero. As a consequence, for the wavelets we are going to construct, the basis transformation from wavelet to single-scale basis will be of optimal computational complexity.

For some applications, it is also essential to have a basis transformation from single-scale to wavelet basis that is of optimal computational complexity. In that case, one has to assume *both* that

$$\Theta_j^\square = \Phi_j^\square,$$

with which (J1) can be dropped since it is implied by (J2), *and* also that

$$\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}^{-1} \text{ is } \textit{uniformly local}. \tag{3.1}$$

Note that, for $\Theta_j^\square = \Phi_j^\square$, $\langle \Upsilon_{j+1}^\square, \Lambda_{j+1}^\square \rangle_{L_2(\square)}^{-1}$ is the basis transformation from $\Phi_{j+1}^\square$ to the two-level basis $\Phi_j^\square \cup \Xi_j^\square$.

All conditions imposed in this section are satisfied by the collections $\Phi_j^\square$, $\tilde{\Phi}_j^\square$, $\Theta_j^\square$, $\Xi_j^\square$ underlying the *finite element wavelets* introduced in [14]. With this construction,

$\mathcal{S}(\Phi_j^\square)$, $\mathcal{S}(\tilde{\Phi}_j^\square)$ are standard Lagrange finite element spaces, so that $\gamma = \tilde{\gamma} = \frac{3}{2}$, of orders d and $\tilde{d}$, respectively, with respect to a j times repeated uniform dyadic refinement of an initial simplicial partition of a polytope. For the present setting, we take this polytope to be a reference *n-simplex*. Thinking of $\tilde{d} \geq d$, these orders are chosen such that there is an $m \in \mathbb{N}$ with $2^m(d-1) = \tilde{d} - 1$, so that with the initial partition at the dual side being the reference simplex itself, and at the primal side being created by applying m dyadic recursive refinements to this simplex, we have $\dim \mathcal{S}(\Phi_j^\square) = \dim \mathcal{S}(\tilde{\Phi}_j^\square)$. So each "element" at the dual side is equal to a macro-element at the primal side consisting of 2^m "elements." The collections $\tilde{\Phi}_j^\square$ at the dual side, and $\Phi_j^\square$, $\Theta_j^\square$, $\Xi_j^\square$ at the primal side are now assembled in the standard finite element fashion from local collections, of a small, fixed dimension, of functions defined on the individual elements or macroelements, respectively. Each of these collections is a copy, or more precisely, a push forward using an affine bijection of such a collection created once and for all on a reference (macro)element. The functionals from $\tilde{\Lambda}_j^\square$ and $\Lambda_j^\square$ are assembled in the same manner from local collections, and are either simply scaled function evaluations in the "nodal points" $I_j^\square$ or local linear combinations of these. Actually, in the present paper, we will repeat the idea of assembling functions and functionals from collections defined on (macro)elements, which in turn are push forwards of collections defined on a reference (macro)element. Now the role of the (macro)elements will be played by the patches Γ_q, and that of the reference (macro)element by $\kappa_q^{-1}(\Gamma_q)$. A difference is that the number of patches is fixed, and that, as a consequence, the dimension of the local collections grows with the level. The major difficulty we have to deal with is that generally the κ_q are not affine, so that the Jacobian determinants are not constants.

In [20], we reconsidered the finite element wavelets and constructed collections with $\Theta_j^\square = \Phi_j^\square$, so that also the resulting dual wavelets are locally supported. In this case, the dual spaces, although consisting of continuous piecewise polynomials, are not standard finite element spaces.

Other examples of collections $\Phi_j^\square$, $\tilde{\Phi}_j^\square$, $\Theta_j^\square$, $\Xi_j^\square$ that satisfy our assumptions, with $\Theta_j^\square = \Phi_j^\square$, and now with $\square$ being the *n-cube*, are given in [12] and underlie the construction of *biorthogonal spline wavelets*. These collections are slight modifications of those developed in [11], and, for $n > 1$, they are simply generated using tensor products from univariate collections $\Phi_j^{[0,1]}$, $\tilde{\Phi}_j^{[0,1]}$, $\Xi_j^{[0,1]}$ defined on $[0,1]$. For given $\tilde{d} \geq d \geq 2$ with $d + \tilde{d}$ even, $\mathcal{S}(\Phi_j^{[0,1]})$ is the spline space of order d, so that $\gamma = d - \frac{1}{2}$, with respect to the knot sequence

$$(\underbrace{0, \ldots, 0}_{d \text{ times}}, r2^{-j}, r2^{-j} + 2^{-j}, \ldots, 1 - r2^{-j}, \underbrace{1, \ldots, 1}_{d \text{ times}}),$$

where $\mathbb{N} \ni r \geq d - 1$ is some parameter that one can choose. The collection $\tilde{\Phi}_j^{[0,1]}$ is such that $P_{\tilde{d}-1}[0,1] \subset \mathcal{S}(\tilde{\Phi}_j^{[0,1]})$ and $\langle \Phi_j^{[0,1]}, \tilde{\Phi}_j^{[0,1]} \rangle_{L_2([0,1])} = Id$, where $\tilde{\gamma}$ grows linearly with $\tilde{d}$. For x not near the endpoints 0 or 1, $\phi_{j,x}^{[0,1]} = 2^{j/2}\phi(2^j \cdot -x)$ and $\tilde{\phi}_{j,x}^{[0,1]} = 2^{j/2}\tilde{\phi}(2^j \cdot -x)$, where $(\phi, \tilde{\phi})$ is a biorthogonal pair constructed in [6]. Also the functionals from $\Lambda_j^\square$ and $\tilde{\Lambda}_j^\square$ are constructed from the collections of univariate functionals $\Lambda_j^{[0,1]}$ and $\tilde{\Lambda}_j^{[0,1]}$ using tensor products, where $\lambda_{j,x}^{[0,1]} = \tilde{\phi}_{j,x}^{[0,1]}$, $\tilde{\lambda}_{j,x}^{[0,1]} = \phi_{j,x}^{[0,1]}$ for $x \notin \{0,1\}$, and where they are simply scaled function evaluations in 0 or 1, respectively, otherwise.

4. Induced, continuous multiresolution analyses on Γ. By lifting the collections of functions on $\square$ to the patches of Γ, and by connecting those that do not vanish at the interfaces continuously with ones from other patches, we will construct nested sequences of primal and dual spaces that satisfy Jackson estimates and Bernstein inequalities.

We define the index sets $I_j \subset \overline{\Gamma}\backslash\partial\Gamma_D$, and analogously J_j, by

$$I_j = (\cup_{q=1}^M \kappa_q(I_j^\square)) \cap (\overline{\Gamma}\backslash\partial\Gamma_D)$$

(see Figure 2.1). By $(\mathcal{M})$ and $\pi(I_j^\square) = I_j^\square$ $(\pi \in \Pi)$, for any $1 \le q, q' \le M$ with $\overline{\Gamma_q} \cap \overline{\Gamma_{q'}} \neq \emptyset$, the sets $\kappa_q(I_j^\square)$ and $\kappa_{q'}(I_j^\square)$ restricted to this interface coincide. For $x \in \overline{\Gamma}$, we set $k(x) = \#\{q : x \in \overline{\Gamma_q}\}$.

For $j \in \mathbb{N}_0$, we define the collection $\Phi_j = (\phi_{j,x})_{x\in I_j} \subset C(\overline{\Gamma})$ by

$$\phi_{j,x}(y) = k(x)^{-\frac{1}{2}} \begin{cases} \phi^\square_{j,\kappa_q^{-1}(x)}(\kappa_q^{-1}(y)) & \text{when } x, y \in \overline{\Gamma_q} \text{ for some } 1 \le q \le M, \\ 0 & \text{elsewhere.} \end{cases} \tag{4.1}$$

Note that by $(\mathcal{S})$, $(\mathcal{V})$, and (2.1), $\phi_{j,x}$ is well defined and indeed continuous, and it vanishes on $\partial\Gamma_D$. By assumption $(\mathcal{L})$, the collection Φ_j is *uniformly local*, by which we mean that $x \in \operatorname{supp}\phi_{j,x}$, and that $d_\Gamma(x,y) \lesssim 2^{-j}$ for any $y \in \operatorname{supp}\phi_{j,x}$, where $d_\Gamma(x,y)$ denotes the geodesic distance of x and y over Γ, i.e., the length of the shortest curve on Γ connecting x and y.

With $\mathbf{E}_{j,q} : \ell_2(I_j^\square) \to \ell_2(I_j)$ defined by

$$(\mathbf{E}_{j,q}\mathbf{c}_j^\square)_x = k(x)^{-\frac{1}{2}} \begin{cases} \mathbf{c}^\square_{j,\kappa_q^{-1}(x)}, & x \in \overline{\Gamma_q}, \\ 0, & \text{otherwise,} \end{cases} \tag{4.2}$$

and similarly $\mathbf{F}_{j,q} : \ell_2(J_j^\square) \to \ell_2(J_j)$, we have $\sum_{q=1}^M \mathbf{E}_{j,q}\mathbf{E}_{j,q}^T = Id$ and $\sum_{q=1}^M \mathbf{F}_{j,q}\mathbf{F}_{j,q}^T = Id$. By construction of Φ_j from $\Phi_j^\square$, we have

$$\langle \Phi_j, \Phi_j\rangle_{L_2(\Gamma)} = \sum_{q=1}^M \mathbf{E}_{j,q}\langle \Phi_j^\square, \Phi_j^\square\rangle_{L_2(\square),|\partial\kappa_q|}\mathbf{E}_{j,q}^T, \tag{4.3}$$

so that, because of $\langle \Phi_j^\square, \Phi_j^\square\rangle_{L_2(\square),|\partial\kappa_q|} \eqsim \langle \Phi_j^\square, \Phi_j^\square\rangle_{L_2(\square)} \eqsim Id$ by $|\partial\kappa_q| \eqsim 1$ and $(\mathcal{R})$, Φ_j *is a uniform* $L_2(\Gamma)$*-Riesz system.*

PROPOSITION 4.1. *Setting* $\Lambda_j = (\lambda_{j,x})_{x\in I_j} \subset C(\overline{\Gamma})'$ *by*

$$\lambda_{j,x}(u) = k(x)^{\frac{1}{2}}\lambda^\square_{j,\kappa_q^{-1}(x)}(u\circ\kappa_q) \quad \textit{when } x \in \overline{\Gamma}_q,$$

we have $\langle \Phi_j, \Lambda_j\rangle_{L_2(\Gamma)} = Id$*. The projector* $P_j : u \mapsto \langle u, \Lambda_j\rangle_{L_2(\Gamma)}\Phi_j$ *onto* $\mathcal{S}(\Phi_j)$ *satisfies*

$$\|(Id-P_j)u\|_{L_2(\Omega)} \lesssim 2^{-dj}\sum_{q=1}^M |u\circ\kappa_q|_{H^d(B(\kappa_q^{-1}(\Omega\cap\Gamma_q);(\vartheta+3\varepsilon)2^{-j})\cap\square)} \quad (\Omega \subset \Gamma,\ u \in \mathcal{H}_d(\Gamma)).$$

Proof. Assumption $(\mathcal{J})$(ii) shows that $\lambda_{j,x}(u)$ is well defined for $u \in C(\overline{\Gamma})$, also when x is on an interface between patches, and, because of (4.1), that $(P_ju)\circ\kappa_q =$

$P_j^{\square}(u\circ\kappa_q)$ when u vanishes on $\partial\Gamma_D$. Condition $(\mathcal{J})$(v) shows that $\langle\Phi_j,\Lambda_j\rangle_{L_2(\Gamma)}=Id$. By Proposition 3.1, we have

$$\begin{aligned}\|(Id-P_j)u\|_{L_2(\Omega)} &\eqsim \sum_{q=1}^{M}\|((Id-P_j)u)\circ\kappa_q\|_{L_2(\kappa_q^{-1}(\Omega\cap\Gamma_q))}\\ &= \sum_{q=1}^{M}\|(Id-P_j^{\square})(u\circ\kappa_q)\|_{L_2(\kappa_q^{-1}(\Omega\cap\Gamma_q))}\\ &\lesssim 2^{-dj}\sum_{q=1}^{M}|u\circ\kappa_q|_{H^d(B(\kappa_q^{-1}(\Omega\cap\Gamma_q);(\vartheta+3\varepsilon)2^{-j})\cap\square)}. \qquad \square\end{aligned}$$

By substituting $\Omega=\Gamma$ in Proposition 4.1, we have the following *Jackson estimate*:

$$\inf_{u_j\in\mathcal{S}(\Phi_j)}\|u-u_j\|_{L_2(\Gamma)}\lesssim 2^{-dj}\|\!|u|\!\|_d \qquad (u\in\mathcal{H}_d(\Gamma)). \tag{4.4}$$

A direct consequence of $(\mathcal{B})$ is the following *Bernstein inequality*: For $s\in[0,\gamma)$,

$$\|\!|u_j|\!\|_s\lesssim 2^{sj}\|u_j\|_{L_2(\Gamma)} \quad (u_j\in\mathcal{S}(\Phi_j)). \tag{4.5}$$

Thanks to properties of a Sobolev scale, (4.5) gives rise to the following extended version that will be used in the appendix.

LEMMA 4.2. *For any $t\le s<\gamma$ with $t\le 0$,*

$$\|\!|u_j|\!\|_s\lesssim 2^{(s-t)j}\|\!|u_j|\!\|_t \quad (u_j\in\mathcal{S}(\Phi_j)).$$

The short proof of this lemma can be found in [22].

As $\Phi_j^{\square}$, via (4.1), gave rise to a uniformly local, uniform $L_2(\Gamma)$-Riesz system Φ_j, analogously the collections $\Upsilon_{j+1}^{\square}=\left[(\Theta_j^{\square})^T\quad(\Xi_j^{\square})^T\right]^T$ and $\tilde\Phi_j^{\square}$ yield *uniformly local, uniform $L_2(\Gamma)$-Riesz systems* $\Upsilon_{j+1}=\left[\Theta_j^T\quad\Xi_j^T\right]^T$ and $\tilde\Phi_j$, respectively.

We have the analogue of Proposition 4.1 at the dual side, with functionals and a projector denoted as $\tilde\Lambda_j=(\tilde\lambda_{j,x})_{x\in I_j}$ and $\tilde P_j$, respectively, and with Φ_j, d, ϑ, ε replaced by $\tilde\Phi_j$, $\tilde d$, $\tilde\vartheta$, $\tilde\varepsilon$. In particular, we have the *Jackson estimate*

$$\inf_{u_j\in\mathcal{S}(\tilde\Phi_j)}\|u-u_j\|_{L_2(\Gamma)}\lesssim 2^{-\tilde dj}\|\!|u|\!\|_{\tilde d} \qquad (u\in\mathcal{H}_{\tilde d}(\Gamma)), \tag{4.6}$$

and furthermore also the *Bernstein inequality*: For any $s\in[0,\tilde\gamma)$,

$$\|\!|u_j|\!\|_s\lesssim 2^{sj}\|u_j\|_{L_2(\Gamma)} \quad (u_j\in\mathcal{S}(\tilde\Phi_j)), \tag{4.7}$$

which can be extended analogously to Lemma 4.2.

Analogously to [12, Prop. 4.3.1], using Lemma 3.4, one may verify the following easily implementable formulas for the representations of the global embeddings in terms of corresponding representations of local embeddings.

PROPOSITION 4.3. *It holds that*

$$\Phi_j = \sum_{q=1}^{M} \mathbf{E}_{j,q} \langle \Phi_j^{\square}, \Lambda_{j+1}^{\square} \rangle_{L_2(\square)} \mathbf{E}_{j+1,q}^T \Phi_{j+1},$$

$$\tilde{\Phi}_j = \sum_{q=1}^{M} \mathbf{E}_{j,q} \langle \tilde{\Phi}_j^{\square}, \tilde{\Lambda}_{j+1}^{\square} \rangle_{L_2(\square)} \mathbf{E}_{j+1,q}^T \tilde{\Phi}_{j+1},$$

$$\Upsilon_{j+1} = \sum_{q=1}^{M} \left[\begin{array}{c|c} \mathbf{E}_{j,q} & 0 \\ \hline 0 & \mathbf{F}_{j,q} \end{array}\right] \langle \Upsilon_{j+1}^{\square}, \Lambda_{j+1}^{\square} \rangle_{L_2(\square)} \mathbf{E}_{j+1,q}^T \Phi_{j+1},$$

$$\Phi_{j+1} = \sum_{q=1}^{M} \mathbf{E}_{j+1,q} \langle \Upsilon_{j+1}^{\square}, \Lambda_{j+1}^{\square} \rangle_{L_2(\square)}^{-1} \left[\begin{array}{c|c} \mathbf{E}_{j,q}^T & 0 \\ \hline 0 & \mathbf{F}_{j,q}^T \end{array}\right] \Upsilon_{j+1}.$$

So, in particular, $\mathcal{S}(\Phi_j) \subset \mathcal{S}(\Phi_{j+1})$, $\mathcal{S}(\tilde{\Phi}_j) \subset \mathcal{S}(\tilde{\Phi}_{j+1})$, *and* $\mathcal{S}(\Upsilon_{j+1}) = \mathcal{S}(\Phi_{j+1})$.

5. Biorthogonal space decompositions and wavelets. We have constructed primal and dual sequences of nested spaces that satisfy Jackson and Bernstein estimates. To conclude existence and stability, with respect to a range of Sobolev norms, of the corresponding biorthogonal space decompositions, the only thing left to show is the existence and uniform $L_2(\Gamma)$-boundedness of the biorthogonal projector.

Results similar to the next lemma are often used in the context of saddle point problems. A proof of (the nontrivial part of) this lemma can be found in, e.g., [14, Theorem 2.1(a)].

LEMMA 5.1. *Let* V, U *be closed subspaces of a Hilbert space* H. *Then the following statements are equivalent:*

(a) $\gamma := \inf_{0 \neq u \in U} \sup_{0 \neq v \in V} \frac{|\langle u,v \rangle|}{\|u\|\|v\|} > 0$, *and for any* $v \in V$, *there exists a* $u \in U$ *with* $\langle u, v \rangle \neq 0$.

(b) *There exists a bounded projector* $Q : H \to H$ *with* $\Im(Q) = V$ *and* $\Im(I - Q) = U^{\perp}$, *which is therefore appropriately called a* biorthogonal projector.

In either case it holds that $\gamma = \|Q\|^{-1}$, *and the adjoint* Q^* *satisfies* $\Im(Q^*) = U$ *and* $\Im(I - Q^*) = V^{\perp}$.

When Σ *and* Δ *are Riesz bases for* U *and* V, *respectively, then* (a) *or* (b) *is equivalent to the existence of a bounded inverse of* $\langle \Sigma, \Delta \rangle : \ell_2(\Delta) \to \ell_2(\Sigma)$. *In that case it holds that*

$$\|\langle \Sigma, \Sigma \rangle^{-1}\|^{-\frac{1}{2}} \|\langle \Delta, \Delta \rangle^{-1}\|^{-\frac{1}{2}} \leq \frac{\|Q\|}{\|\langle \Sigma, \Delta \rangle^{-1}\|} \leq \|\Sigma\| \|\Delta\|.$$

To be able to transfer results valid on the reference parameter domain to the manifold, in particular those concerning $L_2(\square)$- or $L_2(\Gamma)$-angles between spaces, we will have to assume that the coarsest "mesh" is sufficiently fine in order to control the influence of the generally nonconstant Jacobian determinants.

PROPOSITION 5.2. *For* $j \geq j_0$ *being large enough, there exists a uniformly bounded projector* $Q_j : L_2(\Gamma) \to L_2(\Gamma)$ *with* $\Im(Q_j) = \mathcal{S}(\Phi_j)$ *and* $\Im(I - Q_j) = \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}$.

Proof. Setting

$$\Delta_{j,q}^{\square} = \operatorname{diag}(|\partial \kappa_q(x)|)_{x \in I_j^{\square}}, \tag{5.1}$$

by $(\mathcal{L})$ for both $\Phi_j^\square, \tilde{\Phi}_j^\square$, the smoothness of $z \mapsto |\partial\kappa_q(z)|$, and the uniform boundedness of $\|\phi_{j,x}^\square\|_{L_2(\square)}$, $\|\tilde{\phi}_{j,x}^\square\|_{L_2(\square)}$, we have

$$\|\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square),|\partial\kappa_q|} - (\Delta_{j,q}^\square)^{\frac{1}{2}}\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square)}(\Delta_{j,q}^\square)^{\frac{1}{2}}\| \lesssim 2^{-j}. \tag{5.2}$$

By assumption $(\mathcal{J}1)$ and $|\partial\kappa_q| \gtrsim 1$, we have

$$\Re((\Delta_{j,q}^\square)^{\frac{1}{2}}\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square)}(\Delta_{j,q}^\square)^{\frac{1}{2}}) = (\Delta_{j,q}^\square)^{\frac{1}{2}}\Re\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square)}(\Delta_{j,q}^\square)^{\frac{1}{2}} \gtrsim Id,$$

so that for $j \geq j_0$ large enough, $\Re\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square),|\partial\kappa_q|} \gtrsim Id$. Similarly to (4.3), we find that

$$\Re\langle \Phi_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)} = \sum_{q=1}^M \mathbf{E}_{j,q}\Re\langle \Phi_j^\square, \tilde{\Phi}_j^\square\rangle_{L_2(\square),|\partial\kappa_q|}\mathbf{E}_{j,q}^T \gtrsim \sum_{q=1}^M \mathbf{E}_{j,q}\mathbf{E}_{j,q}^T = Id.$$

Since apparently, for $j \geq j_0$, $\langle \Phi_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is uniformly boundedly invertible, and Φ_j and $\tilde{\Phi}_j$ are uniform $L_2(\Gamma)$-Riesz systems, an application of Lemma 5.1 completes the the proof. □

For $j \geq j_0$, the nesting $\mathcal{S}(\tilde{\Phi}_j) \subset \mathcal{S}(\tilde{\Phi}_{j+1})$ gives $Q_j^* = Q_{j+1}^* Q_j^*$ or $Q_j = Q_j Q_{j+1}$, from which it follows that

$$\Im(Q_{j+1} - Q_j) = \mathcal{S}(\Phi_{j+1}) \cap \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}.$$

Analogously, $\mathcal{S}(\Phi_j) \subset \mathcal{S}(\Phi_{j+1})$ implies that

$$\Im(Q_{j+1}^* - Q_j^*) = \mathcal{S}(\tilde{\Phi}_{j+1}) \cap \mathcal{S}(\Phi_j)^{\perp_{L_2(\Gamma)}}.$$

From the Jackson estimates and Bernstein inequalities at primal and dual sides (4.4), (4.5), (4.6), and (4.7), and the existence and uniform $L_2(\Gamma)$-boundedness of the biorthogonal projectors Q_j from Proposition 5.2, we have the following theorem.

THEOREM 5.3 (cf., e.g., [8], [14, Theorem 2.1]). *With $Q_{j_0-1} := 0$, it holds that*

$$\Big\|\Big\| \sum_{j=j_0}^\infty w_j \Big\|\Big\|_s^2 \lesssim \sum_{j=j_0}^\infty 4^{sj}\|w_j\|_{L_2(\Gamma)}^2 \qquad (w_j \in \Im(Q_j - Q_{j-1}),\ s \in (-\tilde{d}, \gamma)), \tag{5.3}$$

and

$$\sum_{j=j_0}^\infty 4^{sj}\|(Q_j - Q_{j-1})u\|_{L_2(\Gamma)}^2 \lesssim \|\!|u|\!\|_s^2 \qquad (u \in \mathcal{H}_s(\Gamma),\ s \in (-\tilde{\gamma}, d)). \tag{5.4}$$

For $s \in (-\min\{\tilde{\gamma}, \tilde{d}\}, \min\{\gamma, d\})$, $(w_j)_{j\geq j_0} \mapsto \sum_{j=j_0}^\infty w_j$, and $u \mapsto ((Q_j - Q_{j-1})u)_{j\geq j_0}$, mappings that are bounded in the sense of (5.3) *and* (5.4) *are each others' inverse.*

Analogous results are valid with (Q_j) replaced by (Q_j^*) and with interchanged roles of (γ, d) and $(\tilde{\gamma}, \tilde{d})$.

Next, we construct a uniform $L_2(\Gamma)$-Riesz basis for $\Im(Q_{j+1} - Q_j)$, whose elements are called *wavelets*.

PROPOSITION 5.4.

(a) *For $j \geq j_0$ being large enough, there exists a uniformly bounded projector $\bar{Q}_j : L_2(\Gamma) \to L_2(\Gamma)$ with $\Im(\bar{Q}_j) = \mathcal{S}(\Theta_j)$ and $\Im(Id - \bar{Q}_j) = \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}$.*

(b) *This projector can be computed as* $\bar{Q}_j u = \langle u, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}\langle \Theta_j, \tilde{\Phi}_j\rangle^{-1}_{L_2(\Gamma)}\Theta_j$.

(c) *The collection of wavelets*

$$\boxed{\Psi_j := \Xi_j - \langle \Xi_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}\langle \Theta_j, \tilde{\Phi}_j\rangle^{-1}_{L_2(\Gamma)}\Theta_j} \tag{5.5}$$

is a uniform $L_2(\Gamma)$*-Riesz basis for* $\mathcal{S}(\Phi_{j+1}) \cap \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}$.

So by taking j_0 *to be the maximum of the values from* (a) *and that of Proposition* 5.2*, for* $s \in (-\min\{\tilde{\gamma}, \tilde{d}\}, \min\{\gamma, d\})$,

$$\Phi_{j_0} \cup \cup_{j\geq j_0} 2^{-sj}\Psi_j \text{ is a Riesz basis for } \mathcal{H}_s(\Gamma),$$

and thus, in view of (2.4)*, when in addition* $|s| < \frac{3}{2}$, $|s| < s_\Gamma \notin \mathbb{N}$, *or* $|s| \leq s_\Gamma \in \mathbb{N}$, *it is a Riesz basis for* $\mathcal{H}^s(\Gamma)$.

Proof. (a) Since Θ_j and $\tilde{\Phi}_j$ are uniform $L_2(\Gamma)$-Riesz bases, by Lemma 5.1 we have to show that, for $j \geq j_0$ large enough, $\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is uniformly boundedly invertible, which follows from (J2) similarly to the proof of Proposition 5.2.

(b) Using that $\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is uniformly boundedly invertible, one easily verifies that $\bar{Q}_j$, as given in (b), indeed has the properties listed in (a).

(c) Let $u \in \mathcal{S}(\Phi_{j+1})$; then $u = \mathbf{c}_j^T\Theta_j + \mathbf{d}_j^T\Xi_j$ with $\|u\|_{L_2(\Gamma)} \eqsim (\|\mathbf{c}_j\|^2 + \|\mathbf{d}_j\|^2)^{\frac{1}{2}}$. If, in addition, $u \in \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}$, then $u = (Id - \bar{Q}_j)u = (Id - \bar{Q}_j)\mathbf{d}_j^T\Xi_j = \mathbf{d}_j^T\Psi_j$, and so with $\|u\|_{L_2(\Gamma)} \lesssim (1 + \|\bar{Q}_j\|_{L_2(\Gamma)\to L_2(\Gamma)})\|\mathbf{d}_j^T\Xi_j\|_{L_2(\Gamma)} \lesssim \|\mathbf{d}_j\| \lesssim \|u\|_{L_2(\Gamma)}$. Noting that $\Psi_j \subset \mathcal{S}(\Phi_{j+1}) \cap \mathcal{S}(\tilde{\Phi}_j)^{\perp_{L_2(\Gamma)}}$, we conclude that it is a uniform $L_2(\Gamma)$-Riesz basis for this space. The last statements are now consequences of Theorem 5.3. ∎

Note that Proposition 4.1 at the dual side implies that $\Psi_j = (\psi_{j,x})_{x\in J_j}$, yielded by (5.5), satisfies

$$\begin{aligned} |\langle\, \psi_{\,j,x}, u\rangle_{L_2(\Gamma)}| &= |\langle \psi_{j,x}, (Id - \tilde{P}_j)u\rangle_{L_2(\Gamma)}| \\ &\lesssim 2^{-\tilde{d}j}\sum_{q=1}^{M} |u\circ\kappa_q|_{H^{\tilde{d}}(B(\kappa_q^{-1}(\operatorname{supp}\psi_{j,x}\cap\Gamma_q);(\tilde{\vartheta}+3\tilde{\varepsilon})2^{-j})\cap\square)} \quad (u \in \mathcal{H}_{\tilde{d}}(\Gamma)). \end{aligned} \tag{5.6}$$

This property of the collections Ψ_j, with $\tilde{\vartheta} + 3\tilde{\varepsilon}$ replaced by an arbitrary but fixed $\tilde{\eta} \geq 0$ and the seminorms $|\cdot|_{H^{\tilde{d}}(\dots)}$ replaced by the norms $\|\cdot\|_{H^{\tilde{d}}(\dots)}$, will be referred to as the *uniform cancellation property of order* $\tilde{d}$.

6. Stability of *approximate* wavelet bases. Similarly to (4.3), the definition of the collections Θ_j and $\tilde{\Phi}_j$ via (4.1) shows that

$$\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)} = \sum_{q=1}^{M} \mathbf{E}_{j,q}\langle \Theta_j^{\square}, \tilde{\Phi}_j^{\square}\rangle_{L_2(\square),|\partial\kappa_q|}\mathbf{E}_{j,q}^T. \tag{6.1}$$

So if, for each q, $z \mapsto |\partial\kappa_q(z)|$ is a *constant function*, then (J2) shows that $\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is diagonal, and the collection of wavelets Ψ_j given in (5.5) is *uniformly local*. Unfortunately, only a restricted class of manifolds can be described as the union of patches that are the images of $\square$ under parametrizations that have constant Jacobians. In case *not all Jacobians are constants*, then, generally, $\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is not diagonal and its inverse is densely populated, so that (5.5) yields wavelets Ψ_j that have *global supports*.

A possibility to circumvent this problem, pursued in [12], is to carry out the whole wavelet construction outlined so far using the modified scalar product $\langle\!\langle\, ,\, \rangle\!\rangle_0$ instead of $\langle\, ,\, \rangle_{L_2(\Gamma)}$. Indeed, $\langle\!\langle \Theta_j, \tilde{\Phi}_j \rangle\!\rangle_0 = \sum_{q=1}^M \mathbf{E}_{j,q} \langle \Theta_j^\square, \tilde{\Phi}_j^\square \rangle_{L_2(\square)} \mathbf{E}_{j,q}^T = \sum_{q=1}^M \mathbf{E}_{j,q}\ \mathbf{E}_{j,q}^T = Id$, and so uniformly local wavelets are obtained. What is more, by employing this scalar product, it is always possible to take the coarsest level $j_0 = 0$.

As was already recognized in [12], this approach, however, has two limitations: First, the obtained wavelets will be orthogonal to the constant function with respect to $\langle\!\langle\, ,\, \rangle\!\rangle_0$. As a consequence, if the function

$$J : \cup_{q=1}^M \Gamma_q \to \mathbb{R} : x \mapsto |\partial \kappa_{q'}(\kappa_{q'}^{-1}(x))| \quad \text{when } x \in \Gamma_q'$$

has discontinuities, or more precisely, cannot be extended to a continuous function on Γ, then wavelets with supports that are not contained in one patch will generally *not* have a zero mean value with respect to the canonical Lebesgue measure on Γ, meaning that they have *no cancellation property* with respect to $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$. The application of wavelets we focus on is that for the solution of differential or integral equations in variational form using the duality pairing with respect to $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$ (taking a different scalar product here yields other disadvantages; cf. [14, section 1.2]). For obtaining nearly sparse representations of these operators in wavelet coordinates, and with that algorithms of optimal computational complexity, the wavelets should have a cancellation property of sufficiently high order (cf. [10, 21] or the surveys [9, 3]) with respect thus to $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$. In a nonadaptive setting, under certain circumstances it might be possible that the fact that only wavelets along the lower dimensional patch interfaces do not have cancellation properties does not spoil optimal complexity. In an adaptive setting, however, such an argument cannot be applied.

The second limitation has to do with the interpretation for $s < 0$ of the statement that $\Phi_{j_0} \cup \cup_{j \geq j_0} 2^{-sj} \Psi_j$ is a Riesz basis for $\mathcal{H}_s(\Gamma)$, which is a consequence of Theorem 5.3. In case biorthogonality is realized with respect to $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$, then an expansion in terms of the basis $\Phi_{j_0} \cup \cup_{j \geq j_0} 2^{-sj} \Psi_j$ should be interpreted as an element of $\mathcal{H}_s(\Gamma)$, i.e., as a functional, using the embedding $L_2(\Gamma) \to \mathcal{H}_s(\Gamma) : u \mapsto (v \mapsto \langle v, u \rangle_{L_2(\Gamma)})$. Replacing $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$ by $\langle\!\langle \cdot, \cdot \rangle\!\rangle_0$ means that also the embedding should be changed into $u \mapsto (v \mapsto \langle\!\langle v, u \rangle\!\rangle_0)$. One can show (cf. [17, section 4]) that if J has discontinuities, then for $s \leq -\frac{1}{2}$ a set $\Phi_{j_0} \cup \cup_{j \geq j_0} 2^{-sj} \Psi_j$ which is a Riesz basis for $\mathcal{H}_s(\Gamma)$ using the embedding $u \mapsto (v \mapsto \langle\!\langle v, u \rangle\!\rangle_0)$ *cannot* be a Riesz basis for $\mathcal{H}_s(\Gamma)$ using the embedding $u \mapsto (v \mapsto \langle v, u \rangle_{L_2(\Gamma)})$. For $s > -\frac{1}{2}$, the property of being a Riesz basis for $\mathcal{H}_s(\Gamma)$ is the same for both embeddings. Again, since in applications duality pairing with respect to $\langle \cdot, \cdot \rangle_{L_2(\Gamma)}$ is used, in this paper the property of a collection of functions to be a Riesz basis for $\mathcal{H}_s(\Gamma)$ for $s < 0$ will always be interpreted with respect to the canonical embedding $u \mapsto (v \mapsto \langle v, u \rangle_{L_2(\Gamma)})$.

In this paper, we propose another approach to solve the problem that generally $\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1}$ is densely populated, so that the wavelets yielded by (5.5) have global supports. As we will see, $\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1}$ can be well approximated by uniformly local matrices, so that close to the collections of the wavelets Ψ_j, there are collections of uniformly local functions of which suitable ones might be applied instead. In the following main theorem of this paper we derive general criteria under which such *approximate wavelets* satisfy the *same* conditions as Ψ_j concerning *both* stability with respect to a range of Sobolev norms *and* the order of the cancellation property, where, moreover, in contrast to Ψ_j, they are uniformly local.

THEOREM 6.1. *If, for $j \geq j_0$,*

(i) $\breve{\Psi}_j = (\breve{\psi}_{j,x})_{x \in J_j} \subset \mathcal{S}(\Phi_{j+1})$ *is uniformly local,*

(ii) $\breve{\Psi}_j$ *has the uniform cancellation property of order* $\tilde{d}$ *(with respect to* $\langle\cdot,\cdot\rangle_{L_2(\Gamma)}$*),*

(iii) *for some* $\omega\in(0,1)$, $\|\Psi_j-\breve{\Psi}_j\|_{L_2(\Gamma)}\lesssim\omega^j$,

then, possibly for a larger value of j_0*, for* $s\in(-\min\{\tilde{\gamma},\tilde{d}\},\min\{\gamma,d\})$,

$$\Phi_{j_0}\cup\cup_{j\geq j_0}2^{-sj}\breve{\Psi}_j \text{ is a Riesz basis for } \mathcal{H}_s(\Gamma),$$

and thus, in view of (2.4)*, when in addition* $|s|<\frac{3}{2}$, $|s|<s_\Gamma\notin\mathbb{N}$*, or* $|s|\leq s_\Gamma\in\mathbb{N}$*, it is a Riesz basis for* $\mathcal{H}^s(\Gamma)$*.*

The rather lengthy proof of this theorem is postponed to the appendix. The new aspect of this theorem is that instead of assuming (iii) with $\omega\leq 2^{-\min\{\tilde{\gamma},\tilde{d}\}}$, which would yield the statement by "brute force" arguments, it is allowed that ω is arbitrarily close to 1 when, in addition, (ii) is valid, which property we like to have anyway. So although in two of our three constructions of approximate wavelets in the next section, ω will be equal to $\frac{1}{2}$, we nevertheless thus end up with Riesz bases for $\mathcal{H}_s(\Gamma)$ for the full range of s allowed by $\tilde{\gamma}$, $\tilde{d}$, γ, and d. It is easily seen that (ii) alone is not sufficient to guarantee that the approximate wavelets generate a Riesz basis for any $\mathcal{H}_s(\Gamma)$.

The proof of Theorem 6.1 is based on perturbation arguments making use of the fact that we know that the true $L_2(\Gamma)$-biorthogonal wavelets generate Riesz bases for the full range of Sobolev spaces. We derived this fact in section 5 by generalizing upon the well-known concept of stable completions developed in [2]. Note that in our setting we did not assume to have explicitly available $L_2(\Gamma)$-biorthogonal collections of scaling functions. Theorem 6.1 and the applications in the following sections show the value of this generalization.

Remark 6.2. The approximate wavelets $\breve{\Psi}_j$ we are going to construct will be of type $\breve{\Psi}_j=\Xi_j-\mathbf{Z}_j\Theta_j$, where $\mathbf{Z}_j$ is a uniformly local $\#J_j\times\#I_j$ matrix. Since the basis transformation $\langle\Upsilon_{j+1},\Lambda_{j+1}\rangle_{L_2(\Gamma)}^T$ from $\Upsilon_{j+1}=\begin{bmatrix}\Theta_j^T & \Xi_j^T\end{bmatrix}^T$ to Φ_{j+1} is uniformly local, so is the basis transformation from $\begin{bmatrix}\Theta_j^T & \breve{\Psi}_j^T\end{bmatrix}^T$ to Φ_{j+1}, and the transformation from the multiscale basis $\Phi_{j_0}\cup\cup_{k=j_0}^{j-1}\breve{\Psi}_k$ to the single-scale basis Φ_j has linear complexity.

In the special case that $\Theta_j=\Phi_j$ and $\langle\Upsilon_{j+1},\Lambda_{j+1}\rangle_{L_2(\Gamma)}^{-T}$ is uniformly local, which by Proposition 4.3 holds assuming (3.1), the basis transformation from Φ_{j+1} to $\begin{bmatrix}\Phi_j^T & \breve{\Psi}_j^T\end{bmatrix}^T$ will also be uniformly local, and so the inverse transformation from single-scale basis Φ_j to multiscale basis $\Phi_{j_0}\cup\cup_{k=j_0}^{j-1}\breve{\Psi}_k$ also has linear complexity. However, since $\mathcal{S}(\breve{\Psi}_j)$ is only approximately $L_2(\Gamma)$-orthogonal to $\mathcal{S}(\Phi_j)$, the corresponding dual wavelets will not be explicitly given.

7. Construction of uniformly local approximate wavelet bases.

7.1. Approximating $\langle\Theta_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)}^{-1}$ using Jacobi iteration. As we will see, for $j\to\infty$, the matrix $\langle\Theta_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is increasingly close to its diagonal, and so it makes sense to approximate its inverse by a few Jacobi iteration steps ($\tilde{d}$ steps will be sufficient). We will denote the resulting collection of approximate wavelets as Ψ_j^{Jc}, where "Jc" refers to Jacobi iteration.

THEOREM 7.1. *With* $\mathbf{D}_j:=\mathrm{diag}\langle\Theta_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)}$*, and for* $j\geq j_0$ *large enough,*

$$\Psi_j^{\mathrm{Jc}}:=\Xi_j-\langle\Xi_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)}\left[\sum_{k=0}^{\tilde{d}-1}(Id-\mathbf{D}_j^{-1}\langle\Theta_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)})^k\mathbf{D}_j^{-1}\right]\Theta_j$$

is uniformly local, and it has the uniform cancellation property of order $\tilde{d}$; and finally, for $s \in (-\min\{\tilde{\gamma}, \tilde{d}\}, \min\{\gamma, d\})$,

$$\Phi_{j_0} \cup \cup_{j \geq j_0} 2^{-sj} \Psi_j^{\mathrm{Jc}} \text{ is a Riesz basis for } \mathcal{H}_s(\Gamma).$$

In view of (2.4)*, when in addition $|s| < \frac{3}{2}$, $|s| < s_\Gamma \notin \mathbb{N}$, or $|s| \leq s_\Gamma \in \mathbb{N}$, the collection is thus a Riesz basis for $\mathcal{H}^s(\Gamma)$.*

Proof. With $\Delta_{j,q}^{\square}$ as defined in (5.1), and by using (J2), similarly to (5.2) we have $\|\langle \Theta_j^{\square}, \tilde{\Phi}_j^{\square} \rangle_{L_2(\square), |\partial \kappa_q|} - \Delta_{j,q}^{\square}\| \lesssim 2^{-j}$. Since

$$\bar{\mathbf{D}}_j := \sum_{q=1}^{M} \mathbf{E}_{j,q} \Delta_{j,q}^{\square} \mathbf{E}_{j,q}^T$$

is diagonal, by (6.1) we have

$$\begin{aligned} \|\mathbf{D}_j - \bar{\mathbf{D}}_j\| &\leq \max_{x,y \in I_j} |(\mathbf{D}_j - \bar{\mathbf{D}}_j)_{x,y}| \leq \max_{x,y \in I_j} |(\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)} - \bar{\mathbf{D}}_j)_{x,y}| \\ &\leq \|\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)} - \bar{\mathbf{D}}_j\| \lesssim 2^{-j}, \end{aligned}$$

and so $\|\mathbf{D}_j - \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}\| \leq \|\mathbf{D}_j - \bar{\mathbf{D}}_j\| + \|\bar{\mathbf{D}}_j - \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}\| \lesssim 2^{-j}$.

As we have seen in the proof of Proposition 5.4, for $j \geq j_0$ large enough, the matrix $\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}$ is uniformly boundedly invertible, and thus, possibly for a larger j_0, so is $\mathbf{D}_j$. We infer that

$$\begin{aligned} (7.1) \qquad &\left\| \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1} - \sum_{k=0}^{\tilde{d}-1} (Id - \mathbf{D}_j^{-1} \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)})^k \mathbf{D}_j^{-1} \right\| \\ &\qquad = \|\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1} ((\mathbf{D}_j - \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}) \mathbf{D}_j^{-1})^{\tilde{d}}\| \lesssim 2^{-\tilde{d}j}, \end{aligned}$$

and thus by $\|\langle \Xi_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}\| \lesssim 1$ that

$$(7.2) \qquad \|\Psi_j - \Psi_j^{\mathrm{Jc}}\|_{L_2(\Gamma)} \lesssim 2^{-\tilde{d}j} \|\Theta_j\|_{L_2(\Gamma)} \lesssim 2^{-\tilde{d}j}.$$

Since furthermore Ψ_j^{Jc} is uniformly local, in view of Theorem 6.1 the only thing left to show is that Ψ_j^{Jc} has the uniform cancellation property of order $\tilde{d}$.

Although Ψ_j has the uniform cancellation property of order $\tilde{d}$, we cannot immediately conclude this from (7.2) for Ψ_j^{Jc}. Indeed, since the wavelets from Ψ_j generally have global supports, invoking (7.2) and the cancellation property of $\psi_{j,x}$ would yield a bound for $|\langle \psi_{j,x}^{\mathrm{Jc}}, u \rangle_{L_2(\Gamma)}|$ in terms of the global H^d-norms of $u \circ \kappa_q$, whereas the definition of the cancellation property requires a bound in terms of the H^d-norms of $u \circ \kappa_q$ in a neighborhood of $\mathrm{supp}(\psi_{j,x}^{\mathrm{Jc}} \circ \kappa_q)$ with diameter of order 2^{-j}. To arrive at this result, we split u into $(Id - \tilde{P}_j)u$ and $\tilde{P}_j u$, and then replace $\tilde{P}_j u$ by a function, equal to $\tilde{P}_j u$ on $\mathrm{supp}\, \psi_{j,x}^{\mathrm{Jc}}$ and still in $\mathcal{S}(\tilde{\Phi}_j)$, that has a support with diameter of order 2^{-j}. The details can be found in [22]. ∎

Remark 7.2. The construction of the approximate wavelets Ψ_j^{Jc} in Theorem 7.1 has some similarities to the construction of approximate "prewavelets" in [23]. There the inverse of a mass matrix with respect to a standard finite element basis is approximated by a number of steps of an iterative method, as the Jacobi or symmetric Gauss–Seidel method. A difference is that in our case the matrix $\mathbf{D}_j$ *converges to*

$\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ as $j\to\infty$, allowing us to derive much stronger results concerning the generation of Riesz bases by the resulting approximate wavelets.

Compared to the approximate wavelets one gets by simply replacing $\langle\cdot,\cdot\rangle_{L_2(\Gamma)}$ by $\langle\!\langle\cdot,\cdot\rangle\!\rangle_0$ in (5.5), for $\tilde{d}\geq 2$ the approximate wavelets $\psi^{\mathrm{Jc}}_{j,x}$ have relatively large supports. Although this has not so much an effect on the multiscale to single-scale transform that can be implemented much more efficiently than is suggested by the sizes of the supports, it is a disadvantage, for example, when it concerns the compression of the stiffness matrix of an integral operator with respect to these approximate wavelets. In the following two subsections, we construct approximate wavelets with smaller supports.

As a preparation, the next proposition facilitates the verification of the third condition from Theorem 6.1, in case different constructions of approximate wavelets are used on different parts of Γ. In the proof, the problem of the generally global supports of the true biorthogonal wavelets is circumvented by approximating them by sufficiently accurate, uniformly local approximate wavelets generated by the Jacobi iteration approach.

PROPOSITION 7.3. *Let $\omega\in(0,1)$ and let $\breve{\Psi}_j=(\breve{\psi}_{j,x})_{x\in J_j}$ be uniformly local. Then $\|\Psi_j-\breve{\Psi}_j\|_{L_2(\Gamma)}\lesssim\omega^j$ if and only if $\sup_{x\in J_j}\|\psi_{j,x}-\breve{\psi}_{j,x}\|_{L_2(\Gamma)}\lesssim\omega^j$.*

Proof. Let $\sup_{x\in J_j}\|\psi_{j,x}-\breve{\psi}_{j,x}\|_{L_2(\Gamma)}\lesssim\omega^j$. Selecting $m\in\mathbb{N}$ such that $2^{-m}\leq\omega$, from the proof of Theorem 7.1 we learn that there exists a uniformly local Ψ^{Jc}_j with $\|\Psi_j-\Psi^{\mathrm{Jc}}_j\|_{L_2(\Gamma)}\lesssim 2^{-mj}\leq\omega^j$, and so $\sup_{x\in J_j}\|\psi_{j,x}-\psi^{\mathrm{Jc}}_{j,x}\|_{L_2(\Gamma)}\lesssim\omega^j$ and thus $\sup_{x\in J_j}\|\psi^{\mathrm{Jc}}_{j,x}-\breve{\psi}_{j,x}\|_{L_2(\Gamma)}\lesssim\omega^j$. Since both Ψ^{Jc}_j and $\breve{\Psi}_j$ are uniformly local, this implies $\|\Psi^{\mathrm{Jc}}_j-\breve{\Psi}_j\|_{L_2(\Gamma)}\lesssim\omega^j$ and thus that $\|\Psi_j-\breve{\Psi}_j\|_{L_2(\Gamma)}\leq\|\Psi_j-\Psi^{\mathrm{Jc}}_j\|_{L_2(\Gamma)}+\|\Psi^{\mathrm{Jc}}_j-\breve{\Psi}_j\|_{L_2(\Gamma)}\lesssim\omega^j$. The proof of the other implication is trivial. ∎

7.2. Ignoring the Jacobian determinants away from the interfaces. In this subsection, we show that *away from the patch interfaces*, we may replace the wavelets from Ψ^{Jc}_j by the corresponding ones from

$$\Psi^{(0)}_j:=\Xi_j-\langle\!\langle\Xi_j,\tilde{\Phi}_j\rangle\!\rangle_0\Theta_j.$$

This is the collection of biorthogonal wavelets one obtains when biorthogonality is realized with respect to $\langle\!\langle\,,\,\rangle\!\rangle_0$ instead of $\langle\,,\,\rangle_{L_2(\Gamma)}$, i.e., when, in the wavelet formula (5.5), all Jacobian determinants are replaced by the constant 1.

Recalling that for $x\in\overline{\Gamma}$, $k(x)=\#\{q: x\in\overline{\Gamma_q}\}$, we set $I^\circ_j=\{x\in I_j: k(x)=1\}$ and

$$J^\circ_j=\{x\in J_j: k(x)=1 \text{ and } \langle\xi_{j,x},\tilde{\phi}_{j,y}\rangle_{L_2(\Gamma)}=0 \text{ for all } y\in I_j\backslash I^\circ_j\};$$

this set is designed such that for $x\in J^\circ_j$, $\psi^{(0)}_{j,x}$ is fully supported inside one patch $\overline{\Gamma_q}$.

THEOREM 7.4. *The set $\breve{\Psi}_j=\{\breve{\psi}_{j,x}: x\in J_j\}$, defined by $\breve{\psi}_{j,x}=\psi^{(0)}_{j,x}$ when $x\in J^\circ_j$, and $\breve{\psi}_{j,x}=\psi^{\mathrm{Jc}}_{j,x}$ when $x\in J_j\backslash J^\circ_j$, is uniformly local and it has the uniform cancellation property of order $\tilde{d}$, and for any $s\in(-\min\{\tilde{\gamma},\tilde{d}\},\min\{\gamma,d\})$ and j_0 large enough,*

$$\Phi_{j_0}\cup\cup_{j\geq j_0}2^{-sj}\breve{\Psi}_j \text{ is a Riesz basis for } \mathcal{H}_s(\Gamma).$$

In view of (2.4), when in addition $|s|<\frac{3}{2}$, $|s|<s_\Gamma\notin\mathbb{N}$, or $|s|\leq s_\Gamma\in\mathbb{N}$, this collection is thus a Riesz basis for $\mathcal{H}^s(\Gamma)$.

Proof. Using that, for $j \geq j_0$ large enough, $\|\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}^{-1} - \mathbf{D}_j^{-1}\| \lesssim 2^{-j}$, which follows as a special case from (7.2), and that the mappings $z \mapsto |\partial\kappa_q(z)|$ are smooth, one easily verifies that for $x \in J_j^\circ$,

$$\|\psi_{j,x} - \psi_{j,x}^{(0)}\| \lesssim 2^{-j}.$$

Since for $x \in J_j \backslash J_j^\circ$, $\|\psi_{j,x} - \psi_{j,x}^{\mathrm{Jc}}\| \lesssim 2^{-\tilde{d}j}$, and $\breve{\Psi}_j$ is uniformly local, in view of Theorem 6.1 and Proposition 7.3 the only thing left to show is that $\breve{\Psi}_j$ has the uniform cancellation property of order $\tilde{d}$. Knowing this for Ψ_j^{Jc}, we have only to consider $\psi_{j,x}^{(0)}$ for $x \in J_j^\circ$.

Let $x \in J_j^\circ$, say, $x \in \Gamma_q$, and let u be a globally continuous, patchwise smooth function on Γ that is zero on $\partial\Gamma_D$. Let v be some arbitrary extension of the mapping $x \mapsto u(x)|\partial\kappa_q(\kappa_q^{-1}(x))|$ on Γ_q to a globally continuous, patchwise smooth function on Γ that is zero on $\partial\Gamma_D$. Since $\operatorname{supp}\psi_{j,x}^{(0)} \subset \overline{\Gamma_q}$, from Proposition 4.1 at the dual side we have

$$\begin{aligned}
|\langle \psi_{j,x}^{(0)}, u\rangle_{L_2(\Gamma)}| &= |\langle\!\langle \psi_{j,x}^{(0)}, v\rangle\!\rangle_0| = |\langle\!\langle \psi_{j,x}^{(0)}, ((Id - \tilde{P}_j)v)|_{\operatorname{supp}\psi_{j,x}^{(0)}}\rangle\!\rangle_0| \\
&\lesssim 2^{-\tilde{d}j}|v \circ \kappa_q|_{H^{\tilde{d}}(B(\kappa_q^{-1}(\operatorname{supp}\psi_{j,x}^{(0)});(\tilde{\vartheta}+3\tilde{\varepsilon})2^{-j})\cap\square)} \\
&\lesssim 2^{-\tilde{d}j}\|u \circ \kappa_q\|_{H^{\tilde{d}}(B(\kappa_q^{-1}(\operatorname{supp}\psi_{j,x}^{(0)});(\tilde{\vartheta}+3\tilde{\varepsilon})2^{-j})\cap\square)},
\end{aligned}$$

which completes the proof. ∎

Note that for $x \in J_j^\circ$, generally it holds only that $\|\psi_{j,x} - \psi_{j,x}^{(0)}\|_{L_2(\Gamma)} \eqsim 2^{-j}$. So in contrast to Ψ_j^{Jc}, for the approximate wavelets $\breve{\Psi}_j$ from this subsection, generally $\|\Psi_j - \breve{\Psi}_j\|_{L_2(\Gamma)} \not\lesssim 2^{-\tilde{d}j}$ when $\tilde{d} > 1$. The same will hold true for the collections $\breve{\Psi}_j$ that will be constructed in the next subsection. As follows from Theorem 6.1, however, this fact does not limit the range of s for which the approximate wavelets generate a Riesz basis for $\mathcal{H}^s(\Gamma)$.

7.3. Approximate wavelets with small supports near the interfaces. As we saw in the previous subsection, for $x \in J_j^\circ$ we can replace $\psi_{j,x}^{\mathrm{Jc}}$ by $\psi_{j,x}^{(0)}$, which, for $\tilde{d} \geq 2$, has a much smaller support. In this subsection, we investigate whether also near the interfaces we can find appropriate approximate wavelets $\breve{\psi}_{j,x}$ with smaller supports.

We set

$$\mathbb{P}_{\tilde{d}-2}(\Gamma) := C(\Gamma) \cap \prod_{q=1}^{M} \kappa_q(\mathbb{P}_{\tilde{d}-2}(\square)),$$

where when $\square$ is the interior of an n-simplex, $\mathbb{P}_{\tilde{d}-2}(\square) := P_{\tilde{d}-2}(\square)$, and when $\square = (0,1)^n$, $\mathbb{P}_{\tilde{d}-2}(\square) := Q_{\tilde{d}-2}(\square)$, being the tensor product space of the univariate polynomial spaces $P_{\tilde{d}-2}(0,1)$ in the n coordinate directions. In the latter case, in addition to the assumption that $P_{\tilde{d}-1}(\square) \subset \mathcal{S}(\tilde{\Phi}_j^\square)$ ((𝒥)(ii) at the dual side), in this subsection we assume that

(𝒥̃e) $$Q_{\tilde{d}-2}(\square) \subset \mathcal{S}(\tilde{\Phi}_j^\square).$$

For $z \in \Gamma$ and $\varepsilon \geq 0$, let $B_\Gamma(z;\varepsilon) = \{y \in \overline{\Gamma} : d_\Gamma(z,y) \leq \varepsilon\}$. With, for some constant $\rho \geq 0$, setting

$$\tilde{V}_{j,x,\rho} = \Big\{v \in \mathbb{P}_{\tilde{d}-2}(\Gamma) : v|_{\partial\Gamma_D \cap B_\Gamma(x;\rho 2^{-j})} = 0\Big\},$$

for $x \in J_j \backslash J_j^\circ$ we will search

$$\breve{\psi}_{j,x} \perp_{L_2(\Gamma)} \tilde{V}_{j,x,\rho} \text{ with } \|\breve{\psi}_{j,x} - \hat{\psi}_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}. \tag{7.3}$$

We note that by taking $\tilde{V}_{j,x,\rho}$ to be the smaller set $\{v \in \mathbb{P}_{\tilde{d}-2}(\Gamma) : v|_{\partial\Gamma_D} = 0\}$, $\breve{\psi}_{j,x}$ would not necessarily have the cancellation property of order $\tilde{d}$, and on the other hand, as we will see later, without incorporating boundary conditions in the definition of $\tilde{V}_{j,x,\rho}$, generally we cannot expect that $\|\breve{\psi}_{j,x} - \psi_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$. For the moment assuming that such $\breve{\psi}_{j,x}$ can be found, a topic that will be treated later in this subsection, Theorem 7.5 shows that they have the uniform cancellation property of order $\tilde{d}$, which, by Theorem 6.1, additionally yields the Riesz basis property for the full range of s. This may look surprising since, ignoring boundary conditions, the condition $\breve{\psi}_{j,x} \perp_{L_2(\Gamma)} \tilde{V}_{j,x,\rho}$ seems only to imply the uniform cancellation property of order $\tilde{d}-1$. Yet, given a $u \in \mathcal{H}_{\tilde{d}}(\Gamma)$, an interpolant $v \in \tilde{V}_{j,x,\rho}$ can be constructed such that $\|u-v\|_{L_2(\operatorname{supp}\breve{\psi}_{j,x})} \lesssim 2^{-(\tilde{d}-1)j}$ and, using $(\tilde{\partial}\mathrm{e})$, such that $(Id - \tilde{P}_j)v$ vanishes on $\operatorname{supp}\breve{\psi}_{j,x}$. Now by writing

$$\begin{aligned}\langle\breve{\psi}_{j,x}, u\rangle_{L_2(\Gamma)} &= \langle\breve{\psi}_{j,x}, u-v\rangle_{L_2(\Gamma)} = \langle\breve{\psi}_{j,x}, (Id-\tilde{P}_j)u\rangle_{L_2(\Gamma)} + \langle\breve{\psi}_{j,x}, \tilde{P}_j(u-v)\rangle_{L_2(\Gamma)}\\ &= \langle\breve{\psi}_{j,x}, (Id-\tilde{P}_j)u\rangle_{L_2(\Gamma)} + \langle\breve{\psi}_{j,x}-\psi_{j,x}, \tilde{P}_j(u-v)\rangle_{L_2(\Gamma)},\end{aligned}$$

and, for the second term, using the additional factor 2^{-j} from $\|\breve{\psi}_{j,x}-\psi_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$, the cancellation property of order $\tilde{d}$ can be shown. For a detailed proof of Theorem 7.5, we refer the reader to [22].

THEOREM 7.5. *Let $\breve{\Psi}_j = \{\breve{\psi}_{j,x} : x \in J_j\} \subset \mathcal{S}(\Phi_{j+1})$ be a uniformly local set, with $\breve{\psi}_{j,x} = \psi^{(0)}_{j,x}$ when $x \in J_j^\circ$, and such that for $x \in J_j\backslash J_j^\circ$, (7.3) is valid. Then, for $j \geq j_0$ large enough, $\breve{\Psi}_j$ has the uniform cancellation property of order $\tilde{d}$, and for $s \in (-\min\{\tilde{\gamma},\tilde{d}\}, \min\{\gamma,d\})$,*

$$\Phi_{j_0} \cup \cup_{j\geq j_0} 2^{-sj}\breve{\Psi}_j \text{ *is a Riesz basis for* } \mathcal{H}_s(\Gamma).$$

In view of (2.4)*, when in addition $|s| < \frac{3}{2}$, $|s| < s_\Gamma \notin \mathbb{N}$, or $|s| \leq s_\Gamma \in \mathbb{N}$, this collection is thus a Riesz basis for $\mathcal{H}^s(\Gamma)$.*

Next, we discuss a *construction* of $\breve{\Psi}_j$ as in Theorem 7.5. Consider, for $x \in J_j\backslash J_j^\circ$, the first order approximation $\hat{\psi}_{j,x}$ for $\psi_{j,x}$ from the collection

$$\hat{\Psi}_j := \Xi_j - \langle\Xi_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}\mathbf{D}_j^{-1}\Theta_j. \tag{7.4}$$

As a special case of (7.2), we have $\|\psi_{j,x} - \hat{\psi}_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$, where generally $\hat{\psi}_{j,x}$ only has the cancellation property of order 1. We will construct $\breve{\psi}_{j,x}$ from $\hat{\psi}_{j,x}$ by adding correction terms. In view of our requirement that $\|\psi_{j,x} - \breve{\psi}_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$, we first show that $\hat{\psi}_{j,x}$ is already nearly orthogonal to $\tilde{V}_{j,x,\rho}$, so that the correction can be small. For this to be true, the incorporation of boundary conditions in the definition of $\tilde{V}_{j,x,\rho}$ is essential.

We set $\bar{I}_j = \cup_{q=1}^{M} \kappa_q(I_j^{\square})$, i.e., without the exclusion of possible points on $\partial\Gamma_D$, and define $\tilde{\phi}_{j,y}$ and $\tilde{\lambda}_{j,y}$ similarly as in (4.1) and Proposition 4.1, respectively, but now also for $y \in \bar{I}_j \backslash I_j$.

LEMMA 7.6. *Let the constant ρ in the definition of $\tilde{V}_{j,x,\rho}$ be sufficiently large such that for all $x \in J_j$ and $y \in \bar{I}_j$ with $\operatorname{supp}\tilde{\phi}_{j,y} \cap \operatorname{supp}\hat{\psi}_{j,x} \neq \emptyset$, $\operatorname{supp}\tilde{\lambda}_{j,y} \subset B_\Gamma(x; \rho 2^{-j})$. Then*

$$|\langle \hat{\psi}_{j,x}, p\rangle_{L_2(\Gamma)}| \lesssim 2^{-j} \|p\|_{L_2(\operatorname{supp}\hat{\psi}_{j,x})} \quad (p \in \tilde{V}_{j,x,\rho}).$$

Proof. Since $p \in \mathbb{P}_{\tilde{d}-2}(\Gamma)$, by the inclusion of possible points on $\partial\Gamma_D$ and $(\tilde{\mathcal{J}}\mathrm{e})$, we have $p = \sum_{y\in\bar{I}_j} \langle p, \tilde{\lambda}_{j,y}\rangle_{L_2(\Gamma)} \tilde{\phi}_{j,y}$. Terms in this sum for $y \in \bar{I}_j \backslash I_j$ vanish on $\operatorname{supp}\hat{\psi}_{j,x}$ by $(\mathcal{J})$(ii) and because p vanishes on $\partial\Gamma_D \cap B_\Gamma(x; \rho 2^{-j})$. Setting $p_{j,x} = \sum_{\{y\in I_j : \operatorname{supp}\tilde{\phi}_{j,y} \cap \operatorname{supp}\hat{\psi}_{j,x} \neq \emptyset\}} \langle p, \tilde{\lambda}_{j,y}\rangle_{L_2(\Gamma)} \tilde{\phi}_{j,y}$, which is a function in $\mathcal{S}(\tilde{\Phi}_j)$, we find that

$$\begin{aligned} |\langle \hat{\psi}_{j,x}, p\rangle_{L_2(\Gamma)}| = |\langle \hat{\psi}_{j,x}, p_{j,x}\rangle_{L_2(\Gamma)}| &= |\langle \hat{\psi}_{j,x} - \psi_{j,x}, p_{j,x}\rangle_{L_2(\Gamma)}| \\ &\lesssim 2^{-j} \|p_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j} \|p\|_{L_2(\operatorname{supp}\hat{\psi}_{j,x})}, \end{aligned}$$

where in the last step we used $(\mathcal{J})$(iv). ∎

Let us first consider the *special case* $\tilde{d} = 2$ making the natural assumption that $|\int \xi_{j,x} d\mu| \gtrsim 2^{-jn/2}$. Let ρ be as in Lemma 7.6. If $x \in J_j \backslash J_j^\circ$ is such that $\partial\Gamma_D \cap B_\Gamma(x; \rho 2^{-j}) \neq \emptyset$, then $\tilde{V}_{j,x,\rho} = \{0\}$, and we can take $\breve{\psi}_{j,x} = \hat{\psi}_{j,x}$. Otherwise, we take $\breve{\psi}_{j,x} := \hat{\psi}_{j,x} - [\int_\Gamma \hat{\psi}_{j,x} d\mu / \int_\Gamma \xi_{j,x} d\mu]\xi_{j,x}$. Obviously $\breve{\psi}_{j,x} \perp_{L_2(\Gamma)} 1$, i.e., $\breve{\psi}_{j,x} \perp \tilde{V}_{j,x,\rho}$, and Lemma 7.6 shows that $|\int_\Gamma \hat{\psi}_{j,x} d\mu| \lesssim 2^{-j(1+n/2)}$, so that indeed $\|\hat{\psi}_{j,x} - \breve{\psi}_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$. In view of our aim to replace $\psi_{j,x}^{\mathrm{Jc}}$ for $x \in J_j \backslash J_j^\circ$ by an approximate wavelet with smaller support, note that the support of $\breve{\psi}_{j,x}$ is *equal* to that of $\hat{\psi}_{j,x}$ (which is equal to that of $\psi_{j,x}^{(0)}$).

For $\tilde{d} > 2$, generally we have to add more than one degree of freedom to find a correction of $\hat{\psi}_{j,x}$ that is orthogonal to $\tilde{V}_{j,x,\rho}$. We will search the correction from the span of $\theta_{j,y}$ with $d_\Gamma(x,y) \lesssim 2^{-j}$. Instead of adding as many degrees of freedom as $\dim(\tilde{V}_{j,x,\rho})$, generally we add more degrees of freedom, but then solve the resulting underdetermined problem in a minimal norm sense to end up with a correction term that is as small as possible. The resulting approximate wavelets will be denoted as $\psi_{j,x}^{\mathrm{ls}}$, where "ls" refers to least squares. In Theorem 7.7 it is stated that if, for sufficiently large δ, we use all $\theta_{j,y}$ for $y \in I_j$ with $d_\Gamma(x,y) \leq \delta 2^{-j}$, then the constrained minimization problem has a unique solution $\psi_{j,x}^{\mathrm{ls}}$, with $\|\psi_{j,x}^{\mathrm{ls}} - \psi_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$. Note that although in our numerical example we end up with $\psi_{j,x}^{\mathrm{ls}}$, which has the *same* support as $\hat{\psi}_{j,x}$, which thus in particular is much smaller than the support of $\psi_{j,x}^{\mathrm{Jc}}$, we cannot prove this in general.

THEOREM 7.7. *Let ρ be as in Lemma 7.6. For a sufficiently large constant $\delta > 0$, and with $\Theta_{j,x}^{\delta} := \{\theta_{j,y} : y \in I_j \cap B_\Gamma(x; \delta 2^{-j})\}$, for any $x \in J_j \backslash J_j^\circ$ the problem of determining*

$$\operatorname*{argmin}_{\psi_{j,x}^{\mathrm{ls}} \in \hat{\psi}_{j,x} + \mathcal{S}(\Theta_{j,x}^{\delta})} \{\|\psi_{j,x}^{\mathrm{ls}} - \hat{\psi}_{j,x}\|_{L_2(\Gamma)} : \psi_{j,x}^{\mathrm{ls}} \perp_{L_2(\Gamma)} \tilde{V}_{j,x,\rho}\}$$

has a unique solution with $\|\psi_{j,x}^{\mathrm{ls}} - \psi_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$, so that Theorem 7.5 applies.

For a proof of this theorem we refer the reader to [22]. From the theory of saddle point problems we know that the constrained minimization problem has a solution if and only if for each $p \in \tilde{V}_{j,x,\rho}$ there exists a $v_j \in \mathcal{S}(\Theta^{\delta}_{j,x})$ with $\langle p, v_j\rangle_{L_2(\Gamma)} > 0$. It can be observed that on a sufficiently large neighborhood of $\operatorname{supp}\hat{\psi}_{j,x}$ with diameter $\eqsim 2^{-j}$, any $p \in \mathbb{P}_{\tilde{d}-2}$ can be well approximated by a linear combination of those $\tilde{\phi}_{j,y}$ ($y \in I_j$) that are fully supported in this neighborhood. Since $\langle \Theta_j, \tilde{\Phi}_j\rangle_{L_2(\Gamma)}$ is nearly diagonal, for any function w_j in the span of these $\tilde{\phi}_{j,y}$, a v_j can be found in the span of the $\theta_{j,y}$, for the same set of y, with $\langle w_j, v_j\rangle_{L_2(\Gamma)} > 0$. By combining both properties, the existence and uniqueness of the constrained minimization problem can be inferred. The estimate $\|\psi^{\mathrm{ls}}_{j,x} - \psi_{j,x}\|_{L_2(\Gamma)} \lesssim 2^{-j}$ can be derived from the fact that $\hat{\psi}_{j,x}$ is already nearly orthogonal to $\tilde{V}_{j,x,\rho}$, as was shown in Lemma 7.6.

Remark 7.8. In case $\Theta_j \neq \Phi_j$, it is not of any interest that $\breve{\Psi}_j - \Xi_j \in \mathcal{S}(\Theta_j)$ (cf. Remark 6.2). In that case, in Theorem 7.7 we may search $\psi^{\mathrm{ls}}_{j,x}$ in the larger space $\hat{\psi}_{j,x} + \mathcal{S}(\Phi^{\delta}_{j+1,x})$, with $\Phi^{\delta}_{j+1,x} := \{\phi_{j+1,y} : x \in I_{j+1} \cap B_{\Gamma}(x; \delta 2^{-j})\}$, which opens the possibility that we may take a smaller δ, and so reduce the support of the resulting $\psi^{\mathrm{ls}}_{j,x}$.

Remark 7.9. Both the construction of $\psi^{\mathrm{Jc}}_{j,x}$ from Theorem 7.1, and that of $\psi^{\mathrm{ls}}_{j,x}$ from Theorem 7.7 requires the evaluation of $L_2(\Gamma)$-scalar products. For general parametrizations κ_q, these scalar products cannot be evaluated exactly, and therefore have to be approximated using numerical quadrature. Theorem 6.1 shows that if the quadrature is organized such that it causes an $L_2(\Gamma)$-error $\lesssim 2^{-\tilde{d}j}$ in the resulting approximate wavelet, then all results concerning cancellation properties and the generation of Riesz bases remain valid.

8. Numerical example. We consider a 2-dimensional Lipschitz manifold $\Gamma = \cup_{i=1}^{4}\overline{\Gamma_q} \subset \mathbb{R}^3$ as illustrated in Figure 8.1, which, together with its parametrization that satisfies ($\mathcal{M}$) is defined as follows. Let P be a tetrahedron in $\mathbb{R}^3$, with vertices on the unit sphere, geometric centroid in $(0,0,0)$, and one of its four facets $F_1, \ldots, F_4$, say, F_4, parallel to and below the $x_3 = 0$ plane. Let $\square$ be the interior of a reference 2-simplex in $\mathbb{R}^2$, with $\mathrm{vol}(\square) = 1$, and for $1 \leq q \leq 4$, let $B_q : \square \to F_q$ some affine bijection. The parametrizations $\kappa_q : \square \to \Gamma_q$ are defined by $\kappa_q(z) = B_q(z)/\|B_q(z)\|$ for $1 \leq q \leq 3$, and by $\kappa_4(z) = B_q(z)/\|B_q(z)\| - \frac{27}{4}(0,0,\lambda_1(z)\lambda_2(z)\lambda_3(z))$, where $(\lambda_1(z), \lambda_2(z), \lambda_3(z))$ are the barycentric coordinates of z with respect to $\square$. So without the perturbation by this cubic bubble, Γ would be the unit sphere. We added this perturbation term so that $J : x \mapsto |\partial\kappa_q(\kappa_q^{-1}(x))|$ when $x \in \Gamma_q$ cannot be extended to a continuous function

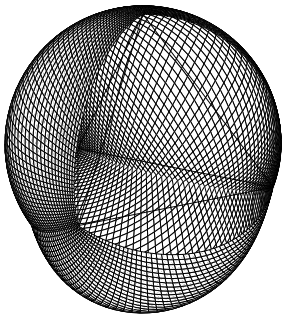

FIG. 8.1. *The manifold Γ, excluding one of the patches F_1, F_2, or F_3, and the tetrahedron P.*

on Γ. This means that constructions based on ignoring the Jacobian determinants will yield wavelets of which those that have supports that intersect an interface between Γ_4 and one of the three other patches have no cancellation properties. Furthermore, in view of our discussion at the beginning of section 6, note that $z \mapsto |\partial\kappa_q(z)|$ are not constant functions.

We consider two examples of collections $\Phi_j^\square$, $\tilde{\Phi}_j^\square$, $\Theta_j^\square$, $\Xi_j^\square$, $\Lambda_j^\square$, $\tilde{\Lambda}_j^\square$, both based on the construction of finite element wavelets from [14]. These collections satisfy all conditions formulated in section 3, where $\square$ is a reference 2-simplex, $\gamma = \tilde{\gamma} = \frac{3}{2}$, $d = 2$, and $\tilde{d} = 2$ or $\tilde{d} = 3$. With S_j being the standard Lagrange finite element space of order 2 with respect to a j times repeated uniform dyadic refinement of $\square$, for $\tilde{d} = 2$, $\mathcal{S}(\Phi_j^\square) = S_j$, and for $\tilde{d} = 3$, $\mathcal{S}(\Phi_j^\square) = S_{j+1}$. The index set $I_j^\square$ is the set of all vertices in the triangulation underlying the finite element space, and $J_j^\square = I_{j+1}^\square \backslash I_j^\square$. For more details, we refer the reader to [22].

We implemented the approximate wavelet constructions from sections 7.2 and 7.3,which away from the patch interfaces both yield the approximate wavelets from the collection $\Psi_j^{(0)} = \Xi_j - \langle\!\langle \Xi_j, \tilde{\Phi}_j \rangle\!\rangle_0 \langle\!\langle \Theta_j, \tilde{\Phi}_j \rangle\!\rangle_0^{-1} \Theta_j$ obtained by ignoring the Jacobian determinants. The pull-backs of these wavelets to the parameter domain are illustrated in Figure 8.2; the functions are continuous piecewise linear with respect to the indicated triangulation.

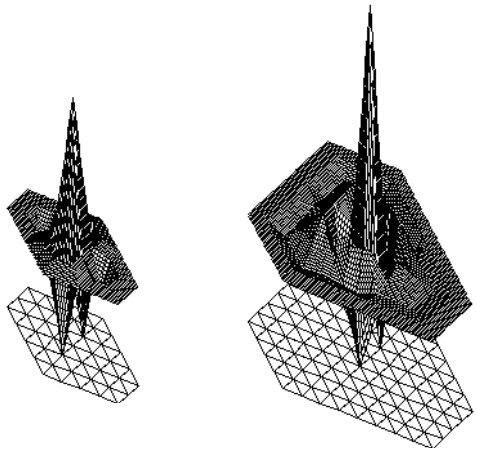

FIG. 8.2. *Wavelets $\psi_{j,x}^{(0)}$ away from the patch interfaces for $\tilde{d} = 2$ and $\tilde{d} = 3$ (one of the two different types), and their supports in terms of the underlying triangulation.*

With the approach from section 7.2, wavelets along the patch interfaces are taken from the collection $\Psi_j^{\mathrm{Jc}} := \Xi_j - \langle \Xi_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)} \big[\sum_{k=0}^{\tilde{d}-1} (Id - \mathbf{D}_j^{-1} \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)})^k \mathbf{D}_j^{-1} \big] \Theta_j$, where $\mathbf{D}_j := \mathrm{diag} \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}$. Illustrations of the naturally joined, patchwise pull-backs of these wavelets can be found in Figure 8.3. For $j = 0$, the Neumann series does not converge, and as a consequence $\sum_{k=0}^{\tilde{d}-1} (Id - \mathbf{D}_j^{-1} \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)})^k \mathbf{D}_j^{-1}$ provides a very poor approximation for $\langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1}$. We redefined $\breve{\Psi}_0 := \Xi_0 - \langle \Xi_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)} \langle \Theta_j, \tilde{\Phi}_j \rangle_{L_2(\Gamma)}^{-1} \Theta_0$.

For the construction from section 7.3, for each $x \in J_j \backslash J_j^\circ$ we have to specify a

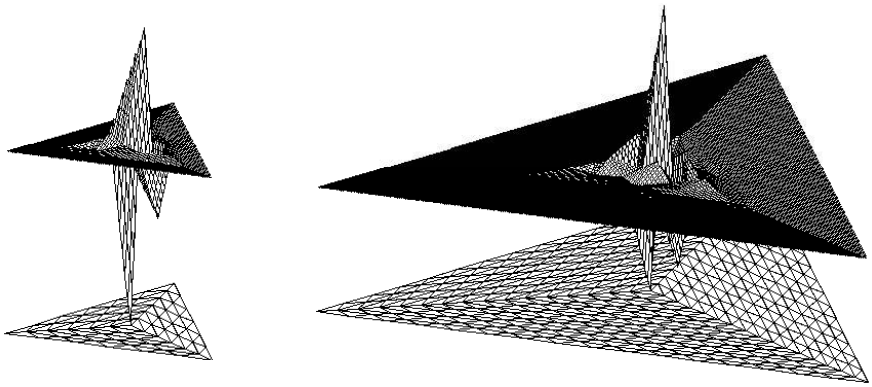

FIG. 8.3. *Wavelets $\psi^{\mathrm{Jc}}_{4,x}$ for $\tilde{d}=2$ and $\psi^{\mathrm{Jc}}_{3,x}$ for $\tilde{d}=3$ near the "north pole," and their supports in terms of the underlying triangulation.*

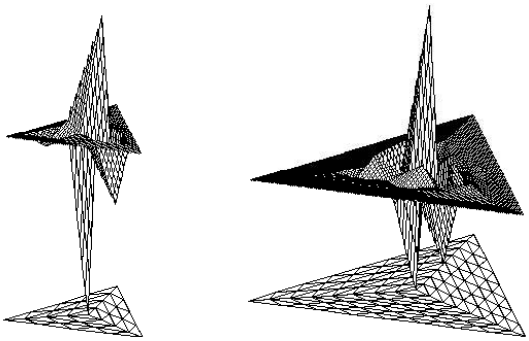

FIG. 8.4. *Wavelets $\psi^{\mathrm{ls}}_{4,x}$ for $\tilde{d}=2$ and $\psi^{\mathrm{ls}}_{3,x}$ for $\tilde{d}=3$ near the "north pole," and their supports in terms of the underlying triangulation.*

subspace $A_{j,x}\subset\mathcal{S}(\Phi_{j+1})$ that defines $\psi^{\mathrm{ls}}_{j,x}$ via

$$\operatorname*{argmin}_{\psi^{\mathrm{ls}}_{j,x}\in\hat{\psi}_{j,x}+A_{j,x}}\{\|\psi^{\mathrm{ls}}_{j,x}-\hat{\psi}_{j,x}\|_{L_2(\Gamma)}:\psi^{\mathrm{ls}}_{j,x}\perp_{L_2(\Gamma)}\mathbb{P}_{\tilde{d}-2}(\Gamma)\}.$$

For $\tilde{d}=2$, we took $A_{j,x}=\mathcal{S}(\{\xi_{j,x}\})$, so that $\psi^{\mathrm{ls}}_{j,x}=\hat{\psi}_{j,x}+\alpha\xi_{j,x}$ with α such that $\int_\Gamma\psi^{\mathrm{ls}}_{j,x}=0$. For $\tilde{d}=3$, we took $A_{j,x}=\mathcal{S}(\{\phi_{j+1,y}:\operatorname{supp}\phi_{j+1,y}\subset\operatorname{supp}\hat{\psi}_{j,x}\})$, where the space turns out to be sufficiently large so that the constrained minimization problem has a solution $\psi^{\mathrm{ls}}_{j,x}$, with $\|\psi^{\mathrm{ls}}_{j,x}-\hat{\psi}_{j,x}\|_{L_2(\Gamma)}\lesssim 2^{-j}$. The naturally joined, patchwise pull-backs of the resulting $\psi^{\mathrm{ls}}_{j,x}$ are illustrated in Figure 8.4. By definition they have the *same supports* as the corresponding $\psi^{(0)}_{j,x}$ that one obtains by ignoring the Jacobian determinants also along the interfaces. As with the Jacobi iteration approach, for $j=0$, we redefined $\breve{\Psi}_0:=\Xi_0-\langle\Xi_j,\tilde{\Phi}_j\rangle_{L_2(\Gamma)}\langle\Theta_j,\tilde{\Phi}_j\rangle^{-1}_{L_2(\Gamma)}\Theta_0$.

Let

$$\breve{\Psi}^{(j)}:=\begin{cases}\Phi_0\cup\cup_{k=0}^{j-1}\breve{\Psi}_k & \text{when } \tilde{d}=2,\\ \Phi_0\cup\cup_{k=0}^{j-2}\breve{\Psi}_k & \text{when } \tilde{d}=3,\end{cases}$$

in both cases being a basis for $C(\Gamma)\cap\prod_{q=1}^4\kappa_q(S_j)$. With

$$\kappa_{\Sigma,\|\cdot\|}:=\sup_{0\neq\mathbf{c}=(c_\sigma)_{\sigma\in\Sigma}}\frac{\left\|\sum_{\sigma\in\Sigma}c_\sigma\frac{\sigma}{\|\sigma\|}\right\|^2}{\|\mathbf{c}\|^2}\Bigg/\inf_{0\neq\mathbf{c}=(c_\sigma)_{\sigma\in\Sigma}}\frac{\left\|\sum_{\sigma\in\Sigma}c_\sigma\frac{\sigma}{\|\sigma\|}\right\|^2}{\|\mathbf{c}\|^2},$$

which, in case $\|\cdot\|$ corresponds to a scalar product, is the spectral norm of the corresponding mass matrix, for $j\leq 6$ we computed $\kappa_{\breve\Psi^{(j)},\|\cdot\|_{L_2(\Gamma)}}$, $\kappa_{\breve\Psi^{(j)},|\!|\!|\cdot|\!|\!|_1}$, and $\kappa_{\breve\Psi^{(j)},|\!|\!|\cdot|\!|\!|_{-1,6}}$, where on $C(\Gamma)\cap\prod_{q=1}^4\kappa_q(S_m)$, $|\!|\!|u|\!|\!|_{-1,m}:=\sup_{v\in C(\Gamma)\cap\prod_{q=1}^4\kappa_q(S_m)}\frac{|\langle u,v\rangle_{L_2(\Gamma)}|}{|\!|\!|v|\!|\!|_1}$. The uniform boundedness in $|\!|\!|\cdot|\!|\!|_1$ of the $L_2(\Gamma)$-orthogonal projector onto $C(\Gamma)\cap\prod_{q=1}^4\kappa_q(S_m)$, which is a consequence of Theorem 5.3, shows that $|\!|\!|\cdot|\!|\!|_{-1}\eqsim|\!|\!|\cdot|\!|\!|_{-1,m}$ on $C(\Gamma)\cap\prod_{q=1}^4\kappa_q(S_j)$ uniformly in m and $j\leq m$.

Since the functions from Φ_0, and for $\tilde d=2$, from $\breve\Psi_0$ and $\breve\Psi_1$, and for $\tilde d=3$, from $\breve\Psi_0$ have global supports anyway, for computing the condition numbers we replaced each of these collections by an orthonormalized version with respect to $\langle\cdot,\cdot\rangle_{L_2(\Gamma)}$, $\langle\!\langle\cdot,\cdot\rangle\!\rangle_1$, or $\langle\!\langle\cdot,\cdot\rangle\!\rangle_{-1,6}$, the latter being the scalar product corresponding to the norm $\|\cdot\|_{-1,6}$. The results for the Jacobi approximation or least squares approximation along the interfaces are presented in Tables 8.1 and 8.2, respectively. Although it turns out that unfortunately, in particular in the $\|\cdot\|_{-1,6}$-norm, the condition numbers were not completely stabilized yet, we stopped our computations at $j=6$ since mainly due to the normalization of the wavelets, in particular with respect to the $\|\cdot\|_{-1,6}$-norm, on higher levels they became too time consuming.

Appendix. Proof of Theorem 6.1. The proof consists of steps (I)–(VI). Although basically (V) and (VI) can be found in [19, Theorem 3.1], which in turn was based on [24, appendix], for convenience we include a complete proof.

(I) Since, as shown in Proposition 5.4, for $j \geq j_0$ large enough, Ψ_j is a uniform $L_2(\Gamma)$-Riesz system, and by condition (iii),

$$\begin{aligned}&\|\langle\breve{\Psi}_j,\breve{\Psi}_j\rangle_{L_2(\Gamma)}-\langle\Psi_j,\Psi_j\rangle_{L_2(\Gamma)}\|\\&=\|\langle\breve{\Psi}_j-\Psi_j,\Psi_j\rangle_{L_2(\Gamma)}+\langle\Psi_j,\breve{\Psi}_j-\Psi_j\rangle_{L_2(\Gamma)}+\langle\breve{\Psi}_j-\Psi_j,\breve{\Psi}_j-\Psi_j\rangle_{L_2(\Gamma)}\|\lesssim\omega^j,\end{aligned}$$

we infer that, possibly for a larger value of j_0, for $j \geq j_0$, $\breve{\Psi}_j$ is a uniform $L_2(\Gamma)$-Riesz system.

(II) Next we investigate whether $\mathcal{S}(\Phi_j)+\mathcal{S}(\breve{\Psi}_j)$ is a uniformly $L_2(\Gamma)$-stable *two-level* decomposition of $\mathcal{S}(\Phi_{j+1})$.

PROPOSITION A.1. *Let V, W be subspaces of a Hilbert space H. Then the following are equivalent:*

(a) *$H = V + W$ and $\alpha := \sup_{0\neq v\in V,\,0\neq w\in W}\frac{|\langle v,w\rangle|}{\|v\|\|w\|}<1$.*

(b) *There exists a bounded projector $Q : H \to H$ with $\Im(Q) = V$ and $\Im(Id-Q) = W$.*

Moreover, $\|Q\| = (1-\alpha^2)^{-\frac{1}{2}}$.

Now let (a)*, or equivalently* (b)*, be satisfied, and let $\breve{W}$ be another subspace of H for which there exists a linear mapping $R : \breve{W} \to W$ with $\|Id - R\| < \frac{1-\alpha}{1+\alpha}$. Then*

$$\breve{\alpha} := \sup_{0\neq v\in V,\,0\neq\breve{w}\in\breve{W}}\frac{|\langle v,\breve{w}\rangle|}{\|v\|\|\breve{w}\|}\leq\alpha+(1+\alpha)\|Id-R\|<1.$$

With $\breve{Q} : H \to H$ being the bounded projector with $\Im(\breve{Q}) = V$ and $\Im(Id-\breve{Q}) = \breve{W}$, it holds that

$$\|Q-\breve{Q}\|\leq\frac{\|Id-R\|}{(1-\alpha^2)^{\frac{1}{2}}(1-\breve{\alpha}^2)^{\frac{1}{2}}}.$$

Proof. If (a) is valid, then $H = V \oplus W$, and so there exists a projector Q with $\Im(Q) = V$ and $\Im(Id - Q) = W$. For any $u \in H$, we have

$$\begin{aligned}\|u\|^2&=\|Qu+(Id-Q)u\|^2\geq\|Qu\|^2-2|\langle Qu,(Id-Q)u\rangle|+\|(Id-Q)u\|^2\\&\geq\|Qu\|^2-2\alpha\|Qu\|\|(Id-Q)u\|+\|(Id-Q)u\|^2\geq(1-\alpha^2)\|Qu\|^2,\end{aligned}$$

or $\|Q\| \leq (1-\alpha^2)^{-\frac{1}{2}}$.

Now let (b) be valid. Suppose there exist nonzero $v \in V$, $w \in W$ such that $\mu := \frac{|\langle v,w\rangle|}{\|v\|\|w\|} > (1-\|Q\|^{-2})^{\frac{1}{2}}$. Then there exist nonzero $v \in V$, $w \in W$ with $\langle v, w\rangle = -\mu\|v\|\|w\|$, moreover, which can be chosen such that $\|w\| = -\mu\|v\|$. From

$$\|Q\|^{-2}\|v\|^2\leq\|v+w\|^2=\|v\|^2+2\langle v,w\rangle+\|w\|^2=(1-\mu^2)\|v\|^2$$

we conclude a contradiction, so that $\sup_{0\neq v\in V,\,0\neq w\in W}\frac{|\langle v,w\rangle|}{\|v\|\|w\|}\leq(1-\|Q\|^{-2})^{\frac{1}{2}}$.

Now let (a) or, equivalently, (b) be valid, and let $\breve{W}$ be a subspace as in the proposition. For any $v \in V$, $\breve{w} \in \breve{W}$,

$$\begin{aligned}|\langle v,\breve{w}\rangle|&=|\langle v,R\breve{w}\rangle+\langle v,(Id-R)\breve{w}\rangle|\leq\alpha\|v\|\|R\breve{w}\|+\|v\|\|(Id-R)\breve{w}\|\\&\leq\alpha\|v\|\|\breve{w}\|+(1+\alpha)\|v\|\|(Id-R)\breve{w}\|\leq(\alpha+(1+\alpha)\|Id-R\|)\|v\|\|\breve{w}\|,\end{aligned}$$

showing the statement about $\breve{\alpha}$. The last statement follows from $\|Q\| = (1-\alpha^2)^{-\frac{1}{2}}$, $\|Id-\breve{Q}\| = (1-\breve{\alpha}^2)^{-\frac{1}{2}}$, and $Q-\breve{Q} = Q(Id-R)(Id-\breve{Q})$ by $QR = 0$ and $Q\breve{Q} = \breve{Q}$. ∎

Returning to the proof of Theorem 6.1, with, for $j \geq j_0$, $Q_j^{(j+1)} := Q_j|_{\mathcal{S}(\Phi_{j+1})}$, it holds that $\Im(Q_j^{(j+1)}) = \mathcal{S}(\Phi_j)$ and $\Im(Id - Q_j^{(j+1)}) = \mathcal{S}(\Psi_j)$. Setting $R_j : \mathcal{S}(\breve{\Psi}_j) \to \mathcal{S}(\Psi_j) : \mathbf{c}_j^T \breve{\Psi}_j \mapsto \mathbf{c}_j^T \Psi_j$, by condition (iii) and (I) we have

$$\|(Id - R_j)\mathbf{c}_j^T \breve{\Psi}_j\|_{L_2(\Gamma)} = \|\mathbf{c}_j^T(\breve{\Psi}_j - \Psi_j)\|_{L_2(\Gamma)} \leq \|\mathbf{c}\| \|\breve{\Psi}_j - \Psi_j\|_{L_2(\Gamma)} \lesssim \|\mathbf{c}_j^T \breve{\Psi}_j\|_{L_2(\Gamma)} \omega^j,$$

or $\|Id - R_j\|_{L_2(\Gamma)\to L_2(\Gamma)} \lesssim \omega^j$. From Proposition A.1 we conclude that, possibly for a larger value of j_0, for $j \geq j_0$ there exists a uniformly $L_2(\Gamma)$-bounded projector $\breve{Q}_j^{(j+1)} : \mathcal{S}(\Phi_{j+1}) \to \mathcal{S}(\Phi_{j+1})$ with

$$\Im(\breve{Q}_j^{(j+1)}) = \mathcal{S}(\Phi_j), \quad \Im(Id - \breve{Q}_j^{(j+1)}) = \mathcal{S}(\breve{\Psi}_j),$$

and

$$\|Q_j^{(j+1)} - \breve{Q}_j^{(j+1)}\|_{L_2(\Gamma)\to L_2(\Gamma)} \lesssim \omega^j. \tag{A.1}$$

(III) By condition (i), $\breve{\Psi}_j$ is uniformly local. Since furthermore, as shown in (I), $\breve{\Psi}_j$ is a uniform $L_2(\Gamma)$-Riesz system that, by condition (ii), has the uniform cancellation property of order $\tilde{d}$, for some $\tilde{\eta} \geq 0$ we have

$$\begin{aligned}
|\langle \mathbf{c}_j^T \breve{\Psi}_j, u\rangle_{L_2(\Gamma)}| &\leq \sum_{x\in J_j} |c_{j,x}||\langle \breve{\psi}_{j,x}, u\rangle_{L_2(\Gamma)}| \quad (\mathbf{c}_j \in \ell_2(J_j),\, u \in \mathcal{H}_{\tilde{d}}(\Gamma)) \\
&\lesssim 2^{-j\tilde{d}} \|\mathbf{c}_j\| \left[\sum_{x\in J_j} \sum_{q=1}^{M} \|u \circ \kappa_q\|^2_{H^{\tilde{d}}(B(\kappa_q^{-1}(\operatorname{supp} \breve{\psi}_{j,x} \cap \Gamma_q); \tilde{\eta} 2^{-j}) \cap \square)} \right]^{\frac{1}{2}} \\
&\lesssim 2^{-j\tilde{d}} \|\mathbf{c}_j^T \breve{\Psi}_j\|_{L_2(\Gamma)} |\!|\!| u |\!|\!|_{\tilde{d}},
\end{aligned}$$

or

$$|\!|\!| \cdot |\!|\!|_{-\tilde{d}} \lesssim 2^{-\tilde{d}j} \|\cdot\|_{L_2(\Gamma)} \quad \text{on } \mathcal{S}(\breve{\Psi}_j). \tag{A.2}$$

By the uniform $L_2(\Gamma)$-boundedness of $\breve{Q}_j^{(j+1)}$ for $j \geq j_0$, a direct consequence of the last result is that $|\!|\!| Id - \breve{Q}_j^{(j+1)} |\!|\!|_{0\to -\tilde{d}} \lesssim 2^{-\tilde{d}j}$. By the Jackson estimate at the dual side (4.6), and the uniform $L_2(\Gamma)$-boundedness of Q_j for $j \geq j_0$, we have $|\!|\!| Id - Q_j^{(j+1)} |\!|\!|_{0\to -\tilde{d}} \leq |\!|\!| Id - Q_j |\!|\!|_{0\to -\tilde{d}} \lesssim 2^{-\tilde{d}j}$, and so $|\!|\!| Q_j^{(j+1)} - \breve{Q}_j^{(j+1)} |\!|\!|_{0\to -\tilde{d}} \lesssim 2^{-\tilde{d}j}$. By the extended Bernstein inequality Lemma 4.2, $|\!|\!| Q_j^{(j+1)} - \breve{Q}_j^{(j+1)} |\!|\!|_{-\tilde{d}\to -\tilde{d}} \lesssim 1$, so that by interpolation using (A.1) we infer that

$$|\!|\!| Q_j^{(j+1)} - \breve{Q}_j^{(j+1)} |\!|\!|_{s\to s} \lesssim \omega^{(1+\frac{s}{\tilde{d}})j} \quad (s \in [-\tilde{d}, 0]). \tag{A.3}$$

(IV) Knowing (A.3), we are ready to investigate the stability of the *multilevel* decomposition defined by the collections $\breve{\Psi}_j$. We are going to construct a projector $\breve{Q}_j$ defined on $\mathcal{H}_s(\Gamma)$ for some range of s, such that, for $j \geq j_0$, $\Im(\breve{Q}_j) = \mathcal{S}(\Phi_j)$ and $\Im(\breve{Q}_{j+1} - \breve{Q}_j) = \mathcal{S}(\breve{\Psi}_j)$.

By writing $Q_j = \sum_{k=j_0}^{j} Q_k - Q_{k-1}$, for any $s \in (-\min\{\tilde{\gamma}, \tilde{d}\}, \min\{\gamma, d\})$ and $u \in \mathcal{H}_s(\Gamma)$, Theorem 5.3 shows that $|\!|\!| Q_j u |\!|\!|_s^2 \lesssim \sum_{k=j_0}^{j} 4^{sk} |\!|\!| (Q_k - Q_{k-1})u |\!|\!|_{L_2(\Gamma)}^2 \leq \sum_{k=j_0}^{\infty} 4^{sk} |\!|\!| (Q_k - Q_{k-1})u |\!|\!|_{L_2(\Gamma)}^2 \lesssim |\!|\!| u |\!|\!|_s^2$ or $|\!|\!| Q_j |\!|\!|_{s\to s} \lesssim 1$.

For $\ell \geq j \geq j_0$, we define $\breve{Q}_j^{(\ell)} : \mathcal{S}(\Phi_\ell) \to \mathcal{S}(\Phi_j)$ by $\breve{Q}_\ell^{(\ell)} = Id$ and, for $j < \ell$, by $\breve{Q}_j^{(\ell)} = \breve{Q}_j^{(j+1)}\breve{Q}_{j+1}^{(\ell)}$. For some arbitrary but fixed $t \in (-\min\{\tilde{\gamma}, \tilde{d}\}, 0]$, we set

$$\rho_j^{(\ell)} := \max_{j_0 \leq k \leq j} \|\!| Q_k \breve{Q}_j^{(\ell)} |\!\|_{t\to t}, \quad \varepsilon_j := \max_{j_0 \leq k \leq j} \|\!| Q_k(\breve{Q}_j^{(j+1)} - Q_j^{(j+1)}) |\!\|_{t\to t}.$$

From $Q_k\breve{Q}_j^{(\ell)} = Q_k(\breve{Q}_j^{(j+1)} - Q_j^{(j+1)})\breve{Q}_{j+1}^{(\ell)} + Q_k\breve{Q}_{j+1}^{(\ell)}$, we find $\rho_j^{(\ell)} \leq (\varepsilon_j + 1)\rho_{j+1}^{(\ell)}$, and so by $\rho_\ell^{(\ell)} = \max_{j_0 \leq k \leq j} \|\!| Q_k |\!\|_{t\to t} \lesssim 1$, and $\varepsilon_j \lesssim \omega^{(1+\frac{t}{d})j}$ by (A.3), we infer that

$$\|\!| \breve{Q}_j^{(\ell)} |\!\|_{t\to t} \leq \rho_j^{(\ell)} \lesssim \prod_{k=j}^{\ell-1}(\varepsilon_k + 1) \lesssim 1 + \sum_{k=j}^{\ell-1} \varepsilon_k \lesssim 1,$$

which thus holds uniformly in j and ℓ.

As a consequence of $Id = \sum_{j=j_0}^\infty (Q_j - Q_{j-1})$ on $\mathcal{H}_t(\Gamma)$ by Theorem 5.3, we have $\mathrm{clos}_{H_t(\Gamma)} \cup_{j\geq j_0} \mathcal{S}(\Phi_j) = \mathcal{H}_t(\Gamma)$. Since for any $u \in \mathcal{H}_t(\Gamma)$, $j \leq k \leq \ell$, and $u_k \in \mathcal{S}(\Phi_k)$, $\breve{Q}_j^{(\ell)}Q_\ell u = \breve{Q}_j^{(k)}u_k + \breve{Q}_j^{(\ell)}Q_\ell(u - u_k)$, from $\|\!| \breve{Q}_j^{(\ell)}Q_\ell |\!\|_{t\to t} \lesssim 1$ we infer that for any $j \geq j_0$, $(\breve{Q}_j^{(\ell)}Q_\ell u)_{\ell\geq j}$ is a Cauchy sequence in $\mathcal{H}_t(\Gamma)$, and we set $\breve{Q}_j u = \lim_{\ell\to\infty} \breve{Q}_j^{(\ell)}Q_\ell u$. We conclude that $\breve{Q}_j : \mathcal{H}_t(\Gamma) \to \mathcal{H}_t(\Gamma)$ is uniformly bounded, with $\Im(\breve{Q}_j) = \mathcal{S}(\Phi_j)$ and $\Im(\breve{Q}_{j+1} - \breve{Q}_j) = \mathcal{S}(\breve{\Psi}_j)$.

(V) Let $s \in (t, \min\{\gamma, d\})$. With $\breve{Q}_{j_0-1} := 0$, we are going to prove that

$$\sum_{j=j_0}^\infty 4^{sj} \|(\breve{Q}_j - \breve{Q}_{j-1})u\|_{L_2(\Gamma)}^2 \lesssim \|u\|_s^2 \quad (u \in \mathcal{H}_s(\Gamma)). \tag{A.4}$$

For $u \in \mathcal{H}_s(\Gamma)$, $w_\ell := (Q_\ell - Q_{\ell-1})u$, Theorem 6.1 shows that $u = \sum_{\ell=j_0}^\infty w_\ell$, $\|u\|_s^2 \eqsim \sum_{\ell=j_0}^\infty 4^{s\ell}\|w_\ell\|_{L_2(\Gamma)}^2$, and $\|w_\ell\|_t \lesssim 2^{t\ell}\|w_\ell\|_{L_2(\Gamma)}$. Since $\|\!| \breve{Q}_j |\!\|_{t\to 0} \lesssim 2^{-tj}$, which follows from $\|\!| \breve{Q}_j |\!\|_{t\to t} \lesssim 1$ and the extended Bernstein inequality Lemma 4.2, and $\breve{Q}_j - \breve{Q}_{j-1}$ vanishes on $\mathcal{S}(\Phi_{j-1})$, we arrive at

$$\begin{aligned}
\sum_{j=j_0}^\infty 4^{sj}\|(\breve{Q}_j - \breve{Q}_{j-1})u\|_{L_2(\Gamma)}^2 &= \sum_{j=j_0}^\infty \sum_{\ell,\ell'=j_0}^\infty 4^{sj}\langle(\breve{Q}_j - \breve{Q}_{j-1})w_\ell, (\breve{Q}_j - \breve{Q}_{j-1})w_{\ell'}\rangle_{L_2(\Gamma)} \\
&= \sum_{\ell,\ell'=j_0}^\infty \sum_{j=j_0}^{\min\{\ell,\ell'\}} 4^{sj}\langle(\breve{Q}_j - \breve{Q}_{j-1})w_\ell, (\breve{Q}_j - \breve{Q}_{j-1})w_{\ell'}\rangle_{L_2(\Gamma)} \\
&\lesssim \sum_{\ell,\ell'=j_0}^\infty \sum_{j=j_0}^{\min\{\ell,\ell'\}} 4^{sj}4^{-tj}\|w_\ell\|_t\|w_{\ell'}\|_t \lesssim \sum_{\ell,\ell'=j_0}^\infty 4^{(s-t)\min\{\ell,\ell'\}}\|w_\ell\|_t\|w_{\ell'}\|_t \\
&\lesssim \sum_{\ell,\ell'=j_0}^\infty 4^{(s-t)\min\{\ell,\ell'\}}2^{(t-s)(\ell+\ell')}(2^{s\ell}\|w_\ell\|_{L_2(\Gamma)})(2^{s\ell'}\|w_{\ell'}\|_{L_2(\Gamma)}) \\
&\lesssim \sum_{\ell=j_0}^\infty 4^{s\ell}\|w_\ell\|_{L_2(\Gamma)}^2 \eqsim \|u\|_s^2,
\end{aligned}$$

where we have used that the infinite matrix $[2^{(s-t)(2\min\{\ell,\ell'\}-\ell-\ell')}]_{\ell,\ell'\geq j_0}$ is bounded.

(VI) For $s \in [-\tilde{d}, \gamma)$, it holds that

$$\|\cdot\|_s \lesssim 2^{sj}\|\cdot\|_{L_2(\Gamma)} \quad \text{on } \Im(\breve{Q}_j - \breve{Q}_{j-1}).$$

Indeed for $s > 0$ this is just the Bernstein inequality (4.5), whereas for $s < 0$ it is a consequence of the extended Bernstein inequality Lemma 4.2 and (A.2). Now let $s \in (-\tilde{d}, \gamma)$, and let $\varepsilon > 0$ be such that $s \pm \varepsilon \in [-\tilde{d}, \gamma)$. Then for any $\breve{w}_j \in \Im(\breve{Q}_j - \breve{Q}_{j-1})$, with $\sum_{j=j_0}^{\infty} 4^{sj} \|\breve{w}_j\|^2_{L_2(\Gamma)} < \infty$, it holds that

$$\Big\| \sum_{j=j_0}^{\infty} \breve{w}_j \Big\|_s^2 = \sum_{j,j'=j_0}^{\infty} \langle\!\langle \breve{w}_j, \breve{w}_{j'} \rangle\!\rangle_s \lesssim \sum_{j=j_0}^{\infty} \sum_{j' \geq j} |\!|\!| \breve{w}_j |\!|\!|_{s+\varepsilon} |\!|\!| \breve{w}_{j'} |\!|\!|_{s-\varepsilon}$$
$$\lesssim \sum_{j=j_0}^{\infty} \sum_{j' \geq j} 2^{\varepsilon j} 2^{-\varepsilon j'} (2^{sj} \|\breve{w}_j\|_{L_2(\Gamma)}) (2^{sj'} \|\breve{w}_{j'}\|_{L_2(\Gamma)}) \lesssim \sum_{j=j_0}^{\infty} 4^{sj} \|\breve{w}_j\|^2_{L_2(\Gamma)}.$$

Since, when $s \in (t, \min\{\gamma, d\})$, (A.4) shows that $\sum_{j=j_0}^{\infty} 4^{sj} \|\breve{w}_j\|^2_{L_2(\Gamma)} \lesssim |\!|\!| \sum_{j=j_0}^{\infty} \breve{w}_j |\!|\!|^2_s$, and Φ_{j_0} is an $L_2(\Gamma)$-Riesz basis for $\Im(\breve{Q}_{j_0})$, and for $j > j_0$, $\breve{\Psi}_{j-1}$ is a uniform $L_2(\Gamma)$-Riesz basis for $\Im(\breve{Q}_j - \breve{Q}_{j-1})$, we conclude that $\Phi_{j_0} \cup \cup_{j \geq j_0} 2^{-sj} \breve{\Psi}_j$ is a Riesz system in $\mathcal{H}_s(\Gamma)$. Finally, since, as follows from Theorem 5.3, $\mathrm{clos}_{H_s(\Gamma)} \cup_{j \geq 0} \mathcal{S}(\Phi_j) = \mathcal{H}_s(\Gamma)$, we conclude it is even Riesz basis for this space, with which the proof of Theorem 6.1 is completed. □

DISCONTINUOUS GALERKIN METHODS FOR QUASI-LINEAR ELLIPTIC PROBLEMS OF NONMONOTONE TYPE*

THIRUPATHI GUDI† AND AMIYA K. PANI†

Abstract. In this paper, both symmetric and nonsymmetric interior penalty discontinuous *hp*-Galerkin methods are applied to a class of quasi-linear elliptic problems which are of nonmonotone type. Using Brouwer's fixed point theorem, it is shown that the discrete problem has a solution, and then, using Lipschitz continuity of the discrete solution map, uniqueness is also proved. A priori error estimates in the broken H^1-norm, which are optimal in h and suboptimal in p, are derived. Moreover, on a regular mesh an *hp*-error estimate for the L^2-norm is also established. Finally, numerical experiments illustrating the theoretical results are provided.

Key words. *hp*-finite elements, discontinuous Galerkin methods, second order quasi-linear elliptic problems, optimal estimates, Brouwer's fixed point theorem

1. Introduction.

In recent years, there has been renewed interest in discontinuous Galerkin methods for the numerical solution of a wide range of partial differential equations. This is due to their flexibility in local mesh adaptivity and their flexibility in handling nonuniform degrees of approximation for solutions whose smoothness exhibits variation over the computational domain. Based on Nitsche's symmetric formulation in 1970, these methods were introduced for second order elliptic and parabolic equations by Arnold [3], Douglas and Dupont [13], and Wheeler [24] and hence are presently called symmetric interior penalty discontinuous Galerkin (SIPG) methods. It is observed that SIPG methods are adjoint consistent, but the stabilizing parameters in these methods depend on the bounds of the coefficients of the problem considered and various constants involved in inverse inequalities. Recently, Oden, Babuška, and Baumann [21] proposed another discontinuous Galerkin method, which is based on a nonsymmetric formulation. Rivière, Wheeler, and Girault [23] and Houston, Schwab, and Süli [16] introduced and analyzed the nonsymmetric interior penalty discontinuous Galerkin (NIPG) method, which is a stabilized discontinuous Galerkin method. For a review, see [22], and for variants of discontinuous formulations, see Brezzi et al. [9], Arnold et al. [4], Houston, Robson, and Süli [17], and the references therein. A significant property of an NIPG method is that it is unconditionally stable with respect to the choice of the penalty parameter. Hence, this advantage has stimulated renewed interest in applying these methods to a large class of partial differential equations.

In the literature, optimal a priori error estimates are derived in the broken H^1-norm, and numerical experiments are conducted for SIPG and NIPG methods for linear self-adjoint elliptic problems; see [4], [23]. Except for [17], there are hardly any results on discontinuous Galerkin approximation of nonlinear elliptic problems. In [17], a one-parameter family of discontinuous Galerkin methods is applied to the

†Industrial Mathematics Group, Department of Mathematics, Indian Institute of Technology Bombay, Powai, Mumbai 400076, India (trpathi@math.iitb.ac.in, akp@math.iitb.ac.in). The second author's research was supported by the DST-DAAD (PPP-05) project.

quasi-linear elliptic problems where the differential operator is strongly monotone and Lipschitz continuous. In particular, the authors have considered a class of elliptic problems

$$-\nabla \cdot (\mu(x,\ |\nabla u|)\nabla u) = f(x)$$

subject to mixed Dirichlet–Neumann boundary conditions. Under the structural conditions on $\mu \in C(\bar{\Omega} \times [0,\infty))$,

$$m_\mu(t-s) \le \mu(x,t)t - \mu(x,s)s \le M_\mu(t-s) \quad \text{for } \ t \ge s \ge 0, \tag{1.1}$$

and for some positive constants m_μ and M_μ, it is shown that the discontinuous Galerkin formulation is monotone, and hence a priori error estimates in broken H^1-norm are derived. For nonlinear problems of the type

$$-\nabla \cdot (a(u)\nabla u) = f \quad \text{in } \Omega, \tag{1.2}$$

$$u = g \quad \text{on } \partial\Omega, \tag{1.3}$$

where $0 < \alpha \le a(u) \le M$, for some $\alpha,\ M \in \mathbb{R}^+$, the nonlinearity may not satisfy (1.1), and hence it is difficult to extend the analysis of [17]. Therefore, an attempt has been made in this paper to study discontinuous Galerkin methods for the problem (1.2)–(1.3). The results presented in this paper can be thought of an extension to discontinuous Galerkin methods of the results established for the nonlinear Dirichlet problem (1.2)–(1.3) by using a Galerkin method in [12]. Both SIPG and NIPG methods are discussed for the problem (1.2)–(1.3), and a priori error estimates are derived in the broken H^1-norm which are optimal in h. These results lead to precisely the same h-optimal and p-suboptimal rates of convergence in the broken H^1-norm as in the case of linear elliptic problems, when it is approximated by an NIPG method; see [23, Theorem 3.1].

The organization of this article is as follows. Section 1 is introductory in nature, and section 2 is devoted to notation, definitions, and preliminaries. In section 3, discontinuous Galerkin methods are discussed for linear nonselfadjoint elliptic problems, and a priori error estimates are derived in the broken H^1-norm, which are optimal in h and suboptimal in p. Section 4 is devoted to SIPG and NIPG methods for the quasi-linear elliptic problems (1.2)–(1.3). Using Brouwer's fixed point theorem, existence of a discrete solution is proved. Then a priori error estimates are derived in the broken H^1-norm, which are optimal in h and suboptimal in p. Further, an a priori error estimate in the L^2-norm is established on regular meshes for (1.2)–(1.3) with piecewise polynomial or zero Dirichlet boundary datum. In section 5, we provide some numerical experiments to illustrate the theoretical results obtained in this article. Finally, in section 6, we present a summary and some extensions.

2. Preliminaries. Let $\Omega \subset \mathbb{R}^2$ be a bounded domain with boundary $\partial\Omega$, where the boundary $\partial\Omega$ is assumed sufficiently smooth in order that a duality argument can be employed in our subsequent analysis. Let $\mathcal{T}_h = \{K_i : 1 \le i \le N_h\}$ be a shape regular finite element subdivision of Ω, where K_i is either a triangle or a rectangle (possibly curvilinear) defined as follows. Let $\hat{K}$ be a shape regular master triangle or rectangle in $\mathbb{R}^2$, and let $\{F_i\}$ be a family of invertible maps such that F_i maps from $\hat{K}$ onto K_i. For a definition of shape regularity, we refer to [10, p. 124]. Let h_i be the diameter of K_i and $h = \max\{h_i : 1 \le i \le N_h\}$. We denote the set of interior edges of $\mathcal{T}_h$ by $\Gamma_I = \{e_{ij} : e_{ij} = \partial K_i \cap \partial K_j,\ |e_{ij}| > 0\}$ and the set of

boundary edges by $\Gamma_\partial = \{e_{i\partial} : e_{i\partial} = \partial K_i \cap \partial\Omega,\ |e_{i\partial}| > 0\}$, where $|e_k|$ denotes the one-dimensional measure of e_k. Let $\Gamma = \Gamma_I \cup \Gamma_\partial$. Since for each $e_k \in \Gamma_I$ there exist $K_i, K_j \in \mathcal{T}_h$ such that $e_k = \partial K_i \cap \partial K_j$ $(i > j)$, we associate with e_k a unit normal vector ν_k which is directed outward from K_i. For $e_k \in \Gamma_\partial$, let ν_k be the unit outward normal to the boundary $\partial\Omega$. For simplicity, we denote $\nu = \nu_k$. Note that our definition of e_k also admits hanging nodes along each edge of the finite elements. On this subdivision $\mathcal{T}_h$, we define the following broken Sobolev space of composite order $\mathbf{s} = \{s_i \geq 0 : 1 \leq i \leq N_h\}$ and exponent r, with $1 \leq r \leq \infty$:

$$W_r^{\mathbf{s}}(\Omega, \mathcal{T}_h) = \{v \in L^r(\Omega) : v|_{K_i} \in W_r^{s_i}(K_i)\ \forall K_i \in \mathcal{T}_h\},$$

where $W_r^{s_i}(K_i)$ is the standard Sobolev space of order s_i with exponent r for each K_i. For $1 \leq r < \infty$, the associated broken norm and seminorm are defined, respectively, by

$$\|v\|_{W_r^{\mathbf{s}}(\Omega,\mathcal{T}_h)} = \left(\sum_{i=1}^{N_h} \|v\|^r_{W_r^{s_i}(K_i)}\right)^{1/r} \quad \text{and} \quad |v|_{W_r^{\mathbf{s}}(\Omega,\mathcal{T}_h)} = \left(\sum_{i=1}^{N_h} |v|^r_{W_r^{s_i}(K_i)}\right)^{1/r},$$

and for the case $r = \infty$, the associated broken norm and seminorm are defined, respectively, by

$$\|v\|_{W_\infty^{\mathbf{s}}(\Omega,\mathcal{T}_h)} = \max_{1\leq i\leq N_h} \|v\|_{W_\infty^{s_i}(K_i)} \quad \text{and} \quad |v|_{W_\infty^{\mathbf{s}}(\Omega,\mathcal{T}_h)} = \max_{1\leq i\leq N_h} |v|_{W_\infty^{s_i}(K_i)},$$

where $||v||_{W_r^{s_i}(K_i)}$ and $|v|_{W_r^{s_i}(K_i)}$ are the standard Sobolev norm and seminorm on K_i. When $r = 2$, we write $H^{\mathbf{s}}(\Omega, \mathcal{T}_h) = W_2^{\mathbf{s}}(\Omega, \mathcal{T}_h)$ and also write the norm and seminorm as

$$||v||_{\mathbf{s},h} = \|v\|_{W_r^{\mathbf{s}}(\Omega,\mathcal{T}_h)} \quad \text{and} \quad |v|_{\mathbf{s},h} = |v|_{W_r^{\mathbf{s}}(\Omega,\mathcal{T}_h)},$$

and when $s = s_i$ for all $1 \leq i \leq N_h$, we write $H^s(\Omega, \mathcal{T}_h)$,$\|v\|_{s,h}$ and $|v|_{s,h}$, respectively. For $s = 0$, we denote the norm by $\|.\|$ which is the standard L^2-norm. We now define the jump and average of a function $v \in H^1(\Omega, \mathcal{T}_h)$ on an edge $e_k \in \Gamma$ as follows. If $e_k \in \Gamma_I$, that is, $e_k = \partial K_i \cap \partial K_j$ $(i > j)$ for some i and j, then we define the jump and average as

$$[v] = v|_{K_i} - v|_{K_j}, \qquad \{v\} = \frac{v|_{K_i} + v|_{K_j}}{2}.$$

In the case $e_k \in \Gamma_\partial$, there exists K_i such that $e_k = \partial K_i \cap \partial\Omega$, and we then define, for notational convenience, the jump and average on e_k as

$$[v] = v|_{K_i\cap\partial\Omega}, \qquad \{v\} = v|_{K_i\cap\partial\Omega}.$$

Let $\hat{P}_{p_i}(\hat{K})$ be the space of polynomials of total degree less than or equal to p_i on the triangle $\hat{K}$, and let $\hat{Q}_{p_i}(\hat{K})$ be the space of polynomials of degree less than or equal to p_i in each variable which are defined on the rectangle $\hat{K}$. Let $\mathcal{Z}_{p_i}(\hat{K})$ denote $\hat{P}_{p_i}(\hat{K})$ or $\hat{Q}_{p_i}(\hat{K})$ whenever $\hat{K}$ is a master triangle or a rectangle, respectively. Now define (see [21], [14])

$$\mathcal{Z}_{p_i}(K_i) = \{v : v = \hat{v} \circ F_i^{-1}, \hat{v} \in \hat{\mathcal{Z}}_{p_i}(\hat{K})\}.$$

The discontinuous finite element space is defined as

$$\mathcal{D}_p(\mathcal{T}_h) = \{v \in L^2(\Omega) : v|K_i \in \mathcal{Z}_{p_i}(K_i)\},$$

where $p = \min\{p_i \geq 1 : 1 \leq i \leq N_h\}$.

We also need the following discontinuous finite element space of piecewise polynomials with uniform degree p:

$$\mathcal{D}_p^*(\mathcal{T}_h) = \{v \in L^2(\Omega) : v|K_i \in \mathcal{Z}_p(K_i) \quad \forall i\}.$$

We also define the following Sobolev space with piecewise polynomial traces:

$$H_p^s(\Omega) = \{v \in H^s(\Omega) : v|_{\partial\Omega} = w|_{\partial\Omega} \quad \text{for some } w \in \mathcal{D}_p^*(\mathcal{T}_h)\}.$$

Assumption P.

1. *The finite element subdivision $\mathcal{T}_h$ satisfies the* bounded local variation *condition in the sense that if $|\partial K_i \cap \partial K_j| > 0$ for any K_i and $K_j \in \mathcal{T}_h$, then there exists a constant κ independent of h_i, h_j such that*

$$\frac{h_i}{h_j} \leq \kappa.$$

In particular, this implies that for any element K_i the number of neighboring elements $K_j \in \mathcal{T}_h$ with $|\partial K_i \cap \partial K_j| > 0$ is bounded by N_κ uniformly for some positive integer N_κ.

2. *The discontinuous finite element space $\mathcal{D}_p(\mathcal{T}_h)$ satisfies the following* bounded local variation: *If $|\partial K_i \cap \partial K_j| > 0$ for any K_i and $K_j \in \mathcal{T}_h$, then there exists a constant ϱ independent of p_i and p_j such that*

$$\frac{p_i}{p_j} \leq \varrho.$$

Here, $|.|$ denotes the one-dimensional Euclidean measure.

We now present some examples which satisfy Assumption P(1).

(i) *Regular subdivision.* A subdivision of Ω into shape regular elements K_i, $1 \leq i \leq N_h$, is such that for any two elements K_i and K_j, the common portion $\partial K_i \cap \partial K_j$ is either empty or a vertex of K_i or an entire edge e of K_i, that is, $e = \partial K_i \cap \partial K_j$ and there is no other element $K_l \in \mathcal{T}_h$ $(l \neq j,\ i)$ such that $|e \cap \partial K_l| > 0$ [10, p. 132].

(ii) 1-*irregular subdivision.* A shape regular subdivision $\{K_i\}_{i=1}^{N_h}$ of Ω is such that for any side of an element K_i, there can be at most one hanging node (cf. Figure 1); see [16] and [17, p. 5].

For $e_k \in \Gamma_I$, there are two elements K_i and K_j such that $e_k = \partial K_i \cap \partial K_j$. Hence, we define the "degree" of polynomial in K_i and K_j restricted to e_k by p_k, by $p_k = (p_i + p_j)/2$. For $e_k \in \Gamma_\partial$, we note that there is one element K_i with $e_k = \partial K_i \cap \partial\Omega$, and hence we denote the degree of polynomial restricted to e_k by $p_k = p_i$.

From Assumption P, it is easy to see that if $e_k \subset \partial K_i$, then there exist constants $c_1(\kappa)$, $c_2(\kappa)$, $c_3(\varrho)$, and $c_4(\varrho)$ which are independent of h and p such that

$$c_1(\kappa)h_i \leq |e_k| \leq c_2(\kappa)h_i, \qquad c_3(\varrho)p_i \leq p_k \leq c_4(\varrho)p_i. \tag{2.1}$$

Let $v \in H^2(\Omega, \mathcal{T}_h)$. We define the following mesh-dependent norms which appear naturally in the analysis of interior penalty discontinuous Galerkin methods:

$$|||v|||^2 = \left(\sum_{i=1}^{N_h} \int_{K_i} |\nabla v|^2 \, \mathrm{dx} \ + \ \mathcal{J}^{1,\beta}(v,\ v) \right) \tag{2.2}$$

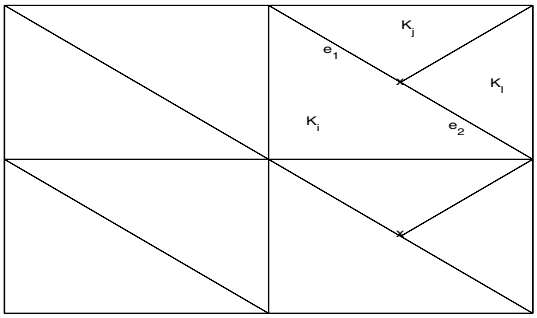

FIG. 1. 1-*irregular mesh.*

and

$$|||v|||_+^2 = \left(\sum_{i=1}^{N_h} \int_{K_i} |\nabla v|^2 \, \mathrm{dx} \; + \; \sum_{e_k \in \Gamma} \frac{|e_k|^\beta}{p_k^2} \int_{e_k} \left\{ \frac{\partial v}{\partial \nu} \right\}^2 \, \mathrm{ds} \; + \; \mathcal{J}^{1,\beta}(v,\; v) \right), \tag{2.3}$$

where

$$\mathcal{J}^{\sigma,\beta}(v,\; w) = \left(\sum_{e_k \in \Gamma} \sigma_k \frac{p_k^2}{|e_k|^\beta} \int_{e_k} [v][w] \, \mathrm{ds} \right),$$

$\sigma|_{e_k} = \sigma_k$, and σ_k, β are positive real numbers.

Approximation properties of finite element spaces. Below, we state without proof a lemma on some *hp*-approximation properties.

LEMMA 2.1. *For $\phi \in H^s(K_i)$, there exists a positive constant C_A (depending on s but independent of ϕ, p_i, and h_i) and a sequence $\phi_{p_i}^{h_i} \in \mathcal{Z}_{p_i}(K_i)$, $p_i = 1, 2, \ldots$, such that*

(i) *for any $0 \le l \le s_i$,*

$$\|\phi - \phi_{p_i}^{h_i}\|_{H^l(K_i)} \le C_A \frac{h_i^{\mu_i - l}}{{p_i}^{s_i - l}} \|\phi\|_{H^{s_i}(K_i)};$$

(ii) *for $s_i > l + \frac{1}{2}$,*

$$\|\phi - \phi_{p_i}^{h_i}\|_{H^l(e_k)} \le C_A \frac{h_i^{\mu_i - l - 1/2}}{p_i^{s_i - l - 1/2}} \|\phi\|_{H^{s_i}(K_i)};$$

(iii) *for $0 \le l \le s_i - 1 + 2/r$,*

$$\|\phi - \phi_{p_i}^{h_i}\|_{W_r^l(K_i)} \le C_A \frac{h_i^{\mu_i - l - 1 + 2/r}}{{p_i}^{s_i - l - 1 + 2/r}} \|\phi\|_{H^{s_i}(K_i)},$$

where $\mu_i = \min(s_i,\; p_i + 1)$.

The proof of properties (i) and (ii) can be found in [6, Lemma 4.5]. Then using properties (1) and (3) in Lemma 1 of [1] and rescaling (see [2, Lemma 2]), it is easy to derive property (iii).

For given $\phi \in H^{\mathbf{s}}(\Omega, \mathcal{T}_h)$, we define $I_h\phi \in \mathcal{D}_p(\mathcal{T}_h)$ by $(I_h\phi)|_{K_i} = \phi_{p_i}^{h_i}(\phi|_{K_i})$ for all $1 \le i \le N_h$. By virtue of Lemma 2.1, $I_h\phi$ satisfies the local approximation properties derived in Lemma 2.1; see [17, p. 737].

Trace inequalities. We state without proof the following trace inequality. For $r = 2$ it is proved in [22, Appendix A.2], and using similar arguments, we can easily obtain the inequality for $r = 4$.

LEMMA 2.2. *Let $\phi \in H^{j+1}(K_i)$, $K_i \in \mathcal{T}_h$. Then there exists a constant $C_{T_1} > 0$ such that*

$$\|\phi\|^r_{W^j_r(e_k)} \le C_{T_1}\left(\frac{1}{h_i}\|\phi\|^r_{W^j_r(K_i)} + \|\phi\|^{r-1}_{W^j_{2r-2}(K_i)}\|\nabla^{(j+1)}\phi\|_{L^2(K_i)}\right), \tag{2.4}$$

where $j = 0, 1$ and $r = 2, 4$.

We recall the following trace inequality on finite element spaces for our future use. For a proof, we refer to [23, Lemma 2.1].

LEMMA 2.3. *Let $v_h \in \mathcal{Z}_{p_i}(K_i)$. Then there exists a constant $C_{T_2} > 0$ such that*

$$\|\nabla^l v_h\|_{L^2(e_k)} \le C_{T_2} p_i h_i^{-1/2}\|\nabla^l v_h\|_{L^2(K_i)}, \quad l = 0, 1. \tag{2.5}$$

Below, we state without proof a lemma on inverse inequalities. For a proof, we refer to [18, p. 6], [7, Theorem 6.1].

LEMMA 2.4 (inverse inequalities). *Let $v_h \in \mathcal{Z}_{p_i}(K_i)$. Then, for $r \ge 2$, there exists a constant $C_I > 0$ such that*

$$\|v_h\|_{L^r(K_i)} \le C_I p_i^{1-2/r} h_i^{(2/r-1)}\|v_h\|_{L^2(K_i)}, \tag{2.6}$$

$$|v_h|_{H^l(K_i)} \le C_I p_i^2 h_i^{-1}|v_h|_{H^{l-1}(K_i)}, \quad l \ge 1, \tag{2.7}$$

and

$$\|v_h\|_{L^r(e_k)} \le C_I p_i^{1-2/r}|e_k|^{(1/r-1/2)}\|v_h\|_{L^2(e_k)}, \tag{2.8}$$

where $e_k \subset \partial K_i$ is an edge.

For our future use, we state the following Poincaré-type inequalities on $H^1(\Omega, \mathcal{T}_h)$. For a proof, we refer to [18, Theorem 3.7]; see also [8] for the case of $r = 2$.

LEMMA 2.5 (Poincaré-type inequalities). *Let $v \in H^1(\Omega, \mathcal{T}_h)$. Then there exists a constant $C_P > 0$ independent of h and v such that, for $1 \le r < \infty$,*

$$\|v\|_{L^r(\Omega)} \le C_P|||v|||.$$

3. Nonselfadjoint linear elliptic problems. For our error analysis of discontinuous Galerkin methods applied to the nonlinear elliptic problem (1.2)–(1.3), we need some results on the corresponding linearized problems. Since the linearized problem is a nonselfadjoint elliptic problem, in this section, we consider the following second order linear nonselfadjoint elliptic partial differential equation:

$$\begin{aligned} -\nabla\cdot(a(x)\nabla u) + \vec{b}(x)\cdot\nabla u + a_0(x)u &= f(x) \quad \text{in } \Omega, \\ u &= g \quad \text{on } \partial\Omega. \end{aligned} \tag{3.1}$$

We adopt the following assumptions on the problem (3.1).

ASSUMPTION R.

1. *There exists $\alpha > 0$ such that $0 < \alpha \le a(x)$ and $a_0(x) \ge 0$ for all $x \in \bar{\Omega}$.*
2. *$a \in W^1_\infty(\Omega)$ and b, $a_0 \in L^\infty(\Omega)$ with $M = \max\{\|a\|_{L^\infty(\Omega)}, \|b\|_{L^\infty(\Omega)}, \|a_0\|_{L^\infty(\Omega)}\}$.*
3. *$f \in L^2(\Omega)$ and $g \in H^{3/2}(\partial\Omega)$.*

Then, from [15, Lemma 9.17] it is well known that there exists a unique solution $u \in H^2(\Omega)$ to the problem (3.1) satisfying

$$\|u\|_{H^2(\Omega)} \le C\left(\|f\|_{L^2(\Omega)} + \|g\|_{H^{3/2}(\partial\Omega)}\right). \tag{3.2}$$

3.1. Weak formulation. For $w,\ v \in H^2(\Omega, \mathcal{T}_h)$, we consider the bilinear form

$$B(w,\ v) = \sum_{i=1}^{N_h} \int_{K_i} (a\nabla w \cdot \nabla v + a_0 wv + (\vec{b} \cdot \nabla w)v) - \sum_{e_k \in \Gamma} \int_{e_k} \left\{ a \frac{\partial w}{\partial \nu} \right\} [v]$$
$$- \theta \sum_{e_k \in \Gamma} \int_{e_k} \left\{ a \frac{\partial v}{\partial \nu} \right\} [w] + \mathcal{J}^{\sigma,\beta}(w,\ v) + \sum_{e_k \in \Gamma} \int_{e_k} \left\{ \vec{b} \cdot \nu v \right\} [w]$$

and the linear form

$$L(v) = \int_\Omega fv - \theta \sum_{e_k \in \Gamma_\partial} \int_{e_k} \left(a \frac{\partial v}{\partial \nu} \right) g + \sum_{e_k \in \Gamma_\partial} \int_{e_k} \sigma_k \frac{p_k^2}{|e_k|^\beta} vg + \sum_{e_k \in \Gamma_\partial} \int_{e_k} \vec{b} \cdot \nu v g,$$

where $\theta = \pm 1$. When $\vec{b} = 0$, we note that $\theta = +1$ corresponds to a symmetric and $\theta = -1$ to a nonsymmetric interior penalty method.

We define a weak formulation which is suitable for the discontinuous Galerkin methods as follows: Find $u \in H^2(\Omega, \mathcal{T}_h)$ such that

$$B(u,\ v) = L(v) \quad \forall v \in H^2(\Omega, \mathcal{T}_h). \tag{3.3}$$

Now the discontinuous Galerkin approximation of u is to seek $u_h \in \mathcal{D}_p(\mathcal{T}_h)$ such that

$$B(u_h,\ v_h) = L(v_h) \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \tag{3.4}$$

Below, we examine the consistency of the above scheme (3.4).

THEOREM 3.1. *If the solution u of problem* (3.1) *is in $H^2(\Omega)$, then u satisfies problem* (3.3). *Conversely, if the solution u of problem* (3.3) *is in $H^1(\Omega) \cap H^2(\Omega, \mathcal{T}_h)$, then u satisfies problem* (3.1) *weakly.*

The proof techniques of Rivière, Wheeler, and Girault [23, Lemma 2.2] or [22, Theorem 3.1] can be easily modified to prove Theorem 3.1, and so the proof is omitted. The solvability of (3.4) will be discussed at the end of section 3. From (3.3)–(3.4) and Theorem 3.1, it is easy to check that

$$B(u - u_h,\ v_h) = 0 \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \tag{3.5}$$

Following [22], [24], we state the following Gårding-type inequality.

LEMMA 3.2. *Let $\beta \geq 1$ and $0 < \sigma_0 \leq \sigma_k \leq \sigma_m$. Further, assume that $\sigma_0 \geq C(\alpha,\ M,\ C_{T_2},\ N_\kappa)$ when $\theta = 1$, and $\sigma_0 > 0$ when $\theta = -1$. Then there exist two constants $C_1 = C(\alpha,\ \sigma_0) > 0$ and $C_2 = C(\alpha,\ \sigma_0,\ M,\ C_{T_2},\ N_\kappa) > 0$ which are independent of h and p such that*

$$B(v_h,\ v_h) \geq C_1 |||v_h|||^2 - C_2 \|v_h\|^2 \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h).$$

A straightforward modification of the analysis of Prudhomme, Pascal, and Oden [22, Theorems 3.4 and 3.5] and of Wheeler [24, Lemma 3] yields the proof of Lemma 3.2, and so we omit the proof. Throughout this article, C denotes a generic constant which is independent of h, p, and u_h but may depend on κ, ϱ, σ_0, σ_m, α, M, C_A, C_{T_1}, C_{T_2}, C_I, C_P, C_1, and C_2.

Using the trace inequality (2.5) and (2.1), it is an easy exercise to prove the following Lemma 3.3. For details, see [22, Theorem 3.3].

LEMMA 3.3. *Let $\beta \geq 1$ and $\phi \in H^2(\Omega, \mathcal{T}_h)$. If σ_k is bounded above by a positive number σ_m, then there exists a positive constant C, independent of h and p, such that*

$$|B(\phi,\ v_h)| \leq C|||\phi|||_+\ |||v_h||| \qquad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h).$$

LEMMA 3.4. *Let $\beta = 1$. Then there exists a positive constant C which depends on C_A, but is independent of h and p, such that*

$$|||\phi - \mathcal{I}_h\phi|||_+ \leq C\left(\sum_{i=1}^{N_h} \frac{h_i^{2\mu_i-2}}{p_i^{2s_i-3}}\|\phi\|^2_{H^{s_i}(K_i)}\right)^{1/2},$$

where $\mu_i = \min\{p_i + 1, s_i\}$.

Proof. Let $\eta^* = \phi - \mathcal{I}_h\phi$. Then, using (2.3), Lemma 2.1, and (2.1), we obtain

$$\begin{aligned}|||\eta^*|||^2_+ &= \sum_{i=1}^{N_h}\int_{K_i}|\nabla\eta^*|^2 + \sum_{e_k\in\Gamma}\int_{e_k}\frac{|e_k|^\beta}{p_i^2}\left\{\frac{\partial\eta^*}{\partial\nu}\right\}^2 + \sum_{e_k\in\Gamma}\int_{e_k}\frac{p_i^2}{|e_k|^\beta}[\eta^*]^2\\ &\leq C\sum_{i=1}^{N_h}\left(\frac{h_i^{2\mu_i-2}}{p_i^{2s_i-2}}\|\phi\|^2_{H^{s_i}(K_i)} + \frac{h_i^{2\mu_i-3+\beta}}{p_i^{2s_i-1}}\|\phi\|^2_{H^{s_i}(K_i)} + \frac{h_i^{2\mu_i-1-\beta}}{p_i^{2s_i-3}}\|\phi\|^2_{H^{s_i}(K_i)}\right). \qquad (3.6)\end{aligned}$$

Since $\beta = 1$, the lemma is proved by taking a square root on both sides of (3.6). ∎

We prove the following lemma, which will be used in the proof of a priori error estimates.

LEMMA 3.5. *Let $\beta = 1$ and $q \in L^2(\Omega)$. Then, for sufficiently small h, there exists a unique $\phi_h \in \mathcal{D}_p(\mathcal{T}_h)$ satisfying*

$$B(v_h,\ \phi_h) = \int_\Omega q v_h \qquad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \qquad (3.7)$$

Moreover, ϕ_h satisfies

$$|||\phi_h||| \leq C\|q\|. \qquad (3.8)$$

Proof. Note that (3.7) leads to a system of linear algebraic equations. So it is enough to prove uniqueness. Set $v_h = \phi_h$ in (3.7) and use Lemma 3.2 to obtain

$$\begin{aligned}C_1|||\phi_h|||^2 - C_2\|\phi_h\|^2 \leq B(\phi_h,\ \phi_h) &= \int_\Omega q\phi_h\\ &\leq \|q\|\ \|\phi_h\|.\end{aligned}$$

Therefore, we arrive at

$$|||\phi_h||| \leq C_1\|q\| + C_2\|\phi_h\|. \qquad (3.9)$$

To estimate $\|\phi_h\|$ in terms of $|||\phi_h|||$, we apply the standard Aubin–Nitsche duality argument. For $\phi_h \in \mathcal{D}_p(\mathcal{T}_h)$, we consider the following auxiliary problem:

$$\begin{aligned}-\nabla\cdot(a(x)\nabla\psi) + \vec{b}(x)\cdot\nabla\psi + a_0(x)\psi &= \phi_h \quad \text{in } \Omega,\\ \psi &= 0 \quad \text{on } \partial\Omega.\end{aligned} \qquad (3.10)$$

Then Assumption R implies that ψ satisfies the following elliptic regularity:

$$\|\psi\|_{H^2(\Omega)} \leq C\|\phi_h\|_{L^2(\Omega)}. \qquad (3.11)$$

We multiply (3.10) by ϕ_h and integrate over Ω, apply integration by parts, and then use Lemmas 3.3 and 3.4 to obtain

$$\begin{aligned}\|\phi_h\|^2 = B(\psi,\ \phi_h) &= B(\psi - \mathcal{I}_h\psi,\ \phi_h) + B(\mathcal{I}_h\psi,\ \phi_h) = B(\psi - \mathcal{I}_h\psi,\ \phi_h) + \int_\Omega q\mathcal{I}_h\psi \\ &\le C\left(h\ |||\phi_h||| + \|q\|\right)\|\psi\|_{H^2(\Omega)}.\end{aligned}$$

From the elliptic regularity (3.11), we now arrive at

$$\|\phi_h\| \le Ch|||\phi_h||| + \|q\|. \tag{3.12}$$

Substituting (3.12) into (3.9), we obtain the estimate (3.8) for sufficiently small h. Hence, (3.7) has a unique solution and this completes the rest of the proof. ∎

3.2. A priori error estimates. Let $\beta = 1$. Since Lemma 3.2 holds for elements in $\mathcal{D}_p(\mathcal{T}_h)$, we split $e = u - u_h$ into $e = \eta + \chi$, where $\eta = u - \mathcal{I}_h u$ and $\chi = \mathcal{I}_h u - u_h$. Then using Lemmas 3.2 and 3.3 and (3.5), we obtain

$$\begin{aligned}C_1|||\chi|||^2 - C_2\|\chi\|^2 \le B(\chi,\ \chi) &= B((\mathcal{I}_h u - u) + (u - u_h),\ \chi) \\ &= B(\mathcal{I}_h u - u,\ \chi) = B(\eta,\ \chi) \\ &\le C|||\eta|||_+\ |||\chi|||.\end{aligned}$$

Therefore,

$$|||\chi||| \le C|||\eta|||_+ + C_2\|\chi\|. \tag{3.13}$$

In order to estimate $\|\chi\|$, we set $q = \chi$ and $v_h = \chi$ in Lemma 3.5. Using (3.5) and Lemma 3.3, we now obtain

$$\begin{aligned}\|\chi\|^2 = B(\chi,\ \phi_h) &= B(\mathcal{I}_h u - u_h,\ \phi_h) = B(\mathcal{I}_h u - u,\ \phi_h) \\ &\le C|||\eta|||_+\ |||\phi_h|||.\end{aligned}$$

Using (3.8), we arrive at

$$\|\chi\| \le C|||\eta|||_+. \tag{3.14}$$

From the estimates (3.13) and (3.14), we obtain

$$|||\chi||| \le C|||\eta|||_+. \tag{3.15}$$

Now using Lemma 3.4, inequality (3.15), and triangle inequality, we deduce the following theorem.

THEOREM 3.6. *Let $\beta = 1$; then for sufficiently small h, there exists a positive constant C which is independent of h and p such that*

$$|||u - u_h||| \le C\left(\sum_{i=1}^{N_h} \frac{h_i^{2\mu_i - 2}}{p^{2s_i - 3}}\|u\|^2_{H^{s_i}(K_i)}\right)^{1/2},$$

where $\mu_i = \min\{s_i,\ p_i + 1\}$.

Existence and uniqueness. We now prove the existence of a unique solution to problem (3.4) using the discrete dual problem (3.7) stated in Lemma 3.5. Assume that there exist two distinct solutions u_h^1 and u_h^2 for the problem (3.4). Let $\xi = u_h^1 - u_h^2$ and set $q = \xi$, $v_h = \xi$ in (3.7). Since $B(u_h^1 - u_h^2, v_h) = 0$ for all $v_h \in \mathcal{D}_p(\mathcal{T}_h)$, we obtain

$$\|\xi\|^2 = B(\xi,\ \phi_h) = B(u_h^1 - u_h^2,\ \phi_h) = 0.$$

Therefore, $u_h^1 = u_h^2$, which leads to a contradiction. Hence, we conclude that there exists a unique solution u_h for problem (3.4). Now uniqueness implies the existence of a discrete solution u_h to problem (3.4).

4. Quasi-linear elliptic problems. In this section, we consider the following nonlinear elliptic boundary value problem:

$$-\nabla \cdot (a(x,u)\nabla u) = f(x) \quad \text{in } \Omega, \tag{4.1}$$

$$u(x) = g(x) \quad \text{on } \partial\Omega, \tag{4.2}$$

where Ω is a bounded domain in $\mathbb{R}^2$ with smooth boundary $\partial\Omega$. As in [12], we make the following assumptions for problem (4.1)–(4.2). There exist positive constants $\alpha,\ M$ such that $0 < \alpha \le a(x,v) \le M$, $x \in \bar{\Omega},\ v \in \mathbb{R}$, $a(x,v) \in C_b^2(\bar{\Omega} \times \mathbb{R})$, where $C_b^2(\bar{\Omega} \times \mathbb{R})$ is the class of twice continuously differentiable functions on $\bar{\Omega} \times \mathbb{R}$ such that all derivatives of $a(x,v)$ up to and including second order are bounded in $\bar{\Omega} \times \mathbb{R}$. Further, for some $\delta \in (0,1)$, $f \in C^{\delta}(\Omega)$ and g can be extended to Ω to be in $C^{2+\delta}(\Omega)$; then it follows from [11] that there exists a unique weak solution u to (4.1)–(4.2) and $u \in C^{2+\delta}(\bar{\Omega})$, where $C^{m+\delta}(\bar{\Omega})$ consists of all functions whose mth order derivatives are Hölder continuous of order δ on $\bar{\Omega}$.

4.1. Weak formulation. For $\psi,\ w,$ and $v \in H^2(\Omega, \mathcal{T}_h)$, we define the form $B(\psi; w,\ v)$, which is linear in $w,\ v$ for fixed ψ, by

$$\begin{aligned} B(\psi; w,\ v) = &\sum_{i=1}^{N_h} \int_{K_i} a(\psi)\nabla w \cdot \nabla v - \sum_{e_k \in \Gamma_I} \int_{e_k} \left(\left\{ a(\psi)\frac{\partial w}{\partial \nu} \right\} [v] + \theta \left\{ a(\psi)\frac{\partial v}{\partial \nu} \right\} [w] \right) \\ &- \sum_{e_k \in \Gamma_\partial} \int_{e_k} \left(a(g)\frac{\partial w}{\partial \nu} v + \theta a(g)\frac{\partial v}{\partial \nu} w \right) + \mathcal{J}^{\sigma,\beta}(w,\ v), \end{aligned}$$

and the linear functional L on $H^2(\Omega,\ \mathcal{T}_h)$ by

$$L(v) = \int_\Omega fv + \theta \sum_{e_k \in \Gamma_\partial} \int_{e_k} a(g)\frac{\partial v}{\partial \nu} g + \sum_{e_k \in \Gamma_\partial} \int_{e_k} \sigma_k \frac{p_i^2}{|e_k|^\beta} vg,$$

where $\theta = \pm 1$. Since for each fixed ψ, $B(\psi; \cdot,\ \cdot)$ is a bilinear form, we note that $\theta = +1$ corresponds to a symmetric and $\theta = -1$ to a nonsymmetric method. We define the weak formulation of (4.1)–(4.2) which is suitable for applying a discontinuous Galerkin method as follows: Find $u \in H^2(\Omega, \mathcal{T}_h)$ such that

$$B(u; u,\ v) = L(v) \quad \forall v \in H^2(\Omega, \mathcal{T}_h). \tag{4.3}$$

Now the discontinuous Galerkin (SIPG and NIPG) approximation of u is to seek $u_h \in \mathcal{D}_p(\mathcal{T}_h)$ such that

$$B(u_h; u_h,\ v_h) = L(v_h) \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \tag{4.4}$$

Below, we state without proof the consistency of the above scheme (4.4).

THEOREM 4.1 (equivalence of (4.1)–(4.2) and (4.3)). *If the solution u of* (4.1)–(4.2) *is in $H^2(\Omega)$, then u satisfies* (4.3). *Conversely, if $u \in H^1(\Omega) \cap H^2(\Omega, \mathcal{T}_h)$ is a solution of* (4.3), *then u satisfies* (4.1)–(4.2) *weakly.*

The proof follows along the lines of the proof given in [23, Lemma 2.2] or [22, Theorem 3.1], so we omit it. With $v = v_h \in \mathcal{D}_p(\mathcal{T}_h) \subset H^2(\Omega, \mathcal{T}_h)$ in (4.3), and using (4.4), we obtain

$$B(u; u,\ v_h) = B(u_h; u_h,\ v_h) \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \tag{4.5}$$

Following Taylor series expansion, we write

$$a(w) = a(u) + \tilde{a}_u(w)(w-u), \tag{4.6}$$

where $\tilde{a}_u(w) = \int_0^1 a_u(w + t[u-w])dt$, and

$$a(w) = a(u) + a_u(u)(w-u) + \tilde{a}_{uu}(w)(w-u)^2, \tag{4.7}$$

where $\tilde{a}_{uu}(w) = \int_0^1 (1-t)a_{uu}(w + t[w-u])dt$.

Note that since $a_u \in C_b^1(\bar{\Omega} \times \mathbb{R})$ and $a_{uu} \in C_b^0(\bar{\Omega} \times \mathbb{R})$, it is easy to see that $\tilde{a}_u \in L^\infty(\Omega \times \mathbb{R})$ and $\tilde{a}_{uu} \in L^\infty(\Omega \times \mathbb{R})$. We use the following notation throughout this section:

$$C_a = \max\left[\ \|\tilde{a}_u\|_{L^\infty(\Omega\times\mathbb{R})},\ \|\tilde{a}_{uu}\|_{L^\infty(\Omega\times\mathbb{R})}\right]. \tag{4.8}$$

For simplicity, we consider the following form $\tilde{B}(\cdot\ ;\ \cdot\ ,\ \cdot)$:

$$\tilde{B}(\psi; w,\ v) = B(\psi; w,\ v) + \sum_{i=1}^{N_h} \int_{K_i} (a_u(\psi)\nabla\psi)w \cdot \nabla v - \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ a_u(\psi)\frac{\partial \psi}{\partial \nu} w \right\} [v].$$

Note that $\tilde{B}$ is linear in w and $v \in H^2(\Omega, \mathcal{T}_h)$ for a fixed ψ. It is clear from the assumptions on $a(u)$ that Lemmas 3.2 and 3.3 hold for $\tilde{B}$. Since $a \in C_b^2(\bar{\Omega} \times \mathbb{R})$ and $u \in C^2(\bar{\Omega})$, there is a unique solution $\psi \in H^2(\Omega)$ to the following elliptic problem:

$$\begin{aligned} -\nabla \cdot (a(u)\nabla\psi + a_u(u)\nabla u\psi) &= \phi_h \quad \text{in } \Omega, \\ \psi &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{4.9}$$

and ψ satisfies the elliptic regularity $\|\psi\|_{H^2(\Omega)} \le C\|\phi_h\|$; see [11, Theorem 2], [12, p. 692]. Hence, Lemma 3.5 holds as well for $\tilde{B}$. Now we linearize problem (4.4) around $\mathcal{I}_h u$ for our subsequent analysis. Set $e = u - u_h$. Subtracting $B(u; u_h,\ v_h)$ from both sides of (4.5), we obtain

$$\begin{aligned} B(u; e,\ v_h) = &\sum_{i=1}^{N_h} \int_{K_i} (a(u_h) - a(u))\nabla u_h \cdot \nabla v_h - \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ (a(u_h) - a(u))\frac{\partial u_h}{\partial \nu} \right\} [v_h] \\ &- \theta \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ (a(u_h) - a(u))\frac{\partial v_h}{\partial \nu} \right\} [u_h]. \end{aligned} \tag{4.10}$$

Since $[u] = 0$ on each $e_k \in \Gamma_I$, we rewrite (4.10) as

$$\begin{aligned} B(u; e,\ v_h) &= \sum_{i=1}^{N_h} \int_{K_i} (a(u_h) - a(u)) \nabla(u_h - u) \cdot \nabla v_h - \int_{\Gamma_I} \left\{ (a(u_h) - a(u)) \frac{\partial u}{\partial \nu} \right\} [v_h] \\ &\quad - \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ (a(u_h) - a(u)) \frac{\partial (u_h - u)}{\partial \nu} \right\} [v_h] + \sum_{i=1}^{N_h} \int_{K_i} (a(u_h) - a(u)) \nabla u \cdot \nabla v_h \\ &\quad - \theta \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ (a(u_h) - a(u)) \frac{\partial v_h}{\partial \nu} \right\} [u_h - u]. \end{aligned} \tag{4.11}$$

Finally, we add the following terms to both sides of (4.11):

$$- \sum_{i=1}^{N_h} \int_{K_i} a_u(u)(u_h - u) \nabla u \cdot \nabla v_h + \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ a_u(u)(u_h - u) \frac{\partial u}{\partial \nu} \right\} [v_h].$$

We split $e = u - u_h = u - \mathcal{I}_h u + \mathcal{I}_h u - u_h$. Now using the Taylor formulae (4.6)–(4.7), equation (4.11) takes the form

$$\tilde{B}(u; \mathcal{I}_h u - u_h,\ v_h) = \tilde{B}(u; \mathcal{I}_h u - u,\ v_h) + \mathcal{F}(u_h; u_h - u,\ v_h), \tag{4.12}$$

where

$$\begin{aligned} \mathcal{F}(u_h; -e,\ v_h) &= \sum_{i=1}^{N_h} \int_{K_i} \tilde{a}_u(u_h) e \nabla e \cdot \nabla v_h - \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ \tilde{a}_u(u_h) e \frac{\partial e}{\partial \nu} \right\} [v_h] \\ &\quad - \theta \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ \tilde{a}_u(u_h) e \frac{\partial v_h}{\partial \nu} \right\} [e] + \sum_{i=1}^{N_h} \int_{K_i} \tilde{a}_{uu}(u_h) e^2 \nabla u \cdot \nabla v_h \\ &\quad - \sum_{e_k \in \Gamma_I} \int_{e_k} \left\{ \tilde{a}_{uu}(u_h) e^2 \frac{\partial u}{\partial \nu} \right\} [v_h]. \end{aligned} \tag{4.13}$$

Note that (4.4) is equivalent to (4.12).

Assumption Q (*hp*-quasi-uniformity [19]). *Along with Assumption* P*, we also assume that the subdivision $\mathcal{T}_h$ and discontinuous space $\mathcal{D}_p(\mathcal{T}_h)$ satisfy the following hp-quasi-uniformity condition:*

$$\left(\max_{1 \le i \le N_h} \frac{h_i}{p_i} \right) \le C_Q \left(\min_{1 \le i \le N_h} \frac{h_i}{p_i} \right), \tag{4.14}$$

where C_Q is a positive constant which is independent of h and p.

Observe that under assumption (4.14), the following holds:

$$\left(\max_{1 \le i \le N_h} \frac{p_i}{h_i} \right) \left(\max_{1 \le i \le N_h} \frac{h_i}{p_i} \right) = \left(\min_{1 \le i \le N_h} \frac{h_i}{p_i} \right)^{-1} \left(\max_{1 \le i \le N_h} \frac{h_i}{p_i} \right) \le C_Q. \tag{4.15}$$

4.2. Existence and uniqueness. For a given $z \in \mathcal{D}_p(\mathcal{T}_h)$, let $S_h : \mathcal{D}_p(\mathcal{T}_h) \to \mathcal{D}_p(\mathcal{T}_h)$ be a map $y = S_h z \in \mathcal{D}_p(\mathcal{T}_h)$ satisfying

$$\tilde{B}(u; \mathcal{I}_h u - y,\ v_h) = \tilde{B}(u; \mathcal{I}_h u - u,\ v_h) + \mathcal{F}(z; z - u,\ v_h) \quad \forall v_h \in \mathcal{D}_p(\mathcal{T}_h). \tag{4.16}$$

For a given z, problem (4.16) leads to a system of linear algebraic equations. So using Lemmas 3.2 and 3.5, it is easy to show that the map S_h is well defined. Now consider the ball

$$\mathcal{O}_\delta(\mathcal{I}_h u) = \{z \in \mathcal{D}_p(\mathcal{T}_h) : \ |||\mathcal{I}_h u - z||| \le \delta\}$$

of radius δ, where δ will be chosen later. We first show that for some $\delta > 0$, S_h maps $\mathcal{O}_\delta(\mathcal{I}_h u)$ into itself. Then appealing to Brouwer's fixed point theorem yields the existence of a solution to problem (4.12), and hence there exists a solution to problem (4.4). The following lemma is a key result for proving the existence of a unique solution to the discrete problem (4.4). Throughout this section we use the following notation to denote the Sobolev norm of u:

$$C_u = \max\left[\ \|u\|_{H^2(\Omega)},\ \|u\|_{H^1(\Omega)}|u|_{W^1_\infty(\Omega)}\right]. \tag{4.17}$$

LEMMA 4.2. *Let $\beta \ge 1$ and $z, v_h \in \mathcal{D}_p(\mathcal{T}_h)$. Set $\chi = z - \mathcal{I}_h u$ and $\eta = u - \mathcal{I}_h u$. Then there exists a constant $C > 0$ which is independent of h and p such that*

$$|\mathcal{F}(z; z-u,\ v_h)| \le CC_a \left[\left(\max_{1\le i\le N_h} \frac{p_i}{h_i}\right)^{1/2} |||\chi|||^2 + C_u h^{1/2}(|||\chi||| + |||\eta|||)\right] |||v_h|||.$$

Proof. Let $z \in \mathcal{D}_p(\mathcal{T}_h)$ and set $\zeta = z - u$. In (4.13), we now replace u_h by z and e by $z - u$ to obtain

$$\begin{aligned}\mathcal{F}(z;\zeta,\ v_h) = &\sum_{i=1}^{N_h}\int_{K_i} \tilde{a}_u(z)\zeta\nabla\zeta\cdot\nabla v_h - \sum_{e_k\in\Gamma_I}\int_{e_k}\left\{\tilde{a}_u(z)\zeta\frac{\partial\zeta}{\partial\nu}\right\}[v_h]\\ &- \theta\sum_{e_k\in\Gamma_I}\int_{e_k}\left\{\tilde{a}_u(z)\zeta\frac{\partial v_h}{\partial\nu}\right\}[\zeta] + \sum_{i=1}^{N_h}\int_{K_i}\tilde{a}_{uu}(z)\zeta^2\nabla u\cdot\nabla v_h\\ &- \sum_{e_k\in\Gamma_I}\int_{e_k}\left\{\tilde{a}_{uu}(z)\zeta^2\frac{\partial u}{\partial\nu}\right\}[v_h].\end{aligned} \tag{4.18}$$

We split $\zeta = \chi - \eta$, where $\chi = z - \mathcal{I}_h u$ and $\eta = u - \mathcal{I}_h u$. Then we estimate from below the bound for each term on the right-hand side of (4.18). For the first term on the right-hand side of (4.18), we split and then bound it as

$$\begin{aligned}\sum_{i=1}^{N_h}\int_{K_i}|\tilde{a}_u(z)\zeta\nabla\zeta\cdot\nabla v_h| \le{}& C_a\sum_{i=1}^{N_h}\int_{K_i}|\chi\nabla\chi\cdot\nabla v_h| + C_a\sum_{i=1}^{N_h}\int_{K_i}|\chi\nabla\eta\cdot\nabla v_h|\\ &+ C_a\sum_{i=1}^{N_h}\int_{K_i}|\eta\nabla\chi\cdot\nabla v_h| + C_a\sum_{i=1}^{N_h}\int_{K_i}|\eta\nabla\eta\cdot\nabla v_h|.\end{aligned} \tag{4.19}$$

Using Hölder's inequality and the inverse inequality (2.6), we estimate the first term on the right-hand side of (4.19) as

$$\begin{aligned}\sum_{i=1}^{N_h}\int_{K_i}|\chi\nabla\chi\cdot\nabla v_h| &\le \sum_{i=1}^{N_h}\|\chi\|_{L^6(K_i)}\|\nabla\chi\|_{L^3(K_i)}\|\nabla v_h\|_{L^2(K_i)}\\ &\le C\sum_{i=1}^{N_h}\|\chi\|_{L^6(K_i)}\frac{p_i^{1/3}}{h_i^{1/3}}\|\nabla\chi\|_{L^2(K_i)}\|\nabla v_h\|_{L^2(K_i)}\end{aligned}$$

$$\leq C\|\chi\|_{L^6(\Omega)}\left(\sum_{i=1}^{N_h}\frac{p_i}{h_i}\|\nabla\chi\|^3_{L^2(K_i)}\right)^{1/3}|v_h|_{1,h}$$

$$\leq C\|\chi\|_{L^6(\Omega)}\left[\max_{K_i}\|\nabla\chi\|^{1/3}_{L^2(K_i)}\left(\sum_{i=1}^{N_h}\frac{p_i}{h_i}\|\nabla\chi\|^2_{L^2(K_i)}\right)^{1/3}\right]|v_h|_{1,h}$$

$$\leq C|||\chi|||\left(\sum_{i=1}^{N_h}\|\nabla\chi\|^2_{L^2(K_i)}\right)^{1/6}\left(\sum_{i=1}^{N_h}\frac{p_i}{h_i}\|\nabla\chi\|^2_{L^2(K_i)}\right)^{1/3}|||v_h|||$$

$$\leq C\left(\max_{1\leq i\leq N_h}\frac{p_i}{h_i}\right)^{1/3}|||\chi|||^2\ |||v_h|||. \tag{4.20}$$

For the second term on the right-hand side of (4.19), we use Hölder's inequality and Lemma 2.1 to obtain

$$\sum_{i=1}^{N_h}\int_{K_i}|\chi\nabla\eta\cdot\nabla v_h| \leq C\sum_{i=1}^{N_h}\|\chi\|_{L^6(K_i)}\|\nabla\eta\|_{L^3(K_i)}\|\nabla v_h\|_{L^2(K_i)}$$

$$\leq C\sum_{i=1}^{N_h}\|\chi\|_{L^6(K_i)}\frac{h_i^{2/3}}{p_i^{2/3}}\|u\|_{H^2(K_i)}\|\nabla v_h\|_{L^2(K_i)}$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}\|\chi\|_{L^6(\Omega)}\left(\sum_{i=1}^{N_h}\|u\|^3_{H^2(K_i)}\right)^{1/3}|v_h|_{1,h}$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}|||\chi|||\left[\max_{K_i}\|u\|^{1/3}_{H^2(K_i)}\left(\sum_{i=1}^{N_h}\|u\|^2_{H^2(K_i)}\right)^{1/3}\right]|||v_h|||$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}|||\chi|||\left(\sum_{i=1}^{N_h}\|u\|^2_{H^2(K_i)}\right)^{1/2}|||v_h|||$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}\|u\|_{H^2(\Omega)}|||\chi|||\ |||v_h|||. \tag{4.21}$$

To estimate the third term on the right-hand side of (4.19), apply Hölder's inequality and the inverse inequality (2.6) to find, following estimate (4.22), that

$$\sum_{i=1}^{N_h}\int_{K_i}|\eta\nabla\chi\cdot\nabla v_h| \leq C\sum_{i=1}^{N_h}\|\eta\|_{L^6(K_i)}\|\nabla\chi\|_{L^3(K_i)}\|\nabla v_h\|_{L^2(K_i)}$$

$$\leq C\sum_{i=1}^{N_h}\frac{h_i^{4/3}}{p_i^{4/3}}\|u\|_{H^2(K_i)}\frac{p_i^{2/3}}{h_i^{2/3}}\|\nabla\chi\|_{L^2(K_i)}\|\nabla v_h\|_{L^2(K_i)}$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}\|u\|_{H^2(\Omega)}|||\chi|||\ |||v_h|||. \tag{4.22}$$

For the last term on the right-hand side of (4.19), we use Lemmas 2.1 and 2.5 to estimate it as

$$\sum_{i=1}^{N_h}\int_{K_i}|\eta\nabla\eta\cdot\nabla v_h| \leq C\sum_{i=1}^{N_h}\|\eta\|_{L^6(K_i)}\|\nabla\eta\|_{L^3(K_i)}\|\nabla v_h\|_{L^2(K_i)}$$

$$\leq C\frac{h^{2/3}}{p^{2/3}}\|u\|_{H^2(\Omega)}|||\eta|||\ |||v_h|||. \tag{4.23}$$

We substitute the estimates (4.20)–(4.23) into (4.19) to obtain

$$\sum_{i=1}^{N_h}\int_{K_i}|\tilde{a}_u(z)\zeta\nabla\zeta\cdot\nabla v_h| \le CC_a\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2\,|||v_h|||$$

$$+\,CC_a\frac{h^{2/3}}{p^{2/3}}\|u\|_{H^2(\Omega)}\left(|||\chi|||+|||\eta|||\right)|||v_h|||. \tag{4.24}$$

As in (4.19) the second term on the right-hand side of (4.18) becomes

$$\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\left\{\tilde{a}_u(z)\zeta\frac{\partial\zeta}{\partial\nu}\right\}[v_h]\right| \le C\left(C_a\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\chi\frac{\partial\chi}{\partial\nu}\right||[v_h]| + C_a\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\chi\frac{\partial\eta}{\partial\nu}\right||[v_h]|\right.$$

$$\left.+\,C_a\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\eta\frac{\partial\chi}{\partial\nu}\right||[v_h]| + C_a\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\eta\frac{\partial\eta}{\partial\nu}\right||[v_h]|\right). \tag{4.25}$$

Using Hölder's inequality, the inverse inequality (2.8), the trace inequalities (2.4)–(2.5), and (2.1), the first term on the right-hand side of (4.25) is estimated as

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\chi\frac{\partial\chi}{\partial\nu}\right||[v_h]| &\le C\sum_{e_k\in\Gamma_I}\left(\frac{|e_k|^{\beta/2}}{p_k}\|\chi\|_{L^4(e_k)}\|\nabla\chi\|_{L^4(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\right)\\ &\le C\sum_{e_k\in\Gamma_I}\frac{|e_k|^{\beta/2-1/4}}{p_k^{1/2}}\|\chi\|_{L^4(e_k)}\|\nabla\chi\|_{L^2(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\le C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{p_k^{1/2}}{|e_k|^{1-\beta/2}}\|\nabla\chi\|_{L^2(K_i)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\qquad\left(\|\chi\|^4_{L^4(K_i)}+h_i\|\chi\|^3_{L^6(K_i)}\|\nabla\chi\|_{L^2(K_i)}\right)^{1/4}\\ &\le C\left(\max_{1\le i\le N_h}\frac{p_i}{h_i^{2-\beta}}\right)^{1/2}|||\chi|||^2\,|||v_h|||.\end{aligned} \tag{4.26}$$

Similarly, we use Hölder's inequality, (2.1), the trace inequality (2.4), and Lemma 2.1 to estimate the second term on the right-hand side of (4.25) as

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\chi\frac{\partial\eta}{\partial\nu}\right||[v_h]| &\le C\sum_{e_k\in\Gamma_I}\left(\frac{|e_k|^{\beta/2}}{p_k}\|\chi\|_{L^4(e_k)}\|\nabla\eta\|_{L^4(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\right)\\ &\le C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{|e_k|^{\beta/2-1/2}}{p_k}\left(\|\chi\|^4_{L^4(K_i)}+h_i\|\chi\|^3_{L^6(K_i)}\|\nabla\chi\|_{L^2(K_i)}\right)^{1/4}\\ &\qquad\left(\|\nabla\eta\|^4_{L^4(K_i)}+h_i\|\nabla\eta\|^3_{L^6(K_i)}\|\nabla^2\eta\|_{L^2(K_i)}\right)^{1/4}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\le C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{h_i^{\beta/2-1/2}}{p_k}\left(\frac{h_i^2}{p_i^2}\|u\|^4_{H^2(K_i)}+h_i\frac{h_i}{p_i}\|u\|^4_{H^2(K_i)}\right)^{1/4}\\ &\qquad\left(\|\chi\|^4_{L^4(K_i)}+h_i\|\chi\|^3_{L^6(K_i)}\|\nabla\chi\|_{L^2(K_i)}\right)^{1/4}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\le C\|u\|_{H^2(\Omega)}\left(\frac{h^{\beta/2}}{p^{3/2}}+\frac{h^{\beta/2}}{p^{5/4}}\right)|||\chi|||\;|||v_h|||.\end{aligned} \tag{4.27}$$

For the third term on the right-hand side of (4.25), apply Hölder's inequality, the trace inequalities (2.4)–(2.5), and Lemma 2.1 to find that

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\eta\frac{\partial\chi}{\partial\nu}\right||[v_h]| &\le C\sum_{e_k\in\Gamma_I}\left(\frac{|e_k|^{\beta/2}}{p_k}\|\eta\|_{L^4(e_k)}\|\nabla\chi\|_{L^4(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\right)\\ &\le C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{|e_k|^{\beta/2-1/2}}{p_k^{1/2}}\|\nabla\chi\|_{L^2(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\qquad\left(\|\eta\|^4_{L^4(K_i)}+h_i\|\eta\|^3_{L^6(K_i)}\|\nabla\eta\|_{L^2(K_i)}\right)^{1/4}\\ &\le C\|u\|_{H^2(\Omega)}\left(\frac{h^{1/2+\beta/2}}{p}+\frac{h^{1/2+\beta/2}}{p^{3/4}}\right)|||\chi|||\ |||v_h|||. \end{aligned}\tag{4.28}$$

For the last term on the right-hand side of (4.25), we use an argument similar to that of (4.28) to obtain

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\eta\frac{\partial\eta}{\partial\nu}\right||[v_h]| &\le C\sum_{e_k\in\Gamma_I}\left(\frac{|e_k|^{\beta/2}}{p_k}\|\eta\|_{L^4(e_k)}\|\nabla\eta\|_{L^4(e_k)}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\right)\\ &\le C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{|e_k|^{\beta/2-1/2}}{p_k}\left(\|\eta\|^4_{L^4(K_i)}+h_i\|\eta\|^3_{L^6(K_i)}\|\nabla\eta\|_{L^2(K_i)}\right)^{1/4}\\ &\qquad\left(\|\nabla\eta\|^4_{L^4(K_i)}+h_i\|\nabla\eta\|^3_{L^6(K_i)}\|\nabla^2\eta\|_{L^2(K_i)}\right)^{1/4}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\ &\le C\|u\|_{H^2(\Omega)}\left(\frac{h^{\beta/2}}{p^{3/2}}+\frac{h^{\beta/2}}{p^{5/4}}\right)|||\eta|||\ |||v_h|||. \end{aligned}\tag{4.29}$$

We substitute the estimates (4.26)–(4.29) into (4.25). Since $\beta\ge 1$, we obtain

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\zeta\frac{\partial\zeta}{\partial\nu}\right||[v_h]| &\le CC_a\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2\ |||v_h|||\\ &\quad+CC_ah^{1/2}\|u\|_{H^2(\Omega)}(|||\chi|||+|||\eta|||)|||v_h|||. \end{aligned}\tag{4.30}$$

In a similar way, we find the following estimates for the third, fourth, and last terms on the right-hand side of (4.18):

$$\begin{aligned}\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\zeta\frac{\partial v_h}{\partial\nu}\right||[\zeta]| &\le CC_a\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2\ |||v_h|||\\ &\quad+CC_ah^{1/2}\|u\|_{H^2(\Omega)}(|||\chi|||+|||\eta|||)|||v_h|||, \end{aligned}\tag{4.31}$$

$$\begin{aligned}\sum_{i=1}^{N_h}\int_{K_i}|(\tilde a_{uu}(z)\nabla u)\zeta^2\cdot\nabla v_h| &\le CC_a|||\chi|||^2\ |||v_h|||\\ &\quad+CC_ah^{1/2}\|u\|_{H^1(\Omega)}|u|_{W^1_\infty(\Omega)}(|||\chi|||+|||\eta|||)|||v_h|||, \end{aligned}\tag{4.32}$$

and

$$\sum_{e_k\in\Gamma}\int_{e_k}\left|\left\{\left(\tilde{a}_{uu}(z)\frac{\partial u}{\partial\nu}\right)\zeta^2\right\}[v_h]\right| \le CC_a|||\chi|||^2\ |||v_h|||$$

$$+\ CC_a h^{1/2}\|u\|_{H^1(\Omega)}|u|_{W^1_\infty(\Omega)}(|||\chi||| + |||\eta|||)|||v_h|||. \tag{4.33}$$

Substituting the estimates (4.24) and (4.30)–(4.33) into (4.18), we complete the rest of the proof. □

LEMMA 4.3. *Let $\beta \ge 1$ and $z \in \mathcal{D}_p(\mathcal{T}_h)$. Set $y = S_h z$. Then there exists a positive constant C which is independent of h and p such that*

$$|||\mathcal{I}_h u - y||| \le CC_a\left[\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\mathcal{I}_h u - z|||^2 + C_u h^{1/2}|||\mathcal{I}_h u - z|||\right]$$
$$+\ CC_a\left[(1 + C_u h^{1/2})|||\mathcal{I}_h u - u|||_+\right].$$

Proof. Let $\chi = \mathcal{I}_h u - z$, $\eta = \mathcal{I}_h u - u$, and $\xi = \mathcal{I}_h u - y$. Set $v_h = \xi$ in (4.16). Then for the first term on the right-hand side of (4.16), use Lemma 3.3 to obtain

$$|\tilde{B}(u;\eta,\xi)| \le C|||\eta|||_+\ |||\xi|||. \tag{4.34}$$

Set $v_h = \xi$ in Lemma 4.2 to arrive at

$$|\mathcal{F}(z; z-u,\ \xi)| \le CC_a\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2\ |||\xi||| \tag{4.35}$$
$$+\ CC_a C_u h^{1/2}\left(|||\chi||| + |||\eta|||\right)\ |||\xi|||.$$

Substituting the estimates (4.34)–(4.35) into (4.16) and using the fact that $|||\eta||| \le |||\eta|||_+$, we obtain

$$|\tilde{B}(u;\xi,\ \xi) \le CC_a\left[\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2 + C_u h^{1/2}\left(|||\chi||| + |||\eta|||\right) + |||\eta|||_+\right]|||\xi|||$$
$$\le CC_a\left[\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2 + C_u h^{1/2}|||\chi|||\right]|||\xi|||$$
$$+\ CC_a(1 + C_u h^{1/2})|||\eta|||_+\ |||\xi|||.$$

Then using the Gårding inequality, that is, Lemma 3.2, we obtain

$$C_1|||\xi||^2 - C_2\|\xi\|^2 \le \tilde{B}(u;\xi,\ \xi)$$
$$\le CC_a\left[\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2 + C_u h^{1/2}|||\chi|||\right]|||\xi|||$$
$$+\ CC_a\left[(1 + C_u h^{1/2})|||\eta|||_+\right]|||\xi|||,$$

and hence

$$|||\xi||| \le CC_a\left[\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}|||\chi|||^2 + C_u h^{1/2}|||\chi|||\right] \tag{4.36}$$
$$+\ CC_a\left[(1 + C_u h^{1/2})|||\eta|||_+\right] + C\|\xi\|.$$

In order to complete the proof of the lemma, it is now sufficient to obtain an estimate for $\|\xi\|$. Setting $q = \xi$ and $v_h = \xi$ in Lemma 3.5, it follows that

$$\begin{aligned}\|\xi\|^2 &= \tilde{B}(u; \mathcal{I}_h u - y,\ \phi_h) = \tilde{B}(u; \mathcal{I}_h u - u,\ \phi_h) + \mathcal{F}(z; z-u, \phi_h)\\ &\le CC_a \left[\left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} |||\chi|||^2 + C_u h^{1/2} |||\chi||| + (1 + C_u h^{1/2}) |||\eta|||_+ \right] |||\phi_h|||.\end{aligned}$$

Therefore, using the fact from Lemma 3.5 that $|||\phi_h||| \le C\|\xi\|$, we obtain

$$\|\xi\| \le CC_a \left[\left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} |||\chi|||^2 + h^{1/2} C_u |||\chi||| + (1 + C_u h^{1/2}) |||\eta|||_+ \right]. \tag{4.37}$$

We combine inequalities (4.36) and (4.37) to complete the rest of the proof. ∎

THEOREM 4.4. *Let $\beta = 1$. Then, for sufficiently small h, there is a $\delta = \delta(h, p)$ such that the map S_h maps $\mathcal{O}_\delta(\mathcal{I}_h u)$ into itself.*

Proof. Let $z \in \mathcal{O}_\delta(\mathcal{I}_h u)$ and set $y = S_h z$. Choose $\delta = \frac{1}{h^\epsilon} |||\mathcal{I}_h u - u|||_+$ for some $0 < \epsilon \le 1/4$. Then using the fact that $z \in \mathcal{O}_\delta(\mathcal{I}_h u)$, and using Lemma 3.4 with $s_i \ge 2,\ p_i \ge 1$ and (4.15), we obtain

$$\begin{aligned}\left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} |||\mathcal{I}_h u - z|||^2 &\le \left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} \delta^2\\ &\le \left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} \frac{1}{h^\epsilon} |||\mathcal{I}_h u - u|||_+ \ \delta\\ &\le C \frac{1}{h^\epsilon} \left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} \left[\sum_{i=1}^{N_h} \frac{h_i^2}{p_i} \|u\|^2_{H^2(K_i)} \right]^{1/2} \delta\\ &\le C \frac{1}{h^\epsilon} \left(\max_{1\le i\le N_h} \frac{p_i}{h_i} \right)^{1/2} \left(\max_{1\le i\le N_h} \frac{h_i^2}{p_i} \right)^{1/2} \|u\|_{H^2(\Omega)}\ \delta\\ &\le CC_Q C_u h^{1/2-\epsilon}\ \delta. \qquad (4.38)\end{aligned}$$

We substitute (4.38) in Lemma 4.3 to obtain

$$\begin{aligned}|||\mathcal{I}_h u - y||| &\le CC_a \left(C_Q C_u h^{1/2-\epsilon}\ \delta + C_u h^{1/2} \delta + (1 + C_u h^{1/2}) h^\epsilon \delta \right)\\ &\le CC_a \left(C_Q C_u h^{1/2-\epsilon} + C_u h^{1/2} + (1 + C_u h^{1/2}) h^\epsilon \right)\ \delta. \qquad (4.39)\end{aligned}$$

Choose h small so that $CC_a \left(C_Q C_u h^{1/2-\epsilon} + C_u h^{1/2} + (1 + C_u h^{1/2}) h^\epsilon \right) \le 1$, and hence S_h maps $\mathcal{O}_\delta(\mathcal{I}_h u)$ into itself. This completes the rest of the proof. ∎

THEOREM 4.5. *Let $\beta = 1$. There is a $\delta = \delta(h,\ p) > 0$ and a positive constant C such that the following holds for any given $z_1, z_2 \in \mathcal{O}_\delta(\mathcal{I}_h u)$ and $0 < \epsilon \le \frac{1}{4}$:*

$$|||S_h z_1 - S_h z_2||| \le CC_a C_Q C_u h^\epsilon\ |||z_1 - z_2|||.$$

Proof. Set $y_1 = S_h z_1$ and $y_2 = S_h z_2$. Using the definition (4.16) of S_h, it is clear that

$$\tilde{B}(u; y_2 - y_1,\ v_h) = \mathcal{F}(z_1; z_1 - u,\ v_h) - \mathcal{F}(z_2; z_2 - u,\ v_h). \tag{4.40}$$

Choose $\delta = \frac{1}{h^\epsilon} |||\eta|||_+$ for some $0 < \epsilon \le 1/4$ with $\eta = u - \mathcal{I}_h u$. Set $\chi = z_1 - z_2$. Using Taylor's formulae (2.4)–(2.5) and (4.18), we rewrite the first terms from each of the

terms on the right-hand side of (4.40) on each K_i as

$$\begin{aligned}\tilde{a}_{uu}(z_1)(z_1-u)^2-\tilde{a}_{uu}(z_2)(z_2-u)^2 &= a(z_1)-a(z_2)+a_u(u)(z_2-z_1)\\ &= a(z_1)-a(z_2)-a_u(z_2)\chi+(a_u(z_2)-a_u(u))\,\chi\\ &= \tilde{R}(z_1,z_2)\chi^2+\tilde{a}_{uu}(z_2)(z_2-u)\chi,\end{aligned}$$

where $\tilde{R}(z_1,z_2)=\int_0^1(1-t)a_{uu}(z_1+t[z_1-z_2])dt$. Similarly, other terms on the right-hand side of (4.40) can be rewritten in a similar fashion. Now, an argument similar to that of Lemma 4.2 implies that

$$\begin{aligned}|\mathcal{F}(z_1;z_1-u,\ v_h)-\mathcal{F}(z_2;z_2-u,\ v_h)| &\le CC_a\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)^{1/2}\Big[\ |||\chi|||^2\ |||v_h|||\\ &\quad+|||z_1-\mathcal{I}_hu|||\ |||\chi|||\ |||v_h|||+|||\mathcal{I}_hu-z_2|||\ |||\chi|||\ |||v_h|||\ \Big]\\ &\le CC_aC_QC_uh^{\epsilon}\ |||\chi|||\ |||v_h|||. \qquad (4.41)\end{aligned}$$

We set $v_h=(y_2-y_1)$ in (4.40) and (4.41). Then, using Lemmas 3.2 and 3.5, we obtain

$$|||y_1-y_2|||\le CC_aC_QC_uh^{\epsilon}\ |||z_1-z_2|||,$$

and this completes the proof. ∎

For sufficiently small h, we deduce from Theorem 4.5 that there is a $\delta>0$ such that the map $S_h:\mathcal{O}_\delta(\mathcal{I}_hu)\to\mathcal{O}_\delta(\mathcal{I}_hu)$ is continuous. Hence, using Theorems 4.4 and 4.5 and Brouwer's fixed point theorem, we conclude for small h that there exists a $u_h\in\mathcal{O}_\delta(\mathcal{I}_hu)$ such that $S_hu_h=u_h$. Then, from Theorem 4.5, it is clear that u_h is the unique fixed point of S_h. Hence, we have proved that there exists a unique solution u_h to problem (4.4).

4.3. A priori error estimates. Note that, from (4.39), u_h satisfies

$$|||\mathcal{I}_hu-u_h|||\le CC_a\left(C_QC_uh^{1/2-\epsilon}+C_uh^{1/2}+(1+C_uh^{1/2})h^{\epsilon}\right)\ \delta.$$

Since $\delta=\frac{1}{h^{\epsilon}}|||\eta|||_+$ for any $0<\epsilon\le 1/4$, we obtain

$$\begin{aligned}|||\mathcal{I}_hu-u_h||| &\le CC_a\left(C_QC_uh^{1/2-\epsilon}+C_uh^{1/2}+(1+C_uh^{1/2})h^{\epsilon}\right)\ \frac{1}{h^{\epsilon}}|||\eta|||_+\\ &\le CC_aC_QC_u|||\eta|||_+. \qquad (4.42)\end{aligned}$$

Using Lemma 3.4, estimate (4.42), and a triangle inequality, we have obtained the following estimate which is optimal in h and suboptimal in p.

THEOREM 4.6. *Let $\beta=1$. Then, for sufficiently small h, there exists a constant $C=C(\alpha,M)$ which is independent of h and p such that the solution u_h of the problem* (4.4) *satisfies*

$$|||u-u_h|||\le CC_aC_QC_u\left(\sum_{i=1}^{N_h}\frac{h_i^{2\mu_i-2}}{p_i^{2s_i-3}}\|u\|^2_{H^{s_i}(K_i)}\right)^{1/2},$$

where $\mu_i=\min\{p_i+1,\ s_i\}$, and C_a, C_Q, and C_u are as in (4.8), (4.14), *and* (4.17), *respectively.*

Remark 4.1. Note that the estimate obtained in Theorem 4.6 is optimal in h and suboptimal in p. However, this results leads to precisely the same h-optimal and p-suboptimal rate of convergence in the broken H^1-norm as in the case of linear elliptic problem, when it is approximated by the NIPG method [23, Theorem 3.1], [16].

4.4. Optimal error estimates in the broken energy norm and the L^2-norm, when $u \in H_p^s(\Omega)$, $s \geq 2$. In the following, with the additional assumptions on the mesh and g, we prove optimal error estimates in the broken energy norm as well as in the L^2-norm. Therefore, along with Assumption Q, we assume that $\mathcal{T}_h$ is a regular subdivision of Ω into triangles or rectangles and $\mathcal{D}_p(\mathcal{T}_h) = \mathcal{D}_p^*(\mathcal{T}_h)$. We also assume that there is a $v \in \mathcal{D}_p^*(\mathcal{T}_h)$ such that $g = v|_{\partial\Omega}$.

We note from [23, pp. 908–913] that by using a continuous interpolant $\mathcal{I}_h^c u \in \mathcal{D}_p(\mathcal{T}_h) \cap \bar{C}^0(\Omega)$ of u instead of $\mathcal{I}_h u$, which may be discontinuous across the edges in Γ_I, the optimal rate of convergence can be recovered. Since the construction of $\mathcal{I}_h^c$ is not discussed in [23], we present below the results related to the construction of $\mathcal{I}_h^c$. The idea of constructing $\mathcal{I}_h^c u \in \mathcal{D}_p^*(\mathcal{T}_h) \cap C^0(\bar{\Omega})$ is to modify the sequence $u_p^{h_i} \in \mathcal{D}_p^*(\mathcal{T}_h)$ in Lemma 2.1 by adding suitable piecewise polynomials on each K_i. For more on the construction of $\mathcal{I}_h^c$, we refer to [5, Theorem 4.1], [6, Theorem 4.6], [1, Theorem 4], and [2, Theorem 3]. Following these constructions, we prove the following lemma.

LEMMA 4.7. *Let $\mathcal{T}_h$ be a regular subdivision. Then, for a given $\phi \in H_p^s(\Omega)$, $s \geq 2$, there exists a positive constant C_{A_c} (depending on s but independent of ϕ, p, and h) and an $\mathcal{I}_h^c\phi \in \mathcal{D}_p^*(\mathcal{T}_h) \cap C^0(\bar{\Omega})$ such that for all K_i and e_k*

(i) $\mathcal{I}_h^c\phi|_{\partial\Omega} = \phi|_{\partial\Omega}$;

(ii) *for any $0 \leq l \leq s$ and $0 \leq l \leq 2$,*

$$\|\phi - \mathcal{I}_h^c\phi\|_{H^l(K_i)} \leq C_{A_c} \frac{h_i^{\mu-l}}{p^{s-l-\delta_1}} \left(\sum_{K_j \in K_i^*} \|\phi\|_{H^s(K_j)}^2 \right)^{1/2},$$

where $\delta_1 = 0$ if $l = 0, 1$ and $\delta_1 = 1$ if $l = 2$;

(iii) *for $s > l + \frac{1}{2}$ and $l = 0, 1$,*

$$|\phi - \mathcal{I}_h^c\phi|_{H^l(e_k)} \leq C_{A_c} \frac{h_i^{\mu-l-1/2}}{p^{s-l-1/2-\delta_2}} \left(\sum_{K_j \in K_i^*} \|\phi\|_{H^s(K_j)}^2 \right)^{1/2},$$

where $\delta_2 = 0$ if $l = 0$ and $\delta_2 = 1/2$ if $l = 1$;

(iv) *for $0 \leq l \leq s - 1 + 2/r$ and $l = 0,\ 1$,*

$$\|\phi - \mathcal{I}_h^c\phi\|_{W_r^l(K_i)} \leq C_{A_c} \frac{h_i^{\mu-l-1+2/r}}{p^{s-l-1+2/r}} \left(\sum_{K_j \in K_i^*} \|\phi\|_{H^s(K_j)}^2 \right)^{1/2},$$

where $\mu = \min(s,\ p+1)$, $K_i^* = \{K_j : |\partial K_i \cap \partial K_j| > 0\}$, and e_k is an edge on ∂K_i.

Remark 4.2. Note that Assumption P(1) implies that the cardinality of K_i^* is bounded by N_κ for all i.

Proof of Lemma 4.7. Statement (i) in the lemma is proved in [6, Theorem 4.6]. For $0 \leq l \leq 1$, the approximation property in (ii) is proved in [2, Theorem 3], [6, Theorem 4.6]. Using the inverse inequality (2.7) and Lemma 2.1, the proof of property (ii) for $l = 2$ is as follows:

$$\begin{aligned}\|\phi - \mathcal{I}_h^c\phi\|_{H^2(K_i)} &\leq \|\phi - \mathcal{I}_h\phi\|_{H^2(K_i)} + \|\mathcal{I}_h\phi - \mathcal{I}_h^c\phi\|_{H^2(K_i)} \\ &\leq \|\phi - \mathcal{I}_h\phi\|_{H^2(K_i)} + C\frac{p^2}{h_i}\|\mathcal{I}_h\phi - \mathcal{I}_h^c\phi\|_{H^1(K_i)}\end{aligned}$$

$$\le \|\phi - \mathcal{I}_h\phi\|_{H^2(K_i)} + C\frac{p^2}{h_i}\|\phi - \mathcal{I}_h\phi\|_{H^1(K_i)} + \frac{p^2}{h_i}\|\phi - \mathcal{I}_h^c\phi\|_{H^1(K_i)}$$
$$\le C\frac{h_i^{\mu-2}}{p^{s-3}}\left(\sum_{K_j\in K^*}\|\phi\|^2_{H^s(K_j)}\right)^{1/2}.$$

Then, using the trace inequality (2.4), we deduce property (iii) of the lemma. Finally, using arguments similar to those of [2, Theorem 3], property (iv) can be easily proved. ∎

Remark 4.3. The approximation property (ii) for $l = 2$ and property (iii) for $l = 1$ are not optimal in terms of p. But as we see in our next analysis, these properties do not affect the accuracy of the approximation u_h.

LEMMA 4.8. *Let $\mathcal{T}_h$ be a regular subdivision and let $\mathcal{D}_p(\mathcal{T}_h) = \mathcal{D}_p^*(\mathcal{T}_h)$. Then, for any $\beta \ge 1$ and given any $\phi \in H_p^s(\Omega)$, $s \ge 2$, there exists a constant C independent of h and p such that*

$$|||\phi - \mathcal{I}_h^c\phi|||_+ \le C\left(\sum_{i=1}^{N_h}\frac{h_i^{2\mu-2}}{p^{2s-2}}\|\phi\|^2_{H^s(K_i)}\right)^{1/2}, \tag{4.43}$$

where $\mu = \min\{p+1, s\}$.

Proof. Let $\eta^* = \phi - \mathcal{I}_h^c\phi$. Since $\mathcal{I}_h^c\phi \in \mathcal{D}_p^*(\mathcal{T}_h) \cap C^0(\bar\Omega)$ and $\mathcal{I}_h^c\phi|_{\partial\Omega} = \phi|_{\partial\Omega}$, the jump $[\phi - \mathcal{I}_h^c\phi] = 0$ on each $e_k \in \Gamma$. Hence, using (2.3) and Lemma 4.7, we obtain

$$|||\phi - \mathcal{I}_h^c\phi|||_+^2 = \sum_{i=1}^{N_h}\int_{K_i}|\nabla\eta^*|^2 + \sum_{e_k\in\Gamma}\int_{e_k}\frac{|e_k|^\beta}{p^2}\left\{\frac{\partial\eta*}{\partial\nu}\right\}^2$$
$$\le C\sum_{i=1}^{N_h}\sum_{K_j\in K_i^*}\left(\frac{h_i^{2\mu-2}}{p^{2s-2}}\|\phi\|^2_{H^s(K_j)} + \frac{h_i^\beta}{p^2}\frac{h_i^{2\mu-3}}{p^{2s-4}}\|\phi\|^2_{H^s(K_j)}\right)$$
$$\le C\sum_{i=1}^{N_h}\left(\frac{h_i^{2\mu-2}}{p^{2s-2}}\|\phi\|^2_{H^s(K_i)} + \frac{h_i^{2\mu-2}}{p^{2s-2}}\|\phi\|^2_{H^s(K_i)}\right).$$

This completes the rest of the proof. ∎

THEOREM 4.9. *Let $\mathcal{T}_h$ be a regular subdivision and let $\mathcal{D}_p(\mathcal{T}_h) = \mathcal{D}_p^*(\mathcal{T}_h)$. Suppose that $u \in H_p^s(\Omega)$, $s \ge 2$. Then, for any $\beta \ge 1$ and for sufficiently small h, there exists a constant $C = C(\alpha, M)$ which is independent of h and p such that the solution u_h of problem* (4.4) *satisfies*

$$|||u - u_h||| \le CC_aC_QC_u\left(\sum_{i=1}^{N_h}\frac{h^{2\mu-2}}{p^{2s-2}}\|u\|^2_{H^s(K_i)}\right)^{1/2},$$

where $\mu = \min\{p+1,\ s\}$, and C_a, C_Q, and C_u are as in (4.8), (4.14), *and* (4.17), *respectively.*

Proof. Under the hypotheses on the mesh, there is an $\mathcal{I}_h^c\phi \in \mathcal{D}_p^*(\mathcal{T}_h)\cap C^0(\bar\Omega)$ such that $\mathcal{I}_h^c\phi|_{\partial\Omega} = \phi|_{\partial\Omega}$. Hence, the jump $[\phi - \mathcal{I}_h^c\phi] = 0$ on each $e_k \in \Gamma$. Then, using Lemmas 3.2 and 4.7, it is easy to prove Lemma 3.5 for any $\beta \ge 1$. Now, note that estimates (4.27) and (4.29) in Lemma 4.2 depend on the approximation property (ii) for $l = 2$. Though there is a suboptimality in this property, we still obtain the results

in Lemma 4.2 by replacing $\mathcal{I}_h u$ by $\mathcal{I}_h^c u$ and for any $\beta \geq 1$. Below, we only indicate the changes to be made in the text of the proof of Lemma 4.2. We now consider the term on the left-hand side of (4.27) with $\eta = u - \mathcal{I}_h^c u$. Then, using Hölder's inequality, the trace inequality (2.4), and Lemma 4.7, we estimate this term as follows:

$$\begin{aligned}
\sum_{e_k\in\Gamma_I}\int_{e_k}\left|\left\{\chi\frac{\partial\eta}{\partial\nu}\right\}[v_h]\right| &\leq C\sum_{e_k\in\Gamma_I}\left(\frac{|e_k|^{\beta/2}}{p}\|\chi\|_{L^4(e_k)}\|\nabla\eta\|_{L^4(e_k)}\left(\int_{e_k}\frac{p^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\right)\\
&\leq C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{|e_k|^{\beta/2-1/2}}{p}\left(\|\chi\|_{L^4(K_i)}^4+h_i\|\chi\|_{L^6(K_i)}^3\|\nabla\chi\|_{L^2(K_i)}\right)^{1/4}\\
&\quad\left(\|\nabla\eta\|_{L^4(K_i)}^4+h_i\|\nabla\eta\|_{L^6(K_i)}^3\|\nabla^2\eta\|_{L^2(K_i)}\right)^{1/4}\left(\int_{e_k}\frac{p^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\
&\leq C\sum_{i=1}^{N_h}\sum_{e_k\in\partial K_i}\frac{h^{\beta/2-1/2}}{p}\left(\frac{h^2}{p^2}\|u\|_{H^2(K_i)}^4+h\frac{h}{p}\frac{1}{p-1}\|u\|_{H^2(K_i)}^4\right)^{1/4}\\
&\quad\left(\|\chi\|_{L^4(K_i)}^4+h_i\|\chi\|_{L^6(K_i)}^3\|\nabla\chi\|_{L^2(K_i)}\right)^{1/4}\left(\int_{e_k}\frac{p^2}{|e_k|^\beta}[v_h]^2\right)^{1/2}\\
&\leq C\|u\|_{H^2(\Omega)}\left(\frac{h^{\beta/2}}{p^{3/2}}+\frac{h^{\beta/2}}{p}\right)|||\chi|||\;|||v_h|||. \qquad (4.44)
\end{aligned}$$

Similarly, a replacement of $\mathcal{I}_h u$ by $\mathcal{I}_h^c u$ in Lemma 4.3 and an application of Lemma 4.8 yield the proofs of Theorems 4.4 and 4.5 for any $\beta \geq 1$. Hence, the estimate (4.42) holds for any $\beta \geq 1$ with $\eta = u - \mathcal{I}_h^c u$. Then an application of Lemma 4.8 completes the rest of the proof. ∎

Now, we proceed to derive the L^2-norm error estimate. Since the SIPG method is adjoint consistent, one can expect optimal L^2-norm error estimates in terms of h. But for the NIPG method, the bilinear form is not adjoint consistent. In general, it may be difficult to prove the optimal L^2 error estimate in terms of h. However, if $u \in H_p^s(\Omega),\ s \geq 2$, it is possible to obtain optimal L^2-norm error estimates in terms of both h and p by increasing the penalty on the uniform regular subdivision. Assume that the hypotheses of Theorem 4.9 hold. Of course, these assumptions are not necessary to derive optimal L^2-norm error estimate in terms of h for the SIPG method. Below, we appeal to the Aubin–Nitsche duality argument to estimate $\|u - u_h\|$.

THEOREM 4.10. *Let $a \in C_b^2(\bar{\Omega}\times\mathbb{R})$ and $u \in W_\infty^1(\Omega)$. Suppose that $\beta \geq 3$ when $\theta = -1$, and $\beta \geq 1$ when $\theta = 1$. Further, assume that the hypotheses of Theorem 4.9 hold. Then there exists a constant $C = C(\alpha,\ M)$ such that for small h*

$$\|u - u_h\| \leq CC_Q C_a C_u^2 \frac{h^\mu}{p^s}\|u\|_{\mathbf{s},h},$$

where $\mu = \min\{p+1,\ s\}$, and C_a, C_Q, and C_u are as in (4.8), (4.14), and (4.17), respectively.

Proof. Our assumptions on a and u imply that there is a unique solution $\phi \in H^2(\Omega)$ to the following linear elliptic problem:

$$\begin{aligned}
-\nabla\cdot(a(u)\nabla\phi) + (a_u(u)\nabla u)\cdot\nabla\phi &= e \quad \text{on } \Omega,\\
\phi &= 0 \quad \text{on } \partial\Omega,
\end{aligned}$$

and ϕ satisfies the following elliptic regularity (see [15, Lemma 9.17]):

$$\|\phi\|_{H^2(\Omega)} \le C\|e\|_{L^2(\Omega)}. \tag{4.45}$$

Note that

$$\|e\|^2 = B(u;e,\ \phi) + \int_\Omega (a_u(u)\nabla u)\cdot e\nabla\phi dx + (\theta-1)\sum_{e_k\in\Gamma}\int_{e_k}\left\{a(u)\frac{\partial\phi}{\partial\nu}\right\}[e]. \tag{4.46}$$

The first term on the right-hand side of (4.46) is rewritten as

$$\begin{aligned} B(u;e,\ \phi) &= B(u;u,\ \phi) - B(u_h;u_h,\ \phi) + B(u_h;u_h,\ \phi) - B(u;u_h,\ \phi)\\ &= (B(u;u,\ \phi-\chi) - B(u_h;u_h,\ \phi-\chi)) + (B(u_h;u_h,\ \phi) - B(u;u_h,\ \phi))\\ &= I + II, \end{aligned} \tag{4.47}$$

where $\chi = \mathcal{I}_h^c\phi$ such that $\chi|_{\partial\Omega} = 0$. For the first term on the right-hand side of (4.47), we note that

$$\begin{aligned} I &= B(u;u,\ \phi-\chi) - B(u_h;u,\ \phi-\chi) + B(u_h;u,\ \phi-\chi) - B(u_h;u_h,\ \phi-\chi)\\ &= \sum_{i=1}^{N_h}\int_{K_i}(a(u)-a(u_h))\nabla u\cdot\nabla(\phi-\chi) + \sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla(u-u_h)\cdot\nabla(\phi-\chi)\\ &\quad - \sum_{e_k\in\Gamma}\int_{e_k}\left\{(a(u_h)-a(u))\frac{\partial(\phi-\chi)}{\partial\nu}\right\}[u-u_h] + \sum_{i=1}^{N_h}\int_{K_i}a(u)\nabla(u-u_h)\cdot\nabla(\phi-\chi)\\ &\quad - \sum_{e_k\in\Gamma}\int_{e_k}\left\{a(u)\frac{\partial(\phi-\chi)}{\partial\nu}\right\}[u-u_h]. \end{aligned} \tag{4.48}$$

Since $u\in W^{1,\infty}(\Omega)$, we use the Cauchy–Schwarz inequality, Lemma 4.8, to bound the first and fourth terms on the right-hand side of (4.48) as

$$\begin{aligned} \left|\sum_{i=1}^{N_h}\int_{K_i}(a(u)-a(u_h))\nabla u\cdot\nabla(\phi-\chi)\right| &\le C_u\|e\|\ \|\phi-\chi\|_{H^1(\Omega)}\\ &\le CC_u\frac{h}{p}\|e\|\ \|\phi\|_{H^2(\Omega)} \end{aligned} \tag{4.49}$$

and

$$\begin{aligned} \left|\sum_{i=1}^{N_h}\int_{K_i}a(u)\nabla(u-u_h)\cdot\nabla(\phi-\chi)\right| &\le M|||e|||\ \|\phi-\chi\|_{H^1(\Omega)}\\ &\le C\frac{h}{p}|||e|||\ \|\phi\|_{H^2(\Omega)}. \end{aligned} \tag{4.50}$$

Now, using Hölder's inequality and Lemmas 4.8 and 2.5, we estimate the second term on the right-hand side of (4.48) as

$$\begin{aligned} \left|\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla(u_h-u)\cdot\nabla(\phi-\chi)\right| &\le C\ \|e\|_{L^3(\Omega)}|||e|||\ \|\phi-\chi||_{W_6^1(\Omega)}\\ &\le C\ |||e|||^2\ \|\phi\|_{H^2(\Omega)}. \end{aligned} \tag{4.51}$$

Next, using arguments similar to those of (4.44), we bound the third term on the right-hand side of (4.48) as

$$\begin{aligned}\left|\sum_{e_k\in\Gamma}\int_{e_k}\left\{(a(u_h)-a(u))\frac{\partial(\phi-\chi)}{\partial\nu}\right\}[u-u_h]\right| &\le CC_a\sum_{e_k\in\Gamma}\frac{|e_k|^{\beta/2}}{p_k}\|e\|_{L^4(e_k)}|\phi-\chi|_{W_4^1(e_k)}\\ &\quad\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[e]^2ds\right)^{1/2}\\ &\le CC_a|||e|||^2\ \|\phi\|_{H^2(\Omega)}. \end{aligned}\tag{4.52}$$

Then, using Lemma 4.7, the fifth term on the right-hand side of (4.48) is estimated as

$$\left|\sum_{e_k\in\Gamma}\int_{e_k}\left\{a(u)\frac{\partial(\phi-\chi)}{\partial\nu}\right\}[u-u_h]\right|\le C\frac{h^{\beta/2+1/2}}{p}|||e|||\ \|\phi\|_{H^2(\Omega)}.\tag{4.53}$$

Hence using (4.45), we obtain, for any $\beta\ge 1$,

$$|I|\le CC_uC_a\left(|||e|||^2+\frac{h}{p}|||e||||+\|e\|\right)\|e\|.\tag{4.54}$$

For the second term in (4.47), that is, II, we note that $[u]=0$ on $e_k\in\Gamma_I$. Thus,

$$\begin{aligned}II&=\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla u_h\cdot\nabla\phi-\int_{\Gamma_I}\left\{((a(u_h)-a(u))\frac{\partial\phi}{\partial\nu}\right\}[u_h-u]\\ &=\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla(u_h-u)\cdot\nabla\phi+\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla u\cdot\nabla\phi\\ &\quad-\int_{\Gamma_I}\left\{((a(u_h)-a(u))\frac{\partial\phi}{\partial\nu}\right\}[u_h-u]. \end{aligned}\tag{4.55}$$

Use Hölder's inequality, the Sobolev imbedding theorem, and Lemma 2.5 to estimate the first term on the right-hand side of (4.55) as

$$\begin{aligned}\left|\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u))\nabla(u_h-u)\cdot\nabla\phi\right| &\le C_a\|e\|_{L^3(\Omega)}|e|_{1,h}\|\phi||_{W_6^1(\Omega)}\\ &\le CC_a|||e|||^2\ \|\phi\|_{H^2(\Omega)}. \end{aligned}\tag{4.56}$$

Now for the third term on the right-hand side of (4.55), using Hölder's inequality, the trace inequality (2.4), and Lemma 2.5, we arrive at

$$\begin{aligned}\left|\sum_{e_k\Gamma_I}\int_{e_k}\left\{((a(u_h)-a(u))\frac{\partial\phi}{\partial\nu}\right\}[u_h-u]\right| &\le CC_a\sum_{e_k\Gamma_I}\int_{e_k}\left|e\frac{\partial\phi}{\partial\nu}\right||[e]|\\ &\le CC_a\sum_{e_k\Gamma_I}\frac{|e_k|^{\beta/2}}{p_k}\|e\|_{L^4(e_k)}\|\phi\|_{W_4^1(e_k)}\mathcal{J}^{1,\beta}(e,e)^{1/2}\\ &\le CC_a\frac{h^{\beta/2-1/2}}{p}|||e|||^2\ \|\phi\|_{H^2(\Omega)}. \end{aligned}\tag{4.57}$$

We rewrite the second term on the right-hand side of (4.55) together with the second term on the right-hand side of (4.46) as

$$\sum_{i=1}^{N_h}\int_{K_i}(a(u_h)-a(u)+a_u(u)(u-u_h))\nabla u\cdot\nabla\phi=\sum_{i=1}^{N_h}\int_{K_i}\tilde{a}_{uu}(u_h)(u-u_h)^2\nabla u\cdot\nabla\phi,$$

and then we use Lemma 2.5 to obtain

$$\begin{aligned}\left|\sum_{i=1}^{N_h}\int_{K_i}\tilde{a}_{uu}(u_h)(u-u_h)^2\nabla u\cdot\nabla\phi\right| &\le C_aC_u\left|\sum_{i=1}^{N_h}\int_{K_i}(u-u_h)^2\cdot\nabla\phi\right|\\ &\le CC_aC_u|||e|||^2\ \|\phi\|_{H^2(\Omega)}. \qquad (4.58)\end{aligned}$$

Hence using (4.45), for any $\beta\ge 1$ we obtain

$$|II|\le CC_uC_a|||e|||^2\ \|e\|. \qquad (4.59)$$

For $\theta=1$, the third term on the right-hand side of (4.46) becomes zero. For $\theta=-1$, using the trace inequality (2.4) and (4.45), the third term on the right-hand side of (3.10) is estimated as

$$\begin{aligned}\sum_{e_k\in\Gamma}\int_{e_k}\left\{a(u)\frac{\partial\phi}{\partial\nu}[e]\right\} &\le C\sum_{e_k\in\Gamma}\left(\int_{e_k}\frac{|e_k|^\beta}{p_k^2}\left|\frac{\partial\phi}{\partial\nu}\right|^2\right)^{1/2}\left(\int_{e_k}\frac{p_k^2}{|e_k|^\beta}[e]^2\right)^{1/2}\\ &\le C\frac{h^{\beta/2-1/2}}{p}|||e|||\ \|e\|. \qquad (4.60)\end{aligned}$$

We combine the estimates (4.54)–(4.60) to obtain

$$\|u-u_h\|\le C\left(|||u-u_h|||+\frac{h}{p}+|\theta-1|\frac{h^{\beta/2-1/2}}{p}\right)|||u-u_h|||.$$

Using Theorem 4.9 completes the rest of the proof. ∎

Remark 4.4. In the proof of Lemma 4.2 and the subsequent results in section 4, we have assumed that the range of $\frac{\partial^l a}{\partial u^l}(x,v),\ x\in\bar{\Omega},\ v\in\mathbb{R},\ l=0,1,2$, is a compact set, say $[m,M]\subset\mathbb{R}$. However, if $u\in H^{5/2}(\Omega)$, we note that asymptotically only the values of $v\in[m_u-\delta^*,M_u+\delta^*]\subset\mathbb{R}$, where $0<\delta^*<1$, $m_u=\inf\{u(x):x\in\bar{\Omega}\}$, and $M_u=\sup\{u(x):x\in\bar{\Omega}\}$, are considered to derive the proof of Lemma 4.2 and the subsequent results. To be more precise, the terms $\tilde{a}_u(z)$ and $\tilde{a}_{uu}(z),\ z\in\mathcal{O}_\delta(\mathcal{I}_hu)$, in (4.18) (see the estimates (4.19)–(4.33)), can be estimated as follows. Since $z\in\mathcal{O}_\delta(\mathcal{I}_hu)$, where $\delta=h^{-\epsilon}|||u-\mathcal{I}_hu|||_+,\ 0<\epsilon\le 1/4$, using the inverse inequality (2.6) and Lemmas 2.5 and 2.1, we find that

$$\begin{aligned}\|z-u\|_{L^\infty(\Omega)} &\le \|z-\mathcal{I}_hu\|_{L^\infty(\Omega)}+\|\mathcal{I}_hu-u\|_{L^\infty(\Omega)}\\ &\le C\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)\|z-\mathcal{I}_hu\|_{L^2(\Omega)}+\|\mathcal{I}_hu-u\|_{L^\infty(\Omega)}\\ &\le C\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)|||z-\mathcal{I}_hu|||+\|\mathcal{I}_hu-u\|_{L^\infty(\Omega)}\\ &\le Ch^{-\epsilon}\left(\max_{1\le i\le N_h}\frac{p_i}{h_i}\right)|||u-\mathcal{I}_hu|||_+ +\|\mathcal{I}_hu-u\|_{L^\infty(\Omega)}\end{aligned}$$

$$\leq Ch^{-\epsilon}\left(\max_{1\leq i\leq N_h}\frac{p_i}{h_i}\right)\left(\sum_{i=1}^{N_h}\frac{h_i^3}{p_i^2}\|u\|^2_{H^{5/2}(K_i)}\right)^{1/2}+C\frac{h}{p}\|u\|_{H^2(\Omega)}$$

$$\leq Ch^{-\epsilon}\left(\max_{1\leq i\leq N_h}\frac{p_i}{h_i}\right)\left(\max_{1\leq i\leq N_h}\frac{h_i^{3/2}}{p_i}\right)\|u\|_{H^{5/2}(\Omega)}+C\frac{h}{p}\|u\|_{H^2(\Omega)}$$

$$\leq Ch^{1/2-\epsilon}\|u\|_{H^{5/2}(\Omega)}. \tag{4.61}$$

Therefore, for sufficiently small h, $\|z\|_{L^\infty(\Omega)} \leq \delta^* + \|u\|_{L^\infty(\Omega)}$, where $0 < \delta^* < 1$. Now, since the nonlinear functions a_u and a_{uu} are continuous, they map the compact set $[m_u - \delta^*, M_u + \delta^*]$ into a compact set in $\mathbb{R}$, and hence the results in Lemma 4.2 and the subsequent results in section 4 remain valid when $a(v)$, $a_u(v)$, and $a_{uu}(v)$ are bounded for bounded u. Finally, we remark that when $u \in H^2(\Omega)$, it may be possible to show the boundedness of $a(v)$ and its derivatives for $v \in [m_u - \delta^*, M_u + \delta^*] \subset \mathbb{R}$ by using better inverse inequalities, say in the first line of (4.61), applying $\|z - \mathcal{I}_h u\|_{L^\infty(K_i)} \leq Cp_i^{1/2}h_i^{-1/4}\|z - \mathcal{I}_h u\|_{L^8(K_i)}$ (see [20, p. 916]), and using the Poincaré inequality in Lemma 2.5 to complete the estimate (4.61).

5. Numerical experiments. In this section, we discuss the performance of the proposed NIPG and SIPG methods for the numerical approximation of the quasi-linear elliptic problem (4.1)–(4.2). For this, we consider the following nonlinear elliptic problem:

$$\begin{aligned} -\nabla\cdot((1+u)\nabla u) &= f \quad \text{in} \quad \Omega,\\ u &= 0 \quad \text{on} \quad \partial\Omega, \end{aligned}$$

where $\Omega = (0,1)\times(0,1)$ and f is taken in such a way that the exact solution is $u = x(1-x)y(1-y)$. We divide Ω into regular uniform triangles. The stabilization parameter σ_k, appearing in the penalty term $\mathcal{J}^{\sigma,\beta}$, is taken as follows: $\sigma_k = 10$ for all e_k. We investigate the convergence of NIPG ($\theta = -1$) and SIPG($\theta = 1$) on a sequence of uniform triangular meshes for each of $p = 1, 2$, and 3, where $p = p_i$ for $1 \leq i \leq N_h$. Similarly, we also investigate the convergence of both methods by enriching the polynomial degree p on a fixed mesh.

Convergence in the broken H^1-norm. We set $\beta = 1$ for both the NIPG and SIPG methods. In Figure 2, we plot the broken H^1-norm of the error against the mesh function h for polynomial degrees $p = 1, 2$, and 3. Here, we observe that for each p, $|||u - u_h|||$ converges to zero at the rate $\mathcal{O}(h^p)$ as the mesh is refined. These experiments illustrate the theoretical results obtained in Theorem 4.6. In Figure 3, we present the convergence of the broken H^1-norm of the error as the degree of the polynomials increases on a fixed mesh.

Convergence in the L^2-norm. According to Theorem 4.10, the NIPG method gives optimal L^2 order of convergence, provided the jump term is superpenalized. We take $\beta = 3$ when $\theta = -1$. Since the SIPG method is optimal in the L^2-norm, we take $\beta = 1$ when $\theta = 1$. We investigate the theoretical results obtained in Theorem 4.10 by performing the experiments with the above values of β. In Figure 4, we plot the L^2-norm of the error against the mesh function h for polynomial degrees $p = 1, 2$, and 3. We note that for each p, $\|u - u_h\|$ converges to zero at the rate $\mathcal{O}(h^{p+1})$ as the mesh is refined. The convergence lines are almost the same for both the NIPG and SIPG methods. These results show that the NIPG method exhibits an optimal order of convergence in the L^2-norm on a regular mesh by imposing the

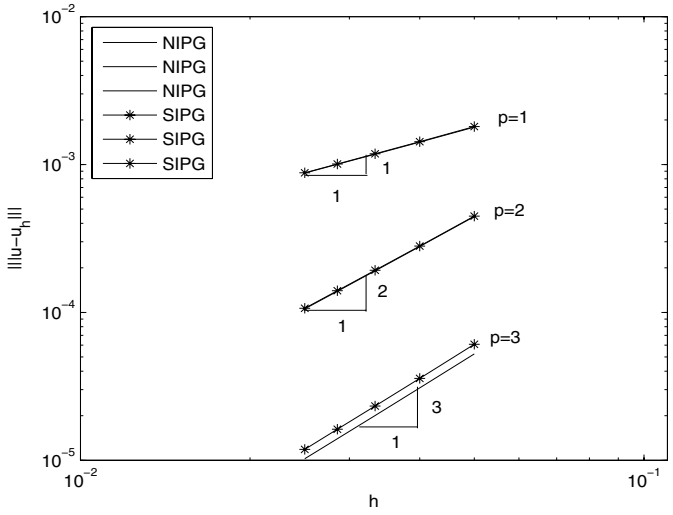

FIG. 2. *Convergence of NIPG and SIPG with h-refinement.*

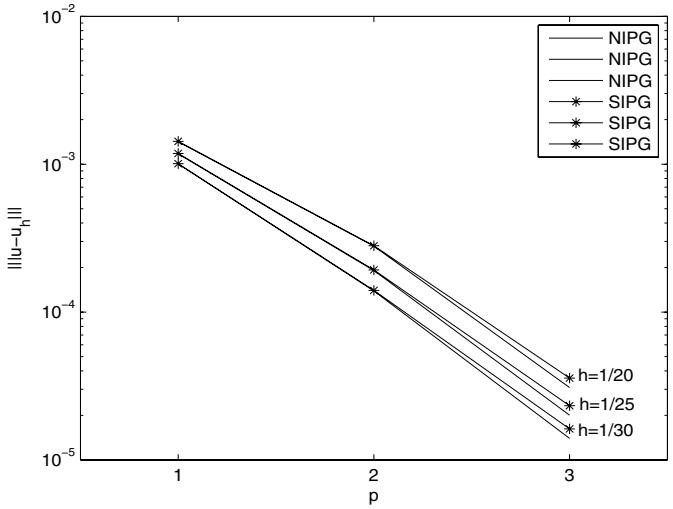

FIG. 3. *Convergence of NIPG and SIPG with p-refinement.*

superpenalty. In Figure 5, we also plot the L^2-norm of the error against the degree of the polynomial p on a fixed mesh. The L^2-norm of the error converges exponentially to zero as p increases. These experiments illustrate the theoretical results obtained in Theorem 4.10.

6. Conclusions. In this paper, we have discussed *hp*-discontinuous Galerkin finite element methods (SIPG and NIPG) for approximating the solutions of nonlinear elliptic boundary value problems of nonmonotone type on a bounded domain in $\mathbb{R}^2$. Using Brouwer's fixed point theorem, we have shown that the discrete problem has a solution under an *hp*-quasi-uniformity condition on the mesh. Further, using Lipschitz

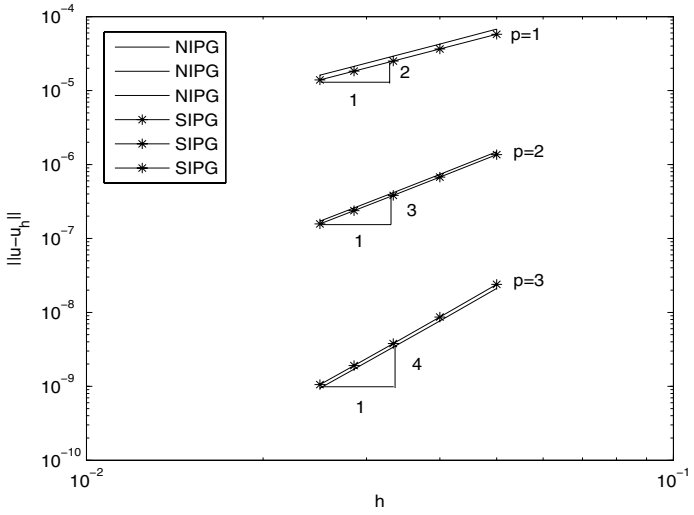

FIG. 4. *Convergence of NIPG and SIPG with h-refinement.*

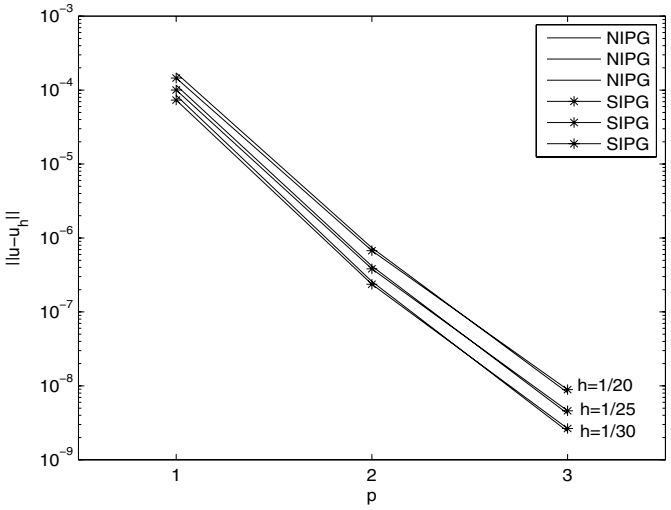

FIG. 5. *Convergence of NIPG and SIPG with p-refinement.*

continuity of the discrete solution map, uniqueness of the discrete solution is also proved. We have proved error estimates in a broken H^1-norm, which are optimal in h and suboptimal in p. These results lead to precisely the same h-optimal and mildly p-suboptimal rates of convergence as in the case of linear elliptic boundary value problems using NIPG methods; see [23], [16]. Further, an optimal error estimate in the L^2-norm on a regular mesh is established by imposing a superpenalty. The results of this article can be easily extended to problems in three space dimensions by making appropriate changes in the analysis. Moreover, it is not difficult to extend our analysis to the problem $-\nabla \cdot (a(u)\nabla u) + f(u) = 0$, where $f(u) \in C_b^2(\bar{\Omega} \times \mathbb{R})$.

With appropriate modifications in the analysis, it is possible to extend the theoretical results of this article to problem (4.1)–(4.2) when $a(u)$ is a bounded uniformly positive-definite matrix.

A CARDINAL FUNCTION ALGORITHM FOR COMPUTING MULTIVARIATE QUADRATURE POINTS*

MARK A. TAYLOR†, BETH A. WINGATE‡, AND LEN P. BOS§

Abstract. We present a new algorithm for numerically computing quadrature formulas for arbitrary domains which exactly integrate a given polynomial space. An effective method for constructing quadrature formulas has been to numerically solve a nonlinear set of equations for the quadrature points and their associated weights. Symmetry conditions are often used to reduce the number of equations and unknowns. Our algorithm instead relies on the construction of cardinal functions and thus requires that the number of quadrature points N be equal to the dimension of a prescribed lower dimensional polynomial space. The cardinal functions allow us to treat the quadrature weights as dependent variables and remove them, as well as an equivalent number of equations, from the numerical optimization procedure. We give results for the triangle, where for all degrees $d \leq 25$, we find quadrature formulas of this form which have positive weights and contain no points outside the triangle. Seven of these quadrature formulas improve on previously known results.

1. Introduction.

Gauss quadrature points, and related points such as Gauss–Lobatto, are commonly used in numerical methods which rely on both accurate high-order polynomial interpolation and quadrature properties. They are heavily relied on by the diagonal-mass-matrix spectral element method, which has been very successful in geophysical applications dominated by wave propagation [17, 15, 10, 11, 30].

Gauss quadrature points are known only for tensor-product domains such as the line, square and cube. It is unclear how to find Gauss-like points for non–tensor-product domains like triangles or tetrahedrons, which makes it difficult to extend the diagonal-mass-matrix spectral element method to these domains. There are two generalizations that have been studied in some detail. The first involves searching for points in these domains with optimal interpolation properties by minimizing the Lebesgue constant [3, 14, 29]. For high polynomial degree, some of the best results have been obtained for Fekete points, which can be computed in a natural way with a cardinal function algorithm [29]. Cardinal functions, or Lagrange interpolating polynomials, are those which have the value 1 at one of the points and 0 at the remaining points. The second generalization involves searching for points in the domain of interest which give an optimal quadrature formula for the integral of polynomials over the domain. Here we consider a set of N points $\{z_1, z_2, \ldots, z_N\}$ and weights $\{w_1, w_2, \ldots, w_N\}$ to be a quadrature formula of strength d if the quadrature approximation for a

domain Ω,

$$\int_\Omega g(\xi)\, d\xi \simeq \sum_{j=1}^{N} w_j g(z_j),$$

is exact for all polynomials g up to degree d. Among all quadrature formulas of strength d, the optimal formulas are those with the fewest possible points N. In this work, we describe an algorithm for computing near-optimal quadrature formulas which is motivated by the Fekete point algorithm and relies heavily on the construction of cardinal functions.

The quadrature problem has been extensively studied independently of spectral element applications and has a long history of both theoretical and numerical development. For a recent review, see [4, 20, 7, 5]. An on-line database containing many of the best-known quadrature formulas is described in [6]. Many of those results were republished in the book [25], where they are available on the included CD-ROM.

One successful approach for numerically finding quadrature formulas dates to [21]. A generalized version was used recently in [31]. Newton's method is used to solve the nonlinear system of algebraic equations for the quadrature weights and locations of the points. Symmetry is used to reduce the complexity of the problem. If the quadrature points are invariant under the action of a group G, then the number of equations can be reduced to the dimension of the subspace of $\mathcal{P}_d$ invariant under G.

Motivated by the cardinal function Fekete point algorithm [29], we propose a new method to reduce the complexity of the quadrature problem: we look for quadrature formulas that have the same number of points as the dimension of a lower dimensional polynomial space. We can then construct a cardinal function basis for this lower dimensional space, make use of the interpolatory quadrature formulas, and derive a remarkable expression analytically relating the variation in the quadrature weights to the variation of the quadrature points. The net result is a significant reduction in the number of equations and unknowns. Symmetry can still be used to further reduce the complexity of the problem if needed. We then apply this algorithm to the triangle, where we are able find optimal quadrature sets of strength 9 through 25, subject only to the cardinal function constraint without imposing any symmetry constraints on the solutions.

2. Orthogonal polynomials. We first define our notation and describe the basis that will be used to represent cardinal functions. Let Ω be a domain in $\Re^n$, with ξ an arbitrary point in Ω. Let $\mathcal{P}_d$ be the finite dimensional vector space of polynomials in the Cartesian components of ξ of at most degree d, and let $N = \dim \mathcal{P}_d$. As an example, if Ω is the right triangle, then

$$\mathcal{P}_d = \operatorname{span}\{\xi_1^n \xi_2^m, m + n \le d\},$$

where $\xi = (\xi_1, \xi_2) \in \Re^2$ and $N = \frac{1}{2}(d+1)(d+2)$.

Our algorithm requires working with a cardinal function basis for $\mathcal{P}_d$. The most practical way to compute cardinal functions numerically is to work instead with their expansions in terms of an orthogonal, easily computed basis for $\mathcal{P}_d$. We denote this basis by $\{g_i(\xi), i = 1, \ldots, N\}$. For simplicity, we require that $g_1(\xi) = 1$. Then since the remaining basis functions are orthogonal to the constant function, we have

$$\int_\Omega g_i\, d\xi = \begin{cases} |\Omega| & \text{for } i = 1, \\ 0 & \text{for } i > 1, \end{cases} \tag{2.1}$$

where $|\Omega|$ is the area of Ω and $d\xi$ represents the uniform area measure.

For this work, all of our numerical calculations were performed in the right triangle. In the triangle there are several suitable choices of orthogonal basis functions. We use the Proriol polynomials $\{g_{m,n}\}$ [22, 18, 8]. The indexes m and n specify the top degree in each coordinate. Here we convert this traditional double index (m, n) into a single index by $i = (m+n+1)(m+n+2)/2-m$, so that $\mathcal{P}_d = \text{span}\{g_i, i = 1, \ldots, N\}$. Recurrence relations to evaluate these polynomials and their derivatives are given in [24].

3. Cardinal functions and quadrature points. We now describe the procedure we use to compute cardinal functions defined by a set of N points

$$\mathbf{z} = \{z_1, z_2, \ldots, z_N\},$$

where each z_i is a point in Ω. If the points are nondegenerate, the cardinal functions can be defined uniquely as the polynomials in ξ which belong to $\mathcal{P}_d$ and satisfy

$$\phi_i(\xi; \mathbf{z}) = \begin{cases} 1 & \text{if } \xi = z_i, \\ 0 & \text{if } \xi = z_j,\ j \neq i. \end{cases} \tag{3.1}$$

The cardinal functions depend implicitly on the defining points, and thus we include a second argument of $\mathbf{z}$. To evaluate cardinal functions numerically, we first express them in terms of the orthogonal basis $\{g_m\}$,

$$\phi_i(\xi; \mathbf{z}) = \sum_m \hat{\phi}_i^m g_m(\xi). \tag{3.2}$$

The expansion coefficients $\hat{\phi}_i^m$ are computed by evaluating (3.2) at the points z_j and solving the $N \times N$ linear system

$$\phi_i(z_j; \mathbf{z}) = \sum_m \hat{\phi}_i^m g_m(z_j).$$

If reasonable care is used, the points $\{z_j\}$ can be chosen so that the system is well conditioned and easily inverted by Gaussian elimination. The resulting cardinal functions form a basis for $\mathcal{P}_d$.

Following conventional spectral method techniques, we evaluate cardinal functions at an arbitrary point ξ by simply evaluating the $g_m(\xi)$ (via recurrence relations) and summing the series in (3.2). Derivatives of cardinal functions with respect to ξ are evaluated in a similar fashion, by first evaluating the derivatives of g_m after differentiating (3.2).

The interpolatory quadrature formula for $\mathcal{P}_d$ can be constructed at these points by solving the system

$$\sum_{j=1}^{N} w_j \phi_i(z_j; \mathbf{z}) = \int_\Omega \phi_i \, d\xi \qquad \forall \phi_i,\ i = 1, \ldots, N.$$

Making use of (2.1) and (3.1), the solution of this system is given by

$$w_i = \int_\Omega \phi_i \, d\xi = |\Omega| \hat{\phi}_i^1. \tag{3.3}$$

By construction, the interpolatory quadrature weights and the points $\{z_i\}$ give a quadrature formula which exactly integrates our N cardinal functions $\{\phi_i\}$. Since $\mathcal{P}_d = \text{span}\{\phi_i\}$, we have

$$\sum_{j=1}^{N} w_j g(z_j) = \int_\Omega g \, d\xi \qquad \forall g \in \mathcal{P}_d.$$

Thus any set of N nondegenerate points $\{z_j\}$ will yield a quadrature formula for $\mathcal{P}_d$, with uniquely determined quadrature weights. The problem now is to find the N points which integrate all of $\mathcal{P}_{d+e}$ for the largest possible e.

4. Derivatives of cardinal functions with respect to z. In the algorithm that follows, we will also need to compute the derivative of a cardinal function ϕ_i with respect to the points z_j used to define ϕ_i. For this we use the following result (which was also derived independently in [23]).

THEOREM 4.1. *For cardinal functions defined by* (3.1)*, we have the vector valued equation*

$$\frac{\partial \phi_i}{\partial z_j}(\xi; \mathbf{z}) = -\phi_j(\xi; \mathbf{z}) \frac{\partial \phi_i}{\partial \xi}(z_j; \mathbf{z}) \tag{4.1}$$

by which we mean

$$\frac{\partial}{\partial (z_i)_k} \phi_i(\xi; \mathbf{z}) = -\phi_i(\xi; \mathbf{z}) \frac{\partial \phi_i}{\partial \xi_k}(z_i; \mathbf{z}), \qquad k = 1 \ldots n,$$

where $(z_i)_k$ is the kth coordinate of the point $z_i \in \Re^n$, and ξ_k is the kth coordinate of the point $\xi \in \Re^n$.

Proof. Consider the derivative with respect to $(z_i)_k$,

$$\frac{\partial}{\partial (z_j)_k} \phi_i(\xi; \mathbf{z}) = \lim_{h \to 0} \frac{\phi_i(\xi; (\mathbf{z} \backslash z_j) \cup \{z_j + h e_k\}) - \phi_i(\xi; \mathbf{z})}{h},$$

where e_k denotes the standard unit direction vector in the kth coordinate. But the difference

$$\phi_i(\xi; (\mathbf{z} \backslash z_j) \cup \{z_j + h e_k\}) - \phi_i(\xi; \mathbf{z})$$

is zero at the points of $\mathbf{z} \backslash z_j$, as is $\phi_j(\xi; \mathbf{z})$, and hence by uniqueness,

$$\phi_i(\xi; (\mathbf{z} \backslash z_j) \cup \{z_j + h e_k\}) - \phi_i(\xi; \mathbf{z}) = C \phi_j(\xi; \mathbf{z})$$

for some constant C.

To evaluate C, first suppose that $j \neq i$. Then evaluate at $\xi = z_j + h e_k$ to obtain (for sufficiently small h)

$$0 - \phi_i(z_j + h e_k; \mathbf{z}) = C \phi_j(z_j + h e_k; \mathbf{z})$$

so that

$$C = -\frac{\phi_i(z_j + h e_k; \mathbf{z})}{\phi_j(z_j + h e_k; \mathbf{z})}.$$

Hence,

$$\begin{aligned}\frac{\partial}{\partial(z_j)_k}\phi_i(\xi;\mathbf{z}) &= \lim_{h\to 0} -\frac{\phi_i(z_j+he_k;\mathbf{z})}{h\phi_j(z_j+he_k;\mathbf{z})}\phi_j(\xi;\mathbf{z}) \\ &= \frac{\phi_j(\xi;\mathbf{z})}{\phi_j(z_j;\mathbf{z})}\lim_{h\to 0}\frac{0-\phi_i(z_j+he_k;\mathbf{z})}{h} \\ &= \frac{\phi_j(\xi;\mathbf{z})}{\phi_j(z_j;\mathbf{z})}\lim_{h\to 0}\frac{\phi_i(z_j;\mathbf{z})-\phi_i(z_j+he_k;\mathbf{z})}{h} \\ &= -\frac{\phi_j(\xi;\mathbf{z})}{1}\frac{\partial\phi_i}{\partial\xi_k}(z_j;\mathbf{z}) \\ &= -\phi_j(\xi;\mathbf{z})\frac{\partial\phi_i}{\partial\xi_k}(z_j;\mathbf{z}).\end{aligned}$$

Similarly, if $j=i$, we evaluate at $\xi = a_i + he_k$ to obtain

$$\begin{aligned}C &= \frac{1-\phi_i(z_i+he_k;\mathbf{z})}{\phi_i(z_i+he_k;\mathbf{z})} \\ &= \frac{\phi_i(z_i;\mathbf{z})-\phi_i(z_i+he_k;\mathbf{z})}{\phi_i(z_i+he_k;\mathbf{z})}\end{aligned}$$

so that

$$\frac{\partial}{\partial(z_i)_k}\phi_i(\xi;\mathbf{z}) = -\phi_i(\xi;\mathbf{z})\frac{\partial\phi_i}{\partial\xi_k}(z_i;\mathbf{z}). \qquad \square$$

Thus the derivative of the ith cardinal function with respect to the jth quadrature point is given by the jth cardinal function times a term independent of ξ and involving only the conventional derivative. The later term can be easily evaluated by differentiating (3.2).

Using (3.3) and (4.1), we can also derive a similar relation showing that the derivative of the ith weight with respect to the jth quadrature point is given by the jth weight times the same term that appears in (4.1):

$$\frac{\partial w_i}{\partial z_j} = -\int_\Omega \phi_j(\xi;\mathbf{z})\frac{\partial\phi_i}{\partial\xi}(z_j;\mathbf{z})\,d\xi = -w_j\frac{\partial\phi_i}{\partial\xi}(z_j;\mathbf{z}). \tag{4.2}$$

5. A cardinal function algorithm for computing quadrature points for $\mathcal{P}_{d+e}$. We now describe an iterative method for improving an initial set of N quadrature points $\mathbf{z}$. In order to integrate a space larger than $\mathcal{P}_d$, we need to find quadrature points which satisfy the nonlinear equation

$$\sum_i w_i g_m(z_i) = \int_\Omega g_m\,d\xi \qquad \forall g_m \in \mathcal{P}_{d+e} \tag{5.1}$$

for some $e > 0$. By using the interpolatory quadrature weights given by (3.3), we automatically integrate all of $\mathcal{P}_d$; thus we need only satisfy the equations for the basis functions in $\mathcal{P}_{d+e}$ which are not in $\mathcal{P}_d$:

$$\sum_i w_i g_m(z_i) = 0 \qquad \forall g_m : d < \text{degree}\, g_m \le d+e$$

and we have replaced the integral on the left-hand side of (5.1) by 0 by virtue of (2.1). Define

$$F_m = \sum_i w_i g_m(z_i)$$

and $F = \{F_m : d < \text{degree}\, g_m \le d + e\}$. Note that since the weights are determined by $\mathbf{z}$, we can treat F as a function solely of $\mathbf{z}$. Then (5.1) is equivalent to $F = 0$, which can be solved using Newton's method:

$$\frac{\partial \mathbf{z}}{\partial t} = -\left(\nabla F\right)^{-1} F.$$

The gradient of F is not necessarily square. In order to invert ∇F we restrict ourselves to the underdetermined case and use the pseudoinverse for $(\nabla F)^{-1}$. If ∇F is of full rank, many solutions exist and this approach gives the minimum norm solution, while in the rank-deficient case it will give the minimum norm least-squares solution [12]. To ensure that the system is underdetermined, we chose e so that there are fewer equations than degrees of freedom in the problem. There is one degree of freedom for each coordinate of each point in $\Re^n$, for a total of $n \dim \mathcal{P}_d$. The number of equations is given by $\dim \mathcal{P}_{d+e} - \dim \mathcal{P}_d$. Thus the degrees-of-freedom constraint is given by $\dim \mathcal{P}_{d+e} \le (n+1) \dim \mathcal{P}_d = (n+1)N$.

Using (4.2), the components of the gradient of F are given by

$$\begin{aligned} \frac{\partial F_m}{\partial z_j} &= \sum_i \left(w_i \frac{\partial g_m(z_i)}{\partial z_j} + \frac{\partial w_i}{\partial z_j} g_m(z_i) \right) \\ &= w_j \frac{\partial g_m}{\partial \xi}(z_j) - w_j \sum_i \frac{\partial \phi_i}{\partial \xi}(\mathbf{z}, z_j) g_m(z_i). \end{aligned} \tag{5.2}$$

Comparing this approach to the traditional Newton method for quadrature, such as in [31], we see that the use of the interpolatory quadrature weights has removed the weights from the iteration and thus reduced the number of unknowns by N. Since these weights exactly integrate $\mathcal{P}_d$, we have also reduced the number of equations by N. The only increase in complexity is the addition of the term involving the derivative of the weights with respect to the quadrature points. But this term is easy to evaluate by virtue of (4.2).

If symmetry is imposed on the quadrature points, then additional reductions in the number of equations and unknowns are possible, as in [21]. However, for the results presented in this paper we typically do not impose any symmetry constraints.

6. Practical considerations. In practice, Newton's method to solve $F = 0$ is used only to accelerate the convergence of a slower, more robust algorithm. We first use the steepest descent algorithm to minimize $\sum_m F_m^2$. This algorithm simply moves the points in the direction of steepest descent given by $\nabla(\sum_m F_m^2)$:

$$\frac{\partial z_j}{\partial t} = -2 \sum_m F_m \frac{\partial F_m}{\partial z_j}.$$

Once this algorithm has found a possible quadrature formula, we switch to Newton's method and iterate until the sequence converges. If the iteration fails to converge, then another initial condition is chosen and the procedure is repeated.

When the steepest descent algorithm is used in such a large (N) dimensional space, it can be expected to find only local minimums, most of which will not represent solutions of $F = 0$. This makes the success of the algorithm highly dependent on the initial condition. Here we will present numerical results for the triangle, where theory offers some guidance as to how to choose initial conditions. Our procedure is the same as that used in [29]. We choose a distribution of points so that their density approximates the extremal measure μ from pluripotential theory [16]. The extremal measure has been connected to the distribution of both quadrature points and Fekete points. For the right triangle $\xi_1 \geq 0$, $\xi_2 \geq 0$, and $\xi_1 + \xi_2 \leq 1$ the extermal measure is given in [1] as

$$\mu(\xi) = \frac{1}{\sqrt{\xi_1 \xi_2 (1 - \xi_1 - \xi_2)}}.$$

It is conjectured that μ is the density of quadrature points with positive weights as the limit N goes to infinity, and it was recently shown that this limit is bounded below by $c\mu$ for some constant c [19]. The same conjecture has also been made for Fekete points [26], where it is known that their density, in the limit as N goes to infinity, is bounded above by $c\mu$ [27].

To distribute a finite set of points to approximate $\mu(\xi)$, we first assume the points lie in a nested family of triangles. We then compute a nested family of triangular shells, each with an area (using the measure $\mu(\xi)d\xi$) proportional to the number of points we have decided to place in that shell. If there are k points to be placed in a given shell, we break that shell into k quadrilateral pieces, all with the same area, and place one point in the center of each piece. For a given number of points, there are a variety of configurations which can be generated by altering the number of points within each shell and the number of shells. The cardinal function algorithm is extremely sensitive to the initial condition, so many of these initial conditions must be tried to find an optimal solution.

7. Results. Our results for the triangle are summarized in Table 1. Except for quadrature formulas associated with $d = 3$ and $d = 4$, we were able to obtain the

TABLE 1

Quadrature points computed with the cardinal function algorithm. In all cases, the quadrature weights are positive and the points are not outside the triangle. Solutions which are not D_3 symmetric are denoted by asym. *Solutions which improve upon previously published results are denoted by* new.

Degree of cardinal functions (d)	Number of points (N)	Degree of exact integration (d+e)	Error	Notes
1	3	2	4.4×10^{-16}	
2	6	4	9.7×10^{-16}

14	120	25	4.3×10^{-14}	asym,new

optimal solution (fewest number of points) subject to the cardinal function constraint on the number of points and the degrees-of-freedom constraint:

$$N = \dim \mathcal{P}_d, \tag{7.1}$$

$$\dim \mathcal{P}_{d+e} \leq 3N. \tag{7.2}$$

All the quadrature points have positive weights and no points lie outside the triangle, although neither of these properties is in any way guaranteed by the cardinal function algorithm. Thus the solutions for $d > 4$ are the best that this algorithm could attain. The truly optimal quadrature points (those with the fewest points for a given strength) would have to be found with a more sophisticated algorithm.

The errors presented in Table 1 are the max norm of the quadrature error over all the orthonormal basis functions:

$$\max_{g_{m,n} \in \mathcal{P}_{d+e}} \left| \sum_i w_i g_{m,n}(z_i) - \int_\Omega g_{m,n} \, d\xi \right|$$

with normalization $\int_\Omega g_{m,n}^2 \, d\xi = |\Omega|$. Many of the quadrature sets are invariant under the symmetry group of rotations and reflections of the triangle, D_3. The solutions which do not have this symmetry are denoted with *asym* in the table.

Quadrature formulas denoted by *new* in the table represent formulas which improve upon the best previously published results, as taken from the extensive database described in [6] and the quadrature points presented in [31] (which were included in the database as of this writing). The new solutions for integration degree $d + e$ from 18 to 25 have fewer points than the previously published results. For $d + e = 13$ and 16, the results presented here have the fewest points among formulas with positive weights and no points outside the triangle. For $d + e = 13$, the previous result with the fewest quadrature points has $N = 36$, but some of those points are outside the triangle and not all the weights are positive [2]. For $d + e = 16$, previous results include formulas with 52 points, some of which are outside the triangle [9], and 55 points, some of which have negative weights [13].

In Table 2, we summarize the results for the triangle from [6], [31], and the cardinal function algorithm.

The coordinates of the points for the first four *new* quadrature formulas are given in Appendix A. The coordinates for all the formulas in the table are available electronically from [28]. Plots for the first four of these quadrature points are shown in Figure 1. In the figure, the right triangle has been mapped linearly to the equilateral triangle in order to make the asymmetry in the points more visible.

8. Summary. We have presented a cardinal function algorithm for computing multivariate quadrature points. The key ideas involve the use of the interpolatory quadrature weights expressed as integrals of cardinal functions and a formula relating the derivatives of cardinal functions with respect to z_i (their defining points) to conventional derivatives in ξ. These two ideas allow us to reduce the number of equations and number of unknowns by N, while still retaining analytic expressions for the gradients necessary to apply steepest decent or Newton iterations. The algorithm was applied to the triangle, where optimal (in the sense of (7.1) and (7.2)) formulas were constructed for integrating polynomials up to degree 25. Seven of these quadrature formulas improve on previously known results. Of these new formulas, 5 out of 7 are asymmetric. It remains an open question whether symmetric formulas can be found

of equal strength and, if not, what is the minimum amount of asymmetry required to obtain a given strength.

By construction, the number of points required for each quadrature formula is given by $N = \dim \mathcal{P}_d$ for some d, meaning they can also be used for interpolation in $\mathcal{P}_d$. This is a useful property for many finite element methods. These discretizations commonly result in equations for functions which are assumed (within each triangular element) to be in the space $\mathcal{P}_d$.

To apply the algorithm to other domains and more than two dimensions requires only the knowledge of an orthogonal basis of polynomials and the ability to evaluate the basis functions at arbitrary points. The use of cardinal functions requires that $N = \dim \mathcal{P}_d$. This constraint can be relaxed by replacing $\mathcal{P}_d$ with any subspace $\mathcal{P}' \subset \mathcal{P}_{d+e}$. The algorithm is unmodified other than that one needs to compute cardinal functions and interpolatory weights for the space $\mathcal{P}'$ instead of $\mathcal{P}_d$.

Appendix A. Tables of quadrature points. We now list the coordinates of the first four quadrature formulas marked with *new* in Table 1. Coordinates for all formulas are available electronically in [28]. For each line, we give the first two barycentric coordinates of each point (equivalent to the x and y coordinates after an equilateral triangle is linearly mapped to the unit right triangle $x \geq 0$, $y \geq 0$,

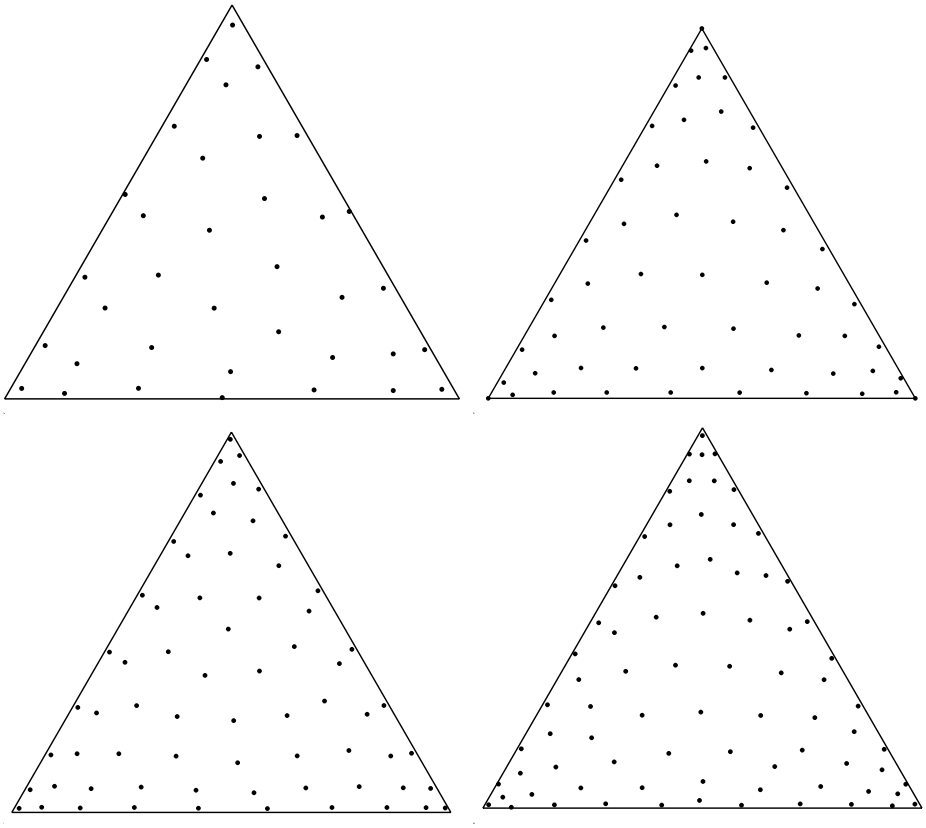

FIG. 1. *Quadrature points for the triangle which, from left to right and top to bottom, exactly integrate polynomials of degree* 13, 16, 18, *and* 20. *No points are outside the triangle, and all quadrature weights are positive.*

and $x + y \leq 1$) followed by the associated quadrature weight. The third barycentric coordinate is defined such that the sum of all three coordinates is one.

BPX-TYPE PRECONDITIONERS FOR SECOND AND FOURTH ORDER ELLIPTIC PROBLEMS ON THE SPHERE*

JAN MAES†, ANGELA KUNOTH‡, AND ADHEMAR BULTHEEL†

Abstract. We develop two Bramble–Pasciak–Xu-type preconditioners for second (resp., fourth) order elliptic problems on the surface of the two-sphere. To discretize the second order problem we construct C^0 linear elements on the sphere, and for the fourth order problem we construct C^1 finite elements of Powell–Sabin type on the sphere. The main reason these BPX preconditioners work depends on this particular choice of basis. We prove optimality and provide numerical examples. Furthermore we numerically compare the BPX preconditioners with the suboptimal hierarchical basis preconditioners.

Key words. BPX preconditioner, C^0 and C^1 finite elements, elliptic equations on surfaces

1. Introduction.

The aim of the present paper is the development of two Bramble–Pasciak–Xu (BPX) [7] preconditioners for second (resp., fourth) order elliptic problems on the two-dimensional sphere. Such problems arise from several applications in physical geodesy, oceanography, and meteorology [8], and they are even of interest for the graphics community, since surface meshes are often parameterized by using so-called harmonic weights, which correspond to a finite element discretization of the Laplace–Beltrami operator; see, e.g., [1] and references therein.

The geometry of the sphere is a major obstacle in constructing suitable approximation spaces for solving partial differential equations. Often a transformation into spherical coordinates is used which gives rise to singularities at the "poles" of the sphere. This complication is induced by the spherical coordinate system itself. Therefore, an important point in our method is the use of homogeneous polynomials in $\mathbb{R}^3$ that allows us to stick with Cartesian coordinates; hence the "pole problem" is avoided. In order to develop the theory we shall restrict ourselves to the following two most simple equations:

$$-\Delta_S u = f \quad \text{on} \quad S, \tag{1.1}$$

and

$$\Delta_S^2 u = f \quad \text{on} \quad S, \tag{1.2}$$

where Δ_S is the Laplace–Beltrami operator on the two-sphere S. In order to work with Cartesian coordinates we write the Laplace–Beltrami operator in terms of the

tangential gradient

$$\nabla_S u := \nabla u - (n \cdot \nabla u)n,$$

with n the outward normal to S. The Laplace–Beltrami operator on S can now be defined as

$$\Delta_S := \nabla_S \cdot \nabla_S.$$

We use C^0 continuous piecewise linear spherical polynomials to discretize the variational problem

$$\int_S \nabla_S u \nabla_S v \; d\omega = \int_S f v \; d\omega \quad \text{for all } v \in H^1(S) \tag{1.3}$$

corresponding to (1.1), and C^1 continuous piecewise quadratic spherical polynomials to discretize the variational problem

$$\int_S \Delta_S u \Delta_S v \; d\omega = \int_S f v \; d\omega \quad \text{for all } v \in H^2(S) \tag{1.4}$$

corresponding to (1.2). For every $f \in L_2(S)$ with $\int_S f \; d\omega = 0$ there exist a weak solution $u \in H^1(S)$ of (1.3) and a weak solution $u \in H^2(S)$ of (1.4). In both cases u is unique up to a constant; see, e.g., [5, 16].

So let $m \in \{1, 2\}$, and suppose $V \subset H^m(S)$ is a space of conforming C^{m-1} finite elements defined on a spherical triangulation of S with mesh size h. Define $a(u, v)$ as the bilinear form induced by (1.3) (resp., (1.4)) given $m = 1$ (resp., $m = 2$), and let A denote the positive definite self-adjoint operator on V defined by

$$a(u, v) = (Au, v), \quad v \in V, \tag{1.5}$$

where $(\cdot, \cdot)$ denotes the inner product of $L_2(S)$. Then we have to solve the linear operator equation

$$Au = b \tag{1.6}$$

for some $u \in V$, where $b \in V$ is defined by $(b, v) = (f, v)$, $v \in V$. The conjugate gradient method is a very efficient solver for large linear systems arising from problems such as (1.6). However, because of stability reasons, it is necessary that these systems have been suitably preconditioned. It is a known fact (see, e.g., [12]) that if for some constants $0 < \gamma, \Gamma < \infty$ and some invertible operator C

$$\gamma(C^{-1}u, u) \le a(u, u) \le \Gamma(C^{-1}u, u), \quad u \in V, \tag{1.7}$$

then the spectral condition number $\kappa(C^{1/2}AC^{1/2})$ is bounded by Γ/γ.

Let us represent the operator A by the stiffness matrix $A_\Phi := (a(\phi_i, \phi_j))_{i,j \in I}$ with respect to some typical nodal basis $\Phi := \{\phi_i \; : \; i \in I\}$ of V. Then it is known that $\kappa(A_\Phi) = \mathcal{O}(h^{-2})$ for problem (1.3) and $\kappa(A_\Phi) = \mathcal{O}(h^{-4})$ for problem (1.4). In order to precondition the system

$$A_\Phi y = b_\Phi, \quad (b_\Phi)_i := (f, \phi_i), \; i \in I, \tag{1.8}$$

one can perform a change of basis. So let $\Psi = \{\psi_i \; : \; i \in I\}$ be another basis of V, and let L be the transfer matrix between the two bases. Then

$$A_\Psi = L^T A_\Phi L,$$

which suggests the use of $C = LL^T$ as preconditioner for the nodal basis discretization.

Several approaches exist to construct a suitable preconditioner, such as the hierarchical basis (HB) preconditioner [31] and the closely related BPX preconditioner [7]. The growth rate of the condition numbers was shown to be logarithmic in the size of the problem for the HB preconditioner [31] and uniformly bounded for the BPX preconditioner in [12, 27]. Originally, these results were formulated for second order problems on two-dimensional planar domains, but they could also be established for fourth order problems on the plane [13, 20, 26]. Recently, we constructed an HB preconditioner for fourth order elliptic problems on the surface of the sphere in [23]. The growth rate of the condition number was shown to be logarithmic which is, as expected, similar to the planar case. It is the aim of the present paper to prove optimality of a BPX preconditioner for problems (1.3) and (1.4), independent of the discretization, and to give numerical evidence of this optimality. We emphasize that the crucial steps in the optimality proof depend on the particular choice of basis and, thus, are not valid for arbitrary C^0 or C^1 finite element constructions on the sphere. For both problems we explicitly construct a suitable basis that is easy to implement.

The outline of the remaining sections is as follows. In section 2, we introduce the C^0 continuous piecewise linear and C^1 continuous piecewise quadratic spherical polynomials that will be used to discretize problem (1.3) (resp., (1.4)). The corresponding BPX preconditioners are constructed in section 3, and we prove their optimality. Finally, in section 4 we conclude with some numerical experiments that confirm the theory with small absolute condition and iteration numbers.

We finish this introduction with a note about notation. We always mean by $a \sim b$ that $a \lesssim b$ and $a \gtrsim b$ hold, where $a \lesssim b$ means that a can be bounded by a constant multiple of b uniformly in any parameters on which a,b may depend, and $a \gtrsim b$ means $b \lesssim a$.

2. Suitable elements on the sphere. In a series of papers [2, 3, 4], Alfeld, Neamtu, and Schumaker develop spline spaces on triangulations on the sphere analogous to the classical spline spaces on planar triangulations. The idea is to work with homogeneous Bernstein–Bézier polynomials in $\mathbb{R}^3$ which are then restricted to the sphere. A function f defined on $\mathbb{R}^3$ is *homogeneous of degree* d provided that $f(\alpha v) = \alpha^d f(v)$ for all real α and all $v \in \mathbb{R}^3$. The space $\mathbb{H}_d$ of *trivariate polynomials of degree* d *that are homogeneous of degree* d is a $\binom{d+2}{2}$ dimensional subspace of the space of trivariate polymials of degree d. Let $\{v_1, v_2, v_3\}$ be a set of linearly independent unit vectors in $\mathbb{R}^3$. We call

$$\mathcal{T} := \{v \in \mathbb{R}^3 \mid v = b_1(v)v_1 + b_2(v)v_2 + b_3(v)v_3 \quad \text{with} \quad b_i(v) \geq 0\}$$

the *trihedron* generated by $\{v_1, v_2, v_3\}$. Each $v \in \mathbb{R}^3$ can be written in the form

$$v = b_1(v)v_1 + b_2(v)v_2 + b_3(v)v_3, \tag{2.1}$$

and we call $b_1(v), b_2(v), b_3(v)$ the *trihedral coordinates of* v *with respect to* $\mathcal{T}$. Given an integer $d \geq 0$, the *homogeneous Bernstein basis polynomials of degree* d *on* $\mathcal{T}$ are the polynomials

$$B^d_{ijk}(v) := \frac{d!}{i!j!k!} b_1(v)^i b_2(v)^k b_3(v)^k, \qquad i + j + k = d,$$

and they form a basis for $\mathbb{H}_d$. We define a *spherical triangle* as the restriction of a trihedron $\mathcal{T}$ to the unit sphere S. The restrictions of the trihedral coordinates (2.1) to a spherical triangle with vertices v_1, v_2, and v_3 are called *spherical barycentric*

coordinates. Any homogeneous polynomial p of degree d and its restriction to a spherical triangle τ has a *Bernstein–Bézier representation* with respect to τ:

$$p(v) := \sum_{i+j+k=d} c_{ijk} B^d_{ijk}(v), \tag{2.2}$$

where the coefficients c_{ijk} are the *Bézier ordinates*.

Homogeneous polynomials in their Bernstein–Bézier representation can be evaluated efficiently using the classical de Casteljau algorithm:

$$p(v) = c^d_{000}(v),$$

where for $1 \le l \le d$

$$\begin{aligned} &c^0_{ijk}(v) := c_{ijk}, \\ &c^l_{ijk}(v) := b_1(v)c^{l-1}_{i+1,j,k} + b_2(v)c^{l-1}_{i,j+1,k} + b_3(v)c^{l-1}_{i,j,k+1}, \quad i+j+k = d-l. \end{aligned}$$

Also continuity conditions can be expressed analogously to the classical bivariate case. Let $\mathcal{T}$ and $\widetilde{\mathcal{T}}$ be trihedra with vertices $\{v_1, v_2, v_3\}$ and $\{v_4, v_2, v_3\}$. A necessary and sufficient condition for p and $\widetilde{p}$ to be C^r continuous across the common boundary is

$$\widetilde{c}_{ijk} = c^i_{0jk}(v_4), \quad i = 0, 1, \dots, r, \quad i+j+k = d. \tag{2.3}$$

We write $\mathbb{H}_d(\Omega)$ for the restriction of $\mathbb{H}_d$ to any subset Ω of the unit sphere S, and refer to $\mathbb{H}_d(\Omega)$ as the *space of spherical polynomials of degree d*. Similarly, we write $\mathbb{H}_d(H)$ for the restriction of $\mathbb{H}_d$ to any hyperplane H in $\mathbb{R}^3 \setminus \{0\}$. This is just the well-known space of bivariate polynomials. All these spaces have the same dimension $\binom{d+2}{2}$. Let Δ be a conforming spherical triangulation of $\Omega \subset S$. Then we define the *space of spherical splines of degree d and smoothness r associated with* Δ to be

$$S^r_d(\Delta) := \{s \in C^r(S) \ : \ s|_\tau \in \mathbb{H}_d(\tau), \ \tau \in \Delta\},$$

where $s|_\tau$ denotes the restriction of s to the spherical triangle τ.

2.1. C^0 linear elements on the sphere. The C^0 continuous piecewise linear spherical polynomials that we describe here are a natural extension of the well-known linear elements introduced by Courant [10]. However, our approach differs significantly from previous constructions (e.g., [6, 16]); see Remark 2.4. Suppose that we are given an initial triangulation Δ_0 of S and that

$$\Delta_0 \subset \Delta_1 \subset \cdots \subset \Delta_j \subset \cdots, \quad j = 0, 1, \dots,$$

is a sequence of dyadically refined triangulations obtained by subdividing the triangles at level j (i.e., the triangles of Δ_j) into 4 congruent subtriangles of level $j+1$. This refinement is regular; i.e. the minimum angle condition is satisfied and

$$\operatorname{diam} \tau \sim 2^{-j}, \quad \tau \in \Delta_j, \quad j = 0, 1, \dots.$$

For each $j = 0, 1, \dots$ we define $v_{i,j}$, $i = 1, \dots, N_j$, as the vertices of the triangulation Δ_j. We create suitable basis functions for the nested spherical spline spaces

$$S^0_1(\Delta_0) \subset S^0_1(\Delta_1) \subset \cdots \subset S^0_1(\Delta_j) \subset \cdots, \quad j = 0, 1, \dots,$$

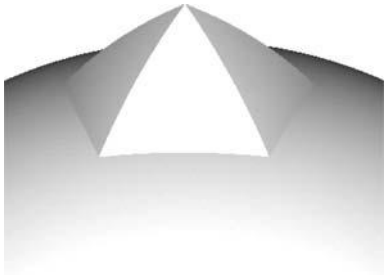

FIG. 2.1. *Graph of* $(\phi_{i,j}(v)+1)v$ *with* $v \in S$ *and* $\phi_{i,j}$ *the spherical Courant element.*

and this approach allows us to point out a strong connection with the classical Courant elements on the plane.

So let us define a nodal basis for $S_1^0(\Delta_j)$ by solving the following interpolation problem: find functions $\phi_{i,j} \in S_1^0(\Delta_j)$, $i = 1, \ldots, N_j$, such that $\phi_{i,j}(v_{k,j}) = \delta_{i,k}$. Obviously this interpolation problem has a unique solution. If we restrict the spline $\phi_{i,j}$ to any spherical triangle τ in Δ_j, we get a spherical Bernstein–Bézier polynomial (2.2) of degree $d = 1$. The interpolation problem determines the three Bézier ordinates c_{ijk} in (2.2) (with $d = 1$) in a unique way. If the spherical triangle τ does not contain vertex $v_{i,j}$, then the three Bézier ordinates equal zero, and hence $\phi_{i,j}$ has local support. If τ contains vertex $v_{i,j}$, then the Bézier ordinate that is associated with this vertex takes the value 1, and the other two Bézier ordinates take the value 0. It is easily checked that the continuity conditions (2.3) for $r = 0$ are satisfied. Figure 2.1 shows the spherical Courant element.

We can look at each spherical basis function $\phi_{i,j}$ as the restriction of a trivariate homogeneous function to the sphere S. In particular, let f be any spherical function and let $d \in \mathbb{N}$; then we define $(f)_d$ as its *homogeneous extension of degree* d, i.e.,

$$(f)_d(v) := |v|^d f\left(\frac{v}{|v|}\right), \quad v \in \mathbb{R}^3 \setminus \{0\}. \tag{2.4}$$

If we restrict the homogeneous extension of degree 1 of $\phi_{i,j}$ to the sphere S, we recover $\phi_{i,j}$, i.e., $\phi_{i,j} \equiv (\phi_{i,j})_1|_S$. Moreover, we even have the following theorem.

THEOREM 2.1. *The restriction of* $(\phi_{i,j})_1$ *to the tangent plane touching* S *at* $v_{i,j}$ *is a classical bivariate Courant element defined on this tangent plane centered around the vertex* $v_{i,j}$.

Proof. First we define the *radial projection* R_T from any plane T that is tangent to S onto S by

$$R_T\overline{v} := v := \frac{\overline{v}}{|\overline{v}|} \in S, \quad \overline{v} \in T, \tag{2.5}$$

where $|v|$ denotes the Euclidean norm of v. Let $T_{i,j}$ be the tangent plane touching S at vertex $v_{i,j} \in \Delta_j$. Because the mapping $R_{T_{i,j}}$ is one-to-one, the inverse $R_{T_{i,j}}^{-1}$ is well defined. Define $\Delta_{i,j}$ as the 1-ring of vertex $v_{i,j}$ in Δ_j. Let $\overline{\Delta}_{i,j}$ be the image of $\Delta_{i,j}$ under $R_{T_{i,j}}^{-1}$. Since great circles are mapped onto straight lines under $R_{T_{i,j}}^{-1}$, $\overline{\Delta}_{i,j}$ consists of planar neighboring triangles with one common vertex $v_{i,j}$. The spline space $S_1^0(\overline{\Delta}_{i,j})$ is just the well-known bivariate linear spline space on the triangulation $\overline{\Delta}_{i,j}$. Let τ be a spherical triangle in $\Delta_{i,j}$ and denote its vertices by v_1, v_2, v_3. Let

$\mathcal{T}$ be the trihedron generated by $\{v_1, v_2, v_3\}$. Then for some $a \in \{1, 2, 3\}$ we have $v_a = v_{i,j}$ (since $\tau \in \Delta_{i,j}$) and

$$(\phi_{i,j})_1(w) = b_a(w)^i, \qquad w \in \mathcal{T},$$

with (b_1, b_2, b_3) the trihedral coordinates of w with respect to $\mathcal{T}$. Consequently, $(\phi_{i,j})_1$ equals zero at the vertices of $\overline{\Delta}_{i,j}$, except that for vertex $v_{i,j} \in \overline{\Delta}_{i,j}$ we get $(\phi_{i,j})_1(v_{i,j}) = 1$. Since $\phi_{i,j} = (\phi_{i,j})_1|_S$, we have $\phi_{i,j}|_\tau \in \mathbb{H}_1(S)$. Let $\overline{\tau}$ be the image of τ under $R^{-1}_{T_{i,j}}$. We find that $(\phi_{i,j})_1|_{\overline{\tau}} \in \mathbb{H}_1(\overline{\tau})$ and thus $(\phi_{i,j})_1|_{T_{i,j}} \in S^0_1(\overline{\Delta}_{i,j})$. This proves that $(\phi_{i,j})_1|_{T_{i,j}}$ is just the well-known classical bivariate Courant element. ∎

This idea can be exploited to extend several properties of the classical Courant elements to the spherical elements $\phi_{i,j}$, such as

$$0 \le \phi_{i,j}(v) \le 1, \quad v \in S.$$

The following lemma is obvious.

LEMMA 2.2 (Riesz L_∞-stability). *The nodal basis functions* $\{\phi_{i,j} \mid i = 1, \dots, N_j\}$ *satisfy*

$$\left\| \sum_{i=1}^{N_j} c_{i,j}\phi_{i,j} \right\|_{L_\infty} \sim \max_i |c_{i,j}|.$$

Proof. There exist a triangle $\tau \in \Delta_j$ and a point $v \in \tau$ such that

$$\left\| \sum_{i=1}^{N_j} c_{i,j}\phi_{i,j} \right\|_{L_\infty} = \left| \sum_{i=1}^{N_j} c_{i,j}\phi_{i,j}(v) \right| \le \max_i |c_{i,j}| \sum_{i|v_{i,j}\in\tau} \|\phi_{i,j}\|_{L_\infty} \lesssim \max_i |c_{i,j}|.$$

The other inequality follows from $|c_{k,j}| = |\sum_{i=1}^{N_j} c_{i,j}\phi_{i,j}(v_{k,j})| \le \|\sum_{i=1}^{N_j} c_{i,j}\phi_{i,j}\|_{L_\infty}$. This completes the proof. ∎

To derive the optimality of the BPX preconditioner we will need the following theorem.

THEOREM 2.3 (Riesz L_p-stability). *For any* $1 < p < \infty$ *we have*

$$\left\| \sum_{i=1}^{N_j} c_{i,j}\phi_{i,j} \right\|^p_{L_p} \sim 2^{-2j} \sum_{i=1}^{N_j} |c_{i,j}|^p.$$

Proof. Since we have already established Riesz L_∞-stability of the basis (Lemma 2.2), the proof is identical to the corresponding proof for the classical Courant elements on the plane from [10]. ∎

Remark 2.4. There exist other constructions of C^0 spherical finite elements in the literature. In [16] problem (1.1) is discretized by approximating the sphere S by a polyhedron S_h. Then linear elements on the surface S_h are used. In [6] spherical linear elements are created, but another definition for spherical barycentric coordinates is used. In [6] the spherical barycentric coordinates are required to form a partition of unity, and therefore they inevitably fail to have many of the important properties that the spherical barycentric coordinates of [2] have. The optimality proof of the BPX preconditioner that we give in section 3 works only for our construction.

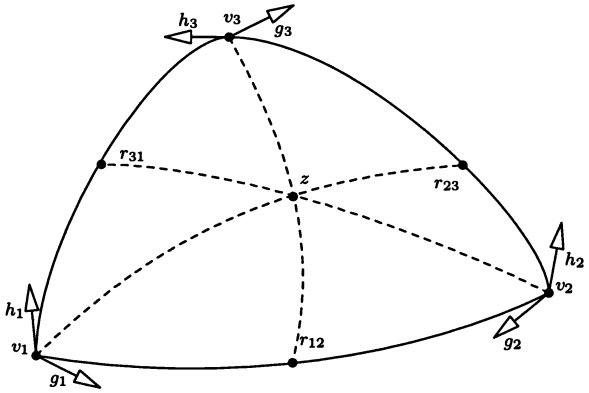

FIG. 2.2. *The spherical Powell–Sabin macroelement.*

2.2. C^1 Powell–Sabin elements on the sphere. In general, maintaining C^1 continuity conditions (2.3) between neighboring triangles results in nontrivial relations and is not always possible for arbitrary given triangulations; see, e.g., [17]. Therefore, to overcome this problem, we will focus on the *Powell–Sabin 6-split* of a triangulation. Starting from an arbitrary spherical triangulation Δ, we introduce further substructures by subdividing each triangle of Δ into 6 subtriangles in a prescribed way. Because of the special structure of this refined triangulation one introduces sufficient degrees of freedom to maintain overall C^1 continuity. The Powell–Sabin 6-split is obtained as follows:

1. Define for each triangle τ_k in Δ an interior point z_k such that if two triangles τ_k and τ_l have a common edge (circle segment), then the arc that joins z_k and z_l intersects this common edge (circle segment) at a point r_{kl} between its vertices. The arc between two points on S is defined as the circle segment connecting these two points obtained as the intersection of S with a plane passing through the two points and the origin.
2. Join the points z_k to the vertices of τ_k.
3. For each edge (circle segment) of τ_k
   - that belongs to the boundary $\partial\Omega$, join z_k to some point of the edge,
   - that is common to a triangle τ_l, join z_k to r_{kl}.

Figure 2.2 shows the split of one triangle. We will refer to this new triangulation as Δ^{PS}. The spline space $S_2^1(\Delta^{PS})$ of piecewise quadratic C^1 spherical polynomials over Δ^{PS} will be called the space of *spherical Powell–Sabin (PS) splines*. Let g_i and h_i be independent unit vectors lying in the tangent plane of S at the vertices v_i, $i = 1, \ldots, N$, of the triangulation Δ. The following interpolation problem can be considered for spherical PS splines. Given any set of values $(\alpha_i, \beta_i, \gamma_i)$, $i = 1, \ldots, N$, find $s(v) \in S_2^1(\Delta^{PS})$ such that

$$s(v_i) = \alpha_i, \quad \frac{\partial s(v_i)}{\partial g_i} = \beta_i, \quad \frac{\partial s(v_i)}{\partial h_i} = \gamma_i, \tag{2.6}$$

for all $i = 1, \ldots, N$. Maes and Bultheel [23] have shown that this interpolation problem has a unique solution, and hence the classical result of [28] can be extended to spherical domains; i.e., the dimension of the spherical spline space $S_2^1(\Delta^{PS})$ equals $3N$.

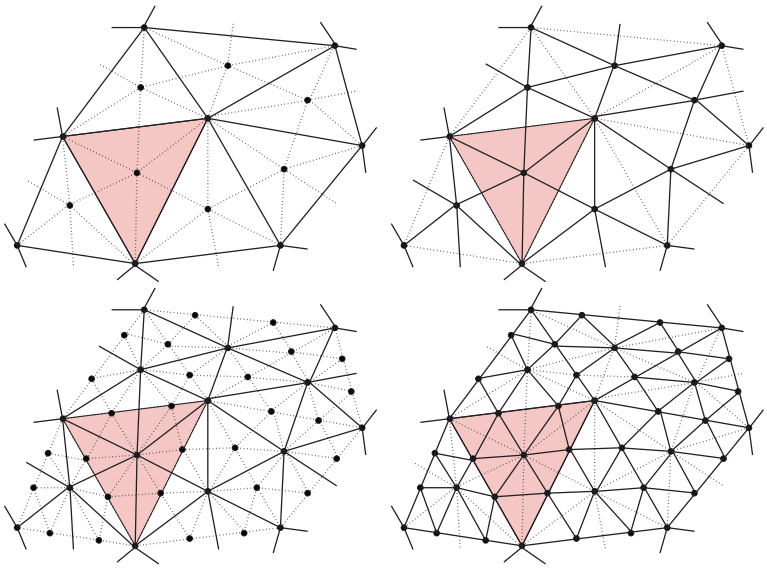

FIG. 2.3. *Principle of $\sqrt{3}$ subdivision. Applying the $\sqrt{3}$ subdivision twice results in triadic subdivision.*

In order to create nested spherical PS spline spaces

$$S_2^1(\Delta_0^{PS}) \subset S_2^1(\Delta_1^{PS}) \subset S_2^1(\Delta_2^{PS}) \subset \cdots$$

it is sufficient that we find a refinement procedure that yields nested sequences

$$\begin{aligned} &\Delta_0^{PS} \subset \Delta_1^{PS} \subset \Delta_2^{PS} \subset \cdots, \\ &\{v_i \in \Delta_0\} \subset \{v_i \in \Delta_1\} \subset \{v_i \in \Delta_2\} \subset \cdots. \end{aligned} \tag{2.7}$$

It was pointed out by Vanraes et al. [30] that applying a $\sqrt{3}$ *refinement scheme* yields nested PS spline spaces. Applying the $\sqrt{3}$ scheme twice yields a triadic scheme. The $\sqrt{3}$ scheme was first introduced by Kobbelt [19] and Labsik and Greiner [21]. Instead of splitting each edge in Δ_0 and performing a 1-to-4 split for each triangle (dyadic refinement), we compute a new vertex for each triangle and retriangulate the old and new vertices. Figure 2.3 shows the principle. Note that the new edges in Δ_1 coincide with the lines of the PS 6-split Δ_0^{PS}. In the new triangles new interior points must be chosen on the one line of the new PS 6-split Δ_1^{PS} that is already fixed, that is, the original edge that crosses the triangle.

Remark 2.5. Although the $\sqrt{3}$ refinement is applicable to arbitrary (spherical) triangulations, it is not rigorously proven whether the corresponding sequence (2.7) satisfies the minimum angle condition and whether

$$\operatorname{diam} \tau \sim \sqrt{3}^{-j}, \quad \tau \in \Delta_j^{PS}, \quad j = 0, 1, \ldots.$$

In our mathematical analysis we will always assume that we are given a nested sequence (2.7) that is regular. By using a PS 12-split as in [26] instead of the PS 6-split one can obtain a provably regularly refined sequence of PS spline spaces by applying dyadic refinement. However, we opt for the PS 6-split because the construction of the corresponding basis functions is less complicated, certainly on the sphere, and

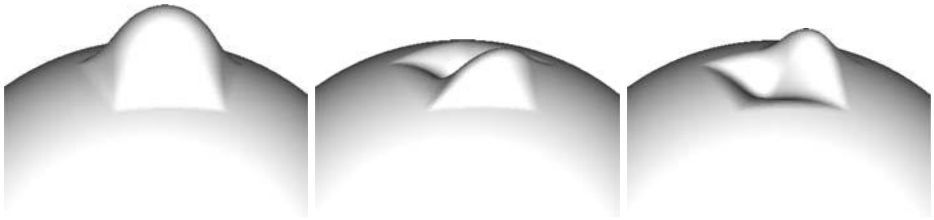

FIG. 2.4. *Graphs of* $(B^k_{i,j}(v)+1)v$ *with* $v \in S$ *for* $k = 1, 2, 3$ *with* $B^k_{i,j}$ *the spherical Hermite PS basis function.*

because the $\sqrt{3}$ refinement is a topologically slower refinement than the dyadic refinement; thus we have more levels of resolution if a prescribed target complexity of the PS spline space must not be exceeded.

With each vertex $v_{i,j} \in \Delta_j$ we associate two directions $g_{i,j}$ and $h_{i,j}$ such that the set $(v_{i,j}, g_{i,j}, h_{i,j})$ forms an orthonormal basis for $\mathbb{R}^3$. For instance, suppose that $v_{i,j}$ has spherical coordinates $(\cos\theta \sin\phi, \sin\theta \sin\phi, \cos\phi)$, $\theta \in [0, 2\pi]$, $\phi \in [0, \pi]$; then take $g_{i,j} = (\cos\theta\cos\phi, \sin\theta\cos\phi, -\sin\phi)$ and $h_{i,j} = (-\sin\theta, \cos\theta, 0)$. Let us introduce the functionals

$$\lambda^1_{i,j}(f) := f(v_{i,j}), \quad \lambda^2_{i,j}(f) := \frac{\partial f(v_{i,j})}{\partial g_{i,j}}, \quad \lambda^3_{i,j}(f) := \frac{\partial f(v_{i,j})}{\partial h_{i,j}}, \quad f \in C^1(S).$$

Then we construct a nodal basis for $S^1_2(\Delta^{PS}_j)$ by solving the following interpolation problems of the form (2.6): find functions $B^k_{i,j} \in S^1_2(\Delta^{PS}_j)$, $k = 1, 2, 3$, $i = 1, \ldots, N_j$, such that

$$\begin{aligned} \lambda^1_{m,j}(B^k_{i,j}) &= \sqrt{3}^{-j}\delta_{k,1}\delta_{i,m}, \\ \lambda^2_{m,j}(B^k_{i,j}) &= \delta_{k,2}\delta_{i,m}, \\ \lambda^3_{m,j}(B^k_{i,j}) &= \delta_{k,3}\delta_{i,m} \end{aligned} \tag{2.8}$$

for all $m = 1, \ldots, N_j$. Note that these basis functions satisfy $B^k_{i,j} \equiv (B^k_{i,j})_2|_S$; i.e. the spherical basis function $B^k_{i,j}$ is equal to the restriction of its homogeneous extension (2.4) of degree 2 to the sphere S. If we restrict $(B^k_{i,j})_2$ to the tangent plane touching S at $v_{i,j}$, we get the corresponding planar Hermite basis function of [29] defined on this tangent plane. The proof is similar to the proof of Theorem 2.1. A detailed proof in a more general setting can be found in [23, Theorem 4.1]. Figure 2.4 shows the three spherical Hermite PS basis functions that are associated with one vertex.

We now show some stability properties of the nodal basis (2.8) that will be useful in the optimality proof of the BPX preconditioner.

LEMMA 2.6 (Riesz L_∞-stability). *The nodal basis defined by* (2.8) *satisfies*

$$\left\| \sum_{i=1}^{N_j} \sum_{k=1}^{3} c^k_{i,j} B^k_{i,j} \right\|_{L_\infty} \sim \sqrt{3}^{-j} \max_{i,k} |c^k_{i,j}|.$$

Proof. First we note that this result is well known for the classical bivariate Hermite basis of PS type on planar triangulations. Indeed, the inequality $\gtrsim$ can be shown using the Markov inequality for polynomials [9], and the inequality $\lesssim$ can be deduced, for instance, from the work in [29, section 6.2]. This result for the bivariate

planar setting can be extended easily to the spherical setting by exploiting the fact that the restriction of $(B^k_{i,j})_2$ to the tangent plane touching S at $v_{i,j}$ is a classical bivariate Hermite basis function. For a detailed proof, see [23, Corollary 4.2]. ∎

THEOREM 2.7 (Riesz L_p-stability). *If s is in $S^1_2(\Delta^{PS}_j)$, then for any $1 < p < \infty$ we have*

$$\|s\|^p_{L_p} \sim \sqrt{3}^{-2j} \left(\sum_{i=1}^{N_j} |\lambda^1_{i,j}(s)|^p + \sqrt{3}^{-jp} \sum_{i=1}^{N_j} \sum_{k=2}^{3} |\lambda^k_{i,j}(s)|^p \right).$$

Proof. Using the Markov inequality for spherical polynomials [25, Prop. 4.3], we infer that $|\lambda^k_{i,j}(s)| \lesssim \sqrt{3}^j \|s\|_{L_\infty(\tau_i)}$ for $k = 2, 3$ with $\tau_i \in \Delta^{PS}_j$ such that $v_{i,j} \in \tau_i$. By mapping τ_i to a standard reference triangle and using the fact that all norms on the finite-dimensional space of polynomials are equivalent, we find that $\|s\|_{L_\infty(\tau_i)} \lesssim \sqrt{3}^{2j/p} \|s\|_{L_p(\tau_i)}$, which implies

$$\sqrt{3}^{-2j} \left(\sum_{i=1}^{N_j} |\lambda^1_{i,j}(s)|^p + \sqrt{3}^{-jp} \sum_{i=1}^{N_j} \sum_{k=2}^{3} |\lambda^k_{i,j}(s)|^p \right) \lesssim \sum_{i=1}^{N_j} \sum_{k=1}^{3} \|s\|^p_{L_p(\tau_i)} \lesssim \|s\|^p_{L_p}.$$

The other inequality follows from the observation that

$$\begin{aligned} |s(v)|^p &= \left| \sum_{i=1}^{N_j} \left(\sqrt{3}^j \lambda^1_{i,j}(s) B^1_{i,j}(v) + \sum_{k=2}^{3} \lambda^k_{i,j}(s) B^k_{i,j}(v) \right) \right|^p \\ &\lesssim \sum_{i=1}^{N_j} \left(\sqrt{3}^{jp} |\lambda^1_{i,j}(s)|^p |B^1_{i,j}(v)|^p + \sum_{k=2}^{3} |\lambda^k_{i,j}(s)|^p |B^k_{i,j}(v)|^p \right), \end{aligned}$$

which holds because at any $v \in S$ there are at most nine nonzero basis functions. We find that

$$\begin{aligned} \|s\|^p_{L_p} &\lesssim \sum_{i=1}^{N_j} \left(\sqrt{3}^{jp} |\lambda^1_{i,j}(s)|^p \int_S |B^1_{i,j}(v)|^p dv + \sum_{k=2}^{3} |\lambda^k_{i,j}(s)|^p \int_S |B^k_{i,j}(v)|^p dv \right) \\ &\lesssim \sqrt{3}^{-2j} \left(\sum_{i=1}^{N_j} |\lambda^1_{i,j}(s)|^p + \sqrt{3}^{-jp} \sum_{i=1}^{N_j} \sum_{k=2}^{3} |\lambda^k_{i,j}(s)|^p \right), \end{aligned}$$

where we have used that $\|B^k_{i,j}\|_{L_\infty} \lesssim \sqrt{3}^{-j}$, which follows from the Riesz L_∞-stability of the basis (Lemma 2.6). ∎

3. Construction of the BPX preconditioners. In this section we construct BPX preconditioners for problems (1.3) and (1.4) and prove that these preconditioners are optimal. Let $m \in \{1, 2\}$, and let $\rho \in \mathbb{R}$ be a scaling factor. If m equals 1, we define S_j as the spline space $S^0_1(\Delta_j)$, we set the scaling factor ρ equal to 2, and we solve problem (1.3). If m equals 2, we define S_j as the spline space $S^1_2(\Delta^{PS}_j)$ and we set the scaling factor ρ equal to $\sqrt{3}$, leading to problem (1.4).

Let Q_j, $j = 0, 1, \ldots$, be a sequence of projectors on S_j which are orthogonal with respect to the inner product $(\cdot, \cdot)$, and let $Q_{-1} \equiv 0$. Let Ω be a subset of the sphere

S, and let $H^m(\Omega)$, $H^m(S)$ be the spherical Sobolev spaces as defined in [22, 25]. We prove the following theorem.

THEOREM 3.1. *Suppose $s \in S_J$. Then*

$$\|s\|^2_{H^m(S)} \sim \sum_{j=0}^{J} \rho^{2mj} \|(Q_j - Q_{j-1})s\|^2_{L_2(S)} . \tag{3.1}$$

Proof. Let Ω be a subset of S such that $\operatorname{diam}(\Omega) \leq 1$. Let T_Ω be the tangent plane touching S at r_Ω, with r_Ω the center of a spherical cap of smallest possible radius containing Ω. Here a spherical cap is defined as the region of a sphere which lies on one side of a given plane that intersects with the sphere. Recall the definition of the radial projection R_{T_Ω} from (2.5). Let $\overline{\Omega}$ be the image of Ω under $R^{-1}_{T_\Omega}$ and define $H^m(\overline{\Omega})$ as the usual Sobolev space on domains in $\mathbb{R}^2$. Let $(s)_m$ be the homogeneous extension (2.4) of degree m of s, and define $\overline{s}$ as the restriction of $(s)_m$ to $\overline{\Omega}$. The norm equivalence $\|s\|_{H^m(\Omega)} \sim \|\overline{s}\|_{H^m(\overline{\Omega})}$ holds; see Lemma 3.2 in [25]. Furthermore, we also have $\|s\|_{L_2(\Omega)} \sim \|\overline{s}\|_{L_2(\overline{\Omega})}$; see Lemma 3.1 in [25]. Now let $s = \sum_{j=0}^{J} s_j$ with each $s_j \in S_j$. Then it follows from the theory of homogeneous polynomials [2, 3] that $(s)_m = \sum_{j=0}^{J} (s_j)_m$; hence $\overline{s} = \sum_{j=0}^{J} \overline{s}_j$ with $\overline{s}_j$ the restriction of $(s_j)_m$ to $\overline{\Omega}$. Furthermore, each $\overline{s}_j$ is a member of the planar spline space $\overline{S}_j$ which is defined as $S^0_1(R^{-1}_{T_\Omega}(\Delta_j|_\Omega))$ for $m = 1$ and as $S^1_2(R^{-1}_{T_\Omega}(\Delta^{PS}_j|_\Omega))$ for $m = 2$. Proposition 2 in [26] claims that

$$\|\overline{s}\|^2_{H^m(\overline{\Omega})} \sim \inf \sum_{j=0}^{J} \rho^{2mj} \|\overline{s}_j\|^2_{L_2(\overline{\Omega})} ,$$

where the infimum must be taken with respect to all admissible representations $\sum_{j=0}^{J} \overline{s}_j$ of $\overline{s}$. From the norm equivalences above, we get

$$\|s\|^2_{H^m(\Omega)} \sim \inf \sum_{j=0}^{J} \rho^{2mj} \|s_j\|^2_{L_2(\Omega)} . \tag{3.2}$$

Now consider a finite collection of domains Ω_k with $\operatorname{diam}(\Omega_k) \leq 1$, covering S. Equation (3.2) is valid for each subdomain Ω_k. Furthermore, we have the equivalences $\|s_j\|^2_{L_2(S)} \sim \sum_k \|s_j\|^2_{L_2(\Omega_k)}$ and $\|s\|^2_{H^m(S)} \sim \sum_k \|s\|^2_{H^m(\Omega_k)}$. Hence,

$$\|s\|^2_{H^m(S)} \sim \inf \sum_{j=0}^{J} \rho^{2mj} \|s_j\|^2_{L_2(S)} ,$$

which immediately implies (3.1); see [15, 26]. ∎

Remark 3.2. Proposition 2 in [26] is formulated in terms of C^1 finite elements, but it is clear that a similar result holds for C^0 finite elements (with obvious modifications).

In view of (1.7) let us define the self-adjoint positive definite operator C_J^{-1} on S_J by

$$(C_J^{-1}u, v) = \sum_{j=0}^{J} \rho^{2mj}((Q_j - Q_{j-1})u, (Q_j - Q_{j-1})v), \tag{3.3}$$

and let A_J be the operator defined by (1.5) for $V = S_J$. By Poincaré's inequality on S, we have

$$a(u,u) \sim \|u\|^2_{H^m(S)} \tag{3.4}$$

under the constraint $\int_S u \, d\omega = 0$. Then Theorem 3.1 and (1.7) imply that

$$\kappa(C_J^{1/2} A_J C_J^{1/2}) = \mathcal{O}(1) \tag{3.5}$$

under the constraint that we fix the solution u of (1.3), (1.4) such that $\int_S u \, d\omega = 0$.

We now replace C_J by a spectrally equivalent and computationally simpler preconditioner $\widehat{C}_J$ given by

$$\widehat{C}_J := \sum_{j=0}^{J} \sum_{i=1}^{N_j} (\cdot, \phi_{i,j}) \phi_{i,j} \tag{3.6}$$

for problem (1.3) and by

$$\widehat{C}_J := \sum_{j=0}^{J} \sum_{i=1}^{N_j} \sum_{k=1}^{3} (\cdot, B_{i,j}^k) B_{i,j}^k \tag{3.7}$$

for problem (1.4). We say that two operators A and B are *spectrally equivalent* if

$$\frac{(Av,v)}{(v,v)} \sim \frac{(Bv,v)}{(v,v)}.$$

Note that, by (3.3), we have

$$C_J^{-1} := \sum_{j=0}^{J} \rho^{2mj} (Q_j - Q_{j-1}). \tag{3.8}$$

Indeed, by the L_2-orthogonality of the operators Q_j we find

$$\begin{aligned}
(C_J^{-1} u, v) &= \left(\sum_{j=0}^{J} \rho^{2mj} (Q_j - Q_{j-1}) u, v \right) \\
&= \left(\sum_{j=0}^{J} \rho^{2mj} (Q_j - Q_{j-1}) u, \sum_{j=0}^{J} (Q_j - Q_{j-1}) v \right) \\
&= \sum_{j=0}^{J} \rho^{2mj} ((Q_j - Q_{j-1}) u, (Q_j - Q_{j-1}) v).
\end{aligned}$$

Let us focus on the biharmonic problem (1.4); i.e., take $m = 2$. By the orthogonality of the projectors Q_j, one finds from (3.8) that

$$C_J = \sum_{j=0}^{J} \sqrt{3}^{-4j} (Q_j - Q_{j-1}).$$

Because of the decaying scaling factors we are allowed to replace C_J by the spectrally equivalent operator

$$\widetilde{C}_J := \sum_{j=0}^{J} \sqrt{3}^{-4j} Q_j.$$

From Theorem 2.7, we have the Riesz L_2-stability

$$\left\| \sum_{i=1}^{N_j} \sum_{k=1}^{3} c_{i,j}^k B_{i,j}^k \right\|_{L_2}^2 \sim \sqrt{3}^{-4j} \sum_{i=1}^{N_j} \sum_{k=1}^{3} |c_{i,j}^k|^2, \tag{3.9}$$

and by the Riesz representation theorem this implies the existence of a dual or biorthogonal basis $\{\widetilde{B}_{i,j}^k\}$ such that

$$\left\| \sum_{i=1}^{N_j} \sum_{k=1}^{3} c_{i,j}^k \widetilde{B}_{i,j}^k \right\|_{L_2}^2 \sim \sqrt{3}^{4j} \sum_{i=1}^{N_j} \sum_{k=1}^{3} |c_{i,j}^k|^2. \tag{3.10}$$

The orthogonal projector Q_j has the representation

$$Q_j f = \sum_{i=1}^{N_j} \sum_{k=1}^{3} (f, \widetilde{B}_{i,j}^k) B_{i,j}^k.$$

Hence,

$$(Q_j f, f) = (Q_j f, Q_j f) = \|Q_j f\|_{L_2}^2 \sim \sqrt{3}^{4j} \sum_{i=1}^{N_j} \sum_{k=1}^{3} |(f, B_{i,j}^k)|^2 = (\widehat{Q}_j f, f),$$

with

$$\widehat{Q}_j := \sqrt{3}^{4j} \sum_{i=1}^{N_j} \sum_{k=1}^{3} (\cdot, B_{i,j}^k) B_{i,j}^k,$$

which shows that $\widehat{C}_J$ defined in (3.7) is spectrally equivalent to C_J such that, by (3.5),

$$\kappa(\widehat{C}_J^{1/2} A_J \widehat{C}_J^{1/2}) = \mathcal{O}(1).$$

The optimality of the preconditioner defined in (3.6) for problem (1.3) can be derived analogously using Theorem 2.3. We have thus proved the main result of this paper.

THEOREM 3.3. *The BPX preconditioners given by*

$$\sum_{j=0}^{J} \sum_{i=1}^{N_j} (\cdot, \phi_{i,j}) \phi_{i,j} \quad \text{and} \quad \sum_{j=0}^{J} \sum_{i=1}^{N_j} \sum_{k=1}^{3} (\cdot, B_{i,j}^k) B_{i,j}^k$$

yield uniformly bounded condition numbers for problem (1.3) *(resp.,* (1.4)).

COROLLARY 3.4. *Any basis of the general form in* [23] *which is stable in the sense of Theorem* 2.7 *gives rise to an optimal BPX preconditioner for* (1.4).

Remark 3.5. In the paper [18] Griebel shows that the conjugate gradient method for the semidefinite system that arises from the Galerkin scheme using the nodal basis

functions of the finest level and of all coarser levels of discretization is equivalent to the BPX-preconditioned conjugate gradient method for the linear system that arises from the Galerkin scheme using only the nodal basis functions of the finest level. In our numerical experiments we take the approach of the semidefinite system using the nodal basis functions at all resolution levels. For details on efficient implementation we refer to [18].

Remark 3.6. The above derivation depends heavily on the use of a biorthogonal basis. Its existence is guaranteed by the Riesz representation theorem. Note the weight change from $\sqrt{3}^{-4j}$ in (3.9) for the finite element basis to $\sqrt{3}^{4j}$ in (3.10) for the biorthogonal basis. For properties of Riesz bases in connection with biorthogonality and multiresolution we refer the reader to [14].

4. Numerical results. In this section we provide the results of numerical experiments illustrating the optimality of the BPX preconditioners developed in the earlier sections. We also compare the results of the BPX preconditioners with those obtained using the corresponding hierarchical preconditioners which are suboptimal.

The first problem that we solve is given by

$$-\Delta_S u = 2x \quad \text{on} \quad S, \tag{4.1}$$

and the exact solution u equals x, which can easily be checked since spherical harmonics are eigenfunctions of the Laplace–Beltrami operator on S [24]. To discretize problem (4.1) we use the basis functions $\phi_{i,j}$. We start from an almost uniform triangulation Δ_0 by projecting the twelve vertices of the regular icosahedron onto the sphere. These twelve points define a mesh consisting of twenty equal spherical triangles; cf. [6]. The finer triangulations Δ_j are constructed by subdividing the triangles of the previous coarser triangulation into four equal subtriangles. Hence the dimension of the spline space increases like $2 + 10 \cdot 4^j$ with the refinement level j. Inner products of the form $(\nabla_S \phi_{i_1,j}, \nabla_S \phi_{i_2,j})$ will have to be computed. Hereto, we use a third order Gaussian quadrature formula on a triangle; see also [4, Prop. 4.1].

The second problem that we solve is given by

$$\Delta_S^2 u = 36xy \quad \text{on} \quad S, \tag{4.2}$$

and the exact solution u equals xy. In order to discretize (4.2) we have to compute inner products of the form $(\Delta_S B_{i_1,j}^{k_1}, \Delta_S B_{i_2,j}^{k_2})$. Since the basis functions $B_{i,j}^k$ are piecewise quadratic polynomials, we can use the formula

$$\Delta_S B_{i,j}^k(v) = \Delta B_{i,j}^k(v) - 6B_{i,j}^k(v), \quad v \in S,$$

with Δ the usual Laplace operator on $\mathbb{R}^3$; see [24]. Then, to evaluate the inner products, we use again a third order Gaussian quadrature formula on a triangle. We show results for the $\sqrt{3}$ refinement procedure where we start from the same quasi-uniform triangulation Δ_0 as in the first problem (4.1). The dimension of the spline space increases like $6 + 30 \cdot 3^j$ with the refinement level j.

Note that the solution u in (4.1) and (4.2) is unique only up to a constant. From [2, Prop. 7.2] we find that constant functions on the sphere are contained in the spherical PS spline space $S_2^1(\Delta_j^{PS})$ but not in the spherical piecewise linear spline space $S_1^0(\Delta_j)$. Hence, the stiffness matrix corresponding to the nodal basis $\{B_{i,j}^k\}$ will have one zero eigenvalue with an eigenvector corresponding to the constant function. The stiffness matrix corresponding to the nodal basis $\{\phi_{i,j}\}$ will have an eigenvalue of $\mathcal{O}(h^2)$ with an

eigenvector that approximates the constant function up to discretization error $\mathcal{O}(h^2)$ with respect to the L_2-norm. Note that the condition numbers that we compute are given by $\kappa(C^{1/2}AC^{1/2}) = \lambda_{\max}/\lambda_{\min}$, where $\lambda_{\max}$ denotes the largest eigenvalue of $C^{1/2}AC^{1/2}$ and $\lambda_{\min}$ its smallest nonzero eigenvalue. For obvious reasons we also omit the smallest eigenvalue of $\mathcal{O}(h^2)$ for the Poisson equation. Note that, from Theorem 3.3 and Remark 3.5, the BPX preconditioner uses all nodal basis functions on all levels. For each redundant basis function we will get a zero eigenvalue.

Tables 4.1 and 4.2 show the results. We have used a *nested iteration conjugate gradient method* to solve the problem; i.e., by means of an outer iteration loop going from a coarse resolution level to the finest resolution level we compute the solution to (4.1) or (4.2) at each level with the BPX-preconditioned conjugate gradient method and we use the solution obtained at the previous coarser level as an initial guess. At each level we stop the conjugate gradient iteration if the H^m-norm of the residual is proportional to the discretization error which is of $\mathcal{O}(h)$. In [11] arguments are given for the fact that nested iteration is an asymptotically optimal method in the sense that it provides the solution u at the finest resolution level J up to discretization error in an overall number of $\mathcal{O}(N_J)$ operations, provided that an optimal preconditioner is used.

Each table has the same setup. The first column shows the dimension of the spline space, and the second column contains the resolution level J. Then we distinguish between the results for the BPX preconditioner and the results for the HB preconditioner. For each preconditioner we display the spectral condition number κ of the system matrix for the linear system of equations that is solved. Moreover, we show the H^m-norm of the residuals corresponding to the approximate solution, and the number of iterations that are needed on this level to reach discretization error accuracy.

Remark 4.1. Computing the H^m-norm of the residual is easy. Let us concentrate on problem (1.2). We have that

$$\begin{aligned}\|u_J - u\|_{H^2}^2 &\sim \|Au_J - b\|_{(H^2)'}^2 \\ &= \left\| \sum_{j=0}^{J} \sum_{i=1}^{N_j} \sum_{k=1}^{3} \langle B_{i,j}^k, A(u_j - u)\rangle \widetilde{B}_{i,j}^k \right\|_{(H^2)'}^2 \\ &\sim \sum_{j=0}^{J} \sum_{i=1}^{N_j} \sum_{k=1}^{3} |\langle B_{i,j}^k, A(u_j - u)\rangle|^2 \\ &= \sum_{j=0}^{J} \sum_{i=1}^{N_j} \sum_{k=1}^{3} \left|\langle B_{i,j}^k, Au_j\rangle - \langle B_{i,j}^k, b\rangle\right|^2 .\end{aligned}$$

Here $\{\widetilde{B}_{i,j}^k\}$ is the dual frame to $\{B_{i,j}^k\}$. The first equivalence is due to the ellipticity of the operator A. The second equivalence is because the dual frame is a Riesz frame for the dual function space $\left(H^2\right)'$. The last expression is just the l_2-norm of the residual of the system (1.8) with respect to the frame $\{B_{i,j}^k\}$ (see also Remark 3.5). This trick works only for elliptic partial differential equations, because the first equivalence above makes use of the ellipticity condition (3.4).

SUPERCONVERGENCE FOR CONTROL-VOLUME MIXED FINITE ELEMENT METHODS ON RECTANGULAR GRIDS*

THOMAS F. RUSSELL†, MARY F. WHEELER‡, AND IVAN YOTOV§

Abstract. We consider control-volume mixed finite element methods for the approximation of second-order elliptic problems on rectangular grids. These methods associate control volumes (covolumes) with the vector variable as well as the scalar, obtaining local algebraic representation of the vector equation (e.g., Darcy's law) as well as the scalar equation (e.g., conservation of mass). We establish $O(h^2)$ superconvergence for both the scalar variable in a discrete L^2-norm and the vector variable in a discrete $H(\mathrm{div})$-norm. The analysis exploits a relationship between control-volume mixed finite element methods and the lowest order Raviart–Thomas mixed finite element methods.

1. Introduction.

We consider the second-order elliptic problem in a domain $\Omega \subset \mathbb{R}^d$, $d = 2$ or 3, written as a first-order system

$$\mathbf{u} = -K\nabla p \text{ in } \Omega, \tag{1.1}$$

$$\nabla \cdot \mathbf{u} = f \text{ in } \Omega, \tag{1.2}$$

$$\mathbf{u} \cdot \mathbf{n} = 0 \text{ on } \partial\Omega. \tag{1.3}$$

The above equations model single-phase flow in porous media, where p is the fluid pressure, the vector $\mathbf{u}$ is the Darcy velocity, K is a symmetric uniformly positive definite and bounded diagonal tensor, representing the rock permeability divided by the fluid viscosity, $\mathbf{n}$ is the outward unit normal to $\partial\Omega$, and f is the source term satisfying the compatibility condition

$$\int_\Omega f\,dx = 0.$$

The choice of homogeneous Neumann boundary condition corresponds to an impermeable boundary, which is the typical physical situation.

In this paper we consider discretizations for (1.1)–(1.3) based on control-volume mixed finite element methods (CVMFEM) and establish $O(h^2)$ superconvergence for the pressure and velocity in a discrete L^2-norm and $H(\mathrm{div})$-norm, respectively. Most of the arguments can be extended to Dirichlet boundary conditions. However, some

loss of superconvergence occurs on the boundary in that case. Global $O(h)$ convergence has been shown by Chou et al. [9, 10]; here we obtain the $O(h^2)$ rate suggested by various numerical results (e.g., [8, 19, 24, 22]). Superconvergence is proved by $O(h^2)$ estimates of the differences between the scalar and vector discrete solutions and appropriate projections of the exact solutions.

CVMFEM, first introduced in [8], can be viewed as a type of mixed covolume method [9, 10, 11]. CVMFEM are closely related to the Raviart–Thomas mixed finite element methods (MFEM) [27, 7, 28], cell-centered finite difference (CCFD) methods [29, 30, 4], mimetic finite difference (MFD) methods [5, 21, 6], and multipoint flux approximation (MPFA) methods [1, 17]. Some of these relationships are explored in detail in [22].

Like MFEM, CVMFEM are designed to provide simultaneous (accurate) approximations of pressure and velocity, and local mass conservation, $\int_Q \nabla\cdot\mathbf{u}_h = \int_Q f$ on each finite element Q, where $\mathbf{u}_h$ is the computed velocity. These properties can be difficult to obtain when K is heterogeneous (in particular, discontinuous) and/or anisotropic, especially when it incorporates irregular geological features. The methods listed above seek to accomplish this for flow in porous media, among other applications.

Unlike MFEM, CVMFEM have vector control volumes (covolumes) that give rise to a local discrete Darcy law analogous to (1.1). An engineer measuring the permeability of a core sample will typically impose a pressure at each end and observe the flux through the core. The discrete CVMFEM control volume that corresponds to the discrete flux unknown through a face, consisting of the two adjacent halves of the elements on either side of the face (see Figure 1), plays the role of this core, with the element pressures representing the imposed pressures at the ends. The vector test function associated with the control volume is essentially a piecewise-constant vector field, similar to a unit vector in the control volume and a zero vector outside it. The algebraic equation produced by this test function is the local discrete Darcy law. Thus, CVMFEM represent both physical principles in (1.1)–(1.3) locally.

In MFEM, the test vector belongs to the vector trial space and therefore has a continuous normal component. Because the test and trial spaces are the same, the mass matrix is symmetric and positive definite (SPD). In CVMFEM, the normal component of the test vector is discontinuous at the ends of the control volume, and can also be discontinuous at the element face for general distorted grids. If K is elementwise constant and the elements are affine (parallelograms in two dimensions), the mass matrix is SPD, despite the distinct test and trial spaces; in general, it is not symmetric, but symmetry can be restored by appropriate numerical integration [19].

On a uniform grid with constant K, the lowest-order Raviart–Thomas MFEM, denoted RT_0, yields a tridiagonal mass matrix with weights 1/6, 2/3, 1/6, and the basic CCFD results in a diagonal mass matrix. As will be seen below, CVMFEM leads to weights 1/8, 3/4, 1/8. These are all of the form c, $1-2c$, c, where $c = 0$ (CCFD), 1/6 (MFEM), or 1/8 (CVMFEM). In [19], some heuristic reasons to favor $c = 1/8$ are presented: on a uniform grid, the second-order truncation error term is half that of $c = 0$ and $c = 1/6$; on a nonuniform grid, only $c = 1/8$ matches one-sided compact finite differences, avoiding any first-order local truncation error; in terms of Fourier modes, the ratio of the discrete eigenvalue to the continuous eigenvalue is generally closer to 1 for $c = 1/8$. Numerical results in [22] for homogeneous K show second-order convergence for both MFEM and CVMFEM; on orthogonal grids, the flux error for CVMFEM improves on that of MFEM by a factor of approximately 2.6; on the distorted grids used, CVMFEM is worse by a factor of about 1.3.

The rest of the paper is organized as follows. In the next section we recall the Raviart–Thomas MFEM for (1.1)–(1.3). Section 3 describes the CVMFEM and its relation to the Raviart–Thomas MFEM. Superconvergence for the velocity is established in section 4. Section 5 is devoted to superconvergence for the pressure.

2. Mixed finite element methods. We will make use of the following standard notation. For a subdomain $G \subset \mathbb{R}^d$, the $L^2(G)$ inner product (or duality pairing) for scalar and vector valued functions is denoted by $(\cdot,\cdot)_G$. We denote the norm in the Sobolev space $W_p^k(G)$, $k \in \mathbb{R}$, $1 \le p \le \infty$ [2], by $\|\cdot\|_{k,p,G}$. Let $\|\cdot\|_{k,G}$ be the norm of the Hilbert space $H^k(G) = W_2^k(G)$. We omit G in the subscript if $G = \Omega$. For a section of a subdomain boundary $S \subset \mathbb{R}^{d-1}$ we write $\langle\cdot,\cdot\rangle_S$ and $\|\cdot\|_{0,S}$ for the $L^2(S)$ inner product (or duality pairing) and norm, respectively.

The mixed variational formulation, which is the basis for the MFEM is as follows. Find $\mathbf{u} \in \mathbf{V}$ and $p \in W$ such that

$$(K^{-1}\mathbf{u}, \mathbf{v}) = (p, \nabla\cdot\mathbf{v}), \quad \mathbf{v} \in \mathbf{V}, \tag{2.1}$$

$$(\nabla\cdot\mathbf{u}, w) = (f, w), \quad w \in W, \tag{2.2}$$

where

$$\mathbf{V} = \{\mathbf{v} \in H(\mathrm{div};\Omega) : \mathbf{v}\cdot\mathbf{n} = 0 \text{ on } \partial\Omega\}, \quad W = L_0^2(\Omega) = \left\{w \in L^2(\Omega) : \int_\Omega w\,dx = 0\right\},$$

and

$$H(\mathrm{div};\Omega) = \{\mathbf{v} : \mathbf{v} \in (L^2(\Omega))^2,\ \nabla\cdot\mathbf{v} \in L^2(\Omega)\}$$

with a norm

$$\|\mathbf{v}\|_{\mathbf{V}} = (\|\mathbf{v}\|^2 + \|\nabla\cdot\mathbf{v}\|^2)^{1/2}.$$

We assume that Ω can be exactly covered by a rectangular-type finite element partition $\mathcal{T}_h$. Let $\mathbf{V}_h \times W_h \subset \mathbf{V} \times W$ be the lowest-order Raviart–Thomas (RT_0) mixed finite element spaces on $\mathcal{T}_h$ [27]. More precisely, for all $Q \in \mathcal{T}_h$,

$$\mathbf{V}_h(Q) = \{\mathbf{v} = (a_1{+}b_1x, a_2{+}b_2y, a_3{+}b_3z)^T \text{ on } Q\}, \quad W_h(Q) = \{w = \text{constant on } Q\},$$

$$\mathbf{V}_h = \{\mathbf{v} \in \mathbf{V} : \mathbf{v}|_Q \in \mathbf{V}_h(Q)\ \forall\, Q \in \mathcal{T}_h\}, \quad W_h = \{w \in W : w|_Q \in W_h(Q)\ \forall\, Q \in \mathcal{T}_h\},$$

where the third component of $\mathbf{v}$ should be removed if $d = 2$. The degrees of freedom of $\mathbf{V}_h$ are the constant normal components on the sides. If these are continuous, then $\mathbf{v} \in H(\mathrm{div};\Omega)$. Key properties of the RT_0 spaces are

$$\nabla\cdot\mathbf{V}_h = W_h \tag{2.3}$$

and the existence of an interpolation operator $\Pi : (H^1(\Omega))^d \to \mathbf{V}_h$ (see [27, 7]) such that for $\mathbf{q} \in (H^1(\Omega))^2$

$$(\nabla\cdot(\Pi\mathbf{q} - \mathbf{q}), w) = 0 \quad \forall\, w \in W_h \tag{2.4}$$

and which satisfies the continuity and approximation properties

$$\|\Pi\mathbf{q}\|_{\mathbf{V}} \le C\|\mathbf{q}\|_1, \tag{2.5}$$

$$\|\mathbf{q} - \Pi\mathbf{q}\|_0 \le Ch|\mathbf{q}|_1. \tag{2.6}$$

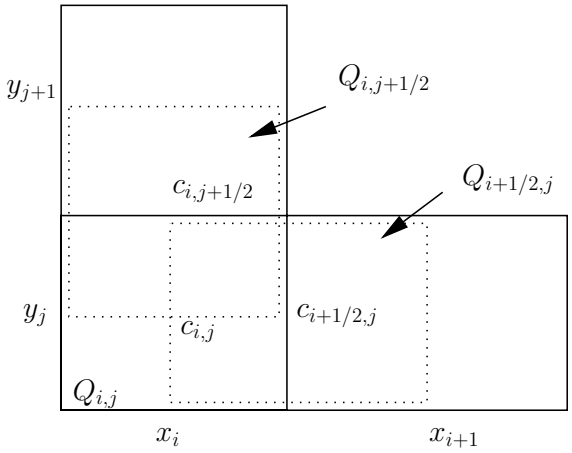

FIG. 1. *Computational grid and control volumes.*

The MFEM for approximating (2.1)–(2.2) is as follows. Find $\tilde{\mathbf{u}}_h \in \mathbf{V}_h$, $\tilde{p}_h \in W_h$ such that

$$(K^{-1}\tilde{\mathbf{u}}_h, \mathbf{v}) = (\tilde{p}_h, \nabla \cdot \mathbf{v}), \quad \mathbf{v} \in \mathbf{V}_h, \tag{2.7}$$

$$(\nabla \cdot \tilde{\mathbf{u}}_h, w) = (f, w), \quad w \in W_h. \tag{2.8}$$

It has been shown in [27] that (2.7)–(2.8) has a unique solution and

$$\|p - \tilde{p}_h\|_W + \|\mathbf{u} - \tilde{\mathbf{u}}_h\|_{\mathbf{V}} = O(h).$$

A number of authors have studied superconvergence for the above method or the closely related CCFD method [25, 14, 30, 15, 16, 18, 4] and have shown results of the form

$$|||p - \tilde{p}_h|||_W + |||\mathbf{u} - \tilde{\mathbf{u}}_h|||_{\mathbf{V}} = O(h^2),$$

where $|||\cdot|||_W$ and $|||\cdot|||_{\mathbf{V}}$ are discrete norms defined in (4.8) and (4.9) below (or some variants of them). The goal of this paper is to obtain similar superconvergence results for the CVMFEM.

3. Control volume mixed finite element methods. Denote the elements of $\mathcal{T}_h$ by $Q_{i,j}$ for $d = 2$ or by $Q_{i,j,k}$ for $d = 3$; see Figure 1 for $d = 2$. For simplicity, in most of the paper we will use the notation and present the arguments for $d = 2$. The case $d = 3$ is a trivial extension.

The center of $Q_{i,j}$ is denoted by $c_{i,j}$. The midpoints of the left and right edges are denoted by $c_{i-1/2,j}$ and $c_{i+1/2,j}$, respectively, with similar notation for the bottom and top edges. With each edge we associate a control volume, where Darcy's law (1.1) is approximated. In particular, letting $c_{i+1/2,j} = (x_{i+1/2}, y_j)$, $c_{i,j} = (x_i, y_j)$, etc., define

$$Q_{i+1/2,j} := (x_i, x_{i+1}) \times (y_{j-1/2}, y_{j+1/2}) \cap \Omega, \tag{3.1}$$

$$Q_{i,j+1/2} := (x_{i-1/2}, x_{i+1/2}) \times (y_i, y_{i+1}) \cap \Omega. \tag{3.2}$$

The control volumes $Q_{i+1/2,j}$ and $Q_{i,j+1/2}$ are referred to as v_1-volumes and v_2-volumes, respectively. The control volumes that have at least one edge on $\partial\Omega$ are called border volumes.

Define the velocity test space

$$\begin{aligned}\mathbf{Y}_h = \{(v_h^1, v_h^2) : v_h^1|_{Q_{i+1/2,j}} &= \text{ constant } \forall\, Q_{i+1/2,j},\ v_h^1 = 0 \text{ on border } v_1\text{-volumes}\\ v_h^2|_{Q_{i,j+1/2}} &= \text{ constant } \forall\, Q_{i,j+1/2},\ v_h^2 = 0 \text{ on border } v_2\text{-volumes}\}.\end{aligned}$$

Thus, for example, the basis function $\mathbf{y}_{i+1/2,j} \in \mathbf{Y}_h$ associated with $c_{i+1/2,j}$ is the vector $(\chi_{i+1/2,j}, 0)$, i.e., $(1,0)$ on $Q_{i+1/2,j}$, $(0,0)$ elsewhere. To see the form of the associated algebraic equation, write (1.1) as $K^{-1}\mathbf{u} + \nabla p = 0$, form the inner product with $\mathbf{y}_{i+1/2,j}$, and integrate

$$\int_{x_i}^{x_{i+1}} \int_{y_{j-1/2}}^{y_{j+1/2}} (K^1)^{-1} u^1 \, dy\, dx + \int_{y_{j-1/2}}^{y_{j+1/2}} (p(x_{i+1}, y) - p(x_i, y))\, dy = 0,$$

where $\mathbf{u} = (u^1, u^2)$ and $K = \operatorname{diag}(K^1, K^2)$. Suppose that K is elementwise constant on $Q_{i,j}$ and $Q_{i+1,j}$. Taking $\mathbf{u} = \mathbf{v}_{i-1/2,j}, \mathbf{v}_{i+1/2,j}, \mathbf{v}_{i+3/2,j} \in \mathbf{V}_h$, the usual RT_0 vector basis functions, we obtain the tridiagonal mass-matrix coefficients

$$1/8\,(K^1_{i,j})^{-1} h_i^x h_j^y,\ 3/8\,(K^1_{i,j})^{-1} h_i^x h_j^y + 3/8\,(K^1_{i+1,j})^{-1} h_{i+1}^x h_j^y,\ 1/8\,(K^1_{i+1,j})^{-1} h_{i+1}^x h_j^y,$$

where h^x and h^y are the element dimensions. For homogeneous K and a uniform grid, this reduces to 1/8, 3/4, 1/8, as noted above.

3.1. Variational formulation for CVMFEM. Following [9], define the bilinear forms $a(\cdot,\cdot) : (L^2(\Omega))^d \times (L^2(\Omega))^d \to \mathbb{R}$, $b(\cdot,\cdot) : \mathbf{Y}_h \times H^1(\Omega) \to \mathbb{R}$, and $c(\cdot,\cdot) : H(\operatorname{div};\Omega) \times L^2(\Omega) \to \mathbb{R}$ as follows:

$$\begin{aligned} a(\mathbf{u}, \mathbf{v}) &:= (K^{-1}\mathbf{u}, \mathbf{v}),\\ b(\mathbf{v}, p) &:= \sum_{i,j} \langle p, (v^1, 0)^T \cdot \mathbf{n}\rangle_{\partial Q_{i+1/2,j}} + \sum_{i,j} \langle p, (0, v^2)^T \cdot \mathbf{n}\rangle_{\partial Q_{i,j+1/2}},\\ c(\mathbf{u}, w) &:= (\nabla \cdot \mathbf{u}, w).\end{aligned}$$

LEMMA 3.1. *If* $(\mathbf{u}, p) \in H(\operatorname{div};\Omega) \times H^1(\Omega)$ *solves* (1.1)–(1.3)*, then* $(\mathbf{u}, p)$ *satisfies the variational formulation*

$$a(\mathbf{u}, \mathbf{v}) + b(\mathbf{v}, p) = 0, \quad \mathbf{v} \in \mathbf{Y}_h, \tag{3.3}$$

$$c(\mathbf{u}, w) = (f, w), \quad w \in W_h. \tag{3.4}$$

Proof. Equation (1.1) implies, for $\mathbf{v} \in \mathbf{Y}_h$,

$$\begin{aligned}(K^{-1}\mathbf{u}, \mathbf{v}) = (-\nabla p, \mathbf{v}) &= \sum_{i,j} (-\nabla p, (v^1, 0)^T)_{Q_{i+1/2,j}} + \sum_{i,j} (-\nabla p, (0, v^2)^T)_{Q_{i,j+1/2}}\\ &= -\sum_{i,j} \langle p, (v^1, 0)^T \cdot \mathbf{n}\rangle_{\partial Q_{i+1/2,j}} - \sum_{i,j} \langle p, (0, v^2)^T \cdot \mathbf{n}\rangle_{\partial Q_{i,j+1/2}},\end{aligned}$$

giving (3.3). Equation (3.4) follows trivially from (1.2). ∎

The CVMFEM may be formulated as follows. Find $(\mathbf{u}_h, p_h) \in \mathbf{V}_h \times W_h$ such that

$$a(\mathbf{u}_h, \mathbf{v}) + b(\mathbf{v}, p_h) = 0, \quad \mathbf{v} \in \mathbf{Y}_h, \tag{3.5}$$

$$c(\mathbf{u}_h, w) = (f, w), \quad w \in W_h. \tag{3.6}$$

Note that (3.5) is a Petrov–Galerkin FEM, since the test functions differ from the trial functions. We next recall the transfer operator $\gamma_h : \mathbf{V}_h \to \mathbf{Y}_h$, introduced in [9]. Define, for all $\mathbf{v} \in \mathbf{V}_h$,

$$\gamma_h \mathbf{v} = \left(\sum_{i,j} v^1(c_{i+1/2,j}) \chi_{i+1/2,j}, \sum_{i,j} v^2(c_{i,j+1/2}) \chi_{i,j+1/2} \right).$$

It has been shown in [9] that for constants $\alpha > 0$ and C independent of h,

$$b(\gamma_h \mathbf{v}, w) = -c(\mathbf{v}, w) \quad \forall\ \mathbf{v} \in \mathbf{V}_h, w \in W_h, \tag{3.7}$$

$$a(\mathbf{v}, \gamma_h \mathbf{v}) \geq \alpha \|\mathbf{v}\|_0^2 \quad \forall\ \mathbf{v} \in \mathbf{V}_h, \tag{3.8}$$

$$\|\gamma_h \mathbf{v}\|_0 \leq C \|\mathbf{v}\|_0. \tag{3.9}$$

4. Velocity superconvergence analysis. In this section we establish superconvergence for the velocity in the CVMFEM. In the treatment of the permeability K we will make use of the following piecewise smooth space. Let $W^{\alpha}_{\mathcal{T}_h}$ consist of functions φ such that $\varphi|_Q \in W^{\alpha}(Q)$ for all $Q \in \mathcal{T}_h$ and $\|\varphi\|_{\alpha,Q}$ is uniformly bounded, independently of h. Let

$$|||\varphi|||_{\alpha} = \max_{Q \in \mathcal{T}_h} \|\varphi\|_{\alpha,Q}.$$

Subtracting (3.5)–(3.6) from (3.3)–(3.4) gives the error equations

$$a(\mathbf{u} - \mathbf{u}_h, \mathbf{v}) + b(\mathbf{v}, p - p_h) = 0, \quad \mathbf{v} \in \mathbf{Y}_h, \tag{4.1}$$

$$c(\mathbf{u} - \mathbf{u}_h, w) = 0, \quad w \in W_h. \tag{4.2}$$

We first note that (4.2) implies

$$0 = c(\mathbf{u} - \mathbf{u}_h, w) = (\nabla \cdot (\mathbf{u} - \mathbf{u}_h), w) = (\nabla \cdot (\Pi \mathbf{u} - \mathbf{u}_h), w) \quad \forall\, w \in W_h$$

using (2.4). Therefore, using (2.3),

$$\nabla \cdot (\Pi \mathbf{u} - \mathbf{u}_h) = 0. \tag{4.3}$$

Let P_h be the L^2-orthogonal projection onto W_h, satisfying for any $\varphi \in L^2(\Omega)$

$$(\varphi - P_h \varphi, w) = 0 \quad \forall w \in W_h. \tag{4.4}$$

Taking $\mathbf{v} = \gamma_h(\Pi \mathbf{u} - \mathbf{u}_h)$ and $w = P_h p - p_h$ in (4.1)–(4.2) implies

$$\begin{aligned} &a(\Pi \mathbf{u} - \mathbf{u}_h, \gamma_h(\Pi \mathbf{u} - \mathbf{u}_h)) \\ &\qquad = -a(\mathbf{u} - \Pi \mathbf{u}, \gamma_h(\Pi \mathbf{u} - \mathbf{u}_h)) - b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), p - p_h), \end{aligned} \tag{4.5}$$

$$c(\Pi \mathbf{u} - \mathbf{u}_h, P_h p - p_h) = 0. \tag{4.6}$$

The second term on the right in (4.5) can be manipulated as follows:

$$\begin{aligned} b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), p - p_h) &= b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), p - P_h p) + b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), P_h p - p_h) \\ &= b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), p - P_h p) - c(\Pi \mathbf{u} - \mathbf{u}_h, P_h p - p_h) \\ &= b(\gamma_h(\Pi \mathbf{u} - \mathbf{u}_h), p - P_h p), \end{aligned}$$

using (3.7) and (4.6) in the last equality. Therefore (4.5) gives

(4.7)
$$a(\Pi\mathbf{u}-\mathbf{u}_h,\gamma_h(\Pi\mathbf{u}-\mathbf{u}_h)) = -a(\mathbf{u}-\Pi\mathbf{u},\gamma_h(\Pi\mathbf{u}-\mathbf{u}_h)) - b(\gamma_h(\Pi\mathbf{u}-\mathbf{u}_h),p-P_hp).$$

Lemma 4.4 implies that

$$|a(\mathbf{u}-\Pi\mathbf{u},\gamma_h(\Pi\mathbf{u}-\mathbf{u}_h)| \le Ch^2|||K^{-1}|||_{1,\infty}\|\mathbf{u}\|_2\|\Pi\mathbf{u}-\mathbf{u}_h\|_0.$$

Using (4.3), Lemma 4.5 gives

$$|b(\gamma_h(\Pi\mathbf{u}-\mathbf{u}_h),p-P_hp)| \le Ch^2\|p\|_3\|\Pi\mathbf{u}-\mathbf{u}_h\|_0.$$

With the above two bounds and (3.8), (4.7) implies the following superconvergence result.

THEOREM 4.1. *For the CVMFEM approximation* $(\mathbf{u}_h,p_h)$*, there exists a constant* C *independent of* h *such that*

$$\|\Pi\mathbf{u}-\mathbf{u}_h\|_0 \le Ch^2|||K^{-1}|||_{1,\infty}(\|\mathbf{u}\|_2+\|p\|_3).$$

Remark 4.1. The velocity superconvergence result of Theorem 4.1 and the pressure superconvergence bound of Theorem 5.1 require global smoothness of $\mathbf{u}$ and p. There are practical cases when the solution is locally smooth on a given region but possesses reduced regularity globally, such as aquifers with faults or multiple rock layers. Such cases could be treated by establishing interior and negative norm bounds, using techniques developed in [26, 14].

The above result immediately implies superconvergence for the velocity in an L^2 sense along the Gaussian lines. Consider an element $Q=[a_1,b_1]\times[a_2,b_2]$. Following [18, 16], for a vector $\mathbf{q}=(q_1,q_2)$ define

$$|||q_1|||_{1,Q}^2 = (b_2-a_2)\int_{a_1}^{b_1}\left|q_1\left(x_1,\frac{a_2+b_2}{2}\right)\right|^2 dx_1,$$

$$|||q_2|||_{2,Q}^2 = (b_1-a_1)\int_{a_2}^{b_2}\left|q_2\left(\frac{a_1+b_1}{2},x_2\right)\right|^2 dx_2,$$

$$|||\mathbf{q}|||^2 = \sum_{i=1}^{2}\sum_{Q\in\mathcal{T}_h}|||q_i|||_{i,Q}^2.$$

Note that for $\mathbf{q}\in\mathbf{V}_h$, $|||\mathbf{q}||| = \|\mathbf{q}\|_0$.

COROLLARY 4.2. *There exists a constant* C *independent of* h *such that*

$$|||\mathbf{u}-\mathbf{u}_h||| \le Ch^2|||K^{-1}|||_{1,\infty}(\|\mathbf{u}\|_2+\|p\|_3).$$

Proof: It was shown in [16] that

$$|||\mathbf{u}-\Pi\mathbf{u}||| \le Ch^2|\mathbf{u}|_2,$$

where $|\cdot|_2$ denotes the H^2-seminorm. Also, using Theorem 4.1,

$$|||\Pi\mathbf{u}-\mathbf{u}_h||| = \|\Pi\mathbf{u}-\mathbf{u}_h\|_0 \le Ch^2|||K^{-1}|||_{1,\infty}(\|\mathbf{u}\|_2+\|p\|_3).$$

The assertion of the corollary follows from the above two bounds and the triangle inequality. ∎

It is also easy to see that $\nabla \cdot (\mathbf{u} - \mathbf{u}_h)$ is superconvergent at the midpoints of the elements. Define, for a scalar function g,

$$|||g||| = \left(\sum_{i,j} |Q_{i,j}| g(c_{i,j})^2 \right)^{1/2}. \tag{4.8}$$

Using (4.3) and (2.4),

$$|||\nabla \cdot (\mathbf{u} - \mathbf{u}_h)||| = |||\nabla \cdot (\mathbf{u} - \Pi\mathbf{u})||| = |||\nabla \cdot \mathbf{u} - \widehat{\nabla \cdot \mathbf{u}}||| \le Ch^2 \|\nabla \cdot \mathbf{u}\|_{2,\infty},$$

where the last inequality follows from Lemma 4.6. Defining

$$|||\mathbf{q}|||_{\mathbf{V}}^2 = |||\mathbf{q}|||^2 + |||\nabla \cdot \mathbf{q}|||^2, \tag{4.9}$$

the above results can be summarized as follows.

COROLLARY 4.3. *There exists a constant C independent of h such that*

$$|||\mathbf{u} - \mathbf{u}_h|||_{\mathbf{V}} \le Ch^2 (\|\mathbf{u}\|_2 + \|\nabla \cdot \mathbf{u}\|_{2,\infty} + \|p\|_3). \tag{4.10}$$

We next proceed with the three lemmas needed in the proof of Theorem 4.1.

LEMMA 4.4. *There exists a constant C independent of h such that, for all $\mathbf{v} \in \mathbf{V}_h$,*

$$|a(\mathbf{u} - \Pi\mathbf{u}, \gamma_h \mathbf{v})| \le Ch^2 |||K^{-1}|||_{1,\infty} \|\mathbf{u}\|_2 \|\mathbf{v}\|_0.$$

Proof. We first show that if $\mathbf{q} \in (P_1(Q))^2$, where P_k is the space of polynomials of degree $\le k$, then

$$\int_Q (\mathbf{q} - \Pi\mathbf{q}) \gamma_h \mathbf{v} \, dx \, dy = 0 \quad \forall \mathbf{v} \in \mathbf{V}_h, \ Q \in \mathcal{T}_h. \tag{4.11}$$

The argument follows the proof of Lemma 3.1 in [16]. Let $Q = [a,b] \times [c,d]$ and let $L_1(x)$ and $\tilde{L}_1(y)$ be the linear Legendre polynomials on $[a,b]$ and $[c,d]$, respectively. It is easy to see that any $\mathbf{q} \in (P^1(Q))^2$ can be decomposed into

$$\mathbf{q}(x,y) = \bar{\mathbf{q}}(x,y) + (\alpha \tilde{L}_1(y), \beta L_1(x))^T,$$

where $\bar{\mathbf{q}} \in \mathbf{V}_h(Q)$. Since $\bar{\mathbf{q}} - \Pi\bar{\mathbf{q}} = 0$, it is enough to establish (4.11) for $\mathbf{q}(x,y) = (\alpha \tilde{L}_1(y), \beta L_1(x))^T$. It is shown in [16] that in this case $\Pi\mathbf{q} = 0$. Therefore

$$\begin{aligned} \int_Q (\mathbf{q} - \Pi\mathbf{q}) \gamma_h \mathbf{v} \, dx \, dy &= \int_Q \mathbf{q} \gamma_h \mathbf{v} \, dx \, dy \\ &= \int_Q (\alpha \tilde{L}_1(y) (\gamma_h \mathbf{v})^1(x,y) + \beta L_1(x) (\gamma_h \mathbf{v})^2(x,y)) \, dx \, dy = 0, \end{aligned}$$

using that for any fixed $x_0 \in [a,b]$, $(\gamma_h \mathbf{v})^1(x_0, y) \in P_0[c,d]$, that for any fixed $y_0 \in [c,d]$, $(\gamma_h \mathbf{v})^2(x, y_0) \in P_0[a,b]$, and the orthogonality properties of $L_1(x)$ and $\tilde{L}_1(y)$.

We now have

$$\begin{aligned} a(\mathbf{u} - \Pi\mathbf{u}, \gamma_h \mathbf{v}) &= (K^{-1}(\mathbf{u} - \Pi\mathbf{u}), \gamma_h \mathbf{v}) \\ &= \sum_{Q \in \mathcal{T}_h} [K_Q^{-1}(\mathbf{u} - \Pi\mathbf{u}, \gamma_h \mathbf{v})_Q + ((K^{-1} - K_Q^{-1})(\mathbf{u} - \Pi\mathbf{u}), \gamma_h \mathbf{v})_Q], \end{aligned}$$

where K_Q^{-1} is the value of K^{-1} at the center of Q. Therefore

$$|a(\mathbf{u}-\Pi\mathbf{u},\gamma_h\mathbf{v})| \le C\|K^{-1}\|_{0,\infty}\sum_{Q\in\mathcal{T}_h}|(\mathbf{u}-\Pi\mathbf{u},\gamma_h\mathbf{v})_Q| + Ch|||K^{-1}|||_{1,\infty}\|\mathbf{u}-\Pi\mathbf{u}\|_0\|\gamma_h\mathbf{v}\|_0. \tag{4.12}$$

Using (4.11), an application of the Bramble–Hilbert lemma [12] implies

$$|(\mathbf{u}-\Pi\mathbf{u},\gamma_h\mathbf{v})_Q| \le Ch^2|\mathbf{u}|_{2,Q}\|\gamma_h\mathbf{v}\|_{0,Q},$$

which combined with (4.12), (2.6), and (3.9) completes the proof. ∎

LEMMA 4.5. *There exists a constant C independent of h such that for all $\mathbf{v}\in\mathbf{V}_h$,*

$$|b(\gamma_h\mathbf{v},p-P_hp)| \le Ch^2\|p\|_3\|\mathbf{v}\|_{\mathbf{V}}.$$

Proof. Let $e_{i+1/2,j}=\partial Q_{i+1/2,j}\cap Q_{i,j}$ and $e_{i,j+1/2}=\partial Q_{i,j+1/2}\cap Q_{i,j}$. Note that in the sums in

$$\begin{aligned} &b(\gamma_h\mathbf{v},p-P_hp)\\ &=\sum_{i,j}\langle p-P_hp,((\gamma_h\mathbf{v})^1,0)^T\cdot\mathbf{n}\rangle_{\partial Q_{i+1/2,j}}+\sum_{i,j}\langle p-P_hp,(0,(\gamma_h\mathbf{v})^2)^T\cdot\mathbf{n}\rangle_{\partial Q_{i,j+1/2}}, \end{aligned}$$

every edge $e_{i+1/2,j}$ and $e_{i,j+1/2}$ appears twice (from the two neighboring covolumes). Using that $\frac{\partial v_1}{\partial x}$ and $\frac{\partial v_2}{\partial y}$ are constants on each element $Q_{i,j}$, we have

$$\begin{aligned} &b(\gamma_h\mathbf{v},p-P_hp)\\ &=\sum_{i,j}\left(h_i^x\frac{\partial v_1}{\partial x}\int_{e_{i+1/2,j}}(p-P_hp)\,dy+h_j^y\frac{\partial v_2}{\partial y}\int_{e_{i,j+1/2}}(p-P_hp)\,dx\right)\\ &=\sum_{i,j}\left(\frac{\partial v_1}{\partial x}\left(h_i^x\int_{e_{i+1/2,j}}p\,dy-\int_{Q_{i,j}}p\,dxdy\right)\right.\\ &\qquad\left.+\frac{\partial v_2}{\partial y}\left(h_j^y\int_{e_{i,j+1/2}}p\,dx-\int_{Q_{i,j}}p\,dxdy\right)\right)\\ &=\sum_{i,j}\left(\left(p,\frac{\partial v_1}{\partial x}\right)_{Q_{i,j},M_x}-\left(p,\frac{\partial v_1}{\partial x}\right)_{Q_{i,j}}+\left(p,\frac{\partial v_2}{\partial y}\right)_{Q_{i,j},M_y}-\left(p,\frac{\partial v_2}{\partial y}\right)_{Q_{i,j}}\right), \end{aligned} \tag{4.13}$$

where $(\cdot,\cdot)_{Q,M_x}$ is the quadrature rule on Q which uses the midpoint rule in x and exact integration in y, and $(\cdot,\cdot)_{Q,M_y}$ uses exact integration in x and the midpoint rule in y. Since the midpoint rule is exact for linear polynomials, the Peano kernel theorem [13, Theorem 3.7.1] implies

$$\begin{aligned} &\left(p,\frac{\partial v_1}{\partial x}\right)_{Q_{i,j},M_x}-\left(p,\frac{\partial v_1}{\partial x}\right)_{Q_{i,j}}=\int_{Q_{i,j}}\varphi(x)\frac{\partial^2 p}{\partial x^2}(x,y)\frac{\partial v_1}{\partial x}\,dxdy\\ &=\int_{Q_{i,j}}\varphi(x)\frac{\partial^2 p}{\partial x^2}(x,y)\nabla\cdot\mathbf{v}\,dxdy-\int_{Q_{i,j}}\varphi(x)\frac{\partial^2 p}{\partial x^2}(x,y)\frac{\partial v_2}{\partial y}\,dxdy\equiv T_1+T_2, \end{aligned} \tag{4.14}$$

where

$$\varphi(x)=\begin{cases}(x-x_{i-1/2})^2/2, & x_{i-1/2}\le x\le x_i,\\ (x-x_{i+1/2})^2/2, & x_i\le x\le x_{i+1/2}.\end{cases}$$

For the first term we have

$$|T_1| \le Ch^2 \|p\|_{2,Q_{i,j}} \|\nabla \cdot \mathbf{v}\|_{0,Q_{i,j}}. \tag{4.15}$$

Integrating by parts in T_2 gives

$$\begin{aligned} T_2 = &\int_{Q_{i,j}} \varphi(x) \frac{\partial^3 p}{\partial x^2 \partial y}(x,y) v_2(x,y)\, dxdy \\ &- \left(\int_{e_{i,j,t}} - \int_{e_{i,j,b}} \right) \varphi(x) \frac{\partial^2 p}{\partial x^2}(x,y) v_2(x,y)\, dx \equiv T_{2,1} + T_{2,2}, \end{aligned} \tag{4.16}$$

where $e_{i,j,t}$ and $e_{i,j,b}$ are the top and the bottom edge of $Q_{i,j}$, respectively. For $T_{2,1}$ we have

$$|T_{2,1}| \le Ch^2 \|p\|_{3,Q_{i,j}} \|\mathbf{v}\|_{0,Q_{i,j}}. \tag{4.17}$$

For $T_{2,2}$ we notice that v_2 is continuous across horizontal edges and the assumed regularity of $p(x,y)$ implies that the trace of $\frac{\partial^2 p}{\partial x^2}$ is well defined. When summing over all elements, each edge integral will appear twice from the expressions for the two neighboring elements, with opposite signs. Therefore

$$\sum_{i,j} T_{2,2} = 0. \tag{4.18}$$

Combining (4.14)–(4.18) implies

$$\sum_{i,j} \left(\left(p, \frac{\partial v_1}{\partial x} \right)_{Q_{i,j}, M_x} - \left(p, \frac{\partial v_1}{\partial x} \right)_{Q_{i,j}} \right) \le Ch^2 \|p\|_3 \|\mathbf{v}\|_{\mathbf{V}}.$$

The second error term in (4.13) can be bounded in a similar way. Note that for $d = 3$, a similar argument goes through with two terms analogous to T_2. ∎

LEMMA 4.6. *For all $g \in W^2_\infty$ there exists a constant C independent of h such that*

$$|||g - P_h g||| \le Ch^2 \|g\|_{2,\infty}.$$

Proof. Let $Q \in \mathcal{T}_h$. The Taylor expansion with integral remainder about the midpoint (x_0, y_0) of Q gives for any $(x,y) \in Q$

$$g(x,y) = g(x_0,y_0) + (x - x_0) \frac{\partial g}{\partial x}(x_0,y_0) + (y - y_0) \frac{\partial g}{\partial y}(x_0,y_0) + R(x,y),$$

where $|R(x,y)| \le Ch^2 \|g\|_{2,\infty,Q}$. Integrating the above equation over Q and using that $\int_Q g = \int_Q P_h g$ gives

$$|Q|(P_h g(x_0,y_0) - g(x_0,y_0)) = \int_Q R(x,y)\, dxdy,$$

which implies

$$|P_h g(x_0,y_0) - g(x_0,y_0)| \le Ch^2 \|g\|_{2,\infty,Q}.$$

The statement of the lemma now follows from the definition (4.8) of $|||\cdot|||$. ∎

5. Pressure superconvergence analysis. In this section we employ a duality argument to derive superconvergence for the pressure at the cell centers. We will make use of the following continuity property of Π [23, 3]. For any $\varepsilon > 0$,

$$\|\Pi \mathbf{q}\|_0 \le C(\|\mathbf{q}\|_\varepsilon + \|\nabla \cdot \mathbf{q}\|_0). \tag{5.1}$$

Consider the auxiliary problem

$$\begin{aligned} -\nabla \cdot K\nabla\varphi &= P_h p - p_h \quad \text{in } \Omega, \\ -K\nabla\varphi \cdot \mathbf{n} &= 0 \quad \text{on } \partial\Omega, \end{aligned} \tag{5.2}$$

which is well posed since $\int_\Omega P_h p = \int_\Omega p_h = 0$. Elliptic regularity [20] implies that there exists $\varepsilon > 0$ such that

$$\|\varphi\|_{1+\varepsilon} \le C\|P_h p - p_h\|_0. \tag{5.3}$$

Note that (5.3) holds for L-shaped domains. Let $\phi = -K\nabla\varphi$. We have

$$\begin{aligned} \|P_h p - p_h\|_0^2 &= (P_h p - p_h, \nabla \cdot \phi) = (P_h p - p_h, \nabla \cdot \Pi\phi) = c(\Pi\phi, P_h p - p_h) \\ &= -b(\gamma_h \Pi\phi, P_h p - p_h) = -b(\gamma_h \Pi\phi, P_h p - p) - b(\gamma_h \Pi\phi, p - p_h) \\ &= -b(\gamma_h \Pi\phi, P_h p - p) + a(\mathbf{u} - \mathbf{u}_h, \gamma_h \Pi\phi), \end{aligned} \tag{5.4}$$

using (4.1) with $\mathbf{v} = \gamma_h \Pi\phi$. By Lemma 4.5,

$$\begin{aligned} |b(\gamma_h \Pi\phi, P_h p - p)| &\le Ch^2 \|p\|_3 \|\Pi\phi\|_{\mathbf{V}} \\ &\le Ch^2 \|p\|_3 (\|\phi\|_\varepsilon + \|\nabla \cdot \phi\|_0) \le Ch^2 |||K|||_{\epsilon,\infty} \|p\|_3 \|P_h p - p_h\|_0 \end{aligned}$$

using (5.1), (5.3), and that $\|\nabla \cdot \Pi\phi\|_0 \le \|\nabla \cdot \phi\|_0$, which follows from $\nabla \cdot \Pi\phi = P_h \nabla \cdot \phi$. For the last term in (5.4) we write

$$\begin{aligned} |a(\mathbf{u} - \mathbf{u}_h, \gamma_h \Pi\phi)| &= |a(\mathbf{u} - \Pi\mathbf{u}, \gamma_h \Pi\phi) + a(\Pi\mathbf{u} - \mathbf{u}_h, \gamma_h \Pi\phi)| \\ &\le C(h^2 |||K^{-1}|||_{1,\infty} \|\mathbf{u}\|_2 \|\Pi\phi\|_0 + \|K^{-1}\|_{0,\infty} \|\Pi\mathbf{u} - \mathbf{u}_h\|_0 \|\gamma_h \Pi\phi\|_0) \\ &\le Ch^2 |||K^{-1}|||_{1,\infty} (\|\mathbf{u}\|_2 + \|p\|_3) \|\Pi\phi\|_0 \\ &\le Ch^2 |||K|||_{\epsilon,\infty} |||K^{-1}|||_{1,\infty} (\|\mathbf{u}\|_2 + \|p\|_3) \|P_h p - p_h\|_0 \end{aligned}$$

using Lemma 4.4, Theorem 4.1, (3.9), (5.1), (5.3), and (5.2). A combination of (5.4) and the above two bounds gives the following pressure superconvergence result.

THEOREM 5.1. *For the CVMFEM approximation* $(\mathbf{u}_h, p_h)$*, there exists a constant* C *independent of* h *such that*

$$\|P_h p - p_h\|_0 \le Ch^2 |||K|||_{\epsilon,\infty} |||K^{-1}|||_{1,\infty} (\|\mathbf{u}\|_2 + \|p\|_3).$$

It is now easy to obtain superconvergence for the pressure at the midpoints of the elements. Let $|||w|||_W = |||w|||$, where $|||w|||$ is defined in (4.8), and note that $|||w|||_W = \|w\|_0$ for all $w \in W_h$.

COROLLARY 5.2. *There exists a constant* C *independent of* h *such that*

$$|||p - p_h|||_W \le Ch^2 |||K|||_{\epsilon,\infty} |||K^{-1}|||_{1,\infty} (\|\mathbf{u}\|_2 + \|p\|_{2,\infty} + \|p\|_3).$$

Proof. The result follows immediately from the triangle inequality

$$|||p - p_h|||_W \le |||p - P_h p|||_W + |||P_h p - p_h|||_W,$$

Lemma 4.6, and Theorem 5.1. ∎

ON TAYLOR MODEL BASED INTEGRATION OF ODES*

M. NEHER†, K. R. JACKSON‡, AND N. S. NEDIALKOV§

Abstract. Interval methods for verified integration of initial value problems (IVPs) for ODEs have been used for more than 40 years. For many classes of IVPs, these methods are able to compute guaranteed error bounds for the flow of an ODE, where traditional methods provide only approximations to a solution. Overestimation, however, is a potential drawback of verified methods. For some problems, the computed error bounds become overly pessimistic, or the integration even breaks down. The dependency problem and the wrapping effect are particular sources of overestimations in interval computations. Berz and his coworkers have developed Taylor model methods, which extend interval arithmetic with symbolic computations. The latter is an effective tool for reducing both the dependency problem and the wrapping effect. By construction, Taylor model methods appear particularly suitable for integrating nonlinear ODEs. We analyze Taylor model based integration of ODEs and compare Taylor model methods with traditional enclosure methods for IVPs for ODEs.

Key words. Taylor model methods, verified integration, ODEs, IVPs

1. Introduction.

The numerical solution of initial value problems (IVPs) for ODEs is one of the fundamental problems in scientific computation. Today, there are many well-established algorithms for approximate solution of IVPs. However, traditional integration methods usually provide only approximate values for the solution. Precise error bounds are rarely available. The error estimates, which are sometimes delivered, are not guaranteed to be accurate and are sometimes unreliable.

In contrast, reliable integration computes guaranteed bounds for the flow of an ODE, including all discretization and roundoff errors in the computation. Originated by Moore in the 1960s [33], interval computations are a particularly useful tool for this purpose. There is a vast literature on interval methods for verified integration [6, 8, 9, 10, 12, 19, 21, 22, 24, 29, 31, 32, 33, 35, 36, 37, 38, 39, 40, 44, 45, 46, 47], but there are still many open questions. The results of interval arithmetic computations are often impaired by overestimation caused by the dependency problem and by the wrapping effect. In verified integration, overestimation may degrade the computed enclosure of the flow, enforce miniscule step sizes, or even bring about premature abortion of an integration.

Berz and his coworkers have developed Taylor model methods, which combine interval arithmetic with symbolic computations [2, 5, 25, 27, 28]. In Taylor model methods, the basic data type is not a single interval, but a *Taylor model* $\mathcal{U} := p_n(x)+\boldsymbol{i}$ consisting of a multivariate polynomial $p_n(x)$ of order n in m variables, and a remainder interval $\boldsymbol{i}$. In computations that involve $\mathcal{U}$, the polynomial part is propagated by symbolic calculations wherever possible and thus not significantly affected by the

dependency problem or the wrapping effect. Only the interval remainder term and polynomial terms of order higher than n, which are usually small, are bounded using interval arithmetic.

Taylor model arithmetic is an extension of interval arithmetic with a comprehensive variety of applicable enclosure sets. Nevertheless, there has been some debate about the usefulness and the limitations of Taylor model methods [42]. To some extent, this may be due to the sometimes cursory description of technical details of Taylor model arithmetic, which may be obvious to the experts of Taylor models, but which are less trivial to others.

The motivation of this paper is to analyze Taylor model methods for the verified integration of ODEs and to compare these methods with existing interval methods. Taylor models are better suited for integrating ODEs than interval methods whenever richness in available enclosure sets and reduction of the dependency problem is an advantage. This is usually the case for IVPs for nonlinear ODEs, especially in combination with large initial sets or with large integration domains. Although parameter intervals or initial sets can be handled by subdivision, this approach is only practical in low dimensions.

The advantage of Taylor model methods is less obvious for linear ODEs, where interval methods should perform equally well. Nevertheless, we include a discussion of Taylor model methods for linear ODEs in this paper for two reasons. First, the discussion is simpler for linear ODEs than for nonlinear ones. Second, if Taylor model methods failed on linear ODEs, they would likely fail on nonlinear ODEs as well. However, some of the most advantageous properties of Taylor models take effect only on nonlinear problems. We use a simple nonlinear model problem to illustrate these advantages.

The paper is structured as follows. In the next section, basic concepts of interval arithmetic and Taylor model methods are reviewed. Interval methods for ODEs are presented in section 3. The naive Taylor model method is described in section 4, which is followed by a discussion of Taylor model methods for linear ODEs. A nonlinear model problem is used to explain preconditioned Taylor model methods for ODEs in section 6. In the last section, numerical examples for linear ODEs are given.

2. Preliminaries.

2.1. Interval arithmetic. Interval arithmetic [1, 14, 33, 41] is a powerful tool for verified computations. In interval arithmetic, operations between intervals are employed to calculate guaranteed bounds for continuous problems with a finite number of basic arithmetic operations. We assume that the reader is familiar with real interval arithmetic and floating-point interval arithmetic. The latter is based on a screen of floating-point numbers. Rigor of a computation is achieved by enclosing real numbers by floating-point intervals (that is, intervals with floating-point upper and lower bounds) and by performing all calculations with directed rounding according to the rules of interval arithmetic [20]. Successful software implementations of floating-point interval arithmetic have for example been given in [3, 17, 18].

The set of compact real intervals is denoted by

$$\mathbb{IR} = \{\, \boldsymbol{x} = [\underline{x}, \overline{x}] \mid \underline{x}, \overline{x} \in \mathbb{R},\ \underline{x} \le \overline{x} \,\}.$$

A real number x is identified with a point interval $\boldsymbol{x} = [x, x]$. The *midpoint* and the *width* of an interval $\boldsymbol{x}$ are denoted by $\mathrm{m}(\boldsymbol{x}) := (\overline{x} + \underline{x})/2$ and $\mathrm{w}(\boldsymbol{x}) := \overline{x} - \underline{x}$, respectively. The set of all m-dimensional interval vectors is denoted by $\mathbb{IR}^m$. In this

paper, intervals are denoted by boldface. Lower-case letters are used for denoting scalars and vectors. Matrices are denoted by upper-case letters.

2.2. Dependency problem and wrapping effect. Interval methods are sometimes affected by overestimation, whence the computed error bounds may be overly pessimistic. Overestimation is often caused by the *dependency problem*, that is, the failure of interval arithmetic to identify different occurrences of the same variable. For example, the range of $f(x) := x/(1+x)$ on $\boldsymbol{x} = [1,2]$ is $[1/2, 2/3]$, but interval arithmetic evaluation yields

$$\frac{\boldsymbol{x}}{1+\boldsymbol{x}} = \frac{[1,2]}{[2,3]} = \left[\frac{1}{3}, 1\right].$$

In general, the dependency problem is not easily removed. To diminish overestimation, alternative evaluation schemes, such as centered forms [33], have been developed. A discussion of computer methods for the range of functions is given in [43].

A second source of overestimation is the *wrapping effect*, which appears when intermediate results of a computation are enclosed by intervals. The wrapping effect was first observed by Moore in 1965 [32]; a recent analysis has been given by Lohner [23].

2.3. Taylor model arithmetic. For reducing both the dependency problem and the wrapping effect, interval arithmetic has been extended with symbolic computations. Symbolic-numeric computations have been proposed under various names since the 1980s [11, 16, 25]. Early implementations in software were also given [11, 15], but to the authors' knowledge, these packages have not been widely distributed and are not available today.

Starting in the 1990s, Berz and his group developed a rigorous multivariate Taylor arithmetic [2, 25, 28]. In these references, a *Taylor model* is defined in the following way. Let $f : D \subset \mathbb{R}^m \to \mathbb{R}$ be a function that is $(n+1)$ times continuously differentiable in an open set containing the box $\boldsymbol{x}$. Let x_0 be a point in $\boldsymbol{x}$, let p_n denote the nth order Taylor polynomial of f around x_0, and let $\boldsymbol{i}$ be an interval such that

$$f(x) \in p_n(x - x_0) + \boldsymbol{i} \quad \text{for all} \quad x \in \boldsymbol{x}. \tag{2.1}$$

Then the pair $(p_n, \boldsymbol{i})$ is called an nth order Taylor model of f around x_0 on $\boldsymbol{x}$.

This original definition of a Taylor model is useful for computations in exact arithmetic, but it must be extended for floating-point computations. For example, there is no Taylor model of $e^x \approx 1 + x + (1/2)x^2 + (1/6)x^3 + \ldots$ of order $n \geq 3$ in IEEE 754 floating-point arithmetic, since the coefficient of x^3 is not exactly representable as a floating-point number. In [29], instead of the Taylor polynomial of f, an arbitrary polynomial p_n with floating-point coefficients is used in (2.1), but the definition of a Taylor model in [29] assumes that the width of $\boldsymbol{i}$ is of order $O\big(\|\mathrm{w}(\boldsymbol{x})\|^n\big)$. In this paper, such an assumption on the width of $\boldsymbol{i}$ is not required.

We use calligraphy letters for denoting Taylor models:

$$\mathcal{U} := p_n(x) + \boldsymbol{i}, \quad x \in \boldsymbol{x},$$

where $\boldsymbol{x} \in \mathbb{IR}^m$, $\boldsymbol{i} \in \mathbb{IR}$ are intervals, and p_n is an m-variate polynomial of order n. $\boldsymbol{x}$ is called the *domain interval* of $\mathcal{U}$, and $\boldsymbol{i}$ is its *remainder interval*. A Taylor model is the set of all m-variate continuous functions f such that

$$f(x) \in p_n(x) + \boldsymbol{i}$$

holds for all $x \in \boldsymbol{x}$. Evaluating $\mathcal{U}$ for all $x \in \boldsymbol{x}$, we obtain the *range* of $\mathcal{U}$:

$$\mathrm{Rg}\,(\mathcal{U}) := \{z = p(x) + \iota \mid x \in \boldsymbol{x}, \iota \in \boldsymbol{i}\}.$$

Example 2.1. *Taylor models of* e^x *and* $\cos x$. Let $\boldsymbol{x} := [-\frac{1}{2}, \frac{1}{2}]$ and $x_0 := 0$. Then Taylor's theorem is a natural starting point for constructing Taylor models. We have

$$e^x = 1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 e^{\xi}, \quad \cos x = 1 - \frac{1}{2}x^2 + \frac{1}{6}x^3 \sin\xi, \quad x,\, \xi \in \boldsymbol{x},$$

from which we derive Taylor models for $f_1(x) := e^x$ and $f_2(x) := \cos x$:

$$\mathcal{U}_1(x) := 1 + x + \tfrac{1}{2}x^2 + [-0.035, 0.035], \quad \mathcal{U}_2(x) := 1 - \tfrac{1}{2}x^2 + [-0.010, 0.010], \quad x \in \boldsymbol{x},$$

respectively.

Taylor model arithmetic has been defined in [2, 25, 28]. We use the same arithmetic rules, even though our Taylor models differ slightly from the Taylor models defined in these references. The difference affects only the function set that is defined by a Taylor model.

In computations that involve a Taylor model $\mathcal{U}$, the polynomial part is propagated by symbolic calculations wherever possible. In floating-point computations, the roundoff errors of the symbolic operations are rigorously estimated and the estimate is added to the remainder interval of the final result. This part of the computation is hardly affected by the dependency problem or the wrapping effect. Only the interval remainder term and polynomial terms of order higher than n (which in applications are usually small) are processed according to the rules of interval arithmetic.

Example 2.2. *Multiplication of two univariate Taylor models of order* 2. Let $\boldsymbol{x} := [-\frac{1}{2}, \frac{1}{2}]$ and

$$\mathcal{U}_1(x) := 1 + x + \tfrac{1}{2}x^2 + [-0.035, 0.035], \;\; \mathcal{U}_2(x) := 1 - \tfrac{1}{2}x^2 + [-0.010, 0.010],$$

where $x \in \boldsymbol{x}$. For all $x \in \boldsymbol{x}$, it holds that

$$\begin{aligned}
\mathcal{U}_1(x) \cdot \mathcal{U}_2(x) &\subseteq (1 + x + \tfrac{1}{2}x^2)(1 - \tfrac{1}{2}x^2) + \big(\tfrac{1}{2} + \tfrac{1}{2}(1+x)^2\big)[-0.010, 0.010] \\
&\quad + (1 - \tfrac{1}{2}x^2)[-0.035, 0.035] + [-0.035, 0.035] \cdot [-0.010, 0.010] \\
&\subseteq (1 + x) - \tfrac{1}{2}x^3 - \tfrac{1}{4}x^4 + [0.625, 1.625] \cdot [-0.010, 0.010] + [0.875, 1] \cdot [-0.035, 0.035] \\
&\quad + [-0.004, 0.004] \\
&\subseteq 1 + x - [-0.063, 0.063] - [-0.016, 0.016] + [-0.202, 0.202] = 1 + x \\
&\quad + [-0.281, 0.281],
\end{aligned}$$

so we may define

$$\mathcal{U}_1(x) \cdot \mathcal{U}_2(x) := 1 + x + [-0.281, 0.281].$$

This product is a Taylor model for the function $e^x \cos x$, $x \in \boldsymbol{x}$:

$$e^x \cos x \in 1 + x + [-0.281, 0.281], \quad x \in \boldsymbol{x}.$$

In Example 2.2, direct interval evaluation for computing the remainder interval of the product has been used for simplicity. Due to the dependency problem, this does not always yield optimal bounds. More accurate estimation schemes have been proposed in [30].

Compositions $\mathcal{U}_1 \circ \mathcal{U}_2$ of Taylor models are evaluated in a similar way as products; $\circ$ denotes the composition operator for functions, namely,

$$(f \circ g)(x) = f\big(g(x)\big).$$

Example 2.3. *Composition of two univariate Taylor models of order* 2. Let $\boldsymbol{x} := [-\frac{1}{2}, \frac{1}{2}]$ and

$$\mathcal{U}_1(x) := 1 + x + \tfrac{1}{2}x^2 + [-0.035, 0.035], \quad \mathcal{U}_2(x) := 1 - \tfrac{1}{2}x^2 + [-0.010, 0.010],$$

where $x \in \boldsymbol{x}$. It is tempting to compute the composition $\mathcal{U}_1 \circ \mathcal{U}_2$ in the following manner:

$$\begin{aligned}
\mathcal{U}_1(x) \circ \mathcal{U}_2(x) &\subseteq 1 + (1 - \tfrac{1}{2}x^2 + [-0.010, 0.010]) + \tfrac{1}{2}(1 - \tfrac{1}{2}x^2 + [-0.010, 0.010])^2 \\
&\quad + [-0.035, 0.035] \\
&\subseteq 2 - \tfrac{1}{2}x^2 + [-0.045, 0.045] + \tfrac{1}{2}(1 - x^2 + \tfrac{1}{4}x^4 + [-0.020, 0.020] - x^2[-0.010, 0.010] \\
&\quad + [-0.001, 0.001]) \\
&\subseteq \tfrac{5}{2} - x^2 + \tfrac{1}{8}x^4 - x^2[-0.005, 0.005] + [-0.056, 0.056] \\
&\subseteq \tfrac{5}{2} - x^2 + [0, 0.008] - [-0.002, 0.002] + [-0.056, 0.056] = \tfrac{5}{2} - x^2 + [-0.058, 0.066].
\end{aligned}$$

Hence, we may define

$$\mathcal{U}_1(x) \circ \mathcal{U}_2(x) := \frac{5}{2} - x^2 + [-0.058, 0.066]. \tag{2.2}$$

However, the above computation does not yield a Taylor model for $e^{\cos x}$ for all $x \in \boldsymbol{x}$. Evaluating (2.2) at $x = 0$, we obtain

$$\mathcal{U}_1(0) \circ \mathcal{U}_2(0) = [2.442, 2.566] \not\ni e = e^{\cos 0}.$$

The reason for this failure lies in the range of $\mathcal{U}_2$, which is not contained in $\boldsymbol{x}$. Compositions of Taylor models are indeed computed as above, but it is required that the domain of $\mathcal{U}_1$ contains the range of $\mathcal{U}_2$.

In our example, it suffices to compute the remainder term for the exponential function on the interval $[-1, 1]$. Using Lagrange's representation of the remainder term, we have

$$\frac{e^\xi}{3!}x^3 \in \Big[-\frac{e}{6}, \frac{e}{6}\Big] \subseteq [-0.454, 0.454] \quad \text{for all } \xi \in [-1, 1] \text{ and all } x \in [-1, 1].$$

Using $[-0.454, 0.454]$ instead of $[-0.035, 0.035]$ in the derivation of (2.2) yields

$$\mathcal{U}_1(x) \circ \mathcal{U}_2(x) := \frac{5}{2} - x^2 + [-0.477, 0.485],$$

which is a verified enclosure of $\mathcal{U}_1(x) \circ \mathcal{U}_2(x)$ for all $x \in \boldsymbol{x}$. Note that it is still not a verified enclosure for all $x \in [-1, 1]$. The latter requires that the interval term of $\mathcal{U}_2$ is also computed for $x \in [-1, 1]$.

A *Taylor model vector* is a vector with Taylor model components. When no ambiguity arises, we call a Taylor model vector simply a Taylor model. Arithmetic operations for Taylor model vectors are defined componentwise.

2.3.1. Floating-point Taylor model arithmetic. On a computer with floating-point arithmetic, a Taylor model is defined by a polynomial with machine representable coefficients and a suitable remainder interval that takes account for the roundoff errors. These roundoff errors can occur

- when a function is represented by a Taylor model, or
- when operations between Taylor models are executed.

Example 2.4. *Addition of two univariate floating-point Taylor models.* For simplicity, we use Taylor models of order 1 and a floating-point number system with a mantissa of four decimal digits. Let

$$\boldsymbol{x} := [-1,1], \quad f_1(x) := 1 + x + \frac{1}{8}x^2,\ x \in \boldsymbol{x}, \quad f_2(x) := 1 + \frac{1}{3}x,\ x \in \boldsymbol{x}.$$

Then linear Taylor models for f_1 and f_2 are given by

$$\mathcal{U}_1(x) := 1 + x + [0, 0.125],\ \ \mathcal{U}_2(x) := 1 + 0.3333x + [-0.0001, 0.0001],\ \ x \in \boldsymbol{x}.$$

For $j = 1, 2$, the inclusion condition

$$f_j(x) \in \mathcal{U}_j(x) \ \text{ for all } \ x \in \boldsymbol{x}$$

does not define $\mathcal{U}_1$ and $\mathcal{U}_2$ uniquely. For example,

$$\widetilde{\mathcal{U}}_1(x) := 1 + x + [-0.125, 0.125],\ \ x \in \boldsymbol{x},$$

is also a valid, but less accurate, Taylor model for f_1.

A Taylor model for $f_1 + f_2$ is obtained by performing $\mathcal{U}_1 + \mathcal{U}_2$ with suitable outward rounding. The interval bound for the roundoff error in $x + 0.3333x$ depends on the domain $\boldsymbol{x}$.

$$\begin{aligned}\mathcal{U}_1(x) + \mathcal{U}_2(x) &\subseteq 2 + (x + 0.3333x) + [-0.0001, 0.1251] \\ &\subseteq 2 + (1.333x + [-0.0003, 0.0003]) + [-0.0001, 0.1251] \\ &= 2 + 1.333x + [-0.0004, 0.1254].\end{aligned}$$

A software implementation of Taylor model arithmetic has been developed by Berz and Makino [3, 26] in the COSY INFINITY package [4]. Using COSY INFINITY, Taylor models have been applied with success to a variety of problems, including global optimization [34], verified multidimensional integration [7], and the verified solution of ODEs and DAEs [6, 13].

2.4. Representation of intervals by Taylor models. For a given vector $c \in \mathbb{R}^m$ and a given diagonal matrix $C \in \mathbb{R}^{m \times m}$ with nonnegative diagonal elements, the range of the Taylor model vector

$$\mathcal{U} := c + Cx, \quad x \in \boldsymbol{x}, \tag{2.3}$$

is an m-dimensional interval vector. Vice versa, each interval vector $\boldsymbol{z} \in \mathbb{IR}^m$ can be represented by a Taylor model vector of the form (2.3). There is freedom of choice in selecting c, C, and $\boldsymbol{x}$. A convenient choice is

$$c = \mathrm{m}(\boldsymbol{z}), \quad C = \operatorname{diag}\left(\frac{1}{2}\mathrm{w}(\boldsymbol{z})\right), \quad \boldsymbol{x} = [-1,1]^m,$$

where $[-1,1]^m$ denotes an interval vector with $[-1,1]$ in each component.

Example 2.5. Let $\boldsymbol{z} = ([1,2],[-2,2])^T$. Then we have

$$\boldsymbol{z} = \mathrm{Rg}\left(\begin{pmatrix}\frac{3}{2}\\ 0\end{pmatrix} + \begin{pmatrix}\frac{1}{2} & 0\\ 0 & 2\end{pmatrix}\begin{pmatrix}x\\ y\end{pmatrix}\right), \quad \begin{pmatrix}x\\ y\end{pmatrix} \in [-1,1]^2.$$

3. Interval methods for ODEs.

3.1. Interval IVPs. We consider the smooth interval IVP

$$u' = f(t,u), \quad u(t_0) \in \boldsymbol{u}_0, \quad t \in \boldsymbol{t} = [t_0, t_{\text{end}}], \tag{3.1}$$

where $f : \mathbb{R} \times \mathbb{R}^m \to \mathbb{R}^m$ is a sufficiently smooth function, $\boldsymbol{u}_0 \in \mathbb{IR}^m$ is a given interval vector in the space variables, and $t_{\text{end}} > t_0$ is a given endpoint of the time interval. (The case $t_{\text{end}} < t_0$ is handled similarly.)

While the ODE is defined in the traditional way, the initial value is allowed to vary in the interval $\boldsymbol{u}_0$. In applications, this variability is used for modeling uncertainties in initial conditions. For each $u_0 \in \boldsymbol{u}_0$, the point IVP

$$u' = f(t,u), \quad u(t_0) = u_0$$

has a classical solution, which is denoted by $u(t; t_0, u_0)$. In the following, we assume that $u(t; t_0, u_0)$ exists and is bounded for all $t \in \boldsymbol{t}$ and for all $u_0 \in \boldsymbol{u}_0$.

Our goal when solving (3.1) is to calculate bounds on the flow of the interval IVP. For each $t \in \boldsymbol{t}$, we wish to calculate an interval $\boldsymbol{u}(t)$ such that

$$u(t; t_0, u_0) \in \boldsymbol{u}(t)$$

holds for all $u_0 \in \boldsymbol{u}_0$. The tube $\boldsymbol{u}(t)$, $t \in \boldsymbol{t}$, then contains all solutions of $u' = f(t,u)$ that emerge from $\boldsymbol{u}_0$.

3.2. Interval methods for IVPs. All enclosure methods for ODEs that we are aware of subdivide the domain of integration into subintervals. At each grid point, the flow of the given ODE is enclosed by a set with a certain geometric structure, for example, an m-dimensional rectangle. In the general case, the shape of the flow has a different geometry, so that the flow is wrapped by some larger set, which serves as the initial set for the next time step. To maintain the validity of the method, all solutions of the ODE emerging from the increased initial set must be enclosed in subsequent time steps. The method thus picks up additional solutions of the ODE (that is, solutions not emerging from the original initial set) during the integration process. If the accumulated flow becomes too large, the method may break down because it can no longer compute a sufficiently tight enclosure. It is essential for any verified integration method to minimize the excess introduced by the wrapping of intermediate enclosures of the flow.

In Moore's *direct interval method* [31, 32, 33], the widths of the enclosures at subsequent time steps are always increasing, even for shrinking flows. For linear autonomous ODEs, the direct interval method is only suited for pure contractions. If the flow is rotated, the rotation of the initial set usually provokes exponential growth of the widths of the computed interval enclosures.

In the *parallelepiped method* [32, 33, 12, 21], the flow of the ODE at intermediate time steps is enclosed by parallelepipeds instead of rectangular boxes. This choice is motivated by the shape of the flow of a linear ODE with interval initial values, which is a parallelepiped at any time. For this problem, the only source of overestimation is the remainder interval accounting for the discretization error and the accumulated roundoff errors, if the computation is performed in floating-point arithmetic. These quantities must be enclosed by the final parallelepiped enclosure, but the wrapping affects only small quantities. The algebraic crux of the parallelepiped method is the verified inversion of certain matrices A_j [21, 36], which often tend to become singular

after some time steps, so that the method breaks down either due to excessive wrapping or because the verified matrix inversion is no longer feasible. Hence, breakdown of the parallelepiped method is a rule rather than an exception.

To preserve good condition numbers in the matrices A_j, Lohner [21] developed the *QR method*. His idea was to stabilize the iteration by orthogonalization of the matrices, so that the algebraic problem of inverting the matrices is reduced to taking the transpose.

Various other interval methods have been proposed to fight the wrapping effect, and there are several techniques which are effective in reducing overestimation of the flow for some problem classes [12, 19, 21, 32, 33]. Nevertheless, the ability of interval methods to minimize wrapping is limited by the fact that interval-based enclosure sets are convex. If the flow is a nonconvex set, as may arise for nonlinear ODEs, any interval wrap must be at least as large as the convex hull of the flow.

4. Taylor model methods for ODEs. Taylor model methods use multivariate polynomials in the initial values plus a small interval remainder term to represent the flow of an IVP. Thus, it is possible to work with nonlinear boundary curves, including nonconvex enclosure sets for crescent-shaped or twisted flows. For nonlinear ODEs, this increased flexibility in admissible boundary curves is an intrinsic advantage of Taylor model methods over traditional interval methods, making Taylor model methods very effective in some cases in reducing the wrapping effect.

We refer to the recent paper of Makino and Berz [29] for the general description of Taylor model methods for ODEs. Our intention here is to explain the fundamental difference between interval methods and Taylor model methods with a simple nonlinear example.

4.1. Quadratic model problem. We consider the quadratic model problem

$$\begin{aligned} u' &= v, \qquad u(0) \in [0.95, 1.05], \\ v' &= u^2, \qquad v(0) \in [-1.05, -0.95], \end{aligned} \tag{4.1}$$

where the differentiation is with respect to t. In an interval method, one would use interval initial values $\boldsymbol{u}_0 = [0.95, 1.05]$ and $\boldsymbol{v}_0 = [-1.05, -0.95]$. In the Taylor model method, the initial set is described by parameters, which we call a and b, and which we choose in the interval $[-0.05, 0.05]$. The initial conditions of the IVP (4.1) at $t = t_0$ are thus given by

$$\begin{aligned} u_0(a, b) &:= 1 + a, \qquad a \in \boldsymbol{a} := [-0.05, 0.05], \\ v_0(a, b) &:= -1 + b, \qquad b \in \boldsymbol{b} := [-0.05, 0.05]. \end{aligned}$$

For illustration, we use order $n = 3$ and step size $h = 0.1$ in the Taylor model integration of (4.1). All numbers are displayed here rounded to six decimal digits. In each integration step, the multivariate Taylor series (with respect to t, a, and b) of the solution of (4.1) is employed. The third-order Taylor polynomial serves as an approximate solution. The truncation error of the series is enclosed by a suitable remainder interval.

The first integration step consists of integrating the IVP

$$\begin{aligned} u' &= v, \qquad u(0) = 1 + a, \\ v' &= u^2, \qquad v(0) = -1 + b \end{aligned} \tag{4.2}$$

for $0 \le t \le h$. We use the Picard iteration to calculate a multivariate Taylor polynomial approximation of the solution to (4.2). Using the initial approximations

$$u^{(0)}(\tau, a, b) = 1 + a,$$
$$v^{(0)}(\tau, a, b) = -1 + b$$

(τ is time), the first step of the Picard iteration yields

$$u^{(1)}(\tau, a, b) = u_0(a, b) + \int_0^\tau v^{(0)}(s, a, b)\, ds = 1 + a - \tau + b\tau,$$
$$v^{(1)}(\tau, a, b) = v_0(a, b) + \int_0^\tau \left(u^{(0)}(s, a, b)\right)^2 ds = -1 + b + \tau + 2a\tau + a^2\tau.$$

After two more Picard iterations (and omitting the higher order terms), we obtain the third order Taylor polynomials

$$u^{(3)}(\tau, a, b) = 1 + a - \tau + b\tau + \frac{1}{2}\tau^2 + a\tau^2 - \frac{1}{3}\tau^3,$$
$$v^{(3)}(\tau, a, b) = -1 + b + \tau + 2a\tau - \tau^2 + a^2\tau - a\tau^2 + b\tau^2 + \frac{2}{3}\tau^3,$$

as multivariate approximations to the solution of (4.2). For a verified enclosure of the flow, the Taylor polynomials have to be furnished with suitable remainder bounds. Their derivation is based on a fixed point iteration [24]. Intervals $\boldsymbol{i}_0$ and $\boldsymbol{j}_0$ are sought such that the inclusions

$$u_0 + \int_0^\tau \left(v^{(3)}(s, a, b) + \boldsymbol{j}_0\right) ds \subseteq u^{(3)}(\tau, a, b) + \boldsymbol{i}_0,$$
$$v_0 + \int_0^\tau \left(u^{(3)}(s, a, b) + \boldsymbol{i}_0\right)^2 ds \subseteq v^{(3)}(\tau, a, b) + \boldsymbol{j}_0$$

simultaneously hold for all $a \in \boldsymbol{a}$, for all $b \in \boldsymbol{b}$, and for all $\tau \in [0, 0.1]$. For the details of the computation of the remainder interval, we refer to [24]. In our example, these inclusions are fulfilled, for example, for

$$\boldsymbol{i}_0 = [-5.09307\text{E-}5, 7.86167\text{E-}5] \quad \text{and} \quad \boldsymbol{j}_0 = [-1.75707\text{E-}4, 1.60933\text{E-}4].$$

An enclosure of the flow of the IVP (4.2) for $t \in [0, 0.1]$ is given by the Taylor models

$$\widetilde{\mathcal{U}}_1(\tau, a, b) := 1 + a - \tau + b\tau + \frac{1}{2}\tau^2 + a\tau^2 - \frac{1}{3}\tau^3 + \boldsymbol{i}_0,$$
$$\widetilde{\mathcal{V}}_1(\tau, a, b) := -1 + b + \tau + 2a\tau - \tau^2 + a^2\tau - a\tau^2 + b\tau^2 + \frac{2}{3}\tau^3 + \boldsymbol{j}_0,$$

where a, $b \in [-0.05, 0.05]$, $\tau \in [0, 0.1]$, and $t = \tau$.

Evaluating $\widetilde{\mathcal{U}}_1$ and $\widetilde{\mathcal{V}}_1$ at $\tau = h = 0.1$, we obtain the enclosure of the flow at $t_1 = 0.1$ (Taylor models are of order at most 2 in the space variables):

$$\begin{aligned} \mathcal{U}_1(a, b) &:= \widetilde{\mathcal{U}}_1(0.1, a, b) = 0.904667 + 1.01a + 0.1b + \boldsymbol{i}_0, \\ \mathcal{V}_1(a, b) &:= \widetilde{\mathcal{V}}_1(0.1, a, b) = -0.909333 + 0.19a + 1.01b + 0.1a^2 + \boldsymbol{j}_0, \end{aligned} \tag{4.3}$$

which is the initial set for the second integration step. The latter is performed with a slight modification. We do not use the interval remainder terms in $\mathcal{U}_1$ and $\mathcal{V}_1$ when computing the polynomial part of the Taylor model in the space and time variables. The Picard iteration is again performed for $\tau \in [0, 0.1]$, with initial approximations

$$u^{(0)}(\tau, a, b) = 0.904667 + 1.01a + 0.1b,$$
$$v^{(0)}(\tau, a, b) = -0.909333 + 0.19a + 1.01b + 0.1a^2.$$

After three iterations (and again omitting higher order terms), we obtain

$$\begin{aligned} u^{(3)}(\tau, a, b) = {} & 0.904667 + 1.01a + 0.1b - 0.909333\tau + 0.19a\tau + 1.01b\tau + 0.409211\tau^2 \\ & + 0.1a^2\tau + 0.913713a\tau^2 + 0.0904667b\tau^2 - 0.274215\tau^3, \\ v^{(3)}(\tau, a, b) = {} & -0.909333 + 0.19a + 1.01b + 0.818422\tau + 0.1a^2 + 1.82743a\tau \\ & + 0.180933b\tau - 0.822644\tau^2 \\ & + 1.0201a^2\tau + 0.202ab\tau + 0.01b^2\tau - 0.74654a\tau^2 + 0.82278b\tau^2 \\ & + 0.522429\tau^3. \end{aligned}$$

To compute the interval remainder term, we must find intervals $\boldsymbol{i}_1$ and $\boldsymbol{j}_1$ fulfilling the inclusions

$$\begin{aligned} \mathcal{U}_1(a, b) + \textstyle\int_0^\tau \left(v^{(3)}(s, a, b) + \boldsymbol{j}_1\right) ds \subseteq u^{(3)}(\tau, a, b) + \boldsymbol{i}_1, \\ \mathcal{V}_1(a, b) + \textstyle\int_0^\tau \left(u^{(3)}(s, a, b) + \boldsymbol{i}_1\right)^2 ds \subseteq v^{(3)}(\tau, a, b) + \boldsymbol{j}_1 \end{aligned} \tag{4.4}$$

for all a, $b \in [-0.05, 0.05]$ and for all $\tau \in [0, 0.1]$. (Note that $\boldsymbol{i}_0$ and $\boldsymbol{j}_0$ are contained in $\mathcal{U}_1$ and $\mathcal{V}_1$, respectively, from (4.3).) Suitable remainder intervals are, for example,

$$\boldsymbol{i}_1 = [-1.12850\text{E-}4, 1.65751\text{E-}4], \quad \boldsymbol{j}_1 = [-3.31917\text{E-}4, 3.24724\text{E-}4].$$

Thus, the flow of the IVP (4.2) for $t \in [0.1, 0.2]$ is contained in the Taylor models

$$\widetilde{\mathcal{U}}_2(\tau, a, b) = u^{(3)}(\tau, a, b) + \boldsymbol{i}_1,$$
$$\widetilde{\mathcal{V}}_2(\tau, a, b) = v^{(3)}(\tau, a, b) + \boldsymbol{j}_1,$$

where a, $b \in [-0.05, 0.05]$, $\tau \in [0, 0.1]$, $t = \tau + 0.1$.

Evaluating at $\tau = 0.1$, we obtain the enclosure of the flow at $t_2 = 0.2$ (Taylor models are of order at most 2 in the space variables):

$$\begin{aligned} \mathcal{U}_2(a, b) := \widetilde{\mathcal{U}}_2(0.1, a, b) = {} & 0.817551 + 1.03814a + 0.201905b + 0.01a^2 + \boldsymbol{i}_1, \\ \mathcal{V}_2(a, b) := \widetilde{\mathcal{V}}_2(0.1, a, b) = {} & -0.835195 + 0.365277a + 1.03632b \\ & + 0.20201a^2 + 0.0202ab + 0.001b^2 + \boldsymbol{j}_1. \end{aligned}$$

For larger values of t, the integration can be continued as in the second integration step described above.

Remark 4.1.

1. The sets $(\mathcal{U}_j, \mathcal{V}_j)$ containing the flow of the IVP (4.2) generally become more and more irregular for increasing j. Integration over a larger domain is shown in Figure 6.1.

2. In the above calculations, the polynomial parts of the Taylor models are independent of the initial domain intervals for a and b and independent of the step size h, but the interval remainder bounds are not.
3. The order of the method refers to the order of the multivariate Taylor polynomials with respect to space and time variables that are calculated in the integration step. When the initial sets are defined by linear functions in a and b, then it follows by induction that the maximum order of the polynomials representing the flow at the grid points (obtained after evaluating t) is always at least one less than the order of the method.

In the above example, we have used the so-called *naive* Taylor model integration method to illustrate the qualitative difference of interval methods and Taylor model methods for solving IVPs. For practical computations, the naive Taylor model method is not very useful. The interval remainder terms are propagated as in the direct interval method. The inclusion (4.4) implies that the diameters of the interval remainder terms are nondecreasing. Often, these diameters grow exponentially, and the method breaks down early. More advanced Taylor model integration methods are discussed in the next section. For clarity, we summarize the major steps of the naive Taylor model method as Algorithm 4.1.

Algorithm 4.1 (naive Taylor model method)

Let the initial set be given as a Taylor model vector in m space variables.

For $j := 0, 1 \ldots, j_{\max} - 1$:

1. Compute the Taylor polynomial p_n (of dimension m in $m+1$ variables) of the solution of the $j+1$st time step, using Picard iteration.
2. Compute a remainder interval vector $\boldsymbol{i}$, using Schauder's fixed point theorem (via interval iteration based on Picard iteration).
3. Evaluate $\widetilde{\mathcal{U}} = p_n + \boldsymbol{i}$ at t_{j+1}. The resulting m-dimensional Taylor model $\mathcal{U}$ contains the flow of the IVP and serves as initial set for the next time step.

4.2. Shrink wrapping and preconditioning. For successful integration over long time spans, sophisticated treatment of the interval terms is required. For this purpose, Berz and Makino invented two schemes which they call *shrink wrapping* and *preconditioning*. Shrink wrapping is a method to absorb the interval remainder term into the symbolic part of the Taylor model. From a geometric viewpoint, it resembles the parallelepiped method. Shrink wrapping uses the same linear map as the parallelepiped method so that it has the same limitations when this map becomes ill-conditioned. Preconditioning aims at maintaining a small condition number for the shrink wrapping map. Thus it stabilizes the integration process, like the QR interval method does.

For clarity of the presentation, we describe shrink wrapping and preconditioning for the special case of linear autonomous ODEs. The generalization to nonlinear ODEs is straightforward. We refer to [29] for the details.

5. Taylor model methods for linear ODEs. For a linear ODE, the flow of an interval IVP is a parallelepiped for all time, so Taylor models seem to have no obvious advantage over interval methods. On the other hand, if Taylor model methods failed on linear ODEs, they would probably not be effective for nonlinear ODEs. The purpose of this section is to show that they can be as good as interval methods for linear ODEs.

We consider the linear autonomous ODE

$$\begin{aligned} u' &= B\,u, \\ u(0) &= \mathcal{U}_0, \end{aligned} \tag{5.1}$$

where B is a given real matrix, $\boldsymbol{x}$ is a given interval vector, and $\mathcal{U}_0 = p_n(x)$, $x \in \boldsymbol{x}$, is a Taylor model vector with zero remainder interval describing the initial set. x is used to denote the vector of the space variables. We assume that the enclosure step in the Taylor model method is feasible with some constant step size $h > 0$ and some order $n \in \mathbb{N}$.

5.1. Naive Taylor model method. In the first integration step, Picard iteration of order n is used to compute the multivariate Taylor polynomial

$$u_{1,n} := P_n(tB)\,p_n(x), \quad \text{where} \quad P_n(tB) := \sum_{k=0}^{n} \frac{(tB)^k}{k!}.$$

Introducing $T := P_n(hB)$, the verification step consists of finding an interval vector $\boldsymbol{i}_1$ such that

$$p_n(x) + \int_0^h B\big(P_n(\tau B)\,p_n(x) + \boldsymbol{i}_1\big)\,d\tau \;\subseteq\; P_n(hB)\,p_n(x) + \boldsymbol{i}_1 = T p_n(x) + \boldsymbol{i}_1$$

holds for all $x \in \boldsymbol{x}$ (see, for example, [24, Ch. 6]). At $t_1 = h$, the flow of the IVP (5.1) is then enclosed by the Taylor model

$$\mathcal{U}_1 := T\,p_n(x) + \boldsymbol{i}_1.$$

Subsequent integration steps are performed in the same manner, but with a slight modification in the verification step. In the jth integration step, $j \geq 2$, $\boldsymbol{i}_j$ is sought such that the inclusion

$$T^{j-1}p_n(x) + \boldsymbol{i}_{j-1} + \int_0^h B\left(P_n(\tau B)\,T^{j-1}p_n(x) + \boldsymbol{i}_j\right)\,d\tau \subseteq T^j p_n(x) + \boldsymbol{i}_j$$

is fulfilled for all $x \in \boldsymbol{x}$. Letting

$$\mathcal{U}_j := T\,\mathcal{U}_{j-1} + \boldsymbol{i}_j, \quad j = 1, 2, \ldots,$$

the *naive Taylor model method* for (5.1) consists of the iteration

$$\mathcal{U}_j = T^j\,\mathcal{U}_0 + \sum_{k=1}^{j} (T\circ)^{j-k}\boldsymbol{i}_k, \quad j = 1, 2, \ldots, \tag{5.2}$$

where

$$(T\circ)^0\boldsymbol{x} := \boldsymbol{x}, \quad (T\circ)^k\boldsymbol{x} := T \cdot \big((T\circ)^{k-1}\boldsymbol{x}\big), \quad k \in \mathbb{N}.$$

Apart from the different computation of the remainder interval, for the initial value problem (5.1), the naive Taylor model method (5.2) coincides with the direct interval method that occurs in [36]. Hence, the naive Taylor model method (5.2) has the same divergence property as the direct interval method, for which it was shown in [36] that after j steps we have

$$\mathrm{w}\big((T\circ)^{j-1}\boldsymbol{i}_1\big) \;=\; |T|^{\,j-1}\,\mathrm{w}(\boldsymbol{i}_1)$$

(for $A = (a_{ij})$, we denote by $|A|$ the matrix with components $|a_{ij}|$). The key point here is that the spectral radius of $|T|^{j-1}$ may be much larger than the spectral radius of T^{j-1}, which describes the natural error growth of a point method. If this is the case, the error bounds for the naive Taylor model method may be much larger than the true error.

5.2. Naive Taylor model method with shrink wrapping. Berz and Makino [29] defined shrink wrapping as a method for absorbing the interval part of the Taylor model into the polynomial part by modifying the polynomial coefficients. The set defined by the sum of the given polynomial and interval is wrapped by a set defined by a pure polynomial. The new set may be larger than the initial set, but it is less prone to the dependency problem and to the wrapping effect in succeeding calculations.

In the verified integration of ODEs, shrink wrapping is usually applied to the Taylor model enclosures of the flow at the grid points, before continuing the integration. In practical computations, shrink wrapping is performed when the size of the interval remainder term exceeds some heuristically chosen bound. After shrink wrapping, the initial set of the subsequent integration step is purely symbolic, which removes the dependency problem and simplifies the verification step. The success of the Taylor model based integration method depends on the successful reduction of the excess introduced in the shrink wrapping process.

The process of applying shrink wrapping to a Taylor model vector

$$\mathcal{U} := p(x) + \boldsymbol{i}, \quad x \in \boldsymbol{x},$$

is described in [29]. Here, we outline only its four basic steps. First, let $\widetilde{\mathcal{U}}$ denote the Taylor model that is obtained when the constant part of p is removed. Second, multiply $\widetilde{\mathcal{U}}$ by the inverse of the matrix associated with its linear part and obtain the Taylor model $\widehat{\mathcal{U}}$. Third, estimate the nonlinear part of $\widehat{\mathcal{U}}$, its Jacobian, and the interval term of $\widehat{\mathcal{U}}$ to obtain the shrink wrap factor $q \geq 1$. Fourth, multiply the polynomial part of $\widetilde{\mathcal{U}}$ with q and add the constant part of $\mathcal{U}$.

We illustrate shrink wrapping with the following nonlinear example. For clarity, we use two scalar Taylor models $\mathcal{U}$ and $\mathcal{V}$ instead of a Taylor model vector. The symbolic variables are denoted by a and b (instead of the vector x).

Example 5.1. Absorption of the interval part into the symbolic part of a Taylor model. We consider the Taylor model vector $(\mathcal{U}, \mathcal{V})^T$, where

$$\left.\begin{aligned} \mathcal{U}(a,b) &:= 2 + 4a + \tfrac{1}{2}a^2 + [-0.2, 0.2], \\ \mathcal{V}(a,b) &:= 1 + 3b + ab + [-0.1, 0.1], \end{aligned}\right\} \quad a,\, b \in [-1, 1]. \tag{5.3}$$

The set defined by (5.3) is shown in Figure 5.1. Following the above outline, we obtain

$$\begin{aligned} \widetilde{\mathcal{U}}(a,b) &= 4a + \tfrac{1}{2}a^2 + [-0.2, 0.2], \\ \widetilde{\mathcal{V}}(a,b) &= 3b + ab + [-0.1, 0.1]. \end{aligned} \tag{5.4}$$

The matrix associated with the linear part of the Taylor model (5.4) is

$$C := \begin{pmatrix} 4 & 0 \\ 0 & 3 \end{pmatrix}.$$

Multiplying (5.4) with C^{-1}, we have

$$\begin{aligned} \widehat{\mathcal{U}}(a,b) &= a + \tfrac{1}{8}a^2 + [-0.05, 0.05], \\ \widehat{\mathcal{V}}(a,b) &= b + \tfrac{1}{3}ab + [-0.034, 0.034]. \end{aligned}$$

Estimating the nonlinear part and the interval terms as described in [29], we compute numbers s, t, and d satisfying

$$s \geq \left|\frac{1}{8}a^2\right|,\ s \geq \left|\frac{1}{3}ab\right| \quad \text{for all } a, b \in [-1, 1],$$
$$t \geq \left|\frac{1}{4}a\right|,\ t \geq \left|\frac{1}{3}b\right|,\ t \geq \left|\frac{1}{3}a\right| \quad \text{for all } a, b \in [-1, 1],$$
$$d \geq 0.05,\ d \geq 0.034.$$

These conditions are fulfilled for $s = t = \frac{1}{3}$ and $d = 0.05$, from which we deduce the shrink wrap factor [29]

$$q = 1 + d \cdot \frac{1}{(1-t)(1-s)} = \frac{89}{80}.$$

The final Taylor model after shrink wrapping is

$$\begin{aligned} \mathcal{U}_{\mathrm{sw}}(a, b) &:= 2 + \frac{89}{20}a + \frac{89}{160}a^2, \\ \mathcal{V}_{\mathrm{sw}}(a, b) &:= 1 + \frac{287}{80}b + \frac{89}{80}ab. \end{aligned} \tag{5.5}$$

As Figure 5.1 shows, the set defined by (5.3) is contained in the set defined by (5.5).

Applying shrink wrapping in the linear model problem (5.1) is rather simple. For simplicity, let us assume that shrink wrapping is performed in every integration step. Then we must compute [29] $q_j := 1 + d_j/2$, where

$$d_j := \left\| \mathrm{w}\big((T^j)^{-1}\boldsymbol{i}_j\big) \right\|_\infty .$$

If T is sufficiently well-conditioned, and if the interval terms are sufficiently small, then the factors d_j are almost zero, and shrink wrapping is feasible for many integration steps.

The naive Taylor model method with shrink wrapping resembles the parallelepiped method. By multiplying the nonconstant coefficients of the Taylor polynomial, for linear autonomous ODEs the interval term is absorbed as in the parallelepiped method.

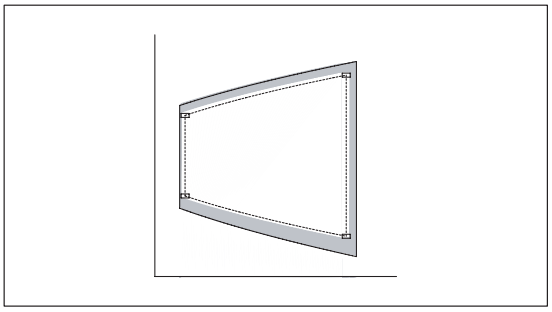

FIG. 5.1. *Sets of the Taylor models before (see* (5.3)*) and after shrink wrapping (see* (5.5)*). The dotted line is the boundary of the set that is described by the polynomial of the original Taylor model. The white area is the set described by the original Taylor model, including the interval term. The excess area introduced by shrink wrapping is shaded in grey.*

While T^j is well-conditioned, d_j is small, and so is the excess area. On the other hand, q_j (and the excess area) becomes large if T^j becomes ill conditioned, which is eventually the case if T has eigenvalues of different magnitude. In this case the integration breaks down due to the growth of the Taylor polynomial coefficients.

The naive Taylor model method with shrink wrapping is outlined as Algorithm 5.1.

Algorithm 5.1 (naive Taylor model method with shrink wrapping)

Let the initial set be given as a Taylor model vector in m space variables.

For $j := 0, 1 \ldots, j_{\max} - 1$:

1. Compute the m-dimensional Taylor model $\mathcal{U} = p_n + \boldsymbol{i}$ (containing the flow of the IVP at t_{j+1}) as in the naive Taylor model method.
2. Absorb $\boldsymbol{i}$ into p_n by shrink wrapping.
3. Continue the integration with the modified polynomial as the initial set for the next time step.

5.3. Preconditioned Taylor models. We showed in the previous section that shrink wrapping has the same limitations as the parallelepiped method in traditional interval arithmetic. To make Taylor model based integration successful for a larger class of IVPs, some stabilization process similar to the QR interval method is required. For restoring good condition numbers of the maps defined by the linear parts of the Taylor models in the integration process, Berz and Makino developed preconditioned Taylor models [29].

In the naive Taylor model method with or without shrink wrapping, the flow of the ODE $u' = f(t, u)$ is represented by a single Taylor model at each grid point. In the preconditioned Taylor model method, the flow of the ODE at $t = t_j$ is represented by a composition of a left and a right Taylor model

$$\mathcal{U}_l \circ \mathcal{U}_r = (p_{l,j} + \boldsymbol{i}_{l,j}) \circ (p_{r,j} + \boldsymbol{i}_{r,j}).$$

DEFINITION 5.2. *The composition*

$$\mathcal{U}(x) := \big(p_l(x) + \boldsymbol{i}_l\big) \circ \big(p_r(x) + \boldsymbol{i}_r\big) \tag{5.6}$$

of two Taylor models

$$\begin{aligned} \mathcal{U}_l(x) &:= p_l(x) + \boldsymbol{i}_l, \ \ x \in \boldsymbol{x}_l, \\ \mathcal{U}_r(x) &:= p_r(x) + \boldsymbol{i}_r, \ x \in \boldsymbol{x}_r, \end{aligned}$$

is called a preconditioned Taylor model *if*

$$\mathrm{Rg}\,(\mathcal{U}_r) \subseteq \boldsymbol{x}_l. \tag{5.7}$$

The range enclosure condition (5.7) is essential in verified integration with preconditioned Taylor models (see discussion below). The factorization into a left and a right Taylor model is not unique. Two preconditioned Taylor models of the form (5.6) can have the same domain $\boldsymbol{z}$ and the same range, but different polynomials and remainder intervals. In verified integration, preconditioning is used to replace some

representation of the flow at an intermediate grid point by a different set of initial values that is more suitable for continuing the integration. Here preconditioning is essentially a substitution in space variables. In the continuation of the integration, the right Taylor model is not involved at all. The following theorem is a reformulation of a proposition given without a proof by Makino and Berz [29].

THEOREM 5.3. *If the initial set of an IVP is given by a preconditioned Taylor model, then integrating the flow of the ODE acts only on the left Taylor model.*

For better understanding of this theorem, which is the key point of the preconditioned integration method, we present first a formal proof, then an example with symbolic integration, and finally a numerical example.

Proof. The space variables are parameters in the integration with respect to time. If $F(x,t)$ is a primitive of $f(x,t)$, that is, if

$$\int f(x,t)\,dt = F(x,t),$$

then substituting $x = g(u)$ does not affect F:

$$\int f(g(u),t)\,dt = F(g(u),t).$$

Preconditioned integration uses $x = (p_{l,j} + \boldsymbol{i}_{l,j})$ and $g(u) = (p_{r,j} + \boldsymbol{i}_{r,j})$. □

Example 5.4. Preconditioned symbolic integration over two time steps. We consider the IVP

$$\begin{aligned} x' &= x(x+y), \quad x(0) = 1+a,\\ y' &= -x(x+y), \quad y(0) = -1+b. \end{aligned}$$

Its unique solution is

$$\begin{aligned} x(t) &= (1+a)e^{(a+b)t},\\ y(t) &= a+b-(1+a)e^{(a+b)t}, \end{aligned}$$

so that at $t = 1$,

$$x(1) = (1+a)e^{a+b}, \quad y(1) = a+b-(1+a)e^{a+b}.$$

To continue the integration, we use the IVP

$$\begin{aligned} u' &= u(u+v), \qquad u(0) = \alpha,\\ v' &= -u(u+v), \quad v(0) = \beta, \end{aligned}$$

and obtain

$$u(1) = \alpha e^{\alpha+\beta}, \quad v(1) = \alpha+\beta-\alpha e^{\alpha+\beta}.$$

Due to the substitution rule, $u(1) = x(2)$ and $v(1) = y(2)$. Indeed, letting

$$\begin{aligned} \alpha &= (1+a)e^{a+b},\\ \beta &= a+b-(1+a)e^{a+b}, \end{aligned}$$

we obtain

$$\begin{aligned} u(1) &= (1+a)e^{2(a+b)} = x(2),\\ v(1) &= (a+b)-(1+a)e^{2(a+b)} = y(2). \end{aligned}$$

The same variable substitution as in Example 5.4 is applied when the initial set for an ODE is given by some preconditioned Taylor model $\mathcal{U}_l \circ \mathcal{U}_r$. To compute an enclosure of the flow, it suffices to integrate the given ODE for the initial values defined by $\mathrm{Rg}\,(\mathcal{U}_l)$, and to compose the integrated Taylor model with $\mathcal{U}_r$. If higher order terms appear in the composition process, they are included in the remainder interval of the result, as in Example 2.2.

In practice, preconditioning is used to replace the integrated preconditioned flow at the end of the jth integration step,

$$\left(\oint \mathcal{U}_{l,j}\right) \circ \mathcal{U}_{r,j}$$

(where $\oint \mathcal{U}$ denotes integrated flow with respect to the given ODE), by a different preconditioned Taylor model

$$\mathcal{U}_{l,j+1} \circ \mathcal{U}_{r,j+1}.$$

The initial set for the $(j+1)$st integration step is defined by $\mathrm{Rg}\,(\mathcal{U}_{l,j+1})$. The method is successful if

- the amount of overestimation in the wrapping of $\left(\oint \mathcal{U}_{l,j}\right) \circ \mathcal{U}_{r,j}$ by $\mathcal{U}_{l,j+1} \circ \mathcal{U}_{r,j+1}$ is sufficiently small, and if
- $\mathrm{Rg}\,(\mathcal{U}_{l,j+1})$ is better suited for continuing the integration than $\oint \mathcal{U}_{l,j}$. For example, preconditioning can be used to reduce the condition number of certain matrices that control the propagation of the global error (see example below) or to reduce the number of nonzero elements in the polynomial part of the left Taylor model.

In Lohner's QR method, an ill-conditioned parallelepiped is wrapped by some well-conditioned m-dimensional rectangle. For preconditioning Taylor models, a large variety of well-conditioned wraps is conceivable. The optimal choice is still an open question for future research.

One important aspect of preconditioned integration is the computation of the remainder bounds in the Picard iteration. If the initial set is given by (5.6), the validity of the enclosure is already guaranteed if the remainder intervals hold for $x \in \mathrm{Rg}\,(\mathcal{U}_r)$. In practice, the remainder bounds are calculated for $x \in \boldsymbol{x}$, a larger set and a potential source of overestimation. In practical computations, overestimation (loss of accuracy) is usually converted to costs (increase of computation time). A common strategy is to limit the admissible size of the remainder intervals by some prescribed bound. Using a larger initial set then has the effect of reducing step sizes and increasing overall computation time.

A simple choice for the left Taylor model (the initial set) in each integration step is a well-conditioned linear map (a parallelepiped). The following description of preconditioned integration is a simplified version of the presentation in [29]. We consider the linear autonomous IVP

$$\begin{aligned} u' &= B\,u, \\ u(0) &= u_0 = c_0 + C_0 x, \end{aligned} \tag{5.8}$$

where B is a real matrix, c_0 is a real vector, C_0 is a diagonal matrix, and x is contained in $[-1,1]^m$. The initial set is given by a Taylor model vector of the form (2.3). A suitable preconditioned Taylor model for this initial set is

$$p_{l,0}(x) = c_0 + C_0 x, \quad \boldsymbol{i}_{l,0} = 0, \quad p_{r,0}(x) = x, \quad \boldsymbol{i}_{r,0} = 0.$$

We assume that the flow at t_j is given by the preconditioned Taylor model

$$\mathcal{U}_j := (p_{l,j} + \boldsymbol{i}_{l,j}) \circ (p_{r,j} + \boldsymbol{i}_{r,j}) = (c_{l,j} + C_{l,j}\, x + \boldsymbol{i}_{l,j}) \circ (c_{r,j} + C_{r,j}\, x + \boldsymbol{i}_{r,j}),$$

where $c_{l,j}$ and $c_{r,j}$ are real vectors, and $C_{l,j}$ and $C_{r,j}$ are real matrices. Using the matrix T from section 5.1, the flow after integration is given by

$$\mathcal{U}_{j+1} := (Tc_{l,j} + TC_{l,j}\, x + \boldsymbol{i}_{l,j+1}) \circ (p_{r,j} + \boldsymbol{i}_{r,j}).$$

For $c_{l,j+1} := Tc_{l,j}$ and any nonsingular matrix $C_{l,j+1}$, the preconditioned Taylor model $\mathcal{U}_{j+1}$ can be rewritten as

$$\begin{aligned}
\mathcal{U}_{j+1} &= (Tc_{l,j} + C_{l,j+1}\, x + [0,0]) \circ \left\{ \left[C_{l,j+1}^{-1} TC_{l,j}\, x + C_{l,j+1}^{-1} \boldsymbol{i}_{l,j+1} \right] \circ (p_{r,j} + \boldsymbol{i}_{r,j}) \right\} \\
&= (c_{l,j+1} + C_{l,j+1}\, x + [0,0]) \circ \Big\{ \left[C_{l,j+1}^{-1} TC_{l,j}\, x + C_{l,j+1}^{-1} \boldsymbol{i}_{l,j+1} \right] \\
&\qquad\qquad \circ (c_{r,j} + C_{r,j}\, x + \boldsymbol{i}_{r,j}) \Big\} \\
&= (c_{l,j+1} + C_{l,j+1}\, x + [0,0]) \circ \left\{ C_{l,j+1}^{-1} TC_{l,j}\ (c_{r,j} + C_{r,j}\, x + \boldsymbol{i}_{r,j}) + C_{l,j+1}^{-1} \boldsymbol{i}_{l,j+1} \right\} \\
&= (c_{l,j+1} + C_{l,j+1}\, x + [0,0]) \\
&\quad \circ \left\{ C_{l,j+1}^{-1} TC_{l,j}\, c_{r,j} + C_{l,j+1}^{-1} TC_{l,j} C_{r,j}\, x + C_{l,j+1}^{-1} TC_{l,j}\, \boldsymbol{i}_{r,j} + C_{l,j+1}^{-1} \boldsymbol{i}_{l,j+1} \right\} \\
&=: (c_{l,j+1} + C_{l,j+1}\, x + [0,0]) \circ (c_{r,j+1} + C_{r,j+1}\, x + \boldsymbol{i}_{r,j+1}).
\end{aligned}$$

The interval term $\boldsymbol{i}_{r,j}$ in the preconditioned Taylor model integration of (5.8) is propagated as the interval term in the parallelepiped and QR interval iteration, if $C_{l,j+1}$ is chosen as in those methods. For $C_{l,j+1} = TC_{l,j}$, the parallelepiped method is obtained, for $TC_{l,j}P_j = Q_j R_j$ (where P_j is a permutation matrix for sorting the columns of $TC_{l,j}$) and $C_{l,j+1} = Q_j$, the QR method. Numerical examples confirming these relations are presented in section 7.

For nonlinear ODEs, the nonlinear terms in the left Taylor model can be shifted to the right Taylor model in the same manner [29]. However, the resulting Taylor model methods then differ from the corresponding interval methods. First, the symbolic parts of the composed Taylor models describe nonlinear enclosures sets of the flow, which need not be convex, in contrast to interval methods. Second, the nonlinear terms in the left Taylor models then also act on the interval terms in the right Taylor models. An analysis of the resulting interval propagation will be the subject of future research.

6. Preconditioned quadratic example. We now demonstrate QR preconditioned Taylor model integration for the quadratic model problem of section 4.1, namely,

$$\begin{aligned}
u' &= v, \qquad u(0) \in [0.95, 1.05], \\
v' &= u^2, \qquad v(0) \in [-1.05, -0.95].
\end{aligned}$$

In each integration step, the left Taylor models are constructed via a QR factorization of the linear parts of the integrated Taylor models of the previous integration step. As in the naive integration of this IVP in section 4.1, order $n = 3$ and step size $h = 0.1$ are used, and all numbers are displayed rounded to six decimal digits.

In the first integration step, the initial set is described by the left Taylor model in space variables at t_0. The right Taylor model at t_0 is the identity map in space variables. Hence, the first integration step is performed as in the naive Taylor model method (cf. section 4.1), and we obtain the integrated left Taylor models (4.3), namely,

$$\left.\begin{aligned} \widetilde{\mathcal{U}}_{l,1}(a,b) &:= 0.904667 + 1.01a + 0.1b + \widetilde{\boldsymbol{i}}_0, \\ \widetilde{\mathcal{V}}_{l,1}(a,b) &:= -0.909333 + 0.19a + 1.01b + 0.1a^2 + \widetilde{\boldsymbol{j}}_0, \end{aligned}\right\} \quad a,\ b \in [-0.05, 0.05],$$

where

$$\widetilde{\boldsymbol{i}}_0 = [-5.09307\text{E-}5, 7.86167\text{E-}5], \quad \widetilde{\boldsymbol{j}}_0 = [-1.75707\text{E-}4, 1.60933\text{E-}4].$$

For reasons that will soon become clear, we normalize the domain such that a and b are contained in $[-1, 1]$. Doing so (without changing the names of the variables), we have

$$\left.\begin{aligned} \widetilde{\mathcal{U}}_{l,1}(a,b) &:= 0.904667 + 0.0505a + 0.005b + \widetilde{\boldsymbol{i}}_0, \\ \widetilde{\mathcal{V}}_{l,1}(a,b) &:= -0.909333 + 0.0095a + 0.0505b + 0.00025a^2 + \widetilde{\boldsymbol{j}}_0, \end{aligned}\right\} \quad a,\ b \in [-1, 1].$$

So far, the right Taylor models have been unaffected by the integration process. Before continuing the integration, however, we precondition the left Taylor models. We extract the linear parts of $\widetilde{\mathcal{U}}_{l,1}$ and $\widetilde{\mathcal{V}}_{l,1}$, and obtain the matrix $C_{l,1}$, from which we compute a QR factorization.

$$\begin{aligned} C_{l,1} := \begin{pmatrix} 0.0505 & 0.005 \\ 0.0095 & 0.0505 \end{pmatrix} &= \begin{pmatrix} 0.982762 & -0.184876 \\ 0.184876 & 0.982762 \end{pmatrix} \cdot \begin{pmatrix} 0.0513858 & 0.0142500 \\ 0 & 0.0487051 \end{pmatrix} \\ &=: QR. \end{aligned}$$

The left Taylor models in the second integration step are built from the constant terms of $\widetilde{\mathcal{U}}_{l,1}$ and $\widetilde{\mathcal{V}}_{l,1}$ and from Q. Thus we get

$$\begin{aligned} \overline{\mathcal{U}}_{l,1}(a,b) &:= 0.904667 + 0.982762a - 0.184876b, \\ \overline{\mathcal{V}}_{l,1}(a,b) &:= -0.909333 + 0.184876a + 0.982762b. \end{aligned}$$

The nonlinear term $0.00025a^2$ in $\widetilde{\mathcal{V}}_{l,1}$ and the interval terms $\widetilde{\boldsymbol{i}}_0$, $\widetilde{\boldsymbol{j}}_0$ are collected in the right Taylor models, which are multiplied by Q^T. We obtain

$$Q^T \cdot \begin{pmatrix} 0 \\ 0.00025a^2 \end{pmatrix} = \begin{pmatrix} 0.0000462190a^2 \\ 0.000245691a^2 \end{pmatrix}$$

and

$$\begin{pmatrix} \overline{\boldsymbol{i}}_0 \\ \overline{\boldsymbol{j}}_0 \end{pmatrix} := Q^T \cdot \begin{pmatrix} \widetilde{\boldsymbol{i}}_0 \\ \widetilde{\boldsymbol{j}}_0 \end{pmatrix} = \begin{pmatrix} [-8.25368\text{E-}5, 1.07014\text{E-}4] \\ [-1.87213\text{E-}4, 1.67575\text{E-}4] \end{pmatrix},$$

which yields

$$\left.\begin{aligned} \overline{\mathcal{U}}_{r,1}(a,b) &:= 0.0513858a + 0.0142500b + 0.0000462190a^2 + \overline{\boldsymbol{i}}_0, \\ \overline{\mathcal{V}}_{r,1}(a,b) &:= 0.0487051b + 0.000245691a^2 + \overline{\boldsymbol{j}}_0, \end{aligned}\right\} \quad a,\ b \in [-1, 1].$$

Before we can continue the integration, we must further modify the preconditioned Taylor models. This is probably the most surprising part of the algorithm. It is also crucial for the validity of the method. After the first time step, the flow of the IVP is contained in the composition of the left and right Taylor models. For continuing the integration, we want to drop the right Taylor model. On one hand, this is only feasible if the left Taylor model contains the flow of the IVP. On the other hand, the set defined by the left Taylor model should not be much larger than the current flow, because that would mean large overestimation. There are two potential solutions for ensuring the desired inclusion property. We can modify the domain of the independent variables, or we may modify the left Taylor model by an additional transformation. We describe both alternatives in the following.

The starting point of the transformation is the range of the right Taylor model. We have

$$\begin{aligned}\mathrm{Rg}\left(\overline{\mathcal{U}}_{r,1}\right) &\subseteq 0.0513858\cdot[-1,1]+0.0142500\cdot[-1,1]+0.0000462190\cdot[0,1]\\ &\qquad +[-8.25368\text{E-}5, 1.07014\text{E-}4]\\ &= [-0.0657183368, 0.065789033]\subseteq[-0.0657183, 0.0657890],\\ \mathrm{Rg}\left(\overline{\mathcal{V}}_{r,1}\right) &\subseteq 0.0487051\cdot[-1,1]+0.000245691\cdot[0,1]+[-1.87213\text{E-}4, 1.67575\text{E-}4]\\ &= [-0.048892151, 0.049118366]\subseteq[-0.0488922, 0.0491184].\end{aligned}$$

Thus we may continue the integration with the initial set for the second time step given by

$$\left.\begin{aligned}\widehat{\mathcal{U}}_{l,1}(a,b) &:= 0.904667+0.982762a-0.184876b,\\ \widehat{\mathcal{V}}_{l,1}(a,b) &:= -0.909333+0.184876a+0.982762b,\end{aligned}\right\}\quad \begin{array}{l}a\in[-0.0657183, 0.0657890],\\ b\in[-0.0488922, 0.0491184]\end{array}$$

(unchanged polynomials, but modified domain).

Alternatively, we can apply a linear transformation on the left and the right Taylor models by a scaling matrix [29]. It is convenient here to denote the linear map (that is, a linear Taylor model $\mathcal{S}$ with zero constant part and zero interval remainder term) associated with a matrix S by the matrix itself. First note that for any nonsingular matrix S,

$$\begin{aligned}(\overline{\mathcal{U}}_{l,1},\overline{\mathcal{V}}_{l,1})\circ(\overline{\mathcal{U}}_{r,1},\overline{\mathcal{V}}_{r,1}) &= (\overline{\mathcal{U}}_{l,1},\overline{\mathcal{V}}_{l,1})\circ(S\circ S^{-1})\circ(\overline{\mathcal{U}}_{r,1},\overline{\mathcal{V}}_{r,1})\\ &\subseteq((\overline{\mathcal{U}}_{l,1},\overline{\mathcal{V}}_{l,1})\circ S)\circ(S^{-1}\circ(\overline{\mathcal{U}}_{r,1},\overline{\mathcal{V}}_{r,1})),\end{aligned}$$

where the subset property is induced by the subdistributivity law of interval arithmetic [1, p. 3]. Letting

$$S := \begin{pmatrix}0.0657890 & 0\\ 0 & 0.0491184\end{pmatrix},$$

we obtain

$$\begin{aligned}(\overline{\mathcal{U}}_{l,1},\overline{\mathcal{V}}_{l,1})\circ S &= \begin{pmatrix}0.904667\\ -0.909333\end{pmatrix}\\ &\quad+\begin{pmatrix}0.982762 & -0.184876\\ 0.184876 & 0.982762\end{pmatrix}\begin{pmatrix}0.0657890 & 0\\ 0 & 0.0491184\end{pmatrix}\begin{pmatrix}a\\ b\end{pmatrix}\\ &= \begin{pmatrix}0.904667\\ -0.909333\end{pmatrix}+\begin{pmatrix}0.0646550 & -0.00908081\\ 0.0121628 & 0.0482716\end{pmatrix}\begin{pmatrix}a\\ b\end{pmatrix}.\end{aligned}$$

Since S has been determined such that the range of each component of $S^{-1}\circ(\overline{\mathcal{U}}_{r,1}, \overline{\mathcal{V}}_{r,1})$ is contained in $[-1,1]$, it is feasible to continue the integration with the left Taylor models

$$\left.\begin{aligned} \mathcal{U}_{l,1}(a,b) &:= 0.904667 + 0.0646550a - 0.00908081b, \\ \mathcal{V}_{l,1}(a,b) &:= -0.909333 + 0.0121628a + 0.0482716b, \end{aligned}\right\} \quad a,\ b \in [-1,1]$$

as initial set for the second time step (modified polynomials, but original domain). The corresponding right Taylor models are

$$\begin{aligned} \begin{pmatrix} \mathcal{U}_{r,1} \\ \mathcal{V}_{r,1} \end{pmatrix} &:= S^{-1} \circ (\overline{\mathcal{U}}_{r,1}, \overline{\mathcal{V}}_{r,1}) \\ &= \begin{pmatrix} 15.2001 & 0 \\ 0 & 20.3590 \end{pmatrix} \begin{pmatrix} 0.0513858a + 0.01425b + 0.000046219a^2 + \overline{\boldsymbol{i}}_0 \\ 0.0487051b + 0.000245691a^2 + \overline{\boldsymbol{j}}_0 \end{pmatrix} \\ &= \begin{pmatrix} 0.781070a + 0.216602b + 0.000702534a^2 + [-0.00125457, 0.00162662] \\ 0.991586b + 0.00500202a^2 + [-0.00381146, 0.00341165] \end{pmatrix}. \end{aligned}$$

Remark 6.1. From a mathematical viewpoint, modification of the domain or of the polynomials are equivalent approaches for factorizing preconditioned Taylor models, but maintaining the integration domain via the scaling matrices is advantageous for the software implementation of the method, because it simplifies the estimation of the higher order terms in the integration step.

In the second integration step, we use the initial set defined by $\mathcal{U}_{l,1}$ and $\mathcal{V}_{l,1}$. Proceeding as before, we obtain the integrated left Taylor models (for $a,\ b \in [-1,1]$)

$$\begin{aligned} \widetilde{\mathcal{U}}_{l,2}(a,b) &:= 0.817551 + 0.0664561a - 0.00433580b + \widetilde{\boldsymbol{i}}_1, \\ \widetilde{\mathcal{V}}_{l,2}(a,b) &:= -0.835195 + 0.0233831a + 0.0471479b \\ &\quad + 0.000418026a^2 - 0.000117424ab + 0.00000824612b^2 + \widetilde{\boldsymbol{j}}_1, \end{aligned}$$

where

$$\widetilde{\boldsymbol{i}}_1 = [-5.72276\text{E-}5, 9.15947\text{E-}5], \quad \widetilde{\boldsymbol{j}}_1 = [-1.80914\text{E-}4, 1.80850\text{E-}4].$$

Finally, the flow at t_2 is made up by the composition of the integrated left Taylor models and the previous right Taylor models. We have

$$\begin{aligned} \mathcal{U}_2(a,b) &:= \widetilde{\mathcal{U}}_{l,2}(\mathcal{U}_{r,1}(a,b), \mathcal{V}_{r,1}(a,b)) = 0.817551 + 0.0519069a + 0.0100952b \\ &\quad + 0.000025a^2 + \ [-3.48708\text{E-}4, 4.09534\text{E-}4], \end{aligned}$$

$$\begin{aligned} \mathcal{V}_2(a,b) &:= \widetilde{\mathcal{V}}_{l,2}(\mathcal{U}_{r,1}(a,b), \mathcal{V}_{r,1}(a,b)) = -0.835195 + 0.0182638a + 0.0518160b \\ &\quad + 0.000507287a^2 - 0.0000505ab - 0.0000025b^2 + [-4.38606\text{E-}4, 4.28392\text{E-}4], \end{aligned}$$

where $a,\ b \in [-1,1]$.

Algorithm 6.1 (QR preconditioned Taylor model method)

Let the initial set be given as a preconditioned Taylor model vector $\mathcal{U}_{l,0} \circ \mathcal{U}_{r,0}$ in m space variables, with $\mathcal{U}_{r,0}$ the identity map and symbolic variables in $[-1, 1]$.

For $j := 0, 1 \ldots, j_{\max} - 1$:

1. Integrate $\mathcal{U}_{l,j}$ (containing the flow of the IVP at t_j) as in the naive Taylor model method. Denote the integrated left Taylor model (containing the flow of the IVP at t_{j+1}) by $\widetilde{\mathcal{U}}_{l,j+1}$. The flow is also contained in $\widetilde{\mathcal{U}}_{l,l+1} \circ \mathcal{U}_{r,j}$.
2. Replace $\widetilde{\mathcal{U}}_{l,j+1} \circ \mathcal{U}_{r,j}$ by $\mathcal{U}_{l,j+1} \circ \mathcal{U}_{r,j+1}$:
   - (i) Compute the QR factorization of the linear part of $\widetilde{\mathcal{U}}_{l,j+1}$.
   - (ii) Shift all but the constant part of $\widetilde{\mathcal{U}}_{l,j+1}$ to $\mathcal{U}_{r,j}$. Make Q the linear part of $\widetilde{\mathcal{U}}_{l,j+1}$. Apply Q^{-1} on $\mathcal{U}_{r,j}$.
   - (iii) Bound the range of the new $\mathcal{U}_{r,j}$.
   - (iv) Apply a scaling matrix S_{j+1} on $\mathcal{U}_{r,j}$ such that each component of the range of $\mathcal{U}_{r,j+1} := S_{j+1}^{-1} \circ \mathcal{U}_{r,j}$ is contained in $[-1, 1]$ and spans $[-1, 1]$ approximately.
   - (v) Set $\mathcal{U}_{l,j+1} := \widetilde{\mathcal{U}}_{l,j+1} \circ S_{j+1}$.

Compared with the naive Taylor model integration performed in section 4.1, the polynomial coefficients are identical except for roundoff errors. This does not invalidate the computations, since all roundoff errors are rigorously bounded by the interval terms. Even though preconditioned integration is the superior method with respect to accuracy in the long run, the interval terms after two integration steps are larger here. The advantage of preconditioning becomes apparent only after several integration steps (see section 6.1). Algorithm 6.1 summarizes the preconditioned Taylor model method with domain normalization.

6.1. Numerical comparison with the QR interval method. Finally, we compare the performance of Lohner's software AWA [21] with the COSY INFINITY integrator written by Makino. We use the quadratic model IVP (4.1) for the comparison. For the computation, Taylor expansions of order 18 were used in both programs. In both programs, the QR method (QR preconditioning) is used. The computed enclosure sets are shown in Figure 6.1.

In the left picture, integration is performed in the time interval $[0, 2.8]$. In the beginning, the enclosures from AWA (rectangular boxes) and COSY INFINITY (nonlinear sets) are of similar quality. Near the end of the integration domain, the enclosures from AWA start exploding. While AWA aborts integration at $t = 3.75$, COSY INFINITY is able to continue the integration much longer (right picture; enclosures of AWA are not shown). We attribute this to the ability of Taylor model methods to use nonconvex enclosure sets of the flow.

This example shows that Taylor model methods may perform much better than interval methods on some problems, but this is not always the case. For some problems, interval methods can be as effective. Moreover, if they succeed, interval methods are often faster than Taylor model methods, because symbolic computations with multivariate polynomials are expensive.

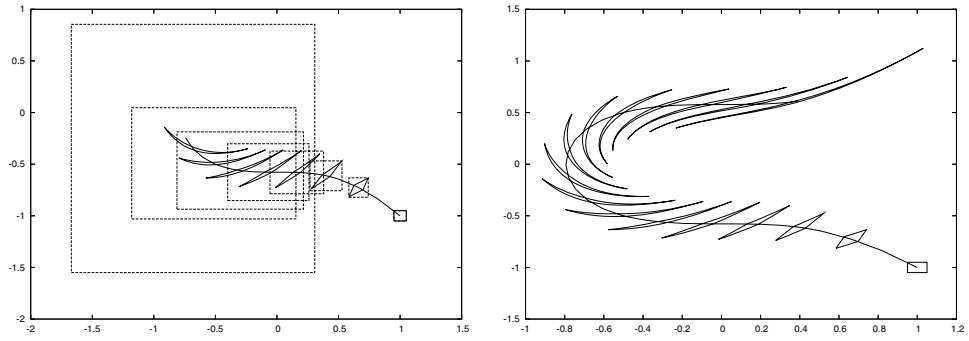

FIG. 6.1. *Integration of quadratic model IVP with AWA and COSY INFINITY for* $t \in [0, 2.8]$ *(left), and with COSY INFINITY for* $t \in [0, 6]$ *(right). Enclosures of the flow are shown for* $t_k = 0.4k$, $k = 0, 1, \ldots$. *The solid line in each picture belongs to the approximate solution that was computed with a Runge–Kutta method (for the model ODE with point initial values).*

7. Linear numerical examples. We compare interval methods and Taylor model methods for the linear autonomous ODE

$$u' = B\,u,$$

where B is a real 3×3 matrix. Numerical results are displayed for three different choices of B. In all examples, the initial values

$$\boldsymbol{u}_0 = \begin{pmatrix} [0.999, 1.001] \\ [0.999, 1.001] \\ [0.999, 1.001] \end{pmatrix}$$

were used. The computations were performed with AWA and with the COSY INFINITY integrator. In all examples, order 12 was chosen for the Taylor polynomial. Using lower orders (6 and 9 were tested) gave less accurate results, and using higher orders (15 was tested) increased the computation times but not the accuracy of the results. For integration with COSY INFINITY, the minimal step size was set to 0.25.

In the tables, the following notation is used.

- AWA iv, AWA pe, and AWA QR denote the direct interval method, the parallelepiped method, and the QR method, respectively.
- TM na, TM sw, and TM QR denote the naive Taylor model method without shrink wrapping, the naive Taylor model method with shrink wrapping, and the Taylor model method with QR preconditioning, respectively.

The observed performance of the methods is in agreement with the theoretical considerations in this paper. Naive Taylor model integration without shrink wrapping performs as the direct interval method (except for Example 1), naive Taylor model integration with shrink wrapping like the parallelepiped method, and QR preconditioned Taylor model integration similar to the QR method.

We call two matrices A and B *floating-point similar* if A is obtained from B by a similarity transform executed in floating-point arithmetic. Floating-point similar matrices are denoted by $A \approx B$. Intervals are sometimes displayed using a short notation with upper and lower indexes. For example, 1.4^{7301}_{5593}E-001 denotes the interval [0.145593,0.147301].

TABLE 7.1
Numerical results for Example 7.1.

Method	t_{end}	Steps	$y_1(t_{\text{end}})$
AWA iv	100	216	1.4^{7301}_{5593}E-001
AWA pe	52.6	131	aborted
AWA QR	100	216	1.4^{7301}_{5593}E-001
TM na	100	391	[−2.378E+26, 2.378E+26]
TM sw	100	272	[−2.282E+112, 2.282E+112]
TM QR	100	122	1.4^{7301}_{5593}E-001

Example 7.1. *Pure contraction (*see Table 7.1*).*

$$B = \begin{pmatrix} -0.4375 & 0.0625 & -0.2651650429 \\ 0.0625 & -0.4375 & -0.2651650429 \\ -0.2651650429 & -0.2651650429 & -0.375 \end{pmatrix} \approx \begin{pmatrix} -\frac{1}{2} & 0 & 0 \\ 0 & -\frac{3}{4} & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

B has three distinct real eigenvalues so that B describes a contraction without rotation. For such problems, the parallelepiped method is not well suited, because the matrices A_j, which have to be inverted, become nearly singular. The interval method breaks down, and the corresponding naive Taylor model method with shrink wrapping computes a practically useless enclosure of the solution.

The direct interval method succeeds here. We also would have expected the naive Taylor model method without shrink wrapping to succeed. While the reason for its failure is not clear, it provides further evidence for our judgement that this method is not very effective. Both the QR interval method and the QR preconditioned Taylor model method succeed here.

TABLE 7.2
Numerical results for Example 7.2.

Method	t	Steps	$y_1(t_{\text{end}})$
AWA iv	76.5	393	aborted
AWA pe	100	449	1.49^{522}_{222}E+000
AWA QR	100	449	1.49^{522}_{222}E+000
TM na	100	396	[−1.517E+45, 1.517E+45]
TM sw	100	343	1.49^{522}_{222}E+000
TM QR	100	343	1.49^{522}_{222}E+000

Example 7.2. *Pure rotation (*see Table 7.2*).*

$$B = \begin{pmatrix} 0 & -0.7071067810 & -0.5 \\ 0.7071067810 & 0 & 0.5 \\ 0.5 & -0.5 & 0 \end{pmatrix} \approx \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

B has eigenvalues $\pm i$ and 0. The flow of this IVP is a rotating interval box. As expected, the direct interval method and the naive Taylor model method fail, whereas the parallelepiped method and the naive Taylor model method with shrink wrapping (and also the QR based methods) succeed.

TABLE 7.3
Numerical results for Example 7.3.

Method	t	Steps	$y_1(t_{\text{end}})$
AWA iv	85.5	507	aborted
AWA pe	75.2	404	aborted
AWA QR	100	516	1.34^{862}_{592}E+000
TM na	100	397	[−1.605E+55, 1.605E+55]
TM sw	100	357	[−3.566E+106, 3.566E+106]
TM QR	100	362	1.34^{862}_{592}E+000

Example 7.3. *Contraction and rotation (*see Table 7.3*).*

$$B = \begin{pmatrix} -0.125 & -0.8321067810 & -0.3232233048 \\ 0.5821067810 & -0.125 & 0.6767766952 \\ 0.6767766952 & -0.3232233048 & -0.25 \end{pmatrix} \approx \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & -\frac{1}{2} \end{pmatrix}$$

In our last example, B has eigenvalues $\pm i$ and $-1/2$, so contraction and rotation are combined. Here, the direct interval method and the naive Taylor model method are bound to fail because of the rotation, whereas the contraction causes the parallelepiped method and the Taylor model method with shrink wrapping to fail.

Only the QR based methods can successfully deal with both contraction and rotation of the initial set. For these methods, the overestimation of the final flow is hardly noticeable. This agrees with the general observation that the QR decomposition is a very effective tool in fighting the wrapping effect, both for the interval method and for the preconditioned Taylor model method.

Conclusion. We have compared traditional enclosure methods with Taylor model based integration. For the verified solution of initial value problems for ODEs, we have shown how Taylor model methods benefit from symbolic computations. Increased flexibility in admissible boundary curves of enclosures is an intrinsic advantage over traditional interval methods, and not only for the solution of ODEs. In future research, we hope to contribute to the further development and increased use of Taylor model methods.

Acknowledgments. The authors thank Martin Berz and Kyoko Makino for several very helpful clarifying discussions on Taylor models, and for making the COSY INFINITY integrator available. Our thanks also go to the referees for helpful comments.

CONDITION ESTIMATES FOR PSEUDO-ARCLENGTH CONTINUATION*

K. I. DICKSON†, C. T. KELLEY†, I. C. F. IPSEN†, AND I. G. KEVREKIDIS‡

Abstract. We bound the condition number of the Jacobian in pseudo-arclength continuation problems, and we quantify the effect of this condition number on the linear system solution in a Newton-GMRES solve. Pseudo-arclength continuation solves parameter dependent nonlinear equations $G(u, \lambda) = 0$ by introducing a new parameter s, which approximates arclength, and viewing the vector $x = (u, \lambda)$ as a function of s. In this way simple fold singularities can be computed directly by solving a larger system $F(x, s) = 0$ by simple continuation in the new parameter s. It is known that the Jacobian F_x of F with respect to $x = (u, \lambda)$ is nonsingular if the path contains only regular points and simple fold singularities. We introduce a new characterization of simple folds in terms of the singular value decomposition, and we use it to derive a new bound for the norm of F_x^{-1}. We also show that the convergence rate of GMRES in a Newton step for $F(x, s) = 0$ is essentially the same as that of the original problem $G(u, \lambda) = 0$. In particular, we prove that the bounds on the degrees of the minimal polynomials of the Jacobians F_x and G_u differ by at most 2. We illustrate the effectiveness of our bounds with an example from radiative transfer theory.

Key words. pseudo-arclength continuation, singularity, GMRES, singular vectors, eigenvalues, rank-one update, turning point, simple fold, fold point, limit point

1. Introduction.

Numerical continuation is the process of solving systems of nonlinear equations $G(u, \lambda) = 0$ for various values of a real parameter λ. Here $u \in R^N$, λ is a real scalar, and $G : R^{N+1} \to R^N$. An obvious approach for implementing numerical continuation, called *parameter continuation* [11, 13, 19], traces out a solution path by repeatedly incrementing λ until the desired value of λ is reached. In each such iteration, the current solution u is used as an initial iterate for the next value of λ. Although parameter continuation is simple and intuitive, it fails at points (u, λ) where the Jacobian G_u is singular. In this paper we consider singularities which are simple folds.

The standard way to remedy the failure of parameter continuation at simple folds is to reparameterize the problem by introducing an approximate arclength parameter, s, so that both u and λ depend on s. This idea, known as *pseudo-arclength continuation* [11, 13, 19], introduces a new parameter s and treats the vector $x = (u, \lambda)$ as a function of s. We then solve a new system $F(x, s) = 0$ by parameter continuation in s. In order for this approach to succeed, the Jacobian F_x of F must be nonsingular. It is known that F_x is nonsingular at simple folds and points where G_u is nonsingular [13].

Our first goal (section 3) is to quantify this nonsingularity. To this end we provide a new characterization of simple folds in terms of the singular value decomposition (SVD) of G_u. From the SVD, we derive a new bound for $\|F_x^{-1}\|_2$. This bound can be used to limit the arclength step in Newton's method. As a byproduct we obtain a refinement of Weyl's monotonicity theorem [23] for the smallest eigenvalue of a symmetric positive semidefinite matrix (section 3.1).

We also examine in section 4 how the conditioning of F_x affects the convergence of the inner GMRES [26] iteration in a Newton-GMRES solver [2, 3, 14, 15]. We show that the eigenvalue clustering of the Jacobian F_x in the reformulated problem is not much different from that of the Jacobian G_u in the original problem. This implies [4, 17] that the convergence speed of GMRES, when used as a linear solver for the Newton step, is not degraded when parameter continuation is replaced by pseudo-arclength continuation.

Finally, in section 5, we illustrate our findings with a numerical example from radiative transfer theory.

2. Background. We briefly review theory and algorithms for solving numerical continuation problems $G(u, \lambda) = 0$, where $\lambda \in R$, $u \in R^N$, and $G : R^{N+1} \to R^N$. We discuss parameter continuation in section 2.1 and pseudo-arclength continuation in section 2.2. We use the abbreviations

$$G_u \equiv \frac{\partial G}{\partial u}, \qquad G_\lambda \equiv \frac{\partial G}{\partial \lambda}.$$

2.1. Simple parameter continuation. Parameter continuation [11, 13, 19] is the simplest method for solving $G(u, \lambda) = 0$. The idea is to start at a point $\lambda = \lambda_{init}$ and solve $G(u, \lambda) = 0$ for $u(\lambda)$, say, by Newton's method. Use the solution $u(\lambda)$ as the initial iterate to solve the next problem $G(u, \lambda + d\lambda) = 0$. Algorithm **paramc** below is a simple implementation of parameter continuation from λ_{init} to $\lambda_{end} = \lambda_{init} + n\, d\lambda$ where n denotes the maximum number of continuation iterations.

---

paramc$(u, G, \lambda_{init}, \lambda_{end}, d\lambda)$
  Set $\lambda = \lambda_{init}$, $u_0 = u$
  while $\lambda \leq \lambda_{end}$ **do**
    Solve $G(u, \lambda) = 0$ with u_0 as the initial iterate to obtain $u(\lambda)$
    $u_0 = u(\lambda)$
    $\lambda = \lambda + d\lambda$
  end while

Corollary 2.1 is a consequence of the implicit function theorem [13, 22] and states that parameter continuation, as realized in Algorithm **paramc**, will succeed near a solution at which G_u is nonsingular. Parameter continuation may fail if the arc of solutions contains singular points, i.e., solutions at which G_u is singular.

COROLLARY 2.1. *Let G be Lipschitz continuously differentiable, $G(u_0, \lambda_0) = 0$, and $G_u(u_0, \lambda_0)$ be nonsingular. Then there is $\delta > 0$, which depends only on $\|G_u^{-1}(u_0, \lambda_0)\|$ and the Lipschitz constants of G_u and G_λ, such that if $|\lambda - \lambda_0| < \delta$ then Newton's method with initial iterate u_0 converges q-quadratically to the solution $u(\lambda)$ of $G(u, \lambda) = 0$, i.e.,*

$$\|u_{n+1} - u(\lambda)\| = O(\|u_n - u(\lambda)\|^2), \tag{2.1}$$

where, for $n \geq 0$,

$$u_{n+1} = u_n - G_u(u_n, \lambda)^{-1} G(u_n, \lambda).$$

Proof. Define the Lipschitz constant

$$\|G_u(u, \lambda) - G_u(v, \mu)\| \leq \gamma_G(\|u - v\| + |\lambda - \mu|).$$

Differentiating $G(u, \lambda) = 0$ with respect to λ gives

$$du/d\lambda = -G_u^{-1} G_\lambda.$$

The implicit function theorem implies that there is δ_1 such that if

$$|\lambda - \lambda_0| \leq \delta_1$$

then there is a solution arc $u(\lambda)$ defined for $|\lambda - \lambda_0| \leq \delta_1$. Since $G_u^{-1} G_\lambda$ is Lipschitz continuous, there is γ_u, which depends only on $\|G_u^{-1}(u_0, \lambda_0)\|$ and the Lipschitz constants of G_u and G_λ, such that

$$\|du/d\lambda\| = \|G_u^{-1} G_\lambda\| \leq \gamma_u.$$

A lower bound for the radius of the ball of attraction for the Newton iteration is [14]

$$\frac{1}{2\gamma_G \|G_u^{-1}(u_0, \lambda_0)\|},$$

so choosing

$$\delta = \min\left(\delta_1, \frac{1}{2\gamma_u \gamma_G \|G_u^{-1}(u_0, \lambda_0)\|}\right)$$

completes the proof. ∎

The implicit function theorem and Corollary 2.1 fail near most singular points. Our objective in this paper is to investigate the simplest class of singular points at which the implicit function theorem fails.

2.2. Pseudo-arclength continuation. Pseudo-arclength continuation [11, 13, 19] avoids the problems of Algorithm **paramc** at singular points by using an approximation of arclength parameterization. The curve in Figure 5.1, for instance, has a singularity with respect to the parameter λ. If we choose arclength s as the parameter λ, and $x = (u^T, \lambda)^T$ in place of u, we can compute the curve with simple parameter continuation. The curve in Figure 5.1 has a simple fold, which is the singularity of interest for this paper. Formally, a simple fold (or fold point, turning point, or limit point) is defined as follows [5, 13, 20, 24].

DEFINITION 2.2. *A solution* (u_0, λ_0) *of* $G(u, \lambda) = 0$ *is a simple fold if*

- $\dim(\mathrm{Ker}(G_u(u_0, \lambda_0))) = 1$ *and*
- $G_\lambda(u_0, \lambda_0) \notin \mathrm{Range}(G_u(u_0, \lambda_0))$.

To develop a pseudo-arclength continuation method, we assume that x depends smoothly on s. Then one can differentiate $G(u, \lambda) = 0$ with respect to s and obtain

$$\frac{dG(u(s), \lambda(s))}{ds} = G_u \dot{u} + G_\lambda \dot{\lambda} = 0. \tag{2.2}$$

Equivalently, one can differentiate $G(x) = 0$ and obtain $G_x\dot{x} = 0$. Here, $\dot{x}$ denotes the derivative with respect to s. Since s is arclength in the Euclidean norm,

$$\|\dot{x}\|^2 = \|\dot{u}\|^2 + |\dot{\lambda}|^2 = 1. \tag{2.3}$$

Having introduced a new parameter s, one adds an equation to $G(u, \lambda) = 0$ so that the number of equations equals the number of unknowns. To do this one introduces the extended system

$$F(x, s) = \begin{pmatrix} G(x) \\ \mathcal{N}(x, s) \end{pmatrix} = \begin{pmatrix} 0 \\ 0 \end{pmatrix}. \tag{2.4}$$

The normalization equation $\mathcal{N} = 0$ is an approximation of (2.3) where

$$\mathcal{N}(x, s) = \dot{x}_0^T(x - x_0) - (s - s_0) = 0. \tag{2.5}$$

Equation (2.5) says that the new point on the path lies on a hyperplane orthogonal to the tangent vector through the current point x_0, and the intersection of that hyperplane with the tangent vector is a distance $ds = s - s_0$ from x_0.

While we prove our results using the normalization (2.5), the bounds also apply to other normalizations [7, 11, 13, 25, 27], which are asymptotically equivalent to (2.5).

Given a known point (x_0, s_0), the pseudo-arclength continuation method increments arclength by ds, and solves (2.4) with the normalization (2.5) by Newton's method with initial iterate x_0. Algorithm **psarc** is a simple implementation of pseudo-arclength continuation.

---

psarc(u, F, s_{end}, ds)
  Set $s = 0$, $x_0 = (u_0^T, \lambda_0)^T$
  while $s \leq s_{end}$ **do**
    Approximate $\dot{x}$
    Solve $F(x, s) = 0$ with fixed s and x_0 as the initial iterate to obtain $x(s)$
    $x_0 = x(s)$
    $s = s + ds$
  end while

Since pseudo-arclength continuation is just simple parameter continuation applied to F with s as the parameter, Corollary 2.1 gives conditions for the convergence of Newton's method in pseudo-arclength continuation, and we restate the corollary in terms of F for completeness.

COROLLARY 2.3. *Let the assumptions of Corollary* 2.1 *hold for* F. *Then there is* $\delta > 0$, *which depends only on* $\|F_x^{-1}(x_0, s_0)\|$ *and the Lipschitz constants of* F_x *and* x, *such that if* $|s - s_0| < \delta$ *then Newton's method with initial iterate* x_0 *converges q-quadratically to the solution.*

One consequence of Corollary 2.3 is that a bound on $\|F_x^{-1}\|$ is an important factor in bounding the arclength step. In the next section we present the main result of this paper, a new bound on $\|F_x^{-1}\|$.

3. Nonsingularity of F_x. For a solution $x_0 = (u_0, \lambda_0)$ to $G(u, \lambda) = 0$, we present an upper bound on $\|F_x^{-1}(x_0, s_0)\|$ in the case that

- $G_u(u_0, \lambda_0)$ is nonsingular or
- (u_0, λ_0) is a simple fold of $G(u, \lambda) = 0$.

In order to derive the bound, we introduce a new characterization of simple folds, which is based on the SVD of G_u. We prove the bound in section 3.2. In section 3.1 we refine Weyl's monotonicity theorem for the smallest eigenvalue of a symmetric positive semidefinite matrix, which we need for the proof.

Let

$$G_u(u,\lambda) = U\Sigma V^T$$

be an SVD of $G_u(u,\lambda)$, where

$$\Sigma = \mathrm{diag}(\sigma_1,\sigma_2,\ldots,\sigma_N), \qquad \sigma_1 \geq \sigma_2 \geq \cdots \geq \sigma_N, \qquad u_N \equiv Ue_N,$$

and e_N is the last column of the $N \times N$ identity matrix. The trailing column u_N of U is a left singular vector associated with the smallest singular value σ_N. When necessary, we will make the dependence on λ or u explicit, by writing, for example, $\sigma_N(u,\lambda)$ or $u_N(u,\lambda)$.

Since the singular values are continuous functions of the elements in $G_u(u,\lambda)$, they are also continuous in λ. If

$$\sigma_{N-1} \geq \bar{\sigma} > 0$$

for all (u,λ) then the nullity of $G_u(u,\lambda)$ is at most one. If in addition $\sigma_N = 0$ then u_N spans the left nullspace of $G_u(u,\lambda)$. From the direct sum

$$\mathrm{Ker}(G_u^T(u_0,\lambda_0)) \oplus \mathrm{Range}(G_u(u_0,\lambda_0)) = R^N$$

we see that $G_\lambda(u_0,\lambda_0)$ is not in the Range $(G_u(u_0,\lambda_0))$ if and only if $G_\lambda(u_0,\lambda_0)^T u_N \neq 0$. Hence we have a new, equivalent definition of a simple fold.

DEFINITION 3.1 (simple fold via SVD). *Let (u_0,λ_0) be a solution of $G(u,\lambda)=0$, and let $u_N(u_0,\lambda_0)$ be a left singular vector of $G_u(u_0,\lambda_0)$ associated with σ_N.*

Then (u_0,λ_0) is a simple fold if

- $\sigma_{N-1}(u_0,\lambda_0) > 0$,
- $\sigma_N = 0$, *and*
- $u_N(u_0,\lambda_0)^T G_\lambda(u_0,\lambda_0) \neq 0$.

We will use Definition 3.1 to motivate the assumptions in Theorem 3.2. Suppose (u_0,λ_0) is a regular point (G_u nonsingular) or a simple fold. Since G is Lipschitz continuously differentiable, we can, by requiring $u_N^T(\lambda_0)u_N(\lambda) > 0$, for example, define u_N as a continuous function of u and λ. Hence $G_\lambda(u,\lambda)^T u_N(u,\lambda)$ is a continuous function of (u,λ). So there is $\alpha > 0$ such that for all (u,λ) sufficiently near (u_0,λ_0),

$$\max\left(\sigma_N(u,\lambda)^2, |u_N(u,\lambda)^T G_\lambda(u,\lambda)|^2 \frac{\mathrm{gap}}{\mathrm{gap}+\xi^2}\right) \geq \alpha > 0, \tag{3.1}$$

where

$$\mathrm{gap} \equiv \sigma_{N-1}(u,\lambda)^2 - \sigma_N(u,\lambda)^2 \tag{3.2}$$

and

$$\xi \equiv |u_N(u,\lambda)^T G_\lambda(u,\lambda)| + \|(I - u_N(u,\lambda)u_N(u,\lambda)^T)G_\lambda(u,\lambda)\|. \tag{3.3}$$

Inequality (3.1) is a way to quantify the statement that all points on a solution arc are either regular points or simple folds by saying that either $\sigma_N > 0$ (regular point) or the conditions in Definition 3.1 hold.

The main result of this paper is the following theorem.

THEOREM 3.2. *Let $\bar{\Omega}$ be the closure of an open subset $\Omega \in R^{N+1}$, and let G be continuously differentiable in $\bar{\Omega}$. Let $x_0 = (u_0, \lambda_0)$ in $\bar{\Omega}$ be a solution to $G(u_0, \lambda_0) = 0$, and $\mathcal{N}(x_0, s_0) = 0$ with $\|\dot{x}_0\| = 1$. Let $\tau \geq 0$ be such that $\|G_u(u_0, \lambda_0)\dot{u}_0 + G_\lambda(u_0, \lambda_0)\dot{\lambda}_0\| \leq \tau$.*

Assume that for all (u, λ) in $\bar{\Omega}$ there exists $\alpha > 0$ such that

$$\sigma_{N-1}(u, \lambda) > 0 \text{ and } \max\left(\sigma_N(u, \lambda)^2, |u_N(u, \lambda)^T G_\lambda(u, \lambda)|^2 \frac{\text{gap}}{\text{gap} + \xi^2}\right) \geq \alpha,$$

where gap *and ξ are defined by* (3.2) *and* (3.3).

If $\tau < \alpha$, then for all $x = (u, \lambda)$ in $\bar{\Omega}$, the smallest singular value $\sigma_{\min}(F_x)$ of the Jacobian F_x of $F(x, s)$ is bounded from below with

$$\sigma_{\min}(F_x) \geq \sqrt{1 - \tau \max\left\{\frac{1}{\alpha}, 1\right\}}.$$

We postpone the proof of Theorem 3.2 until section 3.1 in order to derive an auxiliary result first.

3.1. Lower bound for the smallest eigenvalue. We derive a lower bound for the smallest eigenvalue of the rank-one update $A + yy^T$, where A is a real symmetric positive semidefinite matrix of order N, and y is a real $N \times 1$ vector.

Let $\beta_1 \geq \cdots \geq \beta_N \geq 0$ be the eigenvalues of A. Weyl's monotonicity theorem [23, Theorem (10.3.1)] implies bounds for the smallest eigenvalue of $A + yy^T$:

$$\beta_N \leq \lambda_{\min}(A + yy^T) \leq \beta_{N-1}.$$

Intuitively one would expect that $\lambda_{\min}(A+yy^T)$ is larger if y is close to an eigenvector of β_N. We confirm this by deriving lower bounds for $\lambda_{\min}(A + yy^T)$ that incorporate the contribution of y in the eigenspace of β_N.

THEOREM 3.3. *Let A be an $N \times N$ real symmetric positive semidefinite matrix, u_N an eigenvector of A associated with β_N, $\|u_N\| = 1$, and $y \neq 0$ a real $N \times 1$ vector. Set $y_N \equiv u_N^T y$. Then*

$$\lambda_{\min}(A + yy^T) \geq \max\left\{\beta_N,\ y_N^2\ \frac{\text{gap}}{\text{gap} + \xi^2}\right\}, \tag{3.4}$$

where gap $\equiv \beta_{N-1} - \beta_N$ *and* $\xi \equiv |y_N| + \sqrt{\|y\|^2 - y_N^2}$.

Proof. We first show that

$$\lambda_{\min}(A + yy^T) \geq \min\left\{\beta_N + y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2},\ \beta_{N-1} \frac{y_N^2}{\xi^2}\right\} \tag{3.5}$$

is a lower bound for $\lambda_{\min}(A + yy^T) = \min_{\|x\|=1} x^T(A + yy^T)x$.

Let

$$A = U \begin{pmatrix} \beta_1 & & \\ & \ddots & \\ & & \beta_N \end{pmatrix} U^T$$

be an eigendecomposition of A, and x be any real vector with $\|x\| = 1$. Partition

$$U^T x = \begin{pmatrix} \bar{x} \\ x_N \end{pmatrix}, \qquad U^T y = \begin{pmatrix} \bar{y} \\ y_N \end{pmatrix}$$

so that $\xi = |y_N| + \|\bar{y}\|$. Then

$$x^T(A + yy^T)x \geq \beta_{N-1}\|\bar{x}\|^2 + \beta_N x_N^2 + (y^T x)^2.$$

If $\|\bar{x}\| \geq |y_N|/\xi$ then

$$x^T(A + yy^T)x \geq (\beta_{N-1} y_N^2)/\xi^2,$$

which proves the second part of the bound in (3.5).

If $\|\bar{x}\| < |y_N|/\xi$ then $|y_N| - \|\bar{x}\|\xi > 0$, and it makes sense to use $|x_N| \geq 1 - \|\bar{x}\|$ in

$$|y^T x| = |y_N x_N + \bar{y}^T \bar{x}| \geq |y_N x_N| - \|\bar{x}\|\|\bar{y}\| \geq |y_N| - \|\bar{x}\|\xi.$$

Hence

$$x^T(A + yy^T)x \geq \beta_{N-1}\|\bar{x}\|^2 + \beta_N x_N^2 + (y^T x)^2 \geq \beta_N + y_N^2 + (\text{gap} + \xi^2)\|\bar{x}\|^2 - 2\xi\|\bar{x}\||y_N|.$$

This is a function of $\|\bar{x}\|$ which has a minimum at $\|\bar{x}\| = |y_N|\xi/(\text{gap} + \xi^2)$. Hence

$$x^T(A + yy^T)x \geq \beta_N + y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2},$$

which proves the first part of the bound in (3.5).

With the help of (3.5) we now show the desired bound (3.4). Weyl's theorem [23, Theorem (10.3.1)] implies $\lambda_{\min}(A + yy^T) \geq \beta_N$, which proves the first part of the bound in (3.4). For the second part of the bound in (3.4), we use the fact that the eigenvalues of A are nonnegative; hence $\beta_{N-1} \geq \text{gap}$ and

$$\frac{\beta_{N-1}}{\xi^2} \geq \frac{\text{gap}}{\text{gap} + \xi^2}.$$

Substituting this into (3.5) gives the second part of the bound in (3.4):

$$\begin{aligned} \min(A + yy^T) &\geq \min\left\{ \beta_N + y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2},\, y_N^2 \frac{\beta_{N-1}}{\xi^2} \right\} \\ &\geq \min\left\{ \beta_N + y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2},\, y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2} \right\} = y_N^2 \frac{\text{gap}}{\text{gap} + \xi^2}. \qquad \square \end{aligned}$$

The quantity gap in Theorem 3.3 is the absolute gap between the smallest and next smallest eigenvalues, and ξ is an approximation for $\|y\|$ since $\|y\| \leq \xi \leq \sqrt{2}\|y\|$. The theorem shows that $\lambda_{\min}(A + yy^T)$ is likely to be larger if y has a substantial contribution in the eigenspace of β_N.

Now we are in a position to complete the proof of Theorem 3.2.

3.2. Proof of Theorem 3.2. Define the residual

$$r \equiv G_u(u_0, \lambda_0)\dot{u}_0 + G_\lambda(u_0, \lambda_0)\dot{\lambda}_0.$$

Letting $G_u = G_u(u, \lambda)$, $G_\lambda = G_\lambda(u, \lambda)$, and $F_x = F_x(x, s)$, we have

$$F_x F_x^T = \begin{pmatrix} G_u & G_\lambda \\ \dot{u}_0^T & \dot{\lambda}_0 \end{pmatrix} \begin{pmatrix} G_u^T & \dot{u}_0 \\ G_\lambda^T & \dot{\lambda}_0 \end{pmatrix} = \begin{pmatrix} G_u G_u^T + G_\lambda G_\lambda^T & r \\ r^T & 1 \end{pmatrix}.$$

The eigenvalues of $F_x F_x^T$ are the squares of the singular values of F_x. Applying Theorem 3.3 to $G_u G_u^T + G_\lambda G_\lambda^T$ with $A = G_u G_u^T$, $y = G_\lambda$, $\beta_N = \sigma_N(u,\lambda)^2$, $\beta_{N-1} = \sigma_{N-1}^2(u,\lambda)$, and gap $= \sigma_{N-1}(u,\lambda)^2 - \sigma_N(u,\lambda)^2$ shows $\lambda_{\min}(G_u G_u^T + G_\lambda G_\lambda^T) \geq \alpha$. Hence we can write

$$\begin{pmatrix} G_u G_u^T + G_\lambda G_\lambda^T & 0 \\ 0 & 1 \end{pmatrix}^{-1} F_x F_x^T = I + E,$$

where $\|E\| \leq \tau \max\left\{\frac{1}{\alpha}, 1\right\}$. If $\tau < \min\{\alpha, 1\}$ then $\|E\| < 1$, $I + E$ is nonsingular, and

$$\frac{1}{\|(F_x F_x^T)^{-1}\|} \geq 1 - \tau \max\left\{\frac{1}{\alpha}, 1\right\}.$$

4. Newton-GMRES and eigenvalue clustering. This section discusses the performance of the inner GMRES iteration in the context of continuation with a Newton-GMRES nonlinear solver. Theorem 3.2 gives bounds on the smallest singular value of F_x in terms of the singular values of G_u. These lower bounds lead to bounds on the condition number of F_x. While the results in the previous section address conditioning, they do not directly translate into the performance of iterative methods [12, 14, 30], especially in the nonnormal case. However, we can go further to see that the eigenvalue clustering properties of the matrix F_x do not stray far from those of G_u.

Suppose the eigenvalues of G_u are nicely clustered (in the sense of [4, 17]). Even in the singular case, this would mean that the zero eigenvalue of G_u is an "outlier." We seek to show that adding the row and column does not significantly increase the number of outliers, and that we can then use the estimates in [4, 17].

The idea is that [16]

$$G_u = I + K(u) + E, \tag{4.1}$$

where K_u is a low-rank operator, say, of rank p, and E is small. We then want to write F_x in the same way, and then compare the number of outliers by comparing the ranks of the K-terms. The assumption that (4.1) holds is clearly valid if G_u is a compact perturbation of the identity; examples of this are nonlinear integral equations as well as the compact maps which are implicitly defined by the time-steppers as described in [1, 9, 10, 18, 28, 29].

Assume that E is small enough so that the eigenvalues of $I - K$ are "outliers" in the sense of [4]. Since the degree of the minimal polynomial of $I - K$ is at most $p + 1$, we have a bound for the sequence of residuals $\{r_l\}$ of the GMRES iteration of the form

$$\|r_{\hat{p}+k}\| \leq C\|E\|^k \|r_0\|, \tag{4.2}$$

where $\hat{p} \leq p + 1$ GMRES iterations are needed to remove the contribution of the outlying eigenvalues.

Theorem 4.1 states that the spectral properties of F_x are similar to those of G_u.

THEOREM 4.1. *Let the assumptions of Theorem* 3.2 *hold. Assume that* (4.1) *holds with* $\operatorname{rank}(K(u)) = p$. *Then there is* $\mathcal{K}(u)$ *having rank at most* $p + 2$ *such that*

$$\|F_x - I - \mathcal{K}(u)\| \leq \|E\|.$$

Proof. We write [16]

$$F_x = I_{(N+1)\times(N+1)} + \begin{pmatrix} K & G_\lambda \\ \dot{u}^T & \dot{\lambda} \end{pmatrix} + \begin{pmatrix} E & 0 \\ 0 & 0 \end{pmatrix}.$$

The range of

$$\mathcal{K} = \begin{pmatrix} K & G_\lambda \\ \dot{u}^T & \dot{\lambda} \end{pmatrix}$$

is

$$\begin{pmatrix} \text{Range}(K) \\ 0 \end{pmatrix} + \text{span}\left\{ \begin{pmatrix} G_\lambda \\ 0 \end{pmatrix} \right\} + \text{span}\left\{ \begin{pmatrix} 0 \\ 1 \end{pmatrix} \right\},$$

and hence the rank of $\mathcal{K}$ is at most $p+2$. ∎

So, while the eigenvalues may change, we have not increased the degree of the minimal polynomial of the main term (K versus $\mathcal{K}$) beyond $p+3$. Hence, the methods of [4] can be applied to obtain a bound like (4.2) with $\hat{p} \le p+3$.

5. Example: Chandrasekhar *H*-equation. We now present an example of a solution path containing a simple fold. The equation of interest is called the Chandrasekhar H-equation [6, 14, 21] from radiative transfer theory:

$$H(\mu) = 1 - \left(\frac{c}{2} \int_0^1 H(\nu) \frac{d\nu\mu}{\mu+\nu} \right)^{-1}. \tag{5.1}$$

The goal is to compute $H(\mu)$ for $\mu \in [0,1]$ as a function of c. There is a simple fold at $c = 1$ [21], and the same analysis shows that this is also the case for any discretization of the equation which uses a quadrature rule that integrates constant functions exactly.

In this section we use a Newton-GMRES version of pseudo-arclength continuation [8], fixing the step in arclength to $ds = .02$, using a secant predictor [13], and beginning the continuation at $c = 0$, where $H = 1$ is the solution. The vector with components all equal to one is the solution of the discrete problem as well. We discretize the integral with the composite midpoint rule using 200 nodes. A consequence of this discretization is that all scalar products of discretized functions in the GMRES solves were scaled by $1/200$. Because we do this, all the singular value results will converge as the quadrature rule is refined.

Figure 5.1 is a plot of $\|H\|_1$ against c. A fixed value of ds, as we use here, causes problems as the L^1 norm of H increases. The reason for this is that the solution develops very large derivatives, and the predictor becomes very poor. We stopped the continuation at $c = .9$ on the upper branch for that reason.

For this example we can also compute the L^1 norm as a function of c analytically, and verify the results in Figure 5.1. We can rewrite (5.1) as

$$H(\mu) = 1 + \frac{c}{2} \int_0^1 H(\mu) H(\nu) \frac{d\nu\mu}{\mu+\nu}. \tag{5.2}$$

Integrating (5.2) with respect to μ yields

$$\|H\|_1 = 1 + \frac{c}{2} \int_0^1 \int_0^1 \frac{H(\mu)H(\mu)\mu \, d\mu \, d\nu}{\mu+\nu} = 1 + \frac{c}{4} \|H\|_1^2,$$

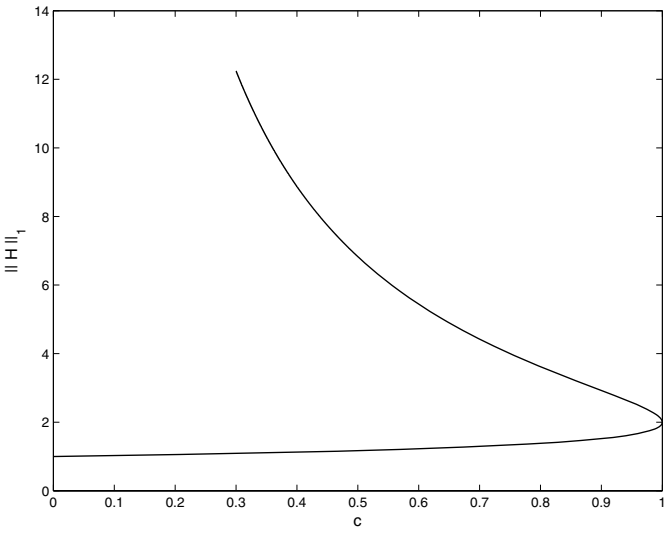

FIG. 5.1. $\|H\|_1$ *as a function of* c.

and so

$$\|H\|_1 = \frac{1 \pm \sqrt{1-c}}{c/2}. \tag{5.3}$$

As a demonstration of the result in section 3, we calculate the smallest singular value of the Jacobian matrix associated with the augmented system for the H-equation with each continuation iteration. We used the MATLAB `svds` command for this. In the language of section 3, we find $\sigma_{\min}(F_{(H,c)})$ for various c where $F_{(H,c)}$ denotes the Jacobian of

$$\begin{pmatrix} G(H,c) \\ \mathcal{N}(H,c,s) \end{pmatrix}.$$

Figure 5.2 shows that the smallest singular value of $F_{(H,c)}$ for each c stays away from zero keeping $F_{(H,c)}$ nonsingular, even at the simple fold ($c = 1$).

It is interesting to compare Figure 5.2 with a plot of the smallest singular value of G_H, which we can also compute on the path. In Figure 5.3, one can see the singularity at $c = 1$ and also see that G_H is becoming more and more poorly conditioned as the L^1 norm of H increases.

The consequences of the remarks in section 4 are that for a problem like the H-equation, which is a nonlinear compact fixed point problem, the number of GMRES iterations per Newton step should be bounded. One must take this expectation with a grain of salt because as one moves along the path, the norm of the solution increases, and so the number of outliers may increase slowly. The observations we present illustrate this.

In Figure 5.4 we plot the average number of GMRES iterations per Newton iteration as a function of c. The lower curve corresponds to the continuation from $c = 0$ to $c = 1$, and the upper from $c = 1$ to $c = .3$. The computation in this figure was done for pseudo-arclength continuation, which we compare with parameter continuation in Figure 5.5. As one moves further on the path, the predictor becomes less effective,

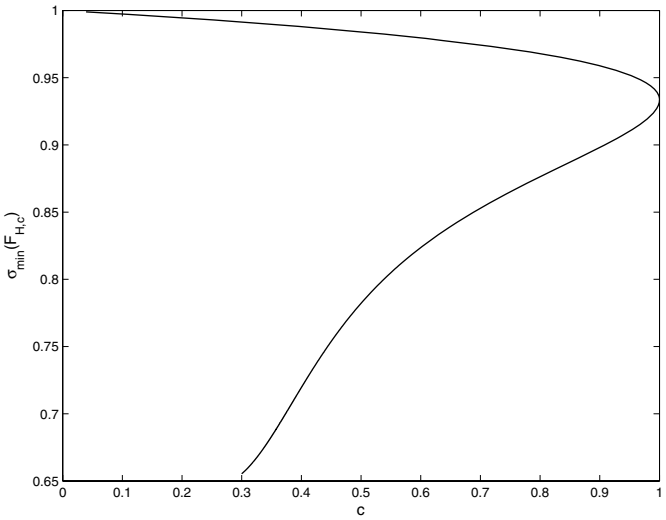

FIG. 5.2. $\sigma_{\min}(F_{(H,c)})$ *as a function of* c.

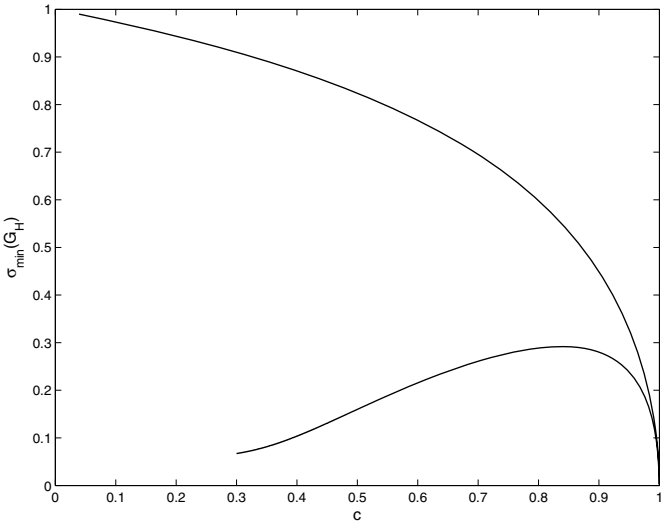

FIG. 5.3. $\sigma_{\min}(G_H)$ *as a function of* c.

and the number of Newton iterations increases. The predictor is also different for the first two points on the path, because we do not have the data we need to build the secant predictor before we have computed two points. The initial point for $c = 0$ is the vector with 1 in each component, which is the solution, so the plots begin with the first nonzero value of c.

Figure 5.5 is the result of a simple parameter continuation for each of the upper and lower branches. The lower curve is for values of $c \in [.3, .9]$, where the problem is quite easy. The linear solver takes fewer GMRES iterations per Newton iteration on this branch, and we observe that the difference in linear iterations from the lower branch in Figure 5.4 is at most 1, consistent with the theory. On the upper branch,

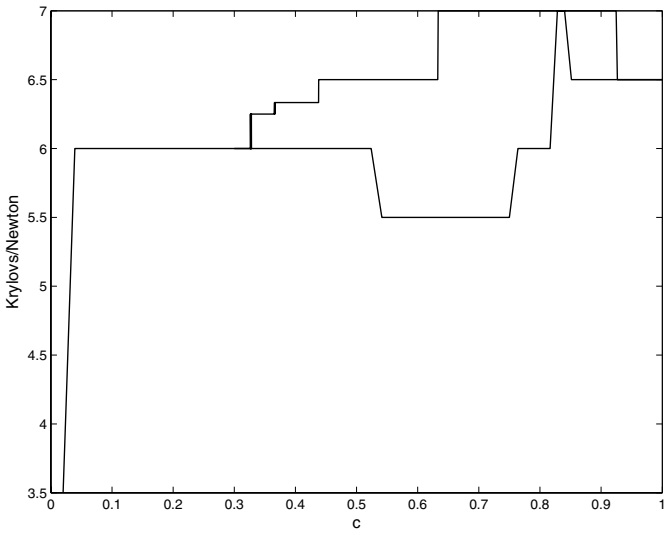

FIG. 5.4. *Krylov's per Newton: Pseudo-arclength continuation.*

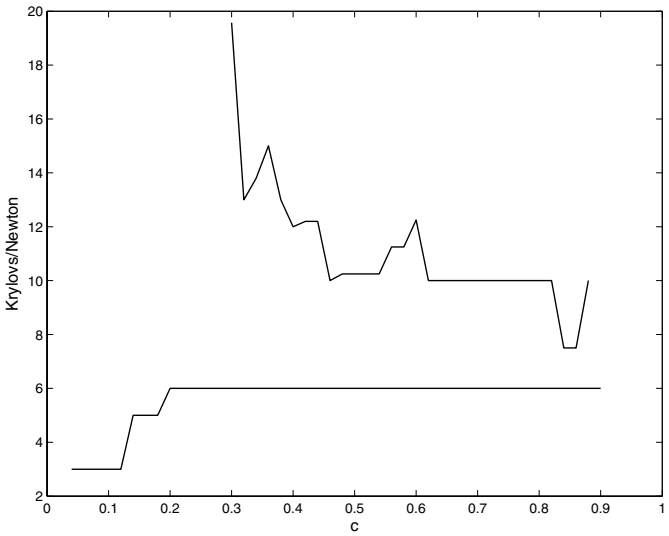

FIG. 5.5. *Krylov's per Newton: Parameter continuation in c.*

where $c \in [.3, .9]$, the performance of parameter continuation is significantly worse than that of pseudo-arclength continuation, and the linear solver performs significantly less well in the parameter continuation solver. This is consistent with the singular value results in Figure 5.3.

6. Conclusion. For simple fold singularities, we have given new bounds on the conditioning of the extended system of nonlinear equations that arise in pseudo-arclength continuation. The two bounds are a lower estimate on the smallest singular value of the Jacobian of the extended system, and an upper bound on the number of eigenvalues that lie outside a cluster of eigenvalues for the Jacobian of the origi-

nal system. The latter of these two bounds implies an upper bound on the number of GMRES iterations needed to achieve a certain termination criterion (4.2). We illustrate the bounds with a numerical experiment.

Acknowledgment. The authors thank Alastair Spence for many helpful discussions.

FINITE ELEMENT APPROXIMATIONS IN A NONLIPSCHITZ DOMAIN*

GABRIEL ACOSTA†, MARÍA G. ARMENTANO‡, RICARDO G. DURÁN‡, AND ARIEL L. LOMBARDI‡

Abstract. In this paper we analyze the approximation by standard piecewise linear finite elements of a nonhomogeneous Neumann problem in a cuspidal domain. Since the domain is not Lipschitz, many of the results on Sobolev spaces, which are fundamental in the usual error analysis, do not apply. Therefore, we need to work with weighted Sobolev spaces and to develop some new theorems on traces and extensions. We show that, in the domain considered here, suboptimal order can be obtained with quasi-uniform meshes even when the exact solution is in H^2, and we prove that the optimal order with respect to the number of nodes can be recovered by using appropriate graded meshes.

Key words. cuspidal domains, Neumann problem, finite elements, graded meshes

1. Introduction.

The finite element method has been widely analyzed in its different forms for all kind of partial differential equations. However, as far as we know, all analyses are restricted to the case of polygonal or smooth domains, and no results have been obtained for the case in which the domain is nonLipschitz, with the exception of the well-known fracture problems.

The goal of this paper is to initiate the analysis of finite element approximations in nonLipschitz domains. As a first step in this direction we consider a model problem in a plane domain with an external cusp.

Several difficulties arise in this problem because many of the results on Sobolev spaces, which are fundamental in the analysis of partial differential equations in variational form, do not apply. For example, the standard trace theorems do not hold in this case, and this fact makes the analysis of nonhomogeneous Neumann problems more difficult.

Given $\alpha > 1$, let $\Omega \subset \mathbb{R}^2$ be the domain defined by

$$\Omega = \{(x, y) : 0 < x < 1,\ 0 < y < x^\alpha\},$$

and let $\Gamma = \Gamma_1 \cup \Gamma_2 \cup \Gamma_3$ be its boundary, with

$$\Gamma_1 = \{0 \le x \le 1, y = 0\},\quad \Gamma_2 = \{x = 1, 0 \le y \le 1\},\quad \text{and}\quad \Gamma_3 = \{0 \le x \le 1, y = x^\alpha\}$$

(see Figure 1).

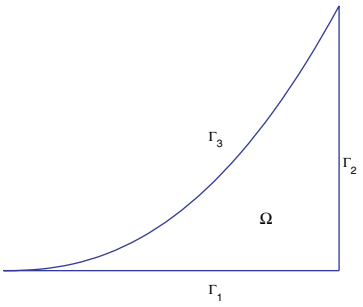

FIG. 1. *Cuspidal domain.*

Some of our arguments require that $\alpha < 3$, and so our main result will be valid under this restriction.

Our model problem is

$$\begin{cases} -\Delta u = f & \text{in } \Omega, \\ \dfrac{\partial u}{\partial \nu} = g & \text{on } \Gamma_3, \\ \dfrac{\partial u}{\partial \nu} = 0 & \text{on } \Gamma_1, \\ u = 0 & \text{on } \Gamma_2, \end{cases} \tag{1.1}$$

where ν denotes the outside normal.

A natural way to approximate the solution of problem (1.1) is to replace Ω with a polygonal domain and to use the standard linear finite element method. It is known that, under appropriate conditions on the data, the solution of this problem is in $H^2(\Omega)$ (see [1]). Therefore, based on the experience of and theory for smooth domains, one would expect that the optimal order of convergence could be obtained by using quasi-uniform meshes. However, numerical examples show that this is not the case (see section 2). The reason for this behavior seems to be the fact that the solution cannot be extended to an H^2 function on the polygonal domain approximating the original domain. Indeed, it is known that the standard extension theorems in Sobolev spaces do not apply for our domain (see, for example, [12]).

We will show that the optimal order with respect to the number of nodes in the H^1 norm can be recovered by using appropriate graded meshes. To obtain this result, we will first prove an extension theorem for the domain Ω which shows that the solution of problem (1.1) can be extended to a function in a weighted H^2 space, with the weight being a power of the distance to the cuspidal point.

The rest of the paper is organized as follows. In section 2 we introduce the finite element approximation of our problem and show that the use of quasi-uniform meshes can give bad results. Section 3 deals with some extension and trace theorems in weighted Sobolev spaces that we need for our error analysis. Finally, in section 4 we prove that optimal order approximations are obtained by using appropriate graded meshes.

2. Finite element approximations. In this section we introduce the finite element approximation of our model problem and show that, if the meshes are quasi uniform, the approximation may be of suboptimal order even when the exact solution is in $H^2(\Omega)$.

Introducing the space

$$V = \{v \in H^1(\Omega) : v|_{\Gamma_2} = 0\},$$

we see that the weak form of problem (1.1) is to find $u \in V$ such that

$$\int_\Omega \nabla u \cdot \nabla v = \int_\Omega fv + \int_{\Gamma_3} gv \qquad \forall v \in V. \tag{2.1}$$

The following existence and regularity results have been proved in [1]. Define $z(t) := g(t, t^\alpha)$. If $f \in L^2(\Omega)$ and $z\, t^{-\frac{\alpha}{2}} \in L^2(0,1)$, this problem has a unique solution. If in addition we assume that $z'\, t^{1-\frac{\alpha}{2}} \in L^2(0,1)$, the solution is in $H^2(\Omega)$ and there exists a constant C such that

$$\|u\|_{H^2(\Omega)} \le C \left\{ \|f\|_{L^2(\Omega)} + \|z\, t^{-\frac{\alpha}{2}}\|_{L^2(0,1)} + \|z'\, t^{1-\frac{\alpha}{2}}\|_{L^2(0,1)} \right\}. \tag{2.2}$$

To approximate the solution of (1.1) we replace Ω with a polygonal domain Ω_h and use the standard linear finite element method. We will construct Ω_h in such a way that $\Omega \subset \Omega_h$ and the nodes on Γ_h, the boundary of Ω_h, are also on Γ.

Let $\{\mathcal{T}_h\}$ be a family of triangulations of Ω_h satisfying the maximum angle condition. Associated with $\{\mathcal{T}_h\}$ we have the finite element space

$$V_h = \{v \in H^1(\Omega_h) : v|_{\Gamma_2} = 0 \,\text{and}\, v|_T \in \mathcal{P}_1 \quad \forall\, T \in \mathcal{T}_h\},$$

where $\mathcal{P}_1$ denotes the space of linear polynomials.

Denote by $\Gamma_{3,h}$ the part of Γ_h approximating Γ_3 and by I_h the piecewise linear interpolation at the endpoints of the segments which lie on $\Gamma_{3,h}$.

Then, our discrete problem is to find $u_h \in V_h$ such that

$$\int_{\Omega_h} \nabla u_h \cdot \nabla v = \int_\Omega fv + \int_{\Gamma_{3,h}} I_h(gv) \quad \forall v \in V_h. \tag{2.3}$$

Observe that the discrete problem corresponds to a boundary problem on Ω_h if we consider f as being extended by zero outside Ω.

One could think that, when the solution is in $H^2(\Omega)$, the numerical approximation obtained with quasi-uniform meshes would be of optimal order. However, the following example shows that this is not the case.

Example 2.1. Consider

$$f(x,y) = s(s-1)(1+y^2/2)x^{s-2} + x^s - 1$$

and

$$z(t) = g(t, t^\alpha) = \frac{-s\alpha t^{\alpha+s-2}(1+t^{2\alpha}/2) + (1-t^s)t^\alpha}{\sqrt{1+\alpha^2 t^{2(\alpha-1)}}}.$$

Then, the solution of (1.1) is

$$u(x,y) = (1-x^s)(1+y^2/2),$$

and an easy calculation shows that $u \in H^2(\Omega)$ whenever $s > \frac{3-\alpha}{2}$.

We take $\alpha = 2$, and different values of s, with $\frac{1}{2} < s < 1$, and solve problem (2.3) by using quasi-uniform meshes. Table 1 shows the order of the error in the H^1 norm in terms of number of nodes and in terms of mesh size.

The reason for this behavior seems to be the fact that the solution cannot be extended to an H^2 function on Ω_h. Indeed, it is well known that the standard extension theorems in Sobolev spaces do not apply for our domain (see, for example, [12]).

TABLE 1
H^1 *order using quasi-uniform meshes for* $\alpha = 2$.

Value of s	Order in number of nodes	Order in h
0.55	0.324	0.626
0.6	0.335	0.647
0.65	0.347	0.671
0.7	0.362	0.698
0.75	0.380	0.733
0.8	0.404	0.781
0.85	0.440	0.849
0.9	0.491	0.948
0.95	0.545	1.053

3. Extension and trace theorems. The standard results on extensions and restrictions in Sobolev spaces do not apply for domains with external cusps. In this section we prove some weaker results using weighted norms.

First, we develop an extension theorem in a weighted Sobolev space for $H^2(\Omega)$ functions with a vanishing normal derivative on Γ_1. In particular, our theorem applies to solutions of (1.1) which, in view of (2.2), are in $H^2(\Omega)$ under appropriate assumptions on the data.

Second, we prove a trace theorem for functions in $H^1(\Omega)$ which will be useful for estimating the error due to the approximation of the nonhomogeneous Neumann-type boundary condition.

Given a domain $\mathcal{D} \subset \mathbb{R}^2$ we introduce the weighted Sobolev space

$$H^2_\alpha(\mathcal{D}) = \left\{ v : r^{\frac{\alpha-1}{2}} D^\gamma v \in L^2(\mathcal{D}) \ \ \forall\, \gamma\,, |\gamma| \le 2 \right\},$$

where $r = \sqrt{x^2+y^2}$, and its natural norm

$$\|v\|^2_{H^2_\alpha(\mathcal{D})} = \sum_{|\gamma|\le 2} \|r^{\frac{\alpha-1}{2}} D^\gamma v\|^2_{L^2(\mathcal{D})}.$$

Our argument proceeds in two steps. First, we extend the given function to the Lipschitz domain

$$\mathcal{D} := \{(x,y) \in \mathbb{R}^2 : \ \ -x < y < x^\alpha\,, \ \ 0 < x < 1\}$$

(see Figure 2) in such a way that the extension belongs to $H^2_\alpha(\mathcal{D})$. Then, we apply known theorems for weighted Sobolev spaces on Lipschitz domains to obtain an extension which belongs to $H^2_\alpha(\mathbb{R}^2)$.

We call W the subspace of $H^2(\Omega)$ defined by

$$W = \left\{ u \in H^2(\Omega) : \ \ \frac{\partial u}{\partial \nu} = 0 \ \text{ on } \ \Gamma_1 \right\}.$$

LEMMA 3.1. *Given* $u \in W$ *there exists a function* $\tilde{u} \in H^2_\alpha(\mathcal{D})$ *such that* $\tilde{u}|_\Omega = u$ *and*

$$\|\tilde{u}\|_{H^2_\alpha(\mathcal{D})} \le C \|u\|_{H^2(\Omega)}.$$

Proof. We extend u in the following way. Given $(x,y) \in \mathcal{D}$ with $y \le 0$, let $\eta = -x^{\alpha-1} y$. Observe that $(x,\eta) \in \Omega$, and therefore we can define

$$\begin{cases} \tilde{u}(x,y) = u(x,y) & \text{for} \quad (x,y) \in \Omega, \\ \tilde{u}(x,y) = u(x,\eta) & \text{for} \quad (x,y) \in \mathcal{D} \setminus \Omega. \end{cases}$$

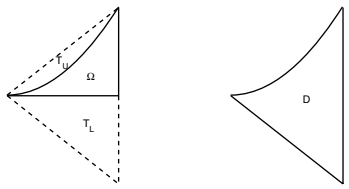

FIG. 2.

To simplify notation define $T_L := \mathcal{D} \setminus \overline{\Omega}$.

We claim that $\tilde{u} \in H^2_\alpha(T_L)$. Observe first that for $(x, y) \in T_L$ we have $x \sim r$, and therefore we can replace the weight $r^{\alpha-1}$ with $x^{\alpha-1}$ in our estimates.

By a change of variables we obtain

$$\int_{T_L} \tilde{u}^2(x,y) x^{\alpha-1} dxdy = \int_\Omega u^2(x,\eta) dxd\eta = \|u\|^2_{L^2(\Omega)}.$$

Now, for $(x, y) \in T_L$ we have

$$\frac{\partial \tilde{u}}{\partial x}(x,y) = \frac{\partial u}{\partial x}(x,\eta) - \frac{\partial u}{\partial \eta}(x,\eta)(\alpha-1)x^{\alpha-2}y$$

and

$$\frac{\partial \tilde{u}}{\partial y}(x,y) = -\frac{\partial u}{\partial \eta}(x,\eta)x^{\alpha-1}.$$

Then, recalling that $\eta = -x^{\alpha-1}y$, we obtain

$$\int_{T_L} \left(\frac{\partial \tilde{u}}{\partial x}\right)^2 x^{\alpha-1} dxdy \le C \left\{ \int_\Omega \left(\frac{\partial u}{\partial x}\right)^2 dxd\eta + \int_\Omega \left(\frac{\partial u}{\partial \eta}\right)^2 \left(\frac{\eta}{x}\right)^2 dxd\eta \right\}$$

but, since $(x, \eta) \in \Omega$, we have $\frac{\eta}{x} \le x^{\alpha-1} \le 1$, and then

$$\int_{T_L} \left(\frac{\partial \tilde{u}}{\partial x}\right)^2 x^{\alpha-1} dxdy \le C\|\nabla u\|^2_{L^2(\Omega)}.$$

Analogously we get

$$\int_{T_L} \left(\frac{\partial \tilde{u}}{\partial y}\right)^2 x^{\alpha-1} dxdy \le C\|\nabla u\|^2_{L^2(\Omega)}.$$

Bounds for the second derivatives of $\tilde{u}$ follow similarly. For instance, we have

$$\begin{aligned}\frac{\partial^2 \tilde{u}}{\partial x^2}(x,y) = {} & \frac{\partial^2 u}{\partial x^2}(x,\eta) - 2(\alpha-1)\frac{\partial^2 u}{\partial \eta \partial x}(x,\eta)x^{\alpha-2}y \\ & - \frac{\partial^2 u}{\partial \eta^2}(x,\eta)(\alpha-1)^2 x^{2(\alpha-2)}y^2 - \frac{\partial u}{\partial \eta}(x,\eta)(\alpha-2)(\alpha-1)x^{\alpha-3}y,\end{aligned}$$

and hence,

$$\begin{aligned}\int_{T_L} \left(\frac{\partial^2 \tilde{u}}{\partial x^2}\right)^2 x^{\alpha-1} dxdy \le C \Bigg\{ & \int_\Omega \left(\frac{\partial^2 u}{\partial x^2}\right)^2 dxd\eta + \int_\Omega \left(\frac{\partial^2 u}{\partial \eta \partial x}\right)^2 \left(\frac{\eta}{x}\right)^2 dxd\eta \\ & + \int_\Omega \left(\frac{\partial^2 u}{\partial \eta^2}\right)^2 \left(\frac{\eta}{x}\right)^4 dxd\eta + \int_\Omega \left(\frac{\partial u}{\partial \eta}\right)^2 \left(\frac{\eta}{x^2}\right)^2 dxd\eta \Bigg\}.\end{aligned}$$

Now, the first three terms on the right-hand side can be bounded by using again that $\frac{\eta}{x} \leq 1$. For the last term we have

$$\int_\Omega \left(\frac{\partial u}{\partial \eta}\right)^2 \left(\frac{\eta}{x^2}\right)^2 dxdy \leq \int_0^1 \int_0^{x^\alpha} \left(\frac{\partial u}{\partial \eta}\right)^2 \frac{1}{\eta^2} d\eta dx \leq C \int_0^1 \int_0^{x^\alpha} \left(\frac{\partial^2 u}{\partial \eta^2}\right)^2 d\eta dx,$$

where the last inequality follows from the Hardy inequality [10] and the fact that $\frac{\partial u}{\partial \eta}(x,0) = 0$. Hence,

$$\int_{T_L} \left(\frac{\partial^2 \tilde{u}}{\partial x^2}\right)^2 x^{\alpha-1} dxdy \leq C|u|^2_{H^2(\Omega)}.$$

In a similar way we can show that

$$\int_{T_L} \left(\frac{\partial^2 \tilde{u}}{\partial y \partial x}\right)^2 x^{\alpha-1} dxdy \leq C|u|^2_{H^2(\Omega)}$$

and

$$\int_{T_L} \left(\frac{\partial^2 \tilde{u}}{\partial y^2}\right)^2 x^{\alpha-1} dxdy \leq C|u|^2_{H^2(\Omega)},$$

where $|\cdot|_{H^2(\Omega)}$ denotes the H^2-seminorm in Ω.

Therefore, we have proved that $\tilde{u} \in H^2_\alpha(T_L)$ and that

$$\|\tilde{u}\|_{H^2_\alpha(T_L)} \leq C\|u\|_{H^2(\Omega)}.$$

On the other hand, using that $\frac{\partial u}{\partial \nu} = 0$ on Γ_1, it is easy to see that $\tilde{u} \in H^2_\alpha(\mathcal{D})$, thus concluding the proof. ∎

Now, using known extension theorems for weighted Sobolev spaces on Lipschitz domains due to Chua [6], we can extend functions in W to $H^2_\alpha(\mathbb{R}^2)$.

THEOREM 3.1. *If $\alpha < 3$ and $u \in W$, there exists a function $\tilde{u} \in H^2_\alpha(\mathbb{R}^2)$ such that $\tilde{u}|_\Omega = u$ and*

$$\|\tilde{u}\|_{H^2_\alpha(\mathbb{R}^2)} \leq C\|u\|_{H^2(\Omega)}.$$

Proof. In view of Lemma 3.1 we have only to show that for $v \in H^2_\alpha(\mathcal{D})$ there exists an extension $\tilde{v} \in H^2_\alpha(\mathbb{R}^2)$ such that

$$\|\tilde{v}\|_{H^2_\alpha(\mathbb{R}^2)} \leq C\|v\|_{H^2_\alpha(\mathcal{D})}.$$

But this follows immediately from the results in [6] because, for $1 < \alpha < 3$, our weight belongs to the class considered in that paper (the Muckenhoupt class A_2) [7, page 145]. ∎

In the rest of this section we prove a trace theorem for functions in $H^1(\Omega)$. In [1] it was proved that

$$\|u\|_{L^2(\Gamma)} \leq C(\|ux^{-\frac{\alpha}{2}}\|_{L^2(\Omega)} + \|\nabla u x^{\frac{\alpha}{2}}\|_{L^2(\Omega)}). \tag{3.1}$$

Our trace theorem is a consequence of this result and the known imbedding theorem

$$H^1(\Omega) \subset L^r(\Omega) \quad \text{for} \quad 2 \leq r \leq \frac{2(\alpha+1)}{\alpha-1}, \tag{3.2}$$

which is a particular case of the results given in [2].

THEOREM 3.2. *Let $u \in H^1(\Omega)$.*
(1) *If $\alpha < 2$, then $u \in L^2(\Gamma)$ and $\|u\|_{L^2(\Gamma)} \le C\|u\|_{H^1(\Omega)}$.*
(2) *If $\alpha \ge 2$, then $x^\beta u \in L^2(\Gamma)$ and $\|x^\beta u\|_{L^2(\Gamma)} \le C\|u\|_{H^1(\Omega)}$ $\forall \beta > \alpha/2 - 1$.*
Proof. Part (1) was proved in [1]. Therefore, we will prove only (2) here.
Using (3.1) for the function $x^\beta u$ we have

$$\|x^\beta u\|_{L^2(\Gamma)} \le C(\|x^\beta u x^{-\frac{\alpha}{2}}\|_{L^2(\Omega)} + \|\nabla(x^\beta u)x^{\frac{\alpha}{2}}\|_{L^2(\Omega)}).$$

It is easy to see that the second term on the right-hand side is bounded by $\|u\|_{H^1(\Omega)}$ because $\alpha \ge 2$ and $\beta > \alpha/2 - 1$. Then, it is enough to show that

$$\|x^\beta u x^{-\frac{\alpha}{2}}\|_{L^2(\Omega)} \le \|u\|_{H^1(\Omega)}. \tag{3.3}$$

Using the Hölder inequality we have

$$\int_\Omega u^2 x^{2\beta-\alpha} \le \left(\int_\Omega u^{2q}\right)^{\frac{1}{q}} \left(\int_\Omega x^{(2\beta-\alpha)\frac{q}{q-1}}\right)^{\frac{q-1}{q}}.$$

Choosing $q = r/2$ with $r = 2(\alpha+1)/(\alpha-1)$ and using the imbedding theorem (3.2) we obtain

$$\|x^\beta u x^{-\frac{\alpha}{2}}\|_{L^2(\Omega)} \le \left(\int_\Omega x^{(2\beta-\alpha)\frac{q}{q-1}}\right)^{\frac{q-1}{2q}} \|u\|_{H^1(\Omega)}.$$

But

$$\int_\Omega x^{(2\beta-\alpha)\frac{q}{q-1}} = \int_\Omega x^{(2\beta-\alpha)\frac{\alpha+1}{2}} < \infty$$

because $\beta > \alpha/2 - 1$, and therefore (3.3) holds. ∎

4. Optimal approximations using graded meshes. In this section we obtain error estimates in H^1 of quasi-optimal order (i.e., optimal up to a logarithmic factor) with respect to the number of nodes by using appropriate graded meshes.

Finite element methods using graded meshes of the type considered here have been analyzed for problems with corner-type singularities in [3, 4, 9]. In [4, 9] the error estimates were obtained under the classic regularity condition on the meshes (the minimum angle condition). This hypothesis has been relaxed in [3], where the author obtained error estimates under the maximum angle condition. This generalization is very important for our problem because we cannot avoid small angles in those elements which are near the cusp.

Consider $1 < \alpha < 3$ and define $\gamma = (\alpha - 1)/2$. Let Ω_h be an approximating polygon and $\mathcal{T}_h$ a triangulation of it, where $h > 0$ is a parameter that goes to 0. For each $T \in \mathcal{T}_h$ we denote by h_T its diameter and by β_T its maximum angle. We assume that there exist positive constants σ and $\beta < \pi$, independent of h, such that the following hypotheses hold:
(1) $\beta_T < \beta$ for all $T \in \mathcal{T}_h$ (the maximal angle condition).
(2) $h_T \sim \sigma\, h^{\frac{1}{1-\gamma}}$ if $(0,0) \in T$.
(3) $h_T \le \sigma\, h \inf_T x^\gamma$ if $(0,0) \notin T$.

Since we know that the solution of our problem has an extension $\tilde{u} \in H^2_\alpha(\Omega_h)$, we are interested in interpolation error estimates for functions in this space. We call $\Pi v \in V_h$ the piecewise linear Lagrange interpolation of v.

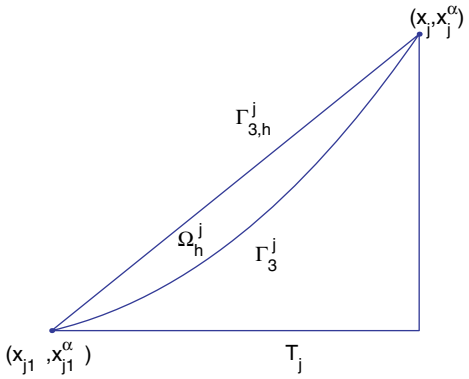

FIG. 3.

THEOREM 4.1. *If $v \in H^2_\alpha(\Omega_h)$ and the family of triangulations satisfies conditions* (1), (2), *and* (3), *there exists a constant C depending only on β, σ, and α such that*

$$\|v - \Pi v\|_{H^1(\Omega_h)} \leq Ch\|v\|_{H^2_\alpha(\Omega_h)}.$$

Proof. The proof follows as in [9, page 392] but using the error estimates obtained by Apel under the maximum angle condition (see Theorem 2.4 in [3, page 63]). ∎

Now we introduce some notation which will be used in the rest of this section. We denote by $\Gamma^j_{3,h}$, $1 \leq j \leq n$, the edges on the boundary of Ω_h, by $(x_{j-1}, x^\alpha_{j-1})$ and (x_j, x^α_j) their endpoints with $x_0 = 0$ and $x_n = 1$, and by Γ^j_3 the part on Γ_3 with the same endpoints. Let Ω^j_h be the region bounded by Γ^j_3 and $\Gamma^j_{3,h}$.

In addition to assumptions (1), (2), and (3) we will need for our error analysis the following hypothesis on the meshes:

(H) For $1 \leq j \leq n$ the region Ω^j_h is contained in only one triangle.

We denote by T_j the triangle containing Ω^j_h and by h_j its diameter (see Figure 3).

It can be seen from our hypotheses that there exists a constant C, independent of h, such that, for $2 \leq j \leq n$,

$$x_j \leq C x_{j-1}. \tag{4.1}$$

In fact, from (H) we have $x_j - x_{j-1} \leq C|\Gamma^j_{3,h}|$ for some constant C depending only on α. Then, $x_j - x_{j-1} \leq Ch_j$, and therefore from assumption (3) we have

$$x_j \leq x_{j-1}\left(1 + Chx^{\gamma-1}_{j-1}\right),$$

and since $j \geq 2$, $x_{j-1} \geq x_1 \sim h^{1/(1-\gamma)}$ by assumption (2), we obtain (4.1).

We will show below that meshes satisfying all our assumptions can indeed be constructed.

The next lemma deals with the error arising from the approximation of the domain by polygonal domains. We will work with an extension $\tilde{u}$ of the solution u of (1.1). Since $u \in W$ we know from Theorem 3.1 that there exists $\tilde{u} \in H^2_\alpha(\mathbb{R}^2)$ such that $\tilde{u}|_\Omega = u$ and

$$\|\tilde{u}\|_{H^2_\alpha(\mathbb{R}^2)} \leq C\|u\|_{H^2(\Omega)}. \tag{4.2}$$

We will use the well-known imbedding $H^1(\mathcal{D}) \subset L^p(\mathcal{D})$ for planar Lipchitz domains and $1 \le p < \infty$ and use the explicit dependence on p of the constant in the continuity of this inclusion (see, for example, [8]), namely,

$$\|v\|_{L^p(\mathcal{D})} \le C\sqrt{p}\,\|v\|_{H^1(\mathcal{D})}. \tag{4.3}$$

LEMMA 4.1. *If $1 < \alpha < 3$, then there exists a constant C, which depends only on α, β, and σ, such that*

$$\|\nabla \tilde{u}\|_{L^2(\Omega_h \setminus \Omega)} \le Ch\sqrt{\log(1/h)}\,\|u\|_{H^2(\Omega)}.$$

Proof. Clearly, for every h, the polygonal domain Ω_h is contained in the triangle

$$T_U = \{0 \le x \le 1,\, 0 \le y \le x\}$$

(see Figure 2). Writing

$$\int_{T_U} |v|^p = \int_{T_U} |v|^p x^{p(\frac{\alpha-1}{2})} x^{-p(\frac{\alpha-1}{2})}$$

and applying the Hölder inequality with $2/p$ and its dual exponent, we obtain

$$\|v\|_{L^p(T_U)} \le C\|v x^{\frac{\alpha-1}{2}}\|_{L^2(T_U)}$$

for any function v and $1 \le p < \frac{4}{\alpha+1}$. Therefore, using (4.2) we conclude that $\tilde{u} \in W^{2,p}(T_U)$ and that

$$\|\tilde{u}\|_{W^{2,p}(T_U)} \le C\|u\|_{H^2(\Omega)}. \tag{4.4}$$

As a consequence, we obtain that, for $\beta > \frac{\alpha-1}{2}$, $\nabla \tilde{u}\, x^\beta \in H^1(T_U)$ and

$$\|\nabla \tilde{u}\, x^\beta\|_{H^1(T_U)} \le C\|u\|_{H^2(\Omega)}. \tag{4.5}$$

Indeed, since $\tilde{u} \in H^2_\alpha(\mathbb{R}^2)$, we already know that $\nabla \tilde{u}\, x^\beta \in L^2(T_U)$, and so we have only to see that the first derivatives of $\nabla \tilde{u}\, x^\beta$ belong to $L^2(T_U)$. But, taking the derivative of $\nabla \tilde{u}\, x^\beta$ and using again that $\tilde{u} \in H^2_\alpha(\mathbb{R}^2)$, we see that it remains only to prove that $\nabla \tilde{u}\, x^{\beta-1} \in L^2(T_U)$.

Now, from (4.4) and a well-known Sobolev imbedding theorem we obtain that $\nabla \tilde{u} \in L^{p^*}(T_U)$ for $1 \le p < \frac{4}{\alpha+1}$ and $p^* = \frac{2p}{2-p}$. Moreover,

$$\|\nabla \tilde{u}\|_{L^{p^*}(T_U)} \le C\|u\|_{H^2(\Omega)}.$$

Therefore, applying the Hölder inequality with $p^*/2$ and its dual exponent q, we have

$$\int_{T_U} |\nabla \tilde{u}|^2 x^{2(\beta-1)} \le \|\nabla \tilde{u}\|^2_{L^{p^*}(T_U)} \|x^{2(\beta-1)}\|_{L^q(T_U)},$$

but since $\beta > \frac{\alpha-1}{2}$, it is possible to choose $p < \frac{4}{\alpha+1}$ such that $\|x^{2(\beta-1)}\|_{L^q(T_U)}$ is finite, thus concluding the proof of (4.5).

Now, let $\beta > \frac{\alpha-1}{2}$ and $2 \le p < \infty$, to be chosen below. Applying the Hölder inequality for $p/2$ and its dual exponent q, we have

$$\int_{\Omega_h \setminus \Omega} |\nabla \tilde{u}|^2 \le \Big(\int_{\Omega_h \setminus \Omega} |\nabla \tilde{u}|^p\, x^{\beta p} \Big)^{\frac{2}{p}} \Big(\int_{\Omega_h \setminus \Omega} x^{-2\beta q} \Big)^{\frac{1}{q}}, \tag{4.6}$$

and therefore, from the Sobolev imbedding (4.3) and (4.5), we obtain

$$\int_{\Omega_h\setminus\Omega} |\nabla \tilde{u}|^2 \le \frac{C}{q-1}\,\|u\|^2_{H^2(\Omega)}\Big(\int_{\Omega_h\setminus\Omega} x^{-2\beta q}\Big)^{\frac{1}{q}} \tag{4.7}$$

for $q \to 1$. Then, we have to estimate

$$\int_{\Omega_h\setminus\Omega} x^{-2\beta q} = \sum_{j=1}^{N}\int_{\Omega_h^j} x^{-2\beta q}. \tag{4.8}$$

Since $\gamma = \frac{\alpha-1}{2}$ and $1<\alpha<3$ we can choose β and $q>1$ such that

$$\gamma < \beta < \min\{2\gamma, 1\} \qquad \text{and} \qquad \beta q < \min\{2\gamma, 1\}.$$

Let us estimate each term in the right-hand side of (4.8). Since $\Omega_h^1 \subset T_1$ we have

$$\int_{\Omega_h^1} x^{-2\beta q} \le \int_{T_1} x^{-2\beta q}.$$

Hence, using now that $h_1 \le \sigma\, h^{\frac{1}{1-\gamma}}$, we obtain

$$\int_{T_1} x^{-2\beta q} \le C h_1^{2(\gamma+1-\beta q)} \le C h^{2\,\frac{\gamma+1-\beta q}{1-\gamma}},$$

and therefore

$$\int_{T_1} x^{-2\beta q} \le C h^2$$

because $q\beta < 2\gamma$.

On the other hand, we have

$$\sum_{j>1}\int_{\Omega_h^j} x^{-2\beta q} \le \sum_{j>1} x_{j-1}^{-2\beta q}|\Omega_h^j|,$$

but by using the well-known error formula for the trapezoidal rule, we obtain

$$|\Omega_h^j| \le C h_j^3 x_{j-1}^{\alpha-2} = C h_j^3 x_{j-1}^{2\gamma-1},$$

where in the case $\alpha > 2$ we have used (4.1). Therefore, since $h_j \le \sigma h\, x_{j-1}^{\gamma}$, we have

$$\begin{aligned}\sum_{j>1}\int_{\Omega_h^j} x^{-2\beta q} &\le C\sum_{j>1} x_{j-1}^{-2\beta q+2\gamma-1} h_j^3 \le C h^2 \sum_{j>1} x_{j-1}^{-2\beta q+4\gamma-1} h_j \\ &\le C h^2 \int_0^1 x^{-2\beta q+4\gamma-1},\end{aligned}$$

where we have used again (4.1). But the last integral is finite because $\beta q < 2\gamma$. Moreover, it is bounded by a constant which remains bounded when $q \to 1$.

Therefore, summing up the estimates obtained, it follows from (4.7) that

$$\|\nabla \tilde{u}\|_{L^2(\Omega_h\setminus\Omega)} \le \frac{C}{\sqrt{q-1}}\,\|u\|_{H^2(\Omega)} h^{\frac{1}{q}}$$

with a constant C which does not blow up when $q \to 1$.

The proof concludes with a standard extrapolation argument taking

$$q = \frac{2\log(1/h)}{2\log(1/h) - 1}. \qquad \square$$

Now, we want to estimate the error arising in the numerical integration of the boundary term. With this goal we introduce an extension $\tilde{g}$ of the function g to $\Gamma_{3,h}$. The procedure is similar to that used in [5]. Calling $\phi(t) = (t, t^\alpha)$ we define $\tilde{g}$ on each $\Gamma_{3,h}^j$ as

$$\tilde{g}(\psi_j(t)) := g(\phi(t)) = z(t), \qquad x_{j-1} \le t \le x_j,$$

where

$$\psi_j(t) = (t, t^\alpha + \delta_j(t))$$

with

$$\delta_j(t) = \frac{x_j^\alpha - x_{j-1}^\alpha}{x_j - x_{j-1}}(t - x_{j-1}) + x_{j-1}^\alpha - t^\alpha.$$

The following lemma gives some estimates for the functions δ_j and their derivatives that will be useful in our error analysis.

LEMMA 4.2. *There exists a constant C, which depends only on α, such that*

(i) $|\delta_1(t)| \le 2h_1^\alpha$ *and* $|\delta_1'(t)| \le Ch_1^{\alpha-1}$.

(ii) $|\delta_j(t)| \le Ch_j^2 x_j^{\alpha-2}$ *and* $|\delta_j'(t)| \le Ch_j x_j^{\alpha-2}$, $2 \le j \le n$.

Proof. The estimates in (i) follow immediately from $\delta_1(t) = x_1^{\alpha-1}t - t^\alpha$, $0 \le t \le x_1$, and $x_1 \le h_1$. Consider now $2 \le j \le n$. Since $\delta_j(x_{j-1}) = \delta_j(x_j) = 0$, δ_j' vanishes at some point in the interval (x_{j-1}, x_j), and therefore

$$|\delta_j'(t)| \le C(x_j - x_{j-1})x_j^{\alpha-2},$$

where we have used (4.1) to bound δ'' in the case $\alpha < 2$. So, the second part of (ii) follows from $x_j - x_{j-1} \le h_j$. Finally, the bound for δ_j follows immediately from the bound for its derivative using again that $\delta_j(x_{j-1}) = 0$ and $x_j - x_{j-1} \le h_j$. $\square$

Observe that if we apply a standard trace result in the polygonal domain Ω_h, the constant depends on h. However, since $\Gamma_{3,h}$ approximates Γ_3, a trace theorem with a constant independent of h can be derived from Theorem 3.2. This is the object of the next lemma.

LEMMA 4.3. *There exists a constant C independent of h such that, for all $v \in V_h$,*

$$\|x^r v\|_{L^2(\Gamma_{3,h})} \le C \|v\|_{H^1(\Omega_h)}$$

for $r > \alpha/2 - 1$ if $\alpha \ge 2$ and $r = 0$ if $\alpha < 2$.

Proof. Since $h_j \le Cx_j$, it follows from (ii) of Lemma 4.2 that

$$|\delta_j(t)| \le Cx_j^{\alpha-1}h_j.$$

Then, since v is linear in each triangle, we have

$$\begin{aligned}\int_{\Gamma_{3,h}^j} v^2 x^{2r} &= \int_{x_{j-1}}^{x_j} \left| v(\phi(t)) + \delta_j(t)\frac{\partial v}{\partial y}(\phi(t)) \right|^2 t^{2r}|\psi_j'(t)| \\ &\le C\int_{x_{j-1}}^{x_j} |v(\phi(t))|^2 t^{2r}|\psi_j'(t)| + C\int_{x_{j-1}}^{x_j} \left| \frac{\partial v}{\partial y}|_{\Gamma_3^j} \right|^2 |\delta_j(t)|^2 t^{2r}|\psi_j'(t)|.\end{aligned}$$

Since

$$\psi_j(t) = \left(t, \frac{x_j^\alpha - x_{j-1}^\alpha}{x_j - x_{j-1}}(t - x_{j-1}) + x_{j-1}^\alpha\right),$$

it follows that $|\psi_j'(t)| \sim |\phi'(t)| \sim C$, and thus

$$\int_{\Gamma_{3,h}^j} v^2 x^{2r} \le C\|x^r v\|_{0,\Gamma_3^j}^2 + Ch_j^3 x_j^{2\alpha-2+2r} \left|\frac{\partial v}{\partial y}|_{\Gamma_3^j}\right|^2. \tag{4.9}$$

If $j = 1$, we have

$$\left|\frac{\partial v}{\partial y}|_{\Gamma_3^1}\right|^2 \sim \left\|\frac{\partial v}{\partial y}\right\|_{L^2(T_1)}^2 h_1^{-1-\alpha},$$

and using that $h_1 \sim x_1$ we obtain

$$\|x^r v\|_{L^2(\Gamma_{3,h}^1)}^2 \le C\|x^r v\|_{L^2(\Gamma_3^1)}^2 + Ch_1^{\alpha+2r} \left\|\frac{\partial v}{\partial y}\right\|_{L^2(T_1)}^2,$$

while if $j > 1$ we have

$$\left|\frac{\partial v}{\partial y}|_{\Gamma_3^j}\right|^2 \sim \left\|\frac{\partial v}{\partial y}\right\|_{0,T_j}^2 h_j^{-2} x_j^{1-\alpha},$$

and then

$$\|x^r v\|_{L^2(\Gamma_{3,h}^j)}^2 \le C\|x^r v\|_{L^2(\Gamma_3^j)}^2 + Ch_j x_j^{\alpha-1+2r} \left\|\frac{\partial v}{\partial y}\right\|_{L^2(T_j)}^2.$$

Therefore, for every j we have

$$\|x^r v\|_{L^2(\Gamma_{3,h}^j)}^2 \le C\left(\|x^r v\|_{L^2(\Gamma_3^j)}^2 + \left\|\frac{\partial v}{\partial y}\right\|_{L^2(T_j)}^2\right), \qquad j = 1, \dots, n,$$

and the lemma follows by summing up the previous inequalities for $j = 1, \dots, n$ and using Theorem 3.2. □

LEMMA 4.4. *There exists a constant C independent of h such that, for all $v \in V_h$,*

(i) *if $\alpha < 2$ and $z' \in L^2(0,1)$,*

$$\left|\int_{\Gamma_3} gv - \int_{\Gamma_{3,h}} I_h(gv)\right| \le Ch\|z'\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}.$$

(ii) *if $2 \le \alpha < 3$, $\beta > \alpha/2 - 1$, and $z' t^{-\beta} \in L^2(0,1)$,*

$$\left|\int_{\Gamma_3} gv - \int_{\Gamma_{3,h}} I_h(gv)\right| \le Ch\|z'\, t^{-\beta}\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}.$$

Proof. First, we observe that since g and $\tilde{g}$ agree at the nodes on $\Gamma_3 \cap \Gamma_{3,h}$, we have

$$\begin{aligned}\left|\int_{\Gamma_3} gv - \int_{\Gamma_{3,h}} I_h(gv)\right| &= \left|\int_{\Gamma_3} gv - \int_{\Gamma_{3,h}} \tilde{g}v + \int_{\Gamma_{3,h}} (\tilde{g}v - I_h(\tilde{g}v))\right| \\ &\le \sum_{j=1}^{n} \left|\int_{\Gamma_3^j} gv - \int_{\Gamma_{3,h}^j} \tilde{g}v\right| + \sum_{j=1}^{n} \int_{\Gamma_{3,h}^j} |\tilde{g}v - I_h(\tilde{g}v)| \\ &=: I + II. \end{aligned} \tag{4.10}$$

For any $v \in V_h$, we have

$$\begin{aligned} I = \sum_{j=1}^{n} \left|\int_{\Gamma_3^j} gv - \int_{\Gamma_{3,h}^j} \tilde{g}v\right| &\le \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |z(t)| \left|v(\phi(t))|\phi'(t)| - v(\psi_j(t))|\psi_j'(t)|\right| \\ &\le \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |z(t)| \, |v(\phi(t)) - v(\psi_j(t))| \, |\phi'(t)| \\ &\qquad + \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |z(t)||v(\psi_j(t))| \left||\phi'(t)| - |\psi_j'(t)|\right| \\ &\le \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |z(t)| \left|\frac{\partial v}{\partial y}|_{\Gamma_3^j}\right| |\delta_j(t)| \, |\phi'(t)| \\ &\qquad + C \int_{x_{j-1}}^{x_j} |z(t)||v(\psi_j(t))| \left|\delta_j'(t)\right| \\ &=: \sum_{j=1}^{n} A_j + B_j \end{aligned}$$

and

$$II = \sum_{j=1}^{n} \int_{\Gamma_{3,h}^j} |\tilde{g}v - I_h(\tilde{g}v)| \le \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |z(t)v(\psi_j(t)) - I_h(z(v \circ \psi_j))(t)| \, |\psi_j'(t)|.$$

Let

$$w_j(t) = (z(t) - \bar{z_j})v(\psi_j(t)), \qquad t \in I_j, j = 1, \ldots, n,$$

where $\bar{z_j}, j = 1, \ldots, n$, are constants to be chosen below. It follows that

$$II \le C \sum_{j=1}^{n} \int_{x_{j-1}}^{x_j} |w_j(t) - I_h w_j(t)| \le C \sum_{j=1}^{n} h_j \int_{x_{j-1}}^{x_j} |w_j'(t)|,$$

where we have used a standard L^1 interpolation error estimate. Since, for $t \in I_j$,

$$\begin{aligned} |w_j'(t)| &\le |z'(t)||v(\psi_j(t))| + |z(t) - \bar{z_j}| \left|\frac{\partial v}{\partial x}(\psi_j(t)) + \frac{\partial v}{\partial y}(\psi_j(t)) \frac{x_j^\alpha - x_{j-1}^\alpha}{x_j - x_{j-1}}\right| \\ &\le |z'(t)||v(\psi_j(t))| + C|z(t) - \bar{z_j}||\nabla v(\psi_j(t))|, \end{aligned}$$

thus,

$$II \le C \sum_{j=1}^{n} h_j \left(\int_{x_{j-1}}^{x_j} |z'(t)||v(\psi_j(t))| + \int_{x_{j-1}}^{x_j} |z(t) - \bar{z_j}||\nabla v(\psi_j(t))| \right).$$

Clearly, since $h_j \le h$ for any $j = 1, \dots, n$ it follows that

$$\begin{aligned} II &\le Ch \sum_{j=1}^{n} \left(\int_{x_{j-1}}^{x_j} |z'(t)||v(\psi_j(t))| + \int_{x_{j-1}}^{x_j} |z(t) - \bar{z_j}||\nabla v(\psi_j(t))| \right) \\ &=: Ch \sum_{j=1}^{n} C_j + D_j. \end{aligned}$$

Now, we consider the case $\alpha < 2$ and we prove the result given in (i).

For $j = 1$, using (i) of Lemma 4.2 and that

$$|\nabla v(\phi(t))| \sim \|\nabla v\|_{L^2(T_1)} h_1^{-\frac{\alpha+1}{2}}, \quad t \in I_1, \quad v \in V_h, \tag{4.11}$$

we obtain, for $\beta = \max\{0, \frac{3}{2} - \alpha\}$,

$$\begin{aligned} A_1 &\le Ch_1^{\alpha+\frac{1}{2}+\beta} \|zt^{-\beta}\|_{L^2(I_1)} |\nabla v|_{T_1}| \le Ch_1^{\frac{\alpha}{2}+\beta} \|zt^{-\beta}\|_{L^2(I_1)} \|\nabla v\|_{L^2(T_1)} \\ &\le Ch^{\left(\frac{\alpha}{2}+\beta\right)\frac{2}{3-\alpha}} \|zt^{-\beta}\|_{L^2(I_1)} \|\nabla v\|_{L^2(T_1)}. \end{aligned}$$

Hence, since $\alpha < 2$, then $\left(\frac{\alpha}{2} + \beta\right) \frac{2}{3-\alpha} \ge 1$, and therefore,

$$A_1 \le Ch \|zt^{-\beta}\|_{L^2(I_1)} \|\nabla v\|_{L^2(T_1)}. \tag{4.12}$$

Similary, for $\beta = \max\{0, \frac{5}{2} - \frac{3}{2}\alpha\}$ we have

$$\begin{aligned} B_1 &\le Ch_1^{\alpha+\beta-1} \|zt^{-\beta}\|_{L^2(I_1)} \|v\|_{L^2(\Gamma^1_{3,h})} \le h^{(\alpha+\beta-1)\frac{2}{3-\alpha}} \|zt^{-\beta}\|_{L^2(I_1)} \|v\|_{L^2(\Gamma^1_{3,h})} \\ &\le Ch \|zt^{-\beta}\|_{L^2(I_1)} \|v\|_{L^2(\Gamma^1_{3,h})}. \end{aligned}$$

For $j > 1$, using (ii) of Lemma 4.2 and that

$$|\nabla v(\phi(t))| \sim h_j^{-1} x_j^{\frac{1-\alpha}{2}} \|\nabla v\|_{L^2(T_j)}, \qquad t \in I_j, \tag{4.13}$$

since $h_j \le Chx_j^{\frac{\alpha-1}{2}}$, we have, for $\beta = \max\{0, \frac{3}{2} - \alpha\}$,

$$\begin{aligned} A_j &\le Ch_j^2 x_j^{\alpha+\beta-\frac{3}{2}} \|zt^{-\beta}\|_{L^2(I_j)} |\nabla v|_{T_j}| = Ch_j x_j^{\beta+\frac{\alpha}{2}-1} \|zt^{-\beta}\|_{L^2(I_j)} \|\nabla v\|_{L^2(T_j)} \\ &\le Chx_j^{\beta+\alpha-\frac{3}{2}} \|zt^{-\beta}\|_{L^2(I_j)} \|\nabla v\|_{L^2(T_j)} \\ &\le Ch \|zt^{-\beta}\|_{L^2(I_j)} \|\nabla v\|_{L^2(T_j)}. \end{aligned} \tag{4.14}$$

Similarly, for $j > 1$ and $\beta = \max\{0, \frac{5}{2} - \frac{3}{2}\alpha\}$, applying the Cauchy–Schwarz inequality we have that

$$\begin{aligned} B_j &\le Ch_j x_j^{\alpha-2+\beta} \|zt^{-\beta}\|_{L^2(I_j)} \|v\|_{L^2(\Gamma^j_{3,h})} \le Chx_j^{\frac{3}{2}\alpha-\frac{5}{2}+\beta} \|zt^{-\beta}\|_{L^2(I_j)} \|v\|_{L^2(\Gamma^j_{3,h})} \\ &\le Ch \|zt^{-\beta}\|_{L^2(I_j)} \|v\|_{L^2(\Gamma^j_{3,h})}. \end{aligned} \tag{4.15}$$

So, since $\frac{3}{2} - \alpha < \frac{5}{2} - \frac{3}{2}\alpha$, if we take $\beta = \max\{0, \frac{5}{2} - \frac{3}{2}\alpha\}$, we obtain for any j

$$\left| \int_{\Gamma_3^j} gv - \int_{\Gamma^j_{3,h}} \tilde{g}v \right| \le Ch \|zt^{-\beta}\|_{L^2(I_j)} \left(\|\nabla v\|_{L^2(T_j)} + \|v\|_{L^2(\Gamma^j_{3,h})} \right), \tag{4.16}$$

and adding for $j = 1, \dots, n$, we have

$$I \le Ch\|zt^{-\beta}\|_{L^2(0,1)} \left(\|\nabla v\|_{L^2(\Omega_h)} + \|v\|_{L^2(\Gamma_{3,h})}\right).$$

Now, since $z(0) = 0$ and $\beta < 1$, by using the Hardy inequality

$$\|zt^{-\beta}\|_{L^2(0,1)} \le C\|z'\|_{L^2(0,1)} \tag{4.17}$$

and Lemma 4.3 for the case $\alpha < 2$, we conclude that

$$I \le Ch\|z'\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}. \tag{4.18}$$

On the other hand, we have that for all $j \ge 1$,

$$C_j = \int_{x_{j-1}}^{x_j} |z'(t)||v(\psi_j(t))| \le \|z'\|_{L^2(I_j)} \|v\|_{L^2(\Gamma_{3,h}^j)}. \tag{4.19}$$

Taking $\bar{z_j} = \frac{1}{x_j - x_{j-1}} \int_{x_{j-1}}^{x_j} z$, it follows from the Poincaré inequality that

$$\|z - \bar{z_j}\|_{L^2(I_j)} \le Ch_j\|z'\|_{L^2(I_j)}.$$

Then, using (4.11) for $j = 1$ and (4.13) for $j > 1$, we obtain

$$\begin{aligned} D_1 &\le Ch_1^{1-\frac{\alpha}{2}}\|z'\|_{L^2(I_1)}\|\nabla v\|_{L^2(T_1)} \le Ch^{\frac{2-\alpha}{3-\alpha}}\|z'\|_{L^2(I_1)}\|\nabla v\|_{L^2(T_1)}, \\ D_j &\le Ch_j^{\frac{1}{2}} x_j^{\frac{1-\alpha}{2}}\|z'\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)} \le Ch^{\frac{1}{2}}\|z'\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)}, \qquad j > 1, \end{aligned}$$

and therefore

$$D_j \le C\|z'\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)} \qquad \forall j \ge 1. \tag{4.20}$$

So, adding inequalities (4.19) and (4.20) for $j = 1, \dots, n$, we have that

$$II \le Ch\left(\|z'\|_{L^2(0,1)}\|v\|_{L^2(\Gamma_{3,h})} + \|z'\|_{L^2(0,1)}\|\nabla v\|_{L^2(\Omega_h)}\right),$$

and using Lemma 4.3 again we conclude that

$$II \le Ch\|z'\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}. \tag{4.21}$$

From this inequality, (4.18), and (4.10) the proof of (i) concludes.

Now, consider the case $\alpha \ge 2$. By the same arguments used in the previous case we have

$$\begin{aligned} A_1 &\le Ch_1^{\alpha+\frac{1}{2}}\|z\|_{L^2(I_1)}|\nabla v|_{T_1}| \le Ch_1^{\frac{\alpha}{2}}\|z\|_{L^2(I_1)}\|\nabla v\|_{L^2(T_1)}, \\ &\le Ch^{\frac{\alpha}{3-\alpha}}\|z\|_{L^2(I_1)}\|\nabla v\|_{L^2(T_1)}, \end{aligned}$$

but $\frac{\alpha}{3-\alpha} \ge 1$, so

$$A_1 \le Ch\|z\|_{L^2(I_1)}\|\nabla v\|_{L^2(T_1)}. \tag{4.22}$$

For $j > 1$,

$$\begin{aligned} A_j &\le Ch_j^2 x_j^{\alpha-\frac{3}{2}}\|z\|_{L^2(I_j)}|\nabla v|_{T_j}| \le Ch_j x_j^{\frac{\alpha}{2}-1}\|z\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)} \\ &\le Chx_j^{\alpha-\frac{3}{2}}\|z\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)} \le Ch\|z\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)}. \end{aligned} \tag{4.23}$$

Similarly, for any $\beta \geq 0$ we have

$$B_1 \leq Ch_1^{\alpha-1}\|zt^{-\beta}\|_{L^2(I_1)}\|vx^{\beta}\|_{L^2(\Gamma^1_{3,h})} \leq h^{(\alpha-1)\frac{2}{3-\alpha}}\|zt^{-\beta}\|_{L^2(I_1)}\|vx^{\beta}\|_{L^2(\Gamma^1_{3,h})}$$

$$\leq Ch\|zt^{-\beta}\|_{L^2(I_1)}\|vx^{\beta}\|_{L^2(\Gamma^1_{3,h})} \tag{4.24}$$

and

$$B_j \leq Ch_j x_j^{\alpha-2}\|zt^{-\beta}\|_{L^2(I_j)}\|vx^{\beta}\|_{L^2(\Gamma^j_{3,h})} \leq Chx_j^{\frac{3}{2}\alpha-\frac{5}{2}}\|zt^{-\beta}\|_{L^2(I_j)}\|vx^{\beta}\|_{L^2(\Gamma^j_{3,h})}$$

$$\leq Ch\|zt^{-\beta}\|_{L^2(I_j)}\|vx^{\beta}\|_{L^2(\Gamma^j_{3,h})}. \tag{4.25}$$

Thus, adding inequalities (4.22), (4.23), (4.24), and (4.25) for $j = 1, \ldots, n$ we conclude that for any $\beta \geq 0$,

$$I \leq Ch\left(\|z\|_{L^2(0,1)}\|\nabla v\|_{L^2(\Omega_h)} + \|zt^{-\beta}\|_{L^2(0,1)}\|vx^{\beta}\|_{L^2(\Gamma_{3,h})}\right).$$

Taking $\frac{\alpha}{2} - 1 < \beta < 1$ and using the Hardy inequality (4.17) and our trace result for the case $2 \leq \alpha < 3$, we obtain

$$I \leq Ch\|z'\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}. \tag{4.26}$$

On the other hand, for any j and $\frac{\alpha}{2} - 1 < \beta < 1$ it follows that

$$C_j \leq \|z't^{-\beta}\|_{L^2(I_j)}\|vx^{\beta}\|_{L^2(\Gamma^j_{3,h})},$$

and by using (4.11) for $j = 1$ and (4.13) for $j > 1$ we get

$$D_j \leq C\|z'\|_{L^2(I_j)}\|\nabla v\|_{L^2(T_j)}, \qquad j \geq 1.$$

Therefore, we conclude that for $\frac{\alpha}{2} - 1 < \beta < 1$,

$$II \leq Ch\left(\|z't^{-\beta}\|_{L^2(0,1)}\|vx^{\beta}\|_{L^2(\Gamma_{3,h})} + \|z'\|_{L^2(0,1)}\|\nabla v\|_{L^2(\Omega_h)}\right).$$

Hence, using Lemma 4.3 again we obtain

$$II \leq Ch\|z't^{-\beta}\|_{L^2(0,1)}\|v\|_{H^1(\Omega_h)}, \tag{4.27}$$

and thus, using (4.26) and (4.27) in (4.10), we conclude the proof of (ii). ∎

We can now prove our main theorem, which gives quasi-optimal error estimates in H^1 for the piecewise linear approximation on appropriate graded meshes.

THEOREM 4.2. *Let u be the solution of (2.1), and let $u_h \in V_h$ be its finite element approximation using the mesh $\mathcal{T}_h$. Assume $\alpha < 3$, $f \in L^2(\Omega)$, $z\,t^{-\frac{\alpha}{2}} \in L^2(0,1)$, and $z't^{-r} \in L^2(0,1)$, with $r = 0$ when $\alpha < 2$ and $r > \alpha/2 - 1$ when $\alpha \geq 2$.*

If the family of meshes satisfies (1), (2), (3), and (H), then there exists a constant C depending only on α, β, and σ such that

$$\|u - u_h\|_{H^1(\Omega)} \leq Ch\sqrt{\log(1/h)}\,\left\{\|f\|_{L^2(\Omega)} + \|z\,t^{-(\alpha/2)}\|_{L^2(0,1)} + \|z'\,t^{-r}\|_{L^2(0,1)}\right\}.$$

Proof. In view of (2.2) and since $r > \alpha/2 - 1$, it is enough to prove

$$\|u - u_h\|_{H^1(\Omega)} \leq Ch\sqrt{\log(1/h)}\,\left\{\|u\|_{H^2(\Omega)} + \|z'\,t^{-r}\|_{L^2(0,1)}\right\}.$$

Since $\Omega \subset \Omega_h$, we have

$$\|u - u_h\|_{H^1(\Omega)} \le \|\tilde{u} - u_h\|_{H^1(\Omega_h)},$$

and therefore it is enough to prove that

$$\|\tilde{u} - u_h\|_{H^1(\Omega_h)} \le Ch\sqrt{\log(1/h)}\, \left\{\|u\|_{H^2(\Omega)} + \|z'\, t^{-r}\|_{L^2(0,1)}\right\}. \tag{4.28}$$

Using the Poincaré inequality, we have

$$\begin{aligned} \|\tilde{u} - u_h\|^2_{H^1(\Omega_h)} &\le C|\tilde{u} - u_h|^2_{H^1(\Omega_h)} \\ &= C\left[\int_{\Omega_h} \nabla(\tilde{u} - u_h)\cdot\nabla(\tilde{u} - \Pi\tilde{u}) + \int_{\Omega_h} \nabla(\tilde{u} - u_h)\cdot\nabla(\Pi\tilde{u} - u_h)\right], \end{aligned} \tag{4.29}$$

but we know from (4.2) and Theorem 4.1 that

$$|\tilde{u} - \Pi\tilde{u}|_{H^1(\Omega_h)} \le Ch\|\tilde{u}\|_{H^2_\alpha(\Omega_h)} \le Ch\|u\|_{H^2(\Omega)}. \tag{4.30}$$

Thus, for the first term in (4.29), using the Young inequality, we have

$$\int_{\Omega_h} \nabla(\tilde{u} - u_h)\cdot\nabla(\tilde{u} - \Pi\tilde{u}) \le \varepsilon|\tilde{u} - u_h|^2_{H^1(\Omega_h)} + C_\varepsilon h^2\|u\|^2_{H^2(\Omega)} \tag{4.31}$$

with ε to be chosen below.

Then, we have only to estimate the second term of (4.29). To simplify notation we introduce $w_h := \Pi\tilde{u} - u_h$. From (2.1) and (2.3) we have

$$\begin{aligned} \int_{\Omega_h} \nabla(\tilde{u} - u_h)\cdot\nabla w_h &= \int_{\Omega} \nabla(\tilde{u} - u_h)\cdot\nabla w_h + \int_{\Omega_h\setminus\Omega} \nabla(\tilde{u} - u_h)\cdot\nabla w_h \\ &= \int_{\Omega} \nabla u\cdot\nabla w_h + \int_{\Omega_h\setminus\Omega} \nabla\tilde{u}\cdot\nabla w_h - \int_{\Omega_h} \nabla u_h\cdot\nabla w_h \\ &= \int_{\Omega_h\setminus\Omega} \nabla\tilde{u}\cdot\nabla w_h + \int_{\Gamma_3} g w_h - \int_{\Gamma_{3,h}} I_h(g w_h). \end{aligned}$$

Then, from Lemmas 4.1 and 4.4, using (4.2) and again the Young inequality we obtain

$$\int_{\Omega_h} \nabla(\tilde{u} - u_h)\cdot\nabla w_h \le C_\varepsilon h^2 \log 1/h \left\{\|u\|^2_{H^2(\Omega)} + \|z'\, t^{-r}\|^2_{L^2(0,1)}\right\} + \varepsilon|w_h|^2_{H^1(\Omega_h)}. \tag{4.32}$$

Hence, from (4.30)

$$\begin{aligned} |w_h|^2_{H^1(\Omega_h)} &\le 2(|\Pi\tilde{u} - \tilde{u}|^2_{H^1(\Omega_h)} + |\tilde{u} - u_h|^2_{H^1(\Omega_h)}) \\ &\le Ch^2\|u\|^2_{H^2(\Omega)} + 2|\tilde{u} - u_h|^2_{H^1(\Omega_h)}. \end{aligned} \tag{4.33}$$

Therefore, from (4.31), (4.32), and (4.33) we get

$$\begin{aligned} &|\tilde{u} - u_h|^2_{H^1(\Omega_h)} \\ &\quad\le C_\varepsilon h^2\|u\|^2_{H^2(\Omega)} + C_\varepsilon h^2 \log 1/h \left\{\|u\|^2_{H^2(\Omega)} + \|z'\, t^{-r}\|^2_{L^2(0,1)}\right\} + C\varepsilon|\tilde{u} - u_h|^2_{H^1(\Omega_h)}, \end{aligned}$$

and so the result follows by choosing ε small enough and using the estimates given in (2.2). ∎

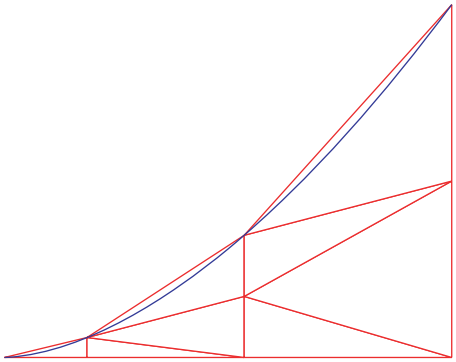

FIG. 4. *Graded mesh with* $\alpha = 2$ *and* $n = 3$.

TABLE 2
H^1 *order using graded meshes for* $\alpha = 2$.

Value of s	Order in number of nodes	Order in h
0.55	0.588	1.054
0.6	0.585	1.049
0.65	0.584	1.047
0.7	0.584	1.046
0.75	0.584	1.047
0.8	0.585	1.048
0.85	0.586	1.049
0.9	0.586	1.051
0.95	0.587	1.052

Now we show that meshes satisfying the hypotheses (1)–(3) and (H) can be constructed. To define the mesh $\mathcal{T}_h$, with $h = 1/n$ we use the following method given in [9, page 393] and [11].

1. Introduce the partition of the interval $(0, 1)$ given by

$$x_j = \left(\frac{j}{n}\right)^{\frac{2}{3-\alpha}} \qquad 0 \le j \le n.$$

2. Take the points $(x_j, 0)$ in Γ_1, (x_j, x_j^α) in Γ_3, and for $j > 1$, divide each of the vertical lines $\{(x_j, y) : 0 \le y \le x_j^\alpha\}$ uniformly into subintervals such that each has length $\sim x_j - x_{j-1}$.

Figure 4 shows an example of one of these meshes.

If N is the number of nodes in the partition $\mathcal{T}_h$, it can be proved that $h^2 \sim 1/N$ [9, page 393], [11]. Therefore, using these meshes we have the following error estimate in terms of the number of nodes:

$$\|u - u_h\|_{H^1(\Omega)} \le C\sqrt{\frac{\log N}{N}}\left\{\|f\|_{L^2(\Omega)} + \|z\, t^{-\frac{\alpha}{2}}\|_{L^2(0,1)} + \|z'\, t^{-r}\|_{L^2(0,1)}\right\}.$$

Observe that this estimate is quasi optimal. Indeed, up to the logarithmic factor, the order with respect to the number of nodes is the same as that obtained for a smooth problem using quasi-uniform meshes.

Table 2 shows the numerical results obtained with these graded meshes for example (2.1).

TWO-SCALE BOOLEAN GALERKIN DISCRETIZATIONS FOR FREDHOLM INTEGRAL EQUATIONS OF THE SECOND KIND*

FANG LIU† AND AIHUI ZHOU‡

Abstract. In this paper, some two-scale Boolean Galerkin discretizations are proposed and analyzed for a class of Fredholm integral equations of the second kind in multidimensions. It is shown by both theory and numerics that this type of multiscale discretization algorithm not only significantly reduces the number of degrees of freedom but also produces very accurate approximations.

Key words. Boolean Galerkin discretization, Fredholm integral equation, multidimension, two-scale

1. Introduction.

It is known that it is a very challenging task to solve an integral equation in multidimensions by using the standard Galerkin discretizations, due to the fact that the resulting linear algebraic systems of integral equations involve dense matrices. However, integral equations of the second kind with smooth kernels in multidimensions have important applications in many areas such as physics, engineering, and finance; see, e.g., [3, 9, 14, 18, 19, 25, 26] and the references cited therein. Hence, an accurate and economic numerical scheme for solving an integral equation in multidimensions is highly desired. In this paper, we propose and analyze some two-scale finite element discretizations for solving multidimensional integral equations of the second kind with smooth kernels. These discretizations are nothing but several coupled standard Galerkin discretizations of two scales. The approximations obtained from the coupled two-scale discretizations have almost the same approximation accuracy, but the computational cost is reduced significantly, as compared with the standard Galerkin approximations. Moreover, it may be significant that this kind of discretization can be carried out in parallel.

We now use the three-dimensional case as an example to demonstrate the key idea of our discretizations. Let $R_{h_1,h_2,h_3}u$ be the standard Galerkin approximation to the exact solution u of an equation on a uniform cuboid grid with mesh size h_1 in the x-direction, h_2 in the y-direction, and h_3 in the z-direction, respectively. Then, a two-scale Boolean Galerkin approximation to u, which is a linear combination of different standard Galerkin approximations over two scales meshes, is constructed as follows:

$$B^h_{H,H,H}u = R_{h,H,H}u + R_{H,h,H}u + R_{H,H,h}u - 2R_{H,H,H}u.$$

‡LSEC, Institute of Computational Mathematics and Scientific/Engineering Computing, Academy of Mathematics and Systems Science, Chinese Academy of Sciences, P.O. Box 2719, Beijing 100080, China (azhou@lsec.cc.ac.cn).

For this new approximation $B^h_{H,H,H}u$, we may establish the estimation (see Theorem 3.1)

$$\|B^h_{H,H,H}u - u_{h,h,h}\|_{0,2} = O(h + H^2)$$

if the piecewise constant functions are used as the approximate spaces and the exact solution u is smooth. Consequently, for example, we obtain an asymptotically optimal approximation $B^h_{H,H,H}u$ in parallel with only $O(h^{-2})$ degrees of freedom when $H = O(\sqrt{h})$ is taken, while the degrees of freedom for $u_{h,h,h}$ are of $O(h^{-3})$.

The two-scale Boolean Galerkin approximation studied in this paper is closely related to the multiscale Boolean interpolation which is first constructed in [10]. This multiscale Boolean technique is originally applied in [12] to reduce computational complexity in the numerical solution of partial differential equations (see also [4, 5, 6, 15, 20, 21, 22]). In the context of solving integral equations, the one-scale Boolean sum technique is used in [13] in conjunction with the degenerate kernel scheme to achieve a higher order of convergence and in [26] in designing a fast multiscale Boolean approximation scheme to get fast approximations. This multiscale Boolean technique is also analogous to the sparse grid method and the multiparameter extrapolation method discussed in [2, 11, 23, 28, 29]. Indeed, the sparse grid method may be viewed as an implicit version of the multiscale Boolean method in [4, 5, 6, 12, 20, 21, 22]. Instead of the multiscale Boolean technique, in the current work, we adopt a two-scale Boolean approach. Very recently, the two-scale Boolean discretization idea has been introduced to numerical partial differential equations in [16, 17]. It is shown that the two-scale Boolean approach is more flexible than the multiscale Boolean technique, which is a key for us to introduce the multiscale techniques to nonlinear problems [16]. Moreover, since the two-scale finite element approximations are computed on regular meshes, existing solvers can be used without any need for an explicit discretization on a sparse grid.

The rest of the paper is organized as follows. In section 2, some preliminary materials are provided. In section 3, three two-scale Boolean Galerkin discretizations are proposed and analyzed for solving multidimensional integral equations of the second kind. In section 4, several numerical experiments, which support our theory, are reported. Finally, in section 5, some concluding remarks are presented.

2. Preliminaries. We begin with the definition of notation. Let $\square = (0,1)^d (d \geq 2)$ be the unit cube in $\mathbb{R}^d$. We use $W^{s,p}(\square)$ to denote the standard Sobolev spaces of functions whose derivatives of order less than or equal to s are in $L^p(\square)$. We denote by $\mathbb{N}_0$ the set of all nonnegative integers. For a function $v \in W^{s,p}(\square)$, a point $x = (x_1, x_2, \ldots, x_d) \in \square$, and an index $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_d) \in \mathbb{N}_0^d$, we let

$$(D^\alpha w)(x) = \left(\frac{\partial^{\alpha_1}}{\partial x_1^{\alpha_1}} \cdots \frac{\partial^{\alpha_d} w}{\partial x_d^{\alpha_d}} \right)(x).$$

The norms and seminorms for the space $W^{s,p}(\square)$ are defined by

$$\|w\|_{s,p} = \begin{cases} \left(\sum_{|\alpha| \leq s} \|D^\alpha w\|_p^p \right)^{\frac{1}{p}} & \text{if } 1 \leq p < \infty, \\ \max_{|\alpha| \leq s} \|D^\alpha w\|_\infty \text{ if } p = \infty \end{cases}$$

and

$$|w|_{s,p} = \begin{cases} \left(\sum_{|\alpha|=s} \|D^\alpha w\|_p^p \right)^{\frac{1}{p}} & \text{if } 1 \le p < \infty, \\ \max_{|\alpha|=s} \|D^\alpha w\|_\infty \text{ if } p = \infty, \end{cases}$$

respectively (see, e.g., [1, 8]). When $p = 2$, we let $H^s(\Box) = W^{s,p}(\Box)$, $\|\cdot\|_s = \|\cdot\|_{s,p}$, and $\|\cdot\| = \|\cdot\|_0$, and we use $(\cdot,\cdot)$ for the standard $L^2(\Box)$ inner product. We will also use the negative norm $\|\cdot\|_{-1}$, which is defined for $w \in H^{-1}(\Box) = (H^1(\Box))^*$ by

$$\|w\|_{-1} = \sup_{\phi \in H^1(\Box)} \frac{(w,\phi)}{\|\phi\|_1}.$$

Throughout this paper, we shall use the letter C to denote a generic positive constant which may stand for different values at its different occurrences.

2.1. Interpolation and L^2-projection. The purposes of this subsection are to describe the multidimensional tensor product interpolation and L^2-projection operators. To this end, we first define the interpolation and L^2-projection operators in one dimension. Due to the higher-dimensional nature of these integral equations, we will use the spaces of the piecewise constant functions as our approximate ones. For a positive integer n we let $\mathbb{Z}_n = \{1, 2, \ldots, n\}$. Let $T^h((0,1))$ be a mesh of the interval $(0,1)$ with the mesh size $h \in [0,1)$, i.e.,

$$T^h((0,1)) = \{(x_{i-1}, x_i) : i \in \mathbb{Z}_n, x_0 = 0, x_n = 1\},$$

$$h = \max\{x_i - x_{i-1} : i \in \mathbb{Z}_n\}.$$

We use $\partial^2 T^h((0,1))$ to denote the set of the midpoints of the subintervals in the mesh $T^h((0,1))$, namely,

$$\partial^2 T^h((0,1)) = \left\{ \frac{x_{i-1} + x_i}{2} : i \in \mathbb{Z}_n \right\}.$$

Define the space of piecewise constant functions in $L^\infty((0,1))$ by setting

$$S^h((0,1)) = \{v \in L^\infty((0,1)) : v\,|_\tau \text{ is constant, } \tau \in T^h((0,1))\}.$$

Let $I_h : C((0,1)) \to S^h((0,1))$ be the Lagrange interpolation and $P_h : L^2((0,1)) \to S^h((0,1))$ be the L^2-projection operator defined by

$$(I_h w)(t) = w(t) \quad \forall t \in \partial^2 T^h((0,1)), \quad \forall w \in C((0,1))$$

and

$$\int_0^1 (P_h w - w)(t) v(t) dt = 0 \quad \forall v \in S^h((0,1)), \quad \forall w \in L^2((0,1)),$$

respectively.

We next describe the multidimensional notation. For $\mathbf{h} = (h_1, \ldots, h_d)$, where $h_j \in [0,1)$, construct a mesh of the unit cube $\Box$ in $\mathbb{R}^d$ by

$$T^{\mathbf{h}}(\Box) = T^{h_1}((0,1)) \times \cdots \times T^{h_d}((0,1))$$

with the associated space of piecewise constant functions on $\square$ by

$$S^{\mathbf{h}}(\square) = S^{h_1}((0,1)) \otimes \cdots \otimes S^{h_d}((0,1)).$$

We remark that $S^{\mathbf{h}}(\square)$ is the tensor product space of the spaces of piecewise constant functions on the interval $(0,1)$. The interpolation operator $I_{\mathbf{h}}$ from $C(\square)$ onto $S^{\mathbf{h}}(\square)$ is constructed by

$$I_{\mathbf{h}} = I_{h_1} \circ \cdots \circ I_{h_d},$$

while the L^2-projection operator $P_{\mathbf{h}}$ from $L^2(\square)$ onto $S^{\mathbf{h}}(\square)$ is set to be

$$P_{\mathbf{h}} = P_{h_1} \circ \cdots \circ P_{h_d}.$$

It is easy to prove by definition that for every $w \in L^2(\square)$, there holds

$$(w - P_{\mathbf{h}} w, v) = 0 \quad \forall\ v \in S^{\mathbf{h}}(\square). \tag{2.1}$$

For $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_d) \in \mathbb{N}_0^d$, we set

$$|\alpha| = \alpha_1 + \cdots + \alpha_d,$$

$$\mathbf{h}^\alpha = h_1^{\alpha_1} \cdots h_d^{\alpha_d}$$

and

$$\mathbf{h}\alpha = (h_1\alpha_1, \ldots, h_d\alpha_d).$$

We define the order $\alpha \le \beta$ for the elements $\alpha, \beta \in \{0,1\}^d$ by $\alpha_i \le \beta_i$ for all $i \in \mathbb{Z}_d$. Furthermore, we denote $\mathbf{0} = (0, \ldots, 0) \in \mathbb{R}^d$ and $\mathbf{e} = (1, \ldots, 1) \in \mathbb{R}^d$ and for $i \in \mathbb{Z}_d, \hat{\mathbf{e}}_i = \mathbf{e} - \mathbf{e}_i$ and $\mathbf{e}_i = (0, \ldots, 0, 1, 0, \ldots, 0) \in \mathbb{R}^d$ whose ith component is one and zero otherwise.

We also need the notion of the mixed Sobolev space (see [16, 21, 22, 26]) defined for $\alpha \in \{0,1\}^d$ and $1 \le p \le \infty$ by

$$W^{\alpha,p}_{\mathrm{mix}}(\square) = \{w \in L^p(\square) : D^\beta w \in L^p(\square) \ \ \forall \ \ \beta \ \text{ with } \ \mathbf{0} \le \beta \le \alpha\}$$

with the associated norm given for $w \in W^{\alpha,p}_{\mathrm{mix}}(\square)$ by

$$\|w\|_{W^{\alpha,p}_{\mathrm{mix}}} = \left(\sum_{\mathbf{0} \le \beta \le \alpha} \|D^\beta w\|_{0,p}^2 \right)^{\frac{1}{2}}.$$

In particular, we denote

$$\mathcal{H}^\alpha(\square) = W^{\alpha,2}_{\mathrm{mix}}(\square).$$

In our discussion, we will also need the space

$$H^{1,2}(\square) = \left\{ w \in H^1(\square) : \frac{\partial^2 w}{\partial x_i \partial x_j} \in L^2(\square),\ i,j = 1, \ldots, d,\ i \ne j \right\} \tag{2.2}$$

with norm

$$\|w\|_{H^{1,2}} = \|w\|_1 + \sum_{\substack{i,j=1 \\ i \ne j}}^{d} \left\| \frac{\partial^2 w}{\partial x_i \partial x_j} \right\|.$$

It is seen that for all $i \in \mathbb{Z}_d$, there holds

$$\|w - P_{\mathbf{he}_i} w\|_{-1} + h_i \|w - P_{\mathbf{he}_i} w\| + h_i \|w - I_{\mathbf{he}_i} w\| \le C h_i^2 \|D^{\mathbf{e}_i} w\| \qquad \forall\ w \in \mathcal{H}^{\mathbf{e}_i}(\square). \tag{2.3}$$

Consequently, if $w \in H^1(\square)$, then

$$\begin{aligned} &\|w - P_{\mathbf{h}} w\|_{-1} + \max\{h_1, \dots, h_d\}(\|w - P_{\mathbf{h}} w\| + \|w - I_{\mathbf{h}} w\|) \\ &\qquad \le C \max\{h_1^2, \dots, h_d^2\} \|w\|_1. \end{aligned} \tag{2.4}$$

It can be verified that for any $\mathbf{0} \le \alpha, \beta \le \mathbf{e}$ with $\alpha + \beta \le \mathbf{e}$, there holds the identity that for every $w \in \mathcal{H}^{\alpha}(\square)$

$$D^{\alpha} I_{\mathbf{h}\beta} w = I_{\mathbf{h}\beta} D^{\alpha} w, \tag{2.5}$$

$$D^{\alpha} P_{\mathbf{h}\beta} w = P_{\mathbf{h}\beta} D^{\alpha} w. \tag{2.6}$$

Thus from the above basic properties of $P_{\mathbf{h}}$, we have the following proposition.

PROPOSITION 2.1. *Assume that $\mathbf{0} \le \alpha \le \mathbf{e}$ with $|\alpha| \ge 2$. If $w \in H^{1,2}(\square)$, then*

$$\left\| \prod_{0 \le \beta \le \alpha, |\beta| = 1} (I - P_{\mathbf{h}\beta}) w \right\|_{-1} + \max_{i \in \mathbb{Z}_d} h_i \left\| \prod_{0 \le \beta \le \alpha, |\beta| = 1} (I - P_{\mathbf{h}\beta}) w \right\| \le C \max_{i \in \mathbb{Z}_d} h_i^3 \|w\|_{H^{1,2}},$$

where I is the identity operator.

Given $\tau \in (0, 1)$, let $w_{\mathbf{h}\alpha + \tau\beta} \in S^{\mathbf{h}\alpha + \tau\beta}(\square)(\mathbf{0} \le \alpha, \beta \le \mathbf{e}$ and $\alpha + \beta = \mathbf{e})$, and set

$$\delta_{\tau}^{\alpha} w_{\mathbf{h}} = \prod_{\alpha_i \ne 0} \delta_{\tau}^{\mathbf{e}_i} w_{\mathbf{h}},$$

where

$$\delta_{\tau}^{\mathbf{e}_i} w_{\mathbf{h}} = w_{\mathbf{h}} - w_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i}, \quad i \in \mathbb{Z}_d.$$

If $d = 2$ and $\mathbf{h} = (h_1, h_2)$, for instance, then

$$\begin{aligned} \delta_{\tau}^{(1,0)} w_{h_1, h_2} &= w_{h_1, h_2} - w_{\tau, h_2}, \\ \delta_{\tau}^{(1,1)} w_{h_1, h_2} &= w_{h_1, h_2} - w_{h_1, \tau} - w_{\tau, h_2} + w_{\tau, \tau}. \end{aligned}$$

Given $h, H \in (0, 1)$, let $w_{H\mathbf{e}} \in S^{H\mathbf{e}}(\square)$, $w_{h\mathbf{e}} \in S^{h\mathbf{e}}(\square)$, and $w_{h\alpha + H\beta} \in S^{h\alpha + H\beta}(\square)$ $(\mathbf{0} \le \alpha, \beta \le \mathbf{e}, \alpha + \beta = \mathbf{e})$, and define

$$B_H^h w_{h\mathbf{e}} = w_{H\mathbf{e}} - \sum_{i=1}^{d} \delta_h^{\mathbf{e}_i} w_{H\mathbf{e}}.$$

PROPOSITION 2.2. *Let $i \in \mathbb{Z}_d$. If $w \in \mathcal{H}^{\mathbf{e}_i}(\square)$, then*

$$\|\delta_H^{\mathbf{e}_i} I_{\mathbf{h}} w\| + \|\delta_H^{\mathbf{e}_i} P_{\mathbf{h}} w\| \le C \max\{h_i, H\} \|D^{\mathbf{e}_i} w\| \tag{2.7}$$

and

$$\|\delta_H^{\mathbf{e}_i} P_{\mathbf{h}} w\|_{-1} \le C \max\{h_i^2, H^2\} \|D^{\mathbf{e}_i} w\|. \tag{2.8}$$

Proof. The estimate (2.7) follows directly from the definition of $\delta_H^{\mathbf{e}_i}$ and (2.3). We now prove (2.8). For $\phi \in H^1(\square)$, since

$$((P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w, P_{H\mathbf{e}_i} P_{\mathbf{h}\hat{\mathbf{e}}_i}\phi) = 0$$

and since there holds

$$\|(I - P_{H\mathbf{e}_i})P_{\mathbf{h}\hat{\mathbf{e}}_i}\phi\| \le CH\|D^{\mathbf{e}_i}P_{\mathbf{h}\hat{\mathbf{e}}_i}\phi\| \le CH\|P_{\mathbf{h}\hat{\mathbf{e}}_i}D^{\mathbf{e}_i}\phi\| \le CH\|\phi\|_1,$$

we conclude that

$$\begin{aligned}|((P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w, \phi)| &= |((P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w, P_{\mathbf{h}\hat{\mathbf{e}}_i}\phi)| \\ &= |((P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w, (I - P_{H\mathbf{e}_i})P_{\mathbf{h}\hat{\mathbf{e}}_i}\phi)| \le CH\|(P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w\|\|\phi\|_1,\end{aligned}$$

which ensures that

$$\|(P_{\mathbf{h}} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w\|_{-1} \le CH(\|(P_{\mathbf{h}\hat{\mathbf{e}}_i} - P_{\mathbf{h}\hat{\mathbf{e}}_i + h_i\mathbf{e}_i})w\| + \|(P_{\mathbf{h}\hat{\mathbf{e}}_i} - P_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i})w\|).$$

Using the estimation

$$\|(P_{\mathbf{h}\hat{\mathbf{e}}_i} - P_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i})w\| \le C\tau\|D^{\mathbf{e}_i}w\|$$

for $\tau \in \{h_i, H\}$, we then have (2.8). This completes the proof. ∎

From Proposition 2.2, we immediately obtain the following proposition.

PROPOSITION 2.3. *If $w \in H^{1,2}(\square)$, then*

$$\|B_H^h I_{h\mathbf{e}}w - I_{h\mathbf{e}}w\| + \|B_H^h P_{h\mathbf{e}}w - P_{h\mathbf{e}}w\| \le C\max\{h_i^2, H^2\}\|w\|_{H^{1,2}} \tag{2.9}$$

and

$$\|B_H^h P_{h\mathbf{e}}w - P_{h\mathbf{e}}w\|_{-1} \le C\max\{h_i^3, H^3\}\|w\|_{H^{1,2}}. \tag{2.10}$$

Proof. For $w_\tau = I_\tau w$ or $P_\tau w$ when $\tau = (\tau_1, \tau_2, \ldots, \tau_d)$, we have

$$w_{h\mathbf{e}} = w_{H\mathbf{e}} + \sum_{|\alpha|=1}^{d} (-1)^{|\alpha|}\delta_h^\alpha w_{H\mathbf{e}}.$$

Thus we obtain

$$B_H^h w_{h\mathbf{e}} - w_{h\mathbf{e}} = -\sum_{|\alpha|=2}^{d} (-1)^{|\alpha|}\delta_h^\alpha w_{H\mathbf{e}}, \tag{2.11}$$

which together with Proposition 2.2 completes the proof. ∎

2.2. The standard Galerkin approximation. Suppose that the kernel $k \in L^2(\square \times \square)$. Then the operator $K : L^2(\square) \to L^2(\square)$ defined by

$$(Ku)(x) = \int_\square k(x,y)u(y)dy, \quad x \in \square, \quad u \in L^2(\square),$$

is a compact integral operator (see, e.g., page 277 of [27]). Consider the Fredholm integral equation of the second kind

$$u + Ku = f, \tag{2.12}$$

where $u \in L^2(\square)$ is the unknown and $f \in L^2(\square)$ is a given function. We assume that -1 is not an eigenvalue of K; namely, the inverse operator $(I+K)^{-1}$ exists as a bounded operator on $L^2(\square)$. In other words, (2.12) has a unique solution u in $L^2(\square)$ satisfying

$$\|u\| \le C\|f\|.$$

The standard Galerkin projection $R_{\mathbf{h}} : L^2(\square) \to S^{\mathbf{h}}(\square)$ is defined by

$$((I+K)(R_{\mathbf{h}}u - u), v) = 0 \quad \forall \ \ v \in S^{\mathbf{h}}(\square), \tag{2.13}$$

namely,

$$(I + P_{\mathbf{h}}K)R_{\mathbf{h}}u = P_{\mathbf{h}}(u + Ku). \tag{2.14}$$

Associated with K and $R_{\mathbf{h}}$, we may define $K^* : L^2(\square) \to L^2(\square)$ by

$$(K^*u)(x) = \int_{\square} k(y,x)u(y)dy, \quad x \in \square, \quad u \in L^2(\square),$$

and $R^*_{\mathbf{h}} : L^2(\square) \to S^{\mathbf{h}}(\square)$ by

$$((I+K^*)(R^*_{\mathbf{h}}u - u), v) = 0 \ \ \forall \ \ v \in S^{\mathbf{h}}(\square).$$

It is seen that both $(I+K)^{-1}$ and $(I+K^*)^{-1}$ exist as bounded operators on $H^1(\square)$ if $k \in H^1(\square \times \square)$ (see, e.g., [24]).

In the next proposition, we provide some standard estimates for the standard Galerkin projections $R_{\mathbf{h}}u$ and $R^*_{\mathbf{h}}u$ for any $u \in \mathcal{H}^{\mathbf{e}}(\square)$ (see, e.g., [7, 14, 24, 26]).

PROPOSITION 2.4. *If $k \in L^2(\square \times \square)$ and $u \in H^1(\square)$, then*

$$\|u - R_{\mathbf{h}}u\| + \|u - R^*_{\mathbf{h}}u\| \le C \inf_{v \in S^{\mathbf{h}}(\square)} \|u - v\| \le C \max\{h_1, \ldots, h_d\}\|u\|_1. \tag{2.15}$$

For the Galerkin approximation $u_{\mathbf{h}} \equiv R_{\mathbf{h}}u$ to the exact solution u of (2.12), we define the *iterated Galerkin approximation* by

$$\tilde{u}_{\mathbf{h}} = f - Ku_{\mathbf{h}}. \tag{2.16}$$

The following estimation is also classic and can be found in the literature (see, e.g., [24, 26]).

PROPOSITION 2.5. *If $k \in H^1(\square \times \square)$, then*

$$\|u - u_{\mathbf{h}}\|_{-1} + \|u - \tilde{u}_{\mathbf{h}}\| \le C \max\{h_1, \ldots, h_d\}\|u - u_{\mathbf{h}}\|.$$

In our analysis, we need the following two results.

PROPOSITION 2.6. *Assume that $u \in \mathcal{H}^{\mathbf{e}_i}(\square)(i \in \mathbb{Z}_d)$. If $k \in H^1(\square \times \square)$, then*

$$\|D^{\mathbf{e}_i} R_{\mathbf{h}\hat{\mathbf{e}}_i} u\| \le C(\|D^{\mathbf{e}_i}u\| + \|u\|). \tag{2.17}$$

Proof. It is obtained from (2.14) that

$$D^{\mathbf{e}_i}(I + P_{\mathbf{h}\hat{\mathbf{e}}_i}K)R_{\mathbf{h}\hat{\mathbf{e}}_i}u = D^{\mathbf{e}_i}P_{\mathbf{h}\hat{\mathbf{e}}_i}(I+K)u,$$

which together with (2.6) leads to

$$D^{\mathbf{e}_i} R_{\mathbf{h}\hat{\mathbf{e}}_i} u = P_{\mathbf{h}\hat{\mathbf{e}}_i}\left(D^{\mathbf{e}_i}(I+K)u - D^{\mathbf{e}_i}KR_{\mathbf{h}\hat{\mathbf{e}}_i}u\right).$$

Hence from

$$\|P_{\mathbf{h}\hat{\mathbf{e}}_i}u\| + \|R_{\mathbf{h}\hat{\mathbf{e}}_i}u\| \le C\|w\|,$$

we arrive at (2.17). This completes the proof. ∎

PROPOSITION 2.7. *Assume that* $u \in \mathcal{H}^{\mathbf{e}_i}(\square)(i \in \mathbb{Z}_d)$.

(1) *If* $k \in L^2(\square \times \square)$, *then*

$$\|\delta_H^{\mathbf{e}_i} R_{\mathbf{h}} u\| \le C \max\{h_i, H\}\|D^{\mathbf{e}_i}u\|. \tag{2.18}$$

(2) *If* $k \in H^1(\square \times \square)$, *then*

$$\|\delta_H^{\mathbf{e}_i} R_{\mathbf{h}} u\|_{-1} \le C \max\{h_i^2, H^2\}\|D^{\mathbf{e}_i}u\|. \tag{2.19}$$

Proof. The estimate (2.18) can be obtained directly from (2.15). It remains to prove (2.19).

Because of the triangle inequality

$$\|\delta_H^{\mathbf{e}_i} R_{\mathbf{h}} u\|_{-1} \le \|R_{\mathbf{h}}u - R_{\mathbf{h}\hat{\mathbf{e}}_i}u\|_{-1} + \|R_{\mathbf{h}\hat{\mathbf{e}}_i}u - R_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i}u\|_{-1}, \tag{2.20}$$

we shall estimate $\|R_{\mathbf{h}}u - R_{\mathbf{h}\hat{\mathbf{e}}_i}u\|_{-1}$ and $\|R_{\mathbf{h}\hat{\mathbf{e}}_i}u - R_{\mathbf{h}\hat{\mathbf{e}}_i + H\mathbf{e}_i}u\|_{-1}$.

To this end, for any $\phi \in H^1(\square)$, we let

$$\psi = R^*_{\mathbf{h}\hat{\mathbf{e}}_i}(I + K^*)^{-1}\phi.$$

Since Proposition 2.6 is also true when $R_{\mathbf{h}\hat{\mathbf{e}}_i}$ is replaced by $R^*_{\mathbf{h}\hat{\mathbf{e}}_i}$, we have

$$\|D^{\mathbf{e}_i} R^*_{\mathbf{h}\hat{\mathbf{e}}_i}(I + K^*)^{-1}\phi\| \le C(\|D^{\mathbf{e}_i}(I + K^*)^{-1}\phi\| + \|(I + K^*)^{-1}\phi\|),$$

which together with (see, e.g., [24])

$$\|(I + K^*)^{-1}\phi\|_1 \le C\|\phi\|_1$$

yields

$$\|D^{\mathbf{e}_i}\psi\| \le C\|\phi\|_1. \tag{2.21}$$

Note that $P_{\tau\mathbf{e}_i}\psi \in S^{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i}(\square)$ for $\tau = h_i$ or H, we obtain

$$\begin{aligned}((R_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i} - R_{\mathbf{h}\hat{\mathbf{e}}_i})u, \phi) &= ((R_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i} - R_{\mathbf{h}\hat{\mathbf{e}}_i})u, (I + K^*)\psi) \\ &= ((I + K)(R_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i} - R_{\mathbf{h}\hat{\mathbf{e}}_i})u, \psi) \\ &= ((I + K)(R_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i} - R_{\mathbf{h}\hat{\mathbf{e}}_i})u, (I - P_{\tau\mathbf{e}_i})\psi)\,.\end{aligned}$$

Since (2.18) is also true when H is replaced by h_i, it follows from using (2.18) and the approximation property of $S^{\tau\mathbf{e}_i}(\square)$ that

$$|((R_{\mathbf{h}\hat{\mathbf{e}}_i + \tau\mathbf{e}_i} - R_{\mathbf{h}\hat{\mathbf{e}}_i})u, \phi)| \le C\tau^2\|D^{\mathbf{e}_i}u\|\|D^{\mathbf{e}_i}\psi\| \le C\tau^2\|D^{\mathbf{e}_i}u\|\|\phi\|_1,$$

which leads to (2.19). ∎

3. The two-scale Boolean Galerkin approximation. This section is devoted to designing and analyzing the two-scale Boolean Galerkin approximation method for solving (2.12). Suppose that $k \in H^1(\square \times \square)$.

Given $H \in (0,1)$, we assume that $H \gg h$ and $T^H((0,1)) \subset T^h((0,1))$. Then the *two-scale Boolean Galerkin approximation* and the *two-scale Boolean iterated Galerkin approximation* are constructed as follows:

$$B^h_{H\mathbf{e}}u = \sum_{i=1}^{d} R_{H\hat{\mathbf{e}}_i + h\mathbf{e}_i}u - (d-1)R_{H\mathbf{e}}u,$$

$$\tilde{B}^h_{H\mathbf{e}}u = \sum_{i=1}^{d} \tilde{R}_{H\hat{\mathbf{e}}_i + h\mathbf{e}_i}u - (d-1)\tilde{R}_{H\mathbf{e}}u.$$

For instance, when $d = 3$, we have

$$B^h_{H,H,H}u = B^h_{H\mathbf{e}}u = R_{h,H,H}u + R_{H,h,H}u + R_{H,H,h}u - 2R_{H,H,H}u,$$

$$\tilde{B}^h_{H,H,H}u = \tilde{B}^h_{H\mathbf{e}}u = \tilde{R}_{h,H,H}u + \tilde{R}_{H,h,H}u + \tilde{R}_{H,H,h}u - 2\tilde{R}_{H,H,H}u,$$

where $\tilde{R}_{h,k,l}u = f - Ku_{h,k,l}$. We want to discuss the superclose property of the two-scale Boolean Galerkin approximation $B^h_{H\mathbf{e}}u$ and investigate the superconvergence property of the Boolean iterated Galerkin approximation $\tilde{B}^h_{H\mathbf{e}}u$.

To analyze the error of the two-scale Boolean Galerkin approximations, we need to establish some estimates for the standard Galerkin projection. First, we need the following conclusions for the L^2-projection.

LEMMA 3.1. *For $i \in \mathbb{Z}_d$, set*

$$g = P_{\mathbf{he}_i}(I + K)(I - P_{\mathbf{he}_i})u. \tag{3.1}$$

If $u \in \mathcal{H}^{\mathbf{e}_i}(\square)$, then

$$\|g\| + h_i\|D^{\mathbf{e}_j}g\| \le Ch_i^2\|D^{\mathbf{e}_i}u\| \quad \forall j \in \mathbb{Z}_d \setminus \{i\}. \tag{3.2}$$

Proof. For $v \in S^{\mathbf{he}_i}(\square)$, we set

$$\phi = (I + K)^* v.$$

Therefore, using the definition of g, we conclude that

$$(g, v) = ((I + K)(I - P_{\mathbf{he}_i})u, v) = ((I - P_{\mathbf{he}_i})u, \phi)\,.$$

Noting that there holds the identity $(I - P_{\mathbf{he}_i})^2 = I - P_{\mathbf{he}_i}$ and noting that the operator $I - P_{\mathbf{he}_i}$ is self-adjoint, it follows that

$$(g, v) = ((I - P_{\mathbf{he}_i})u, (I - P_{\mathbf{he}_i})\phi)\,.$$

The fact that

$$v = P_{\mathbf{he}_i}v \quad \forall v \in S^{\mathbf{he}_i}(\square)$$

implies

$$(g, v) = ((I - P_{\mathbf{he}_i})u, (I - P_{\mathbf{he}_i})K^* v) \quad \forall v \ \in S^{\mathbf{he}_i}(\square).$$

Consequently,

$$|(g,v)| \le Ch_i^2 \|D^{\mathbf{e}_i} u\| \|v\| \quad \forall v \ \in S^{\mathbf{he}_i}(\square).$$

Choosing $v = g$ in the last inequality produces

$$\|g\| \le Ch_i^2 \|D^{\mathbf{e}_i} u\|.$$

Finally, from $P_{\mathbf{he}_i}(I - P_{\mathbf{he}_i}) = 0$, we obtain

$$D^{\mathbf{e}_j} g = D^{\mathbf{e}_j} P_{\mathbf{he}_i} K(I - P_{\mathbf{he}_i})u = P_{\mathbf{he}_i} D^{\mathbf{e}_j} K(I - P_{\mathbf{he}_i})u$$

if $j \in \mathbb{Z}_d \setminus \{i\}$. Hence we have

$$\|D^{\mathbf{e}_j} g\| \le C\|(I - P_{\mathbf{he}_i})u\|, \quad j \in \mathbb{Z}_d \setminus \{i\},$$

which together with (2.3) leads to

$$\|D^{\mathbf{e}_j} g\| \le Ch_i \|D^{\mathbf{e}_i} u\|.$$

This completes the proof. ∎

Using Lemma 3.1, we then obtain the following proposition.

PROPOSITION 3.1. *Suppose that $u \in \mathcal{H}^{\mathbf{e}_i}(\square)(i \in \mathbb{Z}_d)$. Then there exists a function $\psi \in \mathcal{H}^{\mathbf{e}_i}(\square)$ satisfying*

$$R_{\mathbf{h}}((I - P_{\mathbf{he}_i})u) = R_{\mathbf{h}}\psi \tag{3.3}$$

and

$$\|\psi\| + h_i \|D^{\mathbf{e}_j}\psi\| \le Ch_i^2 \|D^{\mathbf{e}_i} u\| \quad \forall j \in \mathbb{Z}_d \setminus \{i\}. \tag{3.4}$$

Proof. Set $g = P_{\mathbf{he}_i}(I + K)(I - P_{\mathbf{he}_i})u$. Then from Lemma 3.1, we conclude that

$$\|g\| + h_i \|D^{\mathbf{e}_j} g\| \le Ch_i^2 \|D^{\mathbf{e}_i} u\| \quad \forall j \in \mathbb{Z}_d \setminus \{i\}. \tag{3.5}$$

If $\psi = (I + K)^{-1} g$, then $\psi \in \mathcal{H}^{\mathbf{e}_i}(\square)$ satisfies (3.3) (see [24]) and has the estimates

$$\|\psi\| \le C\|g\|, \tag{3.6}$$

$$\|D^{\mathbf{e}_j}\psi\| \le C(\|D^{\mathbf{e}_j} g\| + \|g\|) \quad \forall j \in \mathbb{Z}_d \setminus \{i\}. \tag{3.7}$$

Combining (3.5), (3.6), and (3.7), we get (3.4). ∎

Now we turn to studying the hierarchical surplus, the difference between the two-scale Boolean Galerkin and the standard Galerkin approximations.

PROPOSITION 3.2. *Suppose that $\tau \in \{h, H\}^d, i, j \in \mathbb{Z}_d$, and $i \ne j$. If $u \in H^1(\square)$, then*

$$\|\delta_h^{\mathbf{e}_j} R_\tau (I - P_{\tau\mathbf{e}_i})u\| \le CH^2 \|u\|_1 \tag{3.8}$$

and

$$\|\delta_h^{\mathbf{e}_j} R_\tau (I - P_{\tau\mathbf{e}_i})u\|_{-1} \le CH^3 \|w\|_1. \tag{3.9}$$

Proof. Let $\psi \in H^1(\square)$ satisfy (3.3) when $\mathbf{h}$ is replaced by τ. By Propositions 3.1 and 2.7, we have

$$\|\delta_h^{\mathbf{e}_j} R_\tau (I - P_{\tau\mathbf{e}_i})u\| = \|\delta_h^{\mathbf{e}_j} R_\tau \psi\| \le CH \|D^{\mathbf{e}_j}\psi\| \le CH^2 \|u\|_1$$

and

$$\|\delta_h^{\mathbf{e}_j} R_\tau (I - P_{\tau \mathbf{e}_i}) u\|_{-1} = \|\delta_h^{\mathbf{e}_j} R_\tau \psi\|_{-1} \le C H^2 \|D^{\mathbf{e}_j} \psi\| \le C H^3 \|u\|_1. \qquad \square$$

Next, we estimate the error of the two-scale Boolean Galerkin approximation.

THEOREM 3.1. *If $u \in H^{1,2}(\square)$, then*

$$\|B_{H\mathbf{e}}^h u - R_{h\mathbf{e}} u\| \le C H^2 \|u\|_{H^{1,2}}$$

and

$$\|B_{H\mathbf{e}}^h u - R_{h\mathbf{e}} u\|_{-1} \le C H^3 \|u\|_{H^{1,2}}.$$

Consequently,

$$\|u - B_{H\mathbf{e}}^h u\| \le C(h + H^2) \|u\|_{H^{1,2}}$$

and

$$\|u - B_{H\mathbf{e}}^h u\|_{-1} \le C(h^2 + H^3) \|u\|_{H^{1,2}}.$$

Proof. For $w_{h\mathbf{e}} \in S^{h\mathbf{e}}(\square)$, define

$$\delta_H w_{h\mathbf{e}} = B_H^h w_{h\mathbf{e}} - w_{h\mathbf{e}}.$$

Then (2.11) implies

$$\delta_H w_{h\mathbf{e}} = - \sum_{|\beta|=2}^{d} (-1)^{|\beta|} \delta_h^\beta w_{H\mathbf{e}}. \tag{3.10}$$

From the identity

$$I - P_{\mathbf{h}} = - \sum_{0 \le \alpha \le \mathbf{e}, |\alpha| \ge 1} (-1)^{|\alpha|} \prod_{0 \le \beta \le \alpha, |\beta| = 1} (I - P_{\mathbf{h}\beta}),$$

we obtain

$$\|\delta_H R_{h\mathbf{e}} u\| \le \|\delta_H R_{h\mathbf{e}} P_{h\mathbf{e}} u\| + \sum_{0 \le \alpha \le \mathbf{e}, |\alpha| \ge 1} \left\| \delta_H R_{h\mathbf{e}} \prod_{0 \le \beta \le \alpha, |\beta| = 1} (I - P_{h\beta}) u \right\|$$

or

$$\|\delta_H R_{h\mathbf{e}} u\| \le \|\delta_H P_{h\mathbf{e}} u\| + \sum_{0 \le \alpha, |\alpha| = 1} \|\delta_H R_{h\mathbf{e}} (I - P_{h\alpha}) u\|$$

$$+ \sum_{0 \le \alpha \le \mathbf{e}, |\alpha| \ge 2} \left\| \delta_H R_{h\mathbf{e}} \prod_{0 \le \beta \le \alpha, |\beta| = 1} (I - P_{h\beta}) u \right\|.$$

Using the stability

$$\|R_{\mathbf{h}} w\| + \|P_{\mathbf{h}} w\| \le C \|w\| \quad \forall w \in L^2(\square),$$

we can then estimate the term

$$\sum_{0\le\alpha\le\mathbf{e},|\alpha|\ge 2}\left\|\delta_H R_{h\mathbf{e}}\prod_{0\le\beta\le\alpha,|\beta|=1}(I-P_{h\beta})u\right\|$$

as follows:

$$\sum_{0\le\alpha\le\mathbf{e},|\alpha|\ge 2}\left\|\delta_H R_{h\mathbf{e}}\prod_{0\le\beta\le\alpha,|\beta|=1}(I-P_{h\beta})u\right\|$$
$$\le C\sum_{0\le\alpha\le\mathbf{e},|\alpha|\ge 2}\max_{\tau\in\{h,H\}^d}\left\|\prod_{0\le\beta\le\alpha,|\beta|=1}(I-P_{\tau\beta})u\right\|,$$

while the identity

$$\sum_{0\le\alpha,|\alpha|=1}\delta_H R_{h\mathbf{e}}(I-P_{h\alpha})=-\sum_{0\le\alpha,|\alpha|=1}\sum_{|\beta|=2}^{d}(-1)^{|\beta|}\delta_h^{\beta}R_{H\mathbf{e}}(I-P_{H\alpha}),$$

which can be derived directly from (3.10), leads to

$$\left\|\sum_{0\le\alpha,|\alpha|=1}\delta_H R_{h\mathbf{e}}(I-P_{h\alpha})u\right\|\le C\max_{\tau\in\{h,H\}^d}\sum_{i,j\in\mathbb{Z}_d,i\ne j}\|\delta_h^{\mathbf{e}_j}R_\tau(I-P_{\tau\mathbf{e}_i})u\|.$$

Hence we have

$$\|\delta_H R_{h\mathbf{e}}u\|\le\|\delta_H P_{h\mathbf{e}}u\|+C\sum_{i,j\in\mathbb{Z}_d,i\ne j}\|\delta_h^{\mathbf{e}_j}R_{H\mathbf{e}}(I-P_{H\mathbf{e}_i})u\|$$
$$+C\sum_{0\le\alpha\le\mathbf{e},|\alpha|\ge 2}\max_{\tau\in\{h,H\}^d}\left\|\prod_{0\le\beta\le\alpha,|\beta|=1}(I-P_{\tau\beta})u\right\|.$$

Finally, we prove the first estimate of this theorem from the above estimate and Propositions 2.1, 2.3, and 3.2. The second estimate can be proved similarly. ∎

As for the two-scale Boolean iterated Galerkin approximation $\tilde{B}^h_{H\mathbf{e}}u$, we obtain the following theorem.

THEOREM 3.2. *If $u\in H^{1,2}(\square)$, then*

$$\|\tilde{B}^h_{H\mathbf{e}}u-\tilde{R}_{h\mathbf{e}}u\|\le CH^3\|u\|_{H^{1,2}}.$$

Consequently,

$$\|u-\tilde{B}^h_{H\mathbf{e}}u\|\le C(h^2+H^3)\|u\|_{H^{1,2}}.$$

Proof. By the definition of $\tilde{R}_{h\mathbf{e}}u$ and $B^h_{H\mathbf{e}}u$, we have the identity

$$\tilde{B}^h_{H\mathbf{e}}u-\tilde{R}_{h\mathbf{e}}u=-K(B^h_{H\mathbf{e}}u-R_{h\mathbf{e}}u).$$

Hence we obtain

$$\|\tilde{B}^h_{H\mathbf{e}}u-\tilde{R}_{h\mathbf{e}}u\|=\|-K(B^h_{H\mathbf{e}}u-R_{h\mathbf{e}}u)\|$$
$$\le C\|B^h_{H\mathbf{e}}u-R_{h\mathbf{e}}u\|_{-1}\le CH^3\|u\|_{H^{1,2}}.$$

This completes the proof. □

Finally, we construct a defect correction approximation $R_{H\mathbf{e}}u+\tilde{B}^h_{H\mathbf{e}}u-R_{H\mathbf{e}}\tilde{B}^h_{H\mathbf{e}}u$, for which we have the following theorem.

THEOREM 3.3. *If* $u \in H^{1,2}(\square)$, *then*

$$\|u - R_{H\mathbf{e}}u - \tilde{B}^h_{H\mathbf{e}}u + R_{H\mathbf{e}}\tilde{B}^h_{H\mathbf{e}}u\| \le CH(h^2 + H^3)\|u\|_{H^{1,2}}. \tag{3.11}$$

Proof. From the definition of $\tilde{B}^h_{H,H,H}u$, we get

$$(I - R_{H\mathbf{e}})(u - \tilde{B}^h_{H\mathbf{e}}u) = -(I - R_{H\mathbf{e}})K(u - B^h_{H\mathbf{e}}u).$$

Thus, Proposition 2.4 and Theorem 3.2 yield

$$\begin{aligned}\|(I - R_{H\mathbf{e}})(u - \tilde{B}^h_{H\mathbf{e}}u)\| &\le CH\| - K(u - B^h_{H\mathbf{e}}u)\|_1 \\ &\le CH\|u - B^h_{H\mathbf{e}}u\|_{-1} \le CH(h^2 + H^3)\|u\|_{H^{1,2}}.\end{aligned}$$

Noting that $u - R_{H\mathbf{e}}u - \tilde{B}^h_{H\mathbf{e}}u + R_{H\mathbf{e}}\tilde{B}^h_{H\mathbf{e}}u$ is nothing but $(I - R_{H\mathbf{e}})(u - \tilde{B}^h_{H\mathbf{e}}u)$, we conclude that (3.11) is valid. □

4. Numerical experiments. In this paper, we have presented and analyzed three two-scale finite element discretizations for a class of Fredholm integral equations. It is perhaps a little too much of an undertaking to carry out and report numerical experiments for less smooth solutions in the current work, since there are some practical issues that need to be taken into account carefully. For illustration, we choose to report some two- and three-dimensional numerical experiments only for smooth solutions.

In two-dimensional examples, we use four piecewise constant finite elements that are of mesh sizes $h \times H$, $H \times h$, $H \times H$, and $h \times h$, respectively. Our two-scale finite element approximation is denoted by $B^h_{H,H}u = R_{h,H}u + R_{H,h}u - R_{H,H}u$. In three-dimensional cases, we use five piecewise constant finite elements that are of mesh sizes $h \times H \times H$, $H \times h \times H$, $H \times H \times h$, $H \times H \times H$, and $h \times h \times h$, respectively. The two-scale finite element approximation is constructed by $B^h_{H,H,H}u = R_{h,H,H}u+R_{H,h,H}u+R_{H,H,h}u - 2R_{H,H,H}u$. In all of our numerical experiments, we choose $h = H^2$. Our numerical experiments are carried out on SGI Origin 3800 at the State Key Laboratory of Scientific and Engineering Computing, Chinese Academy of Sciences.

Example 1. Consider an integral equation of the second kind in $\mathbb{R}^2$:

$$u(x_1, x_2) + \int_0^1 \int_0^1 x_1 x_2 \exp(y_1 + y_2)u(y_1, y_2)dy_1dy_2 = \exp(-x_1 - x_2) \text{ in } \square \tag{4.1}$$

with an exact solution $u = \exp(-x_1 - x_2) - \frac{1}{2}x_1x_2$, where $\square = (0, 1)^2$.

It is observed from Table 1 that not only does the two-scale finite element approximation $B^h_{H,H}u$ have a high accuracy, but also the number of the degrees of freedom for obtaining $B^h_{H,H}u$ is only of $O(1/h \times 1/H) = O(h^{-3/2})$, while that for the standard finite element solution $B_{h,h}u$ is of $O(h^{-2})$ when $h = H^2$. For instance, the accuracy of the two-scale finite element approximation $B^h_{H,H}u$ with 1,000 degrees of freedom is asymptotically the same as that of the standard finite element solution $R_{h,h}u$ with 10,000 degrees of freedom. The numerical results, stated in Table 1, support our theory (see Theorem 3.1). Hence $B^h_{H,H}u$ is a much better solution in terms of computational cost. Moreover, we can carry out the major computation in parallel. As a result, the computational scale is reduced and the computational time is saved.

Example 1: L^2-*estimates for* $\tilde{B}^h_{H,H}u$.

$\frac{1}{h} \times \frac{1}{H}$	$\|\tilde{B}^h_{H,H}u - \tilde{R}_{h,h}u\|$	$\|u - \tilde{R}_{h,h}u\|$
4×2	0.00011373	0.00325378
16×4	0.00001086	0.00020183
64×8	0.00000074	0.00001260
81×9	0.00000046	0.00000787
100×10	0.00000030	0.00000516

It is shown from Theorem 3.1 that the iterated Galerkin approximation $\tilde{R}_{h,h}u$ and the corresponding two-scale combination solution $\tilde{B}^h_{H,H}u$ have a higher accuracy than the standard Galerkin approximation $R_{h,h}u$ and $B^h_{H,H}u$, respectively, which are supported by our numerical results, too (see Table 2).

For a three-dimensional example, we consider the integral equation

$$u(x_1,x_2,x_3) + \int_0^1\int_0^1\int_0^1 x_1x_2x_3\exp(y_1+y_2+y_3)u(y_1,y_2,y_3)dy_1dy_2dy_3 = \exp(-x_1-x_2-x_3) \text{ in } \square \tag{4.2}$$

with an exact solution $u = \exp(-x_1 - x_2 - x_3) - \frac{1}{2}x_1x_2x_3$, where $\square = (0,1)^3$.

It is not easy to solve (4.2), since the linear system for (4.2) is a dense matrix and the degree of freedom increases rapidly when the mesh size h decreases. More precisely, it is getting more and more difficult to compute $R_{h,h,h}u$ when h is smaller and smaller because of the memory limit and the speed of solving the huge linear system. However, it is relatively easy to get an approximation $B^h_{H,H,H}u$ that is asymptotically the same as that of $R_{h,h,h}u$ when $h = H^2$ (see Table 3). For instance, when $h = 1/100$, it is not possible for us to obtain $\|u - R_{h,h,h}u\|$ through computing $R_{h,h,h}u$ (in our SGI Origin 3800), but it is very easy to get $\|u - B^h_{H,H,H}u\|$.

It is observed from Table 3 that the approximate accuracy of the two-scale finite element approximation $B^h_{H,H,H}u$ with 10,000 degrees of freedom is asymptotically the same as that of the standard finite element solution $R_{h,h,h}u$ with 1,000,000 degrees of freedom, which coincides with our theory (see Theorem 3.1). It is shown by Table 3 that not only is the degree of freedom for obtaining $B^h_{H,H,H}u$ only of $O(1/h \times 1/H \times 1/H) = O(h^{-2})$ while that for the standard finite element solution $R_{h,h,h}u$ is of $O(h^{-3})$ when $h = H^2$, but also the two-scale combination solution $B^h_{H,H,H}u$ has high accuracy. Hence $B^h_{H,H,H}u$ is a much better solution in terms of computational cost. Moreover, it is shown from Theorem 3.2 that the iterated Galerkin solutions $\tilde{R}_{h,h,h}u$ and $\tilde{B}^h_{H,H,H}u$ are more accurate than $R_{h,h,h}u$ and $B^h_{H,H,H}u$, respectively. The results shown in Table 3 are in accordance with our theory, too.

In the computation, however, it takes much more time to get $\tilde{R}_{h,h,h}u$ and $\tilde{B}^h_{H,H,H}u$

TABLE 3
Example 1: L^2*-estimates for* $B^h_{H,H,H}u$ *and* $\tilde{B}^h_{H,H,H}u$.

$\frac{1}{h}\times\frac{1}{H}\times\frac{1}{H}$	$\|u-B^h_{H,H,H}u\|$	$\|u-\tilde{B}^h_{H,H,H}u\|$	$\|u-R_{h,h,h}u\|$	$\|u-\tilde{R}_{h,h,h}u\|$
4×2×2	0.04918028	0.00262928	0.04875677	0.00282859
16×4×4	0.01237953	0.00015595	0.01221095	0.00017483
64×8×8	0.00309985			
81×9×9	0.00244954			
100×10×10	0.00198428			

than to get $R_{h,h,h}u$ and $B^h_{H,H,H}u$, respectively. The reason is that it is time-consuming to compute $KR_{h,h,h}u$ and $KB^h_{H,H,H}u$. As a result, we may conclude that $B^h_{H,H,H}u$ is better than $\tilde{B}^h_{H,H,H}u$ in terms of the efficiency of computation. Similarly, it also takes much more time to get $R_{H,H,H}u-\tilde{B}^h_{H,H,H}u+R_{H,H,H}\tilde{B}^h_{H,H,H}u$ than to get $B^h_{H,H,H}u$, though $R_{H,H,H}u-\tilde{B}^h_{H,H,H}u+R_{H,H,H}\tilde{B}^h_{H,H,H}u$ has a higher accuracy than $B^h_{H,H,H}u$ (see Theorem 3.3). Taking the efficiency into account, it may be concluded that $B^h_{H,H,H}u$ would be a very good approximation and would be recommended.

Example 2. Consider an integral equation of the second kind in $\mathbb{R}^2$:

$$u(x_1,x_2)-\int_0^1\int_0^1\exp(x_1y_1+x_2y_2)u(y_1,y_2)dy_1dy_2=f(x_1,x_2)\ \text{ in }\square \tag{4.3}$$

with an exact solution $u=\exp(x_1+x_2)$ and

$$f(x_1,x_2)=\exp(x_1+x_2)-\prod_{i=1}^{2}((\exp(x_i+1)-1)/(x_i+1)),$$

where $\square=(0,1)^2$. It is noted that the global stiff matrix of (4.3) is symmetric but not positive definite. As a result, we adopt the GMRES method to solve the discrete system of (4.3).

In the three-dimensional case, we consider the following integral equation:

$$u(x_1,x_2,x_3)-\int_0^1\int_0^1\int_0^1\exp\left(\sum_{i=1}^{3}(x_iy_i)\right)u(y_1,y_2,y_3)dy_1dy_2dy_3=f(x_1,x_2,x_3)\text{ in }\square \tag{4.4}$$

with an exact solution $u=\exp(x_1+x_2+x_3)$ and

$$f(x_1,x_2,x_3)=\exp(x_1+x_2+x_3)-\prod_{i=1}^{3}((\exp(x_i+1)-1)/(x_i+1)),$$

where $\square=(0,1)^3$.

It is shown by Tables 4, 5, and 6 that the numerical results of Example 2 support our theory again.

5. Concluding remarks. In this paper, we have proposed and analyzed several two-scale Boolean Galerkin discretizations for Fredholm integral equations of the second kind. It is shown by both theory and numerics that these new discretizations are very efficient for solving integral equations in multidimensions. Since the computational cost and storage requirement of the two-scale discretizations still grow

exponentially with the dimensionality, however, our methods may not be applicable for very high-dimensional problems. What we discussed here is only for piecewise constant elements. Indeed, similar results can be expected for higher-order elements. It should also be mentioned that the same discretizations can be applied to solve integral eigenvalue problems as well as nonlinear integral equations, which is our ongoing research project.

CONVERGENCE ANALYSIS OF A QUASI-CONTINUUM APPROXIMATION FOR A TWO-DIMENSIONAL MATERIAL WITHOUT DEFECTS*

PING LIN†

Abstract. In many applications, materials are modeled by a large number of particles (or atoms), where any particle can interact with any other. The computational cost is very high since the number of atoms is huge. Recently much attention has been paid to a so-called quasi-continuum (QC) method, which is a mixed atomistic/continuum model. The QC method uses an adaptive finite element framework to effectively integrate the majority of the atomistic degrees of freedom in regions where there is no serious defect. However, numerical analysis of this method is still in its infancy. In this paper we will conduct a convergence analysis of the QC method in the case when there is no defect. We will also remark on the case when the defect region is small. The difference between our analysis and conventional analysis is that our exact atomistic solution is not a solution of a continuous partial differential equation, but a discrete lattice scale solution which is not approximately related to any conventional partial differential equation.

Key words. lattice statics, Lennard–Jones potential, global minimization, finite element method, quasi-continuum approximation, material defects

1. Introduction.

The analysis of the structure of material, and defects of material such as dislocations or fractures, often involves the effect of the lattice on the scale. Directly solving the whole system (lattice statics) provides an accurate solution for analysis on this scale. However, because the number of atomistic particles in a material is huge, it is often impossible to directly solve the whole system to obtain the material properties. The fact that in many practical problems defects occur only in some local and small regions may help with the design of approximation or reduction methods for the original huge problem. The quasi-continuum (QC) approximation recently gained attention in the engineering literature (cf. [13, 3, 21, 17]). The idea is that we can consider the region (called the local approximation region), where no defects occur, at the macroscopic scale, and the theory of continuum material elasticity may apply. The model enables a treatment of lattice defects—should these defects arise—and exhibits a continuous transition from the lattice to the continuum realms at intermediate length scales. It is incorporated with the (nonconforming) finite element method and is expected to be an approximation of the full lattice-scale model. There are other models that couple atomistic/finite element methods and that employ some sort of handshaking region at the atomistic/FEM interface [12, 1, 18]. A major strength of the QC method is its ability to adaptively mesh as the deformation gradient changes, such that regions can switch between microscopic and continuum measures of the energy as needed. Further improvement of the method can also be founded in the literature; see, e.g., [20].

While a significant body of knowledge about QC related models and their experimental and numerical tests has been accumulated, not much has been reported

on the analysis of the approximation error of these models. The convergence rate of the QC method is analyzed in [11] via computational results of a specific nanoindentation problem. Other numerical tests can also be found in [21, 19]. In [7] the QC method has been related to a heterogeneous multiscale framework based on a linear homogenization technique. In [14] the QC method is analyzed for a one-dimensional atomic chain without external forces. An analysis with an external force is conducted in [4] for the nearest neighbor interaction. Other relevant work may be found in [8, 2, 9, 6, 15]. The aim of this paper is to present an error analysis between the solution of the original lattice-scale atomic system and the solution of its QC approximation for multidimensional materials with conservative external forces. We will consider only a two-dimensional material in this paper.

Let $X_\ell = (x_\ell, y_\ell)$ represent the coordinates of an atom or particle ℓ (i.e., the location of the atom ℓ in a reference configuration). We collect all these reference positions of atoms in a vector X. The position of the atom ℓ in the deformed configuration is denoted as z_ℓ. We collect all deformed atomic positions in a vector z. See Figure 1.

We shall assume that the atoms interact with each other via a pair-interacting potential $\phi(r)$, where r is the distance between the pairs of atoms. The shape of the function, shown in Figure 2, is usually nonconvex. The popular 6-12 Lennard–Jones

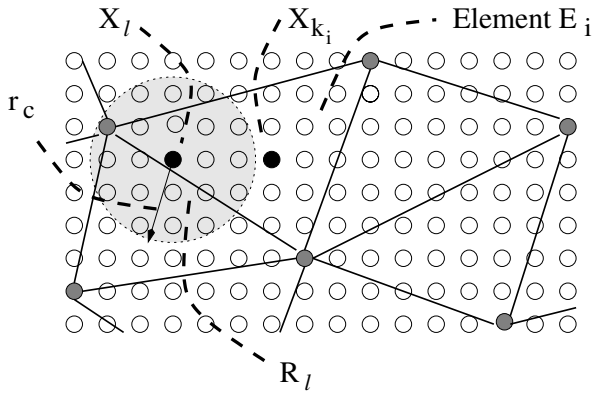

FIG. 3. *Triangulation and notation.*

potential (see Frank and van der Merwe [10])

$$\phi(r) = \phi_{min}\left[-2\left(\frac{r_0}{r}\right)^6 + \left(\frac{r_0}{r}\right)^{12}\right] \tag{1}$$

is one example of such a function. We shall do our analysis for a potential function of this type. Obviously r_0 is the minimal point of $\phi(r)$. We may assume that r_0 is the grid size of atomic position X in the reference configuration (called a lattice constant). Later we shall also assume that the nearest neighbor atomic interaction dominates farther interactions based on the solid material property.

The meaning of the *defect* in this paper is given as follows. If there is no defect, any pair of nearest neighbor atoms, say located at z_k and z_ℓ, should have such a distance $r_{k\ell} = |z_k - z_\ell|$, where $\phi(r_{k\ell})$ is convex (i.e., $r_{k\ell} < r_1$). Basically, if $r_{k\ell} < r_1$ but is close to r_1, the material has or starts to have a defect; if $r_{k\ell} \geq r_1$ (i.e., $r_{k\ell}$ is in the nonconvex region of $\phi(r)$), then we think that the material has a serious defect. If the external forces on the material are so strong that some pairs of nearest neighbor atoms are in the nonconvex region of $\phi(r)$, the convergence analysis may be problematic (if not impossible) since the solution at the lattice scale may not be unique. So in our analysis we shall assume that pairs of nearest neighbor atoms are in the convex region of $\phi(r)$, as described in section 3. In this paper we mainly consider the material with no serious defects. We shall remark on the defect case as well.

Later, when considering the QC approximation we need to triangulate the reference domain, as the finite element method usually does. In order to describe the total potential energy and the approximate energy in a consistent way, we consider a triangulation of the domain at this early stage, which is shown in Figure 3. We shall assume that the triangular mesh satisfies usual regular conditions. R_ℓ is a disc region with radius r_c centered at the atom X_ℓ. Only atoms in the disc R_ℓ will be counted for interaction with the atom X_ℓ. In practice, r_c is taken as twice the potential cut-off radius.

Assume that the external force is conservative and its corresponding external potential is denoted as $F(z)$. Define $f(z) = F_z(z)$. The total potential energy reads

$$E(z) = \frac{1}{2}\sum_{i=1}^{N}\sum_{k=1}^{m_i}\sum_{\ell\in R_k}\phi(|z_k - z_\ell|) + \sum_{i=1}^{N}\sum_{k=1}^{m_i}F(z_k), \tag{2}$$

where, and in what follows, the letter i is specially assigned to the index for the ith triangular element E_i, and the index of the three vertices of the element E_i will be denoted as i_1, i_2, and i_3. k is the index[1] for atoms in the element E_i, m_i is the number of atoms in E_i, and N is the number of triangular elements. $|\cdot|$ represents the Euclidean length of a vector in $\mathbf{R}^2$. Obviously, we should also have $\ell \neq k$ in the summation $\Sigma_{\ell \in R_k}$ since an atom cannot interact with itself. For simplicity of notation we just drop the self-interaction condition $\ell \neq k$ throughout the paper. We shall also assume Dirichlet boundary conditions in a bounded material domain Ω.

According to physical principle (cf. [21]) stable configuration of the material is identified with the minimizer of the potential energy $E(z)$:

$$E(\hat{z}) = \min_z E(z). \tag{3}$$

Let $z = \hat{z} + tv$ (or $z_\ell = \hat{z}_\ell + tv_\ell$). From

$$\frac{d}{dt} E(\hat{z} + tv)|_{t=0} = 0,$$

we can obtain the variational formulation of (3):

$$a(\hat{z}, v) = \frac{1}{2} \sum_{i=1}^{N} \sum_{k=1}^{m_i} \sum_{\ell \in R_k} \frac{\phi'(|\hat{z}_\ell - \hat{z}_k|)}{|\hat{z}_\ell - \hat{z}_k|} (\hat{z}_\ell - \hat{z}_k) \cdot (v_\ell - v_k) = -\sum_{i=1}^{N} \sum_{k=1}^{m_i} f(\hat{z}_k) \cdot v_k \quad \forall v, \tag{4}$$

where the solution $\hat{z}$ satisfies Dirichlet boundary conditions.

The rest of the paper is organized as follows. In section 2 we introduce the QC approximation similarly to the original lattice-scale problem given above. Roughly speaking, it corresponds to a nonconforming finite element approximation of (4). In section 3 we present a few assumptions and justifications for existence and uniqueness of the lattice-scale solution. Finally, in section 4 we estimate the error of the QC approximation in cases with no serious defect. Roughly speaking, we mainly assume (i) all nearest neighbor pairs of atoms in a convex region of ϕ, and (ii) nearest neighbor interaction dominates further interaction. Under these assumptions we show that the error of QC approximation is of $O(h)$ plus a nonconforming error term which is related to the number of atoms in each element and each element's boundaries. Here h is the largest side of the triangulation. We also remark on a possible error estimate in the case when the above assumptions do not hold or serious defects occur in a relatively small region.

2. QC approximation. Now we describe the QC approximation combined with a nonconforming finite element idea to problem (3). Our description follows [21], but our unknown vector is the deformed atomic position vector in order to be consistent with the original lattice-scale problem described above. Essentially our formulation should be the same as that in [21]. A triangulation is already given in the previous section. Assume in each triangle E_i, shown in Figure 4, that the atoms are deformed linearly, which corresponds to using a piecewise linear function to approximate the solution in the finite element context. As mentioned in the previous section, we denote the three vertices of the element E_i by X_{i_1}, X_{i_2}, and X_{i_3}. Let $X_{i_j} = (x_{i_j}, y_{i_j})^T$,

[1] We should use a double index such as (i, k) to represent an atom k in the element E_i. For simplicity of notation without significant ambiguity we use k instead of (i, k).

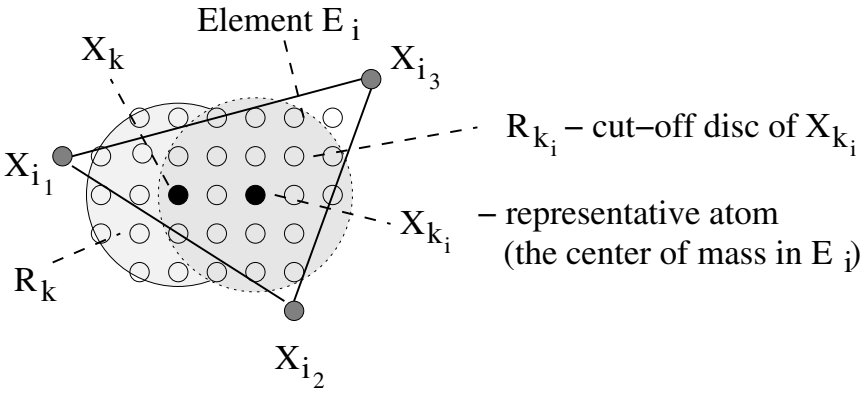

FIG. 4. *One triangular element.*

$j = 1, 2, 3$, be vertices of the triangular element E_i and Δ_i be its area. Define piecewise linear basis functions (denoting $X_\ell = (x_\ell, y_\ell)^T$):

$$\psi_{i_1}(X_\ell) = \frac{x_{i_2}y_{i_3} - x_{i_3}y_{i_2}}{2\Delta_i} + \frac{y_{i_2} - y_{i_3}}{2\Delta_i}x_\ell + \frac{x_{i_3} - x_{i_2}}{2\Delta_i}y_\ell,$$
$$\psi_{i_2}(X_\ell) = \frac{x_{i_3}y_{i_1} - x_{i_1}y_{i_3}}{2\Delta_i} + \frac{y_{i_3} - y_{i_1}}{2\Delta_i}x_\ell + \frac{x_{i_1} - x_{i_3}}{2\Delta_i}y_\ell,$$
$$\psi_{i_3}(X_\ell) = \frac{x_{i_1}y_{i_2} - x_{i_2}y_{i_1}}{2\Delta_i} + \frac{y_{i_1} - y_{i_2}}{2\Delta_i}x_\ell + \frac{x_{i_2} - x_{i_1}}{2\Delta_i}y_\ell.$$

In each element E_i the derivatives $\nabla_{x,i}\psi_{i_j}$ and $\nabla_{y,i}\psi_{i_j}$ of ψ_{i_j} are constant, and we denote the derivative within the element i as $\nabla_i\psi_{i_j} = (\nabla_{x,i}\psi_{i_j}, \nabla_{y,i}\psi_{i_j})^T$. We can express the position of the representative atom k_i (the atom closest to the center of mass of the element E_i) and any atom ℓ in the element E_i using these basis functions, i.e.,

$$Z_{k_i} = \psi_{i_1}(X_{k_i})Z^h_{i_1} + \psi_{i_2}(X_{k_i})Z^h_{i_2} + \psi_{i_3}(X_{k_i})Z^h_{i_3}, \tag{5}$$
$$Z_\ell = \psi_{i_1}(X_\ell)Z^h_{i_1} + \psi_{i_2}(X_\ell)Z^h_{i_2} + \psi_{i_3}(X_\ell)Z^h_{i_3}, \tag{6}$$

where Z^h is a vector collecting all positions of atoms at the vertices of the triangulation, and $Z = (Z_\ell)$ is a vector collecting all positions of atoms (defined by (6)) at every lattice node X_ℓ. We can define their derivatives (constant) as well:

$$\nabla^h_{s,i}Z = \nabla^h_{s,i}Z_{k_i} = \nabla^h_{s,i}Z_\ell = \sum_{j=1}^{3} \nabla_{s,i}\psi_{i_j}Z^h_{i_j}, \tag{7}$$

where s may be x or y and $\ell \in E_i$. We can also write

$$Z_\ell - Z_{k_i} = \sum_{j=1}^{3} \left(\psi_{i_j}(X_\ell) - \psi_{i_j}(X_{k_i})\right) Z^h_{i_j} = \sum_{j=1}^{3} (X_\ell - X_{k_i}) \cdot \nabla_i\psi_{i_j}Z^h_{i_j}$$
$$= (x_\ell - x_{k_i})\nabla^h_{x,i}Z + (y_\ell - y_{k_i})\nabla^h_{y,i}Z. \tag{8}$$

The cut-off disc R_{k_i} could include atoms of a few triangular elements in the so-called nonlocal approximation (cf. [21]). If an atom $\ell \in R_{k_i}$ is not in the element E_i but in

another element $E_{i'}$, then we can express its approximate position in a similar way according to the vertices and basis function associated with $E_{i'}$:

$$Z_\ell = \psi_{i'_1}(X_\ell)Z^h_{i'_1} + \psi_{i'_2}(X_\ell)Z^h_{i'_2} + \psi_{i'_3}(X_\ell)Z^h_{i'_3}.$$

In the case when there is no serious defect, local approximation is enough and no nonlocal approximation is necessary.

The idea of the QC method is the following: The potential energy associated with any atom k in the triangular element E_i is approximately equal to the potential energy associated with the representative atom k_i. That is,

$$\sum_{\ell\in R_k} \phi(|z_\ell - z_k|) \approx \sum_{\ell\in R_{k_i}} \phi(|z_\ell - z_{k_i}|), \tag{9}$$

where R_k and R_{k_i} are cut-off discs of atomic interaction associated with the atom k and the representative atom k_i, respectively. With the QC approximation we can write an approximate total potential energy of (2) as follows:

$$E_{qc}(Z^h) = \frac{1}{2}\sum_{i=1}^{N} m_i \sum_{\ell\in R_{k_i}} \phi(|Z_\ell - Z_{k_i}|) + \sum_{i=1}^{N}\sum_{k=1}^{m_i} F(Z_k), \tag{10}$$

where Z_ℓ, Z_k, and Z_{k_i} are defined as in (6) and (5), and Z^h is a vector collecting all positions of atoms at the vertices of the triangulation, e.g., $Z^h_{i_1}$, $Z^h_{i_2}$, $Z^h_{i_3}$, etc. The approximate stable configuration $\hat{Z}^h$ is identified with the minimizer of the approximate potential energy $E_{qc}(Z^h)$:

$$E_{qc}(\hat{Z}^h) = \min_{Z^h} E_{qc}(Z^h). \tag{11}$$

Note that in [21] deformation gradients defined on triangles are used as minimization variables. We do the minimization with respect to positions of atoms at the vertices of the triangulation in order to make it consistent with the original problem (3), and consequently convergence analysis may be conducted with less difficulty. Let $Z^h = \hat{Z}^h + tV^h$ (or $Z^h_{i_j} = \hat{Z}^h_{i_j} + tV^h_{i_j}$). From $\frac{d}{dt}E_{qc}(\hat{Z}^h + tV^h)|_{t=0} = 0$ we then obtain the approximate variational formulation

$$\begin{aligned} a_h(\hat{Z}, V) &= \frac{1}{2}\sum_{i=1}^{N} m_i \sum_{\ell\in R_{k_i}} \frac{\phi'(|\hat{Z}_\ell - \hat{Z}_{k_i}|)}{|\hat{Z}_\ell - \hat{Z}_{k_i}|}(\hat{Z}_\ell - \hat{Z}_{k_i})\cdot(V_\ell - V_{k_i}) \\ &= -\sum_{i=1}^{N}\sum_{k=1}^{m_i} f(\hat{Z}_k)\cdot V_k \quad \forall V, \end{aligned} \tag{12}$$

where the solution $\hat{Z}^h$ satisfies Dirichlet boundary conditions, and $\hat{Z}_\ell$, $\hat{Z}_{k_i}$, $\hat{Z}_k$, V_ℓ, V_{k_i}, and V_k are defined similarly to Z_ℓ and Z_{k_i} as in (6) and (5) (the only difference is that $Z^h_{i_j}$ is replaced by $\hat{Z}^h_{i_j}$ and $V^h_{i_j}$, $j = 1, 2, 3$). It corresponds to a nonconforming method in the finite element context. The difference between our analysis and conventional finite element analysis is that our exact solution is not a solution of a continuous partial differential equation but a discrete lattice-scale solution which may not be related to any conventional partial differential equation. Let $g(\alpha) = \phi_\alpha(|\alpha|) = \frac{\phi'(|\alpha|)}{|\alpha|}\alpha$. We can write

$$a_h(\hat{Z}, V) = \frac{1}{2}\sum_{i=1}^{N} m_i \sum_{\ell\in R_{k_i}} g(\hat{Z}_\ell - \hat{Z}_{k_i})\cdot(V_\ell - V_{k_i}) \quad \forall V. \tag{13}$$

3. Assumptions and uniqueness of the lattice-scale solution. The objective of this section is mainly to make a few assumptions for conducting the error analysis to be presented in the next section. The derivative of $g(\alpha)$ is important in the analysis. We first state a simple lemma.

LEMMA 1. *If two vectors $\alpha = (\alpha_1, \alpha_2)^T$ and $\beta = (\beta_1, \beta_2)^T$ are not in the same direction, i.e., $\alpha_1\beta_2 \neq \alpha_2\beta_1$, then the matrix*

$$\begin{pmatrix} \alpha_1^2 & \alpha_1\alpha_2 \\ \alpha_1\alpha_2 & \alpha_2^2 \end{pmatrix} + \begin{pmatrix} \beta_1^2 & \beta_1\beta_2 \\ \beta_1\beta_2 & \beta_2^2 \end{pmatrix}$$

is symmetric, positive definite, and has eigenvalues $\geq \frac{|\alpha|^2|\beta|^2}{|\alpha|^2+|\beta|^2}\sin^2\gamma$ and $\leq |\alpha|^2+|\beta|^2$, where γ is the angle between the two vectors α and β.

We can explicitly calculate the derivative of $g(\alpha)$ and obtain

$$\begin{aligned} \phi_{\alpha\alpha}(|\alpha|) = g_\alpha(\alpha) &= \tfrac{\phi''(|\alpha|)}{|\alpha|^2}\begin{pmatrix} \alpha_1^2 & \alpha_1\alpha_2 \\ \alpha_2\alpha_1 & \alpha_2^2 \end{pmatrix} + \tfrac{\phi'(|\alpha|)}{|\alpha|^3}\begin{pmatrix} \alpha_2^2 & -\alpha_1\alpha_2 \\ -\alpha_2\alpha_1 & \alpha_1^2 \end{pmatrix} \\ &= g_{\alpha 1}(\alpha) + g_{\alpha 2}(\alpha), \end{aligned} \tag{14}$$

where $g_{\alpha 1}$ and $g_{\alpha 2}$ represent the first and second terms in the expression of g_α. If $|\alpha|$ is in the convex region of $\phi(|\alpha|)$, then $\phi''(|\alpha|) > 0$ and $\phi'(|\alpha|) \geq 0$ if $|\alpha| \geq r_0$. Therefore, the second term $g_{\alpha 2}(\alpha)$ of (14) is positive semidefinite when $|\alpha| \geq r_0$. In the case $|\alpha| < r_0$,

$$\phi''(|\alpha|) - \frac{|\phi'(|\alpha|)|}{|\alpha|} = \phi''(|\alpha|) + \frac{\phi'(|\alpha|)}{|\alpha|} > 72\phi_{min}\frac{r_0^6}{|\alpha|^8}. \tag{15}$$

Hence, $\phi'(|\alpha|)/|\alpha|$ would be much smaller than $\phi''(|\alpha|)$ when $|\alpha| < r_0$. On the other hand, the potential energy function $\phi(|\alpha|)$ vanishes quickly after the lattice distance r_0 from atomic property (see the figure in [5, p. 143], which suggests nearest neighbor dominance in atomic interactions of solid materials. These facts together with Lemma 1 motivate the assumption below that the nearest neighbor sum of $g_{\alpha 1}$ dominates the sum of g_α.

We now write down our assumptions, and some further explanation follows afterward. We shall analyze the error of the QC approximation in the next section, based on these assumptions.

Assumptions. *Let $\hat{z}$ and Z^h be the lattice-scale solution and the QC approximate solution satisfying Dirichlet boundary conditions, and let $\hat{Z}$ be the piecewise linear interpolation based on Z^h as defined in* (6). *Also, a square lattice grid is used in the reference configuration* (*see Figure* 1).

1. *The distance of any pair of nearest neighbor atoms $\hat{z}_\ell - \hat{z}_{nb_\ell}$ and $\hat{Z}_\ell - \hat{Z}_{nb_\ell}$ is located in the convex region of $\phi(|\alpha|)$. More precisely, the nearest neighbor distance is in the region*

   $$c_1 r_0 < |\alpha| < C_1 r_0, \tag{16}$$

   where $\alpha = \hat{z}_\ell - \hat{z}_{nb_\ell}$ or $\hat{Z}_\ell - \hat{Z}_{nb_\ell}$ and $0 < c_1 < C_1 < r_1/r_0$ (r_1 is the inflection point of $\phi(r)$, e.g., for the 6-12 *Lennard–Jones potential $r_1 = \sqrt[6]{13/7}\ r_0$). Under our problem setting (square reference grid) nearest neighbors of $\ell = (\ell_x, \ell_y)$ should at least include $\{(\ell_x-1, \ell_y), (\ell_x+1, \ell_y), (\ell_x, \ell_y-1), (\ell_x, \ell_y+1)\}$.*
2. *The nearest neighbor interaction dominates farther interactions. In our analysis we use the following for any atom $k = (k_x, k_y)$): $\sum_{\ell\in R_k}(x_\ell - x_k)^2 g_\alpha(\xi_\ell)$ and $\sum_{\ell\in R_k}(y_\ell - y_k)^2 g_\alpha(\xi_\ell)$ are dominated by $\sum_{nb_k}(x_{nb_k} - x_k)^2 g_{\alpha 1}(\xi_{nb_k})$ and*

$\sum_{nb_k}(y_{nb_k}-y_k)^2 g_{\alpha 1}(\xi_{nb_k})$ *(summing over all nearest neighbor atoms* nb_k*), respectively, where* $\xi_\ell = \mu_\ell(\hat{Z}_\ell - \hat{Z}_k) + (1-\mu_\ell)(\hat{z}_\ell - \hat{z}_k)$*. Also, among nearest neighbor atoms* $\{(k_x-1,k_y),(k_x+1,k_y),(k_x,k_y-1),(k_x,k_y+1)\}$ *there are at least two* ξ_ℓ*'s in distinct directions.*

3. *As we mentioned earlier, the external potential* $F(z)$ *is smooth and strictly convex or* $F_{zz}(z) = f_z(z)$ *is positive definite.*

The upper and lower bounds for $|\alpha|$ in assumption 1 can be showed for one-dimensional problems (see [14]). $|\alpha|$ located in the convex region of the pair potential energy may not be true in general but is necessary for the uniqueness of the solution. A lower bound of $|\alpha|$ away from zero is expected since if pairs of atoms are too close, the energy will be too large to reach its minimum. Assumption 2 tries to provide a concrete mathematical description (or understanding) of nearest neighbor dominance for a solid material. In Assumption 3 the strictly convex assumption may be relaxed to being just convex (see the remark after Theorem 1). Thus common external forces, e.g., gravity, Coulomb forces, and the nanoindentation example given in [11], are included in this study.

The existence of the solution of minimization problems (satisfying a finite boundary condition) is obvious from the property of a continuous function since the pair potential energy function ϕ is continuous and has a lower bound and the external energy is continuous in the bounded material domain. Under the assumptions we can also show the uniqueness of the solution of variational problems (4) and (12). For example, assume that if there are two solutions z^1 and z^2 of problem (4), then both z^1 and z^2 satisfy (4). Subtracting the two equations for z^1 and z^2, denoting $d = z^1 - z^2$, and taking $v = d$ we have

$$\frac{1}{2}\sum_{i=1}^{N}\sum_{k=1}^{m_i}\sum_{\ell\in R_k} g_\alpha(\xi_k)(d_k-d_\ell)\cdot(d_k-d_\ell) + \sum_{i=1}^{N}\sum_{k=1}^{m_i} f_z(\eta_k)d_k\cdot d_k = 0,$$

where $\xi_k = \mu(z_k^1 - z_\ell^1) + (1-\mu)(z_k^2 - z_\ell^2)$ $(0<\mu<1)$ and η_k is between z_k^1 and z_k^2. According to assumption 1 (noting that we use only the second inequality $|\alpha| \le C_1 r_0$), the difference of nearest neighbors of both $z_k^1 - z_\ell^1$ and $z_k^2 - z_\ell^2$ is in the convex region of ϕ (i.e., $\le C_1 r_0$) and F is convex so both $\sum_{\ell\in R_k} g_\alpha(\xi_k)(d_k-d_\ell)\cdot(d_k-d_\ell)$ (according to the assumption of the nearest neighbor dominance) and $f_z(\eta_k)d_k\cdot d_k$ are nonnegative. We can then conclude $d=0$ or uniqueness of the solution.

We would like to mention here that using the square lattice grid in the reference configuration does not imply that a square lattice structure is assumed. The real location of atoms is in the deformed configuration, where triangular or hexagonal lattice solutions and other types of lattice solutions are possible, depending on the Dirichlet boundary condition, the external force, and the cut-off of the atomic interaction. In the next section we shall analyze error in the QC approximation.

4. Error analysis of the QC method. Our goal in this section is to estimate the error $\hat{Z} - \hat{z}$, where $\hat{z}$ is the solution of the original problem (3) or (4) and $\hat{Z}$ is the piecewise linear interpolation (defined as (5) or (6)) of the solution $\hat{Z}^h$ of the approximate problem (11) or (12). Define $\tilde{z}$ to be a piecewise linear interpolation of the solution $\hat{z}$, i.e.,

$$\tilde{z}_\ell = \psi_{i_1}(X_\ell)\hat{z}_{i_1} + \psi_{i_2}(X_\ell)\hat{z}_{i_2} + \psi_{i_3}(X_\ell)\hat{z}_{i_3}, \tag{17}$$

if $X_\ell = (x_\ell, y_\ell)^T$ is a point in a triangular element E_i. We first estimate the interpolation error $\hat{z} - \tilde{z}$. In order to write down a discrete Taylor's expansion we introduce

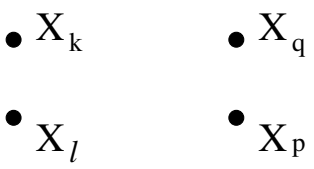

FIG. 5. *Location of four points.*

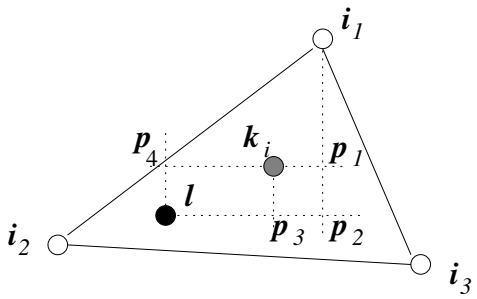

FIG. 6. *Derivation of discrete Taylor's formula.*

notation of the first and second order divided differences as follows. If three points X_ℓ, X_k, and X_p are located in the horizontal direction (say, X_k in the middle) we define

$$D_{x,k}u_\ell = \frac{u_k - u_\ell}{x_k - x_\ell}, \quad D_{x,p}D_{x,k}u_\ell = \frac{D_{x,p}u_k - D_{x,k}u_\ell}{\frac{1}{2}(x_p - x_\ell)}. \tag{18}$$

$D_{y,k}u_\ell$ and $D_{y,p}D_{y,k}u_\ell$ can be defined similarly if three atomic points X_ℓ, X_k, and X_p are located in the vertical direction. If four atomic points X_ℓ, X_k, X_p, and X_q are located, as in Figure 5, we define

$$D_{x,p}D_{y,k}u_\ell = \frac{D_{y,q}u_p - D_{y,k}u_\ell}{x_p - x_\ell}, \quad D_{y,k}D_{x,p}u_\ell = \frac{D_{x,q}u_k - D_{x,p}u_\ell}{y_k - y_\ell}. \tag{19}$$

Denote $\hat{z} = (\hat{z}^1, \hat{z}^2)^T$, and let indices i_1, i_2, and i_3 be the vertices of the element E_i. Let ℓ be the index of any atomic point in the element and representative atom k_i, and let atoms p_1, p_2, p_3, and p_4 be positioned as in Figure 6. Obviously, $x_{i_1} = x_{p_1} = x_{p_2}$, $x_{k_i} = x_{p_3}$, $x_{p_4} = x_\ell$, $y_{p_2} = y_{p_3} = y_\ell$, and $y_{p_1} = y_{k_i} = y_{p_4}$. For simplicity we will consider only ℓ located in a position as shown in Figure 6. For any other locations of ℓ and any other different relative positions of atoms i_1, k_i, and ℓ, the discussion is similar. Mimicking the continuous Taylor's theorem, we can have

$$\hat{z}^1_{i_1} = \hat{z}^1_\ell + \hat{z}^1_{p_2} - \hat{z}^1_\ell + \hat{z}^1_{i_1} - \hat{z}^1_{p_2} = \hat{z}^1_\ell + D_{x,p_2}\hat{z}^1_\ell\,(x_{p_2} - x_\ell) + D_{y,i_1}\hat{z}^1_{p_2}\,(y_{i_1} - y_{p_2}) \tag{20}$$

We can also obtain

$$\begin{aligned}
D_{x,p_2}\hat{z}^1_\ell &= D_{x,p_3}\hat{z}^1_\ell + D_{x,p_2}\hat{z}^1_\ell - D_{x,p_3}\hat{z}^1_\ell \\
&= D_{x,p_3}\hat{z}^1_\ell + \frac{x_{p_2} - x_{p_3}}{x_{p_2} - x_\ell}D_{x,p_2}\hat{z}^1_{p_3} + \frac{x_{p_3} - x_\ell}{x_{p_2} - x_\ell}D_{x,p_3}\hat{z}^1_\ell - D_{x,p_3}\hat{z}^1_\ell \\
&= D_{x,p_3}\hat{z}^1_\ell + \frac{x_{p_2} - x_{p_3}}{x_{p_2} - x_\ell}(D_{x,p_2}\hat{z}^1_{p_3} - D_{x,p_3}\hat{z}^1_\ell) \\
&= D_{x,p_3}\hat{z}^1_\ell + \frac{x_{p_2} - x_{p_3}}{x_{p_2} - x_\ell}D_{x,p_2}D_{x,p_3}\hat{z}^1_\ell\,\frac{1}{2}(x_{p_2} - x_\ell)
\end{aligned}$$

and

$$D_{y,i_1}\hat{z}^1_{p_2} = D_{y,p_4}\hat{z}^1_\ell + D_{y,i_1}\hat{z}^1_{p_2} - D_{y,p_1}\hat{z}^1_{p_2} + D_{y,p_1}\hat{z}^1_{p_2} - D_{y,p_4}\hat{z}^1_\ell = D_{y,p_4}\hat{z}^1_\ell + \frac{y_{i_1}-y_{p_1}}{y_{i_1}-y_{p_2}} D_{y,i_1}D_{y,p_1}\hat{z}^1_{p_2}\ \frac{1}{2}(y_{i_1}-y_{p_2}) + D_{x,p_2}D_{y,p_4}\hat{z}^1_\ell\ (x_{p_2}-x_\ell).$$

Therefore, using $x_{i_1} - x_\ell = x_{p_2} - x_\ell$ and $y_{i_1} - y_{p_2} = y_{i_1} - y_\ell$, we have

$$\begin{aligned}\hat{z}^1_{i_1} &= \hat{z}^1_\ell + D_{x,p_3}\hat{z}^1_\ell\ (x_{i_1}-x_\ell) + D_{y,p_4}\hat{z}^1_\ell\ (y_{i_1}-y_\ell) \\ &\quad + \frac{x_{p_2}-x_{p_3}}{x_{p_2}-x_\ell} D_{x,p_2}D_{x,p_3}\hat{z}^1_\ell\ \frac{1}{2}(x_{p_2}-x_\ell)^2 \\ &\quad + \frac{y_{i_1}-y_{p_1}}{y_{i_1}-y_{p_2}} D_{y,i_1}D_{y,p_1}\hat{z}^1_{p_2}\ \frac{1}{2}(y_{i_1}-y_{p_2})^2 + D_{x,p_2}D_{y,p_4}\hat{z}^1_\ell\ (x_{p_2}-x_\ell)(y_{i_1}-y_{p_2}),\end{aligned} \tag{21}$$

where it is easy to see

$$\frac{x_{p_2}-x_{p_3}}{x_{p_2}-x_\ell} \le 1, \quad \frac{y_{i_1}-y_{p_1}}{y_{i_1}-y_{p_2}} \le 1.$$

Similar expansions can be done for $\hat{z}^1_{i_2}$, $\hat{z}^1_{i_3}$, $\hat{z}^2_{i_1}$, $\hat{z}^2_{i_2}$, and $\hat{z}^2_{i_3}$. Also, denote all the second order divided difference terms in these discrete Taylor's expansion as $D^2\hat{z}^1_{i_j,k_i,\ell}$, $j = 1, 2, 3$. Hence,

$$\begin{aligned}\tilde{z}^1_\ell &= \psi_{i_1}(X_\ell)\hat{z}^1_{i_1} + \psi_{i_2}(X_\ell)\hat{z}^1_{i_2} + \psi_{i_3}(X_\ell)\hat{z}^1_{i_3} \\ &= \psi_{i_1}(X_\ell)\left(\hat{z}^1_\ell + D_{x,p_3}\hat{z}^1_\ell(x_{i_1}-x_\ell) + D_{y,p_4}\hat{z}^1_\ell(y_{i_1}-y_\ell) + O(h^2)D^2\hat{z}^1_{i_1,k_i,\ell}\right) \\ &\quad + \psi_{i_2}(X_\ell)\left(\hat{z}^1_\ell + D_{x,p_3}\hat{z}^1_\ell(x_{i_2}-x_\ell) + D_{y,p_4}\hat{z}^1_\ell(y_{i_2}-y_\ell) + O(h^2)D^2\hat{z}^1_{i_2,k_i,\ell}\right) \\ &\quad + \psi_{i_3}(X_\ell)\left(\hat{z}^1_\ell + D_{x,p_3}\hat{z}^1_\ell(x_{i_3}-x_\ell) + D_{y,p_4}\hat{z}^1_\ell(y_{i_3}-y_\ell) + O(h^2)D^2\hat{z}^1_{i_3,k_i,\ell}\right).\end{aligned} \tag{22}$$

We can obtain a similar expression for $\tilde{z}^2$. Noting that $\sum_{j=1}^3 \psi_{i_j}(X_\ell) = 1$, $\sum_{j=1}^3 (x_{i_j} - x_\ell)\psi_{i_j}(X_\ell) = 0$, and $\sum_{j=1}^3 (y_{i_j} - y_\ell)\psi_{i_j}(X_\ell) = 0$ we then have

$$|\hat{z}^1_\ell - \tilde{z}^1_\ell| \le Ch^2 \sum_{j=1}^3 |D^2\hat{z}^1_{i_j,k_i,\ell}|, \quad |\hat{z}^2_\ell - \tilde{z}^2_\ell| \le Ch^2 \sum_{j=1}^3 |D^2\hat{z}^2_{i_j,k_i,\ell}|, \tag{23}$$

where $D^2\hat{z}_{i_j,k_i,\ell}$ are defined above as a sum of a number of second order divided differences involved with three points in the element E_i, C is a generic positive constant, and h is the maximum size of all triangular elements. Similarly, we can estimate discrete derivatives of the interpolation error,

$$\begin{aligned}\nabla^h_{s,i}\tilde{z} = \nabla^h_{s,i}\tilde{z}_\ell &= \sum_{j=1}^3 \nabla_{s,i}\psi_{i_j}\hat{z}_{i_j} \\ &= \sum_{j=1}^3 \nabla_{s,i}\psi_{i_j}\left(\hat{z}_\ell + D_{x,p_3}\hat{z}_\ell(x_{i_j}-x_\ell) + D_{y,p_4}\hat{z}_\ell(y_{i_j}-y_\ell) + O(h^2)D^2\hat{z}_{i_j,k_i,\ell}\right),\end{aligned}$$

where s represents x or y. Noting that $\sum_{j=1}^3 \nabla_{s,i}\psi_{i_j} = 0$, $\sum_{j=1}^3 (x_{i_j} - x_\ell)\nabla_{x,i}\psi_{i_j} = 1$, $\sum_{j=1}^3 (y_{i_j} - y_\ell)\nabla_{x,i}\psi_{i_j} = 0$, $\sum_{j=1}^3 (x_{i_j} - x_\ell)\nabla_{y,i}\psi_{i_j} = 0$, and $\sum_{j=1}^3 (y_{i_j} - y_\ell)\nabla_{y,i}\psi_{i_j} = 1$ we have

$$|\nabla_{s,i}\hat{z}_\ell - \nabla^h_{s,i}\tilde{z}_\ell| \le Ch \sum_{j=1}^3 |D^2\hat{z}_{i_j,k_i,\ell}|, \text{ for } X_\ell \in E_i, \tag{24}$$

where s is x or y and

$$\nabla_{x,i}\hat{z}_\ell = (D_{x,p_3}\hat{z}^1_\ell, D_{x,p_3}\hat{z}^2_\ell)^T, \quad \nabla_{y,i}\hat{z}_\ell = (D_{y,p_4}\hat{z}^1_\ell, D_{y,p_4}\hat{z}^2_\ell)^T. \tag{25}$$

Note that if ℓ is located at a position such that $x_{k_i} = x_{p_3} = x_\ell$ or $y_{k_i} = y_{p_4} = y_\ell$, then $D_{x,p_3}\hat{z}_\ell$ or $D_{y,p_4}\hat{z}_\ell$ may not be defined, respectively. For these ℓ's we can change $k_i = (k_x, k_y)$ into its neighbor, e.g., $k_i = (k_x + 1, k_y)$ or $k_i = (k_x, k_y + 1)$, in definition (25), respectively. All previous arguments and results about the interpolation error will still be valid. We thus have

$$\|\hat{z} - \tilde{z}\|_2 \le C_2 h^2, \quad \|\nabla_s \hat{z} - \nabla^h_s \tilde{z}\|_2 \le C_2 h, \tag{26}$$

where s represents x or y, $\|\cdot\|_2 = \sqrt{\frac{1}{M}\sum_{i=1}^N \sum_{\ell=1}^{m_i} |(\cdot)_\ell|^2}$ (where $M = \sum_{i=1}^N m_i$), C_2 is a positive constant proportional to the ℓ_2 norm of second order divided differences of $\hat{z}$, and $\nabla_s \hat{z}$ and $\nabla^h_s \tilde{z}$ are vectors with components $\nabla_{s,i}\hat{z}_\ell$ and $\nabla^h_{s,i}\tilde{z}_\ell$, respectively.

Therefore, to estimate $\hat{Z} - \hat{z}$ we need only estimate $\hat{Z} - \tilde{z}$. We first have

$$\begin{aligned} &a_h(\hat{Z}, \hat{Z} - \tilde{z}) - a_h(\tilde{z}, \hat{Z} - \tilde{z}) \\ &= \frac{1}{2}\sum_{i=1}^N m_i \sum_{\ell \in R_{k_i}} \left[g(\hat{Z}_\ell - \hat{Z}_{k_i}) - g(\tilde{z}_\ell - \tilde{z}_{k_i})\right] \cdot \left[(\hat{Z}_\ell - \hat{Z}_{k_i}) - (\tilde{z}_\ell - \tilde{z}_{k_i})\right] \\ &= \frac{1}{2}\sum_{i=1}^N m_i \sum_{\ell \in R_{k_i}} \left[(\hat{Z}_\ell - \hat{Z}_{k_i}) - (\tilde{z}_\ell - \tilde{z}_{k_i})\right]^T g_\alpha(\xi_\ell) \left[(\hat{Z}_\ell - \hat{Z}_{k_i}) - (\tilde{z}_\ell - \tilde{z}_{k_i})\right], \end{aligned} \tag{27}$$

where $\xi_\ell = \mu_\ell(\hat{Z}_\ell - \hat{Z}_{k_i}) + (1 - \mu_\ell)(\tilde{z}_\ell - \tilde{z}_{k_i})$, $0 < \mu_\ell < 1$. From (5), (6), and (17) and similarly to (8), if ℓ is in the element E_i, then

$$\begin{aligned} \hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}) &= (x_\ell - x_{k_i}) \sum_{j=1}^3 \nabla_{x,i}\psi_{i_j}(\hat{Z}^h_{i_j} - \hat{z}_{i_j}) \\ &\quad + (y_\ell - y_{k_i}) \sum_{j=1}^3 \nabla_{y,i}\psi_{i_j}(\hat{Z}^h_{i_j} - \hat{z}_{i_j}) \\ &= (x_\ell - x_{k_i})\nabla^h_{x,i}(\hat{Z} - \tilde{z}) + (y_\ell - y_{k_i})\nabla^h_{y,i}(\hat{Z} - \tilde{z}). \end{aligned} \tag{28}$$

Due to assumptions given in the previous section, at the nearest neighbors $\ell \in nb_{k_i}$ of $k_i = (k_{ix}, k_{iy})$, $\hat{Z}_\ell - \hat{Z}_{k_i}$ and $\tilde{z}_\ell - \tilde{z}_{k_i}$ are located in the convex region of the energy function $\phi(|\alpha|)$. Then corresponding to the nearest neighbors $\ell \in nb_{k_i}$, $\xi_\ell = \mu_\ell(\hat{Z}_\ell - \hat{Z}_{k_i}) + (1 - \mu_\ell)(\tilde{z}_\ell - \tilde{z}_{k_i})$ would be in the convex region (see (16)). Define $nb'_{k_i} = \{(k_{ix} - 1, k_{iy}), (k_{ix} + 1, k_{iy}), (k_{ix}, k_{iy} - 1), (k_{ix}, k_{iy} + 1)\} \subseteq nb_{k_i}$. From (27) and assumption 2, $a_h(\hat{Z}, \hat{Z} - \tilde{z}) - a_h(\tilde{z}, \hat{Z} - \tilde{z})$ is dominated by

$$\begin{aligned} &\sum_{\ell \in nb_{k_i}} \left[(\hat{Z}_\ell - \hat{Z}_{k_i}) - (\tilde{z}_\ell - \tilde{z}_{k_i})\right]^T g_{\alpha 1}(\xi_\ell) \left[(\hat{Z}_\ell - \hat{Z}_{k_i}) - (\tilde{z}_\ell - \tilde{z}_{k_i})\right] \\ &\quad \ge \nabla^h_{x,i}(\hat{Z} - \tilde{z})^T \sum_{\ell \in nb'_{k_i}} (x_\ell - x_{k_i})^2 g_{\alpha 1}(\xi_\ell) \nabla^h_{x,i}(\hat{Z} - \tilde{z}) + \nabla^h_{y,i}(\hat{Z} - \tilde{z})^T \\ &\quad \times \sum_{\ell \in nb'_{k_i}} (y_\ell - y_{k_i})^2 g_{\alpha 1}(\xi_\ell) \nabla^h_{y,i}(\hat{Z} - \tilde{z}). \end{aligned}$$

By easy calculation we have eigenvalues

$$\lambda\left(\sum_{\ell\in nb'_{k_i}}(x_\ell - x_{k_i})^2 g_{\alpha 1}(\xi_\ell)\right) \text{ and } \lambda\left(\sum_{\ell\in nb'_{k_i}}(y_\ell - y_{k_i})^2 g_{\alpha 1}(\xi_\ell)\right) > p > 0. \tag{29}$$

From Lemma 1, (14), and (1), p is independent of lattice constant r_0 but depends only on $\sin^2\gamma$ and $\min_{t\in(0,C_1]}\phi_1''(t)$, where $\phi_1(t) = \phi(r_0 t)$, and the meaning of C_1 and γ are given in Lemma 1 and assumptions 1 and 2. Therefore

$$a_h(\hat{Z}, \hat{Z} - \tilde{z}) - a_h(\tilde{z}, \hat{Z} - \tilde{z}) > \frac{p}{2}\sum_{i=1}^{N} m_i \left(|\nabla^h_{x,i}(\hat{Z} - \tilde{z})|^2 + |\nabla^h_{y,i}(\hat{Z} - \tilde{z})|^2\right), \tag{30}$$

where $|\cdot|$ is the Euclidean length of $\mathbf{R}^2$.

On the other hand, from (12) (taking $V = \hat{Z} - \tilde{z}$) and using (4) (taking $v = \hat{Z} - \tilde{z}$), and noting

$$a_h(\hat{Z}, \hat{Z} - \tilde{z}) = -\sum_{i=1}^{N}\sum_{k=1}^{m_i} f(\hat{Z}_k)\cdot(\hat{Z}_k - \tilde{z}_k), \quad a(\hat{z}, \hat{Z} - \tilde{z}) = -\sum_{i=1}^{N}\sum_{k=1}^{m_i} f(\hat{z}_k)\cdot(\hat{Z}_k - \tilde{z}_k),$$

we have

$$\begin{aligned} &a_h(\hat{Z}, \hat{Z} - \tilde{z}) - a_h(\tilde{z}, \hat{Z} - \tilde{z}) \\ &\quad = \left(a_h(\hat{z}, \hat{Z} - \tilde{z}) - a_h(\tilde{z}, \hat{Z} - \tilde{z})\right) - \left(a_h(\hat{z}, \hat{Z} - \tilde{z}) - a(\hat{z}, \hat{Z} - \tilde{z})\right) \\ &\qquad + \sum_{i=1}^{N}\sum_{k=1}^{m_i}(f(\hat{z}_k) - f(\hat{Z}_k))\cdot(\hat{Z}_k - \tilde{z}_k) = T_1 - T_2 + T_3, \end{aligned}$$

where T_1 and T_2 correspond to the first two bracketed terms in the expression, respectively, and T_3 is the double sum term. We now treat them one by one. We can easily have

$$\begin{aligned} T_1 &= \frac{1}{2}\sum_{i=1}^{N} m_i \sum_{\ell\in R_{k_i}} (g(\hat{z}_\ell - \hat{z}_{k_i}) - g(\tilde{z}_\ell - \tilde{z}_{k_i}))\cdot\left(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i})\right) \\ &= \frac{1}{2}\sum_{i=1}^{N} m_i \sum_{\ell\in R_{k_i}} (\hat{z}_\ell - \hat{z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}))^T\, g_\alpha(\xi'_\ell)\left(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i})\right), \end{aligned}$$

where $\xi'_\ell = \mu'_\ell(\hat{z}_\ell - \hat{z}_{k_i}) + (1 - \mu'_\ell)(\tilde{z}_\ell - \tilde{z}_{k_i})$, $0 < \mu'_\ell < 1$. We can write

$$\hat{z}_\ell - \hat{z}_{k_i} = D_{x,\ell}\hat{z}_{(k_{ix},\ell_y)}(x_\ell - x_{k_i}) + D_{y,(k_{ix},\ell_y)}\hat{z}_{k_i}(y_\ell - y_{k_i}),$$

where k_{ix} is the first component of the index k_i and ℓ_y is the second component of the index ℓ. Hence,

$$\begin{aligned} \hat{z}_\ell - \hat{z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}) = &\left(D_{x,\ell}\hat{z}_{(k_{ix},\ell_y)} - \nabla^h_{x,i}\tilde{z}\right)(x_\ell - x_{k_i}) \\ &+ \left(D_{y,(k_{ix},\ell_y)}\hat{z}_{k_i} - \nabla^h_{y,i}\tilde{z}\right)(y_\ell - y_{k_i}). \end{aligned} \tag{31}$$

So similarly to the argument of (24), in estimating the interpolation error we have $\tilde{z}_\ell - \tilde{z}_{k_i} = \hat{z}_\ell - \hat{z}_{k_i} + O(hr_0)$. Taking the inner product of it with $\hat{z}_\ell - \hat{z}_{k_i}$ and using assumption 1 (the first inequality $c_1 r_0 \le |\alpha|$), we can obtain

$$(\hat{z}_\ell - \hat{z}_{k_i}) \cdot (\tilde{z}_\ell - \tilde{z}_k) \ge |\hat{z}_\ell - \hat{z}_{k_i}|^2 - O(hr_0)|\hat{z}_\ell - \hat{z}_{k_i}| \ge c_1^2 r_0^2 - O(hr_0) C_1 r_0 > 0 \tag{32}$$

if h is sufficiently small. Using the Cauchy–Schwarz inequality, we obtain

$$\begin{aligned} |T_1| \le \frac{1}{2} &\left(\sum_{i=1}^{N} m_i \sum_{\ell \in R_{k_i}} (\hat{z}_\ell - \hat{z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}))^T \, g_\alpha(\xi'_\ell) \, (\hat{z}_\ell - \hat{z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i})) \right)^{\frac{1}{2}} \\ &\times \left(\sum_{i=1}^{N} m_i \sum_{\ell \in R_{k_i}} \left(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}) \right)^T g_\alpha(\xi'_\ell) \left(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i}) \right) \right)^{\frac{1}{2}}. \end{aligned}$$

To get an upper bound of T_1 we need to get an upper bound of eigenvalues in the left-hand side of (29). We then need a lower bound of the size of ξ'_ℓ. From assumption 1 we have $|\hat{z}_\ell - \hat{z}_{k_i}| \ge \bar{c}_1 r_0$ and $|\tilde{z}_\ell - \tilde{z}_{k_i}| \ge \bar{c}_1 r_0$ (using (31)), where $\bar{c}_1 = \min\{c_1, c_1 + O(h)\} > 0$. Then using (32) yields

$$\begin{aligned} |\xi'_\ell|^2 &= \mu_\ell^{'2} |\hat{z}_\ell - \hat{z}_{k_i}|^2 + (1-\mu'_\ell)^2 |\tilde{z}_\ell - \tilde{z}_{k_i}|^2 + 2\mu'_\ell (1-\mu'_\ell)(\hat{z}_\ell - \hat{z}_{k_i}) \cdot (\tilde{z}_\ell - \tilde{z}_{k_i}) \\ &\ge (\mu_\ell^{'2} + (1-\mu'_\ell)^2) \bar{c}_1^2 r_0^2 \ge \frac{1}{2} \bar{c}_1^2 r_0^2. \end{aligned}$$

Combining it with the second inequality of (16) in assumption 1, we thus have

$$\frac{1}{\sqrt{2}} \bar{c}_1 r_0 \le |\xi'_\ell| \le C_1 r_0. \tag{33}$$

Based on this and assumption 2, we can easily verify the eigenvalues

$$\lambda \left(\sum_{\ell \in R_{k_i}} (x_\ell - x_{k_i})^2 g_\alpha(\xi'_\ell) \right) \text{ and } \lambda \left(\sum_{\ell \in R_{k_i}} (y_\ell - y_{k_i})^2 g_\alpha(\xi'_\ell) \right) \le P, \tag{34}$$

where P is a positive constant depending on $\max_{t \in [\frac{1}{\sqrt{2}} \bar{c}_1, C_1]} \phi_1''(t)$ but is independent of lattice constant r_0. From (34), (31), (24), and (28) we then have

$$|T_1| \le C_2 h M^{\frac{1}{2}} \left(\sum_{i=1}^{N} m_i \left(|\nabla_{x,i}^h (\hat{Z} - \tilde{z})|^2 + |\nabla_{y,i}^h (\hat{Z} - \tilde{z})|^2 \right) \right)^{\frac{1}{2}}, \tag{35}$$

where $M = \sum_{i=1}^{N} m_i$ is the total number of atoms and the positive constant C_2 is proportional to the ℓ_2 norm of second order divided difference of $\hat{z}$ as defined in (26) (noting that the constant C in (24) and the constant P in (34) are absorbed into the constant C_2). The third term can be written as

$$T_3 = \sum_{i=1}^{N} \sum_{k=1}^{m_i} (f(\tilde{z}_k) - f(\hat{Z}_k)) \cdot (\hat{Z}_k - \tilde{z}_k) + \sum_{i=1}^{N} \sum_{k=1}^{m_i} (f(\hat{z}_k) - f(\tilde{z}_k)) \cdot (\hat{Z}_k - \tilde{z}_k), \tag{36}$$

where the first sum is less than $-F''_{min}\sum_{i=1}^{N}\sum_{k=1}^{m_i}|\hat{Z}_k-\tilde{z}_k|^2$ ($F''_{min}>0$) due to the strictly convex assumption of the external energy F. The second sum is less than

$$\frac{1}{2F''_{min}}\sum_{i=1}^{N}\sum_{k=1}^{m_i}|f(\hat{z}_k)-f(\tilde{z}_k)|^2+\frac{F''_{min}}{2}\sum_{i=1}^{N}\sum_{k=1}^{m_i}|\hat{Z}_k-\tilde{z}_k|^2$$

due to the Cauchy inequality. From (23) and (26) we then have

$$T_3\le C_2^2h^4M-\frac{F''_{min}}{2}\sum_{i=1}^{N}\sum_{k=1}^{m_i}|\hat{Z}_k-\tilde{z}_k|^2=C_2^2h^4M-\frac{F''_{min}}{2}M\|\hat{Z}-\tilde{z}\|_2^2. \tag{37}$$

Next we consider the second term T_2 (nonconforming part of the error).

From (4) we have

$$\begin{aligned}T_2&=a_h(\hat{z},\hat{Z}-\tilde{z})-a(\hat{z},\hat{Z}-\tilde{z})\\&=\frac{1}{2}\sum_{i=1}^{N}m_i\sum_{\ell\in R_{k_i}}g(\hat{z}_\ell-\hat{z}_{k_i})\cdot(\hat{Z}_\ell-\hat{Z}_{k_i}-(\tilde{z}_\ell-\tilde{z}_{k_i}))\\&\quad-\frac{1}{2}\sum_{i=1}^{N}\sum_{k=1}^{m_i}\sum_{j\in R_k}g(\hat{z}_j-\hat{z}_k)\cdot(\hat{Z}_j-\hat{Z}_k-(\tilde{z}_j-\tilde{z}_k)).\end{aligned}$$

Define

$$Y_j=\psi_{i_1}(X_j)\hat{Z}^h_{i_1}+\psi_{i_2}(X_j)\hat{Z}^h_{i_2}+\psi_{i_3}(X_j)\hat{Z}^h_{i_3}\quad\forall j\in R_k,X_k\in E_i, \tag{38}$$

$$\tilde{y}_j=\psi_{i_1}(X_j)\hat{z}_{i_1}+\psi_{i_2}(X_j)\hat{z}_{i_2}+\psi_{i_3}(X_j)\hat{z}_{i_3}\quad\forall j\in R_k,X_k\in E_i, \tag{39}$$

where Y_j (or $\tilde{y}_j$) is a linear extension of the linear lattice function $\hat{Z}$ (or $\tilde{z}$, respectively) from the triangular element E_i to the neighbor elements; i.e., we have

$$Y_j=\hat{Z}_j\quad\text{and}\quad\tilde{y}_j=\tilde{z}_j\quad\text{if}\quad X_j\in E_i. \tag{40}$$

Then we can write

$$T_2=\frac{1}{2}(A_1+A_2),$$

where

$$\begin{aligned}A_1&=\sum_{i=1}^{N}m_i\sum_{\ell\in R_{k_i}}g(\hat{z}_\ell-\hat{z}_{k_i})\cdot(\hat{Z}_\ell-\hat{Z}_{k_i}-(\tilde{z}_\ell-\tilde{z}_{k_i}))\\&\quad-\sum_{i=1}^{N}\sum_{k=1}^{m_i}\sum_{j\in R_k}g(\hat{z}_j-\hat{z}_k)\cdot(Y_j-Y_k-(\tilde{y}_j-\tilde{y}_k)),\\A_2&=\sum_{i=1}^{N}\sum_{k=1}^{m_i}\sum_{j\in R_k}g(\hat{z}_j-\hat{z}_k)\left[(Y_j-Y_k-(\tilde{y}_j-\tilde{y}_k))-(\hat{Z}_j-\hat{Z}_k-(\tilde{z}_j-\tilde{z}_k))\right].\end{aligned}$$

The term A_1 can be estimated by using Taylor's theorem to the function g and shifting $\hat{z}_k$ to $\hat{z}_{k_i}$ and $\hat{z}_j$ to $\hat{z}_\ell$ with $X_j-X_k=X_\ell-X_{k_i}$ (see Figure 7 for relative positions of atoms j, k, ℓ, and k_i). From the definitions of Y_j and $\tilde{y}_j$ in (38) and (39), and noting

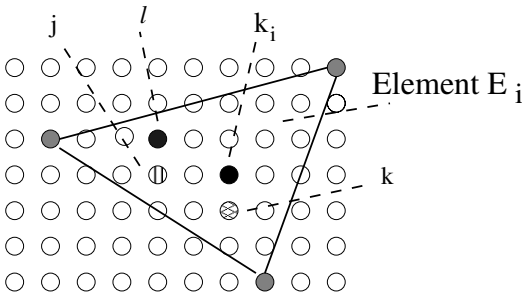

FIG. 7. *Shifting of atom k to k_i and of atom j to ℓ.*

that $X_j - X_k = X_\ell - X_{k_i}$ and ψ_{i_j} $(j = 1, 2, 3)$ are linear, we should have

$$Y_j - Y_k = \hat{Z}_\ell - \hat{Z}_{k_i}, \quad \tilde{y}_j - \tilde{y}_k = \tilde{z}_\ell - \tilde{z}_{k_i}.$$

Therefore,

$$\begin{aligned} A_1 &= \sum_{i=1}^{N} \sum_{k=1}^{m_i} \sum_{j \in R_k} \left(g(\hat{z}_j - \hat{z}_k) - g(\hat{z}_\ell - \hat{z}_{k_i})\right) \left(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i})\right) \\ &= \sum_{i=1}^{N} \sum_{k=1}^{m_i} \sum_{j \in R_k} \left(\hat{z}_j - \hat{z}_k - (\hat{z}_\ell - \hat{z}_{k_i})\right)^T g_\alpha(\xi_A)(\hat{Z}_\ell - \hat{Z}_{k_i} - (\tilde{z}_\ell - \tilde{z}_{k_i})), \end{aligned}$$

where $\xi_A = \mu_A(\hat{z}_j - \hat{z}_k) + (1 - \mu_A)(\hat{z}_\ell - \hat{z}_{k_i})$ and $\mu_A \in [0, 1]$. We can write

$$\begin{aligned} \hat{z}_j - \hat{z}_k - (\hat{z}_\ell - \hat{z}_{k_i}) = &(D_{x,j}\hat{z}_{(k_x, j_y)} - D_{x,\ell}\hat{z}_{(k_{ix}, \ell_y)})(x_\ell - x_{k_i}) \\ &+ (D_{y,(k_x,j_y)}\hat{z}_k - D_{y,(k_{ix},\ell_y)}\hat{z}_{k_i})(y_\ell - y_{k_i}), \end{aligned}$$

where k_x and k_{ix} are the first components of k and k_i, respectively; j_y and l_y are the second components of j and l, respectively, and the differences of first order divided differences are of order $O(h)$. Similarly to the arguments of (32) and (33), we can have $(\hat{z}_j - \hat{z}_k) \cdot (\hat{z}_\ell - \hat{z}_{k_i}) > 0$ and then $\frac{1}{\sqrt{2}}\bar{c}_1 r_0 \le |\xi_A| \le C_1 r_0$. Applying the Cauchy–Schwarz inequality and following the steps in estimating T_1, we can thus have

$$|A_1| \le C_2 h M^{\frac{1}{2}} \left(\sum_{i=1}^{N} m_i \left(|\nabla^h_{x,i}(\hat{Z} - \tilde{z})|^2 + |\nabla^h_{y,i}(\hat{Z} - \tilde{z})|^2 \right) \right)^{\frac{1}{2}}. \tag{41}$$

Next we estimate A_2. Noting (40) we have

$$\begin{aligned} A_2 &= \sum_{i=1}^{N} \sum_{k=1}^{m_i} \sum_{j \in R_k} g(\hat{z}_j - \hat{z}_k) \cdot (Y_j - \tilde{y}_j - (\hat{Z}_j - \tilde{z}_j)) \\ &= \sum_{i=1}^{N} \sum_{j \in S_i} g(\hat{z}_j - \hat{z}_k) \cdot (Y_j - \tilde{y}_j - (\hat{Z}_j - \tilde{z}_j)), \end{aligned}$$

where $S_i = \{j : j \in R_k,\ X_k \in E_i,\ X_j \bar{\in} E_i\}$ and R_k is the cut-off disc of atom X_k. The number of atoms in the set S_i is the number of atoms near the boundary of triangle

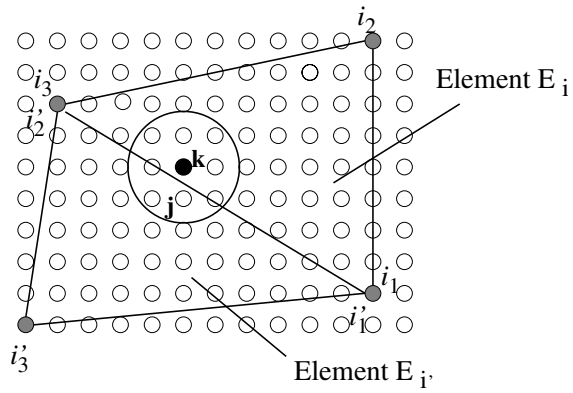

FIG. 8. *Cut-off discs near the boundary of two neighboring elements.*

E_i (see Figure 8). Denote the number as b_i. Also denote the line connecting atoms i_1 and i_3 (or i_1' and i_2') as i_1i_3 and the line connecting j and k as jk and choose an atom $X_{j'}$ on the line i_1i_3 to be the closest to the intersection point of lines i_1i_3 and jk. We then have

$$\psi_{i_1}(X_{j'}) = \psi_{i_1'}(X_{j'}),\ \psi_{i_3}(X_{j'}) = \psi_{i_2'}(X_{j'}),\ \psi_{i_2}(X_{j'}) = 0,\ \psi_{i_3'}(X_{j'}) = 0,$$

and $Y_{j'} - \tilde{y}_{j'} = \hat{Z}_{j'} - \tilde{z}_{j'}$. Therefore,

$$\begin{aligned} Y_j - \tilde{y}_j - (Y_{j'} - \tilde{y}_{j'}) &= \sum_{q=1}^{3} (\psi_{i_q}(X_j) - \psi_{i_q}(X_{j'}))(\hat{Z}^h_{i_q} - \hat{z}_{i_q}) \\ &= (x_j - x_{j'})\nabla^h_{x,i}(\hat{Z} - \tilde{z}) + (y_j - y_{j'})\nabla^h_{y,i}(\hat{Z} - \tilde{z}) \\ \hat{Z}_j - \tilde{z}_j - (Y_{j'} - \tilde{y}_{j'}) &= \sum_{q=1}^{3} (\psi_{i_q'}(X_j) - \psi_{i_q'}(X_{j'}))(\hat{Z}^h_{i_q'} - \hat{z}_{i_q'}) \\ &= (x_j - x_{j'})\nabla^h_{x,i'}(\hat{Z} - \tilde{z}) + (y_j - y_{j'})\nabla^h_{y,i'}(\hat{Z} - \tilde{z}). \end{aligned}$$

From the nearest neighbor dominance and nearest neighbor pairs located in the convex region of ϕ (assumptions 1–3) we can obtain that $|\sum_{j\in R_k} g(\hat{z}_j - \hat{z}_k)(x_j - x_{j'})|$ and $|\sum_{j\in R_k} g(\hat{z}_j - \hat{z}_k)(y_j - y_{j'})|$ are bounded by a constant independent of lattice scale and mesh size (like P in (34)). Then, noting

$$Y_j - \tilde{y}_j - (\hat{Z}_j - \tilde{z}_j) = Y_j - \tilde{y}_j - (Y_{j'} - \tilde{y}_{j'}) + (Y_{j'} - \tilde{y}_{j'}) - (\hat{Z}_j - \tilde{z}_j),$$

we have

$$\begin{aligned} |A_2| &\le C \sum_{i=1}^{N} b_i \left(|\nabla^h_{x,i}(\hat{Z} - \tilde{z})| + |\nabla^h_{y,i}(\hat{Z} - \tilde{z})| + |\nabla^h_{x,i'}(\hat{Z} - \tilde{z})| + |\nabla^h_{y,i'}(\hat{Z} - \tilde{z})| \right) \\ &\le C \left(\sum_{i=1}^{N} \frac{b_i^2}{m_i} \right)^{\frac{1}{2}} \left(\sum_{i=1}^{N} m_i (|\nabla^h_{x,i}(\hat{Z} - \tilde{z})|^2 + |\nabla^h_{y,i}(\hat{Z} - \tilde{z})|^2) \right)^{\frac{1}{2}}. \end{aligned} \tag{42}$$

Hence,

$$|T_2| \le \frac{1}{2}(|A_1| + |A_2|)$$

$$\le C\left(C_2 h M^{\frac{1}{2}} + \sqrt{\sum_{i=1}^{N} \frac{b_i^2}{m_i}}\right)\left(\sum_{i=1}^{N} m_i(|\nabla_{x,i}^h(\hat{Z}-\tilde{z})|^2 + |\nabla_{y,i}^h(\hat{Z}-\tilde{z})|^2)\right)^{\frac{1}{2}}. \tag{43}$$

We can then have the following error estimate.

THEOREM 1. *Let $\hat{Z}$ and $\hat{z}$ be the solutions of* (4) *and* (12)*, respectively, satisfying Dirichlet boundary conditions, and let assumptions* 1–3 *hold. Then we have*

$$\|\hat{Z}-\hat{z}\|_2 + \|\nabla_x^h \hat{Z} - \nabla_x \hat{z}\|_2 + \|\nabla_y^h \hat{Z} - \nabla_y \hat{z}\|_2 \le C\left(C_2 h + \sqrt{\frac{\sum_{i=1}^{N} \frac{b_i^2}{m_i}}{M}}\right), \tag{44}$$

where C is a generic positive constant, ∇_x^h, ∇_y^h, ∇_x, and ∇_y are discrete derivatives, norm $\|\cdot\|_2$ and constant C_2 are defined as in (26) *and* (25)*, $M = \sum_{i=1}^{N} m_i$, is the total number of atoms, m_i is the number of atoms in the triangular element E_i, and b_i is the number of atoms near at least one boundary of E_i and is less than a constant times the number of atoms located at the longest side of E_i.*

Proof. Using (30) and estimates (35), (43), and (37) for T_1, T_2, and T_3, respectively, and letting

$$H_1 = \left(\frac{1}{M}\sum_{i=1}^{N} m_i(|\nabla_{x,i}^h(\hat{Z}-\tilde{z})|^2 + |\nabla_{y,i}^h(\hat{Z}-\tilde{z})|^2)\right)^{\frac{1}{2}} \text{ and } H_2 = \|\hat{Z}-\tilde{z}\|_2,$$

we have

$$\frac{p}{2}H_1^2 M < a_h(\hat{Z}, \hat{Z}-\tilde{z}) - a_h(\tilde{z}, \hat{Z}-\tilde{z}) \le C\left(C_2 h + \sqrt{\frac{\sum_{i=1}^{N} \frac{b_i^2}{m_i}}{M}}\right) H_1 M$$

$$- \frac{F''_{min}}{2} H_2^2 M + C_2^2 h^4 M$$

or (noting $(H_1^2 + H_2^2) \ge (H_1 + H_2)^2/2$ and $H_1 \le H_1 + H_2$)

$$p_{min}(H_1+H_2)^2 < C\left(C_2 h + \sqrt{\frac{\sum_{i=1}^{N} \frac{b_i^2}{m_i}}{M}}\right)(H_1+H_2) + C_2^2 h^4,$$

where $p_{min} = \min\{p, F''_{min}\}/4$. Solving this inequality for $H_1 + H_2$, we thus have

$$H_1 + H_2 < C\left(C_2 h + \sqrt{\frac{\sum_{i=1}^{N} \frac{b_i^2}{m_i}}{M}}\right).$$

Then $\|\nabla_x^h \hat{Z} - \nabla_x^h \tilde{z}\|_2 + \|\nabla_y^h \hat{Z} - \nabla_y^h \tilde{z}\|_2$ can have the same estimate since

$$\|\nabla_x^h \hat{Z} - \nabla_x^h \tilde{z}\|_2 + \|\nabla_y^h \hat{Z} - \nabla_y^h \tilde{z}\|_2 \le \sqrt{2}\left(\frac{1}{M}\sum_{i=1}^{N}\sum_{k=1}^{m_i}(|\nabla_{x,i}^h(\hat{Z}-\tilde{z})|^2 + |\nabla_{y,i}^h(\hat{Z}-\tilde{z})|^2)\right)^{\frac{1}{2}}$$

$$= \sqrt{2}\, H_1.$$

Combining this with the interpolation error estimates (26), we obtain (44). □

The constant C_2 in the error estimate should be of reasonable size if all the components of the solution $\hat{z}$ defined on a reference configuration, as shown in the introduction, formulate a not-too-rough surface.

Remark 1. If the external potential $F(z)$ is convex but not strictly convex, the analysis may still be done with some small modification. For example, the body force energy $F(z) = -\sum_{i=1}^{N}\sum_{k=1}^{m_i} f_k z_k$ is convex but not strictly convex, where the constant f_k is the force applied on atom k. In this case, $T_3 = 0$ in (36) and there is no need to estimate it further. The theorem without the first term $\|\hat{Z} - \hat{z}\|_2$ in (44) remains true. For a general convex (but not strictly convex) external energy $F(z)$, we need to use a Poincaré type of inequality to control $\|\hat{Z} - \tilde{z}\|_2$ resulting from estimating T_3 in (36). Note that $\hat{Z} - \tilde{z}$ is a piecewise linear interpolation based on Z^h and values of $\hat{z}$ at vertices of the triangulation. So $\hat{Z} - \tilde{z} \in C^0$ or H^1 (and satisfying the homogeneous Dirichlet boundary condition) from the finite element theory. Then from the Poincaré inequality, we have

$$\int_\Omega |\hat{Z} - \tilde{z}|^2 \le C_d \left(\int_\Omega |\nabla_x^h(\hat{Z} - \tilde{z})|^2 + |\nabla_y^h(\hat{Z} - \tilde{z})|^2 \right),$$

where Ω is the material domain in the reference configuration and C_d is a generic constant depending on the size of the domain. Since first order derivatives of $\hat{Z} - \tilde{z}$ are constant in each element, we may derive from above inequality the Poincaré inequality in the discrete ℓ_2 norm $\|\cdot\|_2$:

$$\|\hat{Z} - \tilde{z}\|_2^2 \le \bar{C}_d \left(\|\nabla_x^h(\hat{Z} - \tilde{z})\|_2^2 + \|\nabla_y^h(\hat{Z} - \tilde{z})\|_2^2 \right).$$

Then we can estimate T_3 in (36) as the following:

$$|T_3| \le (\delta - F''_{min}) \sum_{i=1}^{N}\sum_{k=1}^{m_i} |\hat{Z}_k - \tilde{z}_k|^2 + \frac{1}{4\delta} \sum_{i=1}^{N}\sum_{k=1}^{m_i} |f(\hat{z}_k) - f(\tilde{z}_k)|^2,$$

where $F''_{min} \ge 0$. Taking $\delta < p/4\bar{C}_d$ (where p is the constant defined in (30)) we may obtain the result of Theorem 1 in the case of the convex external energy.

Remark 2. When a material has defects, there will be a certain amount of pairs of nearest neighbor atoms whose distance is located in the nonconvex region of the pair potential energy ϕ. In this case we may divide the domain of ϕ into two parts I (convex region, $\phi'' > 0$) and II (nonconvex region) (cf. [16]). We call the material parts corresponding to I and II the nondefect and defect parts, respectively, and collect all indices of triangular elements in the nondefect and defect parts into two sets R^I and R^{II}, respectively. Denote $a_h^I(\cdot,\cdot)$ and $a_h^{II}(\cdot,\cdot)$ as the parts of $a_h(\cdot,\cdot)$ corresponding to R^I and R^{II}, respectively. Then our previous argument may apply to $a_h^I(\cdot,\cdot) = a_h(\cdot,\cdot) - a^{II}(\cdot,\cdot)$ under assumptions 1 and 2 (in the nondefect part), assumption 3, and an additional assumption that in the defect part, $\hat{z}$, $\hat{Z}$, $\nabla_x^h\hat{Z}$, $\nabla_x\hat{z}$, $\nabla_y^h\hat{Z}$, and $\nabla_y\hat{z}$ are all bounded. Then we may have the estimate

(45)

$$\|\hat{Z} - \hat{z}\|_2 + \|\nabla_x^h\hat{Z} - \nabla_x\hat{z}\|_2 + \|\nabla_y^h\hat{Z} - \nabla_y\hat{z}\|_2 \le C \left(C_2 h + \sqrt{\frac{\sum_{i\in R^I} \frac{b_i^2}{m_i}}{M}} + \sqrt{\frac{n^d}{M}} \right),$$

where n^d is the number of atoms in the defect part (indices in R^{II}) of the material. So to have a small error of the QC approximation, the number of atoms n^d in the defect part of the material should be relatively small in comparison with the total number of atoms. That is, serious defects should occur only in a small region in order for the QC method to work. The estimate (45) is a macroscopic scale error estimate. It does not provide an error estimate inside the defect region, where a much smaller scale needs to be used. In fact, due to the nonconvex property in the defect region, the lattice solution may not even be unique. Nevertheless, it seems to us that a macroscopic error estimate is all we may expect for the model.

5. Conclusion. The QC approximation (or method) is a kind of representative of a number of recent atomistic/continuum models for steady-state material problems. It may be a useful technique for model reduction of large scale problems in other fields. Numerical analysis is in its infancy despite its great success in simulation of material problems in engineering literature. In this paper we introduce a mathematical description of the method based on the energy minimization and a nonconforming finite element framework. We prove the convergence of the solution of the QC approximation to the solution of the original atomic scale energy minimization problem in two dimensions (using the Lennard–Jones pair potential). Some mathematical understanding of usual atomistic assumptions for solid materials such as nearest neighbor interaction dominance and convex nearest neighbor pair potential energy is made into assumptions for convergence analysis. In the case that these assumptions do not hold, an expected convergence result is also given as a remark. The framework of analysis may apply to problems with different pair potential energies (or with material impurity) and to three-dimensional problems.

Acknowledgment. The author would like to thank the anonymous referees for their valuable suggestions in improving the paper.

CONVERGENCE OF UNSYMMETRIC KERNEL-BASED MESHLESS COLLOCATION METHODS*

ROBERT SCHABACK†

Abstract. This paper proves convergence of variations of the unsymmetric kernel-based collocation method introduced by Kansa in 1986. Since then, this method has been very successfully used in many applications, though it may theoretically fail in special situations, and though it had no error bound or convergence proof up to now. Thus it is necessary to add assumptions or to make modifications. Our modifications prevent numerical failure by dropping strict collocation and allow a rigorous mathematical analysis proving error bounds and convergence rates. These rates improve with the smoothness of the solution, the domain, and the kernel providing the trial spaces, but they are currently not yet optimal and deserve refinement. They are based on rates of approximation to the residuals by nonstationary meshless kernel-based trial spaces, and they are independent of the type of differential operator. The results are applicable to large classes of linear problems in strong form, provided that there is a smooth solution and the test and trial discretizations are chosen with some care. Our analysis does not require assumptions like ellipticity, and it can be extended to ill-posed problems.

Key words. Kansa method, error bounds, stability, ill-posed problems, greedy adaptive solver

1. Introduction.

The final goal of this paper is to prove error bounds and convergence of certain numerical techniques that approximately solve a PDE problem via an unsymmetric or even nonsquare system of linear collocation equations involving meshless kernel-based trial functions. The most popular method of this kind was first proposed by Kansa [8] in 1986, and there are many follow-up papers in engineering journals (see, e.g., [5] for a selection) that can easily be retrieved via the Internet. This is why this paper does not supply additional numerical examples. So far, the method is quite successful in applications with smooth solutions, but it can fail [7] in specially constructed situations. Consequently, it has neither error bounds nor convergence proofs for its original form, and a rigorous mathematical analysis will either require some additional assumptions or make changes to the method itself. We shall do both, but we shall stay general enough not to spoil the applicability to elliptic, parabolic, and hyperbolic problems. Therefore we need a somewhat nonstandard framework, which we sketch here first, to make sure that the reader does not get lost in the technical details we have to provide later.

Consider a linear operator equation

$$L(u) = f,\ L\ :\ U \to F \tag{1.1}$$

between normed linear spaces U and F which is to be solved for any given $f \in F$. The map L takes a *solution* $u \in U$ to its *data* $L(u)$ in F. Thus F will usually be a Cartesian product of *trace* spaces of functions prescribed on the domain or on parts of the boundary. We shall consider a large class of unsymmetric discretization methods to solve such equations approximately, and we need five essential ingredients.

*Received by the editors June 10, 2005; accepted for publication (in revised form) August 18, 2006; published electronically February 9, 2007.

†Institut für Numerische und Angewandte Mathematik, Lotzestraße 16–18, D–37083 Göttingen, Germany (schaback@math.uni-goettingen.de, http://www.num.math.uni-goettingen.de/schaback).

The first ingredient requires the problem to be *continuously dependent on the data*. In quantitative form, this means that the inverse L^{-1} is a bounded linear map from F to U. In particular, we assume an inequality of the form

$$\|u\|_U \le C_a \|L(u)\|_F \text{ for all } u \in U \tag{1.2}$$

with a positive constant C_a describing the stability of the problem. In practical applications this will imply that the *solution space* U and the *data space* F have to be chosen with some care. In particular, U and F must often be chosen on a theoretical basis, e.g., as quite large spaces in which certain general existence results hold and which carry only rather weak norms. Usually, U will be a Sobolev space $W_2^\mu(\Omega)$ while F is a Cartesian product of Sobolev spaces which provide the right-hand sides for the differential equation and the boundary data via trace operators. Continuous dependence serves here as a replacement for more specific analytic assumptions like coercivity of a bilinear form. However, in section 9 we shall abandon the assumption of continuous dependence to be able to treat a certain class of ill-posed problems.

The second ingredient is some *additional regularity*. The actual solution u of a specific problem will often have more regularity than needed for the spaces U and F defining continuous dependence, and therefore we shall focus on a subspace $U_R \subseteq W_2^m(\Omega) \subset W_2^\mu(\Omega) =: U$ of U which we call the *regularity* subspace. The additional regularity of order $m - \mu > 0$ will be the driving force behind convergence rates, as we shall prove later.

The third ingredient is a scale of finite-dimensional *trial* subspaces U_r of U for a *trial discretization parameter* $r > 0$ which uses the additional regularity to provide a *convergent scheme for data approximation*. This is formalized by not necessarily linear maps $I_r : U_R \to U_r$ with error bounds

$$\|L(u - I_r(u))\|_F \le \epsilon_r(u) \text{ for all } u \in U_R. \tag{1.3}$$

It will be this approximation property that yields our convergence rates driven by additional regularity. Note that we do not use a single discretization parameter like the usual h here, because we need two different discretization parameters r and s for trial and test discretization. The trial spaces U_r can be chosen independent of the operator L, and we do not approximate the solution directly but rather the data via the linear operator L.

The fourth ingredient is a scale of *stable test discretizations* F_s of the data space F with respect to the scale of trial spaces U_r. This is formalized by a *test discretization parameter* $s > 0$ and linear maps $\Pi_s : F \to F_s$ into a scale of finite-dimensional *test data* spaces F_s such that the inequalities

$$\begin{aligned} \|L(u_r)\|_F &\le C(r,s)\|\Pi_s L(u_r)\|_{F_s} \text{ for all } u_r \in U_r, \\ c(s)\|\Pi_s L(u)\|_{F_s} &\le \|L(u)\|_F \text{ for all } u \in U \end{aligned} \tag{1.4}$$

hold. We call a specific choice of trial and test discretization schemes *uniformly stable* if both constants can be chosen independent of r and s for a certain range of these parameters. When restricted to the finite-dimensional trial spaces U_r, the inequalities express equivalence of discrete and nondiscrete norms on the data $L(u_r)$. The second inequality will be easily satisfied by discretization, but the first one will be hard, because it bounds a nondiscrete norm by a discrete norm, and this can work only for finite-dimensional spaces. It also implies uniqueness of solutions of the discretized finite systems $\Pi_s L(u_r) = \Pi_s L(u)$, which is a serious problem [7].

To simplify some of the later arguments, we outline here how we proceed to prove the first inequality of (1.4).

THEOREM 1.1. *Assume a* Poincaré–Friedrichs *inequality*

$$\|f\|_F \le c_1(s)\|f\|_{F_R} + c_2(s)\|\Pi_s f\|_{F_s} \text{ for all } f \in F_R \subset F \tag{1.5}$$

on a regularity subspace F_R *of the data space* F. *Second, assume a* Markov–Bernstein *inequality*

$$\|Lu_r\|_{F_R} \le c_3(r)\|Lu_r\|_F \text{ for all } u_r \in U_r \subset U_R \tag{1.6}$$

on a scale of trial spaces $U_r \subset U_R$ *with* $L(U_R) \subseteq F_R$. *Third, let the trial and test discretization parameters* r *and* s *satisfy the* stability criterion

$$c_1(s)c_3(r) < \frac{1}{2}. \tag{1.7}$$

Then the first inequality of (1.4) *holds with* $C(r,s) \le 2c_2(s)$.

Proof. Just consider

$$\begin{aligned} \|L(u_r)\|_F &\le c_1(s)\|L(u_r)\|_{F_R} + c_2(s)\|\Pi_s L(u_r)\|_{F_s} \\ &\le c_1(s)c_3(r)\|Lu_r\|_F + c_2(s)\|\Pi_s L(u_r)\|_{F_s} \\ &\le \tfrac{1}{2}\|Lu_r\|_F + c_2(s)\|\Pi_s L(u_r)\|_{F_s} \end{aligned}$$

for all $u_r \in U_R$. ∎

Note that in (1.5) we shall have $c_1(s) \to 0$ for $s \to 0$, because the inequality means that a function is small in a weak norm if it is bounded in a strong norm and is small on a large discrete set. In (1.6) we have to expect $c_3(r) \to \infty$ for $r \to 0$ because c_3 bounds a strong norm by a weak one on a finite-dimensional space. Thus the stability criterion (1.7) will usually be satisfied if the test discretization is "fine enough" with respect to the trial discretization.

The final ingredient is the class of *numerical methods*. We do not specify details in this overview, but we can always find nonunique trial functions $u^*_{r,s} \in U_r$ with

$$\|\Pi_s L(u - u^*_{r,s})\|_{F_s} \le \delta_{r,s} \tag{1.8}$$

solving $\Pi_s L(u_r) = \Pi_s L(u)$ approximately with a small tolerance. In fact, the approximation $I_r(u)$ is a solution if we have (1.4) and

$$c(s)\epsilon_r(u) \le \delta_{r,s}. \tag{1.9}$$

Note that we do not attempt to solve the discrete system $\Pi_s L(u_r) = \Pi_s L(u)$ exactly, because it will be overdetermined and unsolvable in general. However, under the assumption (1.9) we know that the relaxed problem (1.8) is solvable. In section 8 we show how to tackle such problems. Altogether, we replace strict collocation by a generalized form of "almost interpolation." Now we can formulate the core result of this paper.

THEOREM 1.2. *If the analytic problem is solvable by* $u \in U_R$ *and if we solve* (1.8) *by some* $u^*_{r,s} \in U_r$, *then the following error bound holds:*

$$\|u - u^*_{r,s}\|_U \le C_a \left(\epsilon_r(u) \left(1 + \frac{C(r,s)}{c(s)} \right) + c(s)\delta_{r,s} \right)$$

provided that all of the above ingredients are available. If the discretization is uniformly stable with constants

$$\begin{array}{rcll} & & C(r,s) & \leq & C, \\ 0 < c & \leq & c(s) & \leq & \tilde{c}, \end{array}$$

and if we choose $\tilde{c}\epsilon_r(u) \leq \delta_{r,s} \leq 2\tilde{c}\epsilon_r(u)$ *to satisfy* (1.9)*, we get the bound*

$$\|u - u^*_{r,s}\|_U \leq \epsilon_r(u) C_a \left(1 + \frac{C}{c} + 2\tilde{c}^2\right),$$

which behaves asymptotically like the trial approximation error $\epsilon_r(u)$*.*

Proof. The assertion follows from a simple chain of inequalities:

$$\begin{array}{rcl} \frac{1}{C_a}\|u - u^*_{r,s}\|_U & \leq & \|L(u - u^*_{r,s})\|_F \\ & \leq & \|L(u - I_r(u))\|_F + \|L(I_r(u) - u^*_{r,s})\|_F \\ & \leq & \epsilon_r(u) + c(s)\|\Pi_s L(I_r(u) - u^*_{r,s})\|_{F_s} \\ & \leq & \epsilon_r(u) + c(s)\|\Pi_s L(u - u^*_{r,s})\|_{F_s} \\ & & + c(s)\|\Pi_s L(I_r(u) - u)\|_{F_s} \\ & \leq & \epsilon_r(u) + c(s)\delta_{r,s} + \frac{C(r,s)}{c(s)}\|L(I_r(u) - u)\|_F \\ & \leq & \epsilon_r(u)\left(1 + \frac{C(r,s)}{c(s)}\right) + c(s)\delta_{r,s}. \qquad \square \end{array}$$

But now we shall have to show how this abstract machinery can be set to work. We shall finally derive specific convergence rates for unsymmetric collocation techniques solving strongly posed problems with continuous dependence in Sobolev spaces, including the Poisson problem with Dirichlet data as an illustration. But note that the above formalism is much more general, and there may be various other future ways to apply the framework, e.g., to unsymmetric methods solving problems in weak form.

The following sections will treat the above ingredients one by one, and then we shall patch the results together. Our key tools will be *nonstationary meshless kernel-based trial spaces* which allow approximation schemes with high-order convergence rates while maintaining stability if paired with sufficiently rich test discretizations. It turns out that the use of smooth kernels makes the final convergence order dependent mainly on the regularity of the solution and the problem. The numerical methods for solving (1.8) will consist of certain variations of the original unsymmetric collocation method, and we already have solvability via (1.9). This saves us from the degeneration problems of the standard unsymmetric collocation technique [7].

2. Well-posed problems and regularity. For example, consider a standard Poisson boundary value problem

$$\begin{array}{rcll} -\Delta u & = & f_\Omega & \text{in } \Omega, \\ u & = & f_D & \text{on } \partial\Omega \end{array} \tag{2.1}$$

on a bounded domain $\Omega \subset \mathbb{R}^d$ with Dirichlet data f_D on the piecewise smooth boundary $\partial\Omega$. In such problems, we consider the equations as being given in strong form; i.e., we assume the solution u to be regular enough to pose the equations pointwise as

$$\begin{array}{rcccll} (-\Delta u)(x) & = & (\delta_x \circ (-\Delta))(u) & = & f_\Omega(x) & \text{for all } x \in \Omega, \\ u(x) & = & (\delta_x \circ Id)(u) & = & f_D(x) & \text{for all } x \in \partial\Omega. \end{array} \tag{2.2}$$

This leads to (1.1) if we define $L(u) := (-\Delta u_{|\Omega}, u_{|\partial\Omega})$ on $U := W_2^\mu(\Omega)$ with values in $F := W_2^{\mu-2}(\Omega) \times W_2^{\mu-1/2}(\partial\Omega)$, with given data $f = (f_\Omega, f_D) \in F$.

But we allow much more general linear equations and boundary value operators. Formally, we follow the notation of [3] and others to combine differential and boundary operators into just one equation and write the latter as (1.1) where u is a function from some normed space U of functions. The mapping $L : U \to F$ maps solutions $u \in U$ to their data $L(u) \in F$, and the given problem consists in the inversion of L.

When aiming at methods with error bounds and convergence, we have to take a closer look at the given analytic problem (1.1). In particular, we shall assume that the problem (1.1) is well-posed in the sense that the solution u depends continuously on the data f of the right-hand side of (1.1). But we have to make this more precise. This can be done in various ways, e.g., by *total sets* of data functionals, but this is not quantitative. For later use we impose a norm $\|.\|_F$ on $F := L(U)$ in a suitable way and assume (1.2) with a positive "analytic" constant C_a which describes the norm of the linear map L^{-1} that takes the data $f \in F$ and maps them back to the solution u in the function space U. Clearly, for such a priori inequalities we must be careful with the choice of norms, because they depend on regularity theory, and they always imply that the homogeneous equation has only the trivial solution. The numerical methods following below will work on discretized versions F_s of F, and thus the proper choice of F will also have practical consequences.

So far we have not mentioned any specific numerical algorithm. But if any numerical method has produced an approximate solution $\tilde{u} \in U$ to the problem (1.1), one can calculate the data $\tilde{f} = L(\tilde{u}) \in F$ and the norm $\|\tilde{f} - f\|_F$ to get the a posteriori error bound

$$\|u - \tilde{u}\|_U \le C_a \cdot \|L(u - \tilde{u})\|_F = C_a \cdot \|f - \tilde{f}\|_F \tag{2.3}$$

for free, since the *residuals* $L(u - \tilde{u}) = f - \tilde{f}$ are explicitly known. It means that errors in the solution are bounded by the norm of the residuals, multiplied with the analytic constant. *Thus any numerical technique that produces approximate solutions of well-posed problems with small residuals will automatically guarantee small errors in the solution.* This trivial observation is well known in numerical analysis and serves as a basis for *defect correction* and *residual minimization* techniques, and is important for providing a safe a posteriori foundation for many unsafe and ad hoc numerical calculations published in science and engineering journals. If the underlying problem is continuously dependent on the data and if the naive user at least checks the residuals carefully, the calculations are on the safe side. But, unfortunately, there is no handbook listing all known inequalities of the form (1.2) for typical applications in science and engineering. In particular, it would be very useful to have proven upper bounds for the analytic constants.

Guided by regularity theory for elliptic problems, we focus on operator equations (1.1) where the linear map L splits into maps $L^1, \ldots, L^n$ with $L^i : U \to F^i$, $1 \le i \le n$, such that $F = F^1 \times \cdots \times F^n$ is the data space. We assume $U = W_2^\mu(\Omega)$ for some bounded domain $\Omega \subset \mathbb{R}^d$ and $F^i := W_2^{\mu-\mu_i}(\Omega^i)$, where μ_i is defined via a trace theorem by the order of the operator L^i and the dimension $d_i \le d$ of the partial domain $\Omega^i \subset \overline{\Omega} \subset \mathbb{R}^d$. The space F is then equipped with the sup of the norms of the spaces F^i. The regularity subspace U_R occurring later will then be a space $U_R \subseteq W_2^m(\Omega) \subset U := W_2^\mu(\Omega)$ for some $m \ge \mu$.

In the standard Poisson problem with Dirichlet data we take $L(u) = (-\Delta u, u_{\partial\Omega})$ mapping $U \subseteq W_2^\mu(\Omega)$ into $F = W_2^{\mu-2}(\Omega) \times W_2^{\mu-1/2}(\partial\Omega)$. This is a well-established

continuous dependence setting if the domain is smooth enough to make trace theorems and the regularity order μ valid. See, e.g., [3, 12] for early references which also allow distributional data and negative μ.

3. Approximation from trial spaces. The second ingredient of our framework is some additional regularity defined via a subspace U_R of the space U occurring in the continuous dependence bound (1.2). At this point, the regularity space can be quite general, but we also want an approximation property like (1.3) to hold. Thus we now have to consider our third ingredient, i.e., techniques that construct approximate solutions $\tilde{u}_r$ from a scale of *trial spaces* $U_r \subseteq U$ with a trial discretization parameter r. Note that this includes plenty of methods, with or without meshes, like finite elements, Petrov–Galerkin schemes, spectral methods, and all variations of collocation. It is trivial that the choice of the trial space should be such that the true solution u can be approximated easily by functions from the trial space. In case of solutions with singularities, like for Poisson problems on domains with incoming vertices, one should make sure that the trial space contains the expected singular functions.

One way to make this more precise is to assume that there is a mapping $A_r : U_R \to U_r$ with

$$\|u - A_r(u)\|_U =: \delta_r(u) \text{ for all } u \in U_R \tag{3.1}$$

with a certain error $\delta_r(u)$ which will depend on the regularity subspace U_R.

But the previous section teaches us that we do not need to approximate the exact solution u in the space U by functions $u_r \in U_r \subset U$ directly. It suffices to make sure that the residuals $L(u) - L(u_r)$ are small. Thus the crucial quantity is the residual error $\|L(u - u_r)\|_F$ for any $u \in U$ and an approximation $u_r \in U_r$. In contrast to the theory of finite elements, we do not consider optimal approximations of u by u_r here, nor do we attempt to minimize the above error with respect to u_r. Instead, we are satisfied if the trial space U_r contains for each function $u \in U$ an approximation $u_r := I_r(u)$ with small *residual error* $\epsilon_r(u)$ as in (1.3).

Of course, if an L-independent approximation operator A_r with (3.1) is available, one can take $I_r = A_r$ and assume $\epsilon_r(u) \le \|L\|\delta_r(u)$ because of

$$\epsilon_r(u) = \|L(u - I_r(u))\|_W \le \|L\|\|(u - A_r(u))\|_U \le \|L\|\delta_r(u).$$

But there may be better choices of I_r if L and the special structure of the residual space W are taken into account.

Inspection of (1.3) for F being a Cartesian product of Sobolev spaces reveals that the special approximation $I_r(u)$ should approximate u well *including its derivatives*, as far as they occur in the collection of data spaces F^i forming the space F. In fact, if we go back to our special case $U = W_2^\mu(\Omega)$ and $F = F^1 \times \cdots \times F^n$ with $F^i := L^i(U) := W_2^{\mu-\mu_i}(\Omega^i)$ with a regularity subspace $U_R \subseteq W_2^m(\Omega)$ and $m > \mu$, we should expect approximation bounds like

$$\begin{aligned} \|L^i(u) - L^i(I_r(u))\|_{W_2^{\mu-\mu_i}(\Omega^i)} &\le Cr^{m-\mu}\|L^i(u)\|_{W_2^{m-\mu_i}(\Omega^i)} \\ &\le Cr^{m-\mu}\|u\|_{W_2^m(\Omega)} \text{ for all } u \in W_2^m(\Omega), \end{aligned} \tag{3.2}$$

and this should work for a reasonable choice of $0 \le \mu \le m$ and with rates that just depend on the *regularity gap* $m - \mu$ and not on the order of the operators involved.

Note that the standard trial spaces of h-type finite element techniques consisting of piecewise linear functions fail to provide approximations of more than first-order

derivatives. In contrast to this, trial spaces generated by sufficiently smooth kernel functions can contain approximations to derivatives of any order, without any additional work needed. We shall explain this in the following sections.

In contrast to many engineering applications where a rather simple solution function is calculated via a huge finite element method system of millions of unknowns, we tend to argue in favor of small trial spaces designed to capture the essential features of the solution without taking the detour via a fine-grained space discretization. The consequence will be that the linear systems get unsymmetric, because any solution from a small *trial* space must be *tested* on a fine-grained space discretization, asking for many more degrees of freedom on the "test side" than on the "trial side." Unsymmetry of a method can be a feature instead of a bug. In what follows we shall investigate the relation of test and trial spaces more closely.

4. Kernel-based trial spaces. Now it is time to study maps I_r or A_r with good approximation properties for certain trial spaces U_r in the sense of (1.3) and (3.1). This is independent of PDE solving, and we shall see that nonstationary scales of meshless kernel-based trial spaces work perfectly.

DEFINITION 4.1. *A* kernel *is a function of the form* $K : \Omega \times \Omega \to \mathbb{R}$ *with* $\Omega \subseteq \mathbb{R}^d$. *It is* translation-invariant *if* $K(x,y) = \Phi(x-y)$ *with* $\Omega = \mathbb{R}^d$ *and* $\Phi : \mathbb{R}^d \to \mathbb{R}$. *It is* radial *if it is translation-invariant and of the form*

$$K(x,y) = \Phi(x-y) = \phi(\|x-y\|_2) \text{ with } \phi : [0,\infty) \to \mathbb{R} \text{ and } x,y \in \mathbb{R}^d.$$

Radial kernels are also called radial basis functions.

Note that radial basis functions ϕ can in principle be used in any space dimension, but certain properties of the associated translation-invariant kernel Φ on $\mathbb{R}^d$ may depend [6, 19] on the dimension d.

Kernels provide excellent tools in various disciplines, including approximation theory, partial differential equations, and machine learning [17]. The most important kernels are *reproducing kernels* of some Hilbert space which can be called the "native" Hilbert space for the kernel. Any Hilbert space H of functions on a domain Ω with continuous and linearly independent point evaluations has a kernel K with the reproduction property

$$f(x) = (f, K(x,\cdot)) \text{ for all } f \in H,\ x \in \Omega.$$

Conversely, any (strictly) positive definite [6, 19] and continuous kernel K on Ω is the reproducing kernel of a *native* Hilbert space N_K of continuous functions on Ω. We denote the norm on the native space N_K by $\|.\|_K$.

We focus here on *trial spaces* provided by kernels. Like in wavelet theory, the notions of *translation* and *dilation* play an important role. First, a general kernel $K : \Omega \times \Omega \to \mathbb{R}$ can be translated to points $y_1, \ldots, y_M \in \Omega$ called *centers* to provide trial functions $u_j(x) := K(x, y_j)$, $1 \le j \le M$, on Ω. In many cases, the set $Y := \{y_j : 1 \le j \le M\}$ of centers should fill a bounded domain Ω in such a way that the centers get dense when $M \to \infty$. This is expressed by the *fill distance*

$$h := h(Y,\Omega) := \sup_{x\in\Omega} \inf_{y\in Y} \|x-y\|_2$$

depending on Ω and the M centers in Y, which should converge to zero if M tends to infinity. The fill distance is the radius of the largest open ball with center in Ω that contains none of the centers y_j from Y. We use the notation h here, but later

we shall have two different fill distances for trial and test centers, and then we shall use r and s for clarity.

A *nonstationary* scale of kernel-based trial spaces can now be defined as

$$U_r := \text{span}\,\{K(\cdot, y_j) \,:\, 1 \le j \le M\} \text{ with } r := h(Y, \Omega), \tag{4.1}$$

where the dependence on the location and number of the centers is suppressed in the notation.

In the above *nonstationary* situation, only translations, but no dilations are used. The translated kernel is fixed and independent of the fill distance. There is no rescaling, if the fill distance gets small. This is in contrast to the *stationary* technique in standard and general finite elements [4]. There, the basis functions are rescaled when the fill distance changes, and in the translation-invariant kernel-based case this can be described by a scale of trial spaces

$$U_r := \text{span}\,\left\{\Phi\left(\frac{x - y_j}{r}\right) \,:\, 1 \le j \le M\right\},$$

where now the wavelet style interaction of translation and dilation is apparent.

The mathematics of the stationary and nonstationary cases are quite different. This often leads to misunderstandings. The stationary situation, as included in the meshless generalized finite element method [4], uses polynomial reproduction and the Bramble–Hilbert lemma. If centers are on a grid, it applies the Strang–Fix theory. Convergence orders are closely tied to polynomial reproduction properties, and the choice of kernels is quite restricted, because integrable kernels like the Gaussian do not yield convergent stationary approximations for $h \to 0$ [6]. Stability is usually much better than in the nonstationary case, but convergence rates (if they exist at all, e.g., for thin-plate splines or multiquadrics) are much smaller. We focus on nonstationary kernel-based trial spaces here, because condition problems can be overcome [5, 9], and we are heading for methods with high approximation orders.

We define a map $I_r \,:\, u \to u_r := I_r(u) \in U_r$ of (1.3) via *interpolation in the trial centers* by solving the system

$$u_r(y_k) := \sum_{j=1}^{M} \alpha_j K(y_j, y_k) = u(y_k),\ 1 \le k \le M, \tag{4.2}$$

for the coefficients $\alpha_1, \ldots, \alpha_M$ defining the function $u_r := I_r(u)$ in terms of the basis functions of the nonstationary trial space U_r of (4.1). This interpolation problem is solvable by definition if the kernel K is symmetric and positive definite [6, 19], because then the $M \times M$ matrix with entries $K(y_j, y_k)$ is symmetric and positive definite. Table 4.1 gives some examples. We ignore *conditionally* positive definite kernels here and refer to the literature [6, 16, 19] for details.

The interpolation system (4.2) makes sense for all functions u which have well-defined function values at the trial centers y_k. Thus the mapping I_r is at least defined on $C(\Omega)$, but for solutions u of PDE problems in strong form we use it on a regularity subspace U_R of $C(\Omega) \subset U$.

The book [19] contains a fairly complete account of interpolation error bounds in the nonstationary setting, while bounds for stationary and regular cases are in [6]. But in view of (1.3) and (3.2), we need very general error bounds in Sobolev spaces which are not covered in these books. Here (on the trial side) and later (on the test

TABLE 4.1
Radial basis functions $\phi(r)$, positive definite on $\mathbb{R}^d$.

Function	$\phi(r)$	Range	Smoothness β
Gaussian	$\exp(-r^2)$	$d \geq 1$	all β
inverse multiquadric	$(r^2+c^2)^\gamma,\ \gamma < -d/2,\ c > 0$	$d \geq 1$	all β
Sobolev for $W_2^k(\mathbb{R}^d)$	$r^{k-d/2}K_{k-d/2}(r),\ k > d/2$	$d \geq 1$	$\beta = 2k-d$
Wendland C^2 [18]	$(1-r)_+^4(1+4r)$	$d \leq 3$	3
	$(1-r)_+^5(1+5r)$	$d \leq 5$	3
Wendland C^4 [18]	$(1-r)_+^6(3+18r+35r^2)$	$d \leq 3$	5
	$(1-r)_+^7(1+7r+16r^2)$	$d \leq 5$	5

side for proving (1.5)) we use a general result from [13] which was extended in [20], while the range of admissible parameters was enlarged in [14].

THEOREM 4.2. *Suppose $\Omega \subset \mathbb{R}^d$ is a bounded domain with an interior cone condition. Choose $q \in [1,\infty]$ and constants*

$$0 \leq \mu < \mu + d/2 < \lfloor m \rfloor \tag{4.3}$$

with μ being an integer. Then there are positive constants C, h_0 such that

$$|u|_{W_q^\mu(\Omega)} \leq C\left(h^{m-\mu-d(1/2-1/q)_+}|u|_{W_2^m(\Omega)} + h^{-\mu}\|u\|_{\infty,Y_h}\right) \tag{4.4}$$

holds for every discrete set Y_h in Ω with fill distance at most $h \leq h_0$ and every $u \in W_2^m(\Omega)$.

This can be seen as a quantitative Poincaré–Friedrichs inequality for functions which are small on a finite subset, and it is independent of any trial space. If we replace seminorms by norms and extract $h^{-\mu}$ out of the right-hand side, the rest is a μ-independent norm on $W_2^m(\Omega)$ and we can apply interpolation theory to replace (4.4) by

$$\|u\|_{W_q^\mu(\Omega)} \leq C\left(h^{m-\mu-d(1/2-1/q)_+}\|u\|_{W_2^m(\Omega)} + h^{-\mu}\|u\|_{\infty,Y_h}\right) \tag{4.5}$$

under the assumptions (4.3) *without* the restriction of μ being an integer.

Now we take $h = r$ because we discretize the *trial* side, and we interpolate a function u on Y_r by $I_r(u)$ using points from Y_r as translations in (4.1) to get

$$\|u - I_r(u)\|_{W_2^\mu(\Omega)} \leq Cr^{m-\mu}\|u - I_r(u)\|_{W_2^m(\Omega)} \text{ for all } u \in W_2^m(\Omega). \tag{4.6}$$

Then we use the standard fact that the interpolant $I_r(u)$ solves the minimization problem

$$\|v\|_K \to \min,\ v \in K,\ v(y_j) = u(y_j) \text{ for all } y_j \in Y_r,$$

implying that $\|I_r(u)\|_K \leq \|u\|_K$ holds if we assume u to be in the native space N_K for the kernel K.

Therefore we strengthen the requirement on the regularization subspace U_R and on the regularity of our solution u to

$$u \in N_K = U_R \subseteq W_2^m(\Omega) \subseteq U \tag{4.7}$$

with bounded embeddings, where we always assume (4.3). This is easy if the kernel is smooth enough, and for the kernels in Table 4.1 the inequality

$$2m \leq \beta + d \tag{4.8}$$

is a sufficient condition.

We can now replace (4.6) by

$$\|u - I_r(u)\|_{W_2^\mu(\Omega)} \le C r^{m-\mu} \|u\|_K \text{ for all } u \in N_K$$

with a different constant. This inequality can be coupled with trace theorems for the operators $L^i : W_2^m(\Omega) \to W_2^{m-\mu_i}(\Omega^i)$ to get

$$\|L^i(u - I_r(u))\|_{W_2^{\mu-\mu_i}(\Omega^i)} \le C\|u - I_r(u)\|_{W_2^\mu(\Omega)} \le C r^{m-\mu} \|u\|_K \text{ for all } u \in N_K$$

which yields (3.2) in a slightly restricted form and our third ingredient (1.3) as

$$\|L(u - I_r(u))\|_F \le C r^{m-\mu} \|u\|_K =: \epsilon_r(u) \text{ for all } u \in U_R = N_K \tag{4.9}$$

under the assumptions (4.3), (4.7), and (4.8).

5. Stability of kernel-based test discretizations. We now consider the stability conditions (1.4), our fourth ingredient. We do this for meshless kernel-based trial spaces and for our running example generalizing the Poisson equation. The trial discretization via U_r and a set Y_r of centers is chosen as in section 4. We assume (4.7) and have the approximation result (4.9). On the test side, we use a set X_s of test centers which has a fill distance s on all of $\overline{\Omega}$. For all the operators L^i that arise in L, we will have a selection $X_s^i := X_s \cap \Omega^i$ of points with the same fill distance with respect to Ω^i, because we can assume that all Ω^i are subsets of $\overline{\Omega}$. The projectors Π_s^i on F^i just map functions from $F^i = W_2^{\mu-\mu_i}(\Omega^i)$ to their values on X_s^i. We thus have to assume Sobolev embedding conditions

$$2(\mu - \mu_i) > d_i := \dim(\Omega^i) \le d := \dim(\Omega),\ 1 \le i \le n. \tag{5.1}$$

The discretized spaces F_s^i will be $\mathbb{R}^{|X_s^i|}$ with the L_∞ norm, and we have

$$\Pi_s^i L^i(u) = (L^i(u))(X_s^i),\ \|\Pi_s^i L^i(u)\|_{F_s^i} = \|L^i(u)\|_{\infty, X_s^i}.$$

This implies by Sobolev embedding

$$\|\Pi_s^i L^i(u)\|_{F_s^i} = \|L^i(u)\|_{\infty, X_s^i} \le \|L^i(u)\|_{\infty,\Omega^i} \le C_i \|L^i(u)\|_{W_2^{\mu-\mu_i}(\Omega^i)},$$

where the constant is independent of u and s. We now assemble this into a discretization $F_s := F_s^1 \times \cdots \times F_s^n$ with $\Pi_s := \Pi_s^1 \times \cdots \times \Pi_s^n$ of $F = F^1 \times \cdots \times F^n$ and take the sup norm of the components. Then we have

$$\begin{aligned} \|\Pi_s L(u)\|_{F_s} &= \sup_{1\le i\le n} \|\Pi_s^i L^i(u)\|_{F_s^i} \\ &\le C \sup_{1\le i\le n} \|L^i(u)\|_{W_2^{\mu-\mu_i}(\Omega^i)} \\ &= C\|L(u)\|_F \end{aligned}$$

and get the second inequality of (1.4) with a constant that is independent of s and dependent only on Sobolev embedding. This leaves us to prove the first inequality of (1.4) via Theorem 1.1.

Fortunately, the inequality (4.5) holds for general Sobolev spaces, and we can apply it on the test side for different operators. We get

$$\|L^i(u)\|_{W_2^{\mu-\mu_i}(\Omega^i)} \le C\left(s^{m-\mu}\|L^i(u)\|_{W_2^{m-\mu_i}(\Omega^i)} + s^{-(\mu-\mu_i)}\|L^i(u)\|_{\infty, X_s^i}\right)$$

under the assumptions (5.1) and

$$d_i/2 < \mu - \mu_i < \mu - \mu_i + d_i/2 < \lfloor m - \mu_i \rfloor \text{ for all } i,\ 1 \le i \le n, \tag{5.2}$$

which pose no serious problems if m is large enough. Now we define F_R to be the range of $L(U_R)$ in the Cartesian product of all spaces $W_2^{m-\mu_i}(\Omega^i)$, taking the sup of the component norms. With part of the notation

$$\min_i \mu_i =: \underline{\mu} \le \mu_i \le \overline{\mu} := \max_i \mu_i, \tag{5.3}$$

this yields (1.5) in the form

$$\|L(u)\|_F \quad \le \quad C\left(s^{m-\mu}\|L(u)\|_{F_R} + s^{\underline{\mu}-\mu}\|\Pi_s L(u)\|_{F_s}\right).$$

We now want to consider (1.6). Assume K to be a translation-invariant positive definite kernel of finite smoothness which is Fourier-transformable in $\mathbb{R}^d$ with an exact decay

$$c(1+\|\omega\|_2)^{-\beta-d} \le \hat{K}(\omega) \le C(1+\|\omega\|_2)^{-\beta-d} \text{ for all } \omega \in \mathbb{R}^d, \tag{5.4}$$

where the constants β can be read from Table 4.1. If we again assume (4.8), we can cite the Bernstein-type inequality

$$\|u_r\|_{W_2^m(\Omega)} \le C \cdot \|u_r\|_{W_2^{(d+\beta)/2}(\mathbb{R}^d)} \le Cr^{-(d+\beta)/2}\|u_r\|_{L_\infty(\Omega)} \text{ for all } u_r \in U_r$$

from [15] provided that the trial centers in $Y_r \subset \Omega$ are not too wildly scattered in the sense that the minimal separation distance $q(Y_r)$ is uniformly bounded below by the fill distance $h(Y_r, \Omega)$ via

$$q(Y_r) := \min_{y_j \ne y_i \in Y_r} \|y_j - y_i\|_2 \ge C \sup_{y \in \Omega} \min_{y_i \in Y_r} \|y - y_i\|_2 =: h(Y_r, \Omega) \tag{5.5}$$

such that both quantities behave asymptotically like the trial discretization parameter r. This yields

$$\begin{aligned}
\|L(u_r)\|_{F_R} &= \max_i \|L_i(u_r)\|_{W_2^{m-\mu_i}(\Omega^i)} \\
&\le C\|u_r\|_{W_2^m(\Omega)} \\
&\le Cr^{-(d+\beta)/2}\|u_r\|_{L_\infty(\Omega)} \\
&\le Cr^{-(d+\beta)/2}\|u_r\|_{W_2^\mu(\Omega)} \\
&= Cr^{-(d+\beta)/2}\|u_r\|_U \\
&\le C_a C r^{-(d+\beta)/2}\|L(u_r)\|_F \text{ for all } i,\ 1 \le i \le n,
\end{aligned}$$

under the additional assumption $\mu > d/2$. This result is far from optimal, but it establishes (1.6) and allows us to apply Theorem 1.1 under a stability condition of the form

$$Cs^{m-\mu}r^{-(d+\beta)/2} < \frac{1}{2}. \tag{5.6}$$

This finally implies the following theorem.

THEOREM 5.1. *Assume that the trial kernel K with* (5.4) *is smooth enough to satisfy* (4.8). *Let the trial space consist of quasi-uniform translates on Ω with discretization parameter r, and consider a test discretization on $\overline{\Omega}$ with fill distance s. Then, under the notation* (5.3), *and the additional conditions* (4.3), (5.2), (5.6), *and $\mu > d/2$, the first inequality of* (1.4) *is satisfied with*

$$\|L(u_r)\|_F \quad \le \quad Cs^{\underline{\mu}-\mu}\|\Pi_s L(u_r)\|_{F_s}$$

for all $u_r \in U_r$.

6. Strong convergence in Sobolev spaces. We now assemble what we have in case of our running example with continuous dependence in Sobolev norms. In contrast to the introduction, we proceed here from the user's point of view.

We start with the analytic problem. Consider an operator equation $L(u) = f$ as in (1.1) whose solution u is continuously dependent on the data f. We assume continuous dependence in the sense of (1.2) to hold if we pick spaces $U = W_2^\mu(\Omega)$ and F defined as a Cartesian product of Sobolev trace spaces F^i as in section 2. But note that users have to make sure in each application problem that the a priori inequalities composing (1.2) are actually satisfied. If several choices of μ are possible, the user should know that the final convergence will take place in $U = W_2^\mu(\Omega)$, but large μ have to be paid for by regularity. If convergence of higher-order derivatives is of importance, a sufficiently large μ must be chosen. Since we solve problems in strong form via evaluation of residuals, we have to pick μ large enough to let all data have continuous point evaluations. This is expressed by the requirement (5.1). At this point, the lower bounds for μ will rule out problems with low regularity. Such problems should be tackled with methods using weak data functionals and involving integration. We plan to deal with such methods in the future, in particular with the unsymmetric meshless Petrov–Galerkin method of Atluri and his collaborators [1].

The next step concerns regularity. We assume that the solution should have at least a $U_R \subseteq W_2^m(\Omega)$ regularity with some $m > \mu$. By standard arguments from approximation theory, the difference between m and μ is the driving force for the possible convergence rates. The user has to decide which m is adequate. Larger m will improve the convergence rates, but they may not be justified by the smoothness of the problem.

Then we pick a kernel K which is smooth enough to have its native space N_K contained in $W_2^m(\Omega)$. In view of Table 4.1, this requires (5.4) and (4.8). The solution u must have at least the regularity of $W_2^m(\Omega)$, because it should be in $U_R = N_K \subseteq W_2^m(\Omega)$. The excess regularity of N_K over $W_2^m(\Omega)$ does not pay off later, and thus it is a good idea to stay with a kernel satisfying $\beta + d = 2m$ to have norm equivalence between $W_2^m(\Omega)$ and N_K. Note that the compactly supported radial polynomial kernels of Wendland [18] satisfy this for certain choices of m, β, and d.

Now it is time to pick a meshless trial discretization U_r via a set Y_r of trial centers with fill distance r using the kernel K. Then we can expect an error behavior $\epsilon_r(u) \leq Cr^{m-\mu}$ for $u \in N_K$ for a direct interpolant to the regular solution in the points of Y_r. This rate is the ideal goal we want to achieve for our numerical solution of the given operator equation.

The next step is to pick a test discretization via a set X_s of test centers in $\overline{\Omega}$ with fill distance s. The second inequality of (1.4) holds with $c(s)$ independent of s because we assume continuous residuals and corresponding Sobolev embedding theorems. By Theorem 5.1, the first inequality of (1.4) will then hold with $C(r,s) \leq Cs^{\mu-\mu}$ using (5.3). But we have to make the test discretization fine enough to satisfy (5.6). As expected, this means that the test discretizations must be somewhat finer than the trial discretizations, and the required relation between s and r is

$$s < c \cdot r^{1+\frac{\mu}{m-\mu}}. \tag{6.1}$$

There is plenty of leeway for small trial and large test spaces.

We are now ready to put everything into Theorem 1.2, while we assume that we solve the discretized problem (1.8) with accuracy $\delta_{r,s}$. With new generic constants

we get

$$\|u - u^*_{r,s}\|_{W_2^\mu(\Omega)} \leq C\left(r^{m-\mu}\left(1 + Cs^{\underline{\mu}-\mu}\right) + \delta_{r,s}\right)\|u\|_K. \tag{6.2}$$

Note that this bound has the proper approximation error of order $r^{m-\mu}$ holding between Sobolev spaces $U = W_2^\mu(\Omega)$ and $U_R = N_K \subseteq W_2^m(\Omega)$, but there also is a counteracting term $s^{\underline{\mu}-\mu}$ which is the price we have to pay for working on discrete residuals in the L_∞ norm while bounding the residual error in the norm on Sobolev trace spaces $W_2^{\mu-\mu_i}(\Omega^i)$ in order to use continuous dependence on Sobolev space data. If we choose $\delta_{r,s}$ properly via (1.9) and s via (5.6), we have solvability of the system and an error bound

$$\|u - u^*_{r,s}\|_{W_2^\mu(\Omega)} \leq Cr^{m-2\mu+\underline{\mu}-\frac{\mu(\mu-\underline{\mu})}{m-\mu}}\|u\|_{W_2^m(\Omega)}.$$

Of course, this is not an optimal bound because μ must be positive and even larger than $d/2$. Consequently, there is quite some future work necessary on this bound, though it is improving when m is much larger than μ. In this context, it is not surprising that most of the practical applications of unsymmetric collocation methods have very regular solutions.

To show the minimum regularity requirements for the results of this section, we should track the possible range of m for the Poisson problem in d dimensions. For operators $L^1 := -\Delta$ and L^2 providing Dirichlet boundary data, we have $\mu_1 = 2$ and $\mu_2 = 1/2$ with $d_1 = d$ and $d_2 = d - 1$. Then (5.2) requires $d/2 < \mu - 2$ while (4.3) leads to $\lfloor m \rfloor > 2 + d$ as the minimum regularity requirement. This clearly needs improvement by future work, but it should be mentioned that the resulting error bound is strong enough to include derivatives up to order μ with $2 + d/2 < \mu < \lfloor m \rfloor - d/2 \geq m - 1 - d/2$.

7. Weak convergence in Sobolev spaces. Analysis of the previous section shows that the term $s^{\underline{\mu}-\mu}$ in (6.2) with some positive μ satisfying (5.1) and $\mu > d/2$ makes the final bound worse than expected. Tracing this back to (4.4) shows that one should better look at another variation which allows $\mu = 0$ at that point without spoiling the assumption that the data are still continuous. In fact, (4.4) also allows

$$\|u\|_{L_\infty(\Omega)} \leq C\left(h^{m-d/2}\|u\|_{W_2^m(\Omega)} + \|u\|_{\infty,Y_h}\right) \text{ for all } u \in W_2^m(\Omega) \tag{7.1}$$

if $d/2 < \lfloor m \rfloor$ holds.

But this does not easily fit into the framework required for continuous dependence. Thus we start anew, defining the data spaces F^i as spaces $C(\Omega^i)$ of continuous functions under the L_∞ norm. To make continuous dependence valid, we use embeddings $C(\Omega^i) \subset L_2(\Omega^i) = W_2^0(\Omega^i) \subseteq W_2^{\mu-\mu_i}(\Omega^i)$ for $\mu := \underline{\mu} = \min \mu_i$. Then we apply the standard continuous dependence relating the standard solution space $W_2^\mu(\Omega)$ to the trace spaces $L^i(W_2^\mu(\Omega)) \subseteq W_2^{\mu-\mu_i}(\Omega^i)$, which fortunately hold for small and even negative μ, if the domain is smooth [12, 3]. This yields a new continuous dependence relation via

$$\begin{aligned}
\|u\|_{W_2^\mu(\Omega)} &\leq C \max_i \|L^i(u)\|_{W_2^{\mu-\mu_i}(\Omega^i)} \\
&\leq C \max_i \|L^i(u)\|_{W_2^0(\Omega^i)} \\
&\leq C \max_i \|L^i(u)\|_{C(\Omega^i)} \\
&= C \max_i \|L^i(u)\|_{F^i} \\
&= C\|L(u)\|_F,
\end{aligned}$$

holding only on the subspace U of functions u in $W_2^\mu(\Omega)$ with continuous data $L(u)$. Note that this will lead to a weak convergence result in $U \subset W_2^\mu(\Omega)$, though the problem formulation is still strong. For instance, a problem with Dirichlet data will lead to $\mu = 1/2$ due to the trace map $W_2^\mu(\Omega) \to W_2^{\mu-1/2}(\partial\Omega)$ if all other trace or differential operators have a larger loss in the order of the respective Sobolev trace spaces.

Thus we now repeat our basic argument for $U \subset W_2^\mu(\Omega)$ with $\mu = \underline{\mu} = \min_i \mu_i$. Our choice of regularity space U_R and the kernel K will be as above. This fixes β and m. To derive the approximation order in (1.3) we apply (4.5) to get

$$\begin{aligned}\|L^i(u - I_r(u))\|_{W_\infty^0(\Omega^i)} &\le Cr^{m-\mu_i-d/2}\|L^i(u - I_r(u))\|_{W_2^{m-\mu_i}(\Omega^i)} \\ &\le Cr^{m-\mu_i-d/2}\|u - I_r(u)\|_{W_2^m(\Omega)} \\ &\le Cr^{m-\overline{\mu}-d/2}\|u\|_{W_2^m(\Omega)},\end{aligned}$$

which requires only

$$d/2 < \lfloor m - \mu_i \rfloor,\ 1 \le i \le n, \tag{7.2}$$

and where we now also need $\overline{\mu}$ from (5.3). Thus we get

$$\epsilon_r(u) \le Cr^{m-\overline{\mu}-d/2}$$

for (1.3).

The discretization of the $F^i = C(\Omega^i)$ spaces is again by pointwise evaluation on a set X_s^i of test centers, taking the discrete L_∞ norm, but we now can skip Sobolev embedding which led to the inequalities (5.1) we want to avoid now. Since every data space is equipped with the L_∞ norm, we have $c(s) = 1$ in the second inequality of (1.4). The proof of the first inequality of (1.4) again proceeds via Theorem 1.1. To prove (1.5) we start with (7.1) on the various data:

$$\|L^i(u)\|_{W_\infty^0(\Omega^i)} \le C\left(s^{m-\mu_i-d_i/2}\|L^i(u)\|_{W_2^{m-\mu_i}(\Omega^i)} + \|L^i(u)\|_{\infty,X_s^i}\right)$$

for all $u \in U_R = N_K$ where we need (7.2) again. We define F_R as in the previous section, and then we have (1.5) in the form

$$\|L(u)\|_F \le C\left(s^{m-\overline{\mu}-d/2}\|L(u)\|_{F_R} + \|\Pi_s L(u)\|_{F_s}\right).$$

Unfortunately, the proof for (1.6) given in section 5 proceeds via $\|.\|_\infty$ and thus needs $\mu > d/2$. Of course there is always some a priori inequality of the form (1.6), but we currently have no explicit upper bounds for $c_3(r)$ in terms of r. Anyway, if we take s small enough to satisfy (1.7) with $c_1(s) = Cs^{m-\overline{\mu}-d/2}$, Theorem 1.1 still is valid and yields the first inequality of (1.4) with $C(r, s)$ independent of r and s provided that s is small enough.

Then we continue as in the proof of Theorem 5.1. Since the discretization scheme is uniformly stable for sufficiently small test discretizations s, Theorem 1.2 now gives the error bound

$$\|u - u_{r,s}^*\|_{W_2^\mu(\Omega)} \le Cr^{m-\overline{\mu}-d/2}\|u\|_{W_2^m(\Omega)} \text{ for all } u \in W_2^m(\Omega)$$

provided that the numerical solution of (1.8) observes (1.9) and the test discretization is fine enough in a way we currently cannot specify explicitly. The left-hand norm

is rather weak here, and the approximation order can probably be improved. For instance, a standard two-dimensional Poisson problem with Dirichlet data would lead to

$$\|u - u^*_{r,s}\|_{W_2^{1/2}(\Omega)} \le C r^{m-3} \|u\|_{W_2^m(\Omega)} \text{ for all } u \in W_2^m(\Omega),$$

but an optimal rate for the Sobolev spaces involved would be $m-1/2$ instead of $m-3$. The minimum regularity in this case is $m = 4$ because of (7.2).

Future work should improve the results of this and the previous sections. This may be done by better choices of spaces and norms, plus better versions of the Markov–Bernstein inequality (1.6) which are currently investigated.

8. Numerical methods. We now look at techniques to solve the discrete problem (1.8). It amounts to solving the n linear problems

$$\Pi_s^i L^i(u - u^*_{r,s}) = 0,\ 1 \le i \le n,$$

approximately, where we discretized the operators L^i on the domains Ω^i by taking only point evaluations. This takes the form of collocation

$$L^i(u)(x_{ji}) = L^i(u^*_{r,s})(x_{ji}) = 0,\ 1 \le i \le n,\ 1 \le j \le N_i,$$

where the points of the test discretization X_s are the union of the sets

$$X_s^i := \{x_{j1}, \dots, x_{jN_i}\},\ 1 \le j \le n,$$

and where we dropped the dependence on s in the notation for the x_{ji} and for N_i. For a shorthand notation, we introduce the functionals

$$\lambda_{ji} \ :\ v \mapsto L^i(v)(x_{ji})$$

and rearrange them into a single-indexed list $\lambda_1, \dots, \lambda_N$ with $N = N_1 + \cdots + N_n$.

Since $u^*_{r,s}$ should be in the trial space U_r generated by translations of the kernel K at trial centers forming $Y_r := \{y_1, \dots, y_M\}$, we arrive at a system

$$\sum_{m=1}^{M} \alpha_m \lambda_i^z K(z, y_m) = \lambda_i^z u(z),\ 1 \le i \le N,$$

with M unknowns and N equations. In case $M = N$ this is exactly the unsymmetric collocation technique dating back to Kansa in 1986 [8]. It has no rigid foundation yet, and it can fail in specially constructed situations [7], though it works fine in many applications. In the first years it was applied to small problems with smooth solutions due to serious condition problems, but recently there have been results on preconditioning [5, 9] that allow a wider range of applicability.

In view of Theorem 5.1 and the two previous sections we know that $N \ge M$ holds and the system has full rank M, provided that our stability conditions are satisfied, calling for a somewhat finer discretization on the test than on the trial side. Thus the system will be unsymmetric and overdetermined, but at least there is no rank loss. Furthermore, we know by (1.3) and (1.9) that there is a good approximate solution to the full system. This means that we can allow any numerical method that produces a solution with similar or less deviation.

Since our convergence analysis worked with the L_∞ norm on the discretized F_s spaces, a first choice would be to go for a best L_∞ approximation of the right-hand side. This means solving a linear optimization problem which minimizes η under the constraints

$$-\eta \le \sum_{m=1}^{M} \alpha_m \lambda_i^z K(z, y_m) - \lambda_i^z u(z) \le \eta, \ 1 \le i \le N, \tag{8.1}$$

where $\alpha_1, \ldots, \alpha_M$ are the other variables. If the revised simplex method is applied to the dual problem, each step has an $\mathcal{O}(M^2)$ complexity. The Kuhn–Tucker conditions ensure that one can work with at most $M+1$ active test conditions at each time. This makes the number $N >> M$ of test centers much less relevant than M, and for nicely chosen low-dimensional trial spaces one can get away with rather small computational complexity, as demonstrated in [10, 11].

But one can also try all other techniques that somehow provide a function $u_{r,s}^* \in U_r$ which by a posteriori inspection leads to a small residual norm $\delta_{r,s}$ in (1.8). This can happen to the original Kansa method when executed on a subset of M test points, or by adaptive bootstrapping techniques like the one in [10, 11] which picks suitable test centers and trial centers one by one. Other alternatives are to use pivoting with row exchange or to go for a least-squares solution first. Anyway, if the resulting residual norm $\delta_{r,s}$ is small, the result of Theorem 1.2 is still valid, proving that one actually has a good approximation to the real solution.

As an aside, we note that a simpler theory is possible if we optimize over a nondiscrete residual norm on F. Section 5 will then be obsolete, but one has to solve semi-infinite optimization problems (if F carries a sup-norm) or apply least-squares methods with integrations (if F carries an inner product). Another strategy to avoid stability problems is to add the numerically accessible quadratic constraint $\|u_r\|_K^2 \le C$ to any method trying to make residuals small. This regularization trick has connections to machine learning [17] and should be investigated in future work.

9. Ill-posed problems. For ill-posed problems, continuous dependence fails, but our method and its analysis will still be useful. We assume that the problem still has the form (1.1), but we now assume that the "true solution" $u \in U$ satisfies only

$$L(u) = f + \rho \in F, \tag{9.1}$$

where F contains the available data f and a small residual ρ. The problem $L(u) = f$ may be unsolvable, and (1.2) is not available. We consider a function $\tilde{u} \in U$ to be acceptable as a "solution" if

$$\|L(\tilde{u}) - L(u)\|_F = \|L(\tilde{u}) - f - \rho\|_F$$

is not much larger than $\|\rho\|_F$. We still assume (1.3) and (1.4), but we have to replace (1.8) by

$$\|\Pi_s(f - L(u_{r,s}^*))\|_{F_s} \le \delta_{r,s}, \tag{9.2}$$

because $L(u)$ now is unknown and does not coincide with f. Furthermore, solvability of the above system now requires

$$c(s)(\|\rho\|_F + \epsilon_r(u)) \le \delta_{r,s} \tag{9.3}$$

instead of (1.9) as a sufficient condition. The proof technique of Theorem 1.2 then still implies the following theorem.

THEOREM 9.1. *If the analytic problem is ill-posed, but solvable by $u \in U_R$ in the sense of* (9.1)*, and if we solve* (9.2) *by some $u^*_{r,s} \in U_r$, then there is a bound*

$$\|L(u - u^*_{r,s})\|_U \le c(s)\|\rho\|_F + \left(\epsilon_r(u)\left(1 + \frac{C(r,s)}{c(s)}\right) + c(s)\delta_{r,s}\right).$$

If the discretization is uniformly stable, then there is a choice of $\delta_{r,s}$ via (9.3) *such that the above residual error behaves asymptotically like the trial approximation error $\epsilon_r(u)$ plus $\|\rho\|_F$.*

Proof. We modify the proof of Theorem 1.2 to get

$$\begin{aligned}
\|L(u - u^*_{r,s})\|_F &\le \|L(u - I_r(u))\|_F + \|L(I_r(u) - u^*_{r,s})\|_F \\
&\le \epsilon_r(u) + c(s)\|\Pi_s L(I_r(u) - u^*_{r,s})\|_{F_s} \\
&\le \epsilon_r(u) + c(s)\|\Pi_s L(I_r(u) - u)\|_{F_s} \\
&\quad + c(s)\|\Pi_s(L(u) - f)\|_{F_s} \\
&\quad + c(s)\|\Pi_s(f - L(u^*_{r,s}))\|_{F_s} \\
&\le \epsilon_r(u) + c(s)\delta_{r,s} + \tfrac{C(r,s)}{c(s)}\|L(I_r(u) - u)\|_F + c(s)\|\Pi_s\|\|\rho\|_F \\
&\le c(s)\|\rho\|_F + \epsilon_r(u)\left(1 + \tfrac{C(r,s)}{c(s)}\right) + c(s)\delta_{r,s}. \qquad \square
\end{aligned}$$

For simplicity of the above presentation, we have replaced the second inequality of (1.4) by

$$c(s)\|\Pi_s g\|_{F_s} \le \|g\|_F \text{ for all } g \in F$$

which is no serious complication. However, we should comment on what happens with Theorems 1.1 and 5.1 if we have no analytic constant C_a for carrying out the proof. We replace C_a by the constant $C_a(r)$ arising in a finite-dimensional version

$$\|u_r\|_U \le C_a(r)\|L(u_r)\|_F \text{ for all } u_r \in U_r$$

of (1.2). This is feasible due to norm equivalence, but we leave it to future research to derive upper bounds for $C_a(r)$.

10. Conclusions. We provided convergence proofs for a generalized nonsquare version of Kansa's collocation method, showing that the convergence rates are determined by approximation results for nonstationary meshless kernel-based trial spaces. The rates improve with the smoothness of the solution, the domain, the differential operator, and the kernel. They hold for large classes of analytic problems, provided that there is continuous dependence on the data, and they result from a fairly general framework that possibly has applications to other unsymmetric methods. On the downside, the results still need improvement by proving better a priori inequalities to plug into the framework.

There are many possibilities for enhancement and extension of these results:

1. Find sufficient conditions for nonsingularity of square Kansa-type collocation matrices.
2. Introduce discretization-dependent weights for different parts of residuals into the theory of this paper in order to align dimension- and order-dependent convergence rates.

3. For important problems of applied analysis, state the continuous dependence of the solution on the data in precise form and derive upper bounds for the analytic constants.
4. Implement algorithms of this paper as local components of a global algorithm using localization features like domain decomposition or partitions of unity and efficiency-enhancing features like preconditioning and iterative solvers.
5. For such a global algorithm, perform large-scale numerical experiments and compare observed convergence rates with the theoretical ones of this paper.
6. Generalize all of this to unsymmetric methods for weak problems like the meshless local Petrov–Galerkin (MLPG) method of Atluri and collaborators [2].

Acknowledgments. The author thanks I. Babuška, C. S. Chen, Y. C. Hon, E. Kansa, L. Ling, G. Lube, and H. Wendland for several very stimulating discussions.

HIGH RESOLUTION SCHEMES FOR A HIERARCHICAL SIZE-STRUCTURED MODEL*

JUN SHEN†, CHI-WANG SHU‡, AND MENGPING ZHANG†

Abstract. In this paper we discuss two explicit finite difference schemes, namely a first order upwind scheme and a second order high resolution scheme, for solving a hierarchical size-structured population model with nonlinear growth, mortality, and reproduction rates. We prove stability and convergence for both schemes and provide numerical examples to demonstrate their capability in solving smooth and discontinuous solutions.

Key words. hierarchical size-structured population model, upwind scheme, high resolution scheme, stability, convergence

DOI. 10.1137/050638126

1. Introduction.

In this paper we develop stable and convergent finite difference schemes for a hierarchical size-structured population model given by the equations

$$
\begin{aligned}
&u_t + \left(g(x, Q(x,t))\, u\right)_x + m(x, Q(x,t))\, u = 0, \qquad (x,t) \in (0,L] \times (0,T], \\
&g(0, Q(0,t))u(0,t) = C(t) + \int_0^L \beta(x, Q(x,t))\, u(x,t)dx, \qquad t \in (0,T], \\
&u(x,0) = u^0(x), \qquad x \in [0,L],
\end{aligned} \tag{1.1}
$$

where $u(x,t)$ is the density of individuals having size x at time t, and the nonlocal term $Q(x,t)$ is defined by

$$
Q(x,t) = \alpha \int_0^x w(\xi)u(\xi,t)d\xi + \int_x^L w(\xi)u(\xi,t)d\xi, \qquad 0 \le \alpha < 1, \tag{1.2}
$$

for some given function w. $Q(x,t)$ depends on the density u in a global way and is usually referred to as the *environment*.

A special feature of (1.1) is the boundary condition at size $x = 0$, which involves the function g representing the growth rate of an individual, and a global dependency on the density $u(x,t)$ for all $x \in (0,L]$. The function m in (1.1) represents the mortality rate of an individual. The function β in the boundary condition of (1.1) represents the reproduction rate of an individual, and the function C represents the inflow rate of zero-size individual from an external source. We assume that the functions g, m,

and β are functions of both the size x and the environment Q, which in turn depends globally on the density u; hence the problem is highly nonlinear.

The hierarchical structured population model (1.1) describes population dynamics in which the size of an individual determines its access to resources and hence to its growth or decay. This dependency is based on the environment which is a global function of the density for all sizes. The hierarchy is determined by the size; for example, in a population of animals, very often the size of an individual determines what species its prey can be and by what species it can be eaten, or in a population of forest trees, the taller the tree, the higher the availability of light it has. In (1.2), since $\alpha < 1$, we observe that the environment for size x has a larger weight for the density of those larger than x than for the density of those smaller than x, representing a particular instance of the size hierarchy. We refer to, e.g., [3] for a more detailed discussion of the background and application of the hierarchical size-structured population models.

Hierarchical structured population models have been studied in the literature in, e.g., [2, 3, 5, 6, 11, 13, 19], usually with more restrictive assumptions on the functions g, β, and m. For example, in [3], the model (1.1) was considered for the special situation $g = g(Q)$, $\beta = \beta(Q)$, $m = m(Q)$, and $C = 0$. In [2], the model (1.1) was studied with the functions g and β depending linearly on the size x, m independent of x, and $C = 0$. In [13], (1.1) was investigated with $\alpha = 0$. The model (1.1) with the complete generality as stated above was studied in [1], in which an implicit first order finite difference scheme was analyzed and its stability and convergence, as well as the existence, uniqueness, and well-posedness (in the L^1 norm) of bounded variation weak solutions for (1.1) were proved. However, the scheme in [1] is not very practical for actual numerical simulation, because it is implicit and only first order accurate.

In this paper we develop and analyze two explicit finite difference schemes, namely, a first order upwind scheme and a second order high resolution scheme, for solving (1.1). We prove stability and convergence for both schemes. Many aspects of our proof are based on the techniques in [1, 4, 8, 15], but it is not a routine generalization because of the complication due to the explicit time marching, second order accuracy, and global constraints in the equation. We also provide numerical examples to demonstrate the capability of these schemes in solving smooth and discontinuous solutions. We remark that discontinuous solutions for (1.1) are generic (see, for example, the numerical example in section 4), unless the boundary condition (e.g., the inflow rate C of a zero-size individual from an external source) happens to be compatible with the initial condition.

As in [1], we make the following assumptions on the model functions:

- (H1) $g(x, Q)$ is twice continuously differentiable with respect to x and Q, $g(x, Q) > 0$ for $x \in [0, L)$, $g(L, Q) = 0$, and $g_Q(x, Q) \le 0$.
- (H2) $m(x, Q)$ is nonnegative continuously differentiable with respect to x and Q.
- (H3) $\beta(x, Q)$ is nonnegative continuously differentiable with respect to x and Q. Furthermore, there is a constant $\omega_1 > 0$ such that $\sup_{(x,Q)\in[0,L]\times[0,\infty)} \beta(x, Q) \le \omega_1$.
- (H4) $w(x)$ is nonnegative continuously differentiable.
- (H5) $C(t)$ is nonnegative continuously differentiable.
- (H6) $u^0 \in BV[0, L]$ and $u^0(x) \ge 0$.

In section 2, we present an explicit, first order upwind scheme for solving (1.1) and state its stability and convergence. To save space we omit most details of the proof in this section, since we will provide a similar but technically more complicated proof in the following section for the second order scheme. In section 3, we present an

explicit, second order high resolution scheme for solving (1.1) and prove its stability and convergence. Section 4 contains numerical examples demonstrating the capability of these two numerical schemes. Concluding remarks are given in section 5.

2. A first order upwind finite difference scheme. First, we briefly describe the standard notation to be used in this paper. We assume the spatial domain $[0, L]$ is divided into N cells with cell boundary points denoted by x_j for $0 \le j \le N$, $x_0 = 0$, and $x_N = L$. For simplicity of presentation we will assume that the mesh is uniform of size Δx, namely, $x_j = j\Delta x$. This assumption is not essential for the analysis or the numerical computation; more general meshes can be easily considered. We also denote the time step by Δt. In fact, this time step $\Delta t = \Delta t^n = t^{n+1} - t^n$ could change from one step to the next step, based on stability conditions, but we use the same notation Δt without the superscript n since we will consider only one-step time discretizations (forward Euler or Runge–Kutta). We shall denote by u_j^n and Q_j^n the finite difference approximations of $u(x_j, t^n)$ and $Q(x_j, t^n)$, respectively. We also denote

$$g_j^n = g(x_j, Q_j^n), \;\; \beta_j^n = \beta(x_j, Q_j^n), \;\; m_j^n = m(x_j, Q_j^n), \;\; w_j = w(x_j), \;\; C^n = C(t^n).$$

We define the standard finite difference operators

$$D^-(u_j^n) = \frac{u_j^n - u_{j-1}^n}{\Delta x}, \qquad \Delta_+(u_j^n) = u_{j+1}^n - u_j^n, \qquad \Delta_-(u_j^n) = u_j^n - u_{j-1}^n,$$

and we define the standard discrete L^1 and L^∞ norms and TV seminorm of the grid function u^n by

$$\|u^n\|_1 = \sum_{j=1}^{N} |u_j^n| \Delta x, \qquad \|u^n\|_\infty = \max_{0 \le j \le N} |u_j^n|, \qquad TV(u^n) = \sum_{j=0}^{N-1} |u_{j+1}^n - u_j^n|.$$

The explicit, first order upwind finite difference scheme for (1.1) that we consider in this section is defined by

$$\frac{u_j^{n+1} - u_j^n}{\Delta t} + \frac{g_j^n u_j^n - g_{j-1}^n u_{j-1}^n}{\Delta x} + m_j^n u_j^n = 0, \qquad 1 \le j \le N, \tag{2.1}$$

with the left boundary condition implemented by

$$g_0^n u_0^n = C^n + \sum_{j=1}^{N} \beta_j^n u_j^n \Delta x, \tag{2.2}$$

the environment is computed by

$$Q_j^n = \alpha \sum_{i=1}^{j} w_i u_i^n \Delta x + \sum_{i=j+1}^{N} w_i u_i^n \Delta x, \tag{2.3}$$

and the initial condition is taken as

$$u_j^0 = u^0(x_j), \qquad j = 1, 2, \ldots, N.$$

We denote $\lambda = \frac{\Delta t}{\Delta x}$, and rewrite the scheme (2.1) as

$$u_j^{n+1} = (1 - \lambda g_j^n - \Delta t m_j^n) u_j^n + \lambda g_{j-1}^n u_{j-1}^n, \quad j \ge 1. \tag{2.4}$$

Since we consider only one-step explicit schemes, the right side of (2.4) contains only terms at time level t^n. Hence sometimes we will omit the superscript n when it does not cause confusion.

We first state the L^1 boundedness of the numerical solution u^n for $t^n \le T$, under the assumption that $u_j^n \ge 0$. We will prove the validity of this assumption later.

PROPOSITION 2.1. *If $u_j^n \ge 0$, then $\|u^n\|_1$ is bounded when $t^n \le T$.*

We omit the proof of this proposition since it is similar to and simpler than the proof of Proposition 3.1 in the next section. The L^1 bound is estimated as

$$\|u^n\|_1 \le e^{\omega_1 T}\|u^0\|_1 + \frac{Ce^{\omega_1 T}}{\omega_1} \equiv \omega_2,$$

where ω_1 is the upper bound of $\beta(x,Q)$ given in assumption H3, and the constant ω_2, as well as a sequence of such constants ω_k to be defined later, depend only on the given functions g, m, C, β, and w, the final time T, and the initial condition u^0.

With this L^1 bound on the density u_j^n, we can easily obtain the following upper bound for the environment Q:

$$\begin{aligned} |Q_j^n| &= \left| \alpha \sum_{i=1}^{j} w_i u_i^n \Delta x + \sum_{i=j+1}^{N} w_i u_i^n \Delta x \right| \\ &\le \|w\|_\infty \max_n \|u^n\|_1 \le \omega_2 \|w\|_\infty \equiv Q_{\max}. \end{aligned}$$

We now have a bounded closed domain $\mathcal{D} = \{(x,Q) \in [0,L] \times [0,Q_{max}]\}$ that x and Q reside in; hence by the smoothness assumptions of g, m, β, and w, we have a fixed constant ω_3 such that

$$\sup_{\mathcal{D}} |f(x,Q)| \le \omega_3, \qquad \sup_{0\le x\le L} |h(x)| \le \omega_3$$

for

$$\begin{aligned} f(x,Q) = g(x,Q),\, &g_x(x,Q),\, g_Q(x,Q),\, g_{xx}(x,Q),\, g_{xQ}(x,Q),\, g_{QQ}(x,Q), \\ &m(x,Q),\, m_x(x,Q),\, m_Q(x,Q),\, \beta(x,Q), \\ h(x) = w(x),\, &w'(x). \end{aligned}$$

Thus when $\Delta t \le \Delta t_0 \equiv \frac{1}{2\omega_3}$ and $\lambda \le \lambda_0 \equiv \frac{1}{2\omega_3}$, we have

$$1 - \lambda g_j^n - \Delta t m_j^n \ge 0, \qquad 1 \le j \le N. \tag{2.5}$$

This clearly implies $u_j^n \ge 0$ by (2.4). Notice that we can choose $\lambda = \lambda_0$ as either a constant or a variable depending on the time level t^n. We have thus verified the assumption made in Proposition 2.1 about the nonnegativity of u_j^n.

Next we will state the L^∞ boundedness of the numerical solution.

PROPOSITION 2.2. *$\|u^n\|_\infty$ is bounded for $t^n \le T$.*

We again omit the details of the proof of this proposition since it is similar to and simpler than the proof of Proposition 3.2 in the next section. We point out only that, since g is continuous and $g(0,Q) > 0$ by assumption (H1), we can take

$$\mu = \min_{Q\in[0,Q_{max}]} g(0,Q) > 0. \tag{2.6}$$

We would then have

$$|u_0^n| \le \frac{C+\omega_1\omega_2}{\mu} \tag{2.7}$$

and, for $j \ge 1$,

$$\begin{aligned} |u_j^n| &\le \|u^{n-1}\|_\infty + \sup_{\mathcal{D}} |g_x(x,Q)|\, \|u^{n-1}\|_\infty \Delta t \\ &\le (1+\omega_3\Delta t)\|u^{n-1}\|_\infty. \end{aligned}$$

This, together with (2.7), provides the L^∞ bound as

$$\|u^n\|_\infty \le \max\left\{ e^{\omega_3 T}\|u^0\|_\infty, \frac{1}{\mu}(C+\omega_1\omega_2)\right\} \equiv \omega_4.$$

In order to prove the total variation stability of the scheme, we would need the following results.

LEMMA 2.3. *There exist positive constants ω_5, ω_6, and ω_7 such that*

$$\begin{aligned} &\max_{1\le j\le N} |Q_j^n - Q_{j-1}^n| \le \omega_5\Delta x, \qquad \max_{1\le j\le N} |g_j^n - g_{j-1}^n| \le \omega_5\Delta x, \\ &\max_{1\le j\le N} |m_j^n - m_{j-1}^n| \le \omega_5\Delta x \end{aligned} \tag{2.8}$$

for $1 \le j \le N$,

$$|g_{j+1}^n - 2g_j^n + g_{j-1}^n| \le \omega_6\left(\Delta x^2 + \Delta x|u_{j+1}^n - u_j^n|\right) \tag{2.9}$$

for $1 \le j \le N-1$, and

$$\max_{1\le j\le N} |Q_j^{n+1} - Q_j^n| \le \omega_7\Delta t\left(1+TV(u^n)\right), \quad \max_{1\le j\le N} |g_j^{n+1} - g_j^n| \le \omega_7\Delta t\left(1+TV(u^n)\right),$$

$$\max_{1\le j\le N} |\beta_j^{n+1} - \beta_j^n| \le \omega_7\Delta t\left(1+TV(u^n)\right) \tag{2.10}$$

for $0 \le j \le N$.

We omit the details of the proof of this lemma since it is similar to and simpler than the proof of Lemma 3.3 in the next section. We point out only that ω_5 in (2.8) is given by

$$\omega_5 = \max\left(\omega_3\omega_4,\ \omega_3(1+\omega_3\omega_4)\right),$$

ω_6 in (2.9) is given by

$$\omega_6 = \max\left(\omega_3(2+\omega_5+2\omega_3\omega_4+2\omega_3\omega_4\omega_5),\ \omega_3^2\right),$$

and ω_7 in (2.10) is given by

$$\omega_7 = \max(\omega_3^2,\ \omega_3^3,\ \omega_3\omega_4(\omega_3+\omega_5)L,\ \omega_3^2\omega_4(\omega_3+\omega_5)L).$$

We are now ready to state the total variation stability of the scheme.

PROPOSITION 2.4. *$TV(u^n)$ is bounded for $t^n \le T$.*

We once again omit the details of the proof of this proposition since it is similar to and simpler than the proof of Proposition 3.4 in the next section. We point out only that with

$$\omega_8 = \max\left((\omega_3+\omega_6)\omega_4 L,\ \omega_3+\omega_5+\omega_4\omega_6\right),$$

$$\omega_9 = \omega_8 + \omega_4(\omega_3 + \omega_5),$$

$$\omega_{10} = \max\left(\frac{\omega_4\omega_7}{\mu}(1+L) + \frac{\omega_3^2}{\mu},\ \frac{\omega_4\omega_7}{\mu}(1+L) + \frac{\omega_3}{\mu} + \frac{\omega_3\omega_4}{\mu}(\omega_3+\omega_5)L\right),$$

and

$$\omega_{11} = \omega_9 + \omega_{10},$$

we have

$$TV(u^{n+1}) \le (1 + \omega_{11}\Delta t)TV(u^n) + \omega_{11}\Delta t,$$

which implies the boundedness of $TV(u^n)$ for $t^n \le T$.

Next, we show the Lipschitz stability in t.

PROPOSITION 2.5. *There exists a positive constant M such that for any $q > p$, we have*

$$\sum_{j=1}^{N}\left|\frac{u_j^q - u_j^p}{\Delta t}\right|\Delta x \le M(q-p).$$

Proof. Using (2.1) and Lemma 2.3, we have

$$\begin{aligned}\sum_{j=1}^{N}\left|\frac{u_j^{n+1} - u_j^n}{\Delta t}\right|\Delta x &= \sum_{j=1}^{N}\left|D^-(g_j^n u_j^n) + m_j^n u_j^n\right|\Delta x \\ &= \sum_{j=1}^{N}\left|\left(\frac{g_j^n - g_{j-1}^n}{\Delta x} + m_j^n\right)u_j^n + g_{j-1}^n D^-(u_j^n)\right|\Delta x \\ &\le \omega_4\omega_5 L + \omega_3\omega_4 L + \omega_3 TV(u^n) \le M.\end{aligned}$$

Thus,

$$\sum_{j=1}^{N}\left|\frac{u_j^q - u_j^p}{\Delta t}\right|\Delta x \le \sum_{n=p}^{q-1}\sum_{j=1}^{N}\left|\frac{u_j^{n+1} - u_j^n}{\Delta t}\right|\Delta x \le M(q-p). \qquad \square$$

Following [18] we can define a family of functions $\{U_{\Delta x,\Delta t}\}$ by

$$U_{\Delta x,\Delta t}(x,t) = u_j^n$$

for $x \in [x_{j-1}, x_j)$, $t \in [t^{n-1}, t^n)$, $j = 1,\dots,N$, and $n = 1,\dots,l$. Then, the set of functions $\{U_{\Delta x,\Delta t}\}$ is compact in the topology of $\mathcal{L}^1((0,L)\times(0,T))$, and we have the following result of convergence.

PROPOSITION 2.6. *Under the time step restriction for the validity of previous propositions in this section, there exists a subsequence $\{U_{\Delta x_i,\Delta t_i}\} \subset \{U_{\Delta x,\Delta t}\}$ which converges to a $BV([0,L]\times[0,T])$ function $u(x,t)$ in the sense that*

$$\int_0^L |U_{\Delta x_i,\Delta t_i}(x,0) - u^0(x)|dx \to 0$$

and

$$\int_0^T\int_0^L |U_{\Delta x_i,\Delta t_i}(x,t) - u(x,t)|dxdt \to 0$$

as $i \to \infty$. Furthermore, the function u, satisfying

$$\|u\|_{BV([0,L]\times[0,T])} \le E(\|u^0\|_{BV[0,L]}, \|C\|_{\mathcal{C}^1[0,T]}),$$

is the unique $BV([0,L]\times[0,T])$ solution $u(x,t)$ for (1.1), and the numerical solution $\{U_{\Delta x,\Delta t}\}$ converges to it when $\Delta x \to 0$.

Proof. The convergence of a subsequence to a BV function $u(x,t)$ and the fact that $u(x,t)$ is a BV weak solution of (1.1) follow from Propositions 2.1, 2.2, 2.4, and 2.5 and [18]. The uniqueness of bounded variation weak solutions of (1.1) is proved in [1]. Using this uniqueness we easily deduce the convergence of the numerical solution $\{U_{\Delta x,\Delta t}\}$ toward $u(x,t)$ when $\Delta x \to 0$. ∎

3. A second order high resolution finite difference scheme. The first order scheme defined in the previous section is very diffusive and would need many grid points to achieve acceptable resolution. In this section we develop and analyze a second order high resolution finite difference scheme for (1.1), following the minmod based MUSCL schemes [8, 14]. We remark, however, that the analysis is significantly more complicated because of the global constraints in (1.1). We note that our scheme can be easily generalized to the more accurate generalized MUSCL-type scheme similar to the one in [15] and the total variation bounded modified minmod based scheme in [16] without affecting the analysis. The second order high resolution finite difference scheme that we consider in this section is defined by

$$\frac{u_j^{n+1}-u_j^n}{\Delta t} + \frac{\hat{f}_{j+1/2}^n - \hat{f}_{j-1/2}^n}{\Delta x} + m_j^n u_j^n = 0, \quad 1 \le j \le N, \tag{3.1}$$

where the numerical flux $\hat{f}_{j+1/2}^n$ is defined by

$$\hat{f}_{j+1/2}^n = \begin{cases} g_j^n u_j^n + \frac{1}{2}(g_{j+1}^n - g_j^n)u_j^n + \frac{1}{2} g_j^n mm(\Delta_+ u_j^n, \Delta_- u_j^n) & : \quad j = 2, \ldots, N-2, \\ g_j^n u_j^n & : \quad j = 0, 1, N-1, N, \end{cases}$$

where the minmod function mm is defined by [8]

$$mm(a,b) = \frac{\text{sign}(a) + \text{sign}(b)}{2} \min(|a|, |b|). \tag{3.2}$$

Clearly, this scheme is second order accurate except at the boundary, where it is first order accurate. This guarantees second order accuracy in the global L^1 norm. The global boundary condition at the left is implemented by a second order composite trapezoid rule

$$g_0^n u_0^n = C^n + {\sum_{j=0}^{N}}' \beta_j^n u_j^n \Delta x, \tag{3.3}$$

where the special summation notation is defined by

$${\sum_{j=j_1}^{j_2}}' a_j = \frac{1}{2} a_{j_1} + \frac{1}{2} a_{j_2} + \sum_{j=j_1+1}^{j_2-1} a_j$$

if $j_2 - j_1 \ge 1$, and of course

$${\sum_{j=j_1}^{j_2}}' a_j = 0 \qquad \text{if } \ j_2 \le j_1.$$

The environment is computed also by a second order composite trapezoid rule, except for the integral over the first interval which is computed by the right-ended rectangular rule to avoid using u_0^n. That is,

$$Q_0^n = \omega_1 u_1^n \Delta x + \sum_{i=1}^{N}{}' \, w_i u_i^n \Delta x, \qquad Q_1^n = \alpha\omega_1 u_1^n \Delta x + \sum_{i=1}^{N}{}' \, w_i u_i^n \Delta x,$$

$$Q_j^n = \alpha\omega_1 u_1^n \Delta x + \alpha \sum_{i=1}^{j}{}' \, w_i u_i^n \Delta x + \sum_{i=j}^{N}{}' \, w_i u_i^n \Delta x, \qquad 2 \le j \le N. \tag{3.4}$$

Notice that this approximation to Q_j^n is second order accurate. The initial condition is still taken as

$$u_j^0 = u^0(x_j), \qquad j = 1, 2, \ldots, N.$$

Still using the notation $\lambda = \frac{\Delta t}{\Delta x}$, we can write the scheme (3.1) as

$$u_j^{n+1} = u_j^n - \lambda(\hat{f}_{j+1/2}^n - \hat{f}_{j-1/2}^n) - \Delta t m_j^n u_j^n, \quad j \ge 1. \tag{3.5}$$

We denote

$$A_j^n = \begin{cases} \frac{1}{2}\left(g_{j+1}^n + g_j^n + g_j^n \frac{mm(\Delta_+ u_j^n, \Delta_- u_j^n)}{\Delta_- u_j^n} - g_{j-1}^n \frac{mm(\Delta_- u_j^n, \Delta_- u_{j-1}^n)}{\Delta_- u_j^n}\right) : j = 3, \ldots, N-2, \\ \frac{1}{2}\left(g_{j+1}^n + g_j^n + g_j^n \frac{mm(\Delta_+ u_j^n, \Delta_- u_j^n)}{\Delta_- u_j^n}\right) : j = 2, \\ \frac{1}{2}\left(2g_j^n - g_{j-1}^n \frac{mm(\Delta_- u_j^n, \Delta_- u_{j-1}^n)}{\Delta_- u_j^n}\right) : j = N-1, \\ g_j^n : j = 1, N, \end{cases}$$

$$B_j^n = \begin{cases} \frac{1}{2}(\Delta_+ g_j^n + \Delta_- g_j^n) & : \quad j = 3, \ldots, N-2, \\ \frac{1}{2}\Delta_+ g_j^n & : \quad j = 2, \\ \frac{1}{2}\Delta_- g_j^n & : \quad j = N-1, \\ \Delta_- g_j^n & : \quad j = 1, N, \end{cases}$$

and rewrite the scheme (3.5) as

$$u_j^{n+1} = (1 - \lambda A_j^n - m_j^n \Delta t) u_j^n + \lambda(A_j^n - B_j^n) u_{j-1}^n, \quad j \ge 1. \tag{3.6}$$

We first prove the L^1 boundedness of the numerical solution u^n for $t^n \le T$, under the assumption that $u_j^n \ge 0$. We will prove the validity of this assumption later.

PROPOSITION 3.1. *If $u_j^n \ge 0$, then $\|u^n\|_1$ is bounded when $t^n \le T$.*

Proof. As before, since $u_j^n \ge 0$, $m_j^n \ge 0$, and $g_N^n = 0$, we have

$$\begin{aligned} \frac{\|u^{n+1}\|_1 - \|u^n\|_1}{\Delta t} &= \sum_{j=1}^{N} \frac{u_j^{n+1} - u_j^n}{\Delta t} \Delta x \\ &= -\sum_{j=1}^{N} (\hat{f}_{j+1/2}^n - \hat{f}_{j-1/2}^n) - \sum_{j=1}^{N} m_j^n u_j^n \Delta x \\ &\le -\sum_{j=1}^{N} (\hat{f}_{j+1/2}^n - \hat{f}_{j-1/2}^n) \end{aligned}$$

$$
\begin{aligned}
&= g_0^n u_0^n \\
&= C^n + \frac{1}{2}\beta_0^n u_0^n \Delta x + \frac{1}{2}\beta_N^n u_N^n \Delta x + \sum_{j=1}^{N-1} \beta_j^n u_j^n \Delta x \\
&\le C^n + \frac{1}{2}\beta_0^n u_0^n \Delta x + \omega_1 \|u^n\|_1.
\end{aligned}
$$

We now assume, for the time being, that $u_0^k \le \theta$, where θ is a constant. This assumption will be justified later. If $\Delta x \le 2C/\omega_1\theta$, where again C denotes the upper bound of $C(t)$ for $t \in [0,T]$ and ω_1 is the upper bound of $\beta(x,Q)$, then we have $\frac{1}{2}\beta_0^k u_0^k \Delta x \le C$. For constant Δt, we then immediately have

$$
\begin{aligned}
\|u^n\|_1 &\le (1+\omega_1\Delta t)\|u^{n-1}\|_1 + 2C\Delta t \\
&\le (1+\omega_1\Delta t)^n \|u^0\|_1 + \sum_{j=0}^{n-1} (1+\omega_1\Delta t)^j 2C\,\Delta t \\
&\le e^{\omega_1 T}\|u^0\|_1 + \frac{2Ce^{\omega_1 T}}{\omega_1} \equiv M_2,
\end{aligned}
$$

where the constant M_2, as well as a sequence of such constants M_k to be defined later, depend only on the given functions g, m, C, β, and w, the final time T, and the initial condition u^0. This proof is clearly also valid, with a minor modification, for the situation when Δt is not a constant.

We now look at the bound of Q_j^n. For $0 \le j \le N$, we have, by the definition of Q_j^n in (3.4), that

$$
Q_j^n \le \omega_1 u_1^n \Delta x + \sum_{i=1}^{N}{}' \, w_i u_i^n \Delta x \le \frac{3}{2}\omega_3 M_2 \equiv Q_{\max},
$$

and therefore

$$
g_0^n \ge \min_{0 \le Q \le Q_{\max}} g(0,Q) \equiv \mu > 0. \tag{3.7}
$$

Thus if $\Delta x \le \mu/\omega_1$, we have $g_0^n - \frac{1}{2}\beta_0 \Delta x \ge \mu/2$; hence from (3.3) we deduce

$$
u_0^n \le \frac{2}{\mu}(\omega_1 M_2 + C). \tag{3.8}
$$

The constants on the right-hand side of the inequality above do not depend on θ; hence the assumption on the boundedness of u_0^k is justified. □

As before, we now have a bounded closed domain $\mathcal{D} = \{(x,Q) \in [0,L] \times [0, Q_{\max}]\}$ that x and Q reside in; hence by the smoothness assumptions of g, m, β, and w, we have a fixed constant M_3 such that

$$
\sup_{\mathcal{D}} |f(x,Q)| \le M_3, \qquad \sup_{0 \le x \le L} |h(x)| \le M_3, \qquad \sup_{0 \le t \le T} |\eta(t)| \le M_3
$$

for

$$
\begin{aligned}
f(x,Q) = {} & g(x,Q),\, g_x(x,Q),\, g_Q(x,Q),\, g_{xx}(x,Q),\, g_{xQ}(x,Q),\, g_{QQ}(x,Q), \\
& m(x,Q),\, m_x(x,Q),\, m_Q(x,Q),\, \beta(x,Q), \\
h(x) = {} & w(x),\, w'(x), \qquad \eta(t) = C(t),\, C'(t).
\end{aligned}
$$

It can be easily shown that

$$|A_j^n| \le \frac{3}{2}\max_{\mathcal{D}}|g(x,Q)| \le \frac{3}{2}M_3;$$

thus when $\Delta t \le \Delta t_0 \equiv \frac{1}{2M_3}$ and $\lambda \le \lambda_0 \equiv \frac{1}{3M_3}$, we have

$$1 - \lambda A_j^n - \Delta t m_j^n \ge 0, \qquad 1 \le j \le N. \tag{3.9}$$

Notice that

$$2(A_j^n - B_j^n)$$

$$= \begin{cases} g_j^n\left(1 + \frac{mm(\Delta_+ u_j^n, \Delta_- u_j^n)}{\Delta_- u_j^n}\right) + g_{j-1}^n\left(1 - \frac{mm(\Delta_- u_j^n, \Delta_- u_{j-1}^n)}{\Delta_- u_j^n}\right) & : \quad j = 3, \ldots, N-2, \\ g_j^n\left(2 + \frac{mm(\Delta_+ u_j^n, \Delta_- u_j^n)}{\Delta_- u_j^n}\right) & : \quad j = 2, \\ g_j^n + g_{j-1}^n\left(1 - \frac{mm(\Delta_- u_j^n, \Delta_- u_{j-1}^n)}{\Delta_- u_j^n}\right) & : \quad j = N-1, \\ 2g_{j-1}^n & : \quad j = 1, N, \end{cases}$$

which implies, by the definition of the minmod function (3.2), that

$$A_j^n - B_j^n \ge 0, \qquad 1 \le j \le N. \tag{3.10}$$

This, together with (3.9), clearly implies $u_j^n \ge 0$ by (3.6). Notice that we can choose $\lambda = \lambda_0$ as either a constant or a variable depending on the time level t^n. We have thus verified the assumption made in Proposition 3.1 about the nonnegativity of u_j^n.

Next we will prove the L^∞ boundedness of the numerical solution.

PROPOSITION 3.2. *$\|u^n\|_\infty$ is bounded for $t^n \le T$.*

Proof. First, we have already shown the boundedness of u_0^n in (3.8). As for $j \ge 1$, we use (3.6), (3.9), (3.10), and the nonnegativity of m to obtain

$$\begin{aligned} |u_j^n| &\le (1 - \lambda A_j^{n-1} - \Delta t m_j^{n-1})\|u^{n-1}\|_\infty + \lambda(A_j^{n-1} - B_j^{n-1})\|u^{n-1}\|_\infty \\ &\le \|u^{n-1}\|_\infty - \lambda B_j^{n-1}\|u^{n-1}\|_\infty. \end{aligned}$$

We can easily verify that, for $2 \le j \le N$,

$$Q_j - Q_{j-1} = \frac{1}{2}(\alpha - 1)(w_j u_j + w_{j-1}u_{j-1})\Delta x. \tag{3.11}$$

For $j = 1$, we have a similar formula:

$$Q_1 - Q_0 = (\alpha - 1)\omega_1 u_1. \tag{3.12}$$

Therefore, we have

$$\begin{aligned} g_j^{n-1} - g_{j-1}^{n-1} &= g(x_j, Q_j^{n-1}) - g(x_{j-1}, Q_j^{n-1}) + g(x_{j-1}, Q_j^{n-1}) - g(x_{j-1}, Q_{j-1}^{n-1}) \\ &= g_x(\hat{x}_j, Q_j^{n-1})\Delta x + g_Q(x_{j-1}, \hat{Q}_j^{n-1})(Q_j^{n-1} - Q_{j-1}^{n-1}). \end{aligned}$$

Here and below $\hat{z}_j$ denotes a value between z_{j-1} and z_j for $z = x$ or $z = Q$. By assumption, $\alpha < 1$, $g_Q(x,Q) \le 0$. We clearly have, for $2 \le j \le N$,

$$\begin{aligned} -g_Q(x_{j-1}, \hat{Q}_j^{n-1})(Q_j^{n-1} - Q_{j-1}^{n-1}) &= -\frac{1}{2}g_Q(x_{j-1}, \hat{Q}_j^{n-1})(\alpha - 1)(w_j u_j^{n-1} + w_{j-1}u_{j-1}^{n-1})\Delta x \\ &\le 0, \end{aligned}$$

and also

$$-g_Q(x_0,\hat{Q}_1^{n-1})(Q_1^{n-1}-Q_0^{n-1}) = -g_Q(x_0,\hat{Q}_1^{n-1})(\alpha-1)\omega_1 u_1^{n-1}\Delta x \le 0.$$

Now, noticing that $-B_j \le \max_i(g_{i-1}-g_i)$ for $j \ge 1$, we obtain immediately, for $j \ge 1$,

$$|u_j^n| \le \|u^{n-1}\|_\infty + \sup_{\mathcal{D}} |g_x(x,Q)|\,\|u^{n-1}\|_\infty \Delta t \le (1+M_3\Delta t)\|u^{n-1}\|_\infty.$$

This, together with (3.8), clearly implies

$$\|u^n\|_\infty \le \max\left\{e^{M_3 T}\|u^0\|_\infty,\ \frac{2}{\mu}(\omega_1 M_2 + C)\right\} \equiv M_4. \qquad \square$$

Before proving the total variation stability of the scheme, we would need to prove the following results.

LEMMA 3.3. *There exist positive constants M_5, M_6, and M_7 such that*

$$\begin{aligned} &\max_{1\le j\le N} |Q_j^n - Q_{j-1}^n| \le M_5\Delta x, \qquad \max_{1\le j\le N} |g_j^n - g_{j-1}^n| \le M_5\Delta x, \\ &\max_{1\le j\le N} |m_j^n - m_{j-1}^n| \le M_5\Delta x, \end{aligned} \tag{3.13}$$

for $1 \le j \le N$;

$$\begin{aligned} &|g_{j+1}^n - 2g_j^n + g_{j-1}^n| \le M_6\Delta x\left(\Delta x + |u_j^n - u_{j-1}^n| + |u_{j+1}^n - u_j^n|\right), \\ &\qquad 1 \le j \le N-1, \\ &\quad |B_j^n - B_{j-1}^n| \le M_6\Delta x\left(\Delta x + |u_j^n - u_{j-1}^n| + |u_{j+1}^n - u_j^n|\right), \\ &\quad 4 \le j \le N-2; \end{aligned} \tag{3.14}$$

and

$$|Q_j^{n+1} - Q_j^n| \le M_7 TV(u^n)\Delta t + M_7\Delta t, \qquad |g_j^{n+1} - g_j^n| \le M_7 TV(u^n)\Delta t + M_7\Delta t,$$

$$|\beta_j^{n+1} - \beta_j^n| \le M_7 TV(u^n)\Delta t + M_7\Delta t \tag{3.15}$$

for $0 \le j \le N$.

Proof. By (3.11), we have, for $2 \le j \le N$,

$$|Q_j^n - Q_{j-1}^n| = \left|\frac{1}{2}(\alpha-1)(w_j u_j^n + w_{j-1}u_{j-1}^n)\right|\Delta x \le \|w\|_\infty\|u^n\|_\infty\Delta x \le M_3 M_4\Delta x,$$

which is clearly also valid for $j=0$ by (3.12). Therefore,

$$\begin{aligned} |g_j^n - g_{j-1}^n| &= \left|g(x_j,Q_j^n) - g(x_{j-1},Q_j^n) + g(x_{j-1},Q_j^n) - g(x_{j-1},Q_{j-1}^n)\right| \\ &\le |g_x(\hat{x}_j,Q_j^n)|\Delta x + |g_Q(x_{j-1},\hat{Q}_j)|\,|Q_j^n - Q_{j-1}^n| \\ &\le M_3\Delta x + M_3(M_3M_4\Delta x) = M_3(1+M_3M_4)\Delta x, \end{aligned}$$

$$\begin{aligned} |m_j^n - m_{j-1}^n| &= \left|m(x_j,Q_j^n) - m(x_{j-1},Q_j^n) + m(x_{j-1},Q_j^n) - m(x_{j-1},Q_{j-1}^n)\right| \\ &\le |m_x(\hat{x}_j,Q_j^n)|\Delta x + |m_Q(x_{j-1},\hat{Q}_j)|\,|Q_j^n - Q_{j-1}^n| \\ &\le M_3\Delta x + M_3(M_3M_4\Delta x) = M_3(1+M_3M_4)\Delta x. \end{aligned}$$

We have thus proved (3.13) with

$$M_5 = \max\left(M_3M_4,\ M_3(1+M_3M_4)\right).$$

As to (3.14), for $4 \le j \le N-2$, we can easily verify

$$\begin{aligned}|B_j^n - B_{j-1}^n| &= \left|\frac{1}{2}(g_{j+1}^n - 2g_j^n + g_{j-1}^n) + \frac{1}{2}(g_j^n - 2g_{j-1}^n + g_{j-2}^n)\right| \\ &\le \max_i |g_{i+1}^n - 2g_i^n + g_{i-1}^n|;\end{aligned}$$

hence we need only to prove the first inequality in (3.14). Using (3.11), we have, for $1 \le j \le N-1$,

$$\begin{aligned}|g_{j+1}^n - 2g_j^n + g_{j-1}^n| &= |(g_{j+1}^n - g_j^n) - (g_j^n - g_{j-1}^n)| \\ &= \left|\Delta_+\left(g_x(\hat{x}_j, Q_j^n)\Delta x + g_Q(x_{j-1}, \hat{Q}_j^n)(Q_j^n - Q_{j-1}^n)\right)\right| \\ &\le |g_x(\hat{x}_{j+1}, Q_{j+1}^n) - g_x(\hat{x}_j, Q_j^n)|\Delta x \\ &\quad + |g_Q(x_j, \hat{Q}_{j+1}^n)w_{j+1}u_{j+1}^n - g_Q(x_{j-1}, \hat{Q}_j^n)w_ju_j^n|\frac{(1-\alpha)}{2}\Delta x \\ &\quad + |g_Q(x_j, \hat{Q}_{j+1}^n)w_ju_j^n - g_Q(x_{j-1}, \hat{Q}_j^n)w_{j-1}u_{j-1}^n|\frac{(1-\alpha)}{2}\Delta x \\ &= I + II + III,\end{aligned}$$

where

$$\begin{aligned}I &= |g_x(\hat{x}_{j+1}, Q_{j+1}^n) - g_x(\hat{x}_j, Q_j^n)|\Delta x \\ &= |g_{xx}(\overline{x}_{j+1}, Q_{j+1}^n)(\hat{x}_{j+1} - \hat{x}_j) + g_{xQ}(\hat{x}_j, \overline{Q}_{j+1}^n)(Q_{j+1}^n - Q_j^n)|\Delta x \\ &\le 2M_3\Delta x^2 + M_3M_5\Delta x^2;\end{aligned}$$

and

$$\begin{aligned}II &= \left|g_Q(x_j, \hat{Q}_{j+1}^n)w_{j+1}u_{j+1}^n - g_Q(x_{j-1}, \hat{Q}_j^n)w_ju_j^n\right|\frac{(1-\alpha)}{2}\Delta x \\ &= \Big|(g_Q(x_j, \hat{Q}_{j+1}^n) - g_Q(x_{j-1}, \hat{Q}_j^n))w_{j+1}u_{j+1}^n + g_Q(x_{j-1}, \hat{Q}_j^n)u_{j+1}^n(w_{j+1} - w_j) \\ &\qquad + g_Q(x_{j-1}, \hat{Q}_j^n)w_j(u_{j+1}^n - u_j^n)\Big|\frac{(1-\alpha)}{2}\Delta x \\ &\le \frac{1}{2}\left|g_{Qx}(\hat{x}_j, \hat{Q}_{j+1}^n)\Delta x + g_{QQ}(x_{j-1}, \overline{Q}_{j+1}^n)(\hat{Q}_{j+1}^n - \hat{Q}_j^n)\right| \|w\|_\infty\|u^n\|_\infty\Delta x \\ &\quad + \frac{M_3}{2}\|u^n\|_\infty\|w_x\|_\infty\Delta x^2 + \frac{M_3}{2}\|w\|_\infty|u_{j+1}^n - u_j^n|\Delta x \\ &\le \frac{M_3^2}{2}M_4\Delta x^2 + \frac{M_3^2M_4}{2}\Delta x(2M_5\Delta x) + \frac{M_3^2M_4}{2}\Delta x^2 + \frac{M_3^2}{2}|u_{j+1}^n - u_j^n|\Delta x \\ &\le M_3^2M_4(1+M_5)\Delta x^2 + \frac{M_3^2}{2}\Delta x|u_{j+1}^n - u_j^n|.\end{aligned}$$

Similarly,

$$\begin{aligned}III &= \left|g_Q(x_j, \hat{Q}_{j+1}^n)w_ju_j^n - g_Q(x_{j-1}, \hat{Q}_j^n)w_{j-1}u_{j-1}^n\right|\frac{(1-\alpha)}{2}\Delta x \\ &\le M_3^2M_4(1+M_5)\Delta x^2 + \frac{M_3^2}{2}\Delta x|u_{j+1}^n - u_{j-1}^n|.\end{aligned}$$

Hence we have proved (3.14) with

$$M_6 = \max\left(M_3(2 + M_5 + 2M_3M_4 + 2M_3M_4M_5),\ \frac{M_3^2}{2}\right).$$

For (3.15), $0 \le j \le N$, we have, by the definition of Q_j in (3.4), that

$$|Q_j^{n+1} - Q_j^n| \le \frac{3}{2}\sum_{i=1}^{N} |u_i^{n+1} - u_i^n| w_i \Delta x \le \frac{3}{2} M_3 \sum_{i=1}^{N} |u_i^{n+1} - u_i^n| \Delta x.$$

From (3.6) and the definition of A_i^n and B_i^n, we have, for $1 \le i \le N$,

$$\begin{aligned}
|u_i^{n+1} - u_i^n| &= \left|-\lambda A_i^n u_i^n + \lambda(A_i^n - B_i^n)u_{i-1}^n - m_i^n u_i^n \Delta t\right| \\
&\le \lambda |A_i^n|\,|u_i^n - u_{i-1}^n| + \lambda |B_i^n| |u_{i-1}^n + \|m^n\|_\infty \|u^n\|_\infty \Delta t \\
&\le 2\lambda \sup_{\mathcal{D}} |g(x,Q)|\,|u_i^n - u_{i-1}^n| + \lambda M_4 \max_k |g_k^n - g_{k-1}^n| + M_3 M_4 \Delta t \\
&\le 2\lambda M_3 |u_i^n - u_{i-1}^n| + M_4 M_5 \Delta t + M_3 M_4 \Delta t. \qquad (3.16)
\end{aligned}$$

Thus we have

$$\begin{aligned}
|Q_j^{n+1} - Q_j^n| &\le \frac{3}{2} M_3 \sum_{i=1}^{N} (2\lambda M_3 |u_i^n - u_{i-1}^n| + M_4 M_5 \Delta t + M_3 M_4 \Delta t)\Delta x \\
&= 3M_3^2 TV(u^n)\Delta t + \frac{3}{2} M_3 M_4 (M_3 + M_5) L \Delta t,
\end{aligned}$$

which implies

$$\begin{aligned}
|g_j^{n+1} - g_j^n| &= |g(x_j, Q_j^{n+1}) - g(x_j, Q_j^n)| \\
&= |g_Q(x_j, \tilde{Q}_j)|\,|Q_j^{n+1} - Q_j^n| \le M_3 |Q_j^{n+1} - Q_j^n| \\
&\le 3M_3^3 TV(u^n)\Delta t + \frac{3}{2} M_3^2 M_4 (M_3 + M_5) L \Delta t, \\
|\beta_j^{n+1} - \beta_j^n| &= |\beta(x_j, Q_j^{n+1}) - \beta(x_j, Q_j^n)| \\
&= |\beta_Q(x_j, \tilde{Q}_j)|\,|Q_j^{n+1} - Q_j^n| \le M_3 |Q_j^{n+1} - Q_j^n| \\
&\le 3M_3^3 TV(u^n)\Delta t + \frac{3}{2} M_3^2 M_4 (M_3 + M_5) L \Delta t.
\end{aligned}$$

We have thus proved (3.15) with

$$M_7 = \max\left(3M_3^2,\, 3M_3^3,\, \frac{3}{2} M_3 M_4 (M_3 + M_5) L,\, \frac{3}{2} M_3^2 M_4 (M_3 + M_5) L\right). \qquad \square$$

We are now ready to prove the total variation stability of the scheme.

PROPOSITION 3.4. *$TV(u^n)$ is bounded for $t^n \le T$.*

Proof. First, we rewrite the scheme (3.6) as

$$u_j^{n+1} = u_j^n - \lambda A_j^n (u_j^n - u_{j-1}^n) - \lambda B_j^n u_{j-1}^n - \Delta t m_j^n u_j^n, \qquad j \ge 1.$$

We then have

$$\begin{aligned}
u_{j+1}^{n+1} - u_j^{n+1} &= \left[\left(1 - \lambda A_{j+1}^n\right)\left(u_{j+1}^n - u_j^n\right) + \lambda\left(A_j^n - B_j^n\right)\left(u_j^n - u_{j-1}^n\right)\right] \\
&\quad + \left[-\lambda u_j^n \left(B_{j+1}^n - B_j^n\right)\right] + \left[-\Delta t (m_{j+1}^n u_{j+1}^n - m_j^n u_j^n)\right] \\
&= D_j^n + E_j^n + F_j^n, \qquad j = 1, 2, \ldots, N-1.
\end{aligned}$$

Hence

$$TV(u^{n+1}) = \sum_{j=0}^{N-1} |u_{j+1}^{n+1} - u_j^{n+1}| \le \sum_{j=1}^{N-1} |D_j^n| + \sum_{j=1}^{N-1} |E_j^n| + \sum_{j=1}^{N-1} |F_j^n| + |u_1^{n+1} - u_0^{n+1}|.$$

We now estimate each term separately. First we have

$$\begin{aligned}\sum_{j=1}^{N-1} |D_j^n| &\le \sum_{j=1}^{N-1} (1 - \lambda A_{j+1}^n)|u_{j+1}^n - u_j^n| + \lambda(A_j^n - B_j^n)|u_j^n - u_{j-1}^n| \\ &= \sum_{j=1}^{N-1} |u_{j+1}^n - u_j^n| - \lambda \sum_{j=1}^{N-1} B_j^n |u_j^n - u_{j-1}^n| + \lambda g_1^n |u_1^n - u_0^n| - \lambda g_N^n |u_N^n - u_{N-1}^n| \\ &\le \sum_{j=1}^{N-1} |u_{j+1}^n - u_j^n| + M_5 \Delta t TV(u^n) + \lambda g_1^n |u_1^n - u_0^n|,\end{aligned}$$

where in the first inequality we have used (3.9) and (3.10), and in the last inequality we have used Lemma 3.3, the fact that

$$|B_j| \le \max_i |g_i - g_{i-1}|, \qquad 1 \le j \le N, \tag{3.17}$$

and the fact that $g(x_N, Q) = 0$. Using again Lemma 3.3 and (3.17), we have

$$\begin{aligned}\sum_{j=1}^{N-1} |E_j^n| &\le \sum_{j=4}^{N-2} \lambda |B_{j+1}^n - B_j^n|\,|u_j^n| + \sum_{j=1,2,3,N-1} \lambda |B_{j+1}^n - B_j^n|\,|u_j^n| \\ &\le M_4 M_6 \Delta t \left(\sum_{j=4}^{N-2} \Delta x + \sum_{j=4}^{N-2} (|u_{j+2}^n - u_{j+1}^n| + |u_{j+1}^n - u_j^n|) \right) + 8\lambda M_4 \|B^n\|_\infty \\ &\le M_4 M_6 L \Delta t + 2 M_4 M_6 \Delta t TV(u^n) + 8 M_4 M_5 \Delta t.\end{aligned}$$

The term F_j^n can be estimated as

$$\begin{aligned}|F_j^n| &= \Delta t |m_{j+1}^n u_{j+1}^n - m_j^n u_{j+1}^n + m_j^n u_{j+1}^n - m_j^n u_j^n| \\ &\le M_3 M_4 \Delta t \Delta x + M_3 |u_{j+1}^n - u_j^n| \Delta t.\end{aligned}$$

Hence we have

$$\sum_{j=1}^{N-1} |F_j^n| \le M_3 M_4 L \Delta t + M_3 \Delta t TV(u^n).$$

Let

$$M_8 = \max\{M_4((M_3 + M_6)L + 8M_5),\ M_3 + M_5 + 2M_4 M_6\};$$

we have

$$TV(u^{n+1}) \le M_8 \Delta t + M_8 \Delta t\, TV(u^n) + \sum_{j=1}^{N-1} |u_j^n - u_{j-1}^n| + \lambda g_1^n\, |u_1^n - u_0^n| + |u_1^{n+1} - u_0^{n+1}|.$$

Next we discuss $|u_1^{n+1} - u_0^{n+1}|$. This boundary term has the form

$$\begin{aligned}|u_1^{n+1} - u_0^{n+1}| &= |(1 - \lambda g_1^n - \Delta t m_1^n)u_1^n + \lambda g_0^n u_0^n - u_0^{n+1}| \\ &= |(1 - \lambda g_1^n)(u_1^n - u_0^n) - m_1^n u_1^n \Delta t - \lambda(g_1^n - g_0^n)u_0^n - (u_0^{n+1} - u_0^n)| \\ &\le (1 - \lambda g_1^n)|u_1^n - u_0^n| + M_3 M_4 \Delta t + M_5 M_4 \Delta t + |u_0^{n+1} - u_0^n|.\end{aligned}$$

We then have

$$TV(u^{n+1}) \le M_9 \Delta t + M_9 \Delta t\, TV(u^n) + TV(u^n) + |u_0^{n+1} - u_0^n|,$$

where

$$M_9 = M_8 + M_4(M_3 + M_5).$$

Finally, we must estimate $|u_0^{n+1} - u_0^n|$. From (3.3), we have

$$\begin{aligned}g_0^{n+1}u_0^{n+1} - g_0^n u_0^n &= g_0^{n+1}(u_0^{n+1} - u_0^n) + (g_0^{n+1} - g_0^n)u_0^n \\ &= C^{n+1} - C^n + \sum_{j=0}^{N}{}' \left(\beta_j^{n+1}u_j^{n+1} - \beta_j^n u_j^n\right)\Delta x \\ &= C^{n+1} - C^n + \sum_{j=0}^{N}{}' \left(\beta_j^{n+1}(u_j^{n+1} - u_j^n) + (\beta_j^{n+1} - \beta_j^n)u_j^n\right)\Delta x.\end{aligned}$$

Rearranging terms and using (3.16) and the results of Lemma 3.2, we obtain

$$\begin{aligned}&\left|\left(g_0^{n+1} - \frac{1}{2}\beta_0^{n+1}\Delta x\right)(u_0^{n+1} - u_0^n)\right| \\ &\le |C^{n+1} - C^n| + |g_0^{n+1} - g_0^n|u_0^n + \frac{1}{2}u_0^n \Delta x|\beta_0^{n+1} - \beta_0^n| \\ &\qquad + \sum_{j=1}^{N}(\beta_j^{n+1}|u_j^{n+1} - u_j^n| + |\beta_j^{n+1} - \beta_j^n|u_j^n)\Delta x \\ &\le M_3\Delta t + M_4 M_7 \Delta t(1 + TV(u^n)) + \frac{1}{2}M_4 M_7 \Delta x \Delta t(1 + TV(u^n)) \\ &\quad + M_3 \sum_{j=1}^{N}\left(2\lambda M_3|u_j^n - u_{j-1}^n| + M_4(M_3 + M_5)\Delta t\right)\Delta x + M_4 M_7 L \Delta t(1 + TV(u^n)) \\ &\le \left(M_4 M_7(2 + L) + 2M_3^2\right)\Delta t\, TV(u^n) + \left(M_3 + M_4 M_7(2 + L) + M_3 M_4(M_3 + M_5)L\right)\Delta t,\end{aligned}$$

where in the last inequality we have assumed $\Delta x \le 2$. Notice that, by (3.7), $g_0^{n+1} \ge \mu > 0$. Hence if $\Delta x \le \frac{\mu}{M_3}$, we have $g_0^{n+1} - \frac{1}{2}\beta_0^{n+1}\Delta x \ge \frac{\mu}{2} > 0$. Hence

$$|u_0^{n+1} - u_0^n| \le M_{10} TV(u^n)\Delta t + M_{10}\Delta t$$

with

$$M_{10} = \frac{1}{\mu}\max\left(M_4 M_7(2 + L) + 2M_3^2,\ M_3 + M_4 M_7(2 + L) + M_3 M_4(M_3 + M_5)L\right).$$

Now, with $M_{11} = M_9 + M_{10}$, we have

$$TV(u^{n+1}) \le (1 + M_{11}\Delta t)TV(u^n) + M_{11}\Delta t,$$

which implies the boundedness of $TV(u^n)$. ∎

Next, we show the Lipschitz stability in t.

PROPOSITION 3.5. *There exists a positive constant M such that for any $q > p$, we have*

$$\sum_{j=1}^{N} \left| \frac{u_j^q - u_j^p}{\Delta t} \right| \Delta x \le M(q-p).$$

Proof. Using (3.6), (3.17), and the definition of A_j^n and B_j^n, we obtain

$$\begin{aligned}
\sum_{j=1}^{N} \left| \frac{u_j^{n+1} - u_j^n}{\Delta t} \right| \Delta x &= \sum_{j=1}^{N} \left| \left(\frac{B_j^n}{\Delta x} + m_j^n \right) u_j^n + (A_j^n - B_j^n) D^-(u_j^n) \right| \Delta x \\
&\le \sum_{j=1}^{N} \max_i |g_i^n - g_{i-1}^n| u_j^n + M_3 \sum_{j=1}^{N} u_j^n \Delta x + 3M_3 \sum_{j=1}^{N} |u_j^n - u_{j-1}^n| \\
&\le M_4 M_5 L + M_3 M_4 L + 3M_3 TV(u^n) \le M.
\end{aligned}$$

Thus,

$$\sum_{j=1}^{N} \left| \frac{u_j^q - u_j^p}{\Delta t} \right| \Delta x \le \sum_{n=p}^{q} \sum_{j=1}^{N} \left| \frac{u_j^{n+1} - u_j^n}{\Delta t} \right| \Delta x \le M(q-p). \qquad ∎$$

If we again define a family of functions $\{U_{\Delta x, \Delta t}\}$ by

$$U_{\Delta x, \Delta t}(x,t) = u_j^n$$

for $x \in [x_{j-1}, x_j)$, $t \in [t^{n-1}, t^n)$, $j = 1, \ldots, N$, and $n = 1, \ldots, l$, then we have the following proposition. The proof is the same as that for Proposition 2.6.

PROPOSITION 3.6. *Under the time step restriction for the validity of previous propositions in this section, the numerical solution $\{U_{\Delta x, \Delta t}\}$ converges to the unique $BV([0,L] \times [0,T])$ solution $u(x,t)$ for (1.1) when $\Delta x \to 0$.*

Finally, we remark that the scheme (3.1) is second order in space but only first order in time. We should use the following second order TVD Runge–Kutta time discretization [17]:

$$u^{(1)} = u^n + \Delta t L(u^n), \qquad u^{n+1} = \frac{1}{2} \left(u^n + u^{(1)} + \Delta t L(u^{(1)}) \right), \tag{3.18}$$

where L is the spatial operator. This will yield a second order (in space and time) scheme which shares the same stability and convergence properties as the scheme (3.1). See also [9, 10].

4. Numerical examples. In this section we perform numerical experiments to demonstrate the properties of the schemes developed in previous sections. We take the initial condition as $u^0(x) = -x^2 + x + 1$, with the parameters and functions in (1.1) and (1.2) taken as $L = 1$, $\alpha = 0.5$, $w(x) = 1$, $g(x,Q) = (1-x)(5-x+x^2/2-Q)$, $m(x,Q) = 4 + 2Q + (1-x)^2/2$, $\beta(x,Q) = (1+x)(2-Q)$. As in [1], the choice of these particular functions and initial boundary conditions is simply to demonstrate the accuracy and high resolution properties of our schemes. However, as proven in the previous sections, our schemes will be stable and convergent for all population models (1.1) satisfying assumptions (H1)–(H6).

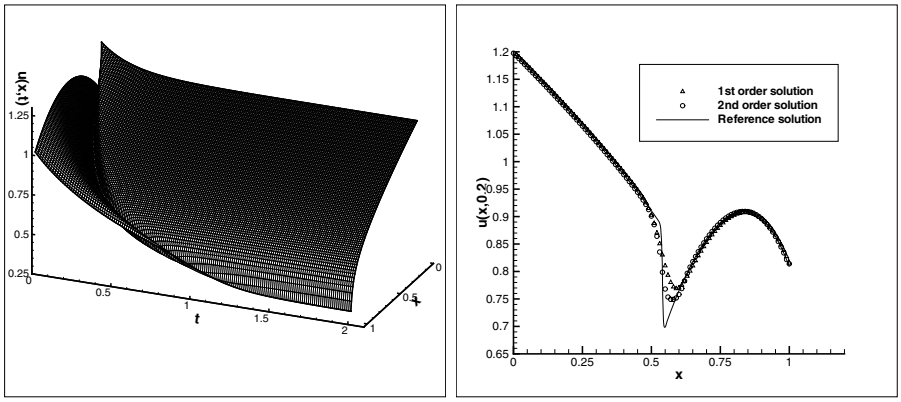

FIG. 4.1. *Left: The evolution of the solution to $t = 2$. Right: Numerical solutions using $N = 100$ uniform grid points using the first order scheme (triangles) and using the second order scheme (circles), versus the reference solution (solid line) obtained by the second order scheme using $N = 2000$ grid points.*

For the second order scheme, based on a local truncation error analysis, it is more accurate to adjust the mesh size for the second interval $x_2 - x_1$ from Δx to $\frac{3}{2}\Delta x$, and the mesh size for the second last interval $x_{N-1} - x_{N-2}$ from Δx to $\frac{1}{2}\Delta x$ (not the actual mesh sizes in the physical space—just that used in the scheme); hence we have made this adjustment in the computation. This apparently does not affect the stability and convergence analysis as the analysis does not require uniform meshes. The time step is chosen as $\Delta t_n = 0.8\Delta x / \|g^n(x,Q) + m^n(x,Q)\Delta x\|_\infty$ for the first order scheme, according to (2.5), and as $\Delta t_n = 0.8\Delta x / \|\frac{3}{2}g^n(x,Q) + m^n(x,Q)\Delta x\|_\infty$ for the second order scheme, according to (3.9).

First we demonstrate that the schemes are nonoscillatory in the presence of solution discontinuities. For this purpose we take $C(t) = 3$, which causes an incompatibility of the boundary data and the initial condition at the origin. The solution then has a discontinuity emitted from the left boundary and traveling to the right, until it moves outside the right boundary. See Figure 4.1, left, for the evolution of the solution until $t = 2$. When $t = 0.5$, the solution still contains a discontinuity. The numerical solutions using $N = 100$ uniformly spaced grid points for both the first order scheme and the second order scheme are plotted in Figure 4.1, right, against a reference solution which is obtained by the second order scheme with $N = 2000$ grid points. We can see clearly that both schemes can resolve the discontinuity without oscillation, and the second order scheme resolves the discontinuity much better without introducing spurious numerical oscillations. This verifies the high resolution property of the second order scheme. The solution for this problem changes very little after $t = 2$. We plot the rather smooth and monotone solution at $t = 20$ for both the first order scheme and the second order scheme in Figure 4.2. For such simple solutions there is no noticeable difference between the two schemes. Both schemes are stable for long time simulation.

Next, we demonstrate that the schemes can achieve their designed accuracy for smooth solutions. For this purpose we take $C(t) = \frac{38}{21} + t$, which ensures the compatibility of the boundary data and the initial condition at the origin. The solution then is continuous but has a discontinuous derivative (a kink) emitted from the left boundary and traveling to the right, until it moves outside the right boundary. When $t = 2$, the kink has already moved out of the right boundary and solution becomes

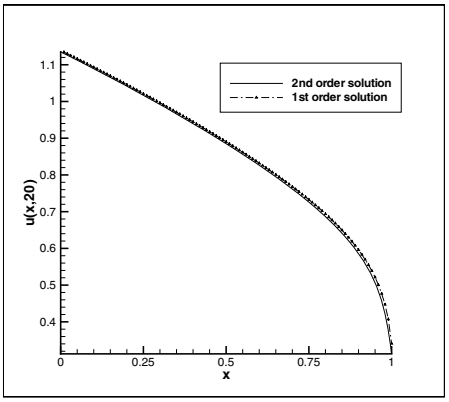

FIG. 4.2. *Solution at $t = 20$. $N = 100$ uniform grid points using the first order scheme (dashed line) and using the second order scheme (solid line).*

TABLE 4.1
L^1 errors and numerical order of accuracy of the first and second order schemes using N uniformly spaced mesh points.

N	First order scheme		Second order scheme	
N	L^1 error	order	L^1 error	order
10	9.49E-02		3.60E-02	
20	4.61E-02	1.04	1.19E-02	1.60
40	2.25E-02	1.03	3.88E-03	1.62
80	1.10E-02	1.03	1.18E-03	1.71
160	5.44E-03	1.02	3.03E-04	1.97

smooth. Since we do not know the exact solution, we use the second order scheme with $N = 10240$ grid points to produce a reference solution and then compute the L^1 errors of the first and second order schemes using coarser meshes; see Table 4.1. We can see that the designed orders of accuracy are obtained by the first and second order schemes for this smooth solution.

5. Concluding remarks. We have developed a first order explicit upwind scheme and a second order explicit high resolution scheme for solving a hierarchical size-structured population model with nonlinear growth, mortality, and reproduction rates, which contains global terms both for the boundary condition and for the coefficients in the equations. Stability and convergence are proved for both schemes for solutions with bounded total variation, which include discontinuous solutions. Numerical results are provided to demonstrate the capability of these schemes in resolving smooth as well as discontinuous solutions. Future work will include the design of higher order WENO schemes [12] with suitable treatment for boundary conditions and global constraints, and the study of schemes for the asymptotic behavior of the solution with techniques such as upwinding of the source, well-balancedness, etc., along the lines of, e.g., [7].

AN ADAPTIVE LEAST-SQUARES MIXED FINITE ELEMENT METHOD FOR ELASTO-PLASTICITY*

GERHARD STARKE†

Abstract. A least-squares mixed finite element method for the incremental formulation of elasto-plasticity using a plastic flow rule of von Mises type with isotropic hardening is presented. This approach is based on the use of the stress tensor, in addition to the displacement field, as independent process variables. The nonlinear least-squares functional is shown to constitute an a posteriori error estimator on which an adaptive refinement strategy may be based. For the finite element implementation under plane strain conditions, quadratic (i.e., next-to-lowest-order) Raviart–Thomas elements are used for the stress approximation, while the displacement is represented by standard quadratic conforming elements. Computational results for a benchmark problem of elasto-plasticity under plane strain conditions are presented in order to illustrate the effectiveness of the least-squares approach.

Key words. least-squares mixed finite element method, elasto-plasticity, isotropic hardening, a posteriori error estimator

DOI. 10.1137/060652609

1. Introduction.

In this paper, a least-squares mixed finite element method for the incremental formulation of elasto-plastic deformation models is studied. This approach works with the stress tensor as an independent process variable, in addition to the displacement field. It is based on a first-order system modelling the elasto-plastic deformation process. The method studied in this paper constitutes an extension of the least-squares mixed finite element approach for linear elasticity presented in [12]. The closely related least-squares approaches investigated in [13, 14] could similarly be generalized to the elasto-plastic case. The main result of this paper is that, under the assumption of a plastic flow rule of von Mises type with isotropic hardening, the nonlinear least-squares functional associated with elasto-plasticity is elliptic with respect to an appropriate product space for the stresses and displacements. Our computational results suggest that the approximation properties actually deteriorate in the perfectly plastic case. This implies that it is not possible to extend our ellipticity result to perfect plasticity. Despite this deterioration of the approximation order in the perfectly plastic case, the adaptive implementation of the least-squares finite element method provides remarkably accurate results, in particular, for the stresses.

Finite element methods of least-squares type have been the object of many studies recently (see, e.g., the survey [7]). These methods may be viewed as an alternative to mixed finite element methods of saddle point structure whenever accurate approximations of the stress tensor are desired. Among its advantages is the greater flexibility in combining finite element spaces for the different process variables which are not restricted by an inf-sup condition. Moreover, if the least-squares functional is elliptic with respect to some norm on the underlying function spaces, then its local eval-

uation provides an a posteriori error estimator. This may be used in an adaptive refinement technique; see [5] for a detailed study of such strategies in the context of least-squares formulations. The most appropriate combination for the elasto-plasticity models treated in this paper consists of Raviart–Thomas elements for the stresses coupled with conforming finite element spaces of the same polynomial degree for the displacement components. This is due to the fact that the same order of approximation is achieved for the individual variables. In particular, next-to-lowest-order Raviart–Thomas spaces are combined with piecewise quadratic conforming finite elements in our computations.

The numerical simulation of elasto-plastic deformation processes has been an intensive area of research for several decades. Two monographs which appeared at the end of the last century cover the state of the art from a more engineering-oriented perspective [22] and a more abstract mathematical view [15]. Error estimation and adaptive refinement strategies for elasto-plasticity based on duality techniques were proposed and studied in [19, 20]. Other approaches to adaptive finite element computations for elasto-plastic deformation processes are described in [1]. Even earlier, several error indicators were investigated about their suitability for problems of elasto-plasticity from an engineering point of view in [4]. The solution of the nonlinear algebraic systems associated with finite element discretizations of elasto-plastic models was the subject of [3, 6, 24]. As in [24], multigrid methods were applied in [16] to the solution of elasto-plastic deformation models discretized by finite elements. The efficiency was tested for benchmark test problems defined in [23], which constitutes another contribution to the same book resulting from a larger project on adaptive finite element methods in computational mechanics in which several research groups were involved. A detailed comparison of our least-squares finite element method with the adaptive approaches mentioned above is beyond the scope of this paper. Such a comparison would certainly depend on the choice of norm in which the approximation of the different variables is desired. At the very least, our least-squares method can be expected to provide more accurate stress approximations, in terms of computational effort, than a displacement-based approach.

The issue of time discretization is omitted almost completely in this paper by restricting ourselves to the implicit Euler scheme. Issues of the time discretization are important, however, in order to obtain accurate simulations of elasto-plastic deformation processes; see [10, 11] for details on this subject. A general framework for the numerical approximation of different models of elasto-plasticity was recently provided in [17].

In section 2, the first-order system model of incremental elasto-plasticity and the corresponding least-squares variational formulation are derived. The equivalence of the least-squares functional to a certain error norm on the product space of stresses and displacements is shown in section 3. This establishes ellipticity of the least-squares variational formulation and implies that the local evaluation of the least-squares functional constitutes an a posteriori error estimator to be used in adaptive refinement strategies. Section 4 contains the reduction to plane strain conditions and the specific finite element spaces appropriate under these circumstances. Finally, in section 5 the numerical results obtained with our adaptive least-squares method for a benchmark problem of elasto-plasticity are presented.

2. Least-squares formulation of incremental elasto-plasticity. Elasto-plastic deformation processes are usually modelled by a first-order system of the form

$$\begin{aligned} \operatorname{div} \boldsymbol{\sigma} &= 0\,, \\ \boldsymbol{\sigma} &= \mathcal{C}(\boldsymbol{\varepsilon}(\mathbf{u}) - \mathbf{p}) \end{aligned} \tag{2.1}$$

for the stress tensor $\boldsymbol{\sigma} : \Omega \to \mathbb{R}^{3\times 3}$ and the displacement field $\mathbf{u} : \Omega \to \mathbb{R}^3$. In (2.1), $\operatorname{div} \boldsymbol{\sigma}$ means row-wise application of the divergence operator, and $\nabla \mathbf{u}$ contains the gradient vectors of the components of $\mathbf{u}$ in each row. Similarly to the model of linear elasticity,

$$\boldsymbol{\varepsilon}(\mathbf{u}) = \frac{1}{2}(\nabla \mathbf{u} + (\nabla \mathbf{u})^T) \tag{2.2}$$

denotes the strain tensor, and

$$\mathcal{C}\boldsymbol{\varepsilon} = 2\mu\boldsymbol{\varepsilon} + \lambda\,(\operatorname{tr}\boldsymbol{\varepsilon})\mathbf{I} \tag{2.3}$$

represents the linear material law. The difference from the elastic case lies in the term $\mathbf{p}$, which stands for the plastic strains satisfying additional constraints. To this end, we need to define the deviatoric stress part

$$\operatorname{dev}(\boldsymbol{\sigma}) = \boldsymbol{\sigma} - \frac{1}{3}\,(\operatorname{tr}\boldsymbol{\sigma})\,\mathbf{I}\,. \tag{2.4}$$

The system (2.1) is extended by the constraint

$$|\operatorname{dev}(\boldsymbol{\sigma})| \le \sqrt{\frac{2}{3}} K(\alpha) \tag{2.5}$$

with a hardening function $K(\alpha)$ and the evolution equations

$$\dot{\mathbf{p}} = \gamma \frac{\operatorname{dev}(\boldsymbol{\sigma})}{|\operatorname{dev}(\boldsymbol{\sigma})|}\,, \quad \dot{\alpha} = \gamma\sqrt{\frac{2}{3}}\,. \tag{2.6}$$

The parameter γ acts as a Lagrange multiplier associated with the constraint (2.5) and therefore satisfies

$$\gamma \ge 0 \quad \text{and} \quad \gamma\left(|\operatorname{dev}(\boldsymbol{\sigma})| - \sqrt{\frac{2}{3}}K(\alpha)\right) = 0\,. \tag{2.7}$$

The hardening parameter $\alpha : \Omega \to \mathbb{R}$ constitutes an additional process variable in the case of elasto-plasticity with hardening. Due to (2.6), elasto-plasticity models become time-dependent with the need to employ an appropriate time-discretization scheme. The model for elasto-plastic deformation processes described above is taken from [22, Chap. 2]. We restrict our exposition to these basic relations required for the derivation of the system arising in each step of a time-discretized model. Details on the mechanical background of elasto-plasticity models and different variational formulations suitable for numerical treatment may be found in [22, 15] or in [21, Chap. 6].

Discretization in time by an implicit Euler scheme leads to a first-order system for the increments $\boldsymbol{\sigma}^{\text{inc}}$ and $\mathbf{u}^{\text{inc}}$ in the representations $\boldsymbol{\sigma} = \boldsymbol{\sigma}^{\text{old}} + \boldsymbol{\sigma}^{\text{inc}}$ and $\mathbf{u} = \mathbf{u}^{\text{old}} + \mathbf{u}^{\text{inc}}$, respectively. The system associated with one time-step in an incremental formulation of elasto-plasticity may be written as

$$\begin{aligned} \operatorname{div}(\boldsymbol{\sigma}^{\text{old}} + \boldsymbol{\sigma}^{\text{inc}}) &= \mathbf{0}\,, \\ \boldsymbol{\sigma}^{\text{inc}} - \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u}^{\text{inc}}); \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}}) &= \mathbf{0}\,. \end{aligned} \tag{2.8}$$

The stress operator $\mathcal{R}(\boldsymbol{\varepsilon}; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}})$ in (2.8) depends, in general, nonlinearly and non-smoothly on $\boldsymbol{\varepsilon}$ as soon as plastic deformation occurs.

For notational convenience the increments $\boldsymbol{\sigma}^{\text{inc}}$ and $\mathbf{u}^{\text{inc}}$ are simply denoted by $\boldsymbol{\sigma}$ and $\mathbf{u}$ (which had a different meaning in (2.1)) throughout the rest of this paper. For simplicity, we will also omit the dependence on $\boldsymbol{\sigma}^{\text{old}}$ and α^{old} in the stress operator and simply write $\mathcal{R}(\boldsymbol{\varepsilon})$ instead of $\mathcal{R}(\boldsymbol{\varepsilon}; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}})$. We introduce the Sobolev spaces

$$H(\operatorname{div}, \Omega) = \{\mathbf{s} \in L^2(\Omega)^3 : \operatorname{div} \mathbf{s} \in L^2(\Omega)\}\,,$$
$$H^1(\Omega) = \{p \in L^2(\Omega) : \nabla p \in L^2(\Omega)^3\}$$

and associated subspaces

$$H_{\Gamma_N}(\operatorname{div}, \Omega) = \{\mathbf{s} \in H(\operatorname{div}, \Omega) : \mathbf{s} \cdot \mathbf{n} = 0 \text{ on } \Gamma_N\}\,,$$
$$H^1_{\Gamma_D}(\Omega) = \{p \in H^1(\Omega) : p = 0 \text{ on } \Gamma_D\}$$

where homogeneous boundary conditions are imposed. The solution of (2.8) for $\boldsymbol{\sigma} : \Omega \to \mathbb{R}^{3\times 3}$ is then sought in $\boldsymbol{\sigma}^N + H_{\Gamma_N}(\operatorname{div}, \Omega)^3$, where $\boldsymbol{\sigma}^N \in H(\operatorname{div}, \Omega)^3$ satisfies the boundary conditions $\boldsymbol{\sigma}^N \cdot \mathbf{n} = \mathbf{g}$ on Γ_N. In connection with the incremental formulation (2.8), $\mathbf{g}$ stands for the increment of the boundary traction. The solution space for $\mathbf{u} : \Omega \to \mathbb{R}^3$ is $H^1_{\Gamma_D}(\Omega)^3$.

For the case of von Mises plasticity with isotropic hardening, the stress response is given by

$$\mathcal{R}(\boldsymbol{\varepsilon}) = \mathcal{C}\left(\boldsymbol{\varepsilon} - \frac{1}{2\mu}\,\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}))\,\frac{\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})}{|\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})|}\right)\,, \tag{2.9}$$

where the return parameter $\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}))$ is implicitly defined as the solution of the equation

$$\begin{aligned}&\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}))\\ &\quad = |\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})| - \sqrt{\frac{2}{3}}K\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\,\frac{\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}))}{2\mu}\right)\,,\end{aligned} \tag{2.10}$$

if $|\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\boldsymbol{\varepsilon})| > \sqrt{2/3}K(\alpha^{\text{old}})$ and $\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\boldsymbol{\varepsilon})) = 0$ otherwise. The return parameter γ_R in (2.10) plays the same role as the Lagrange multiplier γ in (2.6) and satisfies $\gamma_R = 2\mu\,\Delta t\,\gamma$, if Δt denotes the time-step size. The hardening parameter is updated by

$$\alpha = \alpha^{\text{old}} + \sqrt{\frac{2}{3}}\,\frac{\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}))}{2\mu}\,. \tag{2.11}$$

For the theoretical study in the next section, the following conditions on $K(\alpha)$ are assumed to hold for all $\alpha > 0$ (cf. [6]):

$$\begin{aligned}K(\alpha) &\geq K_0 > 0\,,\\ K'(\alpha) &\geq K_1 > 0\,.\end{aligned} \tag{2.12}$$

This is satisfied, for example, for exponential hardening where

$$K(\alpha) = K_0 + H\alpha + (K_\infty - K_0)(1 - e^{-\omega\alpha})$$

with given parameters $K_\infty \geq K_0 > 0$, $H > 0$, and $\omega > 0$ which are denoted as saturation stress, initial yield stress, hardening modulus, and hardening exponent, respectively.

In the case of perfect plasticity, we have $K(\alpha) \equiv K_0$, which means that (2.12) is not satisfied and the theoretical results in section 3 do not hold. Nevertheless we will present computational results for the perfectly plastic case in this paper. Since, for $|\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})| > \sqrt{2/3}K_0$, the return parameter is simply given by

$$\gamma_R(\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})) = |\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})| - \sqrt{\frac{2}{3}}K_0\,,$$

we end up with

$$\mathcal{R}(\boldsymbol{\varepsilon}) = \frac{1}{3}\,\mathrm{tr}(\mathcal{C}\boldsymbol{\varepsilon})\,\mathbf{I} - \mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}}) + \sqrt{\frac{2}{3}}K_0\frac{\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})}{|\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon})|} \tag{2.13}$$

for the stress response. This means that different strain increments $\boldsymbol{\varepsilon}$ and $\bar{\boldsymbol{\varepsilon}}$ lead to the same stress response as long as $\mathrm{tr}(\boldsymbol{\varepsilon}) = \mathrm{tr}(\bar{\boldsymbol{\varepsilon}})$ and $\mathrm{dev}(\boldsymbol{\varepsilon})$ is aligned with $\mathrm{dev}(\bar{\boldsymbol{\varepsilon}})$.

We close this section with the least-squares formulation of the first-order system (2.8). Throughout this paper, $\|\cdot\|$ will simply denote the $L^2(\Omega)$ (or, if applicable, $L^2(\Omega)^d$, $L^2(\Omega)^{d\times d}$) norm. The least-squares functional, associated with (2.8), is given by

$$\mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}}) = \|\mathrm{div}(\boldsymbol{\sigma}^{\mathrm{old}} + \boldsymbol{\sigma})\|^2 + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma} - \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u}))\|^2\,. \tag{2.14}$$

The weighting of the second term in the above functional is motivated from our earlier work on linear elasticity in [13, 12]. Its implementation is straightforward using the explicit formula

$$\mathcal{C}^{-1}\boldsymbol{\sigma} = \frac{1}{2\mu}\boldsymbol{\sigma} - \frac{\lambda}{2\mu(3\lambda + 2\mu)}(\mathrm{tr}\,\boldsymbol{\sigma})\mathbf{I}$$

for the inverse of the operator defined in (2.3). The corresponding least-squares formulation consists in minimizing (2.14) among all suitable $(\boldsymbol{\sigma}, \mathbf{u}) \in H(\mathrm{div}, \Omega)^3 \times H^1(\Omega)^3$. More precisely, our aim is to find $\boldsymbol{\sigma} \in \boldsymbol{\sigma}^N + H_{\Gamma_N}(\mathrm{div}, \Omega)^3$ and $\mathbf{u} \in H^1_{\Gamma_D}(\Omega)^3$ such that

$$\mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}}) \leq \mathcal{F}(\boldsymbol{\sigma}^N + \boldsymbol{\tau}, \mathbf{v}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}}) \tag{2.15}$$

holds for all $\boldsymbol{\tau} \in H_{\Gamma_N}(\mathrm{div}, \Omega)^3$ and $\mathbf{v} \in H^1_{\Gamma_D}(\Omega)^3$. For hardening laws which satisfy (2.12), the well-posedness of the system (2.8) is studied in [15, sect. 8]. If the first-order system (2.8) is guaranteed to possess a unique solution, then it is also the unique minimizer of (2.15).

The analysis carried out in the next section will be based on a Korn inequality of the form

$$\left(\|\mathbf{v}\|^2 + \|\nabla\mathbf{v}\|^2\right) \leq C_K\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 \tag{2.16}$$

to hold for all $\mathbf{v} \in H^1_{\Gamma_D}(\Omega)^3$ with a constant C_K. Korn's inequality (2.16) is known to hold, e.g., if Γ_D does not vanish (cf. [8, sect. VI.3]). In fact, the constant in (2.16) satisfies $C_K \geq 2\mu$, since, if $\mathrm{div}\,\mathbf{v} = 0$,

$$\begin{aligned}
\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2 = 2\mu\|\boldsymbol{\varepsilon}(\mathbf{v})\|^2 &= 2\mu\left(\|\partial_1 v_1\|^2 + \|\partial_2 v_2\|^2 + 2\|\frac{1}{2}(\partial_2 v_1 + \partial_1 v_2)\|^2\right)\\
&\leq 2\mu\left(\|\partial_1 v_1\|^2 + \|\partial_2 v_2\|^2 + \|\partial_2 v_1\|^2 + \|\partial_1 v_2\|^2\right) = 2\mu\|\nabla\mathbf{v}\|^2\\
&\leq 2\mu\left(\|\mathbf{v}\|^2 + \|\nabla\mathbf{v}\|^2\right)\,.
\end{aligned}$$

3. The nonlinear least-squares functional as an error estimator. In this section, the equivalence of the nonlinear least-squares functional in (2.14) to the natural norm of the error is established. To this end, the estimate given in the following lemma is required.

LEMMA 3.1. *Under the assumptions* (2.12)*, there exists a constant* $C_R \in [0,1)$ *such that*

$$\|\mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{v}))) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v})\| \le C_R\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v})\| \tag{3.1}$$

holds for all $\mathbf{u},\mathbf{v} \in H^1_{\Gamma_D}(\Omega)^3$.

Proof. The special form (2.9) of the stress operator $\mathcal{R}(\boldsymbol{\varepsilon})$ implies

$$\begin{aligned}
&\mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{v}))) - \mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v}) \\
&\quad = \frac{1}{\sqrt{2\mu}}\left(\gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{v})))\frac{\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{v}))}{|\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{v}))|}\right. \\
&\qquad\qquad \left. - \gamma_R(\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u})))\frac{\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}))}{|\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}))|}\right).
\end{aligned}$$

On the other hand,

$$\begin{aligned}
\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v})\| &\ge \|\operatorname{dev}(\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v}))\| = \|\sqrt{2\mu}\operatorname{dev}(\boldsymbol{\varepsilon}(\mathbf{u}-\mathbf{v}))\| \\
&= \left\|\frac{1}{\sqrt{2\mu}}\left(\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + 2\mu\,\boldsymbol{\varepsilon}(\mathbf{u})) - \operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + 2\mu\,\boldsymbol{\varepsilon}(\mathbf{v}))\right)\right\| \\
&= \left\|\frac{1}{\sqrt{2\mu}}\left(\operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u})) - \operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{v}))\right)\right\|.
\end{aligned}$$

With the abbreviations $\boldsymbol{\xi} = \operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}))$ and $\boldsymbol{\eta} = \operatorname{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{v}))$ this means that it is sufficient to show

$$\left\|\gamma_R(\boldsymbol{\eta})\frac{\boldsymbol{\eta}}{|\boldsymbol{\eta}|} - \gamma_R(\boldsymbol{\xi})\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right\| \le C_R\|\boldsymbol{\eta}-\boldsymbol{\xi}\|.$$

This inequality certainly holds if

$$\left|\gamma_R(\boldsymbol{\eta})\frac{\boldsymbol{\eta}}{|\boldsymbol{\eta}|} - \gamma_R(\boldsymbol{\xi})\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|}\right| \le C_R|\boldsymbol{\eta}-\boldsymbol{\xi}| \tag{3.2}$$

is satisfied for all $x \in \Omega$.

In order to prove (3.2), we fix $x \in \Omega$ and investigate the function

$$\mathcal{S} : \mathbb{R}^{3\times 3} \to \mathbb{R}^{3\times 3}, \quad \mathcal{S}(\boldsymbol{\xi}) = \gamma_R(\boldsymbol{\xi})\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|} \tag{3.3}$$

more closely. $\mathcal{S}$ is differentiable at all $\boldsymbol{\xi} \in \mathbb{R}^{3\times 3}$ with $|\boldsymbol{\xi}| \ne \sqrt{2/3}K(\alpha^{\mathrm{old}})$. For $|\boldsymbol{\xi}| < \sqrt{2/3}K(\alpha^{\mathrm{old}})$, obviously, $\mathcal{S}'(\boldsymbol{\xi})[\boldsymbol{\chi}] = \mathbf{0}$, while, for $|\boldsymbol{\xi}| > \sqrt{2/3}K(\alpha^{\mathrm{old}})$,

$$\mathcal{S}'(\boldsymbol{\xi})[\boldsymbol{\chi}] = \gamma_R'(\boldsymbol{\xi})[\boldsymbol{\chi}]\frac{\boldsymbol{\xi}}{|\boldsymbol{\xi}|} + \gamma_R(\boldsymbol{\xi})\frac{\boldsymbol{\chi}}{|\boldsymbol{\xi}|} - \gamma_R(\boldsymbol{\xi})\frac{(\boldsymbol{\xi}:\boldsymbol{\chi})\,\boldsymbol{\xi}}{|\boldsymbol{\xi}|^3}$$

holds. $\gamma_R'(\boldsymbol{\xi})$ may be computed from differentiating the defining equation (2.10). This leads to

$$\gamma_R'(\boldsymbol{\xi})[\boldsymbol{\chi}] = \frac{\boldsymbol{\xi}:\boldsymbol{\chi}}{|\boldsymbol{\xi}|} - \frac{1}{3\mu}\gamma_R'(\boldsymbol{\xi})[\boldsymbol{\chi}]\,K'\left(\alpha^{\mathrm{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)$$

or, equivalently,

$$\gamma_R'(\boldsymbol{\xi})[\boldsymbol{\chi}] = \left(1 + \frac{1}{3\mu}\, K'\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)\right)^{-1} \frac{\boldsymbol{\xi} : \boldsymbol{\chi}}{|\boldsymbol{\xi}|}\,. \tag{3.4}$$

This implies

$$\begin{aligned}|S'(\boldsymbol{\xi})[\boldsymbol{\chi}]|^2 = \left(1 + \frac{1}{3\mu}\, K'\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)\right)^{-2} \frac{(\boldsymbol{\xi} : \boldsymbol{\chi})^2}{|\boldsymbol{\xi}|^2} \\ + \gamma_R(\boldsymbol{\xi})^2 \left(\frac{|\boldsymbol{\chi}|^2}{|\boldsymbol{\xi}|^2} - \frac{(\boldsymbol{\xi} : \boldsymbol{\chi})^2}{|\boldsymbol{\xi}|^4}\right),\end{aligned}$$

which leads to

$$\begin{aligned}\frac{|S'(\boldsymbol{\xi})[\boldsymbol{\chi}]|^2}{|\boldsymbol{\chi}|^2} &= \left(1 + \frac{1}{3\mu}\, K'\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)\right)^{-2} \frac{(\boldsymbol{\xi} : \boldsymbol{\chi})^2}{|\boldsymbol{\xi}|^2|\boldsymbol{\chi}|^2} + \frac{\gamma_R(\boldsymbol{\xi})^2}{|\boldsymbol{\xi}|^2}\left(1 - \frac{(\boldsymbol{\xi} : \boldsymbol{\chi})^2}{|\boldsymbol{\xi}|^2|\boldsymbol{\chi}|^2}\right) \\ &\le \max\left\{\left(1 + \frac{1}{3\mu}\, K'\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)\right)^{-2}, \frac{\gamma_R(\boldsymbol{\xi})^2}{|\boldsymbol{\xi}|^2}\right\}\end{aligned}$$

for all $\boldsymbol{\chi} \neq \mathbf{0}$. This may be rewritten as

$$\sup_{\boldsymbol{\chi}\neq 0} \frac{|S'(\boldsymbol{\xi})[\boldsymbol{\chi}]|}{|\boldsymbol{\chi}|} \le \max\left\{\left(1 + \frac{1}{3\mu}\, K'\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right)\right)^{-1}, \frac{\gamma_R(\boldsymbol{\xi})}{|\boldsymbol{\xi}|}\right\}. \tag{3.5}$$

For the first of the two terms on the right-hand side in (3.5), (2.12) implies that it is bounded by $(1 + K_1/(3\mu))^{-1}$. For the second term let C_T denote an upper bound for the largest strain increment in the sense that $|\text{dev}(\boldsymbol{\varepsilon}(\mathbf{u}))| \le C_T$ holds. This implies that

$$|\text{dev}(\boldsymbol{\sigma}^{\text{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}))| \le |\text{dev}(\boldsymbol{\sigma}^{\text{old}})| + 2\mu|\text{dev}(\boldsymbol{\varepsilon}(\mathbf{u}))| \le \sqrt{\frac{2}{3}}K(\alpha^{\text{old}}) + 2\mu C_T$$

is satisfied. Using (2.10) and the fact that K is monotonically increasing (which follows from (2.12)), this leads to

$$\begin{aligned}\frac{\gamma_R(\boldsymbol{\xi})}{|\boldsymbol{\xi}|} &= 1 - \frac{1}{|\boldsymbol{\xi}|}\sqrt{\frac{2}{3}}K\left(\alpha^{\text{old}} + \sqrt{\frac{2}{3}}\frac{\gamma_R(\boldsymbol{\xi})}{2\mu}\right) \le 1 - \frac{1}{|\boldsymbol{\xi}|}\sqrt{\frac{2}{3}}K(\alpha^{\text{old}}) \\ &\le 1 - \frac{\sqrt{\frac{2}{3}}K(\alpha^{\text{old}})}{\sqrt{\frac{2}{3}}K(\alpha^{\text{old}}) + 2\mu C_T} = \frac{1}{1 + \sqrt{\frac{2}{3}}\frac{K(\alpha^{\text{old}})}{2\mu C_T}} \le \frac{1}{1 + \sqrt{\frac{2}{3}}\frac{K_0}{2\mu C_T}}\,.\end{aligned}$$

Therefore, (3.2) holds with

$$C_R = \max\left\{\left(1 + \frac{K_1}{3\mu}\right)^{-1}, \left(1 + \sqrt{\frac{2}{3}}\frac{K_0}{2\mu C_T}\right)^{-1}\right\} < 1\,. \qquad \square$$

Remark. In the case of perfect plasticity, different displacements $\mathbf{u}$ and $\mathbf{v}$ may lead to the same stress states $\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) = \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{v}))$ as can be seen from (2.13). Therefore, (3.1) does not hold with $C_R < 1$ in that case.

THEOREM 3.2. *Let $\boldsymbol{\sigma} \in \boldsymbol{\sigma}^N + H_{\Gamma_N}(\mathrm{div}, \Omega)^3$, $\mathbf{u} \in H^1_{\Gamma_D}(\Omega)^3$ be the solution of the first-order system* (2.8)*. Then, under the assumptions* (2.12)*, there exist positive constants $\underline{\beta}$, $\overline{\beta}$ (which do not depend on the Lamé parameter λ) such that*

$$
\begin{aligned}
&\underline{\beta}\left(\|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2 + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})\|^2\right)\\
&\le \mathcal{F}(\bar{\boldsymbol{\sigma}}, \bar{\mathbf{u}}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}})\\
&\le \overline{\beta}\left(\|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2 + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})\|^2\right)
\end{aligned}
\tag{3.6}
$$

holds for all $\bar{\boldsymbol{\sigma}} \in \boldsymbol{\sigma}^N + H_{\Gamma_N}(\mathrm{div}, \Omega)^3$ and $\bar{\mathbf{u}} \in H^1_{\Gamma_D}(\Omega)^3$.

Proof. For simplicity we set $\mu = 1$ and observe that the equivalence is invariant with respect to the scaling of μ. Using the fact that $(\boldsymbol{\sigma}, \mathbf{u})$ is the exact solution of (2.8), we obtain

$$
\begin{aligned}
\mathcal{F}(\bar{\boldsymbol{\sigma}}, \bar{\mathbf{u}}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}}) &= \|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2\\
&\quad + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}}) - \mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))\|^2\,.
\end{aligned}
\tag{3.7}
$$

For the lower bound in (3.6), we use the decomposition of an arbitrary matrix-valued function $\boldsymbol{\tau} \in L^2(\Omega)^{d\times d}$ into its symmetric and antisymmetric parts,

$$
\boldsymbol{\tau} = \mathrm{sy}\,\boldsymbol{\tau} + \mathrm{as}\,\boldsymbol{\tau} \text{ with } \mathrm{sy}\,\boldsymbol{\tau} = \frac{\boldsymbol{\tau}+\boldsymbol{\tau}^T}{2}\,, \quad \mathrm{as}\,\boldsymbol{\tau} = \frac{\boldsymbol{\tau}-\boldsymbol{\tau}^T}{2}\,.
$$

Obviously, $(\mathrm{sy}\,\boldsymbol{\tau}, \mathrm{as}\,\boldsymbol{\tau})_{0,\Omega} = 0$, which implies

$$
\|\boldsymbol{\tau}\|^2 = \|\mathrm{sy}\,\boldsymbol{\tau}\|^2 + \|\mathrm{as}\,\boldsymbol{\tau}\|^2 \ge \|\mathrm{as}\,\boldsymbol{\tau}\|^2\,.
$$

If this estimate is applied with $\boldsymbol{\tau} = \mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}}) - \mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))$, we obtain

$$
\begin{aligned}
\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}}) - \mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))\|^2 &\ge \|\mathrm{as}(\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}}))\|^2\\
&= \frac{1}{2}\|\mathrm{as}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2
\end{aligned}
\tag{3.8}
$$

(note that $\mathrm{as}(\mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))) = \mathbf{0}$). The combination of (3.7) and (3.8) leads to

$$
\begin{aligned}
\mathcal{F}(\bar{\boldsymbol{\sigma}}, \bar{\mathbf{u}}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}}) \ge \frac{1}{3}\Big(&\|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2 + \|\mathrm{as}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2\\
&+\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}}) - \mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) - \mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))\|^2\Big)\,.
\end{aligned}
$$

Inserting $C^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})$ and using the result of Lemma 3.1, we are further led to

$$\begin{aligned}\mathcal{F}(\bar{\boldsymbol{\sigma}},\bar{\mathbf{u}};\boldsymbol{\sigma}^{\mathrm{old}},\alpha^{\mathrm{old}}) &\geq \frac{1}{3}\Big(\|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2+\|\mathrm{as}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2\\ &\quad+(1-\rho)\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})-\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})\|^2\\ &\quad-\left(\frac{1}{\rho}-1\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})-\mathcal{C}^{-1/2}(\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u}))-\mathcal{R}(\boldsymbol{\varepsilon}(\bar{\mathbf{u}})))\|^2\Big)\\ &\geq \frac{1}{3}\Big(\|\mathrm{div}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2+\|\mathrm{as}\,(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})\|^2\\ &\quad+(1-\rho)\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}})-\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})\|^2\\ &\quad-\left(\frac{1}{\rho}-1\right)C_R^2\,\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u}-\bar{\mathbf{u}})\|^2\Big)=:\frac{1-\rho}{3}\mathcal{G}(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}},\mathbf{u}-\bar{\mathbf{u}})\,,\end{aligned}\tag{3.9}$$

where $\rho\in(0,1)$ is still free to be chosen appropriately below.

If we set $(\boldsymbol{\tau},\mathbf{v})=(\boldsymbol{\sigma}-\bar{\boldsymbol{\sigma}},\mathbf{u}-\bar{\mathbf{u}})\in H_{\Gamma_N}(\mathrm{div},\Omega)^3\times H^1_{\Gamma_D}(\Omega)^3$, then we are left with estimating the quadratic functional

$$\mathcal{G}(\boldsymbol{\tau},\mathbf{v})=\frac{\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2}{1-\rho}+\|\mathcal{C}^{-1/2}\boldsymbol{\tau}-\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2-\frac{C_R^2}{\rho}\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\tag{3.10}$$

from below. The decomposition of $\boldsymbol{\tau}$ into its symmetric and antisymmetric parts and integration by parts lead to

$$\begin{aligned}(\boldsymbol{\tau},\boldsymbol{\varepsilon}(\mathbf{v}))_{0,\Omega}&=(\mathrm{sy}\,\boldsymbol{\tau},\boldsymbol{\varepsilon}(\mathbf{v}))_{0,\Omega}+(\mathrm{as}\,\boldsymbol{\tau},\boldsymbol{\varepsilon}(\mathbf{v}))_{0,\Omega}=(\mathrm{sy}\,\boldsymbol{\tau},\boldsymbol{\varepsilon}(\mathbf{v}))_{0,\Omega}\\ &=(\mathrm{sy}\,\boldsymbol{\tau},\nabla\mathbf{v})_{0,\Omega}=(\boldsymbol{\tau},\nabla\mathbf{v})_{0,\Omega}-(\mathrm{as}\,\boldsymbol{\tau},\nabla\mathbf{v})_{0,\Omega}\\ &=-(\mathrm{div}\,\boldsymbol{\tau},\mathbf{v})_{0,\Omega}-(\mathrm{as}\,\boldsymbol{\tau},\nabla\mathbf{v})_{0,\Omega}\,.\end{aligned}\tag{3.11}$$

Inserting (3.11) into (3.10) we obtain

$$\begin{aligned}\mathcal{G}(\boldsymbol{\tau},\mathbf{v})&=\frac{1}{1-\rho}\left(\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2\right)+\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2\\ &\quad+\left(1-\frac{C_R^2}{\rho}\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2-2(\boldsymbol{\tau},\boldsymbol{\varepsilon}(\mathbf{v}))\\ &=\frac{1}{1-\rho}\left(\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2\right)+\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2\\ &\quad+\left(1-\frac{C_R^2}{\rho}\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2+2\left((\mathrm{div}\,\boldsymbol{\tau},\mathbf{v})+(\mathrm{as}\,\boldsymbol{\tau},\nabla\mathbf{v})\right)\,.\end{aligned}\tag{3.12}$$

For the last term in (3.12), Korn's inequality (2.16) may be used to obtain

$$\begin{aligned}2\left((\mathrm{div}\,\boldsymbol{\tau},\mathbf{v})+(\mathrm{as}\,\boldsymbol{\tau},\nabla\mathbf{v})\right)&\leq\frac{1}{\delta}\left(\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2\right)+\delta\left(\|\mathbf{v}\|^2+\|\nabla\mathbf{v}\|^2\right)\\ &\leq\frac{1}{\delta}\left(\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2\right)+C_K\delta\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\,,\end{aligned}$$

where $\delta\in(0,1)$ is still free to be chosen appropriately. Inserting this into (3.12) yields

$$\begin{aligned}\mathcal{G}(\boldsymbol{\tau},\mathbf{v})&\geq\left(\frac{1}{1-\rho}-\frac{1}{\delta}\right)\left(\|\mathrm{div}\,\boldsymbol{\tau}\|^2+\|\mathrm{as}\,\boldsymbol{\tau}\|^2\right)+\|\mathcal{C}^{-1/2}\boldsymbol{\tau}\|^2\\ &\quad+\left(1-\frac{C_R^2}{\rho}-C_K\delta\right)\|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{v})\|^2\,.\end{aligned}\tag{3.13}$$

If ρ is restricted to the interval $(C_R^2, 1)$, then we may choose

$$\delta = \left(\frac{1-\rho}{C_K} \left(1 - \frac{C_R^2}{\rho} \right) \right)^{1/2}$$

($\delta < 1$ is satisfied due to $C_K \geq 2$). If we insert this into (3.13), we see that

$$\begin{aligned} \mathcal{G}(\boldsymbol{\tau}, \mathbf{v}) \geq \frac{1}{1-\rho} \left(1 - \left(\frac{C_K(1-\rho)}{1 - \frac{C_R^2}{\rho}} \right)^{1/2} \right) \left(\|\operatorname{div} \boldsymbol{\tau}\|^2 + \|\operatorname{as} \boldsymbol{\tau}\|^2 \right) + \|\mathcal{C}^{-1/2} \boldsymbol{\tau}\|^2 \\ + \left(1 - \frac{C_R^2}{\rho} \right) \left(1 - \left(\frac{C_K(1-\rho)}{1 - \frac{C_R^2}{\rho}} \right)^{1/2} \right) \|\mathcal{C}^{1/2} \boldsymbol{\varepsilon}(\mathbf{v})\|^2 \end{aligned} \tag{3.14}$$

holds. Finally, $\rho \in (C_R^2, 1)$ may be chosen such that it satisfies

$$\frac{C_K(1-\rho)}{1 - \frac{C_R^2}{\rho}} < 1 \,.$$

(This is clearly possible, since the left-hand side tends to 0 as ρ approaches 1 and depends continuously on ρ.) We have therefore shown that

$$\mathcal{G}(\boldsymbol{\tau}, \mathbf{v}) \geq \hat{\beta} \left(\|\operatorname{div} \boldsymbol{\tau}\|^2 + \|\mathcal{C}^{-1/2} \boldsymbol{\tau}\|^2 + \|\mathcal{C}^{1/2} \boldsymbol{\varepsilon}(\mathbf{v})\|^2 \right) \tag{3.15}$$

holds with

$$\hat{\beta} = \left(1 - \frac{C_R^2}{\rho} \right) \left(1 - \left(\frac{C_K(1-\rho)}{1 - \frac{C_R^2}{\rho}} \right)^{1/2} \right) > 0,$$

which, combined with (3.9), implies the lower bound in (3.6) with $\underline{\beta} = \hat{\beta}(1-\rho)/3$.

The upper bound in (3.6) follows directly from (3.7) and (3.1), which gives

$$\begin{aligned} \mathcal{F}(\bar{\boldsymbol{\sigma}}, \bar{\mathbf{u}}; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}}) \leq \|\operatorname{div} (\boldsymbol{\sigma} - \bar{\boldsymbol{\sigma}})\|^2 + 2\|\mathcal{C}^{-1/2}(\boldsymbol{\sigma} - \bar{\boldsymbol{\sigma}})\|^2 \\ + 2(1 + C_R)^2 \|\mathcal{C}^{1/2} \boldsymbol{\varepsilon}(\mathbf{u} - \bar{\mathbf{u}})\|^2 \,. \end{aligned}$$

□

Remark. In the case of perfect plasticity, it is no longer possible to show the lower bound in (3.6) along the lines in the above proof. In fact, our numerical results documented in section 5 suggest that the equivalence (3.6) is actually lost in the case of perfect plasticity.

The practical implication of Theorem 3.2 is that, under the assumptions (2.12), the least-squares functional $\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}})$ constitutes an a posteriori estimator for any approximation $(\boldsymbol{\sigma}_h, \mathbf{u}_h)$. By its very definition, for any triangulation $\mathcal{T}_h$ of Ω,

$$\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}}) = \sum_{T \in \mathcal{T}_h} \mathcal{F}_T(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}}) \,. \tag{3.16}$$

This means that the local evaluation of the functional, $\mathcal{F}_T(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\sigma}^{\text{old}}, \alpha^{\text{old}})$, can be used in an adaptive refinement strategy.

Of course, the approximation $(\boldsymbol{\sigma}_h, \mathbf{u}_h)$ to be used in practice comes from the solution of the least-squares minimization problem (2.15) with respect to finite element spaces. It can already be observed from the definition (2.9) that $\mathcal{R}(\varepsilon(\mathbf{u}))$ is not differentiable with respect to $\mathbf{u}$ everywhere. In the proof of Lemma 3.1, it becomes apparent that

$$\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u})) = \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u}) - \mathcal{S}(\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\varepsilon(\mathbf{u})))$$

is not smooth for those $\mathbf{u} \in H^1_{\Gamma_D}(\Omega)^3$ with

$$|\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\varepsilon(\mathbf{u}))| = \sqrt{\frac{2}{3}} K(\alpha^{\mathrm{old}})\,, \tag{3.17}$$

since $\mathcal{S}(\boldsymbol{\xi})$, defined in (3.3), is not smooth for $|\boldsymbol{\xi}| = \sqrt{2/3}K(\alpha^{\mathrm{old}})$. The nonsmoothness of $\mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u}))$ implies that the least-squares functional $\mathcal{F}(\boldsymbol{\sigma}, \mathbf{u}; \boldsymbol{\sigma}^{\mathrm{old}}, \alpha^{\mathrm{old}})$ is also not differentiable for displacements which satisfy (3.17). This causes the Gauss–Newton iteration with a line search strategy (cf. [18, Chap. 10]) commonly used in least-squares finite element computations to slow down as plastic deformations become dominant. The issue of efficiently solving the nonlinear algebraic least-squares problems resulting from the discretization of (2.15) will be discussed elsewhere.

4. Plane strain model and finite element approximation. We restrict our computations in this paper to two-dimensional domains by assuming plane strain conditions, i.e.,

$$\boldsymbol{\varepsilon}(\mathbf{u}) = \begin{bmatrix} \partial_1 u_1 & (\partial_2 u_1 + \partial_1 u_2)/2 & 0 \\ (\partial_2 u_1 + \partial_1 u_2)/2 & \partial_2 u_2 & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

This implies that

$$\mathrm{dev}(\boldsymbol{\varepsilon}(\mathbf{u})) = \begin{bmatrix} (2\partial_1 u_1 - \partial_2 u_2)/3 & (\partial_2 u_1 + \partial_1 u_2)/2 & 0 \\ (\partial_2 u_1 + \partial_1 u_2)/2 & (2\partial_2 u_2 - \partial_1 u_1)/3 & 0 \\ 0 & 0 & -(\partial_1 u_1 + \partial_2 u_2)/3 \end{bmatrix},$$

and therefore $\boldsymbol{\sigma} = \mathcal{R}(\boldsymbol{\varepsilon}(\mathbf{u}))$ is of the general form

$$\boldsymbol{\sigma} = \begin{bmatrix} \sigma_{11} & \sigma_{12} & 0 \\ \sigma_{21} & \sigma_{22} & 0 \\ 0 & 0 & \sigma_{33} \end{bmatrix}. \tag{4.1}$$

If we denote our two-dimensional domain again as Ω, then $\boldsymbol{\sigma}_1 = (\sigma_{11}, \sigma_{12}) \in H(\mathrm{div}, \Omega)$ and $\boldsymbol{\sigma}_2 = (\sigma_{21}, \sigma_{22}) \in H(\mathrm{div}, \Omega)$. Moreover, σ_{33} is constant in the x_3-direction and may be assumed in $L^2(\Omega)$. For the two remaining displacement components we still have $u_1, u_2 \in H^1_{\Gamma_D}(\Omega)$.

The choice of appropriate finite element spaces $\boldsymbol{\Sigma}_h$ and $\mathbf{U}_h$ for the approximation of $\boldsymbol{\sigma}$ and $\mathbf{u}$, respectively, is done with the aim of achieving a certain approximation order with respect to the norm in (3.6). Suitable for the stress approximation is a product space of Raviart–Thomas elements (of degree $k \geq 0$) for $\boldsymbol{\sigma}_1$ and $\boldsymbol{\sigma}_2$ and discontinuous piecewise polynomials (of the same degree $k \geq 0$) for σ_{33}. The interpolation estimate for Raviart–Thomas elements (cf. [9, Prop. III.3.9]) yields

$$\|\mathrm{div}\,(\boldsymbol{\sigma}_i - \boldsymbol{\Pi}_h \boldsymbol{\sigma}_i)\|^2 + \|\boldsymbol{\sigma}_i - \boldsymbol{\Pi}_h \boldsymbol{\sigma}_i\|^2 \leq \overline{C}^2 h^{2(k+1)} \left(|\mathrm{div}\,\boldsymbol{\sigma}_i|^2_{k+1,\Omega} + |\boldsymbol{\sigma}_i|^2_{k+1,\Omega}\right) \tag{4.2}$$

for $i = 1, 2$ with a suitable interpolation operator $\mathbf{\Pi}_h$. Standard piecewise polynomial interpolation, separately on each element $T \in \mathcal{T}_h$, leads to

$$\|\sigma_{33} - Q_h\sigma_{33})\|^2 \leq \overline{C}^2 h^{2(k+1)} |\sigma_{33}|^2_{k+1,\Omega} \tag{4.3}$$

with the corresponding interpolation operator Q_h. Finally, H^1-conforming finite elements which consist of piecewise polynomials of degree $k+1$ lead to

$$\|\nabla(\mathbf{u} - \mathbf{\Psi}_h\mathbf{u})\|^2 \leq \overline{C}^2 h^{2(k+1)} |\mathbf{u}|^2_{k+2,\Omega} \tag{4.4}$$

for the interpolation error. Combined with the result of Theorem 3.2, (4.2), (4.3), and (4.4) imply the error estimate

$$\begin{aligned}\Big(\|\mathrm{div}\,(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\|^2 + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u} - \mathbf{u}_h)\|^2\Big)^{1/2} \\ \leq \left(\frac{\overline{\beta}}{\underline{\beta}}\right)^{1/2} \overline{C} h^{k+1} \left(|\mathrm{div}\,\boldsymbol{\sigma}_1|_{k+1,\Omega} + |\mathrm{div}\,\boldsymbol{\sigma}_2|_{k+1,\Omega} + |\boldsymbol{\sigma}|_{k+1,\Omega} + |\mathbf{u}|_{k+2,\Omega}\right)\end{aligned}$$

for the least-squares finite element approximation.

In particular, for $k = 1$, i.e, using next-to-lowest-order Raviart–Thomas elements combined with discontinuous piecewise linear elements for $\boldsymbol{\sigma}$ and continuous piecewise quadratic elements for $\mathbf{u}$, we obtain

$$\begin{aligned}\Big(\|\mathrm{div}\,(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\|^2 + \|\mathcal{C}^{-1/2}(\boldsymbol{\sigma} - \boldsymbol{\sigma}_h)\|^2 + \|\mathcal{C}^{1/2}\boldsymbol{\varepsilon}(\mathbf{u} - \mathbf{u}_h)\|^2\Big)^{1/2} \\ \leq \left(\frac{\overline{\beta}}{\underline{\beta}}\right)^{1/2} \overline{C} h^2 \left(|\mathrm{div}\,\boldsymbol{\sigma}_1|_{2,\Omega} + |\mathrm{div}\,\boldsymbol{\sigma}_2|_{2,\Omega} + |\boldsymbol{\sigma}|_{2,\Omega} + |\mathbf{u}|_{3,\Omega}\right)\end{aligned} \tag{4.5}$$

for the least-squares finite element approximation. This is actually the combination of finite element spaces that we used in our computations presented in the next section. However, the regularity assumptions $\mathrm{div}\,\boldsymbol{\sigma}_i \in H^2(\Omega)$, $\boldsymbol{\sigma}_i \in H^2(\Omega)^2$ for $i = 1, 2$, $\sigma_{33} \in H^2(\Omega)$, and $\mathbf{u} \in H^3(\Omega)^2$ are rarely fulfilled in applications of practical relevance. The approximation estimate (4.5) therefore serves only as a guideline for the properties of the finite element spaces. In our actual computations the least-squares finite element method is implemented in an adaptive fashion based on (3.16) for a posteriori error estimation.

The implementation of the least-squares finite element method is done by evaluating the integrals in (2.14) with an appropriate quadrature rule. Since the finite element spaces used in our computations include piecewise polynomials up to degree 2, the integrands in the least-squares functional involve polynomials up to degree 4. A 7-point quadrature rule which is exact for polynomials of degree 5 on triangles (see [2, sect. 5.1]) is therefore used in our implementation. The return parameter $\gamma_R(\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\boldsymbol{\varepsilon}(\mathbf{u})))$ is computed at all quadrature nodes. The hardening parameter

$$\alpha = \alpha^{\mathrm{old}} + \sqrt{\frac{2}{3}} \frac{\gamma_R(\mathrm{dev}(\boldsymbol{\sigma}^{\mathrm{old}} + \mathcal{C}\,\boldsymbol{\varepsilon}(\mathbf{u})))}{2\mu}$$

(cf. (2.11)) is approximated by piecewise linear, not necessarily continuous, functions on the triangulation $\mathcal{T}_h$. This leads to the same order of approximation for the hardening parameter α as for the other process variables.

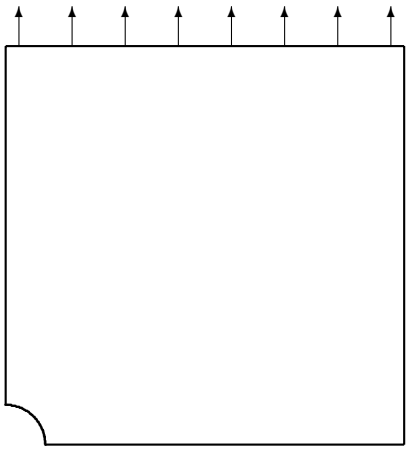

FIG. 5.1. *Computational domain and boundary conditions.*

5. Computational tests. In this section, numerical results for a benchmark problem of elasto-plasticity taken from [23] are presented. The problem to be considered is given by a quadratic plate of an elasto-plastic isotropic material with a circular hole in the center under plane strain conditions. At the upper and lower edges of the plate, traction forces pointing outwards are applied. Because of the symmetry of the domain, it suffices to discretize only a fourth of the total geometry. The computational domain is then given by

$$\Omega = \{\mathbf{x} \in \mathbb{R}^2 : 0 < x_1 < 10, 0 < x_2 < 10, x_1^2 + x_2^2 > 1\}$$

(see Figure 5.1). The boundary conditions on the top edge of the computational domain ($x_2 = 10, 0 < x_1 < 10$) are set to $\boldsymbol{\sigma} \cdot \mathbf{n} = (0, t)^T$, while on the right edge ($x_1 = 10, 0 < x_2 < 10$) and on the circular arc ($x_1^2 + x_2^2 = 1$) the boundary conditions are set to $\boldsymbol{\sigma} \cdot \mathbf{n} = (0, 0)$. Symmetry boundary conditions are prescribed on the rest of the boundary, i.e., $(\sigma_{11}, \sigma_{12}) \cdot \mathbf{n} = 0, u_2 = 0$ on the bottom ($x_2 = 0, 1 < x_1 < 10$), and $u_1 = 0, (\sigma_{21}, \sigma_{22}) \cdot \mathbf{n} = 0$ on the left ($x_1 = 0, 1 < x_2 < 10$). The Poisson ratio is $\nu = 0.29$, which implies for the Lamé constants $\lambda = 1.381\,\mu$. Actually $\mu = 1$ is set in our computations for simplicity, since the stress values do not depend on the size of μ.

Example 1. Our first set of computational experiments uses a combination of linear and exponential isotropic hardening of the form

$$K(\alpha) = K_0 + H\alpha + (K_\infty - K_0)(1 - e^{-\omega\alpha})$$

with $K_0 = 450$, $K_\infty = 750$, $H = 129$, and $\omega = 16.93$ taken from [23]. The load is increased starting from $t = 0$ in steps of $\Delta t = 2.5$. These rather small load steps were chosen in order to rule out artifacts caused by the first-order time discretization used in our computations. For each load step, an initial triangulation consisting of 52 elements is successively refined based on the local evaluation of the least-squares functional. Tables 5.1 to 5.3 show the error reduction, measured in terms of the functional, at different stages of the simulation. For $t = 150$, the results are still well within the elastic domain, which means that the results in Table 5.1 simply correspond to a linear elasticity problem. Inelastic deformation starts around $t = 170$ so that

the results in Table 5.2 already correspond to elasto-plastic computations for $t = 300$. Further increase of the load to $t = 400$ in Table 5.3 leads to a spreading of the zone in which inelastic deformations occur.

In Tables 5.1 to 5.3, the computational results show that the reduction rate of the functional does not deteriorate much as the load is increased and inelastic deformations become more dominant. The optimal convergence behavior achievable with the finite element spaces used here would result in a reduction of the least-squares functional proportional to $(\dim \mathbf{U}_h + \dim \mathbf{\Sigma}_h)^{-2}$. This behavior would be achieved with uniformly refined triangulations under sufficient regularity conditions (see (4.5); note that $\dim \mathbf{U}_h + \dim \mathbf{\Sigma}_h \approx h^{-2}$ in two space dimensions). In Tables 5.1 to 5.3, the number of degrees of freedom is approximately doubled with each refinement. This corresponds to a reduction of the functional by a factor 4 with each refinement, which is approximately achieved in our numerical results, at least on the finer levels.

The antisymmetry, measured by $\|\mathrm{as}\,\boldsymbol{\sigma}_h\|^2_{0,\Omega}$, is also shown in Tables 5.1 to 5.3. Note that (3.8) implies

$$\|\mathrm{as}(\boldsymbol{\sigma}_h - \boldsymbol{\sigma}_h^{\mathrm{old}})\|^2 \le 2\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h; \boldsymbol{\sigma}_h^{\mathrm{old}}, \alpha^{\mathrm{old}})$$

but that the antisymmetry actually accumulates with time. In the elastic case, for $t = 150$, the reduction occurs at about the same rates for the antisymmetric stress and for the least-squares functional. However, in the presence of plastic deformations, for $t = 300$ and $t = 400$, the antisymmetry is actually reduced at a faster rate than the functional. This is due to the fact that the antisymmetric stress is actually an

accumulated quantity, while the least-squares functional shows the full deterioration of the functional with increasing load. It can also be observed from Tables 5.1 to 5.3 that the divergence error, measured by $\|\text{div } \boldsymbol{\sigma}_h\|^2$, decreases slightly faster than the overall functional.

Example 2. We also include numerical results for perfect plasticity, since tabulated benchmark values are available from [23] for this case. This allows us to verify the least-squares approach by a comparison of our results with the benchmark values which will be done further below. In this setting,

$$K(\alpha) \equiv K_0$$

with $K_0 = 450$, which means that the internal hardening variable α is obsolete. For perfect plasticity, the conditions (2.12) are not valid, and therefore the theoretical results from section 3 are not established.

With the same load steps as in Example 1 we obtain the numerical results shown in Tables 5.4 to 5.6. The results for $t = 150$ are, of course, identical to those in Table 5.1, since this still constitutes the same elastic problem as in Example 1. For $t = 300$, a reduction rate which nearly reaches the optimal asymptotic behavior of $\mathcal{F}(\boldsymbol{\sigma}_h, \mathbf{u}_h) \eqsim (\dim \mathbf{U}_h + \dim \mathbf{\Sigma}_h)^{-2}$ is attained. The reduction of the functional is much slower at the load step $t = 400$ and slows down even more for $t = 450$.

Figure 5.2 shows on the left the size of the deviatoric stress, scaled as $|\text{dev}(\boldsymbol{\sigma})|/K_0$, for the load steps $t = 300$, 400, and 450. The zone where plastic deformation occurs is clearly visible and expands with increasing load. The fact that the reduction of the

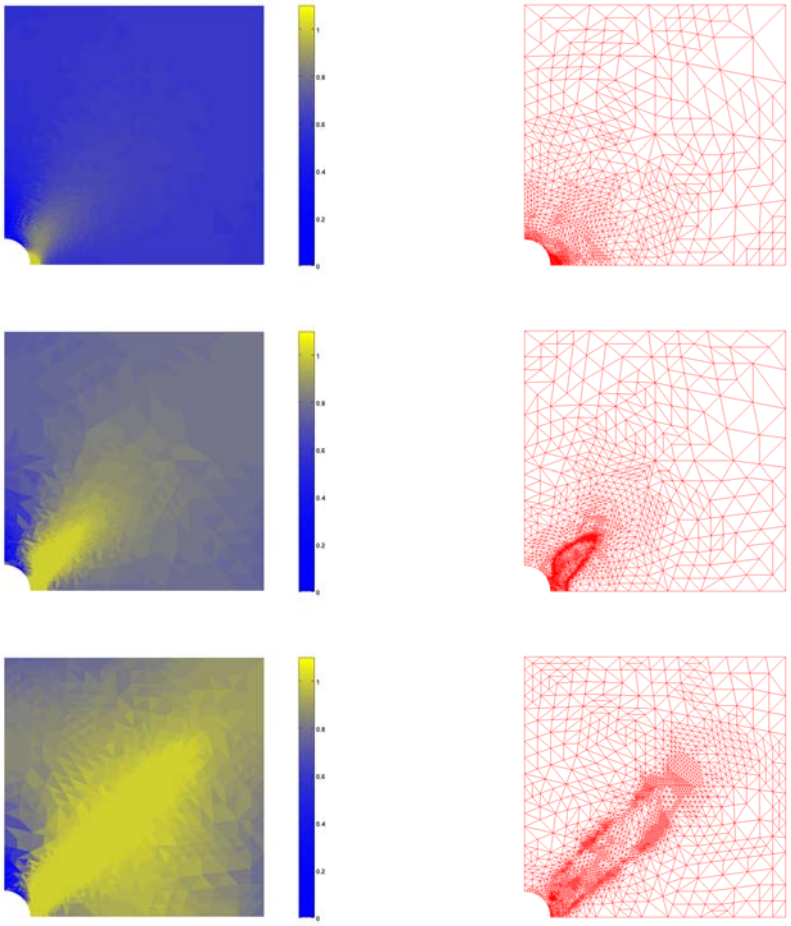

FIG. 5.2. *Deviatoric stress (left) and triangulation after six adaptive refinement steps (right) for* $t = 300$, 400, *and* 450.

functional slows down significantly as the plastic zone occupies most of the computational domain supports our speculation that this causes the ellipticity of the least-squares functional in the sense of Theorem 3.2 to deteriorate. Shown on the right in Figure 5.2 are the triangulations which result after six steps of adaptive refinement based on the elementwise evaluation of the least-squares functional.

Despite this deterioration of the convergence behavior, our results obtained with the least-squares method agree remarkably well with the benchmark results tabulated in [23]. In order to illustrate this, the benchmark results for a selected stress value, $s_{22}(1, 0)$, are shown for a full load cycle in Figure 5.3. The load cycle starts by increasing the traction forces t from 0 to 450 (pointing outwards), then decreasing from 450 to -450, and finally increasing from -450 to 0 again. The solid curve is the result of our computations, and the circles represent the values for the reference solution taken from Table 11.8 in [23]. Throughout the load cycle the difference between our results and the benchmark values is marginally small. Even after the completion of the cycle, our least-squares method gives a value of 514.38 for $s_{22}(1, 0)$

FINITE ELEMENT METHODS FOR THE SIMULATION OF WAVES IN COMPOSITE SATURATED POROVISCOELASTIC MEDIA*

JUAN E. SANTOS† AND DONGWOO SHEEN‡

Abstract. This work presents and analyzes a collection of finite element procedures for the simulation of wave propagation in a porous medium composed of two weakly coupled solids saturated by a single-phase fluid. The equations of motion, formulated in the space-frequency domain, include dissipation due to viscous interaction between the fluid and solid phases with a correction factor in the high-frequency range and intrinsic anelasticity of the solids modeled using linear viscoelasticity. This formulation leads to the solution of a Helmholtz-type boundary value problem for each temporal frequency. For the spatial discretization, nonconforming finite element spaces are employed for the solid phases, while for the fluid phase the vector part of the Raviart–Thomas–Nedelec mixed finite element space is used. Optimal a priori error estimates for *global* standard and *hybridized* Galerkin finite element procedures are derived. An iterative nonoverlapping domain decomposition procedure is also presented and convergence results are derived. Numerical experiments showing the application of the numerical procedures to simulate wave propagation in partially frozen porous media are presented.

1. Introduction.

Wave propagation in composite porous materials has applications in many branches of science and technology, such as seismic methods in the presence of shaley sandstones [8], frozen or partially frozen sandstones [29, 10, 11], gas-hydrates in ocean-bottom sediments [12], and evaluation of the freezing conditions of foods by ultrasonic techniques [26]. A recent review of the theory of wave propagation in fluid-saturated porous media can be found in [7].

A theory to describe wave propagation in frozen porous media was first presented by Leclaire, Cohen-Tenoudji, and Aguirre Puente [24]. This model, valid for uniform porosity, predicts the existence of three compressional and two shear waves; the verification that additional (slow) waves can be observed in laboratory experiments was published by Leclaire, Cohen-Tenoudji, and Aguirre Puente [25]. Later, Carcione and Tinivella [12] generalized this theory to include the interaction between the solid and ice particles and grain cementation with decreasing temperature, used as a parameter to determine the bulk water content. Also, Carcione, Gurevich, and Cavallini [8] applied this theory to study the acoustic properties of shaley sandstones, assuming that sand and clay are *nonwelded* and form a continuous and interpenetrating porous composite skeleton. Both frozen porous media and shaley sandstones are examples of porous materials where the two solid phases are *weakly coupled* or *nonwelded*, i.e., both solids form a continuous and interacting composite structure, interchanging mechan-

ical energy. Similar *weakly coupled* formulations have previously been proposed. For instance, McCoy [28] has proposed a mixture theory appropriate for the combination of two *acoustic phases*.

Later, Santos, Ravazzoli, and Carcione [37] generalized to the nonuniform porosity case the models of Leclaire, Cohen-Tenoudji, and Aguirre Puente [24] and Carcione and Tinivella [12] valid only for uniform porosity. The formulation presented in [37] enabled us to identify the generalized coordinates of the system, which are the two solid displacement vectors and a new variable (denoted by $u^{(2)}$ in this paper) associated with the fluid displacement relative to the solid composite matrix, whose divergence is the change in the fluid content, in formal analogy with the classical Biot theory for a single solid-phase matrix. It also allowed us to identify the generalized forces of the system, which are the fluid pressure p_f and the stress tensors denoted by $\sigma^{(1)}$ and $\sigma^{(3)}$ in this paper.

This article presents a differential and numerical model to describe wave propagation in a heterogeneous poroviscoelastic frame consisting of two weakly coupled solid phases saturated by a single-phase fluid. The equations of motion, stated in the space-frequency domain, generalize those presented in [37, 9] by the inclusion of solid matrix dissipation using a linear viscoelastic model and introducing a frequency dependent correction factor in the mass and viscous coupling coefficients in the high-frequency range [4, 35].

The numerical procedures presented employ the nonconforming rectangular element defined in [17] to approximate the displacement vector in the solid phases. The dispersion analysis presented in [38] shows that employing this nonconforming element allows for a reduction in the number of points per wavelength necessary to reach a desired accuracy. On the other hand, the displacement in the fluid phase is approximated by using the vector part of the Raviart–Thomas–Nedelec mixed finite element space of zero order, which is a conforming space [34, 30]. The error analysis yields optimal a priori error estimates for the *global* standard and *hybridized* Galerkin methods.

Numerical simulation of waves in porous media is computationally expensive due to a large number of degrees of freedom needed to calculate wave fields accurately; the use of a domain decomposition iteration is a convenient approach to overcome this difficulty. Here we define a nonoverlapping domain decomposition iterative scheme and derive convergence results similar to those presented in [14] for solving second-order elliptic problems. This iterative procedure was used for the simulation of waves in a sample of water-saturated partially frozen Berea sandstone [9, 12], perturbed by a point source at seismic frequencies. The sample has an interior plane interface defined by a change in ice content in the pores, and the snapshots of the generated wave fields show clearly the events associated with the different types of waves.

2. The differential model. In this section we review and generalize a model recently presented by one of the authors and some of his colleagues [37] to describe the propagation of waves in a poroviscoelastic domain $\Omega \subset \mathbb{R}^d$, $d = 2, 3$, in which the matrix consists of two different solids indicated by the superindices (1) and (3), saturated by a single-phase fluid indicated by the superindex (2). Thus, for any reference element E of bulk material we have

$$E = E^{(1)} \cup E^{(2)} \cup E^{(3)}.$$

Let $V^{(i)}$ denote the volumetric measure of the phase $E^{(i)}$ and let $V^{(b)}$ and $V^{(sm)}$ denote the volumetric measures of E and the solid matrix $E^{(sm)} = E^{(1)} \cup E^{(3)}$,

respectively, so that

$$V^{(sm)} = V^{(1)} + V^{(3)}, \qquad V^{(b)} = V^{(1)} + V^{(2)} + V^{(3)}.$$

We introduce the bulk volumetric fractions of the different components in the form

$$\phi = \frac{V^{(2)}}{V^{(b)}}, \quad \phi^{(1)} = \frac{V^{(1)}}{V^{(b)}}, \quad \phi^{(3)} = \frac{V^{(3)}}{V^{(b)}},$$

and the solid fractions of the composite matrix

$$S^{(1)} = \frac{V^{(1)}}{V^{(sm)}}, \quad S^{(3)} = \frac{V^{(3)}}{V^{(sm)}}, \quad \text{with} \quad S^{(1)} + S^{(3)} = 1.$$

For some practical applications it is convenient to define the *absolute* or *effective porosity* $\phi^{(a)}$ of the medium, defined as the ratio of the volume of the interconnected pores $V^{(p)}$ and the total volume of the sample, i.e.,

$$\phi^{(a)} = \frac{V^{(p)}}{V^{(b)}}.$$

These sets of fractions can have different meanings depending on the physical model considered. For example, in the case of a sandstone or soil at very low temperature, it is reasonable to consider that a part of the fluid which saturates the pore space is at a liquid state and the rest is frozen. If $E^{(1)}$ represents the mineral grains and $E^{(3)}$ the ice, for a given porosity $\phi^{(a)}$ and *bulk water content* ϕ, the following relations hold:

$$\phi^{(1)} = 1 - \phi^{(a)}, \quad \phi^{(3)} = \phi^{(a)} - \phi, \quad S^{(3)} = \frac{\phi^{(3)}}{1 - \phi}. \tag{2.1}$$

It is useful to introduce an additional fraction $S^{(3)'}$ to account for the *ice content in the pores*, given by

$$S^{(3)'} = \frac{V^{(3)}}{V^{(p)}} = \frac{\phi^{(3)}}{1 - \phi^{(1)}}.$$

A different application of this model would be the case of a shaley sandstone, that is, a porous rock mainly composed of quartz grains and clay particles, saturated by a fluid (such as water, brine, gas, or oil). In this case we assume that the fluid completely saturates the pore space of the composite rock so that $V^{(2)} \equiv V^{(p)}$. Then, if $E^{(1)}$ represents the grains of the rock and $E^{(3)}$ the clay part, for a given *matrix clay content* $S^{(3)}$ and water content ϕ, instead of (2.1) the following hold:

$$\phi = \phi^{(a)}, \quad \phi^{(1)} = S^{(1)}(1 - \phi), \quad \phi^{(3)} = S^{(3)}(1 - \phi).$$

Let us now consider a unit cube $\Omega = \Omega^{(1)} \cup \Omega^{(2)} \cup \Omega^{(3)} \subset \mathbb{R}^d$ of our fluid-saturated poroviscoelastic material with boundary $\Gamma = \partial\Omega$. Since by hypothesis the two solids are nonwelded (or weakly coupled), we assume that they can move independently and consequently we can distinguish three different particle displacement fields for this model. Let $u^{(m)} \equiv u^{(m)}(x,\omega) = (u_1^{(m)}(x,\omega), \ldots, u_d^{(m)}(x,\omega))^t$, $m = 1, 3$, be the averaged solid displacements over the bulk material Ω at the angular frequency ω, and let $\tilde{u}^{(2)} \equiv \tilde{u}^{(2)}(x,\omega) = (\tilde{u}_1^{(2)}(x,\omega), \ldots, \tilde{u}_d^{(2)}(x,\omega))^t$ denote the absolute fluid

displacement. Also, let the relative displacement of the fluid phase with respect to the composite solid matrix be defined by

$$u^{(2)} = \phi(\tilde{u}^{(2)} - S^{(1)}u^{(1)} - S^{(3)}u^{(3)})$$

and set $u = (u^{(1)}, u^{(2)}, u^{(3)})^t$. As explained in [37], the variable

$$\zeta = -\nabla \cdot u^{(2)}$$

represents the change in fluid content. Next we introduce the local stress tensors $\sigma_{jk}^{(1,s)}$ and $\sigma_{jk}^{(3,s)}$ in the solid parts $\Omega^{(1)}$ and $\Omega^{(3)}$, averaged over the bulk material and the fluid pressure p_f. Following [37], we define the second-order tensors

$$\sigma_{jk}^{(1)} = \sigma_{jk}^{(1,s)} - S^{(1)}\phi p_f \delta_{jk}, \quad \sigma_{jk}^{(3)} = \sigma_{jk}^{(3,s)} - S^{(3)}\phi p_f \delta_{jk}$$

associated with the total stresses in $\Omega^{(1)}$ and $\Omega^{(3)}$, respectively. Then the constitutive equations, stated in the space-frequency domain, are as follows [37]:

$$\sigma_{jk}^{(1)}(u) = \big[K_G^{(1)} e^{(1)} - B^{(1)}\zeta + B^{(3)} e^{(3)}\big]\delta_{jk} + 2\mu^{(1)} d_{jk}^{(1)} + \mu^{(13)} d_{jk}^{(3)}, \tag{2.2a}$$

$$\sigma_{jk}^{(3)}(u) = \big[K_G^{(3)} e^{(3)} - B^{(2)}\zeta + B^{(3)} e^{(1)}\big]\delta_{jk} + 2\mu^{(3)} d_{jk}^{(3)} + \mu^{(13)} d_{jk}^{(1)}, \tag{2.2b}$$

$$p_f(u) = -B^{(1)} e^{(1)} - B^{(2)} e^{(3)} + K_{av}\zeta, \tag{2.2c}$$

where

$$d_{jk}^{(m)} = \epsilon_{jk}(u^{(m)}) - \frac{1}{d}\, e^{(m)}\delta_{jk}, \ m = 1, 3, \text{ in } \mathbb{R}^d,$$

denotes the deviatoric tensor in $\Omega^{(m)}$, with $\epsilon_{jk}(u^{(m)})$ being the strain tensor with linear invariant $e^{(m)}$. In [37] the constitutive relations (2.2) were stated in the space-time domain with real coefficients in terms of the bulk and shear moduli of the two solid (dry) frames (denoted by $K_m^{(s1)}, K_m^{(s3)}, \mu_m^{(s1)}$, and $\mu_m^{(s3)}$, respectively), the bulk and shear moduli of the grains in the two solid phases (denoted by $K^{(s1)}, \mu^{(s1)}, K^{(s3)}$, and $\mu^{(s3)}$, respectively), and K_f, the bulk modulus of the fluid phase.

To introduce viscoelasticity we use the correspondence principle stated by M. Biot [3, 5]; i.e., we replace the real poroelastic coefficients $K_G^{(m)}, \mu^{(m)}$, $m = 1, 3$, and K_{av} in the constitutive relations (2.3a)–(2.3c) by complex frequency dependent poroviscoelastic moduli satisfying the same relations as in the elastic case. In this work the linear viscoelastic model presented in [27] is used to make these moduli complex and frequency dependent by using the following formula:

$$M(\omega) = \frac{M_{re}}{R_M(\omega) - iT_M(\omega)},$$

where M represents any of the five moduli mentioned above and the coefficient M_{re} is the relaxed elastic modulus associated with M [6]. The functions $R_M(\omega)$ and $T_M(\omega)$, associated with a continuous spectrum of relaxation times, are given by [27]

$$R_M(\omega) = 1 - \frac{1}{\pi \widehat{Q}_M} \ln \frac{1 + \omega^2 T_{1,M}^2}{1 + \omega^2 T_{2,M}^2}, \qquad T_M(\omega) = \frac{2}{\pi \widehat{Q}_M} \tan^{-1} \frac{\omega(T_{1,M} - T_{2,M})}{1 + \omega^2 T_{1,M} T_{2,M}}.$$

The model parameters $\widehat{Q}_M$, $T_{1,M}$, and $T_{2,M}$ are taken such that the quality factors $Q_M(\omega) = T_M/R_M$ are approximately equal to the constant $\widehat{Q}_M$ in the range of

frequencies where the equations are solved, which makes this model convenient for geophysical applications.

Next, by writing

$$\lambda^{(m)} = K_G^{(m)} - \frac{2}{d}\mu^{(m)}, \quad D^{(3)} = B^{(3)} - \frac{1}{d}\mu^{(13)} \text{ in } \mathbb{R}^d,$$

the constitutive relations (2.2) are then stated in the following equivalent form, which will be used in the analysis that follows:

$$\sigma_{jk}^{(1)}(u) = \left[\lambda^{(1)}e^{(1)} - B^{(1)}\zeta + D^{(3)}e^{(3)}\right]\delta_{jk} + 2\mu^{(1)}\epsilon_{jk}(u^{(1)}) + \mu^{(13)}\epsilon_{jk}(u^{(3)}), \tag{2.3a}$$

$$\sigma_{jk}^{(3)}(u) = \left[\lambda^{(3)}e^{(3)} - B^{(2)}\zeta + D^{(3)}e^{(1)}\right]\delta_{jk} + 2\mu^{(3)}\epsilon_{jk}(u^{(3)}) + \mu^{(13)}\epsilon_{jk}(u^{(1)}), \tag{2.3b}$$

$$p_f(u) = -B^{(1)}e^{(1)} - B^{(2)}e^{(3)} + K_{av}\zeta. \tag{2.3c}$$

Let the positive definite mass matrix $\mathcal{P} = \mathcal{P}(\omega)$ and the nonnegative dissipation matrix $\mathcal{B} = \mathcal{B}(\omega)$ be defined by

$$\mathcal{P} = \begin{bmatrix} p_{11}I & p_{12}I & p_{13}I \\ p_{12}I & p_{22}I & p_{23}I \\ p_{13}I & p_{23}I & p_{33}I \end{bmatrix}, \qquad \mathcal{B} = \begin{bmatrix} b_{11}I & -b_{12}I & -b_{11}I \\ -b_{12}I & b_{22}I & b_{12}I \\ -b_{11}I & b_{12}I & b_{11}I \end{bmatrix},$$

where I denotes the identity matrix in $\mathbb{R}^{d\times d}$. The nonnegative coefficients $p_{jk} = p_{jk}(\omega), b_{jk} = b_{jk}(\omega)$ in the definition of the matrices $\mathcal{P}$ and $\mathcal{B}$ are given by the formulae

$$p_{11}(\omega) = m_{11} + \frac{F_I(\theta)\,(f_{11} - b_{13})}{\omega}, \quad p_{12}(\omega) = m_{12} - \frac{F_I(\theta)f_{12}}{\omega}, \tag{2.4a}$$

$$p_{13}(\omega) = m_{13} - \frac{F_I(\theta)\,(f_{11} - b_{13})}{\omega}, \quad p_{22}(\omega) = m_{22} + \frac{F_I(\theta)f_{22}}{\omega}, \tag{2.4b}$$

$$p_{23}(\omega) = m_{23} + \frac{F_I(\theta)f_{12}}{\omega}, \quad p_{33}(\omega) = p_{33} + \frac{F_I(\theta)\,(f_{11} - b_{13})}{\omega}, \tag{2.4c}$$

$$b_{11}(\omega) = F_R(\theta)\,(f_{11} - b_{13}) + b_{13}, \quad b_{12}(\omega) = F_R(\theta)f_{12}, \quad b_{22}(\omega) = F_R(\theta)f_{22}, \tag{2.4d}$$

with the m_{ij}'s and f_{11}, f_{12}, and f_{22} computed as in [37] in terms of the mass densities $\rho^{(m)}, m = 1, 2, 3$, of each solid and fluid constituent, the fluid viscosity η, and the absolute permeabilities κ_1, κ_3 of the two solid frames. The coefficient b_{13} is a friction coefficient between the two solid phases and is left as a free parameter chosen so that

$$b_{11}b_{22} - b_{12}^2 > 0, \quad \omega > 0, \tag{2.5}$$

which is needed in order that the dissipation function be positive in the variables $u^{(2)}$ and $u^{(1)} - u^{(3)}$.

The complex valued frequency dependent function $F(\theta) = F_R(\theta) + iF_I(\theta)$ is the frequency correction function defined by Biot [4]:

$$F(\theta) = \frac{1}{4}\,\frac{\theta T(\theta)}{1 - \frac{2}{i\theta}T(\theta)}, \quad T(\theta) = \frac{\mathrm{ber}'(\theta) + i\mathrm{bei}'(\theta)}{\mathrm{ber}(\theta) + i\mathrm{bei}(\theta)},$$

with $\mathrm{ber}(\theta)$ and $\mathrm{bei}(\theta)$ being the Kelvin functions of the first kind and zero order. The frequency dependent argument $\theta = \theta(\omega)$ is given in terms of the pore size parameter a_p by the following equations:

$$\theta = a_p\sqrt{\omega\,\rho^{(2)}/\eta}, \quad a_p = 2\sqrt{\kappa A_0/\phi},$$

where $\frac{1}{\kappa} = \frac{1}{\kappa_1} + \frac{1}{\kappa_3}$ and A_0 is the Kozeny–Carman constant [2, 22]. This frequency correction is needed to include the departure of the relative flow from laminar type above a certain critical frequency depending on the pore radius, as explained in [4, 35].

Next, let $\mathcal{L}(u)$ be the second-order differential operator defined by

$$\mathcal{L}(u) = \big(\nabla \cdot \sigma^{(1)}(u), -\nabla p_f(u), \nabla \cdot \sigma^{(3)}(u)\big)^t.$$

Then the equations of motion in Ω, stated in the space-frequency domain, are given as follows [37]:

$$-\omega^2 \mathcal{P} u(x,\omega) + i\omega \mathcal{B} u(x,\omega) - \mathcal{L}(u(x,\omega)) = F(x,\omega), \quad (x,\omega) \in \Omega \times (0,\omega^*), \tag{2.6}$$

where $F(x,\omega) = (F^{(1)}(x,\omega), F^{(2)}(x,\omega), F^{(3)}(x,\omega))^t$ denotes the external source and ω^* is an upper temporal frequency of interest.

A plane wave analysis shows that three different compressional waves (P1, P2, and P3) and two shear waves (S1, S2) can propagate [24, 37]. The P1 and S1 waves correspond to the classical fast P and S waves propagating in elastic or viscoelastic isotropic solids. The additional slow waves are related to motions out of phase of the different phases. The experimental observation of the additional (slow) waves was reported by Leclaire, Cohen-Tenoudji, and Aguirre Puente [25].

Let us denote by ν the unit outer normal on Γ. In the two dimensional (2D) case let χ be a unit tangent on Γ so that $\{\nu, \chi\}$ is an orthonormal system on Γ. In the 3D case let χ^1 and χ^2 be two unit tangents on Γ so that $\{\nu, \chi^1, \chi^2\}$ is an orthonormal system on Γ.

Then, in the 2D case set

$$\mathcal{G}_\Gamma(u) = \big(\sigma^{(1)}(u)\nu \cdot \nu, \sigma^{(1)}(u)\nu \cdot \chi, p_f(u), \sigma^{(3)}(u)\nu \cdot \nu, \sigma^{(3)}(u)\nu \cdot \chi\big)^t, \tag{2.7a}$$

$$S_\Gamma(u) = \big(u^{(1)} \cdot \nu, u^{(1)} \cdot \chi, u^{(2)} \cdot \nu, u^{(3)} \cdot \nu, u^{(3)} \cdot \chi\big)^t, \tag{2.7b}$$

and in the 3D case set

$$\begin{aligned}\mathcal{G}_\Gamma(u) = \big(&\sigma^{(1)}(u)\nu \cdot \nu, \sigma^{(1)}(u)\nu \cdot \chi^1, \sigma^{(1)}(u)\nu \cdot \chi^2, p_f(u),\\ &\sigma^{(3)}(u)\nu \cdot \nu, \sigma^{(3)}(u)\nu \cdot \chi^1, \sigma^{(3)}(u)\nu \cdot \chi^2\big)^t,\end{aligned} \tag{2.8a}$$

$$S_\Gamma(u) = \big(u^{(1)} \cdot \nu, u^{(1)} \cdot \chi^1, u^{(1)} \cdot \chi^2, u^{(2)} \cdot \nu, u^{(3)} \cdot \nu, u^{(3)} \cdot \chi^1, u^{(3)} \cdot \chi^2\big)^t. \tag{2.8b}$$

Let us consider the solution of (2.3) with the following absorbing boundary condition:

$$-\mathcal{G}_\Gamma(u(x,\omega)) = i\omega \mathcal{D} S_\Gamma(u(x,\omega)), \qquad (x,\omega) \in \Gamma \times (0,\omega^*). \tag{2.9}$$

The matrix $\mathcal{D}$ in (2.9) is positive definite and given by

$$\mathcal{D} = \mathcal{M}_c{}^{\frac{1}{2}} \mathcal{S}_c{}^{\frac{1}{2}} \mathcal{M}_c{}^{\frac{1}{2}} = \big(\mathcal{E}_c \mathcal{M}_c{}^{-1}\big)^{\frac{1}{2}} \mathcal{M}_c, \tag{2.10}$$

with $\mathcal{S}_c = \mathcal{M}_c{}^{-\frac{1}{2}} \mathcal{E}_c \mathcal{M}_c{}^{-\frac{1}{2}}$, and in the 3D case,

$$\mathcal{M}_c = \begin{bmatrix} m_{11} & 0 & 0 & m_{12} & m_{13} & 0 & 0 \\ 0 & q_1 & 0 & 0 & 0 & q_2 & 0 \\ 0 & 0 & q_1 & 0 & 0 & 0 & q_2 \\ m_{12} & 0 & 0 & m_{22} & m_{23} & 0 & 0 \\ m_{13} & 0 & 0 & m_{23} & m_{33} & 0 & 0 \\ 0 & q_2 & 0 & 0 & 0 & q_3 & 0 \\ 0 & 0 & q_2 & 0 & 0 & 0 & q_3 \end{bmatrix},$$

$$\mathcal{E}_c = \begin{bmatrix} \lambda_{re}^{(1)} + 2\mu_{re}^{(1)} & 0 & 0 & B_{re}^{(1)} & D_{re}^{(3)} + \mu_{re}^{(13)} & 0 & 0 \\ 0 & \mu_{re}^{(1)} & 0 & 0 & 0 & \frac{1}{2}\mu_{re}^{(13)} & 0 \\ 0 & 0 & \mu_{re}^{(1)} & 0 & 0 & 0 & \frac{1}{2}\mu_{re}^{(13)} \\ B_{re}^{(1)} & 0 & 0 & K_{av,re} & B_{re}^{(2)} & 0 & 0 \\ D_{re}^{(3)} + \mu_{re}^{(13)} & 0 & 0 & B_{re}^{(2)} & \lambda_{re}^{(3)} + 2\mu_{re}^{(3)} & 0 & 0 \\ 0 & \frac{1}{2}\mu_{re}^{(13)} & 0 & 0 & 0 & \mu_{re}^{(3)} & 0 \\ 0 & 0 & \frac{1}{2}\mu_{re}^{(13)} & 0 & 0 & 0 & \mu_{re}^{(3)} \end{bmatrix},$$

with obvious modifications for the 2D case. The boundary condition (2.9) can be derived with a similar argument to that presented in [36] starting from the conservation of momentum equation on Γ and using the fact that the interaction energy among the different types of waves is small compared to the total energy involved.

3. A weak formulation. For $X \subset \mathbb{R}^d$ with boundary ∂X, let $(\cdot,\cdot)_X$ and $\langle \cdot,\cdot \rangle_{\partial X}$ denote the complex $L^2(X)$ and $L^2(\partial X)$ inner products for scalar, vector, or matrix valued functions. Also, for $s \in \mathbb{R}$, $\|\cdot\|_{s,X}$ and $|\cdot|_{s,X}$ will denote the usual norm and seminorm for the Sobolev space $H^s(X)$. In addition, if $X = \Omega$ or $X = \Gamma$, the subscript X may be omitted such that $(\cdot,\cdot) = (\cdot,\cdot)_\Omega$ or $\langle \cdot,\cdot \rangle = \langle \cdot,\cdot \rangle_\Gamma$. Also, set

$$H(\mathrm{div};\Omega) = \{v \in [L^2(\Omega)]^d : \nabla\cdot v \in L^2(\Omega)\}, \quad H^1(\mathrm{div};\Omega) = \{v \in [H^1(\Omega)]^d : \nabla\cdot v \in H^1(\Omega)\},$$

with the norms

$$\|v\|_{H(\mathrm{div};\Omega)} = \left[\|v\|_0^2 + \|\nabla\cdot v\|_0^2\right]^{1/2}; \quad \|v\|_{H^1(\mathrm{div};\Omega)} = \left[\|v\|_1^2 + \|\nabla\cdot v\|_1^2\right]^{1/2}.$$

We will assume that the solution of (2.6) with the boundary condition (2.9) exists and satisfies the regularity assumption

$$\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1 \le C(w)\|F\|_0. \tag{3.1}$$

Let us introduce the space $\mathcal{V} = [H^1(\Omega)]^d \times H(\mathrm{div};\Omega) \times [H^1(\Omega)]^d$. Then multiply (2.3) by $v \in \mathcal{V}$, use integration by parts in the $(\mathcal{L}(u), v)$ term, and apply the boundary condition (2.9) to see that the solution u of (2.6) and (2.9) satisfies *the weak form,*

$$-\omega^2 (\mathcal{P}u, v) + i\omega (\mathcal{B}u, v) + \mathcal{A}(u,v) + i\omega \langle \mathcal{D}\ S_\Gamma(u), S_\Gamma(v)\rangle = (F, v), \qquad v = (v^{(1)}, v^{(2)}, v^{(3)})^t \in \mathcal{V}, \tag{3.2}$$

where $\mathcal{A}(u,v)$ is the bilinear form defined as follows:

$$\mathcal{A}(u,v) = \left(\sigma_{jk}^{(1)}(u), \varepsilon_{jk}(v^{(1)})\right) + \left(\sigma_{jk}^{(3)}(u), \varepsilon_{jk}(v^{(3)})\right) - \left(p_f(u), \nabla\cdot v^{(2)}\right), \qquad u, v \in \mathcal{V}. \tag{3.3}$$

In (3.3), and the rest of the paper, Einstein's convention of sum on repeated indices is used. Note that the bilinear form $\mathcal{A}(u,v)$ can be written in the form

$$\mathcal{A}(u,v) = (\mathbf{E}\ \tilde{\epsilon}(u), \tilde{\epsilon}(v)) = (\mathbf{E}_r\ \tilde{\epsilon}(u), \tilde{\epsilon}(v)) + i\,(\mathbf{E}_i\ \tilde{\epsilon}(u), \tilde{\epsilon}(v))\,,\ u, v \in \mathcal{V},$$

where $\mathbf{E} = \mathbf{E}_r + i\mathbf{E}_i$ is a complex matrix. Furthermore, we assume that the real part $\mathbf{E}_r$ is positive definite since in the elastic limit it is associated with the strain energy density. On the other hand, the imaginary part $\mathbf{E}_i$ is assumed to be positive definite because of the restriction imposed on our system by the first and second laws

of thermodynamics. A similar assumption was used in [33] to obtain restrictions on the imaginary parts of the coefficients in the constitutive relations for the case of a poroviscoelastic matrix saturated by a two-phase fluid. In the 2D case the matrix $\mathbf{E}$ is defined as follows, with the obvious extension to the 3D case:

$$\mathbf{E} = \begin{pmatrix} \widehat{\mathbf{E}} & 0 \\ 0 & \widehat{\mathbf{S}} \end{pmatrix}, \quad \widehat{\mathbf{S}} = \begin{pmatrix} 2\mu^{(1)} & \mu^{(13)} \\ \mu^{(13)} & 2\mu^{(3)} \end{pmatrix},$$

$$\widehat{\mathbf{E}} = \begin{pmatrix} \lambda^{(1)}+2\mu^{(1)} & \lambda^{(1)} & D^{(3)}+\mu^{(13)} & D^{(3)} & B^{(1)} \\ \lambda^{(1)} & \lambda^{(1)}+2\mu^{(1)} & D^{(3)} & D^{(3)}+\mu^{(13)} & B^{(1)} \\ D^{(3)}+\mu^{(13)} & D^{(3)} & \lambda^{(3)}+2\mu^{(3)} & \lambda^{(3)} & B^{(2)} \\ D^{(3)} & D^{(3)}+\mu^{(13)} & \lambda^{(3)} & \lambda^{(3)}+2\mu^{(3)} & B^{(2)} \\ B^{(1)} & B^{(1)} & B^{(2)} & B^{(2)} & K_{av} \end{pmatrix},$$

$$\tilde{\varepsilon}(u) = \begin{pmatrix} \varepsilon_{11}(u^{(1)}) \\ \varepsilon_{22}(u^{(1)}) \\ \varepsilon_{11}(u^{(3)}) \\ \varepsilon_{22}(u^{(3)}) \\ \nabla \cdot u^{(2)} \\ \varepsilon_{12}(u^{(1)}) \\ \varepsilon_{12}(u^{(3)}) \end{pmatrix}.$$

Let us analyze the uniqueness of the solution of our differential model for the case of a unit square $\Omega = (0,1)^2$ in the (x_1, x_2) plane to shorten the argument; the 3D case follows with the same argument. Then, set $F = 0$ and choose $v = u$ in (3.2). Taking the imaginary part in the resulting equation, we obtain

$$\omega\,(\mathcal{B}u, u) + (\mathbf{E}_i\ \tilde{\epsilon}(u), \tilde{\epsilon}(u)) + \omega\,\langle \mathcal{D}\ S_\Gamma(u), S_\Gamma(u)\rangle = 0.$$

Using (2.5) and that $\mathbf{E}_i$ and $\mathcal{D}$ are positive definite and $\mathcal{B}$ is nonnegative, we conclude that

$$u^{(2)} = 0, \quad u^{(1)} - u^{(3)} = 0, \qquad \Omega, \tag{3.4a}$$

$$u^{(1)} = 0, \quad u^{(3)} = 0, \qquad \Gamma, \tag{3.4b}$$

$$u^{(2)} \cdot \nu = 0, \qquad \Gamma. \tag{3.4c}$$

Consider the part Γ_1 of the boundary Γ defined by $\Gamma_1 = \{x = (x_1, x_2) \in \Gamma : x_1 = 1, 0 < x_2 < 1\}$. Notice that (3.4b) and (3.4c) imply that

$$\frac{\partial u_1^{(1)}}{\partial x_2} = \frac{\partial u_2^{(1)}}{\partial x_2} = \frac{\partial u_1^{(3)}}{\partial x_2} = \frac{\partial u_2^{(3)}}{\partial x_2} = 0, \quad \Gamma. \tag{3.5}$$

Owing to (2.9) $\mathcal{G}_\Gamma(u) = 0$ leads to the following relations on Γ_1:

$$\sigma_{11}^{(1)}(u) = (\lambda^{(1)} + 2\mu^{(1)})\,\frac{\partial u_1^{(1)}}{\partial x_1} + (D^{(3)} + \mu^{(13)})\frac{\partial u_1^{(3)}}{\partial x_1} + B^{(1)}\nabla\cdot u^{(2)} = 0, \tag{3.6a}$$

$$\sigma_{11}^{(3)}(u) = (\lambda^{(3)} + 2\mu^{(3)})\frac{\partial u_1^{(3)}}{\partial x_1} + (D^{(3)} + \mu^{(13)})\frac{\partial u_1^{(1)}}{\partial x_1} + B^{(2)}\nabla\cdot u^{(2)} = 0, \tag{3.6b}$$

$$\sigma_{12}^{(1)}(u) = \mu^{(1)}\frac{\partial u_2^{(1)}}{\partial x_1} + \frac{1}{2}\mu^{(13)}\frac{\partial u_2^{(3)}}{\partial x_1} = 0, \tag{3.6c}$$

$$\sigma_{12}^{(3)}(u) = \mu^{(3)}\frac{\partial u_2^{(3)}}{\partial x_1} + \frac{1}{2}\mu^{(13)}\frac{\partial u_2^{(1)}}{\partial x_1} = 0, \tag{3.6d}$$

$$-p_f(u) = B^{(1)}\frac{\partial u_1^{(1)}}{\partial x_1} + B^{(2)}\frac{\partial u_1^{(3)}}{\partial x_1} + K_{av}\nabla\cdot u^{(2)} = 0. \tag{3.6e}$$

Next we observe that (3.6c) and (3.6d) form a homogeneous 2×2 linear system of equations with coefficient matrix $2\,\widehat{\mathbf{S}}$, while (3.6a), (3.6b), and (3.6e) is another homogeneous linear system of equations with matrix coefficients

$$\mathcal{E}^{(\mathbf{p})} = \begin{bmatrix} \lambda^{(1)} + 2\mu^{(1)} & D^{(3)} + \mu^{(13)} & B^{(1)} \\ D^{(3)} + \mu^{(13)} & \lambda^{(3)} + 2\mu^{(3)} & B^{(2)} \\ B^{(1)} & B^{(2)} & K_{av} \end{bmatrix}.$$

We make the assumption (valid in any physically meaningful situation) that the coefficients in the matrix $\mathbf{E}_i$ fulfill

$$\mathrm{Im}(det(\mathcal{E}^{(\mathbf{p})})) > 0, \tag{3.7a}$$

$$\mathrm{Im}(det(\widehat{\mathbf{S}})) > 0. \tag{3.7b}$$

For example, a calculation shows that (3.7) is satisfied if the coefficients $\lambda^{(m)}, \mu^{(m)}$, $m = 1, 3$, and K_{av} are complex with nonzero imaginary parts and the imaginary part of K_{av} is chosen sufficiently small. Thus, under the condition (3.7), from (3.6) we conclude that

$$\frac{\partial u_2^{(1)}}{\partial x_1} = \frac{\partial u_2^{(3)}}{\partial x_1} = 0, \quad \Gamma_1, \tag{3.8a}$$

$$\frac{\partial u_1^{(1)}}{\partial x_1} = \frac{\partial u_1^{(3)}}{\partial x_1} = \nabla\cdot u^{(2)} = 0, \quad \Gamma_1. \tag{3.8b}$$

The same argument applies for the validity of (3.5) and (3.8) in the rest of the boundary. Thus by the Cauchy–Kovalevsky theorem $u^{(1)} = 0,\ u^{(3)} = 0$ in a neighborhood of any point on Γ where the coefficients are analytic and with the possible exception at the corners. Then the unique continuation principle [31] implies

$$u^{(1)} = u^{(3)} = 0, \quad \Omega. \tag{3.9}$$

Now from (3.4a) and (3.9) we have uniqueness. The 3D case follows with the identical argument.

We summarize the result in the following theorem.

THEOREM 3.1. *Under the assumption made in the above argument concerning the validity of* (3.7)*, problem* (2.6) *with the boundary condition* (2.9) *has a unique solution for any* $\omega \neq 0$.

For the analysis that follows a similar result can be demonstrated for the adjoint problem to (2.6) and (2.9). Thus, the solution $\psi = (\psi^{(1)}, \psi^{(2)}, \psi^{(3)})^t$ of the problem

$$-\omega^2 \mathcal{P}\psi - i\omega \mathcal{B}\psi - \mathcal{L}^*(\psi) = F, \quad \Omega \times (0, \omega^*), \tag{3.10a}$$

$$\mathcal{G}_\Gamma^*(\psi) - i\omega \mathcal{D} S_\Gamma(\psi) = 0, \quad \Gamma \times (0, \omega^*), \tag{3.10b}$$

is unique and satisfies the regularity assumption

$$\|\psi^{(1)}\|_2 + \|\psi^{(3)}\|_2 + \|\psi^{(2)}\|_1 + \|\nabla \cdot \psi^{(2)}\|_1 \leq C(\omega)\|F\|_0. \tag{3.11}$$

In (3.10a),

$$\mathcal{L}^*(\psi) = \big(\nabla \cdot \sigma^{(1,*)}(\psi), -\nabla p_f^*(\psi), \nabla \cdot \sigma^{(3,*)}(\psi)\big)^t,$$

where $\sigma^{(m,*)}(\psi), m = 1, 3$, and $p_f^*(\psi)$ are defined as in (2.3) but using the complex conjugates of the coefficients. Similarly, $\mathcal{G}_\Gamma^*(\psi)$ is defined as in (2.7) but using $\sigma^{(m,*)}(\psi), m = 1, 3$, and $p_f^*(\psi)$ in those definitions. As before, existence for (3.10) will be assumed.

4. The global finite element procedure. The numerical procedures will be defined and analyzed in detail in two dimensions and for rectangular elements. The changes for triangular elements and the 3D case will be described in section 9.

Let $\mathcal{T}^h(\Omega)$ be a nonoverlapping partition of Ω into rectangles Q_j of diameter bounded by h such that $\overline{\Omega} = \cup_{j=1}^J \overline{Q}_j$. Denote by ξ_j and ξ_{jk} the midpoints of $\partial Q_j \cap \Gamma$ and $\partial Q_j \cap \partial Q_k$, respectively. Let $\langle\langle \cdot, \cdot \rangle\rangle_{\Gamma_{jk}}$ denote the approximation to the (complex) inner product $\langle \cdot, \cdot \rangle_{\Gamma_{jk}}$ in $L^2(\Gamma_{jk})$ computed using the midpoint quadrature rule; more precisely,

$$\langle\langle u, v \rangle\rangle_{\Gamma_{jk}} = (u\overline{v})(\xi_{jk})|\Gamma_{jk}|,$$

where $|\Gamma_{jk}|$ denotes the measure of Γ_{jk}.

Let us denote by ν_{jk} the unit outer normal on $\partial Q_j \cap \partial Q_k$ from Q_j to Q_k and by ν_j the unit outer normal to ∂Q_j. Let χ_j and χ_{jk} be unit tangents on $\partial Q_j \cap \Gamma$ and $\partial Q_j \cap \partial Q_k$ so that $\{\nu_j, \chi_j\}$ and $\{\nu_{jk}, \chi_{jk}\}$ are orthonormal systems on $\partial Q_j \cap \Gamma$ and $\partial Q_j \cap \partial Q_k$, respectively.

To approximate each component of the solid displacement vector we employ the nonconforming finite element space as in [17], while to approximate the fluid displacement vector we choose the vector part of the Raviart–Thomas–Nedelec space [34, 30] of zero order. More specifically, set

$$\widehat{R} = [-1, 1]^2, \qquad \widehat{\mathcal{NC}}(\widehat{R}) = \mathrm{Span}\{1, \widehat{x}_1, \widehat{x}_2, \alpha(\widehat{x}_1) - \alpha(\widehat{x}_2)\}, \quad \alpha(\widehat{x}_1) = \widehat{x}_1^2 - \frac{5}{3}\widehat{x}_1^4,$$

with the degrees of freedom being the values at the midpoint of each edge of $\widehat{R}$. Also, if $\psi^L(\widehat{x}_1) = \frac{-1+\widehat{x}_1}{2}$, $\psi^R(\widehat{x}_1) = \frac{1+\widehat{x}_1}{2}$, $\psi^B(\widehat{x}_2) = \frac{-1+\widehat{x}_2}{2}$, $\psi^T(\widehat{x}_2) = \frac{1+\widehat{x}_2}{2}$, we have that

$$\widehat{\mathcal{W}}(\widehat{R}) = \mathrm{Span}\big\{(\psi^L(\widehat{x}_1), 0)^t, (\psi^R(\widehat{x}_1), 0)^t, (0, \psi^B(\widehat{x}_2))^t, (0, \psi^T(\widehat{x}_2))^t\big\}.$$

For each Q_j, let $F_{Q_j} : \widehat{R} \to Q_j$ be an invertible affine mapping such that $F_{Q_j}(\widehat{R}) = Q_j$, and define

$$\mathcal{NC}_j^h = \{v = (v_1, v_2)^t : \ v_i = \widehat{v}_i \circ F_{Q_j}^{-1}, \ \widehat{v}_i \in \widehat{\mathcal{NC}}(\widehat{R}), \ i = 1, 2\},$$

$$\mathcal{W}_j^h = \{w : \ w = \widehat{w} \circ F_{Q_j}^{-1}, \ \widehat{w} \in \widehat{\mathcal{W}}(\widehat{R})\}.$$

Setting

$$\mathcal{N}C^h = \{v : v_j = v|_{Q_j} \in \mathcal{N}C_j^h,\ v_j(\xi_{jk}) = v_k(\xi_{jk})\ \forall (j,k)\},$$
$$\mathcal{W}^h = \{w \in H(\mathrm{div};\Omega) :\ w_j = w|_{Q_j} \in \mathcal{W}_j^h\},$$

the global finite element space to approximate the solution u of (3.2) is defined by

$$\mathcal{V}^h = \mathcal{N}C^h \times \mathcal{W}^h \times \mathcal{N}C^h.$$

In order to state the approximation properties of $\mathcal{V}^h$ let us introduce the space

$$\tilde{\Lambda}_s^h = \big\{\tilde{\lambda}_s^h : \tilde{\lambda}_s^h|_{\partial Q_j \cap \partial Q_k} = \tilde{\lambda}_{s,jk}^h \in [P_0(\partial Q_j \cap \partial Q_k)]^2 \equiv \tilde{\Lambda}_{s,jk}^h, \quad \tilde{\lambda}_{s,jk}^h + \tilde{\lambda}_{s,kj}^h = 0\big\},$$

where $P_0(\partial Q_j \cap \partial Q_k)$ denotes the constant functions defined on $\partial Q_j \cap \partial Q_k$. Also, define the projections $\Pi_h : [H^2(\Omega)]^2 \to \mathcal{N}\mathcal{C}^h$ and $P_h^{(m)} : [H^2(\Omega)]^2 \times H^1(\mathrm{div};\Omega) \times [H^2(\Omega)]^2 \to \tilde{\Lambda}_s^h, m = 1,3$, associated with the two solid phases by

$$(\varphi^{(m)} - \Pi_h\varphi^{(m)})(\xi) = 0, \quad \xi = \xi_{jk} \text{ or } \xi_j,$$
$$\Big\langle \sigma^{(m)}(\psi_j)\nu - P_h^{(m)}(\psi_j), 1\Big\rangle_B = 0, \quad B = \partial Q_j \cap \partial Q_k \text{ or } \partial Q_j \cap \Gamma,$$

for all $\varphi \in [H^2(\Omega)]^2$ and $\psi \in [H^2(\Omega)]^2 \times H^1(\mathrm{div};\Omega) \times [H^2(\Omega)]^2$. Then, standard approximation theory implies that, for all $\varphi = (\varphi^{(1)}, \varphi^{(2)}, \varphi^{(3)})^t \in [H^2(\Omega)]^2 \times H^1(\mathrm{div};\Omega) \times [H^2(\Omega)]^2$,

$$\begin{aligned}(4.1)\ \sum_{m=1,3} \Bigg[&\|\varphi^{(m)} - \Pi_h\varphi^{(m)}\|_0 + h\left(\sum_j \|\varphi^{(m)} - \Pi_h\varphi^{(m)}\|_{1,Q_j}^2\right)^{\frac{1}{2}} \\ &+ h^2\left(\sum_j \|\varphi^{(m)} - \Pi_h\varphi^{(m)}\|_{2,Q_j}^2\right)^{\frac{1}{2}} + h^{\frac{1}{2}}\left(\sum_j |\varphi^{(m)} - \Pi_h\varphi^{(m)}|_{0,\partial Q_j}^2\right)^{\frac{1}{2}} \\ &+ h^{\frac{3}{2}}\left(\sum_j |\sigma^{(m)}(\varphi_j)\nu_j - P_h^{(m)}\varphi_j|_{0,\partial Q_j}^2\right)^{\frac{1}{2}}\Bigg] \\ &\le Ch^2\left(\|\varphi^{(1)}\|_2 + \|\varphi^{(3)}\|_2 + \|\nabla\cdot\varphi^{(2)}\|_1\right).\end{aligned}$$

We also notice the orthogonality to constants of the difference $\varphi_j^{(m)} - \varphi_k^{(m)}$ on the interfaces $\partial Q_j \cap \partial Q_k$ of Q_j and Q_k; that is,

$$\big\langle \varphi_j^{(m)} - \varphi_k^{(m)}, 1\big\rangle_{\partial Q_j \cap \partial Q_k} = 0 \text{ for all interfaces } \partial Q_j \cap \partial Q_k, \quad \varphi^{(m)} \in \mathcal{N}\mathcal{C}^h,\ m = 1,3.$$

Next, let us define the projection $\mathbf{Q}_h$ associated with the displacement vector of the fluid phase as follows:

$$\mathbf{Q}_h : [H^1(\Omega)]^2 \to \mathcal{W}^h : \big\langle \big(\mathbf{Q}_h\varphi^{(2)} - \varphi^{(2)}\big)\cdot\nu, 1\big\rangle_B = 0, \quad B = \partial Q_j \cap \partial Q_k \text{ or } B = \partial Q_j \cap \Gamma.$$

Then, it follows from [30, 34] that

$$\|\varphi^{(2)} - \mathbf{Q}_h\varphi^{(2)}\|_0 \le Ch\|\varphi^{(2)}\|_1, \tag{4.2a}$$
$$\|\varphi^{(2)} - \mathbf{Q}_h\varphi^{(2)}\|_{H(\mathrm{div};\Omega)} \le Ch\big(\|\varphi^{(2)}\|_1 + \|\nabla\cdot\varphi^{(2)}\|_1\big). \tag{4.2b}$$

Set

$$\mathcal{A}_h(u,v) = \sum_j \Big[\big(\sigma_{jk}^{(1)}(u), \varepsilon_{jk}(v^{(1)})\big)_{Q_j} + \big(\sigma_{jk}^{(3)}(u), \varepsilon_{jk}(v^{(3)})\big)_{Q_j} - \big(p_f(u), \nabla \cdot v^{(2)}\big)_{Q_j} \Big] \tag{4.3}$$

and

$$\Theta_h(u,v) = -\omega^2 (\mathcal{P}u, v) + i\omega (\mathcal{B}u, v) + \mathcal{A}_h(u,v) + i\omega \langle \mathcal{D}\ S_\Gamma(u), S_\Gamma(v)\rangle .$$

Then the *global* finite element procedure is defined as follows: find $u^h = (u^{(1,h)}, u^{(2,h)}, u^{(3,h)})^t \in \mathcal{V}^h$ such that

$$\Theta_h(u^h, v) = (F, v), \quad v = \big(v^{(1)}, v^{(2)}, v^{(3)}\big)^t \in \mathcal{V}^h. \tag{4.4}$$

Let us denote by $u_j^{(m,h)},\ j = 1, 2$, the components of the vector $u^{(m,h)},\ m = 1, 2, 3$. The following theorem analyzes the uniqueness of the solution of (4.4).

THEOREM 4.1. *Problem* (4.4) *has a unique solution for any* $\omega \neq 0$.

Proof. Set $F = 0$, choose $v = u^h$ in (4.4), and take the imaginary part in the resulting equation to obtain

$$\omega\big(\mathcal{B}u^h, u^h\big) + \sum_{Q_j} \big(\mathbf{E}_i\ \tilde{\epsilon}(u^h), \tilde{\epsilon}(u^h)\big)_{Q_j} + \omega\big\langle \mathcal{D}\ S_\Gamma(u^h), S_\Gamma(u^h)\big\rangle = 0. \tag{4.5}$$

Since each term in the left-hand side of (4.5) is nonnegative, in particular we have that $(\mathcal{B}u^h, u^h) = 0$, and the argument in the proof of Theorem 3.1 can be repeated to show that

$$u^{(2,h)} = 0, \quad u^{(1,h)} = u^{(3,h)}, \quad \Omega. \tag{4.6}$$

To show that $u^{(1,h)} = u^{(3,h)} = 0$, take an element, say Q_1, among the four elements which intersect Γ at the vertices of Ω; two faces of Q_1 are contained in Γ. After a proper transformation, without loss of generality we can assume that $Q_1 = (-1, 1)^2$ with the faces $\Gamma^R = \{(x_1, x_2) \in \Gamma : x_1 = 1\}$ and $\Gamma^T = \{(x_1, x_2) \in \Gamma : x_2 = 1\}$ contained in Γ. Set

$$\begin{aligned} u_1^{(1,h)} &= a_1 + b_1 x_1 + c_1 x_2 + d_1(\alpha(x_1) - \alpha(x_2)), \\ u_2^{(1,h)} &= a_2 + b_2 x_1 + c_2 x_2 + d_2(\alpha(x_1) - \alpha(x_2)). \end{aligned}$$

Since the boundary term in (4.5) must vanish and the matrix $\mathcal{D}$ is positive definite, we conclude that $S_\Gamma(u^h) = 0$ and consequently $u^{(m,h)}(x_1, x_2), m = 1, 3$, must vanish on $\Gamma^R \cup \Gamma^T$. In particular, at the midpoint of $\Gamma^R \cup \Gamma^T$ we have

$$\begin{aligned} u_1^{(1,h)}(1,0) &= a_1 + b_1 - \frac{2}{3} d_1 = 0, \quad u_1^{(1,h)}(0,1) = a_1 + c_1 + \frac{2}{3} d_1 = 0, \\ u_2^{(1,h)}(1,0) &= a_2 + b_2 - \frac{2}{3} d_2 = 0, \quad u_2^{(1,h)}(0,1) = a_2 + c_2 + \frac{2}{3} d_2 = 0. \end{aligned} \tag{4.7}$$

Next, since the second term in the left-hand side of (4.5) is nonnegative and the matrix

$\mathbf{E}_i$ is positive definite, for $(x_1, x_2) \in Q_1$ we must have

$$\varepsilon_{11}(u^{(1,h)}) = b_1 + 2d_1\left(x_1 - \frac{10}{3}x_1^3\right) = 0, \tag{4.8a}$$

$$\varepsilon_{22}(u^{(1,h)}) = c_2 - 2d_2\left(x_2 - \frac{10}{3}x_2^3\right) = 0, \tag{4.8b}$$

$$\varepsilon_{12}(u^{(1,h)}) = \frac{1}{2}\left[c_1 + b_2 - 2d_1\left(x_1 - \frac{10}{3}x_1^3\right) + 2d_2\left(x_2 - \frac{10}{3}x_2^3\right)\right] = 0. \tag{4.8c}$$

From (4.7) and (4.8) it follows that $u_1^{(1,h)}|_{Q_1} = u_2^{(1,h)}|_{Q_1} = 0$, and using (4.6) we also have $u_1^{(3,h)}|_{Q_1} = u_2^{(3,h)}|_{Q_1} = 0$. Let us take an element Q_2 adjacent to Q_1 that intersects Γ and has a common face Γ_{12} with Q_1. Then $u_1^{(1,h)}$ and $u_2^{(1,h)}$ vanish at the midpoints of Γ_2 and Γ_{12} and $\varepsilon_{11}(u^{(1,h)}), \varepsilon_{22}(u^{(1,h)})$, and $\varepsilon_{22}(u^{(1,h)})$ vanish identically on Q_2, so that repeating the above argument we verify that

$$u_1^{(m,h)}|_{Q_2} = u_2^{(m,h)}|_{Q_2} = 0, \quad m = 1, 3. \tag{4.9}$$

Repeating the argument, one can show that (4.9) holds for all elements with a face contained in Γ. Next stripping out such boundary elements, take a boundary element with two faces common with the corner of stripped out domain and repeat the argument to show the validity of (4.9) for those elements. Then continue the process until the domain is exhausted. This completes the proof. ∎

5. A priori error estimates for the global procedure. In this section, we derive an error estimate between the solutions u and u^h defined by (3.2) and (4.4), respectively. The argument in this section is close to that given in [21], which uses a boot-strapping argument similar to [15] for nonconforming finite element methods for Helmholtz-type problems. Also, see [16] for such a boot-strapping argument for conforming finite element methods for the Helmholtz equation.

Set

$$\mathbf{Z_h} = \left(\Pi_h u^{(1)}, \mathbf{Q}_h u^{(2)}, \Pi_h u^{(3)}\right)^t, \quad \delta = u - u^h, \quad \gamma = \mathbf{Z_h} u - u^h.$$

Our first goal is to derive an estimate for $\|\gamma\|_0$, and for that purpose we will solve the adjoint problem (3.10) to (2.6) and (2.9) with γ as a source term. It is convenient to define the following broken norms and seminorms:

$$\|v\|_{s,h}^2 = \sum_j \|v\|_{s,Q_j}^2, \quad |v|_{s,h}^2 = \sum_j |v|_{s,Q_j}^2, \quad |v|_{s,h,\Gamma}^2 = \sum_j |v|_{s,\partial Q_j \cap \Gamma}^2.$$

First note that for $v = (v^{(1)}, v^{(2)}, v^{(3)})^t \in [L^2(\Omega)]^6$ such that $v^{(1)}, v^{(3)} \in [H^1(Q_j)]^2$, $v^{(2)} \in H(\mathrm{div}; Q_j)$. Using integration by parts on each Q_j, we obtain

$$\begin{aligned}\Theta_h(u, v) = &\sum_j (-\omega^2 \mathcal{P}u + i\omega \mathcal{B}u - \mathcal{L}(u), v)_{Q_j} \\ &+ \sum_j \left\langle (\sigma^{(1)}(u)\nu, -p_f(u)\nu, \sigma^{(3)}(u)\nu)^t, (v^{(1)}, v^{(2)}, v^{(3)})^t \right\rangle_{\partial Q_j \setminus \Gamma}.\end{aligned} \tag{5.1}$$

Thus from (4.4) and (5.1) we see that for $v \in \mathcal{V}^h$,

$$\Theta_h(\delta, v) = \sum_j \left[\sum_{m=1,3} \left\langle \sigma^{(m)}(u)\nu, v^{(m)} \right\rangle_{\partial Q_j \setminus \Gamma} - \left\langle p_f(u), v^{(2)} \cdot \nu \right\rangle_{\partial Q_j \setminus \Gamma} \right]. \tag{5.2}$$

Notice that the regularity assumption (3.1) implies that $p_f(u) \in H^{1/2}(\partial Q_j \cap \partial Q_k)$ which, together with the fact that $v_j^{(2)} \cdot \nu_{jk} + v_k^{(2)} \cdot \nu_{kj} = 0$ in the sense of $H^{-1/2}(\partial Q_j \cap \partial Q_k)$, leads to

$$\sum_j \left\langle p_f(u), v^{(2)} \cdot \nu \right\rangle_{\partial Q_j \setminus \Gamma} = 0. \tag{5.3}$$

Hence, thanks to (5.3) and the fact that $v^{(1)}$ and $v^{(3)}$ are orthogonal to constants, (5.2) can be rewritten in the form

$$\Theta_h(\delta, v) = \sum_j \sum_{m=1,3} \left\langle \sigma^{(m)}(u)\nu - P_h^{(m)}(u), v^{(m)} \right\rangle_{\partial Q_j \setminus \Gamma}, \quad v \in \mathcal{V}^h. \tag{5.4}$$

Let $\psi = (\psi^{(1)}, \psi^{(2)}, \psi^{(3)})^t$ be the solution of the adjoint problem to (2.6) and (2.9):

$$-\omega^2 \mathcal{P}\psi - i\omega \mathcal{B}\psi - \mathcal{L}^*(\psi) = \gamma, \quad \Omega \times (0, \omega^*), \tag{5.5a}$$

$$\mathcal{G}_\Gamma^*(\psi) - i\omega \mathcal{D} S_\Gamma(\psi) = 0, \quad \Gamma \times (0, \omega^*). \tag{5.5b}$$

According to (3.11), ψ satisfies the regularity assumption

$$\|\psi^{(1)}\|_2 + \|\psi^{(3)}\|_2 + \|\psi^{(2)}\|_1 + \|\nabla \cdot \psi^{(2)}\|_1 \le C(w)\|\gamma\|_0. \tag{5.6}$$

Using integration by parts on each Q_j and applying the boundary condition (5.5b), we get

$$\begin{aligned} -(\gamma, \mathcal{L}^*(\psi)) &= \mathcal{A}_h(\gamma, \psi) + i\omega \langle \mathcal{D}\ S_\Gamma(\gamma), S_\Gamma(\psi) \rangle \\ &\quad - \sum_j \left[\sum_{m=1,3} \left\langle \gamma^{(m)}, \sigma^{(m,*)}(\psi)\nu \right\rangle_{\partial Q_j \setminus \Gamma} - \left\langle \gamma^{(2)} \cdot \nu, p_f^*(\psi) \right\rangle_{\partial Q_j \setminus \Gamma} \right]. \end{aligned} \tag{5.7}$$

Next, the argument used to show the validity of (5.3) can be applied to see that the last term in the right-hand side of (5.7) vanishes. Thus (5.7) implies that

$$\begin{aligned} \|\gamma\|_0^2 &= (\gamma, -\omega^2 \mathcal{P}\psi - i\omega \mathcal{B}\psi - \mathcal{L}^*(\psi)) \\ &= \Theta_h(\gamma, \psi) - \sum_j \sum_{m=1,3} \left\langle \gamma^{(m)}, \sigma^{(m,*)}(\psi)\nu \right\rangle_{\partial Q_j \setminus \Gamma}. \end{aligned} \tag{5.8}$$

Next, since $\sigma^{(m,*)}(\psi)\nu - P_h^{(m,*)}(\psi)$ has average value zero on $\partial Q_j \setminus \Gamma$, we have that for any $q^{(m)} \in [P_0(Q_j)]^2, m = 1, 3$,

$$\left\langle q^{(m)}, \sigma^{(m,*)}(\psi)\nu - P_h^{(m,*)}(\psi) \right\rangle_{\partial Q_j \setminus \Gamma} = 0, \quad m = 1, 3,$$

so that (5.8) can be stated in the form

$$\|\gamma\|_0^2 = \Theta_h(\gamma, \psi) - \sum_j \sum_{m=1,3} \left\langle \gamma^{(m)} - q^{(m)}, \sigma^{(m,*)}(\psi)\nu - P_h^{(m,*)}(\psi) \right\rangle_{\partial Q_j \setminus \Gamma}. \tag{5.9}$$

Next use (5.4) to see that for $v \in \mathcal{V}^h$,

$$\begin{aligned} \Theta_h(\gamma, v) &= \Theta_h(\delta, v) - \Theta_h(u - \mathbf{Z_h} u, v) \\ &= \sum_j \sum_{m=1,3} \left\langle \sigma^{(m)}(u)\nu - P_h^{(m)}(u), v^{(m)} \right\rangle_{\partial Q_j \setminus \Gamma} - \Theta_h(u - \mathbf{Z_h} u, v). \end{aligned} \tag{5.10}$$

Then use (5.10) in (5.9) to obtain

$$\begin{aligned}\|\gamma\|_0^2 &= \Theta_h(\gamma,\psi-v)-\Theta_h(u-\mathbf{Z_h}u,v)\\ &\quad+\sum_j\sum_{m=1,3}\big\langle\sigma^{(m)}(u)\nu-P_h^{(m)}(u),v^{(m)}\big\rangle_{\partial Q_j\setminus\Gamma}\\ &\quad-\sum_j\sum_{m=1,3}\big\langle\gamma^{(m)}-q^{(m)},\sigma^{(m,*)}(\psi)\nu-P_h^{(m,*)}(\psi)\big\rangle_{\partial Q_j\setminus\Gamma}.\end{aligned}\tag{5.11}$$

Next, since $\psi^{(m)}\in[H^2(\Omega)]^2, m=1,3$, (5.11) can be put in the equivalent form

$$\begin{aligned}\|\gamma\|_0^2 &= \Theta_h(\gamma,\psi-v)-\Theta_h(u-\mathbf{Z_h}u,v)\\ &\quad+\sum_j\sum_{m=1,3}\big\langle\sigma^{(m)}(u)\nu-P_h^{(m)}(u),v^{(m)}-\psi^{(m)}\big\rangle_{\partial Q_j\setminus\Gamma}\\ &\quad-\sum_j\left[\sum_{m=1,3}\big\langle\gamma^{(m)}-q^{(m)},\sigma^{(m,*)}(\psi)\nu-P_h^{(m,*)}(\psi)\big\rangle_{\partial Q_j\setminus\Gamma}\right].\end{aligned}\tag{5.12}$$

Let us bound each term in the right-hand side of (5.12). First, choose $v=(v^{(1)},v^{(2)},v^{(3)})^t=\mathbf{Z_h}\psi\in\mathcal{V}^h$ such that

$$\begin{aligned}&\sum_{m=1,3}\|\psi^{(m)}-v^{(m)}\|_0+h\|\psi^{(m)}-v^{(m)}\|_{1,h}+h^2\|v^{(m)}\|_{2,h}\\ &\qquad\le Ch^2\big(\|\psi^{(1)}\|_2+\|\psi^{(3)}\|_2\big)\le Ch^2\|\gamma\|_0,\end{aligned}\tag{5.13a}$$

$$\|\psi^{(2)}-v^{(2)}\|_0\le Ch\|\psi^{(2)}\|_1\le Ch\|\gamma\|_0,\tag{5.13b}$$

$$\begin{aligned}&\|\nabla\cdot(\psi^{(2)}-v^{(2)})\|_0+h\|\nabla\cdot(\psi^{(2)}-v^{(2)})\|_{1,h}\\ &\qquad\le Ch\|\nabla\cdot\psi^{(2)}\|_1\le Ch\|\gamma\|_0.\end{aligned}\tag{5.13c}$$

For the first term in the right-hand side of (5.12), using (5.13) we see that

$$\begin{aligned}|\Theta_h(\gamma,\psi-v)|&\le C(\omega)\Bigg[\|\gamma\|_0\|\psi-v\|_0+\sum_{m=1,3}\|\gamma^{(m)}\|_{1,h}\|\psi^{(m)}-v^{(m)}\|_{1,h}\\ &\qquad+\|\nabla\cdot\gamma\|_0\|\nabla\cdot(\psi-v)\|_0+|\langle S_\Gamma(\gamma),S_\Gamma(\psi-v)\rangle|\Bigg]\\ &\le C(\omega)h\|\gamma\|_0\big[\|\gamma^{(1)}\|_{1,h}+\|\gamma^{(3)}\|_{1,h}+\|\nabla\cdot\gamma^{(2)}\|_0\\ &\qquad+|\langle S_\Gamma(\gamma),S_\Gamma(\psi-v)\rangle|\big].\end{aligned}\tag{5.14}$$

The boundary integral in the right-hand side of (5.14) can be bounded using (5.6) and the trace inequality as follows:

$$|\langle S_\Gamma(\gamma),S_\Gamma(\psi-v)\rangle|\le C\|\gamma\|_0h^{3/2}\big[\|\gamma^{(1)}\|_{1,h}+|\gamma^{(3)}\|_{1,h}\big],\tag{5.15}$$

where we have used that

$$\sum_j\big\langle\big(\psi^{(2)}-\mathbf{Q}_h\psi^{(2)}\big)\cdot\nu,\gamma^{(2)}\cdot\nu\big\rangle_{\partial Q_j\setminus\Gamma}=0.$$

Hence, using (5.15) in (5.14), we get

$$|\Theta_h(\gamma,\psi-v)|\le C(\omega)h\|\gamma\|_0\left[\|\gamma^{(1)}\|_{1,h}+\|\gamma^{(3)}\|_{1,h}+\|\nabla\cdot\gamma^{(2)}\|_0\right].\tag{5.16}$$

By choosing $q_j^{(m)} = q^m|_{Q_j},\ m = 1, 3$, to be the average value of $\gamma^{(m)}$ on Q_j and using the trace inequality, (4.1) and (5.6), the last term in (5.12) is bounded as follows:

$$\begin{aligned}
&\left| \sum_{m=1,3} \sum_j \big\langle \gamma^{(m)} - q^{(m)}, \sigma^{(m,*)}(\psi)\nu - P_h^{(m,*)}(\psi) \big\rangle_{\partial Q_j \setminus \Gamma} \right| \\
&\quad \le \sum_{m=1,3} \left(\sum_j |\gamma^{(m)} - q^{(m)}|^2_{0,\partial Q_j \setminus \Gamma} \right)^{1/2} \left(\sum_j |\sigma^{(m,*)}(\psi)\nu - P_h^{(m,*)}(\psi)|^2_{0,\partial Q_j \setminus \Gamma} \right)^{1/2} \\
&\quad \le \sum_{m=1,3} \left(\sum_j h \|\gamma^{(m)}\|^2_{1,Q_j} \right)^{1/2} h^{1/2} \big(\|\psi^{(1)}\|_2 + \|\psi^{(3)}\|_2 + \|\nabla \cdot \psi^{(2)}\|_1 \big) \\
&\quad \le Ch\|\gamma\|_0 \big(\|\gamma^{(1)}\|_{1,h} + \|\gamma^{(3)}\|_{1,h} \big). \qquad (5.17)
\end{aligned}$$

Next, using integration by parts in the $\mathcal{A}_h(u - \mathbf{Z_h}u, v)$ term and the boundary condition (5.5b), the second term in the right-hand side of (5.12) can be written in the form

$$\begin{aligned}
\Theta_h(u - \mathbf{Z_h}u, v) &= \sum_j (u - \mathbf{Z_h}u, -\omega^2 \mathcal{P}v - i\omega \mathcal{B}v - \mathcal{L}^*(v))_{Q_j} \\
&\quad + \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}_\Gamma^*(v) \rangle_{\partial Q_j \setminus \Gamma} + \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}_\Gamma^*(v) \rangle_{\partial Q_j \cap \Gamma} \\
&\quad + i\omega \langle \mathcal{D} S_\Gamma(u - \mathbf{Z_h}u), S_\Gamma(v) \rangle \\
&= \sum_j (u - \mathbf{Z_h}u, -\omega^2 \mathcal{P}v - i\omega \mathcal{B}v - \mathcal{L}^*(v))_{Q_j} \\
&\quad + \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}_\Gamma^*(v) - \mathcal{G}_\Gamma^*(\psi) \rangle_{\partial Q_j \cap \Gamma} \\
&\quad + \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}_\Gamma^*(v) \rangle_{\partial Q_j \setminus \Gamma} \\
&\quad + i\omega \langle \mathcal{D} S_\Gamma(u - \mathbf{Z_h}u), S_\Gamma(v - \psi) \rangle \\
&\equiv T_1 + T_2 + T_3 + T_4. \qquad (5.18)
\end{aligned}$$

Let us bound each term in the right-hand side of (5.18). First, using (4.1), (4.2), and (5.13) we see that

$$|T_1| \le Ch\|\gamma\|_0 (\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_1 + \|\nabla \cdot u^{(2)}\|_1).$$

For the T_2 term, applying the trace inequality, (4.1), (4.2), (3.11), and (5.13), one has

$$\begin{aligned}
|T_2| &\le \sum_{m=1,3} \sum_j |u^{(m)} - \Pi_h u^{(m)}|_{0,\partial Q_j \cap \Gamma} |(\sigma^{(m,*)}(v) - \sigma^{(m,*)}(\psi)) \cdot \nu|_{0,\partial Q_j \cap \Gamma} \\
&\quad + \sum_j |(u^{(2)} - \mathbf{Q}_h u^{(2)}) \cdot \nu|_{-1/2,\partial Q_j \cap \Gamma} |p_f^*(v) - p_f^*(\psi)|_{1/2,\partial Q_j \cap \Gamma} \\
&\le C\|\gamma\|_0 [h^2 (\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla \cdot u^{(2)}\|_1)]. \qquad (5.19)
\end{aligned}$$

Next, we decompose T_3 as follows:

$$\begin{aligned} T_3 &= \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}^*_\Gamma(v) - \mathcal{G}^*_\Gamma(\psi)\rangle_{\partial Q_j \setminus \Gamma} \\ &\quad + \sum_j \langle S_\Gamma(u - \mathbf{Z_h}u), \mathcal{G}^*_\Gamma(\psi)\rangle_{\partial Q_j \setminus \Gamma} \\ &\equiv T_{3,1} + T_{3,2}. \end{aligned} \tag{5.20}$$

Then, as in (5.19), the first term is bounded as follows:

$$|T_{3,1}| \le C\|\gamma\|_0[h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla \cdot u^{(2)}\|_1)].$$

The other term in (5.20) can be bounded by again using the fact that $\Pi_h u_j^{(m)} - \Pi_h u_k^{(m)}$ is orthogonal to constants

$$\begin{aligned} |T_{3,2}| \le \Bigg| & \sum_{m=1,3} \sum_j \langle (u^{(m)} - \Pi_h u^{(m)}) \cdot \nu, \sigma^{(m,*)}(\psi)\nu \cdot \nu\rangle_{\partial Q_j \setminus \Gamma} \\ & + \langle (u^{(m)} - \Pi_h u^{(m)}) \cdot \chi, \sigma^{(m,*)}(\psi)\nu \cdot \chi\rangle_{\partial Q_j \setminus \Gamma} \\ & - \sum_j \langle (u^{(2)} - \mathbf{Q}_h u^{(2)}) \cdot \nu, p_f^*(\psi)\rangle_{\partial Q_j \setminus \Gamma} \Bigg| \\ \le C\|\gamma\|_0 & [h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2)], \end{aligned}$$

where we have again used the argument in (5.3) to cancel out the terms involving $u^{(2)}$ in the inequality above. Finally, in order to bound T_4, applying the trace inequality, (4.1), (4.2), and (5.13), we obtain

$$\begin{aligned} |T_4| &\le C \Bigg[\sum_{m=1,3} \sum_j |u^{(m)} - \Pi_h u^{(m)}|_{0,\partial Q_j \cap \Gamma} |v^{(m)} - \psi^{(m)}|_{0,\partial Q_j \cap \Gamma} \\ &\qquad + \sum_j |(u^{(2)} - \mathbf{Q}_h u^{(2)}) \cdot \nu|_{0,\partial Q_j \cap \Gamma} |(v^{(2)} - \psi^{(2)}) \cdot \nu|_{0,\partial Q_j \cap \Gamma} \Bigg] \\ &\le \sum_{m=1,3} \sum_j \|u^{(m)} - \Pi_h u^{(m)}\|^{\frac{1}{2}}_{0,Q_j} \|u^{(m)} - \Pi_h u^{(m)}\|^{\frac{1}{2}}_{1,Q_j} \\ &\quad \times \|\psi^{(m)} - v^{(m)}\|^{\frac{1}{2}}_{0,Q_j} \|\psi^{(m)} - v^{(m)}\|^{\frac{1}{2}}_{1,Q_j} \\ &\quad + \sum_j h^{\frac{1}{2}} |u^{(2)} \cdot \nu|_{\frac{1}{2},\partial Q_j \cap \Gamma} h^{\frac{1}{2}} |\psi^{(2)} \cdot \nu|_{\frac{1}{2},\partial Q_j \cap \Gamma} \\ &\le C\|\gamma\|_0[h^3(\|u^{(1)}\|_2 + \|u^{(3)}\|_2)] + Ch\|u^{(2)}\|_1 \|\psi^{(2)}\|_1 \\ &\le C\|\gamma\|_0[h^3(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + Ch\|u^{(2)}\|_1]. \end{aligned}$$

Collecting the estimates for T_1, T_2, T_3, and T_4, we conclude that

$$|\Theta_h(u - \mathbf{Z_h}u, v)| \le C\|\gamma\|_0[h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla \cdot u^{(2)}\|_1)]. \tag{5.21}$$

Next, use the trace inequality, (4.1), and (5.16) to bound the third term in the

right-hand side of (5.12) as follows:

$$\begin{aligned}
&\left|\sum_j \sum_{m=1,3} \langle \sigma^{(m)}(u)\nu - P_h^m(u), v^{(m)} - \psi^{(m)}\rangle_{\partial Q_j \setminus \Gamma}\right| \\
&\quad \le \sum_{m=1,3} \left(\sum_j |\sigma^{(m)}(u)\nu - P_h^{(m)}(u)|^2_{0,\partial Q_j\setminus\Gamma}\right)^{1/2} \left(\sum_j |v^{(m)} - \psi^{(m)}|^2_{0,\partial Q_j\setminus\Gamma}\right)^{1/2} \\
&\quad \le Ch^{1/2}(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|\nabla\cdot u^{(2)}\|_1) h^{3/2}(\|\psi^{(1)}\|_2 + \|\psi^{(3)}\|_2) \\
&\quad \le Ch^2\|\gamma\|_0(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|\nabla\cdot u^{(2)}\|_1). \qquad (5.22)
\end{aligned}$$

Thus, collecting the bounds in (5.16), (5.17), (5.21), and (5.22), we obtain

$$\begin{aligned}
\|\gamma\|_0 \le C(\omega)[&h(\|\gamma^{(1)}\|_{1,h} + \|\gamma^{(3)}\|_{1,h} + \|\nabla\cdot\gamma^{(2)}\|_0) \\
&+ h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1)]. \qquad (5.23)
\end{aligned}$$

Using the triangle inequality, the last estimate (5.23), and the approximation properties of Π_h and $\mathbf{Q}_h$ in (4.1) and (4.2), we get

$$\begin{aligned}
\|\delta\|_0 \le \|\gamma\|_0 + \|\mathbf{Z}_h u - u\|_0 &\le C(\omega)[h(\|\delta^{(1)}\|_{1,h} + \|\delta^{(3)}\|_{1,h} + \|\nabla\cdot\delta^{(2)}\|_0) \\
&+ h(\|u^{(1)} - \Pi_h u^{(1)}\|_{1,h} + \|u^{(3)} - \Pi_h u^{(3)}\|_{1,h} + \|\nabla\cdot(u^{(2)} - \mathbf{Q}_h u^{(2)})\|_0) \\
&+ h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1)] \\
&\le C(\omega)[h(\|\delta^{(1)}\|_{1,h} + \|\delta^{(3)}\|_{1,h} + \|\nabla\cdot\delta^{(2)}\|_0) \qquad (5.24) \\
&+ h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2) + h(\|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1)].
\end{aligned}$$

We next use a Gärding-type inequality to bound the δ terms in (5.24) in terms of the u terms in that inequality. Using Korn's second inequality [18, 32] and noting that $\mathbf{E}_i$ is positive definite, we get

$$\begin{aligned}
|\mathrm{Im}(\Theta_h(\delta,\delta))| &= \omega(\mathcal{B}\delta,\delta) + \sum_j (\mathbf{E}_i\ \tilde{\epsilon}(\delta), \tilde{\epsilon}(\delta))_{Q_j} + \omega\langle \mathcal{D}\ S_\Gamma(\delta), S_\Gamma(\delta)\rangle \\
&\ge C_1(\omega)[\|\delta^{(1)}\|^2_{1,h} + \|\delta^{(3)}\|^2_{1,h} + \|\nabla\cdot\delta^{(2)}\|^2_0 + \langle S_\Gamma(\delta), S_\Gamma(\delta)\rangle] \\
&\quad - C_2(\omega)\|\delta\|^2_0.
\end{aligned}$$

Hence,

$$\begin{aligned}
&\|\delta^{(1)}\|^2_{1,h} + \|\delta^{(3)}\|^2_{1,h} + \|\nabla\cdot\delta^{(2)}\|^2_0 + \langle S_\Gamma(\delta), S_\Gamma(\delta)\rangle \\
&\quad \le C_3(\omega)|\Theta_h(\delta,\delta)| + C_2(\omega)\|\delta\|^2_0 \\
&\quad \le C_3(\omega)[\|\delta\|^2_0 + |\Theta_h(\delta, u - \mathbf{Z}_h u)| + |\Theta_h(\delta,\gamma)|]. \qquad (5.25)
\end{aligned}$$

Since $\gamma \in \mathcal{V}^h$, the expression for $\Theta_h(\delta,\gamma)$ given in (5.4) can be replaced by using (5.25)

so that

$$
\begin{aligned}
&\|\delta^{(1)}\|_{1,h}^2 + \|\delta^{(3)}\|_{1,h}^2 + \|\nabla\cdot\delta^{(2)}\|_0^2 + \langle S_\Gamma(\delta), S_\Gamma(\delta)\rangle \\
&\le C_3(\omega)\Bigg[\|\delta\|_0^2 - \omega^2(\mathcal{P}\delta, u-\mathbf{Z}_h u) + i\omega(\mathcal{B}\delta, u-\mathbf{Z}_h u) + \mathcal{A}_h(\delta, u-\mathbf{Z}_h u) \\
&\quad + i\omega\langle \mathcal{D}\ S_\Gamma(\delta), S_\Gamma(u-\mathbf{Z}_h u)\rangle + \sum_j \sum_{m=1,3} \langle \sigma^{(m)}(u)\nu - P_h^{(m)}(u), \gamma^{(m)}\rangle_{\partial Q_j\setminus\Gamma}\Bigg].
\end{aligned} \tag{5.26}
$$

Let us bound the last five terms in the right-hand side of (5.26). First, thanks to the approximation properties of Π_h and $\mathbf{Q}_h$ given in (4.1) and (4.2), it follows that

$$
\begin{aligned}
&|-\omega^2(\mathcal{P}\delta, u-\mathbf{Z}_h u) + i\omega(\mathcal{B}\delta, u-\mathbf{Z}_h u)| \\
&\qquad \le C(\omega)[\|\delta\|_0^2 + h^4(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2) + h^2\|u^{(2)}\|_1^2].
\end{aligned} \tag{5.27}
$$

Again, due to (4.1) and (4.2),

$$
\begin{aligned}
|\mathcal{A}_h(\delta, u-\mathbf{Z}_h u)| &\le C(\omega)\Bigg[\sum_{m=1,3}(\|\delta^{(m)}\|_{1,h}\|u^{(m)} - \Pi_h u^{(m)}\|_{1,h}) \\
&\qquad + \|\nabla\cdot\delta^{(2)}\|_0\|\nabla\cdot(u^{(2)} - \mathbf{Q}_h u^{(2)})\|_0\Bigg] \\
&\le \epsilon(\|\delta^{(1)}\|_{1,h}^2 + \|\delta^{(3)}\|_{1,h}^2 + \|\nabla\cdot\delta^{(2)}\|_0^2) \\
&\quad + C(\omega)[h^2(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2) + h^2\|\nabla\cdot u^{(2)}\|_1^2].
\end{aligned} \tag{5.28}
$$

Next, using the trace inequality and approximation properties (4.1) and (4.2) again, we have

$$
\begin{aligned}
&|\omega\langle \mathcal{D}\ S_\Gamma(\delta), S_\Gamma(u-\mathbf{Z}_h u)\rangle| \\
&\quad \le \epsilon\langle \mathcal{D}S_\Gamma(\delta), S_\Gamma(\delta)\rangle + C(\omega)\langle \mathcal{D}S_\Gamma(u-\mathbf{Z}_h u), S_\Gamma(u-\mathbf{Z}_h u)\rangle \\
&\quad \le \epsilon\langle \mathcal{D}S_\Gamma(\delta), S_\Gamma(\delta)\rangle \\
&\qquad + C(\omega)\Bigg[\sum_{m=1,3}\sum_j |u^{(m)} - \Pi_h u^{(m)}|_{0,\partial Q_j\cap\Gamma}^2 + \sum_j |(u^{(2)} - \mathbf{Q}_h u^{(2)})\cdot\nu|_{0,\partial Q_j\cap\Gamma}^2\Bigg] \\
&\quad \le \epsilon\langle \mathcal{D}S_\Gamma(\delta), S_\Gamma(\delta)\rangle + C(\omega)\Bigg[h^3(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2) + \sum_j h^2|u^{(2)}\cdot\nu|_{1,\partial Q_j\cap\Gamma}^2\Bigg] \\
&\quad \le \epsilon\langle \mathcal{D}S_\Gamma(\delta), S_\Gamma(\delta)\rangle + C(\omega)\Bigg[h^3(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2) + \sum_j h^2\|u^{(2)}\|_{\frac{3}{2},Q_j}^2\Bigg] \\
&\quad \le \epsilon\langle \mathcal{D}S_\Gamma(\delta), S_\Gamma(\delta)\rangle + C(\omega)[h^3(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2) + h^2\|u^{(2)}\|_{\frac{3}{2}}^2].
\end{aligned} \tag{5.29}
$$

Finally, owing to the orthogonality property of $\gamma^{(m)}$ to constants on $\partial Q_j\setminus\Gamma$, the trace

inequality, and (4.1), it follows that

$$\begin{aligned}
&\left|\sum_j \sum_{m=1,3} \langle \sigma^{(m)}(u)\nu - P_h^{(m)}(u), \gamma^{(m)}\rangle_{\partial Q_j\setminus\Gamma}\right| \\
&\quad = \left|\sum_j \sum_{m=1,3} \langle \sigma^{(m)}(u)\nu - P_h^{(m)}(u), \gamma^{(m)} - q^{(m)}\rangle_{\partial Q_j\setminus\Gamma}\right| \\
&\quad \le C \sum_{m=1,3} \left(\sum_j |\sigma^{(m)}(u)\nu - P_h^{(m)}(u)|^2_{0,\partial Q_j\setminus\Gamma}\right)^{1/2} \left(\sum_j |\gamma^{(m)} - q^{(m)}|^2_{0,\partial Q_j\setminus\Gamma}\right)^{1/2} \\
&\quad \le Ch^{1/2}(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|\nabla\cdot u^{(2)}\|_1) \sum_{m=1,3} \left(\sum_j h\|\gamma^{(m)}\|_{1,Q_j}\right)^{1/2} \\
&\quad \le Ch \sum_{m=1,3} \|\gamma^{(m)}\|_{1,h}(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|\nabla\cdot u^{(2)}\|_1) \\
&\quad \le Ch\left(\sum_{m=1,3} \|\delta^{(m)}\|_{1,h} + \|u^{(m)} - \Pi_h u^{(m)}\|_{1,h}\right)(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|\nabla\cdot u^{(2)}\|_1) \\
&\quad \le \epsilon(\|\delta^{(1)}\|^2_{1,h} + \|\delta^{(3)}\|^2_{1,h}) + Ch^2(\|u^{(1)}\|_2^2 + \|u^{(3)}\|_2^2 + \|\nabla\cdot u^{(2)}\|_1^2). \qquad (5.30)
\end{aligned}$$

Hence using (5.27), (5.28), (5.29), and (5.30) in (5.26), we have the following estimate:

$$\begin{aligned}
&\|\delta^{(1)}\|_{1,h} + \|\delta^{(3)}\|_{1,h} + \|\nabla\cdot\delta^{(2)}\|_0 + \langle S_\Gamma(\delta), S_\Gamma(\delta)\rangle^{\frac{1}{2}} \\
&\qquad \le C(\omega)[\|\delta\|_0 + h(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}} + \|\nabla\cdot u^{(2)}\|_1)]. \qquad (5.31)
\end{aligned}$$

Next, use (5.31) in (5.24) to obtain

$$\begin{aligned}
\|\delta\|_0 \le C(\omega)[&h\|\delta\|_0 + h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}}) \\
&+ h(\|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1)]. \qquad (5.32)
\end{aligned}$$

Then, for sufficiently small $h > 0$ such that $0 < C(\omega)h < 1$, the term $\|\delta\|_0$ in the right-hand side of (5.32) is absorbed in the left-hand side, and therefore

$$\|\delta\|_0 \le C(\omega)[h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}}) + h(\|u^{(2)}\|_1 + \|\nabla\cdot u^{(2)}\|_1)]. \qquad (5.33)$$

Finally, using (5.33) in (5.31), we arrive at the following error estimate:

$$\begin{aligned}
&\|\delta^{(1)}\|_{1,h} + \|\delta^{(3)}\|_{1,h} + \|\nabla\cdot\delta^{(2)}\|_0 + \langle S_\Gamma(\delta), S_\Gamma(\delta)\rangle \le C(\omega)h[\|u^{(1)}\|_2 \\
&\quad + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}} + \|\nabla\cdot u^{(2)}\|_1].
\end{aligned}$$

We summarize the above in the following theorem.

THEOREM 5.1. *Let $u \in \mathcal{V}$ and $u^h \in \mathcal{V}^h$ be the solutions of* (3.2) *and* (4.4)*, respectively. We then have the following energy-norm error estimate: for sufficiently*

small $h > 0$,

$$\sum_{m=1,3} \|u^{(m)} - u^{(m,h)}\|_{1,h} + \|\nabla \cdot (u^{(2)} - u^{(2,h)})\|_0 + \sum_{m=1,3} |u^{(m)} - u^{(m,h)}|_{0,\Gamma} + |(u^{(2)} - u^{(2,h)}) \cdot \nu|_{0,\Gamma} \le C(\omega) h \big[\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}} + \|\nabla \cdot u^{(2)}\|_1\big].$$

Also, we have the $[L^2(\Omega)]^6$*-error estimate as follows: for sufficiently small* $h > 0$,

$$\|u - u^h\|_0 \le C(\omega)[h^2(\|u^{(1)}\|_2 + \|u^{(3)}\|_2 + \|u^{(2)}\|_{\frac{3}{2}}) + h(\|u^{(2)}\|_1 + \|\nabla \cdot u^{(2)}\|_1)].$$

6. A global hybridized nonconforming finite element procedure. Let us decompose $\Omega \in \mathbb{R}^2$ into nonoverlapping subdomains $\Omega_1, \ldots, \Omega_N$ such that each Ω_j is composed of the union of disjoint rectangles $Q \in \mathcal{T}^h(\Omega)$, with the interfaces $\Gamma_{jk} = \partial\Omega_j \cap \partial\Omega_k$. Also, let $\Gamma_j = \partial\Omega_j \cap \Gamma$. Set

$$\begin{aligned}
\mathcal{T}^h(\Omega_j) &= \{Q \in \mathcal{T}^h(\Omega) : Q \in \Omega_j\},\\
\mathcal{NC}^h(\Omega_j) &= \{v_j : \Omega_j \to \mathbb{C}^2,\ v_j|_Q \in \mathcal{NC}_j^h\ \forall Q \in \mathcal{T}^h(\Omega_j), v_j|_{Q_k}(\xi_{kl}) = v_j|_{Q_l}(\xi_{kl})\ \forall (k,l)\},\\
\mathcal{W}^h(\Omega_j) &= \{w \in H(\mathrm{div};\Omega_j) : w_k = w|_{Q_k} \in \mathcal{W}_k^h\},\\
\mathcal{V}^h(\Omega_j) &= \mathcal{NC}^h(\Omega_j) \times \mathcal{W}^h(\Omega_j) \times \mathcal{NC}^h(\Omega_j).
\end{aligned}$$

Our global hybridized finite element space is then defined by

$$\mathcal{V}_{-1}^h = \{v \in [L^2(\Omega)]^6 : v|_{\Omega_j} \in \mathcal{V}^h(\Omega_j)\}.$$

In order to define a hybridized procedure, we follow the ideas in [1, 19, 20, 14] to impose the continuity constraints across interior interfaces using Lagrange multipliers. Thus we introduce the space $\tilde{\Lambda}_{-1,j}^h$, with $\tilde{\lambda}_{jk}^h \in \tilde{\Lambda}_{-1,j}^h$ associated with $\mathcal{G}_{\Gamma_{jk}}(u_j)$ on Γ_{jk}:

$$\tilde{\Lambda}_{-1,j}^h = \{\tilde{\lambda}_j^h : \tilde{\lambda}_{jk}^h = \tilde{\lambda}_j^h|_{\partial Q \cap \Gamma_{jk}} \in \tilde{\Lambda}_{-1,jk}^h\ \forall Q \in \Omega_j \text{ such that } \overline{Q} \cap \Gamma_{jk} \neq \emptyset\},$$

where

$$\tilde{\Lambda}_{-1,jk}^h = \{\tilde{\lambda}_{jk}^h : \tilde{\lambda}_{jk}^h \in [P_0(\partial Q \cap \Gamma_{jk})]^5\ \forall Q \in \Omega_j \text{ such that } \overline{Q} \cap \Gamma_{jk} \neq \emptyset, \tilde{\lambda}_{jk}^h = \tilde{\lambda}_{kj}^h\}\ \forall j,k.$$

Set

$$\tilde{\Lambda}_{-1}^h = \cup_j \tilde{\Lambda}_{-1,j}^h.$$

The global hybridized nonconforming procedure is defined in the following fashion: find $(\tilde{u}^h, \tilde{\lambda}^h) \in \mathcal{V}_{-1}^h \times \tilde{\Lambda}_{-1}^h$ such that

$$\text{(6.1a)}\quad \sum_j \sum_{Q \in \mathcal{T}^h(\Omega_j)} [-\omega^2(\mathcal{P}\tilde{u}_j^h, v)_Q + i\omega(\mathcal{B}\tilde{u}_j^h, v)_Q + \mathcal{A}_{h,Q}(\tilde{u}_j^h, v)] - \sum_{j,k} \langle\langle \tilde{\lambda}_{jk}^h, S_{\Gamma_{jk}}(v)\rangle\rangle_{\Gamma_{jk}} + i\omega \sum_j \langle \mathcal{D} S_{\Gamma_j}(\tilde{u}_j^h), S_{\Gamma_j}(v)\rangle_{\Gamma_j} = (F, v), \quad v \in \mathcal{V}_{-1}^h,$$

$$\text{(6.1b)}\quad \sum_{j,k} \langle\langle \theta, S_{\Gamma_{jk}}(\tilde{u}_j^h)\rangle\rangle_{\Gamma_{jk}} = 0, \quad \theta \in \tilde{\Lambda}_{-1}^h,$$

where $\mathcal{A}_{h,Q}$ indicates the restriction to Q of the bilinear form $\mathcal{A}_h$ defined in (4.3) and $S_{\Gamma_{jk}}, S_{\Gamma_j}$ are defined as in (2.7)–(2.8). The following theorem gives an existence and uniqueness result for the procedure (6.1).

THEOREM 6.1. *Problem* (6.1) *has a unique solution.*

Proof. It is enough to show uniqueness due to finite dimensionality. For this, set $F = 0$ and add (6.1a) with the choice of $v = \tilde{u}^h$ and (6.1b) with the choice $\theta = \tilde{\lambda}^h$. Then the imaginary part in the resulting equation reduces to

$$\sum_j \sum_{Q\in\mathcal{T}^h(\Omega_j)} [\omega(\mathcal{B}\tilde{u}_j^h, \tilde{u}_j^h)_Q + (\mathbf{E}_i\tilde{\varepsilon}(\tilde{u}_j^h), \tilde{\varepsilon}(\tilde{u}_j^h))_Q] + \omega\langle \mathcal{D}S_{\Gamma_j}(\tilde{u}_j^h), S_{\Gamma_j}(\tilde{u}_j^h)\rangle_{\Gamma_j} = 0. \tag{6.2}$$

Now an argument similar to that given in the proof of Theorem 4.1 shows that

$$\tilde{u}^h = 0 \quad \text{in} \quad \Omega.$$

Thus (6.1a) reduces to

$$\sum_{j,k} \langle\langle \tilde{\lambda}^h, S_{\Gamma_{jk}}(v)\rangle\rangle_{\Gamma_{jk}} = 0, \quad v \in \mathcal{NC}_{-1}^h. \tag{6.3}$$

Now, for each Ω_j and each $Q \in \Omega_j$ with Q facing the boundary Γ, we can choose $v \in \mathcal{V}^h(\Omega_j)$ with the degrees of freedom chosen such that $S_{\Gamma_{jk}}(v)$ is equal to $\tilde{\lambda}^h$ at the midpoint m of one edge of Q and zero degrees of freedom at the other three midpoints of Q to show that $\tilde{\lambda}^h = 0$ at the midpoint m. Repeating the argument for all midpoints of Q and all $Q \in \Omega_j$ whose faces meet $\partial\Omega_j$ for each j yields that $\tilde{\lambda}^h = 0$. This completes the proof. ∎

We next notice the validity of the following lemma, whose obvious proof is omitted.

LEMMA 6.1. *If* $\tilde{u}^h \in \mathcal{V}_{-1}^h$, *then* $\tilde{u}^h \in \mathcal{V}^h$ *if and only if*

$$\sum_{j,k} \langle\langle \theta, S_{\Gamma_{jk}}(\tilde{u}^h)\rangle\rangle_{\Gamma_{jk}} = 0, \quad \theta \in \tilde{\Lambda}_{-1}^h.$$

Remark 6.1. As a consequence of Theorem 6.1 and Lemma 6.1, $\tilde{u}^h$ solves problem (4.4).

7. The domain decomposition iterative procedures. Consider the decomposition of problem (2.6) and (2.9) over Ω_j as follows: for $j = 1, \ldots, N$, find $u_j(x, \omega)$ satisfying

$$-\omega^2\mathcal{P}u_j + i\omega\mathcal{B}u_j - \mathcal{L}(u_j) = F, \quad \Omega_j, \tag{7.1a}$$

$$\mathcal{G}_{\Gamma_{jk}}(u_j) + i\omega\beta_{jk}S_{\Gamma_{jk}}(u_j) = \mathcal{G}_{\Gamma_{kj}}(u_k) - i\omega\beta_{jk}S_{\Gamma_{kj}}(u_k), \qquad \Gamma_{jk}, \tag{7.1b}$$

$$-\mathcal{G}_{\Gamma_j}(u_j) = i\omega\mathcal{D}S_{\Gamma_j}(u_j), \qquad \Gamma_j, \tag{7.1c}$$

where $\mathcal{G}_{\Gamma_{jk}}$ and $\mathcal{G}_{\Gamma_j}$ are defined as in (2.7)–(2.8). Notice that (7.1b) is equivalent to imposing the two consistency conditions

$$\mathcal{G}_{\Gamma_{jk}}(u_j) = \mathcal{G}_{\Gamma_{kj}}(u_k), \qquad \Gamma_{jk},$$
$$\beta_{jk}(S_{\Gamma_{jk}}(u_j) + S_{\Gamma_{kj}}(u_k)) = 0, \qquad \Gamma_{jk}.$$

A weak form of (7.1) at the differential level may be stated as follows: for all j, find $u_j \in [H^1(\Omega_j)]^2 \times H(\mathrm{div};\Omega_j) \times [H^1(\Omega_j)]^2$ such that

$$\begin{aligned} &-\omega^2(\mathcal{P}u_j, v)_{\Omega_j} + i\omega(\mathcal{B}u_j, v)_{\Omega_j} + \mathcal{A}_j(u_j, v) + i\omega\langle \mathcal{D}\ S_{\Gamma_j}(u_j), S_{\Gamma_j}(v)\rangle \\ &\quad + \sum_k \big\langle i\omega\beta_{jk}(\mathcal{S}_{\Gamma_{jk}}(u_j) + \mathcal{S}_{\Gamma_{kj}}(u_k)) - \mathcal{G}_{\Gamma_{jk}}(u_k), v\big\rangle_{\Gamma_{jk}} = (F, v)_{\Omega_j}, \\ &\quad v = (v^{(1)}, v^{(2)}, v^{(3)})^t \in [H^1(\Omega_j)]^2 \times H(\mathrm{div};\Omega_j) \times [H^1(\Omega_j)]^2, \end{aligned} \tag{7.2}$$

where $\mathcal{A}_j$ is the restriction to Ω_j of the bilinear form $\mathcal{A}$ defined in (3.3). Then a Jacobi-type iteration at the differential level may be defined by changing u_j and u_k in (7.2) into $u_j^{\{n\}}$ and $u_k^{\{n-1\}}$, respectively. This motivates the definition of our hybridized nonconforming domain decomposition procedure. For that purpose, we introduce a new set of Lagrange multipliers $\tilde{\tilde{\lambda}}_{jk}^h$ associated with $\mathcal{S}_{\Gamma_{jk}}(u_j)$ at the midpoints ξ_{jk} of the face of element $Q \in \Omega_j$ such that $\overline{Q} \cap \Gamma_{jk} \neq \emptyset$ for all the interior interfaces Γ_{jk}. Let

$$\tilde{\tilde{\Lambda}}_{-1,j}^h = \{\tilde{\tilde{\lambda}}_j^h : \tilde{\tilde{\lambda}}_{jk}^h = \tilde{\tilde{\lambda}}_j^h|_{\partial Q \cap \Gamma_{jk}} \in [P_0(\partial Q \cap \Gamma_{jk})]^5\ \forall Q \in \Omega_j \text{ such that } \overline{Q} \cap \Gamma_{jk} \neq \emptyset\},$$

and set $\tilde{\tilde{\Lambda}}_{-1}^h = \cup_j \tilde{\tilde{\Lambda}}_{-1,j}^h$.

Remark 7.1. Note that we have two copies of $[P_0(\Gamma_{jk})]^5$ on each Γ_{jk}, one from Ω_j to Ω_k and another from Ω_k to Ω_j.

An iterative procedure corresponding to (7.2) is defined as follows: for all $j = 1, \ldots, N$, choose an initial guess $(u_j^{\{h,0\}}, \tilde{\tilde{\lambda}}_j^{\{h,0\}}) \in \mathcal{V}^h(\Omega_j) \times \tilde{\tilde{\Lambda}}_{-1}^h$. Then, for $n = 1, 2, 3, \ldots$, compute $(u_j^{\{h,n\}}, \tilde{\tilde{\lambda}}_j^{\{h,n\}}) \in \mathcal{V}^h(\Omega_j) \times \tilde{\tilde{\Lambda}}_{-1,j}^h$ as the solution of the equations

$$\begin{aligned} &\sum_{Q \in \mathcal{T}^h(\Omega_j)} \big[-\omega^2\big(\mathcal{P}u_j^{\{h,n\}}, v\big)_Q + i\omega\big(\mathcal{B}u_j^{\{h,n\}}, v\big)_Q + \mathcal{A}_{h,Q}(u_j^{\{h,n\}}, v)\big] \\ &\quad + i\omega\big\langle \mathcal{D}\ S_{\Gamma_j}(u_j^{\{h,n\}}), S_{\Gamma_j}(v)\big\rangle_{\Gamma_j} + \sum_k \big\langle i\omega\beta_{jk}\mathcal{S}_{\Gamma_{jk}}(u_k^{\{h,n*\}}), \mathcal{S}_{\Gamma_{jk}}(v)\big\rangle_{\Gamma_{jk}} \\ &= (F, v)_{\Omega_j} - \sum_k \big\langle i\omega\beta_{jk}\mathcal{S}_{\Gamma_{jk}}(u_k^{\{h,n*\}}), \mathcal{S}_{\Gamma_{jk}}(v)\big\rangle_{\Gamma_{jk}} \\ &\quad + \sum_k \big\langle\big\langle \tilde{\tilde{\lambda}}_{kj}^{\{h,n*\}}, \mathcal{S}_{\Gamma_{jk}}(v)\big\rangle\big\rangle_{\Gamma_{jk}}, \quad v \in \mathcal{V}^h(\Omega_j), \end{aligned} \tag{7.3a}$$

$$\tilde{\tilde{\lambda}}_{jk}^{\{h,n\}} = \tilde{\tilde{\lambda}}_{kj}^{\{h,n*\}} - i\omega\beta_{jk}[S_{\Gamma_{jk}}(u_j^{\{h,n\}}) + S_{\Gamma_{kj}}(u_k^{\{h,n*\}})](\xi_{jk}) \quad \text{on } \Gamma_{jk} \forall k, \tag{7.3b}$$

for all $j = 1, \ldots, N$, where n^* is defined according to the iteration type as follows:

Jacobi type: $n^* = n - 1$.

Seidel type: $n^* = \begin{cases} n-1, & j < k, \\ n, & j > k, \end{cases}$

red-black type: $n^* = \begin{cases} n-1, & \Omega_j \text{ is red, i.e., } j \in I_R, \\ n, & \Omega_j \text{ is black, i.e., } j \in I_B. \end{cases}$

Here for the red-black type, the red and black parts of subdomains are given alternatively such that $\overline{\Omega} = \overline{[\cup_{j \in I_R} \Omega_j]} \cup \overline{[\cup_{j \in I_B} \Omega_j]}$. If, for $\{j,k\} \subset I_R$ or $\{j,k\} \subset I_B$, $\overline{\Omega}_j \cap \overline{\Omega}_k \neq \emptyset$, then $\overline{\Omega}_j \cap \overline{\Omega}_k$ consists of a common vertex (in 2D) or a common edge (in 3D) of Ω_j and Ω_k.

8. Convergence of the iterative procedure. Next, we analyze the convergence of the iterative procedure (7.3). For simplicity in the notation we consider the case $\beta_{jk} = \beta I$ with $\beta = \beta_R > 0$ and I being the identity matrix of suitable size.

It follows immediately from (6.1) that for j, k, $(\tilde{u}_j^h, \tilde{\lambda}_{jk}^h) \in \mathcal{V}^h(\Omega_j) \times \tilde{\Lambda}_{-1,j}^h$ satisfy the local equations

$$\sum_{Q \in \mathcal{T}^h(\Omega_j)} \left[-\omega^2(\mathcal{P}\tilde{u}^h, v)_Q + i\omega(\mathcal{B}\tilde{u}^h, v)_Q + \mathcal{A}_{h,Q}(\tilde{u}^h, v)\right]$$

$$-\sum_k \left\langle \left\langle \tilde{\lambda}_{jk}^h, v \right\rangle \right\rangle_{\Gamma_{jk}} + i\omega \left\langle \mathcal{D} S_{\Gamma_j}(\tilde{u}^h), S_{\Gamma_j}(v) \right\rangle_{\Gamma_j} = (F, v)_{\Omega_j},\ v \in \mathcal{V}^h(\Omega_j). \tag{8.1}$$

Also, since $\tilde{\lambda}_{jk}^h = \tilde{\lambda}_{kj}^h$, (6.1b) is equivalent to

$$\tilde{\lambda}_{jk}^h = \tilde{\lambda}_{kj}^h - i\omega\beta \left[S_{\Gamma_{jk}}(\tilde{u}_j^h) + S_{\Gamma_{kj}}(\tilde{u}_k^h)\right](\xi_{jk}) \quad \text{on } \Gamma_{jk} \forall k. \tag{8.2}$$

Since $\tilde{u}^h$ satisfies the error estimates given in Theorem 5.1, in order to show the convergence of the iteration procedure (7.3) it is sufficient to demonstrate that $u_j^{\{h,n\}} \to \tilde{u}_j^h$ and $\tilde{\tilde{\lambda}}_{jk}^{\{h,n\}} \to \tilde{\lambda}_{jk}^h$ as $n \to \infty$ for all j, k. For this, set

$$d_j^n = u_j^{\{h,n\}} - \tilde{u}_j^h, \quad x \in \Omega_j, \qquad \eta_{jk}^n = \tilde{\tilde{\lambda}}_{jk}^{\{h,n\}} - \tilde{\lambda}_{jk}^h \quad \text{on } \Gamma_{jk}.$$

Then, from (7.3)–(8.2), we obtain the following iteration error equations:

$$\sum_{Q \in \mathcal{T}^h(\Omega_j)} \left[-\omega^2 \left(\mathcal{P} d_j^n, v\right)_Q + i\omega \left(\mathcal{B} d_j^n, v\right)_Q + \mathcal{A}_{h,Q}(d_j^n, v)\right]$$

$$+ i\omega \left\langle \mathcal{D}\ S_{\Gamma_j}(d_j^n), S_{\Gamma_j}(v) \right\rangle_{\Gamma_j} - \sum_k \left\langle \left\langle \eta_{jk}^n, \mathcal{S}_{\Gamma_{jk}}(v) \right\rangle \right\rangle_{\Gamma_{jk}} = 0,\ v \in \mathcal{V}^h(\Omega_j), \tag{8.3a}$$

$$\eta_{jk}^n = \eta_{kj}^{n*} - i\omega\beta \left[S_{\Gamma_{jk}}(d_j^n) + S_{\Gamma_{kj}}(d_k^{n*})\right](\xi_{jk}) \quad \text{on } \Gamma_{jk} \forall k. \tag{8.3b}$$

Let us define the pseudoenergy R^n at the nth iteration step as follows:

$$R^n = R^n(d^n, \eta^n) = \sum_{j,k} |\eta_{jk}^n + i\omega\beta S_{\Gamma_{jk}}(d_j^n)(\xi_{jk})|_{0,\Gamma_{jk}}^2. \tag{8.4}$$

A similar argument to that in [21] shows that $d^n \to 0$ in $L^2(\Omega_j)$ and $\eta^n \to 0$ as n goes to ∞, so that the procedures (7.3) converge.

Let us turn to analyze the actual convergence rate by using a fixed point argument. Let $T_F : \mathcal{V}_{-1}^h \times \tilde{\tilde{\Lambda}}_{-1}^h \to \mathcal{V}_{-1}^h \times \tilde{\tilde{\lambda}}_{-1}^h$ be defined as follows: for any $(p, \theta) \in \mathcal{V}_{-1}^h \times \tilde{\lambda}_{-1}^h$, $(u, \eta) = T_F(p, \theta)$ is the solution of the equations

$$\sum_{Q\in\mathcal{T}^h(\Omega_j)} \big[-\omega^2 \left(\mathcal{P}u_j, v\right)_Q + i\omega \left(\mathcal{B}u_j, v\right)_Q + \mathcal{A}_{h,Q}(u_j, v)\big]$$

$$+ i\omega \left\langle \mathcal{D}\ S_{\Gamma_j}(u_j), S_{\Gamma_j}(v)\right\rangle_{\Gamma_j} + \sum_k \left\langle i\omega\beta_{jk}\mathcal{S}_{\Gamma_{jk}}(u_j), \mathcal{S}_{\Gamma_{jk}}(v)\right\rangle_{\Gamma_{jk}} \tag{8.5a}$$

$$= (F, v)_{\Omega_j} - \sum_k \left\langle i\omega\beta_{jk}\mathcal{S}_{\Gamma_{jk}}(p_k), \mathcal{S}_{\Gamma_{jk}}(v)\right\rangle_{\Gamma_{jk}} + \sum_k \left\langle\left\langle \theta_{kj}, \mathcal{S}_{\Gamma_{jk}}(v)\right\rangle\right\rangle_{\Gamma_{jk}},$$

$$v \in \mathcal{V}^h(\Omega_j),$$

$$\eta_{jk} = \theta_{kj} - i\omega\beta_{jk}\left[S_{\Gamma_{jk}}(u_j) + S_{\Gamma_{kj}}(p_k)\right](\xi_{jk}) \quad \text{on } \Gamma_{jk}\forall k, \tag{8.5b}$$

for all $j = 1, \ldots, N$.

Notice that $T_F(p,\theta) = T_0(p,\theta) + T_F(0,0)$ and (p,θ) is a fixed point of T_F if and only if

$$T_F(p,\theta) = (p,\theta) = T_0(p,\theta) + T_F(0,0).$$

Therefore, a fixed point of T_F is a solution of the equation

$$(I - T_0)(p,\theta) = T_F(0,0).$$

An estimate on the spectral radius of the operator T_0 can be obtained using similar arguments to those in [17, 21], as follows.

THEOREM 8.1. *Let $\rho(T_0)$ be the spectral radius of T_0. Then $\rho(T_0) < 1$ and consequently the iterative procedure* (7.3) *is convergent.*

9. The triangular and the three-dimensional cases.

9.1. The triangular element case. Let $\overline{\Omega} = \cup_{j=1}^J \overline{Q}_j$ be a quasi-regular partition of Ω into triangles Q_j's; here, Ω can be a convex polygon. Let us change the definition of the set $\mathcal{NC}_j^h$ in section 4 to $\mathcal{NC}_j^h = [P_1(Q_j)]^2$, with the degrees of freedom being the midpoint values of the edges of Q_j. Also, change the definition of the space $\mathcal{W}_j$ to be the vector part of the Raviart–Thomas–Nedelec mixed finite element space of zero order based on triangles [34, 30], with the degrees of freedom being the values of the normal component of the fluid displacement vector at the midpoints of the edges of Q_j.

An inspection of the analysis shows that all the conclusions presented for the rectangular case in Theorem 4.1 about the existence and uniqueness of the solution u^h of (4.4), the a priori error estimates in derived in Theorem 5.1, and the convergence of the iterative domain decomposition method in Theorem 8.1 remain valid for the new definition of the space $\mathcal{V}^h$.

9.2. The three-dimensional case. Let $Q_j, j = 1, \ldots, J$, be a nonoverlapping partition of Ω. If the Q_j's are tetrahedrons we take $\mathcal{NC}_j^h = [P_1(Q_j)]^3$. If the Q_j's are cubic elements, we set $\widehat{R} = (-1,1)^3$ and

$$\widehat{S}(\widehat{R}) = \mathrm{Span}\big\{1, \widehat{x}, \widehat{y}, \widehat{z}, \alpha(\widehat{x}) - \alpha(\widehat{y}), \alpha(\widehat{x}) - \alpha(\widehat{z})\big\} \tag{9.1}$$

$$= \mathrm{Span}\left\{\frac{1}{2}\widehat{x} \pm \frac{\alpha(\widehat{x})}{2\alpha(1)}, \frac{1}{2}\widehat{y} \pm \frac{\alpha(\widehat{y})}{2\alpha(1)}, \frac{1}{2}\widehat{z} \pm \frac{\alpha(\widehat{z})}{2\alpha(1)}\right\},$$

and choose $\mathcal{NC}_j^h = [S(Q_j)]^3$. The four and six degrees of freedom associated with the tetrahedron case and (9.1) are the values at the centers of the faces. Also, take $\mathcal{W}_j$ to

TABLE 1

be the Raviart–Thomas–Nedelec space of order zero over either tetrahedrons or cubic elements depending on Q_j[30].

Next, change the definitions of the spaces $\mathcal{V}^h$, $\mathcal{V}^h_{-1}$, $\tilde{\Lambda}^h_s, \tilde{\Lambda}^h_{-1,j}$, and $\tilde{\tilde{\Lambda}}^h_{-1,j}$ in the obvious fashion. With these changes in the definitions, all the results derived for the 2D case remain unchanged.

10. Numerical experiments. We performed wave propagation simulation in a sample of water-saturated partially frozen Berea sandstone, with an interior plane interface Γ defined by a change in ice content in the pores. In this case $\Omega^{(1)}$ and $\Omega^{(3)}$ correspond to the sandstone and ice, respectively. The material properties of the system, taken from [9, 12], are given in Table 1. Since we would like to run an experiment in which the slow waves can actually be observed in the low-frequency range, the water viscosity value was taken to be of 10^{-6} centipoise. The computational domain Ω is a square of side length $L = 3$ km with a uniform partition of Ω into squares of side length $h = L/261$. The absolute porosity is $\phi^{(a)} = .18$, with the ice content in the pores changing from $S^{(3)'} = 20$ percent in the lower layer to $S^{(3)'} = 82$ percent in the upper layer.

The source function is a point source representing a force applied to the rock frame in the vertical z direction, located at ($x_s = 1.5$ km, $z_s = 1.88$ km). It has the form $F = (F^{(1)}, F^{(2)}, F^{(3)})^t = (F^{(1)}, 0, 0)^t$,

$$F^{(1)} = \left(0, \frac{\partial \delta_{(x_s,z_s)}}{\partial z}\right)^t g(\omega),$$

where $\delta_{(x_s,z_s)}$ denotes the Dirac distribution and $g(\omega)$ is the Fourier transform of the waveform of central (dominant) frequency $f_0 = 12$ Hz given by

$$g(t) = -2\xi(t - t_0)e^{-\xi(t-t_0)^2},$$

with $\xi = 8\ f_0^2$, $t_0 = 1.25/f_0$.

For the calculation of the elastic coefficients we need values for the bulk and shear moduli of the two solid (dry) frames, denoted by $K_m^{(s1)}, K_m^{(s3)}, \mu_m^{(s1)}$, and $\mu_m^{(s3)}$, respectively. Following [24, 12, 37], it is assumed that $K_m^{(s1)} = 14.4$ GPa and that the

TABLE 2
Wave speeds and attenuation factors for all waves at frequency 12 Hz.

	Ice content 0.82		Ice content 0.20	
Wave	Phase velocity (km/s)	Attenuation (dB)	Phase velocity (km/s)	Attenuation (dB)
Fast P1 wave	4.316	$1.872\,10^{-3}$	3.723	$4.282\,10^{-2}$
Slow P2 wave	1.463	1.825	$7.281\,10^{-1}$	$1.151\,10^{1}$
Slow P3 wave	$9.577\,10^{-2}$	$4.053\,10^{1}$	$1.192\,10^{-1}$	6.562
Fast S1 wave	2.946	1.281	2.384	$2.202\,10^{-1}$
Slow S2 wave	$7.104\,10^{-1}$	$5.582\,10^{-2}$	$1.013\,10^{-1}$	$4.605\,10^{-1}$

modulus $\mu_m^{(s1)}$, $\mu_m^{(s3)}$, and $K_m^{(s3)}$ can be computed using a percolation-type model with critical exponent 3.8 [13] using the relations

$$\mu_m^{(sj)} = \left[\mu_m^{(sj),max} - \mu_m^{(sj),0}\right]\left[\frac{\phi^{(3)}}{1-\phi^{(1)}}\right]^{3.8} + \mu_m^{(sj),0}, \quad j = 1, 3,$$

$$K_m^{(s3)} = \left[K_m^{(s3),max} - K_m^{(s3),0}\right]\left[\frac{\phi^{(3)}}{1-\phi^{(1)}}\right]^{3.8} + K_m^{(s3),0},$$

where $\mu_m^{(s1),max}, \mu_m^{(s3),max}$, and $K_m^{(s3),max}$ are computed using the Kuster and Toksöz model [23], taking the known values of $K^{(s1)}, \mu^{(s1)}, K^{(s3)}, \mu^{(s3)}$ for the background medium with inclusions of air, with properties $K^{(a)}, \mu^{(a)}$ (see Table 1). The moduli $\mu_m^{(s1),0}$, $\mu_m^{(s3),0}$, and $K_m^{(s3),0}$ are appropriate reference values, which we take as

$$\mu_m^{(s1),0} = 13.3 \text{ GPa}, \quad K_m^{(s3),0} = \mu_m^{(s3),0} = 0.$$

The viscoelastic parameters describing the dissipative behavior of the saturated sandstone are given as follows: $T_{1,M} = (2\pi\,10)^{-1}$ms, $T_{2,M} = (2\pi\,10^9)^{-1}$ms, and the mean quality factors are taken to be $\widehat{Q}_M = 300$ for $M = K_G^{(1)}, K_G^{(3)}, \mu^{(1)}, \mu^{(3)}, K_{av}$. The value of the Kozeny–Carman constant was taken to be 5 [22]. Also, the coefficient b_{13} in the definition (2.4) of the mass and viscous coupling coefficients was taken to be zero.

Table 2 displays values of the phase velocity and attenuation factors at 12 Hz for the five different types of waves for the two-layer model used in this experiment.

The following figures present snapshots of the wave fields for this experiment, generated after solving (7.3) for 110 equally spaced temporal frequencies in the interval $(0, 12\,\text{Hz})$ and using an approximate inverse Fourier transform as explained in [16].

Figures 1, 2, and 3 show, respectively, snapshots of the vertical component of the particle velocity of the three phases at $t = 410$ ms, where we can observe that after arriving at the interface Γ, the direct P1 wave labeled P1D has generated the transmitted fast P1 wave labeled P1T-P1D and the slow P2 transmitted and reflected waves labeled P2R-P1D and P2T-P1D, respectively. Also, after arriving at Γ, the direct fast shear wave labeled S1D has generated the transmitted and reflected fast shear waves labeled S1T-S1D and S1R-S1D, respectively. In the snapshots for the ice and fluid phases in Figures 2 and 3 we can also observe the direct slow P2 wave front labeled P2D. The relative amplitudes among the snapshots in Figures 1, 2, and 3 are 1, 0.56873, and 0.023708, respectively. We observe that the slow P2 wave is observed better in the ice and fluid phases than in the solid matrix phase.

AN ADAPTIVE FINITE ELEMENT METHOD FOR THE LAPLACE–BELTRAMI OPERATOR ON IMPLICITLY DEFINED SURFACES*

ALAN DEMLOW† AND GERHARD DZIUK‡

Abstract. We present an adaptive finite element method for approximating solutions to the Laplace–Beltrami equation on surfaces in $\mathbb{R}^3$ which may be implicitly represented as level sets of smooth functions. Residual-type a posteriori error bounds which show that the error may be split into a "residual part" and a "geometric part" are established. In addition, implementation issues are discussed and several computational examples are given.

Key words. Laplace–Beltrami operator, adaptive finite element methods, a posteriori error estimation, boundary value problems on surfaces

1. Introduction.

In this paper we derive residual-based a posteriori error estimates for piecewise linear finite element approximations to solutions of the Laplace–Beltrami equation

$$\begin{aligned} -\Delta_\Gamma u &= f \text{ on } \Gamma, \\ u &= 0 \text{ on } \partial\Gamma. \end{aligned} \tag{1.1.1}$$

Here Γ is a connected two-dimensional surface embedded in $\mathbb{R}^3$, and $-\Delta_\Gamma$ is the Laplace–Beltrami operator on Γ. $\partial\Gamma$ is required to be "piecewise curvilinear" in a sense which we will make precise below. We also allow $\partial\Gamma = \emptyset$, in which case the conditions $\int_\Gamma f \, d\sigma = \int_\Gamma u \, d\sigma = 0$ are required to guarantee existence and uniqueness of u. Here $d\sigma$ is the surface measure on Γ.

A finite element method for (1.1.1) was introduced in [Dz88]. Let Γ_h be a polyhedral approximation to Γ having triangular faces, and let S_h be the continuous functions which are affine on each face of Γ_h. We then let $u_h \in S_h$ solve

$$\int_{\Gamma_h} \nabla_{\Gamma_h} u_h \nabla_{\Gamma_h} v_h \, d\sigma_h = \int_{\Gamma_h} v_h f_h \, d\sigma_h \quad \forall \, v_h \in S_h. \tag{1.1.2}$$

Here ∇_{Γ_h} is the tangential derivative on Γ_h, σ_h is the surface measure on Γ_h, and f_h is an approximation to f on Γ_h. As above, we require the side conditions $\int_{\Gamma_h} f_h \, d\sigma_h = \int_{\Gamma_h} u_h \, d\sigma_h = 0$ if $\partial\Gamma_h = \emptyset$.

A key feature of our theoretical development is that Γ is represented as the 0 level set of a signed distance function d with $|d(x)| = dist(x, \Gamma)$. Our approach requires

access to the derivatives of d (the normal vector and curvature tensor) and also requires that Γ_h lie in a strip about Γ on which a unique orthogonal projection $a(x)$ onto Γ is defined. This projection is instrumental in suitably defining the discrete data f_h and also in carrying out both a priori and a posteriori error analysis. Also, if $\partial\Gamma$ is nonempty we shall require that $\partial\Gamma = a(\partial\Gamma_h)$ so that $\partial\Gamma$ is in a sense piecewise curvilinear. This is similar to requiring polygonal boundaries when performing finite element calculations on domains in $\mathbb{R}^n$ in that it rules out "variational crimes" resulting from boundary approximations.

In practice, Γ often is defined as a level set of a function ζ which is not a distance function. In this situation one must approximate the projection $a(x)$ numerically, and the other necessary geometric information may then be computed in a straightforward fashion. In practical terms, the resulting finite element code requires the user to supply the data f, the level set function ζ and its first and second derivatives, and an initial mesh which lies in a sufficiently narrow strip about Γ to guarantee that the projection a is a bijection between Γ_h and Γ. In what follows we shall discuss some details of our implementation in addition to providing a posteriori error estimates.

Optimal-order $H^1(\Gamma)$ and $L_2(\Gamma)$ a priori estimates for the method (1.1.2) were proved in [Dz88]. Roughly speaking, the finite element error may be broken into an *almost-best-approximation* term typical of finite element methods in $\mathbb{R}^n$, a *geometric error term* which is due to the discretization of Γ, and a *data approximation term* due to the approximation of f on Γ by f_h on Γ_h. On a mesh whose elements have diameter h, the latter two terms are of order h^2 for typical choices of f_h and are thus of higher order when the error is measured in the H^1-norm.

In this paper we provide a posteriori error control in the $H^1(\Gamma)$-norm via residual-type estimators. As in the a priori analysis, the error is split into three terms: a *residual indicator term*, a *geometric error term*, and a *data approximation term*. Computation of these error terms requires pointwise access to geometric information, in particular to the projection a and the normal vector and curvature tensor on Γ. However, the asymptotically dominant term requires no explicit geometric quantities except those which are necessary to compute the discrete data f_h.

A relatively simple setting is assumed here in order to concentrate on effects arising from the discretization of Γ. In particular, we do not consider problems with nonconstant coefficients, the case where $a(\Gamma_h) \neq \Gamma$, lower-order terms, or nonhomogeneous Dirichlet or Neumann boundary conditions. These additional complexities may be handled in much the same way as for problems on polygonal domains in $\mathbb{R}^2$, so we refer, for example, to the works [DR98], [DW00], [BCD04], [MN05], and [AO00], where many of these issues are considered. Under suitable assumptions, our development also holds largely unchanged for surfaces of codimension 1 which are immersed in $\mathbb{R}^n$, $n \geq 2$.

In order to conclude the introduction, we briefly describe other strategies for performing adaptive finite element calculations on surfaces. One possibility is the use of a global parametrization to represent Γ and define a suitable mesh. This approach was taken in [AP05] to perform adaptive finite element calculations on the sphere. The key to this method is a global parametrization which maps a triangulated planar domain onto the sphere in such a way that the resulting curved "triangles" are isotropic (shape-regular). A more general approach using local parametrizations (charts) to represent 2- and 3-manifolds is described in [Ho01].

The technique we present here has several advantages when compared with the two described above. Extending the use of global parametrizations to surfaces other than the sphere is relatively difficult because a new parametrization must be found for

every surface on which computations are to be performed. In addition, the analysis of the Clemént-type interpolant used to prove reliability of a posteriori estimates in [AP05] is specific to the sphere and would have to be redone for other surfaces. In contrast, implementation of our method is quite straightforward for the sphere and may be carried out in a fairly general way for a large class of surfaces. The analysis we give here also is not restricted to any particular surface. The use of local parametrizations described in [Ho01] provides a framework for computations on manifolds which is in some ways more general than that which we propose here. However, the use of overlapping local charts adds to the complexity of both the resulting finite element code and the theoretical analysis. Indeed, the issue of approximation theory when using local charts is not addressed rigorously in [Ho01]. A final advantage of our approach is that it provides rigorous theoretical background for adaptive methods in certain situations in which no parametrization is available, such as implicit computations of surfaces evolving, for example, by mean curvature flow (cf. [Dz91], [BMN05], [CDDRR04]).

This paper is organized as follows: In section 2 we give a number of preliminaries and assumptions necessary for our theoretical development. In section 3 we then prove global a posteriori upper bounds and local lower bounds. In section 4 our implementation is described. In section 5, we demonstrate the flexibility of our approach by describing computational experiments on three different surfaces: a spherical subdomain with a nonempty boundary, a torus (which is nonconvex and has a topological type different than that of the sphere), and an ellipsoid (which requires numerical approximation of the distance function).

2. Preliminaries and assumptions.

2.1. The continuous surface Γ. We assume that Γ is a connected C^2 compact hypersurface which is the zero level set of a signed distance function $|d(x)| = dist(x, \Gamma)$ defined on an open subset U_0 of $\mathbb{R}^3$. If $\partial\Gamma = \emptyset$ we also assume for simplicity that $d < 0$ on the interior of Γ and $d > 0$ on the exterior. $\vec{\nu} = \nabla d$ is then the outward-pointing unit normal on Γ. Note that $|\vec{\nu}| = 1$ wherever d is defined. Let also $\mathbf{H} : \mathbb{R}^3 \to \mathbb{R}^{3\times 3}$ be the Weingarten map defined by

$$\mathbf{H}_{ij}(x) = \vec{\nu}_{i,x_j}(x) = \vec{\nu}_{j,x_i}(x), \tag{2.2.1}$$

that is, $\mathbf{H}(x) = D^2 d(x)$, and let $\kappa_i(x)$, $i = 1, 2$, and 0 be the eigenvalues of $\mathbf{H}(x)$. For $x \in \Gamma$, κ_1 and κ_2 are the principal curvatures.

Next we define the projection

$$a(x) = x - d(x)\vec{\nu}(x). \tag{2.2.2}$$

We then let $U \subset \mathbb{R}^3$ be a strip of width δ about Γ, where $\delta > 0$ is sufficiently small to ensure that the decomposition

$$x = a(x) + d(x)\vec{\nu}(x) \tag{2.2.3}$$

is unique for $x \in U$. We require that

$$\delta < \left[\max_{i=1,2} \|\kappa_i\|_{L_\infty(\Gamma)}\right]^{-1}. \tag{2.2.4}$$

For $x \in U$, we also note the useful formula

$$\kappa_i(x) = \frac{\kappa_i(a(x))}{1 + d(x)\kappa_i(a(x))} \tag{2.2.5}$$

for the curvature of parallel surfaces, cf. Lemma 14.17 of [GT98].

The condition (2.2.4) is sufficient to ensure that the decomposition (2.2.3) is *locally* unique (cf. [GT98, section 14.6]), but we require that it be globally unique. This global requirement is a simplifying assumption which restricts our presentation to embedded surfaces. Immersed surfaces (including surfaces with self-intersections) could also be considered with slight changes to our presentation.

We may uniquely extend a function ψ defined on Γ to U by

$$\psi^\ell(x) = \psi(a(x)) \tag{2.2.6}$$

for $x \in U$. Let

$$\mathbf{P} = \mathbf{I} - \vec{\nu} \otimes \vec{\nu}, \tag{2.2.7}$$

where $\otimes$ is the tensor or outer product $\vec{a} \otimes \vec{b} = \vec{a}\vec{b}^T$ (vectors here are in column form). We then define the tangential gradient

$$\nabla_\Gamma \psi = \nabla \psi^\ell - (\vec{\nu} \cdot \nabla \psi^\ell)\vec{\nu} = \mathbf{P} \nabla \psi^\ell \tag{2.2.8}$$

for ψ defined on Γ and extended to U via (2.2.6). Note that $\nabla_\Gamma \psi$ depends only on the values of ψ on Γ even though its definition formally involves the extension of ψ to Γ. Note also that $-\Delta_\Gamma = -\nabla_\Gamma \cdot \nabla_\Gamma$. Finally, we denote by $H^1(\Gamma)$ the functions on Γ having a tangential gradient in $L^2(\Gamma)$.

2.2. The discrete surface Γ_h and mesh $\mathcal{T}_h$. Let $\Gamma_h \subset U$ be a polyhedron consisting of a set $\mathcal{T}_h$ of triangular faces, that is, $\Gamma_h = \cup_{T \in \mathcal{T}_h} \overline{T}$. Let also $\vec{\nu}_h$ denote the (piecewise constant) unit outer normal on Γ_h, and let $\mathcal{N}$ denote the set of nodes of triangles in $\mathcal{T}_h$. We assume that $a : \Gamma_h \to \Gamma$ is bijective and that $\vec{\nu} \cdot \vec{\nu}_h > 0$ everywhere on Γ_h. We note that it is often simplest to define Γ_h so that $\mathcal{N} \subset \Gamma$, but this is not theoretically required in any way. Also denote by h_T the diameter of $T \in \mathcal{T}_h$. Given $z \in \mathcal{N}$, we define the patch $\omega_z = interior(\cup_{\overline{T} \ni z} \overline{T})$ and let $h_z = \max_{T \subset \omega_z} h_T$. Also, let $\mathcal{E}$ denote the set of edges of triangles in $\mathcal{T}_h$. Finally, $\varphi_z \in S_h$ denotes the canonical basis function associated to z, that is, $\varphi_{z_i}(z_j) = \delta_{ij}$ for $z_i, z_j \in \mathcal{N}$.

Analyses of a posteriori estimates for finite element methods on domains in $\mathbb{R}^n$ typically assume that the underlying mesh is shape-regular, that is, all elements in $\mathcal{T}_h$ have a bounded aspect ratio. Under this assumption, constants depending on the aspect ratio of the elements of the mesh are then bounded and may be absorbed into a global constant of moderate size. This approach is reasonable because typical mesh refinement algorithms preserve shape-regularity.

The situation is somewhat more complicated in the current context of finite element methods on surfaces. The first issue which arises is that the mesh is perturbed after each refinement by projecting newly created nodes onto the continuous surface Γ via a. While these perturbations are asymptotically negligible, we are not aware of a proof that the refinement/perturbation procedure described here maintains shape regularity beginning from an arbitrary shape-regular mesh with nodes on Γ and lying in U. A second problem is that, in contrast to the situation in $\mathbb{R}^n$, shape regularity does not automatically imply that the number of triangles sharing a given node is bounded. However, if the number of elements in the patches of the initial coarse mesh used to begin the refinement algorithm is bounded, we may guarantee that such a bound will hold for all subsequent meshes by applying a suitable refinement algorithm. This is, in particular, the case for the newest-node subdivision algorithm.

As we have not been able to theoretically guarantee that a family of meshes maintains shape regularity under mesh refinement, we take the following approach.

We first prove a posteriori bounds which do not assume shape regularity. In these estimates, lack of shape regularity is penalized by a single factor. In our computational examples we do not include this penalty factor in our estimator but instead monitor it to ensure that mesh quality remains acceptable. In our examples, the penalty term remains of moderate size when refining meshes which initially lie within U.

2.3. Lifts and extensions of functions. Given a function v_h defined on Γ_h, we define the lift $\tilde{v}_h$ by $v_h(x) = \tilde{v}_h(a(x))$ for $x \in \Gamma_h$. We may then extend $\tilde{v}_h$ to U by (2.2.6). For v_h defined on Γ_h and $x \in U$, we thus define

$$v_h^\ell(x) = \tilde{v}_h(a(x)). \tag{2.2.9}$$

The overall effect of (2.2.9) is to extend v_h defined on Γ_h to U. Formally, however, this operation consists of a lift to Γ followed by extension to U. We emphasize that *all* extentions of functions to U referred to in this paper are constant along normals to Γ. Thus for our purposes extensions of functions defined on Γ and of functions defined on Γ_h have essentially the same properties.

Letting $\vec{\nu}_h$ denote the normal on Γ_h, we define for $x \in \Gamma_h$

$$\mathbf{P}_h(x) = \mathbf{I} - \vec{\nu}_h(x) \otimes \vec{\nu}_h(x) \tag{2.2.10}$$

so that, for V defined on U and $x \in \Gamma_h$,

$$\nabla_{\Gamma_h} V(x) = \mathbf{P}_h \nabla V(x). \tag{2.2.11}$$

We see from (2.2.2) and (2.2.9) that, for $x \in \Gamma_h$ and v_h defined on Γ_h,

$$\nabla v_h^\ell(x) = [(\mathbf{P} - d\mathbf{H})(x)] \nabla v_h^\ell(a(x)). \tag{2.2.12}$$

Since $\vec{\nu} \cdot \vec{\nu} \equiv 1$, we have $\vec{\nu}\mathbf{H} = \mathbf{H}\vec{\nu} = 0$ and $\mathbf{P}\mathbf{H} = \mathbf{H}\mathbf{P} = \mathbf{H}$ so that, for $x \in \Gamma_h$,

$$\nabla v_h^\ell(x) = [(\mathbf{I} - d\mathbf{H})(x)][\mathbf{P}(x)] \nabla v_h^\ell(a(x)) = [(\mathbf{I} - d\mathbf{H})(x)] \nabla_\Gamma v_h^\ell(a(x)). \tag{2.2.13}$$

Thus

$$\nabla_{\Gamma_h} v_h(x) = \nabla_{\Gamma_h} v_h^\ell(x) = [\mathbf{P}_h(x)][(\mathbf{I} - d\mathbf{H})(x)][\mathbf{P}(x)] \nabla_\Gamma v_h^\ell(a(x)). \tag{2.2.14}$$

Correspondingly, for $\psi \in H^1(\Gamma)$ (2.2.6) yields

$$\nabla_{\Gamma_h} \psi^\ell(x) = [\mathbf{P}_h(x)][(\mathbf{I} - d\mathbf{H})(x)][\mathbf{P}(x)] \nabla_\Gamma \psi(a(x)). \tag{2.2.15}$$

For $x \in \Gamma_h$, (2.2.13) yields

$$\nabla_\Gamma v_h^\ell(a(x)) = [(\mathbf{I} - d\mathbf{H})(x)]^{-1} \nabla v_h^\ell(x). \tag{2.2.16}$$

The invertibility of $[(\mathbf{I} - d\mathbf{H})(x)]$ on U may be derived from (2.2.4) and (2.2.5). Indeed, if e_1 and e_2 are the eigenvectors of $\mathbf{H}$ corresponding to $\kappa_1(x)$ and $\kappa_2(x)$, then $[(\mathbf{I} - d\mathbf{H})(x)]^{-1} = \vec{\nu} \otimes \vec{\nu} + (1 + d(x)\kappa_1(a(x)))e_1 \otimes e_1 + (1 + d(x)\kappa_2(a(x)))e_2 \otimes e_2$. We shall need to compute $\nabla_\Gamma v_h^\ell$ when $v_h \in S_h$. In such cases we initially have access only to the tangential derivative $\nabla_{\Gamma_h} v_h$ and not to ∇v_h^ℓ, which according to (2.2.16) is necessary to compute $\nabla_\Gamma v_h^\ell$. Since $\nabla_{\Gamma_h} v_h(x) = [\mathbf{P}_h(x)] \nabla v_h^\ell(x)$, we have $0 = \nabla v_h^\ell(x) \cdot \vec{\nu} = \nabla_{\Gamma_h} v_h(x) \cdot \vec{\nu} + (\vec{\nu}_h \cdot \vec{\nu}) \nabla v_h^\ell(x) \cdot \vec{\nu}_h$. Thus

$$\nabla v_h^\ell(x) \cdot \vec{\nu}_h = -\frac{\nabla_{\Gamma_h} v_h(x) \cdot \vec{\nu}}{\vec{\nu}_h \cdot \vec{\nu}}, \tag{2.2.17}$$

and for $x \in \Gamma_h$

$$\nabla v_h^\ell(x) = \left[\mathbf{I} - \frac{\vec{\nu}_h \otimes \vec{\nu}}{\vec{\nu}_h \cdot \vec{\nu}}\right] \nabla_{\Gamma_h} v_h(x). \tag{2.2.18}$$

Combining (2.2.16) and (2.2.18), we thus find that, for $x \in \Gamma_h$,

$$\nabla_\Gamma v_h^\ell(a(x)) = [(\mathbf{I} - d\mathbf{H})(x)]^{-1} \left[\mathbf{I} - \frac{\vec{\nu}_h \otimes \vec{\nu}}{\vec{\nu}_h \cdot \vec{\nu}}\right] \nabla_{\Gamma_h} v_h(x). \tag{2.2.19}$$

Next we state an integral equality which we shall use repeatedly. For $x \in \Gamma_h$, let

$$\mu_h(x)\, \mathrm{d}\sigma_h(x) = \mathrm{d}\sigma(a(x)), \tag{2.2.20}$$

and also let

$$\mathbf{A}_h(x) = \mathbf{A}_h^\ell(a(x)) = \frac{1}{\mu_h(x)} [\mathbf{P}(x)][(\mathbf{I} - d\mathbf{H})(x)][\mathbf{P}_h(x)][(\mathbf{I} - d\mathbf{H})(x)][\mathbf{P}(x)]. \tag{2.2.21}$$

Then from (2.2.14) and (2.2.15), we have

$$\int_{\Gamma_h} \nabla_{\Gamma_h} v_h \nabla_{\Gamma_h} \psi_h \, \mathrm{d}\sigma_h = \int_\Gamma \mathbf{A}_h^\ell \nabla_\Gamma v_h^\ell \nabla_\Gamma \psi_h^\ell \, \mathrm{d}\sigma. \tag{2.2.22}$$

Note that this equality holds without regard to the original domain of definition of v_h and ψ; that is, we may for example replace ψ_h and ψ_h^ℓ with ψ^ℓ and ψ, respectively, where $\psi \in H^1(\Gamma)$. We also emphasize that the quantities d and $\mathbf{H}$ in (2.2.21) are always evaluated on the discrete surface Γ_h, even though $\mathbf{A}_h^\ell$ often appears in integrals over the continuous surface Γ.

Finally we give an explicit formula for the quantity μ_h defined above. The proof of this formula is tedious but elementary, and we sketch it in Appendix A.

PROPOSITION 2.1. *Assume that $x \in \Gamma_h$. Then*

$$\mu_h(x) = (1 - d(x)\kappa_1(x))(1 - d(x)\kappa_2(x))\vec{\nu} \cdot \vec{\nu}_h. \tag{2.2.23}$$

2.4. Interpolation and Poincaré inequality. In this section we define an interpolant and prove error bounds for it. Given $\psi \in L_1(\Gamma)$ and $z \in \mathcal{N}$, we let

$$\psi_z^\ell = \frac{1}{\int_{\omega_z} \varphi_z \, \mathrm{d}\sigma_h} \int_{\omega_z} \varphi_z \psi^\ell \, \mathrm{d}\sigma_h \tag{2.2.24}$$

and define

$$I_h \psi^\ell = \sum_{z \in \mathcal{N}} \psi_z^\ell \varphi_z. \tag{2.2.25}$$

A similar interpolant is used, for example, in [FV06] to prove a posteriori bounds on a domain in $\mathbb{R}^2$. Noting that $\{\varphi_z\}_{z \in \mathcal{N}}$ is a partition of unity, we then have the following relationship:

$$\int_{\Gamma_h} (\psi^\ell - I_h \psi^\ell) \, \mathrm{d}\sigma_h = \sum_{z \in \mathcal{N}} \int_{\omega_z} (\psi^\ell - \psi_z^\ell) \varphi_z \, \mathrm{d}\sigma_h = 0. \tag{2.2.26}$$

LEMMA 2.2 (Poincaré inequality). *Let $\psi \in H^1(\Gamma)$. Let m_z be the number of elements sharing the node z, and let $\tilde{\omega}_z$ be the lift of the patch ω_z onto Γ . Then for each $z \in \mathcal{N}$,*

$$\|\psi^\ell - \psi_z^\ell\|_{L_2(\omega_z)} \le C \max_{T\subset\omega_z} \sqrt{|T|} m_z \max_{T\subset\omega_z} \frac{h_T}{\sqrt{|T|}} \|\mathbf{A}_h\|^{\frac{1}{2}}_{\ell_2,L_\infty(\omega_z)} \|\nabla_\Gamma \psi\|_{L_2(\tilde{\omega}_z)}. \tag{2.2.27}$$

Let also $z \in \overline{e} \in \mathcal{E}$. Then

$$\|\psi^\ell - \psi_z^\ell\|_{L_2(e)} \le C\sqrt{|e|} m_z \max_{T\subset\omega_z} \frac{h_T}{\sqrt{|T|}} \|\mathbf{A}_h\|^{\frac{1}{2}}_{\ell_2,L_\infty(\omega_z)} \|\nabla_\Gamma \psi\|_{L_2(\tilde{\omega}_z)}. \tag{2.2.28}$$

Here $\|\mathbf{A}_h\|_{\ell_2,L_\infty(\omega_z)} = \|\|\mathbf{A}_h\|_{\ell_2\to\ell_2}\|_{L_\infty(\omega_z)}$, where $\|\cdot\|_{\ell_2\to\ell_2}$ is the standard matrix 2-norm, and C does not depend on any essential quantities.

Remark 2.3. The terms in (2.2.27) and (2.2.28) may be classified as follows: In shape-regular meshes the quantities $\max_{T\subset\omega_z}\sqrt{|T|}$ and $\sqrt{|e|}$ may be reduced to h_z and $h_z^{1/2}$, respectively, where h_z is the maximum element diameter in ω_z. The factor m_z accounts for the number of elements sharing the vertex z if this number is not known to be bounded, and the factor $\max_{T\subset\omega_z} h_T/\sqrt{|T|}$ accounts for the aspect ratio of T. If $\mathcal{T}_h$ is shape-regular and m_z is bounded, we thus have

$$\|\psi^\ell - \psi_z^\ell\|_{L_2(\omega_z)} \le C h_z \|\mathbf{A}_h\|^{\frac{1}{2}}_{\ell_2,L_\infty(\omega_z)} \|\nabla_{\Gamma_h} \psi^\ell\|_{L_2(\omega_z)}, \tag{2.2.29}$$

$$\|\psi^\ell - \psi_z^\ell\|_{L_2(e)} \le C h_z^{\frac{1}{2}} \|\mathbf{A}_h\|^{\frac{1}{2}}_{\ell_2,L_\infty(\omega_z)} \|\nabla_\Gamma \psi\|_{L_2(\tilde{\omega}_z)}, \tag{2.2.30}$$

where C does not depend on essential quantities.

Proof. We first show that I_h is locally L_2-stable independent of mesh properties. Note first that

$$\|\psi_z^\ell\|_{L_2(\omega_z)} = |\omega_z|^{1/2}|\psi_z^\ell| \le |\omega_z|^{1/2} \frac{\|\varphi_z\|_{L_2(\omega_z)}}{\|\varphi_z\|_{L_1(\omega_z)}} \|\psi^\ell\|_{L_2(\omega_z)}. \tag{2.2.31}$$

If z is an interior node, we let $\hat{\omega}_z$ be a regular m_z-gon with vertices lying on the unit circle. If z is a boundary node, then we let $\hat{\omega}_z$ be one half of a regular $2m_z$-gon with vertices lying on the unit circle. In either case the reference domain $\hat{\omega}_z$ is convex and may be broken into m_z congruent triangles with the origin being a vertex of each. There is a natural piecewise-affine transformation $F_z : \hat{\omega}_z \to \omega_z$. We denote by $\hat{T}$ the inverse image of $T \subset \omega_z$ and by $\hat{u}$ the inverse image of $u \in H^1(\Gamma_h)$ under this transformation. For $p = 1$ or $p = 2$ and any $\hat{T} \subset \hat{\omega}_z$,

$$\|\varphi_z\|^p_{L_p(\omega_z)} = \sum_{T\subset\omega_z} \int_T \varphi_z^p \,\mathrm{d}\sigma_h = \sum_{T\subset\omega_z} \frac{|T|}{|\hat{T}|} \int_{\hat{T}} \hat{\varphi}_z^p \,\mathrm{d}\hat{x} = |\omega_z| \frac{\int_{\hat{T}} \hat{\varphi}_z^p \,\mathrm{d}\hat{x}}{|\hat{T}|}. \tag{2.2.32}$$

An elementary calculation yields $\sqrt{|\hat{T}|}\frac{\|\hat{\varphi}_z\|_{L_2(\hat{T})}}{\|\hat{\varphi}_z\|_{L_1(\hat{T})}} = \sqrt{\frac{3}{2}}$, which when combined with (2.2.31) and (2.2.32) yields

$$\|\psi_z^\ell\|_{L_2(\omega_z)} \le \sqrt{\frac{3}{2}} \|\psi^\ell\|_{L_2(\omega_z)}. \tag{2.2.33}$$

Thus for any $K \in \mathbb{R}$,

$$\|\psi^\ell - \psi_z^\ell\|_{L_2(\omega_z)} \le \left(1 + \sqrt{\frac{3}{2}}\right) \|\psi^\ell - K\|_{L_2(\omega_z)}. \tag{2.2.34}$$

Choosing $K = \frac{1}{|\hat{\omega}_z|}\int_{\hat{\omega}_z} \hat{\psi}^\ell \,\mathrm{d}\hat{x}$ and noting that $\nabla\hat{\psi}^\ell = \nabla_{\Gamma_h}\psi^\ell \nabla F_z$, we next find that

$$
\begin{aligned}
\|\psi^\ell - K\|^2_{L_2(\omega_z)} &= \sum_{T\subset\omega_z} \frac{|T|}{|\hat{T}|}\int_{\hat{T}} (\hat{\psi}^\ell - K)^2 \,\mathrm{d}\hat{x} \\
&= \frac{1}{|\hat{T}|}\max_{T\subset\omega_z}|T| \int_{\hat{\omega}_z} (\hat{\psi}^\ell - K)^2 \,\mathrm{d}\hat{x} \\
&\le C_P(\hat{\omega}_z)^2 \frac{1}{|\hat{T}|}\max_{T\subset\omega_z}|T| \int_{\hat{\omega}_z} |\nabla\hat{\psi}^\ell|^2 \,\mathrm{d}\hat{x} \\
&= C_P(\hat{\omega}_z)^2 \frac{1}{|\hat{T}|}\max_{T\subset\omega_z}|T| \sum_{T\subset\omega_z}\frac{|\hat{T}|}{|T|}\int_T |\nabla_{\Gamma_h}\psi^\ell \nabla F_z|^2 \,\mathrm{d}\sigma_h \\
&\le C_P(\hat{\omega}_z)^2 \max_{T\subset\omega_z}|T| \max_{T\subset\omega_z}\frac{\|\nabla F_z|_T\|^2_{\ell_2\to\ell_2}}{|T|}\|\nabla_{\Gamma_h}\psi^\ell\|^2_{L_2(\omega_z)}.
\end{aligned}
\tag{2.2.35}
$$

Here C_P is the Poincaré constant for $\hat{\omega}_z$. It is not hard to compute that

$$
\|\nabla F_z|_T\|_{\ell_2\to\ell_2} \le C m_z h_T,
\tag{2.2.36}
$$

where C does not depend on any essential quantities. Combining (2.2.34), (2.2.35), and (2.2.36) and finally applying (2.2.22) yields (2.2.27).

The proof of (2.2.28) is accomplished by employing a trace inequality and slightly modifying the preceding proof. Assume that $e \subset \overline{T} \subset \overline{\omega_z}$. Let $\check{T}$ be the unit simplex in $\mathbb{R}^2$ (note that this is not the same as the reference element employed above), with $\hat{e}$ denoting the transformation of e to $\check{T}$. Letting $\hat{F}_T$ denote the affine transformation of $\check{T}$ to T, we note that $\|\hat{F}_T\|_{\ell_2\to\ell_2} \le h_T$. Employing a trace inequality on $\check{T}$ then yields

$$
\begin{aligned}
\|\psi^\ell - \psi^\ell_z\|_{L_2(e)} &\le \sqrt{|e|}\|\hat{\psi}^\ell - \psi^\ell_z\|_{L_2(\hat{e})} \\
&\le C\sqrt{|e|}(\|\hat{\psi}^\ell - \psi^\ell_z\|_{L_2(\check{T})} + \|\nabla\hat{\psi}^\ell\|_{L_2(\check{T})}) \\
&\le C\sqrt{\tfrac{|e|}{|T|}}(\|\psi^\ell - \psi^\ell_z\|_{L_2(T)} + h_T\|\nabla_{\Gamma_h}\psi^\ell\|_{L_2(T)}).
\end{aligned}
\tag{2.2.37}
$$

$\sqrt{|e|/|T|}h_T\|\nabla_{\Gamma_h}\psi^\ell\|_{L_2(T)}$ is clearly bounded by the right-hand side of (2.2.28), so we must consider only the first term in the last line above.

Letting $\hat{T}$, $\hat{\omega}_z$, and K be as defined as before, we first procede as in (2.2.35) to find that

$$
\begin{aligned}
\sqrt{\tfrac{|e|}{|T|}}\|\psi^\ell - K\|_{L_2(T)} &\le \sqrt{\tfrac{|e|}{|\hat{T}|}}\|\hat{\psi}^\ell - K\|_{L_2(\hat{T})} \\
&\le \sqrt{\tfrac{|e|}{|\hat{T}|}}\|\hat{\psi}^\ell - K\|_{L_2(\hat{\omega}_z)} \\
&\le C\sqrt{|e|}m_z \max_{T\subset\omega_z}\frac{h_T}{\sqrt{|T|}}\|\nabla_{\Gamma_h}\psi^\ell\|_{L_2(\omega_z)}.
\end{aligned}
\tag{2.2.38}
$$

Proceeding as in (2.2.31) through (2.2.34), we next find that

$$
\begin{aligned}
\sqrt{\tfrac{|e|}{|T|}}\|(\psi^\ell - K)_z\|_{L_2(T)} &\le \sqrt{|e|}|(\psi_\ell - K)_z| \\
&\le \sqrt{\tfrac{3}{2}}\sqrt{\tfrac{|e|}{|\omega_z|}}\|\psi^\ell - K\|_{L_2(\omega_z)}.
\end{aligned}
\tag{2.2.39}
$$

Combining (2.2.39) and (2.2.35) yields

$$\begin{aligned}\sqrt{\frac{|e|}{|T|}}\|(\psi^\ell - K)_z\|_{L_2(T)} &\le C\sqrt{|e|}\max_{T\subset\omega_z}\sqrt{\tfrac{|T|}{|\omega_z|}}m_z\max_{T\subset\omega_z}\frac{h_T}{\sqrt{|T|}}\|\nabla_{\Gamma_h}\psi^\ell\|_{L_2(\omega_z)}\\ &\le C\sqrt{|e|}m_z\max_{T\subset\omega_z}\frac{h_T}{\sqrt{|T|}}\|\nabla_{\Gamma_h}\psi^\ell\|_{L_2(\omega_z)}.\end{aligned}\tag{2.2.40}$$

Since $\|\psi^\ell-\psi_z^\ell\|_{L_2(T)} \le \|\psi^\ell-K\|_{L_2(T)}+\|(\psi^\ell-K)_z\|_{L_2(T)}$, combining (2.2.37), (2.2.38), and (2.2.40) with (2.2.22) completes the proof of (2.2.28). ∎

3. The estimator. In this section we develop a computable and reliable estimator for $\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\Gamma)}$.

3.1. Residual equation. We first derive a residual equation. Let $\psi \in H_0^1(\Gamma)$, where $H_0^1(\Gamma)$ is the set of functions in $H^1(\Gamma)$ having a vanishing trace if $\partial\Gamma \neq \emptyset$ and having a vanishing mean value if $\partial\Gamma = \emptyset$. Following [Dz88] and applying (2.2.22), we find that, for $\psi \in H^1(\Gamma)$ and $\psi_h \in S_h$,

$$\begin{aligned}\int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi\,\mathrm{d}\sigma = &\int_{\Gamma_h} f^\ell\mu_h\psi^\ell\,\mathrm{d}\sigma_h - \int_\Gamma[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma\psi\,\mathrm{d}\sigma\\ &- \int_{\Gamma_h}\nabla_{\Gamma_h}u_h\nabla_{\Gamma_h}\psi^\ell\,\mathrm{d}\sigma_h\end{aligned}\tag{3.3.1}$$

and

$$\begin{aligned}\int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi_h^\ell\,\mathrm{d}\sigma &= \int_{\Gamma_h} f^\ell\mu_h\psi_h\,\mathrm{d}\sigma_h - \int_\Gamma[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma\psi_h^\ell\,\mathrm{d}\sigma\\ &\quad - \int_{\Gamma_h}\nabla_{\Gamma_h}u_h\nabla_{\Gamma_h}\psi_h\,\mathrm{d}\sigma_h\\ &= \int_{\Gamma_h}(f^\ell\mu_h - f_h)\psi_h\,\mathrm{d}\sigma_h - \int_\Gamma[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma\psi_h^\ell\,\mathrm{d}\sigma.\end{aligned}\tag{3.3.2}$$

Combining (3.3.1) and (3.3.2), we find that

$$\begin{aligned}\int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi\,\mathrm{d}\sigma &= \int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi\,\mathrm{d}\sigma - \int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi_h^\ell\,\mathrm{d}\sigma\\ &\quad + \int_\Gamma \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma\psi_h^\ell\,\mathrm{d}\sigma\\ &= \int_{\Gamma_h} f^\ell\mu_h(\psi^\ell-\psi_h)\,\mathrm{d}\sigma_h - \int_{\Gamma_h}\nabla_{\Gamma_h}u_h\nabla_{\Gamma_h}(\psi^\ell-\psi_h)\,\mathrm{d}\sigma_h\\ &\quad - \int_\Gamma[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma\psi\,\mathrm{d}\sigma + \int_{\Gamma_h}(f^\ell\mu_h - f_h)\psi_h\,\mathrm{d}\sigma_h.\end{aligned}\tag{3.3.3}$$

Next we note that

$$
\begin{aligned}
&-\int_{\Gamma_h} \nabla_{\Gamma_h} u_h \nabla_{\Gamma_h}(\psi^\ell - \psi_h)\,\mathrm{d}\sigma_h \\
&\qquad = \sum_{T\in\mathcal{T}_h} \int_T \Delta_{\Gamma_h} u_h(\psi^\ell - \psi_h)\,\mathrm{d}\sigma_h - \int_{\partial T} \nabla_{\Gamma_h} u_h \cdot \vec{n}(\psi^\ell - \psi_h)\,\mathrm{d}s \\
&\qquad = \int_{\Gamma_h} \Delta_{\Gamma_h} u_h(\psi^\ell - \psi_h)\,\mathrm{d}\sigma_h - \frac{1}{2}\sum_{T\in\mathcal{T}} \int_{\partial T} [[\nabla_{\Gamma_h} u_h]](\psi^\ell - \psi_h)\,\mathrm{d}s,
\end{aligned} \tag{3.3.4}
$$

where $\Delta_{\Gamma_h} u_h$ is a piecewise polynomial and $\vec{n}$ is the conormal vector to the triangle T (that is, $\vec{n}\cdot\vec{\nu}_h = 0$). In the current situation $\Delta_{\Gamma_h} u_h$ is identically 0, but we include it to make clear how the corresponding term would appear in other situations. Also, let e be an edge shared by elements T_1 and T_2 which have normals $\vec{n}_1$ and $\vec{n}_2$, respectively. Then $[[\nabla_{\Gamma_h} u_h]] = \nabla_{\Gamma_h} u_h|_{T_1}\cdot\vec{n}_1 - \nabla_{\Gamma_h} u_h|_{T_2}\cdot\vec{n}_2$ is the jump in the normal derivative across e. If $e\subset\partial\Gamma_h$ we set $[[\nabla_{\Gamma_h} u_h]]|_e = 0$. Note that $\vec{n}_1$ lies in the plane of T_1 and $\vec{n}_2$ lies in the plane of T_2, so in contrast to the situation which arises on domains in $\mathbb{R}^n$, we generally have $\vec{n}_1 \neq -\vec{n}_2$. Finally, we insert (3.3.4) into (3.3.3) to find

$$
\begin{aligned}
\int_\Gamma \nabla_\Gamma(u - u_h^\ell)\nabla_\Gamma\psi\,\mathrm{d}\sigma &= \int_{\Gamma_h} (f^\ell\mu_h + \Delta_{\Gamma_h} u_h)(\psi^\ell - \psi_h)\,\mathrm{d}\sigma_h \\
&\quad -\frac{1}{2}\sum_{T\in\mathcal{T}} \int_{\partial T} [[\nabla_{\Gamma_h} u_h]](\psi^\ell - \psi_h)\,\mathrm{d}s - \int_\Gamma [\mathbf{P} - \mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell \nabla_\Gamma\psi\,\mathrm{d}\sigma \\
&\quad + \int_{\Gamma_h} (f^\ell\mu_h - f_h)\psi_h\,\mathrm{d}\sigma_h \\
&\quad \equiv \mathrm{I} + \mathrm{II} + \mathrm{III} + \mathrm{IV}.
\end{aligned} \tag{3.3.5}
$$

3.2. A posteriori upper bound (reliability). We begin by bounding term I of (3.3.5). Let $\psi_h = I_h\psi^\ell$, and let $s_z = m_z \max_{T\subset\omega_z} h_T/\sqrt{|T|}$. Also let $R = f^\ell\mu_h + \Delta_{\Gamma_h} u_h$, and let $\{R_z\}_{z\in\mathcal{N}}$ be constants. Recalling that $\{\varphi_z\}_{z\in\mathcal{N}}$ is a partition of unity, recalling (2.2.25) and (2.2.26), and applying Lemma 2.2, we then have

$$
\begin{aligned}
\mathrm{I} &= \sum_{z\in\mathcal{N}} \int_{\omega_z} R(\psi^\ell - \psi_z^\ell)\varphi_z\,\mathrm{d}\sigma_h = \sum_{z\in\mathcal{N}} \int_{\omega_z} (R - R_z)(\psi^\ell - \psi_z^\ell)\varphi_z\,\mathrm{d}\sigma_h \\
&\le C\sum_{z\in\mathcal{N}} \max_{T\subset\omega_z} \sqrt{|T|} s_z \|\mathbf{A}_h\|_{\ell_2, L_\infty(\omega_z)}^{\frac{1}{2}} \cdot \|\varphi_z(R - R_z)\|_{L_2(\omega_z)} h_z \|\nabla_\Gamma\psi\|_{L_2(\tilde{\omega}_z)}.
\end{aligned} \tag{3.3.6}
$$

Next we turn to bounding the term II. Applying Lemma 2.2, we find

$$
\begin{aligned}
\mathrm{II} &= -\frac{1}{2}\sum_{z\in\mathcal{N}} \sum_{\overline{e}\ni z} \int_e \varphi_z [[\nabla_{\Gamma_h} u_h]](\psi^\ell - \psi_z^\ell)\,\mathrm{d}s \\
&\le C\sum_{z\in\mathcal{N}} \sum_{\overline{e}\ni z} \sqrt{|e|} s_z \|\mathbf{A}_h\|_{\ell_2, L_\infty(\omega_z)}^{\frac{1}{2}} \|\varphi_z [[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)} \|\nabla_\Gamma\psi\|_{L_2(\tilde{\omega}_z)}.
\end{aligned} \tag{3.3.7}
$$

Let

$$
\eta_z = s_z \left(\max_{T\subset\omega_z} \sqrt{|T|} \|\varphi_z(R - R_z)\|_{L_2(\omega_z)} + \sum_{\overline{e}\ni z} \sqrt{|e|} \|\varphi_z [[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)} \right). \tag{3.3.8}
$$

Combining (3.3.6) and (3.3.7) and noting that each element T has only three nodes, we thus find that

$$\begin{aligned}\mathrm{I}+\mathrm{II} &\leq C\sum_{z\in\mathcal{N}}\|\mathbf{A}_h\|^{\frac{1}{2}}_{\ell_2,L_\infty(\omega_z)}\eta_z\|\nabla_\Gamma\psi\|_{L_2(\tilde{\omega}_z)}\\ &\leq C\left(\sum_{z\in\mathcal{N}}\|\mathbf{A}_h\|_{\ell_2,L_\infty(\omega_z)}\eta_z^2\right)^{\frac{1}{2}}\left(\sum_{z\in\mathcal{N}}\|\nabla_\Gamma\psi\|^2_{L_2(\tilde{\omega}_z)}\right)^{\frac{1}{2}}\\ &\leq C\left(\sum_{z\in\mathcal{N}}\|\mathbf{A}_h\|_{\ell_2,L_\infty(\omega_z)}\eta_z^2\right)^{\frac{1}{2}}\|\nabla_\Gamma\psi\|_{L_2(\Gamma)},\end{aligned}\tag{3.3.9}$$

where C does not depend on $\mathcal{T}_h$ or any other essential quantities.

In order to bound the term III, we use (2.2.19) to compute

$$\begin{aligned}\mathrm{III} &= -\sum_{z\in\mathcal{N}}\int_{\tilde{\omega}_z}\varphi_z^\ell[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma\psi\,\mathrm{d}\sigma\\ &\leq \sum_{z\in\mathcal{N}}\left\|\sqrt{\varphi_z^\ell}[\mathbf{P}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\right\|_{L_2(\tilde{\omega}_z)}\left\|\sqrt{\varphi_z^\ell}\nabla_\Gamma\psi\right\|_{L_2(\tilde{\omega}_z)}\\ &= \sum_{z\in\mathcal{N}}\left\|\sqrt{\mu_h}\sqrt{\varphi_z}[\mathbf{P}-\mathbf{A}_h][\mathbf{I}-d\mathbf{H}]^{-1}\left[\mathbf{I}-\frac{\vec{\nu}_h\otimes\vec{\nu}}{\vec{\nu}_h\cdot\vec{\nu}}\right]\nabla_{\Gamma_h}u_h\right\|_{L_2(\omega_z)}\\ &\quad\cdot\left\|\sqrt{\varphi_z^\ell}\nabla_\Gamma\psi\right\|_{L_2(\tilde{\omega}_z)}.\end{aligned}\tag{3.3.10}$$

Defining

$$\mathbf{B}_h=\sqrt{\mu_h}[\mathbf{P}-\mathbf{A}_h][\mathbf{I}-d\mathbf{H}]^{-1}[\mathbf{I}-\frac{\vec{\nu}_h\otimes\vec{\nu}}{\vec{\nu}_h\cdot\vec{\nu}}]\tag{3.3.11}$$

and recalling that $\sum_{z\in\mathcal{N}}\varphi_z=\sum_{z\in\mathcal{N}}\varphi_z^\ell\equiv 1$, we finally compute

$$\begin{aligned}\mathrm{III} &\leq \left(\sum_{z\in\mathcal{N}}\|\sqrt{\varphi_z}\mathbf{B}_h\nabla_{\Gamma_h}u_h\|^2_{L_2(\omega_z)}\right)^{1/2}\left(\sum_{z\in\mathcal{N}}\|\sqrt{\varphi_z^\ell}\nabla_\Gamma\psi\|^2_{L_2(\tilde{\omega}_z)}\right)^{1/2}\\ &= \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(\Gamma_h)}\|\nabla_\Gamma\psi\|_{L_2(\Gamma)}.\end{aligned}\tag{3.3.12}$$

Finally we bound the term IV. First we note that, for $z\in\mathcal{N}$ and with ψ_z^ℓ defined as in (2.2.24),

$$\begin{aligned}\|\sqrt{\varphi_z}\psi_z^\ell\|_{L_2(\Omega_z)} &= \sqrt{\int_{\omega_z}\varphi_z\,\mathrm{d}\sigma_h}\frac{1}{\int_{\omega_z}\varphi_z\,\mathrm{d}\sigma_h}\left|\int_{\omega_z}\varphi_z\psi_z^\ell\,\mathrm{d}\sigma_h\right|\\ &\leq \|\sqrt{\varphi_z}\psi^\ell\|_{L_2(\omega_z)}.\end{aligned}\tag{3.3.13}$$

Since $\psi\in H_0^1(\Gamma)$ has either a vanishing trace on $\partial\Omega$ or a vanishing mean value over

Ω, we may apply (3.3.13) and a Poincaré inequality to compute

$$\begin{aligned}
\mathrm{IV} &= \int_{\Gamma_h} (f^\ell \mu_h - f_h)\psi_h \,\mathrm{d}\sigma_h \\
&= \sum_{z\in\mathcal{N}} \int_{\omega_z} (f^\ell \mu_h - f_h)\varphi_z \psi_z^\ell \,\mathrm{d}\sigma_h \\
&\le \sum_{z\in\mathcal{N}} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|_{L_2(\omega_z)} \|\sqrt{\varphi_z}\psi_z^\ell\|_{L_2(\omega_z)} \\
&\le \sum_{z\in\mathcal{N}} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|_{L_2(\omega_z)} \|\sqrt{\varphi_z}\psi^\ell\|_{L_2(\omega_z)} \\
&\le \sum_{z\in\mathcal{N}} \left\| \frac{1}{\sqrt{\mu_h}} \right\|_{L_\infty(\omega_z)} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|_{L_2(\Gamma_h)} \left\| \sqrt{\varphi_z^\ell}\psi \right\|_{L_2(\bar{\omega_z})} \\
&\le \left(\sum_{z\in\mathcal{N}} \left\| \frac{1}{\mu_h} \right\|_{L_\infty(\omega_z)} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|^2_{L_2(\Gamma_h)} \right)^{1/2} \|\psi\|_{L_2(\Gamma)} \\
&\le C_P(\Gamma) \left(\sum_{z\in\mathcal{N}} \left\| \frac{1}{\mu_h} \right\|_{L_\infty(\omega_z)} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|^2_{L_2(\Gamma_h)} \right)^{1/2} \|\nabla_\Gamma \psi\|_{L_2(\Gamma)}.
\end{aligned} \tag{3.3.14}$$

Making the substitution $\psi = u - u_h^\ell$ if $\partial\Gamma \neq \emptyset$ or $\psi = u - u_h^\ell - \frac{1}{|\Gamma|}\int_\Gamma (u - u_h^\ell)\,\mathrm{d}\sigma$ if $\partial\Gamma = \emptyset$ while combining (3.3.3), (3.3.12), and (3.3.14) yields

$$\begin{aligned}
\|\nabla_\Gamma(u - u_h^\ell)\|^2_{L_2(\Gamma)} \le \Bigg[& C \left(\sum_{z\in\mathcal{N}} \|\mathbf{A}_h\|_{\ell_2, L_\infty(\omega_z)} \eta_z^2 \right)^{1/2} + \|\mathbf{B}_h \nabla_{\Gamma_h} u_h\|_{L_2(\Gamma_h)} \\
& + C_P(\Gamma) \left(\sum_{z\in\mathcal{N}} \left\| \frac{1}{\mu_h} \right\|_{L_\infty(\omega_z)} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|^2_{L_2(\Gamma_h)} \right)^{1/2} \Bigg] \\
& \cdot \|\nabla_\Gamma(u - u_h^\ell)\|_{L_2(\Gamma)}.
\end{aligned} \tag{3.3.15}$$

Dividing (3.3.15) through by $\|\nabla_\Gamma(u - u_h^\ell)\|_{L_2(\Gamma)}$ then yields the following theorem.

THEOREM 3.1. *Under the assumptions in section* 2,

$$\|\nabla_\Gamma(u - u_h^\ell)\|_{L_2(\Gamma)} \le \mathcal{R} + \mathcal{G} + \mathcal{D}, \tag{3.3.16}$$

where

$$\mathcal{R} = C \left(\sum_{z\in\mathcal{N}} \|\mathbf{A}_h\|_{\ell_2, L_\infty(\omega_z)} \eta_z^2 \right)^{1/2}, \tag{3.3.17}$$

$$\mathcal{G} = \|\mathbf{B}_h \nabla_{\Gamma_h} u_h\|_{L_2(\Gamma_h)}, \tag{3.3.18}$$

and

$$\mathcal{D} = C_P(\Gamma) \left(\sum_{z\in\mathcal{N}} \left\| \frac{1}{\mu_h} \right\|_{L_\infty(\omega_z)} \|\sqrt{\varphi_z}(f^\ell \mu_h - f_h)\|^2_{L_2(\Gamma_h)} \right)^{1/2}. \tag{3.3.19}$$

Here $\eta_z = s_z(\max_{T\subset\omega_z} \sqrt{|T|}\|\varphi_z(R - R_z)\|_{L_2(\omega_z)} + \sum_{\bar{e}\ni z} \sqrt{|e|}\|\varphi_z[[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)})$ *as in* (3.3.8), *the constants* R_z *in* η_z *may be freely chosen, and* C *does not depend on* $\mathcal{T}_h$ *or* Γ.

We make a few brief remarks concerning Theorem 3.1, beginning with the *residual term* $\mathcal{R}$. First we note that if the nodes of Γ_h lie on Γ, then $\|[(\mathbf{P}-\mathbf{A}_h)(x)]\|_{\ell_2\to\ell_2} \le Ch_T^2$ for $x \in T$ (cf. [Dz88]). Thus up to a higher-order term, $\mathcal{R}$ is bounded by $C(\sum_{z\in\mathcal{N}} \eta_z^2)^{1/2}$. Next we consider the *geometric error term* $\mathcal{G}$. Note first that unlike the residual term $\mathcal{R}$, it contains no unknown constants. Secondly, $\mathcal{G}$ is heuristically of higher order since $\|\mathbf{B}_h\|_{\ell_2\to\ell_2} \le C\|\mathbf{P}-\mathbf{A}_h\|_{\ell_2\to\ell_2} \le Ch_T^2$. The *data approximation term* $\mathcal{D}$ is 0 if we let $f_h = \mu_h f^\ell$ and assume exact quadrature, both of which we shall do in our numerical tests. In [Dz88] the definition $f_h(x) = f^\ell(x) - \frac{1}{|\Gamma_h|}\int_{\Gamma_h} f^\ell \,\mathrm{d}\sigma_h$ is made. This choice has the advantage of not requiring the computation of the ratio μ_h of the continuous to the discrete measure and still leads to optimal-order H^1 and L_2 estimates. However, computation of $\mathcal{R}$ and $\mathcal{G}$ requires access to μ_h in any case, so we shall use the definition $f_h = \mu_h f^\ell$ and thereby exclude $\mathcal{D}$. A final note concerning $\mathcal{D}$ is that it includes the global Poincaré constant $C_P(\Gamma)$. In contrast to the terms $\mathcal{R}$ and $\mathcal{G}$, $\mathcal{D}$ is thus not entirely built up of quantities which are locally determined.

Finally, we note that the dominant term in (3.3.16) does not depend explicitly on geometric information about Γ. Since $\|\mathbf{A}_h-\mathbf{P}\|_{\ell_2,L_\infty(\omega_z)} \le C(\tilde\omega_z)h_z^2$, we may compute $\mathcal{G} \le (\sum_{z\in\mathcal{N}} C(\tilde\omega_z^2)h_z^4\|\sqrt{\varphi_z}\nabla_{\Gamma_h}u_h\|^2_{L_2(\omega_z)})^{1/2}$. Also, $\mathcal{R} \le C(\sum_{z\in\mathcal{N}}\eta_z^2 + C(\Gamma)h_z^2\eta_z^2)^{1/2}$. Finally, as shown in [Dz88], $\mathcal{D}$ is of higher order even if the choice $f_h(x) = f^\ell(x) - \frac{1}{|\Gamma_h|}\int_{\Gamma_h} f^\ell \,\mathrm{d}\sigma_h$ is made. Thus the dominant part of the a posteriori upper bound is $C(\sum_{z\in\mathcal{N}}\eta_T^2)^{1/2}$, exactly as for problems in planar domains.

The estimator given in Theorem 3.1 could in principle be implemented, but it is possible to define a more convenient estimator for practical use. Recalling the comments of section 2.2, we may simplify it by assuming shape-regularity. In addition, residual estimators are typically calculated elementwise instead of patchwise, so we define an alternate estimator which allows mostly elementwise calculations (the only exception is the term involving $\|A_h\|$, which must be patch-based). In our computations we shall apply the estimator naturally derived from the following corollary.

COROLLARY 3.2. *Assume that $f_h = \mu_h f^\ell$, that $\mathcal{T}_h$ is shape-regular, and that m_z is bounded. Then*

(3.3.20)
$$\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\Gamma)} \le \sqrt{2}\left(\sum_{T\in\mathcal{T}_h} C\|\mathbf{A}_h\|_{\ell_2,L_\infty(\omega_T)}\eta_T^2 + \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|^2_{L_2(T)}\right)^{1/2} \equiv \Theta.$$

Here $\omega_T = \cup_{z\in\overline{T}}\omega_z$, $\eta_T = h_T\|R\|_{L_2(T)} + h_T^{1/2}\|[[\nabla_{\Gamma_h}u_h]]\|_{L_2(\partial T)}$, and C depends on $\max_{z\in\mathcal{N}} m_z$ and the minimum angle over all elements of $\mathcal{T}_h$.

The proof of Corollary 3.2 follows by setting $R_z = 0$ in (3.3.8) and noting that, under the assumptions that $\mathcal{T}_h$ is shape-regular and m_z is bounded, h_T is equivalent to h_z for all vertices z of T and to $|e|$ for all $e \subset \partial T$. ∎

3.3. A posteriori lower bound (efficiency). In this section we prove a local a posteriori lower bound which is a counterpart to the upper bound in Corollary 3.2. Such lower bounds verify (up to higher-order terms) that the stated a posteriori estimate does not overestimate the actual error and also are an essential ingredient in proving the convergence of adaptive methods; cf. [MNS02].

PROPOSITION 3.3. *Assume that $f_h = \mu_h f^\ell$, that $\mathcal{T}_h$ is shape-regular, and that m_z is bounded. Then for $T \in \mathcal{T}_h$,*

$$\begin{aligned}\eta_T \le{}& C\|\mathbf{A}_h\|^{1/2}_{\ell_2,L_\infty(\omega_T)}(\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{\omega}_T)} + \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(\omega_T)})\\ &+Ch_T\|R-R_T\|_{L_2(\omega_T)}.\end{aligned} \tag{3.3.21}$$

Here C depends on $\max_{z\in\mathcal{N}:z\in\overline{T}} m_z$ and the minimum angle of the elements in ω_T, and R_T is an arbitrary piecewise linear function.

Proof. We shall follow the well-known proof of Verfürth (cf. [Ver89]). First let $z \in \mathcal{N}$ and $T \subset \omega_z$. Letting z_i, $1 \le i \le 3$, be the nodes of T, we define the bubble function $\phi_T = \prod_{i=1}^3 \varphi_{z_i}$. In addition, let R_T be an arbitrary piecewise linear approximation to R on T. Let also $\tilde{T}$ denote the natural lift of T to Γ. Then using (3.3.5) with $\psi = R_T^\ell\phi_T^\ell$ and $\psi_h = 0$ and noting that $\phi_T = 0$ on $\partial\tilde{T}$, we have

$$\begin{aligned}\int_T RR_T\phi_T\,\mathrm{d}\sigma_h &= \int_{\tilde{T}} \nabla_\Gamma(u-u_h^\ell)\nabla_\Gamma(R_T^\ell\phi_T^\ell)\,\mathrm{d}\sigma\\ &\quad+\int_{\tilde{T}}[\mathbf{I}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\nabla_\Gamma(R_T^\ell\phi_T^\ell)\,\mathrm{d}\sigma\\ &\le (\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{T})} + \|[\mathbf{I}-\mathbf{A}_h^\ell]\nabla_\Gamma u_h^\ell\|_{L_2(\tilde{T})})\|\nabla_\Gamma(R_T^\ell\phi_T^\ell)\|_{L_2(\tilde{T})}\\ &\le (\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{T})} + \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(T)})\\ &\quad\cdot\|\mathbf{A}_h\|^{1/2}_{L_\infty(T)}\|\nabla_{\Gamma_h}(R_T\phi_T)\|_{L_2(T)}.\end{aligned} \tag{3.3.22}$$

Since $R_T\phi_T$ is a polynomial, we may apply an inverse inequality to find

$$\|\nabla_{\Gamma_h}(R_T\phi_T)\|_{L_2(T)} \le Ch_T^{-1}\|R_T\phi_T\|_{L_2(T)} \le Ch_T^{-1}\|R_T\|_{L_2(T)}, \tag{3.3.23}$$

where C depends only on the shape-regularity of T. Thus

$$\begin{aligned}&\int_T R\,R_T\phi_T\,\mathrm{d}\sigma_h\\ &\quad\le Ch_T^{-1}\|\mathbf{A}_h\|^{1/2}_{L_\infty(T)}(\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{T})} + \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(T)})\|R_T\|_{L_2(T)}.\end{aligned} \tag{3.3.24}$$

Applying Theorem 2.2 of [AO00], we next note that

$$\begin{aligned}\|R_T\|^2_{L_2(T)} &\le \|\sqrt{\phi_T}R_T\|^2_{L_2(T)}\\ &\le \left(\|\sqrt{\phi_T}(R-R_T)\|_{L_2(T)} + \left(\int_T RR_T\phi_T\,\mathrm{d}\sigma_h\right)^{1/2}\right)\|R_T\|_{L_2(T)}.\end{aligned} \tag{3.3.25}$$

Combining the previous inequalities, we thus find

$$\begin{aligned}\|R_T\|^2_{L_2(T)} \le{}& C[\|R-R_T\|_{L_2(T)} + h_T^{-1}\|\mathbf{A}_h\|^{1/2}_{L_\infty(T)}(\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{T})}\\ &+\|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(T)})]\|R_T\|_{L_2(T)}.\end{aligned} \tag{3.3.26}$$

Thus

$$\begin{aligned}h_T\|R\|_{L_2(T)} \le{}& C[\|\mathbf{A}_h\|^{1/2}_{L_\infty(T)}(\|\nabla_\Gamma(u-u_h^\ell)\|_{L_2(\tilde{T})} + \|\mathbf{B}_h\nabla_{\Gamma_h}u_h\|_{L_2(T)})\\ &+h_T\|R-R_T\|_{L_2(T)}].\end{aligned} \tag{3.3.27}$$

Next we bound the edge residual $\|[[\nabla_{\Gamma_h} u_h]]\|_{L_2(\partial T)}$. Let e be an edge which is shared by elements $T_1 = T$ and T_2 and whose closure contains the nodes z_1 and z_2. Let $\lambda_{i,j}$, $i,j = 1,2$, be the barycentric coordinate on triangle i corresponding to the vertex z_j, and define $\phi_e|_{T_i} = \lambda_{i,1}\lambda_{i,2}$. Thus $\phi_e \in H_0^1(T_1 \cup T_2)$, and $\phi_e > 0$ on e. Then

$$\|[[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)} \le C\|\sqrt{\phi_e}[[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)}. \tag{3.3.28}$$

Noting that $[[\nabla_{\Gamma_h} u_h]]_e$ is a constant, we employ (3.3.5) with $\psi = (|[[\nabla_{\Gamma_h} u_h]]|_e \phi_e^\ell)$ to find

(3.3.29)

$$\begin{aligned}
\int_e |[[\nabla_{\Gamma_h} u_h]]|^2 \phi_e \,\mathrm{d}s &= \int_{\tilde{T}_1 \cup \tilde{T}_2} \nabla_\Gamma (u - u_h^\ell) \nabla_\Gamma ([[\nabla_{\Gamma_h} u_h]]_e \phi_e^\ell) \,\mathrm{d}\sigma \\
&\quad - \int_{T_1 \cup T_2} R |[[\nabla_{\Gamma_h} u_h]]|_e \phi_e \,\mathrm{d}\sigma_h + \int_{\tilde{T}_1 \cup \tilde{T}_2} [\mathbf{I} - \mathbf{A}_h^\ell] \nabla_\Gamma u_h^\ell \nabla_\Gamma ([[\nabla_{\Gamma_h} u_h]]_e \phi_e) \,\mathrm{d}\sigma \\
&\le |[[\nabla_{\Gamma_h} u_h]]|_e (\|\nabla_\Gamma (u - u_h^\ell)\|_{L_2(\tilde{T}_1 \cup \tilde{T}_2)} \|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\nabla_{\Gamma_h} \phi_e\|_{L_2(T_1 \cup T_2)} \\
&\quad + \|R\|_{L_2(T_1 \cup T_2)} \|\phi_e\|_{L_2(T_1 \cup T_2)} \\
&\quad + \|\mathbf{B}_h \nabla_{\Gamma_h} u_h\|_{L_2(T_1 \cup T_2)} \|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\nabla_{\Gamma_h} \phi_e\|_{L_2(T_1 \cup T_2)}).
\end{aligned}$$

A simple scaling argument yields $\|\phi_e\|_{L_2(T_1 \cup T_2)} \le C h_T$ and $\|\nabla_{\Gamma_h} \phi_e\|_{L_2(T_1 \cup T_2)} \le C$, so that

$$\begin{aligned}
\int_e |[[\nabla_{\Gamma_h} u_h]]|^2 \,\phi_e \,\mathrm{d}s &\le C h_T^{-1/2} \|[[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)} \\
&\quad \cdot [\|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\nabla_\Gamma (u - u_h^\ell)\|_{L_2(\tilde{T}_1 \cup \tilde{T}_2)} \\
&\quad + h_T \|R\|_{L_2(T_1 \cup T_2)} + \|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\mathbf{B}_h \nabla_{\Gamma_h} u_h\|_{L_2(T_1 \cup T_2)}].
\end{aligned} \tag{3.3.30}$$

Combining the previous three inequalities, we find that

$$\begin{aligned}
h_T^{1/2} \|[[\nabla_{\Gamma_h} u_h]]\|_{L_2(e)} &\le C(\|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\nabla_\Gamma (u - u_h^\ell)\|_{L_2(\tilde{T}_1 \cup \tilde{T}_2)} \\
&\quad + h_T \|R\|_{L_2(T_1 \cup T_2)} + \|\mathbf{A}_h\|_{L_\infty(T_1 \cup T_2)}^{1/2} \|\mathbf{B}_h \nabla_{\Gamma_h} u_h\|_{L_2(T_1 \cup T_2)}).
\end{aligned} \tag{3.3.31}$$

Summing (3.3.31) over the three edges of T and combining (3.3.31) with (3.3.27) completes the proof of (3.3.21). ∎

4. Implementation details. In this section we provide some details concerning implementation.

4.1. Computation of geometric quantities. We assume that $\Gamma = \{x \in \mathbb{R}^3 : \zeta(x) = 0\}$, where ζ is sufficiently smooth with a nonzero gradient in a large enough neighborhood of Γ. In addition, we assume that ζ, its gradient, and its Hessian matrix are available and that for $x \in U$ we can approximate $a(x)$ with sufficient accuracy. In the next subsection we describe a simple approach for approximating $a(x)$.

First we note that if $x \in \Gamma$, $\vec{\nu}(x) = \frac{\nabla \zeta}{|\nabla \zeta|}$. Thus for $x \in U$,

$$\vec{\nu}(x) = \frac{\nabla \zeta(a(x))}{|\nabla \zeta(a(x))|}. \tag{4.4.1}$$

In addition, we have for $x \in \Gamma$

$$\mathbf{H}(x) = \nabla_\Gamma \vec{\nu}(x) = \mathbf{P} \nabla \frac{\nabla \zeta(x)}{|\nabla \zeta(x)|}. \tag{4.4.2}$$

For the sake of concreteness, we note that $\nabla \frac{\nabla\zeta(x)}{|\nabla\zeta(x)|}$ is not necessarily symmetric and that $[\nabla \frac{\nabla\zeta}{|\nabla\zeta|}]_{ij} = \frac{\partial}{\partial x_i}\frac{\zeta_{x_j}}{|\nabla\zeta|}$. The eigenvalues κ_1 and κ_2 of H in the directions orthogonal to $\vec{\nu}$ may then be approximated numerically. We also recall the relationship $\kappa_i(x) = \frac{\kappa_i(a(x))}{1+d(x)\kappa_i(a(x))}$ from (2.2.5). Finally, we emphasize that d is the *signed* distance function, that is, $d(x) = sign(\zeta(x))|a(x) - x|$ for $x \in U \setminus \Gamma$.

The above information is sufficient to implement the adaptive method described above. In particular, for $x \in \Gamma_h$ we use (2.2.23) to define the discrete data

$$f_h(x) = \mu_h(x) f(a(x)) = (1 - d(x)\kappa_1(x))(1 - d(x)\kappa_2(x))\vec{\nu}(x) \cdot \vec{\nu}_h(x) f(a(x)). \tag{4.4.3}$$

Here $\vec{\nu}(x)$ is computed via (4.4.1), κ_1 and κ_2 are computed via (2.2.5), and $\vec{\nu}_h$ must be computed from mesh information. Next we note that

$$\|\mathbf{A}_h(x)\|_{\ell_2\to\ell_2} \le \frac{\max(1 - d(x)\kappa_1(x), 1 - d(x)\kappa_2(x))}{|\vec{\nu}(x) \cdot \vec{\nu}_h(x)| \min(1 - d(x)\kappa_1(x), 1 - d(x)\kappa_2(x))} \equiv \overline{A}_h(x) \tag{4.4.4}$$

and

$$\begin{aligned} \|\mathbf{B}_h(x)\|_{\ell_2\to\ell_2} &\le \tfrac{1}{\mu_h(x)}[|d(x)(\kappa_1(x) - \kappa_2(x))| \\ &\quad + |1 - \vec{\nu}(x) \cdot \vec{\nu}_h(x)|(1 + 4\max(1 - d(x)\kappa_1(x), 1 - d(x)\kappa_2(x)))] \\ &\equiv \overline{B}_h(x). \end{aligned} \tag{4.4.5}$$

The expressions on the right-hand sides of (4.4.4) and (4.4.5) may be computed using (4.4.1) and (2.2.5) as before. Since $\mathbf{P} - \mathbf{A}_h$ and $\mathbf{B}_h$ are of higher order, using the above approximations for the norms of $\mathbf{A}_h$ and $\mathbf{B}_h$ should lead to at most a slight overestimation of the overall error while yielding nontrivial computational savings.

4.2. Computation of d and a. The efficient computation of the projection a and distance function d are central to implementing the finite element method and a posteriori estimators described here. In a very few cases, d is available explicitly (for example, $d(x) = |x| - r$ for a sphere of radius r). Even for relatively simple surfaces such as ellipsoids, however, an explicit expression for d is not available and a and d must be approximated. Since d is assumed to be smooth and we need to be concerned only about starting points sufficiently close to Γ, standard methods of nonlinear optimization are, in principle, applicable.

We have tested two different algorithms for computing a: one being Newton's method and the other being an ad hoc first-order method. Before describing the methods we note a relationship which we shall use in our algorithms. For $x \in U$, $\zeta(x) = \int_0^{d(x)} \nabla\zeta(a(x) + t\vec{\nu}(x)) \cdot \vec{\nu}(x)\,\mathrm{d}t = d|\nabla\zeta(x)| + O(d^2)$. Thus

$$d(x) \approx \frac{\zeta(x)}{|\nabla\zeta(x)|}. \tag{4.4.6}$$

Next we describe our implementation of Newton's method. Assume that $x_0 \in U$ and that we wish to compute $a(x_0)$. In order to employ Newton's method, we seek a stationary point of the function $F(x,\lambda) = |x - x_0| + \lambda\zeta(x)$. Note that $\nabla F(x,\lambda) = (2(x - x_0) + \lambda\nabla\zeta(x), \zeta(x))$. Thus $\nabla F(x,\lambda) = 0$ implies that $x \in \Gamma$ and $(x - x_0)$ is parallel to $\nabla\zeta(x)$, that is, $x = a(x_0)$. In order to choose a starting point, we note that $2(x-x_0)+\lambda\nabla\zeta(x) = 0$ implies that $\lambda = 2d(x_0)/|\nabla\zeta(x)|$. Using (4.4.6), we thus choose the starting value $(x_0, \lambda_0) = (x_0, 2\phi(x_0)/|\nabla\phi(x_0)|^2)$ for Newton's method. Given a

tolerance *tol*, we iterate Newton's method until

$$\left(\frac{\zeta(x)^2}{|\nabla\zeta(x)|^2}+\left|\frac{\nabla\zeta(x)}{|\nabla\zeta(x)|}-\frac{x-x_0}{|x-x_0|}\right|^2\right)^{1/2}<tol. \tag{4.4.7}$$

Fulfillment of this stopping criteria guarantees that the returned value $x\approx a(x_0)$ lies in the correct direction from x_0 to within *tol* and that, because of (4.4.6), $d(x)<tol$ up to higher-order terms.

The first-order algorithm which we employed may be described as follows: Since $a(x)=x-d(x)\vec{\nu}(x)$, we may use (4.4.6) and $\vec{\nu}(x)\approx\frac{\nabla\zeta(x)}{|\nabla\zeta(x)|}$ to approximate a by $a(x)\approx x-\frac{\zeta(x)\nabla\zeta(x)}{|\nabla\zeta(x)|^2}$. Iterating this relationship leads to an algorithm which converges to some point on Γ but not generally to $a(x)$. We thus correct the direction $x-x_0$ at each step, yielding the following algorithm.

1. Stipulate *tol* and x_0, and initialize $x=x_0$.
2. While (4.4.7) is not satisfied, iterate the following steps:
   (a) Calculate $\tilde{x}=x-\frac{\zeta(x)\nabla\zeta(x)}{|\nabla\zeta(x)|^2}$ and $dist=sign(\zeta(x_0))|\tilde{x}-x_0|$.
   (b) Set $x=x_0-dist\frac{\nabla\zeta(\tilde{x})}{|\nabla\zeta(\tilde{x})|}$.

In practice, the second of the two algorithms was more efficient than Newton's method. While Newton's method converged in less steps as one would expect, each step is relatively expensive. We also note that we have not rigorously analyzed the error in either of these methods which results from using the stopping criterion (4.4.7). A more rigorous analysis of robust algorithms for approximating a would thus be desirable.

5. Computational examples. In this section we describe several computational examples. All computations were performed using the finite element toolbox ALBERTA [SS05], and graphics were processed using the software GMV [Or05]. Also, the constant C appearing in the estimator Θ in (3.3.20) was taken to 0.25 in all calculations.

5.1. Example 1: Computation on a spherical subdomain. In our first test we consider a problem which was used as an example in the paper [AP05]. This problem demonstrates the ease with which our method handles problems in which the distance function is explicitly available and also provides a convenient place to consider surfaces with boundaries.

Let S^2 be the unit sphere with angular spherical coordinates (ϕ,θ), where ϕ $(0\le\phi<2\pi)$ is the azimuthal angle in the xy-plane and $\theta=\cos^{-1}z$ $(0\le\theta\le\pi)$ is the polar angle from the z-axis. Following [AP05], we let Γ consist of points in S^2 such that $0\le\phi\le\frac{5\pi}{3}$, and let $u(\phi,\theta)=(\sin\theta)^\lambda\sin\lambda\phi$ for $\lambda=.6$. Then u satisfies $-\Delta_\Gamma u=f$ in Γ and $u=0$ on $\partial\Gamma$ with $f=\lambda(\lambda+1)(\sin\theta)^\lambda\sin\lambda\phi$. Note that u is singular at the poles, so we may expect an adaptive algorithm to refine more heavily there.

Computation of the geometric quantities necessary to implement our method is quite straightforward. We employ the distance function $d(x)=|x|-1$ for the sphere (note that we do not actually require access to the distance function for Γ here). In addition, we may easily compute that $\vec{\nu}(x)=\frac{x}{|x|}$, $a(x)=\frac{x}{|x|}$, and $\mathbf{H}_{ij}(x)=\frac{\delta_{ij}}{|x|}-\frac{x_ix_j}{|x|^3}$. The eigenvalues of $\mathbf{H}(x)$ are the principle curvatures of the sphere of radius $|x|$, that is, $\kappa_1=\kappa_2=\frac{1}{|x|}$. Computation of μ_h, $\overline{A}_h$, and $\overline{B}_h$ is similarly straightforward.

In Figure 5.1, the initial mesh of six elements is displayed along with an adaptively refined mesh colored with the solution u_h. A blowup showing refinement near the

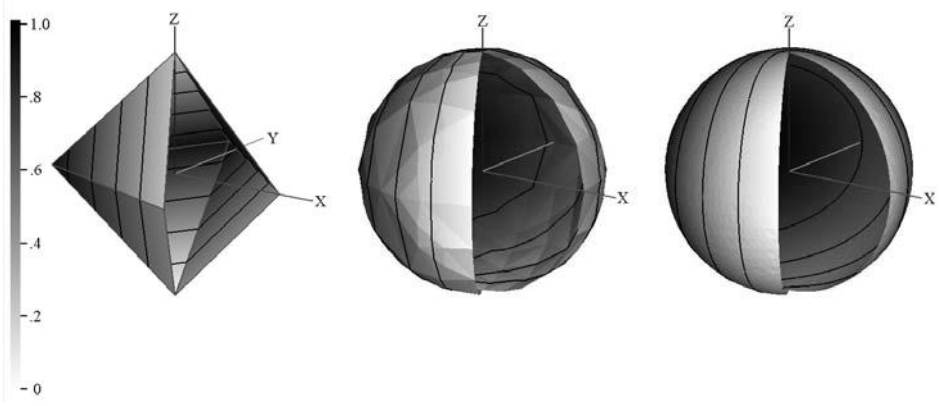

FIG. 5.1. *Experiment* 1: *The initial mesh with* 6 *nodes (left) and adaptively refined meshes with* 151 *(center) and* 5559 *(right) DOF displaying* u_h.

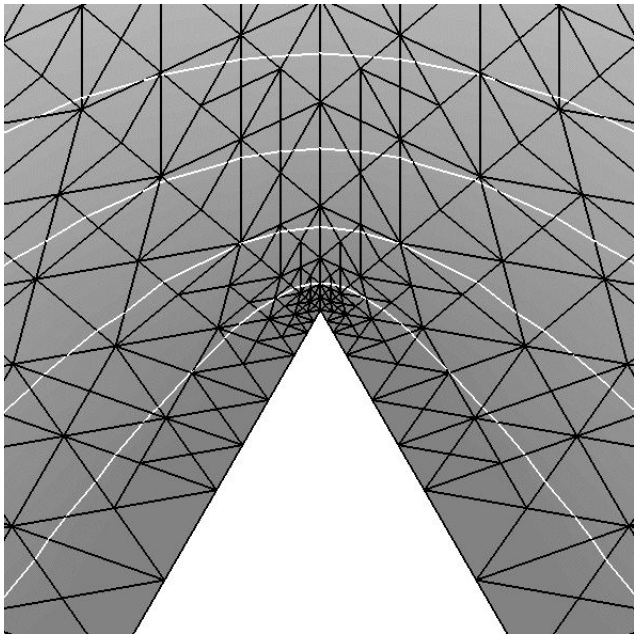

FIG. 5.2. *Experiment* 1: *View of the refined mesh along the* z*-axis, magnified* $80\times$*, with contour lines of* u.

positive z-pole is displayed in Figure 5.2. Finally, a graph displaying the error, the residual estimator Θ defined in (3.3.20), and various geometric quantities is given in Figure 5.3. First note that the quantity $\max_{T\in\mathcal{T}_h} h_T/\sqrt{|T|}$ appears to reach a maximum value of about 3. Thus our assumption in Corollary 3.2 that the mesh is shape-regular is justified for this example. Also, the error $\|\nabla_\Gamma(u - u_h^\ell)\|_{L_2(\Omega)}$ and the residual estimator Θ converge with optimal order and appear to have a constant ratio as the mesh is refined. Finally, the quantities $\|\overline{B}_h|\nabla_{\Gamma_h} u_h|\|_{L_2(\Gamma_h)}$ and $\|1 - \overline{A}_h\|_{L_\infty(\Gamma_h)}$ are plotted and show second-order convergence, confirming experimentally our theoretical observation that these geometric contributions to the error are of

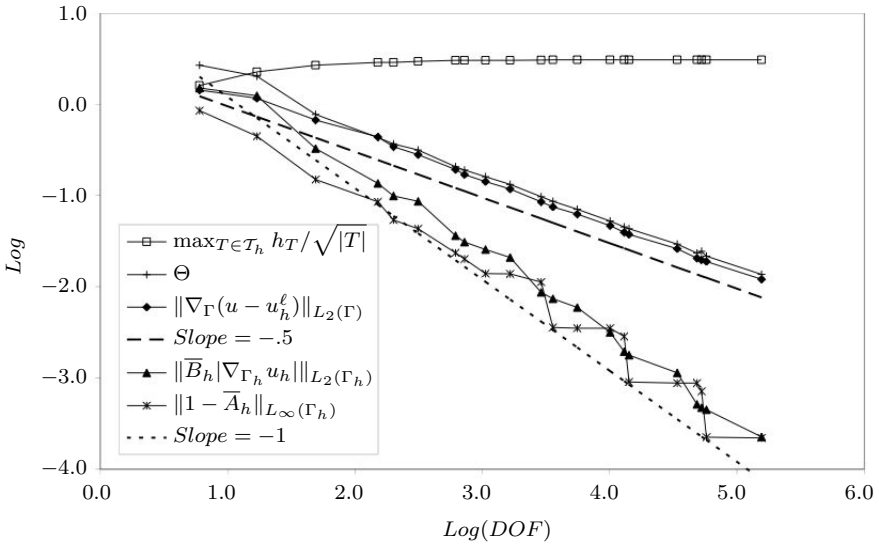

FIG. 5.3. *Experiment* 1: *Error, estimator, and various geometric quantities.*

higher order. It is worth noting here that the quantity $\overline{A}_h$ appears in the estimator as a multiplicative factor. Since it converges to 1, it would thus be reasonable and computationally more efficient to omit it entirely once $\|\overline{A}_h\|_{L_\infty(\Gamma_h)}$ is observed to reach a given tolerance.

5.2. Example 2: Computation on a torus. In our second test we performed a computation on a torus. $d(x) = \sqrt{(r_0 - \sqrt{x^2+y^2})^2 + z^2} - r_1$ is the signed distance function for a torus whose axis of revolution is the z-axis, whose radius of revolution is r_0, and which has thickness $2r_1$. The other necessary geometric quantities may be computed from this formula. We took $r_0 = 1$ and $r_0 = 0.25$. As a test solution we took the function

$$u(x,y,z) = e^{\frac{1}{1.85-x^2}} \sin y, \tag{5.5.1}$$

which has exponential peaks on the outer portions of the torus which lie near the x-axis.

In Figure 5.4 we display $\overline{A}_h$ on the the initial 24-node mesh; note that here $\overline{A}_h$ is about 5 on the outer edge of the torus, so it enters into the calculation in a significant way. Also displayed in Figure 5.4 is a refined mesh having 1248 nodes and displaying the discrete solution u_h. In Figure 5.5 we display the local H_1 error contributions along with the three components $\overline{A}_h$, η_T, and $\overline{B}_h|\nabla_{\Gamma_h}u_h|$ of the estimator Θ. The local residual indicator η_T reflects reasonably well the local error distribution, while the contributions from $\overline{A}_h$ and $\overline{B}_h|\nabla_{\Gamma_h}u_h|$ are relatively insignificant. Also, the maximum ratio $h_T/\sqrt{|T|}$ observed during this calculation was 5.28. This relatively large number reflects the fact that the triangles in the initial mesh displayed in Figure 5.4 already have relatively high aspect ratios.

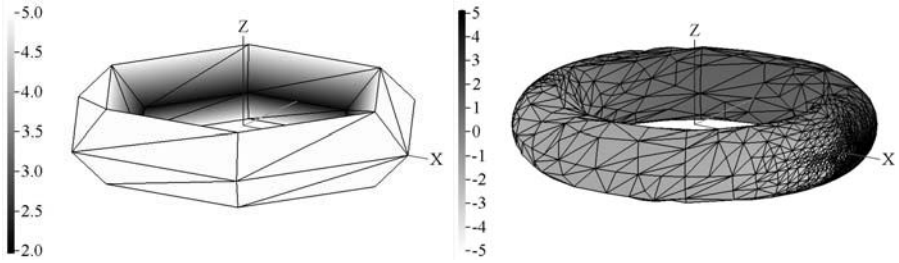

FIG. 5.4. *Experiment* 2: *The initial mesh displaying* $\overline{A}_h$ *(left) and the refined mesh with* 1248 *DOF displaying* u_h *(right).*

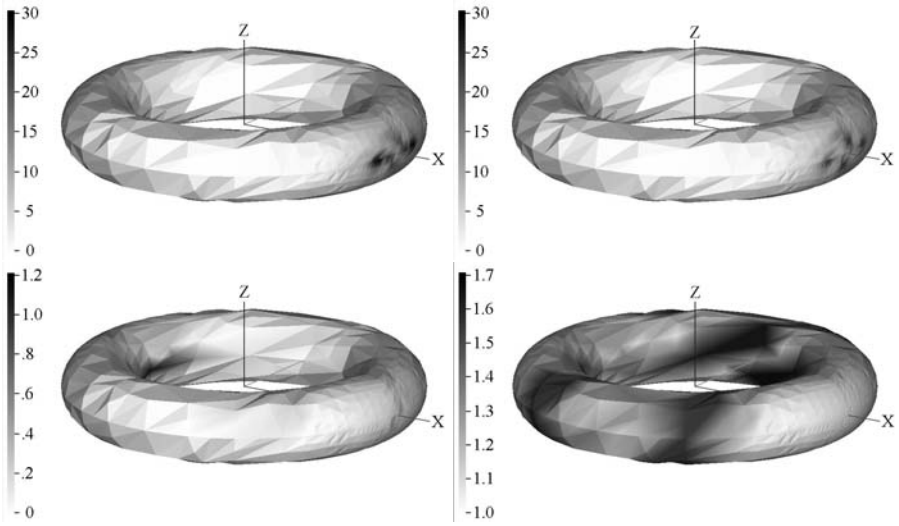

FIG. 5.5. *Experiment* 2: *The local residual* η_T *(top left),* H_1 *error (top right),* $\overline{B}_h|\nabla_{\Gamma_h} u_h|$ *(bottom left), and* $\overline{A}_h$ *(bottom right).*

5.3. Example 3: Computation on an ellipsoid. In our third computational example we let Γ be an ellipsoid satisfying the level set equation

$$x^2 + y^2 + \frac{z^2}{400} = 1. \tag{5.5.2}$$

As a test solution we took $u(x, y, z) = \sin y$ so that u and its derivatives were of moderate size.

In Figure 5.6 we display the local residual contribution η_T and the local geometric error $\overline{B}_h|\nabla_{\Gamma_h} u_h|$ on an adaptively refined mesh having 10383 nodes. Note that the maximum values of η_T and $\overline{B}_h|\nabla_{\Gamma_h} u_h|$ are approximately equal. Thus the geometric error plays a role in the marking of some elements even on a refined mesh. As in Figure 5.3, however, the overall geometric error $\|\overline{B}_h|\nabla_{\Gamma_h}|\|_{L_2(\Gamma_h)}$ declines approximately as DOF^{-1}, while the residual error $(\sum_{T\in\mathcal{T}_h} \eta_T^2)^{1/2}$ declines as $\mathrm{DOF}^{-1/2}$ (we do not display a chart for the current situation as it is entirely analogous to Figure 5.3). Finally, the maximum ratio $h_T/\sqrt{|T|}$ observed in this adaptive calculation (up 64521 DOF) was 3.41, so that mesh quality remained reasonable.

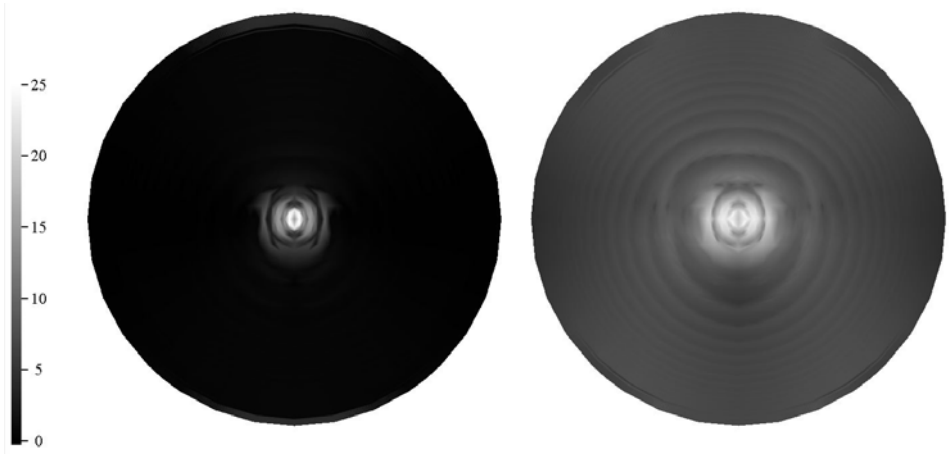

FIG. 5.6. *Experiment* 3: *Mesh with* 10383 *nodes displaying the relative sizes of* $\overline{B}_h|\nabla_{\Gamma_h} u_h|$ *(left) and the local residual* η_T *(right). The view is along the z-axis.*

Appendix. Proof of Proposition 2.1. Proposition 2.1 is potentially of interest in other situations (e.g., when Γ_h is a higher-order polynomial approximation to Γ), so we begin by stating a more general version.

PROPOSITION A.1. *Let* $\hat{T}$ *be the unit simplex in* $\mathbb{R}^2$*, and suppose that* $F : \hat{T} \to U$ *is a* C^1 *mapping whose gradient has two nonzero singular values at each point in* $\hat{T}$*. Suppose* $x \in T := F(\hat{T})$*, let* $\vec{\nu}_h$ *be the normal to* T *at* x*, and let* $\mathrm{d}\sigma_h$ *be a surface measure on* T*. Assume also that* $\vec{\nu} \cdot \vec{\nu}_h > 0$*. Letting* $\mathrm{d}\sigma_h(x)\mu_h(x) = \mathrm{d}\sigma(x)$*, we then have*

$$\mu_h(x) = \vec{\nu} \cdot \vec{\nu}_h (1 - d(x)\kappa_1(x))(1 - d(x)\kappa_2(x)). \tag{A.A.1}$$

Proof. We fix a point $\hat{x} \in \hat{T}$ and let $x = F(\hat{x})$ and $\mathbb{R}^{3\times 2} \ni \mathbf{A} = \nabla F(\hat{x})$. Let $\{\vec{e}_1, \vec{e}_2\}$, $\{\vec{u}_1, \vec{u}_2\}$, and $\{\vec{v}_1, \vec{v}_2\}$ be orthonormal bases for $\mathbb{R}^2$ and the tangent spaces to Γ_h and Γ at x and $a(x)$, respectively. We assume also that $\{\vec{v}_1, \vec{v}_2, \vec{\nu}\}$ are the eigenvectors of $(\mathbf{I} - d\mathbf{H})(x)$ corresponding to the eigenvalues $\lambda_1 = 1 - d(x)\kappa_1(x)$, $\lambda_2 = 1 - d(x)\kappa_2(x)$, and $\lambda_3 = 1$. Letting $\times$ denote the cross product, we have $\mathrm{d}\sigma_h = |\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2|\,\mathrm{d}\hat{x}$ and $\mathrm{d}\sigma = |([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_1) \times ([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_2)|\,\mathrm{d}\hat{x}$.

Next we recall the formula $(\mathbf{B}\vec{x}_1) \times (\mathbf{B}\vec{x}_2) = \mathbf{B}_{adj}(\vec{x}_1 \times \vec{x}_2)$, where $\mathbf{B}$ is symmetric and nonsingular and $\mathbf{B}_{adj} = (\det \mathbf{B})\mathbf{B}^{-1}$. Noting that $(\mathbf{I} - d\mathbf{H})_{adj}$ has eigenvectors $\{\vec{v}_1, \vec{v}_2, \vec{\nu}\}$ with eigenvalues $\{\lambda_2\lambda_3, \lambda_1\lambda_3, \lambda_1\lambda_2\}$, we calculate

$$\begin{aligned}([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_1) \times ([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_2) &= \lambda_2\lambda_3[([\mathbf{P}][\mathbf{A}]\vec{e}_1 \times [\mathbf{P}][\mathbf{A}]\vec{e}_2) \cdot \vec{v}_1]\vec{v}_1 \\ + \lambda_1\lambda_3[([\mathbf{P}][\mathbf{A}]\vec{e}_1 \times [\mathbf{P}][\mathbf{A}]\vec{e}_2) \cdot \vec{v}_2]\vec{v}_2 &+ \lambda_1\lambda_2[([\mathbf{P}][\mathbf{A}]\vec{e}_1 \times [\mathbf{P}][\mathbf{A}]\vec{e}_2) \cdot \vec{\nu}]\vec{\nu}.\end{aligned} \tag{A.A.2}$$

But $([\mathbf{P}][\mathbf{A}]\vec{e}_1 \times [\mathbf{P}][\mathbf{A}]\vec{e}_2) \perp \vec{v}_i$, $i = 1, 2$, $([\mathbf{P}][\mathbf{A}]\vec{e}_1 \times [\mathbf{P}][\mathbf{A}]\vec{e}_2) \cdot \vec{\nu} = (\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2) \cdot \vec{\nu}$, and $\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2 \parallel \vec{\nu}_h$. Thus

$$\begin{aligned}\mathrm{d}\sigma &= |([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_1) \times ([\mathbf{I} - d\mathbf{H}][\mathbf{P}][\mathbf{A}]\vec{e}_2)|\,\mathrm{d}\hat{x} \\ &= \lambda_1\lambda_2[(\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2) \cdot \vec{\nu}]\vec{\nu}\,\mathrm{d}\hat{x} = \lambda_1\lambda_2|\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2|\vec{\nu}_h \cdot \vec{\nu}\,\mathrm{d}\hat{x}.\end{aligned} \tag{A.A.3}$$

Recalling that $\mathrm{d}\sigma_h = |\mathbf{A}\vec{e}_1 \times \mathbf{A}\vec{e}_2|\,\mathrm{d}\hat{x}$ completes the proof. ∎

CONVERGENCE OF FOURTH ORDER COMPACT DIFFERENCE SCHEMES FOR THREE-DIMENSIONAL CONVECTION-DIFFUSION EQUATIONS*

GIVI BERIKELASHVILI†, MURLI M. GUPTA‡, AND MANANA MIRIANASHVILI§

Abstract. We consider a Dirichlet boundary-value problem for the three-dimensional convection-diffusion equations with constant coefficients in the unit cube. A high order compact finite difference scheme is constructed on a 19-point stencil using the Steklov averaging operators. We prove that the finite difference scheme converges in discrete $W_2^m(\omega)$-norm with the convergence rate $O(h^{s-m})$, where the real parameter s satisfies the condition $\max(1.5, m) < s \le m + 4$, $m = 0, 1, 2$, and the exact solution belongs to the Sobolev space $W_2^s(\Omega)$.

Key words. convection-diffusion equation, convergence estimates, three-dimensions, high accuracy, compact approximations, finite differences

1. Introduction.

Let $\Omega = \{x = (x_1, x_2, x_3) : 0 < x_\alpha < 1, \alpha = 1, 2, 3\}$ be the unit cube with boundary Γ. Let D^ν denote the differential operator $D^\nu = \partial^{|\nu|}/(\partial x_1^{\nu_1} \partial x_2^{\nu_2} \partial x_3^{\nu_3})$, where $\nu = (\nu_1, \nu_2, \nu_3)$ are multi-indices with nonnegative integer components, $|\nu| = \nu_1 + \nu_2 + \nu_3$. By $W_2^s(\Omega)$, $s \ge 0$, we denote a Sobolev space with the norm defined by

$$||u||^2_{W_2^s(\Omega)} = \sum_{j=0}^{s} |u|^2_{W_2^j(\Omega)}, \qquad |u|_{W_2^j(\Omega)} = \sum_{|\nu|=j} ||D^\nu u||_{L_2(\Omega)}$$

when s is an integer. If s is a noninteger, let $s = \bar{s} + \varepsilon$, where $\bar{s}$ is the integer part of s and $0 < \varepsilon < 1$. In this case, the norm is defined by

$$||u||^2_{W_2^s(\Omega)} = ||u||^2_{W_2^{\bar{s}}(\Omega)} + |u|^2_{W_2^s(\Omega)},$$

where

$$|u|^2_{W_2^s(\Omega)} = \sum_{|\nu|=\bar{s}} \int_\Omega \int_\Omega \frac{|D^\nu u(x) - D^\nu u(y)|^2}{|x - y|^{3+2\varepsilon}} dx\, dy.$$

In particular, for $s = 0$, we have $W_2^0 = L_2$.

Let $\bar{\omega}$ be the uniform grid in $\bar{\Omega}$ with mesh size h, $\omega = \bar{\omega} \cap \Omega$, $\gamma = \bar{\omega} \backslash \omega$. We define the difference quotients (forward, backward, and central, respectively) in x_α direction as follows:

$$v_{x_\alpha} = \frac{(I^{(+\alpha)} - I)v}{h}, \quad v_{\bar{x}_\alpha} = \frac{(I - I^{(-\alpha)})v}{h}, \quad \partial v = \frac{(I^{(+\alpha)} - I^{(-\alpha)})v}{2h},$$

where $Iv = v$, $I^{(\pm\alpha)}v = v(x \pm hr_\alpha)$, and r_α is the unit vector on the x_α axis.

Let $L_2(\omega)$ be the Hilbert space of all discrete functions $y = y(x)$, defined on the grid ω and vanishing on γ, with the inner product and norm defined by

$$(y, v) = \sum_{x\in\omega} h^3 y(x)v(x), \quad ||y|| = (y, y)^{1/2}.$$

Further, we define the following norms:

$$||y||_{W_2^0(\omega)} = ||y||, \qquad ||y||^2_{W_2^1(\omega)} = \sum_{\alpha=1}^{3} ||y_{\bar{x}_\alpha}||^2_{(\alpha)},$$

$$||y||^2_{W_2^2(\omega)} = ||y_{\bar{x}_1 x_1}||^2 + ||y_{\bar{x}_2 x_2}||^2 + ||y_{\bar{x}_3 x_3}||^2 + 2||y_{\bar{x}_1 \bar{x}_2}||^2_{(1,2)} + 2||y_{\bar{x}_1 \bar{x}_3}||^2_{(1,3)} + 2||y_{\bar{x}_2 \bar{x}_3}||^2_{(2,3)}.$$

In the definitions of the norms $||\cdot||_{(\alpha)}$, $||\cdot||_{(\alpha,\beta)}$ the sums run not only over all interior grid points $x \in \omega$, but also over the boundary points $x \in \gamma$ with the coordinates $x_\alpha = 1$ for $||\cdot||_{(\alpha)}$ and over the boundary points $x \in \gamma$ with the coordinates $x_\alpha = 1$, $x_\beta = 1$ for $||\cdot||_{(\alpha,\beta)}$. The inner product $(\cdot,\cdot)_{(\alpha)}$ is defined in a similar manner.

In this paper, we investigate certain high order compact finite difference schemes for the Dirichlet boundary value problem for three-dimensional convection-diffusion equations with constant coefficients:

$$\Delta u + \sum_{\alpha=1}^{3} \lambda_\alpha \frac{\partial u}{\partial x_\alpha} = f(x),\ x \in \Omega, \quad u(x) = 0,\ \ x \in \Gamma,\ \lambda_\alpha = \text{const}. \tag{1}$$

We obtain discretization error estimates of up to the fourth order that are consistent with the smoothness of the solution sought. By definition (see [1]), these error estimates have the form

$$||y - u||_{W_2^m(\omega)} \le ch^{s-m}||u||_{W_2^s(\Omega)}, \qquad s > m \ge 0, \tag{2}$$

where y is the solution of the finite difference scheme and c denotes a positive generic constant, independent of h and u.

Fourth order finite difference schemes for this problem were considered in [2, 3, 4], and it was numerically exhibited, through a variety of test examples, that the discrete solutions converge to the exact solutions of class $C^6(\bar{\Omega})$ in discrete norm $C(\omega)$, and the rate of convergence was exhibited to be $O(h^4)$ (see also [18]). The case of (1) with variable coefficients has been considered by various authors (see, e.g., [16, 17] for three-dimensional and [19] two-dimensional convection-diffusion equations) who described fourth order compact finite difference schemes and exhibited the fourth order convergence through numerical examples. In [18], an attempt was made to carry out theoretical analysis for the convection diffusion equation (1) with constant coefficients—these authors used an eigenvalue analysis to prove that the coefficient matrix arising from the 19-point discretization of (1) is positive definite when the cell Reynolds number exceeds a critical value and that the discrete solution remains oscillation free in such cases. To our knowledge, no theoretical error estimates have so far been published for (1).

In this paper, we first present the derivation of the 19-point compact finite difference scheme for (1); the resulting finite difference scheme is the same as that introduced and used in previous papers [4, 16]. Next, we derive discretization error estimates of type (2) for the real parameter s satisfying $\max(1.5, \mathrm{m}) < \mathrm{s} \le \mathrm{m}+4$, $m = 0, 1, 2$, under the assumption that the solution of the original boundary-value problem

(1) belongs to the Sobolev space $W_2^s(\Omega)$. These error estimates are derived using certain well-known techniques (see, e.g., [5, 6]) that employ the generalized Bramble–Hilbert lemma. Similar error estimates were previously obtained by Berikelashvili for two-dimensional convection-diffusion equations with constant coefficients in [7].

2. Construction of finite difference schemes. In the Hilbert space $L_2(\omega)$ we define the difference operators

$$\Lambda_\alpha = y_{\bar{x}_\alpha x_\alpha}, \quad \Lambda_{(\alpha)} = \sum_{\substack{k=1 \\ k\neq\alpha}}^{3} \Lambda_k, \quad \alpha = 1, 2, 3.$$

We need the following averaging operators for functions defined on Ω:

$$S_1^- v(x) = \frac{1}{h} \int_{x_1-h}^{x_1} v(t, x_2, x_3)\, dt,$$

$$T_1 v(x) = \frac{1}{h^2} \int_{x_1-h}^{x_1+h} (h - |x_1 - t|) v(t, x_2, x_3)\, dt.$$

The operators S_α^-, T_α are defined in a similar manner for $\alpha = 2, 3$. Notice that these operators commute in the case of different indices and

$$T_\alpha \frac{\partial^2 u}{\partial x_\alpha^2} = \Lambda_\alpha u, \quad T_\alpha \frac{\partial u}{\partial x_\alpha} = (S_\alpha^- u)_{x_\alpha}.$$

Let

$$T = \prod_{k=1}^{3} T_k, \quad T_{(\alpha)} = \prod_{\substack{k=1 \\ k\neq\alpha}}^{3} T_k, \quad \Lambda_{(\alpha)} = \sum_{\substack{k=1 \\ k\neq\alpha}}^{3} \Lambda_k.$$

We assume that the solution u of the boundary-value problem (1) belongs to the Sobolev space $W_2^s(\Omega), s > 1.5$. Applying operator T to (1) we obtain

$$\sum_{\alpha=1}^{3} \Lambda_\alpha T_{(\alpha)} u + \sum_{\alpha=1}^{3} \lambda_\alpha S_\alpha^- T_{(\alpha)} u_{x_\alpha} = Tf. \tag{3}$$

It can be easily verified that, on the set of sufficiently smooth functions, the following operators are equivalent (with errors of order $O(h^4)$):

$$T_\alpha \sim I + \frac{h^2}{12} \Lambda_\alpha$$

and consequently

$$T_{(\alpha)} \sim I + \frac{h^2}{12} \Lambda_{(\alpha)}.$$

Therefore we denote

$$\eta_\alpha = T_{(\alpha)} u - \big(I + \frac{h^2}{12} \Lambda_{(\alpha)}\big) u,$$

which implies

$$\Lambda_\alpha T_{(\alpha)} u = \Lambda_\alpha \left(I + \frac{h^2}{12} \Lambda_{(\alpha)} \right) u + \Lambda_\alpha \eta_\alpha. \tag{4}$$

Similarly,

$$S_\alpha^- T_{(\alpha)} \sim \frac{1}{2} (I + I^{(-\alpha)}) \left(I + \frac{h^2}{6} \Lambda_{(\alpha)} \right) - \frac{h^2}{12} S_\alpha^- T_{(\alpha)} \Delta.$$

The approximation error of this relation is

$$\eta^\alpha = S_\alpha^- T_{(\alpha)} u - \frac{1}{2} (I + I^{(-\alpha)}) \left(I + \frac{h^2}{6} \Lambda_{(\alpha)} \right) u + \frac{h^2}{12} S_\alpha^- T_{(\alpha)} \Delta u,$$

from which it follows that

$$S_\alpha^- T_{(\alpha)} u_{x_\alpha} = \partial_\alpha \left(I + \frac{h^2}{6} \Lambda_{(\alpha)} \right) u - \frac{h^2}{12} T \frac{\partial}{\partial x_\alpha} \Delta u + (\eta^\alpha)_{x_\alpha}. \tag{5}$$

From (3), (4) and (5), we obtain the following equality:

$$\begin{aligned} &\sum_{\alpha=1}^{3} \Lambda_\alpha \left(I + \frac{h^2}{12} \Lambda_{(\alpha)} \right) u + \sum_{\alpha=1}^{3} \lambda_\alpha \partial_\alpha \left(I + \frac{h^2}{6} \Lambda_{(\alpha)} \right) u \\ &+ \frac{h^2}{6} \sum_{1 \le \alpha < \beta \le 3} \lambda_\alpha \lambda_\beta T \frac{\partial^2 u}{\partial x_\alpha \partial x_\beta} + \frac{h^2}{12} \sum_{\alpha=1}^{3} \lambda_\alpha^2 T \frac{\partial^2 u}{\partial x_\alpha^2} + \sum_{\alpha=1}^{3} (\Lambda_\alpha \eta_\alpha + \lambda_\alpha \eta_{x_\alpha}^\alpha) = \varphi, \end{aligned} \tag{6}$$

where

$$\varphi = Tf + \frac{h^2}{12} \sum_{\alpha=1}^{3} \lambda_\alpha T \frac{\partial f}{\partial x_\alpha}. \tag{7}$$

Using

$$\eta^{\alpha\beta} = \frac{h^2}{6} \left(S_\alpha^- S_\beta^- T_\gamma u - \frac{1}{4} (I + I^{(-\alpha)} + I^{(-\beta)} + I^{(-\alpha)} I^{(-\beta)}) u \right),$$

$$\gamma = 6 - \alpha - \beta, \quad \eta_\alpha^\alpha = \frac{h^2}{12} (T_{(\alpha)} u - u),$$

we obtain

$$\frac{h^2}{6} T \frac{\partial^2 u}{\partial x_\alpha \partial x_\beta} = \frac{h^2}{6} \partial_\alpha \partial_\beta u + (\eta^{\alpha\beta})_{x_\alpha x_\beta}, \quad \frac{h^2}{12} T \frac{\partial^2 u}{\partial x_\alpha^2} = \frac{h^2}{12} \Lambda_\alpha u + \Lambda_\alpha \eta_\alpha^\alpha,$$

and from (6) we get

$$\begin{aligned} &\sum_{\alpha=1}^{3} \Lambda_\alpha \left(I + \frac{h^2}{12} \Lambda_{(\alpha)} \right) u + \sum_{\alpha=1}^{3} \lambda_\alpha \partial_\alpha \left(I + \frac{h^2}{6} \Lambda_{(\alpha)} \right) u \\ &+ \frac{h^2}{6} \sum_{1 \le \alpha < \beta \le 3} \lambda_\alpha \lambda_\beta \partial_\alpha \partial_\beta u + \frac{h^2}{12} \sum_{\alpha=1}^{3} \lambda_\alpha^2 \Lambda_\alpha u = \varphi + \psi, \end{aligned} \tag{8}$$

where the remainder term (truncation error) ψ is given by

$$\psi = -\sum_{\alpha=1}^{3}(\Lambda_\alpha \eta_\alpha + \lambda_\alpha \eta^\alpha_{x_\alpha} + \lambda^2_\alpha \Lambda_\alpha \eta^\alpha_\alpha) - \sum_{1\le\alpha<\beta\le 3} \lambda_\alpha \lambda_\beta (\eta^{\alpha\beta})_{x_\alpha x_\beta}. \tag{9}$$

By dropping the remainder term on the right-hand side of (8) and replacing the continuous solution $u(x)$ by the grid function $y(x)$, we obtain the finite difference scheme

$$-\mathcal{L}_h y = \varphi, \quad x \in \omega, \quad y \in L_2(\omega), \tag{10}$$

where the right-hand side φ is defined in (7) and

$$\mathcal{L}_h y \equiv (\mathcal{A}+\mathcal{B}+\mathcal{C})y, \quad \mathcal{A} = -\sum_{\alpha=1}^{3} \Lambda_\alpha \left(I + \frac{h^2}{12}\Lambda_{(\alpha)}\right), \quad \mathcal{C} = -\sum_{\alpha=1}^{3} \lambda_\alpha \partial_\alpha \left(I + \frac{h^2}{6}\Lambda_{(\alpha)}\right),$$

$$\mathcal{B} = -\frac{h^2}{6} \sum_{1\le\alpha<\beta\le 3} \lambda_\alpha \lambda_\beta \partial_\alpha \partial_\beta - \frac{h^2}{12} \sum_{\alpha=1}^{3} \lambda^2_\alpha \Lambda_\alpha, \quad \Lambda_{(\alpha)} = \sum_{\substack{\beta=1 \\ \beta\ne\alpha}}^{3} \Lambda_\beta.$$

3. A priori estimate of discretization error. We start with a few preliminary results.

The operators Λ_α are self-adjoint and negative definite in the Hilbert space $L_2(\omega)$ with respect to the inner product $(.,.)$, and (see, e.g., [8])

$$8I \le -\Lambda_\alpha \le (4/h^2)I, \quad \Lambda_\alpha \Lambda_\beta = \Lambda_\beta \Lambda_\alpha, \ \alpha,\beta = 1,2,3, \ \beta \ne \alpha. \tag{11}$$

Consequently, the operator

$$\Lambda = -\sum_{\alpha=1}^{3} \Lambda_\alpha$$

is self-adjoint and positive definite in $L_2(\omega)$, and

$$24I \le \Lambda \le (12/h^2)I.$$

One can easily verify that

$$||y||_{W_2^1(\omega)} = (\Lambda y, y)^{1/2}, \quad ||y||_{W_2^2(\omega)} = ||\Lambda y||.$$

LEMMA 3.1. *$\mathcal{L}_h$ is a positive definite operator in space $L_2(\omega)$, and for any $y \in L_2(\omega)$, we have the following estimate:*

$$3(\mathcal{L}_h y, y) \ge ||y||^2_{W_2^1(\omega)}. \tag{12}$$

Proof. Taking into account inequality (11), we have

$$(\mathcal{A}y, y) \ge (1/3)(\Lambda y, y) = (1/3)||y||^2_{W_2^1(\omega)} \tag{13}$$

as $I + (h^2/12)\Lambda_{(\alpha)} \ge (1/3)I$. It is easy to verify that $(\partial_\alpha y, v) = -(y, \partial_\alpha v)$ and consequently

$$(\mathcal{C}y, y) = 0. \tag{14}$$

Further, we have

$$(\mathcal{B}y,y)=\frac{h^2}{12}\sum_{\alpha=1}^{3}\lambda_\alpha^2||y_{\bar{x}_\alpha}||_{(\alpha)}^2+\frac{h^2}{6}\sum_{1\le\alpha<\beta\le3}\lambda_\alpha\lambda_\beta(\partial_\alpha y,\partial_\beta y).$$

However,

$$||\partial_\alpha y||^2=\sum_\omega h^3\left(\frac{y_{\bar{x}_\alpha}+y_{x_\alpha}}{2}\right)^2\le\sum_\omega\frac{h^3}{2}(y_{\bar{x}_\alpha}^2+y_{x_\alpha}^2)\le||y_{\bar{x}_\alpha}||_{(\alpha)}^2,$$

which yields

$$(\mathcal{B}y,y)\ge\frac{h^2}{12}\sum_{\alpha=1}^{3}\lambda_\alpha^2||\partial_\alpha y||^2+\frac{h^2}{6}\sum_{1\le\alpha<\beta\le3}\lambda_\alpha\lambda_\beta(\partial_\alpha y,\partial_\beta y)$$

$$=\frac{h^2}{12}||\sum_{\alpha=1}^{3}\lambda_\alpha\partial_\alpha y||^2\ge0. \tag{15}$$

The relations (13)–(15) complete the proof of Lemma 3.1. □

LEMMA 3.2. *For any $y\in L_2(\omega)$ the following estimates are valid:*

$$||\Lambda y||\le c_0||\mathcal{L}_h y||, \tag{16}$$

$$||\mathcal{L}_h^{-1}y||\le c_0||\Lambda^{-1}y||, \tag{17}$$

where $c_0=3+(9\sqrt{2}/4)\lambda$, $\lambda=max(|\lambda_1|,|\lambda_2|,|\lambda_3|)$.

Proof. We have $(\Lambda_1 y,\Lambda_2 y)=-(\Lambda_2 y_{\bar{x}_1},y_{\bar{x}_1})_{(1)}\ge(\partial_2 y_{\bar{x}_1},\partial_2 y_{\bar{x}_1})_{(1)}=(-\Lambda_1\partial_2 y,\partial_2 y)$, and $(\Lambda_1 y,\Lambda_3 y)\ge(-\Lambda_1\partial_3 y,\partial_3 y)$, which yields

$$(\Lambda_1 y,\lambda_2^2\Lambda_2 y+\lambda_3^2\Lambda_3 y+2\lambda_2\lambda_3\partial_2\partial_3 y)\ge||\partial_1(\lambda_2\partial_2+\lambda_3\partial_3)y||^2.$$

Using this inequality we obtain

$$(\mathcal{B}y,-\Lambda_1 y)=(h^2/12)\big(\lambda_1^2||\Lambda_1 y||^2+(\Lambda_1 y,\lambda_2^2\Lambda_2 y+\lambda_3^2\Lambda_3 y+2\lambda_2\lambda_3\partial_2\partial_3 y)$$

$$+2\lambda_1\lambda_2(\partial_1\partial_2 y,\Lambda_1 y)+2\lambda_1\lambda_3(\partial_1\partial_3 y,\Lambda_1 y)\big)$$

$$\ge(h^2/12)||(\lambda_1\Lambda_1+\lambda_2\partial_1\partial_2+\lambda_3\partial_1\partial_3)y||^2\ge0.$$

Analogously, $(\mathcal{B}y,-\Lambda_k y)\ge0$, for $k=2,3$ which yields $(\mathcal{B}y,\Lambda y)\ge0$. From (13), we have $(\mathcal{A}y,\Lambda y)\ge\frac{1}{3}||\Lambda y||^2$, which yields $((\mathcal{A}+\mathcal{B})y,\Lambda y)\ge\frac{1}{3}||\Lambda y||^2$, or

$$||\Lambda y||\le3||(\mathcal{A}+\mathcal{B})y||. \tag{18}$$

It is clear that

$$||\mathcal{C}y||\le\lambda\sum_{\alpha=1}^{3}\left\|\left(I+\frac{h^2}{6}\Lambda_{(\alpha)}\right)\partial_\alpha y\right\|\le\lambda\sum_{\alpha=1}^{3}||\partial_\alpha y||$$

$$\le\sqrt{3}\lambda\left(\sum_{\alpha=1}^{3}||\partial_\alpha y||^2\right)^{1/2}\le\sqrt{3}\lambda||y||_{W_2^1(\omega)}. \tag{19}$$

Using Lemma 3.1 and the discrete analogue of Friedrichs inequality $||y||^2_{W_2^1(\omega)} \geq 24||y||^2$, we obtain

$$||y||_{W_2^1(\omega)} \leq \frac{\sqrt{6}}{4}||\mathcal{L}_h y||, \tag{20}$$

and therefore the relation

$$||\mathcal{C}y|| \leq \frac{3\sqrt{2}}{4}\lambda||\mathcal{L}_h y|| \tag{21}$$

follows from inequality (19). Substituting $\mathcal{A}+\mathcal{B} = \mathcal{L}_h - \mathcal{C}$ into (18) and using (21), we obtain the estimate in (16). The estimate

$$||\Lambda y|| \leq c||\mathcal{L}_h^* y|| \ \ \forall y \in L_2(\omega) \tag{22}$$

can be obtained in a similar manner. Further, $\mathcal{L}_h^*\mathcal{L}_h$ is a self-adjoint positive definite operator in $L_2(\omega)$, and

$$||\mathcal{L}_h^{-1}y|| = ||(\mathcal{L}_h^*\mathcal{L}_h)^{-1}\mathcal{L}_h^* y|| = \sup_{v\neq 0}\frac{|(\mathcal{L}_h^* y, v)|}{||\mathcal{L}_h^*\mathcal{L}_h y||} = \sup_{v\neq 0}\frac{|(\Lambda^{-1}y, \Lambda\mathcal{L}_h v)|}{||\mathcal{L}_h^*\mathcal{L}_h y||}$$
$$\leq ||\Lambda^{-1}y||\sup_{v\neq 0}\frac{||\Lambda\mathcal{L}_h v)||}{||\mathcal{L}_h^*\mathcal{L}_h v||}.$$

Using this result and (22), we obtain (17). This completes the proof of Lemma 3.2. □

Let $z = y - u$, where u is the continuous solution of the boundary-value problem (1) and y is the solution of the finite difference scheme (10). Substituting $y = u+z$ into (10) and taking into account (8), we obtain the following problem for the discretization error z:

$$\mathcal{L}_h z = \psi, \ \ z \in L_2(\omega), \tag{23}$$

where the truncation error ψ is defined in (9).

LEMMA 3.3. *For the solution of problem* (23) *the following estimates hold:*

$$||z||_{W_2^m(\omega)} \leq c_m J_m(u), \ \ m = 0,1,2, \ c_1 = 3, \ c_2 = c_0, \tag{24}$$

where

$$J_0(u) = \sum_{\alpha=1}^{3}\left(||\eta_\alpha|| + \lambda||\eta^\alpha||_{(\alpha)} + \lambda^2||\eta^\alpha_\alpha||\right) + \sum_{1\leq\alpha<\beta\leq 3}\lambda^2||\eta^{\alpha\beta}||_{(\alpha,\beta)},$$
$$J_1(u) = \sum_{\alpha=1}^{3}\left(||\eta_{\alpha\bar{x}_\alpha}||_{(\alpha)} + \lambda||\eta^\alpha||_{(\alpha)} + \lambda^2||\eta^\alpha_{\alpha\bar{x}_\alpha}||_{(\alpha)}\right) + \sum_{1\leq\alpha<\beta\leq 3}\lambda^2||\eta^{\alpha\beta}_{x_\beta}||_{(\alpha)},$$
$$J_2(u) = \sum_{\alpha=1}^{3}\left(||\Lambda_\alpha\eta_\alpha|| + \lambda||\eta^\alpha_{x_\alpha}|| + \lambda^2||\Lambda_\alpha\eta^\alpha_\alpha||\right) + \sum_{1\leq\alpha<\beta\leq 3}\lambda^2||\eta^{\alpha\beta}_{x_\alpha x_\beta}||.$$

Proof. For $m = 0$, (24) can be established using the estimate (17), taking into account that $||\Lambda_\alpha v|| \leq ||\Lambda v||$, $||v_{\bar{x}_\alpha}||_{(\alpha)} \leq ||\Lambda v||$, and $||v_{x_\alpha x_\beta}|| \leq ||\Lambda v||$.

For $m = 1$, we have from (12) and (23):

$$||z||^2_{W_2^1(\omega)} \le 3|(\psi, z)|. \tag{25}$$

Using the definition of ψ in (9) and summing by parts, we obtain

$$(\psi, z) = -\sum_{\alpha=1}^{3} \left((\eta_{\alpha\bar{x}_\alpha}, z_{\bar{x}_\alpha})_{(\alpha)} + \lambda_\alpha (\eta^\alpha, z_{\bar{x}_\alpha})_{(\alpha)} + \lambda_\alpha^2 (\eta^\alpha_{\alpha\bar{x}_\alpha}, z_{\bar{x}_\alpha})_{(\alpha)} \right)$$
$$- \sum_{1\le\alpha<\beta\le 3} \lambda_\alpha \lambda_\beta (\eta^{\alpha\beta}_{x_\beta}, z_{\bar{x}_\alpha})_{(\alpha)}.$$

As $||z_{\bar{x}_\alpha}||_{(\alpha)} \le ||z||_{W_2^1(\omega)}$, using the Cauchy inequality we get $(\psi, z)| \le J_1(u)\, ||z||_{W_2^1(\omega)}$. Using (25) we obtain the desired result (24) for the case $m = 1$.

For $m = 2$, the estimate (24) follows immediately from (23) using (16). Thus, Lemma 3.3 is proved. □

To determine the rate of convergence of the finite difference scheme (10) with the help of Lemma 3.3, it is sufficient to estimate the corresponding norms of the expressions $\eta_\alpha, \eta^\alpha, \eta^\alpha_\alpha$, and $\eta^{\alpha\beta}$ on the right-hand side $J_k(u)$ of (24).

For this we need the next lemma.

LEMMA 3.4. *Assume that the linear functional $l(u)$ is bounded in $W_2^s(E)$, where $s = \bar{s} + \epsilon$, $\bar{s}$ is an integer, $0 < \epsilon \le 1$, and $l(P) = 0$ for every polynomial P of degree $\le \bar{s}$ in three variables. Then, there exists a constant c, independent of u, such that $|l(u)| \le c\ |u|_{W_2^s(\Omega)}$.*

This lemma is a particular case of the Dupont–Scott approximation theorem [9] and represents a generalization of the Bramble–Hilbert lemma [10] (see also [11]).

4. Estimate of the convergence rate. By π_k let us denote the set of all polynomials of degree $\le k$ in three variables.

We assert that the following inequalities hold for $\alpha = 1, 2, 3$:

$$||\eta_\alpha|| \le ch^s |u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4],$$
$$||\eta_{\alpha\bar{x}_\alpha}||_{(\alpha)} \le ch^{s-1} |u|_{W_2^s(\Omega)}, \quad s \in (1.5, 5], \tag{26}$$
$$||\Lambda_\alpha \eta_\alpha|| \le ch^{s-2} |u|_{W_2^s(\Omega)}, \quad s \in (1.5, 6].$$

First we consider the expression η_1. Let $e = e(x) = \{\xi = (\xi_1, \xi_2, \xi_3) :\ |\xi_\alpha - x_\alpha| \le h,\ \alpha = 1, 2, 3\}$. By $\widetilde{u}(t)$ we denote a function obtained from $u(\xi)$ by changing the variables $\xi_\alpha = x_\alpha + t_\alpha h, \alpha = 1, 2, 3$, and mapping the function $e(x)$ onto $\widetilde{e} = \{t = (t_1, t_2, t_3) :\ |t_\alpha| \le 1,\ \alpha = 1, 2, 3\}$. Since $u(\xi) = u(x_1 + t_1 h, x_2 + t_2 h, x_3 + t_3 h) = \widetilde{u}(t)$, the expression

$$\eta_1 = T_2 T_3 u - \left(I + \frac{h^2}{12}\Lambda_2 + \frac{h^2}{12}\Lambda_3 \right) u$$

turns into

$$\eta_1 = \int_{-1}^{1}\int_{-1}^{1} (1 - |t_2|)(1 - |t_3|)\widetilde{u}(0, t_2, t_3)\, dt_2 dt_3$$
$$-\frac{1}{12}\big(\widetilde{u}(0,1,0) + \widetilde{u}(0,-1,0) + \widetilde{u}(0,0,1) + \widetilde{u}(0,0,-1) + 8\widetilde{u}(0,0,0)\big).$$

Consequently, $|\eta_1| \le c||\widetilde{u}||_{C(\widetilde{e})} \le c||\widetilde{u}||_{W_2^s(\widetilde{e})}$ as $W_2^s \subset C$ when $s > 1.5$. Utilizing the fact that η_1, as a functional of $\widetilde{u}$, vanishes on π_3 (which can be verified directly) and using Lemma 3.4, we obtain $|\eta_1| \le c|\widetilde{u}|_{W_2^s(\widetilde{e})}, s \in (1.5, 4]$. Reverting to the old variables, this yields $|\eta_1| \le ch^{s-1.5}|u|_{W_2^s(e)}, s \in (1.5, 4]$. Consequently, we have

$$||\eta_1||^2 = \sum_\omega h^3|\eta_1|^2 \le ch^{2s}\sum_\omega |u|^2_{W_2^s(e)} \le ch^{2s}|u|^2_{W_2^s(\Omega)}.$$

The other estimates in (26) can be obtained analogously, using the fact that the functionals $\eta_{\alpha\bar{x}_\alpha}$ and $\Lambda_\alpha\eta_\alpha$ vanish on π_4 and π_5, respectively.

The boundedness of the other error functionals is evident when $u \in W_2^s(\Omega)$, $s > 3/2$. Only the term $S_\alpha^- T_{(\alpha)}\Delta u$ involved in η^α needs a special consideration. For instance, for $\alpha = 1$ we have

$$S_1^- T_2T_3\Delta u = \left(T_2T_3\frac{\partial u}{\partial x_1}\right)_{\bar{x}_1} + \Lambda_2 S_1^- T_3 u + \Lambda_3 S_1^- T_2 u.$$

It follows from $u \in W_2^s$ that $(\partial u/\partial x_1) \in W_2^{s-1}$ and for fixed x_1 this derivative, as a function of variables x_2, x_3, belongs to $W_2^{s-3/2}$. Therefore the averaging $T_2T_3(\partial u/\partial x_1)$ makes sense and can be estimated by $||u||_{W_2^s(\Omega)}$.

The expressions η^α and $\eta^\alpha_{\bar{x}_\alpha}$ vanish on π_3 and π_4, respectively, and the following estimates can be obtained in a similar manner:

$$||\eta^\alpha|| \le ch^s|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4], \tag{27}$$

$$||\eta^\alpha_{\bar{x}_\alpha}||_{(\alpha)} \le ch^{s-1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 5]. \tag{28}$$

From (27), it follows that

$$||\eta^\alpha|| \le ch^{s-1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 5]. \tag{29}$$

Similarly, for η^α_α, $\eta^\alpha_{\alpha\bar{x}_\alpha}$, and $\Lambda_\alpha\eta^\alpha_\alpha$, which vanish, respectively, on π_1, π_2, and π_3, we have the following estimates:

$$||\eta^\alpha_\alpha|| \le ch^{s+2}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 2],$$

$$||\eta^\alpha_{\alpha\bar{x}_\alpha}||_{(\alpha)} \le ch^{s+1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 3],$$

$$||\Lambda_\alpha\eta^\alpha_\alpha|| \le ch^s|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4].$$

Consequently, we obtain

$$||\eta^\alpha_\alpha|| \le ch^s|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4],$$

$$||\eta^\alpha_{\alpha\bar{x}_\alpha}||_{(\alpha)} \le ch^{s-1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 5], \tag{30}$$

$$||\Lambda_\alpha\eta^\alpha_\alpha|| \le ch^{s-2}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 6].$$

The expressions $\eta^{\alpha\beta}$, $\eta^{\alpha\beta}_{\bar{x}_\beta}$, and $\eta^{\alpha\beta}_{x_\alpha x_\beta}$ vanish, respectively, on π_1, π_2, and π_3. Consequently,

$$||\eta^{\alpha\beta}|| \le ch^{s+2}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 2],$$
$$||\eta^{\alpha\beta}_{\bar{x}_\beta}||_{(\alpha)} \le ch^{s+1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 3].$$
$$||\eta^{\alpha\beta}_{x_\alpha x_\beta}|| \le ch^{s}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4].$$

From this we obtain

$$\begin{aligned} &||\eta^{\alpha\beta}|| \le ch^{s}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 4], \\ &||\eta^{\alpha\beta}_{\bar{x}_\beta}||_{(\alpha)} \le ch^{s-1}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 5], \\ &||\eta^{\alpha\beta}_{x_\alpha x_\beta}|| \le ch^{s-2}|u|_{W_2^s(\Omega)}, \quad s \in (1.5, 6]. \end{aligned} \tag{31}$$

As a result, using estimates (26)–(31) and Lemma 3.3, we arrive at the following proposition.

THEOREM 4.1. *Let the exact solution of the boundary-value problem* (1) *belong to* $W_2^s(\Omega)$, $s > 1.5$. *Then, the discretization error of the finite difference scheme* (10) *in the discrete* W_2^m*-norm is determined by the estimate* (2) *for* s *satisfying* $\max(1.5, m) < s \le m + 4$, $m = 0, 1, 2$.

5. Comparisons with other methods. Let $\sigma = (\sigma_1, \sigma_2, \sigma_3)$ be a multi-index with components $-1, 0$, or 1, $|\sigma| = |\sigma_1| + |\sigma_2| + |\sigma_3|$, and $y_\sigma = y_{i+\sigma_1, j+\sigma_2, k+\sigma_3}$. At the node (ih, jh, kh) the finite difference scheme (10) may be represented in the form

$$\sum_{|\sigma|=0}^{2} a_\sigma y_\sigma = 6h^2\varphi, \tag{32}$$

where

$$\begin{aligned} a_\sigma &= -24 - h^2(\lambda_1^2 + \lambda_2^2 + \lambda_3^2) \quad \text{if } \sigma = (0,0,0), \\ a_\sigma &= 2 + h\sum_{k=1}^{3}\sigma_k\lambda_k + \frac{h^2}{2}\sum_{k=1}^{3}(\sigma_k\lambda_k)^2 \quad \text{if } |\sigma| = 1, \\ a_\sigma &= 1 + \frac{h}{2}\sum_{k=1}^{3}\sigma^k\lambda_k + \frac{h^2}{4}\sum_{k,l=1}^{3}\sigma_k\sigma_l\lambda_k\lambda_l \quad \text{if } |\sigma| = 2. \end{aligned}$$

The left-hand side of (32) is the same as that of the 19-point finite difference scheme defined by Gupta and Zhang [4].

In the case when $u \in W_2^s(\Omega)$, $s > 3.5$, and thus $f \in W_2^{s-2}(\Omega)$ is continuous, the right-hand side of the finite difference scheme (32) can be written as

$$F = 3h^2 f + \frac{h^4}{2}\sum_{\alpha=1}^{3}\lambda_\alpha\partial_\alpha f + \frac{h^2}{2}\sum_{|\sigma|=1} f_\sigma,$$

and the resulting scheme,

$$\sum_{|\sigma|=0}^{2} a_\sigma y_\sigma = F, \tag{33}$$

is exactly the same as in [4].

TABLE 5.1
Maximum errors for (34).

	Re = 1	Re = 1000
$h = 1/16$	1.50×10^{-5}	9.04×10^{-3}
$h = 1/32$	9.45×10^{-7}	1.15×10^{-3}
$h = 1/64$	5.96×10^{-8}	8.36×10^{-5}

Using the imbedding $W_2^2(\omega)$ into $C(\omega)$ for discrete functions of three variables, we obtain for both schemes (32) and (33) the discretization error estimate in uniform metric

$$||y - u||_{C(\omega)} \le ch^{s-2}||u||_{W_2^s(\Omega)}$$

with $s \in (2, 6]$ and $s \in (3.5, 6]$, respectively. This proves the fourth order discretization error estimates for both of the compact difference schemes for three-dimensional convection-diffusion equations.

As an illustration, we present numerical data from Gupta and Zhang [4] where the following convection diffusion equation was solved for various values of the parameter Re:

$$\Delta u - \mathrm{Re}\left[\cos\alpha\cos\beta\frac{\partial u}{\partial x_1} + \cos\alpha\sin\beta\frac{\partial u}{\partial x_2} + \sin\alpha\frac{\partial u}{\partial x_3}\right] = f(x). \tag{34}$$

In Table 5.1, we give data for the parameters $\alpha = 35°$, $\beta = 45°$ and the exact solution given by $u = \sin\pi x_1 \sin\pi x_2 \sin\pi x_3$. The maximum errors of the numerical solutions are exhibited in Table 5.1 for $h = 1/16$, $h = 1/32$, and $h = 1/64$ and for Re = 1 and Re = 1000. As shown in [4], the maximum norms of the numerical errors decay according to $O(h^4)$, and this rate of convergence has now been theoretically established by the results of this paper.

Remark 1. Our results are also valid in the case when the grid $\bar{\omega}$ is uniform in each direction x_1, x_2, and x_3 with steps h_1, h_2, and h_3, respectively. High accuracy compact finite difference schemes for problem (1) cannot, generally, be defined on irregular grids.

Remark 2. Equations of the type (1) often arise in problems of fluid dynamics as a linearized version of the momentum equation, and it is desirable for the corresponding finite difference schemes to have high accuracy, especially for large values of λ_α. Therefore it is important to represent the convergence estimates in terms of the parameter λ. Such estimates, e.g., in $W_2^1(\omega)$-norm for the difference scheme (10) have the form

$$\|z\|_{W_2^1(\omega)} \le cM(\lambda)h^{s-1}\|u\|_{W_2^s(\Omega)}, \quad s \in (1.5, 5],$$

where c is independent of h, λ, and $u(x)$ and

$$M(\lambda) = 1 + \lambda h + \lambda^2 h^2 \quad \text{if } s \in (1.5, 3],$$

$$M(\lambda) = 1 + \lambda h + \lambda^2 h^{5-s} \quad \text{if } s \in (3, 4],$$

$$M(\lambda) = 1 + \lambda^2 h^{5-s} \quad \text{if } s \in (4, 5].$$

Remark 3. As noted above, a few finite difference schemes for (1) (with variable coefficients λ_α) are known for approximation of the considered problem (see, e.g.,

[4, 16, 17] for three-dimensional problems and [19] for two-dimensional problems). However, the rate of convergence (of any order) can be exhibited only computationally in such cases as has been done through a number of test examples in the cited papers.

In some special cases, the fourth order convergence can be proved only when $u \in C^6(\bar{\Omega})$ whereas we have obtained convergence estimate of order h^s for $s \in (1.5, 4]$:

$$\|y - u\| \le ch^s \|u\|_{W_2^s(\Omega)}, \quad s \in (1.5, 4].$$

At present we do not have sufficient mathematical tools to establish estimates such as (12) for variable coefficient operators $\mathcal{L}_h$, and we plan to work on the error estimates for variable coefficient problems in the future.

Remark 4. Certain streamline-diffusion finite element methods (SDFEM) for problem (1) are also known in the literature (see, e.g., [12, 13, 14, 15]). For such methods, typically the convergence is obtained in the so-called streamline-diffusion norm. This norm weakens as the diffusion parameter tends to zero (in our case $\lambda \to \infty$). However, unlike our finite difference scheme (10), theoretical convergence estimates better than $O(h^2)$ are not available for SDFEM.

Acknowledgment. The authors wish to thank the referees for their helpful comments and for pointing out the SDFEM schemes. We hope that the confluence of these two methods (SDFEM and ours) will lead to strong and useful results in the future.

OPTIMAL CONVERGENCE FOR THE IMPLICIT SPACE-TIME DISCRETIZATION OF PARABOLIC SYSTEMS WITH *p*-STRUCTURE*

LARS DIENING†, CARSTEN EBMEYER‡, AND MICHAEL RŮŽIČKA†

Abstract. Parabolic systems with p-structure are considered on convex polyhedral domains under Dirichlet boundary conditions. A fully discrete scheme is studied using C^0-piecewise linear finite elements in space and the backward Euler difference scheme in time. A priori error estimates in quasi norms are proved, and optimal convergence rates are obtained.

Key words. degenerate parabolic system, time discretization, finite element methods, weak and strong solution, error analysis

1. Introduction.

Let $\Omega \subset \mathbb{R}^d$, $d \geq 2$, be a convex polyhedral domain, and let $T \in (0,\infty)$, $I = [0,T]$, and Q_T be the time-space cylinder $I \times \Omega$. For a given right-hand side $\mathbf{f} : Q_T \to \mathbb{R}^d$ and a given initial value $\mathbf{u}_0 : \Omega \to \mathbb{R}^d$ we seek $\mathbf{u} = (u_1, \dots, u_d)^\top : Q_T \to \mathbb{R}^d$ solving the system

$$\begin{aligned} \partial_t \mathbf{u} - \operatorname{div} \mathbf{S}(\nabla \mathbf{u}) &= \mathbf{f} && \text{in } Q_T\,, \\ \mathbf{u}(0) &= \mathbf{u}_0 && \text{in } \Omega\,, \\ \mathbf{u} &= 0 && \text{on } I \times \partial\Omega\,, \end{aligned} \tag{1.1}$$

where $\mathbf{S}$ has p-structure (cf. (2.1), (2.2)). Typical prototypes are

$$\mathbf{S}(\nabla \mathbf{u}) = \big|\nabla \mathbf{u}\big|^{p-2} \nabla \mathbf{u} \quad \text{and} \quad \mathbf{S}(\nabla \mathbf{u}) = \big(1 + \big|\nabla \mathbf{u}\big|^2\big)^{\frac{p-2}{2}} \nabla \mathbf{u}, \tag{1.2}$$

where $1 < p < \infty$.

In this paper we deal with a fully discrete scheme using continuous piecewise linear finite elements in space and the backward Euler time discretization. In the case of the heat equation, which corresponds to the case $p = 2$, it is well known that

$$\|u - U\|^2_{L^\infty(I,L^2(\Omega))} + \int_0^T \|\nabla u - \nabla U\|_2^2 \, dt \leq c\left(k^2 + h^2\right)$$

if the data are suitable. Here U denotes the space-time discretization of u, k is the size of each time step, and h is the mesh size; cf. [24]. The aim of this paper is to generalize this result to problem (1.1). Therefore, we estimate the approximation error in suitable quasi norms. Moreover, we give assumptions on the data that provide the regularity required for $\mathbf{u}$ for deriving these optimal convergence rates.

Extensive research has been carried out for time discretizations and finite element approximations of problems with p-structure; cf. [1, 2, 3, 4, 7, 10, 13, 16, 19, 20, 21, 25]. However, with the exception of [1, 10, 21], all results are suboptimal in the sense that either the order of the error estimate is not optimal or the assumed regularity of the solution is too high and not realistic for general situations. For instance, in the case of the elliptic degenerate p-Laplace equation it is well known that sharp error estimates cannot be obtained if the error is estimated in Sobolev or weighted Sobolev norms. A significant development in the error estimation for such degenerate problems is the quasi-norm approach of Barrett and Liu; cf. [2, 3, 19]. The key idea is to introduce a quasi norm $\|\cdot\|_{(\nabla \mathbf{u})}$ satisfying

$$\|\nabla \mathbf{u} - \nabla \mathbf{U}\|^2_{(\nabla \mathbf{u})} \cong \int_\Omega \big(\mathbf{S}(\nabla \mathbf{u}) - \mathbf{S}(\nabla \mathbf{U})\big) \cdot (\nabla \mathbf{u} - \nabla \mathbf{U})\, dx,$$

where $1 < p < \infty$. Utilizing this quasi norm, sharp error estimates can be established; e.g., for elliptic problems with p-structure it was shown in [2] that

$$\|\nabla u - \nabla u_h\|_{(\nabla u)} \le c \inf_{v_h \in V_h} \|\nabla u - \nabla v_h\|_{(\nabla u),}$$

where u is the weak solution, u_h is the finite element approximation of u, and V_h is the finite element space of continuous piecewise linear functions vanishing on $\partial\Omega$. Moreover, in [10] the finite element interpolation error estimation theory in the quasi norms was established. It was proved that

$$\inf_{v_h \in V_h} \|\nabla u - \nabla v_h\|^2_{(\nabla u)} \le c\, h^2 \int_\Omega |\nabla u|^{p-2} |\nabla^2 u|^2,$$

where h is the mesh size. Since regularity results for problems with p-structure are available (cf. [15, 6, 12, 11]), the integral on the right-hand side is finite and thus the optimal convergence rate for elliptic problems

$$\|\nabla u - \nabla u_h\|^2_{(\nabla u)} \le c\, h^2$$

was obtained. In the case of time discretizations most results again are only suboptimal. Usually, error estimates of the form

$$\|u - u_k\|^2_{l^\infty(I_k, L^2(\Omega))} + \|\nabla u - \nabla u_k\|^2_{l^p(I_k, L^p(\Omega))} \le c\, k^{2\alpha(p)},$$

where u is the solution of the parabolic problem with p-structure, u_k is the backward Euler time discretized solution, and $\alpha(p) \in (0, 1)$, are proved. In [21] optimal estimates for the time discretization by means of the Yoshida approximation are proved; i.e., one has $\alpha(p) = 1$. However, no spatial discretization is treated there and it seems to be difficult to include further nonmonotone nonlinearities in this approach. Recently, abstract error estimates for a full space-time discretization with $\alpha(p) = 1$ were given in [1]. Under additional regularity assumptions explicit error estimates in terms of the time-step size and mesh size are derived there. The approach presented here is completely different.

In this paper we treat parabolic systems with p-structure for all $\frac{2d}{d+2} < p < \infty$. We will estimate the approximation error between the solution $\mathbf{u}$ of problem (1.1) and the solution $\mathbf{U}$ of the fully discrete scheme using continuous piecewise linear finite elements in space and the backward Euler time discretization in quasi norms and show the *optimal* convergence rate

$$\|\mathbf{u} - \mathbf{U}\|^2_{L^\infty(I, L^2(\Omega))} + \int_0^T \|\nabla \mathbf{u} - \nabla \mathbf{U}\|^2_{(\nabla \mathbf{u})}\, dt \le c\,(k^2 + h^2),$$

where k is the time-step size and h the mesh size, which are related by the mesh ratio condition $h^{\alpha(p,d)} \le c\,k$ (cf. (5.1)). This result is derived for the natural regularity of the problem, which is available under rather general assumptions on the data. Note that the condition (5.1) is present even for $p = 2$. We believe that this condition is only of technical character and hope that it can be removed by an appropriate argument.

2. Preliminaries. For matrices $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{d\times d}$ with components A_{ij} and B_{ij} we denote $\mathbf{A}\cdot\mathbf{B} = \sum_{i,j=1}^{d} A_{ij}B_{ij}$. We write $f \cong g$ if and only if there exist constants $c_0, c_1 > 0$, such that

$$c_0 f \le g \le c_1 f\,,$$

where we always indicate on what the constants may depend. We use the usual notation of Lebesgue-, Sobolev-, and Bochner-spaces, respectively, namely $\big(L^p(\Omega), \|\cdot\|_p\big)$, $\big(W^{k,p}(\Omega), \|\cdot\|_{k,p}\big)$, and $\big(L^p(I,X), \|\cdot\|_{L^p(I,X)}\big)$, where X is some Banach space, respectively. We denote $\langle f, g\rangle := \int_\Omega f(x)\,g(x)\,dx$. Moreover, for $f : I\times\Omega \to \mathbb{R}$ we often write $f(t)$ instead of $f(t,\cdot)$.

Concerning the structure of the system (1.1) we assume that the operator induced by $-\operatorname{div}\mathbf{S}(\nabla\mathbf{u})$ has *p-structure*; i.e., there exist $p > 1$, $\kappa \ge 0$, and $\gamma_1, \gamma_2 > 0$ such that

$$\sum_{i,j,k,l=1}^{d} \frac{\partial S_{ij}(\mathbf{A})}{\partial A_{kl}} B_{ij}B_{kl} \ge \gamma_1 \big(\kappa + |\mathbf{A}|\big)^{p-2}|\mathbf{B}|^2 \tag{2.1}$$

is satisfied for all $\mathbf{B}, \mathbf{A} \in \mathbb{R}^{d\times d}$, and that

$$\left|\frac{\partial S_{ij}(\mathbf{A})}{\partial A_{kl}}\right| \le \gamma_2 \big(\kappa + |\mathbf{A}|\big)^{p-2} \tag{2.2}$$

is satisfied for all $i, j, k, l = 1, \dots, d$. Note that the above prototypes (1.2) satisfy these assumptions. Closely related to the operator $\mathbf{S}$ with p-structure is the function $\mathbf{F} : \mathbb{R}^{d\times d} \to \mathbb{R}^{d\times d}$ defined by

$$\mathbf{F}(\mathbf{B}) := (\kappa + |\mathbf{B}|)^{\frac{p-2}{2}}\mathbf{B}\,.$$

This is clarified by the following algebraic lemma.

LEMMA 2.1. *For all $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{d\times d}$ there holds*

$$\big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big)\cdot\big(\mathbf{A} - \mathbf{B}\big) \cong |\mathbf{A} - \mathbf{B}|^2\big(\kappa + |\mathbf{B}| + |\mathbf{A}|\big)^{p-2} \tag{2.3a}$$

$$\cong |\mathbf{F}(\mathbf{A}) - \mathbf{F}(\mathbf{B})|^2 \tag{2.3b}$$

with constants depending on p only.

The proof can be found in the appendix. For $\mathbf{A}, \mathbf{B} : \Omega \to \mathbb{R}^{d\times d}$ we introduce the quasi norm (cf. [2, 3, 19])

$$\|\mathbf{A}\|_{(\mathbf{B})} := \left(\int_\Omega \big(\kappa + |\mathbf{B}(x)| + |\mathbf{A}(x)|\big)^{p-2}|\mathbf{A}(x)|^2\,dx\right)^{\frac{1}{2}}.$$

Lemma 2.1 and the fact that $|\mathbf{B}| + |\mathbf{A} - \mathbf{B}| \cong |\mathbf{B}| + |\mathbf{A}|$ imply the following lemma.

LEMMA 2.2. *For all* $\mathbf{v}, \mathbf{w} \in W^{1,p}(\Omega)$ *there holds*

$$\begin{aligned} \|\nabla \mathbf{v} - \nabla \mathbf{w}\|^2_{(\nabla \mathbf{w})} &\cong \big\langle \mathbf{S}(\nabla \mathbf{v}) - \mathbf{S}(\nabla \mathbf{w}), \nabla \mathbf{v} - \nabla \mathbf{w} \big\rangle \\ &\cong \|\mathbf{F}(\nabla \mathbf{v}) - \mathbf{F}(\nabla \mathbf{w})\|_2^2 \end{aligned} \tag{2.4}$$

with constants depending on p *only.*

Furthermore, for $\delta > 0$ there is a constant $c_\delta > 0$ such that for all $\lambda, \mu, \nu \geq 0$ (cf. [3])

$$(\lambda + \mu)^{p-2} \mu \, \nu \leq \delta (\lambda + \mu)^{p-2} \mu^2 + c_\delta (\lambda + \nu)^{p-2} \nu^2 \, .$$

Due to this inequality, (2.3a), and (6.8) there holds the following result.

LEMMA 2.3. *For* $\delta > 0$ *there exists* $c_\delta > 0$ *such that for all* $\mathbf{A}, \mathbf{B}, \mathbf{C} \in \mathbb{R}^{d \times d}$ *there holds*

$$\begin{aligned} &\big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big) \cdot \big(\mathbf{A} - \mathbf{C}\big) \\ &\quad \leq \delta \, \big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big) \cdot \big(\mathbf{A} - \mathbf{B}\big) + c_\delta \, \big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{C})\big) \cdot \big(\mathbf{A} - \mathbf{C}\big) \end{aligned}$$

and

$$\big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big) \cdot \big(\mathbf{A} - \mathbf{C}\big) \leq \delta \, \big|\mathbf{F}(\mathbf{A}) - \mathbf{F}(\mathbf{B})\big|^2 + c_\delta \, \big|\mathbf{F}(\mathbf{A}) - \mathbf{F}(\mathbf{C})\big|^2 \, .$$

Especially for $\mathbf{v}, \mathbf{w}_1, \mathbf{w}_2 \in W^{1,p}(\Omega)$ we easily deduce from this that

$$\begin{aligned} &\big\langle \mathbf{S}(\nabla \mathbf{v}) - \mathbf{S}(\nabla \mathbf{w}_1), \nabla \mathbf{v} - \nabla \mathbf{w}_2 \big\rangle \\ &\qquad \leq \delta \, \|\nabla \mathbf{v} - \nabla \mathbf{w}_1\|^2_{(\nabla \mathbf{v})} + c_\delta \, \|\nabla \mathbf{v} - \nabla \mathbf{w}_2\|^2_{(\nabla \mathbf{v})} \end{aligned}$$

and

$$\begin{aligned} &\big\langle \mathbf{S}(\nabla \mathbf{v}) - \mathbf{S}(\nabla \mathbf{w}_1), \nabla \mathbf{v} - \nabla \mathbf{w}_2 \big\rangle \\ &\qquad \leq \delta \, \|\mathbf{F}(\nabla \mathbf{v}) - \mathbf{F}(\nabla \mathbf{w}_1)\|_2^2 + c_\delta \, \|\mathbf{F}(\nabla \mathbf{v}) - \mathbf{F}(\nabla \mathbf{w}_2)\|_2^2 \, . \end{aligned} \tag{2.5}$$

3. The continuous problem. In this section we investigate the regularity of solutions of system (1.1). Throughout the remainder of the paper we assume that

$$\begin{aligned} \mathbf{u}_0 &\in W^{1,2}_0(\Omega) \cap W^{1,p}_0(\Omega), \\ \operatorname{div}\big(\mathbf{S}(\nabla \mathbf{u}_0)\big) &\in L^2(\Omega), \\ \mathbf{f} &\in L^{p'}(I, L^{p'}(\Omega)) \cap C(I, L^2(\Omega)) \cap L^2(I, W^{1,2}_0(\Omega)), \\ \partial_t \mathbf{f} &\in L^2(I, L^2(\Omega)), \end{aligned} \tag{3.1}$$

where p' is the dual exponent of p. We call $\mathbf{u}$ a weak solution of problem (1.1) if $\mathbf{u} \in L^\infty(I, L^2(\Omega)) \cap L^p(I, W^{1,p}_0(\Omega))$ with $\partial_t \mathbf{u} \in L^{p'}(I, (W^{1,p}_0(\Omega))^*)$ satisfies for almost all $t \in I$

$$\begin{aligned} \big\langle \partial_t \mathbf{u}, \mathbf{w} \big\rangle_{W^{1,p}_0(\Omega)} + \big\langle \mathbf{S}(\nabla \mathbf{u}), \nabla \mathbf{w} \big\rangle &= \langle \mathbf{f}, \mathbf{w} \rangle \qquad \forall \mathbf{w} \in W^{1,p}_0(\Omega), \\ \mathbf{u}(0) &= \mathbf{u}_0, \end{aligned} \tag{3.2}$$

where $\langle \mathbf{v}, \mathbf{w} \rangle_{W^{1,p}_0(\Omega)}$ denotes the duality pairing in $W^{1,p}_0(\Omega)$. It is well known (cf. [18, 14]) that for $p \geq \frac{2d}{d+2}$ there exists a unique weak solution of (1.1) with

$$\|\mathbf{u}\|^2_{L^\infty(I, L^2(\Omega))} + \|\mathbf{u}\|^p_{L^p(I, W^{1,p}(\Omega))} \leq C \, \big(\, \|\mathbf{f}\|^{p'}_{L^{p'}(I, L^{p'}(\Omega))} + \|\mathbf{u}_0\|^2_2 \big) \, .$$

LEMMA 3.1. *The solution* $\mathbf{u}$ *of* (1.1) *satisfies under the assumptions* (3.1)

$$\|\partial_t \mathbf{u}\|^2_{C(I,L^2(\Omega))} + \int_0^T \left\|\partial_t\big(\mathbf{F}(\nabla \mathbf{u})\big)\right\|_2^2 \, dt \le c(\mathbf{f}, \mathbf{u}_0).$$

Proof. In [14, Theorem 6.2.1][1] (cf. [18] for $p \ge 2$) it is shown that problem (1.1) possesses under the above assumptions a solution $\mathbf{u} \in C^1_w(I, L^2(\Omega)) \cap C_w(I, W^{1,p}_0(\Omega))$; i.e., $\partial_t \mathbf{u}$ is weakly continuous in $L^2(\Omega)$, and $\mathbf{u}$ is weakly continuous in $W^{1,p}_0(\Omega)$. In particular we have

$$\sup_{t\in[0,T]} \|\partial_t \mathbf{u}(t)\|_{L^2(\Omega)} \le c\,, \tag{3.3}$$

which is the first part of the assertion. In order to prove the second part we use the difference quotient with respect to time. Let $D^\tau \mathbf{u}(t,x) := \frac{1}{\tau}(\mathbf{u}(t+\tau,x) - \mathbf{u}(t,x))$, $\tau > 0$. We apply D^τ to (3.2) and set $\mathbf{w} := D^\tau \mathbf{u}$. Then for all t

$$\big\langle \partial_t D^\tau \mathbf{u}, D^\tau \mathbf{u}\big\rangle + \big\langle D^\tau\big(\mathbf{S}(\nabla \mathbf{u})\big), D^\tau \nabla \mathbf{u}\big\rangle = \langle D^\tau \mathbf{f}, D^\tau \mathbf{u}\rangle.$$

This and (2.4) yield

$$\frac{1}{2}\partial_t \|D^\tau \mathbf{u}\|_2^2 + c\left\|D^\tau\big(\mathbf{F}(\nabla \mathbf{u})\big)\right\|_2^2 \le \|D^\tau \mathbf{f}\|_2 \|D^\tau \mathbf{u}\|_2.$$

Integration over $t \in [0, t^*]$, $0 \le t^* \le T$, and taking the supremum over $t^* \in [0,T]$ imply

$$\begin{aligned} &\|D^\tau \mathbf{u}\|^2_{C(I,L^2(\Omega))} + \int_0^T \left\|D^\tau\big(\mathbf{F}(\nabla \mathbf{u})\big)\right\|_2^2 \, dt \\ &\le c\left(\|D^\tau \mathbf{u}(0)\|_2^2 + \|\partial_t \mathbf{f}\|^2_{L^2(I,L^2(\Omega))} + \|\partial_t \mathbf{u}\|^2_{L^2(I,L^2(\Omega))}\right) \\ &\le c\,, \end{aligned}$$

where we used (3.1) and (3.3). The second assertion now follows from the properties of the difference quotient. ∎

4. Backward time discretization. We introduce the notation $t_n := nk$, $N := \lfloor T/k \rfloor$, $I_n := (t_{n-1}, t_n)$,

$$\mathbf{u}^n(x) := \mathbf{u}(t_n, x), \quad \text{and} \quad \overline{\mathbf{u}}^n(x) := k^{-1}\int_{I_n} \mathbf{u}(s,x)\, ds.$$

We define $\mathbf{y}^0 := \mathbf{u}_0$ and successively let $\mathbf{y}^n$, $n = 1, \dots, N$, be the solutions of

$$\begin{aligned} d_t \mathbf{y}^n(x) - \operatorname{div}\big(\mathbf{S}(\nabla \mathbf{y}^n(x))\big) &= \overline{\mathbf{f}}^n(x) \quad \text{in } \Omega, \\ \mathbf{y}^n &= 0 \qquad \text{on } \partial\Omega, \end{aligned} \tag{4.1}$$

where $d_t \mathbf{y}^n := \frac{1}{k}(\mathbf{y}^n - \mathbf{y}^{n-1})$. Since each $\mathbf{y}^n$ is the solution of a stationary problem, $\mathbf{y}^n$ is well defined and unique. Using the test function $\mathbf{y}^n$ and the properties of $\mathbf{S}$ yields

$$\sup_n \|\mathbf{y}^n\|_2^2 + k\sum_n \|\mathbf{y}^n\|^p_{1,p} \le C\left(1 + k\sum_n \left\|\overline{\mathbf{f}}^n\right\|^{p'}_{p'} + \|\mathbf{u}_0\|_2^2\right).$$

[1] Note that in [14] only $\mathbf{f} = \mathbf{0}$ is treated. However, under the above assumptions the proof continues to hold without any changes.

Furthermore, we have the following regularity results.

LEMMA 4.1. *The solutions* $\mathbf{y}^n$ *of* (4.1) *satisfy*

$$\sup_{1\le n\le N}\|\nabla \mathbf{y}^n\|_2^2 + k\sum_{n=1}^{N}\big\|\nabla\big(\mathbf{F}(\nabla \mathbf{y}^n)\big)\big\|_2^2 \le C(\mathbf{f},\mathbf{u}_0).$$

Proof. We only sketch the idea and refer the reader to [11, 12] for details. Let us define $D^\sigma \mathbf{y}^n(x) := \frac{1}{|\sigma|}(\mathbf{y}^n(x+\sigma)-\mathbf{y}^n(x))$, $\sigma\in\mathbb{R}^d\setminus\{0\}$. We multiply (4.1) with $D^{-\sigma}D^\sigma \mathbf{y}^n$ and find

$$\langle d_t D^\sigma \mathbf{y}^n, D^\sigma \mathbf{y}^n\rangle + \big\langle D^\sigma\big(\mathbf{S}(\nabla \mathbf{y}^n)\big), D^\sigma\nabla \mathbf{y}^n\big\rangle = \langle D^\sigma \overline{\mathbf{f}}^n, D^\sigma \mathbf{y}^n\rangle.$$

In view of (2.4) we obtain

$$\frac{1}{2}d_t\,\|D^\sigma \mathbf{y}^n\|_2^2 + c\,\big\|D^\sigma\big(\mathbf{F}(\nabla \mathbf{y}^n)\big)\big\|_2^2 \le \big\|D^\sigma \overline{\mathbf{f}}^n\big\|_2\|D^\sigma \mathbf{y}^n\|_2.$$

Summation over $n=1,\dots,M$ implies

$$\begin{aligned}&\big\|D^\sigma \mathbf{y}^M\big\|_2^2 + k\sum_{n=1}^{M}\big\|D^\sigma\big(\mathbf{F}(\nabla \mathbf{y}^n)\big)\big\|_2^2\\ &\quad\le c\left(\|D^\sigma \mathbf{u}_0\|_2^2 + k\sum_{n=1}^{M}\left(\big\|D^\sigma\overline{\mathbf{f}}^n\big\|_2^2 + \big\|D^\sigma \mathbf{y}^n\big\|_2^2\right)\right).\end{aligned}$$

We take the supremum over $M=1,\dots,N$ and get

$$\begin{aligned}&\sup_n\|D^\sigma \mathbf{y}^n\|_2^2 + k\sum_{n=1}^{N}\big\|D^\sigma\big(\mathbf{F}(\nabla \mathbf{y}^n)\big)\big\|_2^2\\ &\quad\le c\left(\|\nabla \mathbf{u}_0\|_2^2 + \|\nabla \mathbf{f}\|_{L^2(I,L^2(\Omega))}^2 + k\sum_{n=1}^{N}\|D^\sigma \mathbf{y}^n\|_2^2\right).\end{aligned}$$

The discrete Gronwall lemma yields for $k<1/(2c)$

$$\sup_n\|D^\sigma \mathbf{y}^n\|_2^2 + k\sum_{n=1}^{N}\big\|D^\sigma\big(\mathbf{F}(\nabla \mathbf{y}^n)\big)\big\|_2^2 \le C(\mathbf{f},\mathbf{u}_0).$$

The properties of the difference quotient prove the lemma. ∎

LEMMA 4.2. *The solutions* $\mathbf{y}^n$ *of* (4.1) *satisfy*

$$k\sum_{n=1}^{N}\|\mathbf{y}^n\|_{W^{2,\frac{4}{4-p}}(\Omega)}^2 \le C(\mathbf{f},\mathbf{u}_0)\qquad \text{if } p\le 2$$

and

$$k\sum_{n=1}^{N}\|\mathbf{y}^n\|_{\mathcal{N}^{1+\frac{2}{p},p}(\Omega)}^p \le C(\mathbf{f},\mathbf{u}_0)\qquad \text{if } p>2,$$

where $\mathcal{N}^{1+\frac{2}{p},p}(\Omega)$ *denotes a Nikol′skiĭ space (cf.* [17]*).*

Proof. First, we consider the case that $p \le 2$. Hölder's inequality yields

$$
\begin{aligned}
(4.2)\qquad & k\sum_{n=1}^{N} \left\|\nabla^2 \mathbf{y}^n\right\|_{\frac{4}{4-p}}^2 \\
&= k\sum_{n=1}^{N} \left[\int_\Omega (\kappa + |\nabla \mathbf{y}^n|)^{\frac{4-2p}{4-p}} \, (\kappa + |\nabla \mathbf{y}^n|)^{\frac{2p-4}{4-p}} \, |\nabla^2 \mathbf{y}^n|^{\frac{4}{4-p}}\right]^{\frac{4-p}{2}} \\
&\le k\sum_{n=1}^{N} \left[\left(\int_\Omega (\kappa + |\nabla \mathbf{y}^n|)^2\right)^{\frac{2-p}{4-p}} \left(\int_\Omega (\kappa + |\nabla \mathbf{y}^n|)^{p-2} \, |\nabla^2 \mathbf{y}^n|^2\right)^{\frac{2}{4-p}}\right]^{\frac{4-p}{2}} \\
&\le \sup_n \|\kappa + |\nabla \mathbf{y}^n|\|_2^{2-p} \left[k\sum_{n=1}^{N} \int_\Omega (\kappa + |\nabla \mathbf{y}^n|)^{p-2} \, |\nabla^2 \mathbf{y}^n|^2\right].
\end{aligned}
$$

Note that in the case $\kappa = 0$ one carries out the above calculation with some $\widetilde{\kappa} > 0$ and bounds in the last line the term $(\widetilde{\kappa} + |\nabla \mathbf{y}^n|)^{p-2} \, |\nabla^2 \mathbf{y}^n|^2$ by $|\nabla \mathbf{y}^n|^{p-2} \, |\nabla^2 \mathbf{y}^n|^2$. A straightforward calculation shows that $(\kappa + |\nabla \mathbf{y}^n|)^{p-2} \, |\nabla^2 \mathbf{y}^n|^2 \cong \left|\nabla\left(\mathbf{F}(\nabla \mathbf{y}^n)\right)\right|^2$, with constants depending only on p. Thus it follows from Lemma 4.1 that the right-hand side of (4.2) is finite.

Now let us treat the case that $p > 2$. The proof of Lemma 4.1 entails

$$
k\sum_{n=1}^{N} \langle D^\sigma(\mathbf{S}(\nabla \mathbf{y}^n)), D^\sigma \nabla \mathbf{y}^n\rangle \cong k\sum_{n=1}^{N} \left\|D^\sigma\left(\mathbf{F}(\nabla \mathbf{y}^n)\right)\right\|_2^2 \le C(\mathbf{f}, \mathbf{u}_0).
$$

Noting that

$$
\begin{aligned}
\left(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\right) \cdot \left(\mathbf{A} - \mathbf{B}\right) &\cong |\mathbf{A} - \mathbf{B}|^2 \left(\kappa + |\mathbf{A}| + |\mathbf{A} - \mathbf{B}|\right)^{p-2} \\
&\ge |\mathbf{A} - \mathbf{B}|^p,
\end{aligned}
$$

it follows that

$$
k\sum_{n=1}^{N} \int_\Omega \sigma^{-2} \, |\nabla \mathbf{y}^n(x + \sigma) - \nabla \mathbf{y}^n(x)|^p \, dx \le C(\mathbf{f}, \mathbf{u}_0).
$$

Thus, difference quotients of order $\frac{2}{p}$ of $\nabla \mathbf{y}^n$ are bounded in $L^p(\Omega)$. This yields the assertion. ∎

Remark 4.3. Note that one can improve for $p \le 2$ the regularity stated above by using methods from [8], [7, Prop. 3.7], [22, Prop. 3.23]. Essentially one uses $d_t^2 \mathbf{y}^n$ and $-\Delta \mathbf{y}^n$ (treating the term with $d_t \mathbf{y}^n$ as a right-hand side) as test functions to derive better regularity properties for $\mathbf{y}^n$. This implies, with the help of a parabolic embedding theorem, that $\mathbf{y}^n \in l^\infty(I_k, W^{1,r}(\Omega))$ with $r = r(p, d) > 2$. Thus (4.2) can be improved. The improved Lemma 4.2 would lead to an improvement of the mesh ratio condition (5.1). Due to the complicated dependence on p and d we do not proceed this way here, since it does not lead to optimal results.

We will now estimate the error between $\mathbf{u}$ and $\mathbf{y}^n$.

LEMMA 4.4. *There is a constant c independent of k such that*

$$
\begin{aligned}
&\sup_{1 \le n \le N} \|\mathbf{u}^n - \mathbf{y}^n\|_2^2 + \sum_{n=1}^{N} \int_{I_n} \left\|\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{y}^n)\right\|_2^2 \, dt \\
&\quad \le c \sum_{n=1}^{N} \int_{I_n} \left\|\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{u}^n)\right\|_2^2 \, dt.
\end{aligned}
$$

Proof. Averaging (1.1) over I_n we find

$$d_t \mathbf{u}^n - \operatorname{div}(\overline{\mathbf{S}(\nabla \mathbf{u})}^n) = \overline{\mathbf{f}}^n. \tag{4.3}$$

Let $\mathbf{e}^n := \mathbf{u}^n - \mathbf{y}^n$. Taking the difference between (4.3) and (4.1) and multiplying by $\mathbf{e}^n$ we get

$$\left\langle d_t \mathbf{e}^n, \mathbf{e}^n \right\rangle + \left\langle \overline{\mathbf{S}(\nabla \mathbf{u})}^n - \mathbf{S}(\nabla \mathbf{y}^n), \nabla \mathbf{e}^n \right\rangle = 0.$$

Let $1 \le M \le N$. Multiplying by k and summing over n from 1 to M we obtain

$$\frac{1}{2}\langle \mathbf{e}^M, \mathbf{e}^M \rangle + \frac{k^2}{2} \sum_{n=1}^{M} \|d_t \mathbf{e}^n\|_2^2 + \sum_{n=1}^{M} \int_{I_n} \left\langle \mathbf{S}(\nabla \mathbf{u}(t)) - \mathbf{S}(\nabla \mathbf{y}^n), \nabla \mathbf{e}^n \right\rangle dt = 0.$$

Hence,

$$\begin{aligned} &\frac{1}{2}\langle \mathbf{e}^M, \mathbf{e}^M \rangle + \sum_{n=1}^{M} \int_{I_n} \left\langle \mathbf{S}(\nabla \mathbf{u}(t)) - \mathbf{S}(\nabla \mathbf{y}^n), \nabla \mathbf{u}(t) - \nabla \mathbf{y}^n \right\rangle dt \\ &\quad \le \sum_{n=1}^{M} \int_{I_n} \left\langle \mathbf{S}(\nabla \mathbf{u}(t)) - \mathbf{S}(\nabla \mathbf{y}^n), \nabla \mathbf{u}(t) - \nabla \mathbf{u}^n \right\rangle dt. \end{aligned}$$

Inequality (2.5) yields

$$\begin{aligned} &\left\langle \mathbf{S}(\nabla \mathbf{u}(t)) - \mathbf{S}(\nabla \mathbf{y}^n), \nabla \mathbf{u}(t) - \nabla \mathbf{u}^n \right\rangle \\ &\quad \le \delta \left\| \mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{y}^n) \right\|_2^2 + c_\delta \left\| \mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{u}^n) \right\|_2^2. \end{aligned}$$

We absorb the first term of the right-hand side and utilize (2.4) to prove the lemma. ∎

Corollary 4.5. *There is a constant c independent of k such that*

$$\begin{aligned} &\sup_{1 \le n \le N} \|\mathbf{u}^n - \mathbf{y}^n\|_2^2 + k \sum_{n=1}^{N} \left\| \mathbf{F}(\nabla \mathbf{u}^n) - \mathbf{F}(\nabla \mathbf{y}^n) \right\|_2^2 \\ &\qquad \le c \sum_{n=1}^{N} \int_{I_n} \|\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{u}^n)\|_2^2 \, dt. \end{aligned} \tag{4.4}$$

Proof. The left-hand side of (4.4) is bounded by

$$\sup_{1 \le n \le N} \|\mathbf{u}^n - \mathbf{y}^n\|_2^2 + 2 \sum_{n=1}^{N} \int_{I_n} \|\mathbf{F}(\nabla \mathbf{u}^n) - \mathbf{F}(\nabla \mathbf{u}(t))\|_2^2 + \|\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{y}^n)\|_2^2 \, dt \,.$$

The statement now follows from Lemma 4.4. ∎

Lemma 4.6. *There holds*

$$\sum_{n=1}^{N} \int_{I_n} \left\| (\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{u}^n) \right\|_2^2 dt \le c\, k^2 \, \left\| \partial_t \big(\mathbf{F}(\nabla \mathbf{u}) \big) \right\|_{L^2(I, L^2(\Omega))}^2 .$$

Proof. We estimate

$$\begin{aligned}\int_{I_n}\int_\Omega |\mathbf{F}(\nabla \mathbf{u}^n)-\mathbf{F}(\nabla \mathbf{u})|^2\,dx\,dt &= \int_{I_n}\int_\Omega \left|\int_t^{t_n} \partial_\tau\Big(\mathbf{F}\big(\nabla \mathbf{u}(\tau)\big)\Big)\,d\tau\right|^2 dx\,dt\\ &\le k\int_{I_n}\int_\Omega\int_t^{t_n}\left|\partial_\tau\Big(\mathbf{F}\big(\nabla \mathbf{u}(\tau)\big)\Big)\right|^2 d\tau\,dx\,dt\\ &\le k^2\int_{I_n}\int_\Omega |\partial_t\big(\mathbf{F}(\nabla \mathbf{u})\big)|^2\,dx\,dt.\end{aligned}$$

Summing over n, this yields the assertion. ∎

From Lemmas 3.1, 4.4, and 4.6 and Corollary 4.5 we now deduce the following theorem.

THEOREM 4.7. *There is a constant c independent of k such that*

$$\begin{aligned}&\sup_{1\le n\le N}\|\mathbf{u}^n-\mathbf{y}^n\|_2^2 + k\sum_{n=1}^N \big\|\mathbf{F}(\nabla \mathbf{u}^n)-\mathbf{F}(\nabla \mathbf{y}^n)\big\|_2^2\\ &\quad+\sum_{n=1}^N\int_{I_n}\|\mathbf{F}(\nabla \mathbf{u}(t))-\mathbf{F}(\nabla \mathbf{y}^n)\|_2^2\,dt \le c\,k^2.\end{aligned}$$

5. Finite element discretization. Let $\mathcal{T}_h$ be a decomposition of Ω into closed d-simplices, where h denotes the mesh size. We suppose that $\mathcal{T}_h$ is a regular triangulation in the sense of [5, section 3.2]. Moreover, let

$$h^{\alpha(p,d)} \le c\,k\,, \tag{5.1}$$

where $\alpha(p,d)=2-d(1-\frac{p}{2})$ if $p\in(1,2]$ and $\alpha(p,d)=2+(d-2)(1-\frac{2}{p})=d+\frac{2(2-d)}{p}$ if $p\in[2,\infty)$. We define the space of continuous piecewise linear finite elements,

$$V_h := \big\{\boldsymbol{\chi}\in C^0(\Omega;\mathbb{R}^d)\,:\,\boldsymbol{\chi}|_K \text{ is linear for all } K\in\mathcal{T}_h \text{ and } \boldsymbol{\chi}|_{\partial\Omega}=0\big\}\,.$$

Further, let $P_h\mathbf{u}\in V_h$ be some appropriate interpolant of $\mathbf{u}$.[2]

For $\mathbf{U}^0 := P_h\mathbf{u}_0$ let the functions $\mathbf{U}^n\in V_h$, $n=1,\dots,N$, be the solutions of the algebraic equations

$$\big\langle d_t\mathbf{U}^n,\boldsymbol{\chi}^n\big\rangle + \big\langle \mathbf{S}(\nabla\mathbf{U}^n),\nabla\boldsymbol{\chi}^n\big\rangle = \big\langle \overline{\mathbf{f}}^n,\boldsymbol{\chi}^n\big\rangle \qquad \forall\boldsymbol{\chi}^n\in V_h. \tag{5.2}$$

The solvability of (5.2) follows easily from Brouwer's fixed point theorem and the properties of $\mathbf{S}$. We define $\mathbf{U}: I\times\Omega\to\mathbb{R}^d$ by

$$\mathbf{U}(t,x) := \begin{cases}\mathbf{U}^0(x) & \text{for } t=0,\\ \mathbf{U}^n(x) & \text{for } t_{n-1}<t\le t_n.\end{cases}$$

The aim of the this section is to prove the following theorem.

[2] In the case $p>\frac{d}{2}$ one can take the Lagrange interpolation operator (cf. [10])and for smaller values of p the interpolation operator from [23] (cf. [9]).

THEOREM 5.1. *Under the assumptions* (3.1) *and* (5.1) *there is for any* $p > \frac{2d}{d+2}$ *a constant* c *independent of* h *and* k *such that*

$$\sup_{1\le n\le N} \|\mathbf{u}^n - \mathbf{U}^n\|_2^2 + k\sum_{n=1}^{N} \left\|\mathbf{F}(\nabla \mathbf{u}^n) - \mathbf{F}(\nabla \mathbf{U}^n)\right\|_2^2 + \sum_{n=1}^{N}\int_{I_n} \|\mathbf{F}(\nabla \mathbf{u}(t)) - \mathbf{F}(\nabla \mathbf{U}^n)\|_2^2 \, dt \le c\left(h^2 + k^2\right).$$

In terms of quasi norms this reads

$$\|\mathbf{u} - \mathbf{U}\|^2_{L^\infty(0,T;L^2(\Omega))} + \int_0^T \|\nabla \mathbf{u} - \nabla \mathbf{U}\|^2_{(\nabla \mathbf{u}(t))} \, dt \le c\left(h^2 + k^2\right).$$

COROLLARY 5.2. *Under the assumptions* (3.1) *and* (5.1) *there exists for any* $p \in (\frac{2d}{d+2}, 2]$ *a constant* c *independent of* h *and* k *such that*

$$\|\nabla \mathbf{u} - \nabla \mathbf{U}\|_{L^p(I;L^p(\Omega))} \le c\,(h + k).$$

We proceed in several steps. First we estimate $\mathbf{y}^n - \mathbf{U}^n$.

LEMMA 5.3. *There is a constant* c *independent of* h *and* k *such that*

$$\sup_{1\le n\le N} \|\mathbf{y}^n - \mathbf{U}^{\mathbf{n}}\|_2^2 + k\sum_{n=1}^{N} \|\mathbf{F}(\nabla \mathbf{y}^n) - \mathbf{F}(\nabla \mathbf{U}^n)\|_2^2 \le c\left[\sum_{n=0}^{N} \|\mathbf{y}^n - P_h\mathbf{y}^n\|_2^2 + k\sum_{n=1}^{N} \|\mathbf{F}(\nabla \mathbf{y}^n) - \mathbf{F}(\nabla P_h\mathbf{y}^n)\|_2^2\right].$$

Proof. Let $\mathbf{E}^n = \mathbf{y}^n - \mathbf{U}^n$. Taking the difference between (4.1) and (5.2) and multiplying by $P_h\mathbf{E}^n$ we get

$$\left\langle d_t\mathbf{E}^n, P_h\mathbf{E}^n\right\rangle + \left\langle \mathbf{S}(\nabla \mathbf{y}^n) - \mathbf{S}(\nabla \mathbf{U}^n), \nabla P_h\mathbf{E}^n\right\rangle = 0.$$

Notice that $\langle d_t\mathbf{E}^n, \mathbf{E}^n\rangle = \langle d_t\mathbf{E}^n, P_h\mathbf{E}^n\rangle + \langle d_t\mathbf{E}^n, \mathbf{y}^n - P_h\mathbf{y}^n\rangle$ and

$$k\sum_{n=1}^{M} \left\langle d_t\mathbf{E}^n, \mathbf{E}^n\right\rangle = \frac{1}{2}\left\|\mathbf{E}^M\right\|_2^2 - \frac{1}{2}\left\|\mathbf{E}^0\right\|_2^2 + \frac{k^2}{2}\sum_{n=1}^{M} \left\|d_t\mathbf{E}^n\right\|_2^2.$$

Thus, we find

$$\begin{aligned}\frac{1}{2}\left\|\mathbf{E}^M\right\|_2^2 &+ \frac{k^2}{2}\sum_{n=1}^{M} \|d_t\mathbf{E}^n\|_2^2 + k\sum_{n=1}^{M} \left\langle \mathbf{S}(\nabla \mathbf{y}^n) - \mathbf{S}(\nabla \mathbf{U}^n), \nabla \mathbf{y}^n - \nabla \mathbf{U}^n\right\rangle \\ &\le k\sum_{n=1}^{M} \left\langle \mathbf{S}(\nabla \mathbf{y}^n) - \mathbf{S}(\nabla \mathbf{U}^n), \nabla \mathbf{y}^n - \nabla P_h\mathbf{y}^n\right\rangle + \frac{1}{2}\left\|\mathbf{y}^0 - P_h\mathbf{y}^0\right\|_2^2 \\ &\quad + k\sum_{n=1}^{M} \left\langle d_t\mathbf{E}^n, \mathbf{y}^n - P_h\mathbf{y}^n\right\rangle.\end{aligned}$$

Inequality (2.5) yields

$$\begin{aligned}&\left\langle \mathbf{S}(\nabla \mathbf{y}^n) - \mathbf{S}(\nabla \mathbf{U}^n), \nabla \mathbf{y}^n - \nabla P_h\mathbf{y}^n\right\rangle \\ &\quad \le \delta\,\|\mathbf{F}(\nabla \mathbf{y}^n) - \mathbf{F}(\nabla \mathbf{U}^n)\|_2^2 + c_\delta\,\|\mathbf{F}(\nabla \mathbf{y}^n) - \mathbf{F}(\nabla P_h\mathbf{y}^n)\|_2^2.\end{aligned}$$

Furthermore,

$$k\sum_{n=1}^{M}\left\langle d_t\mathbf{E}^n,\mathbf{y}^n-P_h\mathbf{y}^n\right\rangle\le\delta k^2\sum_{n=1}^{M}\|d_t\mathbf{E}^n\|_2^2+c_\delta\sum_{n=1}^{M}\|\mathbf{y}^n-P_h\mathbf{y}^n\|_2^2.$$

We absorb the terms with δ into the left-hand side and use (2.4). Taking the supremum over $M=1,\dots,N$, the assertion follows. □

THEOREM 5.4. *Under the assumptions* (3.1) *and* (5.1) *there is for any* $p>\frac{2d}{d+2}$ *a constant* c *independent of* h *and* k *such that*

$$\sup_{1\le n\le N}\|\mathbf{y}^n-\mathbf{U}^{\mathbf{n}}\|_2^2+k\sum_{n=1}^{N}\|\mathbf{F}(\nabla\mathbf{y}^n)-\mathbf{F}(\nabla\mathbf{U}^n)\|_2^2\le c\,h^2.$$

Proof. Below we will show that under the assumption (5.1) there holds

$$\sum_{n=0}^{N}\|\mathbf{y}^n-P_h\mathbf{y}^n\|_2^2\le c\,h^2. \tag{5.3}$$

Further, it holds that

$$\|\mathbf{F}(\nabla\mathbf{y}^n)-\mathbf{F}(\nabla P_h\mathbf{y}^n)\|_2^2\le c\,\|\nabla\mathbf{y}^n-\nabla P_h\mathbf{y}^n\|_{(\nabla\mathbf{y}^n)}^2\le c\,h^2\,\|\nabla\mathbf{F}(\nabla\mathbf{y}^n)\|_2^2. \tag{5.4}$$

The proof of this inequality can be found in [10] for the cases $d=2,3$ and $p>\frac{d}{2}$. The method there, however, works for any $d\ge 2$. The case $p>1$ will be treated in [9]. Due to Lemma 4.1 we obtain

$$k\sum_{n}\|\mathbf{F}(\nabla\mathbf{y}^n)-\mathbf{F}(\nabla P_h\mathbf{y}^n)\|_2^2\le c\,h^2. \tag{5.5}$$

In view of (5.3), (5.5), and Lemma 5.3 the assertion follows.

Next we prove (5.3). Let us note that $\mathbf{y}^0\in W^{1,2}(\Omega)$ and thus

$$\left\|\mathbf{y}^0-P_h\mathbf{y}^0\right\|_2^2\le c\,h^2.$$

Now let us distinguish two cases.

Case 1. $p\le 2$. It is well known that (cf. [5, Theorem 3.1.5])

$$\|\mathbf{y}^n-P_h\mathbf{y}^n\|_2^2\le c\,h^{2\beta}\,\left\|\nabla^2\mathbf{y}^n\right\|_{\frac{4}{4-p}}^2,$$

where $\beta=2+d\big(\frac12-\frac{4-p}{4}\big)$. Notice that due to (5.1) we have $h^{2-d(1-\frac{p}{2})}\le c\,k$. Thus, $h^{2\beta}=h^2\,h^{2-d(1-\frac{p}{2})}\le c\,h^2\,k$. We get

$$\sum_{n=1}^{N}\|\mathbf{y}^n-P_h\mathbf{y}^n\|_2^2\le c\,h^2\,k\sum_{n=1}^{N}\left\|\nabla^2\mathbf{y}^n\right\|_{\frac{4}{4-p}}^2.$$

In view of Lemma 4.2, estimate (5.3) follows.

Case 2. $p>2$. Since the proof of Theorem 3.1.5 in [5] is based on the chain rule and the formula of change of variables, the result can be easily generalized to Nikol′skiĭ spaces. Thus we have

$$\|\mathbf{y}^n-P_h\mathbf{y}^n\|_2^2\le c\,h^{2\beta}\,\|\mathbf{y}^n\|_{\mathcal{N}^{1+\frac{2}{p},p}(\Omega)}^2,$$

where $\beta = (1+\frac{2}{p}) + d\big(\frac{1}{2}-\frac{1}{p}\big)$. Recalling (5.1), that is, $h^{d+\frac{2(2-d)}{p}} \le c\,k$, we have $h^{2\beta} = h^2\, h^{d+\frac{2(2-d)}{p}} \le c\,h^2\,k$. Hence,

$$\sum_{n=1}^{N} \|\mathbf{y}^n - P_h\mathbf{y}^n\|_2^2 \le c\,h^2\,k \sum_{n=1}^{N} \|\mathbf{y}^n\|^2_{\mathcal{N}^{1+\frac{2}{p},p}(\Omega)}.$$

Using Lemma 4.2 we obtain estimate (5.3). ∎

We now get to the proof of our main result.

Proof of Theorem 5.1. For $t \in I_n$ there holds

$$\|\mathbf{F}(\nabla\mathbf{u}) - \mathbf{F}(\nabla\mathbf{U}^n)\|_2^2 \le c\Big(\|\mathbf{F}(\nabla\mathbf{u}) - \mathbf{F}(\nabla\mathbf{y}^n)\|_2^2 + \|\mathbf{F}(\nabla\mathbf{y}^n) - \mathbf{F}(\nabla\mathbf{U}^n)\|_2^2\Big).$$

Moreover, we have

$$\sup_{t\in I_n} \|\mathbf{u} - \mathbf{U}^n\|_2^2 \le c\Big(\sup_{t\in I_n} \|\mathbf{u} - \mathbf{u}^n\|_2^2 + \|\mathbf{u}^n - \mathbf{y}^n\|_2^2 + \|\mathbf{y}^n - \mathbf{U}^n\|_2^2\Big)$$

and

$$\sup_{t\in I_n} \|\mathbf{u} - \mathbf{u}^n\|^2_{L^2(\Omega)} \le c\,k^2\,\|\partial_t\mathbf{u}\|^2_{L^\infty(I_n,L^2(\Omega))}.$$

From Theorems 4.7 and 5.4 and the calculations above we conclude the assertion. ∎

Proof of Corollary 5.2. Let $\omega := \kappa + |\nabla\mathbf{u}| + |\nabla(\mathbf{u}-\mathbf{U})|$. Hölder's inequality (with $q_1 = \frac{2}{p}$ and $q_2 = \frac{2}{2-p}$) entails

$$\begin{aligned}\int_0^T\!\!\int_\Omega |\nabla(\mathbf{u}-\mathbf{U})|^p\,dx\,dt &= \int_0^T\!\!\int_\Omega \omega^{\frac{(2-p)p}{2}}\,\omega^{\frac{(p-2)p}{2}}\,|\nabla(\mathbf{u}-\mathbf{U})|^p\,dx\,dt\\ &\le \int_0^T\Big[\int_\Omega \omega^p\,dx\Big]^{\frac{2-p}{2}}\Big[\int_\Omega \omega^{p-2}\,|\nabla(\mathbf{u}-\mathbf{U})|^2\,dx\Big]^{\frac{p}{2}}\,dt\\ &\le c\int_0^T \|\nabla(\mathbf{u}-\mathbf{U})\|^2_{(\nabla\mathbf{u})}\,dt.\end{aligned}$$

Here we have used the fact that $\|\omega\|^{2-p}_{L^\infty(0,T;L^p(\Omega)} \le c$. In the case of $\kappa = 0$ we proceed as in the proof of Lemma 4.2. Utilizing Theorem 5.1 we obtain

$$\|\nabla(\mathbf{u}-\mathbf{U})\|^2_{L^p(0,T;L^p(\Omega)} \le c\int_0^T \|\nabla(\mathbf{u}-\mathbf{U})\|^2_{(\nabla\mathbf{u})}\,dt \le c\,(h^2+k^2).$$

This yields the assertion. ∎

6. Appendix. We will prove Lemma 2.1 in several steps.

LEMMA 6.1. *Let* $\alpha > -1$ *and* $\mathbf{A},\mathbf{B} \in \mathbb{R}^{d\times d}$ *with* $|\mathbf{A}| + |\mathbf{B}| > 0$*; then*

$$c_0(\alpha)\,\big(|\mathbf{A}| + |\mathbf{B}|\big)^\alpha \le \int_0^1 |\theta\mathbf{A} + (1-\theta)\mathbf{B}|^\alpha\,d\theta \le c_1(\alpha)\,\big(|\mathbf{A}| + |\mathbf{B}|\big)^\alpha \tag{6.1}$$

with

$$c_0(\alpha) := \min\Big\{\frac{1}{\alpha+1}, \frac{2^{-\alpha}}{\alpha+1}, 2^{-\alpha}\Big\}, \qquad c_1(\alpha) := \max\Big\{\frac{1}{\alpha+1}, \frac{2^{-\alpha}}{\alpha+1}, 2^{-\alpha}\Big\}.$$

The constants c_0 and c_1 are optimal.

Proof. Let $f(\mathbf{A},\mathbf{B})$ denote the middle expression of (6.1). We have

$$\big|(1-\theta)|\mathbf{A}|-\theta|\mathbf{B}|\big| \le |(1-\theta)\mathbf{A}+\theta\mathbf{B}| \le (1-\theta)|\mathbf{A}|+\theta|\mathbf{B}|, \tag{6.2}$$

and for all $\alpha > -1$, $|\mathbf{A}|+|\mathbf{B}| > 0$ it holds that

$$\begin{aligned} \int_0^1 \big|(1-\theta)|\mathbf{A}|-\theta|\mathbf{B}|\big|^\alpha \, d\theta &= \frac{|\mathbf{A}|^{\alpha+1}+|\mathbf{B}|^{\alpha+1}}{(\alpha+1)(|\mathbf{A}|+|\mathbf{B}|)}\,, \\ \int_0^1 \big|(1-\theta)|\mathbf{A}|+\theta|\mathbf{B}|\big|^\alpha \, d\theta &= \frac{|\mathbf{A}|^{\alpha+1}-|\mathbf{B}|^{\alpha+1}}{(\alpha+1)(|\mathbf{A}|-|\mathbf{B}|)}\,, \end{aligned} \tag{6.3}$$

where the last expression can be continuously extended for $|\mathbf{A}| = |\mathbf{B}|$ by $|\mathbf{A}|^\alpha$. Define $g, h : \mathbb{R}^{\ge 0} \times \mathbb{R}^{\ge 0} \to \mathbb{R}$ by

$$g_1(s,t) := \frac{s^{\alpha+1}+t^{\alpha+1}}{(\alpha+1)(s+t)^{\alpha+1}}, \qquad g_2(s,t) := \frac{s^{\alpha+1}-t^{\alpha+1}}{(\alpha+1)(s-t)(s+t)^\alpha},$$

with g_2 continuously extended on $\{s=t\}$ by $g_2(s,s) = 2^{-\alpha}$. Then (6.2) and (6.3) imply

$$\min\big\{g_1(|\mathbf{A}|,|\mathbf{B}|), g_2(|\mathbf{A}|,|\mathbf{B}|)\big\} \le f(\mathbf{A},\mathbf{B}) \le \max\big\{g_1(|\mathbf{A}|,|\mathbf{B}|), g_2(|\mathbf{A}|,|\mathbf{B}|)\big\}. \tag{6.4}$$

Since the g_j are scaling invariant under $(s,t) \mapsto \lambda(s,t)$ it suffices to estimate g_j on the set $N := \{s+t=1, s\ge 0, t\ge 0\}$. On this set N the functions g_j simplify to

$$h_1(s,t) := \frac{s^{\alpha+1}+t^{\alpha+1}}{\alpha+1}, \qquad h_2(s,t) := \frac{s^{\alpha+1}-t^{\alpha+1}}{(\alpha+1)(s-t)};$$

i.e., $h_j(s,t) = g_j(s,t)$ for $(s,t) \in N$. We will see that the $h_j|_N$ assumes its extrema at $(1,0),(0,1),(\frac12,\frac12)$. At these points

$$\begin{aligned} h_1(0,1) = h_1(1,0) &= 1/(\alpha+1)\,, & h_2(0,1) = h_2(1,0) &= 1/(\alpha+1)\,, \\ h_1\big(\tfrac12,\tfrac12\big) &= 2^{-\alpha}/(\alpha+1)\,, & h_2\big(\tfrac12,\tfrac12\big) &= 2^{-\alpha}\,. \end{aligned}$$

Let $(s_0,t_0) \in N \setminus \{(1,0),(0,1),(1/2,1/2)\}$ be another extremum of $h_j|_N$. Then by the method of Langrange multipliers $(\nabla h_j)(s_0,t_0) = \lambda_0\,(1,1)$ for some $\lambda_0 \in \mathbb{R}$. For $(s,t) \in N \setminus \{(1,0),(0,1),(1/2,1/2)\}$ it holds that

$$\begin{aligned} (\nabla h_1)(s,t) &= (s^\alpha, t^\alpha), \\ (\nabla h_2)(s,t) &= \left(\frac{\alpha s^{\alpha+1}+(\alpha+1)s^\alpha t - t^{\alpha+1}}{(\alpha+1)(s-t)^2}, \frac{\alpha t^{\alpha+1}+(\alpha+1)t^\alpha s - s^{\alpha+1}}{(\alpha+1)(s-t)^2}\right). \end{aligned}$$

If $(\nabla h_1)(s_0,t_0) = \lambda_0\,(1,1)$, then $s_0 = t_0$. If $(\nabla h_2)(s_0,t_0) = \lambda_0\,(1,1)$, then $\alpha s_0^{\alpha+1} + (\alpha+1)s_0^\alpha t_0 - t_0^{\alpha+1} = \alpha t_0^{\alpha+1} + (\alpha+1)t_0^\alpha s_0 - s_0^{\alpha+1}$, which also implies $s_0 = t_0$. In both cases $s_0 = t_0$, which contradicts the choice of (s_0,t_0). Therefore, $(1,0),(0,1),(1/2,1/2)$ are the only extrema of h_j on N. Thus the extreme values of g_1 are $1/(\alpha+1)$ and $2^{-\alpha}/(\alpha+1)$, and the extreme values of g_2 are $1/(\alpha+1)$ and $2^{-\alpha}$. This and (6.4) prove (6.1). The optimality of the constants in (6.2) follows from

$$\begin{aligned} f(\mathbf{A},\mathbf{A}) = g_2(|\mathbf{A}|,|\mathbf{A}|) &= 2^{-\alpha}\,, \\ f(\mathbf{A},0) = g_2(|\mathbf{A}|,0) \quad &= 1/(\alpha+1)\,, \\ f(\mathbf{A},-\mathbf{A}) = g_1(|\mathbf{A}|,|\mathbf{A}|) &= 2^{-\alpha}/(\alpha+1)\,. \end{aligned}$$

The assertion follows. ∎

LEMMA 6.2. *For all* $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{d\times d}$ *with* $|\mathbf{A}| + |\mathbf{B}| > 0$, *all* $\alpha > -1$, *and* $\kappa \geq 0$, *there holds*

$$\int_0^1 \big(\kappa + |\theta\,\mathbf{A} + (1-\theta)\mathbf{B}|\big)^{\alpha}\, d\theta \cong \big(\kappa + |\mathbf{B}| + |\mathbf{A}|\big)^{\alpha}, \tag{6.5}$$

with constants depending on p *only.*

Proof. Let $\mathbf{A}_\theta := \theta\mathbf{A} + (1-\theta)\mathbf{B}$. Using the convexity of $t \mapsto (\kappa+t)^{\alpha+2}$ and (6.1) we deduce

$$\begin{aligned}
\int_0^1 (\kappa + |\mathbf{A}_\theta|)^{\alpha}\, d\theta &\geq \int_0^1 \frac{(\kappa + |\mathbf{A}_\theta|)^{\alpha+2}}{(\kappa + |\mathbf{A}| + |\mathbf{B}|)^2}\, d\theta \\
&\geq \frac{(\kappa + \int_0^1 |\mathbf{A}_\theta|\, d\theta)^{\alpha+2}}{(\kappa + |\mathbf{A}| + |\mathbf{B}|)^2} \\
&\geq \frac{(\kappa + \frac{1}{4}(|\mathbf{A}| + |\mathbf{B}|))^{\alpha+2}}{(\kappa + |\mathbf{A}| + |\mathbf{B}|)^2} \\
&\geq 4^{-(\alpha+2)}(\kappa + |\mathbf{A}| + |\mathbf{B}|)^{\alpha}.
\end{aligned}$$

Since $\alpha > -1$, there exists $r > 1$ with $r\alpha > -1$, and the mapping $t \mapsto (\kappa+t)^{r\alpha}t$ is nondecreasing on $[0,\infty)$. We estimate with (6.1)

$$\begin{aligned}
\int_0^1 (\kappa + |\mathbf{A}_\theta|)^{\alpha}\, d\theta &= \int_0^1 \Big((\kappa + |\mathbf{A}_\theta|)^{r\alpha}|\mathbf{A}_\theta|\Big)^{\frac{1}{r}} |\mathbf{A}_\theta|^{-\frac{1}{r}}\, d\theta \\
&\leq \int_0^1 \Big((\kappa + |\mathbf{A}| + |\mathbf{B}|)^{r\alpha}(|\mathbf{A}| + |\mathbf{B}|)\Big)^{\frac{1}{r}} |\mathbf{A}_\theta|^{-\frac{1}{r}}\, d\theta \\
&\leq \frac{2^{1/r}}{1-\frac{1}{r}}\,(\kappa + |\mathbf{A}| + |\mathbf{B}|)^{\alpha}.
\end{aligned}$$

This proves the lemma. ∎

LEMMA 6.3. *Let* $\mathbf{S}$ *satisfy* (2.1), (2.2). *Then for all* $\mathbf{A}, \mathbf{B} \in \mathbb{R}^{d\times d}$ *it holds that*

$$\mathbf{S}(\mathbf{A}) \cdot \mathbf{A} \cong |\mathbf{A}|^2\big(\kappa + |\mathbf{A}|\big)^{p-2}, \tag{6.6}$$

$$\big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big) \cdot \big(\mathbf{A} - \mathbf{B}\big) \cong \big|\mathbf{A} - \mathbf{B}\big|^2\big(\kappa + |\mathbf{B}| + |\mathbf{A}|\big)^{p-2}, \tag{6.7}$$

$$\big|\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big| \cong \big|\mathbf{A} - \mathbf{B}\big|\big(\kappa + |\mathbf{B}| + |\mathbf{A}|\big)^{p-2} \tag{6.8}$$

with constants depending on p *but not on* κ.

Proof. Note that statement (6.6) is a special case of (6.7) by setting $\mathbf{B} = \mathbf{0}$. In the case $\mathbf{B} = \mathbf{A} = \mathbf{0}$, nothing has to be proved. In the case $|\mathbf{A}| + |\mathbf{B}| > 0$, Lemma 6.2 and the assumptions (2.1), (2.2) imply that

$$\begin{aligned}
&\big(\mathbf{S}(\mathbf{A}) - \mathbf{S}(\mathbf{B})\big) \cdot (\mathbf{A} - \mathbf{B}) \\
&\quad = \sum_{i,j,k,l=1}^{d} \int_0^1 \frac{\partial S_{ij}(\theta\mathbf{A} + (1-\theta)\mathbf{B})}{\partial D_{kl}} (A-B)_{ij}(A-B)_{kl}\, d\theta \\
&\quad \cong |\mathbf{A} - \mathbf{B}|^2 \int_0^1 \big(\kappa + |\theta\mathbf{A} + (1-\theta)\mathbf{B}|\big)^{p-2}\, d\theta \\
&\quad \cong |\mathbf{A} - \mathbf{B}|^2\big(\kappa + |\mathbf{B}| + |\mathbf{A}|\big)^{p-2}.
\end{aligned}$$

In the same manner we get

$$\begin{aligned}\big|\mathbf{S}(\mathbf{A})-\mathbf{S}(\mathbf{B})\big| &= \left(\sum_{i,j=1}^{d}\left|\sum_{k,l=1}^{d}\int_0^1 \frac{\partial S_{ij}(\theta\mathbf{A}+(1-\theta)\mathbf{B})}{\partial D_{kl}}\,d\theta\,(A-B)_{kl}\right|^2\right)^{\frac12}\\ &\le c\,|\mathbf{A}-\mathbf{B}|\big(\kappa+|\mathbf{B}|+|\mathbf{A}|\big)^{p-2}.\end{aligned}$$

This yields the upper estimate of (6.8). The lower estimate follows from (6.7). ∎

LEMMA 6.4. *For all* $\mathbf{A},\mathbf{B}\in\mathbb{R}^{d\times d}$ *there holds*

$$\big|\mathbf{F}(\mathbf{A})-\mathbf{F}(\mathbf{B})\big| \cong \big(\kappa+|\mathbf{B}|+|\mathbf{A}|\big)^{\frac{p-2}{2}}|\mathbf{A}-\mathbf{B}|$$

with constants depending on p *but not on* κ.

Proof. For $q:=\frac{p+2}{2}$ we have

$$\mathbf{F}(\mathbf{B}) = (\kappa+|\mathbf{B}|)^{\frac{p-2}{2}}\mathbf{B} = (\kappa+|\mathbf{B}|)^{q-2}\mathbf{B}\,.$$

Thus $\mathbf{F}$ satisfies (2.1), (2.2) with p replaced by q. Now (6.8) reads as follows:

$$\big|\mathbf{F}(\mathbf{A})-\mathbf{F}(\mathbf{B})\big| \cong \big|\mathbf{A}-\mathbf{B}\big|\big(\kappa+|\mathbf{B}|+|\mathbf{A}|\big)^{q-2}.$$

This proves the lemma. ∎

Now, Lemmas 6.3 and 6.4 immediately imply Lemma 2.1.

SAMPLING EIGENVALUES IN HARDY SPACES*

AMIN BOUMENIR† AND VU KIM TUAN†

Abstract. In this work we extend the sampling method to compute eigenvalues of singular non–self-adjoint Sturm–Liouville problems in the presence of a continuous spectrum. We first show that the characteristic function, whose zeros are the eigenvalues, belongs to a Hardy space, and then develop a new sampling formula for its reconstruction. We estimate the truncation error, obtain computable error bounds, and test the method with a few numerical experiments.

Key words. Sturm–Liouville operators, sampling, interpolation, Hardy spaces

1. Introduction.

In this work, we would like to develop a new sampling technique to compute eigenvalues in the presence of a continuous spectrum. Consider the following singular Sturm–Liouville problem, which is a widely used model in scattering theory:

$$\begin{cases} Ly(x) := -y''(x,\lambda) + q(x)y(x,\lambda) = \lambda^2 y(x,\lambda), & x \in [0,\infty), \\ y(0,\lambda) = 0, \end{cases} \tag{1.1}$$

where q is complex valued and satisfies $\int_0^\infty (1+x)\,|q(x)|\,dx < \infty$.

Observe that the differential operator L, which is acting in the Hilbert space $L^2_{dx}(0,\,\infty)$, is regular at $x = 0$ but singular at $x = \infty$. It also follows from the asymptotics of the solutions [12, p. 221] that L is in the limit point case at $x = \infty$, and so no boundary condition is required at $x = \infty$. If q is real valued, then L is self-adjoint, the positive part of its spectrum is continuous, and there are at most a finite number of negative isolated eigenvalues which are known as the bound states in scattering theory. The case $\Im(q(x)) \neq 0$ leads to complex eigenvalues, and our work is concerned with their computational aspects. Recall that classical eigenvalue solvers [2, 3] cannot handle the singular non–self-adjoint case due to the presence of a continuous spectrum. For example, when $L - \lambda I$ has a compact inverse and thus no continuous spectrum is present, finite element or Galerkin-type methods can be used. In the case when the inverse operator is bounded but not compact, then a spectral approximation for bounded operators is possible, as shown in [11]. Also, for closed not necessarily bounded operators in Banach spaces, spectral projectors and analytic properties of the resolvent operator are used to locate the spectrum; see [5, 6, 7]. These methods, which usually either are direct or use the inverse operator, detect the spectrum by contour integration. The next type of numerical methods is shooting-type methods, which integrate numerically the solution of (1.1) and then find the values λ for which the boundary condition $y(0,\lambda) = 0$ is satisfied. For instance, if $y(0,\lambda)$ and all the eigenvalues are real, then a zero crossing argument may help detect simple roots. However, when numerical integration is over an infinite interval and

†Department of Mathematics, University of West Georgia, Carrollton, GA 30118 (boumenir@westga.edu, vu@westga.edu).

there are no boundary conditions at infinity or the roots are off the real line, then the shooting method is extremely hard to implement, if not impossible. To overcome these difficulties, the sampling method reconstructs the function $y(0,\lambda)$ for $\lambda \in \mathbb{C}$ and then finds its roots. For example, in the regular non–self-adjoint case, it interpolates the characteristic function by a rational function and then computes its zeros in the complex plane [1]. A crucial step is the fact that the characteristic function is an entire function and belongs to a Paley–Wiener space, which allows its recovery by the Shannon theorem; see [15]. Unfortunately in (1.1) the presence of a continuous or essential spectrum signals that the characteristic function $y(0,\lambda)$ cannot be an entire function of λ. The main difficulty in any reconstruction problem is uniqueness, which is settled by finding the right space. For example, in a Paley–Wiener space of type π, one must use all values $\{F(n)\}_{n\in\mathbb{Z}}$ in order to recover the function F uniquely. The key to determining the analytic properties of $y(0,\lambda)$ is provided by the Gelfand–Levitan–Marchenko integral representation of the solution [4, p. 77] for $x \geq 0$,

$$y(x,\lambda) = e^{i\lambda x} + \int_x^\infty K(x,t)e^{i\lambda t}dt, \qquad \Im(\lambda) \geq 0. \tag{1.2}$$

We now give a brief outline of the paper. In the second section, we show that if $y(x,\lambda) \in L^2_{dx}(0,\infty)$, then $y(0,\lambda)$, up to a constant, must be a Hardy function. In the third section, we show how to reconstruct or interpolate a function in a Hardy space from a sequence of its values, and in the fourth section, we outline the main steps in the algorithm and convergence results. This leads to the approximation of $y(0,\lambda)$ by rational functions, whose zeros yield the sought eigenvalue approximation of problem (1.1). In the fifth section, we estimate the truncation error and show that it leads to computable error bounds. The last section covers a few examples which illustrate how the method is implemented numerically.

2. The Hardy space. Denote the Hardy space of complex valued functions defined in the right half-plane by

$$\mathcal{H}^2\left(\mathbb{R}^2_+\right) = \Big\{ F(s) : \quad F(\sigma+i\tau) \text{ is analytic } \text{ for } \sigma > 0 \text{ and } \sup_{\sigma>0} \int_{-\infty}^{\infty} |F(\sigma+i\tau)|^2 d\tau < \infty \Big\}.$$

It is also well known that F is a Hardy function if and only if it is the Laplace transform of a function $f(t) \in L^2_{dt}(0,\infty)$:

$$F \in \mathcal{H}^2\left(\mathbb{R}^2_+\right) \quad \Longleftrightarrow \quad F(s) = \mathcal{L}(f)(s) := \int_0^\infty f(t)\, e^{-st}\, dt, \quad \Re(s) > 0. \tag{2.1}$$

In all that follows, $y(x,\lambda)$ is a solution of (1.1) represented by (1.2). Since K is a continuous function, then we have from (1.2)

$$y(0,\lambda) = 1 + \int_0^\infty K(0,t)e^{i\lambda t}dt, \tag{2.2}$$

and thus $y(0,\lambda) - 1$ is a Fourier transform. To say more on the analytic properties of $y(0,\lambda)$ we need the following result.

PROPOSITION 1. *Assume that* $\int_0^\infty (1+x)|q(x)|dx < \infty$*; then* $K(0,t) \in L^1_{dt}(0,\infty) \cap L^2_{dt}(0,\infty)$.

Proof. The proof follows from the estimate [9, p. 16]

$$|K(x,t)| \leq \frac{1}{2}\int_{\frac{x+t}{2}}^{\infty} |q(\eta)|d\eta \; e^{\int_x^\infty \eta|q(\eta)|d\eta} \tag{2.3}$$

and the fact that as $t \to \infty$,

$$\begin{aligned}\int_{\frac{t}{2}}^{\infty} |q(\eta)|d\eta &= \int_{\frac{t}{2}}^{\infty} \frac{(1+\eta)}{(1+\eta)}|q(\eta)|d\eta \\ &\leq \sup_{\frac{t}{2}\leq\eta}\left(\frac{1}{1+\eta}\right)\int_{\frac{t}{2}}^{\infty}(1+\eta)|q(\eta)|d\eta \\ &\leq \frac{2}{2+t}\int_{\frac{t}{2}}^{\infty}(1+\eta)|q(\eta)|d\eta.\end{aligned}$$

In other words, $K(0,t) = O(\frac{1}{2+t})$, and thus $K(0,t) \in L^2_{dt}(0,\infty)$. The Hardy inequality

$$\int_0^\infty \left|\frac{1}{t}\int_t^\infty f(x)\,dx\right| dt \leq \int_0^\infty |f(x)|\,dx$$

also guarantees that $K(0,t) \in L^1_{dt}(0,\infty)$. ∎

PROPOSITION 2. *If* $\int_0^\infty (1+x)\,|q(x)|\,dx < \infty$, *then* $y(0,is) - 1 \in \mathcal{H}^2(\mathbb{R}^2_+)$.

Proof. From (2.2), if we replaced λ by is, then

$$\begin{aligned}y(0,is) - 1 &= \int_0^\infty K(0,t)e^{-st}dt \\ &= \mathcal{L}\left(K(0,t)\right)(s),\end{aligned} \tag{2.4}$$

while by Proposition 1, $K(0,.) \in L^2_{dt}(0,\infty)$. Thus its Laplace transform $y(0,is) - 1$ belongs to the Hardy space $\mathcal{H}^2\left(\mathbb{R}^2_+\right)$; see [8]. ∎

In order to find the eigenvalues of (1.1) by sampling, we first need to reconstruct $y(0,is)$ by interpolation and then solve $y(0,is) = 0$ for $\Re(s) > 0$. As far as the authors are aware, there is no sampling formula in Hardy spaces; see [13]. Therefore we develop a new sampling formula for functions in Hardy spaces in the next section.

3. Sampling in Hardy spaces. Recall the shifted factorial

$$(a)_k = a\,(a+1)\ldots(a+k-1) = \frac{\Gamma\,(a+k)}{\Gamma\,(a)}. \tag{3.1}$$

THEOREM 1. *Let* $F \in \mathcal{H}^2\left(\mathbb{R}^2_+\right)$. *Then*

$$F(s) = \sum_{k=0}^{\infty} \frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{(s+\frac{1}{2})_{k+1}} \sum_{n=0}^{k} \frac{(-k)_n\,(k+1)_n}{(n!)^2} F\left(n+\frac{1}{2}\right), \tag{3.2}$$

where the series converges uniformly on any compact subset of the right half-plane.

Proof. First, if we set $e^{-t} = x$, then (2.1) becomes

$$\begin{aligned}F(s) &= \int_0^\infty e^{-st}f(t)dt \\ &= \int_0^1 g(x)x^{s-1/2}dx, \quad \Re(s) > 0,\end{aligned} \tag{3.3}$$

where $g(x) := f(-\ln x)x^{-1/2}$. It is very easy to see that $F \in \mathcal{H}^2(\mathbb{R}^2_+)$, i.e., $f(t) \in L^2_{dt}(0,\infty)$ if and only if $g(x) \in L^2_{dx}(0,1)$.

Next we need to expand $x^{s-1/2}$ in terms of $x^{n-1/2}$ to bring out the sampled values $F(n)$. Since $\{x^n\}_{n=0}^{\infty}$ is not an orthogonal family in $L^2_{dx}(0,1)$, we use the set $P_n^*(x) = \sqrt{2n+1}\,P_n(1-2x)$, the normalized Legendre orthogonal polynomials on the interval [0, 1]. From their connection with the hypergeometric function

$$P_k(1-2x) = F(-k, k+1; 1, x)$$

we obtain

$$P_k^*(x) = \sqrt{2k+1}\sum_{n=0}^{k}\frac{(-k)_n\,(k+1)_n}{(n!)^2}x^n = \sum_{n=0}^{k} a_{kn}x^n,$$

where

$$a_{kn} := \sqrt{2k+1}\,\frac{(-k)_n\,(k+1)_n}{(n!)^2}.$$

We start with the expansion formula of the power function in a series of Legendre polynomials [14],

$$(a-1)\left(\frac{1-x}{2}\right)^{a-2} = \sum_{k=0}^{\infty}(2k+1)\,\frac{(2-a)_k}{(a)_k}\,P_k(x),$$

where $-1 < x < 1$ and $a > 3/2$. Replacing $\frac{1-x}{2}$ and $a - 5/2$ by x and s, respectively, leads to

$$x^{s-1/2} = \sum_{k=0}^{\infty}\frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}}P_k(1-2x), \qquad 0 < x < 1. \tag{3.4}$$

So

$$x^{s-1/2} = \sum_{k=0}^{\infty} c_k(s)P_k^*(x) = \sum_{k=0}^{\infty} c_k(s)\sum_{n=0}^{k} a_{kn}x^n,$$

where

$$c_k(s) = \frac{\sqrt{2k+1}\,\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}}. \tag{3.5}$$

Since

$$c_k(s) = \int_0^1 x^{s-1/2}P_k^*(x)dx$$

is the Fourier coefficient of $x^{s-1/2} \in L^2_{dx}(0,1)$, $\Re(s) > 0$, and $P_k^*(x) \in L^2_{dx}(0,1)$, we must have $c_k(s) \in \mathcal{H}^2(\mathbb{R}^2_+)$. Now let g be any function from $L^2_{dx}(0,1)$; then

$$\int_0^1 g(x)x^{s-1/2}dx = \int_0^1 g(x)\sum_{k=0}^{\infty} c_k(s)P_k^*(x)\,dx. \tag{3.6}$$

We can interchange the order of integration and infinite summation in the last expression to get

$$
\begin{aligned}
F(s) &= \sum_{k=0}^{\infty} c_k(s) \int_0^1 g(x) P_k^*(x)\, dx \\
&= \sum_{k=0}^{\infty} c_k(s) \int_0^1 g(x) \sum_{n=0}^{k} a_{kn} x^n\, dx \\
&= \sum_{k=0}^{\infty} c_k(s) \sum_{n=0}^{k} a_{kn} \int_0^1 g(x) x^n\, dx \\
&= \sum_{k=0}^{\infty} c_k(s) \sum_{n=0}^{k} a_{kn} F\left(n+\frac{1}{2}\right).
\end{aligned} \tag{3.7}
$$

Thus we can interpolate a function $F \in \mathcal{H}^2\left(\mathbb{R}_+^2\right)$ from a sequence of its values $\{F(n+1/2)\}_{n\geq 0}$.

To see that the series converges uniformly in any compact of $\Re(s) > 0$, let $s \in \Omega$, where Ω is compact, and use (3.7) to write

$$
\begin{aligned}
\left| F(s) - \sum_{k=0}^{N} c_k(s) \int_0^1 g(x) P_k^*(x)\, dx \right| &= \left| \int_0^1 g(x) \sum_{k=N+1}^{\infty} c_k(s) P_k^*(x)\, dx \right| \\
&\leq \|g\|_2 \left\| \sum_{k=N+1}^{\infty} c_k(s) P_k^*(x) \right\|_2 \\
&= \|g\|_2 \sqrt{\sum_{k=N+1}^{\infty} |c_k(s)|^2}, \qquad (3.8)
\end{aligned}
$$

since $P_k^*(x)$ form an orthonormal system in $L^2_{dx}(0,1)$. All that we need to show uniform convergence is

$$
\sup_{s\in\Omega} \sum_{k=N+1}^{\infty} |c_k(s)|^2 \to 0 \quad \text{as} \quad N \to \infty. \tag{3.9}
$$

To estimate the remainder we first express the c_k through the gamma function

$$
\begin{aligned}
c_k(s) &= \frac{\sqrt{2k+1}\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}} \\
&= \sqrt{2k+1} \frac{\Gamma\left(\frac{1}{2}-s+k\right)}{\Gamma\left(s+\frac{1}{2}+k+1\right)} \frac{\Gamma\left(s+\frac{1}{2}\right)}{\Gamma\left(\frac{1}{2}-s\right)} \qquad (3.10)
\end{aligned}
$$

and use its asymptotics

$$
\frac{\Gamma(k+a)}{\Gamma(k+b)} \approx k^{a-b} \quad \text{as } k \to \infty.
$$

We next use the fact that we have

$$
\sup_{s\in\Omega} \left| \frac{\Gamma\left(s+\frac{1}{2}\right)}{\Gamma\left(\frac{1}{2}-s\right)} \right| < \infty
$$

to deduce from (3.10) that

$$|c_k(s)| = O\left(k^{\frac{1}{2}} k^{\frac{1}{2}-\Re(s)-\Re(s)-\frac{3}{2}}\right),$$

$$|c_k(s)|^2 = O\left(k^{-1-4\Re(s)}\right) \tag{3.11}$$

uniformly in Ω, which implies (3.9), and the proof is complete. □

Combining Proposition 2 and Theorem 1, we can write

$$y(0,is) = 1 + \sum_{k=0}^{\infty} c_k(s) \sum_{n=0}^{k} a_{kn} \left[y\left(0, in + \frac{i}{2}\right) - 1 \right]. \tag{3.12}$$

4. Algorithm. We now describe the algorithm that would allow us to use (3.12). Recall that for $-\lambda^2 \in \mathbb{C}$ to be an eigenvalue, we need

$$y(x,i\lambda) \in L^2_{dx}(0,\infty) \quad \text{and} \quad y(0,i\lambda) = 0.$$

Use (1.2) and (2.3) to see that for each fixed λ, with $\Im(\lambda) > 0$, there are two possible solutions whose asymptotic behavior is either $e^{i\lambda x}$ or $e^{-i\lambda x}$, the so-called Jost solutions

$$\phi_{\pm}(x,\lambda) = e^{\pm i\lambda x} + o\,(1) \quad \text{as } x \to \infty, \tag{4.1}$$

and any solution of (1.1) is their combination. Obviously only $\phi_+(x,i\lambda) \in L^2_{dx}(0,\infty)$, and so

$$y(x,i\lambda) = e^{-\lambda x} + \int_x^{\infty} K(x,t) e^{-\lambda t} dt, \qquad \Re(\lambda) > 0. \tag{4.2}$$

Thus we need to solve the following boundary value problem at $x = \infty$, namely,

$$\begin{cases} -y''(x,i\lambda) + q(x) y(x,i\lambda) = -\lambda^2 y(x,i\lambda), \\ \lim\limits_{x\to\infty} y(x,i\lambda) e^{x\lambda} = 1, \end{cases} \tag{4.3}$$

to ensure that the solution is $L^2_{dx}(0,\infty)$. From the computational point of view, the best we can hope for is to replace integration over $(0,\infty)$ by $(0,L)$, where L is large enough. The asymptotic behavior of the solution is used to bound the difference. To this end, integration by parts in (4.2) and the fact $2K(x,x) = \int_x^{\infty} q(\eta)d\eta$ [4] reduces (4.2) to

$$y(x,i\lambda) = e^{-\lambda x} + \frac{e^{-\lambda x}}{2\lambda} \int_x^{\infty} q(\eta)d\eta + \int_x^{\infty} K_t(x,t) \frac{e^{-\lambda t}}{\lambda} dt, \qquad \Re(\lambda) > 0. \tag{4.4}$$

Thus since the solution of (4.3) decays rapidly, we can start integration from $x = L < \infty$, instead of $x = \infty$, and from (4.4) we deduce the initial value problem

$$\begin{cases} -y_L''(x,i\lambda\,) + q(x) y_L(x,i\lambda\,) = -\lambda^2 y_L(x,i\lambda\,), & x \in [0,L], \\ y_L(L,i\lambda) = e^{-\lambda L} + \frac{e^{-\lambda L}}{2\lambda} \int_L^{\infty} q(\eta)d\eta, \\ y_L'(L,i\lambda) = -\lambda e^{-\lambda L} - \frac{e^{-\lambda L}}{2} \int_L^{\infty} q(\eta)d\eta. \end{cases} \tag{4.5}$$

Equation (4.5) allows us to compute the values $y_L(0,i\lambda\,)$ for $\lambda = \frac{1}{2},\ \frac{3}{2},\ \frac{5}{2}, \ldots, n + \frac{1}{2}, \ldots$, which are needed for sampling by formula (3.12).

It is easy to see that the error function

$$\theta(x,i\lambda) = y(x,i\lambda) - y_L(x,i\lambda)$$

satisfies, by linearity,

$$\text{(4.6)}\qquad \begin{cases} -\theta''(x,i\lambda) + q(x)\theta(x,i\lambda\ ) = -\lambda^2\theta(x,i\lambda\ ), & x\in[0,L],\\ \theta(L,i\lambda) = \frac{1}{\lambda}\int_L^\infty K_t(L,t)e^{-\lambda t}dt \quad \text{and} \quad \theta'(L,i\lambda) = \int_L^\infty K_x(L,t)e^{-\lambda t}dt \end{cases}$$

or the equivalent Volterra integral equation, with $0\le x\le L$,

$$\theta(x,i\lambda) = \psi(x,i\lambda) + \int_L^x \frac{\sinh\lambda(x-t)}{\lambda}q(t)\theta(t,i\lambda)dt,$$

where

$$\text{(4.7)}\qquad \psi(x,i\lambda) = \theta(L,i\lambda)\cosh\left(\lambda(x-L)\right) + \theta'(L,i\lambda)\frac{1}{\lambda}\sinh\left(\lambda(x-L)\right).$$

Thus from (4.7) it follows that

$$|\psi(x,i\lambda)| \le \Xi(\lambda)e^{\Re(\lambda)(L-x)},$$

where $\Re(\lambda) > 0$ and

$$\Xi(\lambda) = |\theta(L,i\lambda)| + \frac{1}{|\lambda|}\left|\theta'(L,i\lambda)\right|.$$

Now define the successive iterations by

$$\begin{aligned}\theta_0(x,i\lambda) &= \psi(x,i\lambda),\\ \theta_n(x,i\lambda) &= \int_L^x \frac{\sinh\lambda(x-t)}{\lambda}q(t)\theta_{n-1}(t,i\lambda)dt,\end{aligned}$$

from which it follows that, for $0\le x\le L$,

$$\text{(4.8)}\qquad |\theta_n(x,i\lambda)| \le \frac{1}{n!}\left(\frac{1}{|\lambda|}\int_x^L |q(t)|\,dt\right)^n \Xi(\lambda)e^{\Re(\lambda)(L-x)}.$$

Indeed, (4.8) is true for $n=0$, and if it holds true for $n-1$, then

$$\begin{aligned}|\theta_n(x,i\lambda)| &= \left|\int_L^x \frac{\sinh\left(\lambda(x-t)\right)}{\lambda}q(t)\theta_{n-1}(t,i\lambda)dt\right|\\ &\le \int_x^L e^{\Re(\lambda)(t-x)}\left|\frac{q(t)}{\lambda}\right||\theta_{n-1}(t,i\lambda)|\,dt\\ &\le \Xi(\lambda)\int_x^L e^{\Re(\lambda)(t-x)}e^{\Re(\lambda)(L-t)}\frac{1}{(n-1)!}\left(\frac{1}{|\lambda|}\int_t^L |q(\eta)|\,d\eta\right)^{n-1}\left|\frac{q(t)}{\lambda}\right|dt\\ &\le \frac{1}{n!}\left(\frac{1}{|\lambda|}\int_x^L |q(\eta)|\,d\eta\right)^n \Xi(\lambda)e^{\Re(\lambda)(L-x)}.\end{aligned}$$

Thus for $\Re(\lambda) > 0$ the series $\theta(x,i\lambda) = \sum_{n\ge0}\theta_n(x,i\lambda)$ converges, and we have

$$\text{(4.9)}\qquad |\theta(x,i\lambda)| \le e^{\frac{1}{|\lambda|}\int_x^L |q(\eta)|d\eta}\Xi(\lambda)e^{\Re(\lambda)(L-x)}.$$

We now have the following lemma.

LEMMA 1. *For any $x \geq 0$ and $\Re(\lambda) > 0$ we have $\Xi(\lambda)e^{\Re(\lambda)(L-x)} \to 0$ as $L \to \infty$.*

Proof. Recall that when q satisfies $\int_0^\infty (1+x)\,|q(x)|\,dx < \infty$, then [10, Lemma 3.1.2, p. 178]

$$|K_t(x,t)| \leq \frac{1}{4}\left|q\left(\frac{x+t}{2}\right)\right| + Ce^{\int_0^\infty \zeta|q(\zeta)|d\zeta}\int_x^\infty |q(\zeta)|d\zeta \int_{\frac{x+t}{2}}^\infty |q(\zeta)|d\zeta, \tag{4.10}$$

from which it follows that K_t is integrable at ∞. Thus for $x < L$ we have

$$\begin{aligned}\left|\theta(L,i\lambda)e^{\Re(\lambda)(L-x)}\right| &\leq \frac{1}{|\lambda|}\int_L^\infty |K_t(L,t)|\,e^{-\Re(\lambda)t}dte^{\Re(\lambda)(L-x)}\\ &\leq \frac{1}{|\lambda|}e^{\Re(\lambda)x}\int_L^\infty |K_t(L,t)|\,dt,\end{aligned}$$

which yields that $|\theta(L,i\lambda)e^{\Re(\lambda)(L-x)}| \to 0$ as $L \to \infty$. Since K_x satisfies the same estimates in (4.10) as K_t, a similar argument leads to $\theta'(L,i\lambda)\frac{1}{\lambda}e^{\Re(\lambda)(L-x)} \to 0$ as $L \to \infty$. ∎

Combining the lemma and (4.9), we obtain the convergence result.

PROPOSITION 3. *We have, for $\Re(\lambda) > 0$, $y_L(0,i\lambda) \to y(0,i\lambda)$ as $L \to \infty$.*

Thus we can approximate $y(0,i\lambda)$ by using the values $y_L(0,is)$ for $s = \frac{1}{2},\ \frac{3}{2},\ \frac{5}{2},\ldots,$ in the sampling formula (3.12).

5. Truncation error. In this section, we show that it takes only a few values, N say, to recover a good approximation of $y(0,is)-1$. The truncation error has already been estimated in (3.8), and combining it with (3.11) leads to

$$\begin{aligned}\sqrt{\sum_{k=N+1}^\infty |c_k(s)|^2} &= O\left(\sqrt{\sum_{k=N+1}^\infty k^{-1-4\Re(s)}}\right)\\ &= O\left(N^{-2\Re(s)}\right).\end{aligned}$$

We recall that by (2.4) and (3.3) we can recast (3.8) as

$$\begin{aligned}&\left|y(0,is) - 1 - \sum_{k=0}^N \frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}}\sum_{n=0}^k \frac{(-k)_n\,(k+1)_n}{n!n!}\left(y\left(0,i\left(n+\frac{1}{2}\right)\right)-1\right)\right|\\ &\quad\leq \sqrt{\int_0^1 \left|\frac{1}{\sqrt{x}}K\left(0,-\ln(x)\right)\right|^2 dx}\sqrt{\sum_{k=N+1}^\infty |c_k(s)|^2}\\ &\quad\leq \sqrt{\int_0^\infty |K\left(0,t\right)|^2\,dt}\sqrt{\sum_{k=N+1}^\infty |c_k(s)|^2},\end{aligned}$$

which is valid for $\Re(s) > 0$. Since, by Proposition 1, $K(0,t) \in L^2_{dt}(0,\infty)$ if $\int_0^\infty (1+x)\cdot|q(x)|\,dx < \infty$, we have the following proposition.

PROPOSITION 4. *Assume that* $\int_0^\infty (1+x)\,|q(x)|\,dx < \infty$*; then the truncation error for* $\Re(s) > 0$ *is given by*

$$\left| y(0,is) - 1 - \sum_{k=0}^{N} \frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}} \sum_{n=0}^{k} \frac{(-k)_n\,(k+1)_n}{n!n!} \left(y\left(0, i\left(n+\frac{1}{2}\right)\right) - 1 \right) \right| = O\left(\frac{1}{N^{-2\Re(s)}}\right).$$

Thus we can recover the boundary function $y(0,is)$ by using the $N+1$ values $\left\{y(0, i\left(n+\frac{1}{2}\right)\right\}_{n=0}^{N}$ or their approximations $y_L\left(0, i\left(n+\frac{1}{2}\right)\right)$ for $n = 0, \ldots, N$. Using the previous notation, an error on the sampled values

$$y\left(0, i\left(n+\frac{1}{2}\right)\right) = y_L\left(0, i\left(n+\frac{1}{2}\right)\right) + \theta\left(0, i\left(n+\frac{1}{2}\right)\right)$$

leads to an error $\varepsilon_N(s)$ on the recovered function,

$$y(0,is) = y_\varepsilon(0,is) + \varepsilon_N(s),$$

where

$$y_\varepsilon(0,is) = 1 + \sum_{k=0}^{N} \frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}} \sum_{n=0}^{k} \frac{(-k)_n\,(k+1)_n}{n!n!} \left(y_L(0, i\left(n+\frac{1}{2}\right) - 1 \right).$$

Both truncation errors are included in $\varepsilon_N(s)$, which can be estimated for $\Re(s) > 0$ by

$$|\varepsilon_N(s)| \le \left| \sum_{k=0}^{N} \frac{(2k+1)\left(\frac{1}{2}-s\right)_k}{\left(s+\frac{1}{2}\right)_{k+1}} \sum_{n=0}^{k} \frac{(-k)_n\,(k+1)_n}{n!n!} \theta_n \right| + \sqrt{\int_0^\infty |K(0,t)|^2\,dt} \sqrt{\sum_{k=N+1}^{\infty} |c_k(s)|^2}.$$

Note that $\int_0^\infty |K(0,t)|^2\,dt$ can be estimated in terms of q only by (2.3) and yields a computable error bound.

6. Examples. We use simple examples where the exact values are available, so that a comparison with our numerical results is possible. In Examples 1 and 3 below, we sample with $N = 10$ and $L = 100$, while $N = 5$ only in Example 2.

Example 1. Consider the singular Sturm–Liouville problem

$$\begin{cases} -y''(x,\lambda) - 16H(3-x)y(x,\lambda) = \lambda^2 y(x,\lambda), & 0 \le x, \\ y(0,\lambda) = 0. \end{cases}$$

Its exact solution is

$$y(0,i\lambda) = e^{-3\lambda}\lambda \frac{\sin\left(3\sqrt{16-\lambda^2}\right)}{\sqrt{16-\lambda^2}} + e^{-3\lambda}\cos\left(3\sqrt{16-\lambda^2}\right).$$

The eigenvalues λ^2 obtained by sampling compare well with the "exact" ones:

	Exact	Sampling
λ_1	−1.7341473181761	−1.74403065715701
λ_2	−7.7381824457812	−7.73145171424856
λ_3	−12.287216856980	−12.2871029333224
λ_4	−15.067032974543	−15.0694822812548

Example 2. Consider the singular Sturm–Liouville problem

$$\begin{cases} -y''(x,\lambda) - xH(4-x)y(x,\lambda) = \lambda^2 y(x,\lambda), & 0 \le x, \\ y(0,\lambda) = 0, \end{cases}$$

whose boundary $y(0,\lambda)$ is in terms of the Airy functions

$$\begin{aligned} &y(0,\lambda) \\ &= \frac{\exp(-4\lambda)\left(AiryBi(-4+\lambda^2)\lambda - AiryBi(1,-4+\lambda^2)\right) AiryAi(\lambda^2)}{(AiryBi(-4+\lambda^2)AiryAi(1,-4+\lambda^2) - AiryBi(1,-4+\lambda^2)AiryAi(-4+\lambda^2))} \\ &\quad - \frac{\exp(-4\lambda)(\lambda AiryAi(-4+\lambda^2) - AiryAi(1,-4+\lambda^2))AiryBi(\lambda^2)}{(AiryBi(-4+\lambda^2)AiryAi(1,-4+\lambda^2) - AiryBi(1,-4+\lambda^2)AiryAi(-4.+\lambda^2))}. \end{aligned}$$

The operator has two negative eigenvalues, and a sampling at five points gives the following values:

	Exact	Sampling
λ_1^2	$-0.408\,556\,101$	$-0.407\,847\,606$
λ_2^2	$-2.199\,310\,808$	$-2.199\,274\,885$

Example 3. Here we consider a complex potential, i.e., the non–self-adjoint case. For simplicity we take $q(x) = (-3+4I)\,H(2-x)$, which satisfies the integral condition, since its support is finite. The "exact" eigenvalues are

$$\begin{aligned} \lambda_1^2 &= -2.366244570422974900 + 2.77959479317720 * I, \\ \lambda_2^2 &= 2.331242100943824884 + 1.444609392874578 * I. \end{aligned}$$

Sampling returns the characteristic function $y(0,\lambda)$ whose roots are

$$\begin{aligned} &-24.478660334593254119478447594810 + 1.120663932982268597901489419162 9 * I, \\ &-11.880762137293417570328509302643 - 12.256428855012470888743443305746 * I, \\ &-10.773223452406265088447046330037 + 11.183480685054562021984436680059 * I, \\ &-3.851978749364907686196649687849 6 + 6.820442155522640744736778476141 2 * I, \\ &-3.393876162198283248485872314760 6 - 7.765724107521692527238126019009 5 * I, \\ &-1.892146494123336769367207540188 5 + 3.380811623590107681266342100745 4 * I, \\ &-1.163475053230193440020205285847 4 + .934728826662452880407214691265 73 * I, \\ &-0.963619216785758091591199908854 40 - 3.945514752416201480449973014290 1 * I, \\ &-0.407624028851342922839455836953 23 - 0.000025337806145023868811196176 * I, \\ &0.417362878943329935909122614903 37 - 1.591169234219253978484738460266 3 * I, \\ &1.734562222252534111936564894393 6 - 0.801293335470853715211071161385 91 * I. \end{aligned}$$

Discarding the first nine, since their $\Re(\lambda) < 0$, and keeping the last two yields

$$\begin{aligned} \lambda_1^2 &= -2.366635093395643431 + 2.779786297300938674 * I, \\ \lambda_2^2 &= 2.3576277592060224472 + 1.328189944959602990 * I. \end{aligned}$$

Future work will deal with making the code more automatic in its selection of roots, so as to keep only the ones with a positive real part. We shall also investigate the case of imbedded eigenvalues in the continuous spectrum, which would have interesting applications in quantum mechanics and in scattering theory.

Acknowledgment. The authors sincerely thank the referee for his constructive comments.

MAXIMUM L^2-CONVERGENCE RATES OF THE CRANK–NICOLSON SCHEME TO THE STOKES INITIAL VALUE PROBLEM*

JUERGEN RODENKIRCHEN†

Abstract. Let A denote the Stokes operator and D_{A^α} the domain of its fractional powers A^α. We consider the homogeneous Stokes initial value problem with initial data $u(0) = u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$. For Stokes-like equations the range $\varepsilon \in (0, \frac{1}{4})$ is of special interest, as any solution derived from $\varepsilon \geq \frac{1}{4}$ would necessarily have to satisfy an additional, in practice unverifiable compatibility condition at time $t = 0$. Approximating any strong solution $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ in time direction on a finite time interval $[0,T]$ with a Crank–Nicolson scheme, we show convergence of order $O(\frac{\tau^2}{t^{1-\varepsilon}})$ which is maximal for the assumed regularity of the data and reflects the loss of regularity as $t \to 0$. The error estimates are derived by energy and semigroup methods combined with a parabolic duality argument.

Key words. Stokes equation, approximation, Crank–Nicolson scheme, convergence, compatibility condition

AMS subject classifications. 35Q30, 76D07, 65J10

1. Introduction.

We consider a viscous incompressible flow at time $t \geq 0$ in a bounded open domain $\Omega \subset \mathbb{R}^3$, $\partial\Omega$ being sufficiently smooth (e.g., a compact 2-dimensional C^3-submanifold of $\mathbb{R}^3$; see [23, p. 1082]), described by the Stokes initial and boundary value problem

$$\left.\begin{array}{l} \frac{\partial}{\partial t}u - \Delta u + \nabla p = 0 \ \text{ in } \Omega,\ t > 0, \\ \nabla \cdot u = 0\,, \quad u(\cdot,x)_{|_{\partial\Omega}} = 0, \quad u(0,\cdot) = u_0. \end{array}\right\} \tag{1.1}$$

Here we assume without loss of generality the constant kinematic viscosity $\nu > 0$ to equal 1. The unknown $u = (u_1, u_2, u_3)$, $u_i = u_i(t,x)$ and $p = p(t,x) \geq 0$ denote the velocity field and the scalar kinematic pressure, respectively. Let $H(\Omega)$ be the space of solenoidal L^2-vector fields on Ω (see section 2). Applying Weyl's orthogonal projection $P : L^2(\Omega) \to H(\Omega)$ to (1.1), which in virtue of the Helmholtz decomposition of $L^2(\Omega)$ maps into zero the gradients $\nabla q \in L^2(\Omega)$, we obtain the homogeneous[1] Stokes initial value problem in the form of the evolution system

$$\left.\begin{array}{l} \partial_t u + Au = 0,\ t > 0, \\ u(0) = u_0 \end{array}\right\} \tag{1.2}$$

for the unknown function $u : [0,\infty) \to D_A$. Here ∂_t means the time derivative and $A = -P\Delta$ denotes the Stokes operator on Ω (see section 2).

Let u be a strong solution of (1.2) on a finite time interval $[0,T]$, i.e., a function u differentiable a.e. on $[0,T]$ such that $\partial_t u \in L^1(0,T;H)$, $u(0) = u_0$ and $\partial_t u = -Au(t)$

†Hella KgaA, Rixbecker Strasse 75, 59552 Lippstadt, Germany (juergen.rodenkirchen@t-online.de, juergen.rodenkirchen@hella.com).
[1]The inhomogeneous case with outer force density f being a gradient field $f = \nabla q \in L^2(\Omega)$ is thus included in the considered homogeneous case.

a.e. on $[0,T]$ (see [18, Definition 2.8, p. 109], [14, Definition 6.1.2(i), p. 174]). Then, approximating u on an equidistant time grid of $[0,T]$ (with fixed but arbitrary time step of size $\tau = \frac{T}{N} > 0$, $N \in \mathbb{N}$) by a modified Crank–Nicolson sequence $(U_k^\tau)_{k=1,\dots,N}$, we give explicit τ-dependent estimates of the error $u(t_k) - U_k^\tau$ at time $t = t_k = k \cdot \tau$ in $L^2(\Omega)$. Here the modification is due to two initial steps of Rothe's scheme (see section 3).

The convergence rate of the formally second order Crank–Nicolson scheme is known to depend on the regularity properties of the solution to be approximated (see [2], [8], [11], [17], [31], [32, pp. 110–120]). To obtain full second order convergence in $L^2(\Omega)$, the solution u of (1.2) has to be at least strong H^4-continuous [31], [32]. However, for Stokes-like equations such regularity assumptions cannot realistically be assumed, as any H^3-continuous solution already has to satisfy an additional compatibility condition at time $t = 0$, which turns out to be virtually uncheckable for given data (see [29], [15, p. 91], [27, p. 97], [21, p. 134], [10, p. 281], [25, p. 254]).

The question of how smooth a solution can be in practice has been answered by Rautmann [21, Theorem 4.1, p. 147]: Any solution u of (1.2) which is strongly D_{A^η}-continuous has to satisfy a compatibility condition if $\eta > \frac{5}{4}$. And, conversely (see [21, Theorem 3.1, p. 143]), for $\eta < \frac{5}{4}$ assume $u_0 \in D_{A^\eta}$. Then (1.2) yields a strong D_{A^η}-continuous solution without any nonrealistic compatibility condition to be satisfied at time $t = 0$.

For realistically assumable initial data $u_0 \in D_A$, Heywood and Rannacher proved optimal convergence of order $O(\frac{\tau^2}{t})$ in L^2 [11]. Thus, our aim was to provide error estimates in L^2 of order $O(\frac{\tau^2}{t^{1-\varepsilon}})$ for initial data $u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, with special emphasis on the realistic range $\varepsilon \in (0, \frac{1}{4})$.[2]

2. Preliminaries. Let $H^0(\Omega) = L^2(\Omega)$ and $H^m(\Omega)$, $m \in \mathbb{N}$, denote the Hilbert spaces

$$H^m(\Omega) = \{u \in L^2(\Omega) \mid \partial_x^\alpha u \in L^2(\Omega),\ |\alpha| \le m,\ m \in \mathbb{N}\}$$

equipped with the norms

$$\|u\|_{H^m(\Omega)} = \left(\sum_{|\alpha| \le m} \int_\Omega |\partial_x^\alpha u(x)|^2 dx \right)^{\frac{1}{2}}, \quad \partial_x^\alpha u(x) = \frac{\partial^{|\alpha|}}{\partial_{x_1}^{\alpha_1} \partial_{x_2}^{\alpha_2} \partial_{x_3}^{\alpha_3}} u(x),$$

where $\alpha = (\alpha_1, \alpha_2, \alpha_3)$, $\alpha_i \ge 0$, $|\alpha| = \alpha_1 + \alpha_2 + \alpha_3$, and $|\cdot|$ is the Euclidean norm in $\mathbb{R}^3$ [1]. For abbreviation in the following we let $\|\cdot\|$ and $\langle \cdot, \cdot \rangle$ denote norm and inner product in $L^2(\Omega)$:

$$\langle f, g \rangle = \int_\Omega f(x) \cdot g(x)\, dx, \quad \|f\| = \langle f, f \rangle^{\frac{1}{2}}.$$

Let $D(\Omega) = C^\infty_{0,\sigma}(\Omega)$ be the set of all real divergence-free C^∞ vector functions having compact support in Ω. Then $H(\Omega)$ and $V(\Omega)$ denote the closure of $D(\Omega)$ in $L^2(\Omega)$ and $H^1(\Omega)$, respectively:

$$H(\Omega) = \overline{D(\Omega)}^{\|\cdot\|}, \quad V(\Omega) = \overline{D(\Omega)}^{\|\cdot\|_{H^1(\Omega)}}.$$

[2] Corresponding maximal convergence rates can be derived in higher order spaces including H^2 and $D_{A^{1+\varepsilon}}$ up to the order $\varepsilon < \frac{1}{4}$. This will be studied separately.

In virtue of the Helmholtz decomposition

$$L^2 = H \oplus G, G = \left\{ v \in L^2 \mid \exists\, q \in H^1 \ : \ v = \nabla q \right\} \tag{2.1}$$

of L^2 (see [6], [7], [25, pp. 81–89]), let P be Weyl's orthogonal projection $P : L^2 \to H$ [34]. Then the Stokes operator A is defined as the closure in H of the operator $-P\Delta$, which is positive definite and symmetric on the dense subset $D \subset H$, hence positive and self-adjoint; its domain is $D_A = H^2 \cap V$ (see [5, pp. 270, 275–276], [15, pp. 44–45], [3], [26], [25, pp. 127–132]). For the Stokes resolvent $(A+\lambda)^{-1} : H \to D_A$ there holds the following.

LEMMA 2.1. *The resolvent set of the Stokes operator A contains the origin and there exist positive constants c and λ_0 such that*

$$\|(A+\lambda)^{-1}\| \leq \frac{c}{1+|\lambda|} \quad \forall \lambda \in \mathbb{C} \ : \ \ Re(\lambda) \geq -\lambda_0 \tag{2.2}$$

See [33, p. 74], which leads to the following.

LEMMA 2.2. *$-A$ generates the analytic strictly contractive semigroup $\{e^{-tA};\ t \geq 0\}$ on H, $e^{-tA} : H \to H$ is uniformly bounded for $t \geq 0$, $e^{-tA} H \subset D_A$ for $t > 0$, and*

$$\frac{d}{dt} e^{-tA} u + A e^{-tA} u = 0 \quad \forall\ u \in H. \tag{2.3}$$

See [5, pp. 279–280], [4, pp. 101–108], [12], [13], [19], [35], [25, p. 203].

Let $\alpha \in \mathbb{R}$, $\alpha > 0$. Then the fractional powers $A^{-\alpha}$ exist as bounded operators by means of the spectral representation

$$A^{-\alpha} = \frac{1}{\Gamma(\alpha)} \int_0^\infty t^{\alpha-1} e^{-tA} dt, \tag{2.4}$$

where Γ denotes Euler's Gamma function (see [28, p. 10 and Theorem 2.3.2, p. 44]). These operators are invertible, and thus $A^\alpha = (A^{-\alpha})^{-1}$ define the fractional powers of A for positive exponents (see [25, pp. 134, 203]). In addition, let D_{A^α} be the domain of A^α. Then $D_{A^\alpha} \subset H$. For $\alpha > \beta$, the imbedding $D_{A^\alpha} \hookrightarrow D_{A^\beta}$ is compact and D_{A^α} is dense in D_{A^β} (see [30, p. 98], [4, p. 158]).

For Lemmas 2.3 and 2.4 see [5, Lemma 2.10, p. 280] and [22, Lemma 1.3], respectively.

LEMMA 2.3. *Let $u \in D_{A^\beta}$ and $0 < \alpha \leq e$. Then*

$$\|A^{\alpha+\beta} e^{-tA} u\| \leq t^{-\alpha} \cdot \|A^\beta u\| \quad \forall t > 0. \tag{2.5}$$

LEMMA 2.4. *For each $f \in H$ and each real $\tau > 0$ let*

$$f^* = (1+\tau A)^{-1} f \tag{2.6}$$

denote the Yosida approximation of f. Then $f^* \in D_A$ and

$$\|A^\alpha f^*\| \leq c \cdot \tau^{\beta-\alpha} \cdot \|A^\beta f\| \tag{2.7}$$

for each $f \in D_{A^\beta}$ with $0 \leq \beta \leq \alpha \leq 1$.

Additionally, we will make frequent use of the *Cauchy–Young inequality*: Let $a, b \in \mathbb{R}$ with $a, b > 0$. Then

$$a \cdot b \leq \eta \cdot a^q + c_\eta \cdot b^{q'} \tag{2.8}$$

with $\eta = \frac{r^q}{q}$, $c_\eta = \frac{r^{-q'}}{q'}$, $r > 0$, and $\frac{1}{q} + \frac{1}{q'} = 1$, $q > 1$.

3. A modified Crank–Nicolson scheme. Let $\varepsilon \in (0,1)$, $u_0 \in D_{A^{1+\varepsilon}}$, and consider a unique strong solution $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ of (1.2), which exists in virtue of Lemma 2.2 due to the representation $u(t) = e^{-tA}u_0$. Here $A^{1+\varepsilon}e^{-tA}u_0 = e^{-tA}A^{1+\varepsilon}u_0 \in H$ for all $t > 0$ because the fractional powers $A^{1+\varepsilon}$ commute with e^{-tA} on $D_{A^{1+\varepsilon}}$ (see [23, p. 1087]). Consider a finite time interval $J = [0,T]$, $T > 0$, and let

$$\tau = \frac{T}{N} > 0, \quad t_k = k \cdot \tau, \quad k = 0, 1, \dots, N, \quad N \in \mathbb{N},$$

be an equidistant time grid on J. On J we approximate u by a Crank–Nicolson sequence $(U_k^\tau)_{k=1,\dots,N}$ with step size $\tau > 0$:

$$\frac{U_k^\tau - U_{k-1}^\tau}{\tau} + \frac{1}{2} \cdot A(U_k^\tau + U_{k-1}^\tau) = 0, \quad k = 1, \dots, N, \tag{3.1}$$

where $U_0^\tau = u_0$ is the given initial value. To obtain optimum convergence we modify the Crank–Nicolson scheme (3.1) with two steps of the locally second order Rothe scheme:

$$\frac{U_k^\tau - U_{k-1}^\tau}{\tau} + AU_k^\tau = 0, \quad k = 1, \dots, N, \tag{3.2}$$

at initial times $t = t_1$, t_2. Thus, our final approximation scheme reads

$$\left.\begin{array}{ll} U_k^\tau - U_{k-1}^\tau + \frac{\tau}{2} \cdot A(U_k^\tau + U_{k-1}^\tau) = 0, & k = 3, \dots, N, \\ U_k^\tau = (1 + \tau A)^{-1} U_{k-1}^\tau,\ U_0^\tau = u_0, & k = 1, 2. \end{array}\right\} \tag{3.3}$$

The approximation error at time $t = t_k > 0$ is then measured by means of the error function

$$E_k^\tau = U_k^\tau - u(t_k). \tag{3.4}$$

LEMMA 3.1. *Let $U_0^\tau \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$. Then the solution $(U_k^\tau)_{k=1,\dots,N}$ of (3.3) is unique and $U_k^\tau \in D_{A^{1+\varepsilon}}$ for each $k = 1, \dots, N$.*

Proof. Let $U_0^\tau \in D_{A^{1+\varepsilon}} \hookrightarrow D_A$. Then, in virtue of Lemmas 2.1 and 2.4, we obtain by rewriting (3.3)

$$U_k^\tau = (1 + \tau \cdot A)^{-k} U_0^\tau \in D_A$$

exist uniquely for $k = 1, 2$. Thus,

$$U_k^\tau = \left(1 + \frac{\tau}{2} \cdot A\right)^{-1} \left(1 - \frac{\tau}{2} \cdot A\right) U_{k-1}^\tau \in D_A \tag{3.5}$$

exist uniquely for $k \geq 3, \dots, N$ by successively calculating U_k^τ starting from the last Rothe step $U_2^\tau \in D_A$. Moreover, in virtue of Lemma 2.4 and because the operators A^ε commute with $(1 + \tau \cdot A)^{-1}$ on D_{A^ε} (see [24, p. 65], [12]), we obtain by observing $A^{1+\varepsilon}U_0^\tau \in H$

$$A^\varepsilon U_k^\tau = A^\varepsilon (1 + \tau \cdot A)^{-k} U_0^\tau = (1 + \tau \cdot A)^{-k} A^\varepsilon U_0^\tau \in D_A$$

for $k = 1, 2$. Thus,

$$\begin{aligned} A^\varepsilon U_k^\tau &= A^\varepsilon \left(1 + \frac{\tau}{2} \cdot A\right)^{-1} \left(1 - \frac{\tau}{2} \cdot A\right) U_{k-1}^\tau \\ &= \left(1 + \frac{\tau}{2} \cdot A\right)^{-1} \left[\, A^\varepsilon \left(1 - \frac{\tau}{2} \cdot A\right) U_{k-1}^\tau \,\right] \ \in\ D_A \end{aligned}$$

for $k = 3, \dots, N$ by induction, which implies $U_k^\tau \in D_{A^{1+\varepsilon}}$, $k = 1, \dots, N$. ∎

4. Convergence in $L^2(\Omega)$. Our main result reads as follows.

THEOREM 4.1. *Assume $u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, and let $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ be a strong solution of the Stokes initial value problem* (1.2). *Let $(U_k^\tau)_{k=1,\dots,N} \subset D_{A^{1+\varepsilon}}$ with $\tau = \frac{T}{N}$, $T > 0$, $N \in \mathbb{N}$, be the solution of the modified Crank–Nicolson scheme* (3.3). *Then the error estimate*

$$\|U_m^\tau - u(t_m)\| \le c \cdot \frac{\tau^2}{t_m^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \tag{4.1}$$

holds for each $1 \le m \le N$. The constant $c = c(\varepsilon)$ is independent of τ and t_m, but $c(\varepsilon) \to \infty$ as $\varepsilon \to 0^+$.

For the proof a parabolic duality argument to be introduced later on is essential. As a preparatory step we need a couple of a priori estimates of the error function (3.4), which we collect in Lemmas 4.2–4.4. Note that all constants appearing are positive and generic; i.e., they may have different values in different places.

LEMMA 4.2. *Assume $u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, and let $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ be a strong solution of the Stokes initial value problem* (1.2). *Let the modified Crank–Nicolson scheme* (3.3) *be started at any time $t_n > 0$ with initial value $U_n^\tau \in D_{A^{1+\varepsilon}}$. Then the estimates*

$$\|A^{-(1+\varepsilon)} E_m^\tau\| \le c_1 \cdot \left(\|A^{-(1+\varepsilon)} E_n^\tau\| + \frac{\tau^2}{t_n^{1-\varepsilon}} \cdot \|u_0\| \right), \tag{4.2}$$

$$\|E_m^\tau\| \le c_2 \cdot \left(\|E_n^\tau\| + \frac{\tau^2}{t_n^{1-\varepsilon}} \cdot \|A^{(1+\varepsilon)} u_0\| \right) \tag{4.3}$$

hold for each $m, n \in \mathbb{N}$ with $0 < n \le m \le N$. The constants $c_i = c_i(\varepsilon)$, $i = 1, 2$, are independent of τ and t_m.

Proof. We first show that the estimates (4.2), (4.3) are valid for the nonmodified Crank–Nicolson scheme (3.1): We integrate (1.2) over $[t_{k-1}, t_k]$ and add

$$Z_k := \frac{\tau}{2} \cdot A(u(t_k) + u(t_{k-1}))$$

on both sides to get

$$u(t_k) - u(t_{k-1}) + \int_{t_{k-1}}^{t_k} Au(t)dt + Z_k = Z_k. \tag{4.4}$$

Thus, subtracting (4.4) from (3.1) gives

$$E_k^\tau - E_{k-1}^\tau + \frac{\tau}{2} \cdot A(E_k^\tau + E_{k-1}^\tau) = \phi_k, \tag{4.5}$$

where

$$\phi_k = \int_{t_{k-1}}^{t_k} Au(t)dt - Z_k = \int_{t_{k-1}}^{t_k} Au(t)dt - \frac{\tau}{2} \cdot A(u(t_k) + u(t_{k-1})). \tag{4.6}$$

Equation (4.6) can be rewritten in the equivalent form

$$\phi_k = \int_{t_{k-1}}^{t_k} A \left[\frac{t_k - t}{\tau} \cdot (u(t) - u(t_{k-1})) + \frac{t - t_{k-1}}{\tau} \cdot (u(t) - u(t_k)) \right] dt. \tag{4.7}$$

Observing that u can be differentiated twice (see Lemma 2.2), we can expand u near t in the Taylor series

$$u(t) = u(t_{k-1}) + (t - t_{k-1}) \cdot \partial_t u(t) - \int_{t_{k-1}}^{t} (s - t_{k-1}) \cdot \partial_s^2 u(s) ds \tag{4.8}$$

and

$$u(t) \;=\; u(t_k) - (t_k - t) \cdot \partial_t u(t) - \int_{t}^{t_k} (t_k - s) \cdot \partial_s^2 u(s) ds. \tag{4.9}$$

Using the expansions (4.8), (4.9) in (4.7), we find in virtue of the linearity of A

$$\phi_k \;=\; \phi_{k1} \;+\; \phi_{k2}, \tag{4.10}$$

where

$$\phi_{k1} = -\int_{t_{k-1}}^{t_k} \left[\frac{t_k - t}{\tau} \cdot \int_{t_{k-1}}^{t} (s - t_{k-1}) \cdot A \partial_s^2 u(s) ds \right] dt, \tag{4.11}$$

$$\phi_{k2} = -\int_{t_{k-1}}^{t_k} \left[\frac{t - t_{k-1}}{\tau} \cdot \int_{t}^{t_k} (t_k - s) \cdot A \partial_s^2 u(s) ds \right] dt. \tag{4.12}$$

Note that $A\partial_t^2 u$ exists for $t \geq \tau > 0$ (see [9, Theorem 3, pp. 660–661 and Theorem 3′, p. 672]). Because $E_k^\tau \in D_{A^{1+\varepsilon}}$ for all $k \geq 1$ (see Lemma 3.1) and because of the compact imbedding $D_{A^\alpha} \hookrightarrow D_{A^\beta}$ for $\alpha > \beta$, we can take the inner product of (4.5) with $A^{-2(1+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)$ in H^0, which in virtue of the symmetry of A gives

$$\|A^{-(1+\varepsilon)} E_k^\tau\|^2 - \|A^{-(1+\varepsilon)} E_{k-1}^\tau\|^2 + \frac{\tau}{2} \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2 \leq g_k^\tau \tag{4.13}$$

with right-hand side

$$g_k^\tau = g_{k1}^\tau \;+\; g_{k2}^\tau, \tag{4.14}$$

where

$$g_{ki}^\tau = |\langle \phi_{ki}, A^{-2(1+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\rangle|, \quad i = 1, 2. \tag{4.15}$$

We estimate g_k^τ with the help of the representation (4.11) and (4.12) of ϕ_{ki}, $i = 1, 2$, in virtue of the boundedness of $A^{-(\frac{3}{2}+\varepsilon)}$, recalling the symmetry of A, as follows:

$$\begin{aligned} g_{k1}^\tau = |\langle \phi_{k1}, A^{-2(1+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\rangle| \;&=\; |\langle A^{-(\frac{3}{2}+\varepsilon)}\phi_{k1}, A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\rangle| \\ &\leq \tau^{-1} \cdot \left\| \int_{t_{k-1}}^{t_k} (t_k - t) \cdot \int_{t_{k-1}}^{t} (s - t_{k-1}) \cdot A^{-(\frac{3}{2}+\varepsilon)} A \partial_s^2 u(s) ds\, dt \right\| \cdot T_k, \end{aligned}$$

where

$$T_k^\tau = \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|. \tag{4.16}$$

Using the integral inequality

$$\left\| \int_a^b \varphi(t) dt \right\| \leq (b - a)^{\frac{1}{2}} \cdot \left| \int_a^b \|\varphi(t)\|^2 dt \right|^{\frac{1}{2}}, \tag{4.17}$$

which follows from the Cauchy–Schwarz inequality for each $\varphi \in L^2(a,b;H^0(\Omega))$, we conclude that

$$\begin{aligned} g_{k1}^\tau &\le \tau^{-\frac{1}{2}} \cdot \left| \int_{t_{k-1}}^{t_k} (t_k - t)^2 \cdot \left\| \int_{t_{k-1}}^{t} |(s - t_{k-1})| \cdot A^{-(\frac{1}{2}+\varepsilon)} \partial_s^2 u(s) ds \right\|^2 dt \right|^{\frac{1}{2}} \cdot T_k^\tau \\ &\le \left| \int_{t_{k-1}}^{t_k} (t_k - t)^2 \cdot \int_{t_{k-1}}^{t_k} (s - t_{k-1})^2 \cdot \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s^2 u(s)\|^2 ds\, dt \right|^{\frac{1}{2}} \cdot T_k^\tau \\ &= \frac{\tau^{\frac{3}{2}}}{\sqrt{3}} \cdot \left| \int_{t_{k-1}}^{t_k} (s - t_{k-1})^2 \cdot \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s^2 u(s)\|^2 ds \right|^{\frac{1}{2}} \cdot T_k^\tau \\ &\le \frac{\tau^{\frac{5}{2}}}{\sqrt{3}} \cdot \left| \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s^2 u(s)\|^2 ds \right|^{\frac{1}{2}} \cdot T_k^\tau. \end{aligned}$$

Due to an analog estimate of g_{k2}^τ we arrive at

$$g_k^\tau = g_{k1}^\tau + g_{k2}^\tau \;\le\; 2\frac{\tau^{\frac{5}{2}}}{\sqrt{3}} \cdot \left| \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s^2 u(s)\|^2 ds \right|^{\frac{1}{2}} \cdot T_k^\tau. \tag{4.18}$$

Applying the Cauchy–Young inequality (2.8) to (4.18) we conclude by definition (4.16) of T_k^τ that

$$g_k^\tau \le c_\eta \cdot \tau^4 \cdot \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_t^2 u(t)\|^2 dt + \eta \cdot \tau \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2, \tag{4.19}$$

which in virtue of (4.13) gives

$$\begin{aligned} \|A^{-(1+\varepsilon)} E_k^\tau\|^2 \;-\; \|A^{-(1+\varepsilon)} E_{k-1}^\tau\|^2 \;+\; \tau \cdot \left(\frac{1}{2} - \eta\right) \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2 \\ \le\; c_\eta \cdot \tau^4 \cdot \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_t^2 u(t)\|^2 dt. \end{aligned}$$

Thus, summing up from $k = n+1$ to m and neglecting

$$\tau \cdot \left(\frac{1}{2} - \eta\right) \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2 \ge 0$$

by assuming $\eta \le \frac{1}{2}$, we obtain the a priori estimate

$$\|A^{-(1+\varepsilon)} E_m^\tau\|^2 - \|A^{-(1+\varepsilon)} E_n^\tau\|^2 \le c_\eta \cdot \tau^4 \cdot \int_{t_n}^{t_m} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_t^2 u(t)\|^2 dt. \tag{4.20}$$

Recalling the semigroup representation $u(t) = e^{-tA} u_0$ for the solution of the homogeneous Stokes initial value problem (1.2), we differentiate $\partial_t u + Au = 0$, which in virtue of Lemma 2.2 and the closedness of A implies $\partial_t^2 u(t) = A^2 e^{-tA} u_0$ (see [24, pp. 75–76]). Then Lemma 2.3 can be applied to find

$$\|A^{-(\frac{1}{2}+\varepsilon)} \partial_t^2 u(t)\| \;=\; \|A^{\frac{3}{2}-\varepsilon} e^{-tA} u_0\| \;\le\; c \cdot t^{-\frac{3}{2}+\varepsilon} \cdot \|u_0\|,\; t > 0. \tag{4.21}$$

Finally, estimating the integrand of the right-hand side of (4.20) by (4.21), we are led to

$$\begin{aligned}\|A^{-(1+\varepsilon)}E_m^\tau\|^2 &= \|A^{-(1+\varepsilon)}E_n^\tau\|^2 - c_0\cdot\tau^4\cdot(t_m^{-2+2\varepsilon}-t_n^{-2+2\varepsilon})\cdot\|u_0\|^2\\ &\le \|A^{-(1+\varepsilon)}E_n^\tau\|^2 + c_1\cdot\tau^4\cdot t_n^{-2+2\varepsilon}\cdot\|u_0\|^2\\ &\le c\cdot\Big(\|A^{-(1+\varepsilon)}E_n^\tau\| + \tau^2\cdot t_n^{-1+\varepsilon}\cdot\|u_0\|\Big)^2\end{aligned}$$

with $c=\max\{1,c_1\}$. This proves (4.2) for the nonmodified Crank–Nicolson scheme (3.1).

For (4.3), taking the inner product of (4.5) with $E_k^\tau + E_{k-1}^\tau$ in H^0, a similar procedure as above leads to

$$\|E_k^\tau\|^2 - \|E_{k-1}^\tau\|^2 \;+\; \tau\cdot\left(\frac{1}{2}-\eta\right)\cdot\|A^{\frac12}(E_k^\tau+E_{k-1}^\tau)\|^2 \;\le\; c_\eta\cdot\tau^4\cdot\int_{t_{k-1}}^{t_k}\|A^{\frac12}\partial_t^2u(t)\|^2dt.$$

This gives

$$\|E_m^\tau\|^2 - \|E_n^\tau\|^2 \le c_\eta\cdot\tau^4\cdot\int_{t_n}^{t_m}\|A^{\frac12}\partial_t^2u(t)\|^2dt \tag{4.22}$$

by choosing $\eta\le\frac12$, neglecting $\tau\cdot(\frac12-\eta)\cdot\|A^{\frac12}(E_k^\tau+E_{k-1}^\tau)\|^2\le 0$, and summing up from $k=n+1$ to m. Estimating the integrand of the right-hand side of (4.22) with the help of Lemma 2.3 by

$$\|A^{\frac12}\partial_t^2u(t)\| \;=\; \|A^{\frac32-\varepsilon}e^{-tA}A^{1+\varepsilon}u_0\| \;\le\; c\cdot t^{-(\frac32-\varepsilon)}\cdot\|A^{1+\varepsilon}u_0\| \tag{4.23}$$

for $t>0$ proves (4.3) for the nonmodified Crank–Nicolson scheme (3.1) similarly as above by integrating the right-hand side of (4.22) using (4.23). Next, we show that (4.2), (4.3) hold locally for Rothe's scheme (3.2): Again, we integrate (1.2) over $[t_{k-1},t_k]$, but this time adding

$$\tilde Z_k := \tau\cdot Au(t_k)$$

on both sides yields

$$E_k^\tau - E_{k-1}^\tau + \tau\cdot AE_k^\tau = \varphi_k, \tag{4.24}$$

where

$$\varphi_k \;=\; \int_{t_{k-1}}^{t_k}Au(t)dt - \tau\cdot Au(t_k) \;=\; \int_{t_{k-1}}^{t_k}\int_{t_k}^{t}A\partial_su(s)ds\,dt. \tag{4.25}$$

Similarly as above, taking the inner product of (4.24) with $A^{-2(1+\varepsilon)}(E_k^\tau+E_{k-1}^\tau)$ in H^0, we obtain by substituting (4.25) for the right-hand side of (4.24)

$$\|A^{-(1+\varepsilon)}E_k^\tau\|^2 - \|A^{-(1+\varepsilon)}E_{k-1}^\tau\|^2 + \tau\cdot\|A^{-(\frac12+\varepsilon)}(E_k^\tau+E_{k-1}^\tau)\|^2 \le G_k^\tau \tag{4.26}$$

with

$$\begin{aligned}G_k^\tau \;&=\; |\langle\varphi_k, A^{-2(1+\varepsilon)}(E_k^\tau+E_{k-1}^\tau)\rangle| \;=\; |\langle A^{-(\frac32+\varepsilon)}\varphi_k, A^{-(\frac12+\varepsilon)}(E_k^\tau+E_{k-1}^\tau)\rangle|\\ &\le\; \|\int_{t_{k-1}}^{t_k}\int_{t_{k-1}}^{t}A^{-(\frac32+\varepsilon)}A\partial_su(s)dsdt\|\cdot T_k^\tau,\end{aligned}$$

where T_k^τ is again defined by (4.16). Thus, applications of the integral inequality (4.17) and the Cauchy–Young inequality (2.8) to G_k^τ yield

$$\begin{aligned}
G_k^\tau &\le \tau^{\frac{1}{2}} \cdot \left| \int_{t_{k-1}}^{t_k} \left\| \int_{t_{k-1}}^{t} A^{-(\frac{1}{2}+\varepsilon)} \partial_s u(s) ds \right\|^2 dt \right|^{\frac{1}{2}} \cdot T_k^\tau \\
&\le \tau^{\frac{1}{2}} \cdot \left| \int_{t_{k-1}}^{t_k} (t - t_{k-1}) \cdot \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s u(s)\|^2 ds\, dt \right|^{\frac{1}{2}} \cdot T_k^\tau \\
&= \frac{\tau^{\frac{3}{2}}}{\sqrt{2}} \cdot \left| \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_s u(s)\|^2 ds \right|^{\frac{1}{2}} \cdot T_k^\tau \\
&\le c_\eta \cdot \tau^2 \cdot \int_{t_{k-1}}^{t_k} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_t u(t)\|^2 dt + \eta \cdot \tau \cdot (T_k^\tau)^2.
\end{aligned}$$

From this we find the a priori error bound

$$\|A^{-(1+\varepsilon)} E_m^\tau\|^2 - \|A^{-(1+\varepsilon)} E_n^\tau\|^2 \le c \cdot \tau^2 \cdot \int_{t_n}^{t_m} \|A^{-(\frac{1}{2}+\varepsilon)} \partial_t u(t)\|^2 dt \tag{4.27}$$

by absorbing $\eta \cdot \tau \cdot (T_k^\tau)^2 = \eta \cdot \tau \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2$ for $\eta \le 1$ into the left-hand side of (4.26) and subsequently neglecting the resulting term

$$(1-\eta) \cdot \tau \cdot (T_k^\tau)^2 = (1-\eta) \cdot \tau \cdot \|A^{-(\frac{1}{2}+\varepsilon)}(E_k^\tau + E_{k-1}^\tau)\|^2 \ge 0$$

and summing up from $k = n+1$ to $k = m$.

Observing $\partial_t u(t) = -Ae^{-tA} u_0$ in virtue of Lemma 2.2 and recalling the boundedness of $A^{-(\frac{1}{2}+\varepsilon)}$, we estimate the integrand of the right-hand side of (4.27) with the help of Lemma 2.3 by

$$\|A^{-(\frac{1}{2}+\varepsilon)} \partial_t u(t)\| \;=\; \|A^{\frac{1}{2}-\varepsilon} e^{-tA} u_0\| \le c \cdot t^{-\frac{1}{2}+\varepsilon} \cdot \|u_0\|. \tag{4.28}$$

Thus, integrating (4.27) using (4.28), we are led to

$$\begin{aligned}
\|A^{-(1+\varepsilon)} E_m^\tau\|^2 - \|A^{-(1+\varepsilon)} E_n^\tau\|^2 \;&\le\; c \cdot \tau^2 \cdot \int_{t_n}^{t_m} t^{-1+2\varepsilon} dt \cdot \|u_0\|^2 \\
=\; c \cdot \tau^2 \cdot \int_{t_n}^{t_m} t^{-2+2\varepsilon} \cdot t\, dt \cdot \|u_0\|^2 \;&\le\; c \cdot \tau^2 \cdot t_n^{-2+2\varepsilon} \cdot (t_m^2 - t_n^2) \cdot \|u_0\|^2 \\
=\; c \cdot \tau^4 \cdot t_n^{-2+2\varepsilon} \cdot (m^2 - n^2) \cdot \|u_0\|^2 \;&\le\; c \cdot \tau^4 \cdot t_n^{-2+2\varepsilon} \cdot (m-n)^2 \cdot \|u_0\|^2
\end{aligned}$$

for fixed $n < m$. Therefore,

$$\|A^{-(1+\varepsilon)} E_m^\tau\| \le c \cdot \left(\|A^{-(1+\varepsilon)} E_n^\tau\| \;+\; (m-n) \cdot \frac{\tau^2}{t_n^{1-\varepsilon}} \cdot \|u_0\| \right), \tag{4.29}$$

which is locally (4.2). Similarly there hold

$$\begin{aligned}
\|E_m^\tau\|^2 - \|E_n^\tau\|^2 &\le c \cdot \tau^2 \cdot \int_{t_n}^{t_m} \|A^{\frac{1}{2}} \partial_t u(t)\|^2 dt = c \cdot \tau^2 \cdot \int_{t_n}^{t_m} \|A^{\frac{1}{2}-\varepsilon} e^{-tA} A^{1+\varepsilon} u_0\|^2 dt \\
&\le c \cdot \tau^2 \cdot \int_{t_n}^{t_m} t^{-1+2\varepsilon} dt \cdot \|A^{1+\varepsilon} u_0\|^2 \\
&\le c \cdot \tau^4 \cdot t_n^{-2+2\varepsilon} \cdot (m-n)^2 \cdot \|A^{1+\varepsilon} u_0\|^2,
\end{aligned}$$

and thus

$$\|E_m^\tau\| \le c \cdot \left(\|E_n^\tau\| + (m-n) \cdot \frac{\tau^2}{t_n^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \right), \tag{4.30}$$

which is locally (4.3).

Finally, combining the global estimates (4.2) (resp., (4.3)) for the nonmodified Crank–Nicolson scheme (3.1) with the local estimates, (4.29) (resp., (4.30)) yields the desired estimates for the modified Crank–Nicolson scheme (3.3). ∎

LEMMA 4.3. *Assume $u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, and let $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ be a strong solution of the Stokes initial value problem* (1.2). *Let the modified Crank–Nicolson scheme* (3.3) *be started at time $t_0 = 0$ with initial value $U_0^\tau = u_0 \in D_{A^{1+\varepsilon}}$. Then the estimate*

$$\|E_m^\tau\| \le c \cdot \tau^{1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\| \tag{4.31}$$

holds for $1 \le m \le N$. The constant $c = c(\varepsilon)$ is independent of τ, but $c(\varepsilon) \to \infty$ as $\varepsilon \to 0^+$.

Proof. For Rothe's scheme, we recall

$$\|E_m^\tau\|^2 - \|E_n^\tau\|^2 \le c \cdot \tau^2 \cdot \int_{t_n}^{t_m} \|A^{\frac{1}{2}-\varepsilon} e^{-tA} A^{1+\varepsilon} u_0\|^2 dt \tag{4.32}$$

from the proof of Lemma 4.2. Thus, setting $n = 0$ and observing $E_0^\tau = 0$, we conclude that

$$\begin{aligned} \|E_m^\tau\|^2 &\le c \cdot \tau^2 \cdot \int_0^{t_m} t^{-1+2\varepsilon} dt \cdot \|A^{1+\varepsilon} u_0\|^2 \\ &= \frac{c}{2\varepsilon} \cdot \tau^2 \cdot t_m^{2\varepsilon} \cdot \|A^{1+\varepsilon} u_0\|^2 = \frac{c}{2\varepsilon} \cdot m^{2\varepsilon} \cdot \tau^{2+2\varepsilon} \cdot \|A^{1+\varepsilon} u_0\|^2. \end{aligned}$$

Therefore,

$$\|E_m^\tau\| \le \frac{c}{\sqrt{2\varepsilon}} \cdot m^\varepsilon \cdot \tau^{1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\| \ \le \ \frac{c}{\sqrt{2\varepsilon}} \cdot m \cdot \tau^{1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\| \tag{4.33}$$

because $0 < \varepsilon < 1$. Finally, combining the local estimate (4.33) for Rothe's scheme (3.2) and (4.3) of Lemma 4.2 gives the desired estimate (4.31) for the modified Crank–Nicolson scheme (3.3) as follows. For $0 \le m \le 2$ is nothing to prove, just take (4.33) for the Rothe scheme. For $m > 2$ we have in virtue of (4.3)

$$\begin{aligned} \|E_m^\tau\| &\le c_0 \cdot \left(\|E_2^\tau\| + \tau^2 \cdot t_2^{-1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\| \right) \\ &\le c_0 \cdot \left(2 \cdot c_1 \cdot \tau^{1+\varepsilon} + 2^{-1+\varepsilon} \cdot \tau^{1+\varepsilon} \right) \cdot \|A^{1+\varepsilon} u_0\| \le c_2 \cdot \tau^{1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\| \end{aligned}$$

because E_2^τ is calculated by Rothe's scheme and $E_0^\tau = 0$ by assumption. ∎

Additionally, the following lower order "smoothing" estimate holds (see [20]; see also [17] for the more general case of time-dependent operators).

LEMMA 4.4. *Assume $u_0 \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, and let $u \in C^0([0,\infty), D_{A^{1+\varepsilon}})$ be a strong solution of the Stokes initial value problem* (1.2). *Let the modified Crank–Nicolson scheme* (3.3) *be started at time $t_0 = 0$ with initial value $U_0^\tau = u_0 \in D_{A^{1+\varepsilon}}$. Then the estimate*

$$\|E_m^\tau\| \le c \cdot \frac{\tau^{1-\varepsilon}}{t_m^{1-\varepsilon}} \cdot \|u_0\| \tag{4.34}$$

holds for $1 \leq m \leq N$. *The constant* c *is independent of* τ *and* t_m.

Proof. Let $u_0 \in D_{A^{1+\varepsilon}} \hookrightarrow H$. Then

$$\|E_m^\tau\| \leq c \cdot \frac{\tau}{t_m} \cdot \|u_0\| \tag{4.35}$$

for $m \geq 1$ (see [20, p. 347], [17, Lemma 3.6]). Thus,

$$\|E_m^\tau\| \leq c \cdot \frac{\tau^{1-\varepsilon}}{t_m^{1-\varepsilon}} \cdot \frac{\tau^\varepsilon}{t_m^\varepsilon} \cdot \|u_0\| \;\leq\; c \cdot \frac{\tau^{1-\varepsilon}}{t_m^{1-\varepsilon}} \cdot \|u_0\| \tag{4.36}$$

for $m \geq 1$. ∎

We now introduce the parabolic duality argument (see [16], [17]). For that we recall the self-adjointness of A, i.e., $A = A'$ (see section 2). Consider the "backward evolution system" to the Stokes initial value problem (1.2)

$$\left.\begin{array}{ll} \partial_t v - Av = 0, & T \geq t_m > t \geq 0, \\ v(t_m) = v_m. & \end{array}\right\} \tag{4.37}$$

Its corresponding backward discrete analogon of the modified Crank–Nicolson scheme (3.3) with given initial values $v(t_m) = V_m^\tau$ at time t_m with $0 < m \leq N$ reads

$$\left.\begin{array}{ll} V_k^\tau - V_{k-1}^\tau - \frac{\tau}{2} \cdot A(V_k^\tau + V_{k-1}^\tau) = 0, & k = m, \ldots, 3, \\ V_{k-1}^\tau = (1 + \tau \cdot A)^{-1} V_k^\tau, & k = 2, 1. \end{array}\right\} \tag{4.38}$$

Lemma 4.5. *Let* $v_m \in D_{A^{1+\varepsilon}}$, $\varepsilon \in (0,1)$, $0 < m \leq N$. *Then the backward problems* (4.37) *and* (4.38) *have unique solutions* v *and* $(V_k^\tau)_{k=m-1,\ldots,0}$, *with*

$$\begin{array}{l} v \in C^0([0,t_m], D_{A^{1+\varepsilon}}), \;\; v(t) = e^{-(t_m - t)A} v_m, \;\; t_m > t \geq 0, \\ V_k^\tau \in D_{A^{1+\varepsilon}}, \;\; m > k \geq 0. \end{array}$$

Proof. Let $v_m \in D_{A^{1+\varepsilon}}$. Then $v \in C^0([0,t_m], D_{A^{1+\varepsilon}})$ in virtue of Lemma 2.2 with time reversed. Let $s(t) = t_m - t > 0$. Then $\frac{d}{ds} e^{-sA} v_m + A e^{-sA} v_m = 0$ for $v_m \in D_{A^{1+\varepsilon}} \hookrightarrow H$ by Lemma 2.2. Let $v(t) = e^{-(t_m - t)A} v_m$. Then $\frac{d}{dt} v(t) = -\frac{d}{ds} e^{-sA} v_m$ and $v(t_m) = v_m$. Let $m \geq k \geq 3$. Rewriting (4.38) we obtain

$$V_{k-1}^\tau = \left(1 + \frac{\tau}{2} \cdot A\right)^{-1} \left(1 - \frac{\tau}{2} \cdot A\right) V_k^\tau = \left(1 - \frac{\tau}{2} \cdot A\right) \left(1 + \frac{\tau}{2} \cdot A\right)^{-1} V_k^\tau \in D_{A^{1+\varepsilon}}$$

by successively calculating V_k^τ starting from the given initial value $V_m^\tau \in D_{A^{1+\varepsilon}}$ (see the proof of Lemma 3.1). Thus

$$V_{k-1}^\tau = (1 + \tau \cdot A)^{-(3-k)} V_2^\tau \in D_{A^{1+\varepsilon}}$$

for $k = 2, 1$. ∎

For abbreviation in the following we let

$$u_\mu := u(t_\mu), \;\; v_\mu := v(t_\mu) \tag{4.39}$$

for the solution u and v of (1.2) and (4.37), respectively. Lemma 4.6 provides decisive inner product identities connecting the solutions of (1.2) and (3.3) with the corresponding solutions of the backward problems (4.37) and (4.38), respectively.

LEMMA 4.6. *Let u, $(U_k^\tau)_{k=1,\dots,m}$ be the solutions of* (1.2), (3.3)*, respectively, and v, $(V_k^\tau)_{k=m-1,\dots,0}$ be the solutions of* (4.37), (4.38)*, respectively. Then*

$$\langle u_p, v_p\rangle - \langle u_q, v_q\rangle = 0, \tag{4.40}$$

$$\langle U_p^\tau, V_p^\tau\rangle - \langle U_q^\tau, V_q^\tau\rangle = 0 \tag{4.41}$$

hold for each p, q with $0 \le p \le q \le m \le N$.

Proof. Let u and v be the solutions of (1.2) and (4.37), respectively. Then

$$\begin{aligned}\frac{d}{dt}\langle u(t), v(t)\rangle &= \langle \partial_t u(t), v(t)\rangle + \langle u(t), \partial_t v(t)\rangle\\ &= \langle -Au(t), v(t)\rangle + \langle u(t), Av(t)\rangle\\ &= \langle u(t), -Av(t)\rangle + \langle u(t), Av(t)\rangle = 0\end{aligned}$$

in virtue of Lemmas 2.2 and 4.5 because of the self-adjointness of A. Thus, the identity (4.40) follows by integration over $[t_p, t_q]$.

For the discrete solutions, for $3 \le \mu \le m \le N$, rewriting (3.3) and (4.38) in the equivalent forms

$$U_\mu^\tau = \left(1 + \frac{\tau}{2}\cdot A\right)^{-1}\left(1 - \frac{\tau}{2}\cdot A\right)U_{\mu-1}^\tau, V_{\mu-1}^\tau = \left(1 + \frac{\tau}{2}\cdot A\right)^{-1}\left(1 - \frac{\tau}{2}\cdot A\right)V_\mu^\tau,$$

we find in virtue of the commutativity of $(1 + \frac{\tau}{2}\cdot A)^{-1}$ and $(1 - \frac{\tau}{2}\cdot A)$ on D_A (see [24, p. 65]) and due to the symmetry of the Stokes resolvent (see [12, p. 279])

$$\begin{aligned}\langle U_\mu^\tau, V_\mu^\tau\rangle &= \langle (1+\tfrac{\tau}{2}\cdot A)^{-1}(1-\tfrac{\tau}{2}\cdot A)U_{\mu-1}^\tau, V_\mu^\tau\rangle\\ &= \langle U_{\mu-1}^\tau, (1+\tfrac{\tau}{2}\cdot A)^{-1}(1-\tfrac{\tau}{2}\cdot A)V_\mu^\tau\rangle = \langle U_{\mu-1}^\tau, V_{\mu-1}^\tau\rangle.\end{aligned}$$

Similarly, the same holds true for the corresponding resolvent equations of the Rothe steps ($1 \le \mu \le 2$), and thus

$$\langle U_\mu^\tau, V_\mu^\tau\rangle - \langle U_{\mu-1}^\tau, V_{\mu-1}^\tau\rangle = 0 \tag{4.42}$$

for $1 \le \mu \le m \le N$. The desired identity (4.41) follows by summing up (4.42) from $\mu = p+1$ to q , $0 \le p \le q \le m \le N$. □

In view of Lemmas 4.2–4.6 we are now prepared to finish the following proof.

Proof of Theorem 4.1. For estimating the error $\|E_m^\tau\|$, we will use that

$$\|E_m^\tau\| = \|E_m^\tau\|_H \;\le\; \sup\{|\langle E_m^\tau, v_m\rangle| \;:\; v_m \in H,\ \|v_m\| = 1\}$$

holds for $E_m^\tau \in D_{A^{1+\varepsilon}} \hookrightarrow H$. Thus,

$$\|E_m^\tau\| \le \sup\{|\langle E_m^\tau, v_m\rangle| \;:\; v_m \in D_{A^{1+\varepsilon}},\ \|v_m\| = 1\} \tag{4.43}$$

because D_{A^α} is dense in H for $\alpha > 0$. Therefore, our aim is to derive an identity for the inner product $\langle E_m^\tau, v_m\rangle$, which we then estimate with the help of Lemmas 4.2–4.4 and Lemma 4.6. For that let v and $(V_\mu^\tau)_{\mu=m-1,\dots,0}$ be the solutions of (4.37) and (4.38), respectively, corresponding to the given initial values $v_m = V_m^\tau$ at initial time

t_m with $1 \le m \le N$. In addition, let $M := [\frac{m}{2}]$ be the largest integer less than or equal to $\frac{m}{2}$. Then, applying Lemma 4.6, we obtain by observing $v_m - V_m^\tau = 0$

$$\begin{aligned}\langle E_m^\tau, v_m\rangle &= \langle U_m^\tau, v_m\rangle - \langle u_m, v_m\rangle \\ &= \langle U_m^\tau, v_m - V_m^\tau\rangle + \langle U_m^\tau, V_m^\tau\rangle - \langle u_m, v_m\rangle \\ &= \langle U_m^\tau, V_m^\tau\rangle - \langle u_m, v_m\rangle \\ &= \langle U_M^\tau, V_M^\tau\rangle - \langle u_M, v_M\rangle \\ &= \langle E_M^\tau, v_M\rangle + \langle U_M^\tau, V_M^\tau - v_M\rangle.\end{aligned}$$

Therefore, substituting $U_M^\tau = E_M^\tau + u_M$ into the latter equation, we will estimate the right-hand side of

$$\langle E_m^\tau, v_m\rangle \;=\; \langle E_M^\tau, v_M\rangle \;+\; \langle E_M^\tau, V_M^\tau - v_M\rangle \;+\; \langle u_M, V_M^\tau - v_M\rangle \tag{4.44}$$

in view of (4.43) as follows:

A bound for $|\langle E_M^\tau, v_M\rangle|$. Let $(\tilde V_\mu^\tau)_{\mu=M-1,\dots,0}$ be the solution of (4.38) corresponding to the given initial value $\tilde V_M^\tau = v_M$ at initial time $t_M \le t_m$. Then, using Lemma 4.6, we find

$$\begin{aligned}\langle E_M^\tau, v_M\rangle &= \langle U_M^\tau, v_M\rangle - \langle u_M, v_M\rangle \\ &= \langle U_M^\tau, v_M - \tilde V_M^\tau\rangle - \langle u_M, v_M\rangle + \langle U_M^\tau, \tilde V_M^\tau\rangle \\ &= \langle U_M^\tau, \tilde V_M^\tau\rangle - \langle u_M, v_M\rangle \\ &= \langle U_0^\tau, \tilde V_0^\tau\rangle - \langle u_0, v_0\rangle \\ &= \langle u_0, \tilde V_0^\tau\rangle - \langle u_0, v_0\rangle \\ &= \langle u_0, \tilde V_0^\tau - v_0\rangle \\ &= \langle A^{1+\varepsilon} u_0, A^{-(1+\varepsilon)}(\tilde V_0^\tau - v_0)\rangle\end{aligned}$$

because $U_0^\tau = u_0$ by the assumption of Theorem 4.1. Here the latter equation is due to the symmetry of A. Thus, application of the Cauchy–Schwarz inequality yields

$$|\langle E_M^\tau, v_M\rangle| \le \|A^{1+\varepsilon} u_0\| \cdot \|A^{-(1+\varepsilon)}(\tilde V_0^\tau - v_0)\|. \tag{4.45}$$

Next, in virtue of Lemma 4.5, we can apply (4.2) of Lemma 4.2 with time reversed to the right-hand side of (4.45) to obtain

$$\|A^{-(1+\varepsilon)}(\tilde V_0^\tau - v_0)\| \le c_0 \cdot \frac{\tau^2}{(t_m - t_M)^{1-\varepsilon}} \cdot \|v_m\| \tag{4.46}$$

because $\tilde V_M^\tau - v_M = 0$. Let $m \ge 1$. Then $M = [\frac{m}{2}] \le \frac{m}{2}$, i.e., $t_m - t_M \ge t_{\frac{m}{2}}$ or $\frac{1}{t_m - t_M} \le \frac{2}{t_m}$. Thus, combining (4.45) and (4.46) gives

$$|\langle E_M^\tau, v_M\rangle| \le c \cdot \frac{\tau^2}{t_m^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \cdot \|v_m\|, \tag{4.47}$$

where $c = 2^{1-\varepsilon} \cdot c_0$.

A bound for $|\langle E_M^\tau, V_M^\tau - v_M\rangle|$. Let $M = [\frac{m}{2}] \ge 0$. Then, applying (4.31) of Lemma 4.3 to E_M^τ yields

$$\|E_M^\tau\| \le c_0 \cdot \tau^{1+\varepsilon} \cdot \|A^{1+\varepsilon} u_0\|. \tag{4.48}$$

Let $M \geq 1$, i.e., $m \geq 2$. Then, with similar arguments as above, in virtue of Lemma 4.5, applying (4.34) of Lemma 4.4 with time reversed to $V_M^\tau - v_M$, we conclude that

$$\|v_M - V_M^\tau\| \leq c_1 \cdot \frac{\tau^{1-\varepsilon}}{(t_m - t_M)^{1-\varepsilon}} \cdot \|v_m\| \;\leq\; c_2 \cdot \frac{\tau^{1-\varepsilon}}{t_m^{1-\varepsilon}} \cdot \|v_m\|, \tag{4.49}$$

where $c_2 = 2^{1-\varepsilon} \cdot c_1$. Therefore, applying the Cauchy–Schwarz inequality and combining (4.48) and (4.49), we are led to

$$|\langle E_M^\tau, V_M^\tau - v_M\rangle| \leq c_0 \cdot c_2 \cdot \frac{\tau^2}{t_m^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \cdot \|v_m\| \tag{4.50}$$

for $m \geq 2$.

A bound for $|\langle u_M, V_M^\tau - v_M\rangle|$. Let $(\tilde{U}_\mu^\tau)_{\mu=M+1,\dots,m}$ be the solution of the modified Crank–Nicolson scheme (3.3) corresponding to the given initial value $\tilde{U}_M^\tau = u_M$ at initial time $t_M \leq t_m$. Then, in virtue of Lemma 4.6, observing $V_m^\tau = v_m$, we find

$$\begin{aligned}
\langle u_M, V_M^\tau - v_M\rangle &= \langle u_M, V_M^\tau\rangle - \langle u_M, v_M\rangle \\
&= \langle u_M - \tilde{U}_M^\tau, V_M^\tau\rangle + \langle \tilde{U}_M^\tau, V_M^\tau\rangle - \langle u_M, v_M\rangle \\
&= \langle \tilde{U}_M^\tau, V_M^\tau\rangle - \langle u_M, v_M\rangle \\
&= \langle \tilde{U}_m^\tau, V_m^\tau\rangle - \langle u_m, v_m\rangle \\
&= \langle \tilde{U}_m^\tau - u_m, v_m\rangle.
\end{aligned}$$

Thus, in virtue of the Cauchy–Schwarz inequality, it remains to estimate the right-hand side of

$$|\langle u_M, V_M^\tau - v_M\rangle| \leq \|\tilde{U}_m^\tau - u_m\| \cdot \|v_m\|. \tag{4.51}$$

Applying (4.3) of Lemma 4.2 with $n = M$ to the right-hand side of (4.51) yields

$$\|\tilde{U}_m^\tau - u_m\| \leq c_0 \cdot \frac{\tau^2}{t_M^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \tag{4.52}$$

because $\tilde{U}_M^\tau - u_M = 0$ by construction of $(\tilde{U}_\mu^\tau)$. Next, let $m \geq 2$. Then $M = [\frac{m}{2}] \geq \frac{m-1}{2} \geq \frac{m}{4}$, i.e., $\frac{1}{t_M} \leq \frac{4}{t_m}$. Then, from (4.51) and (4.52), we conclude that

$$|\langle u_M, V_M^\tau - v_M\rangle| \leq c_1 \cdot \frac{\tau^2}{t_m^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \cdot \|v_m\|, \tag{4.53}$$

where $c_1 = 4^{1-\varepsilon} \cdot c_0$. Finally, combining the bounds (4.47), (4.50), and (4.53) with (4.44), we arrive at

$$|\langle E_m^\tau, v_m\rangle| \leq c \cdot \frac{\tau^2}{t_m^{1-\varepsilon}} \cdot \|A^{1+\varepsilon} u_0\| \cdot \|v_m\|, \tag{4.54}$$

which gives the desired estimate (4.1) by applying (4.43) to (4.54). This completes the proof of Theorem 4.1. ∎

THEORETICALLY SUPPORTED SCALABLE FETI FOR NUMERICAL SOLUTION OF VARIATIONAL INEQUALITIES*

ZDENĚK DOSTÁL† AND DAVID HORÁK‡

Abstract. The FETI method with a natural coarse grid is combined with recently proposed optimal algorithms for the solution of bound and/or equality constrained quadratic programming problems in order to develop a scalable solver for elliptic boundary variational inequalities such as those describing equilibrium of a system of bodies in mutual contact. A discretized model problem is first reduced by the duality theory of convex optimization to the quadratic programming problem with bound and equality constraints. The latter is then modified by means of orthogonal projectors to the natural coarse grid introduced by Farhat, Mandel, and Roux [*Comput. Methods Appl. Mech. Engrg.*, 115 (1994), pp. 365–385]. Finally, the classical results on linear scalability for linear problems are extended to boundary variational inequalities. The results are validated by numerical experiments. The experiments also confirm that the algorithm enjoys the same parallel scalability as its linear counterpart.

1. Introduction.

The FETI (finite element tearing and interconnecting) domain decomposition method was originally proposed by Farhat and Roux [26] for parallel solving of the linear problems described by elliptic partial differential equations. Its key ingredient is decomposition of the spatial domain into nonoverlapping subdomains that are "glued" by Lagrange multipliers, so that, after eliminating the primal variables, the original problem is reduced to a small, relatively well conditioned, typically equality constrained quadratic programming problem that is solved iteratively. The time that is necessary for both the elimination and iterations can be reduced nearly proportionally to the number of the processors, so that the algorithm enjoys parallel scalability. Observing that the equality constraints may be used to define so-called natural coarse grid, Farhat, Mandel, and Roux [25] modified the basic FETI algorithm so that they were able to adapt the results by Bramble, Pasciak, and Schatz [5] to prove its numerical scalability, i.e., asymptotically linear complexity. A comprehensive review of the mathematical results related to the FETI methods may be found in the monograph by Tosseli and Widlund [38].

If the FETI procedure is applied to an elliptic variational inequality, the resulting quadratic programming problem has not only the equality constraints but also the nonnegativity constraints. Even though the latter is a considerable complication as compared with linear problems, it seems that the FETI procedure should be even more powerful for the solution of variational inequalities than for linear problems. The reason is that FETI not only reduces the original problem to a smaller and

better conditioned one, but it also replaces for free all the inequalities by the bound constraints. Promising experimental results by Dureisseix and Farhat [22] supported this claim and even indicated numerical scalability of their method. Similar results were achieved also for the FETI–DP (dual–primal) method introduced by Farhat et al. [24]. The FETI–DP method is very similar to the original FETI; the only difference is that it enforces the continuity of displacements at corners on primal level. A new Lagrange multipliers algorithm, FETI–C, based on FETI–DP and on active set strategies with additional planning steps and preconditioning, was introduced by Avery et al. [1] and Dureisseix and Farhat [22]. Its scalability was demonstrated experimentally.

Another approach yielding experimental evidence of scalability was proposed by Dostál et al. [12, 13, 14]. The algorithm combined FETI with a special variant of the augmented Lagrangian method [10]. Scalability was later proved for an algorithm that enforced the equality constraints by the optimal dual penalty [15, 16] and solved the resulting bound constrained problem by recent, in a sense optimal, algorithms [7, 21]. Using the same algorithms, Dostál, Horák, and Stefanica then proved numerical scalability for a FETI–DP algorithm applied to two-dimensional (2D) coercive model problems discretized by means of either nodal [18] or mortar [19] Lagrange multipliers. Most recently, the scalability results were extended to include semicoercive problems [20]. The results used the effective condition number of the dual Schur complement of the stiffness matrix which was proved to be bounded by CH^2/h^2, where C is a constant independent of the discretization and decomposition parameters h and H, respectively. The results did not assume any preconditioning. Indeed, numerical experiments by the present authors, V. Vondrák, and M. Lesoinne indicated that the performance of our FETI–DP based algorithms may be considerably improved by preconditioning.

It should be noted that the effort to develop scalable solvers for variational inequalities was not restricted to FETI. For example, using ideas related to Mandel [34], Kornhuber, Krause, Sander, and Wohlmuth [30, 31, 40, 32, 33] gave experimental evidence of numerical scalability of the algorithm based on monotone multigrid. Probably the first theoretical results concerning development of scalable algorithms were proved by Schöberl [36, 37].

In this paper, we use the FETI method with a natural coarse grid to develop a scalable algorithm for numerical solution of both coercive and semicoercive variational inequalities. The result exploits the classical FETI1 upper bound CH/h [25] on the condition number of the regular part of the corresponding Hessian and remains valid for more general elliptic variational inequalities, including those describing equilibrium of a system of elastic bodies in mutual contact.

The paper is organized as follows. After describing a model problem, we briefly review the FETI methodology [12] that turns the variational inequality into a well conditioned quadratic programming problem with bound and equality constraints. Then we review our algorithms for the solution of the resulting bound and equality constrained quadratic programming problem whose rate of convergence may be expressed in terms of bounds on the spectrum of the dual Schur complement matrix [21, 8, 9]. Finally, we present the main results about optimality of our method and give results of numerical experiments with parallel implementation of the algorithm in PETSc [3].

2. Model problem. For the sake of simplicity, we shall reduce our analysis to a simple model problem, but our reasoning is valid also in more general cases,

including contact problems of 2D and three-dimensional (3D) elasticity, provided that the conditions exploited in the proof of the results by Farhat, Mandel, and Roux [25] are satisfied. Let $\Omega = \Omega^1 \cup \Omega^2$, $\Omega^1 = (0,1) \times (0,1)$, and $\Omega^2 = (1,2) \times (0,1)$ denote open domains with boundaries Γ^1, Γ^2 and their parts $\Gamma^i_u, \Gamma^i_f, \Gamma^i_c$ formed by the sides of Ω^i, $i = 1,2$, as in Figure 1(a) or 1(b). Let $H^1(\Omega^i)$, $i = 1,2$, denote the Sobolev space of the first order in the space $L^2(\Omega^i)$ of the functions on Ω^i whose squares are integrable in the sense of Lebesgue. Let

$$V^i = \left\{ v^i \in H^1(\Omega^i) : v^i = 0 \quad \text{on} \quad \Gamma^i_u \right\}$$

denote the closed subspaces of $H^1(\Omega^i)$, $i = 1,2$, and let

$$V = V^1 \times V^2 \qquad \text{and} \qquad \mathcal{K} = \left\{ (v^1, v^2) \in V : v^2 - v^1 \geq 0 \quad \text{on} \quad \Gamma_c \right\}$$

denote the closed subspace and the closed convex subset of $\mathcal{H} = H^1(\Omega^1) \times H^1(\Omega^2)$, respectively. The relations on the boundaries are in terms of traces. On $\mathcal{H}$ we shall define a symmetric bilinear form

$$a(u,v) = \sum_{i=1}^{2} \int_{\Omega^i} \left(\frac{\partial u^i}{\partial x} \frac{\partial v^i}{\partial x} + \frac{\partial u^i}{\partial y} \frac{\partial v^i}{\partial y} \right) d\Omega$$

and a linear form

$$\ell(v) = \sum_{i=1}^{2} \int_{\Omega^i} f^i v^i d\Omega,$$

where $f^i \in L^2(\Omega^i)$, $i = 1,2$, are the restrictions of

$$f(x,y) = \begin{cases} -1 & \text{for} \quad (x,y) \in (0,1) \times [0.75,1), \\ 0 & \text{for} \quad (x,y) \in (0,1) \times [0,0.75) \quad \text{and} \quad (x,y) \in (1,2) \times [0.25,1), \\ -3 & \text{for} \quad (x,y) \in (1,2) \times [0,0.25) \end{cases}$$

for a coercive problem and

$$f(x,y) = \begin{cases} -3 & \text{for} \quad (x,y) \in (0,1) \times [0.75,1), \\ 0 & \text{for} \quad (x,y) \in (0,1) \times [0,0.75) \quad \text{and} \quad (x,y) \in (1,2) \times [0.25,1), \\ -1 & \text{for} \quad (x,y) \in (1,2) \times [0,0.25) \end{cases}$$

for a semicoercive problem. Thus we can define a problem to find

$$\min \quad q(u) = \frac{1}{2} a(u,u) - \ell(u) \quad \text{subject to} \quad u \in \mathcal{K}. \tag{2.1}$$

We shall consider two variants of the Dirichlet data. In the first case, both the membranes are fixed on the outer edges as in Figure 1(a), so that

$$\Gamma^1_u = \{(0,y) \in \mathbb{R}^2 : y \in [0,1]\}, \qquad \Gamma^2_u = \{(2,y) \in \mathbb{R}^2 : y \in [0,1]\}.$$

Since the Dirichlet conditions are prescribed on parts Γ^i_u, $i = 1,2$, of the boundaries of both the membranes with positive measure, the quadratic form a is coercive, which guarantees both existence and uniqueness of the solution [28, 27]. In the second case, only the left membrane is fixed on the outer edge and the right membrane has no prescribed displacement as in Figure 1(b), so that

$$\Gamma^1_u = \{(0,y) \in \mathbb{R}^2 : y \in [0,1]\}, \qquad \Gamma^2_u = \emptyset.$$

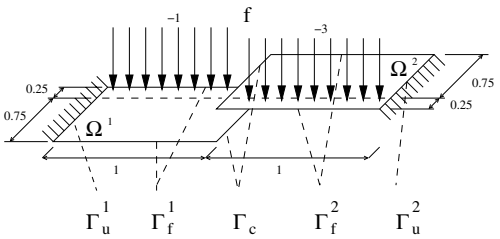

Fig. 1a: Coercive model problem

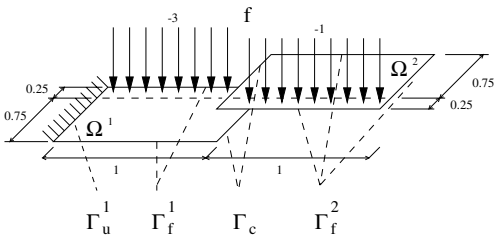

Fig. 1b: Semicoercive model problem

FIG. 1. *Model problems.*

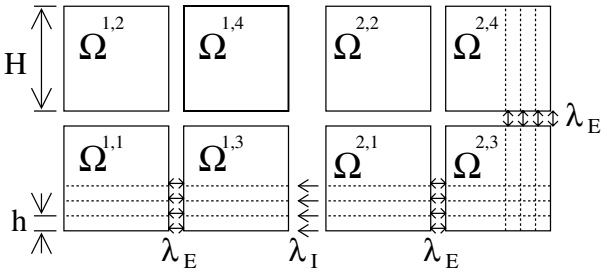

FIG. 2. *Domain decomposition and discretization.*

Even though a is in this case only semidefinite, the form q is still coercive due to the choice of f so that it has again the unique solution [28, 27].

More details about this particular model problem may be found in [12]. The solution of the model problem may be interpreted as the displacement of two membranes under the traction f. The left edge of the right membrane is not allowed to penetrate below the right edge of the left membrane.

3. Domain decomposition and discretization. In our definition of the problem, we have so far used only the natural decomposition of the spatial domain Ω into Ω^1 and Ω^2. However, to enable efficient application of the domain decomposition methods, we can optionally decompose each Ω^i into subdomains $\Omega^{i1}, \ldots, \Omega^{ip}$, $p > 1$, as in Figure 2. The continuity in Ω^1 and Ω^2 of the global solution assembled from the local solutions u^{ij} will be enforced by the "gluing" conditions $u^{ij}(x) = u^{ik}(x)$ that should be satisfied for any x on the interface $\Gamma^{ij,ik}$ of Ω^{ij} and Ω^{ik}. After modifying appropriately the definition of problem (2.1), introducing regular grids in the subdomains Ω^{ij} that match across the interfaces $\Gamma^{ij,kl}$, indexing contiguously the nodes and entries of corresponding vectors in the subdomains, and using the Lagrangian finite element discretization, we get the discretized version of problem (2.1) with auxiliary domain decomposition that reads

$$\min \frac{1}{2} u^\top K u - f^\top u \quad \text{s.t.} \quad B_{\mathcal{I}} u \le 0 \quad \text{and} \quad B_{\mathcal{E}} u = 0. \tag{3.1}$$

In (3.1), K denotes a block diagonal positive semidefinite stiffness matrix, the full rank matrices $B_{\mathcal{I}}$ and $B_{\mathcal{E}}$ describe the discretized nonpenetration and gluing conditions, respectively, and f represents the discrete analogue of the linear term $\ell(u)$. The rows of $B_{\mathcal{E}}$ and $B_{\mathcal{I}}$ are filled with zeros except 1 and -1 in positions that correspond to the nodes with the same coordinates on the artificial or contact boundaries, respectively.

In particular, if b_i denotes a row of $B_{\mathcal{E}}$ or $B_{\mathcal{I}}$, then b_i will not have more than four nonzero entries, and for any displacement vector u, $b_i u$ will denote the difference or jump between the displacements on each side of the boundary. Some more details may be found in [12].

Our next step is to simplify the problem, in particular to replace the general inequality constraints $B_{\mathcal{I}} u \leq 0$ by the nonnegativity constraints using the duality theory. To this end, let us introduce the Lagrangian associated with problem (3.1) by

$$L(u, \lambda_{\mathcal{I}}, \lambda_{\mathcal{E}}) = \frac{1}{2} u^\top K u - f^\top u + \lambda_{\mathcal{I}}^\top B_{\mathcal{I}} u + \lambda_{\mathcal{E}}^\top B_{\mathcal{E}} u, \tag{3.2}$$

where $\lambda_{\mathcal{I}}$ and $\lambda_{\mathcal{E}}$ are the Lagrange multipliers associated with inequalities and equalities, respectively. Introducing the notation

$$\lambda = \begin{bmatrix} \lambda_{\mathcal{I}} \\ \lambda_{\mathcal{E}} \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} B_{\mathcal{I}} \\ B_{\mathcal{E}} \end{bmatrix},$$

we can observe that B is a full rank matrix and write the Lagrangian briefly as

$$L(u, \lambda) = \frac{1}{2} u^\top K u - f^\top u + \lambda^\top B u.$$

It is well known [4] that (3.1) is equivalent to the saddle point problem

$$\text{Find} \quad (\overline{u}, \overline{\lambda}) \quad \text{so that} \quad L(\overline{u}, \overline{\lambda}) = \sup_{\lambda_{\mathcal{I}} \geq 0} \inf_u L(u, \lambda). \tag{3.3}$$

For fixed λ, the Lagrange function $L(\cdot, \lambda)$ is convex in the first variable and the minimizer u of $L(\cdot, \lambda)$ satisfies

$$Ku - f + B^\top \lambda = 0. \tag{3.4}$$

Equation (3.4) has a solution iff

$$f - B^\top \lambda \in \mathrm{Im} K, \tag{3.5}$$

which can be expressed more conveniently by means of a matrix R whose columns span the null space of K as

$$R^\top (f - B^\top \lambda) = 0. \tag{3.6}$$

The matrix R may be formed directly so that each floating subdomain is assigned to a column of R with ones in positions of the nodal variables that belong to the subdomain, and zeros elsewhere. It may be checked that $R^\top B^\top$ is a full rank matrix. The matrix R may also be extracted from K [23]. Now assume that λ satisfies (3.5) and denote by $K^\dagger$ any matrix that satisfies

$$K K^\dagger K = K. \tag{3.7}$$

Let us note that a generalized inverse $K^\dagger$ that satisfies (3.7) may be evaluated at a cost comparable with the Cholesky decomposition of regularized K [23]. It may be verified directly that if u solves (3.4), then there is a vector α such that

$$u = K^\dagger (f - B^\top \lambda) + R\alpha. \tag{3.8}$$

After substituting expression (3.8) into problem (3.3) and changing signs, we shall get the minimization problem to find

$$\min \Theta(\lambda) \quad \text{s.t.} \quad \lambda_{\mathcal{I}} \geq 0 \quad \text{and} \quad R^\top (f - B^\top \lambda) = 0, \tag{3.9}$$

where

$$\Theta(\lambda) = \frac{1}{2} \lambda^\top B K^\dagger B^\top \lambda - \lambda^\top B K^\dagger f. \tag{3.10}$$

Once the solution $\overline{\lambda}$ of (3.9) is known, the vector $\overline{u}$ that solves (3.1) can be evaluated by (3.8) and the formula [12]

$$\alpha = -(R^\top \widetilde{B}^\top \widetilde{B} R)^{-1} R^\top \widetilde{B}^\top \widetilde{B} K^\dagger (f - B^\top \overline{\lambda}), \tag{3.11}$$

where $\widetilde{B} = [\widetilde{B}_{\mathcal{I}}^\top, B_{\mathcal{E}}^\top]^\top$, and the matrix $\widetilde{B}_{\mathcal{I}}$ is formed by the rows b_i of $B_{\mathcal{I}}$ that correspond to the positive components of the solution $\overline{\lambda}$ characterized by $\overline{\lambda}_i > 0$.

4. Natural coarse grid. Even though the problem (3.9) is much more suitable for computations than (3.1) and was used to solve the discretized variational inequalities efficiently [11], further improvement may be achieved by adapting some simple observations and the results of Farhat, Mandel, and Roux [25]. Let us denote

$$F = B K^\dagger B^\top, \qquad \widetilde{d} = B K^\dagger f,$$
$$\widetilde{G} = R^\top B^\top, \qquad \widetilde{e} = R^\top f,$$

and let T denote a regular matrix that defines orthonormalization of the rows of $\widetilde{G}$ so that the matrix

$$G = T \widetilde{G}$$

has orthonormal rows. After denoting

$$e = T \widetilde{e},$$

problem (3.9) reads

$$\min \quad \frac{1}{2} \lambda^\top F \lambda - \lambda^\top \widetilde{d} \quad \text{s.t.} \quad \lambda_{\mathcal{I}} \geq 0 \quad \text{and} \quad G\lambda = e. \tag{4.1}$$

Next we shall transform the problem of minimization on the subset of the affine space to that on the subset of the vector space by looking for the solution of (4.1) in the form $\lambda = \mu + \widetilde{\lambda}$, where $G\widetilde{\lambda} = e$. The following lemma shows that we can even find $\widetilde{\lambda}$ such that $\widetilde{\lambda}_{\mathcal{I}} = 0$.

LEMMA 4.1. *Let B be such that the negative entries of $B_{\mathcal{I}}$ are in the columns that correspond to the nodes in the floating subdomain Ω^2. Then there is $\widetilde{\lambda}_{\mathcal{I}} \geq 0$ such that $G\widetilde{\lambda} = \widetilde{e}$.*

Proof. See [15] (coercive problem) or [16] (semicoercive problem). ∎

To carry out the transformation, denote $\lambda = \mu + \widetilde{\lambda}$ so that

$$\frac{1}{2} \lambda^\top F \lambda - \lambda^\top \widetilde{d} = \frac{1}{2} \mu^\top F \mu - \mu^\top (\widetilde{d} - F\widetilde{\lambda}) + \frac{1}{2} \widetilde{\lambda}^\top F \widetilde{\lambda} - \widetilde{\lambda}^\top \widetilde{d}$$

and the problem (4.1) is, after returning to the old notation, equivalent to

$$\min \quad \frac{1}{2}\lambda^\top F\lambda - \lambda^\top d \quad \text{s.t.} \quad G\lambda = 0 \quad \text{and} \quad \lambda_{\mathcal{I}} \geq -\widetilde{\lambda}_{\mathcal{I}}, \tag{4.2}$$

where $d = \widetilde{d} - F\widetilde{\lambda}$ and $\widetilde{\lambda}_{\mathcal{I}} \geq 0$.

Our final step is based on observation that the problem (4.2) is equivalent to

$$\min \quad \frac{1}{2}\lambda^\top (PFP + \overline{\rho}Q)\lambda - \lambda^\top Pd \quad \text{s.t.} \quad G\lambda = 0 \quad \text{and} \quad \lambda_{\mathcal{I}} \geq -\widetilde{\lambda}_{\mathcal{I}}, \tag{4.3}$$

where $\overline{\rho}$ is arbitrary positive constant and

$$Q = G^\top G \qquad \text{and} \qquad P = I - Q$$

denote the orthogonal projectors on the image space of $G^\top$ and on the kernel of G, respectively. The regularization term is introduced in order to simplify the reference to the results of quadratic programming that assume regularity of the Hessian matrix of the quadratic form. The problem (4.3) turns out to be a suitable starting point for development of an efficient algorithm for variational inequalities due to the classical estimates of the extreme eigenvalues. To formulate them, we shall denote by $\alpha_{\min}(A)$ and $\alpha_{\max}(A)$ the smallest and the largest eigenvalue of a given symmetric matrix A, respectively.

THEOREM 4.2. *There are constants $C_1 > 0$ and $C_2 > 0$ independent of the discretization parameter h and the decomposition parameter H such that*

$$\alpha_{\min}(PFP|\mathrm{Im}P) \ \geq \ C_1 \ \ \textit{and} \ \ \alpha_{\max}(PFP|\mathrm{Im}P) \leq ||PFP|| \ \leq \ C_2\frac{H}{h}. \tag{4.4}$$

Proof. See Theorem 3.2 of Farhat, Mandel, and Roux [25]. □

Note: The statement of Theorem 3.2 in [25] gives only an upper bound on the spectral condition number $\kappa(PFP|\mathrm{Im}P)$. However, the reasoning that precedes and substantiates their estimate proves both bounds of (4.4).

5. Optimal solvers to bound and equality constrained problems. We shall now briefly review our, in a sense, optimal algorithms for the solution of the bound and equality constrained problem (4.3). They combine our semimonotonic augmented Lagrangian method [8] which generates approximations for the Lagrange multipliers for the equality constraints in the outer loop with the working set algorithm for bound constrained auxiliary problems in the inner loop [21]. If a new Lagrange multiplier vector μ is used for the equality constraints, the augmented Lagrangian for problem (4.3) can be written as

$$L(\lambda, \mu, \rho) \ = \ \frac{1}{2}\lambda^\top (PFP + \overline{\rho}Q)\lambda \ - \ \lambda^\top Pd \ + \ \mu^\top G\lambda + \rho\lambda^\top Q\lambda.$$

The gradient of $L(\lambda, \mu, \rho)$ is given by

$$g(\lambda, \mu, \rho) \ = \ (PFP + \overline{\rho}Q)\lambda - Pd + G^T(\mu + \rho G\lambda).$$

Let $\mathcal{I}$ denote the set of the indices of the bound constrained entries of $\lambda \geq -\widetilde{\lambda}$. The *projected gradient* $g^P = g^P(\lambda, \mu, \rho)$ of L at λ is given componentwise by

$$g_i^P \ = \ \begin{cases} g_i & \text{for} \quad \lambda_i > -\widetilde{\lambda}_i \quad \text{or} \quad i \notin \mathcal{I}, \\ g_i^- & \text{for} \quad \lambda_i = -\widetilde{\lambda}_i \quad \text{and} \quad i \in \mathcal{I}, \end{cases}$$

where $g_i^- = \min\{g_i, 0\}$. Our algorithm is a variant of that proposed by Conn, Gould, and Toint [6] for identifying stationary points of more general problems. Its modification by Dostál, Friedlander, and Santos [10] was used by Dostál and Horák to develop a scalable FETI based algorithm, as shown experimentally in [14]. The key to proving optimality results is to combine the adaptive precision control of auxiliary problems in Step 1 with the new update rule for the penalty parameter ρ in Step 4. All the necessary parameters are listed in Step 0, and typical values of these parameters for our model problem are given in brackets.

ALGORITHM 5.1. Semimonotonic augmented Lagrangian method for bound and equality constrained problems (SMALBE).

Step 0. {*Initialization of parameters.*}
Given $\eta > 0$ [$\eta = \|Pd\|$], $\beta > 1$ [$\beta = 10$], $M > 0$ [$M = 1$],
$\rho_0 > 0$ [$\rho_0 = 100$], and μ^0 [$\mu^0 = 0$], set $k = 0$.

Step 1. {*Inner iteration with adaptive precision control.*}
Find λ^k such that $\lambda^k_{\mathcal{I}} \geq -\widetilde{\lambda}_{\mathcal{I}}$
$||g^P(\lambda^k, \mu^k, \rho_k)|| \leq \min\{M\|G\lambda^k\|, \eta\}$.

Step 2. {*Stopping criterion.*}
If $||g^P(\lambda^k, \mu^k, \rho_k)||$ and $||G\lambda^k||$ are sufficiently small,
then λ^k is the solution.
end if.

Step 3. {*Update of the Lagrange multipliers.*}
$\mu^{k+1} = \mu^k + \rho_k G\lambda^k$

Step 4. {*Update the penalty parameter.*}
If $k > 0$ and $L(\lambda^k, \mu^k, \rho^k) < L(\lambda^{k-1}, \mu^{k-1}, \rho_{k-1}) + \rho_k\|G\lambda^k\|^2/2$
then $\rho_{k+1} = \beta\rho_k$
else $\rho_{k+1} = \rho_k$
end if.

Step 5. Increase k and return to Step 1.

Step 1 may be implemented by any algorithm for minimization of the augmented Lagrangian L with respect to λ subject to $\lambda_{\mathcal{I}} \geq -\widetilde{\lambda_{\mathcal{I}}}$, which guarantees convergence of the projected gradient to zero. More about the properties and implementation of SMALBE algorithm may be found in [8].

The unique feature of the SMALBE algorithm is its capability to find an approximate solution to problem (4.3) in a number of steps which is uniformly bounded in terms of the bounds on the spectrum of $PFP + \overline{\rho}Q$ [8]. To get a bound on the number of matrix multiplication, it is necessary to have an algorithm which can solve the problem

$$\text{minimize } L(\lambda, \mu, \rho) \quad \text{s.t.} \quad \lambda_{\mathcal{I}} \geq -\widetilde{\lambda}_{\mathcal{I}} \tag{5.1}$$

with the rate of convergence in terms of the bounds on the spectrum of the Hessian matrix of L.

To describe such an algorithm, let us recall that the unique solution $\overline{\lambda} = \overline{\lambda}(\mu, \rho)$ of (5.1) satisfies the Karush–Kuhn–Tucker (KKT) conditions

$$g^P(\overline{\lambda}, \mu, \rho) = 0. \tag{5.2}$$

Let $\mathcal{A}(\lambda)$ and $\mathcal{F}(\lambda)$ denote the *active set* and *free set* of indices of λ, respectively, i.e.,

$$\mathcal{A}(\lambda) = \{i \in \mathcal{I} : \lambda_i = -\widetilde{\lambda}_i\} \quad \text{and} \quad \mathcal{F}(\lambda) = \{i : \lambda_i > -\widetilde{\lambda}_i \ \text{ or } \ i \notin \mathcal{I}\}.$$

To enable an alternative reference to the KKT conditions [4], let us define the *free gradient* $\varphi(\lambda)$ and the *chopped gradient* $\beta(\lambda)$ by

$$\varphi_i(\lambda) = \begin{cases} g_i(\lambda) & \text{for} \quad i \in \mathcal{F}(\lambda), \\ 0 & \text{for} \quad i \in \mathcal{A}(\lambda) \end{cases} \quad \text{and} \quad \beta_i(\lambda) = \begin{cases} 0 & \text{for} \quad i \in \mathcal{F}(\lambda), \\ g_i^-(\lambda) & \text{for} \quad i \in \mathcal{A}(\lambda) \end{cases}$$

so that the KKT conditions are satisfied iff the *projected gradient* $g^P(\lambda) = \varphi(\lambda) + \beta(\lambda)$ is equal to zero. We call λ *feasible* if $\lambda_i \geq -\widetilde{\lambda}_i$ for $i \in \mathcal{I}$. The projector P to the set of feasible vectors is defined for any λ by

$$P(\lambda)_i = \max\{\lambda_i, -\widetilde{\lambda}_i\} \quad \text{for} \quad i \in \mathcal{I}, \qquad P(\lambda)_i = \lambda_i \quad \text{for} \quad i \notin \mathcal{I}.$$

Let A denote the Hessian of L with respect to λ. The *expansion step* is defined by

$$\lambda^{k+1} = P\left(\lambda^k - \overline{\alpha}\varphi(\lambda^k)\right) \tag{5.3}$$

with the steplength $\overline{\alpha} \in (0, \|A\|^{-1}]$. This step may expand the current active set. To describe it without P, let $\widetilde{\varphi}(\lambda)$ be the *reduced free gradient* for any feasible λ, with entries

$$\widetilde{\varphi}_i = \widetilde{\varphi}_i(\lambda) = \min\{\lambda_i/\overline{\alpha}, \varphi_i\} \quad \text{for} \quad i \in \mathcal{I}, \qquad \widetilde{\varphi}_i = \varphi_i \quad \text{for} \quad i \in \mathcal{E}$$

such that

$$P\left(\lambda - \overline{\alpha}\varphi(\lambda)\right) = \lambda - \overline{\alpha}\widetilde{\varphi}(\lambda). \tag{5.4}$$

If the inequality

$$||\beta(\lambda^k)||^2 \leq \Gamma^2 \widetilde{\varphi}(\lambda^k)^\top \varphi(\lambda^k) \tag{5.5}$$

holds, then we call the iterate λ^k *strictly proportional*. The test (5.5) is used to decide which component of the projected gradient $g^P(\lambda^k)$ will be reduced in the next step.

The *proportioning step* is defined by

$$\lambda^{k+1} = \lambda^k - \alpha_{cg}\beta(\lambda^k).$$

The steplength α_{cg} is chosen to minimize $L(\lambda^k - \alpha\beta(\lambda^k), \mu^k, \rho_k)$ with respect to α, i.e.,

$$\alpha_{cg} = \frac{\beta(\lambda^k)^\top g(\lambda^k)}{\beta(\lambda^k)^\top A \beta(\lambda^k)}.$$

The purpose of the proportioning step is to remove indices from the active set.

The *conjugate gradient step* is defined by

$$\lambda^{k+1} = \lambda^k - \alpha_{cg} p^k, \tag{5.6}$$

where p^k is the conjugate gradient direction [2] which is constructed recurrently. The recurrence starts (or restarts) with $p^s = \varphi(\lambda^s)$ whenever λ^s is generated by the expansion step or the proportioning step. If p^k is known, then p^{k+1} is given by the formulae [2]

$$p^{k+1} = \varphi(\lambda^k) - \gamma p^k, \qquad \gamma = \frac{\varphi(\lambda^k)^\top A p^k}{(p^k)^\top A p^k}. \tag{5.7}$$

The conjugate gradient steps are used to carry out the minimization in the face $\mathcal{W}_{\mathcal{J}} = \{\lambda : \lambda_i = 0 \text{ for } i \in \mathcal{J}\}$ given by $\mathcal{J} = \mathcal{A}(\lambda^s)$ efficiently. The algorithm that we use may now be described as follows.

ALGORITHM 5.2. Modified proportioning with reduced gradient projections (MPRGP).

Let λ^0 be an n-vector such that $\lambda_i \geq -\widetilde{\lambda}_i$ for $i \in \mathcal{I}$, $\overline{\alpha} \in (0, \|A\|^{-1}]$, and $\Gamma > 0$ be given. For $k \geq 0$ and λ^k known, choose λ^{k+1} by the following rules:

Step 1. If $g^P(\lambda^k) = 0$, set $\lambda^{k+1} = \lambda^k$.

Step 2. If λ^k is strictly proportional and $g^P(\lambda^k) \neq 0$, try to generate λ^{k+1} by the conjugate gradient step. If $\lambda_i^{k+1} \geq 0$ for $i \in \mathcal{I}$, then accept it, else generate λ^{k+1} by the expansion step.

Step 3. If λ^k is not strictly proportional, define λ^{k+1} by proportioning.

The MPRGP algorithm has an R-linear rate of convergence in terms of the spectral condition number of the Hessian A of L [21]. More about the properties and implementation of the SMALBE algorithm may be found in [21] and [9].

6. Optimality. To show that Algorithm 5.1 with the inner loop implemented by Algorithm 5.2 is optimal for the solution of problem (or a class of problems) (4.3), we shall introduce new notation that complies with that used in [9].

We shall use

$$\mathcal{T} = \{(H, h) \in \mathbb{R}^2 : H \leq 1,\ 2h \leq H \ \text{ and } \ H/h \in \mathbb{N}\}$$

as the set of indices. Given a constant $C \geq 2$, we shall define a subset $\mathcal{T}_C$ of $\mathcal{T}$ by

$$\mathcal{T}_C = \{(H, h) \in \mathbb{R}^2 : H \leq 1,\ 2h \leq H,\ H/h \in \mathbb{N} \ \text{ and } \ H/h \leq C\}.$$

For any $t \in \mathcal{T}$, we shall define

$$\begin{aligned} A_t &= PFP + \overline{\rho}Q, \quad & b_t &= Pd, \\ C_t &= G, & \ell_{t,\mathcal{I}} &= -\widetilde{\lambda}_{\mathcal{I}}, \ \text{ and } \ \ell_{t,\mathcal{E}} = -\infty \end{aligned}$$

by the vectors and matrices generated with the discretization and decomposition parameters H and h, respectively, so that the problem (4.3) is equivalent to the problem

$$\text{minimize } \ \Theta_t(\lambda_t) \ \text{ s.t. } \ C_t\lambda_t = 0 \ \text{ and } \ \lambda_t \geq \ell_t, \tag{6.1}$$

where $\Theta_t(\lambda) = \frac{1}{2}\lambda^\top A_t\lambda - b_t^\top\lambda$. Using these definitions, Lemma 4.1, and $GG^\top = I$, we obtain

$$\|C_t\| \leq 1 \ \text{ and } \ \|\ell_t^+\| = 0, \tag{6.2}$$

where for any vector v with the entries v_i, v^+ denotes the vector with the entries $v_i^+ = \max\{v_i, 0\}$. Moreover, it follows by Theorem 4.2 that for any $C \geq 2$ there are constants $a^C_{\max} > a^C_{\min} > 0$ such that

$$a^C_{\min} \leq \alpha_{\min}(A_t) \leq \alpha_{\max}(A_t) \leq a^C_{\max} \tag{6.3}$$

for any $t \in \mathcal{T}_C$. Moreover, there are positive constants C_1 and C_2 such that $a^C_{\min} \geq C_1$ and $a^C_{\max} \leq C_2 C$. In particular, it follows that the assumptions of Theorem 5 (i.e., the inequalities (6.2) and (6.3)) of [9] are satisfied for any set of indices $\mathcal{T}_C$, $C \geq 2$, and we have the following result.

THEOREM 6.1. *Let $C \geq 2$ denote a given constant; let $\{\lambda_t^k\}$, $\{\mu_t^k\}$, and $\{\rho_{t,k}\}$ be generated by Algorithm* 5.1 *(SMALBE) for* (6.1) *with $\|b_t\| \geq \eta_t > 0$, $\beta > 1$, $M > 0$, $\rho_{t,0} = \rho_0 > 0$, and $\mu_t^0 = 0$. Let $s \geq 0$ denote the smallest integer such that $\beta^s \rho_0 \geq M^2/a_{\min}$ and assume that Step* 1 *of Algorithm* 5.1 *is implemented by means of Algorithm* 5.2 *(MPRGP) with parameters $\Gamma > 0$ and $\overline{\alpha} \in (0, (a_{\max} + \beta^s \rho_0)^{-1}]$, so that it generates the iterates $\lambda_t^{k,0}, \lambda_t^{k,1}, \ldots, \lambda_t^{k,l} = \lambda_t^k$ for the solution of* (6.1) *starting from $\lambda_t^{k,0} = \lambda_t^{k-1}$ with $\lambda_t^{-1} = 0$, where $l = l_{t,k}$ is the first index satisfying*

$$\|g^P(\lambda_t^{k,l}, \mu_t^k, \rho_{t,k})\| \leq M \|C_t \lambda_t^{k,l}\| \tag{6.4}$$

or

$$\|g^P(\lambda_t^{k,l}, \mu_t^k, \rho_{t,k})\| \leq \epsilon \|b_t\| \min\{1, M^{-1}\}. \tag{6.5}$$

Then for any $t \in \mathcal{T}_C$ and problem (6.1)*, Algorithm* 5.1 *generates an approximate solution $\lambda_t^{k_t}$ which satisfies*

$$M^{-1} \|g^P(\lambda_t^{k_t}, \mu_t^{k_t}, \rho_{t,k_t})\| \leq \|C_t \lambda_t^{k_t}\| \leq \epsilon \|b_t\| \tag{6.6}$$

at $O(1)$ matrix-vector multiplications by the Hessian of the augmented Lagrangian L_t for (6.1) *and $\rho_{t,k} \leq \beta^s \rho_0$.*

7. Numerical experiments. In this section we report some results of numerical solution of the semicoercive model problem of section 2 in order to illustrate the performance of the algorithm, in particular its numerical and parallel scalability. To this end, we have implemented Algorithm 5.1 with the solution of auxiliary bound constraints by Algorithm 5.2 in C exploiting PETSc [3] to solve problem (4.3) with varying decomposition and discretization parameters.

The experiments were run on the Lomond 18-processor Sun HPC 6500 Ultra SPARC-II based SMP system with 400 MHz, 18 GB of shared memory, 90 GB disc space, nominal peak performance 14.4 GFlops, 16 kB level 1 and 8 MB level 2 cache in EPCC Edinburgh, and on the Turing Cray T3E 1200, 788 applications processors, each 1.2 GFlops with 256 MB, 209 GB memory, 28 command processors, 2TB disk space, high-speed network with low latency in the University of Manchester. All the computations were carried out with parameters

$$M = 1, \quad \rho_0 = 10, \quad \Gamma = 1, \quad \lambda^0 = \max\left\{-\widetilde{\lambda}, \frac{1}{2} Bf\right\}, \quad \epsilon = 10^{-4}.$$

The solutions of our benchmarks are in Figure 3. The results of computations are summarized in Tables 1–3.

Table 1 illustrates numerical scalability of Algorithm 5.1. In particular, for varying decompositions and discretization parameters, the upper row of each field of the table gives the corresponding primal dimension/dual dimension/times in seconds, while the number in the lower row gives a number of the conjugate gradient iterations that were necessary for the solution of the problem to the given precision. We can see that the number of the conjugate gradient iterations for a given ratio H/h (in rows) varies very moderately.

Table 2 indicates that the algorithm presented enjoys high parallel scalability. The results for the largest problems are in Table 3.

8. Comments and conclusion. We have presented scalability results related to the application of the augmented Lagrangians with the FETI based domain decomposition method using the natural coarse grid to the solution of variational inequalities by recently developed algorithms for the solution of special quadratic programming problems. In particular, we have shown that the solution of the discretized elliptic variational inequality to a prescribed precision may be found in a number of matrix vector multiplications bounded independently of the discretization parameter provided the

ratio of the decomposition and the discretization parameters is kept bounded. Numerical experiments with a model variational inequality are in agreement with the theory and indicate that the algorithm may be efficient. The results remain valid also for the solution of frictionless 2D and 3D contact problems of elasticity and may be adapted to the solution of problems with Coulomb friction as indicated in [17]. The solution of auxiliary linear problems in the inner loop may be improved by standard preconditioners [29, 35, 38] and may be adapted to the mortar discretization [39]; however, since the preconditioning transforms the bound constraints to more general inequality constraints, it is nontrivial to get improved convergence results in this way. We shall discuss these topics elsewhere.

ERROR CONTROL FOR A CLASS OF RUNGE–KUTTA DISCONTINUOUS GALERKIN METHODS FOR NONLINEAR CONSERVATION LAWS*

ANDREAS DEDNER†, CHARALAMBOS MAKRIDAKIS‡, AND MARIO OHLBERGER†

Abstract. We propose an a posteriori error estimate for the Runge–Kutta discontinuous Galerkin method (RK-DG) of arbitrary order in arbitrary space dimensions. For stabilization of the scheme a general framework of projections is introduced. Finally it is demonstrated numerically how the a posteriori error estimate is used to design both an efficient grid adaption and gradient limiting strategy. Numerical experiments show the stability of the scheme and the gain in efficiency in comparison with computations on uniform grids.

1. Introduction.

In this paper we study a generalized version of the Runge–Kutta discontinuous Galerkin (RK-DG) approximation of Cockburn and Shu (see [10, 7, 11]) for nonlinear scalar conservation laws in several space dimensions. As a prototype conservation law, consider the Cauchy initial value problem

$$\partial_t u + \nabla \cdot f(u) = 0 \qquad \text{in } \mathbb{R}^d \times \mathbb{R}^+ , \tag{1.1}$$

$$u(x,0) = u_0(x) \quad \text{in } \mathbb{R}^d. \tag{1.2}$$

Here $u : \mathbb{R}^d \times \mathbb{R}^+ \to \mathbb{R}$ denotes the dependent solution variable, $f \in C^1(\mathbb{R})$ denotes the flux function, and $u_0 \in \mathrm{BV}(\mathbb{R}^\mathrm{d}) \cap \mathrm{L}^\infty(\mathbb{R}^\mathrm{d})$ the initial data with $u_0 \in [A, B]$ a.e. It is well known (see, for example, [15, 12]) that (1.1)–(1.2) admits a unique entropy weak solution in the class of functions of bounded variation (BV). For later use let us briefly recall that an entropy weak solution is a weak solution of (1.1)–(1.2) which satisfies for all entropy pairs (S, F_S) and all test functions $\phi \in C_0^1(\mathbb{R}^d \times \mathbb{R}^+, \mathbb{R}^+)$:

$$-\int_{\mathbb{R}^d}\int_{\mathbb{R}^+} \left(S(u)\partial_t\phi + F_S(u)\cdot\nabla\phi\right)\, dt\, dx - \int_{\mathbb{R}^d} S(u_0)\phi(x,0)\, dx \le 0\,. \tag{1.3}$$

Recall that (S, F_S) is called an entropy-entropy flux pair or, more simply, an entropy pair for (1.1), iff S is convex and $F_S' = S' f'$.

Numerical methods for nonlinear hyperbolic conservation laws are usually rather complicated since they need to approximate a partial differential equation with nonstandard stability behavior. It turns out that in many successful computational methods the theoretical backup is very limited. This is partly because when constructing high-order methods, stabilization terms have to be added so that in the limit the

solution satisfying (1.3) is computed. These mechanisms include shock capturing terms or limiters that result in complicated and highly nonlinear schemes; see [8] for a comprehensive review of high-order finite difference, finite volume, and finite element methods for hyperbolic conservation laws. The RK-DG approximation of Cockburn and Shu [11] is a very successful method that combines many desirable properties. It is based on totally discontinuous finite element spaces for the space discretization, while the time discretization is based on appropriate Runge–Kutta schemes. The available theory for RK-DG methods for nonlinear problems is limited to certain stability and TVD (total variation diminishing) properties proved in [9, 11] and to error estimates for one dimensional smooth solutions (see [35]). The problem of showing convergence towards the unique entropy solution for the high-order version of these methods seems rather difficult.

In this paper we consider a generalized version of RK-DG methods designed for use with dynamic mesh modification. We are interested in the following question: Is it possible to establish a rigorous error control for RK-DG methods in mesh adaptive computations? An answer to this question will be based on certain a posteriori estimates and does not necessarily depend on available a priori convergence results for the method. As a consequence, it provides a (nonstandard) way of theoretical backup for a method with no available convergence theory. In this context we also refer to [16], where this was done for MUSCL finite difference schemes.

First, we prove a posteriori error estimates for generalized DG methods. We then use these estimates to provide an *hp*-adaptive algorithm that is used together with a rigorous error control. The computational performance of the resulting methods and algorithms is tested in one dimensional examples.

The literature on a posteriori error control and adaptive solution algorithms for (RK-DG) approximations is scant. We refer, for instance, to Hartmann and Houston [18] and Larson and Barth [27], where duality techniques were used for designing adaptive schemes. We also refer to Süli and Houston and coworkers [20, 19, 33] for *hp*-adaptive DG methods for hyperbolic problems. Another approach towards error control for DG methods was introduced by Adjerid et al. [1], where asymptotically correct a posteriori estimates of spatial discretization errors were derived in one dimension for smooth solutions.

2. Formulation of the generalized DG methods and main results. Let $\mathcal{T}$ denote an element decomposition of $\mathbb{R}^d$ with control volumes $T_j \in \mathcal{T}$, $j \in J$ such that $\cup_{T\in\mathcal{T}}\overline{T} = \mathbb{R}^d$. Let h_T denote a length scale associated with each control volume T, e.g., $h_T \equiv \operatorname{diam}(T)$. For two distinct control volumes T_i and T_j in $\mathcal{T}$, the intersection is either an oriented edge ($d = 2$) or face ($d = 3$) S_{ij} with oriented normal ν_{ij}, or else a set of measure at most $d-2$. The set $N(j)$ denotes the index set of neighboring control volumes to T_j, and the index set of the oriented edges or faces of the grid is given by $\mathcal{E} = \{(j,l)|\, T_j \in \mathcal{T},\, l \in N(j),\, j > l\}$. The set of edges or faces of the element decomposition $\mathcal{T}$ will be denoted by Γ. On $\mathcal{T}$ we define the space of (possible) discontinuous piecewise polynomials of degree p by $V_h^p := \{v_h \in BV(\mathbb{R}^d)|\, v_T := v_h|_T \in \mathbb{P}_p \text{ for all } T \in \mathcal{T}\}$. Let us denote by $\Pi_{V_h^p}$ the L^2-projection into V_h^p. Furthermore, following standard notation, $[v_h]|_{S_{ij}} := (v_j|_{S_{ij}} - v_i|_{S_{ij}})\nu_{ij}$ is the jump of v_h on the edge S_{ij}, and $\{v_h\}_{S_{ij}} := 1/2(v_j|_{S_{ij}} + v_i|_{S_{ij}})$ denotes the mean of v_h at an interface.

DEFINITION 2.1 (space-discrete DG approximation). *$u_h \in C^1(0,T;V_h^p)$ is called a semidiscrete DG approximation of* (1.1)–(1.2) *iff*

$$u_h(0) = \Pi_{V_h^p}(u_0), \tag{2.1}$$

$$\frac{d}{dt}(u_h(t), v_h) - (f(u_h(t)), \nabla v_h) + (f_h(u_h(t)), [v_h])_\Gamma = 0 \quad \text{for all } v_h \in V_h^p. \tag{2.2}$$

Here $(\cdot,\cdot)$ denotes the L^2 inner product, $(\cdot,\cdot)_\Gamma$ denotes the L^2 inner product on the set of interfaces in Γ, and f_h denotes a given numerical flux function that is uniquely defined on the interfaces of the element decomposition (see Assumption 2.2).

Note that due to the fact that both u_h and the test space V_h^p are discontinuous, the global definition of the scheme (2.2) is equivalent to the following local one:

$$\frac{d}{dt}(u_j(t), v_j)_{T_j} - (f(u_j(t)), \nabla v_j)_{T_j} + \sum_{l \in N(j)} (f_{jl}(u_j(t), u_l(t)), v_j)_{S_{jl}} = 0 \tag{2.3}$$

$$\text{for all } v_j \in \mathbb{P}_p, T_j \in \mathcal{T}.$$

Here $(\cdot,\cdot)_{T_j}$, $(\cdot,\cdot)_{S_{jl}}$ denote the local inner product on T_j, S_{jl}, respectively, and $f_{jl}(u_j(t), u_l(t))$ is the restriction of $f_h(u_h)$ to S_{jl}. Note that the numerical fluxes f_{jl} are usually defined via a standard finite difference "upwind-type" one dimensional flux, and it is the only source of "artificial viscosity" in the scheme (2.2). We make the following standard assumptions on the numerical flux function.

ASSUMPTION 2.2 (numerical flux function). *The numerical fluxes are supposed to be functions $f_{jl} \in C^1(\mathbb{R}^2, \mathbb{R})$ which satisfy for all $u, v, u', v' \in [A, B]$ the following conditions (respectively, monotony, conservation, regularity, and consistency):*

$$\partial_u f_{jl}(u,v) \geq 0, \qquad \partial_v f_{jl}(u,v) \leq 0, \qquad f_{jl}(u,v) = -f_{lj}(v,u), \tag{2.4}$$

$$f_{jl}(u,u) = n_{jl}|S_{jl}|\mathbf{f}(u), \qquad |f_{jl}(u,v) - f_{jl}(u',v')| \leq LS_{jl}|(|u-u'| + |v-v'|). \tag{2.5}$$

In the literature of DG methods the stabilization due to the "upwinding" of the discrete fluxes is usually accompanied by extra artificial "shock capturing" terms as in [21, 22, 5] or limiting projections as in [11]. (Error estimates for the shock capturing DG method were obtained in [5].) The RK-DG methods introduced by Cockburn and Shu are based on a combination of limiting projections and Runge–Kutta discretization of the ODE (2.2). Therefore, in the next step we are going to introduce limiting projections in the discretization that will be chosen in section 5.

2.1. Generalized semidiscrete DG approximation. We introduce a hybrid scheme that incorporates all the characteristics of a RK-DG scheme used with mesh modification with time, but assumes that the ODE in time is solved exactly in each time step. To this end we introduce a partition of the time interval $(0, T_{\max})$, $\{0 = t^0, \ldots, t^N = T_{\max}\}$, and we define the time step $\Delta t^n := t^{n+1} - t^n$. With each time interval $(t^n, t^{n+1}]$ we associate a (possibly different) finite element space $V_{h,n}^p$ on a grid $\mathcal{T}_n$ defined as

$$V_{h,n}^p := \{v_h \in BV(\mathbb{R}^d) |\, v_h|_T \in \mathbb{P}_p \text{ for all } T \in \mathcal{T}_n\}. \tag{2.6}$$

The associated index set of the grid $\mathcal{T}_n$ is denoted by J^n. In what follows we might often drop the index n in objects related to the finite element space.

To define a local projection operator we proceed as follows: We define $\overline{v_h}$ through $\overline{v_j} := \Pi_{V_h^0}(v)|_{T_j}$ for any $v \in L^2(\Omega)$; i.e., $\overline{v_h}$ is the elementwise average of v. Furthermore, with each n we associate projections $\Lambda_h^{n,t}$ with the following properties.

ASSUMPTION 2.3 (projection operator). *The projection $\Lambda_h^{n,t}$ is supposed to be a continuous function with respect to t on the interval $[t^n, t^{n+1}]$. If $t \in (t^n, t^{n+1}]$, the operators act $\Lambda_h^{n,t} : V_{h,n}^p \to V_{h,n}^p$ and satisfy*

$$\overline{\Lambda_h^{n,t}(v_h(\cdot,t))} = \overline{v_h(t)}, \quad t \in (t^n, t^{n+1}]\,. \tag{2.7}$$

In addition, $\Lambda_h^{n,t^n} : V_{h,n-1}^p \to V_{h,n}^p$ is a projection to the new mesh, with the property

$$\overline{\Lambda_h^{n,t^n}(v_h(\cdot,t^n))} = \overline{v_h(t^n)}\,. \tag{2.8}$$

In the last equation the elementwise average is taken in the new mesh, i.e., corresponds to the projection $\Pi_{V_{h,n}^0}$. At t^n the two operators Λ_h^{n,t^n} and Λ_h^{n-1,t^n} satisfy

$$\|\Lambda_h^{n,t^n}(u_h) - \overline{u_h}\|_\infty \le \|\Lambda_h^{n-1,t^n}(u_h) - \overline{u_h}\|_\infty. \tag{2.9}$$

Properties (2.7), (2.8) lead to a conservation of mass, whereas assumption (2.9) guarantees that the gradients in the discrete solution are not increased between time steps. Note that $\Lambda_h^{n,t}$ accounts for both limiting projections and projections to the new spaces. We define the restriction of $\Lambda_j^{n,t}$ through $\Lambda_j^{n,t} \equiv \Lambda_h^{n,t}$ in $T_j \times [t^n, t^{n+1}]$, $j \in J^n$.

DEFINITION 2.4 (generalized semidiscrete DG approximation). *Suppose that $\Lambda_h^{n,t}$ with the above properties is given, and assume that the fluxes f_{ij} are monotone. u_h is called a generalized semidiscrete DG approximation of (1.1)–(1.2) if $u_h^{-1} := \Pi_{V_{h,0}^p}(u_0)$ and for $n = 0, \dots, N-1$, $u_h^n|_{[t^n,t^{n+1}]} \in C^1(t^n, t^{n+1}; V_{h,n}^p)$ is defined through*

$$u_h^n(t^n) := \Lambda_h^{n,t^n}(u_h^{n-1}(t^n))\,, \tag{2.10}$$

$$\begin{aligned}\frac{d}{dt}(u_j^n(t), v_j)_{T_j} \;=\; & -\sum_{l\in N(j)} (f_{jl}(\Lambda_j^{n,t}(u_h^n(t)), \Lambda_l^{n,t}(u_h^n(t))), v_j)_{S_{jl}} \\ & + (f(\Lambda_j^{n,t}(u_h^n(t))), \nabla v_j)_{T_j} \text{ for all } v_j \in \mathbb{P}_p, j \in J^n, t \in (t^n, t^{n+1})\,.\end{aligned} \tag{2.11}$$

We then define $u_h \in L^\infty(0, T_{\max}; V_{h,n}^p)$ as $u_h(0) := u_h^{-1}$, and $u_h|_{(t^n,t^{n+1}]} := u_h^n|_{(t^n,t^{n+1}]}$.

In section 5 we combine the above method with Runge–Kutta time discretizations to obtain the generalized class of fully discrete RK-DG methods. This class includes the method of Cockburn and Shu, but we consider alternative choices for the limiting projections motivated by the a posteriori result for (2.10)–(2.11), proved in what follows.

2.2. A posteriori error estimate for the semidiscrete DG method. We will show a posteriori estimates for the error $\|(u - u_h)(T_{\max})\|_{L^1}$. To do that we compare u and u_h with $\widetilde{u}_h$ defined as

$$\widetilde{u}_h(t) = \Lambda_h^{n,t}(u_h(t)) \quad \text{for } t \in (t^n, t^{n+1}], \quad n = 0, \dots, N-1. \tag{2.12}$$

Then $\|(\widetilde{u}_h - u_h)(T_{\max})\|_{L^1}$ is an a posteriori quantity, and the control of $\|(u - \widetilde{u}_h)(T_{\max})\|_{L^1}$ will be obtained in what follows by employing Kruzkov estimates.

Note that, by definition, $\widetilde{u}_h$ might be discontinuous at the time nodes t^n. This will be the case either when the spatial mesh is modified at this node, or when we decide to use different projections on $(t^{n-1}, t^n]$ and $(t^n, t^{n+1}]$. In fact, due to the definitions of u_h and the projections, we have

$$\widetilde{u}_h(t^{n+}) - \widetilde{u}_h(t^n) = \Lambda_h^{n,t^n} u_h(t^n) - \Lambda_h^{n-1,t^n} u_h(t^n) = (\Lambda_h^{n,t^n} - \Lambda_h^{n-1,t^n}) u_h(t^n)\,. \tag{2.13}$$

Before stating our main result we introduce the following notation:

$$\widetilde{u}_j = \widetilde{u}_h \quad \text{in } T_j, \qquad \widetilde{u}^n = \widetilde{u}_h \quad \text{in } (t^n, t^{n+1}], \qquad \widetilde{u}^n(t^n) = \widetilde{u}_h(t^{n+}),$$

with the obvious extension for combined indexes.

THEOREM 2.5 (a posteriori error estimate for the semidiscrete DG method). *Let u_h be given by the semidiscrete generalized DG method* (2.10)–(2.11). *For $\widetilde{u}_h$ given by* (2.12) *we have the following a posteriori error estimate:*

$$||(u-u_h)(T_{\max})||_{L^1(B_R(x_0))} \le ||(\widetilde{u}_h - u_h)(T_{\max})||_{L^1(B_R(x_0))} + \eta_h,$$

where $\eta_h := \eta_0 + \sqrt{K_1\eta_1} + \sqrt{K_2\eta_2}$, $\eta_0 := \sum_{j\in J^0}\eta_{0,j}$, $\eta_i := \sum_n \sum_{j\in J^n}\eta^n_{i,j}$, $i = 1, 2$, and the local contributions $\eta^n_{i,j}$ are given as

(2.14)

$$\eta_{0,j} := \int_{T_j} |u_0 - \widetilde{u}^0_j(0)|, \qquad \eta^n_{1,j} := h_j R^n_{T,j} + \frac{1}{2} h_{jl} R^n_{S,j} + h_j R^n_{\Lambda,j},$$

$$\eta^n_{2,j} := ||\overline{\widetilde{u}^n_j} - \widetilde{u}^n_j||_{L^\infty((t^n,t^{n+1})\times T_j)} R^n_{T,j} + \frac{1}{2} \max_{k\in\{j,l\}} ||\overline{\widetilde{u}^n_k} - \widetilde{u}^n_k||_{L^\infty((t^n,t^{n+1})\times S_{jl})} R^n_{S,j}$$

$$+ ||\overline{\widetilde{u}^{n-1}}(t^n) - \widetilde{u}^{n-1}(t^n)||_{L^\infty(T_j)} R^n_{\Lambda,j}. \tag{2.15}$$

Here, we used the notation

$$R^n_{T,j} := \int_{t^n}^{t^{n+1}} \int_{T_j} \left|\partial_t \widetilde{u}_j + \nabla\cdot f(\widetilde{u}_j)\right|, \quad R^n_{\Lambda,j} := \int_{T_j} |\widetilde{u}^n(t^{n+1}) - \widetilde{u}^{n+1}(t^{n+1})|, \tag{2.16}$$

$$R^n_{S,j} := \int_{t^n}^{t^{n+1}} \sum_{l\in N(j)} \int_{S_{jl}} Q_{jl}(\widetilde{u}_j, \widetilde{u}_l)|\widetilde{u}_j - \widetilde{u}_l|, \quad h_{jl} := \max_{l\in N(j)} \operatorname{diam}(T_j \cup T_l), \tag{2.17}$$

$$\text{and} \quad Q_{jl}(u,v) := \frac{2f_{jl}(u,v) - f_{jl}(u,u) - f_{jl}(v,v)}{u-v}. \tag{2.18}$$

K_1, K_2 are constants depending on the total variation of the initial data and on the maximal slope of the flux, but they are independent of the maximal time $T_{\max}$. The independence of $T_{\max}$ is due to the fact that we consider only the semidiscrete scheme. For a detailed definition of the constants, see the proof on page 525.

The error estimator in Theorem 2.5 is composed of the two parts η_1, η_2. The first part corresponds to the standard estimates known for first order schemes [6, 25, 30], and the second part of the estimate corresponds to error terms which are present only in higher order approximations. In the following Corollary 2.6 we have rearranged these terms so that the estimate is more suitable for designing an adaptive scheme.

COROLLARY 2.6. *With the assumptions and notations of Theorem* 2.5, *we have*

$$\eta_h \le \eta_0 + R_h, \quad \text{with} \quad R_h^2 = 2\sum_n \sum_{j\in J^n} \rho^n_j \left(R^n_{T,j} + R^n_{S,j} + R^n_{\Lambda,j}\right), \tag{2.19}$$

$$\text{and} \qquad \rho^n_j := K_1 h_j + K_2 \max_{k\in\{j,\, l\in N(j)\}} ||\overline{\widetilde{u}^n_k} - \widetilde{u}^n_k||_{L^\infty((t^n,t^{n+1})\times T_k)}. \tag{2.20}$$

Proof. The estimate $\eta_h \le \eta_0 + R_h$ is a direct consequence of Theorem 2.5 if we estimate $\sqrt{K_1\eta_1} + \sqrt{K_2\eta_2} \le \sqrt{2K_1\eta_1 + 2K_2\eta_2}$. By rearranging terms in $K_1\eta_1 + K_2\eta_2$ and using $h_{jl} \le h_j + h_l$, we obtain (2.19). ∎

We are now going to discuss some aspects of the error estimate.

Semidiscrete versus fully discrete estimates. The above a posteriori result is extended in a straightforward manner when the ODE (2.1) is discretized by Euler's method. RK-DG methods, though, use high-order Runge–Kutta schemes for time discretization. The proof of a result for high-order Runge–Kutta schemes is nontrivial and requires new ideas. Therefore, an analysis of the fully discrete case is left for future work.

The error bound of Theorem 2.5 is used to design our adaptive algorithm in section 5. To do that we introduce in section 4 the fully discrete generalized RK-DG method and express it as an ODE for each time slab $[t^n, t^{n+1}]$. This is done by using the *natural continuous extension* for Runge–Kutta schemes introduced by Zennaro [34].

First-order versus high-order estimates. In the case $p = 0$ the DG method reduces to a standard finite volume scheme that allows mesh modification with n. Then the first term in $\eta^n_{1,j}$ and the whole $\eta^n_{2,j}$ will be zero. The last term in $\eta^n_{1,j}$ will account for coarsening errors due to mesh modification. Such terms were not included in the previous a posteriori estimates for finite volume schemes [6, 25, 29]. Another implication due to higher-order polynomials used in the finite element spaces is the appearance of $\overline{\widetilde{u}^n_j} - \widetilde{u}^n_j$ in various norms in the term $\eta^n_{2,j}$. A comparison with $\eta^n_{1,j}$ leads to the conclusion that it would be desirable to have $\overline{\widetilde{u}^n_j} - \widetilde{u}^n_j = O(h_j)$. In general this is not guaranteed unless $\widetilde{u}^n_j$ is a result of certain limiting projections which restrict gradients or/and polynomial degrees of u_h. This observation is one of the main motivations for the choice of the limiting projections and the design of the adaptive algorithm in section 5.

Computational "convergence" of the estimators. Theorem 2.5 is a rather general result that covers any projection $\Lambda^{n,t}_h$ with the properties (2.7) and (2.8). In addition, due to the generality of Kruzkov's estimates used in the proof above, an a posteriori bound can be seen as a "worst case scenario" upper bound. It is clear that if in the computational runs the estimators converge to zero, then the error will do the same. In this sense Theorem 2.5 allows for the design of error control algorithms based on upper bound estimates. This issue is discussed in detail in sections 5 and 6. At this point we would like to note that, among many other choices presented in section 5, $h - p$ versions of RK-DG methods allow error control algorithms based on the estimators of Theorem 2.5. In addition, for the test problems discussed in this paper we examine the computational behavior for the RK-DG method with limiters from [10, 7] and the corresponding estimator of Theorem 2.5. Concluding, we are able to provide adaptive error control based algorithms for both $h - p$ and derivative restriction generalized versions of DG methods.

The rest of the paper is organized as follows: In section 3 we prove Theorem 2.5. The proof is based on an abstract Kruzkov estimate for approximations of the entropy solution of the conservation law (Theorem 3.3) and on a weak cell entropy inequality for the method (Lemma 3.4). In section 4 we present the fully discrete generalized RK-DG method and its continuous in time form with the help of the "continuous extension" for Runge–Kutta schemes. In section 5 we present the limiting projections and the adaptive error control-based algorithms for the corresponding DG methods. In section 6 we discuss the computational performance of the various methods in several test cases.

3. Proof of the a posteriori error estimate. In this section we establish an error estimate for approximations of conservation laws. It is an extension to smooth entropies of the corresponding results in [24, 23, 4]. The notation and the form of the

result follows [23, Lemma 4.1]. We start with the definition of the entropy residual.

DEFINITION 3.1 (entropy residual R_S). *Let $\tilde{u} \in L^\infty(\mathbb{R}^d \times \mathbb{R}^+)$ be an arbitrary function. Then, corresponding to the definition of an entropy weak solution, we define the entropy residual R_S by*

$$\langle R_S(\tilde{u}), \phi \rangle := \iint\limits_{\mathbb{R}^d \times \mathbb{R}^+} S(\tilde{u})\partial_t \phi + F_S(\tilde{u}) \cdot \nabla \phi + \int_{\mathbb{R}^d} S(u_0)\phi(\cdot, 0). \tag{3.1}$$

For the error estimate we require a regularization of the Kruzkov entropy $|v-k|$.

DEFINITION 3.2 (δ-regularized Kruzkov entropy). *Let $\bar{S} \in C^2(\mathbb{R}, \mathbb{R}^+)$ be given as $\bar{S}(v) = (6v^2 - v^4)/8$ if $|v| \le 1$ and $\bar{S}(v) = |v| - 3/8$ otherwise. For any $\delta > 0$, $v \in \mathbb{R}$ let us define $S_\delta : \mathbb{R} \to \mathbb{R}^+$ by $S_\delta(v) := \delta \bar{S}(\frac{v}{\delta})$. Furthermore, define $F_{S,\delta} : \mathbb{R}^2 \to \mathbb{R}$ for any $v, k \in \mathbb{R}$ by $F_{S,\delta}(v,k) := \int_\kappa^v f'(w) S'_\delta(w-k)dw$.*

In the following result, u_h stands for any approximation of problem (1.1)–(1.2).

THEOREM 3.3 (abstract Kruzkov estimate). *Let $u_h, u \in L^\infty_{loc}([0,\infty), L^1_{loc}(\mathbb{R}^d))$ be right continuous in t, with values in $L^1_{loc}(\mathbb{R}^d)$. Assume that u is the entropy solution of (1.1)–(1.2). Let $S(v) = S(v-k) = S_\delta(v-k)$ be the δ-regularized Kruzkov entropy and $F_S(v) = F_S(v\,,\,k) = F_{S,\delta}(v\,,\,k)$ the corresponding entropy flux. Let $\Psi \ge 0$ be a test function $\Psi \in C_c^\infty((0,\infty) \times \mathbb{R}^d)$, and assume that u_h satisfies*

$$\begin{aligned} -\langle R_S(u_h), \Psi \rangle &= -\iint_{(0,\infty)\times\mathbb{R}^d} \big(S(u_h - k)\partial_t \Psi + F_S(u_h\,,\,k) \cdot \nabla_x \Psi\big) dtdx \\ &\le \iint_{(0,\infty)\times\mathbb{R}^d} \left(\beta_O B_O(\Psi) + \alpha_G |\partial_t \Psi| + \sum_j \beta_H^j B_H^j \left(\frac{\partial \Psi}{\partial x_j} \right) \right) dxdt \quad \text{for all } k \in \mathbb{R}, \end{aligned}$$

where $\alpha_G, \beta_O, \beta_H^j$ are nonnegative k-independent but possibly δ-dependent *functions in $L^1_{loc}([0,\infty) \times \mathbb{R}^d)$ and $\alpha_G \in L^\infty_{loc}([0,\infty), L^1_{loc}(\mathbb{R}^d))$.*

For fixed $\Delta, \delta > 0$, let $\mathcal{T}_h = \{K\}$ be a given element decomposition of $[0,\infty) \times \mathbb{R}^d$ into elements K such that $\operatorname{diam}(K_t) \le \Delta$ in the case where B_O or B_H^j is not identically zero; here $K_t = \{x : (t,x) \in K\}$. If, in addition, for all $(t,x) \in K$, $1 \le i, j \le d$,

$$|B_O(\Psi)(t,x)| \le C \sup_{x' \in K_t} |\Psi(t,x')|\,, \quad \left| B_H^j \left(\frac{\partial \Psi}{\partial x_j} \right)(t,x) \right| \le C \sup_{x' \in K_t} \left| \frac{\partial \Psi}{\partial x_j}(t,x') \right|\,, \tag{3.2}$$

where C is a constant independent of Ψ and the decomposition $\mathcal{T}_h$, then the following estimate holds: for any $T_{\max} \ge 0$, $x_0 \in \mathbb{R}^d$, $R > 0$, $\rho > 0$ with $M = Lip(f)$, we have

$$\begin{aligned} \int_{|x-x_0|<R} |u_h(T_{\max}, x) - u(T_{\max}, x)| dx &\le \int_{B_0} |u_h(0,x) - u(0,x)| dx \\ &+ C\,(M\,+1) TV(u^0)\;\Delta + C\{k_1 TV(u^0) + k_0\,\chi_{\operatorname{supp}(u_h-u)(T_{\max})}\,(R+\Delta)^d\,\}\,\delta \\ &+ C\left(1 + \frac{T_{\max}(1+M)}{\Delta}\right) \sup_{0\le t\le T_{\max}+\rho} \int_{B_t} \alpha_G(t,x) dx \\ &+ C \iint_{0\le t\le T_{\max}\; x\in B_t^\Delta} \left(\beta_O(t,x) + \frac{1}{\Delta} \sum_{j=1}^d \beta_H^j(t,x) \right) dxdt\,, \end{aligned}$$

where $B_t = B(x_0, R + M(T_{\max} - t) + \Delta)$, $B_t^{\Delta} = B(x_0, R + M(T_{\max} - t) + 2\Delta)$, *and* χ_D *denotes the characteristic function of the set* D.

Proof. The proof follows the lines of [4, 24], where special attention has to be paid to the treatment of the smooth approximation S_δ of the Kruzkov entropies. This is done analogously to [6] and [28]. For a detailed version of the proof, we refer to [13]. ∎

3.1. Estimate on the entropy residual. To apply the abstract theorem of the previous subsection we need to estimate $\langle R_S(\tilde{u}_h), \phi \rangle$ for ϕ being a test function and $\tilde{u}_h$ defined in (2.12). This will be done in the following lemmas.

LEMMA 3.4 (weak cell entropy inequality). *Let* (S, F_S) *denote a smooth entropy pair. Then the following cell entropy inequality holds for* $\widetilde{u}_h$*:*

$$I_j^n := I_{1,j}^n + I_{2,j}^n + I_{3,j}^n + I_{4,j}^n = -D_j^n \le 0, \tag{3.3}$$

where, for $\phi \in C_0^1(\mathbb{R}^d \times \mathbb{R}^+, \mathbb{R}^+)$,

$$\begin{aligned}
I_{1,j}^n &= (\partial_t S(\widetilde{u}_j^n) + \nabla \cdot F_S(\widetilde{u}_j^n), \overline{\phi_j})_{T_j},\\
I_{2,j}^n &= \sum_{l \in N(j)} \Big(F_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n) - F_S(\widetilde{u}_j^n) \cdot \mathbf{n}_{jl}, \overline{\phi_j} \Big)_{S_{jl}},\\
I_{3,j}^n &= (\partial_t \widetilde{u}_j^n + \nabla \cdot f(\widetilde{u}_j^n), (S'(\overline{\widetilde{u}_j^n}) - S'(\widetilde{u}_j^n))\overline{\phi_j})_{T_j},\\
I_{4,j}^n &= \sum_{l \in N(j)} \Big(f_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n) - f(\widetilde{u}_j^n) \cdot \mathbf{n}_{jl}, (S'(\overline{\widetilde{u}_j^n}) - S'(\widetilde{u}_j^n))\overline{\phi_j} \Big)_{S_{jl}},\\
D_j^n &= \sum_{l \in N(j)} \left(\int_{\widetilde{u}_j^n}^{\widetilde{u}_l^n} \partial_w f_{jl}(\widetilde{u}_j^n, w) \int_w^{\widetilde{u}_j^n} S''(s)\, ds\, dw, \overline{\phi_j} \right)_{S_{jl}}.
\end{aligned}$$

Here $F_{jl}(\alpha, \beta) = \int_\alpha^\beta \partial_s f_{jl}(\alpha, s) S'(s) ds + F_S(\alpha)$ *is a discrete entropy flux that is consistent with* F_S.

Proof. Let $p \ge 0$. We start by choosing $v_h = S'(\overline{\widetilde{u}_h^n})\overline{\phi_h}$ in the local form, the scheme (2.11). This yields

$$(\partial_t u_j^n, S'(\overline{\widetilde{u}_j^n})\overline{\phi_j})_{T_j} + \sum_{l \in N(j)} (f_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n), S'(\overline{\widetilde{u}_j^n})\overline{\phi_j})_{S_{jl}} = 0.$$

Next, (2.7) implies $(\partial_t u_j^n, v_j)_{T_j} = (\partial_t \widetilde{u}_j^n, v_j)_{T_j}$ for all $v_h \in V_{h,n}^0$. Therefore

$$(\partial_t \widetilde{u}_j^n, S'(\overline{\widetilde{u}_j^n})\overline{\phi_j})_{T_j} + \sum_{l \in N(j)} (f_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n), S'(\overline{\widetilde{u}_j^n})\overline{\phi_j})_{S_{jl}} = 0.$$

We insert zeros to get

$$\begin{aligned}
0 = {} & (\partial_t \widetilde{u}_j^n + \nabla \cdot f(\widetilde{u}_j^n), S'(\widetilde{u}_j^n)\overline{\phi_j})_{T_j} + \sum_{l \in N(j)} \Big(f_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n) - f(\widetilde{u}_j^n) \cdot \mathbf{n}_{jl}, S'(\widetilde{u}_j^n)\overline{\phi_j} \Big)_{S_{jl}}\\
& + (\partial_t \widetilde{u}_j^n + \nabla \cdot f(\widetilde{u}_j^n), (S'(\overline{\widetilde{u}_j^n}) - S'(\widetilde{u}_j^n))\overline{\phi_j})_{T_j}\\
& + \sum_{l \in N(j)} \Big(f_{jl}(\widetilde{u}_j^n, \widetilde{u}_l^n) - f(\widetilde{u}_j^n) \cdot \mathbf{n}_{jl}, (S'(\overline{\widetilde{u}_j^n}) - S'(\widetilde{u}_j^n))\overline{\phi_j} \Big)_{S_{jl}}.
\end{aligned}$$

We complete the proof with the following identity:

$$
\begin{aligned}
&(f_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)-f(\widetilde{u}_j^n)\cdot\mathbf{n}_{jl})S'(\widetilde{u}_j^n)=(f_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)-f_{jl}(\widetilde{u}_j^n,\widetilde{u}_j^n))S'(\widetilde{u}_j^n)\\
&\quad=\int_{\widetilde{u}_j^n}^{\widetilde{u}_l^n}\partial_w f_{jl}(\widetilde{u}_j^n,w)S'(w)dw+\int_{\widetilde{u}_j^n}^{\widetilde{u}_l^n}\partial_w f_{jl}(\widetilde{u}_j^n,w)\big(S'(\widetilde{u}_j^n)-S'(w)\big)\mathrm{dw}\\
&\quad=F_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)-F_{jl}(\widetilde{u}_j^n,\widetilde{u}_j^n)+\int_{\widetilde{u}_j^n}^{\widetilde{u}_l^n}\partial_w f_{jl}(\widetilde{u}_j^n,w)\int_w^{\widetilde{u}_j^n}S''(s)\mathrm{dsdw}\,. \qquad \square
\end{aligned}
$$

REMARK 3.5. (1) *Note that the dissipation term D_j^n in the cell entropy inequality* (3.3) *is positive because of the monotonicity of the numerical flux and the convexity of S.* (2) *If $p=0$, we have $I_{3,j}^n, I_{4,j}^n=0$.* (3) *As expected for a high-order scheme, the weak cell entropy inequality is, in general, not a real cell entropy inequality in the classical sense. However, its use is important to conclude the following estimates; compare to* [16].

LEMMA 3.6 (entropy residual for the semidiscrete DG approximation). *Let $u_h, \widetilde{u}_h$ as before. Then the following estimate holds true for all $\phi\in C_0^1(\mathbb{R}^d\times(0,T_{\max}),\mathbb{R}^+)$:*

$$
\langle R_S(u_h),\phi\rangle \geq T_1+T_2+T_3+T_4+T_5+T_6, \tag{3.4}
$$

where

$$
\begin{aligned}
T_1&:=\iint_{\mathbb{R}^d\times\mathbb{R}^+}\Big(\partial_t S(\widetilde{u}_h)+\nabla\cdot F_S(\widetilde{u}_h)\Big)\Big(\overline{\phi_h}-\phi\Big),\\
T_2&:=\int_0^T\sum_{j\in J^n}\sum_{l\in N(j)}\Big(F_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)-F_S(\widetilde{u}_j^n),\overline{\phi_h}-\phi\Big)_{S_{jl}},\\
T_3&:=\sum_n\int_{t^n}^{t^{n+1}}\sum_{j\in J^n}\Big(\partial_t\widetilde{u}_j^n+\nabla\cdot f(\widetilde{u}_j^n),(S'(\overline{\widetilde{u}_j^n})-S'(\widetilde{u}_j^n))\overline{\phi_j}\Big)_{T_j},\\
T_4&:=\sum_n\int_{t^n}^{t^{n+1}}\sum_{j\in J^n}\sum_{l\in N(j)}\Big(f_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)-f(\widetilde{u}_j^n)\cdot\mathbf{n}_{jl},(S'(\overline{\widetilde{u}_j^n})-S'(\widetilde{u}_j^n))\overline{\phi_j}\Big)_{S_{jl}},\\
T_5&:=\sum_n\sum_{j\in J^n}\Big(\widetilde{u}_j^n(t^n)-\widetilde{u}_j^{n-1}(t^n),\int_0^1 S'(u_j(\theta))d\theta\ (\overline{\phi_h}(t^n)-\phi(t^n))\Big)_{T_j},\\
T_6&:=\sum_n\sum_{j\in J^n}\Big(\widetilde{u}_j^n(t^n)-\widetilde{u}_j^{n-1}(t^n),(S'(\overline{\widetilde{u}_j^{n-1}(t^n)})-\int_0^1 S'(v^n(\theta))d\theta)\ \overline{\phi_h}(t^n)\Big)_{T_j},
\end{aligned}
$$

where in the definition of T_5 and T_6 we use the abbreviation

$$
v^n(\theta):=\widetilde{u}^{n-1}(t^n)+\theta(\widetilde{u}^n(t^n)-\widetilde{u}^{n-1}(t^n)).
$$

Note that T_1 is the element residual, and T_2 is the jump residual in space. T_3 and T_4 are to be seen as kinds of stability errors coming from the higher-order approximation, and T_5, T_6 account for possible discontinuities in time of the projected function $\widetilde{u}_h$.

Proof. A summation of the cell entropy-like inequality (3.3) on all elements $T_j\in\mathcal{T}_n$ and an integration in time leads to

$$
I_h:=\sum_n\int_{t^n}^{t^{n+1}}\sum_{j\in J^n}\Big(I_{1,j}^n+I_{2,j}^n+I_{3,j}^n+I_{4,j}^n\Big)\leq 0.
$$

Next, let us look at the entropy residual. Using integration by parts in time and locally in space, we get

$$\langle R_S(\widetilde{u}_h),\phi\rangle = -\sum_n \int_{t^n}^{t^{n+1}} \sum_{j\in J^n} \left[\int_{T_j} \partial_t S(\widetilde{u}_j^n)\phi + \nabla\cdot F_S(\widetilde{u}_j^n)\phi + \sum_{l\in N(j)} \int_{S_{jl}} F(\widetilde{u}_j^n)\cdot \mathbf{n}_{jl}\phi \right] + \sum_n \sum_{j\in J^n} \int_{T_j} (S(\widetilde{u}_j^n)(t^{n+1})\phi(t^{n+1}) - S(\widetilde{u}_j^n)(t^n))\phi(t^n)) \,.$$

Due to the conservation property of the numerical flux and since ϕ is continuous we have $\int_0^T \sum_{j\in J^n}\sum_{l\in N(j)} \int_{S_{jl}} F_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n)\phi = 0$. Thus, by rearranging the summation, we get

$$\begin{aligned}\langle R_S(\widetilde{u}_h),\phi\rangle = &-\sum_n \int_{t^n}^{t^{n+1}} \sum_{j\in J^n} \Big(\partial_t S(\widetilde{u}_j^n) + \nabla\cdot F_S(\widetilde{u}_j^n),\phi\Big)_{T_j} \\ &+ \sum_n \int_{t^n}^{t^{n+1}} \sum_{j\in J^n}\sum_{l\in N(j)} \Big(F_{jl}(\widetilde{u}_j^n,\widetilde{u}_l^n) - F(\widetilde{u}_j^n)\cdot\mathbf{n}_{jl},\phi\Big)_{S_{jl}} \\ &- \sum_n \sum_{j\in J^n} \Big(S(\widetilde{u}^n)(t^n) - S(\widetilde{u}^{n-1})(t^n),\phi(t^n)\Big)_{T_j}\,. \end{aligned} \tag{3.5}$$

Note that, regarding the last term, since the above sums are reduced to integrals over the spatial domain, we have decided to split them into sums over $T_j \in \mathcal{T}_n$, although $\widetilde{u}^{n-1}(t^n) \in V^p_{h,n-1}$. Next, using the property (2.8) of the projections, we obtain

$$\sum_n \sum_{j\in J^n} \Big(\widetilde{u}_j^n(t^n) - \widetilde{u}_j^{n-1}(t^n), S'(\overline{\widetilde{u}_j^{n-1}(t^n)})\overline{\phi_h}(t^n)\Big)_{T_j} = 0.$$

Using the definition of $v^n(\theta)$, we rewrite the last summand (3.5) of the residual as follows:

$$\begin{aligned} &-\sum_n \sum_{j\in J^n} \Big(S(\widetilde{u}^n)(t^n) - S(\widetilde{u}^{n-1})(t^n),\phi(t^n)\Big)_{T_j} \\ &= -\sum_n \sum_{j\in J^n} \Big(S(\widetilde{u}^n)(t^n) - S(\widetilde{u}^{n-1})(t^n),\phi(t^n)\Big)_{T_j} \\ &\quad + \sum_n \sum_{j\in J^n} \Big((\widetilde{u}^n - \widetilde{u}^{n-1})(t^n), S'(\overline{\widetilde{u}^{n-1}(t^n)})\overline{\phi_h}(t^n)\Big)_{T_j} \\ &= \sum_n \sum_{j\in J^n} \left((\widetilde{u}^n - \widetilde{u}^{n-1})(t^n), S'(\overline{\widetilde{u}^{n-1}(t^n)})\overline{\phi_h}(t^n) - \int_0^1 S'(v^n(\theta))\mathrm{d}\theta\phi(t^n)\right)_{T_j} \\ &= \sum_n \sum_{j\in J^n} \left((\widetilde{u}^n - \widetilde{u}^{n-1})(t^n), \int_0^1 S'(v^n(\theta))\mathrm{d}\theta\ (\overline{\phi_h}(t^n) - \phi(t^n))\right)_{T_j} \\ &\quad + \sum_n \sum_{j\in J^n} \left((\widetilde{u}^n - \widetilde{u}^{n-1})(t^n), \Big(S'(\overline{\widetilde{u}^{n-1}(t^n)}\Big) - \int_0^1 S'(v^n(\theta))\mathrm{d}\theta\ \overline{\phi_h}(t^n)\right)_{T_j}. \end{aligned}$$

Finally by comparing the residual with I_h, we arrive at the final result, noticing

$$\langle R_S(u_h),\phi\rangle \geq \langle R_S(u_h),\phi\rangle + I_h = T_1 + T_2 + T_3 + T_4 + T_5 + T_6. \qquad \square$$

We conclude by further estimating the T_i terms in (3.4).

LEMMA 3.7 (estimate on the residual). *The following estimates on the contributions to the residual hold true:*

$$|T_1 + T_2 + T_5| \leq ||S'||_{L^\infty} ||\nabla\phi||_{L^\infty} \sum_n \sum_{j \in J^n} \eta_{1,j}^n,$$
$$|T_3 + T_4 + T_6| \leq ||S''||_{L^\infty} ||\phi||_{L^\infty} \sum_n \sum_{j \in J^n} \eta_{2,j}^n,$$

where the local error indicators $\eta_{i,j}^n$ are defined in Theorem 2.5 above.

Proof. The goal of estimating the terms T_i is to get some power of the mesh size h from the differences in the test functions. On the other hand, every power of h that we might gain must be paid for by a higher derivative of either ϕ or S. Since we will later choose ϕ to approximate certain δ-functions and S to approximate the nonsmooth Kruzkov entropies, derivatives of ϕ and S' will blow up with a certain rate, depending on the corresponding approximation parameters. The goal is therefore to restrict to first derivatives of ϕ and second derivatives of S.

Estimate on T_1. To estimate this term, we need a local estimate on the difference of the test functions. As $\Pi_{V_h^0}$ is exact on polynomials of degree $p = 0$, we get $|(\Pi_{V_h^0}(\phi)(x) - \phi(x))|_{T_j}| \leq h_j ||\nabla\phi||_{L^\infty(T_j)}$, which finally leads to the estimate on T_1.

Estimate on T_2. We get, by rearranging the summation in space,

$$T_2 = \int_0^T \sum_{(j,l) \in \mathcal{E}^n} \int_{S_{jl}} (F_{jl}(\widetilde{u}_j, \widetilde{u}_l) - F_{jl}(\widetilde{u}_j, \widetilde{u}_j))(\overline{\phi_j} - \phi) - (F_{jl}(\widetilde{u}_j, \widetilde{u}_l) - F_{jl}(\widetilde{u}_l, \widetilde{u}_l))(\overline{\phi_l} - \phi).$$

From here we get the estimate

$$|T_2| \leq ||S'||_{L^\infty} \sum_n \int_{t^n}^{t^{n+1}} \sum_{(j,l) \in \mathcal{E}^n} h_{jl} ||\nabla\phi||_{L^\infty(T_j \cup T_l)} \int_{S_{jl}} Q_{jl}(\widetilde{u}_j, \widetilde{u}_l) |\widetilde{u}_j - \widetilde{u}_l|$$
$$\leq ||S'||_{L^\infty} ||\nabla\phi||_{L^\infty} \sum_n \sum_{j \in J^n} \frac{1}{2} \int_{t^n}^{t^{n+1}} \sum_{l \in N(j)} h_{jl} \int_{S_{jl}} Q_{jl}(\widetilde{u}_j, \widetilde{u}_l) |\widetilde{u}_j - \widetilde{u}_l|,$$

where we have used the monotonicity of the numerical fluxes f_{jl}.

Analogous to the estimates for T_1, T_2, we derive for T_3 and T_4

$$|T_3| \leq ||S''||_{L^\infty} ||\phi||_{L^\infty} \sum_n \sum_{j \in J^n} \int_{t^n}^{t^{n+1}} ||\overline{\widetilde{u}_j^n} - \widetilde{u}_j^n||_{L^\infty(T_j)} \int_{T_j} |\partial_t \widetilde{u}_h + \nabla \cdot f(\widetilde{u}_h)|,$$

$$|T_4| \leq ||S''||_{L^\infty} ||\phi||_{L^\infty} \sum_n \sum_{j \in J^n} \frac{1}{2} \int_{t^n}^{t^{n+1}} \sum_{l \in N(j)} \max_{k \in \{j,l\}} ||\overline{\widetilde{u}_k^n} - \widetilde{u}_k^n||_{L^\infty(S_{jl})} \cdot \int_{S_{jl}} Q_{jl}(\widetilde{u}_j, \widetilde{u}_l) |\widetilde{u}_j - \widetilde{u}_l|.$$

Estimate on T_5 and T_6.

$$|T_5| \le ||S'||_{L^\infty} ||\nabla\phi(t^n)||_{L^\infty(T_j)} \sum_n \sum_{j\in J^n} h_j \int_{T_j} |\widetilde{u}^n(t^n) - \widetilde{u}^{n-1}(t^n)|,$$

$$|T_6| \le ||S''||_{L^\infty} ||\phi(t^{n+1})||_{L^\infty(T_j)} \cdot \sum_n \sum_{j\in J^n} ||\overline{\widetilde{u}_j^{n-1}}(t^n) - \widetilde{u}_j^{n-1}(t^n)||_{L^\infty(T_j)} \int_{T_j} |\widetilde{u}^n(t^n) - \widetilde{u}^{n-1}(t^n)|.$$

For the last estimate we used

$$\left| S'(\overline{\widetilde{u}_j^{n-1}(t^n)}) - \int_0^1 S'(v^n(\theta))\mathrm{d}\theta \right| \le ||S''||_{L^\infty} \int_0^1 |\overline{\widetilde{u}^{n-1}(t^n)} - \widetilde{u}^{n-1}(t^n) + \theta(\widetilde{u}^n(t^n) - \widetilde{u}^{n-1}(t^n))|\mathrm{d}\theta,$$

which gives us the bound on T_6, since the function under the integral is monotone decreasing in θ due to (2.9). The estimate of the theorem now follows by introducing the notation from Theorem 2.5. ∎

We are ready now to complete the proof of Theorem 2.5.

Proof of Theorem 2.5. Lemma 3.7 shows that $\widetilde{u}_h$ satisfies the assumption of Theorem 3.3 with $\alpha_G := 0$ and $\beta_O, \sum_k \beta_H^k$ given by the following local contributions:

$$\beta_O|_{T_j\times[t^n,t^{n+1})} := \frac{1}{\Delta t\ |T_j|} ||S''||_{L^\infty} \eta_{2,j}^n, \qquad \sum_k \beta_H^k|_{T_j\times[t^n,t^{n+1})} := \frac{1}{\Delta t\ |T_j|}\ \eta_{1,j}^n.$$

Using the definition of the entropy $S = S_\delta$ (see Definition 3.2), we estimate $||S''||_{L^\infty} \le K_S \frac{1}{\delta}$. Theorem 2.5 now follows from Theorem 3.3 by choosing the regularization parameters Δ, δ as

$$\Delta := \sqrt{\frac{\sum_n \sum_{j\in J^n} \eta_{1,j}^n}{K_1}}, \qquad \delta := \sqrt{\frac{\sum_n \sum_{j\in J^n} \eta_{2,j}^n}{K_2}}, \tag{3.6}$$

where $K_1 := (M+1)TV(u^0)$, $K_2 := K_S^{-1}(k_1 TV(u^0) + k_0\, \chi_{\mathrm{supp}(u_h-u)(T_{\max})}\, (R+1)^d)$. ∎

4. Fully discrete RK-DG method and continuous in time extension. In this section we will present the generalized class of RK-DG methods that result from time discretization of the semidiscrete method of Definition 2.4 (see also [11]). Thus let us suppose that we can write the semidiscrete DG method as a system of ODEs for a vector valued function $U : (0, T_{\max}) \to \mathbb{R}^N$, where N corresponds to the degrees of freedom of u_h. Then (2.2) can be written in the general form

$$\frac{\mathrm{d}}{\mathrm{d}t} U(t) = L(U(t), t). \tag{4.1}$$

A general explicit m-stage Runge–Kutta method for (4.1) can be represented as

$$W^l := U^n + \Delta t \sum_{k=1}^{l-1} a_{lk} L^k, \quad L^l := L(W^l, t^n + c_l \Delta t), \quad l = 1, \dots, m, \tag{4.2}$$

$$U^{n+1} := U^n + \Delta t \sum_{k=1}^{m} b_k L^k. \tag{4.3}$$

To ensure consistency, the additional constraints $\sum_{k=1}^{m} b_k = 1$, $c_l = \sum_{k=1}^{l-1} a_{lk} \in [0,1]$ have to be imposed. The scheme is characterized by the values b_k, $k = 1, \dots, m$, and a lower triangular matrix a_{lk}, $l = 2, \dots, m$, $k < l$. For particular strongly stability preserving Runge–Kutta methods we refer to [32] and to the review articles [17, 31].

The Runge–Kutta method, as presented above, gives only approximations at the discrete time steps t^n. In order to obtain a continuous approximation in time, we seek a polynomial approximation U_h in time, such that in each interval $[t^n, t^{n+1}]$ the Runge–Kutta scheme can be written in the form

$$\frac{\mathrm{d}}{\mathrm{dt}} U_h(t) = L_h(U_h(t), t).$$

A way to construct such polynomials is given by the so-called natural continuous extension (NCE) of Runge–Kutta methods, introduced by Zennaro [34]. The main result of [34] can be summarized as follows. Each m-stage Runge–Kutta method of order $\tilde{m}$ has a natural continuous extension U_h of polynomial degree $\tilde{p}$ with $\frac{\tilde{m}+1}{2} \leq \tilde{p} \leq \min\{m^*, \tilde{m}\}$, where m^* is the number of distinct values of the coefficients c_l, in the sense that there exist m polynomials $b_l \in \mathbb{P}^{\tilde{p}}(0,1)$, $l = 1, \dots, m$, such that

$$\begin{aligned} U_h(t^n) &= U^n, \qquad U_h(t^{n+1}) = U^{n+1}, \\ U_h(t^n + s\Delta t) &:= U^n + \Delta t \sum_{k=1}^{m} b_k(s) L^k, \quad 0 \leq s \leq 1. \end{aligned} \tag{4.4}$$

Let us suppose that U_h is given by the m-stage NCE Runge–Kutta scheme (for an explicit construction, see [34]). From (4.4) we get

$$U_h(t^n) = U^n, \qquad \frac{\mathrm{d}}{\mathrm{dt}} U_h(t) = \sum_{k=1}^{m} b_k' \left(\frac{t - t^n}{\Delta t} \right) L^k, \quad t \in [t^n, t^{n+1}]. \tag{4.5}$$

Defining the discrete operator L_h as $L_h(U_h, t) := \sum_{k=1}^{m} b_k'(\frac{t-t^n}{\Delta t}) L^k$, we have reached our desired goal. The Runge–Kutta method can now be written

$$U_h(t^n) = U^n, \qquad \frac{\mathrm{d}}{\mathrm{dt}} U_h(t) = L_h(U_h, t). \tag{4.6}$$

Let us further define the fully discrete RK-DG method in a form equivalent to (4.6). Starting from Definition 2.4, we first define the local operators L_j^n by

$$\langle L_j^n(u_h(t)), v_j \rangle|_{T_j} := (f(u_j^n(t)), \nabla v_j)_{T_j} - \sum_{l \in N(j)} (f_{jl}(u_j^n(t), u_l^n(t)), v_j)_{S_{jl}} \tag{4.7}$$

for all $T_j \in \mathcal{T}_h$, $n = 0, \dots, N$, $v_h \in V_h^p$, and L_h^n through

$$\langle L^n(u_h(t)), v_h \rangle := \sum_{j \in J^n} \langle L_j^n(u_h(t)), v_j \rangle|_{T_j}.$$

Definition 4.1 (fully discrete generalized RK-DG approximation). *Let an m-stage Runge–Kutta method be given according to* (4.2), (4.3)*, and let us suppose that a projection $\Lambda_h^{n,t}$ with the properties* (2.7), (2.8) *is given. Furthermore, let the natural continuous extension of highest possible degree $\tilde{p}$ be given according to* (4.4)*. Let us denote $\Lambda_h^{n,k} := \Lambda_h^{n,t^n + c_k \Delta t}$ for $k = 1, \dots, m$. U_h is called a generalized fully discrete*

RK-DG approximation of (1.1)–(1.2) *if* $U_h^{-1} := \Lambda_h^{0,0}(u_0)$, *and for* $n = 0, \ldots, N-1$, $U_h^n := U_h|_{(t^n,t^{n+1}]} \in C^1(t^n, t^{n+1}; V_{h,n}^p)$ *is defined through*

$$U_h^n(t^n) := \Lambda_h^{n,t^n}(U_h^{n-1}(t^n)), \tag{4.8}$$

$$(W_j^{n,l}, v_j) = (U_j^n(t^n), v_j) + \Delta t \sum_{k=1}^{l-1} a_{lk} \langle L_j^n(\Lambda_h^{n,k}(W_h^{n,k})), v_j \rangle, \tag{4.9}$$

$$(U_j^n(t), v_j) = (U_j^n(t^n), v_j) + \Delta t \sum_{k=1}^{m} b_k \left(\frac{t-t^n}{\Delta t} \right) \langle L_j^n(\Lambda_h^{n,k}(W_h^{n,k})), v_j \rangle \tag{4.10}$$

$$\text{for all } v_j \in \mathbb{P}_p, j \in J^n, t \in [t^n, t^{n+1}].$$

Thus, with the definition of L_h^n, *the fully discrete generalized RK–DG approximation satisfies on each time slab* (t^n, t^{n+1}) *the ODE*

$$(\partial_t U_h^n(t), v_h) = \sum_{k=1}^{m} b_k' \left(\frac{t-t^n}{\Delta t} \right) \langle L_h^n(\Lambda_h^{n,k}(W_h^{n,k})), v_h \rangle \quad \textit{for all} \quad v_h \in V_{h,n}^p. \tag{4.11}$$

REMARK 4.2. *In our numerical experiments we used polynomial degree* $p = 1, 2, 3$ *for the space discretization combined with the NCE Runge–Kutta method of the same degree. In* [34] *extensions of Runge–Kutta methods are constructed with optimal order up to* $p = 4$, *but for* $p = 3$ *and* $p = 4$ *it is necessary to include a stage reuse procedure to obtain the desired order. In our examples we have included stage reuse since this does not increase the computational cost of the scheme.*

5. Choice of the projections and adaptive strategy. In Definition 2.1 we introduced a class of semidiscrete DG methods for arbitrary limiting projections $\Lambda_h^{n,t}$ and computational grids. In this subsection we describe specific choices of projection operators that are motivated by the a posteriori error estimate (Theorem 2.5). Furthermore, we give an adaptive strategy for local mesh refinement.

The numerical solution in the interval $(t^n, t^{n+1}]$ is defined in the following algorithm. We start with a guess $\tilde{\mathcal{T}}^n$ for the grid and $\tilde{\Lambda}_h^{n,t}$ for the limiting projection.

- **given:** grid $\tilde{\mathcal{T}}^n$, projection $\tilde{\Lambda}_h^{n,t}$ for $t \in [t^n, t^{n+1}]$, and $u^n(t^n, x)$
- **do**
  1. Let $\mathcal{T}^n = \tilde{\mathcal{T}}^n$ and $\Lambda_h^{n,t} = \tilde{\Lambda}_h^{n,t}$ for $t \in [t^n, t^{n+1}]$.
  2. Compute $u^n(t, x)$ for $t \in (t^n, t^{n+1}]$ on $\mathcal{T}^n$ using $\Lambda_h^{n,t}$.
  3. Compute indicators and new limiting projection $\tilde{\Lambda}_h^{n,t}$ on $\mathcal{T}^n$;
     i.e., for $j \in J^n$ compute the following:
     - $\rho_j^n, R_{T,j}^n, R_{S,j}^n$ (cf. Corollary 2.6),
     - $\tilde{\Lambda}_h^{n,t}$ for $t \in (t^n, t^{n+1}]$ (cf. section 5.1),
     - $\tilde{R}_{\Lambda,j}^n := \int_{T_j} |\widetilde{u}_j^{n+1} - \tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1})|$.
  4. Compute error indicator for interval $(t^n, t^{n+1}]$ on $\mathcal{T}^n$:
     $R^n := 2 \sum_{j \in J^n} \rho_j^n (R_{T,j}^n + R_{S,j}^n + \tilde{R}_{\Lambda,j}^n)$.
  5. Refine grid $\mathcal{T}^n \to \tilde{\mathcal{T}}^n$, and project $\tilde{\Lambda}_h^{n,t}$ for $t \in (t^n, t^{n+1}]$ onto $\tilde{\mathcal{T}}^n$.
- **while** $R^n > \mathrm{TOL}^n$
- define $\tilde{\mathcal{T}}^{n+1}$ by coarsening $\tilde{\mathcal{T}}^n$ so that
  $R^n + 2 \sum_{j \in \tilde{J}^n} \rho_j^n (\int_{T_j} |\tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1}) - \Pi^{n \to n+1} \tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1})|) < \mathrm{TOL}^n$.
- define $\tilde{\Lambda}_h^{n+1,t^{n+1}} := \Pi^{n \to n+1} \tilde{\Lambda}_h^{n,t^{n+1}}$ and $\tilde{\Lambda}_h^{n+1,t}$ for $t \in (t^{n+1}, t^{n+2}]$ on $\tilde{\mathcal{T}}^{n+1}$ using $\tilde{\Lambda}_h^{n,t^n}$.

The algorithm is based on the assumption that

$$\begin{aligned} &K_1 h_j + K_2 \max_{k\in\{j,l\in N(j)\}} ||\overline{\tilde{\Lambda}_h^{n,t} u_k^n} - \tilde{\Lambda}_h^{n,t} u_k^n||_{L^\infty((t^n,t^{n+1})\times T_k)} \\ \le\, &K_1 h_j + K_2 \max_{k\in\{j,l\in N(j)\}} ||\overline{\Lambda_h^{n,t} u_k^n} - \Lambda_h^{n,t} u_k^n||_{L^\infty((t^n,t^{n+1})\times T_k)}. \end{aligned}$$

With the restrictive choice $\tilde{\Lambda}_h^{n,t}(v) = \overline{v}$ we have $\max_k ||\overline{\tilde{\Lambda}_h^{n,t} u_k^n} - \tilde{\Lambda}_h^{n,t} u_k^n||_{L^\infty} = 0$, and therefore $\rho_j^n = K_1 h_j$, as in the first-order case. In fact, with this limiting operator the DG scheme reduces to the first-order finite volume scheme for which the convergence of the error indicator can be shown rigorously for $h \to 0$. Therefore, with a suitable choice of $\mathcal{T}^n$ the iteration (1)–(5) always terminates, and in practice our scheme requires hardly any iterations. Note that from our strategy it follows that

$$\sum_{j\in J^n} \rho_j^n \left(R_{T,j}^n + R_{S,j}^n + R_{\Lambda,j}^n \right) \le \mathrm{TOL}^n.$$

Thus, the error $||(u - \widetilde{u}_h)(T_{\max})||_{L^1(B_R(x_0))}$ is bounded by some prescribed tolerance TOL which satisfies $\sum_n \mathrm{TOL}^n \le \mathrm{TOL}$. This is summarized in the following lemma.

LEMMA 5.1. *Let η_h denote the global error estimator from Theorem* 2.5*, and let a prescribed tolerance TOL be given. If the computational mesh is adapted due to the strategy described above using the methods described in the following subsections, then it follows that $\eta_h \le \mathrm{TOL}$.*

Thus, the adaptive strategy together with Theorem 2.5 yields a rigorous control on the error $||(u - \widetilde{u}_h)(T_{\max})||_{L^1(B_R(x_0))}$.

5.1. Choice of the projection operator in one space dimension. Our algorithm is based on an initial guess for the projection operator, which we denote with $\tilde{\Lambda}_h^{n,t}$. It is used to define the final projection operators $\Lambda_h^{n,t}$ in the generalized RK-DG method of Definition 2.4 or 4.1. We now introduce two different approaches for constructing $\tilde{\Lambda}_h^{n,t}$. The first approach is based on a restriction of the gradients of the approximate solution based on the error estimate in Corollary 2.6. The second approach is a p-adaptive projection where the local polynomial degree of the approximate solution is chosen in accordance with the error indicators in Corollary 2.6. Together with the local mesh adaption strategy that we will discuss in the next subsection, both methods are then used in an hp-adaptive manner. The operator $\tilde{\Lambda}_h^{n,t}$ is always constructed on a fixed mesh $\mathcal{T}^n$ and then prolonged/restricted onto a modified mesh in such a way that refinement of cells does not change the projected function.

The goal of the choice of the projection $\tilde{\Lambda}_h^{n,t}$ is twofold. On the one hand, we need a projection or limiting of the solution in order to stabilize the scheme. On the other hand, the factor ρ_j^n should be of the order of h_j. Together with a reasonable assumption on the boundedness of the residual terms $R_{T,j}^n, R_{S,j}^n, R_{\Lambda,j}^n$, this requirement guarantees the convergence of the error estimate η_h for $h \to 0$. We expect that in regions where the solution u is smooth the stated requirement is met even if we choose $\Lambda_j^{n,t} = id$, whereas near discontinuities the term $||\overline{u_h} - u_h||_{L^\infty}$ grows without bound. The projection should therefore be active only on mesh cells near discontinuities. Thus, we suggest defining a projection parameter λ_h as

$$\lambda_j^n(t) := \tilde{\lambda}_j^n + \frac{t - t^n}{\Delta t^n} \tilde{\lambda}_j^{n+1}, \qquad \tilde{\lambda}_j^n := \frac{h_j}{\left(h_j + \frac{1}{\Delta t^n} \left(R_{T,j}^n + R_{S,j}^n \right) \right)^{\frac{p+2}{p+1}}} \tag{5.1}$$

and ensuring that our projection operators yield a solution with the property

$$||\overline{\widetilde{u}_j^n(\cdot,t)} - \widetilde{u}_j^n(\cdot,t)||_{L^\infty(T_j)} \leq \lambda_j^n(t). \tag{5.2}$$

We expect that the upper bound λ_j^n is of order h_j near discontinuities, whereas it is of order $h_j^{-\frac{1}{p+1}}$ in smooth regions. As the error $||\overline{u_j^n(\cdot,t)} - u_j^n(\cdot,t)||_{L^\infty(T_j)}$ is expected to converge with order h_j in smooth regions and to remain constant near discontinuities, the upper restriction leads to a projection of the solution near discontinuities, and at the same time $||\overline{\widetilde{u}_j^n(\cdot,t)} - \widetilde{u}_j^n(\cdot,t)||_{L^\infty(T_j)}$ would be at least of order $\mathcal{O}(h_j)$. The bound (5.2) dictates how to construct the operator $\tilde{\Lambda}_j^{n,t}$ from a given projection $\Lambda_j^{n,t}$.

In what follows we propose two possible choices for the projection $\tilde{\Lambda}_h^{n,t}$ in one space dimension, which both satisfy the upper bound (5.2) for given limiter function λ_h. The resulting projections fall into the class of moment-limiters as introduced in [3]. In order to define the methods, let φ_l, $l = 0, \ldots, p_{\max}$, denote the orthogonal basis of Legendre polynomials on the cell $T_j := (x_{j-1/2}, x_{j+1/2})$ such that $\varphi_l \in \mathbb{P}_l(T_j)$. We then have $\varphi_0 = 1$ and thus $\overline{u_j^n(\cdot,t)} = u_{j,0}^n(t)$ with the local expansion $u_j^n(x,t) = \sum_{l=0}^{p_{\max}} u_{j,l}^n(t)\varphi_l(x)$.

5.1.1. P-adaptive method in one dimension. Let $1 \leq l^* \leq p_{\max}$ denote the maximal index such that

$$\sum_{l=1}^{l^*} u_{j,l}^n(t^n)\varphi_l(x) \leq \lambda_j^n(t^n) \quad \text{for all } x \in T_j.$$

Then, the p-adaptive projection on the cell T_j is defined through

$$\tilde{\Lambda}_j^{n,t}(u_h(\cdot,t)) := \sum_{l=0}^{l^*} u_{j,l}^n(t)\varphi_l(x). \tag{5.3}$$

5.1.2. Derivative-restriction method in one dimension. For fixed $t \in [t^n, t^{n+1}]$ let $1 \leq l^* \leq p_{\max}$ denote the maximal index such that

$$\sum_{l=1}^{l^*} u_{j,l}^n(t)\varphi_l(x) \leq \lambda_j^n(t) \quad \text{for all } x \in T_j.$$

In contrast to the p-adaptive strategy, we allow that the derivative of degree l^*+1 is not switched off completely but is reduced in such a way that the bound (5.2) still holds:

$$\tilde{\Lambda}_j^{n,t}(u_h(\cdot,t)) := \sum_{l=0}^{l^*} u_{j,l}^n(t)\varphi_l(x) + \widetilde{u}_{j,l^*+1}^n(t)\varphi_{l^*+1}(x), \tag{5.4}$$

where $\widetilde{u}_{j,l^*+1}^n(t)$ is given as

$$\widetilde{u}_{j,l^*+1}^n(t) := \operatorname{sgn}(u_{j,l^*+1}^n(t)) \ \min\left\{ |u_{j,l^*+1}^n(t)|, \lambda_j^n(t) - \left\| \sum_{l=0}^{l^*} u_{j,l}^n(t)\varphi_l \right\|_{L^\infty(T_j)} \right\}.$$

After the refinement of a cell T_j or the coarsening of a set of cells $(T_{j_k})_{k=1}^l$ the operator $\tilde{\Lambda}_h^{n,t}$ has to be modified to operate on the new grid. Both of the choices described above require the definition of λ_j^n on the new grid cells:

- *refinement* $(T_j \to (T_{j_k})_{k=1}^l)$: let $\lambda_{j_k}^n = \frac{1}{l}\lambda_j^n$;
- *coarsening* $((T_{j_k})_{k=1}^l \to T_j)$: let $\lambda_j^n = \sum_{k=0}^l \lambda_{j_k}^n$.

5.2. Adaptive strategy for local mesh refinement. In this subsection we describe an adaptive strategy for local mesh adaptation that is based on an equidistribution strategy of the error indicator η_h of Theorem 2.5. However, there are two significant modifications of the equidistribution strategy when compared with the strategy presented in [25] or [28]. The first modification is that we distribute the error only among those elements that significantly contribute to the error, and secondly we also incorporate the projection error from mesh coarsening into the adaptive strategy. These modifications are of minor importance for smooth solutions but result in quite different adaptive convergence behavior for problems with discontinuities. In detail, the new adaptive strategy is given as follows.

Using the notation of Corollary 2.6, let us define for a prescribed tolerance TOL the local error indicators η_j^n for some given $\Theta \in (0,1)$ as

$$\eta_j^0(M) := \frac{M}{(1-\Theta)\ \mathrm{TOL}}\eta_{0,j}, \qquad \eta_j^n(M) := \frac{2\ T_{\max}\ M}{\Delta t^n\ (\Theta\ \mathrm{TOL}^n)^2}\rho_j^n(R_{T,j}^n + R_{S,j}^n + \tilde{R}_{\Lambda,j}^n),$$

where we again have used the abbreviation $\tilde{R}_{\Lambda,j}^n := \int_{T_j} |\overline{\widetilde{u}_j^{n+1}}(t^{n+1}) - \tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1})|$. The operator $\tilde{\Lambda}_h^{n,t^{n+1}}$ is again a suitable projection operator defined on the mesh $\mathcal{T}_n$ used to stabilize the scheme and to guarantee that ρ_j^n converges for $h_j \to 0$. The adaptive strategy at the time t^{n+1} is then given as follows. For $\alpha \in (0, 0.5)$, $M \in \mathbb{N}$ let us define the set of significant elements as

$$I_s^n(M) := \{j \in I^n |\ \eta_j^n(M) \geq \alpha\},$$

and let M^n implicitly be defined through $M^n = |I_s^n(M^n)|$, where $|\cdot|$ denotes the cardinality of the set. We define ε^n as

$$\varepsilon^n := \sum_{j \in I^n \setminus I_s^n(M^n)} \eta_j^n(1)$$

and suppose that α is chosen small enough to ensure $\varepsilon^n \in (0, 0.5)$. We then define for given $\beta \in (0,1)$ the sets

$$I_r := \{T_j |\ \eta_j^n(M^n) \geq (1-\varepsilon^n)\}, \qquad \tilde{I}_c := \{T_j |\ \eta_j^n(M^n) \leq \beta(1-\varepsilon^n)\}$$

and mark all elements of the set I_r for refinement and those in the set $\tilde{I}_c$ as candidates for coarsening. Coarsening of the mesh leads to an additional projection error of the approximate solution that contributes to the indicator $R_{\Lambda,j}^n$. We split this error into two parts according to $R_{\Lambda,j}^n \leq \tilde{R}_{\Lambda,j}^n + R_{c,j}^n$ with $R_{c,j}^n := \int_{T_j} |\tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1}) - \Pi^{n\to n+1}\tilde{\Lambda}_h^{n,t^{n+1}} u_j^n(t^{n+1})|$, using the operator $\Pi^{n\to n+1}$ to denote the L^2-projection from one grid to another. We calculate the error terms $\eta_{c,j}^n(M^n) := \eta_j^n(M^n) + \frac{2\ T_{\max}\ M}{\Delta t^n\ (\Theta\ \mathrm{TOL}^n)^2}\rho_j^n R_{c,j}^n$ for all $T_j \in \tilde{I}_c$, define the updated set I_c as

$$I_c := \{T_j \in \tilde{I}_c |\ \eta_{c,j}^n(M^n) \leq \beta(1-\varepsilon^n)\},$$

and mark all elements of the set I_c for coarsening. Finally, all elements in the set I_r are refined, until the refinement set I_r is an empty set. Then, all elements of the set I_c are coarsened.

5.3. Evaluation of the semidiscrete error indicators. In Theorem 2.5 we give an a posteriori error estimate for the semidiscrete DG method from Definition 2.4. Conventionally, Runge–Kutta time discretizations that are used in practice provide values only for the approximate solution at the discrete time steps t^n. Thus, our error indicators could not be evaluated continuously in time. In order to give a suitable interpretation of the fully discrete Runge-Kutta solution (see Definition 4.1) we use the natural continuous extension as defined through (4.4). Thus, the approximate fully discrete solution is continuous in time on each time slab $[t^n, t^{n+1}]$, and all contributions of the error indicators $\eta_{i,j}^n$ of Theorem 2.5 are computable.

6. Adaptive numerical experiments in one space dimension. In this section we numerically examine the RK-DG methods defined in Definition 4.1 together with the projections from subsection 5.1 and the local adaptive grid refinement from subsection 5.2. We study the convergence behavior of the estimator η_h from Theorem 2.5, as well as the convergence of the error itself. As test problems, we look at a linear transport problem with smooth and discontinuous regions in the solution. This example is a scalar prototype for contact discontinuities. As a second very challenging example we choose the Buckley–Leverett equation. Here, the flux function is nonconvex, and thus the solution consists of compound waves. For such fluxes there exist several weak solutions that are compatible with a single entropy, but only one of those solutions is the unique entropy solution in the Kruzkov sense. It is well known that higher-order numerical schemes may have difficulties in selecting this unique Kruzkov entropy solution (see also [2] and [26]). In order to compare the efficiency of the selected RK-DG methods we are going to plot the error estimators and errors against the overall number of grid cells $M_{\text{tot}}(\mathcal{T}_h) := \sum_{n=1}^{N} \sum_{T_j \in \mathcal{T}_h^n} 1$. As M_{tot} is available for uniform refined grids, as well as for adaptively refined grids, and as M_{tot} is proportional to the degrees of freedom for fixed polynomial degree p, this is a good way to compare our adaptive method with standard approaches on uniform grids. Furthermore, let us define the experimental order of convergence of a grid-dependent quantity e_h as

$$EOC(e_{H\to h}) := \log\left(\frac{e(\mathcal{T}_H)}{e(\mathcal{T}_h)}\right) \log^{-1}\left(\frac{M_{\text{tot}}(\mathcal{T}_h)}{M_{\text{tot}}(\mathcal{T}_H)}\right). \tag{6.1}$$

Note that a convergence rate $\mathcal{O}(h^p)$ on uniform grids in one space dimension corresponds to $EOC(e_{2h\to h}) = \frac{p}{2}$, as a refinement from grids with cells of size $2h$ to grids with cells of size h leads to two times the number of grid cells per time step and two times the number of time steps. This yields $M_{\text{tot}}(\mathcal{T}_h) = 4M_{\text{tot}}(\mathcal{T}_{2h})$.

6.1. Linear transport equation. As a first numerical example we look at the linear transport equation

$$\partial_t u + a\partial_x u = 0, \qquad u(\cdot, 0) = u_0(\cdot)$$

with the constant transport velocity $a = 2$. For fixed initial data the solution u is then given by $u(x,t) = u_0(x - at)$. We study the setting on $[-1,1] \times [0,2]$ with periodic boundary conditions for the following nonsmooth initial data:

$$u_0(x) := \begin{cases} 1 - (x+1.5)^2, & \text{for } x < -0.5, \\ \sin((x+0.5)\pi), & \text{for } -0.5 \le x < 0.5, \\ 1 - (x-0.5)^2, & \text{for } 0.5 \le x. \end{cases}$$

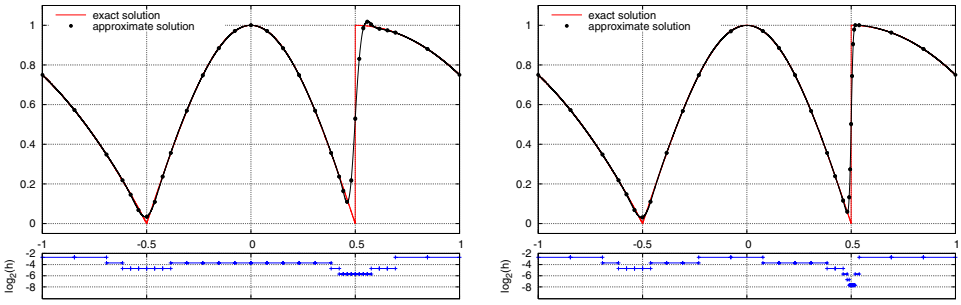

FIG. 6.1. *Comparison of the approximate solutions obtained with the* p-adaptive *method (left-hand side) and the* derivative-restriction *method (right-hand side) on adaptively refined grids with* $p_{\max} = 2$. *For both computations we used the prescribed tolerance* $TOL = 0.5$ *and* $T_{\max} = 2.0$.

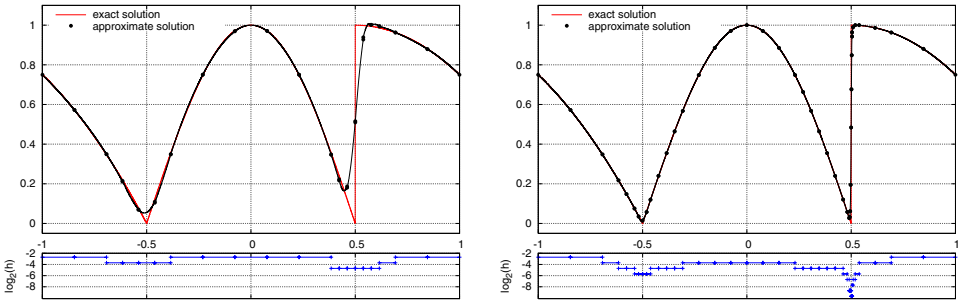

FIG. 6.2. *Comparison of the approximate solutions obtained with the* derivative-restriction *method for* $p_{\max} = 2$ *with* $TOL = 1$ *(right-hand side) and* $TOL = 0.25$ *(left-hand side) on adaptively refined grids at* $T_{\max} = 2.0$.

Since $x - 2a = x - 4$ is equal to x on a $[-1, 1]$ periodic domain it follows that $u(x, 2) = u_0(x)$. We first compare the two projection methods described in subsection 5.1 for $p_{\max} = 2$ (see Figure 6.1). All results are computed with the adaptation strategy from subsection 5.2 with TOL = 0.5. In Figure 6.1 both the exact solution and the approximate solution are shown together with the grid density function.

The comparison of the projection methods for fixed maximal polynomial degree shows that both methods lead to a good resolution of the smooth region as well as of the discontinuity. The *p-adaptive* method (Figure 6.1(left)) produces slight overshoots in front of the discontinuity, but these decrease on finer grids. The refinement strategy together with the *derivative-restriction* method produces a slightly finer grid in the region of the discontinuity, whereas the grid is coarser in the smooth regions.

Results with $p_{\max} = 2$ and the *derivative-restriction* method for different values of TOL are shown in Figure 6.2. It can be clearly seen that the grid is hardly refined in the smooth regions of the solution, whereas the fineness in the region of the discontinuity and also around the kink increases for smaller tolerance values. The coarsest grid level corresponds to a grid with 13 cells. With TOL = 1 only seven cells are added to the final grid—two in the region of the kink and five in the shock region. With TOL = 0.25, 30 cells are added—about 50% of which are located in the shock region.

A comparison of the efficiency of our new method on uniform grids for $p_{\max} = 0, 1, 2$ is shown in Figure 6.3. The increase in efficiency due to an increase of the

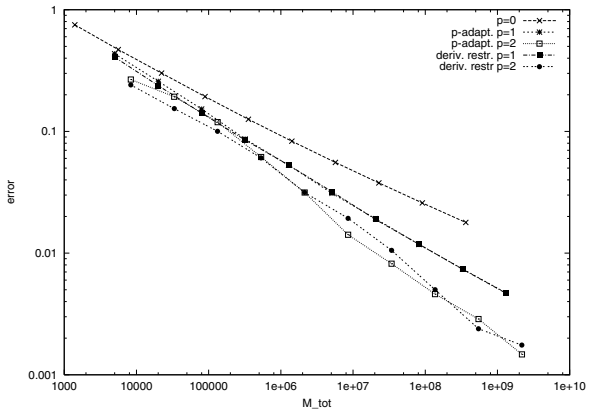

FIG. 6.3. *Convergence study for our new schemes for the linear transport problem on uniformly refined grids.*

	derivative-restriction method		*p-adaptive* method	
$p_{\max}$	$EOC(e_{H\to h})$	$EOC(\eta_{H\to h})$	$EOC(e_{H\to h})$	$EOC(\eta_{H\to h})$
0	0.292	0.193	0.292	0.193
1	0.431	0.228	0.476	0.368
2	0.544	0.342	0.515	0.450

polynomial degree can be clearly seen. Furthermore, the difference between our two projection methods is hardly significant. For $p_{\max} = 1$ there is hardly any difference, and also for $p_{\max} = 2$ there is no clear indication of which method is the more efficient.

Next we compare our adaptive schemes for $p_{\max} = 0, 1, 2$. In Table 6.1 the convergence rates as defined in (6.1) are given for the error $EOC(e_{H\to h})$ and the estimator $EOC(\eta_{H\to h})$. The error and the estimator show better convergence rates for higher polynomial degree. The convergence rates of the error are even better than what we expect to be optimal for discontinuous solutions on uniform computational grids. On uniform grids with mesh size h the optimal rate is supposed to be $h^{\frac{p_{\max}+1}{p_{\max}+2}}$, which corresponds to $EOC(e_{H\to h}) = \frac{1}{2}\frac{p_{\max}+1}{p_{\max}+2}$ (i.e., $0.250, 0.333, 0.375$ for $p_{\max} = 0, 1, 2$). Although the convergence rate of the indicator differs from the convergence rate of the error, the ratio between the prescribed tolerance and the indicator is about constant. In the optimal case this ratio should be close to one. Our adaptive strategy leads to an efficiency index of about $0.5 - 0.8$.

6.2. Buckley–Leverett problem. As a second example we look at the Buckley–Leverett equation, which is a one dimensional model for two-phase flow in porous media where capillary pressure effects are neglected. The unknown variable $u : (-1, 1) \times (0, 0.4) \to \mathbb{R}$ is the saturation of the wetting phase within a two-phase mixture. It satisfies the nonlinear conservation law

$$u_t + \partial_x f(u) = 0 \text{ on } (-1, 1) \times (0, 0.4), \qquad u(\cdot, 0) = u_0 \text{ on } (-1, 1),$$

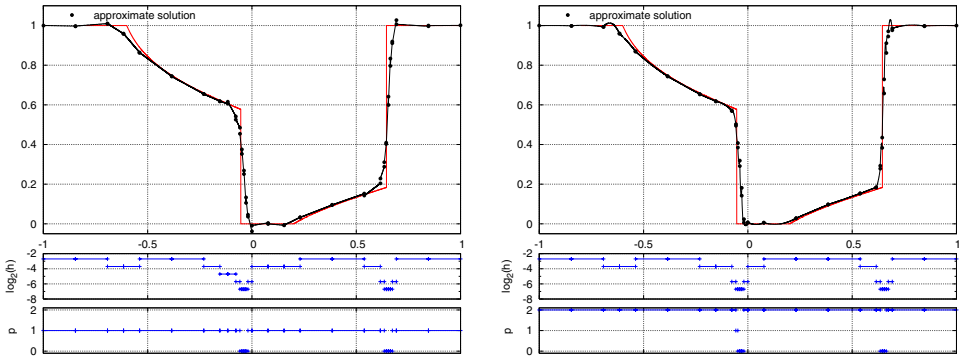

FIG. 6.4. *Comparison of the approximate solutions obtained with the* derivative-restriction *method on adaptively refined grids with* $p_{\max} = 1$ *(left) and* $p_{\max} = 2$ *(right) with* $TOL = 0.5$ *and* $T_{\max} = 0.4$.

where the fractional flow rate f is given as $f(s) = \frac{u^2}{u^2 + \frac{1}{2}(1-u)^2}$. We look at this problem for the following initial data:

$$u_0(x) := \begin{cases} 1 & \text{for } x < -0.6,\ 0.2 \le x, \\ 0 & \text{for } -0.6 \le x < 0.2. \end{cases}$$

Thus, the solution of our Buckley–Leverett problem consists of the solution of two distinct Riemann problems for t smaller than some critical time $T^* > 0.4$. The solution of each Riemann problem is a composed wave consisting of a rarefaction wave and an attached shock.

In Figure 6.4 we plot the exact solution together with the approximation using our adaptive strategy for $p_{\max} = 1, 2$. Since the structure of the solution away from the discontinuities is far simpler than in the advection problem studied above, the advantage of the quadratic ansatz functions is not evident. The grid density function hardly depends on the polynomial degree since almost all grid points are located in the shock regions. Only the kinks at the beginning of the rarefaction waves lead to additional slight refinement. Since the highest grid resolution produced by our refinement strategy is the same for $p_{\max} = 1$ and $p_{\max} = 2$ and the approximation error is dominated by the shocks, the $p_{\max} = 2$ version of the DG method does not lead to a more efficient scheme, as can be seen from Figure 6.5. This must be attributed to the smaller CFL stability restriction required in the higher-order schemes and the resulting smaller time steps. A more complicated structure of the solution—as can be found only in systems in higher space dimension—is required to demonstrate the advantage of an *hp*-adaptive strategy for nonlinear conservation laws with discontinuous solutions.

The results so far show that our adaptive strategy and our projection methods based on the error estimate from Theorem 2.5 lead to good schemes for both linear and nonlinear test problems. We conclude our numerical experiments with results demonstrating the advantage of including the coarsening error in the indicator. Results computed with and without using this "jump" indicator are shown in Figure 6.6. Including the error due to coarsening leads to a higher grid resolution around the kink at the left side of the rarefaction waves. Without this indicator the grid is coarsened to such a degree that the rarefaction wave is not sufficiently resolved and the convergence rate of the adaptive scheme is severely reduced.

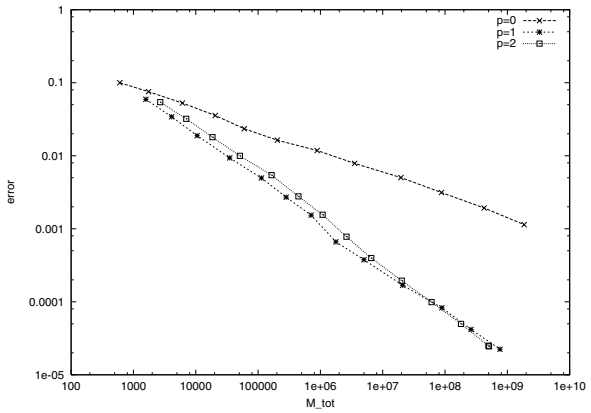

FIG. 6.5. *Convergence study for the* derivative-restriction *approximation of the Buckley–Leverett problem on adaptively refined grids.*

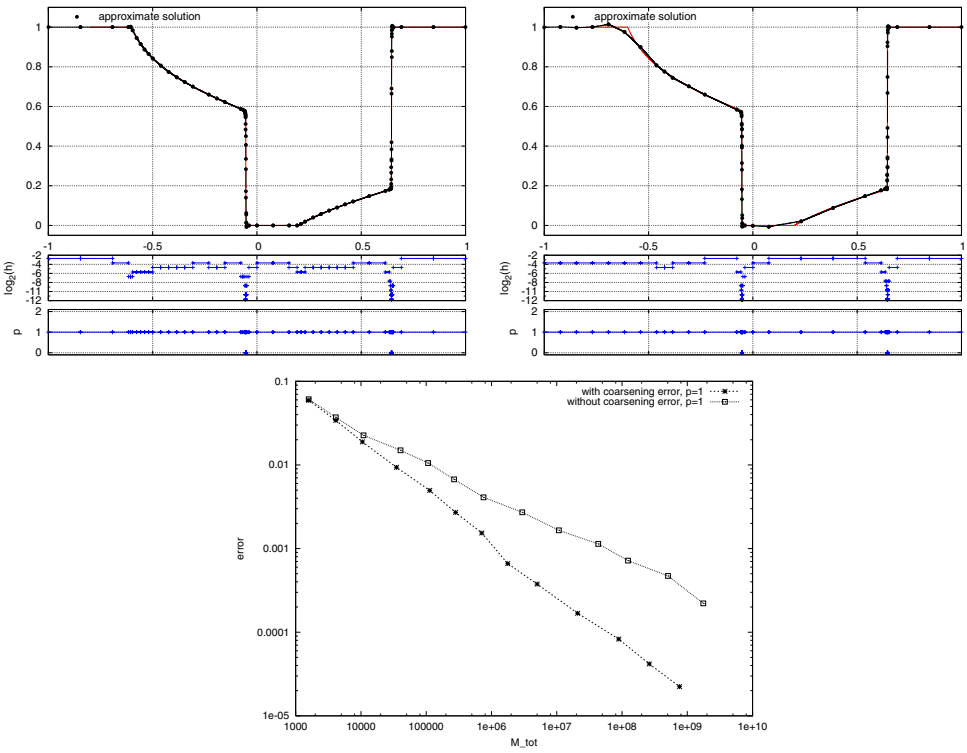

FIG. 6.6. *Comparison of the new adaptive* derivative-restriction *scheme with (top left) and without (top right) incorporated coarsening projection error. In the top row the solutions are plotted at* $T_{\max} = 0.4$ *with* $TOL = 0.125$. *In the bottom figure the error is plotted versus* M_{tot} *for the* derivative-restriction *scheme with and without incorporated coarsening projection error.*

6.3. Local comparison of error indicator and error. In this subsection we compare the local distribution of the error indicator values $(\rho_j^n(R_{T,j}^n + R_{S,j}^n))^{1/2}$, $j \in J^n$, from the a posteriori error estimate in Corollary 2.6 with the distribution of the local L^1-error $||u(t^n) - u_h^n||_{L^1(T_j)}$, $j \in J^n$. We compare the local distribution of

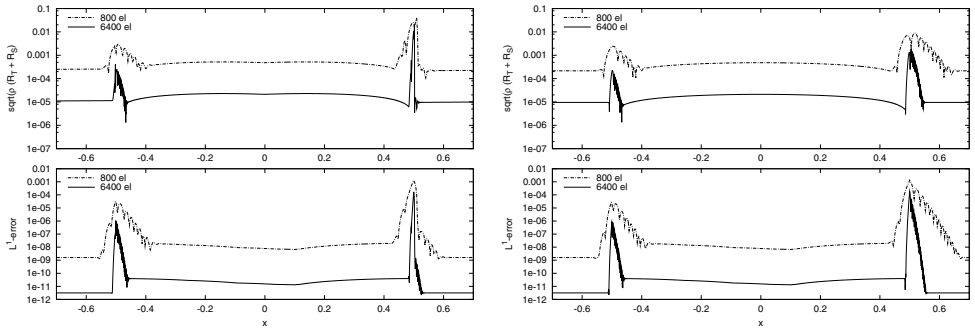

FIG. 6.7. *Comparison of the local indicator values for the limiter of Cockburn and Shu (left) and the p-*adaptive *method (right) for the linear transport problem. The diagrams on the top show the local distribution of the indicator values on uniform grids with* 800 *and* 6400 *elements, while the diagrams at the bottom give the corresponding distribution of the exact local* L^1*-error.*

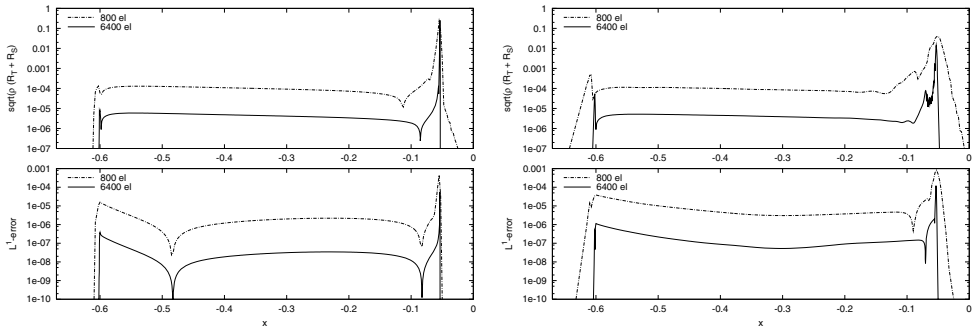

FIG. 6.8. *Comparison of the local indicator values for the limiter of Cockburn and Shu (left) and the p-* adaptive *method (right) for the Buckle–Leverett problem. The diagrams on the top show the local distribution of the indicator values on uniform grids with* 800 *and* 6400 *elements, while the diagrams at the bottom give the corresponding distribution of the exact local* L^1*-error.*

the indicator and exact error for the *p-adaptive* scheme and the method of Cockburn and Shu (see [10, 7]). In Figure 6.7 the comparison is given for the linear transport problem from subsection 6.1 on the interval $(-0.67, 0.67)$, while in Figure 6.8 the comparison for the Buckley–Leverett problem is shown on the interval $(-0.7, 0)$. The underlying computations were done with $p_{\max} = 2$.

From the comparison it can be seen that the local distribution of the error indicator captures very well the behavior of the exact error for both methods. In addition, it can be seen that the error and the indicator decrease with the expected higher-order rate within the smooth regions and show a reduction of the decrease rate near discontinuities or kinks. A more detailed analysis of the convergence behavior of the indicators within the regions of discontinuity reveals that the indicator for the method of Cockburn and Shu does not decrease within the few elements that form the discontinuity, while the indicator for the *p-adaptive* method does decrease significantly. As the local indicator quantities are L^1-quantities, we expect also that the global estimator is not asymptotically reduced for the method of Cockburn and Shu, and thus we have to use the indicators with great care to steer grid adaptivity for this method, as there would be no stopping criteria for the mesh refinement within this shock region. On the other hand, the indicator may be used outside the shock region

without problems and thus could be used in combination with a restriction on the maximal refinement level within the shock regions.

7. Conclusion. We have proved an a posteriori error estimate for a class of semidiscrete discontinuous Galerkin methods on adaptively refined computational meshes (see Theorem 2.5 and section 3). The estimate provides a rigorous error control and is used for the design of stabilizing limiting projection operators (see section 5.1) as well as for the design of a local grid adaptation strategy (see section 5.2). Numerical examples in one space dimension demonstrate that the resulting adaptive schemes converge with higher order compared with the standard first-order method. In addition, it was shown that the error estimator η_h from the a posteriori Theorem 2.5 converges with higher order for higher-order methods. The analysis of the more involved fully discrete case needs additional new ideas and is therefore left for further study. The application of the principle ideas to the multidimensional case and to systems of conservation laws is of special importance and will be the subject of future work. For first results in two space dimensions that show a very nice behavior of the resulting *hp*-adaptive schemes, we refer to [14].

Acknowledgment. We thank Eitan Tadmor for the hint about the existence of the work on NCE Runge–Kutta schemes.

VARIATIONAL MULTISCALE ANALYSIS: THE FINE-SCALE GREEN'S FUNCTION, PROJECTION, OPTIMIZATION, LOCALIZATION, AND STABILIZED METHODS*

T. J. R. HUGHES† AND G. SANGALLI‡

Abstract. We derive an explicit formula for the fine-scale Green's function arising in variational multiscale analysis. The formula is expressed in terms of the classical Green's function and a projector which defines the decomposition of the solution into coarse and fine scales. The theory is presented in an abstract operator format and subsequently specialized for the advection-diffusion equation. It is shown that different projectors lead to fine-scale Green's functions with very different properties. For example, in the advection-dominated case, the projector induced by the H_0^1-seminorm produces a fine-scale Green's function which is highly attenuated and localized. These are very desirable properties in a multiscale method and ones that are not shared by the L^2-projector. By design, the coarse-scale solution attains optimality in the norm associated with the projector. This property, combined with a localized fine-scale Green's function, indicates the possibility of effective methods with local character for dominantly hyperbolic problems. The constructs lead to a new class of stabilized methods, and the relationship between H_0^1-optimality and the streamline-upwind Petrov-Galerkin (SUPG) method is described.

Key words. multiscale, advection-diffusion

1. Introduction.

The variational multiscale (VMS) method [12, 13] was introduced as a framework for incorporating missing fine-scale effects into numerical problems governing coarse-scale behavior. It has provided a rationale for stabilized methods and a platform for the development of new methods (see, e.g., [11, 14, 15, 16, 18] for application to turbulence modeling). The fundamental mathematical object in the method is the so-called *fine-scale Green's function*, introduced in [13]. Although it is a simple matter to characterize coarse-scale and fine-scale subspaces, not much is known about the fine-scale Green's function. In this paper, we study the fine-scale Green's function and present a formula for explicitly computing it from the classical Green's function. This is accomplished by observing that the decomposition of a function into a sum of coarse-scale and fine-scale components is uniquely specified by identifying a projector from the space of all scales onto the coarse-scale subspace. Different projectors produce different decompositions. The problem for the fine-scale Green's function is then posed in terms of the fine-scale subspace. Compared with the problem for the classical Green's function, this amounts to a constrained formulation. The constraint can be released by invoking the Lagrange multiplier method and the unconstrained problem can be solved in terms of the classical Green's function and the projector. The fine-scale Green's function enjoys orthogonality relations with respect

to the projector. If a scalar product is introduced with a corresponding projector, the coarse-scale solution of the original problem is the optimal approximation in terms of the induced norm. The theory summarizing these ideas is presented in section 2 in an abstract operator format for a general linear isomorphism.

These ideas are applied to the advection-diffusion equation in section 3. The fine-scale Green's function is explicitly calculated in one dimension for linear, quadratic, and cubic finite elements when the projector is defined by the H_0^1-seminorm. In this case, the fine-scale Green's function is local in that it is confined to individual elements and is not coupled from one element to another, even in advection-dominated cases. This is a highly desirable property in multiscale analysis and in complete contrast with the classical Green's function which exhibits global support in advection-dominated cases. It also suggests that efficient, approximate, multiscale methods possessing local character may be possible for dominantly hyperbolic phenomena. On the other hand, selecting the L^2-projector results in a fine-scale Green's function with global coupling. These results show clearly that the choice of projector is of key importance in the development of a multiscale method.

The fine-scale Green's function becomes increasingly complicated as the order of the coarse-scale space is increased. However, it is observed that due to the orthogonality properties of the fine-scale Green's function, it only interacts with the highest-order polynomial term in the residual. This means that for a kth-order coarse-scale space, the fine-space Green's function modification to the coarse-scale equation can be replaced by an equivalent stabilization term involving a computable, elementwise constant (i.e., a "τ" in the notation of stabilized methods) and derivatives of the residual and weighting operator of order $k-1$. Remarkably, the modification reduces to elementwise constant terms requiring no quadrature despite the complexity of the fine-scale Green's function. This results in optimal higher-order methods of extraordinary simplicity.

To assess the situation in multiple dimensions, the two-dimensional advection-diffusion equation is studied. Here, rather than proceeding analytically, numerical procedures involving very fine meshes are utilized to determine Green's functions. As in the one-dimensional case, the classical Green's function exhibits global character with support in the form of a tail surrounding the upwind characteristic through the point of application of the Dirac mass. When advection-dominated, this tail is not attenuated with distance. However, the fine-scale Green's function for the H_0^1-projector is highly attenuated under the same circumstances and is essentially confined to a small number of elements (in the coarse-scale space) surrounding the point of application of the Dirac mass. The L^2-projector engenders a fine-scale Green's function which is not localized, and one concludes that the main observations made for the one-dimensional case are essentially true in two dimensions.

The H_0^1-projector produces a method which is highly localized and attains an optimal approximation in the H_0^1-seminorm, a combination of desirable properties. It is also noted that the modification it introduces to a classical Galerkin formulation involves an additional stabilization term in which the coarse-scale residual is weighted by the fine-scale Green's function convolved only with the advective part of the operator, i.e., the diffusive operator does not appear in the weighting. These are features that the H_0^1-optimal method has in common with streamline-upwind Petrov-Galerkin (SUPG) [9].

In section 4 we draw conclusions.

2. The abstract framework.

2.1. The abstract problem. Let V be a Hilbert space endowed with a norm $\|\cdot\|_V$ and a scalar product $(\cdot,\cdot)_V$. Let V^* be the dual of V, and let ${}_{V^*}\langle\cdot,\cdot\rangle_V$ be the pairing between them. Let $\mathcal{L}: V \to V^*$ be a linear isomorphism. Given $f \in V^*$, we consider the abstract problem of finding $u \in V$ such that

$$\mathcal{L}u = f. \tag{2.1}$$

The variational formulation of (2.1) is find $u \in V$ such that

$${}_{V^*}\langle \mathcal{L}u, v\rangle_V = {}_{V^*}\langle f, v\rangle_V \qquad \forall v \in V. \tag{2.2}$$

The solution u can be expressed as $u = \mathcal{G}f$, where $\mathcal{G}: V^* \to V$ is the Green's operator, i.e., $\mathcal{G} = \mathcal{L}^{-1}$.

2.2. The variational multiscale formulation. Let $\bar{V}$ be a closed subspace of V, and let $\mathcal{P}$ be a linear projector onto $\bar{V}$; i.e., $\mathcal{P}^2 = \mathcal{P}$ and $\mathrm{Range}(\mathcal{P}) = \bar{V}$. We assume $\mathcal{P}$ to be continuous in V. Since $\mathcal{P}\bar{v} = \bar{v}$ for all $\bar{v} \in \bar{V}$, we have the obvious inf-sup condition

$$\inf_{\bar{v}\in\bar{V}} \sup_{w\in V} \frac{(\mathcal{P}w, \bar{v})_V}{\|w\|_V \|\bar{v}\|_V} \geq 1. \tag{2.3}$$

We define $V' = \mathrm{Ker}(\mathcal{P})$, which is a closed subspace of V, thanks to the continuity of $\mathcal{P}$. As a consequence,

$$V = \bar{V} \oplus V'; \tag{2.4}$$

i.e., any $v \in V$ can be written uniquely as $v = \bar{v} + v'$, where $\bar{v} \in \bar{V}$ and $v' \in V'$: indeed, $\bar{v} = \mathcal{P}v$ and $v' = v - \mathcal{P}v$. In particular, we split the solution u of (2.1) as $u = \bar{u} + u'$. In the VMS approach, $\bar{V}$ represents the space of computable *coarse scales*, while V' contains the unresolved *fine scales*. The aim of the VMS approach is to obtain $\bar{u} = \mathcal{P}u$.

The variational formulation (2.2) splits into

$${}_{V^*}\langle \mathcal{L}\bar{u}, \bar{v}\rangle_V + {}_{V^*}\langle \mathcal{L}u', \bar{v}\rangle_V = {}_{V^*}\langle f, \bar{v}\rangle_V \qquad \forall \bar{v} \in \bar{V}, \tag{2.5}$$

$${}_{V^*}\langle \mathcal{L}\bar{u}, v'\rangle_V + {}_{V^*}\langle \mathcal{L}u', v'\rangle_V = {}_{V^*}\langle f, v'\rangle_V \qquad \forall v' \in V'. \tag{2.6}$$

We assume that (2.5) is a well-posed problem for $\bar{u}$ alone, meaning that it admits a unique solution $\bar{u} \in \bar{V}$ given u' and f. Analogously, we assume that (2.6) is well-posed for $u' \in V'$ given $\bar{u}$ and f. For that, we ask the inf-sup conditions for $\mathcal{L}$ on $\bar{V}$ and V'

$$\inf_{\bar{w}\in\bar{V}} \sup_{\bar{v}\in\bar{V}} \frac{{}_{V^*}\langle \mathcal{L}\bar{w}, \bar{v}\rangle_V}{\|\bar{w}\|_V \|\bar{v}\|_V} > 0 \quad \text{and} \quad \sup_{\bar{w}\in\bar{V}} \frac{{}_{V^*}\langle \mathcal{L}\bar{w}, \bar{v}\rangle_V}{\|\bar{w}\|_V} > 0 \quad \forall \bar{v} \in \bar{V}\backslash\{0\}, \tag{2.7}$$

$$\inf_{w'\in V'} \sup_{v'\in V'} \frac{{}_{V^*}\langle \mathcal{L}w', v'\rangle_V}{\|w'\|_V \|v'\|_V} > 0 \quad \text{and} \quad \sup_{w'\in V'} \frac{{}_{V^*}\langle \mathcal{L}w', v'\rangle_V}{\|w'\|_V} > 0 \quad \forall v' \in V'\backslash\{0\}. \tag{2.8}$$

If $\mathcal{L}$ is coercive on V, i.e., ${}_{V^*}\langle \mathcal{L}v, v\rangle_V \geq C\|v\|_V^2$ for $C > 0$ and for all $v \in V$, then (2.7)–(2.8) hold.

We associate with (2.6) the *fine-scale Green's operator* $\mathcal{G}': V^* \to V'$, which gives u' from the coarse-scale *residual* $f - \mathcal{L}\bar{u}$, i.e.,

$$u' = \mathcal{G}'(f - \mathcal{L}\bar{u}). \tag{2.9}$$

Having $\mathcal{G}'$, we can eliminate u' from (2.5), and we obtain the VMS formulation for $\bar{u}$:

$$ {}_{V^*}\langle \mathcal{L}\bar{u}, \bar{v}\rangle_V - {}_{V^*}\langle \mathcal{L}\mathcal{G}'\mathcal{L}\bar{u}, \bar{v}\rangle_V = {}_{V^*}\langle f, \bar{v}\rangle_V - {}_{V^*}\langle \mathcal{L}\mathcal{G}' f, \bar{v}\rangle_V \qquad \forall \bar{v} \in \bar{V}. \tag{2.10} $$

Because of (2.4), the formulation (2.10) admits a unique solution, which is precisely $\bar{u} = \mathcal{P}u$.

2.3. The fine-scale Green's operator. We denote by $\mathcal{P}^T : \bar{V}^* \to V^*$ the adjoint of $\mathcal{P}$, i.e.,

$$ {}_{V^*}\langle \mathcal{P}^T\bar{\mu}, v\rangle_V = {}_{\bar{V}^*}\langle \bar{\mu}, \mathcal{P}v\rangle_{\bar{V}} \qquad \forall v \in V,\ \bar{\mu} \in \bar{V}^*, $$

where $\bar{V}^*$ is the dual of $\bar{V}$ and ${}_{\bar{V}^*}\langle\cdot,\cdot\rangle_{\bar{V}}$ is the pairing between them.

In the next result we express $\mathcal{G}'$ in terms of $\mathcal{G}$ and $\mathcal{P}$.

THEOREM 2.1. *Under the assumptions of sections* 2.1 and 2.2*, we have*

$$ \mathcal{G}' = \mathcal{G} - \mathcal{G}\mathcal{P}^T(\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}\mathcal{P}\mathcal{G}, \tag{2.11} $$

$$ \mathcal{G}'\mathcal{P}^T = 0, \quad \textit{and} \quad \mathcal{P}\mathcal{G}' = 0. \tag{2.12} $$

Proof. Since (2.6) is a constrained problem, we can rephrase it making use of a Lagrange multiplier in mixed (unconstrained) form: Find $u' \in V$ and $\bar{\lambda} \in \bar{V}^*$ such that

$$ \mathcal{L}u' + \mathcal{P}^T\bar{\lambda} = r, \tag{2.13} $$

$$ \mathcal{P}u' = 0, \tag{2.14} $$

where $r = f - \mathcal{L}\bar{u}$. The well-posedness of (2.13)–(2.14), for any $r \in V^*$, is guaranteed by our previous assumptions. Indeed, following [2], we need (2.8) and the inf-sup condition for $\mathcal{P}$

$$ \inf_{\bar{\mu}\in\bar{V}^*} \sup_{w\in V} \frac{{}_{\bar{V}^*}\langle \bar{\mu}, \mathcal{P}w\rangle_{\bar{V}}}{\|\bar{\mu}\|_{\bar{V}^*}\|w\|_V}, $$

which is equivalent to (2.3) in this Hilbert space setting. From (2.13) we get $u' = \mathcal{G}(r - \mathcal{P}^T\bar{\lambda})$; substituting in (2.14) gives $\mathcal{P}\mathcal{G}r - \mathcal{P}\mathcal{G}\mathcal{P}^T\bar{\lambda} = 0$; the well-posedness of (2.13)–(2.14) guarantees the invertibility of $\mathcal{P}\mathcal{G}\mathcal{P}^T$; and hence we obtain $\bar{\lambda} = (\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}\mathcal{P}\mathcal{G}r$. Finally, using this in the expression for u' yields

$$ u' = (\mathcal{G} - \mathcal{G}\mathcal{P}^T(\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}\mathcal{P}\mathcal{G})r, \tag{2.15} $$

which gives (2.11).

From (2.11), we immediately have

$$ \mathcal{G}'\mathcal{P}^T = \mathcal{G}\mathcal{P}^T - \mathcal{G}\mathcal{P}^T(\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}(\mathcal{P}\mathcal{G}\mathcal{P}^T) = \mathcal{G}\mathcal{P}^T - \mathcal{G}\mathcal{P}^T = 0 $$

and

$$ \mathcal{P}\mathcal{G}' = \mathcal{P}\mathcal{G} - (\mathcal{P}\mathcal{G}\mathcal{P}^T)(\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}\mathcal{P}\mathcal{G} = \mathcal{P}\mathcal{G} - \mathcal{P}\mathcal{G} = 0, $$

which are (2.12). ∎

Using the expression (2.11) in (2.10), we see that the left-hand side of (2.10) is

$$ {}_{V^*}\langle \mathcal{L}\bar{u}, \bar{v}\rangle_V - {}_{V^*}\langle \mathcal{L}\mathcal{G}'\mathcal{L}\bar{u}, \bar{v}\rangle_V = {}_{\bar{V}^*}\langle (\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}\bar{u}, \bar{v}\rangle_{\bar{V}}\,. \tag{2.16} $$

As $(\mathcal{P}\mathcal{G}\mathcal{P}^T)^{-1}$ is obviously invertible, (2.16) confirms that (2.10) is a well-posed formulation.

In the cases of practical interest, $\bar{V}$ is a finite-dimensional subspace of V. If the dimension of $\bar{V}$ is N, then we can find a set of functionals $\{\mu_i\}_{i=1,\dots,N}$ such that for all $v \in V$

$$ {}_{V^*}\langle \mu_i, v\rangle_V = 0 \quad \forall i = 1,\dots,N \qquad \Leftrightarrow \qquad \mathcal{P}v = 0. \tag{2.17}$$

In other words, the equations ${}_{V^*}\langle \mu_i, v\rangle_V = 0$ for $1 \le i \le N$ characterize v as a fine-scale function, i.e., $v \in V'$. From the mathematical standpoint, $\{\mu_i\}_{i=1,\dots,N}$ is a basis for the image of $\mathcal{P}^T$. Therefore, it is clear that (2.12) is equivalent to

$$ \mathcal{G}'\mu_i = 0 \qquad \forall i = 1,\dots,N \tag{2.18}$$

and

$$ {}_{V^*}\langle \mu_i, \mathcal{G}'\nu\rangle_V = 0 \qquad \forall \nu \in V^* \ \forall i = 1,\dots,N. \tag{2.19}$$

Moreover, after introducing the vector $\boldsymbol{\mu} \in (V^*)^N$ and its transpose,

$$ \boldsymbol{\mu} = \begin{bmatrix} \mu_1 \\ \vdots \\ \mu_N \end{bmatrix} \qquad \text{and} \qquad \boldsymbol{\mu}^T = \begin{bmatrix} \mu_1 & \dots & \mu_N \end{bmatrix}; $$

the vector $\mathcal{G}\boldsymbol{\mu}^T \in V^N$,

$$ \mathcal{G}\boldsymbol{\mu}^T = \begin{bmatrix} \mathcal{G}\mu_1 & \dots & \mathcal{G}\mu_N \end{bmatrix}; $$

the matrix $\boldsymbol{\mu}\mathcal{G}\boldsymbol{\mu}^T \in \mathbb{R}^{N\times N}$,

$$ \boldsymbol{\mu}\mathcal{G}\boldsymbol{\mu}^T = \begin{bmatrix} {}_{V^*}\langle \mu_1, \mathcal{G}\mu_1\rangle_V & \dots & {}_{V^*}\langle \mu_1, \mathcal{G}\mu_N\rangle_V \\ \vdots & \ddots & \vdots \\ {}_{V^*}\langle \mu_N, \mathcal{G}\mu_1\rangle_V & \dots & {}_{V^*}\langle \mu_N, \mathcal{G}\mu_N\rangle_V \end{bmatrix}; $$

and the vector of functionals $\boldsymbol{\mu}\mathcal{G} : (V^*) \to \mathbb{R}^N$ (i.e., $\boldsymbol{\mu}\mathcal{G} \in (V^{**})^N$) such that

$$ \boldsymbol{\mu}\mathcal{G}(\nu) = \begin{bmatrix} {}_{V^*}\langle \mu_1, \mathcal{G}\nu\rangle_V \\ \vdots \\ {}_{V^*}\langle \mu_N, \mathcal{G}\nu\rangle_V \end{bmatrix} \quad \forall \nu \in V^*, $$

it is easy to see that (2.11) is equivalent to

$$ \mathcal{G}' = \mathcal{G} - \mathcal{G}\boldsymbol{\mu}^T \left[\boldsymbol{\mu}\mathcal{G}\boldsymbol{\mu}^T\right]^{-1} \boldsymbol{\mu}\mathcal{G}. \tag{2.20}$$

2.4. Orthogonal projectors and optimization. An interesting case, and the only one considered in what follows, is when $\mathcal{P}$ is an orthogonal projector.

Given a scalar product $(\cdot,\cdot)$ defined on $V \times V$, possibly different than $(\cdot,\cdot)_V$, the related orthogonal projector $\mathcal{P}$ is obviously defined by

$$ (\mathcal{P}w, \bar{v}) = (w, \bar{v}) \qquad \forall w \in V, \forall \bar{v} \in \bar{V}. \tag{2.21}$$

Recall that, in order to fit in the abstract framework of section 2.2, $\mathcal{P}$ must be a continuous operator in V. However, when $\bar{V}$ is a finite-dimensional space, this holds for any scalar product $(\cdot,\cdot)$ which is continuous on $V \times V$.

In this context, V' and $\bar{V}$ are orthogonal complements with respect to $(\cdot,\cdot)$, and the VMS formulation provides the optimal approximation $\bar{u} \in \bar{V}$ of u, with respect to the norm $\|\cdot\|$ induced by the scalar product $(\cdot,\cdot)$.

3. The advection-diffusion model problem. Let d be the space dimension ($d = 1$ and $d = 2$ will be taken into consideration in the examples), and let $\Omega \subset \mathbb{R}^d$ be a regular domain. We consider the advection-diffusion model problem

$$\mathcal{L}u = -\kappa\Delta u + \beta \cdot \nabla u = f \text{ in } \Omega \qquad \text{with } u_{|\partial\Omega} = 0, \tag{3.1}$$

where $f \in L^2(\Omega)$ is the source term, $\kappa > 0$ is the scalar diffusivity, and $\beta : \Omega \to \mathbb{R}^d$ is the advection field, for which we assume $\mathrm{div}(\beta) = 0$. For the variational formulation of (3.1), within the framework of section 2, we set $V = H^1_0 \equiv H^1_0(\Omega)$ whence $V^* = H^{-1}$. Typical finite element spaces will be considered as coarse spaces $\bar{V}$.

In this context, it is convenient to represent the Green's operator $\mathcal{G}$ through the Green's function $g : \Omega \times \Omega \to \mathbb{R}$ such that

$$u(y) = \int_\Omega g(x, y) f(x)\, dx \tag{3.2}$$

for almost every y in Ω. Note that in (3.2) and in what follows the integrals have to be interpreted in the sense of distributions. We refer to [22] for details. Some explicit representations are given in [13].

We recall that $g_{|\partial(\Omega\times\Omega)} = 0$ and, for all $y \in \Omega$, $\mathcal{L}^* g(\cdot, y) = \delta(\cdot - y)$, where δ is the Dirac mass at the origin and $\mathcal{L}^* = -\kappa\Delta - \beta \cdot \nabla$ denotes the dual of $\mathcal{L}$.

Furthermore, we introduce the fine-scale Green's function $g' : \Omega \times \Omega \to \mathbb{R}$, which represents the fine-scale Green's operator $\mathcal{G}'$ and gives the fine-scale component u' of u from the coarse-scale residual $r = f - \mathcal{L}\bar{u}$ by

$$u'(y) = \int_\Omega g'(x, y) r(x)\, dx. \tag{3.3}$$

Recall, however, that the space of fine scales V' as well as the fine-scale Green's function g' depend on the underlying projector $\mathcal{P}$. With an abuse of notation, in the next sections we shall write V' and g' without distinction among the different projectors taken into consideration. In particular, we will deal with the H^1_0-projector $\mathcal{P} = \mathcal{P}_{H^1_0}$, associated with the scalar product $(w, v) = (w, v)_{H^1_0} = \int_\Omega \nabla w(x) \cdot \nabla v(x)\, dx$, and the usual L^2-projector $\mathcal{P} = \mathcal{P}_{L^2}$. Having a set of functionals $\{\mu_i\}_{i=1,\dots,N}$ as in (2.17), i.e., giving

$$\int_\Omega \mu_i(x) v(x)\, dx = 0 \quad \forall i = 1, \dots, N \qquad \Leftrightarrow \qquad \mathcal{P}v = 0, \tag{3.4}$$

then g' is obtained straightforwardly by (2.20) as

(3.5)

$$\begin{aligned} g'(x, y) =& g(x, y) - \left[\int_\Omega g(\tilde{x}, y)\mu_1(\tilde{x})\, d\tilde{x} \quad \cdots \quad \int_\Omega g(\tilde{x}, y)\mu_N(\tilde{x})\, d\tilde{x}\right] \\ & \times \begin{bmatrix} \int_\Omega g(\tilde{x}, \tilde{y})\mu_1(\tilde{x})\mu_1(\tilde{y})\, d\tilde{x}d\tilde{y} & \cdots & \int_\Omega g(\tilde{x}, \tilde{y})\mu_N(\tilde{x})\mu_1(\tilde{y})\, d\tilde{x}d\tilde{y} \\ \vdots & \ddots & \vdots \\ \int_\Omega g(\tilde{x}, \tilde{y})\mu_1(\tilde{x})\mu_N(\tilde{y})\, d\tilde{x}d\tilde{y} & \cdots & \int_\Omega g(\tilde{x}, \tilde{y})\mu_N(\tilde{x})\mu_N(\tilde{y})\, d\tilde{x}d\tilde{y} \end{bmatrix}^{-1} \\ & \times \begin{bmatrix} \int_\Omega g(x, \tilde{y})\mu_1(\tilde{y})\, d\tilde{y} \\ \vdots \\ \int_\Omega g(x, \tilde{y})\mu_N(\tilde{y})\, d\tilde{y} \end{bmatrix}, \end{aligned}$$

while (2.18) and (2.19) mean that, for all $x, y \in \Omega$ and for all $i = 1, \dots, N$,

$$\int_\Omega g'(\tilde{x}, y)\mu_i(\tilde{x})\, d\tilde{x} = 0 \text{ and } \int_\Omega g'(x, \tilde{y})\mu_i(\tilde{y})\, d\tilde{y} = 0. \tag{3.6}$$

In this context, the VMS formulation (2.10) reads as follows: Find $\bar{u} \in \bar{V}$ such that

$$\begin{aligned}\int_\Omega (\kappa \nabla \bar{u}(x) - \beta \bar{u}) \cdot \nabla \bar{v}(x)\, dx - \int_\Omega \int_\Omega \mathcal{L}\bar{u}(x) g'(x,y) \mathcal{L}^* \bar{v}(y)\, dxdy \\ = \int_\Omega f(x)\bar{v}(x)\, dx - \int_\Omega \int_\Omega f(x) g'(x,y) \mathcal{L}^* \bar{v}(y)\, dxdy \qquad \forall \bar{v} \in \bar{V}.\end{aligned} \tag{3.7}$$

3.1. Linear elements and H_0^1-optimality in one dimension. Let $d = 1$ and $\Omega = (0, L)$. Consider a grid of nodes $0 = x_0 < x_1 < \cdots < x_{n_{el}-1} < x_{n_{el}} = L$ and the related subdivision of $(0, L)$ into n_{el} elements (x_{i-1}, x_i), $i = 1, \ldots, n_{el}$. Let $\bar{V} \subset H_0^1$ be the space of piecewise-linear (with respect to the subdivision) functions, which is of dimension $N = n_{el} - 1$.

In this context, the H_0^1-projector $\mathcal{P} = \mathcal{P}_{H_0^1}$ plays a special role; indeed, $(\mathcal{P}v)(x_i) = v(x_i)$ for all $i = 1, \ldots, N$. Then, the VMS approach provides in this case a nodally exact approximation $\bar{u}$ of the exact solution u (see [3, 8, 12, 13]).

In order to have (3.4), we set $\mu_i = \delta(x - x_i)$. The abstract property (3.6) becomes, in this case,

$$g'(x, x_i) = g'(x_i, y) = 0 \qquad \forall i = 1, \ldots, N, \quad 0 \le x, y \le L; \tag{3.8}$$

i.e., g' vanishes if one of its two arguments is a node of the grid. Moreover, (3.5) gives

$$\begin{aligned}g'(x,y) = g(x,y) - \begin{bmatrix} g(x_1,y) & \cdots & g(x_N,y)\end{bmatrix} \\ \times \begin{bmatrix} g(x_1,x_1) & \cdots & g(x_N,x_1) \\ \vdots & \ddots & \vdots \\ g(x_1,x_N) & \cdots & g(x_N,x_N)\end{bmatrix}^{-1} \times \begin{bmatrix} g(x,x_1) \\ \vdots \\ g(x,x_N)\end{bmatrix}.\end{aligned} \tag{3.9}$$

Recalling that $\mathcal{L}^* g(\cdot, y) = \delta(\cdot - y)$, from (3.9) we get

$$\begin{aligned}\mathcal{L}^* g'(\cdot,y) = \delta(\cdot - y) - \begin{bmatrix} g(x_1,y) & \cdots & g(x_N,y)\end{bmatrix} \\ \times \begin{bmatrix} g(x_1,x_1) & \cdots & g(x_N,x_1) \\ \vdots & \ddots & \vdots \\ g(x_1,x_N) & \cdots & g(x_N,x_N)\end{bmatrix}^{-1} \times \begin{bmatrix} \delta(\cdot - x_1) \\ \vdots \\ \delta(\cdot - x_N)\end{bmatrix}.\end{aligned}$$

If $x_{i-1} < y < x_i$, then

$$\mathcal{L}^* g'(\cdot, y) = \delta(\cdot - y) \text{ in } (x_{i-1}, x_i), \tag{3.10}$$

while when $y > x_i$ or $y < x_{i-1}$,

$$\mathcal{L}^* g'(\cdot, y) = 0 \text{ in } (x_{i-1}, x_i). \tag{3.11}$$

This, with (3.8), fully characterizes g': By (3.8) and (3.11), we see that $g'(x, y) = 0$ if x and y belong to two different elements; moreover, (3.8) and (3.10) say that g' is, on each $(x_{i-1}, x_i) \times (x_{i-1}, x_i)$, the so-called *element* Green's function g^{el}, i.e., the Green's function for the restriction of $\mathcal{L}$ to the element (x_{i-1}, x_i), with homogeneous Dirichlet boundary conditions at the endpoints x_{i-1} and x_i. Since $g'(x, y) \neq 0$ only when x and y belong to the same element, (3.3) can be localized within each element

$$u'(y) = \int_{x_{i-1}}^{x_i} g'(x,y) r(x)\, dx \qquad \forall y \in (x_{i-1}, x_i). \tag{3.12}$$

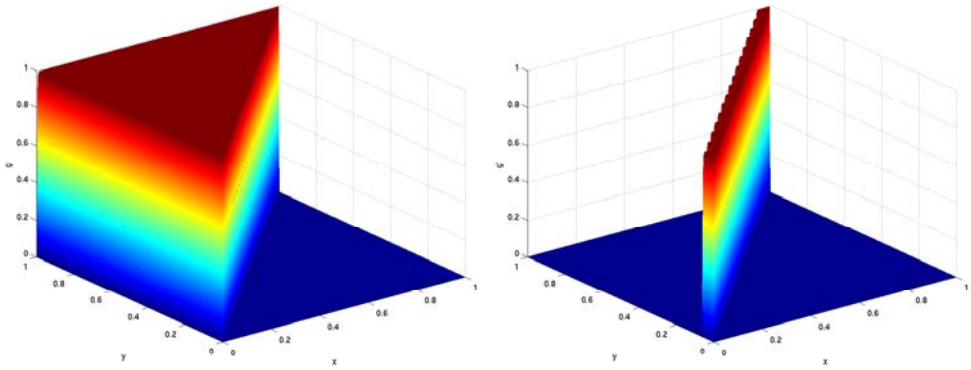

FIG. 3.1. *Comparison between the Green's function g (left) and the fine-scale Green's function g' (right) for the one-dimensional problem and linear elements, with $\mathcal{P} = \mathcal{P}_{H_0^1}$, $\kappa = 10^{-3}$, $\beta = 1$, $L = 1$, and a uniform grid of $n_{el} = 16$ elements. Note that the support of g' is local in that there is no coupling between elements. This is an advantage of $\mathcal{P} = \mathcal{P}_{H_0^1}$.*

See a plot of g' in Figure 3.1 where we consider the case of a uniform mesh of 16 elements (for $\kappa = 10^{-3}$, $\beta = 1$, and $L = 1$) and we compare with the plot of the Green's function g.

As stated above, the structure of g' for this case is well known in the literature [3, 8, 12, 13]. Indeed, recognizing that V' is the space of *bubbles*

$$V' = \bigoplus_{i=1,\dots,n_{el}} H_0^1(x_{i-1}, x_i), \tag{3.13}$$

the fine-scale variational equation (2.6) splits element by element and admits the strong form

$$\mathcal{L}u' = f - \mathcal{L}\bar{u} \text{ on } (x_{i-1}, x_i) \qquad \text{with } u'(x_{i-1}) = u'(x_i) = 0 \tag{3.14}$$

for each $i = 1, \dots, n_{el}$; u' is the solution of the advection-diffusion problem at the element level with the coarse-scale residual acting as the right-hand side. This is why $g' = g^{el}$ at the element level.

Moreover, assuming piecewise-constant coefficients κ, β and source term f, the fine-scale effect on the coarse-scale variational equation is

$$\begin{aligned} \int_0^L \int_0^L \mathcal{L}^* \bar{v}(y) g'(x,y) r(x)\, dxdy &= \sum_{i=1}^{n_{el}} \int_{x_{i-1}}^{x_i} \int_{x_{i-1}}^{x_i} \mathcal{L}^* \bar{v}(y) g'(x,y) r(x)\, dxdy \\ &= \sum_{i=1}^{n_{el}} \frac{\int_{x_{i-1}}^{x_i} \int_{x_{i-1}}^{x_i} g'(x,y)\, dxdy}{x_i - x_{i-1}} \int_{x_{i-1}}^{x_i} r(x) \mathcal{L}^* \bar{v}(x)\, dx, \end{aligned} \tag{3.15}$$

which is recognized as a classical stabilization term depending on the parameter [12, 13]

$$\tau_1 \equiv \tau_{1,(x_{i-1},x_i)} = \frac{\int_{x_{i-1}}^{x_i} \int_{x_{i-1}}^{x_i} g'(x,y)\, dxdy}{x_i - x_{i-1}} = \frac{h}{2\beta} \left(\coth(\alpha) - \frac{1}{\alpha} \right), \tag{3.16}$$

where $\alpha = (h\beta)/(2\kappa)$ is the mesh Peclét number and $h = x_i - x_{i-1}$ is the local mesh-size. We show plots of g' on the shifted element domain $(0, h) \times (0, h)$ in the diffusive and in the advective regime in Figure 3.2. A plot of τ_1 is presented in Figure 3.5.

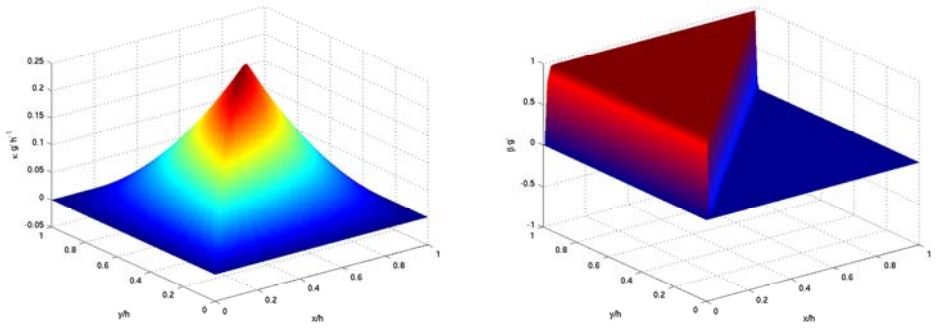

FIG. 3.2. *Fine-scale Green's functions g' at the element level $(0,h)\times(0,h)$ for the one-dimensional problem and linear elements. In the diffusive regime $\alpha = 10^{-2}$ (left), and in the advective regime $\alpha = 10^2$ (right). $\mathcal{P} = \mathcal{P}_{H_0^1}$.*

3.2. Higher-order elements and H_0^1-optimality in one dimension. We consider now higher-order piecewise-polynomial coarse scales on the grid $0 = x_0 < x_1 < \cdots < x_{n_{el}-1} < x_{n_{el}} = L$; i.e., we set

$$\bar{V} = \left\{\bar{v} \in H_0^1(0,L) \text{ such that } \bar{v}_{|(x_{i-1},x_i)} \in \mathbb{P}_k,\ 1 \le i \le n_{el}\right\},$$

where $\mathbb{P}_k$ is the space of polynomials of degree at most k. We still deal with $\mathcal{P} = \mathcal{P}_{H_0^1}$. The case of higher-order elements ($k \ge 2$) has not been studied in the literature of VMS methods, as far as we know. There are indeed additional difficulties with respect to the case of linear elements: V' is still a space of bubbles, but unlike the case $k = 1$, $\bar{V}$ also contains some (polynomial) bubbles, which are therefore missing in V'. This means that V' is a strict subset of bubbles

$$V' \subsetneq \bigoplus_{i=1,\ldots,n_{el}} H_0^1(x_{i-1},x_i), \tag{3.17}$$

or equivalently, V' is a space of bubbles with additional constraints. As a result, the fine-scale variational equation (2.6) can still be split element by element into

$$\int_{x_{i-1}}^{x_i} \mathcal{L}u'(x)v'(x)\,dx = \int_{x_{i-1}}^{x_i} (f(x) - \mathcal{L}\bar{u}(x))v'(x)\,dx \qquad \forall v' \in V', \quad i = 1,\ldots,n_{el}; \tag{3.18}$$

however, (3.18) is no longer equivalent to the strong form (3.14).

We can use the theory of section 2 for dealing with (3.18). Taking advantage of (3.17), we restrict from the beginning to a single element (x_{i-1},x_i) and to the bubbles supported on it. Then, we take as the fine-scale space $V_i' = V'_{|(x_{i-1},x_i)}$. The space of the bubbles which are polynomials of degree at most k plays the role of a coarse space on (x_{i-1},x_i); we set $\bar{V}_i = \bar{V}_{|(x_{i-1},x_i)} \cap H_0^1(x_{i-1},x_i)$. The space of unconstrained bubbles is $V_i = H_0^1(x_{i-1},x_i) = \bar{V}_i \oplus V_i'$. Precisely, $w \in V_i$ belongs to V_i' if and only if (integrating by parts)

$$0 = \int_{x_{i-1}}^{x_i} \frac{d}{dx}w(x)\frac{d}{dx}\bar{v}(x)\,dx = -\int_{x_{i-1}}^{x_i} w(x)\frac{d^2}{dx^2}\bar{v}(x)\,dx \qquad \forall \bar{v} \in \bar{V}_i. \tag{3.19}$$

The second-order derivatives of $\bar{V}_i$ functions are the polynomials of degree at most $k-2$. We need, as $\{\mu_j\}_{j=1,\ldots,N}$ (where $N = k-1$, now), a basis of $\mathbb{P}_{k-2}$. For example,

we can set $\mu_j(x) = (x - x_{i-1})^{j-1}$ for $1 \le j \le N$. The constraint is expressed, as in (2.17), by N scalar equations: $v \in V_i$ belongs to V_i' if and only if

$$\int_{x_{i-1}}^{x_i} \mu_j(x) v(x)\, dx = 0, \qquad 1 \le j \le N. \tag{3.20}$$

The Green's function of the unconstrained bubble problem is the element Green's function g^{el}. Then, we can use the formula (2.20) and derive an expression for g' in terms of g^{el}: on $(0,h)\times(0,h)$ we have

$$\begin{aligned} g'(x,y) = g^{el}(x,y) &- \begin{bmatrix} \int_0^h g^{el}(\tilde{x},y)d\tilde{x} & \cdots & \int_0^h \tilde{x}^{k-2} g^{el}(\tilde{x},y)d\tilde{x} \end{bmatrix} \\ &\times \begin{bmatrix} \int_0^h\int_0^h g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} & \cdots & \int_0^h\int_0^h \tilde{x}^{k-2} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} \\ \vdots & \ddots & \vdots \\ \int_0^h\int_0^h \tilde{y}^{k-2} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} & \cdots & \int_0^h\int_0^h \tilde{x}^{k-2}\tilde{y}^{k-2} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} \end{bmatrix}^{-1} \\ &\times \begin{bmatrix} \int_0^h g^{el}(x,\tilde{y})d\tilde{y} \\ \vdots \\ \int_0^h \tilde{y}^{k-2} g^{el}(x,\tilde{y})d\tilde{y} \end{bmatrix}. \end{aligned} \tag{3.21}$$

We recall that $g'(x,y) = 0$ if x and y belong to different elements, while g' on each $(x_{i-1},x_i)\times(x_{i-1},x_i)$ can be obtained from (3.21) straightforwardly.

We discuss now in more detail the case of quadratic ($k = 2$) and cubic ($k = 3$) coarse-scale elements. If $k = 2$, then (3.21) yields

$$g'(x,y) = g^{el}(x,y) - \frac{\int_0^h g^{el}(\tilde{x},y)d\tilde{x}\int_0^h g^{el}(x,\tilde{y})d\tilde{y}}{\int_0^h\int_0^h g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y}}. \tag{3.22}$$

For $k = 3$, (3.21) gives

$$\begin{aligned} g'(x,y) = g^{el}(x,y) &- \begin{bmatrix} \int_0^h g^{el}(\tilde{x},y)d\tilde{x} & \int_0^h \tilde{x} g^{el}(\tilde{x},y)d\tilde{x} \end{bmatrix} \\ &\times \begin{bmatrix} \int_0^h\int_0^h g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} & \int_0^h\int_0^h \tilde{x} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} \\ \int_0^h\int_0^h \tilde{y} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} & \int_0^h\int_0^h \tilde{x}\tilde{y} g^{el}(\tilde{x},\tilde{y})d\tilde{x}d\tilde{y} \end{bmatrix}^{-1} \\ &\times \begin{bmatrix} \int_0^h g^{el}(x,\tilde{y})d\tilde{y} \\ \int_0^h \tilde{y} g^{el}(x,\tilde{y})d\tilde{y} \end{bmatrix}. \end{aligned} \tag{3.23}$$

Plots of g' on $(0,h)\times(0,h)$ are shown in Figures 3.3 and 3.4. (See [17] for explicit formulas.)

Observe that, from (2.18)–(2.19), g' is L^2-orthogonal to $\mathbb{P}_{k-2}$ in both variables x and y on each $(x_{i-1},x_i)\times(x_{i-1},x_i)$. Still assuming that the coefficients κ and β are piecewise-constant and the source term f is a piecewise-polynomial of degree at most $k-1$, then on (x_{i-1},x_i) we have

$$r(x) = \frac{d^{k-1}r}{dx^{k-1}}\frac{x^{k-1}}{(k-1)!} + \text{ “polynomial of degree } \le k-2\text{”}$$

and

$$\mathcal{L}^*\bar{v}(y) = \frac{d^{k-1}\mathcal{L}^*\bar{v}}{dx^{k-1}}\frac{y^{k-1}}{(k-1)!} + \text{ “polynomial of degree } \le k-2\text{”}.$$

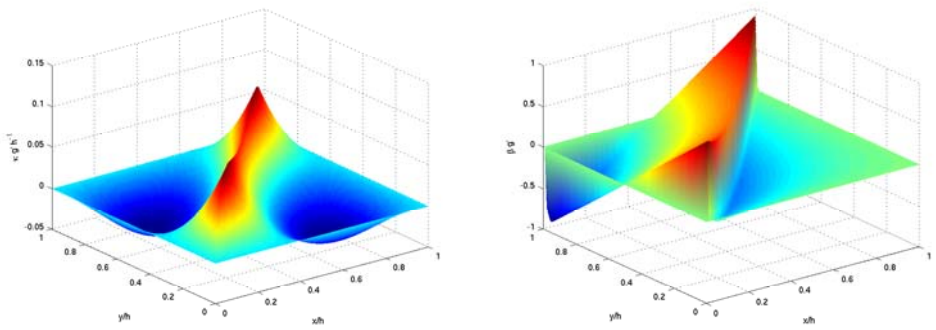

FIG. 3.3. *Fine-scale Green's functions g' at the element level $(0,h)\times(0,h)$ for the one-dimensional problem and quadratic elements. In the diffusive regime $\alpha = 10^{-2}$ (left), and in the advective regime $\alpha = 10^{2}$ (right). $\mathcal{P} = \mathcal{P}_{H_0^1}$.*

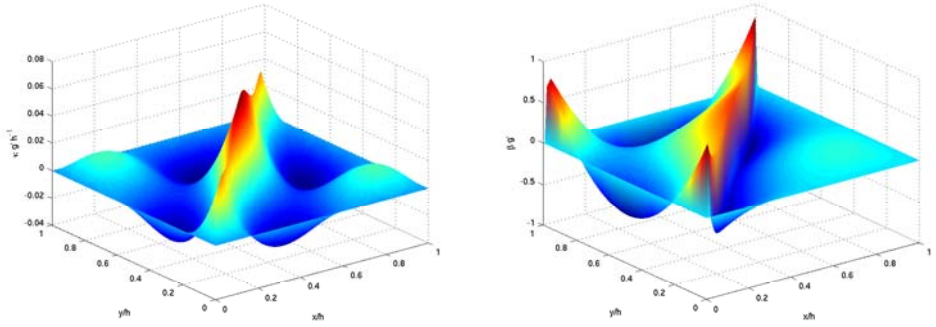

FIG. 3.4. *Fine-scale Green's functions g' at the element level $(0,h)\times(0,h)$ for the one-dimensional problem and cubic elements. In the diffusive regime $\alpha = 10^{-2}$ (left), and in the advective regime $\alpha = 10^{2}$ (right). $\mathcal{P} = \mathcal{P}_{H_0^1}$.*

Therefore, exploiting both the locality and the orthogonality of g' with respect to polynomials of degree $k-2$, the fine-scale effect on the coarse-scale equation can be written as

$$
\begin{aligned}
&\int_0^L \int_0^L \mathcal{L}^*\bar{v}(y) g'(x,y) r(x)\, dxdy \\
&\qquad = \sum_{i=1}^{n_{el}} \int_{x_{i-1}}^{x_i} \int_{x_{i-1}}^{x_i} \mathcal{L}^*\bar{v}(y) g'(x,y) r(x)\, dxdy \\
&\qquad = \frac{1}{((k-1)!)^2} \sum_{i=1}^{n_{el}} \int_{x_{i-1}}^{x_i} \int_{x_{i-1}}^{x_i} y^{k-1} \frac{d^{k-1}\mathcal{L}^*\bar{v}}{dx^{k-1}} g'(x,y) x^{k-1} \frac{d^{k-1} r}{dx^{k-1}}\, dxdy \\
&\qquad = \sum_{i=1}^{n_{el}} \frac{\int_{x_{i-1}}^{x_i}\int_{x_{i-1}}^{x_i} y^{k-1} g'(x,y) x^{k-1} dxdy}{((k-1)!)^2 (x_i - x_{i-1})} \int_{x_{i-1}}^{x_i} \frac{d^{k-1} r}{dx^{k-1}} \frac{d^{k-1}\mathcal{L}^*\bar{v}}{dx^{k-1}}\, dx \\
&\qquad = \sum_{i=1}^{n_{el}} \tau_{k,(x_{i-1},x_i)} \int_{x_{i-1}}^{x_i} \frac{d^{k-1} r}{dx^{k-1}} \frac{d^{k-1}\mathcal{L}^*\bar{v}}{dx^{k-1}}\, dx.
\end{aligned}
\tag{3.24}
$$

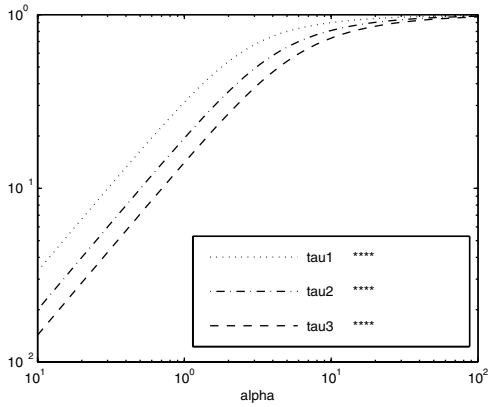

FIG. 3.5. *Stabilization parameters τ_1, τ_2, and τ_3 versus α.*

The stabilization term acts only locally and depends only on the derivative of degree $k-1$ of the residual; its effect is modulated by the parameter

$$\tau_k \equiv \tau_{k,(x_{i-1},x_i)} = \frac{\int_{x_{i-1}}^{x_i}\int_{x_{i-1}}^{x_i} y^{k-1}g'(x,y)x^{k-1}dxdy}{\left((k-1)!\right)^2(x_i - x_{i-1})}.$$

In the case of quadratic elements, from the previous formulas one can derive

$$\tau_2 = \frac{h^3}{72\,\beta}\frac{-3e^{2\alpha}\alpha^{-1} + e^{2\alpha} + 3e^{2\alpha}\alpha^{-2} - 3\alpha^{-2} - 1 - \alpha^{-1}}{e^{2\alpha} - e^{2\alpha}\alpha^{-1} + 1 + \alpha^{-1}},$$

while for cubic elements,

$$\tau_3 = \frac{h^5}{7200\,\beta}\,\frac{15e^{2\alpha}\alpha^{-2} - 6e^{2\alpha}\alpha^{-1} - 15e^{2\alpha}\alpha^{-3} + e^{2\alpha} + 15\alpha^{-3} + 6\alpha^{-1} + 15 + 1}{e^{2\alpha} - 3e^{2\alpha}\alpha^{-1} + 3e^{2\alpha}\alpha^{-2} - 1 - 3\alpha^{-2} - 3\alpha^{-1}}.$$

Plots of τ_1, τ_2, and τ_3 are compared in Figure 3.5.

Remark 1. From Figure 3.5 we see that the τ_k are positive and of order h^{2k-1}/β and $\alpha h^{2k-1}/\beta = h^{2k}/\kappa$ in the advective and in the diffusive regimes, respectively.

Remark 2. For linear elements, in one dimension, the H_0^1-optimal $\bar{u}$ is the nodal interpolant of u, which is a monotonicity preserving approximant. For higher-order elements, the H_0^1-optimal $\bar{u}$ is still nodally exact at the endpoints of each element, but we lose monotonicity inside the elements.

Remark 3. The format of (3.24) is reminiscent of the gradient least-squares stabilized method proposed by Franca and Dutra do Carmo [10].

3.3. L^2-optimality in one dimension and the localization of g'. We have shown that, for the one-dimensional problem and for the H_0^1-projector based VMS formulation (i.e., with $\mathcal{P} = \mathcal{P}_{H_0^1}$), the fine-scale Green's function is supported on the union of the $(x_{i-1}, x_i) \times (x_{i-1}, x_i)$ for $1 \le i \le n_{el}$. In this case, the g' is *fully localized* within each element, in that there is no coupling between elements. This allows a convenient evaluation of the fine-scale effect in the VMS formulation (see (3.15) and (3.24)). This feature, though, is not guaranteed for any projector $\mathcal{P}$. Take, e.g., the L^2-projector $\mathcal{P} = \mathcal{P}_{L^2}$, with piecewise-linear elements. We can still compute g' from (3.5), where now, in order to have (3.4), $\{\mu_i\}_{i=1,\dots,N}$ is a basis for $\bar{V}$ itself. For

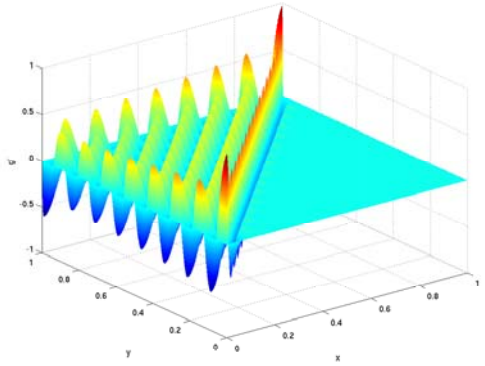

FIG. 3.6. *Fine-scale Green's function g' for the one-dimensional problem and linear elements, with $\mathcal{P} = \mathcal{P}_{L^2}$, $\kappa = 10^{-3}$, $\beta = 1$, $L = 1$, and a uniform grid of $n_{el} = 16$ elements. Note that in the case of $\mathcal{P} = \mathcal{P}_{L^2}$, g' is global and unattenuated when advection dominates.*

$\kappa = 10^{-3}$, $\beta = 1$, $L = 1$, and $n_{el} = 16$ elements, a plot of g' is presented in Figure 3.6; we see that the support of g' includes the entire upwind region $x \leq y$.

Remark 4. In practical applications, g' needs to be approximated, leading to classical stabilized methods. It is obviously more convenient and easy to approximate a highly localized g' than one that is global. This strongly suggests that the selection of the projector is crucial in the development of a multiscale method.

3.4. Linear elements in two dimensions. Turning to problems in two dimensions (as well as in multiple dimensions), we face two important differences.

First, it is technical and more difficult to obtain the analytical expression of the Green's function g and therefore of the fine-scale Green's function g' through (3.5). To overcome this difficulty, in this section we use the standard Galerkin method to numerically compute g and g' on a fine mesh of $524,288$ elements, which is able to resolve the fine scales of the problem under consideration.[1] We take here $\Omega = (0,1)^2$, the diffusivity is $\kappa = 10^{-3}$, and the unit advection velocity is $\beta = [1/2 \quad 1]/\sqrt{1.25}$. Since both g and g' are defined on $(0,1)^2 \times (0,1)^2$, for the purposes of a graphical representation we fix $y = y^* = [39/64 \quad 51/64] \approx [0.6 \quad 0.8]$ (see Figure 3.7), and we plot the Green's function g, and the fine-scale Green's function g' versus the argument x. The plot of $x \mapsto g(x, y^*)$ is presented in Figure 3.8. As is known, $x \mapsto g(x, y^*)$ is singular when $x = y^*$, and indeed the left graph in Figure 3.8 has been truncated at $g = 50$. Roughly speaking, g is supported around the upwind characteristic passing through y^*.

The second major difference, compared to the one-dimensional case, is that if the coarse scales are piecewise-polynomial, then the fine scales are not localized within each element (i.e., they are not bubble functions), and this happens for any choice of projector $\mathcal{P}$, including the H_0^1-projector. Indeed, since the coarse scales are polynomials on the edges of the elements of the triangulation, while the exact solution is arbitrary, the fine scales do not vanish there. Our aims here are the calculation of g'

[1] Let $\{\phi_i\}$ be a basis for piecewise-linear functions on the fine mesh, and think of $V \approx \text{span}\{\phi_i\}$, roughly speaking. Let $\mathbf{L}$ be the matrix representation of $\mathcal{L}$ (i.e., $L_{ij} = {}_{V^*}\langle \mathcal{L}\phi_j, \phi_i \rangle_V$), then the approximation of the Green's operator $\mathcal{G}$ is associated with $\mathbf{G} = \mathbf{L}^{-1}$. The approximation of $\mathcal{G}'$ in matrix form is obtained by $\mathbf{G}' = \mathbf{G} - \mathbf{G} \times \mathbf{P}^T \times (\mathbf{P} \times \mathbf{G} \times \mathbf{P}^T)^{-1} \times \mathbf{P} \times \mathbf{G}$, analogous to (2.11), where $\mathbf{P}$ is the matrix associated with the projector $\mathcal{P}$. The Green's function and fine-scale Green's function can be approximated as $g(x,y) \approx \sum_{i,j} G_{ij}\phi_j(x)\phi_i(y)$ and $g'(x,y) \approx \sum_{i,j} G'_{ij}\phi_j(x)\phi_i(y)$.

and the assessment of its attenuation compared with g and its locality for different choices of $\mathcal{P}$. We test both $\mathcal{P} = \mathcal{P}_{H_0^1}$ and $\mathcal{P} = \mathcal{P}_{L^2}$, which gave, in the one-dimensional case, a fully localized and a globally supported g', respectively. We take the space $\bar{V}$ formed by linear elements on the uniform triangulation shown in Figure 3.7. The plots of $x \mapsto g'(x, y^*)$ for $\mathcal{P} = \mathcal{P}_{H_0^1}$ and $\mathcal{P} = \mathcal{P}_{L^2}$ are presented in Figures 3.9 and 3.10, respectively. The singularity at $x = y^*$ is truncated at $g' = 50$ in the left-hand plots and at $g' = 5$ in the right-hand plots. Observe that in the case $\mathcal{P} = \mathcal{P}_{H_0^1}$, the fine-scale Green's function is more localized around y^*, compared with the case $\mathcal{P} = \mathcal{P}_{L^2}$, for which oscillations are spread over the entire domain. In addition, the g' for the case $\mathcal{P} = \mathcal{P}_{H_0^1}$ seems to be negligible outside a layer of a few elements around y^*. This is better seen in the (right-hand) contour plots of Figure 3.9 and 3.10, where the coarse mesh is overlaid.

Changing the position of y^* inside Ω and taking y^* on an edge or a vertex of the coarse triangulation produces similar results (not shown).

Remark 5. The upwind tail of g is global in the advection-dominated case, whereas it is highly attenuated for g' when $\mathcal{P} = \mathcal{P}_{H_0^1}$ (cf. Figure 3.8 with Figure 3.9). This has important implications for multiscale analysis of dominantly hyperbolic phenomena. In addition, the g' for $\mathcal{P} = \mathcal{P}_{H_0^1}$ is much more localized than that for

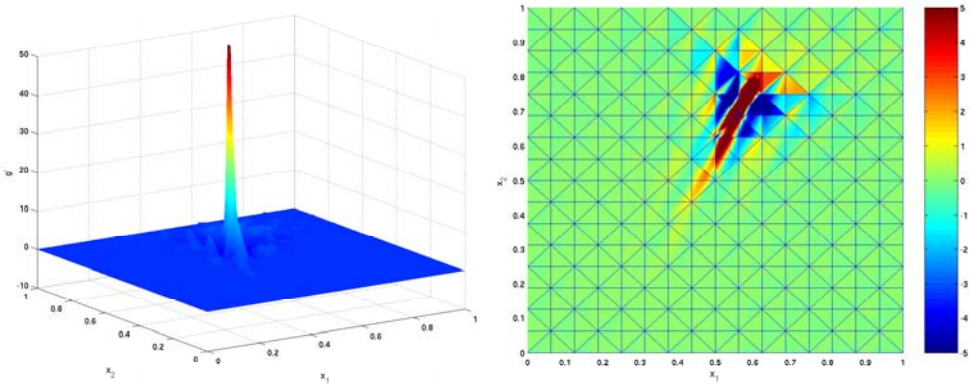

FIG. 3.9. *Plot (left) and contour plot (right) of* $x \mapsto g'(x, y^*)$ *for* $\mathcal{P} = \mathcal{P}_{H_0^1}$.

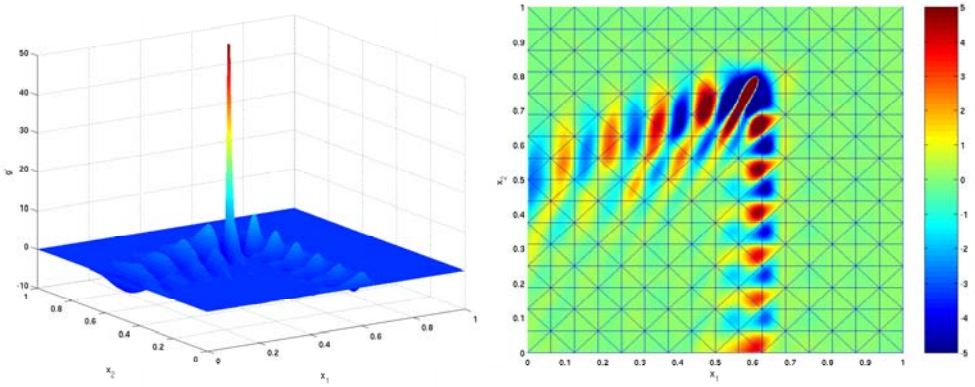

FIG. 3.10. *Plot (left) and contour plot (right) of* $x \mapsto g'(x, y^*)$ *for* $\mathcal{P} = \mathcal{P}_{L^2}$.

$\mathcal{P} = \mathcal{P}_{L^2}$. These results are consistent with the one-dimensional case and suggest that local approximations of g' for $\mathcal{P} = \mathcal{P}_{H_0^1}$ may achieve near H_0^1-optimality in multidimensional, advection-dominated cases.

Let us return to the model problem (3.1) with κ and β defined as above. We now consider a right-hand side $f = +1$ if $x_2 \geq 2x_1$, $f = -1$ if $x_2 < 2x_1$. The exact solution has an internal layer along $x_2 = 2x_1$, due to the discontinuity of f, and boundary layers at $x_1 = 1$ and $x_2 = 1$.

We consider three different meshes: The first two are shown in Figure 3.11, and the third is the same as the one depicted in Figure 3.7. The three meshes are quite coarse for the problem considered. The coarse-scale approximations $\bar{u}$ are given in Figures 3.12–3.14 for $\mathcal{P}_{H_0^1}$ and $\mathcal{P}_{L^2}$. In Figure 3.12 it is very clear that the solution for $\mathcal{P}_{H_0^1}$ is much better than that for $\mathcal{P}_{L^2}$. In Figure 3.13, the solution for $\mathcal{P}_{H_0^1}$ is better than that for $\mathcal{P}_{L^2}$ but not by as wide margin as in Figure 3.12. The trend continues in Figure 3.14, but the solution for $\mathcal{P}_{H_0^1}$ is only slightly better than that for $\mathcal{P}_{L^2}$. We have tested other meshes, obtaining results (not shown) similar to the ones of Figures 3.12–3.14. The superiority of $\mathcal{P}_{H_0^1}$ seems to be a general fact, though it is more apparent for finer meshes than coarser meshes. One might conclude that H_0^1-optimality is not as strong a condition as it is often thought to be and may not be enough in many practical cases for which monotonicity is deemed essential.

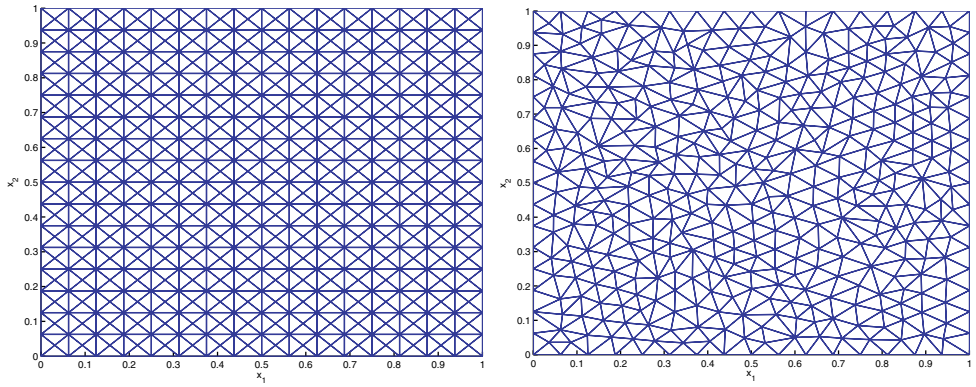

FIG. 3.11. *First two meshes associated with the coarse-scale spaces $\bar{V}$, used for the calculations of the coarse-scale components $\bar{u}$ of the model problem.*

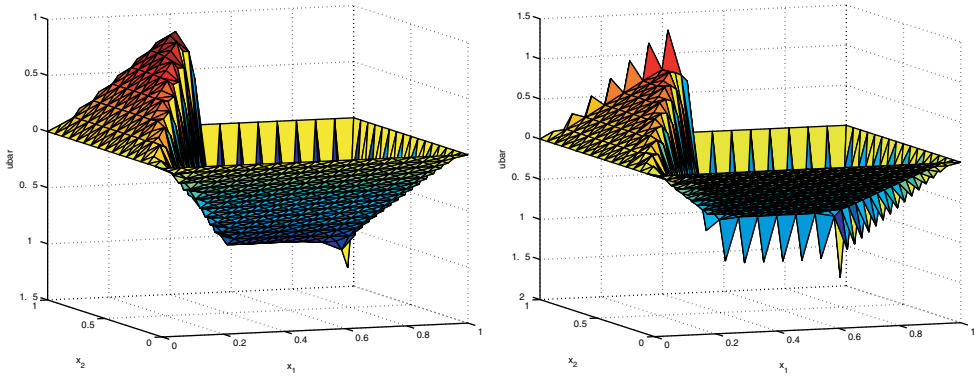

FIG. 3.12. *Coarse-scale component $\bar{u}$ for the model problem. $\mathcal{P} = \mathcal{P}_{H_0^1}$ (left) and $\mathcal{P} = \mathcal{P}_{L^2}$ (right). The coarse-scale space $\bar{V}$ is based on the left-hand mesh in Figure* 3.11.

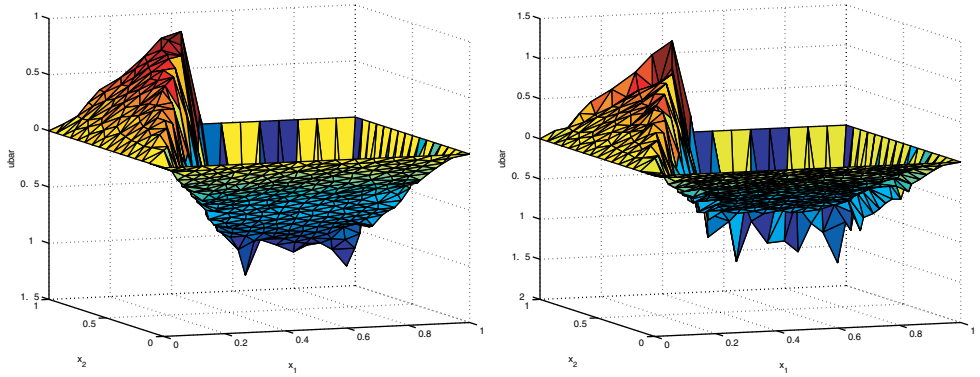

FIG. 3.13. *Coarse-scale component $\bar{u}$ for the model problem. $\mathcal{P} = \mathcal{P}_{H_0^1}$ (left) and $\mathcal{P} = \mathcal{P}_{L^2}$ (right). The coarse-scale space $\bar{V}$ is based on the right-hand mesh in Figure* 3.11.

Remark 6. In the case $\mathcal{P} = \mathcal{P}_{H_0^1}$, because of (3.6) we have, in the sense of distributions, $\int_\Omega g'(x,y)\Delta\bar{v}(y)\,dy = 0$ for all $\bar{v} \in \bar{V}$. Therefore, the fine-scale effect on

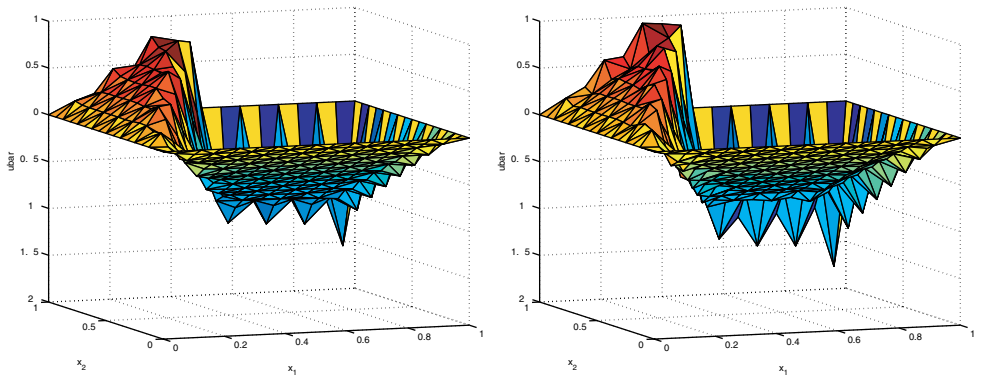

FIG. 3.14. *Coarse-scale component $\bar{u}$ for the model problem. $\mathcal{P} = \mathcal{P}_{H_0^1}$ (left) and $\mathcal{P} = \mathcal{P}_{L^2}$ (right). The coarse-scale space $\bar{V}$ is based on the mesh in Figure* 3.7.

the coarse-scale equation (3.7) becomes

$$\begin{aligned}\int_\Omega \int_\Omega \left(f(x) - \mathcal{L}\bar{u}(x)\right) g'(x,y) \mathcal{L}^* \bar{v}(y)\, dxdy \\ = -\int_\Omega \int_\Omega \left(f(x) - \mathcal{L}\bar{u}(x)\right) g'(x,y) \beta \cdot \nabla \bar{v}(y)\, dxdy.\end{aligned} \tag{3.25}$$

In one dimension, where g' is fully localized, the right-hand side of (3.25) is precisely the classical SUPG stabilization (see [9]); i.e., the residual is weighted only by the advective part of the operator, and the g' gives rise to the elementwise optimal τ, as described in sections 3.1 and 3.2. (Recall that f was assumed to be a piecewise-polynomial of degree at most $k-1$.) Note also that the diffusion operator in the residual in (3.25) may also be eliminated due to the aforementioned orthogonality property. These observations hold in higher dimensions as well, except g' is not fully localized within individual elements. In the classical multidimensional SUPG method [9], instead of (3.25) we have $-\sum_{e=1}^{n_{el}} \int_{\Omega_e} \left(f(x) - \mathcal{L}\bar{u}(x)\right) \tau(x)\, \beta \cdot \nabla \bar{v}(x)\, dx$, where Ω_e, $e = 1, \ldots, n_{el}$, are the elements of the mesh on Ω. The primary difference between SUPG and (3.25) is that g' is replaced by the elementwise constant τ. This approximation may be justified in light of the localized nature of g'. Indeed, SUPG has been shown to converge at optimal rates in higher dimensions (see, e.g., [19]), although in advection-dominated cases, the "stability" norm is not as strong as the H_0^1-seminorm in that it only contains the streamline derivative.

Remark 7. The residual-free bubble approach [4, 5, 6, 7, 8, 20, 21] has been shown in [3] to be equivalent to a multiscale method in which the fine-scale Green's function is approximated by a local element Green's function [12, 13]. Use of a local Green's function, in light of the framework described herein, can be rigorously justified only in the one-dimensional case in which the H_0^1-projector is employed. However, this amounts to a very convenient approximation in practice and one that is known to generate effective stabilized methods [1, 5, 6, 20]. With a better knowledge of g' in the multidimensional case, we would anticipate that improved stabilization schemes could be devised.

4. Conclusions. In this paper we have derived an expression for the fine-scale Green's function arising in VMS analysis. The specification of a projector, defining the direct-sum decomposition into coarse-scale and fine-scale components, renders the

problem for the fine-scale Green's function well-posed. Different projectors give rise to different fine-scale Green's functions, and their properties can vary considerably. It is felt to be beneficial if the fine-scale Green's function is more attenuated than the classical Green's function, and its support is dominantly local. It is found that the projector induced by the H_0^1-seminorm enjoys these properties whereas the projector induced by the L^2-norm does not.

The primary practical result of these studies is in the development of a framework for approximate multiscale methods. Indeed, in general it is not possible to exactly calculate the fine-scale Green's function. Despite its complexity, its orthogonality properties suggests simplified constructs in the form of stabilized methods. This is instantiated precisely in one dimension for the H_0^1-projector, and its possibility in higher dimensions is suggested as well. In fact, it is shown that the H_0^1-optimal method and SUPG have features in common.

The results obtained clarify the relationship between the fine-scale Green's function and the properties of the coarse-scale solution. However, we considered projectors associated only with inner products, and in particular, we studied only the H_0^1- and L^2-projectors. The coarse-scale solution achieves optimality in terms of the corresponding norm. One could conceive of requiring the coarse-scale solution to achieve optimality in other measures giving rise to nonlinear structure. This is an intriguing possibility in that one could, e.g., require monotonicity, or other desirable behavior. In the past, ad hoc procedures have been used to instill such properties in numerical methods, but the present ideas seem to have the potential for studying these issues in a more fundamental way.

Presently, most numerical methods are given as recipes, and they are evaluated ex post facto by the way they satisfy desired objectives. The present developments suggest a different approach: designing numerical methods to satisfy desired objectives ab initio. We are a long way from making this a practical reality, but we believe some small steps have been taken in this direction.

COMPUTING THE GAMMA FUNCTION USING CONTOUR INTEGRALS AND RATIONAL APPROXIMATIONS*

THOMAS SCHMELZER† AND LLOYD N. TREFETHEN†

Abstract. Some of the best methods for computing the gamma function are based on numerical evaluation of Hankel's contour integral. For example, Temme evaluates this integral based on steepest descent contours by the trapezoid rule. Here we investigate a different approach to the integral: the application of the trapezoid rule on Talbot-type contours using optimal parameters recently derived by Weideman for computing inverse Laplace transforms. Relatedly, we also investigate quadrature formulas derived from best approximations to $\exp(z)$ on the negative real axis, following Cody, Meinardus, and Varga. The two methods are closely related, and both converge geometrically. We find that the new methods are competitive with existing ones, even though they are based on generic tools rather than on specific analysis of the gamma function.

Key words. gamma function, Hankel contour, numerical quadrature

1. The gamma function. In his childhood Gauss rediscovered that the sum of the first n positive integers is given by

$$\sum_{k=1}^{n} k = \frac{n\,(n+1)}{2},$$

a formula which can be considered as an interpolation valid even for nonintegers. Starting in 1729 Euler discussed in a series of three letters to Goldbach, well known for the Goldbach conjecture, the problem of the product of the first n integers, which is today known as the factorial of n, $n!$. Davis [6] gives details about the history of the gamma function. We start here with the standard definition

$$\Gamma\,(z) = \int_0^\infty t^{z-1} e^{-t} dt, \qquad \text{Re } z > 0, \tag{1.1}$$

where

$$t^{z-1} = e^{(z-1)\log t} \text{ and } \log t \in \mathbb{R}.$$

The gamma function is analytic in the open right half-plane. Partial integration yields

$$\Gamma\,(z+1) = z\Gamma\,(z)\,, \tag{1.2}$$

and since $\Gamma\,(1) = 1$, we have

$$\Gamma\,(n+1) = n!.$$

Any confusion caused by this identity dates back to Legendre. It is possible to continue the gamma function analytically into the left half-plane. This is often done by a representation of the reciprocal gamma function as an infinite product [1, eq. 6.1.2]:

$$\frac{1}{\Gamma(z)} = \lim_{n\to\infty} \frac{n^{-z}}{n!} z(z+1)\dots(z+n)$$

valid for all z. This representation shows that $\Gamma(z)$ has poles for $z = 0, -1, -2, \dots$. Of more practical use is the reflection formula [1, eq. 6.1.17]:

$$\Gamma(z)\Gamma(1-z) = \frac{\pi}{\sin \pi z}, \qquad z \notin \mathbb{Z}. \tag{1.3}$$

This identity implies $\Gamma(1/2) = \sqrt{\pi}$. It is standard to approximate the gamma function only for $\operatorname{Re} z \geq 1/2$ and to exploit (1.3) for $\operatorname{Re} z < 1/2$.

2. Hankel's representation. An alternative representation for the reciprocal gamma function, which is an entire function, is due to Hankel [11]. Substituting $t = su$ in (1.1) yields

$$F(s) := \frac{\Gamma(z)}{s^z} = \int_0^\infty u^{z-1} e^{-su} du,$$

which can be regarded as the Laplace transform of u^{z-1} for fixed complex z. Hence u^{z-1} can be interpreted as an inverse Laplace transform:

$$u^{z-1} = \mathcal{L}^{-1}\{F(s)\} = \frac{1}{2\pi i}\int_{\mathcal{C}} e^{ku} F(k) dk \ = \frac{1}{2\pi i}\int_{\mathcal{C}} e^{ku} \frac{\Gamma(z)}{k^z} dk.$$

The path $\mathcal{C}$ is any deformed Bromwich contour such that $\mathcal{C}$ winds around the negative real axis in the anticlockwise sense (see Figure 1). Now we substitute $s = ku$, which yields

$$u^{z-1} = \frac{1}{2\pi i}\int_{\mathcal{C}} e^s \frac{\Gamma(z) u^z}{s^z u} ds$$

and hence

$$\frac{1}{\Gamma(z)} = \frac{1}{2\pi i}\int_{\mathcal{C}} s^{-z} e^s ds. \tag{2.1}$$

The numerical evaluation of integrals of the form

$$I = \frac{1}{2\pi i}\int_{\mathcal{C}} e^s f(s) ds \tag{2.2}$$

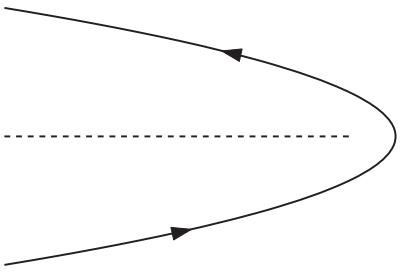

FIG. 1. *A typical Hankel contour, winding around the negative real axis (dashed) in the anticlockwise sense.*

has been discussed by Trefethen, Weideman, and Schmelzer [22]. The function s^{-z} has a branch cut on $\mathbb{R}^- = (-\infty, 0]$ but is analytic everywhere else. Hence (2.2) is independent of $\mathcal{C}$ under mild assumptions. The freedom to choose the path for inverse Laplace transforms has aroused a good deal of research interest. Recently Weideman and co-workers [22, 25, 24] have optimized parameters for the cotangent contours introduced by Talbot [19] as well as for other contours in the form of parabolas and hyperbolas. Here we focus on different numerical methods for which (2.1) is the common basis. In particular we shall compare

1. steepest descent contours,
2. Talbot-type contours,
3. rational approximation of e^s on $(-\infty, 0]$.

The first of these methods is an existing one, and the other two are new. Methods we do not compare are those of Spouge, Lanczos, and Stirling. Comments on these and on what is done in practice can be found in section 7.

In addition we mention in section 6 a generalization of (2.1) for matrices and introduce an idea for solving linear systems of the form $\Gamma(A)x = c$ without computing $\Gamma(A)$.

3. Saddle point method. Saddle point methods in general are extensively discussed in the book by Bender and Orszag [3, sect. 6.6]. The reciprocal gamma function is a standard example for this technique presented in this and many other textbooks. We keep the details to a minimum and follow an approach of Temme [20], who advocates the numerical evaluation of the integral along a steepest descent contour. A zero of the first derivative of an analytic function f indicates a saddle point of $\left|e^f\right|$. Through this point runs a path $\mathcal{C}$ where f has a constant imaginary part and a decreasing real part. This is a very desirable property for asymptotic analysis and numerical quadrature schemes. In order to apply these ideas here we fix the movable saddle by a change of variable $s = zt$. We get

$$\frac{1}{\Gamma(z)} = \frac{e^z z^{1-z}}{2\pi i} \int_{\mathcal{C}} e^{z\phi(t)} dt, \tag{3.1}$$

where $\phi(t) = t - 1 - \ln t$. If z is real and positive, then the integrand in (3.1) decreases exponentially as t moves away from 1 along the steepest descent contour. For complex z, on the other hand, the decrease becomes oscillatory, and in the limit of pure imaginary z, there is no decrease at all. Thus let us assume that z is a positive real number. Let $t = \rho e^{i\theta}$ be the steepest descent path parameterized by the radius ρ and the argument θ. The vanishing imaginary part at $t = 1$ induces the equation

$$0 = \operatorname{Im} \phi(t) = \rho \sin\theta - \theta.$$

Hence the path is given by $\rho = \theta / \sin\theta$. Temme [20] gives the reparameterization

$$\frac{1}{\Gamma(z)} = \frac{e^z z^{1-z}}{2\pi} \int_{-\pi}^{\pi} e^{-z\Phi(\theta)} d\theta,$$

where

$$\Phi(\theta) = 1 - \theta \cot\theta + \ln \frac{\theta}{\sin\theta}$$

with $\Phi(0) = 0$. Note that the real part of $dt/d\theta = \left(\cot\theta - \theta \csc^2\theta\right) + i$ is an odd function of θ.

The integral can be approximated by the midpoint rule, which is exponentially accurate. See [21] for a review of this phenomenon of high accuracy. The approximated integral is

$$I_N(z) = \frac{e^z z^{1-z}}{N} \sum_{k=1}^{N} e^{-z\Phi(\theta_k)}, \tag{3.2}$$

where the nodes are

$$\theta_k = -\pi + \left(k - \frac{1}{2}\right)\frac{2\pi}{N}, \qquad 1 \le k \le N.$$

This set of nodes is exponentially accurate, but it is not optimal for large z, for the nodes closer to $-\pi$ and π contribute negligibly because of the fast decay along the path. We could delete some of these points to make the method even more efficient, truncating the interval to $[-\tau, \tau]$ instead of $[-\pi, \pi]$.

4. Direct contour integration. Instead of working with saddle points, another approach is to apply the trapezoidal rule directly to (2.1). This makes it easy to evaluate $\Gamma(z)$ for complex as well as real arguments. Let $\phi(\theta)$ be an analytic function that maps the real line $\mathbb{R}$ onto the contour $\mathcal{C}$. Then (2.1) can be written as

$$I = \frac{1}{2\pi i} \int_{-\infty}^{\infty} \phi(\theta)^{-z} e^{\phi(\theta)} \phi'(\theta)\, d\theta. \tag{4.1}$$

Because of the term $e^{\phi(\theta)}$, the integrand decreases exponentially as $|\theta| \to \infty$ so that one commits an exponentially small error by truncating $\mathbb{R}$ to a finite interval. For simplicity we shall arbitrarily fix this interval as $[-\pi, \pi]$. In $[-\pi, \pi]$ we take N points θ_k spaced regularly at a distance $2\pi/N$, and our trapezoid approximation to (2.1) becomes

$$I_N = -iN^{-1} \sum_{k=1}^{N} e^{s_k} s_k^{-z} w_k, \tag{4.2}$$

where $s_k = \phi(\theta_k)$ and $w_k = \phi'(\theta_k)$. MATLAB codes are given in Figure 2.

Note that there is still the freedom left to choose a particular path. In Program 31 of the textbook [23], a closed circle with center $c = -11$ and radius $r = 16$ is used with 70 equidistant nodes on it. Although this contour crosses the branch cut, it does so sufficiently far down the real axis that the error introduced thereby is less than 10^{-11}.

A more systematic approach has been pursued by Weideman and co-workers [22, 25, 24], who have proposed, in particular, parameters for parabolic, hyperbolic, and cotangent contours:

1. Parabolic contour

$$s(\theta) = N\left[0.1309 - 0.1194\theta^2 + 0.2500i\theta\right], \tag{4.3}$$

2. Hyperbolic contour

$$s(\theta) = 2.246N\left[1 - \sin(1.1721 - 0.3443i\theta)\right], \tag{4.4}$$

3. Cotangent contour

$$s(\theta) = N\left[0.5017\theta\cot(0.6407\theta) - 0.6122 + 0.2645i\theta\right]. \tag{4.5}$$

```

Using equidistant nodes with respect to θ, all of these contours show geometric convergence at rates approximately $O(3^{-N})$. Figure 3 illustrates this behavior by showing convergence as $N \to \infty$ for six values of z. According to Weideman the convergence rate for the cotangent contour is $O(3.89^{-N})$, which is shown as a dashed line in the figure.

In Figure 4, this behavior is compared in a region of the z-plane to the convergence for the parabolic and hyperbolic contours, the steepest descent contours, and the method of rational approximation to be introduced in the next section. All the methods are geometrically convergent (except steepest descents near the imaginary axis), and the cotangent contours and rational approximations are the best.

For all of these Talbot-type contours we encounter the same nonoptimality effect as for the saddle point method: The decay of the integrand is so fast that the left-

FIG. 6. *A MATLAB routine for computing the gamma function. The fundamental identities* (1.2) *and* (1.3) *are used to reduce all arguments to the strip* $\frac{1}{2} \le \mathrm{Re}\, z < \frac{3}{2}$. *The code makes use of the functions listed in Figure* 2.

most nodes make a negligible contribution. The source of this phenomenon is the fact that Weideman's analysis considers only the factor e^s in (2.1), treating the factor s^{-z} as of order 1, whereas in fact, when z has a large real part, s^{-z} is very small. This effect is ubiquitous when computing with a fixed path and fixed nodes for all $z \in \mathbb{C}$. We could take advantage of it by fine-tuning Weideman's parameters in a manner specific to the gamma function, but we shall not do that here since our interest is in the application of generic methods for integrals of the form (2.2). Also, it is simpler and just as effective to use the fundamental identities (1.2) and (1.3) to reduce all arguments to the strip $\frac{1}{2} \le \mathrm{Re}\, z < \frac{3}{2}$. The effect of such reductions is illustrated for the cotangent contour in Figure 5. A MATLAB routine implementing this strategy is given in Figure 6.

5. Rational approximation. In a recent paper we, along with Weideman, interpreted the trapezoidal rule on a Hankel contour as a rational approximation of $\exp(z)$ on the negative real axis [22]. The analysis of best Chebyshev approximations of this kind is a problem made famous by Cody, Meinardus, and Varga (CMV) [5]; the errors are known to decrease asymptotically at the rate $O(H^N)$, where $H = 1/9.28903\ldots$ is known as *Halphen's constant* [10]. As shown in [22], these approximations can be used directly to evaluate integrals (2.2), bypassing the consideration of Talbot contours and the trapezoid rule. Given N, we define the best type (N, N) approximation to $\exp(s)$ to be the unique real rational function r_N^* of type (N, N) such that

$$\sup_{s\in\mathbb{R}^-} |r_N^*(s) - \exp(s)| = \inf_{r\in R_N} \sup_{s\in\mathbb{R}^-} |r(s) - \exp(s)|\,,$$

where R_N denotes the set of all rational functions of type (N, N). The coefficients of the polynomials in the numerator and denominator of r_N^* are given to very high accuracy in a paper by Carpenter, Ruttan, and Varga [4]. A practical way of determining these approximants on the fly is the Carathéodory–Fejér (CF) method. (In principle, the CF approximation is not best but near-best, but its difference from the true best approximation is negligible for $N \geq 2$ [22].) The function r_N^* can be represented in a partial fraction representation, i.e., by N poles $p_1, \ldots, p_N$ and residues $c_1, \ldots, c_N$ such that

$$r_N^*(s) = \sum_{k=1}^{N} \frac{c_k}{s - p_k} + c_0.$$

We define $\tilde{r}_N(s)$ to be the portion of this expression in the sum, i.e., $\tilde{r}_N(s) = r_N^*(s) - r_N^*(\infty)$, a rational function of type $(N-1, N)$ whose deviation from $\exp(s)$ on $\mathbb{R}^-$ decreases at the same asymptotic rate as that of r_N^* as $N \to \infty$.

These rational approximants can be used as the basis of another method for evaluating $1/\Gamma(z)$. We simply replace e^s in (2.1) by $\tilde{r}_N$ to obtain, with the aid of residue calculus,

$$I_N = \frac{1}{2\pi i} \int_{\mathcal{C}} \tilde{r}_N(s) s^{-z} ds = -\sum_{k=1}^{N} c_k p_k^{-z}, \tag{5.1}$$

which converges for $\mathrm{Re}\ z > 0$ as the decay of the integrand at infinity is fast enough. For $\mathrm{Re}\ z > 1$ we also have

$$I_N = \frac{1}{2\pi i} \int_{\mathcal{C}} r_N^*(s) s^{-z} ds. \tag{5.2}$$

For even N the poles come in conjugate pairs and (5.1) simplifies for real z to

$$I_N = -\sum_{k=1}^{N/2} 2\mathrm{Re}\left(c_k p_k^{-z}\right)$$

provided the first $N/2$ poles are all in the upper half-plane or all in the lower half-plane.

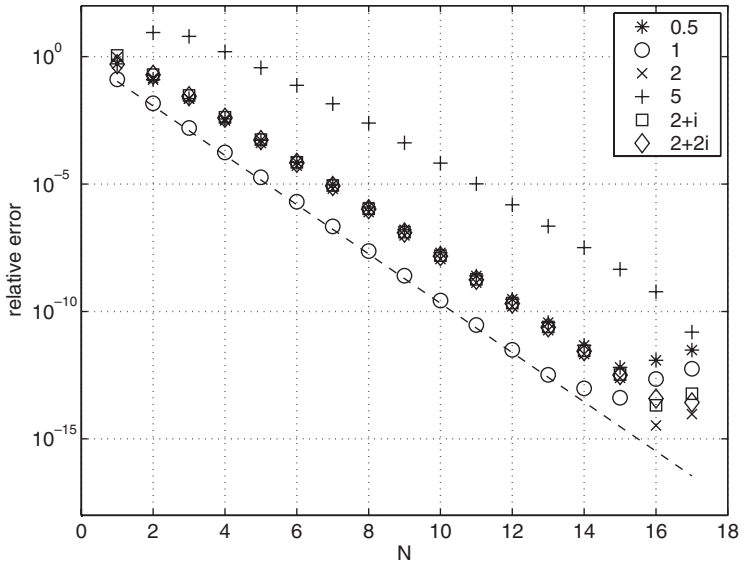

FIG. 7. *Convergence for the near-best rational approximation* (5.1) *of type* $(N-1,N)$ *with no shift. The convergence is about twice as fast as in Figure* 3*, with fifteen integrand evaluations sufficing to produce near machine precision. The dashed line shows* 9.28903^{-N}*, confirming Theorem* 5.2.

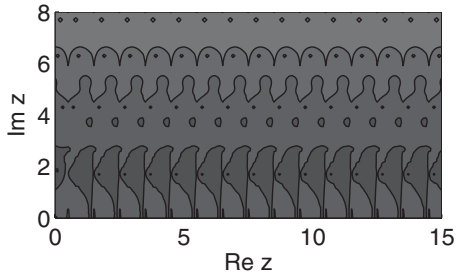

FIG. 8. *Relative error in evaluating* $\Gamma(z)$ *using a CMV approximation,* $N = 16$ *with no shift solely in* $\frac{1}{2} \le \mathrm{Re}\, z < \frac{3}{2}$*, and applying* (1.2) *and* (1.3) *for other points of the z-plane. The shading is the same as in Figure* 4.

For each z satisfying $\mathrm{Re}\, z > 0$ or $\mathrm{Re}\, z > 1$ as appropriate, I_N appears to converge to $1/\Gamma(z)$ at a geometric rate controlled by the same constant $H = 1/9.28903\ldots$ as indicated in Figures 7 and 8. A proof of this claim would follow from the following result, which we believe is true but have not yet proved.

CONJECTURE 5.1. *Let* $\{r_N^*\}$ *be the best approximations over* $\mathbb{R}^-$ *as defined above, let* K *be a compact set in* $\mathbb{C}$*, and let* $\|\cdot\|_K$ *denote the supremum norm over* K*. Then*

$$\limsup_{N\to\infty} \|\exp(s) - r_N^*(s)\|_K^{1/N} \le H = \frac{1}{9.28903\ldots}.$$

Here is the result that follows from the conjecture.

THEOREM 5.2. *Let* $\{\tilde{r}_N\}$ *and* $\{r_N^*\}$ *be the rational approximations defined above and let* z *be fixed with* $\mathrm{Re}\, z > 0$*. Then the approximations* (5.1) *and* (5.2) *(provided*

Re $z > 1$) *satisfy*

$$\limsup_{N\to\infty} \left| \frac{1}{\Gamma(z)} - I_N(z) \right|^{1/N} \leq H = \frac{1}{9.28903\ldots}.$$

Partial proof, assuming the validity of Conjecture 5.1. We introduce a special Hankel contour $\mathcal{C}_\rho$. It consists of a circle of radius ρ enclosing the origin and two rays joining $\rho e^{-i\pi}$ and $\rho e^{+i\pi}$ with the point $-\infty$. An upper bound for the error is deduced on $\mathcal{C}_\rho$. For the case of r_N^*, for example, we get by using (2.1) and (5.2)

$$\left| \frac{1}{\Gamma(z)} - I_N(z) \right| \leq \frac{1}{2\pi} \left\| r_N^*(s) - \exp(s) \right\|_{\mathcal{C}_\rho} \int_{\mathcal{C}_\rho} \left| s^{-z} \right| |ds|,$$

and we note that for any s, $|s^{-z}| \leq |s|^{-a} e^{\pi|b|}$ for $z = a + bi$ with $a > 1$. From here we readily obtain

$$\int_{\mathcal{C}_\rho} \left| s^{-z} \right| |ds| \leq \left(2\pi + \frac{2}{a-1} \right) e^{|b|\pi} \rho^{1-a}.$$

The convergence of $r_N^*(s)$ to $\exp(s)$ on the circle of radius ρ can be estimated by Conjecture 5.1, and therefore

$$\limsup_{N\to\infty} \left| \frac{1}{\Gamma(z)} - I_N(z) \right|^{1/N} \leq H.$$

It remains to show that the result just proved for r_N^* and Re $z > 1$ also holds for $\tilde{r}_N$ and Re $z > 0$. To do this split up the integral to obtain the estimate

$$\left| \frac{1}{\Gamma(z)} - I_N(z) \right| \leq \frac{1}{2\pi} \left\| s\left(\tilde{r}_N(s) - \exp(s)\right) \right\|_{\mathcal{C}_\rho} \int_{\mathcal{C}_\rho} \left| s^{-z-1} \right| |ds|.$$

The function $s\left(\tilde{r}_N - \exp(s)\right)$ in the left-hand term of this estimate approaches a constant as $s \to -\infty$ for each N, since $\tilde{r}_N - \exp(s)$ decreases at the rate $O(s^{-1})$. The essential point in showing that these Nth roots approach H as required is to make sure that the leftmost extremum of $\tilde{r}_N(s) - \exp(s)$ does not occur at a value of s that is exponentially large, in which case the Nth root of this value of s might fail to converge to 1. In fact, the results of Aptekarev [2] and Magnus [13] appear to confirm numerical evidence that the location of this extremum grows just algebraically, but we will not attempt a rigorous proof here. □

The fundamental property $\exp(a+b) = \exp(a)\exp(b)$ for any two complex arguments can be exploited in our algorithm. Given a positive parameter b, the function $\tilde{r}_N^b(s) = \exp(b)\tilde{r}_N(s-b)$ can be regarded as an approximation of $\exp(s)$ in the interval $(-\infty, b]$. In particular, (5.1) is the special case of this approximation for $b = 0$:

$$I_N^b = \frac{1}{2\pi i} \int_{\mathcal{C}} \tilde{r}_N^b(s) s^{-z} ds = -\sum_{k=1}^{N} e^b c_k (p_k + b)^{-z}. \tag{5.3}$$

It is easily proved that the *shifted* rational approximation $\tilde{r}_N^b(s)$ still converges with the same asymptotic rate H^N. In experiments we have observed that a shift of $O(1)$ gives better results especially for real arguments, as illustrated in Figures 7 and 9 and 4(f) and 4(g), where we used a shift of $b = 1$.

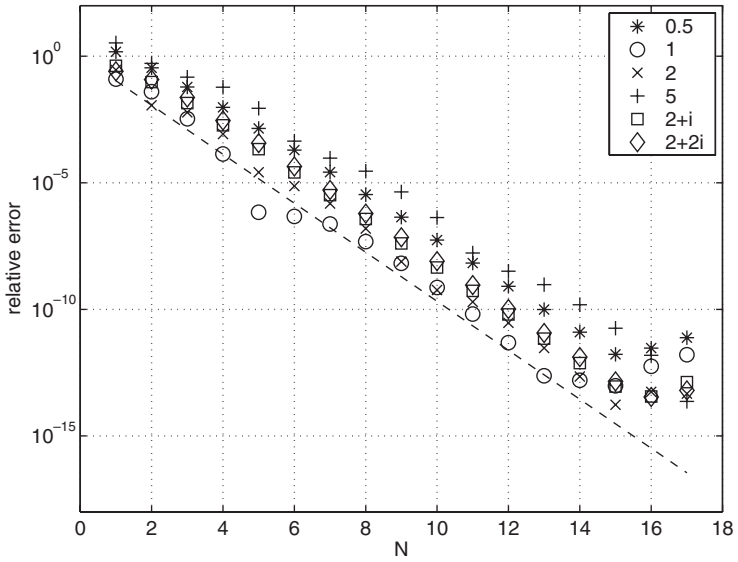

FIG. 9. *Convergence for the near-best rational approximation* (5.1) *of type* $(N-1, N)$ *with shift* $b = 1$. *Though the asymptotic behavior is the same, the constants are better than in Figure* 7, *and the use of such a shift might be a good idea in practice.*

6. Matrix arguments. Hankel's contour integral (2.1) can be generalized to square matrices A, and one can apply the methods introduced here to compute $\Gamma(A)^{-1}$ or to compute the solution vector x in a linear system $\Gamma(A)x = c$ without computing $\Gamma(A)$. We have confirmed this by numerical experiments not reported here. A drawback of such methods is that it is expensive to compute $s_k^{-A}c$ for every node; methods based on the algorithms of Spouge [18] and Lanczos [12] might be more efficient. We are currently not aware of applications where $\Gamma(A)$ is used for matrix arguments.

7. Other methods and existing software. There are a variety of existing methods for computing the gamma function. Are our methods competitive with these? As far as we can tell, the answer seems to be yes; they are "in the ballpark" in the sense of coming within a factor of 1–10 of the best methods, notably

- the method of Lanczos [12],
- the method of Spouge [18],
- the asymptotic Stirling series [1, eq. 6.1.37].

We emphasize that these methods are specialized algorithms designed for computing the gamma function and its close relatives, whereas our ideas are applicable in a much larger framework.

7.1. The method of Spouge. The method of Spouge [18] is attractive because of its simplicity and precise error estimates. Spouge introduced the approximation

$$\Gamma(z+1) \approx (z+\gamma)^{z+1/2} e^{-(z+\gamma)} \sqrt{2\pi} \left[c_0 + \sum_{k=1}^{N} \frac{c_k(\gamma)}{z+k} \right],$$

which is valid for $\mathrm{Re}\,(z+\gamma) > 0$ and dependent on a positive real parameter γ with $N = \lceil \gamma \rceil - 1$, which converges to an equality as $\gamma \to \infty$. Here $c_0 = 1$, and the other

coefficients are given by

$$c_k(\gamma) = \frac{1}{\sqrt{2\pi}} \frac{(-1)^{k-1}}{(k-1)!} (-k+\gamma)^{k-1/2} e^{-k+\gamma}, \qquad 1 \le k \le N.$$

The absolute error for this approximation can be bounded [18, Thm. 1.3.1] by

$$E_N(z) \le \left| \gamma(z) \frac{1}{\sqrt{N+1}(2\pi)^{N+3/2}} \right|.$$

Note that the relative error does not depend on z, making Spouge's method especially attractive for uniform approximations in the right half-plane. The above inequality implies that the method converges at least as fast as (6.28^{-N}), a rate lying midway between (3.89^{-N}) for Talbot contours and (9.29^{-N}) for best rational approximations. Actually, experiments suggest a better convergence rate, closer to $O(10^{-N})$.

7.2. The method of Lanczos. The method of Lanczos [12] is closely related to that of Spouge. Lanczos's method is based on the fast evaluation of the integral

$$F_\gamma(z) = \int_0^e \left[v(1-\log v)\right]^z v^\gamma dv,$$

where γ is a positive free parameter. The integral is approximated by a rational function

$$F_{N,\gamma}(z) = a_0 + \sum_{k=1}^{N} a_k/(z+k).$$

A variety of methods for computing the coefficients are discussed in a recent thesis by Pugh [16]. Their rate of decay depends strongly on a good choice for γ. However, it is unclear if it makes sense to ask about the asymptotic behavior for $N \to \infty$. Little is known about the decay of the error $|F_\gamma(z) - F_{N,\gamma}(z)|$ [16, Chap. 11]. Lanczos claimed that the higher γ becomes, the smaller is the value of the coefficients at which the convergence begins to slow down. At the same time, however, we have to wait longer before the asymptotic stage is reached. Pugh [16] calls this behavior the *Lanczos shelf* and is interested in finding good pairs of γ and N in order to guarantee a certain precision in the right half-plane. Godfrey [9] gives a 15-term expansion that provides an accuracy of about 15 significant digits along the real axis and about 13 digits in the rest of the complex plane. Because of the simple form of $F_{N,\gamma}(z)$, Lanczos's method is particularly suitable for matrix arguments.

7.3. Stirling's method. The asymptotic series that generalizes Stirling's formula[1] is still a standard and powerful method for evaluating the gamma function. There is a great deal of literature discussing efficient strategies and error estimates for these series (see the references in [14]). The goal here is to minimize the number of terms used to achieve the desired accuracy. This can be done in two ways, by either shifting the argument to the right or enforcing a faster asymptotic decay of the relative error using more terms in the series. (For fixed z and $N \to \infty$ the series does not converge.) The method is especially attractive for arguments with a large real part working in an arbitrary precision environment. Using an asymptotic series for $\log\Gamma(z)$, the error is bounded for $\operatorname{Re} z \ge 0$ by $|B_{2N}/(2N-1)|\,|z|^{1-2N}$, where B_{2N} denotes a Bernoulli number. This simple error estimate is due to Spira [17].

[1] Stirling was a student at the same Oxford college we both belong to, Balliol.

7.4. Software. Software libraries and programming environments for scientific computing all have routines to compute the gamma function, although quite a few do not deal with complex arguments. For our small survey we explored online documentation for various products, and yet it often remains unclear exactly which methods are used. For real arguments, a popular trick is to work with a rational Chebyshev approximation on the interval $[1, 2]$ and map this interval by the recurrence relation (1.2) to larger regions of the real line. The routine in the NAG library seems to map this interval to the whole real line, whereas MATLAB[2] uses a Stirling approximation for arguments larger than 12. On the fundamental interval, MATLAB uses a rational Chebyshev approximation of type $(8, 8)$. As the MATLAB routine was originally designed for Fortran, we imagine that many Fortran libraries use essentially the same method.

None of the above products provides a function for complex arguments. For Fortran the IMSL library has a routine of this kind. As there are no references to the work of Lanczos and Spouge in the IMSL documentation, we presume that it is based on asymptotic series. The Gnu Scientific Library provides a C function `gsl_sf_lngamma_complex_e` that evaluates $\log \Gamma(z)$ via the complex Lanczos method.

Mathematica uses the asymptotic Binet formula, which is another name for the Stirling series. We presume Maple uses the same method since the Maple documentation gives a reference to the classic book on special functions [7], which appeared before the methods of Lanczos and Spouge were introduced. Somewhat more interesting are the comments in [15]:

> There are a variety of methods in use for calculating the function $\Gamma(z)$ numerically, but none is quite as neat as the approximation derived by Lanczos. This scheme is entirely specific to the gamma function, seemingly plucked from thin air.

8. Conclusions. We have shown that $\Gamma(z)$ can be evaluated with geometric accuracy by two types of generic related methods:

- applying the trapezoidal rule on Talbot contours.
- using best rational approximations on the negative real axis.

Typically the second method is about twice as fast as the first. However, the first is simpler to implement as the construction of the best rational approximation is not trivial.

Amongst the Talbot contours, the cotangent contour has the best results. Using a shift from $(-\infty, 0]$ to $(-\infty, 1]$, one can improve the results for the best rational approximation a bit. For smaller values of z in the right half-plane, the approximations are excellent, and using the fundamental recurrence relation for the gamma function, one can extend the region of accuracy.

Even though the methods we have introduced are based on generic tools rather than on specific analysis of the gamma function, they are competitive with existing ones. The gamma function is just one of many special functions that have integral representations which can be evaluated efficiently by Talbot-type contours and rational approximations (see [8] for further examples). We believe that these methods can be useful in many areas of scientific computing.

Acknowledgments. We are grateful to André Weideman for discussions throughout this project, to Nico Temme for expert advice on the gamma function, and to

[2]In MATLAB 7.0 the command `type gamma` gives the source code of the corresponding `mex`-file. Previous versions do not offer this possibility.

Alphonse Magnus and Alexander Aptekarev for advice about Conjecture 5.1 and the challenges involved in proving it.

NUMERICAL APPROXIMATION OF A TIME DEPENDENT, NONLINEAR, SPACE-FRACTIONAL DIFFUSION EQUATION*

VINCENT J. ERVIN†, NORBERT HEUER‡, AND JOHN PAUL ROOP§

Abstract. In this article we analyze a fully discrete numerical approximation to a time dependent fractional order diffusion equation which contains a nonlocal quadratic nonlinearity. The analysis is performed for a general fractional order diffusion operator. The nonlinear term studied is a product of the unknown function and a convolution operator of order 0. Convergence of the approximation and a priori error estimates are given. Numerical computations are included, which confirm the theoretical predictions.

Key words. anomalous diffusion, nonlinear parabolic equation, finite element approximation

AMS subject classification. 65N30

DOI. 10.1137/050642757

1. Introduction.

In this paper we study the numerical approximation to time dependent fractional order diffusion equations containing a nonlocal quadratic nonlinearity. Specifically, we consider equations of the form

$$u_t + \mathcal{D}^{2\alpha} u - \nabla \cdot (u\, B(u)) = f(x), \quad x \in \Omega\ ,\ t \in (0,T], \tag{1.1}$$

$$u(x,t) = 0, \quad x \in \partial\Omega\ ,\ t \in (0,T], \tag{1.2}$$

$$u(x,0) = u^0(x), \quad x \in \Omega, \tag{1.3}$$

which arise from models in statistical mechanics. In such a setting, u can be thought of as describing the density of particles filling up a domain $\Omega \subset \mathbb{R}^d$. In (1.1), $\mathcal{D}^{2\alpha}$ denotes a general fractional order diffusion operator of order 2α, $1/2 < \alpha \leq 1$. The term $\nabla \cdot (u\, B(u))$ models particle interactions.

For the classical diffusion case ($\alpha = 1$) the diffusion operator models a Brownian diffusion process. For fractional diffusion ($1/2 < \alpha < 1$) the $\mathcal{D}^{2\alpha}$ operator is commonly referred to as *anomalous diffusion*, where the underlying stochastic process is a Lévy α-stable flight. A key difference between fractional diffusion operators and the usual diffusion operator is that fractional diffusion operators are *nonlocal* operators. Equations containing fractional diffusion have also been investigated in modeling turbulent flow [6, 18], chaotic dynamics of classical conservative systems [19], and contaminant transport in groundwater flow [2, 12].

There are a number of definitions for fractional derivatives in $\mathbb{R}^1$, for example the Riemann–Liouville, Grüwald–Letnikov, and Caputo fractional derivatives [13], the Riemann–Liouville being the most commonly used. In higher dimensions there are also several definitions for the fractional diffusion operator. In this article (see section 2.2) we describe two: the fractional Laplacian operator, and the weighted directional, fractional diffusion operator. For problems posed on bounded domains, a disadvantage of the fractional Laplacian operator is that it is formally defined in terms of the Fourier transform. From practical considerations we have focused our attention on the weighted directional, fractional diffusion operator.

From the fact that $\mathcal{D}^{2\alpha}$ is a strongly elliptic operator, the existence and uniqueness for the space-fractional diffusion equation parallels that of the usual diffusion equation, the difference being in the function spaces, i.e., $H_0^\alpha(\Omega)$ instead of $H_0^1(\Omega)$. (See [7, 8, 14].) The existence of solutions to (1.1)–(1.3) has been studied by Biler and Woyczyński in [4]. For $B(\cdot)$ given by (2.8), (2.9) they showed the existence of a local in time weak solution. In this paper we do not investigate the existence of u satisfying (1.1)–(1.3) but, assuming a sufficiently regular solution u exists, the existence and convergence properties of its approximation u_h. The results presented in this paper extend the work developed in [7], [8] (see also [15]) for a steady-state linear fractional advection dispersion equation.

A finite element approximation scheme is described and shown to be computable in section 3. A priori error estimates for the approximation are presented in section 4. Hölder-type inequalities for Sobolev spaces, used in the analysis, are derived in section 2.4. Our analysis does not rely on the particular form of the fractional diffusion operator, requiring only that it satisfy properties of *continuity* and *coercivity* (see (2.2), (2.3)). Several examples of nonlocal operators $B(\cdot)$ are given in section 2.3. Again, our analysis does not assume a particular form for $B(\cdot)$, only that it is linear and an *operator of order* 0 (see (2.4)). Finally, in section 5 we present some numerical experiments which support the theoretical estimates.

2. Mathematical preliminaries.

2.1. Mathematical notation. In this section we summarize the mathematical notation used and state our assumptions regarding properties satisfied by the fractional diffusion operator $\mathcal{D}^{2\alpha}$ and the operator $B(\cdot)$.

The following notation is used. The $L^2(\Omega)$ inner product is denoted by $(\cdot,\cdot)$, and the $L^p(\Omega)$ norm by $\|\cdot\|_{L^p}$, with the special cases of $L^2(\Omega)$ and $L^\infty(\Omega)$ norms being written as $\|\cdot\|$ and $\|\cdot\|_\infty$, respectively. For $k \in \mathbb{N}$, we denote the norm associated with the Sobolev space $W^{k,p}(\Omega)$ by $\|\cdot\|_{W^{k,p}}$, with the special case $W^{k,2}(\Omega)$ being written as $H^k(\Omega)$ with norm $\|\cdot\|_k$ and seminorm $|\cdot|_k$. For the definition of fractional order Sobolev spaces $W^{s,p}(\Omega)$, $s \in \mathbb{R}^+\backslash\mathbb{N}$, we use the real method of interpolation between two Banach spaces [3, 16].

When $v(\mathbf{x},t)$ is defined on the entire time interval $(0,T)$, we define

$$\|v\|_{\infty,k} := \sup_{0<t<T} \|v(\cdot,t)\|_k\,, \quad \|v\|_{0,k} := \left(\int_0^T \|v(\cdot,t)\|_k^2\,dt\right)^{1/2},$$
$$\|v\|(t) := \|v(\cdot,t)\|.$$

For convenience we let X denote the space

$$X := H_0^\alpha(\Omega) := \text{ closure of } C_0^\infty(\Omega) \text{ in } H^\alpha(\Omega). \tag{2.1}$$

We use $H^{-\alpha}(\Omega)$ to denote the dual space of $H_0^\alpha(\Omega)$, with norm denoted $\|\cdot\|_{-\alpha}$.

Throughout the paper we use C to denote a *generic constant* whose actual value may change from line to line.

We make the following general assumptions regarding the diffusion operator. There exist constants $C_c, C_t > 0$ such that for $v, w \in X$

$$\langle \mathcal{D}^{2\alpha} v, w\rangle \le C_t \|v\|_\alpha \|w\|_\alpha \quad \text{(continuity on } X \times X\text{)}, \tag{2.2}$$

$$\langle \mathcal{D}^{2\alpha} v, v\rangle \ge C_c \|v\|_\alpha^2 \quad \text{(coercivity on } X\text{)}, \tag{2.3}$$

where $\langle\cdot,\cdot\rangle$ denotes the duality pairing of $H^{-\alpha}(\Omega)$ and $H_0^\alpha(\Omega)$.

For the nonlocal operator $B(\cdot)$ we assume the following:

(i) $B(\cdot)$ is linear,

(ii) $B(\cdot)$ is an *operator of order 0*; i.e., for $\beta \ge 0$, $u \in H^\beta(\Omega)$,

$$\|B(u)\|_\beta \le C_B \|u\|_\beta. \tag{2.4}$$

2.2. Examples of fractional diffusion operators satisfying (2.2), (2.3).

1. *Fractional Laplacian operator.* In the context of pseudo differential operators [17], a fractional diffusion operator may be defined in terms of the negative Laplacian operator, $-\Delta$ [4].

We have that for ω the Fourier transform variable,

$$\mathcal{F}(-\Delta u(x)) = |\omega|^2 \hat{u}(\omega).$$

The fractional Laplacian operator is then defined via the inverse Fourier transform as

$$(-\Delta)^{\gamma/2} u(x) := \mathcal{F}^{-1}\left(|\omega|^\gamma \hat{u}(\omega)\right). \tag{2.5}$$

Associated with (2.5), a fractional differential operator of order 2α may be formally defined as

$$\mathcal{D}^{2\alpha} u(x) := (-\Delta)^\alpha u(x). \tag{2.6}$$

For $\mathcal{D}^{2\alpha}$ defined by (2.6), we have for $v, w \in H_0^\alpha(\Omega)$, $\alpha > 1/2$,

$$\begin{aligned}\langle \mathcal{D}^{2\alpha} v, w\rangle &= \left((-\Delta)^{\alpha/2} v,\, (-\Delta)^{\alpha/2} w\right)\\ &\le C_1 \|v\|_\alpha \|w\|_\alpha.\end{aligned}$$

Also,

$$\begin{aligned}\langle \mathcal{D}^{2\alpha} v, v\rangle &= \left((-\Delta)^{\alpha/2} v,\, (-\Delta)^{\alpha/2} v\right)\\ &\ge C_2 \|v\|_\alpha^2.\end{aligned}$$

2. *Weighted directional, fractional diffusion operator.* In [8, 14] the following fractional diffusion operator was introduced and analyzed:

$$D_M^{2\alpha} u(x) := -\int_{\|\nu\|=1} D_\nu^{2\alpha} u(x)\, M(d\nu), \tag{2.7}$$

where $M(d\nu)$ denotes a general probability measure on the unit sphere in $\mathbb{R}^{\acute{d}}$; for $\sigma > 0$,

$$D_\nu^{-\sigma} v(x) := \frac{1}{\Gamma(\sigma)} \int_0^\infty \xi^{\sigma-1} v(x - \xi\nu)\, d\xi \ ,$$

and for $n-1<\beta\le n$, $\sigma=n-\beta$,

$$D_\nu^\beta v(x) \;:=\; (\nu\cdot\nabla)^n\, D_\nu^{-\sigma} v(x) \quad .$$

Properties (2.2), (2.3) were established in [8, 14] for $D_M^{2\alpha}$.

2.3. Examples of operators B(·) satisfying (2.4). Typically $B(\cdot)$ is of the form

$$B(u)(x) \;=\; \int b(x,y)\, u(y)\, dy \;. \tag{2.8}$$

For the ordinary diffusion equation the following operators have been considered. The choice

$$b(x,y) \;=\; c\,(x-y)\,|x-y|^{-\acute{d}} \tag{2.9}$$

has been used in a model for Brownian diffusion of charge carriers interacting via Coulomb forces. For $c>0$, (2.8) has been used to model the mutual gravitational attraction of particles in a cloud [4]. For $\acute{d}=2$ and

$$b(x,y) \;=\; (x_2-y_2,\,-(x_1-y_1))\,|x-y|^{-2} \tag{2.10}$$

the ordinary diffusion equation becomes the vorticity equation for the Navier–Stokes equations.

A general *potential kernel* for $B(\cdot)$ has the form

$$b(x,y) \;=\; c\,(x-y)\,|x-y|^{-\acute{d}+\beta-1} \qquad \text{for } 0<\beta\le \acute{d}-1. \tag{2.11}$$

To determine the order of the operators $B(\cdot)$ defined above we have the following from [9]:

1. For $P(x_1,\dots,x_{\acute{d}})$ a polynomial in $\acute{d}$ variables,

$$\mathcal{F}(P(x_1,\dots,x_{\acute{d}}))(\boldsymbol{\omega}) \;=\; (2\pi)^{\acute{d}}\, P\left(\frac{-i\partial}{\partial\omega_1},\dots,\frac{-i\partial}{\partial\omega_{\acute{d}}}\right)\delta(\boldsymbol{\omega}) \;. \tag{2.12}$$

2. For $r=|x|$, $\rho=|\boldsymbol{\omega}|$, $m\in\{0,1,2,\dots\}$, c_{-1},c_0 constants dependent on $\acute{d}+2m$,

$$\mathcal{F}(r^{-\lambda}) = 2^{\acute{d}-\lambda}\pi^{\acute{d}/2}\,\frac{\Gamma((\acute{d}-\lambda)/2)\,\rho^{\lambda-\acute{d}}}{\Gamma(\lambda/2)}, \qquad \lambda\ne\acute{d}+2m, \tag{2.13}$$

$$\mathcal{F}(r^{-\acute{d}-2m}) = \frac{1}{2}\,\Gamma\left(\frac{\acute{d}}{2}\right)\,\pi^{-\acute{d}/2}\,\left(c_{-1}\rho^{2m}\ln\rho \;+\; c_0\rho^{2m}\right). \tag{2.14}$$

For the kth component of $x/|x|^\lambda = x_k/|x|^\lambda$, $\lambda\ne\acute{d}+2m$, combining (2.12) and (2.13), and using the Fourier transform property of the convolution operator $\star$,

$$\begin{aligned}
\mathcal{F}\left(\frac{x_k}{|x|^\lambda}\right) &= (2\pi)^{\acute{d}}\,\left(\frac{-i\,\partial}{\partial\omega_k}\right)\delta(\boldsymbol{\omega}) \;\star\; 2^{\acute{d}-\lambda}\pi^{\acute{d}/2}\,\frac{\Gamma((\acute{d}-\lambda)/2)\,\rho^{\lambda-\acute{d}}}{\Gamma(\lambda/2)} \\
&= C\int\left(\frac{-i\,\partial}{\partial\sigma_k}\right)\delta(\boldsymbol{\sigma})\,|\boldsymbol{\omega}-\boldsymbol{\sigma}|^{\lambda-\acute{d}}\,d\boldsymbol{\sigma} \\
&= C\,i\int\delta(\boldsymbol{\sigma})\,(\sigma_k-\omega_k)|\boldsymbol{\omega}-\boldsymbol{\sigma}|^{\lambda-\acute{d}-2}\,d\boldsymbol{\sigma} \\
&= C\,i\,\omega_k\,|\boldsymbol{\omega}|^{\lambda-\acute{d}-2} \;. \qquad (2.15)
\end{aligned}$$

The zero extension of $f \in H_0^\gamma(\Omega)$, $\tilde{f}$, satisfies $\tilde{f} \in H^\gamma(\mathbb{R}^{\acute{d}})$. Thus, $f \in H_0^\gamma(\Omega)$ implies $|\boldsymbol{\omega}|^j \mathcal{F}(\tilde{f}) \in L^2(\mathbb{R}^{\acute{d}})$ for $0 \le j \le \gamma$.

For the kth component of $B(u)(x)$ defined by (2.8), (2.11) with $\beta \neq 1$, we have, as $B(\cdot)$ is a convolution operator,

$$\begin{aligned}\int_{\mathbb{R}^{\acute{d}}} |\boldsymbol{\omega}|^{2j} \left|\mathcal{F}(B(u)_k)\right|^2 d\boldsymbol{\omega} &= \int_{\mathbb{R}^{\acute{d}}} |\boldsymbol{\omega}|^{2j} \left|C\,\omega_k\,|\boldsymbol{\omega}|^{-\beta-1}\hat{u}(\boldsymbol{\omega})\right|^2 d\boldsymbol{\omega} \\ &\le C \int_{\mathbb{R}^{\acute{d}}} |\boldsymbol{\omega}|^{2(j-\beta)} \left|\hat{u}\right|^2 (\boldsymbol{\omega})\, d\boldsymbol{\omega}\ .\end{aligned}$$

Thus, if $u \in H_0^\gamma(\Omega)$, then $(B(u))_k \in H^{\beta+\gamma}(\Omega)$ for $k = 1, \dots \acute{d}$. Hence $B(u) \in H^{\beta+\gamma}(\Omega)$. Consequently, $B(\cdot)$ is an operator of order $-\beta$. (Also, then an operator of order 0.) For $\beta = 1$, using (2.14), $B(\cdot)$ is an operator of order -1.

2.4. Hölder-type inequalities for Sobolev spaces. In this section we present a number of estimates which are useful in handling the nonlinear term in the error analysis.

LEMMA 1. *Let $\Omega \subset \mathbb{R}^{\acute{d}}$ be bounded, $\partial\Omega \in C^1$. Then for u and v such that the given norms are finite we have*

$$\|uv\| \le C \begin{cases} \|u\|_s \, \|v\|_{\acute{d}/2-s}, & 0 < s < \frac{\acute{d}}{2}, \\ \|u\|_\infty \, \|v\| & \\ \|u\|_s \, \|v\|, & s > \acute{d}/2. \end{cases} \tag{2.16}$$

Proof. For $z \in W^{j,p}(\Omega) \cap W^{m,r}(\Omega)$ we have the following embedding properties for Sobolev spaces [1, p. 218]. For $1 < r \le p < \infty$,

$$\|z\|_{W^{j,p}} \ \le \ C\,\|z\|_{W^{m,r}}, \tag{2.17}$$

$$\text{where } \frac{1}{p} = \frac{j}{\acute{d}} + \frac{1}{r} - \frac{m}{\acute{d}} \quad \text{and} \quad \begin{cases} j \ge 0, \text{ if } r < p, & \text{or} \\ j > 0, \ \ j \text{ not an integer}, & \text{or} \\ j \ge 0, \ \ 1 < r \le 2. \end{cases}$$

Note that the above inequality (2.17) holds for $m \in \mathbb{R}$, $m > 0$. Using Hölder's inequality, with $p, \tilde{p} > 1$, satisfying $1/p + 1/\tilde{p} = 1$, and the embedding theorem

$$\begin{aligned}\|uv\| &\le \|u\|_{L^{2p}} \, \|v\|_{L^{2\tilde{p}}} \\ &= \|u\|_{W^{0,2p}} \, \|v\|_{W^{0,2\tilde{p}}} \\ &\le C\|u\|_{W^{\acute{d}(p-1)/(2p),2}} \, \|v\|_{W^{\acute{d}/(2p),2}} \\ &= C\|u\|_{\acute{d}(p-1)/(2p)} \, \|v\|_{\acute{d}/(2p)}. \end{aligned} \tag{2.18}$$

The first inequality in (2.16) follows from (2.18) with the choice $s = \acute{d}(p-1)/(2p)$. The second and third inequalities are straightforward to establish. ∎

Remark. The boundary regularity assumption on Ω in Lemma 1, $\partial\Omega \in C^1$, can be relaxed. The Sobolev embedding theorems on bounded domains require sufficient regularity of the domain to enable functions defined in Ω to be appropriately extended to $\mathbb{R}^{\acute{d}}$. In particular, for the analysis presented in sections 3 and 4 it suffices for Ω to be a Lipschitz domain.

The following results are Hölder-type inequalities for Sobolev spaces.

THEOREM 1. *Let $\Omega \subset \mathbb{R}^{\acute{d}}$ be bounded, $\partial\Omega \in C^1$. Then for $0 \le \alpha, \beta \le 1$, $\tilde{\epsilon} > 0$, $p > 1$, $0 < s \le 1/2$, u, and v such that the given norms are finite we have*

(2.19)

$$\|uv\|_\alpha \le C \begin{cases} \|u\|_1 \, \|v\|_{\alpha+\tilde{\epsilon}}, & \acute{d} = 2, \\ \|u\|_{3/2\,-\,s} \, \|v\|_{\alpha+s+\tilde{\epsilon}}, & \acute{d} = 3, \quad 0 < s \le \frac{1}{2}, \end{cases}$$

(2.20)

$$\|uv\|_{\alpha\beta} \le C\|u\|_{\beta\,+\,\acute{d}(p-1)(1-\beta)/2p} \, \|v\|_{\acute{d}(1-\alpha+\alpha p)/(2p)\,+\,\tilde{\epsilon}} \quad \textit{for} \begin{cases} \acute{d} = 2, & 1 < p \\ \acute{d} = 3, & 1 < p \le 3. \end{cases}$$

Proof. We have that

$$\|uv\|_1 \le \|uv\| \, + \, |uv|_1 \tag{2.21}$$

and

$$|uv|_1 \le \|u \, \nabla v\| \, + \, \|\nabla u \, v\|.$$

Proceeding as in the proof of Lemma 1, with $q, \tilde{q} > 1$, $1/q + 1/\tilde{q} = 1$,

$$\begin{aligned} \|u \, \nabla v\| \le \|u\|_{L^{2q}} \, \|\nabla v\|_{L^{2\tilde{q}}} \; &\le \; \|u\|_{W^{0,2q}} \, \|v\|_{W^{1,2\tilde{q}}} \\ &\le C\|u\|_{\acute{d}(q-1)/(2q)} \, \|v\|_{(\acute{d}+2q)/(2q)}. \end{aligned} \tag{2.22}$$

Also, for $\epsilon > 0$

$$\|u \, \nabla v\| \; \le \; C\|u\|_{\acute{d}/2\,+\,\epsilon} \, \|v\|_1. \tag{2.23}$$

Similarly, with $r > 1$

$$\|\nabla u \, v\| \; \le \; C\|u\|_{(\acute{d}+2r)/(2r)} \, \|v\|_{\acute{d}(r-1)/(2r)} \quad \text{and} \quad \|\nabla u \, v\| \; \le \; C\|u\|_1 \, \|v\|_{\acute{d}/2\,+\,\epsilon}. \tag{2.24}$$

Combining (2.21), (2.22), (2.24), (2.18), for $s > 1$, we have

$$\begin{aligned} \|uv\|_1 \; \le \; C \Big(&\|u\|_{\acute{d}(s-1)/(2s)} \, \|v\|_{\acute{d}/(2s)} + \|u\|_{\acute{d}(q-1)/(2q)} \, \|v\|_{(\acute{d}+2q)/(2q)} \\ &+ \|u\|_{(\acute{d}+2r)/(2r)} \, \|v\|_{\acute{d}(r-1)/(2r)} \Big). \end{aligned} \tag{2.25}$$

From (2.22), (2.24)(b), and (2.25) it follows that

$$\|uv\|_1 \; \le \; C \, \|u\|_1 \, \|v\|_{\acute{d}(1+\epsilon)/2}, \quad \acute{d} = 2, 3. \tag{2.26}$$

Also, equating the norms for u in the last two terms of (2.25), we have, for s appropriately chosen,

$$\|uv\|_1 \; \le \; C \, \|u\|_{\acute{d}(q-1)/(2q)} \, \|v\|_{(\acute{d}+2q)/(2q)} \quad \text{for } q > 3, \; \acute{d} = 3. \tag{2.27}$$

Next we interpolate between spaces to obtain the stated estimates.

For u fixed, let operators T_0, T_1 be dependent on v defined by

$$T_0(v) \; = \; T_1(v) \; = \; uv.$$

Using (2.26), we consider T_1 as a bounded linear operator between $H^{\acute{d}(1+\epsilon)/2}$ and H^1, with norm $\leq C\|u\|_1$. Also, using (2.18), we consider T_0 as a bounded linear operator between $H^{\acute{d}/(2p)}$ and L^2, with norm $\leq C\|u\|_{\acute{d}(p-1)/(2p)}$. By interpolation [3, 16] we obtain

$$\begin{aligned}\|uv\|_\alpha &= \|uv\|_{[L^2,H^1]_{\alpha,2}}\\ &\leq \|T_1\|^\alpha \|T_0\|^{1-\alpha}\|v\|_{[H^{\acute{d}/(2p)},H^{\acute{d}(1+\epsilon)/2}]_{\alpha,2}}\\ &\leq C\|u\|_1^\alpha \,\|u\|^{1-\alpha}_{\acute{d}(p-1)/(2p)}\,\|v\|_{\acute{d}(1-\alpha+\alpha p)/(2p)+\tilde{\epsilon}}\\ &\leq C\|u\|_1\,\|v\|_{\acute{d}(1-\alpha+\alpha p)/(2p)+\tilde{\epsilon}} \qquad (2.28)\end{aligned}$$

for $1 < p \leq 3$ in $\mathbb{R}^3$ (i.e., $\acute{d} = 3$) and no restriction in $\mathbb{R}^2$ (i.e., $\acute{d} = 2$). Note that $(\acute{d}(1-\alpha+\alpha p)/(2p))$ is a decreasing function of p. Minimizing with respect to p, we obtain (2.19)(a) and (2.19)(b) for $s = 1/2$.

Next we interpolate with v held fixed. Let $S_1 : H^1 \to H^\alpha$ be the operator defined by $S_1(u) = u\,v$. Using (2.28), we have that S_1 is a bounded linear operator with norm $\leq C\|v\|_{\acute{d}(1-\alpha+\alpha p)/(2p)+\tilde{\epsilon}}$. From (2.18), for $S_0 : H^{\acute{d}(p-1)/(2p)} \to L^2$ given by $S_0(u) = u\,v$, S_0 is a bounded linear operator with norm $\leq C\|v\|_{\acute{d}/(2p)}$. By interpolation we obtain

$$\begin{aligned}\|uv\|_{\alpha\beta} &= \|uv\|_{[L^2,H^\alpha]_{\beta,2}}\\ &\leq \|S_1\|^\beta\|S_0\|^{1-\beta}\|u\|_{[H^{\acute{d}(p-1)/(2p)},H^1]_{\beta,2}}\\ &\leq C\|v\|^\beta_{\acute{d}(1-\alpha+\alpha p)/(2p)+\tilde{\epsilon}}\,\|v\|^{1-\beta}_{\acute{d}/(2p)}\,\|u\|_{\beta+\acute{d}(p-1)(1-\beta)/(2p)}\\ &\leq C\|u\|_{\beta+\acute{d}(p-1)(1-\beta)/(2p)}\,\|v\|_{\acute{d}(1-\alpha+\alpha p)/(2p)+\tilde{\epsilon}}. \qquad (2.29)\end{aligned}$$

For the case (2.19)(b), in view of (2.18), for the choice $q = p$, for $p > 3$, from (2.27),

$$\|uv\|_1 \;\leq\; C\|u\|_{\acute{d}(p-1)/(2p)}\,\|v\|_{\acute{d}/(2p)+1}. \qquad (2.30)$$

Interpolating, as above, with u fixed, we obtain

$$\begin{aligned}\|uv\|_\alpha &\leq C\|u\|_{\acute{d}(p-1)/(2p)}\,\|v\|_{\alpha(\acute{d}/(2p)+1)+(1-\alpha)(\acute{d}/2p)}\\ &= C\|u\|_{\acute{d}(p-1)/(2p)}\,\|v\|_{\acute{d}/(2p)+\alpha}. \qquad (2.31)\end{aligned}$$

Letting $s = \acute{d}/(2p)$ in (2.31), the stated result follows. □

Also used below is the following lemma.

LEMMA 2. *For $\Omega \subset \mathbb{R}^{\acute{d}}$, $\alpha > \acute{d}/4$, $v, w \in X$, $\epsilon > 0$, there exists $C > 0$ such that*

$$(v\,B(w),\,\nabla v) \leq C\frac{(q\,\epsilon)^{-p/q}}{p}\|\nabla\cdot B(w)\|^p\|v\|^2 \,+\, \epsilon\,\|v\|^2_\alpha, \qquad (2.32)$$

where $p = 4\alpha/(4\alpha - \acute{d})$, $q = 4\alpha/\acute{d}$.

Proof. We begin by rewriting the inner product as

$$\begin{aligned}(v\,B(w),\,\nabla v) &= \frac{1}{2}\left(B(w),\,\nabla v^2\right) \;=\; -\frac{1}{2}\left(\nabla\cdot B(w),\,v^2\right)\\ &\leq \frac{1}{2}\,\|v\|^2_{L^4}\,\|\nabla\cdot B(w)\|.\end{aligned}$$

For $\Omega \subset \mathbb{R}^{\acute{d}}$, $H^{\acute{d}/4}(\Omega)$ is continuously imbedded in $L^4(\Omega)$ (cf. (2.17)), and as an interpolation space

$$H^{\acute{d}/4}(\Omega) \;=\; \left[L^2,\, H^{\alpha}\right]_{\frac{\acute{d}}{4\alpha},\,2}\;.$$

Hence,

$$\begin{aligned}\|v\|_{L^4}^2 \le C\,\|v\|_{H^{\acute{d}/4}}^2 \;&\le\; C\left(\|v\|^{1-\acute{d}/4\alpha}\,\|v\|_{\alpha}^{\acute{d}/4\alpha}\right)^2\\ &\le C\|v\|^{2-\acute{d}/2\alpha}\,\|v\|_{\alpha}^{\acute{d}/2\alpha}.\end{aligned}$$

Thus,

$$\|v\|_{L^4}^2\,\|\nabla\cdot B(w)\| \le C\,\|v\|^{2-\acute{d}/2\alpha}\,\|\nabla\cdot B(w)\|\,\|v\|_{\alpha}^{\acute{d}/2\alpha}. \tag{2.33}$$

Applying Young's inequality, $ab \le |a|^p/p + |b|^q/q$ for $1/p + 1/q = 1$, with the choice $p = 4\alpha/(4\alpha - \acute{d})$, $q = 4\alpha/\acute{d}$, the stated results (2.32) follow. ∎

3. Finite element approximation. In this section we formulate a fully discrete finite element method for (1.1)–(1.3). We begin by describing the finite element approximation framework and listing the approximating properties and inverse estimates used in the analysis.

Let $\Omega \subset \mathbb{R}^{\acute{d}}$ be a polygonal domain, and let T_h be a triangulation of Ω made of triangles (in $\mathbb{R}^2$) or tetrahedrons (in $\mathbb{R}^3$). Thus, the computational domain is defined by

$$\Omega = \bigcup K; \qquad K \in T_h.$$

We assume that there exist constants c_1, c_2 such that

$$c_1 h \le h_K \le c_2 \rho_K,$$

where h_K is the diameter of triangle (tetrahedron) K, ρ_K is the diameter of the greatest ball (sphere) included in K, and $h = \max_{K\in T_h} h_K$. For $k \in \mathbb{N}$, let $P_k(A)$ denote the space of polynomials on A of degree no greater than k. Then we define the finite element space X_h as follows:

$$X_h := \left\{v \in X \cap C(\bar{\Omega}) : v|_K \in P_k(K)\;\; \forall K \in T_h\right\}. \tag{3.1}$$

We summarize several properties of finite element spaces and Sobolev spaces which we will use in our subsequent analysis. For $w \in H^{k+1}(\Omega)$ we have (see [10]) that there exists $\mathcal{W} \in X_h$ such that

$$\|w - \mathcal{W}\| \;+\; h\|\nabla(w - \mathcal{W})\| \;\le\; C_I h^{k+1}\|w\|_{k+1}. \tag{3.2}$$

LEMMA 3 (see [5]). *Let $\{T_h\}$, $0 < h \le 1$, denote a quasi-uniform family of subdivisions of a polyhedral domain $\Omega \subset \mathbb{R}^{\acute{d}}$. Let $(\hat{K}, P, N)$ be a reference finite element such that $P \subset W^{l,p}(\hat{K}) \cap W^{m,q}(\hat{K})$ is a finite-dimensional space of functions on $\hat{K}$, N is a basis for P', where $1 \le p \le \infty$, $1 \le q \le \infty$, and $0 \le m \le l$. For $K \in T_h$, let (K, P_K, N_K) be the affine equivalent element, and $V_h = \{v : v$ is measurable and $v|_K \in P_K\ \forall K \in T_h\}$. Then there exists $C = C(l, p, q)$ such that*

$$\left[\sum_{K\in T_h} \|v\|_{W^{l,p}(K)}^p\right]^{1/p} \;\le\; C\,h^{m-l+\min(0,\,\frac{\acute{d}}{p}-\frac{\acute{d}}{q})}\left[\sum_{K\in T_h} \|v\|_{W^{m,q}(K)}^q\right]^{1/q} \tag{3.3}$$

for all $v \in V_h$. ∎

Let Δt denote the step size for t so that $t_n = n\Delta t$, $n = 0, 1, 2, \ldots, N$. For notational convenience, we denote $v^n := v(\cdot, t_n)$ and

$$d_t f^n := \frac{f(t_n) - f(t_{n-1})}{\Delta t}. \tag{3.4}$$

The following norms are also used in the analysis:

$$|||v|||_{\infty,k} := \max_{1 \le n \le N} \|v^n\|_k,$$

$$|||v|||_{0,k} := \left[\sum_{n=1}^{N} \|v^n\|_k^2 \Delta t \right]^{1/2}.$$

Approximating system. *For* $n = 1, 2, \ldots, N$, *find* $u_h^n \in X_h$ *such that*

$$(d_t u_h^n, v) + \langle \mathcal{D}^{2\alpha} u_h^n, v \rangle + (u_h^n B(u_h^{n-1}), \nabla v) = (f^n, v) \quad \forall\, v \in X_h. \tag{3.5}$$

For notational convenience we define $A(w; u, v)$ as

$$A(w; u, v) := \langle \mathcal{D}^{2\alpha} u, v \rangle + (uB(w), \nabla v). \tag{3.6}$$

Then, the linear system of equations (3.5) can be written equivalently as

$$(d_t u_h^n, v) + A(u_h^{n-1}; u_h^n, v) = (f^n, v) \quad \forall\, v \in X_h. \tag{3.7}$$

To ensure computability of the algorithm, we begin by showing that (3.5) is uniquely solvable for u_h^n at each time step n. We use the following induction hypothesis, which simply states that the computed iterates u_h^n are bounded independent of h and n:

$$\text{(IH1)} \qquad \|u_h^j\|_1 \le \mathcal{K}, \quad j = 0, \ldots, n-1. \tag{3.8}$$

Lemma 4. *Assume that* (IH1) *holds; i.e.,* $\|u_h^j\|_1 \le \mathcal{K}$ *for* $j = 0, 1, \ldots, n-1$. *For a sufficiently small step size* Δt, *there exists a unique solution* $u_h^n \in X_h$ *satisfying* (3.5).

Proof. As (3.5) represents a finite system of linear equations, the positivity of $(u_h^n, u_h^n)/\Delta t + A(u_h^{n-1}; u_h^n, u_h^n)$ is a sufficient condition for the existence and uniqueness of u_h^n.

We have, using (2.3) and (2.32),

$$\begin{aligned}
&\frac{(u_h^n, u_h^n)}{\Delta t} + A(u_h^{n-1}; u_h^n, u_h^n) \\
&\quad = \frac{1}{\Delta t}\|u_h^n\|^2 + \langle \mathcal{D}^{2\alpha} u_h^n, u_h^n \rangle + (u_h^n B(u_h^{n-1}), \nabla u_h^n) \\
&\quad \ge \frac{1}{\Delta t}\|u_h^n\|^2 + C_c \|u_h^n\|_\alpha^2 - C_1 \epsilon_2^{-C_2} \|\nabla \cdot B(u_h^{n-1})\|^{C_3} \|u_h^n\|^2 - \epsilon_2 \|u_h^n\|_\alpha^2 \\
&\quad = \left(\frac{1}{\Delta t} - C_1 \epsilon_2^{-C_2} \|\nabla \cdot B(u_h^{n-1})\|^{C_3} \right) \|u_h^n\|^2 + (C_c - \epsilon_2) \|u_h^n\|_\alpha^2 \qquad (3.9) \\
&\quad \ge \left(\frac{1}{\Delta t} - \tilde{C}_1 \epsilon_2^{-C_2} C_B^{C_3} \|u_h^{n-1}\|_1^{C_3} \right) \|u_h^n\|^2 + (C_c - \epsilon_2) \|u_h^n\|_\alpha^2 \qquad (3.10) \\
&\quad \ge \left(\frac{1}{\Delta t} - \tilde{C}_1 \epsilon_2^{-C_2} C_B^{C_3} \mathcal{K}^{C_3} \right) \|u_h^n\|^2 + (C_c - \epsilon_2) \|u_h^n\|_\alpha^2. \qquad (3.11)
\end{aligned}$$

Hence, for Δt chosen sufficiently small we have that (3.5) is uniquely solvable for u_h^n. ∎

The discrete Gronwall's lemma plays an important role in the following analysis.

LEMMA 5 (discrete Gronwall's lemma [11]). *Let Δt, H, and a_n, b_n, c_n, γ_n (for integers $n \geq 0$) be nonnegative numbers such that*

$$a_l \;+\; \Delta t \sum_{n=0}^{l} b_n \;\leq\; \Delta t \sum_{n=0}^{l} \gamma_n\, a_n \;+\; \Delta t \sum_{n=0}^{l} c_n \;+\; H \quad \text{for } l \geq 0.$$

Suppose that $\Delta t\, \gamma_n < 1$ for all n, and set $\sigma_n = (1 - \Delta t\, \gamma_n)^{-1}$. Then,

$$a_l \;+\; \Delta t \sum_{n=0}^{l} b_n \;\leq\; \exp\left(\Delta t \sum_{n=0}^{l} \sigma_n\, \gamma_n\right) \left\{ \Delta t \sum_{n=0}^{l} c_n \;+\; H \right\} \quad \text{for } l \geq 0. \tag{3.12}$$

4. A priori error estimate. In this section we analyze the error between the finite element approximation given by (3.5) and the true solution. A priori error estimates for the approximation are given in Theorem 2.

THEOREM 2. *Assume that for $\acute{d}/4 < \alpha < 1$, (1.1)–(1.3) has a solution u satisfying $u_t \in L^2(0,T;H^{k+1}(\Omega))$, $u_{tt} \in L^2(0,T;L^2(\Omega))$, with $u^0 \in H^{k+1}(\Omega)$. In addition, assume that $\Delta t \leq c\, h$. Then, the finite element approximation (3.5) is convergent to the solution of (1.1)–(1.3) on the interval $(0,T)$ as $\Delta t, h \to 0$. The approximation u_h satisfies the following error estimates:*

(4.1)

$$|||u - u_h|||_{0,\alpha} \leq C\, \left(h^{k+1} \|u_t\|_{0,k+1} \;+\; h^{(k+1-\alpha)}\, |||u|||_{0,k+1} \;+\; \Delta t\, \|u_t\|_{0,1} \;+\; \Delta t \|u_{tt}\|_{0,0} \right),$$

$$|||u - u_h|||_{\infty,0} \leq C\, \Big(h^{k+1} \|u_t\|_{0,k+1} \;+\; h^{(k+1-\alpha)}\, |||u|||_{0,k+1} \;+\; \Delta t\, \|u_t\|_{0,1} \;+\; \Delta t \|u_{tt}\|_{0,0}$$

$$+\, h^{k+1}\, |||u|||_{\infty,k+1} \Big). \tag{4.2}$$

Remarks. 1. $u_t \in L^2(0,T;H^{k+1}(\Omega))$, $u_0 \in H^{k+1}(\Omega)$ implies $u \in L^2(0,T;H^{k+1}(\Omega)) \cap L^\infty(0,T;H^{k+1}(\Omega))$.

2. As previously defined in (3.1), k is the polynomial order of the approximation functions u_h^n.

In order to establish the estimates (4.1), (4.2), we begin by introducing the following notation. Let $u^n = u(t_n)$ represent the solution of (1.1)–(1.3), and u_h^n denote the solution of (3.5).

For $\mathcal{U}^n \in X_h$, define $\Lambda^n, E^n, \epsilon_u$, as

$$\Lambda^n = u^n - \mathcal{U}^n, \qquad E^n = \mathcal{U}^n - u_h^n, \qquad \epsilon_u = u^n - u_h^n.$$

The proof of Theorem 2 is established in three steps:

1. Prove a lemma, assuming the induction hypothesis.
2. Show that the induction hypothesis is true.
3. Prove the error estimates given in (4.1), (4.2).

Step 1. We prove the following lemma.

LEMMA 6. *Under the induction hypothesis $\|u_h^j\|_1 \leq \mathcal{K}$ for $j = 0, 1, \ldots, l-1$, we have that*

$$\|E^l\|^2 \leq G(\Delta t, h), \tag{4.3}$$

where

$$G(\Delta t,h) \;=\; C\Big(h^{2(k+1)}\|u_t\|^2_{0,k+1} \;+\; h^{2(k+1-\alpha)}\,|||u|||^2_{0,k+1} \\ +\;(\Delta t)^2\,\|u_t\|^2_{0,1} + \;(\Delta t)^2\|u_{tt}\|^2_{0,0}\Big).$$

Proof of Lemma 6. We present the proof for $\Omega \subset \mathbb{R}^2$; the case for $\Omega \subset \mathbb{R}^3$ follows analogously.

From (1.1), (1.2) we have that the true solution u satisfies

$$(d_t u^n, v) \;+\; \langle \mathcal{D}^{2\alpha} u^n,\, v\rangle \;+\; (u^n B(u_h^{n-1}),\, \nabla v) = (f^n, v) \;-\; (u_t - d_t u^n, v) \\ -\,(u^n B(u^n - u_h^{n-1}),\, \nabla v), \quad v \in X_h. \tag{4.4}$$

Subtracting (3.5) from (4.4), we obtain the following equation for ϵ_u:

$$(d_t \epsilon_u, v) \;+\; \langle \mathcal{D}^{2\alpha} \epsilon_u,\, v\rangle \;+\; (\epsilon_u B(u_h^{n-1}),\, \nabla v) = -\,(u_t - d_t u^n, v) \\ -\,(u^n B(u^n - u_h^{n-1}),\, \nabla v), \quad v \in X_h. \tag{4.5}$$

Substituting $\epsilon_u = E^n + \Lambda^n$, $v = E^n$ into (4.5), we obtain

$$(d_t E^n, E^n) \;+\; \langle \mathcal{D}^{2\alpha} E^n,\, E^n\rangle \;+\; (E^n B(u_h^{n-1}),\, \nabla E^n) \;=\; F(E^n), \tag{4.6}$$

where

$$F(E^n) := -(d_t \Lambda^n, E^n) \;-\; \langle \mathcal{D}^{2\alpha} \Lambda^n,\, E^n\rangle \;-\; (\Lambda^n B(u_h^{n-1}),\, \nabla E^n) \\ -\,(u_t - d_t u^n, E^n) \;-\; (u^n B(u^n - u_h^{n-1}),\, \nabla E^n).$$

Note that

$$(d_t E^n, E^n) = \frac{1}{\Delta t}\left((E^n, E^n) - (E^{n-1}, E^n)\right) \\ \geq \frac{1}{2\Delta t}\left(\|E^n\|^2 - \|E^{n-1}\|^2\right),$$

and from (2.32)

$$(E^n B(u_h^{n-1}),\, \nabla E^n) \leq \epsilon_2\,\|E^n\|^2_\alpha \;+\; C_1 \epsilon_2^{-C_2} \|\nabla \cdot B(u_h^{n-1})\|^{C_3} \|E^n\|^2. \tag{4.7}$$

Multiplying (4.6) by $2\,\Delta t$, summing from $n = 1$ to l, and using (2.3), we have

$$\left(\|E^l\|^2 - \|E^0\|^2\right) + 2\,(C_c - \epsilon_2) \sum_{n=1}^{l} \Delta t \|E^n\|^2_\alpha \\ \leq\; 2\Delta t \sum_{n=1}^{l} C_1 \epsilon_2^{-C_2} \|\nabla \cdot B(u_h^{n-1})\|^{C_3} \|E^n\|^2 \;+\; 2\Delta t \sum_{n=1}^{l} F(E^n). \tag{4.8}$$

We now estimate each term in $\mathrm{F}(E^n)$:

$$\begin{aligned}(d_t\Lambda^n, E^n) &\le \|E^n\|\,\|d_t\Lambda^n\| \\ &\le \frac{1}{2}\|E^n\|^2 + \frac{1}{2}\|d_t\Lambda^n\|^2. \end{aligned} \tag{4.9}$$

Using (2.2),

$$\begin{aligned}\langle \mathcal{D}^{2\alpha}\Lambda^n,\, E^n\rangle &\le C_t\|E^n\|_\alpha\,\|\Lambda^n\|_\alpha \\ &\le \epsilon_4\|E^n\|_\alpha^2 + \frac{C_t^2}{4\epsilon_4}\|\Lambda^n\|_\alpha^2. \end{aligned} \tag{4.10}$$

Using duality with respect to the L^2 inner product,

$$\begin{aligned}(\Lambda^n B(u_h^{n-1}),\, \nabla E^n) &\le \|\nabla E^n\|_{-(1-\alpha)}\,\|\Lambda^n B(u_h^{n-1})\|_{(1-\alpha)} \\ &\le \epsilon_5\|E^n\|_\alpha^2 + \frac{C_4}{4\epsilon_5}\|\Lambda^n B(u_h^{n-1})\|_{(1-\alpha)}^2. \end{aligned} \tag{4.11}$$

For the next term in $F(E^n)$ we use

$$(u_t - d_t u^n, E^n) \;\le\; \|E^n\|\,\|u_t - d_t u^n\| \;\le\; \frac{1}{2}\|E^n\|^2 + \frac{1}{2}\|u_t - d_t u^n\|^2. \tag{4.12}$$

The remaining term is rewritten as the sum of three terms.

$$\begin{aligned}(u^n B(u^n - u_h^{n-1}),\, \nabla E^n) &= (u^n B(u^n - u^{n-1}),\, \nabla E^n) + (u^n B(u^{n-1} - u_h^{n-1}),\, \nabla E^n) \\ &= (u^n B(u^n - u^{n-1}),\, \nabla E^n) + (u^n B(\Lambda^{n-1}),\, \nabla E^n) \\ &\quad + (u^n B(E^{n-1}),\, \nabla E^n)\ . \end{aligned}$$

Each of these terms is rewritten in a similar fashion as in (4.11):

$$(u^n B(u^n - u^{n-1}),\, \nabla E^n) \le \epsilon_7\|E^n\|_\alpha^2 + \frac{C_4}{4\epsilon_7}\,\|u^n B(u^n - u^{n-1})\|_{(1-\alpha)}^2, \tag{4.13}$$

$$(u^n B(\Lambda^{n-1}),\, \nabla E^n) \le \epsilon_8\|E^n\|_\alpha^2 + \frac{C_4}{4\epsilon_8}\,\|u^n B(\Lambda^{n-1})\|_{(1-\alpha)}^2, \tag{4.14}$$

$$(u^n B(E^{n-1}),\, \nabla E^n) \le \epsilon_9\|E^n\|_\alpha^2 + \frac{C_4}{4\epsilon_9}\,\|u^n B(E^{n-1})\|_{(1-\alpha)}^2. \tag{4.15}$$

Combining (4.8)–(4.15), for $\epsilon_1, \ldots, \epsilon_9$ appropriately chosen, there exist constants

$C_j > 0$ such that

$$\begin{aligned}
\left(\|E^l\|^2 - \|E^0\|^2\right) + C_{12} \sum_{n=1}^{l} \Delta t \|E^n\|_\alpha^2 & \\
&\leq \Delta t \sum_{n=1}^{l} \left(C_{13}\|\nabla \cdot B(u_h^{n-1})\|^{C_3} + C_{14}\right) \|E^n\|^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{15} \|u^n B(E^{n-1})\|_{(1-\alpha)}^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{16} \|d_t \Lambda^n\|^2 + \Delta t \sum_{n=1}^{l} C_{17} \|\Lambda^n\|_\alpha^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{18} \|\Lambda^n B(u_h^{n-1})\|_{(1-\alpha)}^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{19} \|u^n B(u^n - u^{n-1})\|_{(1-\alpha)}^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{20} \|u^n B(\Lambda^{n-1})\|_{(1-\alpha)}^2 \\
&+ \Delta t \sum_{n=1}^{l} C_{21} \|u_t - d_t u^n\|^2. \qquad (4.16)
\end{aligned}$$

We now apply the interpolation property of the approximation space to estimate the terms on the right-hand side (RHS) of (4.16).

$$\begin{aligned}
\sum_{n=1}^{l} \Delta t \|d_t \Lambda^n\|^2 &= \sum_{n=1}^{l} \Delta t \left\| \frac{1}{\Delta t} \int_{t_{n-1}}^{t_n} 1 \, \frac{\partial \Lambda}{\partial t} \, dt \right\|^2 \\
&\leq \sum_{n=1}^{l} \Delta t \left(\frac{1}{\Delta t}\right)^2 \int_\Omega \left(\int_{t_{n-1}}^{t_n} 1 \, dt \right) \left(\int_{t_{n-1}}^{t_n} \left(\frac{\partial \Lambda}{\partial t}\right)^2 dt \right) dx \\
&\leq C h^{2k+2} \|u_t\|_{0,k+1}^2. \qquad (4.17)
\end{aligned}$$

Note that $(d_t u^n - u_t^n)$ may be expressed as

$$d_t u^n - u_t^n = \frac{1}{\Delta t} \int_{t_{n-1}}^{t_n} u_{tt}(\cdot, t)(t_{n-1} - t) \, dt.$$

Also,

$$\begin{aligned}
\left(\frac{1}{\Delta t} \int_{t_{n-1}}^{t_n} u_{tt}(\cdot, t)(t_{n-1} - t) \, dt \right)^2 &\leq \frac{1}{(\Delta t)^2} \int_{t_{n-1}}^{t_n} u_{tt}^2(\cdot, t) \, dt \int_{t_{n-1}}^{t_n} (t_{n-1} - t)^2 \, dt \\
&= \frac{1}{3} \Delta t \int_{t_{n-1}}^{t_n} u_{tt}^2(\cdot, t) \, dt.
\end{aligned}$$

Therefore it follows that

$$\sum_{n=1}^{l} \Delta t \, \|u_t - d_t u^n\|^2 \leq \sum_{n=1}^{l} \Delta t \int_\Omega \frac{1}{3} \Delta t \int_{t_{n-1}}^{t_n} u_{tt}^2(\cdot, t)\, dt\, dx$$
$$= \frac{1}{3} (\Delta t)^2 \|u_{tt}\|_{0,0}^2. \tag{4.18}$$

Next we estimate the terms in (4.16) involving $B(\cdot)$ using (2.4), (2.19), and (3.8). These estimates for $B(\cdot)$ are dimension-specific. We present the case for $\acute{d} = 2$.

For the first term on the RHS,

$$\|\nabla \cdot B(u_h^{n-1})\| \;\leq\; C\|B(u_h^{n-1})\|_1 \;\leq\; C\|u_h^{n-1}\|_1 \;\leq\; C\mathcal{K}\,. \tag{4.19}$$

Using interpolation between L^2 and H^α and Young's inequality, we obtain, for $\delta \in (0, 2\alpha - 1)$,

$$\|u^n B(E^{n-1})\|_{(1-\alpha)}^2 \leq C\, \|B(E^{n-1})\|_{(1-\alpha+\delta)}^2\, \|u^n\|_1^2$$
$$\leq C\|E^{n-1}\|^{2(2\alpha-1-\delta)/\alpha}\, \|E^{n-1}\|_\alpha^{2(1-\alpha+\delta)/\alpha}\, \|u^n\|_1^2$$
$$\leq \epsilon_{10}\|E^{n-1}\|_\alpha^2 \;+\; C\, \|u^n\|_1^{2(\alpha/(2\alpha-1-\delta))}\|E^{n-1}\|^2. \tag{4.20}$$

With the interpolation error bound $\|\Lambda^n\|_{(1-\alpha+\delta)} \leq Ch^{k+\alpha-\delta}\, \|u^n\|_{k+1}$,

$$\|\Lambda^n B(u_h^{n-1})\|_{(1-\alpha)} \leq C\, \|\Lambda^n\|_{(1-\alpha+\delta)} \|B(u_h^{n-1})\|_1$$
$$\leq C\mathcal{K} h^{k+\alpha-\delta}\, \|u^n\|_{k+1}. \tag{4.21}$$

To estimate $\|u^n B(\Lambda^{n-1})\|_{(1-\alpha)}$ we proceed similarly.

$$\|u^n B(\Lambda^{n-1})\|_{(1-\alpha)} \leq C\, \|u^n\|_1\, \|B(\Lambda^{n-1})\|_{(1-\alpha+\delta)}$$
$$\leq Ch^{k+\alpha-\delta}\, \|u^{n-1}\|_{k+1}\, \|u^n\|_1. \tag{4.22}$$

Using

$$\|u^n - u^{n-1}\|_1^2 \;\leq\; \Delta t \int_{t_{n-1}}^{t_n} \|u_t\|_1^2\, dt,$$

we have that

$$\|u^n B(u^n - u^{n-1})\|_{(1-\alpha)}^2 \leq C\, \|u^n\|_{(1-\alpha+\delta)}^2\, \|B(u^n - u^{n-1})\|_1^2$$
$$\leq C\|u^n\|_{(1-\alpha+\delta)}^2\, \|u^n - u^{n-1}\|_1^2$$
$$\leq C\Delta t\, \|u^n\|_{(1-\alpha+\delta)}^2 \int_{t_{n-1}}^{t_n} \|u_t\|_1^2\, dt. \tag{4.23}$$

From (4.17)–(4.23) and $\|E^0\| = 0$, estimate (4.16) becomes (using that $\|u\|_1$ is bounded for $t \in [0, T]$)

$$\|E^l\|^2 \;+\; C_{12} \sum_{n=1}^{l} \Delta t \|E^n\|_\alpha^2 \leq \Delta t \sum_{n=1}^{l} C_{22}\|E^n\|^2$$
$$+ Ch^{2(k+1)}\|u_t\|_{0,k+1}^2 \;+\; Ch^{2(k+1-\alpha)}\, |||u|||_{0,k+1}^2$$
$$+ C(\Delta t)^2\, \|u_t\|_{0,1}^2$$
$$+ C\, h^{2(k+\alpha-\delta)}\, |||u|||_{0,k+1}^2$$
$$+ C\, (\Delta t)^2 \|u_{tt}\|_{0,0}^2. \tag{4.24}$$

Finally, as $\alpha > 0.5$, with $\Delta t < 1/C_{22}$ and the associations $a_l = \|E^l\|^2$, $b_n = C_{12}\|E^n\|_\alpha^2$, $\gamma_n = C_{22}$, $c_n = 0$, $H = \tilde{C}\left(h^{2(k+1)}\|u_t\|_{0,k+1}^2 + h^{2(k+1-\alpha)}\|\!|u|\!\|_{0,k+1}^2 + (\Delta t)^2\|u_t\|_{0,1}^2 + (\Delta t)^2\|u_{tt}\|_{0,0}^2\right)$, applying Gronwall's lemma, we obtain the bound given in (4.3), where $C = \tilde{C}\exp(TC_{22}/(1-\Delta t C_{22}))$. ∎

Step 2. We show that the induction hypothesis (IH1) is true.

Assume that $\|u_h^j\|_1 \le \mathcal{K}$ for $j = 0, 1, \ldots, l-1$. Using the interpolation property, inverse estimate (3.3), and (4.3), we have that

$$\begin{aligned}\|\nabla u_h^l\| &\le \|\nabla(u_h^l - u^l)\| + \|\nabla u^l\| \\ &\le \|\nabla E^l\| + \|\nabla \Lambda^l\| + \|\nabla u^l\| \\ &\le C\left(h^{-1}\|E^l\| + \|\nabla u^l\|\right) \\ &\le Ch^{-1}(h^{k+1-\alpha} + \Delta t) + C\|\nabla u^l\|. \end{aligned} \tag{4.25}$$

Thus as C is independent of l, $u \in L^\infty(0,T;H^1(\Omega))$, for $\Delta t \le ch$, we have that $\|\nabla u_h^l\|$ is bounded.

An analogous argument shows that $\|u_h^l\|$ is also bounded independent of h and l. ∎

Step 3. We derive the error estimates in (4.1) and (4.2).

Proof of Theorem 2. To establish (4.1), from (4.24) and (4.3), and using $T = N\Delta t$,

$$\|\!|E|\!\|_{0,\alpha}^2 \;=\; \sum_{n=1}^{N} \Delta t\,\|E^n\|_\alpha^2 \;\le\; C\,(T+1)G(\Delta t, h).$$

Hence, using the interpolation property and that

$$\|\!|u - u_h|\!\|_{0,\alpha} \;\le\; \|\!|E|\!\|_{0,\alpha} + \|\!|\Lambda|\!\|_{0,\alpha},$$

estimate (4.1) then follows.

Using estimates (4.3) and approximation properties, we have

$$\begin{aligned}\|\!|u - u_h|\!\|_{\infty,0}^2 &\le \|\!|E|\!\|_{\infty,0}^2 + \|\!|\Lambda|\!\|_{\infty,0}^2 \\ &\le G(\Delta t, h) + h^{2k+2}\,\|\!|u|\!\|_{\infty,k+1}^2,\end{aligned}$$

which yields estimate (4.2). ∎

5. Numerical results. In this section we illustrate the predicted convergence results given in Theorem 2 with numerical computations for $\Omega \subset \mathbb{R}^2$. For points $x, y \in \mathbb{R}^2$ we use $x = (x_1, x_2)$ and $y = (y_1, y_2)$. For ease of notation, for $\theta \in [0, 2\pi)$ we let $D_\theta^{-\sigma} u := D_\nu^{-\sigma} u$, where $\nu = [\cos\theta, \sin\theta]^T$.

It is noteworthy to again remark that fractional derivatives/diffusion operators are *nonlocal* operators. Consequently, a sparse coefficient matrix, characteristic of using a finite element basis for the test and trial space, does not occur when approximating space-fractional diffusion equations. For the fractional diffusion operator given by (2.7) it is computationally convenient to use the bilinear form (see (3.5))

$$\mathcal{B}(u_h^n, v) \;:=\; \frac{1}{\Delta t}(u_h^n, v) \;-\; \int_0^{2\pi} a\,(D_\theta^{2\alpha-1} u_h^n,\, D_{\theta+\pi} v)\, M(d\theta) \;+\; (u_h^n\, B(u_h^{n-1}),\, \nabla v).$$

Note that $\mathrm{supp}(D_{\theta+\pi} v) \subseteq \mathrm{supp}(v)$, whereas, in general $\mathrm{supp}(D_{\theta+\pi}^{\alpha} v) \supset \mathrm{supp}(v)$. For a discussion on the implementation of the finite element method approximation for the fractional diffusion operator (5.1) in $\mathbb{R}^2$ see [15].

TABLE 5.1

1/24	$5.960361 \cdot 10^{-4}$	1.50	$4.586714 \cdot 10^{-4}$	1.53

The fractional differential operator used in our computations was (see (2.7))

$$D_M^{2\alpha} u(x) \;:=\; -\frac{1}{\pi} \int_{\theta=0}^{2\pi} D_\theta^{2\alpha} u(x)\, d\theta, \tag{5.1}$$

which we approximate as

$$D_M^{2\alpha} u(x) \;\approx\; -\;\frac{1}{2} D_0^{2\alpha} u(x) \;-\; \frac{1}{2} D_{\pi/2}^{2\alpha} u(x) \;-\; \frac{1}{2} D_{\pi}^{2\alpha} u(x) \;-\; \frac{1}{2} D_{3\pi/2}^{2\alpha} u(x)\;. \tag{5.2}$$

The value of α used was $\alpha = 0.75$.

The approximation space X_h was taken to be the space of continuous piecewise linear functions, i.e., $k = 1$.

From Theorem 2, (4.1), and (4.2), we have the predicted rates of convergence for $\Delta t = Ch^{k+1-\alpha}$ $(= Ch^{1.25}$ for $k = 1$, $\alpha = 0.75)$ of

$$\|\|\|u-u_h\|\|\|_{0,\alpha} \;\sim O(h^{1.25}), \qquad \|\|\|u-u_h\|\|\|_{\infty,0} \;\sim O(h^{1.25}). \tag{5.3}$$

In Tables 5.1–5.6 we give the results for $\|\|\|u-u_h\|\|\|_{0,0}$, which from (4.1) and (5.3) are predicted to satisfy

$$\|\|\|u-u_h\|\|\|_{0,0} \;\sim O(h^{1.25}).$$

TABLE 5.6
Experimental error results for Example 1 *for the usual diffusion operator and* $b(x,y) = (x-y)/|x-y|^2$.

h	$\|\|\|u-u_h\|\|\|_{\infty,0}$	Cvge. rate	$\|\|\|u-u_h\|\|\|_{0,0}$	Cvge. rate
1/4	$1.481271 \cdot 10^{-3}$		$1.203806 \cdot 10^{-3}$	
1/8	$8.093125 \cdot 10^{-4}$	0.87	$6.612167 \cdot 10^{-4}$	0.86
1/12	$5.477165 \cdot 10^{-4}$	0.96	$4.556000 \cdot 10^{-4}$	0.92
1/16	$4.135933 \cdot 10^{-4}$	0.98	$3.436790 \cdot 10^{-4}$	0.98
1/20	$3.314616 \cdot 10^{-4}$	0.99	$2.734522 \cdot 10^{-4}$	1.02
1/24	$2.761739 \cdot 10^{-4}$	1.00	$2.253575 \cdot 10^{-4}$	1.06

For comparison, computations were also performed with the usual diffusion operator in place of $D_M^{2\alpha}u$, namely on the equation

$$u_t \;-\; \Delta u \;-\; \nabla \cdot (u\,B(u)) \;=\; f(x). \tag{5.4}$$

For the usual diffusion operator, Δt was chosen as $\Delta t = Ch$. From Theorem 2, the predicted rate of convergence is then

$$\|\|u-u_h\|\|_{0,0} \;\sim O(h), \qquad \|\|u-u_h\|\|_{\infty,0} \;\sim O(h). \tag{5.5}$$

Example 1. For the problem described in (1.1)–(1.3) we take $\Omega = (0,1)\times(0,1)$, and a known solution $u(x_1,x_2,t) = (4t^2-4t+1)(x_1-x_1^2)(x_2-x_2^2)$, with $u^0(x_1,x_2) = u(x_1,x_2,0)$. The RHS of (1.1) was computed using the true solution, and the approximation to $D_M^{2\alpha}u(x)$ given in (5.2).

Computations were performed for $B(u)$ given by (2.8) with

(a) $b(x,y) = 0$, i.e., $B(u) = 0$ (see Tables 5.1, 5.4),

(b) $b(x,y) = x-y$, i.e., a smooth operator B (see Tables 5.2, 5.5),

(c) $b(x,y) = (x-y)/|x-y|^2$ (see Tables 5.3, 5.6).

The results presented in Tables 5.1–5.6 are consistent with those predicted by Theorem 2, given in (5.3). ("Cvge. rate" stands for convergence rate.)

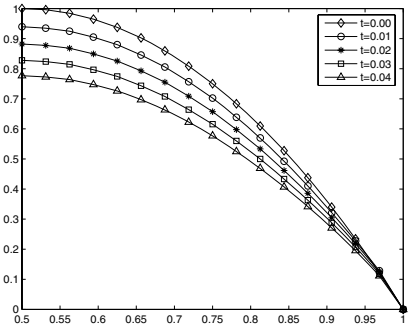

FIG. 5.1. *Time evolution of* (1.1) *for* $c = 0$.

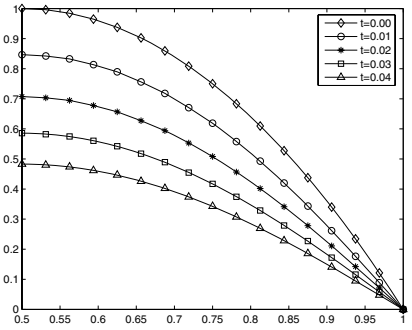

FIG. 5.2. *Time evolution of* (5.4) *for* $c = 0$.

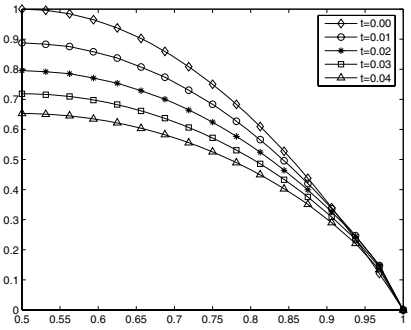

FIG. 5.3. *Time evolution of* (1.1) *for* $c = -1$.

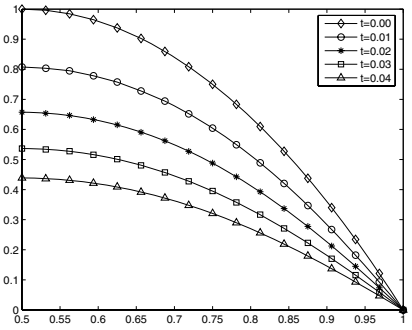

FIG. 5.4. *Time evolution of* (5.4) *for* $c = -1$.

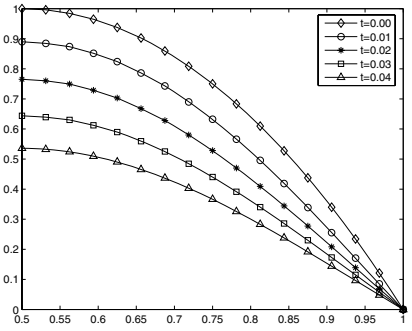

FIG. 5.6. *Time evolution of* (5.4) *for* $c = 1$.

Example 2. In order to demonstrate the influence of the nonlocal quadratic nonlinearity $\nabla \cdot (uB(u))$, we present in Figures 5.1–5.10 the plots of the time evolution of the approximation u_h for the initial value $u^0(x_1, x_2) = 16(x_1 - x_1^2)(x_2 - x_2^2)$. Plots for the fractional diffusion equation are displayed on the left, the usual diffusion equation on the right. Note that u^0 has height 1 at $(1/2, 1/2)$ and is symmetric with respect

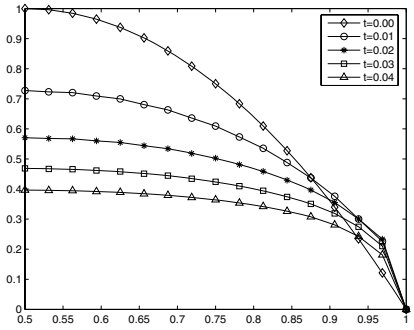

FIG. 5.7. *Time evolution of* (1.1) *for* $c = -5$.

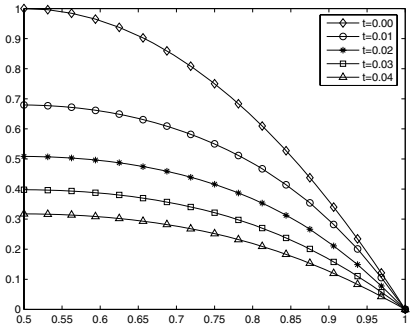

FIG. 5.8. *Time evolution of* (5.4) *for* $c = -5$.

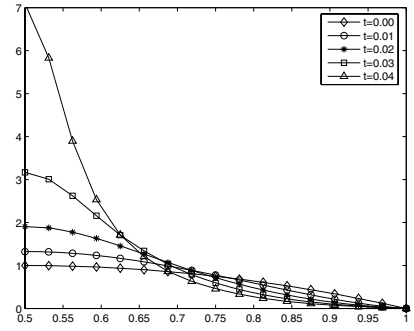

FIG. 5.9. *Time evolution of* (1.1) *for* $c = 5$.

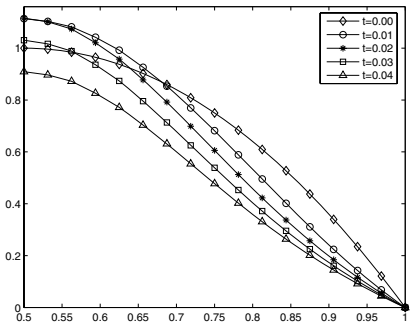

FIG. 5.10. *Time evolution of* (5.4) *for* $c = 5$.

to x_1 and x_2. The profiles given are along the line segment $[x_1, 1/2]$, $1/2 \leq x_1 \leq 1$. The operator $B(u)$ was chosen as in (2.8) with $b(x, y)$ given by (2.9). Values for $c = 0$ (Figures 5.1, 5.2), $c = \pm 1$ (Figures 5.3–5.6), and $c = \pm 5$ (Figures 5.7–5.10) were used.

For the negative values of c the diffusion of u away from the maximum at $(1/2, 1/2)$ is enhanced. For positive values of c the $\nabla \cdot (uB(u))$ term acts "against the diffusion operator" to try and concentrate u at $(1/2, 1/2)$. This behavior is consistent with the case $c < 0$ modeling Brownian diffusion and $c > 0$ being used to model mutual gravitational attraction of particles in clouds (see [4]).

ALMOST SURE AND MOMENT EXPONENTIAL STABILITY IN THE NUMERICAL SIMULATION OF STOCHASTIC DIFFERENTIAL EQUATIONS*

DESMOND J. HIGHAM†, XUERONG MAO‡, AND CHENGGUI YUAN§

Abstract. Relatively little is known about the ability of numerical methods for stochastic differential equations (SDEs) to reproduce almost sure and small-moment stability. Here, we focus on these stability properties in the limit as the timestep tends to zero. Our analysis is motivated by an example of an exponentially almost surely stable nonlinear SDE for which the Euler–Maruyama (EM) method fails to reproduce this behavior for any nonzero timestep. We begin by showing that EM correctly reproduces almost sure and small-moment exponential stability for sufficiently small timesteps on scalar linear SDEs. We then generalize our results to multidimensional nonlinear SDEs. We show that when the SDE obeys a linear growth condition, EM recovers almost surely exponential stability very well. Under the less restrictive condition that the drift coefficient of the SDE obeys a one-sided Lipschitz condition, where EM may break down, we show that the backward Euler method maintains almost surely exponential stability.

Key words. backward Euler, Euler–Maruyama, implicit, one-sided Lipschitz condition, linear growth condition, Lyapunov exponent, stochastic theta method

DOI. 10.1137/060658138

1. Introduction.

Stability theory for numerical simulations of stochastic differential equations (SDEs) typically deals with mean-square behavior. Asymptotic, or almost sure, stability is at least as relevant in typical applications, but does not benefit from a well-developed theory. Our general aim here is to address this imbalance.

We begin with a brief overview of relevant work.

A characterization of asymptotic linear stability for a wide class of SDE methods was given in [10, Lemma 5.1], but this turns out to be of limited use in proving analytical results. Some properties for weak methods were derived in [10, section 6], and results for the related T-stability concept can be found in [19]. The issue of whether the asymptotic linear stability region is bounded was analyzed in [5]. Other authors [7, 8, 17] have tested asymptotic stability via numerical experiments.

The related concept of pth moment stability for $0 < p \leq 2$ is interesting in its own right, and in the linear scalar SDE case it is known that as $p \to 0$ this property is equivalent to asymptotic stability; see Theorem 4.1. We note that some analysis in [1] on stochastic difference equations is relevant to the application of a weak Euler–Maruyama (EM) method to a scalar SDE, and further strengthens the connection between pth moment and asymptotic stability. Similarly, the results in [2] are relevant to EM on a scalar SDE; in this case the emphasis is on polynomial, rather

than the generic exponential, rates of convergence. In [4], moment stability for SDEs with delay is studied in the presence of a suitable Lyapunov function.

Unlike in the mean-square case [10], we are not aware of any numerical methods that, on a reasonable class of SDEs, have been proved to possess an asymptotic stability analogue of deterministic A-stability [9]; "problem stable implies numerical method stable for all stepsizes."

In this work, we focus on a more fundamental property of the form "problem stable implies numerical method stable for sufficiently small stepsizes," where stability is meant in the exponential asymptotic sense and independently of the size of initial data. To show that this is a nontrivial issue, we give a nonlinear example in section 3 where, for arbitrarily small timesteps, the basic EM method may fail to preserve stability. This motivates the subsequent analysis. We find conditions under which EM does preserve exponential asymptotic stability for small timesteps, and we show that introducing implicitness, in the form of the backward Euler method, produces good results on a class of SDEs that includes our motivating example.

More precisely, we prove positive results for scalar-noise SDEs that are linear (section 4) or satisfy linear growth conditions (section 5). Then in section 6 we show that backward Euler is successful under a one-sided Lipschitz condition on the drift. Section 7 shows how the results generalize to multidimensional noise.

2. Notation. Throughout this paper, we let $(\Omega, \mathcal{F}, \{\mathcal{F}_t\}_{t\geq 0}, \mathbb{P})$ be a complete probability space with a filtration $\{\mathcal{F}_t\}_{t\geq 0}$ that is increasing and right continuous, with $\mathcal{F}_0$ containing all $\mathbb{P}$-null sets. Let $B(t)$ be a scalar Brownian motion defined on the probability space. Let $|\cdot|$ denote both the Euclidean norm in $\mathbb{R}^n$ and the trace (or Frobenius) norm in $\mathbb{R}^{n\times m}$. The inner product of x, y in $\mathbb{R}^n$ is denoted by $\langle x, y\rangle$. We use $a \vee b$ to denote $\max(a, b)$, $a \wedge b$ to denote $\min(a, b)$, and a.s. to mean almost surely.

We are concerned with the n-dimensional nonlinear Itô SDE

$$dx(t) = f(x(t))dt + g(x(t))dB(t), \quad t \geq 0, \qquad \text{given } 0 \neq x(0) \in \mathbb{R}^n. \tag{2.1}$$

As a standing hypothesis, we assume that $f, g : \mathbb{R}^n \to \mathbb{R}^n$ are smooth enough for the SDE (2.1) to have a unique global solution $x(t)$ on $[0, \infty)$ (see, for example, [15], for sufficient conditions). We make two remarks.

- Scalar Brownian motion $B(t)$ is used to make the analysis in sections 5 and 6 more accessible. In section 7 we state how our results extend to the case of multidimensional noise.
- The restriction to a deterministic initial condition is convenient and does not lose any generality when asymptotic stability is studied; see, for example, [15, section 4.2].

The EM method applied to (2.1) produces approximations $X_k \approx x(k\Delta t)$, where $X_0 = x(0)$ and

$$X_{k+1} = X_k + \Delta t f(X_k) + g(X_k)\Delta B_k. \tag{2.2}$$

Here $\Delta t > 0$ is the timestep and $\Delta B_k := B((k+1)\Delta t) - B(k\Delta t)$ is the Brownian increment. We will also consider the more general stochastic theta (ST) method which takes the form

$$X_{k+1} = X_k + \Delta t\left((1-\theta)f(X_k) + \theta f(X_{k+1})\right) + g(X_k)\Delta B_k, \tag{2.3}$$

where $\theta \in [0, 1]$ is a fixed parameter. For $\theta = 0$, ST reduces to EM. For $\theta \neq 0$ (2.3) defines X_{k+1} implicitly. We will refer to the $\theta = 1$ case as backward Euler (BE).

3. Motivating example. For the scalar cubic SDE

$$dx(t) = \left(x(t) - x(t)^3\right) dt + 2x(t)dB(t) \tag{3.1}$$

it follows from Theorem 6.1 in section 6 below that

$$\limsup_{t\to\infty} \frac{1}{t} \log|x(t)| \le -1 \quad \text{a.s.} \tag{3.2}$$

The EM method (2.2) applied to (3.1) produces

$$X_{k+1} = X_k \left(1 + \Delta t - \Delta t X_k^2 + 2\Delta B_k\right). \tag{3.3}$$

LEMMA 3.1. *Suppose* $0 < \Delta t < 1$. *If* $|X_1| \ge 2^4/\sqrt{\Delta t}$ *in* (3.3), *then*

$$\mathbb{P}\left(|X_k| \ge \frac{2^{k+3}}{\sqrt{\Delta t}} \ \forall\, k \ge 1\right) \ge \exp\left(-4e^{-2/\sqrt{\Delta t}}\right).$$

Proof. First, we show that

$$|X_k| \ge \frac{2^{k+3}}{\sqrt{\Delta t}} \text{ and } |\Delta B_k| \le 2^k \quad \Rightarrow \quad |X_{k+1}| \ge \frac{2^{k+4}}{\sqrt{\Delta t}}. \tag{3.4}$$

To see this, suppose $|X_k| \ge 2^{k+3}/\sqrt{\Delta t}$. Then

$$\begin{aligned} |X_{k+1}| &\ge |X_k| \left|\Delta t |X_k^2| - 1 - \Delta t - 2|\Delta B_k|\right| \\ &\ge \frac{2^{k+3}}{\sqrt{\Delta t}} \left|2^{2k+6} - 1 - \Delta t - 2|\Delta B_k|\right|. \end{aligned}$$

Hence, $|X_{k+1}| \ge 2^{k+4}/\sqrt{\Delta t}$ if

$$2^{2k+6} - 1 - \Delta t - 2|\Delta B_k| \ge 2;$$

that is,

$$2|\Delta B_k| \le 2^{2k+6} - 3 - \Delta t.$$

Since $2^{2k+6} - 3 - \Delta t \ge 2^{2k+6} - 4 \ge 2^{k+1}\ \forall\, k \ge 0$, the implication (3.4) follows.

From (3.4), given that $|X_1| \ge 2^4/\sqrt{\Delta t}$, the event that $\{|X_k| \ge 2^{k+3}/\sqrt{\Delta t}, \forall\, 1 \le k \le K\}$ contains the event that $\{|\Delta B_k| \le 2^k\ \forall\, 1 \le k \le K\}$. So, because the $\{\Delta B_k\}$ are independent,

$$\mathbb{P}\left(|X_k| \ge \frac{2^{k+3}}{\sqrt{\Delta t}} \ \forall\, 1 \le k \le K\right) \ge \prod_{k=1}^{K} \mathbb{P}\left(|\Delta B_k| \le 2^k\right). \tag{3.5}$$

Now, because $\Delta B_k \sim N(0, \Delta t)$, we have

$$\begin{aligned} \mathbb{P}\left(|\Delta B_k| \ge 2^k\right) &= \mathbb{P}\left(\frac{|\Delta B_k|}{\sqrt{\Delta t}} \ge \frac{2^k}{\sqrt{\Delta t}}\right) \\ &= \frac{2}{\sqrt{2\pi}} \int_{2^k/\sqrt{\Delta t}}^{\infty} e^{-x^2/2}\, dx \\ &\le \frac{2}{\sqrt{2\pi}} \int_{2^k/\sqrt{\Delta t}}^{\infty} e^{-x}\, dx \\ &= \frac{2}{\sqrt{2\pi}} \exp\left(-\frac{2^k}{\sqrt{\Delta t}}\right). \end{aligned}$$

Hence, in (3.5)

$$\mathbb{P}\left(|X_k| \geq \frac{2^{k+3}}{\sqrt{\Delta t}} \ \forall\, 1 \leq k \leq K\right) \geq \prod_{k=1}^{K} \left(1 - \exp\left(-\frac{2^k}{\sqrt{\Delta t}}\right)\right).$$

Since

$$\log(1-u) \geq -2u \qquad \text{for } 0 < u < \frac{1}{2},$$

we then have

$$\begin{aligned} \log\left(\mathbb{P}\left(|X_k| \geq \frac{2^{k+3}}{\sqrt{\Delta t}} \ \forall\, 1 \leq k \leq K\right)\right) &\geq \sum_{k=1}^{K} \log\left(1 - \exp\left(-\frac{2^k}{\sqrt{\Delta t}}\right)\right) \\ &\geq -2\sum_{k=1}^{K} \exp\left(-\frac{2^k}{\sqrt{\Delta t}}\right). \end{aligned} \tag{3.6}$$

Next, using $2^k \geq 2k$,

$$\sum_{k=1}^{K} \exp\left(\frac{-2^k}{\sqrt{\Delta t}}\right) \leq \sum_{k=1}^{K} \exp\left(-\frac{2k}{\sqrt{\Delta t}}\right).$$

The right-hand side is a geometric series that converges monotonically from below to $e^{-2/\sqrt{\Delta t}}/(1 - e^{-2/\sqrt{\Delta t}}) \leq 2e^{-2/\sqrt{\Delta t}}$. Hence, in (3.6),

$$\log\left(\mathbb{P}\left(|X_k| \geq \frac{2^{k+3}}{\sqrt{\Delta t}} \ \forall\, 1 \leq k \leq K\right)\right) \geq -4e^{-2/\sqrt{\Delta t}},$$

and the result follows. □

To interpret Lemma 3.1, we note that given any $x(0) \neq 0$ and any $\Delta t > 0$, there is a nonzero probability that the first Brownian increment, ΔB_1, will cause $|X_1| \geq 2^4/\sqrt{\Delta t}$. Hence, there is a nonzero probability that EM will produce a numerical solution that blows up at a geometric rate. This contrasts with the initial-data-independent exponential stability of the underlying SDE, shown by (3.2).

In sections 4 and 5 we show that this poor behavior cannot happen when EM is applied to linear scalar problems or an appropriate class of nonlinear SDEs. In section 6 we study a class of SDEs that includes (3.1) and show that the correct stability can be retained by moving to an implicit method. We note that in all results, when we state the existence of a suitable upper limit, $\Delta t^\star$, on the stepsize, we implicitly mean that $\Delta t^\star$ does not depend on the initial data.

4. Linear scalar SDEs. In this section we focus on the linear scalar SDE

$$dx(t) = \alpha x(t)dt + \sigma x(t)dB(t), \qquad \text{with } 0 \neq x(0) \in \mathbb{R}, \tag{4.1}$$

where α and σ are real numbers. The following result is classical; see, e.g., [3, 13, 14].

THEOREM 4.1. *The sample Lyapunov exponent of the solution to the SDE* (4.1) *is*

$$\lim_{t\to\infty} \frac{1}{t} \log|x(t)| = \alpha - \frac{1}{2}\sigma^2 \quad \text{a.s.},$$

and the pth moment Lyapunov exponent is

$$\lim_{t\to\infty}\frac{1}{t}\log\mathbb{E}\left(|x(t)|^p\right)=p\alpha+\frac{1}{2}p(p-1)\sigma^2,$$

for any $p>0$. Hence, the zero solution of the SDE (4.1) is a.s. exponentially stable if and only if $\alpha-\frac{1}{2}\sigma^2<0$, while it is pth moment exponentially stable if and only if $\alpha+\frac{1}{2}(p-1)\sigma^2<0$.

We hence observe that the zero solution of the SDE (4.1) is a.s. exponentially stable if and only if it is pth moment exponentially stable for some sufficiently small positive p.

In the following three subsections we show that for small Δt, EM and ST recover almost sure and pth moment exponential stability of (4.1).

4.1. Almost sure exponential stability of Euler–Maruyama.

THEOREM 4.2. *If $\alpha-\frac{1}{2}\sigma^2<0$ in (4.1), then for any $\varepsilon\in(0,1)$ there is a $\Delta t^\star\in(0,1)$ such that for any $\Delta t<\Delta t^\star$, the EM approximation has the property that*

$$\lim_{k\to\infty}\frac{1}{k\Delta t}\log|X_k|\le(1-\varepsilon)\left(\alpha-\frac{1}{2}\sigma^2\right)<0\quad a.s. \tag{4.2}$$

Proof. The EM method (2.2) applied to (4.1) has the form

$$X_{k+1}=X_k(1+\alpha\Delta t+\sigma\Delta B_k). \tag{4.3}$$

It follows that $X_k=x_0\prod_{j=0}^{k-1}(1+\alpha\Delta t+\sigma\Delta B_j)$, and thus

$$\log|X_k|=\log|x_0|+\sum_{j=0}^{k-1}\log|1+\alpha\Delta t+\sigma\Delta B_j|.$$

Dividing both sides by k, letting $k\to\infty$, and then applying the classical strong law of large numbers we obtain

$$\lim_{k\to\infty}\frac{1}{k\Delta t}\log|X_k|=\frac{1}{\Delta t}\mathbb{E}\log|1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z|\quad\text{a.s.,}\quad\text{where } Z\sim N(0,1). \tag{4.4}$$

Writing

$$\begin{aligned}\log|1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z|&=\tfrac{1}{2}\log([1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z]^2)\\&=\tfrac{1}{2}\log(1+2[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]+[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]^2),\end{aligned}$$

and recalling the fundamental inequality

$$\log(1+u)\le u-\frac{1}{2}u^2+\frac{1}{3}u^3,\qquad u\ge-1,$$

we have

$$\begin{aligned}\log|1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z|\le\frac{1}{2}\Big(&2[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]+[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]^2\\&-\frac{1}{2}\big(2[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]+[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]^2\big)^2\\&+\frac{1}{3}\big(2[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]+[\alpha\Delta t+\sigma\sqrt{\Delta t}Z]^2\big)^3\Big).\end{aligned}$$

Making use of the properties $\mathbb{E}(Z^{2n}) = (2n-1)!!$ and $\mathbb{E}(Z^{2n-1}) = 0$, for $n = 1, 2, 3, \ldots$, we can compute

$$(4.5)\quad \begin{cases} \mathbb{E}[\alpha\Delta t + \sigma\sqrt{\Delta t}Z] &= \alpha\Delta t, \\ \mathbb{E}([\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2) &= \alpha^2\Delta t^2 + \sigma^2\Delta t, \\ \mathbb{E}([\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^3) &= \alpha^3\Delta t^3 + 3\alpha\sigma^2\Delta t^2, \\ \mathbb{E}([\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^4) &= \alpha^4\Delta t^4 + 6\alpha^2\sigma^2\Delta t^3 + 3\sigma^4\Delta t^2, \\ \mathbb{E}([\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^5) &= \alpha^5\Delta t^5 + 10\alpha^3\sigma^2\Delta t^4 + 15\alpha\sigma^4\Delta t^3, \\ \mathbb{E}([\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^6) &= \alpha^6\Delta t^6 + 15\alpha^4\sigma^2\Delta t^5 + 45\alpha^2\sigma^4\Delta t^4 + 15\sigma^6\Delta t^3, \end{cases}$$

and hence obtain

$$(4.6)\qquad \mathbb{E}\log|1 + \alpha\Delta t + \sigma\sqrt{\Delta t}Z| \le (\alpha - \tfrac{1}{2}\sigma^2)\Delta t + C_1\Delta t^2,$$

where $C_1 = C_1(\alpha, \sigma) > 0$ is a constant independent of Δt. Now, choose $\Delta t^\star \in (0, 1)$ so small that $C_1\Delta t^\star \le \varepsilon(\frac{1}{2}\sigma^2 - \alpha)$. Then for any $\Delta t < \Delta t^\star$ we can substitute (4.6) into (4.4) to obtain (4.2). □

4.2. Moment exponential stability of Euler–Maruyama.

THEOREM 4.3. *Let $p \in (0, 2]$. If $\alpha + \frac{1}{2}(p-1)\sigma^2 < 0$ in (4.1), then for any $\varepsilon \in (0, 1)$ there is a $\Delta t^\star \in (0, 1)$ such that for any $\Delta t < \Delta t^\star$, the EM approximation has the property that*

$$(4.7)\qquad \lim_{k\to\infty} \frac{1}{k\Delta t}\log\mathbb{E}(|X_k|^p) \le (1-\varepsilon)p\left(\alpha + \frac{1}{2}(p-1)\sigma^2\right) < 0.$$

Proof. It follows from (4.3) that $\mathbb{E}(|X_k|^p) = |x_0|^p\prod_{j=0}^{k-1}\mathbb{E}(|1 + \alpha\Delta t + \sigma\Delta B_j|^p)$, and hence

$$\mathbb{E}(|X_k|^p) = |x_0|^p(\mathbb{E}|1 + \alpha\Delta t + \sigma\sqrt{\Delta}Z|^p)^k, \qquad \text{where } Z \sim N(0, 1).$$

This implies

$$(4.8)\qquad \lim_{k\to\infty} \frac{1}{k\Delta t}\log\mathbb{E}(|X_k|^p) = \frac{1}{\Delta t}\log\mathbb{E}(|1 + \alpha\Delta t + \sigma\sqrt{\Delta}Z|^p).$$

Writing

$$\begin{aligned} |1 + \alpha\Delta t + \sigma\sqrt{\Delta t}Z|^p &= ([1 + \alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2)^{p/2} \\ &= (1 + 2[\alpha\Delta t + \sigma\sqrt{\Delta t}Z] + [\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2)^{p/2}, \end{aligned}$$

and recalling the fundamental inequality

$$(4.9)\qquad (1+u)^{p/2} \le 1 + \frac{p}{2}u + \frac{p(p-2)}{8}u^2 + \frac{p(p-2)(p-4)}{2^3\times 3!}u^3, \qquad u \ge -1,$$

we have

$$\begin{aligned} |1 + \alpha\Delta t + \sigma\sqrt{\Delta t}Z|^p \le 1 &+ \frac{p}{2}\left(2[\alpha\Delta t + \sigma\sqrt{\Delta t}Z] + [\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2\right) \\ &+ \frac{p(p-2)}{8}\left(2[\alpha\Delta t + \sigma\sqrt{\Delta t}Z] + [\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2\right)^2 \\ &+ \frac{p(p-2)(p-4)}{48}\left(2[\alpha\Delta t + \sigma\sqrt{\Delta t}Z] + [\alpha\Delta t + \sigma\sqrt{\Delta t}Z]^2\right)^3. \end{aligned}$$

Making use of (4.5), we obtain

$$\mathbb{E}(|1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z|^p) \le 1+p[\alpha+\tfrac{1}{2}(p-1)\sigma^2]\Delta t + C_3\Delta t^2,$$

where $C_3 = C_3(\alpha,\sigma,p) > 0$ is a constant independent of Δt. Now, choose $\Delta t^\star \in (0,1)$ so small that for all $\Delta t < \Delta t^\star$

$$C_3\Delta t \le \varepsilon p|\alpha+\tfrac{1}{2}(p-1)\sigma^2| \qquad \text{and} \qquad -1 < (1-\varepsilon)p[\alpha+\tfrac{1}{2}(p-1)\sigma^2]\Delta t < 0.$$

Then

$$\mathbb{E}(|1+\alpha\Delta t+\sigma\sqrt{\Delta t}Z|^p) \le 1+(1-\varepsilon)p[\alpha+\tfrac{1}{2}(p-1)\sigma^2]\Delta t.$$

Substituting this into (4.8) we obtain

$$\lim_{k\to\infty}\frac{1}{k\Delta t}\log\mathbb{E}(|X_k|^p) \le \frac{1}{\Delta t}\log\left(1+(1-\varepsilon)p\left[\alpha+\frac{1}{2}(p-1)\sigma^2\right]\Delta t\right).$$

But $\log(1+u) \le u$ for $-1 < u < 0$, and thus (4.7) follows. □

4.3. Exponential stability of the stochastic theta method. If we assume that Δt is chosen so small that $\Delta t\alpha\theta < 1$, then the ST method (2.3) applied to the linear SDE (4.1) may be written in the form

$$X_{k+1} = X_k\left(1+\frac{\alpha}{1-\theta\alpha\Delta t}\Delta t+\frac{\sigma}{1-\theta\alpha\Delta t}\Delta B_k\right).$$

This approximation coincides with the EM method applied to the modified linear SDE

$$dy(t) = \frac{\alpha}{1-\theta\alpha\Delta t}y(t)dt+\frac{\sigma}{1-\theta\alpha\Delta t}y(t)dB(t).$$

Using this observation, it follows almost immediately that the statements of Theorems 4.2 and 4.3 also apply to the ST method.

5. Generalization to multidimensional nonlinear SDEs. To analyze the n-dimensional nonlinear SDE (2.1), we begin by imposing the linear growth assumption

$$|f(x)| \vee |g(x)| \le K|x| \qquad \forall x \in \mathbb{R}^n. \tag{5.1}$$

This implies

$$f(0) = 0, \quad g(0) = 0, \tag{5.2}$$

and we will be concerned with pathwise convergence of the solution $x(t)$ of (2.1) to the zero solution, as $t \to \infty$, and the preservation of this property under discretization. We also note that condition (5.1) ensures that, with probability one, the solution will never reach the origin; see, for example, [15, Lemma 3.2].

We begin by giving sufficient conditions for almost sure exponential stability of the SDE.

THEOREM 5.1. *Let* (5.1) *hold. If*

$$-\lambda := \sup_{x\in\mathbb{R}^n, x\neq 0}\left(\frac{\langle x, f(x)\rangle+\frac{1}{2}|g(x)|^2}{|x|^2}-\frac{\langle x, g(x)\rangle^2}{|x|^4}\right) < 0, \tag{5.3}$$

then the solution of (2.1) *obeys*

$$\limsup_{t\to\infty} \frac{1}{t}\log|x(t)| \le -\lambda \quad \text{a.s.}, \tag{5.4}$$

and given any $\varepsilon \in (0,\lambda)$ *there exists a* $p^\star \in (0,1)$ *such that for all* $0 < p < p^\star$

$$\limsup_{t\to\infty} \frac{1}{t}\log \mathbb{E}(|x(t)|^p) \le -p(\lambda-\varepsilon). \tag{5.5}$$

Proof. See Appendix A. □

Next, we analyze the EM discretization (2.2).

THEOREM 5.2. *Let* (5.1) *and* (5.3) *hold. Then for any* $\varepsilon \in (0,\lambda)$ *there is a constant* $\Delta t^\star \in (0,1)$ *such that for any* $0 < \Delta t < \Delta t^\star$ *the EM approximation* (2.2) *satisfies*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t}\log|X_k| \le -(\lambda-\varepsilon) \quad \text{a.s.} \tag{5.6}$$

Further, for any $\varepsilon \in (0,\lambda)$ *and any sufficiently small* $p > 0$, *there is a constant* $\Delta t^\star \in (0,1)$ *such that for any* $0 < \Delta t < \Delta t^\star$ *the EM approximation* (2.2) *satisfies*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t}\log \mathbb{E}(|X_k|^p) \le -p(\lambda-\varepsilon). \tag{5.7}$$

Proof. By condition (5.2), we compute from (2.2) that

$$\begin{aligned}|X_{k+1}|^2 &= |X_k|^2 + 2\langle X_k, f(X_k)\Delta t + g(X_k)\Delta B_k\rangle + |f(X_k)\Delta t + g(X_k)\Delta B_k|^2\\ &= |X_k|^2(1+\xi_k),\end{aligned}$$

where

$$\xi_k = \frac{1}{|X_k|^2}\left[2\langle X_k, f(X_k)\Delta t + g(X_k)\Delta B_k\rangle + |f(X_k)\Delta t + g(X_k)\Delta B_k|^2\right]$$

if $X_k \neq 0$, otherwise it is set to -1. Clearly, $\xi_k \ge -1$. For any $p \in (0,1)$, by inequality (4.9) we have

$$\begin{aligned}|X_{k+1}|^p &= |X_k|^p(1+\xi_k)^{p/2}\\ &\le |X_k|^p\left(1 + \frac{p}{2}\xi_k + \frac{p(p-2)}{8}\xi_k^2 + \frac{p(p-2)(p-4)}{2^3\times 3!}\xi_k^3\right).\end{aligned}$$

Hence the conditional expectation

$$\begin{aligned}\mathbb{E}(|X_{k+1}|^p\Big|\mathcal{F}_{k\Delta t}) &\le |X_k|^p\ \mathbb{E}\left(1 + \frac{p}{2}\xi_k + \frac{p(p-2)}{8}\xi_k^2 + \frac{p(p-2)(p-4)}{2^3\times 3!}\xi_k^3\Big|\mathcal{F}_{k\Delta t}\right)\\ &= |X_k|^p\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}\left(1 + \frac{p}{2}\xi_k + \frac{p(p-2)}{8}\xi_k^2 + \frac{p(p-2)(p-4)}{2^3\times 3!}\xi_k^3\Big|\mathcal{F}_{k\Delta t}\right),\end{aligned} \tag{5.8}$$

where $\mathbf{1}_A$ denotes the indicator function for A. Now,

$$\begin{aligned}&\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\xi_k|\mathcal{F}_{k\Delta t})\\ &= \mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}\left(\frac{1}{|X_k|^2}\left[2\langle X_k, f(X_k)\Delta t + g(X_k)\Delta B_k\rangle + |f(X_k)\Delta t + g(X_k)\Delta B_k|^2\right]\Big|\mathcal{F}_{k\Delta t}\right).\end{aligned}$$

Since ΔB_k is independent of $\mathcal{F}_{k\Delta t}$, we have $\mathbb{E}(\Delta B_k|\mathcal{F}_{k\Delta t}) = \mathbb{E}(\Delta B_k) = 0$ and $\mathbb{E}((\Delta B_k)^2|\mathcal{F}_{k\Delta t}) = \mathbb{E}((\Delta B_k)^2) = \Delta t$. It is then easy to obtain that

$$\begin{aligned}\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\xi_k|\mathcal{F}_{k\Delta t}) &= \mathbf{1}_{\{X_k\neq 0\}}\left(\frac{1}{|X_k|^2}\left[2\langle X_k, f(X_k)\Delta t\rangle + |f(X_k)|^2\Delta t^2 + |g(X_k)|^2\Delta t\right]\right)\\ &\le \mathbf{1}_{\{X_k\neq 0\}}\left(\frac{1}{|X_k|^2}\left[2\langle X_k, f(X_k)\Delta t\rangle + |g(X_k)|^2\right]\Delta t + K^2\Delta t^2\right), \qquad (5.9)\end{aligned}$$

where (5.1) has been used. Similarly, we can show that

$$\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\xi_k^2|\mathcal{F}_{k\Delta t}) \ge \frac{4}{|X_k|^4}\langle X_k, g(X_k)\rangle^2\Delta t - c_K\Delta t^2 \qquad (5.10)$$

and

$$\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\xi_k^3|\mathcal{F}_{k\Delta t}) \le c_K\Delta t^2, \qquad (5.11)$$

where $c_K > 0$ is a constant dependent only on K. Substituting (5.9), (5.10), and (5.11) into (5.8) and then using (5.3) and (5.1) we derive that

$$\begin{aligned}\mathbb{E}(|X_{k+1}|^p\big|\mathcal{F}_{k\Delta t}) &\le |X_k|^p\mathbf{1}_{\{X_k\neq 0\}}\left(1 + \frac{p}{2|X_k|^2}\left[2\langle X_k, f(X_k)\Delta t\rangle + |g(X_k)|^2\right]\Delta t\right.\\ &\qquad \left. + \frac{p(p-2)}{2|X_k|^4}\langle X_k, g(X_k)\rangle^2\Delta t + C\Delta t^2\right)\\ &= |X_k|^p\mathbf{1}_{\{X_k\neq 0\}}\left\{1 + p\Delta t\left(\frac{\langle X_k, f(X_k)\rangle + \frac{1}{2}|g(X_k)|^2}{|X_k|^2} - \frac{\langle X_k, g(X_k)\rangle^2}{|X_k|^4}\right)\right.\\ &\qquad \left. + \frac{p^2\Delta t\langle X_k, g(X_k)\rangle^2}{2|X_k|^4} + C\Delta t^2\right\}\\ &\le |X_k|^p\left(1 - p\lambda\Delta t + \frac{p^2\Delta t K^2}{2} + C\Delta t^2\right), \qquad (5.12)\end{aligned}$$

where $C = C(K,p) > 0$ is a constant independent of Δt. Now, for any given $\varepsilon \in (0,\lambda)$ and $p \in (0,1)$ sufficiently small for $pK^2 < \varepsilon$, choose $\Delta t^\star \in (0,1)$ sufficiently small for $p\lambda\Delta t^\star < 1$ and $C\Delta t^\star < \frac{1}{2}p\varepsilon$. It then follows from (5.12) that for any $\Delta t < \Delta t^\star$

$$\mathbb{E}(|X_{k+1}|^p\big|\mathcal{F}_{k\Delta t}) \le |X_k|^p(1 - p(\lambda-\varepsilon)\Delta t).$$

Taking expectations on both sides yields

$$\mathbb{E}(|X_{k+1}|^p) \le \mathbb{E}(|X_k|^p)(1 - p(\lambda-\varepsilon)\Delta t).$$

Since this holds for any $k \ge 0$, we have

$$\mathbb{E}(|X_k|^p) \le |x(0)|^p(1 - p(\lambda-\varepsilon)\Delta t)^k \le |x(0)|^p e^{-pk(\lambda-\varepsilon)\Delta t} \quad \forall k \ge 1. \qquad (5.13)$$

This implies (5.7). Moreover, we have

$$\mathbb{P}\{|X_k|^p > k^2 e^{-pk(\lambda-\varepsilon)\Delta t}\} \le \frac{|x(0)|^p}{k^2} \quad \forall k \ge 1.$$

By the Borel–Cantelli lemma, we see that for almost all $\omega \in \Omega$

$$|X_k|^p \le k^2 e^{-pk(\lambda-\varepsilon)\Delta t} \qquad (5.14)$$

holds for all but finitely many k. Hence, there exists a $k_0(\omega)$, for all $\omega \in \Omega$ excluding a $\mathbb{P}$-null set, for which (5.14) holds whenever $k \geq k_0$. Consequently, for almost all $\omega \in \Omega$,

$$\frac{1}{k\Delta t} \log |X_k| \leq -(\lambda - \varepsilon) + \frac{2\log(k)}{pk\Delta t}$$

whenever $k \geq k_0$. Letting $k \to \infty$ we obtain (5.6). □

Let us now apply Theorem 5.2 to the linear SDE system

$$dx(t) = Ax(t)dt + Gx(t)dB(t), \quad t \geq 0, \qquad \text{given } 0 \neq x(0) \in \mathbb{R}^n, \tag{5.15}$$

where $A, G \in \mathbb{R}^{n\times n}$. This corresponds to $f(x) = Ax$ and $g(x) = Gx$ in (2.1). Note

$$\tfrac{1}{2}\lambda_{\min}(A + A^T)|x|^2 \leq \langle x, Ax\rangle = \tfrac{1}{2}\langle x, (A + A^T)x\rangle \leq \tfrac{1}{2}\lambda_{\max}(A + A^T)|x|^2$$

and

$$\lambda_{\min}(G^T G)|x|^2 \leq \langle x, G^T Gx\rangle = |Gx|^2 \leq \|G\|^2|x|^2,$$

where $\lambda_{\max}(\cdot)$ and $\lambda_{\min}(\cdot)$ denote the maximum and minimum eigenvalues of a symmetric matrix, respectively. Moreover,

$$0 \leq \langle x, Gx\rangle^2 = \tfrac{1}{4}\langle x, (G + G^T)x\rangle^2 \leq \tfrac{1}{4}\lambda^2_{\max}(G + G^T)|x|^2,$$

while if $G + G^T$ is either nonpositive definite or nonnegative definite,

$$\langle x, Gx\rangle^2 \geq \tfrac{1}{4}\left[|\lambda_{\max}(G + G^T)| \wedge |\lambda_{\min}(G + G^T)|\right]^2 |x|^4.$$

We hence observe that

$$\frac{\langle x, Ax\rangle + \frac{1}{2}|Gx|^2}{|x|^2} - \frac{\langle x, Gx\rangle^2}{|x|^4} \geq \tfrac{1}{2}\lambda_{\min}(A + A^T) + \tfrac{1}{2}\lambda_{\min}(G^T G) - \tfrac{1}{4}\lambda^2_{\max}(G + G^T),$$

while if $G + G^T$ is either nonpositive definite or nonnegative definite,

$$\frac{\langle x, Ax\rangle + \frac{1}{2}|Gx|^2}{|x|^2} - \frac{\langle x, Gx\rangle^2}{|x|^4} \leq \tfrac{1}{2}\lambda_{\max}(A + A^T) + \tfrac{1}{2}\|G\|^2 - \tfrac{1}{4}\left[|\lambda_{\max}(G + G^T)| \wedge |\lambda_{\min}(G + G^T)|\right]^2.$$

By Theorem 5.2 we reach the following conclusion.

COROLLARY 5.3. *If $G + G^T$ is either nonpositive definite or nonnegative definite and*

$$-\lambda := \tfrac{1}{2}\lambda_{\max}(A + A^T) + \tfrac{1}{2}\|G\|^2 - \tfrac{1}{4}\left[|\lambda_{\max}(G + G^T)| \wedge |\lambda_{\min}(G + G^T)|\right]^2 < 0,$$

then for any $\varepsilon \in (0, \lambda)$ there is a pair of constants $p \in (0, 1)$ and $\Delta t^\star \in (0, 1)$ such that for any $\Delta t < \Delta t^\star$ the EM approximation of the linear SDE (5.15) *has the properties* (5.7) *and* (5.6).

6. Backward Euler. So far, we have proved positive results about EM for sufficiently small Δt. However, we saw in section 3 that this behavior does not extend to the cubic example (3.1). This SDE does not satisfy the linear growth condition (5.1); thus, of course, the theorems in section 5 do not apply. However, (3.1) does satisfy (5.3), since

$$\sup_{x\in\mathbb{R},x\neq 0}\left(\frac{\langle x,f(x)\rangle+\frac{1}{2}|g(x)|^2}{|x|^2}-\frac{\langle x,g(x)\rangle^2}{|x|^4}\right)=\sup_{x\in\mathbb{R},x\neq 0}\left(\frac{x^2-x^4+2x^2}{x^2}-\frac{4x^4}{x^4}\right)\leq -1,$$

and we note that the proof of Theorem 5.1 did not use the condition $|f(x)|\leq K|x|$ explicitly, though $|g(x)|\leq K|x|$ was used. Of course, the linear growth condition (5.1) was used implicitly to guarantee that the solution stays away from the origin with probability one. However, for this property we need only a weaker condition (see [15, Lemma 3.2 on p. 120]). Let us form this improved result as a new theorem.

THEOREM 6.1. *The conclusions of Theorem* 5.1 *still hold if condition* (5.1) *is replaced by the following: for each integer* $i\geq 1$ *there is a* $K_i>0$ *such that*

$$|f(x)|\leq K_i|x| \quad \forall x\in\mathbb{R}^n \text{ with } |x|\leq i, \tag{6.1}$$

while there is a $K>0$ *such that*

$$|g(x)|\leq K|x| \quad \forall x\in\mathbb{R}^n. \tag{6.2}$$

An application of this theorem to the SDE (3.1) shows that its solution obeys (3.2), as claimed in section 3. We also saw from Lemma 3.1 that EM does not preserve this almost sure asymptotic stability for any $\Delta t>0$. Hence, it is not possible to extend Theorem 5.2 to the case where (5.1) is replaced by (6.1) and (6.2).

An interesting open question is whether any other numerical methods preserve exponential asymptotic stability for small Δt under (6.1) and (6.2).

In this section we pursue a different approach. We consider a structural constraint that is known to allow positive results to be proved for the BE method in other contexts. More precisely, we assume that there is a constant $\mu\in\mathbb{R}$ such that

$$\langle x-y,f(x)-f(y)\rangle\leq\mu|x-y|^2 \quad \forall x,y\in\mathbb{R}^n. \tag{6.3}$$

This *one-sided Lipschitz condition* has been applied in the deterministic and stochastic literature [9, 11, 12, 16, 20] to establish results about long-term behavior and boundedness in a manner that is connected with the use of Lyapunov functions [6, 18]. In particular, we note that under (6.3) the condition $\mu\Delta t<1$ ensures that (2.3) with $\theta=1$ can be solved uniquely for X_{k+1}.

The next theorem concerns the exponential stability of BE under conditions (6.3) and (6.2). Although (6.2) implies $g(0)=0$, (6.3) may not force $f(0)=0$, and thus we still need to assume it for the purpose of stability analysis.

THEOREM 6.2. *Let* (6.2) *and* (6.3) *hold and* $f(0)=0$. *Assume also that* $\mu+\frac{1}{2}\rho<0$, *where*

$$\rho:=\sup_{x\in\mathbb{R}^n,x\neq 0}\Big(\frac{|g(x)|^2}{|x|^2}-\frac{2\langle x,g(x)\rangle^2}{|x|^4}\Big). \tag{6.4}$$

Then (5.4) *holds with* $-\lambda=\mu+\frac{1}{2}\rho$, *and for any* $\varepsilon\in(0,|\mu+\frac{1}{2}\rho|)$ *there is a pair of constants* $p\in(0,1)$ *and* $\Delta t^\star\in(0,1)$ *with* $\mu\Delta t^\star<1$ *such that for any* $\Delta t<\Delta t^\star$, *the*

BE method (that is, (2.3) *with* $\theta = 1$*) has the properties that*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t} \log \mathbb{E}(|X_k|^p) \le p\left(\mu + \frac{1}{2}\rho + \varepsilon\right) < 0 \tag{6.5}$$

and

$$\limsup_{k\to\infty} \frac{1}{k\Delta t} \log |X_k| \le \mu + \frac{1}{2}\rho + \varepsilon < 0 \quad \text{a.s.} \tag{6.6}$$

Proof. It is straightforward to adapt the proof of Theorem 5.1 in order to establish (5.4) under (6.2) and (6.3). From (2.3) with $\theta = 1$, we have

$$|X_{k+1}|^2 = \langle X_{k+1}, X_k + g(X_k)\Delta B_k\rangle + \langle X_{k+1}, f(X_{k+1})\Delta t\rangle.$$

By (6.3) and $f(0) = 0$, we have

$$\langle X_{k+1}, f(X_{k+1})\Delta t\rangle \le \mu\Delta t|X_{k+1}|^2.$$

But,

$$\langle X_{k+1}, X_k + g(X_k)\Delta B_k\rangle \le \tfrac{1}{2}|X_{k+1}|^2 + \tfrac{1}{2}|X_k + g(X_k)\Delta B_k|^2.$$

We hence obtain

$$\begin{aligned}
|X_{k+1}|^2 &\le \frac{1}{1-2\mu\Delta t}|X_k + g(X_k)\Delta B_k|^2 \\
&\le \frac{1}{1-2\mu\Delta t}\left(|X_k|^2 + 2\langle X_k, g(X_k)\rangle\Delta B_k + |g(X_k)|^2\Delta B_k^2\right) \\
&= \frac{|X_k|^2}{1-2\mu\Delta t}(1+\zeta_k),
\end{aligned}$$

where

$$\zeta_k = \frac{1}{|X_k|^2}\left(2\langle X_k, g(X_k)\rangle\Delta B_k + |g(X_k)|^2\Delta B_k^2\right)$$

if $X_k \neq 0$, otherwise it is set to -1. Clearly, $\zeta_k \ge -1$. For any $p \in (0,1)$, by inequality (4.9) we can then show that

$$\begin{aligned}
\mathbb{E}(|X_{k+1}|^p\big|\mathcal{F}_{k\Delta t}) \le \frac{|X_k|^p}{(1-2\mu\Delta t)^{p/2}}\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}\Bigg(1 + \frac{p}{2}\zeta_k \\
+ \frac{p(p-2)}{8}\zeta_k^2 + \frac{p(p-2)(p-4)}{2^3\times 3!}\zeta_k^3\Big|\mathcal{F}_{k\Delta t}\Bigg).
\end{aligned} \tag{6.7}$$

In the same way as in the proof of Theorem 5.2 we can show that

$$\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\zeta_k|\mathcal{F}_{k\Delta t}) = \mathbf{1}_{\{X_k\neq 0\}}\frac{|g(X_k)|^2}{|X_k|^2}\Delta t,$$

$$\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\zeta_k^2|\mathcal{F}_{k\Delta t}) \ge \frac{4\langle X_k, g(X_k)\rangle^2}{|X_k|^4}\Delta t - K^4\Delta t^2,$$

and

$$\mathbf{1}_{\{X_k\neq 0\}}\mathbb{E}(\zeta_k^3|\mathcal{F}_{k\Delta t}) \le c_K\Delta t^2,$$

where $c_K > 0$ is a constant dependent only on K. Substituting the three inequalities above into (6.7) and then using (6.4) and (6.2) we derive that

$$\begin{aligned}\mathbb{E}(|X_{k+1}|^p\big|\mathcal{F}_{k\Delta t}) &\le \frac{|X_k|^p}{(1-2\mu\Delta t)^{p/2}}\mathbf{1}_{\{X_k\neq 0\}}\left(1+\frac{p}{2}\frac{|g(X_k)|^2}{|X_k|^2}\Delta t\right.\\ &\quad\left.+\frac{p(p-2)}{8}\left[\frac{4\langle X_k,g(X_k)\rangle^2}{|X_k|^4}\Delta t - K^4\Delta t^2\right]+\frac{p(p-2)(p-4)}{2^3\times 3!}c_K\Delta t^2\right)\\ &\le \frac{|X_k|^p}{(1-2\mu\Delta t)^{p/2}}\left(1+\frac{1}{2}p\rho\Delta t+\frac{1}{2}p^2K^2\Delta t+C\Delta t^2\right),\end{aligned}$$

where $C = C(p,K)$ is a positive constant. Taking expectations on both sides, we arrive at

$$\mathbb{E}(|X_{k+1}|^p) \le \frac{1+\frac{1}{2}p\rho\Delta t+\frac{1}{2}p^2K^2\Delta t+C\Delta t^2}{(1-2\mu\Delta t)^{p/2}}\,\mathbb{E}(|X_k|^p). \tag{6.8}$$

Now, for any $\varepsilon\in(0,|\mu+\frac{1}{2}\rho|)$, we may choose p sufficiently small for $pK^2\le\frac{1}{4}\varepsilon$. Then we have

$$(1-2\mu\Delta t)^{p/2} \ge 1-p\mu\Delta t-\widehat{C}\Delta t^2 > 0, \tag{6.9}$$

for sufficiently small Δt, where $\widehat{C}=\widehat{C}(p,\mu)$ is a positive constant. By further reducing Δt, if necessary, we may ensure that

$$C\Delta t<\tfrac{1}{8}p\varepsilon,\qquad \widehat{C}\Delta t<\tfrac{1}{4}\varepsilon,\qquad |p(\mu+\tfrac{1}{4}\varepsilon)\Delta t|\le\tfrac{1}{2}. \tag{6.10}$$

Using (6.9) and (6.10) in (6.8) gives

$$\mathbb{E}(|X_{k+1}|^p) \le \frac{1+\frac{1}{2}p(\rho+\frac{1}{2}\varepsilon)\Delta t}{1-p(\mu+\frac{1}{4}\varepsilon)\Delta t}\,\mathbb{E}|X_k|^p. \tag{6.11}$$

Note that for any $u\in[-\frac{1}{2},\frac{1}{2}]$

$$\frac{1}{1-u} = 1+u+u^2\sum_{i=0}^{\infty}u^i \le 1+u+u^2\sum_{i=0}^{\infty}(\tfrac{1}{2})^i = 1+u+2u^2.$$

By further reducing Δt, if necessary, so that

$$4p(\mu+\tfrac{1}{4}\varepsilon)^2\Delta t+(\rho+\tfrac{1}{2}\varepsilon)\left(p(\mu+\tfrac{1}{4}\varepsilon)\Delta t+2[p(\mu+\tfrac{1}{4}\varepsilon)\Delta t]^2\right)\le\varepsilon,$$

and using (6.11), we compute that

$$\begin{aligned}\mathbb{E}(|X_{k+1}|^p) &\le \left(1+\tfrac{1}{2}p(\rho+\tfrac{1}{2}\varepsilon)\Delta t\right)\left(1+p(\mu+\tfrac{1}{4}\varepsilon)\Delta t+2[p(\mu+\tfrac{1}{4}\varepsilon)\Delta t]^2\right)\mathbb{E}(|X_k|^p)\\ &\le [1+p(\mu+\tfrac{1}{2}\rho+\varepsilon)\Delta t]\mathbb{E}(|X_k|^p).\end{aligned}$$

From this we can show the assertions (6.5) and (6.6) in the same way as in the proof of Theorem 5.2. □

Let us return to the scalar SDE (3.1), where $f(x) = x - x^3$ and $g(x) = 2x$. In this case, we have $\langle x-y,\, f(x)-f(y)\rangle \le |x-y|^2$, so we may take $\mu = 1$ in (6.3), while

$$\rho := \sup_{x\in\mathbb{R}, x\neq 0} \left(\frac{|g(x)|^2}{|x|^2} - \frac{2\langle x, g(x)\rangle^2}{|x|^4} \right) = -4,$$

whence $\mu + \frac{1}{2}\rho = -1$, which gives another confirmation of (3.2).

By Theorem 6.2, for any given $\varepsilon \in (0,1)$, there is a $\Delta t^\star > 0$ sufficiently small so that if $\Delta t < \Delta t^\star$, the BE approximate solution of the SDE (3.1) obeys

$$\limsup_{k\to\infty} \frac{1}{k\Delta t} \log |X_k| \le -1 + \varepsilon \qquad \text{a.s.},$$

which recovers property (3.2) very well indeed.

It is also interesting to observe that in the scalar case (that is, $n = 1$),

$$\rho = \sup_{x\in\mathbb{R}, x\neq 0} \left(-\frac{|g(x)|^2}{|x|^2} \right) \le 0.$$

In this case, if (6.3) also holds with $\mu < 0$, then the BE method is a.s. exponentially stable as long as the stepsize is sufficiently small. For example, the BE approximate solution to the scalar SDE

$$dx(t) = (\mu x - x^3)dt + g(x)dB(t)$$

is always a.s. exponentially stable as long as the stepsize is sufficiently small, $\mu < 0$, and g obeys the linear growth condition (6.2). However, in the case $\mu \ge 0$, we will need that

$$|g(x)|^2 \ge \rho x^2, \quad x \in \mathbb{R},$$

holds for some $\rho > 2\mu$ in order to conclude that the BE method is a.s. exponentially stable.

7. Multidimensional noise. So far, in order to streamline the presentation, we have only considered scalar noise. In this section we state, without proof, how the nonlinear results generalize to the multinoise case, as follows:

$$dx(t) = f(x(t))dt + \sum_{j=1}^{d} g_j(x(t))dB_j(t), \quad t \ge 0, \qquad \text{given } 0 \neq x(0) \in \mathbb{R}^n. \tag{7.1}$$

Here $(B_1(t), \ldots, B_d(t))$ is a d-dimensional Brownian motion. As before, we assume, as a standing hypothesis, that $f, g_1, \ldots, g_d : \mathbb{R}^n \to \mathbb{R}^n$ are smooth enough for the SDE (7.1) to have a unique global solution $x(t)$ on $[0,\infty)$.

The following generalization of Theorem 6.1 gives a criterion for the almost sure and moment exponential stability of the SDE.

THEOREM 7.1. *Assume that for each integer $i \ge 1$ there is a $K_i > 0$ such that*

$$|f(x)| \le K_i|x| \quad \forall x \in \mathbb{R}^n \text{ with } |x| \le i, \tag{7.2}$$

while there is a $K > 0$ such that

$$|g_j(x)| \le K|x| \quad \forall x \in \mathbb{R}^n \text{ and } 1 \le j \le d. \tag{7.3}$$

If

$$-\lambda := \sup_{x\in\mathbb{R}^n, x\neq 0}\left(\frac{\langle x, f(x)\rangle + \frac{1}{2}\sum_{j=1}^d |g_j(x)|^2}{|x|^2} - \frac{\sum_{j=1}^d \langle x, g_j(x)\rangle^2}{|x|^4}\right) < 0,$$

then the solution of (7.1) *obeys*

$$\limsup_{t\to\infty} \frac{1}{t}\log|x(t)| \leq -\lambda \quad a.s., \tag{7.4}$$

and given any $\varepsilon \in (0,\lambda)$ *there exists a* $p^\star \in (0,1)$ *such that for all* $0 < p < p^\star$

$$\limsup_{t\to\infty} \frac{1}{t}\log \mathbb{E}(|x(t)|^p) \leq -p(\lambda - \varepsilon).$$

This theorem can be proved in a similar way that Theorem 5.1 is proved in the appendix.

The EM method applied to (7.1) produces approximations $X_k \approx x(k\Delta t)$ with $X_0 = x(0)$ and

$$X_{k+1} = X_k + \Delta t f(X_k) + \sum_{j=1}^d g(X_k)\Delta B_{jk}, \tag{7.5}$$

where $\Delta B_{jk} := B_j((k+1)\Delta t) - B_j(k\Delta t)$. Recalling the motivating example in section 3, we will replace the local linear growth condition (7.2) by a global one.

THEOREM 7.2. *Assume that all the conditions of Theorem* 7.1 *hold with condition* (7.2) *replaced by*

$$|f(x)| \leq K|x| \quad \forall x \in \mathbb{R}^n.$$

Then for any $\varepsilon \in (0,\lambda)$ *there is a constant* $\Delta t^\star \in (0,1)$ *such that for any* $0 < \Delta t < \Delta t^\star$ *the EM approximation* (7.5) *satisfies*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t}\log|X_k| \leq -(\lambda - \varepsilon) \quad a.s.$$

Further, for any $\varepsilon \in (0,\lambda)$ *and any sufficiently small* $p > 0$, *there is a constant* $\Delta t^\star \in (0,1)$ *such that for any* $0 < \Delta t < \Delta t^\star$ *the EM approximation* (7.5) *satisfies*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t}\log \mathbb{E}(|X_k|^p) \leq -p(\lambda - \varepsilon).$$

The BE method applied to (7.1) produces approximations $X_k \approx x(k\Delta t)$ with $X_0 = x(0)$ and

$$X_{k+1} = X_k + \Delta t f(X_{k+1}) + \sum_{j=1}^d g_j(X_k)\Delta B_{jk}. \tag{7.6}$$

THEOREM 7.3. *Let* (7.3) *and* (6.3) *hold and* $f(0) = 0$. *Assume also that* $\mu + \frac{1}{2}\rho < 0$, *where*

$$\rho := \sup_{x\in\mathbb{R}^n, x\neq 0}\left(\frac{\sum_{j=1}^d |g_j(x)|^2}{|x|^2} - \frac{2\sum_{j=1}^d \langle x, g_j(x)\rangle^2}{|x|^4}\right).$$

Then (7.4) *holds with* $-\lambda = \mu + \frac{1}{2}\rho$, *and for any* $\varepsilon \in (0, |\mu + \frac{1}{2}\rho|)$ *there is a pair of constants* $p \in (0,1)$ *and* $\Delta t^\star \in (0,1)$ *with* $\mu \Delta t^\star < 1$ *such that for any* $\Delta t < \Delta t^\star$, *the BE method* (7.6) *has the properties that*

$$\limsup_{k\to\infty} \frac{1}{k\Delta t} \log \mathbb{E}(|X_k|^p) \le p\left(\mu + \frac{1}{2}\rho + \varepsilon\right) < 0$$

and

$$\limsup_{k\to\infty} \frac{1}{k\Delta t} \log |X_k| \le \mu + \frac{1}{2}\rho + \varepsilon < 0 \quad \text{a.s.}$$

Theorems 7.2 and 7.3 can be proved in the same way as the scalar noise versions, Theorems 5.2 and 6.2.

Appendix A. Proof of Theorem 5.1.

Proof. The result (5.4) may be proved by generalizing the analysis in [15, pp. 121–123], so we give only an outline. By the Itô formula, we can show that

$$\begin{aligned}\log(|x(t)|^2) &= \log(|x(0)|^2) + M(t) \\ &\quad + \int_0^t 2\left(\frac{\langle x(s), f(x(s))\rangle + \frac{1}{2}|g(x(s))|^2}{|x(s)|^2} - \frac{\langle x(s), g(x(s))\rangle^2}{|x(s)|^4}\right) ds,\end{aligned}$$

where

$$M(t) = \int_0^t \frac{2\langle x(s), g(x(s))\rangle}{|x(s)|^2} dB(s).$$

From the condition $|g(x)| \le K|x|$, it is straightforward to show that

$$\lim_{t\to\infty} \frac{M(t)}{t} = 0 \quad \text{a.s.}$$

Now, if (5.3) holds, then

$$\log(|x(t)|^2) \le \log(|x_0|^2) + M(t) - 2\lambda t.$$

Dividing both sides by $2t$ and then letting $t \to \infty$ we obtain (5.4).

Now we show (5.5). For $0 < p < 1$ we have, from the Itô formula,

$$\begin{aligned} d\left(|x(t)|^p\right) &= d\left(\left(|x(t)|^2\right)^{\frac{1}{2}p}\right) \\ &= \frac{p}{2}\left(|x(t)|^2\right)^{\frac{1}{2}p-1} dx(t) \\ &\quad + \frac{1}{2}\frac{p}{2}\left(\frac{p}{2} - 1\right)\left(|x(t)|^2\right)^{\frac{1}{2}p-2} 4\langle x(t), g(x(t))\rangle^2 \, dt \\ &= p|x(t)|^p \left[\frac{\langle x(t), f(x(t))\rangle + \frac{1}{2}|g(x(t))|^2}{|x(t)|^2} - \frac{\langle x(t), g(x(t))\rangle^2}{|x(t)|^4}\right. \\ &\quad \left. + \frac{p}{2}\frac{\langle x(t), g(x(t))\rangle^2}{|x(t)|^4}\right] dt \\ &\quad + p|x(t)|^p \frac{\langle x(t), g(x(t))\rangle}{|x(t)|^2} \, dB(t). \end{aligned} \tag{A.1}$$

Under (5.1) and (5.3) this implies

$$d\left(|x(t)|^p\right) \le p|x(t)|^p \left(-\lambda + \frac{p}{2}K^2\right) dt + p|x(t)|^p \frac{\langle x(t), g(x(t))\rangle}{|x(t)|^2}\, dB(t).$$

Given $\varepsilon \in (0, \lambda)$ we may choose $p \in (0, 1)$ so small that $pK^2/2 < \varepsilon$, whence

$$\begin{aligned} d\left(e^{(\lambda-\varepsilon)pt}|x(t)|^p\right) &\le e^{(\lambda-\varepsilon)pt}|x(t)|^p \left[(\lambda-\varepsilon)p + p\left(-\lambda + \frac{1}{2}pK^2\right)\right] dt \\ &\quad + e^{(\lambda-\varepsilon)pt} p|x(t)|^p \frac{\langle x(t), g(x(t))\rangle}{|x(t)|^2}\, dB(t) \\ &\le e^{(\lambda-\varepsilon)pt} p|x(t)|^p \frac{\langle x(t), g(x(t))\rangle}{|x(t)|^2}\, dB(t). \end{aligned}$$

We deduce that

$$e^{(\lambda-\varepsilon)pt}\mathbb{E}|x(t)|^p \le \mathbb{E}|x(0)|^p,$$

and (5.5) follows. □

A GALERKIN BOUNDARY ELEMENT METHOD FOR HIGH FREQUENCY SCATTERING BY CONVEX POLYGONS*

S. N. CHANDLER-WILDE† AND S. LANGDON†

Abstract. In this paper we consider the problem of time-harmonic acoustic scattering in two dimensions by convex polygons. Standard boundary or finite element methods for acoustic scattering problems have a computational cost that grows at least linearly as a function of the frequency of the incident wave. Here we present a novel Galerkin boundary element method, which uses an approximation space consisting of the products of plane waves with piecewise polynomials supported on a graded mesh, with smaller elements closer to the corners of the polygon. We prove that the best approximation from the approximation space requires a number of degrees of freedom to achieve a prescribed level of accuracy that grows only logarithmically as a function of the frequency. Numerical results demonstrate the same logarithmic dependence on the frequency for the Galerkin method solution. Our boundary element method is a discretization of a well-known second kind combined-layer-potential integral equation. We provide a proof that this equation and its adjoint are well-posed and equivalent to the boundary value problem in a Sobolev space setting for general Lipschitz domains.

1. Introduction.

The scattering of time-harmonic acoustic waves by bounded obstacles is a classical problem that has received much attention in the literature over the years. Much effort has been put into the development of efficient numerical schemes, but an outstanding question yet to be fully resolved is how to achieve an accurate approximation to the scattered wave with a reasonable computational cost in the case that the scattering obstacle is large compared to the wavelength of the incident field.

The standard boundary or finite element method approach is to seek an approximation to the scattered field from a space of piecewise polynomial functions. However, due to the oscillatory nature of the solution, such an approach suffers from the limitation that a fixed number of degrees of freedom K are required per wavelength in order to achieve a good level of accuracy, with the accepted guideline in the engineering literature being to take $K = 10$ (see, e.g., [53] and the references therein). A further difficulty, at least for the finite element method, is the presence of "pollution errors," phase errors in wave propagation across the domain, which can lead to even more severe restrictions on the value of K when the wavelength is short [9, 39].

Let L be a linear dimension of the scattering obstacle, and set $k = 2\pi/\lambda$, where λ is the wavelength of the incident wave, so that k is the wave number, proportional to the frequency of the incident wave. Then a consequence of fixing K is that the number of degrees of freedom will be proportional to $(kL)^d$, where $d = N$ in the case of the finite element method, $d = N - 1$ in the case of the boundary element method,

and $N = 2$ or 3 is the number of space dimensions of the problem. Thus, as either the frequency of the incident wave or the size of the obstacle grows, so does the number of degrees of freedom, and hence the computational cost of the numerical scheme. As a result, the numerical solution of many realistic physical problems is intractable using current technologies. In fact, for some of the most powerful recent algorithms for three-dimensional (3D) scattering problems (e.g., [13, 21]), the largest obstacles for which numerical results have been reported have diameter not more than a few hundred times the wavelength.

For boundary element methods, the cost of setting up and solving the large linear systems which arise can be reduced substantially through a combination of preconditioned iterative methods [4, 22, 36] combined with fast matrix-vector multiply methods based on the fast multipole method [5, 26, 21] or the FFT [13]. However, this does nothing to reduce the growth in the number of degrees of freedom as kL increases (linear with respect to kL in two dimensions, quadratic in three dimensions). Thus computations become infeasible as $kL \to \infty$.

1.1. Reducing the number of degrees of freedom for kL large. To achieve a dependence of the number of degrees of freedom on kL which is lower than $(kL)^d$, it seems essential to use an approximation space better able to replicate the behavior of the scattered field at high frequencies than piecewise polynomials. To that end, much attention in the recent literature has focused on enriching the approximation space with oscillatory functions, specifically plane waves or Bessel functions.

A common approach (see, e.g., [8, 16, 27, 37, 53]) is to form an approximation space consisting of standard finite element basis functions multiplied by plane waves travelling in a large number of directions, approximately uniformly distributed on the unit circle (in two dimensions) or sphere (in three dimensions). Theoretical analysis (e.g., [8]) and computational results (e.g., [53]) suggest that these methods converge rapidly as the number of plane wave directions increases, with a significant reduction in the number of degrees of freedom required per wavelength, compared to standard finite and boundary element methods. But the number of degrees of freedom is still proportional to $(kL)^d$, and serious conditioning problems occur when the number of plane wave directions is large.

A related idea is to attempt to identify the important wave propagation directions at high frequencies, and to incorporate the oscillatory part of this high frequency asymptotic behavior into the approximation space. This is the idea behind the finite element method of [34] and the boundary element methods of [25, 19, 12, 33, 45]. This idea has been investigated most thoroughly in the case that the scattering obstacle is smooth and strictly convex. In this case the leading order oscillatory behavior is particularly simple on the boundary of the scattering obstacle, so that this approach is perhaps particularly well adapted for boundary element methods. If a direct integral equation formulation is used, in which the solution to be determined is the trace of the total field or its normal derivative on the boundary, the most important wave direction to include is that of the incident wave (see, e.g., [1, 25, 12, 28]). This approach is equivalent, in the case of a sound hard scatterer, to approximating the ratio of the total field to the incident field, with physical optics predicting that this ratio is approximately constant on the illuminated side and approximately zero on the shadow side of the obstacle at high frequencies.

In [1], Abboud, Nédélec, and Zhou consider the two-dimensional (2D) problem of scattering by a smooth, strictly convex obstacle. They suggest that the ratio of the scattered field to the incident field can be approximated with error of order

$N^{-\nu} + ((kL)^{1/3}/N)^{\nu+1}$ using a uniform mesh of piecewise polynomials of degree ν, so that the total number of degrees of freedom N need be proportional only to $(kL)^{1/3}$ in order to maintain a fixed level of accuracy. In fact, this paper appears to be the first in which the dependence of the error estimates on the wave number k is indicated, and the requirement that the number of degrees of freedom is proportional to $(kL)^{1/3}$ is a big improvement over the usual requirement for proportionality to kL. This approach is coupled with a fast multipole method in [25], where impressive numerical results are reported for large scale 3D problems.

The same approach is combined with a mesh refinement concentrating degrees of freedom near the shadow boundary in [12]. The numerical results in [12] for scattering by a circle suggest that, with this mesh refinement, both the number of degrees of freedom and the total computational cost required to maintain a fixed level of accuracy remain constant as $kL \to \infty$. The method of [12] has recently been applied to deal with each of the multiple scatters which occur when a wave is incident on two, separated, smooth convex 2D obstacles [33]. Numerical experiments have also recently been presented in [29], where the convergence of this iterative approach to the multiple scattering problem is analyzed.

In [28] a numerical method in the spirit of [12] is proposed, namely a p-version boundary element method with a k-dependent mesh refinement in a transition region around the shadow boundary. A rigorous error analysis, which combines estimates using high frequency asymptotics of derivatives of the solution on the surface with careful numerical analysis, demonstrates that the approximation space is able to represent the oscillatory solution to any desired accuracy provided the number of degrees of freedom increases approximately in proportion to $(kL)^{1/9}$ as kL increases. And, in fact, numerical experiments in [28], using this approximation space as the basis of a Galerkin method, suggest that a prescribed accuracy can be achieved by keeping the number of degrees of freedom fixed as the wave number increases.

The boundary element method and its analysis that we will present in this paper for the problem of scattering by a convex polygon are most closely related to our own recent work [19, 45] on the specific problem of 2D acoustic scattering by an inhomogeneous, piecewise constant impedance plane. In [19, 45] a Galerkin boundary element method for this problem is proposed, in which the leading order high frequency behavior as $k \to \infty$, consisting of the incident and reflected ray contributions, is first subtracted off. The remaining scattered wave, consisting of rays diffracted by discontinuities in impedance, is expressed as a sum of products of oscillatory and nonoscillatory functions, with the nonoscillatory functions being approximated by piecewise polynomials supported on a graded mesh, with larger elements away from discontinuities in impedance. For the method in [19] it was shown in that paper that the number of degrees of freedom needed to maintain accuracy as $k \to \infty$ grows only logarithmically with k. This result was improved in [45], where it was shown, via sharper regularity results and a modified mesh, that for a fixed number of degrees of freedom the error is bounded independently of k.

1.2. The oscillatory integral problem. In the above paragraphs we have reviewed methods for reducing the dependence on k of the number of degrees of freedom necessary to achieve a required accuracy. Indeed some of the methods we have described above [12, 45, 33, 28] appear, in numerical experiments, to require only a number of degrees of freedom $M = O(1)$ as $k \to \infty$. Further, for one specific scattering problem [45] this has been shown by a rigorous numerical analysis. However, it should be emphasised strongly that this is not the end of the story; $M = O(1)$ as $k \to \infty$

does not imply a computational cost which is $O(1)$ as $k \to \infty$. The reason is that, while M fixed implies a fixed size of the approximating linear system, the matrix entries become increasingly difficult to evaluate, at least by conventional quadrature methods, as $k \to \infty$. This observation is perhaps particularly true for boundary integral equation based methods where the difficulty arises from the high frequency behavior of both the oscillatory basis functions (necessary to keep M fixed as $k \to \infty$) and the oscillatory kernels of the integral operators. As a consequence, each matrix entry is a highly oscillatory integral when k is large. We discuss only briefly in this paper the effective evaluation of the matrix entries in the Galerkin method we will propose, referring the reader to [44] for most of the details. And the methods we describe in [44] are $O(1)$ in computational cost as $k \to \infty$ for many but not all of the matrix entries, so that further work is required to make the algorithm we will propose fully effective at high frequency. But we note that, of the papers cited above, only the methods of Bruno et al. [12], Geuzaine, Bruno, and Reitich [33], and Langdon and Chandler-Wilde [45] appear to achieve an $O(1)$ computational cost as $k \to \infty$.

The issue in evaluating the matrix entries is one of numerical evaluation of oscillatory integrals. In Bruno et al. this is achieved by a "localized integration" strategy described in [12]. This strategy might be termed a "numerical method of stationary phase," in which the integrals are approximated by localized integrals over small, wave number-dependent neighborhoods of the stationary points of the oscillatory integrand. A similar strategy for integrals of the same type arising in high frequency boundary integral methods for 3D problems is developed in [32]. Promising alternative approaches are two older methods for oscillatory integrals due to Filon [31] (recently reanalyzed by Iserles [40, 41]; see [6] for a discussion of its application to the matrix entries in a high frequency collocation boundary element method) and Levin [47], and methods based on deformation of paths of integration into the complex plane to steepest descent paths [38]. We note that, in contrast to [12, 33, 6], where Nyström/collocation methods are used and the oscillatory integrals are one-dimensional, the matrix entries in our Galerkin methods are, of course, 2D oscillatory integrals, so that development of a robust method for their evaluation is a harder problem.

1.3. The main results of the paper. In this paper, we consider specifically the problem of scattering by convex polygons. This is, in at least one respect, a more challenging problem than the smooth convex obstacle since the corners of the polygon give rise to strong diffracted rays which illuminate the shadow side of the obstacle much more strongly than the rays that creep into the shadow zone of a smooth convex obstacle. These creeping rays decay exponentially, so that it is enough to remove the oscillation of the incident field to obtain a sufficiently simple field to approximate by piecewise polynomials, though a wave number-dependent, carefully graded mesh (cf. [12, 28]) must be used to resolve the transition zone between illuminated and shadow regions.

This approach, of removing the oscillation of the incident field and then approximating by a piecewise polynomial, does not suffice for a scatterer with corners. In brief, our algorithm for the convex polygon is as follows, inspired by our previously developed algorithm for scattering by a piecewise constant impedance plane [19], discussed in the last paragraph of section 1.1. From the geometrical theory of diffraction, one expects, on the sides of the polygon, incident, reflected, and diffracted ray contributions. On each illuminated side, the leading order behavior as $k \to \infty$ consists of the incident wave and a known reflected wave. The first stage in our algorithm is to separate this part of the solution explicitly. (On sides in shadow this step is omitted.)

The remaining field on the boundary consists of waves which have been diffracted at the corners and which travel along the polygon sides. We approximate this remaining field by taking linear combinations of products of piecewise polynomials with plane waves, the plane waves travelling parallel to the polygon sides. A key ingredient in our algorithm is to design a graded mesh to go on each side of the polygon for the piecewise polynomial approximation. This mesh has larger elements away from the corners and a mesh grading near the corners depending on the internal angles, in such a way as to equidistribute the approximation error over the subintervals of the mesh, based on a careful study of the oscillatory behavior of the solution.

The major results of the paper are as follows. We begin in section 2 by introducing the exterior Dirichlet scattering problem that we will solve numerically via a second kind boundary integral equation formulation. Our boundary integral equation is well known (e.g., [23]), obtained from Green's representation theorem. The boundary integral operator is a linear combination of a single-layer potential and its normal derivative, so that the integral equation is precisely the adjoint of the equation proposed independently for the exterior Dirichlet problem by Brakhage and Werner [11], Leis [46], and Panič [52]. However, it seems (see, e.g., the introduction to [14]) not to be widely appreciated that these formulations are well-posed for Lipschitz as well as smooth domains in a range of boundary Sobolev spaces; indeed there exists only a brief and partial account of these standard formulations for the Lipschitz domain case in the literature [50] (the treatment in [23] is for domains of class C^2). We remedy this gap in the literature in section 2, showing that our operator is a bijection on the boundary Sobolev space $H^{s-1/2}(\Gamma)$ and the adjoint operator of [11] is a bijection on $H^{s+1/2}(\Gamma)$, both for $|s| \leq 1/2$. Our starting points are known results on the (Laplace) double-layer potential operator on Lipschitz domains [57, 30] coupled with mapping properties of the single-layer potential operator [49]. (We note that this obvious approach of deducing results for the Helmholtz equation as a perturbation from the Laplace case has previously been employed for second kind boundary integral equations in Lipschitz domains in [56, 50, 48].) Of course the results we obtain apply in particular to a polygonal domain in two dimensions.

The design of our numerical algorithm depends on a careful analysis of the oscillatory behavior of the solution of the integral equation (which is the normal derivative of the total field on the boundary Γ). This is the content of section 3 of the paper. In contrast, e.g., to [28], where this information is obtained by difficult high frequency asymptotics, we adapt a technique from [19, 45], where explicit representations of the solution in a half-plane are obtained from Green's representation theorem. In the estimates we obtain of high order derivatives, we take care to obtain as precise information as possible, with a view to the future design of alternative numerical schemes, perhaps based on a *p*- or *hp*-boundary element method.

Section 4 of the paper contains, arguably, the most significant theoretical and practical results. In this section we design an approximation space for the normal derivative of the total field on Γ. As outlined above, on each side we approximate this unknown as the sum of the leading order asymptotics (known explicitly, and zero on a side in shadow) plus an expression of the form $\exp(\mathrm{i}ks)V_+(s) + \exp(-\mathrm{i}ks)V_-(s)$, where s is arc-length distance along the side and $V_\pm(s)$ are piecewise polynomials. We show, as a main result of the paper, that the approximation space based on this representation has the property that the error in best approximation of the normal derivative of the total field is bounded by $C_\nu(n[1+\log(kL)])^{\nu+3/2}M_N^{-\nu-1}$, where M_N is the total number of degrees of freedom, L is the length of the perimeter, n is the number of sides of the polygon, ν is the polynomial degree, and the constant C_ν

depends only on ν and the corner angles of the polygon. This is a strong result, showing that the number of degrees of freedom need only increase like $\log^{3/2}(kL)$ as $kL \to \infty$ to maintain accuracy.

In section 5 we analyze a Galerkin method, based on the approximation space of section 4. We show that the same bound holds for our Galerkin method approximation to the solution of the integral equation, except that an additional stability constant is introduced. We do not attempt the (difficult) task of ascertaining the dependence of this stability constant on k. In section 6 we present some numerical results which fully support our theoretical estimates, and we discuss, briefly, some numerical implementation issues, including conditioning and evaluation of the integrals, that arise. We finish the paper with some concluding remarks and open problems.

We note that the Galerkin method is, of course, not the only way to select a numerical solution from a given approximation space. In [6] we present some results for a collocation method, based on the approximation space results in section 4. The attraction of the Galerkin method we present in section 5 is that we are able to establish stability, at least in the asymptotic limit of sufficient mesh refinement, which we do not know how to do for the collocation method.

2. The boundary value problem and integral equation formulation. Consider scattering of a time-harmonic acoustic plane wave u^i by a sound-soft convex polygon Υ, with boundary $\Gamma := \bigcup_{j=1}^n \Gamma_j$, where Γ_j, $j = 1, \ldots, n$, are the n sides of the polygon with j increasing counterclockwise, as shown in Figure 2.1. We denote by $P_j := (p_j, q_j)$, $j = 1, \ldots, n$, the vertices of the polygon, and we set $P_{n+1} = P_1$ so that, for $j = 1, \ldots, n$, Γ_j is the line joining P_j with P_{j+1}. We denote the length of Γ_j by $L_j := |P_{j+1} - P_j|$, the external angle at each vertex P_j by $\Omega_j \in (\pi, 2\pi)$, the unit normal perpendicular to Γ_j and pointing out of Υ by $\mathbf{n}_j := (n_{j1}, n_{j2})$, and the angle of incidence of the plane wave, as measured counterclockwise from the downward vertical, by $\theta \in [0, 2\pi)$. Writing $\mathbf{x} = (x_1, x_2)$ and $\mathbf{d} := (\sin\theta, -\cos\theta)$, we then have

$$u^i(\mathbf{x}) = \mathrm{e}^{\mathrm{i}k(x_1 \sin\theta - x_2 \cos\theta)} = \mathrm{e}^{\mathrm{i}k\mathbf{x}\cdot\mathbf{d}}.$$

We will say that Γ_j is in shadow if $\mathbf{n}_j \cdot \mathbf{d} \geq 0$ and is illuminated if $\mathbf{n}_j \cdot \mathbf{d} < 0$. If n_s is the number of sides in shadow and it is convenient to choose the numbering so that sides $1, \ldots, n_s$ are in shadow and sides $n_s + 1, \ldots, n$ are illuminated.

We will formulate the boundary value problem we wish to solve for the total acoustic field u in a standard Sobolev space setting. For an open set $G \subset \mathbb{R}^N$, let $H^1(G) := \{v \in L^2(G) : \nabla v \in L^2(G)\}$ (∇v denoting here the weak gradient of v). We recall [49] that if G is a Lipschitz domain, then there is a well-defined trace operator, the unique bounded linear operator $\gamma : H^1(G) \to H^{1/2}(\partial G)$ which satisfies $\gamma v = v|_{\partial G}$ in the case when $v \in C^\infty(\bar{G}) := \{w|_{\bar{G}} : w \in C^\infty(\mathbb{R}^N)\}$. Let $H^1(G; \Delta) := \{v \in H^1(G) : \Delta v \in L^2(G)\}$ (Δ the Laplacian in a weak sense), a Hilbert space with the norm $\|v\|_{H^1(G;\Delta)} := \{\int_G [|v|^2 + |\nabla v|^2 + |\Delta v|^2] \mathrm{d}x\}^{1/2}$. If G is Lipschitz, then [49] there is also a well-defined normal derivative operator, the unique bounded linear operator $\partial_{\mathbf{n}} : H^1(G; \Delta) \to H^{-1/2}(\partial G)$ which satisfies

$$\partial_{\mathbf{n}} v = \frac{\partial v}{\partial \mathbf{n}} := \mathbf{n} \cdot \nabla v,$$

almost everywhere on Γ, when $v \in C^\infty(\bar{G})$. $H^1_{\mathrm{loc}}(G)$ denotes the set of measurable $v : G \to \mathbb{C}$ for which $\chi v \in H^1(G)$ for every compactly supported $\chi \in C^\infty(\bar{G})$.

The polygonal domain Υ is Lipschitz as is its exterior $D := \mathbb{R}^2 \setminus \bar{\Upsilon}$. Let $\gamma_+ : H^1(D) \to H^{1/2}(\Gamma)$ and $\gamma_- : H^1(\Upsilon) \to H^{1/2}(\Gamma)$ denote the exterior and interior trace

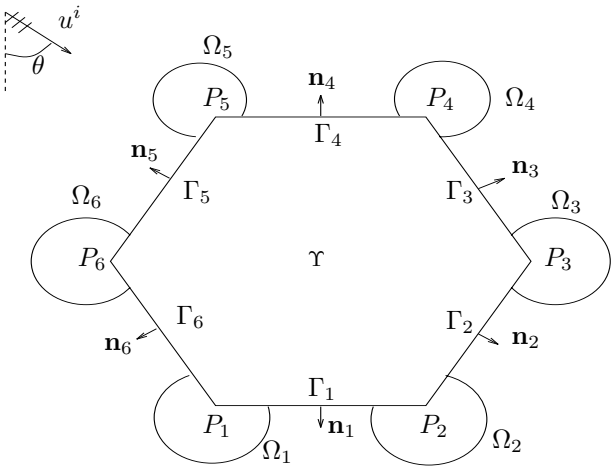

FIG. 2.1. *Our notation for the polygon.*

operators, respectively, and let $\partial_{\mathbf{n}}^+ : H^1(D;\Delta) \to H^{-1/2}(\Gamma)$ and $\partial_{\mathbf{n}}^- : H^1(\Upsilon;\Delta) \to H^{-1/2}(\Gamma)$ denote the exterior and interior normal derivative operators, respectively, the unit normal vector $\mathbf{n}$ directed out of Υ. Then the boundary value problem we seek to solve is the following: given $k > 0$ (the wave number), find $u \in C^2(D) \cap H^1_{\rm loc}(D)$ such that

$$\Delta u + k^2 u = 0 \quad \text{in } D, \tag{2.1}$$

$$\gamma_+ u = 0 \quad \text{on } \Gamma, \tag{2.2}$$

and the scattered field, $u^s := u - u^i$, satisfies the Sommerfeld radiation condition

$$\lim_{r\to\infty} r^{1/2} \left(\frac{\partial u^s}{\partial r}(\mathbf{x}) - \mathrm{i}k u^s(\mathbf{x}) \right) = 0, \tag{2.3}$$

where $r = |\mathbf{x}|$ and the limit holds uniformly in all directions $\mathbf{x}/|\mathbf{x}|$.

THEOREM 2.1 (see, e.g., [49, Theorem 9.11]). *The boundary value problem* (2.1)–(2.3) *has exactly one solution.*

Remark 2.2. While for compatibility with most of the boundary element literature we formulate the above boundary value problem in a standard Sobolev space setting, where one looks for a solution in the energy space $H^1_{\rm loc}(D)$, we note that other alternatives are available. In particular, we might seek the solution in classical function spaces as $u \in C^2(D) \cap C(\overline{D})$; this is commonly done when the boundary is sufficiently smooth [23, 24], but is also reasonable when D is Lipschitz, as it follows from standard elliptic regularity estimates up to the boundary (e.g., [42]) that if D is Lipschitz, then every solution to the Sobolev space formulation is continuous up to the boundary. A weaker requirement than $u \in C^2(D) \cap C(\overline{D})$ is usual in the harmonic analysis literature, namely to seek $u \in C^2(D)$ which satisfies the boundary condition (2.2) in the sense of almost everywhere tangential convergence, and to require that the nontangential maximal function of u is in $L^p(\Gamma)$ for some $p \in (1,\infty)$ (most commonly $p = 2$). For details of this latter formulation for the sound-soft scattering problem for the Helmholtz equation, and proofs of its well-posedness (for $2 - \epsilon < p < \infty$ and some $\epsilon > 0$) via second kind integral equation formulations, see Torres and Welland [56] for the case $\mathrm{Im}\, k > 0$, and Liu [48] and Mitrea [50] for the case $k > 0$.

Suppose that $u \in C^2(D) \cap H^1_{\mathrm{loc}}(D)$ satisfies (2.1)–(2.3). Then, by standard elliptic regularity estimates [35, section 8.11], $u \in C^\infty(\bar{D} \setminus \Gamma_C)$, where $\Gamma_C := \{P_1, \ldots, P_n\}$ is the set of corners of Γ. It is, moreover, possible to derive an explicit representation for u near the corners. For $j = 1, \ldots, n$, let $R_j := \min(L_{j-1}, L_j)$ (with $L_{-1} := L_N$). Let (r, θ) be polar coordinates local to a corner P_j, chosen so that $r = 0$ corresponds to the point P_j, the side Γ_{j-1} lies on the line $\theta = 0$, the side Γ_j lies on the line $\theta = \Omega_j$, and the part of $\bar{D}$ within distance R_j of P_j is the set of points with polar coordinates $\{(r, \theta) : 0 \le r < R_j,\ 0 \le \theta \le \Omega_j\}$. Choose R so that $R \le R_j$ and $\rho := kR < \pi/2$, and let G denote the set of points with polar coordinates $\{(r, \theta) : 0 \le r < R, 0 \le \theta \le \Omega_j\}$ (see Figure 2.2). The following result, in which J_ν denotes the Bessel function of the first kind of order ν, follows by standard separation of variables arguments.

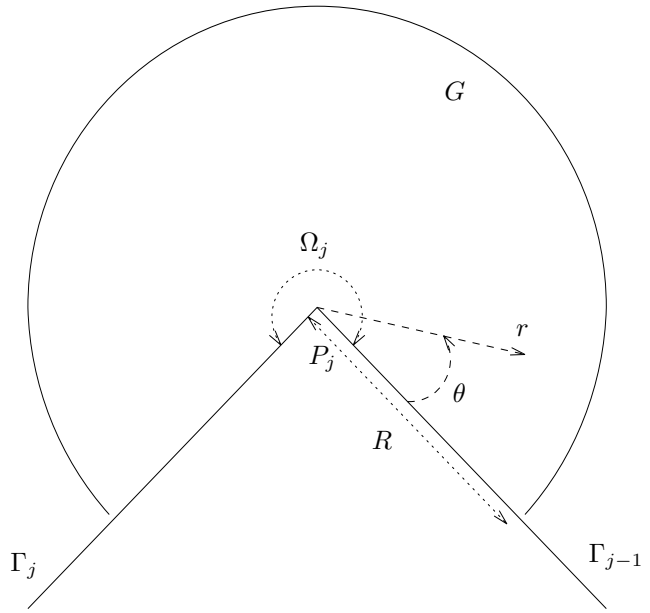

FIG. 2.2. *Neighborhood of a corner.*

THEOREM 2.3 (representation near corners). *Let $g(\theta)$ denote the value of u at the point with polar coordinates (R, θ). Then, where (r, θ) denotes the polar coordinates of $\mathbf{x}$, it holds that*

$$u(\mathbf{x}) = \sum_{n=1}^{\infty} a_n J_{n\pi/\Omega_j}(kr) \sin\left(\frac{n\theta\pi}{\Omega_j}\right), \quad \mathbf{x} \in G, \tag{2.4}$$

where

$$a_n := \frac{2}{\Omega_j J_{n\pi/\Omega_j}(kR)} \int_0^{\Omega_j} g(\theta) \sin\left(\frac{n\theta\pi}{\Omega_j}\right) \mathrm{d}\theta, \quad n \in \mathbb{N}. \tag{2.5}$$

Remark 2.4. The condition $\rho = kR < \pi/2$ ensures that $J_{n\pi/\Omega_j}(kR) \neq 0$, $n \in \mathbb{N}$, in fact (see (3.14)), that $|a_n J_{n\pi/\Omega_j}(kr)| \le C(r/R)^{n\pi/\Omega_j}$, where the constant C is independent of n and $\mathbf{x}$, so that the series (2.4) converges absolutely and uniformly in G. Thus $u \in C(\bar{D})$. Moreover, from this representation and the behavior of the

Bessel function J_ν (cf. Theorem 3.3) it follows that near the corner P_j, $\nabla u(\mathbf{x})$ has the standard singular behavior that

$$|\nabla u(\mathbf{x})| = \mathcal{O}\left(r^{\pi/\Omega_j - 1}\right) \text{ as } r \to 0. \tag{2.6}$$

From [24, Theorem 3.12] and [49, Theorems 7.15 and 9.6] we see that if u satisfies the boundary value problem (2.1)–(2.3), then a form of Green's representation theorem holds, namely

$$u(\mathbf{x}) = u^i(\mathbf{x}) - \int_\Gamma \Phi(\mathbf{x},\mathbf{y})\partial_{\mathbf{n}}^+ u(\mathbf{y})\,\mathrm{d}s(\mathbf{y}), \quad \mathbf{x} \in D, \tag{2.7}$$

where $\mathbf{n}$ is the normal direction directed out of Υ and $\Phi(\mathbf{x},\mathbf{y}) := (\mathrm{i}/4)H_0^{(1)}(k|\mathbf{x}-\mathbf{y}|)$ is the standard fundamental solution for the Helmholtz equation, with $H_0^{(1)}$ the Hankel function of the first kind of order zero. Note that, since $u \in C^\infty(\bar{D} \setminus \Gamma_C)$ and the bound (2.6) holds, we have in fact that $\partial_{\mathbf{n}}^+ u = \partial u/\partial \mathbf{n} \in L^2(\Gamma) \cap C^\infty(\Gamma \setminus \Gamma_C)$.

Starting from the representation (2.7) for u, we will obtain the boundary integral equation for $\partial u/\partial \mathbf{n}$ which we will solve numerically later in the paper. This integral equation formulation is expressed in terms of the standard single-layer potential operator ($\mathcal{S}$) and the adjoint of the double-layer potential operator ($\mathcal{T}$), defined, for $v \in L^2(\Gamma)$, by

$$\mathcal{S}v(\mathbf{x}) := 2\int_\Gamma \Phi(\mathbf{x},\mathbf{y})v(\mathbf{y})\,\mathrm{d}s(\mathbf{y}), \quad \mathcal{T}v(\mathbf{x}) := 2\int_\Gamma \frac{\partial \Phi(\mathbf{x},\mathbf{y})}{\partial \mathbf{n}(\mathbf{x})} v(\mathbf{y})\,\mathrm{d}s(\mathbf{y}), \ \mathbf{x} \in \Gamma \setminus \Gamma_C. \tag{2.8}$$

We note that both $\mathcal{S}$ and $\mathcal{T}$ are bounded operators on $L^2(\Gamma)$. In fact, more generally ([56, Lemma 6.1] or see [49]), $\mathcal{S} : H^{s-1/2}(\Gamma) \to H^{s+1/2}(\Gamma)$ and $\mathcal{T} : H^{s-1/2}(\Gamma) \to H^{s-1/2}(\Gamma)$ for $|s| \le 1/2$, and these mappings are bounded. We state the integral equation we will solve in the next theorem. Our proof of this theorem is based on the proof in [23] for domains of class C^2, modified to use more recent results on layer potentials on Lipschitz domains.

THEOREM 2.5. *If $u \in C^2(D) \cap H^1_{\mathrm{loc}}(D)$ satisfies the boundary value problem (2.1)–(2.3), then, for every $\eta \in \mathbb{R}$, $\partial_{\mathbf{n}}^+ u = \frac{\partial u}{\partial \mathbf{n}} \in L^2(\Gamma)$ satisfies the integral equation*

$$(\mathcal{I} + \mathcal{K})\partial_{\mathbf{n}}^+ u = f \quad \text{on } \Gamma, \tag{2.9}$$

where $\mathcal{I}$ is the identity operator, $\mathcal{K} := \mathcal{T} + \mathrm{i}\eta\mathcal{S}$, and

$$f(\mathbf{x}) := 2\frac{\partial u^i}{\partial \mathbf{n}}(\mathbf{x}) + 2\mathrm{i}\eta u^i(\mathbf{x}), \quad \mathbf{x} \in \Gamma \setminus \Gamma_C.$$

Conversely, if $v \in H^{-1/2}(\Gamma)$ satisfies $(\mathcal{I} + \mathcal{K})v = f$ for some $\eta \in \mathbb{R} \setminus \{0\}$, and u is defined in D by (2.7), with $\partial_{\mathbf{n}}^+ u$ replaced by v, then $u \in C^2(D) \cap H^1_{\mathrm{loc}}(D)$ and satisfies the boundary value problem (2.1)–(2.3). Moreover, $\partial_{\mathbf{n}}^+ u = v$.

Proof. Suppose first that $v \in H^{-1/2}(\Gamma)$ satisfies $(\mathcal{I} + \mathcal{K})v = f$ and define u by $u := u^i - Sv$, where

$$Sv(\mathbf{x}) := \int_\Gamma \Phi(\mathbf{x},\mathbf{y})v(\mathbf{y})\,\mathrm{d}s(\mathbf{y}), \quad \mathbf{x} \in \mathbb{R}^2 \setminus \Gamma.$$

Then [49, Chapter 9, Theorem 6.11] $u \in C^2(\mathbb{R}^2 \setminus \Gamma) \cap H^1_{\mathrm{loc}}(\mathbb{R}^2)$ and satisfies (2.1) in $\mathbb{R}^2 \setminus \Gamma$ and (2.3). Thus u satisfies the boundary value problem as long as $\gamma_+ u = 0$.

Now standard results on boundary traces of the single-layer potential on Lipschitz domains [49] give us that

$$2\gamma_{\pm}Sv = \mathcal{S}v, \quad 2\partial_{\mathbf{n}}^{\pm}(Sv) = (\mp\mathcal{I} + \mathcal{T})v. \tag{2.10}$$

On the other hand, we have that $(\mathcal{I} + \mathcal{T} + \mathrm{i}\eta\mathcal{S})v = f$. Thus

$$2\partial_{\mathbf{n}}^{-}u = 2\frac{\partial u^i}{\partial \mathbf{n}} - (\mathcal{I} + \mathcal{T})v = \mathrm{i}\eta\mathcal{S}v - 2\mathrm{i}\eta\gamma_+ u^i = -2\mathrm{i}\eta\gamma_- u.$$

Applying Green's first identity [49, Theorem 4.4] to $u \in H^1(\Upsilon;\Delta)$, we deduce that

$$-\eta\int_\Gamma |\gamma_- u|^2\,\mathrm{d}s = \mathrm{Im}\int_\Gamma \partial_{\mathbf{n}}^{-}u\,\gamma_-\bar{u}\,\mathrm{d}s = 0.$$

Thus $\gamma_+ u = \gamma_- u = 0$, so that u satisfies the boundary value problem (2.1)–(2.3). Further, $\partial_{\mathbf{n}}^{-}u = 0$ and $\partial_{\mathbf{n}}^{+}u = v + \partial_{\mathbf{n}}^{-}u = v$.

Conversely, if u satisfies the boundary value problem, in which case $\partial_{\mathbf{n}}^{+}u = \frac{\partial u}{\partial \mathbf{n}} \in L^2(\Gamma) \subset H^{-1/2}(\Gamma)$ and (2.7) holds, then, applying the trace results (2.10), we deduce

$$2\gamma_+ u^i = \mathcal{S}\partial_{\mathbf{n}}^{+}u, \quad 2\frac{\partial u^i}{\partial \mathbf{n}} = (\mathcal{I} + \mathcal{T})\partial_{\mathbf{n}}^{+}u.$$

Hence (2.9) holds. ∎

The above theorem, together with Theorem 2.1, implies that the integral equation (2.9) has exactly one solution in $H^{-1/2}(\Gamma)$, provided that we choose $\eta \neq 0$.

Remark 2.6. The idea of taking a linear combination of first and second kind integral equations to obtain a uniquely solvable boundary integral equation equivalent to an exterior scattering problem for the Helmholtz equation dates back to Brakhage and Werner [11], Leis [46], and Panič [52] for the exterior Dirichlet problem and Burton and Miller [15] for the Neumann problem. In fact, the integral equation in [11, 46, 52] is precisely the adjoint of (2.9) (see the discussion and Corollary 2.8 and Remark 2.9 below). The above proof is based on that in [23]. But, while Colton and Kress [23] restrict attention to the case when Γ is sufficiently smooth (of class C^2), the proof of Theorem 2.5 is valid for arbitrary Lipschitz Γ, and in an arbitrary number of dimensions. (Note, however, that, for general Lipschitz Γ, $\mathcal{T}v$, for $v \in H^{-1/2}(\Gamma)$, must be understood as the sum of the normal derivatives of Sv on the two sides of Γ [49, Chapter 7]. This definition of $\mathcal{T}v$ is equivalent to that in (2.8) when $v \in L^2(\Gamma)$ [56, section 4],[50, section 7].)

The following theorem, which shows that the operator $\mathcal{I} + \mathcal{K}$ is bijective on a range of Sobolev spaces, holds for a general Lipschitz boundary Γ (with $\mathcal{T}$ defined as in Remark 2.6 in the general case) in any number of space dimensions ≥ 2.

THEOREM 2.7. *Let $\mathcal{A} := \mathcal{I} + \mathcal{K}$ and suppose that $\eta \in \mathbb{R} \setminus \{0\}$. Then, for $|s| \leq 1/2$, the bounded linear operator $\mathcal{A} : H^{s-1/2}(\Gamma) \to H^{s-1/2}(\Gamma)$ is bijective with bounded inverse $\mathcal{A}^{-1}$.*

Proof. It is enough to show this result for $s = \pm 1/2$; it then follows for all s by interpolation [49]. We note first that, since $H^1(\Gamma)$ is compactly embedded in $L^2(\Gamma)$ so that $L^2(\Gamma)$ is compactly embedded in $H^{-1}(\Gamma)$, and since $\mathcal{S}$ is a bounded operator from $H^{-1}(\Gamma)$ to $L^2(\Gamma)$, it follows that $\mathcal{S}$ is a compact operator on $H^{-1}(\Gamma)$ and $L^2(\Gamma)$. Let $\mathcal{T}_0$ denote the operator corresponding to $\mathcal{T}$ in the case $k = 0$; explicitly, in the case when Γ is a 2D polygon, $\mathcal{T}_0 v$, for $v \in L^2(\Gamma)$, is defined by (2.8) with $\Phi(\mathbf{x},\mathbf{y})$ replaced by $\Phi_0(\mathbf{x},\mathbf{y}) := -(2\pi)^{-1}\log|\mathbf{x}-\mathbf{y}|$. Then $\mathcal{T}_0 - \mathcal{T}$ is a bounded operator

from $H^{-1}(\Gamma)$ to $L^2(\Gamma)$ and thus a compact operator on $H^{-1}(\Gamma)$ and $L^2(\Gamma)$. (To see the boundedness of $\mathcal{T}_0 - \mathcal{T}$ it is perhaps easiest to show that the adjoint operator, $\mathcal{T}_0' - \mathcal{T}'$, is a bounded operator from $L^2(\Gamma)$ to $H^1(\Gamma)$, which follows since $D(\mathcal{T}_0' - \mathcal{T}')$ is a bounded operator on $L^2(\Gamma)$. Here D is the surface gradient operator, $\mathcal{T}'$ and $\mathcal{T}_0'$ are standard double-layer potential operators [49, Theorem 6.17], in particular

$$T'v(\mathbf{x}) := \int_\Gamma \frac{\partial \Phi(\mathbf{x},\mathbf{y})}{\partial \mathbf{n}(\mathbf{y})}\, v(\mathbf{y}) \mathbf{d}s(\mathbf{y}), \quad \mathbf{x} \in \Gamma,$$

and the boundedness of the integral operator $D(\mathcal{T}_0' - \mathcal{T}')$ follows since its kernel is continuous or weakly singular.) Thus $\mathcal{A}$, as an operator on $H^{s-1/2}(\Gamma)$, $s = \pm 1/2$, is a compact perturbation of $\mathcal{I} + \mathcal{T}_0$. But it is known that $\mathcal{I} + \mathcal{T}_0'$ is Fredholm of index zero on $H^{s+1/2}(\Gamma)$ for $|s| \leq 1/2$ (see [57, 30]), from which it follows from [49, Theorem 6.17] that the adjoint operator $\mathcal{I} + \mathcal{T}_0'$ is Fredholm of index zero on $H^{s-1/2}(\Gamma)$ for $|s| \leq 1/2$. Thus $\mathcal{A}$ is Fredholm of index zero on $H^{s-1/2}(\Gamma)$, $s = \pm 1/2$. Since $\mathcal{A}$ is Fredholm with the same index on $H^{-1}(\Gamma)$ and $L^2(\Gamma)$, and $L^2(\Gamma)$ is dense in $H^{-1}(\Gamma)$, it follows from a standard result on Fredholm operators (see, e.g., [54, section 1]) that the null-space of $\mathcal{A}$, as an operator on $H^{-1}(\Gamma)$, is a subset of $L^2(\Gamma)$. But it follows from Theorems 2.1 and 2.5 that $\mathcal{A}v = 0$ has no nontrivial solution in $H^{-1/2}(\Gamma) \supset L^2(\Gamma)$. Thus $\mathcal{A} : H^{s-1/2}(\Gamma) \to H^{s+1/2}(\Gamma)$ is invertible for $s = \pm 1/2$. □

We have observed in Remark 2.6 that an alternative integral equation formulation for the exterior Dirichlet problem was introduced in [11, 46, 52]. In this formulation one seeks a solution to the exterior Dirichlet problem in the form of a combined single- and double-layer potential with some unknown density $\tilde{\phi}$ and arrives at the boundary integral equation $\mathcal{A}'\tilde{\phi} = 2\gamma_+ u^i$, where

$$\mathcal{A}' = \mathcal{I} + \mathcal{T}' + i\eta S$$

is the adjoint of $\mathcal{A}$ in the sense that the duality relation holds that $\langle A\phi, \psi\rangle_\Gamma = \langle \phi, A'\psi\rangle_\Gamma$ for $\phi \in H^{-1/2}(\Gamma)$, $\psi \in H^{1/2}(\Gamma)$, where $\langle \phi, \psi\rangle_\Gamma := \int_\Gamma \phi(y)\psi(y)\mathrm{d}s(y)$ [49, Theorems 6.15 and 6.17]. It is known that $\mathcal{A}'$ maps $H^{s+1/2}(\Gamma)$ to $H^{s+1/2}(\Gamma)$ and that this mapping is bounded for $|s| \leq 1/2$ [56, 49]. This, the duality relation, and Theorem 2.7 imply the invertibility of $\mathcal{A}'$. Precisely, we have the following result.

COROLLARY 2.8. *For $|s| \leq 1/2$ and $\eta \in \mathbb{R} \setminus \{0\}$, the mapping $\mathcal{A}' : H^{s+1/2}(\Gamma) \to H^{s+1/2}(\Gamma)$ is bijective with bounded inverse ${\mathcal{A}'}^{-1}$.*

Remark 2.9. We note that brief details of a proof that the related operator $\tilde{\mathcal{A}}' := \mathcal{I} + \mathcal{T}' + i\eta S S_0^2$, where S_0 denotes S in the case $k = 0$, is invertible as an operator on $L^2(\Gamma)$ if $\eta \in \mathbb{R} \setminus \{0\}$ are given in Mitrea [50]. Moreover, the argument outlined in [50], which follows the same pattern that we have used to prove Theorem 2.7, namely to show that $\tilde{\mathcal{A}}'$ is Fredholm of index zero by perturbation from the Laplace case, and then to establish uniqueness by mirroring the usual uniqueness argument for smooth domains [23] (though the details of this are omitted in [50]), could be applied equally to show that $\mathcal{A}'$ is invertible on $L^2(\Gamma)$ for $\eta \in \mathbb{R} \setminus \{0\}$. Then, arguing by duality in the same way in which we deduce Corollary 2.8, we could deduce that A is invertible on $L^2(\Gamma)$. Thus the argument outlined in [50] offers an alternative route to that written out above for establishing that $\mathcal{A}$ and $\mathcal{A}'$ are invertible as operators on $L^2(\Gamma)$ for $\eta \in \mathbb{R} \setminus \{0\}$.

We also note that for the case $\eta = 0$ when $\mathcal{A}' = \mathcal{I} + \mathcal{T}'$, it is shown that $\mathcal{A}'$ is invertible as an operator on $L^2(\Gamma)$ if $\mathrm{Im}k > 0$ in [56]. This result is sharpened in [50], where it is shown that $\mathcal{A}'$ is also invertible as an operator on $L^2(\Gamma)$ if $k > 0$ is not

an eigenvalue of an appropriately stated interior Neumann problem in Υ. See [50] (and Liu [48]) for further discussion of the case when $k > 0$ is an interior Neumann eigenvalue when $\mathcal{A}'$ has a finite-dimensional kernel.

In the remainder of the paper we will focus on the properties of $\mathcal{A}$ as an operator on $L^2(\Gamma)$. We remark that the result that $\mathcal{I} + \mathcal{T}_0'$ is Fredholm of index zero on $L^2(\Gamma)$ dates back to [58] in the case when Γ is a 2D polygon. Letting $\|\cdot\|_2$ denote the norm on $L^2(\Gamma)$, the technique in [58] (or see [17]) is to show that $\mathcal{T}_0' = \mathcal{T}_1' + \mathcal{T}_2'$, where $\|\mathcal{T}_1'\|_2 < 1$. Since taking adjoints preserves norms and compactness, and since $\mathcal{S}$ and $\mathcal{T} - \mathcal{T}_0$ are compact operators on $L^2(\Gamma)$, it holds in the case of a 2D polygon that $\mathcal{A} = \mathcal{I} + \mathcal{K} = \mathcal{I} + \mathcal{K}_1 + \mathcal{K}_2$, where $\|\mathcal{K}_1\|_2 < 1$ and $\mathcal{K}_2$ is a compact operator on $L^2(\Gamma)$.

Throughout the remainder of the paper we suppose that $\eta \in \mathbb{R}$ with $\eta \neq 0$, so that $\mathcal{A}$ is invertible, and let

$$C_S := \|\mathcal{A}^{-1}\|_2 = \|(\mathcal{I} + \mathcal{K})^{-1}\|_2. \tag{2.11}$$

We note that the value of C_S depends on k, η, and the geometry of Γ. But recently an upper bound has been obtained for C_S as a function of k, η, and the geometry of Γ in the case when Γ is (in two dimensions or three dimensions) the boundary of a piecewise smooth, starlike Lipschitz domain [20, Theorem 4.3], by using Rellich-type identities. In particular, for the commonly recommended choice $|\eta| = k$ (see, e.g., [28]), this bound implies for the convex polygon that

$$C_S \leq \frac{1}{2}\left(1 + 9\theta + 4\theta^2\right) \tag{2.12}$$

for $kR_0 \geq 1$. Here it is assumed that the coordinate system is chosen so that the origin lies inside Γ, and we define $R_0 := \max_{x\in\Gamma} |x|$, $\theta := R_0/\delta_-$, and δ_- to be the perpendicular distance from the origin to the nearest side of the polygon. For example, in the case of a square (for which we carry out computations in section 6, choosing $\eta = k$), taking the origin at the center of the square gives $\theta = \sqrt{2}$ and so $C_S \leq \frac{9}{2}(1 + \sqrt{2}) < 11$ for $kR_0 \geq 1$.

3. Regularity results. In this section we aim to understand the behavior of $\partial u/\partial \mathbf{n}$, the normal derivative of the total field on Γ, which is the unknown function in the integral equation (2.9). Precisely, we will obtain bounds on the surface tangential derivatives of $\partial u/\partial \mathbf{n}$ in which the dependence on the wave number is completely explicit. This will enable us in section 4 to design a family of approximation spaces well adapted to approximating $\partial u/\partial \mathbf{n}$.

To understand the behavior of $\partial u/\partial \mathbf{n}$ near the corners P_j, our technique will be to use the explicit representation (2.4). To understand the behavior away from the corners, we will need another representation for $\partial u/\partial \mathbf{n}$ which we now derive.

Our starting point is the observation that if $U = \{\mathbf{x} = (x_1, x_2), x_1 \in \mathbb{R}, x_2 > 0\}$ is the upper half-plane and $v \in C^2(U) \cap C(\bar{U})$ satisfies the Helmholtz equation in U and the Sommerfeld radiation condition, then [18, Theorem 3.1]

$$v(\mathbf{x}) = 2\int_{\partial U} \frac{\partial \Phi(\mathbf{x}, \mathbf{y})}{\partial y_2} v(\mathbf{y})\, \mathrm{d}s(\mathbf{y}), \quad \mathbf{x} \in U. \tag{3.1}$$

The same formula holds [18] if v is a horizontally or upwards propagating plane wave, i.e., if $v(\mathbf{x}) = \mathrm{e}^{\mathrm{i}k\mathbf{x}.\mathbf{d}}$ with $\mathbf{d} = (d_1, d_2)$, $|\mathbf{d}| = 1$, and $d_2 \geq 0$.

To make use of this observation, we make the following construction. Extend the line Γ_j to infinity in both directions; the resulting infinite line comprises Γ_j and the

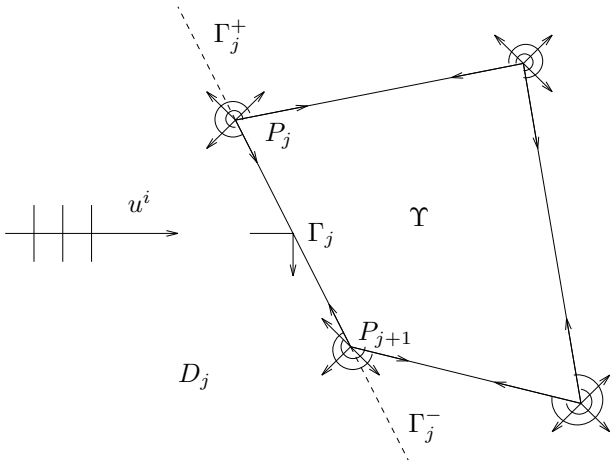

FIG. 3.1. *Extension of Γ_j, for derivation of regularity estimates.*

half-lines Γ_j^+ and Γ_j^-, above P_j and below P_{j+1}, respectively; see Figure 3.1. Let $D_j \subset D$ denote the half-plane on the opposite side of this line to Υ.

Now consider first the case when Γ_j is in shadow, by which we mean that $\mathbf{n}_j.\mathbf{d} \geq 0$. Then it follows from (3.1) that

$$u^s(\mathbf{x}) = 2\int_{\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u^s(\mathbf{y})\,\mathrm{d}s(y), \quad \mathbf{x}\in D_j, \tag{3.2}$$

and also that

$$u^i(\mathbf{x}) = 2\int_{\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u^i(\mathbf{y})\,\mathrm{d}s(y), \quad \mathbf{x}\in D_j. \tag{3.3}$$

Since $u = u^i + u^s$ and $u = 0$ on Γ, we deduce that

$$u(\mathbf{x}) = 2\int_{\Gamma_j^+\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u(\mathbf{y})\,\mathrm{d}s(y), \quad \mathbf{x}\in D_j.$$

In the case when Γ_j is illuminated ($\mathbf{n}_j.\mathbf{d} < 0$), (3.2) holds, but (3.3) is replaced by

$$u^i(\mathbf{x}) = -2\int_{\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u^i(\mathbf{y})\,\mathrm{d}s(y), \quad \mathbf{x}\in \mathbb{R}^2\backslash\bar{D}_j. \tag{3.4}$$

Now let $u^r(\mathbf{x}) := -u^i(\mathbf{x}')$ for $\mathbf{x}\in D_j$, where $\mathbf{x}'$ is the reflection of $\mathbf{x}$ in the line $\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-$. (The physical interpretation of u^r is that it is the plane wave that would be reflected if Γ_j were infinitely long.) From (3.4), for $\mathbf{x}\in D_j$,

$$u^r(\mathbf{x}) = 2\int_{\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x}',\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u^i(\mathbf{y})\,\mathrm{d}s(y) = -2\int_{\Gamma_j^+\cup\Gamma_j\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u^i(\mathbf{y})\,\mathrm{d}s(y),$$

and adding this to (3.2) we find that

$$u(\mathbf{x}) = u^i(\mathbf{x}) + u^r(\mathbf{x}) + 2\int_{\Gamma_j^+\cup\Gamma_j^-} \frac{\partial\Phi(\mathbf{x},\mathbf{y})}{\partial\mathbf{n}(\mathbf{y})} u(\mathbf{y})\,\mathrm{d}s(y), \quad \mathbf{x}\in D_j.$$

Thus on an illuminated side it holds that

$$\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x}) = 2\frac{\partial u^i}{\partial \mathbf{n}}(\mathbf{x}) + 2\int_{\Gamma_j^+\cup\Gamma_j^-} \frac{\partial^2\Phi(\mathbf{x},\mathbf{y})}{\partial \mathbf{n}(\mathbf{x})\partial \mathbf{n}(\mathbf{y})} u(\mathbf{y})\,\mathrm{d}s(\mathbf{y}), \quad \mathbf{x}\in\Gamma_j. \tag{3.5}$$

The same expression, but without the term $2\frac{\partial u^i}{\partial \mathbf{n}}(\mathbf{x})$, holds when Γ_j is in shadow. The high frequency Kirchhoff or physical optics approximation to $\partial u/\partial \mathbf{n}$ is just $\partial u/\partial \mathbf{n} = 2\partial u^i/\partial \mathbf{n}$ on the illuminated sides and zero on the sides in shadow. Thus the integral in (3.5) is an explicit expression for the correction to the physical optics approximation.

The representation (3.5) is very useful in understanding the oscillatory nature of the solution on a typical side Γ_j. In particular we note that, in physical terms, the integral over Γ_j^+ can be interpreted as the normal derivative on Γ_j of the field due to dipoles distributed along Γ_j^+. The point is that the field due to each dipole has the same oscillatory behavior $\mathrm{e}^{\mathrm{i}ks}$ on Γ_j. To exhibit this explicitly, we calculate, using standard properties of Bessel functions [2], that for $\mathbf{x}\in\Gamma_j$, $\mathbf{y}\in\Gamma_j^{\pm}$, with $\mathbf{x}\neq\mathbf{y}$,

$$\frac{\partial^2\Phi(\mathbf{x},\mathbf{y})}{\partial \mathbf{n}(\mathbf{x})\partial \mathbf{n}(\mathbf{y})} = \frac{\mathrm{i}kH_1^{(1)}(k|\mathbf{x}-\mathbf{y}|)}{4|\mathbf{x}-\mathbf{y}|} = \frac{\mathrm{i}k^2}{4}\mathrm{e}^{\mathrm{i}k|\mathbf{x}-\mathbf{y}|}\mu(k|\mathbf{x}-\mathbf{y}|), \tag{3.6}$$

where $\mu(z) := \mathrm{e}^{-\mathrm{i}z}H_1^{(1)}(z)/z$ for $z>0$. The function $\mu(z)$ is singular at $z=0$ but increasingly smooth as $z\to\infty$, as quantified in the next theorem (cf. [19, Lemma 2.5]).

THEOREM 3.1. *For every $\epsilon>0$,*

$$|\mu^{(m)}(z)| \le C_\epsilon (m+1)!\, z^{-3/2-m}$$

for $z\ge\epsilon$ and $m=0,1,\ldots,$ where

$$C_\epsilon = \frac{2\sqrt[4]{5}(1+\epsilon^{-1/2})}{\pi}. \tag{3.7}$$

Proof. From [51, equation (12.31)], $\mu(z) = (-2\mathrm{i}/\pi)\int_0^\infty (t^2-2\mathrm{i}t)^{1/2}\mathrm{e}^{-zt}\,\mathrm{d}t$ for $\mathrm{Re}z>0$, where the branch of $(t^2-2\mathrm{i}t)^{1/2}$ is chosen so that $\mathrm{Re}(t^2-2\mathrm{i}t)^{1/2}\ge 0$. Thus

$$\mu^{(m)}(z) = (-1)^{m+1}\frac{2\mathrm{i}}{\pi}\int_0^\infty t^{m+1/2}(t-2\mathrm{i})^{1/2}\mathrm{e}^{-zt}\,\mathrm{d}t$$

and hence

$$|\mu^{(m)}(z)| \le \frac{2}{\pi}\int_0^\infty t^{m+1/2}(t^2+4)^{1/4}\mathrm{e}^{-zt}\,\mathrm{d}t.$$

Now for $t\in[0,1]$, $(t^2+4)^{1/4}\le 5^{1/4}$ and for $t\in[1,\infty)$, $(t^2+4)^{1/4}\le 5^{1/4}t^{1/2}$. So

$$\begin{aligned}\frac{\pi}{2\sqrt[4]{5}}\,|\mu^{(m)}(z)| &\le \int_0^\infty t^{m+1/2}\mathrm{e}^{-zt}\,\mathrm{d}t + \int_0^\infty t^{m+1}\mathrm{e}^{-zt}\,\mathrm{d}t \\ &= \Gamma(m+3/2)z^{-3/2-m} + \Gamma(m+2)z^{-2-m} \le (1+\epsilon^{-1/2})\Gamma(m+2)z^{-3/2-m}\end{aligned}$$

for $z\ge\epsilon$. ∎

To make use of the above result, let $\mathbf{x}(s)$ denote the point on Γ whose arc-length distance measured counterclockwise from P_1 is s. Explicitly,

$$\mathbf{x}(s) = P_j + \left(s-\tilde{L}_{j-1}\right)\left(\frac{P_{j+1}-P_j}{L_j}\right) \quad \text{for } s\in[\tilde{L}_{j-1},\tilde{L}_j], \quad j=1,\ldots,n,$$

where $\tilde{L}_0 := 0$ and for $j = 1, \ldots, n$, $\tilde{L}_j := \sum_{m=1}^{j} L_m$ is the arc-length distance from P_1 to P_{j+1}. Define

$$\phi(s) := \frac{1}{k}\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x}(s)) \quad \text{for } s \in [0, L], \tag{3.8}$$

where $L := \tilde{L}_n$ so that $\phi(s)$ is the unknown function of arc-length whose behavior we seek to determine. Let

$$\Psi(s) := \begin{cases} \frac{2}{k}\frac{\partial u^i}{\partial \mathbf{n}}(\mathbf{x}(s)) & \text{if } s \in (\tilde{L}_{n_s}, L), \\ 0 & \text{if } s \in (0, \tilde{L}_{n_s}), \end{cases}$$

so that $\Psi(s)$ is the physical optics approximation to $\phi(s)$, and set $\psi_j(s) := u(\tilde{\mathbf{x}}_j(s))$, $s \in \mathbb{R}$, where $\tilde{\mathbf{x}}_j(s) \in \Gamma_j^+ \cup \Gamma_j \cup \Gamma_j^-$ is the point

$$\tilde{\mathbf{x}}_j(s) := P_j + \left(s - \tilde{L}_{j-1}\right)\left(\frac{P_{j+1} - P_j}{L_j}\right), \quad -\infty < s < \infty.$$

From (3.5) and (3.6) we have the explicit representation for ϕ on the side Γ_j that

$$\phi(s) = \Psi(s) + \frac{\mathrm{i}}{2}[\mathrm{e}^{\mathrm{i}ks} v_j^+(s) + \mathrm{e}^{-\mathrm{i}ks} v_j^-(s)], \quad s \in [\tilde{L}_{j-1}, \tilde{L}_j], \quad j = 1, \ldots, n, \tag{3.9}$$

where

$$v_j^+(s) := k \int_{-\infty}^{\tilde{L}_{j-1}} \mu(k|s-t|)\mathrm{e}^{-\mathrm{i}kt}\psi_j(t)\,\mathrm{d}t, \quad s \in [\tilde{L}_{j-1}, \tilde{L}_j], \quad j = 1, \ldots, n,$$
$$v_j^-(s) := k \int_{\tilde{L}_j}^{\infty} \mu(k|s-t|)\mathrm{e}^{\mathrm{i}kt}\psi_j(t)\,\mathrm{d}t, \quad s \in [\tilde{L}_{j-1}, \tilde{L}_j], \quad j = 1, \ldots, n.$$

The terms $\mathrm{e}^{\mathrm{i}ks} v_j^+(s)$ and $\mathrm{e}^{-\mathrm{i}ks} v_j^-(s)$ in (3.9) are the integrals over Γ_j^+ and Γ_j^-, respectively, in (3.5) and can be thought of as the contributions to $\partial u/\partial \mathbf{n}$ on Γ_j due to the diffracted rays travelling from P_j to P_{j+1} and from P_{j+1} to P_j, respectively, including all multiply diffracted ray components.

Thus the equation we wish to solve is (2.9), and we have the explicit representation (3.9) for its solution. At first glance this may not appear to help us, since the unknown solution u appears (as ψ_j) on the right-hand side of (3.9). However, (3.9) is extremely helpful in understanding how ϕ behaves since it explicitly separates out the oscillatory part of the solution. The functions $v_j^{\pm}$ are not oscillatory away from the corners, as the following theorem quantifies. In this theorem and hereafter we let

$$u_M := \sup_{\mathbf{x} \in D} |u(\mathbf{x})| < \infty \tag{3.10}$$

and note that $\|\psi_j\|_\infty \le u_M$, $j = 1, \ldots, n$.

THEOREM 3.2 (solution behavior away from corners). *For $\epsilon > 0$, $j = 1, \ldots, n$, and $m = 0, 1, \ldots$, it holds for $s \in [\tilde{L}_{j-1}, \tilde{L}_j]$ that*

$$|v_j^{+(m)}(s)| \le 2C_\epsilon m! u_M k^m (k(s - \tilde{L}_{j-1}))^{-1/2-m}, \quad k(s - \tilde{L}_{j-1}) \ge \epsilon,$$
$$|v_j^{-(m)}(s)| \le 2C_\epsilon m! u_M k^m (k(\tilde{L}_j - s))^{-1/2-m}, \quad k(\tilde{L}_j - s) \ge \epsilon,$$

where C_ϵ is given by (3.7).

Proof. From Theorem 3.1, for $s \in [\tilde{L}_{j-1} + \epsilon/k, \tilde{L}_j]$

$$\begin{aligned}
|v_j^{+(m)}(s)| &= k^{m+1} \left| \int_{-\infty}^{\tilde{L}_{j-1}} \mu^{(m)}(k|s-t|) \mathrm{e}^{-\mathrm{i}kt} \psi_j(t)\, \mathrm{d}t \right| \\
&\le C_\epsilon (m+1)! k^{m+1} \|\psi_j\|_\infty \int_{-\infty}^{\tilde{L}_{j-1}} (k|s-t|)^{-3/2-m}\, \mathrm{d}t \\
&= C_\epsilon \frac{(m+1)!}{(m+1/2)} k^{-1/2} \|\psi_j\|_\infty (s - \tilde{L}_{j-1})^{-1/2-m} \\
&\le 2C_\epsilon m! u_M k^m (k(s-\tilde{L}_{j-1}))^{-1/2-m}.
\end{aligned}$$

The bound on $v_j^{-(m)}(s)$ is obtained similarly. ∎

The above theorem quantifies precisely the behavior of $\partial u/\partial \mathbf{n}$ away from the corners. Complementing this bound, using Theorem 2.3 we can study the behavior of $\partial u/\partial \mathbf{n}$ near the corners. To state this result it is convenient to extend the definition of ϕ from $[0, L]$ to $\mathbb{R}$ by the periodicity condition $\phi(s + L) = \phi(s)$, $s \in \mathbb{R}$.

THEOREM 3.3 (solution behavior near corners). *If $kR_j = \min(kL_{j-1}, kL_j) \ge \pi/4$ for $j = 1, \ldots, n$, then for $j = 1, \ldots, n$ and $0 < k|s - \tilde{L}_{j-1}| \le \pi/12$, it holds that*

$$\left| \phi^{(m)}(s) \right| \le C u_M \sqrt{m + \frac{1}{2}}\, m! k^m (k|s - \tilde{L}_{j-1}|)^{-\alpha_j - m}, \quad m = 0, 1, \ldots,$$

where

$$\alpha_j := 1 - \frac{\pi}{\Omega_j} \in (0, 1/2) \tag{3.11}$$

and $C = 72\sqrt{2}\, \pi^{-1}\, \mathrm{e}^{1/\mathrm{e} + \pi/6}$.

Proof. To analyze the behavior of u using (2.4) we will use the representation for the Bessel function of order ν [2, equation (9.1.20)],

$$J_\nu(z) = \frac{2(z/2)^\nu}{\pi^{1/2}\Gamma(\nu + 1/2)} \int_0^1 (1 - t^2)^{\nu - 1/2} \cos(zt)\, \mathrm{d}t \text{ for } \mathrm{Re} z > 0,\ \nu > -1/2,$$

where the branch of $(z/2)^\nu$ is chosen so that $(z/2)^\nu > 0$ for $z > 0$ and $(z/2)^\nu$ is analytic in $\mathrm{Re} z > 0$. This representation implies that

$$\cos z \le \frac{J_\nu(z) \pi^{1/2} \Gamma(\nu + 1/2)}{2(z/2)^\nu \int_0^1 (1 - t^2)^{\nu - 1/2}\, \mathrm{d}t} \le 1, \quad 0 \le z \le \pi/2. \tag{3.12}$$

Recalling the definitions of R and G before Theorem 2.3 and the Definition (2.5) of the coefficient a_n, we have that $\rho := kR < \pi/2$ and

$$|a_n| \le \frac{2u_M}{J_{n\pi/\Omega_j}(\rho)}. \tag{3.13}$$

Thus, for $0 < r < R$,

$$\left| a_n J_{n\pi/\Omega_j}(kr) \right| \le \frac{2u_M}{\cos \rho} \left(\frac{r}{R} \right)^{n\pi/\Omega_j}, \tag{3.14}$$

confirming that the series (2.4) converges for $0 \le r < R$. Further, the bound (3.14) justifies differentiating (2.4) term by term to get that for $\mathbf{x} \in \Gamma_{j-1} \cap G$, $\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x}) = kF(kr)$, where

$$F(z) := \frac{\pi}{\Omega_j z} \sum_{n=1}^{\infty} n a_n J_{n\pi/\Omega_j}(z), \quad \mathrm{Re} z > 0, \quad |z| < \rho. \tag{3.15}$$

Since $|\cos z| \le \mathrm{e}^{|\mathrm{Im} z|}$, $z \in \mathbb{C}$, so that $|\cos zt| \le \mathrm{e}^{|\mathrm{Im} z|}$ for $z \in \mathbb{C}$, $0 \le t \le 1$, we see from (3.13) that for $\mathrm{Re} z > 0$,

$$\left| n a_n J_{n\pi/\Omega_j}(z) \right| \le \frac{2u_M n}{\cos \rho} \mathrm{e}^{|\mathrm{Im} z|} \left(\frac{|z|}{\rho} \right)^{n\pi/\Omega_j}. \tag{3.16}$$

Thus the series (3.15) is absolutely and uniformly convergent in $\mathrm{Re} z > 0$, $|z| < \rho_0$, for every $\rho_0 < \rho$, and F is analytic in $\mathrm{Re} z > 0$, $|z| < \rho$. Further, from (3.16) and since for $0 \le \alpha < 1$, $\sum_{n=1}^{\infty} n\alpha^n = \alpha \frac{\mathrm{d}}{\mathrm{d}\alpha} \sum_{n=1}^{\infty} \alpha^n = \frac{\alpha}{(1-\alpha)^2}$, we see that for $\mathrm{Re} z > 0$, $|z| < \rho$,

$$|F(z)| \le \frac{\pi}{\Omega_j |z|} \frac{2u_M}{\cos \rho} \frac{\mathrm{e}^{|\mathrm{Im} z|}}{(1 - |z/\rho|^{\pi/\Omega_j})^2} \left(\frac{|z|}{\rho} \right)^{\pi/\Omega_j}.$$

We can use this bound to obtain bounds on derivatives of F, and hence bounds on derivatives of $\partial u/\partial \mathbf{n}$. For $0 < t \le \rho/3$, $0 < \varepsilon < t$, from Cauchy's integral formula we have that

$$|F^{(m)}(t)| = \frac{m!}{2\pi} \left| \int_{\Gamma_\varepsilon} \frac{F(z)}{(z-t)^{m+1}} \, \mathrm{d}z \right|,$$

where Γ_ε is the circle of radius ε centered on t, which lies in $\mathrm{Re} z > 0$, $|z| < \rho$. Since

$$|F(z)| \le \frac{2\pi u_M \mathrm{e}^{|\mathrm{Im} z|} (t-\varepsilon)^{\pi/\Omega_j - 1}}{\Omega_j \rho^{\pi/\Omega_j} \cos \rho (1 - (2/3)^{\pi/\Omega_j})^2}$$

for $z \in \Gamma_\varepsilon$, we see that

$$|F^{(m)}(t)| \le \frac{2\pi u_M \mathrm{e}^t (t-\varepsilon)^{\pi/\Omega_j - 1} \varepsilon^{-m} m!}{\Omega_j \rho^{\pi/\Omega_j} \cos \rho (1 - (2/3)^{\pi/\Omega_j})^2}. \tag{3.17}$$

Now, for $\alpha > 0$, $\beta > 0$, $(t-\varepsilon)^{-\alpha} \varepsilon^{-\beta}$ is minimized on $(0,t)$ by the choice $\varepsilon = \beta t/(\alpha+\beta)$. Setting $\varepsilon = mt/(m+1-\pi/\Omega_j)$ in (3.17), we see that

$$|F^{(m)}(t)| \le \frac{2\pi u_M \mathrm{e}^t m! (m+1-\pi/\Omega_j)^{m+1-\pi/\Omega_j} t^{\pi/\Omega_j - 1 - m}}{\Omega_j \rho^{\pi/\Omega_j} \cos \rho (1 - (2/3)^{\pi/\Omega_j})^2 m^m (1-\pi/\Omega_j)^{1-\pi/\Omega_j}}.$$

Now

$$\frac{(m+1-\pi/\Omega_j)^{m+1-\pi/\Omega_j}}{m^m} \le \frac{(m+1/2)^{m+1/2}}{m^m} = \left(1 + \frac{1}{2m}\right)^m \sqrt{m+\frac{1}{2}} \le \mathrm{e}^{1/2} \sqrt{m+\frac{1}{2}},$$

$$\frac{2\pi}{\Omega_j (1-\pi/\Omega_j)^{1-\pi/\Omega_j} (1 - (2/3)^{\pi/\Omega_j})^2} \le \frac{18}{(1-\pi/\Omega_j)^{1-\pi/\Omega_j}} \le 18\mathrm{e}^{1/\mathrm{e}},$$

and hence

$$|F^{(m)}(t)| \le \frac{18 \mathrm{e}^{1/\mathrm{e}+1/2+t} \sqrt{m+1/2}\, m! u_M}{\rho^{\pi/\Omega_j} \cos \rho} t^{\pi/\Omega_j - 1 - m}, \quad 0 < t \le \rho/3. \tag{3.18}$$

Since $\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x}) = kF(kr)$, this implies that

$$\left|\frac{\partial^{(m)}}{\partial r^m}\left[\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x})\right]\right| \leq \tilde{C} u_M\, k^{m+1}(kr)^{\pi/\Omega_j - 1 - m}, \quad 0 < r \leq R/3 < \frac{\pi}{6k},$$

where $\tilde{C} = (18\mathrm{e}^{1/\mathrm{e}+1/2+\pi/6}\sqrt{m+1/2}\, m!)/(\rho^{\pi/\Omega_j}\cos\rho)$. Choosing $\rho = \pi/4$, the result follows. ∎

From Theorems 3.2 and 3.3, and (3.9), which gives that

$$v_j^{\pm}(s) = -2\mathrm{i}\mathrm{e}^{\mp \mathrm{i}ks}(\phi(s) - \Psi(s)) - \mathrm{e}^{\pm 2\mathrm{i}ks} v_j^{\mp}(s),$$

we deduce the following corollary, in which $\alpha_{n+1} := \alpha_1$.

COROLLARY 3.4. *Suppose that $kR_j = \min(kL_{j-1}, kL_j) \geq \pi/4$ for $j = 1, \ldots, n$. Then, for $m = 0, 1, \ldots$, there exists $C_m > 0$, dependent only on m, such that if $j \in \{1, \ldots, n\}$, then*

$$|v_j^{+(m)}(s)| \leq C_m u_M k^m (k(s - \tilde{L}_{j-1}))^{-\alpha_j - m}, \quad 0 < k(s - \tilde{L}_{j-1}) \leq \pi/12,$$
$$|v_j^{-(m)}(s)| \leq C_m u_M k^m (k(\tilde{L}_j - s))^{-\alpha_{j+1} - m}, \quad 0 < k(\tilde{L}_j - s) \leq \pi/12.$$

The following limiting case suggests that the bounds in Theorem 3.2 and Corollary 3.4 are optimal in their dependence on k, $s - \tilde{L}_{j-1}$, and $\tilde{L}_j - s$, in the sense that no sharper bound holds uniformly in the angle of incidence. Suppose that Υ lies in the right-hand half-plane with P_1 located at the origin and $\mathbf{d} \cdot \mathbf{n}_1 = 0$, and consider the limit $\min(kL_0, kL_1) \to \infty$ and $\Omega_1 \to 2\pi$. In this limit $\alpha_1 \to 1/2$, and it is plausible that $u(\mathbf{x}) \to u_{\text{k.e.}}(\mathbf{x})$, where $u_{\text{k.e.}}$ is the solution to the following "knife edge" diffraction problem: where $\Gamma_{\text{k.e.}} := \{(x_1, 0) : x_1 \geq 0\}$, given the incident plane wave u^i, find the total field $u_{\text{k.e.}} \in C^2(\mathbb{R}^2 \setminus \Gamma_{\text{k.e.}}) \cap C(\mathbb{R}^2)$ such that $\Delta u_{\text{k.e.}} + k^2 u_{\text{k.e.}} = 0$ in $\mathbb{R}^2 \setminus \Gamma_{\text{k.e.}}$, $u_{\text{k.e.}} = 0$ on $\Gamma_{\text{k.e.}}$, and $u_{\text{k.e.}} - u^i$ has the correct radiating behavior. The solution to this problem which satisfies the physically correct radiation condition is given by [10, equation (8.24)]. This solution implies that $\varphi(s) := \frac{1}{k}\frac{\partial u_{\text{k.e.}}}{\partial \mathbf{n}}((s, 0)) = \pm \mathrm{e}^{\mathrm{i}ks} v(s)$, where the $+/-$ sign is taken on the upper/lower surface of the knife edge and $v(s) := \hat{c}(ks)^{-1/2}$, where $\hat{c} = \mathrm{e}^{-\mathrm{i}\pi/4}\sqrt{2/\pi}$. The function $v(s)$ and its derivatives satisfy the bounds on v_1^+ in Theorem 3.2 and Corollary 3.4 (with $\alpha_j = 1/2$), but do not satisfy any sharper bounds in terms of dependence on k or $s - \tilde{L}_{j-1}$.

4. The approximation space. Our aim now is to use the regularity results of section 3 to design an optimal approximation space for the numerical solution of (2.9). We begin by rewriting (2.9) in parametric form. Defining, for $j = 1, \ldots, n$,

$$a_j := \frac{p_{j+1} - p_j}{L_j}, \quad b_j := \frac{q_{j+1} - q_j}{L_j}, \quad c_j := p_j - a_j \tilde{L}_{j-1}, \quad d_j := q_j - b_j \tilde{L}_{j-1},$$

and noting that $n_{j1} = b_j$, $n_{j2} = -a_j$, we can rewrite (2.9) as

$$\phi(s) + \int_0^L \kappa(s, t)\phi(t)\,\mathrm{d}t = f(s), \quad s \in [0, L], \tag{4.1}$$

where, for $\mathbf{x}(s) \in \Gamma_l$, $\mathbf{y}(t) \in \Gamma_j$, i.e., for $s \in (\tilde{L}_{l-1}, \tilde{L}_l)$, $t \in (\tilde{L}_{j-1}, \tilde{L}_j)$,

$$\kappa(s, t) := -\frac{1}{2}\left[\eta H_0^{(1)}(kR) + \mathrm{i}k\left[(a_l b_j - b_l a_j)t + b_l(c_l - c_j) - a_l(d_l - d_j)\right]\frac{H_1^{(1)}(kR)}{R}\right],$$

with $R = R(s,t) := \sqrt{(a_l s - a_j t + c_l - c_j)^2 + (b_l s - b_j t + d_l - d_j)^2}$ and $f \in L^2(0,L)$ defined by

$$f(s) := 2\mathrm{i}[b_l \sin\theta + a_l \cos\theta + (\eta/k)]\mathrm{e}^{\mathrm{i}k((a_l s + c_l)\sin\theta - (b_l s + d_l)\cos\theta)}.$$

The first step in our numerical method is to separate off the explicitly known leading order behavior, the physical optics approximation $\Psi(s)$. Thus we introduce a new unknown,

$$\varphi := \phi - \Psi \in L^2(0,L). \tag{4.2}$$

Substituting into (4.1) we have

$$\varphi + K\varphi = F, \tag{4.3}$$

where the integral operator $K : L^2(0,L) \to L^2(0,L)$ and $F \in L^2(0,L)$ are defined by

$$K\psi(s) := \int_0^L \kappa(s,t)\psi(t)\,\mathrm{d}t,\ 0 \le s \le L, \quad F := f - \Psi - K\Psi.$$

Equation (4.3) is the integral equation we will solve numerically. By Theorem 2.7, (4.3) has a unique solution in $L^2(0,L)$ and $\|(I+K)^{-1}\|_2 = C_S$, where C_S is defined in (2.11) and I is the identity operator on $L^2(0,L)$.

We will design an approximation space to represent φ based on (3.9). The novelty of the scheme we propose is that on each side Γ_j, $j = 1,\dots,n$, of the polygon, we approximate $v_j^{\pm}$ by conventional piecewise polynomials, rather than approximating φ itself. This makes sense since, as quantified by Theorem 3.2, the functions $v_j^{\pm}$ are smooth (their higher order derivatives are small) away from the corners P_j and P_{j+1}. To approximate $v_j^{\pm}$ we use piecewise polynomials of a fixed degree $\nu \ge 0$ on a graded mesh, the mesh grading adapted in an optimal way to the bounds of Theorems 3.2 and 3.3. In [19] the 2D problem of scattering of a plane wave by a straight boundary of piecewise constant surface impedance was considered. We will construct a similar mesh on each side of the polygon as was used on each interval of constant impedance in [19], except that we use a different grading near the corners, with the grading near each corner dependent on the angle at that corner.

To construct this mesh we choose a constant $c^* > 0$ (we take $c^* = 2\pi$ in the numerical examples in section 6) and set $\lambda^* := c^*/k$. Next, for every $A > \lambda^*$, we define a composite graded mesh on $[0,A]$, with a polynomial grading on $[0,\lambda^*]$ and a geometric grading on $[\lambda^*, A]$ (note that the mesh on $[0,\lambda^*]$ is similar to that classically used near corners (e.g., [17, 7]) for solving Laplace's equation on polygonal domains).

DEFINITION 4.1. *For $A > \lambda^*$, $N = 2,3,\dots$, $\Lambda_{N,A,q} := \{y_0,\dots,y_{N+N_{A,q}}\}$ is the mesh consisting of the points*

$$y_i = \lambda^*\left(\frac{i}{N}\right)^q,\ i = 0,\dots,N, \quad \text{and} \quad y_{N+j} := \lambda^*\left(\frac{A}{\lambda^*}\right)^{j/N_{A,q}},\ j = 1,\dots,N_{A,q}, \tag{4.4}$$

where $N_{A,q} := \lceil N^* \rceil$, i.e., $N_{A,q}$ is the smallest integer greater than or equal to N^*, and

$$N^* := \frac{-\log(A/\lambda^*)}{q\log(1-1/N)}.$$

Let us explain the rationale behind this definition. Having the bounds of Theorems 3.2 and 3.3 in mind, the mesh on $[0, \lambda^*]$ is chosen to be approximately optimal if q is chosen appropriately (see Theorem 4.2 below), in terms of equidistributing the error between the subintervals of the mesh when $s^{-\alpha}$, with $0 < \alpha < 1/2$, is approximated on $[0, \lambda^*]$ in the L^2 norm. That the mesh we propose on $[0, \lambda^*]$ has this property and the appropriate choice of q as a function of α is well known and dates back to Rice [55]. Similarly, the mesh on $[\lambda^*, A]$ is chosen to be approximately optimal, in terms of equidistributing the error between the subintervals of the mesh, when $s^{-1/2}$ is approximated on $[\lambda^*, A]$ in the L^2 norm. Finally, the choice of N^* ensures a smooth transition between the two parts of the mesh, and thus approximately the same L^2 error in the two adjacent subintervals on either side of λ^*. In particular, in the case that $N_{A,q} = N^*$, it holds that $y_{N+1}/y_N = y_N/y_{N-1}$, so that y_{N-1} and y_N are points in both the polynomial and the geometric parts of the mesh. Note that by the mean value theorem, $-\log(1 - 1/N) = 1/(\xi N)$ for some $\xi \in (1 - 1/N, 1)$, and hence

$$N_{A,q} < \frac{N \log(kA/c^*)}{q} + 1. \tag{4.5}$$

For $a < b$ let $\|\cdot\|_{2,(a,b)}$ denote the norm on $L^2(a, b)$, $\|f\|_{2,(a,b)} := \{\int_a^b |f(s)|^2 \mathrm{d}s\}^{1/2}$. Similarly, for $f \in C[a, b]$, let $\|f\|_{\infty,(a,b)} := \sup_{a<s<b} |f(s)|$. For $A > \lambda^*$, $\nu \in \mathbb{N} \cup \{0\}$, $q \geq 1$, let $\Pi_{N,\nu} \subset L^2(0, A)$ denote the set of piecewise polynomials

$$\Pi_{N,\nu} := \{\sigma : \sigma|_{(y_{j-1},y_j)} \text{ is a polynomial of degree} \leq \nu \text{ for } j = 1, \ldots, N + N_{A,q}\},$$

and let P_N^* be the orthogonal projection operator from $L^2(0, A)$ to $\Pi_{N,\nu}$, so that setting $p = P_N^* f$ minimizes $\|f - p\|_{2,(0,A)}$ over all $p \in \Pi_{N,\nu}$.

THEOREM 4.2. *Suppose that $f \in C^\infty(0, \infty)$, $kA > c^*$, and $\alpha \in (0, 1/2)$, and that for $m = 0, 1, 2, \ldots$, there exist constants $c_m > 0$ such that*

$$|f^{(m)}(s)| \leq \begin{cases} c_m k^m (ks)^{-\alpha-m}, & ks \leq 1, \\ c_m k^m (ks)^{-1/2-m}, & ks \geq 1. \end{cases} \tag{4.6}$$

Then, with the choice $q := (2\nu + 3)/(1 - 2\alpha)$, there exists a constant C_ν, dependent only on c^*, ν, and α, such that for $N = 2, 3, \ldots$,

$$\|f - P_N^* f\|_{2,(0,A)} \leq \frac{C_\nu \tilde{c}_\nu (1 + \log(kA/c^*))^{1/2}}{k^{1/2} N^{\nu+1}},$$

where $\tilde{c}_\nu := \max(c_0, c_{\nu+1})$.

Proof. Throughout the proof let C_ν denote a positive constant whose value depends on ν, c^*, and α, not necessarily the same at each occurrence. For $0 \leq a < b \leq A$, let $p_{a,b,\nu}$ denote the polynomial of degree $\leq \nu$ which is the best approximation to f in the L^2 norm on (a, b). Then it follows from Taylor's theorem that

$$\|f - p_{a,b,\nu}\|_{2,(a,b)} \leq C_\nu (b - a)^{\nu+3/2} \|f^{(\nu+1)}\|_{\infty,(a,b)}. \tag{4.7}$$

Now

$$\|f - P_N^* f\|_{2,(0,A)}^2 = \sum_{j=1}^{N+N_{A,q}} \int_{y_{j-1}}^{y_j} |f - P_N^* f|^2 \, \mathrm{d}s = \sum_{j=1}^{N+N_{A,q}} e_j, \tag{4.8}$$

where $e_j := \|f - p_{y_{j-1},y_j,\nu}\|^2_{2,(y_{j-1},y_j)}$. From the definition (4.4) we see that

$$e_1 \le \int_0^{y_1} |f(s)|^2 \,\mathrm{d}s \le c_0^2 k^{-2\alpha} \int_0^{\lambda^*/N^q} s^{-2\alpha} \,\mathrm{d}s \le \frac{C_\nu c_0^2}{kN^{2\nu+3}}. \tag{4.9}$$

Using (4.7) we have, for $j = 2, 3, \ldots, N + N_{A,q}$,

$$e_j \le C_\nu (y_j - y_{j-1})^{2\nu+3} \|f^{(\nu+1)}\|^2_{\infty,(y_{j-1},y_j)}. \tag{4.10}$$

Further, for $j = 2, \ldots, N$,

$$y_j - y_{j-1} = \frac{c^*}{kN^q}\,[j^q - (j-1)^q] \le \frac{c^* q j^{q-1}}{kN^q}, \tag{4.11}$$

and, using (4.6) and since $N/(j-1) \le 2N/j$,

$$\|f^{(\nu+1)}\|_{\infty,(y_{j-1},y_j)} \le c_{\nu+1} k^{-\alpha} y_{j-1}^{-\alpha-\nu-1} \le c_{\nu+1} k^{\nu+1} \left(\frac{2N}{j}\right)^{q(\alpha+\nu+1)}. \tag{4.12}$$

Combining (4.10)–(4.12) we see that for $j = 2, \ldots, N$,

$$e_j \le \frac{C_\nu c_{\nu+1}^2}{kN^{2\nu+3}}. \tag{4.13}$$

For $j = N+1, \ldots, N_{A,q}$, recalling (4.4) and the choice of N^* and then using (4.11),

$$y_j - y_{j-1} = y_{j-1}\left(\frac{y_j - y_{j-1}}{y_{j-1}}\right) \le y_{j-1}\left(\frac{y_N - y_{N-1}}{y_{N-1}}\right) \le y_{j-1}\frac{q}{N-1} \le 2y_{j-1}\frac{q}{N}.$$

Also, from (4.6),

$$\|f^{(\nu+1)}\|_{\infty,(y_{j-1},y_j)} \le c_{\nu+1} k^{-1/2} y_{j-1}^{-\nu-3/2}.$$

Using these bounds in (4.10), we see that the bound (4.13) holds also for $j = N + 1, \ldots, N + N_{A,q}$. Combining (4.8), (4.9), and (4.13),

$$\|f - P_N^* f\|^2_{2,(0,A)} \le \frac{C_\nu \tilde{c}_\nu^2 (N + N_{A,q})}{kN^{2\nu+3}} \le \frac{C_\nu \tilde{c}_\nu^2 (1 + \log(kA/c^*))}{kN^{2\nu+2}},$$

using (4.5). Hence the result follows. ∎

We assume through the remainder of the paper that $c^* > 0$ is chosen so that

$$kL_j \ge c^*, \quad j = 1, \ldots, n. \tag{4.14}$$

For $j = 1, \ldots, n$, recalling (3.11), we define $q_j := (2\nu+3)/(1-2\alpha_j)$ and the two meshes

$$\Gamma_j^+ := \tilde{L}_{j-1} + \Lambda_{N,L_j,q_j}, \quad \Gamma_j^- := \tilde{L}_j - \Lambda_{N,L_j,q_{j+1}}.$$

Letting $\mathrm{e}_\pm(s) := \mathrm{e}^{\pm \mathrm{i}ks}$, $s \in [0, L]$, we then define

$$V_{\Gamma_j^+,\nu} := \{\sigma \mathrm{e}_+ : \sigma \in \Pi_{\Gamma_j^+,\nu}\}, \quad V_{\Gamma_j^-,\nu} := \{\sigma \mathrm{e}_- : \sigma \in \Pi_{\Gamma_j^-,\nu}\}$$

for $j = 1, \ldots, n$, where

$$\Pi_{\Gamma_j^+,\nu} := \{\sigma \in L^2(0,L) : \sigma|_{(\tilde{L}_{j-1}+y_{m-1},\tilde{L}_{j-1}+y_m)} \text{ is a polynomial of degree } \le \nu \text{ for } m = 1, \ldots, N + N_{L_j,q_j}, \text{ and } \sigma|_{(0,\tilde{L}_{j-1})\cup(\tilde{L}_j,L)} = 0\},$$

$$\Pi_{\Gamma_j^-,\nu} := \{\sigma \in L^2(0,L) : \sigma|_{(\tilde{L}_j-\tilde{y}_m,\tilde{L}_j-\tilde{y}_{m-1})} \text{ is a polynomial of degree } \le \nu \text{ for } m = 1, \ldots, N + N_{L_j,q_{j+1}}, \text{ and } \sigma|_{(0,\tilde{L}_{j-1})\cup(\tilde{L}_j,L)} = 0\},$$

with $0 = y_0 < y_1 < \cdots < y_{N+N_{L_j,q_j}} = L_j$ the points of the mesh Λ_{N,L_j,q_j} and $0 = \tilde{y}_0 < \tilde{y}_1 < \cdots < \tilde{y}_{N+N_{L_j,q_{j+1}}} = L_j$ the points of the mesh $\Lambda_{N,L_j,q_{j+1}}$. We define P_N^+ and P_N^- to be the orthogonal projection operators from $L^2(0,L)$ onto $\Pi_{\Gamma_+,\nu}$ and $\Pi_{\Gamma_-,\nu}$, respectively, where $\Pi_{\Gamma_\pm,\nu}$ denotes the linear span of $\bigcup_{j=1,\ldots,n} \Pi_{\Gamma_j^\pm,\nu}$. We also define the functions $v_\pm \in L^2(0,L)$ by

$$v_+(s) := v_j^+(s), \quad v_-(s) := v_j^-(s), \quad \tilde{L}_{j-1} < s < \tilde{L}_j, \ j = 1, \ldots, n.$$

We then have the following error estimate, in which u_M is as defined in (3.10) and we abbreviate $\|\cdot\|_{2,(0,L)}$ by $\|\cdot\|_2$.

THEOREM 4.3. *There exists a constant $C_\nu > 0$, dependent only on c^*, ν, and Ω_1, $\Omega_2, \ldots, \Omega_n$, such that*

$$\|v_+ - P_N^+ v_+\|_2 \le C_\nu u_M \frac{n^{1/2}(1 + \log(k\bar{L}/c^*))^{1/2}}{k^{1/2} N^{\nu+1}},$$

where $\bar{L} := (L_1 \ldots L_n)^{1/n}$, with an identical bound holding on $\|v_- - P_N^- v_-\|_2$.

Proof. From Theorem 3.2, Corollary 3.4, and Theorem 4.2,

$$\|v_+ - P_N^+ v_+\|_2^2 = \sum_{j=1}^n \|v_j^+ - P_N^+ v_j^+\|_{2,(\tilde{L}_{j-1},\tilde{L}_j)}^2 \le n \frac{C_\nu^2 u_M^2 (1 + \log(k\bar{L}))}{k N^{2\nu+2}},$$

and the result follows. ∎

Our approximation space $V_{\Gamma,\nu}$ is the linear span of

$$\bigcup_{j=1,\ldots,n} \{V_{\Gamma_j^+,\nu} \cup V_{\Gamma_j^-,\nu}\}.$$

The dimension of this approximation space, i.e., the number of degrees of freedom, is

$$M_N = 2(\nu+1) \sum_{j=1}^n (N + N_{L_j,q_j}) < 2(\nu+1) n N (1 + N^{-1} + \log(k\bar{L}/c^*)) \tag{4.15}$$

by (4.5). We define P_N to be the operator of orthogonal projection from $L^2(0,L)$ onto $V_{\Gamma,\nu}$. It remains to prove a bound on $\|\varphi - P_N\varphi\|_2$, showing that our mesh and approximation space are well adapted to approximating φ.

To use Theorem 4.3 we note from (3.9) and (4.2) that $\varphi = \frac{\mathrm{i}}{2}(\mathrm{e}_+ v_+ + \mathrm{e}_- v_-)$. But $\mathrm{e}_+ P_N^+ v_+ + \mathrm{e}_- P_N^- v_- \in V_{\Gamma,\nu}$ and $P_N\varphi$ is the best approximation to φ in $V_{\Gamma,\nu}$. Applying

Theorem 4.3 we thus have that

$$\begin{aligned}\|\varphi - P_N\varphi\|_2 &\le \left\|\varphi - \frac{\mathrm{i}}{2}(e_+P_N^+v_+ + e_-P_N^-v_-)\right\|_2 \\ &= \frac{1}{2}\|e_+(v_+ - P_N^+v_+) + e_-(v_- - P_N^-)\|_2 \\ &\le \|e_+\|_\infty\|v_+ - P_N^+v_+\|_2 + \|e_-\|_\infty\|v_- - P_N^-v_-\|_2 \\ &\le C_\nu u_M \frac{n^{1/2}(1+\log^{1/2}(k\bar{L}))}{k^{1/2}N^{\nu+1}}.\end{aligned}$$

Combining this bound with (4.15), we obtain the following main result of the paper. We remind the reader that we are assuming throughout that (4.14) holds.

THEOREM 4.4. *There exist positive constants C_ν and C'_ν, depending only on c^*, ν, and Ω_1, $\Omega_2, \ldots, \Omega_n$, such that*

$$k^{1/2}\|\varphi - P_N\varphi\|_2 \le C_\nu u_M \frac{n^{1/2}(1+\log(k\bar{L}/c^*))^{1/2}}{N^{\nu+1}} \le C'_\nu u_M \frac{(n[1+\log(k\bar{L}/c^*)])^{\nu+3/2}}{M_N^{\nu+1}}.$$

A comment on the factor $k^{1/2}$ on the left-hand side is probably helpful. Reflecting that the solution of the physical problem must be independent of the unit of length measurement and that we are designing our numerical scheme to preserve this property, it is easy to see that the values of both $k^{1/2}\|\varphi\|_2$ and $k^{1/2}\|\varphi - P_N\varphi\|_2$ remain fixed as k changes if we keep kL_j fixed for $j = 1, \ldots, n$ (and also, of course, keep Ω_j, $j = 1, \ldots, n$, c^*, and ν fixed). Thus inclusion of the factor $k^{1/2}$ ensures that the value of $k^{1/2}\|\varphi - P_N\varphi\|_2$ is independent of the unit of length measurement as are the bounds on the right-hand side.

5. Galerkin method. Theorem 4.4 has shown that it is possible to approximate accurately the solution of the integral equation (4.3) with a number of degrees of freedom that grows only very modestly as the wave number increases. To select an approximation, φ_N, from the approximation space $V_{\Gamma,\nu}$ we use the Galerkin method. Let $(\cdot,\cdot)$ denote the usual inner product on $L^2(0,L)$, defined by $(\chi_1,\chi_2) := \int_0^L \chi_1(s)\bar{\chi}_2(s)\,\mathrm{d}s$, so that $\|\chi\|_2 = (\chi,\chi)^{1/2}$. Then our Galerkin method approximation $\varphi_N \in V_{\Gamma,\nu}$ is defined by

$$(\varphi_N,\rho) + (K\varphi_N,\rho) = (F,\rho) \quad \text{for all } \rho \in V_{\Gamma,\nu}; \tag{5.1}$$

equivalently

$$\varphi_N + P_NK\varphi_N = P_NF. \tag{5.2}$$

Our goal now is to show that (5.2) has a unique solution φ_N, to establish a bound on the error $\|\varphi - \varphi_N\|_2$ in this numerical method, and to relate this error to the best approximation error $\|\varphi - P_N\varphi\|_2$. We begin by establishing that $I + P_NK$ is invertible if N is large enough. We remind the reader (see the end of section 2) that we are assuming that $\eta \in \mathbb{R}$, the coupling parameter in the integral equation, is chosen with $\eta \neq 0$, which ensures that $I + K$ is invertible.

THEOREM 5.1. *For all $v \in L^2(0,L)$, $\|P_Nv - v\|_2 \to 0$ as $N \to \infty$.*

Proof. Since $\|P_N\|_2 = 1$, it is enough to show that $P_Nv \to v$ in $L^2(0,L)$ for all $v \in C^\infty[0,L]$, a dense subset of $L^2(0,L)$. But this follows from Theorem 4.2 and the definition of P_N. ∎

THEOREM 5.2. *There exists a constant $N^* \geq 2$, dependent only on Γ, k, and η, such that, for $N \geq N^*$, the operator $I + P_N K : L^2(0, L) \to L^2(0, L)$ is bijective with*

$$C_s := \sup_{N \geq N^*} \|(I + P_N K)^{-1}\|_2 < \infty, \tag{5.3}$$

so that (5.2) *has exactly one solution for $N \geq N^*$.*

Proof. Recalling the discussion at the end of section 2, we note that it holds that $K = K_1 + K_2$, where $\|K_1\|_2 < 1$ and K_2 is a compact operator on $L^2(0, L)$. Since $\|P_N K_1\|_2 \leq \|K_1\|_2 < 1$, $I + P_N K_1$ is invertible and $\|(I + P_N K_1)^{-1}\|_2 \leq (1 - \|K_1\|_2)^{-1}$. Since K_2 is compact and $I + K$ is injective, it follows from Theorem 5.1 and standard perturbation arguments for projection methods (e.g., [7, Theorem 8.2.1], [17]) that $(I + P_N K)^{-1}$ exists and is uniformly bounded for all N sufficiently large. ∎

From (4.3) and (5.2) it follows that $\varphi - \varphi_N = (I + P_N K)^{-1}(\varphi - P_N \varphi)$, and hence

$$\|\varphi - \varphi_N\|_2 \leq \|(I + P_N K)^{-1}\|_2 \|\varphi - P_N \varphi\|_2. \tag{5.4}$$

Combining (5.3) and (5.4) with Theorem 4.4, we obtain our final error estimate.

THEOREM 5.3. *There exist positive constants C_ν and C'_ν, depending only on c^*, ν, and Ω_1, $\Omega_2, \ldots, \Omega_n$, such that*

$$\begin{aligned} k^{1/2}\|\varphi - \varphi_N\|_2 &\leq C_s C_\nu u_M \frac{n^{1/2}(1 + \log(k\bar{L}/c^*))^{1/2}}{N^{\nu+1}} \\ &\leq C_s C'_\nu u_M \frac{(n[1 + \log(k\bar{L}/c^*)])^{\nu+3/2}}{M_N^{\nu+1}} \end{aligned} \tag{5.5}$$

for $N \geq N^*$, where N^* and C_s are as defined in Theorem 5.2.

Note that we will take $c^* = 2\pi$ and $\eta = k$ in all our numerical calculations in the next section. Note also that, while the constants C_ν and C'_ν, from the best approximation theorem, Theorem 4.4, depend only on c^*, ν, and the corner angles of Γ, the numbers N^* and C_s depend additionally on k, L_1, $L_2, \ldots, L_n$, and η. We do not attempt the difficult task of elucidating this dependence in this paper. We note only that, very recently, for the boundary integral equation formulation (2.9) applied to scattering by a circle, Domínguez, Graham, and Smyshlyaev [28] have shown that $\mathcal{I} + \mathcal{K}$ is elliptic if $\eta = \pm k$ and k is sufficiently large, so that every Galerkin method is automatically stable; specifically, (5.3) holds for every N^* if P_N is the orthogonal projection from $L^2(0, L)$ onto the Galerkin approximation space. Further it follows from results in [28] that, at worst, $C_s = O(k^{1/3})$ as $k \to \infty$ in the circle case. Our numerical results in section 6 will suggest the stronger result that for our particular scheme and geometry, the bound of Theorem 5.3 holds with a constant C_s independent of k. We recall from section 2 (2.12) that it has been shown that the corresponding continuous continuity constant $C_S = O(1)$ as $k \to \infty$ if the choice $\eta = k$ is made.

Of course our aim in approximating φ by φ_N is to approximate $\partial_{\mathbf{n}}^+ u$ and hence, via (2.7), the solution u of the scattering problem. Clearly, from (3.8) and (4.2), an approximation to $\partial u / \partial \mathbf{n}$ is

$$\frac{\partial u}{\partial \mathbf{n}}(\mathbf{x}(s)) \approx k(\Psi(s) + \varphi_N(s)), \quad 0 \leq s \leq L.$$

Using this approximation in (2.7), we conclude that

$$u(\mathbf{x}) \approx u_N(\mathbf{x}) := u^i(\mathbf{x}) - k \int_0^L \Phi(\mathbf{x}, \mathbf{x}(s))[\Psi(s) + \varphi_N(s)]\, \mathrm{d}s, \quad \mathbf{x} \in D. \tag{5.6}$$

Theorem 5.3 implies the following error estimate.

THEOREM 5.4. *There exist positive constants C_ν and C'_ν, depending only on c^*, ν, and Ω_1, $\Omega_2, \ldots, \Omega_n$, such that*

$$\frac{\sup_{\mathbf{x}\in D}|u(\mathbf{x})-u_N(\mathbf{x})|}{\sup_{\mathbf{x}\in D}|u(\mathbf{x})|} \le C_s C_\nu \frac{n(1+\log(k\bar{L}/c^*))}{N^{\nu+1}} \le C_s C'_\nu \frac{(n[1+\log(k\bar{L}/c^*)])^{\nu+2}}{M_N^{\nu+1}}$$

for $N \ge N^*$, where N^* and C_s are as defined in Theorem 5.2.

Proof. From (2.7) and (5.6),

$$\begin{aligned}
|u(\mathbf{x})-u_N(\mathbf{x})| &= k\left|\int_0^L \Phi(\mathbf{x},\mathbf{x}(s))\,[\varphi(s)-\varphi_N(s)]\,\mathrm{d}s\right| \\
&\le \frac{k}{4}\left\{\int_0^L |H_0^{(1)}(k|\mathbf{x}-\mathbf{x}(s)|)|^2\,\mathrm{d}s\right\}^{1/2} \|\varphi-\varphi_N\|_2 \\
&\le \frac{k}{4}\left\{2\sum_{j=1}^{n}\int_0^{L_j/2} |H_0^{(1)}(kt)|^2\,\mathrm{d}t\right\}^{1/2} \|\varphi-\varphi_N\|_2 \\
&\le C_\nu k^{1/2} n^{1/2}(1+\log(k\bar{L}/c^*))^{1/2}\|\varphi-\varphi_N\|_2,
\end{aligned}$$

where we have used that $|H_0^{(1)}(t)|$ is a monotonic decreasing function of t on $(0,\infty)$ and that $|H_0^{(1)}(t)| = O(t^{-1/2})$ as $t \to \infty$ (see e.g., [2]). The result now follows from Theorem 5.3. ∎

6. Numerical results. There has been much work on the optimal choice of the parameter η in (2.9) (see, e.g., [3, 43]). Here we choose $\eta = k$ as in [28]. We also set $c^* = 2\pi$ and restrict attention to the case $\nu = 0$. For higher values of ν the implementation of the scheme is similar. Note that, with $c^* = 2\pi$ and $\nu = 0$, there are approximately N degrees of freedom used to represent the solution in the first wavelength on each side adjacent to a corner.

The equation we wish to solve is (5.1) with $\nu = 0$. Writing φ_N as a linear combination of the basis functions of $V_{\Gamma,0}$, we have

$$\varphi_N(s) = \sum_{j=1}^{M_N} v_j \rho_j(s), \quad 0 \le s \le L,$$

where ρ_j is the jth basis function and M_N is the dimension of $V_{\Gamma,0}$. For $p = 1, \ldots, n$, where n is the number of sides of the polygon, we define $n_p^\pm$ to be the number of points in the mesh $\Gamma_p^\pm$, so that $n_p^+ = N + N_{L_p,q_p}$, $n_p^- = N + N_{L_p,q_{p+1}}$, and we denote the points of the mesh $\Gamma_p^\pm$ by $s_{p,l}^\pm$ for $l = 1, \ldots, n_p^\pm$, with $s_{p,1}^\pm < \cdots < s_{p,n_p^\pm}^\pm$. Setting $n_1 := 0$, $n_p := \sum_{j=1}^{p-1}(n_j^+ + n_j^-)$ for $p = 2, \ldots, n-1$, we define, for $p = 1, \ldots, n$,

$$\rho_{n_p+j}(s) := \begin{cases} \mathrm{e}^{\mathrm{i}ks}\chi_{(s^+_{p,j-1},s^+_{p,j})}(s)/\sqrt{s^+_{p,j}-s^+_{p,j-1}}, & j = 1, \ldots, n_p^+, \\ \mathrm{e}^{-\mathrm{i}ks}\chi_{(s^-_{p,j-1},s^-_{p,j})}(s)/\sqrt{s^-_{p,j}-s^-_{p,j-1}}, & j = n_p^+ + 1, \ldots, n_p^+ + n_p^-, \end{cases}$$

where $\chi_{(y_1,y_2)}$ denotes the characteristic function of the interval (y_1, y_2). From (4.15), $M_N = \sum_{j=1}^{n}(n_j^+ + n_j^-) < 2nN(3/2 + \log(k\bar{L}/c^*))$.

Equation (5.1) with $\nu = 0$ is equivalent to the linear system

$$\sum_{j=1}^{M_N} v_j((\rho_j, \rho_m) + (K\rho_j, \rho_m)) = (F, \rho_m), \quad m = 1, \ldots, M_N. \tag{6.1}$$

In order to set up this linear system we need to determine the integrals (ρ_j, ρ_m), $(K\rho_j, \rho_m)$, and (F, ρ_m). We note that many of the integrals $(K\rho_j, \rho_m)$ and (F, ρ_m) are highly oscillatory; in particular, all these integrals become highly oscillatory in the limit as $k \to \infty$ with N fixed. The efficient calculation of these integrals is an aspect of the numerical scheme which requires further research, as discussed in section 1.2. But note that explicit formulae for the analytic evaluation of some of these integrals, and a consideration of the quadrature techniques required to evaluate the rest of them numerically, are presented in [44].

Another important issue is the conditioning of the linear system. Standard analysis of the Galerkin method for second kind equations [7] implies that, where $M := [(\rho_j, \rho_m)]$ is the mass matrix (which is necessarily Hermitian and positive definite) and $A = [(\rho_j, \rho_m) + (K\rho_j, \rho_m)]$ is the whole matrix, it holds that $\mathrm{cond}_2 A \le C_s \mathrm{cond}_2 M$, where C_s is defined by (5.3). Thus Theorem 5.2 implies that $\mathrm{cond}_2 A$ is bounded as $N \to \infty$ if the mass matrix is well conditioned. Unfortunately, it appears that, as $N \to \infty$ with k fixed, M must ultimately become badly conditioned. However, the results below will show only moderate condition numbers of A even for large values of N (see Table 6.1). More positively, in the limit as $k \to \infty$ with N fixed, $\mathrm{cond}_2 M \to 1$. To see this we observe that if (ρ_j, ρ_m) is a nonzero off-diagonal element of the mass matrix (in which case the supports of ρ_j and ρ_m are overlapping subintervals of the meshes Γ_p^+ and Γ_p^- for some side p), it holds that $|(\rho_j, \rho_m)| = |\sin(ko)|\sqrt{o/(kS_1S_2)}$, where S_1 and S_2 are the lengths of the two subintervals, and o is the length of the overlap.

As a numerical example, we consider the problem of scattering by a square with sides of length 2π. In this case $n = 4$ and $\Omega_j = 3\pi/2$, $j = 1, 2, 3, 4$. The corners of the square are $P_1 := (0, 0)$, $P_2 := (2\pi, 0)$, $P_3 := (2\pi, 2\pi)$, $P_4 := (0, 2\pi)$, and the incident angle is $\theta = \pi/4$, so the incident field is directed towards P_4, with P_2 in shadow (as shown in Figure 6.1, where the total acoustic field is plotted for $k = 10$).

In Figure 6.2 we plot $|\varphi_N(s)|$ against s for $k = 10$ and $N = 4, 16, 64, 256$. As we expect, $|\varphi_N(s)|$ is highly peaked at the corners of the polygon, $s = 0$, 2π, 4π, 6π and 8π (which is the same corner as $s = 0$), where $\varphi(s)$ is infinite. Except at these corners, $|\varphi_N(s)|$ appears to be converging pointwise as N increases. (We do not plot $\varphi_N(s)$ itself, which is highly oscillatory.)

In order to test the convergence of our scheme, we take the "exact" solution to be that computed with a large number of degrees of freedom, namely with $N = 256$. For $k = 5$ and $k = 320$ the relative L^2 errors $\|\varphi_N - \varphi_{256}\|_2 / \|\varphi_{256}\|_2$ are shown in Table 6.1 (all L^2 norms are computed by approximating by discrete L^2 norms, sampling at 100000 evenly spaced points around the boundary of the square). For this example, Theorem 5.3 predicts that for $N \ge N^*$, $\|\varphi - \varphi_N\|_2 \le CN^{-1}$, where C is a constant. Thus Theorem 5.3 predicts that for $N > N^*$, the average rate of convergence is

$$EOC := \frac{\log(\|\varphi - \varphi_N\|_2 / \|\varphi - \varphi_{N^*}\|_2)}{\log(N/N^*)} \ge 1 - \frac{\hat{C}}{\log(N/N^*)} \sim 1$$

as $N \to \infty$, where $\hat{C} := \log(\|\varphi - \varphi_N\|_2 / C)$. This behavior is clearly seen in the EOC

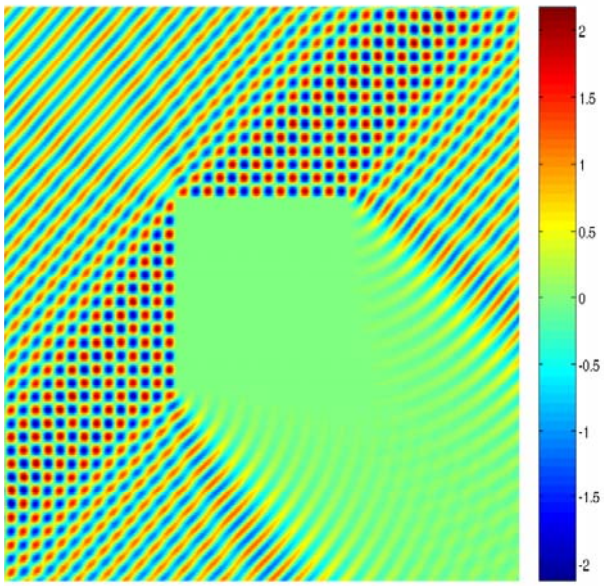

FIG. 6.1. *Total acoustic field, scattering by a square, $k = 10$. Incident field is directed from the top left corner towards the bottom right corner.*

values (defined with $N^* = 8$) in Table 6.1 for both values of k. We also show in Table 6.1 the 2 norm condition number, $\mathrm{cond}_2 A$, of the matrix $A = [(\rho_j, \rho_m) + (K\rho_j, \rho_m)]$ for each example. Unlike methods where the approximation space is formed by multiplying standard finite element basis functions by many plane waves travelling in a large number of directions [27, 53, 37], the condition number does not grow signifi-

cantly as the number of degrees of freedom increases.

In Table 6.2 we fix $N = 64$ and show $\|\varphi_{64}-\varphi_{256}\|_2/\|\varphi_{256}\|_2$ and $k^{1/2}\|\varphi_{64}-\varphi_{256}\|_2$ for increasing values of k. Both measures of errors remain approximately constant in magnitude as k increases. Recall that, keeping N fixed as k increases corresponds to keeping the number of degrees of freedom per wavelength fixed near each corner and increasing the total number of degrees of freedom, M_N, approximately in proportion to $\log(k\bar{L})$. Thus these results are consistent with the approximation error estimate of Theorem 4.2 which suggests that increasing M_N proportional to $\log^{3/2}(k\bar{L})$ is enough to keep the error bounded; indeed these results are suggestive that the bound (5.5) in the Galerkin error estimate, Theorem 5.3, holds with a constant C_s which is independent of k. Note that the condition number of the coefficient matrix A only increases modestly as k increases, and is approximately constant for $k \geq 40$.

In Table 6.3 we show numerical convergence of the total field $u_N(\mathbf{x})$ at the three

points $\mathbf{x} = (-\pi, 3\pi)$ (illuminated), $\mathbf{x} = (3\pi, 3\pi)$, and $\mathbf{x} = (3\pi, -\pi)$ (shadow), for $k = 5$ and $k = 320$. The errors are consistent with the estimate of Theorem 5.4. As might be expected for the computation of linear functionals of φ_N, the relative errors in Table 6.3 are a lot smaller and converge to zero more rapidly than the relative errors in the computation of the boundary data in Tables 6.1 and 6.2.

7. Conclusions. In this paper we have described a novel Galerkin boundary integral equation method for solving problems of high frequency scattering by convex polygons. In section 2, building on previous results for Lipschitz domains [56, 48, 50, 49], we have shown that the standard second kind boundary integral equations for the exterior Dirichlet problem for the Helmholtz equation are well-posed for general Lipschitz domains in a scale of Sobolev spaces. We have understood very completely in section 3 the oscillatory behavior of the normal derivative of the field on the boundary of the polygon. We have then used this understanding to design an optimal graded mesh for approximation of the diffracted field by products of piecewise polynomials and plane waves. Our error analysis demonstrates that the number of degrees of freedom required to achieve a prescribed level of accuracy using the best approximation to the solution from the approximation space grows only logarithmically with respect to the wave number k as $k \to \infty$. Numerical experiments indicate that the same statement holds for the Galerkin approximation from the same approximation space. However, while we have established that the error in the Galerkin approximation space is bounded by the stability constant C_s times the best approximation error, our Theorem 5.3 holds only for a sufficiently refined mesh and we have not established a bound on C_s which is independent of k, to mirror the recently established bound (2.12) on the corresponding continuous stability constant.

There are very many open problems in extending the results of this paper to more general scatterers. In this extension we expect that our mesh design and parts of our analysis will have relevance for representing certain components of the total field. For example, in the case of 2D convex curvilinear polygons, something close to the mesh grading we use may be appropriate on each side of the polygon, especially at higher frequencies when the waves diffracted by the corners become more localized near the corners. In the case of three-dimensional scattering by convex polyhedra, it seems to us that the mesh we propose may be useful in representing the variation of edge scattered waves in the direction perpendicular to the edge.

Acknowledgments. The authors gratefully acknowledge helpful discussions with Markus Melenk (Vienna) and Johannes Elschner (WIAS, Berlin) and the helpful comments of the anonymous referees.

CONVERGENCE OF ADAPTIVE DISCONTINUOUS GALERKIN APPROXIMATIONS OF SECOND-ORDER ELLIPTIC PROBLEMS*

OHANNES A. KARAKASHIAN† AND FREDERIC PASCAL‡

Abstract. A residual-type a posteriori error estimator is introduced and analyzed for a discontinuous Galerkin formulation of a model second-order elliptic problem with Dirichlet–Neumann-type boundary conditions. An adaptive algorithm using this estimator together with specific marking and refinement strategies is constructed and shown to achieve any specified error level in the energy norm in a finite number of cycles. The convergence rate is in effect linear with a guaranteed error reduction at every cycle. Results of numerical experiments are presented.

Key words. discontinuous Galerkin methods, a posteriori estimates, convergence of adaptive methods

1. Introduction.

Let $\Omega \subset \mathbf{R}^d$, $d = 2, 3$, be a bounded open polyhedral domain. We consider the following boundary value problem:

$$-\Delta u = f \quad \text{in } \Omega, \tag{1.1}$$

$$u = g_D \quad \text{on } \Gamma_D, \tag{1.2}$$

$$\nabla u \cdot n = g_N \quad \text{on } \Gamma_N, \tag{1.3}$$

where $\partial\Omega := \Gamma = \Gamma_D \cup \Gamma_N$ and n is the unit normal vector exterior to Ω. We assume that Γ_D has positive measure, $f \in L^2(\Omega)$, $g_N \in L^2(\Gamma_N)$. Assumptions on f, g_D, and g_N are given later.

Recently there has been a flurry of activity concerning a posteriori error estimates for the discontinuous Galerkin (DG) method for elliptic as well as other problems. In [7], Becker, Hansbo, and Larson use a Helmholtz-type decomposition of the error to derive estimates in the energy norm. Bustinza, Gatica, and Cockburn [11] use a similar technique to derive estimates for linear and nonlinear elliptic problems for the local discontinuous Galerkin (LDG) method. (See also the article by Castillo [12] in the same issue.) Creusé and Nicaise [13] consider the interesting issue of anisotropic elements, i.e., those with large aspect ratio, in the context of the stationary Stokes problem. Houston, Schötzau, and Wihler [15] derive energy norm a posteriori estimates for the hp-version of the DG method for elliptic problems. The fact that the penalty parameter γ appears with a different exponent in their a posteriori estimates provides an interesting alternative to ours. We also mention [21] and [16] for L^2-norm or functional error estimation for the DG method.

In [17] we presented residual-type a posteriori estimates in the energy norm for DG approximations of a special case of the boundary value problem (1.1)–(1.3) corresponding to $\Gamma_D = \Gamma$ and $g_D = 0$. In the present work, we extend these estimates to encompass the more general mixed boundary conditions (1.2), (1.3), continuing

work already begun in [18]. These estimates are used to provide a mesh modification strategy which is then shown to be convergent in the energy norm induced by the bilinear form defining the DG method.

The principal goal of an adaptive algorithm is to achieve a user specified error level in a finite number of cycles. While it is typical for the error to be measured in the energy norm ($\|\nabla e\|$ for the standard Galerkin method for second-order elliptic problems, and an appropriate energy norm for the DG method), other interesting and useful measures of the error, "quantities of interest" (QOI), are emerging; see, e.g., [8]. To date, however, no convergence results are known except with respect to the energy norm, given that the proofs make use in an essential way of an orthogonality relation and such relations are not known for other QOI's.

A typical cycle consists of the following basic steps: (1) Given a mesh $\mathcal{T}_H$, calculate the approximation on this mesh. (2) Estimate the error of the approximation at hand using an error estimator. (3) Refine/coarsen $\mathcal{T}_H$ using the information to obtain a new mesh $\mathcal{T}_h$.

The rigorous treatment of the convergence of adaptive algorithms for elliptic problems can be said to have started with the paper of Babuşka and Vogelius [4] where a detailed treatment of the one-dimensional case was given. In 1996 Dörfler [14] gave a convergence proof for the two-dimensional case for the standard Galerkin method using linear elements while outlining an extension to quadratic elements. One of the highlights of this work is that bounds on the convergence rate were provided, which was not the case for [4]. On the other hand, the initial mesh had to be fine enough to essentially resolve the solution. The latter issue provided the starting point for the work of Morin, Nochetto, and Siebert [19], [20], who introduced the concept of *data oscillation* $osc(f, \mathcal{T}_H) = (\sum_{K\in\mathcal{T}_H} \|H(f - f_K)\|^2)^{1/2}$ to circumvent this requirement. The nagging issue of calculating this quantity accurately on a coarse mesh is not resolved and should be treated within the larger and important framework of accounting for the quadrature errors arising from the implementation of the finite element formulation as well as from the calculation of certain terms in the a posteriori estimators. More recently, Binev, Dahmen, and DeVore [9] have proposed a modification of the algorithm in [20] that incorporates coarsening to prove optimal work estimates. More specifically, they have shown that if the solution u can be approximated by a piecewise linear function to an accuracy of $O(n^{-s})$ on a triangulation with n cells, then the algorithm constructs an approximation with the same asymptotic accuracy at a cost of $O(n)$ arithmetic operations.

In this paper we take up the issue of convergence of an adaptive algorithm in the context of a DG formulation for the problem (1.1)–(1.3). The specific DG method used is of an interior penalty type that can be traced to the work of [5] and [2]. We refer to [3] for a survey and unified view of DG methods. Our main result can be summarized as follows: With $a_h^\gamma(\cdot,\cdot)$, $h > 0$, denoting the bilinear form associated with the DG formulation of the problem, we have $a_h^\gamma(e_h, e_h) \le \rho a_H^\gamma(e_H, e_H)$, $\rho < 1$. The principal assumptions which enable this result are the following:

(i) The data of the problem f, g_D, g_N belong to the same polynomial spaces which contain the numerical solution.
(ii) The mesh $\mathcal{T}_h$ is not too fine with respect to the mesh $\mathcal{T}_H$.
(iii) The penalty parameter is not too small; specifically, it must be larger than a constant depending only on the minimum angle of the triangles and the degree of the polynomials in the discontinuous finite element spaces.
(iv) While the marking strategy used is the one used by Dörfler, the refinement strategy is designed to accommodate the DG approach.

While the assumption on the data of the problem may seem to be restrictive, we should note that for one there are practically important cases satisfying these assumptions, e.g., piecewise constant data. Another mitigating argument is that the numerical integration rules cannot distinguish between the data functions and their Lagrange interpolants. Therefore, these assumptions can be relaxed in tandem with an effort to take into account the effect of numerical integration.

The paper is organized as follows. Section 2 is devoted to preliminaries. In addition to establishing notation, we quote a result whose details can be found in [17] and [18] concerning the approximation of discontinuous piecewise polynomial functions by continuous functions of the same type. This result has so far played a key role in the a posteriori estimates as well as in the convergence proof. Section 3 is devoted to the derivation of the residual-type a posteriori estimates extending the results of [17] to include the more general mixed boundary conditions (1.2), (1.3). A novel contribution is estimate (3.12) (Theorem 3.2(iv)). It completes the a posteriori error estimates of [17] by providing lower bounds for the gradients of the error. That the jump terms in (3.12) are multiplied by γ^2 is significant in that γ appears with exponent one in the bilinear form. Interestingly, this fact plays an important role in the proof of convergence of the adaptive algorithm. In section 4 we outline the marking and refinement strategies and prove convergence of the adaptive scheme. It is worth noting that the analysis of the DG formulation presents some complications not present in the standard method. One is due to the fact that the energy norm is mesh dependent. Another more basic one is due to the fact that the bilinear form which defines the method is not coercive on the energy space. Both issues are successfully resolved. Let us also note that while the marking and refinement strategies are couched in two dimensions, we believe that appropriate modifications can be introduced to obtain convergence in three dimensions as well. In particular, only the refinement strategy, Lemma 4.1, and Corollary 4.1 need be extended. Finally, in section 5 we present the results of some numerical experiments.

2. Preliminaries.

2.1. Notation. For a domain $D \subseteq \mathbf{R}^d$ and integer $m \geq 0$, $H^m(D)$ will denote the (Hilbert) Sobolev space with inner product $(u,v)_{m,D} = \sum_{|\alpha|\leq m} \int_D D^\alpha u\, D^\alpha v\, dx$ and norm $\|u\|_{m,D} = (u,u)_{m,D}^{1/2}$ (cf. [1]). To simplify the notation, we shall drop m when its value is zero. Also, we shall often encounter functions that vanish on Γ_D, and thus we let $H^1_{0,\Gamma_D} = \{v \in H^1(\Omega),\ v = 0 \text{ on } \Gamma_D\}$.

Extensive use will be made of edge/surface integrals. Therefore, for a $(d-1)$-dimensional subset e of $\mathbf{R}^d$, we set $\langle u, v\rangle_e = \int_e u\, v\, ds$ and $|u|_e = \langle u, u\rangle_e^{1/2}$.

2.2. Triangulations. Let $\mathcal{T}_h = \{K_i : i = 1, 2, \ldots, m_h\}$ be a family of star-like partitions (triangulations) of the domain Ω parametrized by $0 < h \leq 1$. We assume the following:

(i) The elements of $\mathcal{T}_h$ satisfy the minimal angle condition.

(ii) $\mathcal{T}_h$ is locally quasi-uniform; that is, if two elements K_j and K_ℓ are adjacent in the sense that $\mu_{d-1}(\partial K_j \cap \partial K_\ell) > 0$, then $\mathrm{diam}(\mathrm{K_j}) \approx \mathrm{diam}(\mathrm{K}_\ell)$.

We define $\mathcal{E}_h^I$ and $\mathcal{E}_h^B$ to be the set of all interior and boundary edges (faces in the case $d = 3$), respectively, as follows:

$$\mathcal{E}_h^I = \{e = \partial K_j \cap \partial K_\ell, \quad \mu_{d-1}(\partial K_j \cap \partial K_\ell) > 0\},$$
$$\mathcal{E}_h^B = \{e = \partial K \cap \partial\Omega, \quad \mu_{d-1}(\partial K \cap \partial\Omega) > 0\}, \qquad \mathcal{E}_h = \mathcal{E}_h^I \cup \mathcal{E}_h^B.$$

For each $e \in \mathcal{E}_h^I$, we denote the two triangles that "share" it by K^+ and K^-, respectively. Which of the two is K^+ is completely arbitrary but not irrelevant! If $e \in \mathcal{E}_h^B$, then $e = \partial K^+ \cap \partial\Omega \equiv \partial K \cap \partial\Omega$.

We assume that for each $e \in \mathcal{E}_h^B$, either $e \subset \Gamma_D$ or $e \subset \Gamma_N$. We then set $\mathcal{E}_h^B = \mathcal{E}_h^D \cup \mathcal{E}_h^N$, where $\mathcal{E}_h^D$ and $\mathcal{E}_h^N$ are, respectively, the set of boundary edges on Γ_D and on Γ_N. From the previous assumption, we have $\mathcal{E}_h^D \cap \mathcal{E}_h^N = \emptyset$.

Given a partition or mesh $\mathcal{T}_h$ of Ω, we find it convenient to use the spaces $H^m(\mathcal{T}_h) = \Pi_{K\in\mathcal{T}_h} H^m(K)$. In this context we consider K to be open so that elements of $H^m(\mathcal{T}_h)$ are single-valued. In particular, the "energy space" for the DG method for this problem will be $E_h = H^2(\mathcal{T}_h)$.

We shall also use the discontinuous finite element spaces $V_h^r = \Pi_{K\in\mathcal{T}_h} P_{r-1}(K)$, $r \geq 2$, where $P_k(K)$ is the space of polynomials of total degree k defined on K.

It is essential to be able to define values of functions in $H^m(\mathcal{T}_h)$ and V_h^r on the edges e. Thus, for $v \in H^m(\mathcal{T}_h)$, $m \geq 1$, and $e \in \mathcal{E}_h^I \cup \mathcal{E}_h^B$, v_e^+ will denote the trace on e of the restriction v^+ of v to K^+. Similarly we define v_e^- for $e \in \mathcal{E}_h^I$.

We also define *jumps* and *averages* of such traces as follows:

$$[v] = v_e^+ - v_e^-,\ e \in \mathcal{E}_h^I, \qquad [v] = v_e^+,\ e \in \mathcal{E}_h^B,$$
$$\{v\} = \tfrac{1}{2}\big(v_e^+ + v_e^-\big),\ e \in \mathcal{E}_h^I, \qquad \{v\} = v_e^+,\ e \in \mathcal{E}_h^B.$$

Finally, for $v \in H^2(\mathcal{T}_h)$ we let $\{\partial_n v\} = \frac{1}{2}\big(\nabla v^+ + \nabla v^-\big)\cdot \mathbf{n}^+$, $e \in \mathcal{E}_h^I$, where $\mathbf{n}^+$ is the unit outward normal to K^+ and $[\partial_n v] = \nabla v^+ \cdot \mathbf{n}^+ - \nabla v^- \cdot \mathbf{n}^+$, $e \in \mathcal{E}_h^I$.

2.3. Some useful results. We shall make frequent use of the following trace and inverse inequalities (cf. [10], [17]):

$$|v|_{\partial D}^2 \leq c\left(h_D^{-1}\|v\|_D^2 + h_D\|\nabla v\|_D^2\right) \quad \forall v \in H^1(D), \tag{2.1}$$

where $h_D = \operatorname{diam}(D)$;

$$|v|_{j,D} \leq c h_D^{i-j}|v|_{i,D} \quad \forall v \in P_k(D),\ 0 \leq i \leq j \leq 2. \tag{2.2}$$

We shall also make essential use of the fact that an element of V_h^r can be approximated by *continuous* piecewise polynomial functions, specifically by elements of $V_h^r \cap H^1(\Omega)$; the degree of approximation being controlled, not surprisingly, by the jumps of the discontinuous function. Here we extend the result established in [17] to allow approximation by functions that also satisfy Dirichlet-type conditions on the boundary. We also include a significant observation that the approximation result holds in the L^2-norm as well. We omit the proof since its essential points were provided in [17] and [18].

THEOREM 2.1. *Let $\mathcal{T}_h$ be a conforming or nonconforming mesh consisting of triangles when $d = 2$, and tetrahedra when $d = 3$. Then for any $v_h \in V_h^r$ and multi-index α with $|\alpha| = 0, 1$ the following approximation results hold:*

(i) *Let g be the restriction to Γ of a function in $V_h^r \cap H^1(\Omega)$. Then there exists $\chi \in V_h^r \cap H^1(\Omega)$ satisfying $\chi\big|_\Gamma = g$ and*

$$\sum_{K\in\mathcal{T}_h} \|D^\alpha(v_h - \chi)\|_K^2 \leq c\left(\sum_{e\in\mathcal{E}_h^I} h_e^{1-2|\alpha|}|[v_h]|_e^2 + \sum_{e\in\mathcal{E}_h^B} h_e^{1-2|\alpha|}|v_h - g|_e^2\right). \tag{2.3}$$

(ii) *Let g be the restriction to Γ_D of a function in $V_h^r \cap H^1(\Omega)$. Then there exists $\chi \in V_h^r \cap H^1(\Omega)$ satisfying $\chi\big|_{\Gamma_D} = g$ and*

(2.4)
$$\sum_{K\in\mathcal{T}_h} \|D^\alpha(v_h-\chi)\|_K^2 \le c\left(\sum_{e\in\mathcal{E}_h^I} h_e^{1-2|\alpha|}|[v_h]|_e^2 + \sum_{e\in\mathcal{E}_h^D} h_e^{1-2|\alpha|}|v_h-g|_e^2\right).$$

(iii) *There exists $\chi \in V_h^r \cap H^1(\Omega)$ satisfying*

$$\sum_{K\in\mathcal{T}_h} \|D^\alpha(v_h-\chi)\|_K^2 \le c\sum_{e\in\mathcal{E}_h^I} h_e^{1-2|\alpha|}|[v_h]|_e^2 \tag{2.5}$$

for some constant C independent of h and v_h but which may depend on r and the minimal angle θ_0 of the triangles in $\mathcal{T}_h$.

REMARK 2.1. *The proof of this result is constructive and is based on an averaging process. It should also hold for more general partitions of Ω such as quadrilaterals and parallelepipeds.*

3. A posteriori error estimates.

3.1. The discrete problem. In order to construct a weak formulation for the problem (1.1)–(1.3), we introduce the bilinear form $a_h^\gamma : E_h \times E_h \to \mathbf{R}$:

$$a_h^\gamma(u,v) = \sum_{K\in\mathcal{T}_h} (\nabla u, \nabla v)_K - \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \Big(\langle\{\partial_n u\},[v]\rangle_e + \langle\{\partial_n v\},[u]\rangle_e - \gamma h_e^{-1}\langle[u],[v]\rangle_e\Big),$$

where $h_e = \operatorname{diam}(e)$ and γ is the interior penalty parameter. We point out that we have adopted the averaged value $\{\partial_n v\}_e$ of the normal derivatives attributed to Arnold [2]. The results of this paper also apply to the so-called Baker formulation for which $\{\partial_n v\} = \nabla v^+ \cdot \mathbf{n}^+$.

The bilinear form a_h^γ is consistent with the BVP (1.1)–(1.3) in the following sense: If $u \in H^2(\Omega)$ satisfies (1.1)–(1.3), then

$$a_h^\gamma(u,v) = F(v) := (-\Delta u, v)_\Omega - \sum_{e\in\mathcal{E}_h^D} \left\langle u, \partial_n v - \gamma h_e^{-1} v\right\rangle_e + \sum_{e\in\mathcal{E}_h^N} \langle \partial_n u, v\rangle_e \quad \forall v \in E_h.$$

Thus, we define the DG approximation u_h^γ of the solution u of the BVP (1.1)–(1.3) as the element of V_h^r that satisfies

$$a_h^\gamma(u_h^\gamma, v) = F(v) \quad \forall v \in V_h^r. \tag{3.1}$$

We thus have the orthogonality relation

$$a_h^\gamma(u-u_h^\gamma, v) = 0 \quad \forall v \in V_h^r, \tag{3.2}$$

which will play an important role in the derivation of the a posteriori estimates as well as the proof of the convergence of the adaptive scheme.

Concerning the continuity and coercivity of the form a_h^γ, we can prove the following result.

LEMMA 3.1. (i)

$$|a_h^\gamma(u,v)| \le 2\|u\|_{1,h}\|v\|_{1,h} \qquad \forall u, v \in E_h.$$

(ii) *There exist positive constants* γ_0 *and* c_a *such that for all* $\gamma \geq \gamma_0$

$$a_h^\gamma(v,v) \geq c_a \|v\|_{1,h}^2 \qquad \forall v \in V_h^r,$$

where

$$\|v\|_{1,h} = \left(\sum_{K\in\mathcal{T}_h} \|\nabla v\|_K^2 + \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \left(h_e \left|\{\partial_n v\}\right|_e^2 + \gamma h_e^{-1} |[v]|_e^2 \right) \right)^{1/2}.$$

Let us mention here that γ_0 depends only on r and θ_0. Also, the proof of (i) is merely an application of the Cauchy–Schwarz inequality. To prove (ii), we have to use the trace and inverse inequalities (2.1), (2.2).

3.2. A residual-type a posteriori estimate. This section is devoted to the generalization of the residual-type a posteriori estimates given in [17]. The estimators as well as the exposition follow the lines found in Verfürth [23], with the exception of the technical details stemming from the discontinuous nature of V_h^r.

THEOREM 3.1. *Suppose that* g_D *in* (1.2) *is the restriction to* Γ_D *of a function in* $V_h^r \cap H^1(\Omega)$. *Then with* $e = u - u_h^\gamma$ *there holds*

$$\sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 \leq c \Bigg\{ \sum_{K\in\mathcal{T}_h} h_K^2 \|f + \Delta u_h^\gamma\|_K^2 + \sum_{e\in\mathcal{E}_h^I} h_e \left|\left[\partial_n u_h^\gamma\right]\right|_e^2 + \sum_{e\in\mathcal{E}_h^N} h_e \left|g_N - \partial_n u_h^\gamma\right|_e^2$$

$$+ \gamma^2 \sum_{e\in\mathcal{E}_h^I} h_e^{-1} \left|[u_h^\gamma]\right|_e^2 + \gamma^2 \sum_{e\in\mathcal{E}_h^D} h_e^{-1} \left|g_D - u_h^\gamma\right|_e^2 \Bigg\}. \tag{3.3}$$

In particular, the constant c *is independent of the meshsize and* γ.

Proof. Integrating by parts, we obtain

$$\sum_{K\in\mathcal{T}_h} (\nabla e, \nabla\eta)_K = \sum_{K\in\mathcal{T}_h} (f + \Delta u_h^\gamma, \eta)_K + \sum_{e\in\mathcal{E}_h^I} \left(\langle \{\partial_n e\}, [\eta] \rangle_e + \langle \{\eta\}, [\partial_n e] \rangle_e \right)$$

$$+ \sum_{e\in\mathcal{E}_h^D} \langle \partial_n e, \eta \rangle_e + \sum_{e\in\mathcal{E}_h^N} \langle \partial_n e, \eta \rangle_e \quad \forall \eta \in H^1(\mathcal{T}_h). \tag{3.4}$$

Letting $\eta = e - v_h$, where v_h is piecewise constant on $\mathcal{T}_h$, we have

$$\sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 = \sum_{K\in\mathcal{T}_h} (f + \Delta u_h^\gamma, \eta)_K - \sum_{e\in\mathcal{E}_h^I} \left(\langle \{\partial_n e\}, [u_h^\gamma + v_h] \rangle_e + \langle \{\eta\}, [\partial_n u_h^\gamma] \rangle_e \right)$$

$$- \sum_{e\in\mathcal{E}_h^D} \langle \partial_n e, u_h^\gamma + v_h - g_D \rangle_e + \sum_{e\in\mathcal{E}_h^N} \langle g_N - \partial_n u_h^\gamma, \eta \rangle_e. \tag{3.5}$$

Now, from the orthogonality relation (3.2), for all χ in $V_h^r \cap H^1(\Omega)$ with $\chi\big|_{\Gamma_D} = g_D$, we have

$$\begin{aligned}
0 &= a_h^\gamma(e, u_h^\gamma + v_h - \chi) \\
&= \sum_{K\in\mathcal{T}_h} (\nabla e, \nabla(u_h^\gamma - \chi))_K - \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle \{\partial_n (u_h^\gamma - \chi)\}, [e] \rangle_e \\
&\quad - \sum_{e\in\mathcal{E}_h^I} \langle \{\partial_n e\}, [u_h^\gamma + v_h] \rangle_e - \sum_{e\in\mathcal{E}_h^D} \langle \partial_n e, u_h^\gamma + v_h - g_D \rangle_e \\
&\quad + \sum_{e\in\mathcal{E}_h^I} \gamma h_e^{-1} \langle [e], [u_h^\gamma + v_h] \rangle_e + \sum_{e\in\mathcal{E}_h^D} \gamma h_e^{-1} \langle g_D - u_h^\gamma, u_h^\gamma + v_h - g_D \rangle_e.
\end{aligned}$$

Using this relation in (3.5) to eliminate the terms containing $\partial_n e$, we obtain

$$\begin{aligned}\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2 = &\sum_{K\in\mathcal{T}_h}(f+\Delta u_h^\gamma,\eta)_K - \sum_{K\in\mathcal{T}_h}(\nabla e,\nabla(u_h^\gamma-\chi))_K\\ &-\sum_{e\in\mathcal{E}_h^I}\Big(\langle\{\partial_n(u_h^\gamma-\chi)\},[u_h^\gamma]\rangle_e+\gamma h_e^{-1}\langle[u_h^\gamma],[\eta]\rangle_e+\langle\{\eta\},[\partial_n u_h^\gamma]\rangle_e\Big)\\ &+\sum_{e\in\mathcal{E}_h^D}\Big(\langle\partial_n(u_h^\gamma-\chi),g_D-u_h^\gamma\rangle_e+\gamma h_e^{-1}\langle g_D-u_h^\gamma,\eta\rangle_e\Big)\\ &+\sum_{e\in\mathcal{E}_h^N}\langle g_N-\partial_n u_h^\gamma,\eta\rangle_e\,. \end{aligned}\tag{3.6}$$

We now obtain bounds for the terms on the right-hand side of (3.6). Those that contain η are bounded by $\frac{1}{2}$ times,

$$\begin{aligned}&\frac{1}{\epsilon_1}\sum_{K\in\mathcal{T}_h}h_K^2\|f+\Delta u_h^\gamma\|_K^2+\frac{1}{\epsilon_2}\sum_{e\in\mathcal{E}_h^I}h_e\big|\big[\partial_n u_h^\gamma\big]\big|_e^2+\frac{1}{\epsilon_3}\gamma\sum_{e\in\mathcal{E}_h^I}h_e^{-1}|[u_h^\gamma]|_e^2\\ &+\frac{1}{\epsilon_4}\gamma\sum_{e\in\mathcal{E}_h^D}h_e^{-1}|g_D-u_h^\gamma|_e^2+\frac{1}{\epsilon_5}\sum_{e\in\mathcal{E}_h^N}h_e|g_N-\partial_n u_h^\gamma|_e^2\\ &+\epsilon_1\sum_{K\in\mathcal{T}_h}h_K^{-2}\|\eta\|_K^2+\epsilon_2\sum_{e\in\mathcal{E}_h^I}h_e^{-1}|\{\partial_n\eta\}|_e^2+\epsilon_3\gamma\sum_{e\in\mathcal{E}_h^I}h_e^{-1}|[\eta]|_e^2\\ &+\epsilon_4\gamma\sum_{e\in\mathcal{E}_h^D}h_e^{-1}|\eta|_e^2+\epsilon_5\sum_{e\in\mathcal{E}_h^N}h_e^{-1}|\eta|_e^2,\end{aligned}\tag{3.7}$$

for any $\epsilon_i>0$, $i=1,\dots,5$. To estimate the "η" terms in (3.7) we choose as v_h the best piecewise constant approximation of e that gives, using an approximation result of [6], the estimate

$$\|\eta\|_K\le ch_K\|\nabla e\|_K,\ K\in\mathcal{T}_h.$$

Since the mesh is locally quasi-uniform, using this approximation result and the trace inequality (2.1), we obtain

$$\begin{aligned}\sum_{K\in\mathcal{T}_h}h_K^{-2}\|\eta\|_K^2&\le c\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2,\\ \sum_{e\in\mathcal{E}_h^I}h_e^{-1}\left(|\{\partial_n\eta\}|_e^2+|[\eta]|_e^2\right)&\le c\sum_{e\in\mathcal{E}_h^I}\sum_{K=K^+,K^-}h_e^{-1}(h_K^{-1}\|\eta\|_K^2+h_K\|\nabla\eta\|_K^2)\\ &\le c\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2,\\ \sum_{e\in\mathcal{E}_h^B}h_e^{-1}|\eta|_e^2&\le c\sum_{e\in\mathcal{E}_h^B}\sum_{K=K^+}h_e^{-1}(h_K^{-1}\|\eta\|_K^2+h_K\|\nabla\eta\|_K^2)\\ &\le c\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2.\end{aligned}$$

We can now hide the "η" terms in the left-hand side of (3.6) by taking the ϵ's sufficiently small. In particular, we must take $\epsilon_3\approx 1/\gamma$ and $\epsilon_4\approx 1/\gamma$.

To obtain (3.3), we also need to estimate the terms containing $u_h^\gamma - \chi$. Indeed, these are bounded by

$$\epsilon \sum_{K\in\mathcal{T}_h} \|\nabla e\|_K^2 + \frac{1}{\epsilon}\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-\chi)\|_K^2 + \sum_{e\in\mathcal{E}_h^I} h_e\big|\{\partial_n(u_h^\gamma-\chi)\}\big|_e^2 + \sum_{e\in\mathcal{E}_h^I} h_e^{-1}|[u_h^\gamma]|_e^2 + \sum_{e\in\mathcal{E}_h^D} h_e\big|\partial_n(u_h^\gamma-\chi)\big|_e^2 + \sum_{e\in\mathcal{E}_h^D} h_e^{-1}|g_D-u_h^\gamma|_e^2. \tag{3.8}$$

Using the trace and inverse inequalities, we see that the two terms in (3.8) that contain $\partial_n(u_h^\gamma-\chi)$ are bounded by $\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-\chi)\|_K^2$. In view of Theorem 2.1(ii), the latter is bounded by $\sum_{e\in\mathcal{E}_h^I} h_e^{-1}\,|[u_h^\gamma]|_e^2 + \sum_{e\in\mathcal{E}_h^D} h_e^{-1}|g_D-u_h^\gamma|_e^2$. ∎

THEOREM 3.2. *The following estimates hold:*

(i) *Suppose that f is a piecewise polynomial on $\mathcal{T}_h$. Then for each $K\in\mathcal{T}_h$*

$$h_K^2\|f+\Delta u_h^\gamma\|_K^2 \le c\,\|\nabla e\|_K^2. \tag{3.9}$$

(ii) *For $e=\partial K^+\cap\partial K^-\in\mathcal{E}_h^I$,*

$$h_e\big|\big[\partial_n u_h^\gamma\big]\big|_e^2 \le c(\|\nabla e\|_{K^+}^2+\|\nabla e\|_{K^-}^2). \tag{3.10}$$

(iii) *Suppose that g_N is a piecewise polynomial on $\mathcal{E}_h^N$. Then for $e=\partial K^+\cap\partial\Omega\in\mathcal{E}_h^N$*

$$h_e\big|g_N-\partial_n u_h^\gamma\big|_e^2 \le c\|\nabla e\|_{K^+}^2. \tag{3.11}$$

(iv) *Suppose that g_D is the restriction to Γ_D of a function in $V_h^r\cap H^1(\Omega)$. Then there exists γ_1 depending only on r and θ_0 such that for $\gamma\ge\gamma_1$*

$$\gamma^2\sum_{e\in\mathcal{E}_h^I} h_e^{-1}\big|\big[u_h^\gamma\big]\big|_e^2 + \gamma^2\sum_{e\in\mathcal{E}_h^D} h_e^{-1}\big|g_D-u_h^\gamma\big|_e^2 \le c\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2. \tag{3.12}$$

The constants c in (3.9)–(3.12) depend on r, θ_0 the degrees of f and g_N, but are independent of the meshsize and γ.

Proof. Proofs of assertions (i), (ii), (iii) are similar to the proof of Theorem 3.2 in [17].

Concerning assertion (iv), let $u_h^G\in V_h^r\cap H^1(\Omega)$ with $u_h^G\big|_{\Gamma_D}=g_D$ denote the "standard" continuous Galerkin approximation of u given as the solution of

$$(\nabla u_h^G,\nabla\chi) = (f,\chi)+\sum_{e\in\mathcal{E}_h^N}\langle\chi,g_N\rangle_e \quad \forall\chi\in V_h^r\cap H^1_{0,\Gamma_D}. \tag{3.13}$$

It is easily seen that u_h^G satisfies

$$a_h^\gamma(u_h^G,\chi) = (f,\chi)-\sum_{e\in\mathcal{E}_h^D}\langle g_D,\partial_n\chi\rangle_e+\sum_{e\in\mathcal{E}_h^N}\langle\chi,g_N\rangle_e \quad \forall\chi\in V_h^r\cap H^1_{0,\Gamma_D}, \tag{3.14}$$

and then one gets the following orthogonality relation for u_h^G:

$$a_h^\gamma(u_h^G-u,\chi)=0 \quad \forall\chi\in V_h^r\cap H^1_{0,\Gamma_D}. \tag{3.15}$$

Now for all $\chi \in V_h^r \cap H^1_{0,\Gamma_D}$,

$$\begin{aligned}
a_h^\gamma(u_h^\gamma - u_h^G, u_h^\gamma - u_h^G) &= a_h^\gamma(u - u_h^G, u_h^\gamma - u_h^G) \\
&= a_h^\gamma(u - u_h^G, u_h^\gamma - u_h^G - \chi) \\
&= \sum_{K\in\mathcal{T}_h} (\nabla(u - u_h^G), \nabla(u_h^\gamma - u_h^G - \chi))_K \\
&\quad - \sum_{e\in\mathcal{E}_h^I} \left\langle \left\{\partial_n(u - u_h^G)\right\}, [u_h^\gamma] \right\rangle_e - \sum_{e\in\mathcal{E}_h^D} \left\langle \partial_n(u - u_h^G), u_h^\gamma - g_D \right\rangle_e \\
&= \sum_{K\in\mathcal{T}_h} (\nabla e + \nabla(u_h^\gamma - u_h^G), \nabla(u_h^\gamma - u_h^G - \chi))_K \\
&\quad - \sum_{e\in\mathcal{E}_h^I} \left\langle \{\partial_n e\} + \left\{\partial_n(u_h^\gamma - u_h^G)\right\}, [u_h^\gamma] \right\rangle_e \\
&\quad - \sum_{e\in\mathcal{E}_h^D} \left\langle \partial_n e + \partial_n(u_h^\gamma - u_h^G), u_h^\gamma - g_D \right\rangle_e .
\end{aligned}$$

Then integration by parts of $(\nabla e, \nabla(u_h^\gamma - u_h^G - \chi))_K$ gives

$$\begin{aligned}
&a_h^\gamma(u_h^\gamma - u_h^G, u_h^\gamma - u_h^G) \\
&\quad = \sum_{K\in\mathcal{T}_h} \Big(\big(f + \Delta u_h^\gamma, u_h^\gamma - u_h^G - \chi\big)_K + \big(\nabla(u_h^\gamma - u_h^G), \nabla(u_h^\gamma - u_h^G - \chi)\big)_K \Big) \\
&\qquad - \sum_{e\in\mathcal{E}_h^I} \Big(\big\langle [\partial_n u_h^\gamma], \{u_h^\gamma - u_h^G - \chi\} \big\rangle_e + \big\langle \left\{\partial_n(u_h^\gamma - u_h^G)\right\}, [u_h^\gamma] \big\rangle_e \Big) \\
&\qquad - \sum_{e\in\mathcal{E}_h^D} \left\langle \partial_n(u_h^\gamma - u_h^G), u_h^\gamma - g_D \right\rangle_e - \sum_{e\in\mathcal{E}_h^N} \left\langle \partial_n u_h^\gamma - g_N, u_h^\gamma - u_h^G - \chi \right\rangle_e .
\end{aligned}$$

In view of the coercivity of a_h^γ on V_h^r, using the arithmetic-geometric mean inequality, we obtain

$$\begin{aligned}
c_a \sum_{K\in\mathcal{T}_h} \|\nabla(u_h^\gamma - u_h^G)\|_K^2 &+ (\gamma - \gamma_0) \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e^{-1} |[u_h^\gamma - u_h^G]|_e^2 \\
&\le \frac{\epsilon_1}{2} \sum_{K\in\mathcal{T}_h} \|\nabla(u_h^\gamma - u_h^G)\|_K^2 + \frac{1}{2\epsilon_1} \sum_{K\in\mathcal{T}_h} \|\nabla(u_h^\gamma - u_h^G - \chi)\|_K^2 \\
&\quad + \frac{1}{2\epsilon_2\gamma} \sum_{K\in\mathcal{T}_h} h_K^2 \|f + \Delta u_h^\gamma\|_K^2 + \frac{\epsilon_2\gamma}{2} \sum_{K\in\mathcal{T}_h} h_K^{-2} \|u_h^\gamma - u_h^G - \chi\|_K^2 \\
&\quad + \frac{1}{2\epsilon_2\gamma} \sum_{e\in\mathcal{E}_h^I} h_e |[\partial_n u_h^\gamma]|_e^2 + \frac{\epsilon_2\gamma}{2} \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^N} h_e^{-1} |\{u_h^\gamma - u_h^G - \chi\}|_e^2 \\
&\quad + \frac{\epsilon_1}{2} \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e |\left\{\partial_n(u_h^\gamma - u_h^G)\right\}|_e^2 + \frac{1}{2\epsilon_1} \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e^{-1} |[u_h^\gamma - u_h^G]|_e^2 \\
&\quad + \frac{1}{2\epsilon_2\gamma} \sum_{e\in\mathcal{E}_h^N} h_e |\partial_n u_h^\gamma - g_N|_e^2, \qquad (3.16)
\end{aligned}$$

where c_a and γ_0 are as in Lemma 3.1. Using the trace and inverse inequalities, it

follows that

$$\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e|\left\{\partial_n(u_h^\gamma-u_h^G)\right\}|_e^2 \le c_1\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-u_h^G)\|_K^2, \tag{3.17}$$

$$\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^N} h_e^{-1}|\{u_h^\gamma-u_h^G-\chi\}|_e^2 \le c_2\sum_{K\in\mathcal{T}_h} h_K^{-2}\|u_h^\gamma-u_h^G-\chi\|_K^2, \tag{3.18}$$

where c_1 and c_2 depend only on r and θ_0. Now choose $\chi\in V_h^r\cap H^1_{0,\Gamma_D}$ to approximate $u_h^\gamma-u_h^G$ as in Theorem 2.1(ii). Using (3.18) and (3.17) in (3.16), we have

$$\begin{aligned}
&c_a\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-u_h^G)\|_K^2+(\gamma-\gamma_0)\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D}h_e^{-1}|[u_h^\gamma-u_h^G]|_e^2\\
&\qquad\le\frac{\epsilon_1}{2}(1+c_1)\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-u_h^G)\|_K^2+\frac{1}{2\epsilon_2\gamma}\sum_{K\in\mathcal{T}_h}h_K^2\|f+\Delta u_h^\gamma\|_K^2\\
&\qquad+\frac{1}{2\epsilon_2\gamma}\sum_{e\in\mathcal{E}_h^I}h_e|[\partial_n u_h^\gamma]|_e^2+\frac{1}{2\epsilon_2\gamma}\sum_{e\in\mathcal{E}_h^N}h_e|\partial_n u_h^\gamma-g_N|_e^2\\
&\qquad+\left(\frac{1+c_3}{2\epsilon_1}+\frac{\epsilon_2(1+c_2)c_3\gamma}{2}\right)\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D}h_e^{-1}|[u_h^\gamma-u_h^G]|_e^2,
\end{aligned}\tag{3.19}$$

where c_3 is the constant in (2.4). Now choose ϵ_1 small so that $\epsilon_1(1+c_1)\le c_a$ and choose ϵ_2 small so that $\epsilon_2(1+c_2)c_3\le 1$. Then for $\gamma\ge\gamma_1:=4\big(\gamma_0+\frac{1+c_3}{2\epsilon_1}\big)$ we will have $\gamma-\gamma_0-\frac{1+c_3}{2\epsilon_1}-\frac{\gamma}{2}\ge\frac{1}{4}\gamma$. Note that c_a,γ_0,c_1,c_2,c_3 and consequently $\epsilon_1,\epsilon_2,\gamma_1$ depend only on r and θ_0. Thus, from (3.19) we obtain

$$\begin{aligned}
&\frac{c_a}{2}\sum_{K\in\mathcal{T}_h}\|\nabla(u_h^\gamma-u_h^G)\|_K^2+\frac{1}{4}\gamma\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D}h_e^{-1}|[u_h^\gamma-u_h^G]|_e^2\\
&\le\frac{1}{2\epsilon_2\gamma}\left(\sum_{K\in\mathcal{T}_h}h_K^2\|f+\Delta u_h^\gamma\|_K^2+\sum_{e\in\mathcal{E}_h^I}h_e|[\partial_n u_h^\gamma]|_e^2+\sum_{e\in\mathcal{E}_h^N}h_e|\partial_n u_h^\gamma-g_N|_e^2\right).
\end{aligned}\tag{3.20}$$

Using assertions (3.9)–(3.11) in (3.20), we obtain (3.12). This concludes the proof. ∎

Remark 3.1.

(i) *In view of* (3.20)*, one may obtain lower and upper bounds for* $\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2$ *with only the three terms on the left sides of* (3.9)*,* (3.10)*, and* (3.11)*.*

(ii) *Inequality* (3.12) *is important in that it confirms the right side of* (3.3) *as both an upper and a lower bound for the error* $\sum_{K\in\mathcal{T}_h}\|\nabla e\|_K^2$ *and thus completes Theorem* 3.2 *of* [17].

(iii) *In* [15] *the upper bound analogous to* (3.3) *contains only* γ *and thus constitutes a stronger result than ours in this respect. On the other hand, the fact that the lower bound* (3.12) *contains* γ^2 *is significant and plays an important role in the convergence proof of the adaptive algorithm.*

4. Convergence of the adaptive scheme. In this section we will describe in detail our adaptive algorithm and prove its convergence under appropriate assumptions. The algorithm, which is iterative in nature, consists of constructing a sequence of meshes and corresponding approximations whereby each cycle consists of the following four steps:

1. Given a mesh $\mathcal{T}_H$, a DG approximation u_H^γ is constructed by solving (3.1) exactly (to machine precision). In practice, however, only an approximate solution is found by a fast iterative method, e.g., Multigrid. In that case, the additional errors caused must be taken into account.
2. An (a posteriori) estimation of the error e_H is obtained by calculating, e.g., the right side of (3.3) without the terms containing γ, their exclusion being motivated by (3.20).
3. Based on the information supplied by the a posteriori error estimate certain triangles and edges of $\mathcal{T}_H$ are marked for refinement. This is the *marking* strategy. It is patterned after that of [14].
4. The triangles and edges marked for refinement in step 3 lead to a set of triangles to be refined in a specific way. This is the *refinement* strategy and defines the new mesh $\mathcal{T}_h$.

Our convergence result can be summarized as follows: Let $\mathcal{T}_H$ be a mesh with V_H^r denoting the corresponding discontinuous finite element space, and let $\mathcal{T}_h$ denote a refinement of $\mathcal{T}_H$ obtained by following the above steps. Let u_h^γ and u_H^γ denote the DG solutions in V_h^r and V_H^r, respectively, and e_h and e_H the corresponding errors. Then, under certain assumptions on the data of the BVP (1.1)–(1.3) and for γ sufficiently large, there holds

$$a_h^\gamma(e_h, e_h) \le \rho\, a_H^\gamma(e_H, e_H), \qquad 0 < \rho < 1. \tag{4.1}$$

Let us note that such convergence results are based in an essential manner on an orthogonality relation which in this context is written as

$$a_h^\gamma(e_H, e_H) = a_h^\gamma(e_h, e_h) + a_h^\gamma(u_h^\gamma - u_H^\gamma, u_h^\gamma - u_H^\gamma). \tag{4.2}$$

The convergence of the algorithm hinges on obtaining a fixed reduction in the error, and this depends in a crucial manner on the nonnegative quantity $a_h^\gamma(u_h^\gamma - u_H^\gamma, u_h^\gamma - u_H^\gamma)$ being sufficiently large with respect to the other two terms in (4.2). However, examples of problems can be constructed, in particular when the solution u is oscillatory, whereby $a_h^\gamma(u_h^\gamma - u_H^\gamma,\ u_h^\gamma - u_H^\gamma) = 0$ on an arbitrarily long sequence of meshes, each one obtained from the previous one by full refinement. See, e.g., [19], [20], [14]. It turns out that our assumptions on the data preclude such occurrences, resulting in the linear convergence rate (4.1).

Before engaging in the proof of the theorem, we immediately notice a difficulty presented by the fact that we have $a_h^\gamma(e_H, e_H)$ on the left-hand side of (4.2) instead of $a_H^\gamma(e_H, e_H)$. Another basic problem is that $a_h^\gamma(\cdot,\cdot)$ is not coercive on the energy space. We will show below that $a_h^\gamma(e_h, e_h)$ behaves like a norm, thus giving a meaning to the convergence result $\lim_{h\to 0} a_h^\gamma(e_h, e_h) = 0$ implied by (4.1).

We deal with the first problem by showing that $a_h^\gamma(e_H, e_H)$ is bounded by $a_H^\gamma(e_H, e_H)$ plus a nonnegative quantity that can be absorbed in other terms.

PROPOSITION 4.1. *Suppose the mesh $\mathcal{T}_h$ is not too fine with respect to $\mathcal{T}_H$. Then*

$$\begin{aligned} a_h^\gamma(e_H, e_H) &\le a_H^\gamma(e_H, e_H) + c\gamma \sum_{e\in\mathcal{E}_H^I\cup\mathcal{E}_H^D} h_e^{-1} |\,[e_H]\,|_e^2 \\ &= a_H^\gamma(e_H, e_H) + c\gamma \sum_{e\in\mathcal{E}_H^I} h_e^{-1} |\,[u_H^\gamma]\,|_e^2 + c\gamma \sum_{e\in\mathcal{E}_H^D} h_e^{-1} |g_D - u_H^\gamma|_e^2. \end{aligned} \tag{4.3}$$

Proof. Indeed, we have

$$a_h^\gamma(e_H, e_H) = \sum_{K\in\mathcal{T}_h} \|\nabla e_H\|_K^2 - \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \Big(2\,\langle\{\partial_n e_H\}, [e_H]\rangle_e - \gamma h_e^{-1} |\,[e_H]\,|_e^2\Big). \tag{4.4}$$

Since u is smooth and u_H^γ is a polynomial on each $K \in \mathcal{T}_H$, we have $\sum_{K\in\mathcal{T}_h} \|\nabla e_H\|_K^2 = \sum_{K\in\mathcal{T}_H} \|\nabla e_H\|_K^2$. Now if $e \in \mathcal{E}_h^I$ is a "completely" new edge, i.e., is in the interior of some $K \in \mathcal{T}_H$, then $[e_H]\big|_e = 0$. Also, since Γ is polygonal, edges $e \in \mathcal{E}_h^D$ are parts of edges in $\mathcal{E}_H^D$. Thus

$$\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle\{\partial_n e_H\}, [e_H]\rangle_e = \sum_{e\in\mathcal{E}_H^I\cup\mathcal{E}_H^D} \langle\{\partial_n e_H\}, [e_H]\rangle_e .$$

As for the terms in (4.4) that contain γ, the problem is to contend with the weights h_e^{-1} of the new edges. Again, there are no contributions from the completely new edges. Thus

$$\gamma \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} h_e^{-1} |[e_H]|_e^2 \le \gamma \sum_{e\in\mathcal{E}_H^I\cup\mathcal{E}_H^D} \nu(e) h_e^{-1} |[e_H]|_e^2,$$

where for $e \in \mathcal{E}_H^I \cup \mathcal{E}_H^D$, $\nu(e) = \max\{\frac{h_e}{h_{e'}} \mid e' \in \mathcal{E}_h^I \cup \mathcal{E}_h^D,\ e' \in e\} \ge 2$ is a number that measures the fineness of $\mathcal{T}_h$ with respect to $\mathcal{T}_H$. Assuming that $\nu(e)$ is uniformly bounded, i.e., $\mathcal{T}_h$ is not too fine relative to $\mathcal{T}_H$, we finally obtain (4.3). ∎

We next tackle the lack of coercivity of $a_h^\gamma(.,.)$ on the energy space E_h by showing that, nevertheless, as far as e_h is concerned, $a_h^\gamma(.,.)$ behaves like a norm!

PROPOSITION 4.2. *There exists a constant γ_2 depending only on r and θ_0 such that if $\gamma \ge \gamma_2$, then for some constant $C_1 > 0$ depending only on r and θ_0 there holds*

(4.5)
$$a_h^\gamma(e_h, e_h) \ge \frac{1}{2} \sum_{K\in\mathcal{T}_h} \|\nabla e_h\|_K^2 + C_1\gamma^2 \sum_{e\in\mathcal{E}_h^I} h_e^{-1} |[u_h^\gamma]|_e^2 + C_1\gamma^2 \sum_{e\in\mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2.$$

Proof. We have

$$a_h^\gamma(e_h, e_h) = \sum_{K\in\mathcal{T}_h} \|\nabla e_h\|_K^2 - \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \Big(2\langle\{\partial_n e_h\}, [e_h]\rangle_e - \gamma h_e^{-1} |[e_h]|_e^2\Big). \tag{4.6}$$

Moreover, for all $\chi \in V_h^r \cap H^1(\Omega)$ satisfying $\chi\big|_{\Gamma_D} = g_D$, we have

$$\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle\{\partial_n e_h\}, [e_h]\rangle_e = \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle\{\partial_n e_h\}, [\chi - u_h^\gamma]\rangle_e .$$

On the other hand, by virtue of the orthogonality identity (3.2),

$$0 = a_h^\gamma(e_h, \chi - u_h^\gamma) = \sum_{K\in\mathcal{T}_h} (\nabla e_h, \nabla(\chi - u_h^\gamma))_K - \sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \Big(\langle\{\partial_n(\chi - u_h^\gamma)\}, [e_h]\rangle_e + \langle\{\partial_n e_h\}, [\chi - u_h^\gamma]\rangle_e - \gamma h_e^{-1} \langle[e_h], [\chi - u_h^\gamma]\rangle_e\Big).$$

Thus

$$\begin{aligned}\sum_{e\in\mathcal{E}_h^I\cup\mathcal{E}_h^D} \langle\{\partial_n e_h\}, [e_h]\rangle_e = {} & \sum_{K\in\mathcal{T}_h} (\nabla e_h, \nabla(\chi - u_h^\gamma))_K \\ & + \sum_{e\in\mathcal{E}_h^I} \Big(\langle\{\partial_n(\chi - u_h^\gamma)\}, [u_h^\gamma]\rangle_e + \gamma h_e^{-1} |[u_h^\gamma]|_e^2\Big) \\ & - \sum_{e\in\mathcal{E}_h^D} \Big(\langle\{\partial_n(\chi - u_h^\gamma)\}, g_D - u_h^\gamma\rangle_e - \gamma h_e^{-1} |g_D - u_h^\gamma|_e^2\Big).\end{aligned} \tag{4.7}$$

We now choose χ in (4.7) as in Theorem 2.1(ii). Also, using the trace and inverse inequalities, for any $\epsilon > 0$ we obtain

$$\left| \sum_{e \in \mathcal{E}_h^I \cup \mathcal{E}_h^D} \langle \{\partial_n e_h\}, [e_h] \rangle_e \right| \leq c\epsilon \sum_{K \in \mathcal{T}_h} \|\nabla e_h\|_K^2 + \left(\gamma + \frac{c}{\epsilon}\right) \sum_{e \in \mathcal{E}_h^I} h_e^{-1} |[u_h^\gamma]|_e^2 + \left(\gamma + \frac{c}{\epsilon}\right) \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2. \tag{4.8}$$

Using this in (4.6), we obtain

$$a_h^\gamma(e_h, e_h) \geq (1 - 2c\epsilon) \sum_{K \in \mathcal{T}_h} \|\nabla e_h\|_K^2 - \left(\gamma + \frac{2c}{\epsilon}\right) \left(\sum_{e \in \mathcal{E}_h^I} h_e^{-1} |[u_h^\gamma]|_e^2 + \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2 \right). \tag{4.9}$$

Now note that the last two sums in (4.9) are dominated by $\frac{c}{\gamma^2} \sum_{K \in \mathcal{T}_h} \|\nabla e_h\|_K^2$ as shown by the a posteriori estimate (3.12). Hence, choosing $\epsilon = \frac{1}{8c}$ and then using (3.12), for γ sufficiently large we obtain the desired result. ∎

REMARK 4.1. *The proof of Proposition* 4.2 *also yields*

$$a_h^\gamma(e_h, e_h) \leq \left(1 + \frac{1}{\gamma}\right) \sum_{K \in \mathcal{T}_h} \|\nabla e_h\|_K^2 + C_2 \gamma \sum_{e \in \mathcal{E}_h^I} h_e^{-1} |[u_h^\gamma]|_e^2 + C_2 \gamma \sum_{e \in \mathcal{E}_h^D} h_e^{-1} |g_D - u_h^\gamma|_e^2. \tag{4.10}$$

We now begin the proof of (4.1). Let $\mathcal{T}_h$ be a refinement of $\mathcal{T}_H$. Since $e_H \in E_H \subseteq E_h$, we integrate $\sum_{K \in \mathcal{T}_h} (\nabla e_H, \nabla v)_K$ by parts to obtain

$$\sum_{K \in \mathcal{T}_h} (\nabla e_H, \nabla v)_K = \sum_{K \in \mathcal{T}_h} (f + \Delta u_H^\gamma, v)_K + \sum_{e \in \mathcal{E}_h^I} \left(\langle \{\partial_n e_H\}, [v] \rangle_e + \langle \{v\}, [\partial_n e_H] \rangle_e \right) + \sum_{e \in \mathcal{E}_h^D} \langle \partial_n e_H, v \rangle_e + \sum_{e \in \mathcal{E}_h^N} \langle g_N - \partial_n u_H^\gamma, v \rangle_e \qquad \forall v \in E_h. \tag{4.11}$$

It then follows from (4.11) and the definition of $a_h^\gamma(\cdot, \cdot)$ that

$$\begin{aligned} \sum_{K \in \mathcal{T}_h} (f + \Delta u_H^\gamma, v)_K - \sum_{e \in \mathcal{E}_h^I} \langle [\partial_n u_H^\gamma], \{v\} \rangle_e + \sum_{e \in \mathcal{E}_h^N} \langle g_N - \partial_n u_H^\gamma, v \rangle_e &= a_h^\gamma(e_H, v) \\ &+ \sum_{e \in \mathcal{E}_h^I} \left(\langle \{\partial_n v\}, [e_H] \rangle_e - \gamma h_e^{-1} \langle [e_H], [v] \rangle_e \right) \\ &+ \sum_{e \in \mathcal{E}_h^D} \left(\langle \partial_n v, e_H \rangle_e - \gamma h_e^{-1} \langle e_H, v \rangle_e \right) \quad \forall v \in E_h. \end{aligned} \tag{4.12}$$

At this point we write $a_h^\gamma(e_H, v) = a_h^\gamma(u_h^\gamma - u_H^\gamma, v) + a_h^\gamma(e_h, v)$ and note that $a_h^\gamma(e_h, v) = 0 \; \forall v \in V_h^r$. Also, it turns out that it is crucial to eliminate the troublesome terms containing γ. These considerations lead us to use test functions from the subspaces $V_h^r \cap H^1_{0,\Gamma_D}$ of E_h encountered in the proof of Theorem 3.2. We then have

the key identity

$$\begin{aligned}
&\sum_{K\in\mathcal{T}_h}(f+\Delta u_H^\gamma, v)_K - \sum_{e\in\mathcal{E}_h^I}\langle[\partial_n u_H^\gamma],\{v\}\rangle_e + \sum_{e\in\mathcal{E}_h^N}\langle g_N-\partial_n u_H^\gamma, v\rangle_e \\
&\quad = a_h^\gamma(u_h^\gamma-u_H^\gamma,v) - \sum_{e\in\mathcal{E}_h^I}\langle\{\partial_n v\},[u_H^\gamma]\rangle_e + \sum_{e\in\mathcal{E}_h^D}\langle\partial_n v, g_D-u_H^\gamma\rangle_e \qquad (4.13)\\
&\quad = \sum_{K\in\mathcal{T}_h}(\nabla(u_h^\gamma-u_H^\gamma),\nabla v)_K - \sum_{e\in\mathcal{E}_h^I}\langle\{\partial_n v\},[u_h^\gamma]\rangle_e + \sum_{e\in\mathcal{E}_h^D}\langle\partial_n v, g_D-u_h^\gamma\rangle_e
\end{aligned}$$

$\forall v\in V_h^r\cap H^1_{0,\Gamma_D}$. The principal thrust of the proof of convergence is to use (4.13) to bound the terms $h_K^2\|f+\Delta u_H^\gamma\|_K^2$, $h_e|\,[\partial_n u_H^\gamma]\,|_e^2$, and $h_e|g_N-\partial_n u_H^\gamma|_e^2$ by an appropriate functional of $u_h^\gamma-u_H^\gamma$. This estimation is accomplished by, on the one hand, marking certain triangles and edges of $\mathcal{T}_H$ for refinement (marking strategy) and, on the other hand, ensuring that the test function space $V_h^r\cap H^1_{0,\Gamma_D}$ is large enough to yield the desired estimates. Consequently, the refinement must be done according to some specific rules (refinement strategy).

We next describe our marking strategy, which is modeled after the one in Dörfler [14].

Marking Strategy.

For some number $\theta\in(0,1)$, let $\mathcal{R}_H^K$, $\mathcal{R}_H^I$, and $\mathcal{R}_H^N$ be any subsets of $\mathcal{T}_H$, $\mathcal{E}_H^I$, and $\mathcal{E}_H^N$, respectively, such that

$$\begin{aligned}
\sum_{K\in\mathcal{R}_H^K} h_K^2\|f+\Delta u_H^\gamma\|_K^2 &\ge \theta\sum_{K\in\mathcal{T}_H} h_K^2\|f+\Delta u_H^\gamma\|_K^2,\\
\sum_{e\in\mathcal{R}_H^I} h_e|\,[\partial_n u_H^\gamma]\,|_e^2 &\ge \theta\sum_{e\in\mathcal{E}_H^I} h_e|\,[\partial_n u_H^\gamma]\,|_e^2,\\
\sum_{e\in\mathcal{R}_H^N} h_e|g_N-\partial_n u_H^\gamma|_e^2 &\ge \theta\sum_{e\in\mathcal{E}_H^N} h_e|g_N-\partial_n u_H^\gamma|_e^2.
\end{aligned}$$

With $E_{\mathcal{R}}$ and E denoting the sums on the left and right sides, respectively, we have

$$E_{\mathcal{R}}\ge\theta E. \qquad (4.14)$$

Refinement Strategy.

(I) A marked triangle $K\in\mathcal{R}_H^K$ will be cut into a number of equivalent triangles. This number depends on r, as shown in Figure 4.1.

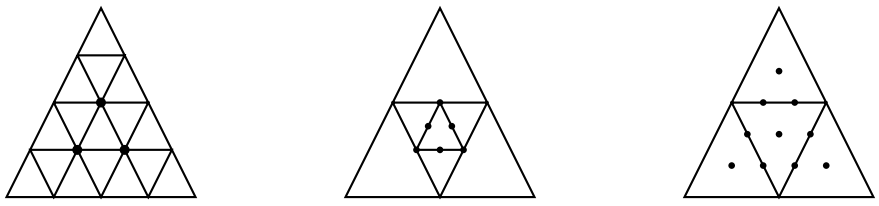

Fig. 4.1.

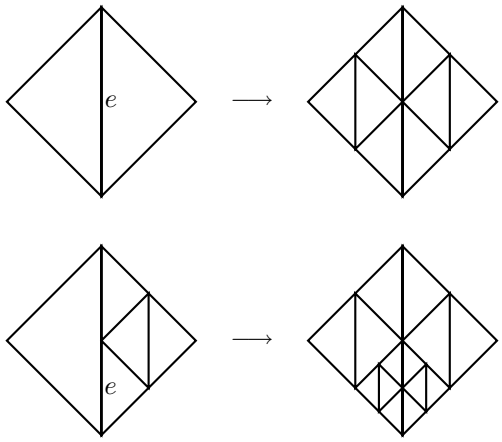

FIG. 4.2.

(II) Let $e = \partial K^+ \cap \partial K^- \in \mathcal{R}_H^I$ be a marked interior edge. Then one or both of K^+ and K^- will be cut in a manner depending on whether e is a full edge of both K^+ and K^- (see Figure 4.2).

(III) Let $e = \partial K \cap \Gamma_N$ be a marked edge in $\mathcal{R}_H^N$. Then K will be cut into four equivalent triangles.

REMARK 4.2. (i) *There may be some overlap between requirements* (I), (II), *and* (III).

(ii) *Additional requirements may also be imposed. For instance, one may wish to curtail the number of hanging nodes after refinement. Indeed, to simplify the programming we impose a maximum of one hanging node per interior edge. The combination of* (I), (II), *and such rules may lead to a finer mesh. This is acceptable since larger spaces* V_h^r *and* $V_h^r \cap H^1_{0,\Gamma_D}$ *will correspond to a finer mesh.*

Estimation of $h_K^2\|f + \Delta u_H^\gamma\|_K^2$. For $K \in \mathcal{R}_H^K$ consider the partition $\mathcal{T}_K$ shown in Figure 4.1, corresponding to a given r with the understanding that the eventual refinement of K may be finer than $\mathcal{T}_K$. We introduce the finite-dimensional spaces S_K given by

$$S_K = \{v \in C^0(K),\ v\big|_{K'} \in P_{r-1}(K')\ \forall K' \in \mathcal{T}_K,\ v = 0 \text{ on } \partial K\}.$$

It is clear that S_K is a subspace of $V_h^r \cap H^1_{0,\Gamma_D}$. Also, it is easily seen that a function in S_K is uniquely determined by its values at the nodes shown in Figure 4.1. Thus $\dim(S_K) \le d := r(r+1)/2 = \dim(P_{r-1}(K))$. Furthermore, for each r, a basis $\{\phi_i\}_{i=1}^d$ for S_K can be constructed by "gluing" together Lagrangian-type functions corresponding to the individual triangles in the partition $\mathcal{T}_K$. Indeed, it is not hard to show that the functions $\{\phi_i\}_{i=1}^d$ are linearly independent.

Now letting $\{\psi_i\}_{i=1}^d$ be the usual Lagrangian basis for $P_{r-1}(K)$ corresponding to the nodes shown in Figure 4.3, we form the "Gramian" matrix G given by $G_{ij} = (\phi_j, \psi_i)_K$, $i, j = 1, \ldots, d$. We have the following lemma.

LEMMA 4.1. *G is nonsingular.*

Proof. We will consider only the case $r = 2$; the remaining cases may be handled in a similar manner or verified by direct (and tedious) calculation. With ν_1, ν_2, ν_3 denoting the three nodes shown in Figure 4.1, let $\mathbf{v^2}, \mathbf{v^3}$ be the vectors emanating from

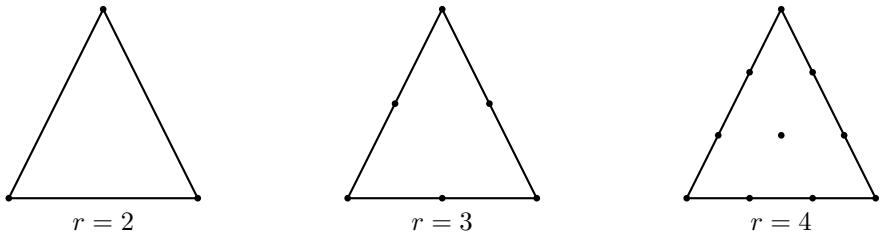

FIG. 4.3.

ν_1 and terminating at ν_2 and ν_3, respectively. Let also ϕ_1, ϕ_2, ϕ_3 be the (pyramidal) basis functions corresponding to the nodes ν_1, ν_2, ν_3 and denote their supports by S^1, S^2, S^3. Clearly,

$$\phi_2(x,y) = \phi_1(x - v_1^2, y - v_2^2) \quad \forall (x,y) \in S^2 \quad \text{and}$$
$$\phi_3(x,y) = \phi_1(x - v_1^3, y - v_2^3) \quad \forall (x,y) \in S^3.$$

Suppose there exists $\psi = ax + by + c \in P_1(K)$ such that $(\phi_j, \psi) = 0$, $j = 1,2,3$. We will show that $a = b = c = 0$, thus implying the linear independence of the rows of G.

$$\begin{aligned} 0 = (\psi, \phi_2)_K &= \int_{S^2} \psi(x,y)\phi_2(x,y)dxdy = \int_{S^2} \psi(x,y)\phi_1(x - v_1^2, y - v_2^2)dxdy \\ &= \int_{S^1} \psi(x + v_1^2, y + v_2^2)\phi_1(x,y)dxdy \\ &= \int_{S^1} \psi(x,y)\phi_1(x,y)dxdy + (av_1^2 + bv_2^2)\int_{S^1} \phi_1(x,y)dxdy. \end{aligned}$$

Now $\int_{S^1} \psi(x,y)\phi_1(x,y)dxdy = (\psi, \phi_1)_K = 0$. On the other hand, ϕ_1 is nonnegative and nonzero; thus we conclude from the above that $av_1^2 + bv_2^2 = 0$. In a similar way, we obtain $av_1^3 + bv_2^3 = 0$. Since the vectors $\mathbf{v^2}, \mathbf{v^3}$ are linearly independent, it follows that $a = b = 0$. Now that this has been shown, the fact that $c = 0$ readily follows from $(\psi, \phi_1)_K = 0$. ∎

COROLLARY 4.1. *Let $P : P_{r-1}(K) \to S_K$ denote the operator given by $(Pv, \chi)_K = (v, \chi)_K$ $\forall \chi \in S_K$. Then $\|P \cdot\|_K$ is a norm equivalent to $\|\cdot\|_K$ on $P_{r-1}(K)$ with constants that are independent of h_K.*

Proof. We only need to check the positivity of $\|P \cdot\|_K$ to see that it is a norm. Indeed, suppose $Pv = 0$ for some $v \in P_{r-1}(K)$. It then follows that $(v, \phi)_K = 0$ $\forall \phi \in S_K$. Since G is nonsingular, it follows that $v = 0$. The equivalence of the norms is a consequence of finite dimensionality. The fact that the constants involved are $O(1)$ follows from a scaling argument. ∎

To estimate $f + \Delta u_H^\gamma$ we take $v = P(f + \Delta u_H^\gamma)$ in (4.13). We get

$$\begin{aligned} \|P(f + \Delta u_H^\gamma)\|_K^2 &= (f + \Delta u_H^\gamma, P(f + \Delta u_H^\gamma))_K \\ &= \sum_{K' \in \mathcal{T}_{h,K}} (\nabla(u_h^\gamma - u_H^\gamma), \nabla P(f + \Delta u_H^\gamma))_{K'} \\ &\quad - \sum_{e \in \mathcal{E}_{h,K}^I} \langle \{\partial_n P(f + \Delta u_H^\gamma)\}, [u_h^\gamma] \rangle_e \\ &\quad + \sum_{e \in \mathcal{E}_h^D \cap \partial K} \langle \partial_n P(f + \Delta u_H^\gamma), g_D - u_h^\gamma \rangle_e, \end{aligned} \tag{4.15}$$

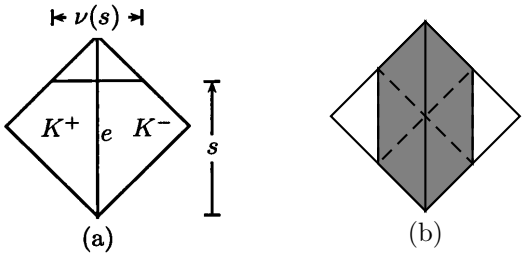

FIG. 4.4.

where $\mathcal{T}_{h,K} = \{K' \in \mathcal{T}_h,\ K' \subseteq K\}$ and $\mathcal{E}^I_{h,K} = \{e \in \mathcal{E}^I_h,\ e \subseteq K\}$.

Now using the trace and inverse inequalities for any $\epsilon > 0$, we have

$$\sum_{K' \in \mathcal{T}_{h,K}} (\nabla(u_h^\gamma - u_H^\gamma), \nabla P(f + \Delta u_H^\gamma))_{K'} \le c\epsilon \|f + \Delta u_H^\gamma\|_K^2 + \frac{c}{\epsilon} \sum_{K' \in \mathcal{T}_{h,K}} h_{K'}^{-2} \|\nabla(u_h^\gamma - u_H^\gamma)\|_{K'}^2. \tag{4.16}$$

Moreover,

$$\sum_{e \in \mathcal{E}^I_{h,K}} \langle \{\partial_n P(f + \Delta u_H^\gamma)\}, [u_h^\gamma] \rangle_e \le c\epsilon \|f + \Delta u_H^\gamma\|_K^2 + \frac{c}{\epsilon} \sum_{e \in \mathcal{E}^I_{h,K}} h_e^{-3} |[u_h^\gamma]|_e^2, \tag{4.17}$$

and

$$\sum_{e \in \mathcal{E}^D_h \cap \partial K} |\langle \partial_n P(f + \Delta u_H^\gamma), g_D - u_h^\gamma \rangle_e| \le c\epsilon \|f + \Delta u_H^\gamma\|_K^2 + \frac{c}{\epsilon} \sum_{e \in \mathcal{E}^D_h \cap \partial K} h_e^{-3} |g_D - u_h^\gamma|_e^2. \tag{4.18}$$

Now using (4.16), (4.17), and (4.18) with a small ϵ in (4.15), it follows from Corollary 4.1 that

$$h_K^2 \|f + \Delta u_H^\gamma\|_K^2 \le c \sum_{K' \in \mathcal{T}_{h,K}} \|\nabla(u_h^\gamma - u_H^\gamma)\|_{K'}^2 + c \sum_{e \in \mathcal{E}^I_{h,K}} h_e^{-1} |[u_h^\gamma]|_e^2 + \sum_{e \in \mathcal{E}^D_h \cap \partial K} h_e^{-1} |g_D - u_h^\gamma|_e^2. \tag{4.19}$$

Estimation of $h_e |[\partial_n u_H^\gamma]|_e^2$. Let $e \in \mathcal{R}^I_H$ be a marked edge. It follows from the refinement strategy (see Figure 4.2) that e is a full edge of both K^+ and K^-, where K^+, K^- may belong to $\mathcal{T}_H$ or one of them at most may have been formed after refinement. We construct a test function $v \in V_h^r \cap H^1_{0,\Gamma_D}$ as follows:

(i) Let $\tilde{v}$ be the extension of $[\partial_n u_H^\gamma]|_e$ to $\tilde{K} := K^+ \cup K^-$ by constants along lines normal to e.

(ii) Let ℓ be the continuous piecewise linear function whose support is the shaded region in Figure 4.4(b) and which assumes the value 1 at the midpoint of e.

We take $v = \tilde{v}\ell$. Note that v belongs to $V_h^r \cap H^1_{0,\Gamma_D}$. Using this v in (4.13), we obtain
